When the selected pipe is set for isochronous transfers, the USBFS performs the following operation in addition to controlling the token issuance interval. The USBFS issues a token even when the NRDY interrupt generation condition is satisfied.

When the selected pipe is for isochronous IN transfers

The USBFS generates an NRDY interrupt when the USBFS issues an IN token but does not successfully receive a packet from a peripheral device (no response or packet error).

The USBFS sets the FRMNUM.OVRN bit to 1, generating an NRDY interrupt, when the time to issue an IN token occurs while the USBFS cannot receive data because the FIFO buffer is full, because the CPU or DMAC/DTC is too slow in reading data from the FIFO buffer.

When the selected pipe is for isochronous OUT transfers

The USBFS sets the OVRN bit to 1, generating an NRDY interrupt and transmitting a zero-length packet, when the time to issue an OUT token comes while there is no data to be transmitted in the FIFO buffer, or because the CPU or DMAC/DTC is too slow in writing data to the FIFO buffer.

The token issuance interval is reset on any of the following conditions:

- When the USBFS is reset through a reset pin
This initializes the IITV[2:0] bits.
- When the PIPEnCTR.ACLR bit is set to 1 by software

(3) Interval counting and transfer control in device controller mode

When the selected pipe is for isochronous OUT transfers

The USBFS generates an NRDY interrupt when it fails to receive a data packet within the interval set in the PIPEPERI.IITV[2:0] bits.

The USBFS also generates an NRDY interrupt when it fails to receive data because of a CRC error or other errors contained in the data packet or because the FIFO buffer is full.

The NRDY interrupt is generated on SOF packet reception. Even if the SOF packet is corrupted, internal interpolation allows the interrupt to be generated when the SOF packet is received. However, when the IITV bits are set to a value other than 0, the USBFS generates an NRDY interrupt on receiving an SOF packet for every interval after interval counting starts.

When the PID[1:0] bits are set to NAK by software after starting the interval timer, the USBFS does not generate an NRDY interrupt on receiving an SOF packet.

The timing for starting interval counting depend on the IITV[2:0] setting as follows:

- When the IITV[2:0] bits = 0:
Interval counting starts at the next frame after the software changes the PID[1:0] bits of the selected pipe to BUF.
- When the IITV[2:0] bits \neq 0:
Interval counting starts on completion of successful reception of the first data packet after the PID[1:0] bits for the selected pipe are changed to BUF.

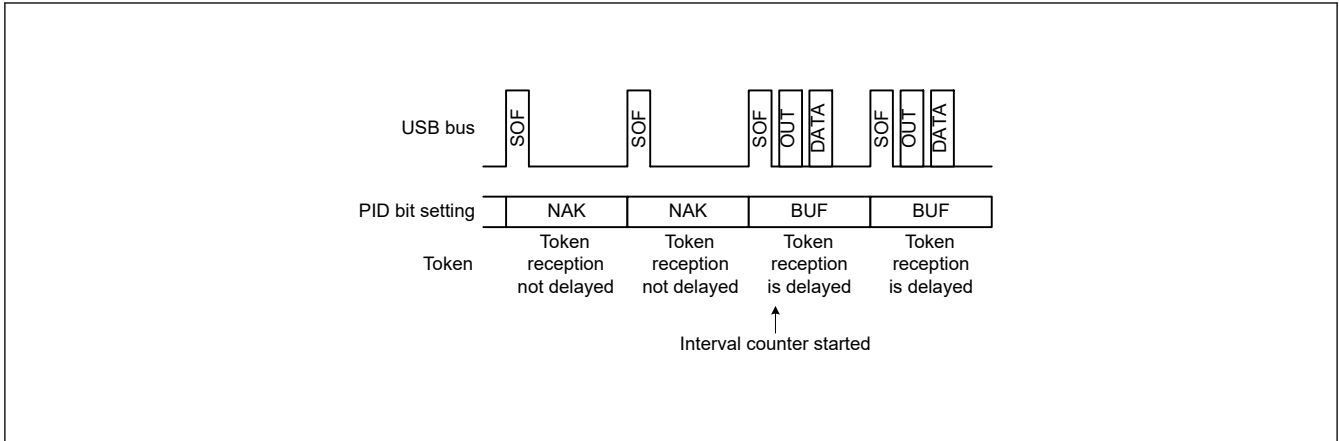

Figure 27.18 Relationship between frames and expected token reception when IITV[2:0] = 0

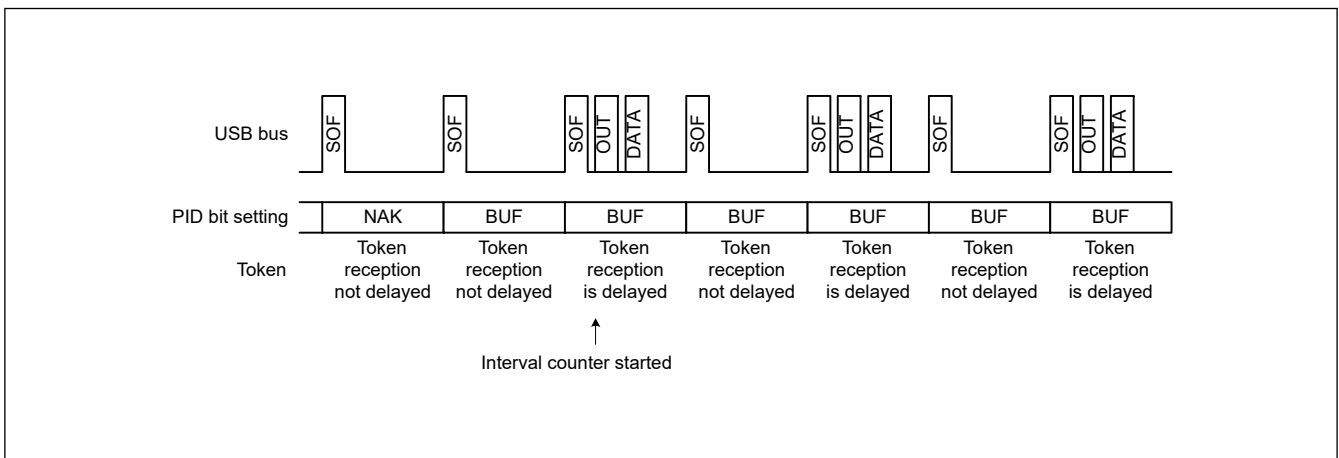

Figure 27.19 Relationship between frames and expected token reception when IITV[2:0] ≠ 0

When the selected pipe is for isochronous IN transfers

The PIPEPERI.IFIS bit must be 1 for this use case. When IFIS = 0, the USBFS transmits a data packet in response to a received IN token regardless of the PIPEPERI.IITV[2:0] setting.

When IFIS is 1 and there is data to be transmitted in the FIFO buffer, the USBFS clears the FIFO buffer when it fails to receive an IN token in the frame at the interval set in the IITV[2:0] bits.

The USBFS also clears the FIFO buffer when it fails to receive an IN token successfully because of a bus error, such as a CRC error, contained in the IN token.

The FIFO buffer is cleared on SOF packet reception. Even if the SOF packet is corrupted, the internal interpolation allows the FIFO buffer to be cleared when the SOF packet is received.

The timing to start interval counting depends on the IITV[2:0] setting, as with OUT transfers.

The interval is counted on any of the following conditions in device controller mode:

- When a hardware reset is applied to the USBFS (which also sets the IITV[2:0] bits to 000b)
- When the PIPEnCTR.ACLRm bit is set to 1 by software
- When the USBFS detects a USB bus reset

(4) Transmit data setup for isochronous transfers in device controller mode

With isochronous data transmission using the USBFS in device controller mode, after data is written to the FIFO buffer, a data packet can be transmitted in the first frame after the SOF packet is detected. This isochronous transfer transmit data setup function can identify the frame that started transmission.

When the double buffering is used, transmission is only enabled for the buffer where data writing was completed first, even after the data write to both buffers is complete. Accordingly, even if multiple IN tokens are received, only the one packet of FIFO buffer data is transmitted.

When the FIFO buffer is ready to transmit data when an IN token is received, the data is transferred and a normal response is returned. However, if the FIFO buffer cannot transmit data, a zero-length packet is transmitted and an underrun error occurs.

Figure 27.20 shows an example transmission using the isochronous transfer transmission data setup function when IITV = 0 (every frame) is set.

Figure 27.20 Example data setup operation

(5) Transmit buffer flush for isochronous transfers in device controller mode

In device controller mode during isochronous data transmission, if the USBFS receives an SOF packet for the next frame without receiving an IN token in the interval frame, it operates as if the IN token is corrupt and clears the buffer that is enabled for transmission, putting that buffer in the writing enabled state.

When double buffering is used and writing to both buffers is complete, the cleared FIFO buffer is assumed to be the one where the data was transmitted in the interval frame, and transmission is enabled for the FIFO buffer that was not cleared on SOF packet reception.

The timing of the buffer flush function depends on the PIPEPERI.IITV[2:0] setting as follows:

- When IITV = 0:
 - The buffer flush operation starts from the first frame after the pipe is enabled.
- When IITV \neq 0:
 - The buffer flush operation starts after the first normal transaction.

Figure 27.21 shows an example buffer flush. When an unanticipated token is received before the interval frame, the USBFS sends the write data or a zero-length packet as an underrun error, depending on the data setup status.

Figure 27.21 Example buffer flush operation

Figure 27.22 shows an example interval error occurrence. There are five types of interval errors, as shown in the figure. An interval error occurs at timing (A), and the buffer flush function is activated.

If an interval error occurs during an IN transfer, the buffer flush function is activated. If it occurs during an OUT transfer, an NRDY interrupt is generated. Use the FRMNUM.OVRN bit to distinguish between this and NRDY interrupts triggered by received packet errors and overrun errors.

For tokens that are shaded in the figure, responses are returned based on the FIFO buffer status.

- IN direction:
 - If the buffer is ready to transfer data, the data is transferred and a normal response is returned
 - If the buffer is not ready to transfer data, a zero-length packet is transmitted and an underrun error occurs
- OUT direction:
 - If the buffer is ready to receive data, the data is received and a normal response is returned
 - If the buffer is not ready to receive data, the received data is discarded and an overrun error occurs

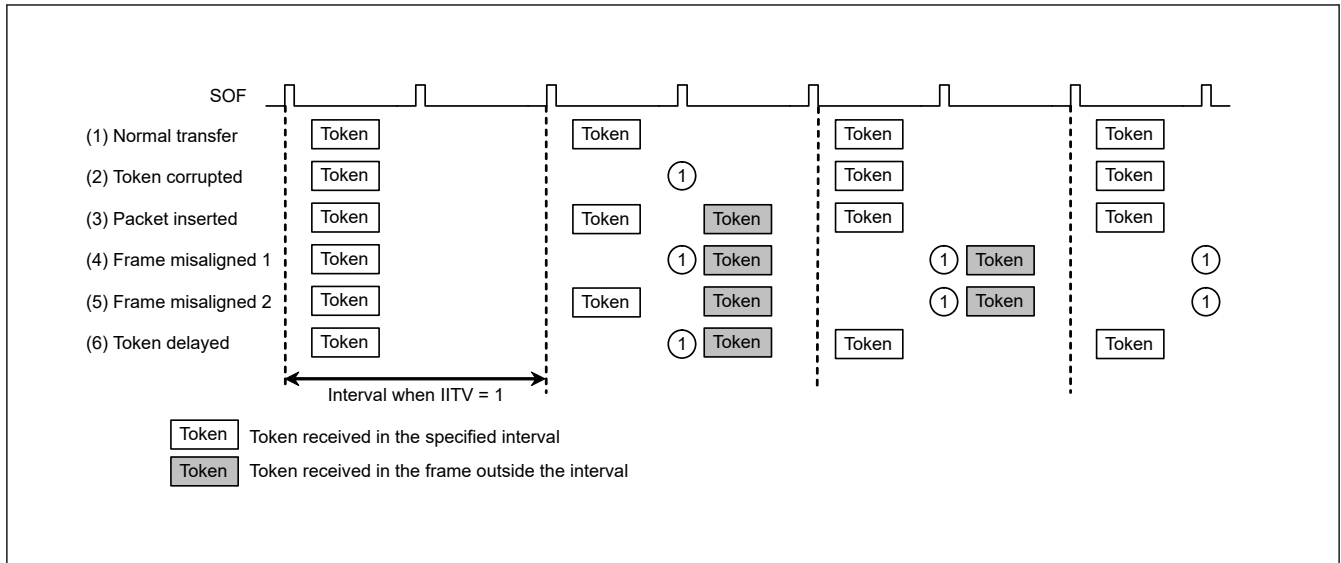

Figure 27.22 Example interval error occurrence when IITV = 1

27.3.13 SOF Interpolation Function

In device controller mode, if packet reception is disabled at intervals of 1 ms because the SOF packet is corrupted or missing, the USBFS interpolates the SOF. SOF interpolation begins when the USBE and SCKE bits in SYSCFG are set to 1 and an SOF packet is received.

The interpolation function is initialized under the following conditions:

- MCU reset
- USB bus reset
- Suspend state detection

The SOF interpolation operates as follows:

- The interpolation function is not activated until an SOF packet is received
- When the first SOF packet is received, interpolation is performed by counting 1 ms on the 48-MHz internal clock
- When the second and subsequent SOF packets are received, interpolation is performed at the previous reception interval
- Interpolation is not performed in the Suspend state or on reception of a USB bus reset

The USBFS supports the following functions controlled by SOF packet reception. These functions operate normally with SOF interpolation if the SOF packet is missing:

- Updating of the frame number
- SOFR interrupt timing
- Isochronous transfer interval count

If an SOF packet is missing during full-speed operation, the FRMNUM.FRNM[10:0] bits are not updated.

27.3.14 Pipe Schedule

27.3.14.1 Conditions for generating transactions

In host controller mode and when the DVSTCTR0.UACT bit is set to 1, the USBFS generates transactions under the conditions shown in Table 27.29.

Table 27.29 Conditions for generating transactions

Transaction	Conditions for generation				
	DIR	PID	IITV0	Buffer state	SUREQ
Setup	—*1	—*1	—*1	—*1	1 setting
Control transfer data stage, status stage, bulk transfer	IN	BUF	Invalid	Receive area exists	—*1
	OUT	BUF	Invalid	Transmit data exists	—*1
Interrupt transfer	IN	BUF	Valid	Receive area exists	—*1
	OUT	BUF	Valid	Transmit data exists	—*1
Isochronous transfer	IN	BUF	Valid	*2	—*1
	OUT	BUF	Valid	*3	—*1

Note 1. An em dash (—) in the table indicates that the condition is unrelated to the generating of tokens. "Valid" indicates that, for interrupt transfers and isochronous transfers, a transaction is generated only in transfer frames that are based on the interval counter. "Invalid" indicates that a transaction is generated regardless of the interval counter.

Note 2. This indicates that a transaction is generated regardless of whether there is a receive area. If there is no receive area, however, the received data is discarded.

Note 3. This indicates that a transaction is generated regardless of whether there is any data to be transmitted. If there is no data to be transmitted, however, a zero-length packet is transmitted.

27.3.14.2 Transfer schedule

This section describes the transfer scheduling within a frame of the USBFS. After the USBFS sends an SOF, the transfer is carried out in the following sequence:

1. Execution of periodic transfers:

A pipe is searched for in the order of pipe 1 → pipe 2 → pipe 6 → pipe 7 → pipe 8 → pipe 9, and then if there is a pipe for which an isochronous or interrupt transfer transaction can be generated, the transaction is generated.

2. Setup transactions for control transfers:

The DCP is checked, and if a setup transaction is possible, it is sent.

3. Execution of bulk transfers, control transfer data stages, and control transfer status stages:

A pipe is searched for in the order of DCP → pipe 1 → pipe 2 → pipe 3 → pipe 4 → pipe 5, and then if there is a pipe for which a transaction for a bulk transfer, a control transfer data stage, or a control transfer status stage can be generated, the transaction is generated.

When a transaction is generated, processing moves to the next pipe transaction regardless of whether the response from the peripheral device is ACK or NAK. If there is time for transfer within the frame, step 3 is repeated.

27.3.14.3 Enabling USB communication

Setting the DVSTCTR0.UACT bit to 1 initiates an SOF transmission, and transaction generation is enabled. Setting the UACT bit to 0 stops SOF transmission and the Suspend state is invoked. If the UACT setting is changed from 1 to 0, processing stops after the next SOF is sent.

27.4 Usage Notes

27.4.1 Settings for the Module-Stop State

USBFS operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The USBFS is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

27.4.2 Clearing the Interrupt Status Register on Canceling Software Standby Mode

Because the input buffer is always enabled in Software Standby mode, an unexpected interrupt might occur under the following conditions:

- When the interrupt is enabled in Normal mode
- When the interrupt is disabled in Software Standby mode
- When the input level of the pin that cancels software standby mode is changed in Software Standby mode

These conditions might cause the associated interrupt flag in the Interrupt Status Register to set unexpectedly. After the MCU cancels the Software Standby mode, the unexpected interrupt might be sent to the interrupt controller. To avoid this, always clear the INTSTS0 and INTSTS1 registers in the canceling sequence.

27.4.3 Clearing the Interrupt Status Register after Setting Up the Port Function

The input buffer is disabled before the PmnPFS.PSEL and PmnPFS.PMR port is set up, so the internal signal is fixed high or low. The input buffer is enabled after the port is set so that the external pin state is propagated to the MCU. An unexpected interrupt might occur at this time, causing the VBINT and OVRCCR bits in INTSTS0 and INTSTS1, or other interrupt status flags to set to 1. To avoid a malfunction, always clear the INTSTS0 and INTSTS1 registers after setting up the port.

27.4.4 Setting Up the Port Function before setting USB function

USB_DP, USB_DM pins are compatible with P814, P815 I/O ports. So before setting USBFS registers to enable USBFS function, set register bit P814PFS.PMR and P815PFS.PMR to 1.

28. Serial Communications Interface (SCI)

This is the SCI_B version of the SCI peripheral module.

SCI_B is referred to as SCI in this chapter.

28.1 Overview

The Serial Communications Interface (SCI) × 6 channels have asynchronous and synchronous serial interfaces:

- Asynchronous interfaces (UART and Asynchronous Communications Interface Adapter (ACIA))
- 8-bit clock synchronous interface
- Simple IIC (master-only)
- Simple SPI
- Simple LIN
- Smart card interface
- Manchester interface

The smart card interface complies with the ISO/IEC 7816-3 standard for electronic signals and transmission protocol. SCIn (n = 0 to 4, 9) has FIFO buffers to enable continuous and full-duplex communication, and the data transfer speed can be configured independently using an on-chip baud rate generator.

In this section, PCLK refers to PCLKA.

Table 28.1 lists the SCI specifications, Table 28.2 shows the functions of each SCI channel, Figure 28.1 shows a block diagram of SCI, Figure 28.2 shows a clock source selector block diagram, and Table 28.3 lists the I/O pins.

Table 28.1 SCI specifications (1 of 4)

Parameter	Specifications
Number of modules	6 (SCIn (n = 0 to 4, 9))
Serial communication modes	<ul style="list-style-type: none"> • Asynchronous • Clock synchronous • Simple IIC • Simple SPI • Simple LIN (SCIn (n = 0, 1)) • Smart card interface • Manchester interface (SCIn (n = 0))
Operation clock (TCLK)	Synchronized clock (PCLK) or independent clock (SCICLK) can be selected
Transfer speed	Bit rate specifiable with the on-chip baud rate generator
Full-duplex communications	<ul style="list-style-type: none"> • Transmitter: Continuous transmission possible using double-buffering • Receiver: Continuous reception possible using double-buffering
Half-duplex communications	Half-duplex communication is possible by using only TXDn pins
Data transfer	Selectable as LSB-first or MSB-first transfer
Inverter for communication pins (RXDn, TXDn)	Selectable inverter for each pins (RXDn, TXDn)
Interrupt sources	Transmit end, transmit data empty, receive data full, receive error, receive data ready, address match. Break Field detection/output, Bus collision detection, Active edge detection. (SCIn (n = 0, 1)). Completion of generation of a start condition, restart condition, or stop condition. (for simple IIC mode)
Loop Back function	Self-diagnosis of communication function by SCI internal transmission / reception is possible
Synchronizer Bypass function	Ability to bypass synchronization circuit between bus clock (PCLK) and operation clock (TCLK)
Module-stop function	Module-stop state can be set for each channels to reduce power consumption
Reception in Software Standby mode	Only SCIO is available
Clock synchronous mode	Data length
	8 bits

Table 28.1 SCI specifications (2 of 4)

Parameter		Specifications
	Adjustment of receive sampling timing	Adjustable receive sampling timing after the default timing in master mode only when using internal clock
	Receive error detection	Overrun error
	Clock source	Selectable to internal clock (master mode) or external clock (slave mode)
	Double-speed mode	Baud rate generator double-speed mode is selectable
	Hardware flow control	Transmission and reception controllable with CTSn_RTSn pins
	Transmission and reception	Selectable to 1-stage register or 16-stage FIFO
Asynchronous mode	Data length	7, 8, or 9 bits
	Transmission stop bit	1 or 2 bits
	Adjustment of receive sampling timing	Adjustable receive sampling timing before/after the default timing
	Adjustment of transmit timing	Adjustable edge timing of transmit waveform controlled by the setting value of registers.
	Parity	Even parity, odd parity, or no parity
	Receive error detection	<ul style="list-style-type: none"> • Parity error • Overrun error • Framing error
	Hardware flow control	Transmission and reception controllable with CTSn_RTSn pin and CTSn pin
	Transmission and reception	Selectable to 1-stage register or 16-stage FIFO
	Address match	Interrupt request/event output can be issued upon detecting a match between received data and the value in the compare match register
	Start-bit detection	Selectable to low level or falling edge detection
	Break detection	Breaks from framing errors detectable by read from CSR register
	Clock source	Selectable to internal or external clock. Transfer rate clock input from the GPT can be used. (SCI1)
	Double-speed mode	Baud rate generator double-speed mode is selectable
	Multi-processor communications function	Serial communication enabled among multiple processors
	RS-485 driver control function	Output DEn signal to enable external transceiver transmit mode
Noise cancellation	Digital noise filters included on signal paths from the RXDn pin inputs	
Smart card interface mode	Error processing	Error signal can be automatically transmitted upon detecting a parity error during reception
		Data can be automatically retransmitted upon receiving an error signal during transmission
Data type	Both direct and inverse convention supported	
Manchester mode	Communication format	Manchester code with the preface and the Start Bit added
	Data length	7, 8, or 9 bits
	Transmission stop bit	1 or 2 bits
	Parity function	Even parity, odd parity, or no parity
	Receive error detection	Parity, overrun, framing, Manchester errors
	Hardware flow control	Transmission and reception controllable with CTSn_RTSn pin and CTSn pin
	Clock source	Only internal clock can be used.
Double-speed mode	Baud rate generator double-speed mode is selectable	

Table 28.1 SCI specifications (3 of 4)

Parameter		Specifications
	Multi-processor communication function	Serial communication among multiple processors
	Manchester encoding / decoding function	Function to perform Manchester encoding / decoding of transmission / reception data and communicate using Manchester code
	Noise cancellation	The signal paths from input on the RXDn pins incorporate digital noise filters
	Preface setting / detection function	The function outputs the configured the preface pattern and detects it.
	Start Bit setting / detection function	The function outputs the configured the Start Bit pattern and detects it.
	Reception retiming function	Timing correction is performed for each bit of the received signal
Simple IIC mode	Transfer format	I ² C bus format (MSB-first only)
	Operating mode	Master (single-master operation only)
	Transfer rate	Up to 400 kbps
	Noise cancellation	The signal paths from input on the SCLn and SDAn pins incorporate digital noise filters and provide an adjustable interval for noise cancellation
Simple SPI mode	Data length	8 bits
	Error detection	Overrun error
	Clock source	Selectable to internal clock (master mode) or external clock (slave mode)
	Double-speed mode	Baud rate generator double-speed mode is selectable
	Transmission / Reception	Selectable either 1 stage register or 16-stage FIFO
	Adjustment of receive sampling timing	Adjustable receive sampling timing after the default timing in master mode only when using internal clock
	SSn input pin function	High impedance state can be invoked on the output pins by driving the SSn pin high.
Simple LIN mode	Clock settings	Configurable among four clock phase and clock polarity settings
	Start Frame Transmission	<ul style="list-style-type: none"> Break Field output possible, Break Field output complete interrupt output possible Bus collision detection possible, bus collision detection interrupt output possible
	Start Frame Reception	<ul style="list-style-type: none"> Break Field detectable, Break Field detected interrupt output possible Control Field 0/1 data comparison function Control Field 1 can set two types of comparison data of primary and secondary Priority interrupt bit can be set in Control Field 1 Handling of Start Frames that do not include a Break Field Handling of Start Frames that do not include a Control Field 0 Bit rate measurement function
	Input/Output control function	<ul style="list-style-type: none"> Selectable polarity for TXDn and RXDn signals Selection of a digital filter for the RXDn signal Half-duplex operation employing RXDn and TXDn signals multiplexed on the same pin Selectable timing for the sampling of data received through RXDn
Bit rate modulation function		Error reduction through correction of outputs from the on-chip baud rate generator
Event link function		Error event output for receive error or error signal detection (SCIn_ERI) (n = 0 to 4, 9)
		Receive data full event output (SCIn_RXI) (n = 0 to 4, 9)
		Transmit data empty event output (SCIn_TXI) (n = 0 to 4, 9)
		Address match event output (SCIn_AM) (n = 0 to 4, 9)
		Active edge detection event output (SCIn_AED) (n = 0, 1)
		Transmit end event output (SCIn_TEI) (n = 0 to 4, 9)

28.2 Register Descriptions

28.2.1 RSR : Receive Shift Register

RSR is a shift register that receives serial data input from the RXD_n pin and converts it into parallel data. When one frame of data is received, the data is automatically transferred to the RDR register. The RSR register cannot be directly accessed by the CPU.

28.2.2 RDR/RDR_BY : Receive Data Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
 SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	FER	PER	—	—	ORER	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	FFER	FPER	DR	MPB	RDAT[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
8:0	RDAT[8:0]	Serial receive data RDAT is a 9-bit register for storing received data. Received data is stored in [6:0] when 7-bit data is selected, in [7:0] when 8-bit data is selected, and in [8:0] when 9-bit data is selected. And 0 is stored in the unused bit. Use RDR_BY for byte access to RDR[7:0].	R
9	MPB	Multi-processor flag 0: Data transmission cycles 1: ID transmission cycles	R
10	DR	Receive data ready flag FRSR.DR can be read.	R
11	FPER	FIFO parity error flag Valid only in Asynchronous mode 0: There is no parity error in the data read from the receive-FIFO 1: There is parity error in the data read from the receive-FIFO	R
12	FFER	FIFO framing error flag Valid only in Asynchronous mode 0: There is no framing error in the data read from the receive-FIFO 1: There is framing error in the data read from the receive-FIFO	R
23:13	—	These bits are read as 0.	R
24	ORER	Overrun Error flag CSR.ORER can be read.	R
26:25	—	These bits are read as 0.	R
27	PER	Parity error flag CSR.PER can be read.	R
28	FER	Framing error flag CSR.FER can be read.	R
31:29	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

In FIFO mode (CCR3.FM = 1), the RDR/RDR_BY is 16-stage FIFO buffer configuration.

When using FIFO mode, use RDR for 32-bit access.

RDAT[8:0] bits (Serial receive data)

After one frame of data is received, the received data is transferred from the RSR register to this register, thus allowing the RSR register to receive the next data.

The RSR and RDR registers have a double-buffered construction to enable continuous reception.

For Non-FIFO mode, read RDR only once when a receive data full interrupt (SCIn_RXI) request is issued. Without reading received data from RDR, if the next one frame is received, an overrun error occurs.

For FIFO mode, continuous reception is executed until 16 stages are stored. If data is read when there is no received data in the receive-FIFO(RDR), the value is undefined. When the receive-FIFO (RDR) are full of received data, subsequent serial receive data is lost.

The CPU cannot write to RDR.

0 is stored in the bit position which isn't received (RDR.bit8 or RDR.bit7) at the time of 7bit or 8bit communication of Asynchronous and Manchester mode.

MPB bit (Multi-processor flag)

In Asynchronous mode and Manchester mode, during multi-processor communication (CCR3.MP = 1), the value of the multi-processor bit corresponding to the received data (RDAT[8:0]) can be read.

FPER bit (FIFO parity error flag)

Indicates whether the data read from the receive-FIFO has a parity error.

0 is stored for non-FIFO mode.

FFER bit (FIFO framing error flag)

Indicates whether the data read from receive-FIFO has a framing error.

0 is stored for non-FIFO mode.

28.2.3 TDR/TDRLL/TDRLH : Transmit Data Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
 SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x04(TDR/TDRLL)
 0x05(TDRLH)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	TSYN C	—	—	MPBT	TDAT[8:0]								
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
8:0	TDAT[8:0]	Serial transmit data TDAT is a 9-bit register for setting transmit data. Transmit data is set in [6:0] when 7-bit data is selected, in [7:0] when 8-bit data is selected, and in [8:0] when 9-bit data is selected. When byte access, write TDR [15:8] and then write TDR [7:0]. Use TDRLL for byte access to TDR[7:0], TDRLH for byte access to TDR[15:8].	R/W
9	MPBT	Multi-processor transfer bit flag Value of the multi-processor bit in the transmission frame. This bit is use in Asynchronous and Manchester mode. When writing to this bit when not used, write the initial value. 0: Data transmission cycles 1: ID transmission cycles	R/W
11:10	—	These bits are read as 1. The write value should be 1.	R/W
12	TSYNC	Transmit SYNC data It is valid when MCR.SBSEL = 1 and MCR.SYNSEL = 1 in Manchester mode. When this bit is not used, write the initial value. 0: The Start Bit is transmitted as DATA SYNC. 1: The Start Bit is transmitted as COMMAND SYNC.	R/W
31:13	—	These bits are read as 1. The write value should be 1.	R/W

Note: S-TYPE-3, P-TYPE-3

In FIFO mode (CCR3.FM = 1), the TDR/TDRLL/TDRLH is 16-stage FIFO buffer configuration.

When using FIFO mode, use TDR for 32-bit access.

TDAT[8:0] bits (Serial transmit data)

The is a 9-bit register for storing transmit data.

When empty space is detected in the TSR register, the transmit data stored in the TDR/TDRLL/TDR LH registers is transferred to TSR, and transmitting is started.

The TSR and TDR/TDRLL/TDR LH registers have a double-buffered construction to realize continuous transmission. When the next data to be transmitted is stored in TDR/TDRLL/TDR LH after one frame of data has been transmitted, the transmitting operation is continued by transfer to the TSR register.

When the SCI detects that the transmit shift register (TSR) is empty, it transmits data written in the transmit-FIFO (TDR/TDRLL/TDR LH) into TSR and starts serial transmission. Continuous serial transmission is executed until there is no transmit data left in the transmit-FIFO (TDR/TDRLL/TDR LH).

For non-FIFO mode, when a transmit data empty interrupt (SCIn_TXI) request is issued and CCR0.TE is 1, write transmit data to the TDR only once.

For FIFO mode, when transmit-FIFO is full of transmit data 16 frames, no more data can be written. If writing of new data is attempted, the data is ignored.

The TDR/TDRLL/TDR LH register can always be read / written from the CPU. And when byte access, write TDR/TDRLL/TDR LH[15:8] and then write TDR/TDRLL/TDR LH[7:0].

MPBT bit (Multi-processor transfer bit flag)

Selects the multi processor bit of transmit frame.

TSYNC bit (Transmit SYNC data)

When Manchester mode and MCR.SBSEL = 1 and MCR.SYNSEL = 1, the type of SYNC selected according to the TSYNC bit becomes the Start Bit of the transmission frame.

28.2.4 TSR : Transmit Shift Register

TSR is a shift register that transmits serial data. To perform serial data transmission, the SCI first automatically transfers transmit data from TDR to TSR, then sends the data to the TXDn pin. The CPU cannot directly access the TSR.

28.2.5 CCR0 : Common Control Register 0

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
 SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	SSE	—	—	TEIE	TIE	—	—	—	RIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	IDSEL	DCME	MPIE	—	—	—	TE	—	—	—	RE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RE	Receive Enable 0: Serial reception is disabled 1: Serial reception is enabled	R/W ^{*1} *3
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	TE	Transmit Enable 0: Serial transmission is disabled 1: Serial transmission is enabled	R/W ^{*1}

Bit	Symbol	Function	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	MPIE	Multi-Processor Interrupt Enable Valid in Asynchronous mode and Manchester mode when CCR3.MP is 1. This bit should set 0 in Smart card interface mode. 0: Non-multi-processor reception 1: Multi-processor reception When the data with the multi-processor bit set to 0 is received, the data is not read, and setting the status flags to 1 is disabled. When the data with the multi-processor bit set to 1 is received, the MPIE bit is automatically cleared to 0, and non-multi-processor reception is resumed. If you want to continue receiving operation using the multiprocessor function, set this bit to 1 sufficiently earlier than receiving the STOP bit of the next received frame (consider the synchronization delay time).	R/W ²
9	DCME	Data Compare Match Enable Valid only in Asynchronous mode 0: Address match function is disabled 1: Address match function is enabled	R/W ²
10	IDSEL	ID Frame Select Valid only in Asynchronous mode with multi-processor 0: Compare data irrespective of the value of the MPB bit 1: Compare data only when the MPB bit is 1 (ID frame)	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
16	RIE	Receive Interrupt Enable 0: SCIn_RXI and SCIn_ERI interrupt requests are disabled 1: SCIn_RXI and SCIn_ERI interrupt requests are enabled	R/W
19:17	—	These bits are read as 0. The write value should be 0.	R/W
20	TIE	Transmit Interrupt Enable 0: SCIn_TXI interrupt request is disabled 1: SCIn_TXI interrupt request is enabled	R/W
21	TEIE	Transmit End Interrupt Enable This bit should set 0 in Smart card interface mode. 0: SCIn_TEI interrupt request is disabled 1: SCIn_TEI interrupt request is enabled	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
24	SSE	SSn Pin Function Enable Valid in Simple SPI mode. In slave mode (CCR3.CKE[1:0] = 1x), set 1 to this bit. 0: SSn pin function is disabled 1: SSn pin function is enabled	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. In Clock synchronous mode (CCR3.MOD[2:0] = 010b), Simple SPI mode (CCR3.MOD[2:0] = 011b), and Simple IIC mode (CCR3.MOD[2:0] = 100b), 1 can be written only when TE = 0 and RE = 0. After setting TE or RE to 1, only 0 can be written in TE and RE. In other mode, writing is enabled under any condition.

Note 2. This bit is a bit that is cleared by hardware. Note that writing to a bit other than this bit with a bit manipulation instruction may cause this bit to be unintentionally set to 1 by a read-modify-write operation.

Note 3. In Clock synchronous mode or Simple SPI mode, and internal clock (master mode), receive-only setting is prohibited in the internal clock (master mode) (TE = 0 and RE = 1 setting prohibited).

RE bit (Receive Enable)

Enables or disables serial receive operation.

When the RE bit is set to 1, serial reception becomes possible after the synchronization delay time has elapsed in Asynchronous mode or the synchronous clock input in Clock synchronous mode or the neg-edge of RXDn in Manchester mode or start bit in Smart card interface mode.

Note that CCR3 should be set prior to setting the RE bit to 1 in order to designate the reception format.

Except Smart card interface mode, even if reception is halted by setting the RE bit to 0, the CSR.RDRF, FER, PER, ORER, MSR.MER, SBER, SYER, PFER, FRSR. DR flags are not affected, and the previous values is retained. In Smart card interface mode, even if reception is halted by setting the RE bit to 0, the CSR.FER, PER, ORER flags are not affected and

the previous value is retained. Also, to stop the reception operation, synchronization delay time is required from when the RE bit is set to 0 until the reception operation is stopped.

TE bit (Transmit Enable)

Enables or disables serial transmission.

When the TE bit is set to 1, serial transmission becomes possible after the synchronization delay time has elapsed. After the synchronization delay time, transmission is started by writing transmit data to TDR. Note that CCR3 should be set prior to setting the TE bit to 1 in order to designate the transmission format. In addition, the synchronization delay time is required until the transmission control circuit is stopped after the TE bit is set to 0.

MPIE bit (Multi-Processor Interrupt Enable)

When the MPIE bit is set to 1 and data with the multi-processor bit set to 0 is received, the data is not read and setting the status flags (CSR.RDRF, ORER, FER, FRSR, DR, MSR.MER, SYER, PFER, SBER) are disabled.

When data with the multi-processor bit set to 1 is received, the MPIE is automatically cleared to 0, and normal reception is resumed. For details, see [section 28.4. Multi-Processor Communication Function](#). If you want to continue receiving operation using the multi-processor function, set this bit to 1 sufficiently earlier than receiving the STOP bit of the next received frame.

When the receive data includes the MPB bit set to 0, the receive data is not transferred from the RSR to the RDR, a receive error is not detected, and setting the flags ORER, FER, MER, SYER, PFER, and SBER to 1 is disabled.

When the receive data includes the MPB bit set to 1, the MPIE bit is automatically cleared to 0, the SCIn_RXI and SCIn_ERI interrupt requests are enabled (if CCR0.RIE is set to 1), and setting the flags ORER, FER, MER, SYER, PFER, and SBER to 1 is enabled.

MPIE should be set to 0 if multi-processor communications function is not to be used.

DCME bit (Data Compare Match Enable)

The DCME bit selects whether the address match function (data compare match function) is enabled or not.

When DCME is 1, if SCI detects the match to the comparison data (CCR4.CMPD) with receive data, DCME is cleared automatically, and after that, SCI operation mode is in receive mode without data compare match function.

See [section 28.3.6. Address Match \(Receive Data Match Detection\) Function](#).

The write value should be 0 other than Asynchronous mode.

IDSEL bit (ID Frame Select)

The IDSEL bit selects whether to compare data irrespective of the value of MPB bit or to compare data only when the MPB bit = 1 (ID frame) when the address match function is valid. Set at the same time as DCME.

RIE bit (Receive Interrupt Enable)

Enables or disables SCIn_RXI and SCIn_ERI interrupt requests.

SCIn_RXI and SCIn_ERI interrupt request is disabled by setting the RIE bit to 0.

An SCIn_ERI interrupt request can be canceled by reading 1 from the CSR.ORER, FER, or PER and then setting the flag to 0 or setting the RIE bit to 0.

In Manchester mode, the MER, SYER, PFER and SBER flags are also the cause of SCIn_ERI interrupt request, so the same processing is necessary. For details of these flags, see [section 28.2.12. MCR : Manchester Control Register](#) and [section 28.2.21. MSR : Manchester Status Register](#).

TIE bit (Transmit Interrupt Enable)

Enables or disables SCIn_TXI interrupt request.

An SCIn_TXI interrupt request is disabled by setting the TIE bit to 0. At the beginning of transmission, set 1 to CCR0.TE and CCR0.TIE simultaneously. The SCIn_TXI interrupt request is then generated.

TEIE bit (Transmit End Interrupt Enable)

Enables or disables a SCIn_TEI interrupt request. A SCIn_TEI interrupt request is disabled by setting the TEIE bit to 0.

In simple IIC mode, the SCIn_TEI is allocated to the interrupt on completion of issuing a start, restart, or stop condition (STIn). In this case, the TEIE bit can be used to enable or disable the STIn.

SSE bit (SSn Pin Function Enable)

Set the SSE bit to 1 if the SSn pin is to be used in control of transmission and reception (in simple SPI mode).

Set the SSE bit to 0 in any other mode. Do not set both the SSE and CTSE bits to enabled (even if this setting is made, operation is the same as that when these bits are set to 0).

In the slave mode (CCR3.CKE[1:0] = 10 or 11), SSE should be set 1.

In the master mode (CCR3.CKE[1:0] = 00 or 01) and single-master, the SSn pin on the master side is not required to control reception and transmission, so SSE should be set 0.

28.2.6 CCR1 : Common Control Register 1

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
 SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x0C

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
0	CTSE	CTS Enable 0: CTS function is disabled (RTS output function is enabled) 1: CTS function is enabled	R/W
1	CTSPEN	CTS External Pin Enable 0: Alternate setting to use CTS and RTS functions as either 1 pin 1: Dedicated setting for separately using CTS and RTS functions with 2 pins	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	SPB2DT	Serial Port Break Data Select The output level of TXDn pin is selected when CCR0.TE = 0 and SPB2IO = 1.*1 0: When TINV is 0, low level is output in TXDn pin. When TINV is 1, high level is output in TXDn pin. 1: When TINV is 0, high level is output in TXDn pin. When TINV is 1, low level is output in TXDn pin.	R/W
5	SPB2IO	Serial Port Break I/O This bit selects whether the value of SPB2DT is output to TXDn pin when CCR0.TE = 0.*1 0: The value of SPB2DT bit is not output in TXDn pin 1: The value of SPB2DT bit is output in TXDn pin	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
8	PE	Parity Enable Valid only in Asynchronous mode and Manchester mode. In Smart Card Interface mode, set 1 to this bit. 0: When transmitting: Do not add parity bit When receiving: Do not check parity bit 1: When transmitting: Add parity bit When receiving: Check parity bit	R/W
9	PM	Parity Mode Valid only when the PE bit is 1 0: Selects even parity 1: Selects odd parity	R/W

Bit	Symbol	Function	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
12	TINV	TXD Invert 0: Transmit data is not inverted and output to TXDn*2 1: Transmit data is inverted and output to TXDn	R/W
13	RINV	RXD Invert 0: Received data from RXDn is not inverted and input*2 1: Received data from RXDn is inverted and input	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
16	SPLP	Loopback Control This bit can be used for internal clock operation in Asynchronous mode, internal mode operation in Manchester mode, internal clock operation in Clock synchronous mode. 0: Normal mode 1: Loopback mode	R/W
19:17	—	These bits are read as 0. The write value should be 0.	R/W
20	SHARPS	Half-Duplex Communication Select In Simple IIC mode, Smart Card Interface mode, or Simple SPI mode, this bit should be set to 0. 0: TXDn pin, RXDn pin independent 1: TXDn/RXDn pin combination use (half-duplex communication using TXDn pin)	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
26:24	NFCS[2:0]	Noise Filter Clock Select Valid in Asynchronous mode and Manchester mode, Simple LIN mode, and Simple IIC mode. In Simple IIC mode, 000 setting is prohibited. The on-chip baud rate generator source clock means the clock selected by CCR2.CKS [1:0]. Select for the clock source of the noise filter. 0 0 0: The base clock signal divided by 1 0 0 1: The on-chip baud rate generator source clock divided by 1 0 1 0: The on-chip baud rate generator source clock divided by 2 0 1 1: The on-chip baud rate generator source clock divided by 4 1 0 0: The on-chip baud rate generator source clock divided by 8 others: Setting prohibited	R/W
27	—	This bit is read as 0. The write value should be 0.	R/W
28	NFEN	Digital Noise Filter Function Enable Valid in Asynchronous mode, Manchester mode, Simple LIN mode, and Simple IIC mode 0: In Asynchronous, Manchester, Simple LIN modes: Disable noise cancellation function for RXDn input signal In Simple IIC mode: Disable noise cancellation function for SCLn and SDAn input signals 1: In Asynchronous, Manchester, Simple LIN modes: Enable noise cancellation function for RXDn input signal In Simple IIC mode: Enable noise cancellation function for SCLn and SDAn input signals	R/W
29	NFM	Noise Filter Mode Valid in asynchronous mode and ABCSE2 = 1 0: 3-point matching mode 1: Majority vote mode	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Use this bit in Asynchronous mode and Manchester mode only. Operation in other mode is not guaranteed.

Note 2. RINV/TINV should be set to 0 in Smart card interface mode and Simple IIC mode.

CTSE bit (CTS Enable)

Set the CTSE bit to 1 if the SSn pin is to be used for inputting of the CTSn control signal to control of transmission and reception. The RTSn signal is output when this bit is set to 0. Set this bit to 0 in smart card interface mode, simple SPI mode, Simple LIN mode, and simple IIC mode. Do not set both the CTSE and SSE bits to enabled (even if this setting is made, operation is the same as that when these bits are set to 0).

CTSPEN bit (CTS External Pin Enable)

When CTSE is 1, select the pins usage method when using the CTS and RTS functions. Set this bit to 1 when assigning the CTS/RTS function to 2 pins and using them at the same time. Set it to 0 except in Asynchronous and Manchester modes.

Table 28.4 shows the relationship between the CTSE bit and CTSPEN bit settings and the functions of the CTSn_RTSn pin and CTSn pin.

Table 28.4 CTSE bit and CTSPEN bit settings and pin functions

CTSE bit	CTSPEN bit	CTS _n _RTS _n pin	CTS _n pin
0	0	RTS _n signal output	Not use
1	0	CTS _n signal input	Not use
1	1	RTS _n signal output	CTS _n signal input
0	1	prohibition	prohibition

SPB2DT bit (Serial Port Break Data Select), SPB2IO bit (Serial Port Break I/O)

The TXD_n pin status determined by combination of CCR0.TE bit, CCR1.SPB2IO bit, and CCR1.SPB2DT bit is indicated in Table 28.5.

Table 28.5 TXD_n pin status

Value of CCR0.TE	Value of CCR1.SPB2IO	Value of CCR1.SPB2DT	TXD _n pin status (when TINV is 0)
0	0	—	Hi-Z (initial value)
0	1	0	Low level output
0	1	1	High level output
1	—	—	Serial transmission data is output

Note: —: Don't care

PE bit (Parity Enable)

When the PE bit to 1, the parity bit is added to transmit data before transmission, and the parity bit is checked in reception.

In the multi-processor format, the parity bit is not added or checked regardless of the PE bit setting.

PM bit (Parity Mode)

The PM bit selects the parity mode for transmission and reception (even or odd). In Multi-processor mode, the PM bit is invalid.

For details on the usage of this bit in Smart card interface mode, see [section 28.7.2. Data Format \(Except in Block Transfer Mode\)](#).

TINV bit (TXD Invert), RINV bit (RXD Invert)

The data of RDR is controlled by RINV and CCR3.SINV. And the data from TXD_n pin is controlled by TINV and CCR3.SINV. The control by RINV/TINV are done to communication pins (RXD_n / TXD_n), so they can control not only data-bits but also other bits (start bit, stop bit, parity bit). For details, see [Figure 28.3](#).

During half-duplex communication and slave operation in Simple SPI mode, use the TXD_n pin for reception, so set the inversion control of the received data with the TINV bit.

Note: Description and a timing chart of the SCI operation are provided when TINV = 0 and RINV = 0 (when the value of TINV and the value of RINV are not specified).

Figure 28.3 Example of receive or transmit data control

SPLP bit (Loopback Control)

When the SPLP bit is 1, SCI blocks the input path from RXDn and connects the output path to TXDn to the reception data register.

Transmit data can be inverted and received by combining it with TINV bit.

Set this bit to 0 for slave operation in Clock synchronous mode, when using an external clock in Asynchronous mode, and when in Simple LIN mode.

SHARPS bit (Half-Duplex Communication Select)

Setting the SHARPS bit to 1 enables half-duplex communication using the TXDn pin. However, the SHARPS bit cannot be used in Simple SPI mode, Simple IIC mode and Smart card interface mode.

If the SHARPS bit is set to 1 and CCR0.TE = 1, CCR0.RE = 0, the TXDn pin becomes the communication output. If this bit is set to 1 and CCR0.TE = 0, CCR0.RE = 1, the TXDn pin becomes the communication input. For details, see [section 28.17. Half-Duplex communication Function](#).

NFCS[2:0] bits (Noise Filter Clock Select)

The NFCS[2:0] bits select the sampling clock for the digital noise filter.

To use the noise filter in Asynchronous mode, Manchester mode, and Simple LIN mode set the NFCS[2:0] bits from 000b to 100b. In Simple IIC mode, set the bits to a value in the range from 001b to 100b. In particular, if the ABCSE or ABCSE2 bit is set to 1 in asynchronous mode, set it to 000b or 001b.

NFEN bit (Digital Noise Filter Function Enable)

The NFEN bit enables or disables the digital noise filter function. When the function is enabled, noise cancellation is applied to the RXDn input signal in Asynchronous mode, Manchester mode, Simple LIN mode, and noise cancellation is applied to the SDAn and SCLn input signals in Simple IIC mode. In any mode other than above, set the NFEN bit to 0 to disable the digital noise filter function. When the function is disabled, input signals are transferred as is, as internal signals.

NFM bit (Noise Filter Mode)

The NFM bit selects the operation mode of the digital noise filter function. For details, see [section 28.14. Noise Cancellation Function](#).

28.2.7 CCR2 : Common Control Register 2

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
 SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

23:22	—	These bits are read as 0. The write value should be 0.	R/W
31:24	MDDR[7:0]	Modulation Duty Setting MDDR corrects the bit rate adjusted by the BRR[7:0] bits.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. S is the value of S in BRR[7:0] bits explanation.

Note 2. n is the decimal notation of the value of n in BRR[7:0] bits explanation.

BCP[2:0] bits (Base Clock Pulse)

The BCP[2:0] bits select the number of base clock cycles in a 1-bit data transfer time in smart card interface mode.

For details, see [section 28.7.4. Receive Data Sampling Timing and Reception Margin](#).

BGDM bit (Baud Rate Generator Double-Speed Mode Select)

The BGDM bit is valid when the on-chip baud rate generator is selected as the clock source (CCR3.CKE[1] = 0) in Asynchronous mode, Manchester mode, Clock synchronous mode, Simple SPI mode. When external clock is selected (CCR3.CKE[1] = 1), set it to 0. For the clock output from the baud rate generator, either single or doubled frequency can be selected. The base clock is generated by the clock output from the baud rate generator. When the BGDM bit is set to 1, the base clock cycle is halved, and the bit rate is doubled.

Set this bit to 0 in modes other than Asynchronous mode, Manchester mode, Clock synchronous mode, or Simple SPI mode.

ABCS bit (Asynchronous Mode Base Clock Select)

Selects the clock cycles for 1-bit period.

Set the ABCS bit to 0 in modes other than Asynchronous mode, Manchester mode, or Simple LIN mode.

ABCSE bit (Asynchronous Mode Extended Base Clock Select)

The pulse number for a base clock at 1-bit period is 6 and the clock of a double frequency is output from baud rate generator. Only when the bit rate is set to 6 dividing frequency of the bus clock can this bit be used to set CCR2.CKS [1:0] = 00b and BRR[7:0] = 0x00.

Set it to 0 in modes other than Asynchronous mode. Even in Asynchronous mode, set it to 0 when using external clock.

ABCSE2 bit (Asynchronous Mode Extended Base Clock Select 2)

The pulse number for a base clock at 1-bit period is 4 and the clock of a double frequency is output from baud rate generator. Only when the bit rate is set to 4 dividing frequency of the bus clock, please use this bit and set CCR2.CKS [1:0] = 00 and BRR[7:0] = 0.

Set it to 0 in modes other than asynchronous mode. Even in asynchronous mode, set it to 0 when using external clock.

Table 28.6 Base clock cycle number per 1-bit

ABCSE2	ABCSE	ABCS	BGDM	The base clock cycles /1bit	The frequency of the baud rate generator
0	0	0	0	16	×1
0	0	0	1	16	×2
0	0	1	0	8	×1
0	0	1	1	8	×2
0	1	— (don't care)	— (don't care)	6	×2
1	0	— (don't care)	— (don't care)	4	×2

BRR[7:0] bit (Bit Rate Setting)

BRR is an 8-bit register that adjusts the bit rate.

SCI has independent baud rate generator control, different bit rates can be set for each. Table 28.7 shows the relationship between the setting (N) in the BRR and the bit rate (B) for Asynchronous mode, multiprocessor transfer, Manchester mode, clock synchronous mode, smart card interface mode, simple SPI mode, and simple IIC mode.

Table 28.7 Relationship between N Setting in BRR and Bit Rate B

Mode	CCR2 settings				BRR[7:0] setting	Error*4
	BGDM bit	ABCS bit	ABCSE bit	ABCSE 2 bit		
Asynchronous, multi-processor, Manchester*2, Simple-LIN*3	0	0	0	0	$N = \frac{TCLK \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	$Error (\%) = \left\{ \frac{TCLK \times 10^6}{B \times 64 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
	1	0	0	0	$N = \frac{TCLK \times 10^6}{32 \times 2^{2n-1} \times B} - 1$	$Error (\%) = \left\{ \frac{TCLK \times 10^6}{B \times 32 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
	0	1	0	0		
	1	1	0	0	$N = \frac{TCLK \times 10^6}{16 \times 2^{2n-1} \times B} - 1$	$Error (\%) = \left\{ \frac{TCLK \times 10^6}{B \times 16 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
	Don't care	Don't care	1	0	$N = \frac{TCLK \times 10^6}{12 \times 2^{2n-1} \times B} - 1$	$Error (\%) = \left\{ \frac{TCLK \times 10^6}{B \times 12 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
	Don't care	Don't care	0	1	$N = \frac{TCLK \times 10^6}{8 \times 2^{2n-1} \times B} - 1$	$Error (\%) = \left\{ \frac{TCLK \times 10^6}{B \times 8 \times 2^{2n-1} \times (N+1)} - 1 \right\} \times 100$
Clock synchronous, simple SPI	0	0 (Initial value)	0 (Initial value)	0 (Initial value)	$N = \frac{TCLK \times 10^6}{8 \times 2^{2n-1} \times B} - 1$	—
	1	0 (Initial value)	0 (Initial value)	0 (Initial value)	$N = \frac{TCLK \times 10^6}{4 \times 2^{2n-1} \times B} - 1$	—
Smart card interface					$N = \frac{TCLK \times 10^6}{S \times 2^{2n+1} \times B} - 1$	$Error (\%) = \left\{ \frac{TCLK \times 10^6}{B \times S \times 2^{2n+1} \times (N+1)} - 1 \right\} \times 100$
Simple IIC*1					$N = \frac{TCLK \times 10^6}{64 \times 2^{2n-1} \times B} - 1$	—

Note: B: Bit rate (bps)
 N: BRR setting for on-chip baud rate generator ($0 \leq N \leq 255$)
 TCLK: Operating frequency (MHz)
 n and S: Determined by the settings of the CCR2 registers as listed in [Table 28.9](#) and [Table 28.10](#). Please be careful about $2^{(2n+1)}$ is used in the expression for Smart card interface, $2^{(2n-1)}$ is used in other mode.

Note 1. Adjust the bit rate so that the widths at high and low level of the SCL output in simple IIC mode satisfy the IIC standard.

Note 2. In Manchester mode, only ABCSE = 0 and ABCSE2 = 0 can be selected.

Note 3. In Simple-LIN mode, BGDM = 0, ABCSE = 0 and ABCSE2 = 0 can be selected.

Note 4. Error means that if the N value calculated by the above formula is not an integer for the baud rate value B to be set, the BRR is set to an approximate integer value in which case it represents the error between the baud rate value and B.

Table 28.8 Calculating widths at high and low Level for SCL

Mode	SCLn	Formula (result in seconds)
IIC	Width at high level (minimum value)	$(N + 1) \times 4 \times 2^{2n-1} \times 7 \times \frac{1}{TCLK \times 10^6}$
	Width at low level (minimum value)	$(N + 1) \times 4 \times 2^{2n-1} \times 8 \times \frac{1}{TCLK \times 10^6}$

Table 28.9 Clock source settings

CCR2 setting	Clock source	n
CKS[1:0] bit		
00	TCLK clock	0
01	TCLK/4 clock	1
10	TCLK/16 clock	2
11	TCLK/64 clock	3

Table 28.10 Base clock settings in Smart card interface mode

CCR2 setting	Base clock cycles for 1-bit period	S
BCP[2:0] setting		
0 0 0	93 clock cycles	93
0 0 1	128 clock cycles	128
0 1 0	186 clock cycles	186
0 1 1	512 clock cycles	512
1 0 0	32 clock cycles	32
1 0 1	64 clock cycles	64
1 1 0	372 clock cycles	372
1 1 1	256 clock cycles	256

[Table 28.11](#) and [Table 28.12](#) list examples of N settings in BRR in Asynchronous mode and Manchester mode. [Table 28.13](#) lists the maximum bit rate settable for each operating frequency. Examples of BRR (N) settings in Clock synchronous mode and Simple SPI mode are listed in [Table 28.16](#). Examples of BRR (N) settings in Smart card interface mode are listed in [Table 28.18](#). Examples of BRR (N) settings in Simple IIC mode are listed in [Table 28.20](#). In Smart card interface mode, the number of base clock cycles S in a 1-bit data transfer time can be selected. For details, see [section 28.7.4. Receive Data Sampling Timing and Reception Margin](#). [Table 28.14](#) and [Table 28.17](#) list the maximum bit rates with external clock input. [Table 28.15](#) lists the maximum bit rates with GPT clock input.

When either the Asynchronous mode base clock select bit (ABCS) or the baud rate generator double-speed mode select bit (BGDM) is set to 1 in Asynchronous mode and Manchester mode, the bit rate becomes twice that listed in [Table 28.11](#) and [Table 28.12](#). When both of those registers are set to 1, the bit rate becomes four times the listed value.

BRME bit (Bit Rate Modulation Enable)

Enables and disables the bit rate modulation function. The bit rate generated by on-chip baud rate generator is evenly corrected when this function is enabled.

Set to 0 in Clock-synchronous mode, Simple SPI mode, Smart Card Interface mode, Manchester mode and Simple LIN mode.

Even in asynchronous mode, set this bit to 0 when ABCSE2 = 1.

CKS[1:0] bits (Clock Select)

The CKS[1:0] bits select the clock source for the on-chip baud rate generator.

For the relationship between the settings of the CKS[1:0] bits and the baud rate, see BRR[7:0] bits explanation.

MDDR[7:0] bits (Modulation Duty Setting)

When the BRME bit is set to 1, the bit rate generated by the on-chip baud rate generator is evenly corrected according to the settings of MDDR (M/256). The relationship between the MDDR setting (M) and the bit rate (B) is given in Table 28.22.

The initial value of MDDR is FFh. Bit 7 in the CCR2 is fixed to 1.

Table 28.22 Relationship between MDDR Setting (M) and Bit Rate (B) When Bit Rate Modulation Function is Used

Mode*1	CCR2 settings			BRR setting	Error
	BG DM bit	AB CS bit	AB CS E bit		
Asynchronous, Multiprocessor transfer	0	0	0	$N = \frac{TCLK \times 10^6}{64 \times 2^{2n-1} \times (256/M) \times B} - 1$	$Error (\%) = \left\{ \frac{TCLK \times 10^6}{B \times 64 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1 \right\} \times 100$
	1	0	0	$N = \frac{TCLK \times 10^6}{32 \times 2^{2n-1} \times (256/M) \times B} - 1$	$Error (\%) = \left\{ \frac{TCLK \times 10^6}{B \times 32 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1 \right\} \times 100$
	0	1	0		
	1	1	0	$N = \frac{TCLK \times 10^6}{16 \times 2^{2n-1} \times (256/M) \times B} - 1$	$Error (\%) = \left\{ \frac{TCLK \times 10^6}{B \times 16 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1 \right\} \times 100$
	x (Arbitrarily)	x (Arbitrarily)	1*2	$N = \frac{TCLK \times 10^6}{12 \times 2^{2n-1} \times (256/M) \times B} - 1$	$Error (\%) = \left\{ \frac{TCLK \times 10^6}{B \times 12 \times 2^{2n-1} \times (256/M) \times (N+1)} - 1 \right\} \times 100$
Simple IIC*2				$N = \frac{TCLK \times 10^6}{64 \times 2^{2n-1} \times (256/M) \times B} - 1$	

- Note: B: Bit rate (bps)
- M: MDDR setting (128 ≤ M ≤ 255)
- N: BRR setting for bound rate generator (0 ≤ N ≤ 255)
- TCLK: Operating frequency (MHz)
- n: Determined by the settings of the CKS[1:0] as listed in Table 28.9.

Note 1. Do not use this function in Clock-synchronous mode, Simple SPI mode, Smart card Interface mode, Manchester mode and Simple LIN mode.

Note 2. Adjust the bit rate so that the widths at high and low level of the SCL output in simple IIC mode satisfy the I2C standard.

Table 28.23 and Table 28.24 list examples of N settings in BRR and M settings in MDDR in Asynchronous mode.

Table 28.23 Examples of BRR and MDDR Settings for Various Bit Rates (Asynchronous Mode) (1) (1 of 3)

460800	0	1	151	0	0	0	6	220	1	-0.09	0	10	173	1	-0.01

Note: This is an example when the CCR2.ABCS = 0 and CCR2.ABCSE = 0.

Note 1. It means that the bit rate modulation function is disable. (CCR2.BRME = 0, M = 256)

28.2.8 CCR3 : Common Control Register 3

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
 SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x14

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	BLK	GM	—	ACSO	CKE[1:0]	—	—	DEN	FM	MP	MOD[2:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RXDE SEL	STP	SINV	LSBF	—	—	CHR[1:0]	BPEN	—	—	—	—	—	—	CPOL	CPHA
Value after reset:	0	0	0	1	0	0	1	0	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
0	CPHA	Clock Phase Select Valid in Clock synchronous mode and Simple SPI mode. Set this bit only when CCR0.TE = 0 and RE = 0. 0: Data is sampled at an odd edge and changes at an even edge (clock is delayed) 1: Data changes at an odd edge and is sampled at an even edge (clock is not delayed)	R/W
1	CPOL	Clock Polarity Select Valid in Clock synchronous mode and Simple SPI mode. Set this bit only when CCR0.TE = 0 and RE = 0. 0: SCKn in idle state is 0 1: SCKn in idle state is 1	R/W
6:2	—	These bits are read as 0. The write value should be 0.	R/W
7	BPEN	Synchronizer Bypass Enable This bit controls whether to bypass the synchronizer circuit between the bus clock and operation clock. 0: Synchronizer circuit is not bypassed 1: Synchronizer circuit is bypassed	R/W
9:8	CHR[1:0]	Character Length Valid in Asynchronous mode and Manchester mode*1 Select the data length for transmission and reception. 0 0: Transmit/receive in 9-bit data length 0 1: Transmit/receive in 9-bit data length 1 0: Transmit/receive in 8-bit data length (initial value) 1 1: Transmit/receive in 7-bit data length*2	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
12	LSBF	LSB First select Set this bit to 0 in Simple IIC mode. Set this bit to 1 in Simple LIN mode. 0: MSB-first 1: LSB-first	R/W
13	SINV	Transmitted/Received Data Invert Set this bit to 0 in Simple IIC mode. The level of communication pins (RXDn/TXDn) are controlled by combination of this bit and CCR1.TINV/RINV. For details, see Figure 28.3 . 0: TDR contents are transmitted to TSR as is. RSR contents are stored to RDR as is. 1: TDR contents are inverted before being transmitted to TSR. RSR contents are inverted and stored to RDR.	R/W
14	STP	Stop Bit Length Valid in Asynchronous mode, Manchester mode, and Simple LIN mode 0: 1 stop bit/break delimiter length is 1-bit 1: 2 stop bits/break delimiter length is 2-bit	R/W
15	RXDESEL	Asynchronous Start Bit Edge Detection Select Valid only in Asynchronous mode Set this bit to 1 in Simple LIN mode. 0: The low level on the RXDn pin is detected as the start bit 1: A falling edge on the RXDn pin is detected as the start bit	R/W
18:16	MOD[2:0]	Communication Mode Select Select the SCI communication mode. 0 0 0: Asynchronous mode (multi-processor mode) 0 0 1: Smart card interface mode 0 1 0: Clock synchronous mode 0 1 1: Simple SPI mode 1 0 0: Simple IIC mode 1 0 1: Manchester mode 1 1 0: Simple LIN mode 1 1 1: Setting prohibited	R/W
19	MP	Multi-Processor Mode Valid in Asynchronous mode and Manchester mode 0: Multi-processor communications function is disabled 1: Multi-processor communications function is enabled	R/W
20	FM	FIFO Mode Select Valid in Asynchronous mode (including Multi-processor mode), Clock synchronous mode, and Simple SPI mode 0: TDR register and RDR register are non-FIFO buffer configuration 1: TDR register and RDR register are FIFO buffer configuration	R/W
21	DEN	Driver Enable 0: RS-485 driver control function disabled 1: RS-485 driver control function enabled	R/W
23:22	—	These bits are read as 0. The write value should be 0.	R/W
25:24	CKE[1:0]	Clock Enable See Table 28.26 for details.	R/W
26	ACS0	Asynchronous Mode Clock Source Select Valid only in Asynchronous mode. These bits for SCI channels other than SCI1 are reserved. 0: External clock input 1: Logical AND of compare matches output from the internal GPT	R/W
27	—	This bit is read as 0. The write value should be 0.	R/W
28	GM	GSM Mode Valid only in Smart card interface mode. 0: Non-GSM mode operation 1: GSM mode operation	R/W

Bit	Symbol	Function	R/W
29	BLK	Block Transfer Mode Valid only in Smart card interface mode. 0: Non-block transfer mode operation 1: Block transfer mode operation	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. In other than Asynchronous mode and Manchester mode, this bit setting is invalid and a fixed data length of 8 bits is used. In the Simple LIN mode, only the data length of 8 bits can be used, so set it to the initial value.

Note 2. LSB first is fixed and the MSB (bit 7) in TDR is not transmitted in transmission.

Note 3. GPT clock is selectable for SCI1.

CPHA bit (Clock Phase Select)

The CPHA bit selects the phase of the clock signal output through the SCKn pin. For details, see [Figure 28.99](#).

Set the bit to 1 in other than Simple SPI mode and Clock synchronous mode.

CPOL bit (Clock Polarity Select)

The CPOL bit selects the polarity of the clock signal output through the SCKn pin. For details, see [Figure 28.99](#).

Set the bit to 1 in other than Simple SPI mode and Clock synchronous mode.

BPEN bit (Synchronizer Bypass Enable)

The BPEN bit selects whether to enable or disable the synchronization bypass function. Set this bit to 1 when the bus clock (PCLK) is also used as operation clock (TCLK). For details, see [Figure 28.2](#) and [section 28.18. Synchronizer Bypass Function](#).

Note: For details of this bit setting, see [section 28.19.17. Notes on CCR3.BPEN bit setting](#).

CHR[1:0] bits (Character Length)

Selects the data length for transmission and reception.

Except for Asynchronous mode and Manchester mode, a fixed data length of 8 bits is used.

LSBF bit (LSB First select)

Select whether to transmit/receive data in MSB-first or LSB-first.

SINV bit (Transmitted/Received Data Invert)

SINV can invert the transmit data bit from TDR to TSR, and can invert the received data from RSR to RDR. The SINV bit does not affect the logic level of the parity bit. To invert the parity bit, invert the CCR1.PM.

STP bit (Stop Bit Length)

Selects the stop bit length in transmission.

In reception, only the first stop bit is checked regardless of the STP bit setting. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.

In addition, it is used as the break delimiter length setting when sending start frame in Simple LIN mode.

RXDESEL bit (Asynchronous Start Bit Edge Detection Select)

Selects the detection method of the start bit for reception in Asynchronous mode. When a break occurs, data receiving operation depends on the settings of the RXDESEL bit. Set this bit to 1 when reception should be stopped while a break occurs or when reception should be started without retaining the RXDn pin input at high level for the period of one data frame or longer after completion of the break.

Set this bit to 1 in Simple LIN mode. Set this bit to 0 in modes except of Asynchronous mode and Simple LIN mode.

MOD[2:0] bits (Communication Mode Select)

Selects the SCI communication mode.

Table 28.25 Relationship between communication mode selection bits (MOD[2:0]) and other operation mode setting bits

Communication mode	Asynchronous				Smart card interface	Clock synchronous	Simple SPI				Simple IIC	Manchester	Simple LIN
CCR3.MOD[2:0]	000b				001b	010b	011b				100b	101b	110b
CCR3.MP	0		1		—	—	—				—	0 1	—
CCR3.FM	0	1	0	1	—	0	1	0	1	—	—	—	
CCR3.DEN	0	1	0	1	0	1	0	1	—	—	—	—	
CCR0.SSE	—				—	—	0	1	0	1	—	—	—

Note: — is prohibited setting.

MP bit (Multi-Processor Mode)

Disables/enables multi-processor communications function. The settings of the PE bit and PM bit are invalid in multi-processor mode.

FM bit (FIFO Mode Select)

When the FM bit is set to 1, the TDR register / RDR register switches to FIFO configuration, and transmit FIFO (TDR register) / receive FIFO (RDR register) can be used for serial transmission/reception.

DEN bit (Driver Enable)

Select RS-485 driver control function disabled or enabled.

CKE[1:0] bits (Clock Enable)

Table 28.26 Association between Clock Enable bits CKE[1:0] and operation mode (1 of 2)

CKE[1:0]	Function
00b	In Asynchronous mode: On-chip baud rate generator The SCKn pin is available for use as an I/O port in accord with the I/O port settings. In Manchester mode and Simple LIN mode: On-chip baud rate generator The SCKn pin functions as I/O port. In Clock synchronous mode and Simple SPI mode: Internal clock (master operation) The SCKn pin functions as the clock output pin. In Smart card interface mode and when CCR3.GM = 0: Output disabled (the SCKn pin is available for use as an I/O port in accord with the I/O port settings). In Smart card interface mode and when CCR3.GM = 1: Output fixed low
01b	In Asynchronous mode: On-chip baud rate generator The clock with the same frequency as the bit rate is output from the SCKn pin. In Manchester mode and Simple LIN mode: Prohibited In Clock synchronous mode and Simple SPI mode: Internal clock (master operation) The SCKn pin functions as the clock output pin. In Smart card interface mode and when CCR3.GM = 0: Clock output In Smart card interface mode and when CCR3.GM = 1: Clock output

Table 28.26 Association between Clock Enable bits CKE[1:0] and operation mode (2 of 2)

CKE[1:0]	Function
10b	<p>In Asynchronous mode: External clock or GPT clock</p> <ul style="list-style-type: none"> When using the external clock 16 times the bit rate should be input from the SCKn pin when CCR2.ABCS bit is 0. Input a clock signal with a frequency 8 times the bit rate when the CCR2.ABCS bit is 1. When using the GPT clock^{*3} The SCKn pin is available for use as an I/O port in accord with the I/O port settings when the GPT clock is used. <p>In Manchester mode and Simple LIN mode: Prohibited</p> <p>In Clock synchronous mode and Simple SPI mode: External clock (slave operation) The SCKn pin functions as the clock input pin.</p> <p>In Smart card interface mode and when CCR3.GM = 0: Prohibited</p> <p>In Smart card interface mode and when CCR3.GM = 1: Output fixed high</p>
11b	<p>In Asynchronous mode: External clock or GPT clock</p> <ul style="list-style-type: none"> When using the external clock 16 times the bit rate should be input from the SCKn pin when CCR2.ABCS bit is 0. Input a clock signal with a frequency 8 times the bit rate when the CCR2.ABCS bit is 1. When using the GPT clock^{*3} The SCKn pin is available for use as an I/O port in accord with the I/O port settings when the GPT clock is used. <p>In Manchester mode and Simple LIN mode: Prohibited</p> <p>In Clock synchronous mode and Simple SPI mode: External clock (slave operation) The SCKn pin functions as the clock input pin.</p> <p>In Smart card interface mode and when CCR3.GM = 0: Prohibited</p> <p>In Smart card interface mode and when CCR3.GM = 1: Clock output</p>

The CKE[1:0] bits select the clock source and SCKn pin function.

The combination of these bit settings and of the CCR3.ACS0 bit sets the internal GPT clock.

In Smart card interface mode, these bits control the clock output from the SCKn pin.

In GSM mode, clock output can be dynamically switched. For details, see [section 28.7.8. Clock Output Control](#).

GM bit (GSM Mode)

Setting the GM bit to 1 allows GSM mode operation.

In GSM mode, the CSR.TEND flag set timing is put forward to 11.0 etu (elementary time unit = 1-bit transfer time) from the start and the clock output control function is appended. For details, see [section 28.7.6. Serial Data Transmission \(Except in Block Transfer Mode\)](#), [section 28.7.8. Clock Output Control](#).

ACS0 bit (Asynchronous Mode Clock Source Select)

Selects the clock source in the Asynchronous mode.

The ACS0 bit is valid in Asynchronous mode (CCR3.MOD[2:0] = 000b) and when an external clock input is selected (CCR3.CKE[1:0] = 10b or 11b). This bit is used to select an external clock input or the logical AND of compare matches output from the internal GPT.

Set the ACS0 bit to 0 in other than Asynchronous mode.

For SCI1, the GTIOCmA output (m = 3, 4) of GPT can be set as the serial transfer base clock. See [Table 28.27](#) for details.

These bits for SCI channels other than SCI1 and SCI2 are reserved. The write values to these bits for other than SCI1 and SCI2 should be 0.

Table 28.27 Association between SCI channels and compare match outputs

SCI	GPT	Compare match output
SCI1	GPT3	GTIOC3A
	GPT4	GTIOC4A

Figure 28.4, Figure 28.5 show a setting example of when GTIOC3A and GTIOC4A are selected for output. This figure shows an example when GPT clock is input to SCI1.

When generating 187.5 kbps of GPT average transfer rate for PCLKD = 32 MHz:

1. Generate a frequency of 4 MHz using GTIOC3A as the base clock.
2. Generate 3/4 clock enable of base clock to set an average transfer rate of 3 MHz/16 = 187.5 kbps using GTIOC4A.

Setting examples of GPT and SCI

- GPT3.GTSSR = 0x80000000, GPT4.GTSSR = 0x80000000 (enable software counter start)
- GPT3.GTPR = 0x00000007, GPT4.GTPR = 0x0000001F (maximum count value of GTCNT)
- GPT3.GTCCRA = 0x00000003, GPT4.GTCCRA = 0x00000007 (compare match value)
- GPT3.GTCR = 0x00000000, GPT4.GTCR = 0x00000000 (Saw-wave PWM mode, timer prescaler is PCLKD)
- GPT3.GTIOR = 0x00000306, GPT4.GTIOR = 0x00000306 (initial output low, output high at GTCCRA compare match, output low at cycle end)
- CCR3.CKE[1:0] = 10b (external clock input or GPT clock input is selected)
- CCR3.ACS0 = 1, CCR2.ABCSE = 1, CCR2.ABCS=0 (GPT clock input is selected with 16 base clock cycles for 1-bit period)
- GPT3.GTSTR = 0x00000018 (software start GTCNT counter)

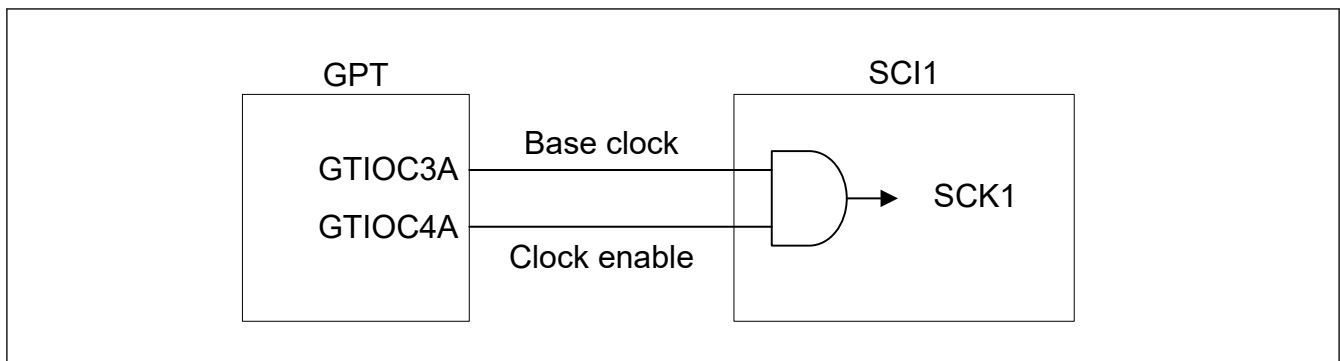

Figure 28.4 Example of GPT and SCI connection

Figure 28.5 Example of average transfer rate setting when GPT clock is input

BLK bit (Block Transfer Mode)

Setting the BLK bit to 1 allows block transfer mode operation.

For details, see [section 28.7.3. Block Transfer Mode](#).

28.2.9 CCR4 : Common Control Register 4

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
 SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x18

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Symbol	Function	R/W
8:0	CMPD[8:0]	Compare Match Data Valid only in Asynchronous mode.	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
16	ASEN	Adjust Receive Sampling Timing Enable Valid in Asynchronous mode using internal clock, Simple LIN mode using internal clock, Clock-synchronous mode operating as master, and Simple SPI mode operating as master. 0: Adjust sampling timing disabled 1: Adjust sampling timing enabled	R/W
17	ATEN	Adjust Transmit Timing Enable Valid only in Asynchronous mode using internal clock. 0: Adjust transmit timing disabled 1: Adjust transmit timing enabled	R/W
18	—	This bit is read as 0. The write value should be 0.	R/W
19	SCKSEL	Master receive clock selection Valid only in Clock synchronous and Simple-SPI mode. 0: Master receive clock is disabled 1: Master receive clock is enabled	R/W
23:20	—	These bits are read as 0. The write value should be 0.	R/W
26:24	AST[2:0]	Adjustment Value for Receive Sampling Timing This bit enables only when ASEN is 1. In Asynchronous mode and Simple LIN mode using internal clock: The sampling timing of RXDn pin is adjusted from the middle of bit by the following formula. Adjustment sampling timing = base clock × the setting value of AST[2:0]. In Clock synchronous mode and Simple SPI mode using internal clock: The RXDn sampling timing can be adjusted by delaying 1 to 4 TCLK 0 0 0: 1-TCLK delay 0 0 1: 2-TCLK delay 0 1 0: 3-TCLK delay 0 1 1: 4-TCLK delay Others: Setting prohibited	R/W
27	AJD	Adjustment Direction for Receive Sampling Timing Valid in Asynchronous mode using internal clock and Simple LIN mode using internal clock. This bit enables only when ASEN is 1. Adjustment direction for RXDn receive sampling timing is determined by this bit. For details, see section 28.3.10. The function of adjust receive sampling timing (Asynchronous Mode) . 0: The sampling timing is adjusted backward to the middle of bit. 1: The sampling timing is adjusted forward to the middle of bit.	R/W

Bit	Symbol	Function	R/W
30:28	ATT[2:0]	Adjustment Value for Transmit Timing Valid in Asynchronous mode using internal clock and Simple LIN mode using internal clock. This bit enables only when ATEN is 1. The selected edge timing of TXDn is adjusted by the following formula. Adjustment edge timing = base clock × the setting value of ATT[2:0] This setting timing is limited by setting the base clock cycles. For details, see section 28.3.11. The function of adjust transmit timing (Asynchronous Mode) .	R/W
31	AET	Adjustment Edge for Transmit Timing Valid in Asynchronous mode using internal clock and Simple LIN mode using internal clock. The adjustable edge is set by this bit. This bit enables only when ATEN is 1. For details, see section 28.3.11. The function of adjust transmit timing (Asynchronous Mode) . 0: When CCR1.TINV is 0, adjust the rising edge timing. When CCR1.TINV is 1, adjust the falling edge timing. 1: When CCR1.TINV is 0, adjust the falling edge timing. When CCR1.TINV is 1, adjust the rising edge timing.	R/W

Note: S-TYPE-3, P-TYPE-3

CMPD[8:0] bits (Compare Match Data)

Set the comparison data for receive data when address match function is enabled (CCR0.DCME = 1). CCR4.CMPD[8:0] should be written while CCR0.DCME is 0.

For the comparison data, it can select length from three types, they are CMPD[6:0] with 7-bit length, CMPD[7:0] with 8-bit length, and CMPD[8:0] with 9-bit length.

Note: If the description in this document and the timing chart do not specify the ASEN / ATEN setting value, it means that the reception sampling adjustment function/transmission timing adjustment function are OFF (CCR4.ASEN = 0, CCR4.ATEN = 0).

ASEN bit (Adjust Receive Sampling Timing Enable)

When the ASEN bit is 1, the receive sampling timing adjustment function is enabled. Control is different in Asynchronous mode, Simple LIN mode, Clock-synchronous mode, and Simple SPI mode.

For details of using internal clock in Asynchronous mode, see [section 28.6.7. Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with internal clock used](#). The operation when the Simple LIN mode internal clock is selected is the same as when the Asynchronous mode internal clock is selected.

For details of Clock synchronous mode operating as master and Simple SPI mode operating as master, see [section 28.6.6. Simultaneous Serial Data Transmission and Reception in Clock Synchronous Mode](#). Only the digital delay of the master mode receive sampling clock can be controlled by this bit.

ATEN bit (Adjust Transmit Timing Enable)

When the ATEN bit is 1, the transmission timing adjustment function is enabled. The transmission timing adjustment function can adjust the edge timing of the waveform output from the TXDn pin. For details, see [section 28.3.11. The function of adjust transmit timing \(Asynchronous Mode\)](#).

SCKSEL bit (Master receive clock selection)

In Clock synchronous or Simple-SPI mode, SCKSEL bit selects whether to enable or disable the internal clock for master reception.

AST[2:0] bits (Adjustment Value for Receive Sampling Timing)

When the ASEN bit is 1, the receive sampling timing can be adjusted according to this bit setting value.

In Asynchronous mode and Simple LIN mode using internal clock.

The sampling timing of RXDn pin is adjusted from the middle of bit by the following formula. This setting value is limited by setting the base clock cycles. For details, see [section 28.3.10. The function of adjust receive sampling timing \(Asynchronous Mode\)](#).

Adjustment sampling timing = base clock × the setting value of AST[2:0].

In Clock-synchronous mode and Simple SPI mode using internal clock

The sampling timing of RXDn pin can be adjusted by delaying 1 to 4 TCLK. For details, see [section 28.6.7. Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with internal clock used.](#)

000: 1-TCLK delay

001: 2-TCLK delay

010: 3-TCLK delay

011: 4-TCLK delay

1xx: Setting prohibited

Note: In Clock-synchronous mode and Simple SPI mode, it is recommended to set delay time within half the period of the SCK clock cycle.

AJD bit (Adjustment Direction for Receive Sampling Timing)

Set the RXDn pin sampling timing adjustment direction from the bit center to the rear or front. For details, see [section 28.3.10. The function of adjust receive sampling timing \(Asynchronous Mode\).](#)

ATT[2:0] bits (Adjustment Value for Transmit Timing)

The edge timing of the TXDn pin specified by the AET bit is adjusted by the base clock × ATT[2:0] setting value. The upper limit of the adjustment time that can be set is limited by the number of base clock cycles. For details, see [section 28.3.11. The function of adjust transmit timing \(Asynchronous Mode\).](#)

AET bit (Adjustment Edge for Transmit Timing)

Set the TXDn pin edge for timing adjustment. For details, see [section 28.3.11. The function of adjust transmit timing \(Asynchronous Mode\).](#)

28.2.10 ICR : Simple IIC Control Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)

Bit	Symbol	Function	R/W
4:0	IICDL[4:0]	SDA Delay Output Select The following cycles are of the clock signal from the on-chip baud rate generator: 0x00: No output delay 0x01: 0 to 1 cycle 0x02: 1 to 2 cycles 0x03: 2 to 3 cycles 0x04: 3 to 4 cycles 0x05: 4 to 5 cycles ⋮ 0x1E: 29 to 30 cycles 0x1F: 30 to 31 cycles	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	IICINTM	IIC Interrupt Mode Select 0: Use ACK/NACK interrupts 1: Use reception and transmission interrupts	R/W

Bit	Symbol	Function	R/W
9	IICSC	Clock Synchronization 0: No synchronization with the clock signal 1: Synchronization with the clock signal	R/W
12:10	—	These bits are read as 0. The write value should be 0.	R/W
13	IICACKT	ACK Transmission Data 0: ACK transmission 1: NACK transmission and reception of ACK/NACK	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W
16	IICSTAREQ	Start Condition Generation 0: A start condition is not generated 1: A start condition is generated *1 *3 *4 *5	R/W
17	IICRSTAREQ	Restart Condition Generation 0: A restart condition is not generated 1: A restart condition is generated *2 *3 *4 *5	R/W
18	IICSTPREQ	Stop Condition Generation 0: A stop condition is not generated. 1: A stop condition is generated *2 *3 *4 *5	R/W
19	—	This bit is read as 0. The write value should be 0.	R/W
21:20	IICSDAS[1:0]	SDA Output Select 0 0: Serial data output 0 1: Generate a start, restart, or stop condition 1 0: Output the low level on the SDA pin 1 1: Place the SDA pin in the high-impedance state	R/W
23:22	IICSCLS[1:0]	SCL Output Select 0 0: Serial clock output 0 1: Generate a start, restart, or stop condition 1 0: Output the low level on the SCL pin 1 1: Place the SCL pin in the high-impedance state	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. In bus free state, perform the start condition generation.

Note 2. In bus busy state, perform restart or stop condition generation when the SCLn pin after acknowledgment described in [Figure 28.86](#) and [Figure 28.87](#) is low level.

Note 3. Do not set more than one from among the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits to 1 at a given time.

Note 4. Execute the generation of a condition after the value of the IICSTIF flag is 0.

Note 5. Do not write 0 to this bit while it is 1. Generation of a condition is suspended by writing 0 to this bit while it is 1.

IICDL[4:0] bits (SDA Delay Output Select)

The IICDL[4:0] bits are used to set a delay for output on the SDA pin relative to the falling edge of the output on the SCLn pin. The available delay settings range from no delay to 31 cycles, with the clock signal from the on-chip baud rate generators the base. The signal obtained by frequency-dividing TCLK by the divisor set in CCR2.CKS[1:0] is supplied as the clock signal from the on-chip baud rate generator.

Set these bits to 00000b unless operation is in simple IIC mode. In simple IIC mode, set the bits to a value in the range from 00001b to 11111b.

IICINTM bit (IIC Interrupt Mode Select)

The IICINTM bit selects the sources of interrupt requests in Simple IIC mode.

IICSC bit (Clock Synchronization)

Set the IICSC bit to 1 if the internally generated SCLn clock signal is to be synchronized when the SCLn pin is placed at the low level and when a wait is inserted by other device, for example.

The SCLn clock signal is not synchronized if the IICSC bit is 0. The SCLn clock signal is generated in accord with the rate selected in the BRR regardless of the level being input on the SCLn pin.

Set the IICSC bit to 1 except during debugging.

IICACKT bit (ACK Transmission Data)

Transmitted data contains ACK bits. Set this bit to 1 when ACK and NACK bits are received.

IICSTAREQ bit (Start Condition Generation)

When a start condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICSTAREQ bit to 1.

To generate the start condition after generating the stop condition, start the generation of the start condition with a half cycle period of the bit rate from the stop condition generation interrupt (STI) request output.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the start condition

IICRSTAREQ bit (Restart Condition Generation)

When a restart condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICRSTAREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the restart condition

IICSTPREQ bit (Stop Condition Generation)

When a stop condition is to be generated, set both the IICSDAS[1:0] and IICSCLS[1:0] bits to 01b as well as setting the IICSTPREQ bit to 1.

[Setting condition]

- Writing 1 to the bit

[Clearing condition]

- Completion of generation of the stop condition

IICSDAS[1:0] bits (SDA Output Select)

The IICSDAS[1:0] bits control output from the SDA_n pin.

IICSCLS[1:0] bits (SCL Output Select)

The IICSCLS[1:0] bits control output from the SCL_n pin.

28.2.11 FCR : FIFO Control Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x24

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
Bit field:	—	—	—	RSTRG[4:0]				RFRS T	—	—	RTRG[4:0]						
Value after reset:	0	0	0	1	1	1	1	1	0	0	0	1	1	1	1	1	
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Bit field:	TFRS T	—	—	TTRG[4:0]				—	—	—	—	—	—	—	—	—	DRES
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	

Bit	Symbol	Function	R/W
0	DRES	Receive Data Ready Error Select Bit Valid in Asynchronous mode. This bit selects the interrupt request for a reception data ready detection. 0: Reception data full interrupt (SCIn_RXI) 1: Receive error interrupt (SCIn_ERI)	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
12:8	TTRG[4:0]	Transmit FIFO Data Trigger Number Valid in Asynchronous mode (including Multiprocessor mode), Clock synchronous mode, and Simple SPI mode. Trigger number must be set to 15 or less. 0x00: Trigger number 0 ⋮ 0x1F: Trigger number 31	R/W
14:13	—	These bits are read as 0. The write value should be 0.	R/W
15	TFRST	Transmit FIFO Data Register Reset This bit enables only when CCR3.FM is 1. The read value is always 0. 0: When set, this bit is invalid and does not affect operation 1: The number of data stored in Transmit-FIFO (TDR register) is 0	W
20:16	RTRG[4:0]	Receive FIFO Data Trigger Number Valid in Asynchronous mode (including Multi processor mode), Clock synchronous mode, and Simple SPI mode. Trigger number must be set to 15 or less. 0x00: Trigger number 0 ⋮ 0x1F: Trigger number 31	R/W
22:21	—	These bits are read as 0. The write value should be 0.	R/W
23	RFRST	Receive FIFO Data Register Reset This bit enables only when CCR3.FM is 1. The read value is always 0. 0: When set, this bit is invalid and does not affect operation 1: The number of data stored in Receive-FIFO(RDR register) is 0	W
28:24	RSTRG[4:0]	RTS Output Active Trigger Number Select Valid in Asynchronous mode (including Multi processor mode) and Clock synchronous mode. This bit enables only when CCR3.FM = 1 and CCR1.CTSE = 0 and CCR0.SSE = 0. Trigger number must be set to 15 or less. 0x00: Trigger number 0 ⋮ 0x1F: Trigger number 31	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

DRES bit (Receive Data Ready Error Select Bit)

Select whether the detection of receive data ready (FRSR.DR flag = 1) is the cause of SCIn_RXI interrupt request or the cause of SCIn_ERI interrupt request.

TTRG[4:0] bits (Transmit FIFO Data Trigger Number)

The TDRE flag is set to 1 when the quantity of transmit data in the transmit-FIFO(TDR register) is equal to or less than the specified transmit triggering number. If CCR0.TIE = 1, SCIn_TXI interrupt request occurs.

Note: Trigger number must be set to 15. When the trigger number is set to 16 or more, unexpected SCIn_TXI interrupt occurs.

TFRST bit (Transmit FIFO Data Register Reset)

When the TFRST bit is set to 1, the number of the transmission data stored in Transmit-FIFO(TDR register) is 0.

RTRG[4:0] bits (Receive FIFO Data Trigger Number)

The CSR.RDRF flag is set to 1 when the quantity of receive data in the receive-FIFO(RDR register) is equal to or greater than the specified receive triggering number. If CCR0.RIE = 1, SCIn_RXI interrupt request occurs. When FCR.RTRG is set to 0, RDRF bit is set if the quantity of data in receive-FIFO is greater than or equal to 1.

Note: Trigger number must be set to 15. When the trigger number is set to 16 or more, unexpected SCIn_RXI interrupt occurs.

RFRST bit (Receive FIFO Data Register Reset)

When the RFRST bit is set to 1, the number of the reception data stored in Receive-FIFO(RDR register) is 0.

RSTRG[4:0] bits (RTS Output Active Trigger Number Select)

When the quantity of receive data stored in the receive-FIFO (RDR register) is equal to or greater than this number, the RTSn signal is in the High state. When FCR.RSTRG is set to 0, RTSn is in the high state if the quantity of data in receive FIFO is greater than or equal to 1.

Note: Trigger number must be set to 15. When the trigger number is set to 16 or more, RTSn goes to a high state at unexpected timing.

28.2.12 MCR : Manchester Control Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0)
 SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0)

Offset address: 0x2C

Bit	Symbol	Function	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

RMPOLE bit (Polarity of Received Manchester Code)

The RMPOLE bit sets the polarity of the received Manchester code. For details, see [section 28.5.7. Serial Data Reception in Manchester Mode](#).

TMPOLE bit (Polarity of Transmit Manchester Code)

The TMPOLE bit sets the polarity of the transmit Manchester code. For details, see [section 28.5.6. Serial data transmission in Manchester mode](#).

ERTEN bit (Manchester Edge Retiming Enable)

The ERTEN bit sets the receive retiming function in Manchester mode.

For information on the receive retiming function, see [section 28.5.9. Receive Retiming](#).

SYNVAL bit (SYNC value Setting)

The SYNVAL bit is valid when the SYNSEL bit of the MCR is set to 0.

The SYNC type can be set by combining this bit and the SBSEL bit.

For the start bit area determined by the combination of this bit and the SBSEL bit, see [Figure 28.54](#) and [Figure 28.55](#).

SYNSEL bit (SYNC Select)

The SYNSEL bit is valid when the SBSEL bit of the MCR is set to 1. This bit determines the destination to be referred to for setting the SYNC type of the start bit area added to Manchester frames.

When this bit is set to 0, the SYNVAL bit of the MCR is referred to.

When this bit is set to 1, the TSYNC bit in the TDR register is referred to.

SBSEL bit (Start Bit Select)

The SBSEL bit sets the start bit area in Manchester frames.

When this bit is set to 1, the start bit area added to each frame consists of three bits, and the SYNSEL and SYNVAL bits in this register are valid.

When this bit is set to 0, the start bit area added to each frame consists of one bit.

TPLEN[3:0] bits (Transmit Preface Length)

The TPLEN[3:0] bits set the preface bit length of the transmit data in Manchester mode.

The settable range is 0x0 to 0xF (0d to 15d). The setting of 0x0 disables the transmit preface, which is not added.

TPPAT[1:0] bits (Transmit Preface Pattern)

The TPPAT[1:0] bits set one of the four preface patterns in Manchester mode. For the transmit data when the TPPAT[1:0] bits are set, see [Figure 28.53](#).

When these bits are set to 00b, the preface area is set to all 0s.

When these bits are set to 01b, the preface area is set to the zero-one-zero-one pattern.

When these bits are set to 10b, the preface area is set to the one-zero-one-zero pattern.

When these bits are set to 11b, the preface area is set to all 1s.

RPLEN[3:0] bits (Receive Preface Length)

The RPLEN[3:0] bits set the preface bit length of the received frames in Manchester mode.

The settable range is 0x0 to 0xF (0d to 15d). The setting of 0x0 disables the receive preface, which is not added. When 0x1 to 0xF is set, the set value is handled as the receive preface bit length.

RPPAT[1:0] bits (Receive Preface Pattern)

The RPPAT[1:0] bits set one of the four preface patterns in Manchester mode. For the transmit and receive data when the RPPAT[1:0] bits are set, see [Figure 28.53](#).

When these bits are set to 00b, the preface area is handled as all 0s.

When these bits are set to 01b, the preface area is handled as the zero-one-zero-one pattern.

When these bits are set to 10b, the preface area is handled as the one-zero-one-zero pattern.

When these bits are set to 11b, the preface area is handled as all 1s.

PFEREN bit (Preface Error Enable)

The PFEREN bit specifies whether to handle a preface error as an interrupt source.

When it is set to 0, a preface error is not handled as an interrupt source. When it is set to 1, a preface error is handled as an interrupt source.

SYEREN bit (Receive SYNC Error Enable)

The SYEREN bit specifies whether to handle a receive SYNC error as an interrupt source.

When it is set to 0, a receive SYNC error is not handled as an interrupt source. When it is set to 1, a receive SYNC error is handled as an interrupt source.

SBEREN bit (Start Bit Error Enable)

The SBEREN bit specifies whether to handle a start bit error as an interrupt source.

When it is set to 0, a start bit error is not handled as an interrupt source. When it is set to 1, a start bit error is handled as an interrupt source.

28.2.13 DCR : Driver Control Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x30

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	DENG[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	DEAST[4:0]				—	—	—	—	—	—	—	—	DEPOL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DEPOL	Driver Effective Polarity Select Valid only in Asynchronous mode. 0: The DEN signal is active-high 1: The DEN signal is active-low	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
12:8	DEAST[4:0]	Driver Assertion Time Valid only in Asynchronous mode. Set the driver assertion time. When DEN = 1, the driver assertion time is inserted in addition to the normal transmission waiting time. Setting DEAST[4:0] = 0x00 is prohibited.	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
20:16	DENGT[4:0]	Driver Negate Time Valid only in Asynchronous mode. Set the driver negation time. When DEN = 1, the driver negate time is inserted after STOP bit transmission end. Setting DENGT[4:0] = 0x00 is prohibited.	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

DEPOL bit (Driver Effective Polarity Select)

Select the active level of the DEN signal.

DEAST[4:0] bits (Driver Assertion Time)

Set the driver assertion time (= time from the activation of the DEN (Driver Enable) signal to the start of the start bit). It is expressed in base clock period.

Driver assertion time

$$= \text{DEAST [4:0] set value} \times \text{base clock period} + \text{transmission waiting time}$$

DENGT[4:0] bits (Driver Negate Time)

Set the driver negation time (= time from the end of the last stop bit of the transmitted message until the DEN (Driver Enable) signal is disabled). It is expressed in base clock period.

Driver negate time

$$= \text{DENGT[4:0] set value} \times \text{base clock period}$$

If the transmission data is written during the driver negate time, transmit starting operation is different depends on the writing timing. The DEN signal remains valid, and transmission of the start bit may start after the transmission wait time has elapsed. Also, the DEN signal may become invalid once, and start bit transmission may start after the Driver assertion time has elapsed.

28.2.14 XCR0 : Simple LIN Control Register 0

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0, 1)
 SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0, 1)

15:13	PIBS[2:0]	Priority Interrupt Bit Select Specify one of bits 0 to 7 of Control Field 1 as the priority interrupt bit. 0 0 0: Bit 0 of Control Field 1 0 0 1: Bit 1 of Control Field 1 0 1 0: Bit 2 of Control Field 1 0 1 1: Bit 3 of Control Field 1 1 0 0: Bit 4 of Control Field 1 1 0 1: Bit 5 of Control Field 1 1 1 0: Bit 6 of Control Field 1 1 1 1: Bit 7 of Control Field 1	R/W ³
16	BFOIE	Break Field Output Completion Interrupt Enable Select whether to include Break Field output completion as a SCIn_TXI interrupt factor. 0: Break Field output completion is not included in SCIn_TXI interrupt factor 1: Break Field output completion is included in SCIn_TXI interrupt factor	R/W
17	BCDIE	Bus Conflict Detection Interrupt Enable Select whether to output an SCIn_ERI interrupt when a bus collision is detected. 0: Bus conflict detection is not included in SCIn_ERI interrupt factor 1: Bus conflict detection is included in SCIn_ERI interrupt factor	R/W
19:18	—	These bits are read as 0. The write value should be 0.	R/W
20	BFDIE	Break Field Detection Interrupt Enable Select whether to output a SCIn_BFD interrupt when a Break Field is detected. 0: Break Field detection interrupt disabled 1: Break Field detection interrupt enabled	R/W
21	COFIE	Counter Overflow Interrupt Enable Select whether to include counter overflow as an SCIn_ERI interrupt factor. 0: Counter overflow is not included in SCIn_ERI interrupt factor 1: Counter overflow is included in SCIn_ERI interrupt factor	R/W
22	AEDIE	Active Edge Detection Interrupt Enable Select whether to output an SCIn_AED interrupt when a valid edge is detected. 0: Active edge detection interrupt disabled 1: Active edge detection interrupt enabled	R/W
23	—	This bit is read as 0. The write value should be 0.	R/W
25:24	BCCS[1:0]	Bus Conflict Detection Clock Selection Select the sampling clock for the bus conflict detection circuit. When CCR2.ABCS = 1, setting BCCS[1] = 1 is prohibited. 0 0: Base clock ^{*2} 0 1: Base clock/2 1 0: Base clock/4 1 1: Setting prohibited	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. You can rewrite TCSS[1:0] only when the timer is stopped (TCST = 0 and SDST = 0 and BMEN = 0)

Note 2. Base clock: 1/16 period of 1 bit period when CCR2.ABCS = 0, 1/8 period of 1 bit period when CCR2.ABCS = 1.

Note 3. This bit is a setting bit required for the start frame reception operation. Rewrite this bit when the start frame reception or transmission is not in progress (XCR1.SDST = 0 and XCR1.TCST = 0).

TCSS[1:0] bits (Timer Count Clock Source Selection)

Select clock source of timer in Simple LIN module.

BFE bit (Break Field Enable)

Set the presence or absence of Break Field of Start Frame.

CF0RE bit (Control Field 0 Enable)

Set the presence or absence of Control Field 0 of Start Frame.

CF1DS[1:0] bits (Control Field1 Compare Data Select)

Select the compare data for Control Field 1.

PIBE bit (Priority Interrupt Bit Enable)

Select whether to enable priority interrupt bit comparison of Control Field 1. When the PIBE bit is 1, regardless of the XCR1.CF1CE [7:0] setting value, the bit specified in PIBS [2:0] is compared with the primary comparison data for Control Field 1 (XCR1.PCF1D [7:0]).

PIBS[2:0] bits (Priority Interrupt Bit Select)

Specify bit N (N = 0-7) of Control Field 1 as the priority interrupt bit.

BFOIE bit (Break Field Output Completion Interrupt Enable)

Select whether to include Break Field output completion as a SCIn_TXI interrupt factor. Set CCR0.TIE = 1 and CCR3.MOD [1:0] = 110b, to output SCIn_TXI upon completion of Break Field output.

BCDIE bit (Bus Conflict Detection Interrupt Enable)

Select whether to output an SCIn_ERI interrupt when a bus collision is detected. In Simple LIN mode (CCR3.MOD [1:0] = 110b), SCIn_ERI output control is performed with the BCDIE bit. When CCR3.MOD [1:0] = 110b and BCDIE = 1, an SCIn_ERI interrupt is issued when a bus collision is detected even if CCR0.RIE = 0.

COFIE bit (Counter Overflow Interrupt Enable)

Select whether to include counter overflow as an SCIn_ERI interrupt factor. Set CCR0.RIE = 1 and CCR3.MOD [1:0] = 110b are required to output SCIn_ERI upon counter overflow.

AEDIE bit (Active Edge Detection Interrupt Enable)

Select whether to output an SCIn_AED interrupt when a valid edge is detected. To output SCIn_AED with valid edge detection, XCR1.BMEN = 1 and CCR3.MOD [1:0] = 110b must be set.

BCCS[1:0] bits (Bus Conflict Detection Clock Selection)

Select the sampling clock for the bus conflict detection circuit.

28.2.15 XCR1 : Simple LIN Control Register 1

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0, 1)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0, 1)

Offset address: 0x38

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CF1CE[7:0]								SCF1D[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PCF1D[7:0]							—	—	BMEN	SDST	—	—	—	TCST	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TCST	Break Field Output Timer Count Start Trigger 0: Break Field output timer count stopped 1: Break Field output timer count start	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	SDST	Start Frame Detection Enable 0: Start Frame/Break Field detection disabled 1: Start Frame/Break Field detection enabled Do not set this bit and TCST bit to 1 at the same time.	R/W
5	BMEN	Bit Rate Measurement Enable Set this bit to 1 simultaneously with the SDST bit. This bit can be set to 0 at any timing. 0: Bit rate measurement disabled 1: Bit rate measurement enabled	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
15:8	PCF1D[7:0]	Priority Compare Data for Control Field 1 The priority compare data for Control Field 1.	R/W
23:16	SCF1D[7:0]	Secondary Compare Data for Control Field 1 The secondary compare data for Control Field 1.	R/W
31:24	CF1CE[7:0]	Control Field 1 Compare Bit Enable Select whether to compare bit N of Control Field 1. (N = 0 -7) 0: Control Field 1 bit N compare disabled 1: Control Field 1 bit N compare enabled	R/W

Note: S-TYPE-3, P-TYPE-3

TCST bit (Break Field Output Timer Count Start Trigger)

[Clearing condition]

- When 0 is written to TCST. Break Field output timer count is stopped and TXDn output becomes idle level.
- When Break Field output for the period set in XCR2.BFLW [15: 0] is completed.

[Setting condition]

- When 1 is written to TCST. Start Break Field output from TXDn. Holds 1 during Break Field output.

SDST bit (Start Frame Detection Enable)

When 1 is written to the SDST bit, Start Frame detection starts. When XCR0.BFE = 1 is set, Break Field can be detected during Start Frame is detected and after Start Frame is detected. When XCR0.BFE = 0 is set, Break Field is not detected.

When 0 is written to the SDST bit, Start Frame detection and Break Field detection are stopped. However, if XSR0.RXDSF = 0 at the time of stop, it is not possible to stop data reception of the SCI core with this bit. Write 0 to CCR0.RE to stop the reception operation or perform reception completion processing (CSR.RDRF clear or RDR read) after reception is completed.

BMEN bit (Bit Rate Measurement Enable)

Set this bit to 1 simultaneously with the SDST bit. When the BMEN bit is set to 1, the valid edge interval of Control Field 0 and Control Field 1 data is measured.

PCF1D[7:0] bits (Priority Compare Data for Control Field 1)

Set the priority compare data for Control Field 1.

SCF1D[7:0] bits (Secondary Compare Data for Control Field 1)

Set the secondary compare data for Control Field 1.

CF1CE[7:0] bits (Control Field 1 Compare Bit Enable)

Select whether to compare bit N of Control Field 1. (N = 0 - 7)

When all of the CF1CE[7:0] bits are set to 0 (CF1CE[7:0] = 0x00), it is always determined that Control Field 1 matches when reception is completed, and XSR0.CF1MF is set. This bit is a comparison enable with PCF1D[7:0] or SCF1D[7:0], and is not a priority interrupt bit comparison enable.

28.2.16 XCR2 : Simple LIN Control Register 2

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0, 1)
 SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0, 1)

Offset address: 0x3C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	BFLW[15:0]															
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CF0CE[7:0]								CF0D[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CF0D[7:0]	Control Field 0 Compare Data The compare data for Control Field 0.	R/W
15:8	CF0CE[7:0]	Control Field 0 Compare Bit Enable Select whether to compare bit N of Control Field 0. (N = 0 - 7) 0: Control Field 0 bit N compare disabled 1: Control Field 0 bit N compare enabled	R/W
31:16	BFLW[15:0]	Break Field Length Setting This register sets the Break Field length. The Break Field length is (BFLW [15:0] setting value + 1) × clock of the timer. The upper limit for setting this register is 0xFFFE. Setting is prohibited for 0xFFFF.	R/W

Note: S-TYPE-3, P-TYPE-3

CF0D[7:0] bits (Control Field 0 Compare Data)

The compare data for Control Field 0.

CF0CE[7:0] bits (Control Field 0 Compare Bit Enable)

Select whether to compare bit N of Control Field 0. (N = 0 - 7)

When all of the CF0CE[7:0] bits are set to 0 (CF0CE[7:0] = 0x00), it is always determined that Control Field 0 matches when reception is completed, and XSR0.CF0MF is set.

BFLW[15:0] bits (Break Field Length Setting)

BFLW[15:0] are 16-bit Break Field length setting bits and the initial value is 0xFFFE.

Set the Break Field length to 1 frame or more. The LIN standard stipulates that the Break Field length is 13 bits or more.

When the Break Field is sending, writing 1 to TCST causes SCI to output the Break Field on TXDn. Up-counting is performed with the clock of the timer selected by XCR0.TCSS[1:0]. When the count value matches the value set in this register, up-counting is stopped and Break Field output from TXDn is also stopped.

When the Break Field is receiving, writing 1 to SDST enables Start Frame detection. SCI starts counting from the negative edge of RXDn. The clock of the timer is selected by XCR0.TCSS[1:0].

When the count value matches the value set in the XCR2, a Break Field has been detected. Up-counting continues until the next valid edge or counter overflow.

28.2.17 CSR : Common Status Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
 SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x48

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	RDRF	TEND	TDRE	FER	PER	MFF	—	ORER	—	—	—	—	—	DFER	DPER	DCMF
Value after reset:	0	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RXDMON	—	—	—	—	—	—	—	—	—	—	ERS	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0.	R
4	ERS	Error Signal Status Flag Valid only in Smart card interface mode. 0: Error signal low not responded 1: Error signal low responded	R
14:5	—	These bits are read as 0.	R
15	RXDMON	Serial Input Data Monitor Bit The state of the RXDn pin without synchronizing by bus clock is shown. 0: When RINV is 0, RXDn pin is the low level. When RINV is 1, RXDn pin is the high level. 1: When RINV is 0, RXDn pin is the high level. When RINV is 1, RXDn pin is the low level.	R
16	DCMF	Data Compare Match Flag Valid only in Asynchronous mode. 0: No matched 1: Matched	R
17	DPER	Data Compare Match Parity Error Flag Valid only in Asynchronous mode. 0: No parity error occurred at address match detection 1: A parity error has occurred at address match detection	R
18	DFER	Data Compare Match Framing Error Flag Valid only in Asynchronous mode. 0: No framing error occurred at address match detection 1: A framing error has occurred at address match detection	R
23:19	—	These bits are read as 0.	R
24	ORER	Overrun Error Flag 0: No overrun error occurred 1: An overrun error has occurred	R
25	—	This bit is read as 0.	R
26	MFF	Mode Fault Error Flag Valid only in Simple SPI mode. 0: No mode fault error 1: Mode fault error	R
27	PER	Parity Error Flag 0: Non-FIFO selected (CCR3.FM = 0): No parity error occurred FIFO selected (CCR3.FM = 1): No parity error in all received data in receive-FIFO 1: Non-FIFO selected (CCR3.FM = 0): A parity error has occurred FIFO selected (CCR3.FM = 1): One or more parity errors occurred in received data in receive-FIFO	R

Bit	Symbol	Function	R/W
28	FER	Framing Error Flag 0: Non-FIFO selected (CCR3.FM = 0): No framing error occurred FIFO selected (CCR3.FM = 1): No framing error in all received data in receive-FIFO 1: Non-FIFO selected (CCR3.FM = 0): A framing error has occurred FIFO selected (CCR3.FM = 1): One or more framing errors occurred in received data in receive-FIFO	R
29	TDRE	Transmit Data Empty Flag 0: Non-FIFO selected (CCR3.FM = 0): Transmit data is in TDR register FIFO selected (CCR3.FM = 1): The quantity of transmit data written in transmit-FIFO exceeds the specified transmit triggering number. 1: Non-FIFO selected (CCR3.FM = 0): No transmit data is in TDR register FIFO selected (CCR3.FM = 1): The quantity of transmit data written in transmit-FIFO is equal to or less than the specified transmit triggering number.	R
30	TEND	Transmit End Flag 0: A character is being transmitted or standing by for transmission. 1: Character transfer has been completed, or sending Break Field.	R
31	RDRF	Receive Data Full Flag 0: Non-FIFO selected (CCR3.FM = 0): No received data is in RDR register FIFO selected (CCR3.FM = 1): The quantity of receive data written in receive-FIFO falls below the specified receive triggering number. 1: Non-FIFO selected (CCR3.FM = 0): Received data is in RDR register FIFO selected (CCR3.FM = 1): The quantity of receive data written in receive-FIFO is equal to or greater than the specified receive triggering number.	R

Note: S-TYPE-3, P-TYPE-3

ERS bit (Error Signal Status Flag)

[Setting condition]

- When an error signal low is sampled.

[Clearing condition]

- When write 1 to CFCLR.ERSC.

DCMF bit (Data Compare Match Flag)

The DCMF bit indicates that SCI detects the match to the comparison data (CCR4.CMPD) with receive data.

Clearing the CCR0.RE bit to 0 does not affect the DCMF flag, which retains its previous state.

[Setting condition]

- Matched to the comparison data (CCR4.CMPD) with receive data, while CCR0.DCME = 1.

[Clearing condition]

- When write 1 to CFCLR.DCMFC.

DPER bit (Data Compare Match Parity Error Flag)

The DPER bit indicates that a parity error occurred at address match detection (reception data match detection).

Clearing the CCR0.RE bit to 0 does not affect the DPER flag, which retains its previous state.

[Setting condition]

- When a parity error is detected by the frame in which an address match was detected.

[Clearing condition]

- When writing 1 to CFCLR.DPERC.

DFER bit (Data Compare Match Framing Error Flag)

The DFER bit indicates that a framing error occurred at address match detection (reception data match detection).

Clearing the CCR0.RE bit to 0 does not affect the DFER flag, which retains its previous state.

[Setting condition]

- When a stop bit of the frame in which an address match was detected is 0.
When it is a 2-stop mode, the 1st bit of the stop bit only determines whether it is 1 and does not check the 2nd bit of the stop bit.

[Clearing condition]

- When writing 1 to CFCLR.DFERC.

ORER bit (Overrun Error Flag)

The ORER bit indicates that an overrun error has occurred during reception and the reception ends abnormally.

Clearing the CCR0.RE bit to 0 does not affect the ORER flag, which retains its previous state. In Simple IIC mode, the ORER bit is not used.

[Setting condition with non-FIFO mode (CCR3.FM = 0)]

- When the next data is received before reading out RDR with no-error reception data stored in RDR.
In RDR, receive data prior to an overrun error occurrence is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, reception data is not forwarded to RDR register.

Note: In Clock synchronous mode and Simple SPI mode, serial reception is stopped.

[Setting condition with FIFO mode (CCR3.FM = 1)]

- When the next serial reception is completed while the receive FIFO is full of 16 receive data.

[Clearing condition]

- When write 1 to CFCLR.ORERC.

MFF bit (Mode Fault Error Flag)

The MFF bit indicates mode fault errors. In a multi-master configuration, determine the mode fault error occurrence by reading the MFF flag.

[Setting condition]

- Input on the SSn pin being at the low level during master operation (CCR3.CKE[1:0] = 00 or 01) in Simple SPI mode.

[Clearing condition]

- When writing 1 to CFCLR.MFFC.

PER bit (Parity Error Flag)

The PER bit indicates that a parity error has occurred during reception and the reception ends abnormally.

Clearing the CCR0.RE bit to 0 does not affect the PER flag, which retains its previous state.

In Clock synchronous mode, Simple SPI mode, and Simple IIC mode, the PER bit is not used.

[Setting condition]

- When a parity error is detected during reception. In FIFO select mode, when one or more parity error is detected in receive-FIFO data.
In non-FIFO mode, although receive data when the parity error occurs is transferred to RDR, no SCI_{In}_RXI interrupt request occurs. Note that when the PER flag is set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When writing 1 to CFCLR.PERC.

FER bit (Framing Error Flag)

The FER bit indicates that a framing error has occurred during reception and the reception ends abnormally.

Clearing the CCR0.RE bit to 0 does not affect the FER flag, which retains its previous state.

In Clock synchronous mode, Simple SPI mode, and Simple IIC mode, the FER bit is not used.

[Setting condition]

- When 0 is sampled as the stop bit during reception. In FIFO select mode, when one or more framing error is detected in receive-FIFO data. In Manchester mode, when both sampling results (1/4 and 3/4 sampling points) are not 1 for 1 stop bit. In Simple LIN mode, even if a condition that changes to 1 occurs when XCR1.SDST = 1, the FER set timing is delayed up to the Break Field evaluation timing at the longest, since it may be a Break Field. If an edge is detected on the RXDn signal before the Break Field evaluation timing, FER is detected. If no edge is detected in the RXDn signal before the Break Field evaluation timing, Break Field is detected.
In 2-stop-bit mode, only the first stop bit is checked whether it is 1 but the second stop bit is not checked. In non-FIFO mode, although receive data when the framing error occurs is transferred to RDR, no SCIn_RXI interrupt request occurs. In addition, when the FER flag is being set to 1, the subsequent receive data is not transferred to RDR.

[Clearing condition]

- When writing 1 to CFCLR.FERC.

TDRE bit (Transmit Data Empty Flag)

[Non-FIFO selected (CCR3.FM = 0)]

The TDRE bit indicates the presence of transmit data in the TDR register.

The condition of CCR0.TE = 0 has priority over the condition of 0.

If other conditions that become 1 and conditions that become 0 are satisfied at the same time, the TDRE flag is set to 0.

[Setting condition]

- When CCR0.TE is 0.
- When data is transmitted from the TDR register to the TSR register.

[Clearing condition]

- When writing 1 to CFCLR.TDREC.
- When the transmission data is written to the TDR register during CCR0.TE = 1.

[FIFO selected (CCR3.FM = 1)]

The TDRE bit indicates that data has been transferred from the transmit-FIFO (TDR) into the transmit shift register (TSR), the quantity of data in transmit-FIFO has fallen below the specified transmit triggering number.

When the condition which becomes 1 and the condition which becomes 0 are formed at the same time, TDRE flag is 0. After that, when the number of data stored in transmit-FIFO is evaluated, and if that is equal to or less than TTRG value, TDRE is set to 1 after 1 PCLK.

[Setting condition]

- When the quantity of transmit data written in transmit-FIFO is equal to or less than the specified transmit triggering number*1.

Note 1. The transmit-FIFO is FIFO register of 16 stages, the maximum number of data that can be written when the TDRE flag is 1 is indicated in 0x10 - FTSR.T[5:0]. Even if more data is written, data is discarded.

[Clearing condition]

- When writing 1 to CFCLR.TDREC.
- When the transmission data is written to transmit-FIFO by the DTC or DMAC (the last block transfer of block transfer).

TEND bit (Transmit End Flag)

[Non-FIFO selected (CCR3.FM = 0), and not Smart card interface mode (CCR3.MOD[2:0] ≠ 001)]

The TEND bit indicates completion of transmission.

[Setting condition]

- When CCR0.TE is 0.
- When the CCR0.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When the TDR register is not updated at the time of transmission of the tail-end bit of a character being transmitted.

- When the TDR register is not updated at the end of DE negate time with DE control function enable (CCR3.DEN = 1).
- When Break Field is sending.

[Clearing condition]

- After the synchronization delay time has elapsed since the transmission data was written to the TDR register during CCR0.TE = 1.
- When writing 1 to CFCLR.TDREC during CCR0.TE = 1.

[Non-FIFO selected (CCR3.FM = 0), and Smart card interface mode (CCR3.MOD [2:0] = 001)]

With no error signal from the receiving side, this bit is set to 1 when additional data for transfer is ready to be transferred to the TDR register.

[Setting condition]

- When CCR0.TE is 0.
- When the CCR0.TE bit is changed from 0 to 1, the TEND flag is not affected and retains the value 1.
- When a specified period has elapsed after the latest transmission of 1 byte, the ERS flag is 0, and the TDR register is not updated. The set timing is determined by register settings as listed below.
 - When GM = 0 and BLK = 0, 12.5etu after the start of transmission
 - When GM = 0 and BLK = 1, 11.5etu after the start of transmission
 - When GM = 1 and BLK = 0, 11.0etu after the start of transmission
 - When GM = 1 and BLK = 1, 11.0etu after the start of transmission

[Clearing condition]

- After the synchronization delay time has elapsed since the transmission data was written to the TDR register during CCR0.TE = 1.
- When writing 1 to CFCLR.TDREC during CCR0.TE = 1.

[FIFO selected (CCR3.FM = 1)]

The TEND bit indicates that the transmit-FIFO does not contain valid data when transmitting the last bit of a serial character, so the transmission is halted.

[Setting condition]

- TEND is set to 1 when transmit-FIFO does not contain transmit data when the last bit of a one-byte serial character is transmitted.
- When the TDR register is not updated at the end of DE negate time with DE control function enable (CCR3.DEN = 1).

[Clearing condition]

- After the synchronization delay time has elapsed since the transmission data was written to the TDR register during CCR0.TE = 1.

RDRF bit (Receive Data Full Flag)

[Non-FIFO selected (CCR3.FM = 0)]

The RDRF bit indicates the presence of receive data in the RDR register.

[Setting condition]

- When the reception ends normally, and receive data is forwarded from the RSR register to the RDR register.

[Clearing condition]

- When writing 1 to CFCLR.RDRFC.
- When the read data is read from the RDR register.

[FIFO selected (CCR3.FM = 1)]

The RDRF bit indicates that receive data has been transferred to the receive FIFO data register (RDR), and the quantity of data in receive-FIFO is equal to or greater than the specified receive triggering number. When FCR.RTRG is set to 0, RDRF is set if the quantity of data in receive-FIFO is greater than or equal to 1.

[Setting condition]

- RDRF is set to 1 when the quantity of receive data in receive-FIFO is equal to or greater than the specified receive triggering number*1.

Note 1. Since the receive-FIFO is 16 stage FIFO register, the maximum quantity of data that can be read when RDRF is 1 is equivalent to the specified receive data count number (FDR.R[5:0]). If an attempt is made to read after all the data in receive-FIFO has been read, the data is undefined.

[Clearing condition]

- When writing 1 to CFCLR.RDRFC.
- When the reception data is read from receive-FIFO by the DTC or DMAC (the last block transfer of a block transfer).

When the condition which becomes 1 and the condition which becomes 0 are formed at the same time, RDRF flag is 0. After that, when the number of stored data in receive-FIFO is evaluated, and if that is equal to or greater than RTRG value, RDRF is set to 1 after 1 PCLK.

Note: When Non-FIFO is selected, except when interruption communication, RDRF and TDRE should not be cleared by CFCLR register.

28.2.18 ISR : Simple IIC Status Register

Base address: SCLn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCLn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x4C

Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	IICSTI F	—	—	IICAC KR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	IICACKR	ACK Reception Data Flag 0: ACK received 1: NACK received	R
1	—	This bit is read as 0.	R
2	—	The read value is undefined.	R
3	IICSTIF	Issuing of Start, Restart, or Stop Condition Completed Flag 0: There are no requests for generating conditions or a condition is being generated. 1: A start, restart, or stop condition is completely generated.	R
5:4	—	The read value is undefined.	R
31:6	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

IICACKR bit (ACK Reception Data Flag)

Received ACK and NACK bits can be read from this bit.

The IICACKR flag is updated at the rising of SCLn clock for the ACK/NACK receiving bit.

IICSTIF bit (Issuing of Start, Restart, or Stop Condition Completed Flag)

After generating a condition, this bit indicates that the generation is completed. When using the IICSTAREQ, IICRSTAREQ, or IICSTPREQ bit to cause generation of a condition, do so after setting the IICSTIF flag to 0.

When the IICSTIF flag is 1 while an interrupt request is enabled by setting the CCR0.TEIE bit, an STIn request is output.

[Setting condition]

- Completion of the generation of a start, restart, or stop condition (however, in cases where this conflicts with any of the conditions for the flag becoming 0 listed below, the clearing condition takes precedence)

[Clearing condition]

- Writing 1 to ICFCLR.IICSTIFC bit
- When operation is not in Simple IIC mode
- Writing 0 to CCR0.TE bit

28.2.19 FRSR : FIFO Receive Status Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x50

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
Bit field:	—	—	FNUM[5:0]					—	—	PNUM[5:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Bit field:	—	—	R[5:0]					—	—	—	—	—	—	—	—	—	DR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	x	0	

Bit	Symbol	Function	R/W
0	DR	Receive Data Ready Flag 0: Receiving is in progress, or no received data remains in the receive-FIFO after a successful reception (receive-FIFO is empty) 1: The following receive data is not received for a fixed period after storing data under the threshold in the receive-FIFO	R
1	—	The read value is undefined.	R
7:2	—	These bits are read as 0.	R
13:8	R[5:0]	Receive-FIFO Data Count Valid in Asynchronous mode (including Multiprocessor mode), Clock synchronous mode, and Simple SPI mode, when CCR3.FM is 1. Indicate the quantity of receive data stored in receive-FIFO	R
15:14	—	These bits are read as 0.	R
21:16	PNUM[5:0]	Parity Error Count Valid only in Asynchronous mode Indicates the quantity of data with a parity error for the receive data stored in the Receive FIFO Data register.	R
23:22	—	These bits are read as 0.	R
29:24	FNUM[5:0]	Framing Error Count Valid only in Asynchronous mode. Indicates the quantity of data with a framing error for the receive data stored in the Receive FIFO Data register.	R
31:30	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

DR bit (Receive Data Ready Flag)

The DR bit indicates that the quantity of data stored in the Receive FIFO Data register (RDR) falls below the specified receive triggering number, and that no next data has been received yet after the elapse of 15 etu from the last stop bit in Asynchronous mode. This bit is valid only Asynchronous mode (including Multiprocessor mode) and FIFO selected. In other mode, this bit does not set to 1.

[Setting conditions]

- DR is set to 1 when the following conditions are met:
 - After receive FIFO Data register (RDR) receives less data than the specified receive triggering number, no next data has been received yet after the elapse of 15 etu*1 from the last stop bit
 - CSR.FER, PER flags are 0.

Note 1. This is equivalent to one and a half (1.5) frames in the 8-bit format with one stop bit (etu: elementary time unit).

[Clearing conditions]

- When all receive data in the receive FIFO Data (RDR register) is read and 1 is written to FFCLR.DRC.
- When CCR3.FM bit is 0.

R[5:0] bits (Receive-FIFO Data Count)

The R[5:0] bits indicate the quantity of receive data stored in the Receive FIFO Data register.

0x00 means no receive data. 0x10 means receive-FIFO is full.

PNUM[5:0] bits (Parity Error Count)

The value indicates the quantity of data stored in the Receive FIFO Data register with a parity error.

FNUM[5:0] bits (Framing Error Count)

The value indicates the quantity of data stored in the Receive FIFO Data registers with a framing error.

28.2.20 FTSR : FIFO Transmit Status Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
 SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x54

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	T[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	T[5:0]	Transmit-FIFO Data Count Valid in Asynchronous mode (including Multiprocessor mode), Clock synchronous mode, and Simple SPI mode, when CCR3.FM is 1. Indicate the quantity of non-transmit data stored in transmit-FIFO	R
31:6	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

T[5:0] bits (Transmit-FIFO Data Count)

The T[5:0] bits indicate the quantity of non-transmitted data stored in transmit-FIFO.

0x00 means no non-transmit data. 0x10 means transmit-FIFO is full.

28.2.21 MSR : Manchester Status Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0)
 SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0)

Offset address: 0x58

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	RSYN C	—	MER	—	SBER	SYER	PFER
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PFER	Preface Error Flag This bit is set when a preface error (pattern mismatch) is detected 0: No preface error detected 1: Preface error detected	R
1	SYER	SYNC Error Flag This bit is set when no edge is detected in the adjustable range during receive retiming 0: No receive SYNC error detected 1: Receive SYNC error detected	R
2	SBER	Start Bit Error Flag This bit is set when a pattern mismatch in the start bit area is detected 0: No start bit error detected 1: Start bit error detected	R
3	—	This bit is read as 0.	R
4	MER	Manchester Error Flag Valid for Manchester mode only 0: No Manchester error occurred 1: Manchester error has occurred	R
5	—	This bit is read as 0.	R
6	RSYNC	Receive SYNC Data Bit It is valid when MCR.SBSEL = 1 in Manchester mode, 0 is read otherwise. 0: The received start bit is DATA SYNC 1: The received start bit is COMMAND SYNC	R
31:7	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

PFER bit (Preface Error Flag)

The PFER bit indicates that a preface error was detected when receiving frames in Manchester mode.

Even when the RE bit in CCR0 is set to 0 (serial reception is disabled), the PFER flag is not affected and retains its previous value.

[Setting condition]

- When detecting a preface error when receiving frames in Manchester mode
The following operations are performed when a preface error occurs.
 - When MCR.PFEREN = 1
The received data is not transferred to the RDR register and no SCIn_RXI interrupt request occurs. Instead, an SCIn_ERI interrupt request occurs. Note that when the PFER flag is set to 1, the subsequently received data is not transferred to the RDR register.
 - When MCR.PFEREN = 0

The received data is transferred to the RDR register and an SCIn_RXI interrupt request occurs. An SCIn_ERI interrupt request is not generated. The subsequent receive operations are not affected even with the PFER flag is set to 1.

[Clearing condition]

- Writing 1 to MFCLR.PFERC.

SYER bit (SYNC Error Flag)

The SYER bit indicates that a receive SYNC error was detected when receiving frames in Manchester mode with MCR.ERTEN = 1 (Manchester edge retiming enabled).

Even when the RE bit in CCR0 is set to 0 (serial reception is disabled), the SYER flag is not affected and retains its previous value.

[Setting condition]

- When detecting a receive SYNC error when receiving frames in Manchester mode
The following operations are performed when a receive SYNC error occurs.
 - When MCR.SYEREN = 1
Although the received data is transferred to the RDR register, no SCIn_RXI interrupt request occurs. Instead, an SCIn_ERI interrupt request occurs. Note that when the SYER flag is set to 1, the subsequently received data is not transferred to the RDR register.
 - When MCR.SYEREN = 0
The received data is transferred to the RDR register and an SCIn_RXI interrupt request occurs. An SCIn_ERI interrupt request is not generated. The subsequent receive operations are not affected even with the SYER flag is set to 1.

[Clearing condition]

- Writing 1 to MFCLR.SYERC.

SBER bit (Start Bit Error Flag)

The SBER bit indicates that a start bit error was detected when receiving frames in Manchester mode.

Even when the RE bit in CCR0 is set to 0 (serial reception is disabled), the SBER flag is not affected and retains its previous value.

[Setting condition]

- When detecting a start bit error when receiving frames in Manchester mode
The following operations are performed when a start bit error occurs.
 - When MCR.SBEREN = 1
The received data is not transferred to the RDR register and no SCIn_RXI interrupt request occurs. Instead, an SCIn_ERI interrupt request occurs. Note that when the SBER flag is set to 1, the subsequently received data is not transferred to the RDR register.
 - When MCR.SBEREN = 0
The received data is transferred to the RDR register and an SCIn_RXI interrupt request occurs. An SCIn_ERI interrupt request is not generated. The subsequent receive operations are not affected even with the SBER flag is set to 1.

[Clearing condition]

- Writing 1 to MFCLR.SBERC.

MER bit (Manchester Error Flag)

When data is received in Manchester mode, Manchester error is detected and displayed. Even when the RE bit in CCR0 is set to 0 (serial reception is disabled), the MER flag is not affected and retains its previous value.

[Setting conditions]

- When receiving in Manchester mode and detecting Manchester code error in data area of received frame.

Received data when an error occurs is transferred to the RDR register, but the SCIn_RXI interrupt request is not generated and the SCIn_ERI interrupt request is generated.

When the Manchester error flag is set to 1, subsequent receive data is not transferred to the RDR register.

For details on Manchester error, [section 28.5.11. Errors in Manchester Mode](#).

[Clearing condition]

- Writing 1 to MFCLR.MERC.

RSYNC bit (Receive SYNC Data Bit)

When Manchester mode (CCR3.MOD[2:0] = 101b) and MCR.SBSEL = 1, this bit indicates the type of SYNC of the received start bit. For other settings, it is fixed to 0.

28.2.22 XSR0 : Simple LIN Status Register 0

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0, 1)
 SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0, 1)

Offset address: 0x5C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CF1RD[7:0]								CF0RD[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	AEDF	COF	PIBDF	CF1MF	CF0MF	BFDF	BCDF	BFOF	—	—	—	—	—	—	RXDSF	SFSF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SFSF	Start Frame Status Flag 0: Start Frame detection disabled or Start Frame detection complete 1: Before Start Frame detection or during detection	R ¹
1	RXDSF	RxDn Input Status Flag 0: RxDn input to SCI is enabled 1: RxDn input to SCI is disabled	R ¹
7:2	—	These bits are read as 0.	R
8	BFOF	Break Field Output Completion Flag 0: Break Field is being output or is not being output 1: Completed BF output	R
9	BCDF	Bus Conflict Detection Flag 0: No bus collision detected 1: Detected a bus collision	R
10	BFDF	Break Field Detection Flag 0: Break Field is not detected 1: Break Field is detected	R
11	CF0MF	Control Field 0 Compare Match Flag 0: Control Field 0 received data does not match the setting data 1: Control Field 0 received data matches the setting data	R
12	CF1MF	Control Field 1 Compare Match Flag 0: Control Field 1 received data does not match the setting data 1: Control Field 1 received data matches the setting data	R
13	PIBDF	Priority Interrupt Bit Detection Flag 0: Priority interrupt bit is not detected 1: Priority interrupt bit is detected	R
14	COF	Counter Overflow Flag 0: Break Field detection counter has not overflowed 1: Break Field detection counter overflowed	R

Bit	Symbol	Function	R/W
15	AEDF	Active Edge Detection Flag 0: No valid edge detected 1: Detected a valid edge	R
23:16	CF0RD[7:0]	Control Field 0 received data Control Field 0 received data.	R
31:24	CF1RD[7:0]	Control Field 1 received data Control Field 1 received data.	R

Note: S-TYPE-3, P-TYPE-3

Note 1. When PCLK is faster than TCLK, the flag set timing is delayed from the receive data full interrupt (SCIn_RXI) output. To see this flag under these conditions, wait at least 1 TCLK cycle after the receive data full interrupt (SCIn_RXI) before reading this register.

SFSF bit (Start Frame Status Flag)

Indicates whether detect Start Frame is being detected.

[Setting condition]

- When 1 is written to XCR1.SDST.
- When a Break Field is detected in the Control Field 0/Control Field 1/Information Field phase and the transition to the Control Field 0 or Control Field 1 reception state occurs.

[Clearing condition]

- When XCR1.SDST is 0.
- When Start Frame detection is completed.

RXDSF bit (RXDn Input Status Flag)

Indicates the RXDn input status to the SCI core. When the RXDSF bit is 1, RXDn input is received only by the simple LIN module and the Break Field is detected and is not input to the SCI core.

BFOF bit (Break Field Output Completion Flag)

Indicates the completion of Break Field output.

The BFOF bit can be cleared to 0 by writing 1 to XFCLR.BFOC.

BCDF bit (Bus Conflict Detection Flag)

Indicates the detection of bus conflict in Simple LIN transmit operation.

The BCDF bit can be cleared to 0 by writing 1 to XFCLR.BCDC.

BFDF bit (Break Field Detection Flag)

Indicates Break Field detection.

The BFDF bit can be cleared to 0 by writing 1 to XFCLR.BFDC.

CF0MF bit (Control Field 0 Compare Match Flag)

Indicates compare match of Control Field 0 and compare data.

The CF0MF bit can be cleared to 0 by writing 1 to XFCLR.CF0MC.

CF1MF bit (Control Field 1 Compare Match Flag)

Indicates compare match detection of Control Field 1 and compare data.

The CF1MF bit can be cleared to 0 by writing 1 to XFCLR.CF1MC.

PIBDF bit (Priority Interrupt Bit Detection Flag)

Indicates compare match detection of Control Field 1 and priority interrupt bit.

The PIBDF bit can be cleared to 0 by writing 1 to XFCLR.PIBDC.

COF bit (Counter Overflow Flag)

Indicates that the 16-bit counter in the simple LIN module has overflowed.

The COF bit can be cleared to 0 by writing 1 to XFCLR.COFC.

AEDF bit (Active Edge Detection Flag)

Indicates active edge detection.

The AEDF bit can be cleared to 0 by writing 1 to XFCLR.AEDC and when read out XSR1.TCNT[15:0].

CF0RD[7:0] bits (Control Field 0 received data)

Stores the received data with a Control Field 0 match detected.

CF1RD[7:0] bits (Control Field 1 received data)

Stores the received data with a Control Field 1 match detected.

28.2.23 XSR1 : Simple LIN Status Register 1

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0, 1)
SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0, 1)

Offset address: 0x60

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TCNT[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TCNT[15:0]	Timer Count Capture Value Stores the 16-bit counter capture value. The initial value is 0000.	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

TCNT[15:0] bits (Timer Count Capture Value)

Stores the capture value of the 16-bit counter of the Simple LIN module.

- When sending Start Frame
The XSR1 holds the previous value.
- When receiving Start Frame with bit rate measurement disabled
If a Break Field is detected in the Break Field detection state (see [Figure 28.81](#)), the Break Field length is captured and held (counter value is captured at the rising edge of RXDn). If a Break Field is detected in a state other than the Break Field detection state, the previous value is retained.
If the counter overflows, it is not captured.
- When receiving Start Frame with bit rate measurement enabled
The count value is captured and held at the valid edge (both RXDn edges). However, in the Break Field detection state, the count value is not captured even if a valid edge occurs. Counter capture value retention is canceled by the XSR1 read. Even if a valid edge occurs before reading, the counter value is not captured.

28.2.24 CFCLR : Common Flag Clear Register

Base address: SCIn_B = 0x4035_8000 + 0x0100 × n (n = 0 to 4, 9)
 SCIn_B_NS = 0x5035_8000 + 0x0100 × n (n = 0 to 4, 9)

Offset address: 0x68

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	RDRF C	—	TDRE C	FERC	PERC	MFFC	—	ORER C	—	—	—	—	—	DFER C	DPER C	DCMF C
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

0	RIST	RE Internal Status 0: RE signal internal state value 0 1: RE signal internal state value 1	R
3:1	—	These bits are read as 0.	R
4	TIST	TE Internal Status 0: TE signal internal state value 0 1: TE signal internal state value 1	R
7:5	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The operation clocks of the communication module and control register can be used asynchronously. Since some control register values are transmitted internally through the synchronization circuit so that they operate correctly even if they are asynchronous, it takes some time for the state to be reflected internally after rewriting the control register.

Communication enable CCR0.TE and CCR0.RE correspond to this register, and when these control bits change from 1 to 0 to rewrite the control bits for the next communication, the TE and RE bits signal it is necessary to rewrite the next control bit after the internal state becomes 0. If a very slow clock is used for the communication module clock, the TE and RE bit states are not reflected internally. At this time, you can check the internal status using this register.

28.3 Operation in Asynchronous Mode

Figure 28.6 shows the general format for asynchronous serial communications. One frame consists of a start bit (low level), transmit or receive data, a parity bit, and stop bits (high level). In asynchronous serial communications, the communications line is usually held in the mark state (high level).

The SCI monitors the communications line. When the SCI detects a start bit, it starts serial communication. The detection condition of the start bit changes according to the CCR3.RXDESEL setting. SCI regards space (Low level) as a start bit when CCR3.RXDESEL is 0. SCI regards a fall edge as a start bit when RXDESEL is 1.

Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communications. Both the transmitter and receiver have a double-buffered structure in addition to FIFO mode, so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

Figure 28.6 Data format in asynchronous serial communications with 8-bit data, parity bit, and 2 stop bits

28.3.1 Serial Data Transfer Format

Table 28.28 lists the serial data transfer formats that can be used in Asynchronous mode. Any of 18 transfer formats can be selected with the CCR1 and CCR3 settings. For details on the multi-processor function, see section 28.4. Multi-Processor Communication Function.

Table 28.28 Serial transfer formats in Asynchronous mode (1 of 2)

CCR3		CCR1		CCR3	Serial transfer format and frame length															
CHR[1:0]		PE	MP	STP	1	2	3	4	5	6	7	8	9	10	11	12	13			
0	0	0	0	0	ST	9-bit data									SP					
0	0	0	0	1	ST	9-bit data									SP	SP				
0	0	1	0	0	ST	9-bit data									P	SP				
0	0	1	0	1	ST	9-bit data									P	SP	SP			
1	0	0	0	0	ST	8-bit data								SP						
1	0	0	0	1	ST	8-bit data								SP	SP					
1	0	1	0	0	ST	8-bit data								P	SP					
1	0	1	0	1	ST	8-bit data								P	SP	SP				
1	1	0	0	0	ST	7-bit data							SP							
1	1	0	0	1	ST	7-bit data							SP	SP						
1	1	1	0	0	ST	7-bit data							P	SP						
1	1	1	0	1	ST	7-bit data							P	SP	SP					

Table 28.28 Serial transfer formats in Asynchronous mode (2 of 2)

CCR3		CCR1		CCR3	Serial transfer format and frame length												
CHR[1:0]		PE	MP	STP	1	2	3	4	5	6	7	8	9	10	11	12	13
0	0	—	1	0	ST	9-bit data									MPB	SP	
0	0	—	1	1	ST	9-bit data									MPB	SP	SP
1	0	—	1	0	ST	8-bit data								MPB	SP		
1	0	—	1	1	ST	8-bit data								MPB	SP	SP	
1	1	—	1	0	ST	7-bit data							MPB	SP			
1	1	—	1	1	ST	7-bit data							MPB	SP	SP		

ST: Start bit
 SP: Stop bit
 P: Parity bit
 MPB: Multi-processor bit

28.3.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In Asynchronous mode, the SCI operates on a base clock with a frequency of 16 times^{*1} the bit rate.

In reception, the SCI samples the falling edge of the start bit using the base clock, and performs internal synchronization.^{*2}

Because receive data is sampled on the rising edge of the 8th pulse^{*1} of the base clock, data is latched at the middle of each bit (when sampling timing does not adjust (CCR4.ASEN = 0 or CCR4.ASEN = 1 and CCR4.AST[2:0] = 000b)), as shown in [Figure 28.7](#) The reception margin in Asynchronous mode is determined by the following formula (1):

$$M = \left| \left(0.5 - \frac{1}{2N} \right) - (L - 0.5)F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100 \text{ [%]} \quad \dots \text{ Formula (1)}$$

Note: M: Reception margin

N: Ratio of bit rate to clock

See [Table 28.6](#) for bit rate to basic clock ratios.

D: Duty cycle of clock (D = 0.5 to 1.0)

L: Frame length (L = 9 to 13)

F: Absolute value of clock frequency deviation

Assuming values of F = 0 and D = 0.5 in formula (1), the reception margin is determined using the following formula:

$$M = \{0.5 - 1/(2 \times 16)\} \times 100 \text{ (%) = 46.875 \%}$$

This represents the computed value. Renesas recommends a margin of 20% to 30% in system design.

Note 1. This is an example when CCR2.ABCS is 0, CCR2.ABCSE is 0 and CCR2.ABCSE2 is 0. When CCR2.ABCS is 1, CCR2.ABCSE is 0 and CCR2.ABCSE2 is 0, a frequency of 8 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 4th pulse of the base clock. When CCR2.ABCSE is 1 and CCR2.ABCSE2 is 0, a frequency of 6 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 3rd pulse of the base clock. When CCR2.ABCSE is 0 and CCR2.ABCSE2 is 1, a frequency of 4 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 2nd pulse of the base clock.

Note 2. The determination condition of the start bit is as follows.

The function of adjust sampling timing is OFF (ASEN = 0):

The determination condition of a start bit is that Low beyond half bit length continues. It is same as the sampling timing. In [Figure 28.7](#), Low period should be kept over 8-cycles to detect a start bit. If Low period does not keep over 8-cycles, the SCI judges this as a noise. So, the SCI does not start reception and wait start bit.

The function of adjust sampling timing is ON (ASEN = 1):

The determination condition of a start bit is that Low keeps up until the sampling timing. Adjusting the sampling timing forward (AJD = 1) increases the possibility of erroneously determining a noise as the start bit.

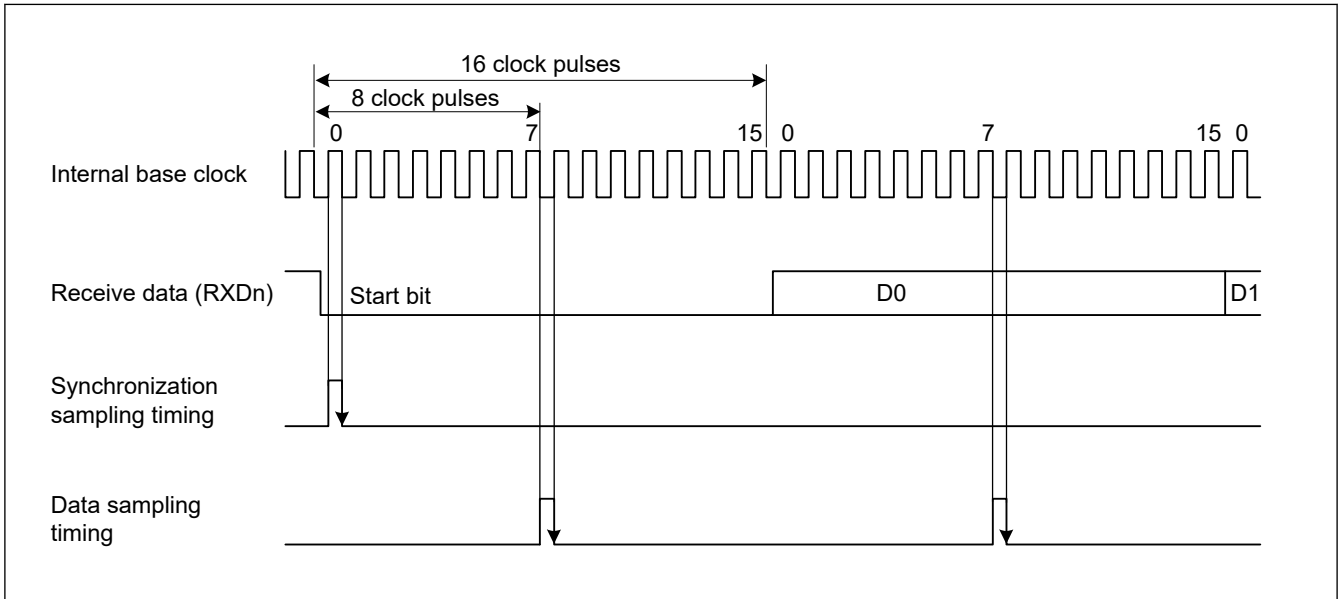

Figure 28.7 Receive data sampling timing in Asynchronous mode

28.3.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input to the SCKn pin can be selected as the transfer clock of the SCI, based on the CCR3.CKE[1:0] settings.

When an external clock is input to the SCKn pin, the clock frequency must be 16 times the bit rate (when CCR2.ABCS = 0) or 8 times the bit rate (when CCR2.ABCS = 1).

In addition, when an external clock is specified, the base clock of GPTn (n = 3, 4) can be selected by the CCR2.ACS0.

When the SCI uses its internal clock, the clock can be output from the SCKn pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is configured so that the rising edge of the clock is in the middle of the transmit data, as shown in Figure 28.8.

When the internal clock is selected, the SCKn pin is outputted after setting the CCR0.TE or CCR0.RE bit to 1.

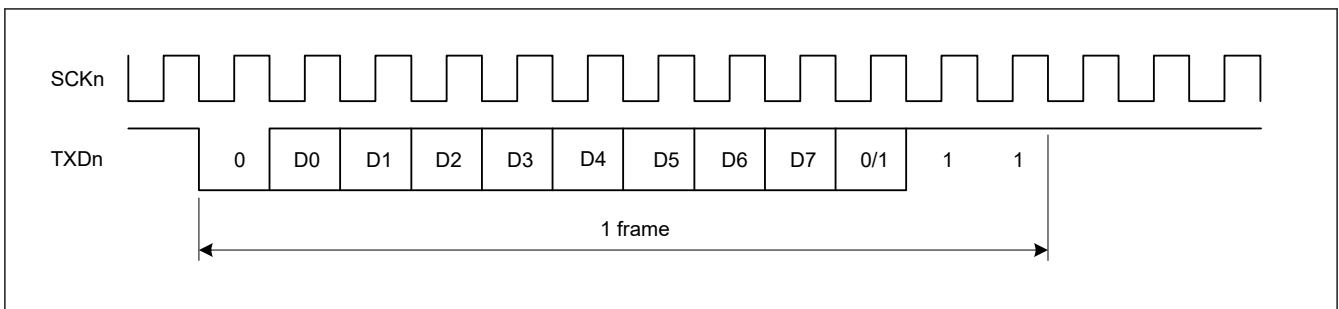

Figure 28.8 Phase relationship between output clock and transmit data in Asynchronous mode when CCR1.PE = 1, CCR3.CHR[1:0] = 10b, MP = 0, and STP = 1

28.3.4 Double-Speed Operation and Frequency of 6 or 4 Times the Bit Rate

When the CCR2.ABCS bit is set to 1, the SCI operates on the bit rate twice that of when ABCS is set to 0. When the CCR2.BGDM bit is set to 1, the cycle of the base clock is half and the bit rate is double that of when BGDM is set to 0. When the CCR3.CKE[1] bit is set to 0 and the on-chip baud rate generator is selected, setting the ABCS and BGDM bits to 1 allows the SCI to operate at a bit rate four times that when the ABCS and BGDM bits are set to 0.

When CCR2.ABCSE is set to 1 and CCR2.ABCSE2 is set to 0, the number of base clock pulses are 6 during a period of 1 bit, and the base clock frequency is half. And RSCI works 16/3 times of bit rate compared with a case of CCR2.ABCS = 0, CCR2.BGDM = 0, CCR2.ABCSE = 0 and CCR2.ABCSE2 = 0.

When CCR2.ABCSE is set to 1 and CCR2.ABCSE2 is set to 1, the number of base clock pulses are 4 during a period of 1 bit, and the base clock frequency is half. And RSCI works 8 times of bit rate compared with a case of CCR2.ABCS = 0, CCR2.BGDM = 0, CCR2.ABCSE = 0 and CCR2.ABCSE2 = 0.

As shown by Formula (1) in [section 28.3.2. Receive Data Sampling Timing and Reception Margin in Asynchronous Mode](#), the reception margin decreases when CCR2.ABCS is set to 1, CCR2.ABCSE is set to 1 or CCR2.ABCSE2 is set to 1. Therefore, if the desired bit rate can be obtained, it is recommended to use the RSCI with CCR2.ABCS set to 1, CCR2.ABCSE set to 1 and CCR2.ABCSE2 set to 1.

28.3.5 CTS and RTS Functions

The CTS function controls transmission using the CTSn pin input. Setting the CCR1.CTSE bit to 1 enables the CTS function. For the functions of CTS and RTS, you can select the alternate setting to set CTSn_RTSn pin as a multiplexed pin that uses either function with one pin or the dedicated setting that uses each function independently with two pins at CTSn pin for CTSn signal and CTSn_RTSn pin for RTSn signal. This setting is done with the CCR1.CTSPEN bit.

When the CTS function is enabled, placing a low level on the CTSn_RTSn pin causes transmission to start.

If FIFO is used and CTSn_RTSn signal is held high before transmission, transmission will not start, so the number of TDR registers written, and the number of data stored are the same (unlike using clock synchronous FIFO).

Driving the CTSn_RTSn pin high while transmission is in progress does not affect transmission of the current frame.

In the RTS function, which uses output on the CTSn_RTSn pin, a low level is output when reception becomes possible. Conditions for output of the low and high levels are shown in this section.

[Conditions for low level output]

Satisfaction of all conditions are listed in this section.

Non-FIFO selected

- The value of the CCR0.RE bit is 1
- When the next reception is possible
 - There are no received data yet to be read and not receiving.
 - CSR.ORER, FER, PER flags are all 0

FIFO selected

- The value of the CCR0.RE bit is 1
- When the next reception is possible
 - When the quantity of receive data written in receive-FIFO(RDR) are less than the setting value of FCR.RSTRG[4:0]
 - CSR.ORER(RDR.ORER) is 0

[Condition for high level output]

- The conditions for low-level output are not satisfied

28.3.6 Address Match (Receive Data Match Detection) Function

The address match function can be used only in Asynchronous mode.

If the CCR0.DCME bit is set to 1², when one frame of data is received, the SCI compares that received data with the data set in CCR4.CMPD. If the SCI detects a match to the comparison data (CCR4.CMPD¹) with the received data, the SCI can issue the SCIn_RXI interrupt request.

If the CCR3.MP bit is set to 0, comparison occurs only for valid data in receive format. In multi-processor mode (CCR3.MP bit = 1), if the CCR0.IDSEL bit is set to 1, receive data where the MPB bit is 1 is subject to comparison for address match and receive data where the MPB bit is 0 is always treated as a non-match.

If the CCR0.IDSEL bit is set to 0, SCI performs address match detection regardless of the MPB bit value of the received data.

Until SCI detects a match to the comparison data (CCR4.CMPD*¹) with receive data, received data is skipped (discarded), and the SCI cannot detect a parity error or framing error.

When SCI detects a match, the CCR0.DCME bit is automatically cleared, and the CSR.DCMF flag is set to 1. If the CCR0.IDSEL bit is set to 1, the CCR0.MPIE bit is automatically cleared. If CCR0.IDSEL is set to 0, the value of the CCR0.MPIE bit is retained. If the CCR0.RIE bit is set to 1, the SCI issues an SCIn_RXI interrupt request.

If the SCI detects a framing error in the receive data for which a match is detected, the CSR.DFER flag is set to 1, and if the SCI detects a parity error in that frame, the CSR.DPER flag is set to 1. The compared receive data and MPB bit is not stored in the RDR register, and CSR.RDRF remains 0.

After the SCI detects a match, and CCR0.DCME is automatically cleared, the SCI receives the next data continuously based on the current register setting.

When the CSR.DFER or CSR.DPER flag is set, the address match is not performed. Before enabling the address match function, set the CSR.DFER and CSR.DPER flags to 0.

Examples of the address match function are shown in [Figure 28.9](#) and [Figure 28.10](#).

Note 1. This comparative target can select one length of 3 types: CMPD[6:0] with 7-bit length, CMPD[7:0] with 8-bit length, and CMPD[8:0] with 9-bit length.

Note 2. Set the CCR0.DCME bit to 1 before receiving the start bit of the received frame that performs address matching.

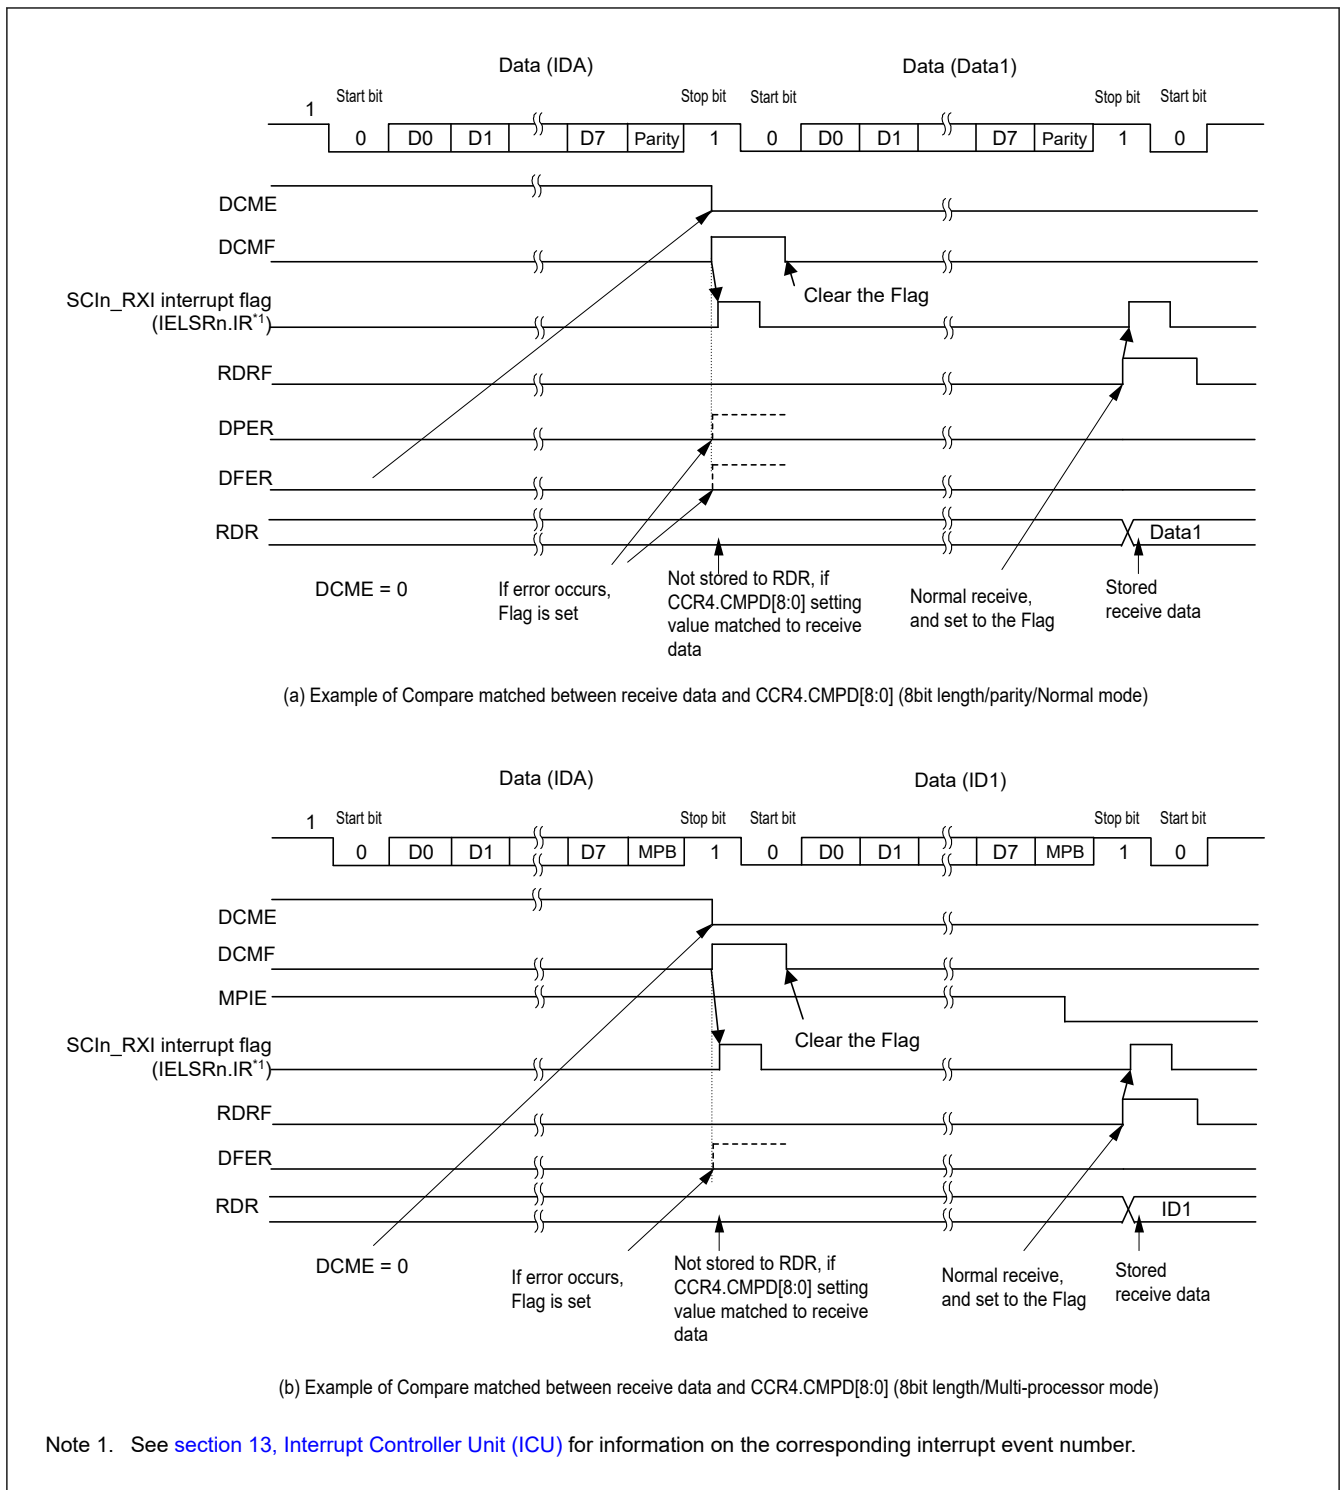

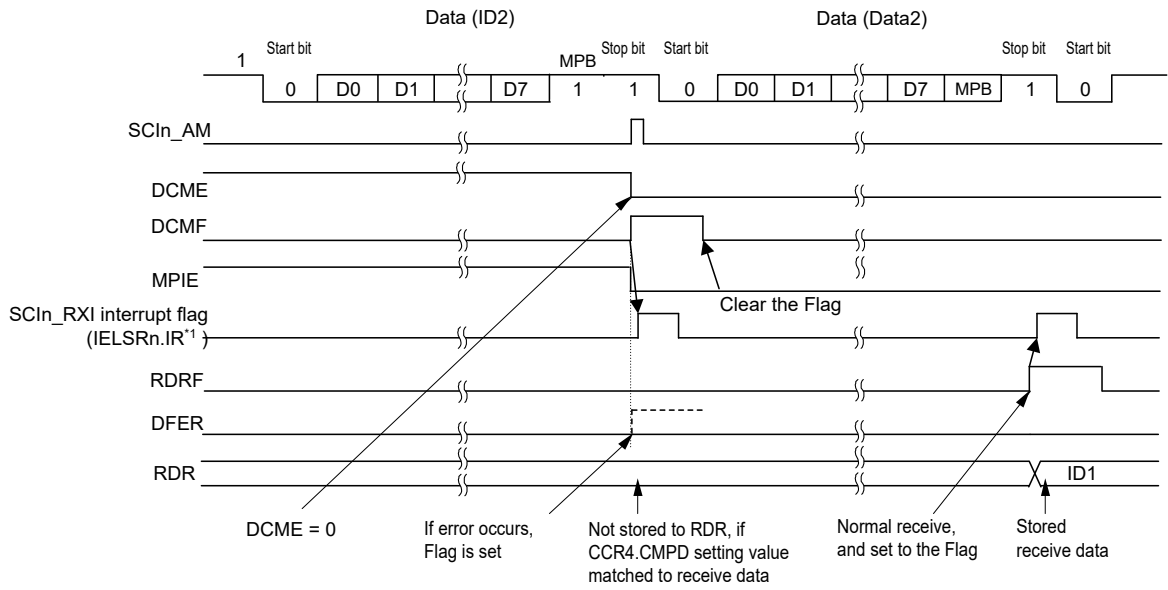

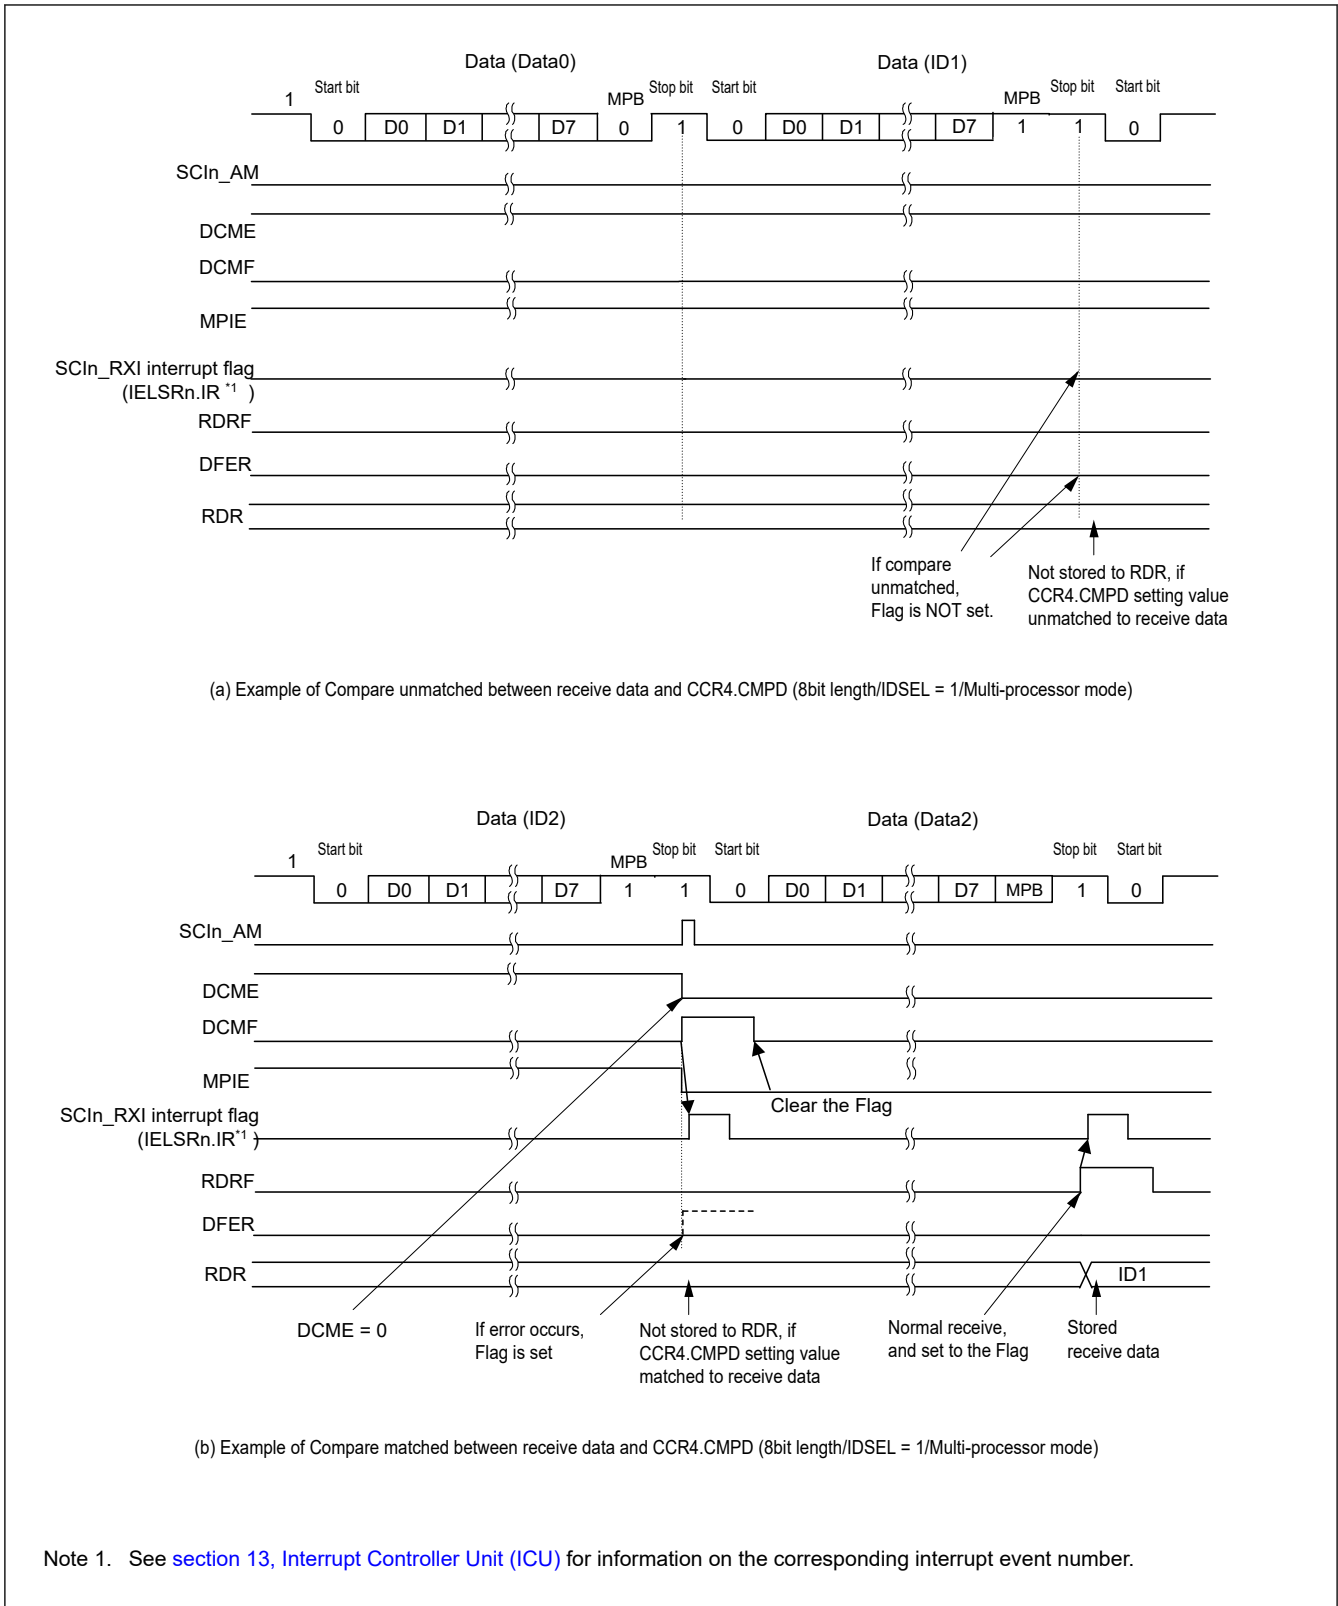

Figure 28.9 Example of address match (1) normal mode and multi-processor mode

Note 1. See [section 13, Interrupt Controller Unit \(ICU\)](#) for information on the corresponding interrupt event number.

Figure 28.10 Example of address match (2) multi-processor mode

28.3.7 SCI Initialization in Asynchronous Mode

Before transmitting and receiving data, start by writing the initial value 0 to the CCR0.TE and CCR0.RE (or writing the initial value to CCR0), then continue through the SCI initialization procedure (select non-FIFO or FIFO) shown in [Table 28.29](#) and [Table 28.30](#). Whenever the operating mode or transfer format is to be changed, the CCR0.TE and CCR0.RE bits must be initialized before the change is made.

When the external clock is used in Asynchronous mode, ensure that the clock signal is supplied during initialization.

Note: Setting the CCR0.RE bit to 0 initializes neither the ORER, FER, RDRF, RDAT, PER, and DR flags in CSR nor RDR. When FIFO selected, even if the TE bit is set as 0, the TEND flag for the selected FIFO buffer is not initialized. Please be also careful at the time of change in the operation mode.

Note: Switching the value of the CCR0.TE bit from 0 to 1 while the CCR0.TIE bit is 1 leads to the generation of an SCIn_TXI interrupt request.

Table 28.29 Example flow of SCI initialization in Asynchronous mode with non-FIFO selected

No.	Step Name	Description
1	Start initialization	—
2	Set CCR0	Set CCR0.TEIE, TIE, RIE, TE, RE to 0. If you have not changed from the initial settings, you can skip this step.
3	Set CCR3	Set up following function and communication mode. Driver control function for RS-485, FIFO no-use, Multi-Processor mode, Communication mode (MOD[2:0] = 000b) Transmission / reception format Clock enable (Leave the initial value when outputting the clock) Leave unused bits at their initial values.
4	Set CCR2	Set up the bit-rate-modulation function ^{*1 *2} , select clock, set bit rate ^{*2}
5	Set CCR1	Set up the Noise-filter function, the loop-back function, communication pin status, the parity check function, and the CTSn_RTsn function.
6	Set CCR4	Set up the adjust sampling timing function and the adjust transmit timing function.
7	Set the I/O port functions	Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.
8	Set CCR3	Set clock enable bit (CKE[1:0]) at this step when outputting the clock. After this register setting, the clock pin will be in the output state immediately.
9	Set CFCLR	Write 1 to the following bits and clear the corresponding flag. CFCLR.RDRFC,FERC,PERC,MFFC,ORERC,DFERC,DPERC,DCMFC,ERSC If it's initialization flow after a reset, you can skip this step.
10	Set CCR0	Set the TE or RE bit to 1. To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time. Setting the TE and RE bits allows TXDn and RXDn to be used.
11	Initialization completed	—

Note 1. If you do not use the bit rate modulation function, you do not need to set it.

Note 2. If you use an external clock, you do not need to set it.

Table 28.30 Example flow of SCI initialization in Asynchronous mode with FIFO selected (1 of 2)

No.	Step Name	Description
1	Start initialization	—
2	Set CCR0	Set CCR0.TEIE, TIE, RIE, TE, RE to 0. If you have not changed from the initial settings, you can skip this step.
3	Set CCR3	Set up following function and communication mode. Driver control function for RS-485, FIFO use, Multi-Processor mode, Communication mode (MOD[2:0] = 000b) Transmission / reception format Clock enable (Leave the initial value when outputting the clock) Leave unused bits at their initial values.
4	Set CCR2	Set up the bit-rate-modulation function ^{*1 *2} , select clock, set bit rate ^{*2}
5	Set CCR1	Set up the Noise-filter function, the loop-back function, communication pin status, the parity check function, and the CTSn_RTsn function.
6	Set CCR4	Set up the adjust sampling timing function and the adjust transmit timing function.
7	Set FCR	Set the TFRST and RFRST to 1 to empty FIFO. Set the DRES, TTRG[4:0], RTRG[4:0], and RSTRG[4:0] bits

Table 28.30 Example flow of SCI initialization in Asynchronous mode with FIFO selected (2 of 2)

No.	Step Name	Description
8	Set the I/O port functions	Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.
9	Set CCR3	If you select a clock output in Asynchronous mode, set the CKE[1:0] bit here. After setting the register, the clock pin will be in the output state immediately. But the clock operates after setting TE or RE to 1.
10	Set CFCLR	Write 1 to the following bits and clear the corresponding flag. CFCLR.RDRFC, FERC, PERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC If it's initialization flow after a reset, you can skip this step.
11	Set FFCLR	Write 1 to The FFCLR.BRKC,DRC and clear the corresponding flag. If it's initialization flow after a reset, you can skip this step.
12	Set CCR0	Set the TE or RE bit to 1. To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time. Setting the TE and RE bits allows TXDn and RXDn to be used.
13	Initialization completed	—

Note 1. If you do not use the bit rate modulation function, you do not need to set it.
 Note 2. If you use an external clock, you do not need to set it.

Figure 28.11 shows an example of the timing when data is transmitted after reset is released, and SCI is set to Asynchronous mode according to Table 28.29 or Table 28.30. As shown in the figure, when the pin function is set to the TXDn pin, the CCR0.TE bit is 0, so the pin is high impedance. When transmit data is written after setting the CCR0.TE bit to 1, data transmission starts. There is a transmission wait time from writing TDR to data transmission starts. In Asynchronous mode, TXDn is high during this period.

Figure 28.11 Data transmission timing example in Asynchronous mode

28.3.8 Serial Data Transmission in Asynchronous Mode

(1) Non-FIFO selected

Figure 28.12, Figure 28.13, Figure 28.14 and Figure 28.15 show examples of serial transmission in Asynchronous mode.

In serial transmission, the SCI operates as described in this section.

- The SCI transfers data from the TDR register to the TSR register when data is written to TDR in the SCIn_TXI interrupt handling routine.
 The SCIn_TXI interrupt request at the beginning of transmission is generated when the CCR0.TE and CCR0.TIE bits are set to 1 simultaneously by a single instruction.
- Transmission starts after the CCR1.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn_RTsn pin causes data transfer from the TDR register to the TSR register. If the CCR0.TIE bit is 1, an SCIn_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to the TDR register in the SCIn_TXI interrupt handling routine before transmission of the current transmit data is complete. When SCIn_TEI interrupt requests are in use, set the CCR0.TIE bit to 0 (SCIn_TXI interrupt requests are disabled) and the CCR0.TEIE bit to 1 (an SCIn_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the TDR register from the handling routine for SCIn_TXI requests.
- Data is sent from the TXDn pin in the following order:
 - Start bit

- Transmit data
 - Parity bit or multi-processor bit (can be omitted depending on the format)
 - Stop bit
4. The SCI checks for update of the TDR register on output of the stop bit.
 5. When the TDR register is updated, setting the CCR1.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn_RTSn pin causes transfer of the next transmit data from the TDR register to the TSR register and transmission of the stop bit, after which serial transmission of the next frame starts.
 6. If the TDR register is not updated, the CSR.TEND flag is set to 1, the stop bit is sent, and the mark state is entered, in which 1 is output. If the CCR0.TEIE bit is 1, the CSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated.

Figure 28.12, Figure 28.13, Figure 28.14 and Figure 28.15 show examples of serial transmission in Asynchronous mode.

Figure 28.12 Example operation for serial transmission in Asynchronous mode (1) with 8-bit data, parity bit, 1 stop bit, CTS function not used, and at the beginning of transmission

Figure 28.13 Example operation for serial transmission in Asynchronous mode (2) with 8-bit data, parity bit, one stop bit, CTS function used, and at the beginning of transmission

Figure 28.14 Example operation for serial transmission in Asynchronous mode (3) with 8-bit data, parity bit, one stop bit, CTS function not used, and from the middle of transmission until transmission completion

Figure 28.15 Example of Operation for Serial Transmission in Asynchronous Mode (4)(with 8-Bit Data, Parity, 1 Stop Bit, CTS Function Not Used, from the Middle of Transmission until Transmission Completion)

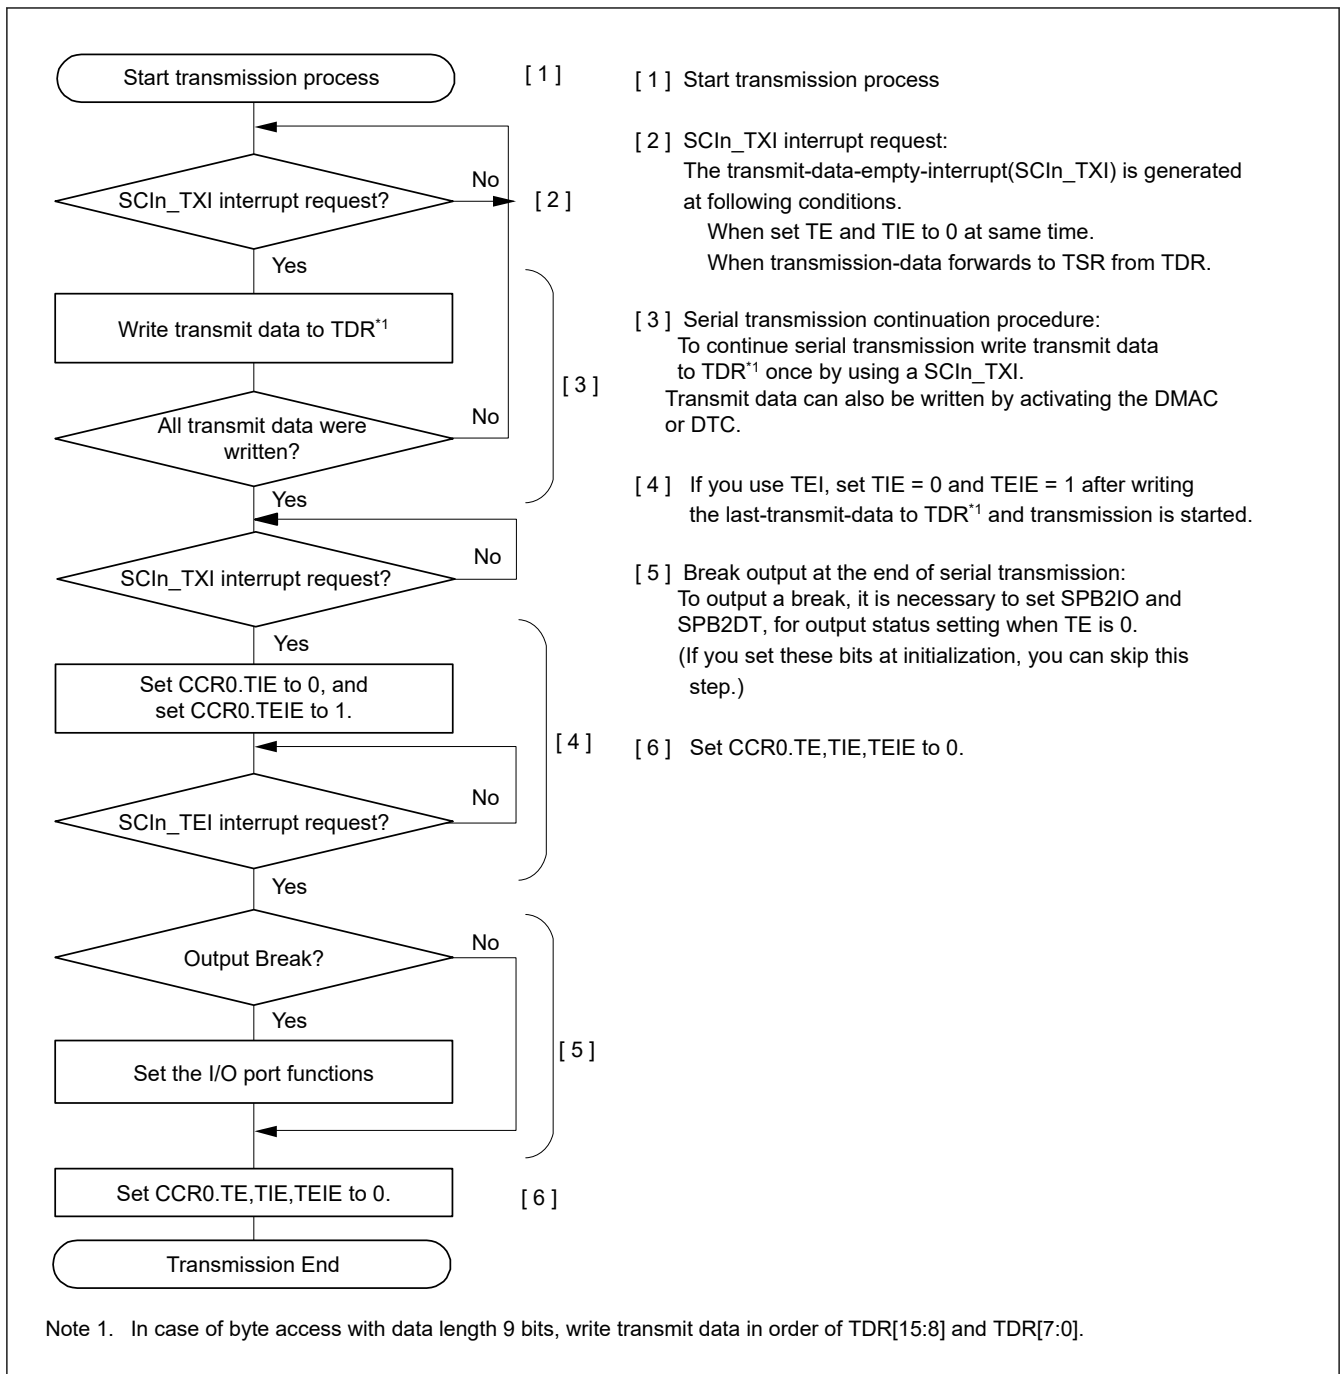

Figure 28.16 Example flow of serial transmission in Asynchronous mode with non-FIFO selected

(2) FIFO selected

Figure 28.17 shows an example of a data format that is written to TDR register in asynchronous mode with FIFO selected.

Data corresponding to the data length is set to TDR[8:0]. Write 0 for unused bits. Write in order from TDR[15:8] to TDR[7:0].

Data Length	Register setting		Transmit data in TDR[15:0]														
	CCR3. CHR[1:0]		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1
7 bit	1	1	-	-	-	-	-	-	MPB T	-	-	TDAT[6:0]					
8 bit	1	0	-	-	-	-	-	-	MPB T	-	TDAT[7:0]						
9 bit	0	Don't Care	-	-	-	-	-	-	MPB T	TDAT[8:0]							

Note: —: Invalid. The write value should be 0.

Figure 28.17 Data format written to transmit-FIFO(TDR) with FIFO selected

In serial transmission, the SCI operates as described in this section.

1. The SCI transfers data from the TDR register to the TSR register when data is written to TDR in the SCIn_TXI interrupt handling routine. The amount of data that can be written to TDR is 16 minus FTSR.T[5:0] bytes. The SCIn_TXI interrupt request at the beginning of transmission is generated when the CCR0.TE and CCR0.TIE bits are set to 1 simultaneously by a single instruction.
2. Transmission starts after the CCR1.CTSE bit is set to 0 (CTS function is disabled) or a low level on the CTSn_RTSn pin causes data transfer from the TDR register to the TSR register. When the amount of transmit data written in TDR is equal to or less than the specified transmit triggering number, CSR.TDRE is set to 1. If the CCR0.TIE bit is 1, an SCIn_TXI interrupt request is generated. Continuous transmission is possible by writing the next transmit data to TDR in the SCIn_TXI interrupt handling routine before transmission of the current transmit data is complete. When SCIn_TEI interrupt requests are in use, set the CCR0.TIE bit to 0 (SCIn_TXI interrupt requests are disabled) and the CCR0.TEIE bit to 1 (an SCIn_TEI interrupt request is enabled) after the last of the data to be transmitted is written to the TDR register from the handling routine for SCIn_TXI requests.
3. Data is sent from the TXDn pin in the following order:
 - Start bit
 - Transmit data
 - Parity bit or multi-processor bit (can be omitted depending on the format)
 - Stop bit
4. On output of the stop bit, the SCI checks whether non-transmitted data remains in the TDR register.
5. When data is set to transmit-FIFO (TDR), setting the CCR1.CTSE bit to 0 (CTS function is disabled) or a low level input on the CTSn_RTSn pin causes transfer of the next transmit data from TDR to TSR and transmission of the stop bit, after which serial transmission of the next frame starts.
6. If data is not set in transmit-FIFO (TDR), the TEND flag in CSR is set to 1, the stop bit is sent, and the mark state is entered in which 1 is output. If the CCR0.TEIE bit is 1, an SCIn_TEI interrupt request is generated.

Figure 28.18 shows an example flow of serial transmission in Asynchronous mode with FIFO selected.

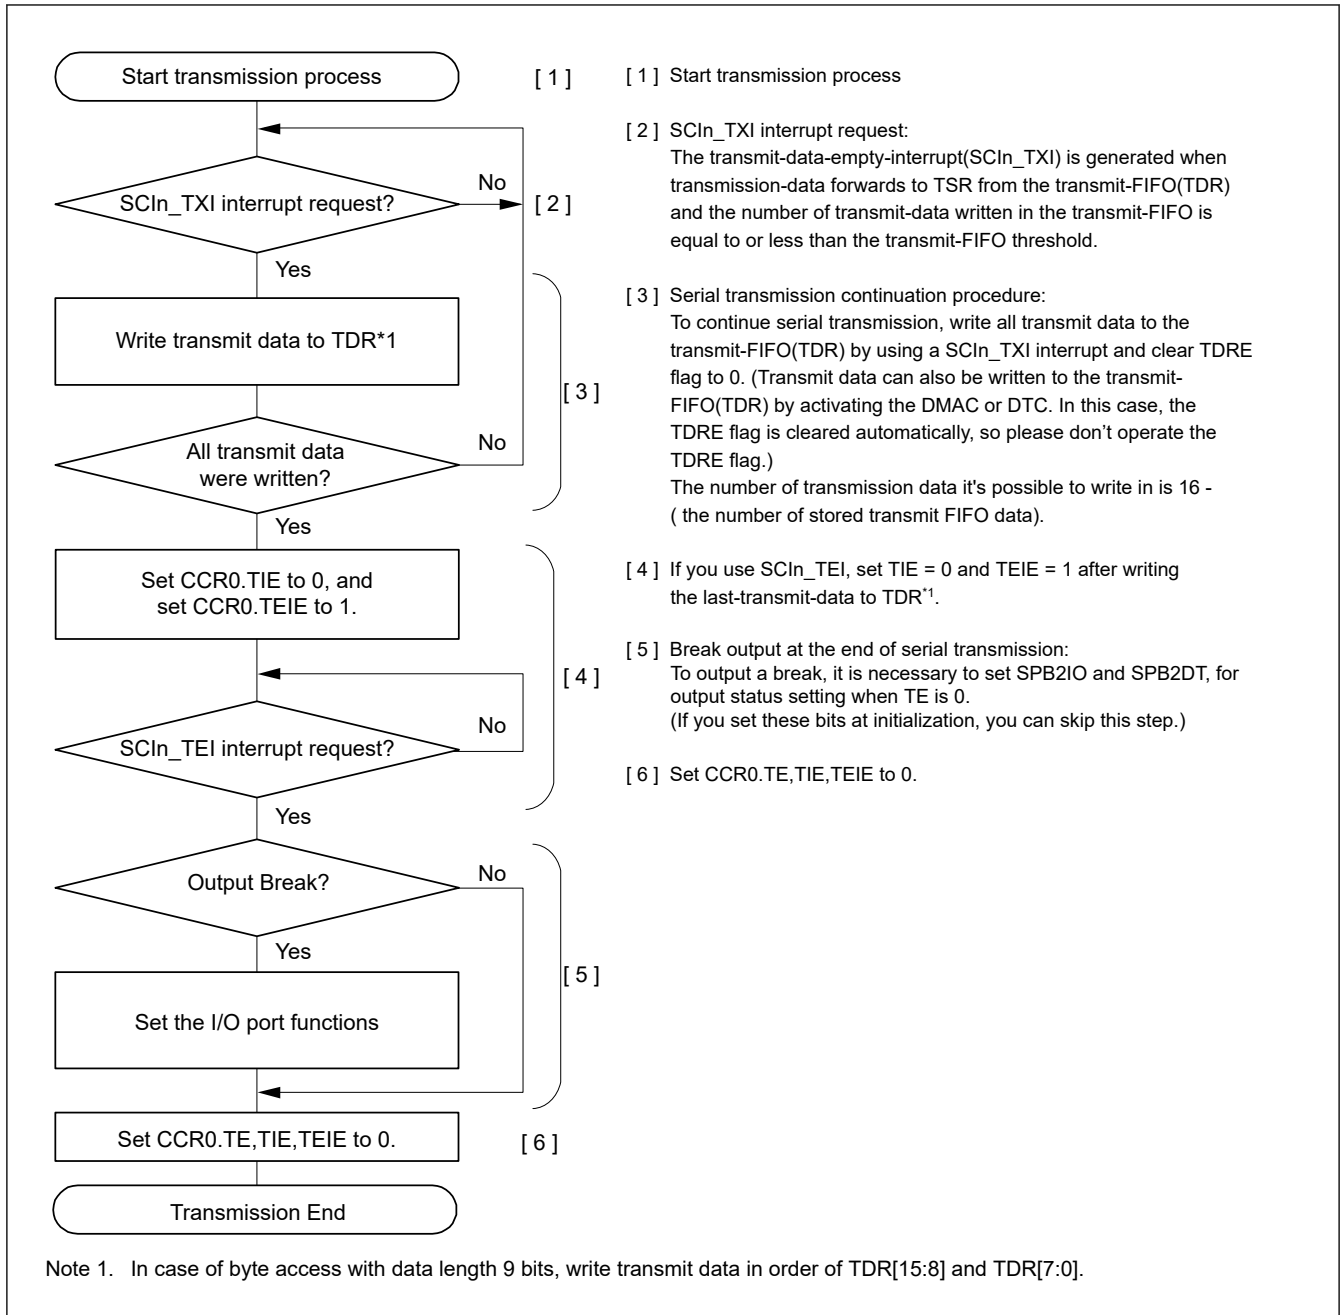

Figure 28.18 Example flow of serial transmission in Asynchronous mode with FIFO selected

28.3.9 Serial Data Reception in Asynchronous Mode

(1) Non-FIFO selected

Figure 28.19 and Figure 28.20 show an example of the operation for serial data reception in Asynchronous mode.

In serial data reception, the SCI operates as follows:

1. When the value of the CCR0.RE bit becomes 1, the output signal on the CTSn_RTsn pin goes low.
2. The SCI monitors the communications line and when it detects a start bit, the SCI performs internal synchronization, stores receive data in RSR, and checks the parity bit and stop bit.
3. If an overrun error occurs, the CSR.ORER flag is set to 1. If the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR register.
4. If a parity error is detected, the CSR.PER flag is set to 1 and receive data is transferred to the RDR register. If the SCR.RIE bit is 1, an SCIn_ERI interrupt request is generated.

5. If a framing error is detected, the CSR.FER flag is set to 1 and receive data is transferred to the RDR register. If the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated.
6. When reception finishes successfully, receive data is transferred to the RDR register. If the CCR0.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data is complete. Reading the received data that was transferred to the RDR register causes the CTSn_RTSn pin to output low.

Figure 28.19 Example of SCI operation for serial reception in Asynchronous mode (1) when the RTS function is not used, and with 8-bit data, parity bit, and 1 stop bit

Figure 28.20 Example of SCI operation for serial reception in Asynchronous mode (2) when RTS function is used, and with 8-bit data, parity bit, and 1 stop bit

[Table 28.31](#) lists the states of the flags in the CSR status register and receive data handling when a receive error is detected. If a receive error is detected, an SCIn_ERI interrupt request is generated but an SCIn_RXI interrupt request is not generated. Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the OREr, FER, and PER bits to 0 before resuming reception. In addition, be sure to read the RDR register during overrun error processing. When a reception is forced to terminate by setting the CCR0.RE bit to 0 during operation, read the RDR register because received data that is not yet read might be left in the RDR.

[Figure 28.21](#) and [Figure 28.22](#) show example flows of serial data reception.

Table 28.31 Flags in CSR Status Register and receive data handling

Flags in the CSR Status Register			Receive data	Receive error type
ORER	FER	PER		
1	0	0	Lost	Overrun error
0	1	0	Transferred to RDR	Framing error
0	0	1	Transferred to RDR	Parity error
1	1	0	Lost	Overrun error + framing error
1	0	1	Lost	Overrun error + parity error
0	1	1	Transferred to RDR	Framing error + parity error
1	1	1	Lost	Overrun error + framing error + parity error

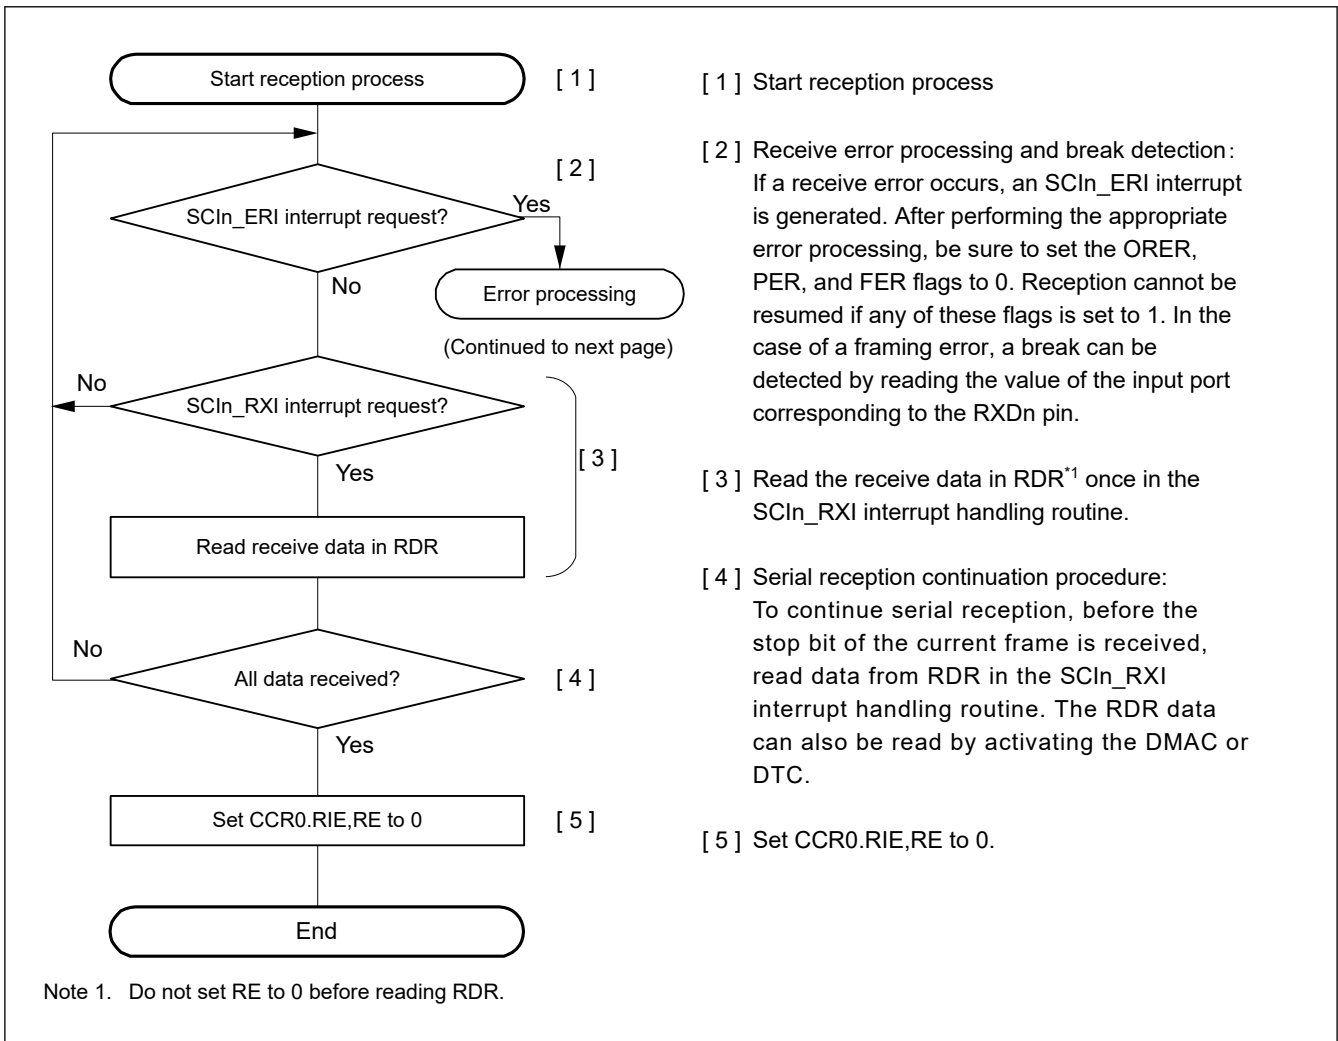

Figure 28.21 Example flow of serial reception in Asynchronous mode with non-FIFO selected and Address Matching Disabled (1)

Figure 28.22 Example flow of serial reception in Asynchronous mode with non-FIFO selected and Address Matching Disabled (2)

(2) FIFO selected

Figure 28.23 shows an example of a data format that is written to Receive-FIFO(RDR) register in Asynchronous mode.

In Asynchronous mode, 0 is written to the MPB bit in the RDR register. Data that corresponds to the data length is written to RDR. Unused bits are written as 0. If software reads RDR, the SCI updates FER, PER, and receive data (RDAT[8:0]) in the RDR register with the next data. The flags ORER, and DR in the RDR register always reflect the associated flags in the CSR register.

Data Length	Register Setting		Receive flag in RDR[31:0], MPB, RDAT[8:0]																
	CCR3.CHR[1:0]		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0	
7bit	1	1	-	-	-	FFER	FPER	DR	MPB	0	0	RDAT[6:0]							
8bit	1	0	-	-	-	FFER	FPER	DR	MPB	0	RDAT[7:0]								
9bit	0	Don't care	-	-	-	FFER	FPER	DR	MPB	RDAT[8:0]									
	CCR3.CHR[1:0]		b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16	
7bit	1	1	-	-	-	FER	PER	-	-	ORER	-	-	-	-	-	-	-	-	
8bit	1	0	-	-	-	FER	PER	-	-	ORER	-	-	-	-	-	-	-	-	
9bit	0	Don't care	-	-	-	FER	PER	-	-	ORER	-	-	-	-	-	-	-	-	

Note: 0 is always read from the MPB flag (RDR [9] bit).
 When a 7-bit data length is selected, 0 is read from the RDAT [8:7] bits.
 When 8-bit data length is selected, 0 is read from the RDAT [8] bit.

Figure 28.23 Data format stored in receive-FIFO(RDR) with FIFO selected

Table 28.32 lists the states of the flags in CSR status register and receive data handling when a receive error is detected with FIFO selected. Figure 28.24 and Figure 28.25 show samples of flowcharts for serial data reception with FIFO selected. In serial data reception, the SCI operates as follows:

1. When the value of the CCR0.RE bit becomes 1, the output signal on the CTSn_RTSn pin goes low.
2. The SCI monitors the communications line and, when it detects a start bit, the SCI performs internal synchronization, stores receive data in the RSR register.
3. If an overrun error occurs during normal communications, the CSR.ORER flag is set to 1. If the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR register.
4. If a parity error is detected, the PER flag and receive data are transferred to the RDR register. If the CCR0.RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
5. If a framing error is detected, the FER flag and receive data are transferred to the RDR register. If the CCR0.RIE bit is set to 1, an SCIn_ERI interrupt request is generated.
6. After a framing error is detected and when SCI detects that the continuous receive data is zero for one frame, reception stops.
7. When the amount of data stored in the RDR register falls below the specified receive triggering number, and the next data is not received after 15 etus from the last stop bit in Asynchronous mode, the FRSR.DR flag is set to 1. When the CCR0.RIE bit is 1 and the FCR.DRES bit is 0, the SCI generates an SCIn_RXI interrupt request. When the FCR.DRES bit is 1, SCI generates an SCIn_ERI interrupt request.
8. When reception finishes successfully, receive data is transferred to the RDR register. The RDRF bit is set to 1 when the amount of receive data written to RDR is equal to or greater than the specified receive triggering number. If the CCR0.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to the RDR register in the SCIn_RXI interrupt handling routine, before an overrun error occurs. If the received data that is transferred to RDR is less than the RTS trigger number, the CTSn_RTSn pin outputs low.

Table 28.32 Flags in the CSR Status Register and Receive Data Handling (FIFO selected) (1 of 2)

CSR value			Receive-FIFO (RDR)	Receive Error Type
ORER	FER*1	PER*1	RDAT[8:0]	
1	0	0	Lost	Overrun error
0	1	0	Transferred RDR	Framing error
0	0	1	Transferred RDR	Parity error

Table 28.32 Flags in the CSR Status Register and Receive Data Handling (FIFO selected) (2 of 2)

CSR value			Receive-FIFO (RDR)	Receive Error Type
ORER	FER ^{*1}	PER ^{*1}	RDAT[8:0]	
1	1	0	Lost	Overrun error + Framing error
1	0	1	Lost	Overrun error + Parity error
0	1	1	Transferred RDR	Framing error + Parity error
1	1	1	Lost	Overrun error + Framing error + Parity error

Note 1. This flag indicates whether there is an error in received data when reception is completed.

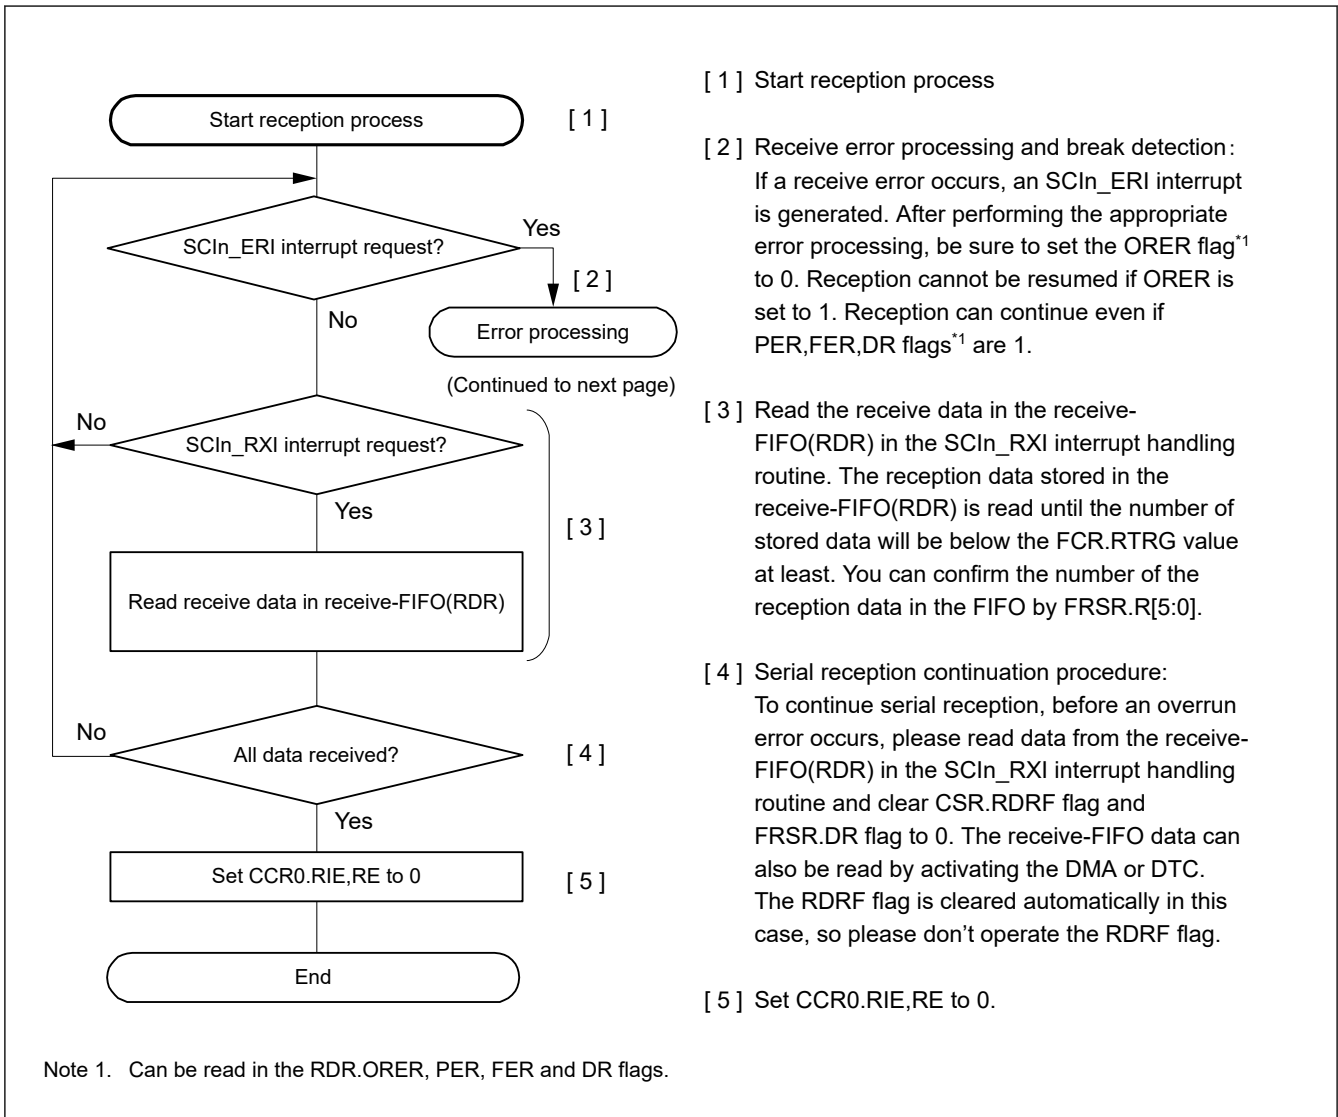

Figure 28.24 Example flow of serial reception in Asynchronous mode with FIFO selected and Address Matching Enabled (1)

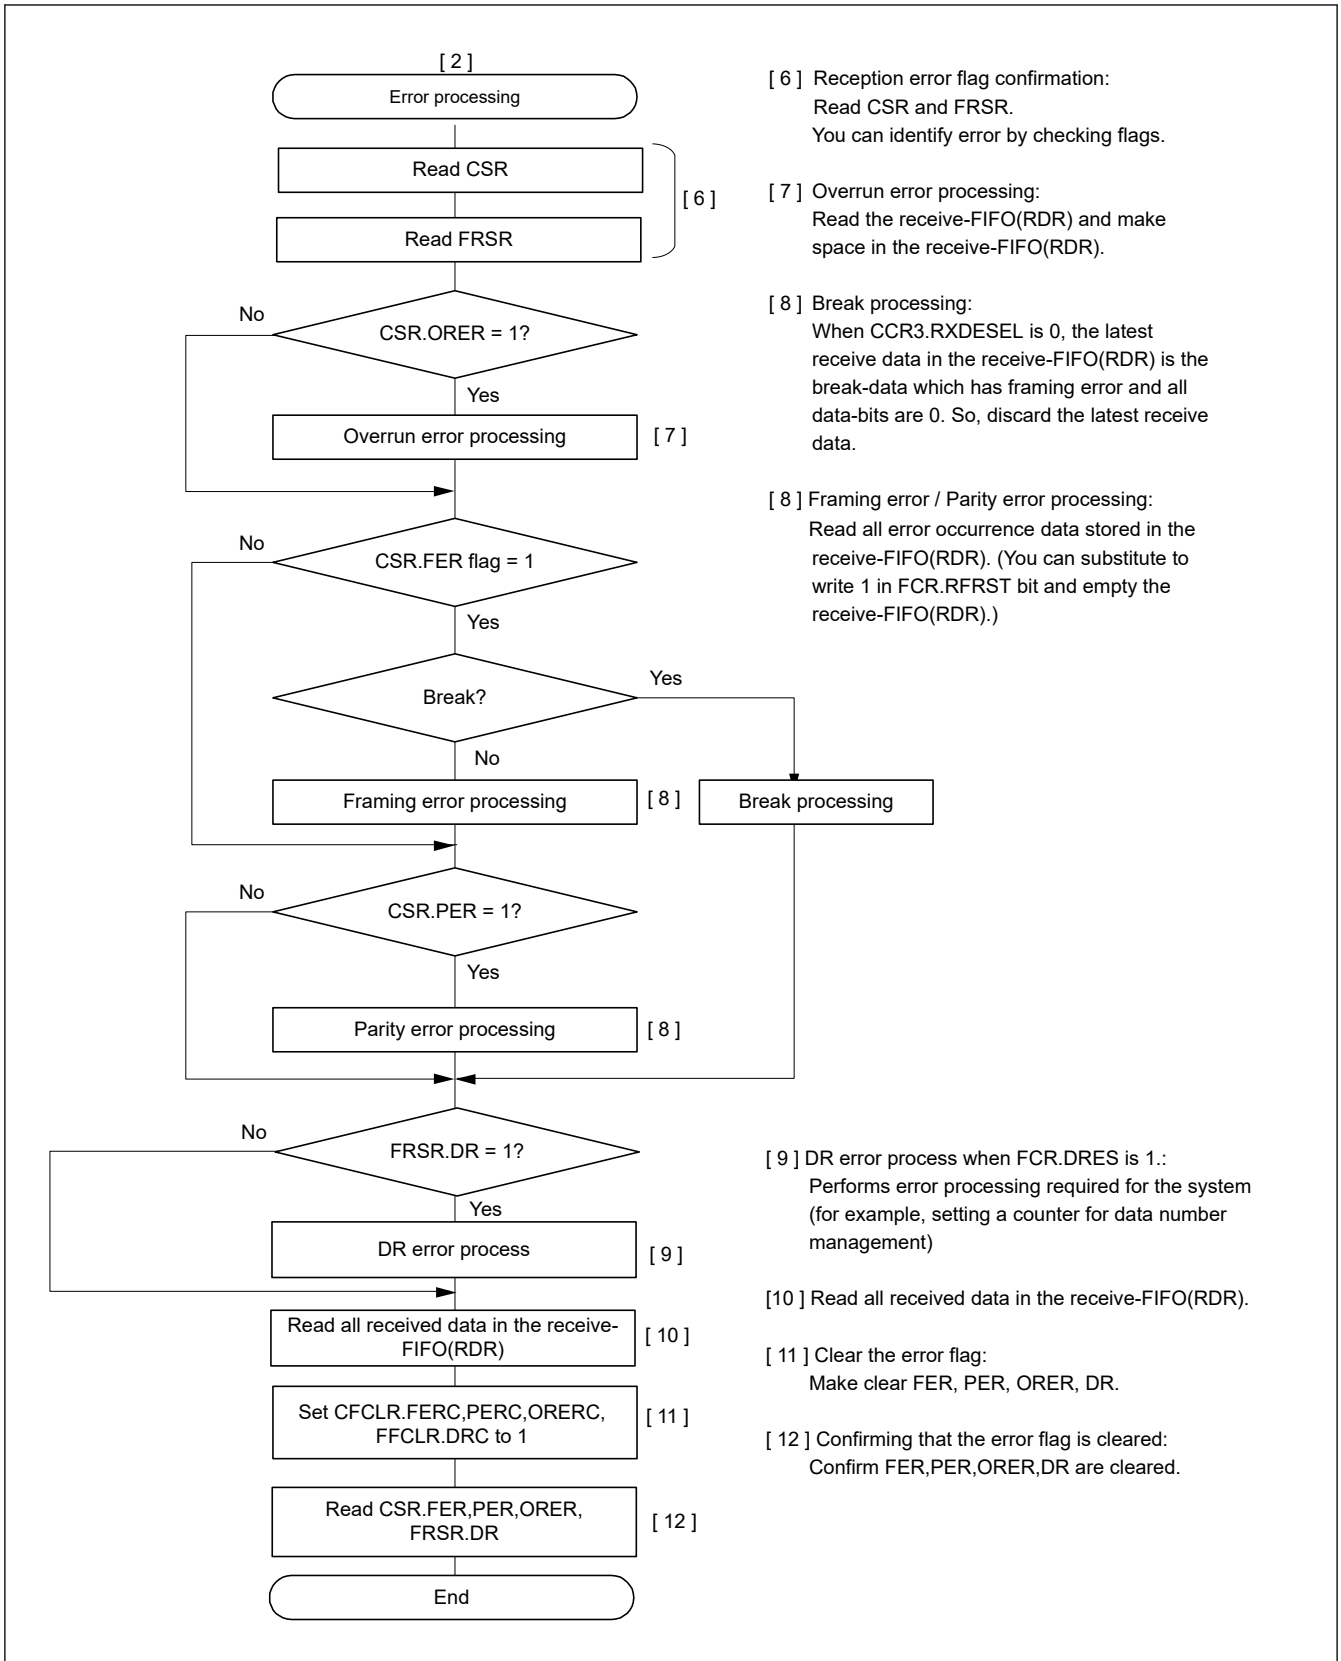

Figure 28.25 Example flow of serial reception in Asynchronous mode with FIFO selected Address Matching Disabled (2)

28.3.10 The function of adjust receive sampling timing (Asynchronous Mode)

When there is the difference between the rising transfer time and the falling transfer time through a photo coupler, the receive sampling timing at middle of bit affects the reception margin. In this case, the receive sampling timing is able to adjust from the middle of bit to the optimum timing by using this function.

The receive sampling timing is adjusted from the middle of bit by following formula. The adjustable direction is set by CCR4.AJD. When adjusting backward (CCR4.AJD = 0), substitute AJD = +1 and substitute AJD = -1 when adjusting forward (CCR4.AJD = 1).

$$\text{Adjusted sampling timing} = \text{the middle of bit} + \text{AJD} \times (\text{base clock} \times \text{the setting value of CCR4.AST}[2:0])$$

The setting timing is limited by base clock cycles per 1 bit. For details, see [Table 28.33](#).

An overview of reception operation of the communication through a photo coupler with this function is shown in [Figure 28.26](#), [Figure 28.27](#) and [Figure 28.28](#), the explanation of operation with this function is shown in [Figure 28.29](#).

Do not use this function when there is no difference between the rising transfer time and the falling transfer time, because there is a possibility of deteriorating the reception margin.

Table 28.33 The acceptable value of setting register (Asynchronous mode using internal clock)

CCR2.ABCSE2	CCR2.ABCSE	CCR2.ABCS	The number of base cycles/1bit	The acceptable value	
				CCR4.AJD	CCR4.AST*1
1	0	x	4	0	000~011
				1	(Note1)
0	1	x	6	0	000~010
				1	(Note1)
0	0	1	8	0	000~011
				1	(Note1)
0	0	0	16	0	000~111
				1	

Note: x: Don't care

Note 1. When the value of CCR4.AST exceeds the acceptable value, sampling is done at default timing. (Adjustment of sampling is not done.)

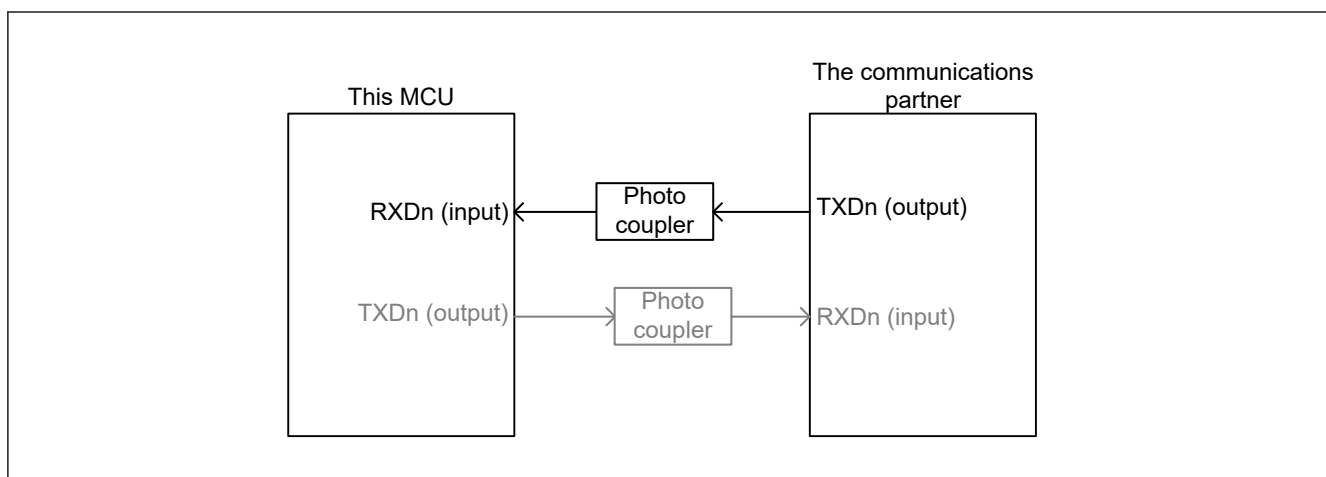

Figure 28.26 block diagram image of the reception through a photo couple

(a) In the case of the falling transfer time >> rising transfer time

The falling edge of reception waveform is made dull like following chart.
 In this case, you can sampling at the middle of bit if you adjust the receive sampling timing to forward (AJD = 1).

(b) In the case of the falling transfer time << rising transfer time

The rising edge of reception waveform is made dull like following chart.
 So, the reception margin of communications partner will be bad. In this case, you can improve the reception margin if you adjust the receive sampling timing to back.

- ▲ The receive sampling timing when unadjusted (middle of bit)
- ▲ The adjusted receive sampling timing

- Note: This waveform shows the operation image of adjustment in reception sampling timing.
- Note 1. The dull period by a photo coupler
 - Note 2. Bit center timing at set communication rate
 - Note 3. When CCR4.AJD is 1, the receive sampling timing is shifted to forward by the setting value of CCR4.AST[2:0].
 - Note 4. When CCR4.AJD is 0, the Receive sampling timing is shifted to backward by the setting value of CCR4.AST[2:0].

Figure 28.27 Overview of reception operation of the communication through a photo coupler

Figure 28.28 Example of improvement in reception margin by the reception sampling timing adjustment function

Figure 28.29 Overview of the adjustment operation for the reception sampling timing (Asynchronous mode using internal clock)

28.3.11 The function of adjust transmit timing (Asynchronous Mode)

In communication via a photo coupler or the like, when either the rising or falling transition time of the TXDn output signal is long, then a communication partner receive dulled waveform. In this case, the reception margin may be affected.

In these cases, make a communication partner to be sampling at middle of bit using the function of adjust transmit timing.

When CCR4.ATEN is 1, this function can adjust the edge timing at the timing calculated by the following formula for the edge set with CCR4.AET.

$$\text{The adjustment edge timing} = \text{the base clock} \times \text{CCR4.ATT}[2:0]$$

In addition, the upper limit of the adjustment edge timing is limited by setting the base clock cycles. For details, see [Table 28.34](#).

A transmission movement image figure of the communication through a photo coupler with this function is shown in [Figure 28.30](#), [Figure 28.31](#) and [Figure 28.32](#), the overview of operation with this function is shown in [Figure 28.33](#) and [Figure 28.34](#).

Do not use this function when there is not the difference between the rising transfer time and the falling transfer time, there is a possibility of deteriorating the reception margin of a communication partner.

Table 28.34 The acceptable value of CCR4.AET and CCR4.ATT (Asynchronous mode using internal clock)

ABCSE2	ABCSE	ABCS	The number of base clock cycles/1bit	The acceptable value	
				AET	ATT [2:0]
1	0	x	4	0	000~011
				1	
0	1	x	6	0	000~101
				1	
0	0	1	8	0	000~111
				1	
0	0	0	16	0	000~111
				1	

Note: x: Don't care

Note: When the value of ACTR.AET/ATT is out of the acceptable value, this SCI module doesn't adjust transmit timing.

Figure 28.30 block diagram image of the transmission through a photo coupler

28.4 Multi-Processor Communication Function

The multi-processor communication function enables the SCI to transmit and receive data between multiple processors by sharing an asynchronous serial communication line that has an added multi-processor bit. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station.

The multi-processor bit is used to distinguish between the ID transmission cycle and the data transmission cycle:

- When the multi-processor bit is set to 1, the transmission cycle is the ID transmission cycle
- When the multi-processor bit is set to 0, the transmission cycle is the data transmission cycle

Figure 28.35 shows an example of communication between processors using a multi-processor format. First, a transmitting station transmits communication data in which the multi-processor bit set to 1 is added to the ID code of the receiving station. Next, the transmitting station transmits communication data in which the multi-processor bit set to 0 is added to the transmit data. After receiving communication data with the multi-processor bit set to 1, the receiving station compares the received ID with the ID of the receiving station itself. If the two match, the receiving station receives communication data that is subsequently transmitted. If the received ID does not match with the ID of the receiving station, the receiving station skips the communication data until it receives data in which the multi-processor bit is set to 1.

RTS control cannot be used at the time of multi-processor communication function use because this is a function corresponding to one-to-many communications.

Figure 28.35 Example of communication using multi-processor format with transmission of data 0xAA to receiving station A

(1) Non-FIFO selected

To support this function, the SCI provides the CCR0.MPIE bit. When the MPIE bit is set to 1, the following operations are disabled until the reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the RDR register
- Detection of a receive error
- Setting of the respective RDRF, ORER, and FER status flags in the CSR register

When the SCI receives a character in which the multi-processor bit is set to 1, the RDR.MPB bit is set to 1 and the CCR0.MPIE bit is automatically cleared, returning the SCI to non-multi-processor reception operation. If the CCR0.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in non-multi-processor Asynchronous mode. The clock used for the multi-processor communication is the same as the clock used in non-multi-processor Asynchronous mode.

(2) FIFO selected

For data transmission, software must write data to TDR.MPBT (Multi-Processor Bit Transfer) that corresponds to transmit data in TDR.TDAT. For data reception, the multi-processor bit that is part of the receive data is written to RDR.MPB and receive data is written to RDR.RDAT.

When the MPIE bit is set to 1, the following operations are disabled until reception of data in which the multi-processor bit is set to 1:

- Transfer of receive data from the RSR register to the RDR.RDAT register
- Detection of a receive error
- Detection of DR
- Setting of the respective RDRF, ORER, and FER status flags in the CSR register

When the SCI receives a character in which the multi-processor bit is set to 1, the RDR.MPB bit is set to 1 and receive data is written to receive-FIFO(RDR.RDAT). The CCR0.MPIE bit is automatically cleared, returning the SCI to normal reception operation. If the CCR0.RIE bit is set to 1, an SCIn_RXI interrupt is generated.

When the multi-processor format is specified, the parity bit function is disabled. Apart from this, there is no difference from operation in normal Asynchronous mode with FIFO selected.

28.4.1 Multi-Processor Serial Data Transmission

(1) Non-FIFO selected

Figure 28.36 shows an example flow of multi-processor data transmission. In the ID transmission cycle, the ID must be transmitted with the TDR.MPBT bit set to 1. In the data transmission cycle, the data must be transmitted with the MPBT bit set to 0. The rest of the operations are the same as operations in Asynchronous mode.

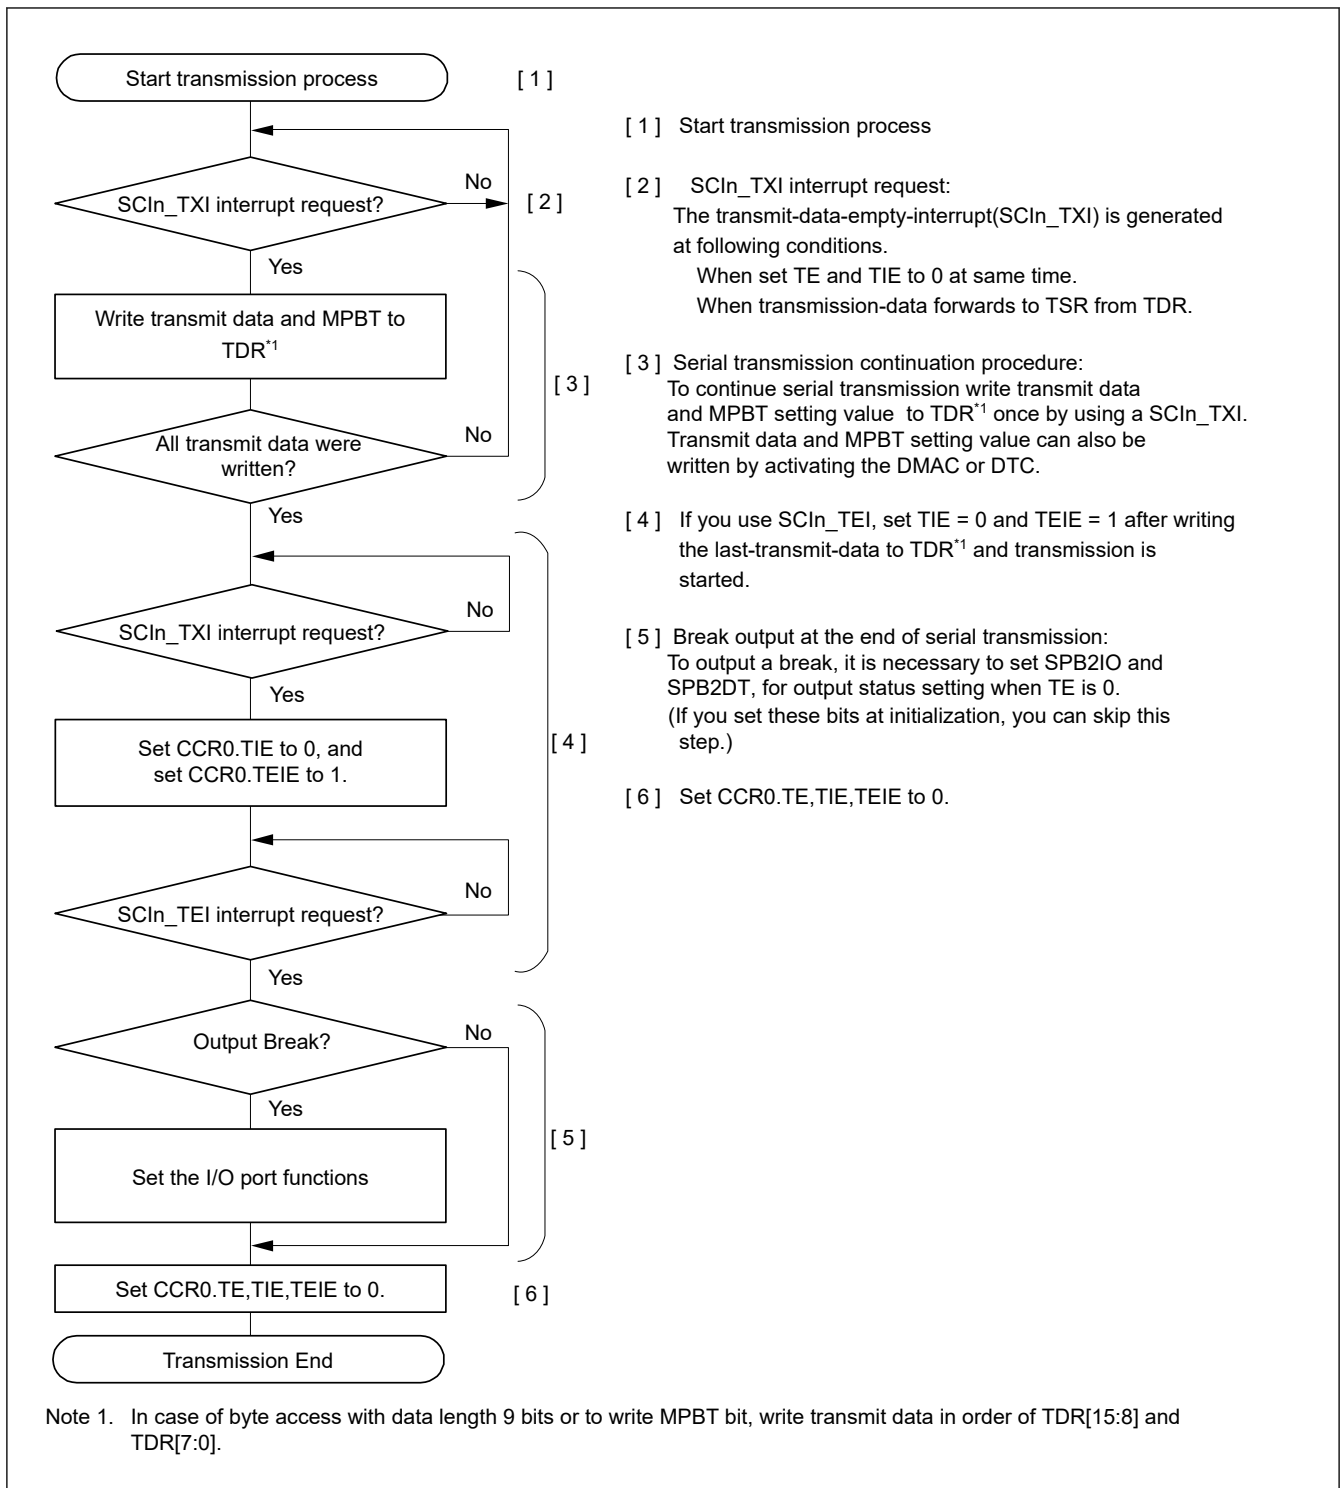

Figure 28.36 Example flow of multi-processor serial transmission with non-FIFO selected

(2) FIFO selected

Figure 28.37 shows an example of data format that is written to transmit-FIFO (TDR) in multi-processor mode. The TDR.MPBT bit is set to 1. Data is set to transmit-FIFO (TDR) with the correct data length. Write 0 for unused bits.

Data Length	Register setting		Transmit data in TDR[15:0]														
	CCR3. CHR[1:0]		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1
7 bit	1	1	-	-	-	-	-	-	MPBT	-	-	TDAT[6:0]					
8 bit	1	0	-	-	-	-	-	-	MPBT	-	TDAT[7:0]						
9 bit	0	Don't Care	-	-	-	-	-	-	MPBT	TDAT[8:0]							

Note: —: Invalid. The write value should be 0.

Figure 28.37 Data format written to transmit-FIFO (TDR) in multi-processor mode with FIFO selected

Figure 28.38 shows an example flow of multi-processor serial transmission with FIFO selected. In the ID transmission cycle, the ID must be transmitted with the TDR.MPBT bit set to 1. In the data transmission cycle, the data must be transmitted with the MPBT bit set to 0. The rest of the operations are the same as operations in Asynchronous mode with FIFO selected.

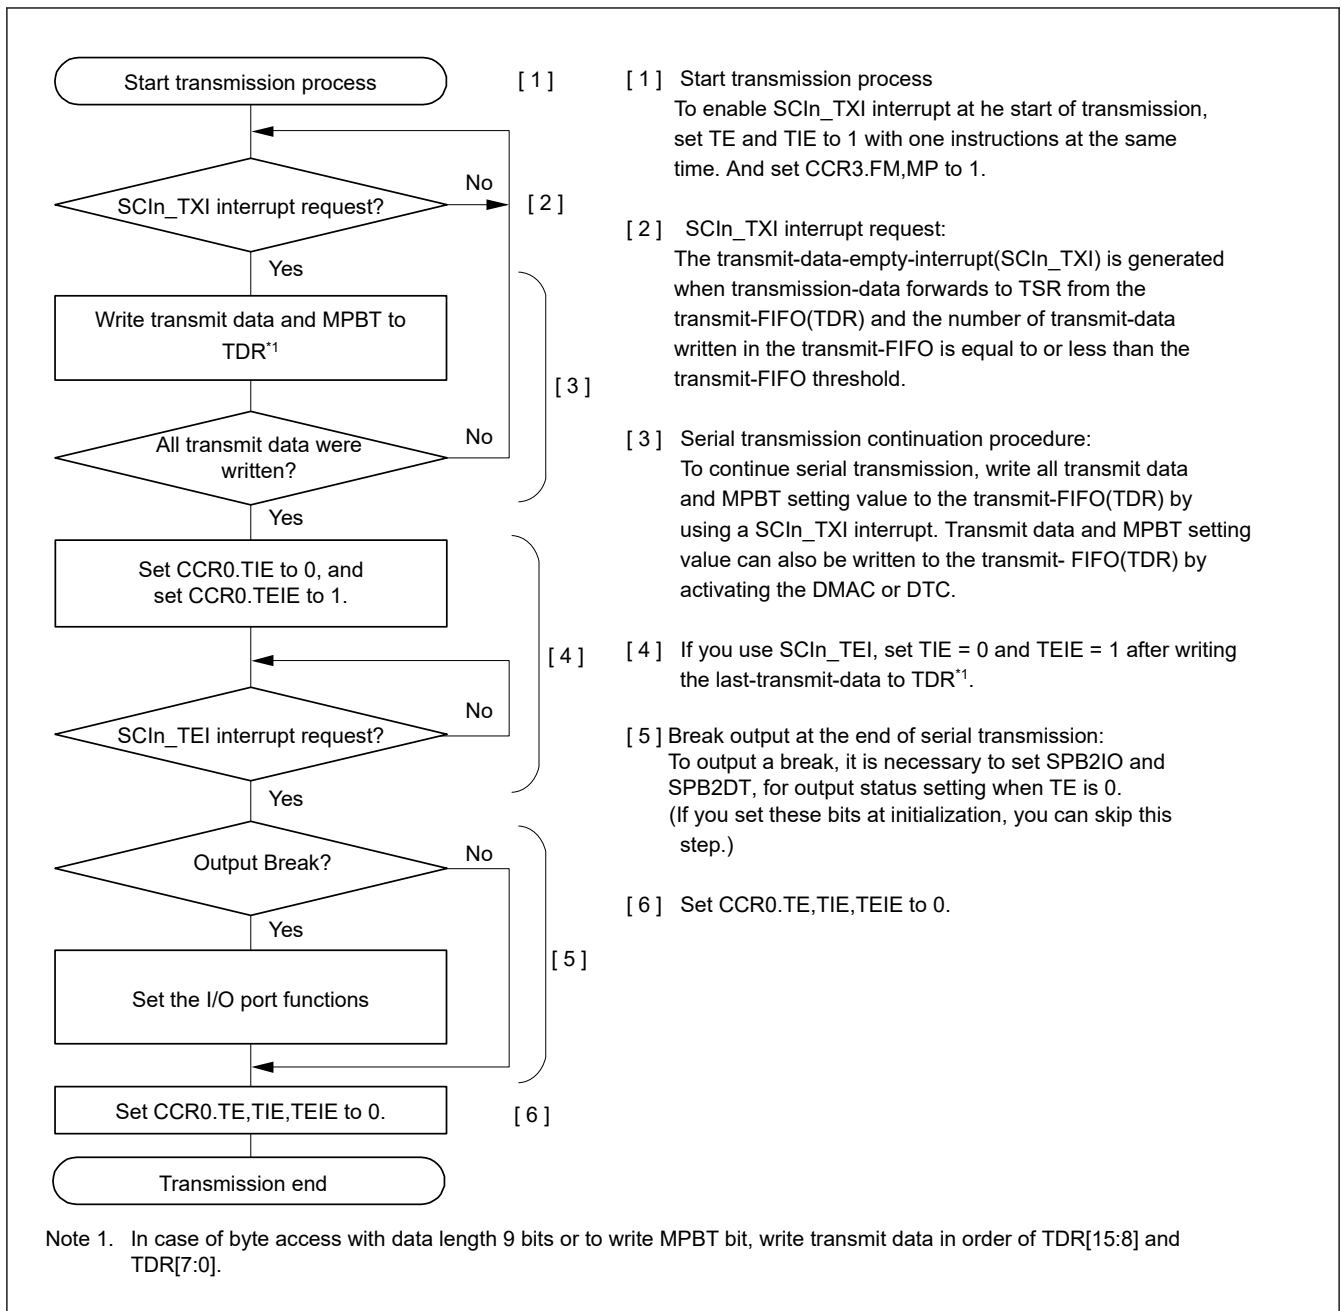

Figure 28.38 Example flow of serial transmission in multi-processor mode with FIFO selected

28.4.2 Multi-Processor Serial Data Reception

(1) Non-FIFO selected

Figure 28.40 and Figure 28.41 are example flows of multi-processor serial reception. When the CCR0.MPIE bit is set to 1, reading communication data is skipped until reception of communication data in which the multi-processor bit is set to 1. When communication data in which the multi-processor bit is set to 1 is received, the received data is transferred to the RDR register, and the SCIn_RXI interrupt request is generated. The rest of the operations are the same as operations in Asynchronous mode.

Figure 28.39 shows an example operation for data reception.

Figure 28.39 Example of SCI reception with 8-bit data, multi-processor bit, and 1 stop bit

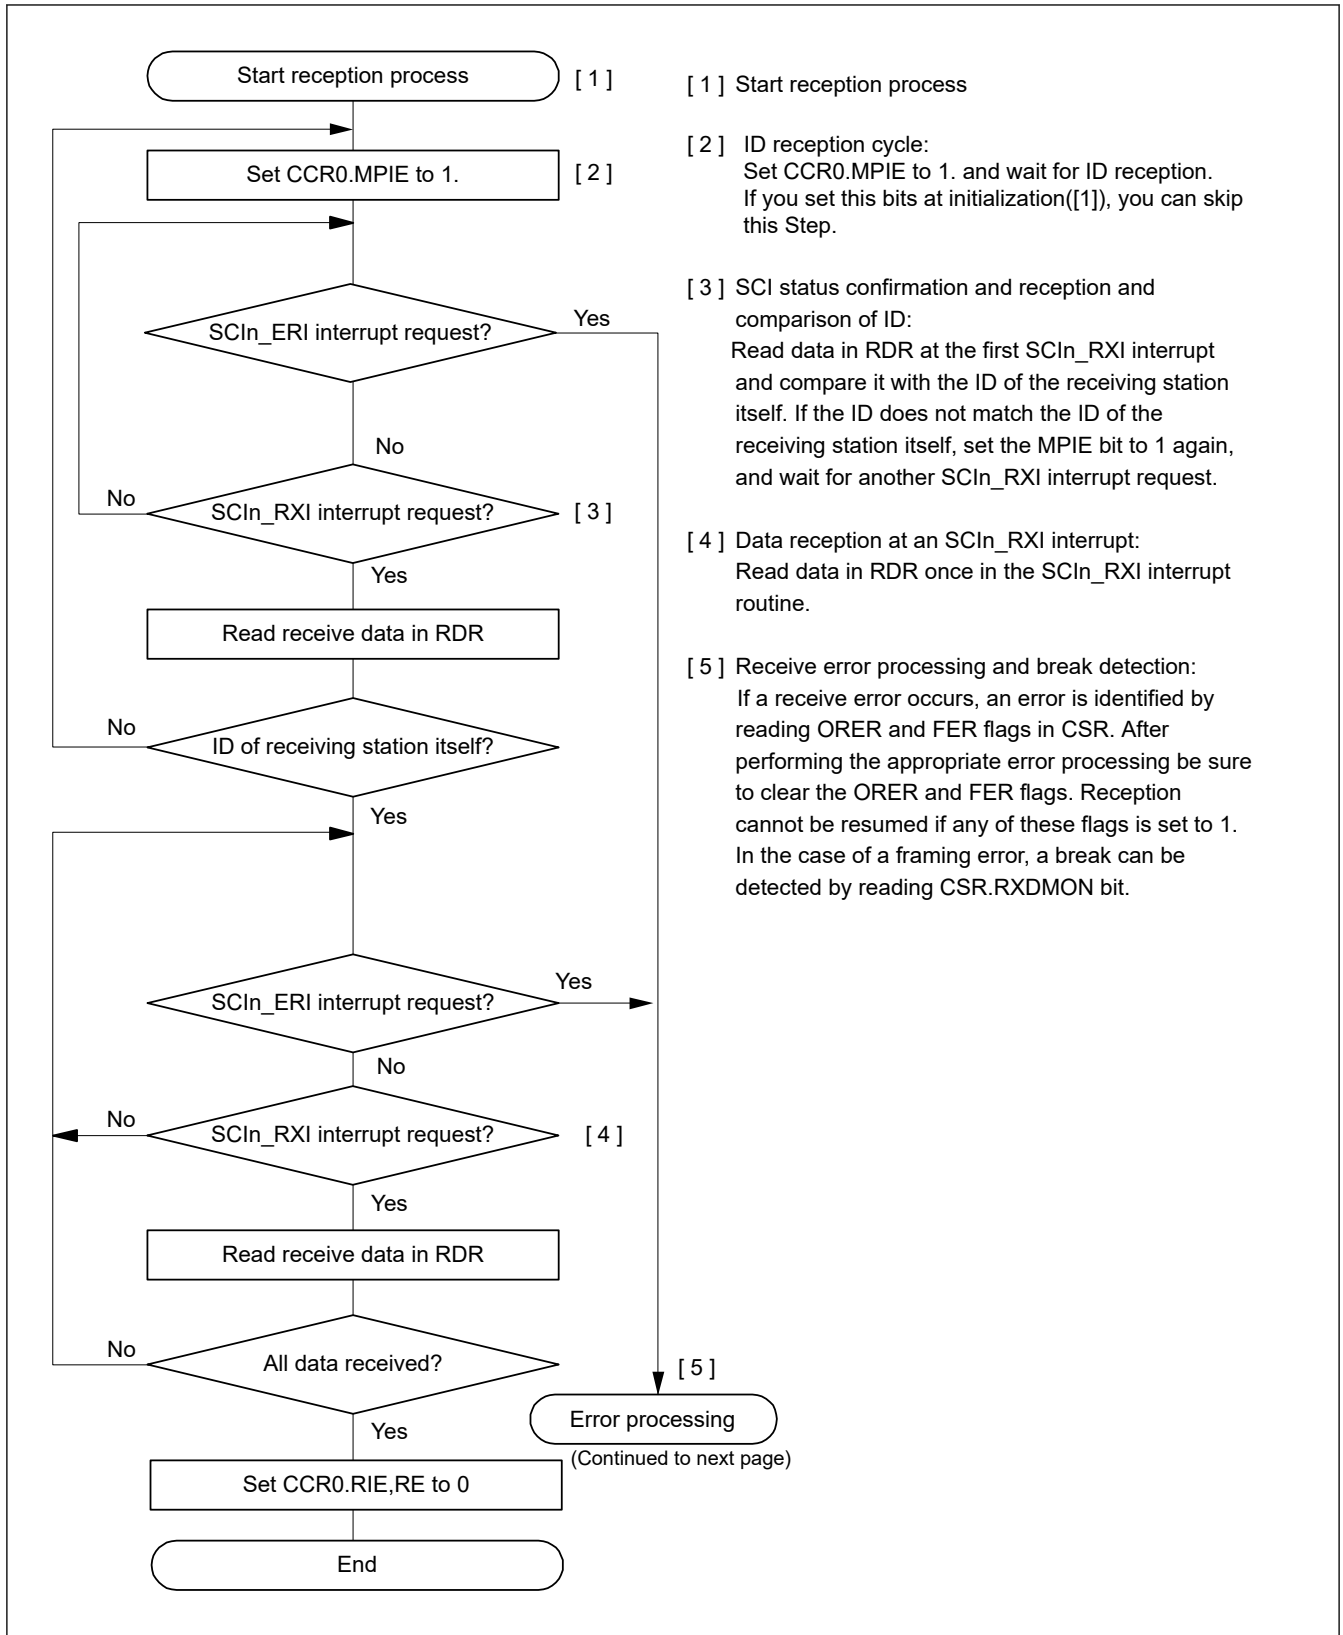

Figure 28.40 Example flow of multi-processor serial reception with non-FIFO selected (1)

Figure 28.41 Example flow of multi-processor serial reception with non-FIFO selected (2)

(2) FIFO selected

Figure 28.42 shows an example of a data format that is written to receive-FIFO (RDR) in multi-processor mode.

In multi-processor mode, the MPB value that is a part of the receive data is written to the RDR.MPB bit. A value of 0 is written to the RDR.FPER and PER flags. Data is written to receive-FIFO (RDR) with the correct data length. Unused bits are written with 0. When software reads the receive-FIFO (RDR) register, the SCI updates RDR.FFER, FPER, and MPB flags, and receive data (RDAT[8:0]) in receive-FIFO (RDR) with the next data. The FER, PER, and ORER flags in the receive-FIFO (RDR) register always reflect the associated flags in the CSR and FRSR registers.

Data Length	Register Setting		Receive data in RDR[31:0]															
	CCR3.CHR[1:0]		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
7bit	1	1	0	0	0	FFER	FPER	DR	MPB	0	0	RDAT[6:0]						
8bit	1	0	0	0	0	FFER	FPER	DR	MPB	0	RDAT[7:0]							
9bit	0	Don't Care	0	0	0	FFER	FPER	DR	MPB	RDAT[8:0]								
Data Length	CCR3.CHR[1:0]		b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
7bit	1	1	0	0	0	FER	PER	0	0	ORER	0	0	0	0	0	0	0	0
8bit	1	0	0	0	0	FER	PER	0	0	ORER	0	0	0	0	0	0	0	0
9bit	0	Don't Care	0	0	0	FER	PER	0	0	ORER	0	0	0	0	0	0	0	0

Note: When data length is 7bit, it can read always 0 in RDAT[8:7].
When data length is 8bit, it can read always 0 in RDAT[8].

Figure 28.42 Data format stored in receive-FIFO (RDR) in multi-processor mode with FIFO selected

Figure 28.43 shows an example flow of multi-processor data reception with FIFO selected. When the CCR0.MPIE is set to 1, reading communication data is skipped until reception of communication data in which the multi-processor bit is set to 1. When communication data in which the multi-processor bit is set to 1 is received, the received data, MPB and associated errors are transferred to the receive-FIFO (RDR) register. The CCR0.MPIE bit is automatically cleared and normal reception continues.

If a framing error occurs and the CSR.FER flag is set to 1, the SCI continues data reception. The rest of the operations are the same as operations in Asynchronous mode with FIFO selected.

Figure 28.43 Example flow of serial reception in multi-processor mode with FIFO selected

Figure 28.44 Example Flowchart of Serial Reception in Multi-Processor Mode (2) (FIFO selected)

28.5 Operation in Manchester mode

In Manchester mode, the transmit or receive serial data is coded in Manchester encoding.

Figure 28.45 shows the conceptual image of Manchester encoding.

Figure 28.45 Example of Manchester Encoding

In Manchester mode, a preface and a start bit area are added to the transmit data in the register to configure a transmit frame. For transmission, data is encoded in Manchester encoding. When data is received, frames having the same format as transmitted frames are detected and Manchester decoding is performed.

For details on the frame format, see [section 28.5.1. Frame Format](#).

28.5.1 Frame Format

[Figure 28.46](#) shows the frame format in Manchester mode.

In the upper half of the figure, relevant setting registers are shown.

The preface area and the data area are encoded in Manchester encoding.

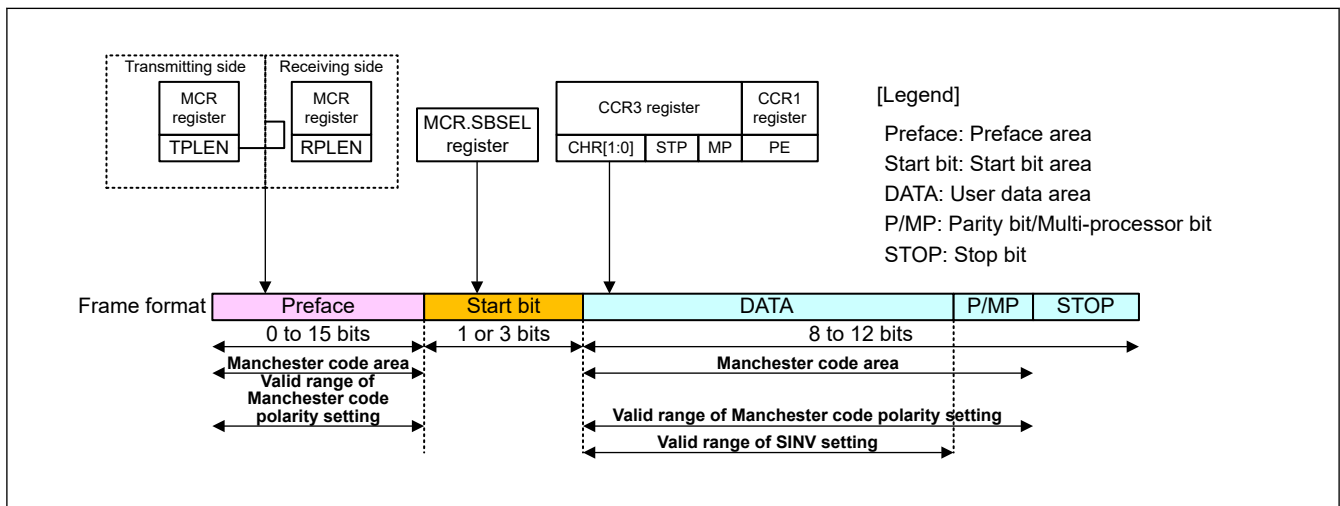

Figure 28.46 Frame Format in Manchester Mode

(1) Preface area

This is a fixed pattern area located at the beginning of each frame.

Different registers are used to set the preface area for transmission and reception. The preface length is determined by setting MCR.TPLEN[3:0] for transmission. It is determined by setting MCR.RPLEN[3:0] for reception.

If it is set to 0, the transmit preface is disabled and is not added.

If it is set to 1d to 15d, a preface whose length is determined by this setting is added.

(For example, if it is set to 1d, a 1-bit preface is added. If it is set to 15d, a 15-bit preface is added.)

The preface pattern is set with MCR.TPPAT[1:0] for transmission and MCR.RPPAT[1:0] for reception, and is selected from four types of patterns.

[Figure 28.47](#) shows how the preface pattern is set. The preface area and the start bit area are added for each communication frame.

Figure 28.47 Preface Pattern Setting Example

(2) Start bit area

This is an area indicating the start of valid data in a frame. It is added after the preface area.

The start bit length is determined by MCR.SBSEL setting. When MCR.SBSEL = “0”, the start bit length is 1 bit.

When MCR.SBSEL = “1”, the start bit length is 3 bits.

When MCR.SBSEL = “1”, the SYNC type can be selected from command SYNC and data SYNC.

Command SYNC means the three start bits are added as a one-to-zero transition.

Data SYNC means the three start bits are added as a zero-to-one transition.

The SYNC type is determined by the MCR.SYNSEL, MCR.SYNVAL and TDR.TSYNC settings.

(When receiving, the received result is applied to MSR.RSYNC.)

When MCR.SBSEL = "0", the start bit is added as a zero-to-one or one-to-zero transition.

The selection is determined by the MCR.SYNVAL setting.

The MCR.SYNSEL bit specifies the destination to be referred to when setting for transmission.

When the MCR.SYNSEL bit is set to 1, the MCR.SYNVAL setting is referred to. When the MCR.SYNSEL bit is set to 0, the TDR.TSYNC setting is referred to.

Figure 28.48 shows the state of the start bit area according to the settings in the MCR.SYNSEL, MCR.SYNVAL and TDR.TSYNC registers in the case of transmission. Figure 28.49 shows that in the case of reception.

The start bit(s) is not affected by the MCR.TMPOL or MCR.RMPOL setting.

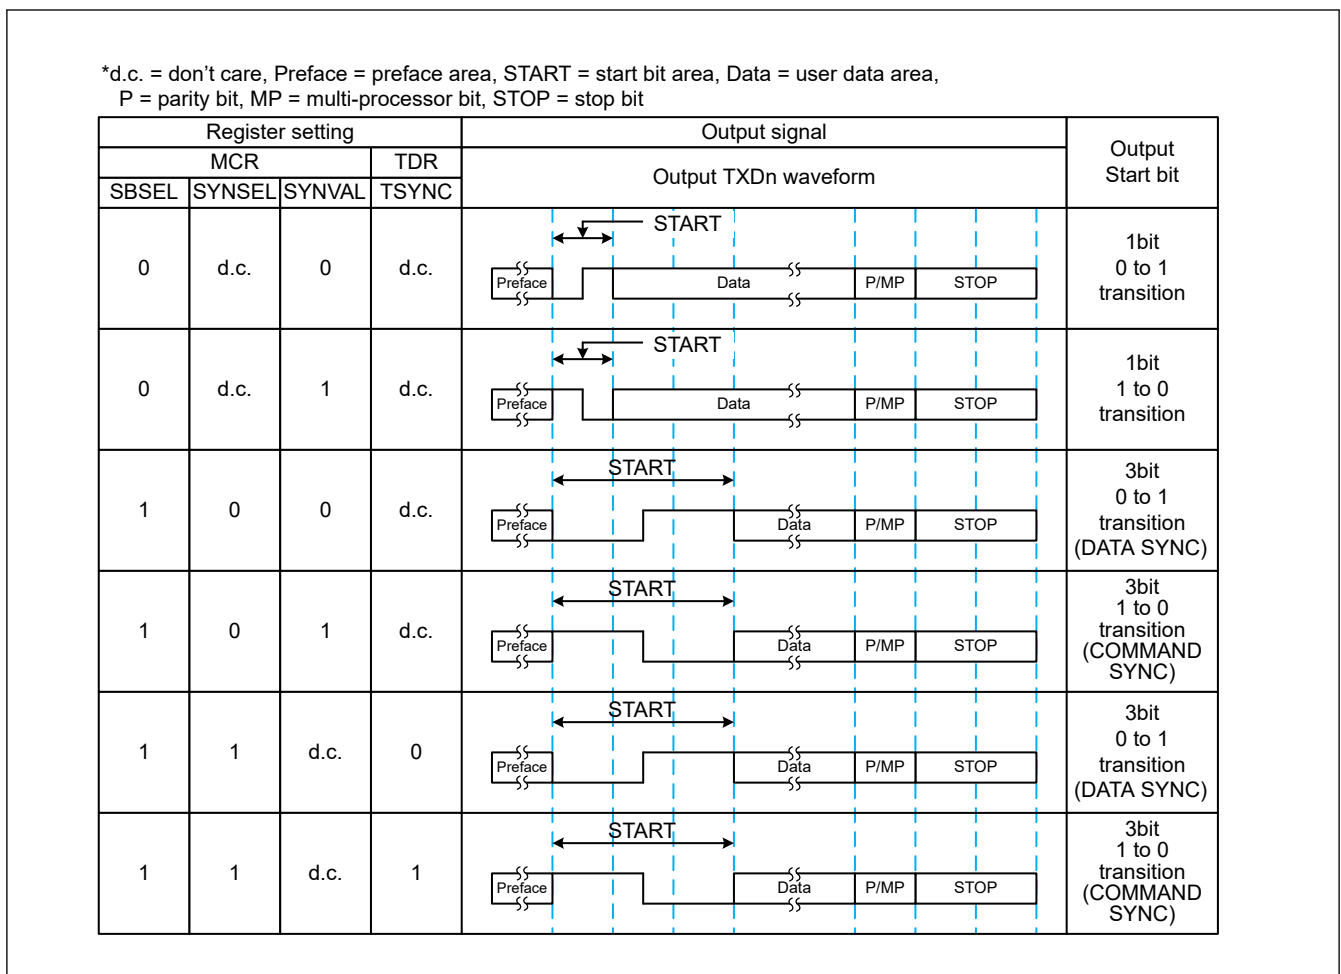

Figure 28.48 Settings Related to and Format of the Start Bit Area at Transmission

d.c. = don't care, Preface = Preface area, START = Start bit area, Data = Data area
 P = Parity bit, MP = Multi-processor bit, STOP = Stop bit

Register setting				Input signal RXDn input waveform	Start bit detection result ¹	Register indication MSR.RSYNC
MCR			TDR			
SBSEL	SYNSEL	SYNVAL	TSYNC			
0	d.c.	0	d.c.		Normal start bit (1 bit: 0-to-1 transition)	0
					Start bit error	0
					Start bit error	0
					Start bit error	0
0	d.c.	1	d.c.		Start bit error	0
					Normal start bit (1 bit: 1-to-0 transition)	0
					Start bit error	0
					Start bit error	0
1	d.c.	d.c.	d.c.		Start bit error	0
					Start bit error	0
					Data SYNC	0
					Command SYNC	1

Note 1. Data other than the start bit is assumed to be normal.

Figure 28.49 Settings Related to and Judgment of the Start Bit Area at Reception

(3) DATA

Since the format of the data area is the same as that of the Asynchronous mode, see [section 28.3.1. Serial Data Transfer Format](#).

As shown in [Figure 28.45](#), Frame Format in Manchester Mode, the stop bit is not included in the Manchester encoding range.

28.5.2 Clock

As the transfer clock in Manchester mode, the clock generated by the on-chip baud rate generator is used by setting the CCR2.CKS[1:0] bit.

Also it is possible to set the oversampling (transfer rate of one-bit period) by CCR2.ABCS bit.

When the CCR2.ABCS bit is set to 0, oversampling x16 is selected with the one-bit period being 16 cycles of the base clock. When the CCR2.ABCS bit is set to 1, oversampling x8 is selected with the one-bit period being 8 cycles of the base clock.

28.5.3 Initialization of the SCI in Manchester Mode

Before transferring data, write 0 to CCR0.TE and CCR0.RE (or write the initial value to CCR0 register) and initialize the SCI following the example of flowchart shown in [Figure 28.50](#).

Whenever the operating mode or transfer format is changed, the CCR0 register must be initialized before the change is made.

Note that setting the CCR0.RE bit to 0 initializes none of the ORER, FER, PER, MER, RDRF, SYER, PFER and SBER flags, and the RDR registers.

Note also that switching the value of CCR0.TE from 0 to 1 when CCR0.TIE is 1 generates a SCIn_TXI interrupt request.

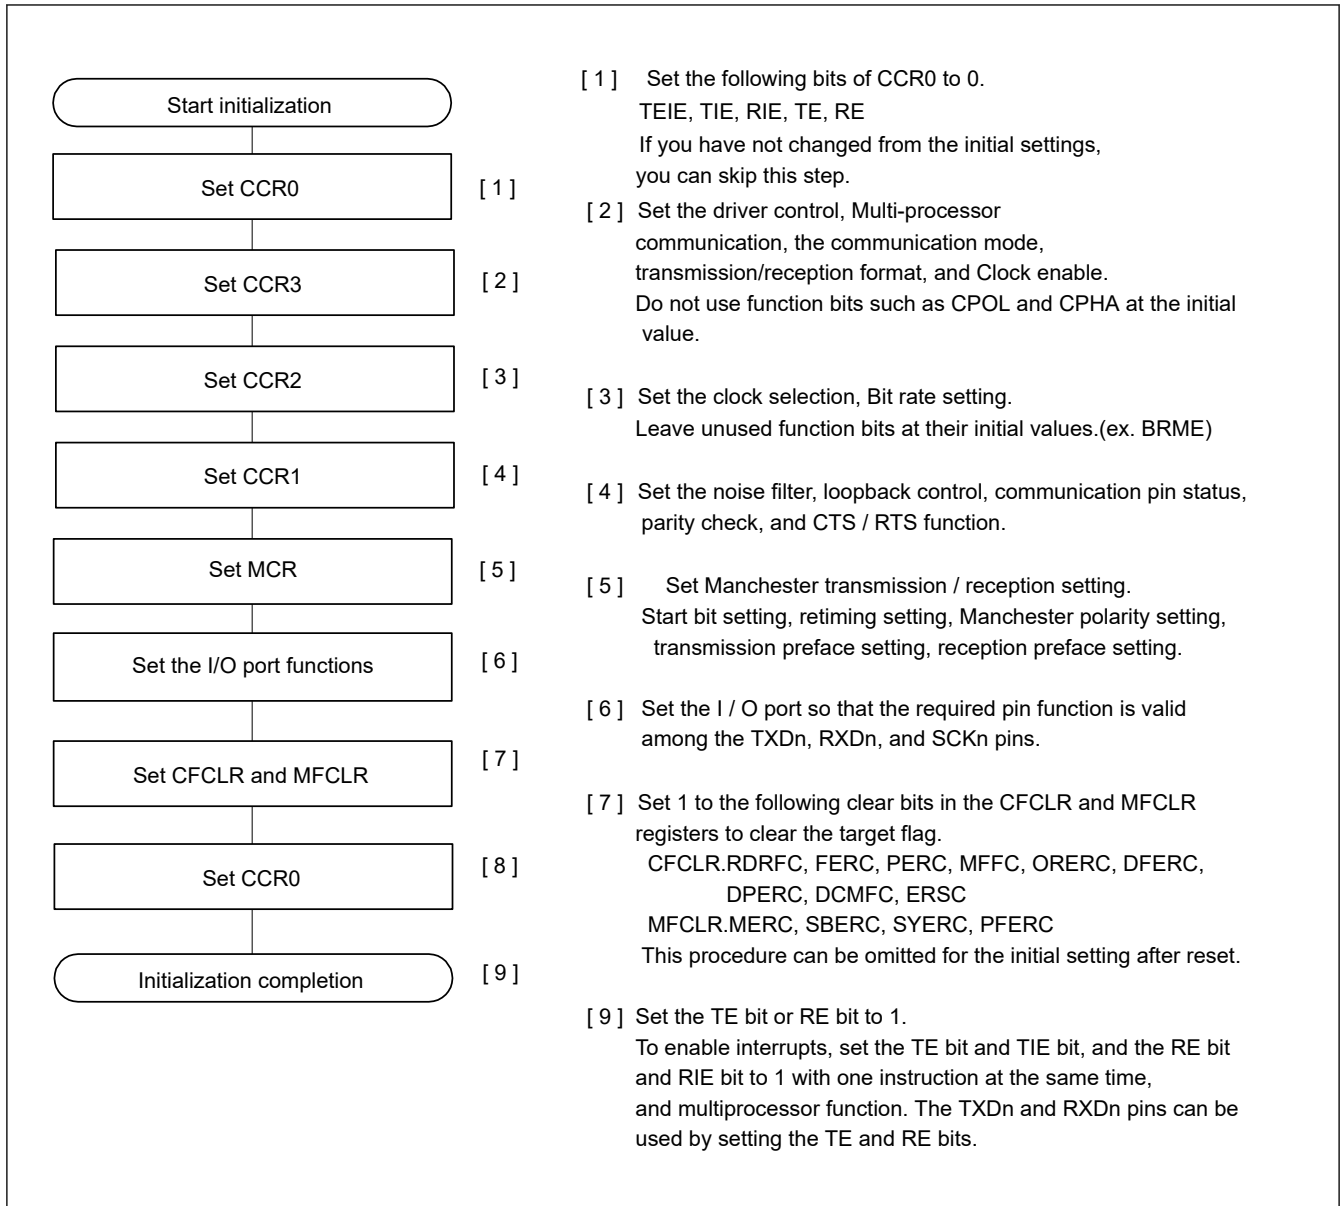

Figure 28.50 SCI Initialization Flow in Manchester Mode

28.5.4 Double-speed operation

When the ABCS bit in CCR2 is set to 1 and eight pulses of the base clock for a 1-bit period is selected, the SCI operates on the bit rate twice that of when ABCS is set to 0.

When the BGDM bit in CCR2 is set to 1, the cycle of the base clock is reduced to half and the SCI operates on the bit rate twice that of when ABCS is set to 0.

When the ABCS and the BGDM bits in CCR2 are set to 1, the SCI operates on the bit rate four times that of when the ABCS and the BGDM bits in CCR2 are set to 0.

28.5.5 CTS and RTS functions

The CTS function uses input on the CTSn pin in transmission control. Setting the CTSE bit in CCR1 to 1 enables the CTS function. The CTSn_RTSn pin can be set as a multiplexed pin which allows one pin to be used for either CTS or RTS function, or as dedicated pins with each pin at CTSn pin for CTS function and CTSn_RTSn pin for RTS function. Use the CTSPEN bit in CCR1 for this setting.

When the CTS function is enabled, reception starts only when the CTSn pin is at the low level.

Applying a high level to the CTSn pin after transmission starts does not affect transmission of the current frame, which continues.

The RTS function uses output on the CTSn_RTSn pin to request transmission. When the SCI is ready to receive, it outputs a low level to the CTSn_RTSn pin. Conditions for output of the low level and high level are as follows:

[Conditions for low-level output]

When all conditions listed below are satisfied:

- The value of the RE bit in CCR0 is 1.
- When The SCI is ready to receive next.
 - When there is no received data yet to be read and not receiving
 - All of the following flags are set to 0: CSR.ORER, FER, and PER, MSR.MER, SYER (when SYEREN = 1), PFER (when PFEREN = 1) and SBER flags (when SBEREN = 1).

[Conditions for high-level output]

- When the conditions for low output are not satisfied

28.5.6 Serial data transmission in Manchester mode

The SCI encodes data in Manchester encoding and sends the resultant data in Manchester mode.

When the polarity setting (MCR.TMPOL) set to 0, logic 0 is coded as a zero-to-one transition in Manchester code and logic 1 is coded as a one-to-zero transition in Manchester code.

When the polarity setting (MCR.TMPOL) set to 1, logic 0 is coded as a one-to-zero transition in Manchester code and logic 1 is coded as a zero-to-one transition in Manchester code.

For this reason, a level transition occurs with the Manchester encoded data in the middle of individual logic data. (See [Figure 28.45](#)).

The transmitter constructs transmit frames in a specific format by adding a preface area to data and setting the start bit(s) according to the polarity setting and sends resultant serial data.

For details on the frame format, see [section 28.5.1. Frame Format](#).

[Figure 28.51](#) shows the flowchart in transmission. At transmission starts, set the CCR0.TIE and CCR0.TE bits to 1 simultaneously with one instruction. Then, a SCIn_TXI interrupt request is generated. [Figure 28.52](#), [Figure 28.53](#), and [Figure 28.54](#) show examples of the operation for serial transmission in Manchester mode.

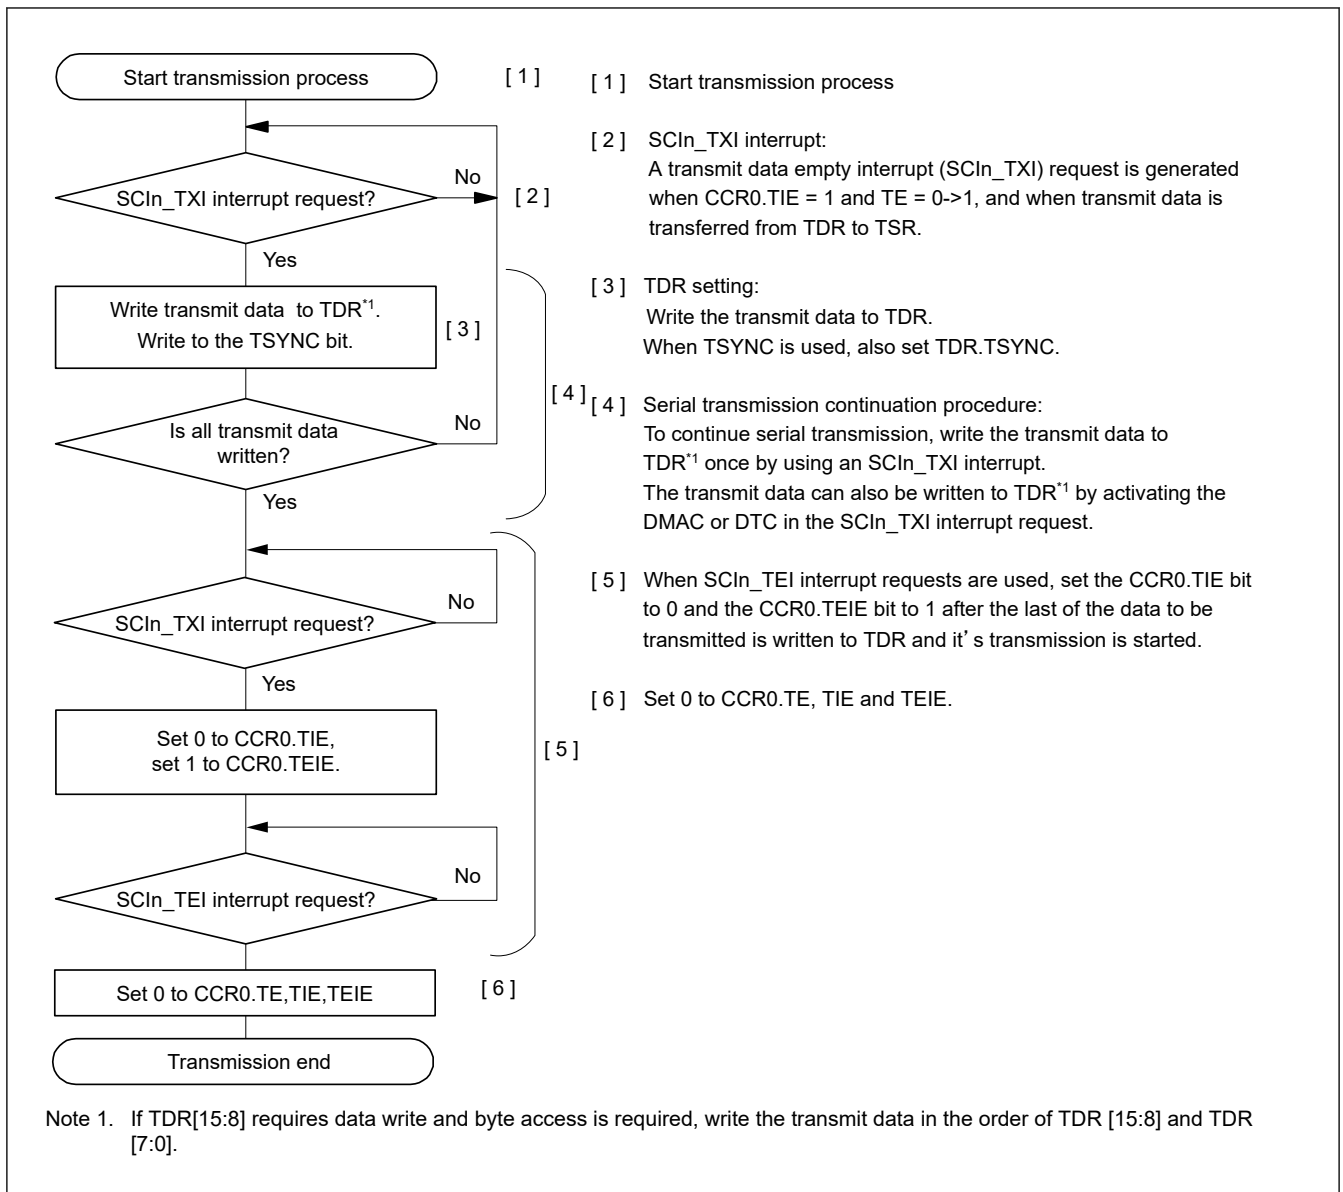

Figure 28.51 Example of Serial Transmission Flowchart in Manchester Mode

Figure 28.52 Example of Start-of-Transmission Operation for Serial Transmission in Manchester mode (with Preface but Without the CTS Function)

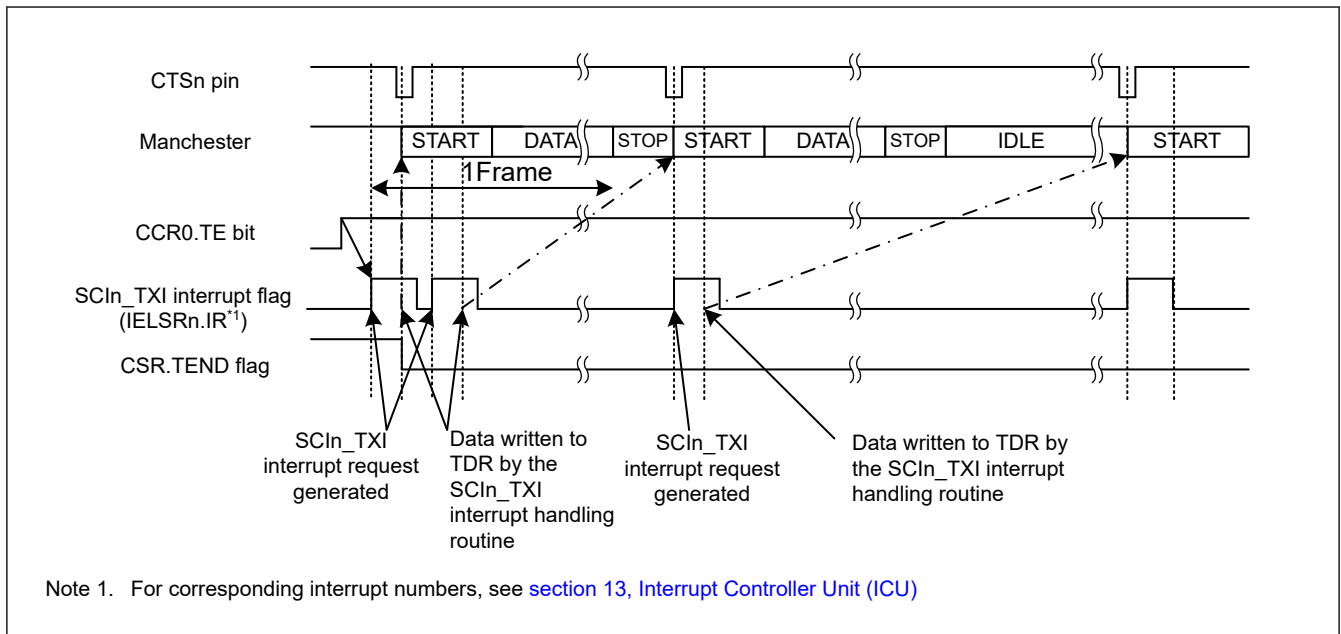

Figure 28.53 Example of Start-of-Transmission Operation for Serial Transmission in Manchester Mode (Without Preface but with the CTS Function)

Figure 28.54 Example of End-of-Transmission Operation for Serial Transmission in Manchester Mode (with Preface but Without the CTS Function)

28.5.7 Serial Data Reception in Manchester Mode

In Manchester mode, the SCI operates on a base clock with a frequency of 16 times^{*1} the bit rate. Reception starts by sampling the falling edges of received data at the base clock. As shown in Figure 28.55, reception starts at a falling edge of the received data and it continues if the received data keeps low for the duration of 1/4 bit. If the received data goes high within the duration of 1/4 bit, the SCI judges it as an error and waits for a falling edge again.

If a high level is expected in the first half of a bit in the received data, the SCI judges a low level that continues for one base clock cycle as an error and ignores the change to the low level.

Note 1. This is the case when CCR2.ABCS = 0. When CCR2.ABCS = 1, the SCI operates on a base clock with a frequency of 8 times the bit rate.

Figure 28.55 Data Reception Sampling Timing in Manchester Mode

In Manchester mode, data reception starts with detection of a preface and start bit area.

The SCI checks the input from the RXDn pin to see whether a preface is added based on the value of MCR.RPLEN.

If the preface is disabled (MCR.RPLEN = 0), it moves on to the detection of a start bit area without detecting a preface.

When a preface is enabled, it identifies a preface pattern setting according to the set value in MCR.RPPAT, and compares it with the RXDn input for a pattern match to detect a preface pattern.

Upon detection of a preface pattern match, it judges it as a normal preface and moves on to the detection of a start bit area.

If detecting a preface pattern mismatch or a Manchester code error in the preface area, it judges it as a preface error and asserts a preface error (PFER).

For start bit detection, the SCI selects an expected value based on the register settings (MCR.SBSEL and SYNVAL), compares it with the RXDn input for a pattern match to detect a start bit area. Upon detection of a start bit pattern match, it judges it as a normal start bit area and moves on to the data processing.

Only when a preface and a start bit area are detected normally, it moves on to the next phase of data reception.

Upon detection of a start bit pattern mismatch, it asserts a start bit error flag (SBER).

In data processing, the SCI shifts the data by the expected received data length based on the register settings (CCR3.CHR[1:0]) through the RSR register. If two sampling points in a bit of the received data are identical, the SCI judges this as a Manchester code error.

For details, see [section 28.5.11. Errors in Manchester Mode](#) (4).

When the parity function is disabled (CCR1.PE = 0), the SCI moves on to the next phase of stop bit detection. When the parity function is enabled (CCR1.PE = 1), the SCI performs parity checking. If detecting a parity error, it asserts a parity error flag (PER), and then moves on to stop bit detection.

In stop bit detection, the SCI checks the following in the stop bit area of the received frame:

It has two sampling points in a bit. If both points are at the high level, the bit is recognized as a normal stop bit and the data is stored in the RDR register. At least one low-level point is judged as an abnormal stop bit, causing a framing error flag (FER) to be set. Even when an error is detected, the received data is stored in the RDR register as abnormal data.

[Figure 28.56](#) shows an example of the operation for serial data reception in Manchester mode.

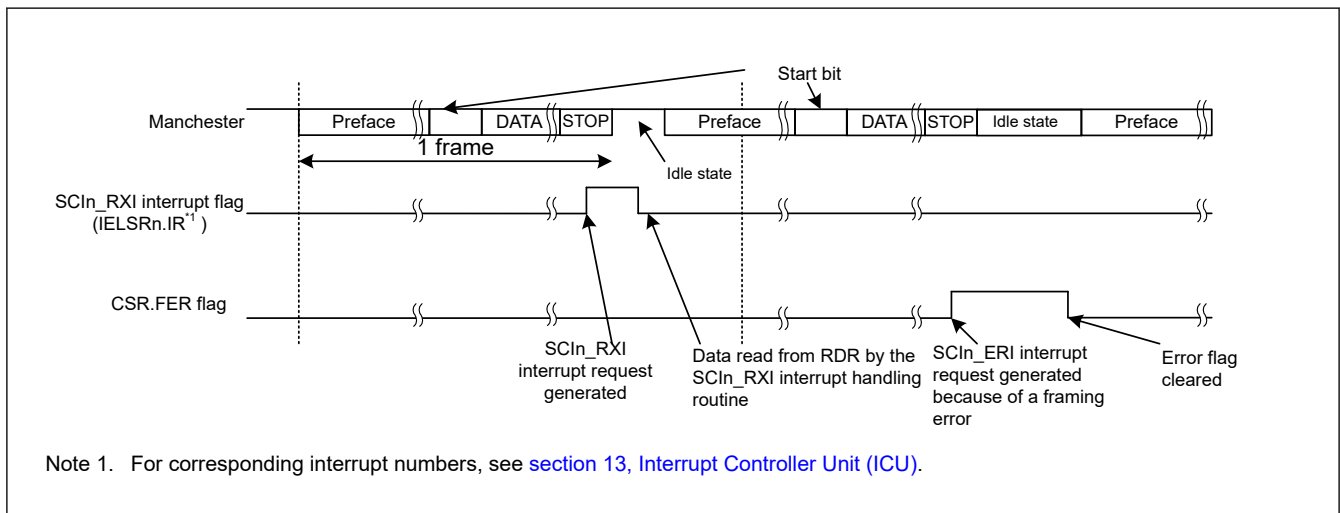

Figure 28.56 Example of Operation for Serial Data Reception in Manchester mode (with a Preface)

For the state of each status flag in the CCR0 register and RXDn input processing when a receive error is detected, see [section 28.5.11. Errors in Manchester Mode](#).

If a receive error is detected, an SCIn_ERI interrupt request is generated but an SCIn_RXI interrupt request is not generated.

Data reception cannot be resumed while the receive error flag is 1. Accordingly, set the ORER, FER, PER, MER, SYER^{*1}, PFER^{*1}, and SBER^{*1} flags to 0 before resuming reception. Also, be sure to read the RDR register during overrun error processing. When a reception is forcibly terminated by setting the CCR0.RE bit to 0 during operation, read the RDR register because received data which has not yet been read may be left in the RDR register.

[Figure 28.57](#) and [Figure 28.58](#) show examples of serial data reception flowchart in Manchester mode.

Note 1. Effective when the corresponding bit is enabled.

Figure 28.57 Example of Serial Data Reception Flowchart in Manchester Mode (Normal Reception)

Figure 28.58 Example of Serial Reception Flowchart in Manchester Mode (Error Processing)

28.5.8 Operation When Multi-Processor Bit Is Used

See [section 28.4. Multi-Processor Communication Function](#) (1) for the operation in Manchester mode when using multi-processor mode because the operation is the same.

A preface and a start bit area are added to the frame format in Manchester mode. See [Figure 28.58](#) for error processing in Manchester mode for the reception flowchart ([Figure 28.41](#)). See [Table 28.37](#) for the operation status when detecting various errors.

28.5.9 Receive Retiming

This function corrects the timing for each central edge of the bit, taking advantage of the fact that each bit has an edge in the center in Manchester code.

The receive retiming function can be turned on or off by setting the ERTEN bit in the MCR register.

When the receive retiming function is turned off ($MCR.ERTEN = 0$), retiming is not performed, causing misalignment between the internal clock and the RXDn input to be accumulated and the receive margin to be reduced.

When the receive retiming function is turned on ($MCR.ERTEN = 1$), retiming is performed for the preface area, the start bit area^{*1}, and the data area (excluding the stop bit).

Note 1. Retiming is not performed for the start bit area if the preface length is 0 and the start bit length is 3.

As an example, the receive retiming when oversampling x16 is selected is shown below.

When detecting an RXDn input edge two to four cycles before the expected receive cycle, the receive processing is shortened by one sampling CLK cycle.

When detecting a RXDn input edge two to three cycles after the expected receive cycle, the receive processing is extended by one sampling CLK cycle.

(Even if the clock is misaligned with the data by more than two cycles, one cycle is corrected for each bit.)

[Figure 28.59](#) shows the conceptual image of receive retiming range.

When detecting an edge in the tolerance area in the figure, data is received as is without making correction.

When detecting an edge in the SyncJump area in the figure, data is corrected for reception.

When detecting an edge in the SyncError area in the figure, data is received as abnormal data with no correction made.

For a Manchester code error (data matches at the 1/4-phase and 3/4-phase sampling points), the SCI reports a code error.

Figure 28.59 Conceptual Image of Reception Retiming Range

28.5.10 Polarity Setting for Manchester Code

The polarity of the Manchester code can be set with the Manchester Control Register (MCR).

It can be set separately for transmission and reception. Use the MCR.TMPOL bit to set the polarity for transmission and the MCR.RMPOL bit to set the polarity for reception.

The Manchester code polarity setting is valid for the preface area, the data area, and the parity or multi-processor area.

When the initial settings (TMPOL/RMPOL = 0) are used for the polarity of Manchester code, logic 0 is encoded as a zero-to-one transition in Manchester code and logic 1 is encoded as a one-to-zero transition in Manchester code. If the settings are changed to TMPOL/RMPOL = 1, logic 0 is encoded as a one-to-zero transition in Manchester code and logic 1 is encoded as a zero-to-one transition in Manchester code. Figure 28.60 shows the conceptual image of the settings and operation.

Separately from the function above, the transmitted and received data in the data area can be inverted by the transmitted/received data inversion function (CCR3.SINV). Since the polarity of Manchester code (MCR.TMPOL/RMPOL) can be set separately from the transmitted/received data invert function (CCR3.SINV), if both are set to inversion (MCR.TMPOL/RMPOL = 1 and CCR3.SINV = 1), the transmitted and received data are set to initial state (inversion + inversion = normal).

The polarity of the start bit area can be set by a register different from the ones mentioned above.

Since a different register is used, the polarity of the start bit area is not affected by the polarity setting for Manchester code mentioned above.

For details on the setting for the start bit area, see section 28.5.1. Frame Format (2).

Figure 28.60 Valid Range of the Manchester Code Polarity Setting

28.5.11 Errors in Manchester Mode

There are the following errors in Manchester mode:

1. Parity error
2. Over run error
3. Framing error
4. Manchester error
5. Preface error
6. Start Bit error
7. Receive SYNC error

For errors (1) to (3), see [section 28.3.9. Serial Data Reception in Asynchronous Mode \(1\)](#) because they are the same as in Asynchronous mode.

Each errors are judged in each area, but they are reflected on flags and operations at the timing of 3/4-bit sampling of the STOP bit area. If a preface error or start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the previous information.

[Table 28.35](#) lists the states of the serial status register when detecting errors and judgment about whether to store data in the RDR.

[Table 28.36](#) lists the errors that can be detected in each area of a Manchester frame.

If a Preface error or Start bit error is detected, subsequent data will not be received. Therefore, no other error detection is performed, and the error flag holds the result of the previous frame reception. Also, if an error is detected in the previous

frame, data will not be received, but errors in the pre-face area and start bit area will update that flag. [Table 28.37](#) shows the flags and actions in this case.

(4) Manchester error

A Manchester error is generated when a Manchester code error is detected.

In Manchester code, there must be an edge (transition) in the center of the bit.

In the data area of a received frame (including the parity/multi-processor bit), the values of the 1/4-bit and 3/4-bit sampling points are checked in each received 1-bit data, and a Manchester code error is determined if these two values match.

If a Manchester code error is detected, the Manchester error flag (MSR.MER) is asserted.

If a Manchester error occurs, it is handled as an interrupt source and event source. If a Manchester error is detected, the next reception is not performed until the corresponding error flag is cleared.

(5) Preface error

A preface error is generated when the preface pattern does not match or a Manchester code error is detected in the preface area. If a preface error is detected, the preface error flag (MSR.PFER) is asserted.

It is possible to set whether to use this error flag as an interrupt source with the setting of the MCR register.

When $MCR.PFEREN = 1$, a preface error is handled as an interrupt source or event source. If a preface error is detected, the next reception is not performed until the corresponding error flag is cleared.

When $MCR.PFEREN = 0$, a preface error is not handled as an interrupt source or event source, and the next reception is not halted. However, a preface error is notified to MSR.PFER.

(6) Start bit error

A start bit error is generated when a mismatch is detected between the start bit area in the received frame and the preset start bit pattern. Upon detection of a start bit error, a start bit error flag (MSR.SBER) is asserted.

It is possible to set whether to use the start bit error as an interrupt source with the setting of the MCR register.

When $MCR.SBEREN = 1$, a start bit error is handled as an interrupt source or event source. If a start bit error is detected, the next reception is not performed until the corresponding error flag is cleared.

When $MCR.SBEREN = 0$, a start bit error is not handled as an interrupt source or event source, and the next reception is not halted. However, a start bit error is notified to MSR.SBER.

(7) Receive SYNC error

When the receive retiming function described in [section 28.5.9. Receive Retiming](#) is enabled, the receive retiming operation is performed.

If no edges are detected within the receive retiming range (SyncError area in [Figure 28.59](#)) when receive timing operation is being performed, a receive SYNC error is generated. Upon detection of a receive SYNC error, a receive SYNC error flag (MSR.SYER) is asserted. In areas not subject to retiming, receive SYNC errors are not detected.

The preface area^{*1}, the start bit area^{*1,*2}, and the data area (excluding the stop bit) for which receive retiming operation is performed are checked.

It is possible to set whether to use the receive SYNC error as an interrupt source with the setting of the MCR register.

When $MCR.SYEREN = 1$, a receive SYNC error is handled as an interrupt source or event source. If a receive SYNC error is detected, the next reception is not performed until the corresponding error flag is cleared.

When $MCR.SYEREN = 0$, a receive SYNC error is not handled as an interrupt source or event source, and the next reception is not halted. However, a receive SYNC error is notified to MSR.SYER.

Note 1. In the case of a frame that starts with a pattern that expects the first half of the bit to be High, it is excluded from retiming.

Note 2. In the start bit area, when there is no preface length and 3 bit start bit is set, it is not subject to retiming.

Also, the 1st bit and the 2nd bit in the start bit area when 3 bit start bit is set are not subject to retiming.

Table 28.35 Flags in the CSR Register and Receive Data Handling in Manchester Mode

Flag in the CSR register			Flag in the MRS register				Received data	Received error status (SCI _n _ERI interrupt / event generation)
ORE R	FER	PER	MER	SBER ^{*1}	PFER ^{*1}	SYER		
0	0	0	0	0	0	0	transfer to RDR	No error
0	1	0	0	0	0	0	transfer to RDR	Framing error
0	0	1	0	0	0	0	transfer to RDR	Parity error
0	1	1	0	0	0	0	transfer to RDR	Framing error + Parity error
0	0	0	1	0	0	0	transfer to RDR	Manchester error
0	1	0	1	0	0	0	transfer to RDR	Framing error + Manchester error
0	0	1	1	0	0	0	transfer to RDR	Parity error + Manchester error
0	1	1	1	0	0	0	transfer to RDR	Framing error + Parity error + Manchester error
1	0	0	0	0	0	0	Lost	Overrun error
1	1	0	0	0	0	0	Lost	Overrun error + Framing error
1	0	1	0	0	0	0	Lost	Overrun error + Parity error
1	1	1	0	0	0	0	Lost	Overrun error + Framing error + Parity error
1	0	0	1	0	0	0	Lost	Overrun error + Manchester error
1	1	0	1	0	0	0	Lost	Overrun error + Framing error + Manchester error
1	0	1	1	0	0	0	Lost	Overrun error + Parity error + Manchester error
1	1	1	1	0	0	0	Lost	Overrun error + Framing error + Parity error + Manchester error
0	Combination of above			0	0	1	transfer to RDR	Errors above + Receive SYNC error ^{*2}
1	Combination of above			0	0	1	Lost	Errors above + Receive SYNC error ^{*2}
hold	hold	hold	hold	0	1	0	Lost	Preface error ^{*3}
hold	hold	hold	hold	1	0	0	Lost	Start bit error ^{*3}
hold	hold	hold	hold	0	1	1	Lost	Preface error ^{*3} + Receive SYNC error ^{*2}
hold	hold	hold	hold	1	0	1	Lost	Start bit error ^{*3} + Receive SYNC error ^{*2}

Note 1. Start bit error and Preface error never become 1 at the same time.

Note 2. When MCR.SYEREN = 1, SCI_n_ERI interrupt / event is generated by SYER factor.

Note 3. If MCR.PFEREN = 1 or MCR.SBEREN = 1, an SCI_n_ERI interrupt / event is generated when the corresponding flag is set.

Table 28.36 Errors Detectable in Each Area

	Preface error (PFER)	Start Bit error (SBER)	Manchester error (MER)	Receive SYNC error (SYER)	Parity error (PER)	Framing error (FER)
Preface area	✓	—	— ^{*1}	✓ ^{*2}	—	—
Start Bit area	—	✓	—	✓ ^{*2}	—	—
Data area	—	—	✓	✓	—	—
Parity area	—	—	✓	✓	✓	—
Multi-processor area	—	—	✓	✓	—	—
Stop Bit area	—	—	—	—	—	✓

Note: ✓: Detected, —: Not detected

Note 1. When an Manchester code error occurs in the preface area, it is defined as a preface error.

Note 2. It may not be subject to Receive SYNC error detection. For details see the text [section 28.5.11. Errors in Manchester Mode \(7\)](#)

Table 28.37 Operation status due to presence / absence of error in previous frame and operation status list in multiprocessor mode (1 of 2)

			MER					1					
No Error	No Error	MER		No Error	Don't Care	Don't Care	Don't Care						
		No Error	No Error				Don't Care	PER	No Error	Don't Care	Don't Care	Don't Care	
No Error	No Error			Don't Care	Don't Care	FER							Don't Care
		There is some error ORER					Don't Care	Don't Care	Don't Care				
No Error	No Error	No Error	No Error	No Error	ORER	Don't Care	Don't Care	Don't Care					

- Note 1. If SYER is detected, the SYER flag is also set. Other operations are as shown in this table.
- Note 2. Other detected error flags including ORER are also set.
- Note 3. If all the error flags are cleared before the STOP bit is judged, the operation will be the same as the case where there is no error in the previous frame of this table.
- Note 4. Since the SCIn_ERI interrupt request is level output, it remains active due to errors in the previous frame regardless of the presence or absence of error in the relevant frame.
- Note 5. Since the error cause is continuously detected, the SCIn_ERI event is not newly output regardless of the presence or absence of errors in the relevant frame.
- Note 6. For PFER, SBER, and SYER, when each enable bit is set to disable, it is treated as no error.

Table 28.38 Operation when MPIE = 1 in multi-processor mode (MPIE = 0)

MPB ^{*1}	Each area of the frame					PFER N	SBERE N	SYERE N	received data	Error flag	Interrupt request	Event signal
	preface	start bit	data	parity	stop							
1	No Error	No Error	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	transfer to RDR	set some flags	output ^{*2}	output ^{*2}
	No PFER	No SBER	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	0				
	SYER ^{*3}	SYER ^{*3}						1	Lost	don't set any flags	not output	not output
	PFER	No Error	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care				
	No Error	SBER	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care				

- Note 1. If the received MPB bit is 0, it is not received the frame, and the operation is the same as lost of the reception data of this table.
- Note 2. If no error is detected, SCIn_RXI interrupt request or event is output, and if it is detected, SCIn_ERI interrupt request or event is output.

Note 3. When SYER is detected in the preface area or the start bit area, the behavior of handling as an error depending on the SYEREN bit changes.

28.6 Operation in Clock Synchronous Mode

Figure 28.61 shows the data format for clock synchronous serial data communications.

In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. For single-character data transfer, data consists of 8-bit. In clock synchronous mode, no parity bit can be added.

In data transmission when CPHA = 1 and CPOL = 1, the SCI outputs data from one falling edge of the synchronization clock to the next falling edge. In data reception, the SCI receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the transmission line holds the last bit as output state. When the CPHA bit is 0 in slave mode, the transmission line holds the first bit output state.

Within the SCI, the transmitter and receiver are independent units, enabling full-duplex communications by using a shared communication clock of the transmitter and the receiver. Furthermore, because both the transmitter and the receiver also have a double-buffered structure, so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.

Figure 28.61 Data format in clock synchronous serial communications with LSB-first order

28.6.1 Clock

If the maximum speed of $SCK = 1/2TCLK$ is set in Clock Synchronous and Simple SPI mode, Do not make PCLK less than half the speed of TCLK. If PCLK is made slower than this, malfunction may occur.

1. When the internal clock is selected

When the SCI operates on an internal clock (CCR3.CKE[1:0] bits are set to 00b or 01b (master mode)), the synchronization clock is output from the SCKn pin. Eight synchronization clock pulses are output during single-character transmission/reception. When no data transfer is performed, the clock is held at high level.*¹ In transmission-only or transmission/reception, the synchronization clock is not output unless transmit data is prepared.

When the internal clock is selected, the clock with a delay from the SCKn signal is used for the master reception sampling clock. This ensures the data setup time and hold time for high-speed communication.

Note 1. The signal is held high while (CCR3.CPHA = 0 and CCR3.CPOL = 1) or (CCR3.CPHA = 1 and CCR3.CPOL = 1). It is held low while (CCR3.CPHA = 0 and CCR3.CPOL = 0) or (CCR3.CPHA = 1 and CCR3.CPOL = 0).

2. When the external clock is selected

When the CCR3.CKE[1:0] bits are set to 10b or 11b (slave mode), data is transmitted and received using the external clock that is input from the SCKn pin.

28.6.2 CTS and RTS Functions

In the CTS function, the CTSn_RTsn pin input controls the start of data reception or transmission when the clock source is the internal clock. Setting the CCR1.CTSE bit to 1 enables the CTS function. In clock synchronous communication, the CTS function can be used for the internal clock and the RTS function can be used for the external clock, so the CTS function and RTS function cannot be used at the same time. When the CTS function is enabled, setting the CTSn_RTsn pin low causes data reception or transmission to start.

Setting the CTSn_RTSn pin high while the data transmission or reception is in progress does not affect transmission or reception of the current frame.

In the RTS function, the CTSn_RTSn pin output is used to request the start of data reception or transmission when the clock source is an external synchronizing clock. The CTSn_RTSn output goes low when serial communication is enabled. Conditions for output of the CTSn_RTSn low and high are shown as follows:

[Conditions for low output]

Satisfaction of all the following conditions:

Non-FIFO selected when all of the following conditions are satisfied

- The value of the CCR0.RE bit or the CCR0.TE bit is 1
- Next serial communication is enabled.
 - No receive data is present before reading and not receiving. (when CCR0.RE bit = 1)
 - When the transmission data written in TDR is ready for transmission.*¹ (when CCR0.TE bit = 1)
- The CSR.ORER flag is 0

Note 1. The CTSn_RTSn pin will be High after starting transmission.

FIFO selected when all of the following conditions are satisfied

- The value of the CCR0.RE bit or the CCR0.TE bit is 1
- Next serial communication is enabled.
 - The number of receive data stored in the receive FIFO (RDR register) is less than the value set in FCR.RSTRG[4:0] (when CCR0.RE bit = 1)
 - When the transmission data written in the transmission FIFO (TDR register) is ready for transmission.*¹ (when CCR0.TE bit = 1)
- The CSR.ORER flag is 0

Note 1. The CTSn_RTSn pin will be High after the last data transmission starts.

[Condition for high output]

- The conditions for low output are not satisfied

28.6.3 SCI Initialization in Clock Synchronous Mode

Before transmitting and receiving data, start by writing the initial value 0x00 to the CCR0 register, then continue through the SCI initialization procedure given in the sections describing non-FIFO and FIFO selection in [section 28.6.2. CTS and RTS Functions](#). Anytime the operating mode or transfer format is to be changed, the CCR0.TE and CCR0.RE must write to 0 before the change can be made.

Note: Setting the CCR0.RE bit to 0 initializes neither the ORER, FER, PER, and RDRF flags in CSR nor the RDR register. When the TE bit is set to 0, the TEND flag for the selected FIFO buffer is not initialized.

Note: Switching the value of the CCR0.TE bit from 1 to 0 when the CCR0.TIE bit is 1 generates an SCIn_TXI interrupt request.

