[2] Measured from differential waveform

[3] Slew rate is measured through the Vswing voltage range centered around differential 0V. This results in a +/-150mV window around differential 0V.

[4] Matching applies to rising edge rate for Clock and falling edge rate for Clock#. It is measured using a +/-75mV window centered on the average cross point where Clock rising meets Clock# falling. The median cross point is used to calculate the voltage thresholds the oscilloscope is to use for the edge rate calculations.

[5] Vcross is defined as voltage where Clock = Clock# measured on a component test board and only applies to the differential rising edge (i.e. Clock rising and Clock# falling).

[6] The total variation of all Vcross measurements in any particular system. Note that this is a subset of Vcross_min/max (Vcross absolute) allowed. The intent is to limit Vcross induced modulation by setting Δ-Vcross to be smaller than Vcross absolute.

Notes:

1. The Refclk jitter is measured after applying the filter functions found in PCI Express Base Specification 5.0, Revision 1.0. See the Test Loads section of the data sheet for the exact measurement setup. The total Ref Clk jitter limits for each data rate are listed for convenience. The worst case results for each data rate are summarized in this table. If oscilloscope data is used, equipment noise is removed from all results.

2. Jitter measurements shall be made with a capture of at least 100,000 clock cycles captured by a real-time oscilloscope (RTO) with a sample rate of 20 GS/s or greater. Broadband oscilloscope noise must be minimized in the measurement. The measured PP jitter is used (no extrapolation) for RTO measurements. Alternately - Jitter measurements may be used with a Phase Noise Analyzer (PNA) extending (flat) and integrating and folding the frequency content up to an offset from the carrier frequency of at least 200 MHz (at 300 MHz absolute frequency) below the Nyquist frequency. For PNA measurements for the 2.5 GT/s data rate, the RMS jitter is converted to peak to peak jitter using a multiplication factor of 8.83. In the case where real-time oscilloscope and PNA measurements have both been done and produce different results the RTO result must be used.

3. SSC spurs from the fundamental and harmonics are removed up to a cutoff frequency of 2 MHz taking care to minimize removal of any non-SSC content.

4. Note that 0.7 ps RMS is to be used in channel simulations to account for additional noise in a real system.

5. Note that 0.25 ps RMS is to be used in channel simulations to account for additional noise in a real system.

6. The PCI Express Base Specification 5.0, Revision 1.0 provides the filters necessary to calculate SRIS jitter values, however, it does not provide specification limits, hence the n/a in the Limit column. SRIS values are informative only. In general, a clock operating in an SRIS system must be twice as good as a clock operating in a Common Clock system. For RMS values, twice as good is equivalent to dividing the CC value by √2. And additional consideration is the value for which to divide by √2. The conservative approach is to divide the ref clock jitter limit, and the case can be made for dividing the channel simulation values by √2, if the ref clock is close to the Tx clock input. An example for Gen4 is as follows. A "rule-of-thumb" SRIS limit would be either 0.5ps RMS/√2 = 0.35ps RMS if the clock chip is far from the clock input, or 0.7ps RMS/√2 = 0.5ps RMS if the clock chip is near the clock input.

7. Additive jitter for RMS values is calculated by solving for b where $b = \sqrt{(c^2 - a^2)}$, and a is rms input jitter and c is rms output jitter.

Revision History

Revision Date	Description
August 13, 2012	1. Updated electrical characteristics tables. 2. Move to final.
September 6, 2014	1. Changed VIH min. from 0.65*VDD to 0.75*VDD 2. Changed VIL max. from 0.35*VDD to 0.25*VDD 3. Added missing mid-level input voltage spec (VIM) of 0.4*VDD to 0.6*VDD. 4. Changed Shipping Packaging from "Trays" to Tubes". 5. Reformatted to new template
August 10, 2015	1. Updated front page text for family consistency 2. Updated block diagram for family consistency 3. Updated pin configuration to indicate that paddle is ground 4. Added epad as pin 25 to pin descritptions 5. Replaced "Driving LVDS" with "Alternate Terminations", adding reference to AN-891. 6. Updated "Clock Input Parameters Table" correcting inconsistency with PCIe SIG specifications. 7. Widened allowable input frequency at each PLL mode frequency. 8. Updated phase jitter parameters with 12k-20M additive phase jitter and added additive phase jitter graph. 9. Updated NLG24 package drawing with actual package info instead of generic drawing.
September 11, 2015	1. Corrected block diagram from clock generator to ZDB buffer
November 4, 2015	1. Minor typographical corrections throughout the data sheet 2. Updated test load diagram to generic diagram. Length of test load listed outside the drawing. 3. Minor updates to electrical tables for formatting. Removed Schmitt trigger info and output high/low voltage specifications for single-ended outputs, since this part does not have any. 4. "Low-Power HCSL Outputs" table: corrected inversion of slew rate setting with specifications. Changed reference from 2 V/ns and 3 V/ns to slow setting and fast setting. Also change references in SMBus Bytes[3:2] 5. "Low-Power HCSL Outputs" table: Removed Vswing parameter since this is an input parameter and is covered in "Clock Input Parameters" Table. 6. Reduced current consumption limits. 7. Minor updates to other electrical tables.
April 22, 2016	1. Updated max frequency of 100MHz PLL mode to 140MHz 2. Updated max frequency of 125MHz PLL mode to 175MHz 3. Updated max frequency of 50MHz PLL mode to 65MHz
August 2, 2021	1. Updated document title. 2. Updated Recommended Applications. 3. Updated Key Specifications. 4. Updated Package Outline Drawings section. 5. Updated Phase Jitter tables.