Table 28.39 Example flow of SCI initialization in clock synchronous mode with non-FIFO selected (1 of 2)

No.	Step Name	Description
1	Start initialization	—
2	Set CCR0	Set the CCR0.TEIE, TIE, RIE, TE, and RE bits to 0* ¹ . If you have not changed from the initial settings, you can skip this step.
3	Set FCR	Set the TFRST and RFRST to 1 to empty FIFO. Set the TTRG[4:0], RTRG[4:0], and RSTRG[4:0] bits.

Table 28.39 Example flow of SCI initialization in clock synchronous mode with non-FIFO selected (2 of 2)

No.	Step Name	Description
4	Set CCR3 except MOD[2:0]	Set CCR3 except of communication mode. <ul style="list-style-type: none"> • FIFO use/no-use • Transmission/reception format • Clock setting • Leave unused bits (CHR[1:0],STP,RXDSEL,MP,DE, ACS0,GM,BLK) at their initial values.
5	Set CCR3.MOD[2:0]	Set communication mode (MOD[2:0] = 010b) ^{*2} .
6	Set CCR2	Select clock, set bit rate ^{*3} . Leave unused bits (BCP[2:0],ABCS, ABCSE, BRME,MDDR[7:0]) at their initial values.
7	Set CCR1	Set up the loop-back function, communication pin status and the CTS/RTS function.
8	Set CCR4	Set up the adjust sampling timing function. Leave unused bits (CMPD[8:0]) at their initial values.
9	Set the I/O port functions	Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.
10	Set CFCLR, FFCLR	Write 1 to the following bits and clear the corresponding flag. CFCLR.RDRFC, FERFC, PERFC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC FFCLR.BRKC, DRC
11	Set CCR0	Set the TE or RE bit to 1. ^{*1 *4} To enable interrupts, set the TE bit and TIE bit, and the RE bit and RIE bit to 1 with one instruction at the same time. Setting the TE and RE bits allows TXDn and RXDn to be used.
12	Initialization completion	—

Note 1. In simultaneous transmit and receive operations, the TE and RE bits in CCR0 should both be to 0 or set to 1 simultaneously.

Note 2. Set CPOL and CPHA before setting the communication mode.

Note 3. If you use an external clock, you do not need to set it.

Note 4. When using the internal clock (master), the setting of reception only is prohibited.

28.6.4 Serial Data Transmission in Clock Synchronous Mode

(1) Non-FIFO selected

Figure 28.62, Figure 28.63, and Figure 28.64 show examples of serial transmission in clock synchronous mode.

In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the TDR register to the TSR register when data is written to TDR in the SCIn_TXI interrupt handling routine. When starting data transmission, set the CCR0.TIE bit and the CCR0.TE bit to 1 simultaneously by a single instruction. Then a SCIn_TXI interrupt request is generated.
2. After transferring data from TDR to TSR, the SCI starts transmission. When the CCR0.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to TDR in the SCIn_TXI interrupt handling routine before transmission of the current transmit data finishes. When SCIn_TEI interrupt requests are in use, set the CCR0.TIE bit to 0 and the CCR0.TEIE bit to 1 after the last of the data to be transmitted is written to the TDR register from the handling routine for SCIn_TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the CCR1.CTSE bit is 1 (CTS function enabled).
4. The SCI checks for update to the TDR register on output of the last bit.
5. When the TDR register is updated, the next transmit data is transferred from TDR to TSR, and serial transmission of the next frame starts.
6. If TDR is not updated, the CSR.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the CCR0.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Figure 28.62, Figure 28.63, and Figure 28.64 show examples of serial data transmission.

Figure 28.62 Example of serial data transmission in clock synchronous mode when the CTS function is not used at the beginning of transmission

Figure 28.63 Example of serial data transmission in clock synchronous mode when the CTS function is used at the beginning of transmission

Figure 28.64 Example of serial data transmission in clock synchronous mode from the middle of transmission until transmission completion

Figure 28.65 Example flow of serial transmission in clock synchronous mode with non-FIFO selected

(2) FIFO selected

Figure 28.66 shows an example of serial transmission in clock synchronous mode with FIFO selected.

In serial data transmission, the SCI operates as follows:

1. The SCI transfers data from the transmit-FIFO (TDR register) to the TSR register when data is written to transmit-FIFO (TDR register) in the SCIn_TXI interrupt handling routine. The amount of data that can be written to transmit-FIFO (TDR register) is 16 - FTSR.T[5:0] bytes. In addition, when starting data transmission, set the CCR0.TIE bit and the CCR0.TE bit to 1 simultaneously by a single instruction. Then a SCIn_TXI interrupt request is generated.
2. After transferring data from transmit-FIFO (TDR register) to TSR, the SCI starts transmission. When the amount of transmit data written in transmit-FIFO (TDR register) is equal to or less than the specified transmit triggering number, the CSR.TDRE is set to 1. When the CCR0.TIE bit is set to 1, an SCIn_TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to transmit-FIFO (TDR register) in the SCIn_TXI interrupt handling routine before transmission of the current transmit data has finished. When SCIn_TEI interrupt requests are in use, set the CCR0.TIE bit to 0 and the CCR0.TEIE bit to 1 after the last of the data to be transmitted is written to the transmit-FIFO (TDR register) from the handling routine for SCIn_TXI requests.
3. 8-bit data is sent from the TXDn pin in synchronization with the output clock when the clock output mode is specified and in synchronization with the input clock when the use of an external clock is specified. Output of the clock signal is suspended until the input CTS signal is low when the CCR1.CTSE bit is 1 (CTS function enabled).
4. The SCI checks whether non-transmitted data remains in transmit-FIFO (TDR register)^{*1} on output of the stop bit.
5. When data is remaining in the transmit-FIFO (TDR register), the next transmit data is transferred from transmit-FIFO (TDR register) to TSR and serial transmission of the next frame starts.

- If no data is remaining in the transmit FIFO (TDR register), the CSR.TEND flag is set to 1. The TXDn pin retains the output state of the last bit. If the CCR0.TEIE bit is 1, an SCIn_TEI interrupt request is generated and the SCKn pin is held high.

Note 1. The number of unsent transmit data stored in the TDR register (transmit FIFO) can be monitored by reading the FTSR.T[5:0] bits.

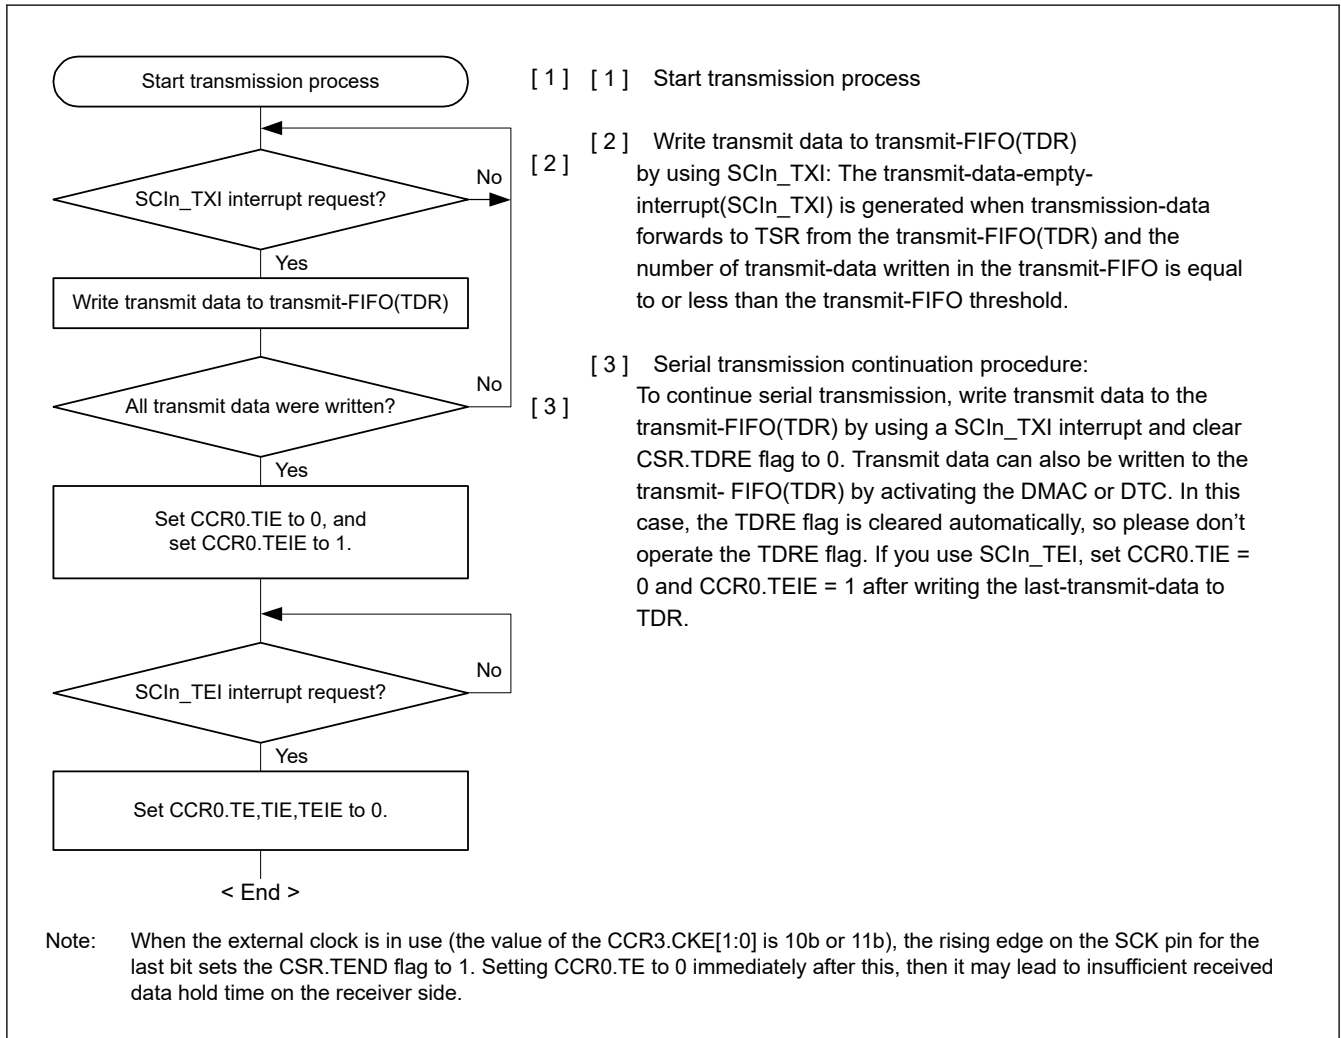

Figure 28.66 Example flow of serial transmission in clock synchronous mode with FIFO selected

28.6.5 Serial Data Reception in Clock Synchronous Mode

(1) Non-FIFO selected

Figure 28.67 and Figure 28.68 show examples of SCI operation for serial reception in clock synchronous mode.

In serial data reception, the SCI operates as follows during serial data reception. Reception-only operation is possible only in slave mode. (In master mode, reception-only operation is prohibited.)

- When the value of the CCR0.RE bit becomes 1, the CTSn_RTSn pin goes low (when the RTS function is used).
- The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores the receive data in the RSR register.
- If an overrun error occurs, the CSR.ORER flag is set to 1. If the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated. Receive data is not transferred to the RDR register.
- When reception completes successfully, receive data is transferred to the RDR register. If the CCR0.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous reception is enabled by reading the received data transferred to the

RDR register in the SCIn_RXI interrupt handling routine before reception of the next receive data completes. Reading the received data that is transferred to RDR causes the CTSn_RTSn pin to output low (when the RTS function is used).

If you want to prevent the CTSn_RTSn pin output from turning low level after the final data is received, clear the CCR0.RE bit to 0 and then read the RDR register.

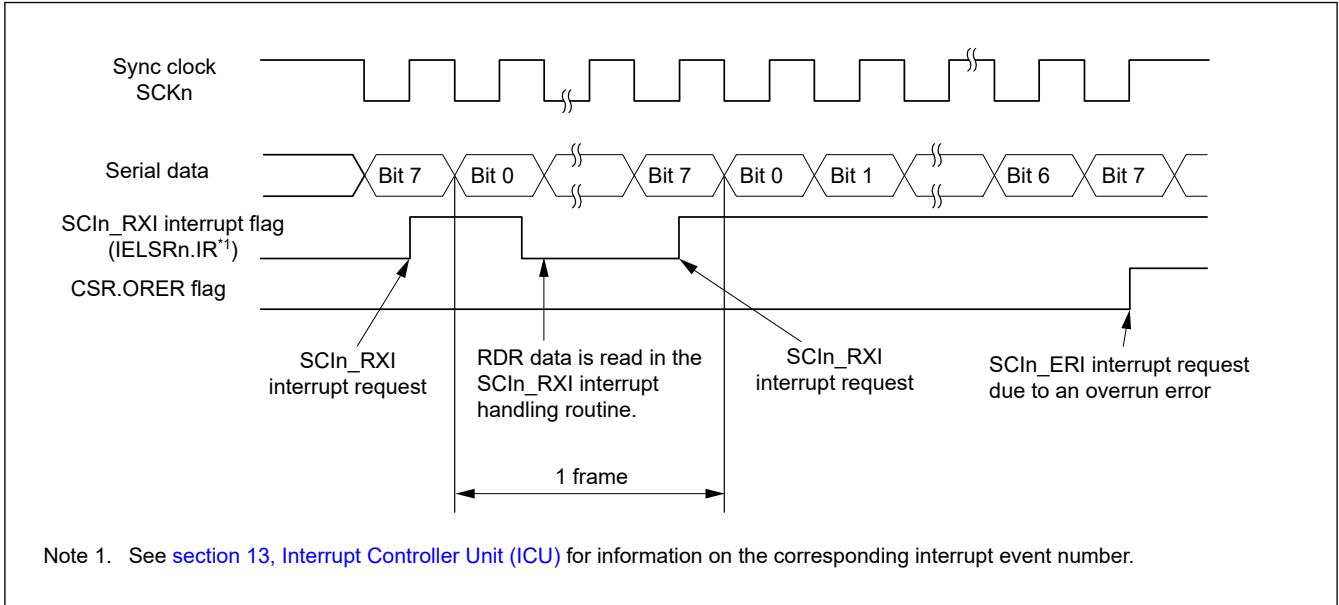

Figure 28.67 Example operation for serial reception in clock synchronous mode (1) when the RTS function is not used

Figure 28.68 Example operation for serial reception in clock synchronous mode (2) when RTS function is used

Data transfer cannot resume while the receive error flag is 1. Therefore, clear the ORER, FER, and PER flags in the CSR register to 0 before resuming data reception. Additionally, always read the RDR register during overrun error processing. When a data reception is forced to terminate by a 0 write to the CCR0.RE bit during operation, read the RDR register because received data that is not yet read might be left in the RDR register.

[Figure 28.69](#) shows an example flow of serial data reception.

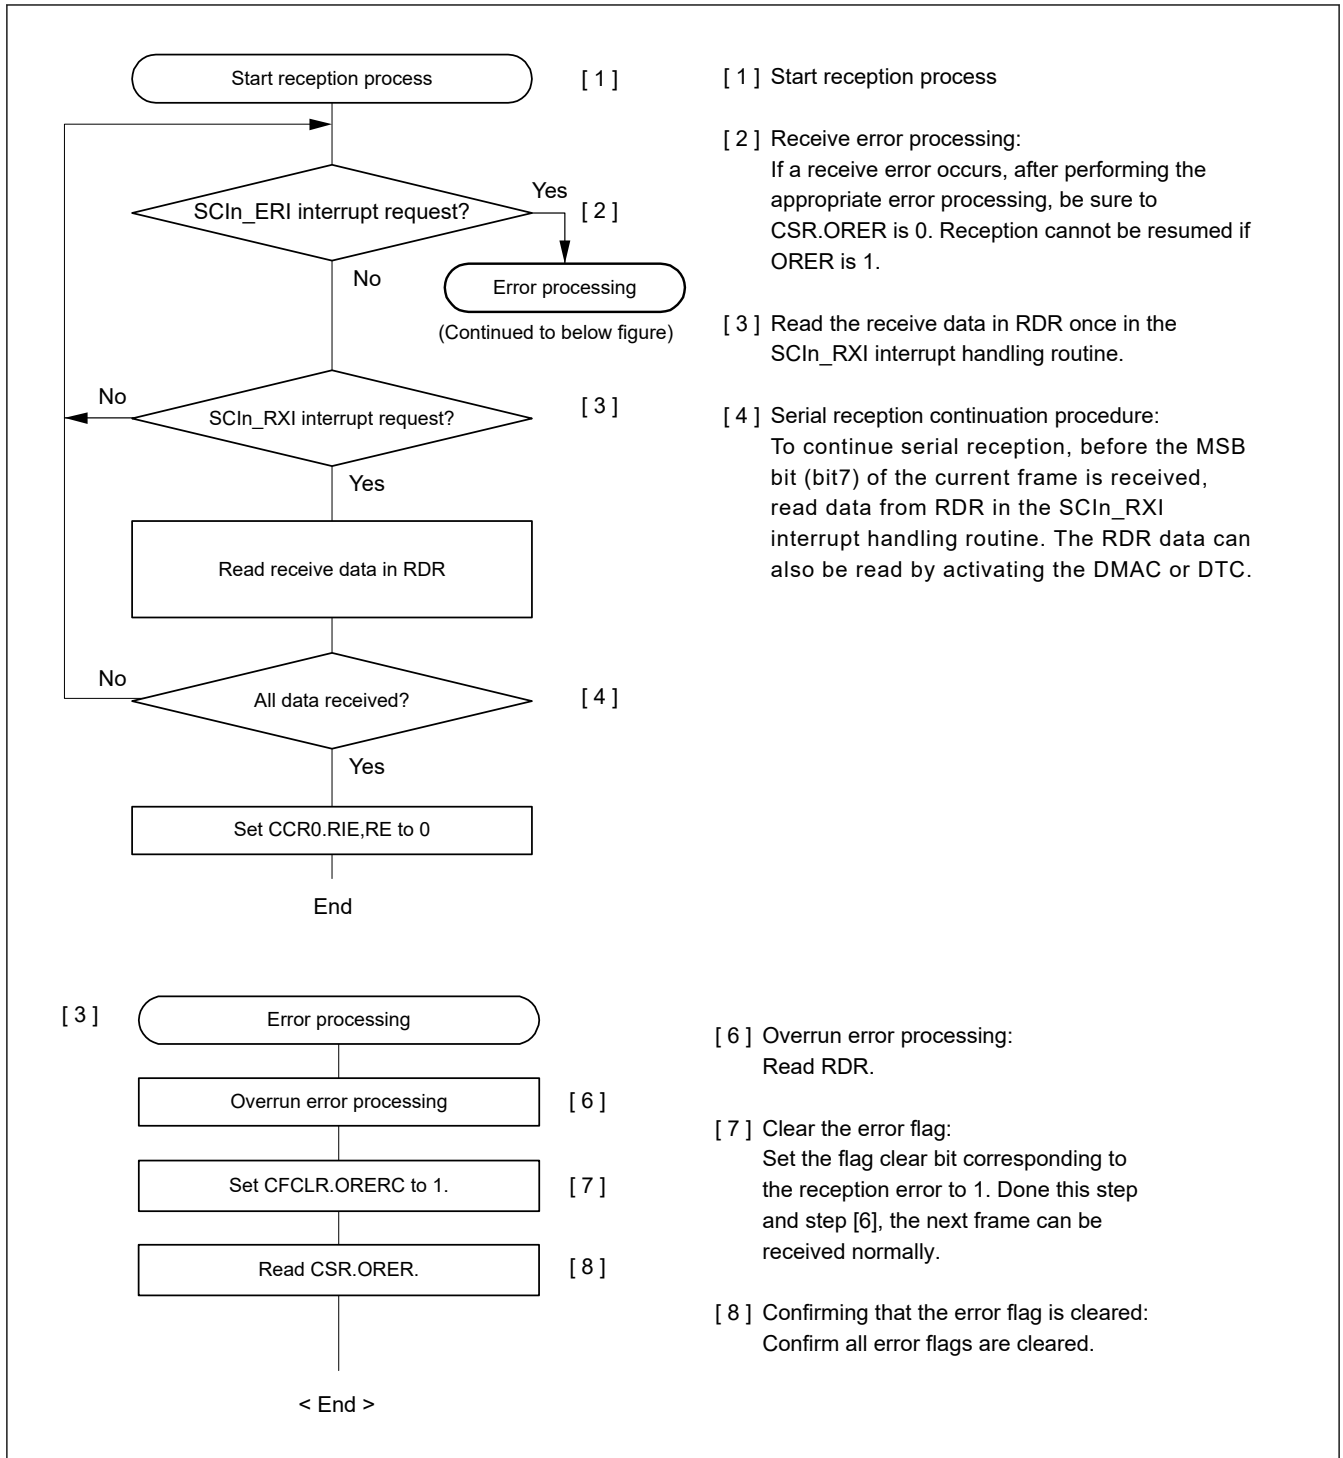

Figure 28.69 Example flow of serial reception in clock synchronous mode with non-FIFO selected

(2) FIFO selected

Figure 28.70 shows an example of serial reception in clock synchronous mode with FIFO selected.

In serial data reception, the SCI operates as follows during serial data reception. Reception-only operation is possible only in slave mode. (In master mode, reception-only operation is prohibited.)

1. When the value of the CCR0.RE bit becomes 1, the CTSn_RTSn pin goes low (when the RTS function is used).
2. The SCI performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and transfers the received data to the receive-FIFO (RDR register).
3. If an overrun error occurs, the CSR.ORER flag is set to 1. If the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated. Received data is not transferred to the receive-FIFO (RDR register)*1.

4. When data reception completes successfully, the receive data is transferred to the receive-FIFO (RDR register)^{*1}. The CSR.RDRF flag is set to 1 when the amount of the receive data stored in receive-FIFO (RDR register) is equal to or greater than the specified receive triggering number. If the CCR0.RIE bit is 1, an SCIn_RXI interrupt request is generated. Continuous data reception is enabled by reading the receive data transferred to receive-FIFO (RDR register)^{*1} in the SCIn_RXI interrupt handling routine before an overrun error occurs. If the amount of received data that is transferred to receive-FIFO (RDR register) is less than the specified receive triggering number, the CTSn_RTSn pin goes low (when the RTS function is used).

Note 1. In clock synchronous mode, RDR.RDAT[8] is not used.

Figure 28.70 Example flow of serial reception in clock synchronous mode with FIFO selected

28.6.6 Simultaneous Serial Data Transmission and Reception in Clock Synchronous Mode

(1) Non-FIFO selected

Figure 28.71 shows an example flow of simultaneous serial transmit and receive operations in clock synchronous mode. After initializing the SCI, use the following procedure for simultaneous serial data transmit and receive operations.

To switch from transmit mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the data transmission by verifying that the CSR.TEND flag is set to 1.
2. Initialize the CCR0 register, and then set the TIE, RIE, TE, and RE bits in the CCR0 register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the data reception.
2. Set the CCR0.TE and RE bits to 0, and then check that the receive error flag (ORER, FER, and PER) in the CSR register is 0.
3. Set the TIE, RIE, TE, and RE bits in the CCR0 register to 1 simultaneously by a single instruction.

When the RTS function is used in the concurrent transmission/reception operation, if you want to prevent the CTSn_RTSn pin output from turning to low after the final data is received as in the reception operation, clear the RE and TE bits in CCR0 to 0 simultaneously, and then read the RDR register.

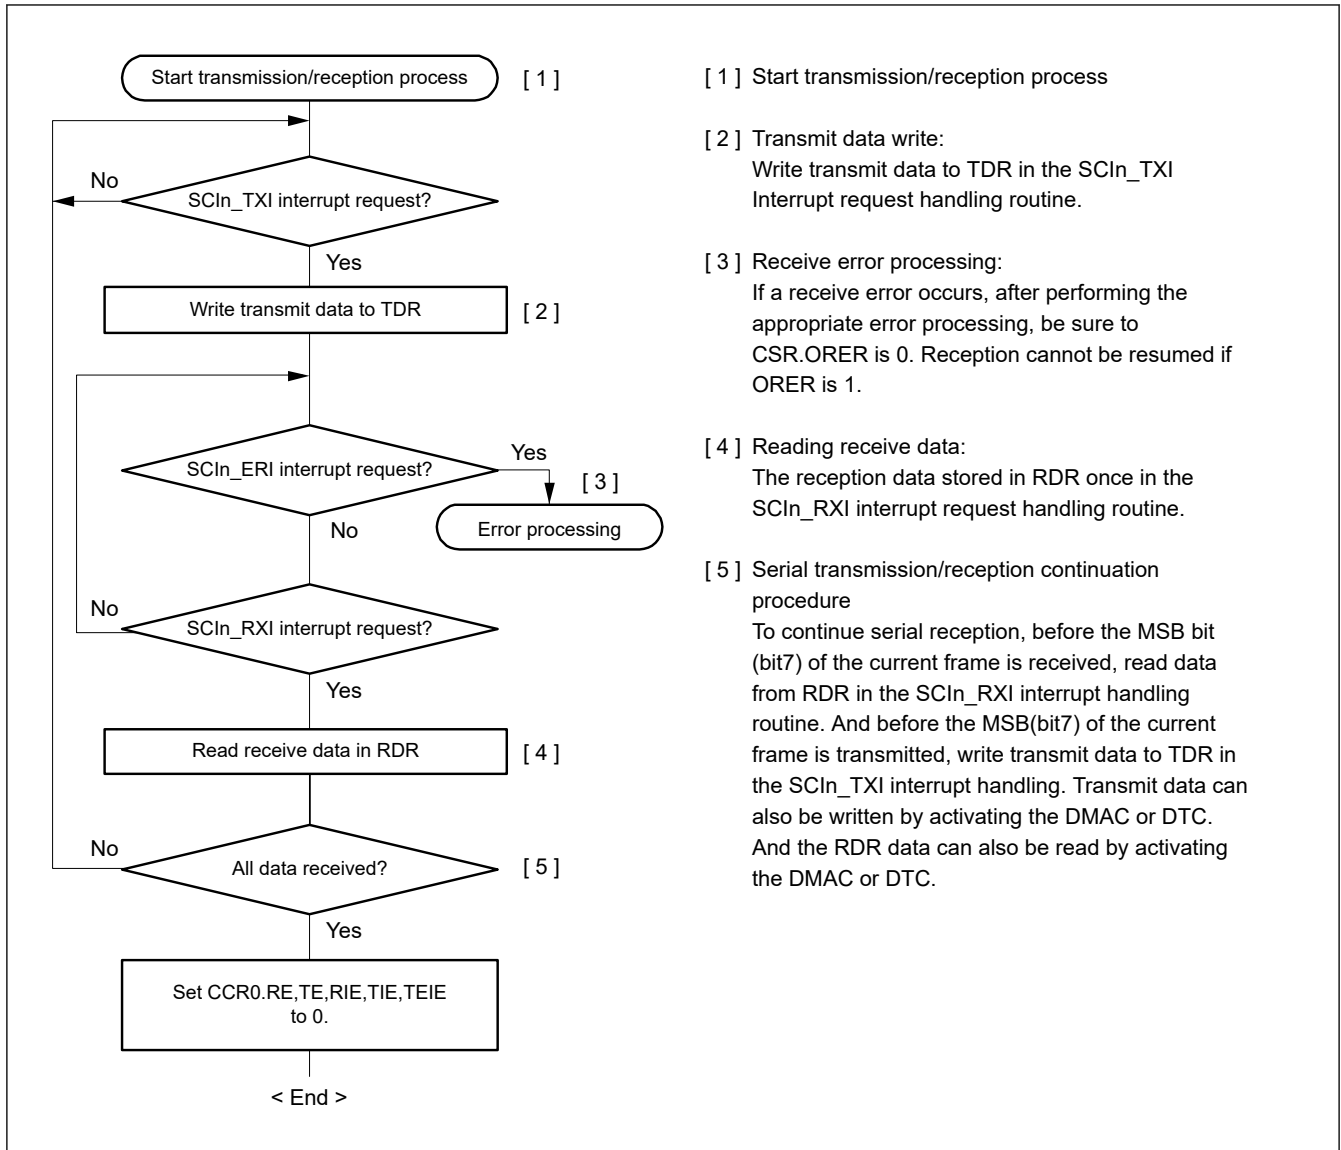

Figure 28.71 Example flow of simultaneous serial transmission and reception in clock synchronous mode with non-FIFO selected

(2) FIFO selected

Figure 28.72 shows an example flow of simultaneous serial transmit and receive operations in clock synchronous mode with FIFO selected.

After initializing the SCI, use the following procedure for simultaneous serial data transmit and receive operations.

To switch from transmit mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the transmission by verifying that the CSR.TEND flag is set to 1.
2. Initialize the CCR0 register, then set the TIE, RIE, TE, and RE bits in the CCR0 register to 1 simultaneously by a single instruction.

To switch from receive mode to simultaneous transmit and receive mode:

1. Check that the SCI completes the reception.
2. Set the CCR0.TE and RE bits to 0.
3. Check that the receive error flags (ORER, FER, and PER) in the CSR register are 0, and then set the TIE, RIE, TE, and RE bits in the CCR0 register to 1 simultaneously by a single instruction.

Since clock synchronous communication performs transmission and reception at the same time, make sure that the number of data to be transmitted and received is the same.

Figure 28.72 Example flow of simultaneous serial transmission and reception in clock synchronous mode with FIFO selected

28.6.7 Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with internal clock used

When the clock synchronous internal clock is used (master mode), the clock enabled by CCR4.SCKSEL bit is used as a reception sampling clock.

This function adjusts the reception sampling timing by delaying the clock by 1 to 4 TCLK and adding a digital delay.

Setting the CCR4.ASEN bit to 1 enables this function. The delay value is set in CCR4.AST[1:0].

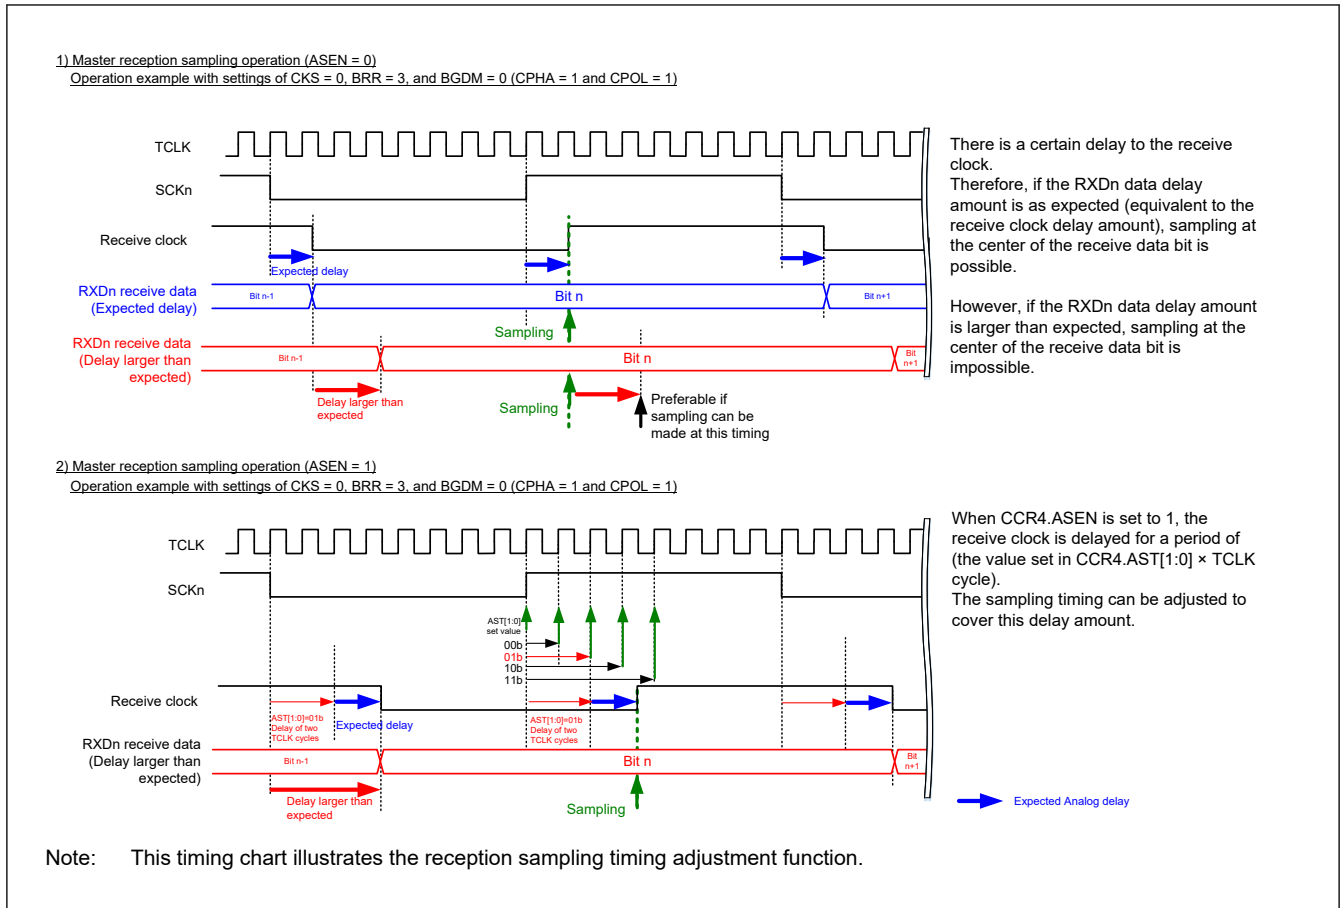

Figure 28.73 Reception Sampling Timing Adjustment Operation in Clock Synchronous Mode (Master)

28.7 Operation in Smart Card Interface Mode

The SCI supports smart card (IC card) interfaces conforming to ISO/IEC 7816-3 (standard for Identification Cards), as an extended function of the SCI.

Smart card interface mode can be selected using the appropriate register.

28.7.1 Example Connection

Figure 28.74 shows an example connection between a smart card (IC card) and the MCU. As shown in Figure 28.74, because the MCU communicates with an IC card using a single transmission line, interconnect the TXDn and RXDn pins and pull up the data transmission line to VCC using a resistor.

Setting the CCR0.TE and CCR0.RE bits to 1 with an IC card disconnected enables closed-loop transmission or reception, allowing self-diagnosis. To supply an IC card with the clock pulses generated by the SCI, input the SCKn pin output to the CLK pin of an IC card.

An output port of the MCU can be used to output a reset signal.

Figure 28.74 Example connection with a smart card (IC card)

28.7.2 Data Format (Except in Block Transfer Mode)

Figure 28.75 shows the data transfer formats in smart card interface mode:

- One frame consists of 8-bit data and a parity bit in Asynchronous mode.
- During transmission, at least 2 etus (elementary time unit – the time required for transferring 1 bit) is set as a guard time from the end of the parity bit until the start of the next frame.
- If a parity error is detected during reception, a low error signal is output for 1 etu after 10.5 etus elapse from the start bit.
- If an error signal is sampled during transmission, the same data is automatically retransmitted after at least 2 etus.

Figure 28.75 Data formats in smart card interface mode

For communications with IC cards of the direct convention type and inverse convention type, follow the procedures in this section.

(1) Direct Convention Type

For the direct convention type, logic levels 1 and 0 indicate the Z and A states, respectively, and data is transferred with LSB-first for the start character, as shown in Figure 28.76. Therefore, data in the start character in the figure is 0x3B.

When using the direct convention type, write 1 to the CCR3.LSBF and write 0 to the CCR3.SINV. Write 0 to the CCR1.PM bit to use even parity, which is prescribed by the smart card standard.

Figure 28.76 Direct convention with LSBF in CCR3 = 1, SINV in CCR3 = 0, and PM in CCR1 = 0

(2) Inverse Convention Type

For the inverse convention type, logic levels 1 and 0 indicate the A and Z states, respectively, and data is transferred with MSB-first for the start character, as shown in Figure 28.77. Therefore, data in the start character in the figure is 0x3F.

When using the inverse convention type, write 0 to the CCR3.LSBF and write 1 to the CCR3.SINV. The parity bit is logic level 0 to produce even parity, which is prescribed by the smart card standard, and corresponds to the Z state. Because the SINV bit of the MCU only inverts data bits D7 to D0, write 1 to the PM bit in CCR1 to invert the parity bit for both transmission and reception.

Figure 28.77 Inverse convention with LSBF in CCR3 = 0, SINV in CCR3 = 1, and PM in CCR1 = 1

28.7.3 Block Transfer Mode

Block transfer mode differs from normal smart card interface mode as follows:

- Even if a parity error is detected during reception, no error signal is output. Because the PER flag in CSR is set by error detection, clear the PER flag before receiving the parity bit of the next frame.
- During transmission, at least 1 etu is set as a guard time from the end of the parity bit until the start of the next frame
- Because the same data is not retransmitted, the TEND flag in CSR is set to 11.5 etus after transmission starts
- In block transfer mode, the ERS flag in CSR indicates the error signal status as in normal smart card interface mode, but the flag is read as 0 because no error signal is transferred

28.7.4 Receive Data Sampling Timing and Reception Margin

Only the internal clock generated by the on-chip baud rate generator can be used as a transfer clock in smart card interface mode.

In this mode, the SCI can operate on a base clock with a frequency of 32, 64, 372, 256, 93, 128, 186, or 512 times the bit rate set up in the CCR2.BCP[2:0] bits. The frequency is always 16 times the bit rate in normal Asynchronous mode.

For data reception, the falling edge of the start bit is sampled with the base clock to perform internal synchronization.

Receive data is sampled on the 16th, 32nd, 186th, 128th, 46th, 64th, 93rd, and 256th rising edges of the base clock so that it can be latched at the middle of each bit as shown in Figure 28.78. The reception margin is determined by the following formula:

$$M = \left| \left(0.5 - \frac{1}{2N} \right) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F) \right| \times 100 \text{ [%]}$$

M: Reception margin (%)

N: Ratio of bit rate to clock (N = 32, 64, 372, 256)

D: Duty cycle of clock (D = 0 to 1.0)

L: Frame length (L = 10)

F: Absolute value of clock frequency deviation

Assuming values of F = 0, D = 0.5, and N = 372 in the specified formula, the reception margin is determined using the following formula:

$$M = \{0.5 - 1/(2 \times 372)\} \times 100 \text{ [%]} = 49.866 \text{ %}$$

Figure 28.78 Receive data sampling timing in smart card interface mode when the clock frequency is 372 times the bit rate

28.7.5 SCI Initialization (Smart Card Interface Mode)

Before transmitting and receiving data, write the initial value 0x00 in the CCR0 register and initialize the SCI following the example flow shown in [Table 28.40](#).

Always set the initial value in the TIE, RIE, TE, RE, TEIE bits in the CCR0 register before switching from transmission to reception mode or from reception to transmission mode. When CCR0.RE is set to 0, the RDR register is not initialized.

In transmission mode, set 1 to the CCR0.TE bit and CCR0.TIE bit simultaneously, then the SCIn_TXI interrupt request is generated.

To change from reception mode to transmission mode, first check that reception has completed, then initialize the SCI. At the end of initialization, set CCR0.TE = 1 and CCR0.RE = 0. Reception completion can be verified by reading the SCIn_RXI request, ORER, or PER flag in CSR.

To change transmission mode to reception mode, first check that transmission has completed, then initialize the SCI. At the end of initialization, set CCR0.TE = 0 and CCR0.RE = 1. Transmission completion can be verified by reading the TEND flag in CSR.

Table 28.40 Example flow of SCI initialization in smart card interface mode

No.	Step Name	Description
1	Start initialization	—
2	Set CCR0	Set CCR0.TEIE, TIE, RIE, TE, RE to 0. If you have not changed from the initial settings, you can skip this step.
3	Set CCR3	Set communication mode (MOD[2:0] = 001b), BLK, GM, and SINV. Leave other bits at their initial values.
4	Set CCR2	Set clock-select and bit-rate. Set BRME to 0.
5	Set CCR1	Set up the Noise filter function, communication terminal status. Set NFEN, PE, CTSE to 0 and set PE to 1.
6	Set the I/O port functions	Make I/O port settings to enable input and output functions as required for TXDn, RXDn, and SCKn pins.
7	Set CCR3	Set CKE[1:0]. When the CKE[0] bit is set to "1" due on GM setting value, the clock is output from the SCKn pin.
8	Set CFCLR	Write 1 to the following bits and clear the corresponding flag. CFCLR.RDRFC,FERC,PERC,MFFC,ORERC,DFERC,DPERC,DCMFC,ERSC
9	Set CCR0	Set the TE or RE to 1. And set the TIE and RIE. Do not simultaneously set the TE and RE bits to 1 if self-diagnosis in not used.
10	Initialization completed	—

Figure 28.79 is a timing chart when data transmission is performed by making transition to the Smart Card Interface mode according to the above flow chart. The figure shows the case when CCR3.GM bit is 0. As shown in the figure, when the pin function is set to the SCKn pin, the SCKn pin is high impedance because the CCR3.CKE [0] bit is 0. When the TXDn pin is set, the TXDn pin is high impedance because the CCR0.TE bit is 0. Start clock output to the SCKn pin with the clock output setting CCR3.CKE [0] to 1, start data transmission by writing transmit data after setting CCR0.TE to 1.

In the smart card interface mode, even if not communicating at CCR0.TE = 0 and CCR0.RE = 0, the clock is continuously output if the clock output setting is used.

Figure 28.79 Example of Timing chart of data transmission in Smart Card Interface Mode

28.7.6 Serial Data Transmission (Except in Block Transfer Mode)

Serial data transmission in smart card interface mode (except in block transfer mode) is different from that in non-smart card interface mode, in that an error signal is sampled and data can be re-transmitted in smart card mode. Figure 28.80 shows the data re-transfer operation during transmission.

1. When an error signal from the receiver end is sampled after 1-frame data is transmitted, the CSR.ERS flag is set to 1. If the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the ERS flag to 0 before the next parity bit is sampled.

2. For a frame in which an error signal is received, the CSR.TEND flag is not set. Data is re-transferred from TDR to TSR, allowing automatic data retransmission.
3. If no error signal is returned from the receiver, the ERS flag is not set to 1.
4. In this case, the SCI determines that transmission of 1-frame data, including the re-transfer, is complete, and the TEND flag is set. If the CCR0.TIE bit is 1, an SCIn_TXI interrupt request is generated. Write transmit data to the TDR to start transmission of the next data.

Figure 28.82 shows an example flow of serial transmission. All the processing steps are automatically performed using an SCIn_TXI interrupt request to activate the DTC or DMAC.

When the CSR.TEND flag is set to 1 in transmission and when the CCR0.TIE bit is 1, an SCIn_TXI interrupt request is generated.

The DTC or DMAC is activated by an SCIn_TXI interrupt request if the SCIn_TXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of transmit data. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During this retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified number of bytes, including retransmission when an error occurs. Because the ERS flag is not automatically cleared, set the RIE bit to 1 before enabling an SCIn_ERI interrupt request to be generated if an error occurs, and clear the ERS flag to 0.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings.

For DTC or DMAC settings, see section 17, Data Transfer Controller (DTC), section 16, DMA Controller (DMAC).

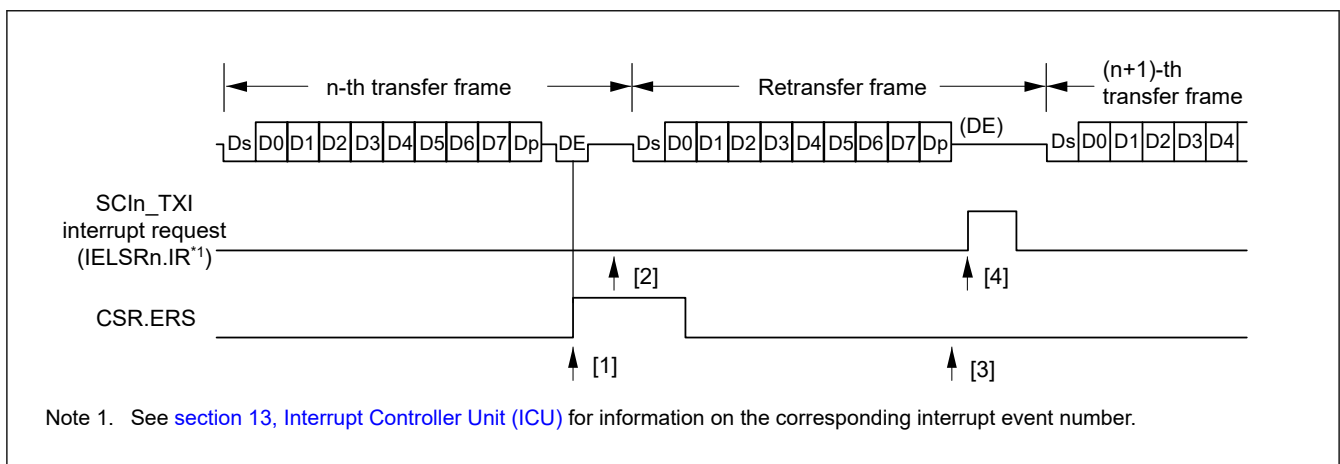

Figure 28.80 Data re-transfer operation in smart card interface transmission mode

The CSR.TEND flag is set at different timings depending on the CCR3.GM bit setting. Figure 28.81 shows the TEND flag generation timing.

Figure 28.81 CSR.TEND flag generation timing during transmission

Figure 28.82 Example flow of smart card interface transmission

28.7.7 Serial Data Reception (Except in Block Transfer Mode)

Serial data reception in smart card interface mode is similar to that in non-smart card interface mode. [Figure 28.83](#) shows the data re-transfer operation in reception mode.

1. If a parity error is detected in the receive data, the CSR.PER flag is set to 1. When the CCR0.RIE bit is 1, an SCIn_ERI interrupt request is generated. Clear the PER flag to 0 before the next parity bit is sampled.
2. For a frame in which a parity error is detected, no SCIn_RXI interrupt is generated.
3. When no parity error is detected, the CSR.PER flag is not set to 1.
4. In this case, data is determined to be received successfully. When the CCR0.RIE bit is 1, an SCIn_RXI interrupt request is generated.

[Figure 28.84](#) shows an example flow of serial data reception. All the processing steps are automatically performed using an SCIn_RXI interrupt request to activate the DTC or DMAC.

In reception, setting the RIE bit to 1 allows an SCIn_RXI interrupt request to be generated. The DTC or DMAC is activated by an SCIn_RXI interrupt request if the SCIn_RXI interrupt request is previously specified as a source of DTC or DMAC activation, allowing the transfer of receive data.

If an error occurs during reception and either the ORER or PER flag in CSR is set to 1, a receive error interrupt (SCIn_ERI) request is generated. Clear the error flag after the error occurrence. If an error occurs, the DTC or DMAC is not activated and receive data is skipped. Therefore, the number of bytes of receive data specified in the DTC or DMAC is transferred.

If a parity error occurs and the PER flag is set to 1 during reception, the receive data is transferred to RDR, allowing the data to be read.

When a reception is forced to terminate by setting CCR0.RE to 0 during operation, read the RDR register because the received data that is not yet read might be left in the RDR.

Note: For operations in block transfer mode, see [section 28.3.9. Serial Data Reception in Asynchronous Mode](#).

Figure 28.83 Data re-transfer operation in smart card interface reception mode

Figure 28.84 Example flow of smart card interface reception

28.7.8 Clock Output Control

When the GM bit in CCR3 is set to 1, the clock output can be controlled by the CKE[1:0] bits in CCR3. For details on the CKE[1:0] bits, see [section 28.2.8. CCR3 : Common Control Register 3](#). When setting the clock output, the base clock described in [section 28.7.4. Receive Data Sampling Timing and Reception Margin](#) the bit rate is set by CCR2.CKS, CCR2.BCP[2:0] and BRR[7:0].

[Figure 28.85](#) shows an example timing for the clock output control when the CKE[1] bit in CCR3 is set to 0 and the CKE[0] bit in CCR3 is controlled.

When the GM bit in CCR3 is 0, output control by the CKE[0] bit in CCR3 is immediately reflected on the SCKn pin, so there is a possibility that pulses with an unintended width may be output from the SCKn pin.

When the GM bit in CCR3 is 1, the output pulse control by the CCR3.CKE [0] controls the pulse width set to be based on the state of the base clock.

Figure 28.85 Clock Output timing

28.8 Operation in Simple IIC Mode

Simple IIC mode format is composed of 8 data bits and an acknowledge bit. By continuing into a slave-address frame after a start condition or restart condition, a master device can specify a slave device as the partner for communications. The currently specified slave device remains valid until a new slave device is specified or a stop condition is satisfied. The 8 data bits in all frames are transmitted in order from the MSB.

The I²C bus format and timing of the I²C bus are shown in [Figure 28.86](#) and [Figure 28.87](#).

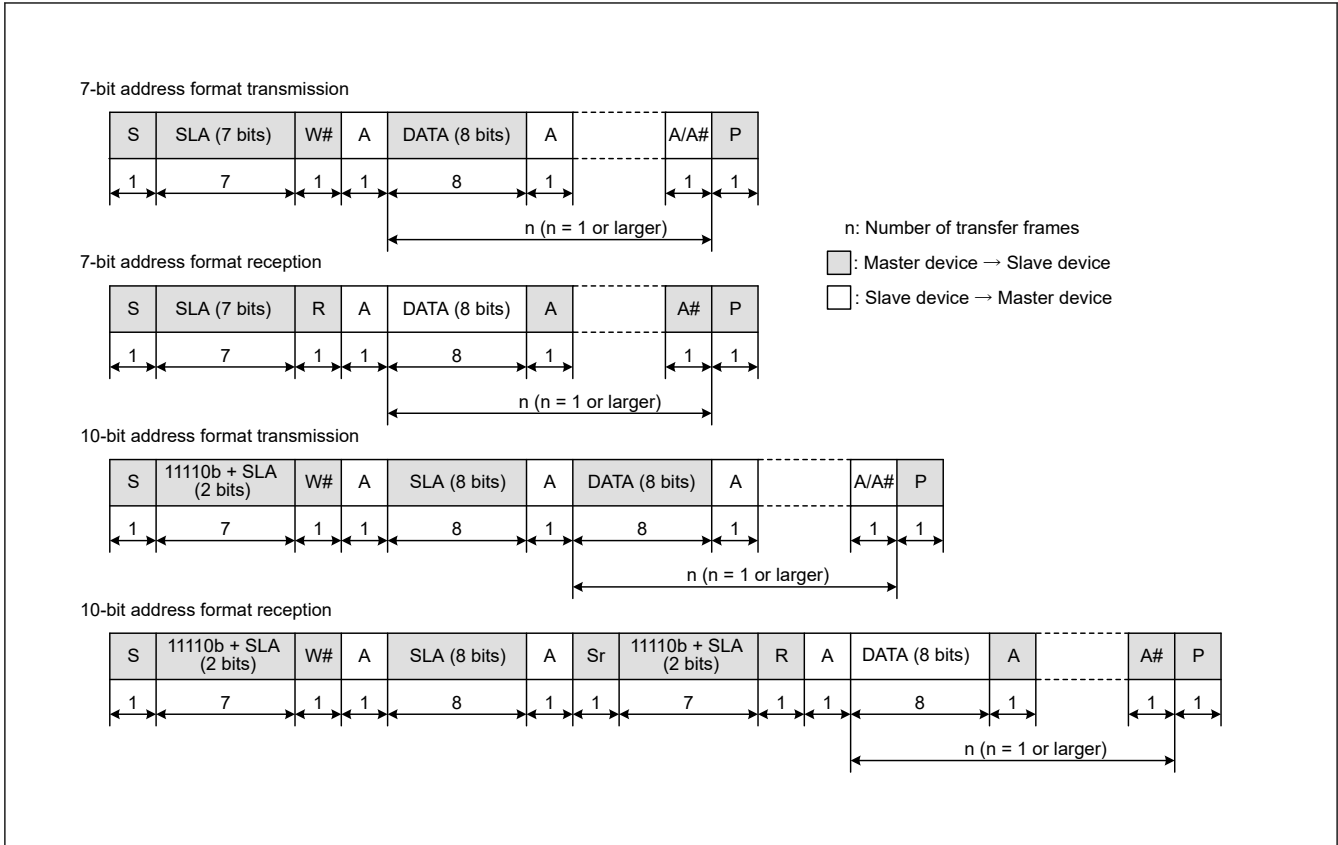

Figure 28.86 I²C bus format

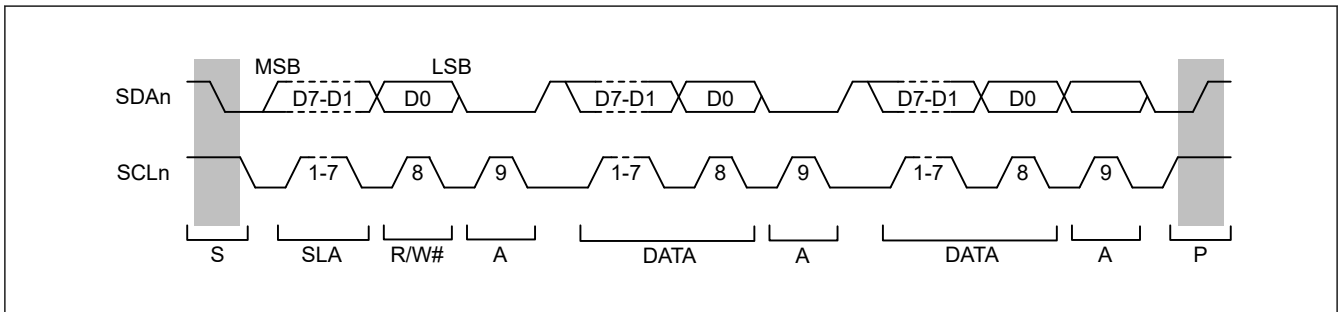

Figure 28.87 I²C bus timing when SLA is 7 bits

- **S:** Indicates a start condition, when the master device changes the level on the SDA_n line from high to low while the SCL_n line is high
- **SLA:** Indicates a slave address, by which the master device selects a slave device
- **R/W#:** Indicates the direction of transfer (reception or transmission). The value 1 indicates transfer from the slave device to the master device and 0 indicates transfer from the master device to the slave device.
- **A/A#:** Indicates an acknowledge bit. This is returned by the slave device for master transmission and by the master device for master reception. Return low indicates ACK and return high indicates NACK.
- **Sr:** Indicates a restart condition, when the master device changes the level on the SDA_n line from high to low while the SCL_n line is high and after the setup time elapses
- **DATA:** Indicates the data being received or transmitted
- **P:** Indicates a stop condition, when the master device changes the level on the SDA_n line from low to high while the SCL_n line is high

28.8.1 Generation of Start, Restart, and Stop Conditions

Writing 1 to the ICR.IICSTAREQ bit causes the generation of a start condition. The generation of a start condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept in the released state
- The hold time for the start condition is set as half of a bit period at the bit rate determined by the CCR2.BRR setting
- The level on the SCLn line falls (from the high level to the low level), the IICSTAREQ bit in ICR is set to 0, and a start-condition generated interrupt is output

Writing 1 to the IICRSTAREQ bit in ICR causes the generation of a restart condition. The generation of a restart condition proceeds through the following operations:

- The SDAn line is released and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the CCR2.BRR setting
- The SCLn line is released (transition from the low to the high level)
- When a high level is detected on the SCLn line, the setup time for the restart condition is set as half of a bit period at the bit rate determined by the CCR2.BRR setting
- The level on the SDAn line falls (from the high level to the low level)
- The hold time for the restart condition is set as half of a bit period at the bit rate determined by the CCR2.BRR setting
- The level on the SCLn line falls (from the high level to the low level), the ICR.IICRSTAREQ bit is set to 0, and a restart-condition generated interrupt is output

Writing 1 to the ICR.IICSTPREQ bit causes the generation of a stop condition. The generation of a stop condition proceeds through the following operations:

- The level on the SDAn line falls (from the high level to the low level) and the SCLn line is kept at the low level
- The period at low level for the SCLn line is set as half of a bit period at the bit rate determined by the CCR2.BRR setting
- The SCLn line is released (transition from the low to the high level)
- When a high level is detected on the SCLn line, the setup time for the stop condition is set as half of a bit period at the bit rate determined by the CCR2.BRR setting
- The SDAn line is released (transition from the low to the high level), the ICR.IICSTPREQ bit is set to 0, and a stop-condition generated interrupt is output

Figure 28.88 shows the timing of operations in the generation of start, restart, and stop conditions.

Figure 28.88 Timing of operations in generation of start, restart, and stop conditions

28.8.2 Clock Synchronization

The SCLn line can be driven low if a wait is inserted by a slave device at the other side of the transfer. Setting the ICR.IICCSC bit to 1 applies control to obtain synchronization when a difference arises between the levels of the internal SCLn clock signal and the level being input on the SCLn pin.

When the ICR.IICCSC bit is set to 1, the level of the internal SCLn clock signal changes from low to high. Counting to determine the period at a high level stops while the low level is being input on the SCLn pin. Counting to determine the period at a high level starts after the transition of the input on the SCLn pin to the high level.

The interval from this time until counting to determine the period at high level starts on the transition of the SCLn pin to the high level, is the total time which contains the SCLn input delay, delay for noise filtering of the input on the SCLn pin (2 or 3 cycles of sampling clock for the noise filter), and delay for internal processing (1 or 2 cycles of PCLK). The period at high level of the internal SCLn clock is extended even when other devices do not place the low level on the SCLn line.

If the ICR.IICCSC bit is 1, synchronization is obtained for the transmission and reception of data by taking the logical AND of the input on the SCLn pin and the internal SCLn clock. If the ICR.IICCSC bit is 0, synchronization with the internal SCLn clock is obtained for the transmission and reception of data.

If a slave device inserts a wait period into the interval until the transition of the internal SCLn clock signal from the low to the high level after a request for the generation of a start, restart, or stop condition is issued, the time until generation is prolonged by that period.

If a slave device inserts a wait period after the transition of the internal SCLn clock signal from the low to the high level, although the generation-completed interrupt is issued without stopping the waiting period, generation of the condition itself is not guaranteed.

Figure 28.89 shows an example operation for synchronizing the clocks.

Figure 28.89 Example operations for clock synchronization

28.8.3 SDAn Output Delay

The ICR.IICDL[4:0] bits can be used to set a delay for output on the SDAn pin relative to falling edges of output on the SCLn pin. Delay settings from 0 to 31 are selectable, representing periods of the corresponding numbers of cycles of the clock signal from the on-chip baud rate generator (derived by frequency-dividing the base clock, TCLK, by the divisor selected in the CCR2.CKS[1:0] bits). A delay for output on the SDAn pin applies to the start condition/restart condition/stop condition signal, 8-bit transmit data, and acknowledge bit.

If the SDAn output delay is shorter than the time for the level on the SCLn pin to fall, the change of the output on the SDAn pin starts while the output level on the SCLn pin is falling, creating a possibility of erroneous operation for slave devices. Ensure that settings for the delay of output on the SDAn pin specify times greater than the time output on the SCLn pin takes to fall (300 ns for IIC in normal mode and fast mode).

Figure 28.90 shows the timing of delays in SDAn output.

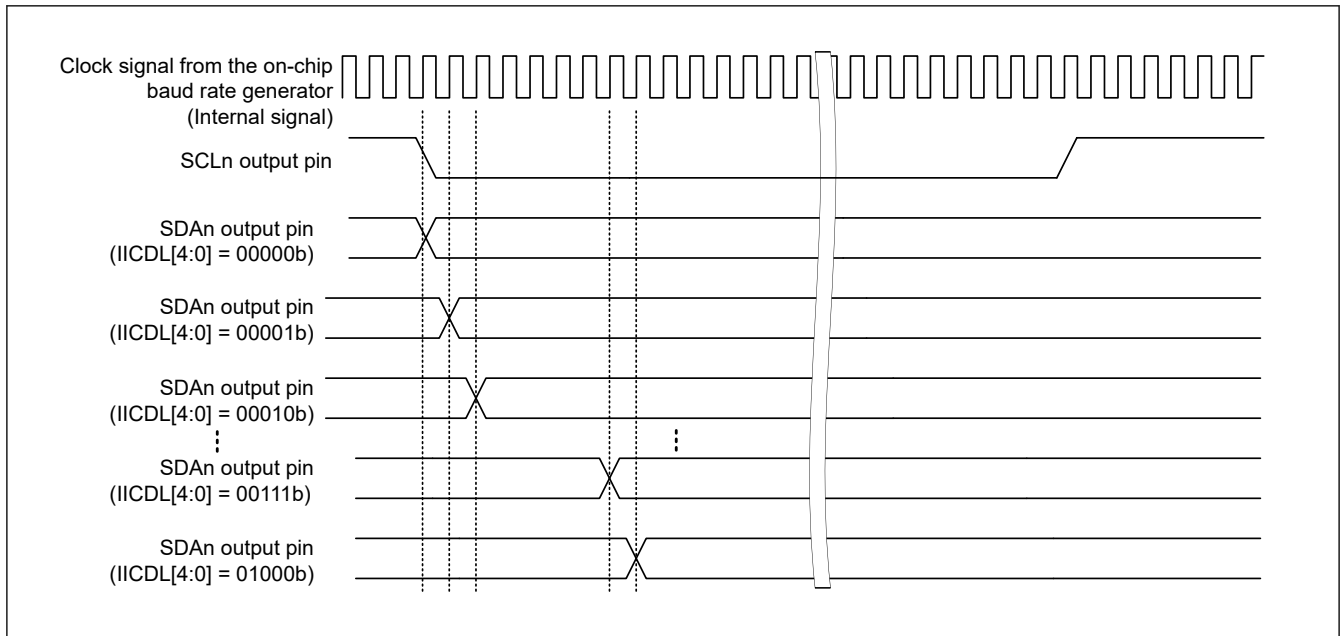

Figure 28.90 Timing of delays in SDAn output

28.8.4 SCI Initialization in Simple IIC Mode

Before transferring data, write the initial value 0x00 to CCR0 and initialize the interface following the example shown in Table 28.41.

Before making any changes to the operating mode or transfer format, be sure to set CCR0 to its initial value. In simple IIC mode, the open-drain setting for the communication ports should be made on the port side.

Table 28.41 Example flow of SCI initialization in simple IIC mode

No.	Step Name	Description
1	Start initialization	—
2	Set CCR0	Set CCR0.TEIE, TIE, RIE, TE, RE to 0. If you have not changed from the initial settings, you can skip this step.
3	Set ICR	Set the IICSDAS[1:0] and IICSCLS[1:0] to 11b. Set the IICDL[4:0] and IICINTM as required. Set the IICACKT and the IICCS bits to 1.
4	Set CCR3	Set the transmission / reception format as the communication mode (MOD [2:0] = 100b) and CKE [1:0] = 00b.
5	Set CCR2	Set the bit rate modulation function ^{*1} , the clock selection, and the bit rate.
6	Set CCR1	Set noise filter, communication pin status, parity check, and CTSn / RTSn function.
7	Set the I/O port functions	Set I/O port settings that allow use (on NMOS open-drain output pins and Hi-Z) of the SCLn and SDAn pin functions.
8	Set CFCLR, ICFLR	Write 1 to the following bits and clear the corresponding flag. CFCLR.RDRFC, FERC, PERC, MFFC, ORERC, DFERC, DPERC, DCMFC, ERSC ICFLR.IICSTIFC
9	Set CCR0 (TE, RE, TIE, RIE)	Set the TE and RE bits to 1. To enable interrupts, set the TE, TIE, RE and RIE bits to 1 with one instruction at the same time (for transmission and when the IICINTM bit is 1, clear the RIE bit). Setting the TE and RE bits to 1 makes the SCLn and SDAn pins functions available.
10	Initialization completed	—

Note: Set the CCR0.TE and RE bits to 0 or 1 at the same time.

Note 1. If you do not use the bit rate modulation function, you do not need to set it.

28.8.5 Operation in Master Transmission in Simple IIC Mode

Figure 28.91 and Figure 28.92 show examples of master transmission and Figure 28.93 shows an example flow of data transmission.

Figure 28.91 shows the operation example when ICR.IICINTM bit is 1 (use reception and transmission interrupts). In this case, you can start DMAC or DTC by SCIn_TXI interrupt. However, if use DMAC or DTC, ACK/NACK cannot be confirmed. If you want to confirm ACK/NACK, prepare the transmit data by CPU.

In simple IIC mode, SCIn_TXI interrupt is generated when communication of one frame is completed. And it is not used SCIn_RXI interrupt in master transmission, so the CCR0.RIE set to 0.

See Table 28.46 for more information on the STI interrupt.

Figure 28.93 shows a flow chart in the case of ICR.IICINTM is 1 and address transmission by CPU and data transmission by DTC or DMAC. When 10-bit slave addresses are in use, steps [3] and [4] are repeated twice.

In simple IIC mode, the transmit data empty interrupt (SCIn_TXI) is generated when communication of one frame is complete, unlike the SCIn_TXI interrupt request generation timing during clock synchronous transmission.

Figure 28.91 Example 1 of operations for master transmission in simple IIC mode with 7-bit slave addresses, transmission interrupts, and reception interrupts (ICR.IICINTM = 1)

When the ICR.IICINTM bit is set to 0 (use ACK/NACK interrupts) during master transmission, the DTC or DMAC is activated by the ACK interrupt as the trigger and required number of data bytes are transmitted. When the NACK is received, error processing such as transmission stop and retransmission is performed using the NACK interrupt as the trigger.

To restart communication for some reason after writing data in the TDR register, use the following procedure:

1. Set the TE and RE bits in the CCR0 register to 0 to stop communication.
2. Set ICR.IICSCLS[1:0] and ICR.IICSDAS[1:0] bits to 11b, release the I²C bus, and clear the generation of a condition.
3. If the RDRF flag in the CSR register is set to 1, the RDR register is read by dummy and the RDRF bit is set to 0.
4. Set the TE and RE bits in the CCR0 register to 1 and start the next communication.

Figure 28.92 Example 2 of operations for master transmission in simple IIC mode with 7-bit slave addresses, ACK interrupts, and NACK interrupts (ICR.IICINTM = 0)

Figure 28.93 Example flow of master transmission in simple IIC mode with transmission interrupts and reception interrupts

28.8.6 Master Reception in Simple IIC Mode

Figure 28.94 shows an example operation in simple IIC mode master reception and Figure 28.96 shows an example flow of master reception.

The value of the ICR.IICINTM bit is assumed to be 1 (use reception and transmission interrupts) and 0 (use ACK and NACK interrupts).

In simple IIC mode, the transmit data empty interrupt (SCIn_TXI) is generated when communication of one frame is complete, unlike the SCIn_TXI interrupt request generation timing during clock synchronous transmission.

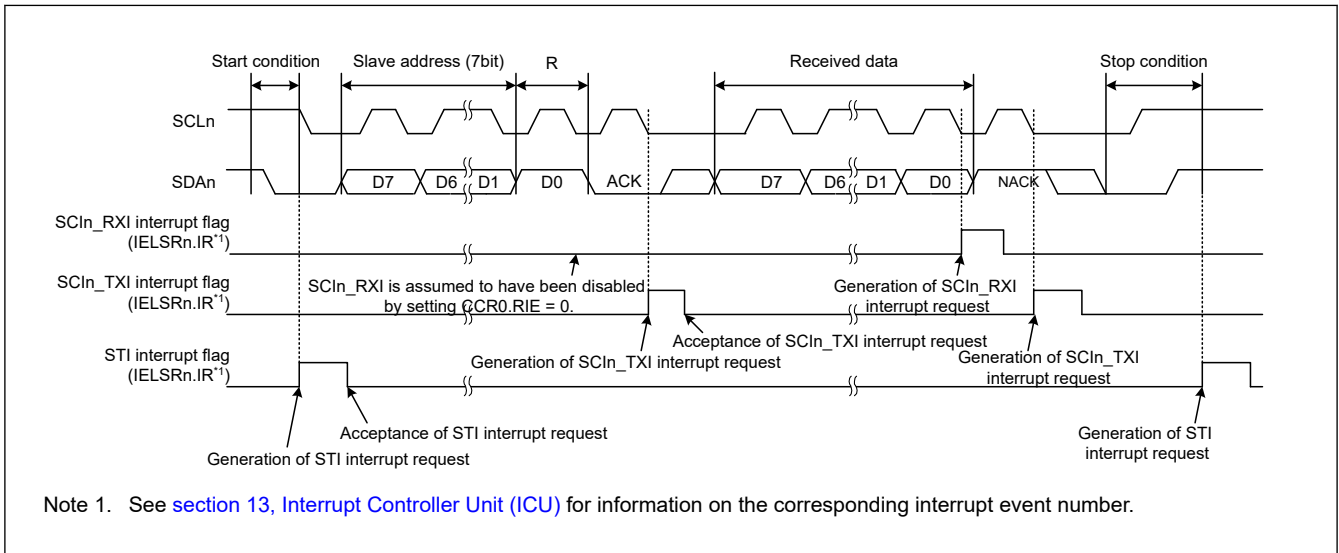

Figure 28.94 Example operations for master reception in simple IIC mode with 7-bit slave addresses, transmission interrupts, and reception interrupts (ICR.IICINTM = 1)

Figure 28.95 Example of Operations for Master Reception in Simple IIC Mode (7bit Slave address, ACK and NACK interrupt in use (ICR.IICINTM = 0))

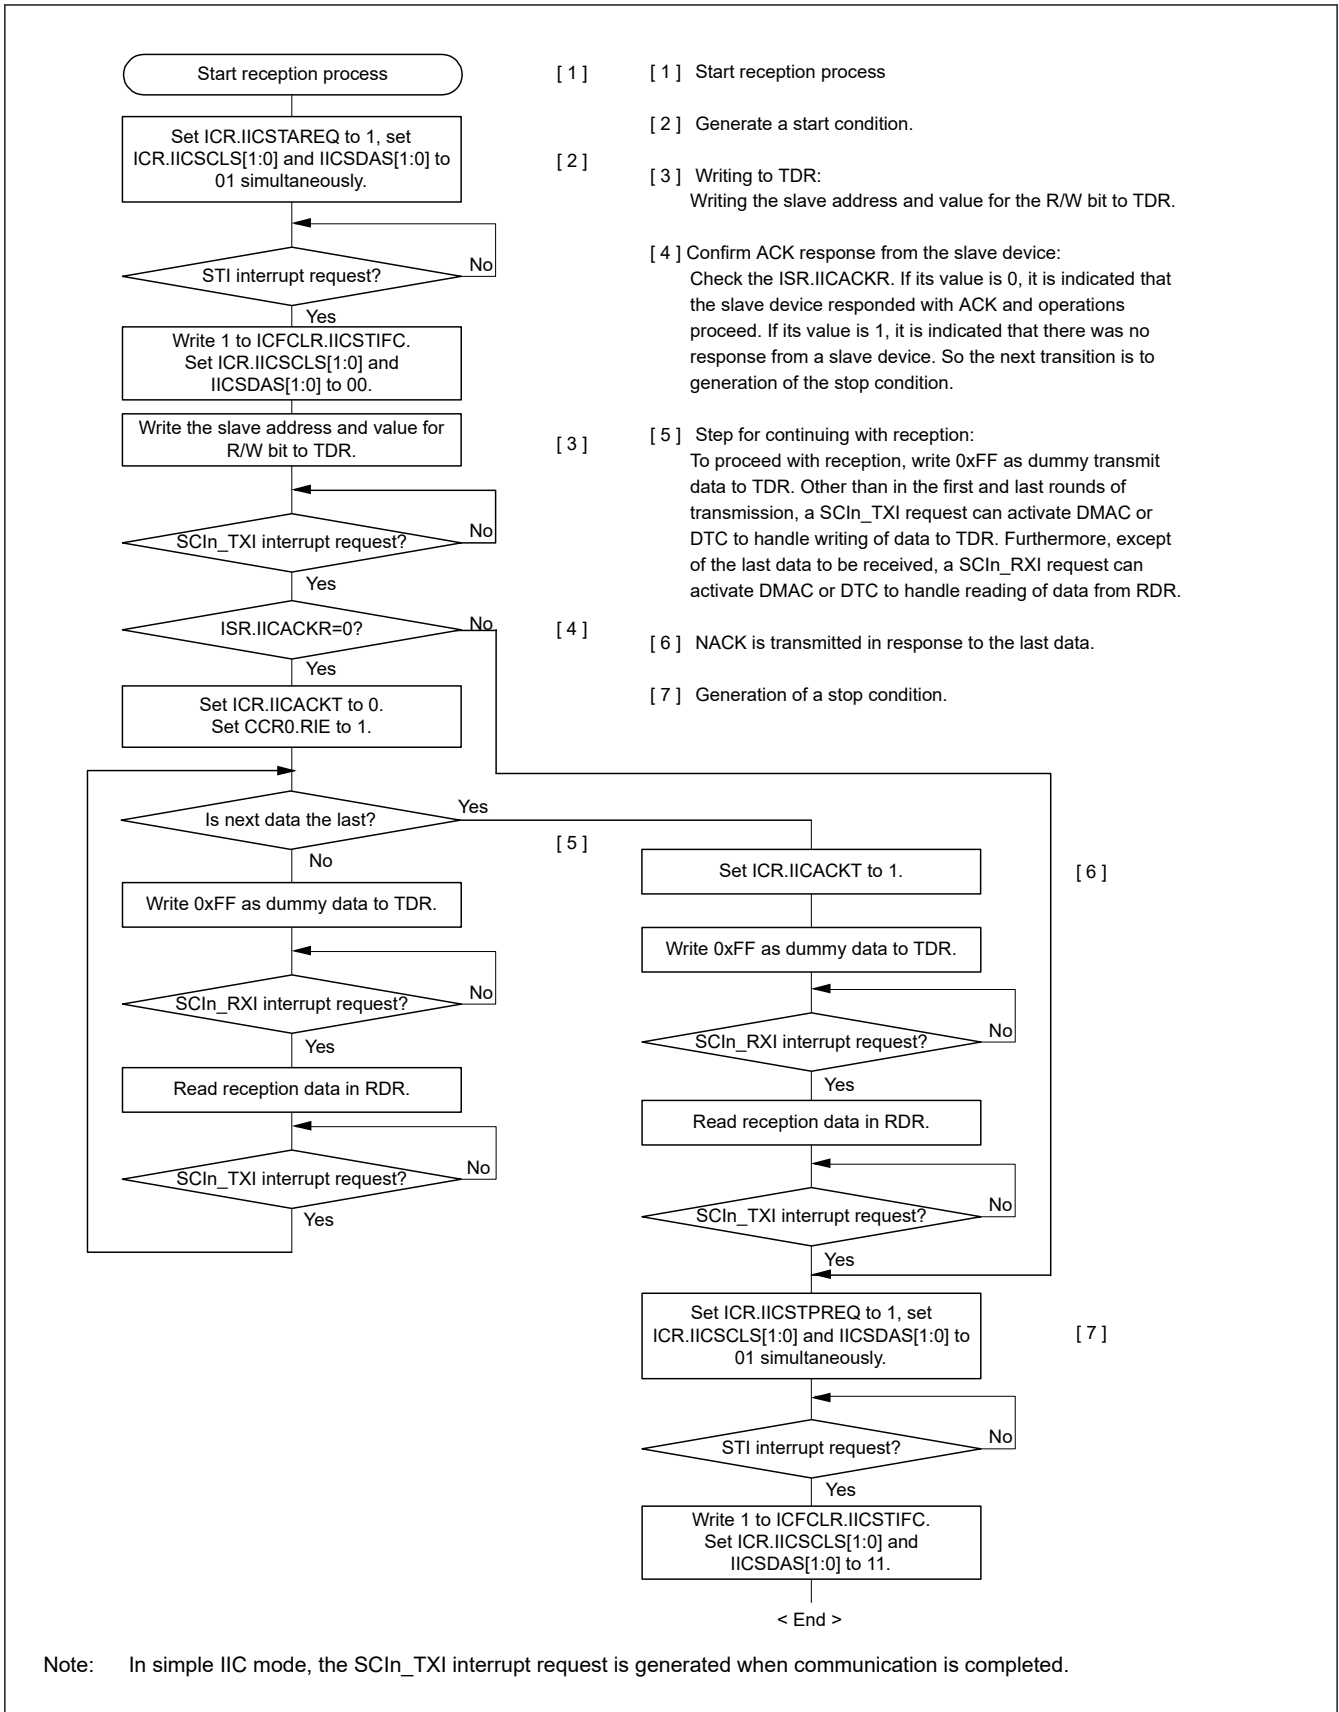

Figure 28.96 Example flow of master reception in simple IIC mode with transmission interrupts and reception interrupts (ICR.IICINTM = 1)

Figure 28.97 Example flow of master reception in simple IIC mode with ACK Interrupts and NACK Interrupts (ICR.IICINTM = 0)

28.9 Operation in Simple SPI Mode

As an extended function, the SCI supports a simple SPI mode that handles transfer among one or multiple master devices and multiple slave devices.

Using the settings for Simple SPI mode setting (CCR3.MOD[2:0] bit = 011b) and setting the CCR0.SSE bit to 1 place the SCI in simple SPI mode. However, the SS_n pin function on the master side is not required for connection of the device used as the master in simple SPI mode when the configuration only has a single master. Therefore, set the CCR0.SSE bit to 0 in such cases.

Figure 28.98 shows an example of connections for simple SPI mode. Control a general port pin to produce the SS_n output signal from the master.

In simple SPI mode, data is transferred in synchronization with clock pulses in the same way as in clock synchronous mode. One character of data for transfer consists of 8 bits of data, and parity bits cannot be appended. The data can be inverted by setting the CCR3.SINV bit to 1.

Because the receiver and transmitter are independent of each other within the SCI module, full-duplex communications are possible, with a shared clock signal. Additionally, because both the transmitter and receiver have a buffered structure, writing the next transmit data while transmission is in progress and reading previously received data while reception is in progress are both possible. This enables continuous transfer.

Figure 28.98 Example connections using simple SPI mode in single master mode with CCR0.SSE bit = 0

28.9.1 States of Pins in Master and Slave Modes

The direction (input or output) of pins for the simple SPI mode interface differs according to whether the device is a master (CCR3.CKE[1:0] = 00b or 01b) or slave (CCR3.CKE[1:0] = 10b or 11b).

Table 28.42 lists the relationship between the pin states, mode, and level on the SSn pin.

Table 28.42 States of pins by mode and input level on SSn pin

Mode	Input on SSn pin	State of MOSIn pin	State of MISOIn pin	State of SCKn pin
Master mode*1	High level (transfer can proceed)	Output for data transmission*2	Input for received data	Clock output*3
	Low level (transfer cannot proceed)	High-impedance	Input for received data (but disabled)	High-impedance
Slave mode	High level (transfer cannot proceed)	Input for received data (but disabled)	High-impedance	Clock input (but disabled)
	Low level (transfer can proceed)	Input for received data	Output for data transmission	Clock input

Note 1. When there is only a single master (CCR0.SSE = 0), transfer is possible regardless of the input level on the SSn pin. This is equivalent to input of a high level on the SSn pin. The SSn pin is not used and is available for other purposes.

Note 2. The MOSIn pin output is in the high-impedance state when serial transmission is disabled (CCR0.TE bit = 0).

Note 3. The SCKn pin output is in the high-impedance state when serial transmission is disabled (CCR0.TE = 0 and CCR0.RE = 0) in a multi-master configuration (CCR0.SSE = 1).

28.9.2 SS Function in Master Mode

Setting the CKE[1:0] bits in the CCR3 to 00b or 01b selects master mode operation. The SSn pin is not used in single-master configurations (CCR0.SSE = 0), so transmission or reception can proceed regardless of the value of the SSn pin.

When the level on the SSn pin is high in a multi-master configuration (CCR0.SSE = 1), a master device outputs clock signals from the SCKn pin before starting transmission or reception to indicate that there are no other masters or another master is performing reception or transmission.

When the level on the SSn pin is low in a multi-master configuration (CCR0.SSE = 1), there are other masters, and a transmission or reception is in progress. The MOSIn output and SCKn pins are placed in the high-impedance state and starting transmission or reception is not possible. In addition, the value of the CSR.MFF bit is 1, indicating a mode fault error. In a multi-master configuration, start error processing by reading CSR.MFF flag. If a mode fault error occurs while transmission or reception is in progress, transmission or reception does not stop, but the MOSIn and SCKn outputs are in the high-impedance state after completion of the transfer. When the SSn pin input becomes high level, the SCKn pin outputs a clock signal and the MOSIn outputs data. Even if the SCKn pin and the MOSIn pin are in the high impedance state, internal transmission or reception operation continues, but it stops after transmission or reception of a single character is complete. In this case, any of SCIn_TXI, SCIn_RXI, and SCIn_TEI interrupts occurs.

Use a general port pin to produce the SS output signal from the master.

28.9.3 SS Function in Slave Mode

Setting the CCR3.CKE[1:0] bits to 10b or 11b selects slave operation. When the SSn pin is high, the MISO output pin is in the high-impedance state and clock input through the SCKn pin is ignored. When the SSn pin is low, clock input through the SCKn pin is valid and transmission or reception can proceed.

If the input on the SSn pin changes from low to high during transmission or reception, the MISO output pin is placed in the high-impedance state. Transmission / reception operation is immediately suspended. If the transmission is in progress, the CSR.TEND flag will not be set, a transmit end interrupt will not be output, and an abnormal stop status will occur. So, do not negate the SSn pin during slave transmission / reception. If an abnormal stop occurs, set CCR0.RE and CCR0.TE to 0 to stop transmission / reception. To resume transmission / reception, set CCR0.RE and CCR0.TE to 1 after at least $TCLK \times 3$ cycles + $PCLK \times 3$ cycles.

28.9.4 Relationship between Clock and Transmit/Receive Data

The CPOL and CPHA bits in the CCR3 register can be used to set up the clock for use in transmission and reception in four different ways. The relation between the clock signal and the transmission and reception of data is shown in [Figure 28.99](#).

The relation is the same for both master and slave operation. This is the same as when the level on the SSn pin is high.

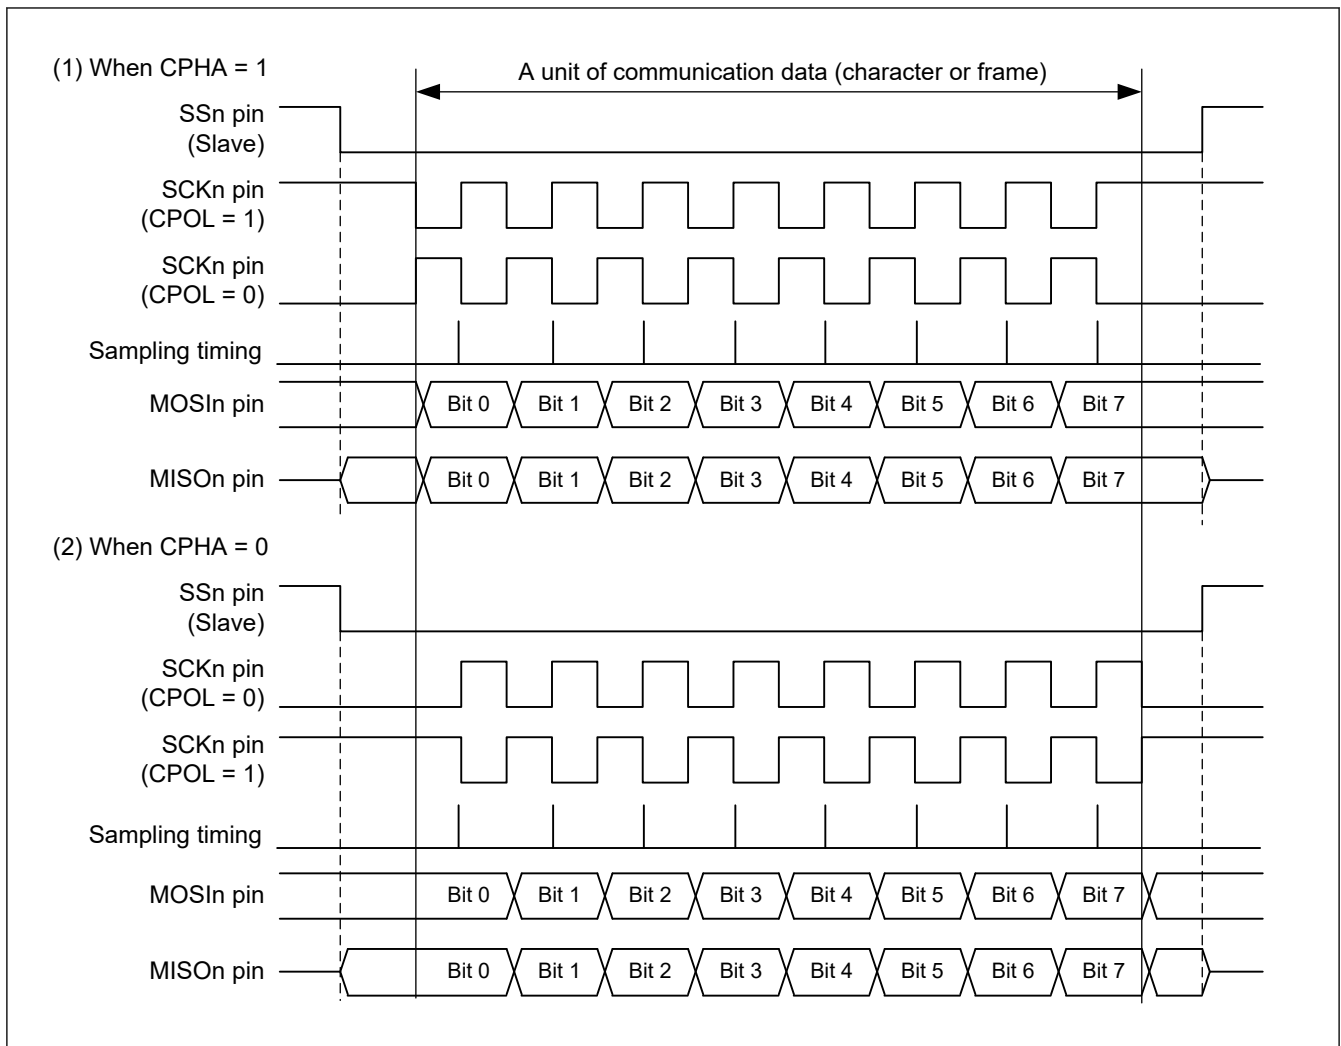

Figure 28.99 Relation between clock signal and transmit or receive data in simple SPI mode

28.9.5 SCI Initialization in Simple SPI Mode

Initialization in simple SPI mode is the same as in clock synchronous mode. See [section 28.6.3. SCI Initialization in Clock Synchronous Mode](#) for an example initialization flow. The CPOL and CPHA bits in the CCR3 register must be set to ensure that the clock signal is suitable for both master and slave devices.

Always initialize the CCR0 register before making any changes to the operating mode or transfer format.

Note: Only the RE bit is set to 0. The CSR.ORER, FER, PER, and RDR flags are not initialized.

Changing the value of the TE bit from 1 to 0 or from 0 to 1 when the TIE bit in the CCR0 register is 1 at the same time, leads to the generation of a transmit data empty interrupt (SCIn_TXI).

28.9.6 Transmission and Reception of Serial Data in Simple SPI Mode

In master operation, ensure that the SSn pin of the slave device on the other side of the transfer is at the low level before starting the transfer and at the high level on completion of the transfer. In multiple master operation with CCR0.SSE = 1 even in master mode, a mode fault error will occur if the SSn pin goes low. Therefore, make sure that no mode fault error has occurred before starting communication, and start communication, and make sure that no mode fault error has occurred even after communication ends. If a mode fault error has occurred, communication may be incomplete, so measures such as retransmission are required. Otherwise, the procedures are the same as in clock synchronous mode.

In slave mode, it operates according to the SSn pin input level. Other steps are the same as those of clock synchronous mode.

28.9.7 Reception Sampling Timing Adjustment Function in Simple SPI Mode with internal clock used

The reception sampling timing adjustment function in simple SPI mode is the same as the reception sampling timing adjustment function in clock synchronous mode. For the description of operation, see [section 28.6.7. Reception Sampling Timing Adjustment Function in Clock Synchronous Mode with internal clock used](#).

28.10 Bit Rate Modulation Function

Using the bit rate modulation function, the bit rate can be evenly corrected using the number specified in the MDDR register among 256 clock cycles of internal clocks which is selected by the CKS[1:0] bits in CCR2.

[Figure 28.100](#) shows an example where the PCLK is selected in the CKS[1:0] bits in CCR2, the BRR bit is set to 0, and the MDDR is set to 160 in Asynchronous mode. In this example, the cycle of the base clock is evenly corrected ($256/160$) and the bit rate is also corrected ($160/256$).

Note: Enabling an internal clock causes bias, and expansion and contraction are generated in the pulse width of the internal base clock.

Do not use this function in clock synchronous mode, simple SPI mode, Smart Card Interface mode, Manchester mode and Simple LIN mode.

Figure 28.100 Example internal base clock when bit rate modulation function is used

28.11 Simple LIN mode

As an extended function of the SCI, the SCI supports the serial communication protocol ([Figure 28.101](#)) consisting of a Start Frame and an Information Frame as Simple LIN. Simple LIN mode is enabled by the CCR3.MOD[2:0] = 110b. Since the Simple LIN mode uses the same circuit as the Asynchronous mode for transmission / reception control other than Break Field, the basic communication settings required for the Asynchronous mode are also required for the Simple LIN mode.

(For the setting value when using simple LIN, see the explanation in [section 28.2. Register Descriptions](#). In particular, note that CCR3.RXDESEL needs to be changed from the initial value and set to 1.)

The Start Frame consists of a Break Field, Control Field 0, and Control Field 1. The Information Frame can be configured with some Data Fields, a Checksum Field.

Figure 28.101 Simple LIN Protocol Example

The following describes operations when the Simple LIN is used. In this section, operations are described with the following conditions:

Communication pin (RXDn / TXDn) level inversion function: OFF (RINV = TINV = 0)

When using the simple LIN with the communication pin (RXDn / TXDn) level inversion function enabled, replace the RXDn and TXDn signal levels with their inverted levels.

28.11.1 Simple LIN Start Frame Transmission

Figure 28.102 shows an example of transmission of the Start Frame consisting of a Break Field, Control Field0, and Control Filed1. (Omit Break Field and Control Field0 according to the Start Frame configuration.)

Figure 28.103 shows a flowchart for Start Frame transmission.

The SCI operates as follows during Start Frame transmission.

1. Make the initial settings for the SCI according to the SCI initialization flow (Figure 28.68) in Asynchronous mode. In Simple LIN mode, do not set CCR0.TE and TIE to 1 at the same time to avoid SCIn_TXI output before the Break Field. Therefore, perform the following two steps sequentially to set the SCI initialization flow (Asynchronous mode) procedure [9].
 - Set the bits except CCR0.TIE. (CCR0.TIE = 0, CCR0.TE = 1, and CCR0.RE = 0)
 - Set CCR0.TIE to 1.
2. When 1 is written to TCST, the Break Field output timer starts counting and outputs a low level (Break Field) from the TXDn pin for the period set in XCR2.BFLW[15:0]. A timer count clock source can be selected by XCR0.TCSS[1:0]. Writing 0 to XCR1.TCST suspends output of the Break Field. After the suspension, set CCR0.TE = 0 and turn off the transmission.
3. When the Simple LIN module timer count value matches the set XCR2.BFLW[15:0] value, the timer stops counting and inverts the TXDn pin output level, and the XSR0.BFOF flag is set to 1^{*1}. Furthermore, if XCR0.BFOIE has been set to 1 at this time, a SCIn_TXI interrupt is generated.
4. After the SCIn_TXI interrupt and confirming XSR0.BFOF = 1, write the transmitted data then the Control Field 0 data is transmitted using the SCI^{*2}.
5. After the Control Field 0 data has been transmitted, write the Control Field 1 data to TDR. And it is transmitted.
6. After the Control Field 1 data has been transmitted, the Information Frame data is transmitted.

Note 1. After XSR0.BFOF is set to 1, if 1 is written to XCR1.TCST without clearing it, no SCIn_TXI interrupt is output at the end of Break Field transmission. Clear XSR0.BFOF before writing 1 to XCR1.TCST.

Note 2. LIN communication requires a Break Delimiter (IDLE period) of 1 bit or more from the end of Break Field output until the next data transmission starts. For this reason, the Break Delimiter length is counted upon completion of Break Field output. If transmit data is written while the Break Delimiter length is being counted, transmission does not start until the Break Delimiter length counting is completed. When transmit data is written after the Break Delimiter length has been counted, transmission starts at the same timing as normal data transmission.

Break Delimiter length count time after Break Field output:

1-bit to 2-bit length (CCR3.STP = 0)

2-bit to 3-bit length (CCR3.STP = 1)

Figure 28.102 Start Frame Transmission Example

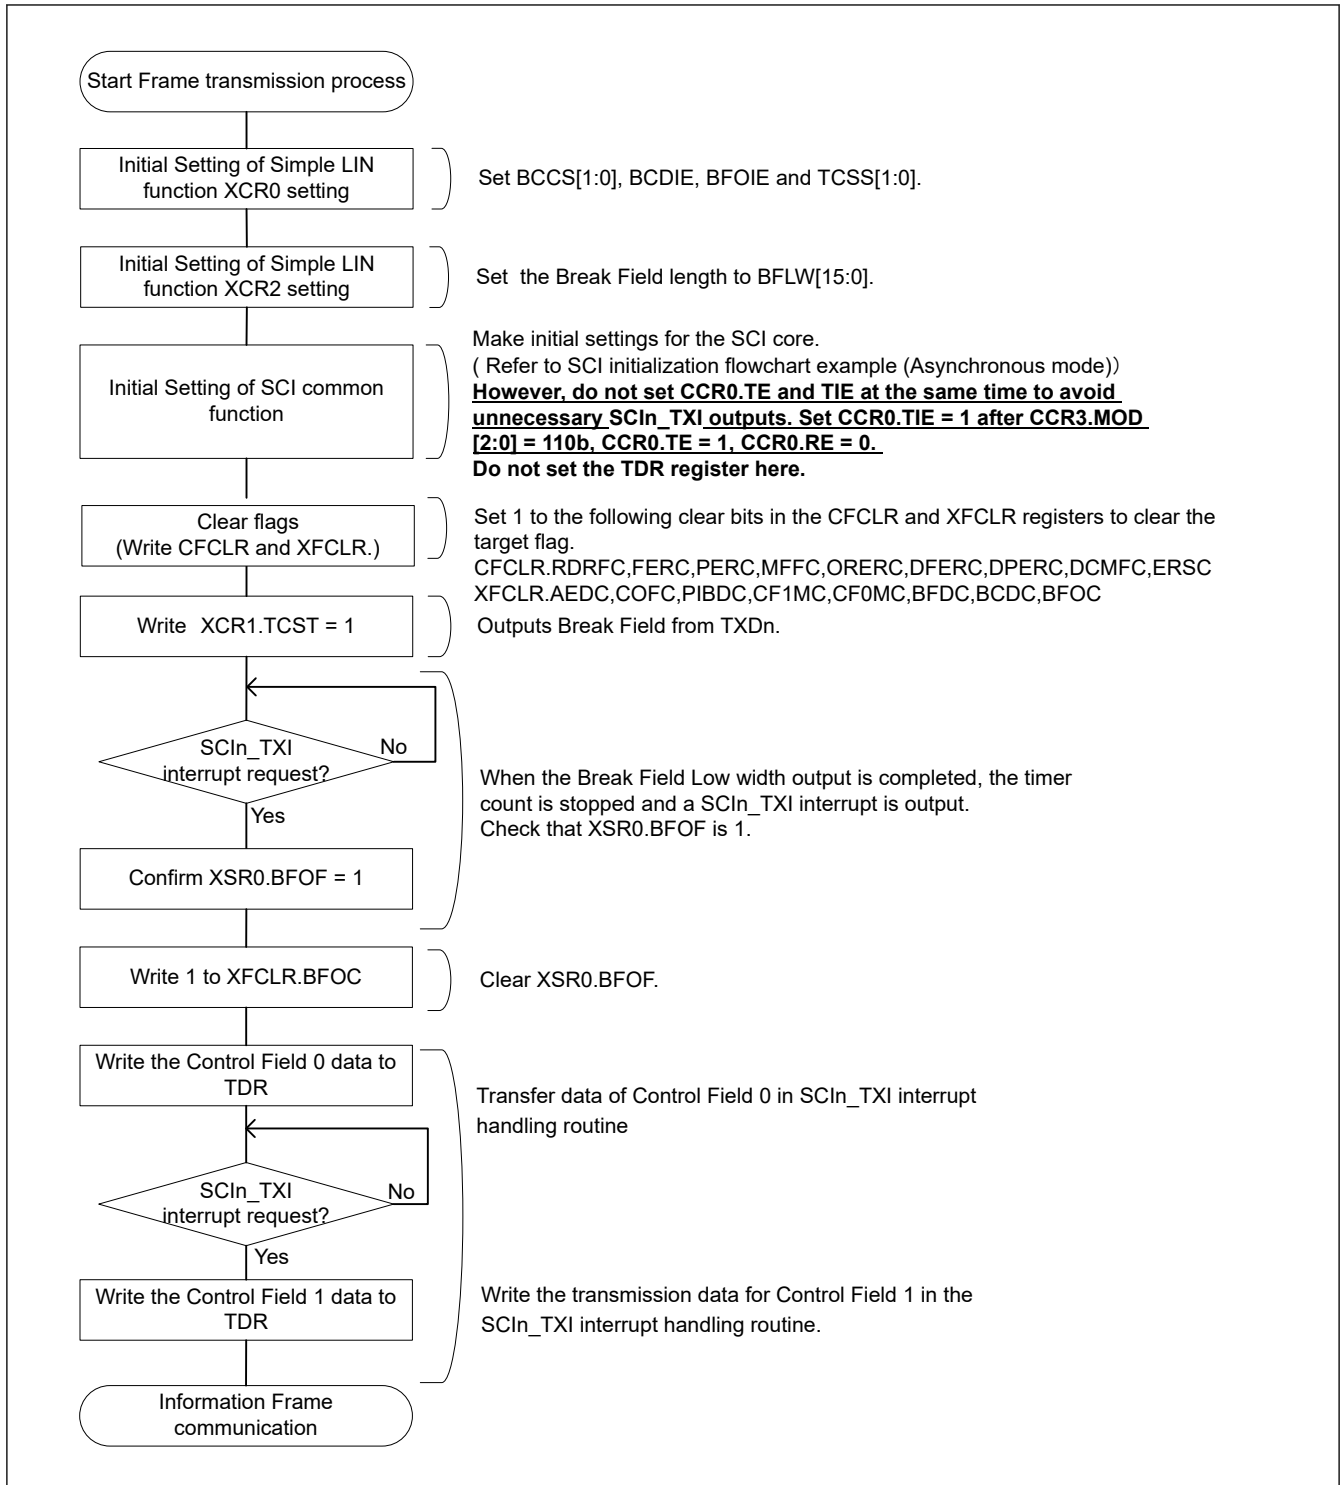

Figure 28.103 Start Frame Transmission Flowchart Example

28.11.2 Simple LIN Start Frame Reception

The SCI can detect Start Frames configured as shown in [Figure 28.104](#).

Figure 28.104 Start Frame Configuration

(1) Simple LIN normal reception of Start Frame (PIB not used)

Figure 28.105 shows an example of normal reception of the Start Frame consisting of a Break Field, Control Field0, and Control Field1. Figure 28.106 shows an example of reception to detect the Break Field during Control Field 1. Figure 28.107 shows a flowchart to receive the Start Frame, and Figure 28.108 shows a state transition diagram.

When receiving the Start Frame, the SCI operates as follows. Omit the processing of Break Field and Control Field0 according to the Start Frame configuration.

- Writing 1 to XCR1.SDST makes it possible to detect the Start Frame. When XCR0.BFE = 1, RXDn input to the SCI core is disabled until the Break Field is detected (because XSR0.RXDSF is set to 1). Once the Break Field is detected, RXDn input can be received to the SCI core (XSR0.RXDSF = 0).
- When a low level is input from the RXDn pin, the Break Field detection count starts. A timer count clock source can be selected by XCR0.TCSS[1:0].
- When a low level that is equal to or longer than the period set in XCR2.BFLW[15:0] is input from the RXDn pin, it is determined as Break Field. At this time, XSR0.BFDF is set to 1. If XCR0.BFDIE has been set to 1 at this time, a SCIn_BFD interrupt is generated. The timer continues counting until the RXDn rising edge or counter overflow.
- After the Break Field is detected, when the input level from the RXDn pin becomes high, the count value is captured to XSR1.TCNT[15:0] when BMEN = 0. At this time, XSR0.RXDSF is cleared to 0 and the SCI core starts receiving the RXDn input.
- The SCI core starts receiving Control Field 0. Because the simple LIN continuously counts the edge interval, it determines a low level that is equal to or longer than the period set in XCR2.BFLW[15:0] as detection of the Break Field. When the Break Field is detected in the Control Field 0 phase, the SCI core waits for reception of Control Field 0 again (Figure 28.106).
- When Control Field 0 has been received, an SCIn_RXI interrupt is generated and the Control Field 0 data is stored in XSR0.CF0RD[7:0]. When the received data matches the set XCR2.CF0D[7:0] value, XSR0.CF0MF is set to 1. If the received data differs from the set XCR2.CF0D[7:0] value, the SCI transitions to the state before the Break Field is detected.
- The SCI core starts receiving Control Field 1. When BFE = 1, the Break Field detection function is continuously enabled while SDST = 1 as in the case of Control Field 0. When the Break Field is detected in the Control Field 1 phase, the SCI core waits for reception of Control Field 0 again.
- When Control Field 1 has been received, an SCIn_RXI interrupt is generated and the Control Field 1 data is stored in XSR0.CF1RD[7:0]. When the received data matches the set XCR1.PCF1D[7:0] value or the set XCR1.SCF1D[7:0] value, XSR0.CF1MF is set to 1. If the received Control Field 1 data matches neither the set XCR1.PCF1D[7:0] value nor the set XCR1.SCF1D[7:0] value, the SCI transitions to the state before the Break Field is detected.
- The SCI core performs Information Frame communication.
- When communication is completed, write 0 to XCR1.SDST and 0 to CCR0.RE to stop reception.

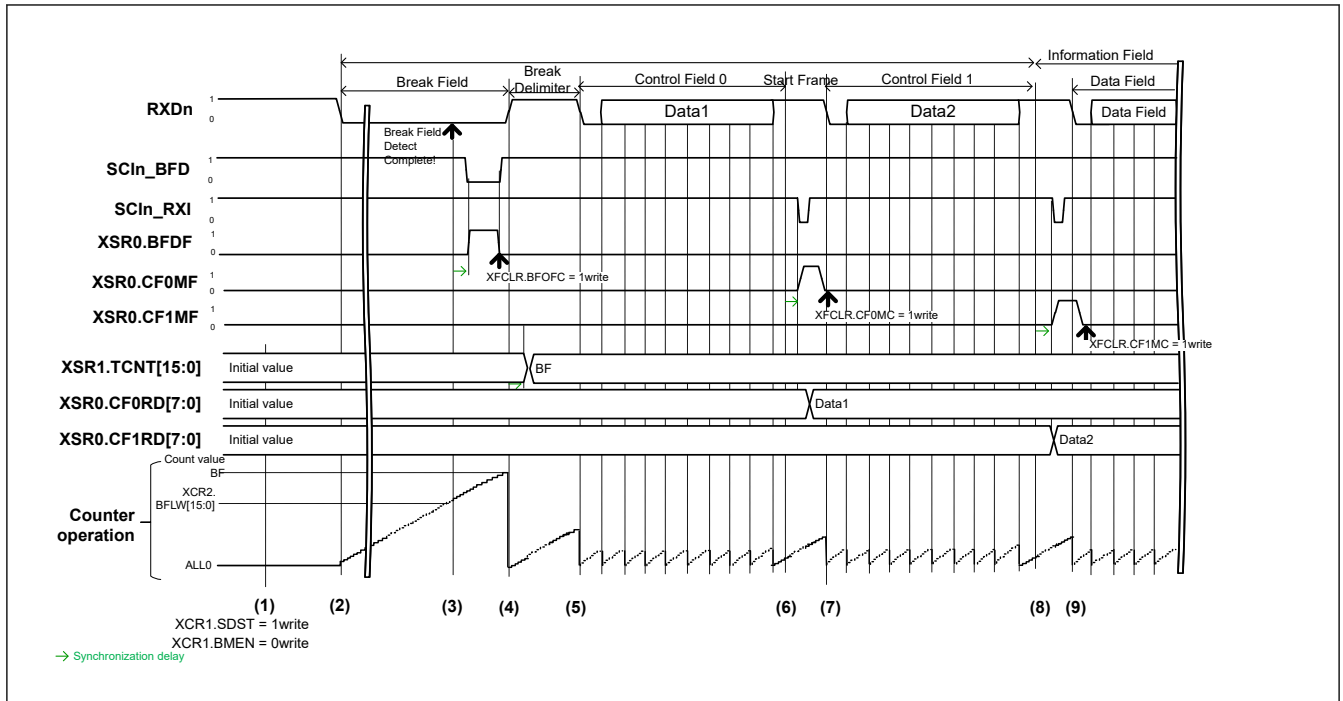

Figure 28.105 Normal Reception Example of Start Frame (PIB Not Used)

Figure 28.106 Start Frame Reception Example (PIB Not Used) Break Field Detected during Control Field 1

Figure 28.107 Example of Start Frame Reception Flowchart

Figure 28.108 State Transition Diagram of Start Frame Reception

(2) Simple LIN Start Frame reception (using the priority interrupt bit)

Figure 28.109 shows an example of Start Frame reception using the priority interrupt bit. The priority interrupt bit is enabled by setting XCR0.PIBE to 1.

The SCI operates as follows during Start Frame reception using the priority interrupt bit.

Steps (1) to (7) are the same as steps (1) to (7) in the Start Frame reception example in Figure 28.105.

(8) When the value specified in the XCR0.PIBS[2:0] bits matches the set XCR1.PCF1D[7:0] value, XSR0.PIBDF is set to 1 and the SCI core performs communication of the Information Frame. If the data received in Control Field 1 matches neither the set XCR1.PCF1D[7:0] value nor the set XCR1.SCF1D[7:0] value and the priority interrupt bit is not detected, the SCI transitions to the state before the Break Field is detected.

(9) Communicate information frame at the SCI core.

Figure 28.109 Start Frame Reception Example (Priority Interrupt Bit Used)

28.11.3 Simple LIN Bus Conflict Detection Function

In Simple LIN mode ($CCR3MOD[2:0] = 110$) when $TE = 1$, the bus conflict detection function works during Break Field output and during data transmission.

Figure 28.110 shows an operation example of the bus conflict detection function. The TXDn pin output and the RXDn pin input are sampled by the bus conflict detection clock set in $XCR0.BCCS[1:0]$. When a mismatch occurs three times in a row, $XSR0.BCDF$ is set to 1, and if $XCR0.BCDIE$ has been set to 1 at this time, an $SCIn_ERI$ interrupt is generated.

When an $SCIn_ERI$ interrupt is generated, stop transmission according to Figure 28.111. Check the bus state to decide whether to resume transmission.

Figure 28.110 Operation Example of the Bus Conflict Detection Function

Figure 28.111 SCIn_ERI Interrupt handling flow at transmission in Simple LIN mode

28.11.4 Simple LIN Bit Rate Measurement Function

This function measures a bit rate between the effective edges of the input signal from the RXDn pin. Figure 28.112 shows an operation example of the bit rate measurement function.

1. Writing 1 to XCR1.SDST and XCR1.BMEN enables bit rate measurement. When this bit is set to 1, the valid edge interval of Control Field 0 and Control Field 1 data is measured. However, bit rate is not measured between the Break Field and the Break Delimiter. Set XCR1.BMEN and XCR1.SDST to 1 simultaneously, only when measuring bit rate.
2. Because bit rate is not measured in the Break Field, the effective edge detection flag is not set to 1 at the rising edge at the end of the Break Field, and the counter capture value is not stored in XSR1.TCNT[15:0].
3. The counter starts counting from the falling edge of the start bit in Control Field 0. The Break Delimiter count value is not captured in XSR1.TCNT[15:0].
4. The rising edge of the start bit is detected as an effective edge, and then the XSR0.AEDF flag is set to 1. If XCR0.AEDIE has been set to 1 at this time, an SCIn_AED interrupt is output. The start bit count value is stored in XSR1.TCNT[15:0]. The XSR1.TCNT[15:0] value is retained until the effective capture value is read.
5. Even if an effective edge is input from the RXDn input pin, the count value of this effective edge timing is not captured because the XSR1.TCNT[15:0] value has not been read and retention has not been released. In this case, an SCIn_AED interrupt is not output.
6. The XSR1.TCNT[15:0] value is read. Then the retention of XSR1.TCNT[15:0] is released and the XSR0.AEDF flag is cleared by hardware.
7. Because the retention of XSR1.TCNT[15:0] has been released, the count value is captured at the effective edge and is retained. At the same time, the XSR0.AEDF flag is set to 1, and if XCR0.AEDIE has been set to 1, an SCIn_AED interrupt is output. The bit rate can be adjusted by calculating it from the count value between effective edges by software and by changing the SCI settings.
8. To disable bit rate measurement, write 0 to XCR1.BMEN.
9. The XSR0.AEDF value and the XSR1.TCNT[15:0] value remain unchanged at the effective edge timing because the bit rate measurement function is disabled.

Figure 28.112 Operation Example of the Bit Rate Measurement Function

28.12 Interrupt Sources

28.12.1 Buffer Operation for SCIn_TXI and SCIn_RXI Interrupts

If the conditions for an SCIn_TXI and SCIn_RXI interrupt are satisfied while the interrupt status flag in the ICU is 1, the ICU does not output the interrupt request but saves it internally with a capacity for retention of one request per source.

28.12.2 Interrupts in Asynchronous, Manchester, Clock Synchronous, and Simple SPI Modes

(1) Non-FIFO selected

Table 28.43 lists interrupt sources in Asynchronous mode, Manchester mode, clock synchronous mode, and simple SPI mode.

A different interrupt vector can be assigned to each interrupt source. Individual interrupt sources can be enabled or disabled with the enable bits in the CCR0 register.

If the CCR0.TIE bit is 1, an SCIn_TXI interrupt request is generated when transmit data is transferred from the TDR register to the TSR register. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the CCR0.TE and CCR0.TIE bits to 1 at the same time. An SCIn_TXI interrupt request can activate the DTC or DMAC to handle data transfer.

An SCIn_TXI interrupt request is not generated by setting the CCR0.TE bit to 1 when CCR0.TIE is 0 or by setting the CCR0.TIE bit to 1 when the CCR0.TE is 1.*¹

When new data is not written by the time of transmission of the last bit of the current transmit data and CCR0.TEIE is 1, the CSR.TEND flag is set to 1 and an SCIn_TEI interrupt request is generated. Additionally, when CCR0.TE is 1, the CSR.TEND flag retains the value 1 until more transmit data is written to the TDR register, and setting CCR0.TEIE to 1 leads to the generation of an SCIn_TEI interrupt request.

Writing data to the TDR register leads to clearing of the CSR.TEND flag and, after a certain time, discarding of the SCIn_TEI interrupt request.

If the CCR0.RIE bit is 1, an SCIn_RXI interrupt request is generated when received data is stored in the RDR register. An SCIn_RXI interrupt request can activate the DTC or DMAC to handle data transfer.

Setting any of the CSR.ORER, FER, PER or MSR.MER*², SYER*², PFER*², and SBER*² flags to 1 when the CCR0.RIE bit is 1 leads to the generation of an SCIn_ERI interrupt request.

An SCIn_RXI interrupt request is not generated in this case. Clearing all these flags (ORER, FER, PER, MER*², SYER*², PFER*² and SBER*²) leads to discarding of the SCIn_ERI interrupt request.

Note 1. To temporarily prohibit SCIn_TXI interrupts on transmission of the last of the data when a new round of transmission is to be started, after handling the transmission-completed interrupt, control activation of the interrupt by using the interrupt request enable bit in the ICU rather than using the CCR0.TIE bit. This approach can prevent the suppression of SCIn_TXI interrupt requests in the transfer of new data.

Note 2. MER, SYER, PFER, and SBER work as a factor of SCIn_ERI interrupt only in Manchester mode. SYER, PFER, and SBER also only work if its enable bits (SYEREN, PFEREN, SBEREN in MECR) are set to "1".

(2) FIFO selected

Table 28.44 lists interrupt sources in FIFO selected mode.

If the CCR0.TIE bit is 1, an SCIn_TXI interrupt request is generated when the stored amount of data in the transmit-FIFO (TDR) register becomes the threshold value indicated in FCR.TTRG or below. An SCIn_TXI interrupt request can also be generated by using a single instruction to set the CCR0.TIE and CCR0.TE bits to 1 simultaneously or by setting CCR0.TIE to 1 when CCR0.TE is 1.

An SCIn_TXI interrupt request is not generated by setting CCR0.TE to 1 when CCR0.TIE is 0 or by setting the CCR0.TIE bit to 1 while the setting of the CCR0.TE bit is 1.

If CCR0.TEIE is 1 and if the next data is not written to the transmit-FIFO (TDR) register by the time the last bit of the transmit data is sent, the CSR.TEND flag is set to 1 and the SCIn_TEI interrupt request is generated.

If CCR0.RIE is 1, the SCIn_RXI interrupt request is generated when the stored amount of data in the transmit-FIFO (TDR) register is equal to or greater than the threshold value indicated in FCR.RTRG. When RTRG is 0, an SCIn_RXI interrupt does not occur even when the amount of data in the receive FIFO is equal to 0.

If the CCR0.RIE bit is 1, when the CSR.ORER flag is set to 1 or data with a framing error or a parity error is stored in the transmit-FIFO (TDR) register, the SCIn_ERI interrupt request is generated. When the amount of data stored in the transmit-FIFO (TDR) register is at the threshold value or above, the SCIn_RXI interrupt request is also generated. The SCIn_ERI interrupt request can be canceled, in which case CSR.ORER, FER, and PER flags are all cleared.

Table 28.43 SCI interrupt sources with non-FIFO selected

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_ERI (n = 0 to 4, 9)	Receive error	CSR.ORER, CSR.FER, CSR.PER, CSR.DFER, CSR.DPER, (MSR.MER, MSR.SYER, MSR.PFER, MSR.SBER)* ¹	CCR0.RIE	Not possible
SCIn_RXI (n = 0 to 4, 9)	Receive data full	CSR.RDRF	CCR0.RIE	Possible
	Address match	CSR.DCMF	CCR0.RIE	Possible
SCIn_TXI (n = 0 to 4, 9)	Transmit data empty	CSR.TDRE	CCR0.TIE	Possible
	TE = 0->1 detection			
SCIn_TEI (n = 0 to 4, 9)	Transmit end	CSR.TEND	CCR0.TEIE	Not possible

Note: Only SCI0 supports Manchester mode.

Note 1. MER, SYER, PFER, and SBER work as a factor of SCIn_ERI interrupt only in Manchester mode. SYER, PFER, and SBER also only work if its enable bits (SYEREN, PFEREN, SBEREN in MCR) are set to 1.

Table 28.44 SCI interrupt sources with FIFO selected

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_ERI (n = 0 to 4, 9)	Receive error	CSR.ORER, CSR.FER, CSR.PER, CSR.DFER, CSR.DPER	CCR0.RIE	Not possible
		FRSR.DR (when FCR.DRES = 1)	CCR0.RIE	Not possible
SCIn_RXI (n = 0 to 4, 9)	Receive data full	CSR.RDRF	CCR0.RIE	Possible
	Receive data ready	FRSR.DR (when FCR.DRES = 0)	CCR0.RIE	Possible
	Address match	CSR.DCMF	CCR0.RIE	Possible
SCIn_TXI (n = 0 to 4, 9)	Transmit data empty	CSR.TDRE	CCR0.TIE	Possible
	TE=0->1 detection			
SCIn_TEI (n = 0 to 4, 9)	Transmit end	CSR.TEND	CCR0.TEIE	Not possible

Note: Only SCI0 supports Manchester mode.

28.12.3 Interrupts in Smart Card Interface Mode

Table 28.45 lists interrupt sources in smart card interface mode. A transmit end interrupt (SCIn_TEI) request and an address match (SCIn_AM) request cannot be used in this mode.

Table 28.45 SCI Interrupt sources in Smart Card Interface Mode

Name	Interrupt source	Interrupt flag	Interrupt enable	DTC or DMAC activation
SCIn_ERI (n = 0 to 4, 9)	Receive error or error signal detection	CSR.ORER, CSR.PER, CSR.ERS	CCR0.RIE	Not possible
SCIn_RXI (n = 0 to 4, 9)	Receive data full	CSR.RDRF	CCR0.RIE	Possible
SCIn_TXI (n = 0 to 4, 9)	Transmit data empty	CSR.TEND	CCR0.TIE	Possible
	When set TE = 0->1			

Data transmission or reception using the DTC or DMAC is also possible in smart card interface mode, similar to normal SCI mode. In transmission, when the CCR0.TEND flag is set to 1, an SCIn_TXI interrupt request is generated. This SCIn_TXI interrupt request activates the DTC or DMAC, allowing transfer of transmit data if the SCIn_TXI request is previously specified as a source of DTC or DMAC activation. The TEND flag is automatically set to 0 when the DTC or DMAC transfers the data.

If an error occurs, the SCI automatically retransmits the same data. During the retransmission, the TEND flag is kept at 0 and the DTC or DMAC is not activated. Therefore, the SCI and DTC or DMAC automatically transmit the specified

number of bytes, including retransmission after an error occurrence. However, the CSR.ERS flag is not automatically set to 0 at error occurrence. Therefore, the ERS flag must be cleared by previously setting the CCR0.RIE bit to 1 to enable an SCIn_ERI interrupt request to be generated at error occurrence.

When transmitting or receiving data using the DTC or DMAC, always enable the DTC or DMAC before making the SCI settings. For DTC or DMAC settings, see [section 17, Data Transfer Controller \(DTC\)](#), [section 16, DMA Controller \(DMAC\)](#).

In reception, an SCIn_RXI interrupt request is generated when receive data is set to the RDR register. This SCIn_RXI interrupt request activates the DTC or DMAC, allowing transfer of the receive data if the SCIn_RXI request is previously specified as a source of DTC or DMAC activation. If an error occurs, the error flag is set. Therefore, the DTC or DMAC is not activated and an SCIn_ERI interrupt request is issued to the CPU instead. The error flag must be cleared.

28.12.4 Interrupts in Simple IIC Mode

[Table 28.46](#) lists the interrupt sources in simple IIC mode. The STI interrupt is allocated to the transmit end interrupt (SCIn_TEI) request. The receive error interrupt (SCIn_ERI) and the address match (SCIn_AM) request cannot be used.

The DTC or DMAC can also be used to handle transfer in simple IIC mode.

When the ICR.IICINTM bit is 1:

- An SCIn_RXI request is generated on the falling edge of the SCLn signal for the 8th bit. If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.
- An SCIn_TXI request is generated on the falling edge of the SCLn signal for the 9th bit (acknowledge bit). If SCIn_TXI is previously set up as an activation source for the DTC or DMAC, the SCIn_TXI request activates the DTC or DMAC to handle transfer of the transmit data.

When the ICR.IICINTM bit is 0:

- An SCIn_RXI request (ACK detection) is generated if the input on the SDAn pin is low on the rising edge of the SCLn signal for the 9th bit (acknowledge bit)
- An SCIn_TXI request (NACK detection) is generated if the input on the SDAn pin is high on the rising edge of the SCLn signal for the 9th bit (acknowledge bit)
- If SCIn_RXI is previously set up as an activation source for the DTC or DMAC, the SCIn_RXI request activates the DTC or DMAC to handle transfer of the received data.

If the DTC or DMAC is used for data transfer in reception or transmission, always set up and enable the DTC or DMAC before setting up the SCI.

When the IICSTAREQ, IICRSTAREQ, and IICSTPREQ bits in ICR are used to generate a start condition, restart condition, or stop condition, the STI request is issued when generation is complete.

Table 28.46 SCI interrupt sources in Simple IIC Mode

Name	Interrupt source		Interrupt flag	Interrupt enable	DTC or DMAC activation
	ICR.IICINTM = 1	ICR.IICINTM = 0			
SCIn_RXI (n = 0 to 4, 9)	Reception end	—	—	CCR0.RIE	Possible* ¹
	—	ACK detection	—		Possible
SCIn_TXI (n = 0 to 4, 9)	Transmission end	—	—	CCR0.TIE	Possible* ¹
	—	NACK detection	—		Possible
SCIn_TEI(STIn) (n = 0 to 4, 9)	Completion of generation of a start, restart, or stop condition		ICR.IICSTIF	CCR0.TEIE	Not possible

Note 1. If the DMAC or DTC are being used, you cannot confirm whether ACK or NACK.

28.12.5 Interrupts in Simple LIN mode

[Table 28.47](#) lists interrupt sources in Simple LIN mode.

Table 28.47 SCI interrupt sources in Simple LIN mode

Name	Interrupt Sources	Interrupt Flag	Flag the needs to be confirmed	Interrupt Enable	DTC/DMAC Activation
SCIn_ERI (n = 0, 1)	Receive error	CSR.ORER, CSR.FER, CSR.PER	—	CCR0.RIE	Not Possible
		XSR0.BCDF		XCR0.BCDIE	
		XSR0.COF		CCR0.RIE, XCR0.COFIE	
SCIn_RXI(n = 0, 1)	Receive data full flag	CSR.RDRF	XSR0.CF0MF XSR0.CF1MF XSR0.PIBDF	CCR0.RIE	XSR0.SFSF = 0: Possible XSR0.SFSF = 1: Not Possible
SCIn_AED (n = 0, 1)	Active edge detection	XSR0.AEDF	—	XCR0.AEDIE	Possible
SCIn_TXI(n = 0, 1)	Transmit data empty interrupt	CSR.TDRE	—	CCR0.TIE	Possible
	When set TE = 0->1				
	Break Field output completion	XSR0.BFOF		CCR0.TIE, XCR0.BFOIE	
SCIn_TEI(n = 0, 1)	Transmit end	CSR.TEND	—	CCR0.TEIE	Not Possible
SCIn_BFD(n = 0, 1)	Break Field Detection	XSR0.BFDF	—	XCR0.BFDIE	Not Possible (Unnecessary)

In Simple LIN mode, in addition to reception errors (ORER, FER, PER), an SCIn_ERI interrupt request is output when a bus conflict is detected during transmission, or when a counter overflow of the Simple LIN module occurs. At this time, a SCIn_RXI interrupt request is not output. The SCIn_ERI interrupt request can be canceled by clearing all the flags.

When transmitting Start Frame, if CCR0.TIE = 1 and XCR0.BFOIE = 1, a SCIn_TXI interrupt request is output when Break Field transmission is completed. When Control Field 0 data is written to the TDR register, data transmission starts. Therefore, transmission using DTC or DMAC is possible.

Set CCR0.TEIE = 1 after writing the last transmit data to the TDR register and transmission starts.

During Start Frame reception (XSR0.SFSF = 1), reception using DTC or DMAC by SCIn_RXI interrupt is not possible. Check the CSR register and XSR0 register, check the reception status (See [Figure 28.83](#)), and then clear the flag. Also read the RDR register (if you do not need to check the received data value, clear the RDRF flag without reading the RDR register). When reception of Control Field 1 is completed (XSR0.CF1MF = 1), Start Frame detection is disabled (XSR0.SFSF = 0) and reception using DTC or DMAC is possible. Be sure to read the RDR register.

When Start Frame / Break Field detection is enabled (XCR1.SDST = 1), if a Break Field longer than the period set in XCR2.BFLW [15:0] is received, the BFDF flag is set and a SCIn_BFD interrupt request is output. Then SCI becomes the Start Frame reception state. Clear the BFDF flag.

When Start Frame / Break Field detection is enabled (XCR1.SDST = 1) and the bit rate measurement function is enabled (XCR1.BMEN = 1), an SCIn_AED interrupt factor is output when an active edge is detected. Read the timer count capture value (XSR1.TCNT [15:0]).

28.13 Event Linking

By using interrupt request signals as event signals, the SCIn can provide linked operation through the ELC for modules selected in advance.

Event signals can be output regardless of the values of the associated interrupt request enable bits.

(1) Error event output (receive error or error signal detected) (SCIn_ERI, n = 0 to 4, 9)

- Indicates abnormal termination because of a parity error during reception in Asynchronous mode
- Indicates abnormal termination because of a framing error during reception in Asynchronous mode
- Indicates abnormal termination because of an overrun error during reception
- Indicates abnormal termination due to a Manchester error during reception (Only in Manchester mode).

- Indicates that a preface error occurred upon reception and abnormal termination occurred (only in Manchester mode and MCR.PFEREN = 1).
- Indicates that a start bit error occurred during reception and abnormal termination occurred (only in Manchester mode and MCR.SBEREN = 1).
- Indicates that a reception sync error occurred during reception and abnormal termination occurred (only in Manchester mode and only when MCR.SYEREN = 1).
- Indicates detection of the error signal during transmission in smart card interface mode
- The CSR.FER and PER flags are 0, and receive data less than the receive FIFO data trigger number is set in a reception FIFO buffer, and it indicates that 15 etus elapse when FIFO is selected and the FCR.DRES bit is 1
- In Simple LIN mode, indicates that the 16-bit counter in the Simple LIN module has overflowed.
- In Simple LIN mode, a bus collision is detected during transmission (CCR0.TE = 1).

(2) Receive data full event output (SCIn_RXI, n = 0 to 4, 9)

- Indicates that ACK is detected if the ICR.IICINTM bit is 0 in simple IIC mode
- Indicates that the 8th-bit SCLn falling edge is detected if the ICR.IICINTM bit is 1 in simple IIC mode
- When the ICR.IICINTM bit is 1 during master transmission in simple IIC mode, set the ELC so that receive data full events are not used

Non-FIFO selected

- Indicates that received data is set in the Receive Data Register (RDR).

FIFO selected

- Using this event output is prohibited.

(3) Transmit data empty event output (SCIn_TXI, n = 0 to 4, 9)

- Indicates that the CCR0.TE bit is changed from 0 to 1
- Indicates that transmission is complete in smart card interface mode
- Indicates that NACK is detected if the ICR.IICINTM bit is 0 in simple IIC mode
- Indicates that the 9th-bit SCLn falling edge is detected if the ICR.IICINTM bit is 1 in simple IIC mode
- In Simple LIN mode, indicates that Break Field output is complete.

Non-FIFO selected

- Indicates that transmit data is transferred from the Transmit Data Register (TDR) to the Transmit Shift Register (TSR).

FIFO selected

- Using this event output is prohibited.

(4) Transmit end event output (SCIn_TEI, n = 0 to 4, 9)

- Indicates the completion of transmission
- Indicates that the starting condition, resumption condition, or termination condition is generated in simple IIC mode
- In Smart Card mode, the transmit end event is not output.

Note: When FIFO is selected, using this event output is prohibited

(5) Address match event output (SCIn_AM, n = 0 to 4, 9)

- Indicates a match of the comparison data (CCR4.CMPD) with one frame of receive data when CCR0.DCME is set to 1 in Asynchronous mode, including multi-processor mode.

(6) Active edge detection event output (SCIn_AED, n= 0, 1)

- In Simple LIN mode, when CCR1.BMEN is 1, it indicates that a valid edge has been detected in the RXD input signal.

28.14 Noise Cancellation Function

Figure 28.113 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a 2-stage flip-flop circuit and a match detection circuit. When the input signals of the noise filter and the output signals of the 2-stage flip-flop circuits completely match, the matched level is conveyed as an internal signal. Unless otherwise matched, the previous value is retained. When the same level is retained for 3 cycles or longer on the sampling clock of the noise filter, it is considered as a valid receive signal. A change in pulse for 3 cycles or shorter is considered as noise, not as a receive signal. (When CCR1.NFM = 0)

When CCR2.ABCSE2 = 1 in asynchronous mode, the above noise cancellation cannot be used because one bit has only 4 base clocks. Therefore, only in this case, set the noise cancellation mode to transmit the majority value internally by a majority vote of 3 sampling values instead of matching 3 consecutive sampling values. (CCR1.NFM = 1)

In Asynchronous mode, Manchester and Simple LIN modes, the noise cancellation function can be applied to the receive signal input to the RXDn pin. The sampling period of the noise filter can be selected from the base clock period and the divided clock of the baud rate generator clock source by CCR1.NFCS[2:0].

- When CCR1.NFCS[2:0] = 000b, CCR2.ABCS = 0 and CCR2.ABCSE = 0, the cycle is 1/16 of a 1-bit period.
- When CCR1.NFCS[2:0] = 000b, CCR2.ABCS = 1 and CCR2.ABCSE = 0, the cycle is 1/8 of a 1-bit period.
- When CCR1.NFCS[2:0] = 000b, CCR2.ABCSE = 1, the cycle is 1/6 of a 1-bit period.
- When CCR1.NFCS[2:0] = 000b, CCR2.ABCSE2 = 1, the cycle is 1/4 of a period 1 transfer bit.
- For the CCR1.NFCS value, select “000b” or “001b” if ABCSE = 1 or ABCSE2 = 1. At least, the sampling period of Noise Filter should not be greater than the base clock due to the CCR2.BRR setting value.

In simple IIC mode, this function can be used for each input on SDAn and SCLn. The sampling clock is selected from divided clock of baud rate generator settings by CCR1.NFCS[2:0].

If the base clock is stopped once with the noise filter enabled and then the base clock input is restarted again, the noise filter operation resumes from the state where the clock was stopped. When CCR0.TE and CCR0.RE are set to 0 during base clock input, all of the noise filter flip-flop values are initialized to 1. Accordingly, if the input data is 1 when reception operation resumes, the function determines that a level match is detected and the result is conveyed as an internal signal. If the input data is 0, the Noise Filter output holds its initial value until all three sampled pin levels match (CCR1.NFM = 0) or two or more match (CCR1.NFM = 1).

Figure 28.113 Digital noise filter circuit block diagram

28.15 RS-485 Driver Control Function

Setting the DEN bit in the SCI common control register3 (CCR3) to 1 enables the RS-485 driver control function and generates a DEN (Driver Enable) signal that enables the external transceiver transmission mode. The DEN signal outputs a valid level for the period with driver assertion time and driver negate time added before and after data transmission. The DEN signal valid level is set by the DEPOL bit in the driver control register (DCR).

The driver assertion time is the time from when the DEN signal is valid until the start bit starts. Set by DEAST [4:0] of driver control register (DCR).

The driver negate time is the time from the end of the last stop bit of the transmitted message to the invalidation of the DEN signal. Set with DENG [4:0] of the driver control register (DCR).

DEAST and DENG are expressed in base clock period (1/4, 1/6, 1/8, or 1/16 bit period, see Table 28.6). For details, see section 28.2.13. DCR : Driver Control Register.

When this function is used (CCR3.DEN = 1), the CSR.TEND set timing and SCIn_TEI interrupt output timing are at the end of the driver negation time.

When transmission is completed and the next transmission data is not written before the DEN signal is negated, the DEN signal is negated once. If the timing for writing the next transmit data is not in time, assert the DEN signal after negating it again, insert the driver assertion time, and transmit the next data. If you want to perform the next transmission with the DEN signal asserted, write the next transmission data to the TDR quickly enough in consideration of the synchronization delay time of the register.

Figure 28.114 The image waveform for RS-485 driver control DE signal output

28.16 Loopback Function

The loopback function can be used in Asynchronous mode with the internal clock, and Manchester mode with the internal clock, and Clock synchronous mode with the internal clock.

When 1 is written to the SPLP bit in the CCR1 register, SCI blocks the external input (RXDn) path and connects the output path of the transmit data register and the input path of the receive data register.

When this function is used with TINV bit = 1, inversion of transmission data becomes reception data. However, this function can be used with TINV = 1 only when operating in clock synchronous mode internal clock.

Table 28.48 shows the relationship between the TINV and SPLP bit settings and the received data.

Table 28.48 TINV and SPLP bit settings and received data

CCR1.TINV	CCR1.SPLP	Receive Data	Communication mode		
			Asynchronous	Manchester	Clock synchronous
			internal clock	internal clock	internal clock
—	0	Receive Data from RXDn pin	Possible	Possible	Possible
0	1	Transmit Data	Possible	Possible	Possible
1	1	Inverted transmit data	Impossible	Impossible	Possible

Note: —: don't care

Figure 28.115 shows the configuration of the shift register input / output path in loopback mode.

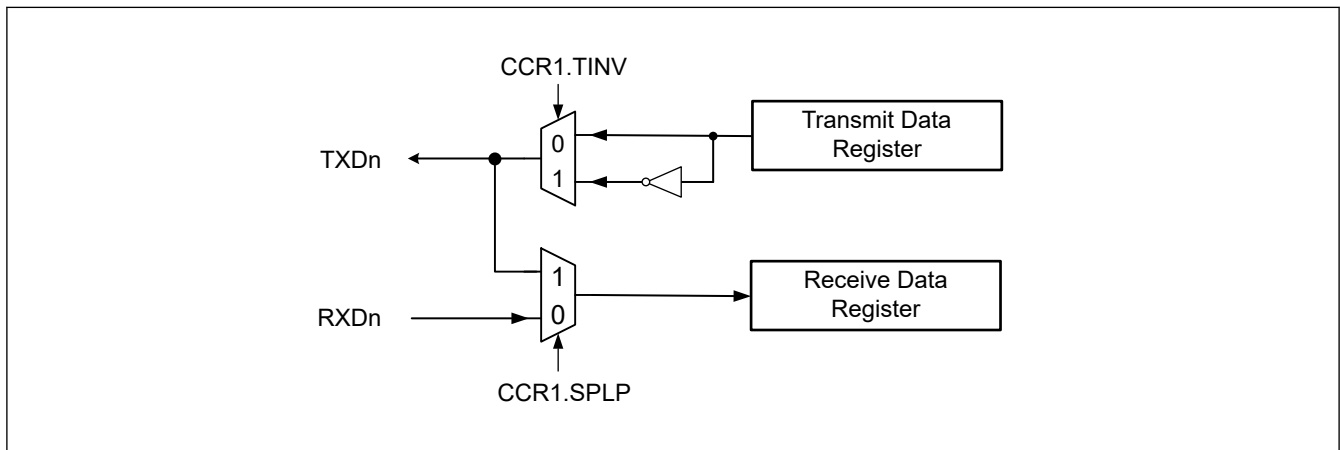

Figure 28.115 Shift register input output configuration image in loopback mode

28.17 Half-Duplex communication Function

Do not use the half-duplex communication function in Simple IIC, Simple SPI and Smart Card Interface modes.

In other communication modes, if the CCR1.SHARPS bit is set to 1, half-duplex communication using the TXDn pin is possible. When half-duplex communication is used, transmission and reception must be performed exclusively. Transmission and reception settings (CCR0.TE = 1 and CCR0.RE = 1) is prohibited.

However, if half-duplex communication is performed as the master reception in clock synchronous mode, perform transmission / reception settings (CCR0.TE = 1 and CCR0.RE = 1) and perform dummy transmission. By dummy transmission (arbitrary transmission data is written to TDR), SCKn is output and reception is enabled. The dummy transmission data is discarded inside the SCI and is not actually transmitted.

During half-duplex communication, only the TXDn pin is used as the communication pin. Output when CCR0.TE = 1, input when CCR0.TE = 0.

28.18 Synchronizer Bypass Function

The SCI has a bus clock (PCLK) and the operation clock (TCLK). And these have each operating circuit. Therefore, there is a synchronization circuit for signal transfer between different clocks, and synchronization delay time is required for signal propagation between different clocks.

However, the synchronization circuit can be bypassed by the CCR3.BPEN bit only when the same clock is input to the bus clock and the operation clock. In this case, eliminates synchronization delay time and improves responsiveness. Figure 28.116 shows the image waveform of the bypass function.

The SCI also has a synchronization circuit between the communication clock (SCKn) and the operation clock (TCLK), but this synchronization circuit cannot be bypassed.

Figure 28.116 Image waveform of Synchronizer bypass function

28.19 Usage Notes

28.19.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable SCI operation. The SCI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

28.19.2 SCI Operation during Low Power State

(1) Transmission

Before using the power consumption reduction function to reduce SCI's power consumption, do the following to confirm transmission end (CSR.TEND = 1):

- Set the output pin state after transmission operation is stopped by CCR1.SPB2DT, SPB2IO.
- Stop the transmission (CCR0.TIE = 0, TE = 0, TEIE = 0)

When transitions to these states are made during transmission, the data being transmitted become indeterminate.

To transmit data in the same operation mode after cancellation of the low power consumption state, set the TE bit to 1, read CSR, and write data to TDR sequentially to start data transmission. To transmit data with a different operation mode, initialize the SCI first.

To start transmission using the DMAC or DTC after cancellation from software standby mode, set the CCR0.TE and CCR0.TIE bit to at the same time. Then SCIn_TXI interrupt flag is generated, which causes the DMAC or DTC to write the transmit data, which starts transmission.

Figure 28.117 shows a sample flowchart for transition to software standby mode during transmission. Figure 28.118 and Figure 28.119 show the port pin states during transition to software standby mode.

(2) Reception

Before specifying the module stop state or making a transition to software standby mode, stop the receive operations (CCR0.RE = 0). If transition is made during data reception, the data being received will be invalid.

Figure 28.120 shows a sample flowchart for reception to software standby mode during reception.

Figure 28.117 Example of Flowchart for Transition to Software Standby Mode during Transmission

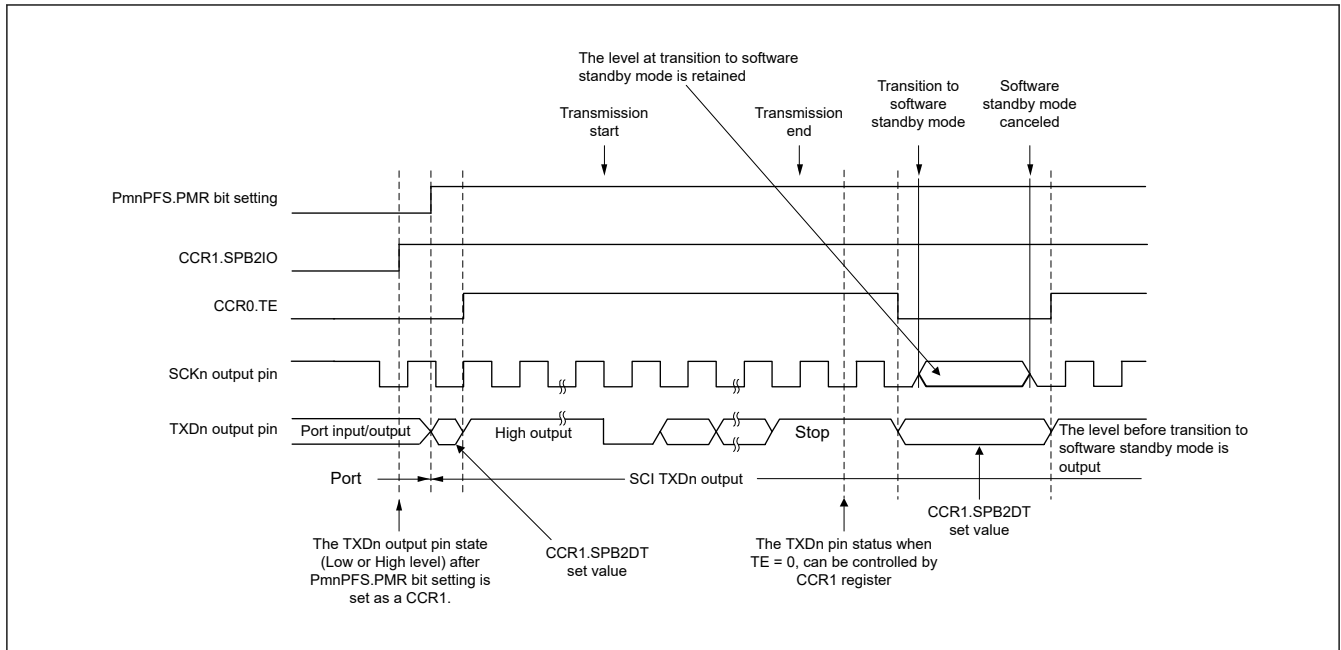

Figure 28.118 Port Pin States during Transition to Software Standby Mode (Internal Clock, Asynchronous Transmission)

Figure 28.119 Port Pin States during Transition to Software Standby Mode (Internal Clock, Clock Synchronous Transmission)

Figure 28.120 Example of Flowchart for Reception to Software Standby Mode during Reception

28.19.3 Break Detection and Processing

(1) Non-FIFO selected

When a framing error is detected, a break can be detected by reading CSR.RXDMON bit value. In a break, the input from the RXDn pin becomes all 0s, and the CSR.FER flag is set to 1 to indicate a framing error, and the CSR.PER flag might also be set to 1 to indicate a parity error. The SCI continues the receive operation even after a break is received. Therefore, even if the FER flag is 0, indicating that no framing error occurred, it is set to 1 again. When the CCR3.RXDESEL bit is 1, the SCI sets the CSR.FER flag to 1 and stops receiving operations until a start bit of the next data frame is detected. If the CSR.FER flag is set to 0, the CSR.FER flag retains 0 during the break.

When the RXDn pin is set to 1 and the break ends, detecting the beginning of the start bit on the first falling edge of the RXDn pin allows the SCI to start the receiving operation.

(2) FIFO selected

After a framing error is detected and when the SCI detects that continuous receive data is 0 for 1 frame, reception stops. When a framing error is detected, a break can be detected by reading the CSR.RXDMON flag value. After the RXDn signal is in high and the break is finished, data reception to the receive-FIFO (RDR) register resumes.

28.19.4 Mark State and Production of Breaks

When the CCR0.TE bit is 0, disabling serial transmission, the state of the TXDn pin can be set using the CCR1.SPB2IO and CCR1.SPB2DT bits. With this approach, a TXDn pin can be placed in the mark state to transmit a break.

Before setting the CCR0.TE bit to 1, enabling serial transmission, set the SPB2IO and SPB2DT bits to put the communication line in the mark state (the state of 1), and change the TXDn pin using I/O port function. To output a break on data transmission, after setting the TXDn pin to output 0 by setting the SPB2IO and SPB2DT bits, change the TXDn pin using the I/O port function and set the CCR0.TE bit to 0. When the CCR0.TE bit is set to 0, the transmitter is initialized regardless of the current state of transmission.

28.19.5 Receive Error Flags and Transmit Operations (Clock Synchronous Mode and Simple SPI Mode)

Transmission can be start by writing transmit-data to TDR even if CSR.ORER is 1. However, reception cannot be started. Note also that the receive error flags cannot be set to 0 even if the CCR0.RE is set to 0 (serial reception is disabled).

28.19.6 Writing Data to TDR

(1) Non-FIFO selected

Data can be written to TDR anytime when CCR0.TE is 1. However, if new data is written to TDR when transmit data is remaining in TDR, the previous data in TDR is lost because it has not been transferred to TSR yet. If you use DTC or DMAC, be sure to write transmit data to TDR in the SCIn_TXI interrupt request handling routine.

(2) FIFO selected

Data can be written to transmit-FIFO(TDR) when CCR0.TE is 1. Check the number of writable data with the FTSR.T [5:0] bit.

28.19.7 Restrictions on Clock Synchronous Transmission (Clock Synchronous Mode and Simple SPI Mode)

When the external clock source is used as a synchronization clock, the following restrictions apply.

(1) Start of transmission

Update TDR by the CPU, DMAC, or DTC and wait at least the following time until the start of the external clock input: (See [Figure 28.121](#))

Take the following time into account: the output AC spec of the MISO pin of this product and the input AC spec of the master reception + 1 PCLK cycle + synchronization delay.

(2) Continuous transmission

Write the next transmit data to TDR before the falling edge^{*1} of the transmit clock for bit 7. Write the transmit data to TDR in consideration of synchronization delay. If the transmit data cannot be written in time, the previous frame data is resent. (See [Figure 28.121](#))

Note 1. When CCR3.CPOL = 1 and CCR3.CPHA = 0, or CCR3.CPOL = 0 and CCR3.CPHA = 1. In the case of CCR3.CPOL = 0 and CCR3.CPHA = 0, or CCR3.CPOL = 1 and CCR3.CPHA = 1, it's the rising edge.

Figure 28.121 Restrictions on Use of External Clock in Clock Synchronous Transmission

28.19.8 Restrictions on Using DMAC or DTC

When using the DMAC or DTC to read RDR, be sure to set the receive data full interrupt (SCIn_RXI) as the activation source of the relevant SCI.

During the operation in transmission / reception using the DMAC or DTC, it should not set transfer information of DMAC or DTC.

28.19.9 Notes on Starting Transfer

At the point where transfer starts when the interrupt status flag (IELSRn.IR flag) in the ICU is 1, follow the procedure in this section to clear interrupt requests before permitting operations (by setting the CCR0.TE or CCR0.RE bit to 1). For details on the interrupt status flag, see [section 13, Interrupt Controller Unit \(ICU\)](#).

1. Confirm that transfer has stopped (the CCR0.TE or CCR0.RE bit is 0)

2. Set the associated interrupt enable bit (CCR0.TIE or CCR0.RIE bit) to 0
3. Read the associated interrupt enable bit (CCR0.TIE or CCR0.RIE bit) to check that it actually becomes 0
4. Set the interrupt status flag, IELSRn.IR, in the ICU to 0

28.19.10 Limitations on Simple SPI Mode

(1) Master mode

- Use a resistor to pull up or pull down the clock line matching the initial settings for the transfer clock set in the CCR3.CPHA and CPOL bits when the CCR0.SSE bit is 1.

This prevents the clock line from being placed in the high-impedance state when the CCR0.TE bit is set to 0 or unexpected edges from being generated on the clock line when the CCR0.TE bit changes from 0 to 1. When the CCR0.SSE bit is 0 in single master mode, pulling up or pulling down the clock line is not required because the clock line is not placed in the high-impedance state even when the SCR.TE bit is set to 0.

- For the clock delay setting (CCR3.CPHA bit is 0), the receive data full interrupt (SCIn_RXI) is generated before the final clock edge on the SCKn pin as indicated in Figure 28.122. If the TE and RE bits in the CCR0 register become 0 before the final edge of the clock signal on the SCKn pin, the SCKn pin is placed in the high-impedance state, so the width of the last clock pulse of the transfer clock is shortened. Additionally, an SCIn_RXI interrupt might lead to the input signal on the SSn pin of a connected slave going to the high level before the final edge of the clock signal on the SCKn pin, leading to incorrect operation of the slave.
- In a multi-master configuration, the SCKn pin output goes to high-impedance while the input on the SSn pin is at the low level if a mode fault error occurs while a character is being transferred, stopping supply of the clock signal to the connected slave. Reset the connected slave to avoid misaligned bits when transfer is restarted.

Figure 28.122 Timing of SCIn_RXI interrupt in simple SPI mode with clock delay

(2) Slave mode

- It takes $1\text{PCLK} + \text{synchronization delay time} + \text{data output delay time (AC spec)}$ from writing the transmit data to the TDR register until the data is output to the RXDn pin. Take these into account when starting external clock input.
- Provide an external clock signal to the master the same as the data length for transfer
- Secure the SSn input setup time (AC spec) from the SSn low-level input to the start of external clock input.
- Control the input on the SSn pin before the start and after the end of data transfer
- When the input level on the SSn pin is to be changed from low to high while a character is being transferred, set the TE and RE bits in the CCR0 register to 0 and, after restoring the settings, restart transfer of the first byte

28.19.11 Notes on Transmit Enable bit (CCR0.TE)

In initial register value, when CCR0.TE = 0, the state of the TXDn pin is high impedance. The TXDn line should not be high impedance by the following one of ways.

1. The pull-up or pull-down resistance is connected to the TXDn line.

2. Set CCR1 and decided level of TXDn terminal during TE is 0.

28.19.12 Notes on Simple LIN mode

In Simple LIN mode (CCR3.MOD[2:0] = 110), the following functions cannot be used.

- Multi-processor communication function
- Bit Rate Modulation function
- Loopback function
- FIFO buffer

28.19.13 Notes on RS-485 Driver Control function

RS-485 Driver control function is valid only in Asynchronous mode.

When RS-485 Driver control function is active (CCR3.DEN = 1), the CSR.TEND set timing / SCIn_TEI output timing changes as follows. Wait for the SCIn_TEI interrupt and set the CCR0.TE bit in SCI to 0.

When RS-485 Driver control function is inactive: When STOP bit output is completed.

When RS-485 Driver control function is active: At the end of DEN negation time.

28.19.14 Notes on Loopback function

The Loopback function is valid in Asynchronous mode with internal clock, in Manchester mode with internal clock and Clock synchronous mode with internal clock.

28.19.15 Notes regarding register access when operation clock (TCLK) is slower than bus clock (PCLK)

If the operating clock (TCLK) is slower than the bus clock (PCLK), the time until this information is transmitted internally after writing to the CCR0.TE and CCR0.RE registers is slower than the bus access time. In particular, when trying to change the setting register after writing 0 and interrupting communication, do not change the setting register before the signal inside the SCI is in the communication stopped state. To prevent this, after setting CCR0.TE and CCR0.RE to 0, check the CESR.TIST and CESR.RIST bits until they are 0 before setting the next register.

28.19.16 Notes on interrupting operation

If 0 is written to CCR0.RE during data reception and the reception operation is interrupted, there is a possibility of an invalid state, do not use the received data (RDR register stored value) and the flag value of each status register. To interrupt the reception operation, stop the interrupt or event link reception side and then write 0 to the CCR0.RE bit.

28.19.17 Notes on CCR3.BPEN bit setting

Set the BPEN bit only once when setting the CCR3 register in the SCI initialization flow.

This bit cannot be changed after the initialization.

When this bit setting is changed, start from the SCI initialization flow again.

29. I²C Bus Interface (IIC)

29.1 Overview

The I²C bus interface (IIC) has 2 channels. The IIC module conforms with and provides a subset of the NXP I²C (Inter-Integrated Circuit) bus interface functions.

Table 29.1 lists the IIC specifications, Figure 29.1 shows a block diagram, and Figure 29.2 shows an example of I/O pin connections to external circuits, with an I²C bus configuration. Table 29.2 lists the I/O pins.

Table 29.1 IIC specifications (1 of 2)

Parameter	Specifications
Communications format	<ul style="list-style-type: none"> I²C-bus format or SMBus format Master or slave mode selectable Automatic securing of the setup times, hold times, and bus-free times for the transfer rate
Transfer rate	<ul style="list-style-type: none"> Fast-mode Plus supported, up to 1 Mbps
SCL clock	For master operation, the duty cycle of the SCL clock is selectable in the range from 4% to 96%
Issuing and detecting conditions	<ul style="list-style-type: none"> Start, restart, and stop conditions are automatically generated Start conditions (including restart conditions) and stop conditions are detectable
Slave address	<ul style="list-style-type: none"> Configurable for up to three different slave addresses 7- and 10-bit address formats supported, including simultaneous use General call addresses, device ID addresses, and SMBus host addresses detectable
Acknowledgment	<ul style="list-style-type: none"> For transmission, automatic loading of the acknowledge bit Transfer of the next transmit data can be automatically suspended on detection of a not-acknowledge bit. For reception, automatic transmission of the acknowledge bit If a wait between the 8th and 9th clock cycles is selected, the software can control the value in the acknowledge field in response to the received value.
Wait function	During reception, the following wait periods are available by holding the SCL clock low: <ul style="list-style-type: none"> Waiting between the eighth and ninth clock cycles Waiting between the ninth clock cycle and the 1st clock cycle of the next transfer
SDA output delay function	Output timing of transmitted data, including the acknowledge bit, can be delayed
Arbitration	<ul style="list-style-type: none"> For multi-master operation: <ul style="list-style-type: none"> SCL clock synchronization is possible when conflict occurs with the SCL signal from another master When issuing the start condition creates conflict on the bus, loss of arbitration is detected by testing for a mismatch between the internal signal for the SDA line and the level on the SDA line In master operation, loss of arbitration is detected by testing for non-matching between the signal on the SDA line and the internal signal for the SDA line Loss of arbitration because the start condition occurs while the bus is busy is detectable, to prevent the issuing of double start conditions Loss of arbitration is detectable on transfer of a not-acknowledge bit because the internal signal for the SDA line and the level on the SDA line do not match Loss of arbitration because a mismatch of internal and line levels for data is detectable in slave transmission
Timeout function	Internal detection of long-interval stops of the SCL clock
Noise cancellation	<ul style="list-style-type: none"> Digital noise filters for both the SCL and SDA signals Programmable window for noise cancellation by the filters
Interrupt sources	<ul style="list-style-type: none"> Transfer error or event occurrence (arbitration-lost, NACK, timeout, start or restart condition, or stop condition) Receive data full, including matching with a slave address Transmit data empty, including matching with a slave address Transmit end
Module-stop function	Module-stop state can be set for each channel to reduce power consumption.
IIC operating modes	<ul style="list-style-type: none"> Master transmit Master receive Slave transmit Slave receive

Table 29.1 IIC specifications (2 of 2)

Parameter	Specifications
Event link function (output)	<ul style="list-style-type: none"> Transfer error or event occurrence (arbitration-lost, NACK, timeout, start or restart condition, or stop condition) Receive data full, including matching with a slave address Transmit data empty, including matching with a slave address Transmit end
Wakeup function*1	CPU can return from Software Standby mode using a wakeup event
TrustZone Filter	Security and Privilege attribution can be set for each channels

Note 1. This function is only available for IIC channel IIC0. IIC1 is not supported.

Figure 29.1 IIC block diagram

Figure 29.2 I/O pin connection to an external circuit (I²C bus configuration example)

The input level of the signals for IIC is CMOS when I²C bus is selected (ICMR3.SMBS = 0), or TTL when SMBus is selected (ICMR3.SMBS = 1).

Table 29.2 IIC I/O pins

Channel	Pin name	I/O	Function
IICn	SCLn	I/O	IICn serial clock I/O pin
	SDAn	I/O	IICn serial data I/O pin

Note: n = 0 to 1

29.2 Register Descriptions

29.2.1 ICCR1 : I²C Bus Control Register 1

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
 IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	ICE	IICRS T	CLO	SOWP	SCLO	SDAO	SCLI	SDAI

Value after reset: 0 0 0 1 1 1 1 1

Bit	Symbol	Function	R/W
0	SDAI	SDA Line Monitor 0: SDAn line is low 1: SDAn line is high	R

Bit	Symbol	Function	R/W
1	SCLI	SCL Line Monitor 0: SCLn line is low 1: SCLn line is high	R
2	SDAO	SDA Output Control/Monitor 0: Read: IIC drives SDA _n pin low Write: IIC drives SDA _n pin low 1: Read: IIC releases SDA _n pin Write: IIC releases SDA _n pin	R/W
3	SCLO	SCL Output Control/Monitor Use an external pull-up resistor to drive the signal high. 0: Read: IIC drives SCLn pin low Write: IIC drives SCLn pin low 1: Read: IIC releases SCLn pin Write: IIC releases SCLn pin	R/W
4	SOWP	SCLO/SDAO Write Protect This bit is read as 1. 0: Write enable SCLO and SDAO bits 1: Write protect SCLO and SDAO bits	W
5	CLO	Extra SCL Clock Cycle Output This bit clears automatically after 1 clock cycle is output. 0: Do not output extra SCL clock cycle (default) 1: Output extra SCL clock cycle	R/W
6	IICRST	I ² C Bus Interface Internal Reset This setting clears the bit counter and the SCLn/SDAn output latch. 0: Release IIC reset or internal reset 1: Initiate IIC reset or internal reset	R/W
7	ICE	I ² C Bus Interface Enable Used in combination with the IICRST bit to select either IIC or internal reset. 0: Disable (SCLn and SDA _n pins in inactive state) 1: Enable (SCLn and SDA _n pins in active state)	R/W

Note: S-TYPE3, P-TYPE3

SDAO bit (SDA Output Control/Monitor) and SCLO bit (SCL Output Control/Monitor)

The SDAO and SCLO bits directly control the SDA_n and SCL_n signals output from the IIC. When writing to these bits, also write 0 to the SOWP bit. Setting these bits results in input to the IIC by the input buffer. When slave mode is selected, a start condition might be detected and the bus might be released, depending on the bit settings.

Do not rewrite these bits during a start condition, stop condition, restart condition, transmission, or reception. Operation after rewriting under these conditions is not guaranteed. When reading these bits, the state of signals output from the IIC can be read.

CLO bit (Extra SCL Clock Cycle Output)

The CLO bit allows output of an extra SCL clock cycle for debugging or error processing. Normally, set this bit to 0. Setting the bit to 1 in a normal communication state causes a communication error. For details on this function, see [section 29.12.2. Extra SCL Clock Cycle Output Function](#).

IICRST bit (I²C Bus Interface Internal Reset)

The IICRST bit initiates an internal state reset of the IIC. Setting this bit to 1 initiates an IIC reset or internal reset. Whether an IIC reset or internal reset is initiated is determined by the settings of this bit in combination with the ICE bit. [Table 29.3](#) lists the IIC resets.

The IIC reset initializes all registers except ICCR1.ICE and ICCR1.IICRST bits and internal states of the IIC. In addition to the internal states of the IIC, the internal reset initializes the following:

- Bit counter (ICMR1.BC[2:0] bits)
- I²C Bus Shift Register (ICDRS)
- I²C Bus Status Registers (ICSR1 and ICSR2)
- SDAO and SCLO Output Control/Monitor (ICCR1.SDAO and ICCR1.SCLO bits)

- I²C Bus Control Register 2 (except ICCR2.BBSY bit)

For the reset conditions for each register, see [section 29.15. State of Registers When Issuing Each Condition](#).

An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the IIC without initializing the port settings and the control and setting registers of the IIC. If the IIC hangs in a low-level output state, resetting the internal states cancels the low-level output state and releases the bus with the SCLn pin and SDAn pin at high impedance.

Note: If an internal reset is initiated using the IICRST bit for a bus hang-up that occurs during communication with the master device in slave mode, the slave and master devices might enter different states, because the bit counter information differs. For this reason, do not initiate an internal reset in slave mode. Initiate recovery processing from the master device. If an internal reset is required because the IIC hangs with the SCLn line in a low-level output state in slave mode, initiate an internal reset, then issue a restart condition from the master device, or issue a stop condition and resume communication from the start condition. If communication is restarted by initiating a reset solely in the slave device without issuing a start or restart condition from the master device, synchronization is lost because the master and slave devices operate asynchronously.

Table 29.3 IIC resets

IICRST	ICE	State	Specifications
1	0	IIC reset	Resets all registers except ICCR1.IICRST and ICCR1.ICE bits, and the internal states of the IIC
	1	Internal reset	Reset the following: <ul style="list-style-type: none"> • ICMR1.BC[2:0] bits • ICSR1, ICSR2, ICDSR registers • SDAO and SCLO Output Control/Monitor (ICCR1.SDAO and ICCR1.SCLO bits) • I²C Bus Control Register 2 (except ICCR2.BBSY bit) • Internal states of the IIC

ICE bit (I²C Bus Interface Enable)

The ICE bit selects the active or inactive state of the SCLn and SDAn pins. It can also be combined with the IICRST bit to initiate two types of resets. See [Table 29.3](#) for the reset descriptions.

Set the ICE bit to 1 when using the IIC. The SCLn and SDAn pins are placed in the active state when the ICE bit is set to 1. Set the ICE bit to 0 when the IIC is not used. The SCLn and SDAn pins are placed in the inactive state when the ICE bit is set to 0. Do not assign the SCLn or SDAn pin to the IIC when setting up the pin function control. Slave address comparison is performed if the pins are assigned to the IIC.

29.2.2 ICCR2 : I²C Bus Control Register 2

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x01

Bit position:	7	6	5	4	3	2	1	0
Bit field:	BBSY	MST	TRS	—	SP	RS	ST	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	ST	Start Condition Issuance Request 0: Do not issue a start condition request 1: Issue a start condition request	R/W
2	RS	Restart Condition Issuance Request 0: Do not issue a restart condition request 1: Issue a restart condition request	R/W

Bit	Symbol	Function	R/W
3	SP	Stop Condition Issuance Request 0: Do not issue a stop condition request 1: Issue a stop condition request	R/W
4	—	This bit is read as 0. The write value should be 0.	R/W
5	TRS	Transmit/Receive Mode 0: Receive mode 1: Transmit mode	R/W ¹
6	MST	Master/Slave Mode 0: Slave mode 1: Master mode	R/W ¹
7	BBSY	Bus Busy Detection Flag 0: I ² C bus released (bus free state) 1: I ² C bus occupied (bus busy state)	R

Note: S-TYPE3, P-TYPE3

Note 1. The MST and TRS bits can be written to when the ICMR1.MTWP bit is set to 1.

ST bit (Start Condition Issuance Request)

The ST bit requests transition to master mode and triggers a start condition. When this bit is set to 1, a start condition is issued when the BBSY flag is set to 0 (bus free state). For details on this function, see [section 29.11. Start, Restart, and Stop Condition Issuing Function](#).

[Setting condition]

- When 1 is written to the ST bit.

[Clearing conditions]

- When 0 is written to the ST bit
- When a start condition is issued (a start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Only set the ST bit to 1 (start condition request) when the BBSY flag is set to 0 (bus free state). Arbitration might be lost if the ST bit is set to 1 (start condition request) when the BBSY flag is 1 (bus busy state).

RS bit (Restart Condition Issuance Request)

The RS bit requests that a restart condition be issued in master mode. When this bit is set to 1 to request a restart condition, a restart condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see [section 29.11. Start, Restart, and Stop Condition Issuing Function](#).

[Setting condition]

- When 1 is written to the RS bit with the BBSY flag in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the RS bit
- When a restart condition is issued (a start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Do not set the RS bit to 1 while issuing a stop condition.

Note: If 1 (restart condition request) is written to the RS bit in slave mode, the restart condition is not issued, but the RS bit remains set to 1. If the operating mode changes to master mode without the bit being cleared, a restart condition might be issued.

SP bit (Stop Condition Issuance Request)

The SP bit requests that a stop condition be issued in master mode. When this bit is set to 1, a stop condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode). For details on this function, see [section 29.11. Start, Restart, and Stop Condition Issuing Function](#).

[Setting condition]

- When 1 is written to the SP bit with both the BBSY flag and the MST bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is written to the SP bit
- When a stop condition is issued (a stop condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When a start condition and a restart condition are detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: Writing to the SP bit is not possible while the BBSY flag is 0 (bus free state).

Note: Do not set the SP bit to 1 while a restart condition is being issued.

TRS bit (Transmit/Receive Mode)

The TRS bit indicates transmit or receive mode. The IIC is in receive mode when the TRS bit is 0 and in transmit mode when the bit is 1. The combination of this bit and the MST bit indicates the IIC operating mode.

The value of the TRS bit automatically changes to 1 for transmit mode or 0 for receive mode when a start condition is issued or detected and the R/W# bit is set. Although writing to the TRS bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not required during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1)
- When a restart condition is issued normally because of a restart condition request (when a restart condition is detected with the RS bit set to 1)
- When the R/W# bit appended to the slave address is set to 0 in master mode
- When the address received in slave mode matches the address enabled in ICSESR, with the R/W# bit set to 1
- When 1 is written to the TRS bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When the R/W# bit appended to the slave address is set to 1 in master mode
- In slave mode, on a match between the received address and the address enabled in ICSESR when the value of the received R/W# bit is 0, including when the received address is the general call address
- In slave mode, when a restart condition is detected (a restart condition is detected with ICCR2.BBSY = 1 and ICCR2.MST = 0)
- When 0 is written to the TRS bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

MST bit (Master/Slave Mode)

The MST bit indicates master or slave mode. The IIC is in slave mode when the MST bit is 0 and is in master mode when the bit is 1. The combination of this bit and the TRS bit indicates the IIC operating mode.

The value of the MST bit automatically changes to 1 for master mode or 0 for slave mode when a start condition is issued or a stop condition is issued or detected. Although writing to the MST bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not required during normal usage.

[Setting conditions]

- When a start condition is issued normally because of a start condition request (when a start condition is detected with the ST bit set to 1)
- When 1 is written to the MST bit with the MTWP bit in ICMR1 set to 1.

[Clearing conditions]

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 0 is written to the MST bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

BBSY flag (Bus Busy Detection Flag)

The BBSY flag indicates whether the I²C bus is occupied (bus busy state) or released (bus free state). The flag is set to 1 when the SDAn line changes from high to low when the SCLn line is high, assuming that a start condition was issued. The flag is set to 0 if a start condition is not detected for the bus free time (ICBRL setting), assuming that a stop condition was issued.

[Setting condition]

- When a start condition is detected.

[Clearing conditions]

- When a start condition is not detected for the bus free time (ICBRL setting) after detecting a stop condition
- When 1 is written to the IICRST bit in ICCR1 with the ICE bit in ICCR1 set to 0 (IIC reset).

29.2.3 ICMR1 : I²C Bus Mode Register 1

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
 IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x02

Bit	Symbol	Function	R/W
2:0	BC[2:0]	Bit Counter 0 0 0: 9 bits 0 0 1: 2 bits 0 1 0: 3 bits 0 1 1: 4 bits 1 0 0: 5 bits 1 0 1: 6 bits 1 1 0: 7 bits 1 1 1: 8 bits	R/W ^{*1}
3	BCWP	BC Write Protect This bit is read as 1. 0: Write enable BC[2:0] bits 1: Write protect BC[2:0] bits	W ^{*1}
6:4	CKS[2:0]	Internal Reference Clock Select Select the internal reference clock source (IICφ) for the IIC. IICφ = (PCLKB / 2 ^{CKS[2:0]}) clock	R/W
7	MTWP	MST/TRS Write Protect 0: Write protect MST and TRS bits in ICCR2 1: Write enable MST and TRS bits in ICCR2	R/W

Note: S-TYPE3, P-TYPE3

Note 1. Rewrite the BC[2:0] bits and set the BCWP bit to 0 at the same time.

BC[2:0] bits (Bit Counter)

The BC[2:0] bits function as a counter indicating the number of bits remaining to be transferred on detection of a rising edge on the SCLn line. Although BC[2:0] are read/write bits, it is not required to access these bits under normal conditions.

To write to these bits, specify the number of bits to be transferred plus one, for an additional acknowledge bit, between transferred frames when the SCLn line is at a low level. The value in the BC[2:0] bits returns to 000b at the end of a data transfer, including the acknowledge bit, or when a start or restart condition is detected.

29.2.4 ICMR2 : I²C Bus Mode Register 2

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x03

Bit position:	7	6	5	4	3	2	1	0
Bit field:	DLCS	SDDL[2:0]			—	TMOH	TMOL	TMOS
Value after reset:	0	0	0	0	0	1	1	0

Bit	Symbol	Function	R/W
0	TMOS	Timeout Detection Time Select 0: Select long mode 1: Select short mode	R/W
1	TMOL	Timeout L Count Control 0: Disable count while SCLn line is low 1: Enable count while SCLn line is low	R/W
2	TMOH	Timeout H Count Control 0: Disable count while SCLn line is high 1: Enable count while SCLn line is high	R/W
3	—	This bit is read as 0. The write value should be 0.	R/W
6:4	SDDL[2:0]	SDA Output Delay Counter 0 0 0: No output delay 0 0 1: 1 IICφ cycle (When ICMR2.DLCS = 0 (IICφ)) 1 or 2 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) 0 1 0: 2 IICφ cycles (When ICMR2.DLCS = 0 (IICφ)) 3 or 4 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) 0 1 1: 3 IICφ cycles (When ICMR2.DLCS = 0 (IICφ)) 5 or 6 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) 1 0 0: 4 IICφ cycles (When ICMR2.DLCS = 0 (IICφ)) 7 or 8 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) 1 0 1: 5 IICφ cycles (When ICMR2.DLCS = 0 (IICφ)) 9 or 10 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) 1 1 0: 6 IICφ cycles (When ICMR2.DLCS = 0 (IICφ)) 11 or 12 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2)) 1 1 1: 7 IICφ cycles (When ICMR2.DLCS = 0 (IICφ)) 13 or 14 IICφ cycles (When ICMR2.DLCS = 1 (IICφ/2))	R/W
7	DLCS	SDA Output Delay Clock Source Select 0: Select internal reference clock (IICφ) as the clock source for SDA output delay counter 1: Select internal reference clock divided by 2 (IICφ/2) as the clock source for SDA output delay counter ^{*1}	R/W

Note: S-TYPE3, P-TYPE3

Note 1. The setting DLCS = 1 (IICφ/2) is only valid when SCL is low. When SCL is high, the DLCS = 1 setting becomes invalid and the clock source becomes the internal reference clock (IICφ).

TMOS bit (Timeout Detection Time Select)

The TMOS bit selects long or short mode for the timeout detection time when the timeout function is enabled (ICFER.TMOE = 1). When this bit is set to 0, long mode is selected. When it is set to 1, short mode is selected. In long mode, the timeout detection internal counter functions as a 16 bit-counter. In short mode, the counter functions as a

14-bit counter. While the SCLn line is in the state that enables this counter as specified in the TMOH and TMOL bits, the counter counts up in synchronization with the internal reference clock (IIC ϕ) as a count source. For details on this function, see [section 29.12.1. Timeout Function](#).

TMOL bit (Timeout L Count Control)

The TMOL bit enables or disables up-counting on the internal counter of the timeout function while the SCLn line is held low and the timeout function is enabled (ICFER.TMOE = 1).

TMOH bit (Timeout H Count Control)

The TMOH bit enables or disables up-counting on the internal counter of the timeout function while the SCLn line is held high and the timeout function is enabled (ICFER.TMOE = 1).

SDDL[2:0] bits (SDA Output Delay Counter)

The SDDL[2:0] bits can be used to delay the SDA output. This counter works with the clock source selected in the DLCS bit. This setting can be used for all types of SDA output, including transmission of the acknowledge bit.

Set the SDA output delay to meet the I²C bus standard for the data enable time/acknowledge enable time,^{*1} or the SMBus standard, within [data hold time (300 ns or more + the SCL clock low-level period) - the data setup time (250 ns)]. If a value outside the standard is set, communication between devices might malfunction or falsely indicate a start or stop condition, depending on the bus state.

For details on this function, see [section 29.5. SDA Output Delay Function](#).

Note 1. Data enable time/acknowledge enable time.

3,450 ns for up to 100 kbps: Standard mode (Sm)

900 ns for up to 400 kbps: Fast mode (Fm)

450 ns for up to 1 Mbps: Fast-mode Plus (Fm+)

29.2.5 ICMR3 : I²C Bus Mode Register 3

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SMBS	WAIT	RDRF S	ACKW P	ACKB T	ACKB R	NF[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	NF[1:0]	Noise Filter Stage Select 0 0: Filter out noise of up to 1 IIC ϕ cycle (single-stage filter) 0 1: Filter out noise of up to 2 IIC ϕ cycles (2-stage filter) 1 0: Filter out noise of up to 3 IIC ϕ cycles (3-stage filter) 1 1: Filter out noise of up to 4 IIC ϕ cycles (4-stage filter)	R/W
2	ACKBR	Receive Acknowledge 0: 0 received as the acknowledge bit (ACK reception) 1: 1 received as the acknowledge bit (NACK reception)	R
3	ACKBT	Transmit Acknowledge 0: Send 0 as the acknowledge bit (ACK transmission) 1: Send 1 as the acknowledge bit (NACK transmission)	R/W ^{*1}
4	ACKWP	ACKBT Write Protect 0: Write protect ACKBT bit 1: Write enable ACKBT bit	R/W

Bit	Symbol	Function	R/W
5	RDRFS	RDRF Flag Set Timing Select Low-hold is released by writing to ACKBT. 0: Set the RDRF flag on the rising edge of the 9th SCL clock cycle. The SCLn line is not held low on the falling edge of the 8th clock cycle. 1: Set the RDRF flag on the rising edge of the 8th SCL clock cycle. The SCLn line is held low on the falling edge of the 8th clock cycle.	R/W ²
6	WAIT	Low-hold is released by reading ICDRR. 0: No wait (The SCLn line is not held low during the period between the 9th clock cycle and the 1st clock cycle.) 1: Wait (The SCLn line is held low during the period between the 9th clock cycle and the 1st clock cycle.)	R/W ²
7	SMBS	SMBus/I ² C Bus Select 0: Select I ² C Bus 1: Select SMBus	R/W

Note: S-TYPE3, P-TYPE3

Note 1. Write to the ACKBT bit only while the ACKWP bit is already 1. If the application writes 1 to the ACKWP and ACKBT bits at the same time, the ACKBT bit is not set to 1.

Note 2. The WAIT and RDRFS bits are only valid in receive mode (invalid in transmit mode).

NF[1:0] bits (Noise Filter Stage Select)

The NF[1:0] bits select the number of stages in the digital noise filter. For details on this function, see [section 29.6. Digital Noise Filter Circuits](#)

Note: Set the noise range to be filtered within a range less than the SCLn line high- or low-level period. If the noise range is set to a value of [SCL clock width: high- or low-level period, whichever is shorter] - [1.5 internal reference clock (IIC ϕ) cycles + analog noise filter: 120 ns (reference values)] or more, the SCL clock is regarded as noise, which might prevent the IIC from operating normally.

ACKBR bit (Receive Acknowledge)

The ACKBR bit stores the acknowledge bit information received from the receive device in transmit mode.

[Setting condition]

- When 1 is received as the acknowledge bit with the TRS bit in ICCR2 set to 1.

[Clearing conditions]

- When 0 is received as the acknowledge bit with the TRS bit in ICCR2 set to 1
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

ACKBT bit (Transmit Acknowledge)

The ACKBT bit sets the acknowledge bit to be sent in receive mode

[Setting condition]

- When 1 is written to this bit with the ACKWP bit set to 1.

[Clearing conditions]

- When 0 is written to this bit with the ACKWP bit set to 1
- When stop condition request is detected with the SP bit in ICCR2 set to 1
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (IIC reset).

ACKWP bit (ACKBT Write Protect)

The ACKWP bit controls write enabling of the ACKBT bit.

RDRFS bit (RDRF Flag Set Timing Select)

The RDRFS bit selects the RDRF flag set timing in receive mode and also selects whether to hold the SCLn line low on the falling edge of the 8th SCL clock cycle.

When the RDRFS bit is 0, the SCLn line is not held low on the falling edge of the 8th SCL clock cycle, and the RDRF flag is set to 1 on the rising edge of the 9th SCL clock cycle.

When the RDRFS bit is 1, the RDRF flag is set to 1 on the rising edge of the 8th SCL clock cycle, and the SCLn line is held low on the falling edge of the 8th SCL clock cycle. The low-hold of the SCLn line is released by a write to the ACKBT bit.

After data is received with this setting, the SCLn line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKBT = 0) or NACK (ACKBT = 1), based on the receive data.

WAIT bit (WAIT)

The WAIT bit controls whether to force a low-hold between the ninth SCL clock cycle and the first SCL clock cycle, until the receive data buffer (ICDRR) is completely read each time single-byte data is received in receive mode.

When the WAIT bit is 0, the receive operation continues without a low-hold between the ninth and the first SCL clock cycle. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.

When the WAIT bit is 1, the SCLn line is held low from the falling edge of the ninth clock cycle until the ICDRR value is read each time single-byte data is received. This enables receive operation in byte units.

Note: When the value of the WAIT bit is to be read, always read ICDRR first.

SMBS bit (SMBus/I²C Bus Select)

Setting the SMBS bit to 1 selects the SMBus and enables the HOAE bit in ICSESR.

29.2.6 ICFER : I²C Bus Function Enable Register

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x05

Bit position:	7	6	5	4	3	2	1	0
Bit field:	FMPE	SCLE	NFE	NACK E	SALE	NALE	MALE	TMOE
Value after reset:	0	1	1	1	0	0	1	0

Bit	Symbol	Function	R/W
0	TMOE	Timeout Function Enable 0: Disable 1: Enable	R/W
1	MALE	Master Arbitration-Lost Detection Enable 0: Disable the arbitration-lost detection function and disable automatic clearing of the MST and TRS bits in ICCR2 when arbitration is lost 1: Enable the arbitration-lost detection function and enable automatic clearing of the MST and TRS bits in ICCR2 when arbitration is lost	R/W
2	NALE	NACK Transmission Arbitration-Lost Detection Enable 0: Disable 1: Enable	R/W
3	SALE	Slave Arbitration-Lost Detection Enable 0: Disable 1: Enable	R/W
4	NACKE	NACK Reception Transfer Suspension Enable 0: Do not suspend transfer operation during NACK reception (disable transfer suspension) 1: Suspend transfer operation during NACK reception (enable transfer suspension)	R/W
5	NFE	Digital Noise Filter Circuit Enable 0: Do not use the digital noise filter circuit 1: Use the digital noise filter circuit	R/W
6	SCLE	SCL Synchronous Circuit Enable 0: Do not use the SCL synchronous circuit 1: Use the SCL synchronous circuit	R/W

Bit	Symbol	Function	R/W
7	FMPE*1	Fast-Mode Plus Enable 0: Do not use the Fm+ slope control circuit for the SCLn and SDAn pins 1: Use the Fm+ slope control circuit for the SCLn and SDAn pins.	R/W

Note: S-TYPE3, P-TYPE3

Note 1. The Fast-mode Plus enable bit (FMPE) is supported by IIC0 (SCL0_A, SDA0_A) and IIC1(SCL1_A, SDA1_A). Bit [7] is the reserved bit in the not supported channel.

TMOE bit (Timeout Function Enable)

The TMOE bit enables or disables the timeout function. For details on this function, see [section 29.12.1. Timeout Function](#).

MALE bit (Master Arbitration-Lost Detection Enable)

The MALE bit specifies whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

NALE bit (NACK Transmission Arbitration-Lost Detection Enable)

The NALE bit specifies whether to cause arbitration to be lost when ACK is detected during transmission of NACK in receive mode, for example when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with a different number of receive bytes.

SALE bit (Slave Arbitration-Lost Detection Enable)

The SALE bit specifies whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmit mode, for example when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs because of noise.

NACKE bit (NACK Reception Transfer Suspension Enable)

The NACKE bit specifies whether to continue or discontinue the transfer operation when NACK is received in transmit mode. Normally, set this bit to 1.

When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended. When the NACKE bit is 0, the next transfer operation continues regardless of the received acknowledge content.

For details, see [section 29.9.2. NACK Reception Transfer Suspension Function](#).

SCLE bit (SCL Synchronous Circuit Enable)

The SCLE bit specifies whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1.

When the SCLE bit is set to 0 (no SCL synchronous circuit used), the IIC does not synchronize the SCL clock with the SCL input clock. With this setting, the IIC outputs the SCL clock at the transfer rate set in ICBRH and ICBRL, regardless of the SCLn line state. For this reason, if the bus load of the I²C bus line is much larger than the specification value, or if the SCL clock output overlaps in multiple masters, a short-cycle SCL clock that does not meet the specification might be output. When no SCL synchronous circuit is used, it also affects the issuing of the start, restart, and stop conditions, and the continuous output of extra SCL clock cycles.

Do not set this bit to 0 except when checking the output of the set transfer rate.

FMPE bit (Fast-Mode Plus Enable)

The FMPE bit specifies whether to use a slope control circuit for Fast-mode Plus (Fm+).

When this bit is set to 1, a slope control circuit conforming to the I²C bus Fast-mode Plus (Fm+) standard (tof) is selected. When this bit is set to 0, a slope control circuit conforming to the I²C bus Standard-mode (Sm) and Fast-mode (Fm) standards (tof) is selected.

Set this bit to 1 when using transmission rates up to 1 Mbps (Fast-mode Plus (Fm+) standard). Set it to 0 when using other transmission rates (up to 100 kbps (Sm) or up to 400 kbps (Fm)) or for SMBus (10 to 100 kbps).

29.2.7 IC SER : I²C Bus Status Enable Register

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x06

Bit position:	7	6	5	4	3	2	1	0
Bit field:	HOAE	—	DIDE	—	GCAE	SAR2 E	SAR1 E	SAR0 E
Value after reset:	0	0	0	0	1	0	0	1

Bit	Symbol	Function	R/W
0	SAR0E	Slave Address Register 0 Enable 0: Disable slave address in SARL0 and SARU0 1: Enable slave address in SARL0 and SARU0	R/W
1	SAR1E	Slave Address Register 1 Enable 0: Disable slave address in SARL1 and SARU1 1: Enable slave address in SARL1 and SARU1	R/W
2	SAR2E	Slave Address Register 2 Enable 0: Disable slave address in SARL2 and SARU2 1: Enable slave address in SARL2 and SARU2	R/W
3	GCAE	General Call Address Enable 0: Disable general call address detection 1: Enable general call address detection	R/W
4	—	This bit is read as 0. The write value should be 0.	R/W
5	DIDE	Device-ID Address Detection Enable 0: Disable device-ID address detection 1: Enable device-ID address detection	R/W
6	—	This bit is read as 0. The write value should be 0.	R/W
7	HOAE	Host Address Enable 0: Disable host address detection 1: Enable host address detection	R/W

Note: S-TYPE3, P-TYPE3

SARyE bit (Slave Address Register y Enable) (y = 0 to 2)

The SARyE bit enables or disables the received slave address and the slave address set in SARLy and SARUy.

When this bit is set to 1, the slave address set in SARLy and SARUy is enabled and is compared with the received slave address. When this bit is set to 0, the slave address set in SARLy and SARUy is disabled and is ignored even if it matches the received slave address.

GCAE bit (General Call Address Enable)

The GCAE bit specifies whether to ignore the general call address (0000 000b + 0 [W]: All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the IIC recognizes the received slave address as the general call address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2) and performs the data receive operation. When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

DIDE bit (Device-ID Address Detection Enable)

The DIDE bit specifies whether to recognize and execute the device-ID address when a device ID (1111 100b) is received in the first frame after a start or restart condition is detected.

When this bit is set to 1, if the received first frame matches the device ID, the IIC recognizes that the device-ID address was received. When the next R/W# bit is 0 (W), the IIC recognizes the second and the subsequent frames as slave addresses and continues the receive operation. When this bit is set to 0, the IIC ignores the received first frame even if it matches the device-ID address, and it recognizes the first frame as a normal slave address.

For details on this function, see [section 29.7.3. Device-ID Address Detection](#).

HOAE bit (Host Address Enable)

The HOAE bit specifies whether to ignore the received host address (0001 000b) when the SMBS bit in ICMR3 is 1.

When this bit is set to 1 while the SMBS bit in ICMR3 is 1, if the received slave address matches the host address, the IIC recognizes the received slave address as the host address independently of the slave addresses set in SARLy and SARUy (y = 0 to 2) and performs the receive operation.

When the SMBS bit in ICMR3 or the HOAE bit is set to 0, the received slave address is ignored even if it matches the host address.

29.2.8 ICIER : I²C Bus Interrupt Enable Register

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x07

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TIE	TEIE	RIE	NAKIE	SPIE	STIE	ALIE	TMOIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TMOIE	Timeout Interrupt Request Enable 0: Disable timeout interrupt (TMOI) request 1: Enable timeout interrupt (TMOI) request	R/W
1	ALIE	Arbitration-Lost Interrupt Request Enable 0: Disable arbitration-lost interrupt (ALI) request 1: Enable arbitration-lost interrupt (ALI) request	R/W
2	STIE	Start Condition Detection Interrupt Request Enable 0: Disable start condition detection interrupt (STI) request 1: Enable start condition detection interrupt (STI) request	R/W
3	SPIE	Stop Condition Detection Interrupt Request Enable 0: Disable stop condition detection interrupt (SPI) request 1: Enable stop condition detection interrupt (SPI) request	R/W
4	NAKIE	NACK Reception Interrupt Request Enable 0: Disable NACK reception interrupt (NAKI) request 1: Enable NACK reception interrupt (NAKI) request	R/W
5	RIE	Receive Data Full Interrupt Request Enable 0: Disable receive data full interrupt (IICn_RXI) request 1: Enable receive data full interrupt (IICn_RXI) request	R/W
6	TEIE	Transmit End Interrupt Request Enable 0: Disable transmit end interrupt (IICn_TEI) request 1: Enable transmit end interrupt (IICn_TEI) request	R/W
7	TIE	Transmit Data Empty Interrupt Request Enable 0: Disable transmit data empty interrupt (IICn_TXI) request 1: Enable transmit data empty interrupt (IICn_TXI) request	R/W

Note: S-TYPE3, P-TYPE3

TMOIE bit (Timeout Interrupt Request Enable)

The TMOIE bit enables or disables timeout interrupt (TMOI) requests when the TMOF flag in ICSR2 is 1. To cancel a TMOI interrupt request, set the TMOF flag or the TMOIE bit to 0.

ALIE bit (Arbitration-Lost Interrupt Request Enable)

The ALIE bit enables or disables arbitration-lost interrupt (ALI) requests when the AL flag in ICSR2 is 1. To cancel an ALI interrupt request, set the AL flag or the ALIE bit to 0.

STIE bit (Start Condition Detection Interrupt Request Enable)

The STIE bit enables or disables start condition detection interrupt (STI) requests when the START flag in ICSR2 is 1. To cancel an STI interrupt request, set the START flag or the STIE bit to 0.

SPIE bit (Stop Condition Detection Interrupt Request Enable)

The SPIE bit enables or disables stop condition detection interrupt (SPI) requests when the STOP flag in ICSR2 is 1. To cancel an SPI interrupt request, set the STOP flag or the SPIE bit to 0.

NAKIE bit (NACK Reception Interrupt Request Enable)

The NAKIE bit enables or disables NACK reception interrupt (NAKI) requests when the NACKF flag in ICSR2 is 1. To cancel an NAKI interrupt request, set the NACKF flag or the NAKIE bit to 0.

RIE bit (Receive Data Full Interrupt Request Enable)

The RIE bit enables or disables receive data full interrupt (IICn_RXI) requests when the RDRF flag in ICSR2 is 1.

TEIE bit (Transmit End Interrupt Request Enable)

The TEIE bit enables or disables transmit end interrupt (IICn_TEI) requests when the TEND flag in ICSR2 is 1. To cancel an IICn_TEI interrupt request, set the TEND flag or the TEIE bit to 0.

TIE bit (Transmit Data Empty Interrupt Request Enable)

The TIE bit enables or disables transmit data empty interrupt (IICn_TXI) requests when the TDRE flag in ICSR2 is 1.

29.2.9 ICSR1 : I²C Bus Status Register 1

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	HOA	—	DID	—	GCA	AAS2	AAS1	AAS0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	AAS0	Slave Address 0 Detection Flag 0: Slave address 0 not detected 1: Slave address 0 detected	R/(W) ^{*1}
1	AAS1	Slave Address 1 Detection Flag 0: Slave address 1 not detected 1: Slave address 1 detected	R/(W) ^{*1}
2	AAS2	Slave Address 2 Detection Flag 0: Slave address 2 not detected 1: Slave address 2 detected	R/(W) ^{*1}
3	GCA	General Call Address Detection Flag 0: General call address not detected 1: General call address detected	R/(W) ^{*1}
4	—	This bit is read as 0. The write value should be 0.	R/W
5	DID	Device-ID Address Detection Flag This bit is set to 1 when the first frame received immediately after a start condition is detected matches a value of (device ID (1111 100b) + 0[W]). 0: Device-ID command not detected 1: Device-ID command detected	R/(W) ^{*1}
6	—	This bit is read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
7	HOA	Host Address Detection Flag This bit is set to 1 when the received slave address matches the host address (0001 000b). 0: Host address not detected 1: Host address detected	R/(W) ^{*1}

Note: S-TYPE3, P-TYPE3

Note 1. Only 0 can be written to clear the flag.

AASy flag (Slave Address y Detection flag) (y = 0 to 2)

The AASy flag indicates whether slave address y was detected.

[Setting conditions]

For 7-bit address format (SARUy.FS = 0):

- When the received slave address matches the SVA[6:0] value in SARLy, with the SARyE bit in ICSEr set to 1 (slave address y detection enabled).
The AASy flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

For 10-bit address format (SARUy.FS = 1):

- When the received slave address matches a value of (11110b + SVA[1:0] in SARUy), and the subsequent address matches the SARLy value, with the SARyE bit in ICSEr set to 1 (slave address y detection enabled).
The AASy flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the AASy flag after reading AASy = 1
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

For 7-bit address format (SARUy.FS = 0):

- When the received slave address does not match the SVA[6:0] value in SARLy, with the SARyE bit in ICSEr set to 1 (slave address y detection enabled).
The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

For 10-bit address format (SARUy.FS = 1):

- When the received slave address does not match a value of (11110b + SVA[1:0] in SARUy), with the SARyE bit in ICSEr set to 1 (slave address y detection enabled).
The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When the received slave address matches a value of (11110b + SVA[1:0] in SARUy), and the subsequent address does not match the SARLy value, with the SARyE bit in ICSEr set to 1 (slave address y detection enabled).
The AASy flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

GCA flag (General Call Address Detection Flag)

The GCA flag indicates whether the general call address was detected.

[Setting condition]

- When the received slave address matches the general call address (0000 000b + 0 [W]), with the GCAE bit in ICSEr set to 1 (general call address detection enabled).
The GCA flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the GCA flag after reading GCA = 1
- When a stop condition is detected
- When the received slave address does not match the general call address (0000 000b + 0 [W]), with the GCAE bit in ICSEr set to 1 (general call address detection enabled).
The GCA flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.

- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

DID flag (Device-ID Address Detection Flag)

The DID flag indicates whether the device-ID address was detected.

[Setting condition]

- When the first frame received immediately after a start or restart condition is detected matches a value of (device ID (1111 100b) + 0 [W]), with the DIDE bit in IC SER set to 1 (device-ID address detection enabled).
The DID flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the DID flag after reading DID = 1
- When a stop condition is detected
- When the first frame received immediately after a start or restart condition is detected does not match a value of (device ID (1111 100b)), with the DIDE bit in IC SER set to 1 (device-ID address detection enabled)
The DID flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When the first frame received immediately after a start or restart condition is detected matches a value of (device ID (1111 100b) + 0 [W]), and the second frame does not match any slave address from 0 to 2, with the DIDE bit in IC SER set to 1 (device-ID address detection enabled)
The DID flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

HOA flag (Host Address Detection Flag)

The HOA flag indicates whether the host address was detected.

[Setting condition]

- When the received slave address matches the host address (0001 000b), with the HOAE bit in IC SER set to 1 (host address detection enabled).
The HOA flag is set to 1 on the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions]

- When 0 is written to the HOA flag after reading HOA = 1
- When a stop condition is detected
- When the received slave address does not match the host address (0001 000b), with the HOAE bit in IC SER set to 1 (host address detection enabled)
The HOA flag is set to 0 on the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

29.2.10 ICSR2 : I²C Bus Status Register 2

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x09

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TDRE	TEND	RDRF	NACK F	STOP	START	AL	TMOF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TMOF	Timeout Detection Flag 0: Timeout not detected 1: Timeout detected	R/(W) ¹

Bit	Symbol	Function	R/W
1	AL	Arbitration-Lost Flag 0: Arbitration not lost 1: Arbitration lost	R/(W) ^{*1}
2	START	Start Condition Detection Flag 0: Start condition not detected 1: Start condition detected	R/(W) ^{*1}
3	STOP	Stop Condition Detection Flag 0: Stop condition not detected 1: Stop condition detected	R/(W) ^{*1}
4	NACKF	NACK Detection Flag 0: NACK not detected 1: NACK detected	R/(W) ^{*1}
5	RDRF	Receive Data Full Flag 0: ICDRR contains no receive data 1: ICDRR contains receive data	R/(W) ^{*1}
6	TEND	Transmit End Flag 0: Data being transmitted 1: Data transmit complete	R/(W) ^{*1}
7	TDRE	Transmit Data Empty Flag 0: ICDRT contains transmit data 1: ICDRT contains no transmit data	R

Note: S-TYPE3, P-TYPE3

Note 1. Only 0 can be written, to clear the flag.

TMOF flag (Timeout Detection Flag)

The TMOF flag is set to 1 when the IIC detects a timeout because the SCLn line state remains unchanged for the set period.

[Setting condition]

- When the SCLn line state remains unchanged for the period specified in the ICMR2.TMOH, TMOL, and TMOS bits while the ICFER.TMOE bit is 1 (timeout function enabled) in master or in slave mode and the received slave address matches.

[Clearing conditions]

- When 0 is written to the TMOF flag after reading TMOF = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

AL flag (Arbitration-Lost Flag)

The AL flag indicates that bus mastership was lost in arbitration because of a bus conflict or some other reason when a start condition was issued or an address and data was transmitted. The IIC monitors the level on the SDA_n line during transmission and, if the level on the line does not match the value of the bit being output, is set the value of the AL flag to 1 to indicate that the bus is occupied by another device.

The IIC can also set the AL flag to indicate the detection of arbitration loss during NACK transmission or during data transmission.

[Setting conditions]

When master arbitration-lost detection is enabled (ICFER.MALE = 1):

- When the internal SDA output state does not match the SDA_n line level on the rising edge of the SCL clock except for the ACK period during data transmission in master transmit mode
- When a start condition is detected while the ST bit in ICCR2 is 1 (start condition requested) or the internal SDA output state does not match the SDA_n line level
- When the ST bit in ICCR2 is 1 (start condition requested), with the BBSY flag in ICCR2 set to 1.

When NACK arbitration-lost detection is enabled (ICFER.NALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock in the ACK period during NACK transmission in receive mode.

When slave arbitration-lost detection is enabled (ICFER.SALE = 1):

- When the internal SDA output state does not match the SDAn line level on the rising edge of the SCL clock, except for the ACK period during data transmission in slave transmit mode.

[Clearing conditions]

- When 0 is written to the AL flag after reading AL = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Table 29.4 Relationship between arbitration-lost generation sources and arbitration-lost enable functions

ICFER			ICSR2	Error	Arbitration-lost generation source
MALE	NALE	SALE	AL		
1	x	x	1	Start condition issuance error	When internal SDA output state does not match SDAn line level when a start condition is detected, while the ST bit in ICCR2 is 1
					When ST in ICCR2 is set to 1 while BBSY in ICCR2 is 1
			1	Transmit data mismatch	When transmit data (including slave address) does not match the bus state in master transmit mode
x	1	x	1	NACK transmission mismatch	When ACK is detected during transmission of NACK in master or slave receive mode
x	x	1	1	Transmit data mismatch	When transmit data does not match the bus state in slave transmit mode

x: Don't care

START flag (Start Condition Detection Flag)

The START flag indicates whether a start or restart condition was detected.

[Setting condition]

- When a start or restart condition is detected.

[Clearing conditions]

- When 0 is written to the START flag after reading START = 1
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

STOP flag (Stop Condition Detection Flag)

The STOP flag indicates whether a stop condition was detected.

[Setting condition]

- When a stop condition is detected.

[Clearing conditions]

- When 0 is written to the STOP flag after reading STOP = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

NACKF flag (NACK Detection Flag)

The NACKF flag indicates whether a NACK was detected.

[Setting condition]

- When acknowledge is not received (NACK received) from the receive device in transmit mode, with the NACKE bit in ICFER set to 1 (transfer suspension enabled).

[Clearing conditions]

- When 0 is written to the NACKF flag after reading NACKF = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1, the IIC suspends data transmission and reception. Writing to ICDRT in transmit mode or reading from ICDRR in receive mode with the NACKF flag set to 1 does not enable data transmit or receive operation. To restart data transmission or reception, set the NACKF flag to 0.

RDRF flag (Receive Data Full Flag)

The RDRF flag indicates whether the ICDRR contains receive data.

[Setting conditions]

- When receive data is transferred from ICDRS to ICDRR
The RDRF flag is set to 1 on the rising edge of the eighth or ninth SCL clock cycle (selected in the RDRFS bit in ICMR3).
- When the received slave address matches after a start or restart condition is detected with the TRS bit in ICCR2 set to 0.

[Clearing conditions]

- When 0 is written to the RDRF flag after reading RDRF = 1
- When data is read from ICDRR
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

TEND flag (Transmit End Flag)

The TEND flag indicates completion of transmission.

[Setting condition]

- On the rising edge of the ninth SCL clock cycle while the TDRE flag is 1.

[Clearing conditions]

- When 0 is written to the TEND flag after reading TEND = 1
- When data is written to ICDRT
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

TDRE flag (Transmit Data Empty Flag)

The TDRE flag indicates whether the ICDRT contains transmit data.

[Setting conditions]

- When data is transferred from ICDRT to ICDRS and ICDRT becomes empty
- When the TRS bit in ICCR2 is set to 1
- When the received slave address matches while the TRS bit is 1.

[Clearing conditions]

- When data is written to ICDRT
- When the TRS bit in ICCR2 is set to 0
- When 1 is written to the IICRST bit in ICCR1 to apply an IIC reset or an internal reset.

Note: When the NACKF flag is set to 1 while the NACKE bit in ICFER is 1, the IIC suspends data transmission and reception. In this case, if the TDRE flag is 0 (next transmit data written), data is transferred to the ICDRS register and the ICDRT register becomes empty on the rising edge of the 9th clock cycle, but the TDRE flag does not set to 1.

29.2.11 ICWUR : I²C Bus Wakeup Unit Register

Base address: IIC0WU = 0x4025_E014
IIC0WU_NS = 0x5025_E014

Offset address: 0x02

Bit position:	7	6	5	4	3	2	1	0
Bit field:	WUE	WUIE	WUF	WUACK	—	—	—	WUAF A
Value after reset:	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
0	WUAF A	Wakeup Analog Filter Additional Selection 0: Do not add the wakeup analog filter 1: Add the wakeup analog filter	R/W
3:1	—	These bits are read as 0. The write value should be 0.	R/W
4	WUACK	ACK Bit for Wakeup Mode Choice of four response modes in combination with ICCR1.IICRST and WUACK. See Table 29.5 .	R/W
5	WUF	Wakeup Event Occurrence Flag 0: Slave address not matching during wakeup 1: Slave address matching during wakeup	R/W
6	WUIE	Wakeup Interrupt Request Enable 0: Disable wakeup interrupt request (IIC0_WUI) 1: Enable wakeup interrupt request (IIC0_WUI)	R/W
7	WUE	Wakeup Function Enable 0: Disable wakeup function 1: Enable wakeup function	R/W

Note: S-TYPE3, P-TYPE3

Table 29.5 Wakeup mode

IICRST	WUACK	Operation mode	Description
0	0	Normal wakeup mode 1	ACK response on 9th SCL, and SCL low-hold after 9th SCL.
0	1	Normal wakeup mode 2	No ACK response immediately and SCL low-hold between 8th and 9th SCL. SCL low-hold release and ACK response on 9th SCL.
1	0	Command recovery mode	ACK response on 9th SCL and no SCL low-hold.
1	1	EEP response mode	NACK response on 9th SCL and no SCL low-hold.

WUF flag (Wakeup Event Occurrence Flag)

The WUF flag indicates whether the slave address is matching during wakeup.

[Setting condition]

- When PCLKB is supplied after the slave address of I²C bus is matched with the address whose enable bits of IC SER (except Device ID address) are set to 1 (enable), the bit is set.

[Clearing conditions]

- When 0 is written to the WUF flag after reading WUF = 1 (when WUSYF flag is set to 1).
- When ICCR1.ICE = 0 and IICRST = 1.

29.2.12 ICWUR2 : I²C Bus Wakeup Unit Register 2

Base address: IIC0WU = 0x4025_E014
IIC0WU_NS = 0x5025_E014

Offset address: 0x03

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	WUSY F	WUAS YF	WUSE N
Value after reset:	1	1	1	1	1	1	0	1

Bit	Symbol	Function	R/W
0	WUSEN	Wakeup Function Synchronous Enable 0: IIC asynchronous circuit enable 1: IIC synchronous circuit enable	R/W
1	WUASYF	Wakeup Function Asynchronous Operation Status Flag 0: IIC synchronous circuit enable condition 1: IIC asynchronous circuit enable condition	R
2	WUSYF	Wakeup Function Synchronous Operation Status Flag 0: IIC asynchronous circuit enable condition 1: IIC synchronous circuit enable condition	R
7:3	—	These bits are read as 1. The write value should be 1.	R/W

Note: S-TYPE3, P-TYPE3

WUSEN bit (Wakeup Function Synchronous Enable)

The WUSEN bit is used in combination with the WUASYF flag (or WUSYF flag) to switch between the PCLKB synchronous and asynchronous operation, when the wakeup effective function is enabled (ICWUR.WUE = 1).

The PCLKB operation switches from synchronous to asynchronous operation:

When the ICCR2.BBSY flag is 0, if 0 is written to the WUSEN bit while the WUASYF flag is 0, the reception occurs independently of the operation of PCLKB (with PCLKB stopped) after it switches to the PCLKB asynchronous operation, on wakeup event detection.

The PCLKB operation switches from asynchronous to synchronous operation:

- When 1 is written to the WUSEN bit, with the WUASYF flag at 1, when a wakeup event is detected. After writing 1, the WUASYF flag immediately becomes 0.
- When the stop condition is detected with a wakeup event undetected.

[Setting condition]

- When 1 is written to the WUSEN bit.
- ICCR1.ICE = 0 and IICRST = 1 (IIC reset)
- ICWUR.WUE = 0

[Clearing conditions]

- When 0 is written to the WUSEN bit.

WUASYF flag (Wakeup Function Asynchronous Operation Status Flag)

The WUASYF flag can place the IIC in PCLKB asynchronous operation when the wakeup effective function is enabled (ICWUR.WUE = 1).

[Setting condition]

- When the ICCR2.BBSY flag is 0, and the WUSEN bit is set to 0 with the ICWUR.WUE bit set to 1.

[Clearing conditions]

- When 1 is written to the WUSEN bit after detecting the wake-up event with ICWUR.WUE bit set to 1.

- When a stop condition is detected with WUSEN bit set to 1 before detecting the wake-up event with WUASY flag set to 1 with ICWUR.WUE bit set to 1.
- When you write 1 in the WUSEN bit with the WUASYF flag detected 1 and the wake-up event in the state of ICWUR.WUE = 1.
- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

WUSYF flag (Wakeup Function Synchronous Operation Status Flag)

It is shown that IIC is in the PCLKB synchronous operation at wake-up effective function (ICWUR.WUE = 1). This flag is a value in which the WUASYF flag is always reserved.

[Setting conditions]

- When 1 is written to the WUSEN bit after detecting the wake-up event with ICWUR.WUE bit set to 1 with WUSYF flag set to 0 with ICWUR.WUE bit set to 1.
- When a stop condition is detected with WUSEN bit set to 1 before detecting the wake-up event with WUSYF flag set to 0 with ICWUR.WUE bit set to 1.
- ICCR1.ICE = 0 and ICCRST = 1 (ICC reset)
- ICWUR.WUE = 0.

[Clearing condition]

- When the ICCR2.BBSY flag is 0 with the ICWUR.WUE bit set to 1 after writing 0 to the WUSEN bit.

29.2.13 SARLy : Slave Address Register Ly (y = 0 to 2)

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x0A + 0x02 × y

Bit position:	7	6	5	4	3	2	1	0
Bit field:	SVA[6:0]							SVA0

Value after reset: 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	SVA0	10-bit Address LSB Slave address setting.	R/W
7:1	SVA[6:0]	7-bit Address/10-bit Address Lower Bits Slave address setting.	R/W

Note: S-TYPE3, P-TYPE3

SVA0 bit (10-bit Address LSB)

When the 10-bit address format is selected (SARUy.FS = 1), the SVA0 bit functions as the LSB of a 10-bit address and is combined with the SVA[6:0] bits to form the lower 8 bits of a 10-bit address.

This bit is valid when the SARyE bit in ICSEr is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1. When the SARUy.FS or SARyE bit is 0, the setting in this bit is ignored.

SVA[6:0] bits (7-bit Address/10-bit Address Lower Bits)

When the 7-bit address format is selected (SARUy.FS = 0), the SVA[6:0] bits function as a 7-bit address. When the 10-bit address format is selected (SARUy.FS = 1), these bits combine with the SVA0 bit to form the lower 8 bits of a 10-bit address.

When the SARyE bit in ICSEr is 0, the setting in these bits is ignored.

29.2.14 SARUy : Slave Address Register Uy (y = 0 to 2)

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x0B + 0x02 × y

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	SVA[1:0]		FS
Value after reset:	0	0	0	0	0	0	0	0

2:1	SVA[1:0]	10-bit Address Upper Bits Slave address setting.	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

FS bit (7-bit/10-bit Address Format Select)

The FS bit selects 7- or 10-bit format for slave address y (in SARLy and SARUy).

When the SARyE bit in ICSEr is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 0, the 7-bit address format is selected for slave address y, the SVA[6:0] setting in SARLy is valid, and the SVA[1:0] and SVA0 settings in SARLy are ignored.

When the SARyE bit in ICSEr is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1, the 10-bit address format is selected for slave address y and the SVA[1:0] and SARLy settings are valid.

When the SARyE bit in ICSEr is 0 (SARLy and SARUy disabled), the SARUy.FS setting is invalid.

SVA[1:0] bits (10-bit Address Upper Bits)

When the 10-bit address format is selected (FS = 1), the SVA[1:0] bits function as the upper 2 bits of a 10-bit address.

These bits are valid when the SARyE bit in ICSEr is set to 1 (SARLy and SARUy enabled) and the SARUy.FS bit is 1. When the SARUy.FS or SARyE bit is 0, the setting in these bits is ignored.

29.2.15 ICBRL : I²C Bus Bit Rate Low-Level Register

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x10

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	BRL[4:0]				
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
4:0	BRL[4:0]	Bit Rate Low-Level Period Low-level period of SCL clock.	R/W
7:5	—	These bits are read as 1. The write value should be 1.	R/W

Note: S-TYPE3, P-TYPE3

BRL[4:0] bits (Bit Rate Low-Level Period)

The BRL[4:0] bits set the low-level period of the SCL clock. ICBRL counts the low-level period with the internal reference clock source (IICφ) specified by the CKS[2:0] bits in ICMR1. ICBRL also generates the data setup time for automatic SCL

low-hold operation, see [section 29.9. Automatic Low-Hold Function for SCL](#). When the IIC is used in slave mode, the BRL[4:0] bits must be set to a value longer than the data setup time*¹.

If the digital noise filter is enabled (NFE bit in ICFER is 1), set the BRL[4:0] bits to a value at least one greater than the number of stages in the noise filter. For details on the number of stages, see the description of the NF[1:0] bits in [section 29.2.5. ICMR3 : I²C Bus Mode Register 3](#).

Note 1. Data setup time (t_{SU}: DAT)

250 ns for up to 100 kbps: Standard-mode (Sm)

100 ns for up to 400 kbps: Fast-mode (Fm)

50 ns for up to 1 Mbps: Fast-mode Plus (Fm+)

29.2.16 ICBRH : I²C Bus Bit Rate High-Level Register

Base address: IICn = 0x4025_E000 + 0x0100 × n (n = 0 to 1)
IICn_NS = 0x5025_E000 + 0x0100 × n (n = 0 to 1)

Offset address: 0x11

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	BRH[4:0]				
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
4:0	BRH[4:0]	Bit Rate High-Level Period High-level period of SCL clock.	R/W
7:5	—	These bits are read as 1. The write value should be 1.	R/W

Note: S-TYPE3, P-TYPE3

BRH[4:0] bits (Bit Rate High-Level Period)

The BRH[4:0] bits set the high-level period of SCL clock. BRH[4:0] bits are valid in master mode. If the IIC is used only in slave mode, do not set the BRH[4:0] bits.

ICBRH counts the high-level period with the internal reference clock source (IICφ) specified in the CKS[2:0] bits in ICMR1.

If the digital noise filter is enabled (the NFE bit in ICFER is 1), set these bits to a value at least one greater than the number of stages in the noise filter. For the number of stages in the noise filter, see the description of the NF[1:0] bits in [section 29.2.5. ICMR3 : I²C Bus Mode Register 3](#).

The IIC transfer rate and the SCL clock duty are calculated using the following expressions (1) to (5):

1. ICFER.SCLE = 0

$$\text{Transfer rate} = 1 / [\{ (BRH + 1) + (BRL + 1) \} / IIC\phi^{*1} + tr^{*2} + tf^{*2}]$$

$$\text{Duty cycle} = [tr + \{ (BRH + 1) / IIC\phi \}] / [tr + tf + \{ (BRH + 1) + (BRL + 1) \} / IIC\phi]$$

2. ICFER.SCLE = 1 and ICFER.NFE = 0 and CKS[2:0] = 000b (IICφ = PCLKB)

$$\text{Transfer rate} = 1 / [\{ (BRH + 3) + (BRL + 3) \} / IIC\phi + tr + tf]$$

$$\text{Duty cycle} = [tr + \{ (BRH + 3) / IIC\phi \}] / [tr + tf + \{ (BRH + 3) + (BRL + 3) \} / IIC\phi]$$

3. ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0] = 000b (IICφ = PCLKB)

$$\text{Transfer rate} = 1 / [\{ (BRH + 3 + nf^{*3}) + (BRL + 3 + nf) \} / IIC\phi + tr + tf]$$

$$\text{Duty cycle} = [tr + \{ (BRH + 3 + nf) / IIC\phi \}] / [tr + tf + \{ (BRH + 3 + nf) + (BRL + 3 + nf) \} / IIC\phi]$$

4. ICFER.SCLE = 1 and ICFER.NFE = 0 and CKS[2:0] ≠ 000b

$$\text{Transfer rate} = 1 / [\{ (BRH + 2) + (BRL + 2) \} / IIC\phi + tr + tf]$$

$$\text{Duty cycle} = [tr + \{ (BRH + 2) / IIC\phi \}] / [tr + tf + \{ (BRH + 2) + (BRL + 2) \} / IIC\phi]$$

5. ICFER.SCLE = 1 and ICFER.NFE = 1 and CKS[2:0] ≠ 000b

$$\text{Transfer rate} = 1 / [\{ (BRH + 2 + nf) + (BRL + 2 + nf) \} / IIC\phi + tr + tf]$$

$$\text{Duty cycle} = [tr + \{ (BRH + 2 + nf) / IIC\phi \}] / [tr + tf + \{ (BRH + 2 + nf) + (BRL + 2 + nf) \} / IIC\phi]$$

Note 1. $IIC\phi = PCLKB \times \text{division ratio}$

Note 2. The SCLn line rise time (tr) and SCLn line fall time (tf) depend on the total bus line capacitance (Cb) and the pull-up resistor (Rp). For details, see the I2C bus standard from NXP Semiconductors.

Note 3. nf = Number of digital noise filters selected in the ICMR3.NF bit.

Table 29.6 Example of ICBRH/ICBRL Settings for Transfer Rate IIC when SCLE = 0

29.2.17 ICDRT : I2C Bus Transmit Data Register

Base address: $IICn = 0x4025_E000 + 0x0100 \times n$ (n = 0 to 1)
 $IICn_NS = 0x5025_E000 + 0x0100 \times n$ (n = 0 to 1)

Offset address: 0x12

Bit position: 7 6 5 4 3 2 1 0

Bit field:

Value after reset: 1 1 1 1 1 1 1 1

When ICDRT detects a space in the I2C Bus Shift Register (ICDRS), it transfers the transmit data that was written to ICDRT to ICDRS and starts transmitting data in transmit mode. The double-buffer structure of ICDRT and ICDRS allows continuous transmit operation if the next transmit data is written to ICDRT while the ICDRS data is being transmitted.

ICDRT can always be read and written to. Write transmit data to ICDRT once when a transmit data empty interrupt (IICn_TXI) request is generated.

29.2.18 ICDRR : I2C Bus Receive Data Register

Base address: $IICn = 0x4025_E000 + 0x0100 \times n$ (n = 0 to 1)
 $IICn_NS = 0x5025_E000 + 0x0100 \times n$ (n = 0 to 1)

Offset address: 0x13

Bit position: 7 6 5 4 3 2 1 0

Bit field:

Value after reset: 0 0 0 0 0 0 0 0

When 1 byte of data is received, the received data is transferred from the I²C Bus Shift Register (ICDRS) to ICDRR to enable the next data to be received. The double-buffer structure of ICDRS and ICDRR allows continuous receive operation if the received data is read from ICDRR while ICDRS is receiving data. ICDRR cannot be written to. Read data from ICDRR once when a receive data full interrupt (IICn_RXI) request is generated.

If ICDRR receives the next receive data before the current data is read from ICDRR (while the RDRF flag in ICSR2 is 1), the IIC automatically holds the SCL clock low 1 cycle before the RDRF flag is set to 1 next.

29.2.19 ICDRS : I²C Bus Shift Register

Base address: n/a
 Offset address: n/a

Bit position:	7	6	5	4	3	2	1	0
Bit field:	[Empty Box]							
Value after reset:	—	—	—	—	—	—	—	—

ICDRS is an 8-bit shift register for data transmit and receive. During transmission, transmit data is transferred from ICDRT to ICDRS and is transmitted from the SDAn pin. During reception, data is transferred from ICDRS to ICDRR after 1 byte of data is received. ICDRS cannot be accessed directly.

29.3 Operation

29.3.1 Communication Data Format

The I²C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a start or restart condition is an address frame that specifies a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a stop condition is issued.

Figure 29.3 shows the I²C bus format, and Figure 29.4 shows the I²C bus timing.

Figure 29.3 I²C bus format

Figure 29.4 I²C bus timing when the SLA setting = 7 bits

- S: Start condition. The master device drives the SDAn line low from high while the SCLn line is high.
- SLA: Slave address, by which the master device selects a slave device.
- R/W#: Indicates the direction of data transfer: from the slave device to the master device when R/W# is 1, or from the master device to the slave device when R/W# is 0.
- A: Acknowledge. The receive device drives the SDAn line low. In master transmit mode, the slave device returns acknowledge. In master receive mode, the master device returns acknowledge.
- A#: Not Acknowledge. The receive device drives the SDAn line high.
- Sr: Restart condition. The master device drives the SDAn line low from the high level after the setup time has elapsed with the SCLn line high.
- DATA: Transmitted or received data.
- P: Stop condition. The master device drives the SDAn line high from low while the SCLn line is high.

29.3.2 Initial Settings

Before starting data transmission or reception, initialize the IIC using the procedure shown in [Figure 29.5](#).

1. Set the ICCR1.ICE bit to 0 to set the SCLn and SDAn pins to the inactive state.
2. Set the ICCR1.IICRST bit to 1 to initiate IIC reset.
3. Set the ICCR1.ICE bit to 1 to initiate internal reset.
4. Set the SARLy, SARUy, ICSEr, ICMR1, ICBRH, and ICBRL registers ($y = 0$ to 2), and set the other registers as required. For initial settings of the IIC, see [Figure 29.5](#).
5. When the required register settings are complete, set the ICCR1.IICRST bit to 0 to release the IIC reset.

This procedure is not required if the IIC initialization is already complete.

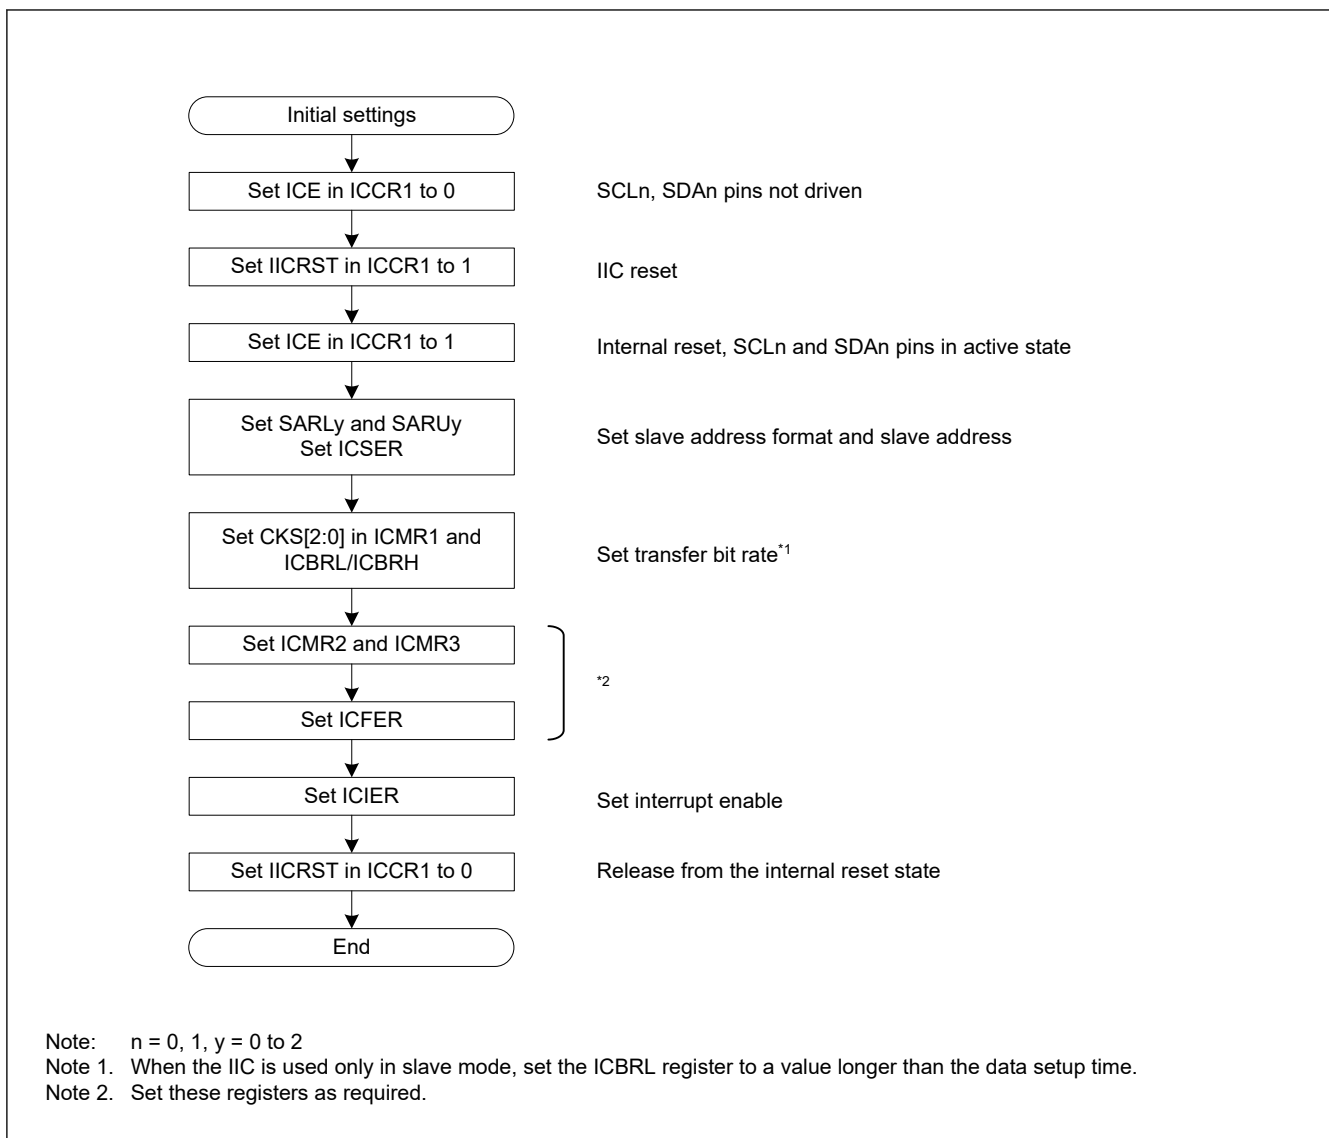

Figure 29.5 Example IIC initialization flow

29.3.3 Master Transmit Operation

In master transmit operation, the IIC outputs the SCL clock and transmitted data signals as the master device, and the slave device returns acknowledgments. Figure 29.6 shows an example of master transmission, and Figure 29.7 to Figure 29.9 show the operation timing in master transmission.

To set up and perform master transmission:

1. Process initial settings. For details, see [section 29.3.2. Initial Settings](#).
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition request). On receiving the request, the IIC issues a start condition. At the same time, the BBSY and START flags in ICSR2 automatically set to 1 and the ST bit automatically is set to 0. At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDAn line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically is set to 1 in response to the setting of the TRS bit to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag automatically is set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1. After the byte containing the slave address and R/W# bit is transmitted, the value of the TRS bit automatically updates to select master transmit or master receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the IIC continues in master transmit mode.

Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.

For data transmission with an address in the 10-bit format, start by writing 11110b, the 2 higher-order bits of the slave address, and W to ICDRT as the first address transmission. For the second address transmission, write the 8 lower-order bits of the slave address to ICDRT.

4. Check that the TDRE flag in ICSR2 is 1, and then write the transmit data to the ICDRT register. The IIC automatically holds the SCLn line low until the transmit data is ready or a stop condition is issued.
5. After all bytes of transmit data are written to the ICDRT register, wait until the value in the TEND flag in ICSR2 returns to 1, and then set the SP bit in ICCR2 to 1 (stop condition requested). On receiving a stop condition request, the IIC issues the stop condition. Regarding issuing a stop condition, see [section 29.11.3. Issuing a Stop Condition](#).
6. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, it automatically sets the TDRE and TEND flags to 0, and sets the STOP flag in ICSR2 to 1.
7. Check that the ICSR2.STOP flag is 1, and then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

Figure 29.6 Example master transmission flow

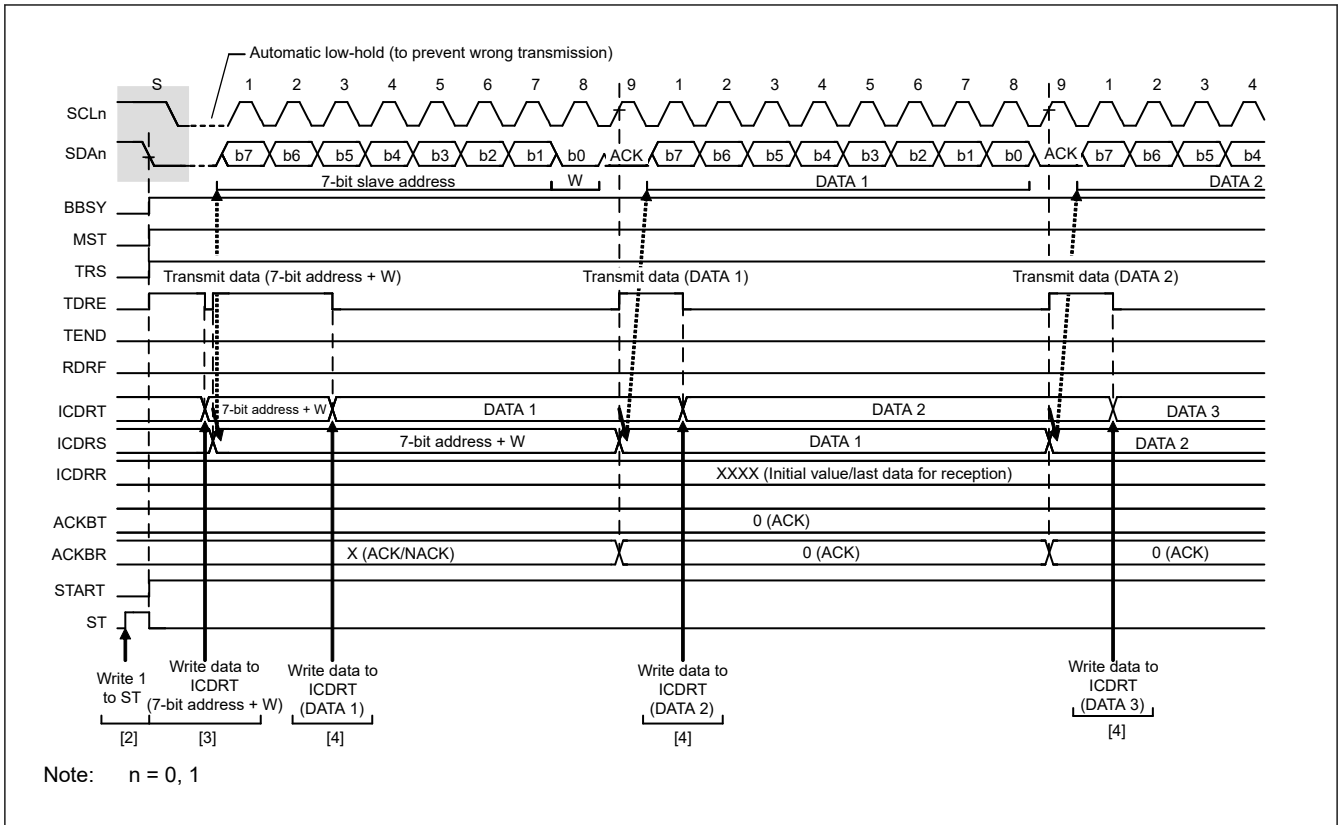

Figure 29.7 Master transmit operation timing (1) with 7-bit address format

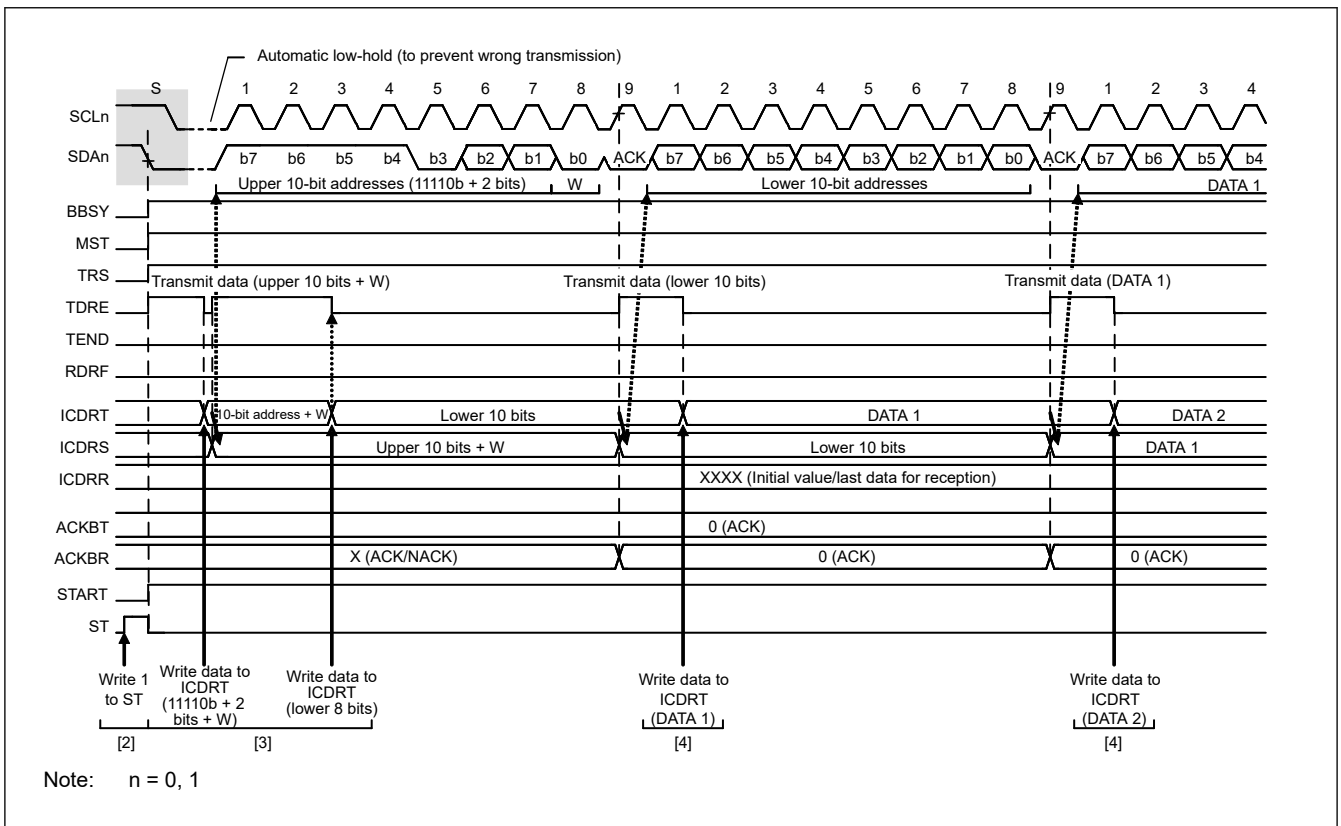

Figure 29.8 Master transmit operation timing (2) with 10-bit address format

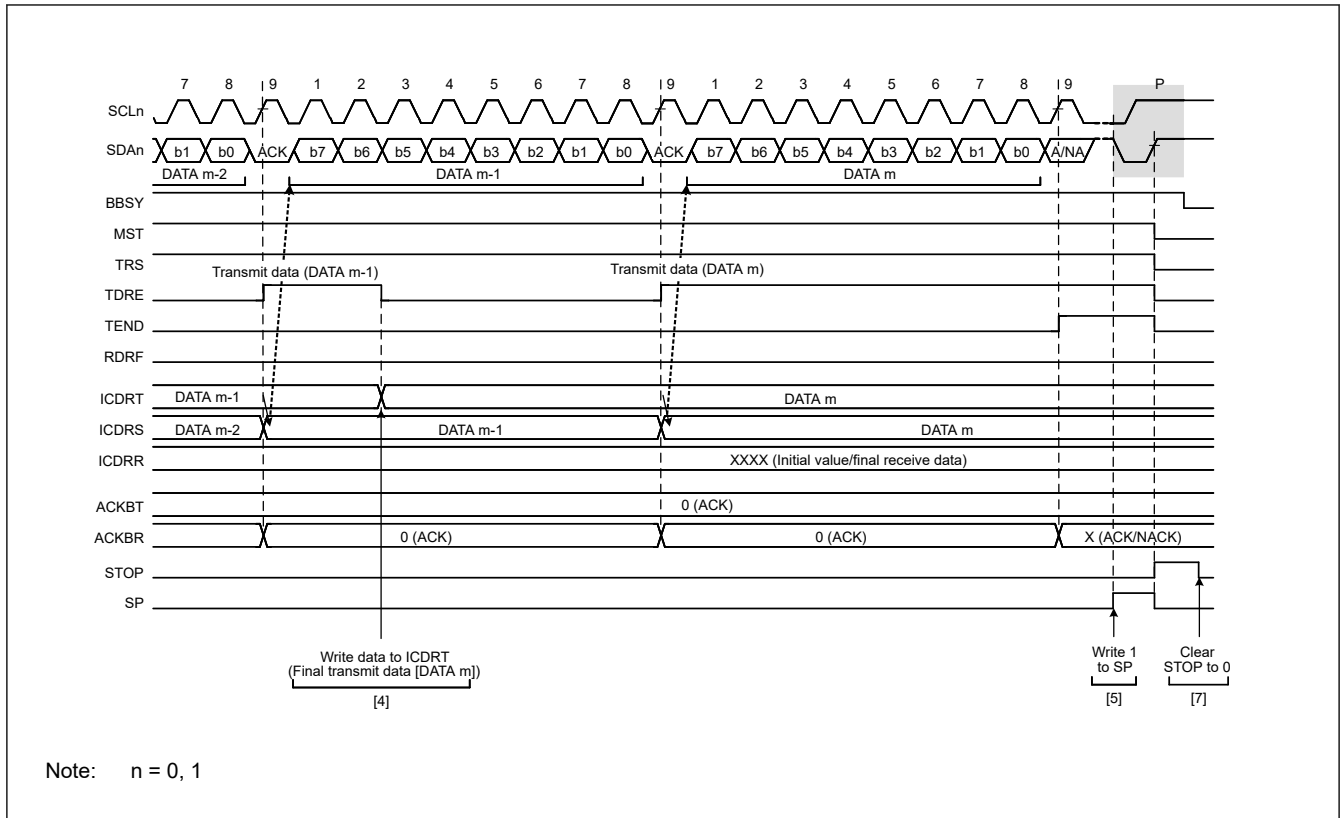

Figure 29.9 Master transmit operation timing (3)

29.3.4 Master Receive Operation

In master receive operation, the IIC as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgments. Because the IIC must start by sending a slave address to the associated slave device, this part of the procedure is performed in master transmit mode, but the subsequent steps are in master receive mode.

Figure 29.10 and Figure 29.11 show examples of master reception (7-bit address format), and Figure 29.12 to Figure 29.14 show the operation timing in master reception.

To set up and perform master reception:

1. Process initial settings. For details, see section 29.3.2. Initial Settings.
2. Read the BBSY flag in ICCR2 to check that the bus is free, and then set the ST bit in ICCR2 to 1 (start condition request). On receiving the request, the IIC issues a start condition. When the IIC detects the start condition, the BBSY and START flags in ICSR2 automatically set to 1, and the ST bit automatically is set to 0. At this time, if the start condition is detected and the levels for the SDA output and the levels on the SDA_n line match while the ST bit is 1, the IIC recognizes that issuance of the start condition as requested by the ST bit is successfully complete, and the MST and TRS bits in ICCR2 automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 also automatically is set to 1 in response to the setting of the TRS bit to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to ICDRT. When the transmit data is written to ICDRT, the TDRE flag automatically is set to 0, the data is transferred from ICDRT to ICDRS, and the TDRE flag again is set to 1. When the byte containing the slave address and R/W# bit is transmitted, the value of the ICCR2.TRS bit automatically updates to select transmit or receive mode based on the value of the transmitted R/W# bit. If the value of the R/W# bit is 1, the TRS bit is set to 0 on the rising edge of the ninth cycle of the SCL clock, placing the IIC in master receive mode. At this time, the TDRE flag is set to 0 and the ICSR2.RDRF flag automatically is set to 1. Because the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition. For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a restart condition. After that, transmitting 11110b, the two higher-order bits of the slave address, and the R bit places the IIC in master receive mode.

4. Dummy read ICDRR after confirming that the RDRF flag in ICSR2 is 1. This makes the IIC start output of the SCL clock and start data reception.
5. After 1 byte of data is received, the RDRF flag in ICSR2 is set to 1 on the rising edge of the 8th or 9th cycle of the SCL clock, as selected in the RDRFS bit in ICMR3. Reading ICDRR at this time produces the received data, and the RDRF flag is automatically set to 0 at the same time. Additionally, the value of the acknowledgment field received during the ninth cycle of the SCL clock is returned as the value set in the ICMR3.ACKBT bit. If the next byte to be received is the second-to-last byte, set the ICMR3.WAIT bit to 1 for wait insertion before reading ICDRR, containing the second-to-last byte. In addition to enabling NACK output, even when interrupts or other operations result in delays in setting the ICMR3.ACKBT bit to 1 (NACK) in step (6), this fixes the SCLn line to the low level on the rising edge of the ninth clock cycle in reception of the last byte, which enables the issuing of a stop condition.
6. When the ICMR3.RDRFS bit is 0, and the slave device must be notified that it is to end transfer for data reception after transfer of the next and final byte, set the ICMR3.ACKBT bit to 1 (NACK).
7. After reading the second-to-last byte from the ICDRR register, if the value of the ICSR2.RDRF flag is 1, write 1 to the SP bit in ICCR2 (stop condition requested), and then read the last byte from ICDRR. When ICDRR is read, the IIC is released from the wait state and issues the stop condition after low-level output in the ninth clock cycle is complete or the SCLn line is released from the low-hold state.
8. On detecting the stop condition, the IIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave receive mode. Additionally, detection of the stop condition sets the ICSR2.STOP flag to 1.
9. Check that the ICSR2.STOP flag is 1, then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

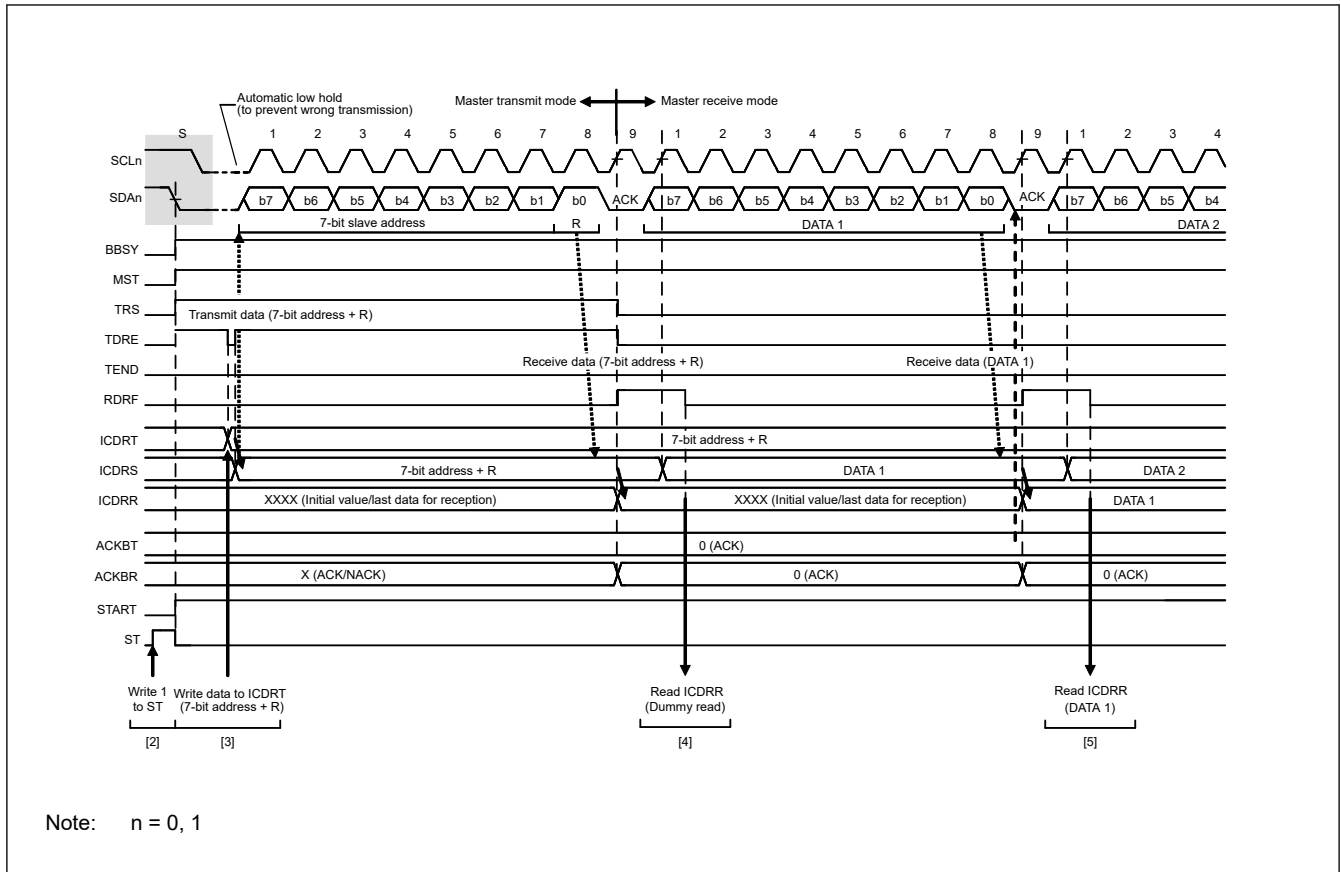

Figure 29.12 Master receive operation timing (1) with 7-bit address format when RDRFS = 0

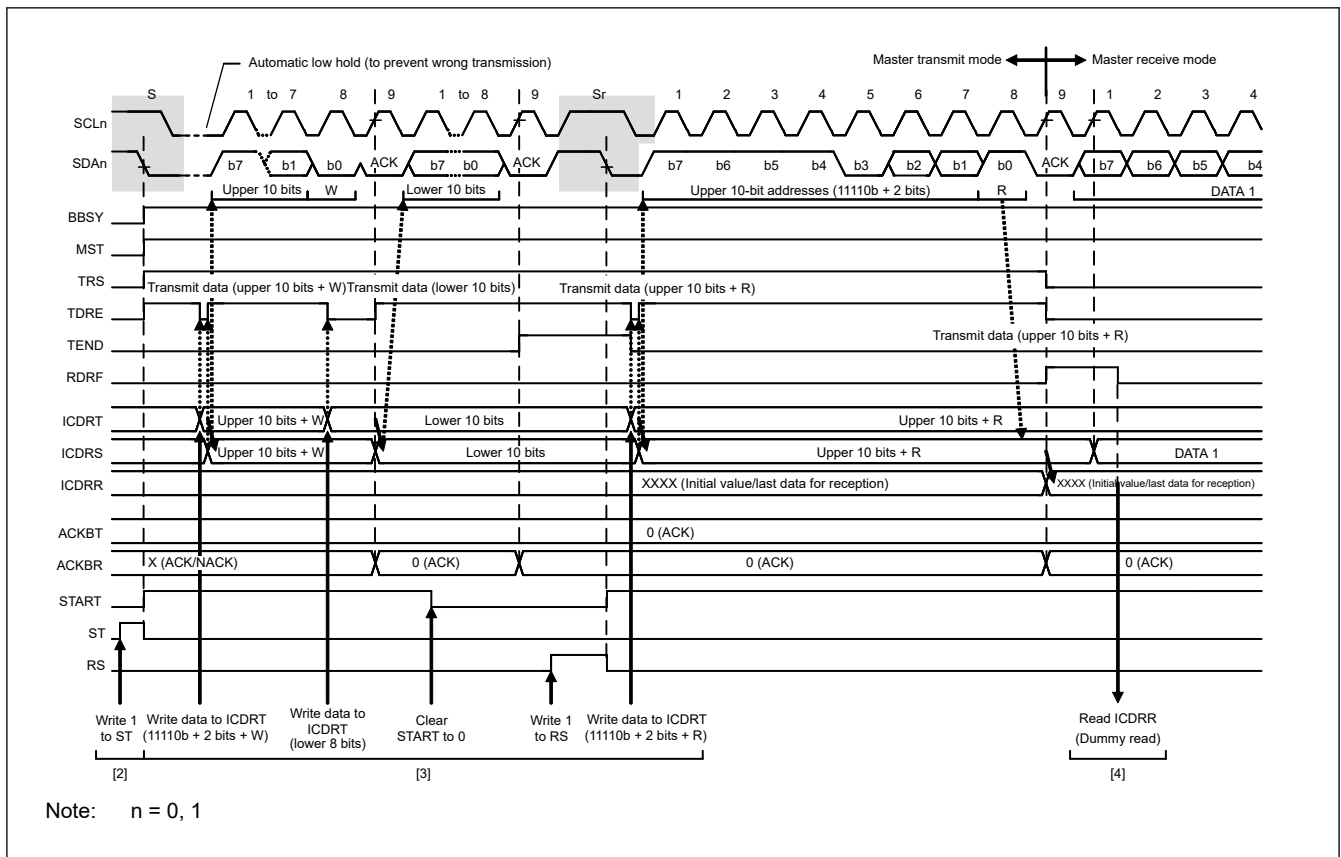

Figure 29.13 Master receive operation timing (2) with 10-bit address format when RDRFS = 0

Figure 29.14 Master receive operation timing (3) when RDRFS = 0

29.3.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL clock, the IIC transmits data as a slave device, and the master device returns acknowledgments.

Figure 29.15 shows an example of slave transmission, and Figure 29.16 and Figure 29.17 show the operation timing in slave transmission.

To set up and perform slave transmission:

1. Initialize the IIC using the procedure in section 29.3.2. Initial Settings.
After initialization, the IIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the IIC sets one of the associated ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 1 on the rising edge of the ninth cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the ninth cycle of the SCL clock. If the value of the R/W# bit is 1, the IIC automatically places itself in slave transmit mode by setting both the ICCR2.TRS bit and the ICSR2.TDRE flag to 1.
3. Check that the ICSR2.TDRE flag is 1, then write the transmit data to the ICDRT register. If the IIC receives no acknowledge from the master device (receives an NACK signal) while the ICFER.NACKF bit is 1, the IIC suspends transfer of the next data.
4. Wait until the ICSR2.TEND flag is set to 1 while the ICSR2.TDRE flag is 1, after the ICSR2.NACKF flag is set to 1 or the last byte for transmission is written to the ICDRT register. When the ICSR2.NACKF flag or the TEND flag is 1, the IIC drives the SCLn line low on the ninth falling edge of the SCL clock.
5. When the ICSR2.NACKF or ICSR2.TEND flag is 1, dummy read ICDRR to complete the processing. This releases the SCLn line.
6. On detecting the stop condition, the IIC automatically sets the ICSR1.HOA, GCA, and AASy flags (y = 0 to 2), the ICSR2.TDRE and TEND flags, and the ICCR2.TRS bit to 0, and enters slave receive mode.
7. Check that the ICSR2.STOP flag is 1, then set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

Figure 29.15 Example slave transmission flow

Figure 29.16 Slave transmit operation timing (1) with 7-bit address format

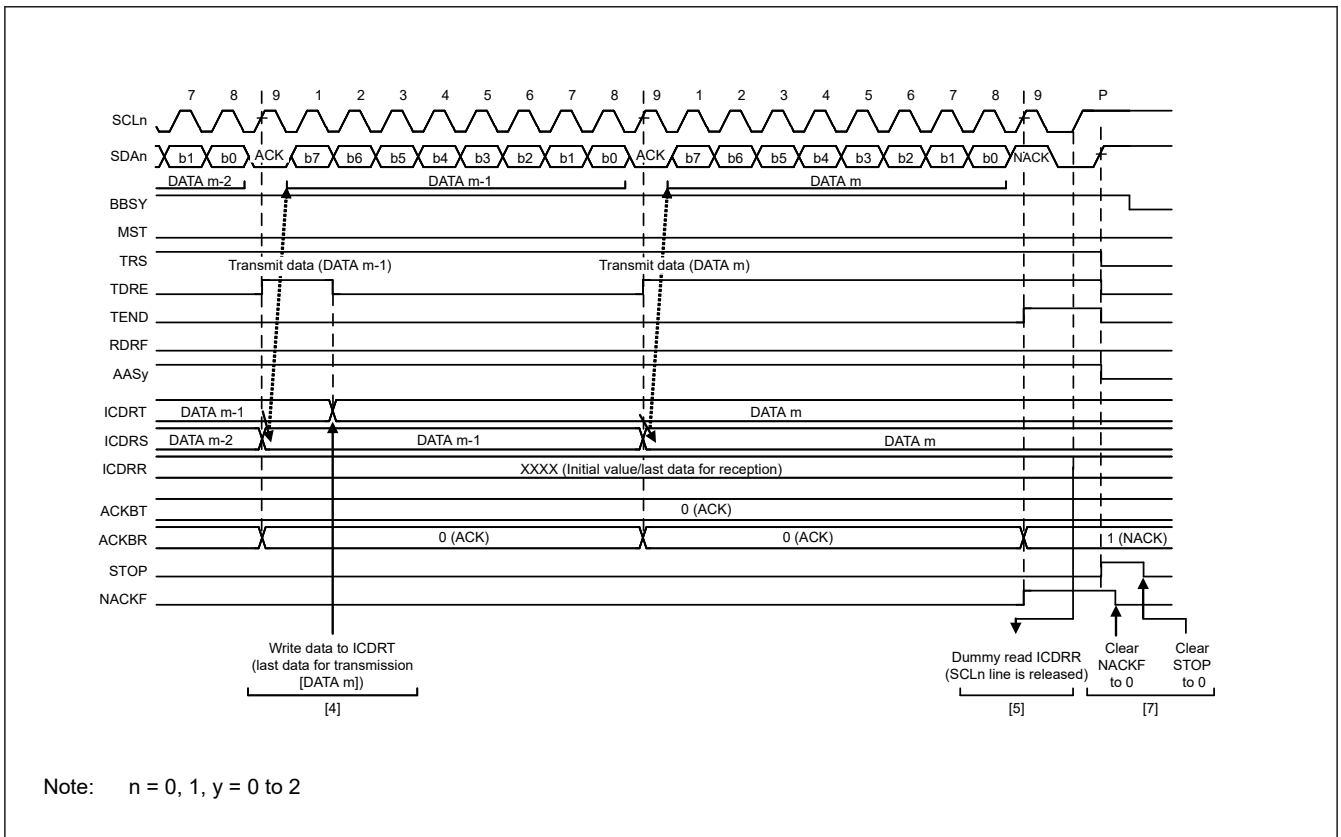

Figure 29.17 Slave transmit operation timing (2)

29.3.6 Slave Receive Operation

In slave receive operation, the master device outputs the SCL clock and transmit data, and the IIC returns acknowledgments as a slave device.

Figure 29.18 shows an example of slave reception, and Figure 29.19 and Figure 29.20 show the operation timing in slave reception.

To set up and perform slave reception:

1. Initialize the IIC using the procedure in [section 29.3.2. Initial Settings](#).
After initialization, the IIC stays in the standby state until it receives a slave address that matches.
2. After receiving a matching slave address, the IIC sets one of the associated ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 1 on the rising edge of the ninth cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the ninth cycle of the SCL clock. If the value of the R/W# bit is 0, the IIC continues to place itself in slave receive mode and sets the RDRF flag in ICSR2 to 1.
3. Check that the ICSR2.STOP flag is 0 and the ICSR2.RDRF flag is 1, then dummy read ICDRR. The dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected.
4. When ICDRR is read, the IIC automatically sets the ICSR2.RDRF flag to 0. If reading of ICDRR is delayed and a next byte is received while the RDRF flag is still set to 1, the IIC holds the SCLn line low until 1 SCL cycle before the point where RDRF must be set. In this case, reading ICDRR releases the SCLn line from being held low.
When the ICSR2.STOP flag is 1 and the ICSR2.RDRF flag is also 1, read ICDRR until all the data is completely received.
5. On detecting the stop condition, the IIC automatically clears the ICSR1.HOA, GCA, and AASy flags (y = 0 to 2) to 0.
6. Check that the ICSR2.STOP flag is 1, then set the ICSR2.STOP flag to 0 for the next transfer operation.

Figure 29.18 Example slave reception flow

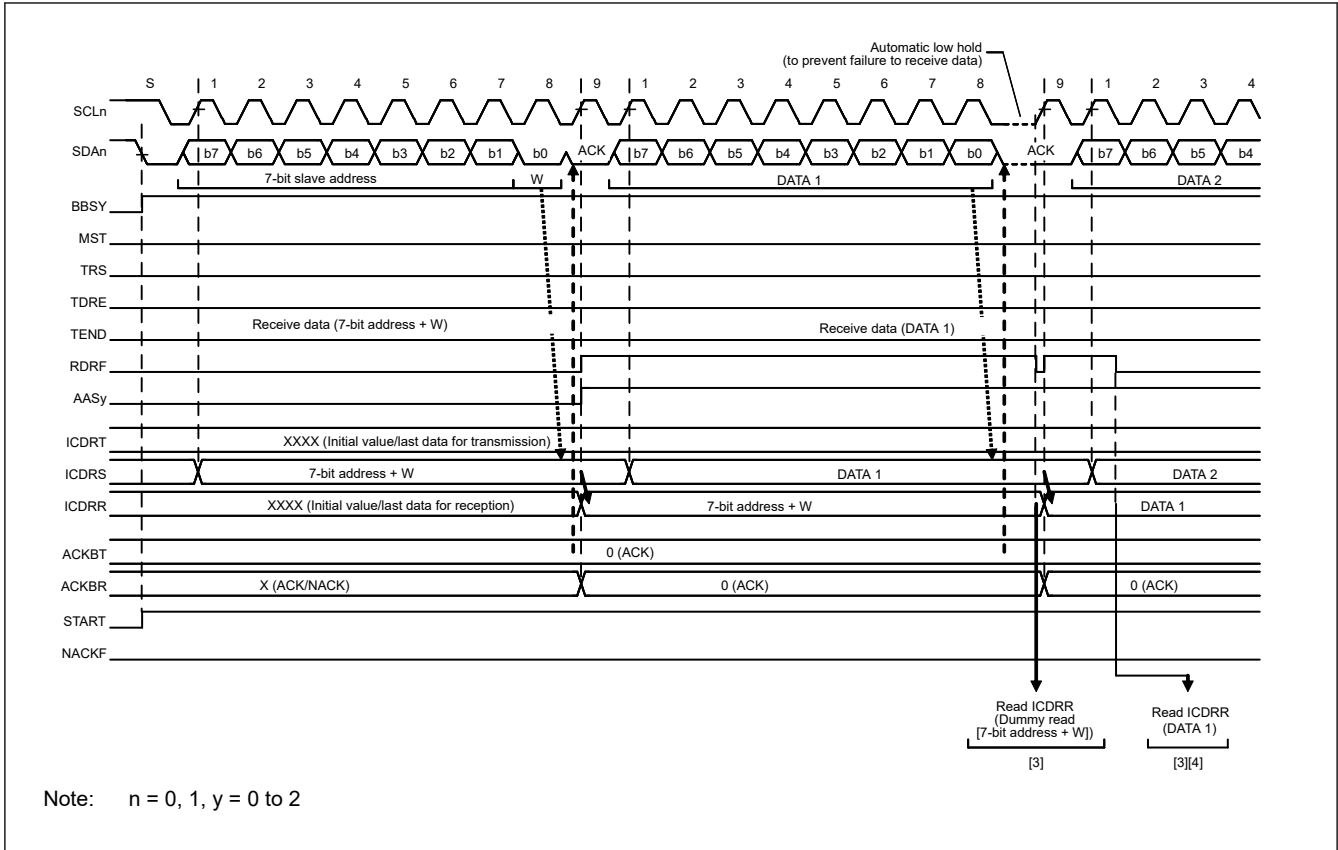

Figure 29.19 Slave receive operation timing (1) with 7-bit address format when RDRFS = 0

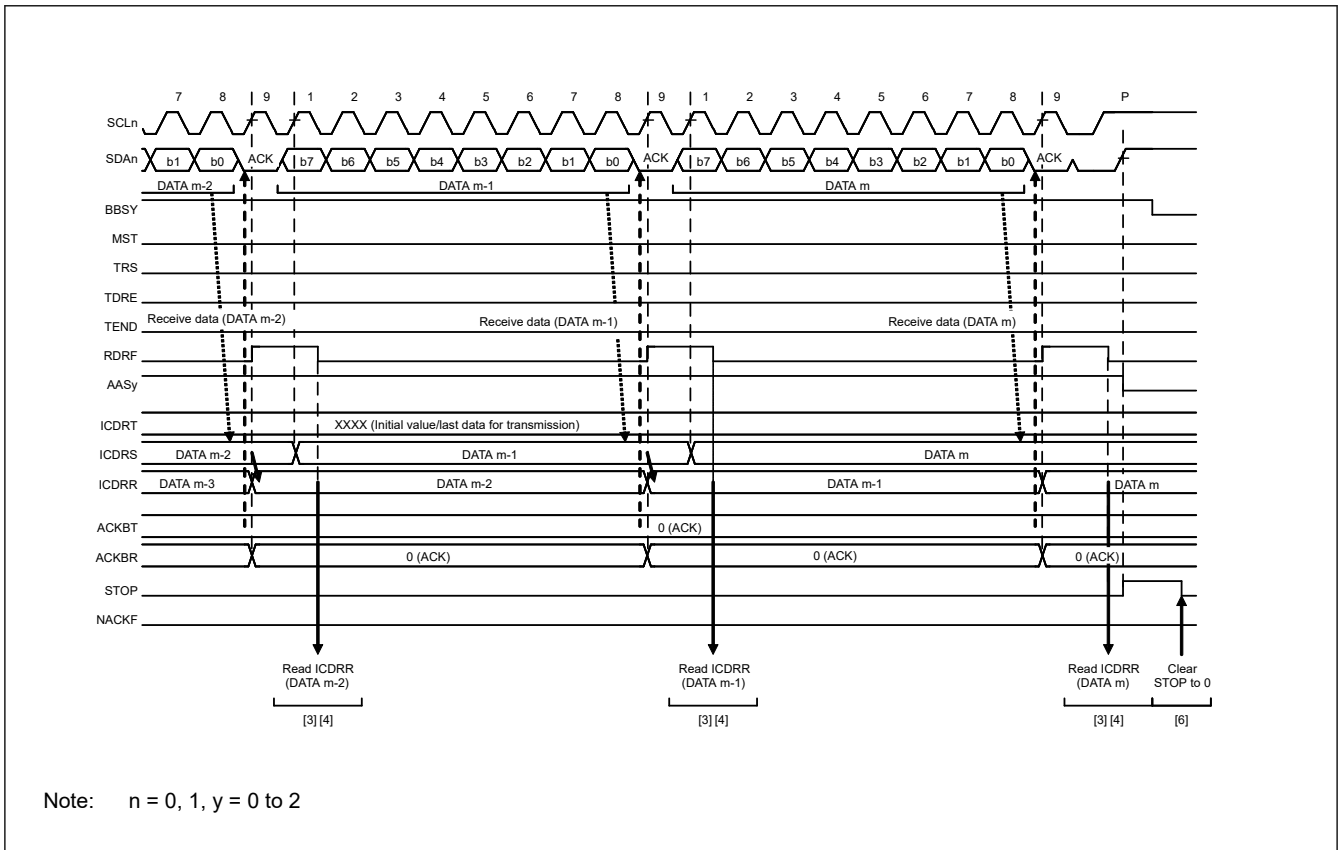

Figure 29.20 Slave receive operation timing (2) when RDRFS = 0

29.4 SCL Synchronization Circuit

For generation of the SCL clock, the IIC starts counting the value for the high-level period specified in ICBRH when it detects a rising edge on the SCLn line, and it drives the SCLn line low when it completes counting. When the IIC detects the falling edge of the SCLn line, it starts counting the value for the low-level period specified in ICBRL, and then it stops driving the SCLn line, releasing the line, when it completes counting. The IIC repeats this process to generate the SCL clock.

If multiple master devices are connected to the I²C bus, a collision of SCL signals might arise because of contention with another master device. In such cases, the master devices must synchronize their SCL signals. Because this synchronization of SCL signals must be bit-by-bit, the IIC is equipped with an SCL synchronization circuit to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCLn line while in master mode.

When the IIC detects a rising edge on the SCLn line and starts counting the high-level period specified in ICBRH.BRH[4:0], and the level on the SCLn line falls because an SCL signal is being generated by another master device, the IIC performs the following:

1. Stops counting when it detects the falling edge.
2. Drives the level on the SCLn line low.
3. Starts counting the low-level period specified in ICBRL.BRL[4:0].

When the IIC finishes counting the low-level period, it stops driving the SCLn line low to release the line. If the low-level period of the SCL clock signal from the other master device is longer than the low-level period set in the IIC, the low-level period of the SCL signal is extended. When the low-level period for the other master device ends, the SCL signal rises because the SCLn line is released.

When the IIC finishes outputting the low-level period of the SCL clock, the SCLn line is released and the SCL clock rises. That is, when SCL signals from more than one master are contending, the high-level period of the SCL signal is synchronized with that of the clock with the narrower period, and the low-level period of the SCL signal is synchronized with that of the clock with the broader period. However, such synchronization of the SCL signal is only enabled when the SCLE bit in ICFER is set to 1.

Figure 29.21 Generation and synchronization of SCL signal from IIC

29.5 SDA Output Delay Function

The IIC module incorporates a function for delaying output on the SDA line. The delay can be applied to all output on the SDA line, including issuing of the start, restart, and stop conditions, data, and the ACK and NACK signals.

With this function, SDA output is delayed from the detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval during which the SCL clock is low. This approach helps prevent erroneous operation of communications devices, with the aim of satisfying the 300-ns minimum data-hold time requirement of the SMBus specification. The output delay function is enabled by setting the SDDL[2:0] bits in ICMR2 to a value other than 000b, and disabled by setting the same bits to 000b.

When the SDA output delay function is enabled, for example, the DLCS bit in ICMR2 selects the clock source for the SDA output delay counter, either as the internal base clock (IICφ) for the IIC module or as the internal base clock divided by 2 (IICφ/2). The counter counts the number of cycles set in the SDDL[2:0] bits in ICMR2. When the delay cycles count is reached, the IIC module places the required output (start, restart, or stop condition, data, or an ACK or NACK signal) on the SDA line.

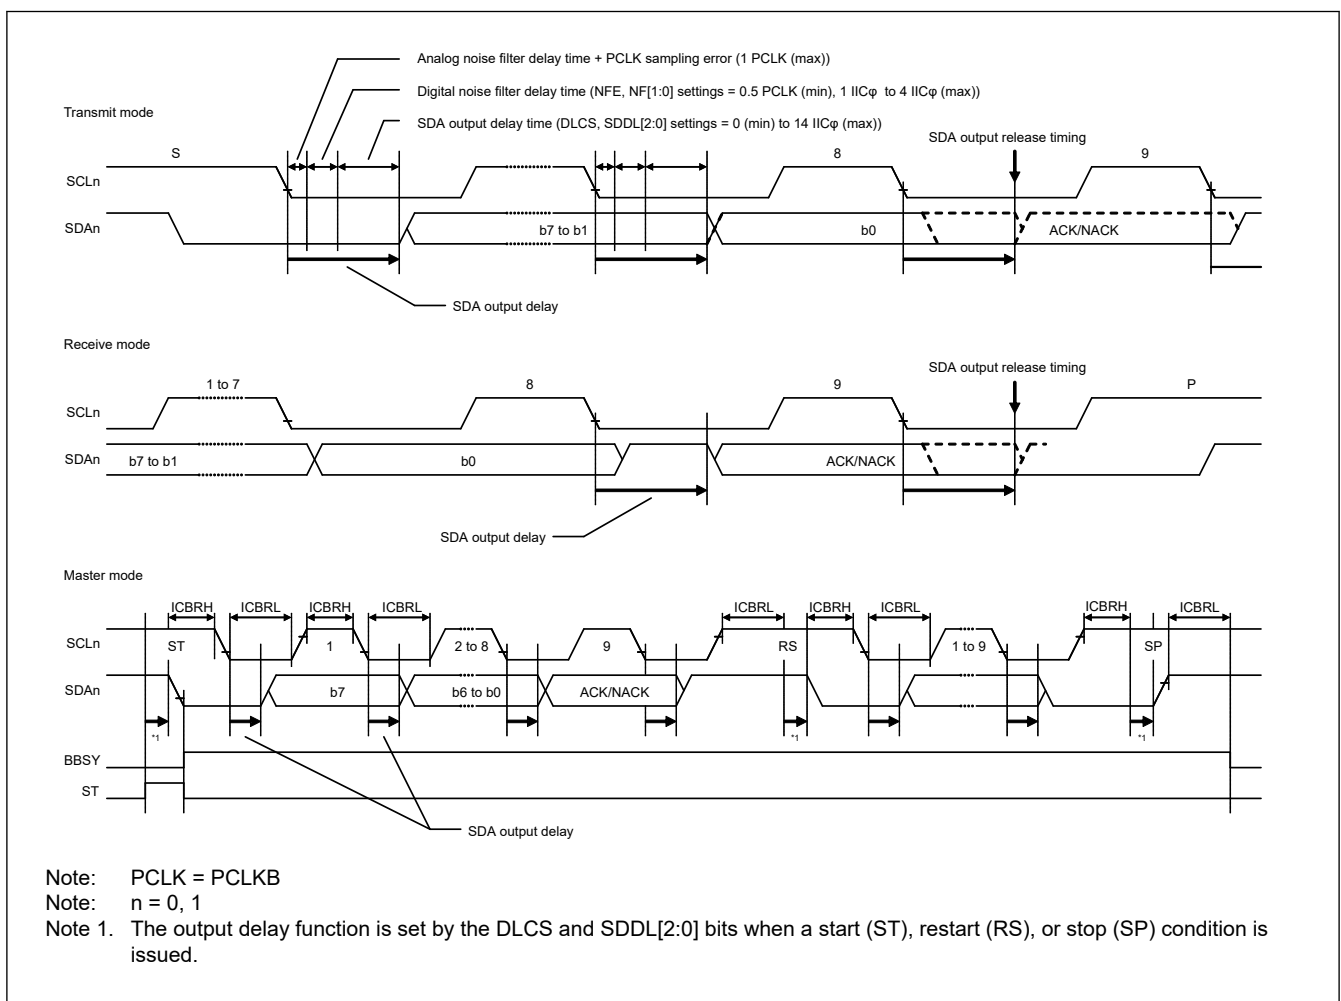

Figure 29.22 SDA output delay function

29.6 Digital Noise Filter Circuits

The internal circuitry sees the states of the SCLn and SDA n pins through analog and digital noise-filter circuits. Figure 29.23 shows a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of the IIC consists of four flip-flop circuit stages connected in series and a match-detection circuit. The number of valid stages in the digital noise filter is selected in the NF[1:0] bits in ICMR3. The selected number of valid stages determines the noise-filtering capability as a period from 1 to 4 IICφ cycles.

The input signal to the SCLn pin (or SDAn pin) is sampled on falling edges of the IIC ϕ signal. When the input signal level matches the output level of the number of valid flip-flop circuit stages as selected in the NF[1:0] bits in ICMR3, the signal level is seen in the subsequent stage. If the signal levels do not match, the previous value is saved.

If the ratio between the frequency of the internal operating clock (PCLKB) and the transfer rate is small, for example, if data transfer is 400 kbps with PCLKB = 4 MHz, the characteristics of the digital noise filter might lead to the elimination of required signals as noise. In such cases, it is possible to disable the digital noise-filter circuit by setting the ICFER.NFE bit to 0, and use only the analog noise filter circuit.

Figure 29.23 Digital noise filter circuit block diagram

29.7 Address Match Detection

The IIC can set three unique slave addresses in addition to the general call address and host address. The slave addresses can be 7-bit or 10-bit slave addresses.

29.7.1 Slave-Address Match Detection

The IIC can set three unique slave addresses and has a slave address detection function for each unique slave address. When the SARyE bit ($y = 0$ to 2) in ICSER is set to 1, the slave addresses set in SARUy and SARLy ($y = 0$ to 2) can be detected.

When the IIC detects a match of the set slave address, the associated AASy flag ($y = 0$ to 2) in ICSR1 is set to 1 on the rising edge of the ninth SCL clock cycle, and the RDRF flag in ICSR2 or the TDRE flag in ICSR2 is set to 1 by the subsequent R/W# bit. This causes a receive data full interrupt (IICn_RXI) or transmit data empty interrupt (IICn_TXI) to be generated. The AASy flag identifies which slave address is specified.

Figure 29.24 to Figure 29.26 show the AASy flag set timing in three cases.

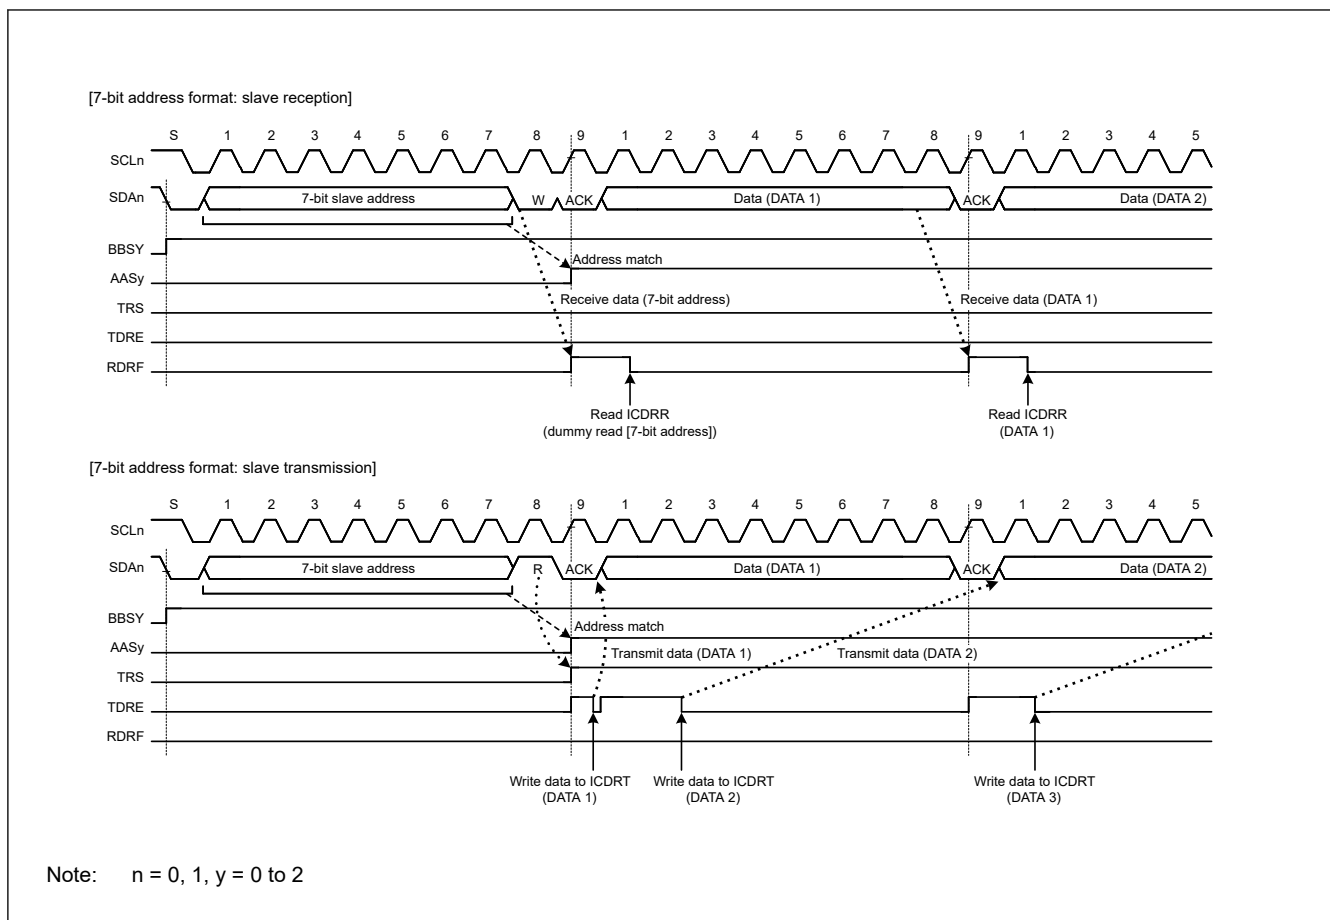

Figure 29.24 AASy flag set timing with 7-bit address format

Figure 29.25 AASy flag set timing with 10-bit address format

Figure 29.26 AASy flag set and clear timing with mixed 7-bit and 10-bit address formats

29.7.2 Detection of General Call Address

The IIC provides detection of the general call address (0000 000b + 0 [W]). This is enabled by setting the GCAE bit in IC SER to 1.

If the address received after a start or restart condition is issued is 0000 000b + 1[R] (start byte), the IIC recognizes this as the address of a slave device with an all-zero address, but not as the general call address.

When the IIC detects the general call address, both the GCA flag in IC SR1 and the RDRF flag in IC SR2 set to 1 on the rising edge of the ninth cycle of the SCL clock. This leads to the generation of a receive data full interrupt (IICn_RXI). The value of the GCA flag can be checked to confirm that the general call address was transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

Figure 29.27 Timing of GCA flag setting during reception of general call address

29.7.3 Device-ID Address Detection

The IIC module provides detection of device-ID address compliant with the I²C bus specification (revision 03). When the IIC receives 1111 100b as the first byte after a start or restart condition is issued with the DIDE bit in ICSER set to 1, it recognizes the address as a device ID, sets the DID flag in ICSR1 to 1 on the rising edge of the ninth SCL clock cycle when the subsequent R/W# bit is 0, then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, the IIC sets the associated AASy flag (y = 0 to 2) in ICSR1 to 1.

When the first byte received after the issue of a start or restart condition matches the device ID address (1111 100b) again and the subsequent R/W# bit is 1, the IIC does not compare the second and subsequent bytes and sets the ICSR2.TDRE flag to 1.

In the device ID address detection function, the IIC sets the DID flag to 0 if a match with the IIC slave address is not obtained or a match with the device ID address is not obtained after a match with the IIC slave address and a restart condition is not detected. If the first byte after detection of a start or restart condition matches the device ID address (1111 100b), and the R/W# bit is 0, the IIC sets the DID flag to 1 and compares the second and subsequent bytes with the slave address of the IIC. If the R/W# bit is 1, the DID flag holds the previous value and the IIC does not compare the second and subsequent bytes. Therefore, the reception of a device ID address can be checked by reading the DID flag after confirming that TDRE = 1.

Additionally, prepare the device ID fields (3 bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal transmit data. For details on the information that must be included in device ID fields, contact NXP Semiconductors.

Figure 29.28 AASy and DID flag set and clear timing during reception of device ID

29.7.4 Host Address Detection

The IIC provides host address detection when operating in SMBus. When the HOAE bit in ICSER is set to 1 while the SMBS bit in ICMR3 is 1, the IIC can detect the host address (0001 000b) in slave receive mode (MST and TRS bits = 00b in ICCR2).

When the IIC detects the host address, the HOA flag in ICSR1 is set to 1 on the rising edge of the 9th SCL clock cycle, and at the same time, the RDRF flag in ICSR2 is set to 1 when the R/W# bit is 0 (Wr bit). This causes a receive data full interrupt (IICn_RXI) to be generated. The HOA flag indicates that the host address was sent from another device.

If the bit following the host address (0001 000b) is an Rd bit (R/W# bit = 1), the IIC can also detect the host address. After the host address is detected, the IIC operates in the same manner as in normal slave operation.

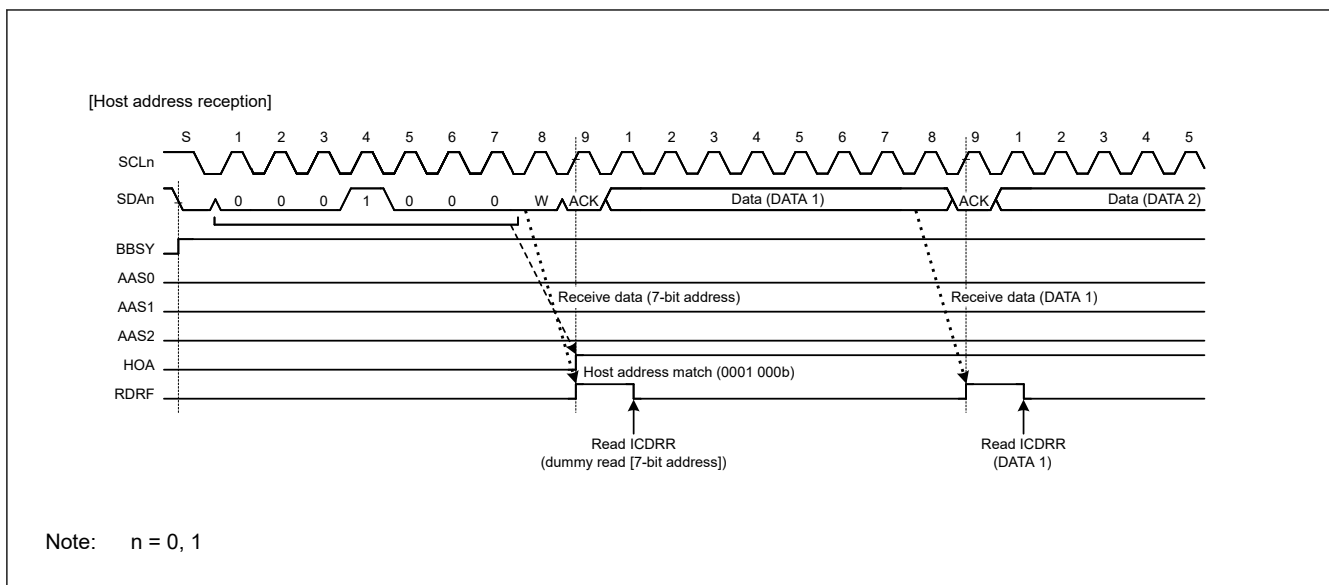

Figure 29.29 HOA flag set timing during reception of host address

29.8 Wakeup Function

The IIC provides a wakeup function that causes the MCU to transition from Software Standby mode to normal operation. The wakeup function enables the reception of data when the peripheral module clock (PCLKB) is stopped, and generates a wakeup interrupt signal on a match of the slave address of the received data. This wakeup interrupt signal triggers the return to normal operation. After the wakeup interrupt occurs, switch the IIC to PCLKB synchronous operation so that communication can continue.

The wakeup function has four operation modes:

- Normal wakeup mode 1
- Normal wakeup mode 2
- Command recovery mode
- EEP response mode

Table 29.9 describes the behavior in these modes.

Table 29.9 Wakeup operation modes

Operation mode	ACK response timing	ACK response before wakeup to PCLKB synchronous operation	SCL state during wakeup to PCLKB synchronous operation
Normal wakeup mode 1	Before wakeup to PCLKB synchronous operation ^{*1}	ACK	Fixed low
Normal wakeup mode 2	After wakeup to PCLKB synchronous operation ^{*2}	Before wakeup: no response (NACK level retained) After wakeup: ACK response	Fixed low
Command recovery mode	Before wakeup to PCLKB synchronous operation ^{*1}	ACK	Open
EEP response mode	Before recovery to PCLKB synchronous operation ^{*1}	NACK	Open

Note 1. Switching timing from PCLKB asynchronous operation to PCLKB synchronous operation is the falling edge of the 9th clock of the SCL.

Note 2. Switching timing from PCLKB asynchronous operation to PCLKB synchronous operation is the falling edge of the 8th clock of the SCL.

The following can be selected as wakeup interrupt sources:

- Host address detection (valid when IC SER.HOAE = 1)
- General call address detection (valid when IC SER.GCAE = 1)

- Slave address 0*1 detection (valid when IC SER.SAR0E = 1)
- Slave address 1*1 detection (valid when IC SER.SAR1E = 1)
- Slave address 2*1 detection (valid when IC SER.SAR2E = 1)

Note 1. Only 7-bit address can be set. Set the FS bit in SARU_y (y = 0 to 2) to 0.

Precautions on the use of the wakeup function

- Do not change the content of the IIC registers except the IC IER register and WUSEN bit in ICWUR2 while the WUASYF flag in ICWUR2 is 1 (during PCLKB asynchronous operation).
- Set ICWUR.WUE and ICWUR.WUIE to 1, and ICCR2.MST and ICCR2.TRS to 0 (slave reception mode) before switching to PCLKB asynchronous mode.
- The device ID and the 10-bit slave address cannot be selected for the wakeup interrupt source. Set the DIDE bit in IC SER and FS bit in SARU_y (y = 0 to 2) to 0.
- Set bits TIE, TEIE, RIE, NAKIE, SPIE, STIE, ALIE, and TMOIE in the IC IER register to 0 (interrupt disabled) after switching to PCLKB asynchronous operation (ICWUR2.WUASYF = 1).
- When the wakeup function is enabled, do not use the timeout function (ICWUR.WUE = 1)
- Even when a wakeup interrupt is generated during PCLKB asynchronous operation (when ICWUR2.WUASYF = 1), if the slave addresses match in PCLKB synchronous mode (ICWUR2.WUASYF = 0), the wakeup interrupt does not occur and the WUF flag is not set.
- If the timing of writing 0 to the ICWUR2.WUSEN bit and the timing of detecting a start condition conflict, the IIC might start the next reception in PCLKB synchronous operation mode. In this case, ICWUR2.WUASYF flag becomes 1 (switch to PCLKB asynchronous mode) when data communication is complete, a stop condition is detected, and detection of a wakeup event starts.
- If you want to switch from PCLKB asynchronous operation to PCLKB synchronous operation without address match detection, it will switch in the stop condition detection. When the ICWUR2.WUSEN bit was set to 1 in a bus free state, it is continued PCLKB asynchronous operation (Reception operation: waiting communication frame). ICWUR2.WUASYF flag becomes to 1 when IIC detect the stop condition of the next communication frame, and IIC switches to PCLKB synchronous operation.
- After writing 0 to the WUSEN bit in ICWUR2, do not change registers relate to the IIC operation mode setting (ICMR3, IC SER, and SARL_y) until the mode is switched to PCLKB asynchronous operation from PCLKB synchronous operation (while the ICWUR2.WUASYF flag is 1). If the register value changes during this period by an interrupt handling or another factor, the IIC might malfunction before switching to the asynchronous operation.
- During PCLKB asynchronous operation (ICWUR2.WUASYF = 0 (or WUASYF = 1)), do not refer to each flag of IC SR1, IC SR2 register and ICCR2.BBSY flag.

29.8.1 Normal Wakeup Mode 1

This section describes the behavior, the timing, and an example operation of normal wakeup mode 1.

In normal wakeup mode 1, a wakeup interrupt triggered by the match of the slave address initiates the transition to normal operation as follows:

- Before wakeup: ACK is sent in response to the data received with its own slave address of the IIC.
- During wakeup: ACK response is made on the 9th clock cycle of SCL, after which SCL is held low*1.
- After wakeup: Normal operation continues.

Note 1. Between the 9th clock cycle and 1st clock cycle during wakeup, ICMR1.WAIT = 1 is invalid.

If the slave address does not match, the SCL line is not held low after the 9th clock cycle of SCL, and the slave operation continues. [Figure 29.30](#) shows an operation example, and [Figure 29.32](#) shows the detailed timing.

If the transition from Software Standby mode is triggered by an interrupt other than a wakeup interrupt, for example the IRQn, the WUF flag is not set to 1. [Figure 29.31](#) shows an operation example.

Figure 29.30 Example operation of normal wakeup mode 1 when wakeup is triggered by a wakeup interrupt on match of the slave address

Note: See [Precautions on the use of the wakeup function](#).

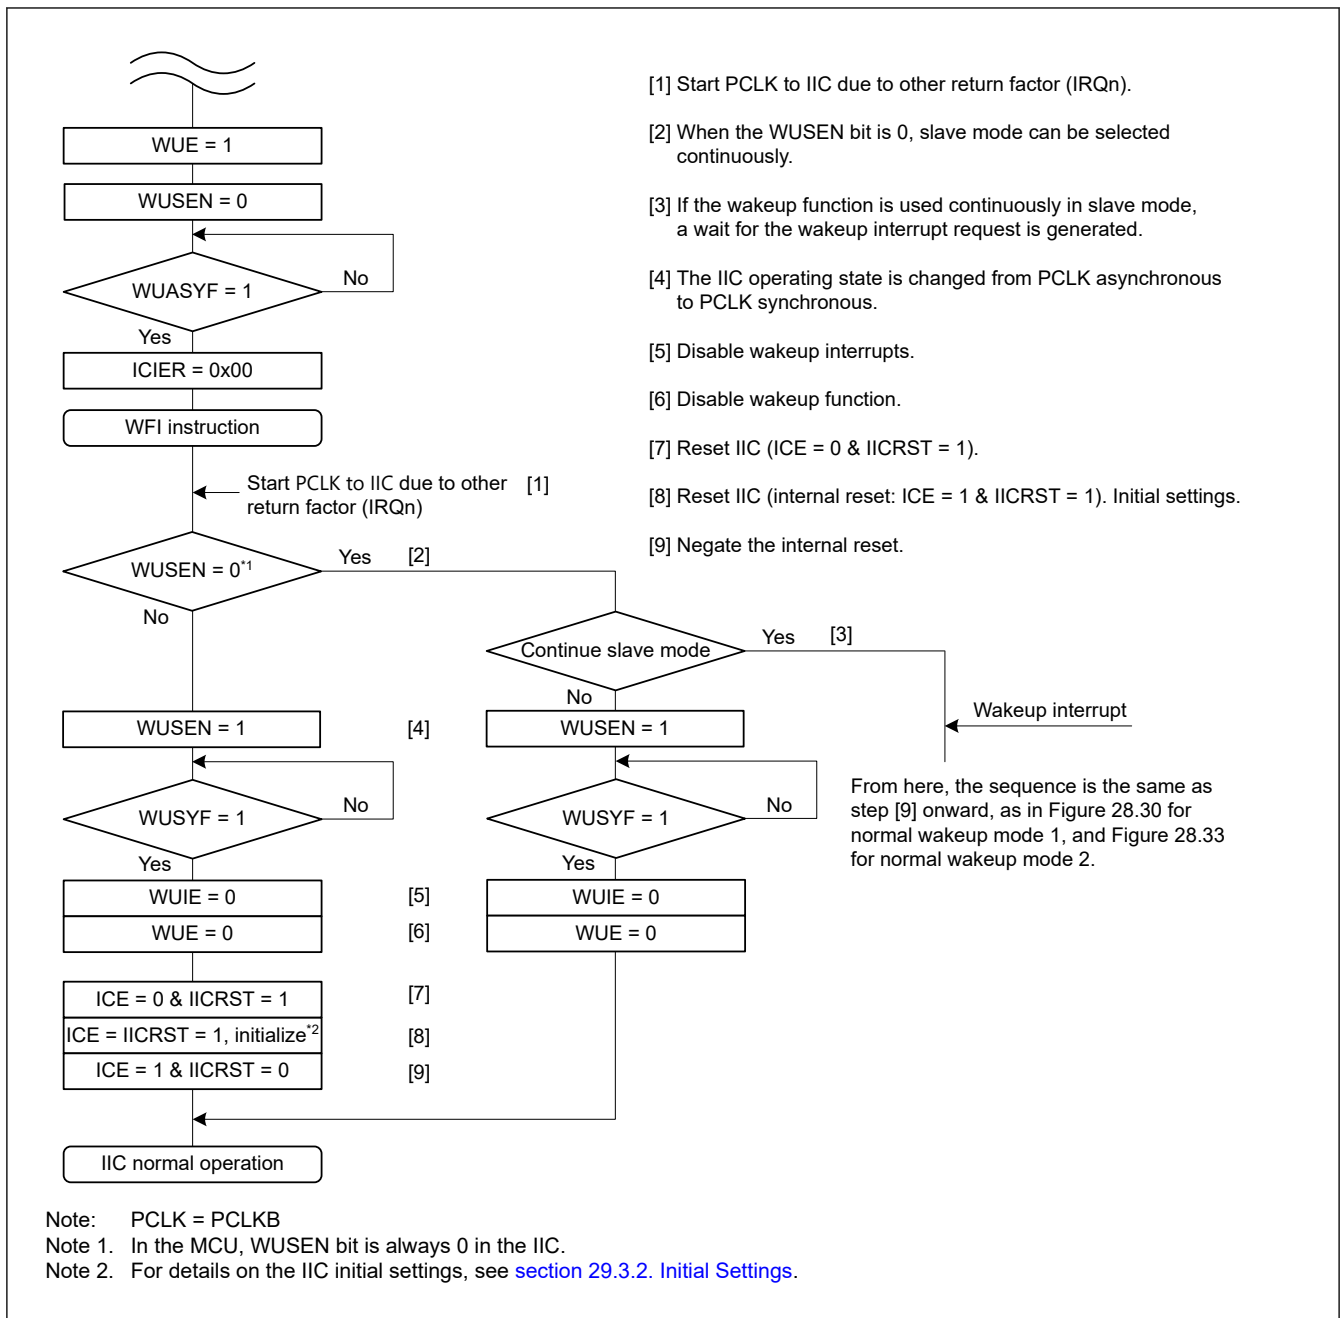

Figure 29.31 Example operation of normal wakeup modes 1 and 2 when wakeup is triggered by an interrupt other than IIC wakeup interrupt, for example, the IRQn

Note: For details on the IIC initial settings, see [section 29.3.2. Initial Settings](#).

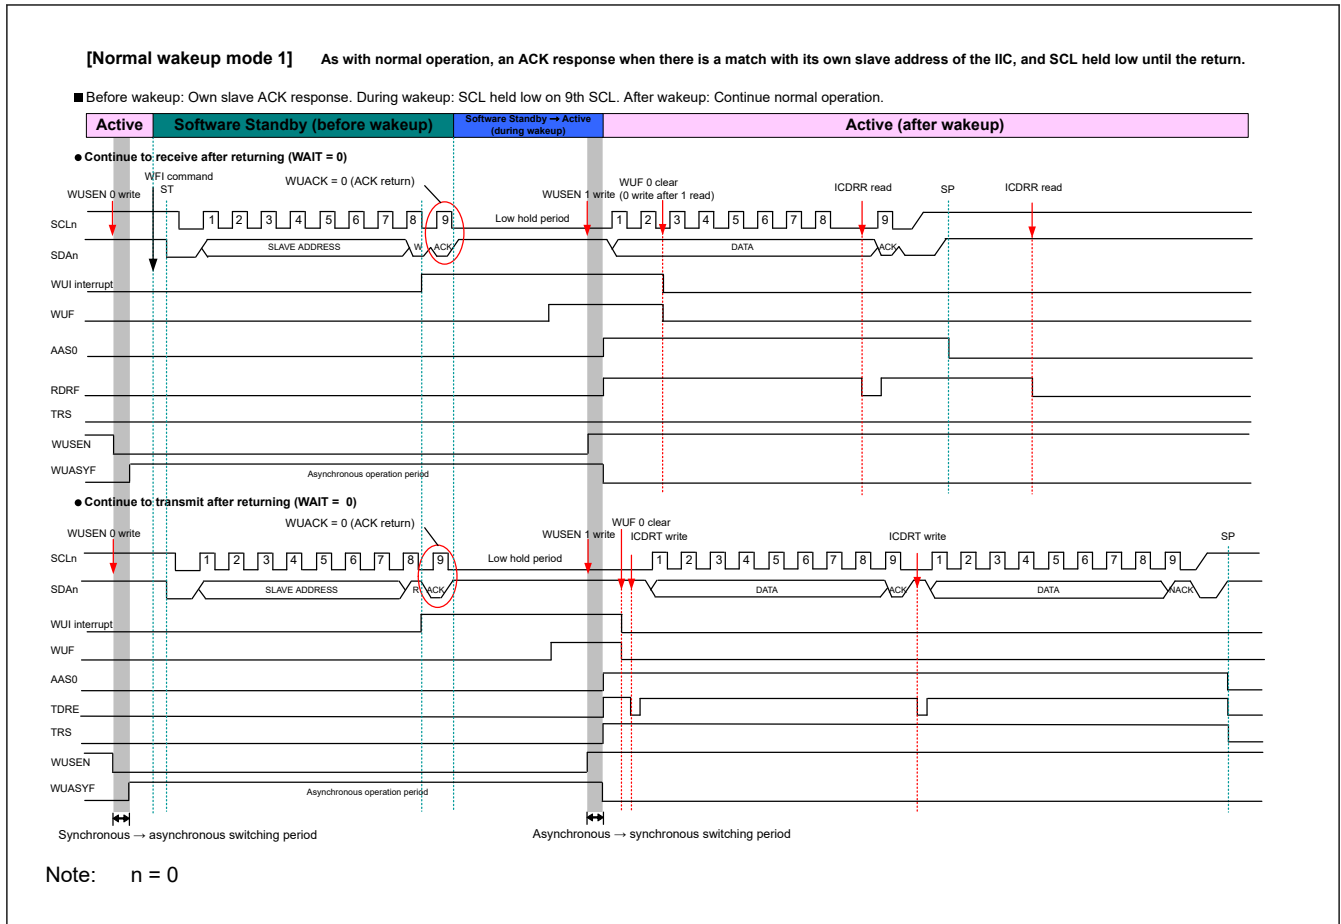

Figure 29.32 Timing of normal wakeup mode 1

29.8.2 Normal Wakeup Mode 2

This section describes the behavior, the timing, and an example operation of normal wakeup mode 2.

In normal wakeup mode 2, a wakeup interrupt triggered by a match of the slave address initiates the transition to normal operation as follows:

- Before wakeup: No response to data received with its own slave address until the end of the 8th SCL cycle.
- During wakeup: SCL line held low during the 8th and 9th clock cycles.
- After wakeup: ACK returns on the 9th clock cycle of SCL, and normal operation continues.

If the slave address does not match, the SCL line is not held low after the 8th SCL clock cycle, and the slave operation continues. Figure 29.33 shows an example operation, and Figure 29.34 shows the detailed timing.

If the transition from Software Standby mode is triggered by an interrupt other than a wakeup interrupt, such as the IRQn, for example, the WUF flag is not set to 1. Figure 29.31 shows an operation example.

Figure 29.33 Example operation of normal wakeup mode 2 when wakeup is triggered by a wakeup interrupt on match of the slave address

Note: See [Precautions on the use of the wakeup function.](#)

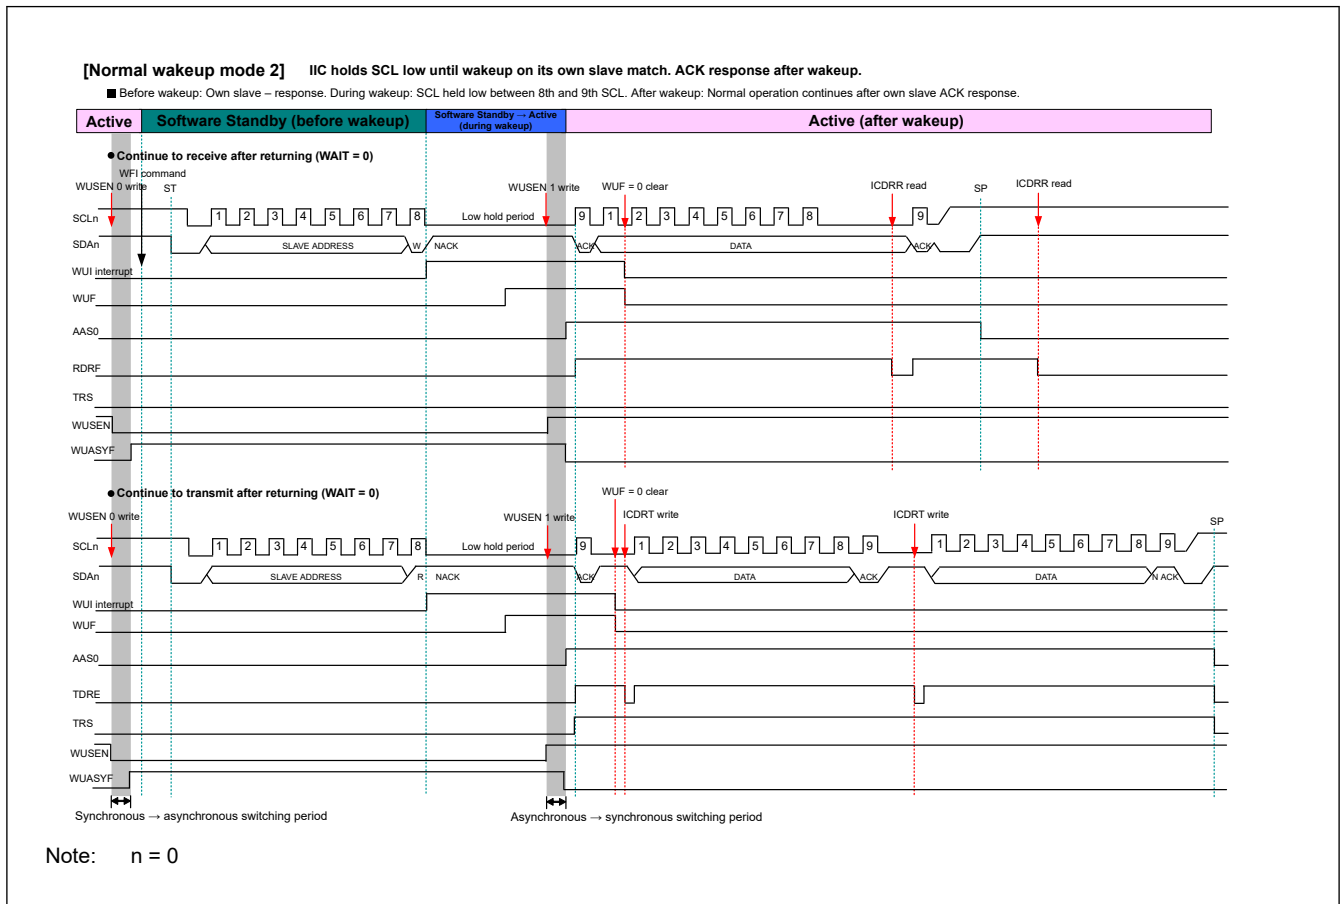

Figure 29.34 Timing of normal wakeup mode 2

29.8.3 Command Recovery Mode and EEP Response Mode (Special Wakeup Modes)

This section describes the behavior, the timing, and example operations of the command recovery and EEP response modes. In the command recovery and EEP response modes, the SCL line is not held low during the wakeup period (after the rise of the 9th clock cycle of SCL). Therefore, other I2C devices can use the I2C bus during this period.

A wakeup interrupt triggered by a match of the slave address initiates the transition to normal operation as follows:

- Before wakeup: In response to the data received with its own slave address, the IIC returns ACK (command recovery mode) or NACK (EEP response mode).
- During wakeup: The SCL line is not held low.
- After wakeup: Normal operation continues after IIC initialization.

If the slave address does not match, the slave operation continues.

Note: Because the SCL line is not held low during wakeup, transmission or reception of the data that follows the slave address is not possible.

Note: The command recovery and EEP response modes are internal reset states (ICE = IICRST = 1). Therefore, the match of the slave address does not set the flags, HOA, GCA, ASS0, ASS1, and ASS2 in the ICSR1 register.

Figure 29.35 shows an example operation in recovery and EEP response modes. Figure 29.37 shows the detailed timing.

If the transition from Software Standby mode is triggered by an interrupt other than a wakeup interrupt, such as IRQn for example, the WUF flag is not set to 1. Follow the processing shown in Figure 29.36.

Figure 29.35 Example operation of command recovery mode and EEP response mode when wakeup is triggered by a wakeup interrupt on match of the slave address

Note: See [Precautions on the use of the wakeup function](#).

Figure 29.36 Example operation of command recovery and EEP response modes when wakeup is triggered by an interrupt other than IIC wakeup interrupt, for example, the IRQn

Figure 29.37 Timing of command recovery and EEP response modes

29.9 Automatic Low-Hold Function for SCL

29.9.1 Function to Prevent Wrong Transmission of Transmit Data

If the I²C Bus Shift Register (ICDRS) is empty and data has not been written to the I²C Bus Transmit Data Register (ICDRT) with the IIC in transmission mode (TRS bit = 1 in ICCR2), the SCLn line is automatically held low over the subsequent intervals. This low-hold period is extended until the transmit data is written, which prevents the unintended transmission of erroneous data.

Master transmit mode:

- Low-level interval after a start or restart condition is issued
- Low-level interval between the 9th clock cycle of one transfer and the 1st clock cycle of the next.

Slave transmit mode:

- Low-level interval between the 9th clock cycle of one transfer and the 1st clock cycle of the next.

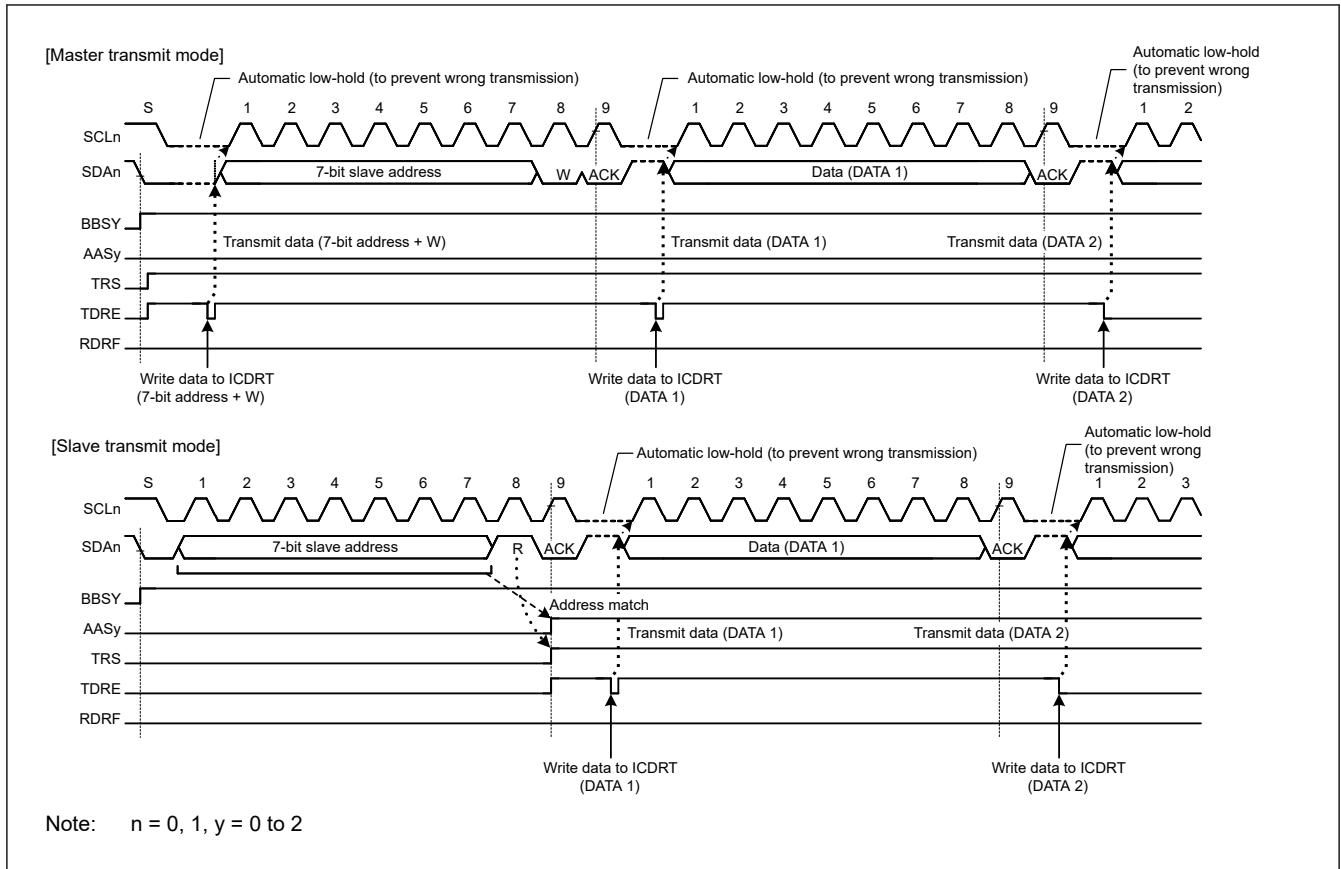

Figure 29.38 Automatic low-hold operation in transmit mode

29.9.2 NACK Reception Transfer Suspension Function

This function suspends transfer operation when NACK is received in transmit mode (TRS bit = 1 in ICCR2). This function is enabled when the NACKE bit in ICFER is set to 1. If the next transmit data is already written (TDRE flag = 0 in ICSR2) when NACK is received, the next data transmission on the falling edge of the 9th SCL clock cycle is automatically suspended. This prevents the SDAn line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is suspended by this function (NACKF flag = 1 in ICSR2), transmit and receive operations are discontinued. To restore transmit or receive operation, after issuing the restart condition, you need to set the NACKF flag to 0 and try again, or set the NACKF flag to 0 after issuing the stop condition and then start again from issuing the start condition.

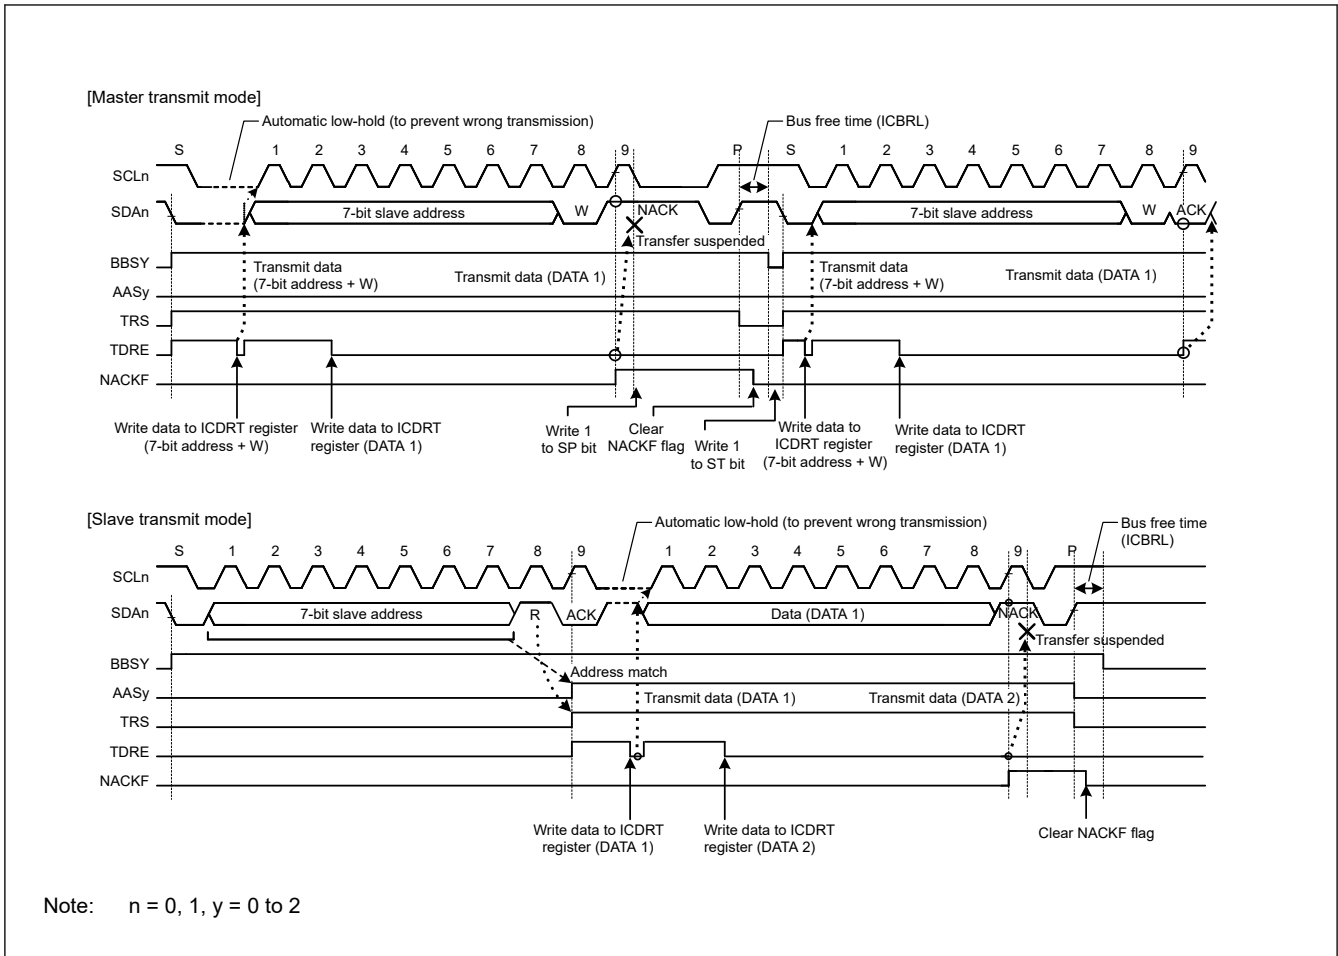

Figure 29.39 Suspension of data transfer when NACK is received, when NACKE = 1

29.9.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (ICDRR) read is delayed for a period of one transfer frame or more with receive data full (RDRF flag = 1 in ICSR2) in receive mode (TRS = 0 in ICCR2), the IIC holds the SCLn line low automatically immediately before the next data is received to prevent a failure to receive data.

This function is enabled even if the read processing of the final receive data is delayed and, in the meantime, the IIC slave address is designated after a stop condition is issued. This function does not interfere with other communication because the IIC does not hold the SCLn line low when a mismatch with its own slave address occurs after a stop condition is issued.

Periods in which the SCLn line is held low can be selected with a combination of the WAIT and RDRFS bits in ICMR3.

(1) 1-byte receive operation and automatic low-hold function using the WAIT bit

When the WAIT bit in ICMR3 is set to 1, the IIC performs a 1-byte receive operation using the WAIT bit function. Additionally, when the ICMR3.RDRFS bit is 0, the IIC automatically sends the ACKBT bit value in ICMR3 for the acknowledge bit in the period from the falling edge of the 8th SCL clock cycle to the falling edge of the 9th SCL clock cycle, and automatically holds the SCLn line low on the falling edge of the 9th SCL clock cycle using the WAIT bit function. This low-hold is released by reading data from ICDRR, which enables byte-wise receive operation.

The WAIT bit function is enabled for receive frames after a match with the IIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

(2) 1-byte receive operation (ACK/NACK transmission control) and automatic low-hold function using the RDRFS bit

When the RDRFS bit in ICMR3 is set to 1, the IIC performs a 1-byte receive operation using the RDRFS bit function. When the RDRFS bit is set to 1, the RDRF flag in ICSR2 is set to 1 (receive data full) on the rising edge of the eighth SCL clock cycle, and the SCLn line is automatically held low on the falling edge of the eighth SCL clock cycle. This low-hold

is released by writing a value to the ACKBT bit in ICMR3, but cannot be released by reading data from ICDRR, which enables receive operation through the ACK or NACK transmission control based on the data received in byte units.

The RDRFS bit function is enabled for receive frames after a match with the IIC slave address, including the general call address and host address, is obtained in master or slave receive mode.

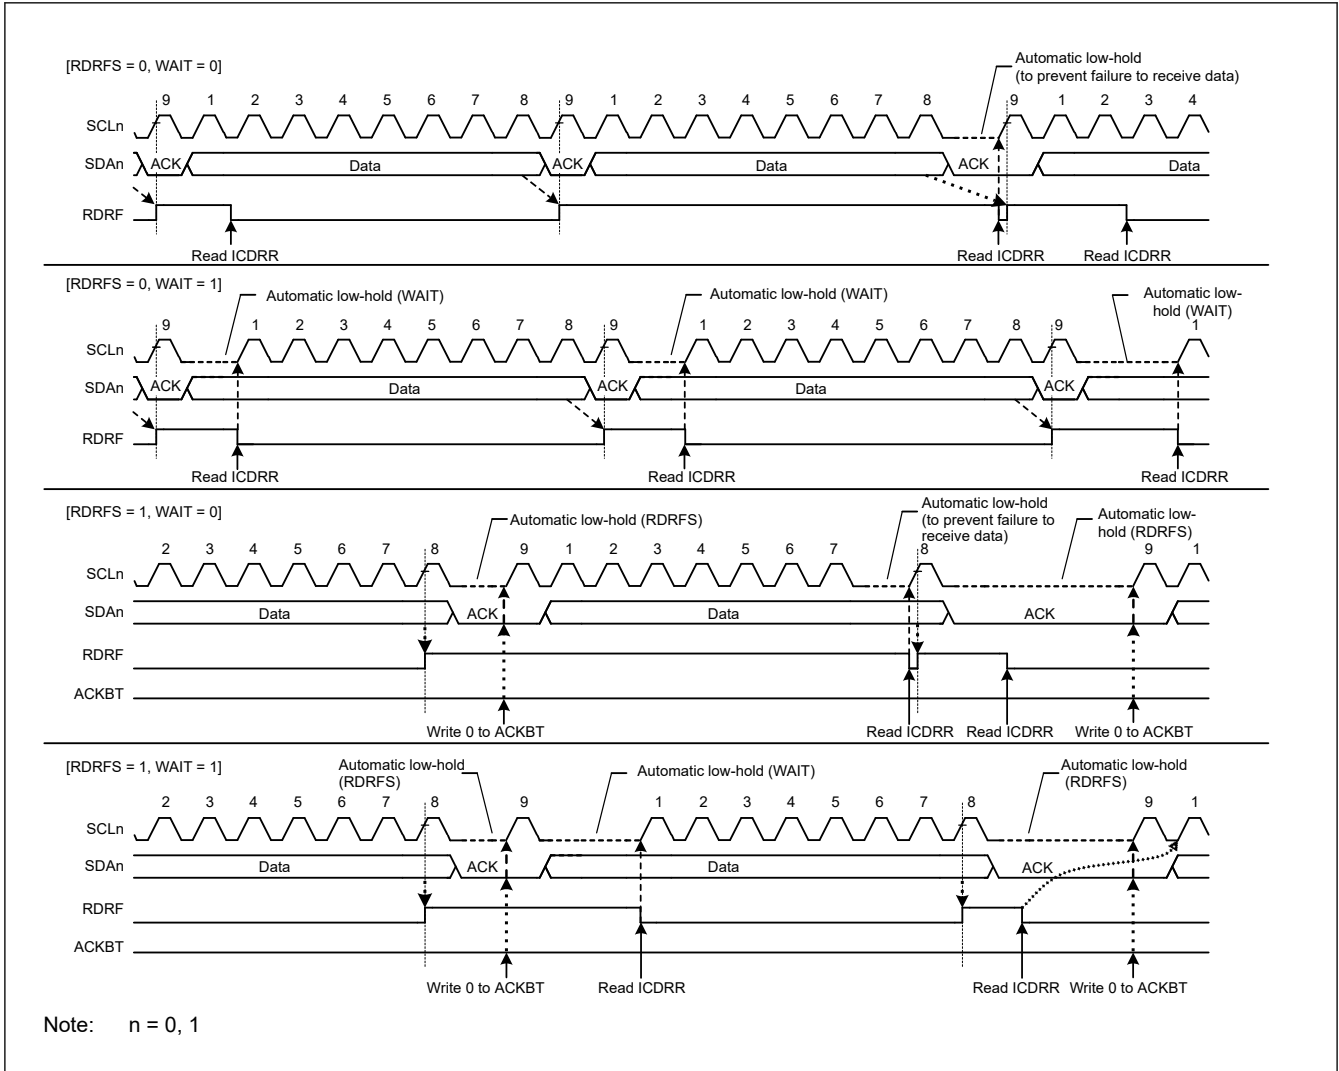

Figure 29.40 Automatic low-hold operation in receive mode using the RDRFS and WAIT bits

29.10 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the I²C bus standard, the IIC provides functions to prevent double-issue of a start condition, detect arbitration-lost during transmission of NACK, and detect arbitration-lost in slave transmit mode.

29.10.1 Master Arbitration-Lost Detection (MALE Bit)

The IIC drives the SDA_n line low to issue a start condition. However, if the SDA_n line was already driven low by another master device issuing a start condition, the IIC regards its own start condition as an error and considers this a loss in arbitration. Priority is given to transfer by the other master device. Similarly, if a request to issue a start condition is made by setting the ST bit in ICCR2 to 1 while the bus is busy (BBSY flag = 1 in ICCR2), the IIC regards this as a double-issuing-of-start-condition error and considers itself to have lost in arbitration. This prevents a failure of transfer resulting from a start condition being issued while transfer is in progress.

When a start condition is issued successfully, if the transmit data including the address bits (internal SDA output level) and the level on the SDA_n line do not match (high output as the internal SDA output, meaning the SDA_n pin is in the high-impedance state and a low level is detected on the SDA_n line), the IIC loses in arbitration.

After a loss in arbitration of mastership, the IIC immediately enters slave receive mode. If a slave address, including the general call address, matches its own address at this time, the IIC continues in slave operation.

A loss in arbitration of mastership is detected when the following conditions are met while the MALE bit in ICCFER is 1 (master arbitration-lost detection enabled).

[Master arbitration-lost conditions]

- Mismatching of the internal level for output on SDA and the level on the SDA_n line after a start condition was issued by setting the ST bit in ICCR2 to 1 while the BBSY flag in ICCR2 is set to 0 (erroneous issuing of a start condition)
- Setting of the ST bit in ICCR2 to 1 (start condition double-issue error) while the BBSY flag is 1
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDA_n line in master transmit mode (MST and TRS bits = 11b in ICCR2).

Figure 29.41 Examples of master arbitration-lost detection when MALE = 1

Figure 29.42 Arbitration-lost when start condition is issued when MALE = 1

29.10.2 Function to Detect Loss of Arbitration during NACK Transmission (NALE Bit)

This function causes arbitration to be lost if the internal SDA output level does not match the level on the SDA_n line (high output as the internal SDA output, meaning the SDA_n pin is in the high-impedance state) and the low level is detected on the SDA_n line during transmission of NACK in receive mode. Arbitration is lost because of a conflict between NACK and ACK transmissions when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such a conflict occurs when multiple master devices send or receive the same information through a single slave device. [Figure 29.43](#) shows an example of arbitration-lost detection during transmission of NACK.

Figure 29.43 Example of arbitration-lost detection during transmission of NACK when NALE = 1

The following explains arbitration-lost detection using an example in which two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives 2 bytes of data from the slave device, and master B receives 4 bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in either master A or master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Master A sends NACK when it has received 2 final bytes of

data from the slave device. Meanwhile, master B sends ACK because it has not received the required 4 bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like this occurs, master A cannot detect the ACK transmitted by master B and issues a stop condition. The stop condition issue conflicts with the SCL clock output of master B, which disrupts communication.

When the IIC receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost. If arbitration is lost during transmission of NACK, the IIC immediately cancels the slave match condition and enters slave receive mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

Similarly, in the ARP command processing of SMBus, the function to detect loss of arbitration during transmission of NACK is also available for eliminating the extra clock cycle processing, such as 0xFF transmission processing, which is required if the UDID (Unique Device Identifier) of the assigned address does not match in the Get UDID general processing after the Assign Address command.

The IIC detects arbitration-lost during transmission of NACK when the following condition is met with the NALE bit in ICFER set to 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

- When the internal SDA output level does not match the SDAn line (ACK is received) during transmission of NACK (ACKBT bit = 1 in ICMR3).

29.10.3 Slave Arbitration-Lost Detection (SALE Bit)

This function causes arbitration to be lost if the transmit data (internal SDA output level) and the level on the SDAn line do not match (high output as the internal SDA output, meaning the SDAn pin is in the high-impedance state), and the low level is detected on the SDAn line in slave transmit mode. This arbitration-lost detection function is mainly used when transmitting a UDID (Unique Device Identifier) over an SMBus.

When the IIC loses slave arbitration, the IIC is immediately released from the slave-matched state and enters slave receive mode. This function can detect conflicts of data during transmission of UDIDs over an SMBus and eliminates subsequent redundant processing for the transmission of 0xFF.

The IIC detects slave arbitration-lost when the following condition is met with the SALE bit in ICFER set to 1 (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

- When transmit data excluding acknowledge (internal SDA output level) does not match the SDAn line in slave transmit mode (MST and TRS bits = 01b in ICCR2).

Figure 29.44 Example of slave arbitration-lost detection when SALE = 1

29.11 Start, Restart, and Stop Condition Issuing Function

29.11.1 Issuing a Start Condition

The IIC issues a start condition when the ST bit in ICCR2 is set to 1. When the ST bit is set to 1, a start condition request is made, and the IIC issues a start condition when the BBSY flag in ICCR2 is 0 (bus free state). When a start condition is issued normally, the IIC automatically shifts to the master transmit mode.

To issue a start condition:

1. Drive the SDA_n line low (high level to low level).
2. Ensure that the time set in ICBRH and the start condition hold time elapse.
3. Drive the SCL_n line low (high level to low level).
4. Detect low level on the SCL_n line and ensure the low-level period of the SCL_n line set in ICBRL elapses.

29.11.2 Issuing a Restart Condition

The IIC issues a restart condition when the RS bit in ICCR2 is set to 1. When the RS bit is set to 1, a restart condition request is made, and the IIC issues a restart condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1 (master mode).

To issue a restart condition:

1. Release the SDA_n line.
2. Ensure the low-level period of the SCL_n line set in ICBRL elapses.
3. Release the SCL_n line (low level to high level).
4. Detect a high level on the SCL_n line and ensure the time set in ICBRL and the restart condition setup time elapse.
5. Drive the SDA_n line low (high level to low level).
6. Ensure the time set in ICBRH and the restart condition hold time elapse.
7. Drive the SCL_n line low (high level to low level).
8. Detect a low level on the SCL_n line and ensure the low-level period of the SCL_n line set in ICBRL elapses.

Note: When issuing restart condition requests, write the slave address to ICDRT after confirming that ICCR2.RS = 0. Data written while ICCR2.RS = 1 is not forwarded because of the retransmission condition before the occurrence.

Figure 29.45 Start and restart condition issue timing using the ST and RS bits

Figure 29.46 shows the operation timing when a restart condition is issued after the master transmission.

[To issue a restart condition after the master transmission:]

1. Initialize the IIC using the procedure in [section 29.3.2. Initial Settings](#).
2. Read the BBSY flag in ICCR2 to check that the bus is open, then set the ST bit in ICCR2 to 1 (start condition issuance request). On receiving the request, the IIC issues a start condition. At the same time, the BBSY and the START flags in ICSR2 are automatically set to 1 and the ST bit is automatically set to 0. If the start condition is detected and the internal levels for the SDA output state and the levels on the SDA_n line match while the ST bit is 1, the IIC recognizes that a start condition is successfully issued as requested by the ST bit has been successfully completed. The MST and TRS bits in ICCR2 are automatically set to 1, placing the IIC in master transmit mode. The TDRE flag in ICSR2 is also automatically set to 1 when the TRS bit is set to 1.
3. Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. After the data for transmission is written to ICDRT, the TDRE flag is automatically set to 0, data is transferred from ICDRT to ICDRS, and the TDRE flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS bit is automatically updated to select master transmit or master receive mode according to the value of the transmitted R/W# bit. If the value of the R/W# bit is 0, the IIC continues in master transmit mode. If the ICSR2.NACKF flag is 1 at this time, indicating that no slave device recognized the address or that there was an error in communications, write 1 to ICCR2.SP bit to issue a stop condition. To transmit data with an address in the 10-bit format, start by writing 1111 0b, the 2 upper bits of the slave address, and W to ICDRT as the first address transmission. Then, as the second address transmission, write the 8 lower bits of the slave address to ICDRT.
4. After confirming that the TDRE flag in ICSR2 is 1, write data for transmission to the ICDRT register. The IIC automatically holds the SCL_n line low until data for transmission is ready, a restart condition is issued or a stop condition is issued.
5. After all bytes of data for transmission are written to the ICDRT register, wait until the value of the TEND flag in ICSR2 returns to 1. Then after checking that the START flag in ICSR2 is 1, set the START flag in ICSR2 to 0.
6. Set the RS bit in ICCR2 to 1 (restart condition issue request). On receiving the request, the IIC issues a restart condition.
7. After checking that the START flag in ICSR2 is 1, write the value for transmission (the slave address and the R/W# bit) to ICDRT.

Figure 29.46 Restart condition issue timing after master transmission.

29.11.3 Issuing a Stop Condition

The IIC issues a stop condition when the SP bit in ICCR2 is set to 1. When the SP bit is set to 1, a stop condition request is made, and the IIC issues a stop condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1 (master mode).

To issue a stop condition:

1. Drive the SDAn line low (high level to low level).
2. Ensure the low-level period of the SCLn line set in ICBRL elapses.
3. Release the SCLn line (low level to high level).
4. Detect a high level on the SCLn line and ensure the time set in ICBRH and the stop condition setup time elapse.
5. Release the SDAn line (low level to high level).
6. Ensure the time set in ICBRL and the bus free time elapse.
7. Clear the BBSY flag to 0 to release the bus mastership.

Figure 29.47 Stop condition issue timing using the SP bit

29.12 Bus Hanging

If the clock signals from the master and slave devices are out of synchronization because of noise or other factors, the I²C bus might hang with a fixed level on the SCLn line or SDAn line.

To manage bus hanging, the IIC has a timeout function to detect hanging by monitoring the SCLn line, and a function for outputting an extra SCL clock cycle to release the bus from:

- A timeout function to detect hanging by monitoring the SCLn line
- The IIC reset function
- An internal reset function.

By checking the SCLO, SDAO, SCLI, and SDAI bits in ICCR1, it is possible to see whether the IIC or its communicating partner is placing the low level on the SCLn or SDAn line.

29.12.1 Timeout Function

The timeout function can detect when the SCLn line is stuck longer than the predetermined time. The IIC can detect an abnormal bus state by monitoring that the SCLn line is stuck low or high for a predetermined time.

The timeout function monitors the SCLn line state and counts the low- or high-level period using the internal counter. The timeout function resets the internal counter each time the SCLn line changes (rises or falls), but continues to count unless the SCLn line changes. If the internal counter overflows because no SCLn line changes, the IIC can detect the timeout and report the bus hung state.

This timeout function is enabled when the ICFER.TMOE bit is 1. It detects a hung state when the SCLn line is stuck low or high during the following conditions:

- The bus is busy (ICCR2.BBSY flag is 1) in master mode (ICCR2.MST bit is 1)
- The IIC slave address is detected (ICSR1 register is not 0x00) and the bus is busy (ICCR2.BBSY flag is 1) in slave mode (ICCR2.MST bit is 0)
- The bus is open (ICCR2.BBSY flag is 0) while a start condition is requested (ICCR2.ST bit is 1).

The internal counter of the timeout function uses the internal reference clock (IICφ) set in the CKS[2:0] bits in ICMR1 as a count source. It functions as a 16-bit counter when long mode is selected (TMOS bit = 0 in ICMR2) or a 14-bit counter when short mode is selected (TMOS bit = 1).

The SCLn line level (low, high, or both levels) during which this counter is activated can be selected in the TMOH and TMOL bits in ICMR2. If both TMOL and TMOH bits are set to 0, the internal counter is disabled.

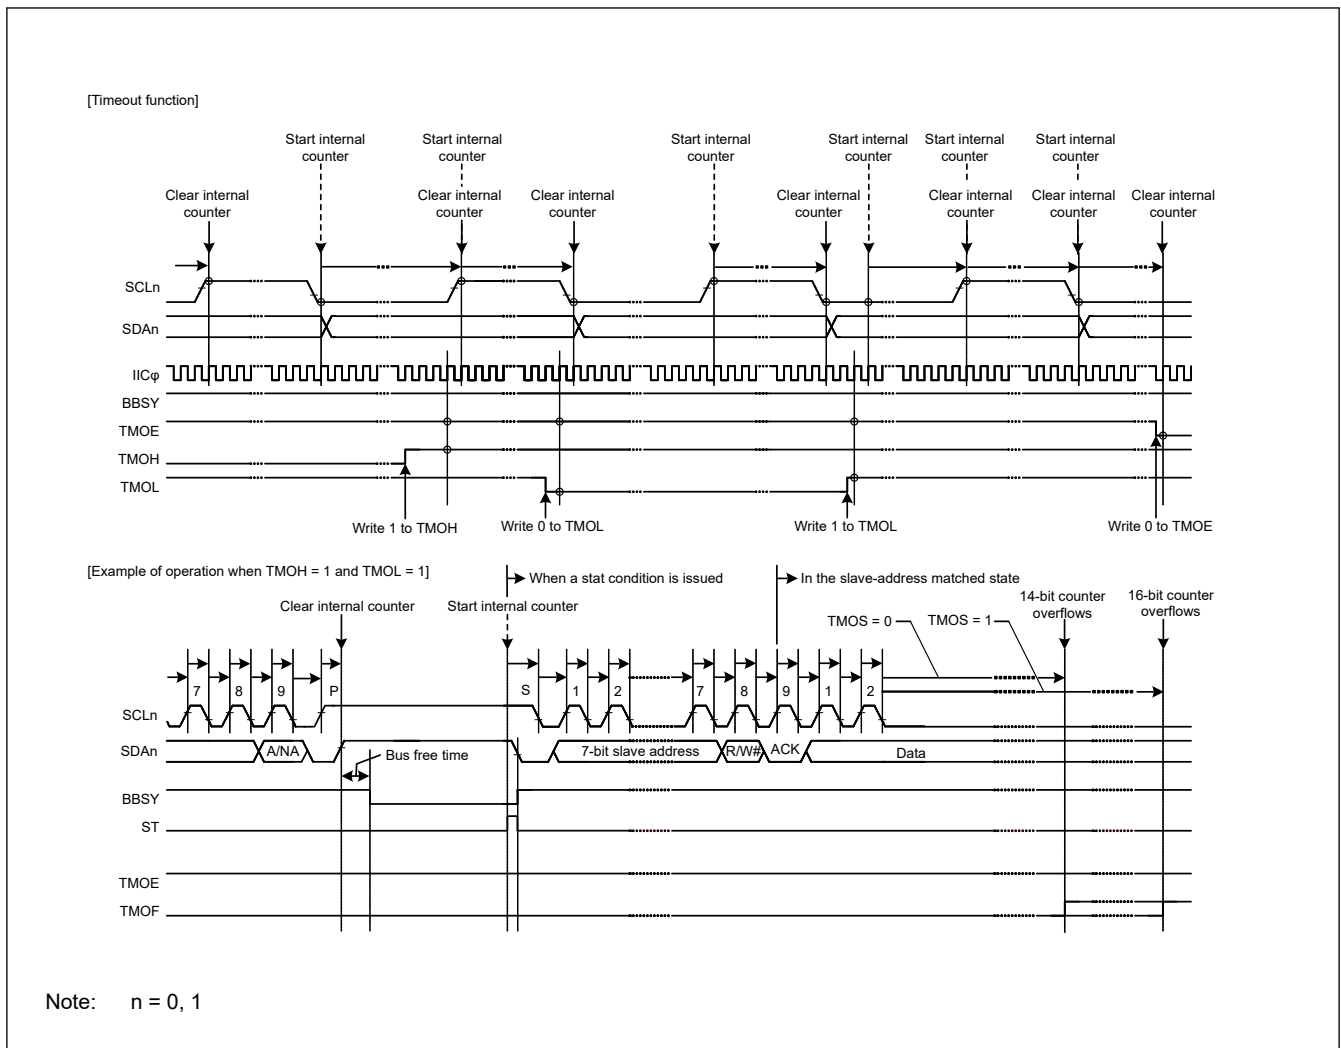

Figure 29.48 Timeout function using the TMOE, TMOS, TMOH, and TMOL bits

29.12.2 Extra SCL Clock Cycle Output Function

In master mode, this function outputs extra SCL clock cycles to release the SDAn line of the slave device from being held low because the master is out of synchronization with the slave device. This function is mainly used in master mode to release the SDAn line of the slave device from being fixed low by including extra cycles of SCL output from the IIC. It uses single cycles of the SCL clock for a bus error where the IIC cannot issue a stop condition because the slave device is holding the SDAn line at the low level. Do not use this function in normal situations. Using it when communications are proceeding correctly leads to malfunctions.

When the CLO bit in ICCR1 is set to 1 in master mode, a single cycle of the SCL clock at the frequency specified in the CKS[2:0] bits in ICMR1, and in the ICBRH and ICBRL registers, is output as an extra clock cycle. After output of this single cycle of the SCL clock, the CLO bit is automatically set to 0. At this time, if ICCR2.BBSY = 1, the SCL pin goes low, and when ICCR2.BBSY = 0, the SCL pin goes high. After confirming that the CLO bit is 0 by software, write 1 to the CLO bit to output the additional clock continuously.

When the IIC module is in master mode and the slave device is holding the SDAn line low because synchronization with the slave device is lost because of effects like noise, the output of a stop condition is not possible. This function can be used to output extra cycles of SCL one by one to make the slave device release the SDAn line from being held low, and so recover the bus from an unusable state. Release of the SDAn line by the slave device can be monitored by reading the SDAI bit in ICCR1. After confirming the release of the SDAn line by the slave device, complete communications by reissuing the stop condition.

[Output conditions for using the CLO bit in ICCR1]

- When the bus is open (BBSY flag in ICCR2 = 0) or in master mode (MST bit = 1 and BBSY flag = 1 in ICCR2)

- When the communication device does not hold the SCLn line low.

Figure 29.49 shows the operation timing of the extra SCL clock cycle output function (CLO bit).

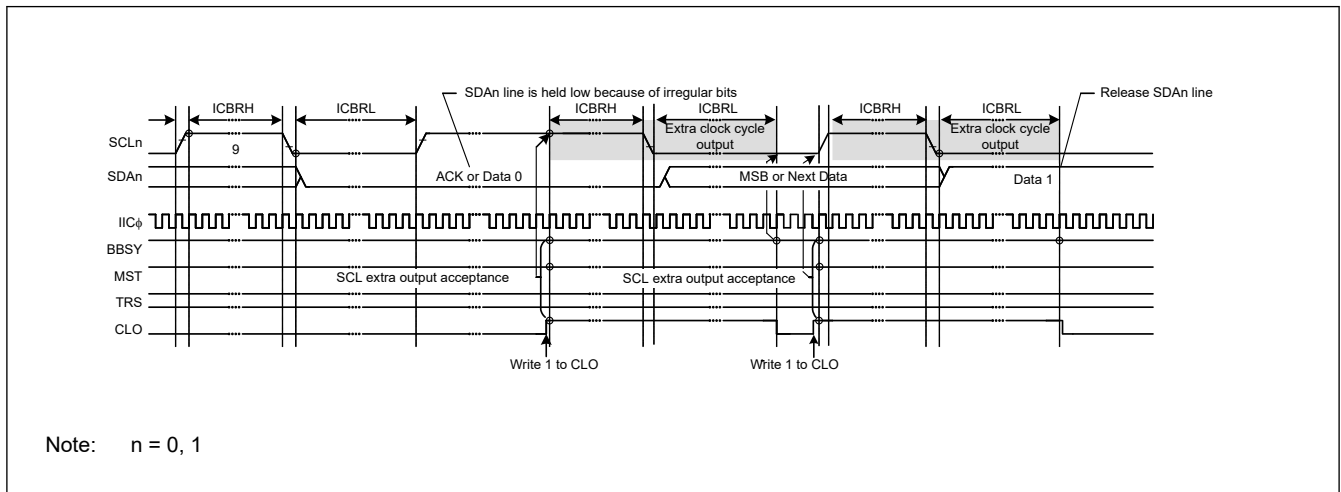

Figure 29.49 Extra SCL clock cycle output function using the CLO bit

29.12.3 IIC Reset and Internal Reset

The IIC module incorporates a function for resetting itself. It uses two types of resets:

- An IIC reset, which initializes all registers, including the BBSY flag in ICCR2.
- An internal reset, which releases the IIC from the slave-address matched state and initializes the internal counter while saving other settings.

After issuing a reset, always set the IICRST bit in ICCR1 to 0. Both types of resets are valid for release from bus-hung states, because both restore the output state of the SCLn and SDAn pins to the high-impedance state.

Issuing a reset during slave operation might lead to a loss of synchronization between the master device clock and the slave device clock, so avoid this when possible. In addition, monitoring of the bus state, such as for the presence of a start condition, is not possible during an IIC reset (ICE and IICRST bits = 01b in ICCR1).

For a detailed description of the IIC and internal resets, see [section 29.15. State of Registers When Issuing Each Condition](#).

29.13 SMBus Operation

The IIC supports data communication conforming to the SMBus Specification (version 2.0). To perform SMBus communication, set the SMBS bit in ICMR3 to 1. To use the transfer rate within a range of 10 to 100 kbps of the SMBus standard, set the CKS[2:0] bits in ICMR1, the ICBRH, and ICBRL registers. In addition, specify the values in the DLCS bit in ICMR2 and the SDDL[2:0] bits in ICMR2 to meet the data hold time specification of 300 ns or more. When the IIC is used only as a slave device, the transfer rate setting is not required, but ICBRL must be set to a value longer than the data setup time (250 ns).

For the SMBus device default address (1100 001b), use one of the slave address registers L0 to L2 (SARL0, SARL1, and SARL2), and set the associated FS bit (7- or 10-bit address format select) in SARUy (y = 0 to 2) to 0 (7-bit address format).

When transmitting the UDID (Unique Device Identifier), set the SALE bit in ICFER to 1 to enable the slave arbitration-lost detection function.

29.13.1 SMBus Timeout Measurement

(1) Measuring slave device timeout

The following period (timeout interval: $T_{LOW:SEXT}$) must be measured for slave devices in SMBus communication:

- From start condition to stop condition.

To measure timeout for slave devices, measure the period from start condition detection to stop condition detection with the GPT using the IIC start condition detection interrupt (STIn) and stop condition detection interrupt (SPIn). The measured timeout period must be within the total clock low-level period [slave device] $T_{LOW:SEXT}$: 25 ms (maximum) of the SMBus standard.

If the time measured with the GPT exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (minimum) of the SMBus standard, the slave device must release the bus by writing 1 to the IICRST bit in ICCR1 to issue an internal reset of the IIC. When an internal reset is issued, the IIC stops driving the bus for the SCLn and SDAn pins, making them output high-impedance, which releases the bus.

(2) Measuring master device timeout

The following periods (timeout interval: $T_{LOW:MEXT}$) must be measured for master devices in SMBus communication:

- From start condition to acknowledge bit
- Between acknowledge bits
- From acknowledge bit to stop condition.

To measure timeout for master devices, measure these periods with the GPT using the IIC start condition detection interrupt (STIn), stop condition detection interrupt (SPIn), transmit end interrupt (IICn_TEI), or receive data full interrupt (IICn_RXI). The measured timeout period must be within the total clock low-level extended period (master device) $T_{LOW:MEXT}$: 10 ms (maximum) of the SMBus standard, and the total of all $T_{LOW:MEXT}$ values from start condition to stop condition must be within $T_{LOW:SEXT}$: 25 ms (maximum).

For the ACK receive timing (rising edge of the 9th SCL clock cycle), monitor the TEND flag in ICSR2 in master transmit mode (master transmitter) and the RDRF flag in ICSR2 in master receive mode (master receiver). Perform byte-wise transmit operations in master transmit mode, and hold the RDRFS bit in ICMR3 at 0 until the byte immediately before reception of the final byte in master receive mode. While the RDRFS bit is 0, the RDRF flag is set to 1 on the rising edge of the 9th SCL clock cycle.

If the period measured with the GPT exceeds the total clock low-level extended period (master device) $T_{LOW:MEXT}$: 10 ms (maximum) of the SMBus standard or the total of measured periods exceeds the clock low-level detection timeout $T_{TIMEOUT}$: 25 ms (minimum) of the SMBus standard, the master device must stop the transaction by issuing a stop condition. In master transmit mode, immediately stop the transmit operation (stop writing data to ICDRT).

Figure 29.50 SMBus timeout measurement

29.13.2 Packet Error Code (PEC)

The MCU provides a CRC calculator that enables transmission of a Packet Error Code (PEC) or allows checking of the received data in SMBus data communication for the IIC. For the CRC-generating polynomials of the CRC calculator, see [section 36, Cyclic Redundancy Check \(CRC\)](#).

In master transmit mode, the PEC data can be generated by writing all transmit data to the CRC Data Input Register (CRCDIR) in the CRC calculator.

In master receive mode, the PEC data can be checked by writing all receive data to CRCDIR in the CRC calculator and comparing the obtained value in the CRC Data Output Register (CRCDOR) with the received PEC data.

To send ACK or NACK based on the match or mismatch result when the final byte is received as a result of the PEC code check, set the RDRFS bit in ICMR3 to 1 before the rising edge of the 8th SCL clock cycle during reception of the final byte, and hold the SCLn line low on the falling edge of the 8th clock cycle.

29.13.3 SMBus Host Notification Protocol (Notify ARP Master Command)

In communicating over an SMBus, a slave device can temporarily act as a master device to notify the SMBus host (or ARP master) of its own slave address, or to request its own slave address from the SMBus host.

For a product using the MCU to operate as an SMBus host or ARP master, the host address (0001 000b) sent from the slave device must be detected as a slave address, and so the IIC provides a function for detecting the host address. To detect the host address as a slave address, set the SMBS bit in ICMR3 and the HOAE bit in ICSE to 1. Operation after the host address is detected is the same as normal slave operation.

29.14 Interrupt Sources

The IIC issues five types of interrupt requests:

- Transfer error or event generation (arbitration-lost, NACK detection, timeout detection, start condition detection, and stop condition detection)
- Receive data full
- Transmit data empty
- Transmit end
- Address match during wakeup function

[Table 29.10](#) lists details about the interrupt requests. The receive data full and transmit data empty interrupts can activate data transfer by the DTC or DMAC.

Table 29.10 Interrupt sources

Symbol	Interrupt source	Interrupt flag	DTC or DMAC activation	Interrupt condition
IICn_EEI* ⁵	Transfer error or event occurrence	AL	Not possible	AL = 1, ALIE = 1
		NACKF		NACKF = 1, NAKIE = 1
		TMOF		TMOF = 1, TMOIE = 1
		START		START = 1, STIE = 1
		STOP		STOP = 1, SPIE = 1
IICn_RXI* ² * ⁵	Receive data full	RDRF	Possible	RDRF = 1, RIE = 1
IICn_TXI* ¹ * ⁵	Transmit data empty	RDRF	Possible	TDRE = 1, TIE = 1
IICn_TEI* ³ * ⁵	Transmit end	TEND	Not possible	TEND = 1, TEIE = 1
IIC0_WUI* ⁴	Slave address match during wakeup function	WUF	Not possible	Slave address match Slave receive complete RWAK operation ASY0 = 1 WUIE = 1

Note: There is a delay between the execution of a write instruction for a peripheral module by the CPU and the actual writing to the module. When an interrupt flag is cleared or masked, read the relevant flag again to check whether clearing or masking is complete, then return from interrupt handling. Not doing so creates the possibility of repeated processing of the same interrupt.

- Note 1. Because IICn_TXI is edge-detected, it does not require clearing. Additionally, the TDRE flag in ICSR2 (condition for IICn_TXI) is automatically set to 0 when transmit data is written to the ICDRT register or a stop condition is detected (STOP flag = 1 in ICSR2).
- Note 2. Because IICn_RXI is edge-detected, it does not require clearing. Additionally, the RDRF flag in ICSR2 (condition for IICn_RXI) is automatically set to 0 when data is read from ICDRR.
- Note 3. When using the IICn_TEI interrupt, clear the TEND flag in ICSR2 in the IICn_TEI interrupt handling. The TEND flag in ICSR2 automatically is set to 0 when transmit data is written to the ICDRT register or a stop condition is detected (STOP flag = 1 in ICSR2).
- Note 4. Only channel 0 has a wakeup function, so IIC0_WUI is for channel 0 only.
- Note 5. Channel number (n = 0 to 1).

Clear or mask each flag during interrupt handling.

29.14.1 Buffer Operation for IICn_TXI and IICn_RXI Interrupts

If the conditions for generating an IICn_TXI or IICn_RXI interrupt are satisfied while the associated IR flag is 1, the interrupt request is not output for the ICU but is saved internally. One request per source can be saved internally.

An interrupt request that is saved in the ICU is output when the ICU.IELSRn.IR flag becomes 0. Internally saved interrupt requests are automatically cleared under normal conditions. They can also be cleared by writing 0 to the interrupt enable bit within the associated peripheral module.

29.15 State of Registers When Issuing Each Condition

The IIC has two dedicated resets, IIC reset and Internal reset. [Table 29.11](#) lists the registers states when issuing each condition.

Table 29.11 Register states when issuing each condition (1 of 2)

Registers		Reset	IIC reset (ICE = 0, IICRST = 1)	Internal reset (ICE = 1, IICRST = 1)	Start or restart condition detection	Stop condition detection	
ICCR1	ICE, IICRST	In reset	Saved	Saved	Saved	Saved	
	SCLO, SDAO		In reset	In reset			
	Others			Saved			
ICCR2	BBSY	In reset	In reset	Saved	Set	In reset

29.16 Event Link Output

The IIC0 module handles the event output for the Event Link Controller (ELC) for the following sources:

(1) Transfer error event

When a transfer error event occurs, the associated event signal can be output to another module by the ELC.

(2) Receive data full

When a receive data register becomes full, the associated event signal can be output to another module by the ELC.

(3) Transmit data empty

When a transmit data register becomes empty, the associated event signal can be output to another module by the ELC.

(4) Transmit end

On completion of the transfer, the associated event signal can be output to another module by the ELC.

29.16.1 Interrupt Handling and Event Linking

Each of the IIC interrupt types (see [Table 29.10](#)) has an enable bit to control enabling and disabling of the associated interrupt signal. An interrupt request signal is output to the CPU when an interrupt source condition is satisfied while the associated enable bit is set.

The associated event link output signals are sent to other modules as event signals by the ELC when the interrupt source conditions are satisfied, regardless of the interrupt enable bit settings. For details on interrupt sources, see [Table 29.10](#).

29.17 Usage Notes

29.17.1 Settings for the Module-Stop Function

The Module Stop Control Register B (MSTPCRB) can enable or disable IIC operation. The IIC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

29.17.2 Notes on Starting Transfer

If the IR flag associated with the IIC interrupt is 1 when transfer is started (ICCR1.ICE bit = 1), follow the procedure in this section to clear the interrupts before enabling operations. Starting transfer with the IR flag set to 1 while the ICCR1.ICE bit is 1 leads to an interrupt request being internally saved after transfer starts, and this can lead to unexpected behavior of the IR flag.

To clear interrupts before starting transfer operation:

1. Confirm that the ICCR1.ICE bit is 0.

2. Set the relevant interrupt enable bits, such as ICIER.TIE to 0.
3. Read the relevant interrupt enable bits, such as ICIER.TIE, and confirm that the value is 0.
4. Set the IR flag to 0.

30. CAN with Flexible Data-rate (CANFD)

30.1 Overview

The CAN with Flexible Data-rate (CANFD) supports the following functions:

- CAN with Flexible Data-rate.*¹

Note 1. This feature is not available in the classical CAN function.

The CANFD module has a flexible message buffer and FIFO structure that meet the requirements of various applications. It also provides test modes to achieve high testability of the module that can be useful for power-on testing.

This specification describes of the CANFD module.

The CANFD mode is only available in certain products that support it.

30.1.1 CANFD Module

Table 30.1 CANFD module specifications (1 of 2)

Parameter		Specifications
Communication		CAN functionality conforms to CANFD ISO 11898-1 (2015)
Protocol engine version		RS-CANFD_PE V3.0
Data transfer rate	CANFD* ¹	Up to 1 Mbps for arbitration phase and up to 8 Mbps for data phase, individually for CAN channel
	Classical CAN	Up to 1 Mbps
Operation frequency of Peripheral module clock		120 MHz (PCLKA) RAM clock: 240 MHz (PCLKE)
Data Link Layer (DLL) clock		8 MHz to 80MHz The following clocks can be selected. <ul style="list-style-type: none"> • CANMCLK : External Oscillator Clock • CANFDCLK : CANFD Core Clock
Input/Output pins		CRXn/CTXn (n = 0, 1)
CAN channels		2 channels
Selectable ID type		11-bit Standard ID
		11-bit Standard ID + 18-bit Extended ID
Selectable frame type		Data frame (RTR = 0) (CAN and CANFD frames)
		Remote frame (RTR = 1) (only CAN frames)
Variable data byte count for data frames		DLC range: 0 to F
Message buffer		Up to 16 reception message buffers
		4 transmit message buffers per channel
		1 transmission queue per channel Automatic message transfer into transmission queues supported
FIFO number		2 reception FIFO buffers 1 COMMON FIFO individually configurable as: <ul style="list-style-type: none"> • Reception FIFO • Transmission FIFO
Automatic delay interval timer for transmission		The delay timer can be applied to: <ul style="list-style-type: none"> • Transmission FIFO

Table 30.1 CANFD module specifications (2 of 2)

Parameter	Specifications
Enhanced reception filtering	Support of 11 bits and 29 bits CAN identifier
	Programmable 29 bits CAN identifier acceptance filter mask for each entry
	Programmable routing capability for each FIFO and reception message buffers (up to 2 routing destinations)
	RTR and IDE masking
	Data Length Code (DLC) filter
	Message buffer payload overload protection
	Payload filter
	Updating Acceptance Filter List (AFL) entry during communication
General software support	Automatic label information added to receive message (for upper software layer support)
Timer	TX and RX Time Stamp function
Power down function	Module start stop function for each CAN node (Channel and Global Sleep mode)
RAM	RAM ECC protected (2 bits error detection, 1-bit error correction)
Module-stop function	Module-stop state can be set for each channels to reduce power consumption.
TrustZone Filter	Security and Privilege attribution can be set for each channels.

Note 1. The CANFD mode is available only for CANFD supported product.

Figure 30.1 Overview of the CANFD module

- CRXn/CTXn:
Input/Output pins of the CANFD module
- Protocol controller:
Handles CAN protocol processing such as bus arbitration, bit timing at transmission and reception, stuffing, error handling

- Message buffer RAM (MBRAM):
This RAM is used to store messages after reception or for transmission using a normal message buffer or a FIFO. Each message entry has an individual ID, data length code, data field, message pointer for upper layer application usage and a time stamp.
This RAM is used to store the message acceptance filtering entries. Each acceptance filter entry has an individual ID, data length code, data field, message pointer for upper layer application usage and message direction pointer.
- Acceptance filter list RAM (AFLRAM):
Performs filtering of received messages. The entries in the Acceptance filter list RAM are used for the filtering process.
- Two timers:
 - Reception Timestamp function
 - Transmission separation time for FIFO buffers
- Interrupt generator:
Generates several types of global and channel interrupts
- CAN Special Function Registers (SFRs):
Registers associated with CAN. See [section 30.2. Register Descriptions](#).

30.1.2 Clock restriction

For the CAN communication the following restriction for the clocks should be satisfied:

- $PCLKE / 2 = PCLKA \geq CANFDCLK$
- $PCLKE / 2 = PCLKA \geq CANMCLK$

To avoid missing events the CAN engine clock (CANFDCLK or CANMCLK) frequency must be less than the PCLKA clock frequency.

To avoid loss of CAN message, the PCLKA should be set to a clock with a frequency depend on the CAN communication Baud Rate. The constraint of a baud rate and a PCLKA clock is shown in [Table 30.2](#).

Table 30.2 Clock restriction

	Baud rate	PCLKA
CANFD	1 Mbps Nominal 8 Mbps Data	PCLKA \geq 40 MHz
	500 Kbps Nominall 5 Mbps Data	PCLKA \geq 32 MHz
Classical CAN	1 Mbps Data	PCLKA \geq 32 MHz

The frequency of CANFDCLK and CANMCLK depend on the required baud rate. For information how to configure the baud rate, refer to [section 30.4.1.3. Baud Rate](#).

30.2 Register Descriptions

30.2.1 Register Table

The reset value shown for the RAM area, consisting of CFDGAFLLIDr, CFDGAFLLMr, CFDGAFLLP0r, CFDGAFLLP1r, CFDRMBBCPb, CFDRFMBBCPb, CFDCFMBBCP0, CFDTMBBCPb, CFDTHLACC0, CFDTHLACC1 and CFDRPGACCK is valid after initialization of a hardware reset. See [section 30.4.2. CAN Module Configuration after Hardware Reset](#) for details of the initialization process.

If a write access with a size of 8 or 16 bits is performed for the RAM area, then the CANFD module does a read-modify write-access to the RAM location, because the RAM requires a 32-bit access through the ECC module.

For single bit error, the correct data is written back. For multiple bit errors, unknown data is written back.

Do not access the space where the register is not assigned.

The read data from the space where the register is not assigned is unknown.

30.2.2 CFDC0NCFG : Nominal Bitrate Configuration Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0000

Value after reset: 0

Bit	Symbol	Function	R/W
9:0	NBRP[9:0]	Channel Nominal Baud Rate Prescaler Nominal baud rate prescaler division ratio	R/W
16:10	NSJW[6:0]	Resynchronization Jump Width 0x00: 1 Tq 0x01: 2 Tq ⋮ 0x7E: 127 Tq 0x7F: 128 Tq	R/W
24:17	NTSEG1[7:0]	Timing Segment 1 0x00: Reserved 0x01: 2 Tq 0x02: 3 Tq 0x03: 4 Tq ⋮ 0xFE: 255 Tq 0xFF: 256 Tq	R/W
31:25	NTSEG2[6:0]	Timing Segment 2 0x00: Reserved 0x01: 2 Tq ⋮ 0x7E: 127 Tq 0x7F: 128 Tq	R/W

Note: S-TYPE-3, P-TYPE-3
 Note: Tq means time quantum.

This register configures the transmission/reception nominal baud rate parameters of the channels.

NBRP[9:0] bits (Channel Nominal Baud Rate Prescaler)

The NBRP[9:0] bits are used to define the peripheral bus clock periods contained in a time quantum.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

NSJW[6:0] bits (Resynchronization Jump Width)

The NSJW[6:0] bits set the synchronization jump width. A value from 1 to 128 time quanta can be set.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

NTSEG1[7:0] bits (Timing Segment 1)

The NTSEG1[7:0] bits set the segment TSEG1 to compensate for edges on the CAN bus with a positive phase error. These bits contain the propagation segment.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

Additionally, configure a Tq value only between 2 and 256, inclusive. See [section 30.4.1.2. CAN Bit Timing](#) for more details.

NTSEG2[6:0] bits (Timing Segment 2)

The NTSEG2[6:0] bits set the segment TSEG2 to compensate for edges on the CAN bus with a negative phase error.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET or CH_HALT mode.

Additionally, configure a Tq value only between 2 and 128, inclusive.

30.2.3 CFDC0CTR : Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0004

31	ROM ^{*1}	Restricted Operation Mode 0: Restricted operation mode disabled 1: Restricted operation mode enabled	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. These bits are not available in the classical CAN function.

Channel Control register controls the modes of the related channel. It is used to enable generation of interrupts if errors are detected on the CAN bus connected to this channel. It is also used to configure the channel in test mode.

CHMDC[1:0] bits (Channel Mode Control)

The CHMDC[1:0] bits can be used to configure modes of the CAN channel.

CAN mode transitions are described in more details in [section 30.3.3. Channel Modes](#).

Setting CHMDC[1:0] bits to 11b has no effect. When the CANFD module is in GL_HALT mode, these bits can only be set to 10b or 01b. These bits cannot be set in CH_SLEEP mode.

These bits can change automatically when transitioning to Halt mode by the CFDC0CTR.BOM settings.

If CPU write access to CFDC0CTR.CHMDC occurs at the same time when the CAN channel enters Halt mode (at the start of bus-off when CFDC0CTR.BOM = 01b, or at the end of bus-off when CFDC0CTR.BOM = 10b), then the CPU write access has the highest priority.

The CAN channel changes the value of CFDC0CTR.CHMDC within the Channel Control Registers for the specified cases only if the CFDC0CTR.CHMDC value is 00b (Operation mode).

CSLPR bit (Channel Sleep Request)

When the CSLPR bit is 1, a Sleep mode request is generated for the corresponding CAN channel

When this bit is 0, a request to exit Sleep mode is generated for the related CANFD channel.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_SLEEP mode.

RTBO bit (Return from Bus-Off)

When the protocol controller of the CAN channel enters bus-off state, you can force a recovery from bus-off state by setting the RTBO bit in the Channel Control Register to 1.

The error state changes from bus-off state to integrating with a maximum delay of 1 CAN bit time.

When the RTBO bit is set to 1, the REC and TEC registers are initialized and the Bus-Off Status bit (Channel Bus-off Status, CFDC0STS.BOSTS) is set to 0.

Registers other than the REC and TEC registers are not initialized by this command. Even if CFDC0CTR.BORIE is set, a bus-off recovery interrupt is not generated by this recovery from the bus-off state.

The RTBO bit cannot be set in CH_SLEEP mode. Setting this bit in any state other than bus-off state has no effect and the bit is cleared immediately. The read value is always 0.

Return from the Bus-Off command should be used only when CFDC0CTR.BOM is set to 00b.

Only write to this bit when the related CANFD channel is in CH_OPERATION mode. This bit is automatically cleared when set by software.

BEIE bit (Bus Error Interrupt Enable)

When the BEIE and the CFDC0ERFL.BEF bits are both 1, an error interrupt request is generated.

This bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

EWIE bit (Error Warning Interrupt Enable)

When the EWIE and the CFDC0ERFL.EWF bits are both 1, an error interrupt request is generated.

The EWIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

EPIE bit (Error Passive Interrupt Enable)

An error interrupt request is generated when the EPIE bit and the CFDC0ERFL.EPF are both 1.

The EPIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

BOEIE bit (Bus-Off Entry Interrupt Enable)

When the BOEIE and the CFDC0ERFL.BOEF bits are both 1, an error interrupt request is generated.

The BOEIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

BORIE bit (Bus-Off Recovery Interrupt Enable)

When the BORIE and the CFDC0ERFL.BORF bits are both 1, an error interrupt request is generated.

The BORIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

OLIE bit (Overload Interrupt Enable)

When the OLIE and the CFDC0ERFL.OVLF bits are both 1, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

BLIE bit (Bus Lock Interrupt Enable)

When the BLIE and the CFDC0ERFL.BLF bits are both 1, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

ALIE bit (Arbitration Lost Interrupt Enable)

When the ALIE and the CFDC0ERFL.ALF bits are both 1, an error interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

TAIE bit (Transmission Abort Interrupt Enable)

When the TAIE bit is 1 and a transmission is successfully aborted from a TX MB belonging to the corresponding CAN channel, an interrupt request is generated.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

EOCOIE bit (Error Occurrence Counter Overflow Interrupt Enable)

When the EOCOIE bit is 1 and the CFDC0FDSTS.EOCO bit belonging to the corresponding CAN channel is 1, an error interrupt request is generated.

The EOCOIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

SOCOIE bit (Successful Occurrence Counter Overflow Interrupt Enable)

When the SOCOIE bit is 1 and the CFDC0FDSTS.SOCO bit belonging to the corresponding CAN channel is 1, an error interrupt request is generated.

The SOCOIE bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET mode.

TDCVFIE bit (Transceiver Delay Compensation Violation Interrupt Enable)

When the TDCVFIE bit is 1 and the CFDC0FDSTS.TDCVF bit belonging to the corresponding CAN channel is 1, an error interrupt request is generated.

The TDCVFIE bit cannot be set in CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET mode. Do not set this bit when in Classical CAN mode.

Note: This bit is not available in the classical CAN function.

BOM[1:0] bits (Channel Bus-Off Mode)

The BOM[1:0]bits control the timing of the recovery from Bus-Off mode of the CANFD Channel.

Do not write to these bits in CH_SLEEP mode. Only write to these bits when the related CANFD channel is in CH_RESET mode.

Only write to these bits when the related CANFD channel is in CH_RESET mode.

ERRD bit (Channel Error Display)

The ERRD bit controls the display mode of the error flag bits [14:8] in the Channel Error Flag Register (CFDC0ERFL).

If the ERRD bit is 0 and more than one error occur at the same time, the error flag bits are set for all the errors that occurred at the same time. No further errors are flagged until CFDC0ERFL[14:8] is cleared.

Do not write to the ERRD bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

CTME bit (Channel Test Mode Enable)

The CTME bit enables the channel test modes.

Do not write to this bit in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_HALT mode.

CTMS[1:0] bits (Channel Test Mode Select)

The CTMS[1:0] bits are used to select the required test mode.

Do not write to these bits in CH_SLEEP or CH_RESET mode. Only write to these bits when the related CANFD channel is in CH_HALT mode.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

BFT bit (Bit Flip Test)

The BFT bit checks the internal CRC generator logic of the protocol controller.

It inverts the first bit (ID bit) of the CAN message data stream being received, so that the internal generated CRC result will not match the received CRC value of the frame. Refer to the bit stuffing rule, when using this feature, as there is the possibility of receiving a stuff error (due to the inversion) rather than a CRC error.

The internal generated CRC value is always observed in the following registers:

- CFDC0ERFL.CRCREG (Classical CAN frames)
- CFDC0FDCRC.CRCREG (CANFD frames).^{*1}

Note 1. This feature is not available in the classical CAN function.

Some restriction exist when using this bit:

Other CAN node will send a reference message and the receiver node(s) can invert one bit of incoming bit stream.

Note: The transmitter and receiver modes share the same CRC generator, therefore it is not necessary to consider the modes separately when testing.

The Bit Flip test mode is enabled if the BFT (new control signal that inverts the first bit of the bit stream) and CTME bits are both 1 and CFDC0CTR.CTMS is 0x00.

If this function is used by a transmitting node, a bit error or an arbitration lost will occur.

Do not write to the BFT bit in CH_SLEEP mode. Users should not use this function when the Self test mode 1 (Internal Loop back mode). Only write to this bit when the related CANFD channel is in CH_HALT mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

ROM bit (Restricted Operation Mode)

When the ROM and CTME bits are both 1, the restricted operation mode is enabled. This mode should only be used in basic test mode (CFDC0CTR.CTMS[1:0] = 00b).

The ROM bit cannot be set in CH_SLEEP mode. Only write to this bit when the related CANFD channel is in CH_HALT mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. Do not set this bit when in Classical CAN mode.

Note: This bit is not available in the classical CAN function.

30.2.4 CFDC0STS : Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TEC[7:0]								REC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit field:	—	—	—	—	—	—	—	ESIF	COMSTS	RECSTS	TRMSTS	BOSTS	EPSTS	CSLPSTS	CHLTSTS	CRSTSTS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Bit	Symbol	Function	R/W
0	CRSTSTS	Channel Reset Status 0: Channel not in Reset mode 1: Channel in Reset mode	R
1	CHLTSTS	Channel Halt Status 0: Channel not in Halt mode 1: Channel in Halt mode	R
2	CSLPSTS	Channel Sleep Status 0: Channel not in Sleep mode 1: Channel in Sleep mode	R
3	EPSTS	Channel Error Passive Status 0: Channel not in error passive state 1: Channel in error passive state	R
4	BOSTS	Channel Bus-Off Status 0: Channel not in bus-off state 1: Channel in bus-off state	R
5	TRMSTS	Channel Transmit Status 0: Channel is not transmitting 1: Channel is transmitting	R
6	RECSTS	Channel Receive Status 0: Channel is not receiving 1: Channel is receiving	R
7	COMSTS	Channel Communication Status 0: Channel is not ready for communication 1: Channel is ready for communication	R
8	ESIF ¹	Error State Indication Flag 0: No CANFD message has been received when the ESI flag was set 1: At least one CANFD message was received when the ESI flag was set	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
23:16	REC[7:0]	Reception Error Count These bits increment or decrement the counter value according to error status of the CAN channel during reception.	R
31:24	TEC[7:0]	Transmission Error Count These bits increment or decrement the counter value according to error status of the CAN channel during transmission.	R

Note: S-TYPE-3, P-TYPE-3

Note 1. This bit is not available in the classical CAN function.

Channel Status Register shows the mode, error and transmission or reception status of the related channel together with its reception and transmission error count values.

CRSTSTS bit (Channel Reset Status)

The CRSTSTS bit indicates whether the related CAN channel is in Reset mode.

This bit is set automatically when the related CAN channel enters Channel Reset mode. When the mode is changed from Reset mode to Sleep mode, the CRSTSTS bit remains 1.

This bit is cleared automatically when the related CAN channel exits the Channel Reset mode, except when changing to Sleep mode.

CHLTSTS bit (Channel Halt Status)

The CHLTSTS bit indicates whether the related CAN channel is in Halt mode.

This bit is set automatically when the related CAN module enters Halt mode, and is cleared automatically when the related CAN module exits Halt mode.

CSLPSTS bit (Channel Sleep Status)

The CSLPSTS bit indicates whether the related CAN channel is in Sleep mode.

This bit is set automatically when the related CANFD channel enters Sleep mode, and is cleared automatically when the related CANFD channel exits Sleep mode.

EPSTS bit (Channel Error Passive Status)

The EPSTS bit indicates whether the related CANFD channel has entered the error passive state.

This bit is set automatically when the value of the CAN Transmission or Reception Counter Register exceeds the value of 0x7F.

This bit is cleared automatically when the related CANFD channel exits the error passive state or enters Reset mode.

BOSTS bit (Channel Bus-Off Status)

The BOSTS bit indicates whether the related CANFD channel has entered the error bus-off state.

This bit is set automatically when the value of the related CAN Transmission Error Count Register exceeds 0xFF and the related CANFD channel is in the bus-off state (CAN Transmission Error Count Register > 0xFF).

This bit is cleared automatically when the related CANFD channel exits bus-off state.

TRMSTS bit (Channel Transmit Status)

The TRMSTS bit indicates whether the related CANFD channel is transmitting a message.

This bit is set automatically when the related CANFD channel is operating as a transmitter node or is in the bus-off state.

This bit is cleared automatically when the related CANFD channel is in the bus-idle state or starts operating as a receiver node.

RECSTS bit (Channel Receive Status)

The RECSTS bit indicates whether the related CANFD channel is receiving a message.

This bit is set automatically when the related CANFD channel is operating as a receiver node.

This bit is cleared automatically when the related CANFD channel is in the bus-idle state or starts operating as a transmitter node.

COMSTS bit (Channel Communication Status)

The COMSTS bit indicates whether the related CANFD channel is ready for communication.

This bit is set automatically when the related CANFD channel is ready to perform communication following the detection of 11 consecutive recessive bits after exiting the Reset or Halt mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET or CD_HALT mode.

Note: This bit is 1 during bus-off state.

ESIF bit (Error State Indication Flag)

The ESIF bit is set when the ESI bit is sampled recessively for a reception CAN message without any error. When in Loopback or Mirror mode, the self-transmitted messages are considered reception messages.

If a set from the CANFD channel occurs simultaneously with a clear by a write access, then the bit is set.

This bit is cleared by writing 0 to it. This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

Note: This bit is not available in the classical CAN function.

REC[7:0] bits (Reception Error Count)

The REC[7:0] bits increment or decrement the counter value according to error status of the CANFD channel during reception, and display the value of the REC error counter.

The value in bus-off state is indeterminate.

These bits are cleared automatically when the CANFD module enters GL_RESET or the CANFD channel is in CH_RESET mode.

TEC[7:0] bits (Transmission Error Count)

The TEC[7:0] bits increment or decrement the counter value according to error status of the CANFD channel during transmission, and display the value of the TEC error counter.

Only write to these bits when in test mode and CANFD channel is in CH_HALT mode.

These bits are cleared automatically when CANFD module is in GL_RESET or CANFD channel is in CH_RESET mode.

30.2.5 CFDC0ERFL : Error Flag Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x000C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

13	B0ERR	Bit 0 Error 0: Channel bit 0 error not detected 1: Channel bit 0 error detected	R/W
14	ADERR	Acknowledge Delimiter Error 0: Channel acknowledge delimiter error not detected 1: Channel acknowledge delimiter error detected	R/W
15	—	This bit is read as 0. The write value should be 0.	R/W
30:16	CRCREG[14:0]	CRC Register value These bits show the CRC value calculated for the CAN2.0 CAN frame.	R
31	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Channel Error Flag register shows the status of various error conditions detectable regardless of the setting of the related CAN Channel Error Interrupt Enable Register. It also shows the status of the various bus errors detectable by the CAN channel. Refer to the CAN specification (ISO 11898-1) to check when each error condition occurs.

For this register, only a single bit can be cleared by software. Do not use the bit clear instruction to clear the bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

Example in assembler language to clear the CFDC0ERFL.BEF bit:

```
mov.b #0x0FE, CFDC0ERFL ;
```

BEF bit (Bus Error Flag)

The BEF bit indicates a detection of a CAN channel bus error state, flagged by bits [14:8] in this register.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when a bus error is detected, and is cleared automatically when the related CANFD channel is in CH_RESET mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then the bit is set.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

EWf bit (Error Warning Flag)

The EWf bit indicates whether an error warning condition has been detected for the CAN channel.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when either TEC or REC exceeds 0x5F.

The setting of this bit only occurs when the TEC or REC initially exceeds 0x5F. Therefore, if the TEC or REC remains > 0x5F and the EWf bit is cleared by software, it is not set again until both the TEC and REC go below 0x60 and either TEC or REC crosses over again from a value 0x5F to a value > 0x5F.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

EPF bit (Error Passive Flag)

The EPF bit indicates a detection of a CAN channel error passive state.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when the CAN error state becomes error passive state.

The setting of this bit only occurs when the TEC or REC initially exceeds 0x7F. Therefore, if the TEC or REC remains > 0x7F and the bit is cleared by software, it is not set again until both the TEC and REC go below 0x80 and either TEC or REC crosses over again from a value ≤ 0x7F to a value > 0x7F.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

BOEF bit (Bus-Off Entry Flag)

The BOEF bit indicates a detection of a CAN channel bus-off entry state.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when the CAN error state enters the bus-off state.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If a set condition occurs simultaneously with a clear condition, then the bit is set.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

BORF bit (Bus-Off Recovery Flag)

The BORF bit indicates a detection of a CAN channel bus-off recovery state.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically if CAN channel recovers from bus-off state in the following conditions:

- When CFDC0CTR.BOM is 00b and normal recovery (11 consecutive recessive bits x 128 times detected) occurs
- When CFDC0CTR.BOM is 10b and normal recovery (11 consecutive recessive bits x 128 times detected) occurs
- When CFDC0CTR.BOM is 11b and normal recovery (11 consecutive recessive bits x 128 times detected) occurs.

The bit is not set if CAN channel recovers from bus-off state in the following conditions:

- When CAN Reset mode is requested
- When CFDC0CTR.RTBO is set to 1 (the CAN channel returns to error active)
- When CFDC0CTR.BOM is 01b
- When CFDC0CTR.BOM is 11b and a halt request is asserted before the CAN channel reaches the end of the bus-off state.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If a set condition occurs simultaneously with a clear condition, the flag is set.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

OVLf bit (Overload Flag)

The OVLf flag indicates a detection of a CAN channel overload state.

The OVLf bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when an overload condition is detected. If a set condition occurs simultaneously with a clear condition, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

BLF bit (Bus Lock Flag)

The BLF bit indicates a detection of a CAN channel bus lock condition.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

This bit is set automatically when 32 consecutive dominant bits are detected on the CAN bus while the CAN channel is in Operation mode.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

It is cleared automatically when the related CANFD channel is in CH_RESET mode.

ALF bit (Arbitration Lost Flag)

The ALF bit indicates a detection of a CAN channel bus arbitration lost condition.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

The bit is set automatically when an arbitration lost condition is detected on the CAN bus while the CAN channel is in Operation mode.

If a set condition occurs simultaneously with a clear condition, then the bit is set. It is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

SERR bit (Stuff Error)

The SERR bit indicates a detection of a CAN stuff error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a stuff error is detected. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

FERR bit (Form Error)

The FERR bit indicates a detection of a CAN form error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.

3. If yes, continue, else go back to step 1.

This bit is set automatically when a form error is detected. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

AERR bit (Acknowledge Error)

The AERR bit indicates a detection of a CAN acknowledge error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when an acknowledge error is detected. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION.

CERR bit (CRC Error)

The CERR bit indicates a detection of a CAN CRC error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a CRC error is detected. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

B1ERR bit (Bit 1 Error)

The B1ERR bit indicates a detection of a recessive bit error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a recessive bit error (expected recessive bit, sampled as dominant bit) is detected. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

B0ERR bit (Bit 0 Error)

The B0ERR bit indicates a detection of a dominant bit error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a dominant bit error (expected dominant bit, sampled as recessive bit) is detected. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

ADERR bit (Acknowledge Delimiter Error)

The ADERR bit indicates a detection of an acknowledge delimiter bit error.

This bit is cleared by writing 0 to it, and can only be set by CANFD module logic. Writing 1 has no effect.

To clear this bit, use the following sequence:

1. Clear the corresponding flag bit.
2. Read if the flag bit is cleared.
3. If yes, continue, else go back to step 1.

This bit is set automatically when a form error is detected during the acknowledge delimiter state of frame transmission. If CFDC0CTR.ERRD bit is 1 and if the set and clear conditions occur at the same time for this bit, then this bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode. If CFDC0CTR.ERRD bit is 0 and the set and clear conditions occur at the same time for this bit, then it is cleared if a bit at CFDC0ERFL[14:8] is already set. Otherwise, this bit is set if CFDC0ERFL[14:8] is 0000000b.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

CRCREG[14:0] bits (CRC Register value)

The CRCREG[14:0] bits read the calculated CRC value when CFDC0CTR.CTME bit is 1 for the channel.

If CFDC0CTR.CTME bit is 0, then these bits are always read as 0.

These bits show the CAN2.0 CRC value calculated by the CANFD channel logic when the CTME bit is enabled.

The CFDC0ERFL.CRCREG value is updated in the first bit of the CRC field of the CAN frame (reception and transmission).

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

30.2.6 CFDC0DCFG : Data Bitrate Configuration Register

This register is not available in the classical CAN function.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not write any other value to these bits.

DSJW[3:0] bits (Resynchronization Jump Width)

The DSJW[3:0] bits set the synchronization jump width. A value from 1 to 16 time quanta can be set.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

30.2.7 CFDC0FDCFG : CANFD Configuration Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0104

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

30	CLOE ^{*2 *3}	Classical CAN Enable 0: Classical CAN mode disabled 1: Classical CAN mode enabled	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. The value after reset is 0 for products that support the CAN-FD protocol, and 1 for products that support only classical CAN protocol.

Note 2. These bits are not available in the classical CAN function.

Note 3. This bit can only be written for products that support the CAN-FD protocol. For products that support only classical CAN protocol, this bit is reserved and fixed to 1.

The CANFD Configuration Register configures which communication direction (transmitter/receiver) errors are counted.

ECCCFG[2:0] bits (Error Occurrence Counter Configuration)

The ECCCFG[2:0] bits select which type of CAN frame configuration and direction, including protocol errors are counted.

Do not write to these bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

TDCOC bit (Transceiver Delay Compensation Offset Configuration)*1

The TDCOC bit selects which offset is used when defining the position of the secondary sample point (SSP) for the CANFD channel. If the bit is set to 0, the position of the SSP is the measured transceiver delay plus the fixed offset. If the bit is 1, the position of the SSP is defined only by the offset.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

TDCE bit (Transceiver Delay Compensation Enable)*1

The TDCE bit enables the transceiver delay compensation for the CANFD channel.

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

ESIC bit (Error State Indication Configuration)*1

The ESIC bit controls the transmission of either the ESI flag information or the message of ESI flag information (CFDCFFDCSTS.CFESI or CFDTMFDCSTRb.TMESI).

Do not write to this bit in CH_OPERATION or CH_SLEEP mode.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

TDCO[7:0] bits (Transceiver Delay Compensation Offset)*1

The TDCO[7:0] bits set the secondary sample point offset. How this value is used, depends on the CFDC0FDCFG.TDCOC setting.

If CFDC0FDCFG.TDCOC = 0, the transceiver delay compensation result is equal to the Trv_Delay (measured delay) + the value in CFDC0FDCFG.TDCO, rounded down to the nearest integer number of time quanta. Otherwise, the result is equal to the value in CFDC0FDCFG.TDCO. See [section 30.4.1.5. Transmitter Delay Compensation](#) for details on how CFDC0FDCFG.TDCO is used.

The actual offset value is interpreted as TDCO + 1. For example, if 4 is set in TDCO, the offset is 5 clock cycles. Clock cycle is 1 cycle of CAN channel DLL clock.

Do not write to the TDCO[7:0] bits in CH_OPERATION or CH_SLEEP mode.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode. Do not set this bit when in Classical CAN mode.

FDOE bit (FD-Only Enable)*1

The FDOE bit enables the reception and transmission of CANFD-only frames. If enabled, communication in Classical CAN frame format is disabled. Transmission of Classical CAN frames is not possible because the FDF bit of the message buffer is a don't care (CFDCFFDCSTS.CFFDF/CFDTMFDCTRb.TMFDf).

If messages with Classical CAN frame format are received, the protocol controller treats them as invalid frames and response with error frames. When a Classical CAN frame is configured for transmitting, the FDF bit is sent as recessive, therefore an FD frame is sent. If the data length code (DLC) is configured of greater than 8 bytes, the remaining data bytes are padded with 0xCC.

The FDOE bit cannot be written in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Do not set CFDC0FDCFG.FDOE and CFDC0FDCFG.CLOE simultaneously.

REFE bit (RX Edge Filter Enable)

The REFE bit enables the RX edge filter during the IDLE detection (bus integration). When the bit is enabled, two consecutive dominant time quanta are required to detect a synchronization edge.

The REFE bit cannot be written in CH_OPERATION, CH_HALT and CH_SLEEP mode. Do not set this bit when in Classical CAN mode.

CLOE bit (Classical CAN Enable)*1

The CLOE bit enables the Classical CAN mode. If this bit is 1, the protocol controller can only send classical frames and response with a form or CRC error on FD frames.

Do not set CFDC0FDCFG.CLOE and CFDC0FDCFG.FDOE simultaneously.

CFDC0FDCFG.CLOE	CFDC0FDCFG.FDOE	Channel mode
0	0	CANFD mode
0	1	FD-only mode
1	0	Classical CAN mode
1	1	Reserved

The CANFD mode is available only for CANFD supported product.

Do not write to this bit in CH_OPERATION, CH_HALT or CH_SLEEP mode.

Only write to these bits when the CANFD channel is in CH_RESET mode.

Note 1. These bits are not available in the classical CAN function.

30.2.8 CFDC0FDCTR : CANFD Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0108

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SOCC LR	EOCC LR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EOCCLR	Error Occurrence Counter Clear 0: No error occurrence counter clear 1: Clear error occurrence counter	R/W
1	SOCCLR	Successful Occurrence Counter Clear 0: No successful occurrence counter clear 1: Clear successful occurrence counter	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The CANFD Control Register controls the error and successful occurrence counters.

EOCCLR bit (Error Occurrence Counter Clear)

The EOCCLR bit is used to clear the error occurrence counter.

Do not write to this bit in CH_SLEEP or CH_RESET mode. The read value is always 0.

This bit is cleared automatically by the CANFD module logic and when the related CANFD channel is in CH_RESET mode.

SOCCLR bit (Successful Occurrence Counter Clear)

The SOCCLR bit is used to clear the successful occurrence counter.

Do not write to this bit in CH_SLEEP or CH_RESET mode. The read value is always 0.

This bit is cleared automatically by the CANFD module logic and when the related CANFD channel is in CH_RESET mode.

30.2.9 CFDC0FDSTS : CANFD Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x010C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	SOC[7:0]							EOC[7:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TDCV F	—	—	—	—	—	SOCO	EOCO	TDCR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	TDCR[7:0] ^{*1}	Transceiver Delay Compensation Result	R
8	EOCO	Error Occurrence Counter Overflow 0: Error occurrence counter has not overflowed 1: Error occurrence counter has overflowed	R/W
9	SOCO	Successful Occurrence Counter Overflow 0: Successful occurrence counter has not overflowed 1: Successful occurrence counter has overflowed	R/W
14:10	—	These bits are read as 0. The write value should be 0.	R/W
15	TDCVF ^{*1}	Transceiver Delay Compensation Violation Flag 0: Transceiver delay compensation violation has not occurred 1: Transceiver delay compensation violation has occurred	R/W
23:16	EOC[7:0]	Error Occurrence Counter These bits show the error occurrence counter value.	R

Bit	Symbol	Function	R/W
31:24	SOC[7:0]	Successful occurrence counter These bits show the successful occurrence counter value.	R

Note: S-TYPE-3, P-TYPE-3

Note 1. These bits are not available in the classical CAN function.

The CANFD Status Register indicates the transceiver compensation delay result and its related FIFO message lost status.

TDCR[7:0] bits (Transceiver Delay Compensation Result)

The TDCR[7:0] bits are set when the transceiver delay has been measured.

The measured delay is a multiple of the CAN channel DLL clock. The result depends on the CFDC0FDCFG.TDCOC configuration and the offset value in CFDC0FDCFG.TDCO. See [section 30.4.1.5. Transmitter Delay Compensation](#) for details on how this value is derived.

The TDCR[7:0] bits are updated at the falling edge between FDF and the RES bit when CFDC0FDCFG.TDCOC = 0 and the transceiver delay compensation is enabled (CFDC0FDCFG.TDCE = 1).

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

Note: These bits are not available in the classical CAN function.

EOCO bit (Error Occurrence Counter Overflow)

The EOCO bit indicates whether the related CAN channel error occurrence counter has overflowed. This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when CFDC0FDSTS.EOC is 0xFF and a CAN bus error is detected based on the configuration defined in CFDC0FDCFG.EOCCFG.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

SOCO bit (Successful Occurrence Counter Overflow)

The SOCO bit indicates whether the related CAN channel successful occurrence counter has overflowed. This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when CFDC0FDSTS.SOC is 0xFF and a successful message reception or successful message transmission occurs.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

Write to this bit only when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

TDCVF bit (Transceiver Delay Compensation Violation Flag)

The CANFD module captures internally the transmitted data bit-by-bit. This data is then compared against the received CAN bus level which is delayed by the transceiver loop delay.

The transceiver delay has some variations depending on the physical parameters such as temperature. The result bit CFDC0FDSTS.TDCR is updated by each message. However, temporary maximum delay violation could be missed. Therefore, the TDCVF bit captures this violation.

This bit is cleared by writing 0 to it. Writing 1 has no effect.

This bit is set automatically when the transceiver delay compensation is greater than the maximum delay compensation (6 data bit times - 2 clk_dlc) and the internal bit is overrun.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

CRCREG[20:0] bits (CRC Register value)

The CRCREG[20:0] bits contain the CRC value calculated by the CANFD channel logic when the CFDC0CTR.CTME bit is enabled.

The CFDC0FDCRC.CRCREG value is updated in the first bit of the CRC field of the CANFD frame (reception and transmission).

When the CFDC0CTR.CTME bit is 0, the CRCREG[20:0] bits are always read as 0.

When bit 17th of the CRC field is used, CRCREG[20:17] are always read as 0.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

SCNT[3:0] bits (Stuff bit count)

The SCNT[3:0] bits contain the stuff count value of the CANFD frame. These bits indicate the number of inserted stuff bits (modulo 8, Graycoded) for a CANFD frame when the CFDC0CTR.CTME bit is enabled in CFDC0FDCRC.SCNT[3:1]. SCNT[0] is the parity bit.

When the CFDC0CTR.CTME bit is 0, the SCNT[3:0] bits are always read as 0.

The SCNT value is updated in the first bit of CRC field of the CANFD frame (reception and transmission).

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

30.2.11 CFDGCFG : Global Configuration Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ITRCP[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

12	TSSS	Timestamp Source Select 0: Source clock for timestamp counter is peripheral clock 1: Source clock for timestamp counter is bit time clock	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
31:16	ITRCP[15:0]	Interval Timer Reference Clock Prescaler FIFO interval timer prescaler value	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. This bit is not available in the classical CAN function.

The Global Configuration Register is used to select the transmission priority to be used for all the TX message buffers and the clock source for the CAN protocol engine of CAN channel. The CFDGCFG register is also used to select the source for the timestamp clock and to configure the frequency for the timestamp clock and interval timer reference clock.

TPRI bit (Transmission Priority)

The TPRI bit selects the transmission priority for CAN channel.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

Message buffer number priority should not be used together with TX queue transmission.

DCE bit (DLC Check Enable)

The DCE bit enables data length code (DLC) check for CAN channel.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

DRE bit (DLC Replacement Enable)

When the DRE bit is 1 and the DCE is 1, the CANFD stores the configured value (CFDGAFLP0r.GAFLDLC) of the DLC in the destination RX message buffer or FIFO buffer if the DLC check passes. Otherwise, the DLC value in the destination RX message buffer or FIFO buffer is unchanged.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

MME bit (Mirror Mode Enable)

The MME bit enables the Mirror mode for CAN channel.

Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

DCS bit (Data Link Controller Clock Select)

The DCS bit selects CANFDCLK or CANMCLK as the clock source for CAN communication.

Do not write to this bit in GL_SLEEP or GL_OPERATION mode. Only write to this bit when CANFD module is in GL_RESET mode.

CMPOC bit (CANFD Message Payload Overflow Configuration)

The CMPOC bit controls the message payload acceptance mechanism when the received payload is higher than the message buffer payload size CFDRMNb.RMPLS, CFDRFCCa.RFPLS, and CFDFCC.CFPLS. The received message payload is always compared with the available message payload size in the message buffer.

Do not write to this bit in GL_SLEEP or GL_OPERATION mode. Only write to this bit when CANFD module is in GL_RESET mode.

When this bit is set and payload overflow occurs, the DLC value is stored in the RX message buffer or FIFO buffer unchanged.

Note: This bit is not available in the classical CAN function.

TSP[3:0] bits (Timestamp Prescaler)

The value configured in the TSP[3:0] bits defines the period of the clock source used for the timestamp counter. Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

TSSS bit (Timestamp Source Select)

The TSSS bit allows the selection of the clock source for the timestamp counter. Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode. Additionally, do not set this bit to 1 when CANFD communication is used.*1

Note: The bit time clock varies depending on the nominal and data rate bit configuration.

Note 1. This feature is not available in the classical CAN function.

ITRCP[15:0] bits (Interval Timer Reference Clock Prescaler)

The ITRCP[15:0] bits allow the definition of a reference clock for the FIFO interval timer source clock. When these bits are 0x0000, the timer is disabled. Do not write to this bit in GL_SLEEP mode. Only write to this bit when CANFD module is in GL_RESET mode.

30.2.12 CFGDCTR : Global Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0018

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11	CMPOFIE ^{*1}	CANFD Message Payload Overflow Flag Interrupt Enable 0: CANFD message payload overflow flag interrupt disabled 1: CANFD message payload overflow flag interrupt enabled	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W
16	TSRST	Timestamp Reset 0: Timestamp not reset 1: Timestamp reset	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. This bit is not available in the classical CAN function.

The Global Control Register controls the global mode of the CANFD module and the timestamp function. The register also enables and disables the global error interrupts.

GMDC bits (Global Mode Control)

The GMDC bits can be used to configure the modes for the CANFD module. Additionally, if CFDGCTR.GSLPR bit is 1 when the CANFD module is in Reset mode, the CANFD module enters Global Sleep mode.

Setting the GMDC bits to 11b has no effect. Mode transition is described in detail in [section 30.3.2. Global Modes](#).

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

GSLPR bit (Global Sleep Request)

The GSLPR bit globally selects the sleep request for CANFD module including CAN channels. Channel sleep request is set automatically for channels.

Only write to this bit when the CANFD module is in GL_RESET or GL_SLEEP mode.

DEIE bit (DLC Check Interrupt Enable)

When the DEIE bit is 1, an interrupt is generated if a DLC error is detected in the received frames.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

MEIE bit (Message Lost Error Interrupt Enable)

When the MEIE bit is 1, an interrupt is generated if a message lost condition occurs.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

THLEIE bit (TX History List Entry Lost Interrupt Enable)

When the THLEIE bit is 1, an interrupt is generated if a TX history list entry lost condition occurs.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

CMPOFIE bit (CANFD Message Payload Overflow Flag Interrupt Enable)

When the CMPOFIE bit is 1, an interrupt is generated when a CANFD message payload overflow condition occurs.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

Note: This bit is not available in the classical CAN function

TSRST bit (Timestamp Reset)

When the TSRST bit is 1, the Global Timestamp Register is reset to 0x0000.

Do not write to this bit when the CANFD module is in GL_SLEEP or GL_RESET mode.

Read value is always 0.

This bit is cleared automatically by the CANFD module logic.

30.2.13 CFDGSTS : Global Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x001C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	GRAM INIT	GSLP STS	GHLT STS	GRST STS	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1

Bit	Symbol	Function	R/W
0	GRSTSTS	Global Reset Status 0: Not in Reset mode 1: In Reset mode	R
1	GHLTSTS	Global Halt Status 0: Not in Halt mode 1: In Halt mode	R
2	GSLPSTS	Global Sleep Status 0: Not in Sleep mode 1: In Sleep mode	R
3	GRAMINIT	Global RAM Initialization 0: RAM initialization is complete 1: RAM initialization is ongoing	R
31:4	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The Global Status Register indicates the global status of the CANFD module.

GRSTSTS bit (Global Reset Status)

The GRSTSTS bit indicates the status of Global CANFD module Reset mode.

This bit is set automatically when the CANFD module enters GL_RESET mode. When the mode changes from GL_RESET mode to GL_SLEEP mode, this bit remains set.

This bit is cleared automatically when the CANFD module exits the GL_RESET mode.

GHLTSTS bit (Global Halt Status)

The GHLTSTS bit indicates the status of Global CANFD module Halt mode.

This bit is set automatically when the CANFD module enters GL_HALT mode.

This bit is cleared automatically when the CANFD module exits the GL_HALT mode.

GSLPSTS bit (Global Sleep Status)

The GSLPSTS bit indicates the status of Global CANFD module Sleep mode.

This bit is set automatically when the CANFD module enters GL_SLEEP mode.

This bit is cleared automatically when the CANFD module exits the GL_SLEEP mode.

GRAMINIT bit (Global RAM Initialization)

The GRAMINIT bit indicates the status of Global CANFD module RAM initialization.

This bit is set automatically when the CANFD module enters GL_SLEEP mode after a hardware reset.

This bit is cleared automatically when the CANFD module completed RAM initialization.

This bit is cleared when the test_mode input port is set to 1.

30.2.14 CFDGERFL : Global Error Flag Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0020

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—		EEF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	CMPO F	THLE S	MES	DEF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	DEF	DLC Error Flag 0: DLC error not detected 1: DLC error detected	R/W
1	MES	Message Lost Error Status 0: Message lost error not detected 1: Message lost error detected	R
2	THLES	TX History List Entry Lost Error Status 0: TX history list entry lost error not detected 1: TX history list entry lost error detected	R
3	CMPOF ^{*1}	CANFD Message Payload Overflow Flag 0: CANFD message payload overflow not detected 1: CANFD message payload overflow detected	R/W
15:4	—	These bits are read as 0. The write value should be 0.	R/W
16	EEF0	ECC Error Flag 0: ECC error not detected during TX-SCAN 1: ECC error detected during TX-SCAN	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. This bit is not available in the classical CAN function.

The Global Error Flag register indicates the detection of global errors.

DEF bit (DLC Error Flag)

The DEF bit indicates the error status of the DLC.

Do not write to this bit when the CANFD module is in GL_SLEEP or GL_RESET mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when a DLC error is detected in a received frame.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set

The bit is cleared by writing 0 to it.

This bit is cleared automatically in GL_RESET mode.

MES bit (Message Lost Error Status)

The MES bit indicates status of the message lost error.

This bit is set automatically when a FIFO message lost error is detected.

This bit is cleared automatically when:

- All FIFO message lost flags are cleared
- The CANFD module is in GL_RESET mode.

THLES bit (TX History List Entry Lost Error Status)

The THLES bit indicates status of the TX history list entry lost error.

This bit is set automatically when a TX history list entry lost error is detected.

This bit is cleared automatically when:

- All TX history list entry lost flags are cleared
- The CANFD module is in GL_RESET mode.

CMPOF bit (CANFD Message Payload Overflow Flag)

The CMPOF bit is set automatically when a CANFD message payload overflow is detected on at least one channel.

Do not write to this bit when the CANFD module is in GL_SLEEP or GL_RESET mode.

This bit is cleared by writing 0 to it. Writing 1 to this bit has no effect.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is cleared automatically in GL_RESET mode.

Note: This bit is not available in the classical CAN function

EEF0 bit (ECC Error Flag)

The EEF0 bit specifies whether an ECC error has occurred.

Do not write to this bit when the CANFD module is in GL_SLEEP or GL_RESET mode. Writing 1 to this bit has no effect.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

The bit is cleared by writing 0 to it. This bit is cleared automatically in GL_RESET mode.

30.2.15 CFDGTINTSTS : Global TX Interrupt Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00A4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	THIF0	CFTIF0	TQIF0	TAIO	TSIF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TSIF0	TX Successful Interrupt Flag 0: Channel n TX Successful Interrupt flag not set 1: Channel n TX Successful Interrupt flag set	R
1	TAIO	TX Abort Interrupt Flag 0: Channel n TX Abort Interrupt flag not set 1: Channel n TX Abort Interrupt flag set	R

Bit	Symbol	Function	R/W
2	TQIF0	TX Queue Interrupt Flag 0: Channel n TX Queue Interrupt flag not set 1: Channel n TX Queue Interrupt flag set	R
3	CFTIF0	COM FIFO TX Mode Interrupt Flag 0: Channel n COM FIFO TX Mode Interrupt flag not set 1: Channel n COM FIFO TX Mode Interrupt flag set	R
4	THIF0	TX History List Interrupt 0: Channel n TX History List Interrupt flag not set 1: Channel n TX History List Interrupt flag set	R
31:5	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The Global TX Interrupt Status register indicates the detection of transmit specific interrupts.

TSIF0 bit (TX Successful Interrupt Flag)

The TSIF0 bit is set to 1 when the TX Successful Interrupt flag of the related channel is set (when the interrupt is enabled). This bit is cleared automatically:

- When the related TX MB Result Status bits are cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TAI0 bit (TX Abort Interrupt Flag)

The TAI0 bit is set to 1 when the TX Abort Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX MB Result Status bits are cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

TQIF0 bit (TX Queue Interrupt Flag)

The TQIF0 bit is set to 1 when the TX Queue Interrupt flag of the related channel is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX Queue Interrupt flag is cleared (when the interrupt is enable disabled)
- When in GL_RESET or CH_RESET mode.

CFTIF0 bit (COM FIFO TX Mode Interrupt Flag)

The CFTIF0 bit is set to 1 when the related COM TX FIFO Mode Interrupt flag (CFDCFSTS.CFTXIF) is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related COM TX FIFO Mode Interrupt flag (CFDCFSTS.CFTXIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

THIF0 bit (TX History List Interrupt)

The THIF0 bit is set to 1 when the related TX History List Interrupt flag (CFDTHLSTS.THLIF) is set (when the interrupt is enabled).

This bit is cleared automatically:

- When the related TX History List Interrupt flag (CFDTHLSTS.THLIF) is cleared (when the interrupt enable is disabled)
- When in GL_RESET or CH_RESET mode.

30.2.16 CFDTGTSC : Global Timestamp Counter Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0024

Bit	Symbol	Function	R/W
15:0	TS[15:0]	Timestamp value	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The Global Timestamp Counter register stores the timestamp based on the selected configuration.

TS[15:0] bits (Timestamp value)

The Timestamp value is stored in the Global Timestamp Counter register based on the configuration of TSSS, TSBTCS and TSP. The accuracy of the timestamp counter cannot be guaranteed when transitioning to halt state.

The Timestamp value is stored in this register based on the configuration of TSSS, TSBTCS and TSP.

Do not write to bits TS[15:0] when the CANFD module is in GL_RESET or GL_SLEEP mode.

The TS[15:0] bits are cleared automatically in GL_RESET mode.

30.2.17 CFDGAFLECTR : Global Acceptance Filter List Entry Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0028

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	AFLDAE	Acceptance Filter List Data Access Enable 0: Acceptance Filter List data access disabled 1: Acceptance Filter List data access enabled	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The Global Acceptance Filter List Entry Control Register is used to select the Global Acceptance Filter List page for reading or writing entries into the Global Acceptance Filter List.

AFLDAE bit (Acceptance Filter List Data Access Enable)

The AFLDAE bit prevents write access to the Acceptance Filter List when cleared after configuration of the Acceptance Filter List.

Data can be read from the Acceptance Filter List independent of the status of this bit.

Bit	Symbol	Function	R/W
31	GAFLIDE	Global Acceptance Filter List Entry IDE Field 0: Standard identifier of rule entry ID is valid for acceptance filtering 1: Extended identifier of rule entry ID is valid for acceptance filtering	R/W

Note: S-TYPE-3, P-TYPE-3

The Global Acceptance Filter List ID Registers are used to configure the ID field for the rules of entries in the Global Acceptance Filter List.

GAFLID[28:0] bits (Global Acceptance Filter List Entry ID Field)

The GAFLID[28:0] bits represent the CAN identifier (ID) field of each entry in the Global Acceptance Filter List.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

GAFLLB bit (Global Acceptance Filter List Entry Loopback Configuration)

The GAFLLB bit selects whether entry in the Global Acceptance Filter List gets the attribute RX or TX.

This attribute determines the validity of the entry in Mirror mode, Loopback test mode, and during standard (non-loopback) reception. See section 30.5.5. Loopback Modes for detailed description of the validity of the Global Acceptance Filter List entry depending on transmitter/receiver case, the type of loopback mode, and RX/TX attribute.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

GAFLRTR bit (Global Acceptance Filter List Entry RTR Field)

The GAFLRTR bit allows the configuration of the specified frame format (data frame or remote frame) for each entry of the Global Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the RTR bit of the received CAN message.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

GAFLIDE bit (Global Acceptance Filter List Entry IDE Field)

The GAFLIDE bit allows the configuration of the ID format (standard ID or extended ID) for each entry in the Global Acceptance Filter List. For each rule entry in a CAN channel, the acceptance filter process compares this bit against the IDE bit of the received CAN message.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

30.2.20 CFDGAFLMr : Global Acceptance Filter List Mask Registers (r = 1 to 16)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0124 + 0x0010 × (r - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31	GAFLIDEM	Global Acceptance Filter List IDE Mask 0: IDE bit is not used for ID matching 1: IDE bit is used for ID matching	R/W

Note: S-TYPE-3, P-TYPE-3

The Global Acceptance Filter List Mask Registers are used to configure the Mask field of each rule for entries in the Global Acceptance Filter List.

GAFLIDM[28:0] bits (Global Acceptance Filter List ID Mask Field)

GAFLIDM[28:0] bits are the filter mask bits for the related bits in the CAN Identifier field of each Global Acceptance Filter List entry.

0	Corresponding STD-ID/EXT-ID bit is not used for ID matching
1	Corresponding STD-ID/EXT-ID bit is used for ID matching

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

GAFLIFL1 bit (Global Acceptance Filter List Information Label 1)

The GAFLIFL1 bit allows the configuration of a 2-bit information label to be attached to a received message accepted by the associated entry in the Global Acceptance Filter List. This bit is a MSB bit of an information label.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

This bit is stored in the Information Label Field [1] (CFDRMFDSTSb.RMIFL [1], CFDRFFDSTSb.RFIFL [1], CFDCFFDCSTS.CFIFL [1]) of the storage location of an incoming message.

GAFLRTRM bit (Global Acceptance Filter List Entry RTR Mask)

The GAFLRTRM bit allows the configuration of the RTR mask bit for each entry in the Global Acceptance Filter List.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

GAFLIDEM bit (Global Acceptance Filter List IDE Mask)

The GAFLIDEM bit allows the configuration of the IDE mask bit for each entry in the Global Acceptance Filter List.

When the IDE mask bit is 0, the ID comparison depends on the received IDE bit.

If the received IDE bit is 0, the STD-ID comparison takes place.

If the received IDE bit is 1, the EXT-ID comparison takes place.

Do not write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to this bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

30.2.21 CFDGAFLP0r : Global Acceptance Filter List Pointer 0 Registers (r = 1 to 16)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0128 + 0x0010 × (r - 1)

Bit	Symbol	Function	R/W
3:0	GAFLDLC[3:0]	Global Acceptance Filter List DLC Field Minimum number of data bytes in a data frame required for acceptance	R/W
6:4	—	These bits are read as 0. The write value should be 0.	R/W
7	GAFLI FLO	Global Acceptance Filter List Information Label 0	R/W
12:8	GAFLRMDP[4:0]	Global Acceptance Filter List RX Message Buffer Direction Pointer RX message buffer number for storage of received messages	R/W
14:13	—	These bits are read as 0. The write value should be 0.	R/W
15	GAFLRMV	Global Acceptance Filter List RX Message Buffer Valid 0: Single message buffer direction pointer is invalid 1: Single message buffer direction pointer is valid	R/W
31:16	GAFLPTR[15:0]	Global Acceptance Filter List Pointer	R/W

Note: S-TYPE-3, P-TYPE-3

The Global Acceptance Filter List Pointer 0 Registers are used to configure the data length code (DLC), software pointer, single message buffer select, and message buffer direction pointer for each rule entry in the Global Acceptance Filter List.

GAFLDLC[3:0] bits (Global Acceptance Filter List DLC Field)

The GAFLDLC[3:0] bits allow the configuration of a minimum data length code (DLC) value for a message to be accepted by the associated entry in the Global Acceptance Filter List (automatic DLC filter function).

DLC filter process is only passed if the DLC value of the message accepted by an entry in the Global Acceptance Filter List is equal to or higher than the DLC value configured for this associated Global Acceptance Filter List entry. Automatic DLC filter function is disabled for the corresponding rule entry when this field is set to 0.

Table 30.3 shows DLC value that can be configured.

Table 30.3 Configuration of DLC value (1 of 2)

Format	DLC[3]	DLC[2]	DLC[1]	DLC[0]	Description
CAN and CANFD	0	0	0	0	DLC of received message = 0 or more (DLC filter check is disabled)
CAN and CANFD	0	0	0	1	DLC of received message = 1 or more
CAN and CANFD	0	0	1	0	DLC of received message = 2 or more
CAN and CANFD	0	0	1	1	DLC of received message = 3 or more
CAN and CANFD	0	1	0	0	DLC of received message = 4 or more
CAN and CANFD	0	1	0	1	DLC of received message = 5 or more

Table 30.3 Configuration of DLC value (2 of 2)

Format	DLC[3]	DLC[2]	DLC[1]	DLC[0]	Description
CAN and CANFD	0	1	1	0	DLC of received message = 6 or more
CAN and CANFD	0	1	1	1	DLC of received message = 7 or more
CAN	1	x	x	x	DLC of received message = 8 or more
CANFD	1	0	0	0	DLC of received message = 8 or more ^{*1}
CANFD	1	0	0	1	DLC of received message = 12 or more ^{*1}
CANFD	1	0	1	0	DLC of received message = 16 or more ^{*1}
CANFD	1	0	1	1	DLC of received message = 20 or more ^{*1}
CANFD	1	1	0	0	DLC of received message = 24 or more ^{*1}
CANFD	1	1	0	1	DLC of received message = 32 or more ^{*1}
CANFD	1	1	1	0	DLC of received message = 48 or more ^{*1}
CANFD	1	1	1	1	DLC of received message = 64 ^{*1}

Note 1. This setting is not available in the classical CAN function.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

GAFLIFL0 bit (Global Acceptance Filter List Information Label 0)

The GAFLIFL0 bit allows the configuration of a 2-bit information label that can be attached to a received message accepted by the related Global Acceptance Filter List entry. This bit is a LSB bit of an information label.

You cannot write to this bit when CFDGAFLECTR.AFLDAE bit is 0.

Only write to the bit when the related CANFD channel is in CH_RESET or CH_HALT mode.

This bit is stored in Information Label Field[0] (CFDRMFDSTSb.RMIFL[0], CFDRFFDSTSb.RFIFL[0], CFDCFFDCSTS.CFIFL[0]) of the storage location of an incoming message.

GAFLRMDP[4:0] bits (Global Acceptance Filter List RX Message Buffer Direction Pointer)

The GAFLRMDP[4:0] bits allow the configuration of a single reception message buffer as the destination target for a received message that passes the acceptance check of the related Global Acceptance Filter List entry. The value entered is the single destination message buffer number.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

CFDRMNB.NRXMB[4:0] is the value entered in the RX Message Buffer Number Register to configure the number of RX message buffers. The value to be entered in CFDGAFLP0r.GAFLRMDP[4:0] bits should only be between 0x00 and CFDMNB.NMB[4:0] to 1 less.

If CFDRMNB.NRXMB[4:0] = 0x00, the GAFLRMV bit should be configured as 0.

GAFLRMV bit (Global Acceptance Filter List RX Message Buffer Valid)

The GAFLRMV bit allows the enabling or disabling of a single reception message buffer as the target for a received message that passes the acceptance check of the related Global Acceptance Filter List entry.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

GAFLPTR[15:0] bits (Global Acceptance Filter List Pointer)

The GAFLPTR[15:0] bits allow the configuration of a 16-bit pointer to be attached to a received message accepted by the related Global Acceptance Filter List entry. The pointer is added during message storage in the Message Buffer area and can be used by the application as a support function. The pointer information can be used for example, to support PDU Identifier allocation for the received message in AUTOSAR systems.

Do not write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

30.2.22 CFDGAF1P1r : Global Acceptance Filter List Pointer 1 Registers (r = 1 to 16)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x012C + 0x0010 × (r - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	GAFL FDP8	—	—	—	—	—	—	GAFL FDP1	GAFL FDP0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	GAFLFDP0	Global Acceptance Filter List FIFO Direction Pointer FIFO direction pointer bits for received message storage 0: Disable RX FIFO 0 as target for reception 1: Enable RX FIFO 0 as target for reception	R/W
1	GAFLFDP1	Global Acceptance Filter List FIFO Direction Pointer FIFO direction pointer bits for received message storage 0: Disable RX FIFO 1 as target for reception 1: Enable RX FIFO 1 as target for reception	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	GAFLFDP8	Global Acceptance Filter List FIFO Direction Pointer FIFO direction pointer bits for received message storage 0: Disable Common FIFO as target for reception 1: Enable Common FIFO as target for reception	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The Global Acceptance Filter List Pointer 1 registers are used to configure the FIFO direction pointer fields in each Rule Entry of the Global Acceptance Filter List.

GAFLFDP8, GAFLFDP1, GAFLFDP0 bits (Global Acceptance Filter List FIFO Direction Pointer)

These bits allow the configuration of FIFO Buffers as the target for a received message passing the acceptance check of the related Global Acceptance Filter List entry. Each bit of the GAFLFDP8, GAFLFDP1, GAFLFDP0 is configuring a dedicated FIFO.

Users cannot write to these bits when CFDGAFLECTR.AFLDAE bit is 0.

For storage in Common FIFO, target for reception can only be those Common FIFO Buffers that are configured as RX FIFO.

Only write to these bits when the related CANFD channel is in CH_RESET or CH_HALT mode.

Users should only configure up to 2 destination FIFO Buffers or 1 destination FIFO Buffers plus one RX Message Buffer.

RMNS[15:0] bits (RX Message Buffer New Data Status)

The RMNS[15:0] bits indicate the status of new data for the corresponding RX message buffer. RMNS bit [0] corresponds to RX message buffer [0] and so on.

The bit position of CFDRMND corresponds to the buffer number of RXMB.

Do not write to these bits when the CANFD module is in GL_RESET or GL_SLEEP mode. Writing 1 has no effect.

These bits cannot be cleared when message storage in the corresponding RX message buffer is in progress.

Do not use the bit clear instruction to clear these bits. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

These bits are set automatically when storage of new messages are in the corresponding RX message buffer. These bits are cleared by writing 0. These bits are cleared automatically when the CANFD module is in GL_RESET mode.

When CFDRMNB.RMPLS = 000b (maximum 8 bytes payload), the duration of message storage is 6 PCLKA cycles.

When CFDRMNB.RMPLS > 000b, the duration of message storage is 6 PCLKA cycles + 1 for each 4 bytes (maximum of 20 PCLKA cycles for 64 bytes).

Note: This feature is not available in the classical CAN function.

30.2.25 CFDRFCCa : RX FIFO Configuration/Control Registers a (a = 0 to 1)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x003C + 0x04 × a

31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. These bits are not available in the classical CAN function.

The RX FIFO Configuration/Control Registers are used to configure and control the two RX FIFOs.

RFE bit (RX FIFO Enable)

The RFE bit enables the FIFO. When this bit is set to 0, the RX FIFO is cleared to empty.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode.

This bit can only be set if the configured FIFO depth is greater than 0x000 (CFDRFCCa.RFDC > 0x000) and less than 0x110.

Set the RFE bit with a separate write access to the CFDRFCCa register, after all the other bits in the CFDRFCCa register are set.

This bit is cleared automatically when the CANFD module is in GL_RESET mode.

RFIE bit (RX FIFO Interrupt Enable)

The RFIE bit enables generation of the FIFO interrupt.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

RFPLS[2:0] bits (Rx FIFO Payload Data Size Configuration)

The RFPLS[2:0] bits define the message data payload allocation in the RAM.

This is the maximum number of bytes which can be received by this FIFO.

Only write to these bits when the CANFD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

RFDC[2:0] bits (RX FIFO Depth Configuration)

The RFDC[2:0] bits select the depth of the FIFO in terms of the number of messages. If the FIFO depth is configured to 0 messages, the FIFO cannot be used.

Only write to these bits when the CANFD module is in GL_RESET mode.

RFIM bit (RX FIFO Interrupt Mode)

The RFIM bit selects the interrupt generation condition for the FIFO.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

Only write to this bit when the CANFD module is in GL_RESET mode.

RFIGCV[2:0] bits (RX FIFO Interrupt Generation Counter Value)

The RFIGCV[2:0] bits select the counter value of the FIFO for generation of FIFO interrupts. These values represent fractions of the FIFO depth for which an interrupt is generated.

Do not write to these bits when the CANFD module is in GL_SLEEP mode.

The setting of the RFIGCV[2:0] bits should be synchronized with the RFDC[2:0] bits.

Only write to these bits when the CANFD module is in GL_RESET mode.

30.2.26 CFDRFSTSa : RX FIFO Status Registers a (a = 0 to 1)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0044 + 0x04 × a

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	RFMC[5:0]					—	—	—	—	RFIF	RFMLT	RFLL	RFEMP	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	RFEMP	RX FIFO Empty 0: FIFO not empty 1: FIFO empty	R
1	RFLL	RX FIFO Full 0: FIFO not full 1: FIFO full	R
2	RFMLT	RX FIFO Message Lost 0: No message lost in FIFO 1: FIFO message lost	R/W
3	RFIF	RX FIFO Interrupt Flag 0: FIFO interrupt condition not satisfied 1: FIFO interrupt condition satisfied	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
13:8	RFMC[5:0]	RX FIFO Message Count Number of messages stored in FIFO	R
31:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The RX FIFO Status Registers show the status of messages stored in the corresponding FIFO buffers.

RFEMP bit (RX FIFO Empty)

The RFEMP bit is set automatically when:

- The RFMC bit is 0
- RX FIFO is disabled by setting the CFDRFCCa.RFE bit to 0
- The CANFD module is in GL_RESET mode.

RFPC bits (RX FIFO Pointer Control)

When the value 0xFF is written to the RFPC bits, the pointer of the corresponding RX FIFO buffer is moved to the next FIFO entry. Only write 0xFF to these registers when the corresponding RX FIFO buffer is enabled and not empty.

The read value from these bits is always 0x00.

Only write to these bits when the CANFD module is in GL_HALT or GL_OPERATION mode.

Do not write to the RX FIFO Pointer Control registers when DMA is enabled.

30.2.28 CFDCFCC : Common FIFO Configuration/Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0054

31:24	CFITT[7:0]	Common FIFO Interval Transmission Time Delay the start of transmission from the FIFO if configured in TX mode, delay is a multiple of basic Interval Timer Clock Source unit	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. These bits are not available in the classical CAN function.

CFE bit (Common FIFO Enable)

The CFE bit enables the FIFO when set. FIFO is disabled when this bit is cleared.

This bit can also be used, by clearing it, to abort transmission from Common FIFO when configured in TX mode, or to stop reception into the Common FIFO in RX mode.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFOs configured as TX FIFO.

This bit can only be set if the configured FIFO depth is greater than 0x000 (CFDCFCC.CFDC > 0x000) and less than 0x110 (0x110 > CFDCFCC.CFDC > 0x000).

Set the CFE bit with a separate write access to the CFDCFCC register, after all the other bits in this register are set.

This bit is cleared automatically when the CANFD module is in GL_RESET mode.

This bit is also cleared automatically when the related channel is in CH_RESET mode if the FIFO is configured in TX mode.

CFRXIE bit (Common FIFO RX Interrupt Enable)

The CFRXIE bit enables generation of FIFO interrupts when the interrupt flag is set after reception of a frame in the corresponding FIFO buffer.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

CFTXIE bit (Common FIFO TX Interrupt Enable)

The CFTXIE bit enables generation of common FIFO interrupts when the interrupt flag is set after transmission of a frame from the corresponding FIFO buffer.

Do not write to this bit when the CANFD module is in GL_SLEEP mode.

CFPLS[2:0] bits (Common FIFO Payload Data Size Configuration)

The CFPLS[2:0] bits define the message data payload allocation in the RAM. This is the maximum number of bytes which can be received or transmitted by the FIFO buffer.

For details, see [section 30.6. FIFO Buffers and Normal Message Buffer Configuration](#).

Only write to this bit when the CANFD module is in GL_RESET mode.

Note: These bits are not available in the classical CAN function.

CFM bit (Common FIFO Mode)

The CFM bit selects the mode of the FIFO. When a hardware reset is applied, all the Common FIFO buffers are configured in RX FIFO mode.

Do not write to these bits in GL_OPERATION or GL_SLEEP mode.

Only write to these bits when the CANFD module is in GL_RESET mode.

CFITSS bit (Common FIFO Interval Timer Source Select)

The CFITSS bit selects the basic clock source for the Interval Transmission Timer.

Do not write to this bit when the CANFD module is in GL_SLEEP mode. In addition, do not write to this bit when the CFE bit is set to 1.

Do not write 1 to this bit when CANFD communication is used.*1

Note: The bit time clock can vary depending on the nominal and data rate bit configuration.

Note 1. This feature is not available in the classical CAN function.

CFITR bit (Common FIFO Interval Timer Resolution)

The CFITR bit selects the resolution of the reference clock for the Interval Transmission Timer (peripheral clock is the source for the reference clock).

Do not write to this bit when the CANFD module is in GL_SLEEP mode. Also, do not write to this bit when the CFE bit is set to 1.

CFIM bit (Common FIFO Interrupt Mode)

The CFIM bit selects the interrupt generation condition for the FIFO buffer.

Do not write to this bit in GL_SLEEP mode.

Only write to this bit when the CANFD module is in GL_RESET mode.

CFIGCV[2:0] bits (Common FIFO Interrupt Generation Counter Value)

The CFIGCV[2:0] bits select the message counter value for the generation of FIFO interrupts. These values represent fractions of the FIFO depth at which the interrupt is to be generated.

Do not write to these bits when the CANFD module is in GL_SLEEP mode.

The setting of these bits should be synchronized with the CFDC[2:0] bits.

Only write to these bits when the CANFD module is in GL_RESET mode.

CFTML[1:0] bits (Common FIFO TX Message Buffer Link)

The CFTML[1:0] bits select the normal transmit message buffer position where the TX FIFO is linked to, for transmission scanning.

Do not write to these bits in GL_OPERATION or GL_SLEEP mode.

Only write to this bit when the CANFD module is in GL_RESET mode.

CFDC[2:0] bits (Common FIFO Depth Configuration)

The CFDC[2:0] bits select the depth of the common FIFO in terms of the number of messages. If the FIFO depth is configured to 0 message, the FIFO cannot be used.

Only write to these bits when the CANFD module is in GL_RESET mode.

CFITT[7:0] bits (Common FIFO Interval Transmission Time)

The CFITT[7:0] bits select the delay in the start of transmission for all messages transmitted from this FIFO buffer when configured in TX mode. The delay is a multiple of the basic interval timer clock source period (reference clock × 1, reference clock × 10, or bit time clock of the related CAN channel).

Do not write to these bits when the CANFD module is in GL_SLEEP mode.

Do not write to these bits when the CFE bit is set to 1.

When CFDGCFG.ITRCP[15:0] = 0x0000, set the CFITT[7:0] bits to 0x0000.

30.2.29 CFDCFSTS : Common FIFO Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0058

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	CFMC[5:0]					—	—	—	CFTXI F	CFRXI F	CFML T	CFFLL	CFEM P	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	CFEMP	Common FIFO Empty 0: FIFO not empty 1: FIFO empty	R
1	CFFLL	Common FIFO Full 0: FIFO not full 1: FIFO full	R
2	CFMLT	Common FIFO Message Lost 0: Number of message lost in FIFO 1: FIFO message lost	R/W
3	CFRXIF	Common RX FIFO Interrupt Flag 0: FIFO interrupt condition not satisfied after frame reception 1: FIFO interrupt condition satisfied after frame reception	R/W
4	CFTXIF	Common TX FIFO Interrupt Flag 0: FIFO interrupt condition not satisfied after frame transmission 1: FIFO Interrupt condition satisfied after frame transmission	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
13:8	CFMC[5:0]	Common FIFO Message Count Number of messages stored in FIFO	R
31:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CFEMP bit (Common FIFO Empty)

The CFEMP bit is set automatically when:

- The CPU has read all messages from the FIFO configured in RX mode
- All messages have been transmitted from the FIFO configured in TX mode
- The FIFO is disabled by setting the CFE bit to 0
- The CANFD module is in GL_RESET mode

- The related CANFD channel is in CH_RESET when FIFO configured in TX mode.

The CFEMP bit is cleared automatically when:

- The first reception message is stored in the FIFO buffer when configured in RX mode
- The first message to be transmitted is stored in the FIFO buffer when configured in TX mode.

CFLL bit (Common FIFO Full)

The CFLL bit is set automatically when the number of CAN messages stored in the FIFO matches the configured FIFO depth.

The CFLL bit is cleared automatically when:

- The number of CAN messages stored in the FIFO is less than the configured FIFO depth
- The FIFO is disabled by setting the CFE bit to 0
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode when FIFO buffer is configured in TX mode.

CFMLT bit (Common FIFO Message Lost)

The CFMLT bit is set automatically whenever a message is lost due to attempted storage of a new message when FIFO is already full in RX mode.

If a set from the CAN channel occurs simultaneously with a clear by a write access, then this bit is set.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFO configured as TX FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

The CFMLT bit is cleared:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode
- When the related CANFD channel is in CH_RESET mode if the FIFO buffer is configured in TX mode.

CFRXIF bit (Common RX FIFO Interrupt Flag)

The CFRXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFO configured as TX FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

This bit is set automatically when the configured interrupt condition is satisfied for Common FIFO buffers when configured in RX mode.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

The CFRXIF bit is cleared:

- By writing 0 to it
- When the CANFD module is in GL_RESET mode

CFTXIF bit (Common TX FIFO Interrupt Flag)

The CFTXIF bit is not cleared automatically if the Common FIFO buffer is disabled.

Only write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode and the related CANFD channel is not in CH_RESET mode for FIFO buffer configured as TX FIFO. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

30.2.31 CFDFESTS : FIFO Empty Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0060

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CFEMP	—	—	—	—	—	—	—	RFXEMP[1:0]
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
1:0	RFXEMP[1:0]	RX FIFO Empty Status 0: Corresponding FIFO not empty 1: Corresponding FIFO empty	R
7:2	—	These bits are read as 0.	R
8	CFEMP	Common FIFO Empty Status 0: Corresponding FIFO not empty 1: Corresponding FIFO empty	R
31:9	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The FIFO Empty Status register shows status of the empty bits of the FIFO buffers.

RFXEMP[1:0] bits (RX FIFO Empty Status)

The RFXEMP[1:0] bits are set when the CANFD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

CFEMP bit (Common FIFO Empty Status)

The CFEMP bits are set when the CANFD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

30.2.32 CFDFESTS : FIFO Full Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0064

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit field:	—	—	—	—	—	—	—	CFFLL	—	—	—	—	—	—	—	RFXFLL[1:0]
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	RFXFLL[1:0]	RX FIFO Full Status 0: Corresponding FIFO not full 1: Corresponding FIFO full	R
7:2	—	These bits are read as 0.	R
8	CFFLL	Common FIFO Full Status 0: Corresponding FIFO not full 1: Corresponding FIFO full	R
31:9	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The FIFO Full Status Register shows status of the full bits of the FIFO buffers.

RFXFLL[1:0] bits (RX FIFO Full Status)

The RFXFLL[1:0] bits are cleared when CANFD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

CFFLL bits (Common FIFO Full Status)

The CFFLL bits are cleared when the CANFD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

30.2.33 CFDFMSTS : FIFO Message Lost Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0068

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CFMLT	—	—	—	—	—	—	—	RFXMLT[1:0]
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	RFXMLT[1:0]	RX FIFO Message Lost Status 0: Corresponding FIFO Message Lost flag not set 1: Corresponding FIFO Message Lost flag set	R
7:2	—	These bits are read as 0.	R
8	CFMLT	Common FIFO Message Lost Status 0: Corresponding FIFO Message Lost flag not set 1: Corresponding FIFO Message Lost flag set	R
31:9	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The FIFO Message Lost Status Register shows status of the Msg Lost bits of the FIFO buffers.

RFXMLT[1:0] bits (RX FIFO Message Lost Status)

The RFXMLT[1:0] bits are cleared when the CANFD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the RX FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the RX FIFO Status Registers.

CFMLT bits (Common FIFO Message Lost Status)

The CFMLT bits are cleared when the CANFD module is in GL_RESET mode.

Each bit is set automatically when the corresponding bit is set in the Common FIFO Status Registers.

Each bit is cleared automatically when the corresponding bit is cleared in the Common FIFO Status Registers.

30.2.34 CFDRFISTS : RX FIFO Interrupt Flag Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x006C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RFXIF[1:0]
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	RFXIF[1:0]	RX FIFO[x] Interrupt Flag Status 0: Corresponding RX FIFO Interrupt flag not set 1: Corresponding RX FIFO Interrupt flag set	R
31:2	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The FIFO Interrupt Flag Status Register shows status of the interrupt flag bits of the RX FIFO buffers.

RFXIF[1:0] bits (RX FIFO[x] Interrupt Flag Status)

Each bit is set automatically when the corresponding interrupt flag bit is set in the RX FIFO Status Registers.

The RFXIF[1:0] bits are cleared when the CANFD module is in GL_RESET mode.

Each bit is cleared automatically when the corresponding interrupt flag bit is cleared in the RX FIFO Status Registers.

30.2.35 CFDCDTCT : DMA Transfer Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00C8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CFDM AE	—	—	—	—	—	—	RFDM AE1	RFDM AE0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RFDMAE0	DMA Transfer Enable for RXFIFO 0 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
1	RFDMAE1	DMA Transfer Enable for RXFIFO 1 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	CFDMAE	DMA Transfer Enable for Common FIFO 0 0: DMA transfer request disabled 1: DMA transfer request enabled	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The DMA Transfer Control Register controls the start and stop of DMA transfer operation.

RFDMAEe (e = 0 to 1) bit (DMA Transfer Enable for RXFIFO e)

The RFDMAEe bit cannot be set in GL_SLEEP or GL_RESET mode.

This bit is cleared when the CANFD module is in GL_RESET mode.

CFDMAE bit (DMA Transfer Enable for Common FIFO)

The CFDMAE bit enables or disables DMA transfer request for common FIFO

The CFDMAE bit cannot be set in GL_SLEEP or GL_RESET mode.

Do not enable a DMA transfer for a Common FIFO that is configured as TX FIFO.

This bit is cleared when the CANFD module is in GL_RESET mode.

30.2.36 CFDCDTSTS : DMA Transfer Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00CC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CFDM ASTS	—	—	—	—	—	—	RFDM ASTS1	RFDM ASTS0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RFDMASTS0	DMA Transfer Status for RX FIFO 0 0: DMA transfer stopped 1: DMA transfer on going	R
1	RFDMASTS1	DMA Transfer Status for RX FIFO 1 0: DMA transfer stopped 1: DMA transfer on going	R
7:2	—	These bits are read as 0.	R
8	CFDMASTS	DMA Transfer Status only for Common FIFO 0: DMA transfer stopped 1: DMA transfer on going	R
31:9	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The DMA Transfer Status Register shows the status of the DMA transfer.

RFDMASTSe (e = 0 to 1) bit (DMA Transfer Status for RX FIFO e)

Each bit is set automatically when the corresponding DMA enable bit is set and the corresponding DMA FIFO is not empty. Each bit is cleared automatically when the DMA transfer stops either because the DMA is disabled or the DMA FIFO is empty.

When CFDCDTCT.RFDMAEe (see CFDCDTCT.RFDMAEe bit in [section 30.2.35. CFDCDTCT : DMA Transfer Control Register](#)) is set to 0 while DMA transfer for the corresponding FIFO is on going, the RFDMASTSe bit becomes 0 when the DMA transfer is complete.

This bit is cleared when the CANFD module is in GL_RESET mode.

CFDMASTS bit (DMA Transfer Status only for Common FIFO)

Each bit is set automatically when the corresponding DMA enable bit is set and the corresponding DMA FIFO is not empty. Each bit is cleared automatically when the DMA transfer stops either because the DMA is disabled or the DMA FIFO is empty.

When CFDCDTCT.CFDMAE (see CFDCDTCT.CFDMAE bit in [section 30.2.35. CFDCDTCT : DMA Transfer Control Register](#)) is set to 0 while DMA transfer for the corresponding FIFO is on going, the CFDMASTS bit becomes 0 when the DMA transfer is complete.

This bit is cleared when the CANFD module is in GL_RESET mode.

30.2.37 CFDTMCI : TX Message Buffer Control Registers i (i = 0 to 3)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0070 + 0x01 × i

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	TMOM	TMTA R	TMTR

Value after reset: 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	TMTR	TX Message Buffer Transmission Request 0: TX Message buffer transmission not requested 1: TX message buffer transmission requested	R/W
1	TMTAR	TX Message Buffer Transmission Abort Request 0: TX message buffer transmission request abort not requested 1: TX message buffer transmission request abort requested	R/W
2	TMOM	TX Message Buffer One-shot Mode 0: TX message buffer not configured in one-shot mode 1: TX message buffer configured in one-shot mode	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The TX Message Buffer Control Registers configure the TX message buffer functions.

TMTR bit (TX Message Buffer Transmission Request)

When the TMTR bit is set, the CANFD module logic tries to transmit the message stored in the corresponding message buffer.

Only write to this bit when the related CANFD module is in CH_HALT or CH_OPERATION mode.

Do not set this bit if the corresponding TX message buffer is linked to a COM FIFO in TX mode or is a part of TX Queue.

This bit cannot be directly cleared by a CPU write access.

This bit can only be set when the Transmission Result flag bits (CFDTMSTSj.TMTRF) in the CFDTMSTSj register corresponding to the message buffer are cleared to 00b.

The TMTR bit is automatically cleared by the:

- CANFD module logic at the end of a successful transmission
- CANFD module logic at the end of a transmission abort, requested by the corresponding CFDTMCI.TMTAR bit
- CANFD module logic when there is a detection of a CAN bus error or arbitration loss if CFDTMCI.TMOM bit is set for the message buffer
- CANFD module logic when the CANFD module is in GL_RESET mode or the related channel is in CH_RESET mode.

TMTAR bit (TX Message Buffer Transmission Abort Request)

When the TMTAR bit is set, the CANFD module logic tries to abort the transmission of the frame stored in the corresponding message buffer.

In most cases, transmission cannot be aborted if the internal scan for transmission is complete and the message buffer has already been selected for transmission. In this case, frame may be transmitted successfully from the message buffer. The message buffer selection is released by entering CH_HALT mode.

However, message buffer selected for transmission can be aborted by an abort request when the CAN node detects a new message on the bus (RX pin) before it starts transmission from the selected message buffer.

Only write to the TMTAR bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode. This bit can only be set when the related transmit request TMTR bit is set.

The TMTAR bit cannot be cleared by a CPU write access. Clearing of this bit by CANFD has priority over setting by a CPU write access.

The TMTAR bit is automatically cleared by:

- The CANFD module logic at the end of a successful transmission
- The CANFD module logic at the end of a transmission abort
- The CANFD module logic when there is detection of a CAN bus error or arbitration loss
- The CANFD module logic when the CANFD module is in GL_RESET mode or the related channel enters CH_RESET mode.

TMOM bit (TX Message Buffer One-shot Mode)

When the TMOM bit is set, the CANFD module logic tries to transmit the message only once.

If the transmission is successful, the CFDTMSTsj.TMTRF bits are set to 10b or 11b. Otherwise, the transmission is automatically aborted and CFDTMSTsj.TMTRF bits are set to 01b due to a bus error or a bus arbitration lost.

The TMOM bit remains set if the transmission has completed successfully or aborted due to an error or a loss of arbitration.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Set this bit at the same time as the TMTR bit. Clear this bit with a write access.

If a message has already been requested for transmission, do not write to this bit until the message has been successfully transmitted or transmission has been aborted.

The TMOM bit is automatically cleared by the CANFD module logic when the CANFD module is in GL_RESET mode or the related channel is in CH_RESET mode.

30.2.38 CFDTMSTsj : TX Message Buffer Status Registers j (j = 0 to 3)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0074 + 0x01 × j

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	TMTA RM	TMTR M	TMTRF[1:0]	TMTS TS	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TMTSTS	TX Message Buffer Transmission Status 0: No on-going transmission 1: On-going transmission	R
2:1	TMTRF[1:0]	TX Message Buffer Transmission Result Flag 0 0: No result 0 1: Transmission aborted from the TX message buffer 1 0: Transmission successful from the TX message buffer and transmission abort was not requested 1 1: Transmission successful from the TX message buffer and transmission abort was requested	R/W
3	TMTRM	TX Message Buffer Transmission Request Mirrored 0: TX message buffer transmission not requested 1: TX message buffer transmission requested	R
4	TMTARM	TX Message Buffer Transmission Abort Request Mirrored 0: TX message buffer transmission request abort not requested 1: TX message buffer transmission request abort requested	R
7:5	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The TX Message Buffer Status Registers show status of the transmission and transmission abort for the corresponding message buffers.

TMTSTS bit (TX Message Buffer Transmission Status)

The TMTSTS bit is set automatically at the start of the transmission from the corresponding TX message buffer.

This bit is cleared automatically when:

- Transmission stops
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

TMTRF[1:0] bits (TX Message Buffer Transmission Result Flag)

The TMTRF[1:0] bits show the result for the corresponding TX message buffer. The status is as follows:

- 00: Transmission in progress or has not been requested
- 01: Transmission has been aborted from the corresponding TX message buffer
- 10: Transmission was successful from the corresponding TX message buffer and the CFDTMCi.TMTAR bit was not set for this TX message buffer
- 11: Transmission was successful from the corresponding TX message buffer, but the CFDTMCi.TMTAR bit was set for this TX message buffer.

Only write to these bits when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

The TMTRF[1:0] bits are cleared automatically when the CANFD module is in GL_RESET mode or the related channel is in CH_RESET mode.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

TMTRM bit (TX Message Buffer Transmission Request Mirrored)

The TMTRM bit is set when the CFDTMCi.TMTR bit in the corresponding CFDTMCi register is set.

This bit is cleared when the CFDTMCi.TMTR bit in the corresponding CFDTMCi register is cleared.

TMTARM bit (TX Message Buffer Transmission Abort Request Mirrored)

The TMTARM bit is set when the CFDTMCi.TMTAR bit in the corresponding CFDTMCi register is set.

This bit is cleared when the CFDTMCi.TMTAR bit in the corresponding CFDTMCi register is cleared.

30.2.39 CFDTMTRSTS : TX Message Buffer Transmission Request Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0078

Bit position: 31

3 0

Bit field:

Value after reset: 0

Bit	Symbol	Function	R/W
3:0	CFDTMTRSTS[3:0]	TX Message Buffer Transmission Request Status 0: Transmission not requested for corresponding TX message buffer 1: Transmission requested for corresponding TX message buffer	R
31:4	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

These bits show the TX Message Buffer Transmission Request Status for the corresponding TX Message Buffer. The bit 0 of a CFDTMTRSTS register corresponds to the TX message buffer 0.

The bit position of CFDTMTRSTS corresponds to the buffer number of TX message buffer.

CFDTMTRSTS[3:0] bits (TX Message Buffer Transmission Request Status)

The CFDTMTRSTS[3:0] bits show status of the CFDTMCi.TMTR bits of the TX Message Buffer Control Registers.

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Control Registers (CFDTMCi), and only when the message buffer does not belong to a TX Queue.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Control Registers
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

30.2.40 CFDTMTARSTS : TX Message Buffer Transmission Abort Request Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x007C

Bit position: 31

3 0

Bit field:

Value after reset: 0

Bit	Symbol	Function	R/W
3:0	CFDTMTARSTS[3:0]	TX Message Buffer Transmission Abort Request Status 0: Transmission abort not requested for corresponding TX message buffer 1: Transmission abort requested for corresponding TX message buffer	R
31:4	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

These bits show the TX Message Buffer Transmission Abort Request Status for the corresponding TX Message Buffer. The bit 0 of a CFDTMTARSTS register corresponds to the TX message buffer 0.

The bit position of CFDTMTARSTS corresponds to the buffer number of TX message buffer.

CFDTMTARSTS[3:0] bits (TX Message Buffer Transmission Abort Request Status)

The CFDTMTARSTS[3:0] bits show status of the CFDTMCI.TMTAR bits of the TX Message Buffer Control Registers.

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Control Registers, and when the message buffer belongs to a TX Queue.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Control Registers
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

30.2.41 CFDTMTCSTS : TX Message Buffer Transmission Completion Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0080

Bit position: 31

3 0

Bit field:

Value after reset: 0

Bit	Symbol	Function	R/W
3:0	CFDTMTCSTS[3:0]	TX Message Buffer Transmission Completion Status 0: Transmission not complete for corresponding TX message buffer 1: Transmission completed for corresponding TX message buffer	R
31:4	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

These bits show the TX Message Buffer Transmission Completion Status for the corresponding TX Message Buffer. The bit 0 of a CFDTMTCSTS register corresponds to the TX message buffer 0.

The bit position of CFDTMTCSTS corresponds to the buffer number of TX message buffer.

CFDTMTCSTS[3:0] bits (TX Message Buffer Transmission Completion Status)

The CFDTMTCSTS[3:0] bits show status of successful completion of the TX Message Buffer Status Registers.

Each bit is set automatically when the corresponding bit is set in the TX Message Buffer Status Registers.

Each bit is cleared automatically when:

- The corresponding bit is cleared in the TX Message Buffer Status Registers
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

If a CAN channel enters CH_RESET mode, then the bits related to that channel are cleared.

30.2.42 CFDTMTASTS : TX Message Buffer Transmission Abort Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0084

Bit position: 31

3 0

Bit field:

Value after reset: 0

Bit	Symbol	Function	R/W
3:0	CFDGMTASTS[3:0]	TX Message Buffer Transmission Abort Status 0: Transmission not aborted for corresponding TX message buffer 1: Transmission aborted for corresponding TX message buffer	R
31:4	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

These bits show the TX Message Buffer Transmission abort Status for the corresponding TX Message Buffer. The bit 0 of a CFDGMTASTS register corresponds to the TX message buffer 0.

The bit position of CFDGMTASTS corresponds to the buffer number of TX message buffer.

CFDGMTASTS[3:0] bits (TX Message Buffer Transmission Abort Status)

The CFDGMTASTS[3:0] bits show status of the successful transmission abort of the corresponding TX message buffer.

Each bit is set automatically when the CFDMSTSj.TMTRF bits are set to 01b in the corresponding TX Message Buffer Status Register.

Each bit is cleared automatically when:

- The CFDMSTSj.TMTRF bits are cleared in the corresponding TX Message Buffer Status Register
- The CANFD module is in GL_RESET mode
- The related CANFD channel is in CH_RESET mode.

30.2.43 CFDMTIEC : TX Message Buffer Interrupt Enable Configuration Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0088

Bit position: 31

3 0

Bit field:

Value after reset: 0

Bit	Symbol	Function	R/W
3:0	TMIEg[3:0]	TX Message Buffer Interrupt Enable 0: TX message buffer interrupt disabled for corresponding TX message buffer 1: TX message buffer interrupt enabled for corresponding TX message buffer	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

These bits show the TX Message Buffer Interrupt Enable for the corresponding TX Message Buffer.

The bit 0 of a CFDMTIEC register corresponds to the TX message buffer 0.

The bit position of CFDMTIEC corresponds to the buffer number of TX message buffer.

g = [0...3]

TMIEg[3:0] bits (TX Message Buffer Interrupt Enable)

If the TMIEg[3:0] bits are set, an interrupt is generated at the end of a successful transmission from the corresponding message buffer.

See [section 30.7. Interrupts and DMA](#) for TX Message Buffer Interrupt specification.

Do not write to the TMIEg[7:0] bits when:

- The CANFD module is in GL_SLEEP mode
- The related CANFD channel is in CH_SLEEP mode
- The corresponding TX message buffer is linked to a Common FIFO with the CFDCFCC.CFTML bits.

30.2.44 CFDTXQCC : TX Queue Configuration/Control Register

Base address: CANFD_n = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFD_n_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x008C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TXQDC[1:0]	TXQIM	—	TXQTXIE	—	—	—	—	—	TXQE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TXQE	TX Queue Enable 0: TX Queue disabled 1: TX Queue enabled	R/W
4:1	—	These bits are read as 0. The write value should be 0.	R/W
5	TXQTXIE	TX Queue TX Interrupt Enable 0: TX Queue TX interrupt disabled 1: TX Queue TX interrupt enabled	R/W
6	—	This bit is read as 0. The write value should be 0.	R/W
7	TXQIM	TX Queue Interrupt Mode 0: When the last message is successfully transmitted 1: At every successful transmission	R/W
9:8	TXQDC[1:0]	TX Queue Depth Configuration 0x00: 0 messages 0x01: Reserved 0x10: 3 messages 0x11: 4 messages	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The TX Queue Configuration/Control Registers are used to configure the TX Queue transmission.

TXQ is composed of TXMB0 to TXMB3 (at the maximum) when TXQE is enabled.

TXQE bit (TX Queue Enable)

The TXQE bit cannot be set if the configured TX Queue depth is 0x00 (CFDTXQCC.TXQDC == 0x00).

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in CH_RESET or CH_SLEEP mode.

The TXQE bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

TXQTXIE bit (TX Queue TX Interrupt Enable)

When the TXQTXIE bit is set, an interrupt is generated based on the setting of the TXQIM bit.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in CH_SLEEP mode.

TXQIM bit (TX Queue Interrupt Mode)

The TXQIM bit selects the interrupt generation condition for the TX Queue.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

TXQDC[1:0] bits (TX Queue Depth Configuration)

The TXQDC[1:0] bits select the depth of the transmission queue. The message buffer selection starts from MB[0] up to MB[3] depending on the configured depth.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the related CANFD channel is in any of the following modes:

- CH_SLEEP
- CH_HALT
- CH_OPERATION.

30.2.45 CFDTXQSTS : TX Queue Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0090

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	TXQMC[2:0]		—	—	—	—	—	TXQT XIF	TXQF LL	TXQE MP	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	TXQEMP	TX Queue Empty 0: TX Queue not empty 1: TX Queue empty	R
1	TXQFLL	TX Queue Full 0: TX Queue not full 1: TX Queue full	R
2	TXQTXIF	TX Queue TX Interrupt Flag 0: TX Queue interrupt condition not satisfied after a frame TX 1: TX Queue interrupt condition satisfied after a frame TX	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
10:8	TXQMC[2:0]	TX Queue Message Count Number of messages in the TX Queue.	R
31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The TX Queue Status Registers show the status of the TX Queue of corresponding CAN channel.

TXQEMP bit (TX Queue Empty)

The TXQEMP bit is set automatically when the TX Queue is disabled or no messages are stored in the TX Queue.

This bit is set automatically when:

- The last message is transmitted from the TX Queue
- The related CANFD channel is in CH_RESET mode.

The bit is cleared automatically when the first message to be transmitted is stored in the TX Queue.

- The Common FIFO is enabled.

30.2.47 CFDTLCC : TX History List Configuration/Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0098

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	THLD TE	THLIM	THLIE	—	—	—	—	—	—	—	THLE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	THLE	TX History List Enable 0: TX History List disabled 1: TX History List enabled	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
8	THLIE	TX History List Interrupt Enable 0: TX History List Interrupt disabled 1: TX History List Interrupt enabled	R/W
9	THLIM	TX History List Interrupt Mode 0: Interrupt generated if TX History List level reaches $\frac{3}{4}$ of the TX History List depth 1: Interrupt generated for every successfully stored entry	R/W
10	THLDTE	TX History List Dedicated TX Enable 0: TX FIFO + TX Queue 1: Flat TX MB + TX FIFO + TX Queue	R/W
31:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The TX History List Configuration/Control Register configures the TX History List functions.

THLE bit (TX History List Enable)

The THLE bit enables the TX History List buffer when it is set.

You cannot write to this bit when the related CANFD channel is in CH_RESET or CH_SLEEP mode.

This bit is cleared automatically when the related CANFD channel is in CH_RESET mode.

THLIE bit (TX History List Interrupt Enable)

The THLIE bit enables the generation of the TX History List interrupt when it is set.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

THLIM bit (TX History List Interrupt Mode)

The THLIM bit selects the interrupt generation condition for the FIFO.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode.

THLDTE bit (TX History List Dedicated TX Enable)

The THLDTE bit selects the condition for storing an entry in the TX History List after successful transmission.

You cannot write to this bit when the CANFD module is in GL_SLEEP mode.

Do not write to this bit when the CANFD module is in GL_HALT or GL_OPERATION mode.

30.2.48 CFDTLSTS : TX History List Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x009C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	THLMC[3:0]				—	—	—	—	THLIF	THLELT	THLFL	THLEMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	THLEMP	TX History List Empty 0: TX History List not empty 1: TX History List empty	R
1	THLFL	TX History List Full 0: TX History List not full 1: TX History List full	R
2	THLELT	TX History List Entry Lost 0: No entry lost in TX History List 1: TX History List entry Lost	R/W
3	THLIF	TX History List Interrupt Flag 0: TX History List interrupt condition not satisfied 1: TX History List interrupt condition satisfied	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
11:8	THLMC[3:0]	TX History List Message Count Number of messages stored in TX History List	R
31:12	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The TX History List Status register shows the status of data stored in the TX History List buffer.

THLEMP bit (TX History List Empty)

The THLEMP bit is set automatically when the CPU has read all the entries from the TX History List buffer.

This bit is cleared automatically when the first entry is stored to the TX History List.

This bit is set automatically when:

- TX History List is disabled
- The related CANFD channel is in CH_RESET mode.

THLFL bit (TX History List Full)

The THLFL bit is set automatically when the number of entries in the TX History List buffer matches the TX History List depth.

Each TX History List can store up to 8 entries.

This bit is cleared automatically when:

- The number of entries in the TX History List buffer is less than the TX History List depth
- The TX History List is disabled
- The related CANFD channel is in CH_RESET mode.

THLELT bit (TX History List Entry Lost)

The THLELT bit is set when a new entry cannot be stored because the related TX History List buffer is already full.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

THLIF bit (TX History List Interrupt Flag)

The THLIF bit is set when the configured interrupt condition is satisfied.

Only write to this bit when the related CANFD channel is in CH_HALT or CH_OPERATION mode. Writing 1 has no effect.

Do not use the bit clear instruction to clear this bit. Use the MOV instruction to ensure that only the specified bit is cleared. Other bits remain 1.

If the set from the CAN channel occurs simultaneously with the clear by the write access, then the bit is set.

This bit is cleared:

- By writing 0 to it
- When the related CANFD channel is in CH_RESET mode.

The bit is cleared by writing 0 to it.

This bit is automatically cleared in CH_RESET mode.

THLMC[3:0] bits (TX History List Message Count)

The THLMC[3:0] bits show the number of transmitted messages stored in the TX History List.

These bits are cleared automatically when the related CANFD channel is in CH_RESET mode.

30.2.49 CFDTHLACC0 : TX History List Access Register 0

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0740

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	TMTS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	BN[1:0]	BT[2:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	BT[2:0]	Buffer Type 0 0 1: Flat TX message buffer 0 1 0: TX FIFO message buffer number 1 0 0: TX Queue message buffer number	R
4:3	BN[1:0]	Buffer Number Number of the message buffer	R

Bit	Symbol	Function	R/W
15:5	—	These bits are read as 0.	R
31:16	TMTS[15:0]	Transmit Timestamp Transmit timestamp value for software drivers	R

Note: S-TYPE-3, P-TYPE-3

The TX History List Access Registers 0 provide access to the entry in the TX History List based on the read timestamp value.

BT[2:0] bits (Buffer Type)

The BT[2:0] bits indicate whether data has been stored following a transmission from a FIFO buffer, a TX Queue or a TX message buffer.

BN[1:0] bits (Buffer Number)

The BN[1:0] bits show the message buffer from which transmission was successfully completed. If a message from a Common FIFO is transmitted, then these bits show the message buffer that is linked to the Common FIFO for transmission.

TMTS[15:0] bits (Transmit Timestamp)

The TMTS[15:0] bits indicate the timestamp for use by software drivers.

30.2.50 CFDTHLACC1 : TX History List Access Register 1

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0744

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TIFL[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TID[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	TID[15:0]	Transmit ID These bits indicate that message buffer reference ID, TX FIFO reference ID, or AFL pointer field is stored for software drivers.	R
17:16	TIFL[1:0]	Transmit Information Label These bits indicate that message buffer information label, TX FIFO information label, or AFL information label is stored for software drivers.	R
31:18	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

The TX History List Access Registers 1 provide access to entry in the TX History List based on the read pointer value.

TID[15:0] bits (Transmit ID)

The TID[15:0] bits indicate whether the message buffer reference ID (CFDTMFDCTRb.TMPTR) or the TX FIFO reference ID (CFDCFFDCSTS.CFPTR) is for use by software drivers.

TIFL[1:0] bits (Transmit Information Label)

The TIFL[1:0] bits indicate whether the message buffer information label (CFDTMFDCTRb.TMIFL) or the TX FIFO information label (CFDCFFDCSTS.CFIFL) is for use by software drivers.

30.2.51 CFDTLPCCTR : TX History List Pointer Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00A0

Bit position: 31 7 0

Value after reset: 0

Bit	Symbol	Function	R/W
7:0	THLPC[7:0]	TX History List Pointer Control Increments the write pointer to the TX History List in the corresponding channel	W
31:8	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

The TX History List Pointer Control Registers are used to increment the read pointer of the TX History List.

THLPC[7:0] bits (TX History List Pointer Control)

When 0xFF is written to the THLPC[7:0] bits, the read pointer of the TX History List is moved to the next TX History List entry address.

The read value from these bits is always 0x00. Only write to these bits when the related CANFD channel is in CH_HALT or CH_OPERATION mode.

Only write 0xFF to these registers when the corresponding TX History List is enabled and not empty.

30.2.52 CFDGRSTC : Global SW reset Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00D8

Bit position: 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16

Value after reset: 0

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Value after reset: 0

Bit	Symbol	Function	R/W
0	SRST	SW Reset 0: Normal state 1: SW reset state	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code These bits control the validity of rewriting of a SRST bit.	W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

SRST bit (SW Reset)

When the SRST bit is set, the CANFD module is in the same state as hardware reset. When a reset is required, write 1 then write 0 to this bit.

This bit is cleared when the CANFD module is in GL_SLEEP mode.

When this bit is cleared, the RAM initialization sequence does not operate. The configuration of RAM is performed by software.

The RAM is not initialized when software reset is performed during the initialization of RAM. Software must perform the initialization of RAM.

KEY[7:0] bits (Key Code)

When 0xC4 is written in the KEY[15:8] bits, a write to the SRST bit is valid.

The read value from these bits is always 0x00.

CFDGRSTC.SRST bit and the CFDGRSTC.KEY bit should be written simultaneously.

30.2.53 CFDTSTCFG : Global Test Configuration Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00A8

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

19:16	RTMPS[3:0]	RAM Test Mode Page Select Select a RAM test mode page	R/W
31:20	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The Global Test Configuration Register is used to configure the RAM test mode page.

RTMPS[3:0] bits (RAM Test Mode Page Select)

The RTMPS[3:0] bits select the RAM page mode for CPU read/write access when the CANFD module is configured in RAM test mode.

See [section 30.9.2.1. RAM Test Mode](#) for the RAM test mode specification.

Do not write to these bits when the CANFD module is in GL_RESET or GL_SLEEP mode.

Only enter values from 0 to 8 (0x008) for the message buffer RAM.

Only write to these bits when the CANFD module is in GL_HALT mode.

These bits are cleared automatically when the related CANFD channel is in GL_RESET mode.

30.2.54 CFDGTSTCTR : Global Test Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00AC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

1:0	—	These bits are read as 0. The write value should be 0.	R/W
2	RTME	RAM Test Mode Enable 0: RAM test mode disabled 1: RAM test mode enabled	R/W
31:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The Global Test Control register is used to control the global test modes of the CANFD module.

RTME bit (RAM Test Mode Enable)

When the RTME bit is set, the CANFD module is configured in RAM test mode. See [section 30.9.2.1. RAM Test Mode](#) for RAM test mode specification.

Only write to this bit when the CANFD module is in GL_HALT mode.

Clear this bit when the CANFD module is in GL_HALT mode.

This bit is cleared automatically when the CANFD module is in GL_RESET mode.

30.2.55 CFDFDCFG : Global FD Configuration Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00B0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TSCCFG[1:0]	—	—	—	—	—	—	—	—	RPED
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RPED	RES Bit Protocol Exception Disable 0: Protocol exception event detection enabled 1: Protocol exception event detection disabled	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
9:8	TSCCFG[1:0]	Timestamp Capture Configuration 0 0: Timestamp capture at the sample point of SOF (start of frame) 0 1: Timestamp capture at frame valid indication 1 0: Timestamp capture at the sample point of RES bit 1 1: Reserved	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

RPED bit (RES Bit Protocol Exception Disable)

The RPED bit configures the protocol exception event handling according to ISO 11898-1.

When this bit is enabled, the protocol exception event detection is disabled, and the protocol controller transmits an error frame when the protocol exception event is detected (RES bit is sampled recessive).

Only write to this bit when the CANFD module is in GL_RESET mode.

TSCCFG[1:0] bits (Timestamp Capture Configuration)

The TSCCFG[1:0] bits configure the different capture points of the timestamp for transmission and reception.

When CFDFDCFG.TSCCFG[1:0] = 10b, the timestamp capture is performed for CANFD frames at RES bit and for Classical frames at the start of frame.

Only write to these bits when the CANFD module is in GL_RESET mode.

30.2.56 CFDGLOCKK : Global Lock Key Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00B8

Bit position: 31 15 0

Value after reset: 0

Bit	Symbol	Function	R/W
15:0	LOCK[15:0]	Lock Key Key bits for unlocking the protection of test modes	W
31:16	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

The Global Lock Key register is a write-only register that is used to unlock the protection for special test bits.

See section 30.9.2. Global Test Modes for Lock key specification.

LOCK[15:0] bits (Lock Key)

The unlock key sequence must be written in the LOCK[15:0] bits to configure the CANFD module in RAM test modes.

The read value from these bits is always 0x0000.

You cannot write to these bits when the CANFD module is in GL_SLEEP or GL_RESET mode.

Do not write to these bits when the CANFD module is in GL_OPERATION mode.

30.2.57 CFDRPGACCK : RAM Test Page Access Registers k (k = 0 to 63)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0280 + 0x0004 × k

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	RDTA[31:0]	RAM Data Test Access RAM data bytes	R/W

Note: S-TYPE-3, P-TYPE-3

RDTA[31:0] bits (RAM Data Test Access)

Data can be read from or written into the RDTA[31:0] bits when the CANFD module is configured in RAM test mode.

Only write to this bit when the CANFD module is in GL_HALT mode and RAM test mode is enabled.

Software data should be read/written in the RAM Test Page Access registers during RAM test mode.

30.2.58 CFDGAFLIGNENT : Global AFL Ignore Entry Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00C0

Bit position: 31 3 0

Value after reset: 0

Bit	Symbol	Function	R/W
3:0	IRN[3:0]	Ignore Rule Number Define rule number which ignores an AFL entry.	R/W
31:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

IRN[3:0] bits (Ignore Rule Number)

The IRN[3:0] bits define the rule number which updates an AFL entry.

Enter only values between 0 and 15 (0x0F) inclusive.

Only write to these bits when the CFDGAFLIGNCTR.IREN bit is 0.

You cannot write to these bits when the CANFD module is in GL_SLEEP mode.

30.2.59 CFDGAFIGNCTR : Global AFL Ignore Control Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x00C4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	IREN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	IREN	Ignore Rule Enable 0: AFL entry number is not ignored 1: AFL entry number is ignored	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code These bits control the validity of rewriting the IREN bit.	W
31:16	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

IREN bit (Ignore Rule Enable)

When the IREN bit is set, the entry number (selected by CFDGAFIGNENT register) is ignored.

This bit is cleared automatically when the CANFD module is in GL_RESET mode.

KEY[7:0] bits (Key Code)

When 0xC4 is written in the KEY[7:0] bits, a write to the IREN bit is valid.

The read value from these bits is always 0x00.

CFDGAFIGNCTR.IREN bit and the CFDGAFIGNCTR.KEY bit should be written simultaneously

30.2.60 CFDRMIEC : RX Message Buffer Interrupt Enable Configuration Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0038

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	RMIE[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	RMIE[15:0]	RX Message Buffer Interrupt Enable 0: RX Message Buffer Interrupt disabled for corresponding RX message buffer 1: RX Message Buffer Interrupt enabled for corresponding RX message buffer	R/W

Note: S-TYPE-3, P-TYPE-3

These bits show the RX Message Buffer Interrupt Enable for the corresponding RX Message Buffer. CFDRMIEC bit 0 corresponds to RX Message Buffer 0 and so on.

The bit position of CFDRMIEC corresponds to the buffer number of RXMB.

RMIE[15:0] bit (RX Message Buffer Interrupt Enable)

If this bit is set, then an interrupt will be generated at the end of a successful reception from the corresponding Message Buffer.

For details, see [section 30.7.1. Interrupts](#).

Users cannot write to this bit when the CANFD module is in GL_SLEEP mode.

30.2.61 Message Buffer Component Structure**30.2.61.1 Start Addresses**

The start address for each of the Message Buffer component is calculated using the number of related Message Buffer components.

The start addresses for each register in the Message Buffer component are depicted in [Table 30.4](#).

Table 30.4 Message Buffer Component Register Start Addresses

b = Message buffer component index	MBCP	p	Register	Start Address
[0...15] b = [0...7]	RMBCPb[0]	x	RMID	0x0920 + b × 0x004C
		x	RMPTR	0x0924 + b × 0x004C
		x	RMFDSTS b	0x0928 + b × 0x004C
		[1...15]	RMDFBp	0x092C + b × 0x004C + p × 0x0004
[0...15] b = [8...15]	RMBCPb[0]	x	RMIDb	0x0D20 + (b-8) × 0x004C
		x	RMPTRb	0x0D24 + (b-8) × 0x004C
		x	RMFDSTS b	0x0D28 + (b-8) × 0x004C
		[1...15]	RMDFBp	0x0D2C + (b-8) × 0x004C + p × 0x0004
[0...1]	RFMBCPb[0]	x	RFIDb	0x0520 + b × 0x004C
		x	RFPTRb	0x0524 + b × 0x004C
		x	RFFDSTS b	0x0528 + b × 0x004C
		[1...15]	RFDFBp	0x052C + b × 0x004C + p × 0x0004
[0]	CFMBCPb[0]	x	CFID	0x05B8
		x	CFPTR0	0x05BC
		x	CFFDCST S0	0x05C0
		[1...15]	CFDFp0	0x05C4 + p × 0x0004
[0...3]	TMBCPb[0]	x	TMIDb	0x0604 + b × 0x004C
		x	TMPTRb	0x0608 + b × 0x004C
		x	TMFDCTR b	0x060C + b × 0x004C
		[1...15]	TMDFBp	0x0610 + b × 0x004C + p × 0x0004

The message buffer configuration consists of four types of Message Buffer components:

- RX Message Buffer Component (CFDRMBCPb[0])
- RX FIFO Access Message Buffer Component (CFDRFMBCPb[0])
- Common FIFO Access Message Buffer Component (CFDCFMBCP0[0])
- TX Message Buffer Component (CFDTMBCPb[0]).

Where b = the Message Buffer component index that has a range that varies based on the type of Message Buffer component.

For a summary of this configuration, see [Figure 30.28](#). For a detailed description of the number of and the different types of message buffers, see [section 30.6. FIFO Buffers and Normal Message Buffer Configuration](#).

As described in [section 30.2. Register Descriptions](#), each Message Buffer component consists of the following registers:

- Identifier (ID)
- Pointer (PTR)
- Data Field (DFp).

Where p = the Data Field register index that has a range that varies based on the type of message buffer component.

Rc is the Message Buffer Component register where c = Message Buffer Component register index that has a range that varies based on the type of Message Buffer component.

A description of the registers, their associated bits and their accessibility are shown below the summary and detailed figures of each component.

In each of the figures, a cell that contains ‘-‘ means reserved and has the same behavior as reserved bits for registers in [section 30.2.61. Message Buffer Component Structure](#).

30.2.61.2 CFDRMBCPb[0] : RX Message Buffer Component b (b = 0 to 15)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: See [Table 30.4](#)

Bit	Symbol	Function	R/W
15:0	Rc[15:0]	RX Message Buffer Component c Refer to Table 30.5 , Table 30.6 and the descriptions that follow for a detailed description of each register and its related bits, contained within this message buffer component.	R/W

Note: S-TYPE-3, P-TYPE-3

Where the total number of CFDRMBCPb = 16 as shown in [Figure 30.28](#) (c = RX Message Buffer Component Register index = [0...18])

Rc[15:0] bit (RX Message Buffer Component c)

The RX Message Buffer Component is made up of the following registers: CFDRMIDb, CFDRMPTRb, CFDRMFDSTsb, and CFDRMDFbp. Refer to [Table 30.6](#) for details of how to interpret the structure of this buffer component and how to access the respective registers.

Table 30.5 RX Message Buffer Component Summary (1 of 2)

30.2.61.3 CFDRMIDb : RX Message Buffer ID Registers (b = 0 to 15)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0920 + 0x004C × b (b = 0 to 7)
 0x0D20 + 0x004C × (b - 8) (b = 8 to 15)

Bit position: 31 30 29 0

Value after reset: 0

Bit	Symbol	Function	R/W
28:0	RMID[28:0]	RX Message Buffer ID Field STD-ID/EXT-ID fields	R
29	—	This bit is read as 0.	R

Bit	Symbol	Function	R/W
30	RMRTR	RX Message Buffer RTR Bit 0: Data frame 1: Remote frame	R
31	RMIDE	RX Message Buffer IDE Bit 0: STD-ID is stored 1: EXT-ID is stored	R

Note: S-TYPE-3, P-TYPE-3

The RX Message Buffer ID Register b (b = 0 to 15) store the ID field, IDE bit, and RTR bit of the received message.

RMID[28:0] bits (RX Message Buffer ID Field)

The RMID[28:0] are the bits of the STD-ID/EXT-ID fields of the message stored in the RX message buffer.

See section 30.2.61.1. Start Addresses for details on how to interpret the structure of this buffer component.

RMRTR bit (RX Message Buffer RTR Bit)

The RMRTR bit shows whether a data frame or a remote frame was stored in the RX message buffer.

Note: There are no remote frames in CANFD format. When a CANFD frame is received, the register reflects the state of the received value (the RRS bit in FD frame format).

RMIDE bit (RX Message Buffer IDE Bit)

The RMIDE bit shows whether message with Standard Identifier or Extended Identifier was stored in the RX message buffer.

30.2.61.4 CFDRMPTRb : RX Message Buffer Pointer Registers (b = 0 to 15)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0924 + 0x004C × b (b = 0 to 7)
0x0D24 + 0x004C × (b - 8) (b = 8 to 15)

Bit	Symbol	Function	R/W
15:0	RMTS[15:0]	RX Message Buffer Timestamp Field Timestamp value stored for the message in the RX message buffer	R
27:16	—	These bits are read as 0.	R
31:28	RMDLC[3:0]	RX Message Buffer DLC Field Number of data bytes received in a CAN frame.	R

Note: S-TYPE-3, P-TYPE-3

The RX Message Buffer Pointer Register b (b = 0 to 15) store the DLC and Timestamp fields for the received message.

RMTS[15:0] bits (RX Message Buffer Timestamp Field)

The RMTS[15:0] bits store the timestamp value taken at the capture point as configured by CFDGFD CFG.TSCCFG of the received message.

RMDLC[3:0] bits (RX Message Buffer DLC Field)

The RMDLC[3:0] bits store the number of data bytes that were received in the RX message buffer.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes that were received.

Note: The maximum capacity of the buffer belongs to CFDRMNB.RMPLS and this is not available in the classical CAN function.

30.2.61.5 CFDRMFDSTSb : RX Message Buffer CANFD Status Registers (b = 0 to 15)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0928 + 0x004C × b (b = 0 to 7)
 0x0D28 + 0x004C × (b - 8) (b = 8 to 15)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RMESI ^{*1}	Error State Indicator bit 0: CANFD frame received from error active node 1: CANFD frame received from error passive node	R
1	RMBRS ^{*1}	Bit Rate Switch bit 0: CANFD frame received with no bit rate switch 1: CANFD frame received with bit rate switch	R
2	RMFDF ^{*1}	CAN FD Format bit 0: Non CANFD frame received 1: CANFD frame received	R
7:3	—	These bits are read as 0.	R
9:8	RMIFL[1:0]	RX Message Buffer Information Label Field	R
15:10	—	These bits are read as 0.	R
31:16	RMPTR[15:0]	RX Message Buffer Pointer Field	R

Note: S-TYPE-3, P-TYPE-3

Note 1. This bit is not available in the classical CAN function.

The RX Message Buffer CANFD Status Register b (b = 0 to 15) show the status of the FDF, BRS and ESI bits, and pointer of the received CANFD frame.

RMESI bit (Error State Indicator bit)

The RMESI bit has the same value as the ESI bit of the received CANFD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

RMBRS bit (Bit Rate Switch bit)

The RMBRS bit has the same value as the BRS bit of the received CANFD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

RMFDF bit (CAN FD Format bit)

The RMFDF bit has the same value as the FDF bit of the received CANFD frame.

Note: This bit is not available in the classical CAN function.

RMIFL[1:0] bits (RX Message Buffer Information Label Field)

The RMIFL[1:0] bits store the information label value from the related Global Acceptance Filter List entry.

RMPTR[15:0] bits (RX Message Buffer Pointer Field)

The RMPTR[15:0] bits store the pointer value from the related Global Acceptance Filter List entry.

30.2.61.6 CFDRMDFb_p : RX Message Buffer Data Field p Registers (p = 0 to 15, b = 0 to 15)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)
 Offset address: 0x092C + 0x004C × b + 0x0004 × p (b = 0 to 7, p = 0 to 15)
 0x0D2C + 0x004C × (b - 8) + 0x0004 × p (b = 8 to 15, p = 0 to 15)

Bit	Symbol	Function	R/W
7:0	RMDB_LL[7:0]	RX Message Buffer Data Byte (p × 4)	R
15:8	RMDB_LH[7:0]	RX Message Buffer Data Byte ((p × 4) + 1)	R
23:16	RMDB_HL[7:0]	RX Message Buffer Data Byte ((p × 4) + 2)	R
31:24	RMDB_HH[7:0]*1	RX Message Buffer Data Byte ((p × 4) + 3)	R

Note: S-TYPE-3, P-TYPE-3
 Note 1. These bits are not available in the classical CAN function.

The RX Message Buffer Data Field p Register b (p = 0 to 15, b = 0 to 15) store the data bytes (p × 4) to data bytes ((p × 4) + 3) of the received message.

RMDB_LL[7:0] bits (RX Message Buffer Data Byte (p × 4))

The RMDB_LL[7:0] bits store data bytes (p × 4) of the message in the RX message buffer.
 Unused data bytes are filled with 0x00.

RMDB_LH[7:0] bits (RX Message Buffer Data Byte ((p × 4) + 1))

The RMDB_LH[7:0] bits store data bytes ((p × 4) + 1) of the message in the RX message buffer.
 Unused Data Bytes will be filled with 0x00.

RMDB_HL[7:0] bits (RX Message Buffer Data Byte ((p × 4) + 2))

The RMDB_HL[7:0] bits store data bytes ((p × 4) + 2) of the message in the RX message buffer.
 Unused data bytes are filled with 0x00.

RMDB_HH[7:0] bits (RX Message Buffer Data Byte ((p × 4) + 3))

The RMDB_HH[7:0] bits store data bytes ((p × 4) + 3) of the message in the RX message buffer.
 Unused data bytes are filled with 0x00.

30.2.61.7 CFDRFMBCPb[0] : RX FIFO Access Message Buffer Component b (b = 0 to 1)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)
 Offset address: see Table 30.4

Bit	Symbol	Function	R/W
31:0	Rc[31:0]	RX FIFO Access Message Buffer Component c See Table 30.7 , Table 30.8 and the descriptions that follow for a detailed description of each register and its related bits, contained within this message buffer component.	R

Note: S-TYPE-3, P-TYPE-3

Where the total number of CFDRFMBCPb = 2 as shown in [Figure 30.28](#) (c = RX FIFO Access Message Buffer Component Register index = [0...18])

Rc[31:0] bits (RX FIFO Access Message Buffer Component c)

The RX FIFO Access Message Buffer component comprises of the following registers:

- CFDRFIDb
- CFDRFPTRb
- CFDRFFDSTSb
- CFDRFDFbp

See [Table 30.8](#) for details on how to interpret the structure of this buffer component and how to access the respective registers.

30.2.61.8 CFDRFIDb : RX FIFO Access ID Register b (b = 0 to 1)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0520 + 0x004C × b

Bit position: 31 30 29 0

Value after reset: 0

Bit	Symbol	Function	R/W
28:0	RFID[28:0]	RX FIFO Buffer ID Field STD-ID/EXT-ID fields	R
29	—	This bit is read as 0.	R
30	RFTR	RX FIFO Buffer RTR bit 0: Data frame 1: Remote frame	R
31	RFIDE	RX FIFO Buffer IDE bit 0: STD-ID has been received 1: EXT-ID has been received	R

Note: S-TYPE-3, P-TYPE-3

The RX FIFO Access ID Registers b (b = 0 to 1) store the ID field, IDE bit and RTR bit of the message.

RFID[28:0] bits (RX FIFO Buffer ID Field)

The RFID[28:0] bits are the bits of the STD-ID/EXT-ID fields of the message in the FIFO buffer.

For alignment of these bits in standard and extended frame format, see Identifier Bits Alignment.

RFTR bit (RX FIFO Buffer RTR bit)

The RFTR bit shows whether a data frame or a remote frame was stored in the FIFO buffer.

Note: There are no remote frames in CANFD format. When a CANFD frame was received, the register reflects the state of the received value (RRS bit in FD frame format).

RFIDE bit (RX FIFO Buffer IDE bit)

The RFIDE bit shows whether message with the Standard Identifier or Extended Identifier was received in the FIFO buffer.

30.2.61.9 CFDRFPTRb : RX FIFO Access Pointer Register b (b = 0 to 1)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0524 + 0x004C × b

Bit position: 31 28 15 0

Value after reset: 0

Bit	Symbol	Function	R/W
15:0	RFTS[15:0]	RX FIFO Timestamp Value Timestamp value of the received CAN frame	R
27:16	—	These bits are read as 0.	R
31:28	RFDLC[3:0]	RX FIFO Buffer DLC Field Number of data bytes received in a CAN frame	R

Note: S-TYPE-3, P-TYPE-3

The FIFO Access Pointer Registers b (b = 0 to 1) store the DLC and Timestamp fields for the received message.

RFTS[15:0] bits (RX FIFO Timestamp Value)

The RFTS[15:0] bits store the timestamp value taken at the capture point as configured by the CFDGFD CFG.TSCCFG bit of the received message.

RFDLC[3:0] bits (RX FIFO Buffer DLC Field)

The RFDLC[3:0] bits store the number of data bytes that were received in the RX FIFO buffer.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes that were received.

30.2.61.10 CFDRFFDSTSb : RX FIFO Access CANFD Status Register b (b = 0 to 1)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0528 + 0x004C × b

Bit position: 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	RFESI*1	Error State Indicator bit 0: CANFD frame received from error active node 1: CANFD frame received from error passive node	R
1	RFBRS*1	Bit Rate Switch bit 0: CANFD frame received with no bit rate switch 1: CANFD frame received with bit rate switch	R
2	RFFDF*1	CAN FD Format bit 0: Non CANFD frame received 1: CANFD frame received	R
7:3	—	These bits are read as 0.	R

Bit	Symbol	Function	R/W
9:8	RFIFL[1:0]	RX FIFO Buffer Information Label Field	R
15:10	—	These bits are read as 0.	R
31:16	CFDRFPTR[15:0]	RX FIFO Buffer Pointer Field	R

Note: S-TYPE-3, P-TYPE-3

Note 1. This bit is not available in the classical CAN function.

The RX FIFO Access CANFD Status Registers b (b = 0 to 1) show the status of the FDF, BRS, and ESI bits, including the pointer of the received CANFD frame.

RFESI bit (Error State Indicator bit)

The RFESI bit has the same value as the ESI bit of the received CANFD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

RFBRS bit (Bit Rate Switch bit)

The RFBRS bit has the same value as the BRS bit of the received CANFD frame.

When the received FDF bit is 0, this means a CAN2.0 frame is received and 0 is stored to this bit.

Note: This bit is not available in the classical CAN function.

RFFDF bit (CAN FD Format bit)

The RFFDF bit has the same value as the FDF bit of the received CANFD frame.

Note: This bit is not available in the classical CAN function.

RFIFL[1:0] bits (RX FIFO Buffer Information Label Field)

The RFIFL[1:0] bits store the information label value from the related Global Acceptance Filter List entry.

CFDRFPTR[15:0] bits (RX FIFO Buffer Pointer Field)

The CFDRFPTR[15:0] bits store the pointer value from the related Global Acceptance Filter List entry.

30.2.61.11 CFDRFDFb_p : RX FIFO Access Data Field p Register b (p = 0 to 15, b = 0 to 1)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x052C + 0x004 × p + 0x04C × b

Value after reset: 0

Bit	Symbol	Function	R/W
7:0	RFDB_LL[7:0]	RX FIFO Buffer Data Byte (p × 4)	R
15:8	RFDB_LH[7:0]	RX FIFO Buffer Data Byte ((p × 4) + 1)	R
23:16	RFDB_HL[7:0]	RX FIFO Buffer Data Byte ((p × 4) + 2)	R
31:24	RFDB_HH[7:0]	RX FIFO Buffer Data Byte ((p × 4) + 3)	R

Note: S-TYPE-3, P-TYPE-3

The RX FIFO Access Data Field p Registers b (p = 0 to 15, b = 0 to 1) store data bytes ((p × 4) to data byte ((p × 4) + 3) of the received message.

RFDB_LL[7:0] bits (RX FIFO Buffer Data Byte ($p \times 4$))

The RFDB_LL[7:0] bits store data bytes ($p \times 4$) of the message present in the FIFO buffer.
 Unused data bytes are filled with 0x00 according to the configured data payload size CFDRFCCa.RFPLS.

RFDB_LH[7:0] bits (RX FIFO Buffer Data Byte ($(p \times 4) + 1$))

The RFDB_LH[7:0] bits store data bytes ($(p \times 4) + 1$) of the message present in the FIFO buffer.
 Unused data bytes are filled with 0x00.

RFDB_HL[7:0] bits (RX FIFO Buffer Data Byte ($(p \times 4) + 2$))

The RFDB_HL[7:0] bits store data bytes ($(p \times 4) + 2$) of the message present in the FIFO buffer.
 Unused data bytes are filled with 0x00.

RFDB_HH[7:0] bits (RX FIFO Buffer Data Byte ($(p \times 4) + 3$))

The RFDB_HH[7:0] bits store data bytes ($(p \times 4) + 3$) of the message present in the FIFO buffer.
 Unused data bytes are filled with 0x00.

30.2.61.12 CFDCFMBP0[0] : Common FIFO Access Message Buffer Component

Base address: CANFDn = $0x4038_0000 + 0x2000 \times n$ ($n = 0, 1$)
 CANFDn_NS = $0x5038_0000 + 0x2000 \times n$ ($n = 0, 1$)

Offset address: See [Table 30.4](#)

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	Rc[31:0]	Common FIFO Access Message Buffer Component c Refer to Table 30.9 , Table 30.10 and the descriptions that follow for a detailed description of each register and its related bits, contained within this message buffer component.	R

Note: S-TYPE-3, P-TYPE-3

Where the total number of CFDCFMBP0 = 1 as shown in [Figure 30.28](#) ($c =$ Common FIFO Message Buffer Component Register index = [0...18])

Rc[31:0] bit (Common FIFO Access Message Buffer Component c)

The Common FIFO Access Message Buffer Component is made up of the following registers: CFDCFID, CFDCFPTR, CFFDSTS0, and CFDCDFDp. Refer to [Table 30.10](#) for details of how to interpret the structure of this buffer component and how to access the respective registers.

Table 30.9 Common FIFO Access Message Buffer Component Summary (1 of 2)

30.2.61.13 CFDCFID : Common FIFO Access ID Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x05B8

Bit position: 31 30 29 28 0

Value after reset: 0

Bit	Symbol	Function	R/W
28:0	CFID[28:0]	Common FIFO Buffer ID Field STD-ID / EXT-ID fields	R/W

Bit	Symbol	Function	R/W
15:0	CFTS[15:0]	Common FIFO Timestamp Value Timestamp value of the received CAN frame (FIFO in RX mode).	R/W
27:16	—	These bits are read as 0. The write value should be 0.	R/W
31:28	CFDLC[3:0]	Common FIFO Buffer DLC Field Number of data bytes received in a CAN frame, or to be transmitted in a CAN frame.	R/W

Note: S-TYPE-3, P-TYPE-3

The Common FIFO Access Pointer Registers store the DLC and Timestamp fields.

In TX mode, you can read data from the FIFO buffer, only for the current entry based on the write pointer value, and not for the other entries.

CFTS[15:0] bits (Common FIFO Timestamp Value)

The CFTS[15:0] bits store the timestamp value taken at the capture point as configured by the CFDGFDCFG.TSCCFG bit of the received message (if FIFO is configured in RX mode).

In TX mode, you can read and write from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

CFDLC[3:0] bits (Common FIFO Buffer DLC Field)

The CFDLC[3:0] bits store the number of data bytes that were received in the FIFO buffer or are to be transmitted.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes.

In TX mode, you can read and write from the FIFO buffers. Do not read data for the other entries in the FIFO when configured in TX mode.

In RX mode, you can only read data from the FIFO buffers.

30.2.61.15 CFDCFFDCSTS : Common FIFO Access CANFD Control/Status Register

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x05C0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CFPTR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CFIFL[1:0]	—	—	—	—	—	—	CFDF	CFBR	CFESI
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CFESI*1	Error State Indicator bit 0: CANFD frame received or to transmit by error active node 1: CANFD frame received or to transmit by error passive node	R/W
1	CFBRS*1	Bit Rate Switch bit 0: CANFD frame received or to transmit with no bit rate switch 1: CANFD frame received or to transmit with bit rate switch	R/W
2	CFDF*1	CAN FD Format bit 0: Non CANFD frame received or to transmit 1: CANFD frame received or to transmit	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W
9:8	CFIFL[1:0]	COMMON FIFO Buffer Information Label Field	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
31:16	CFPTR[15:0]	Common FIFO Buffer Pointer Field	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. This bit is not available in the classical CAN function.

The Common FIFO Access CANFD Control/Status Registers show the status of the FDF, BRS and ESI bits, including the pointer of the received CANFD frame or the CANFD frame to transmit.

In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

CFESI bit (Error State Indicator bit)

In TX mode, you can read and write from FIFO buffers. In this mode, when the CANFD module is not in error passive, the CFESI bit equals the write value. Otherwise, it is a don't care and the bit is transmitted as 1 on the CAN bus, indicating this is an error passive node.

In RX mode, you can only read data from FIFO buffers.

In RX mode, the CFESI bit is updated with the ESI bit value of the CANFD frame when it has been received, indicating the error state of the transmitting node. In RX mode, 0 is stored to this bit when the received FDF bit is 0, this means a CAN 2.0 frame is received.

Note: This bit is not available in the classical CAN function.

CFBRS bit (Bit Rate Switch bit)

In TX mode, you can read and write from FIFO buffers. In this mode, the CANFD module either transmits a 0 to indicate no bit rate switch in the frame to be transmitted or a 1 to indicate a bit rate switch in the frame to be transmitted.

In RX mode, you can only read data from FIFO buffers.

In RX mode, the CFBRS bit is updated with the BRS bit value of the CANFD frame when it has been received, indicating whether there is a bit rate switch (1) or (0) on the CANFD frame.

In RX mode, 0 is stored to the CFBRS bit when the received FDF bit is 0, this means a CAN 2.0 frame is received.

Note: This bit is not available in the classical CAN function.

CFFDF bit (CAN FD Format bit)

In TX mode, you can read and write from FIFO buffers. In this mode, the CANFD module either transmits a 0 to indicate a CAN 2.0 frame is to be transmitted or a 1 to indicate a CANFD frame is to be transmitted.

In RX mode, you can only read data from FIFO buffers.

In RX mode, the CFFDF bit is updated with the FDF bit value of the CAN frame when it has been received, indicating whether it is a CAN 2.0 frame (0) or a CANFD frame (1).

Note: This bit is not available in the classical CAN function.

CFIFL[1:0] bits (COMMON FIFO Buffer Information Label Field)

If the Common FIFO is configured in TX mode, the value programmed in CFDCFFDCSTS.CFIFL[1:0] is stored together with additional message information, to the TX History List after successful transmission of the message.

The information label value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX mode).

In TX mode, you can read and write from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

CFPTR[15:0] bits (Common FIFO Buffer Pointer Field)

If the Common FIFO is configured in TX mode, the value programmed in CFDCFFDCSTS.CFPTR[15:0] is stored together with additional message information, to the TX History List after successful transmission of the message.

The pointer value from the related Global Acceptance Filter List entry is stored in these bits (if FIFO is configured in either RX mode).

In TX mode, you can read and write from FIFO buffers.

In RX mode, you can only read data from FIFO buffers.

30.2.61.16 CFDCDFDp : Common FIFO Access Data Field p Registers (p = 0 to 15)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x05C4 + 0x004 × p

Bit	Symbol	Function	R/W
7:0	CFDB_LL[7:0]	Common FIFO Buffer Data Bytes (p × 4)	R/W
15:8	CFDB_LH[7:0]	Common FIFO Buffer Data Bytes ((p × 4) + 1)	R/W
23:16	CFDB_HL[7:0]	Common FIFO Buffer Data Bytes ((p × 4) + 2)	R/W
31:24	CFDB_HH[7:0]	Common FIFO Buffer Data Bytes ((p × 4) + 3)	R/W

Note: S-TYPE-3, P-TYPE-3

The FIFO Access Data Field p Registers (p = 0 to 15) store data bytes (p × 4) to data bytes ((p × 4) + 3) of the message.

In TX mode, you can read data from the FIFO, only for the current entry based on the write pointer value, and not for the other entries.

CFDB_LL[7:0] bits (Common FIFO Buffer Data Bytes (p × 4))

The CFDB_LL[7:0] bits store data bytes (p × 4) of the message present in the FIFO buffer.

In TX mode, you can read and write from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In RX mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCC.CFPLS.*¹

CFDB_LH[7:0] bits (Common FIFO Buffer Data Bytes ((p × 4) + 1))

The CFDB_LH[7:0] bits store data bytes ((p × 4) + 1) of the message present in the FIFO buffer.

In TX mode, you can read and write from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In RX mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCC.CFPLS.*¹

CFDB_HL[7:0] bits (Common FIFO Buffer Data Bytes ((p × 4) + 2))

The CFDB_HL[7:0] bits store data bytes ((p × 4) + 2) of the message present in the FIFO buffer.

In TX mode, you can read and write from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In RX mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCC.CFPLS.*¹

CFDB_HH[7:0] bits (Common FIFO Buffer Data Bytes ((p × 4) + 3))

The CFDB_HH[7:0] bits store data bytes ((p × 4) + 3) of the message present in the FIFO buffer.

In TX mode, you can read and write from the FIFO buffers.

In RX mode, you can only read data from the FIFO buffers.

In RX mode, unused data bytes are filled with 0x00, according to their configured data payload size CFDCFCC.CFPLS.*¹

Note 1. In RX mode, unused data bytes are filled with 0x00 according to the configured data payload size CFDCFCC.CFPLS, which is a CANFD feature not found in classical CAN.

30.2.61.17 CFDTMBCPb[0] : TX Message Buffer Component b (b = 0 to 3)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: See [Table 30.4](#)

Bit position: 31 0

Bit field:

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	Rc[31:0]	TX Message Buffer Component c Refer to Table 30.11 , Table 30.12 and the descriptions that follow for a detailed description of each register and its related bits, contained within this message buffer component.	R

Note: S-TYPE-3, P-TYPE-3

Where the total number of CFDTMBCPn = 4 as shown in [Figure 30.28](#) (c = TX Message Buffer Component Register index = [0...18])

Rc[31:0] bit (TX Message Buffer Component c)

TX Message Buffer Component c

The TX Message Buffer Component is made up of the following registers: CFDTMIDb, CFDTMPTRb, CFDTMFDCTRb, and CFDTMDFbp. Refer to [Table 30.12](#) for details of how to interpret the structure of this buffer component and how to access the respective registers.

Table 30.11 TX Message Buffer Component Summary

TX Message Buffer Component (TMBCP)

30.2.61.18 CFDTMIDb : TX Message Buffer ID Registers (b = 0 to 3)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0604 + 0x004C × b

Bit position: 31 30 29 0

Value after reset: 0

Bit	Symbol	Function	R/W
28:0	TMID[28:0]	TX Message Buffer ID Field STD-ID/EXT-ID fields	R/W
29	THLEN	Tx History List Entry 0: Entry not stored in THL after successful TX 1: Entry stored in THL after successful TX	R/W
30	TMRTR	TX Message Buffer RTR bit 0: Data frame 1: Remote frame	R/W
31	TMIDE	TX Message Buffer IDE bit 0: STD-ID is transmitted 1: EXT-ID is transmitted	R/W

Note: S-TYPE-3, P-TYPE-3

Each TX Message Buffer ID Register b (b = 0 to 3) are used to store the ID, IDE, RTR fields and history configuration of the message to be transmitted from the associated buffer.

TMID[28:0] bits (TX Message Buffer ID Field)

The TMID[28:0] bits are bits of the STD-ID/EXT-ID fields of the message stored in this TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

THLEN bit (Tx History List Entry)

The THLEN bit controls the storage of an entry corresponding to the transmitted message in the TX History list at the end of a successful transmission.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMRTR bit (TX Message Buffer RTR bit)

The TMRTR bit selects whether a data frame or remote frame is to be transmitted from this TX message buffer.

Note: There are no remote frames in CANFD format. For a CANFD transmission (CFDTMFDCTRb.CFFDF = 1), this bit is always transmitted dominant (data frame).

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMIDE bit (TX Message Buffer IDE bit)

The TMIDE bit selects whether a message with EXT-ID or STD-ID is to be transmitted from this TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

30.2.61.19 CFDTMPTRb : TX Message Buffer Pointer Register (b = 0 to 3)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0608 + 0x004C × b

Bit position: 31 28 0

Bit field:	TMDLC[3:0]	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Value after reset: 0

Bit	Symbol	Function	R/W
27:0	—	The read values are undefined. The write value should be 0.	R/W
31:28	TMDLC[3:0]	TX Message Buffer DLC Field Number of data bytes to be transmitted in a CAN frame.	R/W

Note: S-TYPE-3, P-TYPE-3

Each TX Message Buffer Pointer Register b (b = 0 to 3) is used to store the DLC fields of the message to transmit from the associated buffer.

TMDLC[3:0] bits (TX Message Buffer DLC Field)

The TMDLC[3:0] bits select the number of data bytes to be transmitted from this TX message buffer when the corresponding TMRTR bit is configured as 0.

See Table 5 in ISO 11898-1 (2015) Specification for details in defining the number of data bytes to be transmitted.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

30.2.61.20 CFDTMFDCTRb : TX Message Buffer CANFD Control Register (b = 0 to 3)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x060C + 0x004C × b

Bit position: 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16

Bit field:	TMPTR[15:0]														
------------	-------------	--	--	--	--	--	--	--	--	--	--	--	--	--	--

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit field:	—	—	—	—	—	—	TMIFL[1:0]	—	—	—	—	—	—	TMFD F	TMBR S	TMESI
------------	---	---	---	---	---	---	------------	---	---	---	---	---	---	--------	--------	-------

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	TMESI*1	Error State Indicator bit 0: CANFD frame to transmit by error active node 1: CANFD frame to transmit by error passive node	R/W
1	TMBRS*1	Bit Rate Switch bit 0: CANFD frame to transmit with no bit rate switch 1: CANFD frame to transmit with bit rate switch	R/W
2	TMFDF*1	CAN FD Format bit 0: Non CANFD frame to transmit 1: CANFD frame to transmit	R/W
7:3	—	The read values are undefined. The write value should be 0.	R/W
9:8	TMIFL[1:0]	TX Message Buffer Information Label Field	R/W
15:10	—	The read values are undefined. The write value should be 0.	R/W
31:16	TMPTR[15:0]	TX Message Buffer Pointer Field	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. This bit is not available in the classical CAN function.

The TX Message Buffer CANFD Control Registers b (b = 0 to 3) show the status of the FDF, BRS and ESI bits, including the pointer fields of the CANFD frame to be transmitted.

TMESI bit (Error State Indicator bit)

If the channel is not in error passive, then the TMESI bit equals the write value, otherwise it is a don't care and the bit is transmitted as 1 on the CAN bus, indicating this is an error passive node.

Do not write to the TMESI bit when the related CANFD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

TMBRS bit (Bit Rate Switch bit)

Do not write to the TMBRS bit when the related CANFD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

TMFDF bit (CAN FD Format bit)

Do not write to the TMFDF bit when the related CANFD channel is in CH_SLEEP mode.

Note: This bit is not available in the classical CAN function.

TMIFL[1:0] bits (TX Message Buffer Information Label Field)

The TMIFL[1:0] bits store the information label value to be copied, together with additional message information, in the TX History List after successful transmission of the message.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMPTR[15:0] bits (TX Message Buffer Pointer Field)

The TMPTR[15:0] bits store the pointer value to be copied, together with additional message information in the TX History List after successful transmission of the message.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

30.2.61.21 CFDTMDFb_p : TX Message Buffer Data Field Register (p= 0 to 15 , b= 0 to 3)

Base address: CANFDn = 0x4038_0000 + 0x2000 × n (n = 0, 1)
 CANFDn_NS = 0x5038_0000 + 0x2000 × n (n = 0, 1)

Offset address: 0x0610 + 0x004 × p + 0x004C × b

Bit	Symbol	Function	R/W
7:0	TMDB_LL[7:0]	TX Message Buffer Data Byte (p × 4)	R/W
15:8	TMDB_LH[7:0]	TX Message Buffer Data Byte ((p × 4) + 1)	R/W
23:16	TMDB_HL[7:0]	TX Message Buffer Data Byte ((p × 4) + 2)	R/W
31:24	TMDB_HH[7:0]	TX Message Buffer Data Byte ((p × 4) + 3)	R/W

Note: S-TYPE-3, P-TYPE-3

Each TX Message Buffer Data Field p Register b (p = 0 to 15, b = 0 to 3) is used to store data bytes (p × 4) to data bytes ((p × 4) + 3) of the message to transmit from the associated buffer.

TMDB_LL[7:0] bits (TX Message Buffer Data Byte (p × 4))

TMDB_LL[7:0] bits store data bytes (p × 4) of the message in the TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMDB_LH[7:0] bits (TX Message Buffer Data Byte ((p × 4) + 1))

TMDB_LH[7:0] bits store data bytes ((p × 4) + 1) of the message in the TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMDB_HL[7:0] bits (TX Message Buffer Data Byte ((p × 4) + 2))

TMDB_HL[7:0] bits store data bytes ((p × 4) + 2) of the message in the TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

TMDB_HH[7:0] bits (TX Message Buffer Data Byte ((p × 4) + 3))

TMDB_HH[7:0] bits store data bytes ((p × 4) + 3) of the message in the TX message buffer.

Do not write to these bits when the related CANFD channel is in CH_SLEEP mode.

30.3 Modes of Operation

30.3.1 Overview

The modes of the CANFD module can be classified into 2 groups:

- Global modes
- Channel modes

30.3.2 Global Modes

These modes are applicable for the complete CANFD module and therefore are called Global modes. The global modes of the CANFD module are:

- Global Sleep
- Global Reset
- Global Halt

- Global Operation.

Figure 30.2 shows the possible transitions between the Global modes.

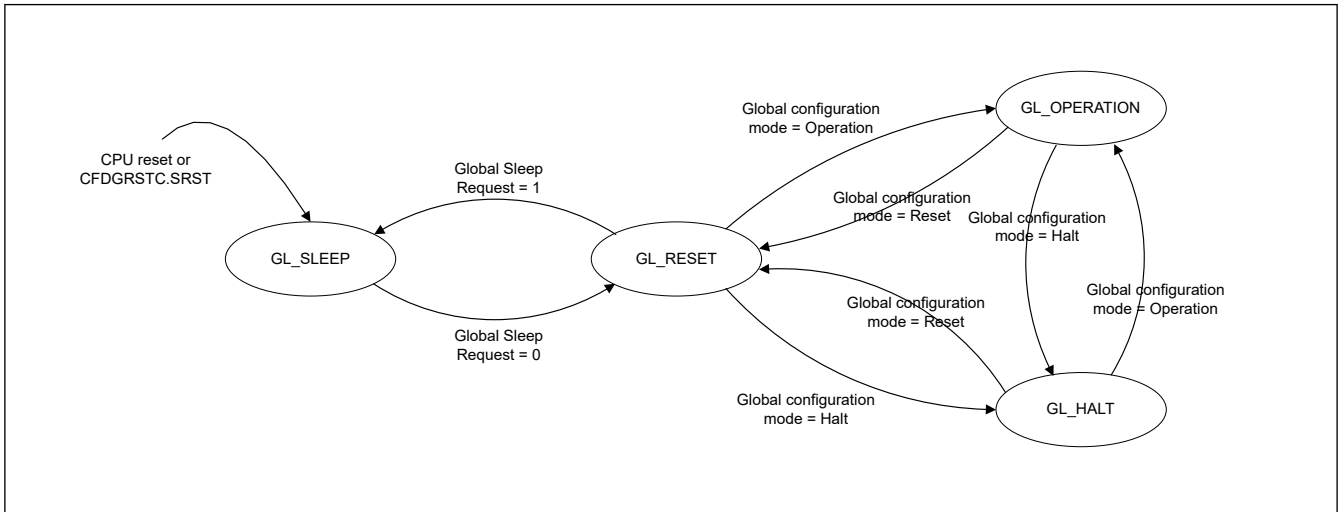

Figure 30.2 Transition between CANFD Global modes

Change in the Global mode can affect the Channel mode. Table 30.13 shows the effect of a Global mode transition on a Channel mode.

Table 30.13 Possible CANFD Channel modes and Global modes

Current Global mode	Target Global mode			
	Sleep	Reset	Halt	Operation
Sleep		Ch-Sleep: Keep Ch-Reset: N/A Ch-Halt: N/A Ch-Oper: N/A		
Reset	Ch-Sleep: Keep Ch-Reset: → Ch-Sleep Ch-Halt: N/A Ch-Oper: N/A		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: N/A Ch-Oper: N/A	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: N/A Ch-Oper: N/A
Halt		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: → Ch-Reset Ch-Oper: N/A		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: Keep Ch-Oper: N/A
Operation		Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: → Ch-Reset Ch-Oper: → Ch-Reset	Ch-Sleep: Keep Ch-Reset: Keep Ch-Halt: Keep Ch-Oper: → Ch-Halt	

30.3.2.1 Global Sleep Mode

After the release of a hardware reset or after setting and clearing a CFDGRSTC.SRST bit, the CANFD module automatically enters Global Sleep mode.

The CANFD module also enters the Global Sleep mode when the Global Sleep Request bit is set while it is in Global Reset mode. This control bit cannot be set in Global Halt mode or Global Operation mode.

Setting the Global Sleep Request bit sets Channel Sleep Request bit and forces the channel into the Channel Sleep mode.

Sleep mode is used for power saving purpose. When CANFD module is in Global Sleep mode, only the clock for CPU write access to the Global Sleep Mode Request bit is active. All other clocks are stopped and all other functions of the CANFD module are suspended.

Read access from all registers is still possible and all register values are preserved.

After setting the Global Sleep Request bit, it is necessary to confirm that the Global Sleep status has been updated, indicating successful transition to Global Sleep mode before the Global Sleep Request bit can be cleared again.

Figure 30.3 Procedure for entering Global Sleep mode

Figure 30.4 Procedure for exiting Global Sleep mode

30.3.2.2 Global Reset Mode

The CANFD module enters this mode in the following ways:

- Global Mode Control bit `CFDGCTR.GMDC` in the Global Control Register is configured for Global Reset mode while the CANFD module is in Global Halt or Global Operation mode
- Global Sleep Mode Request bit is cleared while CANFD module is in Global Sleep mode.

In Global Reset mode, all CANFD module functions are suspended and all status and flag registers are initialized.

Additionally all FIFOs and TX Queues are disabled and transmission control bits are cleared.

Configuration registers (except the test mode registers) are not initialized in this mode to their MCU reset values and the CANFD module can be configured.

See [section 30.3.4. Global Mode and Channel Mode Transition Interactions](#) for a detailed description of the behavior of all registers when transition to Global Reset mode is performed.

Setting the Global mode to Reset by setting the Global Mode Control bits `CFDGCTR.GMDC` in the Global Control Register to 01b sets Channel Mode Control bits `CFDC0CTR.CHMDC` in the Channel Control Registers to 01b and forces the channel into the Channel Reset mode.

For channels that are already in Channel Reset mode or Channel Sleep mode, this automatic transition is not performed (`CFDC0CTR.CHMDC` of related channel already set to 01b).

After setting Global Mode Control bit `CFDGCTR.GMDC` to Reset mode, it is necessary to confirm that the Reset Mode Status bit `CFDGSTS.GRSTSTS` in the Global Status Register has been updated, indicating successful transition to Global Reset mode before `CFDGCTR.GMDC` can be changed again.

Figure 30.5 Procedure for entering Global Reset mode

Figure 30.6 Procedure for exiting Global Reset mode

30.3.2.3 Global Halt Mode

The CANFD module enters this mode in the following ways:

- Global Mode Control bit `CFDGCTR.GMDC` in the Global Control Register is configured for Global Halt mode while the CANFD module is in Global Reset mode:
 - the channel in either Channel Reset or Channel Sleep mode remains in this mode
- Global Mode Control bit `CFDGCTR.GMDC` in the Global Control Register is configured for Global Halt mode while the CANFD module is in Global Operation mode:
 - the channel in Channel Reset, Channel Halt, or Channel Sleep mode remains in this mode
 - the channel in Channel Operation mode transitions to Channel Halt mode
 - Global Halt Mode Status bit is set when the channel has left Channel Operation mode.

If a transmission or reception is ongoing for a channel, the transition to Channel Halt mode is delayed until completion of the communication.

Similarly, if a channel is in bus-off, the full bus-off recovery sequence may be delayed depending on the channel configuration.

In Global Halt mode, all communications are suspended and CANFD logic does not cause any change to the Status and Flag registers (only when a channel is in the bus-off that its REC and TEC values are cleared). Additionally, the test mode configuration and control registers are not initialized in this mode.

The Global Halt mode should be used to configure global module test modes.

See [section 30.3.4. Global Mode and Channel Mode Transition Interactions](#) for a detailed description of the behavior of all registers when transition to Global Halt mode is performed.

Setting the Global mode to Halt by setting the Global Mode Control bit `CFDGCTR.GMDC` in the Global Control Register to 10b sets Channel Mode Control bits `CFDC0CTR.CHMDC` in the Channel Control Registers to 10b for the channel that are in Channel Operation mode and forces these channels into the Channel Halt mode.

For the channel that are already in Channel Reset, Channel Halt, or Channel Sleep mode, this automatic transition is not performed.

Therefore, the Global Halt mode request can be used to shut down all CANFD channel communications without loss of messages and disruption on the related CAN bus (no interruption of reception/transmission processes on the channels).

After setting the Global Mode Control bit `CFDGCTR.GMDC` to Halt mode, it is necessary to confirm that the Halt Mode Status bit `CFDGSTS.GHLTSTS` in the Global Status Register has been updated to indicate a successful transition to Global Halt mode. Do not specify any other SFR setting until confirming `CFDGSTS.GHLTSTS` is set.

Figure 30.7 Procedure for entering Global Halt mode

Figure 30.8 Procedure for exiting Global Halt mode

30.3.2.4 Global Operation Mode

The CANFD module enters this mode when the Global Mode Configuration bits are set to Global Operation mode.

The CANFD channel can only be set to Channel Operation mode and start CAN communication when CANFD is in Global Operation mode.

After setting the Global Mode Control bit `CFDGCTR.GMDC` to Global Operation mode, it is necessary to confirm that the Global Reset Mode Status bit `CFDGSTS.GRSTSTS` and the Global Halt Mode Status bit `CFDGSTS.GHLTSTS` in the Global Status Register have been cleared to indicate a successful transition to Global Operation mode before `CFDGCTR.GMDC` can be modified again.

Figure 30.9 Procedure for entering Global Operation mode

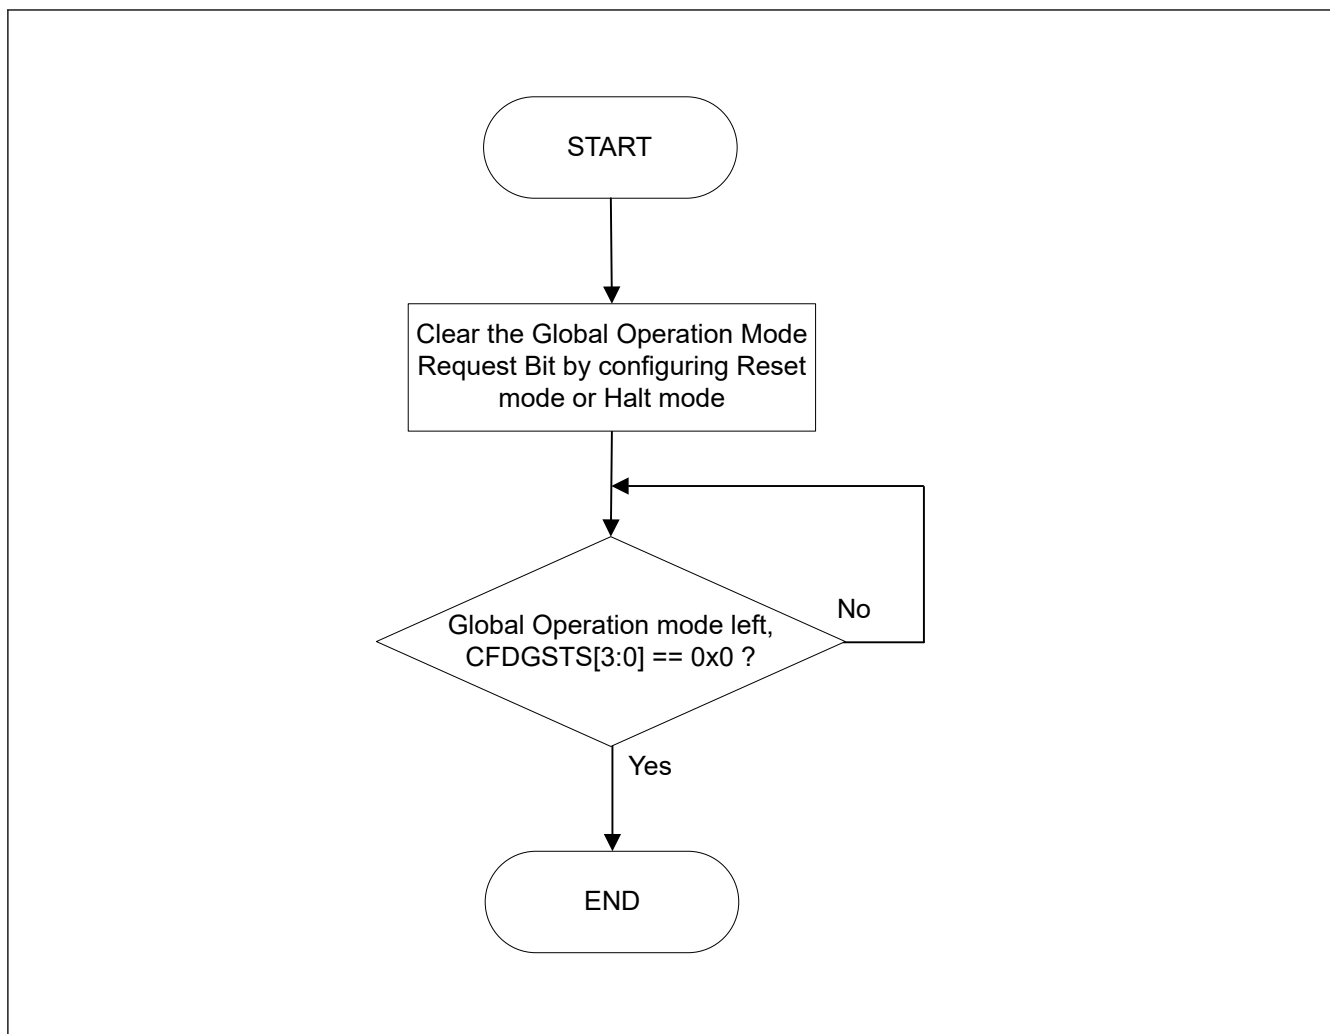

Figure 30.10 Procedure for exiting Global Operation mode

30.3.3 Channel Modes

A CAN channel can be in one of the following four channel modes:

- Reset
- Halt
- Operation
- Sleep.

Figure 30.11 shows the possible transitions between the channel modes.

Figure 30.11 Transition between CAN channel modes

30.3.3.1 CAN Channel Sleep Mode

After the release of a hardware reset or after setting and clearing the CFDGRSTC.SRST bit, a CAN channel of the CANFD module automatically enters Channel Sleep mode.

A CAN channel also enters Channel Sleep mode when the related Channel Sleep Mode Request bit is set while the CAN channel is in Channel Reset mode. Do not set this control bit in Channel Halt mode or Channel Operation mode.

Entering the CAN Channel Sleep mode instantly stops the clock supplied to the CAN channel unit and therefore reduces power consumption.

After setting the Channel Sleep Mode Request bit, it is necessary to confirm that the Channel Sleep mode status has been updated to indicate a successful transition to Channel Sleep mode before the Channel Sleep Mode Request bit can be cleared again.

During Channel Sleep mode, do not write to channel related registers. Read operation is still possible.

30.3.3.2 CAN Channel Reset Mode

A CANFD CAN channel enters this mode in the following ways:

- Channel Mode Control bit CFDC0CTR.CHMDC in the Channel Control Registers is configured for Channel Reset mode while the related CAN channel is in Channel Halt mode or Channel Operation mode
- Channel Sleep Mode Request bit is cleared while the related CAN channel is in Channel Sleep mode
- Global Mode Control bit CFDGCTR.GMDC is set to Global Reset mode and CAN channel is not in Channel Sleep mode or Channel Reset mode.

In Channel Reset mode, all CAN channel status and flag registers are initialized.

Additionally all channel related transmission control bits are cleared and the channel related TX Queue is disabled.

Configuration registers (except the Channel Test Mode registers) are not initialized in this mode and the CAN channel can be configured for communication.

See [section 30.3.4. Global Mode and Channel Mode Transition Interactions](#) for a detailed description of the behavior of all registers when transition to Channel Reset mode is performed.

After setting the Channel Mode Control bit CFDC0CTR.CHMDC to Channel Reset mode, it is necessary to confirm that the Reset Mode Status bit CFDC0STS.CRSTSTS in the related Channel Status Registers has been updated to indicate a successful transition to Channel Reset mode before the related CFDC0CTR.CHMDC bit can be modified again.

See [Table 30.14](#) for the behavior of transitioning to Channel Reset mode while CAN communication is ongoing.

30.3.3.3 CAN Channel Halt Mode

A CANFD CAN channel enters this mode in the following ways:

- Channel Mode Control bit CFDC0CTR.CHMDC in the Channel Control Registers is configured for Channel Halt mode while the related CAN channel is in Channel Reset mode or Channel Operation mode
- Global Mode Control bit CFDGCTR.GMDC is set to Global Halt mode and CAN channel is in Channel Operation mode.

In Channel Halt mode, all channel CAN communication is suspended but all status and flag registers remain unchanged during Channel Halt mode entry (except for the bus-off case where REC and TEC values are cleared for this channel).

In addition, the Channel Test Mode Configuration and Control registers are not initialized in this mode.

The Channel Halt mode should be used to configure channel test modes.

See [section 30.3.4. Global Mode and Channel Mode Transition Interactions](#) for a detailed description of the behavior of all registers when transition to Channel Halt mode is performed.

After setting the Channel Mode Control bit CFDC0CTR.CHMDC to Channel Halt mode, it is necessary to confirm that the Halt Mode Status bit CFDC0STS.CHLTSTS in the related Channel Status Register has been updated to indicate a successful transition to Channel Halt mode before the related CFDC0CTR.CHMDC can be modified again.

See [Table 30.14](#) for the transition behavior to Channel Halt mode while CAN communication is ongoing.

Table 30.14 Transition behavior in CAN Reset mode and Halt mode

Mode	State		
	Receiver	Transmitter	Bus-Off
CAN Channel Reset mode (CFDC0CTR.CHMDC = 01b)	The CAN channel enters Channel Reset mode without waiting for the completion of the ongoing reception.*1	The CAN channel enters Channel Reset mode without waiting for the completion of the ongoing transmission.*1	The CAN channel enters Channel Reset mode without waiting for the completion of the bus-off recovery.
CAN Channel Halt mode (CFDC0CTR.CHMDC = 10b)	CAN channel enters Channel Halt mode at the end of the ongoing reception or error.*2	CAN channel enters Channel Halt mode after completion of the ongoing transmission.	When CFDC0CTR.BOM is set to 00b, a Channel Halt mode request is accepted only after the completion of the full bus-off recovery sequence. When CFDC0CTR.BOM is set to 10b, the CAN channel transits automatically to Channel Halt mode after waiting for the completion of the bus-off recovery. When CFDC0CTR.BOM is set to 01b, the CAN channel transits automatically to Channel Halt mode without waiting for the completion of the bus-off recovery. When CFDC0CTR.BOM is set to 11b, the CAN channel enters Channel Halt mode as soon as Channel Halt mode is requested (without waiting for the completion of the bus-off recovery).

Note 1. If the entry to Channel Reset mode is required only at the end of an ongoing communication, then Channel Halt mode can be requested first to prevent interruption of CAN communication by direct transition to Channel Reset mode. After the CAN channel enters Channel Halt mode, the Channel Reset mode can be requested.

Note 2. If CAN communication is locked at dominant level after an error flag, software can detect this situation by monitoring the channel related BusLock flag and resolve lock condition by setting the CAN channel to Channel Reset mode.

30.3.3.4 CAN Channel Operation Mode

The Channel Operation mode is activated by setting the CFDC0CTR.CHMDC bits to 00b. If 11 consecutive recessive bits are detected after entering the CAN Operation mode, the CFDC0STS.COMSTS bit is set and the CAN channel:

- Enables the functions of the channel communication by allowing the channel to become an active node on the CAN network
- Releases the internal fault confinement logic including receive and transmit error counters

At this point, the CAN channel can start transmission and reception of CAN messages.

Within the CAN Channel Operation mode, the channel may be in four different sub-modes, depending on which type of communication functions are performed (see Figure 30.12):

- Channel idle: The CAN channel is neither receiving nor transmitting
- Channel receives: The channel is receiving a CAN message sent by another CAN node
- Channel transmits: The channel is transmitting a CAN message

Note: The channel may receive its own message simultaneously when Self-test mode is enabled.

- Channel is in bus-off state: The CAN channel is cut-off from CAN bus communication.

After setting the Channel Mode Control bit CFDC0CTR.CHMDC to Channel Operation mode, it is necessary to confirm that the Channel Reset Mode Status bit CFDC0STS.CRSTSTS and the Channel Halt Mode Status bit CFDC0STS.CHLTSTS in the Channel Status Register have been updated to indicate a successful transition to Channel Operation mode before the related CFDC0CTR.CHMDC bit can be changed again.

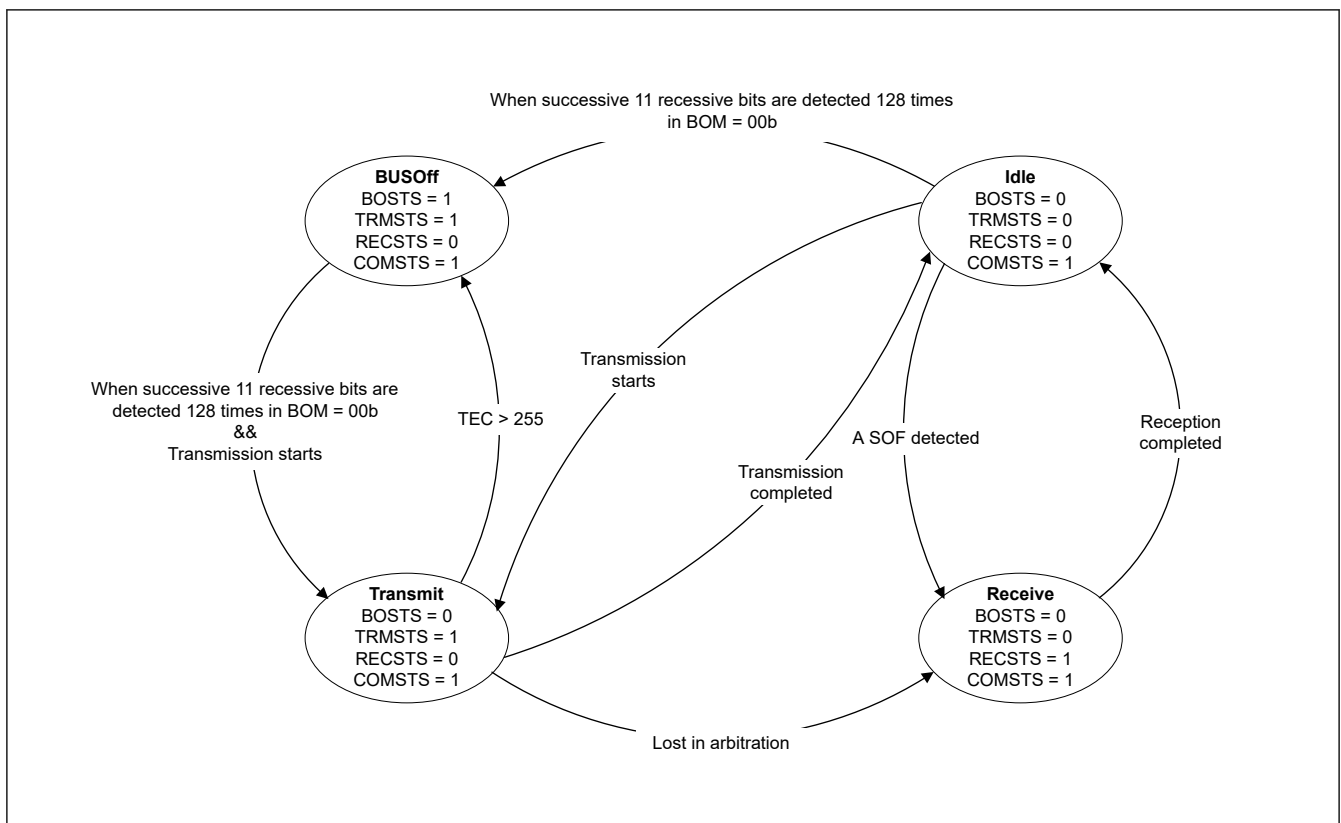

Figure 30.12 Sub-modes of CAN Channel Operation mode (only when BOM = 00b)

30.3.3.5 CAN Channel Bus-Off State

The CAN channel bus-off state is entered according to the fault confinement rules of the CAN specification. The following modes can be configured for returning to the CAN Channel Operation mode from the bus-off state:

- CFDC0CTR.BOM = 00b:
Bus-Off recovery is compliant to ISO 11898-1, namely the CAN channel re-enters CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. TEC and REC counters are initialized to 0. The Bus-Off Recovery Flag CFDC0ERFL.BORF is set in this case.
- CFDC0CTR.BOM = 01b:

The CAN channel changes the value of the CFDC0CTR.CHMDC bits within the CAN Channel Control Register to 10b and switches immediately to Channel Halt mode automatically after entering bus-off state. TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDC0ERFL.BORF is not set in this case.

- CFDC0CTR.BOM = 10b:
The CAN channel changes the value of the CFDC0CTR.CHMDC bits within the CAN Channel Control Register to 10b as soon as it reaches bus-off state and enters Channel Halt mode automatically after the CAN channel has completed the bus-off recovery sequence (after 11 consecutive recessive bits are detected 128 times). TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDC0ERFL.BORF is set in this case.
- CFDC0CTR.BOM = 11b:
Bus-off recovery is initiated but CAN channel can immediately enter Channel Halt mode when still in bus-off state if a request is made to enter Channel Halt mode.
TEC and REC counters are initialized to 0 and the Bus-Off Recovery Flag CFDC0ERFL.BORF is not set.
Without setting CFDC0CTR.CHMDC [1:0] = 10b and when 11 recessive bits is detected 128 times continuously, transition conditions become the same as CFDC0CTR.BOM = 00b.

Note: If the recovery from bus-off occurs normally in this mode (after waiting for 128 sequences of 11 consecutive recessive bits), and no halt request has been generated during this period, then the Bus-Off Recovery flag CFDC0ERFL.BORF is set.

When software writes to the CFDC0CTR.CHMDC bit at the same time as the CAN channel enters Halt mode (at the start of bus-off when CFDC0CTR.BOM = 01b, or at the end of bus-off when CFDC0CTR.BOM = 10b), the software request has the highest priority.

Note: In the above case, the automatic setting of the CFDC0CTR.CHMDC bit to Channel Halt mode request is performed when the CFDC0CTR.CHMDC bit value is previously 00b (Channel Operation mode).

Additionally, it is possible to force the CAN channel to recover from the bus-off state by setting CFDC0CTR.RTBO to 1. The error state changes from bus-off state to integrating state with a maximum delay of 1 CAN bit time, and the CAN communication becomes possible again after 11 consecutive recessive bits are detected. The Bus-Off Recovery Flag is not set in this case, and the TEC and REC counters are initialized to 0.

Before setting CFDC0CTR.RTBO to 1, all pending transmissions from the TX message buffers, TX Queues and/or Common FIFO in TX mode should be disabled.

The disable of the pending transmission message buffer, TX Queue or FIFO must be confirmed by the corresponding acknowledge flags.

For the TX message buffer, the acknowledge flags are the Transmission Result Flags (CFDTMSTSj.TMTRF). For the TX Queue, it is the TX Queue Empty flag (CFDTXQSTS.TXQEMP). For the FIFO, it is the FIFO Empty flag (CFDCFSTS.CFEMP).

The CFDC0CTR.RTBO bit should be used for bus-off recovery only when CFDC0CTR.BOM is set to 00b.

Setting this bit in any state other than bus-off has no effect and the bit is cleared immediately.

Table 30.15 shows the settings for the Bus-Off Entry flag CFDC0ERFL.BOEF and the Bus-Off Recovery flag CFDC0ERFL.BORF for the different configurations of CFDC0CTR.BOM.

Table 30.15 Behavior of Bus-off Entry and Recovery flags

BOM	BOEF bit set	BORF bit set
00b	Always (on entry to bus-off)	Always (on exit from bus-off)
00b CFDC0CTR.RTBO set to 1	Always (on entry to bus-off)	Only if normal bus-off recovery occurs before software sets CFDC0CTR.RTBO to 1'
01b	Always (on entry to bus-off)	Never
10b	Always (on entry to bus-off)	Always (on exit from bus-off)
11b	Always (on entry to bus-off)	Only if normal bus-off recovery occurs before software issues a Halt request

For an efficient software procedure, it is not necessary to wait for the bus-off recovery sequence to end.

It is possible to perform a transmission re-initialization during bus-off recovery. To do this, follow the recommended software flow in [Figure 30.13](#).

Figure 30.13 Transmission re-initialization during bus-off

30.3.4 Global Mode and Channel Mode Transition Interactions

The interaction between Global mode setting and Channel mode setting is as follows:

- Changing the Channel Mode Control bit CFDC0CTR.CHMDC in the Channel Control Registers does not affect the Global Mode Control bit CFDGCTR.GMDC.
- Changing the Global Mode Control bit CFDGCTR.GMDC affects the channel mode control as described in [Table 30.16](#).

Table 30.16 Interaction between Global and Channel mode transition

Global mode change	Channel mode	Channel mode transition action
Sleep → Reset	Sleep	Channel remains in Sleep mode
Sleep → Halt	— (Global mode change not possible)	
Sleep → Operation	— (Global mode change not possible)	
Reset → Sleep	Sleep	Channel remains in Sleep mode
	Reset	Channel Sleep request bit is set automatically, channel enters Sleep Mode
Reset → Halt	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
Reset → Operation	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
Halt → Sleep	— (Global mode change not possible)	
Halt → Reset	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel mode control is set to Reset mode, channel enters Reset mode
Halt → Operation	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel remains in Halt mode
Operation → Sleep	— (Global mode change not possible)	
Operation → Reset	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel mode control is set to Reset mode, channel enters Reset mode
	Operation	Channel mode control is set to Reset mode, channel enters Reset mode
Operation → Halt	Sleep	Channel remains in Sleep mode
	Reset	Channel remains in Reset mode
	Halt	Channel remains in Halt mode
	Operation	Channel mode control is set to Halt mode, channel enters Halt mode after communication finished

30.3.4.1 Timing of Global Mode Change

The transition time for the Global mode changes are shown in the following table.

Table 30.17 Maximum transition time for the global mode (1 of 2)

From	To	Maximum transition time
GL_SLEEP	GL_RESET	3 peripheral clock cycles*2
GL_RESET	GL_SLEEP	3 peripheral clock cycles
GL_RESET	GL_HALT	10 peripheral clock cycles
GL_RESET	GL_OPERATION	10 peripheral clock cycles

Table 30.17 Maximum transition time for the global mode (2 of 2)

From	To	Maximum transition time
GL_HALT	GL_RESET	2 CAN bit times
GL_HALT	GL_OPERATION	3 peripheral clock cycles
GL_OPERATION	GL_RESET	2 CAN bit times
GL_OPERATION	GL_HALT	3 CAN frames*1 *3

Note 1. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked RX lines or continued error conditions.

Note 2. Exit GL_SLEEP mode only when CFDGSTS.GRAMINIT is cleared.

Note 3. TQ, CAN frame and CAN bits are related to the individual channels. For the maximum transition time, the channel with the lowest baud rate must be used.

30.3.4.2 Timing of Channel Mode Change

The transition time for the Channel mode changes are shown in the following table.

Table 30.18 Maximum transition time for the channel mode

From	To	max. transition time
CH_SLEEP	CH_RESET	3 peripheral clock cycles
CH_RESET	CH_SLEEP	3 peripheral clock cycles
CH_RESET	CH_HALT	3 CAN bit times
CH_RESET	CH_OPERATION	4 CAN bit times
CH_HALT	CH_RESET	2 CAN bit times
CH_HALT	CH_OPERATION	4 CAN bit times*3
CH_OPERATION	CH_RESET	2 CAN bit times
CH_OPERATION	CH_HALT	2 CAN frames*1 *2

Note 1. The time specified for this transition does not include the case where channel enters bus-off state. For bus-off, the timing depends on the configuration of the CFDC0CTR.BOM[1:0] bits.

Note 2. The given transition time is the time without any errors on the bus. In case of an error condition, the transition time can lengthen to an uncalculated result. The transition time can also come to a stuck condition for locked RX lines or continued error conditions.

Note 3. In general, if the baudrate prescaler value CFDC0NCFG.NBRP is changed in CH_HALT mode, the transition time can deviate. The internal prescaler is a free running down counter that creates the TQ clock, and new BRP value is captured when the counter reaches the value 0.

30.4 Initialization

Before joining CAN communications, configure the following settings:

- Clock setting
- Bit timing setting (nominal and data rate)
- Baud Rate setting (nominal and data rate)
- CANFD setting
- Acceptance Filter setting (configuration of Global Acceptance Filter List)
- Reception, Transmission and GW-FIFO setting
- CAN Operation mode setting

30.4.1 Initialization of CAN Clock, Bit Timing and Baud Rate

30.4.1.1 Bit Timing Conditions

The following lines describe the composition of each segment and the restriction that apply to the segment setting.

1. Each segment setting
SS = Fixed to 1 TQ

TSEG1 = See to (CFDC0NCFG) and (CFDC0DCFG)^{*1}

TSEG2 = See to (CFDC0NCFG) and (CFDC0DCFG)^{*1}

SJW = See to (CFDC0NCFG) and (CFDC0DCFG)^{*1}

SS + TSEG1 + TSEG2 = 5 to 49 TQs for Data Bit Rate and 8 to 385 for Nominal Bit Rate

2. Restriction on TSEG1, TSEG2 and SJW

$TSEG1(N) > TSEG2(N) \geq SJW(N)$

$TSEG1(D) \geq TSEG2(D) \geq SJW(D)$ ^{*1}

When only classical frames are used, configure the bit fields TSEG1 and TSEG2 of CFDC0DCFG to valid values.

Note 1. This feature is not available in the classical CAN function.

Table 30.19 shows an example of how to set the bit timing to achieve the required Sample Point settings.

Table 30.19 Bit timing examples

1 bit	Set value (TQ)				Sample point ^{*1} (%)
	SS	TSEG1	TSEG2	SJW	
5TQ	1	2	2	1	60.00
8TQ	1	4	3	1	62.50
	1	5	2	1	75.00
10TQ	1	6	3	1	70.00
	1	7	2	1	80.00
12TQ	1	8	3	1	75.00
	1	9	2	1	83.33
15TQ	1	10	4	1	73.33
	1	11	3	1	80.00
16TQ	1	10	5	1	68.75
	1	11	4	1	75.00
20TQ	1	12	7	1	65.00
	1	13	6	1	70.00
24TQ	1	15	8	1	66.66
	1	16	7	1	70.83
50TQ	1	39	10	4	80.00

Note 1. Sample point (in case of 75%)

Figure 30.14 Sample point (in case of 75%)

30.4.1.2 CAN Bit Timing

In the CAN protocol, each bit in a communication frame is composed of three segments that can be configured individually for channel using the related CFDC0NCFG and CFDC0DCFG*¹ registers.

Note 1. This register is not available in the classical CAN function.

Figure 30.15 shows the segment composition of a bit and the sample point in it.

Of these segments, the Time Segment 1 (TSEG1) and Time Segment 2 (TSEG2) are used to specify the position of the sample point, so that the timing at which each bit on the CAN bus is sampled can be altered by changing the values of these segments.

The minimum resolution for this timing is referred to as Time Quantum (TQ), which is determined by the clock frequency supplied to the CAN channel and the divide-by-N value of the baud rate prescaler (nominal and data rate).

Figure 30.15 Segment composition of a bit and the sample point

1. SS: Synchronization Segment
This segment is used to synchronize bits by monitoring a recessive-to-dominant edge during the interframe space. This comprises of intermission, suspend transmission, bus idle, during bus idle, and all nodes that can start transmission.
2. TSEG1: Time Segment 1
This segment absorbs physical delays on the CAN network. A physical delay on the network is two times the total sum of a bus delay, input comparator delay, and output driver delay. It can be lengthened by SJW.
3. TSEG2: Time Segment 2
This segment is used to correct a phase error by performing resynchronization. It can be shortened by SJW. While sending or receiving a message, communication frames between some nodes may get out of sync due to a drift in the oscillator frequency or a delay in the transmission path. This is referred to as a phase error.
4. SJW: Resynchronization Jump Width
This is the maximum width by which bits that have become out of sync due to a phase error may be corrected.

Figure 30.15 shows only one symbolic sample point.

30.4.1.3 Baud Rate

Either the CANFD core clock (CANFDCLK) or the external oscillator clock (CANMCLK) can be selected globally as CAN communication clock.

The transfer speed is determined by the DLL clock, the divide-by-N value of the baud rate prescaler, and the number of TQs in one bit.

$$\text{baudrate} = \frac{\text{DLL Clock}}{(\text{number_of_time_quanta_per_bit}) \times (\text{BRP} + 1)}$$

Figure 30.16 shows a block diagram of the circuit that generates the CAN channel communication clock and Table 30.20 shows a baud rate examples.

Figure 30.16 Block diagram of the circuit that generates the CAN channel communication clock

Table 30.20 Nominal baud rate calculation formula and example CAN communication configurations

Baud rate calculation formula	(DLL clock) (baud rate prescaler divide-by-N value*1) × (number of TQs in one bit)								
	80 MHz	40 MHz	32 MHz	30 MHz	24 MHz	20 MHz	16 MHz	10 MHz	8 MHz*2
1 Mbps	8TQ (10) 20TQ (4)	8TQ (5) 20TQ (2)	8TQ (4) 16TQ (2)	10TQ (3) 15TQ (2)	8TQ (3) 12TQ (2) 24TQ (1)	10TQ (2) 20TQ (1)	8TQ (2) 16TQ (1)	10TQ (1)	8TQ (1)

250 Kbps	8TQ (40) 20TQ (16)	8TQ (20) 20TQ (8)	8TQ (16) 16TQ (8)	10TQ (12) 15TQ (8) 20TQ (6)	8TQ (12) 12TQ (8) 24TQ (4)	10TQ (8) 20TQ (4)	8TQ (8) 16TQ (4)	10TQ (4) 20TQ (2)	8TQ (4) 16TQ (2)
125 Kbps	8TQ (80) 20TQ (32)	8TQ (40) 20TQ (16)	8TQ (32) 16TQ (16)	10TQ (24) 15TQ (16) 20TQ (12)	8TQ (24) 12TQ (16) 24TQ (8)	10TQ (16) 20TQ (8)	8TQ (16) 16TQ (8)	10TQ (8) 20TQ (4)	8TQ (8) 16TQ (4)
83.3 Kbps	8TQ (120) 12TQ (80) 16TQ (60) 24TQ (40)	8TQ (60) 12TQ (40) 16TQ (30) 24TQ (20)	8TQ (48) 12TQ (32) 16TQ (24) 24TQ (16)	8TQ (45) 10TQ (36) 12TQ (30) 15TQ (24) 20TQ (18) 24TQ (15)	8TQ (36) 12TQ (24) 16TQ (18) 24TQ (12)	8TQ (30) 10TQ (24) 12TQ (20) 15TQ (16) 16TQ (15) 20TQ (12) 24TQ (10)	8TQ (24) 12TQ (16) 16TQ (12) 24TQ (8)	8TQ (15) 10TQ (12) 12TQ (10) 15TQ (8) 20TQ (6) 24TQ (5)	8TQ (12)
33.3 Kbps	8TQ (300) 12TQ (200) 16TQ (150) 20TQ (120) 24TQ (100)	8TQ (150) 12TQ (100) 16TQ (75) 20TQ (60) 24TQ (50)	8TQ (120) 10TQ (96) 12TQ (80) 15TQ (64) 16TQ (60) 20TQ (48) 24TQ (40)	10TQ (90) 12TQ (75) 15TQ (60) 20TQ (45)	8TQ (90) 10TQ (72) 12TQ (60) 15TQ (48) 16TQ (45) 20TQ (36) 24TQ (30)	8TQ (75) 10TQ (60) 12TQ (50) 15TQ (40) 16TQ (30) 20TQ (30) 24TQ (25)	8TQ (60) 10TQ (48) 12TQ (40) 15TQ (32) 16TQ (30) 20TQ (24) 24TQ (20)	10TQ (30) 12TQ (25) 15TQ (20) 20TQ (15)	8TQ (30)

Note: Shown in () are the baud rate prescaler divide-by-N value.
 Note 1. Baud rate prescaler divide-by-N value = P + 1 (P = 0 - 1023) P: value selected by the BRP bits in the Channel Configuration Registers.
 Note 2. Minimum frequency to achieve maximum nominal baud rate of 1 Mbps.

Table 30.21 Baud rate calculation example for nominal and data bit rate CAN communication configurations

Baud rate calculation formula	(DLL clock) (baud rate prescaler divide-by-N value*1) × (number of TQs in one bit)		
	80 MHz	40 MHz	20 MHz
Nominal 1 Mbps Data 8 Mbps	80TQ (1)	40TQ (1)	20TQ (1)
	10TQ (1)	5TQ (1)	Not possible
Nominal 1 Mbps Data 5 Mbps	80TQ (1)	40TQ (1)	20TQ (1)
	16TQ (1)	8TQ (1)	Not possible
Nominal 500 Kbps Data 2 Mbps	160TQ (1)	80TQ (1)	40TQ (1)
	40TQ (1)	20TQ (1)	10TQ (1)

Note: Shown in () are the baud rate prescaler divide-by-N values and this table is not available in the classical CAN function.
 Note 1. Baud rate prescaler divide-by-N value = P + 1 (P = 0 - 1023) P: value selected by the BRP bits in the Channel Configuration Registers.

For optimum clock tolerance in networks using the FD frame format, the length of the time quantum should be the same in nominal bit time and in data bit time. This means CFDC0NCFG.NBRP = CFDC0DCFG.DBRP.

Additionally, if transceiver delay compensation is used, do not program the CFDC0DCFG.DBRP bit to be greater than 1, as 1 means divide by 2.

30.4.1.4 Setting of CAN Clock, Bit Timing and Baud Rate

Figure 30.17 shows the procedure for setting the CAN clock and the baud rate for each channel.

These settings should be performed during Channel Reset mode (Configuration mode) for the CAN channels.

Before going to channel communication state, the baud rate must be configured, otherwise the mode does not switch correctly.

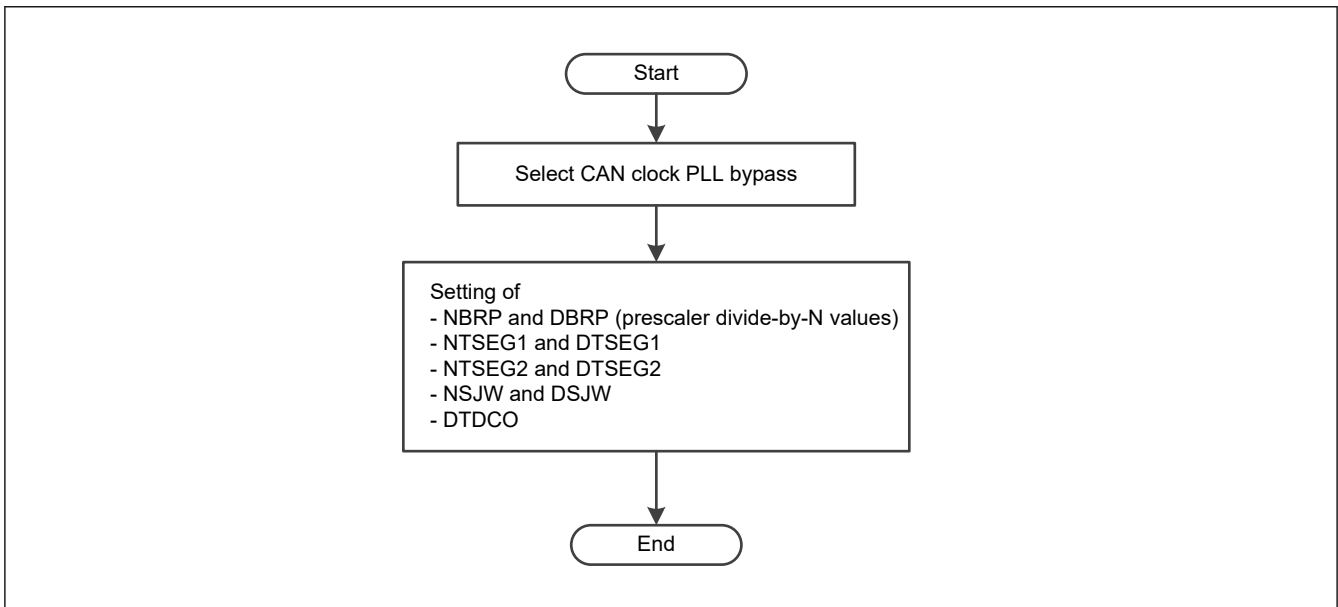

Figure 30.17 Procedure for setting the CAN bit timing and baud rate

30.4.1.5 Transmitter Delay Compensation

This chapter is not valid for classical CAN.

When a high baud rate is used such as 5 to 8 Mbps for the data phase, the transmitter delay can become greater than TSEG1. In this case, the transmitter always detects a bit-error in the data phase of the CANFD frame. The TDC compensates for the inability of the transmitter to receive its own transmitted bit at the sample point of that bit.

There is another symbolic sample point known as the Secondary Sample Point (SSP) that is used only during the data phase of CANFD frames. This is derived from the Transceiver Delay Compensation Result bit (CFDC0FDSTS.TDCR) as shown in Figure 30.18.

The resolution of the configuration, measured and offset values is based on the CAN channel DLL clock.

Figure 30.18 Transmitter delay compensation

The measured Trv_Delay is based on the number of clk_dlc clock cycles. The delay is counted up by one for each started clock until the dominant value is seen on CRXn. Figure 30.19 shows the measured result. Trv_Delay counted to maximum 127 with a clk_dlc clock.

Figure 30.19 Trv_Delay measurement example

The SSP is calculated by taking the result from CFDC0FDSTS.TDCR and rounding the value down to the nearest integer number of data time quanta.

Figure 30.20 shows the positioning of the secondary sample point. When CFDC0FDCFG.TDCOC is equal to 0, the SSP is equal to the Trv_Delay (measured delay) + CFDC0FDCFG.TDCO, rounded down to the nearest integer number of time quanta. Usually, the TDCO value should have the size of (SyncSegmentdata + TSEG1data) to position the SSP to a theoretical location of the sample point.

If the CFDC0FDCFG.TDCOC is equal to 1, the SSP is defined by CFDC0FDCFG.TDCO. If CFDC0DCFG.DBRP is greater than 0, the value is also rounded down to the nearest integer number of time quanta.

Figure 30.20 Position of the secondary sample point

The maximum delay ($Trv_Delay + TDCO$) which can be compensated by the CANFD module is $(6 \text{ data bits} - 2clk_dlc)$.

The ISO 11898-1 allows you to set different values for BRP_data and BRP_nom .

If different values are used for $CFDC0NCFG.NBRP$ and $CFDC0DCFG.DBRP$, then two CAN nodes may be out of synchronization at the point when the bit rate changes from nominal bit rate to data bit rate after sample point of the BRS bit. This condition is shown in Figure 30.21.

The length of the time quantum should be the same in the nominal bit time and in the data bit time. This means $CFDC0NCFG.NBRP = CFDC0DCFG.DBRP$.

Different bit rates can be achieved by selecting different configuration values for the Time Segments. The nominal bit rate can be configured from 8 to 385 TQs and the data bit rate from 5 to 49 TQs.

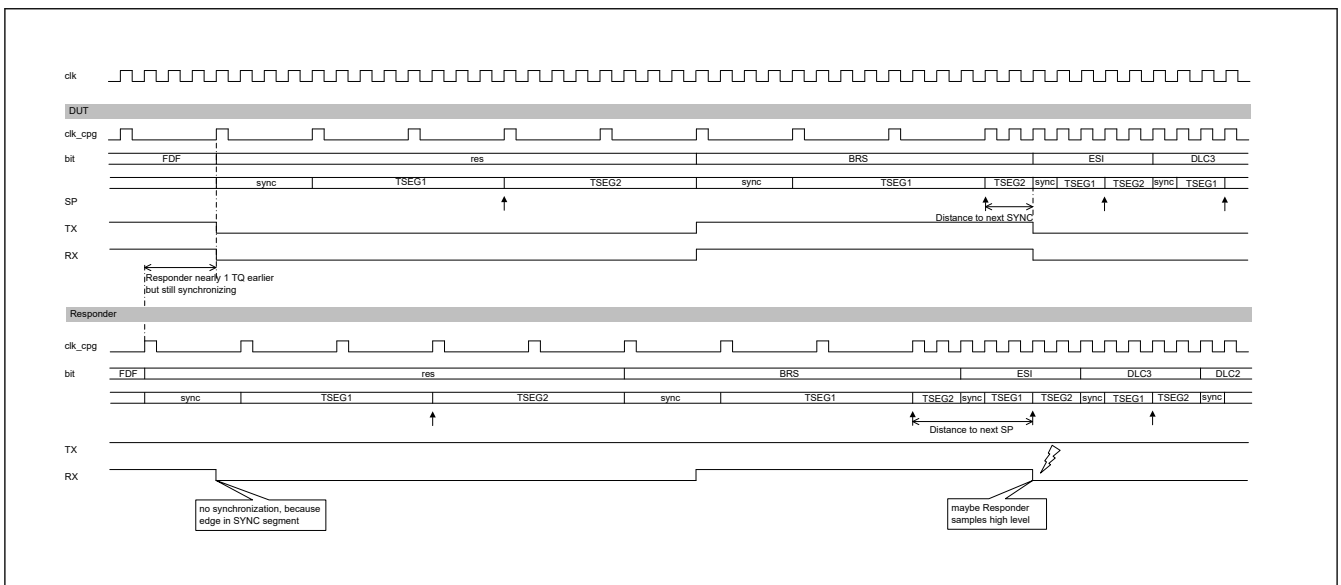

Figure 30.21 Loss of synchronization between two CAN nodes

The transmitter delay compensation measurement result is updated at the falling edge from FDF bit to RES bit when configured accordingly ($CFDC0FDCFG.TDCE = 1$, $CFDC0FDCFG.TDCOC = 0$).

Figure 30.22 shows the read flow to get the measured transmitter delay compensation result.

Figure 30.22 TDC result read flow

30.4.2 CAN Module Configuration after Hardware Reset

After a hardware reset (power on reset) or after setting and clearing a `CFDGRSTC.SRST` bit, the CANFD module enters Global Sleep mode automatically.

To enable configuration of the CANFD module, you must exit Sleep mode by clearing the Global Sleep Request bit `CFDGCTR.GSLPR` to 0.

After a hardware reset, the module starts RAM initialization, the `CFDGSTS.GRAMINIT` bit in the Global Status Register is set automatically to indicate that the CANFD logic is initializing the RAM.

After RAM initialization is complete, this bit is cleared automatically.

RAM initialization is necessary to avoid setting of false ECC error flag after HW reset the random data presented in the RAM.

Do not access registers of CANFD in either read or write until RAM initialization is complete and the `CFDGSTS.GRAMINIT` bit is cleared.

Before going to communication mode, the Global Acceptance Filter List and message FIFO buffers must be configured. In addition, CAN channel must be configured such as CAN bit timing. For this configuration, CAN channel must be released from Channel Sleep mode and must be configured for communication in Channel Reset mode (Configuration mode).

[Figure 30.23](#) shows the configuration procedure. For details about each step, see [section 30.5. Acceptance Filtering Function using Global Acceptance Filter List \(AFL\)](#), [section 30.6. FIFO Buffers and Normal Message Buffer Configuration](#), [section 30.7. Interrupts and DMA](#) and [section 30.4.1.3. Baud Rate](#).

The CANFD module does not perform the RAM initialization sequence after executing a software reset by setting `CFDGRSTC.SRST`.

Figure 30.23 Configuration procedure after a hardware reset

30.5 Acceptance Filtering Function using Global Acceptance Filter List (AFL)

30.5.1 Overview

The CANFD module can handle message acceptance filtering with a global Acceptance Filter List (called AFL). Each element of the AFL defines a filter rule for messages received on a specific channel.

The following actions are performed based on the AFL entries:

- Acceptance filtering based on received CAN Identifier and masking
- DLC filtering based on received DLC value
- Message data payload according to the CFDGCFG.CMPOC bit*¹
- Storage of accepted messages in the message buffer objects defined in the related AFL entry
- Attaching a 16-bit pointer to the stored messages defined in the related AFL entry, for example to support AUTOSAR applications
- Attaching a 2-bit information label to the stored messages defined in the related AFL entry

Note 1. This feature is not available in the classical CAN function.

The CANFD module allows a maximum of 16 AFL entries.

During acceptance filtering process, each AFL entry in a channel is checked against the received message by the acceptance filter unit. The check starts from the lowest AFL entry number for this channel.

AFL search stops when a match of the received identifier with a configured identifier/mask combination occurs or when the received identifier has been compared against all AFL entries defined for the related channel. If no match occurs, then the received message is rejected. No notification is given to the application in this case.

Additionally, an automatic DLC filtering is performed for each accepted message if DLC check is globally enabled. If the DLC value of the received message is equal to or higher than the configured DLC value in the matching AFL entry, the DLC check is passed.

If DLC replacement (CFDGCFG.DRE bit) is enabled, DLC value configured in the matching AFL entry is greater than 0x0 and DLC check passes, then the configured value of DLC in the matching AFL entry is stored in the destination RXMB or FIFO Buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional data bytes received on the CAN Bus are not stored in the destination RXMB or FIFO Buffer. These additional data bytes are stored as 0x00 in the destination RXMB or FIFO Buffer.

If DLC replacement is enabled and DLC value of matching AFL entry is 0x0, then the received value of DLC is stored in the destination RX MB or FIFO Buffer.

If DLC replacement (the CFDGCFG.DRE bit) is disabled and DLC check passes, then the received value of DLC on the CAN bus is stored in the destination RXMB or FIFO buffer.

If the received value of DLC is greater than the configured DLC value in the matching AFL entry, then the additional data bytes received from the CAN bus are also stored in the destination RXMB or FIFO buffer.

If DLC value of the received message is less than the configured DLC value in the matching AFL entry, then DLC check fails. In this case, the received message is rejected and is not stored in any RXMB or FIFO buffer.

Additionally, DLC check failure is flagged by the DLC Error Flag in the Global Error Flag Register. If configured, an error interrupt is also generated. The DLC replacement configuration has no impact if the DLC check fails.

If a message has passed both acceptance filtering and DLC filtering, it is stored in a single reception message buffer and/or in FIFO buffers configured for reception function.

This message storage target information is also defined in the same AFL entry. Do not set a target at the AFL entry which is not configured.

Each accepted received message can be stored into a maximum of 2 different target destinations (single reception message buffer and/or FIFO buffers).

The programming of more than 2 target destinations is not allowed. If more destinations are programmed, then the internal timing might lead to a race condition that prevents the storage of received messages in the message RAM.. Correct configuration of the numbers of target destination is the responsibility of the application.

Additional protection mechanism is made for the case when a received message contains more data payload Bytes than possible to store in the target destination (CFDRMNB.RMPLS, CFDRFCCa.RFPLS or CFDCFCC.CFPLS).

If CFDGCFG.CMPOC = 0, the message is completely rejected and is stored in the target destination. When CFDGCFG.CMPOC = 0 and RX or Common FIFO full including the received message contains more data payload bytes than possible to store in the target destination (CFDRMNB.RMPLS, CFDRFCCa.RFPLS or CFDCFCC.CFPLS), the corresponding CFDFMSTS.RFxMLT or CFDFMSTS.CFxMLT bit is not set to 1, respectively.

When $CFDGCFCF.CMPOC = 1$, the received data bytes greater than $CFDRMNB.RMPLS$ is rejected. When $CFDGCFCF.CMPOC = 1$ and RX or Common FIFO full including the received message contains more data payload bytes than possible to store in the target destination ($CFDRMNB.RMPLS$, $CFDRFCCa.RFPLS$ or $CFDCFCF.CFPLS$), the corresponding $CFDFMSTS.RFxMLT$ or $CFDFMSTS.CFxMLT$ bit is set to 1, respectively.

Depending on the $CFDGCFCF.DRE$ bit, the original received DLC or the DLC value configured at the AFL entry is stored.

Regardless of the $CFDGCFCF.CMPOC$ bit setting, $CFDGERFL.CMPOF$ is set to 1 if a payload overflow condition is detected.

The DLC filtering is performed before the payload overflow function. So for one reception frame, only one flag can be set at the same time with $CFDGERFL.DEF$ or $CFDGERFL.CMPOF$ *1.

Note 1. This bit is not available in the classical CAN function.

30.5.2 Allocation of AFL Entries

The number of AFL entries per channel can be configured using the dedicated field in the related Global Acceptance Filter Configuration Registers (see [Figure 30.24](#)).

Figure 30.24 Configuration of AFL for each channel

The minimum number of entries for one channel is 0 (no entries defined for the channel) and the maximum number of entries is 16.

All entries are unique for a channel and overlapping or sharing of entries is not supported. Correct configuration of the AFL is the responsibility of the application.

The CANFD module does not flag errors related to the configuration of the AFL.

30.5.3 AFL Entry Description

Each AFL entry consists of 16 bytes. The fields in all entries are identical.

Each entry contains the following information for acceptance filtering and DLC filtering:

- Identifier (11 bits for Standard Frame format, 29 bits for Extended Frame format):
Acceptance filter unit checks the identifier field of the received message against the identifier field of each AFL entry (full 29 bits masking of identifier bits is possible, see information that follows).
- IDE bit:
Acceptance filter unit checks the IDE bit of the received message against this bit and selects the relevant part of the identifier field for acceptance filtering (masking of IDE bit is possible, see the information that follows).
- RTR bit:
Acceptance filter unit only accepts data frames ($RTR = 0$) or remote frames ($RTR = 1$) according to the setting of this bit (masking of RTR bit is possible, see the information that follows).
- Loopback Configuration bit:
This bit can enable or disable the AFL entry depending on the Loopback Configuration or Mirror mode condition.
- Mask for Identifier bits (29 bits):

Each bit in the identifier mask can mask the corresponding identifier bit in the AFL entry during acceptance filtering, see [Figure 30.25](#).

- **Mask for IDE bit:**
If this Mask bit masks the IDE bit of the AFL entry in both Standard Identifier and Extended Identifier format, messages can be accepted by this AFL entry. The identifier of the received message is compared against the Standard Identifier part of the AFL entry for Standard Identifier format messages and against the Extended Identifier part of the AFL entry for Extended Identifier format messages.
- **Mask for RTR bit:**
If this Mask bit masks the RTR bit of the AFL entry in both frame formats, data frame and remote frame formats are accepted by this AFL entry.
- **Pointer information (16 bits):**
This 16-bit pointer is attached to a received message accepted by the related AFL entry. The pointer is added during message storage in the message buffer area and can be used by application as support function. The pointer information can be used for example to support PDU identifier allocation for the received message in AUTOSAR systems.
- **Information label (2 bits):**
This 2-bit label is attached to a received message accepted by the related AFL entry. The label is added during message storage in the message buffer area and can be used by application as support function.
- **DLC value for automatic DLC filtering:**
If the DLC value of the received message is equal or higher than the configured DLC value, the DLC check is passed.

If the DLC value in this AFL entry is configured to 0, DLC filtering is effectively disabled for this entry (all accepted messages pass DLC filtering).

Each AFL entry contains the following information for the handling of received messages:

- Message buffer number of one single reception message buffer as target for received message storage
- Single reception message buffer enable bit to configure the single reception message buffer number to be valid or invalid, as target for received message storage
- FIFO direction pointer - each bit of the FIFO direction pointer configures a dedicated FIFO as possible target for a received message

There is no hardware protection against such storage of message. Therefore, the FIFO direction pointer must be configured carefully.

Figure 30.25 Acceptance function

30.5.4 Entering Entries in the AFL

Application software can enter one full entry into the AFL using the following registers:

- Global AFL ID Entry Register: Part 1 of the AFL entry
- Global AFL Mask Entry Register: Part 2 of the AFL entry
- Global AFL Pointer 0 Entry Register: Part 3 of the AFL entry
- Global AFL Pointer 1 Entry Register: Part 4 of the AFL entry.

16 sets of these registers form a group of AFL entries. The AFL should only be configured in CH_RESET or CH_HALT mode.

Follow the configuration shown in [Figure 30.26](#) to program the AFL.

After entering all entries in Configuration mode, locking of the AFL access should be performed to protect unwanted write access to the AFL.

Write protection is active during all Global modes (GL_RESET, GL_HALT, and GL_OPERATION) if the lock bit is set.

Read access to AFL is still possible during all Global modes even when AFL data access is disabled (consistency check of AFL contents is possible during run time).

Figure 30.26 AFL configuration flow
 R01UH1130EJ0100 Rev.1.00
 Oct 23, 2024

30.5.5 Loopback Modes

If the Loopback Configuration bit is set, the AFL entry is only valid in Loopback test mode (Self-test mode 0 or Self-test mode 1) or in mirror mode when receiving messages that were transmitted by the respective CAN channel itself.

The AFL entry is not valid for received messages in loopback mode transmitted by other CAN nodes on the bus. The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID respectively.

If the Loopback Configuration bit is 0, the AFL entry is only valid for:

- Received messages transmitted by other CAN nodes on the bus in normal (non-loopback mode) and mirror modes
- Received messages transmitted by other CAN nodes or the CAN channel itself in Loopback test mode.

The mirror mode can be enabled with the CFDGCFG.MME bit in the Global Configuration Register. If CFDGCFG.MME bit is set, then a successfully transmitted message can be stored back in an RX message buffer or FIFO buffer if a matching entry is configured in the AFL for that channel.

The Loopback Configuration bit in the matching AFL entry must be set to store this frame.

If Mirror mode and Loopback test mode are configured at the same time, the Loopback test mode behavior applies.

Table 30.22 shows the behavior of the acceptance filter unit depending on the setting of the related input signals.

Table 30.22 Behavior of acceptance filter based on the loopback configuration setting in AFL entry

Mirror Mode Enable (MME Configuration bit)	Loopback in test mode (Self-test mode 0 or Self-test mode 1)	Channel mode	Loopback Configuration bit in AFL entry	AFL entry
0	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Invalid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid
1	0	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Invalid
			1	Valid
	1	Receiver	0	Valid
			1	Invalid
		Transmitter	0	Valid
			1	Valid

Note: The expression valid or invalid for the related entry means that this AFL entry is or is not compared against the received message ID, respectively.

30.5.6 IDE Masking

When the GAFLIDEM bit is 0 in an AFL entry, the IDE bit configured in the AFL entry is not used for ID matching. In this case, the use of ID[10:0] or ID[28:0] matching is based on the received IDE bit.

Consider the following example:

- The ID and Mask fields of an AFL entry x is configured as follows:
 - CFDGAFLLID [x] = 0xC0553A20 → IDE = 1, RTR = 1, LLB = 0, ID[10:0] = 0x220 / ID[28:0] = 0x00553A20
 - CFDGAFLLMr = 0x0000FFFF → IDEM = 0, RTRM = 0, IDM[10:0] = 0x7FF / IDM[28:0] = 0x0000FFFF

- The comparison result for the four different received IDs with AFL entry x is described as follows:
 - If a frame with IDE = 0 and ID = 0x220 is received, this is considered as a match
 - If a frame with IDE = 0 and ID = 0x320 is received, this is not a match
 - If a frame with IDE = 1 and ID = 0x1FFF3A20 is received, this is considered as a match
 - If a frame with IDE = 1 and ID = 0x08803220 is received, this is not a match.

30.5.7 Updating AFL Entry during Communication

You can update the AFL entry without disabling all CAN communications. Choose the entry number to be updated by setting the AFL entry number, and ignore the enable bit.

This entry number is ignored from the AFL matching while the entry is being updated.

Figure 30.27 shows the update flow for an AFL entry.

Figure 30.27 Update flow for an AFL entry

The method to update an AFL entry is as follows:

1. Set the entry number to CFDGAFALIGNENT register.
2. Set the value 0xC401 (key code and enable bit) to CFDGAFALIGNCTR register.
3. CFDGAFLECTR.AFLDAE is set to 1.
4. Set the new rule to CFDGAFLIDr, CFDGAFLMr, CFDGAFLP0r, CFDGAFLP1r registers.
5. CFDGAFLECTR.AFLDAE is cleared to 0.
6. Set the value 0xC400 (key code and clear enable bit) to CFDGAFALIGNCTR register.

Note: This entry number is ignored during the periods from (2) to (5).

(1) Example 1: Deleting an entry

Deleting entry3 when the total number of entries is 6 channel.

total entry = 6	entry0	0	ID = 0x050	
	entry1	1	ID = 0x051	
	entry2	2	ID = 0x052	
	entry3	3	ID = 0x053	← delete rule
	entry4	4	ID = 0x054	
	entry5	5	ID = 0x055	

How to delete an entry

1. Set 0x00000003 to CFDGAFLIGNENT register.
2. Set 0x0000C401 to CFDGAFLIGNCTR register.
3. Set 0x00000100 to CFDGAFLECTR register.
4. Set the same rule as the previous rule by accessing CFDGAFLIDr, CFDGAFLMr, CFDGAFLP0r, CFDGAFLP1r (r = 3, this is entry3).
5. Set 0x00000000 to CFDGAFLECTR register.
6. Set 0x0000C400 to CFDGAFLIGNCTR register.

Entry3 is now deleted.

total entry = 5 entry2 = entry3	entry0	0	ID = 0x050	
	entry1	1	ID = 0x051	
	entry2	2	ID = 0x052	
	entry3	3	ID = 0x052	← set the same rule as the previous rule
	entry4	4	ID = 0x054	
	entry5	5	ID = 0x055	

(2) Example 2: Adding an entry

Adding a new entry to entry3 when the total number of entries is 6.

total entry = 5 entry2 = entry3	entry0	0	ID = 0x050	← add new rule in this position
	entry1	1	ID = 0x051	
	entry2	2	ID = 0x052	
	entry3	3	ID = 0x052	
	entry4	4	ID = 0x054	
	entry5	5	ID = 0x055	

How to add an entry

1. Set 0x00000003 to CFDGAFLIGNENT register.
2. Set 0x0000C401 to CFDGAFLIGNCTR register.
3. Set 0x00000100 to CFDGAFLECTR register.
4. Set the new rule by accessing CFDGAFLIDr, CFDGAFLMr, CFDGAFLP0r, CFDGAFLP1r (r = 3, this is entry3).
5. Set 0x00000000 to CFDGAFLECTR register.
6. Set 0x0000C400 to CFDGAFLIGNCTR register.

The new entry is now added.

total entry = 6	entry0	0	ID = 0x050	← add new rule
	entry1	1	ID = 0x051	
	entry2	2	ID = 0x052	
	entry3	3	ID = 0x056	
	entry4	4	ID = 0x054	
	entry5	5	ID = 0x055	

The AFL filter can be used to set CFDGAFLCFG, and addition/deletion of an entry is possible. Therefore, it is necessary to set the maximum number to be used to CFDGAFLCFG.

30.6 FIFO Buffers and Normal Message Buffer Configuration

This section describes the process for configuring the number of RX message buffers, the FIFO buffers, and the flat TX message buffers in the CANFD module. The message buffers are mapped as shown in [Figure 30.28](#).

The RX message buffers can be accessed with the RX Message Buffer Registers.

The RX FIFO buffers and the common FIFO buffers configured in RX mode or TX mode can only be accessed with the FIFO Access Registers.

If the common FIFO is configured in TX mode, you can only write data into the FIFO buffer using the FIFO Access registers.

If the common FIFO is configured in RX mode, you can only read data from the FIFO Access Registers.

The TX message buffers can be accessed with the TX Message Buffer Registers.

If unused message buffer locations are read, the message buffer locations are read as unknown values.

Figure 30.28 Message buffer configuration

30.6.1 Normal RX Message Buffers

In CANFD module, the frames received can be stored in normal RX message buffers based on the configuration of the AFL entries.

Additionally, the number of normal RX message buffers required in the system can be chosen up to a fixed maximum limit.

30.6.1.1 Normal RX Message Buffer Configuration

In CANFD module, the number of normal RX message buffers can be configured by writing to the RX Message Buffer Number Register.

The limiting values for the configuration of number of message buffers are:

- Minimum value = 0x00 (no normal RX MB)
- Maximum value = 0x10

Do not use values outside these limits.

The AFL entries for routing the received messages to normal RX message buffers must be configured to match the requirements of the system.

The AFL entries must also be configured properly, and an AFL entry for normal RX message buffers should not exceed the number of message buffers configured in the RX Message Buffer Number Register.

Note: There is no internal check procedure provided in CANFD module against wrong configuration of the AFL.

The data field size of the RX message buffer can be configured with the CFDRMNB.RMPLS bit. The default size is 8 bytes and the maximum data payload size is 64 bytes.

When the receiving frame exceeds the data field size, then the acceptance depends on the configuration of CFDGCFG.CMPOC (message rejecting or data payload cut).

Note: RMPLS and CMPOC bit is not available in the classical CAN function, so, these feature is not valid for classical CAN.

30.6.2 FIFO Buffers

The CANFD module provides a fixed number of FIFO buffers to support storage of frames for reception and transmission functions.

The number of reception-only FIFO buffers is fixed to 2. However, common FIFO buffer channel can be configured to store messages for transmission or reception function.

These FIFO buffers can be enabled or disabled, and the following parameters can be configured to match the system requirements:

- Size
- Interrupt structure
- Message lost mechanism
- Message overwrite mechanism of the FIFO buffers
- Location of the TX FIFO.

When the receiving frame exceeds the data field size, the acceptance depends on the configuration of the `CFDGCFG.CMPOC` bit (message rejecting or data payload cut).

30.6.2.1 FIFO Buffers Configuration

In CANFD module, the FIFO buffers can be configured to match the system requirements.

The total number of FIFO buffers = 2 RX FIFO buffers + 1 common FIFO buffer = 3 FIFO buffers.

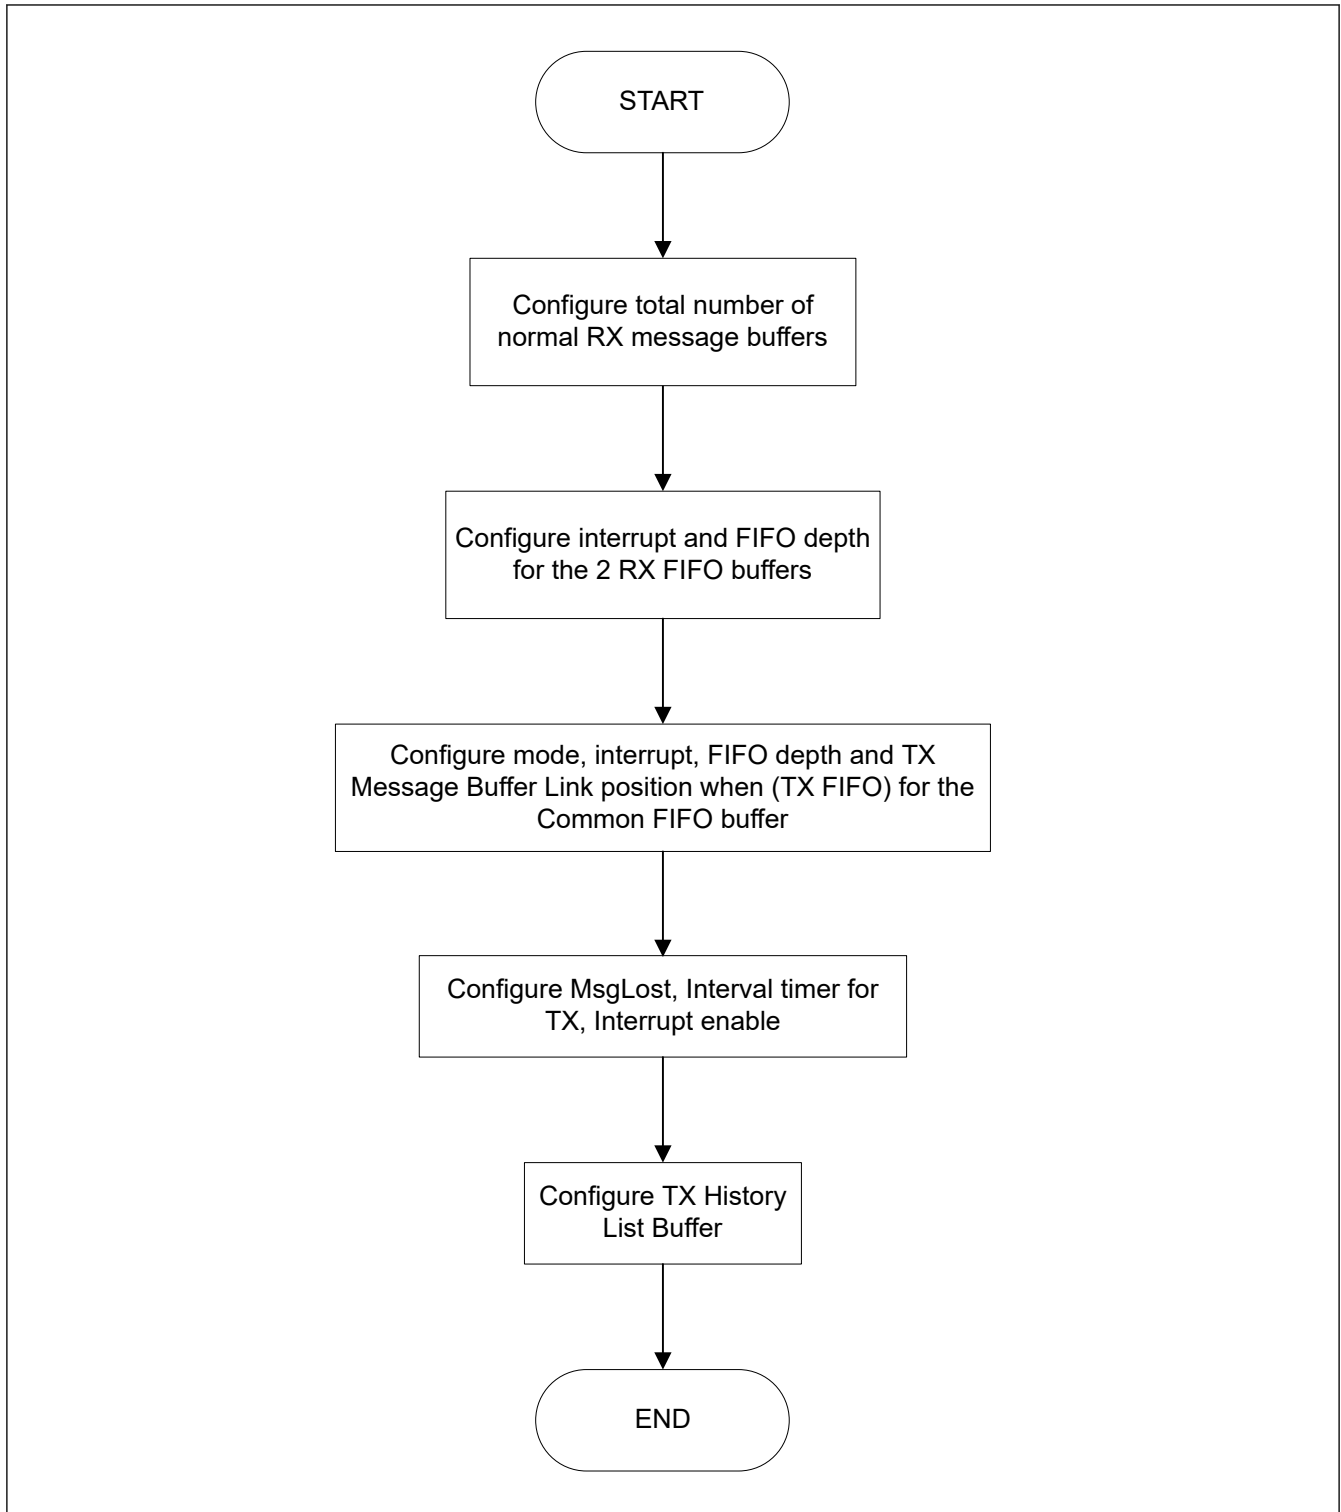

Figure 30.29 FIFO buffer configuration flow in CANFD module

As shown in [Figure 30.29](#), the various FIFO buffers can be configured by writing to the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

For the 2 RX FIFO buffers, the following parameters can be configured:

- Interrupts
- FIFO depth
- FIFO payload data size.

For the common FIFO buffer, the following parameters can be configured:

- Mode
- Interrupts FIFO depth
- FIFO payload data size
- FIFO TX link position.

(1) FIFO mode configuration of Common FIFO buffer

The mode of the common FIFO buffer can be configured by writing to the CFDCFCC.CFM[1:0] bits in the Common FIFO Configuration/Control Register. The possible modes of configuration for Common FIFO buffer are:

- 0b RX mode (default mode after hardware reset)
- 1b TX mode

Messages can only be read from the RX FIFO buffers and the Common FIFO buffer configured in RX mode. Messages are stored by the CAN module in these FIFO buffers based on the AFL entries.

Messages can be read and written into the Common FIFO buffer configured in TX mode. These messages are transmitted on the appropriate CAN channel.

The pointers can only be incremented when a new message is stored in the FIFO buffer and decremented when a message is transmitted on the corresponding CAN channel by the CANFD module.

After a hardware reset, the Common FIFO buffer is configured in RX mode by default. Only enable the FIFO buffers after configuring the Common FIFO buffer in the required modes.

(2) FIFO TX message buffer link configuration

When the common FIFO is configured as TX FIFO, the FIFO buffer must be linked to a normal TX message buffer to participate in the transmission scan.

Do not write data into a TX message buffer that is linked to a Common FIFO buffer. Also, the TX message buffer linked to a Common FIFO buffer should not be a part of the TX Queue.

The TX message buffer link of each Common FIFO buffer can be configured by writing to the CFDCFCC.CFTML[1:0] bits in the Common FIFO Configuration/Control Registers. Available options for TX message buffer link configuration are:

- 0x00: TX Message Buffer 0
- 0x01: TX Message Buffer 1
- 0x10: TX Message Buffer 2
- 0x11: TX Message Buffer 3

(3) FIFO depth configuration

The depth of each FIFO buffer can be configured by writing to the CFDRFCCa.RFDC[2:0] bits and CFDCFCC.CFDC[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The 6 available options for depth configuration are:

- 0x000: 0 Message (FIFO buffer cannot be enabled)
- 0x001: 4 Messages
- 0x010: 8 Messages
- 0x011: 16 Messages
- 0x100: 32 Messages
- 0x101: 48 Messages

The RAM allocation for RX message buffers along with FIFO buffers is limited to 16 messages with 64 data bytes (76 bytes including ID and PTR). Configuration of the RX message buffers, along with FIFO buffers, that exceeds this maximum limit should not be done.

CANFD module logic does not check the validity of the configuration.

Note: If the FIFO depth of a common FIFO is 4 messages or more (CFDCFCC.CFDC[2:0] > 000b), then the Common FIFO TX message buffer link is valid when the FIFO is disabled or enabled.
If FIFO depth is 0 messages, then the Common FIFO TX message buffer link is not valid when the FIFO is disabled or enabled.

(4) FIFO payload size configuration

The data size of each FIFO buffer can be configured by writing to the CFDRFCCa.RFPLS[2:0] bits and CFDCFCC.CFPLS[2:0] bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The eight available options for depth configuration are:

- 000b: 8 bytes
- 001b: 12 bytes
- 010b: 16 bytes
- 011b: 20 bytes
- 100b: 24 bytes
- 101b: 32 bytes
- 110b: 48 bytes
- 111b: 64 bytes

The RAM allocation for RX message buffers along with FIFO buffers is limited to 16 messages with 64 data bytes (76 bytes including ID and PTR). Configuration of the RX message buffers, along with FIFO buffers, that exceeds this maximum limit should not be done.

CANFD module logic does not check the validity of the configuration.

Note: This feature is not available in the classical CAN function.

(5) FIFO interrupt configuration

The Interrupt generation conditions for the FIFO buffers can be configured by writing to the CFDRFCCa.RFIM and CFDCFCC.CFIM bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers. The two available options are:

- 0:
 - RX FIFO mode: Interrupt generated when the Common FIFO counter reaches CFDRFCCa.RFIGCV/CFDCFCC.CFIGCV value
 - TX FIFO mode: Interrupt generated when the Common FIFO transmits the last message successfully
- 1:
 - RX FIFO mode: Interrupt generated at the end of storage of every received message
 - TX FIFO mode: Interrupt generated for every successfully transmitted message

If the Interrupt Mode bit is 0 for a RX FIFO, then interrupt is generated based on the configuration of the CFDRFCCa.RFIGCV[2:0] bits.

Similarly, if the Interrupt Mode bit is 0 for a Common FIFO configured in RX mode, then interrupt is generated based on the configuration of CFDCFCC.CFIGCV[2:0] bits.

The eight available options for configuring the FIFO counter value for generation of an interrupt are:

- 000b: Interrupt generated when FIFO is 1/8th Full
- 001b: Interrupt generated when FIFO is 1/4th Full
- 010b: Interrupt generated when FIFO is 3/8th Full
- 011b: Interrupt generated when FIFO is 1/2 Full
- 100b: Interrupt generated when FIFO is 5/8th Full
- 101b: Interrupt generated when FIFO is 3/4th Full

- 110b: Interrupt generated when FIFO is 7/8th Full
- 111b: Interrupt generated when FIFO is Full.

In this case, an interrupt is generated when the message count matches the configured value.

However, there are some limitations on the configuration of the CFDRFCCa.RFIGCV[2:0] and CFDCFCC.CFIGCV[2:0] bits depending on the FDC[2:0] bits (FIFO Depth Configuration), see [Table 30.23](#).

Table 30.23 FIFO interrupt generation counter and FIFO depth configuration

RFDC[2:0] (CFDC[2:0])	RFIGCV[2:0] (CFIGCV[2:0])							
	111b	110b	101b	100b	011b	010b	001b	000b
000b	Don't care (FIFO cannot be enabled)							
001b	Allowed	Not allowed	Allowed	Not allowed	Allowed	Not allowed	Allowed	Not allowed
010b	Allowed							
011b	Allowed							
100b	Allowed							
101b	Allowed							
110b	Allowed							
111b	Allowed							

30.6.2.2 FIFO Buffers Control

The FIFO interrupt must be enabled by setting any one of the following bits in the RX FIFO Configuration/Control Registers:

- CFDRFCCa.RFIE

In addition, the FIFO interrupt must be enabled by setting any one of the following bits in the Common FIFO Configuration/Control Register:

- CFDCFCC.CFRXIE
- CFDCFCC.CFTXIE

After configuration is complete, each FIFO can be enabled by setting the CFDRFCCa.RFE and CFDCFCC.CFE bits in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Register to allow transmission and reception of messages.

30.7 Interrupts and DMA

30.7.1 Interrupts

The CANFD module generates several interrupts. The interrupt output, which is connected to the Interrupt Controller Unit (ICU), can be controlled by the corresponding interrupt enable bit.

The status flag is set independent from this enable bit.

The channel transmission interrupt has an additional status flag register. The status bits are set when the corresponding interrupt enables are set.

The status flag register supports the identification of the interrupt source for the channel transmission, as this interrupt is driven by several trigger sources.

The interrupts in the CANFD module can be classified into two groups, global interrupts and channel interrupts:

- Global interrupts:
The CANFD module can generate 3 global interrupts:
 - Global interrupt for successful reception into the 2 RX FIFO buffers
 - Global error interrupt.
 - Global Interrupt for successful reception into the 16 RX message buffers

- Channel interrupts:
Channel of the CANFD module can generate 3 channel interrupts:
 1. Channel transmission
 - Transmission completion from channel
 - Transmission abort from channel
 - Transmission from TX Queue for a channel
 - Channel THL interrupt
 - Successful transmission from a Common FIFO in TX mode for a channel.
 2. Channel error interrupt
 3. Successful reception in a Common FIFO in RX mode for a channel.

The interrupts are cleared when the corresponding flag bits are cleared or the Interrupt enable bits are cleared.

Table 30.24 gives an overview of interrupt sources for the different interrupt outputs. The interrupt outputs are active-high.

Table 30.24 Interrupt source overview

Parameter	Interrupt	Name	Interrupt source	Interrupt clearing
Global Interrupts	Successful reception into at least one RX FIFO	CAN_RXF	Interrupt flag of corresponding RX FIFO for which interrupt is enabled	Clear the interrupt flag of corresponding RX FIFO buffer for which interrupt is enabled
	Global Error	CAN_GLERR	Any of the following: <ul style="list-style-type: none"> ● DLC Error flag ● Message Lost Status bit ● TX History Entry Lost Status bit ● CANFD Message Payload overflow flag 	Clear all of : <ul style="list-style-type: none"> ● DLC Error flag ● Message Lost flags in all of the FIFO Status Registers ● TX History List Entry Lost flag ● CANFD Message Payload overflow flag
	Successful reception into at least one RXMB	CANn_RXMB (n = 0, 1)	Interrupt flag of corresponding RXMB for which interrupt is enabled	Clear the interrupt flag of corresponding RXMB buffer for which interrupt is enabled
Channel Transmission Interrupts	Channel successful transmission	CANn_TX (n = 0, 1)	Any channel related TXMB Successful flag when interrupt is enabled*1	Clear all channel related TXMB Result status bits for which the interrupt is enabled
	Channel Abort		Any channel related TXMB Abort flag when interrupt is enabled*1	Clear all channel related TXMB Result Status bits for which the interrupt is enabled globally
	Channel transmission from TX Queue		Related channel TX Queue Interrupt flag	Clear related channel TX Queue Interrupt flag
	Channel THL Interrupt		Channel THL Interrupt status flag	Clear the relevant THL Interrupt status flag
	Channel COM FIFO TX Interrupt		Interrupt Flag for Common FIFOs in TX mode belonging to the related channel	Clear the interrupt flags of Common FIFOs in TX mode belonging to the related channel
Channel Error Interrupt	Channel Error	CANn_CHERR (n = 0, 1)	Any channel related error flag in the Channel Error Flag Register for which interrupt is enabled in the Channel Error Interrupt Enable Register	Clear all channel related error flags in the Channel Error Flag Register for which interrupt is enabled in the Channel Error Interrupt Enable Register
Channel COM RX FIFO Interrupt	Channel COM FIFO RX Interrupt	CANn_COMFRX (n = 0, 1)	Interrupt flag for Common FIFOs in RX mode belonging to the related channel	Clear the interrupt flags of Common FIFOs in RX mode belonging to the related channel

Note 1. These interrupts are only set for TX Message Buffers that do not belong to an enabled TX Queue and are not pointing to a common FIFO.
Separate interrupts are provided for common FIFO buffers and TX Queue.

Figure 30.30 Global interrupt block diagram

Figure 30.31 Channel interrupt block diagram

30.7.2 DMA Transfer

The CANFD module has message buffers that can be associated with a DMA channel:

- Reception DMA

- 2 RX FIFO message buffers
- Common FIFO Message Buffer

Figure 30.32 shows the potential DMA channels.

Figure 30.32 Message buffer connectable to a DMA channel

A DMA channel transfer request is generated for each FIFO entry to the DMAC when the related CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE is set to 1 and the belonging FIFO is not empty.

Reception FIFO Interrupt should be disabled for this particular FIFO (CFDRFCCa.RFIE or CFDCFCC.CFRXIE)

Use the regular start address for the DMA access window address. See Figure 30.33.

Table 30.25 DMA channel access window address

b = Message buffer component index	Message Buffer Component	Register	P	Regular Start Address
b = [0...1]	RFMBCPb[0]	CFDRFIDb	x	0x0520 + b × 0x004C
		CFDRFPTRb	x	0x0524 + b × 0x004C
		CFDRFFDSTsb	x	0x0528 + b × 0x004C
		CFDRFDFbp	[0...15]	0x052C + p × 0x0004 + b × 0x004C
—	CFMBCP0[0]	CFDCFID	x	0x05B8
		CFDCFPTR	x	0x05BC
		CFDCFFDCSTS	x	0x05C0
		CFDCFDFp	[0...15]	0x05C4 + p × 0x0004

DMA FIFO pointer decrement is done automatically by reading the last configured data payload byte (CFDRFCCa.RFPLS or CFDCFCC.CFPLS).

Note: The DMA must read the exact length of the configured data payload size (CFDRFCCa.RFPLS or CFDCFCC.CFPLS).

Note: This feature is not available for classical CAN function because CFDRFCCa.RFPLS and CFDCFCC.CFPLS are not in classical CAN.

Do not write to the FIFO control registers when DMA is enabled. The DMA enable of the particular DMA FIFO (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE) can be set at any time. Figure 30.33 shows a configuration flow for an initial setup.

Figure 30.33 DMA enable flow

To disable a DMA transfer request, you must disable the particular DMA enable bit (CFDCDTCT.RFDMAE or CFDCDTCT.CFDMAE). If the disable is made during an ongoing transfer, then the transfer must be completed first before further action can be taken. The transfer status can be identified by the CFDCDTSTS.RFDMASTS or CFDCDTSTS.CFDMASTS bit. See [Figure 30.34](#) for the DMA disable flow. When the DMA is disabled, consideration should be made for the remaining or new incoming messages to this particular reception FIFO.

When the FIFO is not disabled, reception to the FIFO continues.

Figure 30.34 DMA disable flow

30.8 Reception and Transmission

30.8.1 Reception

In the CANFD module, CAN messages received on any of the channels are stored in RX message buffers, RX FIFO buffers, or Common FIFO buffers configured in RX mode depending on the Acceptance Filter List entries.

- Up to 16 RX message buffers can be configured
- 2 RX FIFO buffers available
- 1 Common FIFO Buffer can be configured in RX mode

30.8.1.1 Message Storage in RX Message Buffers

When a message is successfully received and stored in a RX message buffer, the corresponding New Data flag is set in the RX Message Buffer New Data Register.

The CAN message can be read from the corresponding RX message buffer.

If a new message is stored into a RX message buffer before the previous message in this message buffer can be read, then the original message is overwritten. There is no mechanism for preventing a new message from overwriting the current message in the RX message buffer. If such a loss of messages is not acceptable, then RX FIFO should be used for storing related messages.

Note: Users should do the same processing as the existing software flow also when using interrupt. (see [Figure 30.36](#))

Note: Unused data bytes are filled with 0x00 depending on the DLC value.

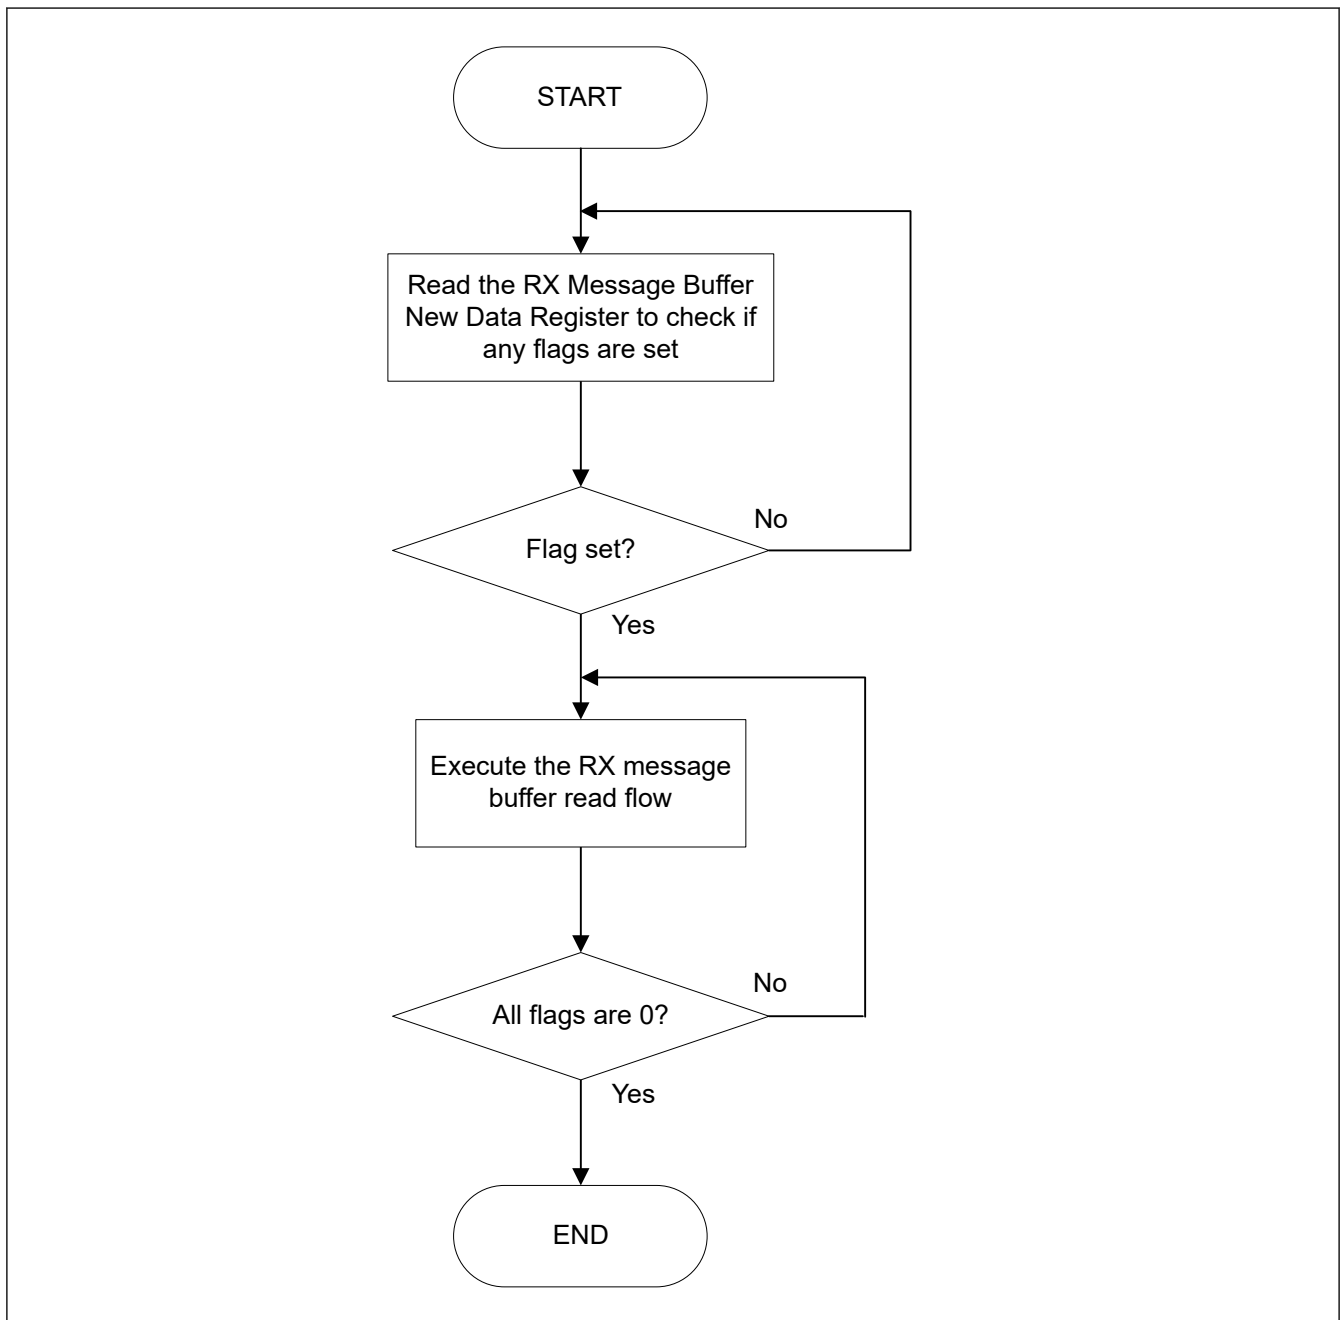

Figure 30.35 Access flow of RX message buffer (Polling)

Figure 30.36 RX Message Buffer Message Access Flow (interrupt)

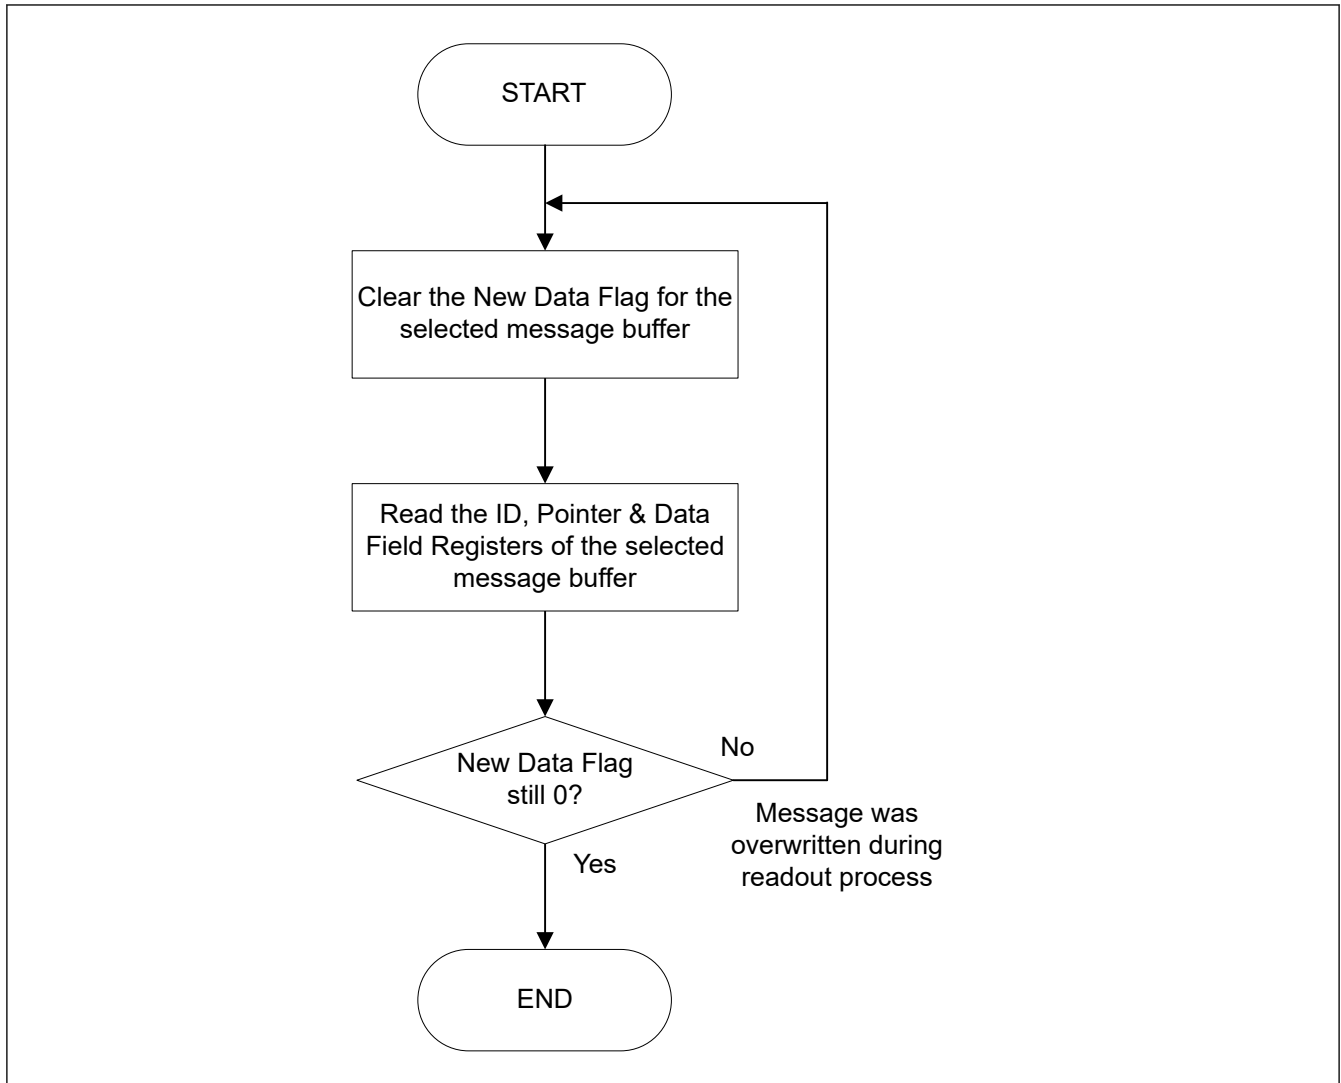

Figure 30.37 Read flow of RX message buffer

30.8.1.2 Message Storage in FIFO Buffers

The AFL entries for routing the received messages to RX FIFO buffers or Common FIFO buffer configured in RX mode should be configured based on system requirements.

The `CFDGAFLP1r.GAFLFDP[8,1:0]` field in the matching AFL entry selects the FIFO buffers to which the related reception message is stored.

When the received message is stored in one or more RX FIFO buffers or Common FIFO buffer configured in RX mode, the message counter value is incremented in the corresponding RX FIFO Status Registers or Common FIFO Status Register.

Depending on the configuration of the FIFO buffers, an interrupt might also be generated.

The message can be read from the corresponding FIFO Access registers.

Note: Because many messages can be stored in the FIFO buffers, reading more than one message may be required to read the latest message stored in a FIFO buffer.

If the message count value matches the FIFO depth, the FIFO Full flag is set.

When the value `0xFF` is written to the corresponding FIFO Pointer Control Register, the message count is decremented by 1.

Only write `0xFF` to the FIFO Pointer Control register after reading the complete message from the FIFO Access registers of the corresponding FIFO.

When all the messages stored in the FIFO are read, the FIFO Empty flag is set.

If a new message is stored into the FIFO when the FIFO message count matches the FIFO depth (FIFO full condition), the FIFO Message Lost flag is set and the new message is lost (no overwrite of already stored messages takes place).

An appropriate value can be configured as warning level to generate an interrupt before the FIFO full condition occurs to avoid loss of a message due to an overrun condition.

Note: The message lost can be set only in RX mode by CAN, and the flag is not set when the CPU is overloading the FIFO buffers.

The RX FIFO buffers and the Common FIFO buffers configured in RX mode can be disabled at any time by clearing the CFDRFCCa.RFE or CFDCFCC.CFE bit in the RX FIFO Configuration/Control Registers and the Common FIFO Configuration/Control Registers.

When the CFDRFCCa.RFE or CFDCFCC.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO buffers are lost and no further messages can be stored into the FIFO.

When the RX FIFO buffers or Common FIFO buffer configured in RX mode is assigned as a DMA channel, software should not access the FIFO Access Register of this FIFO buffer or write 0xFF to the FIFO Pointer Control Register (CFDCFPCTR.CFPC or CFDRFPCTR.RFPC). This can lead to unintended FIFO message decrement. The DMA channel controls the FIFO decrement automatically.

Note: If the interrupt flag is set for a FIFO buffer and then the FIFO is disabled, the interrupt flag is not cleared automatically. The interrupt flag should be cleared before disabling the FIFO.

Figure 30.38 Access flow of FIFO buffer message (example for polling case)

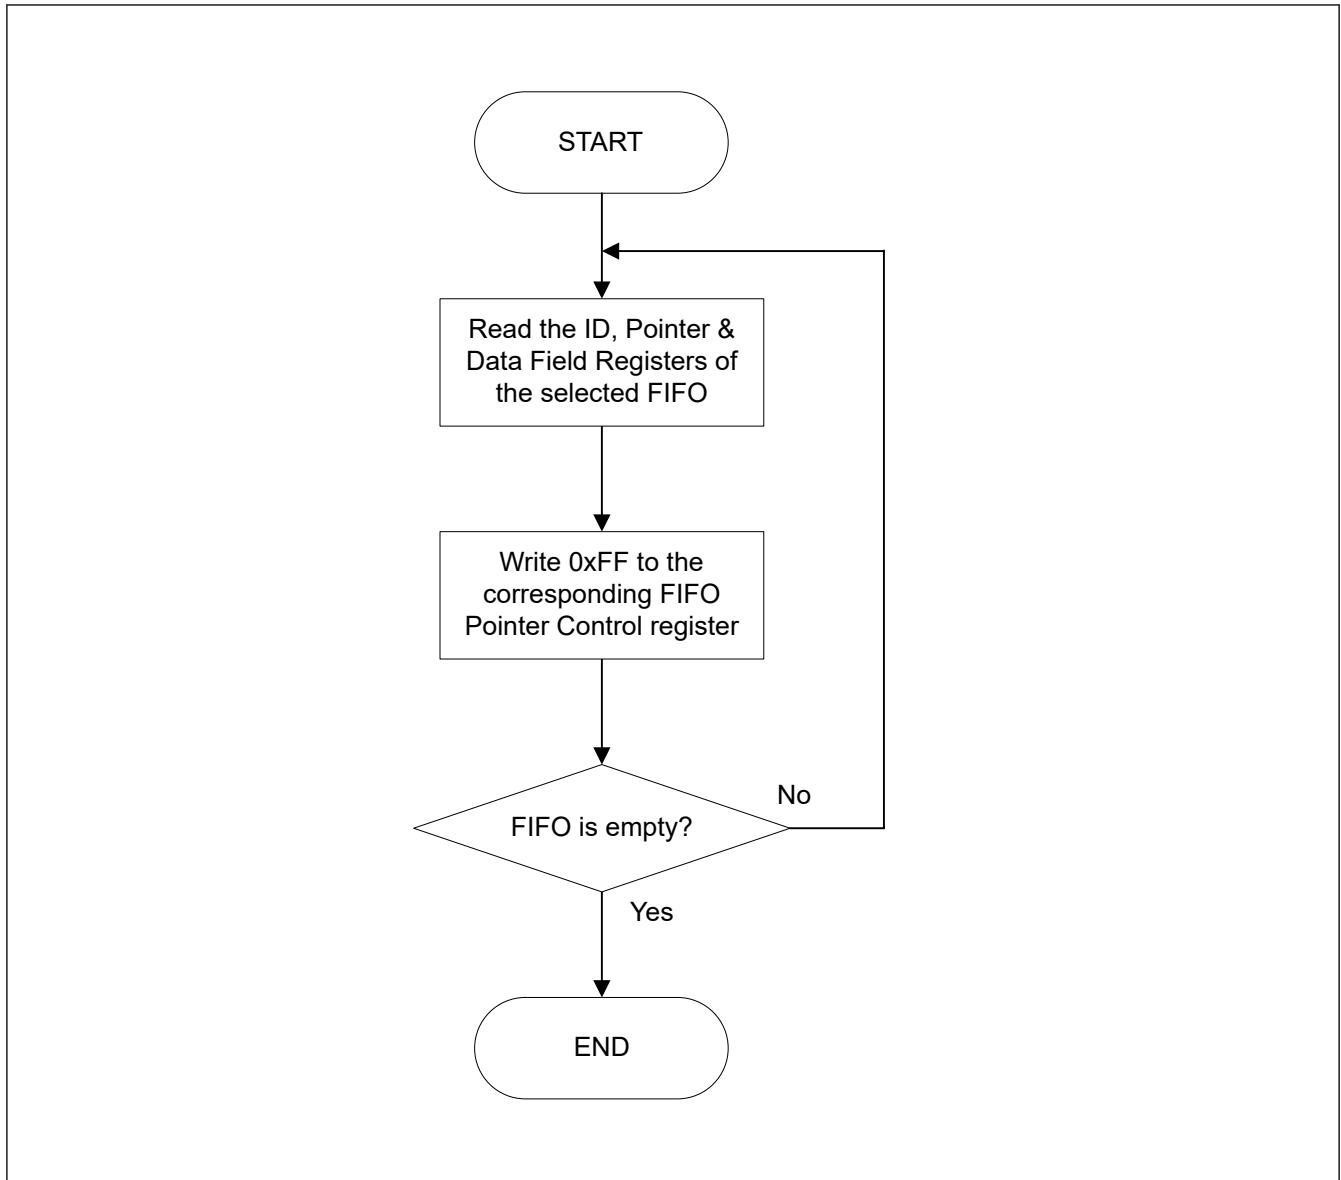

Figure 30.39 Read flow of RX FIFO buffer message (example for polling case)

Note: When the next frame is received before clearing the completion interrupt flag of reception, the completion interrupt of reception is not set again.

Even when an interruption flag is cleared after the completion processing of reception, the already received interrupt flag is not set.

It is necessary to perform the completion processing of reception even before the next completion of frame reception, and to clear an interruption flag.

When processing does not meet the condition, after checking that receiving data is empty, interrupt flag is cleared and it checks that receiving data is empty again.

30.8.1.3 Timestamp

The timestamp counter is a free-running counter that can be used to check reception time of an incoming message or transmission time of successful transmitted messages. The Timestamp counter value is captured based on the `CFDGFDCFG.TSCCFG[1:0]` configuration (at the sample point of start of frame, point in time when the frame is valid, or for CANFD frames also at the sample point of the RES bit). For reception, it is stored together with the message ID and data into the target RX message buffer or RX FIFO.

For transmit message, the timestamp counter value is stored as part of the TX History List entry.

The counter can be clocked with the peripheral clock or with the CAN channel bit timing clock. The counter source clock can be configured with the CFDGCFG.TSSS bit of the Global Configuration Register. If this bit is 0, the peripheral clock is used. If the bit is 1, the selected CAN channel bit time clock is used.

The channel selection is performed with the CFDGCFG.TSBTCS bit of the Global Configuration Register.

Care must be taken when using selected CAN channel bit time clock as the clock source. When entering Channel Halt mode or Channel Reset mode, for this channel, the timestamp counter is stopped. For other CAN channels, the timestamp counter value is not updated.

If peripheral clock is selected as the timestamp counter clock source, Channel modes do not affect the timestamp counter function.

The source clock for the timestamp counter can be divided by a factor defined by the CFDGCFG.TSP bits (timestamp prescaler) in the Global Configuration Register.

The timestamp counter can be reset to 0x0000 with the CFDGCTR.TSRST bit (timestamp reset).

30.8.2 Transmission

There are several possible transmission configurations:

- Normal transmission
- FIFO transmission
- TX Queue transmission

A fixed number of transmission message buffers (4 TX message buffers) are dedicated. These message buffers are only used for transmission and cannot be configured for reception.

Additionally transmission from TX Queue or Common FIFO in TX mode can be configured in the following way (see Figure 30.40):

- TX Queue: Up to four transmission message buffers can be grouped to form a TX Queue with a common access window.
Upper transmission message buffers are used to form the TXQ.
TXQ has an access window.
 - TXQ is transmission Message Buffer 0.

- Common FIFO (TX mode): Common FIFO in TX mode is linked to a dedicated channel. Channel has a fixed number of one Common FIFO assigned to it. Within the channel, a Common FIFO configured in TX mode, can be freely linked (assigned) between 0 and 3 transmission message buffers (only one FIFO to one transmission message buffer).
The Common FIFO buffer then replaces the transmission message buffer linked to it.
Transmission Control and Status registers of these transmission message buffers should not be used.

See Figure 30.28 for information about Common FIFO buffer assignment to related channel.

Note: Common FIFO buffer should not be linked to TX message buffers that are already part of a TX Queue.

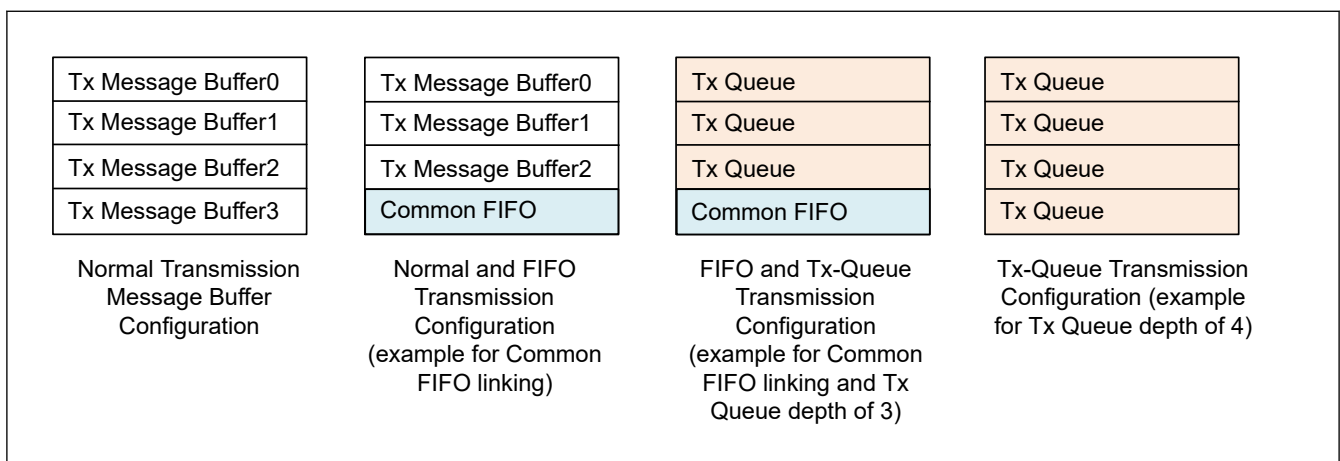

Figure 30.40 Configuration of channel transmission message buffer

30.8.2.1 Transmission Priority

If two or more transmission message buffers of a channel are configured for transmission, then the transmission priority in the CANFD module can be selected from the following two modes:

- CAN ID priority
- Message buffer number priority.

The transmission priority mode is common for all message buffers. It can be configured with the `CFDGCFG.TPRI` bit in the Global Configuration Register.

For message buffer number priority transmission, the smallest message buffer number with transmission request has the highest priority for transmission. This also includes the TX message buffers linked to the Common FIFO buffer configured in TX mode.

However, message buffer number priority should not be used if TX Queue is enabled.

For CAN ID priority transmission, ID priority complies with the CAN bus arbitration rule (as specified in ISO 11898-1 specification). All TX message buffers can enter the ID priority comparison for message buffers configured for transmission. This also includes the TX message buffers linked to the Common FIFO buffer configured in TX mode and includes the TX Queue message buffers.

If the ID of two or more message buffers is the same, then the smaller message buffer number has higher priority for transmission.

Note: For Common FIFO buffer configured in TX mode, only the message currently being pointed to by the FIFO read pointer can be included in the transmission arbitration.

If the message is being transmitted from the FIFO, then the next pending message within the same FIFO is considered in the transmission arbitration.

In contrast to this, all transmission message buffers of a TX Queue participate in internal transmission arbitration.

[Figure 30.41](#) shows the transmission configuration flow.

Figure 30.41 Flow for transmission configuration

30.8.2.2 Normal Transmission

Each transmission message buffer has two modes of message transmission:

1. Regular transmission mode

If the message buffer is placed in regular transmission mode, the data frame or remote frame set in that message buffer can be transmitted.

Completion of regular transmission can be checked through the related TX Message Buffer Transmission Result flag bits (CFDTMSTSj.TMTRF) in the TX Message Buffer Status Registers. These bits are set to 10b or 11b when the regular transmission is successful.

When arbitration is lost or an error occurs, message transmission is further attempted if no transmission abort request is set for this transmission message buffer.

New internal transmission arbitration for this channel is performed for all message buffers with transmission request.

2. One-shot transmission mode

When the CFDTMCi.TMOM bit of the TX Message Buffer Control Registers is set for a transmission message buffer, the message buffer is placed in One-shot transmission mode and attempts to transmit a message only once.

Completion of One shot transmission can be checked through the related TX Message Buffer Transmission Result Flag bits (CFDTMSTSj.TMTRF) in the TX Message Buffer Status Registers. The CFDTMSTSj.TMTRF bits are set to 10b or 11b when One-shot transmission is successful.

The CFDTMSTSj.TMTRF bits are set to 01b when arbitration is lost or an error occurs during transmission of the related message buffer.

Additional message transmission is not attempted in this case.

The regular transmission request procedure after a configuration is shown in [Figure 30.42](#).

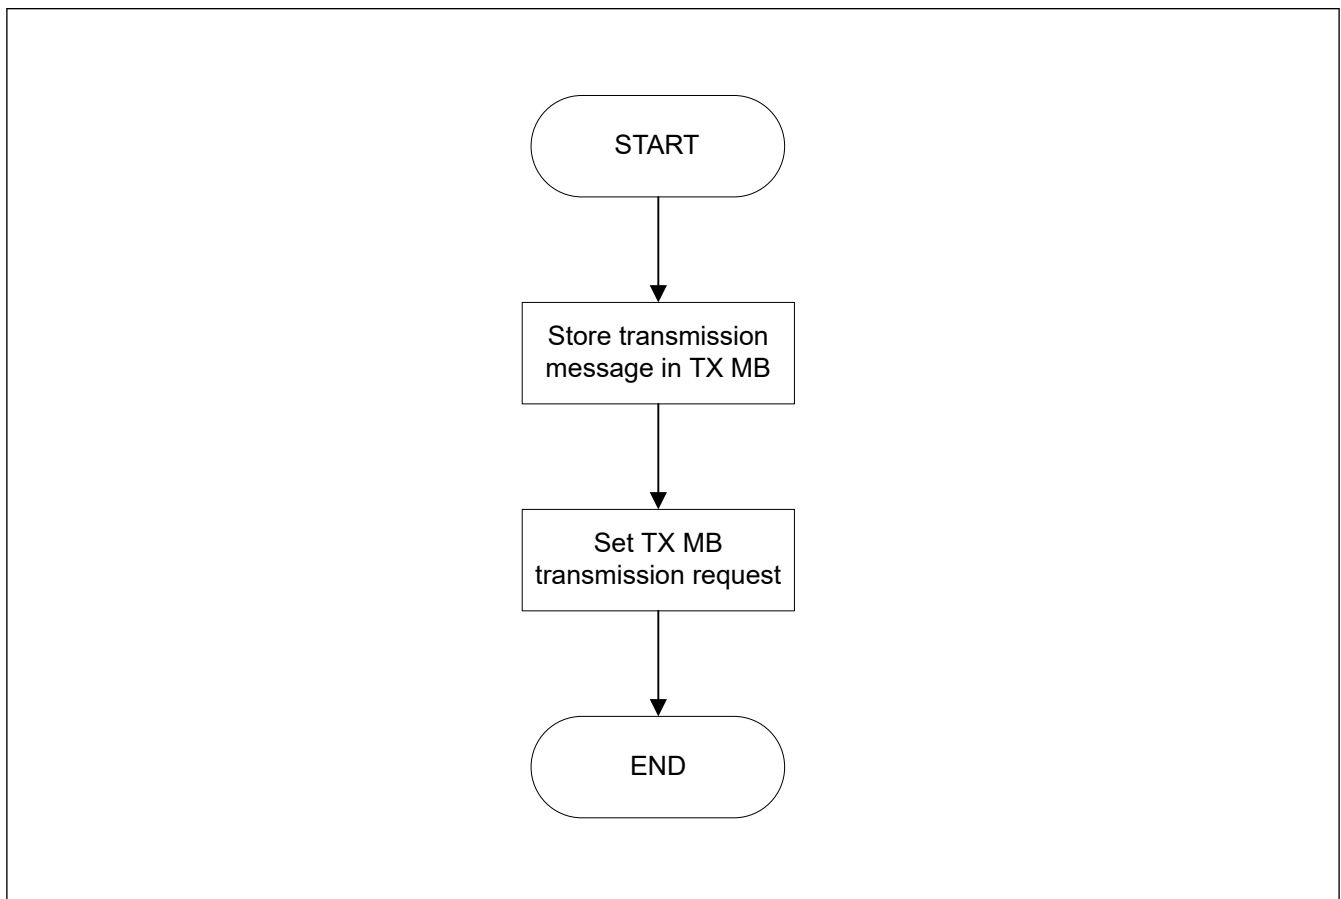

Figure 30.42 Transmission request procedure using normal TX Message Buffer mode

(1) Setting for TX Message Buffer Control Register

[Table 30.26](#) shows configuration of a normal CAN transmission mode.

Table 30.26 Configuration of CAN transmission mode (1 of 2)

Transmission request CFDTMCi.TMTR	Transmission abort request CFDTMCi.TMTAR	One-shot enable CFDTMCi.TMOM	Communication activity
0	0	0	Message buffer disabled
0	0	1	Message buffer disabled

Table 30.26 Configuration of CAN transmission mode (2 of 2)

Transmission request CFDTMCi.TMTR	Transmission abort request CFDTMCi.TMTAR	One-shot enable CFDTMCi.TMOM	Communication activity
1	0	0	Configured as a transmission message buffer for a data frame or a remote frame
1	0	1	Configured as a one-shot transmission message buffer for a data frame or a remote frame
1	1	0	Transmission abort requested
1	1	1	One-shot transmission abort requested

The configuration bits can be configured in the TX Message Buffer Control Registers.

Figure 30.43 shows timings for successful transmission for two message buffers.

Figure 30.43 Timing of request and flag bits for successful transmission

1. If the CFDTMCi.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, the message buffer scanning procedure determines the highest priority message buffer for transmission. When the transmission message buffer is determined, the CFDTMSTSj.TMTSTS bit in the related TX Message Buffer Status Registers is set (transmitting/transmitter), and CAN channel starts the transmission *1.
2. At the first bit of CRC, the transmission scanning procedure starts for the next possible transmission when pending transmission requests exist.
3. If the message has been successfully transmitted, the CFDTMSTSj.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 10b and CFDTMSTSj.TMTSTS and the CFDTMCi.TMTR bits are cleared. When the TMIE bit in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated. To clear the related interrupt line, clear the CFDTMSTSj.TMTRF flag bits.
4. Before starting the next transmission, clear the CFDTMSTSj.TMTRF bits. Load the next message in the transmission message buffer and set the CFDTMCi.TMTR bit again. CFDTMCi.TMTR bit cannot be set again before CFDTMSTSj.TMTRF[1:0] bits are cleared.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTSj.TMTSTS bit is cleared. The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit. If an error occurs either during transmission or following the loss of arbitration, then during the error frame, the transmission scanning procedure is performed again to search for the highest priority transmission message buffer.

Note: The setting point of CFDTMSTSj.TMTSTS is not always fixed at the start of the SOF. It may be delayed up to the start of the standard ID due to the synchronization logic implemented for the PLL bypass.

Figure 30.44 shows timings for transmission abort for two message buffers.

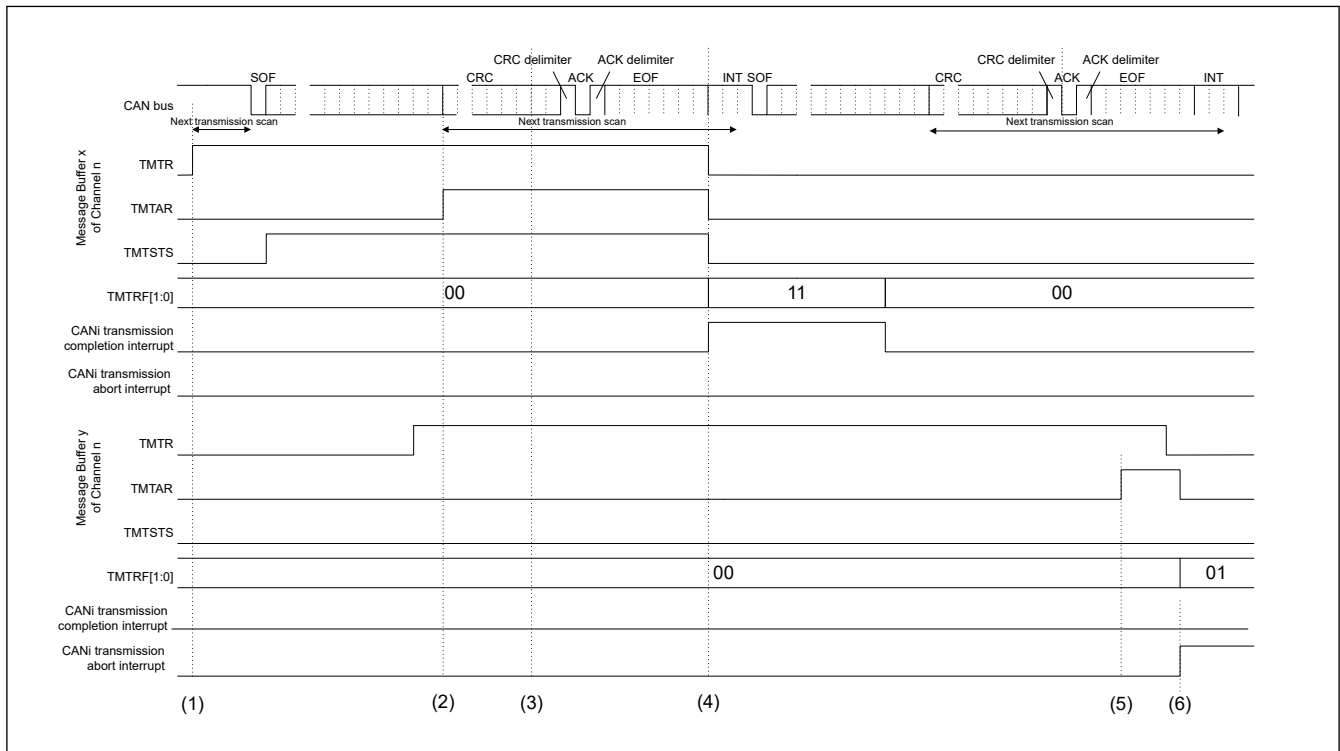

Figure 30.44 Timing of request and flag bits for transmission abort

1. If the CFDTM_{Ci}.TMTR bit in the TX Message Buffer Control Registers is set in the bus idle state, the message buffer scanning procedure determines the highest priority message buffer for transmission. When the transmission message buffer is determined, the CFDTMSTS_j.TMTSTS bit in the TX Message Buffer Status Registers is set (transmitting/transmitter), and CAN channel starts the transmission*1.
2. If the CFDTM_{Ci}.TMTAR bit is set when the related message buffer is already selected for transmission or currently transmitting, the message is not aborted, if no error occurs or arbitration is lost.
3. At the first CRC bit, the transmission scanning procedure starts for the next transmission. In this example, timing chart message buffer y is not selected as the next transmission message buffer.
4. If the message has been successfully transmitted, the CFDTMSTS_j.TMTRF[1:0] bits in the corresponding TX Message Buffer Status Registers are set to 11b and the CFDTMSTS_j.TMTSTS and CFDTM_{Ci}.TMTR bits are cleared. When the TMIE bit in the TX Message Buffer Interrupt Enable Configuration Registers is set (interrupt enabled), the CAN successful transmission interrupt request is generated. To clear the related interrupt line, clear the CFDTMSTS_j.TMTRF[1:0] bits.
5. Another CAN node is transmitting on the CAN bus (CFDTMSTS_j.TMTSTS is not set). If the CFDTM_{Ci}.TMTAR bit is set when the related channel is under transmission scan, the transmission request cannot be cleared.
6. After internal processing time, the transmission is aborted and the CFDTMSTS_j.TMTRF[1:0] bits are set to 01b. If the message buffer is not transmitting or selected as the next transmission message buffer or under transmit scan, then the abort is immediately accepted and the corresponding CFDTMSTS_j.TMTRF[1:0] bits in the TX Message Buffer Status Registers are set to 01b. In addition, CFDTM_{Ci}.TMTR, and CFDTM_{Ci}.TMTAR bits are cleared automatically. When the transmission abort interrupt enable TAIE bit of the related Channel Control Register is set then an interrupt is generated for successful transmission abort. To clear the related interrupt line the CFDTMSTS_j.TMTRF[1:0] bits have to be cleared.

Note 1. If arbitration is lost after the CAN channel starts the transmission, the CFDTMSTS_j.TMTSTS bit is cleared.

The transmission scanning procedure is performed again to search for the highest priority transmission message buffer from the beginning of the first CRC bit.

If an error occurs, either during transmission, or following the loss of arbitration, then during the error frame, the transmission scanning procedure is performed again to search for the highest priority transmission message buffer.

30.8.2.3 TX FIFO Transmission

One common FIFO buffer is assigned to CANFD module. The FIFO buffer can be linked to any normal TX message buffer position for this channel with the CFDCFCC.CFTML bits in the Common FIFO Configuration/Control Register if configured in TX mode.

When the transmission scan starts and the FIFO buffer corresponding to this TX message buffer is enabled, the relevant message in the FIFO buffer participates in the transmission scan.

Configuration of a TX message buffer linked to a FIFO buffer configured in TX mode should not be done.

(1) TX FIFO Operation

CAN messages can be written into the TX FIFO by writing to the corresponding FIFO Access registers.

When the value 0xFF is written into the corresponding FIFO Pointer Control Register, the message count of the related FIFO is incremented by 1.

Only write to the FIFO Pointer Control register after writing the complete message to the corresponding FIFO Access registers. If the message count matches the FIFO depth, the FIFO Full flag is set.

The oldest message in the TX FIFO is included in the scan for transmission by the corresponding CANFD module channel logic.

When a message is successfully transmitted from the TX FIFO, the message count value is decremented by 1. When all the messages from the FIFO are transmitted, the FIFO Empty flag is set.

The interrupt generation conditions for the TX FIFO buffer can be configured by configuring the CFDCFCC.CFIM bit in the corresponding Common FIFO Configuration/Control Register.

If CFDCFCC.CFIM bit is 0, then interrupt is generated when the last message is successfully transmitted from the TX FIFO buffer.

If CFDCFCC.CFIM bit is 1, then interrupt is generated for every successfully transmitted message from the TX FIFO buffer.

The Common FIFO can set interrupt when CAN frame transmission is complete.

The Common FIFO buffer configured in TX Mode can be disabled by clearing the CFDCFCC.CFE bit in the Common FIFO Configuration/Control Register. If this bit is cleared to 0, the FIFO Empty flag is set as follows:

- Immediately if the message from the TX FIFO is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX FIFO is already scheduled for transmission or already in transmission.

Note: The Common FIFO buffer is considered as disabled after clearing the CFDCFCC.CFE bit only when the Empty flag is set for the corresponding Common FIFO buffer.

Other possible messages pending from the TX FIFO are lost and their transmission must be requested again. Before CFDCFCC.CFE is set again, ensure that CFDCFSTS.CFEMP bit is set and that there are no pending abort from the TX FIFO.

When the CFDCFCC.CFE bit is cleared, the message read and write pointers of the FIFO are cleared and are no longer active. Therefore, all messages in the FIFO buffers are lost and no further message can be stored into the FIFO.

The FIFO transmission request procedure after configuration is shown in [Figure 30.45](#).

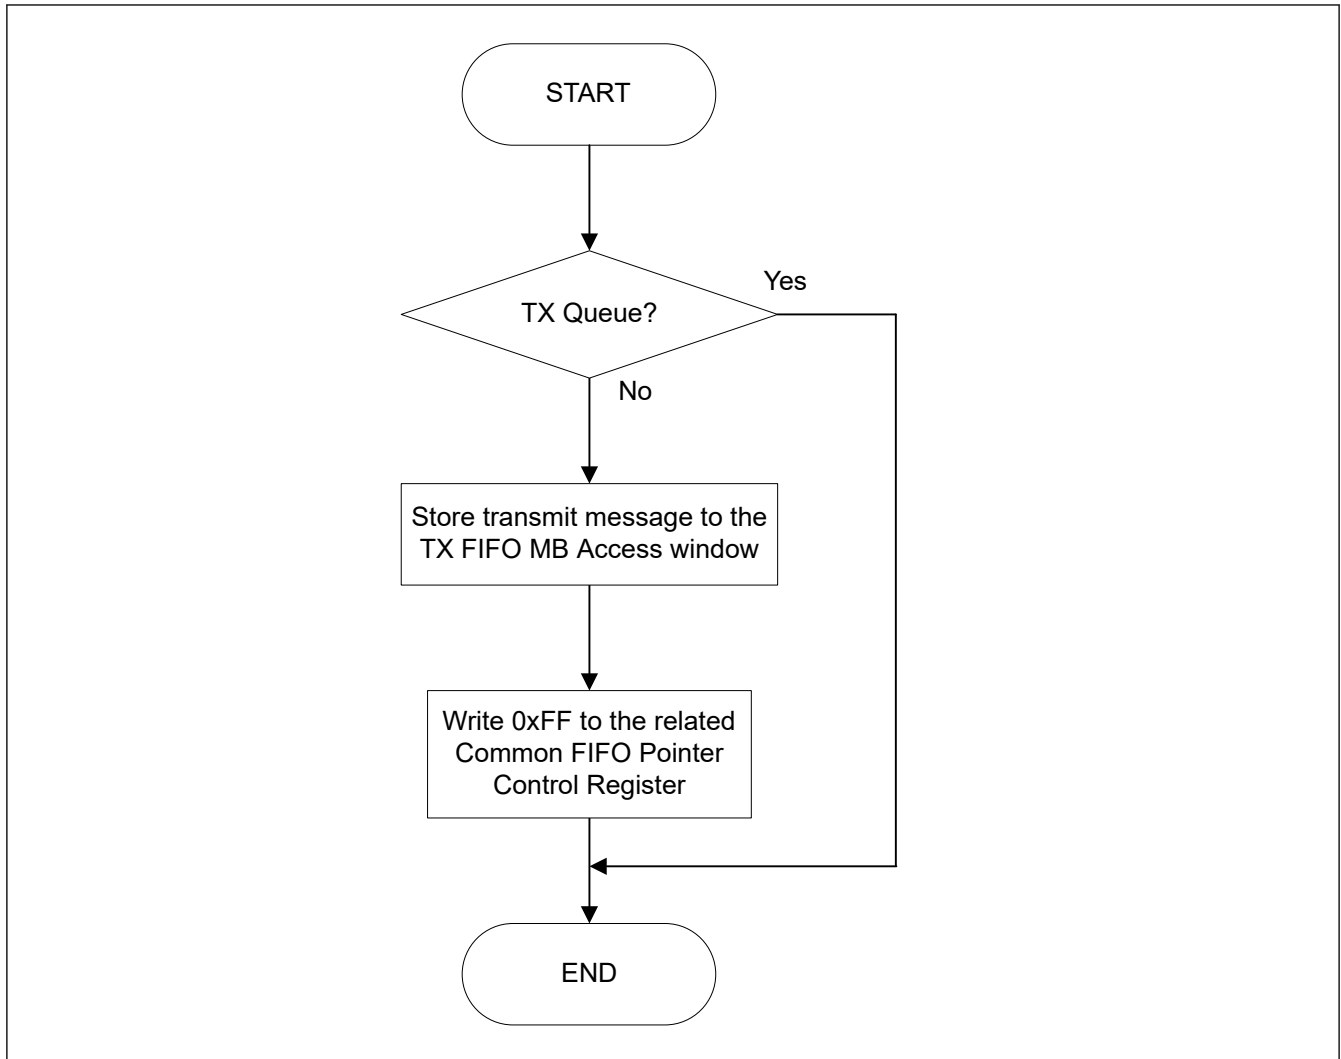

Figure 30.45 Request procedure for TX FIFO transmission

(2) Interval Timer for FIFO Transmission

For each Common FIFO in TX mode, it is possible to specify a delay between two consecutive messages that are configured for transmission from the same FIFO buffer. This delay is called interval time. This interval time starts after the first message has been successfully transmitted from the FIFO buffer after the CFDCFCC.CFE bit is set.

When the Common FIFO in TX mode is enabled, the first message is transmitted without considering this interval time.

The interval timer stops counting when:

- FIFO is disabled by clearing the CFDCFCC.CFE bit.
- CAN channel is in CH_RESET mode.

The interval time is specified by the CFDCFCC.CFITT value from 0 to 255 timer units in the Common FIFO Configuration/Control Register.

The timer unit can be defined based on two different source clocks for the interval timer. To disable the interval timer for FIFO transmission, select a value of 0.

The timer source can be selected with the configuration bit CFITSS in the Common FIFO Configuration/Control Register.

If CAN channel bit time clock is configured as the clock source, and the CAN channel enters CH_HALT, CH_RESET, or CH_SLEEP mode, the interval timer is stopped for that channel.

If peripheral clock is selected as the interval timer clock source, the interval timer is stopped only when the CAN channel is in CH_RESET or CH_SLEEP mode.

The reference clock can be used to configure the interval time in fixed time units. It is based on the peripheral clock. The reference clock prescaler value `CFDGCFG.ITRCP` in the Global Configuration Register defines the relation between the peripheral clock frequency/period and the reference clock period.

See [Table 30.27](#) for `CFDGCFG.ITRCP` configuration values to achieve different reference clock periods based on the peripheral clock frequency and period.

Table 30.27 Configuration example for the reference clock of the FIFO interval timer

Reference clock/Peripheral clock	1 μ s	100 μ s	500 μ s
16 MHz/62.5 ns	16	1600	8000
20 MHz/50 ns	20	2000	10000
32 MHz/31.25 ns	32	3200	16000
50 MHz/20 ns	50	5000	25000

The reference clock resolution can be specified by the interval timer reference clock resolution value `CFDCFCC.CFITR` in the Common FIFO Configuration/Control Register.

The interval time is based on the reference clock period multiplied by the configured value ($\times 1$ or $\times 10$). The reference clock based interval timer can be used to satisfy the requirements of the ISO 15765-2 Separation Time. The whole range for the separation time from 100 μ s to 127 ms can be covered.

The specified interval time starts after successful transmission event (after EOF7 state of the CAN protocol).

When the interval time has elapsed, the next transmission request is raised by the related TX FIFO. Therefore, the interval time defines the minimum time between two messages transmitted from one FIFO.

The next message is sent at earliest after this interval time. [Figure 30.46](#) shows an example timing of the internal processing.

Figure 30.46 Example for interval processing time

The configuration for the timing in [Figure 30.46](#) is as follows:

- Peripheral clock frequency = 50 MHz
- Interval timer reference clock (`CFDGCFG.ITRCP`) = 500 times
- Reference clock from the settings in [Figure 30.46](#) = 10 μ s
- Common FIFO interval timer source selection (`CFDCFCC.CFITSS`) = 0
- Common FIFO interval timer resolution (`CFDCFCC.CFITR`) = 0
- Common FIFO interval transmission time (`CFDCFCC.CFITT`) = 10 times
- Theoretical message separation interval = 100 μ s

1. Internal FIFO interval timer is restarted with the occurrence of successful transmission result. This restart is not synchronized to the reference clock trigger. Therefore, the first interval is counting less or equal to 1 reference clock interval.
2. With the next reference clock trigger the FIFO interval timer is decremented.

3. When the FIFO interval timer reached the value 0, the FIFO transmit request is set.
4. When the FIFO is selected for transmission, the transmission starts. Due to internal processing, this usually takes less than 3 CAN bit time, between the internal FIFO transmit request set in step 3. and the actual transmission.

In the worst case when multiple events such as a reception scan, an internal message routing, a transmit scan on all channels occur, it can take up to 120 peripheral clock cycles.

As shown in Figure 30.46, it is not guaranteed that the minimum interval is always equal to the configured value. If a minimum time must never be breached, configure CFDCFCC.CFITT to the required minimum value plus 1.

If additional TX message buffers or TX FIFO are configured for transmission of the same channel, the real delay between two messages transmitted from a TX FIFO can be much longer than specified by the interval time. This is due to higher priority message transmission from these TX message buffers or TX FIFO.

Figure 30.47 shows a block diagram of the FIFO interval time generation circuit.

Figure 30.47 Block diagram of FIFO interval timer

30.8.2.4 TX Queue

Each enabled TX Queue for a specific channel consists of 3 to 4 TX message buffers, which are accessed through one access window.

- The first TX Queue can be configured with a depth of three up to four buffers and uses TX Message Buffer No. 0 as access window (referred to as TXQ)

All the TXQ messages enter the priority comparison for the transmission, which should be only ID Priority (CFDGCFCFG.TPRI = 0).

The registers for TXQ are:

- CFDTXQCC
- CFDTXQSTS
- CFDTXQPCTR

See related access registers TX Message Buffer ID Registers (TMID[m]), TX Message Buffer Pointer Registers (TMPTR[m]), TX Message Buffer Data Field 0 Registers, and TX Message Buffer Data Field 1 Registers (TMDF[0:1][m]) when access window TXQ0 is used.

The depth of each TXQ buffer can be configured by writing to the CFDTXQCC.TXQDC[1:0] bits of the TX Queue Configuration/Control Register. TXQ can be set from TXMB0 to TXMB3 as a queue buffer at the maximum.

The 4 available options for the depth configuration of TXQ buffer are:

- 0x00: TX Queue disabled
- 0x01: reserved
- 0x10: 3 Messages
- 0x11: 4 Messages

Do not access all the TX message buffers forming the TX Queue directly (except TX Message Buffer No. 0, which act as TX Queue access window).

When a system writes in TXQ, it writes in send data, after checking the state of TXQ.

Do not access or configure the related TX Message Buffer Control Registers.

The messages stored to the TX Queue access window are internally stored to a free buffer of the TX Queue.

When the buffer is full, no further access should be done to the queue, until it is no longer full. If access is a software write when the buffer of TXQ is full, send data is overwritten.

The TX Queue can be disabled by clearing the TXQE bit in the TX Queue Configuration/Control Register. If this bit is cleared, the TX Queue Empty flag is set as follows:

- Immediately if the message from the TX Queue is neither scheduled for the next transmission nor in transmission
- Following the transmission completion, the detection of an error on the CAN bus, loss of arbitration or transition to Channel or Global Halt mode if the transmission from the TX Queue is already scheduled for transmission or already in transmission.

Note: The TX Queue is disabled only when the Empty flag is set after clearing the TXQE bit for the corresponding TX Queue.

Other possible messages pending from the TX Queue are lost and their transmission must be requested again.

Before TXQE is set again, ensure that the CFDTXQSTS.TXQEMP bit is set and that there is no pending abort from the TX Queue.

When the TXQE bit is cleared, all messages in the TX Queue buffers are lost and no further message should be stored in the TX Queue.

When a message has been stored to the TX Queue, write 0xFF in the TX Queue Pointer Control Register. This sets the transmit request automatically and changes the internal message buffer pointer to the next free message buffer location of the TX Queue.

Note: If two messages with the same ID are stored in the TX Queue, the order of transmission of these messages can be different from the order in which they were stored in the TX Queue.

To avoid this condition, it is important to confirm that the previous message with the same ID was successfully transmitted before a new message with the same ID is stored in the TX Queue.

For the TX Queue, a dedicated interrupt can be enabled by setting the TXQIE bit of the TX Queue Configuration/Control Register.

The interrupt mode can be configured with the CFDTXQCC.TXQIM bit of the same register either to generate an interrupt for every transmitted message or for the last transmitted message.

The TX Queue transmission request procedure after configuration is shown in [Figure 30.48](#).

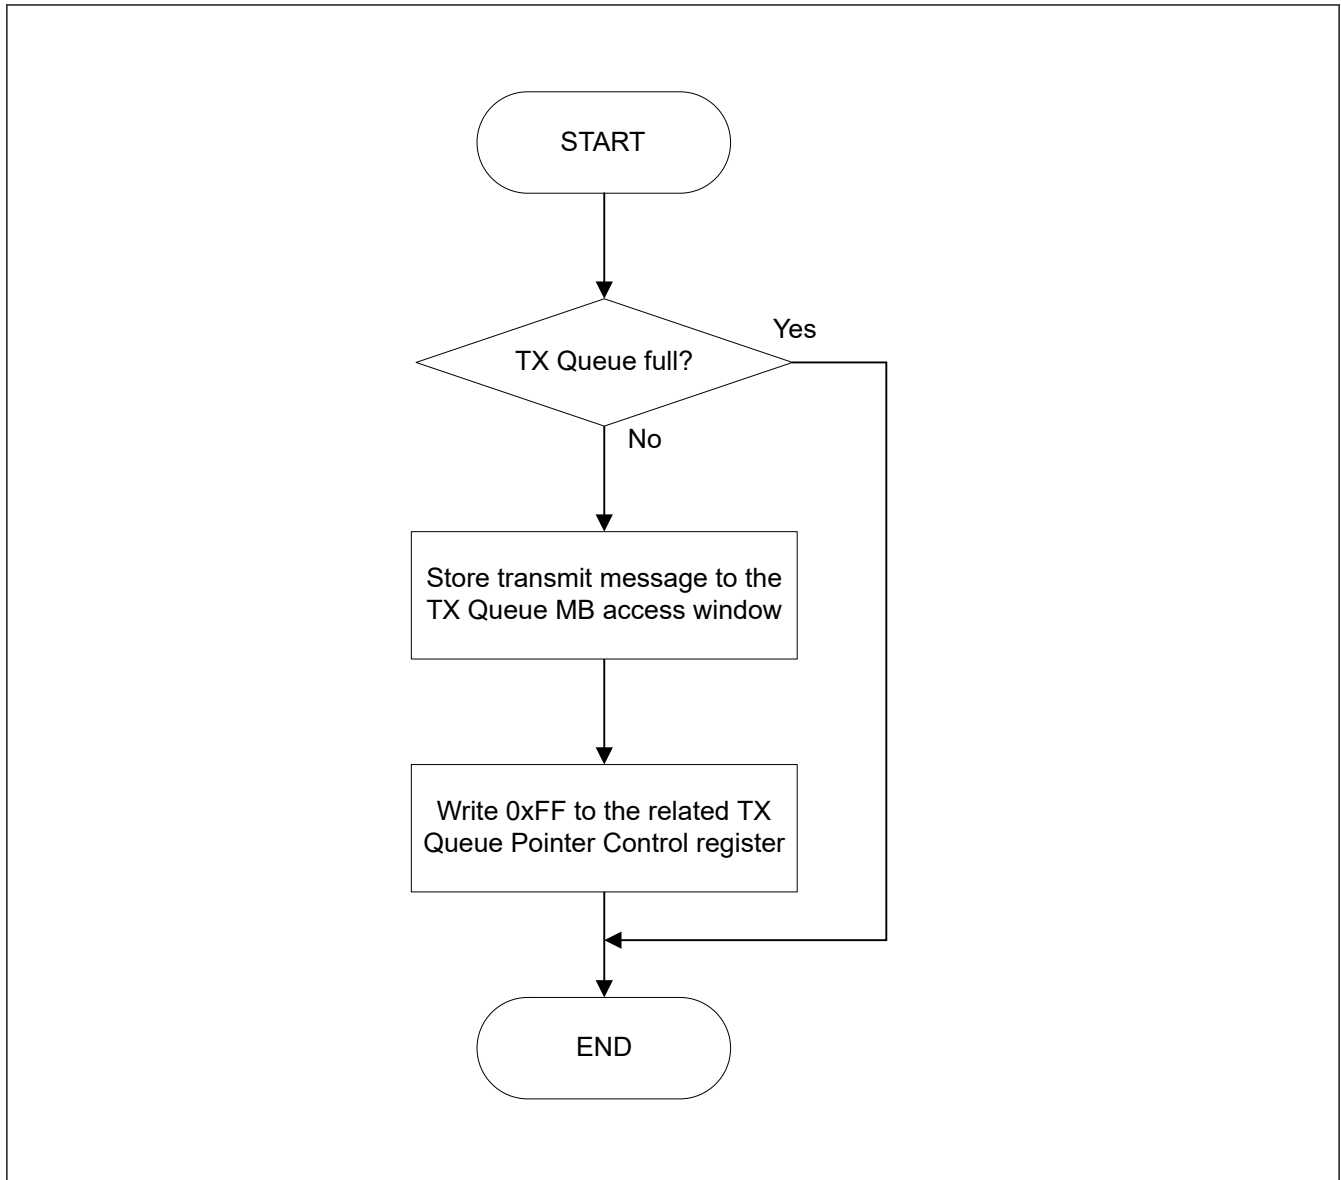

Figure 30.48 TX Queue transmission request

30.8.2.5 TX History List

The TX History List function records the information of the successfully transmitted message in the TX History List Buffers. Two TX History List buffers are provided and THL buffer can store up to 8 TX History List entries.

The CFDTLCC.THLDTE bit of the TX History List Configuration/Control Register can be used to configure if only message information from TX FIFO or TX Queue is stored, or if all transmit message information from TX Queue, TX FIFO, or normal TX message buffers is stored in the TX History List.

Each transmit message can be individually configured for acceptance to the TX History List with the CFDCFID.THLEN bit in the Message Buffer Pointer Register.

The message information is stored to the TX History List Buffer of a CAN channel after the message is successfully transmitted.

Storing to the list is not synchronized with the status of CFDTMSTSj.TMTRF[1:0] bits in the TX Message Buffer Status Register.

Due to internal processing, the storage to the list can happen with a delay after the successful transmission indication.

Storing the TX History List data can be recognized by the condition that the THLIF is set to 1 when the THLIE bit is configured to 1 or when the TX History List counter CFDTLSTS.THLMC[5:0] is increased.

In worst case when multi events like reception scan, internal message routing on happen.

- Maximum delay time from setting the CFDTMSTSj.TMTRF to store the TX History List data is 70 peripheral bus clock cycles.

The History list records the following information of a transmitted message:

- Buffer type:
 - 001: TX Message Buffer
 - 010: TX FIFO
 - 100: TX Queue
- Buffer number:
TX message buffer, TX Queue message buffer or TX message buffer link for the Common FIFO buffer from which transmission occurred. The number depends on the buffer type. See [Table 30.28](#).
- Transmission ID:
Transmission pointer stored in the transmission message
- Transmit timestamp:
Message timestamp captured at capture point as configured by CFDFGDCFG.TSCCFG.
- Transmission information label:
Transmission information label stored in the transmission message.

Table 30.28 TX History List Buffer number entry

Buffer Number	BT[2:0] Buffer Type		
	001b TX Message Buffer	101b TX FIFO	100b TX Queue
00b	Message Buffer 0	Number shown corresponds to the common FIFO. TX Message Buffer Link CFTML of the related Common FIFO configuration	Number shown corresponds to the Message Buffer belonging to the TX Queue which the frame was transmitted
01b	Message Buffer 1		
10b	Message Buffer 2		
11b	Message Buffer 3		

The Transmission ID entry is used to identify which message of a TX FIFO or TX Queue has been successfully transmitted because the TX FIFO or TX Queue number alone is not sufficient.

Therefore, a unique number can be attached to each transmission message stored in a TX FIFO or TX Queue. This unique identification number should be written to the CFDCFFDCSTS.CFPTR[15:0] part of the Common FIFO Access Pointer Register for a TX FIFO or to the CFDTMFDCTRb.TMPTR[15:0] part of the TX Message Buffer Pointer Register of the TX Queue access window message buffer.

When the message is successfully transmitted, this identification number is stored together with the other message related information to the TX History List and can be read using the Transmission ID (TID) of the TX History List Access Register.

Also, for normal TX message buffers, the CFDTMFDCTRb.TMPTR[15:0] part of the TX Message Buffer Pointer Register is stored in the Transmission History List and the information label is the same.

[Figure 30.49](#) shows a transmission preparation flow when TX History List is used.

Read access to the TX History List Access Register is done for every single entry.

After reading one entry, 0xFF must be written to the corresponding TX History List Pointer Control Register to be able to access the next entry until TX History List is empty.

[Figure 30.50](#) shows an example flow for processing the TX History List information.

The TX History Lists have dedicated interrupts, which can be configured with the CFDTHLCC.THLIM bit of the corresponding TX History List Configuration/Control Register and enabled with the CFDTHLCC.THLIE bit of the same

registers, either to generate an interrupt when the History List reached a filling level of 75% or for every new TX History List entry.

An entry lost indication is flagged by the CFDTHLSTS.THLELT bit in the TX History List Status Register. The status of this bit is also shown by the THLES bit in the Global Error Flag Register.

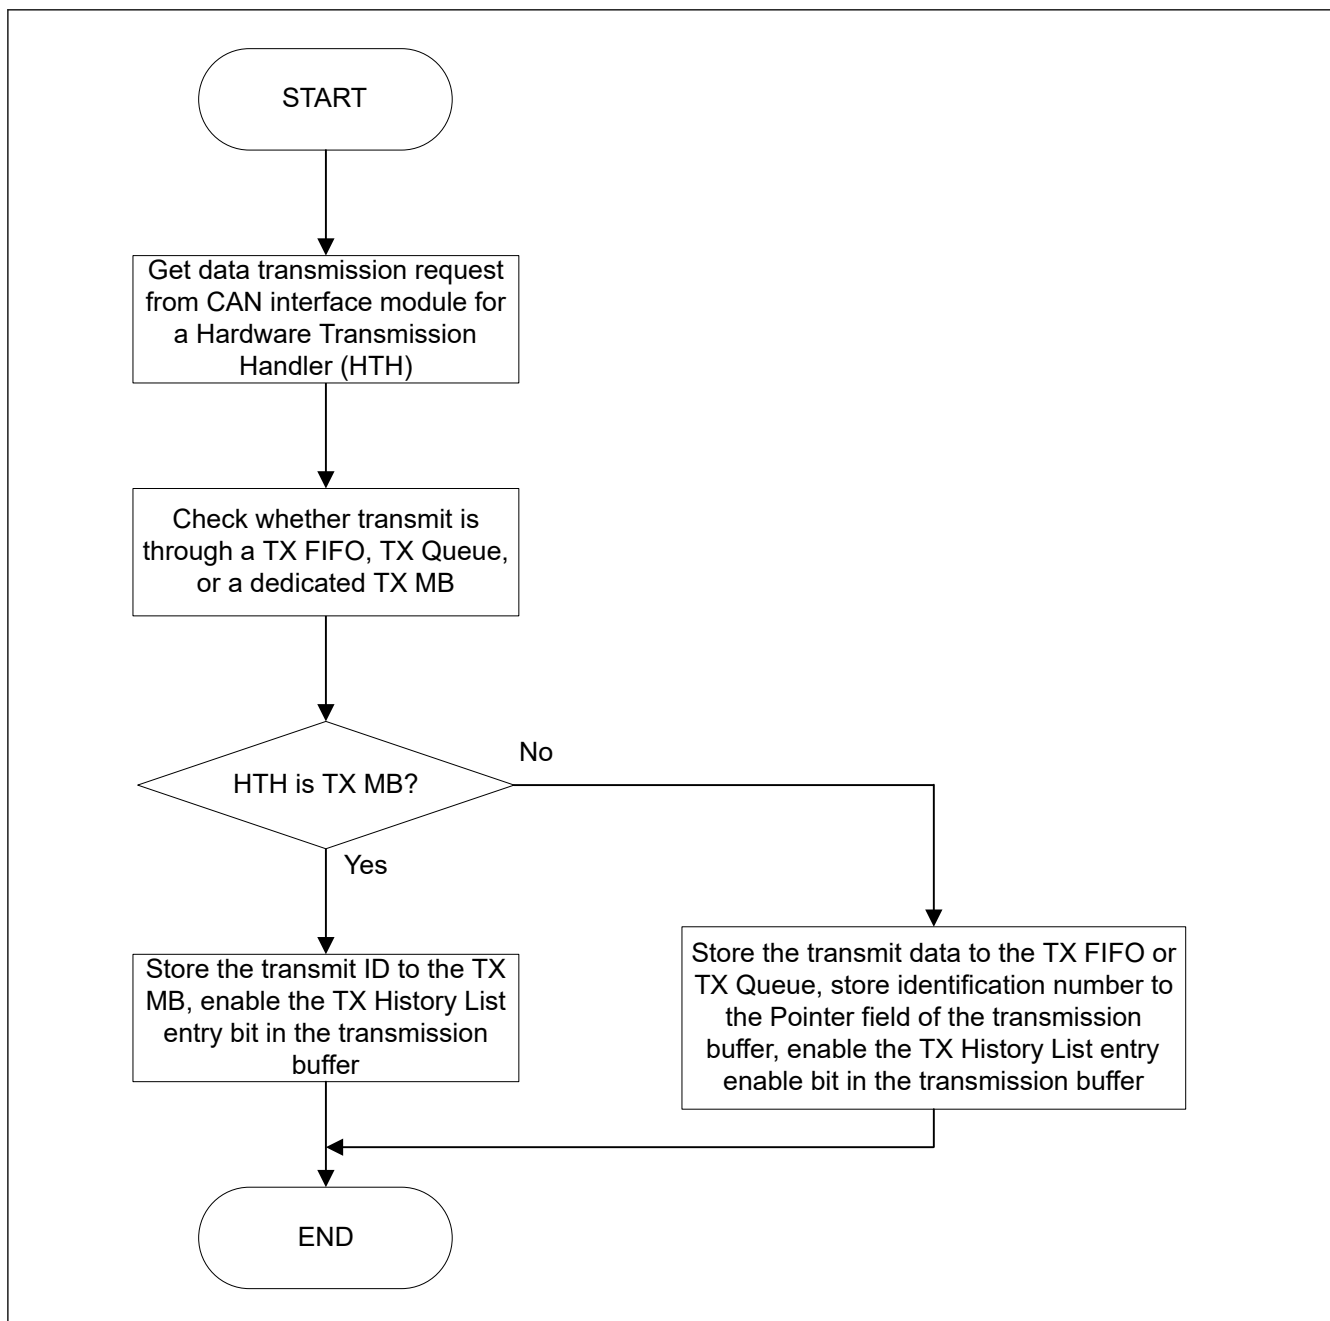

Figure 30.49 TX History List preparation flow

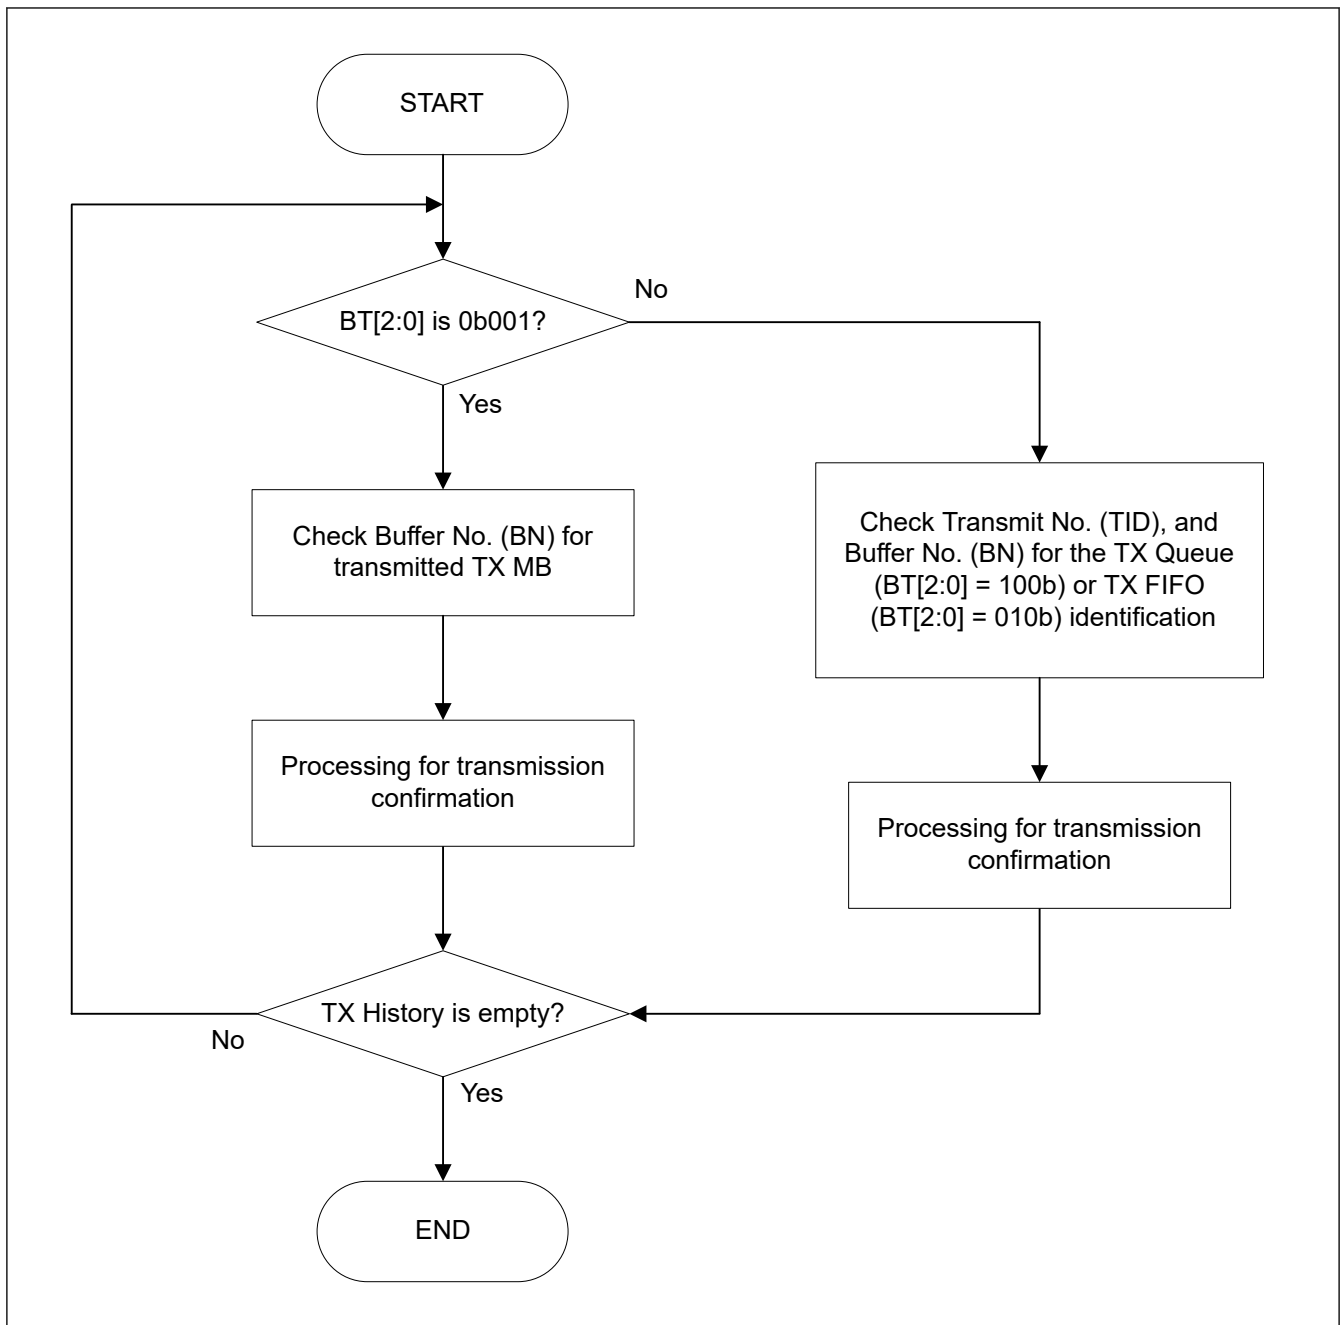

Figure 30.50 TX History List processing flow

30.8.2.6 TX Data Padding

This chapter is not valid for classical CAN.

If the data length code (DLC) of the transmitting message has a higher number of data bytes than the buffer size, the data bytes beyond the restricted range are replaced by bytes with the value of 0xCC.

This can happen for Common FIFO configured as (TX mode) when the transmit message DLC is higher than the CFDCFCC.CFPLS.

This can also happen in FD only mode, if a Classical frame is configured with a DLC bigger than 8.

30.9 Test Mode

The CANFD module can be configured into test modes to allow testing of certain features. These features are provided only for special purposes and care must be taken when configuring the CANFD module in test modes.

Note: All test modes are mutually exclusive unless it is explicitly stated that some functions can be enabled across other test modes.

Do not enable any combination of the various test modes specified in this section.

The test modes can be broadly split into 2 groups:

- Channel specific test modes
- Global test modes.

30.9.1 Channel Specific Test Modes

CAN channel can be configured into the following test modes:

- Basic test mode
- Listen-only mode
- Self-test mode 0 (External loop back mode)
- Self-test mode 1 (Internal loop back mode)
- Restricted operation mode.

30.9.1.1 Basic Test Mode

The basic test mode should be used when there is requirement for a particular test setting to be enabled other than when in Listen-only and Self-test modes.

30.9.1.2 Listen-only Mode

The ISO 11898-1 recommends an optional bus-monitoring mode. In this mode, the CAN channel is able to receive valid data frames and valid remote frames. However, it sends only recessive bits on the CAN bus and is not allowed to transmit.

If the CAN engine is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is routed internally so that the CAN engine monitors this as dominant. The external TX pin remains in recessive state.

This mode can be used for baud rate detection. In this mode, an error interrupt is generated if a bus error occurs and the interrupt is enabled.

In this mode, it is not permitted to request transmission from any normal TX message buffer or TX FIFO.

30.9.1.3 Self-test Mode 0 (External loopback mode)

In Self-test mode 0, the CAN engine treats its own transmitted messages as received messages through the CAN transceiver and stores them into its receive message buffers.

To be independent from external stimulation, the engine generates its own Acknowledge bit.

This test can be used for CAN transceiver tests and the RX/TX pins should be connected to the transceiver.

30.9.1.4 Self-test Mode 1 (Internal loopback mode)

In Self-test mode 1, the CAN engine treats its own transmitted messages as received messages and stores them into the receive buffer. This mode is provided for self-test functions. To be independent from external stimulation, the CAN engine generates its own Acknowledge bit. In this mode the CAN engine performs an internal feedback from TX internal to RX internal. The actual value of the external RX input is disregarded by the CAN engine.

The external TX pin outputs only recessive bits. The RX/TX pins do not need to be connected to the CAN bus or any external device.

Note: The channel pins are also disconnected from the internal CAN bus communication line.

30.9.1.5 Restricted Operation Mode

This chapter is not valid for classical CAN.

In Restricted operation mode, the CAN node is able to receive valid data and remote frames generating the Acknowledge bit.

Active error or overload frames cannot be transmitted, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication after an error or overload condition occurs.

Additionally, the Receive and Transmit Error Counter (REC and TEC) are frozen independently from the occurrence of errors. The mode is specified in ISO 11898-1 and the setting of transmit request is permitted.

30.9.2 Global Test Modes

The CANFD module can be configured into the following test modes:

- RAM test mode
- Bit Flip Test

The test modes in the following table are protected by a special software procedure to enable the mode. This software procedure enables write access to the test mode by a specific unlock key as shown in the table.

Test mode	Unlock key 1	Unlock key 2
RAM test mode	0x7575	0x8A8A

If the software sequence of the two consecutive unlock key write accesses (half-word or word access) is interrupted by any other write access to the register or if incorrect data is written to the Global Unlock Key Register, the corresponding test mode cannot be set and the sequence must be restarted.

After the two unlock key write accesses, the next write access should be to set the corresponding test mode enable bit. If this is not followed, the unlock mechanism reset and the test mode enable bit cannot be set and the unlock sequence must be restarted.

Figure 30.51 Unlock software protection routine

30.9.2.1 RAM Test Mode

The CANFD module can be configured in RAM test mode by setting the `CFDGTSTCTR.RTME` bit in the Global Test Control Register when the corresponding lock key is previously written. This is a special test mode, in which, the complete RAM area can be accessed.

Note: The actual RAM size is bigger than the RAM area initialized after a hardware reset. Therefore, ECC error flag (of the ECC macro) may be set if CPU reads data from this uninitialized RAM area while CANFD module is in RAM test mode.

In this mode, the RAM area is split into number of pages (pn) of 256 bytes, each which can be accessed with the `CFDRPGACCK` register.

The page should be selected for read/write access by writing to the `CFDGTSTCFG.RTMPS[3:0]` bits in the Global Test Control Register. Data can then be read from or written in to the RAM Test Page Access Registers.

[Figure 30.52](#) shows the structure of the pages in the RAM when performing a RAM test mode.

Figure 30.52 RAM page structure

The total available RAM size is 2072 bytes for the Message Buffer RAM.

The pn and CFDGTSTCFG.RTMPS[3:0] values for the MB RAMs are calculated in the following way:

$pn = \text{ceil}(\text{total RAM size in bytes} / \text{number of bytes per page})$

- MB RAM:
 - $pn = \text{ceil}(2072 / 256) = 9 \text{ pages}$
 - $\text{CFDGTSTCFG.RTMPS}[3:0] = 0 \text{ to } 8 \text{ inclusive}$
 - (User should not access more than 24 Bytes in the last page)

Figure 30.53 shows the software flow for RAM test mode.

Figure 30.53 Software flow for RAM test mode

To exit this test mode, the CFDGTSTCTR.RTME bit must be cleared. The CFDGTSTCTR.RTME bit is cleared by writing 0 to it.

The CFDGTSTCTR.RTME bit is cleared automatically when the CANFD module enters Global Reset mode from the test mode.

30.9.2.2 Bit Flip Test

Bit Flip Test can invert the bit (the 1st bit of ID) of the beginning of the bit stream to receive.

If this function is used by a transmitting node, a bit error or an arbitration lost will occur.

If this function is used by a receiving node, a CRC error or a stuff error will occur.

Users should refer to the bit stuffing rule when using this feature, as there is the possibility of receiving a stuff error (due to the inversion) rather than a CRC error.

The following sequence should be used to perform CRC Error testing. In the sequence below CANFD module is the receiver.

1. Set the CFDC0CTR.BFT bit to 1'b1, in order to invert the first bit of the incoming bit stream from sending node
2. Wait for the CANn_CHERR (n = 0, 1) output signal to set to 1'b1
3. Read either the CFDC0ERFL.CRCREG or the CFDC0FDCRC.CRCREG (depending on the received frame type: Classical or FD). The value should be different from the received CRC value of the reference message from sending node.
4. Check that CFDC0ERFL.CERR is 1'b1

As the CRC generator logic is shared for RX and TX there is no need to create a separate TX CRC Error test.

30.10 RAM Area Configuration

The RAM area used in CANFD (refers to as MRAM) can be split into the following groups as shown in [Figure 30.54](#).

- AFL Rule Table area
- PFL Rule Table area
- Message Buffer^{*1} area (RX MB + FIFO Buffer)
- OTB area
- THL area
- TX MB area.

Physically, the RAM is the Message Buffer RAM^{*2} (RX MB, RX FIFO, Common FIFO^{*3} TX MB, THL, OTB, AFL Rule Table, PFL Rule Table).

Note 1. Refers to as MB

Note 2. Refers to as MRAM

Note 3. Refers to as CFIFO

Figure 30.54 RAM area grouping

The MRAM area starts with the TX MB area at address 0x0000. The TX MB area is followed immediately by the THL area which is then followed immediately by the OTB area. The size of the TX MB, THL, and OTB areas is fixed. The OTB area is followed by the Message Buffer area. The Message Buffer area size depends on the configuration of the flat RXMBs, RXFIFOs, and CFIFO. When all are configured, the RX MB area is followed by the RX FIFO area which is followed by the CFIFO area.

The configured MRAM area can then be calculated as follows:

$$\text{MRAM_cfg} = \text{RXMB_MRAM_cfg} + \text{RXFIFO_MRAM_cfg} + \text{CFIFO_MRAM_cfg} + \text{TXMB_MRAM_cfg} + \text{THL_MRAM_cfg} + \text{OTB_MRAM_cfg} + \text{AFL_MRAM_cfg} + \text{PFL_MRAM_cfg}$$

$$\text{RXMB_MRAM_cfg} = (12 \text{ bytes} + \text{CFDRMNB.RMPLS}) \times \text{CFDRMNB.NRXMB}$$

$$\text{RXFIFO_MRAM_cfg} = \text{SUM} ((12 \text{ bytes} + \text{CFDRFCCa.RFPLS}) \times \text{CFDRFCCa.RFDC})$$

$$\text{CFIFO_MRAM_cfg} = (12 \text{ bytes} + \text{CFDCFCC.CFPLS}) \times \text{CFDCFCC.CFDC}$$

$$\text{TXMB_MRAM_cfg} = 304 \text{ bytes}$$

$$\text{THL_MRAM_cfg} = 64 \text{ bytes}$$

$$\text{OTB_MRAM_cfg} = 160 \text{ bytes}$$

$$\text{PFL_MRAM_cfg} = 72 \text{ bytes}$$

$$\text{AFL_MRAM_cfg} = 256 \text{ bytes}$$

“a” means RX FIFO index = [0...no_of_RFIFOs - 1]

no_of_RFIFOs : Number of configured RX FIFOs

Note: For CFDRFCCa.RFDC, CFDCFCC.CFDC, CFDRMNB.RMPLS, CFDRMNB.NRXMB, CFDRFCCa.RFPLS, and CFDCFCC.CFPLS the related number of bytes must be used.

Table 30.29 shows the calculation of the different RAM areas used for the AFL entries, OTB buffers, TX/RX message buffers, RX/Common FIFOs, and PFL entries.

Table 30.29 MRAM area calculation

RAM name	RAM property	RAM area calculation method	RAM values
AFL	Average rule entries	—	16
	Number of bytes in a rule entry	Fixed	16
	Number of bytes in AFL area	Average rule entries × Number of bytes in a rule entry	256
PFL	Average rule entries	—	2
	Number of bytes in a rule entry	Fixed	36
	Number of bytes in PFL area	Average rule entries × Number of bytes in a rule entry	72
TX MB	Number of TX MBs	Fixed	4
	Number of bytes required for each TX MB	Fixed	76
	Number of bytes in TX MB area	Number of TX MBs × Number of bytes required for each TX MB	304
THL	Number of entries in one THL buffer	Fixed	8
	Number of bytes required for each THL entry	Fixed	8
	Number of bytes in THL area	Number of entries in one THL buffer × Number of bytes required for each THL entry	64
OTB	Average number of buffers	—	2
	Number of bytes for OTB entry	Fixed	80
	Number of bytes in OTB area	Average number of buffers × Number of bytes for OTB entry	160
Message Buffer	Number of RX MBs	Fixed	32
	Number of RX FIFOs	Fixed	2
	Number of Common FIFO	Fixed	1
	Average number of messages for RX MB and FIFO buffers	—	16
	Number of bytes for each stored message	Fixed	—
	Average size of a Message Buffer in bytes	—	76
	Number of bytes in Message Pool area	Average number of messages for RX MB and FIFO buffers × Average size of a Message Buffer in bytes	1216
	Number of bytes message RAM	Number of bytes in Message Pool area + Number of bytes in OTB area + Number of bytes in THL area + Number of bytes in TX MB area + Number of bytes in PFL area + Number of bytes in AFL area	2072

30.10.1 Examples

Figure 30.55 shows one possible configuration.

Figure 30.55 RX MB + FIFO buffers RAM area configuration examples

30.10.2 OTB Area

The OTB area starts immediately after the area allocated for THL buffers. The OTB is a special purpose buffer used by the CANFD. This section of RAM area can be accessed only by the CPU in RAM Test mode. Buffer requires 80 bytes and the average number of buffers is 2. Therefore, the total number of bytes allocated for the OTB is 2 × 80 bytes.

30.10.3 RAM Initialization Cycle

The number of RAM initialization cycles and the RAM number of pages are shown in [Table 30.30](#).

Table 30.30 RAM initialization cycle

MRAM area size	RAM initialization cycles [PCLKA cycle]	RAM Test RTMPS range
2072	520	0x0 to 0x8

30.11 Usage notes

30.11.1 Module-stop function

CANFD operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The CANFD module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

31. CANFD ECC (CNECC)

31.1 Overview

MBRAM have ECC function of 2-bit ECC error detection and 1-bit ECC error detection and correction*1. The ECC module adds 7 bits ECC data to 32 bits RAM data.

Note 1. The ECC module cannot detect 3 or more bits error. In this case, the ECC module detects 1-bit or 2-bit error, does not detect errors, or corrects the erroneous bit to erroneous data by setting. When all RAM data are fixed to 0 or 1, it is detected as 2-bit ECC error.

31.2 Register Descriptions

31.2.1 EC710CTL : ECC Control Register

Base address: ECCMBn = 0x4036_F200 + 0x0100 × n (n = 0, 1)
ECCMBn_NS = 0x5036_F200 + 0x0100 × n (n = 0, 1)

Offset address: 0x00

17	ECDEDF0	ECC Dual Bit Error Address Detection Flag 0: There is no bit error in EC710EAD0 after reset or clearing ECER2F bit 1: Address captured in EC710EAD0 shows that 2-bit error occurred and captured	R
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

ECEMF bit (ECC Error Message Flag)

The ECEMF bit shows that there is error in present read data bus. This bit is updated by every RAM output data.

When RAM output data is undefined and the ECERVF bit is set to 1, the value of this bit is undefined.

[Setting condition]

There is bit error in present RAM output data under the condition that error judgement is enabled.

[Clearing condition]

- Under the condition that there is no 1-bit error in input data to decode circuit
- When ECC error judgement is disabled (ECERVF = 0).

ECER1F bit (ECC Error Detection and Correction Flag)

The ECER1F bit shows that the bit errors are detected in the one part of RAM read data [38:0] at RAM read access when the error judgment is enabled.

When the 1-bit error interrupt output is enabled, error interrupt is generated by setting this flag.

This bit is read-only, so writing 1 or 0 has no effect.

At clearing, write 1 to the ECER1C bit.

When 1-bit error is detected again under the condition that this bit is set, the interrupt is not generated.

[Setting condition]

When the error judgment is enabled and there is 1-bit error to RAM output data (when not setting ECER1C = 1).

[Clearing condition]

- Writing ECER1C = 1
- When ECC error judgement is disabled (ECERVF = 0).

ECER2F bit (2-bit ECC Error Detection Flag)

The ECER2F bit shows that the bit errors are detected in the two parts of RAM read data [38:0] at RAM read access when the error judgment is enabled.

When the 2-bit error interrupt output is enabled, error interrupt is generated by setting this flag.

This bit is read-only, so writing 1 or 0 has no effect.

At clearing, write 1 to the ECER2C bit.

When 2-bit error is detected again under the condition that this bit is set, the interrupt is not generated.

[Setting condition]

When the error judgment is enabled and there is 2-bit error to RAM output data (when not setting ECER2C = 1).

[Clearing condition]

- Writing ECER2C = 1
- When ECC error judgement is disabled (ECERVF = 0).

EC1EDIC bit (ECC 1-bit Error Detection Interrupt Control)

The EC1EDIC controls the interrupt output at detecting 1-bit error. By setting 1 to this bit, the 1-bit error interrupt is outputted when 1-bit error detected.

EC2EDIC bit (ECC 2-bit Error Detection Interrupt Control)

The EC2EDIC controls the interrupt output at detecting 2-bit error. By setting 1 to this bit, the 2-bit error interrupt is outputted when 2-bit error detected.

EC1ECP bit (ECC 1-bit Error Correction Permission)

The EC1ECP sets enable or disable to correct the 1-bit error when ECC error detection and correction is valid. By setting 1 to this bit, the non-corrected data is outputted if 1-bit error is detected.

ECERVF bit (ECC Error Judgment Enable Flag)

Setting the ECERVF bit to 1 enables the judgment of error. The correction of output data and the interrupt output depend on setting of the EC1ECP bit, EC2EDIC bit, and EC1EDIC bit.

The write access to this bit is valid when the write value of the EMCA[1:0] is 01b. So only the 16 bits or 32 bits operation command is valid in the case of the write access to this bit.

ECER1C bit (Accumulating ECC Error Detection and Correction Flag Clear)

The ECER1C bit clears the status flag of the ECER1F bit.

The read value is always 0. By writing 0, the internal condition is not changed. When the competition between writing 1 to this bit and setting the ECER1F bit, the former has priority.

The ECER1F bit is cleared by writing 1 to this bit while the ECER1F bit is set. Additionally, the Overflow Detection flag (ECOVFF), ECC Dual Bit Error flag (ECDEDF0) and ECC Single Bit Error flag (ECSEDF0) are also cleared.

ECER2C bit (2-bit ECC Error Detection Flag Clear)

The ECER2C bit clears the status flag of the ECER2F bit.

The read value is always 0. By writing 0, the internal condition is not changed. When the competition between writing 1 to this bit and setting the ECER2F bit, the former has priority.

The ECER2F bit is cleared by writing 1 to this bit while the ECER2F bit is set. Additionally, the Overflow Detection flag (ECOVFF), ECC Dual Bit Error flag (ECDEDF0), and ECC Single Bit Error flag (ECSEDF0) are also cleared.

ECOVFF bit (ECC Overflow Detection Flag)

The ECOVFF bit is set and the overflow interruption is outputted by detecting the new error address under the condition that error address is already captured in the EC710EAD0 register. The overflow interrupt is outputted again when this bit is set and new error is detected.

This bit is read-only, so writing 1 or 0 has no effect.

To clear this bit, write 1 to the ECER2C bit and the ECER1C bit.

[Setting condition]

When new error address is captured under the condition that error address is already captured in the EC710EAD0 register (when not setting ECER2C = 1 or ECER1C = 1).

[Clearing condition]

- Writing ECER2C = 1 or ECER1C = 1
- When ECC error judgement is disabled (ECERVF = 0).

EMCA[1:0] bit (Access Control to ECC Mode Select bit)

The EMCA[1:0] bits are the write trigger reserved bits to the ECERVF bit. The read value is always 0. When the value of these bits is 01b, it is possible to have write access to the ECERVF bit. If these bits are not 01b, write access to the ECERVF bit is ignored and the value is not written.

ECSEDF0 bit (ECC Single bit Error Address Detection Flag)

The ECSEDF0 bit shows that the error is captured in the error address register when error detection is valid. This bit is set by 1-bit error detection.

When 1-bit error is detected after the 2-bit error address is already captured in the EC710EAD0 register, this bit is not updated but the EC710EAD0 register is updated.

This bit is read-only, so writing 1 or 0 has no effect. To clear these bits, write 1 to the ECER1C bit.

[Setting condition]

When there is 1-bit error to RAM output data and error address is captured in EC710EAD0 under the condition that the error judgment is permitted (when not setting ECER1C = 1).

[Clearing condition]

- Writing ECER1C = 1
- When ECC error judgement is disabled (ECERVF = 0).

ECDEDF0 bit (ECC Dual Bit Error Address Detection Flag)

The ECDEDF0 bit shows that the error is captured in the error address register when error detection is valid. This bit is set by 2-bit error detection.

When 2-bit error is detected after the 1-bit error address is already captured in the EC710EAD0 register, this bit is not updated and the EC710EAD0 register is updated.

This bit is read-only, so writing 1 or 0 has no effect. To clear these bits, write 1 to the ECER2C bit.

[Setting condition]

When there is 2-bit error to RAM output data and error address is captured in EC710EAD0 under the condition that the error judgment is permitted (when not setting ECER2C = 1).

[Clearing condition]

- Writing ECER2C = 1
- When ECC error judgement is disabled (ECERVF = 0).

31.2.2 EC710TMC : ECC Test Mode Control Register

Base address: ECCMBn = 0x4036_F200 + 0x0100 × n (n = 0, 1)
ECCMBn_NS = 0x5036_F200 + 0x0100 × n (n = 0, 1)

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ETMA[1:0]	—	—	—	—	—	—	ECTM CE	—	—	—	—	—	—	ECDC S	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	ECDCS	ECC Decode Input Select 0: Input lower 32 bits of RAM output data to data area of decode circuit 1: Input ECEDB31-0 in EC710TED register to data area of decode circuit	R/W
6:2	—	These bits are read as 0. The write value should be 0.	R/W
7	ECTMCE	ECC Test Mode Control Enable 0: The access to test mode register and bit is disabled 1: The access to test mode register and bit is enabled	R/W
13:8	—	These bits are read as 0. The write value should be 0.	R/W
15:14	ETMA[1:0]	ECC Test Mode Bit Access Control These bits enable or disable write access to ECTMCE bit.	R/W

Note: S-TYPE-3, P-TYPE-3

ECDCS bit (ECC Decode Input Select)

The ECDCS bit selects either the lower 32 bits data value from RAM or value from the internal test register (EDEDDB[31:0] in EC710TED) as input signal to decoder.

The write access to this bit is valid under the condition of ECTMCE = 1 (it is possible to set them at the same time.)

This bit is cleared by setting ECTMCE = 0.

ECTMCE bit (ECC Test Mode Control Enable)

The ECTMCE bit selects the access enable or disable to test register and test control bit.

The write access to this bit is valid under the condition that the value of the ETMA[1:0] bits is 10b.

ETMA[1:0] bits (ECC Test Mode Bit Access Control)

The ETMA[1:0] bits are the write trigger reserved bits to the ECTMCE bit. The read value is always 0. When the value of these bits is 10b, it is possible to have write access to the ECTMCE bit. If these bits are not 10b, the write access to the ECTMCE bit is ignored and the value is not written.

31.2.3 EC710TED : ECC Test Substitute Data Register

Base address: ECCMBn = 0x4036_F200 + 0x0100 × n (n = 0, 1)
 ECCMBn_NS = 0x5036_F200 + 0x0100 × n (n = 0, 1)

Offset address: 0x0C

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	ECEDB[31:0]	ECC Test Substitute Data Substitute data in ECC test mode.	R/W

Note: S-TYPE-3, P-TYPE-3

This register is for the 32 bits data for ECC decode. It is possible to read and write using 32 bits operation command when ECTMCE = 1. When ECTMCE = 0, all bits are always 0.

ECEDB[31:0] bits (ECC Test Substitute Data)

When ECDCS in EC710TMC register is 1, the value of this register is bits [31:0] of the input data to the decode circuit.

31.2.4 EC710EAD0 : ECC Error Address Register

Base address: ECCMBn = 0x4036_F200 + 0x0100 × n (n = 0, 1)
 ECCMBn_NS = 0x5036_F200 + 0x0100 × n (n = 0, 1)

Offset address: 0x10

Bit position: 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
9:0	ECEAD[9:0]	ECC Error Address	R

Bit	Symbol	Function	R/W
31:10	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

This is a read-only register to hold the ECC error address.

ECEAD[9:0] bits (ECC Error Address)

When ECC error is detected for permitting ECC error judgment, RAM address is captured by the detected signal as a trigger and is hold as the error occurring address. The error address is not captured when the error occurred again to the one held by the same factor.

If 2-bit error occurred under the condition that 1-bit error address is already captured, the 2-bit error address is over-written and the ECDEDF0 bit is set to 1.

If 1-bit error occurred under the condition that 2-bit error address is already captured, the 1-bit error address is not overwritten and the ECSEDF0 bit is not set to 1.

31.3 Operation

31.3.1 ECC Function Setting

Figure 31.1 shows a procedure for ECC function setting.

Figure 31.1 Setting procedure for ECC function

31.3.2 ECC Decoder Testing

ECC interrupts can be intentionally generated by ECC test mode. [Figure 31.2](#) shows a procedure for ECC decoder testing.

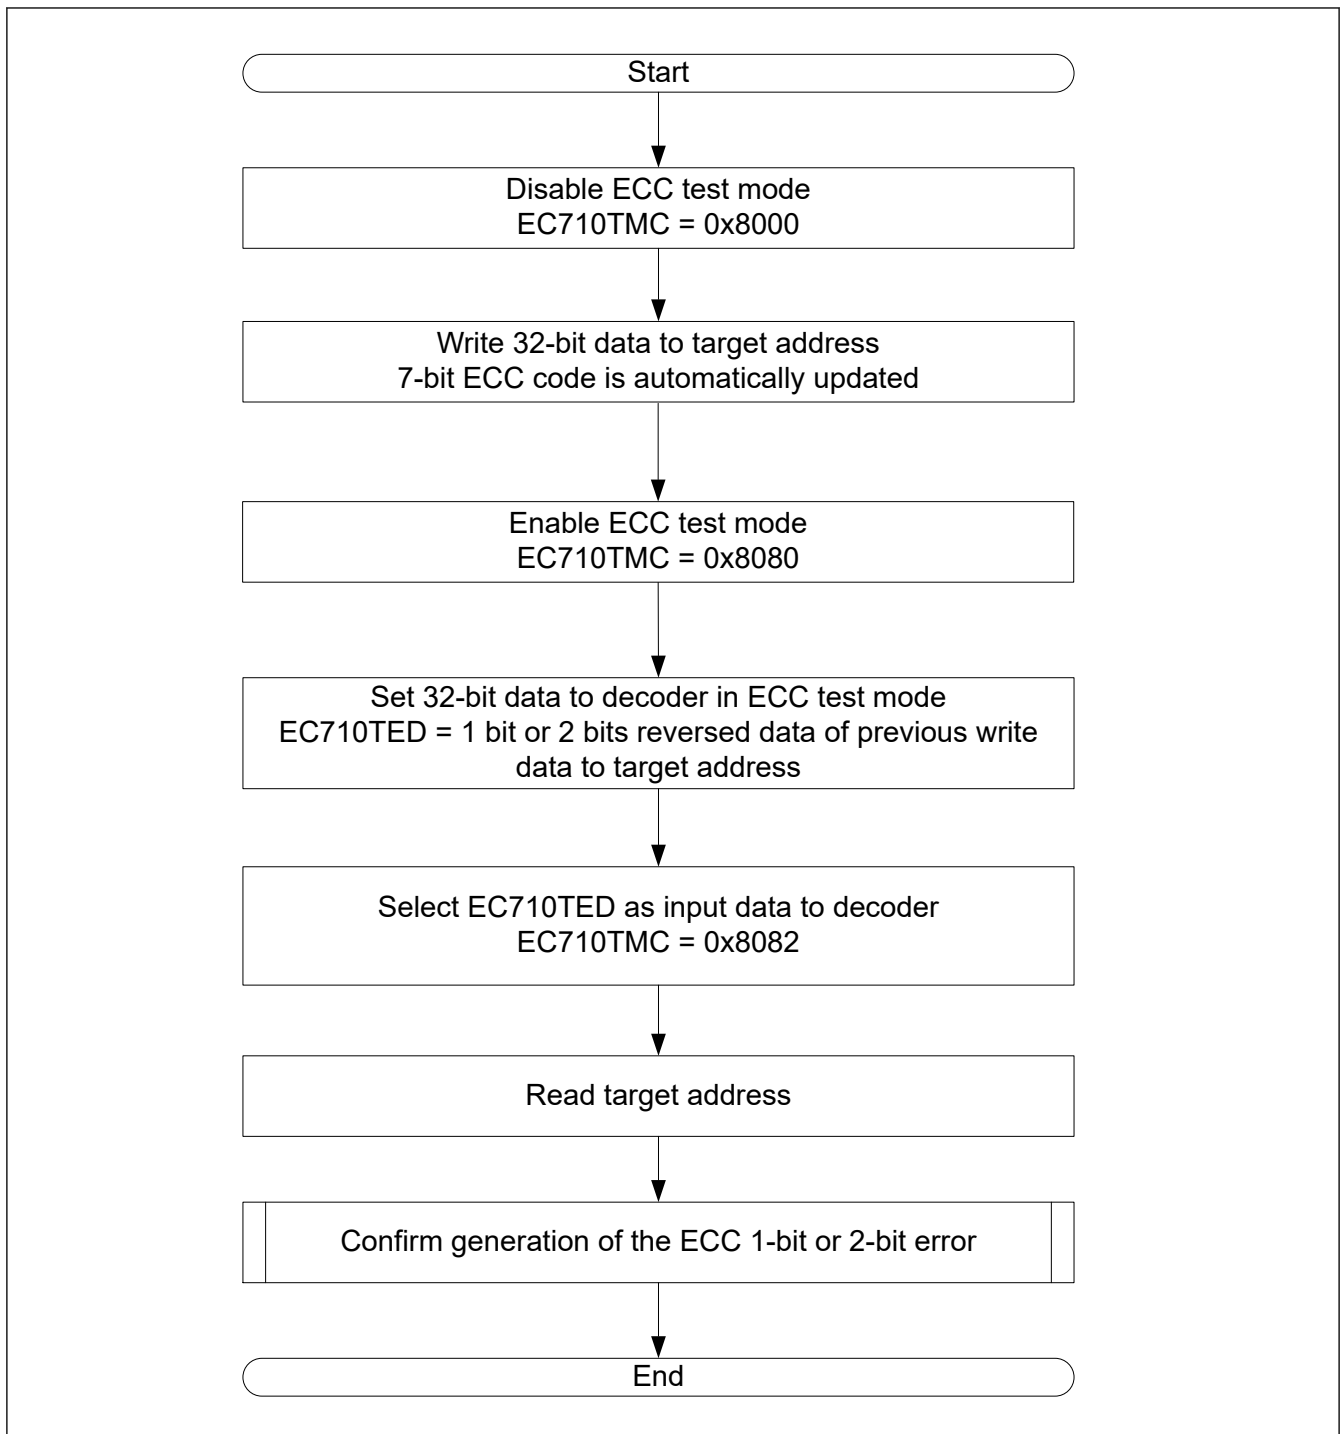

Figure 31.2 Testing procedure for ECC decoder

31.4 Interrupts

The ECC module issues three interrupt requests:

- CAN_n_MRAM_ERI (n = 0, 1)

Interrupt sources of each interrupt request include:

- 1-bit ECC error
- 2-bit ECC error
- ECC error overflow.

32. Serial Peripheral Interface (SPI)

This is the SPI_B version of the SPI peripheral module.

SPI_B is referred to as SPI in this chapter.

32.1 Overview

The Serial Peripheral Interface (SPI) has 2 channels. The SPI provides high-speed full-duplex synchronous serial communications with multiple processors and peripheral devices. [Table 32.1](#) lists the SPI specifications, [Figure 32.1](#) shows a block diagram of SPI, [Figure 32.2](#) shows a clock source selector block diagram and [Table 32.2](#) lists the I/O pins.

In this section, PCLK refers to PCLKA.

Table 32.1 SPI specifications (1 of 2)

Parameter	Specifications
Number of channels	Two channels
SPI transfer functions	<ul style="list-style-type: none"> Use of MOSI (master out/slave in), MISO (master in/slave out), SSL (slave select), and RSPCK (SPI clock) signals allows serial communications through SPI operation (4-wire method) or clock synchronous operation (3-wire method) Transmit-only operation available Receive-only operation is available Communication mode selectable to full-duplex, transmit-only or receive-only RSPCK polarity switching RSPCK phase switching
Data format	<ul style="list-style-type: none"> MSB-first or LSB-first selectable Transfer bit length selectable from 4 to 32 bits 32 bit × 4 stages FIFO is available as transmit buffer or receive buffer Byte swap operating function Transmit/receive data can be inverted.
Operation clock (TCLK)	Synchronized clock (PCLK) or independent clock (SPICLK) can be selected.
Bit rate	<ul style="list-style-type: none"> In master mode, the on-chip baud rate generator generates RSPCK by frequency-dividing TCLK (the division ratio ranges from divided by 2 to divided by 4096) In slave mode, the minimum TCLK clock divided by 2 can be input as RSPCK (TCLK divided by 2 is the maximum RSPCK frequency) Width at high level: 1 TCLK cycle; width at low level: 1 TCLK cycle
Buffer configuration	<ul style="list-style-type: none"> Double buffer configuration for the transmit and receive buffers
Error detection	<ul style="list-style-type: none"> Mode fault error detection Underrun error detection Overrun error detection*¹ Parity error detection Receive data ready detection

Communication protocol	<ul style="list-style-type: none"> Motorola SPI TI SSP(Synchronous Serial Protocol)

Table 32.1 SPI specifications (2 of 2)

Parameter	Specifications
Synchronization bypass function	Synchronization circuit can be bypassed only when the same clock is input to bus clock (PCLK) and operation clock (TCLK).
Control in master transfer	<ul style="list-style-type: none"> • Transfers of up to eight commands each can be executed sequentially in looped execution • For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity and phase, transfer data length, MSB- or LSB-first, burst, RSPCK delay, SSL negation delay, and next-access delay • Transfers can be initiated by writing to the transmit buffer • MOSI signal value specifiable in SSL negation • RSPCK auto-stop function
Interrupt sources	Interrupt sources: <ul style="list-style-type: none"> • Receive buffer full / Receive data ready interrupt • Transmit buffer empty interrupt • SPI error interrupt (mode fault error, under run error, over run error, parity error, receive data ready) • SPI idle interrupt (SPI idle) • Communication end interrupt
Event link function	The following events can be output to the Event Link Controller (ELC): <ul style="list-style-type: none"> • Receive buffer full / receive data ready signal • Transmit buffer empty signal • Mode fault, underrun, overrun, parity error, or receive data ready signal • SPI idle signal • Communication end signal
Other functions	<ul style="list-style-type: none"> • Switching between CMOS output and open-drain output • SPI initialization function • Loopback mode • SPE bit status polling function
Module-stop function	Module-stop state can be set for each channels to reduce power consumption.
TrustZone Filter	Security and Privilege attribution can be set for each channels.

Note 1. In master reception and when the RSPCK auto-stop function is enabled, an overrun error does not occur because the transfer clock is stopped on overrun error detection.

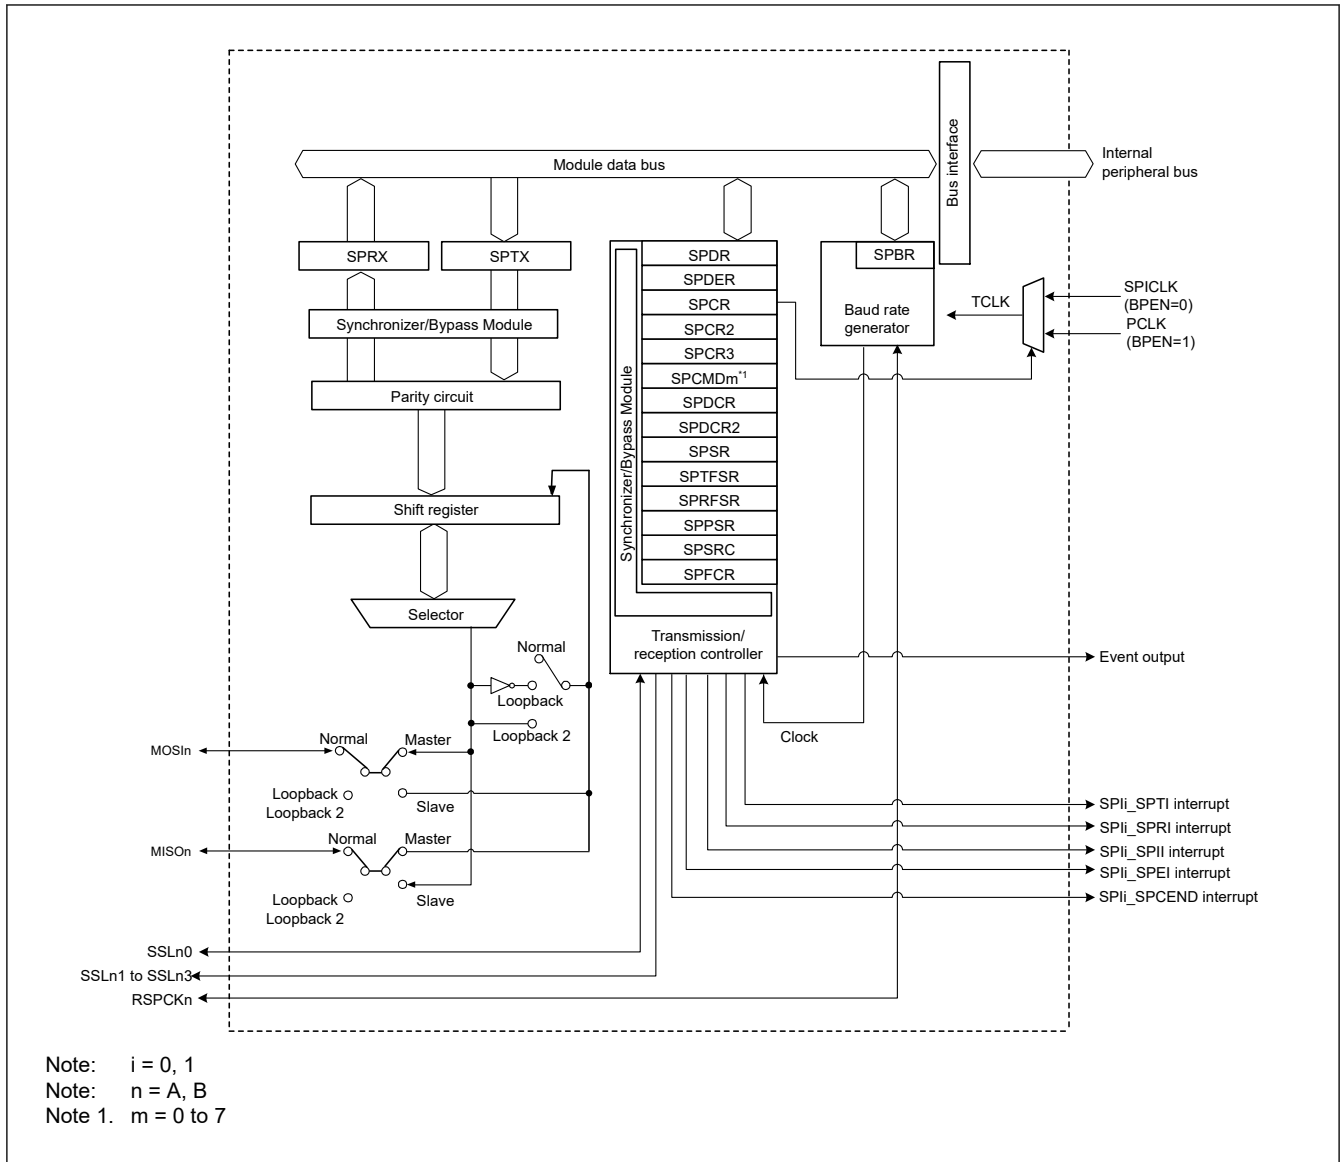

Figure 32.1 SPI block diagram

Figure 32.2 Clock source selector block diagram

The SPI automatically switches the I/O direction of the SSLn0 pin. SSLn0 is set as an output when the SPI is a single master, and as an input when the SPI is a multi-master or a slave. The RSPCKn, MOSIn, and MISO_n pins are automatically set as inputs or outputs based on the master or slave setting and the level input on the SSLn0 pin. For details, see [section 32.3.2. Controlling the SPI Pins](#).

Table 32.2 SPI I/O pins

Channel	Pin name	I/O	Description
SPI0	RSPCKA	I/O	Clock input/output pin
	SSLA0	I/O	Slave selection input/output
	SSLA1 to SSLA3	Output	Slave selection output
	MOSIA	I/O	Master transmit data input/output
	MISOA	I/O	Slave transmit data input/output
SPI1	RSPCKB	I/O	Clock input/output pin
	SSLB0	I/O	Slave selection input/output
	SSLB1 to SSLB3	Output	Slave selection output
	MOSIB	I/O	Master transmit data input/output
	MISOB	I/O	Slave transmit data input/output

Note: Pin names are indicated as "...A" or "...An" for SPI0, and "...B" or "...Bn" for SPI1 (n = 0, 1, 2, or 3).

32.2 Register Descriptions

32.2.1 SPDR : SPI Data Register

Base address: $SPIn_B = 0x4035_C000 + 0x0100 \times n$ ($n = 0, 1$)
 $SPIn_B_NS = 0x5035_C000 + 0x0100 \times n$ ($n = 0, 1$)

Offset address: 0x00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	SPD[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SPD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	SPD[31:0]	These bits are the interface with the buffers that hold data for transmission and reception by the SPI.	R/W

Note: S-TYPE-3, P-TYPE-3

SPDR is the interface with the buffers that hold data for transmission and reception by the SPI. When accessing this register in words, access SPDR. The transmit buffer (SPTX) and receive buffer (SPRX) are independent but both are mapped to SPDR. Figure 32.3 shows the configuration of the SPDR register.

Figure 32.3 Structure of SPDR

32 bits × 4 stage transmit FIFO and 32 bits × 4 stage receive FIFO are provided. These 8 stage FIFO are mapped to one address in the SPDR. Transmit buffers (SPTXn, n = 0 to 3) can be written by writing data to SPDR to transmit written data.

Upon completion of receiving data, receive buffers store received data. When an overrun error occurs, data in the receive buffer is not updated.

(1) Bus Interface

The SPI data register has 32 bits × 4 stage transmit FIFO and 32 bits × 4 stage receive FIFO (32 bytes in total). These 32 bytes are mapped to the 4-byte space of SPDR. Write transmit data from the LSB. Received data is stored from the LSB.

SPDR register write operation and read operation are described below.

1. Write

A transmit buffer write pointer is provided for transmit buffers. When data is written to SPDR, the pointer automatically switches to the next buffer. The following illustrates the structure of the transmit buffer bus interface (write).

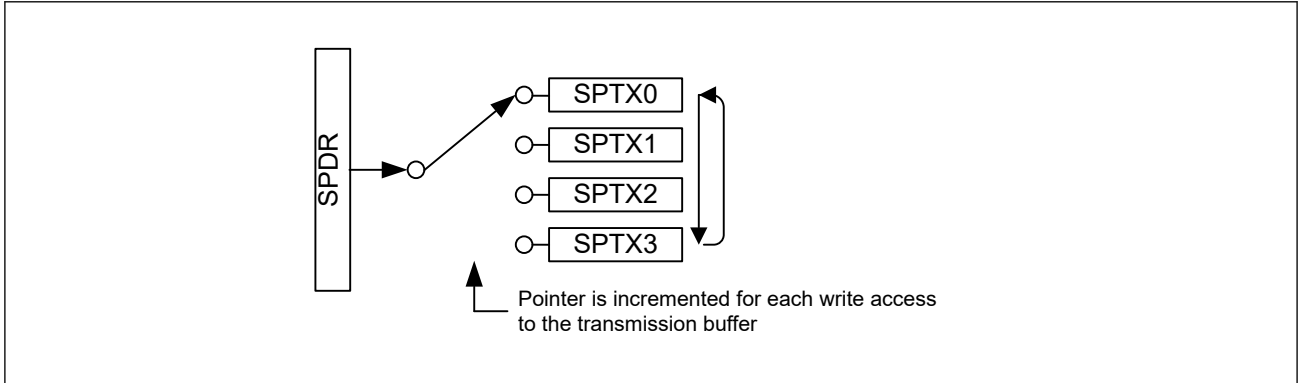

Figure 32.4 Structure of SPDR (Write)

The transmit buffer (SPTX0 to SPTX3) switching order:
 SPTX0→SPTX1→SPTX2→SPTX3→SPTX0→SPTX1→...

When writing transmit data to transmit buffers (SPTX_n), write transmit data of frames +1 specified by the Transmission FIFO threshold setting bits of SPI data control register 2 (SPDCR2.TTRG[1:0]) while an SPI transmit buffer empty interrupt is present (SPSR.SPTEF flag = 1). Writing to the transmit buffer (SPTX_n, n = 0 to 3) in the state where there is no empty stage in the transmit FIFO does not update the buffer value.

2. Read

Values can be read from receive buffers (SPRX_n, n = 0 to 3) or transmit buffers (SPTX_n, n = 0 to 3) by reading the SPDR register. Reading a receive buffer or reading a transmit buffer can be selected by the SPI receive data or transmit data select bit (SPDCR.SPRDTD) in the SPI data control register.

The SPDR register is read according to the independent receive buffer read pointer and the transmit buffer read pointer. The following illustrates the structure of the receive buffer and transmit buffer bus interface (read).

Figure 32.5 Structure of SPDR (Read)

When a receive buffer is read, the receive buffer read pointer automatically switches to the next buffer. The receive buffer read pointer switches in the same order as the transmit buffer write pointer. The transmit buffer read pointer is updated during the SPDR write access, but it is not updated during the transmit buffer read access. When a transmit buffer is read, the value written to SPDR last can be read.

32.2.2 SPDECR : SPI Delay Control Register

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)

31:19	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

SCKDL[2:0] bit (RSPCK Delay)

[In the Motorola-SPI case]

The RSPCK delay bits (SCKDL) are used to set the period (RSPCK delay) from SSL signal assertion start until RSPCK oscillates while the SCKDEN bit in the SPI command register (SPCMD) is 1. If SCKDL is modified while the MSTR bit and the SPE bit in the SPI control register (SPCR) are 1, subsequent operation is not guaranteed.

To use the SPI in slave mode, set SCKDL[2:0] bits to 000b.

[In the TI-SSP case]

The RSPCK delay bits (SCKDL) are used to set the period (RSPCK delay) from SSL signal assertion start until RSPCK oscillates while the SCKDEN bit in the SPI command register (SPCMD) is 1. Also that is used to set the period until the SSL signal is negated. If SCKDL is modified while the MSTR bit and the SPE bit in the SPI control register (SPCR) are 1, subsequent operation is not guaranteed.

To use the SPI in slave mode, set SCKDL[2:0] bits to 000b.

SLNDL[2:0] bit (SSL Negation Delay)

[In the Motorola-SPI case]

The SSL negation delay bits (SLNDL) are used to set the period (SSL negation delay) after the SPI in master mode sends the final RSPCK edge during serial transfer until it negates the SSL signal while the SLNDEN bit in the SPI command register (SPCMD) is 1. If SLNDL is modified while the MSTR bit and the SPE bit in the SPI control register (SPCR) are 1, subsequent operation is not guaranteed.

To use the SPI in slave mode except TI-SSP, set SLNDL[2:0] bits to 000b.

[In the TI-SSP case]

The SSL negation delay bits (SLNDL) are used to set the period (OE negation delay) after the SPI in master mode sends the final RSPCK edge during serial transfer until it negates the OE signal while the SLNDEN bit in the SPI command register (SPCMD) is 1. Also, that is used to set the period from when the SPI in slave mode detects the last RSPCK edge of serial transfer to when the OE signal is negated. If SLNDL is modified while the SPE bit in the SPI control register (SPCR) are 1, subsequent operation is not guaranteed.

SPNDL[2:0] bit (SPI Next-Access Delay)

The SPI next-access delay register (SPDECR.SPNDL) is used to set the SSL signal inactive period (next-access delay) after completion of serial transfer while the SPNDEN bit in the SPI command register (SPCMD) is 1. If SPNDL is modified while the MSTR bit and the SPE bit in the SPI control register (SPCR) are 1, subsequent operation is not guaranteed.

These bits are used to set the next-access delay value when the SPNDEN bit in SPCMD is 1. To use the SPI in slave mode, set SPNDL[2:0] bits to 000b.

32.2.3 SPCR : SPI Control Register

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x08

27:26	—	These bits are read as 0. The write value should be 0.	R/W
29:28	TXMD[1:0]	Communication Mode Select 0 0: Transmit-Receive 0 1: Transmit only Others: Receive only	R/W
30	MSTR	SPI Master/Slave Mode Select 0: Slave mode 1: Master mode	R/W
31	BPEN	Synchronization Circuit Bypass Enable 0: Non-Bypass 1: Bypass	R/W

Note: S-TYPE-3, P-TYPE-3

The SPI control register (SPCR) is used to set operating mode of the SPI. If the set BPEN, MSTR, TXMD[1:0], SPFRF, SPMS, MODFEN, BFDS, SCKASE, PTE, SPOE, SPPE bit value is modified while the SPE bit = 1, subsequent operation is not guaranteed.

SPE bit (SPI Function Enable)

This bit is used to enable or disable SPI functions. Setting this bit to 1 enables SPI functions. When the MODF flag in the SPI status register (SPSR) is 1, the SPE bit is cleared to 0 and the SPE bit cannot be set to 1 until the MODF flag is cleared to 0. (See [section 32.3.10. Error Detection](#)) Setting the SPE bit to 0 disables SPI functions and initializes a part of module functions. (See [section 32.3.11. Initializing the SPI](#))

SPPE bit (Parity Enable)

This bit is used to enable or disable the parity function.

SPOE bit (Parity Mode)

This bit is used to specify even parity or odd parity.

In even parity mode, the parity bit is determined so that the sum of 1 (parity bit + transmit characters or receive characters) becomes an even number. In the same way, in odd parity mode, a parity bit is determined so that the sum of 1 (parity bit + transmit characters or receive characters) becomes an odd number. The SPOE bit is valid only when the SPPE bit in SPCR is set to 1.

PTE bit (Parity Self-Diagnosis Enable)

This bit is used to enable or disable self-diagnosis of the parity circuit to confirm that the parity function is normal.

SCKASE bit (RSPCK Auto-Stop Function Enable)

This bit is used to enable or disable the RSPCK auto-stop function. When this function is enabled, the RSPCK clock stops immediately before an overrun error occurs during data reception in master mode. For details, see [section 32.3.10.1. Overrun errors](#).

BFDS bit (Between Burst Transfer Frames Delay Select)

This bit controls whether insert the delay time between the burst transfer frames.

Valid in the master mode (SPCR.MSTR = 1) for frames with the SPCMDn.SSLKP bit set to 1.

This bit should be set to 0 in slave mode. The usage of SSL delay control between transfer frames is shown as below. For details, see [section 32.3.12.1. Master mode operation](#).

1. Non-burst transmits
2. Burst transmit with delay between frames
 - 2-1. From the 1st frame to the last previous frame
 - 2-2. The last frame
3. Burst transmit with no delay between frames
 - 3-1. From the 1st frame to the last previous frame

3-2. The last frame

Table 32.3 Usage of SSL delay control between transfer frames (Master mode)

	SPCMDn. SSLKP bit	SPCR.BF DS bit	SSL delay control register*1 (RSPCK clock delay, SSL negation delay, next access delay)
1	0	0	Any given value. You can control each delay value according to setting for RSPCK clock delay, SSL negation delay and next access delay
2-1	1	0	
2-1	0	0	
3-1	1	1	Any given value. But delay is inserted only below. <ul style="list-style-type: none"> RSPCK clock delay of the 1st frame SSL negation delay and next access delay of the last frame
3-2	0	1	

Note 1. Whether the setting value of following bits are valid or not depends on the setting value of the SPCMD.SPNDEN bit. (See [section 32.2.6. SPCMDm : SPI Command Register \(m = 0 to 7\).](#))
The SPDECR.SCKDL[2:0] bits: RSPCK delay
The SPDECR.SLNDL[2:0] bits: SSL negate delay
The SPDECR.SPNDL[2:0] bits: Next access delay

< Setting / operation example > (Motorola SPI, BFDS = 1 Case)

SPCMD0.SSLKP = 1 → Burst transfer / no interframe delay between 0 and 1 (SSL keep active)

SPCMD1.SSLKP = 1 → Burst transfer / no interframe delay between 1 and 2 (SSL keep active)

SPCMD2.SSLKP = 1 → Burst transfer / no interframe delay between 2 and 3 (SSL keep active)

SPCMD3.SSLKP = 1 → Burst transfer / no interframe delay between 3 and 4 (SSL keep active)

SPCMD4.SSLKP = 0 → do not Burst Transfer, and inactive SSL. (BFDS setting is invalid because it does not Burst Transfer.)

SPCMD5.SSLKP = 1 → Burst transfer / no interframe delay between 5 and 6 (SSL keep active)

SPCMD6.SSLKP = 1 → Burst transfer / no interframe delay between 6 and 7 (SSL keep active)

SPCMD7.SSLKP = 0 → do not Burst Transfer, and inactive SSL. (BFDS setting is invalid because it does not Burst Transfer.)

MODFEN bit (Mode Fault Error Detection Enable)

This bit is used to enable or disable detection of a mode fault error. (See [section 32.3.10. Error Detection.](#)) The SPI determines SSL0 pin input or output direction according to the combination of the MODFEN and MSTR bits. (See [section 32.3.2. Controlling the SPI Pins.](#))

SPEIE bit (SPI Error Interrupt Enable)

This bit is used to enable or disable an SPI error interrupt request when the SPI detects a mode fault error or an underrun error and sets the MODF flag in the SPI status register (SPSR) to 1, when the SPI detects an overrun error and sets the OVRF flag in SPSR to 1, or when the SPI detects a parity error and sets the PERF flag in SPSR to 1. (See [section 32.3.10. Error Detection](#))

SPRIE bit (SPI Receive Buffer Full Interrupt Enable)

This bit is used to enable or disable a receive buffer full interrupt request of the SPI.

SPIIE bit (SPI Idle Interrupt Enable)

This bit is used to enable or disable an idle interrupt request of the SPI after the SPI detects the idle state and sets the IDLNF flag in the SPI status register (SPSR) to 0.

SPDRES bit (SPI receive data ready error select)

When a receive data ready is detected (SPSR.SPDRF = 1), select whether to use SPI_i_SPRI (i = 0, 1) interrupt request or SPI_i_SPEI (i = 0, 1) interrupt request.

SPTIE bit (SPI Transmit Buffer Empty Interrupt Enable)

This bit is used to enable or disable a transmit buffer empty interrupt request of the SPI.

A transmit buffer empty interrupt request at the beginning of transmission is generated by setting the SPE bit to 1 simultaneously when or after the SPTIE bit is set to 1. Note that a transmit buffer empty interrupt is generated while the SPTIE bit is 1 even though SPI functions are disabled (SPE bit = 0).

CENDIE bit (SPI Communication End Interrupt Enable)

This bit controls generation of a communication end interrupt request.

SPMS bit (SPI Mode Select)

This bit is used to select SPI operation (4-wire) or clock synchronous operation (3-wire).

For clock synchronous operation, the SSL pin is not used but three pins RSPCK, MOSI, and MISO are used for communication. When SPMS = 1 (clock synchronous operation (3-wire)), the setting of the SPFRF bit is invalid.

To perform clock synchronous operation in master mode (SPCR.MSTR = 1), set the CPHA bit in the SPI command register (SPCMD) to 0 or 1. To perform clock synchronous operation in slave mode (SPCR.MSTR = 0), set the CPHA bit to 1. If this bit is set to 0 for clock synchronous operation in slave mode (SPCR.MSTR = 0), subsequent operation is not guaranteed.

The communication status according to the settings of the MSTR bit, TXMD[1:0] bits, SPFRF bit, and SPMS bit of the SPI control register (SPCR) as follows.

Table 32.4 SPI Communication Status

SPCR.MSTR	SPCR.TXMD[1]	SPCR.TXMD[0]	SPCR.SPFRF	SPCR.SPMS	Communication Status	Communication Status No
1	0	0	0	0	Transmit-Receive Master / Motorola SPI / SPI operation (4-wire)	1-(1)
1	0	0	1	0	Transmit-Receive Master / TI-SSP / SPI operation (4-wire)	1-(2)
1	0	0	—	1	Transmit-Receive Master / Clock synchronous operation (3-wire)	1-(3)
1	0	1	0	0	Transmit only Master / Motorola SPI / SPI operation (4-wire)	1-(4)
1	0	1	1	0	Transmit only Master / TI-SSP / SPI operation (4-wire)	1-(5)
1	0	1	—	1	Transmit only Master / Clock synchronous operation (3-wire)	1-(6)
1	1	—	0	0	Receive only Master / Motorola SPI / SPI operation (4-wire)	1-(7)
1	1	—	1	0	Receive only Master / TI-SSP / SPI operation (4-wire)	1-(8)
1	1	—	—	1	Receive only Master / Clock synchronous operation (3-wire)	1-(9)
0	0	0	0	0	Transmit-Receive Slave / Motorola SPI / SPI operation (4-wire) (default)	0-(1)
0	0	0	1	0	Transmit-Receive Slave / TI-SSP / SPI operation (4-wire)	0-(2)
0	0	0	—	1	Transmit-Receive Slave / Clock synchronous operation (3-wire)	0-(3)
0	0	1	0	0	Transmit only Slave / Motorola SPI / SPI operation (4-wire)	0-(4)
0	0	1	1	0	Transmit only Slave / TI-SSP / SPI operation (4-wire)	0-(5)
0	0	1	—	1	Transmit only Slave / Clock synchronous operation (3-wire)	0-(6)
0	1	—	0	0	Receive only Slave / Motorola SPI / SPI operation (4-wire)	0-(7)
0	1	—	1	0	Receive only Slave / TI-SSP / SPI operation (4-wire)	0-(8)
0	1	—	—	1	Receive only Slave / Clock synchronous operation (3-wire)	0-(9)

SPFRF bit (SPI Frame Format Select)

This bit selects the communication protocol.

The format of the SPI terminal (RSPCK, SSL0 to 7) can be set according to the set communication protocol.

When SPMS = 1 (clock synchronous operation (3-wire)), this bit is invalid because SSL is not used.

TXMD[1:0] bit (Communication Mode Select)

This bit is used to select the transmit-receive, transmit-only, and receive-only serial communication.

When TXMD[1:0] is set to 01 for communication, transmit-only is performed without reception.

When TXMD[1] is set to 1 for communication, receive-only is performed without transmission.

When TXMD[1:0] is set to 01 for communication, a receive buffer full interrupt request cannot be used.

When TXMD[1] is set to 1 for communication, a transmit buffer empty interrupt request cannot be used.

(See [section 32.3.6. Communication Operating Mode.](#))

MSTR bit (SPI Master/Slave Mode Select)

This bit is used to select master mode or slave mode of the SPI. The SPI determines input/output directions of pins RSPCK, MOSI, MISO, and SSL1 to SSL3 according to the MSTR bit setting.

BPEN bit (Synchronization Circuit Bypass Enable)

This bit selects whether to enable or disable the synchronization bypass function. Set this bit to 1 when the bus clock (PCLK) is also used as operation clock (TCLK), see [Figure 32.2.](#)

32.2.4 SPCR2 : SPI Control Register 2

Base address: SPln_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
 SPln_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x0C

21	MOIFE	MOSI Idle Fixed Value Enable 0: The MOSI output value is the last data of previous transfer. 1: The MOSI output value is the set MOIFV bit value.	R/W
31:22	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. See SW flow in the [section 32.3.12.1. Master mode operation.](#)

RMFM[4:0] bit (Frame processing count setting in Master Receive only)

The number of received frames can be adjusted when operating in master receive only. Valid only when the master mode (SPCR.MSTR = 1) and the communication operation mode select bits (SPCR.TXMD [1:0]) are 10b.

Only the start bit in master mode reception automatically stops communication after starts frame processing according to the value set in this bit after reception starts.

If the RMFM [4:0] bits are rewritten while the SPE bit of the SPI control register (SPCR) is 1, subsequent operations are not guaranteed.

RMEDTG bit (End Trigger in Master Receive only)

This bit is used to end reception when master receive only. Valid only when the master mode (SPCR.MSTR = 1) and the communication mode select bits (SPCR.TXMD [1:0]) are 10b.

RMSTTG bit (Start Trigger in Master Receive only)

This bit is used to start reception when master receive only. Valid only when the master mode (SPCR.MSTR = 1) and the communication mode select bits (SPCR.TXMD [1:0]) are 10b.

Writing 1 to this bit during reception is not accepted. Write again after reception is completed.

SPDRC[7:0] bit (SPI received data ready detect adjustment)

The receive data ready detection function can be disabled or, if used, the period until detection can be set from 1 to 255 TCLK.

The value set in the SPDRC [7:0] bits is used to 1 set the SPDRF flag. For details, see the description of SPDRF in [section 32.2.9. SPSR : SPI Status Register.](#)

If the set value is changed while the SPE bit is 1, subsequent operations are not guaranteed.

SPLP bit (SPI Loopback)

When the SPLP bit is set to 1, the SPI shuts down the route between the MISO pin and the shift register (when the MSTR bit in the SPI control register is 1) or shuts down the route between the MOSI pin and the shift register, inverts the input route value in the shift register, and then connects the route to the output route (when the MSTR bit in the SPI control register is 0) (loopback mode).

SPLP2 bit (SPI Loopback 2)

When the SPLP2 bit is set to 1, the SPI shuts down the route between the MISO pin and the shift register (when the MSTR bit in the SPI control register is 1) or shuts down the route between MOSI pin and the shift register and then connects the route to the output route without inverting the input route value in the shift register (when the MSTR bit in the SPI control register is 0) (loopback mode). If this bit is set to 1 together with the SPLP bit, setting this bit takes precedence.

MOIFV bit (MOSI Idle Fixed Value)

This bit is used to select the MOSI pin output value during the SSL negation period (including SSL retention period in burst transfer) when the MOIFE bit is 1 in master mode.

If this bit is modified with the SPE bit in the SPI control register (SPCR) set to 1, subsequent operation is not guaranteed.

MOIFE bit (MOSI Idle Fixed Value Enable)

This bit is used for the SPI in master mode to fix the MOSI output value during the SSL negation period (including SSL retention period in burst transfer). When MOIFE bit = 0, the SPI outputs the last data of the previous serial transfer to MOSI during the SSL negation period. When MOIFE bit = 1, the SPI outputs the fixed MOIFV bit value to MOSI.

If this bit is modified with the SPE bit in the SPI control register (SPCR) set to 1, subsequent operation is not guaranteed.

32.2.5 SPCR3 : SPI Control Register 3

Base address: $SPIn_B = 0x4035_C000 + 0x0100 \times n$ (n = 0, 1)

R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

SSLiP bits (SSL Signal Polarity Bits)

These bits are used to specify the polarity of SSL signals. The set SSLiP bit (i = 0 to 3) values indicate the active polarity of SSLi signals.

If any of these SSLiP bits is modified with the SPE bit in the SPI control register (SPCR) set to 1, subsequent operation is not guaranteed.

Note: SSL0 is different from SSL1-SSL3. When slave or multi-master, it functions as an input.

For details, see [section 32.3.3.2. Single-master/single-slave with the MCU as a slave](#), and [section 32.3.3.5. Multi-master/multi-slave with the MCU as a master](#).

SPBR[7:0] bit (SPI Bit Rate)

The SPI bit rate bits (SPBR) is used to set the bit rate in master mode. If SPBR is modified while the MSTR bit in the SPI control register (SPCR) is 1, subsequent operation is not guaranteed.

When the SPI is used in slave mode, the bit rate depends on the input clock bit rate regardless of the SPCMD.BRDV setting. (Specify a bit rate that meets electrical characteristics.)

The bit rate is determined by a combination of the set SPBR value and the set BRDV[1:0] bits value in the SPI command register (SPCMD0 to SPCMD7).

The bit rate is calculated by the following expression, where n is the set SPBR value (0 to 255) and N is the set BRDV[1:0] bits value (0 to 3).

$$\text{Bit rate} = \frac{f(\text{TCLK})}{2 \times (n + 1) \times 2^N}$$

The following table shows an example of correspondence between bit rates and set values of SPBR and BRDV[1:0].

Table 32.5 Corresponding Between Bit Rates and Set Values (Example)

SPBR Value (n)	BRDV Value (N)	Division Ratio	Bit Rate				
			TCLK = 32 MHz	TCLK = 36 MHz	TCLK = 40 MHz	TCLK = 50 MHz	TCLK = 120MHz
0	0	2	16.0 Mbps	18.0 Mbps	20.0 Mbps	25.0 Mbps	60.0Mbps
1	0	4	8.00 Mbps	9.00 Mbps	10.0 Mbps	12.5 Mbps	30.0Mbps
2	0	6	5.33 Mbps	6.00 Mbps	6.67 Mbps	8.33 Mbps	20.0Mbps
3	0	8	4.00 Mbps	4.50 Mbps	5.00 Mbps	6.25 Mbps	15.0Mbps
4	0	10	3.20 Mbps	3.60 Mbps	4.00 Mbps	5.00 Mbps	12.0Mbps

5	1	24	1.33 Mbps	1.50 Mbps	1.67 Mbps	2.08 Mbps	5.0Mbps
5	2	48	677 kbps	750 kbps	833 kbps	1.04 Mbps	2.5Mbps
5	3	96	333 kbps	375 kbps	417 kbps	521 kbps	1.25Mbps
255	3	4096	7.81 kbps	8.80 kbps	9.78 kbps	12.2 kbps	29.3kbps

SPSLN[2:0] bit (SPI Sequence Length)

These bits are used to set the sequence length for the SPI in master mode to perform sequence operation. According to the sequence length specified by SPSLN[2:0] bits, the SPI in master mode changes SPI command registers 0 to 7 (SPCMD0 to SPCMD7) to be referenced and the reference sequence. For details, see [section 32.3.13.1. Master mode operation](#).

The SPI in slave mode always references SPCMD0.

32.2.6 SPCMDm : SPI Command Register (m = 0 to 7)

Base address: SPln_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPln_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x14 + 0x04 × m

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	SSLA[2:0]			—	—	—	SPB[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	SCKD EN	SLND EN	SPND EN	LSBF	—	—	—	—	SSLK P	—	—	—	BRDV[1:0]		CPOL	CPHA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CPHA	RSPCK Phase 0: Data is sampled at an odd edge and changes at an even edge. 1: Data changes at an odd edge and is sampled at an even edge.	R/W
1	CPOL	RSPCK Polarity 0: RSPCK in idle state is 0. 1: RSPCK in idle state is 1.	R/W

26:24	SSLA[2:0]	SSL Signal Assertion 0 0 0: SSL0 0 0 1: SSL1 0 1 0: SSL2 0 1 1: SSL3 Others: Setting prohibited	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The SPI has eight SPI command registers (SPCMD0 to SPCMD7) that are used to set the transfer format of the SPI in master mode. Furthermore, some bits in SPCMD0 are used to set the transfer format of the SPI in slave mode. The SPI in master mode sequentially references SPCMD0 to SPCMD7 according to the setting of the SPSLN[2:0] bits in the SPI Control register 3 (SPCR3), and then performs serial transfer specified in the referenced SPCMD.

SPI set the SPCMD register before setting data to be transmitted by referencing the SPCMD when the transmit buffer is empty (while the next-transfer data has not been set).

The SPCMD referenced by the SPI in master mode is indicated by SPCP[2:0] in the SPI status register (SPSR). If SPCMD0 is modified while the SPI in slave mode is enabled (SPCR.SPE = 1), subsequent operation is not guaranteed.

CPHA bit (RSPCK Phase)

This bit is used to set the RSPCK phase of the SPI in master mode or slave mode. To perform data communication between SPI modules, the same RSPCK phase must be set for both modules.

When SPCR.SPMS = 0 and SPCR.SPFRF = 1 (in TI SSP mode), setting CPHA = 0 is invalid.

CPOL bit (RSPCK Polarity)

This bit is used to set the RSPCK polarity of the SPI in master mode or slave mode. To perform data communication between SPI modules, the same RSPCK polarity must be set for both modules.

BRDV[1:0] bit (Bit Rate Division)

This register is used to determine the bit rate with a combination of the set values of the BRDV[1:0] bits and the SPI bit rate register (SPCR3.SPBR). The set SPBR value determines the base bit rate. The set BRDV[1:0] bits value is used to select undivided, 2-divided, 4-divided, or 8-divided base bit rate. SPCMD0 to SPCMD7 enable setting of different BRDV[1:0] values. This makes it possible to perform serial transfer with a different bit rate for each command.

SSLKP bit (SSL Signal Level Hold)

This bit is used to set whether to hold or negate the SSL signal level of the current command during a period from the SSL negation timing for the current command to the SSL assertion timing for the next command when the SPI in master mode performs serial transfer. Setting this bit to 1 enables burst transfer in SPI operation master mode. For details, see [section 32.3.12.1. Master mode operation](#).

To use the SPI in slave mode, set SSLKP bit to 0.

LSBF bit (SPI LSB First)

This bit is used to set the data format of the SPI in master mode or slave mode to MSB first or LSB first.

SPNDEN bit (SPI Next-Access Delay Enable)

This bit is used to set the period (next-access delay) after the SPI in master mode inactivates the SSL signal at the end of serial transfer until it enables SSL signal assertion of the next access. When SPNDEN bit = 0, the SPI sets the next-access delay to 1 RSPCK + 5TCLK. When SPNDEN bit = 1, the SPI inserts the next-access delay in accordance with the SPI next-access delay register (SPDECR.SPNDL) setting.

To use the SPI in slave mode, set SPNDEN bit to 0.

SLNDEN bit (SSL Negation Delay Setting Enable)

[In the Motorola-SPI case]

This bit is used to set the period (SSL negation delay) after the SPI in master mode stops RSPCK oscillation until it inactivates the SSL signal. When SLNDEN bit = 0, the SPI sets the SSL negation delay to 1 RSPCK. When SLNDEN bit = 1, the SPI negates the SSL signal with the RSPCK delay in accordance with the slave select negation delay register (SPDECR.SLNDL) setting.

To use the SPI in slave mode, set SLNDEN bit to 0.

[In the TI-SSP case]

This bit is used to set the period from when the master mode SPI stops RSPCK oscillation to when the OE signal is inactivated, or when the slave mode SPI detects the last edge of RSPCK and then negates the OE signal. When the SLNDEN bit is 0, the SSL negate delay is 1 RSPCK in master mode and 1 TCLK in slave mode. When SLNDEN bit = 1, the SPI negates the SSL signal with the RSPCK delay in accordance with the slave select negation delay register (SPDECR.SLNDL) setting.

When using SPI in slave mode except TI SSP setting, set the SLNDEN bit to 0.

SCKDEN bit (RSPCK Delay Setting Enable)

[In the Motorola-SPI case]

This bit is used to set the period (RSPCK delay) after the SPI in master mode activates the SSL signal until it oscillates RSPCK. When SCKDEN bit = 0, the SPI sets the RSPCK delay to 1 RSPCK. When SCKDEN bit = 1, the SPI starts RSPCK oscillation with the RSPCK delay in accordance with the RSPCK delay register (SPDECR.SCKDL) setting.

To use the SPI in slave mode, set SCKDEN bit to 0.

[In the TI-SSP case]

This bit is used to set the period from the start of assertion of the SSL signal to the RSPCK oscillation (RSPCK delay) and the period of the SSL signal to negation by the SPI in master mode. When SCKDEN bit = 0, the SPI does not set the RSPCK delay. When SCKDEN bit = 1, the SPI starts RSPCK oscillation with the RSPCK delay in accordance with the RSPCK delay register (SPDECR.SPCKDL) setting.

To use the SPI in slave mode, set SCKDEN bit to 0.

SPB[4:0] bit (SPI Data Length)

These bits are used to set the transfer data length of the SPI in master mode or slave mode.

SSLA[2:0] bit (SSL Signal Assertion)

These bits are used to control SSL signal assertion for the SPI in master mode to perform serial transfer. The set SSLA[2:0] bits value controls assertion of the SSL3 to SSL0 signals. The signal polarity when the SSL signal is asserted depends on the set value of the SPI slave select polarity register (SPCR3.SSLiP). When SSLA[2:0] bits are set to 000b in multi-master mode, serial transfer is performed with all SSL signals negated (because SSL0 is input).

To use the SPI in slave mode, set SSLA[2:0] bits to 000b.

32.2.7 SPDCR : SPI Data Control Register

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
 SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x40

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	SPFC[1:0]	—	—	—	SINV	SPRD TD	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BYSW	Byte Swap Operating Mode Select 0: Byte Swap OFF 1: Byte Swap ON	R/W
2:1	—	These bits are read as 0. The write value should be 0.	R/W
3	SPRDTD	SPI Receive Data or Transmit Data Select 0: The SPDR reads the receive buffer. 1: The SPDR reads the transmit buffer	R/W
4	SINV	Serial data invert bit 0: Not invert serial data 1: Invert serial data.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
9:8	SPFC[1:0]	Frame Count 0 0: 1 frame 0 1: 2 frames 1 0: 3 frames 1 1: 4 frames	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The SPI data control register (SPDCR) controls the data format.

If the value set in this register is changed while the SPE bit is 1, subsequent operations are not guaranteed.

BYSW bit (Byte Swap Operating Mode Select)

It is a setting bit, that is to swap a transmit/receive data in byte units. A data after byte swap is different by a data length (setting of SPCMD.SPB[4:0]).

When byte swap, A data length (setting of SPB[4:0]) must be set to 32bit or 16bit. Other case of data length (i.e. 4 to 15, 17 to 31-bit length), byte swap is not guaranteed. For the arrangement of data before and after swapping data lengths of 32 bits and 16 bits, see [section 32.3.4.3. Byte Swap Transmission](#) and [section 32.3.4.4. Byte Swap Reception](#).

When the parity function set to valid, the behavior is not guaranteed.

SPRDTD bit (SPI Receive Data or Transmit Data Select)

This bit is used to select receive buffer or transmit buffer from which the SPI data register (SPDR) value is read.

When the transmit buffer is read, the value that was written to SPDR immediately before is read.

SINV bit (Serial data invert bit)

This bit is used to invert transmit data and receive data.

When the SINV bit is set to 1, transmit buffer (SPTX) data is inverted to invert transmit data and receive data, and then the inverted data is stored in the receive buffer (SPRX). The parity bit is the value corresponding to the inverted transmission/reception data.

SPFC[1:0] bit (Frame Count)

Used for the condition to set the CENDF flag in slave receive only mode.

For details on the CENDF flag setting conditions, see [section 32.2.9. SPSR : SPI Status Register](#).

Note that this bit is invalid except in the slave receive only mode.

32.2.8 SPDCR2 : SPI Data Control Register 2

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x44

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	TTRG[1:0]	—	—	—	—	—	—	—	RTRG[1:0]	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	RTRG[1:0]	Receive FIFO threshold setting 0 0: threshold 0 0 1: threshold 1 1 0: threshold 2 1 1: threshold 3	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
9:8	TTRG[1:0]	Transmission FIFO threshold setting 0 0: threshold 0 0 1: threshold 1 1 0: threshold 2 1 1: threshold 3	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

SPI data control register 2 (SPDCR2) controls the FIFO threshold. If the value set in this register is changed while the SPE bit is 1, subsequent operations are not guaranteed.

RTRG[1:0] bit (Receive FIFO threshold setting)

Set the receive FIFO threshold.

When the number of data stored in the receive FIFO > the number of frames set by RTRG[1:0], the receive buffer full flag is set.

TTRG[1:0] bit (Transmission FIFO threshold setting)

Set the transmit FIFO threshold.

When the number of empty stages in the transmit FIFO > the number of frames set in TTRG[1:0], the transmit buffer empty flag is set.

32.2.9 SPSR : SPI Status Register

Base address: SPI_n_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
 SPI_n_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x50

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	SPRF	CEND F	SPTE F	UDRF	PERF	MODF	IDLNF	OVRF	SPDR F	—	—	—	—	—	—	—
Value after reset:	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	SPECM[2:0]			—	SPCP[2:0]			—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R
10:8	SPCP[2:0]	SPI Command Pointer 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
11	—	This bit is read as 0. The write value should be 0.	R

22:15	—	These bits are read as 0. The write value should be 0.	R
23	SPDRF	SPI Receive Data Ready Flag 0: Receive data ready not detected 1: Receive data ready detected	R
24	OVRF	Overrun Error Flag 0: No overrun error is present. 1: An overrun error is present.	R
25	IDLNF	SPI Idle Flag 0: The SPI is in the idle state. 1: The SPI is in the transfer state.	R
26	MODF	Mode Fault Error Flag 0: Neither mode fault error nor underrun error is present. 1: A mode fault error or underrun error is present.	R
27	PERF	Parity Error Flag 0: No parity error is present. 1: A parity error is present.	R
28	UDRF	Underrun Error Flag 0: When MODF=0, neither mode fault error nor underrun error is present. When MODF=1, a mode fault error is present. 1: When MODF=0, neither mode fault error nor underrun error is present. When MODF=1, an underrun error is present.	R

Bit	Symbol	Function	R/W
29	SPTEF	SPI Transmit Buffer Empty Flag 0: The number of empty stages in the transmit FIFO \leq the value set in SPDCR2.TTRG 1: The number of empty stages in the transmit FIFO $>$ the value set in SPDCR2.TTRG	R
30	CENDF	Communication End Flag 0: The SPI is not communicating or communicating. 1: The SPI communication completed.	R
31	SPRF	SPI Receive Buffer Full Flag 0: The number of data stored in the receive FIFO \leq number of frames set by the SPDCR2.RTRG bit. 1: The number of data stored in the receive FIFO $>$ number of frames set by the SPDCR2.RTRG bit.	R

Note: S-TYPE-3, P-TYPE-3

The SPI status register (SPSR) stores flags that indicate SPI's operating status.

SPCP[2:0] bit (SPI Command Pointer)

These bits indicate SPI command registers 0 to 7 (SPCMD0 to SPCMD7) indicated by the current pointer in the SPI sequence control. For details about the SPI sequence control, see [section 32.3.13.1. Master mode operation](#).

SPECM[2:0] bit (SPI Error Command)

These bits indicate SPI command registers 0 to 7 (SPCMD0 to SPCMD7) indicated by the command pointer (SPCP[2:0] bits) when an error was detected in the SPI sequence control. The SPI updates the SPECM[2:0] bits value only when an error is detected. When no error is present (OVRF, MODF, and PERF flags in SPSR are 0), the SPECM[2:0] bits value has no meaning. For the SPI's error detection function, see [section 32.3.10. Error Detection](#). For the SPI's sequence control, see [section 32.3.13.1. Master mode operation](#).

SPDRF bit (SPI Receive Data Ready Flag)

During communication (SPCR.SPE = 1), a certain period of time has elapsed while the number of data stored in the reception FIFO \leq the reception FIFO threshold.

This bit is set to 0 when the reception operation is not performed (SPCR.TXMD[1:0] = 01b).

[Setting condition]

All the following two conditions are met.

- SPCR2.SPDRC[7:0] \neq 0x00.
- After the receive FIFO has been written, when the number of data stored in the receive FIFO \leq the receive FIFO threshold and the value set by SPDRC[7:0] has elapsed

[Clearing condition]

- When 1 is written to the SPSRC.SPDRFC bit.

OVRF bit (Overrun Error Flag)

This flag indicates whether an overrun error is present. When the RSPCK clock auto-stop function is enabled (SPCR.SCKASE = 1) in master mode (SPCR.MSTR = 1), no overrun error occurs and, therefore, this flag is not set to 1. For details, see [section 32.3.10.1. Overrun errors](#).

[Setting condition]

When serial transfer is completed in one of the following two conditions with data stored in the receive FIFO for the number of FIFO stages.

- SPCR.TXMD[1:0] = 00b. (transmit-receive mode)
- SPCR.TXMD[1:0] = 10b. (receive only)

[Clearing condition]

- When 1 is written to the SPSRC.OVRFC bit.

IDLNF bit (SPI Idle Flag)

This flag indicates transfer status of the SPI.

[Setting condition]

[Transmit-Receive, Transmit-only Master mode]

- None of the clearing conditions (Transmit-Receive / Transmit-only in Master mode) below is met.

[Receive-only Master mode]

- When 1 is written to RMSTTG of SPCR2.

[Slave mode]

- The SPE bit in SPCR is 1 (SPI function enabled).

[Clearing conditions]

Communication status: 1-(1) to (6) * For details of communication status, see [Table 32.4](#).

[Transmit-Receive, Transmit-only Master mode]

Any of the following two conditions is met.

- The SPE bit in SPCR is 0 (SPI initialization).
- All the following three conditions are met.
 - The next transfer data is not set in the transmission buffer (SPTXn, n = 0 to 3)
 - The SPCP bits in SPSR are 000b (at the beginning of sequence control).
 - The operation completed by the next access delay (the master main state machine has transitioned to the idle state)

[Receive-only Master mode]

Communication status: 1-(7) to (9)

Any of the following two conditions is met.

- The SPE bit in SPCR is 0 (SPI initialization).
- Any of the following 3 conditions is met.
 - When RMFM[4:0] = 0x00, after writing 1 to RMEDTG, the operation completed by the next access delay (the master main state machine has transitioned to the idle state)
 - When RMFM[4:0] ≠ 0x00, after writing 1 to RMEDTG, the operation completed by the next access delay (the master main state machine has transitioned to the idle state)
 - When RMFM[4:0] ≠ 0x00, the operation completed by the next access delay after processing is completed for the number of received frames set in RMFM[4:0] (the master main state machine has transitioned to the idle state)

[Slave mode]

Communication status: 0-(1) to (9)

- The SPE bit in SPCR is 0 (SPI initialization).

MODF bit (Mode Fault Error Flag)

This flag indicates whether a mode fault error or an underrun error is present. The UDRF flag allows you to see which error (mode fault error or underrun error) has occurred.

[Setting condition]

[Multi-master mode]

- The SSL0 pin input level becomes active level while the SPCR.MSTR bit = 1 (master mode) and the SPCR.MODFEN bit = 1 (mode fault error detection enabled), and then the SPI has detected a mode fault error.

[Slave, Motorola-SPI mode]

Any of the following two conditions is met.

- The SSL0 pin is negated before the RSPCK cycles necessary for data transfer end while the SPCR.MSTR bit = 0 (slave mode), SPCR.SPFRF bit = 0 (Motorola-SPI) and the SPCR.MODFEN bit = 1 (mode fault error detection enabled), and then the SPI has detected a mode fault error.
- Serial transfer is started before transmit data output becomes ready while the SPCR.SPE bit = 1 (SPI function enabled), and then the SPI has detected an underrun error.

[Slave, TI-SSP mode]

Any of the following two conditions is met.

- The SSL0 pin is asserted before the RSPCK cycles necessary for data transfer end while the SPCR.MSTR bit = 0 (slave mode), SPCR.SPFRF bit = 1 (TI-SSP) and the SPCR.MODFEN bit = 1 (mode fault error detection enabled), and then the SPI has detected a mode fault error.
- Serial transfer is started before transmit data output becomes ready while the SPCR.SPE bit = 1 (SPI function enabled), and then the SPI has detected an underrun error.

The SSL0 signal active level depends on the SPCR3.SSLiP bits (SSL signal polarity bits).

[Clearing condition]

- When 1 is written to the SPSRC.MODFC bit.

PERF bit (Parity Error Flag)

This flag indicates whether a parity error is present.

[Setting condition]

When the serial transfer ends and a parity error is detected with the SPPE bit of SPCR set to 1 under any of the following 2 conditions.

- SPCR.TXMD[1:0] = 00b. (transmit-receive master mode or transmit-receive slave mode)
- SPCR.TXMD[1:0] = 10b. (receive-only master mode or receive-only slave mode)

[Clearing condition]

- When 1 is written to the SPSRC.PERFC bit.

UDRF bit (Underrun Error Flag)

This flag indicates that a mode fault error or an underrun error is present.

[Setting condition]

- Serial transfer is started before transmit data output becomes ready while the SPCR.MSTR bit = 0 and the SPCR.TXMD[1:0] bit = 00b or 01b (transmit-receive slave mode or transmit-only slave mode) and the SPCR.SPE bit = 1 (SPI function enabled), and then the SPI has detected an underrun error.

[Clearing condition]

- When 1 is written to the SPSRC.UDRFC bit.

SPTEF bit (SPI Transmit Buffer Empty Flag)

This flag indicates the transmit buffer (SPTX) status in the SPI data register (SPDR).

[Setting condition]

Any of the following 3 conditions is met.

- The SPE bit is set to 0 (SPI initialization).
- When the number of empty transmission FIFO stages > the value set in SPDCR2.TTRG[1:0].
- When 1 is written to SPFCR.SPFRST.

[Clearing condition]

Any of the following two conditions is met.

- At the time of final access when transmission data is written to SPDR (SPTXn, n = 0 to 3) in one processing routine using DTC / DMAC.
- When 1 is written to the SPSRC.SPTEFC bit.

Writing a value to the SPDR register is enabled only while the SPTEF flag = 1. If a value is written to the SPDR register while the SPTEF flag = 0, transmit buffer data is not updated.

CENDF bit (Communication End Flag)

This flag indicates communication end status of SPI. It turns 1 at communication end and turns 0 at starting next communication.

[Setting condition]

[Transmit-Receive / Transmit-only Master mode]

Communication status: 1-(1) to (6) * For details of communication status, see [Table 32.4](#).

The following 3 conditions are met.

- The next transfer data is not set in the transmission buffer (SPTXn, n = 0 to 3)
- The SPSR.SPCP[2:0] are 000b. (It means the head of the sequential control.)
- The operation completed by the next access delay (the master main state machine has transitioned to the idle state)

[Receive-only Master mode]

Communication status: 1-(7) to (9)

Any of the following 3 conditions is met.

- When RMFM[4:0] = 0x00, after writing 1 to RMEDTG, the operation completed by the next access delay (the master main state machine has transitioned to the idle state)
- When RMFM[4:0] ≠ 0x00, after writing 1 to RMEDTG, the operation completed by the next access delay (the master main state machine has transitioned to the idle state)
- When RMFM[4:0] ≠ 0x00, the operation completed by the next access delay after processing is completed for the number of received frames set in RMFM[4:0] (the master main state machine has transitioned to the idle state)

[Transmit-Receive / transmit-only slave, Motorola-SPI mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0)]

Communication status: 0-(1), (4)

The following 3 conditions are met.

- The next transfer data is not set in the transmission buffer
- The transmission shift register is empty. (It means SPI does not do serial transfer.)
- SSL0 was negated.

[Transmit-Receive / transmit-only slave, TI-SSP mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0)]

Communication status: 0-(2), (5)

The following 3 conditions are met.

- The next transfer data is not set in the transmission buffer
- The transmission shift register is empty. (It means SPI does not do serial transfer.)
- When the SSL0 negate delay is completed.

[Transmit-Receive / transmit only slave mode at clock synchronous (3-wire: the SPCR.SPMS bit is 1)]

Communication status: 0-(3), (6)

The following 3 conditions are met.

- The next transfer data is not set in the transmission buffer
- The transmission shift register is empty. (It means SPI does not do serial transfer.)
- The last even edge of RSPCK of the frame was detected. (When the SPCMD.CPHA bit is 1.)

[Receive only slave, Motorola-SPI mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0)]

Communication status: 0-(7)

The following condition is met.

- SSL0 input was negated after getting frames for SPDCR.SPFC set value in the receive buffer.

[Receive only slave, TI-SSP mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0)]

Communication status: 0-(8)

The following condition is met.

- SSL0 negate delay is completed after getting frames for SPDCR.SPFC set value in the receive buffer.

[Receive only slave mode at clock synchronous (3-wire: the SPCR.SPMS bit is 1)]

Communication status: 0-(9)

The following condition is met.

- The last even edge of RSPCK of the Last frame received for SPFC sets value. (When the SPCMD.CPHA bit is 1.)

[Clearing condition]

[Transmit-Receive / Transmit-only Master mode]

Communication status: 1-(1) to (6)

Any of the following 2 conditions is met.

- The next transmit data was written to the transmit buffer (SPTX).
- When 1 is written to the SPSRC.CENDFC bit.

[Receive -only Master mode]

Communication status: 1-(7) to (9)

Any of the following 2 conditions is met.

- When 1 is written to the SPCR2.RMSTTG bit with SPE = 1.
- When 1 is written to the SPSRC.CENDFC bit.

[Transmit-receive / transmit only slave mode]

Communication status: 0-(1) to (6)

Satisfy one of following.

- The next transmit data was written to the transmit buffer (SPTX).
- When 1 is written to the SPSRC.CENDFC bit.

[Receive only slave mode at SPI serial communication (4-wire: the SPCR.SPMS bit is 0)]

Communication status: 0-(7) to (8)

Satisfy one of following.

- SSL0 assertion of next data was detected.
- When 1 is written to the SPSRC.CENDFC bit.

[Receive only slave mode at clock synchronous (3-wire: the SPCR.SPMS bit is 1)]

Communication status: 0-(9)

Satisfy one of following.

- The first edge of RSPCK of the next data was detected.
- When 1 is written to the SPSRC.CENDFC bit.

SPRF bit (SPI Receive Buffer Full Flag)

This flag indicates the receive buffer (SPRX) status in the SPI data register (SPDR).

[Setting condition]

When the number of data stored in the receive FIFO > the number of frames set in the SPDCR2.RTRG[1:0] bits in Transmit-Receive, receive-only mode. However, the SPRF flag does not change from 0 to 1 while the OVRF flag = 1. (See section 32.3.10. Error Detection.)

[Clearing condition]

Any of the following 3 conditions is met.

- At the last access when read data is read from SPDR (SPRXn, n = 0 to 3) in one processing routine using DTC / DMAC
- When 1 is written to the SPSRC.SPRFC bit
- When 1 is written to the SPFCR.SPFRST bit

32.2.10 SPTFSR : SPI Transfer FIFO Status Register

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
 SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x58

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	TFDN[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	TFDN[2:0]	Transmit FIFO data empty stage number 0 0 0: Number of empty stages 0 ⋮ 1 0 0: Number of empty stages 4	R
31:3	—	These bits are read as 0. The write value should be 0.	R

TFDN[2:0] bit (Transmit FIFO data empty stage number)

Displays the number of empty transmission FIFO stages. By clearing the SPCR.SPE bit, TFDN[2:0] will be the initial value after reset (= all empty).

32.2.11 SPRFSR : SPI Receive FIFO Status Register

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
 SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x5C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	RFDN[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Function	R/W
2:0	RFDN[2:0]	Receive FIFO data store stage number 0 0 0: Number of store stages 0 ⋮ 1 0 0: Number of store stages 4	R
31:3	—	These bits are read as 0. The write value should be 0.	R

Note: S-TYPE-3, P-TYPE-3

RFDN[2:0] bit (Receive FIFO data store stage number)

Displays the number of stores receive FIFO stages. RFDN [2:0] is cleared by clearing the SPCR.SPE bit.

32.2.12 SPPSR : SPI Polling Register

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x60

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SPEP S
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPEPS	SPI Polling Status 0: SPCR.SPE is 0 1: SPCR.SPE is 1	R
31:1	—	These bits are read as 0. The write value should be 0.	R

SPEPS bit (SPI Polling Status)

This bit indicates status of SPCR.SPE bit after synchronization from bus clock (PCLK) to operation clock (TCLK).

32.2.13 SPSRC : SPI Status Clear Register

Base address: SPIn_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPIn_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x68

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	SPRF C	CEND FC	SPT FC	UDRF C	PERF C	MODF C	—	OVRF C	SPDR FC	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
22:0	—	The write value should be 0.	W
23	SPDRFC	SPI Receive Data Ready Flag Clear By writing 1, the SPI Receive Data Ready Flag can be cleared. Reading value is always 0.	W

Bit	Symbol	Function	R/W
24	OVRFC	Overrun Error Flag Clear By writing 1, the Overrun Error Flag can be cleared. Reading value is always 0.	W
25	—	The write value should be 0.	W
26	MODFC	Mode Fault Error Flag Clear By writing 1, the Mode Fault Error Flag can be cleared. Reading value is always 0.	W*1
27	PERFC	Parity Error Flag Clear By writing 1, the Parity Error Flag can be cleared. Reading value is always 0.	W
28	UDRFC	Underrun Error Flag Clear By writing 1, the Underrun Error Flag can be cleared. Reading value is always 0.	W*2
29	SPTEFC	SPI Transmit Buffer Empty Flag Clear By writing 1, the SPI Transmit Buffer Empty Flag can be cleared. Reading value is always 0.	W
30	CENDFC	Communication End Flag Clear By writing 1, the Communication End Flag can be cleared. Reading value is always 0.	W
31	SPRFC	SPI Receive Buffer Full Flag Clear By writing 1, the SPI Receive Buffer Full Flag can be cleared. Reading value is always 0.	W

Note: S-TYPE-3, P-TYPE-3

Note 1. Before setting MODFC and UDRFC, make sure that SPSR.MODF and UDRF are set to 1.

Note 2. When clearing the UDRF flag, clear the MODF flag at the same time (MODFC = 1).

The SPI status clear register (SPSRC) is a register that clears the status flag (SPSR) that indicates the operating status of SPI.

32.2.14 SPFCR : SPI FIFO Clear Register

Base address: SPI_n_B = 0x4035_C000 + 0x0100 × n (n = 0, 1)
SPI_n_B_NS = 0x5035_C000 + 0x0100 × n (n = 0, 1)

Offset address: 0x6C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SPFR ST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SPFRST	SPI FIFO clear By writing 1, the pointer in the FIFO and the stored data are initialized. Reading value is always 0.	W
31:1	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

The FIFO clear register (SPFCR) is used to clear the FIFO.

If SPFCR is rewritten while the SPE bit of the SPI control register (SPCR) is 1, subsequent operations are not guaranteed.

SPFRST bit (SPI FIFO clear)

Initializing the pointer and stored data in the transmit / receive FIFO by writing 1

32.3 Operation

In this section, the serial transfer period refers to the period from the beginning of driving valid data to the fetching of the final valid data.

32.3.1 Overview of SPI Operation

The SPI is capable of synchronous serial transfers in the following modes:

- Slave mode (SPI operation)
- Single-master mode (SPI operation)
- Multi-master mode (SPI operation)
- Slave mode (clock synchronous operation)
- Master mode (clock synchronous operation)

The SPI mode can be selected by using the MSTR, MODFEN, SPMS, and SPFRF bits in SPCR. Table 32.6 lists the relationship between SPI modes and SPCR settings, and a description of each mode.

Table 32.6 Relationship between SPCR settings and SPI modes (1 of 2)

Mode	Slave (SPI operation)	Single-master (SPI operation)	Multi-master (SPI operation)	Slave (clock synchronous operation)	Master (clock synchronous operation)
MSTR bit setting	0	1	1	0	1
MODFEN bit setting	0 or 1	0	1	0	0
SPMS bit setting	0	0	0	1	1
SPFRF bit setting	valid	valid	valid	Invalid	Invalid
RSPCKn pins	Input	Output	Output/Hi-Z	Input	Output
MOSIn pin	Input	Output	Output/Hi-Z	Input	Output
MISO pin	Output/Hi-Z	Input	Input	Output	Input
SSLn0 pins	Input	Output	Input	Hi-Z ^{*1}	Hi-Z ^{*1}
SSLn1 to SSLn3 pins	Hi-Z ^{*1}	Output	Output/Hi-Z	Hi-Z ^{*1}	Hi-Z ^{*1}
SSL polarity change function	Supported	Supported	Supported	—	—
Max transfer rate	TCLK/2	TCLK/2	TCLK/2	TCLK/2	TCLK/2
Clock source	RSPCK input	On-chip baud rate generator	On-chip baud rate generator	RSPCK input	On-chip baud rate generator
Clock polarity	Two				
Clock phase	Two ^{*6}	Two ^{*6}	Two ^{*6}	One (CPHA = 1)	Two
Transfer data length	4 to 32 bits				
Burst transfer	Possible (CPHA = 1)	Possible (CPHA = 0, 1)	Possible (CPHA = 0, 1)	—	—
RSPCK delay control	Not supported	Supported	Supported	Not supported	Supported
SSL negotiation delay control	Not supported ^{*7}	Supported	Supported	Not supported	Supported
Next-access delay control	Not supported	Supported	Supported	Not supported	Supported
Transfer trigger	SSL input active or RSPCK oscillation	Write to transmit buffer on generation of transmit buffer empty interrupt request (SPTEF = 1)	Write to transmit buffer on generation of transmit buffer empty interrupt request (SPTEF = 1)	RSPCK oscillation	Write to transmit buffer on generation of transmit buffer empty interrupt request (SPTEF = 1)
Sequence control	Not supported	Supported	Supported	Not supported	Supported
Transmit buffer empty detection	Supported ^{*5}				
Receive buffer full detection	Supported ^{*2}				
Overrun error detection	Supported ^{*2}	Supported ^{*2 *4}	Supported ^{*2 *4}	Supported ^{*2}	Supported ^{*2}

Table 32.6 Relationship between SPCR settings and SPI modes (2 of 2)

Mode	Slave (SPI operation)	Single-master (SPI operation)	Multi-master (SPI operation)	Slave (clock synchronous operation)	Master (clock synchronous operation)
Parity error detection	Supported*3 *2				
Mode fault error detection	Supported (MODFEN = 1)	Not supported	Supported	Not supported	Not supported
Underrun error detection	Supported*5	Not supported	Not supported	Supported*5	Not supported

Note 1. This function is not supported in this mode.

Note 2. When SPI is transmit-master mode or transmit-slave mode (see Table 32.4), detection of receive buffer full, overrun error, and parity error are not performed.

Note 3. When the SPCR.SPPE bit is 0, parity error detection is not performed.

Note 4. When the SPCR.SCKASE bit is 1, overrun error detection does not proceed.

Note 5. When SPI is receive only slave mode, none of transmit buffer empty and underrun error is detected.

Note 6. CPHA = 0 is invalid in TI SSP mode. (If it is set, the operation is the same as when CPHA = 1.)

Note 7. Supported only in TI SSP mode.

32.3.2 Controlling the SPI Pins

Based on the settings of the MSTR, MODFEN, and SPMS bits in SPCR and the PmnPFS.NCODR bit for I/O Ports, the SPI can switch pin states. Table 32.7 lists the relationship between pin states and bit settings. Setting the PmnPFS.NCODR bit for an I/O port to 0 selects the CMOS output. Setting it to 1 selects the open-drain output. The I/O port settings must follow this relationship.

Table 32.7 Relationship between pin states and bit settings (1 of 2)

Mode	Pin	Pin state*2	
		PmnPFS.NCODR bit for I/O ports = 0	PmnPFS.NCODR bit for I/O ports = 1
Single-master mode (SPI operation) (MSTR = 1, MODFEN = 0, SPMS = 0)	RSPCKn	CMOS output	Open-drain output
	SSLn0 to SSLn3	CMOS output	Open-drain output
	MOSIn	CMOS output	Open-drain output
	MISOOn	Input	Input
Multi-master mode (SPI operation) (MSTR = 1, MODFEN = 1, SPMS = 0)	RSPCKn*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
	SSLn0	Input	Input
	SSLn1 to SSLn3*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
	MOSIn*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
	MISOOn	Input	Input
Slave mode (SPI operation) (MSTR = 0, SPMS = 0)	RSPCKn	Input	Input
	SSLn0	Input	Input
	SSLn1 to SSLn3*5	Hi-Z*1	Hi-Z*1
	MOSIn	Input	Input
	MISOOn*4	CMOS output/Hi-Z	Open-drain output/Hi-Z
Master mode (clock synchronous operation) (MSTR = 1, MODFEN = 0, SPMS = 1)	RSPCKn	CMOS output	Open-drain output
	SSLn0 to SSLn3*5	Hi-Z*1	Hi-Z*1
	MOSIn	CMOS output	Open-drain output
	MISOOn	Input	Input

Table 32.7 Relationship between pin states and bit settings (2 of 2)

Mode	Pin	Pin state ^{*2}	
		PmnPFS.NCODR bit for I/O ports = 0	PmnPFS.NCODR bit for I/O ports = 1
Slave mode (clock synchronous operation) (MSTR = 0, SPMS = 1)	RSPCKn	Input	Input
	SSLn0 to SSLn3 ^{*5}	Hi-Z ^{*1}	Hi-Z ^{*1}
	MOSIn	Input	Input
	MISO _n	CMOS output	Open-drain output

Note 1. This function is not supported in this mode.

Note 2. SPI settings are not reflected in multiplexed pins for which the SPI function is not selected.

Note 3. Motorola-SPI: When SSLn0 is at the active level, the pin state is Hi-Z. Whether or not the input signal is at the active level determines the setting of the SPCR3.SSLOP bit.

TI-SSP: From when SSL0 is at the active level until communication is completed, the pin state is Hi-Z under the condition SPCR.SPE = 1.

Note 4. Motorola-SPI: When SSLn0 is at the non-active level or the SPCR.SPE bit is 0, the pin state is Hi-Z. Whether or not the input signal is at the active level determines the setting of the SPCR3.SSLOP bit.

TI-SSP: When SSL0 is except the communication period or when the SPE bit of SPCR is 0 (assertion after SPE = 1 and communication is completed), the pin status changes to Hi-Z.

Note 5. These pins are available for use as I/O port pins.

The SPI in single-master mode (SPI operation) or multi-master mode (SPI operation) determines the MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) based on the MOIFE and MOIFV bit settings in SPCR2, as listed in [Table 32.8](#).

Table 32.8 MOSI signal value determination during SSL negation

MOIFE bit	MOIFV bit	MOSIn signal value during SSL negation
0	0, 1	Final data from previous transfer
1	0	Low
1	1	High

32.3.3 SPI System Configuration Examples

This configuration example describes that 0 level of SSL_n signals is active level.

When connecting and using in a multi-slave or multi-master mode, the transfer format of the connected device should be unified to either Motorola-SPI or TI-SSP.

32.3.3.1 Single-master/single-slave with the MCU as a master

[Figure 32.6](#) shows a single-master/single-slave SPI system configuration example where the MCU is used as a master. In the single-master/single-slave configuration, the SSL_n outputs of the MCU (master) are not used. The SSL input of the SPI slave is fixed to the low level, and the SPI slave is maintained in the selected state.^{*1}

Note 1. In the transfer format configured when the SPCMDm.CPHA bit is 0, the SSL signal for some slave devices cannot be fixed to an active level. In this case, always connect the SSL_n output of the MCU to the SSL input of the slave device.

The MCU (master) drives the RSPCK_n and MOSIn signals. The SPI slave drives the MISO signal.

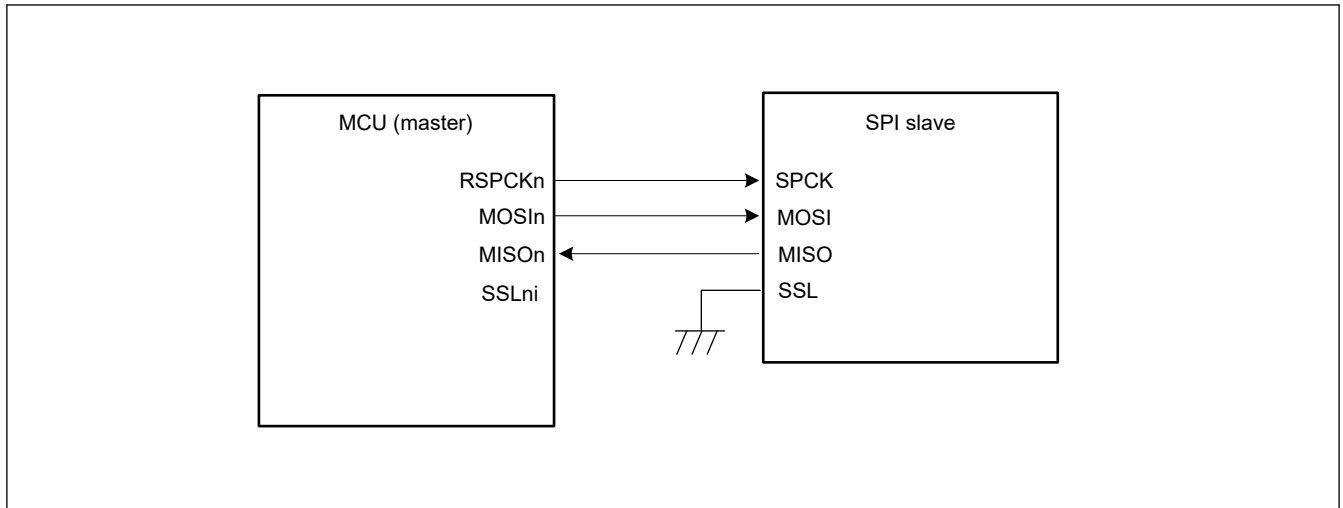

Figure 32.6 Single-master/single-slave configuration example with the MCU as a master

32.3.3.2 Single-master/single-slave with the MCU as a slave

Figure 32.7 shows a single-master/single-slave SPI system configuration example where the MCU is used as a slave. When the MCU operates as a slave, the SSLn0 pin is used as SSL input. The SPI master drives the RSPCK and MOSI signals. The MCU (slave) drives the MISO signal.*1

Note 1. When SSLn0 is at a non-active level, the pin state is Hi-Z.

In the single-slave configuration when the SPCMDm.CPHA bit is set to 1, the SPCR.SPFRF bit is set to 0, and SPCR.SPMS is set to 0, the SSLn0 input of the MCU (slave) is fixed to the low level and the MCU (slave) is maintained in the selected state. This enables serial transfer execution (Figure 32.8). However, the communication end interrupt does not output when SSL0 input is fixed as Figure 32.8.

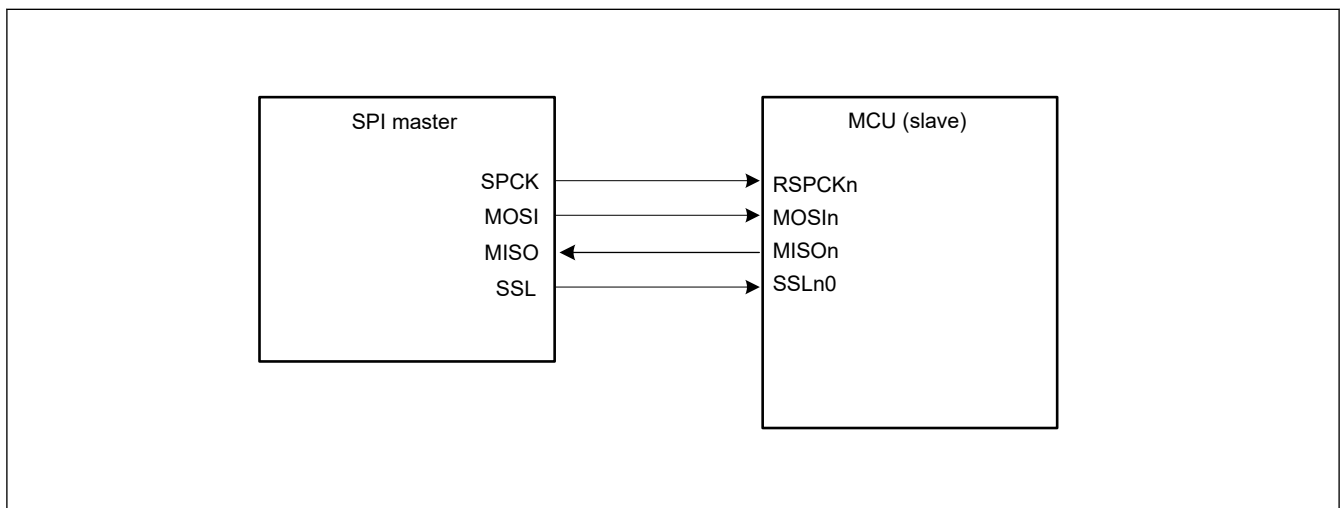

Figure 32.7 Single-master/single-slave configuration example with the MCU as a slave and CPHA = 0

Figure 32.8 Single-master/single-slave configuration example with the MCU as a slave and CPHA = 1

32.3.3.3 Single-master/multi-slave with the MCU as a master

Figure 32.9 shows a single-master/multi-slave SPI system configuration example where the MCU is used as a master. In this example, the SPI system includes the MCU (master) and four slaves (SPI slave 0 to SPI slave 3).

The RSPCKn and MOSIn outputs of the MCU (master) are connected to the RSPCK and MOSI inputs of SPI slaves 0 to 3. The MISO outputs of SPI slaves 0 to 3 are all connected to the MISO_n input of the MCU (master). The SSLn0 to SSLn3 outputs of the MCU (master) are connected to the SSL inputs of SPI slaves 0 to 3, respectively.

The MCU (master) drives the RSPCKn, MOSIn, and SSLn0 to SSLn3 signals. Out of the SPI slaves 0 to 3, the slave that receives low-level input into the SSL input drives the MISO signal.

Figure 32.9 Single-master/multi-slave configuration example with the MCU as a master

32.3.3.4 Single-master/multi-slave with the MCU as a slave

Figure 32.10 shows a single-master/multi-slave SPI system configuration example where the MCU is used as a slave. In this example, the SPI system includes an SPI master and two MCUs (slaves X and Y).

The SPCK and MOSI outputs of the SPI master are connected to the RSPCKn and MOSIn inputs of the MCUs (slaves X and Y). The MISO outputs of the MCUs (slaves X and Y) are all connected to the MISO input of the SPI master. The SSLX and SSLY outputs of the SPI master are connected to the SSLn0 inputs of the MCUs (slaves X and Y, respectively).

The SPI master drives the SPCK, MOSI, SSLX, and SSLY signals. Of the MCUs (slaves X and Y), the slave that receives low-level input into the SSLn0 input drives the MISO signal.

Figure 32.10 Single-master/multi-slave configuration example with the MCU as a slave

32.3.3.5 Multi-master/multi-slave with the MCU as a master

[Figure 32.11](#) shows a multi-master/multi-slave SPI system configuration example where the MCU is used as a master. In this example, the SPI system includes two MCUs (masters X and Y) and two SPI slaves (SPI slaves 1 and 2).

The RSPCKn and MOSIn outputs of the MCUs (masters X and Y) are connected to the RSPCK and MOSI inputs of SPI slaves 1 and 2. The MISO outputs of SPI slaves 1 and 2 are connected to the MISOOn inputs of the MCUs (masters X and Y). Any generic port Y output from the MCU (master X) is connected to the SSLn0 input of the MCU (master Y). Any generic port X output of the MCU (master Y) is connected to the SSLn0 input of the MCU (master X). The SSLn1 and SSLn2 outputs of the MCUs (masters X and Y) are connected to the SSL inputs of the SPI slaves 1 and 2. In this configuration example, because the system can be comprised solely of SSLn0 input, and SSLn1 and SSLn2 outputs for slave connections, the SSLn3 output of the MCU is not required.

The MCU drives the RSPCKn, MOSIn, SSLn1, and SSLn2 signals when the SSLn0 input level is high. When the SSLn0 input level is low, the MCU detects a mode fault error, sets RSPCKn, MOSIn, SSLn1, and SSLn2 to Hi-Z, and releases the SPI bus directly to the other master. Of the SPI slaves 1 and 2, the slave that receives low-level input into the SSL input drives the MISO signal.

Figure 32.11 Multi-master/multi-slave configuration example with the MCU as a master

When setting TI SSP, enter the following levels for port X and port Y.

- Start of communication: the value of SPCR3.SSL0P of the other master.
- End of communication: the inverted value of SPCR3.SSL0P of the other master.

32.3.3.6 Master and slave in clock synchronous mode with the MCU configured as a master

Figure 32.12 shows a master and slave in clock synchronous mode configuration example where the MCU is used as a master. In this configuration, SSLn_i of the MCU (master) are not used.

The MCU (master) drives the RSPCK_n and MOSIn signals. The SPI slave drives the MISO signal.

Figure 32.12 Clock synchronous master/slave configuration example with the MCU as a master

32.3.3.7 Master and slave in clock synchronous mode with the MCU as a slave

Figure 32.13 shows a master and slave in clock synchronous mode configuration example where the MCU is used as a slave. When the MCU operates as a slave (clock synchronous operation), the MCU (slave) drives the MISOOn signal and the SPI master drives the SPCK and MOSI signals. In addition, SSLn0 to SSLn3 of the MCU (slave) are not used.

The MCU (slave) can only execute serial transfers in the single-slave configuration when the SPCMDm.CPHA bit is set to 1.

Figure 32.13 Clock synchronous master/slave configuration example with the MCU as a slave and CPHA = 1

32.3.4 Data Formats

The data format of the SPI depends on the settings in SPI Command Register *m* (SPCMDm) and the parity enable bit in SPI Control Register (SPCR.SPPE). Regardless of whether the MSB or LSB is first, the SPI treats the range from the LSB bit in the SPI Data Register (SPDR) to the bit associated with the selected data length, as transfer data.

This section shows the format of one frame of data before or after transfer.

Data format with parity disabled

When parity is disabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register *m* (SPCMDm.SPB[4:0]).

Data format with parity enabled

When parity is enabled, transmission or reception of data proceeds with the length in bits selected in the SPI data length setting in SPI Command Register m (SPCMD m .SPB[4:0]). In this case, however, the last bit is a parity bit.

Figure 32.14 Data format with parity disabled and enabled

32.3.4.1 Operation when parity is disabled (SPCR.SPPE = 0)

When parity is disabled, data for transmission is copied to the shift register with no pre-processing. This section describes the connection between the SPI Data Register (SPDR) and the shift register in terms of the combination of MSB- or LSB-first order and data length.

(1) MSB-first transfer with 32-bit data

Figure 32.15 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, a SPI data length of 32 bits, and MSB-first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T31 to T30, and continuing to T00.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R31 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

Figure 32.15 MSB-first transfer with 32-bit data and parity disabled

(2) MSB-first transfer with 24-bit data

Figure 32.16 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, an SPI data length of 24 bits for an example that is not 32 bits, and MSB-first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are copied to the shift register. Data for transmission is shifted out from the shift register from T23 to T22, and continuing to T00.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R23 to R00 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

Figure 32.16 MSB-first transfer with 24-bit data and parity disabled

(3) LSB-first transfer with 32-bit data

Figure 32.17 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity disabled, an SPI data length of 32 bits, and LSB-first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are reordered bit-by-bit to obtain the order T00 to T31 for copying to the shift register. Data for transmission is shifted out from the shift register in order from T00 to T01, and continuing to T31.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R00 to R31 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

Figure 32.17 LSB-first transfer with 32-bit data and parity disabled

(4) LSB-first transfer with 24-bit data

Figure 32.18 shows the operation of the SPI Data Register (SPDR) and the shift register in transfers with parity disabled, an SPI data length of 24 bits for an example that is not 32, and LSB-first selected.

In transmission, the lower 24 bits (T23 to T00) from the current stage of the transmit buffer are reordered bit-by-bit to obtain the order T00 to T23 for copying to the shift register. Data for transmission is shifted out from the shift register from T00 to T01, and continuing to T23.

In reception, received data is shifted in bit-by-bit through bit[8] of the shift register. When the R00 to R23 bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer.

Figure 32.18 LSB-first transfer with 24-bit data and parity disabled

32.3.4.2 Operation when parity is enabled (SPCR.SPPE = 1)

When parity is enabled, the lowest-order bit of the data for transmission becomes a parity bit. Hardware calculates the value of the parity bit.

(1) MSB-first transfer with 32-bit data

Figure 32.19 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 32 bits, and MSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T31 to T01. This replaces the final bit, T00, and the whole value is copied to the shift register. Data is transmitted in the order T31, T30, ..., T01, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R31 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R31 to P is checked for parity.

Figure 32.19 MSB-first transfer with 32-bit data and parity enabled

(2) MSB-first transfer with 24-bit data

Figure 32.20 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, a SPI data length of 24 bits, and MSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T23 to T01. This replaces the final bit, T00, and the whole value is copied to the shift register. Data is transmitted in the order T23, T22, ..., T01, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R23 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R23 to P is checked for parity.

Figure 32.20 MSB-first transfer with 24-bit data and parity enabled

(3) LSB-first transfer with 32-bit data

Figure 32.21 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, an SPI data length of 32 bits, and LSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T30 to T00. This replaces the final bit, T31, and the whole value is copied to the shift register. Data is transmitted in the order T00, T01, ..., T30, and P.

In reception, received data is shifted in bit-by-bit through bit[0] of the shift register. When the R00 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R00 to P is checked for parity.

Figure 32.21 LSB-first transfer with 32-bit data and parity enabled

(4) LSB-first transfer with 24-bit data

Figure 32.22 shows the operation of the SPI Data Register (SPDR) and the shift register in a transfer with parity enabled, a SPI data length of 24 bits, and LSB-first selected.

In transmission, the value of the parity bit (P) is calculated from bits T22 to T00. This replaces the final bit, T23, and the whole value is copied to the shift register. Data is transmitted in the order T00, T01, ..., T22, and P.

In reception, received data is shifted in bit-by-bit through bit[8] of the shift register. When the R00 to P bits are collected after input of the required number of RSPCK cycles, the value in the shift register is copied to the receive buffer. On copying of data to the shift register, the data from R00 to P is checked for parity.

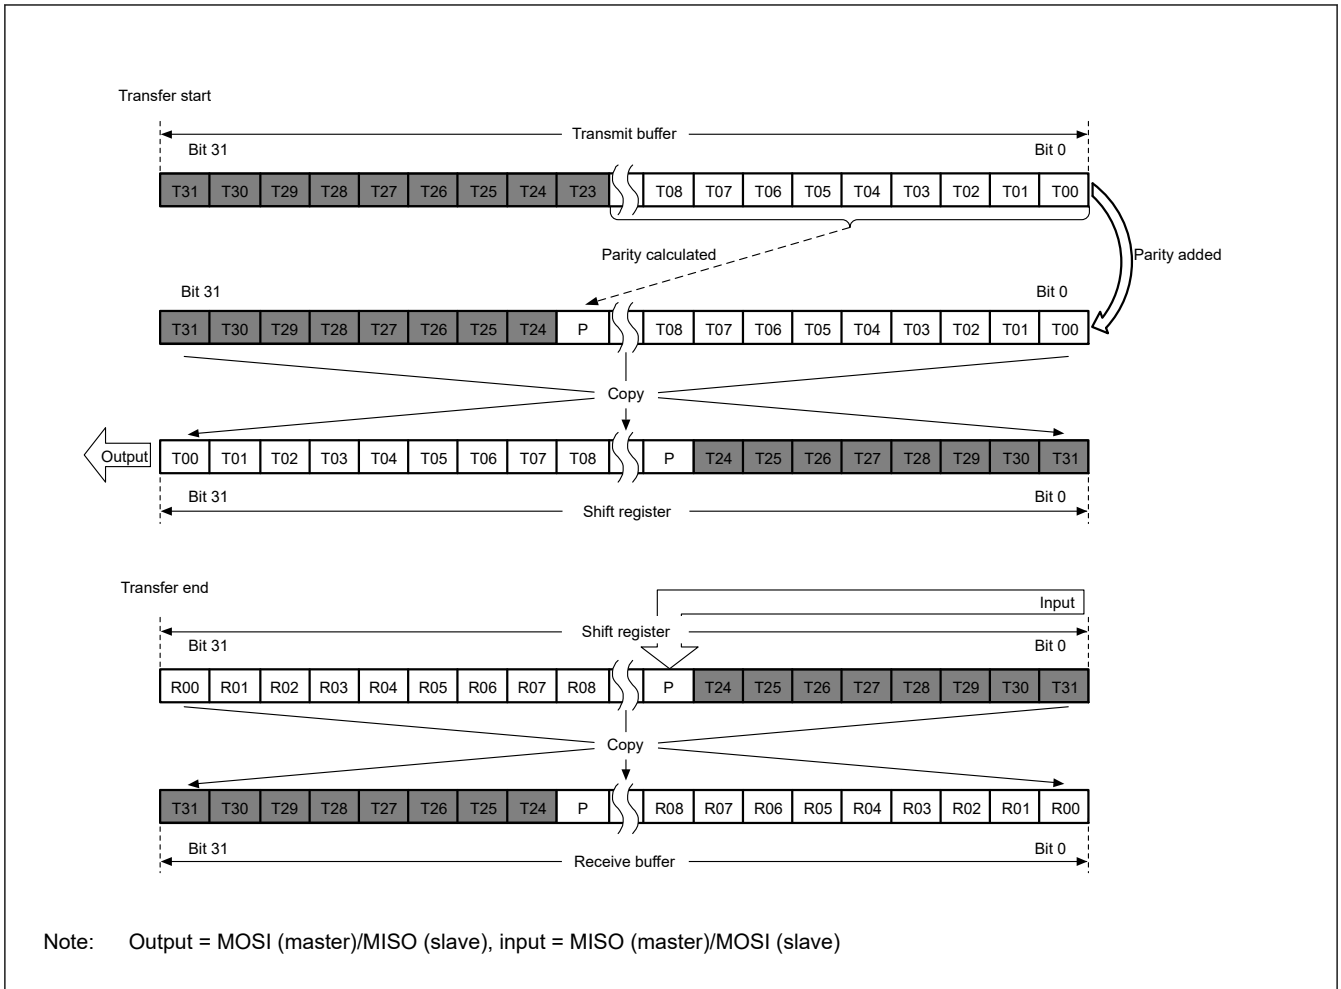

Figure 32.22 LSB-first transfer with 24-bit data and parity enabled

32.3.4.3 Byte Swap Transmission

When byte swapping is enabled, the data in the transmission buffer, swapped in 8-bit units, is copied to the shift register. Figure 32.23 shows the relationship between the SPDR (transmit buffer) and the shift register when transferring data with a 32-bit data length, using a combination of MSB / LSB first and with / without byte swap.

(1) MSB-first transfer. (When the byte swap is disabled.)

Data (Byte3 [T31 to T24] to Byte0 [T07 to T00]) in the transmit buffer are copied to the shift register. Bit values in the shift register are shifted and transmitted in the order of T31 → T30 → ... → T00 as transmit data.

(2) MSB-first transfer. (When the byte swap is enabled.)

Byte values of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte0 [T07 to T00] to Byte3 [T31 to T24].

Bit values in the shift register are shifted and transmitted in the order of T07 → T06 → ... → T00 → T15 → T14 → ... → T08 → T23 → T22 → ... → T16 → T31 → T30 → ... → T24 as transmit data.

(3) LSB-first transfer. (When the byte swap is disabled.)

Bit values of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte0 [T00 to T07] to Byte3 [T24 to T31].

Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → ... → T31 as transmit data.

(4) LSB-first transfer. (When the byte swap is enabled.)

Bit values of each byte of the transmit buffer (Byte3 [T31 to T24] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte3 [T24 to T31] to Byte0 [T00 to T07].

Bit values in the shift register are shifted and transmitted in the order of T24 → T25 → ... → T31 → T16 → T17 → ... → T23 → T08 → T09 → ... → T15 → T00 → T01 → ... → T07 as transmit data.

Figure 32.23 Byte swap with MSB/LSB transfer (32bit)

Figure 32.24 shows the relationship between the SPDR (transmit buffer) and the shift register when transferring data with a 16-bit data length, using a combination of MSB / LSB first and with / without byte swap.

1. MSB-first transfer. (When the byte swap is disabled.)
Data (Byte1 [T15 to T08] to Byte0 [T07 to T00]) in the transmit buffer are copied to the shift register in the order of Byte1 [T15 to T08] to Byte0 [T07 to T00], Byte1 [T15 to T08] to Byte0 [T07 to T00]. Bit values in the shift register are shifted and transmitted in the order of T15 → T14 → ... T00 as transmit data.
2. MSB-first transfer. (When the byte swap is enabled.)
Byte values of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte0 [T07 to T00] to Byte1 [T15 to T08], Byte0 [T07 to T00] to Byte1 [T15 to T08]. Bit values in the shift register are shifted and transmitted in the order of T07 → T06 → ... T00 → T15 → T14 → ... T08 as transmit data.
3. LSB-first transfer. (When the byte swap is disabled.)
Bit values of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte0 [T00 to T07] to Byte1 [T08 to T15], Byte0 [T00 to T07] to Byte1 [T08 to T15]. Bit values in the shift register are shifted and transmitted in the order of T00 → T01 → ... T15 as transmit data.
4. LSB-first transfer. (When the byte swap is enabled.)
Bit values of each byte of the transmit buffer (Byte1 [T15 to T08] to Byte0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte1 [T08 to T15] to Byte0 [T00 to T07], Byte1 [T08 to T15] to Byte0 [T00 to T07]. Bit values in the shift register are shifted and transmitted in the order of T08 → T09 → ... T15 → T00 → T01 → ... T07 as transmit data.

Figure 32.24 Byte swap with MSB/LSB transfer (16bit)

- Note:
1. When using the byte swap, set 16 bits or 32 bits to the data length (SPCMDm.SPB[4:0] setting). If setting the other length, the behavior is not guaranteed.
 2. When the byte swap is valid, set the parity function as invalid (SPCR.SPPE bit = 0). If setting the parity function as valid (SPPE bit = 1), the behavior is not guaranteed.
 3. Set SPDCR.BYSW bit, when SPCR.SPE bit is 0. If rewriting BYSW bit, when SPE bit is 1, the behavior after it is not guaranteed.

32.3.4.4 Byte Swap Reception

When byte swap is enabled, the data in the shift register, swapped in 8-bit units, is copied to the receive buffer. Figure 32.25 shows the relationship between the shift register and SPDR (reception buffer) when transferring data with a 32-bit data length, using a combination of MSB / LSB first and with / without byte swap.

(1) MSB-first transfer (When the byte swap is disabled)

The first received data (R31) is stored in bit 0 of the shift register, and received data is shifted in the order of R31 → R30 → ... → R00.

When necessary RSPCK cycles are input and data is stored from Byte3 [R31 to R24] to Byte0 [R07 to R00], the shift register value is copied to the receive buffer.

(2) MSB-first transfer (When the byte swap is enabled)

The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07 → R06 → ... → R00 → R15 → R14 → ... → R08 → R23 → R22 → ... → R16 → R31 → R30 → ... → R24.

When necessary RSPCK cycles are input and data is stored from Byte0 [R07 to R00] to Byte3 [R31 to R24], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

(3) LSB-first transfer (When the byte swap is disabled)

The first received data (R00) is stored in bit 0 of the shift register, and received data is shifted in the order of R00 → R01 → ... → R31.

When necessary RSPCK cycles are input and data is stored from Byte0 [R00 to R07] to Byte3 [R24 to R31], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

(4) LSB-first transfer (When the byte swap is enabled)

The first received data (R24) is stored in bit 0 of the shift register, and received data is shifted in the order of R24 → R25 → ... → R31 → R16 → R17 → ... → R23 → R08 → R09 → ... → R15 → R00 → R01 → ... → R07.

When necessary RSPCK cycles are input and data is stored from Byte3 [R24 to R31] to Byte0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

Figure 32.25 Byte swap with MSB/LSB transfer (32-bit)

Figure 32.26 shows the relationship between the shift register and SPDR (reception buffer) when transferring data with a 16-bit data length, using a combination of MSB / LSB first and with / without byte swap.

1. MSB-first transfer (when the byte swap is disabled)

The first received data (R15) is stored in bit 0 of the shift register, and received data is shifted in the order of R15 → R14 → ... R00. When necessary RSPCK cycles are input and data is stored from Byte3 [R31 to R24] to Byte0 [R07 to R00], the shift register value is copied to the receive buffer.
2. MSB-first transfer (when the byte swap is enabled)

The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07 → R06 → ... R00 → R15 → R14 → ... R08. When necessary RSPCK cycles are input and data is stored from Byte0 [R07 to R00] to Byte1 [R15 to R08], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].
3. LSB-first transfer (when the byte swap is disabled)

The first received data (R00) is stored in bit 15 of the shift register, and received data is shifted in the order of R00 → R01 → ... R07 → R08 → R09 → ... R15. When necessary RSPCK cycles are input and data is stored from Byte0 [R00 to R07] to Byte1 [R08 to R15], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07-R00].
4. LSB-first transfer (when the byte swap is enabled)

The first received data (R08) is stored in bit 15 of the shift register, and received data is shifted in the order of R08 → R09 → ... R15 → R00 → R01 → ... R07. When necessary RSPCK cycles are input and data is stored from Byte1 [R08

to R15] to Byte0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte3 [R31 to R24] to Byte0 [R07 to R00].

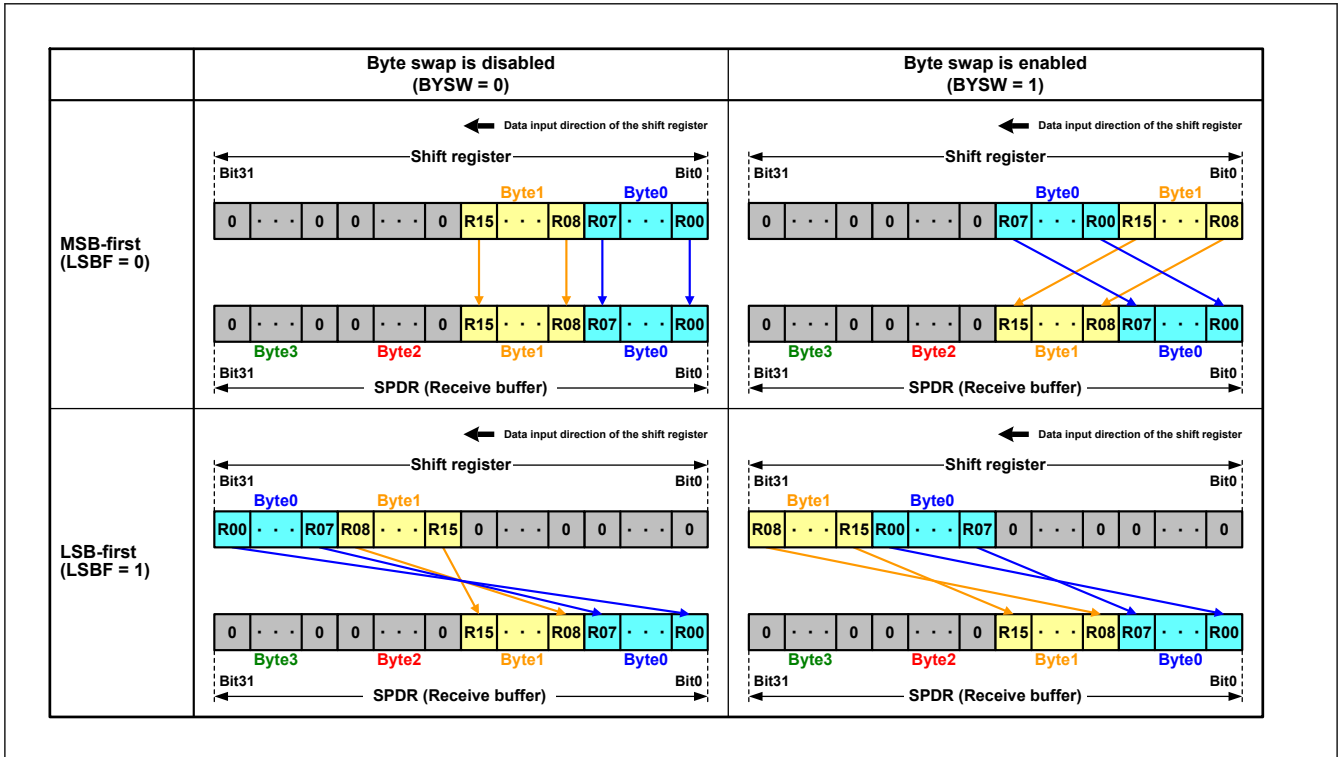

Figure 32.26 Byte swap with MSB/LSB transfer(16-bit)

- Note:
1. When using the byte swap, set 16 bits or 32 bits to the data length (SPCMDm.SPB[4:0] setting). If setting the other length, the behavior is not guaranteed.
 2. When the byte swap is valid, set the parity function as invalid (SPCR.SPPE bit = 0). If setting the parity function as valid (SPPE bit = 1), the behavior is not guaranteed.
 3. Set SPDCR.BYSW bit, when SPCR.SPE bit is 0. If rewriting BYSW bit, when SPE bit is 1, the behavior after it is not guaranteed.

32.3.5 Transfer Formats

32.3.5.1 When CPHA = 0

Figure 32.27 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 0. Do not perform clock synchronous operation (SPCR.SPMS = 1) when the SPI operates in slave mode (SPCR.MSTR = 0) and the CPHA bit is 0. In Figure 32.27, RSPCKn (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0, and RSPCKn (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI settings. For details, see section 32.3.2. Controlling the SPI Pins.

When the SPCMDm.CPHA bit is 0, the driving of valid data to the MOSIn and MISOOn signals begins at an SSLni signal assertion. The first RSPCKn signal change that occurs after the SSLni signal assertion becomes the first transfer data fetch. After this, data is sampled every 1 RSPCKn cycle. The change timing for MOSIn and MISOOn signals is 1/2 RSPCK cycles after the transfer data fetch timing. The CPOL bit setting does not affect the RSPCKn signal operation timing as it only affects the signal polarity.

t1 denotes the RSPCK delay, the period from an SSLni signal assertion to RSPCKn oscillation. t2 denotes the SSL negation delay, the period from the termination of RSPCKn oscillation to an SSLni signal negation. t3 denotes the next-access delay, the period in which SSLni signal assertion is suppressed for the next transfer after the end of serial transfer. t1, t2, and t3 are controlled by a master device running on the SPI system. For a description of t1, t2, and t3 when the SPI is in master mode, see section 32.3.12.1. Master mode operation.

[In the Motorola-SPI case]

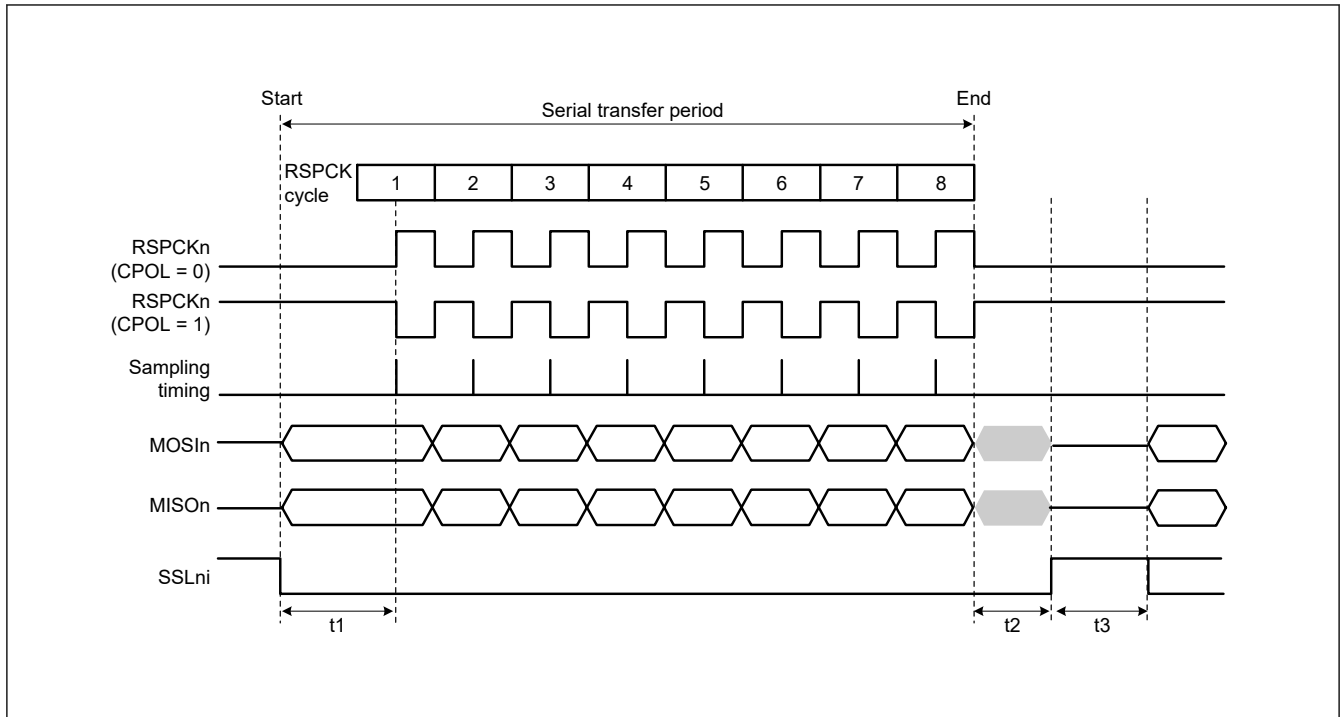

Figure 32.27 SPI transfer format when CPHA = 0, SPFRF = 0

[In TI-SSP case]

Not supported in CPHA = 0

32.3.5.2 When CPHA = 1

Figure 32.28 shows an example transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 1. However, when the SPCR.SPMS bit is 1, the SSLni signals are not used, and only the three signals RSPCKn, MOSIn, and MISO handle communications. In Figure 32.28, RSPCKn (CPOL = 0) indicates the RSPCKn signal waveform when the SPCMDm.CPOL bit is 0 and RSPCKn (CPOL = 1) indicates the RSPCKn signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the SPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the SPI mode (master or slave mode). For details, see section 32.3.2. Controlling the SPI Pins.

When the SPCMDm.CPHA bit is 1, the driving of invalid data to the MISO signal begins at an SSLni signal assertion. The output of valid data to the MOSIn and MISO signals begins at the first RSPCKn signal change that occurs after the SSLni signal assertion. After this, data is updated every 1 RSPCK cycle. The transfer data fetch timing is 1/2 RSPCK cycles after the data update timing. The SPCMDm.CPOL bit setting does not affect the RSPCKn signal operation timing. It only affects the signal polarity.

t1, t2, and t3 are the same as those when CPHA = 0. For a description of t1, t2, and t3 when the SPI of the MCU is in master mode, see section 32.3.12.1. Master mode operation.

[In the Motorola-SPI case]

Figure 32.28 SPI transfer format when CPHA = 1, SPFRF = 0

[In the TI-SSP case]

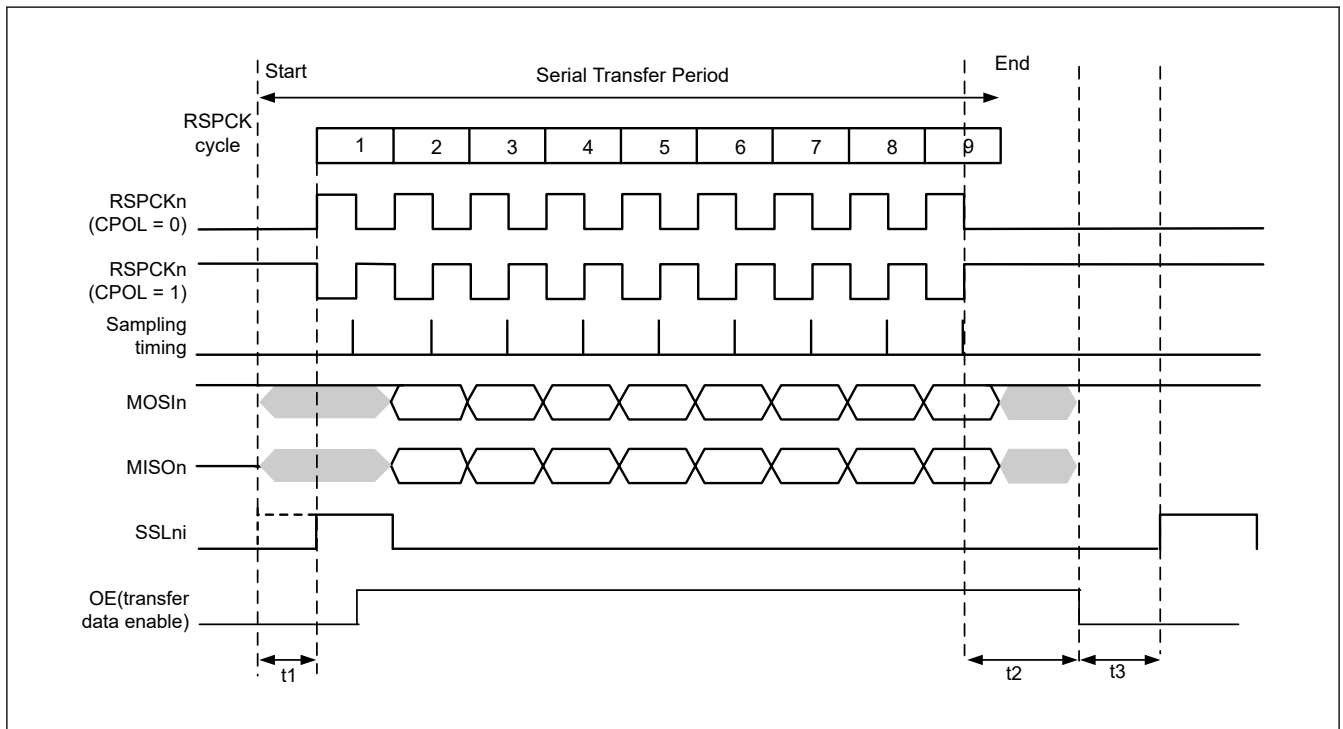

Figure 32.29 SPI transfer format when CPHA = 1, SPFRF = 1

32.3.6 Communication Operating Mode

Transmit-Receive serial communication, transmit-only operation, and Receive-only operation are selected by setting the Communication Mode Select bits (TXMD [1:0]) of the SPI control register (SPCR).

SPDR access described in [Figure 32.30](#), [Figure 32.31](#), [Figure 32.32](#) shows an access to the SPI data register (SPDR). W shows a write cycle.

32.3.6.1 Transmit-Receive Serial Communication (TXMD[1:0] = 00b)

Figure 32.30 shows an example of operation when the communication mode select bit (TXMD[1:0]) in the SPI control register (SPCR) is set to 00b. In the example, the SPI performs an 8-bit serial transfer when the SPDCR2.TTRG is 0, the SPDCR2.RTRG is FIFO stage - 1, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

Figure 32.30 Operation example when SPCR.TXMD[1:0] = 00b

The operation of the flags at timings (1) and (2) in Figure 32.30 is as follows:

1. When serial transfer ends while the number of SPDR receive buffer store matches the number of frames set in SPDCR2.RTRG, the SPI generates a receive buffer full interrupt request (SPi_SPRI), the SPI sets the SPSR.SPRF flag to 1, and copies the received data in the shift register to the receive buffer.
2. When serial transfer ends with data for the number of FIFO stages stored in the SPDR receive buffer, the SPI sets the SPSR.OVRF flag to 1, and discards the received data in the shift register. For details about the operation of the SPSR.OVRF flag, see section 32.3.10.1. **Overflow errors.**

In Transmit-Receive serial communication (TXMD[1:0] = 00b), transmit data is transmitted and receive data is received. Therefore, the SPRF flag and the OVRF flag are set to 1 at timings (1) and (2) respectively.

32.3.6.2 Transmit-Only Serial Communications (TXMD[1:0] = 01b)

Figure 32.31 shows an example of operation when the communication mode select bit (TXMD[1:0]) in the SPI control register (SPCR) is set to 01b. In this example, the SPI performs an 8-bit serial transfer when the SPDCR2.TTRG is 0, the SPDCR2.RTRG is 0, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

Figure 32.31 Operation example when SPCR.TXMD[1:0] = 01b

The operation of the flags at timings (1) to (3) in Figure 32.31 is as follows:

1. Make sure there is no data left in the receive buffer (the SPSR.SPRF flag is 0) and the SPSR.OVRF flag is 0 before entering transmit-only mode (SPCR.TXMD[1:0] = 01b).
2. When a serial transfer ends without receiving data in the receiving FIFO of SPDR, if the transmit-only mode is selected (SPCR.TXMD[1:0] = 01b), the SPSR.SPRF flag retains the value of 0, and the SPI does not copy the data in the shift register to the receive buffer.
3. Because the receive buffer of SPDR does not hold data that was received in the previous serial transfer, even when a serial transfer ends, the SPSR.OVRF flag retains the value of 0, and the data in the shift register is not copied to the receive buffer.

In transmit-only mode (SPCR.TXMD[1:0] = 01b), the SPI transmits data but does not receive data. Therefore, the SPSR.SPRF and SPSR.OVRF flags remain 0 at timings (1) to (3).

32.3.6.3 Receive-Only Serial Communication (TXMD[1:0] = 10b)

Figure 32.32 shows an example of operation when the communication mode select bit (TXMD[1]) in the SPI control register (SPCR) is set to 1. In this example, the SPI performs an 8-bit serial transfer when the SPDCR2.TTRG is FIFO stage - 1, the SPDCR2.RTRG is 0, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

Figure 32.32 Example of Operation when SPCR.TXMD[1:0] = 10b

The following describes operation of flags at timings (1) and (2) in the figure above.

1. When serial transfer ends while the number of SPDR receive buffer store matches the number of frames set in SPDCR2.RTRG, the SPI generates a receive buffer full interrupt request (SPli_SPRI), the SPI sets the SPSR.SPRF flag to 1, and copies the received data in the shift register to the receive buffer
2. When serial transfer ends with data for the number of FIFO stages stored in the SPDR receive buffer, the SPI sets the SPSR.OVRF flag to 1 and discards the received data in the shift register.

32.3.7 Transmit Buffer Empty and Receive Buffer Full Interrupts

Figure 32.33 show examples of operation of the transmit buffer empty interrupt (SPli_SPTI ($i = 0, 1$)) and the receive buffer full interrupt (SPli_SPRI). The SPDR register accesses shown in these figures indicate the conditions of access to the register, where W denotes a write cycle and R a read cycle. In Figure 32.33, the SPI performs an 8-bit serial transfer when SPCR.TXMD[1:0] bits are 00b, the SPDCR2.TTRG bit is 0, the SPDCR2.RTRG bit is 0, the SPCMDm.CPHA bit is 0, and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

Figure 32.33 Operation example of the SPli_SPTI and SPli_SPRI interrupts when CPHA = 0 and CPOL = 0 in master mode

The operation of the SPI at timings (1) to (5) in Figure 32.33 is as follows:

1. When transmit data is written to SPDR with the transmit buffer of SPDR is before the next transfer data is set, the SPI writes data to the transmit buffer. When transmit data is written to SPDR in one processing routine using DTC / DMAC, the SPSR.SPTEF flag is cleared to 0 at the last access.
2. If the shift register is empty, the SPI copies the data in the transmit buffer to the shift register. At this time, if transmit FIFO empty stage number > TTRG value, then the SPI generates a transmit buffer empty interrupt request (SPI_i_SPTI), and sets the SPSR.SPTEF flag to 1. How a serial transfer is started depends on the SPI mode. For details, see [section 32.3. Operation](#), and [section 32.3.13. Clock Synchronous Operation](#).
3. When transmit data is written to SPDR either by the transmit buffer empty interrupt routine, or by the processing of the transmit buffer empty using the SPTEF flag, the SPI writes data to the transmit buffer. When the transmit data is written to SPDR in one processing routine using DTC / DMAC, the SPTEF flag is cleared to 0 at the last access. Because the data being transferred serially is stored in the shift register, the SPI does not copy the data in the transmit buffer to the shift register.
4. When the serial transfer ends with the receive buffer of SPDR > FIFO stage number, the SPI copies the receive data in the shift register to the receive buffer, generates a receive buffer full interrupt request (SPI_i_SPRI), and sets the SPRF flag to 1. Because the shift register becomes empty on completion of the serial transfer, if the next transfer data is set in the transmit FIFO before the serial transfer ended, the SPI sets the SPTEF flag to 1 and copies data in the transmit buffer to the shift register. Even when received data is not copied from the shift register to the receive buffer in an overrun error status, on completion of the serial transfer, the SPI determines that the shift register is empty, so data transfer from the transmit buffer to the shift register is enabled.
5. When SPDR is read either by the receive buffer full interrupt routine or processing of the receive buffer full interrupt using the SPRF flag, the receive data can be read. If the received data is read from SPDR in one processing routine using DTC / DMAC, the SPRF flag is cleared to 0 at the last access.

When transmit data is written to the SPDR register while no empty stages in the transmit FIFO, the SPI does not update data in the transmit buffer. When writing to SPDR, always use either a transmit buffer empty interrupt request or check the empty or processing of the transmit buffer empty interrupt using the SPTEF flag. To use a transmit buffer empty interrupt, set the SPTIE bit in SPCR to 1. If the SPI function is disabled (the SPCR.SPE bit is 0), set the SPTIE bit to 0.

When serial transfer ends while data is stored in the receive FIFO for the number of FIFO stages, the SPI does not copy data from the shift register to the receive buffer, and it detects an overrun error (see [section 32.3.10. Error Detection](#)). To prevent a receive data overrun error, read the received data using a receive buffer full interrupt request before the next serial transfer ends. To use an SPI receive buffer full interrupt, set the SPCR.SPRIE bit to 1.

Transmission and reception interrupts or the associated IELSR_n.IR flags (where n is the interrupt vector number) in the ICU can be used to confirm the states of the transmit and receive buffers.

Similarly, the SPTEF and SPRF flags can be used to confirm the states of the transmit and receive buffers. See [section 13, Interrupt Controller Unit \(ICU\)](#) for the interrupt vector numbers.

32.3.8 Idle Interrupt

When the SPCP[2:0] of the SPI status register (SPSR) becomes 000b (start of sequence control), the IDLNF flag in the SPI status register (SPSR) is set to 1 and an idle interrupt request is made during master mode operation. An interrupt request is also made by clearing the SPCR.SPE bit to 0.

[In the Motorola-SPI case]

[Figure 32.34](#) shows an example of idle interrupt operation during normal operation.

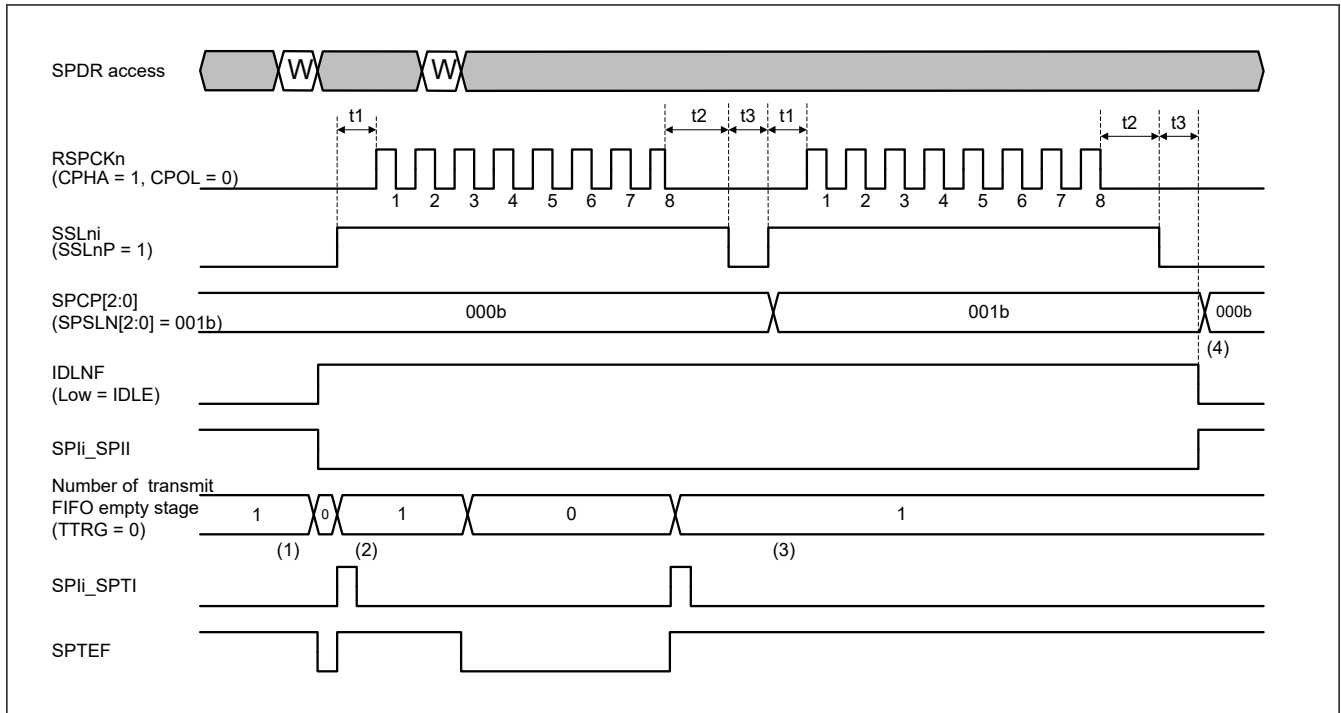

Figure 32.34 Example of Idle Interrupt Operation (Master mode / Motorola-SPI)

1. At the start of transmission, if the next transfer data is not set in the transmission buffer, the IDLNF flag is 0 (IDLE). Writing transmit data sets the IDLNF flag to 1 (BUSY). When the SPIIE bit in the SPI control register (SPCR) is set to 1 before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPIIE bit to 0 before starting transmission.
2. After transmission has started, the IDLNF flag remains 1 (BUSY) regardless of the transmit buffer state.
3. The SPCP[2:0] bits change the command to the next command at the end of t3 cycle. When the next command is not 000b, the IDLNF flag remains unchanged even when the next transmit data has not been written.
4. The IDLNF flag is cleared to 0 (IDLE) at the end of t3 cycle because the next command is 000b and the next transmit data is not present. When the SPIIE bit is 1 currently, an SPIi_SPII (i = 0, 1) interrupt is output.

[In the TI-SSP case]

Figure 32.35 shows an example of idle interrupt operation during normal operation.

Figure 32.35 Example of Idle Interrupt Operation (Master mode / TI-SSP)

1. At the start of transmission, if the next transfer data is not set in the transmission buffer, the IDLNF flag is 0 (IDLE). Writing transmit data makes sets the IDLNF flag to 1 (BUSY). When the SPIIE bit in the SPI control register (SPCR) is set to 1 before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPIIE bit to 0 before starting transmission.
2. After transmission has started, the IDLNF flag remains 1 (BUSY) regardless of the transmit buffer state.
3. The SPCP[2:0] bits change the command to the next command at the end of t3 cycle. When the next command is not 000b, the IDLNF flag remains unchanged even when the next transmit data has not been written.
4. The IDLNF flag is cleared to 0 (IDLE) at the end of t3 cycle because the next command is 000b and the next transmit data is not present. When the SPIIE bit is 1 currently, an SPIi_SPII interrupt is output.

32.3.9 Communication End Interrupt

32.3.9.1 Transmit-Receive/Transmit in Master Mode

See the description of the CENDF bit in [section 32.2.9. SPSR : SPI Status Register](#) for the setting / clearing conditions of the communication completion flag during Transmit-Receive/Transmit-only in Master Mode.

[In the Motorola-SPI case]

[Figure 32.36](#) shows an example of communication end interrupt operation during transmit-receive/transmit master mode.

Figure 32.36 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Master mode/ Motorola-SPI)

1. The CENDF flag is 0 and the level of SPIi_SPCEND (i = 0, 1) is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the end of t3 cycle because the next command is 000b and there is no next transmit data, and then the SPIi_SPCEND interrupt output when the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

[In the TI-SSP case]

Figure 32.37 shows an example of communication end interrupt operation during transmit-receive/transmit-only master mode.

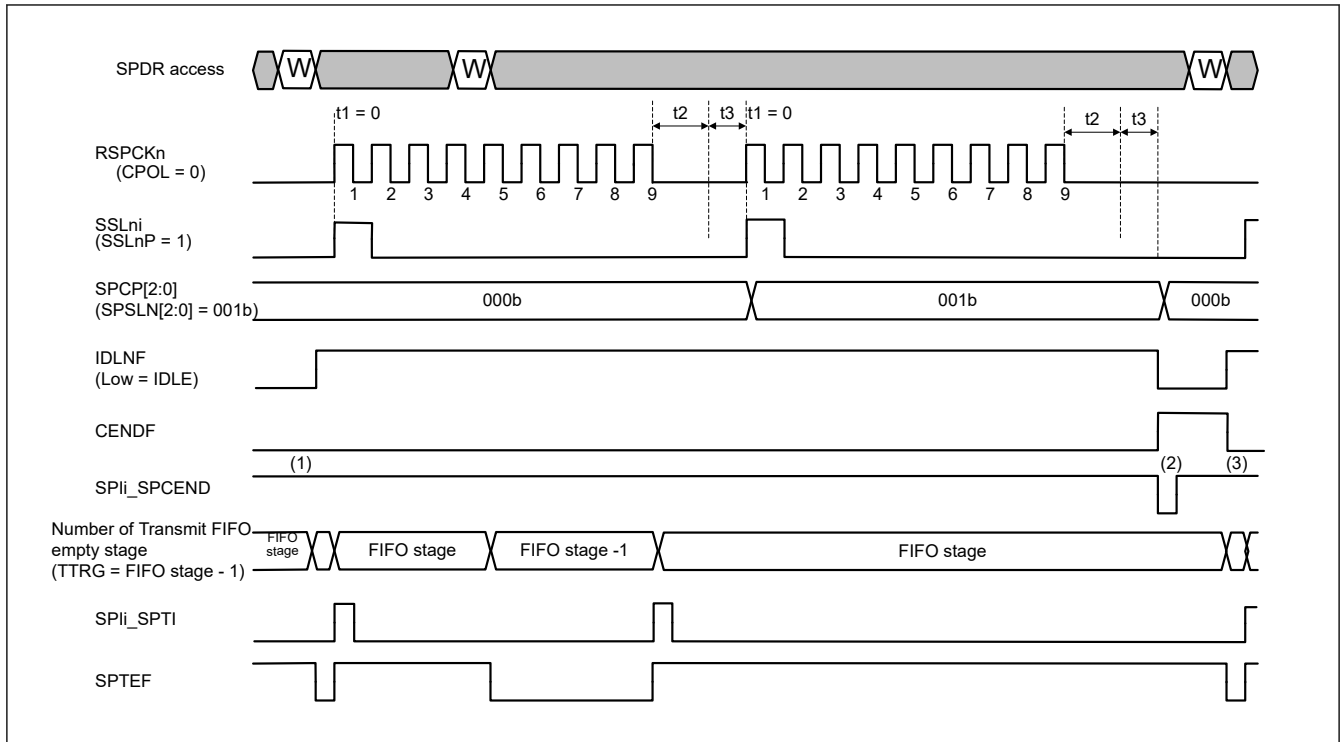

Figure 32.37 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit-only Master mode/TI-SSP)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the end of t3 cycle because the next command is 000b and there is no next transmit data, and then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

In slave mode operation, the output timing of the communication end interrupt is deferent due to the value of the SPCR.SPMS bit (SPI mode select bit), and the clear timing of the communication end interrupt is deferent due to the communication mode (transmit-receive or transmit-only or receive-only).

32.3.9.2 Receive-only in Master Mode

See the description of the CENDF bit in [section 32.2.9. SPSR : SPI Status Register](#) for the setting / clearing conditions of the communication completion flag during Receive-only in Master Mode.

[Figure 32.38](#) shows an example of communication end interrupt operation during receive-only master mode at RMFM[4:0] = 0.

Figure 32.38 Example of Communication End Interrupt Operation (Receive-only Master mode / Motorola-SPI) at RMFM [4:0] = 0

1. The CENDF flag is 0 and the level of SPi_SPCEND is 1 before communication start. These have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the end of t3 cycle by writing 1 to RMEDTG during the communication frame. Then the SPi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared when writing 1 to RMSTTG. Also when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

Figure 32.39 shows an example of communication end interrupt operation during receive-only master mode at RMFM[4:0] ≠ 0.

Figure 32.39 Example of Communication End Interrupt Operation (Receive-only Master mode / Motorola-SPI) at RMFM [4:0] ≠ 0

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start. These have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the end of t3 cycle after receiving the number of frames set by RMFM[4:0]. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared when writing 1 to RMSTTG. Also when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

32.3.9.3 Transmit-Receive/Transmit in Slave Mode on SPI Operation (4-wire)

See the description of the CENDF bit in [section 32.2.9. SPSR : SPI Status Register](#) for the setting / clearing conditions of the communication completion flag during Transmit-Receive/Transmit-only in Slave Mode (4-wire).

[In the Motorola-SPI case]

[Figure 32.40](#) shows an example of communication end interrupt operation during transmit-receive/transmit slave mode on SPI operation.

Figure 32.40 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Slave mode on SPI Operation/Motorola-SPI)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the timing of SSLn0 negate when the next transfer data is not set in the transmit FIFO and the transmit shift register is empty. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

[In the TI-SSP case]

Figure 32.41 shows an example of communication end interrupt operation during transmit-receive/transmit-only slave mode on SPI operation.

Figure 32.41 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit-only Slave mode on SPI Operation / TI-SSP)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the RSPCKn last data bit sampling when the next transfer data is not set in the transmit FIFO and the transmit shift register is empty. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared when the next transmission data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

32.3.9.4 Receive Only in Slave Mode on SPI Operation (4-wire)

See the description of the CENDF bit in [section 32.2.9. SPSR : SPI Status Register](#) for the setting / clearing conditions of the communication completion flag during Receive-only in Slave Mode (4-wire).

[In the Motorola-SPI case]

[Figure 32.42](#) shows an example of communication end interrupt operation during receive only slave mode on SPI operation (4-wire).

Figure 32.42 Example of Communication End Interrupt Operation (Receive only Slave mode on SPI Operation / Motorola-SPI)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.
2. After the frames for SPFC set value in the SPI data control register (SPDCR) are stored in the receive buffer, the CENDF flag becomes 1 (communication completed) at the timing of SSLn0 negation. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared at the SSLn0 assert when the next transmission start. Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

[In the TI-SSP case]

[Figure 32.43](#) shows an example of communication end interrupt operation during receive only slave mode on SPI operation (4-wire).

Figure 32.43 Example of Communication End Interrupt Operation (Receive-only Slave mode on SPI Operation / TI-SSP)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.
2. The CENDF flag will be 1 (Communication End) at the RSPCK last data bit sampling when the last frame transmission ends. Then the SPIi_SPCEND interrupt outputs with PCLK 1 cycle width if the CENDIE bit is 1.
3. The CENDF flag is cleared at the SSLn0 assert when the next transmission start. Or when 1 is written to the SPSRC.CENDFC bit, then the CENDF flag is 0.

32.3.9.5 Transmit-Receive/Transmit in Slave Mode on Clock Synchronous Operation (3-wire)

See the description of the CENDF bit in [section 32.2.9. SPSR : SPI Status Register](#) for the setting / clearing conditions of the communication completion flag during Transmit-Receive/Transmit-only in Slave Mode on Clock Synchronous (3-wire).

[Figure 32.44](#) shows an example of communication end interrupt operation during transmit-receive/transmit slave mode on clock synchronous operation (3-wire).

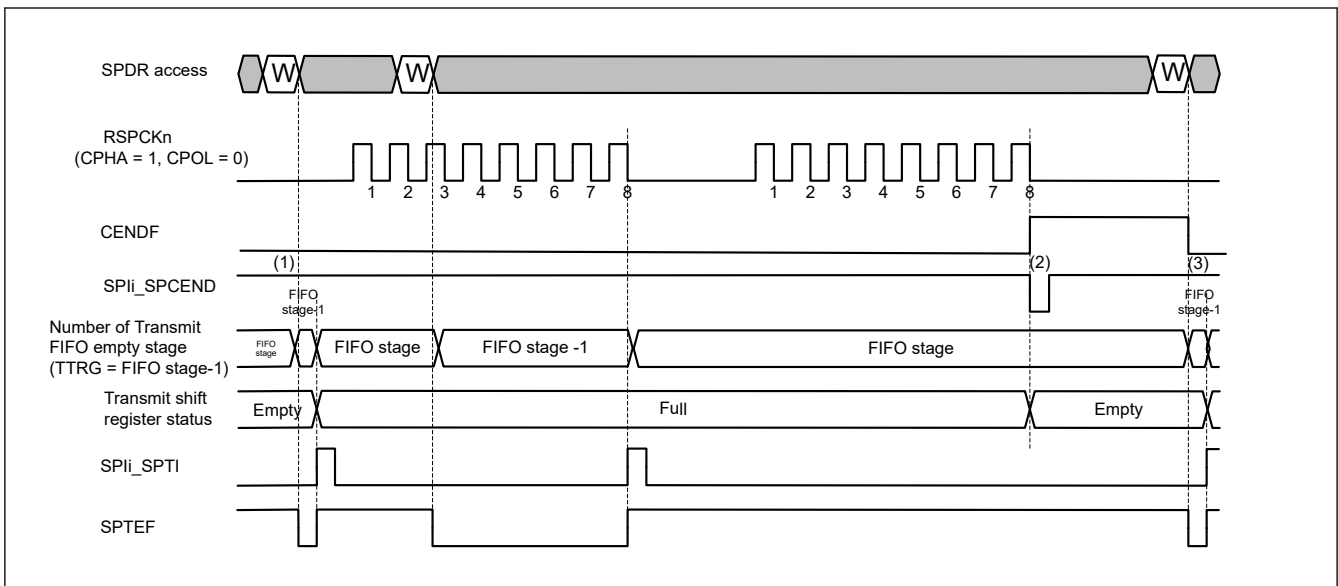

Figure 32.44 Example of Communication End Interrupt Operation (Transmit-Receive/Transmit Slave mode on Clock Synchronous Operation)

1. The CENDF flag is 0 and the level of SPIi_SPCEND is 1 before communication start, and these have kept during communication.

- When the next transfer data is not set in the transmit FIFO and the transmit shift register is empty, then the `SPIi_SPCEND` interrupt outputs with `PCLK` 1 cycle width if the `CENDIE` bit is 1.
- The `CENDF` flag is cleared when the next transmission data is written to the transmit buffer (`SPTX`). Or when 1 is written to the `SPSRC.CENDFC` bit, then the `CENDF` flag is 0.

32.3.9.6 Receive Only in Slave Mode on Clock Synchronous Operation (3-wire)

See the description of the `CENDF` bit in [section 32.2.9. SPSR : SPI Status Register](#) for the setting / clearing conditions of the communication completion flag during Receive -only in Slave Mode on Clock Synchronous (3-wire).

[Figure 32.45](#) shows an example of communication end interrupt operation during receive only slave mode on clock synchronous operation.

Figure 32.45 Example of Communication End Interrupt Operation (Receive-only Slave mode on Clock Synchronous Operation)

- The `CENDF` flag is 0 and the level of `SPIi_SPCEND` is 1 before communication start, and these have kept during communication.
- The `CENDF` flag is set to 1 (communication completed) at the timing of the last data bit sampling of `RSPCKn` in the last frame communication when the last frame of the SPI data control register (`SPDCR`) `SPFC` set value is received. Then the `SPIi_SPCEND` interrupt outputs with `PCLK` 1 cycle width if the `CENDIE` bit is 1.
- The `CENDF` flag is cleared at the first edge of `RSPCKn` for the next transmission. Or when 1 is written to the `SPSRC.CENDFC` bit, then the `CENDF` flag is 0.

32.3.9.7 Common Operation

In this chapter, the operation common to each mode / area option communication in [section 32.3.9.1. Transmit-Receive/ Transmit in Master Mode](#) to [section 32.3.9.6. Receive Only in Slave Mode on Clock Synchronous Operation \(3-wire\)](#) is explained. When the enable of SPI communication end interrupt (`CENDIE`) is 0, at the time of communication completion, a flag of communication end (`CENDF`) is set and an event of communication end is output, but no interrupt is output. However, if the enable of communication end interrupt (`CENDIE`) is set to 1 before clearing the flag of communication end (`CENDF`) while the enable of SPI function (`SPE`) is 1, the communication end interrupt (`SPIi_SPCEND`) is output.

Figure 32.46 Example of Communication End Interrupt Operation (Enable control)

1. When the enable of SPI communication end interrupt (CENDIE) is 1, at the time of communication completion, the following three are the same timing.
 - A flag of communication end (CENDF)
 - An event of communication end
 - The communication end interrupt (SPIi_SPCEND)
2. When the enable of SPI communication end interrupt (CENDIE) is 0, at the time of communication completion, the following two are the same timing, but no interrupt.
 - A flag of communication end (CENDF)
 - An event of communication end
3. After (2), if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) and the flag of communication end (CENDF) are 1, the communication end interrupt (SPIi_SPCEND) is output after 1 TCLK.
4. After (2), even if the enable of communication end interrupt (CENDIE) is set when the enable of SPI function (SPE) or the flag of communication end (CENDF) is 0, the communication end interrupt (SPIi_SPCEND) is not output.

32.3.10 Error Detection

In normal SPI serial transfers, data written to the transmit buffer of SPDR is transmitted, and received data can be read from the receive buffer of SPDR. If access is made to SPDR, an abnormal transfer might occur, depending on the status of the transmit or receive buffer or the status of the SPI at the beginning or end of serial transfer.

If an abnormal transfer occurs, the SPI detects the event as an underrun error, overrun error, parity error, or mode fault error. [Table 32.9](#) lists the relationship between non-normal transfer operations and the SPI error detection function.

Table 32.9 Relationship between non-normal transfer operations and SPI error detection (1 of 2)

Operation	Occurrence condition	SPI operation	Error detection
1	SPDR is written while no empty stages in the transmit FIFO.	<ul style="list-style-type: none"> • The contents of the transmit buffer are kept • Write data is missing 	None
2	SPDR is read while no data stored in receive FIFO.	The contents of the receive buffer and previously received data are output.	None
3	Serial transfer is started in slave mode when the SPI is not able to transmit data.	<ul style="list-style-type: none"> • Serial transfer is suspended • Transmit or receive data is missing • Driving of the MISO_n output signal is stopped • SPI function is disabled 	Underrun error
4	Serial transfer ends when data is stored in the receive FIFO for the number of FIFO stages.	<ul style="list-style-type: none"> • Keeps the contents of the receive FIFO • Missing receive data 	Overrun error

Table 32.9 Relationship between non-normal transfer operations and SPI error detection (2 of 2)

Operation	Occurrence condition	SPI operation	Error detection
5	An incorrect parity bit is received during full-duplex synchronous serial communication with the parity function enabled in following mode: <ul style="list-style-type: none"> • Transmit-receive master mode • Receive-only master mode • Transmit-receive slave mode • Receive-only slave mode 	The parity error flag is asserted	Parity error
6	The SSLn0 input signal is asserted when the serial transfer is idle in multi-master mode.	<ul style="list-style-type: none"> • Driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals is stopped • SPI function is disabled 	Mode fault error
7	The SSLn0 input signal is asserted during serial transfer in multi-master mode.	<ul style="list-style-type: none"> • Serial transfer is suspended • Transmit or receive data is missing • Driving of the RSPCKn, MOSIn, SSLn1 to SSLn3 output signals is stopped • SPI function is disabled 	Mode fault error
8	[In the Motorola-SPI case] The SSLn0 input signal is negated during serial transfer in slave mode.	<ul style="list-style-type: none"> • Serial transfer is suspended • Transmit or receive data is missing • Driving of the MISO_n output signal is stopped • SPI function is disabled 	Mode fault error
9	[In the TI-SSP case] The SSLn0 input signal is asserted during serial transfer in slave mode.	<ul style="list-style-type: none"> • Serial transfer is suspended • Transmit or receive data is missing • Driving of the MISO_n output signal is stopped • SPI function is disabled 	Mode fault error
10	After data is stored in the receive FIFO with SPDRES = 1, the number of stored data is less than the threshold value and no receive data is written for the set value of SPDRC [7:0]	Assert the receive data ready flag	Receive data ready

In operation 1 described in [Table 32.9](#), the SPI does not detect an error. To prevent data omission during writes to SPDR, the writes to SPDR must be executed using a transmit buffer empty interrupt request (when the SPSR.SPTEF flag is 1).

Similarly, the SPI does not detect an error in operation 2. To prevent extraneous data from being read, SPDR read must be executed with an SPI receive buffer full interrupt request (when the SPSR.SPRF flag is 1).

For information on the other errors, see the following sections:

- Underrun error, indicated in operation 3, see [section 32.3.10.4. Underrun errors](#)
- Overrun error, indicated in operation 4, see [section 32.3.10.1. Overrun errors](#)
- Parity error, indicated in operation 5, see [section 32.3.10.2. Parity errors](#)
- Mode fault error, indicated in operations 6 to 9, see [section 32.3.10.3. Mode fault errors](#)
- For the transmit and receive interrupts, see [section 32.3.7. Transmit Buffer Empty and Receive Buffer Full Interrupts](#).
- For the reception data ready in operations 10, see [section 32.3.10.5. Received data ready](#).

32.3.10.1 Overrun errors

If a serial transfer ends when the receive buffer of SPDR is full, the SPI detects an overrun error and sets the SPSR.OVRF flag to 1. When the OVRF flag is 1, the SPI does not copy data from the shift register to the receive buffer, so the data prior to the error occurrence is retained in the receive buffer. To set the OVRF flag to 0, issue a system reset or 1 is written to the SPSRC.OVRFC bit.

[Figure 32.47](#) shows an example of operation of the OVRF and SPRF flags. The SPSRC and SPDR accesses shown in [Figure 32.47](#) indicate the condition of accesses to the SPSRC and SPDR register, where W denotes a write cycle, and R a read cycle. In this example, the SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCK_n in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

Figure 32.47 Operation example of the OVRF and SPRF flags

The operation of the flags at timings (1) to (4) in [Figure 32.47](#) is as follows:

1. When serial transfer ends while data is stored for the number of FIFO stages, the SPI detects an overrun error and sets the OVRF flag to 1. The SPI does not copy shift register data to the receive buffer. The SPI does not detect a parity error even when SPPE = 1. In master mode, the SPI copies the value of pointer to the SPI command register (SPCMDm) to the SPECMD[2:0] bits in the SPI status register (SPSR).
2. When SPDR is read, the SPI outputs the data in the receive buffer. At this time, the SPRF flag is cleared to 0 at the last access when the received data is read from SPDR in one processing routine using DTC / DMAC.
3. If the serial transfer ends with the OVRF flag set to 1 (overrun error occurred), the SPI does not copy data in the shift register to the receive buffer (the SPRF flag does not set to 1). A receive buffer full interrupt is not generated. Even when the SPPE bit is 1, parity errors are not detected. In an overrun error state when the SPI does not copy the received data from the shift register to the receive buffer, on termination of the serial transfer, the SPI determines that the shift register is empty. This enables data transfer from the transmit buffer to the shift register.
4. When 1 is written to the SPSRC.OVRFC bit, the SPSR.OVRF flag is cleared.

The occurrence of an overrun can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. When executing a serial transfer, you must ensure that overrun errors are detected early, for example by reading SPSR immediately after SPDR is read.

If an overrun error occurs and the OVRF flag sets to 1, normal reception operations cannot be performed until the OVRF flag is set to 0.

When the RSPCK auto-stop function is enabled (SPCR.SCKASE = 1) in master mode, an overrun error does not occur. [Figure 32.48](#) and [Figure 32.49](#) show the clock stop waveform when a serial transfer continues while the receive buffer is full in master mode.

Figure 32.48 Clock stop waveform when serial transfer continues with data is stored for the number of FIFO stages in master mode (CPHA = 1)

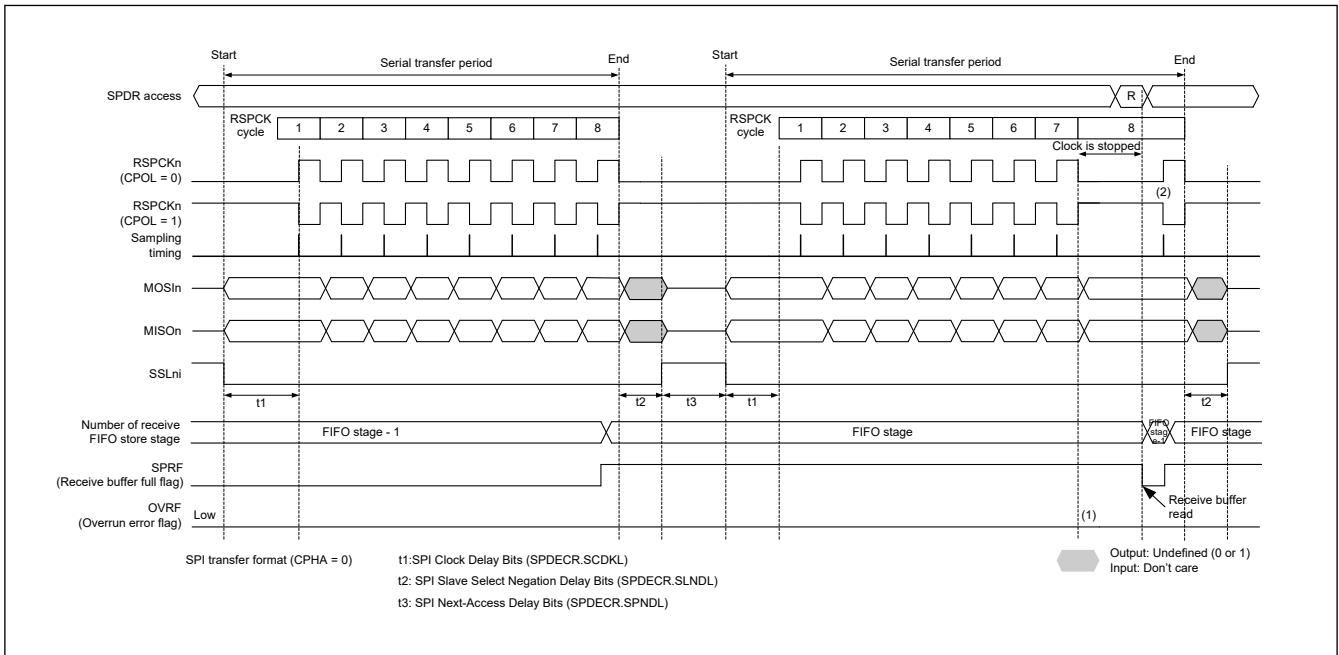

Figure 32.49 Clock stop waveform when serial transfer continues with data is stored for the number of FIFO stages in master mode (CPHA = 0)

The operation of the flags at timings (1) and (2) in Figure 32.48 and Figure 32.49 is as follows:

1. While data is stored in the receive FIFO for the number of FIFO stages, the RSPCK clock is deactivated and no overrun error occurs.
2. If SPDR is read while the clock is stopped, data in the receive buffer can be read. The RSPCK clock restarts.

Overrun error does not occur when RSPCK automatic stop function is enabled for transfer with no delay of between frames during burst transfer in master mode. Figure 32.50 and Figure 32.51 show the clock stop waveform, when there is no delay between frames at burst transfer and the serial transfer continues in the data is stored in the receive FIFO for the number of FIFO stages.

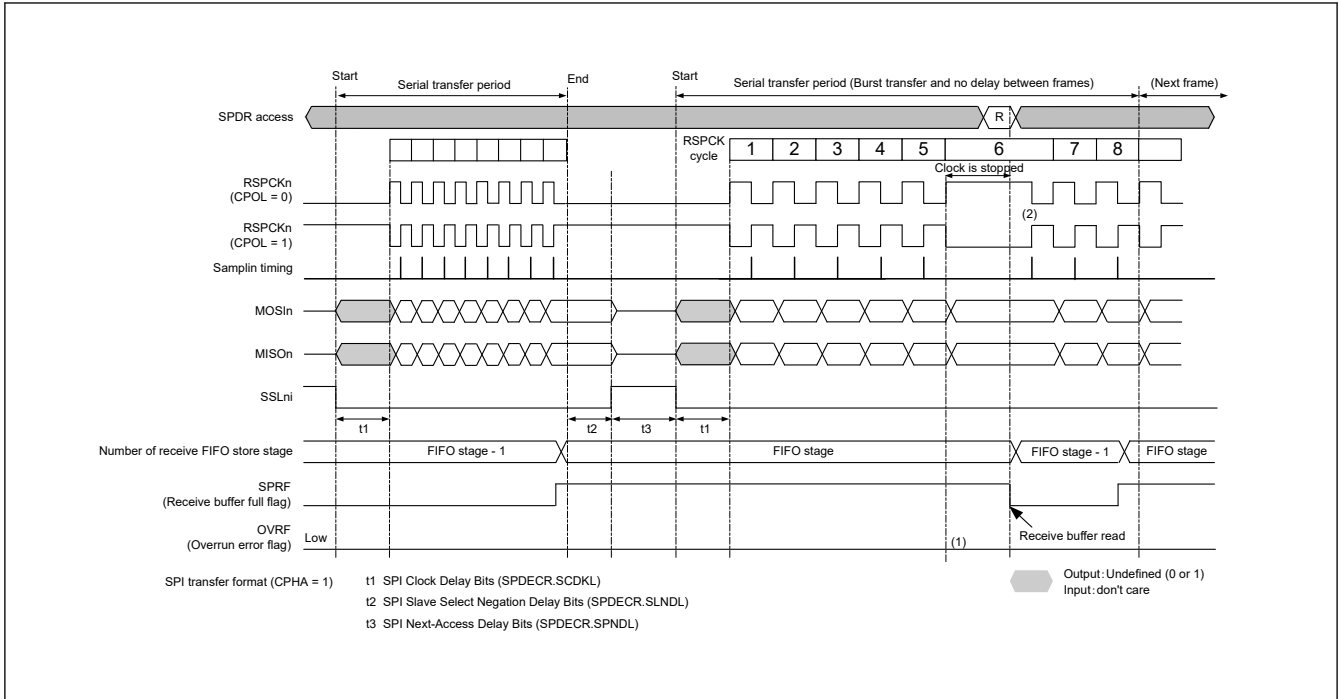

Figure 32.50 Clock Stop Waveform when Serial Transfer Continues in the Receive Buffer Full with data is stored for the number of FIFO stages (at burst transfer and no delay between frames CPHA = 1)

Figure 32.51 Clock Stop Waveform when Serial Transfer Continues with data is stored for the number of FIFO stages in Master Mode (at burst transfer and no delay between frames CPHA = 0)

The following describes operation of flags at timings (1) and (2) in the figure above.

1. While the data is stored for the number of FIFO stages, the RSPCK clock is deactivated and no overrun error occurs.
2. Receive buffer data can be read by reading SPDR during clock stop. After the receive buffer data has been read the RSPCK clock restarts.

32.3.10.2 Parity errors

After transfer in transmit-receive or receive-only master mode, transmit-receive slave mode or receive only slave mode while the SPPE bit in the SPI control register (SPCR) is 1, the SPI checks occurrence of a parity error. When the SPI detects a parity error in received data, the PERF flag in the SPI status register (SPSR) is set to 1. While the OVRF flag is 1, the SPI does not copy shift register data to the receive buffer. Therefore, parity error in received data is not detected. To clear the PERF flag in SPSR to 0, issue a system reset or 1 is written to the SPSRC.PERFC bit.

Figure 32.52 shows an example of operation of the OVRF and PERF flags. The SPSR access shown in Figure 32.52 indicates the condition of access to the register, where W denotes a write cycle, and R a read cycle. In this example, full-duplex serial communication is performed while the SPCR.SPPE bit is 1. The SPI performs an 8-bit serial transfer when SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given for RSPCKn in the waveform represent the number of RSPCK cycles, such as the number of transferred bits.

Figure 32.52 Operation example of the OVRF and PERF flags

The operation of the flags at timings (1) to (3) in Figure 32.52 is as follows:

1. When the SPI does not detect an overrun error and terminates the serial transfer, the SPI copies shift register data to the receive buffer. When the SPI checks the received data and detects a parity error at this time, the PERF flag is set to 1. In master mode, the SPI copies the value of pointer to the SPI command register (SPCMDm) to the SPECMD[2:0] bits in the SPI Data control register 2 (SPDCR2).
2. When 1 is written to the SPSRC.PERFC bit, then clear the PERF flag.
3. When the SPI detects an overrun error and serial transfer is terminated, the data in the shift register is not copied to the receive buffer. The SPI does not perform parity error detection at this time.

Parity errors can be checked for by either reading the SPSR register or using an SPI error interrupt and reading the SPSR register. When executing a serial transfer, such checks are required to ensure early detection of parity errors. When the SPI is used in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPDCR2.SPECMD[2:0] bits.

32.3.10.3 Mode fault errors

The SPI operates in multi-master mode when the SPCR.MSTR bit is 1, the SPCR.SPMS bit is 0, and the SPCR.MODFEN bit is 1.

If the active level is input for the SSLn0 input signal of the SPI in multi-master mode, the SPI detects a mode fault error regardless of the status of the serial transfer, and sets the SPSR.MODF flag to 1.

On detecting the mode fault error, the SPI copies the value of the pointer to SPCMD to the SPECMD[2:0] bits.

The active level of the SSLn0 signal is determined by the SPCR3.SSL0P bit.

When the MSTR bit is 0, the SPI operates in slave mode.

When the SPCR.MODFEN bit = 1 and the SPMS bit = 0 in slave mode, if the SSLn0 input signal is negated during the serial transfer period (from valid data drive start to final valid data latch), the SPI detects a mode fault error, while any of the following 2 conditions is met.

[In the Motorola-SPI case]

When the SSLn0 input signal is negated while serial data transfer.

[In the TI-SSP case]

When the SSLn0 input signal is asserted while serial data transfer. However, during burst transfer, no error is detected even if the SSLn0 input signal is asserted during the last bit of frame.

When the SPI detects a mode fault error, it stops driving output signals and clears the SPE bit in the SPCR register. When the SPE bit is cleared, the SPI function is disabled (as described in [section 32.3.12. SPI Operation](#)). In a multi-master configuration, the mastership can be released by stopping driving output signals and disabling the SPI function by using a mode fault error.

Whether a mode fault error is present can be checked by reading SPSR or by reading an SPI error interrupt and SPSR. To detect a mode fault error without using an SPI error interrupt, poll SPSR. When the SPI is used in master mode, the pointer value to SPCMD when an error is present can be checked by reading the SPECMD[2:0] bits in SPSR.

While the MODF flag = 1, the SPI ignores writing 1 to the SPE bit. To enable the SPI function after a mode fault error is detected, clear the MODF flag to 0 without fail.

32.3.10.4 Underrun errors

While the SPI is operating in slave mode (SPCR.MSTR bit = 0) and the communication mode select bit (TXMD[1:0]) in the SPI control register (SPCR) is set to 00b or 01b, if serial transfer is started before transmit data output is ready with the SPCR.SPE bit set to 1 (SPI function enabled), the SPI detects an underrun error and sets the SPSR.MODF and SPSR.UDRF flags to 1.

On detecting an underrun error, the SPI stops the driving of output signals and clears the SPCR.SPE bit to 0 (see [section 32.3.11. Initializing the SPI](#)).

The occurrence of underrun errors can be checked either by reading SPSR or by using an SPI error interrupt and reading SPSR. Detecting underrun errors without using the SPI error interrupt requires polling of SPSR.

When the MODF flag is 1, writing 1 to the SPE bit is ignored by the SPI. To enable the SPI function after the detection of an underrun error, the MODF flag must be set to 0.

32.3.10.5 Received data ready

When SPCR.TXMD[1:0] = 00b, 01b, or 11b, and SPCR2.SPDR[7:0] ≠ 0x00, after receiving data in the receive FIFO during communication (SPE = 1), SPSR.SPDRF flag is set to 1 when the received data is not stored even after the number of received FIFOs is equal to or less than ≤ the threshold value and the value set in SPDR[7:0] has elapsed.

When the receive data ready is detected, the interrupt and event link output can be selected as SPIi_SPRI or SPIi_SPEI with the SPCR.SPDR[7:0] bit.

Figure 32.53 shows an example of reception data ready detection operation.

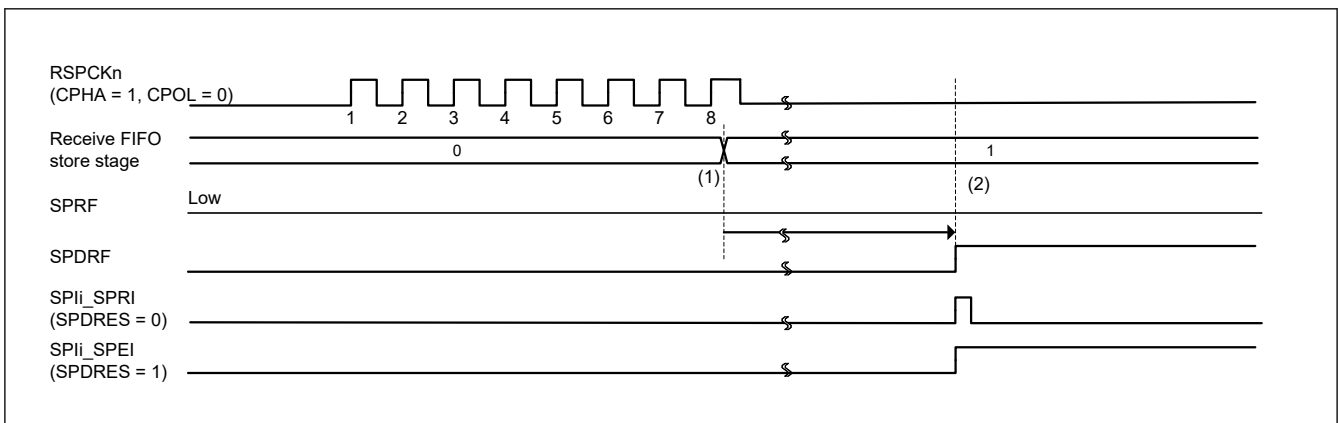

Figure 32.53 Received data ready

The following describes the operation at the timings indicated by (1) and (2) in the figure.

(1) Store the received data in the receive FIFO. SPRF is 0, because receive FIFO store stage \leq number of frames set by SPDCR2.RTRG[1:0].

(2) Set SPDRF and assert SPI_i_SPRI or SPI_i_SPEI because there is no writing to the receive FIFO for the amount of SPDRFC [7:0] set from above (1).

32.3.11 Initializing the SPI

If 0 is written to the SPCR.SPE bit or if the SPI sets the SPE bit to 0 because it detected a mode fault error or an underrun error, the SPI disables the SPI function and initializes some of the module functions. When a system reset is generated, the SPI initializes all of the module functions. This section describes initialization by clearing of the SPCR.SPE bit and by a system reset.

32.3.11.1 Initialization by clearing of the SPCR.SPE bit

When the SPCR.SPE bit is set to 0, the SPI initializes by:

- Suspending any serial transfer that is being executed
- Stopping the driving of output signals (Hi-Z) in slave mode
- Initializing the internal state of the SPI
- Initializing the transmit buffer of the SPI (the SPSR.SPTEF flag sets to 1)

Initialization by clearing of the SPE bit does not initialize the control bits of the SPI. For this reason, the SPI can be started in the same transfer mode in use prior to initialization when the SPE bit is set to 1 again.

The SPSR.CENDF, SPSR.SPRF, SPSR.OVRF, SPSR.MODF, SPSR.PERF, and SPSR.UDRF flags are not initialized, and the value of the SPDCR2.SPECM[2:0] and SPDCR2.SPCP[2:0] bits are not initialized. Therefore, even after the SPI is initialized, data from the receive buffer can be read to check the communication completion status and the error status during an SPI transfer.

The transmit buffer is initialized to an empty state (the SPSR.SPTEF flag sets to 1). Therefore, if the SPCR.SPTIE bit is set to 1 after SPI initialization, a transmit buffer empty interrupt is generated. To disable any transmit buffer empty interrupts when the SPI is initialized, write 0 to the SPTIE bit simultaneously while writing 0 to the SPE bit.

32.3.11.2 Initialization by system reset

A system reset completely initializes the SPI by initializing all SPI control bits, status bits, and data registers, in addition to the requirements described in [section 32.3.11.1. Initialization by clearing of the SPCR.SPE bit](#).

32.3.12 SPI Operation

32.3.12.1 Master mode operation

The only difference between single- and multi-master mode operation is the use of mode fault error detection (see [section 32.3.10. Error Detection](#)). In single-master mode, the SPI does not detect mode fault errors whereas in multi-master mode, it does. This section explains operations that are common to both modes.

(1) Starting a serial transfer

When data is written to the SPI data register (SPDR) while the next transfer data is not set in the transmit FIFO, the SPI updates the transmit buffer (SPTX_n, n = 0 to 3) data in SPDR. When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR, the SPI copies data from the transmit buffer to the shift register and starts serial transfer. On copying transmit data to the shift register, the SPI changes the status of the shift register to full. On termination of the serial transfer, it changes the status of the shift register to empty. The status of the shift register cannot be referenced.

The polarity of the SSL_n output pins depends on the SPCR3.SSL_nP (n = 0 to 3) bits settings. For details on the SPI transfer format, see [section 32.3.5. Transfer Formats](#).

(2) Terminating a serial transfer

[Except Receive-only in Master Mode]

After the SPI detects the RSPCK_n edge corresponding to the final sampling timing regardless of the CPHA bit value in the SPI command register (SPCMD), the SPI terminates serial transfer. When the number of data stored in the receive FIFO is less than the number of FIFO stages, data is copied from the shift register to the receive buffer in the SPI data register (SPDR) after serial transfer.

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMD_m.SPB[4:0] bit settings. The polarity of the SSL_ni output pin depends on the SPCR3.SSL_nP (n = 0 to 3) bits settings. For details on the SPI transfer format, see [section 32.3.5. Transfer Formats](#).

[Receive-only in Master Mode]

When any of the following 2 conditions is met, then SPI terminating the serial transfer.

- After the SPI detects the RSPCK_n edge corresponding to the final sampling timing regardless of the CPHA bit value in the SPI command register (SPCMD), the SPI terminates serial transfer.
- When writing SPCR2.RMEDTG = 1 during the serial transfer period, SPI terminating the serial transfer.

When the number of data stored in the receive FIFO is less than the number of FIFO stages, data is copied from the shift register to the receive buffer in the SPI data register (SPDR) after serial transfer.

The final sampling timing varies depending on the transfer data bit length. The data length of the SPI in master mode depends on the set value of the SPB[4:0] bits in the SPI command register (SPCMD). The SSL_ni output signal polarity depends on the set SPI SSL_i signal polarity bit (SPCR3.SSL_iP) (i = 0 to 3) value. For details about the SPI transfer format, see [section 32.3.5. Transfer Formats](#).

(3) Sequence control

The transfer format in master mode is determined as follows.

The transfer format used in master mode is determined by the SPCR3, SPCMD_m, and SPDECR registers.

The SPCR3.SPSSLN[2:0] bits determine the sequence configuration for serial transfers that are executed by the SPI in master mode. The following items are set in the SPCMD_m register:

- SSL_ni pin output signal value
- MSB- or LSB-first
- Data length
- Some of the bit rate settings
- RSPCK_n polarity and phase
- Whether SPDECR.SCKDL is to be referenced
- Whether SPDECR.SLNDL is to be referenced
- Whether SPDECR.SPNDL is to be referenced

SPCR3.SPBR holds some of the bit rate settings, including SPDECR.SCKDL (SPI clock delay), SPDECR.SLNDL (SSL negation delay), and SPDECR.SPNDL (next-access delay).

Based on the sequence length assigned in SPCR3.SPSSLN, the SPI makes up a sequence comprised of a part or all of the SPCMD_m register. The SPI contains a pointer to the SPCMD_m register that makes up the sequence. The value of this pointer can be checked by reading the SPDCR2.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD₀, and incorporates the SPCMD₀ settings into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command in the sequence, the SPI sets the pointer to SPCMD₀, and in this way the sequence is executed repeatedly.

Figure 32.54 Procedure for determining the form of a serial transfer in master mode

In this section, a frame is the combination of the data in SPDR and the settings in SPCMDm.

Figure 32.55 Conceptual diagram of frames

Figure 32.56 shows the correspondence between the commands and the transmit and receive buffers in the sequence of operations specified by the settings.

Figure 32.56 Correspondence between SPI Command Register and transmit and receive buffers in sequence operations

(4) Burst transfers

This section describes burst transfer during transmit-receive/transmit-only operation.

[In the Motorola-SPI case]

If the SPCMDm.SSLKP bit that the SPI references during the current serial transfer is 1, the SPI maintains the SSLni signal level during the serial transfer until the beginning of the SSLni signal assertion for the next serial transfer. If the SSLni signal level for the next serial transfer is the same as the SSLni signal level for the current serial transfer, the SPI can execute continuous serial transfers while keeping the SSLni signal assertion status (burst transfer).

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register (SPCR) is 0.

Figure 32.57 shows an example of an SSLni signal operation for a burst transfer that is implemented using the SPCMD0 and SPCMD1 register settings. This section describes SPI operations (1) to (8) shown in Figure 32.57.

Note: The polarity of the SSLni output signal depends on the SPCR3.SSLnP (n = 0 to 3) bits settings.

Figure 32.57 Example of burst transfer operation using the SSLKP bit (BFDS = 0, SPFRF = 0)

The SPI operation at times (1) to (8) in the figure is as follows:

1. Based on the SPCMD0 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
2. The SPI executes serial transfers in accordance with the SPCMD0 settings.
3. The SPI inserts an SSL negation delay.
4. Because the SPCMD0.SSLKP bit is 1, the SPI keeps the SSLni signal value specified in SPCMD0. This period additionally continues for 5 TCLK cycles (at minimum) that is the same as the next-access delay time of SPCMD0. If the shift register is empty after the passage of the minimum period, this period is sustained until the transmit data is stored in the shift register for the next transfer.
5. Based on the SPCMD1 settings, the SPI asserts the SSLni signal and inserts RSPCK delays.
6. The SPI executes serial transfers in accordance with the SPCMD1 settings.
7. Insert SSL negate delay.
8. Because the SPCMD1.SSLKP bit is 0, the SPI negates the SSLni signal. In addition, a next-access delay is inserted in accordance with SPCMD1.

If the SSLni signal output settings in the SPCMDm register where 1 is assigned to the SSLKP bit are different from the SSLni signal output settings in the SPCMDm register to be used in the next transfer, the SPI switches the SSLni signal status to SSLni signal assertion as shown in (5) in Figure 32.57. This corresponds to the command for the next transfer.

Note: If such an SSLni signal switching occurs, the slaves that drive the MISO_n signal compete, and collision of signal levels might occur.

The SPI in master mode references the SSLni signal operation within the module when the SSLKP bit is not used. When the SPCMDm.CPHA bit is 0, the SPI can accurately start serial transfers by using the SSLni signal assertion for the next transfer that is detected internally.

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register (SPCR) is 1.

Figure 32.58 shows an example of SSLni signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in Figure 32.58. The SSLni output signal polarity depends on the set SPCR3.SSLnP (n = 0 to 3) value.

Figure 32.58 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 1, SPFRF = 0)

1. Assert the SSLni signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmission.
2. Perform serial transfer according to SPCMD0. Wait last clock until the next transmit data is stored in the shift register, if the shift register is empty during RSPCK negate period between frames.
3. The value of SSLni signal according to SPCMD0 was hold, because the SPCMD0.SSLKP bit is 1. RSPCK negate period between frames is 0.5RSPCK, if the shift register is not empty.
4. Perform serial transfer according to SPCMD1.
5. Insert SSLni negate delay for the last frame.
6. The SSLni signal is negated because the SSLKP bit in SPCMD1 is 0. Furthermore, the next-access delay is inserted according to SPCMD1.

[In the TI-SSP case]

SPI asserts the SSLni signal for one cycle at the start of serial transfer.

Serial transfer can be executed continuously by asserting the SSLni signal for one cycle at the start of the next serial transfer (burst transfer).

- When the SSLni signal level holding bit (SSLKP) of the SPI command register (SPCMD) is 1 and the burst transfer frame delay selection bit (BFDS) of the SPI control register (SPCR) is 1, SPCMD0 to SPCMD1 are shown in [Figure 32.59](#). The following shows an example of SSLni signal operation and serial data MISO_n/MOSI_n when burst transfer is realized using the settings. The SSLni output signal polarity depends on the set SPI SSLi signal polarity bit (SPCR3.SSLiP) (i = 0 to 3) value.

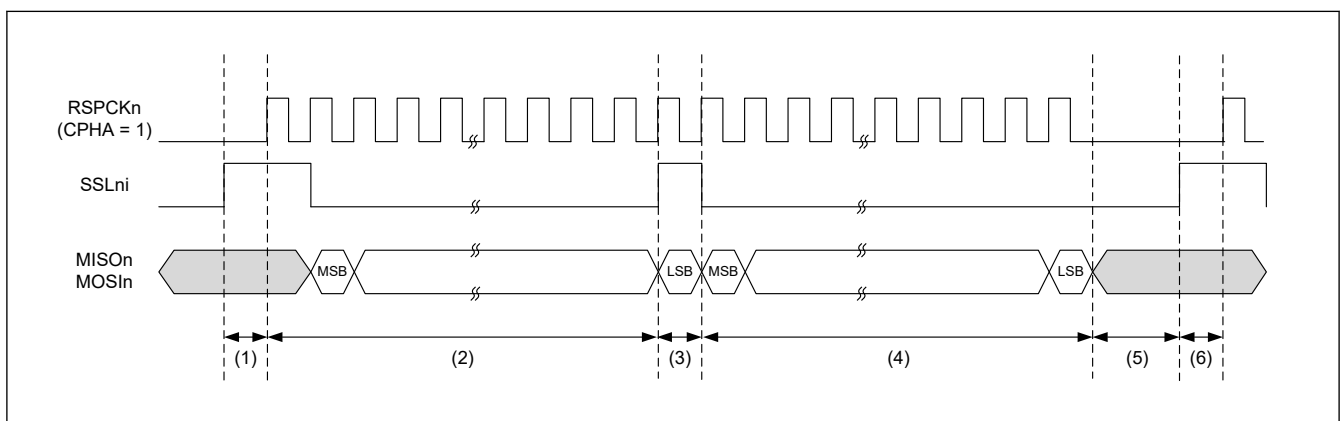

Figure 32.59 Example of Burst Transfer Operation (SPFRF = 1)

1. Assert the SSLni signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmission.
2. Perform serial transfer according to SPCMD0.
3. Final data transfer and SSLni assertion are performed simultaneously. If the shift register is empty during the RSPCK negation period between frames, wait for the output of the last clock until the transmission data for the next transfer is stored in the shift register.

4. Perform serial transfer according to SPCMD1.
5. Insert OE negate delay for the last frame.
6. Insert the next access delay according to SPCMD1.

If the SSLni signal output setting in SPCMD with the SSLKP bit set to 1 differs from the SSLni signal output setting in SPCMD to be used for the next transfer, the SPI changes the SSLni signal state when the SSLni signal corresponding to the next-transfer command is asserted ((5)). Note that, if an SSLni signal change like this takes place, slaves that drive the MISO_n signal may conflict with each other, which may cause collision of signal level.

This section describes burst transfer during receive-only operation.

[In the Motorola-SPI case]

When the SSLKP bit in the SPI command register (SPCMD), which the SPI references in the current serial transfer, is 1, the SPI retains the SSLni signal level during serial transfer until the SSLni signal assertion of the next serial transfer starts. When the SSLni signal level in the next serial transfer is the same as the SSLni signal level in the current serial transfer, the SPI can continuously perform serial transfer while holding the SSLni signal assertion status (burst transfer).

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register (SPCR) is 0.

Figure 32.60 shows an example of SSLni signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (8) shown in Figure 32.60. The SSLni output signal polarity depends on the set SPI SSLni signal polarity bit (SPCR3.SSLiP) (i = 0 to 3) value.

Figure 32.60 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 0, SPFRF = 0)

1. Assert the SSLni signal and insert an RSPCK delay according to SPCMD0.
2. Perform serial transfer according to SPCMD0.
3. Insert an SSLni negation delay.
4. The SSLni signal value in SPCMD0 is retained because the SSLKP bit in SPCMD0 is 1. This period additionally continues for 5 TCLK cycles (at minimum) that is the same as the next-access delay time of SPCMD0.
5. Assert the SSLni signal and insert an RSPCK delay according to SPCMD1.
6. Perform serial transfer according to SPCMD1.
7. Insert SSLni negate delay.
8. The SSLni signal is negated because the SSLKP bit in SPCMD1 is 0. Furthermore, the next-access delay is inserted according to SPCMD1.

If the SSLni signal output setting and the SSLni signal output setting between SPCMDs used for burst transfer are different, SPI switches the SSLni signal state when the SSLni signal corresponding to the next transfer command is asserted (5). Note that, if an SSLni signal change like this takes place, slaves that drive the MISO_n signal may conflict with each other, which may cause collision of signal level.

The SPI in master mode references the SSLni signal operation in the module when SSLKP is not used.

Even when the CPHA bit in SPCMD is 0, the SPI can accurately start serial transfer by using the next transfer SSLni signal assertion detected internally. For this reason, burst transfer in master mode is enabled regardless of the set CPHA bit value. (See section 32.3.11. Initializing the SPI.)

- When Between Burst Transfer Frames Delay Select bit (BFDS) of SPI control register (SPCR) is 1.

Figure 32.61 shows an example of SSLni signal operation when burst transfer is achieved by using the settings of SPCMD0 and SPCMD1. The following describes SPI operations of (1) to (6) shown in Figure 32.61. The SSLni output signal polarity depends on the set SPI SSLi signal polarity bit (SPCR3.SSLiP) (i = 0 to 3) value.

Figure 32.61 Example of Burst Transfer Operation Using SSLKP Bit (BFDS = 1, SPFRF = 0)

1. Assert the SSLni signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmission.
2. Perform serial transfer according to SPCMD0.
3. Since it is not the last frame, the SSLni signal value at SPCMD0 is retained. RSPCKn negation between frames is 0.5 RSPCKn for the next frame.
4. Perform serial transfer according to SPCMD1.
5. Insert SSLni negate delay for the last frame.
6. The SSLni signal is negated. Furthermore, the next-access delay is inserted according to SPCMD1.

Note: Last frame: Frame set by RMFM[4:0] bits when SPCR2.RMFM[4:0] ≠ 0x00
 Or, a frame in which SPCR2.RMEDTG = 1 has been accepted.

[In the TI-SSP case]

SPI asserts the SSLni signal for one cycle at the start of serial transfer.

Serial transfer can be executed continuously by asserting the SSLni signal for one cycle at the start of the next serial transfer (burst transfer).

- When the SSLni signal level holding bit (SSLKP) of the SPI command register (SPCMD) is 1 and the burst transfer frame delay selection bit (BFDS) of the SPI control register (SPCR) is 1, SPCMD0 to SPCMD1 are shown in Figure 32.62. The following shows an example of SSLni signal operation and serial data MISO_n / MOSI_n when burst transfer is realized using the settings. The SSLni output signal polarity depends on the set SPI SSLi signal polarity bit (SPCR3.SSLiP) (i = 0 to 3) value.

Figure 32.62 Example of Burst Transfer Operation (SPFRF = 1)

1. Assert the SSLni signal and insert an RSPCK delay according to SPCMD0. The RSPCK delay is inserted only the first frame of burst transmission.

2. Perform serial transfer according to SPCMD0.
3. Final data transfer and SSLni assertion are performed simultaneously.
4. Perform serial transfer according to SPCMD1.
5. Insert OE negate delay for the last frame.
6. Insert the next access delay according to SPCMD1.

Note: Last frame: Frame set by RMFM[4:0] bits when SPCR2.RMFM[4:0] \neq 0x00
Or, a frame in which SPCR2.RMEDTG = 1 has been accepted.

If the SSLni signal output setting between the SPCMDs used for burst transfer differs from the SSLni signal output setting, SPI switches the SSLni signal state when the SSLni signal corresponding to the next transfer command is asserted (5). Note that, if an SSLni signal change like this takes place, slaves that drive the MISO_n signal may conflict with each other, which may cause collision of signal level.

(5) RSPCK delay (t1)

The RSPCK delay value of the SPI in master mode depends on the SPCMDm.SCKDEN bit setting and the SPDECR.SCKDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced during a serial transfer by pointer control, and determines an RSPCK delay using the SPCMDm.SCKDEN bit and SPDECR.SCKDL[2:0] bits, as listed in [Table 32.10](#). For a definition of RSPCK delay, see [section 32.3.5. Transfer Formats](#).

RSPCK delay insert to only the first frame of burst transmission, when transmit without “Between Burst Transfer Frames Delay”. (The SPCMD.SSLKP bit is 1 and the SPCR.BFDS bit is 1.)

Table 32.10 Relationship between the SPCMDm.SCKDEN bit, SPDECR.SCKDL[2:0] bits, and RSPCK delay

SPCMDm.SCKDEN bit	SPDECR.SCKDL[2:0] bits	RSPCK delay	
		Motorola-SPI	TI-SSP
0	000b to 111b	1 RSPCK	0 RSPCK
1	000b	1 RSPCK	1 RSPCK
	001b	2 RSPCK	2 RSPCK
	010b	3 RSPCK	3 RSPCK
	011b	4 RSPCK	4 RSPCK
	100b	5 RSPCK	5 RSPCK
	101b	6 RSPCK	6 RSPCK
	110b	7 RSPCK	7 RSPCK
	111b	8 RSPCK	8 RSPCK

(6) SSL negation delay (t2)

The SSL negation delay value of the SPI in master mode depends on the SPCMDm.SLN DEN bit setting and the SPDECR.SLN DL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced by pointer control during a serial transfer, and determines an SSL negation delay using the SPCMDm.SLN DEN bit and SPDECR.SLN DL[2:0] bits, as listed in [Table 32.11](#). For a definition of SSL negation delay, see [section 32.3.5. Transfer Formats](#).

An SSL negation delay is inserted to only the last frame of the burst transmission, that is, transmit without between burst transfer frames delay. (SPCMD.SSLKP bit is 1 and SPCR.BFDS bit is 1).

Table 32.11 Relationship between the SPCMDm.SLN DEN bit, SPDECR.SLN DL[2:0] bits, and SSL negation delay (1 of 2)

SPCMDm.SLN DEN bit	SPDECR.SLN DL[2:0] bits	SSL negation delay
0	000b to 111b	1 RSPCK

Table 32.11 Relationship between the SPCMDm.SLN DEN bit, SPDECR.SLN DL[2:0] bits, and SSL negation delay (2 of 2)

SPCMDm.SLN DEN bit	SPDECR.SLN DL[2:0] bits	SSL negation delay
1	000b	1 RSPCK
	001b	2 RSPCK
	010b	3 RSPCK
	011b	4 RSPCK
	100b	5 RSPCK
	101b	6 RSPCK
	110b	7 RSPCK
	111b	8 RSPCK

(7) Next-access delay (t3)

The next-access delay value of the SPI in master mode depends on the SPCMDm.SPNDEN bit setting and the SPDECR.SPNDL[2:0] bits setting. The SPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and then determines a next-access delay during serial transfer using the SPCMDm.SPNDEN bit and SPDECR.SPNDL[2:0] bits, as listed in [Table 32.12](#). For a definition of next-access delay, see [section 32.3.5. Transfer Formats](#).

A next-Access delay is inserted to only the last frame of the burst transmission, that is, transmit without between burst transfer frames delay. (SPCMD.SSLKP bit is 1 and SPCR.BFDS bit is 1).

Table 32.12 Relationship between the SPCMDm.SPNDEN bit, SPDECR.SPNDL[2:0] bits, and next-access delay

SPCMDm.SPNDEN bit	SPDECR.SPNDL[2:0] bits	Next-access delay
0	000b to 111b	1 RSPCK + 5 TCLK
1	000b	1 RSPCK + 5 TCLK
	001b	2 RSPCK + 5 TCLK
	010b	3 RSPCK + 5 TCLK
	011b	4 RSPCK + 5 TCLK
	100b	5 RSPCK + 5 TCLK
	101b	6 RSPCK + 5 TCLK
	110b	7 RSPCK + 5 TCLK
	111b	8 RSPCK + 5 TCLK

(8) Initialization flow

[Figure 32.63](#) shows an example of SPI initialization flow when the SPI is in master mode. For information on how to set up the Interrupt Controller Unit (ICU), DMAC or DTC, and I/O ports, see the descriptions given in the individual blocks.

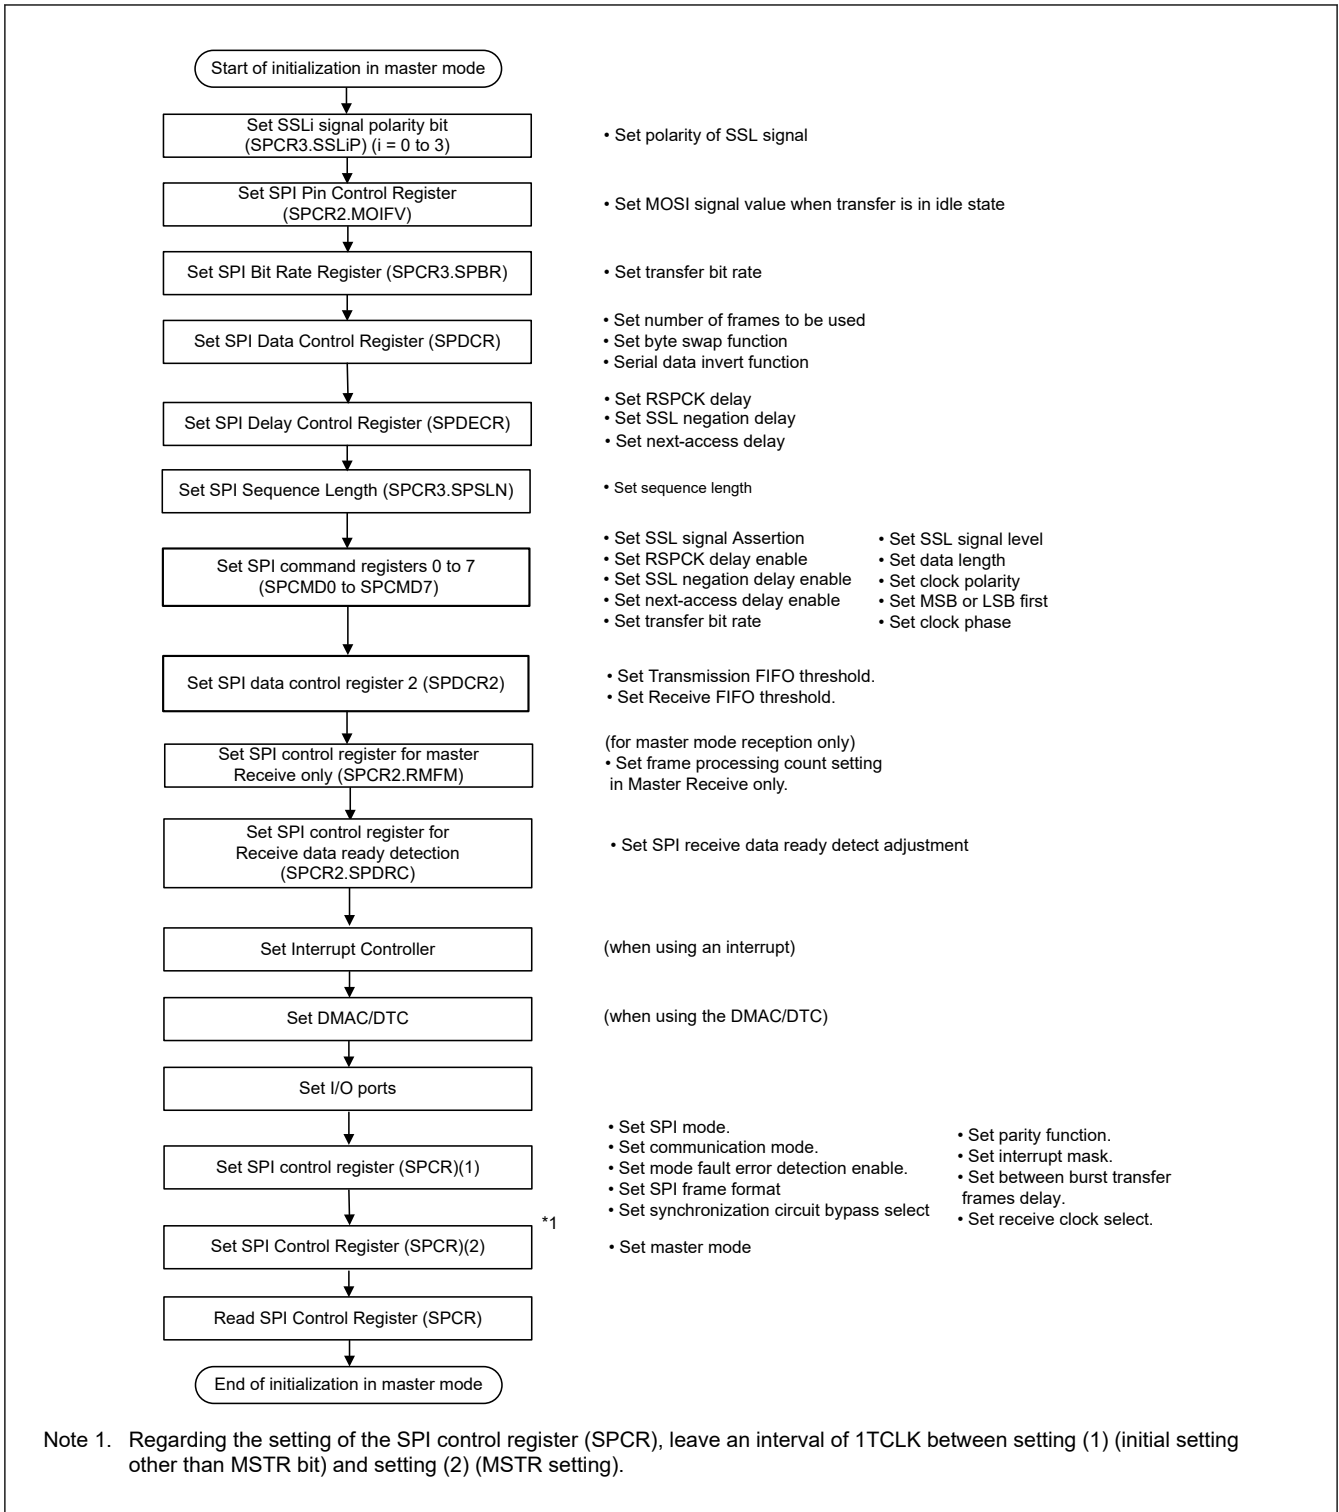

Figure 32.63 Example of initialization flow in master mode for SPI operation

(9) Software processing flow

Figure 32.64 to Figure 32.67 show examples of the software processing flow.

Transmit processing flow

When transmitting data, with the SPIi_SPII or SPIi_SPCEND interrupt enabled, the CPU is notified of the completion of data transmission after the last data write for transmission.

Figure 32.64 Transmission flow in master mode

Receive processing flow

The SPI has receive only operation in slave mode.

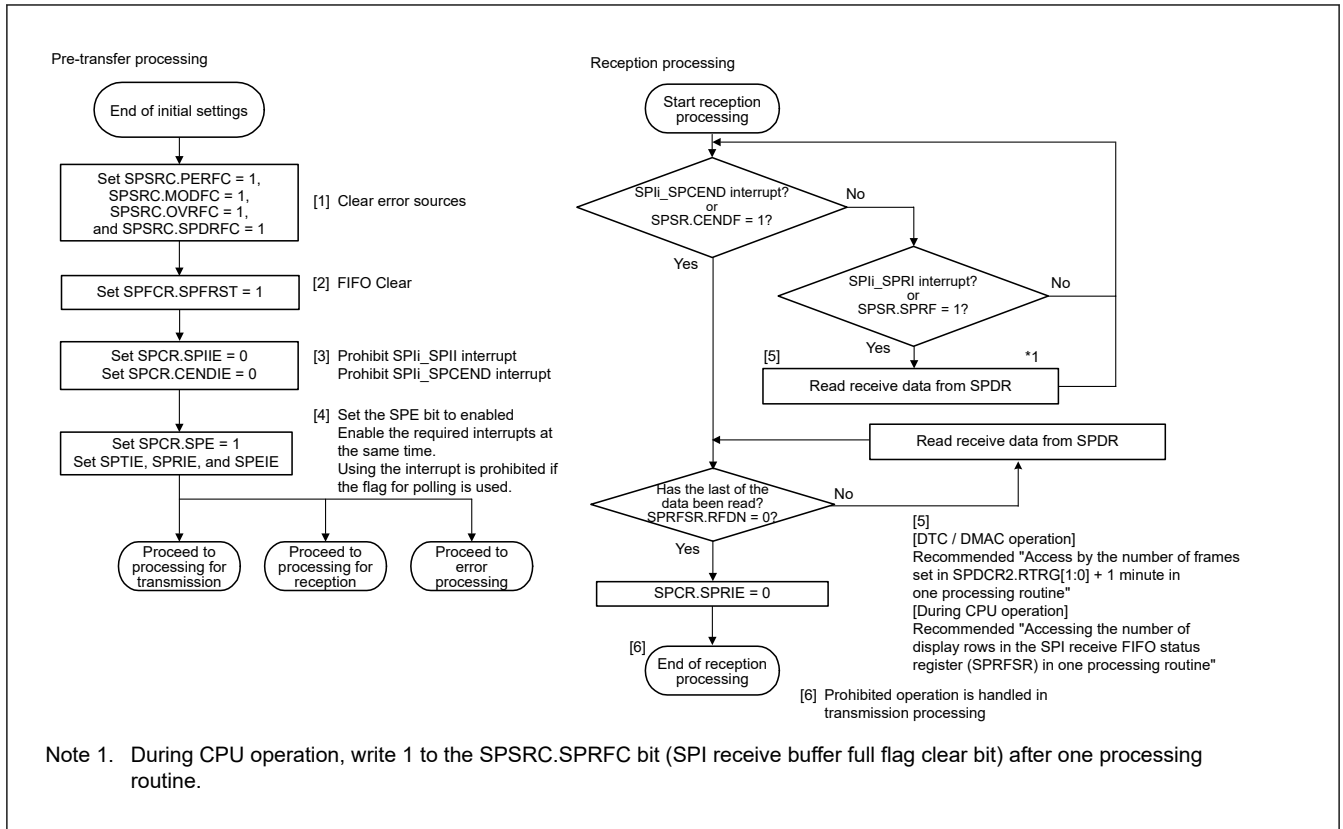

Figure 32.65 Reception flow in master mode

Receive only processing flow in master mode

Figure 32.66 Software Processing Flowchart in Master Mode (Reception-only)

Error processing flow

The SPI detects the following errors:

- Mode fault error
- Underrun error
- Overrun error
- Parity error

When a mode fault error is generated, the SPCR.SPE bit is automatically cleared, stopping operations for transmission and reception. For errors from other sources, the SPCR.SPE bit is not cleared and operations for transmission and reception continue. Therefore, Renesas recommends clearing the SPCR.SPE bit to stop operations for errors other than mode fault errors. Not doing so leads to updating of the SPDCR2.SPECM[2:0] bits.

When an error is detected using an interrupt, clear the ICU.IELSRn.IR flag in the error processing routine. If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPIi_SPTI or SPIi_SPRI interrupt request. If the SPIi_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.

Figure 32.67 Error processing flow in master mode

32.3.12.2 Slave mode operation

(1) Starting a serial transfer

When the SPCMD0.CPHA bit is 0, if the SPI detects an SSLn0 input signal assertion, it must drive valid data to the MISO_n output signal. For this reason, when the CPHA bit is 0, the assertion of the SSLn0 input signal triggers the start of a serial transfer.

When the CPHA bit is 1, if the SPI detects the first RSPCK_n edge in an SSLn0 signal asserted condition, it must drive valid data to the MISO_n output signal. For this reason, when the CPHA bit is 1, the first RSPCK_n edge in an SSLn0 signal asserted condition triggers the start of a serial transfer.

Regardless of the CPHA bit setting, the SPI drives the MISO_n output signal on SSLn0 signal assertion. The data that is output by the SPI is either valid or invalid, depending on the CPHA bit setting.

For details on the SPI transfer format, see [section 32.3.5. Transfer Formats](#). The polarity of the SSLn0 input signal depends on the SPCR3.SSL0P setting.

(2) Terminating a serial transfer

Regardless of the SPCMD0.CPHA bit setting, the SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When the number of data stored in the receive FIFO is less than the number of FIFO stages, on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR register. On termination of a serial transfer, the SPI changes the status of the shift register to empty, regardless of the receive buffer state. A mode fault error occurs if the SPI detects an SSLn0 input signal negation from the beginning of serial transfer to the end of serial transfer (see [section 32.3.10. Error Detection](#)).

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length is determined by the SPCMD0.SPB[4:0] bits setting. The polarity of the SSLn0 input signal is determined by the SPCR3.SSL0P bit setting. For details on the SPI transfer format, see [section 32.3.5. Transfer Formats](#).

(3) Notes on single-slave operations

[In the Motorola-SPI case]

If the SPCMD0.CPHA bit is 0, the SPI starts serial transfers when it detects the assertion edge for an SSLn0 input signal. In the configuration shown in [Figure 32.8](#), if the SPI is used in single-slave mode, the SSLn0 signal is fixed at an active state. Therefore, when the CPHA bit is set to 0, the SPI cannot correctly start a serial transfer. For the SPI to correctly execute transmit and receive operations in slave mode when the SSLn0 input signal is fixed at an active state, the CPHA bit must be set to 1. Do not fix the SSLn0 input signal if there is a requirement for setting the CPHA bit to 0.

[In the TI-SSP case]

When SPI is used as a single slave in the configuration shown in the [Figure 32.8](#), the SSLn0 input signal is always fixed to the inactive state, so the SPI cannot start the serial transfer.

When using a single slave, use the configuration shown in the example in [Figure 32.7](#).

(4) Burst transfer

[In the Motorola-SPI case]

If the SPCMD0.CPHA bit is 1, continuous serial transfer (burst transfer) can be executed while retaining the assertion state for the SSLn0 input signal. When the CPHA bit is 1, the serial transfer period is the period from the first RSPCKn edge to the sampling timing for the reception of the final bit in an SSLn0 signal active state. Even when the SSLn0 input signal remains at the active level, the SPI can accommodate burst transfers, because it can detect the start of an access.

When the CPHA bit is 0, the second and subsequent serial transfers during burst transfer cannot be executed correctly.

[In the TI-SSP case]

In serial transfer, data transfer starts after the SSLn0 input signal is asserted for RSPCK 1 cycle. Since frame transfer starts from the SSLn0 input signal, SSLn0 must be asserted between frames.

(5) Initialization flow

[Figure 32.68](#) shows an example of initialization flow for SPI operation when the SPI is in slave mode. For a description of how to set up the ICU, DMAC or DTC, and I/O ports, see the descriptions given in the individual blocks.

Figure 32.68 Example initialization flow in slave mode for SPI operation

(6) Software processing flow

Figure 32.69 to Figure 32.72 show examples of the flow of software processing.

Transmit processing flow

Figure 32.69 Transmission flow in slave mode

Receive processing flow

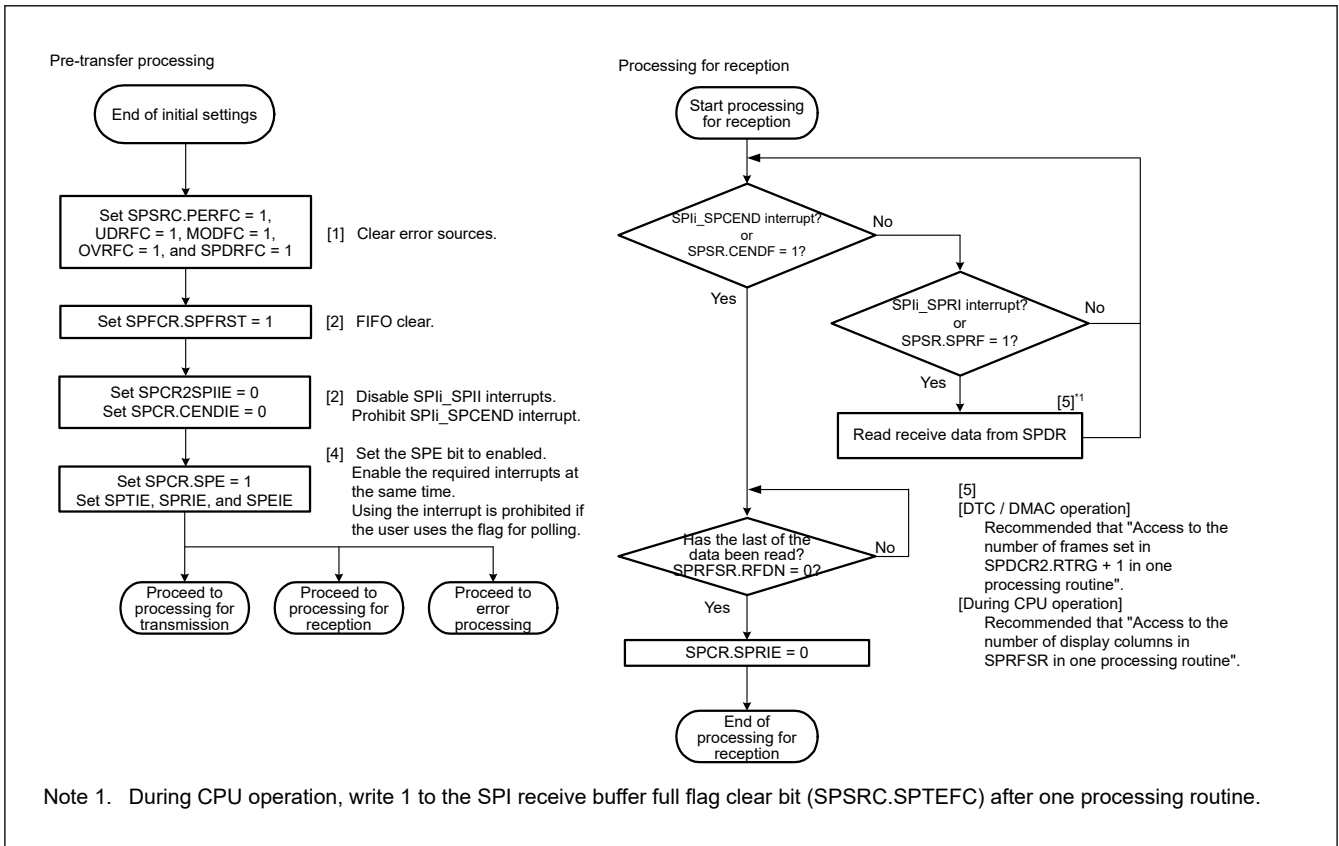

Figure 32.70 Reception flow in slave mode

Master Reception-only processing flow

Figure 32.71 Software Processing Flowchart in Master Mode (Reception-only)

Error processing flow

In slave mode operation, even when a mode fault error is generated, the SPSR.MODF flag can be cleared regardless of the state of the SSLn0 pin.

When an error is detected by using an interrupt, clear the ICU.IELSRn.IR flag in the error processing routine. If this is not done, the ICU.IELSRn.IR flag might continue to indicate the SPIi_SPTI or SPIi_SPRI interrupt request. If the SPIi_SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the SPI.

Figure 32.72 Error processing flow for slave mode

32.3.13 Clock Synchronous Operation

Setting the SPCR.SPMS bit to 1 selects clock synchronous operation of the SPI. In clock synchronous operation, the SSL_ni pin is not used, and the RSPCK_n, MOS_n, and MISO_n pins handle communications. All SSL_ni pins are available as I/O port pins.

Although clock synchronous operation does not require the use of the SSL_ni pin, operation of the module is the same as in SPI operation. In both master mode and slave mode operations, communications can be performed with the same flow as in SPI operation. However, mode fault errors are not detected, because the SSL_ni pin is not used.

Additionally, do not perform operation if clock synchronous operation is enabled when the SPCMD_m.CPHA bit is set to 0 in slave mode (SPCR.MSTR = 0).

32.3.13.1 Master mode operation

(1) Starting serial transfer

When data is written to the SPI data register (SPDR) while the next transfer data is not set in the transmit FIFO, the SPI updates the transmit buffer (SPTX_n, n = 0 to 3) data in SPDR. While the shift register is empty, the SPI copies transmit buffer data to the shift register to start serial transfer. After the SPI copies transmit data to the shift register, it changes the shift register status to full. Upon completion of serial transfer, the SPI changes the shift register status to empty. The shift register status cannot be monitored.

For details about the SPI transfer format, see section 32.3.5. Transfer Formats. In clock synchronous operation, however, the SSL_n0 output signal is not used for communication.

(2) Terminating serial transfer

The SPI terminates the serial transfer after transmitting an RSPCKn edge corresponding to the sampling timing. If the number of data stored in the receive FIFO < the number of FIFO stages, on termination of serial transfer, the SPI copies data from the shift register to the receive buffer of the SPI Data Register (SPDR).

The final sampling timing varies depending on the bit length of transfer data. In master mode, the SPI data length depends on the SPCMDm.SPB[4:0] bits setting. Transfer in clock synchronous operation is conducted without the SSLn0 output signal. For details on the SPI transfer format, see [section 32.3.5. Transfer Formats](#).

(3) Sequence control

The transfer format used in master mode is determined by the SPCR3, SPCMDm, and SPDECR registers. Although the SSLni signals are not output in clock synchronous operation, these settings are valid.

The SPCR3.SPSSLN[2:0] bits determine the sequence configuration for serial transfers that are executed by the SPI in master mode. The following parameters are specified in the SPCMDm register:

- SSLni output signal value
- MSB or LSB first
- Data length
- Some of the bit rate settings
- RSPCKn polarity and phase
- Whether SPDECR.SCKDL is to be referenced
- Whether SPDECR.SLNDL is to be referenced
- Whether SPDECR.SPNDL is to be referenced

SPCR3.SPBR holds some of the bit rate settings such as SPDECR.SCKDL, an SPI clock delay value, SPDECR.SLNDL, an SSL negation delay, and SPDECR.SPNDL, a next-access delay value.

Based on the sequence length that is assigned to SPCR3, the SPI makes up a sequence comprised of a part or all of SPCMDm register. The SPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPDCR2.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the SPI function is enabled, the SPI loads the pointer to the commands in SPCMD0 register, and incorporates the SPCMD0 register setting into the transfer format at the beginning of serial transfer. The SPI increments the pointer each time the next-access delay period for a data transfer ends. On completion of the serial transfer that corresponds to the final command comprising the sequence, the SPI sets the pointer to the SPCMD0 register, and in this manner the sequence is executed repeatedly.

Figure 32.73 Procedure for determining the form of serial transmission in master mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm).

Figure 32.74 Conceptual diagram of frames

Figure 32.75 shows the relationship between the command and the transmit and receive buffers in the sequence of operations specified by the settings.

Figure 32.75 Correspondence between SPI Command Register and transmit and receive buffers in sequence operations

(4) Initialization flow

Figure 32.76 shows an example of initialization flow for clock synchronous operation when the SPI is used in master mode. For information on how to set up the ICU, DMAC or DTC, and I/O ports, see the descriptions given in the individual blocks.

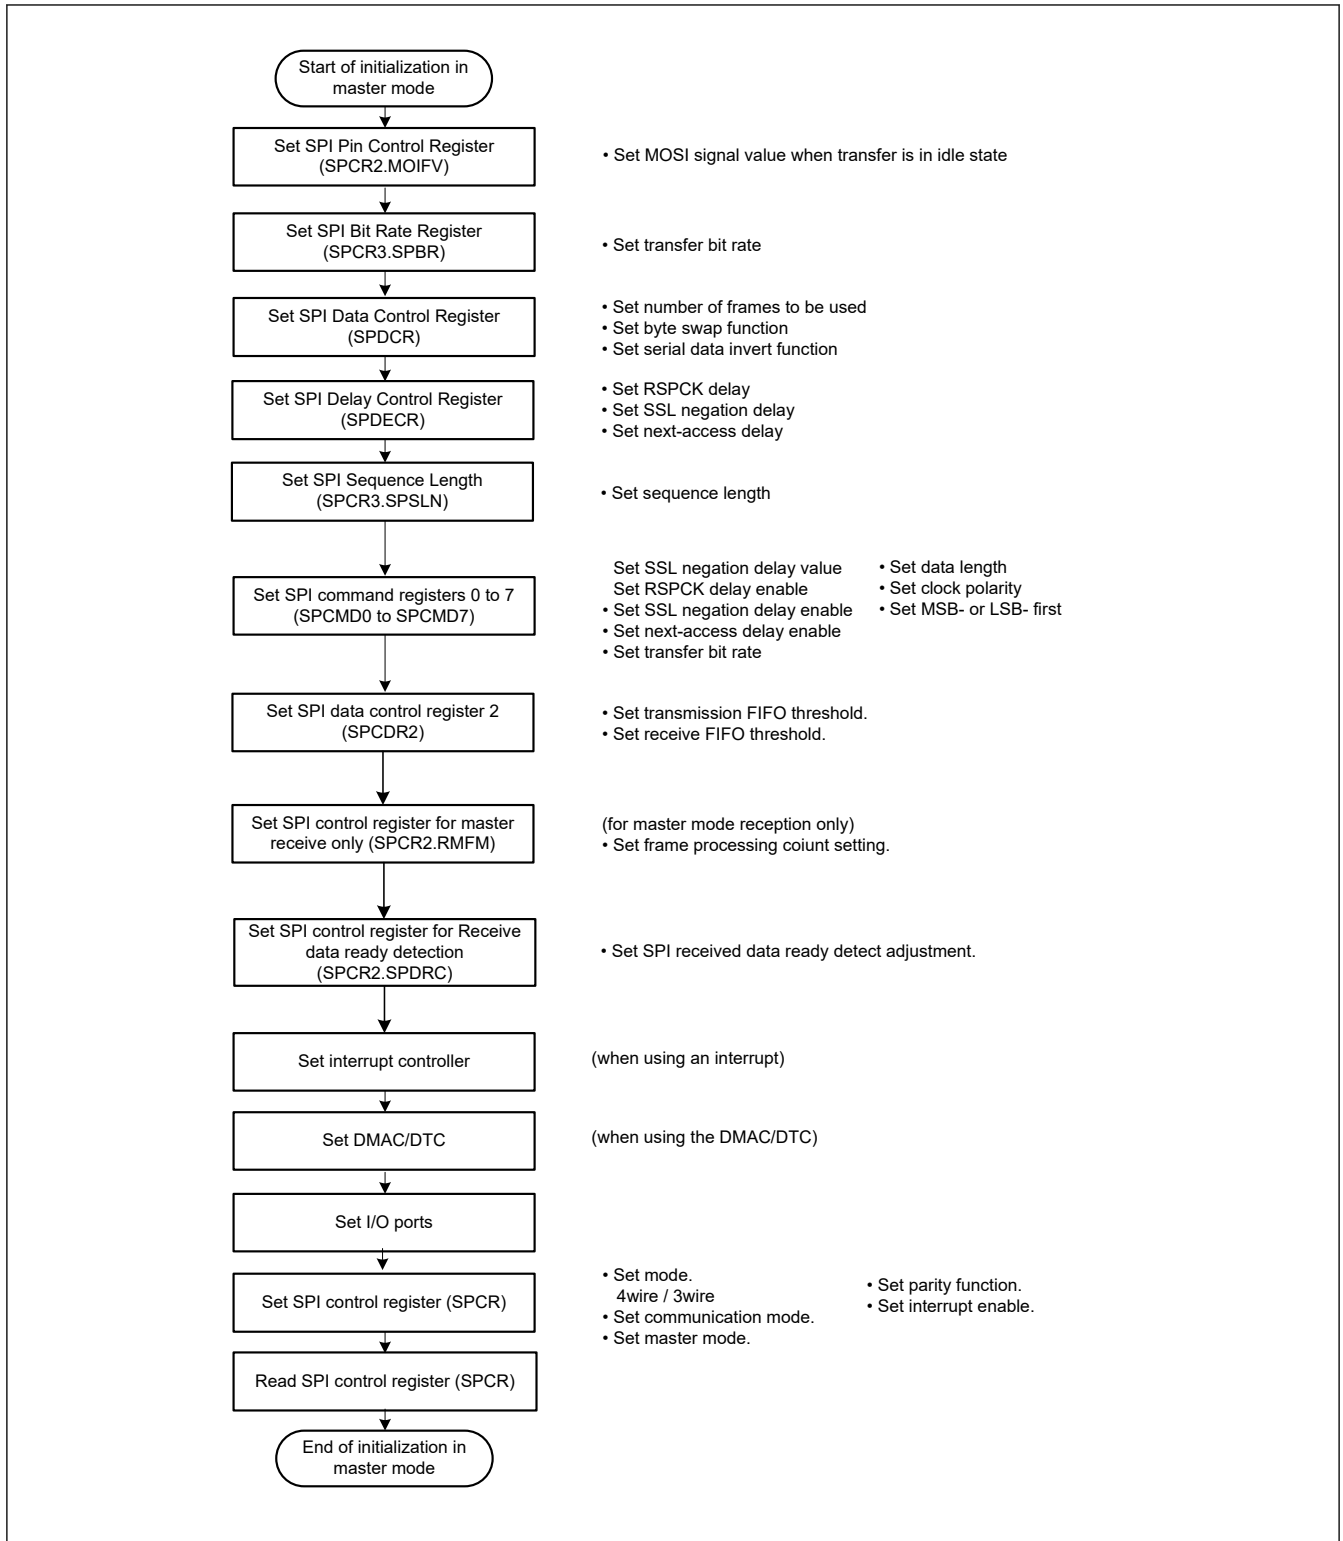

Figure 32.76 Example of initialization flow in master mode for clock synchronous operation

(5) Software processing flow

Software processing during clock synchronous master operation is the same as that for SPI master operation. For details, see (9) Software processing flow in [section 32.3.12.1. Master mode operation](#). Mode fault errors do not occur in clock synchronous operation.

32.3.13.2 Slave mode operation

(1) Starting serial transfer

When the SPCR.SPMS bit is 1, the first RSPCKn edge triggers the start of a serial transfer in the SPI, and the SPI drives the MISO_n output signal. The SSL_{n0} input signal is not used in clock synchronous operation. For details on the SPI transfer format, see [section 32.3.5. Transfer Formats](#).

(2) Terminating serial transfer

The SPI terminates the serial transfer after detecting an RSPCKn edge corresponding to the final sampling timing. When the number of data stored in the receive FIFO < the number of FIFO stages, on termination of serial transfer, the SPI copies received data from the shift register to the receive buffer of the SPDR register. On termination of a serial transfer, the SPI changes the status of the shift register to empty regardless of the receive buffer.

The final sampling timing changes depending on the bit length of transfer data. In slave mode, the SPI data length depends on the SPCMD0.SPB[4:0] bits setting. For details on the SPI transfer format, see [section 32.3.5. Transfer Formats](#).

(3) Initialization flow

[Figure 32.77](#) shows an example of initialization flow for clock synchronous operation when the SPI is used in slave mode. For a description of how to set up the ICU, DMAC or DTC, and I/O ports, see the descriptions given in the individual blocks.

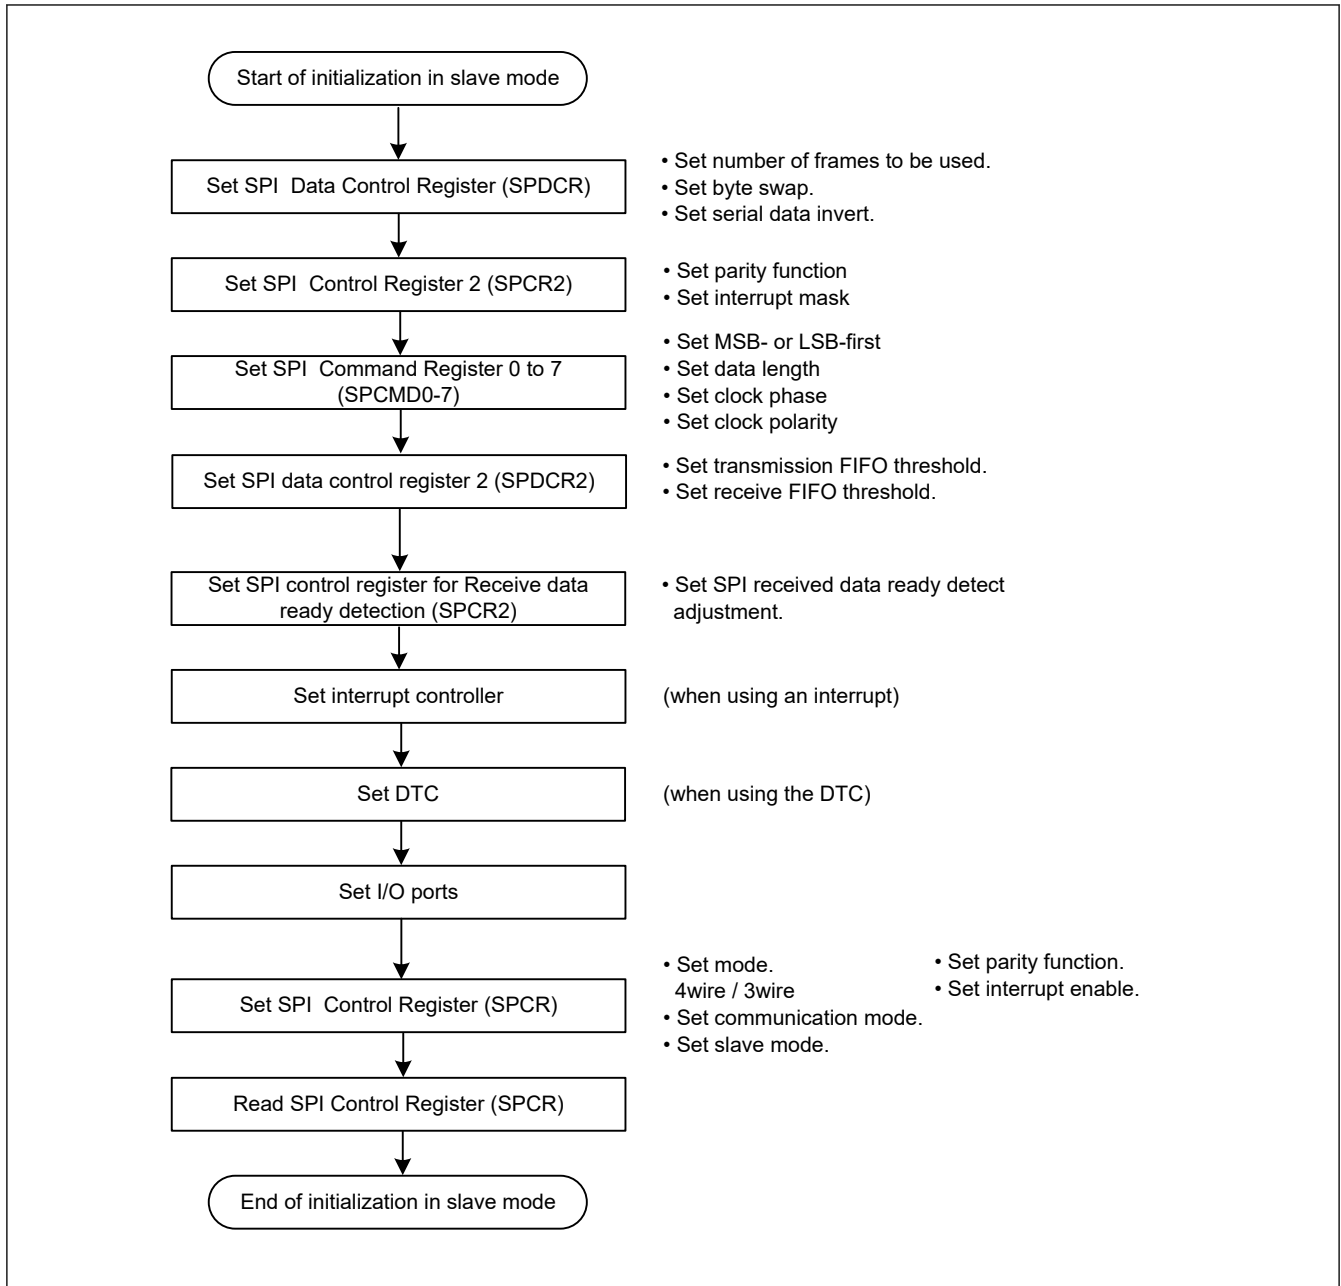

Figure 32.77 Example of initialization flow in slave mode for clock synchronous operation

(4) Software processing flow

Software processing during clock synchronous slave operation is the same as that for SPI slave operation. For details, see [\(6\) Software processing flow](#). Mode fault errors do not occur in clock synchronous mode.

32.3.14 Loopback Mode

When 1 is written to the SPCR2.SPLP2 bit or SPCR2.SPLP bit, the SPI shuts off the path between the MISO pin and the shift register if the SPCR.MSTR bit is 1, or between the MOS pin and the shift register if the SPCR.MSTR bit is 0, and connects the input and output paths of the shift register, establishing a loopback mode. The SPI does not shut off the path between the MOS pin and the shift register if the SPCR.MSTR bit is 1, or between the MISO pin and the shift register if the SPCR.MSTR bit is 0. This is called loopback mode. When a serial transfer is executed in loopback mode, the transmit data for the SPI or the reversed transmit data becomes the received data for the SPI.

[Table 32.13](#) lists the relationship between the SPLP2 and SPLP bits and the received data. [Figure 32.78](#) shows the configuration of the shift register I/O paths when the SPI in master mode is set to loopback mode (SPCR2.SPLP2 = 0, SPCR2.SPLP = 1).

Table 32.13 SPLP2 and SPLP bit settings and received data

SPCR2.SPLP2 bit	SPCR2.SPLP bit	Received data
0	0	Input data from the MOSIn pin or MISO pin
0	1	Inverted transmit data
1	0	Transmit data
1	1	Transmit data

Figure 32.78 Configuration of shift register I/O paths in loopback mode for master mode

32.3.15 Self-Diagnosis of Parity Bit Function

The parity circuit consists of a parity bit adding unit used for transmit data and an error detecting unit used for received data. To detect defects in the parity bit adding unit and error detecting unit, the parity circuit performs self-diagnosis as shown in [Figure 32.79](#).

Figure 32.79 Self-diagnosis flow for parity circuit

32.3.16 Interrupt Sources

The SPI has the following interrupt sources:

- Receive buffer full
- Transmit buffer empty

- SPI error (mode-fault, underrun, overrun, or parity error)
- SPI idle
- Communication-end

The DMAC or DTC can be activated by the receive buffer full or transmit buffer empty interrupt to perform data transfer.

Because the vector address for the SPIi_SPEI (SPI error interrupt) is allocated to interrupt requests on mode-fault, underrun, overrun, and parity errors, the actual interrupt source must be determined from the flags. Interrupt sources for the SPI are listed in Table 32.14. An interrupt is generated on satisfaction of one of the interrupt conditions in Table 32.14. Clear the receive buffer full and transmit buffer empty sources through a data transfer.

When using the DMAC or DTC to perform data transmission and reception, you must first set up the DMAC or DTC to be in a transfer-enabled status before setting the SPI. For information on setting up the DMAC or DTC, see section 16, [DMA Controller \(DMAC\)](#) and section 17, [Data Transfer Controller \(DTC\)](#).

If the conditions for generating a transmit buffer empty or receive buffer full interrupt occur while the ICU.IELSRn.IR flag is 1, the interrupt is not output as a request for the ICU but is retained internally (the capacity for retention is one request per source). A retained interrupt request is output when the ICU.IELSRn.IR flag becomes 0. A retained interrupt request is automatically discarded when it is output as an actual interrupt request. The interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) for an internally retained interrupt request can also be set to 0.

Table 32.14 SPI interrupt sources

Interrupt source	Symbol	Interrupt condition	DTC/DMAC activation
Receive buffer full	SPIi_SPRI	The receive buffer becomes full (SPSR.SPRF flag is 1) while the SPCR.SPRIE bit is 1 or The receive data become ready (SPSR.SPDRF flag is 1) while the SPCR.SPDRS bit is 0	Possible
Transmit buffer empty	SPIi_SPTI	The transmit buffer becomes empty (SPSR.SPTEF flag is 1) while the SPCR.SPTIE bit is 1	Possible
SPI error (mode-fault, underrun, overrun, or parity error)	SPIi_SPEI	The SPSR.MODF, OVRF, or PERF flag sets to 1, or the SPSR.SPDRS and SPDRF flag set to 1 while the SPCR.SPEIE bit is 1	Impossible
SPI idle	SPIi_SPII	The SPSR.IDLNF flag sets to 0 while the SPCR.SPIIE bit is 1	Impossible
Communication-end	SPIi_SPCEND	CENDIE = 1 and CENDF = 1	Impossible

32.4 Event Link Controller Event Output

The Event Link Controller (ELC) can produce the following event output signals:

- Receive buffer full event output
- Transmit buffer empty event output
- Mode-fault, underrun, overrun, or parity error event output
- SPI idle event output
- Transmission-completed event output

The event link output signal is output regardless of the interrupt enable bit setting.

32.4.1 Receive Buffer Full Event Output

When the number of data stored in the receive FIFO > the threshold value, or when the number of data stored in the receive FIFO ≤ the threshold value and SPDRES = 0 has elapsed after writing to the receive FIFO, and the SPDRC [7:0] has elapsed outputs an event.

32.4.2 Transmit Buffer Empty Event Output

An event is output when the number of empty transmission FIFO stage > the threshold or when the SPCR.SPE bit changes from 0 to 1.

32.4.3 Mode-Fault, Underrun, Overrun, Parity Error, or received data ready Event Output

This event signal is output when mode-fault, underrun, overrun, or parity error is detected. See [section 32.5.4. Constraints on Mode-Fault, Underrun, Overrun, Parity Error, or Receive Data Ready Event Output](#) if using this event signal.

(1) Mode-fault

[Table 32.15](#) lists the conditions for occurrence of a mode-fault event.

Table 32.15 Conditions for mode-fault occurrence

SPI mode	SPCR.MODFEN bit	SSLn0 pin	Remarks
SPI operation (SPMS = 0) Slave (SPCR.MSTR = 0) Motorola-SPI (SPCR.SPFRF = 0)	1	Not active	Event is output only when the SSLn0 pin is deactivated during transmission
SPI operation (SPMS = 0) Slave (SPCR.MSTR = 0) TI-SSP (SPCR.SPFRF = 1)	1	active	Event is output only when the SSLn0 pin is activated during transmission

(2) Underrun

This event signal is output in response to an underrun when a serial transfer starts while the transmission data is not ready, and the value of the SPCR.MSTR bit is 0 and the SPCR.SPE bit is 1. Under these conditions, the MODF and UDRF flags are set to 1.

(3) Overrun

This event signal is output in response to an overrun when a serial transfer completes while the receive buffer contains unread data and the value of the SPCR.TXMD[1:0] bits are 00b or 10b. Under these conditions, the OVRF flag is set to 1.

(4) Parity error

This event signal is output in response to a parity error detected on completion of a serial transfer while the value of the SPPE bit in SPCR is 1.

(5) Receive Data Ready

When TXMD[1:0] of SPCR = 00b or 10b and SPDRES = 1 as the receive data ready event output condition, the number of data stored in the receive FIFO is received after writing the receive FIFO. An event will be output when the set value of SPDR[7:0] has elapsed while the number is less than the FIFO threshold.

32.4.4 SPI Idle Event Output

(1) In master mode

In Transmit-Receive / Transmit-only master mode, an event is output when the IDLNF flag in SPSR changes from 1 to 0.

The IDLNF flag changes from 1 to 0 only when either of the conditions 1) and 2) below is met.

- The SPE bit in SPCR is cleared to 0 (SPI initialized) during transmission.
- All of the following three conditions are met.
 - The transmit buffer (SPTXn, n = 0 to 3) is empty (next transfer data has not been set).
 - The SPCP [2:0] bits in SPSR are 000b (at the start of sequence control).
 - Operation completed by the next access delay (when the master main state machine transitions to the idle state).

In receive only master mode

Any of the following 2 conditions is met.

- SPE bit of SPCR is 0 (SPI initialization)
- When any of the following is met
 - When RMFM [4:0] = 0x00, after writing 1 to RMEDTG, operation completed by the next access delay (when the master main state machine transitions to the idle state).

- When RMFM [4:0] ≠ 0x00, after writing 1 to RMEDTG, operation completed by the next access delay (when the master main state machine transitions to the idle state).
- When RMFM [4:0] ≠ 0x00, the SPI internal sequencer transitions to the idle state after operation completed by the next access delay (when the master main state machine transitions to the idle state).

(2) In slave mode

In slave mode, an event is output when the SPCR.SPE bit is set to 0 (SPI is initialized).

32.4.5 Communication End Event Output

In master mode, an event is output when the IDLNF flag (SPI idle flag) changes from 1 to 0. In slave mode, an event occurs with conditions shown in Table 32.16 and Table 32.17

Table 32.16 Communication End Event Generating Conditions (transmit-receive/transmit slave mode)

	Transmit Buffer Status	Shift Register Status	Others
SPI operation (SPMS = 0, SPFRF = 0)	Empty	Empty	SSLn0 input is negated
SPI operation (SPMS = 0, SPFRF = 1)	Empty	Empty	SSL negation delay completed
Clock synchronous operation (SPMS = 1)	Empty	Empty	The last even edge of RSPCK of last data was detected (CPHA = 1)

Table 32.17 Communication End Event Generating Conditions (receive only slave mode)

	Others
SPI operation (SPMS = 0, SPFRF = 0)	After storing the frames corresponding to the SPFC setting value in the receive buffer, negate SSLn0 input.
SPI operation (SPMS = 0, SPFRF = 1)	After storing the frames corresponding to the SPFC setting value in the receive buffer, SSL negation delay completed
Clock synchronous operation (SPMS = 1)	RSPCK last even edge detection when receiving the last frame for the SPFC set value (CPHA = 1)

Regardless of master mode or slave mode, no event is output when 0 is written to the SPCR.SPE bit during transmission or when the SPCR.SPE bit is cleared due to a mode fault error or an underrun error.

A communication end event is output at the following timing. The communication end event output timing in master operation is omitted because it is output at the same timing as an idle event.

Figure 32.80 Communication End Event Output Timing (Transmit slave mode, Motorola SPI operation)

Figure 32.81 Communication End Event Output Timing (Transmit slave mode, TI-SSP Operation)

Figure 32.82 Communication End Event Output Timing (Transmit slave mode, Clock Synchronous Operation)

Figure 32.83 Communication End Event Output Timing (Receive only slave mode, Motorola SPI operation)

Figure 32.84 Communication End Event Output Timing (Receive only slave mode, TI-SSP Operation)

Figure 32.85 Communication End Event Output Timing (Receive only slave mode, Clock Synchronous Operation)

32.4.6 Synchronization bypass function

SPI has an internal clock (PCLK) and an operation clock (TCLK), and each has its own operation circuit. Therefore, a synchronization circuit is inserted between the signals between different clocks, and a signal delay between different clocks requires a synchronization delay time.

However, the synchronization circuit can be bypassed by the BPEN = 1 of the SPI control register (SPCR) only when the same clock is input as the internal bus clock and the operation clock. In this case, the synchronization delay time is excluded, and responsiveness is improved.

In addition, SPI has a synchronization circuit between the communication clock (RSPCK) and the operation clock (TCLK), but this synchronization circuit cannot be bypassed.

32.5 Usage Notes

32.5.1 Settings for the Module-Stop State

The Module Stop Control Register B (MSTPCRB) can enable or disable the SPI operation. The SPI is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details on the Module Stop Control Register B, see [section 10, Low Power Modes](#).

32.5.2 Constraint on Low-Power Functions

When using the module-stop function and entering a low-power mode other than CPU Sleep mode or CPU Deep Sleep mode, set the SPCR.SPE bit to 0 before completing communication.

32.5.3 Constraints on Starting Transfer

If the ICU.IELSRn.IR flag is 1 when transfer starts, the interrupt request is internally retained, which can lead to unanticipated behavior of the ICU.IELSRn.IR flag.

To prevent this, use the following procedure to clear interrupt requests before enabling operations (by setting the SPCR.SPE bit to 1):

1. Confirm that transfer stopped (the SPCR.SPE bit is 0).
2. Set the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) to 0.
3. Read the associated interrupt enable bit (SPCR.SPTIE bit or SPCR.SPRIE bit) and confirm that its value is 0.
4. Set the ICU.IELSRn.IR flag to 0.

32.5.4 Constraints on Mode-Fault, Underrun, Overrun, Parity Error, or Receive Data Ready Event Output

Using the mode-fault, underrun, overrun, parity error, or receive data ready event is prohibited if the SPI is in multi-master mode (when the SPCR.SPMS bit is 0, the SPCR.MSTR bit is 1, and the SPCR.MODFEN bit is 1).

32.5.5 Constraints on the SPSR.SPRF and SPSR.SPTEF Flags

If the polling flags, SPRF and SPTEF, are used, using the interrupts is prohibited, and you must set the SPCR.SPRIE and SPCR.SPTIE bits to 0. Either the interrupts or the flags can be used, but not both.

33. Octal Serial Peripheral Interface (OSPI)

This is the OSPI_B version of the OSPI peripheral module.

OSPI_B is referred to as OSPI in this chapter.

33.1 Overview

The xSPI (eXpanded Serial Peripheral Interface) protocol specifies the interface for Non-Volatile Memory Devices, which provides high data throughput, low signal count, and limited backward compatibility with legacy SPI devices. The electrical interface can deliver up to 200 Mbytes per second raw data throughput. The OSPI is compliant with JEDEC standard JESD251(Profile 1.0 and 2.0), JESD251-1 and JESD252.

JESD251 specifies two interface profiles where profile 1.0 is Octal SPI and profile 2.0 is HyperBus™ (HyperRAM™ and HyperFlash™).

OSPI supports QSPI protocol.

Table 33.1 lists the OSPI specifications, Figure 33.1 shows a block diagram, and Table 33.2 lists the I/O pins.

Table 33.1 OSPI specifications

Item	Description
Protocol	Compliant with the xSPI protocol
Data transmission and reception	Issue the transaction for up to 2 Slave as Master Only one of the memory devices can operate at a time.
Transfer speed	Support the transfer at xSPI200
Mode	<ul style="list-style-type: none"> ● Support Protocol modes below <ul style="list-style-type: none"> – 1/4/8pin with SDR/DDR (1S-1S-1S, 4S-4D-4D, 8D-8D-8D) – 2/4pin with SDR (1S-2S-2S, 2S-2S-2S, 1S-4S-4S, 4S-4S-4S) ● Configurable address length ● Configurable initial access latency cycle ● Support XiP mode
OSPI function	<ul style="list-style-type: none"> ● Support Write Data Mask ● Support In-band Reset ● Memory-mapping <ul style="list-style-type: none"> – Support up to 256 MB address space each CS – Prefetch function for burst-read with low latency – Outstanding buffer for burst-write with high throughput ● Manual command <ul style="list-style-type: none"> – Configurable up to 4 commands – Status Register Polling function ● Input Strobe port timing shift
Transfer target	<ul style="list-style-type: none"> ● ch1 : GLCDC1 bus master ● ch0 : Other bus master
Interrupt source	Error interrupt Completion interrupt
Module-stop function	Module-stop state can be set to reduce power consumption
TrustZone Filter	Security attribution can be set for IO register area External address space is defined as Non-secure

Figure 33.1 Block diagram

Table 33.2 OSPI I/O pins

Pin name	I/O	Function
OM_SCLK	Output	Clock Positive
OM_SCLKN	Output	Clock Negative
OM_CS0	Output	Chip Select for slave0
OM_CS1	Output	Chip Select for slave1
OM_DQS	I/O	Read Data Strobe / Write Data Mask
OM_SIO0	I/O	Data 0 input/output
OM_SIO1	I/O	Data 1 input/output
OM_SIO2	I/O	Data 2 input/output
OM_SIO3	I/O	Data 3 input/output
OM_SIO4	I/O	Data 4 input/output
OM_SIO5	I/O	Data 5 input/output
OM_SIO6	I/O	Data 6 input/output
OM_SIO7	I/O	Data 7 input/output
OM_RESET	Output	Master reset status for slave0,1
OM_RSTO1	Input	Slave reset status for slave1
OM_ECSINT1	Input	Interrupt for slave1 / Error Correction Status for slave1
OM_WP1	Output	Write Protect for slave1

Note: For OM_SIO7-0, OM_SCLK, OM_SCKN and OM_DQS pins, 36Ω±5% resistor need to be put on the board to comply with JESD251 I/O driver definition. It is recommended for the operation with proper signal quality.

33.2 Register Descriptions

33.2.1 OSPI Configuration Registers

These registers configure xSPI Master function. These registers should be configured in the initialization phase before issuing xSPI transaction.

33.2.1.1 WRAPCFG : OSPI Wrapper Configuration Register

Base address: OSPI0_B = 0x4026_8000
 OSPI0_B_NS = 0x5026_8000

Offset address: 0x000

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
12:8	DSSFTCS0[4:0]	OM_DQS shift for slave0 This field configures the number of delay cell for a OM_DQS port. It is used to adjust the OM_DQS sampling timing. When automatic calibration is enabled, it could be updated automatically. In this case, it shall not be written by user. 0x00: No shift 0x01: Add a delay of 1 cell ⋮ 0x1E: Add a delay of 30 cells 0x1F: Add a delay of 31 cells	R/W
23:13	—	These bits are read as 0. The write value should be 0.	R/W
28:24	DSSFTCS1[4:0]	OM_DQS shift for slave1 The function is same as one of slave0.	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to configure xSPI Master function.

33.2.1.2 COMCFG : OSPI Common Configuration Register

Base address: OSPI0_B = 0x4026_8000
 OSPI0_B_NS = 0x5026_8000

Offset address: 0x004

Bit	Symbol	Function	R/W
1:0	ARBMD[1:0]	Channel arbitration mode This field selects the behavior when system bus accesses from ch0 and ch1 to slave devices occurred simultaneously. It is used only for memory-mapping mode. 0 0: Round-Robbin (ch0-ch1-ch0-ch1...)*1 0 1: Always ch0 win 1 0: Always ch1 win*1 1 1: Reserved	R/W
15:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
16	OEASTEX	Output Enable Asserting extension This bit extends 1 cycle output enable of OM_SIO7-0 and OM_DQS during output enable asserting. When set to 1, OM_CS _n (n = 0, 1) asserting should be extended (LIOCFGCS _n .CSASTEX = 1 (n = 0, 1)). This bit shall not be used in case of no latency cycle. Because OSPI output data could be conflicted with OSPI input data. 0: No extend 1 cycle Output enable 1: Extend 1 cycle Output enable	R/W
17	OENEGEX	Output Enable Negating extension This bit extends 1 cycle output enable of OM_SIO7-0 and OM_DQS during output enable negating. This bit should not be used in case of no latency cycle. Because OSPI output data could be conflicted with OSPI input data. 0: No extend 1 cycle Output enable 1: Extend 1 cycle Output enable	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. ch1 can only be used for GLCDC1 bus master.

This register has functions to configure xSPI Master function.

33.2.1.3 BMCFGCH_n : OSPI Bridge Map Configuration Register chn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x008 + 0x004 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CMBTIM[7:0]								—	—	—	—	—	—	—	PREEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MWRSIZE[7:0]								MWR COMB	—	—	—	—	—	—	WRMD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	WRMD	System bus Write Response mode This bit selects the timing of System bus write response in memory-mapping mode. When set to 1, it returns the response after transmitting a frame on xSPI bus. When enabled this mode, Memory Write Combination mode must be disabled. 0: Return response after storing to Internal Write Buffer 1: Return response after issuing write transaction to xSPI bus	R/W
6:1	—	These bits are read as 0. The write value should be 0.	R/W
7	MWRCOMB	Memory Write Combination mode This bit selects to combine the OSPI data in write access of memory-mapping mode. When set to 0, OSPI data size depends on system bus's burst type and size. When this field is set to "1", the data size depends on MWRSIZE[7:0] field.*1 When set to 1, any write transaction could be held in this xSPI master temporarily. 0: Disable combination mode 1: Enable combination mode	R/W

Bit	Symbol	Function	R/W
15:8	MWRSIZE[7:0]	<p>Memory Write Size These bits select the size to combine incremental address in memory-mapping mode. It transmits an xSPI frame with the data combined up to the configured size while the address is incremental. When detected non-incremental address or a read transaction before reaching to the target size, it transmits the pending data into xSPI bus.</p> <p>0x00: Combine incremental address up to 4 bytes 0x01: Combine incremental address up to 8 bytes ⋮ 0x0E: Combine incremental address up to 60 bytes 0x0F: Combine incremental address up to 64 bytes 0xFF: Combine incremental address up to 2 bytes Others: Setting prohibited</p>	R/W
16	PREEN	<p>Prefetch enable This bit enables prefetch function for read transaction in memory-mapping mode. It could reduce the latency for read transaction with incremental address.</p> <p>0: Disable prefetch function 1: Enable prefetch function</p>	R/W
23:17	—	These bits are read as 0. The write value should be 0.	R/W
31:24	CMBTIM[7:0]	<p>Combination timer This field specifies expiration period of combination timer. This timer is counted by PCLKA. 0x00 means disabling the combination timer. When the timer is expired, the data in the combination buffer is pushed to memory device.</p>	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Writing to OSPI memory space other than 64 bit is prohibited during combination mode.

This register has functions to configure xSPI Master function.

33.2.1.4 CMCFG0CSn : OSPI Command Map Configuration Register 0 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x010 + 0x010 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	ADDRPCD[7:0]								ADDRPEN[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	ARYA MD	WPBS TMD	ADDSIZE[1:0]	FFMT[1:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	FFMT[1:0]	<p>Frame format These bits configure xSPI frame format in memory-mapping mode. Please see Table 33.7 for detail.</p> <p>0 0: Normal format: Command 1 byte, Address ADDSIZE, Data up to system bus transaction. 0 1: 8D-8D-8D profile 1.0 format: Command 2 bytes, Address ADDSIZE, Data up to system bus transaction 1 0: 8D-8D-8D profile 2.0 Command Modifier format: Command & Modifier 6 bytes, Data up to system bus transaction 1 1: 8D-8D-8D profile 2.0 Commands with Extended Command Modifier format: Command & Modifier 6 bytes, Data up to system bus transaction</p>	R/W

Bit	Symbol	Function	R/W
3:2	ADDSIZE[1:0]	Address size These bits configure the number of address byte in memory-mapping mode. In case of 8D-8D-8D profile 2.0, it should be configured to 4 bytes. 0 0: 1 byte (256-byte address space) 0 1: 2 bytes (64 KB address space) 1 0: 3 bytes (16 MB address space) 1 1: 4 bytes (4 GB address space)	R/W
4	WPBSTMD	Wrapping burst mode When this field is set to 1, the wrapping boundary between system bus access and xSPI memory shall be mached. 0: Separate xSPI transfer at the wrapping address boundary 1: Not separate xSPI transfer at the wrapping address boundary	R/W
5	ARYAMD	Array address mode When this field is set to 1, address for memory is mapped as {A[25:10], A[9:4], 6{RSV}, A[3:0]} where A[25:0] is normal address, and RSV is reserved value(0b). This field is effective only when FFMT=1d. 0: Normal address mode 1: Array address mode	R/W
15:6	—	These bits are read as 0. The write value should be 0.	R/W
23:16	ADDRPEN[7:0]	Address Replace Enable These bits select the bits to replace for MSByte of System bus address in memory-mapping mode. 0: No replacement (xSPI frame address field is same as System bus address) 1: Replacement	R/W
31:24	ADDRPCD[7:0]	Address Replace Code These bits configure the code to replace the MSByte of System bus address in memory-mapping mode. It replaces the corresponding bits when Address Replace Enable bit is set to 1.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to configure xSPI Master function.

33.2.1.5 CMCFG1CSn : OSPI Command Map Configuration Register 1 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x014 + 0x010 × n

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 1 0

Bit	Symbol	Function	R/W
15:0	RDCMD[15:0]	Read command These bits configure the command field of read transaction in memory-mapping mode. Normal format and 8D-8D-8D profile 2.0 format use only upper 1 byte. 8D-8D-8D profile 1.0 format uses 2 bytes.	R/W
20:16	RDLATE[4:0]	Read latency cycle These bits configure the latency cycle of read transaction in memory-mapping mode. 0x00: No latency 0x01: 1 cycle ⋮ 0x08: 8 cycle (default) ⋮ 0x1E: 30 cycles 0x1F: 31 cycles Others: Setting prohibited	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to configure xSPI Master function.

33.2.1.6 CMCFG2CSn : OSPI Command Map Configuration Register 2 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x018 + 0x010 × n

Bit	Symbol	Function	R/W
15:0	WRCMD[15:0]	Write command These bits configure the command field of write transaction in memory-mapping mode. Normal format and 8D-8D-8D profile 2.0 format use only upper 1 byte. 8D-8D-8D profile 1.0 format uses 2 bytes.	R/W
20:16	WRLATE[4:0]	Write latency cycle These bits configure the latency cycle of write transaction in memory-mapping mode. 0x00: No latency 0x01: 1 cycle ⋮ 0x08: 8 cycle (default) ⋮ 0x1E: 30 cycles 0x1F: 31 cycles Others: Setting prohibited	R/W
31:21	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to configure xSPI Master function.

33.2.1.7 LIOCFGCSn : OSPI Link I/O Configuration Register CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x050 + 0x004 × n

Bit	Symbol	Function	R/W													
9:0	PRTMD[9:0]	<p>Protocol mode These bits configure the protocol mode and the pin to sample data inputs. In case of using not SPI clock but Data strobe for sampling in SDR mode, it is required to set PRTMD[9] to 1.</p> <p>0x000: 1S-1S-1S 0x3B2: 4S-4D-4D 0x3FF: 8D-8D-8D 0x048: 1S-2S-2S 0x049: 2S-2S-2S 0x090: 1S-4S-4S 0x092: 4S-4S-4S Others: Setting prohibited</p>	R/W													
10	LATEMD	<p>Latency mode This bit selects the behavior of initial access latency phase for both direct-manual mode and memory-mapping mode. When set to 0, the latency cycle is equal to each configured cycle from transmitting address field. When set to 1, the latency cycle is incremented from the last byte-pair of Address field and is extended 2 times of each configured cycle depending on OM_DQS port. It is used only for profile 2.0 frame format of 8D-8D-8D protocol mode with 6 bytes command/address field. Please refer to xSPI protocol for detail.</p> <table border="1"> <thead> <tr> <th>Value: Function</th> <th>Frame format</th> <th>Usage</th> </tr> </thead> <tbody> <tr> <td rowspan="2">0: Configurable latency</td> <td>profile 2.0</td> <td>The configurable latency cycle should be set as minus 1.</td> </tr> <tr> <td>Others</td> <td>Latency cycle increments after address field.</td> </tr> <tr> <td rowspan="2">1: Variable latency</td> <td>profile 2.0</td> <td>Latency cycle increments from address [23:16]. And it should not be set to 1.</td> </tr> <tr> <td>Others</td> <td>Not support</td> </tr> </tbody> </table>	Value: Function	Frame format	Usage	0: Configurable latency	profile 2.0	The configurable latency cycle should be set as minus 1.	Others	Latency cycle increments after address field.	1: Variable latency	profile 2.0	Latency cycle increments from address [23:16]. And it should not be set to 1.	Others	Not support	R/W
Value: Function	Frame format	Usage														
0: Configurable latency	profile 2.0	The configurable latency cycle should be set as minus 1.														
	Others	Latency cycle increments after address field.														
1: Variable latency	profile 2.0	Latency cycle increments from address [23:16]. And it should not be set to 1.														
	Others	Not support														
11	WRMSKMD	<p>Write mask mode This bit selects to use OM_DQS port as write data mask. It could be useful for write access of odd byte. It is used only for 8D-8D-8D protocol mode.</p> <p>0: Write mask disable 1: Write mask enable</p>	R/W													
15:12	—	These bits are read as 0. The write value should be 0.	R/W													
19:16	CSMIN[3:0]	<p>CS minimum idle term This bit configures the minimum cycle between xSPI frames.</p> <p>0x0: 1 cycle 0x1: 2 cycles ⋮ 0x7: 8 cycles (default) ⋮ 0xE: 15 cycles 0xF: 16 cycles Others: Setting prohibited</p>	R/W													
20	CSASTEX	<p>CS asserting extension This bit extends 1 cycle chip select pins when asserting.</p> <p>0: No extension 1: Extend 1 cycle</p>	R/W													
21	CSNEGEX	<p>CS negating extension This bit extends 1 cycle chip select pins when negating.</p> <p>0: No extension 1: Extend 1 cycle</p>	R/W													
22	SDRDRV	<p>SDR driving timing This bit configures the timing of data output in SDR. This bit should not be set to 1 in case of no latency cycle. Because OSPI output data could be conflicted with OSPI input data.</p> <p>0: Drive at 1/2 cycle before CK rising-edge 1: Drive at CK rising-edge</p>	R/W													

Bit	Symbol	Function	R/W
23	SDRSMPMD	SDR Sampling mode This bit selects the edge of sampling in SDR. In DDR, regardless of this setting, it samples OM_SIO _n (n = 0 to 7) ports with both edges of OM_DQS. When set to 1, it samples at rising-edge before falling-edge. 0: Samples data input at falling-edge 1: Samples data input at rising-edge	R/W
27:24	SDRSMPST[3:0]	SDR Sampling window shift These bits shift the timing of CK sampling in SDR. In case of using OM_DQS in SDR, there is no influence on the behavior. In case of DDR or using OM_DQS in SDR, it should be set to 0. 0x0: Sample without delay 0x1: Sample at 1 cycle delay ⋮ 0x6: Sample at 6 cycle delay 0x7: Sample at 7 cycle delay Others: Setting prohibited	R/W
31:28	DDRSMPST[3:0]	DDR sampling window extend These bits configure the cycle of extending the sampling window in DDR. In DDR, the input data is sampled during the expected cycle soon after latency cycle. The input data out of range is ignored. It can be configured depending on OM_DQS propagation delay. 0x0: Expand no cycle 0x1: Expand 1 cycle ⋮ 0x6: Expand 6 cycles 0x7: Expand 7 cycles Others: Setting prohibited	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to configure xSPI Master function.

33.2.2 OSPI Control Registers

These registers control xSPI Master function.

33.2.2.1 BMCTL0 : OSPI Bridge Map Control Register 0

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x060

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	CH1CS1ACC[1:0]	CH1CS0ACC[1:0]	CH0CS1ACC[1:0]	CH0CS0ACC[1:0]	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
1:0	CH0CS0ACC[1:0]	System bus ch0 to slave0 memory area access enable This field enables the access from ch0 to CS0 memory. 0 0: Read/Write disable 0 1: Read enable, Write disable 1 0: Read disable, Write enable 1 1: Read/Write enable	R/W

Bit	Symbol	Function	R/W
3:2	CH0CS1ACC[1:0]	System bus ch0 to slave1 memory area access enable This field enables the access from ch0 to CS1 memory. 0 0: Read/Write disable 0 1: Read enable, Write disable 1 0: Read disable, Write enable 1 1: Read/Write enable	R/W
5:4	CH1CS0ACC[1:0]	System bus ch1 to slave0 memory area access enable This field enables the access from ch1 to CS0 memory.*1 0 0: Read/Write disable 0 1: Read enable, Write disable 1 0: Read disable, Write enable 1 1: Read/Write enable	R/W
7:6	CH1CS1ACC[1:0]	System bus ch1 to slave1 memory area access enable This field enables the access from ch1 to CS1 memory.*1 0 0: Read/Write disable 0 1: Read enable, Write disable 1 0: Read disable, Write enable 1 1: Read/Write enable	R/W
31:8	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. ch1 can only be used for GLCDC1 bus master.

This register has functions to control xSPI Master function.

This register shall be configured in the initialization phase. When setting is needed to be changed after beginning xSPI transaction, please stop all communication, see [section 33.3.7.2. Flow of Communication Stop](#) before changing the value of BMCTL0.

33.2.2.2 BMCTL1 : OSPI Bridge Map Control Register 1

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x064

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	PBUF CLRC H1	PBUF CLRC H0	MWRP USHC H1	MWRP USHC H0	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	The write value should be 0.	W
8	MWRPUSHCH0	Memory Write Data Push for ch0 This field requests to push the pending data in combination mode.*1 0: No command 1: Push request	W
9	MWRPUSHCH1	Memory Write Data Push for ch1*2 The function is same as one of ch0.*1	W
10	PBUFCLRCH0	Prefetch Buffer clear for ch0 This field requests to clear the prefetch buffer when the prefetch function is enabled.*1 It should not be set during memory access (COMSTT.MEMACCCH0 = 1). 0: No command 1: Clear request	W

Bit	Symbol	Function	R/W
11	PBUFCLRCH1	Prefetch Buffer clear for ch1*2 This function is same as one of ch0.*1	W
31:12	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

Note 1. Prefetch/Combination behavior is not defined when cycle base race condition between asserting these bits and system bus access is occurred.

Note 2. ch1 can only be used for GLCDC1 bus master

This register has functions to control xSPI Master function.

33.2.2.3 CMCTLCHn : OSPI Command Map Control register chn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x0068 + 0x004 × n (n = 0, 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	XIPEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	XIPEXCODE[7:0]								XIPENCODE[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	XIPENCODE[7:0]	XiP mode enter code These bits configure the code to enter XiP mode in memory-mapping mode.	R/W
15:8	XIPEXCODE[7:0]	XiP mode exit code These bits configure the code to exit XiP mode in memory-mapping mode.	R/W
16	XIPEN	XiP mode enable This bit enables XiP mode in memory-mapping mode. When set to 1, XiP enter code is inserted in the latency field, and the command field in next transaction is omitted. When set to 0, XiP exit code is inserted in the latency field. And it is set to 0 automatically when transmitting XiP disable pattern. It should not be used for 8D-8D-8D protocol mode profile 2.0 frame format. 0: Disable XiP mode 1: Enable XiP mode	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

33.2.2.4 CDCTL0 : OSPI Command Manual Control Register 0

Base address: OSPI0_B = 0x4026_8000
 OSPI0_B_NS = 0x5026_8000

Offset address: 0x070

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	PERREP[3:0]				—	—	—	PERITV[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	TRNUM[1:0]		CSSEL	—	PERMD	TRREQ
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	TRREQ	Transaction request This bit requests to issue the transaction of manual-command. When set to 1, it starts the transaction. It is cleared to 0 when the transaction completed. The transaction is canceled by clearing to 0 while the transaction is ongoing. 0: No transaction 1: Request transaction	R/W
1	PERMD	Periodic mode This bit enables the periodic transaction mode. When set to 1, it repeats a transaction periodically and compares the read value with the expected value. It alternates the status polling operation for external memory. 0: Direct manual-command mode 1: Periodic manual-command mode	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	CSSEL	Chip select This bit selects a target memory to issue manual-command. 0: CS0 1: CS1	R/W
5:4	TRNUM[1:0]	Transaction number These bits configure the number of transactions in normal manual-command mode. In periodic manual-command, regardless of this setting, the read data of last command is compared. 0 0: Issue 1 command (using command buffer 0) 0 1: Issue 2 commands (using command buffer 0-1) 1 0: Issue 3 commands (using command buffer 0-2) 1 1: Issue 4 commands (using command buffer 0-3)	R/W
15:6	—	These bits are read as 0. The write value should be 0.	R/W
20:16	PERITV[4:0]	Periodic transaction interval These bits configure the interval of transaction in periodic manual-command mode. Too short interval compared with CPU bus cycle could result in no store into command buffer0. The interval should be longer than 4 times of CPU bus cycle. 0x00: 2 (= 2 ¹) cycles 0x01: 4 (= 2 ²) cycles ⋮ 0x1E: 2,147,483,648 (= 2 ³¹) cycles 0x1F: 4,294,967,296 (= 2 ³²) cycles	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
27:24	PERREP[3:0]	Periodic transaction repeat These bits configure the number of transaction repetitions in periodic manual-command mode. 0x0: 1 (= 2 ⁰) time 0x1: 2 (= 2 ¹) times ⋮ 0xE: 16384 (= 2 ¹⁴) times 0xF: 32768 (= 2 ¹⁵) times	R/W
31:28	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

33.2.2.5 CDCTL1 : OSPI Command Manual Control Register 1

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x074

Bit	Symbol	Function	R/W
31:0	PEREXP[31:0]	Periodic transaction expected value These bits configure the expected value to compare with the read value in periodic manual-command mode. For example, in case of comparing 1 byte, the lower byte should be configured.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

33.2.2.6 CDCTL2 : OSPI Command Manual Control Register 2

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x078

Bit	Symbol	Function	R/W
31:0	PERMSK[31:0]	Periodic transaction masked value These bits configure the masked value for the expected value in periodic manual-command mode. When set 1 to any bit, the corresponding bit configured as expected value (CDCTL1.PEREXP[31:0]) is ignored. In 8D-8D-8D, the data bytes are transferred only in byte pairs on xSPI bus. It means the dummy read data could be stored. It should be masked for unused bits. For example, in case of read lower 1 byte, it should be configured to 0xFFFFFFFF0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

33.2.2.7 CDTBUF_n : OSPI Command Manual Type Buf n (n = 0 to 3)

Base address: OSPI0_B = 0x4026_8000
 OSPI0_B_NS = 0x5026_8000

Offset address: 0x080 + 0x010 × n

Bit	Symbol	Function	R/W
1:0	CMDSIZE[1:0]	<p>Command Size These bits configure the size of command field. In case of 8D-8D-8D, it should be fixed to 10b. It should not be configured both command size and address size to zero.</p> <p>0 0: 0 bytes (No command phase) 0 1: 1 byte 1 0: 2 bytes Others: Setting prohibited</p>	R/W
4:2	ADDSSIZE[2:0]	<p>Address size These bits configure the size of address field.</p> <p>0 0 0: 0 bytes (No address phase) 0 0 1: 1 byte 0 1 0: 2 bytes 0 1 1: 3 bytes 1 0 0: 4 bytes Others: Setting prohibited</p>	R/W
8:5	DATASIZE[3:0]	<p>Write/Read Data Size These bits configure the size of data field. In 8D-8D-8D, the data bytes are transferred only in byte pairs on xSPI bus. For example, even if configuring 1 byte for read, 2 bytes data is received. The last byte should be ignored. The 0 bytes must not configured for read transaction.</p> <p>0x0: 0 bytes (No data phase) 0x1: 1 byte ⋮ 0x7: 7 bytes 0x8: 8 bytes Others: Setting prohibited</p>	R/W
13:9	LATE[4:0]	<p>Latency cycle These bits configure the latency cycle in manual-command mode.</p> <p>0x0: No latency 0x1: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles</p>	R/W
14	—	This bit is read as 0. The write value should be 0.	R/W
15	TRTYPE	<p>Transaction Type This bit selects the type of transaction.</p> <p>0: Read transaction (Readout data from slave device) 1: Not read transaction</p>	R/W

Bit	Symbol	Function	R/W
31:16	CMD[15:0]	Command (1-2 bytes) These bits configure the command field in manual-command mode. The number of bytes configured in Command Size bit is transferred. 1S-1S-1S, 4S-4D-4D: CMD[15:8] is command field, CMD[7:0] is not used. 8D-8D-8D profile 1.0: CMD[15:8] is command field, CMD[7:0] is extension field. 8D-8D-8D profile 2.0: CMD[15:0] is upper 2 bytes of command & modifier field. (bit 47-32 in xSPI protocol)	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

33.2.2.8 CDABUFn : OSPI Command Manual Address Buf n (n = 0 to 3)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x084 + 0x10 × n

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	ADD[31:0]	Address These bits configure the address field in manual-command mode. 1S-1S-1S, 4S-4D-4D, 8D-8D-8D profile 1.0: It is address field. 8D-8D-8D profile 2.0: It is lower 4 bytes of command & modifier field. (bit 31-0 in xSPI protocol)	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

33.2.2.9 CDD0BUFn : OSPI Command Manual Data 0 Buf n (n = 0 to 3)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x088 + 0x10 × n

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	DATA[31:0]	Write/Read Data These bits configure the data field in manual-command mode. In case of write transaction, the write data should be configured. In case of read transaction, the read data is stored.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

33.2.2.10 CDD1BUF_n : OSPI Command Manual Data 1 Buf _n (n = 0 to 3)

Base address: OSPI0_B = 0x4026_8000
 OSPI0_B_NS = 0x5026_8000

Offset address: 0x08C + 0x10 × n

Bit position: 31

0

Bit field:

DATA[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	DATA[31:0]	Write/Read Data These bits configure the data field in manual-command mode. In case of write transaction, the write data should be configured. In case of read transaction, the read data is stored.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

33.2.2.11 LPCTL0 : OSPI Link Pattern Control Register 0

Bit	Symbol	Function	R/W
0	PATREQ	Pattern request This bit requests to issue the pattern. When set to 1, it starts the pattern. It is cleared to 0 when the pattern completed. 0: No request XiP Disable pattern 1: Request XiP Disable pattern	R/W
2:1	—	These bits are read as 0. The write value should be 0.	R/W
3	CSSEL	Chip select This bit selects a target memory to issue a pattern. 0: slave0 (CS0) 1: slave1 (CS1)	R/W
5:4	XDPIN[1:0]	XiP Disable pattern pin These bits select the data output pins to transmit XiP Disable pattern. 0 0: 1 pin 0 1: 2 pins 1 0: 4 pins 1 1: 8 pins	R/W
15:6	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
20:16	XD1LEN[4:0]	XiP Disable pattern 1st phase length These bits select the length of 1st phase in XiP disable pattern. The pattern with zero-length both 1st phase and 2nd phase should not be configured. 0x0: 0 cycles 0x1: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
22:21	—	These bits are read as 0. The write value should be 0.	R/W
23	XD1VAL	XiP Disable pattern 1st phase value This bit selects the value of 1st phase in XiP disable pattern. 0: Low drive 1: High drive	R/W
28:24	XD2LEN[4:0]	XiP Disable pattern 2nd phase length These bits select the length of 2nd phase in XiP disable pattern. 0x00: 0 cycles 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
30:29	—	These bits are read as 0. The write value should be 0.	R/W
31	XD2VAL	XiP Disable pattern 2nd phase value This bit selects the value of 2nd phase in XiP disable pattern. 0: Low drive 1: High drive	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

33.2.2.12 LPCTL1 : OSPI Link Pattern Control Register 1

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x104

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	RSTSU[2:0]			—	RSTWID[2:0]			—	—	RSTREP[1:0]	CSSE L	—	PATREQ[1:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	PATREQ[1:0]	Pattern request These bits request to issue the pattern. When set to 01b or 10b, it starts the pattern. It is cleared to 00b when the pattern completed. 0 0: No request 0 1: Request Reset pattern 1 0: Request CS only pattern 1 1: Setting prohibited	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	CSSEL	Chip select This bit selects a target memory to issue a pattern. 0: slave0 (CS0) 1: slave1 (CS1)	R/W

Bit	Symbol	Function	R/W
5:4	RSTREP[1:0]	Reset pattern repeat These bits select the repeating time to toggle CS from LOW to HIGH. 0 0: 4 times (Specified on Reset Signaling Protocol) 0 1: 5 times 1 0: 6 times 1 1: 7 times	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
10:8	RSTWID[2:0]	Reset pattern width These bits configure the width of cycle in reset pattern and CS only pattern. It toggles CS with the configured cycle. 0 0 0: 2 (= 2 ¹) cycles 0 0 1: 4 (= 2 ²) cycles ⋮ 1 1 0: 128 (= 2 ⁷) cycles 1 1 1: 256 (= 2 ⁸) cycles	R/W
11	—	This bit is read as 0. The write value should be 0.	R/W
14:12	RSTSU[2:0]	Reset pattern data output setup time These bits configure the number of setup cycle for data output based on the edge of CS in reset pattern. It needs enough setup time because xSPI slave samples any data at the rising edge of CS. This cycle of setup time should be less than the cycle of reset pattern width (RSTWID[2:0]). 0 0 0: 1 cycle 0 0 1: 2 cycles ⋮ 1 1 0: 7 cycles 1 1 1: 8 cycles	R/W
31:15	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

33.2.2.13 LIOCTL : OSPI Link I/O Control Register

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x108

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RSTC S0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WPCS 1	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
0	—	This bit is read as 1. The write value should be 1.	R/W
1	WPCS1	WP drive for slave1 This bit controls the value of OM_WP1 port. It can be useful only for xSPI slave with write protect port. 0: Drive Low level 1: Drive High level	R/W
15:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
16	RSTCS0	Reset drive This bit controls the value of OM_RESET port. It could be useful only for xSPI slave with reset port. 0: Drive Low level 1: Drive High level	R/W
17	—	This bit is read as 1. The write value should be 1.	R/W
31:18	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

33.2.2.14 CCCTL0CSn : OSPI Command Calibration Control Register 0 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x130 + 0x020 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	CASFTEND[4:0]				—	—	—	CASFTSTA[4:0]					
Value after reset:	0	0	0	1	1	1	1	1	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	CAITV[4:0]				—	—	—	—	—	—	—	CANOWR	CAEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CAEN	Automatic Calibration Enable This bit enables the automatic calibration. When set to 1, it transmits the calibration sequence periodically and adjusts the value of phase shift. When set to 0 during the calibration sequence, it stops after completed ongoing calibration sequence, and then this bit is cleared. 0: Disable automatic calibration 1: Enable automatic calibration	R/W
1	CANOWR	Calibration no write mode This bit selects to omit write command in calibration sequence. It can be used for any slave device with fixed calibration pattern data. 0: Calibration sequence with write command 1: Calibration sequence without write command	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
12:8	CAITV[4:0]	Calibration interval These bits configure the interval between calibration patterns. 0x00: 2 (= 2 ¹) cycle wait 0x01: 4 (= 2 ²) cycle wait ⋮ 0x1E: 2,147,483,648 (= 2 ³¹) cycle wait 0x1F: 4,294,967,296 (= 2 ³²) cycle wait	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
20:16	CASFTSTA[4:0]	Calibration OM_DQS shift start value These bits configure the start value of OM_DQS shift.	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
28:24	CASFTEND[4:0]	Calibration OM_DQS shift end value These bits configure the end value of OM_DQS shift. It should be equal or more than the start value (CASFTSTA[4:0]).	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function.

33.2.2.15 CCCTL1CSn : OSPI Command Calibration Control Register 1 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x134 + 0x020 × n

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	CARDLATE[4:0]				—	—	—	CAWRLATE[4:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CADATASIZE[3:0]			CAADDSIZE[2:0]		CACMDSIZE[1:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CACMDSIZE[1:0]	Command Size These bits configure the size of command field. In case of 8D-8D-8D, it should be fixed to 10b. It should not be configured both command size and address size to zero. 0 0: 0 bytes (No command phase) 0 1: 1 byte 1 0: 2 bytes 1 1: Setting prohibited	R/W
4:2	CAADDSIZE[2:0]	Address size These bits configure the size of address field. 0 0 0: 0 bytes (No address phase) 0 0 1: 1 byte 0 1 0: 2 bytes 0 1 1: 3 bytes 1 0 0: 4 bytes Others: Setting prohibited	R/W
8:5	CADATASIZE[3:0]	Write/Read Data Size These bits configure the size of data field. In 8D-8D-8D, it should be configured with even byte. 0x0: 1 byte 0x1: 2 bytes ⋮ 0xE: 15 bytes 0xF: 16 bytes	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W
20:16	CAWRLATE[4:0]	Write Latency cycle These bits configure the latency cycle in calibration frame. 0x00: No latency 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
23:21	—	These bits are read as 0. The write value should be 0.	R/W
28:24	CARDLATE[4:0]	Read Latency cycle These bits configure the latency cycle in calibration frame. 0x00: No latency 0x01: 1 cycle ⋮ 0x1E: 30 cycles 0x1F: 31 cycles	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

33.2.2.16 CCCTL2CSn : OSPI Command Calibration Control Register 2 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x138 + 0x020 × n

Bit	Symbol	Function	R/W
15:0	CAWRCMD[15:0]	Calibration pattern write command These bits configure the calibration pattern write command.	R/W
31:16	CARDCMD[15:0]	Calibration pattern read command These bits configure the calibration pattern read command.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

33.2.2.17 CCCTL3CSn : OSPI Command Calibration Control Register 3 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x13C + 0x020 × n

Bit	Symbol	Function	R/W
31:0	CAADD[31:0]	Calibration pattern address These bits configure the calibration pattern address.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

33.2.2.18 CCCTL4CSn : OSPI Command Calibration Control Register 4 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x140 + 0x020 × n

Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

33.2.2.19 CCCTL5CSn : OSPI Command Calibration Control Register 5 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x144 + 0x020 × n

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

33.2.2.20 CCCTL6CSn : OSPI Command Calibration Control Register 6 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x148 + 0x020 × n

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

33.2.2.21 CCCTL7CSn : OSPI Command Calibration Control Register 7 CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x14C + 0x020 × n

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CADATA[31:0]	Calibration pattern data These bits configure the calibration pattern data.	R/W

Note: S-TYPE-3, P-TYPE-3

This register has functions to control xSPI Master function. It should be updated while Automatic Calibration Enable is disabled.

33.2.3 OSPI Status Registers

These registers monitor the status of xSPI Master.

33.2.3.1 COMSTT : OSPI Common Status Register

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x184

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
Bit field:	—	—	—	—	—	—	—	—	—	RSTO CS1	INTCS 1	ECSC S1	—	—	—	—	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Bit field:	—	—	—	—	—	—	—	—	—	WRBU FNEC H1	WRBU FNEC H0	PBUF NECH 1	PBUF NECH 0	—	—	MEMA CCCH 1	MEMA CCCH 0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MEMACCCH0	Memory access ongoing from ch0 This bit is only valid in the section 33.3.7.2. Flow of Communication Stop and section 33.3.7.6. Flow of Memory-mapping Stop flows. 0: System bus bridge ch0 is not accessing to memory. 1: System bus bridge ch0 is accessing to memory.	R
1	MEMACCCH1	Memory access ongoing from ch1*1 This function is same as ch0.	R
3:2	—	These bits are read as 0.	R
4	PBUFNECH0	Prefetch Buffer Not Empty for ch0 0: Empty 1: Not empty	R
5	PBUFNECH1	Prefetch Buffer Not Empty for ch1*1 This function is same as ch0.	R
6	WRBUFNECH0	Write Buffer Not Empty for ch0 This bit is only valid in the section 33.3.7.2. Flow of Communication Stop and section 33.3.7.6. Flow of Memory-mapping Stop flows. 0: Empty 1: Not empty	R
7	WRBUFNECH1	Write Buffer Not Empty for ch1*1 This function is same as ch0.	R
19:8	—	These bits are read as 0.	R
20	ECSCS1	ECS monitor for slave1 This bit indicates the value of OM_ECSINT1 port. 0: Low level 1: High level	R
21	INTCS1	INT monitor for slave1 This bit indicates the value of OM_ECSINT1 port. 0: Low level 1: High level	R
22	RSTOCS1	RSTO monitor for slave1 This bit indicates the value of OM_RSTO1 port. 0: Low level 1: High level	R
31:23	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

Note 1. ch1 can only be used for GLCDC1 bus master.

This register indicates the status of xSPI Master.

33.2.3.2 CASTTCSn : OSPI Calibration Status Register CSn (n = 0, 1)

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x188 + 0x004 × n

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CASUC[31:0]	Calibration Success These bits indicate the calibration success for each OM_DQS shift value. It is updated when completed each calibration sequence. CASUC[x] indicates calibration success in OM_DQS shift value = x.	R

Note: S-TYPE-3, P-TYPE-3

This register indicates the status of xSPI Master.

33.2.4 OSPI Interrupt Registers

These registers control the interrupt function of xSPI Master.

33.2.4.1 INTS : OSPI Interrupt Status Register

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x190

Bit position: 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	CMDCMP	Command Completed This bit is set to 1 when completed the requested manual-command. In direct manual-command, it means all transactions completed. In periodic manual-command, it means the read data matches with the expected data. 0: No detection 1: Detection	R
1	PATCMP	Pattern Completed This bit is set to 1 when completed the requested pattern. 0: No detection 1: Detection	R
2	—	This bit is read as 0.	R
3	PERTO	Periodic transaction timeout This bit is set to 1 when the read value does not match with the expected value in periodic manual-command mode. 0: No detection 1: Detection	R

Bit	Symbol	Function	R/W
4	DSTOCS0	OM_DQS timeout for slave0 This bit is set to 1 when lost OM_DQS in read transaction with using OM_DQS. It means not receiving the data during expected read phase. In this case, xSPI master stops the read transaction and the following transaction. This error may issue error response to system bus. 0: No detection 1: Detection	R
5	DSTOCS1	OM_DQS timeout for slave1 This function is same as DSTOCS0. 0: No detection 1: Detection	R
8:6	—	These bits are read as 0.	R
9	ECSCS1	ECC error detection for slave1 This bit is set to 1 when detected the falling edge on OM_ECSINT1 port. It can be useful only for xSPI slave with ECC detection function. 0: No detection 1: Detection	R
12:10	—	These bits are read as 0.	R
13	INTCS1	Interrupt detection for slave1 This bit is set to 1 when detected the falling edge on OM_ECSINT1 port. It can be useful only for xSPI slave with interrupt function. 0: No detection 1: Detection	R
19:14	—	These bits are read as 0.	R
20	BUSERRCH0	System bus error for ch0 This bit is set to 1 when an error response occurs on system bus channel0.	R
21	BUSERRCH1	System bus error for ch1 ^{*1} This function is same as CH0.	R
27:22	—	These bits are read as 0.	R
28	CAFAILCS0	Calibration failed for slave0 This bit is set to 1 when failed calibration. 0: No detection 1: Detection	R
29	CAFAILCS1	Calibration failed for slave1 This function is same as CAFAILCS0. 0: No detection 1: Detection	R
30	CASUCCS0	Calibration success for slave0 This bit is set to 1 when success calibration. 0: No detection 1: Detection	R
31	CASUCCS1	Calibration success for slave1 This function is same as CASUCCS0. 0: No detection 1: Detection	R

Note: S-TYPE-3, P-TYPE-3

Note 1. ch1 can only be used for GLCDC1 bus master.

This register indicates the status of interrupt. The bits in this register are cleared to 0 when writing 1 on the corresponding bit of INTC register.

33.2.4.2 INTC : OSPI Interrupt Clear Register

Base address: OSPI0_B = 0x4026_8000
OSPI0_B_NS = 0x5026_8000

Offset address: 0x194

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CASU CCS1 C	CASU CCS0 C	CAFAI LCS1 C	CAFAI LCS0 C	—	—	—	—	—	—	BUSE RRCH 1C	BUSE RRCH 0C	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	INTCS 1C	—	—	—	ECSC S1C	—	—	—	DSTO CS1C	DSTO CS0C	PERT OC	—	PATC MPC	CMDC MPC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMDCMPC	Command Completed interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
1	PATCMPC	Pattern Completed interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
2	—	The write value should be 0.	W
3	PERTOC	Periodic transaction timeout interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
4	DSTOCS0C	OM_DQS timeout for slave0 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
5	DSTOCS1C	OM_DQS timeout for slave1 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
8:6	—	The write value should be 0.	W
9	ECSCS1C	ECC error detection for slave1 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
12:10	—	The write value should be 0.	W
13	INTCS1C	Interrupt detection for slave1 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
19:14	—	The write value should be 0.	W
20	BUSERRCH0C	System bus error for ch0 interrupt clear 0: No change interrupt status 1: Clear interrupt status	W
21	BUSERRCH1C	System bus error for ch1 interrupt clear*1 0: No change interrupt status 1: Clear interrupt status	W

Note: S-TYPE-3, P-TYPE-3

Note 1. ch1 can only be used for GLCDC1 bus master.

This register enables the interrupt.

33.3 Operation

xSPI Master interface has the functions to issue the transaction for external memory with xSPI Slave interface. It allows to write to registers in external memory or read from it.

This xSPI Master mainly has two modes to issue the transaction. One is a manual-command mode; Software configures all fields of xSPI frame and starts the transaction by software request. The other is a memory-mapping mode; it automatically converts system bus for pre-configured memory area into xSPI transaction. It enables to access from system bus to external memory area outside of chip via xSPI bus.

This section describes the xSPI bus operation, the direct control of xSPI frame (manual-command), the control of memory access (memory-mapping), the error operation, and the flow to operation.

33.3.1 xSPI Bus

This section describes the xSPI bus operation.

Figure 33.2 shows an example of connections between OSPI and memory devices.

In this case, OM_CS0 should be connected to the RAM device and OM_CS1 should be connected to the Flash device.

Pull-up resistors should be specified according to the instructions for each device.

Figure 33.2 Example of Connection between this and memory devices

33.3.1.1 Supported Protocol Mode

This xSPI Master supports various protocol modes. It is configured by Protocol mode bits (LIOCFCGSn.PRTMD[9:0]). Table 33.3 shows the summary of protocol modes.

Table 33.3 Supported protocol mode (1 of 2)

Protocol mode	Function	PRTMD[9:0]	Note
1S-1S-1S	Command, Address and Data field are transferred at SDR with using 1 data input pin and 1 data output pin. Read data is sampled with CK.	0x000	Specified by xSPI protocol
4S-4D-4D	Command field is transferred at SDR with using 4 data pins. Address and Data fields are transferred at DDR with using 4 data pins. Read data is sampled with OM_DQS.	0x3B2	Specified by xSPI protocol
8D-8D-8D	Command, Address and Data fields are transferred at DDR with using 8 data pins. Read data is sampled with OM_DQS.	0x3FF	Specified by xSPI protocol
1S-2S-2S	Command field is transferred at SDR with using 1 data pin. Address and Data fields are transferred at SDR with using 2 data pins. Read data is sampled with CK.	0x048	—

Table 33.3 Supported protocol mode (2 of 2)

Protocol mode	Function	PRTMD[9:0]	Note
2S-2S-2S	Command, Address and Data fields are transferred at SDR with using 2 data pins. Read data is sampled with CK.	0x049	—
1S-4S-4S	Command field is transferred at SDR with using 1 data pin. Address and Data fields are transferred at SDR with using 4 data pins. Read data is sampled with CK.	0x090	—
4S-4S-4S	Command, Address, and Data fields are transferred at SDR with using 4 data pins. Read data is sampled with CK.	0x092	—

Note: In case of XiP mode enable, XiP code is inserted in Latency field. It is valid only for memory-mapping mode.

The bytes of Command and Address fields are transferred in highest order to lowest order sequence. The sequential bytes of Data field are transferred in lowest address to highest address order. In case of using multiple pins, the least significant bit of each byte is placed on OM_SIO0 with each higher order bit on the successively higher numbered OM_SIO_n (n = 1 to 7) signals.

Figure 33.3 shows timing-chart for 1S-1S-1S protocol mode. The OM_SIO0 signal is used for output data and the OM_SIO1 signal is used for input data.

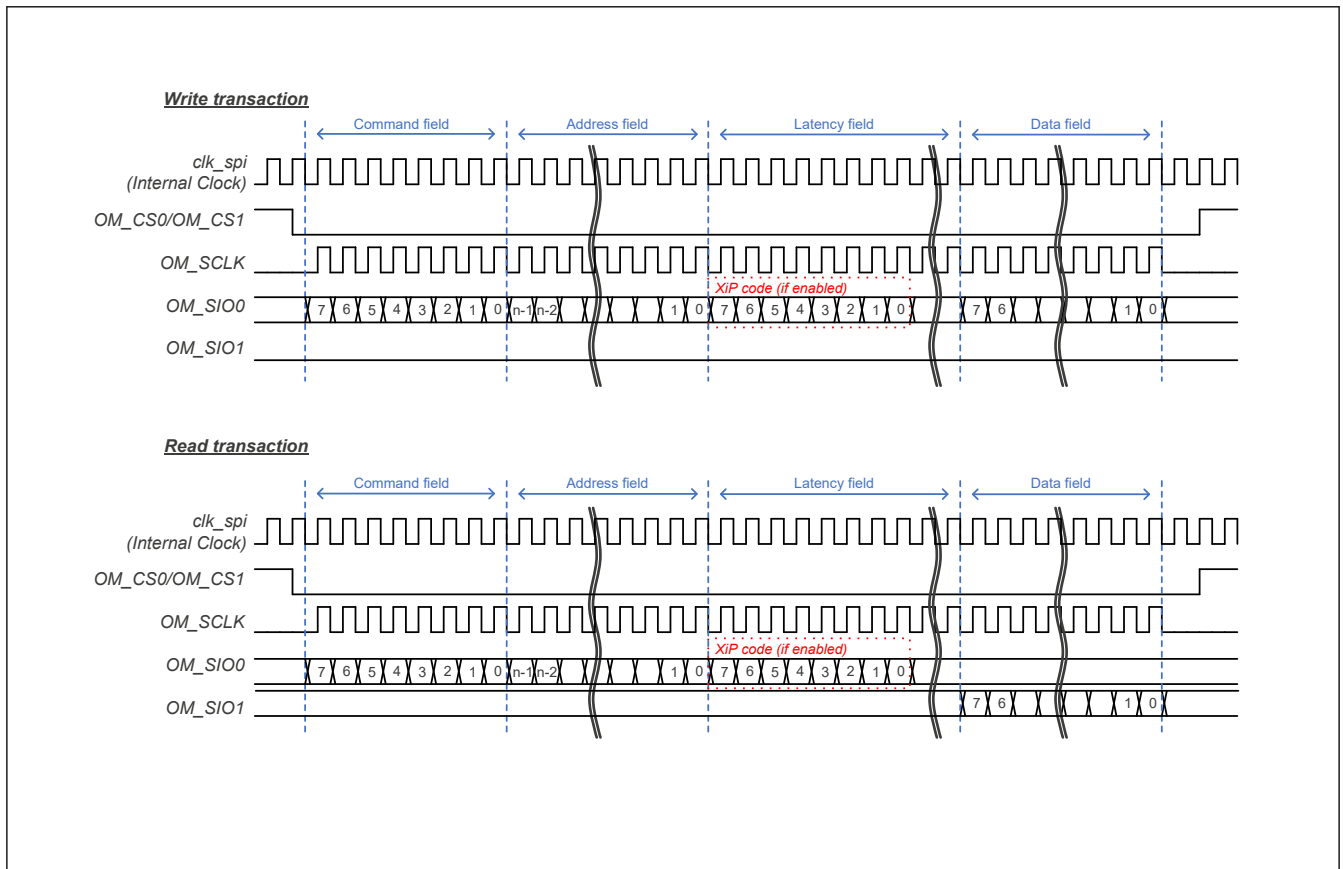

Figure 33.3 1S-1S-1S timing-chart

Figure 33.4 shows timing-chart for 1S-2S-2S protocol mode.

Figure 33.4 1S-2S-2S timing-chart

Figure 33.5 shows timing-chart for 4S-4D-4D protocol mode.

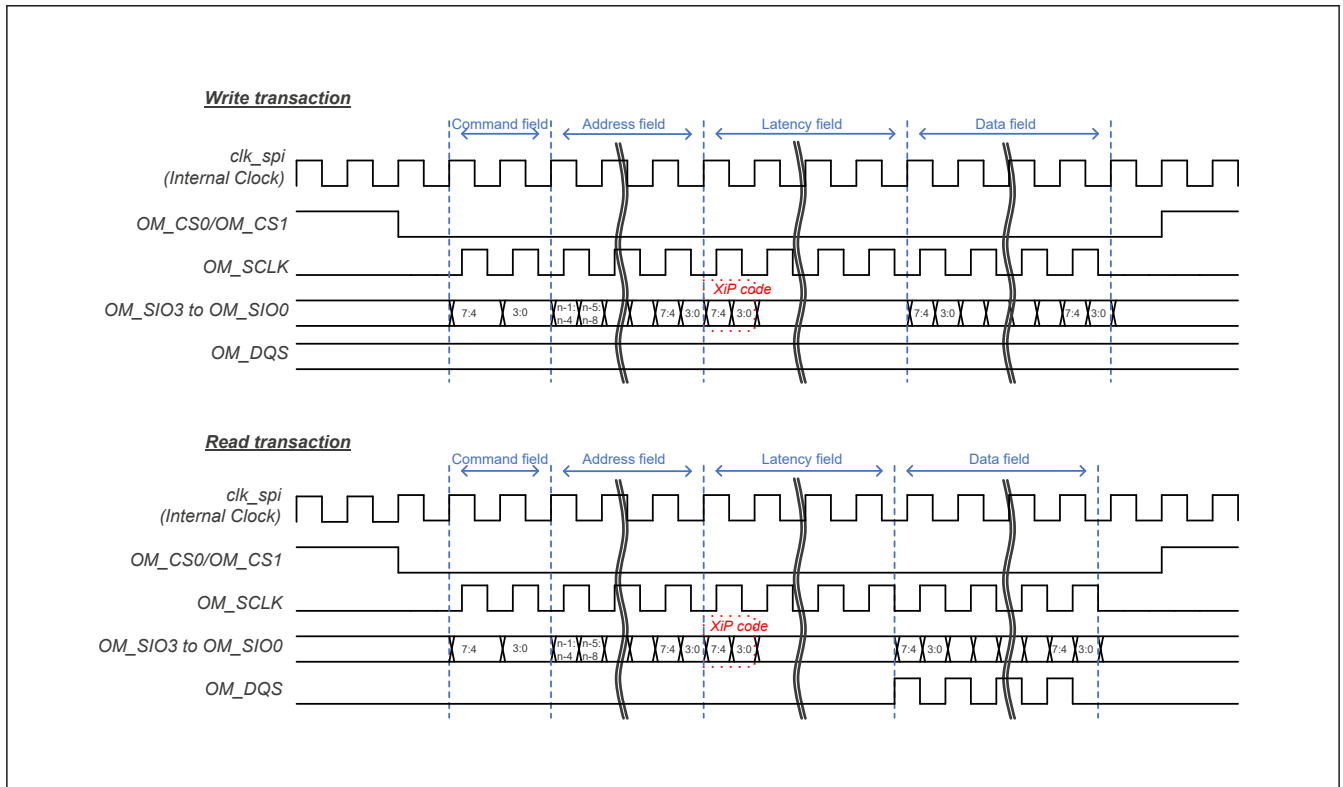

Figure 33.5 4S-4D-4D timing-chart

Figure 33.6 shows timing-chart for 8D-8D-8D profile 1.0 protocol mode. In 8D-8D-8D, the data is always transmitted with byte-pair. In case each field is odd byte, last one byte is padded with invalid data.

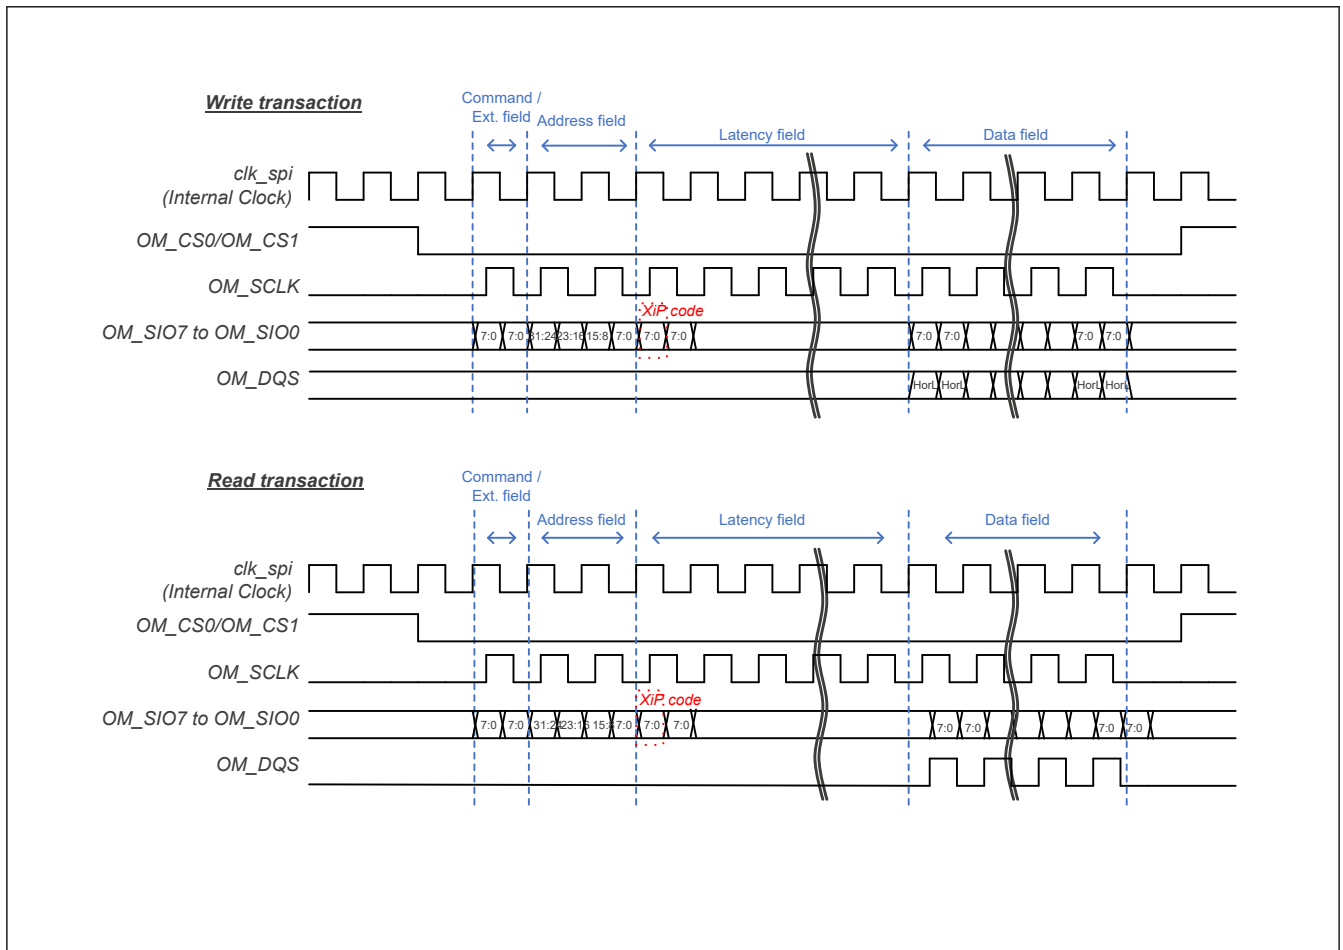

Figure 33.6 8D-8D-8D profile 1.0 timing-chart

Figure 33.7 shows timing-chart for 8D-8D-8D profile 2.0 protocol mode. In 8D-8D-8D, the data is always transmitted with byte-pair. In case each field is odd byte, last one byte is padded with invalid data.

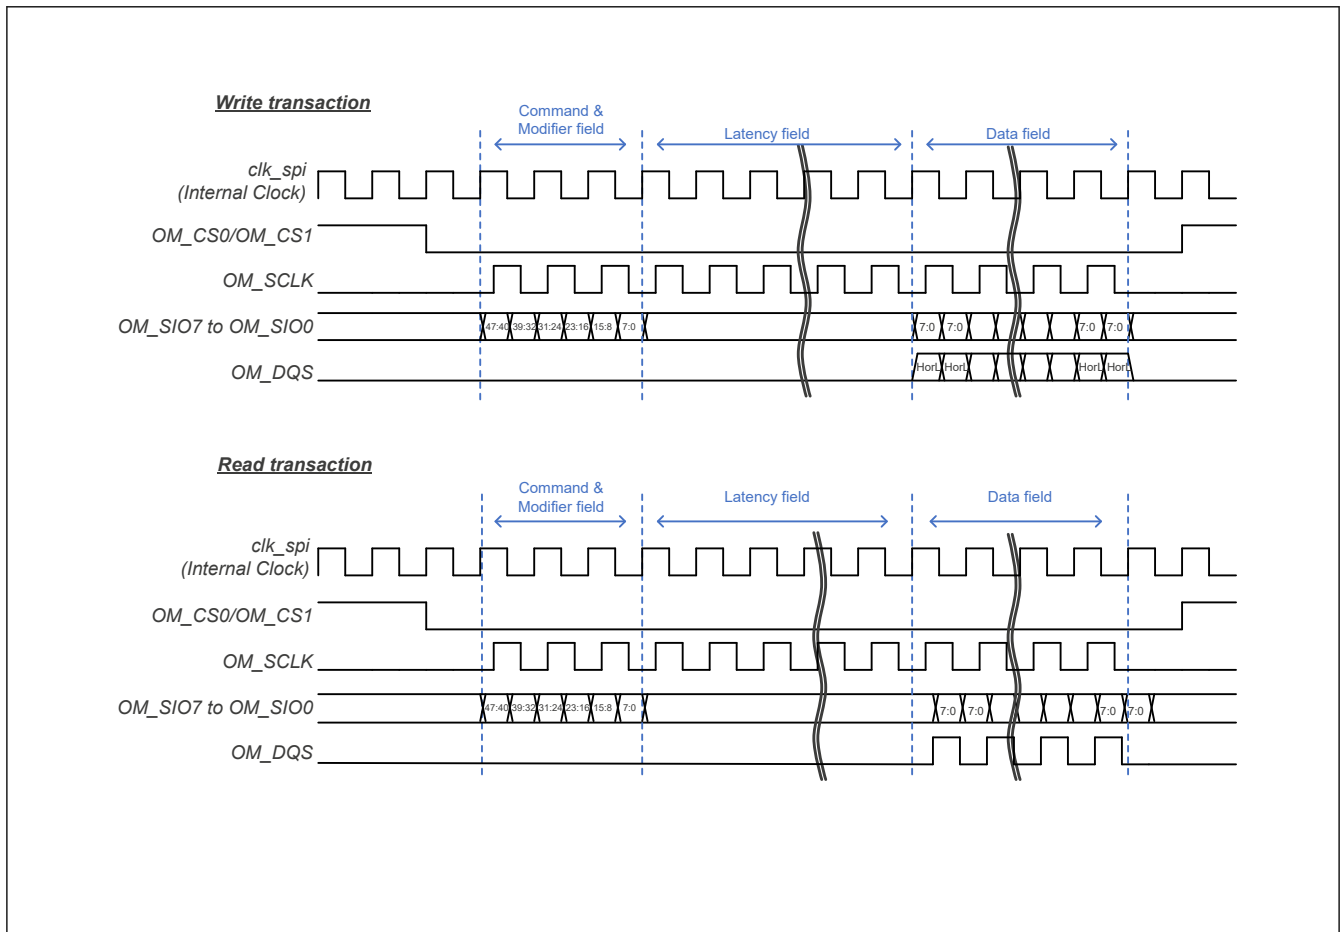

Figure 33.7 8D-8D-8D profile 2.0 timing-chart

33.3.1.2 xSPI Frame Interval

The interval between xSPI frames is configured with CS minimum idle term bits (LIOCFGCSn.CSMIN[3:0]). It depends on the specification of xSPI slave device.

33.3.1.3 OSPI Signals Timing Control

This xSPI Master supports both SDR and DDR. It is possible to sample input data with Data-Strobe (OM_DQS) signal at SDR. For various modes and easy implementation, this xSPI Master could adjust the timing to drive/sample xSPI interface signals statically. Table 33.4 shows the summary of xSPI Interface signal timing control.

Table 33.4 Summary of OSPI signals timing control (1 of 2)

Signal	Mode	Default operation	Timing control (n = 0, 1)
OM_CS0, OM_CS1 drive	—	Asserting 1 cycle before the rising-edge of first OM_SCLK	1 cycle extension for asserting with LIOCFGCSn.CSASTEX bit
		Negating 1.5 cycle after the falling-edge of last OM_SCLK	1 cycle extension for negating with LIOCFGCSn.CSNEGEX bit
OM_SCLK drive	SDR without OM_DQS	Reference point	—
	SDR with OM_DQS		
	DDR with OM_DQS	Reference point	—

Table 33.4 Summary of OSPI signals timing control (2 of 2)

Signal	Mode	Default operation	Timing control (n = 0, 1)
OM_SIO _n (n = 0 to 7) output drive	SDR without OM_DQS	Falling edge of clk_spi (Internal Clock)	0 or 0.5 cycle shift with LIOCFGCSn.SDRDRV bit
	SDR with OM_DQS		
	DDR with OM_DQS	Both edges of clk_spi (Internal Clock)	—
OM_SIO _n (n = 0 to 7) input sample	SDR without OM_DQS	Falling edge of OM_SCLK on expected data size	0 to 7 cycle shift (1 cycle unit) with LIOCFGCSn.SDRSMPSFT[3:0] bits 0 or 0.5 cycle shift with LIOCFGCSn.SDRSMPMD bit
	SDR with OM_DQS	Falling edge of OM_DQS signal on expected data size	Sample at rising edge with LIOCFGCSn.SDRSMPMD bit 0 to 1 cycle phase shift with WRAPCFG.DSSFTCSn[4:0] bits 0 to 7 cycle extension with LIOCFGCSn.DDRSMPEX[3:0] bits
	DDR with OM_DQS	Both edges of OM_DQS signal on expected data size	0 to 1 cycle phase shift with WRAPCFG.DSSFTCSn[4:0] bits 0 to 7 cycle extension with LIOCFGCSn.DDRSMPEX[3:0] bits

Note: In DDR on xSPI protocol, OM_DQS should be aligned for center of data. It means to shift the phase by 0.25 cycle (90 degrees). This xSPI master supports to adjust this phase depending on the usage conditions.

Figure 33.8 shows the default operation and timing control for SDR without OM_DQS.

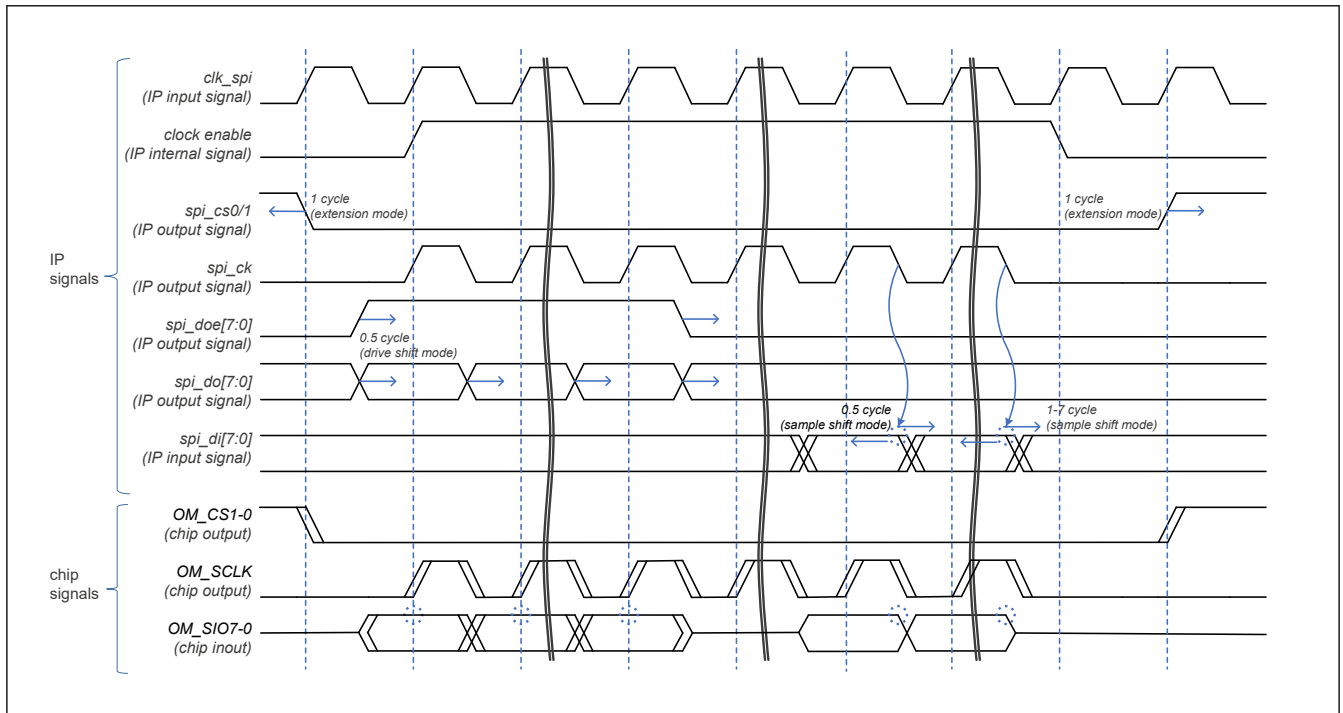

Figure 33.8 Timing control for SDR without OM_DQS

Figure 33.9 shows the default operation and timing control for SDR with OM_DQS.

Figure 33.9 Timing control for SDR with OM_DQS

Figure 33.10 shows the default operation and timing control for DDR with OM_DQS.

Figure 33.10 Timing control for DDR with OM_DQS

33.3.1.4 Automatic calibration

This xSPI master supports the function to adjust OM_DQS shift value (WRAPCFG.DSSFTCSn (n = 0, 1)) automatically. When this function is enabled (CCCTL0CSn.CAEN = 1), this xSPI master transmits the calibration sequence periodically and adjusts the value of phase shift.

When all read compare is mismatched in read transaction during the calibration sequence, the calibration fail bit (INTS.CAFAILCSn = 1 (n = 0, 1)) is asserted and OM_DQS shift value is not updated. When at least one read compare is matched, the calibration success bit (INTS.CASUCCESSn = 1 (n = 0, 1)) is asserted and OM_DQS shift value is updated. The result of each OM_DQS shift value is monitored by Calibration Status register (CASTTCSn). Figure 33.11 shows automatic calibration.

Figure 33.11 Automatic calibration

33.3.2 Manual-command

This section describes the manual-command mode. The manual-command has two functional modes: direct mode and periodic mode.

33.3.2.1 Direct Mode

This mode sequentially can issue up to four xSPI transactions configured and requested by Software. A series of transaction can be issued by a transaction request (CDCTL0.TRREQ = 1 with PERMD = 0). The number of transactions (CDCTL0.TRNUM[1:0]) can be configured up to 4. It can be used to change the mode or read the status of xSPI slave device.

Table 33.5 shows the configured register bits for direct manual-command. The operating flow is illustrated in Figure 33.25.

Table 33.5 Manual-command configuration for direct mode

Transaction	Transaction type	Command	Command size	Address	Address size	Data (x = 0, 1)	Data size	Latency cycle
1st Transaction	CDTBUF0. TRTYPE	CDTBUF0. CMD[15:0]	CDTBUF0. CMDSIZE[1:0]	CDABUF0. ADD[31:0]	CDTBUF0. ADDSIZE[2:0]	CDDxBUF0. DATA[31:0]	CDTBUF0. DATASIZE[3:0]	CDTBUF0. LATE[4:0]
2nd Transaction	CDTBUF1. TRTYPE	CDTBUF1. CMD[15:0]	CDTBUF1. CMDSIZE[1:0]	CDABUF1. ADD[31:0]	CDTBUF1. ADDSIZE[2:0]	CDDxBUF1. DATA[31:0]	CDTBUF1. DATASIZE[3:0]	CDTBUF1. LATE[4:0]
3rd Transaction	CDTBUF2. TRTYPE	CDTBUF2. CMD[15:0]	CDTBUF2. CMDSIZE[1:0]	CDABUF2. ADD[31:0]	CDTBUF2. ADDSIZE[2:0]	CDDxBUF2. DATA[31:0]	CDTBUF2. DATASIZE[3:0]	CDTBUF2. LATE[4:0]
4th Transaction	CDTBUF3. TRTYPE	CDTBUF3. CMD[15:0]	CDTBUF3. CMDSIZE[1:0]	CDABUF3. ADD[31:0]	CDTBUF3. ADDSIZE[2:0]	CDDxBUF3. DATA[31:0]	CDTBUF3. DATASIZE[3:0]	CDTBUF3. LATE[4:0]

33.3.2.2 Periodic Mode

This mode periodically issues an xSPI read transaction configured and requested by Software. And it can compare the read value up to 4 bytes with expected value. The transaction is issued by a transaction request (CDCTL0.TRREQ = 1 with PERMD = 1). It can be used to alternate the status polling operation of xSPI slave device.

The periodic term is configured in Periodic transaction interval bits (CDCTL0.PERITV[4:0]). The expected value is configured in Periodic transaction expected and masked value bits (CDCTL1.PEREXP[31:0] and CDCTL2.PERMSK[31:0]). Table 33.6 shows the configured register bits for periodic manual-command. The operating flow is illustrated in Figure 33.26.

Table 33.6 Manual-command configuration for periodic mode

Transaction	Transaction type	Command	Command size	Address	Address size	Data (x = 0, 1)	Data size	Latency cycle
Read Transaction	CDTBUF0. TRTYPE	CDTBUF0. CMD[15:0]	CDTBUF0. CMDSIZE[1: 0]	CDABUF0. ADD[31:0]	CDTBUF0. ADD SIZE[2:0]	CDDxBUF0. DATA[31:0]	CDTBUF0. DATASIZE[3: 0]	CDTBUF0. LATE[4:0]

33.3.3 Memory-mapping

This section describes the memory-mapping mode. This mode automatically converts system bus access for pre-configured memory area into xSPI transaction.

33.3.3.1 Configuration

In this operation, the payload of address and data field are delivered from system bus signals. The information of command field and size are delivered from the configured register bits. [Table 33.7](#) shows the register bits configured for memory-mapping.

Table 33.7 Memory-mapping configuration for memory area access (n = 0, 1)

System bus Transaction	Format Change mode	Command	Command size	Address	Address size	Data	Data size	Latency cycle
Write for slave n memory area	Normal	CMCFG2CSn. WRCMD[15:8]	1 byte	SAWADDR[x:0]	CMCFG0C Sn. ADD SIZE[1:0]	SWDATA	Up to SAWLEN and SAWSIZE	CMCFG2CSn. WRLATE[4:0]
	8D-8D-8D profile 1.0	CMCFG2CSn. WRCMD[15:0]	2 bytes					
	8D-8D-8D profile 2.0 Command Modifier	CMCFG2CSn. WRCMD[15:8]	1 byte	{SAWADDR[27:4], 0000000000000b, SAWADDR[3:1]}	5 bytes			
	8D-8D-8D profile 2.0 Extended Command Modifier	CMCFG2CSn. WRCMD[15:13]	3 bits	{0b, SAWADDR[31:4], 0000000000000b, SAWADDR[3:1]}	45 bits			
Read for slave n memory area	Normal	CMCFG1CSn. RDCMD[15:8]	1 byte	SARADDR[x:0]	CMCFG0C Sn. ADD SIZE[1:0]	SRDATA	Up to SARLEN and SAR SIZE	CMCFG1CSn. RDLATE[4:0]
	8D-8D-8D profile 1.0	CMCFG1CSn. RDCMD[15:0]	2 bytes					
	8D-8D-8D profile 2.0 Command Modifier	CMCFG1CSn. RDCMD[15:8]	1 byte	{SARADDR[27:4], 0000000000000b, SARADDR[3:1]}	5 bytes			
	8D-8D-8D profile 2.0 Extended Command Modifier	CMCFG1CSn. RDCMD[15:13]	3 bits	{0b, SARADDR[31:4], 0000000000000b, SARADDR[3:1]}	45 bits			

Note: The MSByte of Address can be replaced with Address Replace Enable and Code bits (CMCFG0CSn.ADDRPEN[7:0] / ADDRPCD[7:0]).

33.3.3.2 Write Access Operation

At accepting write access for memory area from system bus, this xSPI Master stores all payload data in internal bridge buffer and then issues a write transaction into xSPI slave. [Figure 33.12](#) shows the operation summary.

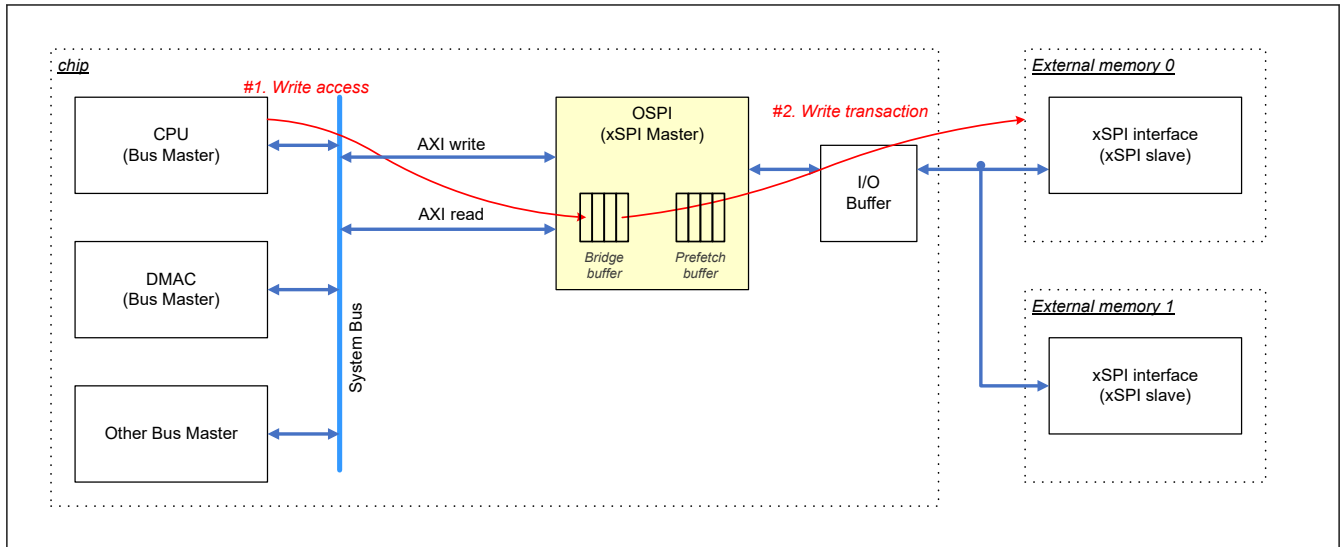

Figure 33.12 Write access for memory area

The operation of xSPI bus changes depending on system bus's burst type. When the burst type is single type or incremental type, one system bus transaction triggers for one xSPI frame. When the burst type is wrap type and the CMCFG0CSn.WPBSTMD is 0, one system bus transaction triggers two xSPI frames. [Figure 33.13](#) shows the relationship between AXI and xSPI frames.

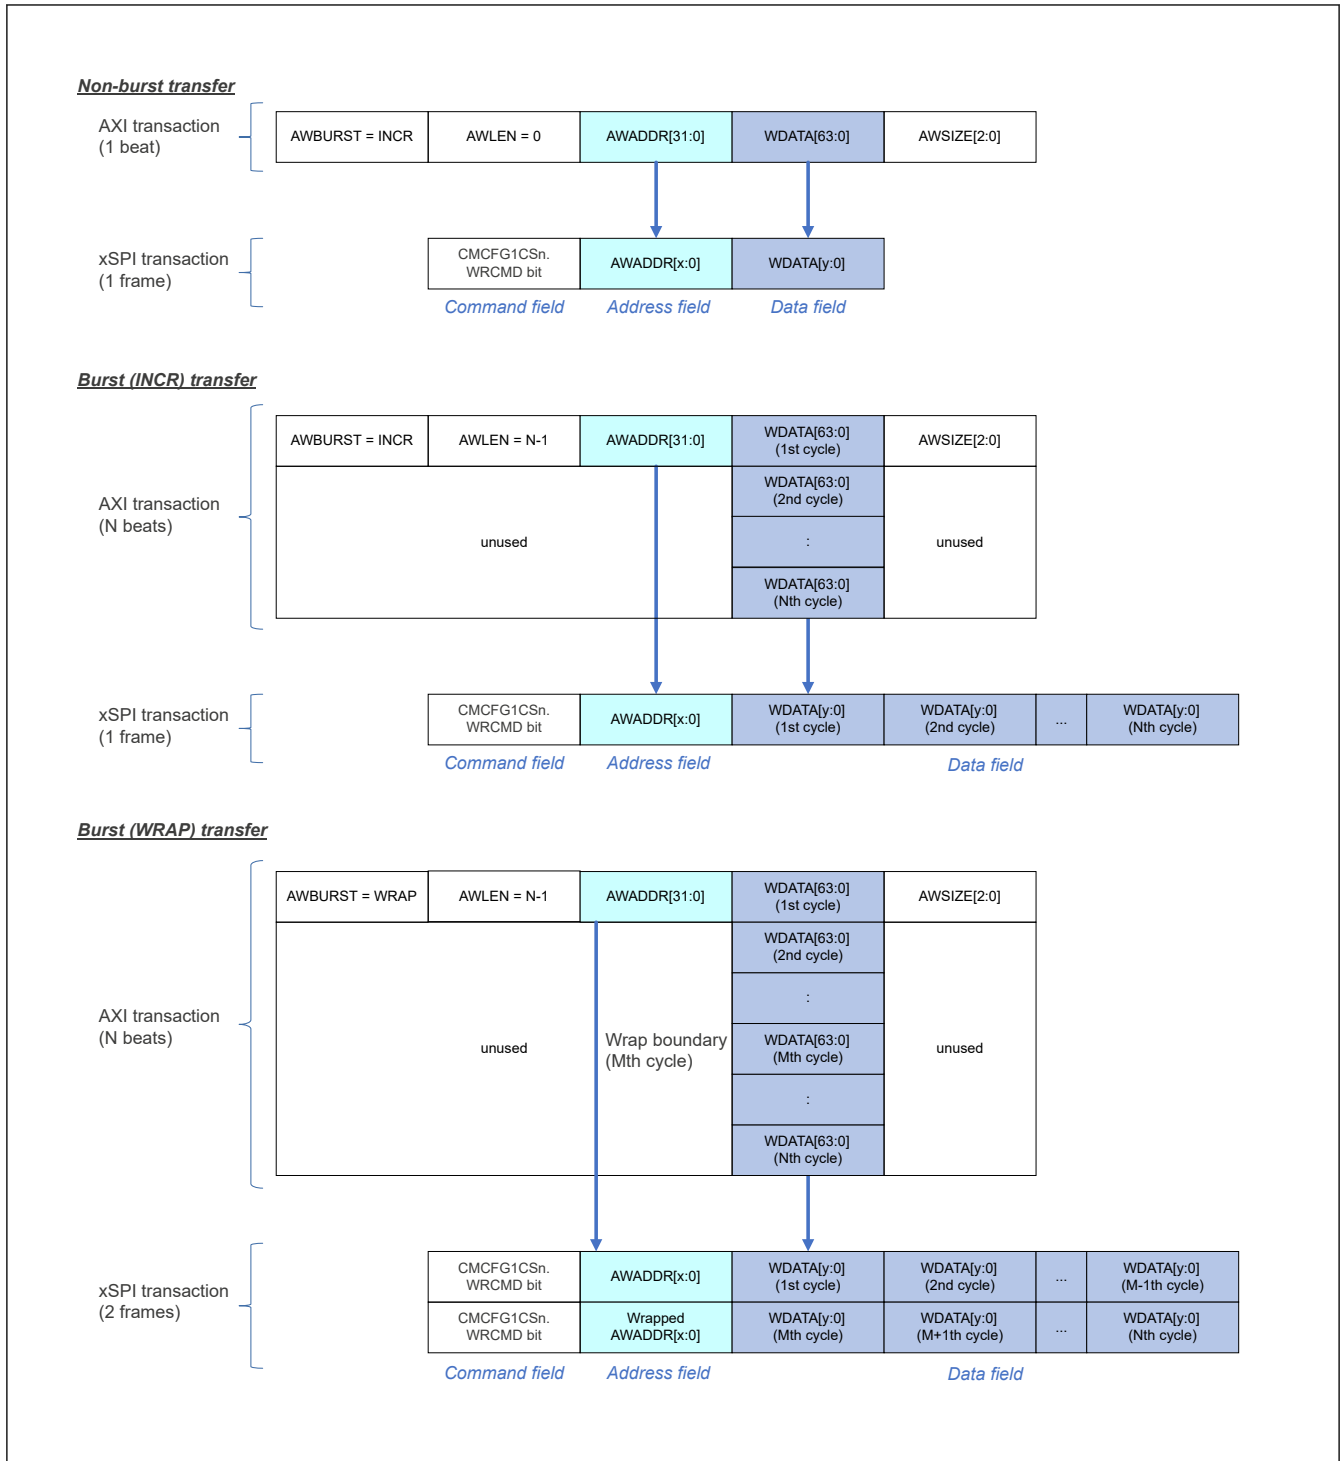

Figure 33.13 xSPI frame format in write access (Normal format)

33.3.3.3 Combination Function

At the system bus write access for memory area, this xSPI master has the function to combine the write data for high throughput on xSPI bus. When this function is enabled (BMCFGCHn.MWRCOMB = 1), this xSPI master transmits a xSPI frame with the selected size while the sequential address is incremental^{*1}. When one of the below conditions is detected, even though not reaching to the target size (BMCFGCHn.MWRSIZE[7:0]), this xSPI master transmits the pending data into xSPI bus.

- Non-incremental address is detected.
- Different burst type is detected.

- Read transaction is detected.
- Access for different slave is detected.
- Memory Write Data Push bit (BMCTL1.MWRPUSHCHn (n = 0, 1)) is set.

This function could be useful for any slave device to request a chunk of data at a time. In the case, system bus master shall continue to provide the fixed data size with incremental address. e.g. there is any device to request to write in page unit.

Figure 33.14 shows the operation when enable the combination function.

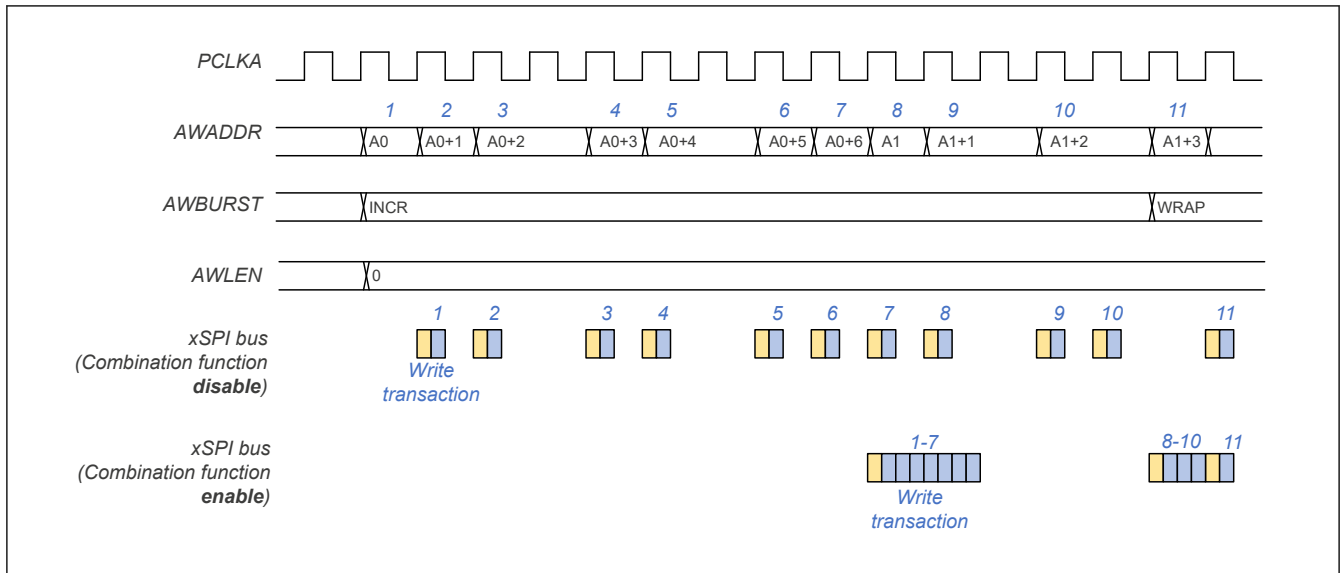

Figure 33.14 Combination function

Note 1. The access which comply all below condition is considered as incremental address.

- Transaction type is INCR.
- The access's start address is continuous to the previous last write address.
 - The access's start position of WSTRB is treated as start address.
 - Previous access's last WSTRB is treated last write address.

Figure 33.15 shows data combined example with AXI access.

Figure 33.15 Data combined example with AXI access

33.3.3.4 Read Access Operation

At the read access for memory area, soon after detected the read access, this xSPI Master issues a read transaction into xSPI slave. Figure 33.16 shows the operation summary.

Figure 33.16 Read access for memory area

The operation of xSPI bus changes depending on burst type. When the type is single or increment type, one system bus's read transaction triggers one xSPI frame. When the type is wrap type and the CMCFG0CSn.WPBSTMD is 0, one system bus read transactions triggers two xSPI frames. Figure 33.17 shows the relationship between AXI and xSPI frames.

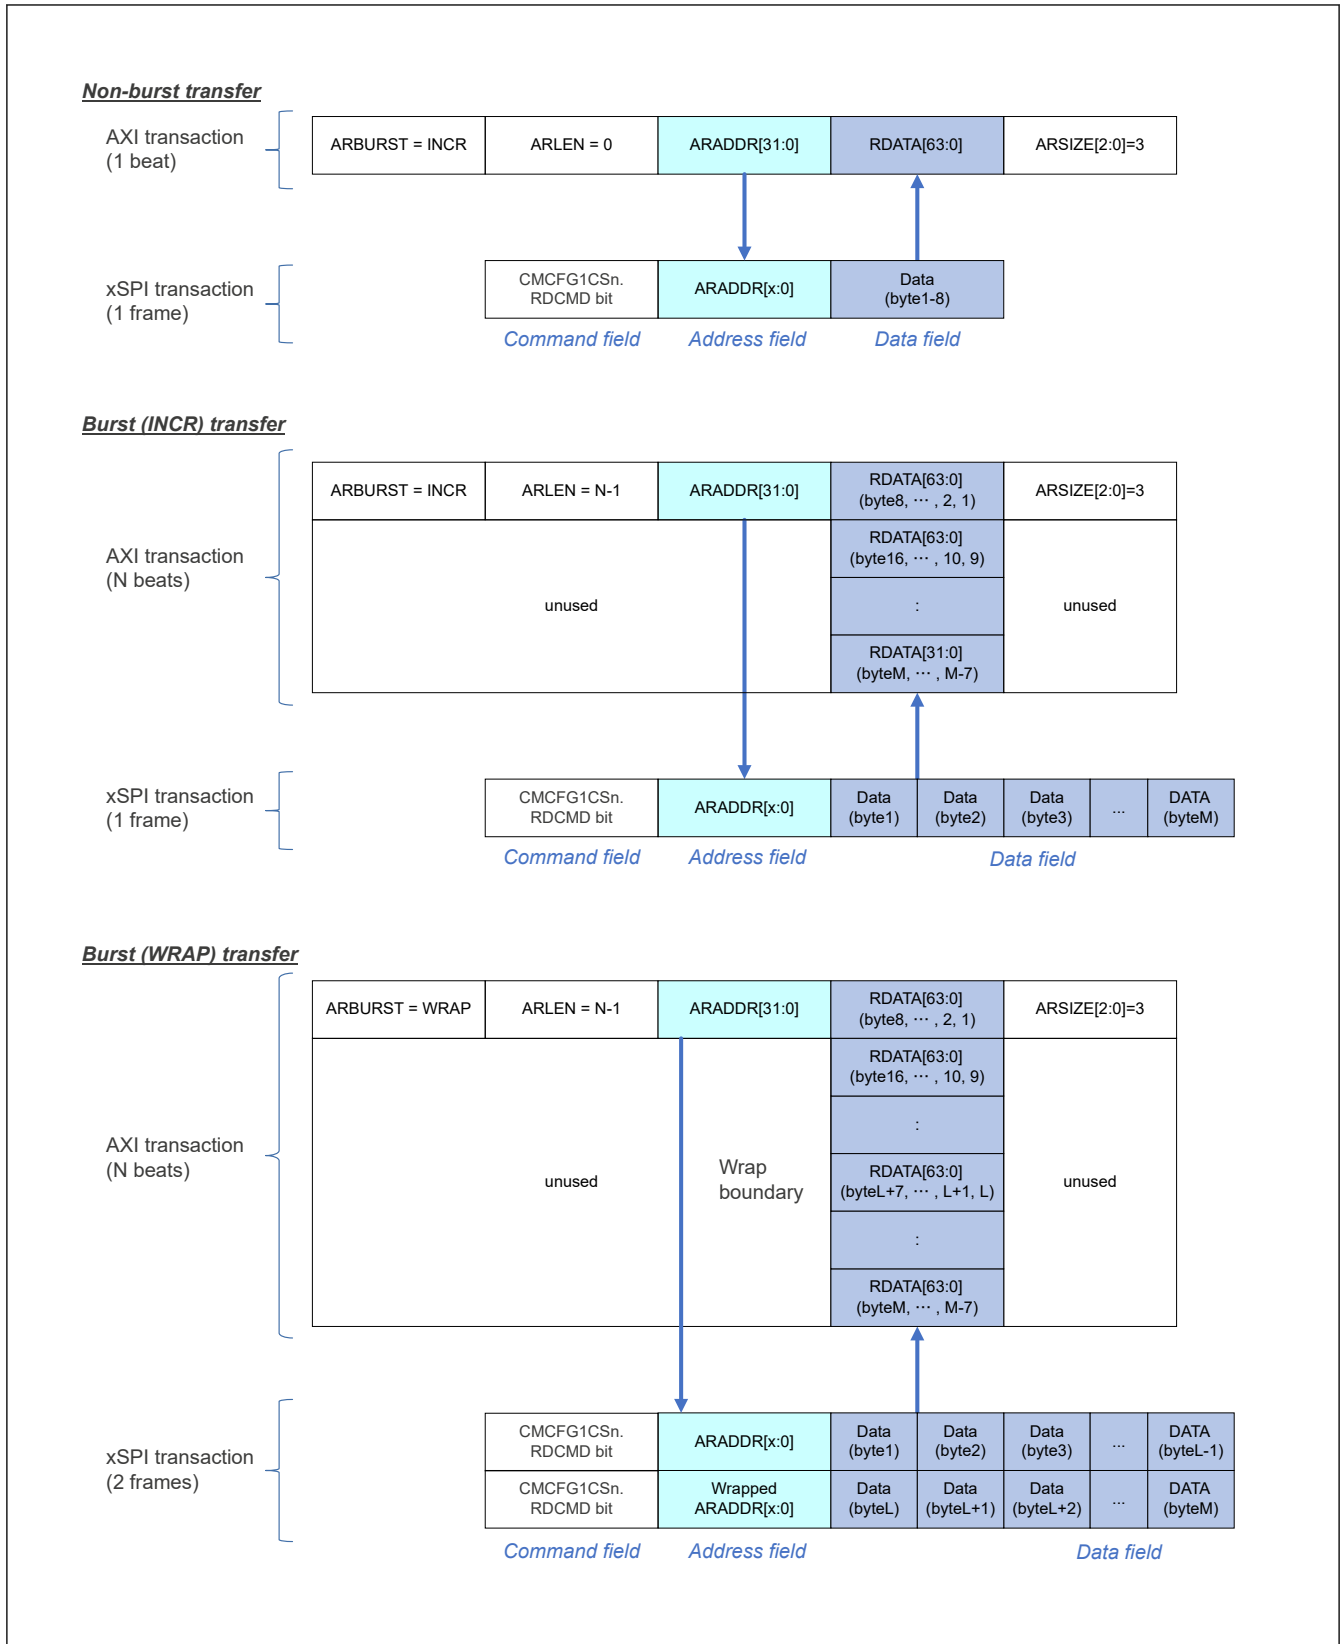

Figure 33.17 xSPI frame format in read access (Normal format)

33.3.3.5 Prefetch Function

At the read access for memory area from system bus, this xSPI Master has the function to prefetch the read data for reducing the latency. When enabled this function (BMCFGCHn.PREEN = 1), this xSPI Master continues to read the

incremental address and store the read data from xSPI slave in internal prefetch buffer. And this xSPI master searches in prefetch buffer for the following read access from system bus. If found the target read data in prefetch buffer, this xSPI Master returns the data from prefetch buffer. If not found, this xSPI Master clears prefetch buffer and newly issues a read transaction into xSPI slave. This function is effective in application such as the consecutive read addresses are close. But it is not effective in application such as the consecutive read addresses are not incremental because xSPI read frame for prefetch uses xSPI bus. [Figure 33.18](#) shows the operation summary.

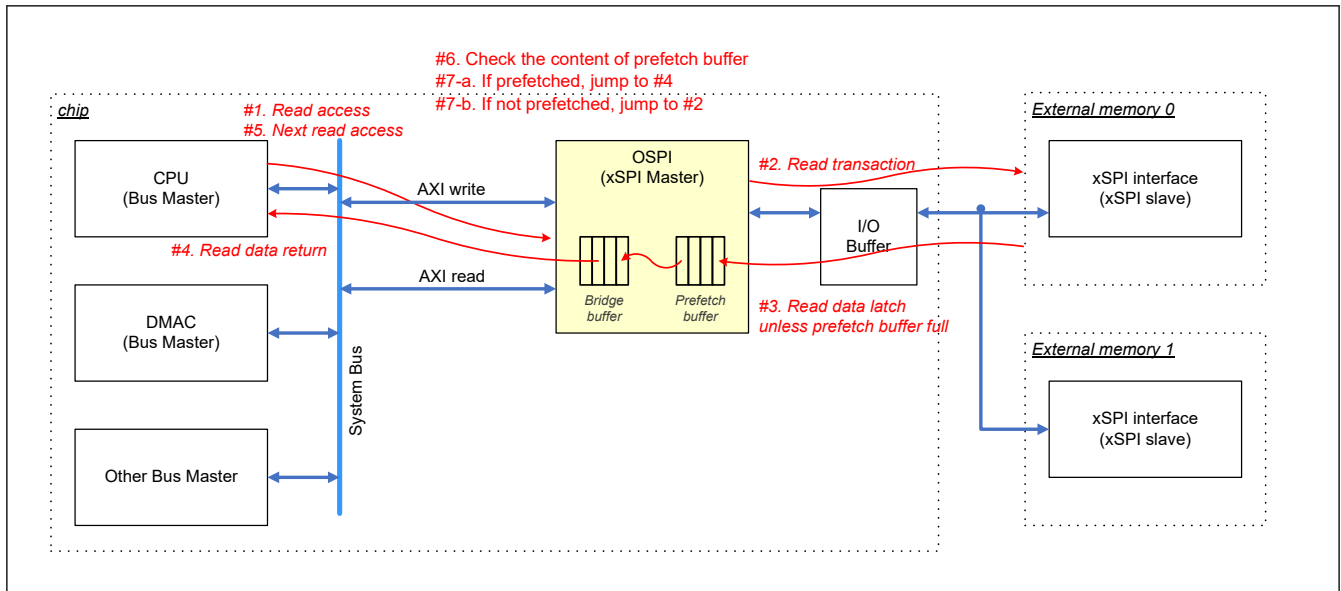

Figure 33.18 Read access for memory area with prefetch enabled

- Note: When enabled this prefetch function, Bus Master could read from not a slave device but the internal prefetch buffer. When accessed to the same address from multiple Bus Masters, this xSPI Master does not guarantee to read the latest data. If Bus Master wish to read the latest data from a slave device, it should read after cleared the prefetch buffer (BMCTL1.PBUFCLRCHn (n = 0, 1)).
- Note: Prefetch buffer is implemented as FIFO-based, and when read access is issued, the data before the access address is discarded from the buffer. And when next access is issued to the region which is discarded at previous access, this module issues the xSPI read access again to fill the prefetch buffer.
- Note: OSPI has the 1line buffer which keeps the last 8Byte read data from prefetch buffer. When read access is issued to the same address to the data in 1line buffer, OSPI returns read data from 1line buffer.

33.3.3.6 XiP Mode

Some slave devices have a mode (XiP mode) in which the command phase is not required for lower latency. While in this mode, the xSPI master skips sending the command and the slave device implicitly performs the command that was executed in the previous transaction. When enabled XiP mode bit (CMCTLCHn.XIPEN = 1), this xSPI master inserts XiP enter code (CMCTLCHn.XIPENCODE[7:0]) in latency field. When disabled XiP mode bit (CMCTLCHn.XIPEN = 0), this xSPI master inserts XiP exit code (CMCTLCHn.XIPEXCODE[7:0]) in latency field. This function is available only for memory-mapping mode.

And when this xSPI master transmits XiP disable pattern, this master clears XiP mode bit and disables XiP mode configured for both channels. Note that it is not possible to disable XiP mode for only one channel by transmitting XiP disable pattern.

- Note: When enough latency cycle does not exist for XiP code, this xSPI Master could not insert XiP code.
- Note: XiP mode could be used only for unidirectional access to a slave. The write transaction and read transaction should be separated.
- Note: The XiP exit code is inserted once when disabled. More details, See [Figure 33.30](#).

33.3.4 Pattern Control

This xSPI Master has the function to transmit 3 type of patterns which is not xSPI frame format. The pattern is triggered by setting trigger bit (LPCTL0-1.PATREQ).

33.3.4.1 XiP Disable Pattern

XiP Disable pattern transmits any pattern with the configured length and value (LPCTL0.XD1LEN[4:0] / XD1VAL / XD2LEN[4:0] / XD2VAL). It uses OM_SCLK, OM_SIO7-0 signals. The number of output pin can be configured by XiP Disable pattern pin bits (LPCTL0.XDPIN[1:0]). It may be used to disable XiP mode for legacy SPI. Figure 33.19 shows the timing-chart.

Figure 33.19 XiP Disable pattern

33.3.4.2 Reset Pattern

Reset pattern transmits the pattern specified in Serial Flash Reset Signaling Protocol. Figure 33.20 shows the timing chart. CS Low/High width is configured with Reset Pattern Length bits (LPCTL1.RSTWID[2:0]). xSPI slave will sample the data input at the rising edge of CS. Setup time for data output is configured with Reset pattern data output setup time bits (LPCTL1.RSTSU[2:0]). The setup time should be less than Reset pattern width always.

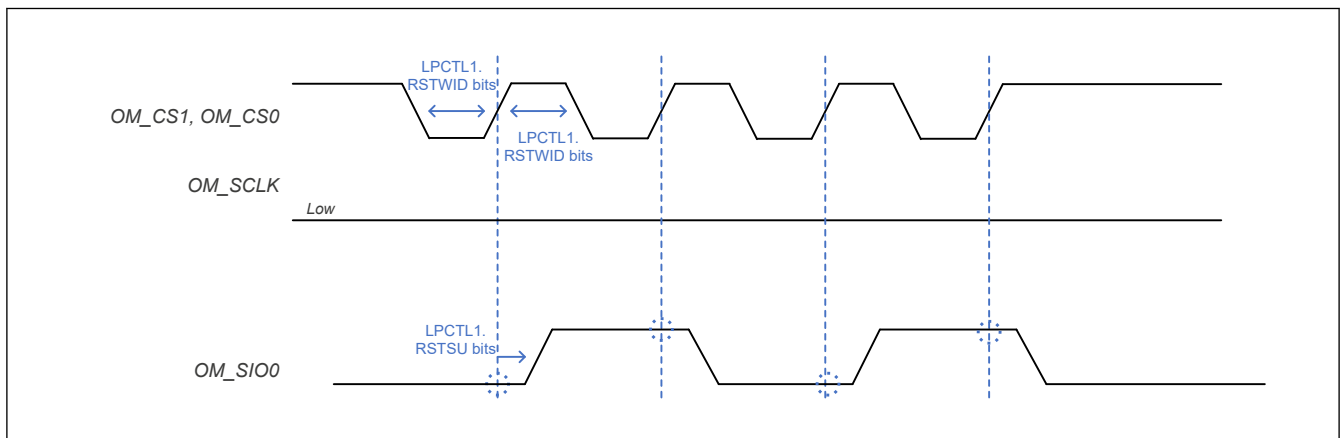

Figure 33.20 Reset pattern

Note: In the protocol, CS Low/High width is defined as minimum 500 ns and Setup time is defined as minimum 6 ns.

33.3.4.3 CS Only Pattern

CS Only pattern activates CS port with the configured length bits (LPCTL1.RSTWID[2:0]). It may be used to resume from Deep Power Down state. Figure 33.21 shows the timing-chart.

Figure 33.21 CS Only pattern

33.3.5 Integrity Checking

This xSPI Master can detect some errors. [Table 33.8](#) shows the error list and the detail behavior.

Table 33.8 Error list (n = 0, 1)

Error type	Event	Flag bit	Note (action)
Calibration failed	When the read data did not match the expected value during automatic calibration.	INTS.CAFAILCSn	It results in writing unexpected data to xSPI slave.
System bus error	When an error response occurred on AXI slave interface for memory-mapping.	INTS.BUSERRCHn	This xSPI master shall be reset for fatal error.
ECC error detection	When detected the falling edge on OM_ECSINT1 port. It can be useful only for xSPI slave with ECC detection function.	INTS.ECSCS1	Only notify the error event of xSPI slave.
OM_DQS timeout	When OM_DQS does not toggle in read transaction with using OM_DQS.	INTS.DSTOCSn	Both xSPI master and xSPI slave should be reset for fatal error.
Periodic transaction timeout	When the read value does not match with the expected value in periodic manual-command mode.	INTS.PERTO	Depending on the status of function.

33.3.6 Interrupts

This xSPI Master has an interrupt port.

It can monitor with Interrupt Status Register (INTS). In case of initialization phase, it can be programmable with Interrupt Enable register (INTE). [Table 33.9](#) shows OSPI interrupt sources, and [Table 33.10](#) shows the related register bit.

Note: Interrupt pulse port signal is not asserted when the corresponding bit of INTE is set after the interrupt event is detected.

Table 33.9 OSPI interrupt sources

Name	Interrupt sources	DMAC activation
OSPI0_ERR	Error	Not possible
OSPI0_CMP	Complete	Not possible

Table 33.10 Interrupt register bit

Flag bit	Enable bit	Clear bit	Interrupt sources
CASUCCS1	CASUCCS1E	CASUCCS1C	OSPI0_CMP
CASUCCS0	CASUCCS0E	CASUCCS0C	
CAFAILCS1	CAFAILCS1E	CAFAILCS1C	OSPI0_ERR
CAFAILCS0	CAFAILCS0E	CAFAILCS0C	
BUSERRCH1	BUSERRCH1E	BUSERRCH1C	OSPI0_ERR

CMDCMP	CMDCMPE	CMDCMPC	OSPI0_CMP

33.3.7 Flows of Operations

33.3.7.1 Flow of Configuration

Figure 33.22 shows flow of configuration.

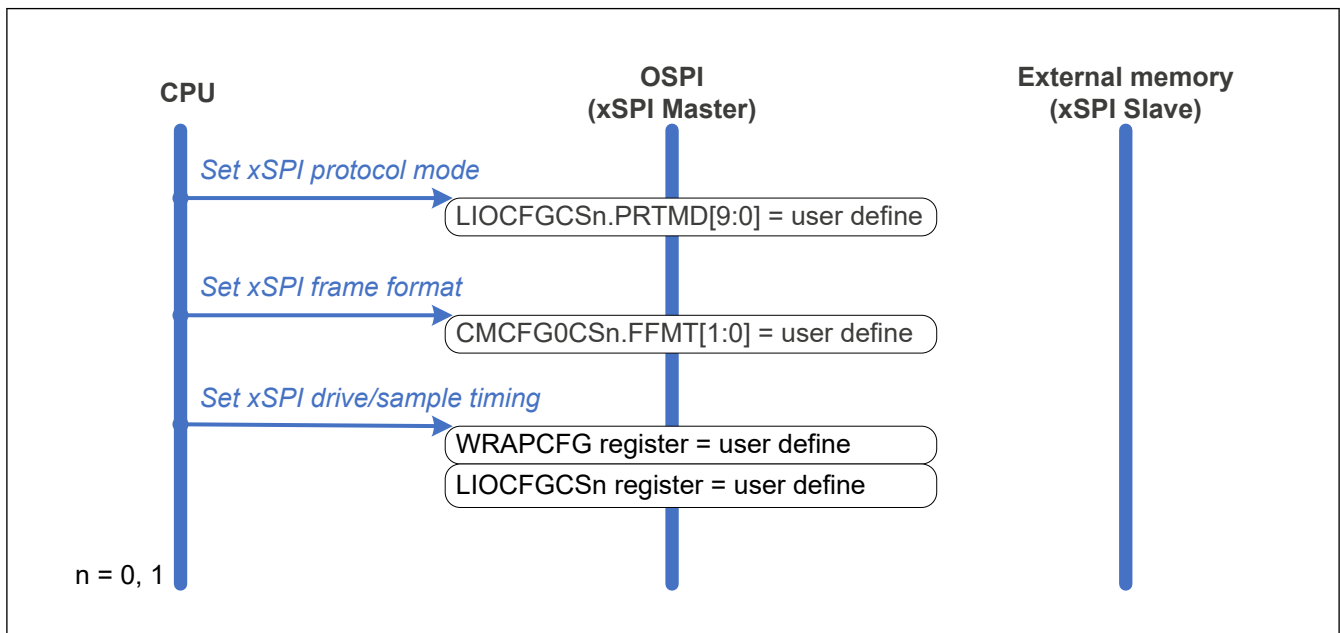

Figure 33.22 Flow of configuration

33.3.7.2 Flow of Communication Stop

Figure 33.23 shows flow of communication stop.

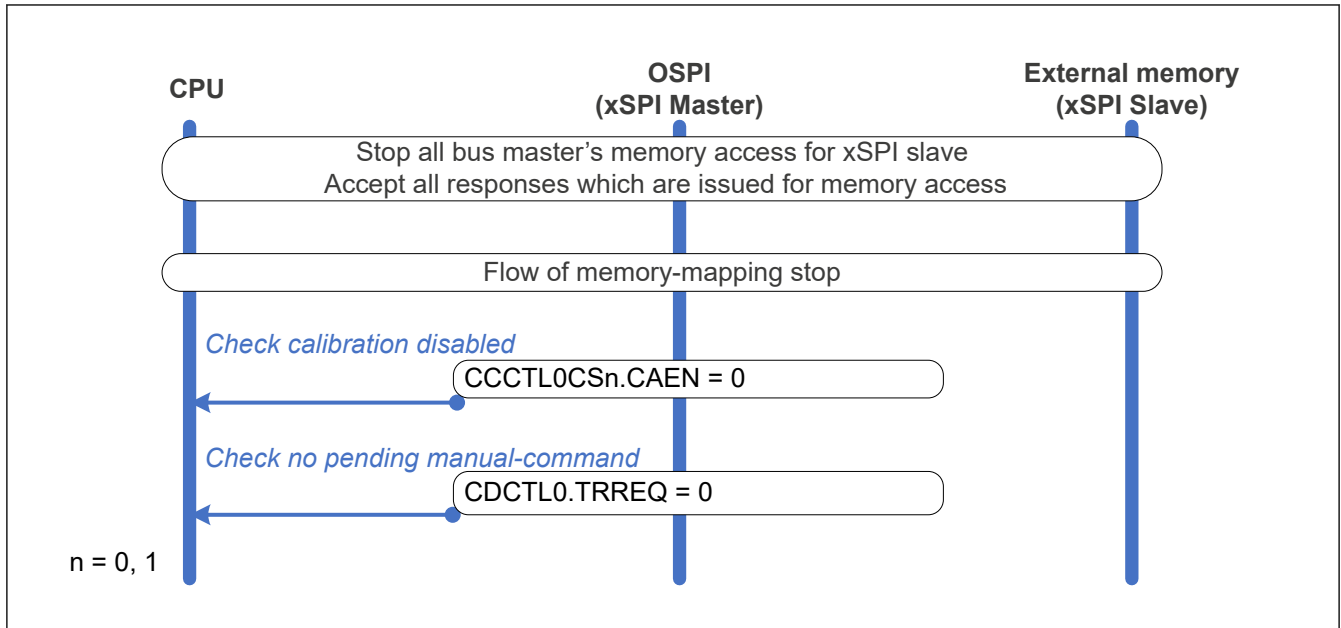

Figure 33.23 Flow of communication stop

Note: In case of re-config of any configuration register, all communication with xSPI slave shall be stopped surely to avoid race condition between register setting and memory access. It means that the automatic calibration is disabled, and there is no pending manual-command and memory-mapping access.

33.3.7.3 Flow of Automatic Calibration

Figure 33.24 shows flow of automatic calibration.

Figure 33.24 Flow of automatic calibration

33.3.7.9 Flow of Read While Write

Figure 33.31 shows example flow of read while write.

Figure 33.31 Flow of read while write

33.3.8 Usage Notes

33.3.8.1 Constraint on Memory Access

The memory access has the following constraints:

- Prohibit to access last 128 byte area of memory support area.
- Not using prefetch function if application access to the last 128 byte area
- Enable prefetch function when read HyperFlash by DRW.

33.3.8.2 Constraint on Burst Length

AXI bus master must have a Burst Length of 16 or less.

33.3.8.3 Memory Write Combination Mode

When `BMCFGCHn.MWRCOMB` is 1, memory write combination mode is enabled. However, combination does not work if the bus master is CPU, and OSPI data is under 32bit. [Table 33.11](#) shows the possibility of data write for each bus master.

Table 33.11 Data write possibility for each bus master

Bus Master	Combination Enable	Combination Disable
CPU under 64 bit Access	Not possible	Possible
CPU 64 bit Access	Possible	Possible
DMAC/DTC	Possible	Possible
DRW	Possible	Possible

33.3.8.4 Module-stop function

OSPI operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The OSPI module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

33.3.8.5 Restriction in 8D-8D-8D profile 1.0 format

"When read or write access to the Octal Serial Peripheral Interface (OSPI) is performed from the following bus masters with 8-bit wide, access to odd addresses is prohibited as it will not be worked correctly. See [Table 33.12](#) for the applicable conditions and their workarounds for each bus master"

Table 33.12 Workaround for the restriction in 8D-8D-8D profile 1.0 format

Bus master		Conditions that require workaround	Workaround
CPU	Normal memory	Debugger is connected	Access only even addresses.
	Device memory	Always	Access only even addresses.
DMAC/DTC	DMAC	DMTMD.SZ[1:0] = 00b	Access only even addresses.
	DTC	MRA.SZ[1:0] = 00b	Access only even addresses.
DRW		Settings of CONTROL2.WRITEFORMAT[1:0] bits and ORIGIN register	Set CONTROL2.WRITEFORMAT[1:0] only in 16 bpp or 32 bpp, and set even addresses only in the ORIGIN register.

33.3.8.6 Byte data order in 8pin-DDR mode

In 8pin-DDR mode, OSPI read and write data in the order of byte0 at rising edge and byte1 at falling edge.

Some memory devices read and write in the swapped order in 8pin-DDR mode. For these devices, if 8pin-DDR read the data which is written in other than 8pin-DDR mode, this data should be written in swapped order.

34. Decryption On The Fly (DOTF)

All operations of DOTF are not guaranteed.

34.1 Overview

DOTF has a function to decode read data of the AXI bus using AES core.

Table 34.1 lists the DOTF specifications and for a system using DOTF, see section 33.1. Overview.

Table 34.1 DOTF Specification

Item	Description
Clock Source	Register clock : PCLKB AES core clock : PCLKA
AES core function	<ul style="list-style-type: none"> Utilize for on-the-fly decryption of encrypted software stored in external memory. Block size: 128-bit Key size: 128-bit, 192-bit, 256-bit Support the following block cipher mode. <ul style="list-style-type: none"> Counter (CTR) mode following NIST SP800-38A Support side channel counter measure function. Supports self-test function. Counter[127:0] = {IV[127:28], Address[31:4]}, where Address is the memory mapped address of the encrypted data, aligned to the AES block size of 128 bits (16 bytes). The IV shall be chosen according to the recommendations provided in appendix B of SP800-38A. See section 33, Octal Serial Peripheral Interface (OSPI) and section 4.1. Address Space for details. See NIST SP800-38A for details of AES counter mode operation.
Tamper Resistance	Countermeasures available for side-channel attacks, including SPA/DPA and timing attacks
Module-stop function	Module-stop state can be set to reduce power consumption. same as OSPI module stop
TrustZone Filter	Security and Privilege attribution can be set for each channel. same as TZF of OSPI

34.2 Block Diagram

The block diagram of DOTF is shown in Figure 34.1. See Figure 33.1 for a diagram including the OSPI.

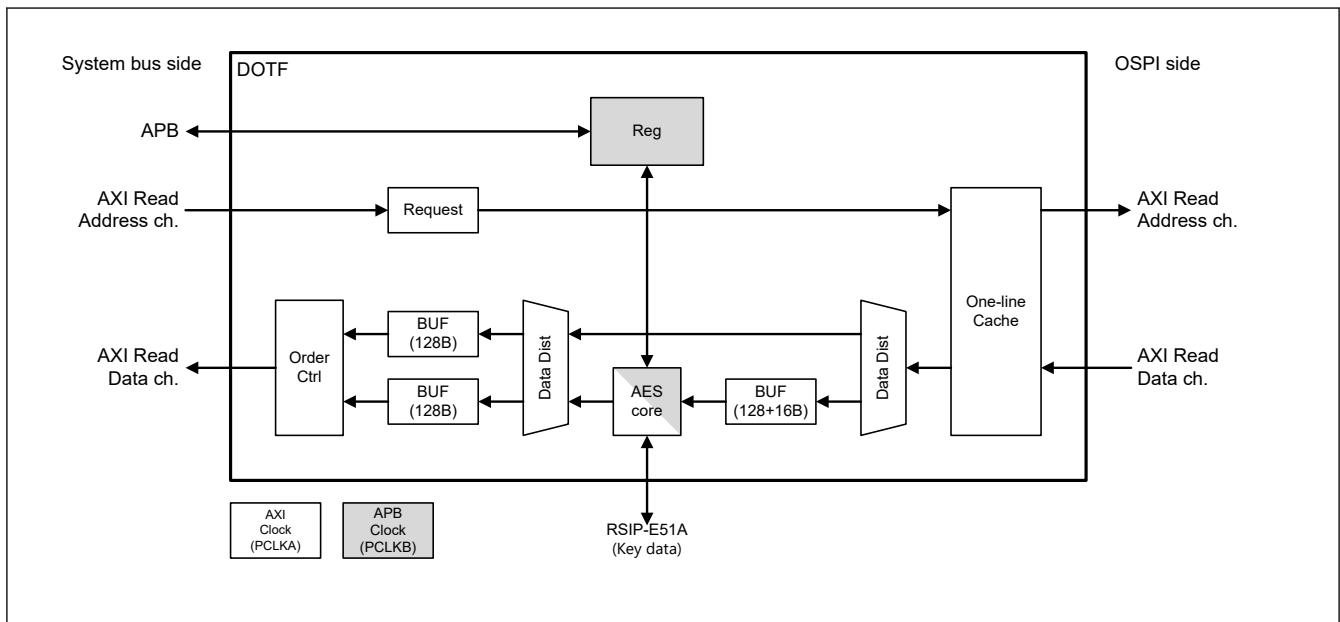

Figure 34.1 Block diagram

34.3 Register Descriptions

DOTF allows the entire area to be an accessible area, but the area where decryption processing is performed can be specified as the entire area or one contiguous area. The region can be specified by setting the start and end addresses to the CONVAREAST and CONAREAED registers, respectively.

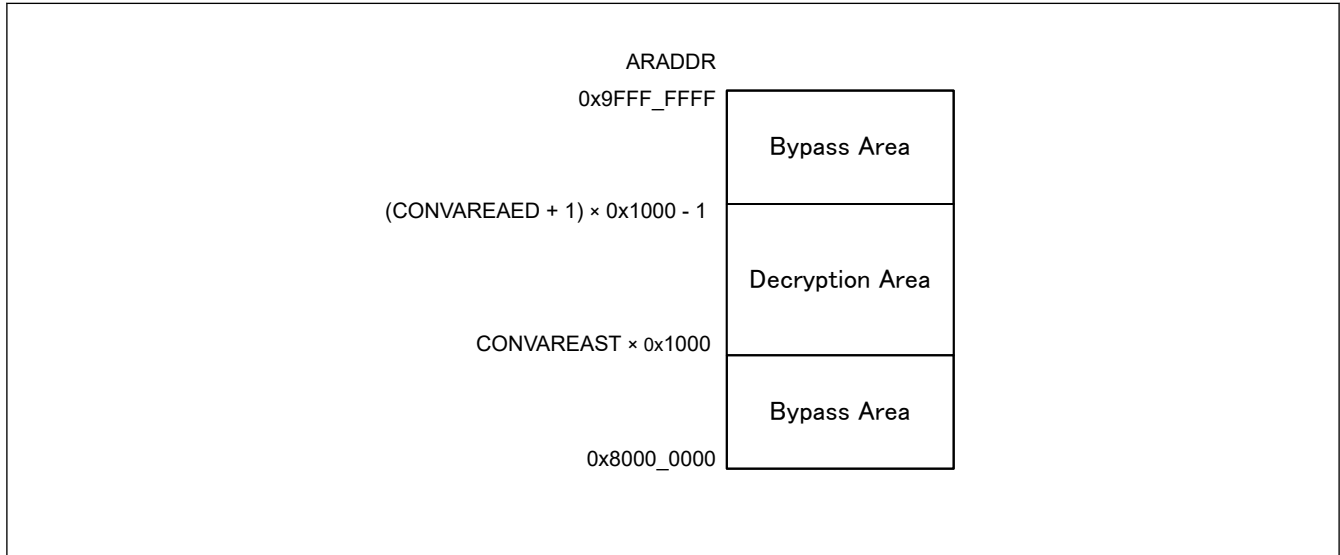

Figure 34.2 Image of decryption area setting

34.3.1 CONVAREAST : DOTF Conversion Area Start Address Register

Base address: DOTF0 = 0x4026_8800
 DOTF0_NS = 0x5026_8800

Offset address: 0x00

Value after reset: 0

Bit	Symbol	Function	R/W
11:0	—	These bits are read as 0.	R/W
31:12	CONVAREAST[31:12]	The first address of the decryption processing area. The actual address is CONVAREAST[31:12] × 0x1000.	R/W

Note: S-TYPE-3, P-TYPE-3

Specify the first address of the decryption processing area. Set before the AXI transfer request and do not make any further changes. Setting CONVAREAST[31:12] > CONVAREAED[31:12] is prohibited.

34.3.2 CONVAREAD : DOTF Conversion Area End Address Register

Base address: DOTF0 = 0x4026_8800
 DOTF0_NS = 0x5026_8800

Offset address: 0x04

Value after reset: 0

Bit	Symbol	Function	R/W
11:0	—	These bits are read as 0.	R/W
31:12	CONVAREAED[31:12]	The end address of the decryption processing area. The actual address is CONVAREAED[31:12] × 0x1000.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Setting CONVAREAST[31:12] > CONVAREAED[31:12] is prohibited.

Specify the tail address of the decryption processing area. Set before the AXI transfer request and do not make any further changes. Setting CONVAREAST[31:12] > CONVAREAED[31:12] is prohibited.

34.4 Operation

DOTF has one AXI Read Slave Interface and one AXI Read Master Interface.

An AXI transfer request received on the AXI Slave Address channel is issued to the AXI Master's Read Address channel, and the Slave data is received from the Master's AXI Read data channel and sent to the AXI Slave Read data channel.

At this time, the necessity of decryption is determined by the requested address area, and the decrypted data is transmitted through AES core if necessary. When decryption is not required, the received response is sent without conversion.

34.5 System flow

The initialization flow after HW reset is shown in [Figure 34.3](#).

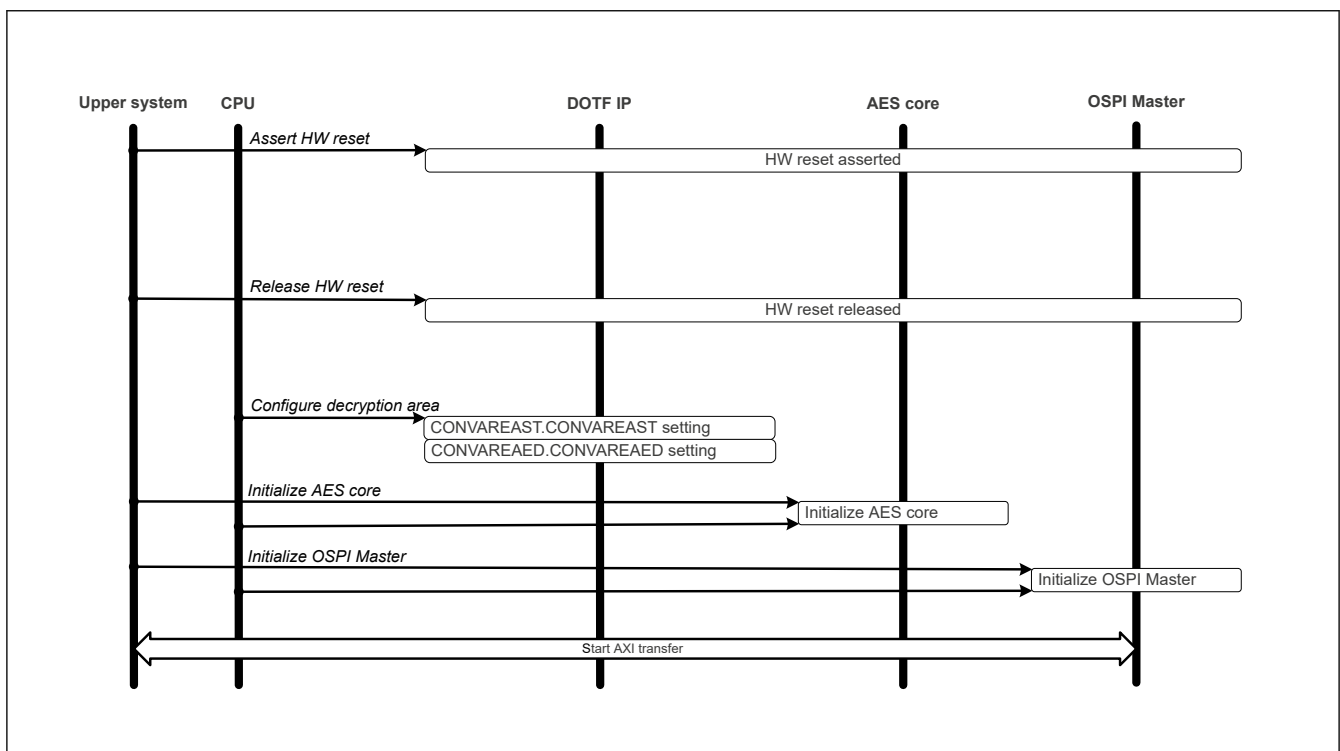

Figure 34.3 Initialization flow

34.6 Usage notes

34.6.1 Module-stop function

DOTF operation can be disabled or enabled using Module Stop Control Register B (MSTPCRB). The DOTF module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

35. Serial Sound Interface Enhanced (SSIE)

35.1 Overview

The Serial Sound Interface Enhanced (SSIE) can transmit and receive audio data to and from various devices that support any of audio data formats, such as I²S, monaural, and TDM.

Table 35.1 lists the SSIE specifications, Figure 35.3, Figure 35.4 and Figure 35.5 show a block diagram of SSIE, and Table 35.4 lists the I/O pins.

Table 35.1 SSIE specifications

Item		Description
Number of channels		Two channels, SSIE0 and SSIE1
Communication mode		<ul style="list-style-type: none"> Master/slave Transmission/reception (SSIE0:full duplex communication, SSIE1:half-duplex communication)
Communication format		<ul style="list-style-type: none"> I²S format Monaural format TDM format
Serial data		<ul style="list-style-type: none"> MSB first Data can be left-justified or right-justified. Data delay (1 clock cycle) or no delay selectable for the period from SSILRCKn/SSIFSn (n = 0, 1) to SSITXD0/SSIRXD0/SSIDATA1 System word length: 8, 16, 24, 32, 48, 64, 128, or 256 bits Data word length: 8, 16, 18, 20, 22, 24, or 32 bits Padding polarity: Low or high
Bit clock (SSIBCKn (n = 0, 1))	In master mode	<ul style="list-style-type: none"> Two clock sources available (AUDIO_CLK/GPT output (GTIOC2A)) Clock source division ratio: 1/1, 1/2, 1/4, 1/6, 1/8, 1/12, 1/16, 1/24, 1/32, 1/48, 1/64, 1/96, and 1/128. 29	TUIEN	Transmit Underflow Interrupt Output Enable 0: Disables transmit underflow interrupt output 1: Enables transmit underflow interrupt output	R/W
30	CKS	Selects an Audio Clock for Master-mode Communication*1 0: Selects the AUDIO_CLK input 1: Selects the GTIOC2A (GPT output)	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Writing to these bits while SSIE is in a communication state (SSISR.IIRQ = 0) is prohibited. If the value of these bits is changed by rewriting, subsequent operation is unpredictable.

Note 2. If the TEN bit or REN bit is rewritten, make sure that the SSISR.IIRQ bit is in the desired status. If the value of the TEN or REN bit is changed by rewriting, subsequent operation is unpredictable. For example, when transmission or reception is enabled, check that SSISR.IIRQ is 0; when transmission or reception is disabled, check that SSISR.IIRQ is 1.

With this register, select an audio clock, control interrupt requests, select data formats, and set an operation mode.

TEN and REN bits (Transmission and Reception Enable)

The TEN and REN bits enable/disable transmission and reception. When 1 is written to one of these bits, the corresponding communication operation starts in synchronization with a start trigger by the SSILRCK_n/SSIFS_n (n = 0, 1) signal. For details, see [section 35.6.2. Transmission](#) to [section 35.6.4. Transmission and Reception](#). When 0 is written to this bit, the current communication operation stops at the next frame boundary. To use SSIE for both transmission and reception, always write 1 to these bits together. When stopping the communication using SSIE, always disable both transmission and reception (write 0 to the TEN and REN bits).

If you want to stop SSIE before a frame boundary is reached, perform a software reset procedure.

MUEN bit (Mute Enable)

The MUEN bit sets/clears the mute function for the data output from the SSITXD0/SSIDATA1 pin. When this bit is set to 1 in the middle of a frame, the SSITXD0/SSIDATA1 output changes to 0 at the next frame boundary. When this bit is set to 0 in the middle of a frame, the SSITXD0/SSIDATA1 output changes to the data of transmit FIFO data register at the next frame boundary. Note that this bit controls data only. Status flags and interrupt signals are normally generated.

Changing the value of this bit must be performed only after setting the communication format to be used.

Figure 35.5 Transmit data with the mute function set

CKDV[3:0] bits (Selects Bit Clock Division Ratio)

The CKDV[3:0] bits set the division ratio of the bit clock based on AUDIO_MCK in master-mode communication (MST=1). In slave-mode communication (MST = 0), setting of these bits are invalid.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in [section 35.2.3. SSIFCR : FIFO Control Register](#).

Figure 35.6 Sampling frequencies in master-mode communication

DEL bit (Selects Serial Data Delay)

The DEL bit sets whether or not there will be a delay between SSILRCKn/SSIFS_n (n = 0, 1) and SSITXD0/SSIRXD0/SSIDATA1.

For the I²S or TDM format, set the DEL bit to 0. When the monaural format is used, setting of this bit changes the high period width of SSILRCKn/SSIFS_n (n = 0, 1). For details, see [section 35.3.2. Monaural Format](#). When using a compatible communication format, specify a setting of this bit that enables communication.

Figure 35.7 Setting of delay in serial data

PDTA bit (Selects Placement Data Alignment)

The PDTA bit sets how to align placement data. With the setting of data word length as 32 bits (SSICR.DWL[2:0] = 110b), this bit is invalid.

At transmission, see [Figure 35.8](#).

	First transmission data	Second transmission data	Third transmission data	Fourth transmission data

Figure 35.9 Alignment of placement data at reception

SDTA bit (Selects Serial Data Delay)

The SDTA bit sets how to align serial data and padding bits. For communication without padding bits, this bit is invalid.

Figure 35.10 Alignment setting of serial data with padding bits

SPDP bit (Selects Serial Padding Polarity)

The SPDP bit sets polarity of padding bits.

Figure 35.11 Padding bit polarity

LRCKP bit (Selects the Initial Value and Polarity of LR Clock/Frame Synchronization Signal)

The LRCKP bit sets the initial value and polarity of SSILRCKn/SSIFS_n (n = 0, 1). Set this bit according to the communication format to be used in SSIE. See [Table 35.5](#) Initial output value and polarity of SSILRCKn/SSIFS_n (n = 0, 1) pin. For the slave-mode communication (MST = 0), only the start trigger is used.

Writing to these bits must be performed when the LR clock supply to the SSILRCKn/SSIFS_n (n = 0, 1) pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in [section 35.2.7. SSIOFR : Audio Format Register](#).

Table 35.5 Initial output value and polarity of SSILRCKn/SSIFS_n (n = 0, 1) pin

Communication Format	Expected Initial State	Setting Value of LRCKP
I ² S	High	0
Monaural	Low	1
TDM	Low	1

Note: When the format to be used is compatible with the I²S, monaural, or TDM format, specify settings to enable communication with the respective formats.

Figure 35.12 LR clock/frame synchronization polarity setting

BCKP bit (Selects Bit Clock Polarity)

The BCKP bit sets the bit clock polarity.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in [section 35.2.3. SSIFCR : FIFO Control Register](#).

Table 35.6 Bit clock polarity

Communication	Master/Slave	Timing	BCKP = 0	BCKP = 1
Reception	Slave	At SSILRCKn/SSIFS _n (n = 0, 1) sampling	SSIBCK _n (n = 0, 1) rising edge	SSIBCK _n (n = 0, 1) falling edge
	Master/slave	At SSIRXD0/SSIDATA1 sampling	SSIBCK _n (n = 0, 1) rising edge	SSIBCK _n (n = 0, 1) falling edge
Transmission	Master	At change of SSILRCKn/SSIFS _n (n = 0, 1) output	SSIBCK _n (n = 0, 1) falling edge	SSIBCK _n (n = 0, 1) rising edge
	Master/slave	At change of SSITXD0/SSIDATA1 output	SSIBCK _n (n = 0, 1) falling edge	SSIBCK _n (n = 0, 1) rising edge

MST bit (Master Enable)

The MST bit sets master-/slave-mode communication.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in [section 35.2.3. SSIFCR : FIFO Control Register](#).

SWL[2:0] bits (Selects System Word Length)

The SWL[2:0] bits set the number of bits in one system word. Padding bits are sent and received in relation with one data word set with DWL[2:0]. See [Table 35.13](#) for details.

Writing to these bits must be performed when the LR clock supply to the SSILRCKn/SSIFS_n (n = 0, 1) pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in [section 35.2.7. SSIOFR : Audio Format Register](#).

DWL[2:0] bits (Selects Data Word Length)

The DWL[2:0] bits set the number of bits in one data word. The data word length (number of bits per data word) must not exceed the system word length (number of bits per system word). For details, see [Table 35.13](#).

FRM[1:0] bits (Selects Frame Word Number)

The FRM[1:0] bits set the frame word number in individual communication formats.

Writing to these bits must be performed when the LR clock supply to the SSILRCKn/SSIFS_n (n = 0, 1) pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in [section 35.2.7. SSIOFR : Audio Format Register](#).

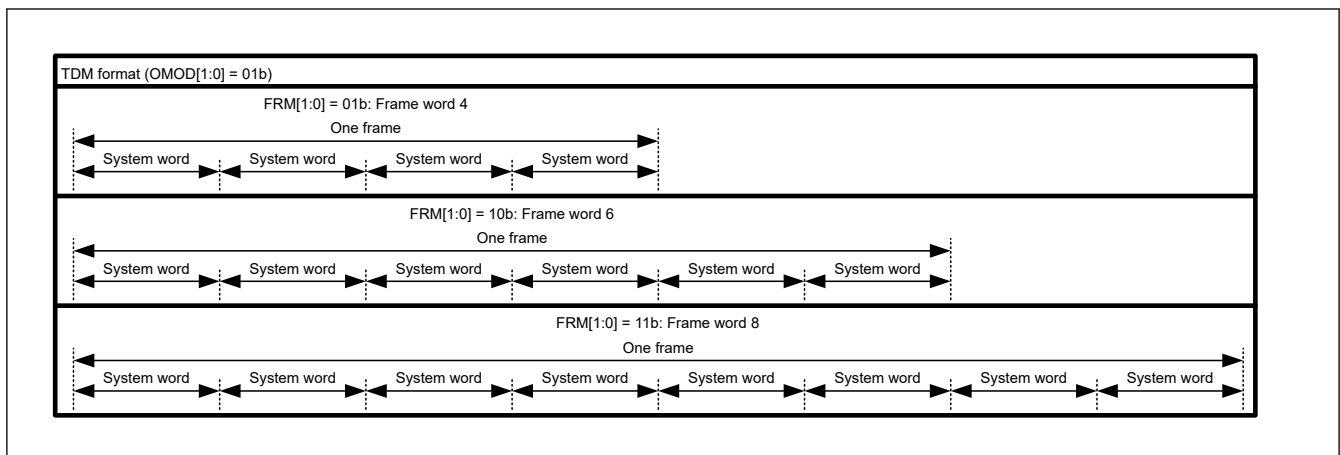

Figure 35.13 Frame word number

IEN bit (Idle Mode Interrupt Output Enable)

The IEN bit enables/disables output of idle mode interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.IIRQ = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.IIRQ = 1.

ROIEN bit (Receive Overflow Interrupt Output Enable)

The ROIEN bit enables/disables output of receive overflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.ROI_{RQ} = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.ROI_{RQ} = 1.

RUIEN bit (Receive Underflow Interrupt Output Enable)

The RUIEN bit enables/disables output of receive underflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.RUI_{RQ} = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.RUI_{RQ} = 1.

TOIEN bit (Transmit Overflow Interrupt Output Enable)

The TOIEN bit enables/disables output of transmit overflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.TOI_{RQ} = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.TOI_{RQ} = 1.

TUIEN bit (Transmit Underflow Interrupt Output Enable)

The TUIEN bit enables/disables output of transmit underflow interrupts. By enabling this bit (set it to 1), an interrupt is output at a rising edge of SSISR.TUI_{RQ} = 1. An interrupt is also output when this bit is changed from 0 to 1 while SSISR.TUI_{RQ} = 1.

CKS bit (Selects an Audio Clock for Master-mode Communication)

The CKS bit sets the audio clock in master-mode communication (MST = 1). In slave-mode communication (MST = 0), setting of this bit is invalid.

Writing to this bit must be performed when the supply of AUDIO_MCK is stopped. For details about the timing, see the detailed description of the AUCKE bit in [section 35.2.3. SSIFCR : FIFO Control Register](#).

35.2.2 SSISR : Status Register

Base address: SSIE_n = 0x4025_D000 + 0x0100 × n (n = 0, 1)
SSIE_n_NS = 0x5025_D000 + 0x0100 × n (n = 0, 1)

31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register is configured with status flags that indicate SSIE operational state.

IIRQ flag (Idle Mode Status Flag)

The IIRQ flag is a status flag that indicates the idle state. It indicates whether SSIE is in the idle state or communication state.

For details, see [Figure 35.14](#) and [Figure 35.15](#).

Figure 35.14 IIRQ setting timing (transmission)

- Transmitter (dedicated to transmission)

[Clearing condition]

While transmission was enabled (SSICR.TEN = 1 and SSICR.REN = 0), the transmit data for a transmission frame was written to the SSIFTDR register, and a start trigger was generated by the SSILRCKn/SSIFS_n (n = 0, 1) signal.

[Clearing timing]

1 SSIBCK_n (n = 0, 1) cycle + 2 PCLKB cycles after generation of the start trigger that is the clearing condition.

[Setting condition]

While transmission and reception were disabled (SSICR.TEN = 0 and SSICR.REN = 0), transmission of one frame was complete.

[Setting timing]

Two PCLKB cycles after the end of transmission (at a frame boundary) that is the setting condition.

Figure 35.15 IIRQ setting timing (reception)

- Receiver (dedicated to reception)

[Clearing condition]

While reception was enabled (SSICR.TEN = 0 and SSICR.REN = 1, a start trigger was generated by the SSILRCKn/SSIFSs (n = 0, 1) signal.

[Clearing timing]

1 SSIBCKn (n = 0, 1) cycle + 2 PCLKB cycles after generation of the start trigger that is the clearing condition.

[Setting condition]

While transmission and reception were disabled (SSICR.TEN = 0 and SSICR.REN = 0), reception of one frame was complete.

[Setting timing]

Two PCLKB cycles after the end of reception (at a frame boundary) that is the setting condition.

- Transceiver (transmission and reception)

[Clearing condition]

While transmission and reception were enabled (SSICR.TEN = 1 and SSICR.REN = 1), the transmit data for a transmission frame was written to the SSIFTDR register, and a start trigger is generated by the SSILRCKn/SSIFSs (n = 0, 1) signal.

[Clearing timing]

1 SSIBCKn (n = 0, 1) cycle + 2 PCLKB cycles after generation of the start trigger that is the clearing condition.

[Setting condition]

While transmission and reception were disabled (SSICR.TEN = 0 and SSICR.REN = 0), transmission of one frame was complete.

[Setting timing]

Two PCLKB cycles after the end of transmission (at a frame boundary) that is the setting condition.

ROIRQ flag (Receive Overflow Error Status Flag)

The ROIRQ flag is a status flag that indicates a receive overflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that received data is supplied at a higher rate than requested. Data is not transferred from the receive shift register to SSIFRDR where a receive overflow error is generated. For the procedure to recover from the overflow error, see [section 35.6.6. Error Handling](#). This flag is not cleared by a receive FIFO data register reset (SSIFCR.RFRST).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.REN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition:

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in [Figure 35.19](#))
2. One PCLKB cycle after writing 1 to SSICR.REN.*3

[Setting condition]

At completion of receiving new data while SSIFRDR is full.

[Setting timing]

Three cycles of PCLKB after reception is completed.

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:

- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- One PCLKB cycle passes after 1 has been written to SSICR.REN.

Note 3. After communication is enabled (by changing the value of SSICR.REN bit from 0 to 1), the reception error flags (RUIRQ and ROIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the reception error flags might be unable to be read.

Figure 35.16 ROIRQ setting timing

RUIRQ flag (Receive Underflow Error Status Flag)

The RUIRQ flag is a status flag that indicates a receive underflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that SSIFRDR is read while it is empty. Data read from SSIFRDR where a receive underflow error is generated is invalid. See section 35.6.6. Error Handling for the error recovery procedure. This flag is not cleared by a receive FIFO data register reset (SSIFCR.RFRST). Note, however, that this flag is not set even if the SSIFRDR register is read while the receive FIFO data register is reset (by setting SSIFCR.RFRST to 1).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.REN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in Figure 35.19)
2. One PCLKB cycle after writing 1 to SSICR.REN.*3

[Setting condition]

Reading from SSIFRDR while it is empty.

[Setting timing]

At completion of reading from SSIFRDR. See Figure 35.17.

- Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.
- Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:
- A software reset (SSIFCR.SSIRST = 1) is done.
 - After 1 has been read, writing of 0 is complete.
 - One PCLKB cycle passes after 1 has been written to SSICR.REN.
- Note 3. After communication is enabled (by changing the value of SSICR.REN bit from 0 to 1), the reception error flags (RUIRQ and ROIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the reception error flags might be unable to be read.

Figure 35.17 RUIRQ setting timing

TOIRQ flag (Transmit Overflow Error Status Flag)

The TOIRQ flag is a status flag that indicates a transmit overflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that an attempt has been made to write data to the SSIFTDR register when the register is full of data. The data writing that causes a transmit overflow is ignored. For the procedure to recover from the overflow error, see section 35.6.6. Error Handling. This flag is not cleared by a transmit FIFO data register reset (SSIFCR.TFRST).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit*2
2. Enabling communication (changing SSICR.TEN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in [Figure 35.19](#))
2. One PCLKB cycle after writing 1 to SSICR.TEN.*³

[Setting condition]

An attempt was made to write data to the SSIFTDR register when the register is full of data.

[Setting timing]

At completion of writing to SSIFTDR. For details, see [Figure 35.18](#).

- Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.
- Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:
- A software reset (SSIFCR.SSIRST = 1) is done.
 - After 1 has been read, writing of 0 is complete.
 - One PCLKB cycle passes after 1 has been written to SSICR.TEN.
- Note 3. After communication is enabled (by changing the value of SSICR.TEN bit from 0 to 1), the transmission error flags (TOIRQ and TUIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the transmission error flags might be unable to be read.

Figure 35.18 TOIRQ setting timing

TUIRQ flag (Transmit Underflow Error Status flag)

The TUIRQ flag is a status flag that indicates a transmit underflow error. This flag is set by automatic determination but it must be cleared by register access. This flag indicates that writing the serial data required for a frame to SSIFTDR did not catch up with transmission of the frame. Even if this flag is cleared after it has been set, the SSITXD0/SSIDATA1 output remains to be 0. To output the data written to the transmit FIFO data register (SSIFTDR) to the SSITXD0/SSIDATA1 pin, follow the communication stop procedure in Figure 35.56 and error-handling procedure in Figure 35.57. For the procedure to recover from an error, see section 35.6.6. Error Handling. This flag is not cleared by a reset of transmit FIFO data register (by the SSIFCR.TFRST signal).

[Priority order for setting and clearing]

Setting is prioritized.*1

[Clearing condition]

When either of the following operations is done:

1. Writing 0 to this bit after reading 1 from this bit^{*2}
2. Enabling communication (changing SSICR.TEN from 0 to 1).

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit
2. One PCLKB cycle after writing 1 to SSICR.TEN.^{*3}

Figure 35.19 TUIRQ clearing timing

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1). The software reset has priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following three conditions is met:

- A software reset (SSIFCR.SSIRST = 1) is done.
- After 1 has been read, writing of 0 is complete.
- One PCLKB cycle passes after 1 has been written to SSICR.TEN.

Note 3. After communication is enabled (by changing the value of SSICR.TEN bit from 0 to 1), the transmission error flags (TOIRQ and TUIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the transmission error flags might be unable to be read.

[Setting condition]

When communication continues over a frame boundary, the transmit data required for the next frame has not been written to SSIFTDR. For details, see [Figure 35.20](#) and [Figure 35.21](#).

[Setting timing]

Three PCLKB cycles after the frame boundary. For details, see [Figure 35.20](#).

Figure 35.20 TUIRQ setting timing (when communication continues)

Figure 35.21 TUIRQ setting timing (when communication stops)

31	AUCKE	AUDIO_MCK Enable in Mastermode Communication* ¹ 0: Disables supply of AUDIO_MCK 1: Enables supply of AUDIO_MCK	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Writing to these bits while SSIE is in a communication state (SSISR.IIRQ = 0) is prohibited. If the value of these bits is changed by rewriting, subsequent operation is unpredictable.

This register sets a software reset, byte swap, and enable/disable of interrupt requests.

RFRST bit (Receive FIFO Data Register Reset)

The RFRST bit sets a software reset of the receive FIFO data register (SSIFRDR). Writing 1 to this bit initializes the internal state related to SSIFRDR. The register bits subject to the software reset triggered by this bit are indicated by shading in [Table 35.7](#). Because this bit is not automatically cleared after it has been set, write 0 to this bit to release the register bits from the software reset. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedural step.

This bit is subject to the software reset by the SSIRST bit. Because the software reset by the SSIRST bit has priority over the reset by this bit, setting this bit is ignored when the SSIRST bit is set.

TFRST bit (Transmit FIFO Data Register Reset)

The TFRST bit sets a software reset of the transmit FIFO data register (SSIFTDR). Writing 1 to this bit initializes the internal state related to SSIFTDR. The register bits subject to the software reset triggered by this bit are indicated by shading in Table 35.8. Because this bit is not automatically cleared after it has been set, write 0 to this bit to release the register bits from the software reset. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedural step.

This bit is subject to the software reset by the SSIRST bit. Because the software reset by the SSIRST bit has priority over the reset by this bit, setting this bit is ignored when the SSIRST bit is set.

RIE bit (Receive Data Full Interrupt Output Enable)

The RIE bit enables/disables output of receive data full interrupts. Use a receive data full interrupt as an interrupt to trigger data reading from the receive FIFO data register. Write 1 to this bit after specifying the setting condition for receive data full interrupt (by using the SSISCR.RDFS bit). [Figure 35.22](#) shows the timing of generating the receive data full interrupt.

Figure 35.22 Timing of receive data full interrupt

TIE bit (Transmit Data Empty Interrupt Output Enable)

The TIE bit enables/disables output of transmit data empty interrupts. Use a transmit data empty interrupt as an interrupt to trigger data writing to the transmit FIFO data register. Write 1 to this bit after specifying the setting condition for transmit data empty interrupt (by using the SSISCR.TDES bit). [Figure 35.23](#) shows the timing of generating the transmit data empty interrupt.

Figure 35.23 Timing of transmit data empty interrupt

BSW bit (Byte Swap Enable)

The BSW bit enables/disables byte swap of register access for the transmit FIFO data register (SSIFTDR) and the receive FIFO data register (SSIFRDR). This bit is valid only with 16-bit access or 32-bit access to SSIFTDR and SSIFRDR. For details, see [Figure 35.24](#).

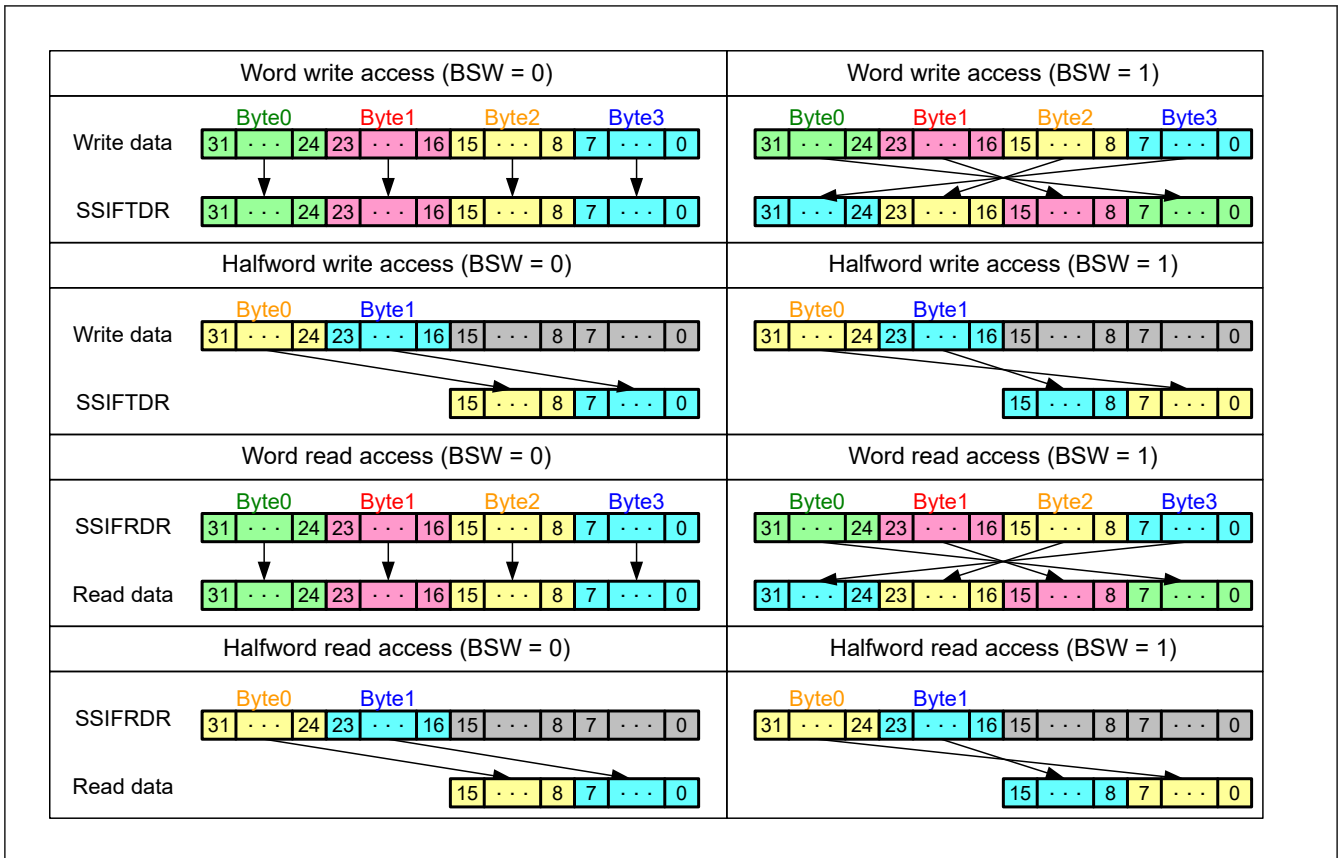

Figure 35.24 Operation example of byte swap

SSIRST bit (Software Reset)

The SSIRST bit sets a software reset of SSIE. Writing 1 to this bit initializes the internal state of SSIE. The register bits subject to the software reset triggered by this bit are indicated by shading in [Table 35.9](#). Because this bit is not automatically

cleared after it has been set, write 0 to this bit to release the register bits from the software reset. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedural step.

To stop communication of SSIE immediately, after turning off the peripheral functions, write 1 to this bit. Initialization by a software reset is performed without any relation with the bit clock.

Table 35.9 Bits subject to software reset by the SSIRST bit

AUCKE bit (AUDIO_MCK Enable in Mastermode Communication)

The AUCKE bit enables/disables supply to AUDIO_MCK while in master-mode communication (MST = 1).

Changing the value of this bit must be performed only after specifying the settings related to AUDIO_MCK (by using the CKS, MST, BCKP, and CKDV bits in the SSICR register).

Figure 35.25 Stop/resume of AUDIO_MCK

Note: In slave-mode communication (SSICR.MST = 0), SSIE needs supply of SSIBCKn (n = 0, 1). To stop BCK on the master side, make sure that SSIE is in the idle state (SSISR.IIRQ = 1). If BCK is stopped before SSIE becomes idle, take the procedure to start communication in [Figure 35.52](#) or wait for an idle state by taking the procedure to resume communication in [Figure 35.58](#).

In master-mode communication (SSICR.MST = 1), SSIE operates with the audio clock (AUDIO_MCK). To stop SSIE completely, make sure that SSIE is in the idle state (SSISR.IIRQ = 1) and then write 0 to SSIFCR.AUCKE. If 0 is written to SSIFCR.AUCKE before SSIE becomes idle, take the procedure to start communication in [Figure 35.52](#).

[Figure 35.26](#) and [Figure 35.27](#) show the timings of signal operation in the period from setting this bit to 1 to the output to the SSIBCKn (n = 0, 1) pin.

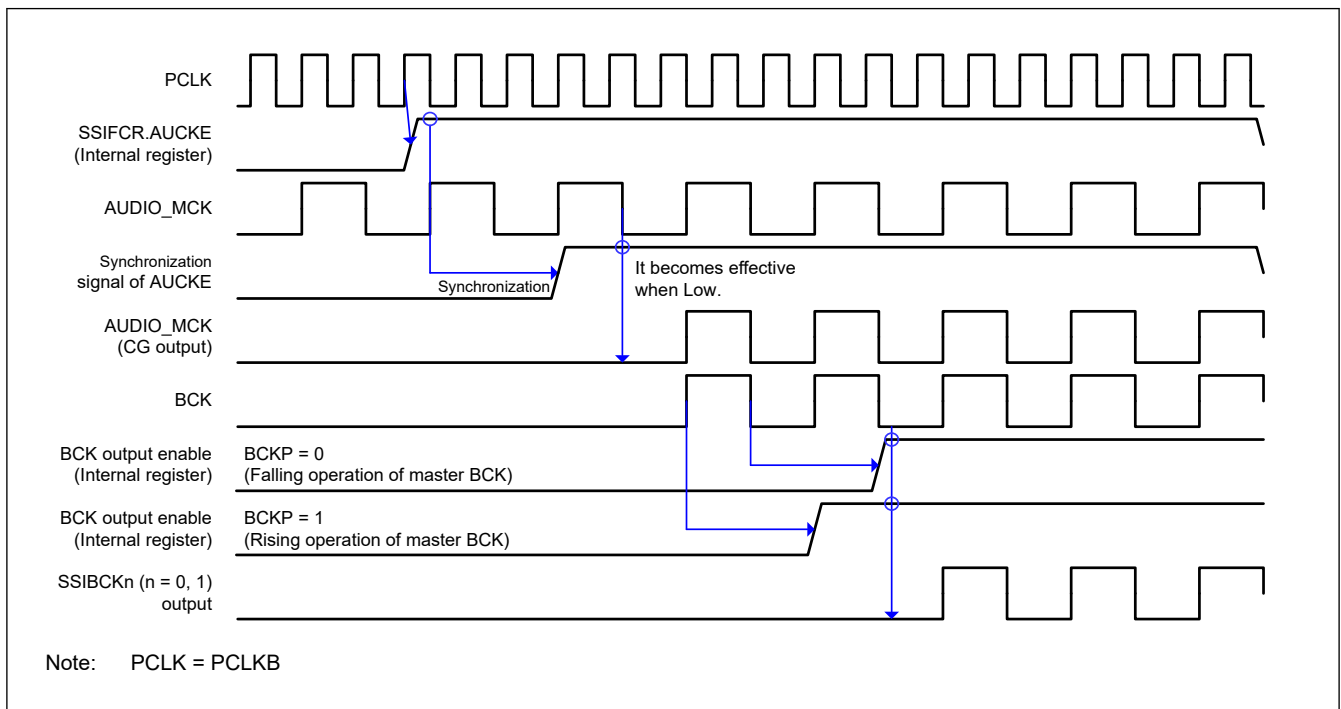

Figure 35.26 Timing diagram for the operation from system reset to start of master-mode communication

Figure 35.27 Timing diagram for the operation from stop of communication to start of master-mode communication

Note: If the supply of AUDIO_MCK stops, the value of the SSIBCKn (n = 0, 1) pin is held. Therefore, the SSIBCKn (n = 0, 1) signal might stop in the H (high level) state.

35.2.4 SSIFSR : FIFO Status Register

Base address: SSIE_n = 0x4025_D000 + 0x0100 × n (n = 0, 1)
 SSIE_n_NS = 0x5025_D000 + 0x0100 × n (n = 0, 1)

23:17	—	These bits are read as 0. The write value should be 0.	R/W
29:24	TDC[5:0]	Transmit Data Count Number of valid data stored in the transmit FIFO data register	R
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register is configured with status flags that indicate the status of the transmit FIFO data register and the receive FIFO data register.

RDF flag (Receive Data Full Flag)

The RDF flag indicates that the receive FIFO data register (SSIFRDR) has unread received data not less than the amount set with the SSISCR.RDFS bits plus one. This flag is set by automatic determination but it must be cleared by register access.

[Priority order for setting and clearing]

Clearing is prioritized.

[Clearing condition]

Either of the following two:^{*1}

1. Writing 0 to this bit after reading 1 from this bit (CPU operation)^{*2}
2. Last access (DTC/DMAC operation) to read data from SSIFRDR by an interrupt routine using the DTC and DMAC.

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in [Figure 35.19](#))
2. After the PCLKB cycle in which the last access instruction is issued to read data from SSIFRDR by an interrupt routine using the DTC and DMAC.

[Setting condition]

SSIFRDR has free space not less than the amount set with the SSISCR.RDFS bits plus one.

[Setting timing]

At completion of transfer from the shift register that results in SSIFRDR having data not less than the amount set with the SSISCR.RDFS bits plus one.

Note 1. These bits are cleared by a software reset (SSIFCR.SSIRST = 1) and receive FIFO data register reset (SSIFCR.RFRST = 1). Reset conditions available for these bits are the software reset and receive FIFO data register reset as well as the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following four conditions is met:

- A software reset is done (SSIFCR.SSIRST = 1).
- A receive FIFO data register reset is done (SSIFCR.RFRST = 1).
- After 1 has been read, writing of 0 is complete.
- Last access is performed to read data from SSIFRDR by an interrupt routine using the DTC and DMAC.

Figure 35.28 Timing diagram for setting and clearing RDF

RDC[5:0] bits (Receive Data Count)

The RDC[5:0] bits indicate the number of valid data that are stored in the receive FIFO data register (SSIFRDR). With these bits as 0x00, there is no received data. With 0x20, the register is filled with received data and there is no free space.

TDE flag (Transmit Data Empty Flag)

The TDE flag indicates that the transmit FIFO data register (SSIFTDR) has free space not less than the amount set with the SSISCR.TDES bits plus one. This flag is set by automatic determination but it must be cleared by register access.

[Priority order for setting and clearing]

Clearing is prioritized.*1

[Clearing condition]

Either of the following two:

1. Writing 0 to this bit after reading 1 from this bit (CPU operation)*2
2. Last access (DTC/DMAC operation) to write data to SSIFTDR by an interrupt routine using the DTC and DMAC.

[Clearing timing]

Clearing timing corresponding to the above clearing condition

1. When 0 is written to this bit after reading 1 from this bit (same as the timing in [Figure 35.19](#))
2. Last access (DTC/DMAC operation) to write data to SSIFTDR by an interrupt routine using the DTC and DMAC.

[Setting condition]

SSIFTDR has free space not less than the amount set with the SSISCR.TDES bits plus one.

[Setting timing]

While operating on PCLKB, SSIFTDR is found to have free space not less than “size set in the SSISCR.TDES bits + 1.”

Note 1. This bit is cleared by a software reset (SSIFCR.SSIRST = 1) and transmit FIFO data register reset (SSIFCR.TFRST = 1). The software reset and transmit FIFO data register reset have priority over all the clearing conditions described above.

Note 2. After reading 1 from this bit, this bit is cleared when one of the following four conditions is met:

- A software reset is done (SSIFCR.SSIRST = 1).
- A transmit FIFO data register reset is done (SSIFCR.TFRST = 1).
- After 1 has been read, writing of 0 is complete.
- Last access is performed to write data to SSIFTDR by an interrupt routine using the DTC and DMAC.

Figure 35.29 Timing diagram for setting and clearing TDE

TDC[5:0] bits (Transmit Data Count)

The TDC[5:0] bits indicate the number of valid data that are stored in the transmit FIFO data register (SSIFTDR). With these bits as 0x00, there is no data to be transmitted. With 0x20, there is no space to write data.

35.2.5 SSIFTDR : Transmit FIFO Data Register

Base address: SSIE_n = 0x4025_D000 + 0x0100 × n (n = 0, 1)
 SSIE_n_NS = 0x5025_D000 + 0x0100 × n (n = 0, 1)

Offset address: 0x18

Bit position: 31

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	SSIFTDR[31:0]	Transmit FIFO Data	W

Note: S-TYPE-3, P-TYPE-3

This register stores data to be serially transmitted. 0 is returned when this register is read.

When you use this register for transmission, specify data writing to this register as the DTC/DMAC operation that is triggered by a transmit data empty interrupt. Determine the access size to this register according to the data word length to be communicated in [Table 35.10](#).

Table 35.10 Register access restriction to FIFOs (1 of 2)

Access Size		Byte	Halfword	Word
SSICR.DWL[2:0]	Data Word Length			
000b	8	✓	—	—
001b	16	—	✓	—
010b	18	—	—	✓
011b	20	—	—	✓
100b	22	—	—	✓
101b	24	—	—	✓

Table 35.10 Register access restriction to FIFOs (2 of 2)

Access Size		Byte	Halfword	Word
SSICR.DWL[2:0]	Data Word Length			
110b	32	—	—	✓
111b	Setting prohibited	—	—	—

Figure 35.30 shows register access to the transmit FIFO data register.

Figure 35.30 Example of register access to the transmit FIFO data register

Figure 35.31 shows the configurations and operation examples of the transmit FIFO data register and transmit shift register. The configurations are for storing data to FIFO and not related with communication.

Figure 35.31 Configuration of the transmit FIFO data register and transmit shift register, and FIFO operation example

35.2.6 SSIFRDR : Receive FIFO Data Register

Base address: SSIE_n = 0x4025_D000 + 0x0100 × n (n = 0, 1)
 SSIE_n_NS = 0x5025_D000 + 0x0100 × n (n = 0, 1)

Offset address: 0x1C

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	SSIFRDR[31:0]	Receive FIFO Data	R

Note: S-TYPE-3, P-TYPE-3

When you use this register for reception, specify data reading from this register as the DTC/DMAC operation that is triggered by a transmit data empty interrupt. Determine the access size to this register according to the data word length to be communicated in [Table 35.10](#).

Register access to the receive FIFO data register is same as for the transmit FIFO data register.

[Figure 35.32](#) shows the configurations and operation examples of the receive FIFO data register and receive shift register.

Figure 35.32 Configuration of the receive FIFO data register and receive shift register, and FIFO operation example

35.2.7 SSIOFR : Audio Format Register

Base address: SSIE_n = 0x4025_D000 + 0x0100 × n (n = 0, 1)
 SSIE_n_NS = 0x5025_D000 + 0x0100 × n (n = 0, 1)

Offset address: 0x20

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	BCKA STP	LRCO NT	—	—	—	—	—	—	—	OMOD[1:0]
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	OMOD[1:0]	Audio Format Select* ³ * ⁴ 0 0: I ² S format 0 1: TDM format 1 0: Monaural format 1 1: Setting prohibited	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	LRCONT	Whether to Enable LRCK/FS Continuation* ¹ * ² 0: Disables LRCK/FS continuation 1: Enables LRCK/FS continuation	R/W
9	BCKASTP	Whether to Enable Stopping BCK Output When SSIE is in Idle Status* ¹ * ² 0: Always outputs BCK to the SSIBCK _n (n = 0, 1) pin 1: Automatically controls output of BCK to the SSIBCK _n (n = 0, 1) pin	R/W
31:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. This bit is valid only in master-mode communication (SSICR.MST = 1). The setting is invalid in slave-mode communication (SSICR.MST = 0).

Note 2. The BCKASTP and LRCONT bits must not be set to 1 together.

Note 3. While SSIE is communicating (SSISR.IIRQ = 0), writing to these bits is prohibited. If the value of these bits is changed by writing, subsequent operation is unpredictable.

Note 4. If the communication format of other-party device is compatible with a communication format of SSIE, specify and use the communication format that enables communication with the other-party device.

This register is used to set an audio format (which involves the settings of communication format, LR clock/frame synchronization continuation mode, and BCK output stop).

OMOD[1:0] bits (Audio Format Select)

The OMOD[1:0] bits set an audio format. Writing to these bits must be performed when the LR clock supply to the SSILRCK_n/SSIFS_n (n = 0, 1) pin is stopped. For details about the output of LR clock, see the detailed description of the LRCONT bit in [section 35.2.7. SSIOFR : Audio Format Register](#).

LRCONT bit (Whether to Enable LRCK/FS Continuation)

The LRCONT bit enables or disables the output from SSILRCK_n/SSIFS_n (n = 0, 1) pin when the communication mode is master-mode communication (SSICR.MST = 1) and SSIE is in the idle state (SSISR.IIRQ = 1).

Even in the idle state, a signal can output from the SSILRCK_n/SSIFS_n (n = 0, 1) pin when this bit is set to 1 (to enable LR clock/frame synchronization continuation) in master mode (SSICR.MST = 1).

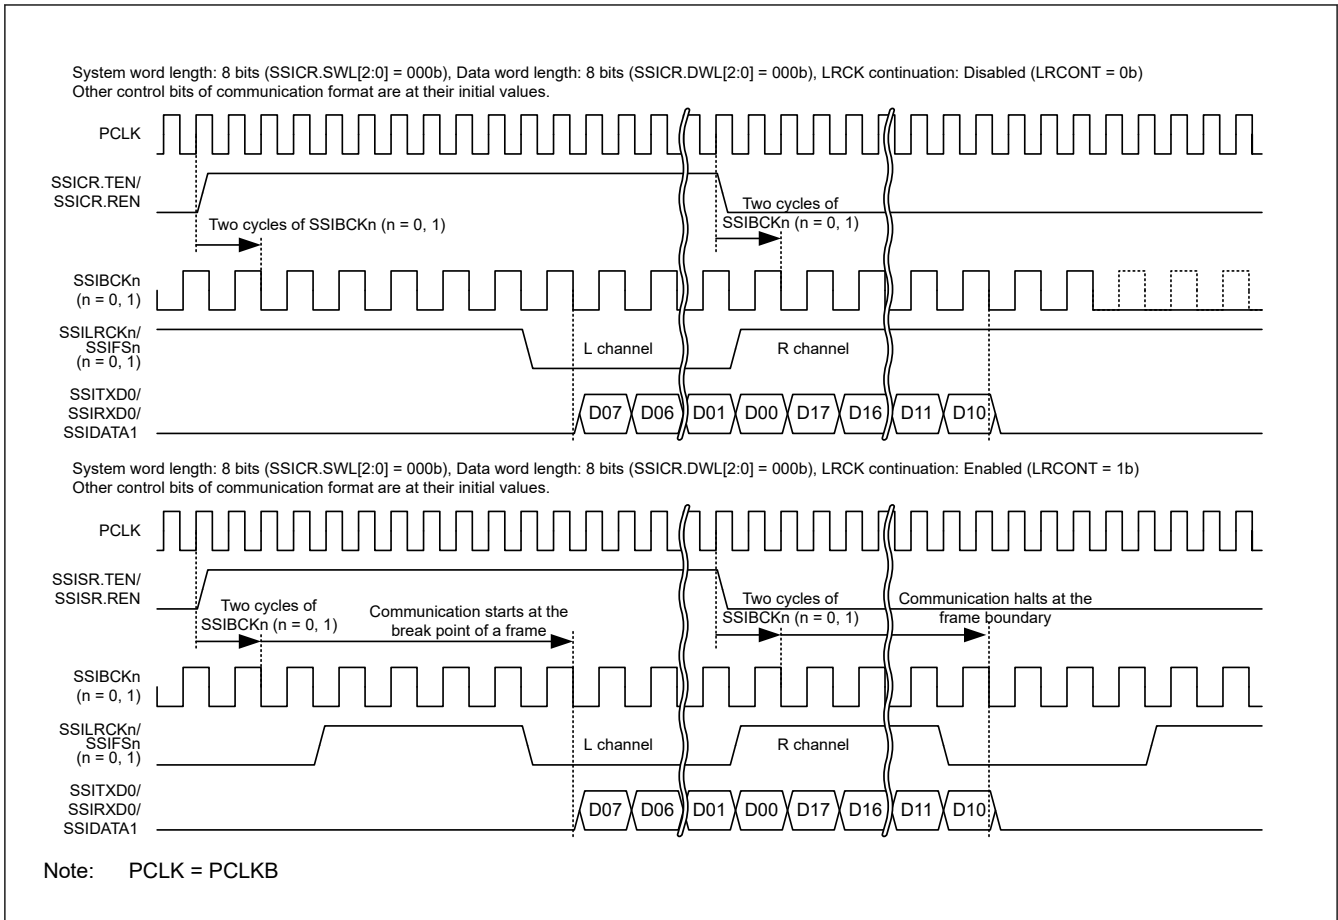

Figure 35.33 Example of LR clock/frame synchronization continuation operation

BCKASTP bit (Whether to Enable Stopping BCK Output When SSIE is in Idle Status)

The BCKASTP bit turns on or off the function to output BCK to the SSIBCKn (n = 0, 1) pin according to the communication shown in Figure 35.34 and Figure 35.35 in master-mode communication (SSICR.MST = 1).

Changing the value of this bit must be performed only after setting the communication format to be used.

This bit must be used in the following way:

Write 0 to the BCKASTP bit, and then start communication. During the communication, write 1 to the BCKASTP bit. By this operation, the bit clock output to the SSIBCKn (n = 0, 1) pin stops automatically when the communication stops. To resume the communication, set SSIE to the idle state (SSICR.IIRQ = 1), enable the supply of AUDIO_MCK (SSIFCR.AUCKE = 1), and then write 0 to the BCKASTP bit.

When the communication mode is master-mode communication (SSICR.MST = 1) and SSIE is in the idle state (SSICR.IIRQ = 1):

Table 35.11 BCKASTP bit status and SSIBCKn (n = 0, 1) pin output

BCKASTP Bit	SSIBCKn (n = 0, 1) Pin Output Status
0	Output
1	Stopped

Note: The BCKASTP bit cannot be used when the other-party device (which is a slave) requires the clock output from the SSIBCKn (n = 0, 1) pin before and during communication. In such a case, use the BCKASTP bit to stop the clock only after communication. For the timing of enabling the clock stop function, see Figure 35.34.

Figure 35.34 Example operation of the BCKASTP bit (idle state)

When the communication mode is master-mode communication (SSICR.MST = 1) and the BCK output stop function is enabled (BCKASTP = 1):

Details of the BCK output to the SSIBCKn (n = 0, 1) pin are as follows:

Output start timing: BCK is output in appropriate timing so that a valid edge is generated when the LR clock/frame synchronization signal shifts to a valid value.

Output stop timing: 1 to 1.5 clock cycles after a frame boundary.

For details about the timings, see the timing diagram in [Figure 35.35](#).

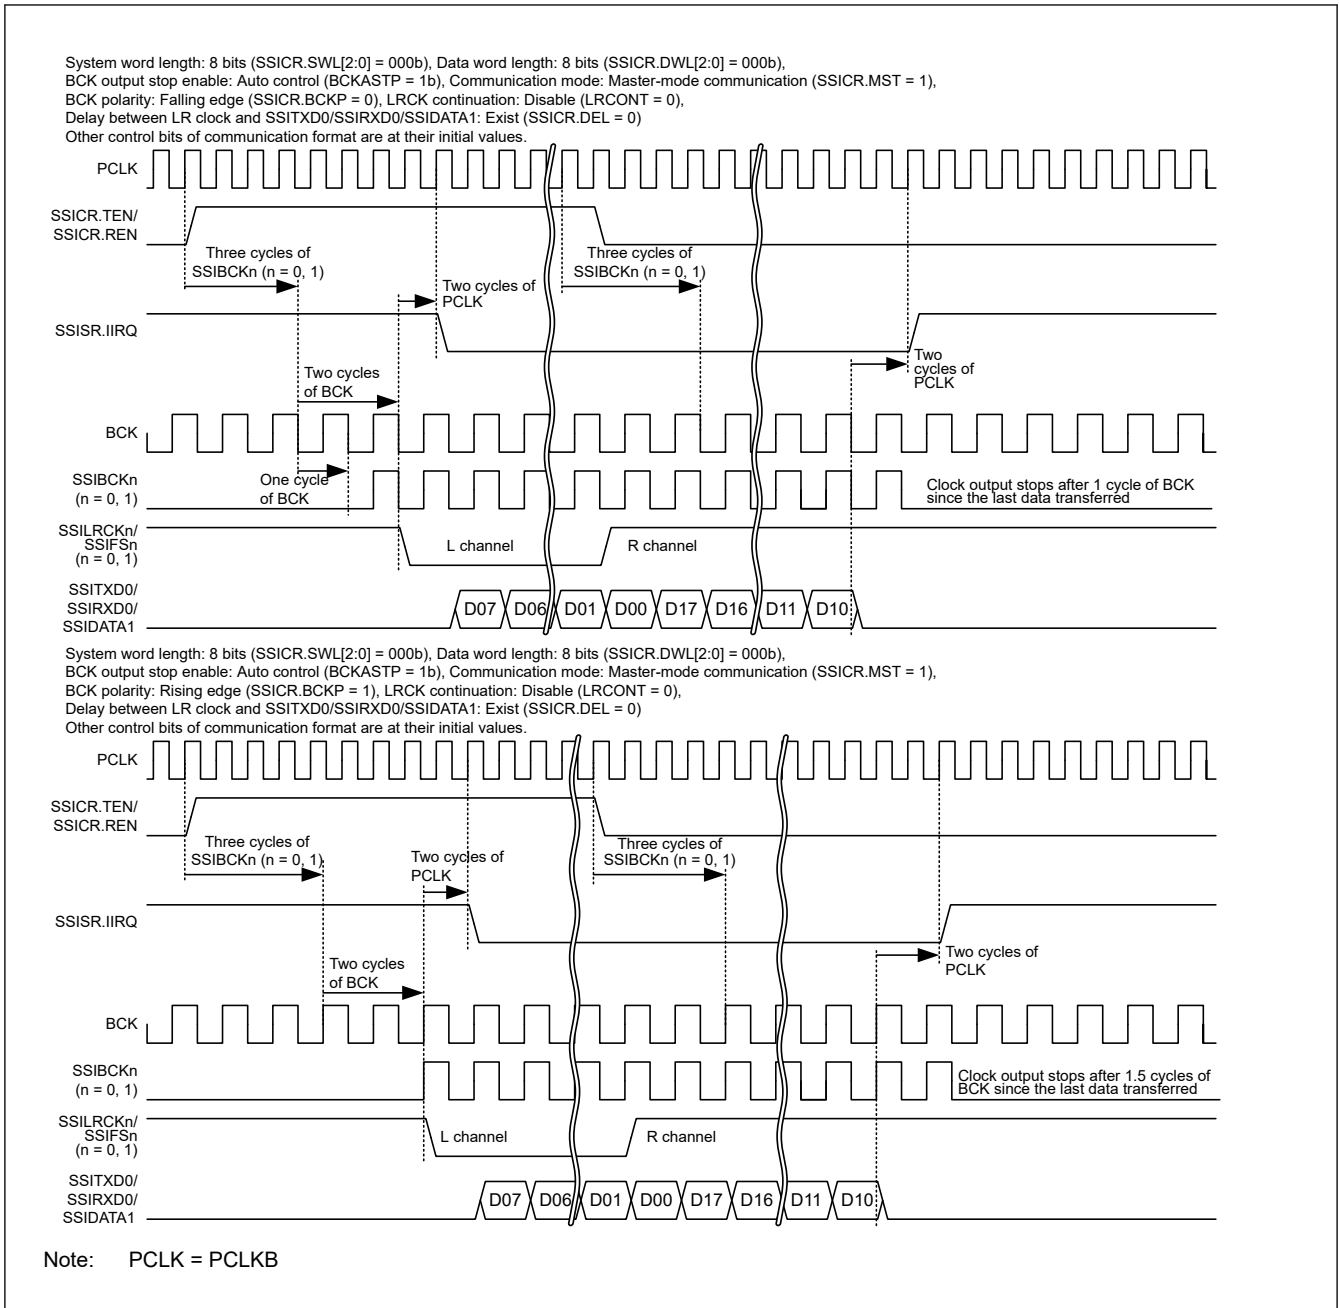

Figure 35.35 Example operation of the BCKASTP bit (communication operation with BCKASTP = 1)

35.2.8 SSISCR : Status Control Register

Base address: SSIE_n = 0x4025_D000 + 0x0100 × n (n = 0, 1)
 SSIE_n_NS = 0x5025_D000 + 0x0100 × n (n = 0, 1)

Offset address: 0x24

Bit field:	—	—	—	TDES[4:0]				—	—	—	RDFS[4:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
4:0	RDFS[4:0]	RDF Setting Condition Select* ¹ 0x00: SSIFRDR has one stage or more data size. 0x01: SSIFRDR has two stages or more data size. ⋮ 0x1E: SSIFRDR has thirty-one stages or more data size. 0x1F: SSIFRDR has thirty-two stages or more data size.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
12:8	TDES[4:0]	TDE Setting Condition Select* ¹ 0x00: SSIFTDR has one stage or more free space. 0x01: SSIFTDR has two stages or more free space. ⋮ 0x1E: SSIFTDR has thirty-one stages or more free space. 0x1F: SSIFTDR has thirty-two stages or more free space.	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Writing to these bits while SSIE is in a communication state (SSISR.IIRQ = 0) is prohibited. If written, the operation performed immediately after writing is not guaranteed.

RDFS[4:0] bits (RDF Setting Condition Select)

The RDFS[4:0] bits set the setting condition of the receive data full flag (RDF).

TDES[4:0] bits (TDE Setting Condition Select)

The TDES[4:0] bits set the setting condition of the transmit data empty flag (TDE).

35.3 Communication Formats

SSIE supports three communication formats. Table 35.12 shows supported communication formats.

Table 35.12 Supported communication formats

Communication Format	SSIOFR.OMOD[1:0]
I ² S format	00
TDM format	01
Monaural format	10

The following describes the serial data structure shared by communication formats. A serial data structure is defined by the system word length (set in SSICR.SWL[2:0]) and the data word length (set in SSICR.DWL[2:0]). If the data word length is shorter than the system word length, padding bits are transferred in the serial data. For details, see Figure 35.36.

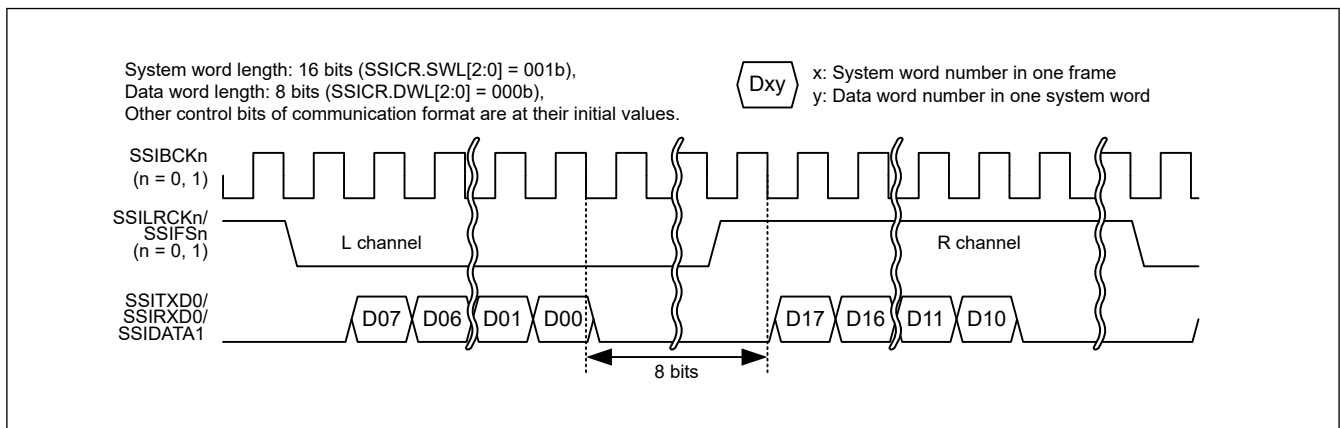

Figure 35.36 Example of padding bit transfer (I²S format: system word length > data word length)

Table 35.13 lists the number of padding bits to be transferred with each combination of system word length (SSICR.SWL[2:0]) and data word length (SSICR.DWL[2:0]). “-” indicates that the setting is prohibited.

Table 35.13 Number of padding bits

	SSICR.DWL[2:0]	000b	001b	010b	011b	100b	101b	110b	111b
SSICR.SWL[2:0]	System Word Length	8	16	18	20	22	24	32	Setting prohibited
000b	8	0	—	—	—	—	—	—	—
001b	16	8	0	—	—	—	—	—	—
010b	24	16	8	6	4	2	0	—	—
011b	32	24	16	14	12	10	8	0	—
100b	48	40	32	30	28	26	24	16	—
101b	64	56	48	46	44	42	40	32	—
110b	128	120	112	110	108	106	104	96	—
111b	256	248	240	238	236	234	232	224	—

35.3.1 I²S Format

The I²S format is a communication format used for connection with I²S-compatible serial devices. With this format setting (SSIOFR.OMOD[1:0] = 00b), one frame is configured with two system words, one for the channel L and the other for channel R. The SSILRCKn/SSIFS_n (n = 0, 1) signals are at a low level for the channel L and at a high level for the channel R. Set the polarity of the signals with the SSICR.LRCKP bit. Figure 35.37 shows the I²S format without padding. See Figure 35.36 for the format with padding.

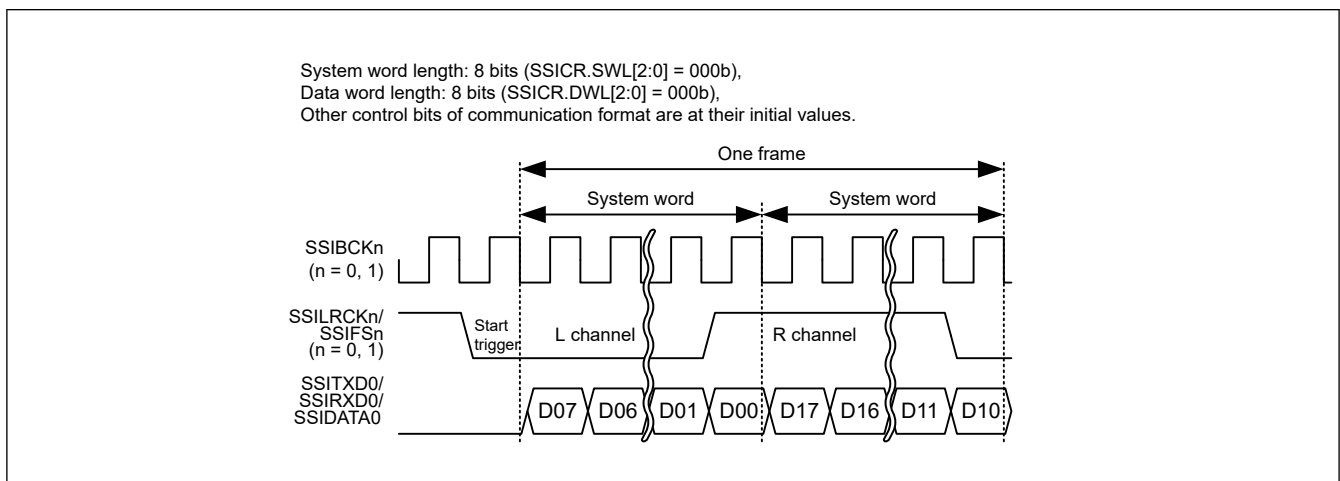

Figure 35.37 I²S format (without padding: system word length = data word length)

For the state of external pins when SSIE is in the idle state, see section 35.5.1. Idle State.

Note: SSIE has the SSILRCKn/SSIFS_n (n = 0, 1) pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCKn/SSIFS_n (n = 0, 1) pin only as a trigger to start communication.

35.3.2 Monaural Format

The monaural format is a communication format used for connection with monaural-compatible serial devices. When the monaural format is specified (SSIOFR.OMOD[1:0] = 10b) for use, one frame consists of one system word. Also, a rising edge of the SSILRCKn/SSIFS_n (n = 0, 1) signal indicates a communication start trigger. Figure 35.38 and Figure 35.39 respectively show the monaural formats without and with padding.

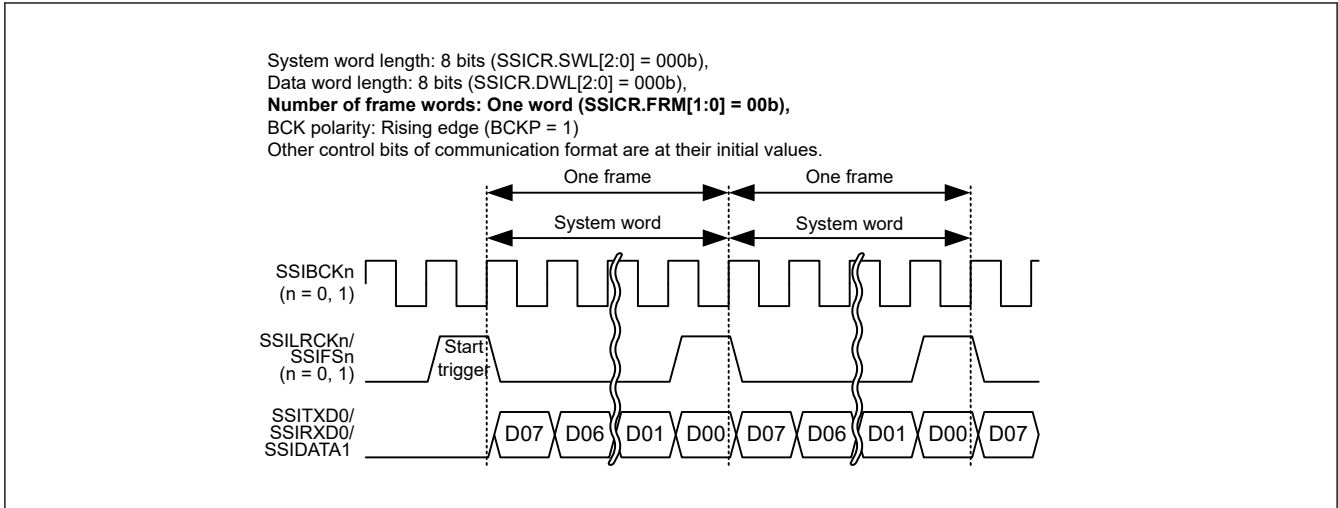

Figure 35.38 Short frame in monaural format (without padding: system word length = data word length)

Figure 35.39 Short frame in monaural format (with padding: system word length > data word length)

The monaural formats supported by SSIE consist of short frames and long frames. See [section 35.3.2.1. Short frame](#) and [section 35.3.2.2. Long frame](#) for the difference between these two frames.

For the state of external pins state when SSIE is in the idle state, see [section 35.5.1. Idle State](#).

Note: SSIE has the SSILRCKn/SSIFSs (n = 0, 1) pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCKn/SSIFSs (n = 0, 1) pin only as a trigger to start communication.

35.3.2.1 Short frame

When a short frame is used (SSICR.DEL = 0), the SSILRCKn/SSIFSs (n = 0, 1) signal indicating the start of serial data is set to high level only for 1 cycle of SSIBCKn (n = 0, 1). Data transfer starts at the falling edge of the signal.

35.3.2.2 Long frame

When a long frame is used (SSICR.DEL = 1), the SSILRCKn/SSIFSs (n = 0, 1) signal indicating the start of serial data is set to high level only for 2 cycles of SSIBCKn (n = 0, 1). See [Figure 35.40](#). Data transfer starts at the rising edge of the signal.

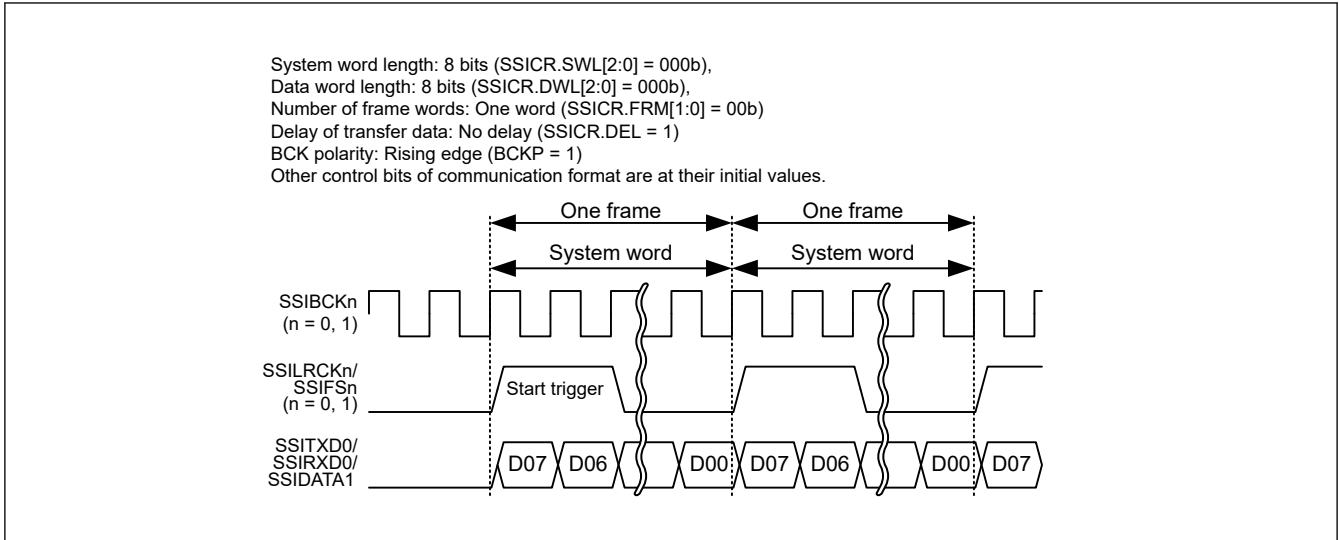

Figure 35.40 Long frame in monaural format (without padding)

35.3.3 TDM Format

The TDM format is a communication format used for connection with TDM-compatible multi-channel devices. With this format setting (SSIOFR.OMOD[1:0] = 01b), one frame is configured with four to eight system words set with the SSICR.FRM[1:0] bits. With this format, the SSILRCKn/SSIFS_n (n = 0, 1) signal is at a high level for the first one system word and at a low level for the rest. The pulse generated on the SSILRCKn/SSIFS_n (n = 0, 1) signal is defined as the SYNC pulse and its rising edge means a start of one frame. [Figure 35.41](#) and [Figure 35.42](#) respectively show the TDM formats without and with padding.

Figure 35.41 TDM format (without padding: system word length = data word length)

Figure 35.42 TDM format (with padding: system word length > data word length)

For the state of external pins when SSIE is in the idle state, see [section 35.5.1. Idle State](#).

Note: SSIE has the SSILRCKn/SSIFS_n (n = 0, 1) pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCKn/SSIFS_n (n = 0, 1) pin only as a trigger to start communication.

35.4 Communication Modes

SSIE supports the following communication modes. Table 35.15 lists the control bits that are not available with each communication mode. See section 35.4.1. Slave-mode Communication to section 35.4.5. Transmission and Reception for details of these communication modes.

Table 35.14 Communication modes

Communication Mode	SSICR.MST Bit	SSICR.REN Bit	SSICR.TEN Bit
Slave-mode transmission	0	0	1
Slave-mode reception	0	1	0
Slave-mode transmission and reception	0	1	1
Master-mode transmission	1	0	1
Master-mode reception	1	1	0
Master-mode transmission and reception	1	1	1

Table 35.15 Control bits that cannot be used in each communication mode

Control Bit	Slave-mode Reception	Slave-mode Transmission	Slave-mode Transmission and Reception	Master-mode Reception	Master-mode Transmission	Master-mode Transmission and Reception
SSICR.CKS	Invalid	Invalid	Invalid	Available	Available	Available
SSICR.CKDV	Invalid	Invalid	Invalid	Available	Available	Available
SSICR.MUEN	Invalid	Available	Available	Invalid	Available	Available
SSICR.TEN	Invalid	Available	Available	Invalid	Available	Available
SSICR.REN	Available	Invalid	Available	Available	Invalid	Available
SSIFCR.AUCKEN	Invalid	Invalid	Invalid	Available	Available	Available
SSIFCR.TIE	Invalid	Available	Available	Invalid	Available	Available
SSIFCR.RIE	Available	Invalid	Available	Available	Invalid	Available
SSIFCR.TFRST	Invalid	Available	Available	Invalid	Available	Available
SSIFCR.RFRST	Available	Invalid	Available	Available	Invalid	Available
SSIOFR.BCKASTP	Invalid	Invalid	Invalid	Available	Available	Available
SSIOFR.LRCONT	Invalid	Invalid	Invalid	Available	Available	Available
SSIOFR.OMOD	Available	Available	Available	Available	Available	Available
SSISCR.TDES	Invalid	Available	Available	Invalid	Available	Available
SSISCR.RDFS	Available	Invalid	Available	Available	Invalid	Available

“Invalid” means it has no effect on operation. Writing is possible.

35.4.1 Slave-mode Communication

SSIE operates in slave mode with SSICR.MST = 0. The SSIBCK_n (n = 0, 1) and SSILRCK_n/SSIFS_n (n = 0, 1) signals to be used for serial-data communication must be supplied from an external device. If these signals do not match the communication format set for SSIE, operation is not guaranteed.

35.4.2 Master-mode Communication

SSIE operates in master mode with SSICR.MST = 1. The SSIBCK_n (n = 0, 1) and SSILRCK_n/SSIFS_n (n = 0, 1) signals to be used for serial data communication must be internally generated from the audio clock. These signals use the format according to the setting of SSIE. If the communication format the slave device uses does not match the communication format set for SSIE, the operation is unpredictable.

35.4.3 Transmission

SSIE transmits serial data to the other-party device when the SSICR.TEN bit is 1 and the SSICR.REN bit is 0. If the communication format the other-party device uses does not match the communication format set for SSIE, the operation is unpredictable.

35.4.4 Reception

SSIE receives serial data from the other-party device when the SSICR.TEN bit is 0 and the SSICR.REN bit is 1. If the communication format the other-party device uses does not match the communication format set for SSIE, the operation is unpredictable.

35.4.5 Transmission and Reception

SSIE transmits and receives serial data to and from the other-party device when the SSICR.TEN bit is 1 and the SSICR.REN bit is 1. If the communication format the other-party device uses does not match the communication format set for SSIE, the operation is unpredictable.

35.5 Operation

SSIE has the following two main operation states [Figure 35.43](#) shows SSIE state transition.

- Idle state (SSISR.IIRQ = 1)
- Communication state (SSISR.IIRQ = 0).

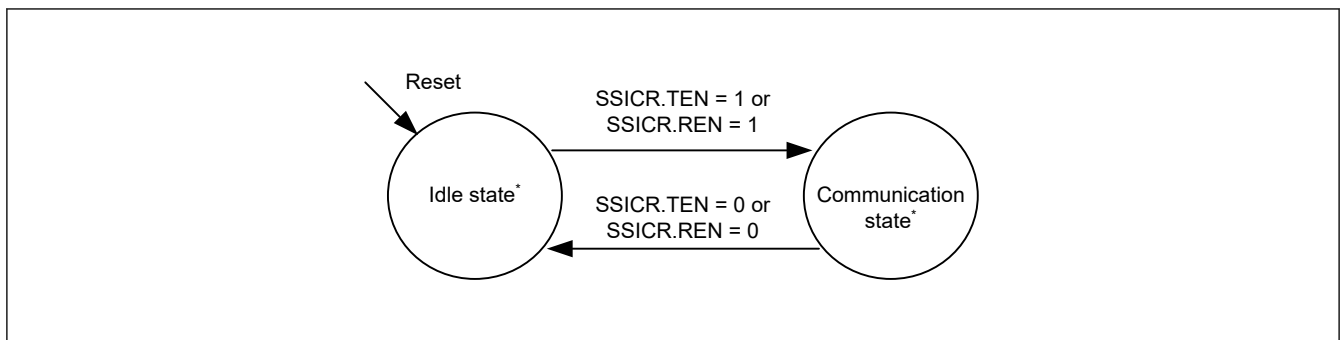

Figure 35.43 SSIE state transition

Note: See [section 35.6.1. Start Communication](#) for details of the idle state.
See [section 35.6.2. Transmission](#) for details of the communication state.

35.5.1 Idle State

In this state, communication of SSIE is halted. If, however, the SSICR.MST bit is 1, output of the BCK and LR clock/frame synchronization signals to external pins can be controlled according to the settings of SSIOFR.BCKASTP and SSIOFR.LRCONT bits. This function is common to all formats. For details, see [Table 35.16](#).

Table 35.16 Output from external pins in the idle state (1 of 2)

SSICR.MST	SSIOFR.BCKASTP	SSIOFR.LRCONT	Output from Pins		
			SSIBCK _n (n = 0, 1)	SSILRCK _n /SSIFS _n (n = 0, 1)	SSITXD0/SSIDATA1
0	—	—	Stop	Stop	Stop

Table 35.16 Output from external pins in the idle state (2 of 2)

SSICR.MST	SSIOFR.BCKASTP	SSIOFR.LRCONT	Output from Pins		
			SSIBCKn (n = 0, 1)	SSILRCKn/SSIFS _n (n = 0, 1)	SSITXD0/SSIDATA1
1	0	0	Supply	Stop	Stop
1	0	1	Supply	Supply	Stop
1	1	0	Stop	Stop	Stop
1	1	1	Stop	Supply	Stop

Figure 35.44 Example of disabling LR clock/frame synchronization continuation by SSIOPFR.LRCONT

Note: To stop the output to the SSILRCKn/SSIFS_n (n = 0, 1) pin with SSIOPFR.LRCONT when SSIE is in the idle state in master-mode communication (SSICR.MST = 1), note the following: The output stops when the value of the SSIOPFR.LRCONT bit is changed from 1 to 0. Make sure that the other-party device is not affected.

Figure 35.45 Example of stopping SSIBCKn (n = 0, 1) with SSIOFR.BCKASTP

Note: To stop the output to the SSIBCKn (n = 0, 1) pin with SSIOFR.BCKASTP in master-mode communication (SSICR.MST = 1) and while SSIE is in the idle state, note the following: The output stops when the value of the SSIOFR.BCKASTP bit is changed from 0 to 1. So, make sure that the other-party device is not affected.

35.5.2 Communication States

In this state, SSIE is during communication. [Figure 35.46](#) shows transitions of communication states and [Table 35.17](#) lists the conditions for transition. If the transition condition is not satisfied, the state does not transit.

Figure 35.46 Communication state transition

Table 35.17 Condition for communication state transition

Condition Number	Condition for Transition
1	Writing SSICR.TEN = 1 or SSICR.REN = 1 while SSICR.SDTA = 0 or in the setting without padding bits.
2	Writing SSICR.TEN = 1 or SSICR.REN = 1 while SSICR.SDTA = 1 and in the setting with padding bits.
3	The following three conditions are all met: <ul style="list-style-type: none"> • SSICR.TEN = 1 or SSICR.REN = 1 • In the setting with padding bits • The last bit of the data words has been transferred.
4	Both the following two conditions are met: <ul style="list-style-type: none"> • SSICR.SDTA = 1 or without padding bits • While SSICR.TEN = 0 and SSICR.REN = 0, the last bit of the data words in a frame has been transferred.
5	Transfer of the last padding bit is completed while SSICR.TEN = 1 or SSICR.REN = 1
6	Both the following two conditions are met: <ul style="list-style-type: none"> • SSICR.SDTA = 0 and with padding bits • While SSICR.TEN = 0 and SSICR.REN = 0, the last padding bit has been transferred.

See Table 35.13 for the setting with/without padding bits.

35.5.2.1 Data communication state

In this state, SSIE is during communication. Data of the data word length set with the SSICR.DWL[2:0] bits is transmitted, received, or transmitted and received.

- State Transition in the Setting without Padding Bits

During communication (SSISR.IIRQ = 0), SSIE is during data communication for all the time. By disabling transmission and reception (SSICR.TEN = 0, SSICR.REN = 0), SSIE transits to the idle state. For details, see Figure 35.47 and Figure 35.48.

Figure 35.47 Continuation of the data communication

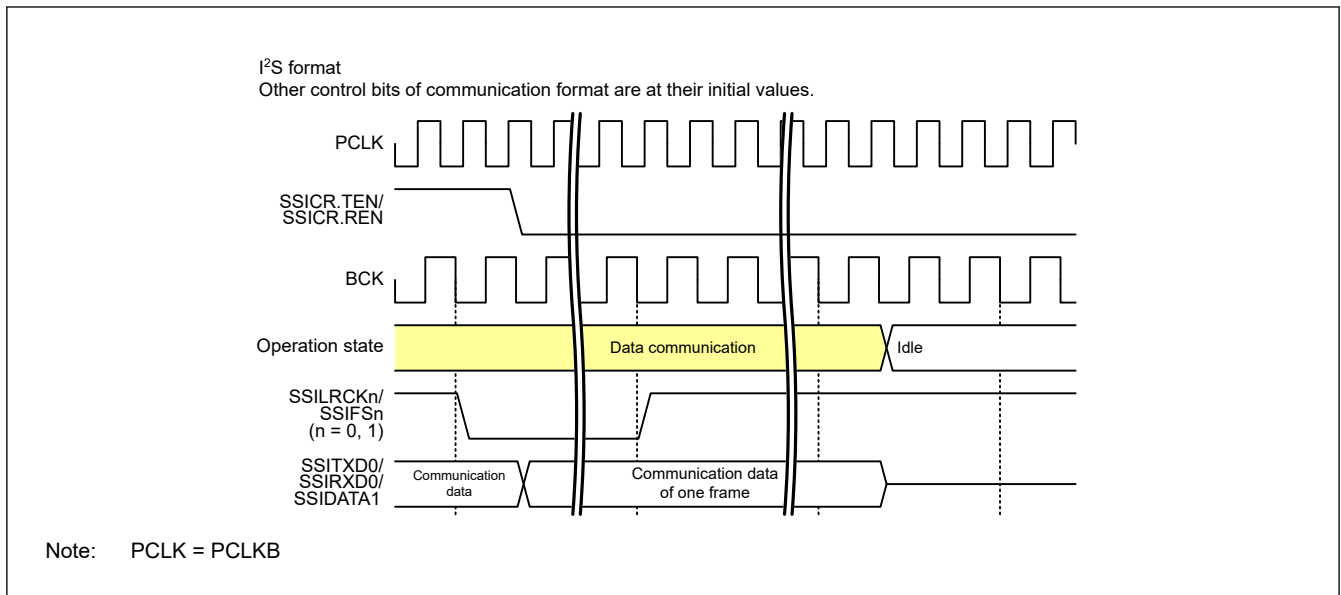

Figure 35.48 Halt from the data communication (without padding bits)

- State Transition in the Setting with Padding Bits

When SSIE ends transfer of the last bit of a data word during communication (SSISR.IIRQ = 0), SSIE transitions from the data communication state to the padding communication state in Figure 35.49. Except in the status with SSICR.SDTA = 1 and transmission and reception disabled (SSICR.TEN = 0 and SSICR.REN = 0), SSIE transitions from the data communication state to the idle state when it stops communication in Figure 35.50.

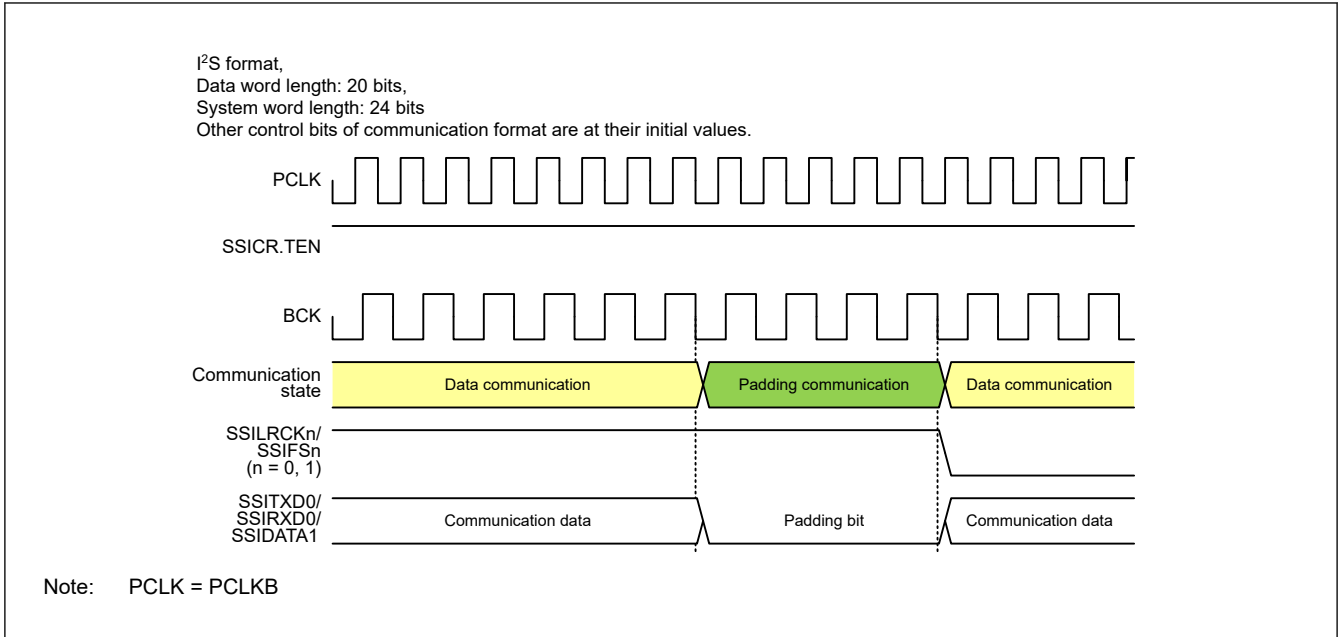

Figure 35.49 Transition from data communication to padding communication

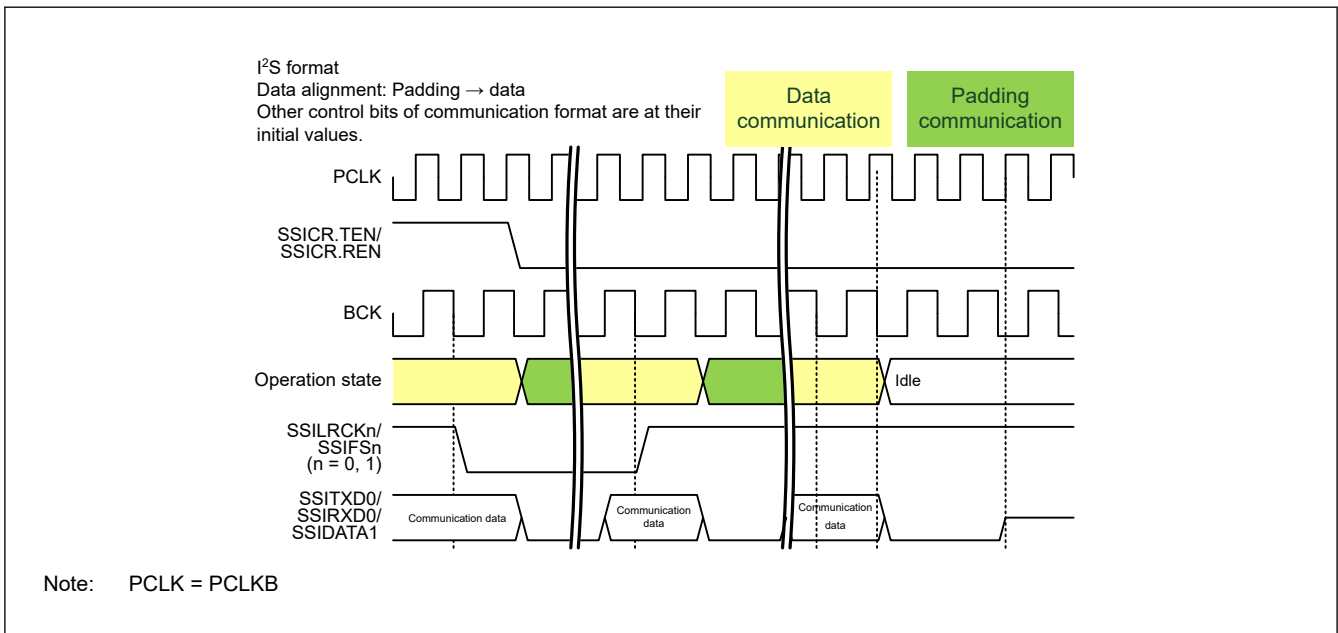

Figure 35.50 Halt from data communication (with padding bits)

35.5.2.2 Padding communication

In this state, SSIE is during communication. The padding bits set with the SSICR.SWL[2:0] bits and SSICR.DWL[2:0] bits are transmitted, received, or transmitted and received.

- State Transition in the Setting with Padding Bits

When SSIE ends transfer of the last padding bit during communication (SSISR.IIRQ = 0), SSIE transitions to the data communication state in Figure 35.49. If SSIE is in the status with SSICR.SDTA = 0 and transmission and reception disabled (SSICR.TEN = 0 and SSICR.REN = 0), SSIE transitions from the padding communication state to the idle state when it stops communication in Figure 35.51.

Figure 35.51 Halt from the padding communication

35.6 Communication Operation

Figure 35.52 shows the communication flow of SSIE.

Figure 35.52 SSIE communication operation

The procedure of each operation is described from [section 35.6.1. Start Communication](#) to [section 35.6.7. Resume Communication](#).

35.6.1 Start Communication

This section describes how to start communication of SSIE. [Figure 35.53](#) shows the procedure to start communication. Be sure to follow the procedure. See [section 35.6.2. Transmission](#) for transmission operation and [section 35.6.3. Reception](#) for reception operation.

Figure 35.53 Procedure to start communication (CPU operation procedure)

SSIE can perform continuous communication based on interrupts by the DTC/DMAC. For transmission, write 1 to SSIFCR.TIE, SSICR.TUIEN, and SSICR.TOIEN. For reception, write 1 to SSIFCR.RIE, SSICR.RUIEN, and SSICR.ROIEN.

35.6.2 Transmission

The transmission procedure in [Figure 35.54](#) must be followed throughout a transmission operation.

After transmission is enabled (SSICR.TEN = 1 and SSICR.REN = 0), SSIE starts transmission when a start trigger is generated by SSILRCKn/SSIFS_n (n = 0, 1) with the serial data for at least a frame contained in the transmit FIFO data register (SSIFTDR). SSIE outputs a transmit data empty interrupt to the DTC/DMAC according to the TDE setting condition (SSISCR.TDES) and the status of transmit data empty interrupt enable (SSIFCR.TIE) bit specified in the communication start procedure. This interrupt requests writing to the transmit FIFO data register (SSIFTDR). In the communication start procedure, specify writing to the transmit FIFO data register (SSIFTDR) as the DTC/DMAC operation in response to the transmit data empty interrupt. With this setting, SSIE can continuously transmit data not through the CPU. The transmit data empty interrupt is generated when the free space size of transmit FIFO data register reaches the value set in SSISCR.TDES. The number of times of writing must be specified in accordance with the free space size of the transmit FIFO data register indicated by the transmit data empty interrupt. If an error occurs, perform the error-handling procedure as instructed in the communication stop procedure.

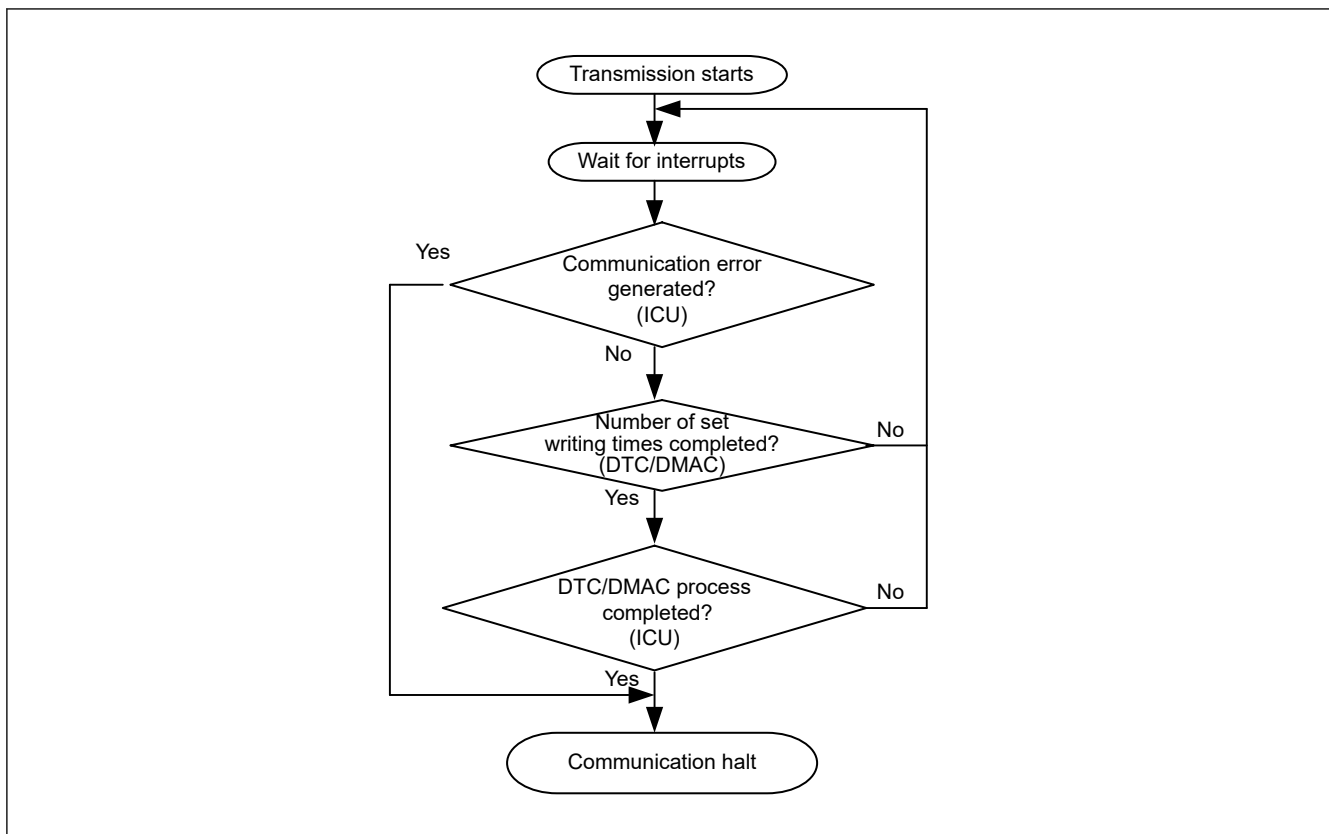

Figure 35.54 Transmission procedure

Note: The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.TDE to write data to SSIFTDR. The number of times of writing data to SSIFTDR by detecting the value 1 of SSIFSR.TDE must be in accordance with the free space size of the transmit FIFO data register specified by SSISCR.TDES. After as much transmit data as the free space size is written to SSIFTDR, the SSIFSR.TDE flag must be cleared. Continuous transmission is enabled by repeating data writing. If the SSIFSR.TDE flag is not cleared, the flag is not cleared automatically.

35.6.3 Reception

The reception procedure in [Figure 35.55](#) must be followed throughout a reception operation.

After reception is enabled (SSICR.TEN = 0 and SSICR.REN = 1), SSIE starts reception when a start trigger is generated by SSILRCKn/SSIFS_n (n = 0, 1). SSIE outputs a receive data full interrupt to the DTC/DMAC according to the RDF setting condition (SSISCR.RDFS) and the status of receive data full interrupt enable (SSIFCR.RIE) bit specified in the communication start procedure. This interrupt requests data reading from the receive FIFO data register (SSIFRDR). In the communication start procedure, specify reading from the receive FIFO data register (SSIFRDR) as the DTC/DMAC operation in response to the receive data full interrupt. With this setting, SSIE can continuously read data not through the CPU. The receive data full interrupt is generated when data as much as the capacity of receive FIFO data register has been stored. The number of times of reading must be specified in accordance with the data size of the receive FIFO data register

indicated by the receive data full interrupt. If an error occurs, perform the error-handling procedure as instructed in the communication stop procedure.

Figure 35.55 Reception procedure

Note: The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.RDF to read data from SSIFRDR. The number of times of reading data from SSIFRDR by detecting the value 1 of SSIFSR.RDF must be in accordance with the receive data storage capacity of the receive FIFO data register specified by SSISCR.RDFS. After received data is read from SSIFRDR, the SSIFSR.RDF flag must be cleared. Continuous reception is enabled by repeating data reading. If the SSIFSR.RDF flag is not cleared, the flag is not cleared automatically.

35.6.4 Transmission and Reception

After transmission and reception are enabled (SSICR.TEN = 1 and SSICR.REN = 1), SSIE starts transmission and reception when a start trigger is generated by SSILRCKn/SSIFS_n (n = 0, 1) with the serial data for at least a frame contained in the transmit FIFO data register (SSIFTDR). SSIE can continuously transmit and receive data by performing the procedures described in [section 35.6.2. Transmission](#) and [section 35.6.3. Reception](#), respectively. For how to stop transmission and reception, see [section 35.6.5. Halt Communication](#).

35.6.5 Halt Communication

This section describes how to halt communication of SSIE. [Figure 35.56](#) shows the procedure to halt communication. Be sure to follow the procedure.

Figure 35.56 Procedure to halt communication (CPU operation procedure)

To halt the communication of SSIE, supply of the following clocks are required until the SSISR.IIRQ bit indicates an idle state.

- Input clock from the SSIBCK_n (n = 0, 1) pin when SSICR.MST = 0
 - AUDIO_MCK when SSICR.MST = 1
- To resume communication of SSIE in the previous setting, see [section 35.6.7. Resume Communication](#).

Note: When communication of SSIE is halted according to the procedure to halt communication in [Figure 35.56](#), resume communication according to the procedure to resume communication in [Figure 35.58](#).

35.6.6 Error Handling

SSIE has the following four errors.

- Transmit underflow error
- Transmit overflow error
- Receive underflow error

- Receive overflow error.

When an underflow error or overflow error is generated, SSIE need to be restarted. Follow the procedure to halt communication in [Figure 35.56](#) and error-handling procedure in [Figure 35.57](#).

Figure 35.57 Error-handling procedure

Four error operations are described as follows. When the interrupt output enable bit of the SSICR register is enabled and error flags are set, an error interrupt is generated. See [section 35.2.2. SSISR : Status Register](#) for the setting conditions of error flags.

(1) Transmit Underflow Error

If a transmit underflow error occurs, review the number of times of writing data to the transmit FIFO data register (SSIFTDR) in response to a transmit data empty interrupt. After a transmit underflow error occurs, SSIE outputs 0s as data. To normally output the serial data written to the transmit FIFO data register (SSIFTDR) to the SSITXD0/SSIDATA1 pin, follow the procedure to halt communication in [Figure 35.56](#) and error-handling procedure in [Figure 35.57](#). After this error occurs, serial data is consumed as usual. If you resume communication, write the serial data from the beginning.

(2) Transmit Overflow Error

If a transmit overflow error occurs, review the number of times of writing data to the transmit FIFO data register (SSIFTDR) in response to transmit data empty interrupts. The serial data written to the transmit FIFO data register (SSIFTDR) that caused the transmit overflow error becomes invalid. This error can occur regardless of whether a transmission operation is being done. To recover from the error, follow the procedure to halt communication in [Figure 35.56](#) and error-handling procedure in [Figure 35.57](#). When you resume communication, deal with the invalid serial data appropriately.

(3) Receive Underflow Error

If a receive underflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The values read from the receive FIFO data register (SSIFRDR) that caused the receive underflow error are undefined. This error can occur regardless of whether a reception operation is being done. To recover from the error, follow the procedure to halt communication in [Figure 35.56](#) and error-handling procedure in [Figure 35.57](#).

(4) Receive Overflow Error

If a receive overflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The receive data that caused the receive overflow error cannot be stored in the receive FIFO data register (SSIFRDR). To recover from the error, follow the procedure to halt communication in [Figure 35.56](#) and error-handling procedure in [Figure 35.57](#).

35.6.7 Resume Communication

When you resume the communication using SSIE, follow the communication resume procedure in [Figure 35.58](#). The communication resume procedure is designed on the assumption that you resume the communication stopped by the

communication stop procedure without changing any settings. If you want to change clock and slave/master settings, use and follow the communication start procedure in [Figure 35.53](#). For details about the transmission operation and reception operation after starting communication, see [section 35.6.2. Transmission](#) and [section 35.6.3. Reception](#), respectively.

Figure 35.58 Procedure to resume communication (CPU operation procedure)

35.7 Interrupts

[Table 35.18](#) lists the interrupt sources. Set enable/disable of interrupt output of each source with the TUIEN, TOIEN, RUIEN, ROIEN, and I IEN bits in the SSICR register and the TIE and RIE bits in the SSIFCR register.

Table 35.18 SSIE interrupt sources

Channel	Interrupt source	Description	Interrupt flag	DMAC/DTC activation
SSIE0	SSIE0_SSIF	<ul style="list-style-type: none"> • Transmit underflow interrupt • Transmit overflow interrupt • Receive underflow interrupt • Receive overflow interrupt • Idle interrupt 	SSISR.TUIRQ SSISR.TOIRQ SSISR.RUIRQ SSISR.ROIRQ SSISR.IIRQ	Not possible
	SSIE0_SSIRXI	Receive data full interrupt	SSIFSR.RDF	Possible
	SSIE0_SSITXI	Transmit data empty interrupt	SSIFSR.TDE	Possible
SSIE1	SSIE1_SSIF	<ul style="list-style-type: none"> • Transmit underflow interrupt • Transmit overflow interrupt • Receive underflow interrupt • Receive overflow interrupt • Idle interrupt 	SSISR.TUIRQ SSISR.TOIRQ SSISR.RUIRQ SSISR.ROIRQ SSISR.IIRQ	Not possible
	SSIE1_SSIRT	<ul style="list-style-type: none"> • Receive data full interrupt • Transmit data empty interrupt 	SSIFSR.RDF SSIFSR.TDE	Possible

35.7.1 SSIE_n_SSIF Interrupt (n = 0, 1)

This interrupt source combines five interrupts. Enable output of necessary interrupts before using SSIE. The five interrupts are operated by using the flags assigned to individual interrupts and interrupt output enable bits. To clear an interrupt, set the interrupt enable to 0 or clear the interrupt flag to 0.

Figure 35.59 Timing Diagram of the common interrupt source, SSIE_n_SSIF

- Transmit underflow interrupt

As the transmit underflow interrupt, SSISR.TUIRQ is output while SSICR.TUIEN = 1. When you use SSIE for transmission, enable the output of this interrupt (SSICR.TUIEN = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in [Figure 35.56](#) and error-handling procedure in [Figure 35.57](#).

- Transmit overflow interrupt

As the transmit overflow interrupt, SSISR.TOIRQ is output while SSICR.TOIEN = 1. When you use SSIE for transmission, enable the output of this interrupt (SSICR.TOIEN = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in [Figure 35.56](#) and error-handling procedure in [Figure 35.57](#).

- Receive underflow interrupt

As the receive underflow interrupt, SSISR.RUIRQ is output while SSICR.RUIEN = 1. When you use SSIE for reception, enable the output of this interrupt (SSICR.RUIEN = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in [Figure 35.56](#) and error-handling procedure in [Figure 35.57](#).

- Receive overflow interrupt

As the receive overflow interrupt, SSISR.ROIRQ is output while SSICR.ROIEN = 1. When you use SSIE for reception, enable the output of this interrupt (SSICR.ROIEN = 1). If this interrupt occurs, follow instructions in the procedure to halt communication in [Figure 35.56](#) and error-handling procedure in [Figure 35.57](#).

- Idle mode interrupt

As the idle mode interrupt, SSISR.IIRQ is output while SSICR.IIEN = 1. This interrupt is used to make sure that communication has stopped fully.

35.7.2 SSIE0_SSITXI Interrupt [Full-duplex communication]

The transmit data empty interrupt is a pulse interrupt that is output when the following condition is met:

- SSIFCR.TIE = 1 and SSIFSR.TDE = 1
 SSIE operation: When the value of SSIFSR.TDE changes from 0 to 1 while the value of SSIFCR.TIE is 1
 CPU instruction: When the value of SSIFCR.TIE changes from 0 to 1 while the value of SSIFSR.TDE is 1

This interrupt is subject to the interrupt suppression function. If an interrupt condition for this interrupt occurs when the DTC/DMAC is busy (when the DTC/DMAC cannot accept interrupts), the interrupt suppression function holds the output of this interrupt. The held interrupt will be output after the DTC/DMAC is enabled to accept interrupts. For details, see [Figure 35.60](#).

Figure 35.60 SSIE1_SSITXI interrupt timing diagram

35.7.3 SSIE0_SSIRXI Interrupt [Full-duplex communication]

The receive data full interrupt is a pulse interrupt that is output when the following condition is met:

- SSIFCR.RIE = 1 and SSIFSR.RDF = 1.
 SSIE operation: When the value of SSIFSR.RDF changes from 0 to 1 while the value of SSIFCR.RIE is 1
 CPU instruction: When the value of SSIFCR.RIE changes from 0 to 1 while the value of SSIFSR.RDE is 1

This interrupt is subject to the interrupt suppression function. If an interrupt condition for this interrupt occurs when the DTC/DMAC is busy (when the DTC/DMAC cannot accept interrupts), the interrupt suppression function holds the output of this interrupt. The held interrupt will be output after the DTC/DMAC is enabled to accept interrupts. The behavior of this interrupt is the same as the behavior shown in [Figure 35.60](#).

35.7.4 SSIE1_SSIRT Interrupt [Half-duplex communication]

This interrupt is output by two sources, transmit data empty interrupt and receive data full interrupt. When this interrupt is generated, read the interrupt flag and specify the interrupt source.

This interrupt is subject to the interrupt suppression function. If an interrupt condition for this interrupt occurs when the DTC/DMAC is busy (when the DTC/DMAC cannot accept interrupts), the interrupt suppression function holds the output of this interrupt. The held interrupt will be output after the DTC/DMAC is enabled to accept interrupts. For details, see [Figure 35.61](#).

Figure 35.61 SSIE1_SSIRT interrupt timing diagram

35.8 Software Resets

SSIE has three software reset bits to reset its states.

- SSIE software reset (SSIFCR.SSIRST)
- Transmit FIFO data register reset (SSIFCR.TFRST)
- Receive FIFO data register reset (SSIFCR.RFRST).

This section describes the procedures for the three types of software resets.

35.8.1 Software Reset Procedure

(1) SSIE Software Reset

For the SSIE software reset bit (SSIFCR.SSIRST), follow the procedure shown in [Figure 35.62](#). After a reset, the same setting is applied when it is resumed. To change the settings of clocks and slave/master mode, follow the procedure to start communication in [Figure 35.53](#). See [section 35.6.2. Transmission](#) and [section 35.6.3. Reception](#) respectively for transmission and reception after communication is resumed.

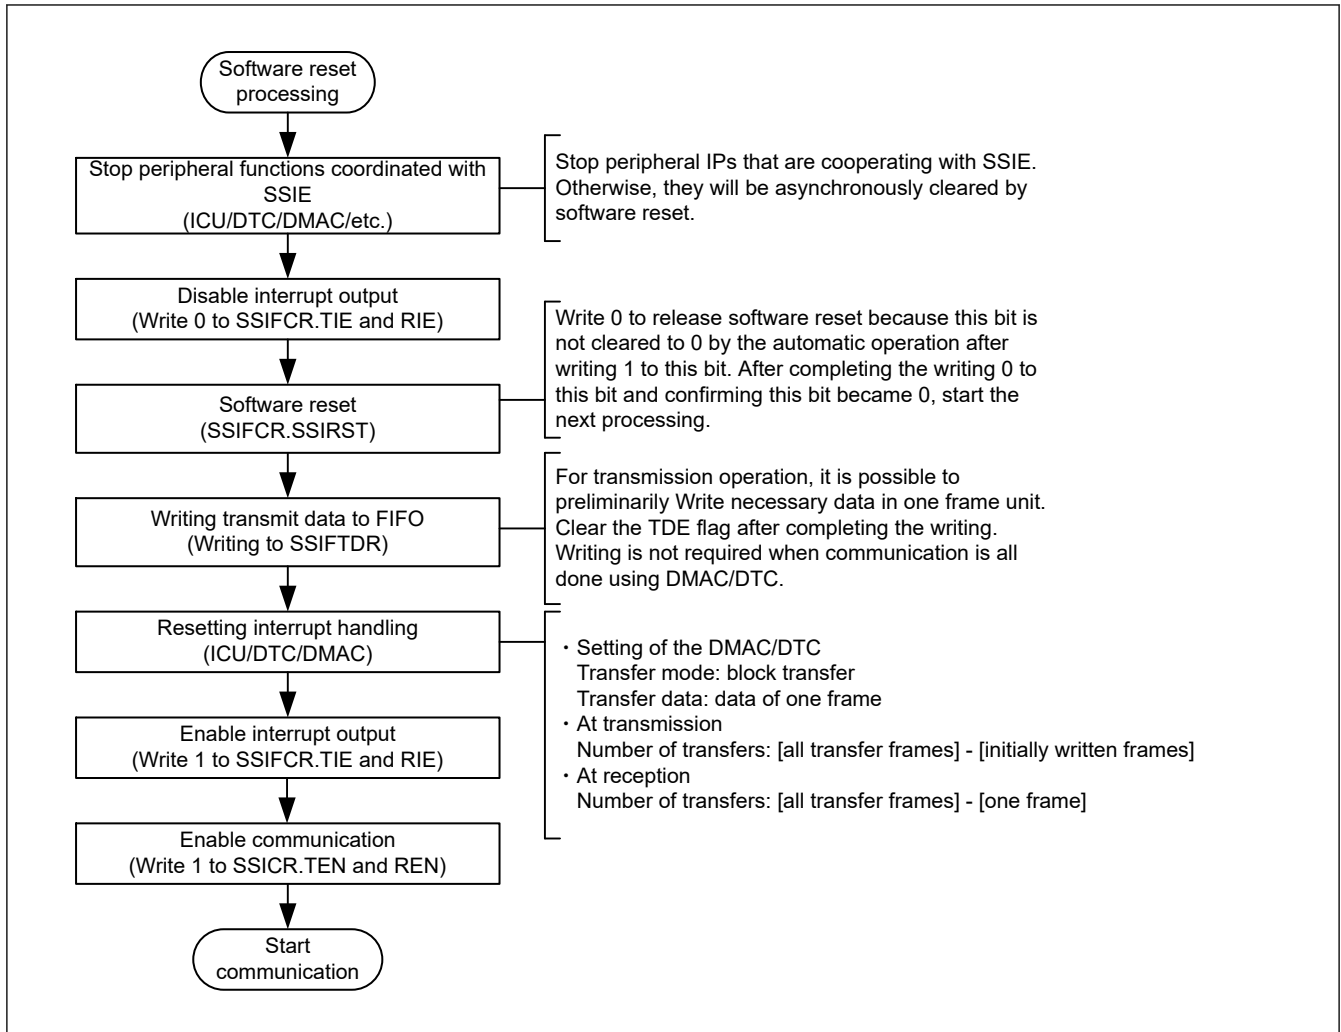

Figure 35.62 Software reset procedure (CPU operation procedure)

(2) Transmit FIFO data register reset

To perform a transmit FIFO data register reset, follow instructions in the procedure to start communication in [Figure 35.53](#) and procedure to resume communication in [Figure 35.58](#).

(3) Receive FIFO data register reset

To perform a receive FIFO data register reset, follow instructions in the procedure to start communication in [Figure 35.53](#) and procedure to resume communication in [Figure 35.58](#).

35.9 Usage Notes

35.9.1 Notes for Slave-mode Communication

35.9.1.1 SSIBCKn (n = 0, 1) control

In slave-mode communication (SSICR.MST = 0), SSIE needs supply of SSIBCKn (n = 0, 1). To stop BCK on the master side, make sure that SSIE is in the idle state (SSISR.IIRQ = 1). If BCK is stopped before SSIE becomes idle, take the procedure to start communication in [Figure 35.53](#) or wait for an idle state by taking the procedure to resume communication in [Figure 35.58](#).

35.9.1.2 SSILRCKn/SSIFS_n (n = 0, 1) pin

SSIE has the SSILRCK_n/SSIFS_n (n = 0, 1) pin, which indicates the synchronization of communication. When SSIE is in slave mode (SSICR.MST = 0), the communication format SSIE uses must match that of the other-party device to communicate. SSIE uses the signal input by the SSILRCK_n/SSIFS_n (n = 0, 1) pin only as a trigger to start communication.

35.9.2 Notes for Master-mode Communication

35.9.2.1 AUCKE control

In master-mode communication (SSICR.MST = 1), SSIE operates with the audio clock (AUDIO_MCK). To stop SSIE completely, make sure that SSIE is in the idle state (SSISR.IIRQ = 1) and then write 0 to SSIFCR.AUCKE.

35.9.2.2 LRCONT control

To stop the output to the SSILRCK_n/SSIFS_n (n = 0, 1) pin with SSIOFR.LRCONT when SSIE is in the idle state in master-mode communication (SSICR.MST = 1), note the following: The output stops when the value of the SSIOFR.LRCONT bit is changed from 1 to 0. Make sure that the other-party device is not affected. For details, see [Figure 35.44](#).

35.9.2.3 BCKASTP control

To stop the output to the SSIBCK_n (n = 0, 1) pin with SSIOFR.BCKASTP in master-mode communication (SSICR.MST = 1) and while SSIE is in the idle state, note the following: The output stops when the value of the SSIOFR.BCKASTP bit is changed from 0 to 1. So, make sure that the other-party device is not affected. For details, see [Figure 35.45](#).

The BCKASTP bit cannot be used when the other-party device (which is a slave) requires the clock output from the SSIBCK_n (n = 0, 1) pin before and during communication.

35.9.3 Notes for Communication Flow

35.9.3.1 When an error interrupt is generated

SSIE has the following four errors.

- Transmit underflow error
- Transmit overflow error
- Receive underflow error
- Receive overflow error

When an underflow error or overflow error is generated, SSIE need to be restarted. Follow the procedure to halt communication in [Figure 35.56](#) and error-handling procedure in [Figure 35.57](#).

(1) Transmit Underflow Error

If a transmit underflow error occurs, review the number of times of writing data to the transmit FIFO data register (SSIFTDR) in response to a transmit data empty interrupt. After a transmit underflow error occurs, SSIE outputs 0s as data. To normally output the serial data written to the transmit FIFO data register (SSIFTDR) to the SSITXD0/SSIDATA1 pin, follow the procedure to halt communication in [Figure 35.56](#) and error-handling procedure in [Figure 35.57](#). After this error occurs, serial data is consumed as usual. If you resume communication, write the serial data from the beginning.

(2) Transmit Overflow Error

If a transmit overflow error occurs, review the number of times of writing data to the Transmit FIFO Data Register (SSIFTDR) in response to transmit data empty interrupts. The serial data written to the Transmit FIFO Data Register (SSIFTDR) that caused the transmit overflow error becomes invalid. This error can occur regardless of whether a transmission operation is being done. To recover from the error, follow the procedure to halt communication in [Figure 35.56](#) and error-handling procedure in [Figure 35.57](#). When you resume communication, deal with the invalid serial data appropriately.

(3) Receive Underflow Error

If a receive underflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The values read from the receive FIFO data register (SSIFRDR) that caused the receive underflow error are undefined. This error can occur regardless of whether a reception operation is being done. To recover from the error, follow the procedure to halt communication in [Figure 35.56](#) and error-handling procedure in [Figure 35.57](#).

(4) Receive Overflow Error

If a receive overflow error occurs, review the number of times of reading data from the receive FIFO data register (SSIFRDR) in response to receive data full interrupts. The receive data that caused the receive overflow error cannot be stored in the receive FIFO data register (SSIFRDR). To recover from the error, follow the procedure to halt communication in [Figure 35.56](#) and error-handling procedure in [Figure 35.57](#).

35.9.3.2 Transmit data empty interrupt

The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.TDE to write data to SSIFTDR. The number of times of writing data to SSIFTDR by detecting the value 1 of SSIFSR.TDE must be in accordance with the free space size of the transmit FIFO data register specified by SSISCR.TDES. After as much transmit data as the free space size is written to SSIFTDR, the SSIFSR.TDE flag must be cleared. Continuous transmission is enabled by repeating data writing. If the SSIFSR.TDE flag is not cleared, the flag is not cleared automatically.

35.9.3.3 Receive data full interrupt

The communication flow defined in SSIE uses the DTC/DMAC. If you do not use the DTC/DMAC, perform polling of the value 1 of SSIFSR.RDF to read data from SSIFRDR. The number of times of reading data from SSIFRDR by detecting the value 1 of SSIFSR.RDF must be in accordance with the receive data storage capacity of the receive FIFO data register specified by SSISCR.RDFS. After received data is read from SSIFRDR, the SSIFSR.RDF flag must be cleared. Continuous reception is enabled by repeating data reading. If the SSIFSR.RDF flag is not cleared, the flag is not cleared automatically.

35.9.3.4 Switching transfer modes

1. For state transition from transmission, reception, and transmission and reception, disable transmission and reception (SSICR.TEN = 0, SSICR.REN = 0).
2. Confirm it is in the idle state (SSISR.IIRQ = 1).
3. In the idle state, set the SSICR.TEN bit or the SSICR.REN bit again and resume transfer.

35.9.3.5 Resume communication after halting SSIE

When communication of SSIE is halted according to the procedure to halt communication in [Figure 35.56](#), resume communication according to the procedure to resume communication in [Figure 35.58](#).

35.9.4 Write Access Restriction

35.9.4.1 SSICR register

If the TEN bit or REN bit is rewritten, make sure that the SSISR.IIRQ bit is in the desired status. If the value of the TEN or REN bit is changed by rewriting, subsequent operation is unpredictable. For example, when transmission or reception is enabled, check that SSISR.IIRQ is 0; when transmission or reception is disabled, check that SSISR.IIRQ is 1.

(1) TEN Bit and REN Bit

These bits enable/disable transmission and reception. When 1 is written to one of these bits, the corresponding communication operation starts in synchronization with a start trigger by the SSILRCKn/SSIFS_n (n = 0, 1) signal. For details, see [section 35.6.2. Transmission](#), [section 35.6.3. Reception](#), and [section 35.6.4. Transmission and Reception](#). When 0 is written to this bit, the current communication operation stops at the next frame boundary. To use SSIE for both transmission and reception, always write 1 to these bits together. When stopping the communication using SSIE, always disable both transmission and reception (write 0 to the TEN and REN bits).

35.9.4.2 SSISR register

(1) Clearing TUIRQ and TOIRQ

After communication is enabled (by changing the value of SSICR.TEN bit from 0 to 1), the transmission error flags (TOIRQ and TUIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the transmission error flags might be unable to be read.

(2) Clearing RUIRQ and ROIRQ

After communication is enabled (by changing the value of SSICR.REN bit from 0 to 1), the reception error flags (RUIRQ and ROIRQ in the SSISR register) are cleared. If, however, the SSISR register is read continuously, the cleared status of the reception error flags might be unable to be read.

35.9.4.3 Communication state

Writing to the bits with orange-shaded area in [Table 35.19](#) is prohibited. If written, the operation performed immediately after writing is not guaranteed.

Table 35.19 Bits protected from writing during communication

Symbol	Address (BASE+)		+0								+1							
			31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

35.9.5 Module-stop function

SSIE operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The SSIE module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

36. Cyclic Redundancy Check (CRC)

36.1 Overview

The Cyclic Redundancy Check (CRC) calculator generates CRC codes to detect errors in the data. The bit order of CRC calculation results can be switched for LSB-first or MSB-first communication. Additionally, various CRC-generation polynomials are available. The snoop function allows monitoring reads from and writes to specific addresses. This function is useful in applications that require CRC code to be generated automatically in certain events, such as monitoring writes to the serial transmit buffer and reads from the serial receive buffer.

Table 36.1 lists the CRC calculator specifications and Figure 36.1 shows a block diagram.

Table 36.1 CRC calculator specifications

Item	Description	
Data size	8-bit	32-bit
Data for CRC calculation*1	CRC code generated for data in 8n-bit units (where n is a natural number)	CRC code generated for data in 32n-bit units (where n is a natural number)
CRC processor unit	Operation executed on 8 bits in parallel	Operation executed on 32 bits in parallel
CRC generating polynomial	One of three generating polynomials that is selectable: [8-bit CRC] <ul style="list-style-type: none"> $X^8 + X^2 + X + 1$ (CRC-8) [16-bit CRC] <ul style="list-style-type: none"> $X^{16} + X^{15} + X^2 + 1$ (CRC-16) $X^{16} + X^{12} + X^5 + 1$ (CRC-CCITT) 	One of two generating polynomials that is selectable: [32-bit CRC] <ul style="list-style-type: none"> $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$ (CRC-32) $X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$ (CRC-32C)
CRC calculation switching	The bit order of CRC calculation results can be switched for LSB-first or MSB-first communication	
Module-stop function	Module-stop state can be set to reduce power consumption	
CRC snoop	Monitor reads from and writes to a certain register address	
TrustZone Filter	Security and Privilege attribution can be set	

Note 1. This function cannot divide data used in CRC calculations. Write data in 8-bit or 32-bit units.

Figure 36.1 CRC calculator block diagram

36.2 Register Descriptions

36.2.1 CRCCR0 : CRC Control Register 0

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x00

Bit position: 7 6 5 4 3 2 1 0

Bit field:	DORCLR	LMS	—	—	—	GPS[2:0]	
------------	--------	-----	---	---	---	----------	--

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
2:0	GPS[2:0]	CRC Generating Polynomial Switching 0 0 1: 8-bit CRC-8 ($X^8 + X^2 + X + 1$) 0 1 0: 16-bit CRC-16 ($X^{16} + X^{15} + X^2 + 1$) 0 1 1: 16-bit CRC-CCITT ($X^{16} + X^{12} + X^5 + 1$) 1 0 0: 32-bit CRC-32 ($X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$) 1 0 1: 32-bit CRC-32C ($X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$) Others: No calculation is executed	R/W
5:3	—	These bits are read as 0. The write value should be 0.	R/W
6	LMS	CRC Calculation Switching 0: Generate CRC code for LSB-first communication 1: Generate CRC code for MSB-first communication	R/W
7	DORCLR	CRCDOR/CRCDOR_HA/CRCDOR_BY Register Clear 0: No effect 1: Clear the CRCDOR/CRCDOR_HA/CRCDOR_BY register	W

Note: S-TYPE3, P-TYPE3

GPS[2:0] bits (CRC Generating Polynomial Switching)

The GPS[2:0] bits select the CRC generating polynomial.

LMS bit (CRC Calculation Switching)

The LMS bit selects the bit order of generated CRC code. Transmit the lower byte of the CRC code first for LSB-first communication and the upper byte first for MSB-first communication. For details on transmitting and receiving CRC code, see [section 36.3. Operation](#).

DORCLR bit (CRCDOR/CRCDOR_HA/CRCDOR_BY Register Clear)

Write 1 to the DORCLR bit to set the CRCDOR/CRCDOR_HA/CRCDOR_BY register to 0x00000000. This bit is read as 0. Only 1 can be written to it.

36.2.2 CRCCR1 : CRC Control Register 1

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x01

Bit position: 7 6 5 4 3 2 1 0

Bit field:	CRCS EN	CRCS WR	—	—	—	—	—
------------	---------	---------	---	---	---	---	---

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	CRCSWR	Snoop-On-Write/Read Switch 0: Snoop-on-read 1: Snoop-on-write	R/W
7	CRCSEN	Snoop Enable 0: Disabled 1: Enabled	R/W

Note: S-TYPE3, P-TYPE3

CRCSWR bit (Snoop-On-Write/Read Switch)

The CRCSWR bit selects the direction of access in the CRC snoop function.

When this bit is set to 0 (initial value), the CRC snoop operation to read a specific register is enabled. Similarly, when this bit is set to 1, the CRC snoop operation to write a specific register is enabled.

CRCSEN bit (Snoop Enable)

When the CRCSEN bit is set to 1, the CRC snoop operation is enabled. When this bit is set to 0, the CRC snoop operation is disabled.

36.2.3 CRCDIR/CRCDIR_BY : CRC Data Input Register

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x04

Bit position: 31 0

Bit field:

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	n/a	CRC input data The CRCDIR register is a 32-bit read/write register to write data for CRC-32 or CRC-32C calculation. The CRCDIR_BY (CRCDIR[31:24]) is an 8-bit read/write register to write data for CRC-8, CRC-16, or CRC-CCITT calculation.	R/W

Note: S-TYPE3, P-TYPE3

36.2.4 CRCDOR/CRCDOR_HA/CRCDOR_BY : CRC Data Output Register

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x08

Bit position: 31 0

Bit field:

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	n/a	CRC output data The CRCDOR register is a 32-bit read/write register for CRC-32 or CRC-32C calculation. The CRCDOR_HA (CRCDOR[31:16]) register is a 16-bit read/write register for CRC-16 or CRC-CCITT calculation. The CRCDOR_BY (CRCDOR[31:24]) register is an 8-bit read/write register for CRC-8 calculation. Because its initial value is 0x00000000, rewrite the CRCDOR/CRCDOR_HA/CRCDOR_BY register to perform the calculations using a value other than the initial value. Data written to the CRCDIR/CRCDIR_BY register is CRC calculated and the result is stored in the CRCDOR/CRCDOR_HA/CRCDOR_BY register. If the CRC code is calculated following the transferred data and the result is 0x00000000, there is no CRC error.	R/W

Note: S-TYPE3, P-TYPE3

36.2.5 CRCSAR : Snoop Address Register

Base address: CRC = 0x4031_0000
CRC_NS = 0x5031_0000

Offset address: 0x0C

Bit	Symbol	Function	R/W
13:0	CRCSA[13:0]	Register Snoop Address These bits store the TDR or RDR address in the SCI module to snoop	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

CRCSA[13:0] bits (Register Snoop Address)

The CRCSA[13:0] bits specify the lower address 14 bits of the register monitored by the CRC snoop operation.

Only the following addresses can be used for the CRCSA[13:0] bits:

[secure region address]

- 0x4035_8004: SCI0.TDR, 0x4035_8000: SCI0.RDR
- 0x4035_8104: SCI1.TDR, 0x4035_8100: SCI1.RDR
- 0x4035_8204: SCI2.TDR, 0x4035_8200: SCI2.RDR
- 0x4035_8304: SCI3.TDR, 0x4035_8300: SCI3.RDR
- 0x4035_8404: SCI4.TDR, 0x4035_8400: SCI4.RDR
- 0x4035_8904: SCI9.TDR, 0x4035_8900: SCI9.RDR

[non-secure region address]

- 0x5035_8004: SCI0.TDR, 0x5035_8000: SCI0.RDR
- 0x5035_8104: SCI1.TDR, 0x5035_8100: SCI1.RDR
- 0x5035_8204: SCI2.TDR, 0x5035_8200: SCI2.RDR
- 0x5035_8304: SCI3.TDR, 0x5035_8300: SCI3.RDR
- 0x5035_8404: SCI4.TDR, 0x5035_8400: SCI4.RDR
- 0x5035_8904: SCI9.TDR, 0x5035_8900: SCI9.RDR

36.3 Operation

36.3.1 Basic Operation

The CRC calculator generates CRC codes for use in LSB-first or MSB-first transfer.

The following examples show CRC code generation for input data (0xF0) using the 16-bit CRC-CCITT generating polynomial ($X^{16} + X^{12} + X^5 + 1$). In these examples, the value of the CRC Data Output Register (CRCDOR_HA) is cleared before CRC calculation.

When an 8-bit CRC (with the polynomial $X^8 + X^2 + X + 1$) is in use, the valid bits of the CRC code are obtained in CRCDOR_BY. When a 32-bit CRC is in use, the valid bits of the CRC code are obtained in CRCDOR.

Figure 36.2 and Figure 36.3 show the LSB-first and MSB-first data transmission examples respectively. Figure 36.4 and Figure 36.5 show the LSB-first and MSB-first data reception examples.

Figure 36.2 LSB-first data transmission

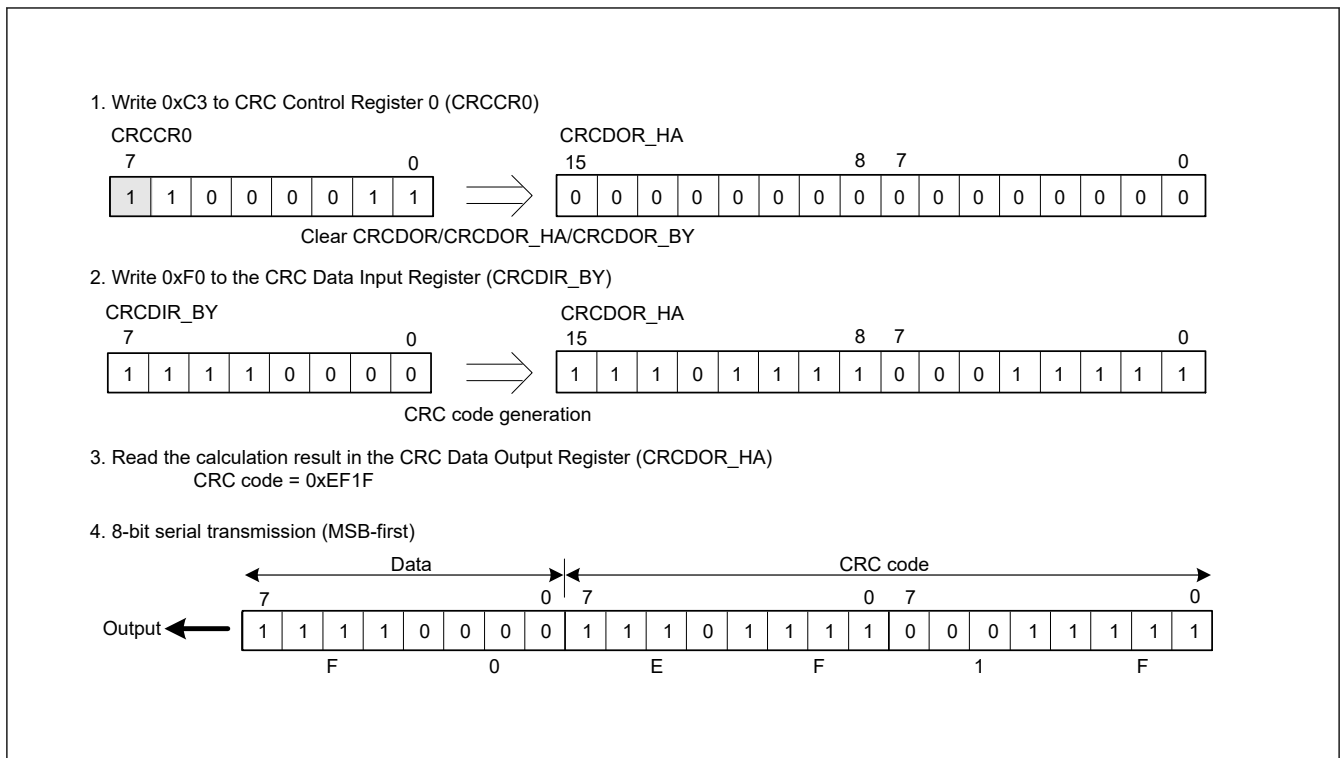

Figure 36.3 MSB-first data transmission

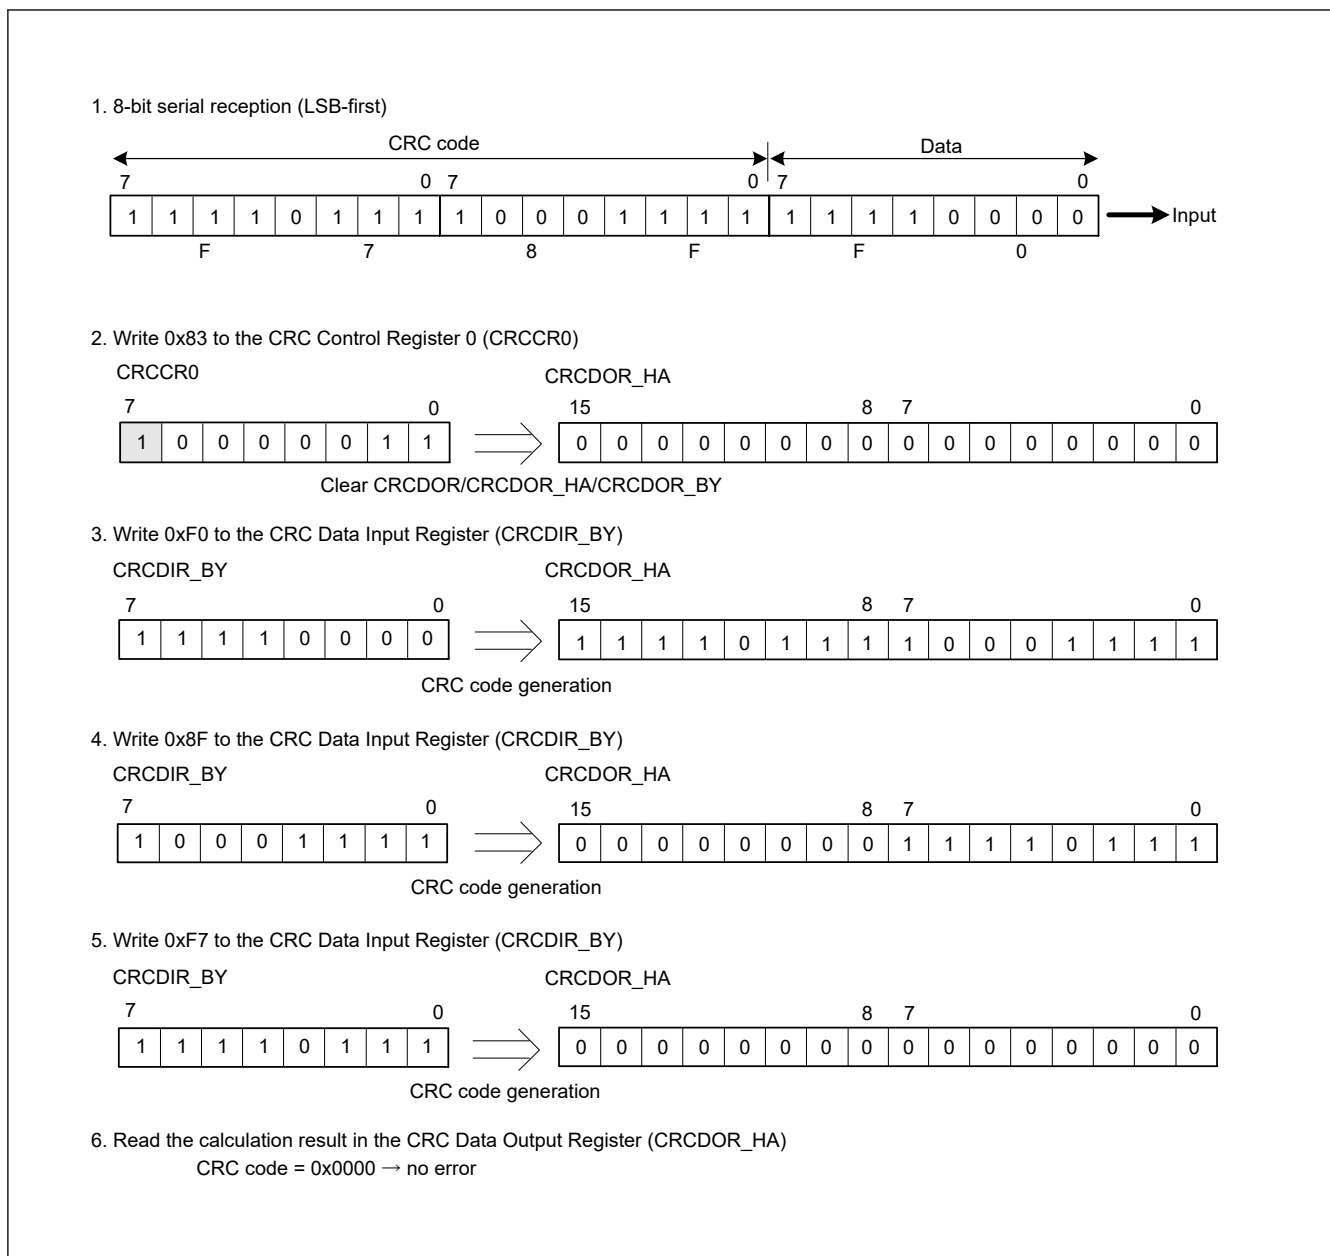

Figure 36.4 LSB-first data reception

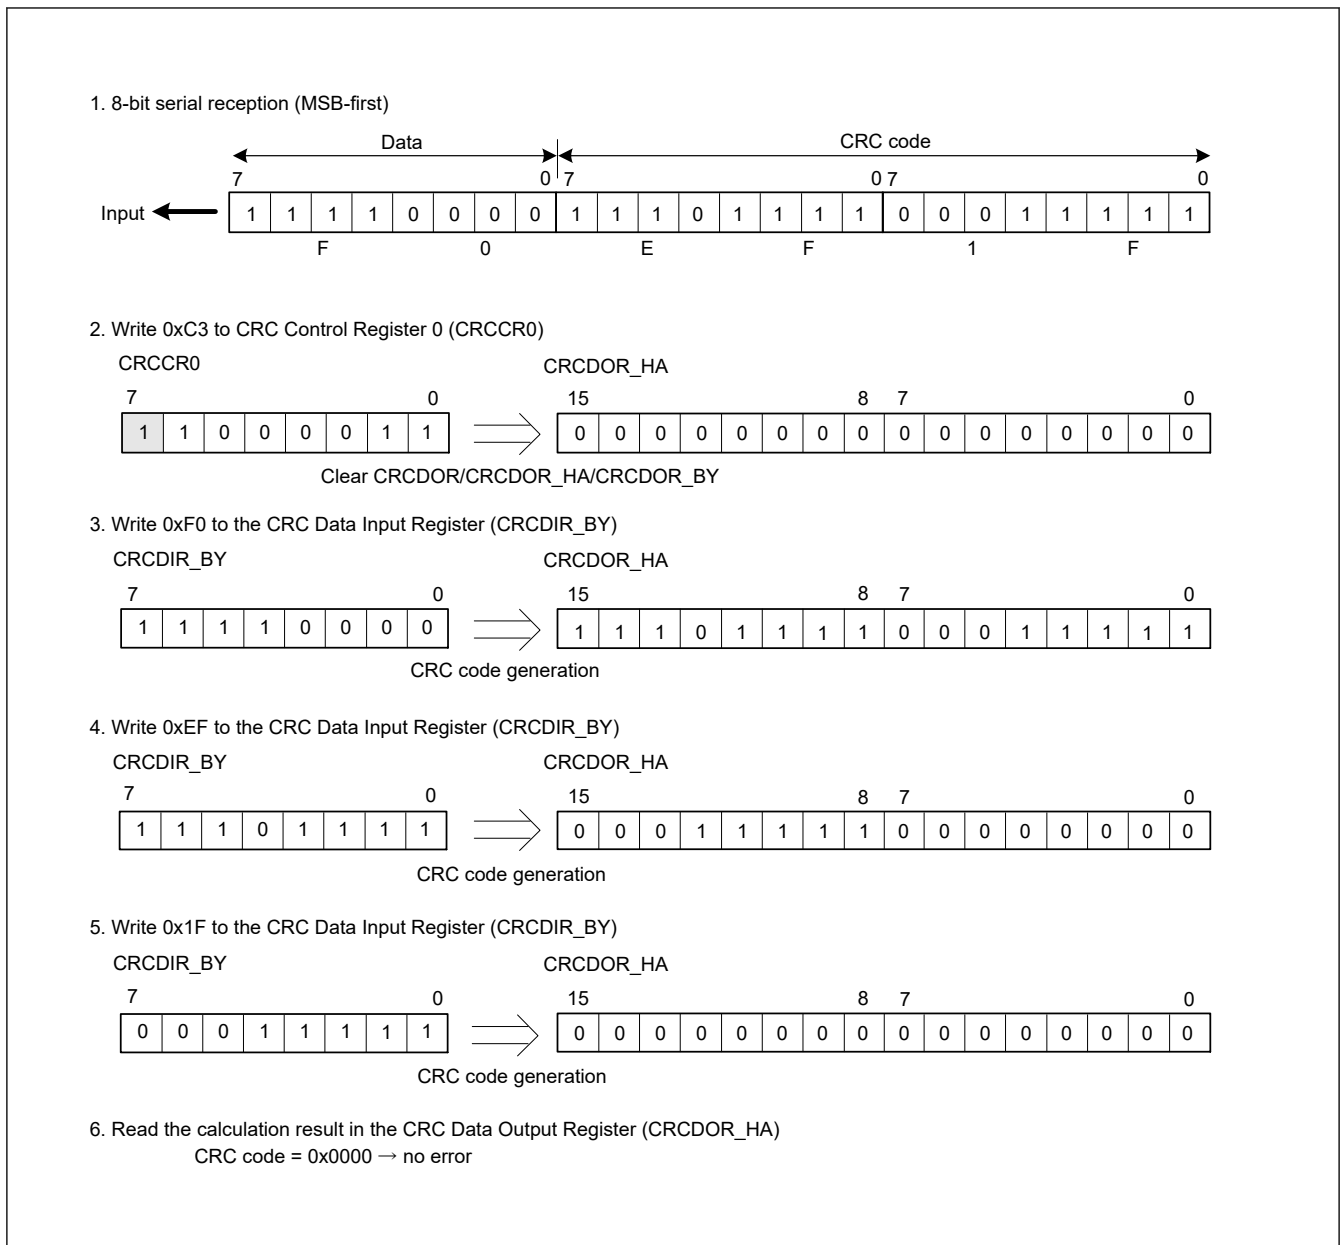

Figure 36.5 MSB-first data reception

36.3.2 CRC Snoop Function

The CRC snoop function monitors reads from and writes to a specific register and performs CRC calculation on the monitored data automatically. Because the CRC snoop function recognizes writes to and reads from a specific register address as a trigger to automatically perform CRC calculation, there is no need to write data to the CRCDIR register. All I/O register specified in the [section 36.2.5. CRCSAR : Snoop Address Register](#) are subject to the CRC snoop. The CRC snoop is useful in monitoring writes to the SCIn.TDR (n = 0 to 4, 9) register, and reads from the SCIn.RDR (n = 0 to 4, 9) register.

To use this function, write the lower address 14 bits of a specific register to bits CRCSA13 to CRCSA0 in the CRCSAR register, and set CRCSEN bit in the CRCCR1 register to 1. Then, set the CRCSWR bit in the CRCCR1 register to 1 to enable snooping on writes to the target register, or set the CRCSWR bit in the CRCCR1 register to 0 to enable snooping on reads from the target register. It is possible that access to a target I/O register may be executed before the CRCSWR bit write completed. In this case, the data is not stored in the CRCDIR register. To avoid this issue, before accessing I/O register, read back the CRCSWR bit that was written to confirm that the write completed.

When both the CRCSEN and CRCSWR bits are set to 1, and data is written to a target register in a bus master module such as the CPU, DMAC, and DTC, the CRC calculator stores the data in the CRCDIR register and performs CRC calculation. Similarly, when the CRCSEN bit is set to 1, CRCSWR bit to 0, and data is read from a target register in a bus master

module such as the CPU, DMAC, and DTC, the CRC calculator stores the data in the CRCDIR register and performs CRC calculations.

When the CRC code is generated by using CRC-8, CRC-16, and CRC-CCITT generating polynomial, the target register is accessed in 1 byte (8 bits). RDR_BY and TDR_LL should be used to access RDR and TDR. Similarly, when the CRC code is generated by using CRC-32 and CRC-32C generating polynomial, the target register is accessed in words (32 bits). Note that for RDR and TDR, CRC codes are generated that contain data other than RDAT and TDAT.

When CRC is marked as secure by PSARC.PSARC1 bit, the CRC snoop function is available for secure access to the specified I/O registers. When CRC is marked as non-secure by PSARC.PSARC1 bit, the CRC snoop function is available for non-secure access to the specified I/O registers.

36.4 Usage Notes

36.4.1 Settings for the Module-Stop State

The Module Stop Control Register C (MSTPCRC) can enable or disable CRC calculator operation. The CRC calculator is initially stopped after a reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

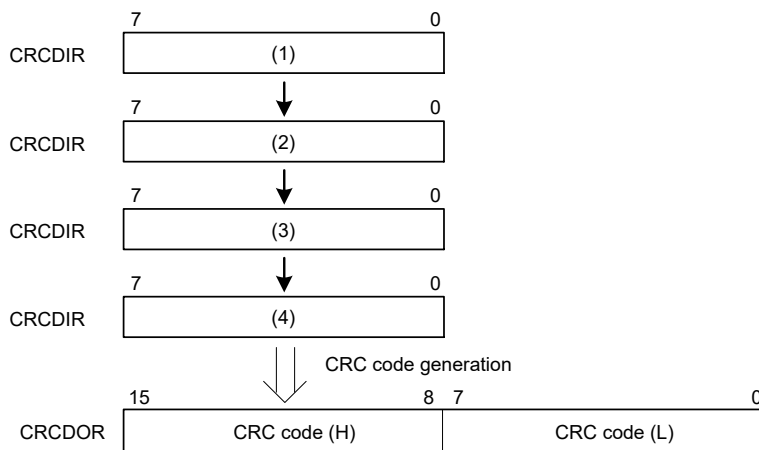

36.4.2 Note on Transmission

The transmission sequence for the CRC code differs based on whether the transmission is LSB-first or MSB-first. [Figure 36.6](#) shows an LSB-first and MSB-first data transmission.

When transmitting 32-bit data (for operation executed on 8 bits in parallel)

1. CRC code

After specifying the method for generation calculation, write data to CRCDIR in order of (1), (2), (3), and (4).

2. Transmit data

(i) When transmission is LSB-first

(ii) When transmission is MSB-first

Figure 36.6 LSB-first and MSB-first data transmission

37. Boundary Scan

37.1 Overview

The boundary scan function provides a serial I/O interface based on the JTAG (Joint Test Action Group), IEEE Std.1149.1, and IEEE Standard Test Access Port and Boundary Scan Architecture. [Table 37.1](#) lists the boundary scan specifications, [Figure 37.1](#) shows a block diagram, and [Table 37.2](#) lists the I/O pins.

Table 37.1 Boundary scan specifications

Parameter	Specifications
Execution condition	Boundary scan must be executed when the RES pin is driven low.
Test modes	<ul style="list-style-type: none"> • BYPASS mode • EXTEST mode • SAMPLE/PRELOAD mode • CLAMP mode • HIGHZ mode • IDCODE mode

Figure 37.1 Boundary scan function block diagram

Table 37.2 Boundary scan I/O pins

Pin name	I/O	Description
TCK	Input	Test clock input pin Clock signal for boundary scan. The input clock duty cycle is 50% when the boundary scan function is used.
TMS	Input	Test mode select pin
TDI	Input	Test data input pin
TDO	Output	Test data output pin

Note: This device does not support the TRST pin for the JTAG interface.

37.2 Register Descriptions

[Table 37.3](#) lists the boundary scan registers.

Table 37.3 Boundary scan registers

Register name	Symbol	Value after reset
Instruction Register	JTIR	0xE
ID Code Register	JTIDR	0x0841_9447
Bypass Register	JTBPR	Undefined
Boundary Scan Register	JTBSR	Undefined

Usage notes for the boundary scan registers:

- Instructions can be input to the Instruction Register (JTIR) through the TDI pin by serial transfer.
- The Bypass Register (JTBPR), which is a 1-bit register, is connected between the TDI and TDO pins in BYPASS mode.
- The Boundary Scan Register (JTBSR), which is configured according to the BSDL description, is connected between the TDI and TDO pins when test data is being shifted in.

Table 37.4 shows the availability of serial transfer for the registers.

Table 37.4 Serial transfer for registers

Register name	Serial input	Serial output
Instruction Register (JTIR)	Available	Available
ID Code Register (JTIDR)	Available	Available
Bypass Register (JTBPR)	Available	Available
Boundary Scan Register (JTBSR)	Available	Available

37.2.1 JTIR : Instruction Register

Bit	Symbol	Function	R/W																
3:0	TS[3:0]	Test Bit Set The command configuration for these bits	—																
		<table border="1"> <thead> <tr> <th>TS[3:0]</th> <th>Instruction</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>EXTEST</td> </tr> <tr> <td>0x1</td> <td>SAMPLE/PRELOAD</td> </tr> <tr> <td>0x3</td> <td>IDCODE (Renesas code)</td> </tr> <tr> <td>0x5</td> <td>CLAMP</td> </tr> <tr> <td>0x6</td> <td>HIGHZ</td> </tr> <tr> <td>0xF</td> <td>BYPASS</td> </tr> <tr> <td>Others</td> <td>Reserved</td> </tr> </tbody> </table>	TS[3:0]	Instruction	0x0	EXTEST	0x1	SAMPLE/PRELOAD	0x3	IDCODE (Renesas code)	0x5	CLAMP	0x6	HIGHZ	0xF	BYPASS	Others	Reserved	
TS[3:0]	Instruction																		
0x0	EXTEST																		
0x1	SAMPLE/PRELOAD																		
0x3	IDCODE (Renesas code)																		
0x5	CLAMP																		
0x6	HIGHZ																		
0xF	BYPASS																		
Others	Reserved																		

JTAG instructions can be transferred to the JTIR register by serial input from the TDI pin. The JTIR register is initialized when a power-on reset occurs, or when the TAP controller is in the Test-Logic-Reset state.

37.2.2 JTIDR : ID Code Register

Bit	Symbol	Function	R/W
31:0	DID[31:0]	Device ID These bits store the fixed value that indicates the device IDCODE (0x0841_9447).	—

The JTIDR register data is output from the TDO pin when the IDCODE instruction is executed. After a reset release, the DID[31:0] of JTIDR changes into the Arm® debug code. See the *Arm® CoreSight™ SoC-400 Technical Reference Manual* (ARM DDI 0480F).

37.2.3 JTBPR : Bypass Register

The JTBPR register is a 1-bit register and is connected between the TDI and TDO pins when the JTIR register is set to BYPASS mode. The JTBPR register cannot be read from or written to by the CPU.

37.2.4 JTBSR : Boundary Scan Register

The JTBSR register is a shift register for controlling the external input and output pins of this device, and is distributed across the pads. To apply the JTBSR register in boundary-scan testing, issue the EXTEST, SAMPLE/PRELOAD, CLAMP and HIGHZ instructions. The BSDL file describes the associations between the JTBSR register bits and the pins of this device. The value after reset is undefined.

37.3 Operation

During a reset, the JTAG ports, TCK, TMS, TDI and TDO are assigned as default pin functions. The TCK, TMS and TDI pins are pulled up by the pull-up resistors. Boundary scan testing can be executed after the setup time elapses when POR is negated and RES is driven low.

37.3.1 TAP Controller

[Figure 37.2](#) shows the state transition diagram of the TAP controller. All transitions are controlled by the TMS signal.

Figure 37.2 State transition diagram of TAP controller

37.3.2 Commands

(1) BYPASS

The BYPASS instruction drives the Bypass Register (JTBPB). This instruction shortens the shift path, facilitating the transfer of serial data to other LSIs on a printed circuit board at higher speeds. While this instruction is being executed, the test circuit has no effect on the system circuits.

The JTBPB register is connected between the TDI and TDO pins. Bypass operation is initiated from the Shift-DR operation. The TDO is low in the first clock cycle in the Shift-DR state. In the subsequent clock cycles, values input to the TDI pin are output from the TDO pin.

(2) EXTEST

The EXTEST instruction is used to test external circuits when this device is installed on the printed circuit board. If this instruction is executed, output pins are used to output test data (specified in the SAMPLE/PRELOAD instruction) from the Boundary Scan Register (JTBSR) to the other devices, and input pins are used to input the test result.

(3) SAMPLE/PRELOAD

The SAMPLE/PRELOAD instruction is used to input data from the internal circuits of this device to the JTBSR register, output data from the scan path, and reload the data to the scan path. While this instruction is executed, input signals are directly input to this device and output signals are also directly output to the external circuits. This device system circuit is not affected by this instruction.

In SAMPLE operation, the JTBSR register latches a snapshot of the data transferred from the input pins to the internal circuit or data transferred from the internal circuit to the output pins. The latched data is read from the scan path. The JTBSR register latches the data snapshot on the rising edge of the TCK pin in the Capture-DR state. The data snapshot is only transferred from the internal circuit to the output pins during a reset.

In PRELOAD operation, the initial value is written from the scan path to the parallel output latch of the JTBSR register prior to the EXTEST instruction execution. If EXTEST is executed without executing this PRELOAD operation, undefined values are output from the beginning to the end (transfer to the output latch) of the EXTEST sequence. (In the EXTEST instruction, output parallel latches are always output to the output pins.)

(4) IDCODE

When the IDCODE instruction is selected, the ID Code Register (JTIDR) value is output to the TDO pin in the Shift-DR state of the TAP controller. In this case, the JTIDR register value is output LSB-first. During this instruction execution, the test circuit does not affect the system circuit.

(5) CLAMP

When the CLAMP instruction is selected, output pins output the JTBSR register value that was specified in the SAMPLE/PRELOAD instruction in advance. While the CLAMP instruction is selected, the status of the JTBSR register is maintained regardless of the TAP controller state.

The JTBPR register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction is selected.

(6) HIGHZ

When the HIGHZ instruction is selected, all output pins enter high-impedance state. While the HIGHZ instruction is selected, the JTBSR register is maintained regardless of the state of the TAP controller.

The JTBPR register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction is selected.

37.4 Usage Notes

The boundary scan function is subject to the following constraints:

- The boundary scan must be executed when the RES pin is driven low
- Serial data input/output is in LSB order, as shown in [Figure 37.3](#)

Figure 37.3 Serial data input/output

The following pins cannot be boundary-scanned:

- Power supply pins (VCC, VCC2, VCC_DCDC, VCL, VSS, VSS_DCDC, VBATT, AVCC0, AVSS0, VCC_USB, VSS_USB)
- Analog reference pins (VREFH0, VREFL0, VREFH, VREFL)
- Clock pins (EXTAL, XTAL, XCIN, and XCOU)
- Reset pin (RES)
- USBFS pin (USB_DP, USB_DM)
- The boundary-scan pins (TCK, TMS, TDI, and TDO).
- The switching regulator pin (VLO)

38. Security Features

38.1 Features

- Armv8-M TrustZone Technology
 - Implementation Defined Attribution Unit (IDAU) is implemented
 - Security Attribution Unit (SAU) is implemented
 - 8 regions
 - Master Security Attribution Unit (MSAU) is implemented (IDAU for master other than CPU)
 - Code flash
 - Up to 2 regions (secure/non-secure) in linear mode
 - Up to 4 regions (2 secure regions/2 non-secure regions) in dual mode
 - Data flash
 - Up to 2 regions (secure/non-secure)
 - SRAM
 - Up to 2 regions (secure/non-secure) per SRAM
 - Standby SRAM
 - Up to 2 regions (secure/non-secure)
 - VBATT backup registers
 - Up to 2 regions (secure/non-secure)
 - Peripheral
 - Security attributes can be set individually for each unit/channel
 - CSC^{*1}
 - CSC region is defined as non-secure
 - SDRAM^{*1}
 - SDRAM region is defined as non-secure
 - OSPI^{*1}
 - OSPI region is defined as non-secure
- Privileged control
 - Access permissions for memory except Standby SRAM and VBATT backup register are controlled by MPU managed by the privileged code
 - Privilege attributes of Standby SRAM and VBATT backup register are controlled by the registers of each controller
 - Individual privileged or Unprivileged attribution for each peripheral.
- Device lifecycle management
- Three debug levels
 - AL2: Non-secure and secure debug functions are enabled and accessible from the debugger
 - AL1: Only non-secure debug functions is enabled, and the debugger can access only defined non-secure debug accessible regions
 - AL0: No debug functions are available.
- Key injection
- Secure factory programming
 - Supports image programming in ciphertext format in an untrusted factory
- Cryptographic accelerator

- See [section 39, Renesas Secure IP \(RSIP-E51A\)](#).
- Secure pin multiplexing
 - All I/O port pins can be configured individually as secure or non-secure
 - Peripheral pin function is valid when the security attribute of peripheral and I/O port match. See [section 19, I/O Ports](#).

Note 1. There is no TrustZone filter in the external RAM and external device area. Therefore, even if these regions are marked as secure in the SAU settings, non-secure masters except the CPU can access them.

38.2 Tamper Detection

The device is provided with I/O ports capable of detecting an external tamper attempt. In the case of a tamper event:

- Timestamping
The RTC can take a timestamp to log the event, and an interrupt can be generated. See [section 24, Realtime Clock \(RTC\)](#).
- VBATT backup registers
VBATT backup registers are zeroized (set to zero) following detection of a tamper event. See [section 11, Battery Backup Function](#).

38.3 Arm Security Features

38.3.1 Arm TrustZone Technology

Arm TrustZone technology divides the system and the application into secure and non-secure domains. A secure application can issue both secure and non-secure transactions, but a non-secure application can only issue non-secure transactions. Secure transactions can only access secure memory and resources, and non-secure transactions can only access non-secure memory and resources. Secure transactions can be issued only using secure region addresses and non-secure transactions can be issued only using non-secure region addresses. [Figure 38.1](#) shows the security attributes of transactions that can be issued by each master.

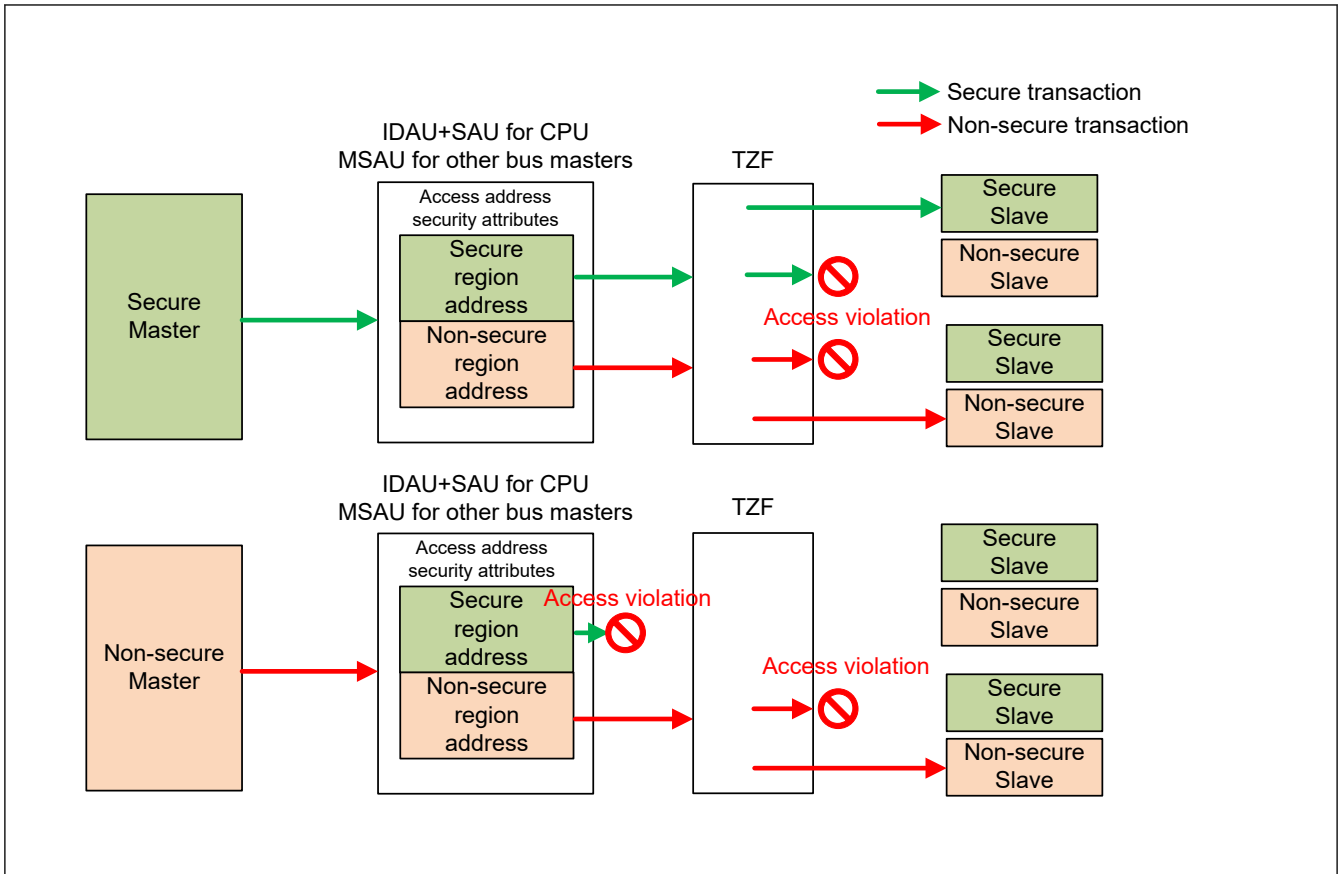

Figure 38.1 Transactions that can be issued by each master

For more details, see the *Arm® v8-M Architecture Reference Manual* and *Arm® Platform Security Architecture Trusted Base System Architecture for Arm®v8-M 1.0*.

38.3.2 Privileged Control

Systems and applications are divided into privileged and unprivileged domains. The CPU can limit or exclude access to some resources by executing code in privileged or unprivileged mode. Privileged mode can access both privileged and unprivileged domains, but unprivileged mode can access only the unprivileged domain.

For more details, see the *Arm® v8-M Architecture Reference Manual* and *Arm® Platform Security Architecture Trusted Base System Architecture for Arm®v8-M 1.0*.

38.3.3 Security Attribution

The TrustZone for Armv8.1-M implementation consists of the Security Attribution Unit (SAU) and Implementation Defined Attribution Unit (IDAU). The 4GB memory space is partitioned into Secure (S) and Non-secure (NS) memory regions. The Secure memory space is further divided into two types, Non-secure Callable (NSC) and Secure.

- Note:
- S = Secure addresses are used for memory and peripherals that are only accessible by secure software or secure masters.
 - NSC = A special type of secure location. This type of memory is the only type in which an Armv8.1-M processor permits to hold a Secure Gateway (SG) instruction that enables software to transition from Non-secure to Secure state.
 - NS = Non-secure addresses are used for memory and peripherals accessible by all software running on the device.

38.3.3.1 Implementation Defined Attribution Unit (IDAU)

The IDAU defines the code, SRAM and peripheral region into the secure alias region and the non-secure alias region by the address bit [28]. The secure code region and secure SRAM region are assigned the NSC security attributes. The security map defined by IDAU is fixed in hardware and cannot be changed by software.

38.3.3.2 Master Security Attribution Unit (MSAU)

MSAU is IDAU that defines system-specific security address map for masters other than CPU. The MSAU defines secure and non-secure alias regions but does not define the Non-secure Callable (NSC) and region number. Masters other than the CPU can issue a security transaction using the secure alias address defined by MSAU. However, non-secure masters are prohibited from issuing secure transactions using an address in the secure alias region. Figure 38.2 shows the defined security map of IDAU and MSAU. The security map defined by MSAU is fixed in hardware and cannot be changed by software.

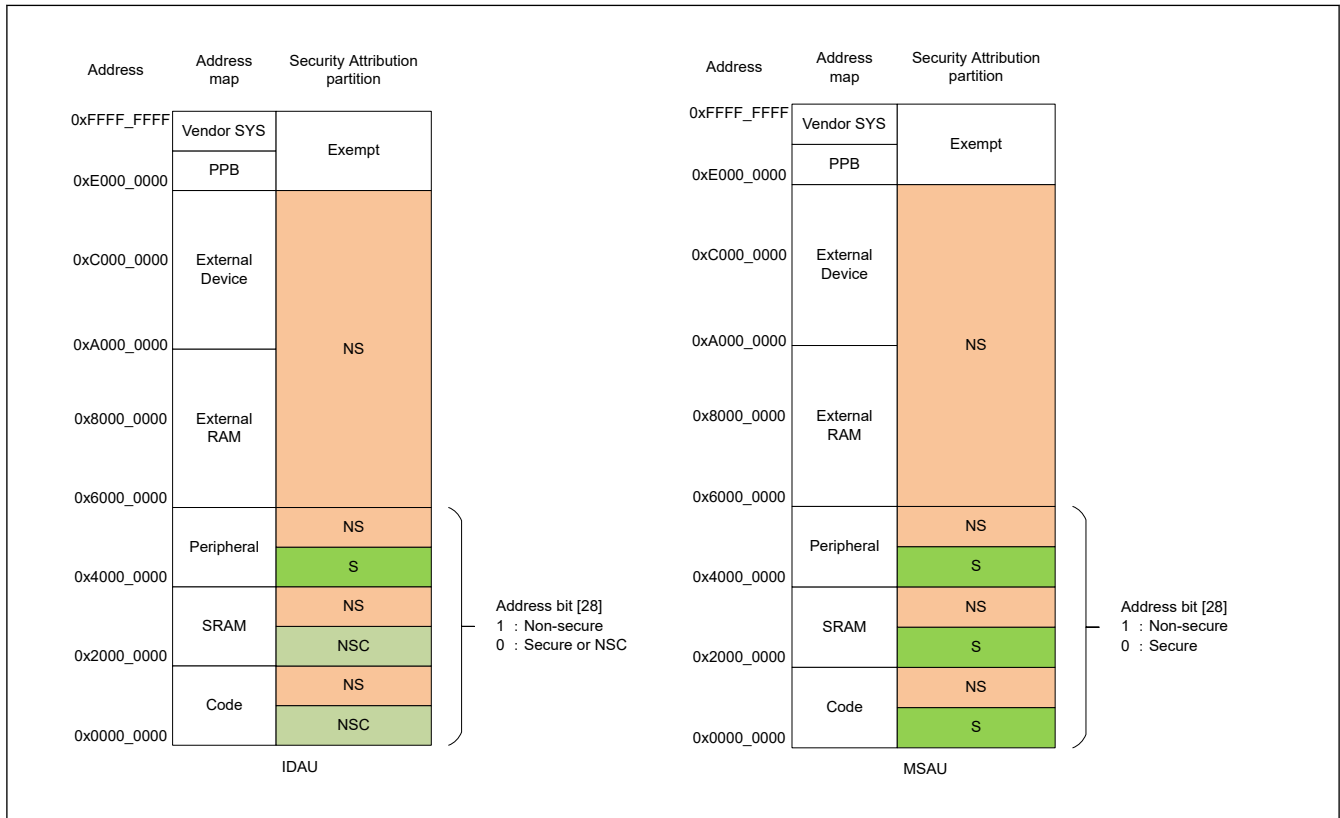

Figure 38.2 IDAU and MSAU defined security map

38.3.3.3 Secure Attribution Unit (SAU)

The SAU is a programmable unit that determines the security of an address. The SAU is programmable in the Secure state and has a programmers' model similar to the MPU. If an address maps to regions defined by both IDAU and SAU, the region of the highest security level is selected. Secure master can issue secure and non-secure transactions using the address of each security alias region. Non-secure master cannot issue secure transactions using the address of the secure alias region. Figure 38.3 shows the final determination of the address map security level.

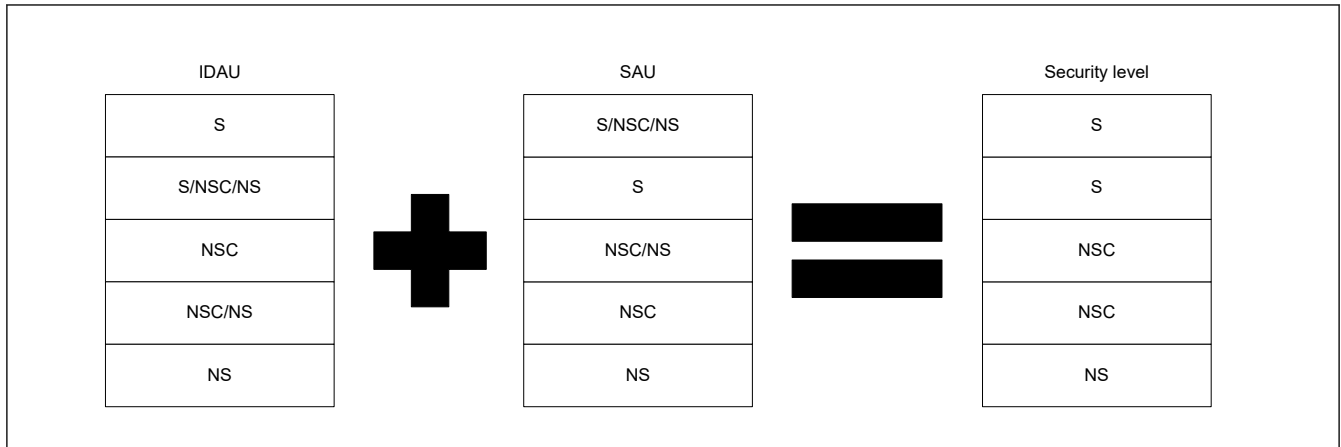

Figure 38.3 Final determination of address map security level

When using TrustZone to perform secure and non-secure region separation, SAU MUST be set according to the following. The regions set as NS attribute in IDAU MUST be set to NS in the SAU as well. The regions set to NS attribute in IDAU are:

0x1000_0000 to 0x1FFF_FFFF (SAU Region 1 in [Figure 38.4](#))

0x3000_0000 to 0x3FFF_FFFF (SAU Region 3 in [Figure 38.4](#))

0x5000_0000 to 0xDFFF_FFFF (SAU Region 3 in [Figure 38.4](#))

At least one NSC region MUST be created within any region defined as NSC by the IDAU. The regions set to NSC attribute by the IDAU are:

0x0000_0000 to 0x0FFF_FFFF (SAU Region 0 in [Figure 38.4](#))

0x2000_0000 to 0x2FFF_FFFF (SAU Region 2 in [Figure 38.4](#))

If you do not wish to define any isolation by means of using TrustZone, do not change SAU_CTRL.ALLNS = 0 and SAU_CTRL.ENABLE = 0 (initial value).

Figure 38.4 SAU settings and resulting security attributes

38.3.3.4 Region Number

The SAU and IDAU also define region numbers for each of the memory regions and security attributes. This region number is used by software to determine if a contiguous range of memory shares common security attributes. Figure 38.5 shows the defined region number of IDAU.

Address	Address map	Security Attribution partition	Region number
0xFFFF_FFFF	Vendor SYS	Exempt	0
0xE000_0000	PPB		
0xC000_0000	External Device	NS	6
0xA000_0000			
0x8000_0000	External RAM		
0x6000_0000			
0x4000_0000	Peripheral	S	5
0x2000_0000	SRAM	NS	4
		NSC	3
0x0000_0000	Code	NS	2
		NSC	1

Figure 38.5 IDAU defined region numbers

38.3.3.5 Memory Security Attribution of TrustZone filter

The memories are divided into S and NS regions. The memory security attribution of code flash and data flash is stored into nonvolatile memory by a boot firmware command when the device lifecycle is in the OEM state and the authentication level is AL2. These memory security attributions are applied before application execution. They cannot be updated by the application but are readable using dedicated registers. The memory security attributions of SRAM, standby SRAM, and VBATT backup registers are set by a dedicated security attribution register writable only by secure access.

The code flash can be divided in up to two regions in linear mode and four regions in dual mode. The partitioning is the same between bank0 and bank1 in the dual mode. The data flash can be divided in up to two regions. SRAM, standby SRAM, and VBATT backup registers can be divided in up to two regions. Figure 38.6 shows the memory mapping. Table 38.1 shows size of the memory region and Table 38.2 shows access permission of the memory region.

It is prohibited to place Secure or Non-secure Callable regions in a block swappable area in linear mode because the secure application would be placed in the non-secure region after block swapping.

Bank swapping by the Non-secure user may change the code in the Secure or Non-secure callable areas. The following is recommended to prevent this.

- Set BANKSEL_SEL.BANKSWP[2:0] = 000b to disable the bank swapping for Non-secure users.
- Make the code in Secure or Non-secure callable areas for both banks the same when allow Non-secure user to swap banks.

See section 38.7. Field Updating in Dual Mode.

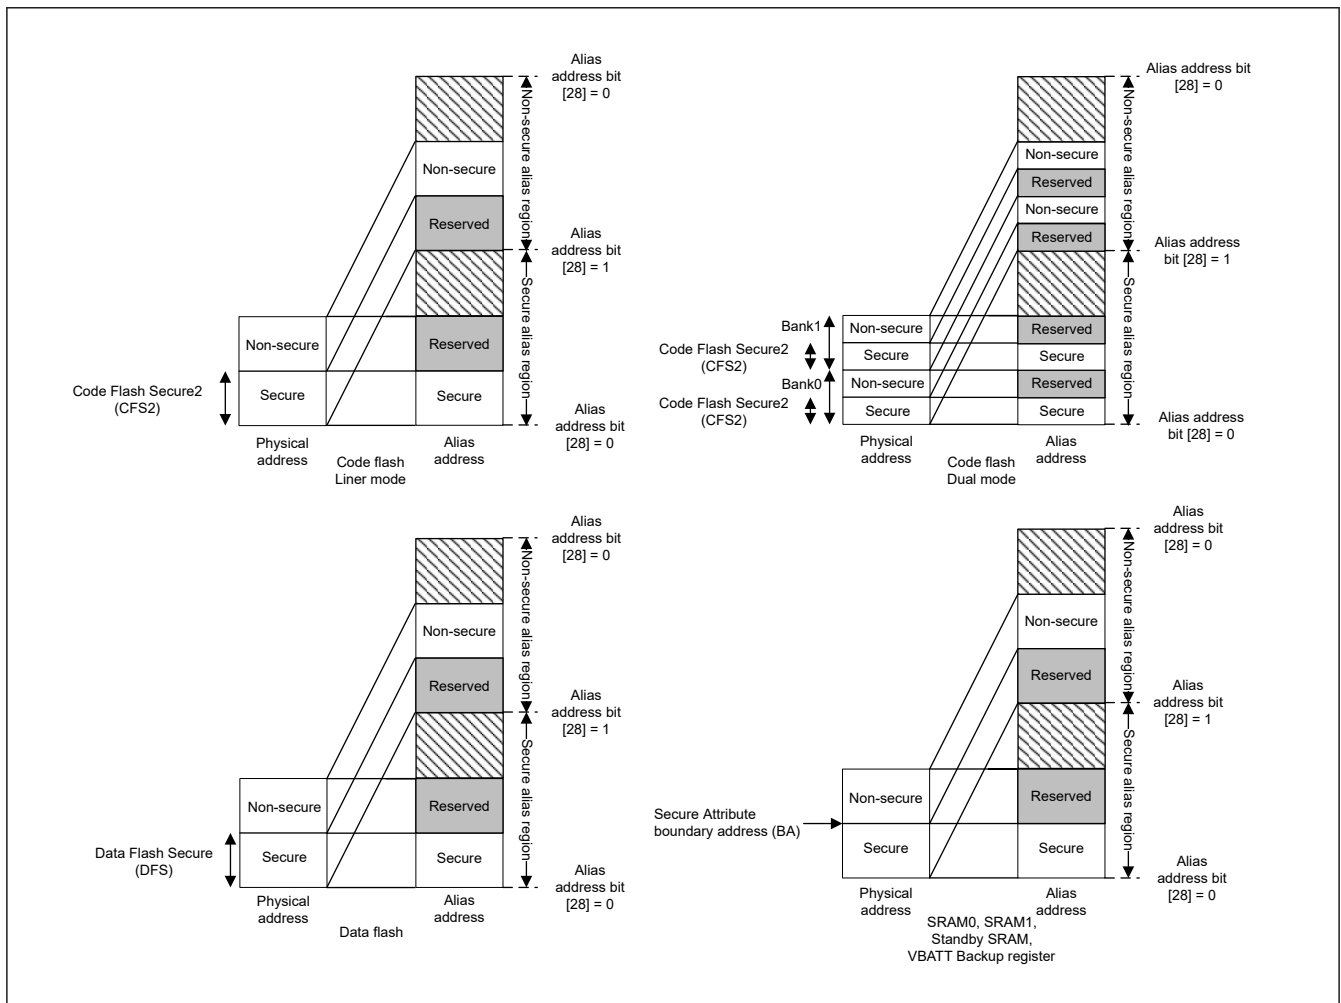

Figure 38.6 Memory mapping

Table 38.1 Size of memory region (1 of 2)

Memory region		Start address	Size
Linear mode	Code flash secure	0x0200_0000	CFS2 size (32 KB)
	Code flash non-secure	0x1200_0000 + CFS2 size (32 KB)	Code flash size - CFS2 size (32 KB)
Dual mode	Code flash bank0 secure	0x0200_0000	CFS2 size (32 KB)
	Code flash bank0 non-secure	0x1200_0000 + CFS2 size (32 KB)	Code flash size/2 - CFS2 size (32 KB)
	Code flash bank1 secure	0x0220_0000	CFS2 size (32 KB)
	Code flash bank1 non-secure	0x1220_0000 + CFS2 size (32 KB)	Code flash size/2 - CFS2 size (32 KB)
Data flash secure		0x2700_0000	DFS size (1 KB)
Data flash non-secure		0x3700_0000 + DFS size (1 KB)	Data flash size - DFS size (1 KB)
SRAM0 secure		0x2204_0000	BA (8 KB)
SRAM0 non-secure		0x3204_0000 + BA (8 KB)	SRAM0 size - BA (8 KB)
SRAM1 secure		0x2206_0000	BA (8 KB)
SRAM1 non-secure		0x3206_0000 + BA (8 KB)	SRAM1 size - BA (8 KB)
Standby SRAM secure		0x2600_0000	BA (128 bytes)
Standby SRAM non-secure		0x3600_0000 + BA (128 bytes)	Standby SRAM size - BA (128 bytes)
VBATT backup register secure		0x4001_ED00	BA (32 bytes)

Table 38.1 Size of memory region (2 of 2)

Memory region	Start address	Size
VBATT backup register non-secure	0x5001_ED00 + BA (32 bytes)	Backup register size - BA (32 bytes)

Note: The number in parentheses indicates the smallest unit that can be set by the user.

Note: BA is the setting value of the security attribution boundary address register for each memory region.

Table 38.2 Access permission of the memory region

Memory region	Secure transaction	Non-secure transaction
Each memory region configured as S or NSC	Allowed	Write ignored/Read ignored TrustZone access error is generated
Each memory region configured as NS	Write ignored/Read ignored TrustZone access error is generated	Allowed

38.3.3.6 Peripheral Security Attribution of TrustZone filter

Each peripheral can be configured as secure or non-secure. Peripherals are divided into two types.

Type1 peripheral has one security attribution and access to all registers is controlled by one security attribution. Type1 peripheral security attribution is set to the PSARx (x = B to E) register by the secure application.

Type2 peripheral has the security attribution for each register or for each bit and access to each register or bit field is controlled according to these security attributions. Type2 peripheral security attribution is set to the Security Attribution register in each module by the secure application. For details on the Security Attribution register, see each section.

Table 38.3 shows the classification of peripheral type.

Table 38.3 Classification of peripheral type

Type1	Type2
SCI, SPI, OSPI, USBFS, IIC, RSIP-E51A, CANFD, DRW, GLCDC, DOC, SSIE, CRC, CAC, ACMPHS, TSN, ADC12, DAC12, POEG, AGT, GPT, ULPT, RTC, IWDT, and WDT	System control (Resets, PVD, Clock Generation Circuit, Low Power Modes, Battery Backup Function), Flash memory controller, Flash cache, SRAM controller, CPU cache, DMAC, DTC, ICU, MPU, BUS, Security setting, ELC, and I/O ports

Table 38.4 shows the access permission of type1 peripherals. The access permission of type2 peripherals is different by peripherals. See the register description of each peripherals for details.

Table 38.4 Access permission of type1 peripherals

	Secure access	Non-secure access
Peripheral configured as S	Allowed	Write ignored/Read ignored TrustZone Access error is generated
Peripheral configured as NS	Write ignored/Read ignored TrustZone access error is generated	Allowed

38.3.4 TrustZone Access Error

Table 38.5 shows the behavior when TrustZone access error occurs. The behavior varies depending on the master or the slave area to be accessed.

Table 38.5 Behavior of TrustZone access error

DAP	CPU	DMAC/DTC	DRW	GLCDC
<ul style="list-style-type: none"> Only error response is returned^{*1} 	<ul style="list-style-type: none"> IDAU/SAU detects SecureFault exception TrustZone filter detects BusFault exception Can issue a reset^{*2} 	<ul style="list-style-type: none"> Stop transfer Issue NMI or reset^{*2} Generate interrupt (DMA0_TRANSERR) 	<ul style="list-style-type: none"> Stop next transfer Issue NMI or reset^{*2} Generate interrupt (DRW_IRQ)^{*3} 	<ul style="list-style-type: none"> Issue NMI or reset^{*2}

Note: This behavior is not applicable for bufferable write access. For more information on when a bufferable write access error is detected, see [section 14.7.2. Operations When a Bus Error Occurs](#).

- Note 1. When a TrustZone access error occurs by a debugger access, exception, NMI, or reset does not occur. Only the error response is returned.
- Note 2. The operation after error detection is selected by the BUSOAD.SRERROAD bit.
- Note 3. Access error flag in STATUS.BUSIRQ is set. The interrupt occurs when it is enabled in IRQCTL.BUSIRQEN bit.

38.4 Device Lifecycle Management

Device Lifecycle Management (DLM) identifies the current development/production/deployment phase of the device and controls the capabilities of the debug function, the serial programming interface, and Renesas test mode. Figure 38.7 shows the available device lifecycle states and Table 38.6 shows the lifecycle state definitions and capabilities in each state.

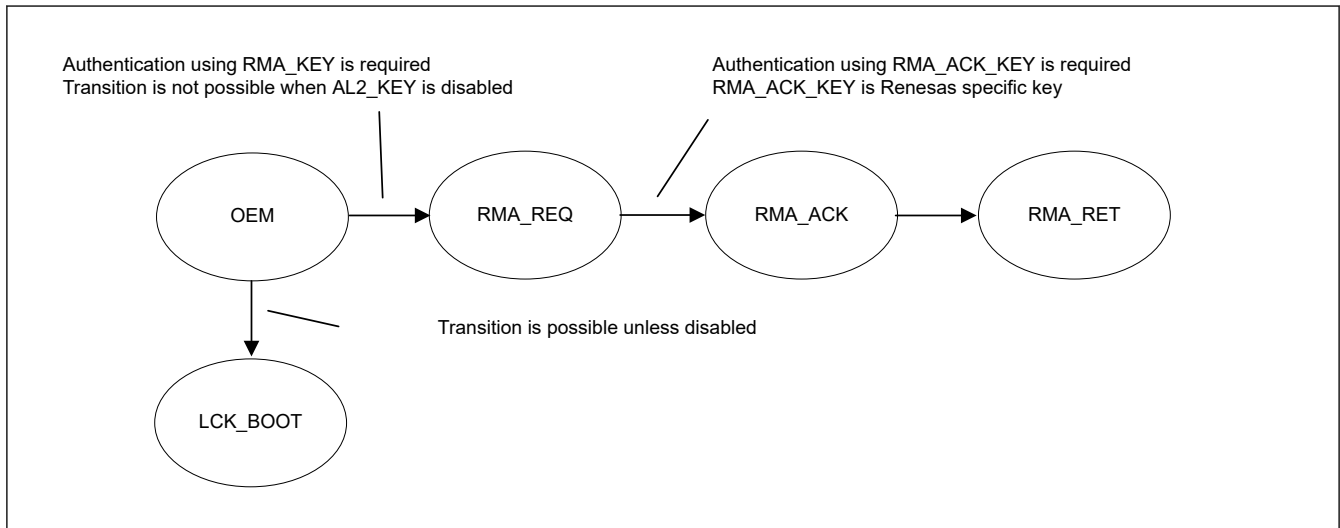

Figure 38.7 Device lifecycle states

Table 38.6 Lifecycle state definition and capabilities in each state

Lifecycle	Definition	Protection level	Debug function	Serial programming	Renesas test mode
OEM	“Original Equipment Manufacturer” The device is owned by the customer. The customer receives the device in this state.	PL2 or PL1 or PL0	Depend on the authentication level		Not available
LCK_BOOT	“LoCKed BOOT interface” The debug interface and the serial programming interface are permanently disabled.	PL0	Not available	Not available	Not available
RMA_REQ	“Return Material Authorization REQuest” Request for RMA. The customer must send the device to Renesas in this state.	PL0	Not available	Available Cannot access code/ data flash area	Not available
RMA_ACK	“Return Material Authorization ACKnowledged” Failure analysis in Renesas	PL2	Available in the secure and non-secure debug	Available Cannot access code/ data flash area	Available
RMA_RET	“Return Material Authorization RETurn” The device is back to the customer. The device does not boot.	PL0	Not available	Not available	Not available

38.4.1 Changing the Lifecycle State

Use the boot firmware commands to change the device lifecycle state. These commands are available via the boot firmware's UART and USB interfaces, plus SWD/JTAG. See the boot firmware application note for details of the command. The lifecycle state cannot be updated by an application, but the current lifecycle state can be read through the dedicated registers.

As shown in Figure 38.7, each transition is one-way and the state cannot be regressed.

Transition from OEM to RMA_REQ requires key authentication using the RMA_KEY which must have been previously injected by the customer. The key length of the RMA_KEY is 128 bits. Inject the RMA_KEY as shown in [section 38.5. Secure Key Injection](#). RMA_KEY can be injected in AL2.

The key authentication uses a challenge and response authentication or authentication using the MCU's unique ID. The response (challenge and response authentication) or the authentication code (using the MCU's unique ID) can be calculated as follows:

Response = AES-128 CMAC (RMA_KEY, 128-bit challenge)

Authentication code = AES-128 CMAC (RMA_KEY, 128-bit MCU unique ID)

The contents of the flash memory except permanently locked blocks or registers are erased when transitioning to RMA_REQ. The contents of the permanently locked blocks or registers can be read by Renesas at failure analysis. A flash block can permanently be locked by setting the PBPS/PBPS_SEC and BPS_SEL registers to permanently disable programming and erasure of the block. The SAS register can be permanently locked by the FSPR bit, permanently disabling programming and erasure of the register. Transition to RMA_REQ is not possible if the AL2_KEY is disabled. The MCU does not respond after changing the device lifecycle state to RMA_REQ. To continue to use boot firmware commands, you must enter boot mode again after a reset. See the boot firmware application note for details.

Transition from OEM to LCK_BOOT is possible unless that transition has been explicitly disabled. Use the parameter setting command in AL2 or AL1 to prohibit the transition to LCK_BOOT. The LCK_BOOT transition prohibition is a permanent setting and cannot be undone. The debug interface and serial programming interface are permanently disabled in LCK_BOOT.

38.4.2 Protection and Authentication Level

The protection level (PL) and the authentication level (AL) determine the availability of the debug function and the serial programming interface. PL and AL are fixed except in the OEM state. For PL and for AL, three levels can be set for each in the OEM state. AL indicates a temporary authentication status and is initialized to PL after an MCU power-on reset. Both PL and AL can be changed only by the boot firmware and cannot be changed by the application. [Figure 38.8](#) shows the available Protection Level and Authentication Level states and transitions. [Table 38.7](#) shows the availability of the debug function and the serial programming interface in each level.

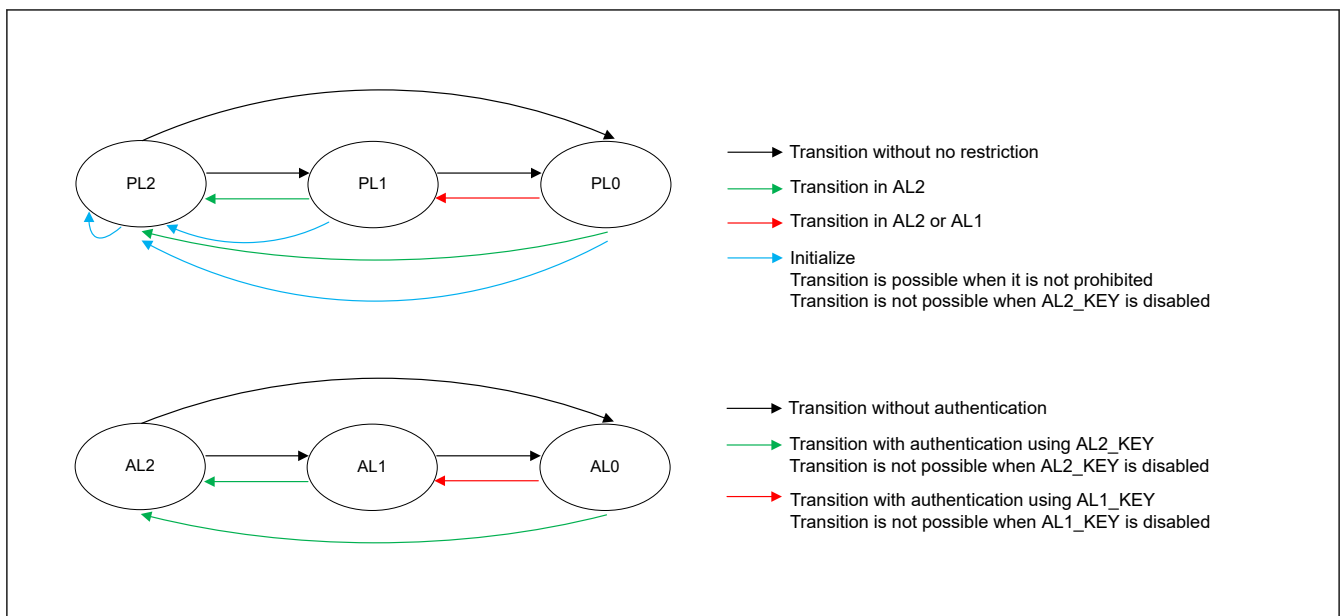

Figure 38.8 PL and AL states and transitions

Table 38.7 Availability of the debug function and the serial programming interface in each authentication level (1 of 2)

AL	Debug function	Serial programming interface
AL2	Non-secure and Secure debug functions are enabled and accessible from the debugger	All functions are available

Table 38.7 Availability of the debug function and the serial programming interface in each authentication level (2 of 2)

AL	Debug function	Serial programming interface
AL1	Only non-secure debug function is enabled, and debugger can access only defined non-secure debug accessible regions	Available but cannot program, erase, or read secure code or data flash area
AL0	No debug functions are available	Available but cannot access code or data flash area

Use the boot firmware commands to change PL and AL. See the boot firmware application note for details of the command.

Changing to a lower PL can be done with no restriction. Changing to a higher PL requires that the MCU be at that AL or higher. For example, when the current AL is AL1, changing to PL1 is possible but changing to PL2 is impossible. PL can be reset by the Initialize command unless the command itself is disabled. The Initialize command will set the PL to PL2 and the content in the flash memory will be erased. If there are any permanently locked blocks or registers, the Initialize command does not execute. In other words, when all the bits of the PBPS and PBPS_SEC registers are 1 and the FSPR bit is 1, the Initialize command is executable. The Initialize command can be disabled permanently in all AL states by the parameter setting command to prevent users from erasing the contents of flash memory. The Initialize command is disabled also when AL2_KEY is disabled. The MCU does not respond after executing the Initialize command. To continue to use the boot firmware commands, enter boot mode again after a reset. See the boot firmware application note for details.

Changing to a lower AL can be done without authentication. Changing to a higher AL requires key authentication using AL2_KEY or AL1_KEY, as appropriate. These keys are 128-bit keys. Injection of AL2_KEY or AL1_KEY is performed as shown in [section 38.5. Secure Key Injection](#). AL2_KEY can be injected in AL2, AL1_KEY can be injected in AL2 or AL1. The key authentication uses a challenge and response authentication. The response can be calculated as follows:

Response = AES-128 CMAC (KEY, 128 bits challenge)

AL2_KEY can be disabled permanently in AL2 by parameter setting command. AL1_KEY can be disabled permanently in AL2 or AL1 by parameter setting command.

38.4.3 Serial Programming

Whether a serial programmer can be connected and the range of flash memory that can be accessed depends on the device lifecycle state and AL as shown in [Table 38.6](#) and [Table 38.7](#). In addition, the accepted serial programming commands differ depending on the device lifecycle state and AL. See the boot firmware application note for details of the commands.

38.4.4 Device Lifecycle State and PL Change Example

The following section describes a typical device lifecycle state and PL change example.

- Secure developer
 - Set the memory security attribution of the code flash and data flash using the boot firmware command
 - Program and debug the secure application. If the memory security attribution is not set, all area of the code flash and data flash is secure.
 - If the AL2_KEY and RMA_KEY are required, inject them using the boot firmware commands.
 - Prepare the MCU for the Non-secure developer
 - If the Non-secure Developer will not be permitted to use the Initialize command, disable it using the boot firmware command.
 - If the AL2_KEY will not be used and the Non-secure Developer will not be permitted to use the Initialize function, disable the AL2_KEY using the boot firmware command.
 - Change the PL from PL2 to PL1 using the boot firmware command
- Non-secure developer
 - Program and debug the non-secure application.
 - If the AL1_KEY is required, inject it using the boot firmware command.
 - Prepare the MCU for end-product deployment
 - Disable the Initialize command using the boot firmware command (if required)
 - If the AL1_KEY will not be used, disable the AL1_KEY using the boot firmware command.

- Change the PL from PL1 to PL0 using the boot firmware command

38.4.5 Failure Analysis

If the customer requests failure analysis by Renesas, it is necessary to send the device after changing the device lifecycle state to RMA_REQ. If the device lifecycle state is not RMA_REQ, Renesas cannot perform the failure analysis. After failure analysis, Renesas changes the lifecycle to RMA_RET and returns the device to the customer.

Note: RMA_KEY is required to change the device lifecycle state to RMA_REQ or the MCU's Unique ID must be used as part of an authentication code. See [section 38.4.1. Changing the Lifecycle State](#) for details.

38.5 Secure Key Injection

To inject a user key into the MCU, perform the following steps.

Renesas provides the Security Key Management Tool, available on the Renesas web site, to assist with key injection preparation.

1. Create a 256-bit installation key.
This key is called the User Factory Programming Key (UFPK) and is used to wrap a user key
2. Get the wrapped version (W-UFPK) of the UFPK through the Renesas Key Wrapping Service.
3. Wrap the user key using the UFPK.
4. Send the W-UFPK and the wrapped user key to the MCU using a boot firmware interface.
The user key is unwrapped, wrapped with the MCU's hardware unique key, and stored in nonvolatile memory. DLM keys are stored in unmapped flash. Application keys are stored at the address specified with the key injection command.

[Figure 38.9](#) shows an example of key injection and [Table 38.8](#) shows the keys that can be injected.

Figure 38.9 Key injection

Table 38.8 Keys that can be injected

DLM transition	AL transition
RMA_KEY	AL2_KEY, AL1_KEY

38.6 Secure Factory Programming

In addition to secure key injection support for injecting user keys (DLM and debug authentication keys), the MCU supports the programming of a firmware image in ciphertext format to prevent assets from being leaked during production programming. This enables secure factory programming in a non-secure environment. Secure factory programming is supported by the boot firmware. [Figure 38.10](#) shows an example of secure factory programming of an encrypted firmware image. The customer wraps the Image Encryption Key with the UFPK and encrypts the image with the Image Encryption Key using AES128-CCM. When the customer sends the W-UFPK, the wrapped Image Encryption Key, and encrypted image to the MCU through the serial programming interface, the MCU decrypts and programs the firmware image.

To further support secure factory programming in a non-secure environment, the DLM state, Protection Level, and Authentication Keys can all be set via a single boot firmware command. Points to note about this boot firmware command include:

- Encrypted firmware programming can be performed only when the MCU is in the OEM state.
- This command will change the Protection Level of the MCU. The initial PL must be PL2. The final PL must be PL0.
- If the DLM state will remain in the OEM state, AL2 key must be injected. Do not inject AL1 key.
- The MCU can be transitioned to the LCK_BOOT state. In this case, AL keys cannot be injected.
- AL2 key must be wrapped with the same UFPK as the Image Encryption Key.
- This command will erase all code and data flash area except option-setting memory before programming encrypted firmware image. If there are any permanently locked blocks, this command can not be executed.
- Prohibit to execute this command if the current register setting or write value to the registers related to startup area selection and startup bank selection are other than the following.
 - SAS.BTFLG = 1b
 - BANKSEL.BANKSWP[2:0] = 111b
 - BANKSEL_SEC.BANKSWP[2:0] = 111b
- All option-setting memory values must be included in the encrypted firmware image, including settings that are not used with default values. However, if the following areas are write-protected, the write data in these areas should not be included in the image. If included, this command will terminate with an error.
 - SAS register
 - Lockable Area 0 to 2 in the data flash option setting memory

Figure 38.10 Secure factory encrypted image programming

38.7 Field Updating in Dual Mode

Be careful when performing in-field firmware update to keep the contents of secure (S or NSC) or Non-secure (NS) regions after bank swapping in the dual mode. Figure 38.11 and Figure 38.12 show the performing in-field update of information flow of secure or non-secure regions in the dual mode.

Figure 38.11 and Figure 38.12 show updating the Secure and the Non-secure regions respectively when operating in dual bank mode. Initially, BANK0 contains Version 1 of the firmware, and BANK1 is blank. As shown in Figure 38.11, to update the S or NSC firmware to Version 2, first copy the Version 1 NS firmware in BANK0 to BANK1, update the S or NSC to Version 2, and then execute the bank swap.

As shown in Figure 38.12, to update the NS firmware to Version 2, first copy the Version 1 S and NSC firmware from BANK0 to BANK1. Note that this process must be done by a secure service. After that, non-secure users should update the NS firmware to Version 2 and execute the bank swap.

Figure 38.11 Field updating flow of secure or non-secure callable regions

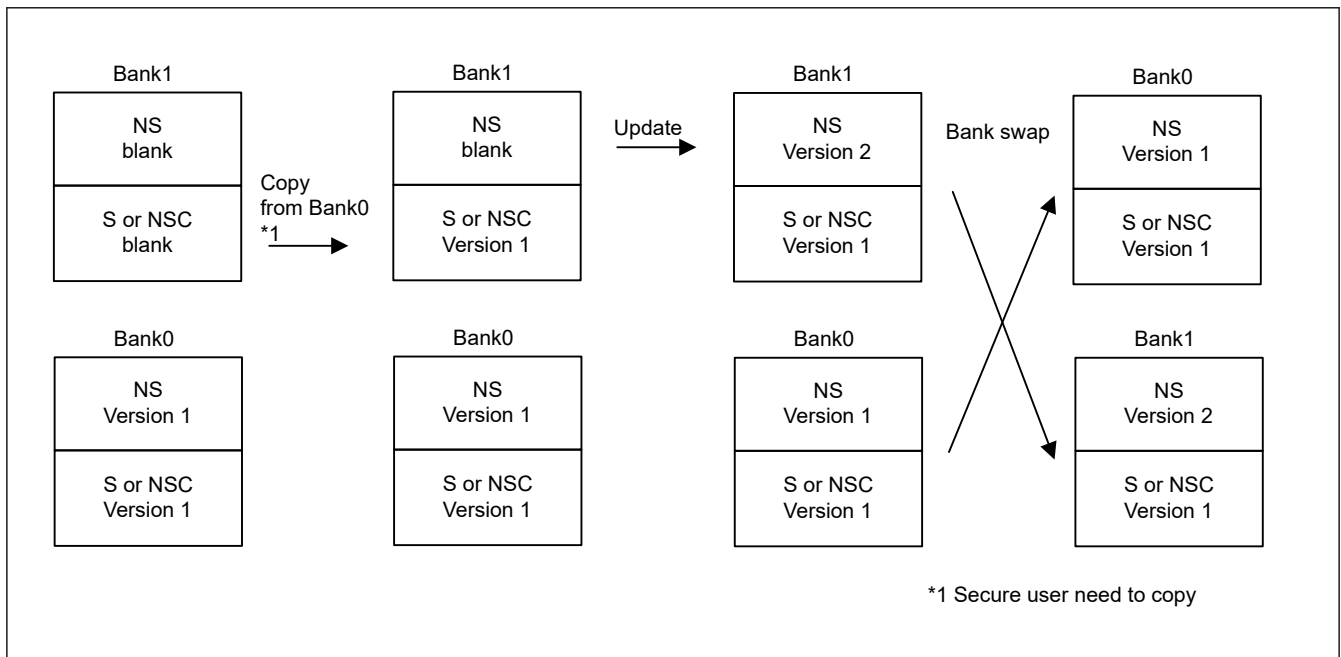

Figure 38.12 Field updating flow of non-secure region

38.8 Register Description

38.8.1 PSARB : Peripheral Security Attribution Register B

Base address: PSCU = 0x4020_4000
 PSCU_NS = 0x5020_4000

Offset address: 0x04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PSAR B31	PSAR B30	PSAR B29	PSAR B28	PSAR B27	—	—	—	—	PSAR B22	—	—	PSAR B19	PSAR B18	—	PSAR B16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	PSAR B11	—	PSAR B9	PSAR B8	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 0. The write value should be 0.	R/W
8	PSARB8	I2C Bus Interface 1 Security Attribution Target module: IIC1 and the MSTPCRB.MSTPB8 bit 0: Secure 1: Non-secure	R/W
9	PSARB9	I2C Bus Interface 0 Security Attribution Target module: IIC0 and the MSTPCRB.MSTPB9 bit 0: Secure 1: Non-secure	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	PSARB11	Universal Serial Bus 2.0 FS Interface 0 Security Attribution Target module: USBFS0 and the MSTPCRB.MSTPB11 bit 0: Secure 1: Non-secure	R/W
15:12	—	These bits are read as 0. The write value should be 0.	R/W
16	PSARB16	Octa Memory Controller Security Attribution Target module: OSPI and the MSTPCRB.MSTPB16 bit 0: Secure 1: Non-secure	R/W
17	—	This bit is read as 0. The write value should be 0.	R/W
18	PSARB18	Serial Peripheral Interface 1 Security Attribution Target module: RSPI1 and the MSTPCRB.MSTPB18 bit 0: Secure 1: Non-secure	R/W
19	PSARB19	Serial Peripheral Interface 0 Security Attribution Target module: RSPI0 and the MSTPCRB.MSTPB19 bit 0: Secure 1: Non-secure	R/W
21:20	—	These bits are read as 0. The write value should be 0.	R/W
22	PSARB22	Serial Communication Interface 9 Security Attribution Target module: SC19 and the MSTPCRB.MSTPB22 bit 0: Secure 1: Non-secure	R/W
26:23	—	These bits are read as 0. The write value should be 0.	R/W
27	PSARB27	Serial Communication Interface 4 Security Attribution Target module: SC14 and the MSTPCRB.MSTPB27 bit 0: Secure 1: Non-secure	R/W

Bit	Symbol	Function	R/W
28	PSARB28	Serial Communication Interface 3 Security Attribution Target module: SCI3 and the MSTPCRB.MSTPB28 bit 0: Secure 1: Non-secure	R/W
29	PSARB29	Serial Communication Interface 2 Security Attribution Target module: SCI2 and the MSTPCRB.MSTPB29 bit 0: Secure 1: Non-secure	R/W
30	PSARB30	Serial Communication Interface 1 Security Attribution Target module: SCI1 and the MSTPCRB.MSTPB30 bit 0: Secure 1: Non-secure	R/W
31	PSARB31	Serial Communication Interface 0 Security Attribution Target module: SCI0 and the MSTPCRB.MSTPB31 bit 0: Secure 1: Non-secure	R/W

Note: S-TYPE-1, P-TYPE-1.

The PSARB register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

38.8.2 PSARC : Peripheral Security Attribution Register C

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x08

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PSAR C31	—	—	—	PSAR C27	PSAR C26	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PSAR C15	—	PSAR C13	—	—	—	—	PSAR C8	PSAR C7	—	—	—	—	—	PSAR C1	PSAR C0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PSARC0	Clock Frequency Accuracy Measurement Circuit Security Attribution register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register. Target module: CAC and the MSTPCRC.MSTPC0 bit 0: Secure 1: Non-secure	R/W
1	PSARC1	Cyclic Redundancy Check Calculator Security Attribution Target module: CRC and the MSTPCRC.MSTPC1 bit 0: Secure 1: Non-secure	R/W
6:2	—	These bits are read as 0. The write value should be 0.	R/W
7	PSARC7	Serial Sound Interface Enhanced (channel 1) Security Attribution Target module: SSIE1 and the MSTPCRC.MSTPC7 bit 0: Secure 1: Non-secure	R/W
8	PSARC8	Serial Sound Interface Enhanced (channel 0) Security Attribution Target module: SSIE0 and the MSTPCRC.MSTPC8 bit 0: Secure 1: Non-secure	R/W
12:9	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
13	PSARC13	Data Operation Circuit Security Attribution Target module: DOC and the MSTPCRC.MSTPC13 bit 0: Secure 1: Non-secure	R/W
14	—	This bit is read as 0. The write value should be 0.	R/W
15	PSARC15	Graphic (GLCDC, DRW) Security Attribution Target module: GLCDC, DRW and the MSTPCRC.MSTPC4, MSTPCRC.MSTPC6 bits 0: Secure 1: Non-secure	R/W
25:16	—	These bits are read as 0. The write value should be 0.	R/W
26	PSARC26	Controller Area Network with Flexible Data-Rate 1 Security Attribution Target module: CANFD1 and the MSTPCRC.MSTPC26 bit 0: Secure 1: Non-secure	R/W
27	PSARC27	Controller Area Network with Flexible Data-Rate 0 Security Attribution Target module: CANFD0 and the MSTPCRC.MSTPC27 bit 0: Secure 1: Non-secure	R/W
30:28	—	These bits are read as 0. The write value should be 0.	R/W
31	PSARC31	RSIP-E51A Security Attribution Target module:RSIP-E51A and the MSTPCRC.MSTPC31 bit 0: Secure 1: Non-secure	R/W

Note: S-TYPE-1, P-TYPE-1.

The PSARC register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

38.8.3 PSARD : Peripheral Security Attribution Register D

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x0C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	PSAR D28	PSAR D27	—	—	—	—	PSAR D22	—	PSAR D20	—	—	—	PSAR D16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	PSAR D15	PSAR D14	PSAR D13	PSAR D12	PSAR D11	—	—	—	—	—	PSAR D5	PSAR D4	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	PSARD4	Asynchronous General Purpose Timer 1 Security Attribution Target module: AGT1 and the MSTPCRD.MSTPD4 bit 0: Secure 1: Non-secure	R/W
5	PSARD5	Asynchronous General Purpose Timer 0 Security Attribution Target module: AGT0 and the MSTPCRD.MSTPD5 bit 0: Secure 1: Non-secure	R/W
10:6	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
11	PSARD11	Port Output Enable for GPT Group 3 Security Attribution Target module: POEG Group D and the MSTPCRD.MSTPD11 bit 0: Secure 1: Non-secure	R/W
12	PSARD12	Port Output Enable for GPT Group 2 Security Attribution Target module: POEG Group C and the MSTPCRD.MSTPD12 bit 0: Secure 1: Non-secure	R/W
13	PSARD13	Port Output Enable for GPT Group 1 Security Attribution Target module: POEG Group B and the MSTPCRD.MSTPD13 bit 0: Secure 1: Non-secure	R/W
14	PSARD14	Port Output Enable for GPT Group 0 Security Attribution Target module: POEG Group A and the MSTPCRD.MSTPD14 bit 0: Secure 1: Non-secure	R/W
15	PSARD15	12-Bit A/D 1 Converter Security Attribution Target module: ADC12_1 and the MSTPCRD.MSTPD15 bit 0: Secure 1: Non-secure	R/W
16	PSARD16	12-Bit A/D 0 Converter Security Attribution Target module: ADC12_0 and the MSTPCRD.MSTPD16 bit 0: Secure 1: Non-secure	R/W
19:17	—	These bits are read as 0. The write value should be 0.	R/W
20	PSARD20	12-Bit D/A Converter Security Attribution Target module: DAC12 and the MSTPCRD.MSTPD20 bit 0: Secure 1: Non-secure	R/W
21	—	This bit is read as 0. The write value should be 0.	R/W
22	PSARD22	Temperature Sensor Security Attribution Target module: TSN and the MSTPCRD.MSTPD22 bit 0: Secure 1: Non-secure	R/W
26:23	—	These bits are read as 0. The write value should be 0.	R/W
27	PSARD27	High Speed Analog Comparator 1 Security Attribution Target module: ACMPHS1 and the MSTPCRD.MSTPD27 bit 0: Secure 1: Non-secure	R/W
28	PSARD28	High Speed Analog Comparator 0 Security Attribution Target module: ACMPHS0 and the MSTPCRD.MSTPD28 bit 0: Secure 1: Non-secure	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-1, P-TYPE-1.

The PSARD register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

38.8.4 PSARE : Peripheral Security Attribution Register E

Base address: PSCU = 0x4020_4000
 PSCU_NS = 0x5020_4000

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PSAR E31	PSAR E30	PSAR E29	PSAR E28	PSAR E27	PSAR E26	—	—	—	—	PSAR E21	PSAR E20	PSAR E19	PSAR E18	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	PSAR E9	PSAR E8	—	—	—	—	PSAR E3	PSAR E2	PSAR E1	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	PSARE1	WDT Security Attribution Target module: WDT 0: Secure 1: Non-secure	R/W
2	PSARE2	IWDT Security Attribution Target module: IWDT 0: Secure 1: Non-secure	R/W
3	PSARE3	Real Time Clock Security Attribution Target module: RTC 0: Secure 1: Non-secure	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W
8	PSARE8	ULPT1 Security Attribution Target module: ULPT1 and the MSTPCRE.MSTPE8 bit 0: Secure 1: Non-secure	R/W
9	PSARE9	ULPT0 Security Attribution Target module: ULPT0 and the MSTPCRE.MSTPE9 bit 0: Secure 1: Non-secure	R/W
17:10	—	These bits are read as 0. The write value should be 0.	R/W
18	PSARE18	General PWM Timer Channel 13 Security Attribution Target module: GPT13 and the MSTPCRE.MSTPE18 bit 0: Secure 1: Non-secure	R/W
19	PSARE19	General PWM Timer Channel 12 Security Attribution Target module: GPT12 and the MSTPCRE.MSTPE19 bit 0: Secure 1: Non-secure	R/W
20	PSARE20	General PWM Timer Channel 11 Security Attribution Target module: GPT11 and the MSTPCRE.MSTPE20 bit 0: Secure 1: Non-secure	R/W
21	PSARE21	General PWM Timer Channel 10 Security Attribution Target module: GPT10 and the MSTPCRE.MSTPE21 bit 0: Secure 1: Non-secure	R/W
25:22	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
26	PSARE26	General PWM Timer Channel 5 Security Attribution Target module: GPT5 and the MSTPCRE.MSTPE26 bit 0: Secure 1: Non-secure	R/W
27	PSARE27	General PWM Timer Channel 4 Security Attribution Target module: GPT4 and the MSTPCRE.MSTPE27 bit 0: Secure 1: Non-secure	R/W
28	PSARE28	General PWM Timer Channel 3 Security Attribution Target module: GPT3 and the MSTPCRE.MSTPE28 bit 0: Secure 1: Non-secure	R/W
29	PSARE29	General PWM Timer Channel 2 Security Attribution Target module: GPT2 and the MSTPCRE.MSTPE29 bit 0: Secure 1: Non-secure	R/W
30	PSARE30	General PWM Timer Channel 1 Security Attribution Target module: GPT1 and the MSTPCRE.MSTPE30 bit 0: Secure 1: Non-secure	R/W
31	PSARE31	General PWM Timer Channel 0 Security Attribution Target module: GPT0 and the MSTPCRE.MSTPE31 bit 0: Secure 1: Non-secure	R/W

Note: S-TYPE-1, P-TYPE-1.

The PSARE register specifies the security attribution for each module and the corresponding bit in Module Stop Control Register.

38.8.5 MSSAR : Module Stop Security Attribution Register

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x14

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	MSSA R31	—	—	—	—	—	—	—	—	MSSA R22	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	MSSA R15	—	—	—	—	—	—	—	—	—	—	—	—	—	MSSA R1	MSSA R0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MSSAR0	SRAM0 Clock Stop Security Attribution Target module: the MSTPCRA.MSTPA0 bit 0: Secure 1: Non-secure	R/W
1	MSSAR1	SRAM1 Clock Stop Security Attribution Target module: the MSTPCRA.MSTPA1 bit 0: Secure 1: Non-secure	R/W
14:2	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15	MSSAR15	Standby RAM Clock Stop Security Attribution Target module: the MSTPCRA.MSTPA15 bit 0: Secure 1: Non-secure	R/W
21:16	—	These bits are read as 0. The write value should be 0.	R/W
22	MSSAR22	DMAC/DTC Clock Stop Security Attribution Target module: the MSTPCRA.MSTPA22 bit 0: Secure 1: Non-secure	R/W
30:23	—	These bits are read as 0. The write value should be 0.	R/W
31	MSSAR31	ELC Clock Stop Security Attribution Target module: the MSTPCRC.MSTPC14 bit 0: Secure 1: Non-secure	R/W

Note: S-TYPE-1, P-TYPE-1.

The MSSAR register specifies the security attribution for the corresponding bit in Module Stop Control Register.

38.8.6 PPARB : Peripheral Privilege Attribution Register B

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x1C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	PPAR B31	PPAR B30	PPAR B29	PPAR B28	PPAR B27	—	—	—	—	PPAR B22	—	—	PPAR B19	PPAR B18	—	PPAR B16

Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Function	R/W
7:0	—	These bits are read as 1. The write value should be 1.	R/W
8	PPARB8	I2C Bus Interface 1 Privilege Attribution Target module: IIC1 and the MSTPCRB.MSTPB8 bit 0: Privileged 1: UnPrivileged	R/W
9	PPARB9	I2C Bus Interface 0 Privilege Attribution Target module: IIC0 and the MSTPCRB.MSTPB9 bit 0: Privileged 1: UnPrivileged	R/W
10	—	This bit is read as 1. The write value should be 1.	R/W
11	PPARB11	Universal Serial Bus 2.0 FS Interface 0 Privilege Attribution Target module: USBFS0 and the MSTPCRB.MSTPB11 bit 0: Privileged 1: UnPrivileged	R/W
15:12	—	These bits are read as 1. The write value should be 1.	R/W
16	PPARB16	Octa Memory Controller Privilege Attribution Target module: OSPI and the MSTPCRB.MSTPB16 bit 0: Privileged 1: UnPrivileged	R/W
17	—	This bit is read as 1. The write value should be 1.	R/W

Bit	Symbol	Function	R/W
18	PPARB18	Serial Peripheral Interface 1 Privilege Attribution Target module: RSPI1 and the MSTPCRB.MSTPB18 bit 0: Privileged 1: UnPrivileged	R/W
19	PPARB19	Serial Peripheral Interface 0 Privilege Attribution Target module: RSPI0 and the MSTPCRB.MSTPB19 bit 0: Privileged 1: UnPrivileged	R/W
21:20	—	These bits are read as 1. The write value should be 1.	R/W
22	PPARB22	Serial Communication Interface 9 Privilege Attribution Target module: SC19 and the MSTPCRB.MSTPB22 bit 0: Privileged 1: UnPrivileged	R/W
26:23	—	These bits are read as 1. The write value should be 1.	R/W
27	PPARB27	Serial Communication Interface 4 Privilege Attribution Target module: SC14 and the MSTPCRB.MSTPB27 bit 0: Privileged 1: UnPrivileged	R/W
28	PPARB28	Serial Communication Interface 3 Privilege Attribution Target module: SC13 and the MSTPCRB.MSTPB28 bit 0: Privileged 1: UnPrivileged	R/W
29	PPARB29	Serial Communication Interface 2 Privilege Attribution Target module: SC12 and the MSTPCRB.MSTPB29 bit 0: Privileged 1: UnPrivileged	R/W
30	PPARB30	Serial Communication Interface 1 Privilege Attribution Target module: SC11 and the MSTPCRB.MSTPB30 bit 0: Privileged 1: UnPrivileged	R/W
31	PPARB31	Serial Communication Interface 0 Privilege Attribution Target module: SC10 and the MSTPCRB.MSTPB31 bit 0: Privileged 1: UnPrivileged	R/W

Note: S-TYPE-2, P-TYPE-1.

The PPARB register specifies the privilege attribution for each module and the corresponding bit in Module Stop Control Register.

38.8.7 PPARC : Peripheral Privilege Attribution Register C

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x20

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31	PPARE31	General PWM Timer Channel 0 Privilege Attribution Target module: : GPT0 and the MSTPCRE.MSTPE31 bit 0: Privileged 1: UnPrivileged	R/W

Note: S-TYPE-2, P-TYPE-1.

The PPARE register specifies the privilege attribution for each module and the corresponding bit in Module Stop Control Register.

38.8.10 MSPAR : Module Stop Privilege Attribution Register

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x2C

Bit	Symbol	Function	R/W
30:0	—	These bits are read as 1. The write value should be 1.	R/W
31	MSPAR31	ELC Clock Stop Privilege Attribution Target module: the MSTPCRC.MSTPC14 bit 0: Privileged 1: UnPrivileged	R/W

Note: S-TYPE-2, P-TYPE-1.

The MSPAR register specifies the privilege attribution for the corresponding bit in the Module Stop Control Register.

38.8.11 CFSAMONA : Code Flash Security Attribution Monitor Register A

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x30

Note 1. The value in a blank product is 0x1FF. It is set to the value written by your application.

Bit	Symbol	Function	R/W
14:0	—	These bits are read as 0.	R
23:15	CFS2[8:0]	Code Flash Secure Area Indicate the area of secure region for code flash.	R
31:24	—	These bits are read as 0.	R

Note: S-TYPE-5, P-TYPE-5.

38.8.12 DFSAMON : Data Flash Security Attribution Monitor Register

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x34

Note 1. The value in a blank product is 0x3F. It is set to the value written by your application.

Bit	Symbol	Function	R/W
9:0	—	These bits are read as 0.	R
15:10	DFS[5:0]	Data Flash Secure Area Indicate the area of secure region for data flash.	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE-5, P-TYPE-5.

38.8.13 DLMMON : Device Lifecycle Management State Monitor Register

Base address: PSCU = 0x4020_4000
PSCU_NS = 0x5020_4000

Offset address: 0x38

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	DLMMON[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	*1	*1	*1	*1

Note 1. The value in a blank product is 0100b. These bits depend on DLM status.

Bit	Symbol	Function	R/W
3:0	DLMMON[3:0]	Device Lifecycle Management State Monitor Indicate DLM status value. 0x0: Reserved 0x1: Reserved 0x2: Reserved 0x3: Reserved 0x4: OEM 0x5: Reserved 0x6: LCK_BOOT 0x7: RMA_REQ 0x8: RMA_ACK 0x9: RMA_RET Others: Reserved	R
31:4	—	These bits are read as 0.	R

Note: S-TYPE-5, P-TYPE-5.

38.8.14 MSAOAD : Master Security Attribution Operation After Detection Register

Base address: BUS = 0x4000_3000

Offset address: 0x1010

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	OAD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	OAD	Operation after detection 0: NMI 1: Reset	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15:8	KEY[7:0]	Key Code These bits enable or disable writing of the OAD bit.	W

Note: S-TYPE-6, P-TYPE-2.

OAD bit (Operation after detection)

The OAD bit specifies operation when the access violation is detected. When OAD = 0, error response is returned and NMI is generated. When OAD = 1, reset request is generated. When writing to the OAD bit, write 0xA5 simultaneously to the KEY[7:0] bits using halfword access.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits enable or disable writing to the OAD bit. When writing to the OAD bit, write 0xA5 simultaneously to the KEY[7:0] bits. If this value is not written to the KEY[7:0] bits, the OAD bit is not updated.

38.8.15 MSAPT : Master Security Attribution Protect Register

Base address: BUS = 0x4000_3000

Offset address: 0x1014

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	PROTECT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PROTECT	Protection of register 0: MSAOAD register writing is possible. 1: MSAOAD register writing is protected. Read is possible.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code These bits enable or disable writing of the PROTECT bit.	W

Note: S-TYPE-6, P-TYPE-2.

PROTECT bit (Protection of register)

The PROTECT bit enables or disables writes to the associated registers to be protected.

MSAPT.PROTECT controls the MSAOAD register.

When the PROTECT bit is set simultaneously, write 0xA5 to the KEY[7:0] bits using half word access.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits enable or disable writing to the PROTECT bit. When writing to the PROTECT bit, write 0xA5 simultaneously to the KEY[7:0] bits. If this value is not written to the KEY[7:0] bits, the PROTECT bit is not updated.

38.9 Usage Note

38.9.1 Security or Privilege Bit Write Timing

When writing a security or privilege attribution bit, confirm that the write is complete by reading the security or privilege register until it matches the value written. The protection is not effective until the write to the security or privilege register is complete.

39. Renesas Secure IP (RSIP-E51A)

39.1 Overview

This security engine consists of an isolated subsystem comprising an access management circuit, storage area, encryption/decryption circuit, and random number generation circuit. In combination with the RSIP library, the security engine can prevent eavesdropping (to maintain confidentiality), falsification of information (to ensure integrity), and impersonation (to verify authenticity).

Because key information required for encryption and decryption is stored only in the security engine and all accesses from the outside can be blocked, the security engine enables building a more robust security system.

Only access control circuit, random number generation circuit, and unique ID are supported. The operation of other circuits is not guaranteed.

Table 39.1 lists the security engine specifications. Figure 39.1 shows the security engine block diagram.

Table 39.1 Security engine specifications (1 of 2)

Parameter	Specifications
Access control	Access management circuit <ul style="list-style-type: none"> In case of irregular access to the security engine due to a tampered program or CPU runaway, this circuit blocks all subsequent accesses and stops data output from the security engine
Symmetric cryptography	AES: Compliant with NIST FIPS PUB 197 <ul style="list-style-type: none"> Key length: 128, 192, or 256 bits Data block size: 128 bits AES supports following block cipher mode ECB, CBC, CTR: Compliant with NIST SP 800-38A CCM: Compliant with NIST SP 800-38C GCM: Compliant with NIST SP 800-38D XTS: Compliant with IEEE 1619-2007 AES supports following authentication algorithm CMAC: Compliant with NIST SP 800-38B GMAC: Compliant with NIST SP 800-38D AES does not support the KEY size of 192-bit in CCM, GCM, XTS, CMAC and GMAC.
Random number generation	128-bit true random number generation circuit
Asymmetric cryptography	RSA <ul style="list-style-type: none"> Maximum number of operable bits: 4224 bits Supported key sizes: 1024-bit, 2048-bit, 3072-bit, and 4096-bit Signature generation, signature verification, public-key encryption, private-key decryption ECC <ul style="list-style-type: none"> Maximum number of operable bits: 576 bits Support for curve <ul style="list-style-type: none"> NIST P-192, P-224, P-256, P-384 and P-521 Brainpool P256r1, P384r1, and P512r1 Ed25519 secp256k1 Signature generation, signature verification, key generation
Message digest computation	HASH <ul style="list-style-type: none"> Block size: <ul style="list-style-type: none"> 512-bit(SHA-224, SHA-256) 1024-bit(SHA-512/224, SHA-512/256, SHA-384, SHA-512) Key size: 512-bit or less HASH supports following secure hash algorithms SHA-224, SHA-256, SHA-512/224, SHA-512/256, SHA-384 and SHA-512: Compliant with FIPS PUB 180-4 HASH supports following message authentication algorithm HMAC: Compliant with FIPS PUB 198

Table 39.1 Security engine specifications (2 of 2)

Parameter	Specifications
Hardware Unique Key	<ul style="list-style-type: none"> • A read-only, 256-bit Hardware Unique Key (HUK) is exclusively accessible by the security engine access management circuit through a dedicated bus. • Key derivation functions (KDFs) combine the Hardware Unique Key with the key generation information. The derived keys implement the key wrapping for user key secure storage. • The HUK uniqueness prevents the illicit cloning and copying of keys to another MCU of the MCU group. • The HUK itself is stored in wrapped (encrypted, non-plain) format in an isolated memory area. Therefore, it is protected from illicit access and copy.
Application Key Management	<ul style="list-style-type: none"> • Wrapped keys are only valid within the security engine.
Unique ID	<ul style="list-style-type: none"> • A read-only, 128-bit ID unique to an MCU (Unique ID) is accessible from the access management circuit. • Key derivation functions (KDFs) combine the Unique ID with the key generation information. Such derived keys are used to unwrap the HUK within the security engine boundary.
Decryption-on-the-fly	The security engine outputs the key data of the decryption-on-the-fly IP (DOTF) through a dedicated bus
Tamper Resistance	Countermeasures available for side-channel attacks, including SPA/DPA and timing attacks.
Module-stop function	Module-stop state can be set to reduce power consumption
TrustZone Filter	Security and Privilege attribution can be set

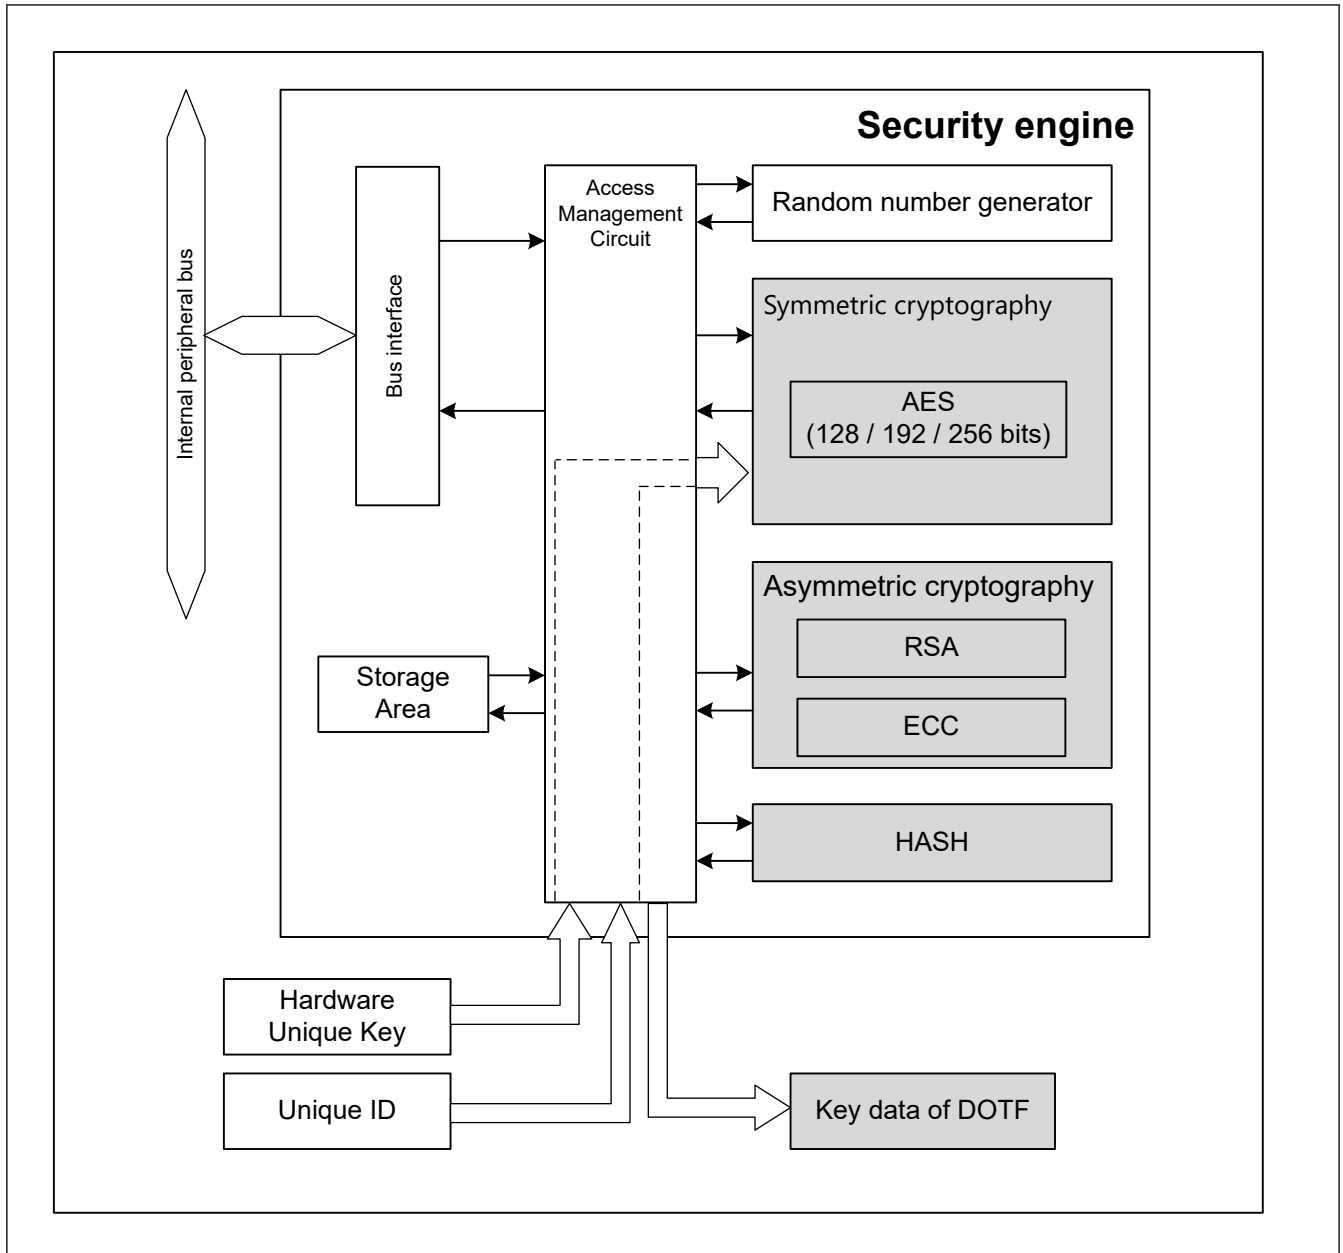

Figure 39.1 Security engine block diagram

39.2 Operation

39.2.1 Symmetric cryptography

Figure 39.2 shows conceptual block diagram of the symmetric cryptography installed in the security engine.

The symmetric cryptography uses the input key information and converts the plaintext data to ciphertext or ciphertext data to plaintext through the hardware.

The encryption/decryption process can be completed without exposing the key data and the process's intermediate data outside of the security engine. This process is performed by the encryption/decryption circuit and storage area of the security engine internally.

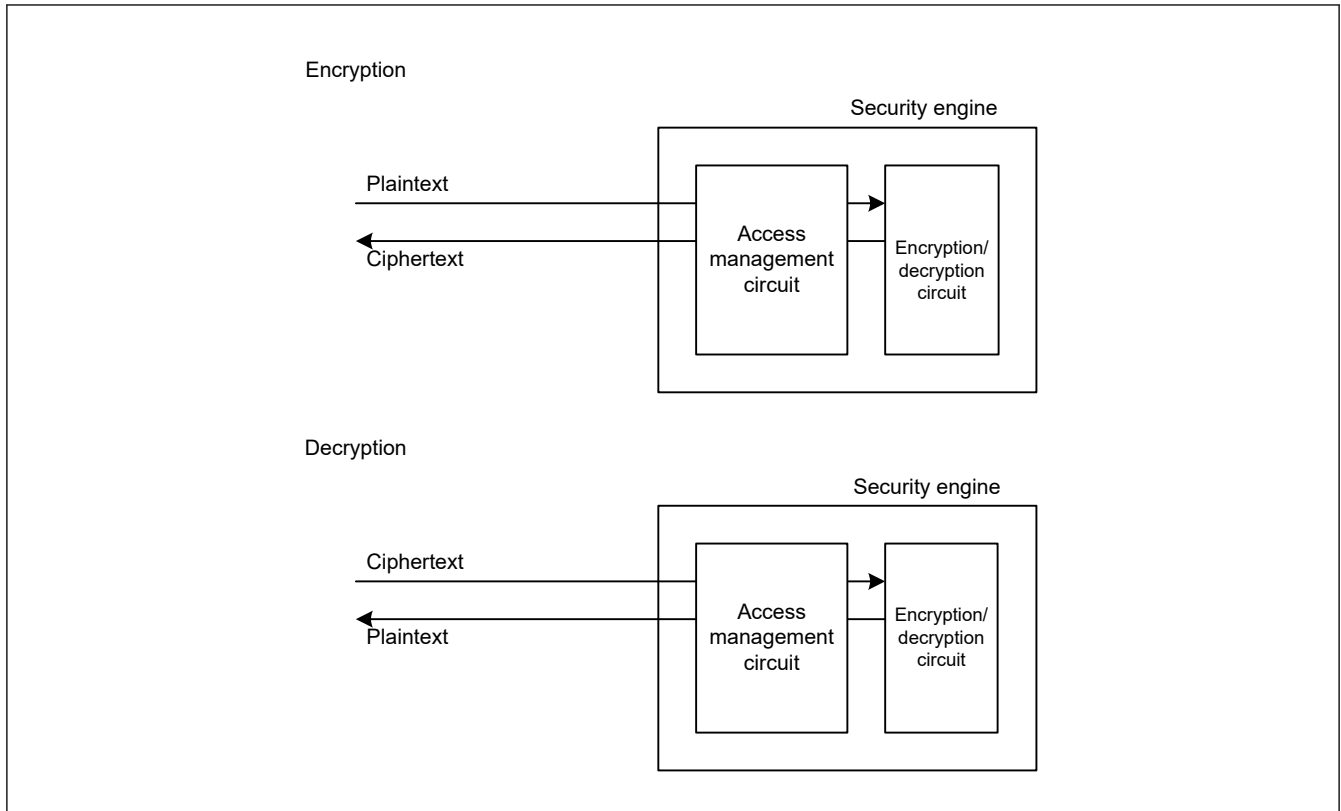

Figure 39.2 Conceptual diagram of the symmetric cryptography

39.2.2 Asymmetric Cryptography

Figure 39.3 shows conceptual block diagram of the asymmetric cryptography installed in the security engine.

The asymmetric cryptography uses the input key information and converts the plaintext data to ciphertext or ciphertext data to plaintext or generates/verifies the signature.

The encryption/decryption or signature generation/verification process can be completed without exposing the key data and the process's intermediate data outside of the security engine. This process is performed by the cryptographic circuit and storage area of the security engine internally.

Figure 39.3 Conceptual diagram of the asymmetric cryptography

39.2.3 Hash generator

Figure 39.4 shows conceptual block diagram of the hash generator installed in the security engine.

The hash generator generates uses the input key information (if required for the hash calculation) and generates the message digest or tag.

The calculation process can be completed without exposing any key data and the process's intermediate data outside of the security engine. This process is performed by the hash circuit and storage area of the security engine internally.

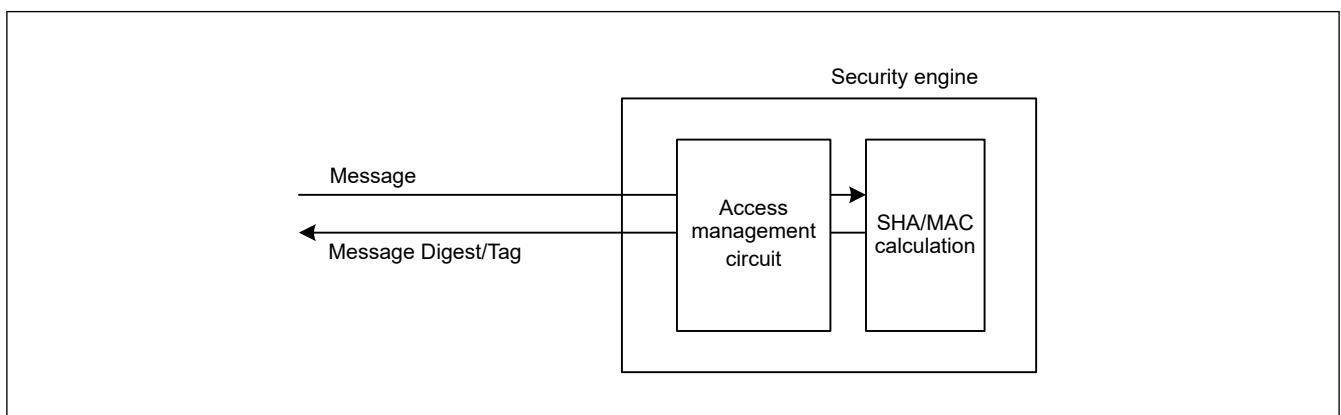

Figure 39.4 Conceptual diagram of the hash generator

39.2.4 Encryption and Decryption

Follow the procedure below to encrypt and decrypt the data:

1. Input the key information to the security engine.
2. Input the target data to the security engine. Plaintext data is converted to ciphertext and ciphertext data to plaintext.
3. Read the converted data.

The encryption/decryption circuit has input and output buffers, and can perform encryption/decryption in parallel with data input/output. Figure 39.5 shows the encryption engine timing.

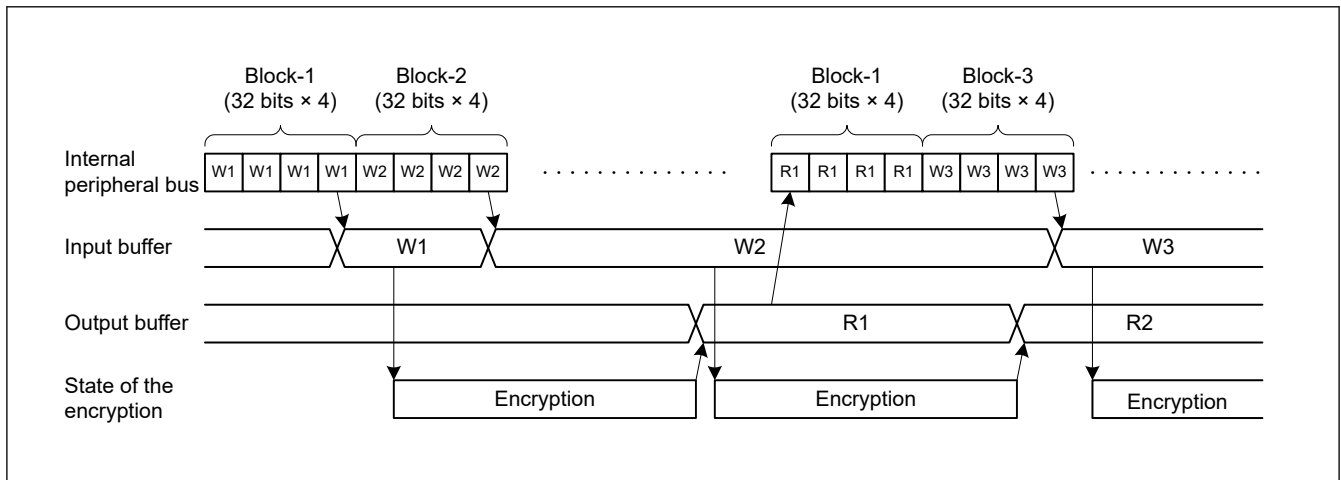

Figure 39.5 Encryption and decryption timing (AES)

39.3 Usage Notes

39.3.1 Software Standby Mode

When Software Standby mode is entered while the security engine is in process, proper processing cannot be resumed after cancelling Software Standby mode. Software Standby mode should therefore be entered while the security engine is not running.

39.3.2 Module-Stop Function Setting

The security engine operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The security engine module is initially stopped after reset. Releasing the module-stop state enables access to the registers.

39.3.3 SPA/DPA Protections

SPA/DPA protections can optionally be enabled for encryption/decryption processing.

39.3.4 Restrictions on Open process

While open process of security engine's API (R_RSIP_Open) is running, the following restrictions is applied.

- Available CPU frequency is up to 240MHz
- Do not change frequency of CPUCLK, ICLK and PCLKn (n = A to E)
- Do not change MSTPCRn registers (n = A to E)
- Do not transition to CPU Sleep mode, CPU Deep Sleep mode, Software Standby mode and Deep Software Standby mode 1/2/3."

40. 12-Bit A/D Converter (ADC12)

40.1 Overview

The MCU includes 12-bit successive approximation A/D converter (ADC12) units. In unit 0, up to 8 analog input channels are selectable. In unit 1, up to 5 analog input channels, temperature sensor output, internal reference voltage, VBATT 1/3 voltage monitor output can be selected for conversion in respective units.

The A/D conversion accuracy is selectable from 12-bit, 10-bit, 8-bit conversion, making it possible to optimize the trade-off between speed and resolution in generating a digital value.

The ADC12 supports the following operating modes:

- Single scan mode to convert analog inputs of selected channels in ascending order of channel number
- Continuous scan mode to convert analog inputs of selected channels continuously in ascending order of channel number
- Group scan mode to divide analog inputs of channels into two groups (group A and B) and convert the analog inputs of selected channels for each group in ascending order of channel number.

In group scan mode, select two groups (group A and B). You can individually select the scan start conditions for each group (group A, B) and start scanning of each group at different times. In addition, when group A priority control operation is set, the ADC12 accepts group A scan start during group B A/D conversion, suspending group B conversion. This allows you to assign higher priority to A/D conversion start for group A.

In double trigger mode, the analog input of a selected channel is converted in single scan mode or group scan mode (group A), and data converted by the first and second A/D conversion start triggers are stored in different registers, providing duplexing of A/D converted data.

Self-diagnosis is performed once at the beginning of each scan, and one of the three reference voltage values generated in ADC12 is A/D converted.

The temperature sensor output and the internal reference voltage is selectable at the same time as the analog input of the channel. First A/D conversion is performed for the analog input of the channel, next the temperature sensor output and then for the internal reference voltage.

The ADC12 also provides a compare function (window A and window B). The compare function specifies the upper reference value for window A and lower reference value for window B, and outputs an interrupt when the A/D converted value of the selected channel meets the comparison conditions.

The A/D data storage buffer is a ring buffer consisting of 16 buffers to sequentially store A/D converted data.

[Table 40.1](#) lists the ADC12 specifications and [Table 40.2](#) lists the functions. [Figure 40.1](#) shows a block diagram of ADC12 and [Table 40.3](#) lists the I/O pins.

Table 40.1 ADC12 specifications (1 of 3)

Parameter	Specifications
Number of units	Two units
Input channels	Up to 13 channels (AN000 to AN002, AN004 to AN008, AN100 to AN102, AN104, AN105)
Analog function	Temperature sensor output, internal reference voltage, VBATT 1/3 voltage monitor output
Conversion method	Successive approximation method
Resolution	12-bit, 10-bit, 8-bit
Conversion time	0.4 μ s/channel (when 12-bit A/D conversion clock PCLKC (ADCLK) is operating at 60 MHz)
A/D conversion clock	Peripheral module clock PCLKA and A/D conversion clock PCLKC (ADCLK) can be set with the following division ratios: PCLKA to PCLKC (ADCLK) frequency ratio = 1:1, 2:1, 4:1, 8:1, 1:2, 1:4

Table 40.1 ADC12 specifications (2 of 3)

Parameter	Specifications
Data registers ^{*1}	<ul style="list-style-type: none"> • 13 registers for analog input • One register for A/D-converted data duplication in double trigger mode • Two registers for A/D-converted data duplication during extended operation in double trigger mode • One register for temperature sensor output • One register for internal reference voltage • One register for VBATT 1/3 voltage monitor output • One register for self-diagnosis • A/D conversion results are stored in A/D data registers • 12-bit, 10-bit, 8-bit accuracy for A/D conversion results • A/D-converted value addition mode, in which the sum of all A/D-converted results is stored in the A/D data registers as a value with the conversion accuracy bit count + extended bits • Double-trigger mode (selectable in single scan and group scan modes): <ul style="list-style-type: none"> – The first unit of A/D-converted analog input data on one selected channel is stored in the data register for the channel, and the second unit is stored in the duplication register. • Extended operation in double trigger mode (available for specific triggers): <ul style="list-style-type: none"> – A/D-converted analog input data on one selected channel is stored in the duplication register provided for the associated trigger.
Operating modes ^{*2}	<ul style="list-style-type: none"> • Single scan mode: <ul style="list-style-type: none"> – A/D conversion is performed only once on the analog inputs of arbitrarily selected channels, on the temperature sensor output, on the internal reference voltage. • Continuous scan mode: A/D conversion is performed repeatedly on the analog inputs of the selected channels on the temperature sensor output, and on the internal reference voltage. • Group scan mode: <ul style="list-style-type: none"> – Analog inputs of selected channels, the temperature sensor output, and the internal reference voltage are divided into groups A and B. Then A/D conversion of the analog inputs selected on a group basis is performed once. – The scan start conditions can be independently selected for group A, B, allowing A/D conversion of group A, B to be started independently. • Group scan mode (when group priority operation is selected): <ul style="list-style-type: none"> – If a priority group trigger is input during scanning of a lower-priority group, the scanning of the lower-priority group is stopped and then scanning of the priority group is started. The order of priority is group A > group B. – It is possible to select whether to restart scanning (rescan) of the lower-priority group upon completion of the priority group scan. It is also possible to specify rescanning to be started from the first channel of the selected channels or from the channel for which A/D conversion has not been completed.
Conditions for A/D conversion start	<ul style="list-style-type: none"> • Software trigger • Synchronous triggers from the Event Link Controller (ELC) and GPT • Asynchronous triggering by the external trigger pins, ADTRG0 (unit 0) and ADTRG1 (unit 1)
Functions	<ul style="list-style-type: none"> • Dedicated sample-and-hold function with optional constant sampling and 2 channels in unit 0 • Variable sampling state count • Self-diagnosis of A/D converter • Selectable A/D-converted value addition mode or average mode • Analog input disconnection detection function (discharge and precharge functions) • Double-trigger mode (duplication of A/D conversion data) • Automatic clear function for A/D data registers • Digital comparison of values in the comparison register and data register, and comparison between values in the data registers • Ring buffer

Table 40.1 ADC12 specifications (3 of 3)

Parameter	Specifications
Interrupt sources	<ul style="list-style-type: none"> In single scan mode (double trigger deselected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) can be generated on completion of single scan. <ul style="list-style-type: none"> A compare interrupt request (ADC12i_CMPAI (i = 0, 1)/ADC12i_CMPBI (i = 0, 1)) can be generated in response to a match with a digital comparison condition. A window compare ELC event signal (ADC12i_WCMPI (i = 0, 1)) can be generated in response to a match with a digital comparison condition. A window compare ELC event signal (ADC12i_WCMPUM (i = 0, 1)) can be generated in response to a mismatch with a digital comparison condition. In single scan mode (double trigger selected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of two scans. In continuous scan mode, an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of all the selected channel scans. In group scan mode (double trigger deselected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of group A scan, and an A/D scan end interrupt request for group B (ADC12i_GBADI (i = 0, 1)) can be generated on completion of group B scan. In group scan mode (double trigger selected), an A/D scan end interrupt request (ADC12i_ADI (i = 0, 1)) and ELC event signal (ADC12i_ADI (i = 0, 1)) is generated on completion of two group A scans, and an A/D scan end interrupt request for group B (ADC12i_GBADI (i = 0, 1)) can be generated on completion of group B scan. ADC12i_ADI (i = 0, 1), ADC12i_GBADI (i = 0, 1), ADC12i_WCMPI (i = 0, 1), and ADC12i_WCMPUM (i = 0, 1) can activate the Data Transfer Controller (DTC).
ELC interface	<ul style="list-style-type: none"> An event is generated upon completion of group A scan in group-scan mode. An event is generated upon completion of group B scan in group-scan mode. An event is generated when all scans complete. Scan can be started by a trigger from the ELC. An event is generated according to conditions of the compare function window in single-scan mode.
Reference voltage	<ul style="list-style-type: none"> Unit 0: VREFH0 is the analog reference voltage. VREFL0 is the analog reference ground. Unit 1: VREFH1 is the analog reference voltage. VREFL1 is the analog reference ground.
Analog channel input SA judgement function	Input channels of analog can be valid only when the security attribution of ADC12n (n = 0, 1) match the security attribution of PORT (PmSAR). When the security attribution of ADC12n (n = 0, 1) does not match the PORT security attribution, the conversion result of ADC input channel will be unexpected. Internal reference voltage, Temperature sensor output and VBATT 1/3 voltage monitor output have no Security Attribution judgement function.
Module-stop function	Module-stop state can be set to for each units reduce power consumption.*3
TrustZone Filter	Security and Privilege attribution can be set for each unit

Note 1. Changing the A/D conversion accuracy also changes the A/D conversion time. For details, see [section 40.3.6. Analog Input Sampling and Scan Conversion Time](#).

Note 2. When selecting the temperature sensor output, the internal reference voltage, do not use continuous scan mode or group scan mode.

Note 3. For details, see [section 10, Low Power Modes](#).

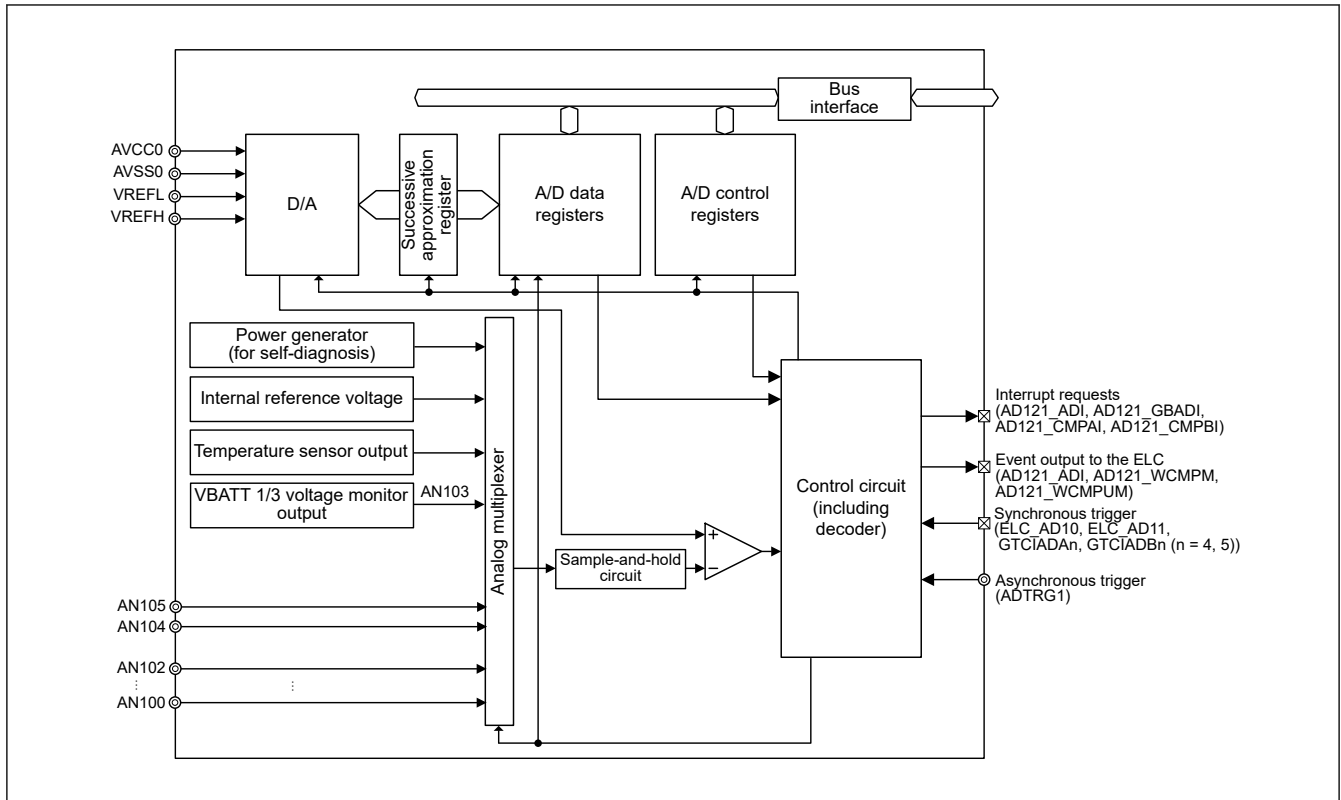

Figure 40.2 ADC12 block diagram (unit 1)

Table 40.3 lists the ADC12 I/O pins.

Table 40.3 ADC12 I/O pins (unit 0)

Pin name	I/O	Function
AVCC0	Input	Analog block power supply pin (Connect to VCC when ADC12/DAC12 is not used.)
AVSS0	Input	Analog block power supply ground pin (Connect to VSS when ADC12/DAC12 is not used.)
VREFH0	Input	Analog reference voltage supply pin
VREFL0	Input	Analog reference ground pin
AN000 to AN002, AN004 to AN008	Input	Analog input pins 0 to 2, 4 to 8
ADTRG0	Input	External trigger input pin for starting A/D conversion

Table 40.4 ADC12 I/O pins (unit 1)

Pin name	I/O	Function
AVCC0	Input	Analog block power supply pin
AVSS0	Input	Analog block power supply ground pin
VREFH	Input	Analog reference voltage supply pin
VREFL	Input	Analog reference ground pin
AN100 to AN102, AN104, AN105	Input	Analog input pins 0 to 2, 4, 5
ADTRG1	Input	External trigger input pin for starting A/D conversion

40.2 Register Descriptions

40.2.1 ADDRn : A/D Data Registers n

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: $0x020 + 0x2 \times n$ ($n = 0$ to $8, m = 0$)
 $0x020 + 0x2 \times n$ ($n = 0$ to $5, m = 1$)

Bit	Symbol	Function	R/W
15:0	ADDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 40.5 and Table 40.6 .	R

Note: S-TYPE-3, P-TYPE-3

ADDRn registers are 16-bit read-only registers to store A/D conversion results.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

[Table 40.5](#) shows the example of bit assignment for 12-bit accuracy.

Table 40.5 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, these registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 40.6 shows example of the bit assignment for 12-bit accuracy.

Table 40.6 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results													
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

40.2.2 ADDBLDR : A/D Data Duplexing Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
 ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x018

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
15:0	ADDBLDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 40.7 and Table 40.8.	R

Note: S-TYPE-3, P-TYPE-3

ADDBLDR register is a 16-bit read-only register to store A/D conversion results in response to a second trigger in double-trigger mode.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 40.7 shows the example of bit assignment for 12-bit accuracy.

Table 40.7 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.			Converted Value 11 to 0: 12-bit A/D-converted value												
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 40.8 shows example of the bit assignment for 12-bit accuracy.

Table 40.8 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.				Added Value 13 to 0: 14-bit sum of A/D conversion results											
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

40.2.3 ADDBLDRn : A/D Data Duplexing Register n (n = A, B)

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
 ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x084 (n = A)
 0x086 (n = B)

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
15:0	ADDBLDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 40.9 and Table 40.10.	R

Note: S-TYPE-3, P-TYPE-3

ADDBLDRn registers are 16-bit read-only registers to store A/D conversion results in response to respective triggers during extended operation in double-trigger mode.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)

- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 40.9 shows the example of bit assignment for 12-bit accuracy.

Table 40.9 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, these registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 40.10 shows example of the bit assignment for 12-bit accuracy.

Table 40.10 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified		Added Value 15 to 0: 16-bit sum of A/D conversion results													
	When 1, 2, 3, or 4 conversion times is specified		These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results											
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified		Added Value 15 to 0: 16-bit sum of A/D conversion results													
	When 16 conversion times is specified		Added Value 13 to 0: 14-bit sum of A/D conversion results													These bits are read as 0.

40.2.4 ADTSDR : A/D Temperature Sensor Data Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x01A

Bit	Symbol	Function	R/W
15:0	ADTSDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 40.11 and Table 40.12 .	R

Note: S-TYPE-3, P-TYPE-3

ADTSDR register is a 16-bit read-only register to store A/D conversion result of the temperature sensor output.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

[Table 40.11](#) shows the example of bit assignment for 12-bit accuracy.

Table 40.11 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

[Table 40.12](#) shows example of the bit assignment for 12-bit accuracy.

Table 40.12 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.			Added Value 13 to 0: 14-bit sum of A/D conversion results												
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

40.2.5 ADOCDR : A/D Internal Reference Voltage Data Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x01C

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit field: ADOCDR [15:0]

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
15:0	ADOCDR [15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 40.13 and Table 40.14 .	R

Note: S-TYPE-3, P-TYPE-3

ADOCDR register is a 16-bit read-only register to store A/D conversion result of the internal reference voltage.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

[Table 40.13](#) shows the example of bit assignment for 12-bit accuracy.

Table 40.13 Example of bit assignment for 12-bit accuracy

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.			Converted Value 11 to 0: 12-bit A/D-converted value													
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value													These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a

specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 40.14 shows example of the bit assignment for 12-bit accuracy.

Table 40.14 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.				Added Value 13 to 0: 14-bit sum of A/D conversion results											
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

40.2.6 ADVMDR : A/D VBATT Monitor Data Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
 ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x026

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit field: ADDR [15:0]

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
15:0	ADDR[15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 40.15 and Table 40.16	R

Note: S-TYPE-3, P-TYPE-3

ADVMDR register is a 16-bit read-only register to store A/D conversion result of the VBATT 1/3 voltage. For VBATT 1/3 voltage measurement, VBATTMNSLR.VBTMNSSEL need to be set. For more information, see section 11, Battery Backup Function. ADVMDR register is an alias for the ADDR3 register.

The following conditions determine the formats for data in the A/D data registers:

- Setting of the A/D Data Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- The setting in the A/D Conversion Accuracy Select bits (ADCER.ADPRC[1:0]) (12-bit, 10-bit, 8-bit is selectable.)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 40.15 shows the example of bit assignment for 12-bit accuracy.

Table 40.15 Example of bit assignment for 12-bit accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, this register indicates the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, this register indicates the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 40.16 shows example of the bit assignment for 12-bit accuracy.

Table 40.16 Example of bit assignment for 12-bit accuracy when A/D-converted value addition mode is selected

Accuracy		b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 1, 2, 3, or 4 conversion times is specified	These bits are read as 0.			Added Value 13 to 0: 14-bit sum of A/D conversion results												
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified	Added Value 15 to 0: 16-bit sum of A/D conversion results															
	When 16 conversion times is specified	Added Value 13 to 0: 14-bit sum of A/D conversion results														These bits are read as 0.	

40.2.7 ADDR : A/D Self-Diagnosis Data Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x01E

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DIAGST[1:0]		—	—	AD[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
11:0	AD[11:0]	Converted Value 11 to 0 12-bit A/D-converted value	R
13:12	—	These bits are read as 0.	R
15:14	DIAGST[1:0]	Self-Diagnosis Status For details on self-diagnosis, see section 40.2.13. ADCER : A/D Control Extended Register . 0 0: Self-diagnosis not executed after power-on. 0 1: Self-diagnosis was executed using the 0 V voltage. 1 0: Self-diagnosis was executed using the reference voltage ^{*1} × 1/2. 1 1: Self-diagnosis was executed using the reference voltage ^{*1} .	R

Note: S-TYPE-3, P-TYPE-3

Note: The example of the bit assignment for the right-justified data with 12-bit accuracy is indicated.

Note 1. The reference voltage refers to VREFH0 for unit 0 and to VREFH for unit 1.

ADRD is a 16-bit read-only register that holds the A/D conversion results based on the self-diagnosis of the ADC12. In addition to the AD[11:0] bits indicating the A/D-converted value, it includes the Self-Diagnosis Status bit (DIAGST[1:0]).

The settings of the A/D data register format and the A/D conversion accuracy determines the formats for data in this register.

The A/D-converted value addition and average modes cannot be applied to the A/D self-diagnosis function. For details on self-diagnosis, see [section 40.2.13. ADCER : A/D Control Extended Register](#).

This section describes the data formats for each condition. The register diagram and the register bit table shown in this section indicate example of the bit assignment for the left and right-justified data with 12-bit accuracy.

Table 40.17 Bit assignment for each right-justified accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	DIAGST[1:0]	—	—	—	AD[11:0]	—	—	—	—	—	—	—	—	—	—	—

Table 40.18 Bit assignment for each left-justified accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Left-justified data with 12-bit accuracy	AD[11:0]	—	—	—	—	—	—	—	—	—	—	—	—	—	DIAGST[1:0]	—

40.2.8 ADCSR : A/D Control Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x000

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit field:	ADST	ADCS[1:0]	—	—	—	TRGE	EXTRG	DBLE	GBADIE	—	DBLANS[4:0]				
------------	------	-----------	---	---	---	------	-------	------	--------	---	-------------	--	--	--	--

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
4:0	DBLANS[4:0]	Double Trigger Channel Select These bits select one analog input channel for double-trigger operation. The setting is only valid in double-trigger mode.	R/W
5	—	This bit is read as 0. The write value should be 0.	R/W
6	GBADIE	Group B Scan End Interrupt and ELC Event Enable Group B scan only works in group scan mode. 0: Disable ADC12i_GBADI (i = 0, 1) interrupt generation on group B scan completion. 1: Enable ADC12i_GBADI (i = 0, 1) interrupt generation on group B scan completion.	R/W

Bit	Symbol	Function	R/W
7	DBLE	Double Trigger Mode Select 0: Deselect double-trigger mode. 1: Select double-trigger mode.	R/W
8	EXTRG	Trigger Select* ¹ 0: Start A/D conversion by the synchronous trigger (GPT, ELC). 1: Start A/D conversion by the asynchronous trigger (ADTRGn* ²).	R/W
9	TRGE	Trigger Start Enable 0: Disable A/D conversion to be started by the synchronous or asynchronous trigger 1: Enable A/D conversion to be started by the synchronous or asynchronous trigger	R/W
12:10	—	These bits are read as 0. The write value should be 0.	R/W
14:13	ADCS[1:0]	Scan Mode Select 0 0: Single scan mode 0 1: Group scan mode 1 0: Continuous scan mode 1 1: Setting prohibited	R/W
15	ADST	A/D Conversion Start 0: Stop A/D conversion process. 1: Start A/D conversion process.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. To start A/D conversion using an external pin (asynchronous trigger):

After a high-level signal is input to the external pin (ADTRGn), write 1 to both the TRGE and EXTRG bits in the ADCSR register and drive the ADTRGn pin low. With these settings, the scan conversion process starts on detection of the falling edge of ADTRGn. The pulse width of the low-level input must be at least PCLKA 1.5 clock cycles.

Note 2. n = 0 (unit 0), 1 (unit 1)

The ADCSR register sets double-trigger mode and A/D conversion start trigger, enables or disables scan end interrupt, selects the scan mode, and starts or stops A/D conversion.

DBLANS[4:0] bits (Double Trigger Channel Select)

The DBLANS[4:0] bits select one channel for A/D conversion data duplication in double-trigger mode. This can be selected by setting the binary value of the channel number to be duplicated. The A/D conversion results of the analog input of the channel selected in the DBLANS[4:0] bits are stored in A/D Data Register y when conversion is started by the first trigger, and stored in the A/D Data Duplexing Register when conversion is started by the second trigger.

In double-trigger mode, the channels selected in the ADANSA0 register, are invalid, and the channel selected in the DBLANS[4:0] bits is A/D converted instead.

When double-trigger mode is used in group scan mode, double-trigger control is only applied to group A and not to group B.

Also, in double trigger mode, the analog inputs of multiple channels, temperature sensor outputs, or internal reference voltage cannot be selected for group A, but can be selected for groups B.

Only set the DBLANS[4:0] bits when the ADST bit is 0. Do not set the DBLANS[4:0] bits at the same time that you write 1 to the ADST bit.

To enter A/D-converted value addition/average mode when in double-trigger mode, set the same channel in the ADADS0 register as the channel selected in the DBLANS[4:0] bits.

A/D-converted data from the self-diagnosis function temperature sensor output and internal reference voltage cannot be used in double-trigger mode.

GBADIE bit (Group B Scan End Interrupt and ELC Event Enable)

The GBADIE bit enables or disables group B scan end interrupt (ADC12i_GBADI (i = 0, 1)) in group scan mode.

DBLE bit (Double Trigger Mode Select)

The DBLE bit selects or deselects double-trigger mode. Double-trigger mode can only be operated by the synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSA[5:0] bits.

Double-trigger operation is as follows:

1. The ADC12i_ADI (i = 0, 1) interrupt is not output on completion of the first conversion but on completion of the second conversion.
2. The A/D conversion results from the duplication channel (selected in DBLANS[4:0]) started by the first trigger are stored in A/D Data Register y and those started by the second trigger are stored in the A/D Data Duplexing Register.

When the DBLE bit is set (double-trigger mode is selected), the channels specified in the ADANSA0 register are invalid. Double-trigger mode is deselected by setting DBLE to 0. Setting DBLE to 1 again enables the same double-trigger operation described in 1. and 2. for first time scanning with the first trigger.

Do not select double-trigger mode in continuous scan mode. When using double trigger mode in group scan mode, A/D conversion of the temperature sensor output and internal reference voltage should not be selected for group A. Software triggering cannot be used in double-trigger mode. Always set the ADST bit to 0 before setting the DBLE bit. Do not set the DBLE bit at that same time as writing 1 to the ADST bit.

EXTRG bit (Trigger Select)

The EXTRG bit selects the synchronous or asynchronous trigger as the trigger for starting A/D conversion.

In group scan mode, the setting of this bit takes effect on the trigger selected for group A. For group B, A/D conversion is started by the selected synchronous trigger regardless of this bit setting.

TRGE bit (Trigger Start Enable)

The TRGE bit enables or disables A/D conversion by the synchronous and asynchronous triggers. In group scan mode, set this bit to 1.

ADCS[1:0] bits (Scan Mode Select)

The ADCS[1:0] bits select the scan mode.

In single scan mode, A/D conversion is performed for the analog inputs of the channels selected in the ADANSA0 register, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, the scan conversion stops.

In continuous scan mode, when the ADCSR.ADST bit is 1, A/D conversion is performed for the analog inputs of the channels selected with the ADANSA0 register, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion repeats from the first channel. If the ADCSR.ADST bit is set to 0 during continuous scan, A/D conversion stops even if scanning is in progress.

In group scan mode:

- Group A scanning is started by the synchronous trigger (GPT, ELC) selected in the TRSA[5:0] bits in the ADSTRGR register. A/D conversion is performed on group A analog inputs of the channels selected in the ADANSA0 register, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops.
- Group B scanning is started by the synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSB[5:0] bits. A/D conversion is performed on group B analog inputs of the channels selected in the ADANSB0 register, in ascending order of channel number. When 1 cycle of A/D conversion completes for all the selected channels, A/D conversion stops.

If the conversion processes in group A and group B occur at the same time, those conversions cannot be controlled separately. In this case, set group A Priority Control Setting bit (ADGSPCR.PGS) in the A/D Group Scan Priority Control Register (ADGSPCR) to 1 to assign a priority to group A conversion.

In group scan mode, select different channels and triggers for group A and group B.

Only set the ADCS[1:0] bits when the ADST bit is 0. Do not set the ADCS[1:0] bits at the same time that you write 1 to the ADST bit.

Table 40.19 Selectable targets for A/D conversion depending on scan and double-trigger mode settings

Scan mode setting	Double-trigger mode setting	Targets for A/D conversion				
		Self-diagnosis	Analog input (group A)	Analog input (group B)	Temperature sensor output	Internal reference voltage
Single scan	DBLE = 0	✓	✓	—	✓	✓
	DBLE = 1	—	✓ (1 ch only)	—	—	—
Continuous scan	DBLE = 0	✓	✓	—	✓	✓
	DBLE = 1	—	—	—	—	—
Group scan	DBLE = 0	✓	✓	✓	✓	✓
	DBLE = 1	—	✓ (1 ch only)	✓	✓	✓

Note: ✓: Selectable, —: Not selectable

ADST bit (A/D Conversion Start)

The ADST bit starts or stops the A/D conversion process. Before the ADST bit is set to 1, set the A/D conversion clock, the conversion mode, and the conversion target analog input.

[Setting conditions]

- 1 is written.
- The synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSA[5:0] bits is detected when ADCSR.EXTRG is 0 and ADCSR.TRGE is 1.
- The synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSB[5:0] bits is detected when ADCSR.TRGE is set to 1 in group scan mode.
- The asynchronous trigger is detected when the ADCSR.TRGE and ADCSR.EXTRG bits are set to 1 and the ADSTRGR.TRSA[5:0] bits are set to 0x00.
- When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADGSPCR.GBRP bit is set to 1, and each time A/D conversion on the group with the lowest priority is started.

[Clearing conditions]

- 0 is written.
- The A/D conversion of all the selected channels, the temperature sensor output the internal reference voltage completes in single scan mode.
- Group A scan completes in group scan mode.
- Group B scan completes in group scan mode.
- When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), the ADGSPCR.GBRSCN bit is set to 1, and A/D conversion on the group with the lowest priority started by trigger completes.

Note: When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), do not set the ADST bit to 1.

Note: When group priority operation mode is enabled (ADCSR.ADCS[1:0] = 01b and ADGSPCR.PGS = 1), do not set the ADST bit to 0. When forcing A/D conversion to terminate, follow the procedure for clearing the ADST bit.

40.2.9 ADANSA0 : A/D Channel Select Register A0

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x004

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ANSA 15	ANSA 14	ANSA 13	ANSA 12	ANSA 11	ANSA 10	ANSA 09	ANSA 08	ANSA 07	ANSA 06	ANSA 05	ANSA 04	ANSA 03	ANSA 02	ANSA 01	ANSA 00

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

Note 1. 00 to 08 (unit 0), 00 to 05 (unit 1) is available.

ADANSA0 register selects analog input channels for A/D conversion. In group scan mode, this register selects group A channels.

Only set the ADANSA0 register when the ADCSR.ADST bit is 0.

ANSAn bits (A/D Conversion Channels Select)

The ADANSA0 register selects any combination of analog input channels for A/D conversion. The channels and the number of channels can be arbitrarily set.

In double trigger mode, the channels selected in the ADANSA0 register are invalid, and the channel selected in the ADCSR.DBLANS[4:0] bits is selected in group A instead.

When group scan mode is selected, do not select the channels specified in A/D Channel Select Register B0 (ADANSB0).

VBATT 1/3 voltage monitor output correspond to ADC120.ADANSA0.ANSA03 or ADC121.ADANSA0.ANSA03 bit.

Security attribution function between ADC12n ($n = 0, 1$) and PORT. Detail conversion result please see [section 40.3.12. Security Attribution between ADCn \(\$n = 0, 1\$ \) and PORT \(PmSAR \(\$m = 0\$ to 9, A, B\)\)](#).

15:0	ANSB15 to ANSB00 ^{*1}	A/D Conversion Channels Select Bit 15 (ANSB15) is associated with ANm15 and bit 0 (ANSB00) is associated with ANm00. 0: Do not select associated input channel. 1: Select associated input channel.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

Note 1. 00 to 08 (unit 0), 00 to 05 (unit 1) is available.

ADANSB0 selects analog input channels for A/D conversion in group B when group scan mode is selected. The ADANSB0 register is not used in any scan mode other than group scan mode.

Only set the ADANSB0 register when the ADCSR.ADST bit is 0.

ANSBn bits (A/D Conversion Channels Select)

The ADANSB0 register selects any combination of analog input channels in group B for A/D conversion when group scan mode is selected. The ADANSB0 register is used for group scan mode only and not for any other modes.

Do not select channels specified in group A as selected in the ADANSA0 register or the ADCSR.DBLANS[4:0] bits in double-trigger mode.

VBATT 1/3 voltage monitor output correspond to ADC120.ADANSB0.ANSB03 or ADC121.ADANSB0.ANSB03.

Security attribution function between ADC12n (n = 0, 1) and PORT (PmSAR). Detail conversion result please see [section 40.3.12. Security Attribution between ADCn \(n = 0, 1\) and PORT \(PmSAR \(m = 0 to 9, A, B\)\)](#).

40.2.11 ADADS0 : A/D-Converted Value Addition/Average Channel Select Register 0

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
 ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x008

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADS15 to ADS00*1	A/D-Converted Value Addition/Average Channel Select Bit 15 (ADS15) is associated with ANm15 and bit 0 (ADS00) is associated with ANm00. 0: Do not select associated input channel. 1: Select associated input channel.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

Note 1. 00 to 08 (unit 0), 00 to 05 (unit 1) is available.

ADSn bits (A/D-Converted Value Addition/Average Channel Select)

The ADSn bits determine which A/D-converted channels are subject to A/D-converted value addition/averaging. When an ADSn bit associated with a channel selected for A/D conversion is set to 1, A/D conversion of the analog input of the respective channel is performed successively 1, 2, 3, 4, or 16 times, as specified in the ADC[2:0] bits in the ADADC register.

When the ADADC.AVEE bit is 0, the value obtained by addition is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition is stored in the A/D data register.

The ADSn bits apply only to channels that are selected for A/D conversion in:

- The ANSAn bits in the ADANSA0 register or the DBLANS[4:0] bits in the ADCSR register
- The ANSBn bits in the ADANSB0 register

For channels on which the A/D conversion is performed and for which addition/average mode is not selected, a normal 1-time conversion is executed, and the conversion result is stored in the A/D data register.

Only set ADADS0 register bits when the ADCSR.ADST bit is 0.

Figure 40.3 shows a scanning operation sequence in which the ADADS0 register bits (channel c and g) are set to 1. In this figure:

- Addition mode is selected (ADADC.AVEE = 0)
- The number of conversions is set to 4 (ADADC.ADC[1:0] = 11b)
- The analog input channels (a to h) are selected by ADANSA0 register in continuous scan mode (ADCSR.ADCS[1:0] = 10b).

The conversion process begins with analog input A (channel a). The analog input C (channel c) conversion is performed successively 4 times and the added value is returned to A/D Data Register c (ADDRc). Next, the analog input D (channel d) conversion process is started. The analog input G (channel g) is performed successively 4 times and the added value is

returned to A/D Data Register g (ADDRg). After conversion of analog input H (channel h), the conversion operation repeats in the same sequence starting with analog input A (channel a).

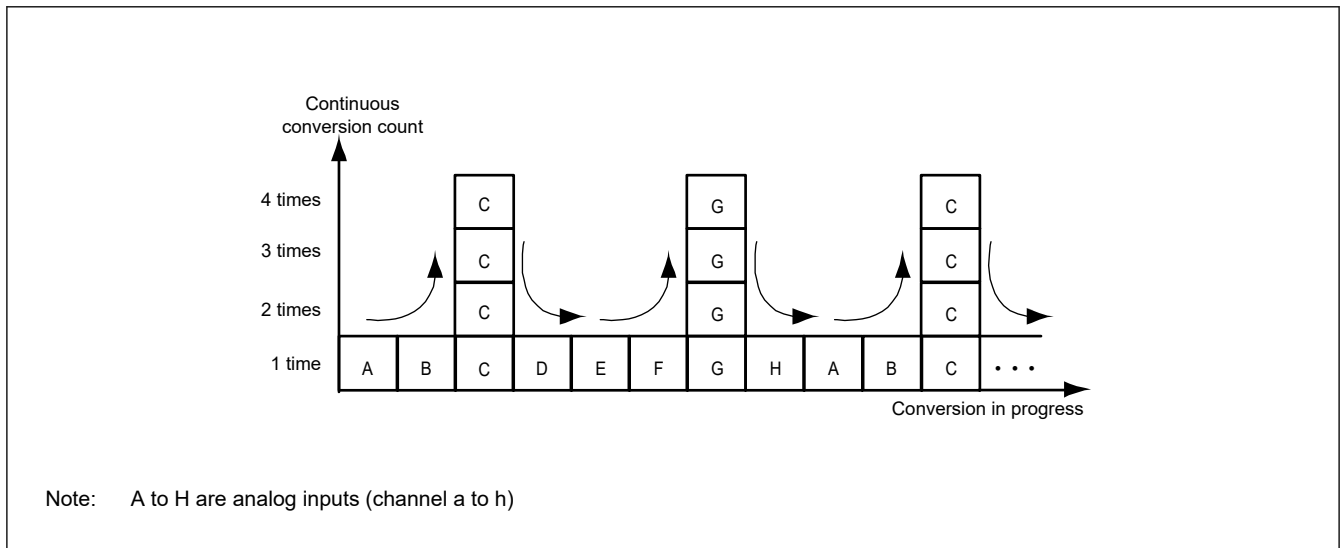

Figure 40.3 Scan conversion sequence with ADADC.ADC[2:0] = 011b, set 1 for analog inputs C and G by ADADS0

40.2.12 ADADC : A/D-Converted Value Addition/Average Count Select Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x00C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	AVEE	—	—	—	—	ADC[2:0]		

Value after reset: 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
2:0	ADC[2:0]	Addition/Average Count Select 0 0 0: 1-time conversion (no addition, same as normal conversion) 0 0 1: 2-time conversion (1 addition) 0 1 0: 3-time conversion (2 additions) 0 1 1: 4-time conversion (3 additions) 1 0 1: 16-time conversion (15 additions) Others: Setting prohibited	R/W
6:3	—	These bits are read as 0. The write value should be 0.	R/W
7	AVEE	Average Mode Select 0: Enable addition mode 1: Enable average mode	R/W

Note: S-TYPE-3, P-TYPE-3

ADADC sets the addition or average mode and addition count for A/D conversion. [Table 40.20](#) lists the settable combinations of ADADC register.

Table 40.20 Settable combinations of ADADC register

Mode select	Resolution	Conversion time				
		1-time	2-time	3-time	4-time	16-time
Addition mode (AVEE = 0)	8-bit	✓	✓	✓	✓	—
	10-bit	✓	✓	✓	✓	—
	12-bit	✓	✓	✓	✓	✓
Average mode (AVEE = 1)	8, 10, 12 bits	—	✓	—	✓	—

Note: ✓: Selectable, —: Not selectable

ADC[2:0] bits (Addition/Average Count Select)

The ADC[2:0] bits set the addition count in all channels for which A/D conversion and addition/average mode are selected, including the channel selected in double trigger mode with the ADCSR.DBLANS[4:0] bits. The count also applies to A/D conversion of the temperature sensor output and the internal reference voltage.

When self-diagnosis is executed (ADCER.DIAGM = 1), do not set the ADC[2:0] bits to any value other than 000b.

AVEE bit (Average Mode Select)

The AVEE bit selects addition or average mode in all channels for which A/D conversion and addition/average mode are selected, including the channels selected in double-trigger mode in the ADCSR.DBLANS[4:0] bits, temperature sensor output, internal reference voltage.

40.2.13 ADCER : A/D Control Extended Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
 ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x00E

Bit	Symbol	Function	R/W
11	DIAGM	Self-Diagnosis Enable 0: Disable ADC12 self-diagnosis 1: Enable ADC12 self-diagnosis	R/W
14:12	—	These bits are read as 0. The write value should be 0.	R/W
15	ADRFMT	A/D Data Register Format Select 0: Select right-justified for the A/D data register format 1: Select left-justified for the A/D data register format	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. The reference voltage refers to VREFH0 for unit 0 and to VREFH for unit 1.

ADPRC[1:0] bit (A/D Conversion Accuracy Specify)

The ADPRC[1:0] bits set the A/D conversion accuracy. Changing the A/D conversion accuracy also changes the bit width of valid data stored in the result register and the A/D conversion time. For details, see [section 40.3.6. Analog Input Sampling and Scan Conversion Time](#). Only set the ADPRC[1:0] bits while the ADCSR.ADST bit is 0.

ACE bit (A/D Data Register Automatic Clearing Enable)

The ACE bit enables or disables automatic clearing (all 0) of the ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR or ADVMDR register after any of these registers is read by the CPU or DTC. Automatic clearing of the A/D data registers enables detection of failures that are not updated in the A/D data registers. For details, see [section 40.3.7. Usage Example of A/D Data Register Automatic Clearing Function](#).

DIAGVAL[1:0] bits (Self-Diagnosis Conversion Voltage Select)

The DIAGVAL[1:0] bits select the voltage value used in self-diagnosis fixed voltage mode. For details, see the DIAGLD bit description.

Do not execute self-diagnosis by setting the DIAGLD bit to 1 when the DIAGVAL[1:0] bits are set to 00b.

DIAGLD bit (Self-Diagnosis Mode Select)

The DIAGLD bit selects whether the three voltage values are rotated, or the fixed voltage is used in self-diagnosis.

Setting the DIAGLD bit to 0 selects conversion of the voltages in rotation mode, where 0 V, the reference voltage $\times 1/2$, and the reference voltage are converted, in that order. After reset and when self-diagnosis voltage rotation mode is selected, self-diagnosis is executed from 0 V. The self-diagnosis voltage value does not return to 0 V when scan conversion completes. When scan conversion is restarted, rotation starts at the voltage value following the previous value.

Setting the DIAGLD bit to 1 selects fixed voltage, in which the fixed voltage specified in the ADCER.DIAGVAL[1:0] bits is converted. If fixed mode is switched to rotation mode, rotation starts at the fixed voltage value.

Only set the DIAGLD bit when the ADCSR.ADST bit is 0.

DIAGM bit (Self-Diagnosis Enable)

The DIAGM bit enables or disables self-diagnosis.

Self-diagnosis is used to detect a failure of the ADC12. In self-diagnosis mode, one of the three voltage values (0 V, the reference voltage $\times 1/2$, or the reference voltage) is converted. When conversion completes, information on the converted voltage and the conversion result is stored into the A/D Self-Diagnosis Data Register (ADRD). The ADRD register can be read to determine whether the conversion result falls within the normal or abnormal range.

Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages is converted. In double trigger mode (ADCSR.DBLE = 1), self-diagnosis (DIAGM = 0) is deselected. When self-diagnosis is selected in group scan mode, self-diagnosis is executed separately for group A and group B.

Only set the DIAGM bit when the ADCSR.ADST bit is 0.

ADRFMT bit (A/D Data Register Format Select)

The ADRFMT bit specifies flush-right or flush-left for data to be stored in the ADDRy, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR, ADVMDR, ADCMPDR0/1, ADWINLLB, ADWINULB, or ADRD register.

Only set the ADRFMT bit when the ADCSR.ADST bit is 0.

40.2.14 ADSTRGR : A/D Conversion Start Trigger Select Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x010

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	TRSA[5:0]						—	—	TRSB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	TRSB[5:0]	A/D Conversion Start Trigger Select for Group B Select the A/D conversion start trigger for group B in group scan mode.	R/W
7:6	—	These bits are read as 0. The write value should be 0.	R/W
13:8	TRSA[5:0]	A/D Conversion Start Trigger Select Select the A/D conversion start trigger in single scan mode and continuous scan mode. In group scan mode, the A/D conversion start trigger for group A is selected.	R/W
15:14	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

TRSB[5:0] bits (A/D Conversion Start Trigger Select for Group B)

The TRSB[5:0] bits select the trigger to start scanning of the analog input selected in group B. The TRSB[5:0] bits must only be set in group scan mode and are not used in any other scan mode. For the scan conversion start trigger for group B, setting a software trigger or an asynchronous trigger is prohibited. In group scan mode, set the TRSB[5:0] bits to a value other than 0x00 and set the ADCSR.TRGE bit to 1.

When group A is given priority in group scan mode, setting the ADGSPCR.GBRP bit to 1 allows group B to continuously operate in single scan mode. When setting the ADGSPCR.GBRP bit to 1, set the TRSB[5:0] bits to 0x3F. The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time (t_{SCAN}). If the issuance period is less than t_{SCAN} , A/D conversion by the trigger might have no effect.

When the GPT module is selected as an A/D conversion start trigger, a delay for synchronization processing occurs. For details, see [section 40.3.6. Analog Input Sampling and Scan Conversion Time](#).

[Table 40.21](#) lists the A/D conversion startup sources selected in the TRSB[5:0] bits.

Table 40.21 Selection of A/D conversion start sources in the TRSB[5:0] bits (1 of 2)

GTCIADA3 (unit 0), GTCIADB3 (unit 0)	GPT	0	1	1	1	0	0

TRSA[5:0] bits (A/D Conversion Start Trigger Select)

The TRSA[5:0] bits select the trigger to start A/D conversion in single scan mode and continuous scan mode, or the trigger to start scanning of group A analog inputs in group scan mode. When scanning is executed in group scan mode or double trigger mode, software trigger or asynchronous trigger is prohibited.

- When using a synchronous trigger (GPT, ELC), set the TRGE bit in the ADCSR register to 1 and set the EXTRG bit in the ADCSR register to 0.
- When using the asynchronous trigger (ADTRGn (n = 0, 1)), set the TRGE bit in the ADCSR register to 1 and set the EXTRG bit in the ADCSR register to 1.
- Software trigger (ADCSR.ADST) is enabled regardless of the settings of the ADCSR.TRGE bit, the ADCSR.EXTRG bit, or the TRSA[5:0] bits.

The issuance period for a conversion trigger must be more than or equal to the actual scan conversion time (tSCAN). If the issuance period is less than tSCAN, A/D conversion by a trigger might have no effect.

When the GPT module is selected as an A/D conversion start trigger, a delay for synchronization processing occurs. For details, see [section 40.3.6. Analog Input Sampling and Scan Conversion Time](#).

[Table 40.22](#) lists the A/D conversion start sources selected in the TRSA[5:0] bits.

15:12	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

TSSAD bit (Temperature Sensor Output A/D-Converted Value Addition/Average Mode Select)

When the TSSAD bit is set to 1, A/D conversion of the temperature sensor output is selected and performed successively the number of times specified in the ADC[2:0] bits in ADADC. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D Temperature Sensor Data Register (ADTSDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADTSDR.

Only set the TSSAD bit while the ADCSR.ADST bit is 0.

OCSAD bit (Internal Reference Voltage A/D-Converted Value Addition/Average Mode Select)

When the OCSAD bit is set to 1, A/D conversion of the internal reference voltage is selected and performed successively the number of times specified in the ADC[2:0] bits in ADADC. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D Internal Reference Voltage Data Register (ADOCDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADOCDR.

Only set the OCSAD bit while the ADCSR.ADST bit is 0.

TSSA bit (Temperature Sensor Output A/D Conversion Select)

The TSSA bit selects A/D conversion of the temperature sensor output for group A in single scan mode, continuous scan mode, or group scan mode. When A/D conversion of the temperature sensor output is selected and performed, set the ADCSR.DBLE bit to 0.

Only set the TSSA bit while the ADCSR.ADST bit is 0.

OCSA bit (Internal Reference Voltage A/D Conversion Select)

The OCSA bit selects A/D conversion of the internal reference voltage for group A in single scan mode, continuous scan mode, or group scan mode. When A/D conversion of the internal reference voltage is selected and performed, set the ADCSR.DBLE bit to 0.

Only set the OCSA bit while the ADCSR.ADST bit is 0. In addition, wait for 400 ns or more after the OCSA bit is set to 1 before starting A/D conversion.

TSSB bit (Temperature Sensor Output A/D Conversion Select for Group B)

The TSSB bit selects A/D conversion of the temperature sensor output for group B in group scan mode. Only set the TSSB bit while the ADCSR.ADST bit is 0. Do not set the TSSB bit to 1 while the TSSA bit is 1.

OCSB bit (Internal Reference Voltage A/D Conversion Select for Group B)

The OCSB bit selects A/D conversion of the internal reference voltage for group B in group scan mode. Only set the OCSB bit while the ADCSR.ADST bit is 0. Do not set the OCSB bit to 1 while the OCSA bit is 1. Moreover, start the A/D conversion after waiting for 400 ns or more after the OCSB bit is set to 1.

40.2.16 ADSSTRn/ADSSTRT/ADSSTRO/ADSSTRV: A/D Sampling State Register (n = 0 to 8)

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ (m = 0, 1)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ (m = 0, 1)

Offset address: $0x0E0 + 0x1 \times n$ (n = 0 to 8, m = 0)
 $0x0E0 + 0x1 \times n$ (n = 0 to 5, m = 1)
 0x0DE (ADSSTRT)
 0x0DF (ADSSTRO)
 0x0E3 (ADSSTRV)

Bit	Symbol	Function	R/W
7:0	SST[7:0]	Sampling Time Setting These bits set the sampling time in the range from 5 to 255 states.	R/W

Note: S-TYPE-3, P-TYPE-3

The ADSSTRn register sets the sampling time for analog input.

The sampling time can be adjusted if the impedance of the analog input signal source is too high to secure sufficient sampling time, or if the ADCLK clock is slow. The set value indicates the time for one ADCLK cycle, and the required sampling time is specified by the voltage conditions. For details, see [section 51.5. ADC12 Characteristics](#).

ADSSTRV register is an alias for the ADSSTR3 register.

The lower limit of the sampling time setting depends on the frequency ratio:

- If the frequency ratio of PCLKA to PCLKC (ADCLK) = 1:1, 2:1, 4:1, or 8:1 the sampling time must be set to a value of more than 5 states
- If the frequency ratio of PCLKA to PCLKC (ADCLK) = 1:2 or 1:4, the sampling time must be set to a value of more than 6 states.

Table 40.23 shows the relationship between the A/D Sampling State Register and the associated channels. For details, see [section 40.3.6. Analog Input Sampling and Scan Conversion Time](#).

Only set the SST[7:0] bits when the ADCSR.ADST bit is 0.

Table 40.23 Relationship between A/D sampling state register and associated channels

Bit name	Associated channels
ADSSTRn.SST[7:0] bits (n = 0 to 8 (unit 0), 0 to 5 (unit 1))*1	AN000 to AN008, AN100 to AN105
ADSSTRT.SST[7:0] bits	Temperature sensor output
ADSSTRO.SST[7:0] bits	Internal reference voltage
ADSSTRV.SST[7:0] bits	VBATT 1/3 voltage monitor output*2

Note 1. When the self-diagnosis function is selected, the sampling time set in the ADSSTR0.SST[7:0] bits is applied.

Note 2. For the stabilization time, see [section 11, Battery Backup Function](#).

40.2.17 ADShCR : A/D Sample and Hold Circuit Control Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ (m = 0)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ (m = 0)

Offset address: 0x066

Bit	Symbol	Function	R/W
7:0	SSTSH[7:0]	Channel-Dedicated Sample-and-Hold Circuit Sampling Time Setting Sampling time (4 to 255 states).	R/W
9:8	SHANS[1:0]	Channel-Dedicated Sample-and-Hold Circuit Bypass Select Select whether to use or bypass channel-dedicated sample-and-hold circuits for AN000, AN001 (unit 0). 0: Bypass the circuits 1: Use the circuits	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

SSTSH[7:0] bits (Channel-Dedicated Sample-and-Hold Circuit Sampling Time Setting)

The SSTSH[7:0] bits set the sampling time for the channel-dedicated sample-and-hold circuits. If one state is 1 ADCLK (A/D conversion clock) cycle and the ADCLK clock is 60 MHz, one state is 16.7 ns. The initial value is 24 states. The sampling time can be adjusted if the impedance of the analog input signal source is too high to secure sufficient sampling time, or if the ADCLK clock is slow.

Only set the SSTSH[7:0] bits while the ADCSR.ADST bit is 0. The sampling time must be set to a value that is 4 states or more and 255 or less.

SHANS[1:0] bits (Channel-Dedicated Sample-and-Hold Circuit Bypass Select)

The SHANS[1:0] bits select whether to use or bypass the channel-dedicated sample-and-hold circuits for AN000, AN001 (unit 0). In unit 0, the SHANS[0] bit is associated with AN000, the SHANS[1] bit with AN001.

If any channel from among AN000, AN001 (unit 0) is selected for group B while operation is in group scan mode under group A priority control, use this setting to bypass the dedicated sample-and-hold circuit of the channel.

Only set the SHANS[1:0] bits while the ADCSR.ADST bit is 0 and the ADSHMSR.SHMD bit is 0.

40.2.18 ADSHMSR : A/D Sample and Hold Operation Mode Selection Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0)

Offset address: 0x07C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SHMD
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SHMD	Sampling Operation Selection 0: Sampling Operation Selection 1: Enable continuous sampling function	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

SHMD bit (Sampling Operation Selection)

Setting SHMD to 1 enables the constant sampling function of the channel-dedicated sample-and-hold selected in the ADSHCR.SHANS[1:0] bits. Only set the SHMD bit while the ADCSR.ADST bit is 0.

When the sampling function is enabled, the sample-and-hold circuit operates sampling while the ADC12 is not operating, and it operates holding while the ADC12 is operating.

Note: The ADCSR.ADST bit must become 1 after a time of 400 ns or more elapses after the SHMD bit is set to 1 (when the permissible signal source impedance is 1 kΩ). The sampling period of the sample-and-hold circuit must be 400 ns or more (when the permissible signal source impedance is 1 kΩ).

40.2.19 ADDISCR : A/D Disconnection Detection Control Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x07A

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	PCHG	ADNDIS[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	ADNDIS[3:0]	Disconnection Detection Assist Setting 0x0: The disconnection detection assist function is disabled 0x1: Setting prohibited Others: The number of states for the discharge or precharge period.	R/W
4	PCHG	Precharge/discharge select 0: Discharge 1: Precharge	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The ADDISCR register selects either precharge or discharge, and the period of precharge or discharge for the A/D disconnection detection assist function. Only set the ADDISCR register when the ADCSR.ADST bit is 0. When the temperature sensor output or internal reference voltage is converted, the A/D converter executes discharge automatically.

Disable the disconnection detection assist function if any of the following functions are used:

- The temperature sensor
- The internal reference voltage
- A/D self-diagnosis
- VBATT 1/3 voltage monitor

ADNDIS[3:0] bits (Disconnection Detection Assist Setting)

The ADNDIS[3:0] bits specify the period of precharge or discharge. When ADNDIS[3:0] = 0000b, the disconnection detection assist function is disabled. Setting the ADNDIS[3:0] bits to 0001b is prohibited. Except when ADNDIS[3:0] = 0000b or 0001b, the specified value indicates the number of states for the period of precharge or discharge. When the ADNDIS[3:0] bits are set to any values other than 0000b or 0001b, the disconnection detection assistance function is enabled. The ADNDIS[4:0] should be set while the ADCSR.ADST bit is 0. When the ADNDIS[3:0] bits are set to any values other than 0000b, and the disconnection detection assistance is enabled, the disconnection detection assistance for the channel-dedicated sample-and-hold circuit used for analog inputs are also enabled. When the temperature sensor output or internal reference voltage is converted or self-diagnosis is used, the disconnection detection assistance cannot be used. In that case, the ADNDIS[3:0] bits should be set to 0000b.

PCHG bit (Precharge/discharge select)

The PCHG bit selects either precharge or discharge.

40.2.20 ADGSPCR : A/D Group Scan Priority Control Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x080

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	GBRP	LGRR S	—	—	—	—	—	—	—	—	—	—	—	—	GBRS CN	PGS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PGS	Group Priority Operation Setting* ¹ 0: Operate without group priority control. 1: Operate with group priority control.	R/W
1	GBRSCN	Lower-Priority Group Restart Setting (enabled only when PGS = 1 and reserved when PGS = 0.) 0: Disable rescanning of the group that was stopped in group priority operation 1: Enable rescanning of the group that was stopped in group priority operation.	R/W
13:2	—	These bits are read as 0. The write value should be 0.	R/W
14	LGRRS	Restart Channel Select Enabled only when PGS = 1 and GBRSCN = 1. 0: Start rescanning from the first channel for scanning 1: Start rescanning from the channel for which A/D conversion is not completed.	R/W
15	GBRP	Single Scan Continuous Start* ² (enabled only when PGS = 1 and reserved when PGS = 0.) 0: Single scan is not continuously activated. 1: Single scan for the group with the lower-priority is continuously activated.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting PGS to 1. Operation is not guaranteed if these bits are set to any other value.

Note 2. When the GBRP bit is set to 1, single scan is performed continuously for the group with the lower-priority regardless of the setting in the GBRSCN bit.

PGS bit (Group Priority Operation Setting)

The PGS bit controls group priority operation in group scan mode. Set the PGS bit to 1 to enable group priority operation.

The ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode) before setting the PGS bit to 1. Operation is not guaranteed if the bits are set to any other value.

When the PGS bit is set to 0, a clear operation must be performed by software as described in [section 40.6.3. Constraints on Stopping A/D Conversion](#). When the PGS bit is set to 1, use the settings described in [section 40.3.4.3. Group Priority Operation](#).

GBRSCN bit (Lower-Priority Group Restart Setting)

The GBRSCN bit controls the restarting of scan operation in group priority operation.

When the GBRSCN bit is set to 1, if the scan operation of a lower-priority group is stopped by a trigger input of a priority group, the lower-priority group scanning is restarted on completion of the priority group scanning. If a trigger of a lower-priority group is input during scanning of the priority group, the lower-priority group scanning is started on completion of the priority group scanning.

When the GBRSCN bit is set to 0, triggers input during scanning are ignored. Set the GBRSCN bit while the ADCSR.ADST bit is 0.

LGRRS bit (Restart Channel Select)

This bit sets the channel from which rescanning is to be started in group priority operation. The setting of the LGRRS bit is valid when the PGS and GBRSCN bits are 1.

If the LGRRS bit is 0, scanning of a lower-priority group that was stopped in group priority operation is restarted from the first channel after scanning of the priority group completes.

If the LGRRS bit is 1, scanning of a lower-priority group that was stopped in group priority operation is restarted (upon completion of scanning of the priority group) from the channel for which A/D conversion is not complete. If A/D conversion of the addition setting channel was not completed the specified number of times when scanning stopped, A/D conversion of the addition setting channel is performed again the specified number of times when scanning restarts.

Set the LGRRS bit while the ADCSR.ADST bit is 0.

GBRP bit (Single Scan Continuous Start)

The GBRP bit is set when a single scan operation is to be performed continuously on the group with the lower-priority.

Setting the GBRP bit to 1 starts a single scan of the group with the lower-priority. On completion of the scan, another single scan of the group with the lower-priority is started automatically. If scanning has been stopped during group priority

operation, single scan of the group with the lower-priority is automatically restarted on completion of the A/D conversion of the priority group.

Before setting the GBRP bit to 1, disable input of a trigger for the lower-priority group. If the GBRP bit is set to 1, rescanning is performed only on the group with the lower-priority even if the GBRSCN bit is set to 0.

40.2.21 ADCMPCR : A/D Compare Function Control Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x090

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPAIE	WCMPPE	CMPBIE	—	CMPAE	—	CMPBE	—	—	—	—	—	—	—	CMPAB[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	CMPAB[1:0]	Window A/B Composite Conditions Setting These bits are valid when both window A and window B are enabled (CMPAE = 1 and CMPBE = 1). 0 0: Output ADC12i_WCMPM ($i = 0, 1$) when window A OR window B comparison conditions are met. Otherwise, output ADC12i_WCMPUM ($i = 0, 1$). 0 1: Output ADC12i_WCMPM ($i = 0, 1$) when window A EXOR window B comparison conditions are met. Otherwise, output ADC12i_WCMPUM ($i = 0, 1$). 1 0: Output ADC12i_WCMPM ($i = 0, 1$) when window A AND window B comparison conditions are met. Otherwise, output ADC12i_WCMPUM ($i = 0, 1$). 1 1: Setting prohibited.	R/W
8:2	—	These bits are read as 0. The write value should be 0.	R/W
9	CMPBE	Compare Window B Operation Enable 0: Disable compare window B operation. Disable ADC12i_WCMPM ($i = 0, 1$) and ADC12i_WCMPUM ($i = 0, 1$) outputs. 1: Enable compare window B operation.	R/W
10	—	This bit is read as 0. The write value should be 0.	R/W
11	CMPAE	Compare Window A Operation Enable 0: Disable compare window A operation. Disable ADC12i_WCMPM ($i = 0, 1$) and ADC12i_WCMPUM ($i = 0, 1$) outputs. 1: Enable compare window A operation.	R/W
12	—	This bit is read as 0. The write value should be 0.	R/W
13	CMPBIE	Compare B Interrupt Enable 0: Disable ADC12i_CMPBI ($i = 0, 1$) interrupt when comparison conditions (window B) are met. 1: Enable ADC12i_CMPBI ($i = 0, 1$) interrupt when comparison conditions (window B) are met.	R/W
14	WCMPPE	Window Function Setting 0: Disable window function Window A and window B operate as a comparator to compare the single value on the lower side with the A/D conversion result. 1: Enable window function Window A and window B operate as a comparator to compare the two values on the upper and lower sides with the A/D conversion result.	R/W
15	CMPAIE	Compare A Interrupt Enable 0: Disable ADC12i_CMPAI ($i = 0, 1$) interrupt when comparison conditions (window A) are met. 1: Enable ADC12i_CMPAI ($i = 0, 1$) interrupt when comparison conditions (window A) are met.	R/W

Note: S-TYPE-3, P-TYPE-3

CMPAB[1:0] bits (Window A/B Composite Conditions Setting)

The CMPAB[1:0] bits are valid when both window A and window B are enabled (CMPAE = 1 and CMPBE = 1) in single scan mode. These bits specify the compare function match/mismatch event output conditions and monitoring conditions of ADWINMON.MONCOMB. Only set the CMPAB[1:0] bits while the ADCSR.ADST bit is 0.

CMPBE bit (Compare Window B Operation Enable)

The CMPBE bit enables or disables the compare window B operation. Set the CMPBE bit while the ADCSR.ADST bit is 0. Set this bit to 0 before setting the following registers:

- A/D Channel Select Registers A0, B0 (ADANSA0, ADANSB0)
- OCSB, TSSB, OCSA, or TSSA bits in the A/D Conversion Extended Input Control Register (ADEXICR)
- CMPCHB[5:0] bits in the Window B Channel Select Register (ADCMPBNSR)

CMPAE bit (Compare Window A Operation Enable)

The CMPAE bit enables or disables the compare window A operation. Set the CMPAE bit while the ADCSR.ADST bit is 0. Set this bit to 0 before setting the following registers:

- A/D Channel Select Registers A0, B0 (ADANSA0, ADANSB0)
- OCSB, TSSB, OCSA, or TSSA bits in the A/D Conversion Extended Input Control Register (ADEXICR)
- Window A Channel Select Registers 0 (ADCMPANSR0)
- Window A Extended Input Select Register (ADCMPANSER)

CMPBIE bit (Compare B Interrupt Enable)

The CMPBIE bit enables or disables the ADC12i_CMPBI (i = 0, 1) interrupt output when the comparison conditions (window B) are met.

WCMPE bit (Window Function Setting)

The WCMPE bit enables or disables the window function. Set the WCMPE bit while the ADCSR.ADST bit is 0.

CMPAIE bit (Compare A Interrupt Enable)

The CMPAIE bit enables or disables the ADC12i_CMPAI (i = 0, 1) interrupt output when the comparison conditions (window A) are met.

40.2.22 ADCMPANSR0 : A/D Compare Function Window A Channel Select Register 0

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ (m = 0, 1)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ (m = 0, 1)

Bit	Symbol	Function	R/W
15:0	CMPCHA15 to CMPCHA00*1	Compare Window A Channel Select Bit 15 (CMPCHA15) is associated with ANm15 and bit 0 (CMPCHA00) is associated with ANm00. 0: Disable compare function for associated input channel 1: Enable compare function for associated input channel	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

Note 1. 00 to 08 (unit 0), 00 to 05 (unit 1) is available.

CMPCHAN bits (Compare Window A Channel Select)

The compare function is enabled by writing 1 to the CMPCHAN bits with the same number as the A/D conversion channel selected in the ADANSA0.ANSAn bits and the ADANSB0.ANSBn bits.

Set the CMPCHAN bits while the ADCSR.ADST bit is 0.

40.2.23 ADCMPANSER : A/D Compare Function Window A Extended Input Select Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x092

Bit position:	7	6	5	4	3	2	1	0

Note: S-TYPE-3, P-TYPE-3

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

Note 1. 00 to 08 (unit 0), 00 to 05 (unit 1) is available.

CMPLCHAN bits (Compare Window A Comparison Condition Select)

The CMPLCHAN bits specify the comparison conditions for channels to which Window A comparison conditions are applied. These bits can be set for each analog input to be compared. When the comparison result of each analog input meets the set condition, the ADCMPDR0.CMPSTCHAN flag sets to 1 and a compare interrupt (ADC12i_CMPAI (i = 0, 1)) is generated.

Comparison conditions when the window function is disabled			
CMPLCHAN = 0		CMPLCHAN = 1	
ADCMPDR0 value ≤ A/D converted value	Not met	ADCMPDR0 value < A/D converted value	Met
ADCMPDR0 value > A/D converted value	Met	ADCMPDR0 value ≥ A/D converted value	Not met

7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CMPLTSA bit (Compare Window A Temperature Sensor Output Comparison Condition Select)

The CMPLTSA bit specifies comparison conditions when the temperature sensor output is the target for the Window A comparison condition. When the temperature sensor output comparison result meets the set condition, the ADCMPSESR.CMPSTTSA flag sets to 1 and a compare interrupt (ADC12i_CMPAI (i = 0, 1)) is generated.

CMPLOCA bit (Compare Window A Internal Reference Voltage Comparison Condition Select)

The CMPLOCA bit specifies comparison conditions when the internal reference voltage is the target for the Window A comparison condition. When the internal reference voltage comparison result meets the set condition, the ADCMPSESR.CMPSTOCA flag sets to 1 and a compare interrupt (ADC12i_CMPAI (i = 0, 1)) is generated.

40.2.26 ADCMPDRn : A/D Compare Function Window A Lower-Side/Upper-Side Level Setting Register (n = 0, 1)

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
 ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x09C + (0x2 × n)

Bit position: 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bit field:

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Note: S-TYPE-3, P-TYPE-3

The ADCMPDRy (y = 0, 1) register specifies the reference data when the compare window A function is used. ADCMPDR0 sets the lower reference for window A, and ADCMPDR1 sets the upper reference for window A.

ADCMPDRy are read/write registers.

ADCMPDRy are writable even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion*1.

Set these registers so that the upper reference is not less than the lower reference (ADCMPDR1 ≥ ADCMPDR0). ADCMPDR1 are not used when the window function is disabled.

Note 1. The lower and the upper references are changed when each register is written. For example, when the upper reference value is changed and the lower reference value is being changed, the MCU compares the upper reference (after rewrite), and the lower reference (before rewrite) with the A/D conversion result. See [Figure 40.5](#). If the comparison during the rewriting of these two references is erroneous, then rewrite these reference values when both ADCSR.ADST and the target Compare Window Operation Enable bit (ADCMPCR.CMPAE or ADCMPCR.CMPBE) are 0.

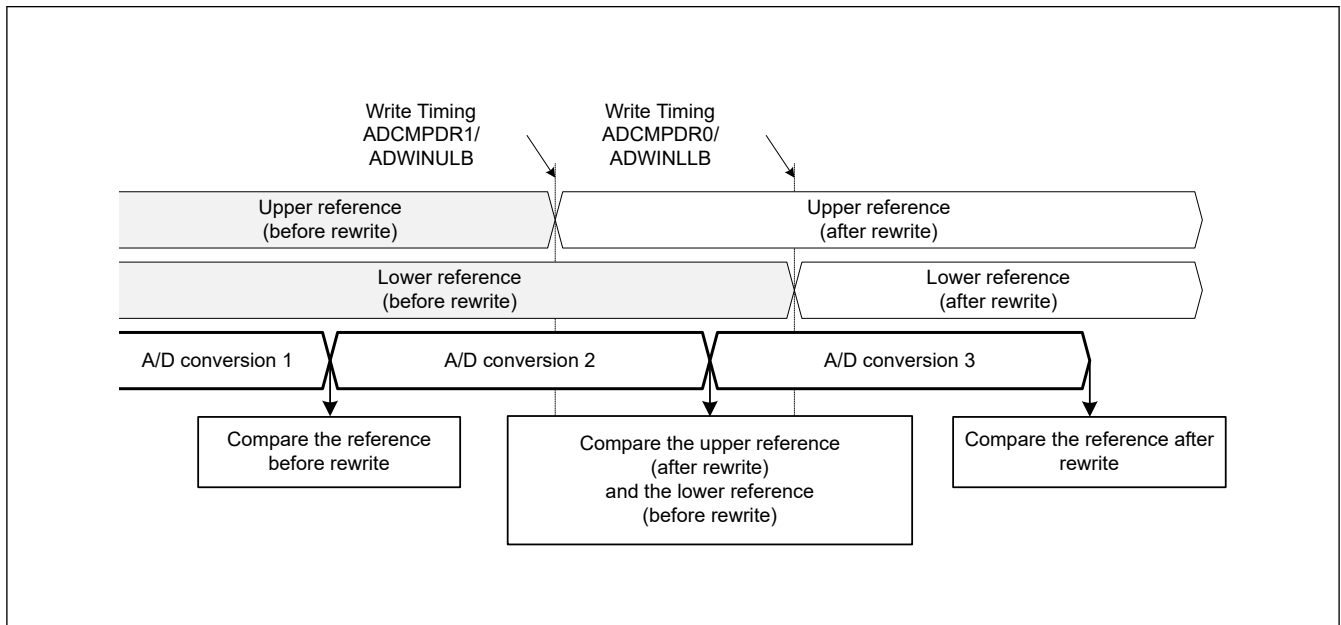

Figure 40.5 Comparison between upper and lower references before and after a rewrite

The ADCMPDRy registers use different formats depending on the following conditions:

- The value of A/D Data Register Format Select bit (flush-right or flush-left)
- The value of the A/D Conversion Accuracy Select bit (12-bit, 10-bit, 8-bit)
- The value of A/D-Converted Value Addition/Average Channel Select bits (A/D-converted value addition mode selected or not selected).

The data formats for each condition are shown as follows:

1. When A/D-converted value addition mode is not selected
 - Flush-right data with 12-bit accuracy — Lower 12 bits ([11:0]) are valid
 - Flush-right data with 10-bit accuracy — Lower 10 bits ([9:0]) are valid
 - Flush-right data with 8-bit accuracy — Lower 8 bits ([7:0]) are valid
 - Flush-left data with 12-bit accuracy — Upper 12 bits ([15:4]) are valid
 - Flush-left data with 10-bit accuracy — Upper 10 bits ([15:6]) are valid
 - Flush-left data with 8-bit accuracy — Upper 8 bits ([15:8]) are valid
2. When A/D-converted value addition mode is selected
 - Flush-right data with 12-bit accuracy — Lower 14 bits ([13:0]) are valid
 - Flush-right data with 10-bit accuracy — Lower 12 bits ([11:0]) are valid
 - Flush-right data with 8-bit accuracy — Lower 10 bits ([9:0]) are valid
 - Flush-left data with 12-bit accuracy — Upper 14 bits ([15:2]) are valid
 - Flush-left data with 10-bit accuracy — Upper 12 bits ([15:4]) are valid
 - Flush-left data with 8-bit accuracy — Upper 10 bits ([15:6]) are valid

40.2.27 ADWINnLB : A/D Compare Function Window B Lower-Side/Upper-Side Level Setting Register (n = L, U)

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ (m = 0, 1)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ (m = 0, 1)

Offset address: 0x0A8 (n = L)
 0x0AA (n = U)

Note: S-TYPE-3, P-TYPE-3

The ADWINULB and ADWINLLB registers specify the reference data when the compare window B function is used. ADWINLLB sets the lower reference for window B, and ADWINULB sets the upper reference for window B.

ADWINnLB are read/write registers.

ADWINnLB are writable even during A/D conversion. The reference data can be dynamically changed by rewriting register values during A/D conversion^{*1}.

Set these registers so that the upper reference is not less than the lower reference ($ADWINULB \geq ADWINLLB$). ADWINULB are not used when the window function is disabled.

Note 1. The lower and the upper references are changed when each register is written. For example, when the upper reference value is changed and the lower reference value is being changed, the MCU compares the upper reference (after rewrite), and the lower reference (before rewrite) with the A/D conversion result. See [Figure 40.6](#). If the comparison during the rewriting of these two references is erroneous, then rewrite these reference values when both ADCSR.ADST and the target Compare Window Operation Enable bit (ADCMPCR.CMPAE or ADCMPCR.CMPBE) are 0.

Figure 40.6 Comparison between upper and lower references before and after a rewrite

The ADWINnLB registers use different formats depending on the following conditions:

- The value of A/D Data Register Format Select bit (flush-right or flush-left)
- The value of the A/D Conversion Accuracy Select bit (12-bit, 10-bit, 8-bit)
- The value of A/D-Converted Value Addition/Average Channel Select bits (A/D-converted value addition mode selected or not selected).

The data formats for each condition are shown as follows:

1. When A/D-converted value addition mode is not selected
 - Flush-right data with 12-bit accuracy — Lower 12 bits ([11:0]) are valid
 - Flush-right data with 10-bit accuracy — Lower 10 bits ([9:0]) are valid
 - Flush-right data with 8-bit accuracy — Lower 8 bits ([7:0]) are valid
 - Flush-left data with 12-bit accuracy — Upper 12 bits ([15:4]) are valid
 - Flush-left data with 10-bit accuracy — Upper 10 bits ([15:6]) are valid
 - Flush-left data with 8-bit accuracy — Upper 8 bits ([15:8]) are valid
2. When A/D-converted value addition mode is selected
 - Flush-right data with 12-bit accuracy — Lower 14 bits ([13:0]) are valid
 - Flush-right data with 10-bit accuracy — Lower 12 bits ([11:0]) are valid
 - Flush-right data with 8-bit accuracy — Lower 10 bits ([9:0]) are valid
 - Flush-left data with 12-bit accuracy — Upper 14 bits ([15:2]) are valid
 - Flush-left data with 10-bit accuracy — Upper 12 bits ([15:4]) are valid
 - Flush-left data with 8-bit accuracy — Upper 10 bits ([15:6]) are valid

40.2.28 ADCMPSTR0 : A/D Compare Function Window A Channel Status Register 0

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x0A0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMPSTCHA TCHA 15	CMPSTCHA TCHA 14	CMPSTCHA TCHA 13	CMPSTCHA TCHA 12	CMPSTCHA TCHA 11	CMPSTCHA TCHA 10	CMPSTCHA TCHA 09	CMPSTCHA TCHA 08	CMPSTCHA TCHA 07	CMPSTCHA TCHA 06	CMPSTCHA TCHA 05	CMPSTCHA TCHA 04	CMPSTCHA TCHA 03	CMPSTCHA TCHA 02	CMPSTCHA TCHA 01	CMPSTCHA TCHA 00
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	CMPSTCHA15 to CMPSTCHA00 ^{*1}	Compare Window A Flag When Window A operation is enabled (ADCMPCR.CMPAE = 1b), these bits indicate the comparison result of channels to which Window A comparison conditions are applied. Bit 15 (CMPSTCHA15) is associated with ANm15 and bit 0 (CMPSTCHA00) is associated with ANm00. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Bits associated with non-existent pins are reserved. This bit is read as 0. The write value should be 0.

Note 1. 00 to 08 (unit 0), 00 to 05 (unit 1) is available.

CMPSTCHAN flags (Compare Window A Flag)

The CMPSTCHAN flags indicate the comparison results for channels to which Window A comparison conditions are applied. When a comparison condition set in ADCMPLR0.CMPLCHA is met at the end of A/D conversion, the associated CMPSTCHAN flag sets to 1. When the ADCMPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTCHAN flags is invalid.

[Setting condition]

- The condition set in ADCMPLR0.CMPLCHA is met when ADCMPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

40.2.29 ADCMPSER : A/D Compare Function Window A Extended Input Channel Status Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x0A4

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	CMPS TOCA	CMPS TTSA
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CMPSTTSA	Compare Window A Temperature Sensor Output Compare Flag When Window A operation is enabled (ADCMPPCR.CMPAE = 1), this bit indicates the temperature sensor output comparison result. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W
1	CMPSTOCA	Compare Window A Internal Reference Voltage Compare Flag When Window A operation is enabled (ADCMPPCR.CMPAE = 1), this bit indicates the internal reference voltage comparison result. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The ADCMPSER register stores compare results of compare function window A.

CMPSTTSA flag (Compare Window A Temperature Sensor Output Compare Flag)

The CMPSTTSA flag indicates the temperature sensor output comparison result. When the comparison condition set in ADCMPPLER.CMPLTSA is met at the end of A/D conversion, this flag sets to 1. When the ADCMPPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI ($i = 0, 1$)) is generated when this flag sets to 1.

Writing 1 to the CMPSTTSA flag is invalid.

[Setting condition]

- The condition set in ADCMPPLER.CMPLTSA is met when ADCMPPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

CMPSTOCA flag (Compare Window A Internal Reference Voltage Compare Flag)

The CMPSTOCA flag indicates the internal reference voltage comparison result. When the comparison condition set in ADCMPPLER.CMPLOCA is met at the end of A/D conversion, this flag sets to 1. When the ADCMPPCR.CMPAIE bit is 1, a compare interrupt request (ADC12i_CMPAI ($i = 0, 1$)) is generated when this flag sets to 1.

Writing 1 to the CMPSTOCA flag is invalid.

[Setting condition]

- The condition set in ADCMPPLER.CMPLOCA is met when ADCMPPCR.CMPAE = 1.

[Clearing condition]

- Writing 0 after reading 1.

40.2.30 ADCMPBNSR : A/D Compare Function Window B Channel Select Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x0A6

Bit	Symbol	Function	R/W																																																
5:0	CMPCHB[5:0]	Compare Window B Channel Select These bits select channels to be compared with the compare Window B conditions. <table border="1"> <thead> <tr> <th>CMPCHB[5:0]</th> <th>Unit 0</th> <th>Unit 1</th> </tr> </thead> <tbody> <tr><td>0x00</td><td>AN000</td><td>AN100</td></tr> <tr><td>0x01</td><td>AN001</td><td>AN101</td></tr> <tr><td>0x02</td><td>AN002</td><td>AN102</td></tr> <tr><td>0x03</td><td>AN003 / VBATT 1/3 voltage monitor output</td><td>AN103 / VBATT 1/3 voltage monitor output</td></tr> <tr><td>0x04</td><td>AN004</td><td>AN104</td></tr> <tr><td>0x05</td><td>AN005</td><td>AN105</td></tr> <tr><td>0x06</td><td>AN006</td><td>Do not select</td></tr> <tr><td>0x07</td><td>AN007</td><td>Do not select</td></tr> <tr><td>0x08</td><td>AN008</td><td>Do not select</td></tr> <tr><td>0x09</td><td>Do not select</td><td>Do not select</td></tr> <tr><td>⋮</td><td>⋮</td><td>⋮</td></tr> <tr><td>0x20</td><td>Temperature sensor</td><td></td></tr> <tr><td>0x21</td><td>Internal reference voltage</td><td></td></tr> <tr><td>0x3F</td><td>Do not select</td><td></td></tr> <tr><td>Others</td><td>Setting prohibited</td><td></td></tr> </tbody> </table>	CMPCHB[5:0]	Unit 0	Unit 1	0x00	AN000	AN100	0x01	AN001	AN101	0x02	AN002	AN102	0x03	AN003 / VBATT 1/3 voltage monitor output	AN103 / VBATT 1/3 voltage monitor output	0x04	AN004	AN104	0x05	AN005	AN105	0x06	AN006	Do not select	0x07	AN007	Do not select	0x08	AN008	Do not select	0x09	Do not select	Do not select	⋮	⋮	⋮	0x20	Temperature sensor		0x21	Internal reference voltage		0x3F	Do not select		Others	Setting prohibited		R/W

7	CMPPLB	Compare Window B Comparison Condition Setting This bit sets comparison conditions for channels for Window B. The comparison conditions are shown in Figure 40.7 . <ul style="list-style-type: none"> 0: When window function is disabled (ADCMPCR.WCMPE = 0): ADWINLLB value > A/D-converted value When window function is enabled (ADCMPCR.WCMPE = 1): A/D-converted value < ADWINLLB value, or ADWINULB value < A/D-converted value 1: When window function is disabled (ADCMPCR.WCMPE = 0): ADWINLLB value < A/D-converted value When window function is enabled (ADCMPCR.WCMPE = 1): ADWINLLB value < A/D-converted value < ADWINULB value 	R/W																																																

Note: S-TYPE-3, P-TYPE-3

CMPCHB[5:0] bits (Compare Window B Channel Select)

The CMPCHB[5:0] bits specify the channels to be compared with the compare Window B conditions from AN000 to AN002, AN004 to AN008, AN100 to AN102, AN104, AN105, the temperature sensor, the internal reference voltage and the VBATT 1/3 voltage monitor output. The compare Window B function is enabled by specifying the hexadecimal number of the A/D conversion channel selected in the ADANSA0, ADANSB0 registers.

Set the CMPCHB[5:0] bits while the ADCSR.ADST bit is 0.

CMPLB bit (Compare Window B Comparison Condition Setting)

The CMPLB bit specifies the comparison conditions for channels for Window B. When the comparison result of an analog input meets the set condition, the associated ADCMPBSR.CMPSTB flag sets to 1 and a compare interrupt request (ADC12i_CMPBI (i = 0, 1)) is generated.

Compare conditions when the window function is disabled			
CMPLB = 0		CMPLB = 1	
ADWINLLB value ≤ A/D converted value	Not met	ADWINLLB value < A/D converted value	Met
ADWINLLB value > A/D converted value	Met	ADWINLLB value ≥ A/D converted value	Not met
Compare conditions when the window function is enabled			
CMPLB = 0			
A/D converted value > ADWINULB value		Met	
ADWINLLB value ≤ A/D converted value ≤ ADWINULB value		Not met	
A/D converted value < ADWINLLB value		Met	
CMPLB = 1			
A/D converted value ≥ ADWINULB value		Not met	
ADWINLLB value < A/D converted value < ADWINULB value		Met	
A/D converted value ≤ ADWINLLB value		Not met	

Figure 40.7 Explanation of compare conditions for compare function Window B

40.2.31 ADCMPBSR : A/D Compare Function Window B Status Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
 ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0AC

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	CMPS TB

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	CMPSTB	Compare Window B Flag When Window B operation is enabled (ADCMPCR.CMPBE = 1), this bit indicates the comparison result of channels to which Window B comparison conditions are applied, temperature sensor output, internal reference voltage. 0: Comparison conditions are not met. 1: Comparison conditions are met.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

CMPSTB flag (Compare Window B Flag)

The CMPSTB flag indicates the comparison result of channels to which Window B comparison conditions are applied, the temperature sensor output, internal reference voltage. When the comparison condition set in ADCMPBNSR.CMPLB is met at the end of A/D conversion, this flag sets to 1. When the ADCMPCR.CMPBIE bit is 1, a compare interrupt request (ADC12i_CMPBI (i = 0, 1)) is generated when this flag sets to 1.

Writing 1 to the CMPSTB flag is invalid.

[Setting condition]

- The condition set in ADCMPBNSR.CMPLB is met when ADCMPCR.CMPBE = 1.

[Clearing condition]

- Writing 0 after reading 1.

40.2.32 ADWINMON : A/D Compare Function Window A/B Status Monitor Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x08C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	MONC MPB	MONC MPA	—	—	—	MONC OMB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	MONCOMB	Combination Result Monitor This bit indicates the combination result. This bit is valid when both Window A and Window B operations are enabled. 0: Window A/B composite conditions are not met. 1: Window A/B composite conditions are met.	R
3:1	—	These bits are read as 0.	R
4	MONCMPA	Comparison Result Monitor A 0: Window A comparison conditions are not met. 1: Window A comparison conditions are met.	R
5	MONCMPB	Comparison Result Monitor B 0: Window B comparison conditions are not met. 1: Window B comparison conditions are met.	R
7:6	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

MONCOMB bit (Combination Result Monitor)

The read-only MONCOMB bit indicates the combined result of comparison condition results A and B based on the combination condition set in the ADCMPCR.CMPAB[1:0] bits.

[Setting condition]

- The combined result meets the combination condition set in the ADCMPCR.CMPAB[1:0] bits when ADCMPCR.CMPAE = 1 and ADCMPCR.CMPBE = 1.

[Clearing conditions]

- The combined result does not meet the combination condition set in the ADCMPCR.CMPAB[1:0] bits.
- ADCMPCR.CMPAE = 0 or ADCMPCR.CMPBE = 0.

MONCMPA bit (Comparison Result Monitor A)

The read-only MONCMPA bit is read as 1 when the A/D-converted value of the Window A target channel meets the condition set in ADCMPLR0 and ADCMPLER. Otherwise, it is read as 0.

[Setting condition]

- The A/D-converted value meets the condition set in the ADCMPLR0 and ADCMPLER registers when ADCMPCR.CMPAE = 1.

[Clearing conditions]

- The A/D-converted value does not meet the condition set in the ADCMPLR0 and ADCMPLER registers when ADCMPCR.CMPAE = 1.
- ADCMPCR.CMPAE = 0 (automatically cleared when the ADCMPCR.CMPAE value changes from 1 to 0).

MONCMPB bit (Comparison Result Monitor B)

The read-only MONCMPB bit is read as 1 when the A/D-converted value of the Window B target channel meets the condition set in the ADCMPBNSR.CMPLB bit. Otherwise, it is read as 0.

[Setting condition]

- The A/D-converted value meets the condition set in ADCMPBNSR.CMPLB when ADCMPCR.CMPBE = 1.

[Clearing conditions]

- The A/D-converted value does not meet the condition set in ADCMPBNSR.CMPLB when ADCMPCR.CMPBE = 1.
- ADCMPCR.CMPBE = 0 (automatically cleared when the ADCMPCR.CMPBE value changes from 1 to 0).

40.2.33 ADBUFEN : A/D Data Buffer Enable Register

Base address: ADC12m = 0x4033_2000 + 0x0200 × m (m = 0, 1)
ADC12m_NS = 0x5033_2000 + 0x0200 × m (m = 0, 1)

Offset address: 0x0D0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	BUFEN
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BUFEN	Data Buffer Enable 0: The data buffer is not used. 1: The data buffer is used.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The ADBUFEN register sets whether to enable the data buffer.

BUFEN bit (Data Buffer Enable)

This bit enables the use of the data buffer.

When BUFEN = 1b, A/D conversion result (addition result) other than self-diagnosis result is stored in ADBUFn.

Disable the data storage operation (BUFEN = 0b) before reading ADBUFPTR.

Do not use the data buffer for data duplexing, or group scan.

40.2.34 ADBUFPTR : A/D Data Buffer Pointer Register

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: 0x0D2

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	PTRO VF	BUFPtr[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	BUFPtr[3:0]	Data Buffer Pointer These bits indicate the number of data buffer to which the next A/D converted data is transferred.	R/W
4	PTROVF	Pointer Overflow Flag 0: The data buffer pointer has not overflowed. 1: The data buffer pointer has overflowed.	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

ADBUFPtr is a register that indicates the data buffer pointer and overflow status.

BUFPtr[3:0] bit (Data Buffer Pointer)

These bits indicate the number of data buffer to which the next A/D converted data is transferred.

When data has been transferred to data buffer 15, the pointer value becomes 0000b and the PTROVF bit is set to 1.

When the next data has been transferred, the data in data buffer 0 is overwritten.

Writing 0x00 to this register clears the value of these bits. Writing a value other than 0x00 is disabled.

PTROVF bit (Pointer Overflow Flag)

This bit indicates whether the data buffer pointer has overflowed. This bit is set to 1 when the pointer value becomes 0000b (overflow).

Writing 0x00 to this register clears this bit value. Writing a value other than 0x00 is disabled.

40.2.35 ADBUFn : A/D Data Buffer Registers n (n = 0 to 15)

Base address: $ADC12m = 0x4033_2000 + 0x0200 \times m$ ($m = 0, 1$)
 $ADC12m_NS = 0x5033_2000 + 0x0200 \times m$ ($m = 0, 1$)

Offset address: $0x0B0 + 0x2 \times n$ ($n = 0$ to 15)

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	ADBUF[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	ADBUF[15:0]	Converted Value 15 to 0 Functions vary depending on the selected mode and accuracy. See Table 40.24 and Table 40.25 .	R

Note: S-TYPE-3, P-TYPE-3

ADBUFn registers are 16-bit read-only registers that sequentially store all A/D conversion results. The automatic clear function is not applied to these registers.

ADBUFn settings are the same as the A/D data register format settings.

The following conditions determine the formats for data in the ADBUFn registers:

- Setting of the Register Format Select bit (ADCER.ADRFMT) (flush-left or flush-right)
- Setting of the Addition/Average Count Select bits (ADADC.ADC[2:0]) (1, 2, 3, 4, or 16 times)
- Setting of the Average Mode Enable bit (ADADC.AVEE) (addition or average).

This section describes the data formats for these conditions in different modes.

(1) When A/D-converted value addition/average mode is not selected

Table 40.24 shows the bit assignment for each accuracy.

Table 40.24 Bit assignment for each accuracy

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	These bits are read as 0.				Converted Value 11 to 0: 12-bit A/D-converted value											
Left-justified data with 12-bit accuracy	Converted Value 11 to 0: 12-bit A/D-converted value												These bits are read as 0.			

(2) When A/D-converted value average mode is selected

A/D-converted value average mode can be selected when 2 or 4 times is specified in the A/D-converted value addition mode. When A/D converted value average mode is selected, These registers indicate the mean of A/D-converted values on a specific channel. The value is stored in the A/D data register based on the setting of the A/D Data Register Format Select bit in the same way as for normal A/D conversion.

(3) When A/D-converted value addition mode is selected

For 12-bit, 10-bit, 8-bit accuracy, 1, 2, 3, or 4 times can be selected in the A/D-converted value addition mode. A/D conversion results are stored in the A/D data register as a 2-bit-extended value of the specified conversion accuracy.

For 12-bit accuracy, 16 times can also be selected in the A/D-converted value addition mode. In A/D-converted value addition mode, these registers indicate the value that is obtained by adding A/D-converted values on a specific channel. A/D conversion results are stored in the A/D data register as a 4-bit-extended value of the specified conversion accuracy.

When A/D-converted value addition mode is selected, the value is stored in the A/D data register based on the settings of the A/D Data Register Format Select bits.

Table 40.25 shows the bit assignment for each accuracy.

Table 40.25 Bit assignment for each accuracy when A/D-converted value addition mode is selected

Accuracy	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Right-justified data with 12-bit accuracy	When 16 conversion times is specified		Added Value 15 to 0: 16-bit sum of A/D conversion results													
	When 1, 2, 3, or 4 conversion times is specified		These bits are read as 0.		Added Value 13 to 0: 14-bit sum of A/D conversion results											
Left-justified data with 12-bit accuracy	When 1, 2, 3, or 4 conversion times is specified		Added Value 15 to 0: 16-bit sum of A/D conversion results													
	When 16 conversion times is specified		Added Value 13 to 0: 14-bit sum of A/D conversion results													These bits are read as 0.

40.3 Operation

40.3.1 Scanning Operation

In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.

Scan conversion is performed in any of the three operating modes:

- Single scan mode
- Continuous scan mode
- Group scan mode

In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until software sets the ADCSR.ADST bit to 0. In group scan mode, the selected channels in group A, B are scanned once after scan starts in response to the respective synchronous trigger.

In single scan mode and continuous scan mode, A/D conversion is performed for the ANn channels selected in the ADANSA0 register, starting from the channel with the smallest number n. In group scan mode, A/D conversion is performed for the ANn channels in group A selected in the ADANSA0 register, and for the ANn channels in group B selected in the ADANSB0 register, starting from the channel with the smallest number n.

When self-diagnosis is selected, it is executed once at the beginning of each scan and one of the three reference voltages is converted.

The temperature sensor output and internal reference voltage can be selected at the same time as the analog input of the channels, and A/D conversion is performed on the analog input of channels, temperature sensor output, and internal reference voltage, in that order.

Double trigger mode can be used with single scan mode or group scan mode. With double trigger mode enabled (ADCSR.DBLE = 1), A/D conversion data of a channel selected in the ADCSR.DBLANS[4:0] bits is duplicated only if the conversion is started by the synchronous trigger (GPT, ELC) selected in the ADSTRGR.TRSA[5:0] bits. In group scan mode, only group A can use double trigger mode.

In the extended operation of double trigger mode, the A/D conversion operation is generated from the synchronous trigger combination selected in the ADSTRGR.TRSA[5:0] bits. In addition to normal double trigger mode operation, A/D conversion data with odd number trigger (ELC_AD00 (unit 0), ELC_AD10 (unit 1), GTCIADAn (Unit0) and GTCIADAm (Unit1) (n = 0 to 3, m = 4, 5)) is stored in A/D Data Duplexing Register A (ADDBLDRA), and A/D conversion data with even number trigger (ELC_AD01 (unit 0), ELC_AD11 (unit 1), GTCIADBn (Unit0) and GTCIADBm (Unit1) (n = 0 to 3, m = 4, 5)) is stored in A/D Data Duplexing Register B (ADDBLDRB). In the extended operation of double trigger mode, when one of the trigger combinations occurs at the same time, the data duplexing register settings for the specified triggers do not work, and A/D conversion data is stored in A/D Data Duplexing Register B (ADDBLDRB).

The ADC12 ignores a synchronous trigger that occurs during the A/D conversion started by another synchronous trigger.

When any of the channels AN000, AN001 (unit 0) are set as a channel-dedicated sample-and-hold circuit in the SHANS[1:0] bits in ADSHCR, the target analog input specified is sampled and held before the first A/D conversion of each scan.

40.3.2 Single Scan Mode

40.3.2.1 Basic Operation (Without Channel-Dedicated Sample-and-Hold Circuits)

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (GPT, ELC), or an asynchronous trigger input, A/D conversion is performed for the ANn channels selected in the ADANSA0 register, starting from the channel with the smallest number n.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D data register (ADDRy).
3. When A/D conversion of all the selected channels is completed, an ADC12i_ADI (i = 0, 1) interrupt request is generated.
4. The ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion of all the selected channels is completed. The ADC12 then enters a wait state.

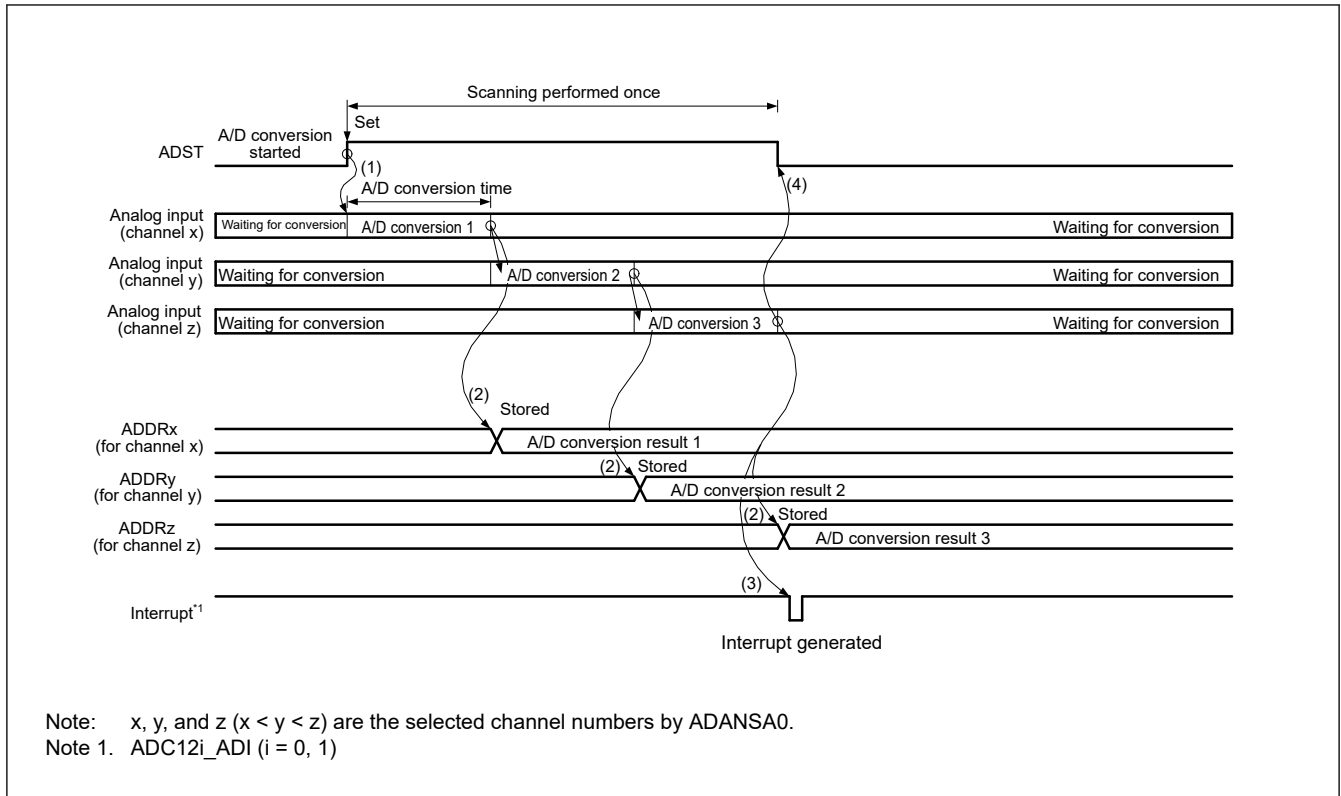

Figure 40.8 Example basic operation in single scan mode when the analog inputs (channel x to z) are selected

40.3.2.2 Basic Operation (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Disabled)

When the channel-dedicated sample-and-hold circuit is used, sample-and-hold operation is first performed, and then A/D conversion is performed on the analog input of all the specified channels once. The channels whose dedicated sample-and-hold circuit is to be used can be selected in the SHANS[1:0] bits in ADSHCR.

The operation is as follows:

1. Analog input sampling of all channels whose dedicated sample-and-hold circuit is to be used starts when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (GPT, ELC), or asynchronous trigger input.
2. After the sample-and-hold operation, A/D conversion is performed on the ANn channels selected in the ADANSA0 register, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D data register (ADDRy).
4. When A/D conversion of all the selected channels completes, an ADC12i_ADI ($i = 0$) interrupt request is generated (no register setting).
5. The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then, the ADC12 enters a wait state.

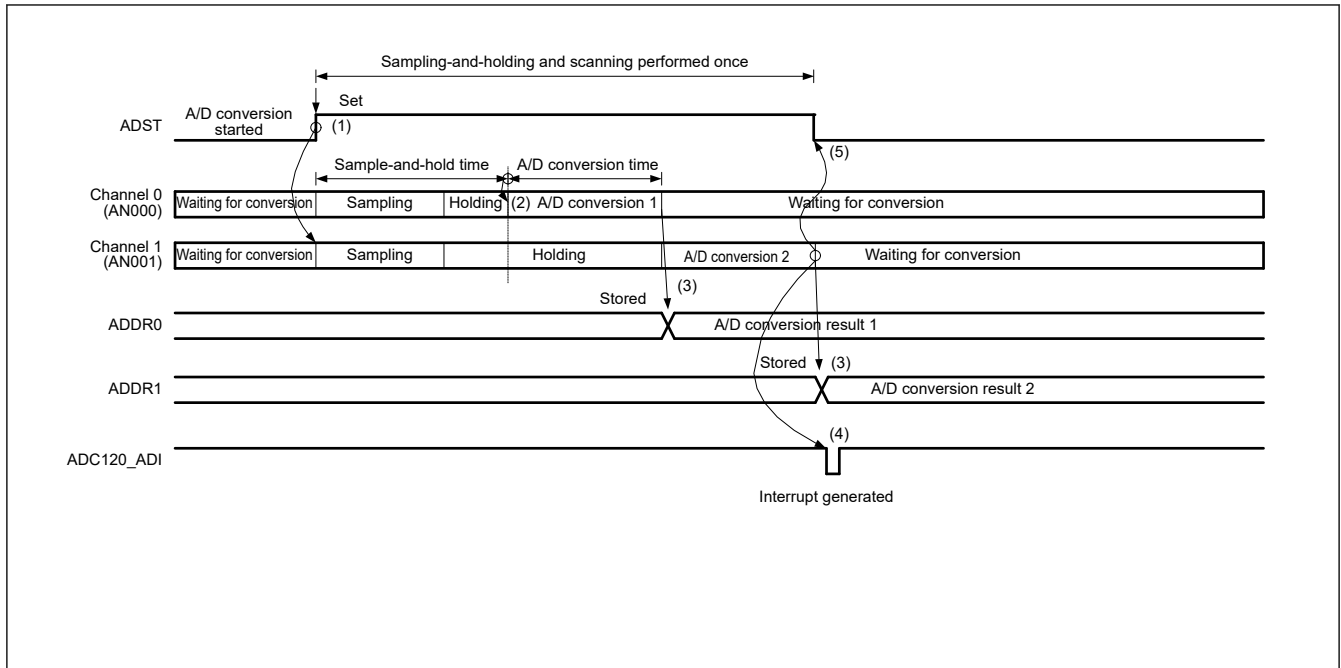

Figure 40.9 Example operation in single scan mode when the channel-dedicated sample-and-hold circuits are used and AN000, AN001 are selected

40.3.2.3 Basic Operation (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Enabled)

When a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operations are performed first, followed by A/D conversion on the analog inputs on all selected channels, once. The ADSHCR.SHANS[1:0] bits specify the channels for which the channel-dedicated sample-and-hold circuits are to be used.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[1:0] bits start continuous sampling.
2. Analog input holding starts for all the channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (GPT, ELC), or input of an asynchronous trigger.
3. After the stabilization time of the sample-and-hold circuits elapses, A/D conversion is performed on the ANn channels selected in the ADANSA0 register, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D data register (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting).
6. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then, the ADC12 enters a wait state. If this is followed by single scanning, set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).
7. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.

Figure 40.10 Example operation in single scan mode when channel-dedicated sample-and-hold circuits are used, AN000, AN001 are selected, and continuous sampling is enabled

40.3.2.4 Channel Selection and Self-Diagnosis (Without Channel-Dedicated Sample-and-Hold Circuits)

When channels and self-diagnosis are selected, A/D conversion is first performed for the reference voltage VREFH0, VREFH ($\times 0$, $\times 1/2$, or $\times 1$), then A/D conversion is performed once on the analog input of the selected channels as follows:

1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger input, a synchronous trigger input (GPT, ELC), or an asynchronous trigger input.
2. When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADDRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 register, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D data register (ADDRy).
4. When A/D conversion of all the selected channels is completed, an ADC12i_ADI (i = 0, 1) interrupt request is generated.
5. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion of all the selected channels is completed. The ADC12 then enters a wait state.

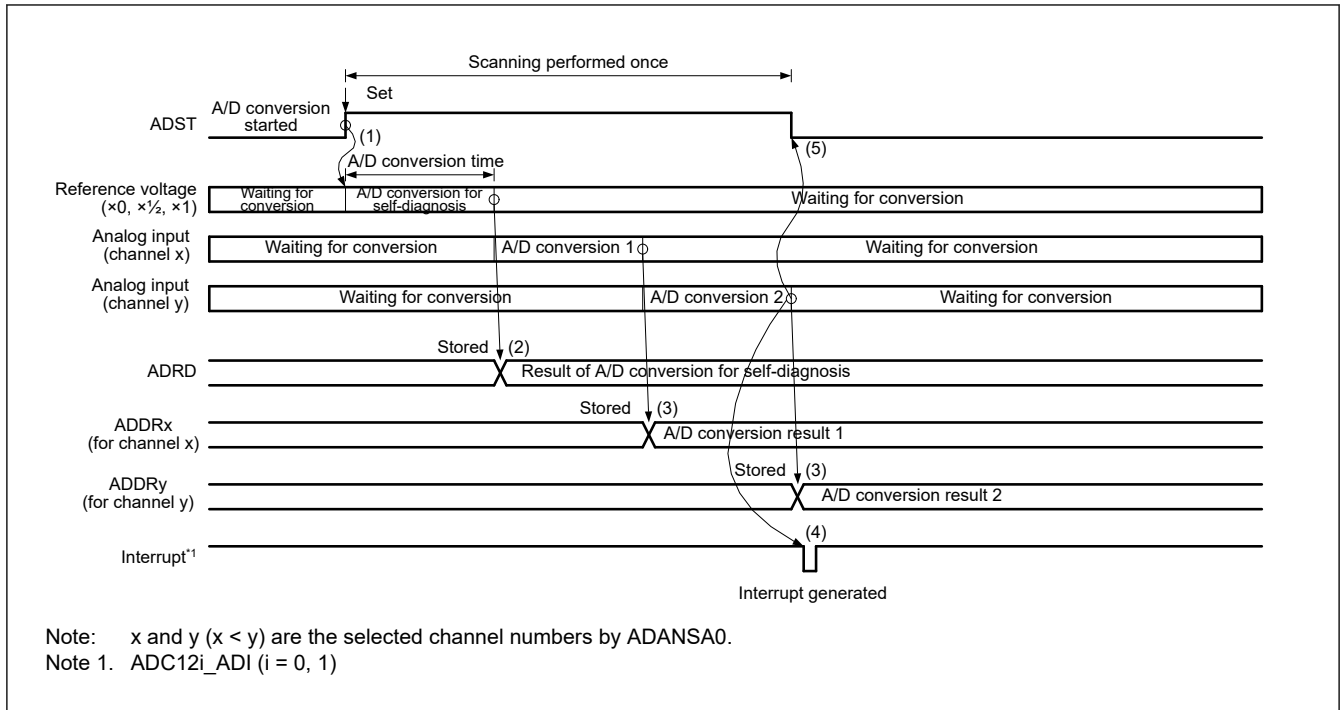

Figure 40.11 Example basic operation in single scan mode when the analog inputs (channel x and y) are selected with self- diagnosis

40.3.2.5 Channel Selection and Self-Diagnosis (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Disabled)

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is disabled, the sample-and-hold operation is performed first, and then A/D conversion is performed once for the reference voltage VREFH0 (unit 0) ($\times 0$, $\times 1/2$, or $\times 1$) supplied to the ADC12. After that, A/D conversion is performed only once on the analog input of the selected channels.

The operation is as follows:

1. Analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (GPT, ELC), or asynchronous trigger input.
2. After the sample-and-hold operation, A/D conversion for self-diagnosis starts.
3. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADDRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 register, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting).
6. The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then, the ADC12 enters a wait state.

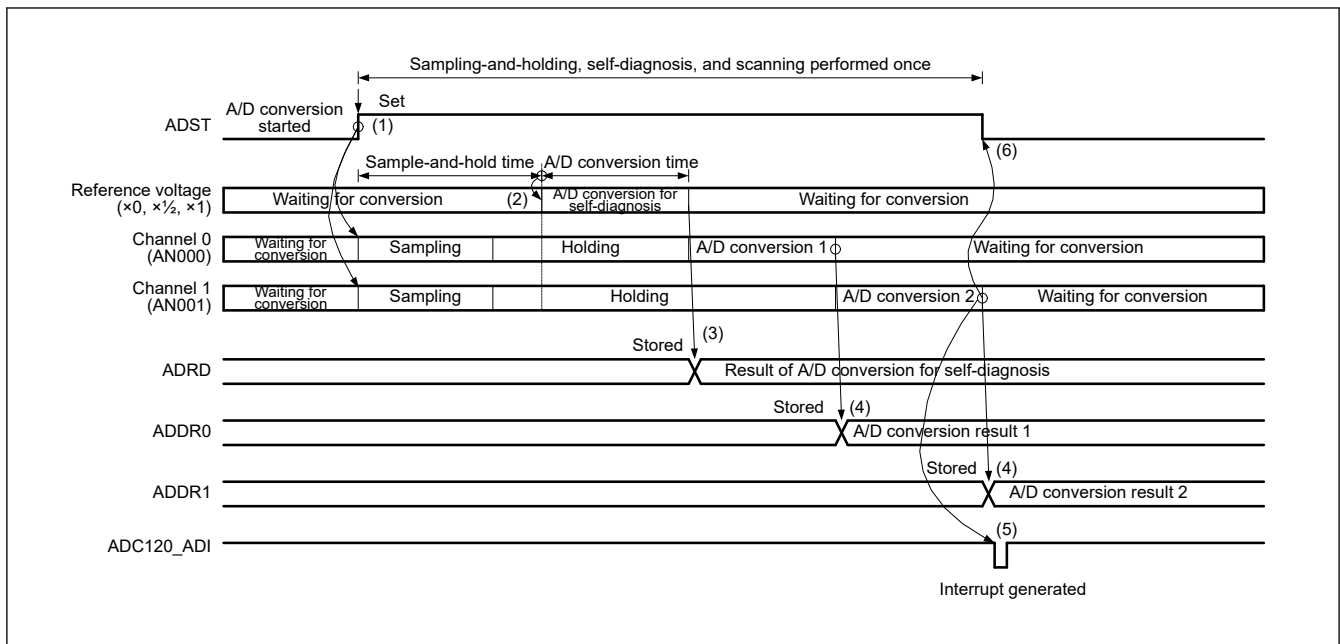

Figure 40.12 Example operation in single scan mode when channel-dedicated sample-and-hold circuits are used, AN000, AN001 are selected with self-diagnosis, and continuous sampling is disabled

40.3.2.6 Channel Selection and Self-Diagnosis (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Enabled)

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operations are performed first, followed by A/D conversion of the reference voltage VREFH0 (unit 0) supplied to the ADC12. After that, A/D conversion is performed only once on the analog input of the selected channels.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[1:0] bits start continuous sampling.
2. Analog input holding starts for all the channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (GPT, ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 kΩ) elapse after the ADSHMSR.SHMD bit is set to 1.
3. After the stabilization time of the sample-and-hold circuits elapse, A/D conversion for self-diagnosis starts.
4. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 register, starting from the channel with the smallest number n.
5. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
6. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting).
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels completes. Then, the ADC12 enters a wait state. If this is followed by single scanning, set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).
8. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.

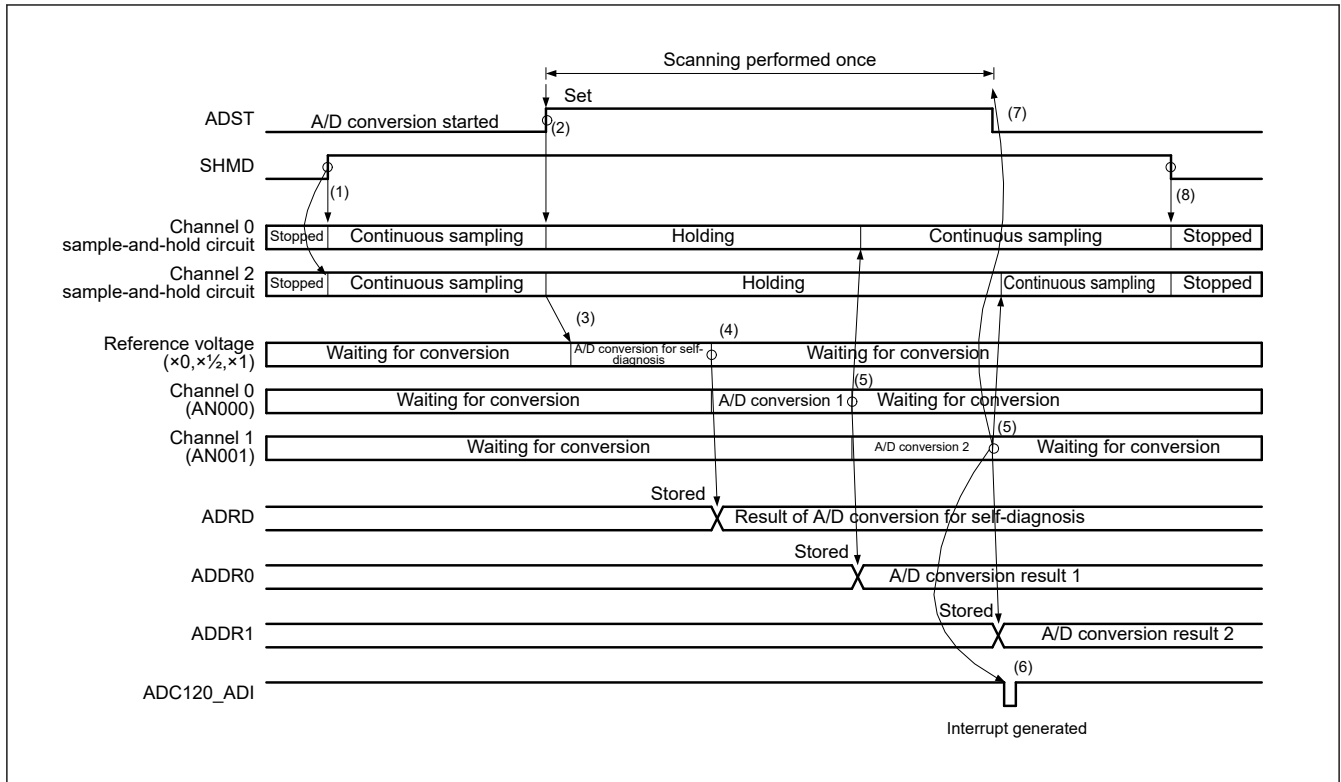

Figure 40.13 Example operation in single scan mode when channel-dedicated sample-and-hold circuits are used, AN000, AN001 are selected with self-diagnosis, and continuous sampling is enabled

40.3.2.7 A/D Conversion of Temperature Sensor Output or Internal Reference Voltage

When the channels and temperature sensor output or internal reference voltage are selected at the same time, A/D conversion is performed first on the analog input of the selected channels, and once on the temperature sensor output or internal reference voltage. When both temperature sensor output and internal reference voltage are selected, A/D conversion of the temperature sensor output and internal reference voltage is performed, in that order. With the channels deselected, selecting only the temperature sensor output or internal reference voltage is also possible.

The operation is as follows:

1. When a software trigger, synchronous trigger (GPT, ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (A/D conversion start), A/D conversion is performed for the ANn channels selected in the ADANSA0 register, starting from the channel with the smallest number n.
2. On completion of A/D conversion on the channels, the result is stored in the associated A/D Data Register y (ADDRy), and then A/D conversion of the temperature sensor output starts.
3. On completion of A/D conversion of the temperature sensor output, the result is stored in the associated A/D Temperature Sensor Data Register (ADTSDR), and then A/D conversion of the internal reference voltage starts.
4. On completion of A/D conversion of the internal reference voltage, the result is stored in the associated A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC12i_ADI (i = 0, 1) interrupt request is generated (no register setting).
5. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 on completion of A/D conversion. Then, the ADC12 enters a wait state.

Figure 40.14 Example basic operation in single scan mode when AN000 and temperature sensor output or internal reference voltage are selected

40.3.2.8 A/D Conversion in Double-Trigger Mode

When double trigger mode is selected in single scan mode, two rounds of single scan operation started by a synchronous trigger (GPT, ELC) are performed in sequence.

Deselect self-diagnosis and set the temperature sensor output A/D conversion select bit (ADEXICR.TSSA and ADEXICR.TSSB) and the internal reference voltage A/D conversion select bit (ADEXICR.OCSA and ADEXICR.OCSB) to 0.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 register is invalid.

In double trigger mode, select a synchronous trigger (GPT, ELC) with the ADSTRGR.TRSA[5:0] bits. Additionally, set the ADCSR.EXTRG bit to 0 and the ADCSR.TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input (GPT, ELC), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
3. The ADCSR.ADST bit is automatically set to 0 and the ADC12 enters a wait state. An ADC12i_ADI (i = 0, 1) interrupt request is not generated.
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger input, A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion is completed, the result is stored in the A/D Data Duplexing Register (ADDBLDR), which is exclusively used in double-trigger mode.
6. An ADC12i_ADI (i = 0, 1) interrupt request is generated.
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion is completed. Then the ADC12 enters a wait state.

Figure 40.15 Example operation in single scan mode when double-trigger mode is selected and the analog input (channel x) is duplicated

40.3.2.9 Extended Operations when Double-Trigger Mode is Selected

When double trigger mode is selected in single scan mode, and a synchronous trigger (ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1), GTCIADA0 (unit 0) and GTCIADA4 (unit 1) / GTCIADB0 (Unit0) and GTCIADB4 (unit 1), GTCIADA1 (unit 0) and GTCIADA5 (unit 1) / GTCIADB1 (Unit0) and GTCIADB5 (unit 1), GTCIADA2 (Unit 0) / GTCIADB2 (Unit0) or GTCIADA3 (Unit 0) / GTCIADB3 (Unit0)) is selected as the trigger for the start of A/D conversion, two rounds of single scan operation are performed.

Deselect self-diagnosis and set the temperature sensor output A/D conversion select bit (ADEXICR.TSSA and ADEXICR.TSSB), and the internal reference voltage A/D conversion select bit (ADEXICR.OCSA and ADEXICR.OCSB) to 0.

Duplication of A/D conversion data is enabled by setting the channel number to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 register is invalid.

In extended double trigger mode, select a synchronous trigger combination by setting the ADSTRGR.TRSA[5:0] bits to 0x0B, set the ADCSR.EXTRG bit to 0, and set the ADCSR.TRGE bit to 1. Do not use a software trigger.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a synchronous trigger input, A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
2. When A/D conversion completes, the A/D conversion result is stored in the associated A/D Data Register (ADDRy) and in A/D Data Duplexing Register A (ADDBLDRA) or A/D Data Duplexing Register B (ADDBLDRB) when the ELC_ADI0 or ELC_ADI1 trigger is input respectively (i = 0, 1).
3. The ADCSR.ADST bit is automatically set to 0 and the ADC12 enters a wait state. An ADC12i_ADI (i = 0, 1) interrupt request is not generated.
4. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger (ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1)), A/D conversion starts on the single channel selected in the ADCSR.DBLANS[4:0] bits.
5. When A/D conversion completes, the A/D conversion result is stored in the A/D Data Duplexing Register (ADDBLDR) and in A/D Data Duplexing Register A (ADDBLDRA) or A/D Data Duplexing Register B (ADDBLDRB) when the ELC_ADI0 or ELC_ADI1 trigger is input respectively (i = 0, 1).
6. An ADC12i_ADI (i = 0, 1) interrupt request is generated.
7. The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion and is automatically set to 0 when A/D conversion completes. The ADC12 then enters a wait state.

Figure 40.16 Example extended operation in double trigger mode with duplication selected for the analog input (channel x) and ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1)

40.3.3 Continuous Scan Mode

40.3.3.1 Basic Operation (Without Channel-Dedicated Sample-and-Hold Circuits)

In continuous scan mode, A/D conversion is performed repeatedly on the analog input of the specified channels.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (GPT, ELC), or an asynchronous trigger input, A/D conversion is performed for AN_n channels selected in the ADANSA0 register, starting from the channel with the smallest number n.
2. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the associated A/D Data Register (ADDR_y).
3. When A/D conversion of all the selected channels is completed, an ADC12_i_ADI (i = 0, 1) interrupt request is generated. The ADC12 sequentially starts A/D conversion for the AN_n channels selected in the ADANSA0 register, starting from the channel with the smallest number n.
4. The ADCSR.ADST bit is not automatically cleared, and steps 2. and 3. are repeated as long as ADCSR.ADST remains 1 (A/D conversion start). When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
5. When the ADCSR.ADST bit is later set to 1 (A/D conversion start), A/D conversion starts again for the AN_n channels selected in the ADANSA0 register, starting from the channel with the smallest number n.

Figure 40.17 Example basic operation in continuous scan mode when the analog inputs (channel x to z) are selected

40.3.3.2 Basic Operation (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Disabled)

When the channel-dedicated sample-and-hold circuit is used with the continuous sampling disabled, sample-and-hold operation is performed first, and then A/D conversion is repeated on the analog input of all the specified channels. The channels whose dedicated sample-and-hold circuit is to be used can be selected in the SHANS[1:0] bits in ADSHCR.

The operation is as follows:

1. Analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (GPT, ELC), or asynchronous trigger input.
2. After the sample-and-hold operation, A/D conversion is performed for the ANn channels selected in the ADANSA0 register, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy).
4. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting). At the same time, analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used.
5. The ADST bit is not automatically cleared, and steps 2 to 4 are repeated as long as the bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADST bit is then set to 1 (A/D conversion start), analog input sampling starts again for all the channels whose dedicated sample-and-hold circuit is to be used.

Figure 40.18 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used and AN000 and AN001 are selected

40.3.3.3 Basic Operation (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Enabled)

When a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, sample-and-hold operations are performed first, after which the analog inputs on all the selected channels are A/D-converted as described in this section. The channels for which the channel-dedicated sample-and-hold circuits are to be used can be selected in the ADSHCR.SHANS[1:0] bits.

The operation is as follows:

1. When the ADSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[1:0] bits start continuous sampling.
2. Analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (GPT, ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 k Ω) elapse after the ADSHMSR.SHMD bit is set to 1.
3. After the stabilization time of the sample-and-hold circuits elapses, A/D conversion is performed for the ANn channels selected in the ADANSA0 register, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting). Also, analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.
6. The ADCSR.ADST bit is not automatically cleared, and steps 3 to 5 are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
7. When the ADSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.
8. When the ADSHMSR.SHMD bit is then set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[1:0] bits start continuous sampling.
9. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.

Note: If continuous scanning is performed when only those channels with the sample-and-hold circuits are selected, time for continuous sampling cannot be secured in the second and subsequent continuous scans. When continuous sampling by the channel-dedicated sample-and-hold circuits is enabled for continuous scanning, select one or more channels among AN002 to AN008, temperature sensor output, internal reference voltage and VBATT 1/3 voltage monitor output for unit 0, and AN100 to AN105, temperature sensor output, internal reference voltage and VBATT

1/3 voltage monitor output for unit 1, and set the continuous sampling time for the sample-and-hold circuits to at least 400 ns (when the permissible signal source impedance is 1 kΩ).

Figure 40.19 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used, AN000, AN001, and AN004 are selected, and continuous sampling is enabled

40.3.3.4 Channel Selection and Self-Diagnosis (Without Channel-Dedicated Sample-and-Hold Circuits)

When channels and self-diagnosis are selected at the same time, A/D conversion is first performed for the reference voltage VREFH0, VREFH ($\times 0$, $\times 1/2$, or $\times 1$) supplied to the ADC12, and A/D conversion is performed on the analog input of the selected channels. This sequence is repeated as described in the section that follows.

The operation is as follows:

1. A/D conversion for self-diagnosis is first started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger input, a synchronous trigger input (GPT, ELC), or an asynchronous trigger input.
2. When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADDRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 register, starting from the channel with the smallest number n.
3. Each time A/D conversion of a single channel is completed, the A/D conversion result is stored in the corresponding A/D Data Register (ADDRy).
4. When A/D conversion of all the selected channels is completed, an ADC12i_ADI ($i = 0, 1$) interrupt request is generated. At the same time, the ADC12 starts A/D conversion for self-diagnosis and then on the ANn channels selected in the ADANSA0 register, starting from the channel with the smallest number n.
5. The ADCSR.ADST bit is not automatically cleared, and steps 2. to 4. are repeated as long as the ADCSR.ADST bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADST bit is later set to 1 (A/D conversion start), the A/D conversion for self-diagnosis is started again.

Figure 40.20 Example basic operation in continuous scan mode when the analog inputs (channel x and y) are selected with self-diagnosis

40.3.3.5 Channel Selection and Self-Diagnosis (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Disabled)

When the channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is disabled, sample-and-hold operation is performed first, and then A/D conversion is performed for the reference voltage VREFH0 (unit 0) (×0, ×1/2, or ×1) supplied to the ADC12, and then A/D conversion is performed on the analog input of the selected channels, and this sequence is repeated.

The operation is as follows:

1. Analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, synchronous trigger input (GPT, ELC), or asynchronous trigger input.
2. After the sample-and-hold operation, A/D conversion for self-diagnosis starts.
3. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 register, starting from the channel with the smallest number n.
4. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D data register (ADDRy).
5. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting). At the same time, analog input sampling starts for all channels whose dedicated sample-and-hold circuit is to be used.
6. The ADST bit is not automatically cleared, and steps 2 to 5 are repeated as long as the bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
7. When the ADST bit is then set to 1 (A/D conversion start), analog input sampling starts again for all the channels whose dedicated sample-and-hold circuits are to be used.

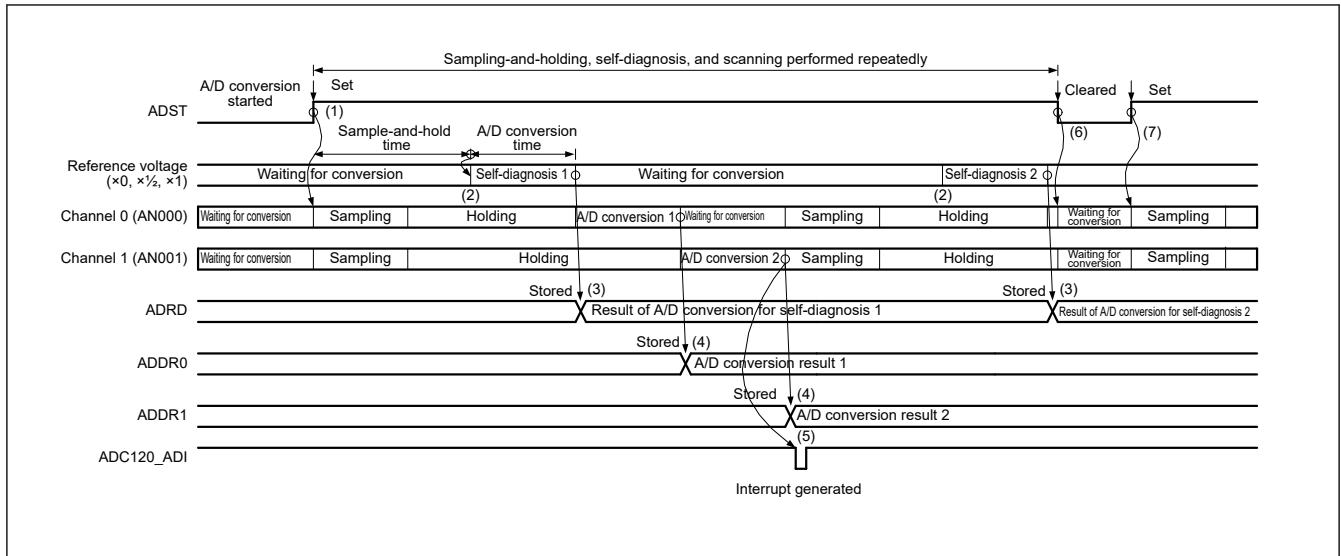

Figure 40.21 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used and AN000 and AN001 are selected with self-diagnosis

40.3.3.6 Channel Selection and Self-Diagnosis (With Channel-Dedicated Sample-and-Hold Circuits and Continuous Sampling Enabled)

When channels and self-diagnosis are selected and a channel-dedicated sample-and-hold circuit is used while continuous sampling is enabled, the sample-and-hold operation is performed first, and followed by A/D conversion of the reference voltage VREFH0 (unit 0) ($\times 0$, $\times 1/2$, or $\times 1$) supplied to the ADC12. After that, A/D conversion is performed on the analog input of the selected channels, and this sequence is repeated.

The operation is as follows:

1. When the ADSSHMSR.SHMD bit is set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[1:0] bits start continuous sampling.
2. Analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used when the ADCSR.ADST bit is set to 1 (A/D conversion start) by a software trigger, input of a synchronous trigger signal (GPT, ELC), or input of an asynchronous trigger. Set the ADCSR.ADST bit to 1 after at least 400 ns (when the permissible signal source impedance is 1 k Ω) elapse after the ADSSHMSR.SHMD bit is set to 1.
3. After the stabilization time of the sample-and-hold circuits elapses, A/D conversion for self-diagnosis starts.
4. When A/D conversion for self-diagnosis completes, the A/D conversion result is stored in the A/D Self-Diagnosis Data Register (ADRD). A/D conversion is then performed for the ANn channels selected in the ADANSA0 register, starting from the channel with the smallest number n.
5. Each time A/D conversion of a single channel completes, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy), and the sample-and-hold circuit restarts continuous sampling.
6. When A/D conversion of all the selected channels completes, an ADC12i_ADI (i = 0) interrupt request is generated (no register setting). Also, analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.
7. The ADCSR.ADST bit is not automatically cleared, and steps 3 to 6 are repeated as long as the bit remains 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
8. When the ADSSHMSR.SHMD bit is set to 0, the sample-and-hold circuits stop.
9. When the ADSSHMSR.SHMD bit is then set to 1, the sample-and-hold circuits selected in the ADSHCR.SHANS[1:0] bits start continuous sampling.
10. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), analog input holding starts for all channels for which the channel-dedicated sample-and-hold circuits are to be used.

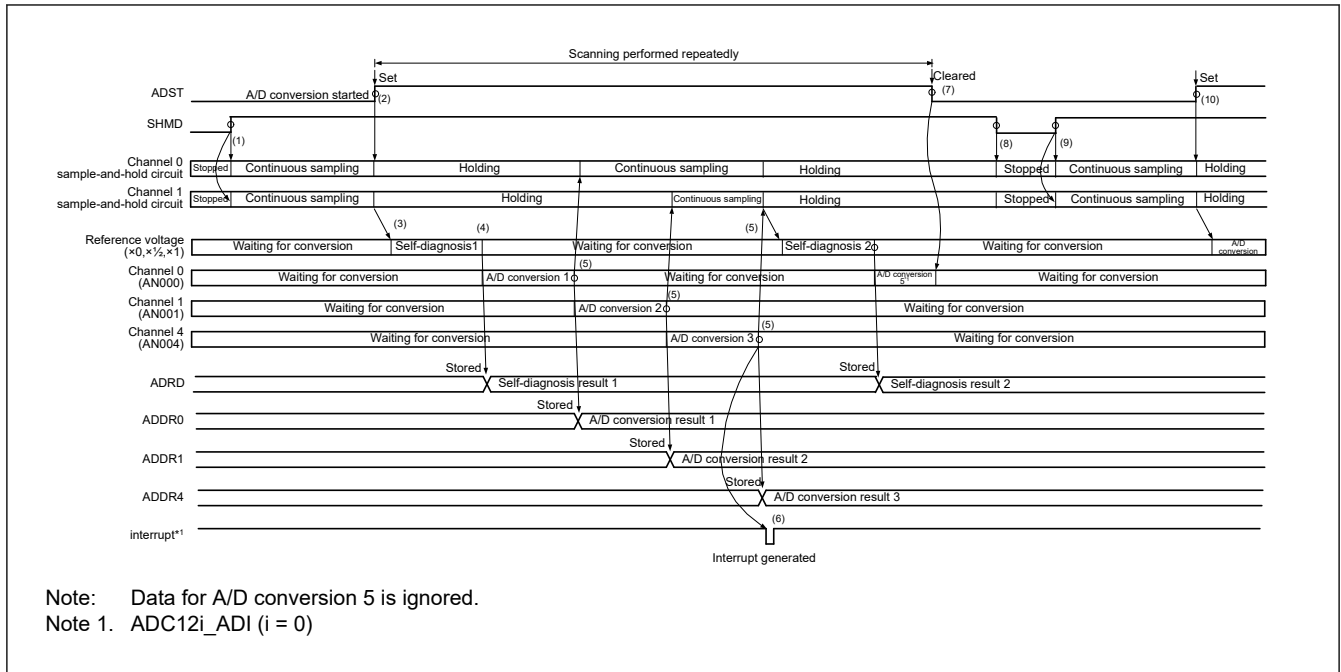

Figure 40.22 Example operation in continuous scan mode when channel-dedicated sample-and-hold circuits are used, AN000, AN001, and AN004 are selected with self-diagnosis, and continuous sampling is enabled

40.3.3.7 A/D Conversion of Temperature Sensor Output or Internal Reference Voltage

When the channels and temperature sensor output or internal reference voltage are selected at the same time, A/D conversion is first performed on the analog input of the selected channels, and then the A/D conversion of the temperature sensor output or internal reference voltage is repeated. When both the temperature sensor output and internal reference voltage are selected, A/D conversion of the temperature sensor output and internal reference voltage is performed, in that order.

With the channels deselected, selecting only the temperature sensor output or internal reference voltage is also possible.

The operation is as follows:

1. When a software trigger, synchronous trigger (GPT, ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (A/D conversion start), A/D conversion is performed for the ANn channels selected in the ADANSA0 register, starting from the channel with the smallest number n.
2. On completion of A/D conversion on the channels, the result is stored in the associated A/D Data Register y (ADDRy), and then A/D conversion of temperature sensor output starts.
3. On completion of A/D conversion of the temperature sensor output, the result is stored in the associated A/D Temperature Sensor Data Register (ADTSDR), and then A/D conversion of the internal reference voltage starts.
4. On completion of A/D conversion of the internal reference voltage, the result is stored in the associated A/D Internal Reference Voltage Data Register (ADOCDR), and an ADC12i_ADI (i = 0, 1) interrupt request is generated. In addition, the ADC12 continuously starts A/D conversion for the ANn channels selected in the ADANSA0 register, starting from the channel with the lowest number n.
5. The ADCSR.ADST bit is not cleared automatically, and steps 2 to 4 are repeated as long as this bit remains set to 1. When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the ADC12 enters a wait state.
6. When the ADCSR.ADST bit is then set to 1 (A/D conversion start), A/D conversion starts again for the ANn channels selected in the ADANSA0 register, starting from the channel with the lowest number n.

Figure 40.23 Example basic operation in continuous scan mode when AN000 and temperature sensor output or internal reference voltage are selected

40.3.4 Group Scan Mode

40.3.4.1 Basic Operation

In group scan mode, A/D conversion is performed once on the analog input of all the specified channels in group A and B after scanning is started by a synchronous trigger (GPT, ELC). The scan operation of each group is similar to the scan operation in single scan mode.

The synchronous triggers can be selected in the ADSTRGR.TRSA[5:0] bits for group A and in the ADSTRGR.TRSB[5:0] bits for group B. Use different triggers for group A and B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger.

The group A channels to be A/D-converted are selected using the ADANSA0 register and the ADEXICR.TSSA and OCSA bits. The group B channels to be A/D-converted are selected using the ADANSB0 register and the ADEXICR.TSSB and OCSB bits. Group A and B cannot use the same channels.

When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed for Group A and B.

The following sequence describes operation in group scan mode using a synchronous trigger from the ELC. In this example, the ELC_AD00 (unit 0) and ELC_AD10 (unit 1) trigger from the ELC is used to start conversion of group A and the ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger from the ELC is used to start conversion of group B. In addition, ELC_AD00 (unit 0) and ELC_AD10 (unit 1) and ELC_AD01 (unit 0) and ELC_AD11 (unit 1) are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of group A is started by ELC_AD00 (unit 0) and ELC_AD10 (unit 1).
2. When group A scanning completes, an ADC12i_ADI (i = 0, 1) interrupt is generated (no register setting).
3. Scanning of group B is started by ELC_AD01 (unit 0) and ELC_AD11 (unit 1).
4. When group B scanning completes, an ADC12i_GBADI (i = 0, 1) interrupt is generated if the ADCSR.GBADIE bit is 1 (ADC12i_GBADI (i = 0, 1) interrupt when scanning completion is enabled).

Figure 40.24 Example basic operation in group scan mode when synchronous triggers from the ELC are used

40.3.4.2 A/D Conversion in Double-Trigger Mode

When double trigger mode is selected in group scan mode, two rounds of single scan operation started by a synchronous trigger (GPT, ELC) are performed as a sequence for group A. For group B, single scan operation started by a synchronous trigger (GPT, ELC) is performed once.

In group scan mode, the synchronous trigger can be selected in the ADSTRGR.TRSA[5:0] bits for group A and in the ADSTRGR.TRSB[5:0] bits for group B. Use different triggers for group A, B to prevent simultaneous A/D conversion of the two groups. Do not use a software trigger or an asynchronous trigger.

When an ELC_AD00 (unit 0) and ELC_AD10 (unit 1)/ELC_AD01 (unit 0) and ELC_AD11 (unit 1) is selected as group A synchronous triggers by setting the ADSTRGR.TRSA[5:0] bits to 0x0B, operation proceeds in extended double trigger mode.

The group A channel to be A/D-converted is selected using the DBLANS[4:0] bits in the ADCSR register, while the group B channels to be A/D-converted are selected using the ADANSB0 register. Group A, B cannot use the same channels.

When double-trigger mode is selected in group scan mode, set the A/D conversion select bits for both the temperature sensor output (ADEXICR.TSSA) and the internal reference voltage (ADEXICR.OCSA) to 0 (deselected).

Self-diagnosis cannot be selected when double trigger mode is selected in group scan mode.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated in the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1.

The following sequence describes operation in group scan mode with double trigger mode selected and using a synchronous trigger from the ELC. In this example, the ELC_AD00 (unit 0) and ELC_AD10 (unit 1) trigger is used to start conversion of group A and the ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger is used to start conversion of group B. In addition, ELC_AD00 (unit 0) and ELC_AD10 (unit 1) and ELC_AD01 (unit 0) and ELC_AD11 (unit 1) are selected for the GPT event in the associated ELC.ELSRn registers.

The operation is as follows:

1. Scanning of group B is started by the ELC_AD00 (unit 0) and ELC_AD10 (unit 1) trigger from the ELC.
2. When group B scanning completes, an ADC12i_GBADI (i = 0, 1) interrupt is generated if the GBADIE bit in ADCSR is 1 (ADC12i_GBADI (i = 0, 1) interrupt when scanning completion is enabled).

3. The first scan of group A is started by the first ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger.
4. When the first scan of group A completes, the conversion result is stored in the associated A/D Data Register y (ADDRy). An ADC12i_ADI (i = 0, 1) interrupt request is not generated.
5. The second scan of group A is started by the second ELC_AD01 (unit 0) and ELC_AD11 (unit 1) trigger.
6. When the second scan of group A completes, the conversion result is stored in ADDBLDR. An ADC12i_ADI (i = 0, 1) interrupt is generated.

Figure 40.25 Example basic operation in group scan mode with double-trigger mode when synchronous triggers from the ELC are used

40.3.4.3 Group Priority Operation

Group priority operation is performed by setting the ADGSPCR.PGS bit to 1 in group-scan mode. The priority of groups is group A > group B.

When setting the PGS bit in the ADGSPCR register to 1, follow the procedure described in [Figure 40.26](#). If the procedure is not followed, A/D conversion operation and stored data are not guaranteed.

As the basic operation in group-scan mode, a trigger input generated during A/D conversion of group A, B is ignored, and the A/D conversion operation of each group is similar to the operation in single-scan mode.

In group priority operation, if a trigger for a priority group is input during scanning of a lower-priority group, A/D conversion for the lower-priority group is stopped and A/D conversion for the priority group is performed.

If the setting of the ADGSPCR.GBRSCN bit is 0, the lower-priority group enters a wait state when A/D conversion for the priority group completes. A trigger input of the lower-priority group generated during A/D conversion is ignored.

If the setting of the ADGSPCR.GBRSCN bit is 1, A/D conversion for the lower-priority group automatically restarts upon completion of A/D conversion for the priority group. A trigger input of the lower-priority group generated during A/D conversion on the priority group takes effect, and A/D conversion for the lower-priority group is automatically performed upon completion of A/D conversion on the priority group.

If the ADGSPCR.GBRSCN bit is 1 and the ADGSPCR.LGRRS bit is 0, A/D conversion for the lower-priority group is restarted from the first channel. If the setting of the ADGSPCR.LGRRS bit is 1, A/D conversion for the lower-priority group is restarted from the channel for which the conversion stopped. However, if the self-diagnosis function is used, the A/D conversion is restarted from the channel for which the conversion stopped after self-diagnosis completed.

[Table 40.26](#) summarizes operations in response to the input of a trigger during A/D conversion with the settings of the ADGSPCR.GBRSCN bit.

If the setting of the ADGSPCR.GBRP bit is 1, A/D conversion operation for the lowest-priority group is to continuously perform single scans.

For the trigger settings in group-scan mode, select a synchronous trigger for group A by using the ADSTRGR.TRSA[5:0] bits, a synchronous trigger for group B by using the ADSTRGR.TRSB[5:0] bits. Each trigger must be different from each other. Set the ADSTRGR.TRSB[5:0] bits to 0x3F when setting the ADGSPCR.GBRP bit to 1.

The channels to be scanned must be selected in the registers shown in [section 40.3.4. Group Scan Mode](#).

Figure 40.26 Flowchart for ADGSPCR.PGS bit setting

Table 40.26 Control of A/D conversion operations according to ADGSPCR.GBRSCN bit setting

A/D conversion operation	Trigger input	ADGSPCR.GBRSCN = 0	ADGSPCR.GBRSCN = 1
When A/D conversion for group A is in progress	Input of trigger for group A	Trigger input is ineffective.	Trigger input is ineffective.
	Input of trigger for group B	Trigger input is ineffective.	A/D conversion for group B is performed after A/D conversion for group A completes.
When A/D conversion for group B is in progress	Input of trigger for group A	A/D conversion for group B is discontinued and A/D conversion for group A starts.	<ul style="list-style-type: none"> A/D conversion for group B is discontinued and A/D conversion for group A starts. A/D conversion for group B starts after A/D conversion for group A completes.
	Input of trigger for group B	Trigger input is ineffective.	Trigger input is ineffective.

To use group priority operation mode, select the operation mode to be implemented and set the registers according to the following table.

Table 40.27 Group priority operation setting and operation mode for two groups (ADGSPCR.PGS = 1)

ADGSPCR			Operation category
GBRSCN	LGRRS	GBRP	
0	x	0	Group priority operation for two groups (groups A and B) <ul style="list-style-type: none"> When a trigger of group A is input, A/D conversion for group B is terminated (and will not be restarted).
1	0	0	Group priority operation for two groups (groups A and B) <ul style="list-style-type: none"> After A/D conversion for group B stopped, when A/D conversion for group A completes, A/D conversion for the group B channels selected in the ADANSB0 register restarts according to the conversion order of smaller channel number.
1	1	0	Group priority operation for two groups (groups A and B) <ul style="list-style-type: none"> After A/D conversion for group B stopped, when A/D conversion for group A completes, A/D conversion for the group B channels selected in the ADANSB0 register restarts according to the conversion order of smaller channel number, beginning from the channel for which A/D conversion stopped.*1
x	0	1	Group priority operation for two groups (groups A and B) <ul style="list-style-type: none"> Single scanning for group B is continuously performed without a start trigger input. After A/D conversion for group B stopped, when A/D conversion for group A completes, single scanning for the channels selected in the ADANSB0 register restarts according to the conversion order of smaller channel number.
1	1	1	Group priority operation for two groups (groups A and B) <ul style="list-style-type: none"> Single scanning for group B is continuously performed without a start trigger input. After A/D conversion for group B stopped, when A/D conversion for group A completes, single scanning for the channels selected in the ADANSB0 register restarts according to the conversion order of smaller channel number, beginning from the channel for which A/D conversion stopped.*1

Note: x: Don't care.

Note 1. When the self-diagnosis function is enabled (ADCER.DIAGM = 1), A/D conversion for the channel that has been stopped is started after self-diagnosis is performed.

(1) Group priority operation for two groups (when ADGSPCR.PGS = 1)

Operation examples 1-1 to 1-3 show group priority operations in group-scan mode (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0).

Operation example 1-1: "Group A trigger input during group B scan" when rescanning is enabled

- When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the analog input channels selected in the ADANSB0 register starts according to the conversion order from the channel with the smallest number n.
- On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
- When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1. Then A/D conversion for the group A analog input channels selected in the ADANSA0

register starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).

4. On completion of A/D conversion on the channels, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. An ADC120_ADI interrupt request is generated.
6. If the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning of the group that was stopped in group priority operation), A/D conversion for the group B analog input channels selected in the ADANSB0 register restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1.
7. On completion of A/D conversion on the channels, the result is stored in the corresponding A/D Data Register y (ADDRy).
8. If the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan), a group B scan end interrupt request is generated.
9. When A/D conversion for all the channels completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state.

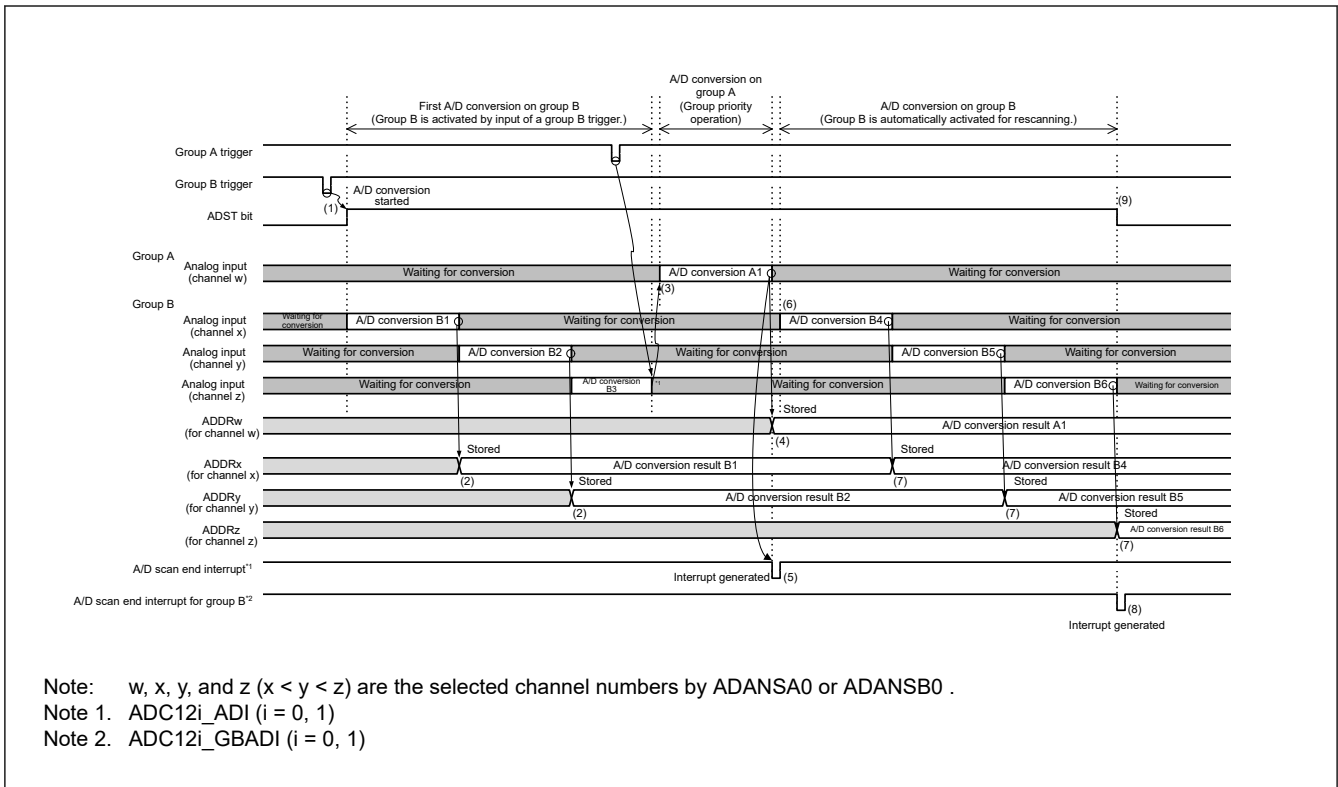

Figure 40.27 Example of group priority operation 1-1: Group A trigger input during group B scanning when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-2: “Group A trigger input during rescanning of group B” when rescanning is enabled

Figure 40.28 shows the operation when a group A trigger is input during rescanning operation for group B.

Even during rescanning operation, when a trigger for group A is input, A/D conversion on group B stops and A/D conversion for group A starts. A/D conversion for group B starts after A/D conversion for group A completes.

Operations for setting the ADCSR.ADST bit, storing the A/D conversion result in the corresponding A/D Data Register y (ADDRy), and generating interrupt requests are the same as those in operation example 1-1.

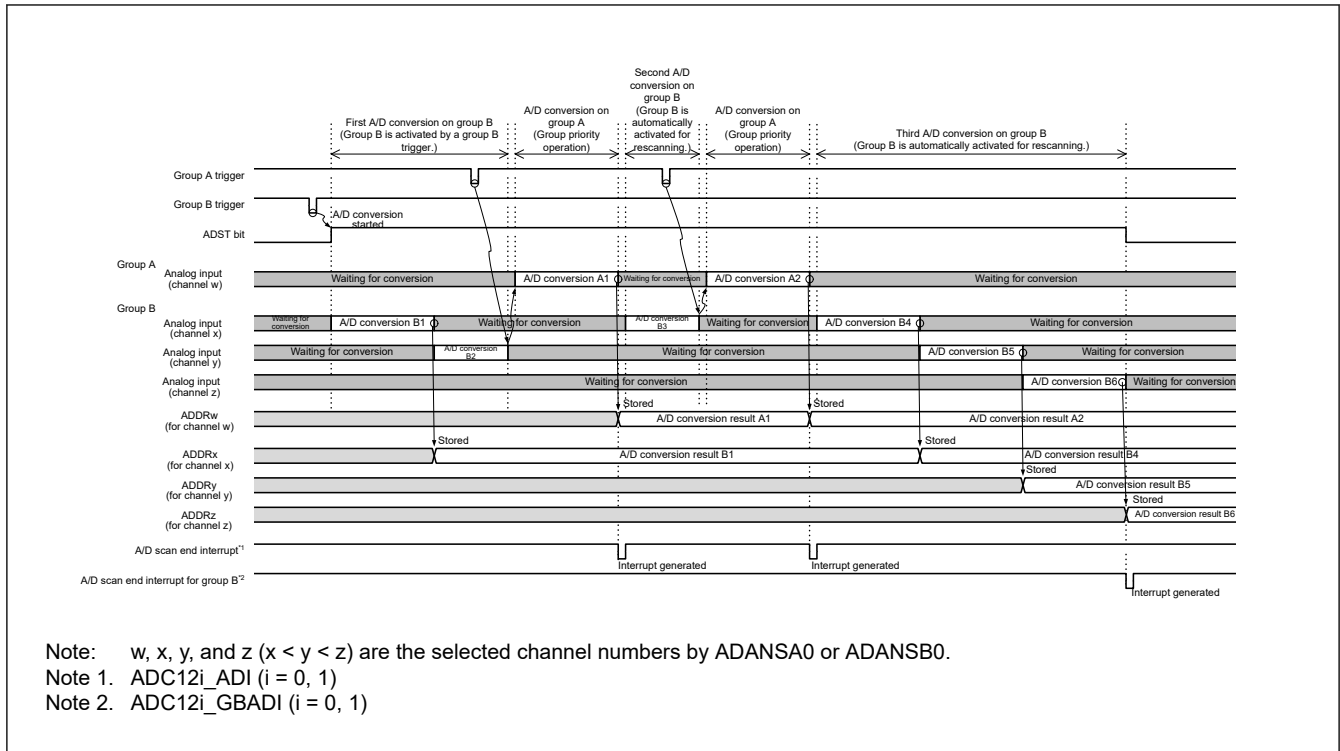

Figure 40.28 Example of group priority operation 1-2: Group A trigger input during rescanning of group B when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-3: “Group B trigger input during group A scan” when rescanning is enabled

The following describes the operation when the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning of the group that was stopped in group priority operation) and a trigger for group B is input during scanning operation for group A. If the setting of the ADGSPCR.GBRSCN bit is 0, any trigger for group B that is input during scanning operation for group A is invalid.

1. When input of a trigger for group A sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the group A analog input channels selected in the ADANSA0 register starts according to the conversion order from the channel with the smallest number n.
2. When a trigger for group B is input during A/D conversion for group A, group B is ready for A/D conversion.
3. On completion of A/D conversion for each channel in group A, the result is stored in the corresponding A/D Data Register y (ADDRy).
4. An ADC120_ADI interrupt request is generated.
5. When A/D conversion for group A completes, while the ADCSR.ADST bit remains 1, A/D conversion for the group B analog input channels selected in the ADANSB0 register starts according to the conversion order from the channel with the smallest number n.
 As with the case of operation example 1-1, if a trigger for group A is input during A/D conversion for group B, A/D conversion for group A starts. Then A/D conversion for group B starts upon completion of A/D conversion for group A.
6. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
7. Upon completion of A/D conversion for group B, a group B scan end interrupt request is generated if the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan).
8. When A/D conversion for all the channels completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state.

Figure 40.29 Example of group priority operation 1-3: Group B trigger input during group A scan when rescanning is enabled (when ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-4 shows the group priority operation in group-scan mode (when ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0).

Operation example 1-4: “Group A trigger input during group B scan” when rescanning is disabled

1. When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), A/D conversion for the analog input channels selected in the ADANSB0 register starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1, and then A/D conversion for the group A analog input channels selected in the ADANSA0 register starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).
4. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. On completion of A/D conversion for group A, an ADC120_ADI interrupt request is generated.
6. When A/D conversion for group A completes, the ADCSR.ADST bit is automatically cleared and the A/D converter enters a wait state. A/D conversion for group B is not performed until a trigger for group B is input the next time.

Figure 40.30 Group priority operation example 1-4: “Group A trigger is input during group B scan” when rescanning is disabled (when ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, and ADGSPCR.LGRRS = 0)

Operation example 1-5 shows the group priority operation in group-scan mode (when ADGSPCR.GBRP = 1, and ADGSPCR.LGRRS = 0).

Operation example 1-5: Continuously activating single-scan operation for group B

1. When ADGSPCR.GBRP = 1 is set, the ADCSR.ADST bit is set to 1 (starting A/D conversion) and A/D conversion for the analog input channels selected in the ADANSB0 register starts according to the conversion order from the channel with the smallest number n.
2. On completion of A/D conversion for each channel in group B, the result is stored in the corresponding A/D Data Register y (ADDRy).
3. When a trigger for group A is input during A/D conversion for group B, A/D conversion for group B stops while the ADCSR.ADST bit remains 1, and then A/D conversion for group A analog input channels selected in the ADANSA0 register starts according to the conversion order from the channel with the smallest number n. If A/D conversion stops before it is completed, the conversion result is not stored in the A/D Data Register y (ADDRy).
4. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).
5. On completion of A/D conversion for group A, an ADC120_ADI interrupt request is generated.
6. If ADGSPCR.GBRP = 1 is set (performing single scan continuously), A/D conversion for the group B analog input channels selected in the ADANSB0 register restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1 (starting A/D conversion).
7. On completion of A/D conversion of a single channel, the result is stored in the corresponding A/D Data Register y (ADDRy).

8. If the setting of the ADCSR.GBADIE bit is 1 (enabling interrupt generation on completion of group B scan), a group B scan end interrupt request is generated.
9. If ADGSPCR.GBRP = 1 is set (performing single scan continuously), A/D conversion for the group B analog input channels selected in the ADANSB0 register restarts according to the conversion order from the channel with the smallest number n while the ADCSR.ADST remains 1 (starting A/D conversion).

Steps 6 to 9 are repeated as long as the ADGSPCR.GBRP bit remains 1. Do not clear the ADCSR.ADST bit as long as the ADGSPCR.GBRP bit is 1. To forcibly stop A/D conversion while ADGSPCR.GBRP = 1, follow the procedure shown in Figure 40.43.

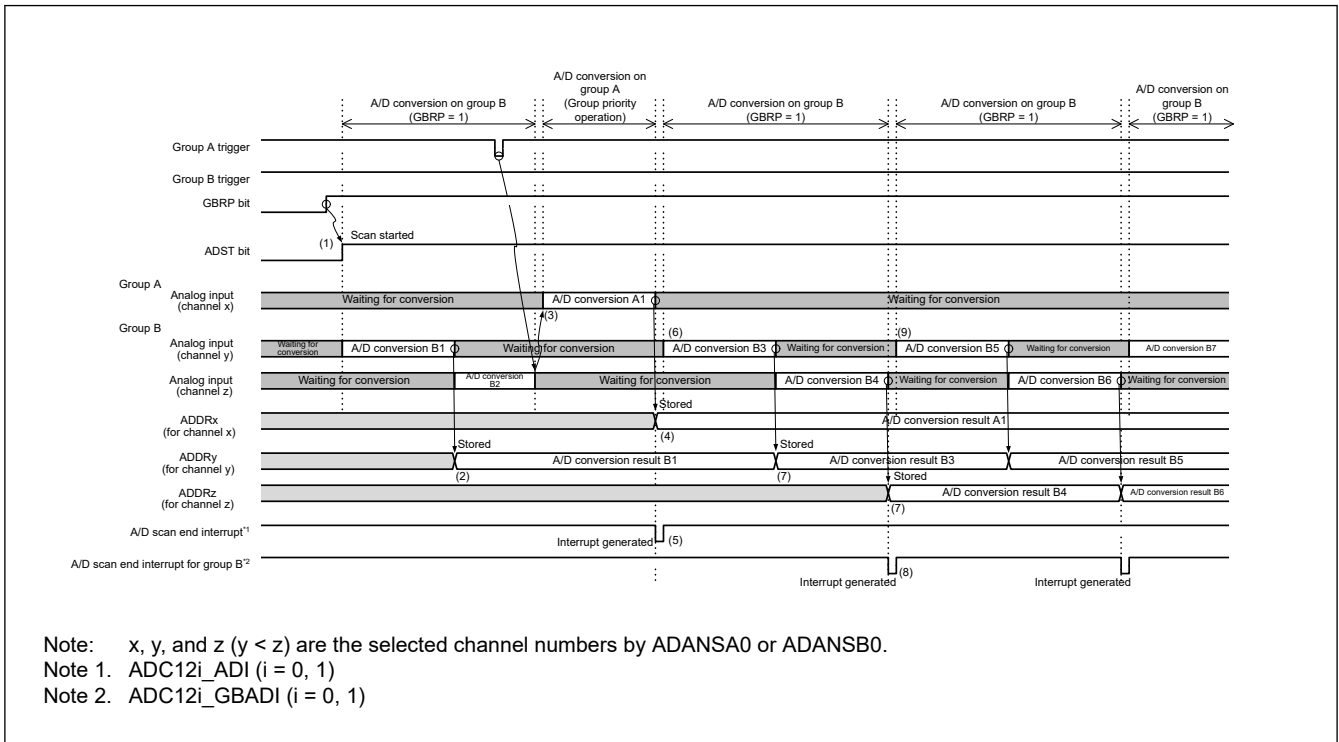

Figure 40.31 Group priority operation example 1-5: Continuously activating single scan for group B (when ADGSPCR.GBRP = 1, ADGSPCR.LGRRS = 0)

Note: To continuously activate single-scan operation for group B, disable group B trigger input.

40.3.5 Compare Function for Windows A and B

40.3.5.1 Compare Function Windows A and B

The compare function compares a reference value with the A/D conversion result. The reference value can be set for Window A and Window B independently. When the compare function is in use, the self-diagnosis function and double trigger mode cannot be used. The main differences between Window A and Window B are their different interrupt output signals and the constraint on Window B of only one selectable channel.

This section provides an example operation that combines continuous scan mode and the compare function.

The operation is as follows:

1. When the ADCSR.ADST bit is set to 1 (A/D conversion start) by software, a synchronous trigger (GPT, ELC) or an asynchronous trigger, A/D conversion starts in the order of the selected channels, temperature sensor, and internal reference voltage.
2. On completion of A/D conversion, the A/D conversion result is stored in the associated A/D Data Register y (ADDRy, ADTSDR, or ADOCDR). When ADCMPCR.CMPAE = 1, if bits in the ADCMPANSR0 register or the ADCMPANSER register are set for Window A, the A/D conversion result is compared with the set ADCMPDR0/1 register value. When ADCMPCR.CMPBE = 1, if bits in the ADCMPBNSR register are set for Window B, the A/D conversion result is compared with the ADWINULB/ADWINLLB register setting.

3. As a result of the comparison, when Window A meets the condition set in ADCMPLR0/1 or ADCMPLER, the Compare Window A Flag (ADCMPSTR0.CMPSTCHAN, ADCMPSTR.CMPSTTSA or ADCMPSTR.CMPSTOCA) sets 1. At this time, if the ADCMPSTR.CMPAIE bit is 1, an ADC12i_CMPAI (i = 0, 1) interrupt request is generated. In the same way, when Window B meets the condition set in ADCMPBSR.CMPLB, the Compare Window B Flag (ADCMPBSR.CMPSTB) sets to 1. At this time, if the ADCMPSTR.CMPBIE bit is 1, an ADC12i_CMPBI (i = 0, 1) interrupt request is generated.
4. On completion of all selected A/D conversions and comparisons, scan restarts.
5. After the ADC12i_CMPAI (i = 0, 1) and ADC12i_CMPBI (i = 0, 1) interrupts are accepted, the ADCSR.ADST bit is set to 0 (A/D conversion stop) and processing is performed for channels for which the compare flag is set to 1.
6. When all compare flags of Window A are cleared, the ADC12i_CMPAI (i = 0, 1) interrupt request is canceled. In the same way, when all compare flags of Window B are cleared, the ADC12i_CMPBI (i = 0, 1) interrupt request is reset. To perform comparison again, restart the A/D conversion.

Figure 40.32 Example of compare function operation, when the analog inputs (channel w to z) are compared

40.3.5.2 Event Output of Compare Function

The event output of the compare function specifies the upper-side reference voltage value and the lower-side reference voltage value for window A and window B, respectively. The output compares the A/D converted value of the selected channel with the upper and lower side reference voltage value and outputs events (ADC12i_WCMPLM (i = 0, 1)/ADC12i_WCMPUM (i = 0, 1)) based on event conditions (A OR B, A AND B, A XOR B) and comparison result of window A and window B.

If more than one channel is selected for window A, and even when one channel in window A meets the comparison condition, the comparison result of window A is met. When using this function, perform A/D conversion in single scan mode.

Any channels from analog input, internal reference voltage, temperature sensor output and VBATT 1/3 voltage monitor output are selectable for window A.

One channel from analog input, internal reference voltage, temperature sensor output and VBATT 1/3 voltage monitor output is selectable for window B.

The following sequence is an example of how to set up and use the event output of the compare function:

1. Confirm that the value in the ADCSR.ADCS bits is 00b (single scan mode).
2. Select the channel for window A in the ADCMPANSR0 and ADCMPANSER registers. Set the window comparison conditions in the ADCMPLR0/1 and ADCMPLER registers. Set the upper-side and lower-side reference values in the ADCMPDR0/1 registers.
3. Select the channel and comparison conditions for Window B in the ADCMPBNSR register, and set the upper and lower reference values in the ADWINULB and ADWINLLB registers.
4. Set the composite conditions for window A/B, window A/B operation enable, and interrupt output enable in the ADCMPCR register.

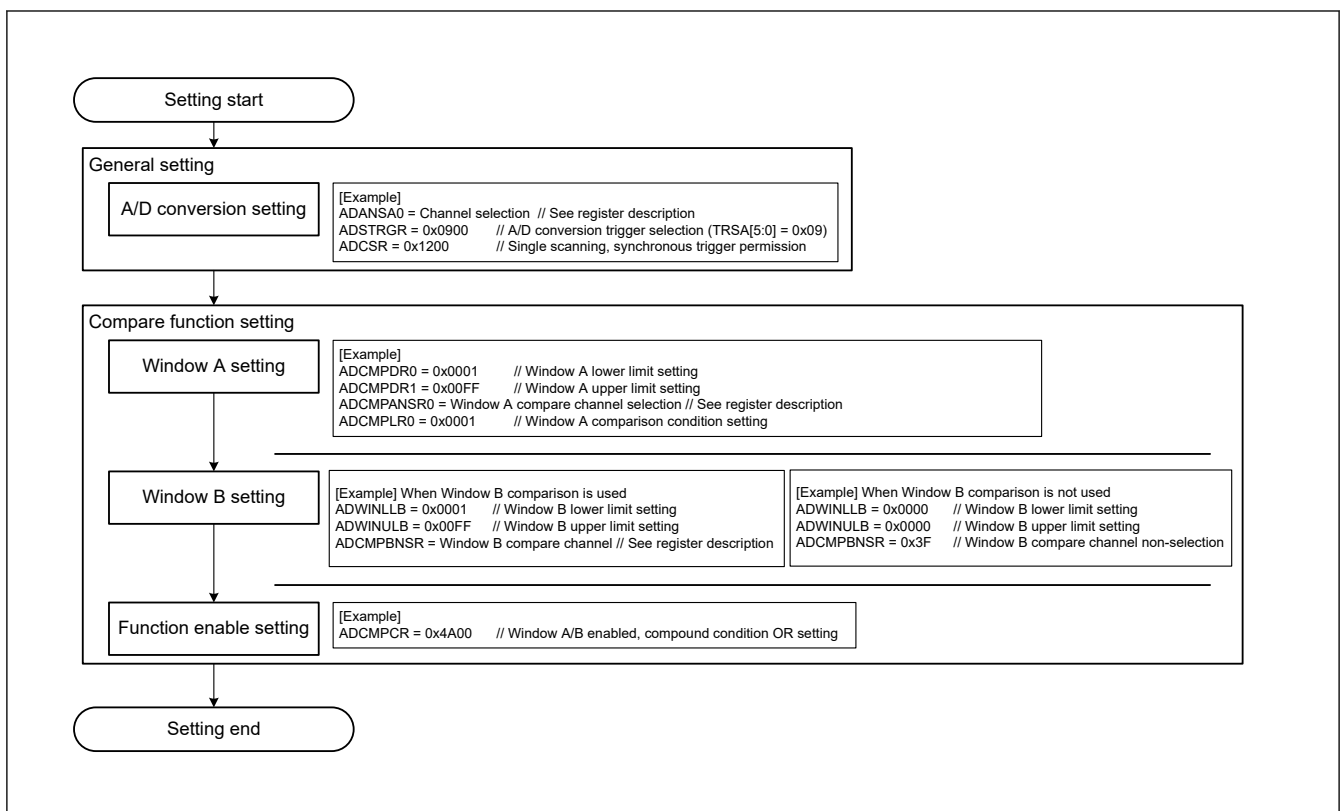

Figure 40.33 Setting example when using the event output of the compare function

For event output usage when using only window A for the compare function, note the following:

- Enable both Window A and Window B (ADCMPCR.CMPAE = 1, ADCMPCR.CMPBE = 1)
- Set the compound condition of Window A and Window B to “OR condition” (ADCMPCR.CMPAB[1:0] = 00b)
- Set the compared channel of Window B to “No selection” (ADCMPBNSR.CMPCHB[5:0] = 0x3F)
- Set the compare condition of Window B to “0 < results < 0 always means mismatch”. (ADCMPCR.WCMPE = 1, ADWINLLB[15:0] = ADWINULB[15:0] = 0x0000, and ADCMPBNSR.CMPLB = 1)

Figure 40.34 shows the event output operation example of compare function.

A scan end event (ADC12i_ADI (i = 0, 1)) is output with the same timing as single scan completion. A match or mismatch event (ADC12i_WCMPEM (i = 0, 1)/ADC12i_WCMPUM (i = 0, 1)) is output with 1 PCLKA cycle delay depending on the ADCMPCR.CMPAB[1:0] settings.

Note: The match and mismatch events are exclusive, so both events are never output simultaneously.

Figure 40.34 Example operation of the compare function event output, when the analog inputs (channel x and y) are compared

Note: Event output of compare function outputs match/mismatch from the comparison results of Window A and Window B, based on the ADCMPCR.CMPAB[1:0] settings.

Note: The comparison result of Window A is the logical addition of the comparison results of the comparison target channels of Window A. The comparison results of Window A and Window B are updated by each A/D conversion, and are kept even when single scan ends. Set ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0 to clear the comparison results to 0.

40.3.5.3 Restrictions on Compare Function

The following constraints apply for the compare function:

- The compare function cannot be used together with the self-diagnosis function or double-trigger mode. The compare function is not available for ADDR, ADDBLDR, ADDBLDRA, and ADDBLDRB.
- Specify single scan mode when using match/mismatch event outputs.
- When the temperature sensor output, internal reference voltage is selected for Window A, Window B operations are prohibited.
- When the temperature sensor output, internal reference voltage is selected for Window B, Window A operations are prohibited.
- Setting the same channel for Window A and Window B is prohibited.
- Specify single scan mode when using the buffer function. It is prohibited to use double trigger mode together.
- Set the reference voltage values so that the high-potential reference voltage value is equal to or larger than the low potential reference voltage value.

40.3.6 Analog Input Sampling and Scan Conversion Time

Scan conversion can be activated either by a software trigger, a synchronous trigger (GPT, ELC), or an asynchronous trigger (ADTRGn (n = 0, 1)). After the start-of-scanning-delay time (t_D) has elapsed, processing by the channel-dedicated sample-and-hold circuits, processing for disconnection detection assistance, and processing of conversion for self-diagnosis all proceed, followed by processing for A/D conversion.

Figure 40.35 shows the scan conversion timing, in which scan conversion is activated by a software trigger or a synchronous trigger (GPT, ELC). Figure 40.36 shows the scan conversion timing, in which scan conversion is activated by an asynchronous trigger (ADTRGn (n = 0, 1)). The scan conversion time (t_{SCAN}) includes the start-of-scanning-delay time (t_D), channel-dedicated sample-and-hold circuit processing time (t_{SPLSH})^{*1}, disconnection detection assistance processing time (t_{DIS})^{*2}, self-diagnosis A/D conversion processing time (t_{DIAG} and t_{DSD})^{*3}, A/D conversion processing time (t_{CONV} and t_{DSD}), channel-dedicated sample-and-hold circuit end time (t_{SHED})^{*4} and end-of-scanning-delay time (t_{ED}).

The A/D conversion processing time (t_{CONV}) consists of input sampling time (t_{SPL}) and time for conversion by successive approximation (t_{SAM}). The sampling time (t_{SPL}) is used to charge sample-and-hold circuits in the A/D converter. If there is not sufficient sampling time due to the high impedance of an analog input signal source, or if the A/D conversion clock (ADCLK) is slow, sampling time can be adjusted using the ADSSTRn register.

The time for conversion by successive approximation (t_{SAM}) is the following:

- 13 ADCLK states with 12-bit accuracy selected.
- 11 ADCLK states with 10-bit accuracy selected.
- 9 ADCLK states with 8-bit accuracy selected.

Table 40.28 shows the time for conversion by successive approximation (t_{SAM}).

The scan conversion time (t_{SCAN}) in single scan mode for which the number of selected channels is n can be determined as follows:

$$t_{SCAN} = t_D + t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + t_{ED} + (t_{CONV} \times n) + t_{ED}^{*5}$$

The scan conversion time for the first cycle in continuous scan mode is t_{SCAN} for single scan minus t_{ED} . The scan conversion time for the second and subsequent cycles in continuous scan mode is fixed in the following:

$$t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + t_{DSD} + t_{SHED} + (t_{CONV} \times n) + t_{SHED}^{*5}$$

Note 1. When no channel-dedicated sample-and-hold circuits are used, $t_{SPLSH} = 0$.

Note 2. When disconnection detection assistance is not selected, $t_{DIS} = 0$.

Note 3. When the self-diagnosis function is not used, $t_{DIAG} = 0$, $t_{DSD} = 0$.

Note 4. When no channel-dedicated sample-and-hold circuits are used, $t_{SHED} = 0$, assuming continuous scan mode is active. In single scan mode and group scan mode, t_{SHED} is included in the end-of-scanning-delay (t_{ED}).

Note 5. When input sampling times (t_{SPL}) of all selected channels are the same, this element equals $t_{CONV} \times n$. If each channel has a different sampling time, this element equals that of t_{SPL} and t_{SAM} set to each selected channel.

Table 40.28 shows the times for conversion during scanning.

Table 40.28 Conversion times during scanning (in numbers of cycles of ADCLK and PCLKA)

Item			Symbol	Type/Conditions			Unit
				Synchronous trigger ^{*4}	Asynchronous trigger	Software trigger	
Scan start processing time ^{*1 *2}	A/D conversion on group A under group A priority control.	Group B is to be stopped (Group A is activated after group B is stopped by of an A/D conversion source from group A).	t_D	3 PCLKA + 6 ADCLK 5 PCLKA + 3 ADCLK ^{*5}	—	—	Cycles
		Group B is not to be stopped (activation by an A/D conversion source from group A).		2 PCLKA + 4 ADCLK	—	—	
	A/D conversion when self-diagnosis is enabled.	A/D conversion for self-diagnosis is to be started.		2 PCLKA + 6 ADCLK	4 PCLKA + 6 ADCLK	6 ADCLK	
	All other	2 PCLKA + 4 ADCLK		2 PCLKA + 4 ADCLK	4 ADCLK		
Channel-dedicated sample-and-hold processing time ^{*1}	Sampling time		t_{SPLSH}	t_{SH}	Without continuous sampling: setting in ADSHCR.SSTSH[7:0] (initial value = 18h × ADCLK) With continuous sampling: 0		
	Wait time between sampling and A/D Conversion				t_w	12	
Disconnection detection assistance processing time			t_{DIS}	Setting in ADNDIS[3:0] (initial value = 0x0) × ADCLK			
Self-diagnosis conversion processing time ^{*1}	Sampling time		t_{DIAG}	t_{SPL}	Setting in ADSSTR00 (initial value = 0x0B) × ADCLK ^{*3}	—	—
	Time for conversion by successive approximation	12-bit conversion accuracy			t_{SAM}	15 ADCLK	—
		10-bit conversion accuracy		13 ADCLK		—	—
		8-bit conversion accuracy		11 ADCLK		—	—
	Wait time between self-diagnosis conversion end and analog channel sampling start.			t_{DED}	2 ADCLK		
Wait time between last channel conversion end and self-diagnosis sampling start in continuous scan mode.		t_{DSD}	2 ADCLK				
A/D conversion processing time ^{*1}	Sampling time		t_{CONV}	t_{SPL}	Setting in ADSSTRn (n = 0 to 8 (unit 0), 0 to 5 (unit 1), T, O, V) (initial value = 0x0B) × ADCLK + 0.5 ADCLK		
	Time for conversion by successive approximation	12-bit conversion accuracy			t_{SAM}	13 ADCLK	
		10-bit conversion accuracy		11 ADCLK			
		8-bit conversion accuracy		9 ADCLK			
Channel-dedicated sample-and-hold end processing time			t_{SHED}	2 ADCLK			
Scan end processing time ^{*1}			t_{ED}	1 PCLKA + 3 ADCLK 2 PCLKA + 3 ADCLK ^{*5}			

Note 1. See [Figure 40.35](#) and [Figure 40.36](#) for an illustration of times t_D , t_{SPLSH} , t_{DIAG} , t_{CONV} , and t_{ED} .

Note 2. This is the maximum time required from software writing or trigger input to A/D conversion start.

Note 3. The sampling time setting must satisfy the electrical characteristics.

Note 4. This does not include the time consumed in the path from timer output to trigger input.

Note 5. If ADCLK is faster than PCLKA (PCLKA to ADCLK frequency ratio = 1:2 or 1:4), the scan end processing time changes.

Figure 40.35 Scan conversion timing when activated by software or a synchronous trigger input (GPT, ELC)

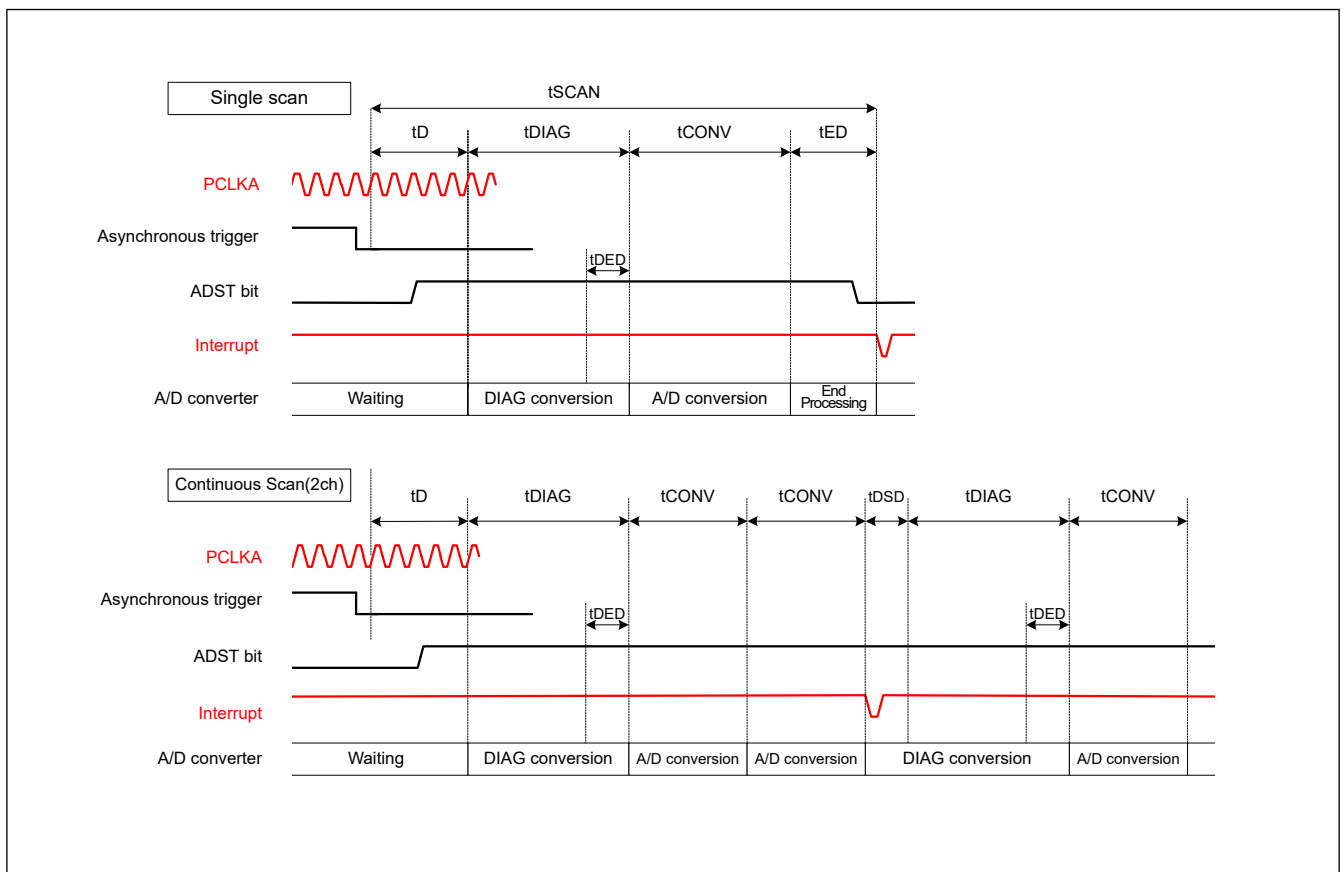

Figure 40.36 Scan conversion timing when activated by an asynchronous trigger input (ADTRGn (n = 0, 1))

40.3.6.1 Timing of Suspension and Starting of Scanning in Operation under Group Priority Control

The timings for suspension and starting of scanning in operation under group priority control that must be considered are listed below.

1. The timing for suspending a scan of a group with a lower-priority and the timing for starting a scan of a group with a higher-priority.
2. The time at which scanning by the group with a lower-priority is resumed on completion of scanning by the higher-priority group when the trigger for scanning by the lower-priority group is accepted during scanning by the higher-priority group.
3. The timing for performing sequential single scans by a lower-priority group.

Figure 1.37 shows the timing diagram of each of the above cases.

Figure 40.37 Timing diagram of suspension and starting of scanning in operation under group priority control

40.3.7 Usage Example of A/D Data Register Automatic Clearing Function

Setting the ADCER.ACE bit to 1 automatically clears the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR, ADVMDR) to 0x0000 when the A/D data registers are read by the CPU or DTC or DMAC.

This function enables detection of update failures of the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR, ADVMDR). This section describes examples in which the function to automatically clear the ADDRy register is enabled and disabled.

- If the ADCER.ACE bit is 0 (automatic clearing is disabled) and for some reason, if the A/D conversion result (0x0222) is not written to the ADDRy register, the ADDRy value retains the old data (0x0111). In addition, if this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, the old data (0x0111) can be saved in the general-purpose register. When checking whether there is an update failure, it is necessary to frequently save the old data in SRAM or in a general-purpose register.
- If the ADCER.ACE bit is 1 (automatic clearing is enabled), when ADDRy = 0x0111 is read by the CPU or DTC or DMAC, ADDRy is automatically set to 0x0000. Next, if the A/D conversion result of 0x0222 cannot be transferred to ADDRy for some reason, the cleared data (0x0000) remains as the ADDRy value. If this ADDRy value is read into a general-purpose register using an A/D scan end interrupt, 0x0000 is saved in the general-purpose register. Occurrence of an ADDRy update failure can be determined by checking that the read data value is 0x0000.

40.3.8 A/D-Converted Value Addition/Average Mode

A/D-converted value addition/average mode can be used when A/D conversion of the analog input of the selected channels, the temperature sensor output, the internal reference voltage and VBATT 1/3 voltage monitor output is selected.

In A/D-converted value addition mode, the same channel is A/D-converted 1, 2, 3, 4, or 16 consecutive times, and the sum of the converted values is stored in the data register. The conversion count of the addition function can be set to 16 only when 12-bit accuracy is selected. In A/D-converted value average mode, the same channel is A/D-converted 2 or 4 consecutive times, and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that are present. This function, however, cannot always guarantee an improvement in A/D conversion accuracy.

The A/D-converted value addition/average function can be used when A/D conversion of the analog inputs of the selected channels or A/D conversion of the temperature sensor output or A/D conversion of the internal reference voltage or A/D conversion of the VBATT 1/3 voltage monitor output is selected. The A/D-converted value addition/average function can also be used for channels for which the double-trigger function is selected.

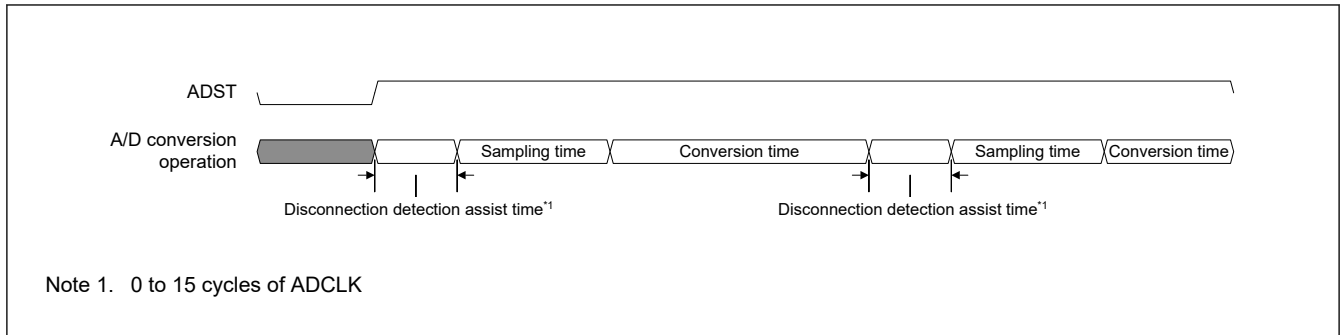

The addition function for self-diagnosis is not provided.

40.3.9 Disconnection Detection Assist Function

The ADC12 incorporates a function to fix the charge for sampling capacitance to the specified state (VREFH0 or VREFL0 for unit 0, VREFH or VREFL for unit 1) before the start of A/D conversion. This function enables disconnection detection in wiring of analog inputs.

When using the disconnection detection assist function for the channel-dedicated sample-and-hold circuit, set the ADHMSR.SHMD bit to 0 (select disable continuous sampling function).

Figure 40.38 shows the A/D conversion operation when the disconnection detection assist function is used. Figure 40.39 shows an example of disconnection detection when precharge is selected. Figure 40.40 shows an example of disconnection detection when discharge is selected.

Note 1. 0 to 15 cycles of ADCLK

Figure 40.38 Operation of A/D conversion when disconnection detection assist function is used

Note 1. The converted result should be used after it is fully evaluated because the result data when disconnection occurs varies depending on the external circuit.

Figure 40.39 Example of disconnection detection when precharge is selected

Figure 40.40 Example of disconnection detection when discharge is selected

40.3.10 Starting A/D Conversion with an Asynchronous Trigger

A/D conversion can be started by the input of an asynchronous trigger. To start A/D conversion by an asynchronous trigger, set the pin function in the $PmnPFS$ register, set the A/D Conversion Start Trigger Select bits ($ADSTRGR.TRSA[5:0]$) to $0x00$, then input a high-level signal to the asynchronous trigger ($ADTRG_n$ ($n = 0, 1$) pin). Finally, set both the $ADCSR.TRGE$ and $ADCSR.EXTRG$ bits to 1. Figure 40.41 shows timing of the asynchronous trigger input.

An asynchronous trigger cannot be selected in the A/D conversion start trigger for group B used in group scan mode. For details on setting the pin function, see section 19, I/O Ports.

Figure 40.41 Asynchronous trigger input timing

40.3.11 Starting A/D Conversion with a Synchronous Trigger from a Peripheral Module

A/D conversion can be started by a synchronous trigger (GPT, ELC). To do this, set the ADCSR.TRGE bit to 1 and the ADCSR.EXTRG bit to 0, and select the relevant sources in the ADSTRGR.TRSA[5:0] bits and ADSTRGR.TRSB[5:0] bits.

40.3.12 Security Attribution between ADCn (n = 0, 1) and PORT (PmSAR (m = 0 to 9, A, B))

Only when the security attribution of ADC12n (n = 0, 1) match the security attribution of PORT (PmSAR), the correspond analog input channel can be set for ADC conversion. Otherwise the conversion result is unexpected.

Table 40.29 shows the condition of ADC for each Security Attribution setting.

Table 40.29 Analog input pin conditions by security settings

Security Attribution setting*1		ADC input channel select		Setting Combination result
ADC12n (n = 0, 1) security setting PSARD	PORT security setting PmSAR	ADANSA0 ADANSB0		
0 (Secure)	0 (Secure)	1 (channel correspond bit)		Input Valid
1 (Non-secure)	1 (Non-secure)	1 (channel correspond bit)		Input Valid
1 (Non-secure)	0 (Secure)	1 (channel correspond bit)		Input invalid and the conversion result is unexpected
0 (Secure)	1 (Non-secure)	1 (channel correspond bit)		Input invalid and the conversion result is unexpected

Note 1. VBATT 1/3 voltage monitor output do not have the Security Attribution judgement function.

40.3.13 Using Data Buffers

A ring buffer function consisting of 16 A/D data buffers is available. This function sequentially stores A/D conversion results other than self-diagnosis result (including addition/average results) in data buffers (ADBUF_n, n = 0 to 15).

Each conversion result is stored at the timing when the A/D conversion result is stored in the data register, and most recent 16 conversion result data are retained.

The figure-below shows the schematic of data buffers, pointer, and overflow flag operations. When the BUFEN bit is set to 1, the A/D conversion result is transferred at each end of A/D conversion. The pointer indicates the number of data buffer to which the next transferred data is to be written. When data is written to up to buffer 15, the pointer is reset to 0000b and the overflow flag is set to 1. Subsequently transferred data overwrites the previously written data.

The overflow flag is reset to the initial value by writing 0x00 to the ADBUFPTR register.

Figure 40.42 Data Buffers, Pointer, and Overflow Flag Operations

40.4 Interrupt Sources and DTC, DMAC Transfer Requests

40.4.1 Interrupt Requests

The ADC12 can send scan end interrupt requests ADC12i_ADI (i = 0, 1) and ADC12i_GBADI (i = 0, 1) to the CPU. The ADC12 also generates the ADC12i_CMPAI (i = 0, 1)/ADC12i_CMPBI (i = 0, 1) interrupt for the CPU in response to matches with a condition for comparison.

An ADC12i_ADI (i = 0, 1) interrupt is always generated. An ADC12i_GBADI (i = 0, 1) interrupt can be generated by setting the ADCSR.GBADIE bit to 1. Similarly, ADC12i_CMPAI (i = 0, 1) and ADC12i_CMPBI (i = 0, 1) interrupts can be generated by setting the ADCMPCR.CMPAIE and ADCMPCR.CMPBIE bit to 1.

In addition, the DTC or DMAC can be started when an ADC12i_ADI (i = 0, 1) or an ADC12i_GBADI (i = 0, 1) interrupt is generated. Using an ADC12i_ADI (i = 0, 1) or ADC12i_GBADI (i = 0, 1) interrupt to activate the DTC or DMAC to read the converted data enables continuous conversion without a burden on software.

Table 40.30 describes the interrupt sources and ELC events available for the ADC12.

Table 40.30 The interrupt source and ELC event of ADC12 (1 of 2)

Operation			Interrupt request or ELC event	Interrupt request	DTC or DMAC activation	ELC event request	Function
Scan mode	Double trigger mode	Compare function Window A/B					
Single scan mode	Deselected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of single scan
		Selected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of single scan
			ADC12i_CMPAI (i = 0, 1)	✓	—	—	ADC12i_CMPAI (i = 0, 1) generated on a match comparison condition of Window A
			ADC12i_CMPBI (i = 0, 1)	✓	—	—	ADC12i_CMPBI (i = 0, 1) generated on a match comparison condition of Window B
			ADC12i_WCMPPM (i = 0, 1)	—	✓	✓	ADC12i_WCMPPM (i = 0, 1) generated on a match condition of the Window A/B compare function
			ADC12i_WCMPUM (i = 0, 1)	—	✓	✓	ADC12i_WCMPUM (i = 0, 1) generated on a mismatch condition of the Window A/B compare function
	Selected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of scans in the even numbered times
Continuous scan mode	Deselected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of scan of all selected channels
		Selected	ADC12i_CMPAI (i = 0, 1)	✓	—	—	ADC12i_CMPAI (i = 0, 1) generated on a match comparison condition of Window A
			ADC12i_CMPBI (i = 0, 1)	✓	—	—	ADC12i_CMPBI (i = 0, 1) generated on a match comparison condition of Window B

Table 40.30 The interrupt source and ELC event of ADC12 (2 of 2)

Operation			Interrupt request or ELC event	Interrupt request	DTC or DMAC activation	ELC event request	Function
Scan mode	Double trigger mode	Compare function Window A/B					
Group scan mode	Deselected	Deselected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of group A scan
			ADC12i_GBADI (i = 0, 1)	✓	✓	—	ADC12i_GBADI (i = 0, 1) dedicated to group B generated at the end of group B scan
		Selected	ADC12i_ADI (i = 0, 1)	✓	✓	✓	ADC12i_ADI (i = 0, 1) generated at the end of group A scan
			ADC12i_GBADI (i = 0, 1)	✓	✓	—	ADC12i_GBADI (i = 0, 1) dedicated to group B generated at the end of group B scan

			ADC12i_GBADI (i = 0, 1)	✓	✓	—	ADC12i_GBADI (i = 0, 1) dedicated to group B generated at the end of group B scan

Note: ✓ available
—: unavailable

For details on DTC settings, see [section 17, Data Transfer Controller \(DTC\)](#).

40.5 Event Link Function

40.5.1 Event Output to the ELC

The ELC uses the ADC12i_ADI (i = 0, 1) interrupt request signal as an event signal ADC12i_ADI (i = 0, 1), enabling link operation for the preset module. The ADC12i_GBADI (i = 0, 1) interrupt and ADC12i_CMPAI (i = 0, 1)/ADC12i_CMPBI (i = 0, 1) interrupts cannot be used as an event signal. For details, see [Table 40.30](#).

An event signal can be output regardless of the settings of the corresponding interrupt request enable bits. For the scan end event (ADC12i_ADI (i = 0, 1)), a high-level pulse for one PCLKA cycle is output at the same output timing as the interrupt output (ADC12i_ADI (i = 0, 1)) shown in [Table 40.30](#). For a compare function match (ADC12i_WCMPM (i = 0, 1)) and mismatch event (ADC12i_WCMPUM (i = 0, 1)) to the ELC, a high-level pulse for one PCLKA cycle is output at the timing delayed by one cycle (PCLKA) from the interrupt output (ADC12i_ADI (i = 0, 1)) shown in [Table 40.30](#).

To use compare function match (ADC12i_WCMPM (i = 0, 1)) or mismatch event (ADC12i_WCMPUM (i = 0, 1)) to the ELC, specify single-scan mode.

40.5.2 ADC12 Operation through an Event from the ELC

The ADC12 can start A/D conversion by the preset event specified in the ELSRn settings for the ELC as follows:

- Select the ELC_AD00 (unit 0) signal in the ELC.ELSR8 register
- Select the ELC_AD01 (unit 0) signal in the ELC.ELSR9 register

- Select the ELC_AD10 (unit 1) signal in the ELC.ELSR10 register
- Select the ELC_AD11 (unit 1) signal in the ELC.ELSR11 register.

If an ELC event occurs during A/D conversion, the event is disabled.

40.6 Usage Notes

40.6.1 Constraints on Setting the Registers

Set each register while the ADCSR.ADST bit is 0.

40.6.2 Constraints on Reading the Data Registers

The following registers must be read in halfword units:

- A/D Data Registers
- A/D Data Duplexing Register
- A/D Data Duplexing Register A
- A/D Data Duplexing Register B
- A/D Temperature Sensor Data Register
- A/D Internal Reference Voltage Register
- A/D VBATT monitor Data Register
- A/D Self-Diagnosis Data Register
- A/D Data Buffer Registers n (N = 0 to 15)

If a register is read twice in byte units, that is, the upper byte and lower byte are read separately, the A/D-converted value read initially might disagree with the A/D-converted value read subsequently. To prevent this, never read the data registers in byte units.

40.6.3 Constraints on Stopping A/D Conversion

(1) A/D Conversion Stop Procedure

To stop A/D conversion when an asynchronous trigger or a synchronous trigger is selected as the condition for starting A/D conversion, follow the procedure shown in [Figure 40.43](#).

Figure 40.43 Procedures for clearing the ADCSR.ADST bit by software

To specify the following settings after performing the clear operation by software, provide a wait period for at least two ADCLK cycles.

- Enabling scan end interrupts
- Enabling scan end events for the event link controller
- Starting A/D conversion by software
- Enabling trigger input

(2) Notes on Modes and Status Bits

If necessary, individually initialize or set again the voltage status for self-diagnosis, the judgment of the even number or odd number specified for double-trigger mode, and the monitor flags of the compare function.

- To set again the voltage status for self-diagnosis, set the ADCER.DIAGLD bit to 1 and then set a desired value in the ADCER.DIAGVAL[1:0] bits.
- If the setting of the ADCSR.DBLE bit is changed from 0 to 1, the double-trigger mode operation starts from the first scanning.
- To initialize the monitor flags of the compare function (MONCMPA, MONCMPB, and MONCOMB), set the ADCMPCR.CMPAE and ADCMPCR.CMPBE bits to 0.
- To initialize the data storage buffer pointer, set the ADBUFPTR register to 0x00.
- To initialize the continuous sampling function (ADSHMSR.SHMD = 1), set ADShMSR.SHMD to 0. To use the continuous sampling function again after initialization, set ADShMSR.SHMD to 1 after waiting for 1 cycle of ADCLK or longer.

40.6.4 A/D Conversion Restart and Termination Timing

A maximum of 6 ADCLK cycles is required for the idle analog unit of the ADC12 to restart on setting the ADCSR.ADST bit to 1. A maximum of 2 ADCLK cycles is required for the operating analog unit of the ADC12 to terminate on setting the ADCSR.ADST bit to 0. A maximum of 1 PCLKA + 1 ADCLK cycles is required for the operating analog unit of the ADC12 to terminate on setting the ADCSR.ADST bit to 0 when PCLKA to ADCLK frequency ratio is 1:2 or 1:4.

40.6.5 Constraints on Scan End Interrupt Handling

When scanning the same analog input twice using any trigger, the first A/D-converted data is overwritten with the second A/D-converted data. This occurs when the CPU does not complete the reading of the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated.

40.6.6 Settings for the Module-Stop Function

The Module Stop Control Register can enable or disable ADC12 operation. The ADC12 is initially stopped after a reset. The registers become accessible on release from the module-stop state. After release from the module-stop state, wait for at least 1 μ s before starting A/D conversion. For details, see [section 10, Low Power Modes](#).

40.6.7 Notes on Entering the Low-Power States

Before entering the module-stop state or Software Standby mode, be sure to stop A/D conversion. Set the ADCSR.ADST bit to 0 and secure certain period until the analog unit of the ADC12 stops. Follow the procedure shown in [Figure 40.43](#) to clear the ADCSR.ADST bit with software. Then, wait for 2 clock cycles of ADCLK before entering the module-stop state or Software Standby mode.

40.6.8 Notes on Canceling Software Standby Mode

After software standby mode is canceled, wait at least 1 μ s after the stabilization time for the oscillator elapses and before starting A/D conversion. For details, see [section 10, Low Power Modes](#).

40.6.9 Error in Absolute Accuracy When Disconnection Detection Assistance Is in Use

Using disconnection detection assistance leads to an error in absolute accuracy of the ADC12. This error arises because an erroneous voltage is input to the analog input pins due to the resistive voltage division between the pull-up or pull-down resistor (R_p) and the resistance of the signal source (R_s). This error in absolute accuracy is calculated from the following formula:

$$\text{Maximum error in absolute accuracy (LSB)} = \left(2^{\text{Resolution}} - 1\right) \times R_s / (R_s + R_p)$$

Only use disconnection detection assistance after thorough evaluation.

40.6.10 Constraints on Operating Modes and Status Bits

Initialize or set again individually, if necessary, the voltage values in self-diagnosis, the value of the first scan or second scan in double trigger mode, the data buffer pointer, and status monitor in the compare function.

- Select the voltage values in self-diagnosis (ADCER.DIAGVAL[1:0]) after setting ADCER.DIAGLD to 1.
- Double-trigger mode operates as the first scan after setting ADCSR.DBLE from 0 to 1.
- The status monitor bits (MONCMPA, MONCMPB, MONCOMB) in the compare function are initialized after setting ADCMPCR.CMPAE and ADCMPCR.CMPBE to 0.

40.6.11 Notes on Board Design

The board should be designed so that digital circuits and analog circuits are separated from each other as far as possible. In addition, digital circuit signal lines and analog circuit signal lines should not intersect or be placed near each other. If these rules are not followed, noise can occur on analog signals and A/D conversion accuracy is affected. The analog input pins, reference power supply pin (VREFH0, VREFH), reference ground pin (VREFL0, VREFL), and analog power supply (AVCC0) should be separated from digital circuits using the analog ground (AVSS0). The analog ground (AVSS0) should be connected to a stable digital ground (VSS) on the board (single-point ground plane connection).

40.6.12 Constraints on Noise Prevention

To prevent the analog input pins from being destroyed by abnormal voltage such as excessive surge, insert a capacitor between AVCC0 and AVSS0 and between VREFH0 and VREFL0 and between VREFH and VREFL. Additionally, connect a protection circuit to protect the analog input pins as shown in [Figure 40.44](#).

Figure 40.44 Example protection circuit for analog inputs

40.6.13 Port Settings When Using the ADC12 Input

When using the high-precision channels, do not use PORT0 as digital output ports. Renesas recommends that you do not use the digital output that is also used as the AD analog input if normal-precision channel is used. If the digital output that is also used as the AD analog input is used for output signals, perform A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results.

40.6.14 Relationship between ADC12 Units 0 and 1 and the ACOMP

For the A/D conversion targets in [Table 40.31](#), unit 0 and 1 cannot perform A/D conversion at the same time.

Table 40.31 A/D conversion targets that are mutually exclusive with each other

A/D conversion target	
Unit 0	Unit 1
Temperature sensor	
Internal reference voltage	
VBATT 1/3 voltage monitor output	

The A/D conversion targets in [Table 40.32](#) should not be selected as ACOMP input during A/D conversion, because these pins are multiplexed with the ADC12 and ACOMP.

Table 40.32 A/D conversion targets that are mutually exclusive with ACOMP

A/D conversion target		
Unit 0	Unit 1	ACOMP
AN000	-	ACOMP0.IVCMP2
AN002	-	ACOMP0.IVCMP3
AN005	-	ACOMP0.IVCMP0
AN007/DA0	-	ACOMP0.IVREF3
Internal reference voltage	-	ACOMP0.IVREF2
-	AN100	ACOMP1.IVCMP2
-	AN101	ACOMP1.IVREF0
-	AN102	ACOMP1.IVCMP3
-	AN104	ACOMP1.IVREF1
-	Internal reference voltage	ACOMP1.IVREF2

40.6.15 Calculation for Sampling Time

The sampling time can be easily estimated by the following figure and formula. This is the time to reach the voltage within 1/4 LSB.

$$t_{SPL} = (R_{EXT} + R_{AD}) \times (C_{EXT} + C_{AD}) \times \ln(C_{AD} / (C_{EXT} + C_{AD}) \times 2^{N+2})$$

R_{EXT} shows external signal source impedance

C_{EXT} shows external capacitance (pin capacitance^{*1} + PCB parasitic capacitance)

$N = 12, 10$ or 8 (conversion resolution)

$C_{AD} = 5$ pF (internal capacitance)

$R_{AD} = 1.0$ k Ω (internal resistance, case of high-speed channels)

$R_{AD} = 2.0$ k Ω (internal resistance, case of normal-speed channels)

Note 1. Typical value of analog input pin is 5 pF

For example, if R_{EXT} is 1 k Ω , C_{EXT} is 10 pF and N is 12 bits, t_{SPL} of high-speed channel is 258 ns.

This formula simplifies the general use case. This formula is not guaranteed and should be used only for estimation.

Figure 40.45 Sample and hold circuit simplified diagram

40.6.16 Notes on simultaneous operation with other modules

The following combinations may degrade the ADC accuracy depending on the specific timing of operation.

1. AN000 without channel-dedicated sample-and-hold and AN104 mutually.
2. AN007 and AN105 mutually.
3. AN000, AN001 using channel-dedicated sample-and-hold when ADC unit 1, DAC12 or ACMPHS is operated.
4. High-precision channels of ADC unit1 when AN000, AN001 using channel-dedicated sample-and-hold are operated.
5. All channels of ADC unit 1 when ACMPHS is operated.
6. All channels of ADC unit 1 when DAC12 is operated.

To mitigate deterioration, it is recommended to take following measures.

- Performing A/D conversion with average mode.
- For even better results, performing A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results. (For the condition No.3, only performing average mode may not be effective depending on the noise. Eliminating the maximum and minimum is recommended.)
- For the condition No.6, using DA AD synchronous conversion set by DAADSCR.DAADST and DAADUSR.AMADESEL1 bits of DAC12.

Depending on the environment, ADC accuracy may be deteriorated even under conditions not listed here.

41. 12-Bit D/A Converter (DAC12)

41.1 Overview

The MCU provides a 12-bit D/A Converter (DAC12) with an output amplifier. [Table 41.1](#) lists the DAC12 specifications, [Figure 41.1](#) shows a block diagram, and [Table 41.2](#) lists the I/O pins.

Table 41.1 DAC12 specifications

Parameter	Specifications
Resolution	12 bits
Output channels	1 channel
Interference reduction between analog modules	Methods provided to minimize interference between D/A and A/D conversion: <ul style="list-style-type: none"> • D/A converted data update timing is controlled by the synchronous D/A conversion enable input signal from the ADC12 (unit 1) • Degradation of A/D conversion accuracy caused by interference is reduced by controlling the DAC12 inrush current generation timing with the enable signal.
Module-stop function	Module-stop state can be set to reduce power consumption
Event link function (input)	The DA0 conversion can be started on input of an event signal
D/A output amplifier control function	Controls whether the output amplifier (for both amplifier-through and amplifier-bias controls) is used
Destination of D/A output control function	Controls whether the output to the external pin or to the internal modules (ACMPHS) is used
TrustZone Filter	Security and Privilege attribution can be set

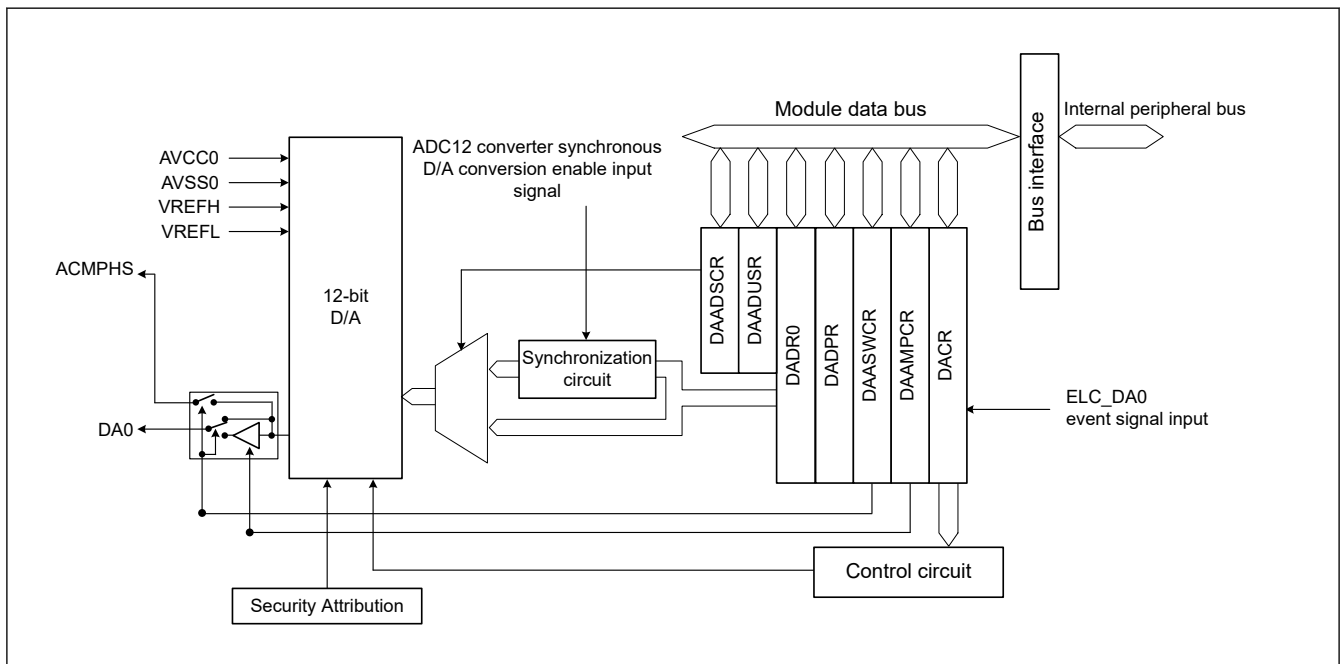

Figure 41.1 DAC12 block diagram

[Table 41.2](#) lists the pin configuration of the DAC12.

Table 41.2 DAC12 I/O pins (1 of 2)

Pin name	I/O	Function
AVCC0	Input	<ul style="list-style-type: none"> • Analog power and analog reference top voltage supply pin for ADC12 and DAC12. • Connect to VCC when these modules are not used.
AVSS0	Input	<ul style="list-style-type: none"> • Analog ground and analog reference ground supply pin for ADC12 and DAC12. • Connect to VSS when these modules are not used.
VREFH	Input	Analog reference top voltage supply pin for the ADC12 (unit 1) and the DAC12

Table 41.2 DAC12 I/O pins (2 of 2)

Pin name	I/O	Function
VREFL	Input	Analog reference ground pin for the ADC12 (unit 1) and the DAC12
DA0	Output	Channel 0 output pin for the analog signals processed by the DAC12

41.2 Register Descriptions

41.2.1 DADRn : D/A Data Register n (n = 0)

Base address: DAC12 = 0x4033_3000
 DAC12_NS = 0x5033_3000

Offset address: 0x00 + 0x02 × n

Bit position: 15 0

Bit field:

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Note: S-TYPE-3, P-TYPE-3

DADRn register is 16-bit read/write registers that store data for D/A conversion. When an analog output is enabled, the values in DADRn are converted and output to the analog output pins.

12-bit data can be formatted as left- or right-justified in the DADPR.DPSEL bit setting. In right-justified format (DADPR.DPSEL = 0), the lower 12 bits, [11:0], are valid. In left-justified format (DADPR.DPSEL = 1), the upper 12 bits, [15:4], are valid.

41.2.2 DACR : D/A Control Register

Base address: DAC12 = 0x4033_3000
 DAC12_NS = 0x5033_3000

Offset address: 0x04

Bit position: 7 6 5 4 3 2 1 0

Bit field:

Value after reset: 0 0 0 1 1 1 1 1

Bit	Symbol	Function	R/W
4:0	—	These bits are read as 1. The write value should be 1.	R/W
5	—	This bit is read as 0. The write value should be 0.	R/W
6	DAOE0	D/A Output Enable 0 0: Disable analog output of channel 0 (DA0) 1: Enable D/A conversion of channel 0 (DA0)	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Only set this register while the ADC12 is halted when the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled). Only set DACR while the ADCSR.ADST bit is 0 and after selecting the software trigger, for the ADC12 trigger to securely stop the ADC12. This MCU only supports ADC12 (unit 1).

DAOE0 bit (D/A Output Enable 0)

The DAOE0 bit controls D/A conversion, amplifier operation, and analog output in combination with the DAAMPCR.DAAMP0 bit and the DAASWCR.DAASW0 bit. See [Table 41.3](#).

When the DAOE0 bit is 0, D/A conversion is not processed, and no conversion result is output.

When interference reduction between D/A and A/D conversions is enabled (DAADSCR.DAADST = 1), set the DAOE0 bit while the ADCSR.ADST bit of the ADC12 (unit 1) is set to 0. Then, select the software trigger for the ADC12 (unit 1) trigger to securely stop the ADC12 (unit 1).

The event link function can be used to set the DAOE0 bit to 1. The DAOE0 bit is set to 1 when the event specified in the ELSR12 register of the ELC (ELC_DA0 event) occurs, and output of the D/A conversion results starts.

Table 41.3 D/A conversion and analog output control

DACR	DAAMPCR	DAASWCR	Operation	Amplifier operation	Analog external output*1	Analog internal output*2
DAOE0	DAAMP0	DAASW0				
0	x	x	Stop	Stop	Hi-Z	Hi-Z
1	0	0	Run	Stop	Amplifier-through	Hi-Z
1	0	1	Run	Stop	Hi-Z	Amplifier-through
1	1	0	Run	Run	Amplifier output	Hi-Z
1	1	1	Run	Run	Hi-Z	Hi-Z

Note: x : Don't care

Note 1. output to pin

Note 2. output to ACMPHS

41.2.3 DADPR : DADRn Format Select Register

Base address: DAC12 = 0x4033_3000
 DAC12_NS = 0x5033_3000

Offset address: 0x05

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0. The write value should be 0.	R/W
7	DPSEL	DADRn Format Select 0: Right-justified format 1: Left-justified format	R/W

Note: S-TYPE-3, P-TYPE-3

41.2.4 DAADSCR : D/A A/D Synchronous Start Control Register

Base address: DAC12 = 0x4033_3000
 DAC12_NS = 0x5033_3000

Offset address: 0x06

Bit	Symbol	Function	R/W
6:0	—	These bits are read as 0. The write value should be 0.	R/W
7	DAADST	D/A A/D Synchronous Conversion 0: Do not synchronize DAC12 with ADC12 (unit 1) operation (disable interference reduction between D/A and A/D conversion). 1: Synchronize DAC12 with ADC12 (unit 1) operation (enable interference reduction between D/A and A/D conversion).	R/W

Note: S-TYPE-3, P-TYPE-3

To minimize interference between D/A and A/D conversion, the DAADSCR register enables synchronization of the start timing of D/A conversion with the ADC12 synchronous D/A conversion enable input signal.

Only set this register while the ADC12 (unit 1) is halted, that is, while the ADCSR.ADST bit is 0 after selecting the software trigger as the ADC12 (unit 1) trigger.

Select unit 1 as the target ADC12 unit before setting the DAADST bit to 1. Set DAADUSR.AMADESEL1 bit to 1 to select unit 1. This MCU only supports ADC12 unit 1.

DAADST bit (D/A A/D Synchronous Conversion)

Setting the DAADST bit to 0 allows the DADRn register value to be converted into analog data at any time. Setting the DAADST bit to 1 allows synchronization of D/A conversion with the synchronous D/A conversion enable input signal from the ADC12 (unit 1). With this bit set, D/A conversion does not start until the ADC12 (unit 1) completes A/D conversion, even when the DADRn register is changed.

Set this bit while the ADCSR.ADST bit is set to 0. Then, select the software trigger for the ADC12 (unit 1) trigger to securely stop the ADC12 (unit 1). Set the DAADUSR.AMADESEL1 bit to 1 before setting the DAADST bit to 1.

The event link function cannot be used when the DAADST bit is set to 1. Stop the event link function by setting the ELSR12 register of the ELC.

41.2.5 DAAMPCR : D/A Output Amplifier Control Register

Base address: DAC12 = 0x4033_3000
 DAC12_NS = 0x5033_3000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	DAAMP0	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	DAAMP0	Amplifier Control 0 0: Do not use channel 0 output amplifier 1: Use channel 0 output amplifier	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The DAAMPCR register selects D/A output with or without using the amplifier.

DAAMP0 bit (Amplifier Control 0)

When the DAAMP0 bit is 0, analog values are output for D/A output of channel 0 without using the amplifier. When the DAAMP0 bit is 1, analog values are output for D/A output of channel 0 through the amplifier.

When the DACR.DAOE0 bit is 0, the amplifier is not used regardless of the setting of the DAAMP0 bit. See Table 41.3 for details.

41.2.6 DAASWCR : D/A Amplifier Stabilization Wait Control Register

Base address: DAC12 = 0x4033_3000
 DAC12_NS = 0x5033_3000

Offset address: 0x1C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	DAASW0	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0. The write value should be 0.	R/W
6	DAASW0	D/A Amplifier Stabilization Wait 0 and D/A internal output control 0: For output to external pin: Amplifier stabilization wait off (output) for channel 0 For output to internal module: Disable output for channel 0 1: For output to external pin: Amplifier stabilization wait on (high-Z) for channel 0 For output to internal module: Enable output for channel 0	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The DAASWCR register controls D/A output with the output amplifier or D/A output for internal modules. This register is used in the initialization procedure to wait for stabilization of the D/A output amplifier. DAASW0 bit in DAASWCR should be set to 1 when the DACR.DAOE0 bit is 0. See [section 41.7.5. Initialization Procedure with the Output Amplifier](#).

DAASW0 bit (D/A Amplifier Stabilization Wait 0)

Set the DAASW0 bit to 1 in the initialization procedure to wait for the stabilization of the D/A channel 0 output amplifier. When DAASW0 is set to 1, D/A conversion operates, but the conversion result of D/A is not output from channel 0 to the DA0 pin. When the DAASW0 bit is 0, the stabilization wait time stops, and the D/A conversion result of channel 0 is output through the output amplifier to the DA0 pin. When the amplifier is not used (DAAMPCR.DAAMP0 bit is 0) and DAASW0 is set to 1, D/A conversion result of channel 0 is output to the internal modules.

41.2.7 DAADUSR : D/A A/D Synchronous Unit Select Register

Base address: DAC12 = 0x4033_3000
 DAC12_NS = 0x5033_3000

Offset address: 0x10C0

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	AMADSEL1	—

Value after reset: 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	—	This bit is read as 0. The write value should be 0.	R/W
1	AMADSEL1	A/D Unit 1 Select 0: Do not select unit 1 1: Select unit 1	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

The DAADUSR register selects the target ADC12 unit for D/A and A/D synchronous conversions. Set the AMADSEL1 bit to 1 to select unit 1 as the target synchronous unit for the MCU. When setting the DAADSCR.DAADST bit to 1 for synchronous conversions, select the target unit in this register in advance.

Only set the DAADUSR register while the ADCSR.ADST bit of the ADC12 is set to 0 and the DAADSCR.DAADST bit is set to 0.

41.3 Operation

When the DAOE0 bit in DACR is set to 1, DAC12 is enabled and the conversion result is output.

This following example shows D/A conversion. [Figure 41.2](#) shows the timing of this operation.

To process D/A conversion:

1. Set the data for D/A conversion in the DADR0 register and the data format in the DADPR.DPSEL bit.
2. Set the DACR.DAOE0 bit to 1 to start D/A conversion. The conversion result is output from the analog output pin DA0 after the conversion time t_{DCONV} elapses. The conversion result continues to be output until DADR0 is written to again or the DAOE0 bit is set to 0. The output value (reference) is expressed by the following formula:

$$\frac{\text{Setting in DADR0}}{4096} \times VREFH$$

3. To start conversion again, write another value to DADR0. The conversion result is output after the conversion time t_{DCONV} elapses.
When the DAADSCR.DAADST bit is 1 (interference reduction between D/A and A/D conversion is enabled), a maximum of one A/D conversion time is required for D/A conversion to start. When ADCLK is faster than the peripheral clock, a longer time might be required.
4. To disable analog output, set the DAOE0 bit to 0.

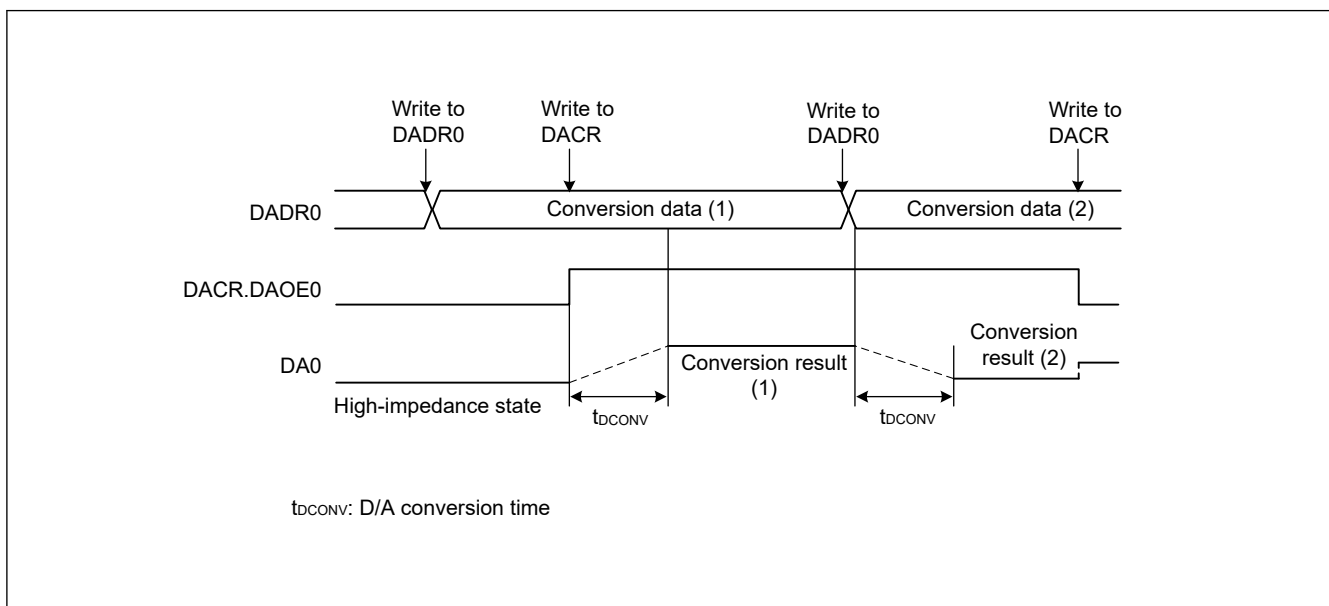

Figure 41.2 Example of DAC12 operation

41.3.1 Reducing Interference between D/A and A/D Conversion

When D/A conversion starts, the DAC12 generates inrush current. Because the DAC12 and ADC12 (unit 1) share the same analog power supply, the generated inrush current can interfere with ADC12 (unit 1) operation.

While the DAADSCR.DAADST bit is 1, D/A conversion does not start immediately on updating the DADR_m register. Instead:

- If the DADR_m register data is modified while the ADC12 is halted, D/A conversion starts in 1 PCLKA cycle.
- If the DADR_m register data is modified while the ADC12 is performing a 12-bit A/D conversion, D/A conversion starts on A/D conversion completion. Therefore, it takes up to one A/D conversion time period for the DADR_m register data update to be reflected as the D/A conversion circuit output. Until the D/A conversion completes, the DADR_m register value does not correspond to the analog output value.

When the DAADSCR.DAADST bit is 1, it is not possible to check through software whether the DADR_m register value was D/A-converted.

The following sequence provides an example of channel 0 D/A conversion, in which the DAC12 is synchronized with the ADC12 (unit 1). [Figure 41.3](#) shows the timing of this operation.

To perform D/A conversion on channel 0 in synchronization with the ADC12 (unit 1):

1. Confirm that the ADC12 (unit 1) is halted and set the DAADUSR.AMA DSEL1 bit to 1.
2. Confirm that the ADC12 (unit 1) is halted and set the DAADSCR.DAADST bit to 1.
3. Confirm that the ADC12 (unit 1) is halted and set the DACR.DAOE0 bit to 1.
4. Set the DADR0 register. If ADCLK is faster than the peripheral clock, D/A conversion might be delayed for longer than one A/D conversion time.

- If the ADC12 (unit 1) is halted (ADCSR.ADST = 0) when the DADR0 register is modified, D/A conversion starts in 1 PCLKA cycle.
- If the 12-bit A/D conversion is in progress (ADCSR.ADST = 1) when the DADR0 register is modified, D/A conversion starts on A/D conversion completion. If the DADR0 register is modified twice during A/D conversion, the first update might not be converted.

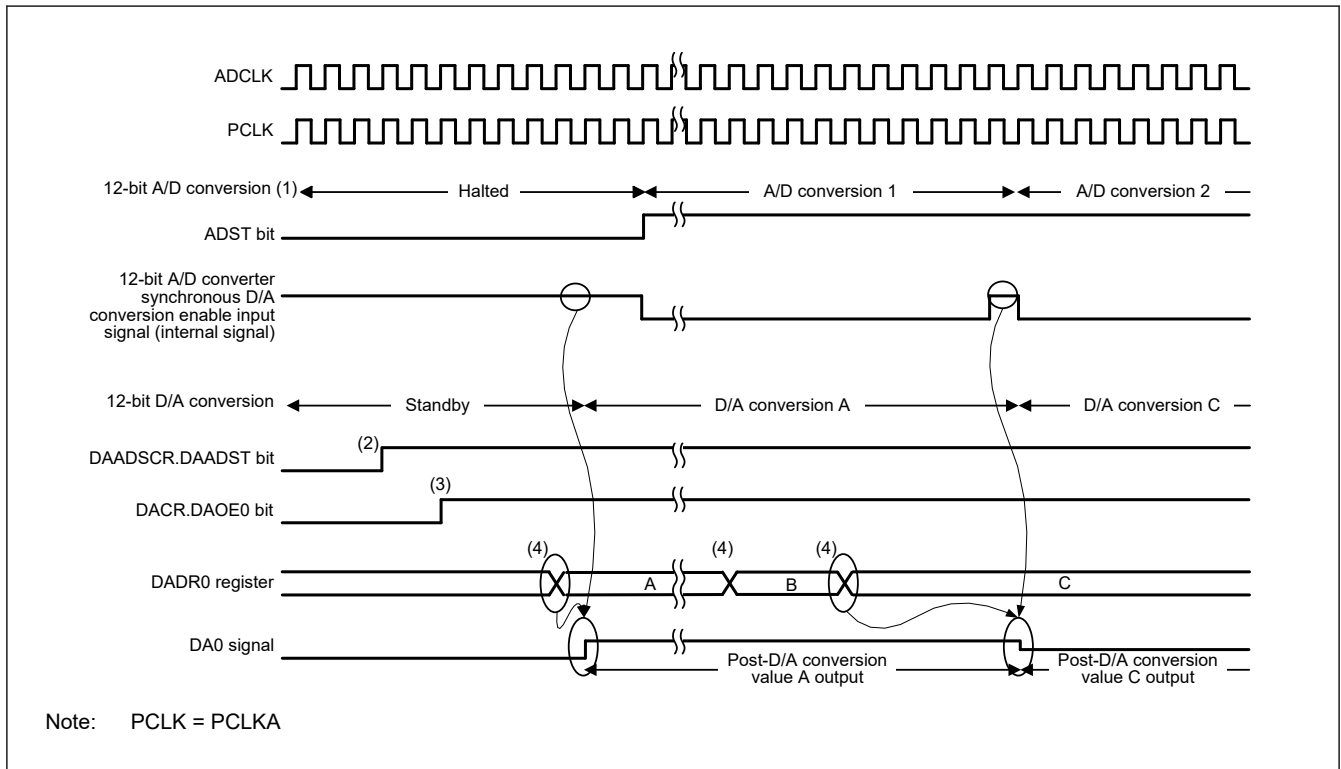

Figure 41.3 Example conversion when DAC12 is synchronized with ADC12 (unit 1)

When ADCLK is faster than PCLKA, the DAC12 might not be able to capture the synchronous D/A conversion enable input signal from the ADC12 (unit 1) during the 1 ADCLK cycle that is output between A/D conversion 1 and A/D conversion 2, as shown in Figure 41.4. In this case, post-D/A conversion value A is continuously output as the DA0 signal.

Figure 41.4 Example when the DAC12 cannot capture the synchronous D/A conversion enable input signal from the ADC12 (unit 1)

41.4 Event Link Operation Setting Procedure

This section describes the procedures used in event link operation.

41.4.1 DA0 Event Link Operation Setting Procedure

To set up DA0 event link operation:

1. Set the DADPR.DPSEL bit and the data for D/A conversion in the DADR0 register.
2. Set the ELC_DA0 event signal to be linked to each peripheral module in the ELSR12 register.
3. Set the ELCR.ELCON bit to 1. This enables event link operation for all modules with the event link function selected.
4. Set the event output source module to activate the event link. After the event is output from the module, the DACR.DAOE0 bit becomes 1, and D/A conversion starts on channel 0.
5. Set the ELSR12 register to 0x0000 to stop event link operation of DAC12 channel 0. All event link operation is stopped when the ELCR.ELCON bit is set to 0.

41.5 Analog Output Control by Security Attribution

Analog output to DA0 pin is controlled by the security attribution of Port and DAC12 as shown in [Table 41.4](#).

Analog output to ACPHPS is not controlled by the security attribution.

Table 41.4 Analog output control by security attribution (1 of 2)

Security Attribution		Analog Output
DAC12 (PSARD)	P014 (PmSAR (m = 0 to 9, A, B))	P014 pin output
0 (secure)	1 (non-secure)	enable
0 (secure)	0 (secure)	enable
1 (non-secure)	1 (non-secure)	enable
1 (non-secure)	0 (secure)	disable

Table 41.4 Analog output control by security attribution (2 of 2)

Security Attribution		Analog Output
DAC12 (PSARD)	P014 (PmSAR (m = 0 to 9, A, B))	P014 pin output
1 (non-secure)	0 (secure)	disable

41.6 Usage Notes on Event Link Operation

- When the event link function is used, do not use the amplifier output function.
- When the event specified for the ELC_DA0 event signal is generated while a write to the DACR.DAOE0 bit is performed, the write cycle is stopped, and the generated event takes precedence in setting the bit to 1.
- Use of the event link function is prohibited when the DAADSCR.DAADST bit is set to 1 to reduce interference between D/A and A/D conversions.

41.7 Usage Notes

41.7.1 Settings for the Module-Stop Function

DAC12 operation can be disabled or enabled using the Module Stop Control Register. The DAC12 is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

41.7.2 DAC12 Operation in the Module-Stop State

When the MCU enters the module-stop state with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in the module-stop state, disable D/A conversion by setting the DACR.DAOE0 bit to 0.

41.7.3 DAC12 Operation in Software Standby Mode

When the MCU enters Software Standby mode with D/A conversion enabled, the D/A outputs are retained, and the analog power supply current is the same as during D/A conversion. If the analog power supply current must be reduced in Software Standby mode, disable D/A conversion by setting the DACR.DAOE0 bit to 0.

41.7.4 Constraint on Entering Deep Software Standby Mode

When the MCU enters Deep Software Standby mode with D/A conversion enabled, the outputs of the DAC12 are placed in a high impedance state.

41.7.5 Initialization Procedure with the Output Amplifier

Use the following initialization procedures with the output amplifier. The example shows the case for channel 0.

To initialize the DAC12 with the output amplifier:

1. Write 0x0000 to the DADR0 register.
2. Set the DAASWCR.DAASW0 bit to 1.
3. Set the DAAMPCR.DAAMP0 bit to 1.
4. Set the DACR.DAOE0 bit to 1 to start operation of the amplifier.
5. Clear the DAASWCR.DAASW0 bit to 0 after waiting for the duration of D/A conversion time t_{DCONV} .
6. Write the value to be converted in the DADR0 register.

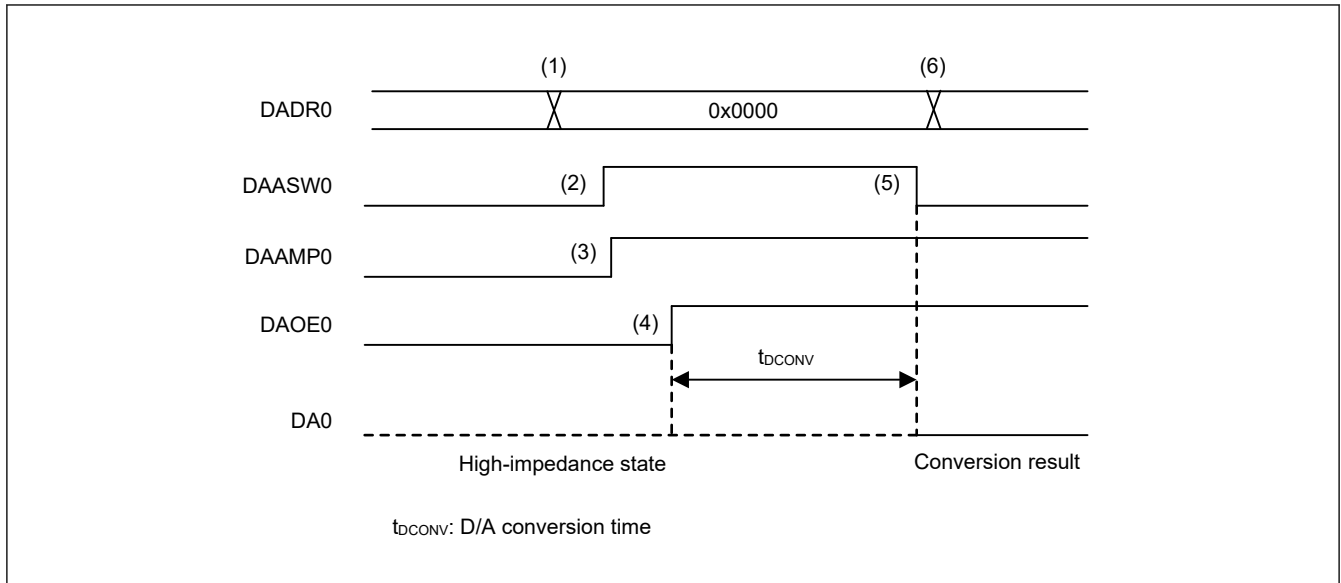

Figure 41.5 Example of the initial flow with the output amplifier in DAC12

While the amplifier is running, clearing the DACR.DAOE0 bit to 0 allows the amplifier to stop operation. To use the amplifier again, repeat steps 1 to 6.

41.7.6 Initialization Procedure of the Output to internal modules

Use the following initialization procedures for the output to internal modules.

1. Set the DAASWCR.DAASW0 bit to 1.
2. Set the DACR.DAOE0 bit to 1.
3. Write the value to be converted in the DADR0 register.

When you stop output of the DAC12, set DAASWCR.DAASW0 to 0 after setting DACR.DAOE0 to 0.

41.7.7 Constraint on Usage When Interference Reduction between D/A and A/D Conversion Is Enabled

When the DAADSCR.DAADST bit is 1, enabling interference reduction between D/A and A/D conversion, do not place the ADC12 in the module-stop state. Doing so can halt D/A conversion in addition to A/D conversion.

42. Temperature Sensor (TSN)

42.1 Overview

The on-chip Temperature Sensor (TSN) determines and monitors the die temperature for reliable operation of the device. The sensor outputs a voltage directly proportional to the die temperature, and the relationship between the die temperature and the output voltage is fairly linear. The output voltage is provided to the ADC12 for conversion and can be further used by the end application.

Table 42.1 lists the TSN specifications, and Figure 42.1 shows a block diagram.

Table 42.1 TSN specifications

Item	Description
Temperature sensor voltage output	Temperature sensor outputs a voltage to the 12-bit A/D converter
Module-stop function	Module-stop state can be set to reduce power consumption
Temperature sensor calibration data	Reference data measured for each chip at factory shipment is stored in a register
TrustZone Filter	Security and Privilege attribution can be set

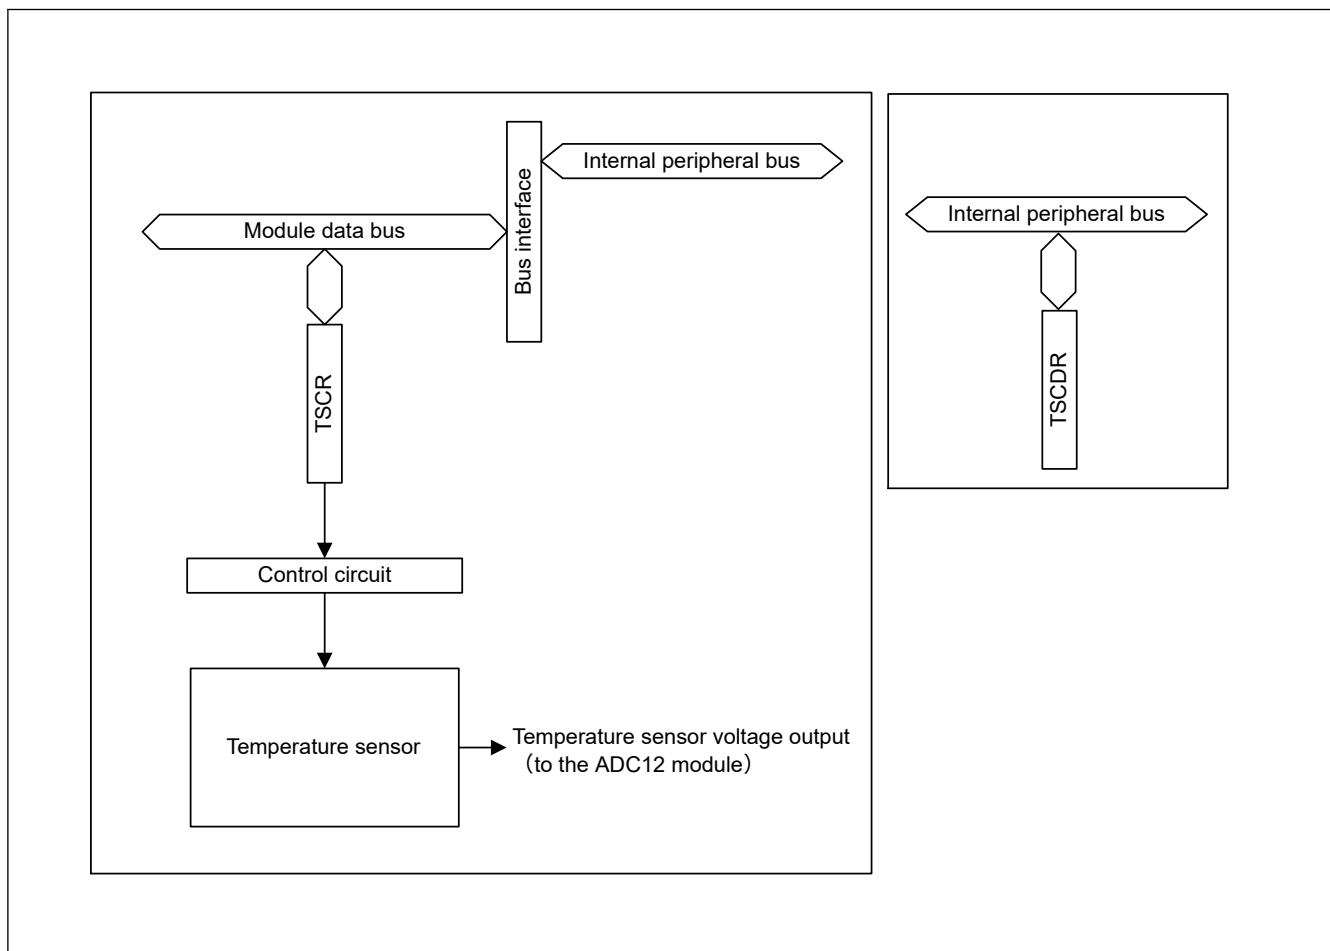

Figure 42.1 TSN block diagram

42.2 Register Descriptions

42.2.1 TSCR : Temperature Sensor Control Register

Base address: TSN = 0x4023_5000
 TSN_NS = 0x5023_5000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	TSEN	—	—	TSOE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
3:0	—	These bits are read as 0. The write value should be 0.	R/W
4	TSOE	Temperature Sensor Output Enable 0: Disable output from the temperature sensor to the ADC12 1: Enable output from the temperature sensor to the ADC12	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	TSEN	Temperature Sensor Enable 0: Stop the temperature sensor 1: Start the temperature sensor.	R/W

Note: S-TYPE3, P-TYPE3

The TSCR is a register which controls the temperature sensor. The timing constraints shown in [Figure 42.3](#) apply to the settings of the TSCR register.

TSOE bit (Temperature Sensor Output Enable)

The TSOE bit enables or disables the temperature sensor output to ADC12.

TSEN bit (Temperature Sensor Enable)

The TSEN bit starts or stops the temperature sensor.

42.2.2 TSCDR : Temperature Sensor Calibration Data Register

Base address: TSD = 0x4011_B000
 TSD_NS = 0x5011_B000

Offset Address: 0x017C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	TSCDR[15:0]															
Value after reset:	Chip-specific value															

Bit	Symbol	Function	R/W
15:0	TSCDR[15:0]	Temperature Sensor Calibration Data Chip-specific value	R
31:16	—	These bits are read as 0.	R

Note: S-TYPE5, P-TYPE5

The TSCDR register stores temperature sensor calibration data measured for each chip at factory shipment.

Temperature sensor calibration data is the output voltage of the temperature sensor under the conditions $T_j = 125^\circ\text{C}$ and $AVCC0 = VREFH0 = 3.3\text{ V}$ converted to a digital value by the 12-bit A/D converter.

The TSCDR register is a read-only 32-bit register. Read from this register in 32-bit units.

Temperature sensor calibration data is stored in the lower 12 bits of the TSCDR register.

42.3 Using the Temperature Sensor

The temperature sensor outputs a voltage that varies with the temperature. This voltage is converted to a digital value by the 12-bit A/D converter. To obtain the die temperature, convert this value into the temperature.

42.3.1 Preparation for Using the Temperature Sensor

The ambient temperature (T) is proportional to the temperature sensor voltage output (V_s), so ambient temperature is calculated with the following formula:

$$T = (V_s - V_1) / \text{slope} + T_1$$

- T: Ambient temperature of MCU as calculation result ($^\circ\text{C}$)
- V_s : Voltage output by the temperature sensor on temperature measurement (V)
- T_1 : Temperature experimentally measured at one point ($^\circ\text{C}$)
- V_1 : Voltage output by the temperature sensor on measurement of T_1 (V)
- T_2 : Temperature experimentally measured at a second point ($^\circ\text{C}$)
- V_2 : Voltage output by the temperature sensor on measurement of T_2 (V)
- Slope: Temperature gradient of the temperature sensor (V / $^\circ\text{C}$), $\text{slope} = (V_2 - V_1) / (T_2 - T_1)$

Characteristics vary between sensors, so Renesas recommends measuring two different sample temperatures as follows:

1. Use the 12-bit A/D converter to measure the voltage V_1 output by the temperature sensor at temperature T_1 .
2. Again use the 12-bit A/D converter to measure the voltage V_2 output by the temperature sensor at a different temperature T_2 .
3. Obtain the temperature gradient ($\text{slope} = (V_2 - V_1) / (T_2 - T_1)$) from these results.
4. Subsequently, obtain temperatures by substituting the slope into the formula for the temperature characteristic ($T = (V_s - V_1) / \text{slope} + T_1$).

In order to make the temperature T_a and T_j as close as possible, perform the measurement with the power consumption of the MCU as low as possible.

If you are using the temperature gradient given in [section 51, Electrical Characteristics](#), use the A/D converter to measure the voltage V_1 output by the temperature sensor at temperature T_1 , then calculate the temperature characteristic using the following formula:

$$T = (V_s - V_1) / \text{slope} + T_1$$

Note: This method produces less accurate temperatures than measurement at two points.

In this MCU, the TSCDR register stores the temperature value (CAL125) of the temperature sensor measured under the condition $T_a = T_j = 125^\circ\text{C}$ and $AVCC0 = VREFH0 = 3.3\text{ V}$. If you use this value as the sample measurement result at the first point, you can omit the preparation before using the temperature sensor.

V_1 is calculated from CAL125:

$$V_1 = 3.3 \times \text{CAL125} / 4096 \text{ [V]} \text{ (In case of 12 bit accuracy)}$$

Using this value, the measured temperature can be calculated according to the following formula:

$$T = (V_s - V_1) / \text{slope} + 125 \text{ [}^\circ\text{C]}]$$

- T: Ambient temperature of MCU as calculation result ($^\circ\text{C}$)
- V_s : Voltage output by the temperature sensor when the temperature is measured (V)
- V_1 : Voltage output by the temperature sensor when $T_a = T_j = 125^\circ\text{C}$ and $AVCC0 = VREFH0 = 3.3\text{ V}$ (V)

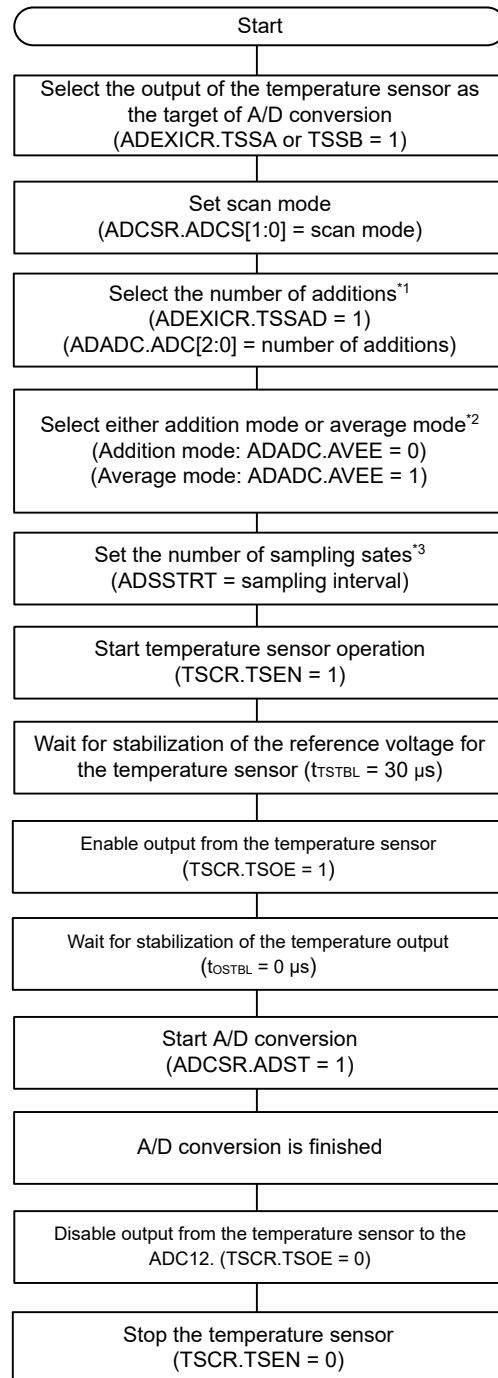

- Slope: Temperature gradient of the temperature sensor^{*1} / 1000 (V/°C)

Note 1. See [section 51, Electrical Characteristics](#)

42.3.2 Procedures for Using the Temperature Sensor

[Figure 42.2](#) shows the procedure for using the TSN.

For details, see [section 40, 12-Bit A/D Converter \(ADC12\)](#).

Note 1. This setting is not required if addition/average mode is not set.

Note 2. The ADADC.ADC[2:0] setting is limited to some values in additions/average mode. For details on the available ADADC.ADC[2:0] settings in additions/average mode, see [section 40, 12-Bit A/D Converter \(ADC12\)](#).

Note 3. Set the sampling time to more than the value described in [section 51, Electrical Characteristics](#).

Figure 42.2 Procedure example for using the TSN

[Figure 42.3](#) shows the timing from the start of temperature sensor operation until the completion of A/D conversion when the ADC12 is in single scan mode (the conversion target is the temperature sensor output only). The times shown in the figure are described in [Table 42.2](#)

Figure 42.3 Timing from start of temperature sensor operation until completion of A/D conversion

Table 42.2 Time until completion of A/D conversion after start of temperature sensor operation

Parameter	Symbol	Time
Wait time for temperature sensor reference voltage stabilization	t_{STBL}	30 μ s (min)
Wait time for temperature sensor output stabilization	t_{OSTBL}	0 μ s (min)
A/D converter input sampling time	t_{SPL}	ADSSTRn setting \times ADCLK period
A/D conversion time	t_{SAM}	See the table in section 40.3.6. Analog Input Sampling and Scan Conversion Time .
Scan conversion end delay	t_{ED}	

42.4 Usage Notes

42.4.1 Settings for the Module-Stop Function

TSN operation can be disabled or enabled using the associated bit in Module Stop Control Register D (MSTPCRD). The TSN is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

42.4.2 Settings for the Software Standby Mode

Before entering Software Standby Mode, set TSCR.TSOE bit to 0 after stopping A/D conversion, then set TSCR.TSEN bit to 0 to stop the TSN.

43. High-Speed Analog Comparator (ACMPHS)

43.1 Overview

The High-Speed Analog Comparator (ACMPHS) can be used to compare an analog input voltage with a reference voltage and to provide a digital output based on the result of conversion. Both the analog input voltage and the reference voltage can be provided to the ACMPHS from internal sources (D/A converter output or internal reference voltage) and an external source. Such flexibility is useful in applications that require go/no-go comparisons to be performed between analog signals without necessarily requiring A/D conversion.

[Table 43.1](#) lists the ACMPHS specifications, [Figure 43.1](#) shows a block diagram, and [Table 43.2](#) shows the input source configurations.

Table 43.1 ACMPHS specifications

Parameter	Specifications
Number of channels	2 channels: ACMPHSn (n = 0, 1)
Analog input voltage	<ul style="list-style-type: none"> Output from internal D/A converter Input from an external source (compatible with internal A/D converter input pin (one selectable))
Reference voltage	<ul style="list-style-type: none"> Internal reference voltage (Vref) Output from internal D/A converter Input from an external source (compatible with internal A/D converter input pin (one selectable))
ACMPHS output	<ul style="list-style-type: none"> Comparison result output to terminal PIN Generation of ELC event output Monitor output from register Generation of interrupt request output
Interrupt request signal	<ul style="list-style-type: none"> Interrupt request generated on valid edge detection from comparison result (when CMPCTL.CSTEN = 0*¹) Selectable to rising edge, falling edge, or both edges (when CMPCTL.CSTEN = 0*¹) Rising edge only (when CMPCTL.CSTEN = 1*¹)
Digital filter function	<ul style="list-style-type: none"> Selectable to one of three sampling frequencies Not using the filter function is selectable
Module-stop function	Module-stop state can be set for each groups to reduce power consumption.
TrustZone Filter	Security and Privilege attribution can be set for each group

Note 1. Interrupt request signal selection restriction detail refers to [section 43.5. ACMPHS Interrupts](#) and [section 43.6. ACMPHS Output to the Event Link Controller \(ELC\)](#).

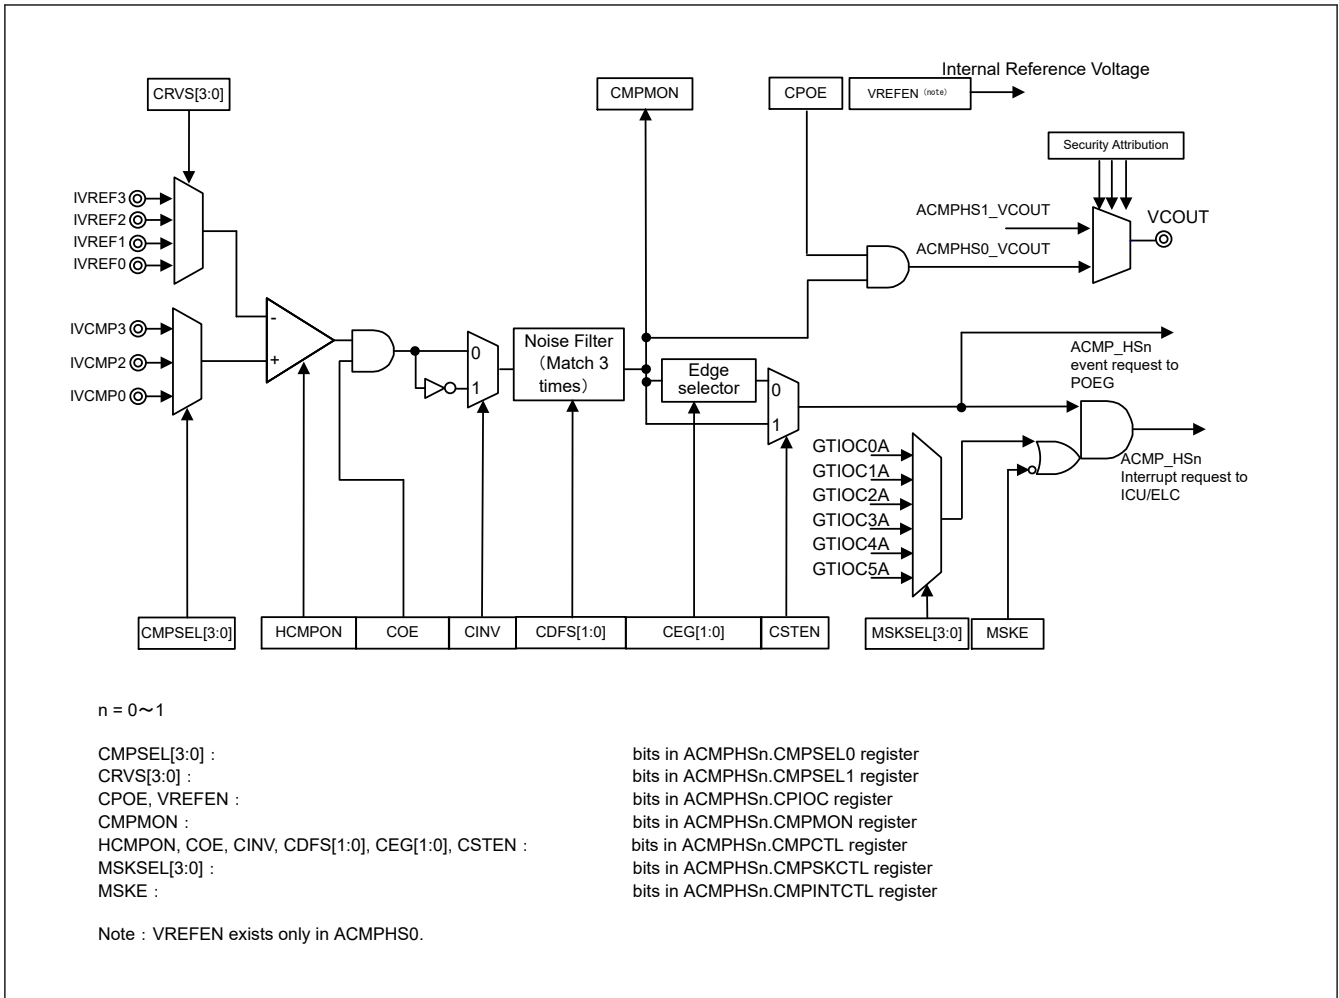

Figure 43.1 ACMPHS block diagram

Table 43.2 Input source configuration of the ACMPHS

Comparator	Reference voltage input source				Analog voltage input source			Output pin
	IVREF3	IVREF2	IVREF1	IVREF0	IVCMP3	IVCMP2	IVCMP0	
ACMPHS0	DA0 ^{*3}	Vref ^{*1}	AN104	AN101	AN002	AN000	AN005	VCOUT ^{*2}
ACMPHS1	DA0 ^{*3}	Vref ^{*1}	AN104	AN101	AN102	AN100	—	

Note 1. Internal voltage reference.

Note 2. ACMPHS0 to ACMPHS1 compare outputs are bundled with the VCOUT pin.

Note 3. When D/A converter 0 output is not used, the signal can be used as AN007 analog input.

43.2 Register Descriptions

43.2.1 CMPCTL : Comparator Control Register

Base address: ACMPHS_n = 0x4023_6000 + 0x0100 × n (n = 0, 1)
 ACMPHS_n_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x000

Bit position:	7	6	5	4	3	2	1	0
Bit field:	HCMP ON	CDFS[1:0]		CEG[1:0]		CSTE N	COE	CINV

Value after reset: 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	CINV	Comparator Output Polarity Selection* ¹ * ² 0: Do not invert comparator output 1: Invert comparator output	R/W
1	COE	Comparator Output Enable 0: Disable comparator output (output signal is low level) 1: Enable comparator output	R/W
2	CSTEN	Interrupt Select* ³ 0: Output through the edge selector 1: Output directly	R/W
4:3	CEG[1:0]	Selection of Valid Edge (Edge Selector) 0 0: Do not detect edge 0 1: Detect rising edge 1 0: Detect falling edge 1 1: Detect both edges	R/W
6:5	CDFS[1:0]	Noise Filter Selection * ¹ * ² * ³ * ⁴ 0 0: Do not use noise filter 0 1: Use noise filter sampling frequency of PCLKB/2 ³ 1 0: Use noise filter sampling frequency of PCLKB/2 ⁴ 1 1: Use noise filter sampling frequency of PCLKB/2 ⁵	R/W
7	HCOMPON	Comparator Operation Control* ⁵ 0: Stop operation (comparator outputs a low-level signal) 1: Enable operation (enables input to the comparator pins)	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Disable the ACMPHS output (COE = 0) before changing the CDFS[1:0] and CINV bits.

Note 2. If the CDFS[1:0] and CINV bits are changed, an ACMPHS interrupt request and an ELC event might be generated. Before changing these bits, set the ELSRn register to 0 (the ACMPHS output is not linked). After changing these bits, clear the IR flag in the IELSRn register to 0 to clear the interrupt status.

Note 3. Set the CSTEN bit to 1 and the CDFS[1:0] bits to 00b if the ACMPHS interrupt causes release of Software Standby mode. CSTEN is supported only by the ACMPHS0. ACMPHS1.CMPCTL.CSTEN must be set to 0.

Note 4. If the CDFS[1:0] bits are changed from 00b (noise filter not used) to a value other than 00b (noise filter used), perform sampling four times and update the filter output, and then use the ACMPHS interrupt request or the ELC event.

Note 5. A stabilization wait time is required to permit ACMPHS operation after enabling it (HCOMPON = 1). The operation stabilization wait time for ACMPHS modules 0 to 1 is 300 ns.

Note: Set this register before setting registers in the POEG when using comparator output as a POEG source.

The CMPCTL register controls the ACMPHS operation, enables or disables the ACMPHS output, selects the noise filter, selects the valid edge of the interrupt signal, and selects the interrupt.

43.2.2 CMPSEL0 : Comparator Input Select Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x004

Bit position: 7 6 5 4 3 2 1 0

Bit field:	—	—	—	—	CMPSEL[3:0]		
------------	---	---	---	---	-------------	--	--

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
3:0	CMPSEL[3:0]	Comparator Input Selection* ¹ * ² * ³ 0x00: Do not input 0x01: Select IVCMP0 0x04: Select IVCMP2 0x08: Select IVCMP3 Others: Setting prohibited	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Use the following procedure to change the CMPSEL[3:0] bits. Writing a value other than 0x00 while the value of the CMPSEL0 register is not 0x00 is invalid. Writing 1 to two or more bits is also invalid. In both cases, the previous value is retained.

To change the CMPSEL[3:0] bits:

1. Set the CMPCTL.COE bit to 0.
2. Set the CMPSEL0 register to 0x00.
3. Set a new value in the CMPSEL[3:0] bits, with 1 set in only one of the bits.
4. Wait for the input switching stabilization wait time (200 ns).
5. Set the CMPCTL.COE bit to 1.
6. Clear the IR flag in the IELSRn register to clear the interrupt status.

Note 2. For details, see [Table 43.2](#).

Note 3. If ACMPHSn level detection signal is used as a POEG source, write access to these bits after the setting of any register in the POEG may generate a POEG source.

43.2.3 CMPSEL1 : Comparator Reference Voltage Select Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
 ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x008

Bit	Symbol	Function	R/W
3:0	CRVS[3:0]	Reference Voltage Selection*1*2*3*4 0x00: Do not input 0x01: Select IVREF0 0x02: Select IVREF1 0x04: Select IVREF2 0x08: Select IVREF3 Others: Setting prohibited	R/W
7:4	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. Use the following procedure to change the CRVS[3:0] bits. Writing a value other than 0x00 while the value of the CMPSEL1 register is not 0x00 is invalid. Writing 1 to two or more bits is also invalid. In both cases, the previous value is retained.

To change the CRVS[3:0] bits:

1. Set the CMPCTL.COE bit to 0.
2. Set the CMPSEL1 register to 0x00.
3. Set a new value to the CRVS[3:0] bits, with 1 set in only one of the bits.
4. Wait for the input switching stabilization wait time (200 ns).
5. Set the CMPCTL.COE bit to 1.
6. Clear the IR flag in the IELSRn register to clear the interrupt status.

Note 2. For details, see [Table 43.2](#).

Note 3. When the on-chip D/A converter output voltage is used, set the D/A converter to generate comparator C reference voltage before enabling comparator operation (CMPCTL.HCMPON bit = 1). For details on setting the D/A converter, see [section 41, 12-Bit D/A Converter \(DAC12\)](#).

Note 4. If ACMPHSn level detection signal is used as a POEG source, write access to these bits after the setting of any register in the POEG may generate a POEG source.

43.2.4 CMPMON : Comparator Output Monitor Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
 ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x00C

Bit	Symbol	Function	R/W
0	COMPON	Comparator Output Monitor* ¹ 0: Comparator output is low 1: Comparator output is high	R
7:1	—	These bits are read as 0. The write value should be 0.	R

Note: S-TYPE-3, P-TYPE-3

Note 1. When ACMPHS operation is enabled (CMPCTL.HCMPON = 1 and CMPCTL.COE = 1) but the noise filter is not in use (CDFS[1:0] = 00b), design the software so that the COMPON bit is read twice and the values are only used after the two consecutive values match.

43.2.5 CPIOC : Comparator Output Control Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x010

Bit position: 7 6 5 4 3 2 1 0

Bit field:	VREF EN	—	—	—	—	—	—	CPOE
------------	------------	---	---	---	---	---	---	------

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	CPOE	External Pin Output Enable Comparison result by the comparator is output to an external pin. 0: Output to the comparator external pin is disabled (the output signal is fixed to low) 1: Output to the comparator external pin is enabled	R/W
6:1	—	These bits are read as 0. The write value should be 0.	R/W
7	VREFEN	Internal Vref Enable* ¹ 0: Disable internal Vref 1: Enable internal Vref	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. For ACMPHS modules 0 to 1, VREFEN exists only in ACMPHS0.CPIOC. When using the internal Vref in ACMPHS0 to ACMPHS1, set the VREFEN bit in ACMPHS0.CPIOC to 1. Bit [7] in ACMPHS1.CPIOC should be 0 regardless of whether or not the internal Vref is used.

43.2.6 CPINTCTL : Comparator Interrupt Control Register

Base address: ACMPHSn = 0x4023_6000 + 0x0100 × n (n = 0, 1)
ACMPHSn_NS = 0x5023_6000 + 0x0100 × n (n = 0, 1)

Offset address: 0x040

Bit position: 7 6 5 4 3 2 1 0

Bit field:	—	—	—	—	—	—	—	MSKE
------------	---	---	---	---	---	---	---	------

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	MSKE	Comparator Interrupt Periodic Mask Enable 0: Disable interrupt masking (Default) 1: Enable interrupt masking by GPT output signal selected by CPMSKCTL.MSKSEL[2:0]	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register controls the interrupt to ICU/ELC, while the event to POEG(Port Output Enable) is not controlled by this register.

43.2.7 CPMSKCTL : Comparator Interrupt Mask Control Register

Base address: $ACMPHSn = 0x4023_6000 + 0x0100 \times n$ ($n = 0, 1$)
 $ACMPHSn_NS = 0x5023_6000 + 0x0100 \times n$ ($n = 0, 1$)

Offset address: 0x044

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	MSKSEL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	MSKSEL[2:0]	Comparator Interrupt Periodic Mask Selection 0 0 0: Enable interrupt masking by GTIOC0A output signal 0 0 1: Enable interrupt masking by GTIOC1A output signal 0 1 0: Enable interrupt masking by GTIOC2A output signal 0 1 1: Enable interrupt masking by GTIOC3A output signal 1 0 0: Enable interrupt masking by GTIOC4A output signal 1 0 1: Enable interrupt masking by GTIOC5A output signal Others: Setting prohibited.	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

This register controls the interrupt to ICU/ELC, while the event to POEG(Port Output Enable) is not controlled by this register.

43.3 Operation

The ACMPHS compares a reference voltage to an analog input voltage. Operation is not guaranteed when the values of registers are changed during ACMPHS operation. Table 43.3 shows the procedures for setting the registers associated with ACMPHS.

Table 43.3 Procedure for setting registers associated with ACMPHSn (n = 0, 1) (1 of 2)

Step	Register	Bit	Setting
1	Associated MSTPCRD register	MSTPD28 to MSTPD27	0: Input clock supply.
2	Associated pin function control register (PFS)	ASEL	1: Select the function of pins IVREF and IVCMP.
3	ACMPHSn.CPIOC	VREFEN	1: When using the internal Vref.
4	Associated D/A convertor		When using the D/A convertor, select in the register.
5	CMPSEL0, CMPSEL1	CMPSEL[3:0] CRVS[3:0]	Select the ACMPHSn input, with 1 set in only one of the bits.
6	CMPCTL	CDFS[1:0], CEG[1:0], and CINV	Set up ACMPHSn control.
		HCOMPON	1: Enable ACMPHSn operation.
7	CPMSKCTL	MSKCTL[2:0]	Select the interrupt mask source signal (from GPT)
8	CPINT	MSKE	1: Enable interrupt mask function if need
9	Waiting for the ACMPHS stabilization time (minimum 300 ns).		
10	CMPCTL	COE	1: Enable ACMPHSn output.
11	CPIOC	CPOE	Set the VCOUT output
	Associated pin function control register (PFS)	PSEL, PMR	Select the VCOUT port function.
12	IELSRn	IR, IELS[8:0]	When using an interrupt, select the interrupt status flag and the ICU event link.*1
13	ELSRn	ELS[8:0]	When using an ELC, select the event link*2.
14	Operation started		

Table 43.3 Procedure for setting registers associated with ACMPHSn (n = 0, 1) (2 of 2)

Step	Register	Bit	Setting
15	CMPCTL	COE	0: When changing IVREF or IVCMP, to disable ACMPHSn output.
16	CMPSEL1	CRVS[3:0]	Change the CMPSEL1 bits as follows: 1. Set bits CMPSEL1 to 0000 0000b. 2. Set a new value to the CMPSEL1 bits, with 1 set in only one of the bits.
	CMPSEL0	CMPSEL[3:0]	Change the CMPSEL0 bits as follows: 1. Set bits CMPSEL0 to 0000 0000b. 2. Set a new value to the CMPSEL0 bits, with 1 set in only one of the bits.
17	Waiting for the ACMPHS switching stabilization time (minimum 200 ns).		
18	CMPCTL	COE	1: Enable ACMPHSn output.
19	Operation restarted		

Note 1. After ACMPHSn is set, an unnecessary interrupt might occur until operation becomes stable, so initialize the interrupt flag.

Note 2. After ACMPHSn is set, an unnecessary interrupt might occur until operation becomes stable, so initialize the event link select.

Figure 43.2 and Figure 43.3 show an example of ACMPHS operation. The VCOUT output becomes 1 when the analog input voltage is higher than the ACMPHS reference input voltage, and the VCOUT output becomes 0 when the analog input voltage is lower than the reference voltage. When the ACMPHS output changes, an interrupt request and an ELC event are output.

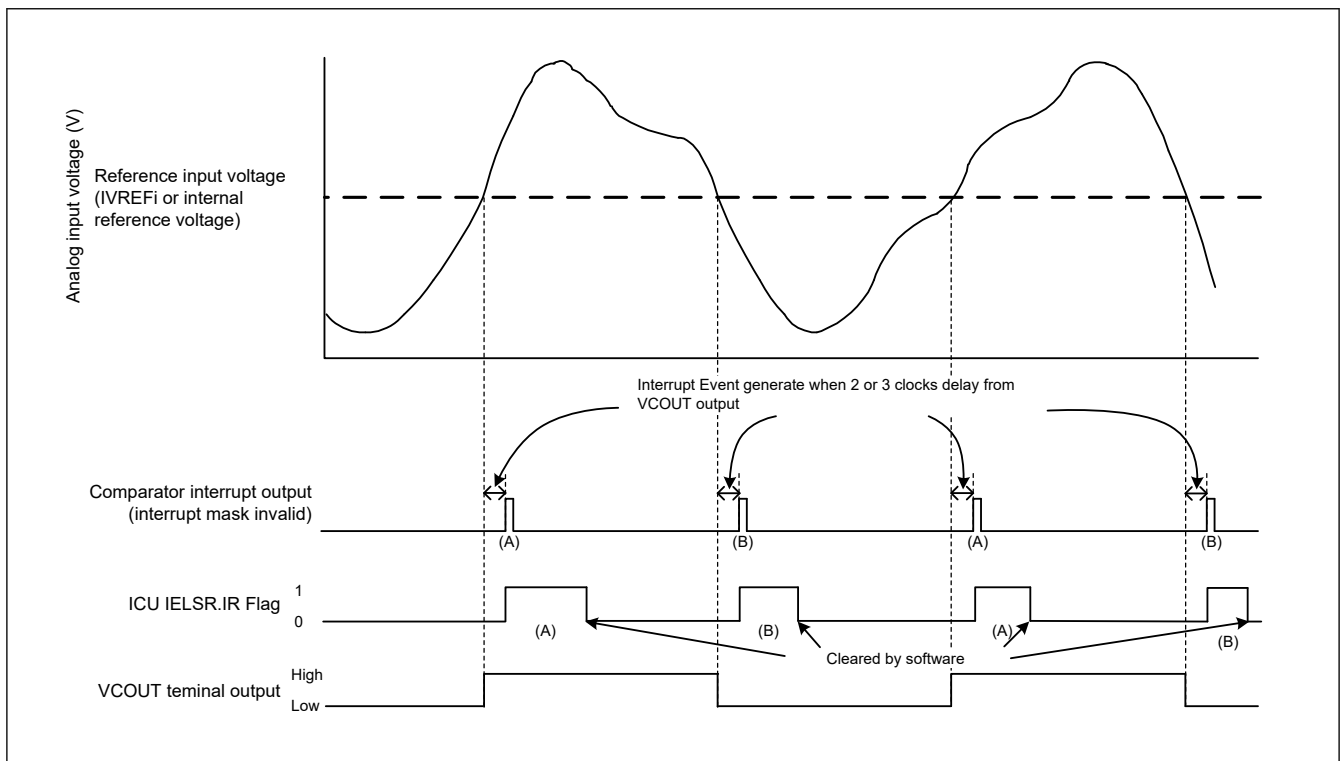

Figure 43.2 ACMPHS operation example (interrupt mask function invalid)

Figure 43.2 applies when CPOE = 1 (pin output enabled), CDFS[1:0] = 00b (filter not used), and CEG[1:0] = 11b (both-edge detection selected). When CINV = 0, CEG[1:0] = 01b (rising-edge detection selected for non-inversion output signal from the ACMPHS), the IELSR.IR flag changes as shown by (A) only. When CINV = 0, CEG[1:0] = 10b (falling-edge detection selected for non-inversion output signal from the ACMPHS), the IR flag changes as shown by (B) only. When CPOE = 1, VCOUT directly outputs.

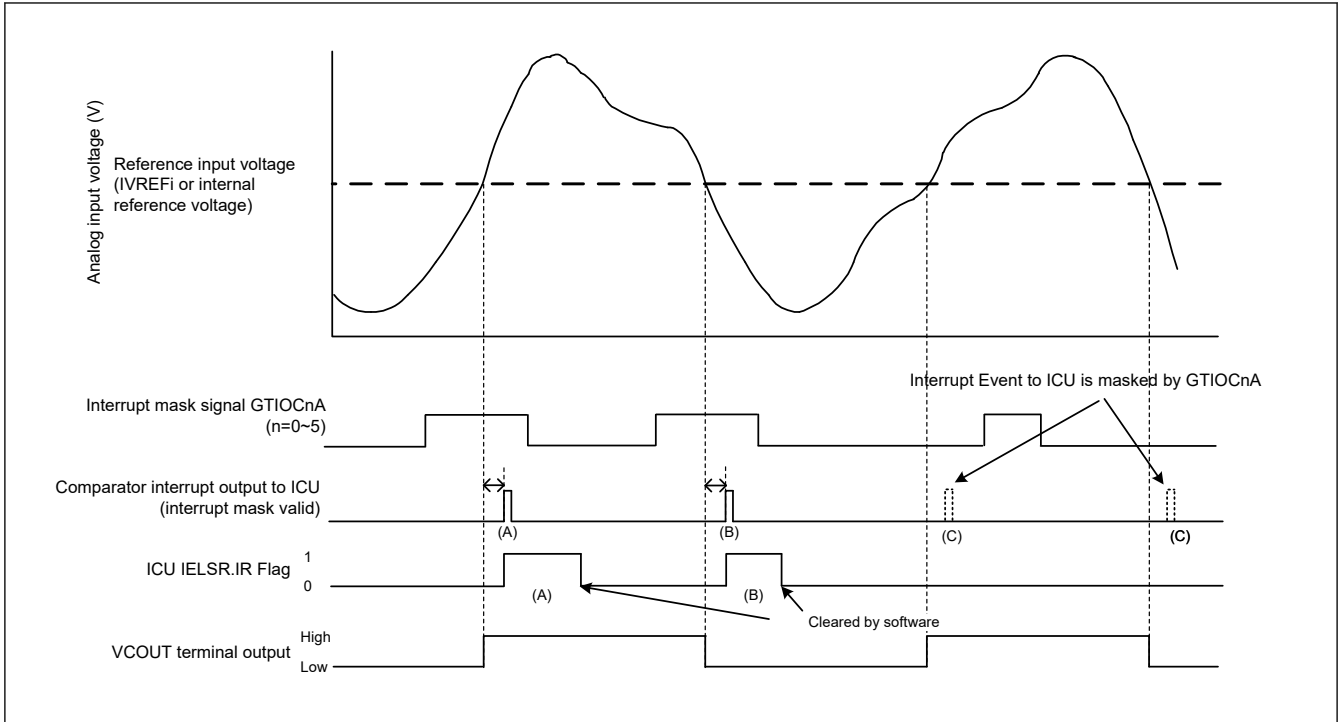

Figure 43.3 ACMPHS operation example (interrupt mask function valid)

Figure 43.3 applies when CPOE = 1 (pin output enabled), CDFS[1:0] = 00b (filter not used), CEG[1:0] = 11b (both-edge detection selected). When CINV = 0, CEG[1:0] = 01b (rising-edge detection selected for non-inversion output signal from the ACMPHS), the IELSR.IR flag changes as shown by (A) only. When CINV = 0, CEG[1:0] = 10b (falling-edge detection selected for non-inversion output signal from the ACMPHS), the IR flag changes as shown by (B) only.

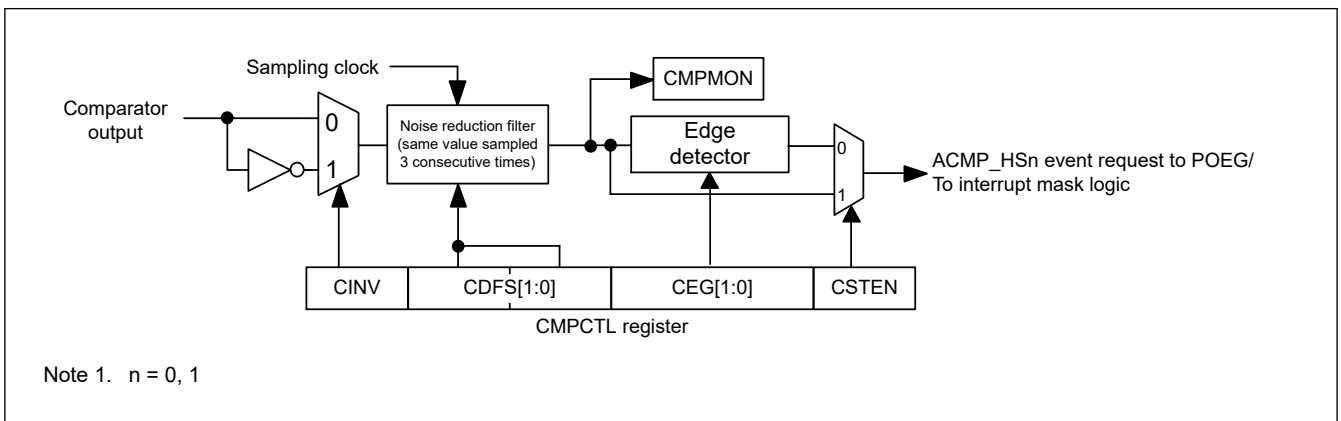

When MSKE = 1 and MSKSEL[2:0] = 000b, the interrupt signal output to ICU is masked by GTIOC0A when GTIOC0A = low level as shown by (C), while it passes through when GTIOC0A = high level.

When CPOE = 1, VCOOUT directly outputs, regardless of the MSKE setting.

43.4 Noise Filter

The ACMPHS contains a noise filter. The sampling clock can be selected in the CMPCTL.CDFS[1:0] bits. The comparator output signal is sampled every sampling clock, and if the same value is sampled three times, the noise filter output at the next sampling clock cycle is used as the ACMPHS output.

Figure 43.4 shows the configuration of the noise filter and edge detector, and Figure 43.5 shows an example of noise filter and interrupt operation.

Note 1. n = 0, 1

Figure 43.4 Noise filter and edge detection configuration

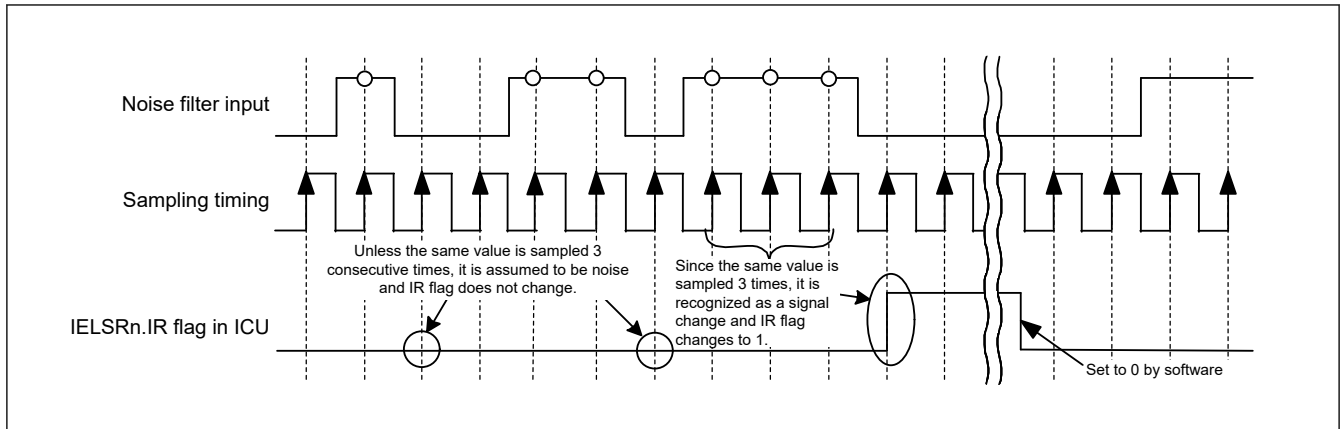

Figure 43.5 Noise filter and interrupt operation example

The operation example in [Figure 43.5](#) applies when the `CMPCTL.CDFS[1:0]` bits are 01b, 10b, or 11b (noise filter used).

43.5 ACMPHS Interrupts

The ACMPHS generates two interrupt requests from sources `ACMPHSn` ($n = 0, 1$). To use an ACMPHS interrupt, select it in the `IELSR` register in the Interrupt Controller Unit (ICU). Select the interrupt request in the `CMPCTL.CSTEN` bit either through the edge selector, or not.

Interrupt event to ICU/ELC can be masked by GPT output (`GTIOCnA` ($n = 0$ to 5)), it's controlled by `CPINTCTL.MSKE` bit and `CPMSKCTL.MSKSEL[2:0]` bits. Detail refer to [Figure 43.3](#).

Event to POEG can't be masked by GPT output (`GTIOCnA` ($n = 0$ to 5)), it's not controlled by `CPINTCTL.MSKE` bit and `CPMSKCTL.MSKSEL[2:0]` bits.

When using the ACMPHS interrupt through the edge selector, set at least one of the `CMPCTL.CEG[1:0]` bits to 1 (to a value other than 00b for no edge selection). Set the `CMPCTL.CSTEN` bit to 0 (output through the edge selector) in Normal mode, CPU Sleep mode, and CPU Deep Sleep mode.

To use the ACMPHS interrupt in Software Standby mode, set the `CMPCTL.CSTEN` bit to 1 (direct output), set the `CMPCTL.CDFS[1:0]` bit to 00b (digital noise filter not used), and set `CMPCTL.CINV` as follows:

- When detecting compare result 0 to 1, set `CMPCTL.CINV` to 0 (comparator output not inverted)
- When detecting compare result 1 to 0, set `CMPCTL.CINV` to 1 (comparator output inverted).

An `ACMPHS0` interrupt request can be used to release Software Standby mode. `ACMPHS1` cannot be used.

`ACMPHS0/ACMPHS1` both can not be used in Deep Software Standby mode.

For details on the register settings related to ACMPHS interrupt requests, see [section 43.2.1. `CMPCTL` : Comparator Control Register](#), [section 43.2.6. `CPINTCTL` : Comparator Interrupt Control Register](#) and [section 43.2.7. `CPMSKCTL` : Comparator Interrupt Mask Control Register](#).

43.6 ACMPHS Output to the Event Link Controller (ELC)

The ELC uses the ACMPHS interrupt request signal as an ELC event signal, enabling link operation for the preset module. To use the ACMPHS ELC event, select them in the `ELSR` register in the ELC. When using the ELC event request, set the `CMPCTL.CSTEN` bit to 0 (output through the edge selector). Also set at least one of the `CMPCTL.CEG[1:0]` bits to 1 (to a value other than 00b for no edge selection).

Interrupt event to ELC can be masked by GPT output (`GTIOCnA` ($n = 0$ to 5)), it's controlled by `CPINTCTL.MSKE` bit and `CPMSKCTL.MSKSEL[2:0]` bits.

43.7 ACMPHS Pin Output

The comparison result from the ACMPHS can be output to external pins. Use the `CMPCTL.CINV` and `CPIOC.CPOE` bits to set the output polarity (non-inverted or inverted output) and enable or disable output. To output the ACMPHS comparison result to the `VCOUT` output pin, set the associated port `mn` pin function control register (`PmnPFS`) in the I/O register.

Only when the security attribution of Port and ACMPHS match, the ACMPHS comparison result is output to the VCOUT pin as shown in the [Table 43.4](#).

Table 43.4 The output condition of VCOUT pin by the security setting

PORT Security Attribution (PmSAR (m = 0 to 9, A, B))	ACMPHS0 Security Attribution PSARD	ACMPHS1 Security Attribution PSARD	VCOUT pin output
0 (secure)	0 (secure)	0 (secure)	both ACMPHS0/1 output enable
1 (non-secure)	0 (secure)	0 (secure)	both ACMPHS0/1 output disable
0 (secure)	0 (secure)	1 (non-secure)	ACMPHS0_VCOUT output enable ACMPHS1_VCOUT output disable
1 (non-secure)	0 (secure)	1 (non-secure)	ACMPHS0_VCOUT output disable ACMPHS1_VCOUT output enable
0 (secure)	1 (non-secure)	0 (secure)	ACMPHS0_VCOUT output disable ACMPHS1_VCOUT output enable
1 (non-secure)	1 (non-secure)	0 (secure)	ACMPHS0_VCOUT output enable ACMPHS1_VCOUT output disable
0 (secure)	1 (non-secure)	1 (non-secure)	both ACMPHS0/1 output disable
1 (non-secure)	1 (non-secure)	1 (non-secure)	both ACMPHS0/1 output enable

43.8 Usage Notes

43.8.1 Settings for the Module-Stop Function

ACMPHS operation can be disabled or enabled using the Module Stop Control Register. The ACMPHS is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

43.8.2 Settings for the DAC12

ACMPHS is connected to the internal module output of the D/A converter. For details, see [section 41, 12-Bit D/A Converter \(DAC12\)](#).

43.8.3 Relationship with the ADC12

Constraints apply on the simultaneous use of ACMPHS analog input and ADC12 analog input. For details, see [section 40.6.14, Relationship between ADC12 Units 0 and 1 and the ACMPHS](#).

43.8.4 ACMPHS Operation in Module-Stop State

When the module-stop state is entered while ACMPHS is operating, analog circuits in the ACMPHS are not stopped and the analog power supply current is the same as that when ACMPHS is being used. If the analog power supply current needs to be reduced in the module-stop state, set the CMPCTL.HCMPON bit to 0 to stop the ACMPHS.

43.8.5 ACMPHS Operation in Software Standby Mode

When Software Standby mode is entered while ACMPHS is operating, analog circuits in the ACMPHS are not stopped and the analog power supply current is the same as that when ACMPHS is being used. If the analog power supply current needs to be reduced in Software Standby mode, set the CMPCTL.HCMPON bit to 0 to stop the ACMPHS.

43.8.6 Setting the D/A Converter for Generating Reference Voltage

Set the D/A converter to generate reference voltage and wait for the D/A converter output settling time before enabling the comparator. Similarly, before making any changes to the settings of the D/A converter, stop the comparator temporarily. After the changes are made, wait for the D/A converter output settling time before enabling the comparator.

44. Data Operation Circuit (DOC)

This is the DOC_B version of the DOC peripheral module.

DOC_B is referred to as DOC in this chapter.

44.1 Overview

The data operation circuit (DOC) is used to compare, add, and subtract 16 or 32-bit data. An interrupt can be generated when the following conditions apply.

- When the 16 or 32-bit compared values match the detection condition
- When the result of 16 or 32-bit data addition overflows
- When the result of 16 or 32-bit data subtraction underflows

Table 44.1 lists the data operation circuit specifications and Figure 44.1 shows a block diagram of the data operation circuit.

Table 44.1 DOC specifications

Item	Description
Data operation function	<ul style="list-style-type: none"> • 16 or 32-bit data comparison, comparison to detect data above or below thresholds, and window comparison • 16 or 32-bit data addition, and subtraction
Module-stop function	The module-stop state can be set to reduce power consumption.
Interrupts	<ul style="list-style-type: none"> • The compared values match the detection condition • The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1) • The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)
Event link function (output)	<ul style="list-style-type: none"> • The result of data comparison is consistent with detection condition • The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1) • The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)
TrustZone Filter	Security and Privilege attribution can be set

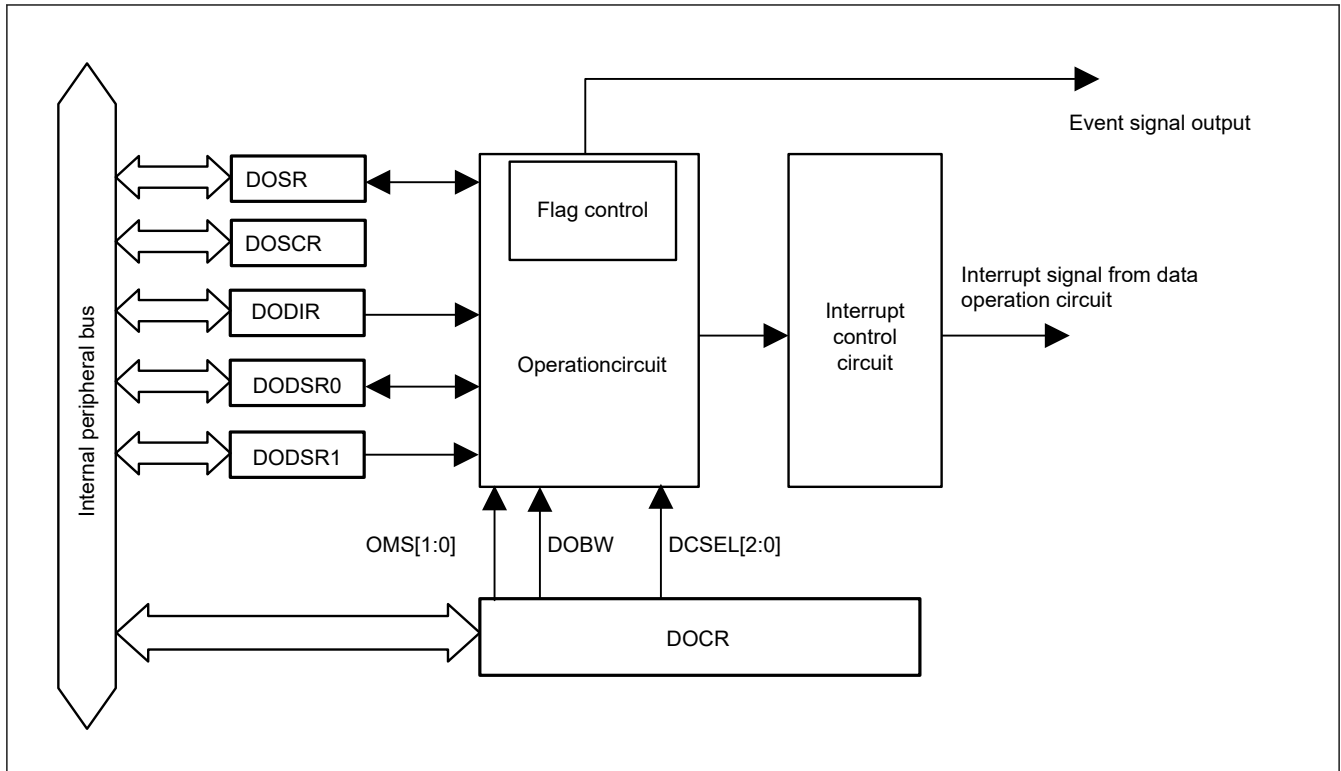

Figure 44.1 DOC block diagram

44.2 DOC Register Descriptions

44.2.1 DOCR : DOC Control Register

Base address: DOC_B = 0x4031_1000
 DOC_B_NS = 0x5031_1000

Offset address: 0x00

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	DCSEL[2:0]		DOBW	—	OMS[1:0]		

Value after reset: 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
1:0	OMS[1:0]	Operating Mode Select 0 0: Data comparison mode 0 1: Data addition mode 1 0: Data subtraction mode 1 1: Setting prohibited	R/W
2	—	This bit is read as 0. The write value should be 0.	R/W
3	DOBW	Data Operation Bit Width Select 0: 16-bit 1: 32-bit	R/W
6:4	DCSEL[2:0] ¹	Detection Condition Select 0 0 0: Mismatch (DODSR0 ≠ DODIR) 0 0 1: Match (DODSR0 = DODIR) 0 1 0: Lower (DODSR0 > DODIR) 0 1 1: Upper (DODSR0 < DODIR) 1 0 0: Inside window (DODSR0 < DODIR < DODSR1) 1 0 1: Outside window (DODIR < DODSR0, DODSR1 < DODIR) Others: Setting prohibited	R/W

Bit	Symbol	Function	R/W
7	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE3, P-TYPE3

Note 1. Valid only when data comparison mode is selected.

The DOCR is a register which can set the operation mode of data operation circuit and interrupt enable/disable.

OMS[1:0] bits (Operating Mode Select)

These bits select the operating mode of the data operation circuit.

DOBW bit (Data Operation Bit Width Select)

This bit selects the bit width of data operation.

DCSEL[2:0] bits (Detection Condition Select)

These bits are valid only when data comparison mode is selected.

These bits select the condition for detection in data comparison mode.

44.2.2 DOSR : DOC Flag Status Register

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x04

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	DOPCF

Value after reset: 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	DOPCF	Data Operation Circuit Flag Indicates the result of an operation.	R
7:1	—	These bits are read as 0.	R

Note: S-TYPE3, P-TYPE3

The DOSR register indicates the status of the data operation.

DOPCF flag (Data Operation Circuit Flag)

[Setting conditions]

- DOCR.OMS[1:0] bits = 00b (Data comparison mode): The compared value matches the detection condition selected by DOCR.DCSEL[2:0] bits
- DOCR.OMS[1:0] bits = 01b (Data addition mode): The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1)
- DOCR.OMS[1:0] bits = 10b (Data subtraction mode): The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)

[Clearing condition]

- Writing 1 to the DOSCR.DOPCFCL bit

44.2.3 DOSCR : DOC Flag Status Clear Register

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	DOPC FCL

Value after reset: 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	DOPCFCL	DOPCF Clear 0: Maintains the DOPCF flag state. 1: Clears the DOPCF flag.	W
7:1	—	The write value should be 0.	W

Note: S-TYPE3, P-TYPE3

The DOSCR is a register which can clear the status of data operation. This register is read as 0x00.

DOPCFCL bit (DOPCF Clear)

Setting this bit to 1 clears the DOPCF flag.

44.2.4 DODIR : DOC Data Input Register

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x0C

Bit position:	31	0
---------------	----	---

Bit field:	
------------	--

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	n/a	It stores data used in the operations. Access the DODIR with the bit width of data operation selected by the DOCR.DOBW bit.	R/W

Note: S-TYPE3, P-TYPE3

44.2.5 DODSR0 : DOC Data Setting Register 0

Base address: DOC_B = 0x4031_1000
DOC_B_NS = 0x5031_1000

Offset address: 0x10

Bit position:	31	0
---------------	----	---

Bit field:	
------------	--

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	n/a	Access the DODSR0 with the bit width of data operation selected by the DOCR.DOBW bit. This register stores data for use as a reference in data comparison mode. When selecting window comparison (DOCR.DCSEL[2:0] = 100b, 101b), set a value less than DODSR1 (DODSR1 > DODSR0). This register also stores the results of operations in data addition and data subtraction modes.	R/W

Note: S-TYPE3, P-TYPE3

44.2.6 DODSR1 : DOC Data Setting Register 1

Base address: DOC_B = 0x4031_1000
 DOC_B_NS = 0x5031_1000

Offset address: 0x14

Bit position: 31

0

Bit field:

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	n/a	Access the DODSR1 with the bit width of data operation selected by the DOCR.DOBW bit. This register stores data for use as a reference in data comparison mode. When selecting window comparison (DOCR.DCSEL[2:0] = 100b, 101b), set a value greater than DODSR0 (DODSR1 > DODSR0). This register is only used for window comparisons.	R/W

Note: S-TYPE3, P-TYPE3

44.3 Operation

44.3.1 Data Comparison Mode

Figure 44.2 to Figure 44.7 shows an example of the steps involved in data comparison mode operation by the data operation circuit.

The following is an example of operation when the bit width of data operation is 32-bit.

1. Writing 00b to the DOCR.OMS[1:0] bits selects data comparison mode, and setting the DOCR.DCSEL[2:0] to selects detection condition.
2. The 32-bit reference data is set in DODSR0 and DODSR1.*¹
3. 32-bit data for comparison is written to DODIR.
4. If a value written to DODIR match the detection condition set by DOCR.DCSEL[2:0], the DOCR.DOPCF flag is set to 1 and an ELC event and a data operation circuit interrupt are generated.

Note: The comparison operation is executed only by writing to the DODIR

Note 1. The DODSR1 register setting is required only when window comparison is selected. Set a value greater than DODSR0 (DODSR1 > DODSR0).

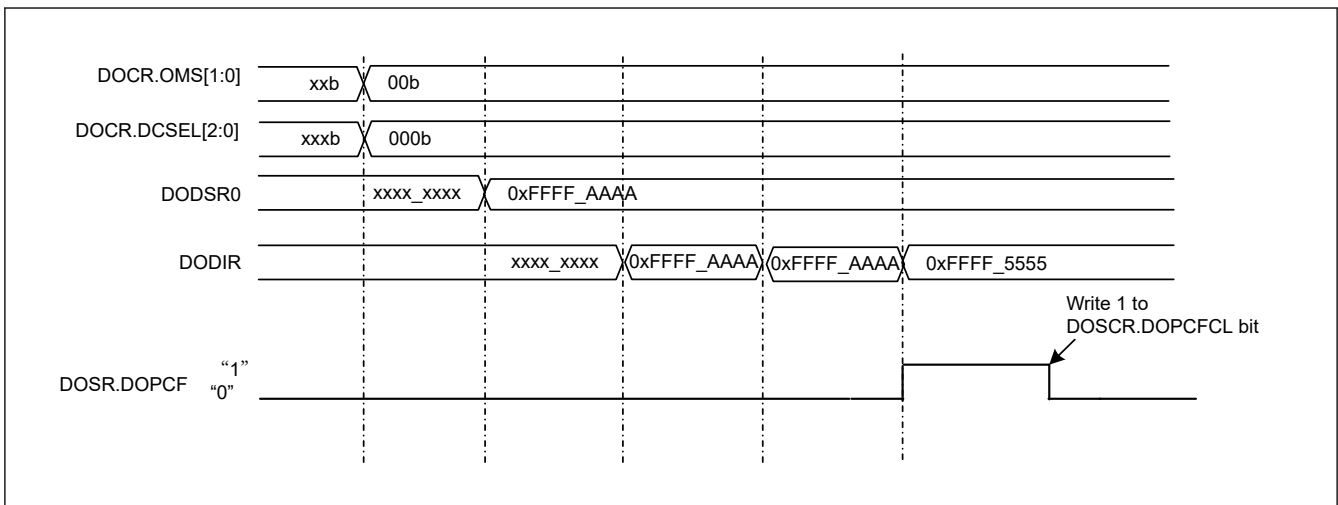

Figure 44.2 Example of Operation in Data Comparison Mode (Detection condition: Mismatch)

Figure 44.3 Example of Operation in Data Comparison Mode (Detection condition: Match)

Figure 44.4 Example of Operation in Data Comparison Mode (Detection condition: Lower)

Figure 44.5 Example of Operation in Data Comparison Mode (Detection condition: Upper)

Figure 44.6 Example of Operation in Data Comparison Mode (Detection condition: Inside window)

Figure 44.7 Example of Operation in Data Comparison Mode (Detection condition: Outside window)

44.3.2 Data Addition Mode

Figure 44.8 shows an example of the steps involved in data addition mode ^{*1} operation by the data operation circuit.

The following is an example of operation when the bit width of data operation is 32-bit.

1. Writing 01b to the DOCR.OMS[1:0] bits selects data addition mode.
2. 32-bit data is set in the DODSR0 register as the initial value.
3. 32-bit data to be added is written to DODIR. The result of the operation is stored in DODSR0.
4. Writing of 32-bit data continues until all data for addition have been written to DODIR.
5. If the result of an operation is greater than 0xFFFF_FFFF, the DOSR.DOPCF flag is set to 1 and an ELC event and a data operation circuit interrupt are generated.

Note 1. Addition is executed only by writing to the DODIR.

Figure 44.8 Example of Operation in Data Addition Mode

44.3.3 Data Subtraction Mode

Figure 44.9 shows an example of the steps involved in data subtraction mode ^{*1} operation by the data operation circuit.

The following is an example of operation when the bit width of data operation is 32-bit.

1. Writing 10b to the DOCR.OMS[1:0] bits selects data subtraction mode.
2. 32-bit data is set in the DODSR0 register as the initial value.
3. 32-bit data to be subtracted is written to DODIR. The result of the operation is stored in DODSR0.
4. Writing of 32-bit data continues until all data for subtraction have been written to DODIR.
5. If the result of an operation is less than 0x0000_0000, the DOSR.DOPCF flag is set to 1 and an ELC event and a data operation circuit interrupt are generated.

Note 1. Subtraction is executed only by writing to the DODIR.

Figure 44.9 Example of Operation in Data Subtraction Mode

44.4 Interrupt Source

The data operation circuit generates the data operation circuit interrupt (DOC_DOPCI) as an interrupt request. When an interrupt source is generated, the data operation circuit flag corresponding to the interrupt is set to 1, and then interrupt request signal is generated. Table 44.2 describes the interrupt request.

Table 44.2 Interrupt request from DOC

Interrupt request	Status flag	Interrupt source
DOC interrupt	DOPCF	<ul style="list-style-type: none"> The compared values match the detection condition. The result of data addition is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1). The result of data subtraction is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1).

44.5 Event Link Output

The DOC outputs event signals for the event link controller (ELC) under the following conditions, and these can be used to initiate operations by other modules selected in advance.

- The compared values match the detection condition
- The data addition result is greater than 0xFFFF (DOCR.DOBW = 0) or 0xFFFF_FFFF (DOCR.DOBW = 1)
- The data subtraction result is less than 0x0000 (DOCR.DOBW = 0) or 0x0000_0000 (DOCR.DOBW = 1)

44.6 Interrupt Handling and Event Linking

The DOC has a bit to enable or disable interrupts. An interrupt request signal is output for the CPU when an interrupt source is generated while the corresponding enable bit is enabled.

In contrast, an event link output signal is sent to other modules as an event signal via the ELC when an interrupt source is generated, regardless of the setting of the corresponding interrupt enable bit.

44.7 Usage Notes

44.7.1 Settings for the Module-Stop State

The module Stop Control Register C (MSTPCRC) can enable or disable DOC operation. The DOC is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

45. SRAM

45.1 Overview

The MCU provides an on-chip, high-density SRAM module with parity-bit checking. SRAM0 is the Non-parity. SRAM1 is Parity check.

Table 45.1 lists the SRAM specifications.

Table 45.1 SRAM specifications

Parameter	SRAM0	SRAM1
SRAM capacity	128 KB	512 KB
SRAM address	0x2204_0000 to 0x2205_FFFF (Secure alias), 0x3204_0000 to 0x3205_FFFF (Non-secure alias)	0x2206_0000 to 0x220D_FFFF (Secure alias), 0x3206_0000 to 0x320D_FFFF (Non-secure alias)
Access	Wait states are inserted into the read cycle by default. If the ICLK frequency is higher than 120 MHz, a wait state is required. If the ICLK frequency is 120 MHz or less, a wait state is not required.	
Data retention function	Not available in Deep Software Standby mode	
Module-stop function	Module-stop state can be set to reduce power consumption	
Error checking	No error checking	Even-parity (Data: 8 bits, Parity: 1 bit)
Security	TrustZone Filter is integrated for memory access and SFR access. Access to the memory space is controlled by setting the memory Security Attribution (SA). And access to I/O space (SFR) space is controlled by setting the register SA. See section 45.3.3. TrustZone Filter function .	

45.2 Register Descriptions

45.2.1 SRAMSABARn : SRAM Error Address Register (n = 0 to 2)

Base address: CPSCU = 0x4000_8000
CPSCU_NS = 0x5000_8000

Offset address: 0x400 + 0x04 × n

Bit position: 31

0

Bit field:

n/a

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 1 1 1 1 1 1 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	n/a	Boundary address between Secure and Non-secure. (Start address of Non-secure region)	R/W

Note: S-TYPE-1, P-TYPE-1

Note: This register is write-protected by PRCR_S.PRC4 register.

SRAMSABARn specifies the boundary address between the Secure and Non-secure regions of each SRAM. Write the absolute address to the SRAMSABARn. When writing to SRAMSABARn, writing from b31 to b21 is ignored and the value written from b12 to b0 should be 0.

The region lower than the boundary address is marked as Secure, and higher than or equal to the boundary address is marked as Non-secure.

The boundary address is as follow.

0x2200_0000 + SRAMSABARn (Secure alias)

0x3200_0000 + SRAMSABARn (Non-secure alias)

For SRAMSABAR0

When the boundary address is 0x00040000, whole SRAM0 is marked as Non-secure.

When the boundary address is 0x00060000 or large, whole SRAM0 is marked as Secure.

For SRAMSABAR1

When the boundary address is 0x00060000 or less, whole SRAM1 is marked as Non-secure.

When the boundary address is 0x000E0000 or large, whole SRAM1 is marked as Secure.

45.2.2 SRAMSAR : SRAM Security Attribution Register

Base address: CPSCU = 0x4000_8000
CPSCU_NS = 0x5000_8000

Offset address: 0x10

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	SRAM WTSA	STBR AMSA	—	—	—	—	—	SRAM SA1	SRAM SA0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	SRAMSA0	SRAM0 Register Security Attribution 0: Secure 1: Non-secure	R/W
1	SRAMSA1	SRAM1 Register Security Attribution 0: Secure 1: Non-secure	R/W
6:2	—	These bits are read as 0. The write value should be 0.	R/W
7	STBRAMSA	Standby SRAM Register Security Attribution 0: Secure 1: Non-secure	R/W
8	SRAMWTSA	SRAMWTSC Security Attribution 0: Secure 1: Non-secure	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-1, P-TYPE-1

Note: Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed but Non-secure write access is not allowed and TrustZone access error is not generated.

Note: This register is write-protected by PRCR_S.PRC4 register.

SRAMSA0 bit (SRAM0 Register Security Attribution)

The SRAMSA0 bit specifies security attributes of SRAMCR0, SRAMECCRG0, SRAMESCLR.CLR00, and SRAMESCLR.CLR01.

SRAMSA1 bit (SRAM1 Register Security Attribution)

The SRAMSA1 bit specifies security attributes of SRAMCR1 and SRAMESCLR.CLR1.

STBRAMSA bit (Standby SRAM Register Security Attribution)

The STBRAMSA bit specifies security attributes of STBRAMCR and SRAMESCLR.CLR5.

SRAMWTSA bit (SRAMWTSC Security Attribution)

The SRAMWTSA bit specifies security attributes of SRAMWTSC.

45.2.3 SRAMPRCR_S : SRAM Protection Control Register for Secure

Base address: SRAM = 0x4000_2000

Offset address: 0x00

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KW[7:0]								—	—	—	—	—	—	—	PR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PR	Register Write Control 0: Writing to registers are disabled 1: Writing to registers are enabled	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KW[7:0]	Write Key Code Key code protection to the PR bit	R/W

Note: S-TYPE-6, P-TYPE-2

Note: It is necessary to write by half word access.

Byte write access is prohibited. When byte write access is executed, operation is not guaranteed.

PR bit (Register Write Control)

The PR bit controls the write mode of the SRAMWTSC, SRAMCR1, and STBRAMCR registers that are marked as Secure by SRAMSAR register. When this bit is set to 1, writing to the SRAMWTSC, SRAMCR1, and STBRAMCR marked as Secure is enabled.

While writing to this register it is necessary to write 0xA5 to the KW[7:0] bits simultaneously.

KW[7:0] bits (Write Key Code)

The KW[7:0] bits enable or disable writing to the PR bit. When you write to the PR bit, write 0xA5 to the KW[7:0] bits simultaneously. When a value other than 0xA5 is written to KW[7:0], the PR bit is not updated. The KW[7:0] bits are always read as 0x00.

45.2.4 SRAMPRCR_NS : SRAM Protection Control Register for Non-secure

Base address: SRAM_NS = 0x5000_2000

Offset address: 0x04

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KW[7:0]								—	—	—	—	—	—	—	PR
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PR	Register Write Control 0: Writing to registers are disabled 1: Writing to registers are enabled	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KW[7:0]	Write Key Code Key code protection to the PR bit	R/W

Note: S-TYPE-7, P-TYPE-2

Note: It is necessary to write by half word access.

Byte write access is prohibited. When byte write access is executed, operation is not guaranteed.

PR bit (Register Write Control)

The PR bit controls the write mode of the SRAMWTSC, SRAMCR1, and STBRAMCR registers that are marked as Non-secure by SRAMSAR register. When this bit is set to 1, writing to the SRAMWTSC, SRAMCR1, and STBRAMCR marked as Non-secure is enabled.

While writing to this register it is necessary to write 0xA5 to the KW[7:0] bits simultaneously.

KW[7:0] bits (Write Key Code)

The KW[7:0] bits enable or disable writing to the PR bit. When you write to the PR bit, write 0xA5 to the KW[7:0] bits simultaneously. When a value other than 0xA5 is written to KW[7:0], the PR bit is not updated. The KW[7:0] bits are always read as 0x00.

45.2.5 SRAMWTSC : SRAM Wait State Control Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x08

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	WTEN
Value after reset:	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
0	WTEN	SRAM Wait Enable 0: No wait 1: Add wait state in read access cycle to SRAMs	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3 (SRAMSAR.SRAMWTSA), P-TYPE-2

This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

WTEN bit (SRAM Wait Enable)

The WTEN bit sets the wait cycle insertion to the access cycle of SRAM. When 1 is set to the WTEN bit, 1 wait cycle is inserted to the read access cycle of SRAM. Also when the WTEN bit is 1, the access to the same region^{*1} and the same mat^{*2} is continuous and 1 wait cycle is inserted to the second access cycle. When the access frequency is more than 120 MHz, it is necessary to set 1 wait cycle to the WTEN bit.

Note 1. The region of SRAM is divided into 128 KB units.

Note 2. The mat is divided into 0x0 to 0x7 and 0x8 to 0xF in the lower 4 bits of the address.

For example, the same region and the same mat is 2 areas of SRAM0, and 8 areas of SRAM1 in the figure below. If 1 area is accessed continuously, 1 wait cycle is inserted. If ECC function is enabled or bypass is enabled, ECC region is accessed, and so if access to the same mat continues, 1 wait cycle is inserted.

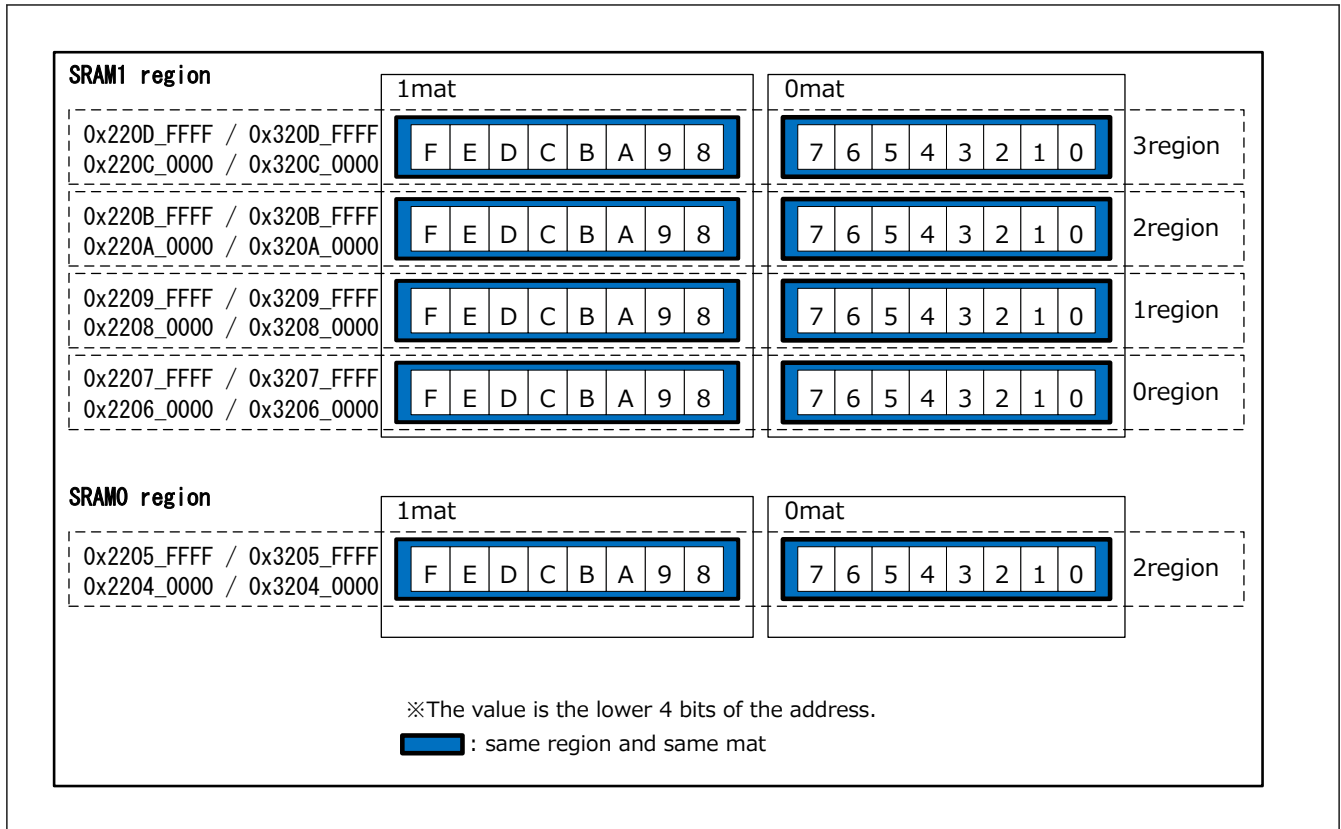

Figure 45.1 Mat configuration of each SRAM

45.2.6 SRAMCR1 : SRAM Control Register 1

Base address: SRAM = 0x4000_2000
 SRAM_NS = 0x5000_2000

Offset address: 0x14

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	OAD

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	OAD	Operation after Detection for Parity Error Detection 0: Non-maskable interrupt 1: Reset.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3 (SRAMSAR.SRAMSA1), P-TYPE-2

This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

Do not write to this register while access to SRAM is in progress. See [section 45.4.2. Note of write to SRAMCR1 register](#) for writing to this register.

OAD bit (Operation after Detection for Parity Error Detection)

The OAD bit selects a reset or non-maskable interrupt when a parity error is detected.

45.2.7 SRAMESR : SRAM Error Status Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x40

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	ERRS	—	—	—	—	—	—	—	—	—	—	—	ERR1	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	—	These bits are read as 0.	R
2	ERR1	SRAM1 Parity Error Status 0: Parity error has not occurred. 1: Parity error has occurred.	R
13:3	—	These bits are read as 0.	R
14	ERRS	Standby SRAM Parity Error status 0: Parity error has not occurred. 1: Parity error has occurred.	R
15	—	This bit is read as 0.	R

Note: S-TYPE-5, P-TYPE-2

This register is cleared by the corresponding bit in the SRAMESCLR register or resets other than Bus Error Reset and Memory Error Reset. If error and clear occur at the same time, clear has priority. Also updating register stops during accessing from debugger.

ERR1 bit (SRAM1 Parity Error Status)

The ERR1 bit shows whether there is a parity error or not in the SRAM1.

The ERR1 bit is set if a parity error is detected.

When the ERR1 bit is set to 1, a reset or non-maskable interrupt request is generated according to the SRAMCR1.OAD.

ERRS bit (Standby SRAM Parity Error status)

The ERRS bit shows whether there is a parity error or not in the Standby SRAM.

The ERRS bit is set to 1 if there is an error.

When the ERRS bit is set to 1, a reset or non-maskable interrupt request is generated according to the STBRAMCR.OAD.

45.2.8 SRAMESCLR : SRAM Error Status Clear Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x48

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	CLRS	—	—	—	—	—	—	—	—	—	—	—	—	CLR1	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	—	These bits are read as 0. The write value should be 0.	R/W ¹
2	CLR1	SRAM1 Parity Error Status Clear Writing to the CLR1 clears SRAMESR.ERR1. 1: Clear Parity error. Read value is always 0.	R/W ¹

Bit	Symbol	Function	R/W
13:3	—	These bits are read as 0. The write value should be 0.	R/W
14	CLRS	Standby SRAM Parity Error Status Clear Writing to the CLRS clears SRAMESR. ERRS. 1: Clear Parity error. Read value is always 0.	R/W ¹
15	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-4 (SRAMSAR.SRAMSAn, STBRAMSA), P-TYPE-2

Note 1. For each bit, only 1 can be written to clear the error status.

CLR1 bit (SRAM1 Parity Error Status Clear)

The CLR1 bit can clear the SRAM1 parity error status bit in the SRAMESR. If error and clear occur at the same time, clear has priority.

The SRAMESR.ERR1 bit can be cleared when writing 1 to CLR1.

CLRS bits (Standby SRAM Parity Error Status Clear)

The CLRS bits can clear the Standby SRAM Parity error bit in the SRAMESR. If error and clear occur at the same time, clear has priority.

The SRAMESR.ERRS bit can be cleared when writing 1 to CLRS.

45.2.9 SRAMEAR2 : SRAM Error Address Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x58

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	n/a	When an SRAM error occurs, it stores an error address.	R

Note: S-TYPE-5, P-TYPE-2

This register is cleared by the corresponding bit in the SRAMESCLR register or resets other than Bus Error Reset and Memory Error Reset. If error and clear occur at the same time, clear has priority. Also updating register stops during accessing from debugger.

The error address is as follow.

0x2200_0000 + SRAMEAR2 (Secure alias)

0x3200_0000 + SRAMEAR2 (Non-secure alias)

This register stores the error address where parity error is detected. These bits hold the error address that occurred first.

45.3 Operation

45.3.1 Module Stop Function

Power consumption can be reduced by setting module stop control register A (MSTPCRA) to stop supply of the clock signal to SRAM.

SRAMn (n = 0, 1) is controlled by MSTPAn (n = 0, 1) bit in MSTPCRA register and, in the case of 1, SRAMn becomes the clock stop state.

The SRAM is thus placed in the module-stop state by stopping supply of the clock signals. The SRAM operates after a reset.

SRAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to SRAM is in progress.

Access to the SRAM in the module-stop state is prohibited. If access is attempted, correct operation is not guaranteed.

For details on the MSTPCRA register, see [section 10, Low Power Modes](#).

45.3.2 Parity Calculation Function

The IEC60730 standard requires the checking of SRAM data. When data is written, a parity bit is added to every 8-bit data in the SRAM, and when data is read, the parity is checked. When a parity error occurs, a parity-error notification is generated. This function can also be used to trigger a reset.

The parity-error notification can be specified as a non-maskable interrupt or a reset in the OAD bit of the SRAMCR1 register. When the OAD bit is set to 1, a parity error is output to the reset function. When the OAD bit is set to 0, a parity error is output to the ICU as a non-maskable interrupt.

Parity Error often occurs due to noise. It is possible to confirm whether the parity error is caused by noise or destruction of data by following the parity operation flowchart. [Figure 45.2](#) and [Figure 45.3](#) shows flowcharts of SRAM parity check operation..

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, do not perform the read access in a row after the write access.

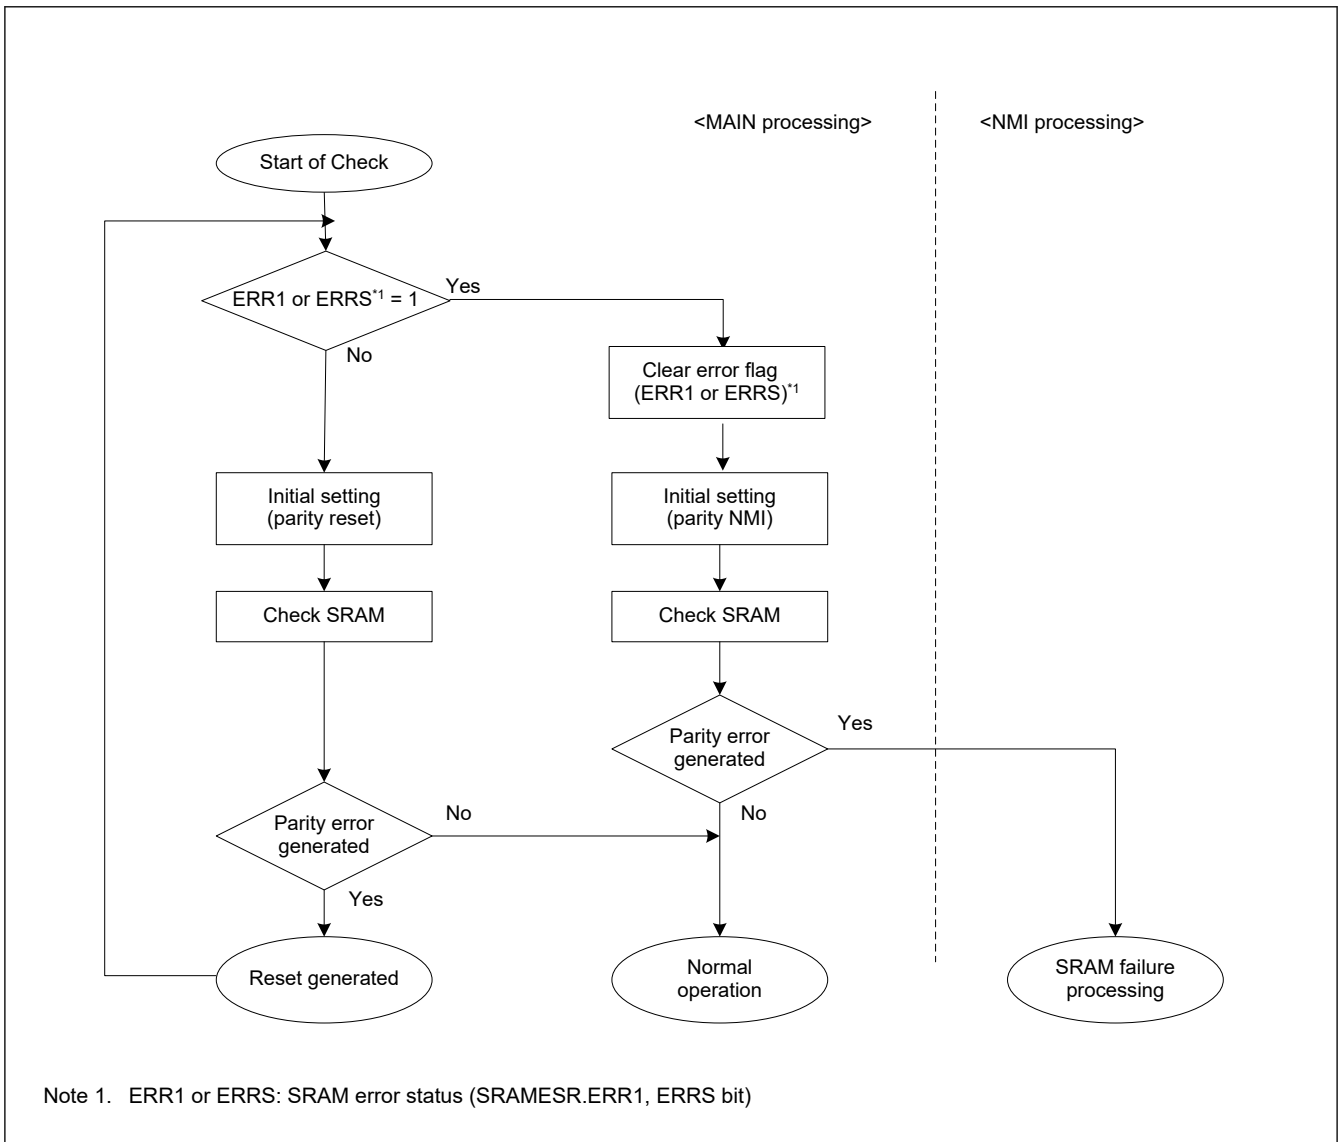

Figure 45.2 Flow of SRAM parity check when SRAM parity reset is enabled

Figure 45.3 Flow of SRAM parity check when SRAM parity interrupt is enabled

45.3.3 TrustZone Filter function

45.3.3.1 TrustZone Filter for SRAM Registers

SRAM registers can be protected with a Security Attribution (SA) from Non-secure or Secure transaction. When SA indicates that SRAM registers are Secure status, Non-secure transaction cannot access them because TrustZone Filter detects an error and protects the access. When SA indicates that SRAM registers are Non-secure status, Secure transaction cannot access them because Trust Zone Filter detects an error and protects the access. SA for SRAM registers is just one to be used commonly among SRAM registers.

In the case of a failed access due to TrustZone error, error response is generated.

Table 45.2 Register protection (1 of 2)

SA	Transaction	Write access	Read access
Secure	Secure	Permitted	Permitted
	Non-secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)

Table 45.2 Register protection (2 of 2)

SA	Transaction	Write access	Read access
Non-secure	Secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
	Non-secure	Permitted	Permitted

45.3.3.2 TrustZone Filter for SRAM Memory Regions

SRAM0, SRAM1 regions can be divided into Secure and Non-secure independently. The access permissions for these regions are as below.

Table 45.3 Memory protection

SA	Transaction	Write access	Read access
Secure	Secure	Permitted	Permit
	Non-secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
Non-secure	Secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
	Non-secure	Permitted	Permitted

TrustZone filter error for SRAM memory generates an error notification.

45.3.4 Interrupt Source

The SRAM interrupt source includes a Parity error and TrustZone filter error. Parity error can choose non-maskable interrupt or reset by SRAMCR1.OAD bit. The SRAM interrupt occurs when one error status in the SRAMESR register is set to 1, the SRAM interrupt continues to occur until the SRAMESR register flag is cleared. When Common memory error occur (NMISR.CMST=1 or RSTSR1.CMSR=1), please read SRAMESR and check SRAM interrupt source. When the access from debugger, the error is detected and corrected, but no error flag is set, reset and non-maskable interrupt are maskable. For details on the debug mode, see [section 2, CPU](#).

Table 45.4 SRAM Interrupt Source

Name	Interrupt Source	DTC Activation	DMAC Activation
PARITYERR	Parity error (SRAMs with parity)	Not possible	Not possible
TZFLT	TrustZone filter error	Not possible	Not possible

45.3.5 Wait state

When ICLK frequencies is higher than 120 MHz, do not set 0x00 in wait enable bit for the SRAMWTSC register, in order to insert a wait cycle. When the wait is not inserted, the operation is not guaranteed.

Depending on the operating frequency of ICLK, the WAIT setting for SRAM access has the following conditions.

[ICLK frequency]:

- 240 MHz ≥ ICLK > 120 MHz = 1 wait
- 120 MHz ≥ ICLK = No-wait

45.4 Usage Note

45.4.1 Instruction fetch from SRAM area

When using SRAM to operate a program, initialize the SRAM area so that the CPU can correctly prefetch data. A parity error might occur if the CPU prefetches from an area that is not initialized. Initialize the additional 12-byte area from the end address of the program with the 8-byte boundary. Renesas recommends using the NOP instruction for data initialization.

45.4.2 Note of write to SRAMCR1 register

This chapter provides examples of how to configure SRAMCR1.

All of the followings have to be satisfied:

1. CPU does not execute program stored in SRAM
2. All bus masters other than CPU does not access SRAM
3. SRAMCR1 is Device-nGnRnE set by MPU
4. SRAMCR1 have to be configured with the following procedure:
 1. DMB instruction
 2. Write to SRAMCR1 register
 3. DMB instruction

45.4.3 Notes on Using Error Checking of SRAM

Data in SRAM are undefined when the power is turned on. Therefore, parity check errors occur if the data are read before initialization. The SRAM are read in 8-byte (64-bit) units. Initialize them on 8-byte boundaries.

46. Standby SRAM

46.1 Overview

An on-chip SRAM is provided to retain data in Deep Software Standby mode. [Table 46.1](#) lists the Standby SRAM specifications.

Table 46.1 Standby SRAM specifications

Item	Description
SRAM capacity	1 KB
SRAM address	0x2600_0000 to 0x2600_03FF (Secure alias), 0x3600_0000 to 0x3600_03FF (Non-secure alias)
Access	Wait states are inserted into the access cycle by default. If the ICLK frequency is higher than 120 MHz, a wait state is required. If the ICLK frequency is 120 MHz or less, a wait state is not required.
Data retention function	Data can be retained in Deep Software Standby mode 1. In Deep Software Standby mode 2 and 3, data cannot be retained. See section 46.3.1. Data Retention for details.
parity	Even parity (data: 8 bits, parity: 1 bit)
Module-stop function	Module-stop state can be set to reduce power consumption. See section 46.3.2. Module-stop Function for details.
Security	Permits the read and write operations to Standby RAM following TrustZone Filter function. See section 46.3.4. TrustZone Filter function for details.

46.2 Register Descriptions

46.2.1 STBRAMSABAR : Standby SRAM Security Attribute Boundary Address Register

Base address: CPSCU = 0x4000_8000
CPSCU_NS = 0x5000_8000

Offset address: 0x420

Bit position: 31 0

Bit field:

Value after reset: 0 1 1 1 1 1 1 1 1 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
31:0	n/a	Boundary address between Secure and Non-secure.	R/W

Note: S-TYPE-1, P-TYPE-1

Note: This register is write-protected by PRCR_S.PRC4 register.

STBRAMSABAR specifies the boundary address between the Secure and Non-secure regions of Standby SRAM. Write the absolute address to the STBRAMSABAR. When writing to STBRAMSABAR, writing from b31 to b15 is ignored and the value written from b6 to b0 should be 0.

The region lower than the boundary address is marked as Secure, and higher than or equal to the boundary address is marked as Non-secure. Therefore, when the boundary address is 0x00000000, whole Standby SRAM is marked as Non-secure, and when the boundary address is 0x00000400 or large, whole Standby SRAM is marked as Secure.

The boundary address is as follow.

- 0x2600_0000 + STBRAMSABAR (Secure alias)
- 0x3600_0000 + STBRAMSABAR (Non-secure alias)

46.2.2 STBRAMPABAR_NS : Standby SRAM Privilege Attribute Boundary Address Register for Non-secure

Base address: CPSCU_NS = 0x5000_8000

Offset address: 0x490

Bit position: 31 0

Bit field: n/a

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	n/a	Boundary address between Privileged and Unprivileged.	R/W

Note: S-TYPE-7, P-TYPE-2

Note: This register is write-protected by PRCR_NS.PRC4 register.

STBRAMPABAR_NS specifies the boundary address between the Privileged and Unprivileged regions of Standby SRAM Non-secure regions set by STBRAMSABAR. Write the absolute address to the STBRAMPABAR_NS. When writing to STBRAMPABAR_NS, writing from b31 to b15 is ignored and the value written from b6 to b0 should be 0.

The region lower than the boundary address is marked as Privileged, and higher than or equal to the boundary address is marked as Unprivileged. Therefore, when the boundary address is 0x00000000, or less than or equal to start address of Standby SRAM Non-secure regions set by STBRAMSABAR, whole Standby SRAM is marked as Unprivileged, and when the boundary address is 0x00000400 or large, or higher than or equal to end address of Standby SRAM Non-secure regions set by STBRAMSABAR, whole Standby SRAM is marked as Privileged.

The boundary address is as follow.

- 0x3600_0000 + STBRAMPABAR_NS (Non-secure alias)

46.2.3 STBRAMPABAR_S : Standby SRAM Privilege Attribute Boundary Address Register for Secure

Base address: CPSCU = 0x4000_8000

Offset address: 0x494

Bit position: 31 0

Bit field: n/a

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	n/a	Boundary address between Privileged and Unprivileged.	R/W

Note: S-TYPE-6, P-TYPE-2

Note: This register is write-protected by PRCR_S.PRC4 register.

STBRAMPABAR_S specifies the boundary address between the Privileged and Unprivileged regions of Standby SRAM Secure regions set by STBRAMSABAR. Write the absolute address to the STBRAMPABAR_S. When writing to STBRAMPABAR_S, writing from b31 to b15 is ignored and the value written from b6 to b0 should be 0.

The region lower than the boundary address is marked as Privileged, and higher than or equal to the boundary address is marked as Unprivileged. Therefore, when the boundary address is 0x00000000, or less than or equal to start address of Standby SRAM Secure regions set by STBRAMSABAR, whole Standby SRAM is marked as Unprivileged, and when the boundary address is 0x00000400 or large, or higher than or equal to end address of Standby SRAM Secure regions set by STBRAMSABAR, whole Standby SRAM is marked as Privileged.

The boundary address is as follow.

- 0x2600_0000 + STBRAMPABAR_S (Secure alias)

46.2.4 STBRAMCR : Standby SRAM Control Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x110

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	OAD	Operation after detection 0: Non-maskable interrupt. 1: Reset.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3 (SRAMSAR.STBRAMSA), P-TYPE-2

This register can be written only when the PR bit in the SRAMPRCR_S or SRAMPRCR_NS register is 1.

Do not write to this register while access to Standby SRAM is in progress.

OAD bit (Operation after detection)

This bit is specified to generate either reset or non-maskable interrupt when parity error is detected.

46.2.5 STBRAMEAR : Standby SRAM Error Address Register

Base address: SRAM = 0x4000_2000
SRAM_NS = 0x5000_2000

Offset address: 0x150

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	n/a	When an SRAM error occurs, it stores an error address.	R

Note: S-TYPE-5, P-TYPE-2

This register is cleared by the corresponding bit in SRAMESCLR register, or resets other than Bus Error Reset and Memory Error Reset. If error and clear occur at the same time, clear has priority. Also during accessing from debugger it is to stop updating register.

The error address is as follow.

- 0x2600_0000 + STBRAMEAR (Secure alias)
- 0x3600_0000 + STBRAMEAR (Non-secure alias)

This register stores the error address where parity error is detected. These bits hold the error address that occurred first. These bits are cleared by clearing parity error from SRAMESCLR.

46.3 Operation

46.3.1 Data Retention

The power supply to the Standby SRAM in Deep Software Standby mode is enabled by the DPSBYCR.SRKEEP bit. If the DPSBYCR.SRKEEP bit are set to 1b, data in the Standby SRAM is retained in Deep Software Standby mode 1. For details on the DPSBYCR.SRKEEP bit, see [section 10, Low Power Modes](#).

46.3.2 Module-stop Function

Power consumption can be reduced by setting module stop control register A (MSTPCRA) to stop supply of the clock signal to SRAM.

If the Standby SRAM bit in MSTPCRA is set to 1, supply of the clock signal to the Standby SRAM is stopped.

The Standby SRAM is thus placed in the module-stop state by stopping supply of the clock signals. The Standby SRAM operates after a reset.

The Standby SRAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to the standby SRAM is in progress.

Access to the Standby SRAM in the module-stop state is prohibited. If access is attempted, correct operation is not guaranteed.

For details on the MSTPCRA register, see [section 10, Low Power Modes](#).

46.3.3 Parity Calculation Function

The IEC60730 standard requires the checking of STBRAMCR data. When data is written, a parity bit is added to every 8-bit data in the Standby SRAM which has 32-bit data width, and when data is read, the parity is checked. When a parity error occurs, a parity error notification is generated. This function can also be used to trigger a reset.

The parity-error notification can be specified as a non-maskable interrupt or a reset in the OAD bit of the STBRAMCR register. When the OAD bit is set to 1, a parity error is output to the reset function. When the OAD bit is set to 0, a parity error is output to the ICU as a non-maskable interrupt.

Parity errors often occur because of noise. To confirm whether the cause of the parity error is noise or corruption, follow the parity check flows shown in [Figure 46.1](#) and [Figure 46.2](#).

When a read access is executed in a row after a write access, read access is executed with priority. Therefore, during initialization, do not perform the read access in a row after the write access.

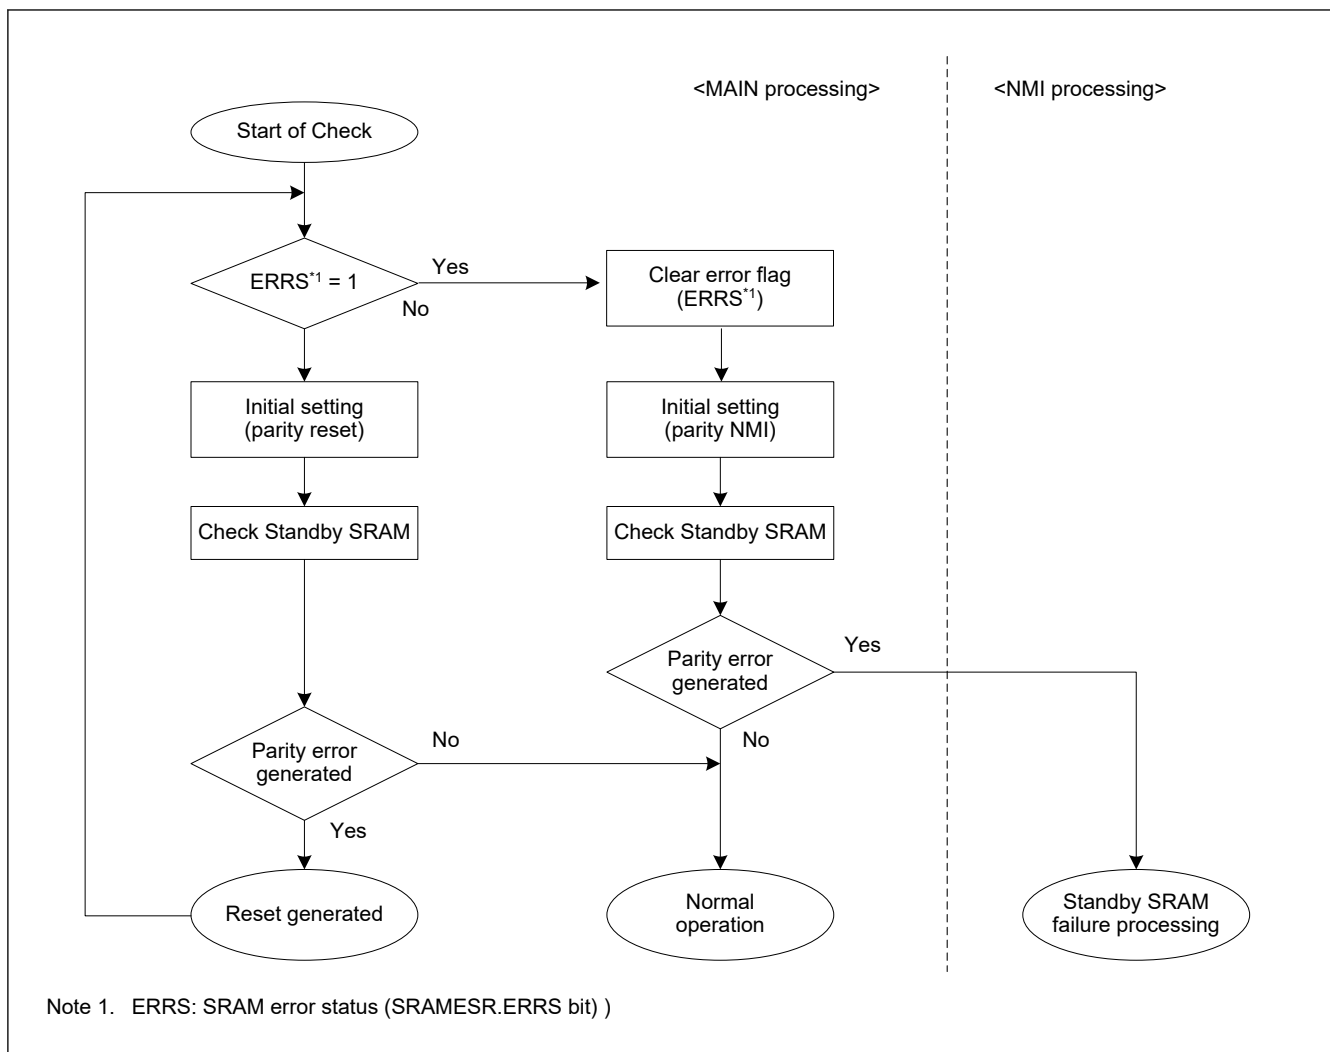

Figure 46.1 Flow of Standby SRAM parity check when SRAM parity reset is enabled

Figure 46.2 Flow of Standby SRAM parity check when SRAM parity interrupt is enabled

46.3.4 TrustZone Filter function

46.3.4.1 TrustZone Filter for Standby SRAM registers

Standby SRAM registers can be protected with a Security Attribution (SA) from Non-secure or Secure transaction. When SA indicates that Standby SRAM registers are Secure status, Non-secure transaction can not access them because TrustZone Filter detects finds an error and protects the access. When SA indicates that SRAM registers are Non-secure status, Secure transaction can not access them because Trust Zone Filter detects finds an error and protects the access. SA for Standby SRAM registers is just one to be used commonly among Standby SRAM registers.

In the case of a failed access due to TrustZone error, error response is generated.

Table 46.2 Standby SRAM register protection

SA	Transaction	Write access	Read access
Secure	Secure	Permitted	Permitted
	Non-secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
Non-secure	Secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
	Non-secure	Permitted	Permitted

46.3.4.2 TrustZone Filter for Standby SRAM memory regions

Standby SRAM regions can be divided into Secure and Non-secure. The access permissions for these regions are as below.

Table 46.3 Standby SRAM memory protection by Security Attribution

SA	Transaction	Write access	Read access
Secure	Secure	Permitted	Permitted
	Non-secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
Non-secure	Secure	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
	Non-secure	Permitted	Permitted

Standby SRAM regions can be divided into Privileged and Unprivileged. The access permissions for these regions are as below.

Table 46.4 Standby SRAM memory protection by Privilege Attribution

PA	Transaction	Write access	Read access
Privileged	Privileged	Permitted	Permitted
	Unprivileged	Protected (TrustZone Filter error)	Protected (TrustZone Filter error)
Unprivileged	Privileged	Permitted	Permitted
	Unprivileged	Permitted	Permitted

TrustZone Filter error for Standby SRAM memory generates an error notification.

For details, see [section 38, Security Features](#).

46.3.5 Interrupt Source

The Standby SRAM interrupt source includes a Parity error and TrustZone filter error.

Parity error can choose non-maskable interrupt or reset by STBRAMCR.OAD bit.

The Standby SRAM interrupt occurs when the SRAMESR.ERRS is set to 1. the Standby SRAM interrupt continues to occur until the SRAMESR.ERRS is cleared.

When Common memory error occur(NMISR.CMST=1 or RSTSR1.CMSR=1), please read SRAMESR and check SRAM interrupt source. When the access from debugger, no error flag is set, reset and non-maskable interrupt are maskable.

For more detail on the debug mode, see [section 2, CPU](#).

Table 46.5 Standby SRAM Interrupt Source

Name	Interrupt Source	DTC Activation	DMAC Activation
PARITYERR	Parity error	Not possible	Not possible
TZFLT	TrustZone filter error	Not possible	Not possible

46.3.6 Wait state

When ICLK frequencies is higher than 120 MHz, do not set 0x00 in wait enable bit for the SRAMWTSC register, in order to insert a wait cycle. When the wait is not inserted, the operation is not guaranteed.

Depending on the operating frequency of ICLK, the WAIT setting for Standby SRAM access has the following conditions.

[ICLK frequency]:

- $240 \text{ MHz} \geq \text{ICLK} > 120 \text{ MHz} = 1 \text{ wait}$
- $120 \text{ MHz} \geq \text{ICLK} = \text{No-wait}$

46.4 Usage Notes

46.4.1 Instruction Fetch from the Standby SRAM Area

When using Standby SRAM to operate a program, initialize the Standby SRAM area so that the CPU can correctly prefetch data. A parity error might occur if the CPU prefetches from an area that is not initialized. Initialize the additional 12-byte area from the end address of the program with the 4-byte boundary. Renesas recommends using the NOP instruction for data initialization.

46.4.2 Notes on Self-Diagnosis of the Standby SRAM

A write buffer is mounted for the Standby Standby SRAM. When the same address is read after a write operation, data in the write buffer, rather than in the memory cell of the Standby SRAM may be read. When the Standby SRAM is self-diagnosed, confirm that the data have been written by following the procedure below so that data will not be read from the write buffer.

1. Write data to the address targeted for diagnosis.
2. Write data to an address which is at least 4 addresses away from the that in step1.
3. Read the data from the address in step1.

47. Flash Memory

This MCU incorporates code flash memory, data flash memory, and option-setting memory. The code flash memory stores instructions and operands, and the data flash memory stores data. For option-setting memory, see [section 6, Option-Setting Memory](#).

47.1 Overview

[Table 47.1](#) lists the specifications of the flash memory, and [Figure 47.1](#) is block diagrams of the flash memory related modules.

The I/O pins used in boot mode, see [Table 47.37](#).

The FCU (flash control unit) controls programming and erasure of the flash memory. The FACL (flash application command interface) controls the FCU according to the specified FACL commands.

Regarding the configuration of the code flash memory, see [Figure 47.2](#) to [Figure 47.3](#), and for the configuration of the data flash memory, see [Figure 47.4](#).

Table 47.1 Specifications of flash memory (1 of 2)

Item	Code flash memory	Data flash memory
Memory capacity	User area: 1 Mbytes max	Data area: 12 Kbytes
Value after erasure	0xFF	Undefined
Programming/erasing method	<ul style="list-style-type: none"> Programming and erasing the code flash memory and data flash memory, and programming the option-setting memory are handled by the FACL commands specified in the FACL command issuing area (Secure: 0x4010_0000, Non-secure: 0x5010_0000) (self-programming). Programming/erasure through transfer by a serial-programmer via a serial interface (serial programming) 	
Protection	Protects against erroneous rewriting of the flash memory	
Dual bank function	The dual-bank structure makes a safe update possible in cases where programming is suspended. <ul style="list-style-type: none"> Linear mode: the code flash memory is used as one area. Dual mode: the code flash memory is divided into two areas. 	Not available
Block swap function	The block swap structure makes a safe update for a part of Non-secure application possible in case where programming is suspended.	Not available
Background operations (BGOs)	<ul style="list-style-type: none"> The code flash memory can be read while the code flash memory is being programmed or erased. The data flash memory can be read while the code flash memory is being programmed or erased. The code flash memory can be read while the data flash memory is being programmed or erased. 	
Units of programming and erasure	<ul style="list-style-type: none"> Units of programming for the user area: 128 bytes Units of erasure for the user area: Block units 	<ul style="list-style-type: none"> Unit of programming for the data area: 4/8/16 bytes Unit of erasure for the data area: 64/128/256 bytes
Other functions	Interrupts can be accepted during self-programming. In the initial settings of this MCU, an expansion area of the option-setting memory can be set.	
On-board programming (four types)	Programming/erasure in boot mode (for the SCI interface) <ul style="list-style-type: none"> The asynchronous serial interface (SCI9) is used. The transfer rate is adjusted automatically. Programming/erasure in boot mode (for the USB interface) <ul style="list-style-type: none"> USBFS is used. Dedicated hardware is not required, so direct connection to a PC is possible. Programming/erasure in On-chip debug mode <ul style="list-style-type: none"> JTAG or SWD interface is used Programming and erasure by self-programming <ul style="list-style-type: none"> This allows code flash memory programming/erasure without resetting the system. 	

Table 47.1 Specifications of flash memory (2 of 2)

Item	Code flash memory	Data flash memory
Unique ID	A 16-byte ID code provided for each MCU	
FACI command	Program : 128 bytes Block erase: 1 block (8 KB or 32 KB) P/E suspend P/E resume Forced Stop Status Clear Configuration set (16 bytes)	Program: 4/8/16 bytes Block Erase: 1 block (64 bytes) Multi Block Erase: 64/128/256 bytes P/E suspend P/E resume Forced Stop Blank Check: 4 bytes to data flash memory capacity Status Clear Configuration set (4/16 Bytes) Increment Counter: 1bit Refresh Counter Read Counter: 8 Bytes
Security function	Protects against illicit tampering with or reading out of data in flash memory Startup area select setting protection <ul style="list-style-type: none"> • BTFLG and FSUACR registers are protected by the FSPR bit. Flash memory protection for TrustZone <ul style="list-style-type: none"> • Protection for flash memory area (P/E) • Protection for flash memory area (read) • Protection for register • Protection during FACI command operation. • Code flash P/E mode entry protection • Data flash configuration area protection • Anti-rollback Counter 	
Safety function	Software protection <ul style="list-style-type: none"> • FACI command protection by FENTRYR register. • Flash memory is protected by FWEPROR register • The user area is protected by the block protect setting Error protection <ul style="list-style-type: none"> • Error is detected when unintended commands or prohibited settings occur. The FACI command is not accepted after an error detection. Boot area protection <ul style="list-style-type: none"> • The start-up area select function allows customer to safely update the boot firmware. The size of the start-up area is 8 KB. 	
Interrupt request	<ul style="list-style-type: none"> • FRDYI (flash sequencer ready (processing end)) : Enabled by FRDYIE bit. • FIFERR (flash sequencer error) : Enabled by CFAEIE/CMDLKIE/DFAEIE bits 	
Address conversion	Start-up area select function is supported in linear mode Dual mode and Linear mode <ul style="list-style-type: none"> • Bank swap function is supported in dual mode • Block swap function is supported in linear mode 	

Figure 47.1 shows how modules related to flash memory can be configured. The flash sequencer is configured with the FCU and FACI. The FCU executes basic control for rewriting of the flash memory. The FACI receives FACI commands using peripheral bus, and controls FCU operations accordingly.

In response to a reset, the FACI transfers data from the flash memory to the option byte storage registers.

Figure 47.1 Block diagram of flash memory-related modules

47.2 Structure of Memory

Figure 47.2 shows the memory map of code flash memory in linear mode. Figure 47.3 shows the memory map of code flash memory in dual mode. This MCU can use the code flash memory as 2 bank areas by using the dual bank function. This dual-bank structure allows a safe update of a program while a user program is running.

The user area of the code flash memory in this MCU is divided into 8 KB and 32 KB blocks, which serve as the units of erasure.

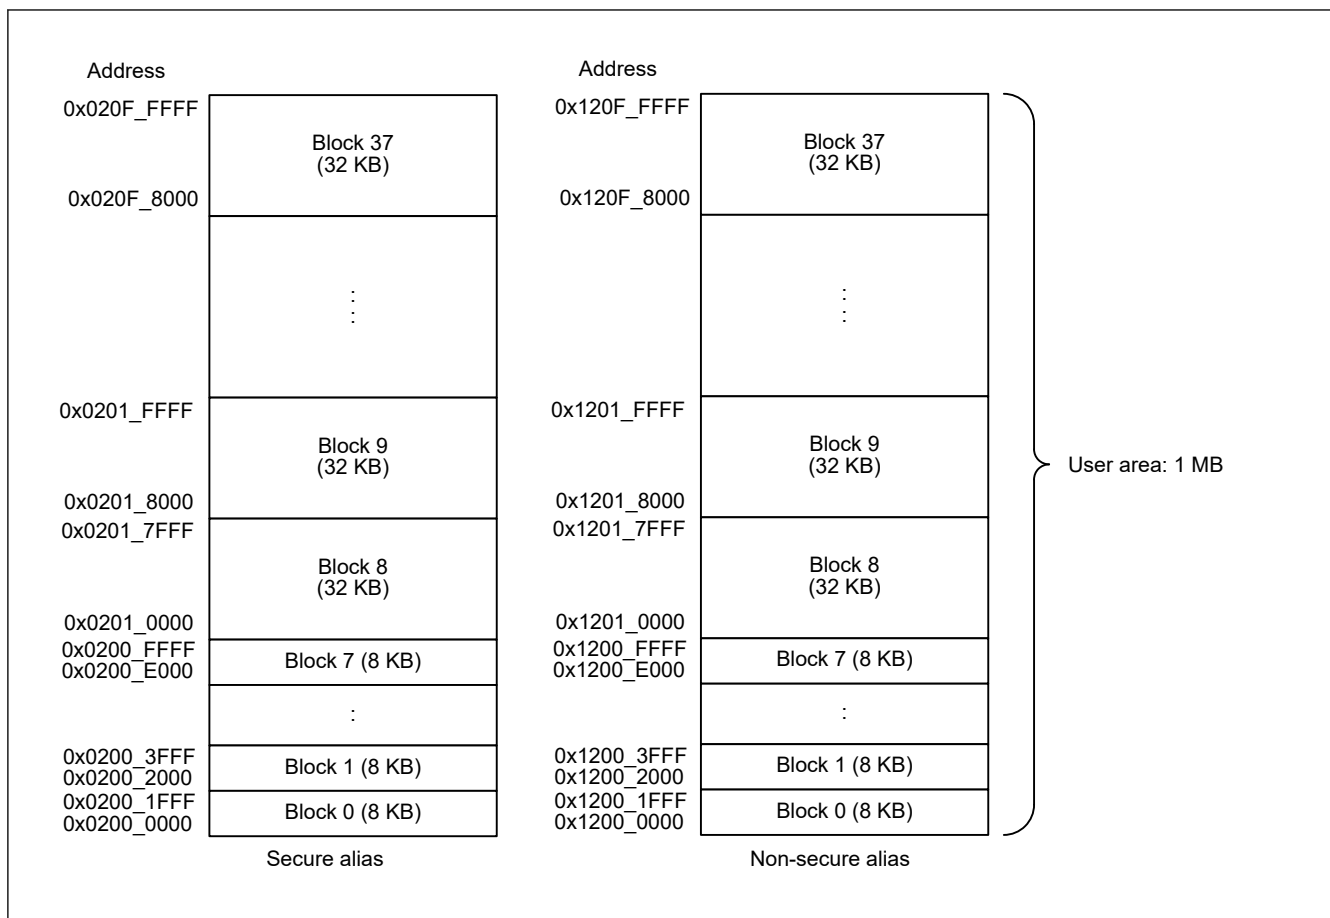

Figure 47.2 Map of the Code Flash Memory in Linear Mode

Table 47.2 Read and programming/erasure address for the code flash memory in Linear Mode

Product	Address	Number of blocks
1 MB product	Secure alias : 0x0200_0000 to 0x020F_FFFF Non-secure alias : 0x1200_0000 to 0x120F_FFFF	0 to 37

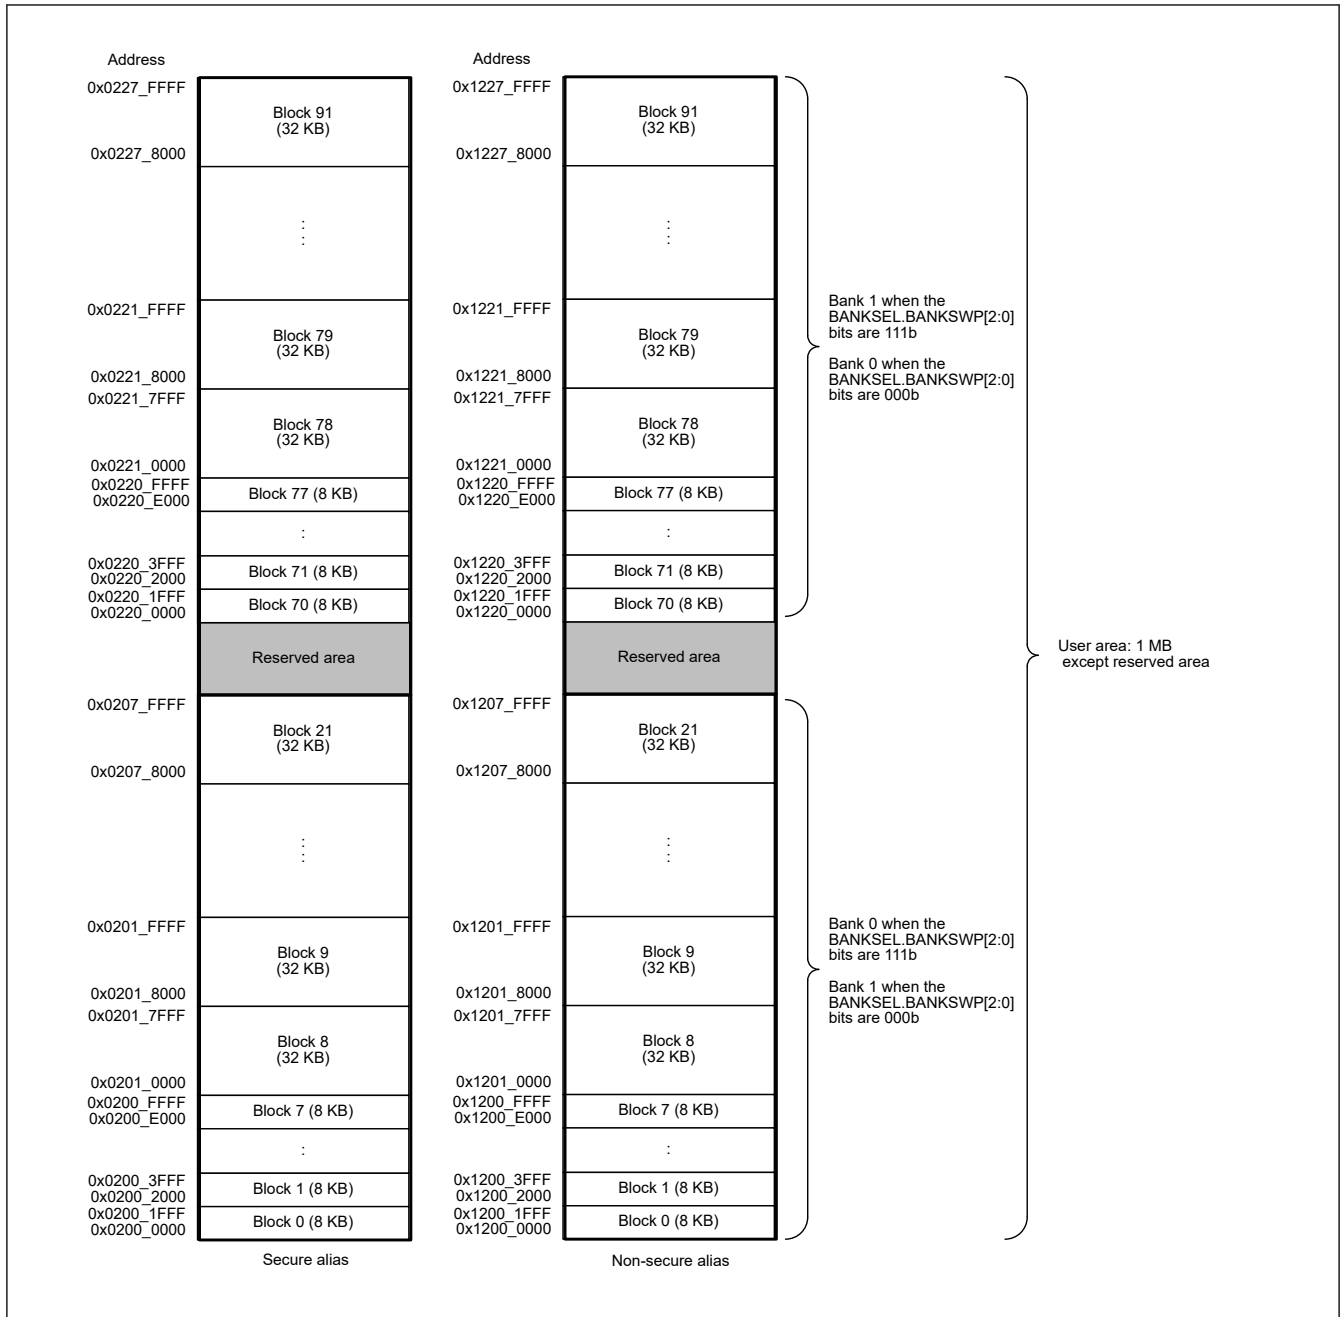

Figure 47.3 Map of the Code Flash Memory in Dual Mode

Table 47.3 Read and programming/erasure address for the code flash memory in Dual Mode

Product	Address	Number of blocks
1 MB product, lower side bank	Secure alias : 0x0200_0000 to 0x0207_FFFF Non-secure alias : 0x1200_0000 to 0x1207_FFFF	0 to 21
1 MB product, upper side bank	Secure alias : 0x0220_0000 to 0x0227_FFFF Non-secure alias : 0x1220_0000 to 0x1227_FFFF	70 to 91

The data area of the data flash memory in this MCU is divided into 64 byte blocks, with each being a unit for erasure. [Figure 47.4](#) shows the mapping of the data flash memory.

Figure 47.4 Map of the Data Flash Memory

47.3 Address Space

Using the hardware interface with flash memory requires access to all registers of the hardware, which is for issuing FACI commands. Table 47.4 provides information about the hardware interface.

Table 47.4 Information on the hardware interface area

Area	Address	Capacity
Area containing various registers of the hardware	See section 47.4. Register Descriptions.	See section 47.4. Register Descriptions.
FACI command-issuing area	Secure alias : 0x4010_0000 Non-secure alias : 0x5010_0000	4 bytes

For the address information of the flash memory, see Figure 47.2.

47.4 Register Descriptions

47.4.1 FCACHEE : Flash Cache Enable Register

Base address: FCACHE = 0x4001_C100
FCACHE_NS = 0x5001_C100

Offset address: 0x000

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FCACHEEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FCACHEEN	Flash Cache Enable 0: FCACHE is disabled 1: FCACHE is enabled	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See section 47.4.4. FSAR : Flash Security Attribution Register.

FCACHEEN bit (Flash Cache Enable)

FCACHEE.FCACHEEN bit enable and disables the function of Flash Cache of FCACHE1, FCACHE2 and FLPF.

FCACHEE.FCACHEEN bit dose not influence for FCACHEIV.FCACHEIV.

When FCACHE is enabled, it works for accesses marked as cacheable.

It is prohibited to disable FCACHE after enabling.

47.4.2 FCACHEIV : Flash Cache Invalidate Register

Base address: FCACHE = 0x4001_C100
FCACHE_NS = 0x5001_C100

Offset address: 0x004

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FCACHEIV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FCACHEIV	Flash Cache Invalidate 0: Read: Do not invalidate. Write: The setting is ignored. 1: Invalidate FCACHE is invalidated.	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-5, P-TYPE-2

This register is not controlled by any security attribute register.

FCACHEIV bit (Flash Cache Invalidate)

When 1 is written to FCACHEIV.FCACHEIV bit, the Flash cache data of FCACHE1, FCACHE2 and FLPF is invalidated.

Invalidate FCACHE with keeping FCACHE enabled after programming or erasing the code flash or the option setting memory.

47.4.3 FLWT : Flash Wait Cycle Register

Base address: FCACHE = 0x4001_C100
FCACHE_NS = 0x5001_C100

Offset address: 0x01C

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	FLWT[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	FLWT[2:0]	Flash Wait Cycle 0 0 0: 0 wait (ICLK ≤ 48 MHz) 0 0 1: 1 wait (48 MHz < ICLK ≤ 96 MHz) 0 1 0: 2 wait (96 MHz < ICLK ≤ 144 MHz) 0 1 1: 3 wait (144 MHz < ICLK ≤ 192 MHz) 1 0 0: 4 wait (192 MHz < ICLK ≤ 240 MHz) Others: Setting prohibited	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 47.4.4. FSAR : Flash Security Attribution Register](#).

FLWT[2:0] bits (Flash Wait Cycle)

The Flash Wait Cycle Register (FLWT) sets the access wait count for the flash memory.

For faster clock frequencies, set FLWT.FLWT before changing the clock frequency. For slower clock frequencies, set FLWT.FLWT after changing the clock frequency.

For information on the frequency setting, see [section 8, Clock Generation Circuit](#).

47.4.4 FSAR : Flash Security Attribution Register

Base address: FCACHE = 0x4001_C100
FCACHE_NS = 0x5001_C100

Offset address: 0x040

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	FACIC MRSA	FACIC MISA	FCKM HZSA	—	—	—	—	—	—	FCAC HESA	FLWT SA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FLWTSA	FLWT Security Attribution Target register : FLWT 0: Secure 1: Non-secure	R/W
1	FCACHESA	FCHACHEEN Security Attribution Target register : FCHACHEEN 0: Secure 1: Non-secure	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
8	FCKMHZSA	FCKMHZ Security Attribution Target register : FCKMHZ 0: Secure 1: Non-secure	R/W
9	FACICMISA	FACI command Issuing Security Attribution Target area : Flash access area 0: Secure 1: Non-secure	R/W
10	FACICMRSA	FACI command Registers Security Attribution Target registers : FASTAT, FAEINT, FRDYIE, FSADDR, FEADDR, FBPROT1, FSTATR, FENTRYR, FSUINTR, FCMDR, FBCCNT, FBCSTAT, FPSADDR, FSUASMON, FCPSR, FPCKAR, FWEPROR 0: Secure 1: Non-secure	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-1, P-TYPE-1

Note: Set the PRCR.PRC4 bit to 1 (write enabled) before rewriting this register.

FLWTSA bit (FLWT Security Attribution)

This bit sets the security attribute of FLWT.

FCACHESA bit (FCHACHEEN Security Attribution)

This bit sets the security attribute of FCHACHEEN.

FCKMHZSA bit (FCKMHZ Security Attribution)

This bit sets the security attribute of Flash access area.

FACICMISA bit (FACI command Issuing Security Attribution)

This bit sets the security attribute of Flash access area.

FACICMRSA bit (FACI command Registers Security Attribution)

This bit sets the security attribute of FACI command security registers.

47.4.5 UIDRn : Unique ID Registers n (n = 0 to 3)

Address: 0x0300_8190 + n × 4 (Secure)
0x1300_8190 + n × 4 (Non-secure)

Bit	Symbol	Function	R/W
31:0	UID	Unique ID	R

Note: S-TYPE-5, P-TYPE-5

The UIDRn is a read-only register that stores a 16-byte ID code (unique ID) for identifying the individual MCU. The UIDRn register should be read in 32-bit units. When reading by the signature request command of the serial programming interface, the data is read in order from the data with the large address. That is, the data in 0x0300_819F is read first, and in 0x0300_8190 is read last.

47.4.6 PNRn : Part Numbering Register n (n = 0 to 3)

Address: 0x0300_80F0 + n × 4 (Secure)
0x1300_80F0 + n × 4 (Non-secure)

Bit	Symbol	Function	R/W
31:0	PNR	Part Number	R

Note: S-TYPE-5, P-TYPE-5

The PNRn is a read-only register that stores a 16-byte part numbering. The PNRn register should be read in 32-bit units. Each byte corresponds to the ASCII code representation of the product part number as detailed in [Table 1.13](#). The first character ("R", 0x52 in ASCII code) of the part number is stored in the byte with the smallest address (0x0300_80F0). When reading by the signature request command of the serial programming interface, the data is read in order from the data with the small address. That is, the data in 0x0300_80F0 is read first, and in 0x0300_80FF is read last.

47.4.7 MCOVER : MCU Version Register

Address: 0x0300_81B0 (Secure)
0x1300_81B0 (Non-secure)

Bit	Symbol	Function	R/W
7:0	MCUVE	MCU Version	R

Note: S-TYPE-5, P-TYPE-5

The MCOVER is a read-only register that stores a MCU version. The MCOVER register should be read in 8-bit units.

47.4.8 FWEPROR : Flash P/E Protect Register

Base address: SYSC = 0x4001_E000
SYSC_NS = 0x5001_E000

Offset address: 0xA54

Bit position: 7 6 5 4 3 2 1 0

Bit field:	—	—	—	—	—	—	FLWE[1:0]
------------	---	---	---	---	---	---	-----------

Value after reset: 0 0 0 0 0 0 1 0

Bit	Symbol	Function	R/W
1:0	FLWE[1:0]	Flash Programming and Erasure 0 0: Prohibits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing. 0 1: Permits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing. 1 0: Prohibits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing. 1 1: Prohibits Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2

It is possible that Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command processing are prohibited by software.

The FWEPROR register is initialized by a reset from the following:

- All reset source except for VBATT_POR reset
- Transition to Deep Software Standby mode
- Transition to Software Standby mode.

FLWE[1:0] bits (Flash Programming and Erasure)

The FLWE[1:0] bits are used to set the flash P/E protection. The value after reset is 10b.

If these bits are set to other than 01b that does not allow programming and erasure of the flash memory, the following commands cannot be executed. Issuing any of the following commands leads to setting of the FLWEERR bit in the FSTATR register to 1.

Program / Block Erase / Multi Block Erase / Blank Check / Configuration set command

47.4.9 FASTAT : Flash Access Status Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0x10

Bit position: 7 6 5 4 3 2 1 0

Bit field:	CFAE	—	—	CMDL K	DFAE	—	—	—
------------	------	---	---	-----------	------	---	---	---

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
2:0	—	These bits are read as 0. The write value should be 0.	R/W
3	DFAE	Data Flash Memory Access Violation Flag 0: No data flash memory access violation has occurred 1: A data flash memory access violation has occurred.	R/W ¹

Bit	Symbol	Function	R/W
4	CMDLK	Command Lock Flag 0: The flash sequencer is not in the command-locked state 1: The flash sequencer is in the command-locked state.	R
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	CFAE	Code Flash Memory Access Violation Flag 0: No code flash memory access violation has occurred 1: A code flash memory access violation has occurred.	R/W ¹

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 47.4.4. FSAR : Flash Security Attribution Register](#)

Note 1. Only 0 can be written to clear the flag after 1 is read.

The FASTAT register indicates whether a code flash or data flash memory access violation has occurred. If any of the CFAE, CMDLK, and DFAE bits is set to 1, the flash sequencer enters the command-locked state (see [section 47.11.2. Error Protection](#)). To release it from the command-locked state, issue a status clear command or Forced Stop command to the flash sequencer.

DFAE bit (Data Flash Memory Access Violation Flag)

The DFAE bit indicates whether a data flash memory access violation occurred. When this bit is set to 1, the ILGLERR bit in the FSTATR register is set to 1, placing the flash sequencer in the command-locked state.

[Setting conditions]

FACI commands issued in the data flash P/E mode are as follows:

- The setting of the FSADDR or FEADDR register is the reserved portion of the data area
- The Configuration set command is issued while the setting of the FSADDR register is out of 0x2703_0050 to 0x2703_03FF.
- FACI command is issued to data flash memory with the wrong security attribution.

[Clearing conditions]

- When this bit is written as 0 after it is set to 1
- When the flash sequencer starts to process the Status Clear or Forced Stop command.

CMDLK bit (Command Lock Flag)

The CMDLK bit indicates that the flash sequencer is in the command-locked state.

[Setting conditions]

- The flash sequencer detects an error and enters the command-locked state.

[Clearing conditions]

- When the flash sequencer starts to process the Status Clear or Forced Stop command.

CFAE bit (Code Flash Memory Access Violation Flag)

The CFAE bit indicates whether a code flash memory access violation has occurred. When this bit is set to 1, the ILGLERR bit in the FSTATR register is set to 1, placing the flash sequencer in the command-locked state.

[Setting conditions]

FACI commands issued in the code flash P/E mode are as follows:

- The setting of the FSADDR register is the reserved portion of the user area
- The Configuration set command is issued while the setting of the FSADDR register is from 0x0200_A100 to 0x0200_A2F0 in self-programming mode
- FACI command is issued to code flash memory with the wrong security attribution.

[Clearing conditions]

- When this bit is written as 0 after it is set to 1

- When the flash sequencer starts to process the Status Clear or Forced Stop command.

47.4.10 FAEINT : Flash Access Error Interrupt Enable Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0x14

Bit position:	7	6	5	4	3	2	1	0
Bit field:	CFAEIE	—	—	CMDLKIE	DFAEIE	—	—	—

Value after reset: 1 0 0 1 1 0 0 0

Bit	Symbol	Function	R/W
2:0	—	These bits are read as 0. The write value should be 0.	R/W
3	DFAEIE	Data Flash Memory Access Violation Interrupt Enable 0: Generation of an FIFERR interrupt request is disabled when FASTAT.DFAE is set to 1 1: Generation of an FIFERR interrupt request is enabled when FASTAT.DFAE is set to 1.	R/W
4	CMDLKIE	Command Lock Interrupt Enable 0: Generation of an FIFERR interrupt request is disabled when FASTAT.CMDLK is set to 1 1: Generation of an FIFERR interrupt request is enabled when FASTAT.CMDLK is set to 1.	R/W
6:5	—	These bits are read as 0. The write value should be 0.	R/W
7	CFAEIE	Code Flash Memory Access Violation Interrupt Enable 0: Generation of an FIFERR interrupt request is disabled when FASTAT.CFAE is set to 1 1: Generation of an FIFERR interrupt request is enabled when FASTAT.CFAE is set to 1.	R/W

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 47.4.4. FSAR : Flash Security Attribution Register](#).

The FAEINT register enables or disables generation of a flash access error (FIFERR) interrupt request.

DFAEIE bit (Data Flash Memory Access Violation Interrupt Enable)

The DFAEIE bit enables or disables generation of an FIFERR interrupt request when a data flash memory access violation occurs, setting the DFAE bit in the FASTAT register to 1.

CMDLKIE bit (Command Lock Interrupt Enable)

The CMDLKIE bit enables or disables generation of an FIFERR interrupt request when the flash sequencer enters the command-locked state, setting the CMDLK bit in the FASTAT register to 1.

CFAEIE bit (Code Flash Memory Access Violation Interrupt Enable)

The CFAEIE bit enables or disables generation of an FIFERR interrupt request when a code flash memory access violation occurs, setting the CFAE bit in the FASTAT register to 1.

47.4.11 FRDYIE : Flash Ready Interrupt Enable Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0x18

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	FRDYIE

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	FRDYIE	Flash Ready Interrupt Enable 0: Generation of an FRDY interrupt request is disabled 1: Generation of an FRDY interrupt request is enabled.	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 47.4.4. FSAR : Flash Security Attribution Register](#)

The FRDYIE register enables or disables generation of a flash ready (FRDY) interrupt request.

FRDYIE bit (Flash Ready Interrupt Enable)

The FRDYIE bit enables or disables generation of an FRDY interrupt request when the FRDY bit in the FSTATR register is changed from 0 to 1 on completion of processing by the flash sequencer of the Program, Block Erase, Multi Block Erase, Blank Check, and Configuration set command.

47.4.12 FSADDR : FACI Command Start Address Register

Base address: FACI = 0x4011_E000
FACI_NS = 0x5011_E000

Offset address: 0x30

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	FSADDR[31:0]	Start Address for FACI Command Processing	R/W*1

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 47.4.4. FSAR : Flash Security Attribution Register](#)

Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0.
Note that b0 and b1 are read-only.

Table 47.5 FACI command address boundary

Command	Address Boundary
Program (code flash memory)	128 byte
Program (data flash memory)	4, 8, 16 byte
Block Erase (code flash memory)	8 KB or 32 KB
Block Erase (data flash memory)	64 byte
Multi Block Erase (data flash memory)	64 byte
Blank Check (data flash memory)	4 byte
For code flash configuration set	16 byte
For data flash configuration set	4, 16 byte

The FSADDR register specifies the address where the target area for command processing starts when the FACI command for Program, Block Erase, Multi Block Erase, Blank Check, or Configuration set is issued.

The FSADDR value is initialized when the SUINIT bit in the FSUINITR register is set to 1. It is also initialized by a reset.

FSADDR[31:0] bits (Start Address for FACI Command Processing)

The FSADDR[31:0] bits specify the start address for FACI command processing. Bits [31:29] and [27:24] are ignored in FACI command processing for the code flash memory. Bits [31:29] and [27:13] are ignored in FACI command processing for the data flash memory. Bit [28] is used the security alias for flash sequencer command. When bit [28] is "0", flash sequencer can update secure region with secure access. When bit [28] is "1", flash sequencer can update non-security region with secure and non-secure access. Bits associated with the address bits of lower order than the address boundary listed in [Table 47.5](#) are also ignored.

For information on the addresses of the code flash memory and the data flash memory, see [section 47.2. Structure of Memory](#).

For information on the addresses of the configuration setting, see [section 47.9.3.15. Configuration Set Command](#).

47.4.13 FEADDR : FACL Command End Address Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0x34

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	FEADDR[31:0]	End Address for FACL Command Processing	R/W ¹

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 47.4.4. FSAR : Flash Security Attribution Register](#)

Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0. Note that bit [0] and bit [1] are read-only.

The FEADDR register specifies the end address of the target area for Multi Block Erase and Blank Check command processing. When incremental mode is selected as the addressing mode for Blank Checking (when FBCCNT.BCDIR = 0), the address specified in the FSADDR register should be equal to or smaller than the address in the FEADDR register. Conversely, the address in the FSADDR register should be equal to or larger than the address in the FEADDR register when decremental mode is selected as the addressing mode for Blank Check (i.e. when FBCCNT.BCDIR = 1). If the BCDIR, FSADDR, and FEADDR bit settings are inconsistent with the specified rules, the flash sequencer enters the command-locked state (see [section 47.11.2. Error Protection](#)).

The FEADDR value is initialized when the SUINIT bit in the FSUINITR register is set to 1. It is also initialized by a reset.

FEADDR[31:0] bits (End Address for FACL Command Processing)

The FEADDR[31:0] bits specify the end address for Multi Block Erase and Blank Check command processing. In command processing, bits 31 to 17 and any bits that do not reach the address boundaries listed in the [section 47.4.12. FSADDR : FACL Command Start Address Register](#) are ignored.

For information on the addresses of the flash memory, see [section 47.2. Structure of Memory](#).

47.4.14 FMEPROT : Flash P/E Mode Entry Protection Register

Base address: FACL = 0x4011_E000

Offset address: 0x44

Value after reset: 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 x 1

Bit	Symbol	Function	R/W
0	CEPROT	Code Flash P/E Mode Entry Protection 0: FENTRYC bit is not protected 1: FENTRYC bit is protected.	R/W ¹ *2 *4
1	—	The read value is undefined. The write value should be 0.	R/W
7:2	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code	W ³

Note: S-TYPE-6, P-TYPE-2

Note 1. Writing to this bit is only possible when the FRDY bit in the FSTATR register is 1. Writing to this bit while the FRDY bit = 0 is ignored.

Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY bits is 0xD9.

Note 3. Written values are not retained by these bits (always read as 0x00).

Note 4. Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed. Non-secure write access is denied, but TrustZone access error is not generated.

CEPROT bit (Code Flash P/E Mode Entry Protection)

The CEPROT bit specifies the protection setting of the FRNTRYC bit in the FENTRYR register.

[Setting condition]

- 1 being written to the CEPROT bit while writing to FMEPROT is enabled.

[Clearing condition]

- 0 being written to the CEPROT bit while writing to FMEPROT is enabled.

47.4.15 FCNTSELR : Flash Counter Select Register

Base address: FACL = 0x4011_E000

Offset address: 0x048

Bit position:	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	CNTSEL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
2:0	CNTSEL[2:0]	Counter Select 0 0 0: Anti-rollback counter is not selected 0 0 1: ARC_SEC is selected. Counter size is 64 bits. 0 1 1: Anti-rollback counter is not selected. 1 x x: ARC_NSEC is selected. Counter configuration is 64 or 256 bits. See , Table 47.6 Table 47.7 and Table 47.8 in details counter select condition. Others: Setting prohibited	R/W
7:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-6, P-TYPE-2

Note: If the security attribution is configured as Secure:

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

- Secure and Non-secure access are allowed.

CNTSEL[2:0] bits (Counter Select)

FCNTSELR specifies 2 types of anti-rollback counter (ARC_SEC or ARC_NSEC) in "Increment Counter", "Refresh Counter", or "Read Counter" command.

FCNTSELR value is initialized when SUNIT bit in FSUINTR is set to "1"

Note: This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.

Before using the ARC_NSEC counter, it is necessary to set whether the counter is to be used with 4line x 64 bits or 1line x 256 bits using the Data Flash configuration set command. The bits to be set are CNF_ARCNS0 and CNF_ARCNS1. If the CNF_ARCNS1 bit is set to 1, the ARC_NSEC counter cannot be used. Once the counter type is decided, it cannot be changed.

Table 47.6 Select condition of ARC_NSEC (64 bits) in Increment/Refresh/Read Counter Command

FCNTSELR[2:0]	Target Counter	Counter Configuration
100	ARC_NSEC[63:0]	Counter number is 4. Counter size is 64bit.
101	ARC_NSEC[127:64]	
110	ARC_NSEC[191:128]	
111	ARC_NSEC[255:192]	

Table 47.7 Select condition of ARC_NSEC (256 bits) in Increment/Refresh Counter Command

FCNTSELR[2:0]	Target Counter	Counter Configuration
100	ARC_NSEC[255:0]	Counter number is 1. Counter size is 256bit.
101		
110		
111		

Table 47.8 Select condition of ARC_NSEC (256 bits) in Read Counter Command

FCNTSELR[2:0]	Target Counter	Counter Configuration
100	ARC_NSEC[63:0]	Counter number is 1. Counter size is 256bit.
101	ARC_NSEC[127:64]	
110	ARC_NSEC[191:128]	
111	ARC_NSEC[255:192]	

47.4.16 FCNTDATARn : Flash Counter Data Register n (n = 0, 1)

Base address: FACI = 0x4011_E000

Offset address: 0x04C + 0x004 × n (n = 0, 1)

Bit position: 31

0

Bit field:

Value after reset:

Unique value for each chip

Bit	Symbol	Function	R/W
31:0	CNTRDAT	Counter Read Data Reading data of 32 bits (LSB side of counter values) is output to FCNTDATAR0. Reading data of 32 bits (MSB side of counter values) is output to FCNTDATAR1.	R

Note: S-TYPE-6, P-TYPE-2

FCNTDATAR0 and FCNTDATAR1 indicate anti-rollback counter values (64bits) that read by "Read Counter" command.

CNTRDAT bit (Counter Read Data)

[Setting condition]

- FACI has accepted "Read Counter" command.

[Clearing condition]

- FACI has accepted flash sequencer command except for "Read Counter" command.
- Flash sequencer enters "Command Lock" state

47.4.17 FBPROT0 : Flash Block Protection Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0x78

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	BPCN 0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BPCN0	Block Protection for Non-secure Cancel 0: Block protection is enabled 1: Block protection is disabled.	R/W ^{*1 *2}
7:1	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code	W ^{*3}

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 47.4.4. FSAR : Flash Security Attribution Register](#)

Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.

Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x78.

Note 3. Written values are not retained by these bits (always read as 0x00).

The FBPROT0 register is used to disable the block protect function for Non-secure. When the block protect setting is locked by the permanent block setting, it cannot be disabled by this register.

The FBPROT0 value is initialized when the SUNIT bit in the FSUINITR is set to 1, because the FENTRYR value is initialized to 0x0000. It is also initialized by a reset.

BPCN0 bit (Block Protection for Non-secure Cancel)

The BPCN0 bit disables the block protect setting for Non-secure function.

[Setting condition]

- When the write-enabling conditions are satisfied and the FENTRYR is not 0x0000, write 1 to this bit.

[Clearing conditions]

- 8 bits being written to FBPROT0 while the FRDY bit is 1.
- A value other than 0x78 specified in the KEY bits and 16 bits are written to FBPROT0 while the FRDY bit is 1.
- 0 being written to the BPCN0 bit while writing to FBPROT0 is enabled.
- The FENTRYR register value is 0x0000.

47.4.18 FBPROT1 : Flash Block Protection for Secure Register

Base address: FACL = 0x4011_E000

Offset address: 0x7C

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]								—	—	—	—	—	—	—	BPCN 1
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BPCN1	Block Protection for Secure Cancel 0: Block protection is enabled 1: Block protection is disabled.	R/W ^{*1 *2}
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15:8	KEY[7:0]	Key Code	W ³

Note: S-TYPE-6, P-TYPE-2

Note: Associated SA: FSAR register. See [section 47.4.4. FSAR : Flash Security Attribution Register](#)

Note 1. Writing to this bit is only possible when the FRDY bit in the FSTATR register is 1. Writing to this bit while FRDY bit = 0 is ignored.

Note 2. Writing to this bit is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0xB1.

Note 3. Written values are not retained by these bits (always read as 0x00).

The FBPROT1 register is used to disable the block protect function for Secure developer. When the block protect setting is locked by the permanent block setting, it cannot be disabled by this register.

The FBPROT1 value is initialized when the SUNIT bit in the FSUINTR is set to 1, because the FENTRYR value is initialized to 0x0000. It is also initialized by a reset.

BPCN1 bit (Block Protection for Secure Cancel)

The BPCN1 bit disables the block protect setting for Secure function.

[Setting condition]

- When the write-enabling conditions are satisfied and the FENTRYR is not 0x0000, write 1 to BPCN1.

[Clearing conditions]

- 8 bits being written to FBPROT1 while the FRDY bit is 1.
- A value other than 0xB1 specified in the KEY bits and 16 bits are written to FBPROT1 while the FRDY bit is 1.
- 0 being written to the BPCN1 bit while writing to FBPROT1 is enabled.
- The FENTRYR register value is 0x0000.

47.4.19 FSTATR : Flash Status Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0x80

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	ILGCO MERR	FESE TERR	SECE RR	OTER R	TZFE RR	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	FRDY	ILGLE RR	ERSE RR	PRGE RR	SUSR DY	DBFU LL	ERSS PD	PRGS PD	—	FLWE ERR	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
5:0	—	These bits are read as 0.	R
6	FLWEERR	Flash Write/Erase Protect Error Flag 0: An error has not occurred 1: An error has occurred.	R
7	—	This bit is read as 0.	R
8	PRGSPD	Programming Suspend Status Flag 0: The flash sequencer is not in the programming suspension processing state or programming suspended state 1: The flash sequencer is in the programming suspension processing state or programming suspended state.	R
9	ERSSPD	Erase Suspend Status Flag 0: The flash sequencer is not in the erasure suspension processing state or the erasure suspended state 1: The flash sequencer is in the erasure suspension processing state or the erasure suspended state.	R

Bit	Symbol	Function	R/W
10	DBFULL	Data Buffer Full Flag 0: The data buffer is empty 1: The data buffer is full.	R
11	SUSRDY	Suspend Ready Flag 0: The flash sequencer cannot receive P/E suspend commands 1: The flash sequencer can receive P/E suspend commands.	R
12	PRGERR	Programming Error Flag 0: Programming has completed successfully 1: An error has occurred during programming.	R
13	ERSERR	Erase Error Flag 0: Erasure has completed successfully 1: An error has occurred during erasure.	R
14	ILGLERR	Illegal Command Error Flag 0: The flash sequencer has not detected an illegal FACI command or illegal flash memory access 1: The flash sequencer has detected an illegal FACI command or illegal flash memory access.	R
15	FRDY	Flash Ready Flag 0: Program, Block Erase, Multi Block Erase, P/E suspend, P/E resume, Forced Stop, Blank Check, Configuration set, Increment counter, Refresh counter, or Read counter command processing is in progress. 1: None of the above is in progress.	R
18:16	—	These bits are read as 0.	R
19	TZFERR	TrustZone Filter Error 0: A TrustZone filter error has not been detected. 1: A TrustZone filter error has been detected.	R
20	OTERR	Other Error 0: An error has not been detected. 1: An error has been detected.	R
21	SECERR	Security Error 0: A write protection error against MSUASMON.FSPR bit has not been detected. 1: A write protection error against MSUASMON.FSPR bit has been detected.	R
22	FESETERR	FENTRY Setting Error 0: A setting error in the FENTRYR register has not been detected. 1: A setting error in the FENTRYR register has been detected.	R
23	ILGCOMERR	Illegal Command Error 0: An illegal FACI command error has not been detected. 1: An illegal FACI command error has been detected.	R
31:24	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 47.4.4. FSAR : Flash Security Attribution Register](#)

The FSTATR register indicates the state of the flash sequencer.

FLWEERR flag (Flash Write/Erase Protect Error Flag)

The FLWEERR flag indicates a violation of the flash memory overwrite protection setting in the FWEPROR register. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The flash sequencer starts processing the Forced Stop command.

PRGSPD flag (Programming Suspend Status Flag)

The PRGSPD flag indicates that the flash sequencer is in the programming suspension processing state or programming suspended state.

[Setting condition]

- The flash sequencer starts processing in response to the programming suspend command.

[Clearing conditions]

- Reception of the P/E resume command by the flash sequencer (after write access to the FACI command-issuing area is complete)
- The flash sequencer starts processing the Forced Stop command.

ERSSPD flag (Erasure Suspend Status Flag)

The ERSSPD flag indicates that the flash sequencer is in the erasure suspension processing state or erasure suspended state.

[Setting condition]

- The flash sequencer starts processing in response to an erasure suspend command.

[Clearing condition]

- Reception of the P/E resume command by the flash sequencer (after write access to the FACI command-issuing area is complete)
- The flash sequencer starts processing of the Forced Stop command.

DBFULL flag (Data Buffer Full Flag)

The DBFULL flag indicates the state of the data buffer when the program command is issued. The flash sequencer incorporates a buffer for write data (data buffer). When data for writing to the flash memory are written to the FACI command-issuing area while the data buffer is full, the flash sequencer inserts a wait cycle in the peripheral bus.

[Setting condition]

- The data buffer becomes full while program commands are issued.

[Clearing condition]

- The data buffer becomes empty.

SUSRDY flag (Suspend Ready Flag)

The SUSRDY flag indicates whether the flash sequencer can receive a P/E suspend command.

[Setting condition]

- After starting programming/erasure processing, the flash sequencer enters a state in which P/E suspend commands can be received.

[Clearing conditions]

- Reception of the P/E suspend command or Forced Stop command by the flash sequencer (after write access to the FACI command-issuing area is complete)
- During programming or erasure, the flash sequencer enters the command-locked state
- Programming or erasure has completed.

PRGERR flag (Programming Error Flag)

The PRGERR flag indicates the result of programming of the flash memory. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred during programming.

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

ERSERR flag (Erasure Error Flag)

The ERSERR flag indicates the result of erasure of the flash memory. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting condition]

- An error has occurred during erasure.

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

ILGLERR flag (Illegal Command Error Flag)

The ILGLERR flag indicates that the flash sequencer has detected an illegal FACI command or flash memory access. If this flag is 1, the flash sequencer is in the command-locked state.

[Setting conditions]

- See [section 47.11.2. Error Protection](#).

[Clearing condition]

- The flash sequencer starts processing of the Status Clear or Forced Stop command.

FRDY flag (Flash Ready Flag)

The FRDY flag indicates the command processing state of the flash sequencer.

[Setting conditions]

- The flash sequencer completes command processing
- The flash sequencer receives a P/E suspend command and suspends programming of the flash memory
- The flash sequencer received the Forced Stop command and ended command processing.

Note: In the case of program command processing, the FRDY flag might be set to 1 even if the flash sequencer does not complete command processing. For details, see [section 47.9.3.7. Program Command](#).

[Clearing conditions]

- The flash sequencer received an FACI command
- For Program and Configuration setting, the first write access to the FACI command-issuing area
- For other commands, the last write access to the FACI command-issuing area.

TZFERR flag (TrustZone Filter Error)

This flag indicates the TrustZone protection error in the FACI command.

See [Table 47.30](#). When this bit is "1", flash sequencer enters "Command Lock" state.

[Setting conditions]

- An error has been detected.

[Clearing conditions]

- Status Clear or Forced Stop command processing is completed.

OTERR flag (Other Error)

This flag indicates that an FACI command has been issued when the condition of accepting commands is not satisfied.

See [Table 47.30](#). When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

SECERR flag (Security Error)

This flag indicates that write protection by the MSUASMON.FSPR bit is violated.
See [Table 47.30](#). When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

FESETERR flag (FENTRY Setting Error)

This flag indicates that a value of 0xAA81 is written in the FENTRYR register or the value in the FENTRYR register differs when P/E is suspended and resumed.

See [Table 47.30](#). When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

ILGCOMERR flag (Illegal Command Error)

This flag indicates that the flash sequencer has detected an illegal FACI command.

See [Table 47.30](#). When this flag is 1, the flash sequencer is in the command-lock state.

[Setting condition]

- An error has occurred.

[Clearing condition]

- The status clear or forced stop command processing is complete.

47.4.20 FENTRYR : Flash P/E Mode Entry Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0x84

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]							FENT RYD	—	—	—	—	—	—	—	FENT RYC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	FENTRYC	Code Flash P/E Mode Entry 0: Code flash is in read mode 1: Code flash is in P/E mode.	R/W ^{*1,2}
6:1	—	These bits are read as 0. The write value should be 0.	R/W
7	FENTRYD	Data Flash P/E Mode Entry 0: Data flash is in read mode 1: Data flash is in P/E mode.	R/W ^{*1,2}
15:8	KEY[7:0]	Key Code	W ^{*3}

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 47.4.4. FSAR : Flash Security Attribution Register](#)

Note 1. These bits can be written when the FRDY bit in the FSTATR register is 1. Writing to these bits are ignored when the FRDY bit is 0.

Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0xAA.

Note 3. Written values are not retained by these bits (always read 0x00).

FENTRYR is used to specify code flash P/E mode or data flash P/E mode. To specify the code flash P/E mode or data flash P/E mode so that the flash sequencer can receive FACL commands, set either the FENTRYD or FENTRYC bit to 1 to place the flash sequencer in P/E mode.

FENTRYR is initialized when the SUNIT bit in FSUINTR is set to 1. It is also initialized by a reset.

Note: Writing a value of 0XAA81 to this register causes the IGLERR bit in the FSTATR register to be set to 1, resulting in the flash sequencer being placed in the command-locked state.

FENTRYC bit (Code Flash P/E Mode Entry)

The FENTRYC bit specifies P/E mode for the code flash memory.

[Setting condition]

- Write 1 to the FENTRYC bit while writing to FENTRYR is enabled and FENTRYR is 0x0000.

[Clearing conditions]

- Write 8 bits to FENTRYR while the FRDY bit is 1
- A value other than 0xAA is specified in the KEY[7:0] bits and 16 bits are written to FENTRYR while the FRDY bit is 1
- Write 0 to the FENTRYC bit while writing to FENTRYR is enabled
- Write to FENTRYR while writing is enabled and its value is other than 0x0000
- The protection of FMEPROT register is enabled.

FENTRYD bit (Data Flash P/E Mode Entry)

The FENTRYD bit specifies P/E mode for the data flash memory.

[Setting condition]

- Write 1 to the FENTRYD bit while writing to FENTRYR is enabled and FENTRYR is 0x0000.

[Clearing conditions]

- Write 8 bits to FENTRYR while the FRDY bit is 1
- Writing of 16 bits to FENTRYR with a value other than 0xAA specified for the KEY[7:0] bits while the FRDY bit is 1
- Write 0 to the FENTRYD bit while writing to FENTRYR is enabled
- Write to FENTRYR while writing is enabled and its value is other than 0x0000.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the FENTRYD or FENTRYC bits.

47.4.21 FSUINTR : Flash Sequencer Setup Initialization Register

Base address: FACL = 0x4011_E000
 FACL_NS = 0x5011_E000

Offset address: 0x8C

Bit	Symbol	Function	R/W
0	SUNIT	Set-Up Initialization 0: The FSADDR, FEADDR, FBPROT0, FBPROT1, FENTRYR, FBCCNT, FCPSR, and FCNTSELR flash sequencer setup registers keep their current values 1: The FSADDR, FEADDR, FBPROT0, FBPROT1, FENTRYR, FBCCNT, FCPSR, and FCNTSELR flash sequencer setup registers are initialized.	R/W ^{1*2}
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
15:8	KEY[7:0]	Key Code	W*3

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 47.4.4. FSAR : Flash Security Attribution Register](#)

Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.

Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x2D.

Note 3. Written values are not retained by these bits (always read 0x00).

FSUINTR is used for initialization of the flash sequencer setup.

SUINIT bit (Set-Up Initialization)

The SUINIT bit initializes the following flash sequencer setup registers:

- FSADDR
- FEADDR
- FBPROT0
- FBPROT1
- FENTRYR
- FBCCNT
- FCPSR
- FCNTSELR

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the SUINIT bit.

47.4.22 FCMR : FACL Command Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0xA0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CMDR[7:0]								PCMDR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	PCMDR[7:0]	Pre-command Flag The command just before the latest command is stored.	R
15:8	CMDR[7:0]	Command Flag The latest command is stored.	R

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 47.4.4. FSAR : Flash Security Attribution Register](#)

FCMR records the two most recent commands accepted by the flash sequencer.

PCMDR[7:0] bits (Pre-command Flag)

The PCMDR[7:0] bits indicate the command received immediately before the latest command received by the flash sequencer.

CMDR[7:0] bits (Command Flag)

The CMDR[7:0] bits indicate the latest command received by the flash sequencer.

Table 47.9 States of FCMDR after receiving commands

Command	CMDR	PCMDR
Program	0xE8	Previous command
Block erase	0xD0	0x20
Multi block erase	0xD0	0x21
P/E suspend	0xB0	Previous command
P/E resume	0xD0	Previous command
Status Clear	0x50	Previous command
Forced Stop	0xB3	Previous command
Blank Check	0xD0	0x71
Configuration set	0x40	Previous command
Increment Counter	0xD0	0x35
Refresh Counter	0xD0	0x37
Read Counter	0xD0	0x39

47.4.23 FBCCNT : Blank Check Control Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0xD0

Bit position: 7 6 5 4 3 2 1 0

Bit field:	—	—	—	—	—	—	—	BCDIR
------------	---	---	---	---	---	---	---	-------

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	BCDIR	Blank Check Direction 0: Blank checking is executed from the lower addresses to the higher addresses (incremental mode) 1: Blank checking is executed from the higher addresses to the lower addresses (decremental mode).	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 47.4.4. FSAR : Flash Security Attribution Register](#)

FBCCNT specifies the addressing mode in processing the Blank Check command. FBCCNT is initialized when the SUNIT bit in FSUINTR is set to 1. It is also initialized by a reset.

BCDIR bit (Blank Check Direction)

The BCDIR bit specifies the addressing mode for Blank Check.

47.4.24 FBCSTAT : Blank Check Status Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0xD4

Bit position: 7 6 5 4 3 2 1 0

Bit field:	—	—	—	—	—	—	—	BCST
------------	---	---	---	---	---	---	---	------

Value after reset: 0 0 0 0 0 0 0 0

Bit	Symbol	Function	R/W
0	BCST	Blank Check Status Flag 0: The target area is in the non-programmed state, that is, the area has been erased but has not yet been reprogrammed 1: The target area has been programmed with 0s or 1s.	R
7:1	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-2
 Note: Associated SA: FSAR register. See [section 47.4.4. FSAR : Flash Security Attribution Register](#)

FBCSTAT stores the results of checking in response to the Blank Check command.

BCST flag (Blank Check Status Flag)

The BCST flag indicates the results of checking in response to the Blank Check command.

47.4.25 FPSADDR : Data Flash Programming Start Address Register

Base address: FACI = 0x4011_E000
 FACI_NS = 0x5011_E000

Offset address: 0xD8

Bit	Symbol	Function	R/W
16:0	PSADR[16:0]	Programmed Area Start Address The address of the first programmed area	R
31:17	—	These bits are read as 0. The write value should be 0.	R

Note: S-TYPE-3, P-TYPE-2
 Note: Associated SA: FSAR register. See [section 47.4.4. FSAR : Flash Security Attribution Register](#)

FPSADDR indicates the address of the first programmed area found in processing of the Blank Check command.

PSADR[16:0] bits (Programmed Area Start Address)

The PSADR[16:0] bits indicate the address of the first programmed area found in processing of the Blank Check command. The address is an offset from the address where the data flash memory starts. The setting of these bits is only valid if the BCST bit in the FBCSTAT register is 1 and while the FRDY bit in the FSTATR register is 1. When the BCST bit in the FBCSTAT register is 0, the PSADR[16:0] bits hold the address produced by the previous check.

47.4.26 FSUASMON : Flash Startup Area Select Monitor Register

Base address: FACI = 0x4011_E000
 FACI_NS = 0x5011_E000

Offset address: 0xDC

Bit	Symbol	Function	R/W
14:0	—	These bits are read as 0. The write value should be 0.	R
15	FSPR	Protection Programming Flag to set Boot Flag and Startup Area Control 0: Protected state 1: Non-protected state.	R
30:16	—	These bits are read as 0. The write value should be 0.	R
31	BTFLG	Flag of Startup Area Select for Boot Swap 0: The startup area is the alternate block (block 1) 1: The startup area is the default block (block 0).	R

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 47.4.4. FSAR : Flash Security Attribution Register](#).

FSPR bit (Protection Programming Flag to set Boot Flag and Startup Area Control)

The FSPR bit indicates the protection state against the configuration set command for the BTFLG bit, and FSUACR Register.

In response to a reset or configuration set command, the FSCI transfers data from flash memory to this register.

BTFLG bit (Flag of Startup Area Select for Boot Swap)

The BTFLG bit indicates whether the address of the startup area is exchanged for the boot swap function or not.

In response to a reset or configuration set command, the FSCI transfers data from flash memory to this register.

47.4.27 FCPSR : Flash Sequencer Processing Switching Register

Base address: FSCI = 0x4011_E000
FSCI_NS = 0x5011_E000

Offset address: 0xE0

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ESUS PMD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ESUSPMD	Erase Suspend Mode 0: Suspension priority mode 1: Erasure priority mode.	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 47.4.4. FSAR : Flash Security Attribution Register](#)

FCPSR selects the erasure suspension mode. FCPSR is initialized when the SUNIT bit in FSUNITR is set to 1. It is also initialized by a reset.

ESUSPMD bit (Erasure Suspend Mode)

The ESUSPMD bit selects the erasure suspension mode when a P/E suspend command is issued while the flash sequencer is executing erasure processing (see [section 47.9.3.10. P/E Suspend Command](#)). This bit should be set before issuing Block Erase or Multi Block Erase command.

47.4.28 FPCKAR : Flash Sequencer Processing Clock Notification Register

Base address: FACL = 0x4011_E000
FACL_NS = 0x5011_E000

Offset address: 0xE4

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]							PCKA[7:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0	0

Bit	Symbol	Function	R/W
7:0	PCKA[7:0]	Flash Sequencer Operating Clock Notification These bits are used to set the operating frequency of the flash sequencer while processing FACL commands.	R/W ^{*1,2}
15:8	KEY[7:0]	Key Code	W ^{*3}

Note: S-TYPE-3, P-TYPE-2

Note: Associated SA: FSAR register. See [section 47.4.4. FSAR : Flash Security Attribution Register](#)

Note 1. This bit can be written when the FRDY bit in the FSTATR register is 1. Writing to this bit is ignored when the FRDY bit is 0.

Note 2. Writing to these bits is only possible when 16 bits are written and the value written to the KEY[7:0] bits is 0x1E.

Note 3. Written values are not retained by these bits (always read 0x00).

FPCKAR specifies the operating frequency of the flash sequencer while processing FACL commands. The highest operating frequency for the given product is set as the initial value.

PCKA[7:0] bits (Flash Sequencer Operating Clock Notification)

The PCKA[7:0] bits specify the operating frequency of the flash sequencer while processing FACL commands. Set the desired frequency for these bits before issuing an FACL command. Specifically, convert the frequency in MHz to a binary number and set it for these bits.

Example:

Frequency is 35.9 MHz (PCKA = 0x24)

Round up the first decimal place of 35.9 MHz to a whole number (= 36) and convert it into a binary number.

If the value set in these bits is smaller than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics cannot be guaranteed. If the value set in these bits is greater than the actual operating frequency of the flash sequencer, the flash memory programming/erasure characteristics can be guaranteed but the FACL command processing time such as the time programming/erasure takes will increase. The minimum FACL command processing time is obtained when the operating frequency of the flash sequencer is the same as the PCKA value.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the PCKA bit.

47.4.29 FSUACR : Flash Startup Area Control Register

Base address: FACL = 0x4011_E000

Offset address: 0xE8

Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	KEY[7:0]							—	—	—	—	—	—	SAS[1:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	SAS[1:0]	Startup Area Select 0 0: Startup area is selected by BTFLG bit 0 1: Startup area is selected by BTFLG bit 1 0: Startup area is temporarily switched to the default area (block 0) 1 1: Startup area is temporarily switched to the alternate area (block 1).	R/W ^{*1} *3
7:2	—	These bits are read as 0. The write value should be 0.	R/W
15:8	KEY[7:0]	Key Code	W ^{*2}

Note: S-TYPE-6, P-TYPE-2

Note 1. Following described the write condition of these bits (these conditions are required at the same time).

1. Access size to this register is 16 bits
2. The value of KEY[7:0] is 0x66
3. The FSPR bit is 1.

Note 2. Written values are not retained by these bits (always read 0x00).

Note 3. Only Secure access can write to this register. Both Secure access and Non-secure read access are allowed. Non-secure write access is denied, but TrustZone access error is not generated.

FSUACR sets the startup area for the boot swap function. Do not use this register in dual mode (the DUALSEL.BANKMD[2:0] bits are 000b). In dual mode, starting up proceeds from startup area 0.

SAS[1:0] bits (Startup Area Select)

The SAS[1:0] bits select the startup area. Three methods are available for changing the startup area.

KEY[7:0] bits (Key Code)

The KEY[7:0] bits control writing permission to the SAS [1:0] bits.

47.4.30 FCKMHZ : Data Flash Access Frequency Register

Base address: FLAD = 0x4011_C000
FLAD_NS = 0x5011_C000

Offset address: 0x40

Bit position: 7 6 5 4 3 2 1 0

Bit field: FCKMHZ[7:0]

Value after reset: 0 0 1 1 1 1 0 0

Bit	Symbol	Function	R/W
7:0	FCKMHZ[7:0]	Data Flash Access Frequency Register These bits optimize the speed of reading the data flash memory.	R/W

Note: S-TYPE-3, P-TYPE-2

Note: If the security attribution is configured as Secure:

- Secure access and Non-secure read access are allowed
- Non-secure write access is ignored, and TrustZone access error is not generated.

If the security attribution is configured as Non-secure:

- Secure and Non-secure access are allowed.

This register optimizes the speed of reading the data flash memory.

Set the frequency of the peripheral module clock (FCLK) of internal peripheral bus which is the clock for access to the data flash memory, in MHz units. For example, 35.9 MHz should be rounded up and set the frequency to 36. Number of cycles required for access to the data flash memory are inserted according to the frequency. When changing the frequency of the FCLK, follow the procedure below to modify the value of the data flash access frequency register (FCKMHZ) in either of the following ways according to whether operation is at a lower frequency before or after the change.

- When changing the speed from low to high: Modify FCKMHZ. After confirming the change by reading FCKMHZ, change the frequency.
- When changing the speed from high to low: Change the frequency. After the frequency is changed, modify FCKMHZ.

47.5 Flash Cache

47.5.1 Feature of flash cache

The FCACHE (Flash Cache) speeds up read access from bus master to the flash memory. The FCACHE includes:

- FCACHE1, for CPU instruction fetches
- FCACHE2, for CPU operand access and access from DMAC/DTC
- FLPF, for the prefetch access in CPU instruction fetches

Table 47.10 Flash Cache 1 (FCACHE1) overview

Cache Target Region	Secure alias : 0x0200_0000 - 0x020F_FFFF Non-secure alias : 0x1200_0000 - 0x120F_FFFF
Target Bus Master	CPU instruction Fetch
Capacity	256 Bytes
Associativity	8WAY set associative
	128 bits/entry (128 bit aligned data), 2 entries/way
Access Cycle	Cache Hit : 0 wait Cache Miss : wait number of Flash Wait Cycle Register

Table 47.11 Flash Cache 2 (FCACHE2) overview

Cache Target Region	Secure alias : 0x0200_0000 - 0x020F_FFFF Non-secure alias : 0x1200_0000 - 0x120F_FFFF
Target Bus Master	CPU Operand Access and Access from other than CPU
Capacity	16 Bytes
Associativity	Full Associative
	128 bits/entry (128 bit aligned data), 1 entry
Access Cycle	Cache Hit : 0 wait Cache Miss : wait number of Flash Wait Cycle Register

Table 47.12 Prefetch Buffer (FLPF) overview

Cache Target Region	Secure alias : 0x0200_0000 - 0x020F_FFFF Non-secure alias : 0x1200_0000 - 0x120F_FFFF
Capacity	32 Bytes
Associativity	Full Associative
	128 bits/entry (128 bit aligned data), 2 entries
Request Address	Next address of previous CPU Instruction
Access Cycle	Cache Hit : 0 wait Cache Miss : wait number of Flash Wait Cycle Register

Figure 47.5 Block diagram of FCACHE

47.6 Operating Modes Associated with Flash Memory

Figure 47.6 is a diagram of the mode transitions associated with the flash memory. For the procedures for setting the modes, see section 6, Option-Setting Memory.

Figure 47.6 Mode Transitions Associated with Flash Memory

The flash memory area where programming and erasure are permitted and the boot program after a reset are different according to each mode. The differences between modes are listed in [Table 47.13](#).

Table 47.13 Differences between Modes

Parameter	Normal operating mode	Serial programming mode (SCI or USB boot mode)	On-chip debug mode (JTAG or SWD boot mode)
Programmable and erasable areas	<ul style="list-style-type: none"> Code flash memory Data flash memory Option setting memory (programming only) 	<ul style="list-style-type: none"> Code flash memory Data flash memory Option-setting memory (programming only) 	<ul style="list-style-type: none"> Code flash memory Data flash memory Option setting memory (programming only)
Erasure in block units	Possible	Possible	Possible
Boot program at a reset	User area program	Embedded program for serial programming	Depends on debug command

47.7 Overview of Functions

By using a dedicated flash-memory programmer to program the flash memory through a serial interface (serial programming) or JTAG/SWD interface (on-chip debug mode), the device can be rewritten regardless of whether this is before or after it is mounted on the target system.

Furthermore, security functions to prohibit rewriting or reading of the user program written to the flash memory are incorporated, and this can prevent falsification and illicit reading of the programs by third parties.

Programming by the user program (self-programming) is available to suit applications where the application on the target system may require updating after manufacturing or shipment. Protection features for the safe rewriting of the flash memory are also incorporated. Furthermore, interrupt processing during self-programming is supported, so programming can proceed at the same time as processing for external communications, etc., and this is the case in various situations. [Table 47.14](#) lists the overview of the methods of programming and the corresponding operating modes.

Table 47.14 Programming methods

Programming method	Functional overview	Operating mode
Serial programming	A dedicated flash-memory programmer through the SCI or USBFS interface enables on-board programming of the flash memory after the device is mounted on the target system.	Serial programming mode
	A dedicated flash-memory programmer through the SCI or USBFS interface and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system.	
Self-programming	<p>A user program written to memory in advance of serial programming execution can also program the flash memory. The background operation capability makes it possible to fetch instructions or otherwise read data from the code flash memory while the data flash memory is programmed. As a result, a program resident in the code flash memory is able to program the data flash memory.</p> <p>For background operations that are not possible, instructions in the code flash memory cannot be fetched and data cannot be accessed while the code flash memory is being programmed by self-programming. In such cases, a program for programming from the internal SRAM or external memory must be transferred in advance and executed.</p>	Normal operating mode
JTAG or SWD programming	<p>A dedicated flash-memory programmer or an on-chip debugger through JTAG or SWD enables on-board programming of the flash memory after the device is mounted on the target system.</p> <p>A dedicated flash-memory programmer or an on-chip debugger through JTAG or SWD and a dedicated programming adapter board allow off-board programming of the flash memory, for example, programming of the device before it is mounted on the target system.</p>	On-chip debug mode

[Table 47.15](#) lists the functions of the flash memory. Serial programmer commands realize each function of serial programming, while reading of the flash memory by an FACI command or the user program realizes each function of self-programming.

Table 47.15 Basic Functions

Function	Functional overview	Availability	
		Serial programming	Self-programming
Blank check	Checks a specified block to ensure that writing to it has not already proceeded. Results of reading from data flash memory to which nothing is written after erasure are not guaranteed, so use blank checking to confirm that writing to memory has not proceeded after erasure.	Not supported	Supported (data flash programming only)
Block erasure	Erases the memory contents in the specified block	Supported	Supported
Programming	Writes to the specified address	Supported	Supported
CRC	Calculates the CRC in the specified range of the flash memory and transfers it to the flash programmer	Supported	Not supported
Read	Reads data programmed in the flash memory	Supported	Not supported (read by user program is possible)
Start-up program protection functions	Configures the start-up program protection functions	Supported	Supported
Option function selection	Selects the option function, and modifies the initial setting of this MCU	Supported	Supported
Dual bank function	Switches different modes (linear or dual)	Supported	Supported
Block swap function	Setting block swap functions	Supported	Supported
Block protection	Setting block protection	Supported	Supported
Device lifecycle transition	Transitions the device lifecycle	Supported	Not supported
Memory security attribution	Setting the memory security attribution	Supported	Not supported
Key	Injects key	Supported	Supported (except the key related to device lifecycle transition)
All erasure	Erase the flash memory to the state after shipment	Supported	Not supported

The flash memory supports various security functions.

[Table 47.16](#) lists the security functions supported by the flash memory.

Table 47.16 Lists of Security Functions

Function	Description
Security flag for Start-up area select	Start-up area selection can be protected by setting of security flag (FSPR).
Permanently block protection	Programming or erasure of each block of code flash memory can be protected permanently.
Protection for TrustZone	Programming or erasure area, readable area, register access, and FACI command operation are protected by ARM TrustZone security.
Data flash configuration area protection	When target area of configuration set command includes protection area by lock bit, flash sequencer detects an error and enters command lock state.
Anti-rollback Counter	Anti-rollback counter used only by Secure applications for firmware updates.
Programming or erasure mode protection	Only Secure developer can enter the programming or erasure mode for code flash.

47.8 Operating Modes of the Flash Sequencer

The flash sequencer has three operating modes as shown in [Figure 47.7](#). Transitions between modes are initiated by changing the value of the FENTRYR register.

When the value of the FENTRYR register is 0x0000, the flash sequencer is in read mode. In this mode, it does not receive FACI commands. The code flash memory and data flash memory are both readable.

When the value of the FENTRYR register is 0x0001, the flash sequencer is in code flash P/E mode where the code flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is readable. In addition, the code flash memory is not readable if background operation (BGO) is disabled. If BGO is enabled, the code flash memory

that is not selected by FSADDR register is readable when the FRDY bit in the FSTATR register is 0. As for the condition for enabling BGO, see [section 47.15.2. Background Operation](#).

When the value of the FENTRYR register is 0x0080, the flash sequencer is in data flash P/E mode where the data flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is not readable. However, the code flash memory is readable.

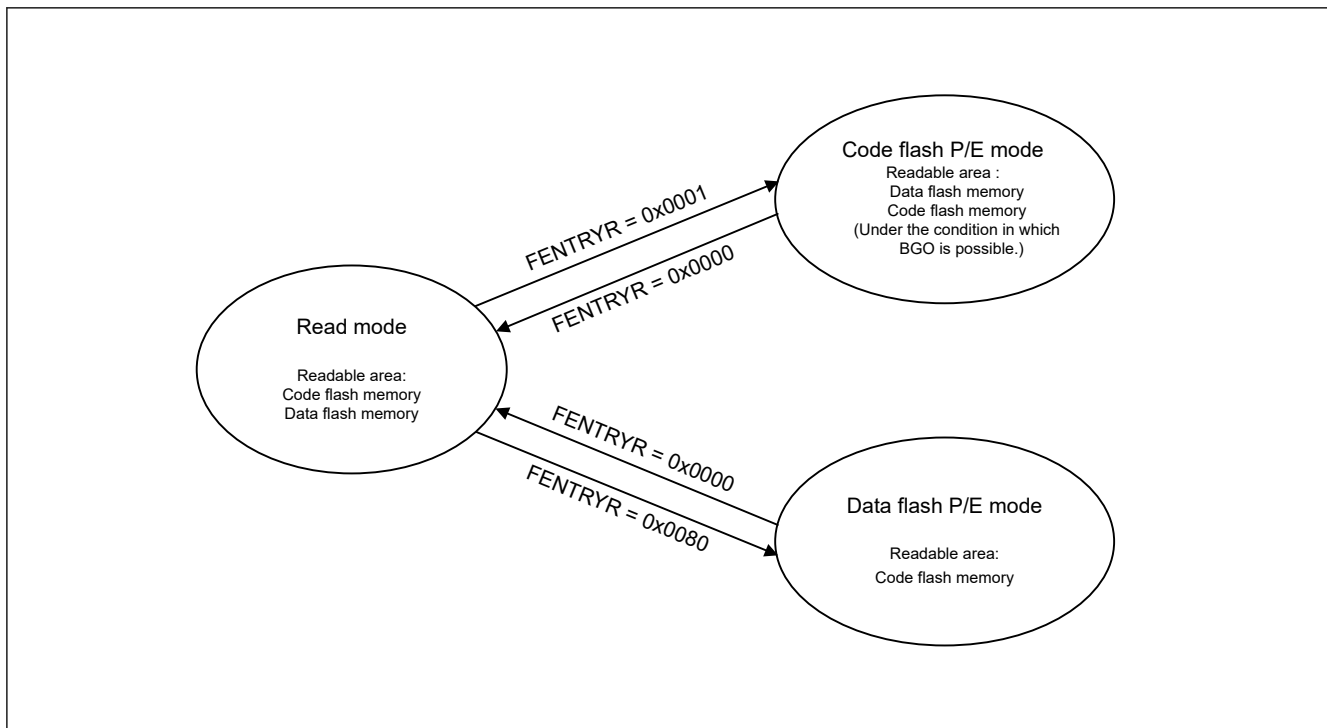

Figure 47.7 Modes of the flash sequencer

47.9 FACI Commands

47.9.1 List of FACI Commands

The FACI controls the FCU according to the specified FACI commands.

This section describes information about the FACI commands and [Table 47.17](#) lists the FACI commands.

Table 47.17 FACI commands (1 of 2)

FACI command	Function
Program	Programs the user area and data area. Units of programming are 128 bytes for the user area and 4, 8, or 16 bytes for the data area.
Block erase	Erases user area and data area. The erase unit is 8 KB or 32 KB for user area, and 64 bytes for data flash.
Multi block erase	Erases data area. The erase unit is 64, 128, 256 bytes for data flash.
P/E suspend	Suspends programming or erasure processing.
P/E resume	Resumes suspended programming or erasure processing.
Status clear	Initializes the IGLERR, ERSERR, PRGERR, ILGCOMERR, FESETERR, SECERR, and OTERR bits in the FSTATR register and the CMDLK, CFAE, OTERR and TZFERR bits in the FASTAT register, and the flash sequencer released from command-locked state.

Table 47.17 FACI commands (2 of 2)

FACI command	Function
Forced stop	Forcibly stops processing of FACI commands and initializes the FSTATR and FASTAT registers.
Blank check	Checks if data areas are blank. Units of Blank Check: 4 bytes to data flash memory capacity (specified in 4-byte units).
Configuration set	Sets the option-setting memory. Units of setting: <ul style="list-style-type: none"> • 16 bytes (Code flash memory) • 4/16 bytes (Data flash memory)
Increment Counter (Secure access only)	Increments Anti-rollback counter value . The target of counter is selected by FCNTSELR register. Update data unit is 1bit.
Refresh Counter recovery flow (Secure access only)	This is used to anti-rollback counter recovery flow. The target of counter is selected by FCNTSELR register. This command can refresh anti-rollback counter area without increasing counter value.
Read Counter (Secure access only)	Read Anti-rollback counter value. The target of counter is selected by FCNTSELR register. Reading data is output to FCNTDATAR0 and FCNTDATAR1 registers. Read unit is 64bit.

The FACI commands are issued by writing to the FACI command-issuing area (see [Table 47.4](#)). When write access as shown in [Table 47.18](#) proceeds in the specified state, the flash sequencer executes the processing associated with the given command (see [section 47.9.2. Relationship between the Flash Sequencer State and FACI Commands](#)).

Table 47.18 FACI command formats (1 of 2)

FACI commands	Number of write access	Write data to the FACI command-issuing area			
		1st access	2nd access	3rd to (N+2)th access	(N+3)th access
Program (user area) N = 64	67	0xE8	0x40 (=N)	WD1 to WD64	0xD0
Program (data area) 4-byte programming: N = 2 8-byte programming: N = 4 16-byte programming: N = 8	N+3	0xE8	0x02 (=N) 0x04 (=N) 0x08 (=N)	WD1 to WDN	0xD0
Block Erase (user area 8K/32K Bytes)	2	0x20	0xD0	—	—
Block Erase (data area 64 bytes)	2	0x20	0xD0	—	—
Multi block erase (data area 64/128/256 bytes)	2	0x21	0xD0	—	—
P/E suspend	1	0xB0	—	—	—
P/E resume	1	0xD0	—	—	—
Status Clear	1	0x50	—	—	—
Forced Stop	1	0xB3	—	—	—
Blank Check	2	0x71	0xD0	—	—
Configuration set (Code flash memory) N = 8	11	0x40	0x08 (=N)	WD1 to WD8	0xD0
Configuration set (Data flash memory) N = 2 (4 Bytes) N = 8 (16 Bytes)	N+3	0x40	0x02 (=N) 0x08 (=N)	WD1 to WDN	0xD0
Increment Counter	2	0x35	0xD0	—	—

Table 47.18 FACI command formats (2 of 2)

FACI commands	Number of write access	Write data to the FACI command-issuing area			
		1st access	2nd access	3rd to (N+2)th access	(N+3)th access
Refresh Counter	2	0x37	0xD0	—	—
Read Counter	2	0x39	0xD0	—	—

Note: WDN (N = 1, 2, ...): Nth 16-bit data to be programmed.

The flash sequencer clears the FSTATR.FRDY bit to 0 at the start of a command processing other than the Status Clear command, and sets this bit to 1 on completion.

If the FRDYIE.FRDYIE bit setting is 1, a flash ready (FRDY) interrupt is generated when the FSTATR.FRDY bit is set to 1.

47.9.2 Relationship between the Flash Sequencer State and FACI Commands

The FACI commands are accepted according to the mode/state of the flash sequencer. FACI commands should be issued after transitioning of the flash sequencer to the code flash P/E mode or data flash P/E mode and after checking the state of the flash sequencer.

Use the FSTATR and FASTAT registers to check the state of the flash sequencer. In addition, the occurrence of errors in general can be checked by reading the CMDLK bit in the FASTAT register. The value of the CMDLK bit is the logical OR of the following bits in the FSTATR register:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- TZFERR
- ERSERR
- PRGERR
- FLWEERR.

Table 47.19 lists the available FACI commands in each operating mode.

Table 47.19 Operating mode and available FACI commands

Operating mode	FENTRYR	Available FACI commands
Read mode	0x0000	None
Code flash P/E mode	0x0001	Program Block erase P/E suspend P/E resume Status Clear Forced Stop Configuration set
Data flash P/E mode	0x0080	Program Block erase Multi block erase P/E suspend P/E resume Status Clear Forced Stop Blank Check Configuration set Increment Counter Refresh Counter Read Counter

Table 47.20 shows the state of the flash sequencer and acceptable FACI commands. An appropriate mode is assumed to have been set before the commands are executed.

Table 47.20 Acceptable FACI commands and state of the flash sequencer

	Program, block erase or multi block erase command processing	Configuration set, configuration clear, increment counter, refresh counter or read counter command processing	Program, block erase or multi block erase command suspension processing	Blank check command processing	Programming suspended	Erasure suspended	Programming while erasure is suspended	Command-locked state (FRDY = 1)	Command-locked state (FRDY = 0)	Processing of forced stop command	Other state
FRDY bit	0	0	0	0	1	1	0	1	0	0	1
SUSRDY bit	1	0	0	0	0	0	0	0	0	0	0
ERSSPD bit	0	0	0/1	0/1	0	1	1	0/1	0/1	0	0
PRGSPD bit	0	0	0/1	0/1	1	0	0	0/1	0/1	0	0
CMDLK bit	0	0	0	0	0	0	0	1	1	0	0
Program	X	X ^{*3}	X	X	X	O ^{*2}	X	X	X	X	O
Block erase or multi block erase	X	X ^{*3}	X	X	X	X	X	X	X	X	O
P/E suspend	O	X ^{*3}	X	X	X	X	X	—	X	X	—
P/E resume	X	X ^{*3}	X	X	O	O	X	X	X	X	X
Status clear	X	X ^{*3}	X	X	O	O	X	O	X	X	O
Forced stop	O	O ^{*3}	O	O	O	O	O	O	O	O	O
Blank check	X	X ^{*3}	X	X	O ^{*1}	O ^{*1}	X	X	X	X	O ^{*1}
Configuration set	X	X ^{*3}	X	X	X	X	X	X	X	X	O
Increment Counter	X	X ^{*3}	X	X	X	X	X	X	X	X	O ^{*1}
Refresh Counter	X	X ^{*3}	X	X	X	X	X	X	X	X	O ^{*1}
Read Counter	X	X ^{*3}	X	X	X	X	X	X	X	X	O ^{*1}

Note: O: Acceptable
 X: Not acceptable (places the sequencer in the command-locked state)
 —: Ignored

Note 1. Only acceptable in data flash P/E mode.

Note 2. Acceptable when programming area is other than erase suspending block.

Note 3. When configuration set is processing and when FSTATR.DBFULL bit is 1, do not issue this command.

47.9.3 Usage of FACI Commands

47.9.3.1 Overview of Command Usage in Code Flash P/E Mode

Figure 47.8 show an overview of FACI command usage in code flash P/E mode. For the available commands in code flash P/E mode, see Table 47.19.

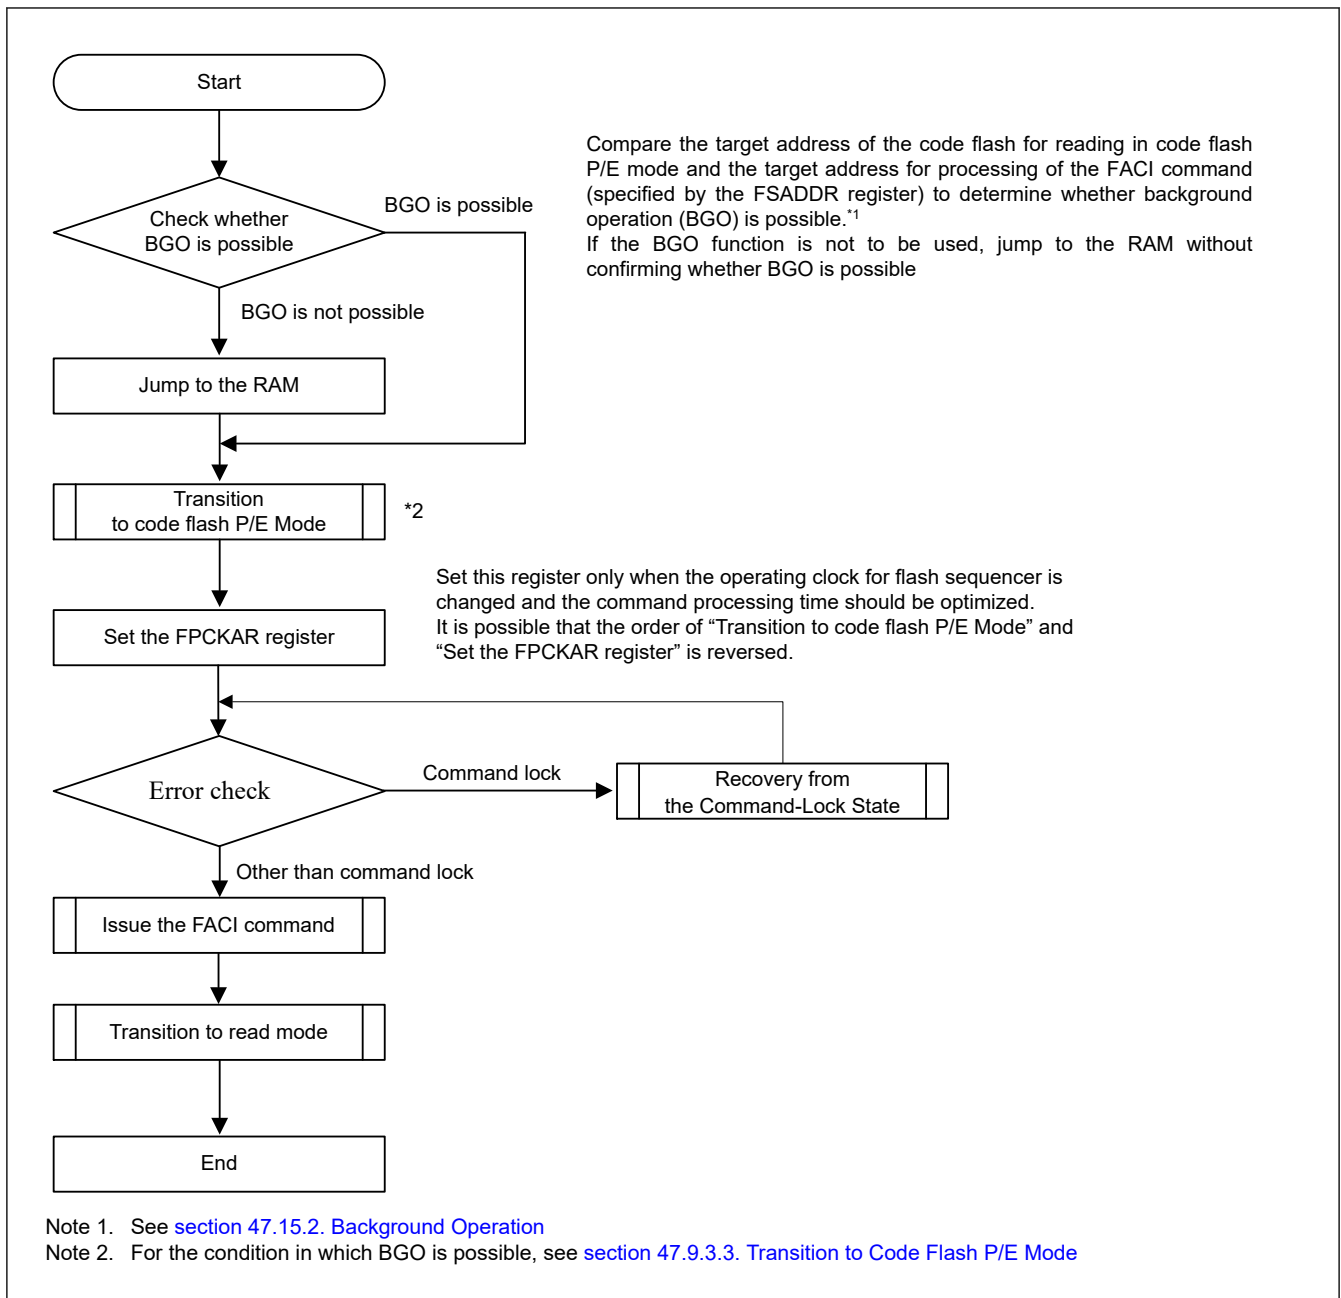

Figure 47.8 Overview of command usage in code flash P/E mode

47.9.3.2 Overview of Command Usage in Data Flash P/E Mode

Figure 47.9 shows an overview of FACL command usage in data flash P/E and Table 47.19 lists the available commands in data flash P/E mode.

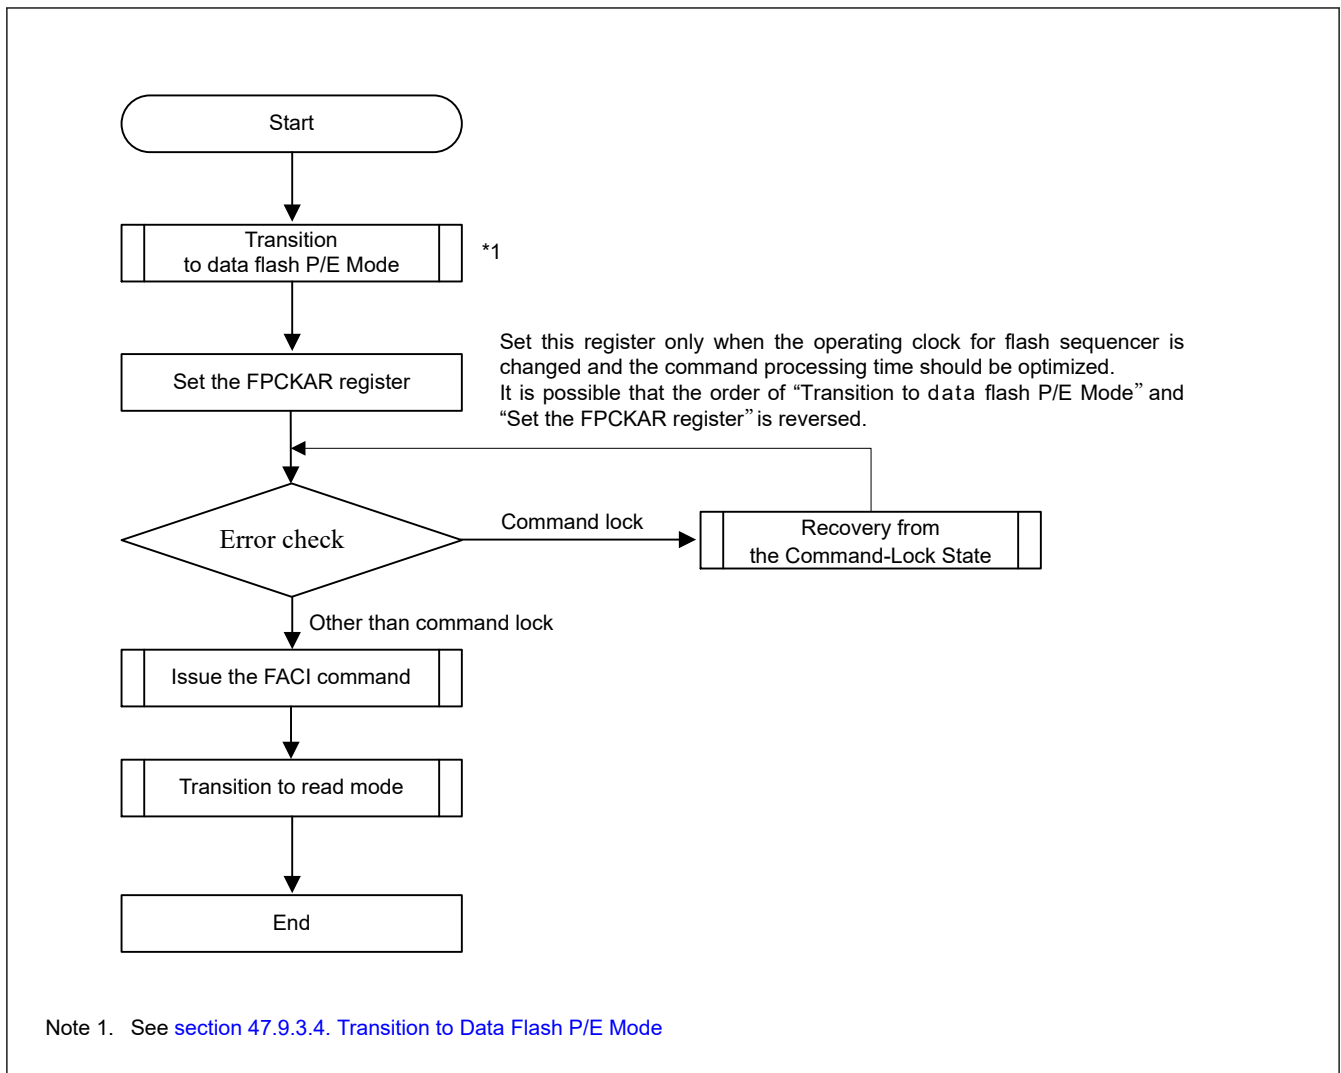

Figure 47.9 Overview of command usage in data flash P/E mode

47.9.3.3 Transition to Code Flash P/E Mode

To issue FACL commands for the code flash memory, a transition to code flash P/E mode is required by setting the FENTRYC bit in the FENTRYR register to 1.

Figure 47.10 shows the procedure to transition to code flash P/E mode.

Figure 47.10 Procedure to transition to code flash P/E mode

47.9.3.4 Transition to Data Flash P/E Mode

To issue FACY commands for the data flash memory, a transition to data flash P/E mode is required by setting the FENTRYD bit in the FENTRYR register to 1.

Figure 47.11 shows the procedure to transition to data flash P/E mode.

Figure 47.11 Procedure to transition to data flash P/E mode

47.9.3.5 Transition to Read Mode

To read the flash memory, a transition to read mode is required by setting the FENTRYR register to 0x0000. The transition to read mode should be made after the flash sequencer completes the processing and while operation is not in the command-locked state.

Figure 47.12 shows the procedure to transition to read mode.

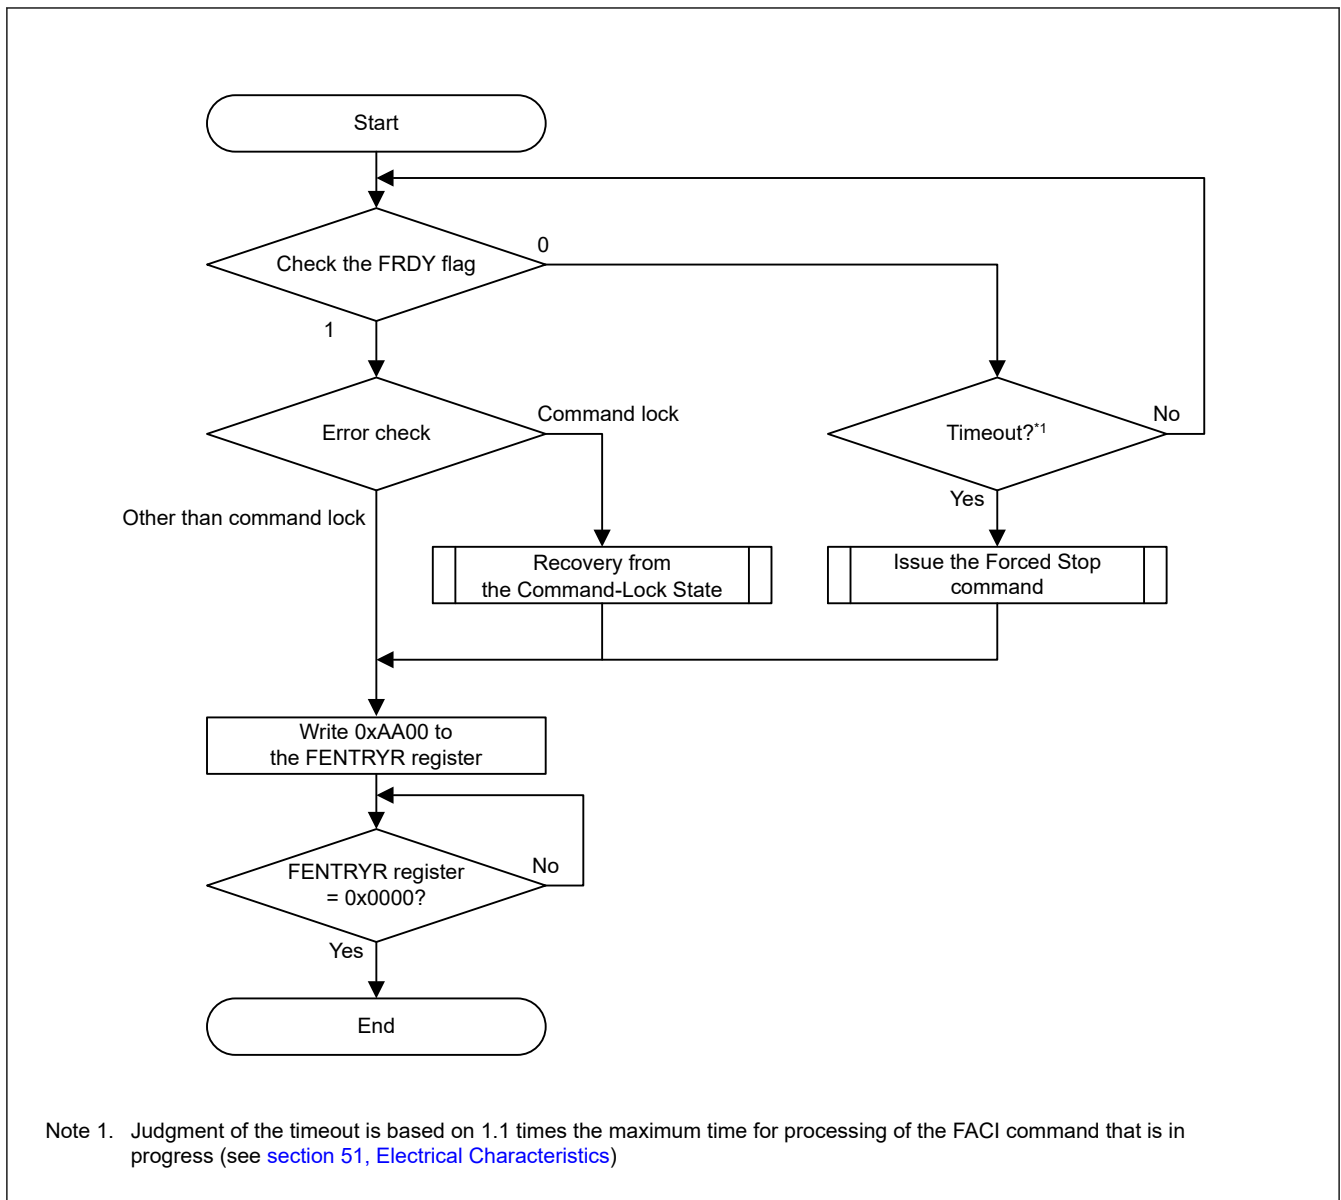

Figure 47.12 Procedure to transition to read mode

47.9.3.6 Recovery from the Command-Locked State

When the flash sequencer enters the command-locked state, FACL commands cannot be accepted. To release the sequencer from the command-locked state, use the status clear command, forced stop command, or FASTAT register.

When the command-locked state is detected by checking for an error before issuing the P/E suspend command, the FRDY bit in the FSTATR register might be 0 even though command processing has not completed. If processing is not complete by the maximum programming/erasure time specified in the electrical characteristics, this is a timeout and the flash sequencer must be stopped with the forced stop command.

The FLWEERR bit in the FSTATR register does not change from 1 to 0 with the status clear command. When these bits are set to 1, use the forced stop command to release from the command-locked state. Bits other than FRDY and FLWEERR in FSTATR register that indicate the command-locked state can be changed from 1 to 0 with the status clear or forced stop command.

[Figure 47.13](#) shows the recovery flow from the command-locked state.

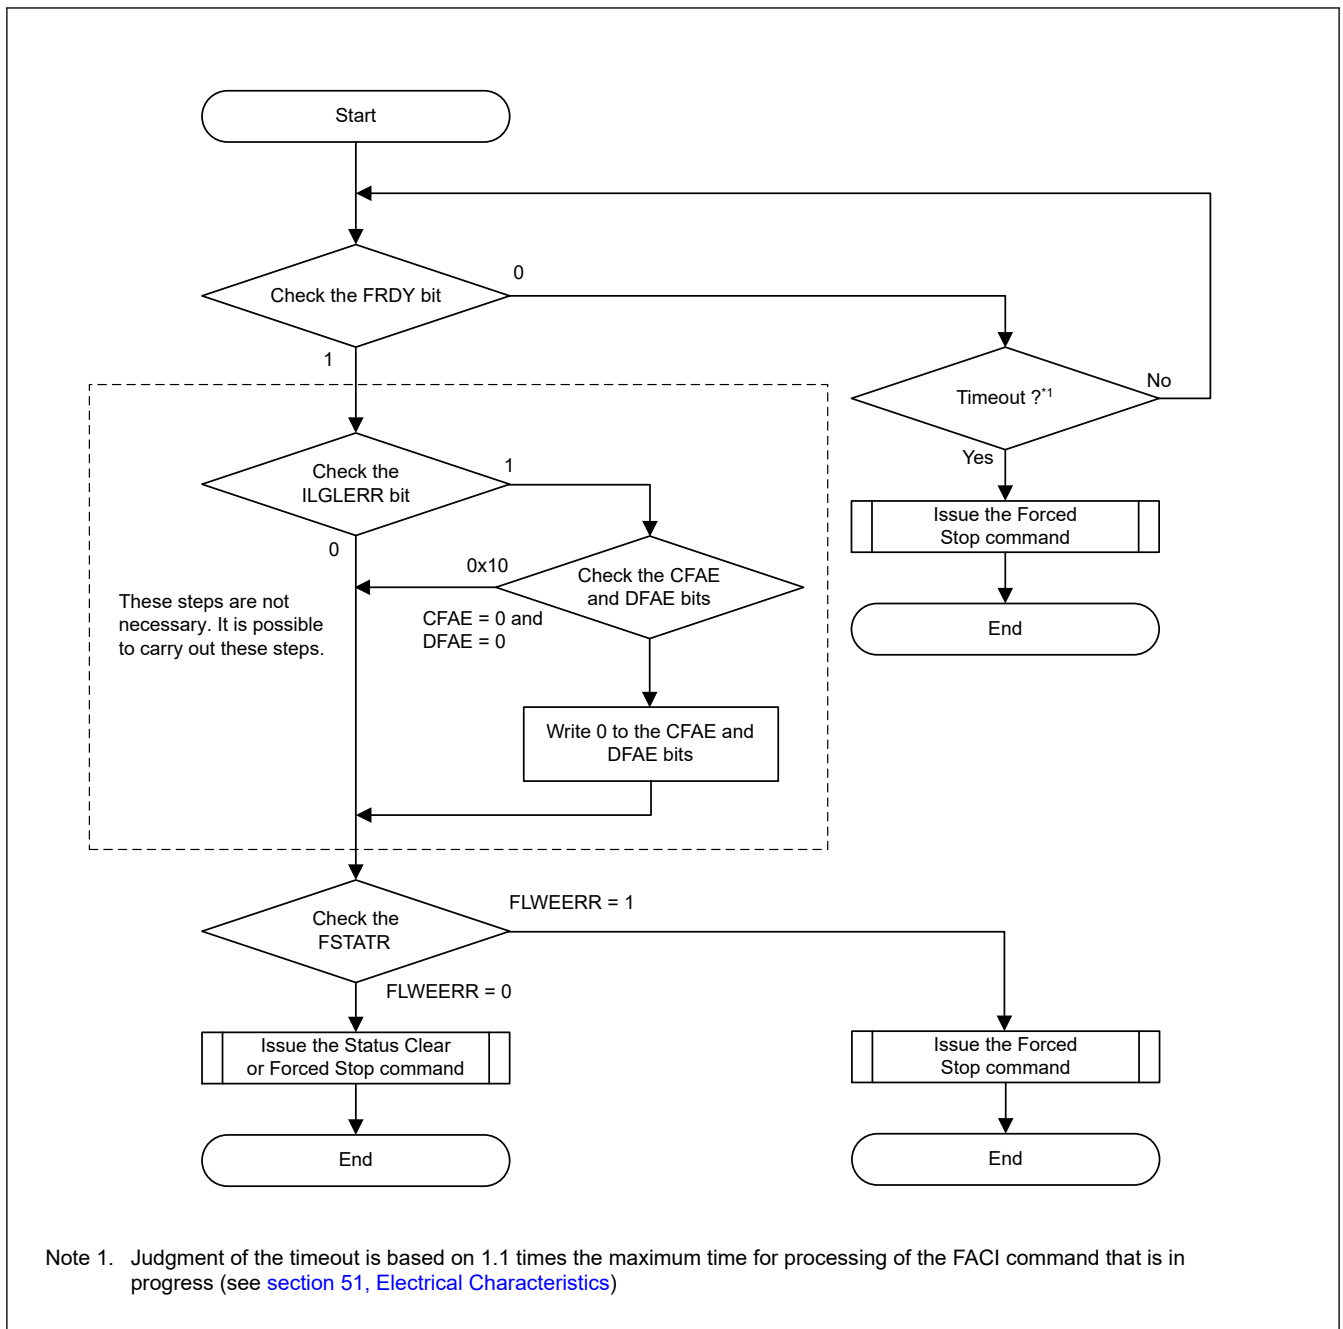

Figure 47.13 Recovery flow from the command-locked state

47.9.3.7 Program Command

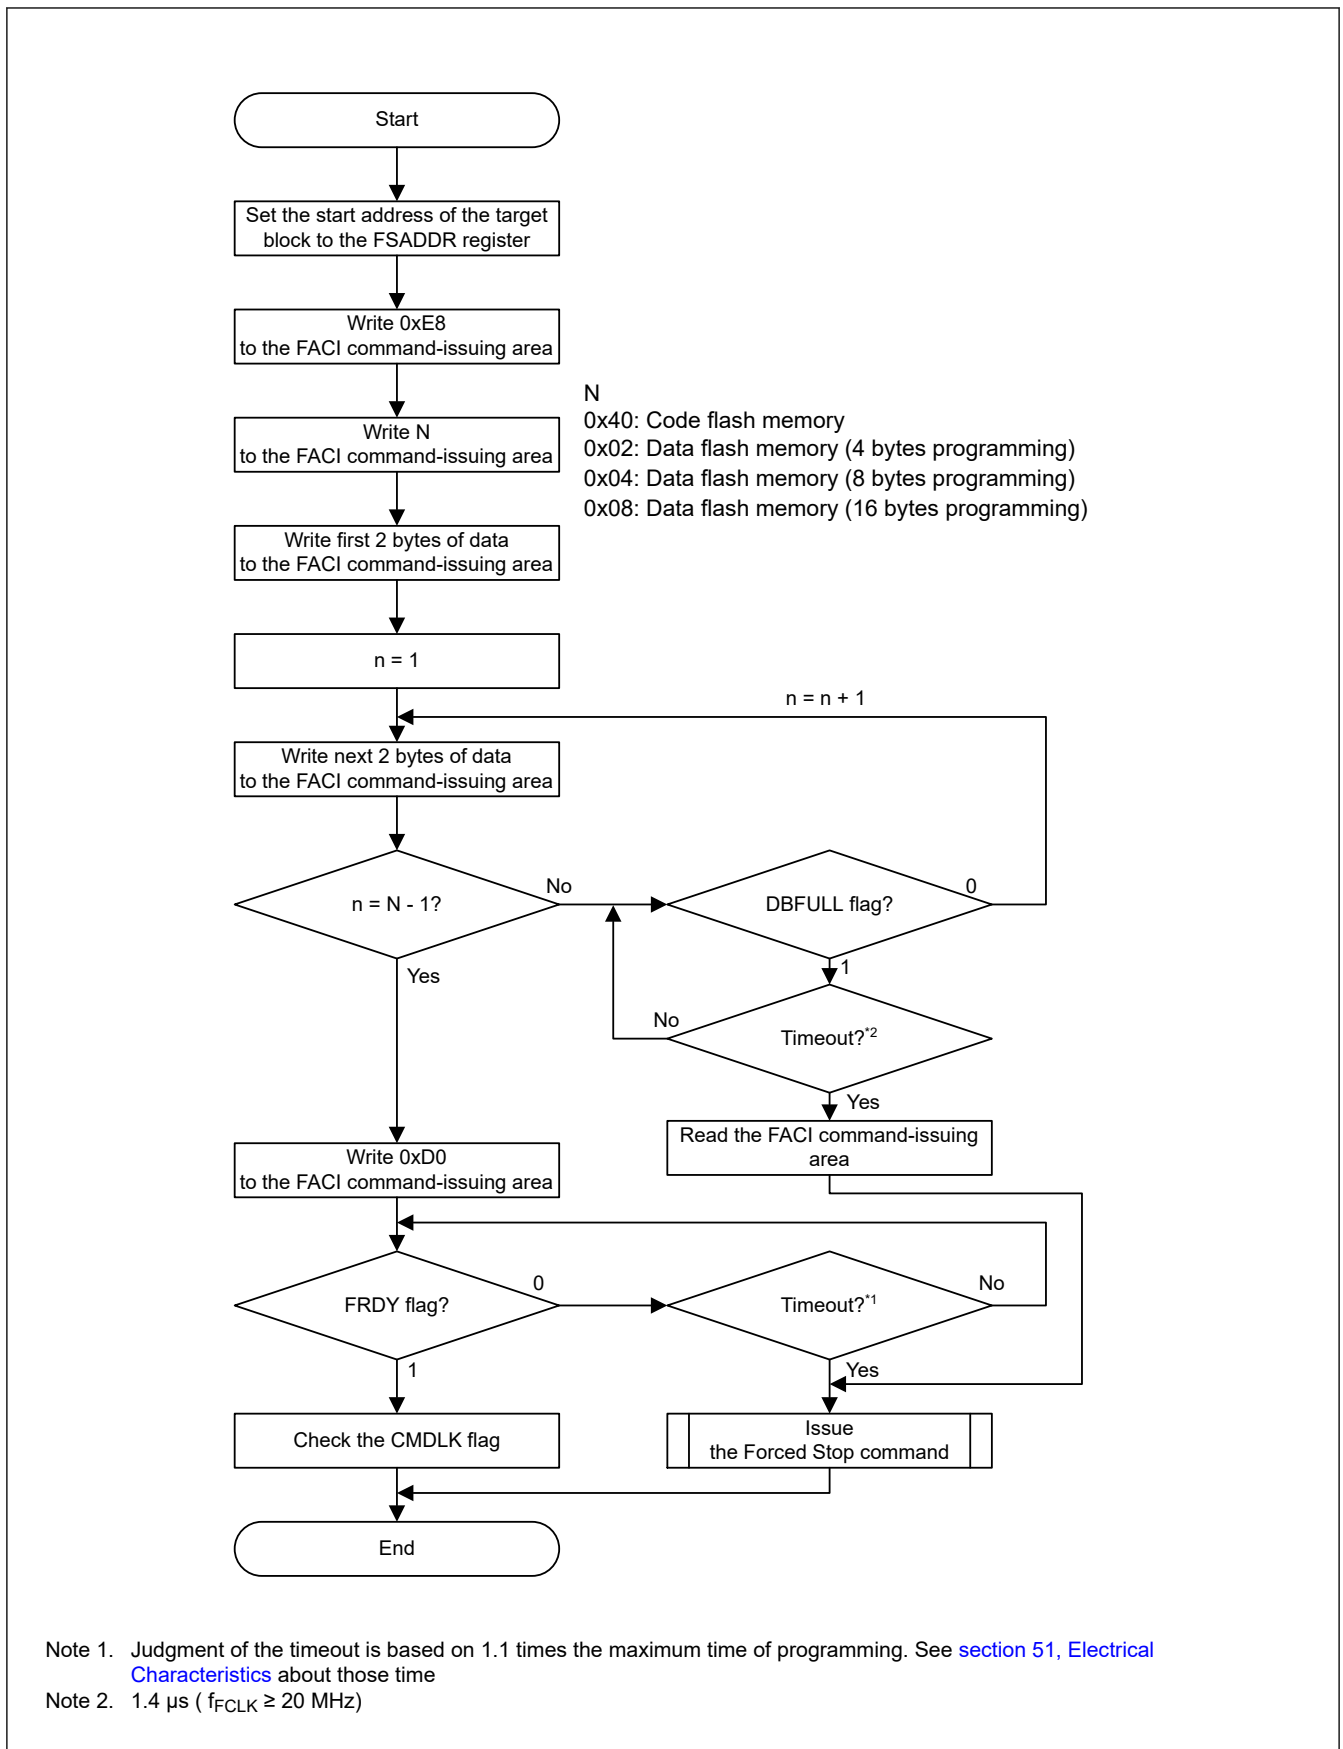

Program commands are used to write to the user and data areas. Before issuing the FACI program command, set the first address of the target block in the FSADDR register.

Program processing is started by writing the last 16 bits of program data (WD64 for code flash and WD2, WD4, and WD8 for data flash in Table 47.18) to the FACI command-issuing area before 0xD0, the final value of the FACI command, is written. Therefore, if it takes time from writing the last 16 bits of program data to writing the final FACI command value 0xD0 (for example, due to interrupt processing), the FSTATR.FRDY bit is set to 1 when program processing is completed even if 0xD0 has not been written. In this case, the program processing has been completed, but the FACI command reception has not been completed. If a subsequent FACI command is issued in this state, an illegal command error will occur. To avoid illegal command errors, disable interrupts with processing that issues FACI commands while program commands are issued (from writing 0xE8 to writing 0xD0).

If the target area for program command processing includes an area that is not for writing, write 0xFFFF to the corresponding area. If a program command is issued while the FACI internal data buffer is full, a wait period may occur on

the peripheral bus, which may affect the communication performance of other peripheral modules. To avoid the occurrence of a waiting period, set the DBFULL bit in the FSTATR register to 0 when issuing a FOCI command. Writing to the data area will not cause the data buffer to become full.

[Figure 47.14](#) shows the usage of the program command.

Note 1. Judgment of the timeout is based on 1.1 times the maximum time of programming. See [section 51, Electrical Characteristics](#) about those time

Note 2. 1.4 μs (f_{CLK} ≥ 20 MHz)

Figure 47.14 Usage flow of the program command

47.9.3.8 Block Erase Command

The block erase command is used for erasing user area or data area. The erase unit is one block. Before issuing a block erase command, set the first address of the target block to FSADDR register. Writing 0xD0 at the second write access of the FACL command triggers the FACL to start the block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Set the FCPSR registers before issuing the block erase command. Additionally, FCPSR must be set when the erasure-suspended mode is to be switched.

Figure 47.15 shows the usage of the block erase command.

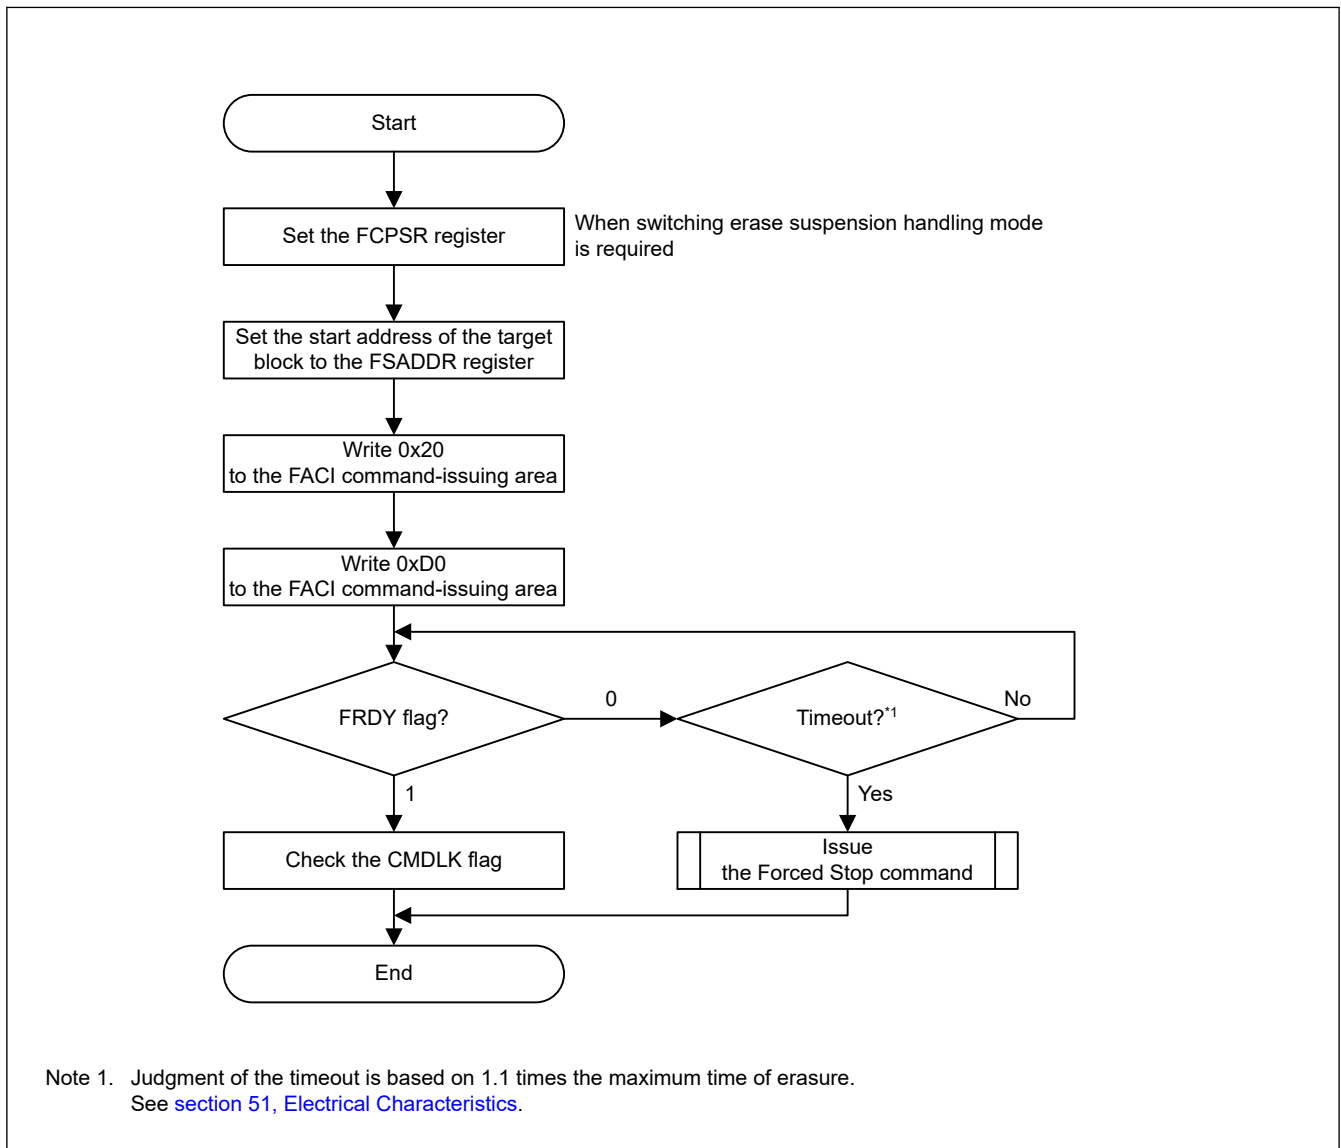

Figure 47.15 Usage flow of the block erase command

47.9.3.9 Multi Block Erase Command

The multi block erase command is used for erasing data area. The erase unit is 64, 128, or 256 bytes. Before issuing the multi block erase command, set the start address to FSADDR register and the end address to FEADDR register. Writing 0xD0 at the second write access of the FACL command triggers FACL to start the multi block erase command processing. Completion of command processing can be confirmed with the FRDY bit of FSTATR register.

Set the FCPSR registers before issuing the multi block erase command. Additionally, FCPSR must be set when the erasure-suspended mode is to be switched.

The erase size is specified by both the FSADDR and FEADDR settings. [Table 47.21](#) describes how to set the FSADDR and FEADDR.

Table 47.21 Settings for the erase size

Erase size	FSADDR	FEADDR
64 bytes	FSA0 to FSA5 = 0 (64 byte-boundary)	FSADDR + 0x3C
128 bytes	FSA0 to FSA6 = 0 (128 byte-boundary)	FSADDR + 0x7C
256 bytes	FSA0 to FSA7 = 0 (256 byte-boundary)	FSADDR + 0xFC

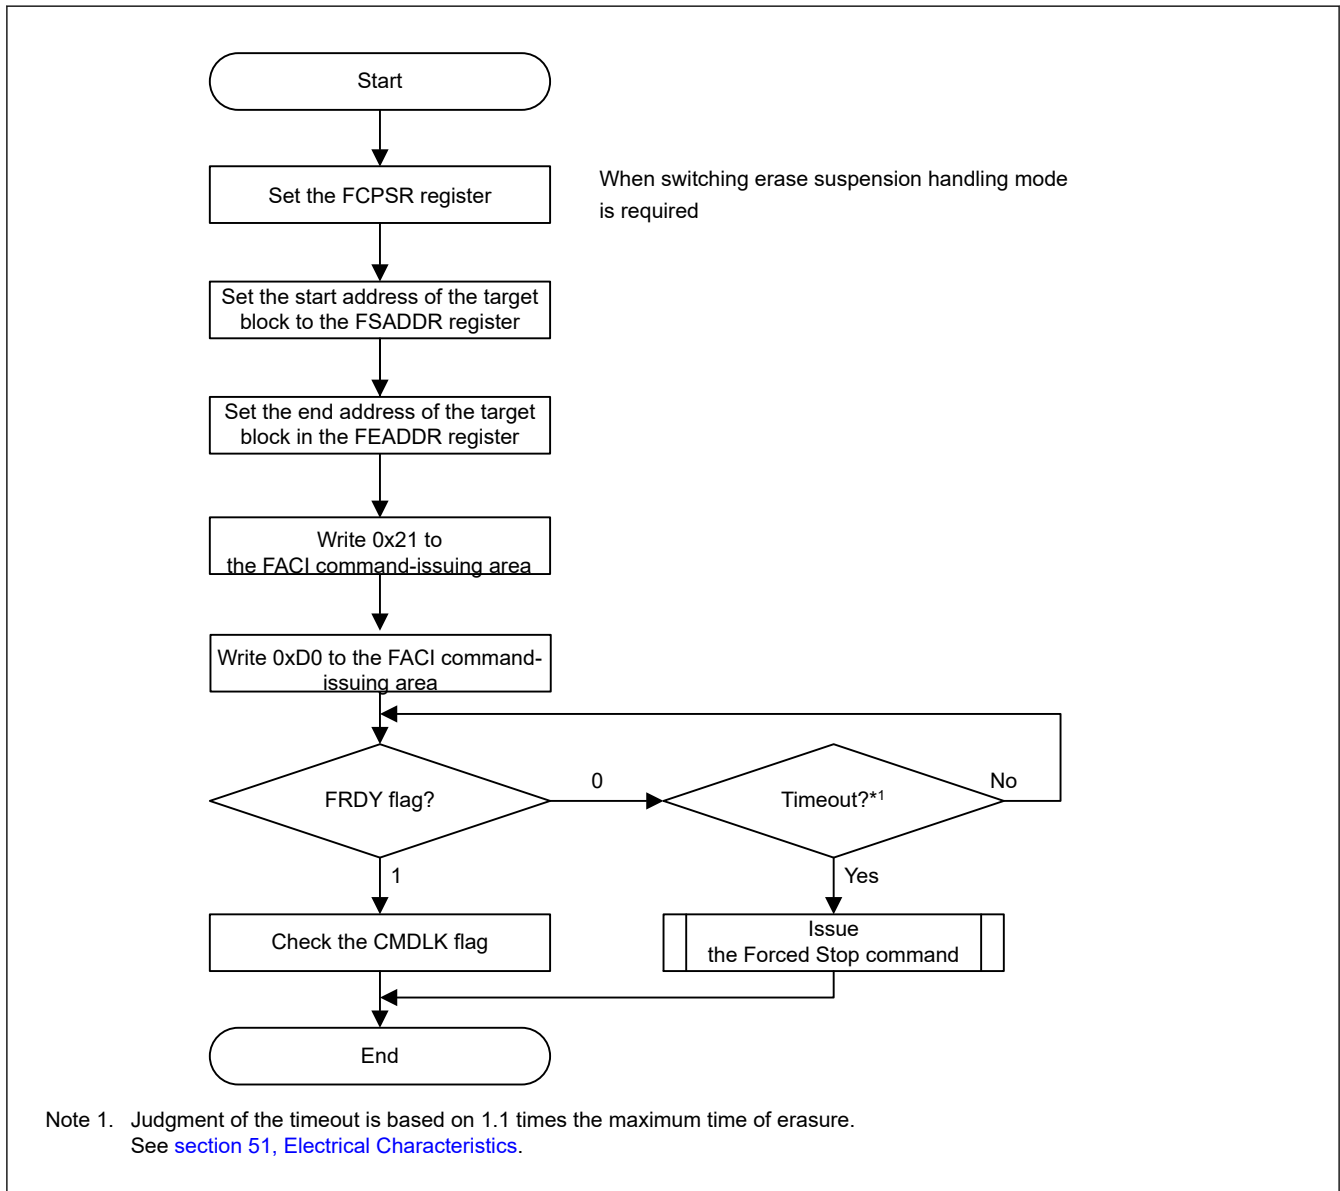

Figure 47.16 Usage flow of the multi block command

47.9.3.10 P/E Suspend Command

The P/E suspend command is used to suspend programming/erasure. Before issuing a P/E suspend command, check that the CMDLK bit in the FASTAT register is 0, and that the execution of programming/erasure is performed normally. To confirm that the P/E suspend command can be received, check that the SUSRDY bit in the FSTATR register is 1. After issuing a P/E suspend command, read the CMDLK bit to confirm that no error occurs.

If an error occurs during programming/erasure, the CMDLK bit is set to 1. When programming/erasure processing has finished from the time when the SUSRDY bit is 1 to when the P/E suspend command is received, no error occurs and the

suspended state is not entered (the FRDY bit in the FSTATR register is 1 and the ERSSPD and PRGSPD bits in FSTATR are 0).

When a P/E suspend command is received and the programming/erasure suspend processing finishes normally, the flash sequencer enters the suspended state, the FRDY bit is set to 1, and the ERSSPD or PRGSPD bit is 1. After issuing a P/E suspend command, check that the ERSSPD or PRGSPD bit is 1 and the suspended state is entered, then proceed with the subsequent flow. If a P/E resume command is issued in the subsequent flow even when the suspended state is not entered, an illegal command error occurs and the flash sequencer shifts to the command-locked state (see [section 47.11.2. Error Protection](#)).

If the erasure suspended state is entered, programming to blocks other than an erasure target block can be performed. Additionally, the programming and erasure suspended states can shift to read mode by clearing the FENTRYR register.

[Figure 47.17](#) shows the usage of the P/E suspend command.

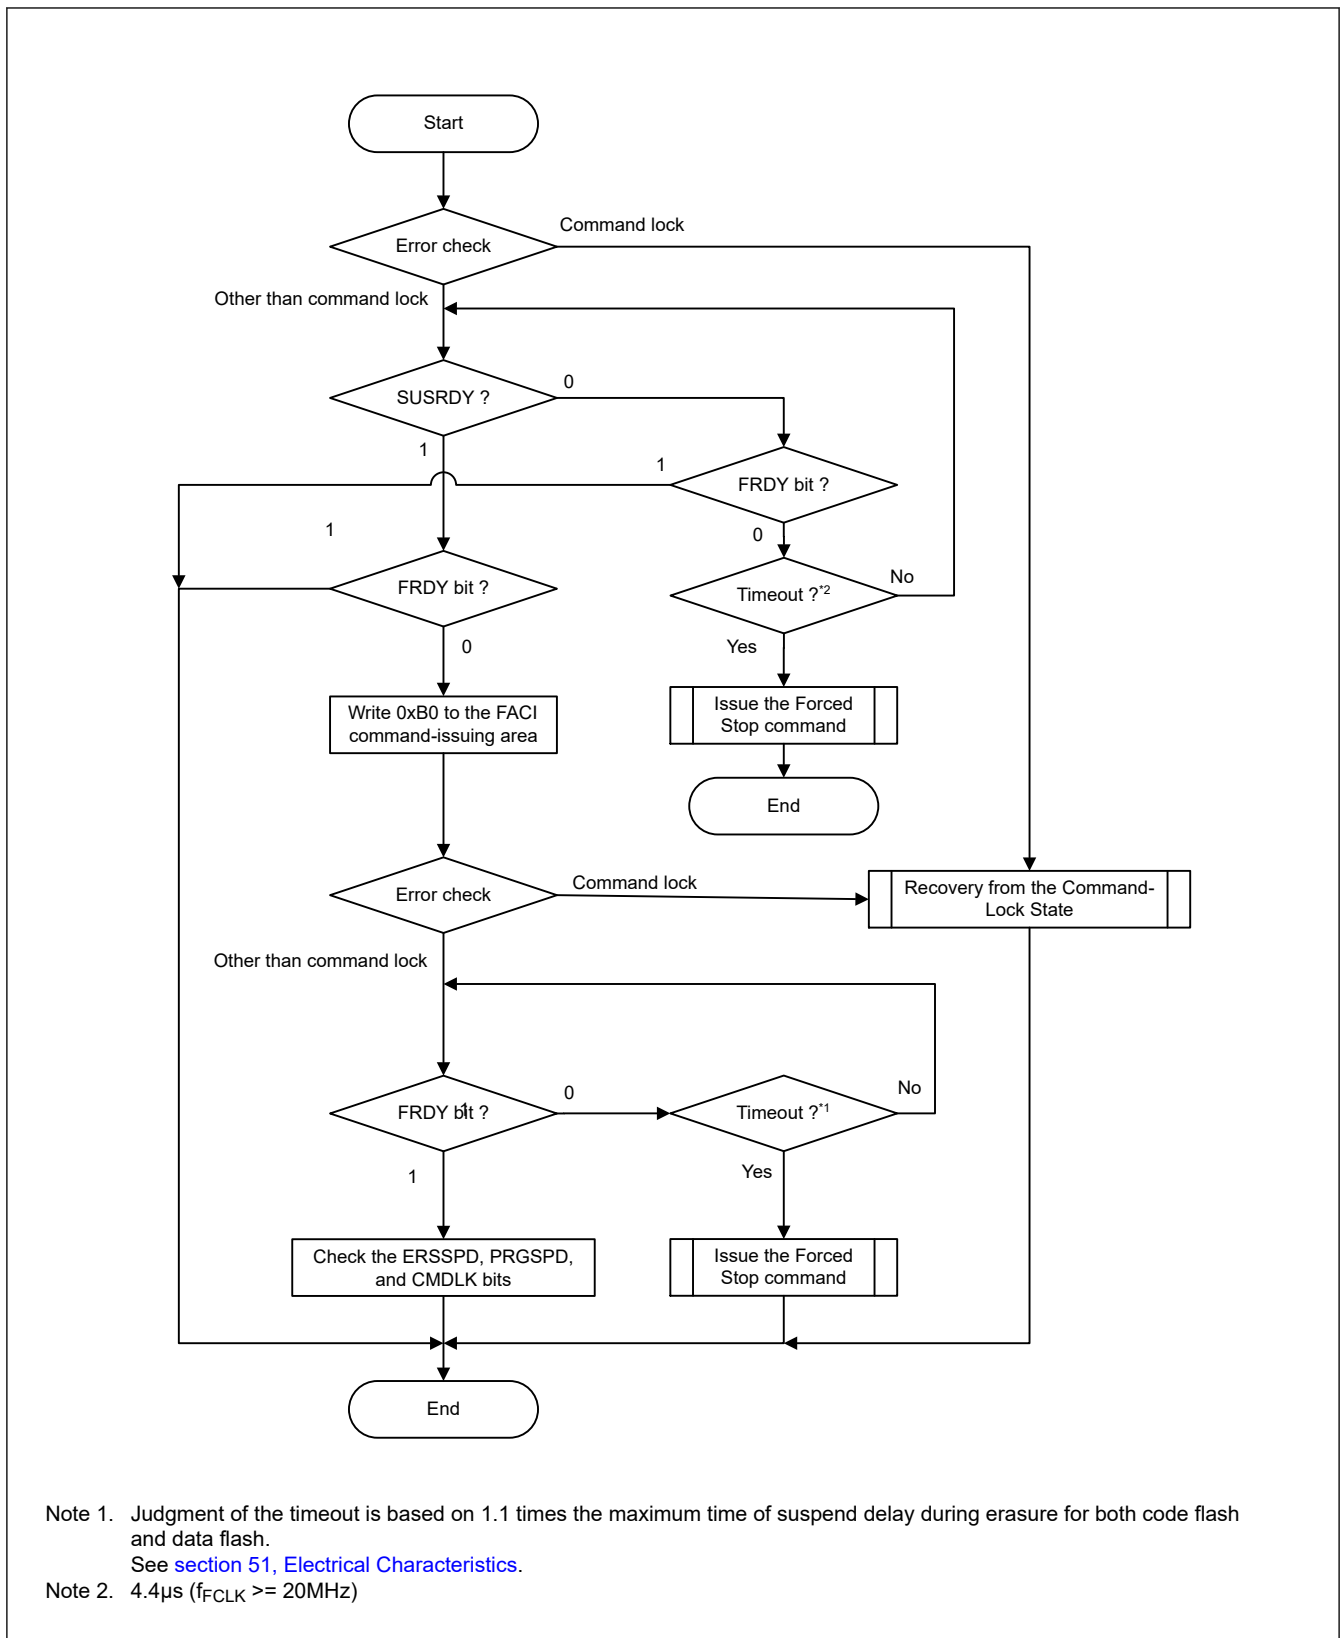

Figure 47.17 Usage flow of the P/E suspend command

(1) Suspension during Programming

When issuing a P/E suspend command during flash memory programming, the flash sequencer suspends programming processing. Figure 47.18 shows the suspend programming operation. When receiving programming-related command, the flash sequencer clears the FRDY bit in the FSTATR register to 0 to start programming. If the flash sequencer enters the

state in which the P/E suspend command can be received after programming starts, it sets the SUSRDY bit in the FSTATR register to 1.

When a P/E suspend command is issued, the flash sequencer receives the command and clears the SUSRDY bit to 0. If the flash sequencer receives a P/E suspend command while a programming pulse is applied, the flash sequencer continues with the pulse. After the specified pulse application time, the flash sequencer finishes pulse application, starts the programming suspend processing, and sets the PRGSPD bit in the FSTATR register to 1.

When a suspended processing finishes, the flash sequencer sets the FRDY bit to 1 to enter the programming suspended state. When receiving a P/E resume command in the programming suspended state, the flash sequencer clears the FRDY and PRGSPD bits to 0 and resumes programming.

Figure 47.18 shows the timing for suspension during programming.

Figure 47.18 Suspension during programming

(2) Suspension during Erasure (Suspension Priority Mode)

The flash sequencer has a suspension priority mode for the suspension of erasure. Figure 47.19 shows the suspend operation of erasure when the erasure suspend mode is set to the suspension priority mode (the ESUSPMD bit in the FCPSR register is 0).

When receiving an erasure-related command, the flash sequencer clears the FRDY bit in the FSTATR register to 0 to start erasure. If the flash sequencer enters the state in which the P/E suspend command can be received after erasure starts, it sets the SUSRDY bit in the FSTATR register to 1.

When a P/E suspend command is issued, the flash sequencer receives the command and clears the SUSRDY bit to 0.

When receiving a suspend command during erasure, the flash sequencer starts the suspend processing and sets the ERSSPD bit in the FSTATR register to 1 even when it is applying an erasure pulse. When the suspended processing finishes, the flash sequencer sets the FRDY bit to 1 to enter the erasure suspended state. When receiving a P/E resume command in the erasure suspended state, the flash sequencer clears the FRDY and ERSSPD bits to 0 and resumes erasure. Operations of the FRDY, SUSRDY, and ERSSPD bits at the suspension and resumption of erasure are the same, regardless of the erasure suspend mode.

The setting of the erasure suspend mode affects the control method of erasure pulses. In suspension priority mode, when receiving a P/E suspend command while erasure pulse A that has not been previously suspended is being applied, the flash sequencer suspends the application of erasure pulse A and enters the erasure suspended state. When receiving a P/E suspend command while reapplying erasure pulse A after erasure is resumed with a P/E resume command, the flash sequencer

continues to apply erasure pulse A. After the specified pulse application time, the flash sequencer finishes erasure pulse application and enters the erasure suspended state.

When the flash sequencer receives a P/E resume command next and erasure pulse B is being applied, the flash sequencer receives a P/E suspend command again, and the application of erasure pulse B is then suspended. In suspension priority mode, delays due to suspension can be minimized because the application of an erasure pulse is suspended once per pulse, and priority is given to the suspend processing.

If the interval of suspension after resume is longer than t_{REST1} (Resume time: priority on suspension, resume after the 1st suspend for the same pulse), suspend delay will be always t_{SESD1} (Suspend delay: priority on suspension, the 1st suspend for the same pulse).

If the interval of suspension after resume is shorter than t_{REST1} , suspend delay becomes either t_{SESD1} or t_{SESD2} (Suspend delay: priority on suspension, the 2nd suspend for the same pulse).

(The value of t_{REST1} / t_{SESD1} / t_{SESD2} , see [section 51, Electrical Characteristics](#).)

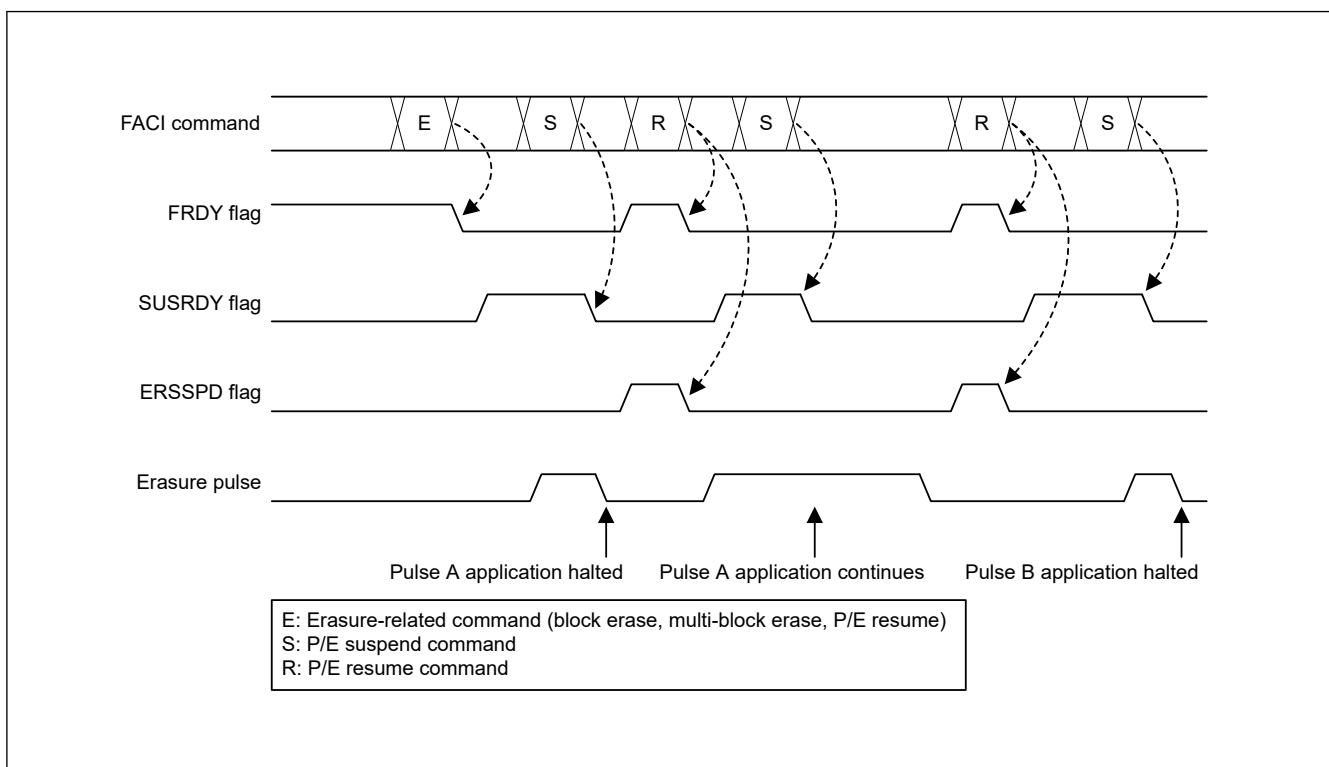

Figure 47.19 Suspension during erasure (suspension priority mode)

(3) Suspension during Erasure (Erasure Priority Mode)

The flash sequencer has an erasure priority mode for the suspension of erasure. [Figure 47.20](#) shows the suspend operation of erasure when the erasure suspend mode is set to the erasure priority mode (the ESUSPMD bit in the FCPSR register is 1). The control method of erasure pulses in erasure priority mode is the same as that of programming pulses for the programming suspend processing.

If the flash sequencer receives a P/E suspend command while an erasure pulse is applied, the flash sequencer continues to apply the pulse. In this mode, the required time for the erasure processing can be reduced compared to the suspension priority mode because the re-application of erasure pulses does not occur when a P/E resume command is issued.

Figure 47.20 Suspension during erasure (erasure priority mode)

47.9.3.11 P/E Resume Command

The P/E resume command is used to resume suspended programming or erasure. If the FENTRYR setting has been modified during suspension, issue a P/E resume command only after resetting FENTRYR to the previous value that was held before the P/E suspend command was issued. Figure 47.21 shows usage of the P/E resume command.

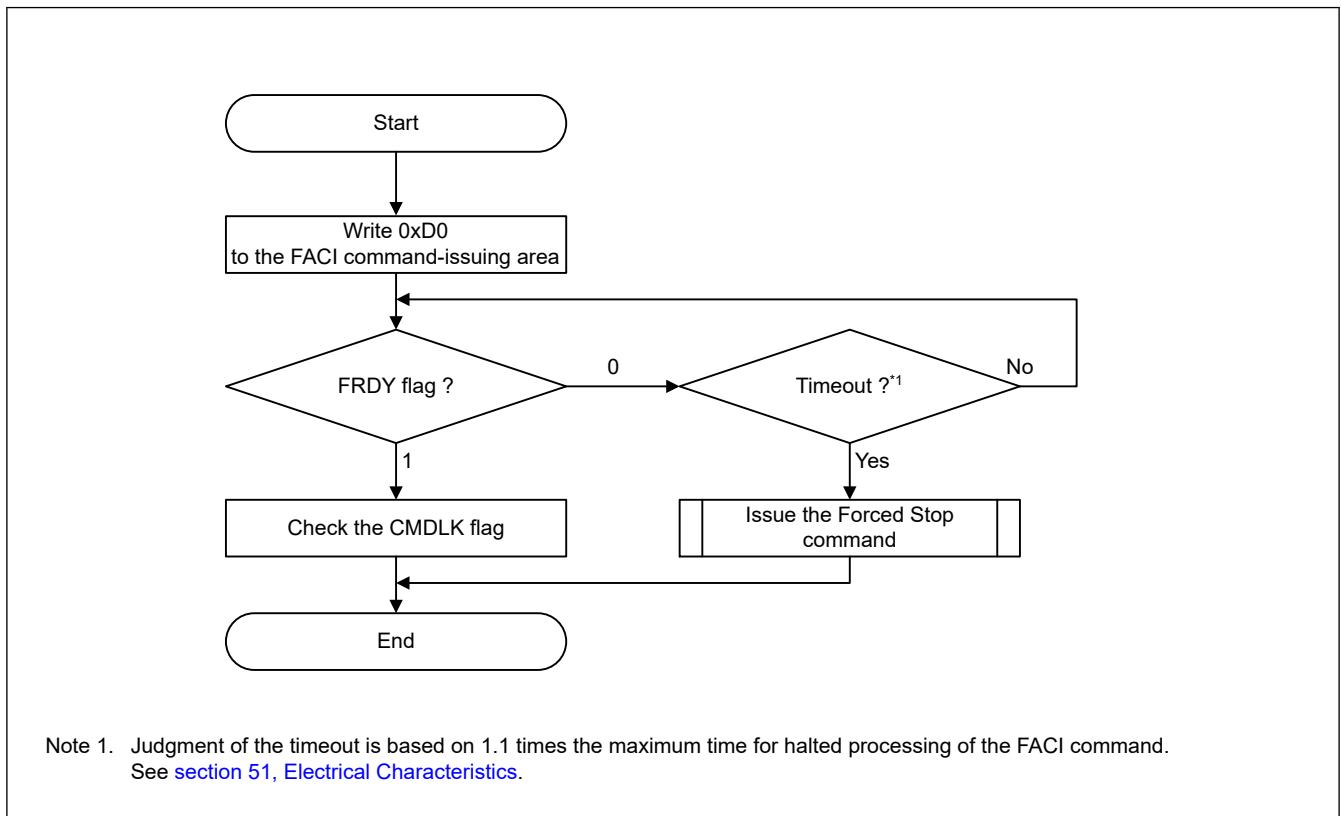

Figure 47.21 Usage flow of the P/E resume command

47.9.3.12 Status Clear Command

The status clear command is used to clear the command-locked state (see [section 47.9.3.6. Recovery from the Command-Locked State](#)).

You can use the status clear command to clear the following bits in the FSTATR register in the command-locked state:

- ILGLERR
- ILGCOMERR
- FESETERR
- SECERR
- OTERR
- ERSERR
- PRGERR
- TZFERR

[Figure 47.22](#) shows usage of the status clear command.

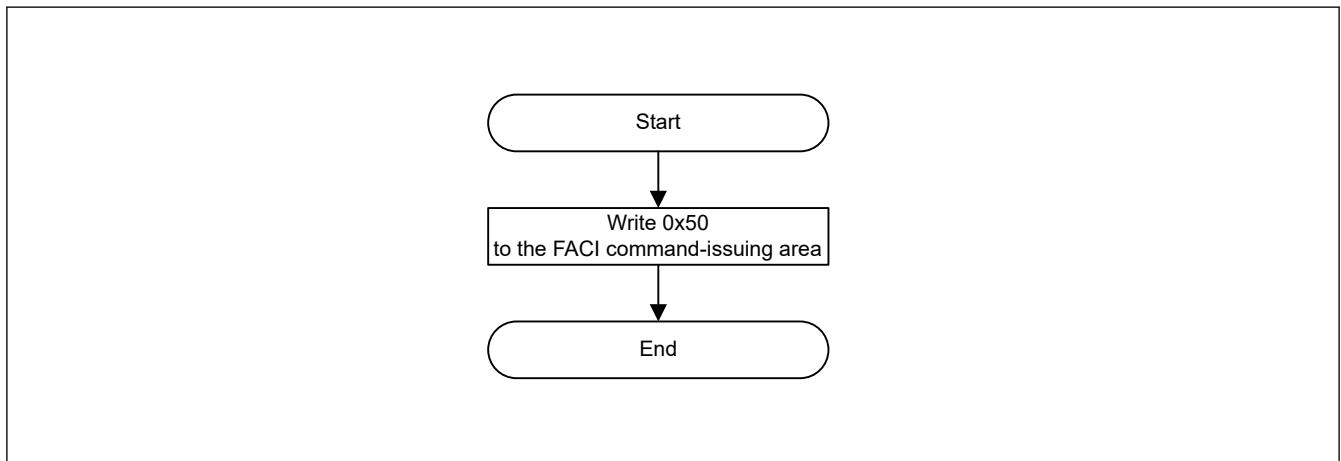

Figure 47.22 Usage flow of the status clear command

47.9.3.13 Forced Stop Command

The forced stop command is used to forcibly end command processing by the flash sequencer. Although this command halts command processing more quickly than the P/E suspension command, values from the programming or erasure that are in progress are not guaranteed. Additionally, resumption of processing is not possible. Processing of programming or erasure that is halted by the forced stop command is also defined as one programming round.

Executing the forced stop command also initializes part of the FACL, the whole FCU, the FSTATR and FASTAT registers. This command can be used in the procedure for recovery from the command-locked state and for processing in response to a timeout of the flash sequencer (see [section 47.9.3.6. Recovery from the Command-Locked State](#)).

[Figure 47.23](#) shows usage of the forced stop command.

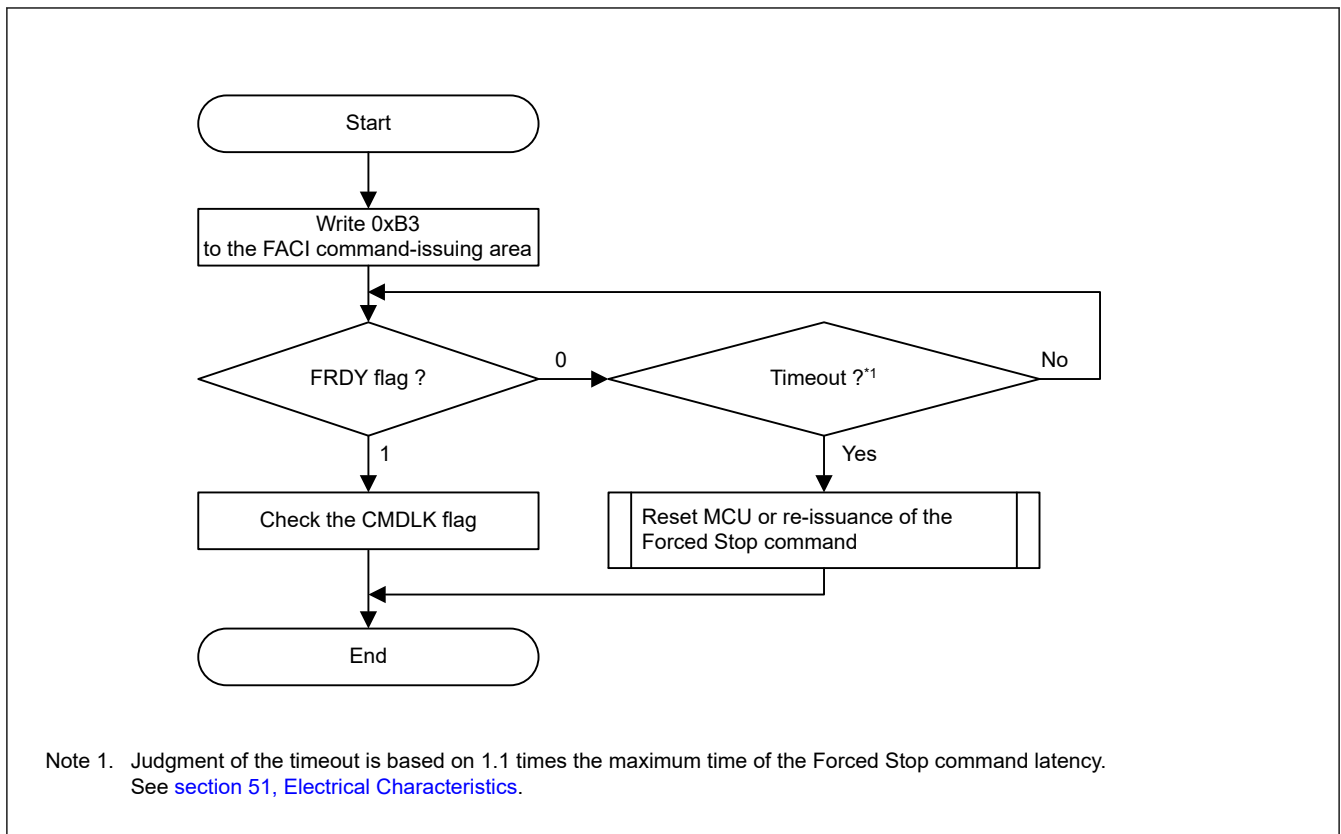

Figure 47.23 Usage flow of the forced stop command

(1) Notes on Using the Forced Stop Command during Command Issue

When using the forced stop command at the timeout occurrence by DBFULL bit of the program command, writing in the FACI command-issuing area is sometimes processed as writing in data of the program command. See [Table 47.4](#) in [section 47.3. Address Space](#) for information on the FACI command-issuing area to force a command lock. Then issue a forced stop command with return method from the command lock status (see [Figure 47.14](#)). Locking commands is possible in any case where the unit for reading the FACI command issuing area is 8, 16, or 32 bits.

47.9.3.14 Blank Check Command

The blank check command is used to confirm that an area is in the non-programmed state. Values read from the data flash memory that have been erased but not yet programmed again that is in the non-programmed state, are undefined.

Before issuing the Blank Check command, set addressing mode, start address, and end address of the target area for Blank Check to the FBCCNT, FSADDR, and FEADDR registers. When Blank Check addressing mode is set to decremental mode (i.e. FBCCNT.BCDIR = 1), address specified in FSADDR should be equal to or larger than address in FEADDR.

On the other hand, the address in FSADDR should be equal to or smaller than address in FEADDR when Blank Check addressing mode is set to incremental mode (i.e. FBCCNT.BCDIR = 0).

If the settings of the BCDIR bit, FSADDR, and FEADDR are inconsistent, the flash sequencer enters the command-locked state. The size of the target area for Blank Check is in the range from 4 bytes to the data flash memory capacity and is set in units of 4 bytes.

Write 0x71 and 0xD0 to the FACI command-issuing area to start Blank Check. Completion of processing can be confirmed by the FRDY bit of the FSTATR register. At the end of processing, the result of Blank Check is stored in the BCST bit in the FBCSTAT register. If non-programmed data exists within the target area for Blank Check, flash sequencer stops Blank Check command operation. In this case, address of non-programmed data is indicated to FPSADDR register.

[Figure 47.24](#) shows usage of the blank check command.

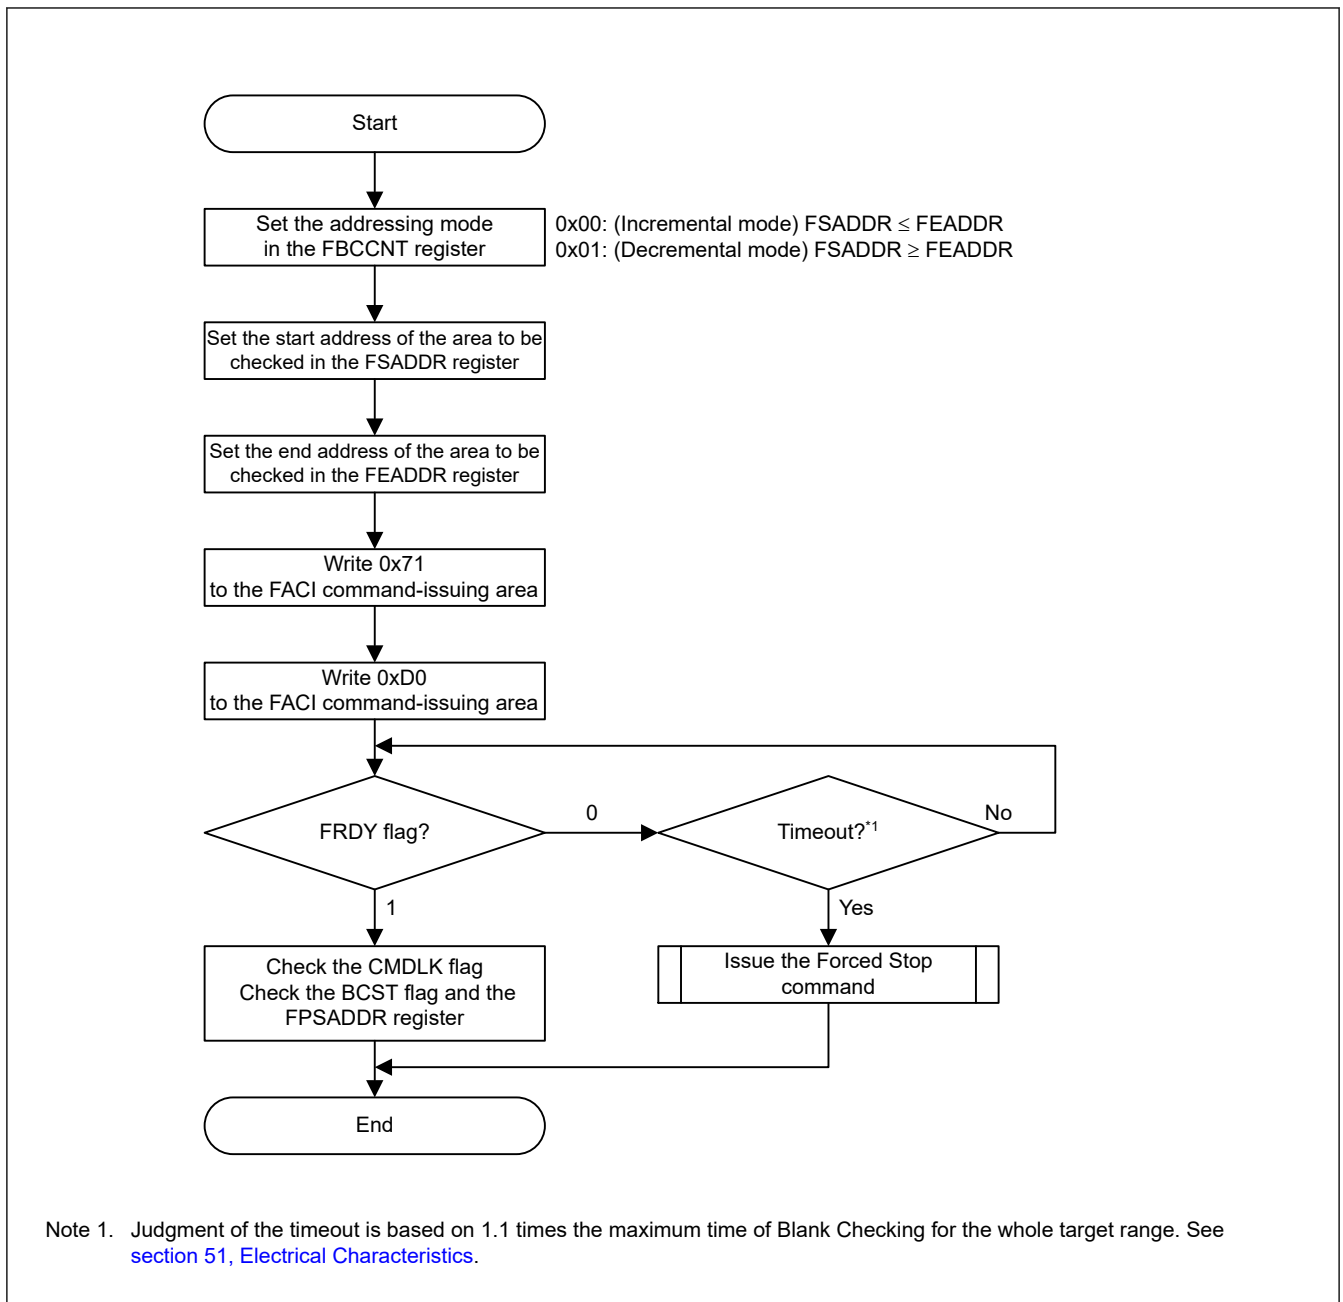

Figure 47.24 Usage flow of the blank check command

47.9.3.15 Configuration Set Command

The Configuration set command is used to set option-setting memory. Before issuing the Configuration set command, set the specified address (shown in [Table 47.22](#)) in the FSADDR register. Writing 0xD0 to the FSCI command-issuing area in the final access for issuing the FSCI command starts FSCI processing of the Configuration set command.

[Figure 47.25](#) shows usage of the configuration set command.

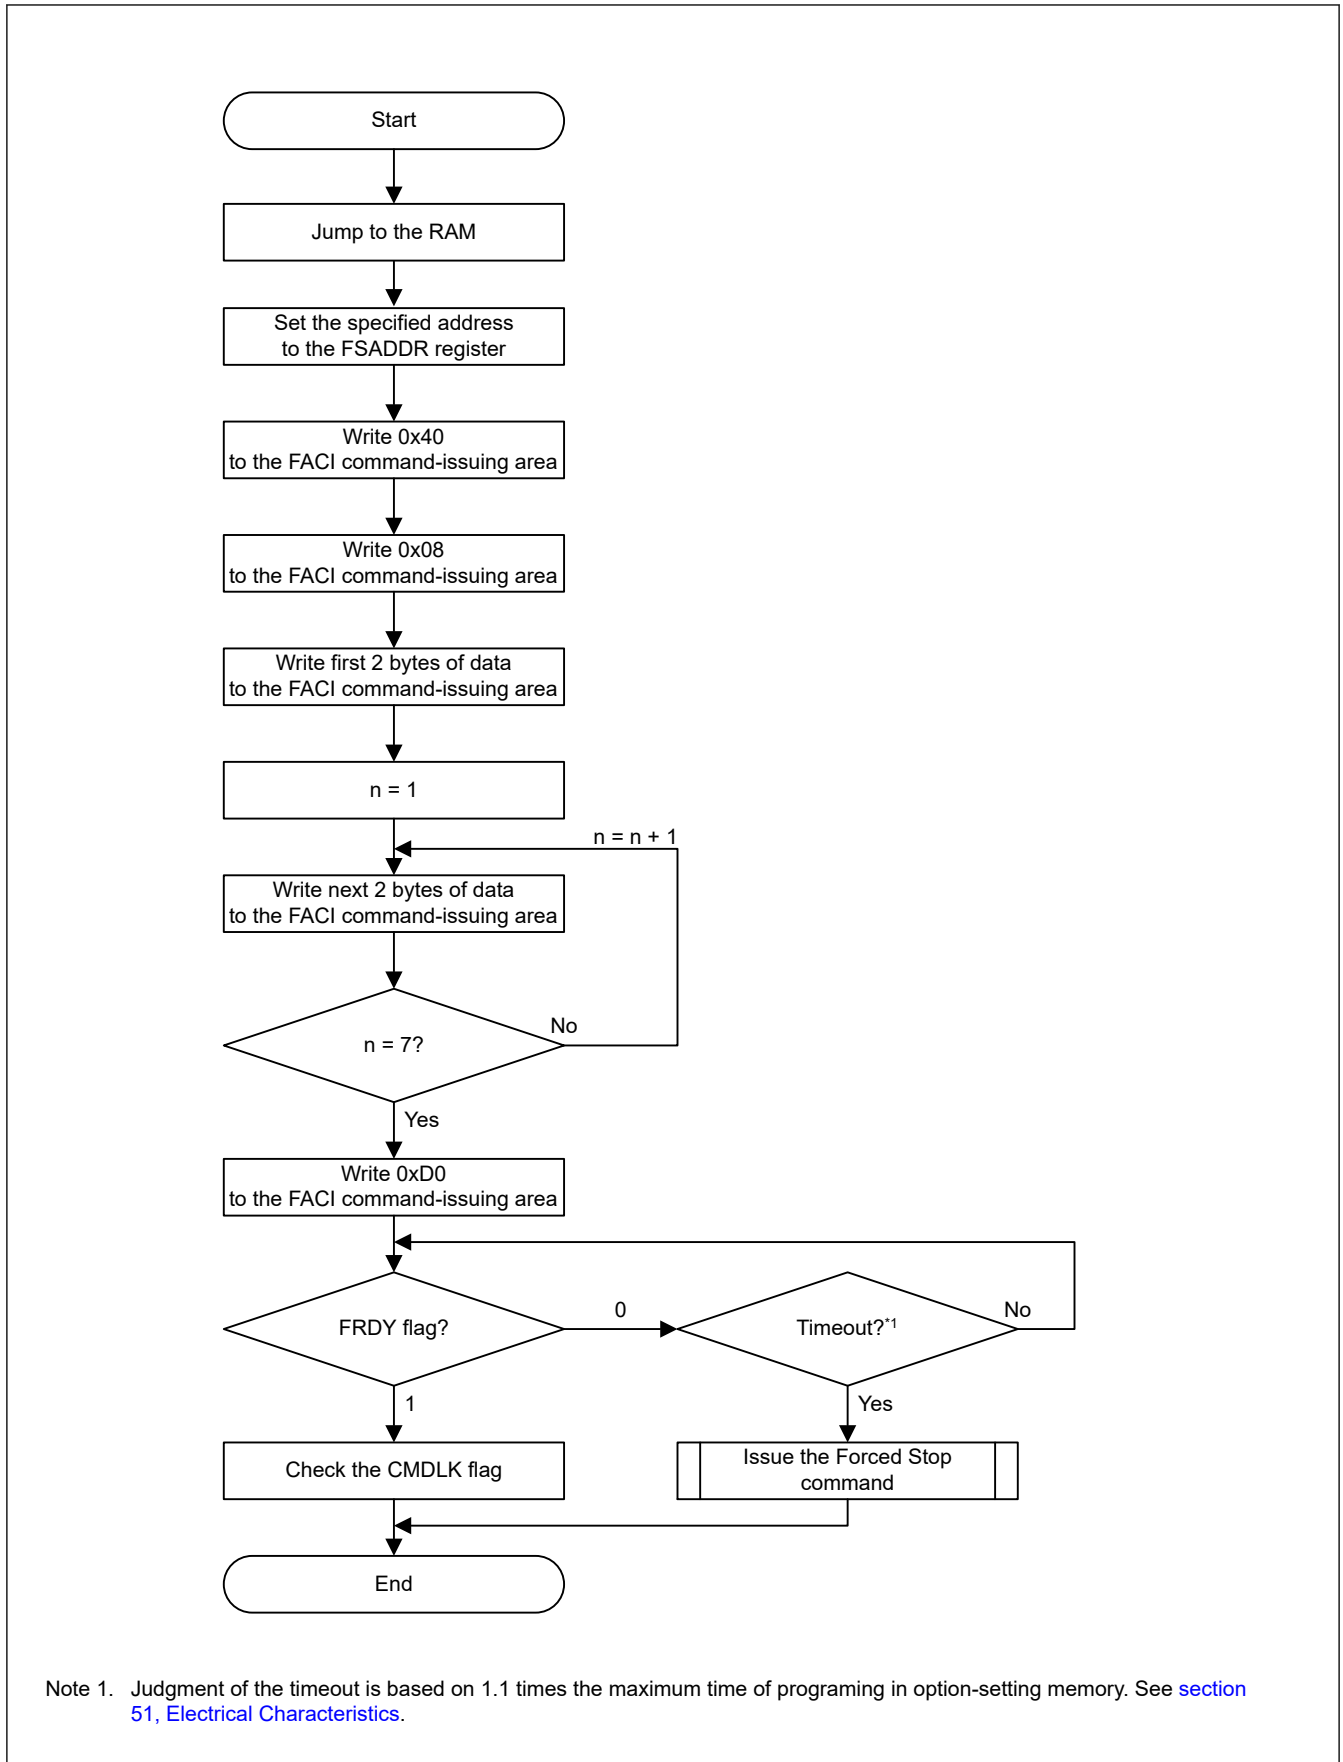

Figure 47.25 Usage flow of the configuration set command

The correspondence between the possible target data for configuration setting and the address value set in the FSADDR register is shown in Table 47.22. For details, see section 47.4.12. FSADDR : FACS Command Start Address Register.

Table 47.22 Address Used by Configuration Set Command for Secure alias (Code flash memory)

Address	FSADDR Register Value	Setting Data	Operation of additional writing		Timing when the Setting is Enabled
			SAS.FSPR bit is 1	SAS.FSPR bit is 0	
0x0300_A100	0x0300_A100	Option Function Select Register 0 (OFS0)	Writable	Writable	At a reset
0x0300_A104		Option Function Select Register 2 (OFS2)			
0x0300_A110	0x0300_A110	Dual Mode Select Register (DUALSEL)	Writable	Writable	At a reset
0x0300_A134	0x0300_A130	Start-up Area Setting Register (SAS)	Writable	Not writable*1	When a reset or command is executed
0x1300_A180	0x1300_A180	Option Function Select Register 1 (OFS1)	Writable	Writable	At a reset
0x1300_A190	0x1300_A190	Bank Select Register (BANKSEL)	Writable	Writable	At a reset
0x1300_A1C0	0x1300_A1C0	Block Protect Setting Register (BPS)	Writable*2	Writable*2	When a reset or command is executed
0x1300_A1E0	0x1300_A1E0	Permanent Block Protect Setting Register (PBPS)	Writable*3 (from 1 to 0 only)	Writable*3 (from 1 to 0 only)	When a reset or command is executed
0x0300_A200	0x0300_A200	Option Function Select Register 1 Secure (OFS1_SEC)	Writable	Writable	At a reset
0x0300_A210	0x0300_A210	Bank Select Register Secure (BANKSEL_SEC)	Writable	Writable	At a reset

0x0300_A260	0x0300_A260	Permanent Block Protect Setting Register Secure (PBPS_SEC)	Writable*5 (from 1 to 0 only)	Writable*5 (from 1 to 0 only)	When a reset or command is executed
0x0300_A280	0x0300_A280	Option Function Select Register 1 Select (OFS1_SEL)*6	Writable	Writable	At a reset
0x0300_A290	0x0300_A290	Bank Select Register Select (BANKSEL_SEL)	Writable	Writable	At a reset
0x0300_A2C0	0x0300_A2C0	Block Protect Setting Register Select (BPS_SEL)	Writable*6	Writable*6	At a reset

- Note 1. The SAS.FSPR bit cannot be restored to 1 by using the Configuration set command once it is set to 0. Therefore, setting the start-up area select flags again becomes impossible. (when the Configuration set command is issued to the address of 0x0100A134, the command is locked.) Exercise extra caution when handling the SAS.FSPR bit.
- Note 2. Once PBPS[n] bit is set to 0, the BPS[n] bit cannot be restored to 1 by using the Configuration set command.
- Note 3. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration set command. The PBPS[n] bit cannot be set to 0 by using the Configuration set command when the BPS[n] bit is 1.
- Note 4. Once PBPS_SEC[n] bit is set to 0, the BPS_SEC[n] bit cannot be restored to 1 by using the Configuration set command.
- Note 5. Once these bits are set to 0, the bits cannot be restored to 1 by using the Configuration set command. The PBPS_SEC[n] bit cannot be set to 0 by using the Configuration set command when the BPS_SEC[n] bit is 1.
- Note 6. When the Permanent Block Protect bit is enabled, Block protect setting register cannot be written.

Table 47.23 Address Used by Configuration Set Command for Secure alias (Data flash memory) (1 of 2)

Address	FSADDR	Setting Data	Operation of additional writing		Timing when the Setting is Enabled
	Register Value		Lock bit is 1	Lock bit is 0	
0x2703_0098~ 0x2703_017C	0x2703_0098~ 0x2703_017C	Lockable Configuration Data Area 0 (LK_CD_A0)	Writable*1	Not Writable*1	At a reset
0x2703_0180~ 0x2703_027C	0x2703_0180~ 0x2703_027C	Lockable Configuration Data Area 1 (LK_CD_A1)	Writable*1	Not Writable*1	At a reset
0x2703_0280~ 0x2703_035C	0x2703_0280~ 0x2703_035C	Lockable Configuration Data Area 2 (LK_CD_A2)	Writable*1	Not Writable*1	At a reset

Table 47.23 Address Used by Configuration Set Command for Secure alias (Data flash memory) (2 of 2)

Address	FSADDR	Setting Data	Operation of additional writing		Timing when the Setting is Enabled
	Register Value		Lock bit is 1	Lock bit is 0	
0x2703_0380~ 0x2703_0384	0x2703_0380~ 0x2703_0384	Configuration Data Lock Bit Area 0 (CD0_LK)	Writable	Writable	When a reset or command is executed
0x2703_0388~ 0x2703_038C	0x2703_0388~ 0x2703_038C	Configuration Data Lock Bit Area 1 (CD1_LK)	Writable (from 1 to 0 only)	Writable (from 1 to 0 only)	When a reset or command is executed
0x2703_0390	0x2703_0390	Configuration Data Lock Bit Area 2 (CD2_LK)	Writable (from 1 to 0 only)	Writable (from 1 to 0 only)	When a reset or command is executed
0x2703_03C0	0x2703_03C0	Anti-Rollback Counter Lock Setting (ARCLS)	Writable (from 1 to 0 only)	Writable (from 1 to 0 only)	When a reset or command is executed
0x2703_03C2		Anti-Rollback Counter Configuration Setting for ARC_NSEC (ARCCS)	Writable*2	Writable*2	When a reset or command is executed

Note 1. For details of relation of write-protection area and lock bit, see [section 47.12.4. Data Flash Configuration Area Protection](#).

Note 2. The ARC_NSEC counter selection bit cannot be changed after set to 00b or 01b. When using the ARC_NSEC counter, this counter can be selected either of 4 lines of 64 bits (00b setting) or 1 line of 256 bits (01b setting).

47.9.3.16 Increment Counter Command

The Increment Counter command is used to security function, safety function. "Increment Counter" command is used for updating 2 types of anti-rollback counter (ARC_SEC and ARC_NSEC). The counter update is executed increment processing and cannot be decrement processing.

Writing "0xD0" at 2nd write access of flash sequencer command triggers FACI to start "Increment Counter" command processing. Completion of command processing can be confirmed by FRDY bit of FSTATR register.

If "Command Lock" status occurs during command execution, refresh the counter with "Refresh Counter" command after "Command Lock" state is released.

Note 1. 50msec(FCLK \geq 20MHz)

Figure 47.26 Usage of the Increment Counter Command

Anti-rollback counter value is not increased the following conditions by "Increment Counter" command.

- Target counter is protected by ARCSEC_LK or ARCNSEC_LK0~3.
- Target counter value is maximum. (Error does not occur)
- Target counter is ARC_NSEC when CNF_ARCNSEC0~1 is invalid setting.

47.9.3.17 Refresh Counter Command

The Refresh Counter command is used to security function, safety function. "Refresh Counter" command is used for update of anti-rollback counter when power failure is occurred while "Increment Counter" command processing. Counter value is not changed by "Refresh Counter" command.

Writing "0xD0" at 2nd write access of flash sequencer command triggers FACL to start "Increment Counter" command processing. Completion of command processing can be confirmed by FRDY bit of FSTATR register.

If "Command Lock" status occurs during command execution, refresh the counter with "Refresh Counter" command after "Command Lock" state is released.

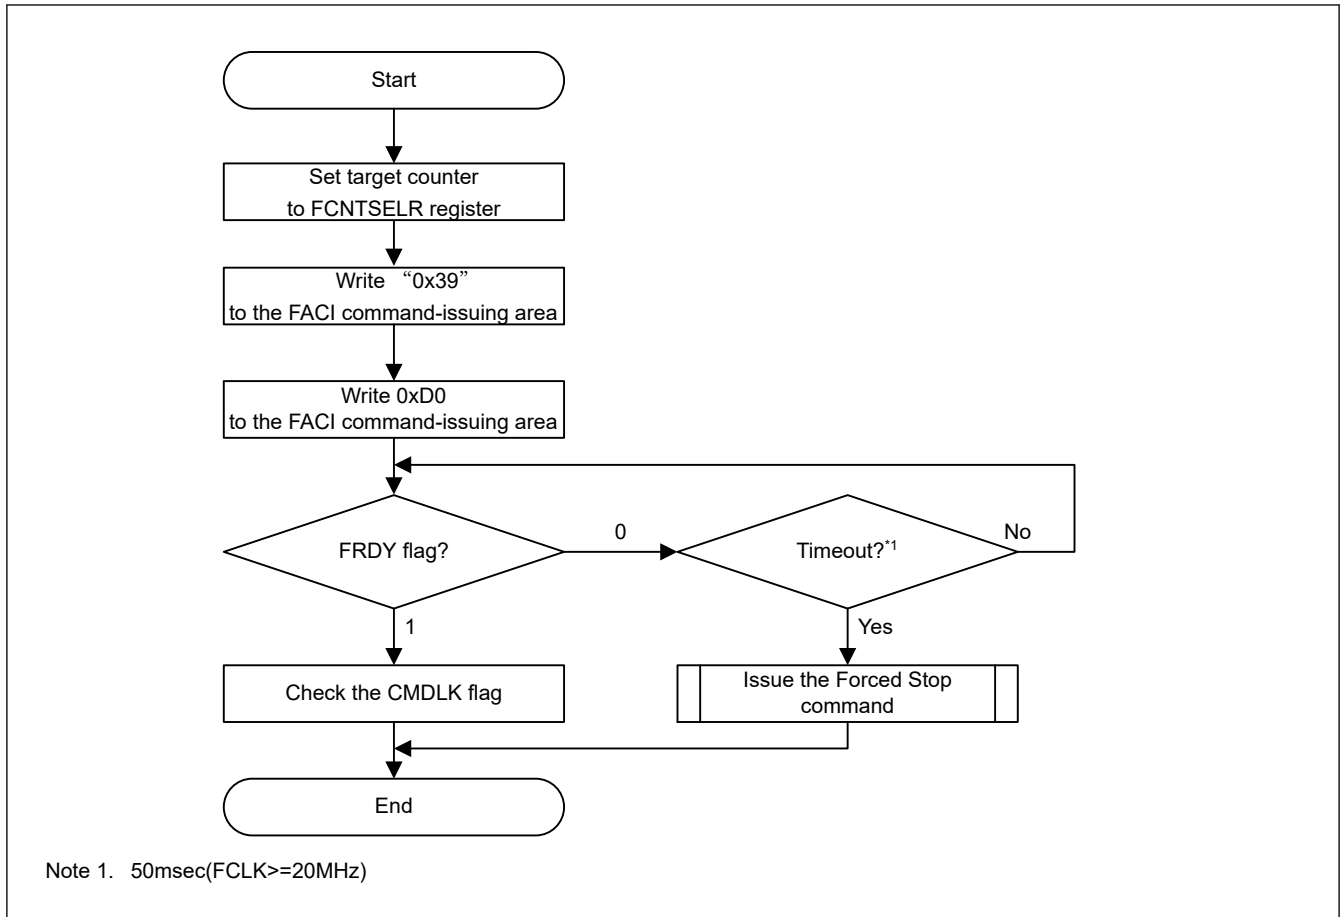

Figure 47.27 Usage of the Refresh Counter Command

47.9.3.18 Read Counter Command

The Read Counter command is used to security function, safety function. "Read Counter" command is used for reading 2 types of anti-rollback counter (ARC_SEC and ARC_NSEC). Flash sequencer automatically judges valid area of anti-rollback counter, reads 64 bits data, and stores to FCNTDATAR0 and FCNTDATAR1 registers.

Writing "0xD0" at 2nd write access of flash sequencer command triggers FACL to start "Read Counter" command processing. Completion of command processing can be confirmed by FRDY bit of FSTATR register.

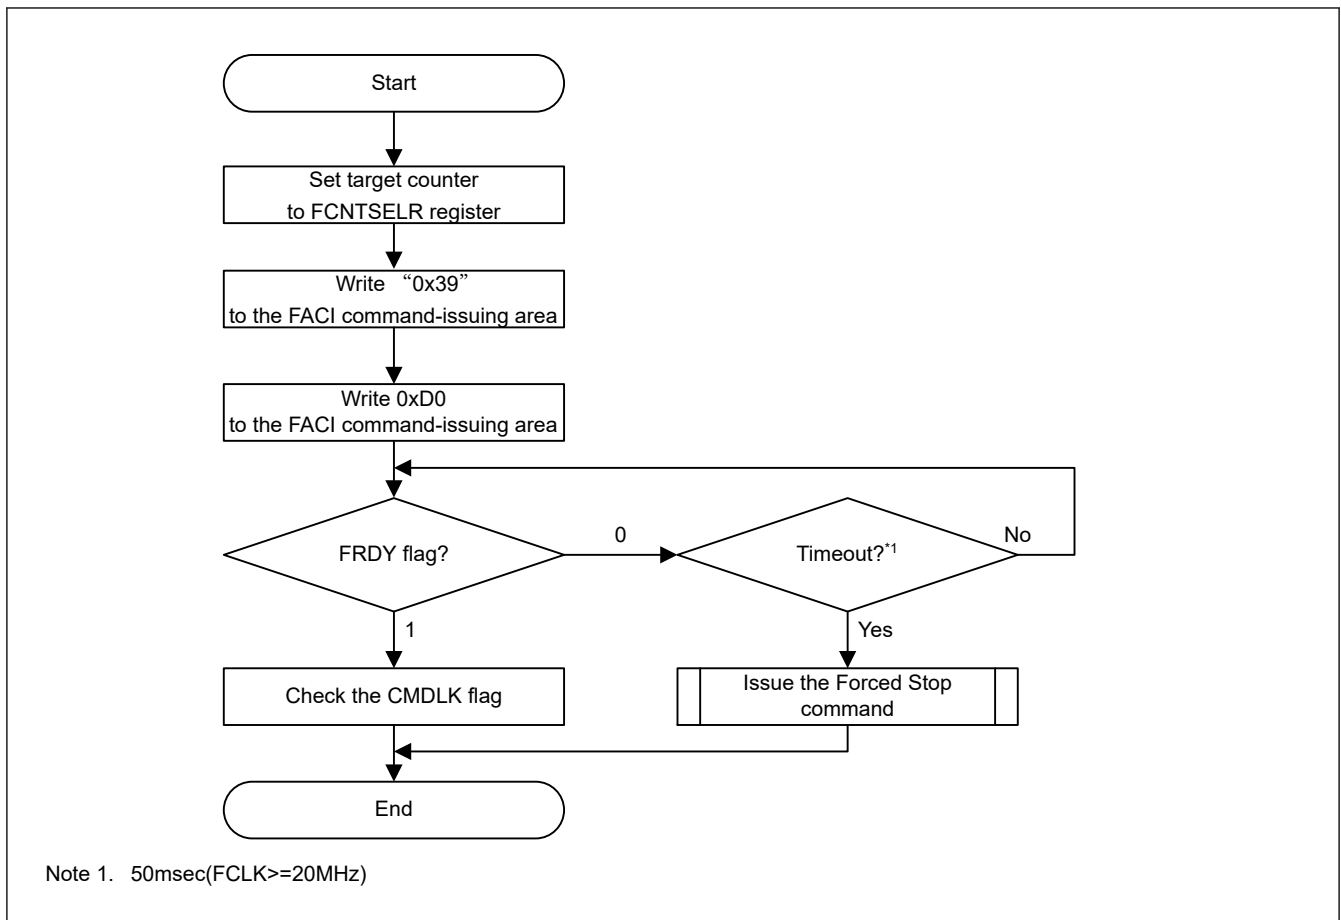

Figure 47.28 Usage of the Read Counter Command

47.10 Suspend Operation

Reading from the flash memory is not possible during programming or erasure if the conditions for background operation given in [Table 47.39](#) are not satisfied. When a P/E suspend command is issued to suspend the programming or erasure of the flash memory, reading from the flash memory is enabled. Regarding P/E suspend commands, there are one suspend command mode for programming and two suspend command modes for erasure (suspension priority mode and erasure priority mode). To resume suspended programming or erasure, the P/E resume command is available. For details on the suspend operation, see [Figure 47.17](#).

47.11 Protection Function

47.11.1 Software Protection

Software protection disables programming and erasure of the code flash memory through the settings of control registers and block protect setting in the user area. If an attempt is made to issue an FACL command against software protection, the flash sequencer enters the command-locked state.

47.11.1.1 Protection through FWEPROR

Unless the FWEPROR.FLWE[1:0] bits are set to 01b, programming cannot proceed in any mode.

47.11.1.2 Protection by FENTRYR

When the FENTRYR register is set to 0x0000, the flash sequencer enters read mode. In read mode, FACL commands cannot be accepted. If an attempt is made to issue an FACL command in read mode, the flash sequencer enters the command-locked state.

47.11.1.3 Protection by Block Protect Setting

Each block in user area has the block protect setting (BPS or BPS_SEC). When the FBPROT0 or FBPROT1 register is 0x0000 and the block protect bit is 0, issuing the Program or Block Erase command to user area of the code flash causes the command-locked state. To program or erase the block whose block protect bit is 0, set the FBPROT0 or FBPROT1 register to 0x0001.

The block protect setting can be locked by the permanent block protect setting (PBPS or PBPS_SEC). When the permanent block protect setting and the block protect setting are 0, issuing a Program or Block erase command to user area of the code flash causes the flash sequencer to enter the command-locked state regardless of the FBPROT0 and FBPROT1 register settings.

Valid block protect setting (BPS or BPS_SEC) depends on the Block Protect Select bit (BPS_SEL).

See [section 47.12.2. Permanent Block Protect Setting](#) for details of the block protect setting and permanent block protect setting. See [section 47.4.17. FBPROT0 : Flash Block Protection Register](#) and [section 47.4.18. FBPROT1 : Flash Block Protection for Secure Register](#) for more information.

For details of block protect setting (BPS or BPS_SEC) and block protect select (BPS_SEL), see [section 6, Option-Setting Memory](#).

The protected area by the block protect setting is always determined by the address of the FSADDR register setting regardless of the address swapping function setting (the startup area select, the block swap in linear mode, and the startup bank select in dual mode). [Table 47.24](#) to [Table 47.29](#) show the relation of user area and the block protect setting in each function setting.

(1) In case of the linear mode

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned to the block of user area (for example, address is 0x00_0000 to the last block address).
- BPS[0]/BPS_SEC[0] and BPS[1]/BPS_SEC[1] are assigned to the block of user area depending on the startup area select setting (SAS.BTFLG bit). (See [section 47.11.3. Start-Up Program Protection](#)).
- The second half of FLI user area is assigned to block protect setting depending on the block swap select setting (BANKSEL.BLCKSWP[3:0] bits). See [section 47.11.5. Block Swap Function](#).

[Table 47.24](#) shows the block protect setting when the startup area select is disabled (not swapping).

[Table 47.25](#) and later show example of the block protect setting when the address conversion function is used.

Table 47.24 Example of Block Protect setting when SAS.BTFLG is 1

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes
The last block address	32 KB	BPS[n] or BPS_SEC[n]	Block n	—
⋮	⋮	⋮	⋮	—
0x01_8000 to 0x01_FFFF	32 KB	BPS[9] or BPS_SEC[9]	Block 9	—
0x01_0000 to 0x01_7FFF	32 KB	BPS[8] or BPS_SEC[8]	Block 8	—
0x00_E000 to 0x00_FFFF	8 KB	BPS[7] or BPS_SEC[7]	Block 7	—
0x00_C000 to 0x00_DFFF	8 KB	BPS[6] or BPS_SEC[6]	Block 6	—
⋮	⋮	⋮	⋮	—
0x00_2000 to 0x00_3FFF	8 KB	BPS[1] or BPS_SEC[1]	Block 1	Not swap block 0 and block 1 in this startup area select setting
0x00_0000 to 0x00_1FFF	8 KB	BPS[0] or BPS_SEC[0]	Block 0	Not swap block 0 and block 1 in this startup area select setting

Table 47.25 Example of Block Protect setting when SAS.BTFLG is 0

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes
The last block address	32 KB	BPS[n] or BPS_SEC[n]	Block n	—
⋮	⋮	⋮	⋮	—
0x01_8000 to 0x01_FFFF	32 KB	BPS[9] or BPS_SEC[9]	Block 9	—
0x01_0000 to 0x01_7FFF	32 KB	BPS[8] or BPS_SEC[8]	Block 8	—
0x00_E000 to 0x00_FFFF	8 KB	BPS[7] or BPS_SEC[7]	Block 7	—
0x00_C000 to 0x00_DFFF	8 KB	BPS[6] or BPS_SEC[6]	Block 6	—
⋮	⋮	⋮	⋮	—
0x00_2000 to 0x00_3FFF	8 KB	BPS[1] or BPS_SEC[1]	Block 0	Swap block 0 and block 1 in this startup area select setting
0x00_0000 to 0x00_1FFF	8 KB	BPS[0] or BPS_SEC[0]	Block 1	Swap block 0 and block 1 in this startup area select setting

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes
⋮	⋮	⋮	⋮	—
0x01_8000 to 0x01_FFFF	32 KB	BPS[9] or BPS_SEC[9]	Block 9	—
0x01_0000 to 0x01_7FFF	32 KB	BPS[8] or BPS_SEC[8]	Block 8	—
0x00_E000 to 0x00_FFFF	8 KB	BPS[7] or BPS_SEC[7]	Block 7	—
0x00_C000 to 0x00_DFFF	8 KB	BPS[6] or BPS_SEC[6]	Block 6	—
⋮	⋮	⋮	⋮	—
0x00_2000 to 0x00_3FFF	8 KB	BPS[1] or BPS_SEC[1]	Block 1	—
0x00_0000 to 0x00_1FFF	8 KB	BPS[0] or BPS_SEC[0]	Block 0	—

(2) In case of the dual mode (DUALSEL.BANKMD[2:0] = 000b)

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned the block of bank 0 user area (for example, address is 0x00000000 to the last block address in the lower side bank).
- BPS[70] to BPS[70 + n] or BPS_SEC[70] to BPS_SEC[70 + n] are assigned to the block of bank 1 user area (for example, address is 0x00200000 to the last block address in the upper side bank).

Bank0 is upper side bank (BANKSEL.BANKSWP[2:0] = 000b)

- BPS[0] to BPS[n] or BPS_SEC[0] to BPS_SEC[n] are assigned to the block of bank1 user area (e.g. Address is 0x00_0000 to The last block address in lower side bank).
- BPS[70] to BPS[70+n] or BPS_SEC[70] to BPS_SEC[70+n] are assigned to the block of bank0 user area (e.g. Address is 0x20_0000 to The last block address in upper side bank).

Table 47.28 and Table 47.29 show example of the block protect setting in the dual mode. See section 47.11.4. Dual Bank Function for details of dual bank function (DUALSEL.BANKMD[2:0] and BANKSEL.BANKSWP[2:0] bits).

Table 47.28 Example of Block Protect setting when BANKSEL.BANKSWP[2:0] is 111b (1 of 2)

FSADDR[23:0]	Block size	Block protect setting	User area block number	Notes

47.11.2 Error Protection

Error protection detects the issuing of illegal FACI commands, illegal access, and flash sequencer malfunction. FACI command acceptance is disabled (command-locked state) in response to the detection of these errors. The flash memory cannot be programmed or erased while the flash sequencer is in the command-locked state. For release from the command-locked state, issue the Status Clear or Forced Stop command. The Status Clear command can only be used while the FRDY bit in the FSTATR register is 1. The Forced Stop command can be used regardless of the value of the FRDY bit. While the CMDLKIE bit in the FAEINT register is 1, a flash access error (FIFERR) interrupt is generated if the flash sequencer enters the command-locked state (the CMDLK bit in the FFASTAT register is set to 1).

If the flash sequencer enters the command-locked state in response to a command other than the P/E suspend command during programming or erasure processing, the flash sequencer continues the processing for programming or erasure. In this

state, the P/E suspend command cannot be used to suspend the processing for programming or erasure. If a command is issued in the command-locked state, the ILGLERR bit becomes 1 and the other bits retain the values set from previous error detection.

Table 47.30 shows the error protection types and status bit values after error detections.

Table 47.30 Error protection type (1 of 3)

Error type	Description	ILGOMERR	FESETERR	SECERR	OTERR	TZFERR	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE	
FENTRYR setting error	The value set in FENTRYR is not 0x0000, 0x0001, or 0x0080	0	1	0	0	0	1	0	0	0	0	0	
	The FENTRYR setting at suspension is different from that at resumption	0	1	0	0	0	1	0	0	0	0	0	
Illegal command error	An undefined size is specified in the first cycle of the command. (not byte-write)	1	0	0	0	0	1	0	0	0	0	0	
	An undefined code is written in the first access of the FACL command	1	0	0	0	0	1	0	0	0	0	0	
	The value specified in the last access of the multiple-access FACL command is not 0xD0	1	0	0	0	0	1	0	0	0	0	0	
	The value (N) specified in the second write access of the FACL command in the program or configuration set command is wrong	1	0	0	0	0	1	0	0	0	0	0	
	Blank Check command is issued with inconsistent BCDIR, FSADDR, and FEADDR settings (see section 47.4.13. FEADDR : FACL Command End Address Register)	1	0	0	0	0	1	0	0	0	0	0/1*1	
	A multi block erase command is issued with inconsistent FSADDR and FEADDR settings. <ul style="list-style-type: none"> FSADDR > FEADDR FEADDR is set to reserved area. 	1	0	0	0	0	1	0	0	0	0	0/1*1	
	Increment Counter, Refresh Counter, or Read Counter command is issued with inconsistent FCNTSEL[2:0] setting. (Include CNF_ARCNS0,1 setting is the mismatch.)	1	0	0	0	0	1	0	0	0	0	0	0
	An FACL command not acceptable in each mode is issued (see Table 47.19)	1	0	0	0	0	1	0	0	0	0	0	0
	An FACL command is issued when command acceptance conditions are not satisfied (see Table 47.20)	0/1	0/1	0/1	0/1	0	1	0/1	0/1	0/1	0/1	0/1	0/1
A program, block erase or multi block erase command is issued against the area protected by the block protect setting (see section 47.11.1.3. Protection by Block Protect Setting)	1	0	0	0	0	1	0	0	0	0	0	0	

Table 47.30 Error protection type (2 of 3)

Error type	Description	ILCOMERR	FESETERR	SECERR	OTERR	TZFERR	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE
Illegal command error	Configuration set command is issued against Data flash configuration area protected by lock bit setting	1	0	0	0	0	1	0	0	0	0	0
	Increment Counter or Refresh Counter command is issued against anti-rollback area protected by lock bit setting	1	0	0	0	0	1	0	0	0	0	0
	A program command is issued against the erase area in erase suspend	1	0	0	0	0	1	0	0	0	0	0
	A command is issued against flash sequencer command illegal status(see Table 47.17).	0/1	0/1	0/1	0/1	0	1	0/1	0/1	0/1	0/1	0/1
Erase error	An error occurs during erasure	0	0	0	0	0	0	1	0	0	0	0
Programming error	An error occurs during programming	0	0	0	0	0	0	0	1	0	0	0
Code flash memory access violation	An FACL command is issued to the reserved portion of the user area in code flash P/E mode	0	0	0	0	0	1	0	0	0	1	0
	Configuration set command is issued to the reserved configuration area in code flash P/E mode.	0/1	0	0	0	0	1	0	0	0	1	0
	Program, block erase, or configuration set command is issued to TrustZone protection area in code flash P/E mode.	0/1	0	0	0	1	1	0	0	0	1	0
Data flash memory access violation	A program or block erase command is issued to the reserved data area in data flash P/E mode	0	0	0	0	0	1	0	0	0	0	1
	A multi block erase command is issued to the reserved data area in data flash P/E mode. (FSADDR is set to reserved data area).	1	0	0	0	0	1	0	0	0	0	1
	Blank Check command is issued to reserved data area in data flash P/E mode. (FSADDR is set to reserved data area).	1	0	0	0	0	1	0	0	0	0	1
	Configuration set command has been issued to reserved configuration area in data flash P/E mode.	0/1	0	0	0	0	1	0	0	0	0	1
	A program, block erase, multi block erase, blank check, configuration set, increment counter, refresh counter, or read counter command is issued to TrustZone protection area in data flash P/E mode.	0	0	0	0	0	1	0	0	0	0	1
Security error	Configuration set command for the SAS.BTFLG bit setting is issued when the SAS.FSPR bit is 0 (see section 47.9.3.15. Configuration Set Command)	0	0	1	0	0	1	0	0	0	0	0

Table 47.30 Error protection type (3 of 3)

Error type	Description	ILGOMERR	FESETERR	SECERR	OTERR	TZFERR	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE
Others	An FACI command-issuing area is accessed in read mode	0	0	0	1	0	1	0	0	0	0	0
	An FACI command-issuing area is read in code flash P/E mode or data flash P/E mode	0	0	0	1	0	1	0	0	0	0	0
Flash write erase protection error	A flash memory write protection error is detected by the FWEPROR register setting ² during command processing by the flash sequencer	0	0	0	0	0	0	0/1	0/1	1	0	0

Note 1. DFAE value depends on the FSADDR setting.

Note 2. For details on the FWEPROR register, see [section 47.4.8. FWEPROR : Flash P/E Protect Register](#).

47.11.3 Start-Up Program Protection

Protection of the startup program is for protection of the program to be started after a reset (the startup program). This function provides a way to safely update the startup program when rewriting is suspended during a reset.

The startup area is 8 Kbytes in size and is assigned to the user area in the code flash memory. This function uses the values of the SAS.BTFLG bit and the FSUACR.SAS[1:0] bits to change the area where the startup program is stored in block units (see [Figure 47.29](#) to [Figure 47.32](#)).

In protection of the startup program, the state of the selection of the startup area can be fixed by the FSPR bit. However, the SAS.FSPR bit never be restored to 1 once the flag is set to 0. Exercise extra caution when handling the SAS.FSPR bit.

In addition, this protection cannot be used when dual mode is selected by the bank mode switching function (when the BANKMD[2:0] bits are 000b).

For details of SAS.FSPR bit and DUALSEL.BANKMD[2:0] bits, see [section 6, Option-Setting Memory](#).

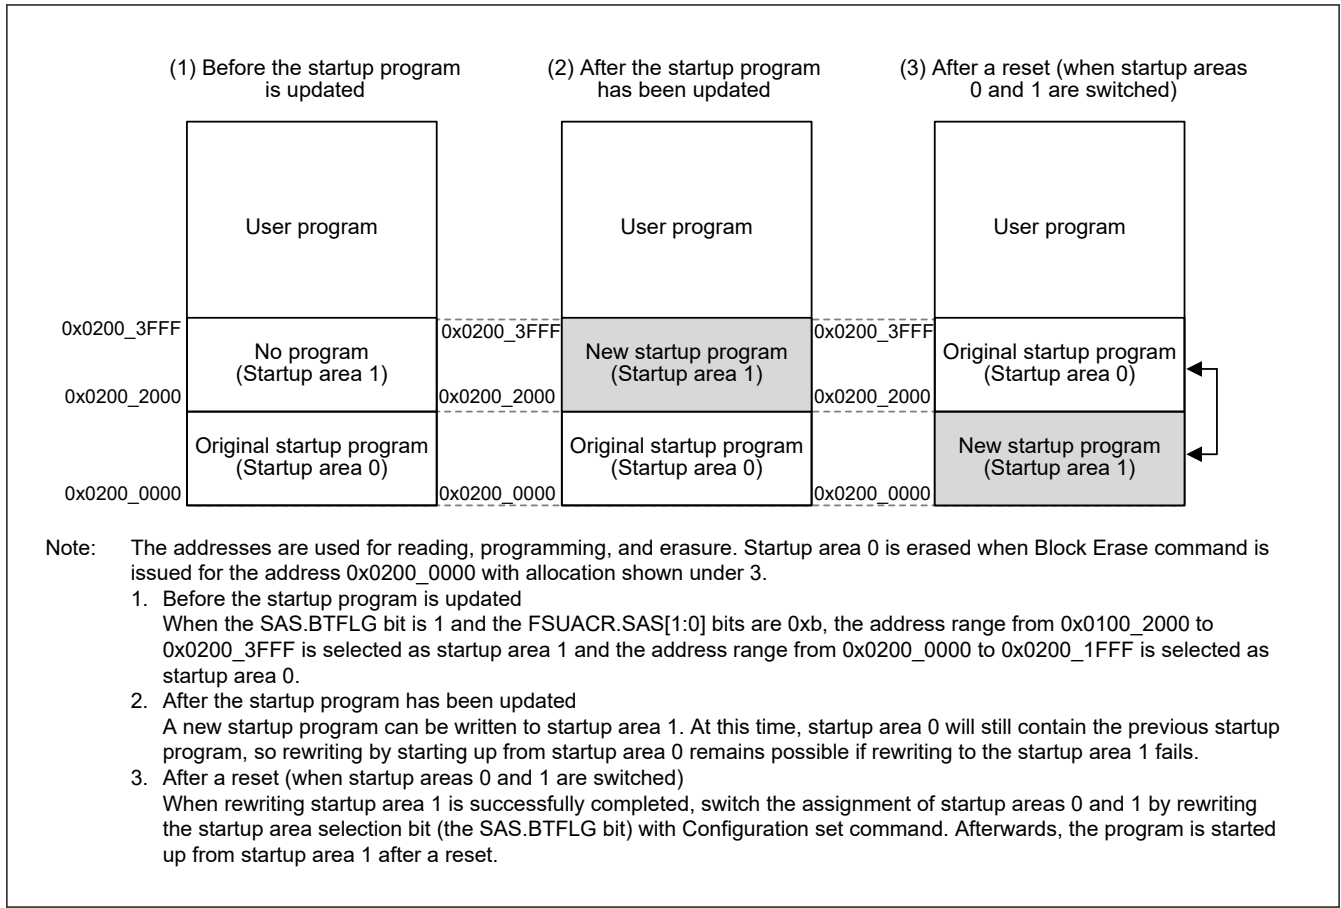

Figure 47.29 Concept of Protection of the Startup Program for Secure alias

Figure 47.30 Example 1 of Transitions for Startup Program Protection Settings for Secure alias

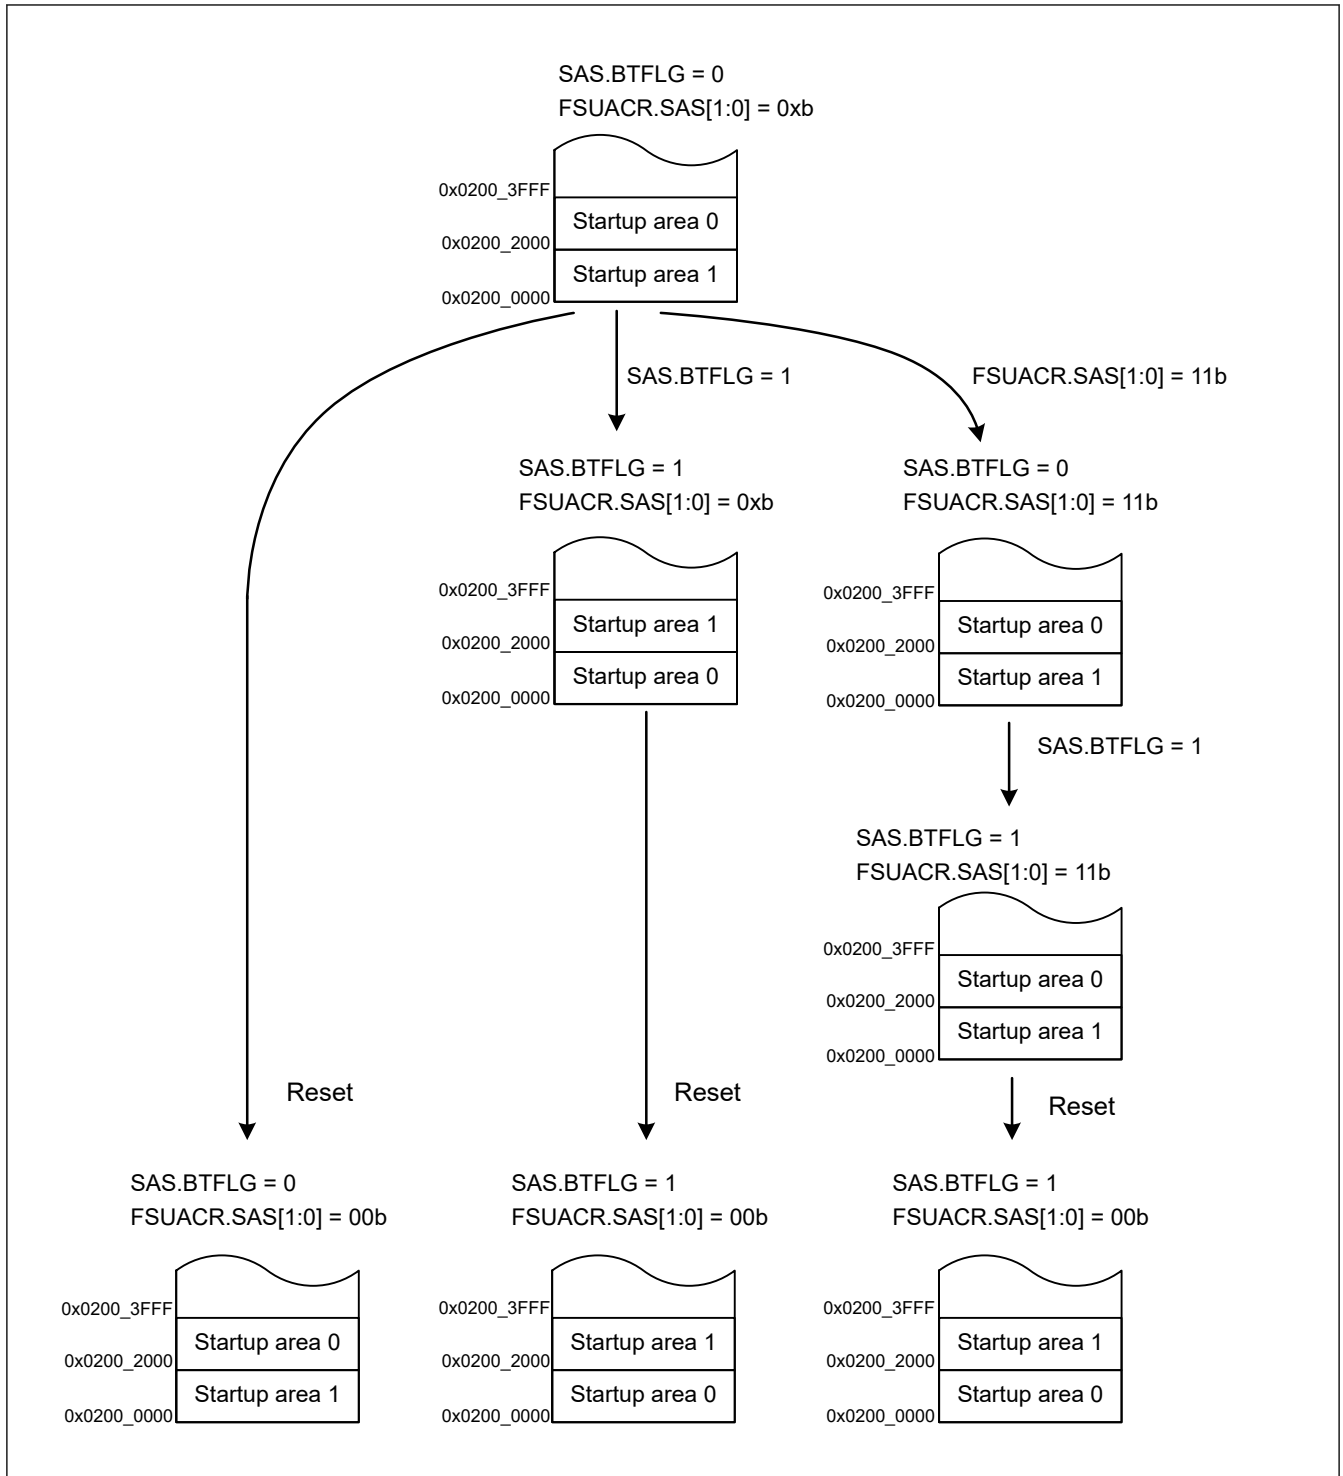

Figure 47.31 Example 2 of Transitions for Startup Program Protection Settings for Secure alias

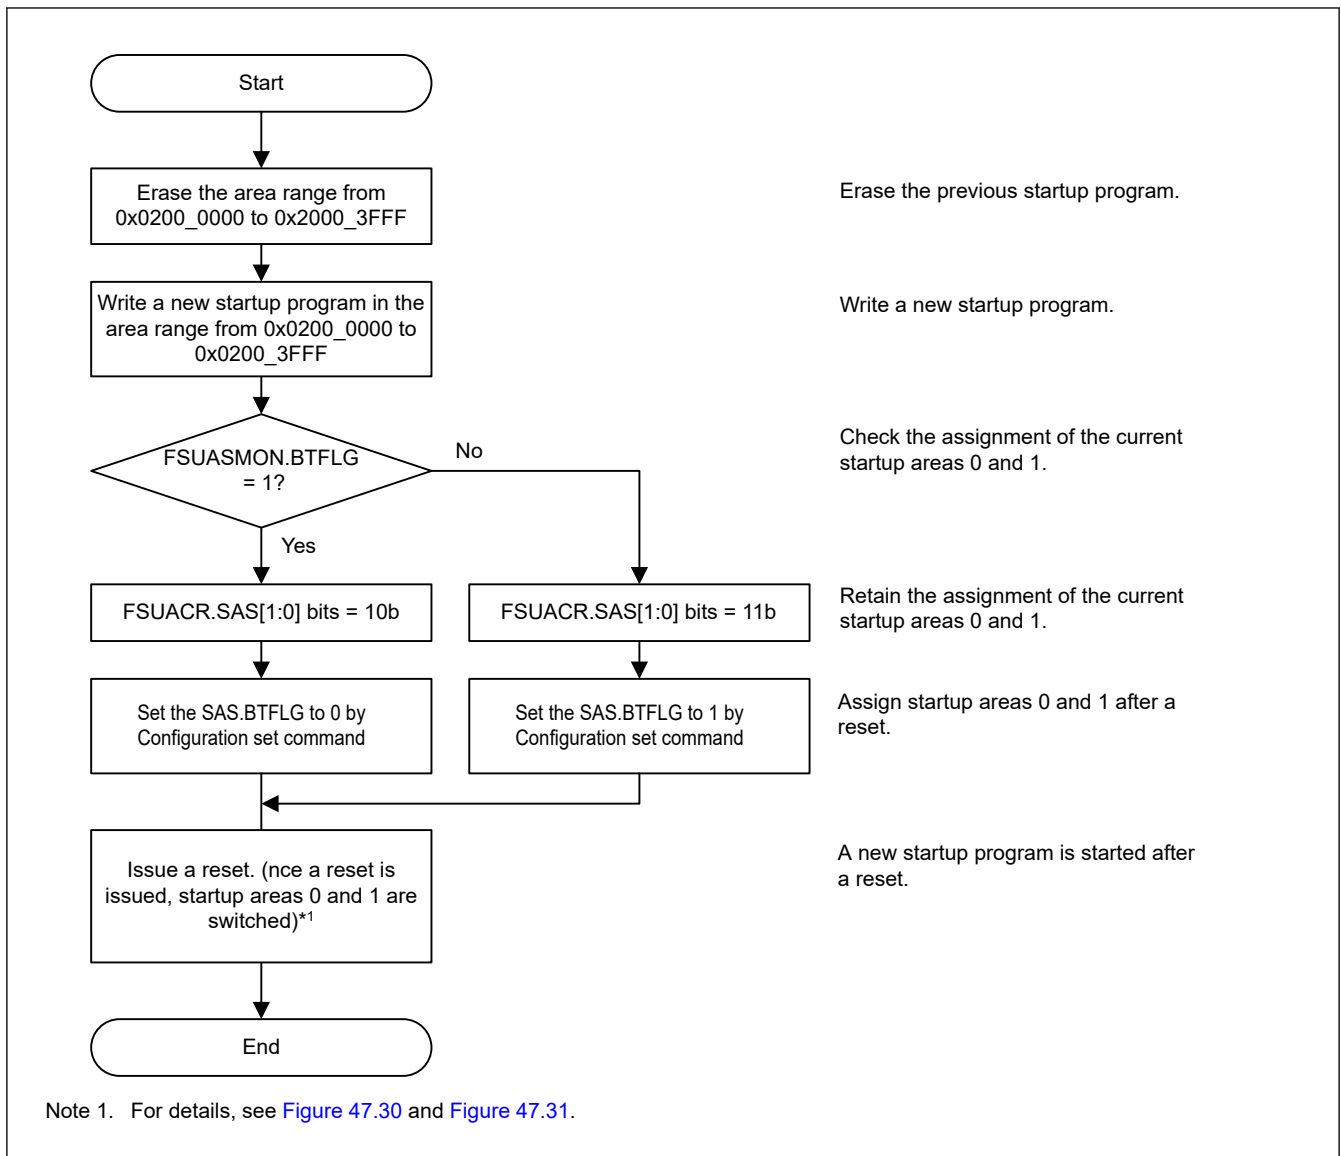

Figure 47.32 Concept of Protection of the Startup Program for Secure alias

47.11.4 Dual Bank Function

This protection uses the functions of bank mode switching and startup bank selection to update a program while a user program is running and to provide a safe method of updating in cases where programming is suspended during a reset.

47.11.4.1 Switching Bank Modes

The bank mode switching function selects either linear mode in which the user area in the code flash memory is used as one area, or dual mode in which the user area is divided into two bank areas. [Figure 47.33](#) shows an example of flow of switching bank modes. A reset after setting the DUALSEL.BANKMD[2:0] bits in the option setting memory determines the mode of the bank mode switching function. Selecting dual mode enables the startup bank selection function.

When dual mode is selected by bank mode switching function (the DUALSEL.BANKMD[2:0] bits are 000b), start-up program protection function cannot be used.

For details of DUALSEL.BANKMD[2:0] bits, see [section 6, Option-Setting Memory](#).

Figure 47.33 Example of Flow of Switching Bank Modes for Secure alias

47.11.4.2 Selecting the Startup Bank

Startup bank selection provides a way to safely update the program by selecting a bank area to be started in dual mode (when the DUALSEL.BANKMD[2:0] bits are 000b) when programming is suspended during a reset. Figure 47.34 is a schematic view of startup bank selection and Table 47.31 shows an example of the flow of startup bank selection. A reset after setting the value of the BANKSEL.BANKSWP[2:0] bits in the option-setting memory changes the addresses of banks 0 and 1 and booting up a program proceeds from the updated area. When the address is switched by using startup bank selection, the programming/erasure target for the FACI commands is also switched. This function is invalid in linear mode. For details of DUALSEL.BANKMD[2:0] bits and BANKSEL.BANKSWP[2:0] bits, see section 6, Option-Setting Memory.

Figure 47.34 Example of Startup Bank Selection for Secure alias

Table 47.31 Example of Startup Bank Selection Flow for Secure alias

No.	Step Name	Description
1	Erase block	Erase blocks to be programmed in the address range from 0x0220_0000 to 0x0227_FFFF
2	Program a new software	Program a new software in the address range from 0x0220_0000 to 0x0227_FFFF
3	Read the value	Read the value of the BANKSEL.BANKSWP[2:0] bits.
4	Write an inverted value	Write an inverted value in the BANKSEL.BANKSWP[2:0] bits*1.
5	Issue a reset	Issue a reset (A reset switches the banks.)

Note 1. Set the inverse of the read value of the BANKSEL.BANKSWP[2:0] bits (000b or 111b).

47.11.5 Block Swap Function

This protection uses the functions of block swap selection to update a program while a user program is running and to provide a safe method of updating in cases where programming is suspended during a reset.

47.11.5.1 Selecting the Block Swap

Block swap selection provides a way to safely update the program when programming is suspended during a reset. [Figure 47.35](#) is a schematic view of block swap selection and [Figure 47.36](#) shows an example of the flow of block swap selection. A reset after setting the value of the BANKSEL.BLCKSWP bit in the option-setting memory changes the addresses of block A and B. When the address is switched, the Programming/erasure target for the FACI commands is also switched.

In addition, this protection cannot be used when dual mode is selected by the bank mode switching function (when the DUALSEL.BANKMD[2:0] bits are 000b).

For details of DUALSEL.BANKMD[2:0] bits and BANKSEL.BLCKSWP bit, see [section 6, Option-Setting Memory](#).

Figure 47.35 Example of Block Swap Selection for Secure alias

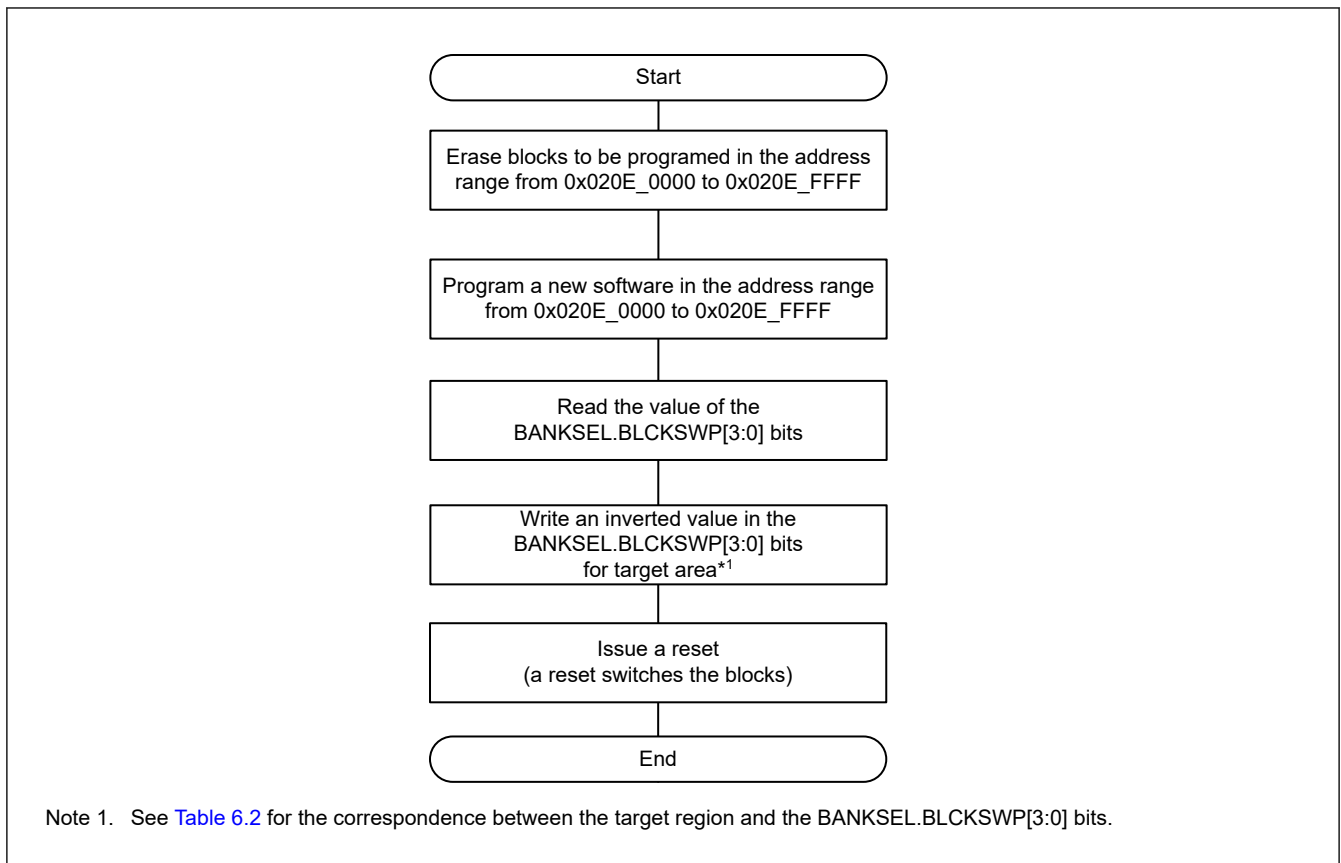

Figure 47.36 Example of Block Swap Selection Flow for Secure alias

47.12 Security Function

The flash sequencer supports the following security functions:

- Security flag for startup area
- Permanent block protect setting
- Flash memory protection for TrustZone
- Code Flash P/E mode Entry Protection
- Data flash configuration area protection
- Anti-rollback Counter

47.12.1 Security Flag for Startup Area Select

The security flag (SAS.FSPR) for the startup area is located in the option-setting memory.

When the SAS.FSPR bit is 0, issuing the configuration set command to change the SAS.BTFLG bit causes the flash sequencer to be in the command-locked state. Also, when the SAS.FSPR bit is 0, it is invalid to write to the Startup Area Select bits SAS[1:0] in the FSUACR register. The SAS.FSPR bit enables protection.

47.12.2 Permanent Block Protect Setting

The permanent block protect setting is the clear protection for the block protection setting. User area cannot be permanently updated by the FACL command when the permanent block protect setting is enabled. See [section 47.11.1.3. Protection by Block Protect Setting](#) for more details.

The block protect setting and the permanent block protect setting have the write/clear protection against the configuration set command. The flash sequencer does not detect an error when the configuration set command is issued to the write/clear protected settings.

Figure 47.37 and Table 47.32 show the write/clear protection against the block protect setting (BPS[n]) and the permanent protect setting (PBPS[n]). Figure 47.38 and Table 47.33 show the write/clear protection against the block protect setting for Secure (BPS_SEC[n]) and permanent protect setting for Secure (PBPS_SEC[n]).

Effective permanent block protect setting (PBPS or PBPS_SEC) depends on block protect select (BPS_SEL). For details of permanent block protect setting (PBPS or PBPS_SEC) and block protect select (BPS_SEL), see section 6, Option-Setting Memory.

Figure 47.37 Status transition of flash sequencer by BPS[n] and PBPS[n]

Table 47.32 Write/clear protection of BPS[n] , PBPS[n] and BPS_SEL[n]

Current state		Updatable state by configuration set command				
BPS[n]	PBPS[n]	BPS[n] = 1	BPS[n] = 0	PBPS[n] = 1	PBPS[n] = 0	BPS_SEL[n] = 1
1	1	✓	✓	✓	X	✓
1	0	—	—	—	—	—
0	1	✓	✓	✓	✓	✓
0	0	X	✓	X	✓	X

- Note:
- ✓ indicates updatable by configuration set command.
 - X indicates not updatable by configuration set command (error does not occur).
 - — indicates not reaching to this state.

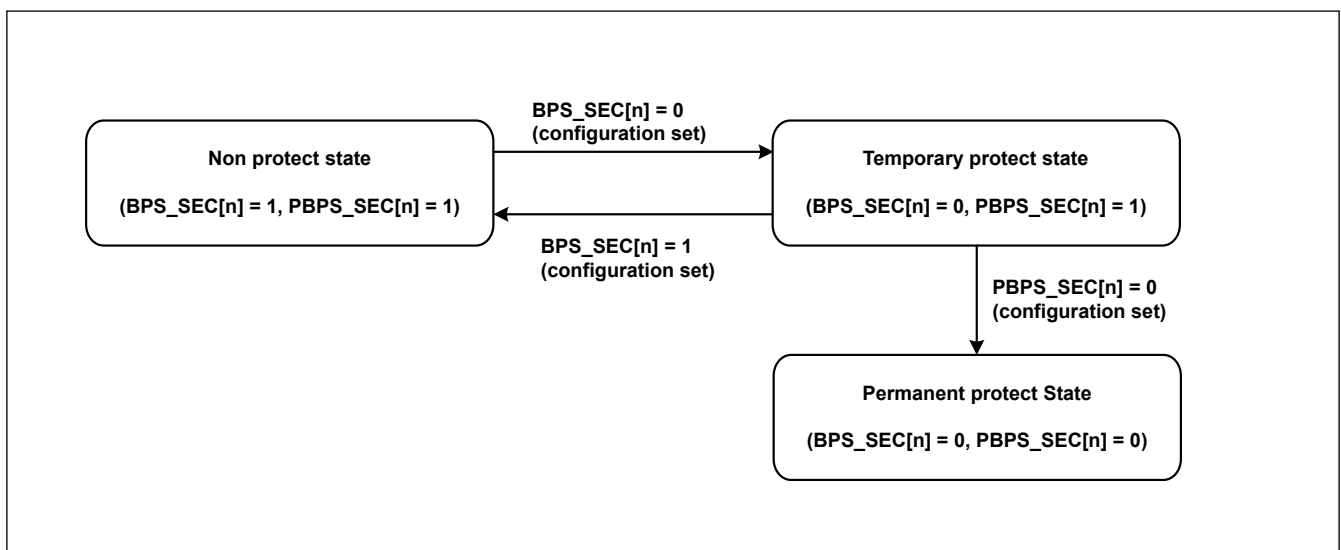

Figure 47.38 Status transition of flash sequencer by BPS_SEC[n] and PBPS_SEC[n]

Table 47.33 Write/clear protection of BPS_SEC[n], PBPS_SEC[n] and BPS_SEL[n]

Current state		Updatable state by configuration set command				
BPS_SEC[n]	PBPS_SEC[n]	BPS_SEC[n] = 1	BPS_SEC[n] = 0	PBPS_SEC[n] = 1	PBPS_SEC[n] = 0	BPS_SEL[n] = 0
1	1	✓	✓	✓	X	✓
1	0	—	—	—	—	—
0	1	✓	✓	✓	✓	✓
0	0	X	✓	X	✓	X

Note:

- ✓ indicates updatable by configuration set command.
- X indicates not updatable by configuration set command (error does not occur).
- indicates not reaching to this state.

47.12.3 Flash Memory Protection for TrustZone

Information in this section focuses on the flash sequencer operation.

The flash memory provides the following types of protect function against Non-secure access:

- Protection for flash memory area (P/E)
- Protection for flash memory area (read)
- Protection for registers
- Code flash P/E mode entry protection

47.12.3.1 Protection for Flash Memory Area (P/E)

This function protects the Secure region of the code flash and data flash from FACI commands of Non-secure access. The condition of protection depends on the FACI command, the access attribution, and the memory boundary setting.

For details of Secure region, see [section 38, Security Features](#).

See [Table 47.34](#) for information on protection of the flash memory area (P/E).

Table 47.34 Protection for the flash memory area (P/E) (1 of 2)

FACI command	Target area			Issuing FACI command by Non-secure access	Issuing FACI command by Secure access
Program Block Erase	Code flash memory	User area (Non-secure area)	Secure alias ^{*1}	X	X
			Non-secure alias ^{*2}	✓	✓
		User area (Secure area)	Secure alias ^{*1}	X	✓
			Non-secure alias ^{*2}	X	X
	Data flash memory	Data area (Non-secure area)	Secure ^{*1} alias	X	X
			Non-secure alias ^{*2}	✓	✓
		Data area (Secure area)	Secure alias ^{*1}	X	✓
			Non-secure alias ^{*2}	X	X

Table 47.34 Protection for the flash memory area (P/E) (2 of 2)

FACI command	Target area			Issuing FACI command by Non-secure access	Issuing FACI command by Secure access
Multi Block Erase Blank Check	Data flash memory	Data area (Non-secure area)	Secure alias ^{*3}	X	X
			Non-secure alias ^{*4}	✓	✓
		Data area (Secure area)	Secure alias ^{*3}	X	✓
			Non-secure alias ^{*4}	X	X
Configuration set	Code flash memory	Configuration area (Non-secure area)	Secure alias ^{*1}	X	X
			Non-secure alias ^{*2}	✓	✓
		Configuration area (Secure area)	Secure alias ^{*1}	X	✓
			Non-secure alias ^{*2}	X	X
	Data flash memory	Configuration area (Secure area only)	Secure alias ^{*1}	X	✓
			Non-secure alias ^{*2}	X	X
Increment Counter Refresh Counter Read Counter	Data flash memory	Anti-rollback counter area(Secure area only)	-	X	✓

Note:
 • ✓ indicates FACI command operation is not prohibited.
 • X indicates FACI command operation is prohibited. Error occurs when the area is selected, and the FACI command is executed.

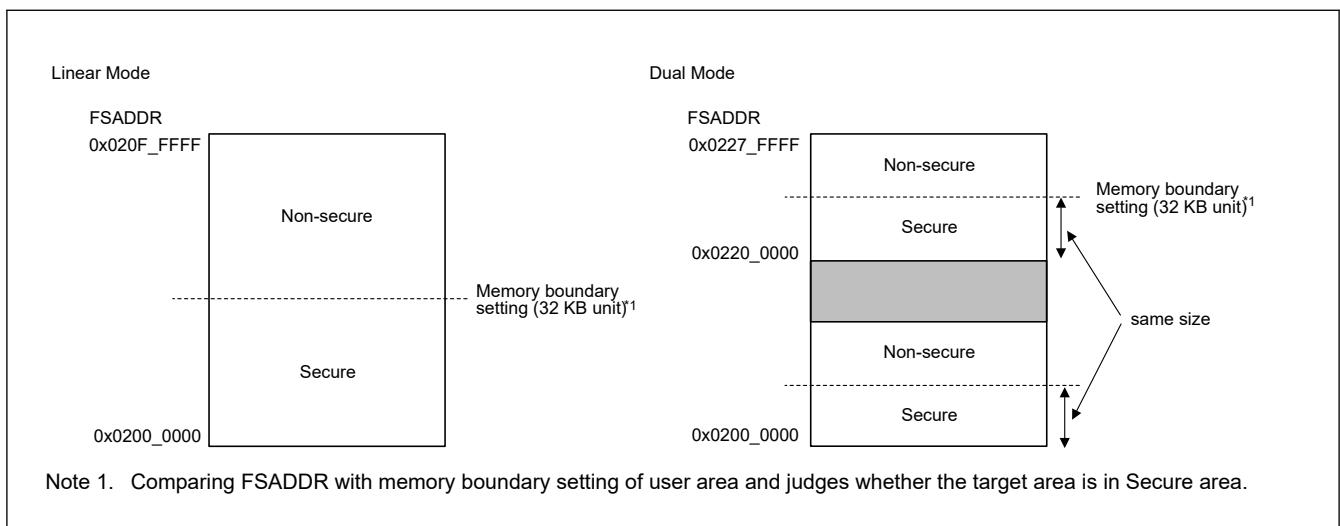

- Note 1. The Secure alias is judged when the address of FSADDR[28] is 0.
- Note 2. The Non-secure alias is judged when the address of FSADDR[28] is 1.
- Note 3. The Secure alias is judged when the address of FSADDR[28] and FEADDR[28] are 0.
- Note 4. The Non-secure alias is judged when the address of FSADDR[28] and FEADDR[28] are 1.

When the target area of FACI command is the user area of code flash, the flash sequencer compares the FSADDR register setting with the memory boundary setting of the code flash and determines whether the target area is in the Secure region.

In linear mode, the memory boundary can be set to 0x0200_0000 to 0x020F_8000 in 32 KB unit.

In dual mode, the memory boundary can be set to 0x0200_0000 to 0x0220_0000 in 32 KB unit. When the memory boundary is set to 0x0220_0000 or greater in the dual mode, the entire user area is defined as the Secure region.

Figure 47.39 shows details of the Secure and Non-secure attribute of user area in the code flash.

Note 1. Comparing FSADDR with memory boundary setting of user area and judges whether the target area is in Secure area.

Figure 47.39 Secure and Non-secure region in user area for Secure alias

When the target area of the issuing FACI command is the data area of data flash, the flash sequencer compares the FSADDR/FEADDR register setting with the memory boundary setting of the data flash and determines whether the target area is in Secure region. The memory boundary can be set to 0x0270_0000 to 0x0270_FC00 in 1 KB unit. Figure 47.40 shows details of the Secure and Non-secure attribute of data area in the data flash.

Figure 47.40 Secure and Non-secure region in data area for Secure alias

See Figure 47.41 in the details of Secure and Non-secure region of option-setting memory. The flash sequencer judges that target area is Secure region from the FSADDR register setting.

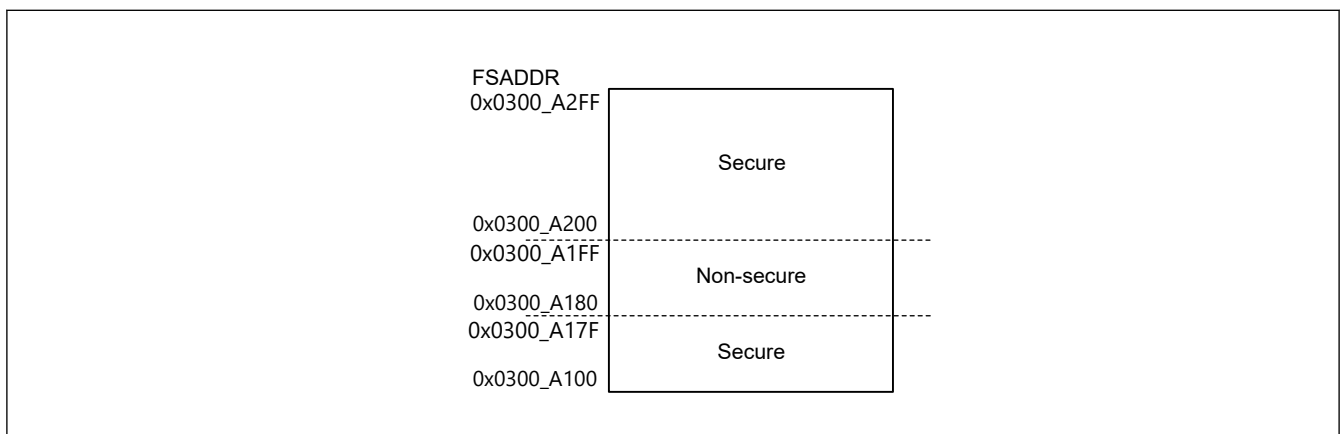

Figure 47.41 Secure and Non-secure region in option-setting memory for Secure alias

47.12.3.2 Protection for Flash Memory Area (Read)

This function protects the Secure region of code flash and data flash from Non-secure bus access.

For details of Secure region, see [section 38, Security Features](#) .

47.12.3.3 Protection for Register

The flash sequencer registers have write-access protection against Non-secure access. Table 47.35 shows details of the protected registers of the flash sequencer.

Table 47.35 Protected registers of the flash sequencer for TrustZone (1 of 2)

Protection target register	Security attribute setting	Notes
FCKMHZ register	SA register setting (FSAR.FCKMHZSA)	For details of section 47.4.4. FSAR : Flash Security Attribution Register
Flash Access area	SA register setting (FSAR.FACICMISA)	For details of section 47.4.4. FSAR : Flash Security Attribution Register

Table 47.35 Protected registers of the flash sequencer for TrustZone (2 of 2)

Protection target register	Security attribute setting	Notes
FACI registers* ¹ and FWEPROR registers	SA register setting (FSAR.FACICMRSA)	For details of section 47.4.4. FSAR : Flash Security Attribution Register
FCTRCNTR, FCTRLSR FCTRADDR, and FCTRSTATR registers	SA register setting (FSAR.FACITRSA)	For details of section 47.4.4. FSAR : Flash Security Attribution Register
FMEPROT, FCNTSELR, FCNTDATAR0 to 1, FBPROT1 and FSUACR registers	Always Secure	—

Note 1. The target FACI registers are FASTAT, FAEINT, FRDYIE, FSADDR, FEADDR, FBPROT0, FSTATR, FENTRYR, FSUINITR, FCMDR, FBCCNT, FBCSTAT, FPSADDR, FSUASMON, FCPSR, and FPCKAR.

47.12.3.4 Code Flash P/E Mode Entry Protection

The flash sequencer has protection function of code flash P/E by the FMEPROT register for the Secure developer. Secure function can prevent disturbance of reading code flash memory by this protection function. See [section 47.4.14. FMEPROT : Flash P/E Mode Entry Protection Register](#).

For applications that do not require Non-secure region programming/erasure other than from Secure function, it is recommended to always disable Non-secure function of code flash programming/erasure by enabling the protection function of FMEPROT register.

For details, see [Figure 47.42](#) of the code flash P/E sequence example by Non-secure function.

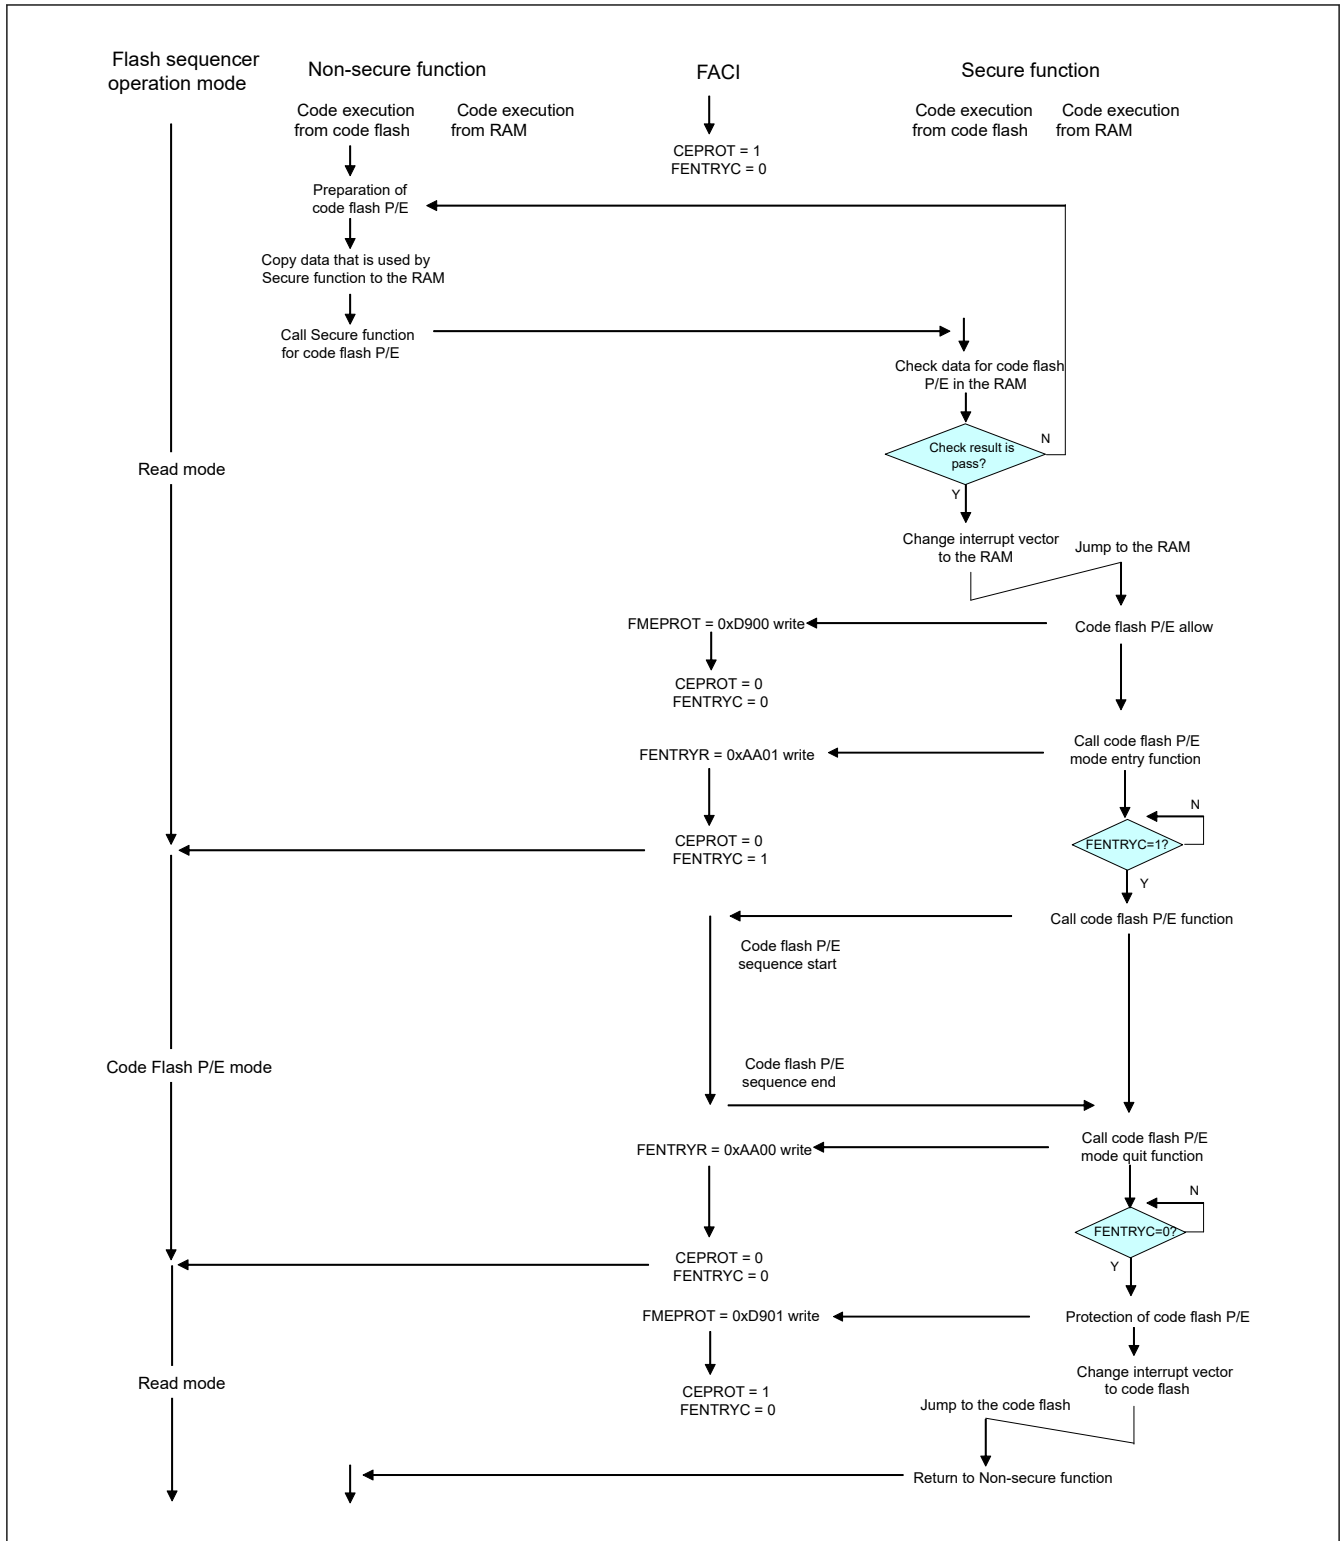

Figure 47.42 Code Flash P/E Sequence Example by Non-secure function (Using Secure function for code flash P/E)

47.12.4 Data Flash Configuration Area Protection

Data flash configuration area has 3 types of lockable area (LK_CD_A0, LK_CD_A1, and LK_CD_A2) by lock bit. When target area of "Configuration set" command includes protection area by lock bit, flash sequencer detects an error and enters "Command Lock" state.

LK_CD_A0 and LK_CD_A1 are protected 4 bytes data by 1 lock bit.

LK_CD_A2 are protected 16 bytes data by 1 lock bit. See in details of protection for flash memory area (P/E). See [Table 47.36](#) in detail of protection condition of lockable area in data flash configuration area.

Table 47.36 Protection Condition of Lockable area in Data Flash Configuration Area for Secure alias

Lockable Area		Protection Size	Lock Bit	Remarks
Area Name	address			
LK_CD_A0	0x2703_0098 ~ 0x2703_009B	4 bytes	CD0_LK6	In the case of the 16-byte Configuration set command, data cannot be updated if any of the lock bits corresponding to the update address is 0.
	0x2703_009C ~ 0x2703_009F	4 bytes	CD0_LK7	
	:	:	:	
	0x2703_0170 ~ 0x2703_0173	4 bytes	CD0_LK60	
	0x2703_0174 ~ 0x2703_0177	4 bytes	CD0_LK61	
	0x2703_0178 ~ 0x2703_017B	4 bytes	CD0_LK62	
	0x2703_017C ~ 0x2703_017F	4 bytes	CD0_LK63	
LK_CD_A1	0x2703_0180 ~ 0x2703_0183	4 bytes	CD1_LK0	
	0x2703_0184 ~ 0x2703_0187	4 bytes	CD1_LK1	
	:	:	:	
	0x2703_0270 ~ 0x2703_0273	4 bytes	CD1_LK60	
	0x2703_0274 ~ 0x2703_0277	4 bytes	CD1_LK61	
	0x2703_0278 ~ 0x2703_027B	4 bytes	CD1_LK62	
	0x2703_027C ~ 0x2703_027F	4 bytes	CD1_LK63	
LK_CD_A2	0x2703_0280 ~ 0x2703_028F	16 bytes	CD2_LK0	
	0x2703_0290 ~ 0x2703_029F	16 bytes	CD2_LK1	
	:	:	:	
	0x2703_0340 ~ 0x2703_034F	16 bytes	CD2_LK12	
	0x2703_0350 ~ 0x2703_035F	16 bytes	CD2_LK13	

47.12.5 Anti-Rollback Counter

See [section 6.2.14. ARCLS : Anti-Rollback Counter Lock Setting](#) to [section 6.2.17. ARC_NSECn : Anti-Rollback Counter for Non-secure Application n \(n = 0 to 7\)](#) for Anti-rollback counter related Option flash memory.

Anti-rollback counter cannot be decremented and is used in the firmware update. Only Secure applications are available. Anti-rollback counter shifts one bit to the left with the increment counter command from the initial value of 0. The least significant bit (bit 0) is set to 1. When anti-rollback counter is maximum value, flash sequencer does not change counter by Increment Counter command (does not occur error).

There are three commands that control the counters. For details, see [section 47.9.3.16. Increment Counter Command](#), [section 47.9.3.17. Refresh Counter Command](#), and [section 47.9.3.18. Read Counter Command](#).

[Figure 47.43](#) shows anti-rollback counter increment image when increment counter command is issued.

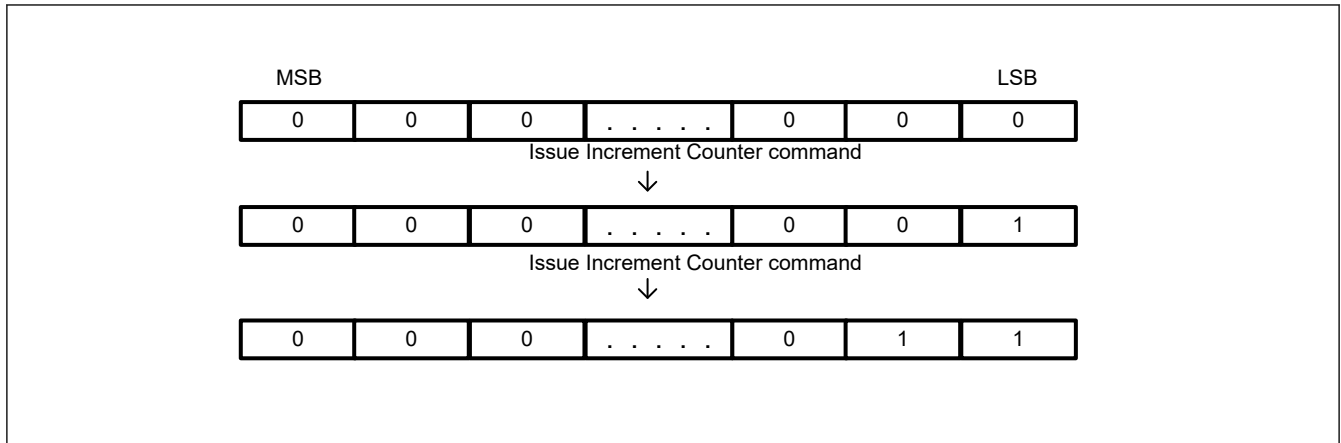

Figure 47.43 Increment image of anti-rollback counter

Anti-rollback counter has 2 types of counters (ARC_SEC and ARC_NSEC) and lock bit (ARCSEC_LK, ARCNSEC_LK0 to 3) for protection each counter.

ARC_NSEC can be configured as 1 × 256 or 4 × 64 bits by configuration area setting (CNF_ARCNS0 and CNF_ARCNS0) and cannot be updated in invalid setting.

47.12.5.1 Anti-Rollback Counter Recovery Flow

Figure 47.44, Figure 47.45 and Figure 47.46-4 shows the recovery flow in the case of anti-rollback counter for secure application. The recovery flow for rest anti-rollback counter should be considered necessary processing to depend on customer's application by Secure software developer. As an example, the flow in dual mode is shown. In linear mode, the same operation can be performed using start-up area select, but application size that be managed by anti-rollback counter should be limited to 8 KB.

Example Operation: Update from Bank0 selected in Dual mode

Notation

UCF: Update Complete Flag set/clear by Secure software.
 ICF: Increment Complete Flag set/clear by Secure software.
 Set status: Indicate that update processing is completed.
 Clear status: Indicate that the update processing is not completed.

User area bank0 (Valid)	Secure application/v0 etc.
User area bank1 (Invalid)	
Data Flash Config. Area	UCF/set
	ICF/set
Code Flash Config. Area	Bank0 select
Anti-rollback counter	Counter/v0

Step 0 Status before update

Secure application is before version update in bank0.

User area bank0 (Valid)	Secure application/v0 etc.
User area bank1 (Invalid)	Secure application/v1 etc.
Data Flash Config. Area	UCF/clear
	ICF/clear
Code Flash Config. Area	Bank0 select
Anti-rollback counter	Counter/v0

Step 1 Write new secure application, Clear UCF and ICF

UCF and ICF are cleared by configuration set command.
 Next, new secure application etc. is written to invalid user area by program/erase command.

How to select recovery flow:

It can check that power failure is occurred by below status.

- UCF is clear status.
- Counter value is old version.

Recovery flow:

It should resume from step1.

Figure 47.44 Recovery flow of secure application update in Dual mode at power failure (1/3)

Example Operation: Update from Bank0 selected in Dual mode

Notation

UCF: Update Complete Flag set/clear by Secure software.
 ICF: Increment Complete Flag set/clear by Secure software.
 Set status: Indicate that update processing is completed.
 Clear status: Indicate that the update processing is not completed.

User area bank0 (Valid)	Secure application/v0 etc.
User area bank1 (Invalid)	Secure application/v1 etc.
Data Flash Config. Area	UCF/set
	ICF/clear
Code Flash Config. Area	Bank0 select
Anti-rollback counter	Counter/v0

Step 2 Set UCF

UCF is set by configuration set command.

How to select recovery flow:

Same as step1.

Recovery flow:

Same as step1.

User area bank0 (Valid)	Secure application/v0 etc.
User area bank1 (Invalid)	Secure application/v1 etc.
Data Flash Config. Area	UCF/set
	ICF/set
Code Flash Config. Area	Bank0 select
Anti-rollback counter	Counter/v1

Step 3 Update counter version, Set ICF

Secure application version counter is update by increment counter command. Next, ICF is set by configuration set command.

How to select recovery flow(a):

It can check that power failure is occurred by below status.

- UCF is set status.
- ICF is clear status.
- Counter value is old version.

Recovery flow(a):

It should issue refresh counter command. Next, after clearing UCF, it should resume from step1.

How to select recovery flow(b):

It can check that power failure is occurred by below status.

- UCF is set status.
- ICF is clear status.
- Counter value is new version.

Recovery flow(b):

It should issue refresh counter command and set ICF. Next, it should resume from step4.

User area bank0 (Valid)	Secure application/v0 etc.
User area bank1 (Invalid)	Secure application/v1 etc.
Data Flash Config. Area	UCF/clear
	ICF/clear
Code Flash Config. Area	Bank1 select
Anti-rollback counter	Counter/v1

Step 4 Update bank selection

BANKSWP[2:0] bits are changed to bank1 selection by configuration set command.

How to select recovery flow:

It can check that power failure is occurred by below status.

- UCF is set status.
- ICF is set status.
- Counter value is new version.
- BANKSWP[2:0] bits are bank0 selection.

Recovery flow:

It should resume from step4.

Figure 47.45 Recovery flow of secure application update in Dual mode at power failure (2/3)

Example Operation: Update from Bank0 selected in Dual mode

Notation

UCF: Update Complete Flag set/clear by Secure software.
 ICF: Increment Complete Flag set/clear by Secure software.
 Set status: Indicate that update processing is completed.
 Clear status: Indicate that the update processing is not completed.

User area bank0 (Invalid)	Secure application/v0 etc.
User area bank1 (valid)	Secure application/v1 etc.
Data Flash Config. Area	UCF/set
	ICF/clear
Code Flash Config. Area	Bank1 select
Anti-rollback counter	Counter/v1

Step 5 Switch valid user area

Bank1 is changed to valid area after system reset.
 New secure application should check that update processing is completed successfully by checking UCF, ICF, and anti-rollback counter

Figure 47.46 Recovery flow of secure application update in Dual mode at power failure (3/3)

47.13 Boot Mode

There are two serial programming modes; the boot mode (for the SCI interface) with SCI9 and the boot mode (for the USB interface) with USBFS. Table 47.37 lists the I/O pins used in boot mode. Table 47.38 lists the available communication interface used in the boot mode.

Table 47.37 I/O Pins Used in Boot Mode

Pin Name	I/O	Mode to be Used	Use
MD	Input	Boot mode (for the SCI interface) Boot mode (for the USB interface) Boot mode (for the JTAG interface) Boot mode (for the SWD interface)	Selection of operating mode
P208/RXD9	Input	Boot mode(for the SCI interface)	For host communication (to receive data through SCI)
P209/TXD9	Output		For host communication (to transmit data through SCI)
USB_DP, USB_DM	I/O	Boot mode(for the USB interface)	Data input/output of USB
USB_VBUS	Input		Detection of connection and disconnection of USB cables
P211/TCK	Input	Boot mode (for the JTAG interface)	Clock pin of JTAG
P210/TMS	Input		Mode Select pin of JTAG
P208/TDI	Input		Data In pin of JTAG
P209TDO	Output		Data Out pin of JTAG
P211/SWCLK	Input	Boot mode (for the SWD interface)	Clock pin of SWD
P210/SWDIO	I/O		Data In-Out pin of SWD

Table 47.38 Available Communication Interface Used in Boot Mode (1 of 2)

	Yes	No	No
Main clock oscillator or external clock is connected	Yes	No	No
Sub clockoscillator is connected*1	Yes or No	Yes	No
Available interface	JTAG, SWD, SCI or USB	JTAG, SWD, SCI or USB	JTAG, SWD or SCI

Table 47.38 Available Communication Interface Used in Boot Mode (2 of 2)

Tool connection time*2	Up to 1 second	Up to 2 seconds	Up to 3 seconds
------------------------	----------------	-----------------	-----------------

Note 1. The drive capability of the sub clock oscillator is set to standard by SOMCR.SODRV bit. Note that if you use the crystal corresponding the low drive capability on your board, the crystal may not oscillate in the boot mode.

Note 2. See the boot firmware manual for the detail connection time.

47.13.1 Boot Mode (for the SCI Interface)

In boot mode (for the SCI interface), the host sends control commands and data for programming, and the flash memory is programmed or erased accordingly. An on-chip SCI handles transfer between the host and this MCU in asynchronous mode. Tools for transmission of control commands and the data for programming must be prepared in the host.

When this MCU is activated in boot mode (for the SCI interface), the program on the dedicated area the MCU is executed. The boot program automatically adjusts the bit rate of the SCI and controls programming/erasure by receiving control commands from the host.

Figure 47.47 shows the system configuration for operations in boot mode (for the SCI interface).

Figure 47.47 System Configuration for Operations in Boot Mode (for the SCI Interface)

47.13.2 Boot Mode (for the USB Interface)

In boot mode (with the USB interface), the flash memory can be programmed or erased by sending control commands and program data from the host. An on-chip USB is used for communications between the host and this MCU. The host requires tools for sending control commands and data for programming. Figure 47.48 shows the configuration of a system for use in boot mode (for the USB interface). The USB cable must be connected on reset release.

Figure 47.48 System Configuration in Boot Mode (for the USB Interface)

47.14 Using the Serial Programmer for Rewriting

A serial programmer can be used to rewrite flash memory in boot mode.

(1) Serial Programming

This MCU is mounted on the system board at the time of serial programming. Providing a connector to the board enables rewriting of this MCU by the serial programmer to proceed.

47.14.1 Environments for Serial Programming

The recommended environments for rewriting the flash memory of the MCU with data are described below.

Figure 47.49 Environments for Rewriting the Flash Memory

47.15 Programming through Self-Programming

47.15.1 Overview

This MCU supports programming of the flash memory by the user program itself. The FACL commands can be used with user programs for writing to the flash memory. This allows upgrading of user programs and rewriting of constant data fields.

The program for rewriting must be transferred to the internal RAM or external memory in advance when the BGO is not available or when rewriting the option-setting memory.

Figure 47.50 Schematic View of Self-Programming

For comprehensive information on the self-programming, see [section 47.9. FACL Commands](#).

47.15.2 Background Operation

The background operation (BGO) can be used to execute the flash rewrite routine on the code flash memory when the data flash memory or other area of code flash memory is rewritten.

Background operations can be used when the combination of the flash memory for rewriting and the flash memory for reading is any of those listed below.

Table 47.39 Conditions under which Background Operation is Usable

		Range for rewriting	Range for reading
Common to linear and dual modes		Code flash memory	Data flash memory
		Data flash memory	Code flash memory
Liner mode	Products with 1 Mbytes of code flash memory	First half (0.5 Mbytes) of the code flash memory addresses Secure alias: 0x0200_0000 to 0x0207_FFFF Non-secure alias: 0x1200_0000 to 0x1207_FFFF	Second half (0.5 Mbytes) of the code flash memory addresses Secure alias: 0x0208_0000 to 0x020F_FFFF Non-secure alias: 0x1208_0000 to 0x120F_FFFF
		Second half (0.5 Mbytes) of the code flash memory addresses Secure alias: 0x0208_0000 to 0x020F_FFFF Non-secure alias: 0x1208_0000 to 0x120F_FFFF	First half (0.5 Mbytes) of the code flash memory addresses Secure alias: 0x0200_0000 to 0x0207_FFFF Non-secure alias: 0x1200_0000 to 0x1207_FFFF
Dual mode	When the BANKSEL_SEC.BANKSWP[2:0] or BANKSEL.BANKSWP[2:0] bits are 111b	Bank 1 area of the code flash memory	Bank 0 area of the code flash memory
	When the BANKSEL_SEC.BANKSWP[2:0] or BANKSEL.BANKSWP[2:0] bits are 000b	Bank 0 area of the code flash memory	Bank 1 area of the code flash memory

47.16 Reading Flash Memory

47.16.1 Reading Code Flash Memory

Special settings are not required to read code flash memory after release from the reset state. Data can simply be read out through access to addresses in the code flash memory.

When reading code flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state), all bits are read as 1.

47.16.2 Reading Data Flash Memory

Special settings are not required to read data flash memory after release from the reset state. Data can simply be read out through access to addresses in the data flash memory.

Values read from data flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state) are undefined. Use blank checking when you need to confirm that an area is in the non-programmed state.

47.17 Usage Notes

(1) Reading Area Where Programming/Erase was Interrupted and Area Targeted for Suspension

The data stored in the area where programming or erasure has been suspended or the area where programming or erasure has been suspended by using the suspend command are undefined. To avoid faulty operation caused by reading undefined data, take care not to fetch instructions or read data from areas where programming or erasure was suspended and where programming or erasure was suspended by using the suspend command.

(2) Suspension During Programming/Erase

When processing of programming/erasure is stopped by issuing the P/E suspend command, the programming/erasure processing can be resumed by issuing the P/E resume command. If the flash sequencer enters the command-locked state for any reason and issues the forced stop command after the suspended processing is normally completed and the ERSSPD flag or PRGSPD flag is set to 1, the suspended processing cannot be resumed. In addition, the values in the area where the processing was suspended are not guaranteed. Erase that area

(3) Prohibition of Additional Programming

Programming a given area of the code flash memory or data flash memory twice is not possible. To program the code flash memory or data flash memory where has been programmed, erase the target area. Programming can be added to the option-setting memory.

(4) Resets During Programming/Erase, or Blank Checking

In the case of a reset due to the signal on the RES pin during programming/erasure, or blank checking of the flash memory, wait for at least t_{RESW} (see [section 51, Electrical Characteristics](#)) of the reset input period once the operating voltage is within the range stipulated in the electrical characteristics, then release the device from the reset state.

(5) Allocation of Vectors for Interrupts and Other Exceptions During Programming/Erase

Generation of an interrupt or other exception during programming/erasure may lead to fetching of the vector from the code flash memory. Under conditions where BGO cannot be used, set the address of the vector to an address that is not in the code flash memory. Alternatively, make sure that no handling of interrupts or exceptions proceeds during programming/erasure.

(6) Items Prohibited During Programming/Erase, or Blank Checking

High voltage is applied to the flash memory during programming/erasure, or blank checking. To prevent damage to the flash memory, do not perform the following operations.

- Have the operating voltage from the power supply go beyond the permitted range.
- Change the FWEPROR.FLWE[1:0]bits.
- Change the OPCCR.OPCM[2:0] bits.
- Change the SCKDIVCR.FCK[2:0]bits.
- Change the SCKSCR.CKSEL[2:0]bits.
- Transition to the software standby mode, or Deep Software Standby mode.

(7) Programming/Erase in Low-Speed Modes

Do not programming/erasure the flash memory when low-speed mode is selected with the operating power control register (OPCCR).

(8) Setting dual bank mode and programming in Boot Mode

The initial mode of the MCU shipped from Renesas is linear mode. In customer's factory when programming dual bank mode and customer's applications on MCU set in linear mode, it is recommended that only area1 in Figure 47.51 is programmed in boot mode and area2 is kept blank. After reset, MCU starts in dual mode and the application is in bank0. Use self-programming when programming area2 for updating in the field. See section 38.7. Field Updating in Dual Mode for details

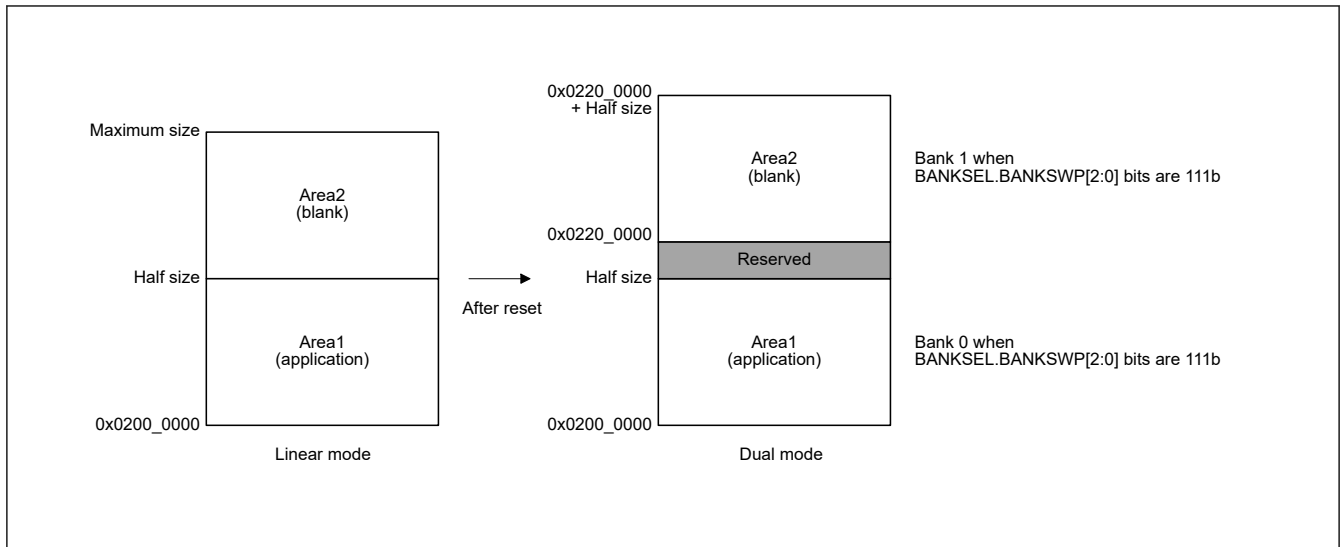

Figure 47.51 Programming the application for the dual mode in the linear mode

(9) Emulator Connection

Renesas provides the emulator which supports both debugging using SWD or JTAG communication and serial programming using SCI communication.

Table 47.40 shows the pinout of 10 pin or 20 pin socket pinouts when using this emulator. The pinout of SWD and JTAG is ARM standard, and MD, TXD, RXD pins are added for the serial programming using SCI communication.

Table 47.40 Pin assign for emulator

Pin No.	SWD	JTAG	Serial Programming using SCI
1	VCC	VCC	VCC
2	P210/SWDIO	P210/TMS	NC
4	P211/SWCLK	P211/TCK	P201/MD
6	P209/SWO	P209/TDO	P209/TXD9
8	P208	P208/TDI	P208/RXD9

48. 2D Drawing Engine (DRW)

48.1 Overview

This MCU incorporates a 2D drawing engine (DRW). [Table 48.1](#) lists the DRW specifications.

Table 48.1 DRW Specifications

Item		Descriptions
Vector drawing engine		Extended rendering primitives supported in hardware <ul style="list-style-type: none"> • Lines • Polygons • Circles and ellipses • Quadratic Béziers • Texture mapping
BitBLT function		Types of BitBLT operations <ul style="list-style-type: none"> • Fill • Copy • Stretch BitBLT • Rotate and scale • Alpha blending • Bilinear filtering • Color conversion • Subpixel exact placement
Color format	Frame buffer	Four types <ul style="list-style-type: none"> • A (8) • RGB (565) • ARGB (4444) • ARGB (8888)
	Texture	11 types <ul style="list-style-type: none"> • CLUT (1)/I (1) • CLUT (2)/I (2) • CLUT (4)/I (4) • CLUT (8)/I (8) • A (8) • ACLUT (44) • RGB (565) • ARGB (4444) • ARGB (1555) • RGB (888) • ARGB (8888)
Texture		<ul style="list-style-type: none"> • Run-length encoding (RLE) unit • 256-entry color look-up table (CLUT) • Color keying unit
Render		Two modes for rendering process <ul style="list-style-type: none"> • Register mode • Display list mode
Data arrangement		Little endian
Performance counter		<ul style="list-style-type: none"> • Two independent 32-bit counters • Trigger is selectable from 14 events
Interrupt sources		Three interrupt sources <ul style="list-style-type: none"> • 2D Drawing Engine bus error interrupt (DRWBUSIRQ) • Current render process finished interrupt (DRWENUMIRQ) • Display list interrupt (DRWDLISTIRQ)
Module-stop function		Module-stop state can be set to reduce power consumption
TrustZone Filter		Security and Privilege attribution can be set

The 2D Drawing Engine provides two inputs (texture read and frame buffer read) and one output (frame buffer write). The internal color format is always ARGB (8888). The color formats from the inputs are converted to the internal format on read and converted back on write.

The 2D Drawing Engine also supports a display list mode, which makes it possible to decouple the CPU and graphics controller efficiently and perform rendering in parallel with other CPU activities.

Figure 48.1 shows examples of objects that can be drawn in hardware with the 2D Drawing Engine, Figure 48.2 shows a simplified rendering pipeline setup, and Figure 48.3 shows a block diagram of the module.

Figure 48.1 Examples of drawing objects

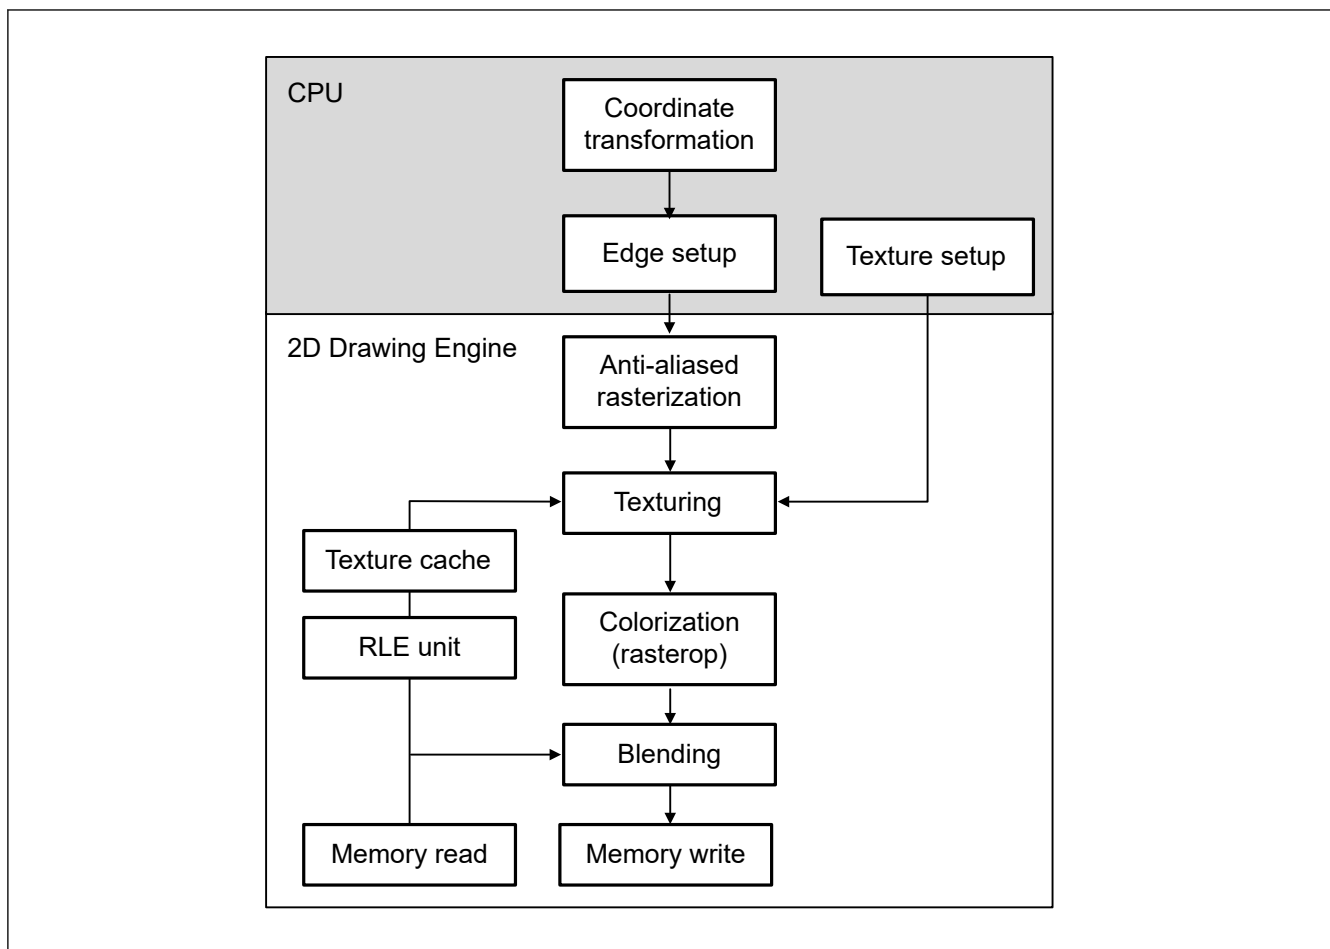

Figure 48.2 Simplified rendering pipeline setup

Figure 48.3 2D Drawing Engine block diagram

The 2D Drawing Engine accesses the DRW bus as a bus master through separate caches for:

- Reading and writing pixel data from and to the framebuffer
- Reading textures
- Reading display lists.

The control registers are accessed through the internal peripheral bus interface.

48.2 Register Descriptions

48.2.1 CONTROL : Geometry Control Register

Base address: DRW = 0x4034_4000
 DRW_NS = 0x5034_4000

Offset address: 0x00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Note: S-TYPE-3, P-TYPE-3

48.2.3 IRQCTL : Interrupt Control Register

Base address: DRW = 0x4034_4000
 DRW_NS = 0x5034_4000

Offset address: 0xC0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	BUSIR QCLR	BUSIR QEN	DLISTI RQCLR	ENUM IRQCLR	DLISTI RQEN	ENUM IRQEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ENUMIRQEN	ENUMIRQ Interrupt Mask Enable 0: Disable (mask) ENUMIRQ enumeration interrupt 1: Enable (unmask) ENUMIRQ enumeration interrupt.	W

Bit	Symbol	Function	R/W
1	DLISTIRQEN	DLISTIRQ Interrupt Mask Enable 0: Disable (mask) DLISTIRQ display list interrupt 1: Enable (unmask) DLISTIRQ display list interrupt.	W
2	ENUMIRQCLR	Clear ENUMIRQ 0: Do not clear ENUMIRQ enumeration interrupt 1: Clear ENUMIRQ enumeration interrupt.	W
3	DLISTIRQCLR	Clear DLISTIRQ 0: Do not clear DLISTIRQ display list interrupt 1: Clear DLISTIRQ display list interrupt.	W
4	BUSIRQEN	BUSIRQ Interrupt Mask Enable 0: Disable (mask) BUSIRQ bus error interrupt 1: Enable (unmask) BUSIRQ bus error interrupt.	W
5	BUSIRQCLR	Clear BUSIRQ 0: Do not clear BUSIRQ bus error interrupt 1: Clear BUSIRQ bus error interrupt.	W
31:6	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

48.2.4 CACHECTL : Cache Control Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xC4

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	CFLU SHTX	CENA BLETX	CFLU SHFX	CENA BLEFX
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CENABLEFX	Framebuffer Cache Enable 0: Disable the framebuffer cache 1: Enable the framebuffer cache.	W
1	CFLUSHFX	Flush Framebuffer Cache 0: Do not flush the framebuffer cache 1: Flush the framebuffer cache.	W
2	CENABLETX	Texture Cache Enable 0: Disable the texture cache 1: Enable the texture cache.	W
3	CFLUSHTX	Flush Texture Cache 0: Do not flush the texture cache 1: Flush the texture cache.	W
31:4	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

48.2.5 STATUS : Status Control Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x00

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	BUSE RRMD L	BUSE RRMT XMRL	BUSE RRMF B	—	BUSIR Q	DLISTI RQ	ENUM IRQ	DLIST ACTIV E	CACH EDIRT Y	BUSY WRIT E	BUSY ENUM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	BUSYENUM	Enumeration Unit Status 0: Enumeration unit idle 1: Enumeration unit is busy, new primitive cannot be started.	R
1	BUSYWRITE	Framebuffer Writeback Status 0: Framebuffer writeback finished 1: Framebuffer writeback busy, framebuffer type cannot be changed.	R
2	CACHEDIRTY	Framebuffer Cache Status 0: Framebuffer cache is not dirty 1: Framebuffer cache is dirty, and frame should not be flipped.	R
3	DLISTACTIVE	Display List Reader Status 0: Display list reader is idle 1: Display list reader is busy, and no direct write access to registers allowed.	R
4	ENUMIRQ	Enumeration Interrupt Triggered 0: Enumeration not finished or interrupt disabled 1: Enumeration finished interrupt triggered.	R
5	DLISTIRQ	Display List Interrupt Triggered 0: Display list not finished or interrupt disabled 1: Display list finished interrupt triggered.	R
6	BUSIRQ	Bus Error Interrupt Triggered 0: No bus error occurred or interrupt disabled 1: Bus error interrupt triggered.	R
7	—	This bit is read as 0.	R
8	BUSERRMFB	Framebuffer Bus Error Interrupt Triggered 0: No framebuffer bus error occurred or interrupt disabled 1: Framebuffer bus error interrupt triggered.	R
9	BUSERRMTXMRL	Texture Bus Error Interrupt Triggered*1 0: No texture bus error occurred or interrupt disabled 1: Texture bus error interrupt triggered.	R
10	BUSERRMDL	Display List Bus Error Interrupt Triggered 0: No display list bus error occurred or interrupt disabled 1: Display list bus error interrupt triggered.	R
31:11	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

Note 1. Because the RLE unit is also reading data through the texture bus, an error during RLE data access is also reflected in this bit.

48.2.6 HWREVISION : Hardware Version and Feature Set ID Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x04

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	ACBL END	—	COLO RKEY	TEXC LUT ₂₅₆	RLEU NIT	—	TEXC LUT	PERF COUN T	TXCA CHE	FBCA CHE	DLR	—
Value after reset:	0	0	0	0	1	1	1	1	1	0	1	1	1	1	1	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	REV[11:0]											
Value after reset:	0	0	0	0	0	0	0	1	0	0	0	0	0	1	1	1

Bit	Symbol	Function	R/W
11:0	REV[11:0]	Revision Number of DRW is stored.	R
16:12	—	These bits are read as 0.	R
17	DLR	Display List Reader Available 0: No display list reader 1: Display list reader is available	R
18	FBCACHE	Framebuffer Cache Available 0: No framebuffer cache 1: Framebuffer cache is available	R
19	TXCACHE	Texture Cache Available 0: No texture cache 1: Texture cache is available	R
20	PERFCOUNT	Two Performance Counter Available 0: No performance counter 1: Two performance counters available	R
21	TEXCLUT	Texture CLUT Available 0: No texture CLUT 1: Texture CLUT is available	R
22	—	This bit is read as 0.	R
23	RLEUNIT	RLE Unit Available 0: No RLE unit 1: RLE unit is available	R
24	TEXCLUT256	Texture CLUT size 0: Texture CLUT size is 16 entries 1: Texture CLUT size is 256 entries	R
25	COLORKEY	Color Key Available 0: No color key 1: Color key is available	R
26	—	This bit is read as 1.	R
27	ACBLEND	Alpha Channel Blending Available 0: Full alpha channel blending is not available 1: Full alpha channel blending is available	R
31:28	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

48.2.7 COLOR1 : Base Color Register

Base address: DRW = 0x4034_4000
 DRW_NS = 0x5034_4000

Offset address: 0x64

Bit position: 31 24 23 16 15 8 7 0

Value after reset: 0

Bit	Symbol	Function	R/W
7:0	COLOR1B[7:0]	Blue Channel of Color 1 Specifies blue channel of color 1.	W
15:8	COLOR1G[7:0]	Green Channel of Color 1	W
23:16	COLOR1R[7:0]	Red Channel of Color 1	W
31:24	COLOR1A[7:0]	Alpha Channel of Color 1 Specifies alpha channel of color 1. 0x00: Transparent ⋮ 0xFF: Opaque.	W

Note: S-TYPE-3, P-TYPE-3

48.2.8 COLOR2 : Secondary Color Register

Base address: DRW = 0x4034_4000
 DRW_NS = 0x5034_4000

Offset address: 0x68

Bit position: 31 24 23 16 15 8 7 0

Value after reset: 0

Bit	Symbol	Function	R/W
7:0	COLOR2B[7:0]	Blue Channel of Color 2 Specifies blue channel of color 2.	W
15:8	COLOR2G[7:0]	Green Channel of Color 2 Specifies green channel of color 2.	W
23:16	COLOR2R[7:0]	Red Channel of Color 2 Specifies red channel of color 2.	W
31:24	COLOR2A[7:0]	Alpha Channel of Color 2 Specifies alpha channel of color 2. 0x00: Transparent ⋮ 0xFF: Opaque.	W

Note: S-TYPE-3, P-TYPE-3

48.2.9 PATTERN : Pattern Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x74

Bit position: 31

8 7

0

Bit field:

Value after reset: 0

Bit	Symbol	Function	R/W
7:0	PATTERN[7:0]	Bitmap of the Pattern Specifies bitmap of the pattern.	W
31:8	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

48.2.10 LnSTART : Limiter n Start Value Register (n = 1 to 6)

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x10 + 0x4 × (n - 1)

Bit position: 31

0

Bit field:

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	LSTART[31:0]	Start Value of the nth Limiter Specifies start value of the nth limiter.	W

Note: S-TYPE-3, P-TYPE-3

48.2.11 LnXADD : Limiter n X-Axis Increment Register(n = 1 to 6)

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x28 + 0x4 × (n - 1)

Bit position: 31

0

Bit field:

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	LXADD[31:0]	X-Axis Increment Specifies x-axis increment.	W

Note: S-TYPE-3, P-TYPE-3

48.2.12 LnYADD : Limiter n Y-Axis Increment Register(n = 1 to 6)

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x40 + 0x4 × (n - 1)

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	LYADD[31:0]	Y-Axis Increment Specifies y-axis increment.	W

Note: S-TYPE-3, P-TYPE-3

48.2.13 LmBAND : Limiter m Band Width Parameter Register(n = 1, 2)

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x58 + 0x4

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	LBAND[31:0]	Limiter m Band Width Parameter Specifies limiter m band width parameter.	W

Note: S-TYPE-3, P-TYPE-3

48.2.14 TEXORIGIN : Texture Base Address Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xBC

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	TEXORIGIN[31:0]	Texture Base Address Specifies texture base address.	W

Note: S-TYPE-3, P-TYPE-3

48.2.15 TEXPITCH : Texels Per Texture Line Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xB4

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	TEXPITCH[31:0]	Texels Per Texture Line Specifies texels per texture line. Valid range is from 0 to 2048.	W

Note: S-TYPE-3, P-TYPE-3

48.2.16 TEXMASK : Texture Size or Texture Address Mask Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xB8

Bit position: 31 11 10 0

Value after reset: 0

Bit	Symbol	Function	R/W
10:0	TEXUMASK[10:0]	U Mask in Texture Mode Specifies the U mask. Set to texture_width - 1. <ul style="list-style-type: none">In texture wrapping mode (CONTROL2.TEXTURECLAMPX = 0): Texture_width must be a power of 2In texture clamping mode (CONTROL2.TEXTURECLAMPX = 1): All widths up to 2048 are allowed.	W
31:11	TEXVMASK[20:0]	V Mask in Texture Mode Specifies the V mask. Set to DRWTEXPITCH (texture_height - 1). <ul style="list-style-type: none">In texture wrapping mode (CONTROL2.TEXTURECLAMPY = 0): Texture_height must be a power of 2In texture clamping mode (CONTROL2.TEXTURECLAMPY = 1): All heights up to 1024 are allowed.	W

Note: S-TYPE-3, P-TYPE-3

48.2.17 LUSTART : U Limiter Start Value Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x90

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	LUSTART[31:0]	U Limiter Start Value Specifies U limiter start value.	W

Note: S-TYPE-3, P-TYPE-3

48.2.18 LUXADD : U Limiter X-Axis Increment Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x94

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	LUXADD[31:0]	U Limiter X-Axis Increment Specifies U limiter x-axis increment.	W

Note: S-TYPE-3, P-TYPE-3

48.2.19 LUYADD : U Limiter Y-Axis Increment Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x98

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	LUYADD[31:0]	U Limiter Y-Axis Increment Specifies U limiter y-axis increment.	W

Note: S-TYPE-3, P-TYPE-3

48.2.20 LVSTARTI : V Limiter Start Value Integer Part Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x9C

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
0	LVSTARTI[31:0]	V Limiter Start Value Integer Part Specifies integer part of V limiter start value.	W

Note: S-TYPE-3, P-TYPE-3

48.2.21 LVSTARTF : V Limiter Start Value Fractional Part Register

Base address: DRW = 0x4034_4000
 DRW_NS = 0x5034_4000

Offset address: 0xA0

Bit position: 31 16 15 0

Value after reset: 0

Bit	Symbol	Function	R/W
15:0	LVSTARTF[15:0]	V Limiter Start Value Fractional Part Specifies fractional part of V limiter start value.	W
31:16	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

48.2.22 LVXADDI : V Limiter X-Axis Increment Integer Part Register

Base address: DRW = 0x4034_4000
 DRW_NS = 0x5034_4000

Offset address: 0xA4

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	LVXADDI[31:0]	V Limiter X-Axis Increment Integer Part Specifies integer part of V limiter x-axis increment.	W

Note: S-TYPE-3, P-TYPE-3

48.2.23 LVYADDI : V Limiter Y-Axis Increment Integer Part Register

Base address: DRW = 0x4034_4000
 DRW_NS = 0x5034_4000

Offset address: 0xA8

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	LVYADDI[31:0]	V Limiter Y-Axis Increment Integer Part Specifies integer part of V limiter y-axis increment.	W

Note: S-TYPE-3, P-TYPE-3

48.2.24 LVYXADDF : V Limiter Increment Fractional Parts Register

Base address: DRW = 0x4034_4000
 DRW_NS = 0x5034_4000

Offset address: 0xAC

Bit position: 31 16 15 0

Value after reset: 0

Bit	Symbol	Function	R/W
15:0	LVXADDF[15:0]	V Limiter X-Axis Increment Fractional Part Specifies fractional part of V limiter x-axis increment.	W
31:16	LVYADDF[15:0]	V Limiter Y-Axis Increment Fractional Part Specifies fractional part of V limiter y-axis increment.	W

Note: S-TYPE-3, P-TYPE-3

48.2.25 TEXCLADDR : CLUT Start Address Register

Base address: DRW = 0x4034_4000
 DRW_NS = 0x5034_4000

Offset address: 0xDC

Bit position: 31 8 7 0

Value after reset: 0

Bit	Symbol	Function	R/W
7:0	CLADDR[7:0]	Texture CLUT Start Address Specifies texture CLUT start address.	W
31:8	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

48.2.26 TEXCLDATA : CLUT Data Register

Base address: DRW = 0x4034_4000
 DRW_NS = 0x5034_4000

Offset address: 0xE0

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	CLDATA[31:0]	Texture CLUT Data Specifies texture CLUT data.	W

Note: S-TYPE-3, P-TYPE-3

48.2.27 TEXTCLOFFSET : CLUT Offset Register

Base address: DRW = 0x4034_4000
 DRW_NS = 0x5034_4000

Offset address: 0xE4

Bit position: 31 8 7 0

Value after reset: 0

Bit	Symbol	Function	R/W
7:0	CLOFFSET[7:0]	Texture CLUT Offset Specifies texture CLUT offset. CLOFFSET[7:0] is OR gated with the original index.	W
31:8	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

48.2.28 COLKEY : Color Key Register

Base address: DRW = 0x4034_4000
 DRW_NS = 0x5034_4000

Offset address: 0xE8

Bit position: 31 24 23 16 15 8 7 0

Value after reset: 0

Bit	Symbol	Function	R/W
7:0	COLKEYB[7:0]	Blue Channel of Color Key Specifies blue channel of color key.	W
15:8	COLKEYG[7:0]	Green Channel of Color Key Specifies green channel of color key.	W
23:16	COLKEYR[7:0]	Red Channel of Color Key Specifies red channel of color key.	W
31:24	—	The write value should be 0.	W

Note: S-TYPE-3, P-TYPE-3

48.2.29 SIZE : Bounding Box Dimension Register

Base address: DRW = 0x4034_4000
 DRW_NS = 0x5034_4000

Offset address: 0x78

Bit position: 31 16 15 0

Value after reset: 0

Bit	Symbol	Function	R/W
15:0	SIZEX[15:0]	Bounding Box Width Specifies the width of bounding box in pixels. Valid range is 0 to 1024.	W
31:16	SIZEY[15:0]	Bounding Box Height Specifies the height of bounding box in pixels. Valid range is 0 to 1024.	W

Note: S-TYPE-3, P-TYPE-3

48.2.30 PITCH : Framebuffer Pitch And Spanstore Delay Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x7C

Bit position: 31 16 15 0

Bit field:

SSD[15:0]	PITCH[15:0]
-----------	-------------

Value after reset: 0

Bit	Symbol	Function	R/W
15:0	PITCH[15:0]	Pitch of the Framebuffer A negative width can be used to render bottom-up instead of top-down.	W
31:16	SSD[15:0]	Spanstore Delay Specifies the number of scan lines to delay spanstore operations.	W

Note: S-TYPE-3, P-TYPE-3

48.2.31 ORIGIN : Framebuffer Base Address Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0x80

Bit position: 31 0

Bit field:

ORIGIN[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	ORIGIN[31:0]	Address of the First Pixel in Framebuffer Writing to ORIGIN[31:0] triggers the start of rendering.	W

Note: S-TYPE-3, P-TYPE-3

48.2.32 DLISTSTART : Display List Start Address Register

Base address: DRW = 0x4034_4000
DRW_NS = 0x5034_4000

Offset address: 0xC8

Bit position: 31 0

Bit field:

DLISTSTART[31:0]

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	DLISTSTART[31:0]	Display List Start Address Setting a new display list base address triggers execution of the new display list. Execution stops only when a new list is set or the current list terminates.	W

Note: S-TYPE-3, P-TYPE-3

48.2.33 PERFTRIGGER : Performance Counters Control Register

Base address: DRW = 0x4034_4000
 DRW_NS = 0x5034_4000

Offset address: 0xD4

Bit position: 31 16 15 0

Value after reset: 0

Bit	Symbol	Function	R/W
15:0	PERFTRIGGER1[15:0]	Trigger of Performance Counter 1 Select the internal event that increments the PERFCOUNT1 register. 0x0000: Disable performance counter 0x0001: Select 2D Drawing Engine active cycles 0x0002: Select framebuffer read access 0x0003: Select framebuffer write access 0x0004: Select texture read access 0x0005: Select invisible pixels (enumerated but selected with alpha 0%) 0x0006: Select invisible pixels while internal FIFO is empty (lost cycles) 0x0007: Select display list reader active cycles 0x0008: Select framebuffer read hits 0x0009: Select framebuffer read misses 0x000A: Select framebuffer write hits 0x000B: Select framebuffer write misses 0x000C: Select texture read hits 0x000D: Select texture read misses 0x001F: Select every clock cycle (for use as timer). Others: Setting prohibited.	W
31:16	PERFTRIGGER2[15:0]	Trigger of Performance Counter 2 Select the internal event that increments the PERFCOUNT2 register. See the above settings for performance counter 2.	W

Note: S-TYPE-3, P-TYPE-3

48.2.34 PERFCOUNTk : Performance Counter k (k = 1, 2)

Base address: DRW = 0x4034_4000
 DRW_NS = 0x5034_4000

Offset address: 0xCC (PERFCOUNT1)
 0xD0 (PERFCOUNT2)

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
31:0	PERFCOUNT[31:0]	Performance Counter k Value Specifies counter k value. The counter is reset by writing PERFCOUNTk = 0x0000_0000.	R/W

Note: S-TYPE-3, P-TYPE-3

48.3 Drawing Features

48.3.1 Drawing Features Summary

48.3.1.1 Color formats

Supported color formats are:

(1) Framebuffer formats

- 8-bit: A (8)
- 16-bit: RGB (565), ARGB (4444)
- 32-bit: ARGB (8888).

(2) Texture formats

- 1-bit: CLUT (1)/I (1)
- 2-bit: CLUT (2)/I (2)
- 4-bit: CLUT (4)/I (4)
- 8-bit: A (8), CLUT (8)/I (8), ACLUT (44)
- 16-bit: ARGB (4444), ARGB (1555), RGB (565)
- 24-bit: RGB (888) (run length encoded (RLE) unit)
- 32-bit: ARGB (8888).

CLUT formats use a 256-entry color Lookup table.

48.3.1.2 BitBLT features

The 2D Drawing Engine supports the BitBLT features using its vector drawing function to draw a rectangle and texture it based on the selected BitBLT function. This approach results in the following BitBLT features:

- Fill
- Copy
- Stretch BitBLT
- Rotate and scale
- Alpha blending
- Bilinear filtering
- Color conversion
- Subpixel exact placement.

48.3.1.3 Vector drawing features

The vector 2D Drawing Engine uses a half-plane rendering approach, which simplifies implementation of edge antialiasing and blurring features without much overhead. When combining some of its functional units, the module can draw not only linear primitives such as lines or polygons, but also quadratic equation-based primitives such as circles and ellipsoids. The following primitives are supported:

- Lines
- Polygons
- Circles and ellipses
- Quadratic curves (software driver support)

- 2D texture mapping
- Bilinear filtering of the textures.

48.3.2 Vector Drawing

For a detailed explanation of the algorithms, see [section 48.6. Rendering Pipeline](#). Supported vector drawing includes:

(1) Lines

- Arbitrary width
- Round endpoints
- Truncated endpoints
- Alpha gradients
- Soft edges (blurring)
- Render attribute: color, pattern, or texture.

(2) Polygons

- Triangles and quadrangles (complex polygons are tessellated by software)
- Alpha gradients
- Soft edges (blurring)
- Per edge controls for anti-aliasing
- Render attribute: color, pattern, or texture.

(3) Circles and ellipses

- All conic sections
- Filled or with arbitrary width
- Arcs of 0° to 360°
- Soft edges
- Alpha gradients
- Render attribute: color, pattern, or texture.

(4) Quadratic Bézier

- Approximated by circle arcs
- Arbitrary width
- Round or truncated endpoints
- Outlines, blurring
- Alpha gradients
- Render attribute: color.

(5) Texture mapping

- 2D array of pixels that can be mapped implicitly or explicitly on all primitives provided by the 2D Drawing Engine
- Translation, rotation, and scaling/shearing
- Bilinear filtering of the textures
- 3D-like texturing accomplished with line-by-line mapping, if constant in one axis.

48.3.3 BitBLT

A dedicated BitBLT unit is not required in the 2D Drawing Engine. The rendering pipeline described for vector drawing is used as the BitBLT unit and already provides a 1 pixel/cycle throughput. For details, see [section 48.6. Rendering Pipeline](#).

48.3.3.1 Fill

A rectangle in the framebuffer can be filled with any value. Possible color formats are 8-, 16-, or 32-bpp format. The driver optimizes the fill to gain the full benefit of 32-bit parallel rasterization. If the selected color format is less than 32 bpp, the driver corrects the alignment and fills 32 bits per clock, resulting in 2 to 4 times faster fill performance for 8- and 16-bpp formats.

48.3.3.2 Copy

A rectangle in the framebuffer can be filled with any rectangular data from the texture input. When the texture input points to the framebuffer, copying from framebuffer to framebuffer is possible. To avoid copy problems because of overlapping source and destination areas, the copy start point can be selected from top left to bottom right. Possible color formats are 8-, 16-, or 32-bpp format.

The driver optimizes the copy to gain the full benefit of 32-bit parallel rasterization. If the selected color format is less than 32 bpp, the driver corrects the alignment and copies 32 bits per clock, resulting in 2 to 4 times faster copy performance for 8- and 16-bpp formats.

48.3.3.3 Stretch BitBLT

This is similar to the normal copy operation. Because the copy is done as a type of texture mapping, the full texture mapping feature set can be used. Any scaling ratios in the x and y directions is selectable, and filtering can be enabled independently for each axis.

48.3.3.4 Rotate and scale

This is similar to the normal copy operation. Because the copy is done as a type of texture mapping, the full texture mapping feature set can be used. Any scaling ratios in the x and y direction and any rotation angle is selectable. The x and y directions can be rotated and scaled independently, and filtering for the scalers can be enabled independently for each axis.

48.3.3.5 Alpha blending

Alpha blending is a fundamental block in the rendering pipeline, so the full alpha blend feature set is available for any BitBLT operation. It is possible to copy an area and blend it over the destination by using any constant global alpha value (register value) or by using an alpha mask. The alpha mask is part of the texture data and can be either a per-pixel value together with a pixel color (ARGB formats) or an alpha-only format using a register color.

In addition to the color channels, the alpha channel can be blended. The formula for the alpha channel can be set independently from the formula for the color channels.

48.3.3.6 Bilinear filtering

The texture unit can be used to scale, rotate, or shear images. The texturing result can be filtered in the x and y directions independently. When selecting both filters, the result is a bilinear filtered texture. Using the unit twice with two independent textures would generate trilinear filtered bitmaps, improving the visual impression for high dynamic scale ratios.

48.3.3.7 Color conversion

Color conversion is required when using different texture formats than the framebuffer format. To save texture memory, several formats are supported with less bpp than the framebuffer normally has. The 2D Drawing Engine always operates internally with 32-bpp ARGB (8888). All input data is converted into 32 bpp, and is finally converted back into the framebuffer format.

48.4 Input and Output Data Formats

48.4.1 Source and Destination Data

There are two possible inputs, the framebuffer and the texture or pattern input. The output is always the framebuffer.

Every drawing operation is internally rendered in 32 bpp ARGB (8888). If the input color does not provide an alpha channel, the blue channel is taken as the alpha channel. This alpha can be substituted with any alpha (for example, by an external constant) during the colorization step in the 2D Drawing Engine.

48.4.2 Framebuffer Color Formats

Table 48.2 shows the supported framebuffer color formats.

Table 48.2 Framebuffer color formats

Framebuffer memory occupation	Format	Remarks
8 bpp	A (8)	This color format uses 1 byte per pixel. The alpha channel is internally replicated on the red, blue, and green channels and can be substituted with any color during the color step in the 2D Drawing Engine.
16 bpp	RGB (565)	This color format uses 2 bytes per pixel with 5 bits for red and blue and 6 bits for green. The blue color is taken as the alpha channel during color conversion. The alpha can be substituted with any alpha during the colorization step in the 2D Drawing Engine.
	ARGB (4444)	This color format uses 2 bytes per pixel with 4 bits for each color and alpha channel.
32 bpp	ARGB (8888)	This color format uses 4 bytes per pixel with 8 bits for each color and alpha channel.

The framebuffer color format is selected in the Surface Control Register with the CONTROL2.READFORMAT[2:0] bits.

48.4.3 Texture Color Formats

Table 48.3 shows the supported texture color formats.

Table 48.3 Texture color formats

Texture memory occupation	Format	Remarks
1 bpp	CLUT (1)/I (1)	In this mode, a 1-bit index is used to address one of 256 predefined colors in the color lookup table. If the CLUT is not used, the index is taken as a luminance value.
2 bpp	CLUT (2)/I (2)	In this mode, a 2-bit index is used to address one of 256 predefined colors in the color lookup table. If the CLUT is not used, the index is taken as a luminance value.
4 bpp	CLUT (4)/I (4)	In this mode, a 4-bit index is used to address one of 256 predefined colors in the color lookup table. If the CLUT is not used, the index is taken as a luminance value.
8 bpp	CLUT (8)/I (8)	In this mode, an 8-bit index is used to address one of 256 predefined colors in the color lookup table. If the CLUT is not used, the index is taken as a luminance value.
	A (8)	This color format uses 1 byte per pixel. The alpha channel is internally replicated on the red, blue, and green channels and can be substituted with any color during the colorization step in the 2D Drawing Engine.
	ACLUT (44)	This color format uses 1 byte per pixel. 4 bits are used as an alpha value and 4 bits are used as an index to a color palette. This approach saves space if 16 colors are sufficient to describe the image, because the next bigger alpha format would be 2-byte ARGB (4444).
16 bpp	RGB(565)	This color format uses 2 bytes per pixel with 5 bits for red and blue and 6 bits for green. The blue color is taken as the alpha channel during color conversion. The alpha can be substituted with any alpha during the colorization step in the 2D Drawing Engine.
	ARGB (4444)	This color format uses 2 bytes per pixel with 4 bits for each color and alpha channel.
	ARGB (1555)	This color format uses 2 bytes per pixel. Every color channel has 5 bits and the topmost single bit is taken as an alpha value. This can be used to hold an image with a transparency mask.
24 bpp	RGB (888)	This color format uses 3 bytes per pixel with 8 bits for each color channel. This format is only available as run length encoded data (RLE compression).
32 bpp	ARGB (8888)	This color format uses 4 bytes per pixel with 8 bits for each color and alpha channel.

The texture color format is selected in the Surface Control Register with the CONTROL2.WRITEFORMAT[3:0] bits.

48.5 Texture Data Processing

Figure 48.4 shows the processing of texture data.

Figure 48.4 Texture data processing

48.5.1 Texture Color Format

Table 48.4 shows the supported texture data formats.

Table 48.4 Texture color formats

Texel bit width	Texel format
32 bits	ARGB (8888)
24 bits	RGB (888)
16 bits	ARGB (4444), ARGB (1555), RGB (565)
8 bits	CLUT (8)I (8), A (8), ACLUT (44)
4 bits	CLUT (4)I (4)
2 bits	CLUT (2)I (2)
1 bit	CLUT (1)I (1)

48.5.2 Run Length Encoded (RLE) Unit

The RLE unit decompresses Targa-like compressed textures and hands the decompressed texel data over to the texture unit. The key features are:

- Support for Targa format
- Avoid the additional Targa limitation to scan lines
- Support for clipping of compressed images, in which the 2D Drawing Engine is allowed to copy only a portion of a larger original texture
- Control of the RLE unit in drawing list operation
- Bypassing of the RLE unit logic if uncompressed textures are fetched from the framebuffer.

(1) Texture cache

The RLE unit feeds the texture cache. The texture cache can be disabled by setting `CACHECTL.CENABLETX = 0`.

Caution: A texture cache flush operation (`CACHECTL.CFLUSHTX = 1`) is necessary at the beginning and end of every new RLE texture.

The texture cache and the RLE unit can be bypassed by setting `CONTROL2.RLEENABLE = 0`.

48.5.2.1 RLE Texel formats

Table 48.5 lists the data formats supported by the RLE unit.

Table 48.5 Texel formats supported by the RLE unit

Memory texel format	RLE parameters	RLE coded unit format (<code>CONTROL2.RLEPIXELWIDTH[1:0]</code>)	Delivered format
32-bit ARGB (8888)		32 bits* ¹ (11b)	32 bits
24-bit RGB (888)		24 bits (10b)	32 bits
16-bit ARGB (4444), ARGB (1555), RGB (565)		16 bits (01b)	16 bits
8-bit CLUT (8)I (8), A (8), ACLUT (44)		Included in Targa and RLE formats	8 bits (00b)
4-bit CLUT (4)I (4)	Optional for RLE* ²	8 = 2 x 4 bits	4 + 4 bits
2-bit CLUT (2)I (2)	No RLE		
1-bit CLUT (1)I (1)			

Note 1. 24-bit RGB (888) encoded texels are delivered as ARGB (8888) with Alpha set to 1.

Note 2. Encoding of textures with 4 bits per texel is not defined by the Targa specification but can be done by:

- Combining two 4-bit texels to one byte
- Padding with four 0-bit at the end of the file, if the number of texels is odd
- Encoding as with 8-bit texels.

(1) Texel addressing for RLE textures

The address of a texel is the byte address of the first byte of the texel. The origin of the texture is given by the register `TEXORIGIN`.

Note: The RLE code must begin at a word boundary of the memory.

Caution: When the FIFO is filled, there is no provision to inhibit read access beyond the end of the RLE code. To avoid memory access violations, the RLE code must be padded by 32 memory words, where every bit of each word is set to 1.

48.5.2.2 Targa RLE format

Run-length encoded (RLE) images include two types of data elements:

- Run-length packets
- Raw packets.

The first field (1 byte) of each packet is called the repetition count field. The second field is called the pixel value field (1, 2, 3, or 4 bytes). For run-length packets, the pixel value field contains a single pixel value. For raw packets, the field is a variable number of pixel values.

The highest order bit of the repetition count indicates whether the packet is a raw packet or a run-length packet, as follows:

- If bit [7] of the repetition count is set to 1, the packet is a run-length packet
- If bit [7] of the repetition count is set to zero, the packet is a raw packet.

The lower 7 bits of the repetition count specify how many pixel values are represented by the packet. For a run-length packet, this count indicates how many successive pixels have the pixel value specified in the pixel value field. For raw packets, this count specifies how many pixel values are actually contained in the next field. This 7-bit value is actually encoded as 1 less than the number of pixels in the packet (a value of 0 implies 1 pixel while a value of 0x7F implies 128 pixels).

(1) Run-length packet

Run-length packets are composed of two parts. The first is a repetition count and the second is the pixel value to repeat.

Table 48.6 Run-length packet

Field name	Field size
Packet type (must be 1 for run-length)	1 bit
Pixel count (number of pixels encoded in this packet - 1)	7 bits
Pixel data (the shared pixel value to be used)	Pixel depth (field 5.5)

(2) Raw packet

The raw packet always includes two fields. The first field is the repetition count and the second field is the pixel data field.

Table 48.7 Raw packet

Field name	Field size
Packet type (must be 0 for raw packet)	1 bit
Pixel count (number of pixels encoded by this packet - 1)	7 bits
Pixel data	Pixel depth x pixel count - 1

48.5.3 Color Lookup Table (CLUT)

The color lookup table receives an index that addresses one out of the 256 predefined colors.

The predefined color format can be selected as:

- CONTROL2.CLUTFORMAT = 0: ARGB (8888)
- CONTROL2.CLUTFORMAT = 1: RGB (565).

The CLUT is filled by the use of two registers:

- TEXCLDATA
The ARGB (8888) color definition is written to this register, while the CLUT address is taken from TEXCLADDR.
- TEXCLADDR.
This is set to the first address of the CLUT to write to and is automatically incremented after each write to TEXCLDATA.

An offset for indexed formats (CLUT (1), CLUT (2), CLUT (4), and CLUT (8)) can be set up in the TEXCLOFFSET register to allow selecting an offset part of the CLUT. The CLUT index is calculated by CLUT (x) or TEXCLOFFSET.CLOFFSET[7:0].

48.5.3.1 CLUT/I pixel data formats

(1) CLUT (1)/I (1) format

The CLUT (1)/I (1) format expresses 1 pixel by using a total of 1 bit.

Memory byte	Pixel
7 (MSB)	P7
6	P6
5	P5
4	P4
3	P3
2	P2
1	P1
0 (LSB)	P0

The left-most pixel is stored at the lowest bit of the memory byte.

(2) CLUT (2)/I (2) format

The CLUT (2)/I (2) format expresses 1 pixel by using a total of 2 bits.

Memory byte	Pixel
7 (MSB)	P3
6	
5	P2
4	
3	P1
2	
1	P0
0 (LSB)	

The left-most pixel is stored at lowest 2 bits of the memory byte.

(3) CLUT (4)/I (4) format

The CLUT (4)/I (4) format expresses 1 pixel by using a total of 4 bits.

Memory byte	Pixel
7 (MSB)	P1
6	
5	
4	
3	P0
2	
1	
0 (LSB)	

The left-most pixel is stored at lowest 4 bits of the memory byte.

48.5.4 Color Keying

The 2D Drawing Engine provides a color keying unit in front of the texture unit. It operates as follows:

1. If enabled, the incoming color is compared with a transparent color, defined by COLKEY.
2. If the value matches, the alpha and color values are set to 0 to mark the color as transparent and handle it as if alpha was pre-multiplied.
3. If the value does not match, then alpha is set to 1.
4. Additional operations such as $\alpha_{in} \times \alpha_{const}$ are still possible.

With this approach, an object such as a round icon can be cut out from a rectangular texture and still can be faded by a constant alpha over the background.

48.6 Rendering Pipeline

48.6.1 Coordinate Transformation

Coordinate transformation such as rotation, translation, projection, and scaling must be done on the application side. This is not part of the 2D Drawing Engine hardware or driver. Because all coordinates fed into the 2D Drawing Engine are in fixed point format, these calculations can be made in fixed point format and do not require a floating point unit.

48.6.2 Rasterization

During rasterization, the vector data of the object must be converted to pixel data. To convert the data, the program sets up the edge interpolation hardware, called a limiter, for each edge of the object that calculates a decision value. The limiter determines which side of the edge the pixel is positioned on. The 2D Drawing Engine includes six internal hardware limiters. In principle, the limiter registers contain the distance between the pixel being processed and the edge.

In the linear setup, a limiter describes a half plane. The intersection of all half planes is the object. If three half planes intersect, a triangle is created as shown in [Figure 48.5](#).

Figure 48.5 Intersection of half planes

The limiter output is clamped to an interval of [0:1]. In limiters 1 and 2 it is possible to apply a band filter before the clamping operation. In this case, the limiter is not describing a half plane but a small band. With this approach, a single limiter can describe a thick line of infinite length.

The output of the different limiters can be combined by the combiner units with a maximum or minimum operation. Maximum operation describes the union of both half planes, and minimum operation describes the intersection of both half planes. The final output is then used as an alpha value. Edge anti-aliasing can be done with no additional effort with this hardware.

To calculate the decision value for each possible pixel with a limiter, the bounding box of the object must be calculated. Then, the decision value for the top left corner of the bounding box must be calculated for each edge. Finally, the increments for a step in the x direction and a step in the y direction must be calculated. This is done by the CPU in the driver.

With this information, the 2D Drawing Engine scans the whole bounding box and calculates the decision value for every pixel incrementally. For a block diagram of the entire rasterization unit, see [section 48.1. Overview](#).

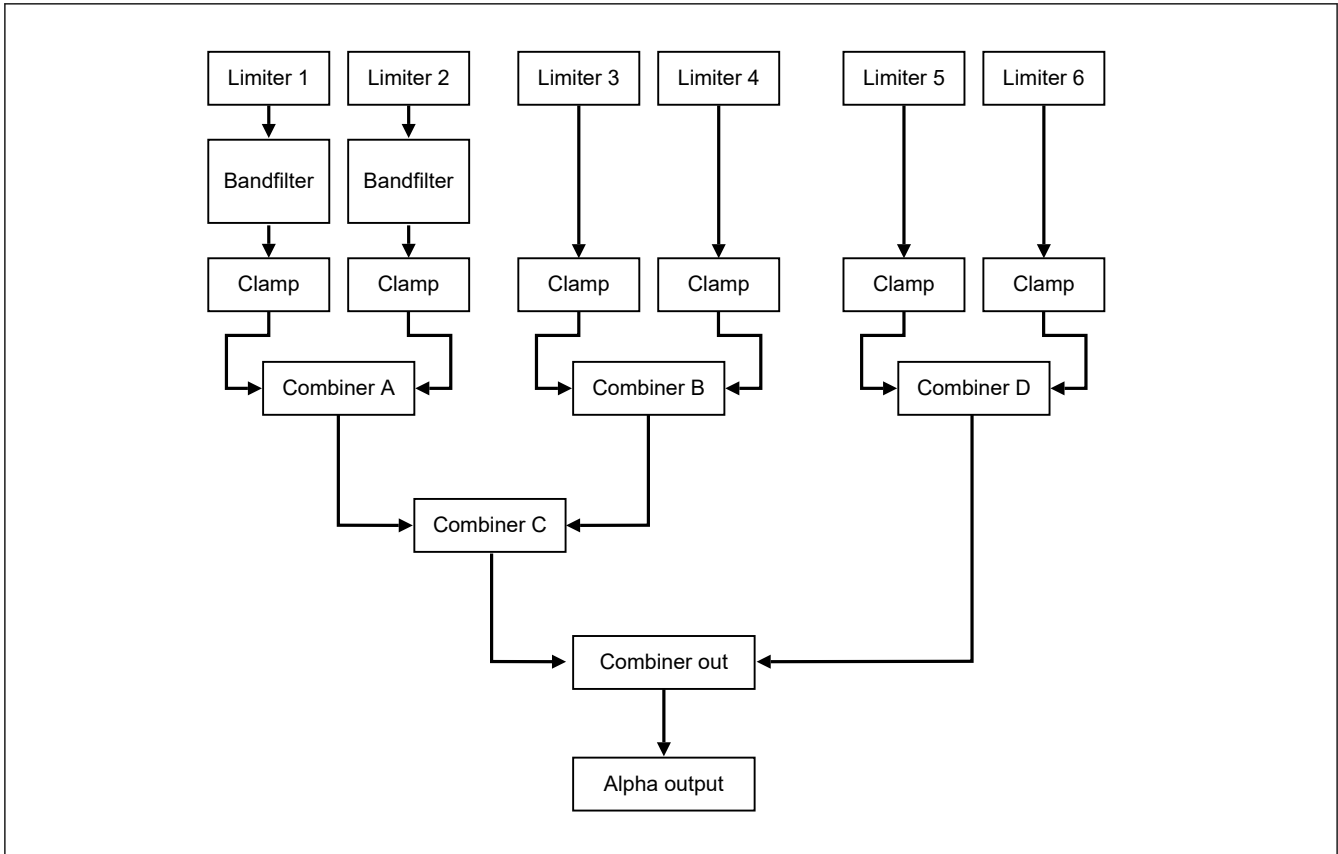

Figure 48.6 Block diagram of rasterization unit

The limiters calculate distances and the combiner units combine them to an alpha value. The combiner units define the conditions for whether or not a pixel is in the bounding box. The alpha value must be greater than 0.

Note: It is possible to have all limiters switched off.

48.6.2.1 Edge setup linear case

(1) Mathematical background

To setup a linear edge, consider the line equation in the classical form.

This can be written as:

$$y = \tilde{a}x + \tilde{b}$$

This can be rewritten as:

$$0 = f(x, y) = \tilde{a}x - y + \tilde{b} = ax + by + c$$

$$\text{with } a = \tilde{a}, b = -1, c = \tilde{b}$$

This is a more general form. Consider a vector form of this equation:

$$\vec{p} = \begin{pmatrix} x \\ y \end{pmatrix}, \vec{n} = \begin{pmatrix} a \\ b \end{pmatrix} \Rightarrow f(x, y) = ax + by + c = \vec{p} \cdot \vec{n} + c$$

If a point \vec{p}_0 is on the line:

$$0 = f(x, y) = \vec{p}_0 \cdot \vec{n} + c \Rightarrow c = -\vec{p}_0 \cdot \vec{n}$$

Rewriting the constant, the equation becomes:

$$c = -\vec{p}_0 \cdot \vec{n} \Rightarrow f(x, y) = (\vec{p} - \vec{p}_0) \cdot \vec{n}$$

The vector \vec{n} is called the normal vector and is perpendicular to the line. The setup can be seen in [Figure 48.7](#).

Figure 48.7 Distance of a point to a line

The projection of $\vec{p} - \vec{p}_0$ to \vec{n} is the distance d of the point P to the line. In this case, $f(x, y)$ describes the distance to the line of the pixel with coordinates (x, y) .

To calculate the distance of every pixel of the bounding box incrementally, first the distance to the line at origin must be calculated:

$$f(0, 0) = -\vec{p}_0 \cdot \vec{n} = c$$

Next the increments for a step in the x direction and a step in the y direction must be calculated:

$$f(\vec{p} + \vec{e}_x) = (\vec{p} + \vec{e}_x - \vec{p}_0) \cdot \vec{n} = f(\vec{p}) + \vec{e}_x \cdot \vec{n} = f(\vec{p}) + a$$

$$f(\vec{p} + \vec{e}_y) = (\vec{p} + \vec{e}_y - \vec{p}_0) \cdot \vec{n} = f(\vec{p}) + \vec{e}_y \cdot \vec{n} = f(\vec{p}) + b$$

$$\text{with } \vec{e}_x = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \vec{e}_y = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$$

Consequently, the new distance can be calculated from the old distance with the increments a and b . A step in the x direction changes the distance by a , and a step in the y direction changes the distance by b . The distance of the origin to the line is c .

With this information, the entire bounding box can be scanned. If the bounding box top left corner is not at the origin, an offset must be added.

(2) Limiter operation

The 2D Drawing Engine contains six limiters. Each limiter contains three registers:

- LnSTART
- LnXADD
- LnYADD.

See [Figure 48.8](#) for details. It is possible to drive the limiters in a threshold mode, in which all values above 0.5 are set to 1, and all values below or equal to 0.5 are set to 0. This feature is used when anti-aliasing is not wanted.

Note: In [Figure 48.8](#), the following abbreviations are used:

start = LnSTART
 xadd = LnXADD
 yadd = LnYADD

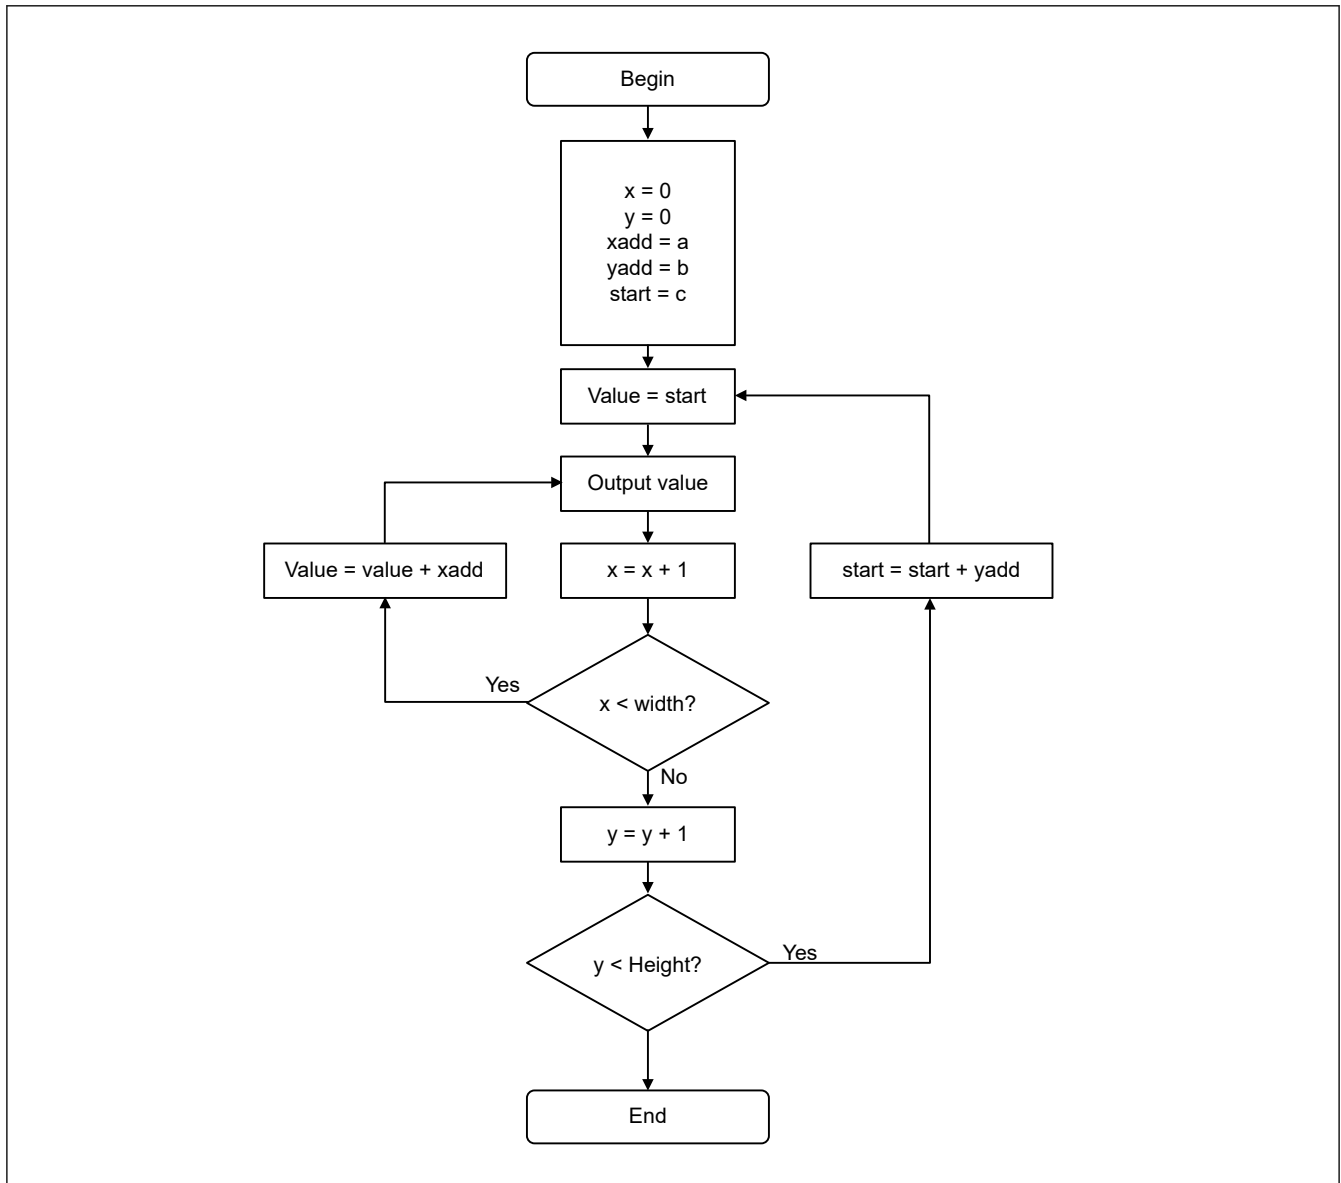

Figure 48.8 Operation flow of the linear limiter

(3) Example

If a straight line is given by the points P0 and P1, then the values are calculated as follows:

$$\Delta\vec{p} = \vec{p}_1 - \vec{p}_0 = \begin{pmatrix} x_1 - x_0 \\ y_1 - y_0 \end{pmatrix} = \begin{pmatrix} \Delta x \\ \Delta y \end{pmatrix}$$

The normal vector (perpendicular but not unit size) is then:

$$\vec{n} = \begin{pmatrix} -\Delta y \\ \Delta x \end{pmatrix}$$

The not normalized distance between edge and origin is then:

$$\vec{p}_0 \cdot \vec{n} = -x_0\Delta y + y_0\Delta x$$

The limiter parameters would be:

$$\text{start} = -x_0\Delta y + y_0\Delta x$$

$$\text{xadd} = -\Delta y$$

$$\text{yadd} = \Delta x$$

In the normalized case, the normal vector is:

$$\vec{n} = \begin{pmatrix} -\Delta y \\ \Delta x \end{pmatrix} \cdot \frac{1}{\sqrt{\Delta x^2 + \Delta y^2}}$$

The distance between edge and origin is:

$$\vec{p}_0 \cdot \vec{n} = \left(-x_0 \cdot \Delta y + y_0 \cdot \Delta x \right) \cdot \frac{1}{\sqrt{\Delta x^2 + \Delta y^2}}$$

The limiter parameters would be:

$$\text{start} = \left(-x_0\Delta y + y_0\Delta x \right) \cdot \frac{1}{\sqrt{\Delta x^2 + \Delta y^2}}$$

$$\text{xadd} = -\Delta y \cdot \frac{1}{\sqrt{\Delta x^2 + \Delta y^2}}$$

$$\text{yadd} = \Delta x \cdot \frac{1}{\sqrt{\Delta x^2 + \Delta y^2}}$$

Normalization is only required if anti-aliasing is used. The driver contains an optimized inverse square root function to speed up the normalization process.

48.6.2.2 Edge setup quadratic case

(1) Mathematical background

It is also possible to set up the limiters to incrementally calculate the following equation:

$$f(x, y) = ax^2 + by^2 + cx + dy + f$$

At the origin, the value is:

$$f(0, 0) = f$$

The step in the x direction is:

$$f(x + 1, y)$$

$$= a(x + 1)^2 + by^2 + c(x + 1) + dy + f$$

$$= ax^2 + 2ax + a + by^2 + cx + c + dy + f$$

$$= f(x, y) + 2ax + c + a$$

$$\text{dx}(x) = f(x + 1, y) - f(x, y) = 2ax + c + a$$

The step in the y direction is:

$$f(x, y + 1)$$

$$= ax^2 + b(y + 1)^2 + cx + d(y + 1) + f$$

$$= ax^2 + by^2 + 2by + b + cx + d(y + 1) + f$$

$$= f(x, y) + 2by + d + b$$

$$\text{dy}(y) = f(x, y + 1) - f(x, y) = 2by + d + b$$

In the quadratic case, the increments dx and dy depend on x and y and are not constant. They can be calculated incrementally:

$$\text{d}^2x = \text{dx}(x + 1) - \text{dx}(x) = 2a(x + 1) + c + a - (2ax + c + a) = 2a$$

$$\text{d}^2y = \text{dy}(y + 1) - \text{dy}(y) = 2b(y + 1) + d + b - (2by + d + b) = 2b$$

At the origin, the increments are:

$$dx(0) = c + a \text{ and } dy(0) = d + b$$

By incrementing the value by dx and dy for every step in the x and y direction and incrementing dx , dy by d^2x , and d^2y for every step in the x and y direction, the quadratic equation can be easily calculated for the whole bounding box.

(2) Limiter operation

In the quadratic case, two linear limiters are combined to operate as one quadratic limiter, called limiter 1 and limiter 2. The registers are:

- L1START, L1XADD, L1YADD
- L2START, L2XADD, L2YADD.

See [Figure 48.9](#) for details. The gray box is an addition that performs a different operation, as in the linear setup. It is possible to drive the limiters in a threshold mode, in which all values above 0.5 are set to 1, and all values below or equal to 0.5 are set to 0. This feature is used when anti-aliasing is not needed.

Note: In [Figure 48.9](#), the following abbreviations are used:

- start1 = L1START, start2 = L2START
- xadd1 = L1XADD, xadd2 = L2XADD
- yadd1 = L1YADD, yadd2 = L2YADD.

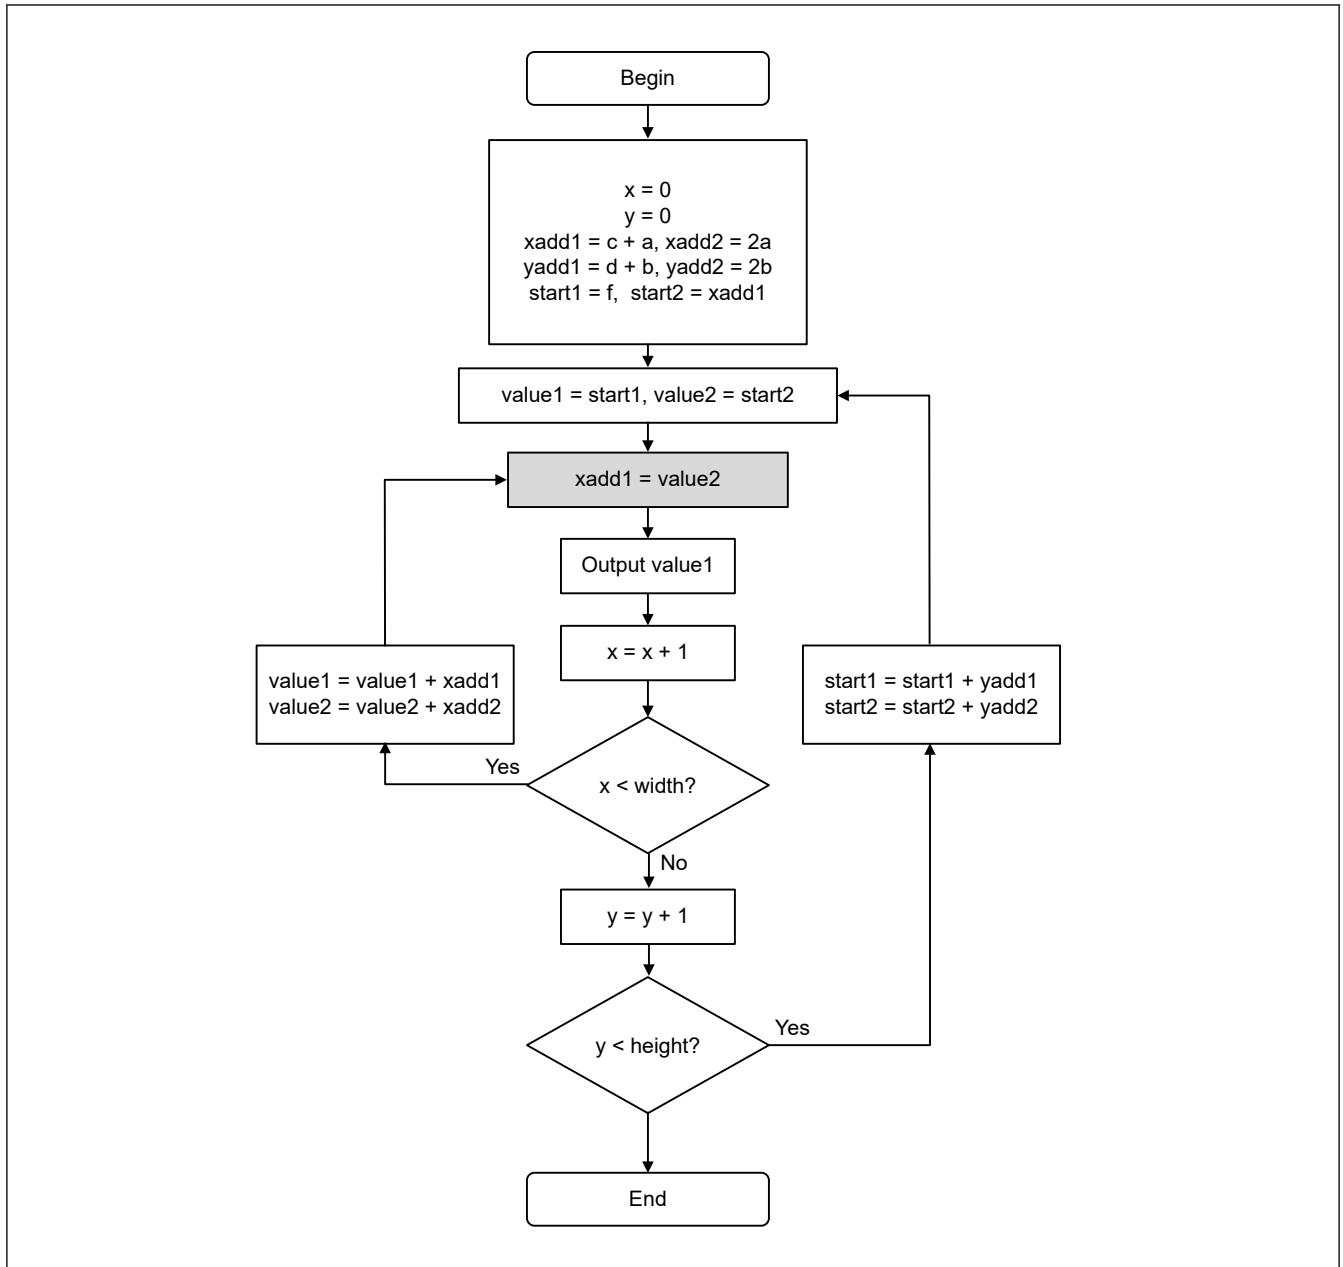

Figure 48.9 Operation flow of the quadratic limiter

(3) Example

Consider the equation for a circle with the center at $\vec{c} = \begin{pmatrix} s \\ t \end{pmatrix}$ and radius r:

$$0 = f(x, y) = (x - s)^2 + (y - t)^2 - r^2$$

This equation can be rewritten as:

$$f(x, y) = x^2 - 2xs + s^2 + y^2 - 2yt + t^2 - r^2$$

This can be sorted to fit to the original equation:

$$f(x, y) = x^2 + y^2 - 2sx - 2ty + (s^2 + t^2 - r^2)$$

With the following assignments, the circle equation can be calculated incrementally:

$$a = 1$$

$$b = 1$$

$$c = -2s$$

$$d = -2t$$

$$f = s^2 + t^2 - r^2$$

For the limiters with the results calculated in (1) [Mathematical background](#), this would result in:

$$\text{start1} = f = s^2 + t^2 - r^2$$

$$\text{xadd1} = c + a = -2s + 1$$

$$\text{yadd1} = d + b = -2t + 1$$

$$\text{start2} = \text{xadd1}$$

$$\text{xadd2} = 2a = 2$$

$$\text{yadd2} = 2b = 2$$

48.6.2.3 Band filter

The output of limiter 1 and 2 can be modified to use a band filter. The band filter has a single filter parameter w .

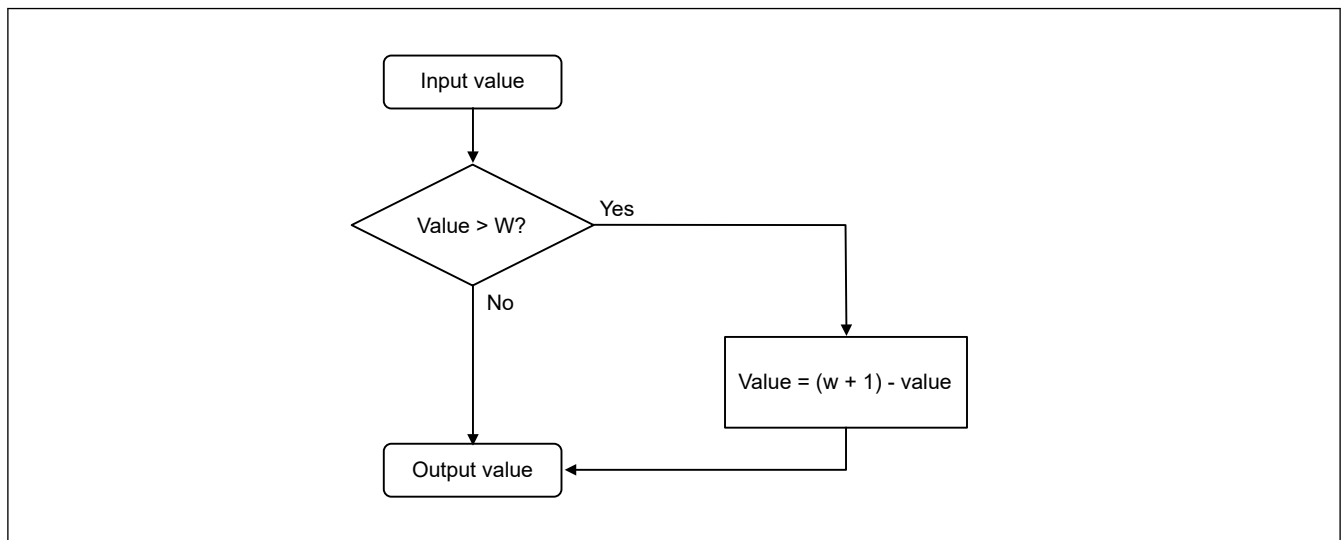

Figure 48.10 Band filter

Figure 48.11 Band filter output after clamp with $w = 7$

48.6.2.4 Clamping unit

The clamping unit cuts the limiter output to the interval $[0:1]$.

Figure 48.12 Clamping unit

The clamping unit can be put into threshold mode, in which all values greater than 0.5 are set to 1, and all values below or equal to 0.5 are set to 0. This feature is used when anti-aliasing is not needed, such as for shared edges.

48.6.2.5 Combiner unit

The combiner unit can be operated in minimum mode and in maximum mode. In minimum mode the smaller value is output, and in maximum mode the larger value is output. The minimum mode represents the intersection, and the maximum mode represents the union of the two regions.

Figure 48.13 Combiner operated in minimum mode with intersection

Figure 48.14 Combiner operated in maximum mode with union

48.6.2.6 Rasterization optimization

During rasterization, it is necessary to step through the whole bounding box one pixel at a time. This requirement can lead to an unnecessary number of steps for pixels that are not drawn. The 2D Drawing Engine provides optimization methods designed to reduce the number of steps required during rasterization. One optimization relies on the fact that any convex primitive can have only one span per line (a span is a contiguous horizontal line). This form of optimization detects a span start and saves the information for the next line. Another optimization is to detect a span end and stop rasterization for the current line.

(1) Spanstore

Consider the case in [Figure 48.15](#).

Figure 48.15 Triangle where the first edge is monotone growing

If the gray triangle must be rendered, half of the pixels processed by the rendering engine in the dotted bounding box would not be drawn. This situation can be optimized with the spanstore operation. When spanstore is activated and a span start is detected, the x position of the span start is detected.

In the next line the rendering starts with the stored x position. This only works if the edge is monotonically increasing ($y_1 > y_2 \Rightarrow x_1 \geq x_2$).

Consider the case in [Figure 48.16](#).

Figure 48.16 Triangle where the first edge is monotone falling

In this case, the normal spanstore operation cannot be performed. For this, the y direction of the rendering is reversed, and spanstore can operate again.

Consider the last case in [Figure 48.17](#).

Figure 48.17 Triangle where the first edge is first monotone falling and then monotone growing

In this case, the triangle must be split and rendered as two parts for the spanstore optimization to work.

It is also possible to delay spanstore activation for a number of lines. This approach is used for rasterizing circles, as shown in [Figure 48.18](#).

Figure 48.18 Full circle where the first edge is monotone falling for the first half and monotone growing for the second half

In this case, spanstore cannot be activated in the top left corner but can be activated in the bottom left corner. The empty corners in the top right and the bottom right cannot be rasterized because of the spanabort optimization.

(2) Spanabort

The second optimization assumes that the object that must be drawn is convex, which means there is only one span per scan line to be drawn. A non-convex object includes an object such as a triangle that is not filled and only consists of a thick border.

For a convex object, the rasterization can be stopped when the end of the first span is detected. No other constraints apply to this optimization for convex objects.

(3) Optimization efficiency

The efficiency of the optimizations can be seen for a typical case in [Figure 48.19](#). In this case, the triangle is always rendered as single piece and is not separated into multiple triangles for higher optimizations. For this, the spanstore delay is used.

Figure 48.19 Efficiency of spanstore and spanabort optimizations with enumeration coverage equal to pixels of primitive/pixels of bounding box

48.6.3 Texturing

The texture unit can cover any primitive with a picture. The picture can be stretched, sheared, rotated, and translated in one step. To avoid aliasing, the result can be filtered bilinear in the u and v directions.

48.6.3.1 Mathematical background

The arbitrary mapping problem is completely determined by a mapping from 3 points in the object space (x, y) to 3 points in the texture space (u, v).

Consider the following mapping:

$$\vec{p}_0 = \begin{pmatrix} x_0 \\ y_0 \end{pmatrix} \Rightarrow \begin{pmatrix} \widetilde{p}_0 \end{pmatrix} = \begin{pmatrix} u_0 \\ v_0 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

$$\vec{p}_1 = \begin{pmatrix} x_1 \\ y_1 \end{pmatrix} \Rightarrow \begin{pmatrix} \widetilde{p}_1 \end{pmatrix} = \begin{pmatrix} u_1 \\ v_1 \end{pmatrix} = \begin{pmatrix} w \\ 0 \end{pmatrix}$$

$$\vec{p}_2 = \begin{pmatrix} x_2 \\ y_2 \end{pmatrix} \Rightarrow \begin{pmatrix} \widetilde{p}_2 \end{pmatrix} = \begin{pmatrix} u_2 \\ v_2 \end{pmatrix} = \begin{pmatrix} 0 \\ h \end{pmatrix}$$

where w is the width of the texture and h is the height of the texture.

Examine [Figure 48.20](#) in the object space. To simplify calculations the difference vectors are taken as calculations:

$$\vec{d}_1 = \vec{p}_1 - \vec{p}_0$$

$$\vec{d}_2 = \vec{p}_2 - \vec{p}_0$$

This is equivalent to transforming from coordinate system O to coordinate system O' .

Figure 48.20 Texture mapping, object space, and transformation from coordinate system O to O' to simplify calculations

Figure 48.21 Texture mapping, texture space, and texture with width w and height h

In O' , the mapping is:

$$\vec{p}'_0 = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \Rightarrow \begin{pmatrix} \widetilde{p}_0 \\ \widetilde{v}_0 \end{pmatrix} = \begin{pmatrix} u_0 \\ v_0 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

$$\vec{d}'_1 = \begin{pmatrix} dx_1 \\ dy_1 \end{pmatrix} \Rightarrow \begin{pmatrix} \widetilde{p}_1 \\ \widetilde{v}_1 \end{pmatrix} = \begin{pmatrix} u_1 \\ v_1 \end{pmatrix} = \begin{pmatrix} w \\ 0 \end{pmatrix}$$

$$\vec{d}'_2 = \begin{pmatrix} dx_2 \\ dy_2 \end{pmatrix} \Rightarrow \begin{pmatrix} \widetilde{p}_2 \\ \widetilde{v}_2 \end{pmatrix} = \begin{pmatrix} u_2 \\ v_2 \end{pmatrix} = \begin{pmatrix} 0 \\ h \end{pmatrix}$$

This is a linear mapping that can be described by a 2×2 matrix.

$$\begin{pmatrix} \widetilde{p} \\ \widetilde{v} \end{pmatrix} = M \cdot \vec{p}' = \begin{bmatrix} m_{11} & m_{12} \\ m_{21} & m_{22} \end{bmatrix} \cdot \vec{p}'$$

$$\Rightarrow \begin{pmatrix} w \\ 0 \end{pmatrix} = M \cdot \vec{d}'_1 \wedge \begin{pmatrix} 0 \\ h \end{pmatrix} = M \cdot \vec{d}'_2$$

If the equations are expanded and sorted, the result is two equation systems each with two unknowns. These can be described more easily with a new matrix.

Let $A = \begin{bmatrix} dx_1 & dy_1 \\ dx_2 & dy_2 \end{bmatrix}$ then the equation can be rewritten as:

$$\begin{pmatrix} w \\ 0 \end{pmatrix} = A \cdot \begin{pmatrix} m_{11} \\ m_{12} \end{pmatrix} \wedge \begin{pmatrix} 0 \\ h \end{pmatrix} = A \cdot \begin{pmatrix} m_{21} \\ m_{22} \end{pmatrix}$$

This can be easily solved with determinants.

$$\text{Let } c = \frac{1}{\det A} = \frac{1}{dx_1 \cdot dy_2 - dx_2 \cdot dy_1}$$

The resulting constants are:

$$m_{11} = c \cdot w \cdot dy_2 = \frac{du}{dx}$$

$$m_{12} = -c \cdot w \cdot dx_2 = \frac{du}{dy}$$

$$m_{21} = -c \cdot h \cdot dy_1 = \frac{dv}{dx}$$

$$m_{22} = c \cdot h \cdot dx_1 = \frac{dv}{dy}$$

To calculate the start values for u and v at the top of the bounding box, the transformation from O' to O must be reversed. Let U_s and V_s be the start values, then:

$$\begin{pmatrix} U_s \\ V_s \end{pmatrix} = M \cdot \begin{pmatrix} -\vec{p}_0 \end{pmatrix} = c \cdot \begin{pmatrix} -w \cdot (x_0 \cdot dy_2 - y_0 \cdot dx_2) \\ h \cdot (x_0 \cdot dy_1 - y_0 \cdot dx_1) \end{pmatrix}$$

(1) Examples

U and v are in the texture space. Enter the following into any case:

- Copy case
 $dx_1 = 1, dx_2 = 0, dy_1 = 0, dy_2 = 1$
- Scaling case x scaling copy case
 $dx_1 = f, dx_2 = 0, dy_1 = 0, dy_2 = 1$
 with f being the scaling factor in the x direction similar for the y direction.
- Rotation case
 $dx_1 = \cos a, dx_2 = -\sin a, dy_1 = \sin a, dy_2 = \cos a$
 with the angle between d1 and the x axis in the clockwise direction.

48.6.3.2 Limiter operation

The texture limiters operate exactly the same as the spatial limiters shown in [Figure 48.8](#)

The register layout for the u limiter is the same.

- LUSTART = U_s
- LUXADD = du/dx
- LUYADD = du/dy .

The register layout for the v limiter is slightly different. TEXPITCH is multiplied to save one hardware multiplier.

- LVSTARTI = $\text{floor}(V_s) \cdot \text{TEXPITCH}$
 Contains the integer part of the start value.
- LVSTARTF = $(V_s - \text{floor}(V_s)) \cdot \text{TEXPITCH}$
 Contains the fractional part of the start value.
- LVXADDI = $\text{floor}(dv/dx) \cdot \text{TEXPITCH}$
 Contains the integer part of dv/dz .
- LUYADD = $\text{floor}(dv/dy) \cdot \text{TEXPITCH}$
 Contains the integer part of dv/dy .
- LVYXADDF = $(dv/dy - \text{floor}(dv/dy)) \cdot \text{TEXPITCH} + ((dv/dx - \text{floor}(dv/dx)) \cdot \text{TEXPITCH})$
 Contains the fractional part of dv/dy and dv/dx combined in one register.
- TEXMASK
 Contains a mask for u and v separately to wrap around values of u and v. This is useful for staying inside the limits of the texture or repeat a texture. Wrap around textures have to have a size multiple of 2.
- TEXPITCH
 Contains the width of the texture in pixels in framebuffer memory. This information is required to calculate the new address if stepping to a new line.
- TEXORIGIN
 Contains the base address of the texture.

48.6.4 Colorization

After a pixel is found to be part of the geometry, its color is calculated. The 2D Drawing Engine supports a very general color calculation scheme, allowing support for several color modes. This color scheme uses an interpolation between two color registers, COLOR1 and COLOR2. See Figure 48.22 for details. COLOR1 and COLOR2 are marked as A, B in the figure for clarity.

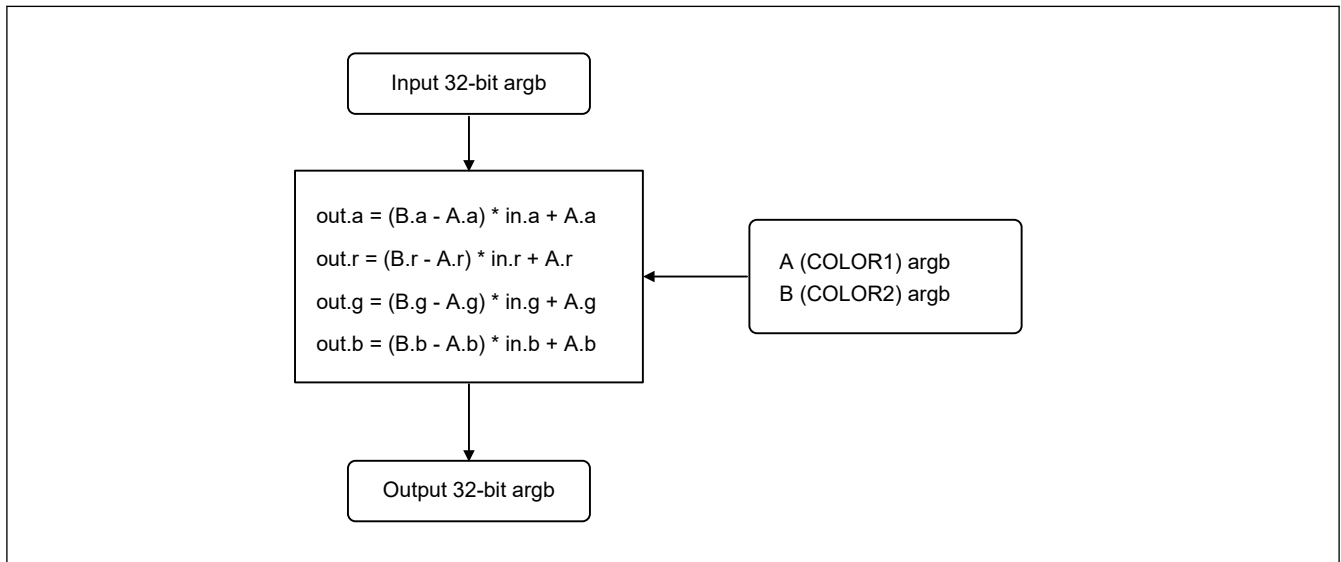

Figure 48.22 Colorization step and interpolation between the two color registers, A (COLOR1) and B (COLOR2)

This general approach can be used to support several different color modes that can be individually applied to any color or alpha channel of the input.

Table 48.8 Colorization operations

Operation	Settings for A and B*1
Copy	A = 0, B = 0xff
Replace with a constant value v	A = v, B = v
Multiply by a constant value v	A = 0, B = v
Colorize an alpha texture with the RGB value v	A.a = 0, A.r = B.r, A.g = B.g, A.b = B.b, B.a = 0xff, B.r = v.r, B.g = v.g, B.b = v.b
Invert a channel	A = 0xff, B = 0
Invert multiply with v	A = v, B = 0
Interpolate between color v and color u	A = v, B = u

Note 1. A = COLOR1, B = COLOR2

48.6.5 Blending

48.6.5.1 Color channel blending

The last step before the pixel is written to the framebuffer is to blend the pixel with the data that is already written to the framebuffer. If blending is activated, the framebuffer, referred to as DST, must be read. SRC is the output from the colorization unit.

The following color blend modes are supported:

- SRC_ZERO
- SRC_ONE
- SRC_ALPHA

- SRC_ONE_MINUS_ALPHA
- DST_ZERO
- DST_ONE
- DST_ALPHA
- DST_ONE_MINUS_ALPHA.

The selection of the color channel blend modes is performed with the following flags:

- BSF: blend source factor is alpha
- BSI: blend source factor invert
- BDF: blend destination factor is alpha
- BDI: blend destination factor invert.

The formula for the blending is:

$$\text{dst} = \text{src} \cdot f_S + \text{dst} \cdot f_D$$

where:

$$\text{BSF} = 0, \text{BSI} = 0 \Rightarrow f_S = 1$$

$$\text{BSF} = 1, \text{BSI} = 0 \Rightarrow f_S = \alpha$$

$$\text{BSF} = 0, \text{BSI} = 1 \Rightarrow f_S = 0$$

$$\text{BSF} = 1, \text{BSI} = 1 \Rightarrow f_S = 1 - \alpha$$

$$\text{BDF} = 0, \text{BDI} = 0 \Rightarrow f_D = 1$$

$$\text{BDF} = 1, \text{BDI} = 0 \Rightarrow f_D = \alpha$$

$$\text{BDF} = 0, \text{BDI} = 1 \Rightarrow f_D = 0$$

$$\text{BDF} = 1, \text{BDI} = 1 \Rightarrow f_D = 1 - \alpha$$

Table 48.9 lists all possible color channel blend modes.

Table 48.9 Color channel blend modes

Mode	BSF	BSI	BDF	BDI	Blend equation
SRC_ONE DST_ONE	0	0	0	0	SRC + DST
SRC_ONE	0	0	0	1	SRC
SRC_ONE DST_ALPHA	0	0	1	0	SRC + DST × ALPHA
SRC_ONE DST_ONE_MINUS_ALPHA	0	0	1	1	SRC + DST × (1 - ALPHA)
SRC_ZERO DST_ONE	0	1	0	0	DST
SRC_ZERO DST_ZERO	0	1	0	1	0
SRC_ZERO DST_ALPHA	0	1	1	0	DST × ALPHA
SRC_ZERO DST_ONE_MINUS_ALPHA	0	1	1	1	DST × (1 - ALPHA)
SRC_ALPHA DST_ONE	1	0	0	0	SRC × ALPHA + DST
SRC_ALPHA	1	0	0	1	SRC × ALPHA
SRC_ALPHA DST_ALPHA	1	0	1	0	SRC × ALPHA + DST × ALPHA
SRC_ALPHA DST_ONE_MINUS_ALPHA	1	0	1	1	SRC × ALPHA + DST × (1 - ALPHA)
SRC_ONE_MINUS_ALPHA DST_ONE	1	1	0	0	SRC × (1 - ALPHA) + DST
SRC_ONE_MINUS_ALPHA	1	1	0	1	SRC × (1 - ALPHA)
SRC_ONE_MINUS_ALPHA DST_ALPHA	1	1	1	0	SRC × (1 - ALPHA) + DST × ALPHA
SRC_ONE_MINUS_ALPHA DST_ONE_MINUS_ALPHA	1	1	1	1	SRC × (1 - ALPHA) + DST × (1 - ALPHA)

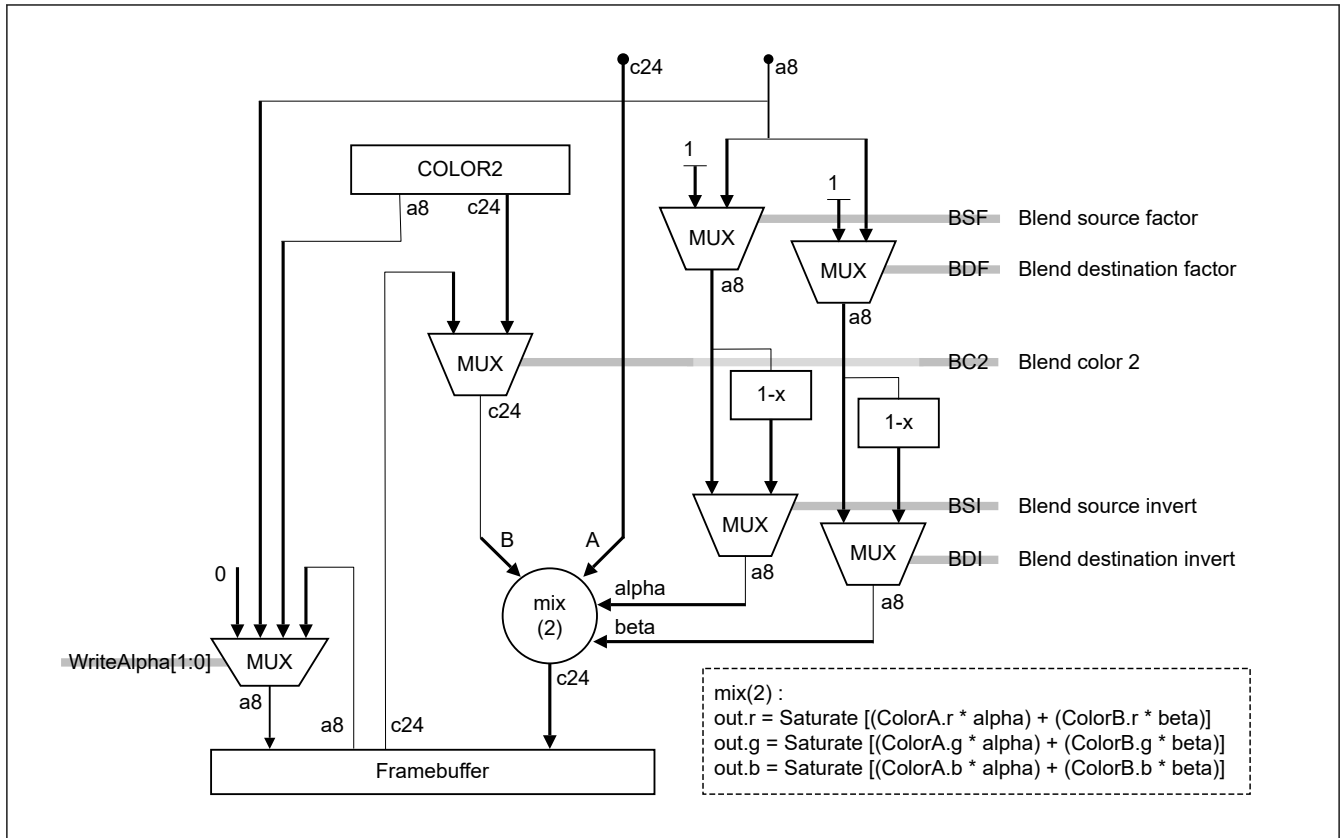

Figure 48.23 Color channel blend unit when CONTROL2.USEACB = 0

48.6.5.2 Alpha channel blending

The alpha channel can be blended in addition to the color channels. Alpha channel blending is enabled by setting CONTROL2.USEACB = 1. Alpha channel blending uses the same formulas and same blend modes as for the color channels. The alpha channel formulas can be set independently from the color channels.

The following alpha channel blend modes are supported:

- SRC_A_ZERO
- SRC_A_ONE
- SRC_A_SRC_A
- SRC_A_ONE_MINUS_SRC_A
- DST_A_ZERO
- DST_A_ONE
- DST_A_SRC_A
- DST_A_ONE_MINUS_SRC_A.

The alpha channel blend modes selected with the following flags:

- BSFA: blend source factor is SRC_A
- BSIA: blend source factor invert
- BDFA: blend destination factor is SRC_A
- BDIA: blend destination factor invert.

The formula for the blending is:

$$dst_alpha = src_a \cdot f_{S_a} + dst_a \cdot f_{D_a}$$

where:

$$\text{BSFA} = 0, \text{BSIA} = 0 \Rightarrow f_{S_a} = 1$$

$$\text{BSFA} = 1, \text{BSIA} = 0 \Rightarrow f_{S_a} = \text{src_a}$$

$$\text{BSFA} = 0, \text{BSIA} = 1 \Rightarrow f_{S_a} = 0$$

$$\text{BSFA} = 1, \text{BSIA} = 1 \Rightarrow f_{S_a} = 1 - \text{src_a}$$

$$\text{B DFA} = 0, \text{BDIA} = 0 \Rightarrow f_{D_a} = 1$$

$$\text{B DFA} = 1, \text{BDIA} = 0 \Rightarrow f_{D_a} = \text{src_a}$$

$$\text{B DFA} = 0, \text{BDIA} = 1 \Rightarrow f_{D_a} = 0$$

$$\text{B DFA} = 1, \text{BDIA} = 1 \Rightarrow f_{D_a} = 1 - \text{src_a}$$

Table 48.10 lists all possible alpha channel blend modes.

Table 48.10 Alpha channel blend modes

Mode	BSF	BSI	BDF	BDI	Blend equation
SRC_A_ONE DST_A_ONE	0	0	0	0	$\text{SRC_A} + \text{DST_A}$
SRC_A_ONE	0	0	0	1	SRC_A
SRC_A_ONE DST_A_SRC_A	0	0	1	0	$\text{SRC_A} + \text{DST_A} \times \text{SRC_A}$
SRC_A_ONE DST_A_ONE_MINUS_SRC_A	0	0	1	1	$\text{SRC_A} + \text{DST_A} \times (1 - \text{SRC_A})$
SRC_A_ZERO DST_A_ONE	0	1	0	0	DST_A
SRC_A_ZERO DST_A_ZERO	0	1	0	1	0
SRC_A_ZERO DST_A_SRC_A	0	1	1	0	$\text{DST_A} \times \text{SRC_A}$
SRC_A_ZERO DST_A_ONE_MINUS_SRC_A	0	1	1	1	$\text{DST_A} \times (1 - \text{SRC_A})$
SRC_A_SRC_A DST_A_ONE	1	0	0	0	$\text{SRC_A} \times \text{SRC_A} + \text{DST_A}$
SRC_A_SRC_A	1	0	0	1	$\text{SRC_A} \times \text{SRC_A}$
SRC_A_SRC_A DST_A_SRC_A	1	0	1	0	$\text{SRC_A} \times \text{SRC_A} + \text{DST_A} \times \text{SRC_A}$
SRC_A_SRC_A DST_A_ONE_MINUS_SRC_A	1	0	1	1	$\text{SRC_A} \times \text{SRC_A} + \text{DST_A} \times (1 - \text{SRC_A})$
SRC_A_ONE_MINUS_SRC_A DST_A_ONE	1	1	0	0	$\text{SRC_A} \times (1 - \text{SRC_A}) + \text{DST_A}$
SRC_A_ONE_MINUS_SRC_A	1	1	0	1	$\text{SRC_A} \times (1 - \text{SRC_A})$
SRC_A_ONE_MINUS_SRC_A DST_A_SRC_A	1	1	1	0	$\text{SRC_A} \times (1 - \text{SRC_A}) + \text{DST_A} \times \text{SRC_A}$
SRC_A_ONE_MINUS_SRC_A DST_A_ONE_MINUS_SRC_A	1	1	1	1	$\text{SRC_A} \times (1 - \text{SRC_A}) + \text{DST_A} \times (1 - \text{SRC_A})$

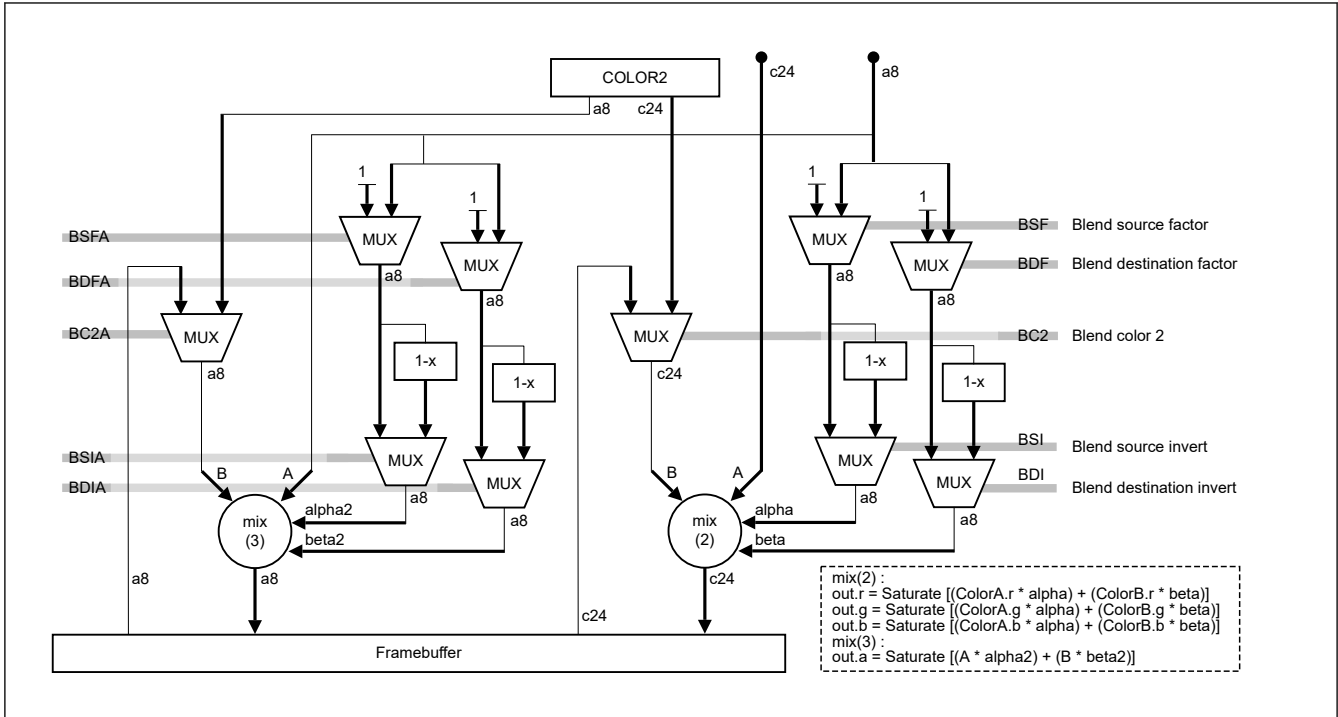

Figure 48.24 Alpha- and color-channel blend unit when CONTROL2.USEACB = 1

48.7 Rendering Modes

The rendering process can be performed in two different modes, register mode and display list mode.

48.7.1 Register Mode

In register mode, when operation is based on register settings, the host CPU configures and initiates each render process separately. To start a new render process, the host CPU must wait until the previous one is completed. In this mode, the host CPU is heavily engaged throughout the entire drawing procedure and is consequently to a large extent unavailable for other tasks.

The host CPU must set up all registers for performing a certain drawing operation before it can start the rendering process. A new register setup can only be started when the previous render process has completed. Before starting a new register setup, make sure that:

- STATUS.DLISTACTIVE = 0: Display list reader is idle
- STATUS.BUSENUM = 0: Pixel selection unit is idle.

Lastly, write the framebuffer start address to the ORIGIN register. This write triggers the 2D Drawing Engine to start rendering.

48.7.2 Display List Mode

In display list mode, the host CPU creates a display list in memory prior to starting the 2D Drawing Engine. Such a display list contains a bundle of render operations. When started, the 2D Drawing Engine executes the display list autonomously in parallel with the host CPU, which is not involved with drawing operations most of the time. Use of a display list allows a fully asynchronous operation of the host CPU and the 2D Drawing Engine and offers the best possible system performance.

In this mode, the display list reader reads a memory block containing instructions on how to set the 2D Drawing Engine control registers and executes these control register writes accordingly.

(1) Display list start

To start execution of a display list, which already resides in memory, the start address of the display list is written to the display list start address register DLISTSTART. Because rewriting DLISTSTART also stops any ongoing display list execution, make sure that the previous display list process is completed by either of the following two methods:

- Check that `STATUS.DLISTACTIVE = 0`, which indicates idle status of the display list reader
- Wait for the display list interrupt `DRWDLISTIRQ`, which indicates completion of the previous display list process.

Caution: Direct writing to 2D Drawing Engine registers while the display list mode is active (`STATUS.DLISTACTIVE = 1`) might lead to a 2D Drawing Engine hang-up. To prevent this, always check that the display list reader is idle (`STATUS.DLISTACTIVE = 0`) before writing to any 2D Drawing Engine register.

(2) Display list format

Display lists are stored using direct register-to-value mappings, which means that the display list contains a one byte index that addresses a certain register and the value to be written to the register. The register index is derived from the address offset of the register address and can be calculated by dividing the address offset by 4. For the index of each register, see [section 48.2. Register Descriptions](#).

As the 2D Drawing Engine registers are always 32 bits wide, each data unit (called a data word) to be written to a register is of the same size. An address word that contains the indices of the register to be written is stored in a packed notation with up to four indices stored in one 32-bit address word.

A display list command always starts with an address word, followed by up to four data words, one for each register. The indices are read and interpreted from LSB to MSB, so the register of the low byte index is written first.

(3) Example

In the following example:

- `DWORD 0x201A_1930` // start of list address word
- `DWORD 0x0000_0013` // data word 1 (for register 0x30)
- `DWORD 0xFFFF_FFAA` // data word 2 (for register 0x19)
- `DWORD 0x4033_6480` // data word 3 (for register 0x1A)
- `DWORD 0x0001_0000` // data word 4 (for register 0x20)
- `DWORD...` // next address word.

This stream of dwords updates the DRW registers as follows:

- Write `0x0000_0013` to register `0x30 = 48`, which is `IRQCTL`
- Write `0xFFFF_FFAA` to register `0x19 = 25`, which is `COLOR1`
- Write `0x4033_6480` to register `0x1A = 26`, which is `COLOR2`
- Write `0x0001_0000` to register `0x20 = 32`, which is `ORIGIN`.

(4) Address word indices

Besides referencing a register, the indices of an address word can also have other meanings, depending on their value.

Table 48.11 Address indices function (1 of 2)

Index	Function	
0x00 to 0x7F	Register indices Two register indices trigger additional actions:	
	0x20 = 32:	A write to <code>ORIGIN</code> to set a new frame buffer address is delayed until the ongoing frame buffer write-back is complete, when <code>STATUS.BUSYWRITE = 0</code> .
	0x32 = 50:	A write to <code>DLISTSTART</code> sets a new display list start address stops the current display list and starts the new one.
0x80	Gap index, which is used to fill unused bytes of an address word. For example, if fewer than four indices are required, the remaining bytes are filled with <code>0x80</code> . In this case, the number of the subsequent data words must be reduced accordingly.	

Table 48.11 Address indices function (2 of 2)

Index	Function	
0xFF	If the first index of an address word contains the special index 0xFF, the subsequent (second) index is interpreted as follows:	
	Bit [0] set:	Display list end.
	Bit [1] set:	Issue a full pipeline flush and wait (necessary before flip).
	Bit [2] set:	Wait for writeback complete (necessary before framebuffer format change).
	Bits [3:7]	Set all to 0s.
	Bit [1] and [2] settings are mutually exclusive. All indices after the special index 0xFF are ignored, and the next address word is read, if no display list end (bit [0] = 1) was set.	
	The remaining two indices must be set to 0x00.	

Caution Gap indices 0x80 must not be placed between other indices, for example as "index1 - 0x80 - index3 - index4". Always fill all indices after 0x80 with the gap index.

Caution If any of the special indices 0x80 and 0xFF are used, no register index can follow after them in the same address word.

Table 48.12 2D Drawing Engine registers overview (1 of 2)

Register function	Symbol	Index
Control registers:		
Geometry control 0	CONTROL	0
Surface control	CONTROL2	1
Interrupt control	IRQCTL	48
Cache control	CACHECTL	49
Status control	STATUS	N/A ^{*1}
Hardware version and feature set ID	HWREVISION	N/A ^{*1}
Color registers:		
Base color	COLOR1	25
Secondary color	COLOR2	26
Pattern	PATTERN	29
Limiter registers:		
Limiter 1 start value	L1START	4
Limiter 2 start value	L2START	5
Limiter 3 start value	L3START	6
	L4START	7
Limiter 5 start value	L5START	8
Limiter 6 start value	L6START	9
Limiter 1 x-axis increment	L1XADD	10
Limiter 2 x-axis increment	L2XADD	11
Limiter 3 x-axis increment	L3XADD	12
Limiter 4 x-axis increment	L4XADD	13
Limiter 5 x-axis increment	L5XADD	14
Limiter 6 x-axis increment	L6XADD	15
Limiter 1 y-axis increment	L1YADD	16
Limiter 2 y-axis increment	L2YADD	17
Limiter 3 y-axis increment	L3YADD	18

Table 48.12 2D Drawing Engine registers overview (2 of 2)

Register function	Symbol	Index
Limiter 4 y-axis increment	L4YADD	19
Limiter 5 y-axis increment	L5YADD	20
Limiter 6 y-axis increment	L6YADD	21
Limiter 1 band width parameter	L1BAND	22
Limiter 2 band width parameter	L2BAND	23
Texture registers:		
Texture base address	TEXORIGIN	47
Texels per texture line	TEXPITCH	45
Texture size or texture address mask	TEXMASK	46
U limiter start value	LUSTART	36
U limiter x-axis increment	LUXADD	37
U limiter y-axis increment	LUYADD	38
V limiter start value integer part	LVSTARTI	39
V limiter start value fractional part	LVSTARTF	40
V limiter x-axis increment integer part	LVXADDI	41
V limiter y-axis increment integer part	LVYADDI	42
V limiter increment fractional parts	LVYXADDF	43
Color lookup table start address	TEXCLADDR	55
Write Data to DRWTEXCLADDR; after each data write, DRWTEXCLADDR is incremented by 1.	TEXCLDATA	56
Offset to the index for the indexed texture formats i8, i4, i2, and i1	TEXCLOFFSET	57
Compare value for R,G, B components of internal texel color representation.	COLKEY	58
Miscellaneous registers:		
Bounding box dimension	SIZE	30
Framebuffer pitch and spanstore delay	PITCH	31
Address of the first pixel in framebuffer	ORIGIN	32
Display list start address	DLISTSTART	50
Performance counters control	PERFTRIGGER	53
Performance counter 1	PERFCOUNT1	51
Performance counter 2	PERFCOUNT2	52

Note 1. These registers are read-only and cannot be accessed in display list mode, and they therefore have no index.

48.7.3 Stopping the Render Process

Stopping an ongoing render process requires a specific procedure, which is described in [section 48.10. Stopping the 2D Drawing Engine Render Process](#).

48.8 Interrupts

The 2D Drawing Engine generates three interrupts:

- DRWBUSIRQ
- DRWENUMIRQ
- DRWDLISTIRQ.

48.8.1 Interrupt sources

(1) DRWBUSIRQ

This is the 2D Drawing Engine bus error interrupt. It occurs when the 2D Drawing Engine attempts to access an undefined address range through the following registers:

- Framebuffer Base Address Register ORIGIN
- Texture Base Address Register TEXORIGIN
- Display List Start Address Register (DLISTSTART).

The bus error interrupt DRWBUSIRQ is then generated. The bus error interrupt only serves for debugging purposes. The interrupt source can be determined by the BUSERRMFB, BUSERRMTXMRL, and BUSERRMDL bits of the STATUS register.

Note: After a DRWBUSIRQ occurrence, you must apply a system reset.

(2) DRWENUMIRQ

This is the current render process finished interrupt.

(3) DRWDLISTIRQ

This is the display list interrupt. It is asserted on completion of a display list process. DRWDLISTIRQ is activated if one of the following conditions is true:

- The entire display list is complete
- The display list processing stops because a new display list start is triggered by a write to the Display List Start Address Register (DLISTSTART).

48.8.2 Interrupt Control

The three 2D Drawing Engine interrupts are combined into a single shared interrupt, DRW_IRQ, to the CPU. Each interrupt can be masked (disabled), or unmasked (enabled) by setting its associated enable bit in the Interrupt Control Register (IRQCTL).

The occurrence of an enabled interrupt (one with its mask bit set to 1 in IRQCTL) is monitored in the Status Control Register (STATUS) with its associated interrupt status bit is set to 1. The shared 2D Drawing Engine interrupt DRW_IRQ is then generated.

To clear the interrupt, the host CPU must write 1 to the interrupt clear bit in IRQCTL. The interrupt clear bit returns to 0 automatically.

Figure 48.25 Interrupt Controller Unit (ICU)

48.9 Performance Counters

The 2D Drawing Engine features two independent 32-bit performance counter registers (PERFCOUNT k ($k = 1, 2$)) to count the number of occurrences of a certain event. The events to be counted can be set up independently for each performance counter register with the Performance Counter Control Registers, PERFTRIGGER.PERFTRIGGER2 for PERFCOUNT2 and PERFTRIGGER.PERFTRIGGER1 for PERFCOUNT1.

Table 48.13 lists the performance counter trigger events that can be selected.

Table 48.13 Performance counter trigger events

PERFTRIGGER.PERFTRIGGERK	Event
0	Disable performance counter
1	2D Drawing Engine active cycles
2	Framebuffer read access
3	Framebuffer write access
4	Texture read access
5	Invisible pixels (enumerated but selected with alpha 0%)
6	Invisible pixels while internal FIFO is empty (lost cycles)
7	Display list reader active cycles
8	Framebuffer read hits
9	Framebuffer read misses
10	Framebuffer write hits
11	Framebuffer write misses
12	Texture read hits
13	Texture read misses
31	Every clock cycle (for use as timer)

48.10 Stopping the 2D Drawing Engine Render Process

If a render process has started either in register or display list mode, the 2D Drawing Engine processes the data autonomously until the render process is finished. Depending on the rendering, this process might take several milliseconds.

If the 2D Drawing Engine is to be disabled because, for example, the MCU enters a low power mode, proceed as follows to stop the ongoing rendering:

- Set the following registers as follows:
 - SIZE = 0x00010001
Set bounding box dimensions to 1 pixel x 1 line.
 - CONTROL2 = 0x00000000
Color format A (8), no texture, CLUT.
 - ORIGIN = UnmappedAddress
The UnmappedAddress is an address that is not available for 2D Drawing Engine access.
The recommended UnmappedAddress is given here under the key word "UnmappedAddress".
 Alternatively do the same in display list mode:
 - DWORD 0x8020011E // start of "address word" list
 - DWORD 0x00010001 // SIZE = 0x00010001
 - DWORD 0x00000000 // CONTROL2 = 0x00000000
 - DWORD UnmappedAddress // ORIGIN = UnmappedAddress
- Wait for the Bus Error corresponding to the unmapped address violation, which indicates access to an unmapped address and the stop of the render process.
 - UnmappedAddress = 0xFFFFFFFF
- Disable the 2D Drawing Engine, if wanted.

48.11 MathML sample

#1

$$y = \tilde{a}x + \tilde{b}$$

#2

$$0 = f(x, y) = \tilde{a}x - y + \tilde{b} = ax + by + c$$

$$\text{with } a = \tilde{a}, b = -1, c = \tilde{b}$$

#3

$$\vec{p} = \begin{pmatrix} x \\ y \end{pmatrix}, \vec{n} = \begin{pmatrix} a \\ b \end{pmatrix} \Rightarrow f(x, y) = ax + by + c = \vec{p} \cdot \vec{n} + c$$

#4

The projection of $\vec{p} - \vec{p}_0$ to \vec{n} is the distance d of the point P to the line. In this case, $f(x, y)$ describes the distance to the line of the pixel with coordinates (x, y) .

#5

$$\Delta\vec{p} = \vec{p}_1 - \vec{p}_0 = \begin{pmatrix} x_1 - x_0 \\ y_1 - y_0 \end{pmatrix} = \begin{pmatrix} \Delta x \\ \Delta y \end{pmatrix}$$

#6

Consider the equation for a circle with the center at $\vec{c} = \begin{pmatrix} s \\ t \end{pmatrix}$ and radius r :

#7

$$0 = f(x, y) = (x - s)^2 + (y - t)^2 - r^2$$

#8

$$0 = f(x, y) = \vec{p}_0 \cdot \vec{n} + c \Rightarrow c = -\vec{p}_0 \cdot \vec{n}$$

#9 OLD

$$\vec{p}_0 = \begin{pmatrix} x_0 \\ y_0 \end{pmatrix} \Rightarrow \overline{(\vec{p}_0)} = \begin{pmatrix} u_0 \\ v_0 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

#9 NEW

$$\vec{p}_0 = \begin{pmatrix} x_0 \\ y_0 \end{pmatrix} \Rightarrow \overline{(\vec{p}_0)} = \begin{pmatrix} u_0 \\ v_0 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

#10 OLD

$$\vec{n} = \begin{pmatrix} -\Delta y \\ \Delta x \end{pmatrix} / (\sqrt{\Delta x^2 + \Delta y^2})$$

#10 NEW

$$\vec{n} = \begin{pmatrix} -\Delta y \\ \Delta x \end{pmatrix} \cdot \frac{1}{\sqrt{\Delta x^2 + \Delta y^2}}$$

#11

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix}$$

#11-2

$$\begin{bmatrix} m_{11} & m_{12} \\ m_{21} & m_{22} \end{bmatrix}$$

#12

start2 = xadd1

#13

$$f(x + 1, y)$$

#14

$$\begin{pmatrix} w \\ 0 \end{pmatrix} = A \cdot \begin{pmatrix} m_{11} \\ m_{12} \end{pmatrix} \wedge \begin{pmatrix} 0 \\ h \end{pmatrix} = A \cdot \begin{pmatrix} m_{21} \\ m_{22} \end{pmatrix}$$

#15

$$\text{sqrt}(x^2 + y^2) = \frac{\sqrt{x^2 + y^2}}{k}$$

#16

$$k = \prod_{i=0}^{\infty} \frac{1}{\sqrt{1 + 2^{-2i}}} \approx 0.6072529350088812561694$$

48.12 Usage notes

48.12.1 Module-stop function

DRW operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The DRW module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

48.12.2 Restriction for OSPI

There is a restriction to using OSPI, see [section 33.3.8.5. Restriction in 8D-8D-8D profile 1.0 format](#).

49. Graphics LCD Controller (GLCDC)

49.1 Overview

The multifunctional Graphics LCD Controller (GLCDC) supports multiple data formats and panels. Key GLCDC features include:

- GLCDC0 and GLCDC1 bus master function for accessing graphics data
- Superimposition of three planes (single color background plane, graphics 1 plane, and graphics 2 plane)
- Supports many types of 32- and 16-bit/pixel graphics data and 8-, 4-, and 1-bit LUT data formats
- Digital interface signal output supporting the video image size up to WVGA(800 x 480).

Figure 49.1 shows a block diagram of the GLCDC.

Figure 49.1 GLCDC block diagram

TrustZone Filter		Security and Privilege attribution can be set.

49.1.1 GLCDC Configuration

Figure 49.2 shows the configuration of the GLCDC.

The GLCDC includes the following blocks:

- Background screen generation block: Generates the background screen (including the blanking interval), selects the background color, and generates the synchronization signals for controlling the screens.
- Graphics data interface blocks (2 blocks): Convert the graphics data/CLUT data read through the GLCDC0 and GLCDC1 bus into ARGB (8888) data for internal processing, and transfer the clocks (PCLKA → PXCLK).
- Alpha blending blocks (2 blocks): Superimpose graphics data on the lower-layer screen and perform alpha blending based on the register settings and the alpha blending values for the current screen graphics data.
- TCON block: Generates the vertical and horizontal synchronization and enable signals suited for the specifications of the connected panel, from the internal vertical and horizontal synchronization signals.
- Data format conversion block: Processes data into the specific internal RGB888 format into the data of the specific format suited for the specifications of the panel with dither correction for output image data length.
- Panel-oriented correction processing block: Corrects brightness and contrast, and performs gamma correction suited for the characteristics of the connected panel, allowing either brightness and contrast correction or gamma correction to be performed first.
- Clock generator block: Generates the pixel and the panel clocks on a specific frequency from either LCD_EXTCLK or LCDCLK.

Figure 49.2 GLCDC configuration

49.1.2 Screen Format

Figure 49.3 shows the screen format overview of the GLCDC.

Figure 49.3 Screen format

The background screen generation block generates the essential timing signals for operations in the module as a whole. The graphics data interface blocks, alpha blending blocks, gamma correction block, output control block, and TCON block operate based on the synchronization and enable signals, which are sequentially transferred from the background screen generation block.

49.1.3 Graphics and Color Palette (CLUT) Data Formats

The GLCDC handles three display screens, one of which is a background screen. For the background screen, frame data is RGB888 graphics data stored in the registers, and for the other two screens, frame data is stored in the memory connected to the GLCDC0 and GLCDC1 bus as 32- or 16-bit/pixel graphics data or 8-, 4-, or 1-bit/pixel color palette (CLUT) data. The frame data of the relevant screen is read by the graphics data interface block, read into the GLCDC, and extended (converted) into ARGB8888 data for superimposition and blending. [Figure 49.4](#) shows the frame data formats.

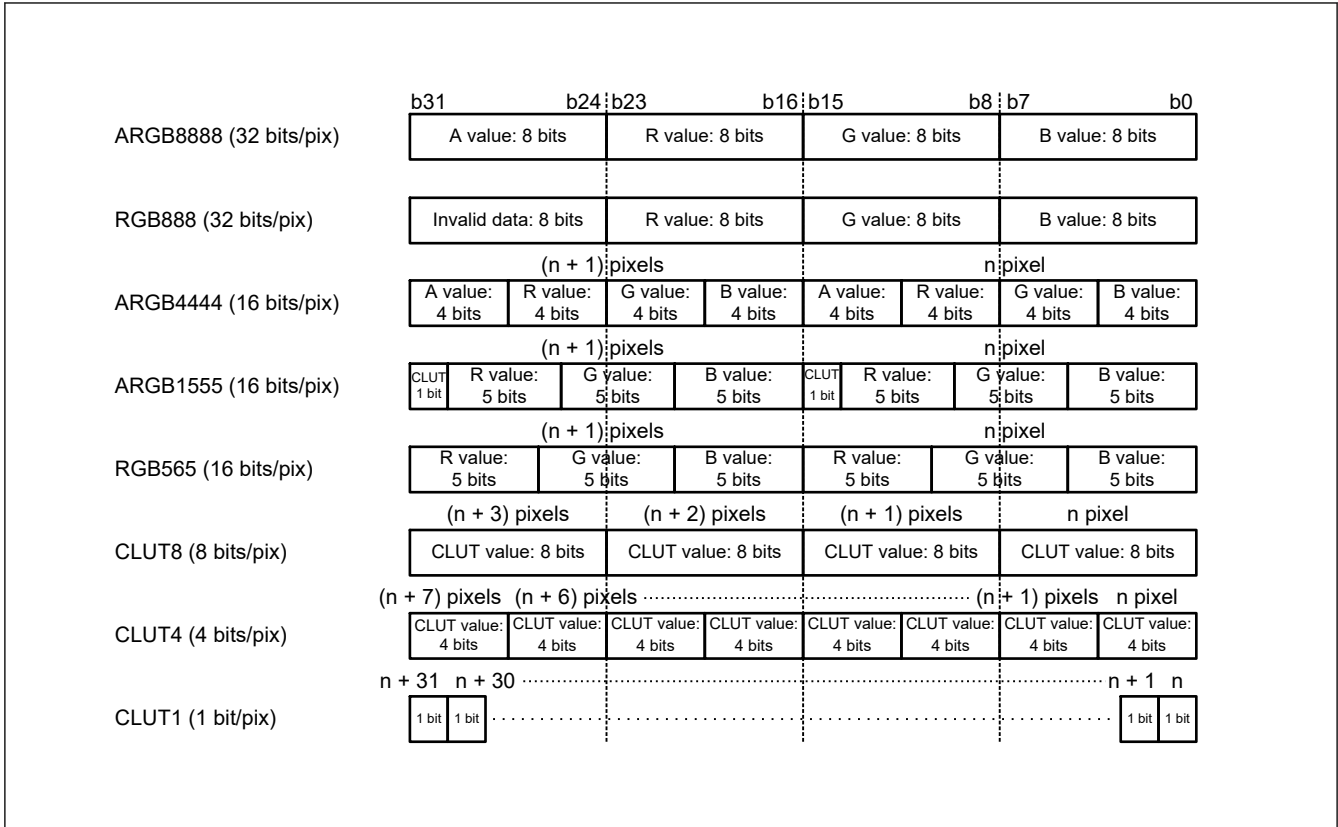

Figure 49.4 Frame data format

The A value (alpha blending value) represents the blending ratio of pixel data for displaying the lower-layer and current graphics screens after superimposition. The blending process is performed in accordance with the equations given in [section 49.1.7. Graphics Data Interface](#). The CLUT value represents the color palette memory address (plane 0 or 1 is selected in the registers), and the data in the color palette is ARGB8888 (32 bits/pixel) graphics data. Addresses 0x01/0x00 are accessed with CLUT1, 0x0F to 0x00 with CLUT4, and 0xFF to 0x00 with CLUT8. Addresses 0x80/0x00 are accessed with ARGB1555 data.

49.1.4 Output Control for Data Format

The GLCDC can output data in accordance with the following formats and register settings:

- Data formats
 - Parallel: RGB888, RGB666, and RGB565
 - Serial: RGB888
 - Lower bits are processed in one of the following modes when 10-bit signals are reduced to 8-, 6-, and 5-bit signals:
 - Truncate mode
 - Round-off mode
 - 2×2 pattern dither processing + truncate mode
- Pixel arrangement
 - RGB
 - BGR
- Scan direction select for serial RGB888
 - Forward scan
 - Reverse scan
- Data output delay of serial RGB888

- 0 to 3 clock cycles.
- Pin assignment
 - Little endian
 - Big endian

For details on dither processing, see [section 49.2.48. OUT_PDTHA : Output Control Block Panel Dither Correction Register](#).

Bit assignment of LCD signals for parallel RGB888 format

[Table 49.3](#) shows RGB signal inputs assigned to the LCD signal outputs for the parallel RGB888 output format.

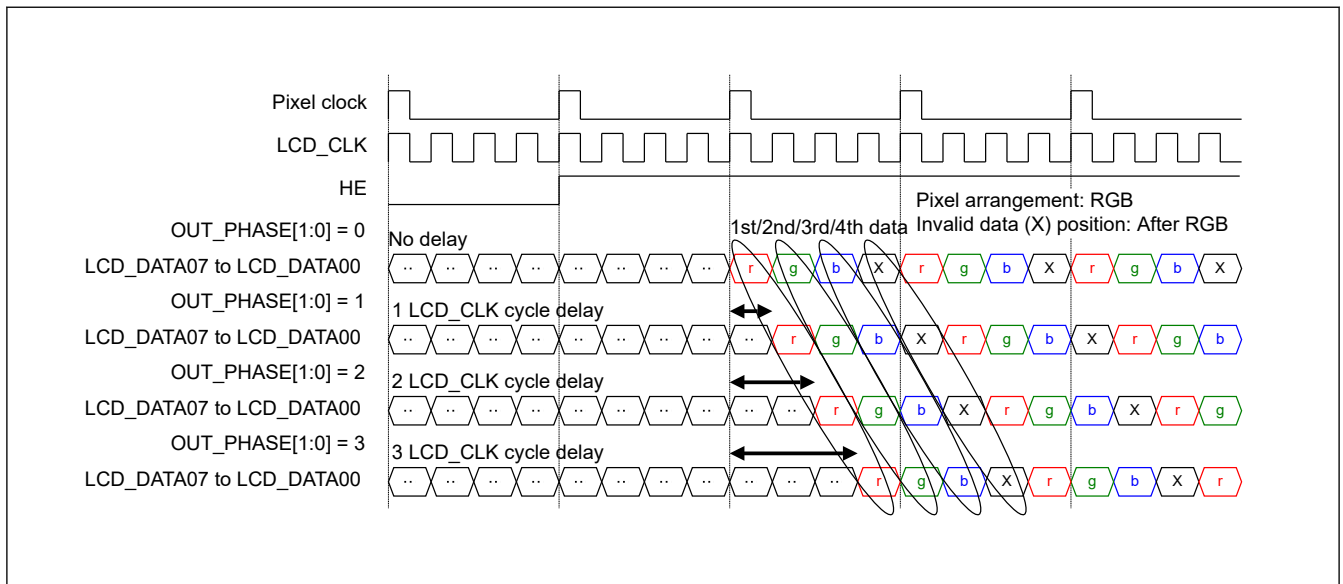

Figure 49.5 Serial RGB888 (4x speed) output timing

49.1.5 Output Control for Panel-Oriented Correction Process

The following panel-oriented correction processes are provided:

- Brightness correction
- Contrast correction
- RGB gamma correction

Brightness correction always precedes contrast correction, but RGB gamma correction can either precede or follow brightness and contrast correction, based on the register settings. In panel-oriented correction, 10-bit RGB data obtained by extending 8-bit RGB data output from graphics 2 is used, and 10-bit RGB data is also output to the output control (data format conversion) block. Figure 49.6 shows the configuration of the panel-oriented correction circuit.

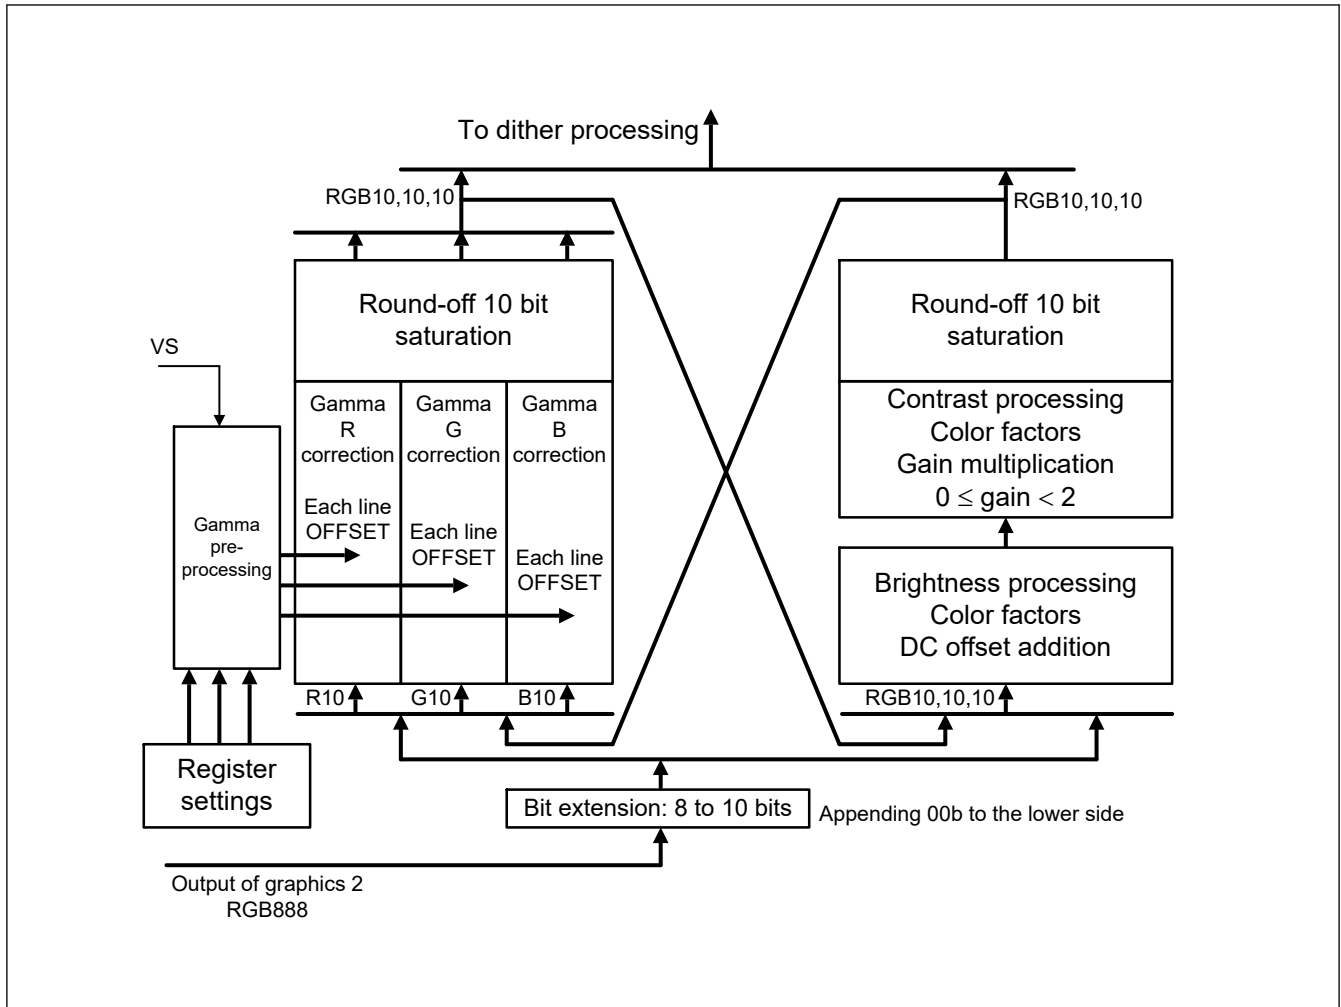

Figure 49.6 Configuration of panel-oriented correction circuit

49.1.6 Output Control for TCON

Any of the four signals generated from the internal vertical and horizontal synchronization signals (STVA, STVB, STHA, and STHB) that have passed through the data format conversion block can be selected for output on four pins, LCD_TCON0, LCD_TCON1, LCD_TCON2, and LCD_TCON3. The generated signals are completely independent of the image data. They are not affected by the output image format or any internal data process, and no register settings for signal generation affect the output image format or any internal data process. The data enable signal DE, which is to be generated by the TCON block, is the logical AND of the two signals STVB and STHB, which were previously generated by the TCON block. Consequently, three signals in total can actually be generated if DE is to be output.

49.1.7 Graphics Data Interface

Two circuit systems are provided for reading graphics data (graphics 1 and 2), each of which incorporates an access control block, data buffer, CLUT memory, data extension block, and asynchronous interface block.

Figure 49.7 Calculation of graphics data access address

Graphics (or CLUT) data is accessed and output to the pixel operation block as ARGB8888 data (32 bits/pixel).

The GLCDC0 and GLCDC1 bus is accessed in word (32-bit) units in 16-beat increment burst reads, in accordance with the preset parameters in the two-dimensional addressing mode, in which the macro line structure is accounted for as shown in Figure 49.7, and data is stored in the data buffer. Even if invalid data is at the raster line end, all the data is stored in the data buffer, and the invalid data is skipped when data is read internally. Regardless of the format of the graphics data, data is extended to ARGB8888 data before being output to the alpha blending blocks.

49.1.8 Blending

The following processes are performed for the graphics areas specified in the registers. The lower-layer graphics plane is output without any processing to the display area outside the graphics area.

- Display plane selection
- RGB-index chroma-key
- Alpha blending

Figure 49.8 shows the relationship between the graphics display selection and rectangular alpha blending area.

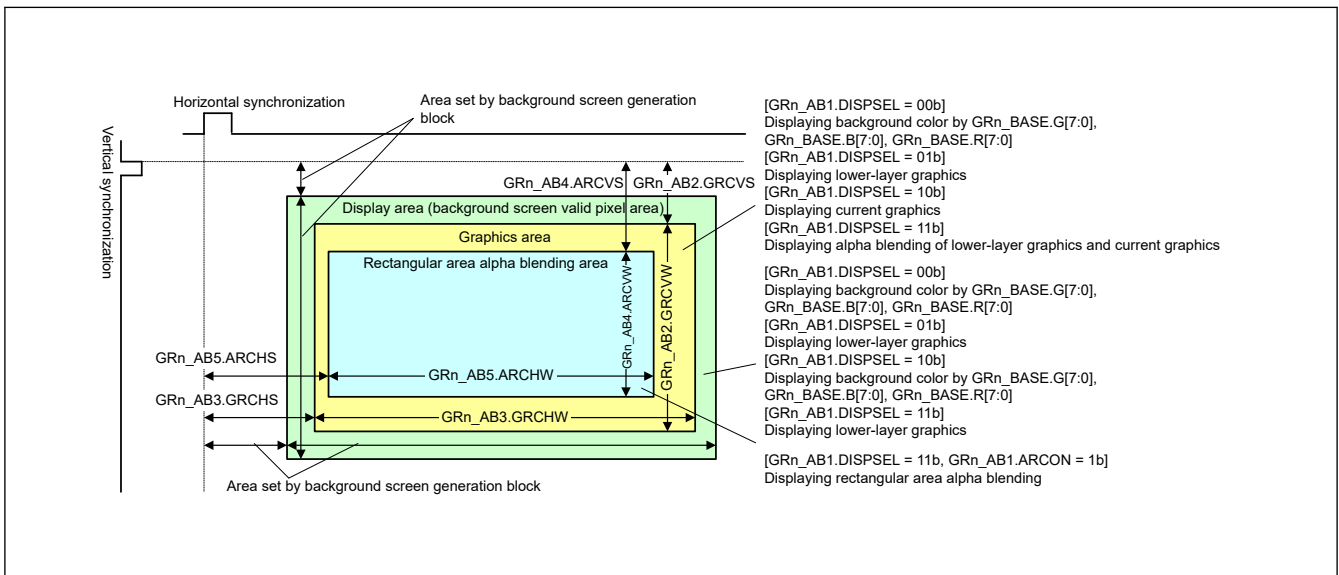

Figure 49.8 Graphics display selection

(1) Display plane selection

Based on the register settings, the following data is output to the graphics area:

- Background color:

- RGB data specified in the registers.
- Lower-layer graphics:
 - RGB data input from the previous module
 - Output from the background screen generation block for graphics 1
 - Output from graphics 1 for graphics 2
- Current graphics:
 - RGB data obtained by the graphics data interface block extending the graphics data read by the graphics 1 or 2 module through the GLCDC0 and GLCDC1 bus or CLUT data to ARGB8888 format data.
- Blending:
 - RGB data obtained by blending the lower-layer graphics data and current graphics data obtained by the graphics data interface block extension to ARGB8888 format data, based on the alpha blending values or the register settings.

It is possible to modify the register values related to these functions while display operation is in progress, and to allow reflection of the updates to the internal operations when the VS (vertical synchronization signal) is asserted, if reflection of the register settings to the internal operations on vertical synchronization is enabled.

(2) RGB-index chroma-key

If the RGB value of the ARGB8888 data input from the graphics data interface block agrees with the value set in the GRn_AB8 register, the ARGB8888 data is entirely replaced with the value preset in the GRn_AB9 register. All the ARGB8888 data input from the graphics data interface block is subject to this process. If your application excludes CLUT memory output from this process, you must disable the corresponding process in GRn_AB7.CKON.

(3) Alpha blending

If blending is selected in the selected display plane, lower-layer graphics and current graphics are alpha-blended based on the register settings using either of the following two functions.

Alpha-blending in a rectangular area

The following process is performed for the rectangular area (in the graphics area) preset in the registers:

1. Lower-layer graphics and current graphics planes are blended in accordance with the A value set in the registers.
2. After the number of frames set in the registers passes, the A value is updated to the A value + Δ (register setting).
3. The lower-layer graphics and current graphics planes are blended in accordance with this updated A value.
4. The process of updating the A value after the number of frames set in the registers passes is repeated (A value: min/max value saturation).

Alpha-blending in pixel units

The lower-layer graphics and current graphics planes are blended in accordance with the A value of the ARGB8888 data input from the graphics data interface block.

Figure 49.9 shows the update of the alpha blending value in the rectangular alpha blending area.

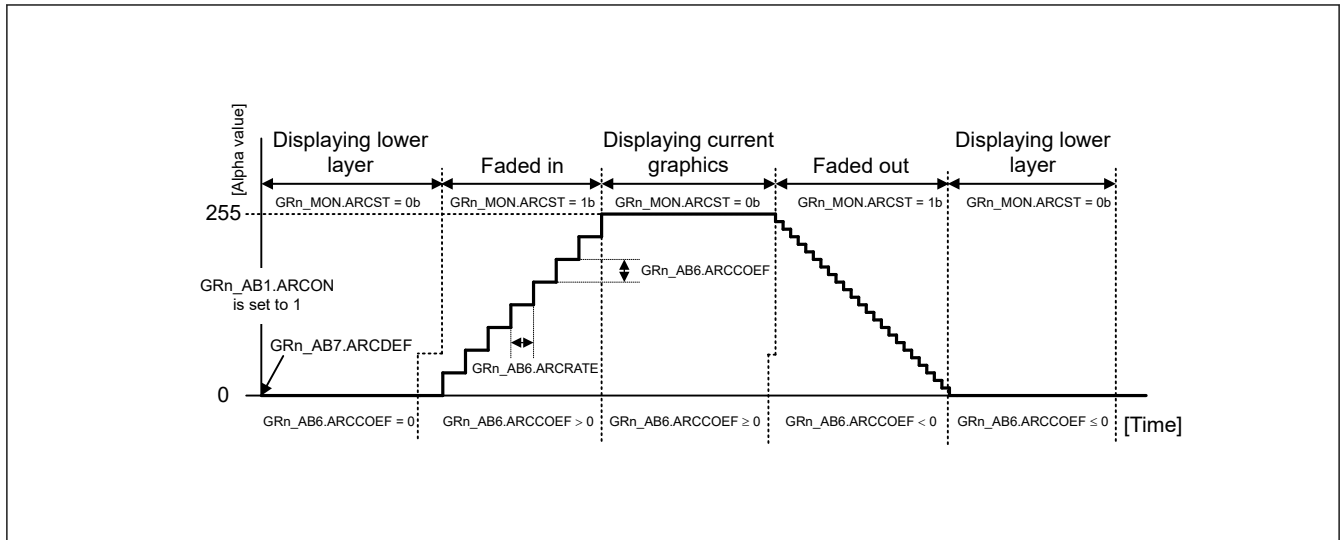

Figure 49.9 Updating of alpha blending value

Alpha blending is based on the following formulas:

When A value = 255

Rout/Gout/Bout = current graphics data

When A value ≠ 255

$R_{out} = (R_{in1} \times A + R_{in0} \times (256 - A))/256$

$G_{out} = (G_{in1} \times A + G_{in0} \times (256 - A))/256$

$B_{out} = (B_{in1} \times A + B_{in0} \times (256 - A))/256$

where,

A: alpha blending value

Rin1/Gin1/Bin1: current graphics data

Rin0/Gin0/Bin0: lower-layer graphics data

49.2 Register Descriptions

49.2.1 GRm_CLUTn[y] : Color Palette (m = 1 to 2, n = 0 to 1, y = 0 to 255)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x0+0x4 × y (GR1_CLUT0[y])
0x0400+0x4 × y (GR1_CLUT1[y])
0x0800+0x4 × y (GR2_CLUT0[y])
0x0C00+0x4 × y (GR2_CLUT1[y])

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	A[7:0]								R[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	G[7:0]								B[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	B[7:0]	B Value of Color Palette n Plane for Graphics m Plane B value of color palette n plane for graphics m plane. Unsigned 8-bit integer.	R/W

Bit	Symbol	Function	R/W
15:8	G[7:0]	G Value of Color Palette n Plane for Graphics m Plane G value of color palette n plane for graphics m plane. Unsigned 8-bit integer.	R/W
23:16	R[7:0]	R Value of Color Palette n Plane for Graphics m Plane R value of color palette n plane for graphics m plane. Unsigned 8-bit integer.	R/W
31:24	A[7:0]	Alpha Blending Value of Color Palette n Plane for Graphics m Plane Alpha blending value of color palette n plane for graphics m plane. Unsigned 8-bit integer.	R/W

Note: S-TYPE-3, P-TYPE-3

B[7:0] bits (B Value of Color Palette n Plane for Graphics m Plane)

The B[7:0] bits set the B value when this color palette is used.

G[7:0] bits (G Value of Color Palette n Plane for Graphics m Plane)

The G[7:0] bits set the G value when this color palette is used.

R[7:0] bits (R Value of Color Palette n Plane for Graphics m Plane)

The R[7:0] bits set the R value when this color palette is used.

A[7:0] bits (Alpha Blending Value of Color Palette n Plane for Graphics m Plane)

The A[7:0] bits set the alpha blending value when this color palette is used.

All the planes can always be accessed through the register access bus (PABI), regardless of the plane specified to be used by the graphics data access block. The updates are reflected to the internal operations directly, not in synchronization with the vertical synchronization signal. To keep reflection of the CLUT memory contents to the internal operations in synchronization with the vertical synchronization signal, first write data through the register access bus to the plane that is not being used for internal operations, and then modify the GRn_CLUTINT.SEL bit for controlling the plane that is to be used.

49.2.2 BG_EN : Background Plane Setting Operation Control Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1000

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SWRS T
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	VEN	—	—	—	—	—	—	—	EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EN	Background Plane Operation Enable 0: Disable background plane operation 1: Enable background plane operation	R/W
7:1	—	These bits are read as 0. The write value should be 0.	R/W
8	VEN	Control of GLCDC Internal Register Value Reflection to Internal Operations This bit is set to 0 by an internal source. 0: Disable GLCDC register values from being reflected in internal operations at start of screen generation 1: Enable GLCDC register values to be reflected in internal operations at start of screen generation	R/W
15:9	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
16	SWRST	Software Reset Control 0: Place entire module in software reset state 1: Release entire module from software reset state	R/W
31:17	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

EN bit (Background Plane Operation Enable)

The EN bit enables or disables the operation of the background plane generation module. When the operation is stopped (this bit is cleared to 0) after the operation is enabled (set to 1), the operation is stopped at the end of screen generation, unlike when a software reset occurs.

When setting this bit to 1, set the BG_EN.VEN bit to 1 simultaneously to enable register value reflection to internal operations. When clearing this bit to 0, also clear the BG_EN.VEN bit to 0 simultaneously. Before clearing this bit to 0, confirm that the BG_MON.VEN bit is cleared to 0, to make sure that the signal for controlling reflection of the register values to internal operations is negated. Operation is not guaranteed if this bit and the BG_EN.VEN bit are set to 1, or if the settings in other registers are modified before the BG_MON.EN bit is cleared to 0.

VEN bit (Control of GLCDC Internal Register Value Reflection to Internal Operations)

The VEN bit enables or disables reflection of the GLCDC internal register to the GLCDC internal operation on assertion of the vertical synchronization signal (input). When this bit is set to 1, the signal of GLCDC internal register values reflection control is set to 1 at the immediate start of the screen, and are automatically cleared to 0 at the end of the vertical valid pixel of the same screen. Set this bit to 1 only when 0. Operation is not guaranteed if this bit is set to 1 when 1. Also, while this bit is 1, do not modify any register whose value is reflected to the internal operations at the start of the screen in the GLCDC or on assertion of the vertical synchronization signal (input). Otherwise, operation is not guaranteed.

SWRST bit (Software Reset Control)

The SWRST bit controls a software reset of the entire GLCDC, not only the background plane generation module. When this bit is cleared to 0, the GLCDC enters the reset state from any operation state. This bit must be set to 1 before the registers are set or operation enabled. Although the registers (except the CLUT memory and the some of the operation control registers) can be set while this bit is set to 1 (immediately after), before accessing the CLUT memory, enabling operation, or reflecting the register values to the internal operation by the vertical synchronization signal, confirm that PXCLK/LCD_CLK and PCLKA are supplied and that the BG_MON.SWRST bit, which monitors the entire module software reset state, is set to 1. Operation is not guaranteed if the software accesses CLUT memory, enables operation, or reflects the register vales to the internal operation on the vertical synchronization signal while PXCLK/LCD_CLK and PCLKA are not supplied or the BG_MON.SWRST bit is not set to 1. The peripheral bus clock (PCLKA) must be supplied to the GLCDC when this bit is used to apply or cancel a software reset. If PCLKA is not supplied, writing to this bit is impossible.

The bits in this register control the GLCDC states. The internal states can be read from the associated bits in the status monitor registers and BG_EN.VEN (this register). Because the GLCDC, which operates on multiple clock signals, requires a certain period for state transition, you must confirm that the internal state has stabilized (state transition is complete) when settings are modified. Operation is not guaranteed if settings are modified again before the internal state stabilizes (state transition is complete). However, clearing a software reset to 0 immediately makes the whole GLCDC reset, setting it to 1 releases the reset state. These operations do not require the clock supply of PXCLK.

49.2.3 BG_PERI : Background Plane Setting Free-Running Period Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1004

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	FV[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	1	1	1
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	FH[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	1	1	1

Bit	Symbol	Function	R/W
10:0	FH[10:0]	Background Plane Horizontal Synchronization Signal Period Period based on pixel clocks (PXCLK). The valid range is 0x017 to 0x3FF. 0x017: 24 cycles (pixels) 0x3FF: 1024 cycles (pixels)	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	FV[10:0]	Background Plane Vertical Synchronization Signal Period Period based on lines. The valid range is 0x013 to 0x3FF. 0x013: 20 lines 0x3FF: 1024 lines	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

FH[10:0] bits (Background Plane Horizontal Synchronization Signal Period)

The FH[10:0] bits set the horizontal synchronization signal period of the background plane. This field contains 11 bits and can be set to any number from 0x000 to 0x7FF. However, the valid range is 0x017 to 0x3FF.

FV[10:0] bits (Background Plane Vertical Synchronization Signal Period)

The FV[10:0] bits set the vertical synchronization signal period of the background plane. This field contains 11 bits and can be set to any number from 0x000 to 0x7FF. However, the valid range is 0x013 to 0x3FF.

49.2.4 BG_SYNC : Background Plane Setting Synchronization Position Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1008

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	VP[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	HP[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Function	R/W
3:0	HP[3:0]	Background Plane Horizontal Synchronization Signal Assertion Position Position based on pixel clocks (PXCLK). 0x0: Setting prohibited Others: HP th cycle (pixel)	R/W
15:4	—	These bits are read as 0. The write value should be 0.	R/W
19:16	VP[3:0]	Background Plane Vertical Synchronization Assertion Position Position based on lines. 0x0: Setting prohibited Others: VP th line	R/W
31:20	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

HP[3:0] bits (Background Plane Horizontal Synchronization Signal Assertion Position)

The HP[3:0] bits set the horizontal synchronization signal assertion position of the background plane. The signal is held asserted for a 4-pixel clock width.

VP[3:0] bits (Background Plane Vertical Synchronization Assertion Position)

The VP[3:0] bits set the vertical synchronization signal assertion position of the background plane. The signal is held asserted for a 1H width, and the assertion timing within a single horizontal line is specified in BG_SYNC.HP[3:0].

49.2.5 BG_VSIZE : Background Plane Setting Full Image Vertical Size Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x100C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	VP[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	VW[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
10:0	VW[10:0]	Background Plane Vertical Valid Pixel Width Width based on lines. 0x010: 16 lines ⋮ 0x3FC: 1020 lines Others: Setting prohibited	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	VP[10:0]	Background Plane Vertical Valid Pixel Start Position Position based on of lines. 0x003: 3rd line ⋮ 0x3EF: 1007 lines Others: Setting prohibited	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

VW[10:0] bits (Background Plane Vertical Valid Pixel Width)

The VW[10:0] bits set the vertical valid pixel width of the background plane. This field contains 11 bits and can be set to any number from 0x000 to 0x7FF. However, the valid range is 0x010 to 0x3FC. Operation is not guaranteed if a value outside the valid range is set.

VP[10:0] bits (Background Plane Vertical Valid Pixel Start Position)

The VP[10:0] bits set the vertical valid pixel start position of the background plane. This field contains 11 bits and can be set to any number from 0x000 to 0x7FF. However, the valid range is 0x003 to 0x3EF. Operation is not guaranteed if a value outside the valid range is set.

Specify the vertical valid pixel area between the assertion position of the vertical synchronization signal + 2 and the (background plane end - 1)th line. Operation is not guaranteed if the area is specified outside this range.

49.2.6 BG_HSIZE : Background Plane Setting Full Image Horizontal Size Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1010

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	HP[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	HW[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
10:0	HW[10:0]	Background Plane Horizontal Valid Pixel Width Width based on pixel clocks (PXCLK). 0x010: 16 cycles ⋮ 0x3F8: 1016 cycles Others: Setting prohibited	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	HP[10:0]	Background Plane Horizontal Valid Pixel Start Position Position based on pixel clocks (PXCLK). 0x006: 6th cycle (pixel) ⋮ 0x3EE: 1006 cycles Others: Setting prohibited	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

HW[10:0] bits (Background Plane Horizontal Valid Pixel Width)

The HW[10:0] bits set the horizontal valid pixel width of the background plane. This field contains 11 bits and can be set to any number from 0x000 to 0x7FF. However, the valid range is 0x010 to 0x3F8. Operation is not guaranteed if a value outside the valid range is set. When serial RGB is selected as the output format for the output control block, add two to the horizontal valid pixel width and set the resulting value to these bits.

HP[10:0] bits (Background Plane Horizontal Valid Pixel Start Position)

The HP[10:0] bits set the horizontal valid pixel start position of the background plane. This field contains 11 bits and can be set to any number from 0x000 to 0x7FF. However, the valid range is 0x006 to 0x3EE. Operation is not guaranteed if a value outside the valid range is set.

Specify the horizontal valid pixel area between the assertion position of the horizontal synchronization signal + 5 and pixel number (line end - 2). Operation is not guaranteed if the area is specified outside this range.

The background plane generation module outputs the values that are specified in the Background Color Register (BG_BGC) for the area defined by the Full Image Vertical Size Register (BG_VSIZE) and Full Image Horizontal Size Register (BG_HSIZE), and it outputs 0x00 as the RGB values for the blanking interval area.

49.2.7 BG_BGC : Background Plane Setting Background Color Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1014

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	R[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	G[7:0]								B[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	B[7:0]	Background Plane Valid Pixel Area B Value B value for background plane valid pixel area. Unsigned 8-bit integer.	R/W
15:8	G[7:0]	Background Plane Valid Pixel Area G Value G value for background plane valid pixel area. Unsigned 8-bit integer.	R/W
23:16	R[7:0]	Background Plane Valid Pixel Area R Value R value for background plane valid pixel area. Unsigned 8-bit integer.	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

B[7:0] bits (Background Plane Valid Pixel Area B Value)

The B[7:0] bits set the B value of image data to be output to the valid pixel area of the background plane.

G[7:0] bits (Background Plane Valid Pixel Area G Value)

The G[7:0] bits set the G value of image data to be output to the valid pixel area of the background plane.

R[7:0] bits (Background Plane Valid Pixel Area R Value)

The R[7:0] bits set the R value of image data to be output to the valid pixel area of the background plane.

49.2.8 BG_MON : Background Plane Setting Status Monitor Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1018

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SWRS T
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	VEN	—	—	—	—	—	—	—	EN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	EN	Background Plane Operation Monitor 0: Operation is stopped 1: Operation is in progress	R
7:1	—	These bits are read as 0. The write value should be 0.	R
8	VEN	Entire Module Internal Operation Reflection Control Signal Monitor 0: Signal for controlling reflection of the register values to internal operations on assertion of vertical synchronization signal is negated 1: Signal for controlling reflection of the register values to internal operations on assertion of vertical synchronization signal is asserted	R
15:9	—	These bits are read as 0.	R
16	SWRST	Entire Module SW Reset State Monitor 0: Entire module is in software reset state 1: Entire module is released from software reset state	R
31:17	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

EN bit (Background Plane Operation Monitor)

The EN bit indicates whether the background plane generation module is operating or not. To stop the operation of the background plane generation module by clearing BG_EN.EN to 0, read this bit to confirm that the operation of the background plane is complete. Clearing BG_EN.EN to 0 does not stop the operation until completion of the background plane, unlike when BG_EN.SWRST is cleared to 0.

VEN bit (Entire Module Internal Operation Reflection Control Signal Monitor)

The VEN bit indicates the value of the signal for controlling reflection of the GLCDC internal register values to the internal operations. This signal is asserted at the start of a screen immediately after setting BG_EN.VEN to 1 and negated at the VE negate timing output from the background screen generation block.

SWRST bit (Entire Module SW Reset State Monitor)

The SWRST bit indicates the software reset state of the entire module when PXCLK is supplied. This bit value indicates the result of the peripheral module clock A (PCLKA) resampling the result of the pixel clock (PXCLK) sampling the BG_EN.SWRST bit. Even if PXCLK is not supplied, clearing the BG_EN.SWRST to 0 clears this bit to 0.

49.2.9 GRn_VEN : Graphics n Register Update Control Register (n = 1 to 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1100 + 0x100 × (n-1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PVEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	PVEN	Control of Graphics n Register Value Reflection to Internal Pixel Operations This bit is cleared to 0 by an internal source. 0: Disable reflection of register values to internal operations on assertion of vertical synchronization signal (VS) 1: Enable reflection of register values to internal operations on assertion of the vertical synchronization signal (VS)	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

PVEN bit (Control of Graphics n Register Value Reflection to Internal Pixel Operations)

The PVEN bit enables or disables reflection of the register values to the internal operations of the pixel operation circuit on assertion of the vertical synchronization signal (input). When this bit is set to 1, the register values are immediately reflected to the internal operations on assertion of the vertical synchronization signal (input), and are automatically cleared to 0. Set this bit to 1 only when 0. Operation is not guaranteed if this bit is set to 1 when 1. Also, if the signal output is asserted from the background plane generation module that controls reflection of the register values to the internal operations of all the modules, the register values are always reflected to the internal operations on assertion of the vertical synchronization signal (input), regardless of the value of this bit. While this bit is 1, do not modify any register whose value is reflected to the internal operations on assertion of the vertical synchronization signal (input) in this block. Otherwise, operation is not guaranteed.

This bit must not be 1 at the same time as the BG_EN.VEN bit (control of background plane register value reflection to internal operations) in the Operation Control Register (BG_EN), one of the background plane setting registers. Otherwise, operation is not guaranteed.

49.2.10 GR_n_FLMRD : Graphics n Frame Buffer Read Control Register (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1104 + 0x100 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RENB
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	RENB	Graphics Data Read Enable Graphics data is the frame buffer data. 0: Disable reading 1: Enable reading	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GR_n_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

RENB bit (Graphics Data Read Enable)

The RENB bit enables or disables reading of the graphics data (frame buffer data in memory connected through the GLCDC0 and GLCDC1 bus). If the current graphics data is required, data read must be enabled (GR_n_FLMRD.RENB = 1) before the background panel operation is enabled, register value internal operation reflection control is enabled, or the register value internal operation reflection control of graphics 1 and 2 is enabled.

If the current graphics data is not required, data read must be disabled (GR_n_FLMRD.RENB = 0) before the background panel operation is enabled, register value internal operation reflection control is enabled, or the register value internal operation reflection control of graphics 1 and 2 is enabled.

49.2.11 GR_n_FLM1 : Graphics n Frame Buffer Control Register 1 (n = 1 to 2)

Base address: GLCDC = 0x4034_2000
 GLCDC_NS = 0x5034_2000

Offset address: 0x1108 + 0x100 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	BSTMD[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Function	R/W
1:0	BSTMD[1:0]	Burst Transfer Control for Graphics Data Access Graphics data is the frame buffer data. 1 1: 16-beat increment burst transfer (64-byte boundary) Others: Setting prohibited	R/W
31:2	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GR_n_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

BSTMD[1:0] bits (Burst Transfer Control for Graphics Data Access)

The BSTMD[1:0] bits control burst transfers for accessing the graphics data (frame buffer data in memory connected to memory through the GLCDC0 and GLCDC1 bus). In this GLCDC, these bits are fixed to 11b. Operation is not guaranteed if these bits are set to any other value.

49.2.12 GR_n_FLM2 : Graphics n Frame Buffer Control Register 2 (n = 1 to 2)

Base address: GLCDC = 0x4034_2000
 GLCDC_NS = 0x5034_2000

Offset address: 0x110C + 0x100 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	BASE[31:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	BASE[31:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
31:0	BASE[31:0]	Base Address for Accessing Graphics Data Start address in the frame buffer where graphics data is to be stored. Fix GR _n _FLM2.BASE[5:0] to 0 during 64-byte burst transfer.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GR_n_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

BASE[31:0] bits (Base Address for Accessing Graphics Data)

The BASE[31:0] bits specify the base address (start address in the first frame buffer) for graphics data access. Because the GLCDC only supports the 16-beat increment burst transfer mode, in which data is aligned with a 64-byte boundary, the lower 6 bits (GRn_FLM2.BASE[5:0]) must be fixed to 0.

49.2.13 GRn_FLM3 : Graphics n Frame Buffer Control Register 3 (n = 1 to 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1110 + 0x100 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	LNOFF[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	—	These bits are read as 0. The write value should be 0.	R/W
31:16	LNOFF[15:0]	Macro Line Offset Address for Accessing Graphics Data Macro line offset address for accessing graphics data (frame buffer data). Signed, 16-bit integer.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

LNOFF[15:0] bits (Macro Line Offset Address for Accessing Graphics Data)

The LNOFF[15:0] bits specify the macro line offset address for accessing graphics data (offset to be added to the current address at the macro line end for calculating the start address of the next macro line). Because the GLCDC only supports the 16-beat increment burst transfer mode, in which data is aligned with a 64-byte boundary, the lower 6 bits (GRn_FLM3.LNOFF[5:0]) must be fixed to 0.

49.2.14 GRn_FLM5 : Graphics n Frame Buffer Control Register 5 (n = 1 to 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1118 + 0x100 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	LNNUM[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	DATANUM[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
15:0	DATANUM[15:0]	Number of Data Transfer Times Per Line for Accessing Graphics Data Number of data transfers per macro line for accessing graphics data (frame buffer data), where one transfer is defined as 16-beat burst access (64-byte boundary). 0x0000 Once ⋮ 0xFFFF 65536 times ⋮	R/W
26:16	LNNUM[10:0]	Number of Lines Per Frame for Accessing Graphics Data Number of macro lines per frame for accessing graphics data (frame buffer data). 0x000: 1 macro line ⋮ 0x3FB: 1020 macro lines Others: Setting prohibited	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

DATANUM[15:0] bits (Number of Data Transfer Times Per Line for Accessing Graphics Data)

The DATANUM[15:0] bits specify the number of data transfers per macro line for accessing graphics data, where one transfer is defined as a 16-beat burst access through the GLCDC0 and GLCDC1 bus. For all the data transfers, at least 2 bytes of valid pixel data are required (16 pixels in LUT1 format and 16 pixels or more in the other formats). If the number of bytes per macro line cannot be divided by 64 (4 bytes × 16-beat), DATANUM is obtained by rounding up to the whole number.

LNNUM[10:0] bits (Number of Lines Per Frame for Accessing Graphics Data)

The LNNUM[10:0] bits specify the number of lines per frame for accessing graphics data. When graphics data for the number of lines set to these bits is read, it signals the end of the frame and the base address is loaded.

The following are two use cases for macro lines. In these use cases, the frame size is 480 pixels × 272 lines and the pixel format is RGB565 (16 bpp).

Case 1) One macro line is configured to be equivalent to the frame raster width. The number of macro lines is equivalent to the number of vertical lines.

DATANUM: 0x000E (15 times = $16 \times 480 / 512$)

LNNUM: 0x10F (272 macro lines = $272 / 1$)

Case 2) One macro line is configured to be repeated during the display frame. The number of macro lines is not equivalent to the number of vertical lines. In the example, one macro line has 16 times the raster width.

DATANUM: 0x00EF (240 times = $16 \times 480 / 512 \times 16$)

LNNUM: 0x010 (17 macro lines = $272 / 16$)

49.2.15 GRn_FLM6 : Graphics n Frame Buffer Control Register 6 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x111C + 0x100 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	FORMAT[2:0]			—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
27:0	—	These bits are read as 0. The write value should be 0.	R/W
30:28	FORMAT[2:0]	Data Format for Accessing Graphics Data Data format for accessing graphics data (frame buffer data). 0 0 0: RGB565 (16 bits/pixel) 0 0 1: RGB888 (32 bits/pixel, 8 bits on the MSB side are invalid) 0 1 0: ARGB1555 (16 bits/pixel, 1 bit of A is LUT data) 0 1 1: ARGB4444 (16 bits/pixel) 1 0 0: ARGB8888 (32 bits/pixel) 1 0 1: CLUT8 (8 bits/pixel) 1 1 0: CLUT4 (4 bits/pixel) 1 1 1: CLUT1 (1 bit/pixel)	R/W
31	—	This bit is read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

FORMAT[2:0] bits (Data Format for Accessing Graphics Data)

The FORMAT[2:0] bits specify the data format for accessing graphics data. CLUT1, CLUT4, CLUT8 contain the addresses 0x01 or 0x00, 0x0F to 0x00, and 0xFF to 0x00, respectively, for accessing the color palette. ARGB1555 contains the address for accessing the color palette (0x80 or 0x00) in the MSB and RGB data in the other bits. ARGB8888 and ARGB4444 contain the upper 8-bit or 4-bit alpha blending values and RGB data. RGB888 and RGB565 contain RGB data only.

49.2.16 GRn_AB1 : Graphics n Alpha Blending Control Register 1 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1120 + 0x100 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	ARCON	—	—	—	ARCDISPON	—	—	—	GRCDISPON	—	—	DISPSEL[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
1:0	DISPSEL[1:0]	Graphics Display Plane Control 0 0: Background color display (value set in the GRn_BASE register) 0 1: Lower-layer graphics display 1 0: Current graphics display 1 1: Blended display of lower-layer graphics (input image from the previous stage) and current graphics (data read from the GLCDC0 and GLCDC1 bus)	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	GRCDISPON	Graphics Image Area Border Display Control 0: Turn display off 1: Turn display on	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	ARCDISPON	Image Area Border Display Control for Rectangular Area Alpha Blending 0: Turn display off 1: Turn display on	R/W
11:9	—	These bits are read as 0. The write value should be 0.	R/W

Bit	Symbol	Function	R/W
12	ARCON	Rectangular Area Alpha Blending Control 0: Turn blending off 1: Turn blending on	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

DISPSEL[1:0] bits (Graphics Display Plane Control)

The DISPSEL[1:0] bits control the graphics display plane. When the plane is selected as the lower-layer graphics, the image input from the previous stage is displayed (the background plane for GR1, and output from GR1 for GR2); as the background color, the background color specified in the GLCDC registers is displayed; and as the current graphics, the ARGB8888 data obtained by expanding the graphics data read by the GLCDC from the GLCDC0 and GLCDC1 bus is displayed. When the current graphics display is selected (these bits are set to 10b), RGB888 data is displayed, regardless of the alpha blending value in the pixel. Table 49.8 and Figure 49.10 show the relationship between the register setting and display area.

GRCDISPON bit (Graphics Image Area Border Display Control)

The GRCDISPON bit turns on or off the border display for the graphics image area. When the display is turned on (this bit is set to 1), the graphics image area is bordered with the preset color. The border is 1 pixel wide on the outermost periphery of the area with the display data set as 0xFF for each RGB color.

ARCDISPON bit (Image Area Border Display Control for Rectangular Area Alpha Blending)

The ARCDISPON bit turns on or off the border display for the image area where rectangular area alpha blending is performed. When the display is turned on (this bit is set to 1), the image area for the rectangular alpha blending is bordered with the preset color. The border is 1 pixel wide on the outermost periphery of the area and the display data set as 0xFF for each RGB color.

ARCON bit (Rectangular Area Alpha Blending Control)

The ARCON bit turns on or off alpha blending in a rectangular area. When alpha blending is turned on (this bit is set to 1), pixels are processed in accordance with the alpha blending control specified in the relevant registers for the specified rectangular area, not in accordance with the alpha value input from the graphics data interface for each pixel. In the areas outside the rectangular area in the graphics area, pixels are processed in accordance with the alpha value input from the graphics data interface for each pixel.

Table 49.8 Display selections

GRn_AB1. DISPSEL[1:0] (display plane)	GRn_AB1. ARCON (rectangular)	GRn_AB7. CKON (chroma key)	Within rectangular alpha blending area	Outside rectangular alpha blending area within graphics area	Outside graphics area within display area	Outside display area
00b	0	0	—	Background color	Background color	Lower layer R = G = B = 0x00
01b	0	0	—	Lower layer	Lower layer	Lower layer R = G = B = 0x00
10b	0	0	—	Current	Background color	Lower layer R = G = B = 0x00
11b	0	0	—	Current + alpha blending in pixel units	Lower layer	Lower layer R = G = B = 0x00
11b	0	1	—	Current + RGB-index chroma key + alpha blending in pixel units	Lower layer	Lower layer R = G = B = 0x00
11b	1	0	Current + rectangular alpha blending	Current + alpha blending in pixel units	Lower layer	Lower layer R = G = B = 0x00
11b	1	1	Current + rectangular alpha blending	Current + RGB-index chroma key + alpha blending in pixel units	Lower layer	Lower layer R = G = B = 0x00

Note: Operation is not guaranteed when any other value is set.

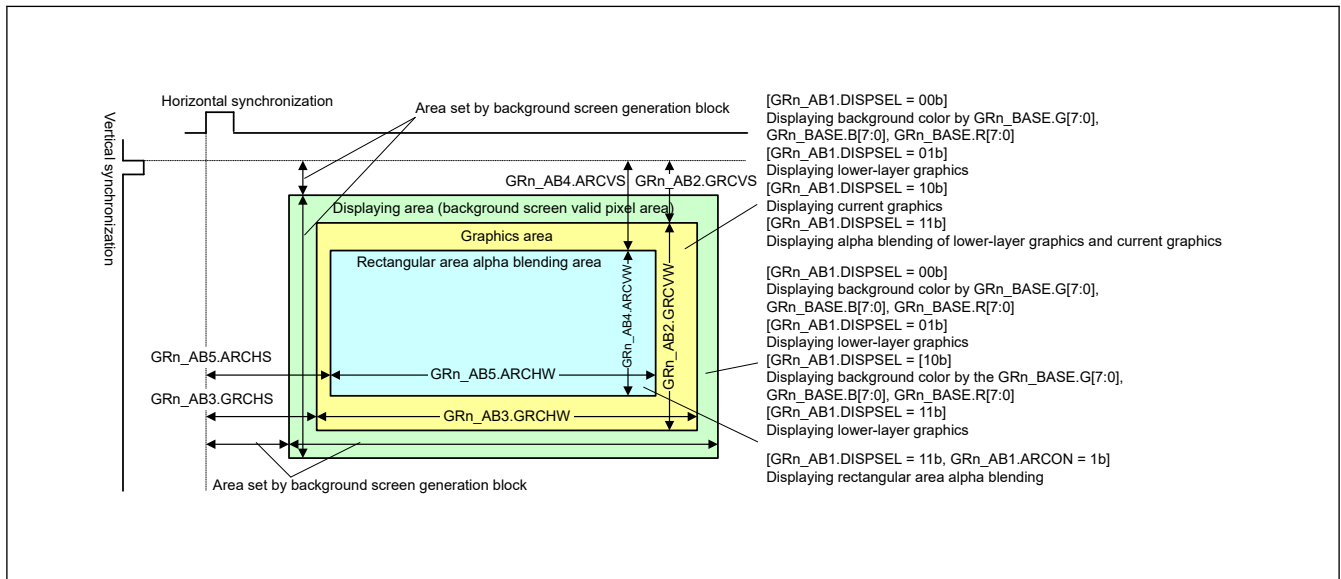

Figure 49.10 Selection of graphics display plane

49.2.17 GRn_AB2 : Graphics n Alpha Blending Control Register 2 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
 GLCDC_NS = 0x5034_2000

Offset address: 0x1124 + 0x100 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	GRCVS[10:0]

15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	GRCVS[10:0]	Vertical Start Position of Graphics Image Area Position in lines. 0x002: 2nd line ⋮ 0x3EE: 1006th line Others: Setting prohibited	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GRCVW[10:0] bits (Vertical Width of Graphics Image Area)

The GRCVW[10:0] bits specify the vertical width of the graphics image area.

GRCVS[10:0] bits (Vertical Start Position of Graphics Image Area)

The GRCVS[10:0] bits specify the vertical start position of the graphics image area, in reference to assertion of the vertical synchronization signal (VS). For the relationship with the graphics display plane, see [Figure 49.10](#).

49.2.18 GR_n_AB3 : Graphics n Alpha Blending Control Register 3 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1128 + 0x100 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	GRCHS[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	GRCHW[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
10:0	GRCHW[10:0]	Horizontal Width of Graphics Image Area Width in pixels. 0x010: 16 pixels ⋮ 0x3F8: 1016 pixels Others: Setting prohibited	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/(W)
26:16	GRCHS[10:0]	Horizontal Start Position of Graphics Image Area Position in pixels. 0x005: 5th pixel ⋮ 0x3ED: 1005th pixel Others: Setting prohibited	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GR_n_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GRCHW[10:0] bits (Horizontal Width of Graphics Image Area)

The GRCHW[10:0] bits specify the horizontal width of the graphics image area.

GRCHS[10:0] bits (Horizontal Start Position of Graphics Image Area)

The GRCHS[10:0] bits specify the horizontal start position of the graphics image area, in reference to assertion of the horizontal synchronization signal (VS). For the relationship with the graphics display plane, see [Figure 49.10](#).

49.2.19 GR_n_AB4 : Graphics n Alpha Blending Control Register 4 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
 GLCDC_NS = 0x5034_2000

Offset address: 0x112C + 0x100 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
Bit field:	—					ARCVS[10:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Bit field:	—					ARCVW[10:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
10:0	ARCVW[10:0]	Vertical Width of Rectangular Area Alpha Blending Image Area Width in lines. 0x001: 1 line ⋮ 0x3FC: 1020 lines Others: Setting prohibited	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	ARCVS[10:0]	Vertical Start Position of Rectangular Area Alpha Blending Image Area Position in lines. 0x002: 2nd line ⋮ 0x3EE: 1006th line Others: Setting prohibited	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GR_n_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

ARCVW[10:0] bits (Vertical Width of Rectangular Area Alpha Blending Image Area)

The ARCVW[10:0] bits specify the vertical width of the rectangular area alpha blending image area.

ARCVS[10:0] bits (Vertical Start Position of Rectangular Area Alpha Blending Image Area)

The ARCVS[10:0] bits specify the vertical start position of the rectangular area alpha blending image area, in reference to assertion of the vertical synchronization signal (VS). For the relationship with the graphics display plane, see [Figure 49.10](#).

49.2.20 GR_n_AB5 : Graphics n Alpha Blending Control Register 5 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
 GLCDC_NS = 0x5034_2000

Offset address: 0x1130 + 0x100 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	
Bit field:	—					ARCHS[10:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
Bit field:	—					ARCHW[10:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Function	R/W
10:0	ARCHW[10:0]	Horizontal Width of Rectangular Area Alpha Blending Image Area Width in pixels. 0x001: 1 pixel ⋮ 0x3F8: 1016 pixels Others: Setting prohibited	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	ARCHS[10:0]	Horizontal Start Position of Rectangular Area Alpha Blending Image Area Position in pixels. 0x005: 5th pixel ⋮ 0x3ED: 1005th pixel Others: Setting prohibited	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

ARCHW[10:0] bits (Horizontal Width of Rectangular Area Alpha Blending Image Area)

The ARCHW[10:0] bits specify the horizontal width of the rectangular area alpha blending image area.

ARCHS[10:0] bits (Horizontal Start Position of Rectangular Area Alpha Blending Image Area)

The ARCHS[10:0] bits specify the horizontal start position of the rectangular area alpha blending image area, in reference to assertion of the horizontal synchronization signal (HS). For the relationship with the graphics display plane, see [Figure 49.10](#).

49.2.21 GRn_AB6 : Graphics n Alpha Blending Control Register 6 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1134 + 0x100 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	ARCCOEF[8:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	ARCRATE[7:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	ARCRATE[7:0]	Frame Rate for Alpha Blending in Rectangular Area 0x00: 1 frame ⋮ 0xFF: 256 frames	R/W
15:8	—	These bits are read as 0. The write value should be 0.	R/W
24:16	ARCCOEF[8:0]	Alpha Coefficient for Alpha Blending in Rectangular Area Valid settings: -255 to 255. Bit [8]: Sign 0: Add 1: Subtract Bits [7:0]: Variation, as an absolute value	R/W
31:25	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

ARCRATE[7:0] bits (Frame Rate for Alpha Blending in Rectangular Area)

The ARCRATE[7:0] bits specify the frame rate for alpha blending in a rectangular area.

ARCCOEF[8:0] bits (Alpha Coefficient for Alpha Blending in Rectangular Area)

The ARCCOEF[8:0] bits specify the alpha coefficient for alpha blending in a rectangular area.

In alpha blending in a rectangular area, current graphics are faded in or out with the GRn_AB7.ARCDEF[7:0], GRn_AB6.ARCCOEF[8:0], and GRn_AB6.ARCRATE[7:0] settings. If the alpha value is set in the GR_ARC_DEF[7:0] bits, the GR_ARC_DEF[7:0] bits and the alpha blending in a rectangular area are turned on. Each time the vertical synchronization signal (VS) rises the number of times set in the GR_ARC_RATE[7:0] bits, the value in GR_ARC_COEF[8:0] is added to or subtracted from the alpha value. Figure 49.11 shows change in the alpha value.

Figure 49.11 Changes in alpha value

49.2.22 GRn_AB7 : Graphics n Alpha Blending Control Register 7 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1138 + 0x100 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	ARCDEF[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CKON
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	CKON	RGB-Index Chroma-Key Processing Control 0: Disable chroma-key processing 1: Enable chroma-key processing	R/W
15:1	—	These bits are read as 0. The write value should be 0.	R/W
23:16	ARCDEF[7:0]	Initial Alpha Value for Alpha Blending in Rectangular Area	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

CKON bit (RGB-Index Chroma-Key Processing Control)

The CKON bit turns RGB-index chroma-key processing on or off. This function is enabled only if this bit is 1 when the graphics display plane is the blended display (GRn_AB1.DISPSEL[1:0] = 11b). And it is reflected to the graphics area except alpha blending in a rectangular area. For details, see [Table 49.8](#).

ARCDEF[7:0] bits (Initial Alpha Value for Alpha Blending in Rectangular Area)

The ARCDEF[7:0] bits specify the initial alpha value for alpha blending in a rectangular area. For changes in the alpha value during fade-in or fade-out of the current graphics using this bit, see [Figure 49.11](#).

49.2.23 GRn_AB8 : Graphics n Alpha Blending Control Register 8 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x113C + 0x100 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	CKKG[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CKKB[7:0]							CKKR[7:0]								
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CKKR[7:0]	R Signal for RGB-Index Chroma-Key Processing R signal for RGB-index chroma-key processing. Unsigned 8-bit value.	R/W
15:8	CKKB[7:0]	B Signal for RGB-Index Chroma-Key Processing B signal for RGB-index chroma-key processing. Unsigned 8-bit value.	R/W
23:16	CKKG[7:0]	G Signal for RGB-Index Chroma-Key Processing G signal for RGB-index chroma-key processing. Unsigned 8-bit value.	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

If RGB-index chroma-key processing is enabled when the RGB values of the current bit graphics agree with the values of the associated chroma-key bits, the image data of the current graphics (ARGB8888, including the alpha blending values) is replaced by the values in the GRn_AB9 register. In alpha blending in pixel units at later stages, the latest alpha values are used.

CKKR[7:0] bits (R Signal for RGB-Index Chroma-Key Processing)

The CKKR[7:0] bits specify the value to be compared with the R value of the current graphics in the RGB-index chromakey processing.

CKKB[7:0] bits (B Signal for RGB-Index Chroma-Key Processing)

The CKKB[7:0] bits specify the value to be compared with the B value of the current graphics in the RGB-index chromakey processing.

CKKG[7:0] bits (G Signal for RGB-Index Chroma-Key Processing)

The CKKG[7:0] bits specify the value to be compared with the G value of the current graphics in the RGB-index chroma-key processing.

49.2.24 GRn_AB9 : Graphics n Alpha Blending Control Register 9 (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: $0x1140 + 0x100 \times (n - 1)$

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	CKA[7:0]								CKG[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	CKB[7:0]								CKR[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	CKR[7:0]	R Value after RGB-Index Chroma-Key Processing Replacement R value after RGB-index chroma-key processing replacement. Unsigned 8-bit value.	R/W
15:8	CKB[7:0]	B Value after RGB-Index Chroma-Key Processing Replacement B value after RGB-index chroma-key processing replacement. Unsigned 8-bit value.	R/W
23:16	CKG[7:0]	G Value after RGB-Index Chroma-Key Processing Replacement G value after RGB-index chroma-key processing replacement. Unsigned 8-bit value.	R/W
31:24	CKA[7:0]	A Value after RGB-Index Chroma-Key Processing Replacement A value after RGB-index chroma-key processing replacement.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GRn_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

If the RGB-index chroma-key processing is enabled and the pixel data is to be replaced (the RGB values of the current graphics agree with the GRn_AB8 values), alpha blending in pixel units is performed in later stages in accordance with this image data.

CKR[7:0] bits (R Value after RGB-Index Chroma-Key Processing Replacement)

The CKR[7:0] bits specify the R value after RGB-index chroma-key processing replacement.

CKB[7:0] bits (B Value after RGB-Index Chroma-Key Processing Replacement)

The CKB[7:0] bits specify the B value after RGB-index chroma-key processing replacement.

CKG[7:0] bits (G Value after RGB-Index Chroma-Key Processing Replacement)

The CKG[7:0] bits specify the G value after RGB-index chroma-key processing replacement.

CKA[7:0] bits (A Value after RGB-Index Chroma-Key Processing Replacement)

The CKA[7:0] bits specify the A value after RGB-index chroma-key processing replacement.

49.2.25 GR_n_BASE : Graphics n Background Color Control Register (n = 1, 2)

Base address: GLCDC = 0x4034_2000
 GLCDC_NS = 0x5034_2000

Offset address: 0x114C + 0x100 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—								G[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	B[7:0]								R[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
7:0	R[7:0]	Background Color R Value Background color R value. Unsigned 8-bit value.	R/W
15:8	B[7:0]	Background Color B Value Background color B value. Unsigned 8-bit value.	R/W
23:16	G[7:0]	Background Color G Value Background color G value. Unsigned 8-bit value.	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GR_n_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

When the background color is selected in the display selection (GR_n_AB1.DISPSEL[1:0] = 00b), this RGB data is output to the entire display image area. When the current graphics setting is selected (GR_n_AB1.DISPSEL[1:0] = 10b), the RGB data is output to the outside of the graphics image area within the display image area.

R[7:0] bits (Background Color R Value)

The R[7:0] bits specify the background color R value.

B[7:0] bits (Background Color B Value)

The B[7:0] bits specify the background color B value.

G[7:0] bits (Background Color G Value)

The G[7:0] bits specify the background color G value.

49.2.26 GR_n_CLUTINT : Graphics n CLUT Table Interrupt Control Register (n = 1, 2)

Base address: GLCDC = 0x4034_2000
 GLCDC_NS = 0x5034_2000

Offset address: 0x1150 + 0x100 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—															SEL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—					LINE[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	LINE[10:0]	Number of Detection Lines 0x000: 1 line ⋮ 0x3FF: 1024 lines	R/W
15:11	—	These bits are read as 0. The write value should be 0./	R/W
16	SEL	CLUT Table Control 0: Select CLUT table 0 1: Select CLUT table 1	R/W
31:17	—	These bits are read as 0. The write value should be 0./	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GR_n_VEN.PVEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

LINE[10:0] bits (Number of Detection Lines)

The LINE[10:0] bits specify the number of lines to be detected. When the number of lines specified in this bit are detected, the event is recognized outside the module on the HS assertion. To retain the status of the recognized event and assert the GLCDC interrupt request signal, set the prescribed value to the State Detection Control Register (SYSCNT_DTCTEN) and Interrupt Request Enable Control Register (SYSCNT_INTEN), which are system control registers. Although this function is provided to both graphics 1 and 2, it is only enabled in graphics 2 in this GLCDC.

SEL bit (CLUT Table Control)

The SEL bit controls the CLUT plane to be used for internal operations. Access to the color palette (CLUT) through the register access bus is always valid for both planes 0 and 1, regardless of the setting in this bit, and the written value is immediately reflected to the internal operations (not in synchronization with the vertical synchronization signal).

To keep reflection of the CLUT memory contents to the internal operations in synchronization with the vertical synchronization signal, first write data through the register access bus to the plane that is not being used for the internal operations, and then modify the bits intended for controlling the plane that is to be used for the internal operations.

49.2.27 GR_n_MON : Graphics n Status Monitor Register (n = 1, 2)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1154 + 0x100 × (n - 1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	UNDFLST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ARCS T
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	ARCST	Status Monitor for Alpha Blending in Rectangular Area 0: Fade-in/fade-out not in progress 1: Fade-in/fade-out in progress	R
15:1	—	These bits are read as 0.	R
16	UNDFLST	Underflow Status Monitor 0: No underflow occurred in internal operations 1: Underflow occurred in internal operations	R
31:17	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

ARCST bit (Status Monitor for Alpha Blending in Rectangular Area)

The ARCST bit indicates whether or not alpha blending (fade-in/fade-out) in a rectangular area is in progress. When alpha blending in a rectangular area is turned on (GRn_AB1.ARCON is set to 1) and the register value is to be reflected to the internal operations on assertion of the vertical synchronization signal (VS), this bit sets to 1 immediately on assertion of the vertical synchronization signal. When alpha blending in a rectangular area is turned off (GRn_AB1.ARCON cleared to 0) or when the alpha blending (fade-in/fade-out) in a rectangular area is complete (alpha blended value reaches the minimum or maximum value), this bit clears to 0. If the alpha coefficient for the alpha blending in a rectangular area (GRn_AB6.ARCCOEF[8:0]) is set to 0x000 and the initial alpha value for alpha blending in a rectangular area (GRn_AB7.ARCDEF[7:0]) is set to any value other than 0xFF or 0x00, the alpha blending value does not reach the minimum or maximum value, and this bit remains 1 (no timeout processing is performed).

UNDFLST bit (Underflow Status Monitor)

The UNDFLST bit indicates whether or not an underflow has occurred in the internal operations. The underflow interrupt request flag sets when an underflow occurs, and retains its value until it is cleared by software. However, this bit monitors the internal status, and so the flag automatically clears to 0 when the graphics data bus interface initializes on assertion of the vertical synchronization signal. Even when the current graphics data is not required (GRn_AB1.DISPSEL[1:0] = 0xb), this bit sets to 1 during the period from the graphics image valid area start to the next frame vertical synchronization signal (VS) assertion timing set in the registers.

49.2.28 GAMn_LATCH : Gamma n Register Update Control Register (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1300 (GAMG_LATCH)
0x1340 (GAMB_LATCH)
0x1380 (GAMR_LATCH)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	VEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	VEN	Control of Gamma Correction × Module Register Value Reflection to Internal Operations 0: Disable reflection of register values to internal operations on assertion of vertical synchronization signal (VS) 1: Enable reflection of register values to internal operations on assertion of the vertical synchronization signal (VS)	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

VEN bit (Control of Gamma Correction × Module Register Value Reflection to Internal Operations)

The VEN bit enables or disables reflection of the register values to the internal operations in the gamma correction circuit on assertion of the vertical synchronization signal (input). When this bit is set to 1, the register values are immediately reflected to the internal operations on assertion of the vertical synchronization signal (input), and then this bit automatically clears to 0. Also, if the signal is asserted that controls reflection of the register values to the internal operations of all the modules output from the background plane generation module, the register values are reflected to the internal operations on assertion of the vertical synchronization signal (input), regardless of the value of this bit. While this bit is 1, do not modify any register whose value is reflected to the internal operations on assertion of the vertical synchronization signal (input) in the GLCDC. Otherwise, operation is not guaranteed.

This bit must not be 1 at the same time as the BG_EN.VEN bit (control of background plane register value reflection to internal operations) in the Operation Control Register (BG_EN), one of the background plane setting registers. Otherwise, operation is not guaranteed.

Although there are three VEN bits, one for each G, R, and B color, only the GAMG_LATCH.VEN bit controls the gamma correction with the reflection of the GAM_SW.GAMON bit. To enable gamma correction, set the GAMG_LATCH.VEN bit once after setting the GAM_SW.GAMON bit.

The VEN bit is set to 1 by writing 1, and automatically clears to 0 immediately on assertion of the vertical synchronization signal.

49.2.29 GAM_SW : Gamma Correction Block Function Switch Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1304

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	GAMON
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	GAMON	Gamma Correction On/Off Control 0: Turn off gamma correction 1: Turn on gamma correction	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMG_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GAMON bit (Gamma Correction On/Off Control)

The GAMON bit turns on or off gamma correction.

49.2.30 GAMn_LUT1 : Gamma n Correction Block Table Setting Register 1 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1308 (GAMG_LUT1)
0x1348 (GAMB_LUT1)
0x1388 (GAMR_LUT1)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	GAIN00[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	GAIN01[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	GAIN01[10:0]	Gain Value of Area 1 Unsigned 11-bit fixed point value. 0x000: 0.000 (0/1024) ⋮ 0x400: 1.000 (1024/1024) ⋮ 0x7FF: 1.999 (2047/1024)	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	GAIN00[10:0]	Gain Value of Area 0 0x000: 0.000 (0/1024) ⋮ 0x400: 1.000 (1024/1024) ⋮ 0x7FF: 1.999 (2047/1024)	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

Gamma correction for each color is carried out as follows:

- Din (input signal): 10 bits. To correct the output of graphics 2, 00b is appended as the lower 2 bits for extension
- Dout (output signal): 10 bits
- TH (threshold): 10 bits (register setting); up to 15 can be set
- GAIN (gain): 0/1024 to 2047/1024 for each area (register setting), can be set for up to 16 areas
- OFFSET (offset value): 21 bits (result of internal calculation; calculation of up to 15 points)

The following is automatically calculated from the assertion of the vertical synchronization signal (VS) to the start of valid pixel data internally:

- $D_{out} = ((D_{in} - TH(n)) \times GAIN(n) + OFFSET(n))$
- $OFFSET(n) = OFFSET(n - 1) + (TH(n) - TH(n - 1)) \times GAIN(n - 1)$, where $OFFSET(n) = 0$

Note: Because the gain is a positive number (≥ 0), the correction line shows a monotonic increase.

Figure 49.12 Calculation of gamma correction value

GAIN01[10:0] bits (Gain Value of Area 1)

The GAIN01[10:0] bits specify the gain value of area 1 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

GAIN00[10:0] bits (Gain Value of Area 0)

The GAIN00[10:0] bits specify the gain value of area 0 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

49.2.31 GAMn_LUT2 : Gamma n Correction Block Table Setting Register 2 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
 GLCDC_NS = 0x5034_2000

Offset address: 0x130C (GAMG_LUT2)
 0x134C (GAMB_LUT2)
 0x138C (GAMR_LUT2)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Symbol	Function	R/W
10:0	GAIN03[10:0]	Gain Value of Area 3 Unsigned 11-bit fixed point value. 0x000: 0.000 (0/1024) ⋮ 0x400: 1.000 (1024/1024) ⋮ 0x7FF: 1.999 (2047/1024)	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	GAIN02[10:0]	Gain Value of Area 2 Unsigned 11-bit fixed point value. 0x000: 0.000 (0/1024) ⋮ 0x400: 1.000 (1024/1024) ⋮ 0x7FF: 1.999 (2047/1024)	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GAIN03[10:0] bits (Gain Value of Area 3)

The GAIN03[10:0] bits specify the gain value of area 3 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

GAIN02[10:0] bits (Gain Value of Area 2)

The GAIN02[10:0] bits specify the gain value of area 2 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

49.2.32 GAMn_LUT3 : Gamma n Correction Block Table Setting Register 3 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1310 (GAMG_LUT3)
0x1350 (GAMB_LUT3)
0x1390 (GAMR_LUT3)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GAIN05[10:0] bits (Gain Value of Area 5)

The GAIN05[10:0] bits specify the gain value of area 5 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

GAIN04[10:0] bits (Gain Value of Area 4)

The GAIN04[10:0] bits specify the gain value of area 4 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

49.2.33 GAMn_LUT4 : Gamma n Correction Block Table Setting Register 4 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1314 (GAMG_LUT4)
0x1354 (GAMB_LUT4)
0x1394 (GAMR_LUT4)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	GAIN06[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	GAIN07[10:0]

Bit	Symbol	Function	R/W
10:0	GAIN07[10:0]	Gain Value of Area 7 Unsigned 11-bit fixed point value. 0x000: 0.000 (0/1024) ⋮ 0x400: 1.000 (1024/1024) ⋮ 0x7FF: 1.999 (2047/1024)	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	GAIN06[10:0]	Gain Value of Area 6 Unsigned 11-bit fixed point value. 0x000: 0.000 (0/1024) ⋮ 0x400: 1.000 (1024/1024) ⋮ 0x7FF: 1.999 (2047/1024)	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GAIN07[10:0] bits (Gain Value of Area 7)

The GAIN07[10:0] bits specify the gain value of area 7 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

GAIN06[10:0] bits (Gain Value of Area 6)

The GAIN06[10:0] bits specify the gain value of area 6 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

49.2.34 GAMn_LUT5 : Gamma n Correction Block Table Setting Register 5 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1318 (GAMG_LUT5)
0x1358 (GAMB_LUT5)
0x1398 (GAMR_LUT5)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

26:16	GAIN08[10:0]	Gain Value of Area 8 Unsigned 11-bit fixed point value. 0x000: 0.000 (0/1024) ⋮ 0x400: 1.000 (1024/1024) ⋮ 0x7FF: 1.999 (2047/1024)	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GAIN09[10:0] bits (Gain Value of Area 9)

The GAIN09[10:0] bits specify the gain value of area 9 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

GAIN08[10:0] bits (Gain Value of Area 8)

The GAIN08[10:0] bits specify the gain value of area 8 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

49.2.35 GAMn_LUT6 : Gamma n Correction Block Table Setting Register 6 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x131C (GAMG_LUT6)
0x135C (GAMB_LUT6)
0x139C (GAMR_LUT6)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	GAIN10[10:0]

15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	GAIN10[10:0]	Gain Value of Area 10 Unsigned 11-bit fixed point value. 0x000: 0.000 (0/1024) ⋮ 0x400: 1.000 (1024/1024) ⋮ 0x7FF: 1.999 (2047/1024)	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GAIN11[10:0] bits (Gain Value of Area 11)

The GAIN11[10:0] bits specify the gain value of area 11 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

GAIN10[10:0] bits (Gain Value of Area 10)

The GAIN10[10:0] bits specify the gain value of area 10 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

49.2.36 GAMn_LUT7 : Gamma n Correction Block Table Setting Register 7 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
 GLCDC_NS = 0x5034_2000

Offset address: 0x1320 (GAMG_LUT7)
 0x1360 (GAMB_LUT7)
 0x13A0 (GAMR_LUT7)

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

26:16	GAIN12[10:0]	Gain Value of Area 12 Unsigned 11-bit fixed point value. 0x000: 0.000 (0/1024) ⋮ 0x400: 1.000 (1024/1024) ⋮ 0x7FF: 1.999 (2047/1024)	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GAIN13[10:0] bits (Gain Value of Area 13)

The GAIN13[10:0] bits specify the gain value of area 13 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

GAIN12[10:0] bits (Gain Value of Area 12)

The GAIN12[10:0] bits specify the gain value of area 12 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

49.2.37 GAMn_LUT8 : Gamma n Correction Block Table Setting Register 8 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
 GLCDC_NS = 0x5034_2000

Offset address: 0x1324 (GAMG_LUT8)
 0x1364 (GAMB_LUT8)
 0x13A4 (GAMR_LUT8)

Bit	Symbol	Function	R/W
10:0	GAIN15[10:0]	Gain Value of Area 15 Unsigned 11-bit fixed point value. 0x000: 0.000 (0/1024) ⋮ 0x400: 1.000 (1024/1024) ⋮ 0x7FF: 1.999 (2047/1024)	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	GAIN14[10:0]	Gain Value of Area 14 Unsigned 11-bit fixed point value. 0x000: 0.000 (0/1024) ⋮ 0x400: 1.000 (1024/1024) ⋮ 0x7FF: 1.999 (2047/1024)	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

GAIN15[10:0] bits (Gain Value of Area 15)

The GAIN15[10:0] bits specify the gain value of area 15 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

GAIN14[10:0] bits (Gain Value of Area 14)

The GAIN14[10:0] bits specify the gain value of area 14 to be used for gamma correction in terms of an unsigned 11-bit fixed point (0/1024 to 2047/1024). The location of the decimal point is between bits [10] and [11].

49.2.38 GAMn_AREA1 : Gamma n Correction Block Area Setting Register 1 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
 GLCDC_NS = 0x5034_2000

Offset address: 0x1328 (GAMG_AREA1)
 0x1368 (GAMB_AREA1)
 0x13A8 (GAMR_AREA1)

Bit	Symbol	Function	R/W
9:0	TH03[9:0]	Start Threshold of Area 3 Unsigned 10-bit integer.	R/W
19:10	TH02[9:0]	Start Threshold of Area 2 Unsigned 10-bit integer.	R/W
29:20	TH01[9:0]	Start Threshold of Area 1 Unsigned 10-bit integer.	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

Set the start threshold TH (n) of area n (n = 0 to 15) to satisfy the following conditions. Otherwise, operation is not guaranteed.

$$TH(n) < TH(n + 1)$$

$$n = 0 \text{ to } 15 \text{ and } TH(0) = 0x000, TH(16) = 0x3FF$$

$$TH(n) = TH(n + 1) \text{ is valid only if } TH(n) = 0x3FF.$$

For details on calculation of the gamma correction value, see [section 49.2.30. GAMn_LUT1 : Gamma n Correction Block Table Setting Register 1 \(n = G, B, R\)](#) and [Figure 49.12](#)

TH03[9:0] bits (Start Threshold of Area 3)

The TH03[9:0] bits specify the start threshold of area 3 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH02[9:0] bits (Start Threshold of Area 2)

The TH02[9:0] bits specify the start threshold of area 2 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH01[9:0] bits (Start Threshold of Area 1)

The TH01[9:0] bits specify the start threshold of area 1 to be used for gamma correction in terms of an unsigned 10-bit integer.

49.2.39 GAMn_AREA2 : Gamma n Correction Block Area Setting Register 2 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x132C (GAMG_AREA2)
0x136C (GAMB_AREA2)
0x13AC (GAMR_AREA2)

Bit	Symbol	Function	R/W
9:0	TH06[9:0]	Start Threshold of Area 6 Unsigned 10-bit integer.	R/W
19:10	TH05[9:0]	Start Threshold of Area 5 Unsigned 10-bit integer.	R/W
29:20	TH04[9:0]	Start Threshold of Area 4 Unsigned 10-bit integer.	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

TH06[9:0] bits (Start Threshold of Area 6)

The TH06[9:0] bits specify the start threshold of area 6 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH05[9:0] bits (Start Threshold of Area 5)

The TH05[9:0] bits specify the start threshold of area 5 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH04[9:0] bits (Start Threshold of Area 4)

The TH04[9:0] bits specify the start threshold of area 4 to be used for gamma correction in terms of an unsigned 10-bit integer.

49.2.40 GAMn_AREA3 : Gamma n Correction Block Area Setting Register 3 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
 GLCDC_NS = 0x5034_2000

Offset address: 0x1330 (GAMG_AREA3)
 0x1370 (GAMB_AREA3)
 0x13B0 (GAMR_AREA3)

Bit	Symbol	Function	R/W
9:0	TH09[9:0]	Start Threshold of Area 9 Unsigned 10-bit integer.	R/W
19:10	TH08[9:0]	Start Threshold of Area 8 Unsigned 10-bit integer.	R/W
29:20	TH07[9:0]	Start Threshold of Area 7 Unsigned 10-bit integer.	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

TH09[9:0] bits (Start Threshold of Area 9)

The TH09[9:0] bits specify the start threshold of area 9 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH08[9:0] bits (Start Threshold of Area 8)

The TH08[9:0] bits specify the start threshold of area 8 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH07[9:0] bits (Start Threshold of Area 7)

The TH07[9:0] bits specify the start threshold of area 7 to be used for gamma correction in terms of an unsigned 10-bit integer.

49.2.41 GAMn_AREA4 : Gamma n Correction Block Area Setting Register 4 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1334 (GAMG_AREA4)
0x1374 (GAMB_AREA4)
0x13B4 (GAMR_AREA4)

Value after reset: 0

Bit	Symbol	Function	R/W
9:0	TH12[9:0]	Start Threshold of Area 12 Unsigned 10-bit integer.	R/W
19:10	TH11[9:0]	Start Threshold of Area 11 Unsigned 10-bit integer.	R/W
29:20	TH10[9:0]	Start Threshold of Area 10 Unsigned 10-bit integer.	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

TH12[9:0] bits (Start Threshold of Area 12)

The TH12[9:0] bits specify the start threshold of area 12 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH11[9:0] bits (Start Threshold of Area 11)

The TH11[9:0] bits specify the start threshold of area 11 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH10[9:0] bits (Start Threshold of Area 10)

The TH10[9:0] bits specify the start threshold of area 10 to be used for gamma correction in terms of an unsigned 10-bit integer.

49.2.42 GAMn_AREA5 : Gamma n Correction Block Area Setting Register 5 (n = G, B, R)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1338 (GAMG_AREA5)
0x1378 (GAMB_AREA5)
0x13B8 (GAMR_AREA5)

Value after reset: 0

Bit	Symbol	Function	R/W
9:0	TH15[9:0]	Start Threshold of Area 15 Unsigned 10-bit integer.	R/W
19:10	TH14[9:0]	Start Threshold of Area 14 Unsigned 10-bit integer.	R/W
29:20	TH13[9:0]	Start Threshold of Area 13 Unsigned 10-bit integer.	R/W

Bit	Symbol	Function	R/W
31:30	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when GAMx_LATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

TH15[9:0] bits (Start Threshold of Area 15)

The TH15[9:0] bits specify the start threshold of area 15 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH14[9:0] bits (Start Threshold of Area 14)

The TH14[9:0] bits specify the start threshold of area 14 to be used for gamma correction in terms of an unsigned 10-bit integer.

TH13[9:0] bits (Start Threshold of Area 13)

The TH13[9:0] bits specify the start threshold of area 13 to be used for gamma correction in terms of an unsigned 10-bit integer.

49.2.43 OUT_VLATCH : Output Control Block Register Update Control Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x13C0

Bit position: 31 0

Value after reset: 0

Bit	Symbol	Function	R/W
0	VEN	Control of Output Control Module Register Value Reflection to Internal Operations 0: Disable reflection of register values to internal operations on assertion of vertical synchronization signal (VS) 1: Enable reflection of register values to internal operations on assertion of vertical synchronization signal (VS).	R/W
31:1	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

VEN bit (Control of Output Control Module Register Value Reflection to Internal Operations)

The VEN bit enables or disables reflection of the register values to the internal operations in the output control circuit on assertion of the vertical synchronization signal (input). When this bit is set to 1, the register values are immediately reflected to the internal operations on assertion of the vertical synchronization signal (input), and then this bit automatically clears to 0. Also, if the signal is asserted that controls reflection of the register values to the internal operations of all the modules output from the ground plane generation module, the register values are reflected to the internal operations on assertion of the vertical synchronization signal (input), regardless of the value of this bit. While this bit is 1, do not modify any register whose value is reflected to the internal operations on assertion of the vertical synchronization signal (input) in the GLCDC. Otherwise, operation is not guaranteed.

This bit must not be 1 at the same time as the BG_EN.VEN bit (control of background plane register value reflection to internal operations) in the Operation Control Register (BG_EN), or one of the background plane setting registers. Otherwise, operation is not guaranteed.

49.2.44 OUT_SET : Output Control Block Output Interface Register

Base address: GLCDC = 0x4034_2000
 GLCDC_NS = 0x5034_2000

Offset address: 0x13C4

Bit	Symbol	Function	R/W
1:0	PHASE[1:0]	Data Output Delay Control in Serial RGB Format Data delay in LCD_CLK cycles. 0 0: 0 cycle 0 1: 1 cycle 1 0: 2 cycles 1 1: 3 cycles	R/W
3:2	—	These bits are read as 0. The write value should be 0.	R/W
4	DIRSEL	Scan Direction Select of Serial RGB Format 0: Forward scan 1: Reverse scan	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
9:8	FRQSEL[1:0]	Clock Frequency Division Control 0 0: No frequency division, parallel RGB 0 1: Setting prohibited 1 0: Quarter frequency (serial RGB) 1 1: Setting prohibited	R/W
11:10	—	These bits are read as 0. The write value should be 0.	R/W
13:12	FORMAT[1:0]	Output Format Select 0 0: RGB888 — select RGB888 as dither output format 0 1: RGB666 — select RGB666 as dither output format 1 0: RGB565 — select RGB565 as dither output format 1 1: Serial RGB — select RGB888 as dither output format. Select dither output format in OUT_PDTHA.FORM[1:0]	R/W
23:14	—	These bits are read as 0. The write value should be 0.	R/W
24	SWAPON	Pixel Order Control 0: RGB order 1: BGR order	R/W
27:25	—	These bits are read as 0. The write value should be 0.	R/W
28	ENDIANON	Bit Endian Control 0: Descending order (little endian) 1: Ascending order (big endian)	R/W
31:29	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Rewriting these bits is prohibited during operation. Set the settings before operation is enabled. Operation is not guaranteed if the bit is rewritten during operation.

For details on assignment of pixel data to the output pins (LCD_DATA23 to LCD_DATA00) by setting these bits (except for OUT_SET.FRQSEL[1:0]), see [Figure 49.3](#) to [Figure 49.6](#).

PHASE[1:0] bits (Data Output Delay Control in Serial RGB Format)

The PHASE[1:0] bits control data output delay in serial RGB format. When the delay is 0 cycle (these bits are 00b), pixel data (R, B, or invalid data, depending on the setting in this register) is output one pixel clock (PXCLK) cycle after the

49.2.46 OUT_BRIGTH2 : Output Control Block Brightness Correction Register 2

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x13CC

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	BRTB[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	BRTR[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
9:0	BRTR[9:0]	Brightness Adjustment of R Signal Brightness (DC) adjustment of R signal. Unsigned 10-bit integer, +512 with offset.	R/W
15:10	—	These bits are read as 0. The write value should be 0.	R/W
25:16	BRTB[9:0]	Brightness Adjustment of B Signal Brightness (DC) adjustment of B signal. Unsigned 10-bit integer, +512 with offset.	R/W
31:26	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when OUT_VLATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

BRTR[9:0] bits (Brightness Adjustment of R Signal)

The BRTR[9:0] bits specify the brightness (DC) adjustment of the R signal.

Brightness correction of the R signal is performed as follows:

- Rout: Output of brightness correction (input of contrast correction), unsigned, 10 bits
- Rin: Input of brightness correction, unsigned, 10 bits
- BRTR: Setting in this bit
- $R_{out} = R_{in} + BRTR - 512$.

BRTB[9:0] bits (Brightness Adjustment of B Signal)

The BRTB[9:0] bits specify the brightness (DC) adjustment of the B signal.

Brightness correction of the B signal is performed as follows:

- Bout: Output of brightness correction (input of contrast correction), unsigned, 10 bits
- Bin: Input of brightness correction, unsigned, 10 bits
- BRTB: Setting in this bit
- $B_{out} = B_{in} + BRTB - 512$.

49.2.47 OUT_CONTRAST : Output Control Block Contrast Correction Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x13D0

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	CONTG[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

15:8	CONTB[7:0]	Contrast Adjustment of B Signal Unsigned 8-bit fixed point value adjusting GAIN on B signal. 0x00: 0/128 = 0.000 ⋮ 0x80: 128/128 = 1.000 ⋮ 0xFF: 255/128 = 1.992	R/W
23:16	CONTG[7:0]	Contrast Adjustment of G Signal Unsigned 8-bit fixed point value adjusting GAIN on G signal. 0x00: 0/128 = 0.000 ⋮ 0x80: 128/128 = 1.000 ⋮ 0xFF: 255/128 = 1.992	R/W
31:24	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when OUT_VLATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

CONTR[7:0] bits (Contrast Adjustment of R Signal)

The CONTR[7:0] bits specify the contrast (GAIN) adjustment of R signal. The location of the decimal point is between bits [7] and [6].

CONTB[7:0] bits (Contrast Adjustment of B Signal)

The CONTB[7:0] bits specify the contrast (GAIN) adjustment of B signal. The location of the decimal point is between bits [7] and [6].

CONTG[7:0] bits (Contrast Adjustment of G Signal)

The CONTG[7:0] bits specify the contrast (GAIN) adjustment of G signal. The location of the decimal point is between bits [7] and [6].

Contrast correction of each pixel is performed as follows (x = R, G, B):

- Dxout: Output of contrast correction, unsigned, 10 bits
- Dxin: Input of contrast correction (output of brightness correction), unsigned, 10 bits
- CONTx: Setting in this bit

- $Dx_{out} = Dx_{in} \times CONTx$.

49.2.48 OUT_PDTHA : Output Control Block Panel Dither Correction Register

31:22	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when OUT_VLATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

PA[1:0], PB[1:0], PC[1:0], PD[1:0] bits (Pattern Value (A, B, C, D) of 2×2 Pattern Dither)

The PA[1:0], PB[1:0], PC[1:0], and PD[1:0] bits specify the pattern value A, B, C, and D of 2×2 pattern dither. [Figure 49.13](#) shows the configuration of the dither correction block.

FORM[1:0] bits (Output Format Select)

The FORM[1:0] bits specify the output format of the dither process. These bits must be set in accordance with the OUT_SET.FORMAT[1:0] bits of the Output Interface Register. For serial RGB (OUT_SET.FORMAT[1:0] = 11b), set these bits to 00b. Otherwise, operation is not guaranteed.

SEL[1:0] bits (Operation Mode)

The SEL[1:0] bits specify the dither operation mode. The dither process is performed for the bits equal to or shorter than the pixel data length selected in the output format select bits (OUT_PDTHA.FORM[1:0]). OUT_PDTHA.PA[1:0], PB[1:0], PC[1:0], and PD[1:0] are used for 2×2 pattern dither.

Figure 49.13 shows the configuration of the dither correction block.

Figure 49.13 Configuration of dither correction block

Figure 49.14 shows the addition value selection method for 2×2 pattern dither.

Figure 49.14 Addition value selection method for 2 × 2 pattern dither

A basic pattern is repeated as follows. Four frames constitute 1 cycle.

- A: Value obtained after OUT_PDTHA.PA[1:0] bit value is shifted in accordance with the output format
- B: Value obtained after OUT_PDTHA.PB[1:0] bit value is shifted in accordance with the output format
- C: Value obtained after OUT_PDTHA.PC[1:0] bit value is shifted in accordance with the output format
- D: Value obtained after OUT_PDTHA.PD[1:0] bit value is shifted in accordance with the output format

Renesas recommends setting the bits as follows: PA[1:0] = 11b, PB[1:0] = 00b, PC[1:0] = 10b, PD[1:0] = 01b

When 2 × 2 pattern dither (OUT_PDTHA.SEL[1:0] = 10b) is to be set, the valid pixel area of the background plane must be an integer multiple of the basic pattern. If serial RGB is selected as the output format for the output control block, add two to the horizontal valid pixel width and set the resulting value to the background plane horizontal valid pixel width bits (BG_HSIZE.HW[10:0]).

49.2.49 OUT_CLKPHASE : Output Control Block Output Phase Control Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x13E4

12	FRONTGAM	Correction Control 0: Process brightness/contrast correction followed by gamma correction 1: Process gamma correction followed by brightness/contrast correction	R/W
31:13	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: This setting is reflected to the internal operations on assertion of the vertical synchronization signal (input) when OUT_VLATCH.VEN = 1 or when the register value reflection control signal to internal operations for all the modules is asserted.

TCON3EDGE bit (LCD_TCON3 Output Phase Control)

The TCON3EDGE bit controls the output phase of LCD_TCON3. When this bit is set to 1, LCD_TCON3 is output in synchronization with the falling edge of LCD_CLK, and when it is set to 0, LCD_TCON3 is output in synchronization with the rising edge.

TCON2EDGE bit (LCD_TCON2 Output Phase Control)

The TCON2EDGE bit controls the output phase of LCD_TCON2. When this bit is set to 1, LCD_TCON2 is output in synchronization with the falling edge of LCD_CLK, and when it is set to 0, LCD_TCON2 is output in synchronization with the rising edge.

TCON1EDGE bit (LCD_TCON1 Output Phase Control)

The TCON1EDGE bit controls the output phase of LCD_TCON1. When this bit is set to 1, LCD_TCON1 is output in synchronization with the falling edge of LCD_CLK, and when it is set to 0, LCD_TCON1 is output in synchronization with the rising edge.

TCON0EDGE bit (LCD_TCON0 Output Phase Control)

The TCON0EDGE bit controls the output phase of LCD_TCON0. When this bit is set to 1, LCD_TCON0 is output in synchronization with the falling edge of LCD_CLK, and when it is cleared to 0, LCD_TCON0 is output in synchronization with the rising edge.

LCDEEDGE bit (LCD_DATA Output Phase Control)

The LCDEEDGE bit controls the output phase of the LCD_DATA pins (LCD_DATA23 to LCD_DATA00). When this bit is set to 1, the LCD_DATA pins are output in synchronization with the falling edge of LCD_CLK, and when it is set to 0, the LCD_DATA pins are output in synchronization with the rising edge.

FRONTGAM bit (Correction Control)

The FRONTGAM bit controls the correction sequence. When this bit is set to 1, gamma correction is followed by brightness and contrast correction, and when it is set to 0, gamma correction follows brightness and contrast correction. In both cases, each RGB data output from the graphics 2 module is extended from 8 bits to 10 bits (with 00b appended to

the lower side), and is input to the preceding stage of the correction circuit. The output is rounded to 10 bits and is input to the dither correction circuit. Although the sequence of RGB gamma correction and brightness/contrast correction can be reversed using this bit, brightness correction always precedes contrast correction.

49.2.50 TCON_TIM : TCON Reference Timing Setting Register

Base address: GLCDC = 0x4034_2000
 GLCDC_NS = 0x5034_2000

Offset address: 0x1404

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	OFFSET[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
10:0	OFFSET[10:0]	Horizontal Synchronization Signal Generation Reference Timing Offset from the assertion of the internal horizontal synchronization signal in pixels. 0x000: 1 pixel ⋮ 0x3FF: 1024 pixels	R/W
15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	HALF[10:0]	Vertical Synchronization Signal Generation Change Timing Delay from the assertion of the internal horizontal synchronization signal in pixels. 0x000: 1 pixel (no delay) ⋮ 0x3FF: 1024 pixels	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

OFFSET[10:0] bits (Horizontal Synchronization Signal Generation Reference Timing)

The OFFSET[10:0] bits specify the reference timing to be used when the horizontal synchronization signal is generated in the TCON. Set the offset from the assertion of the internal horizontal synchronization signal (HS) in terms of pixels. [Figure 49.15](#) shows the horizontal synchronization signal generation reference timing in the TCON.

Figure 49.15 Reference timing in the TCON for horizontal synchronization signal generation

HALF[10:0] bits (Vertical Synchronization Signal Generation Change Timing)

The HALF[10:0] bits specify the vertical synchronization signal change timing when the signal is generated in the TCON. Set the change timing as a delay from the assertion of the internal horizontal synchronization signal (HS) in terms of pixels. Figure 49.16 shows the vertical synchronization signal change timing in the TCON.

Figure 49.16 Timing in the TCON for vertical synchronization signal change

Also, Figure 49.17 shows the relationship between the TCON block and the output format block in the output control block. These blocks are based on shared control signals (same timing) and image data, and the internal delay is the same. The delay difference specified in the register settings is the source of the timing differences on the external pins.

- TCON block: 3 delay cycles of the pixel clock (PXCLK)
- Data format block:
 - Parallel RGB: 3 delay cycles of the pixel clock (PXCLK)
 - Serial RGB: 3 delay cycles of the pixel clock (PXCLK):
 - The delay of the pixel head data including invalid data
 - No delay of the serial RGB data.

Figure 49.17 Internal configuration of output control block

49.2.51 TCON_STVx1 : TCON Vertical Timing Setting Register x1 (x = A, B)

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1408 (TCON_STVA1)
0x1410 (TCON_STVB1)

15:11	—	These bits are read as 0. The write value should be 0.	R/W
26:16	VS[10:0]	Vertical Synchronization Signal STVx1 First Change Timing Signal delay in lines. 0x000: 0 line (no delay) ⋮ 0x7FF: 2047 lines	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

The vertical timing setting registers (TCON_STVA1/TCON_STVB1 and TCON_STVA2/TCON_STVB2) have the same configuration, and x is either A or B in the descriptions.

VW[10:0] bits (Vertical Synchronization Signal STVx1 Second Change Timing)

The VW[10:0] bits specify the second change (negation) timing of the vertical synchronization signal STVx1, which is generated in the TCON. Set the second change timing as a delay from the first change point in terms of lines. The change position in a horizontal line is defined in TCON_TIM.HALF[10:0] in the Reference Timing Setting Register (TCON_TIM), as is the first change timing.

VS[10:0] bits (Vertical Synchronization Signal STVx1 First Change Timing)

The VS[10:0] bits specify the first change (assertion) timing of the vertical synchronization signal STVx1, which is generated in the TCON. Set the change timing as a delay from the input vertical synchronization signal (VSIN) in terms of lines. The change position in a horizontal line is defined in TCON_TIM.HALF[10:0] in the Reference Timing Setting Register (TCON_TIM), as is the first change timing. Figure 49.18 shows the change timing of vertical synchronization signal to be generated.

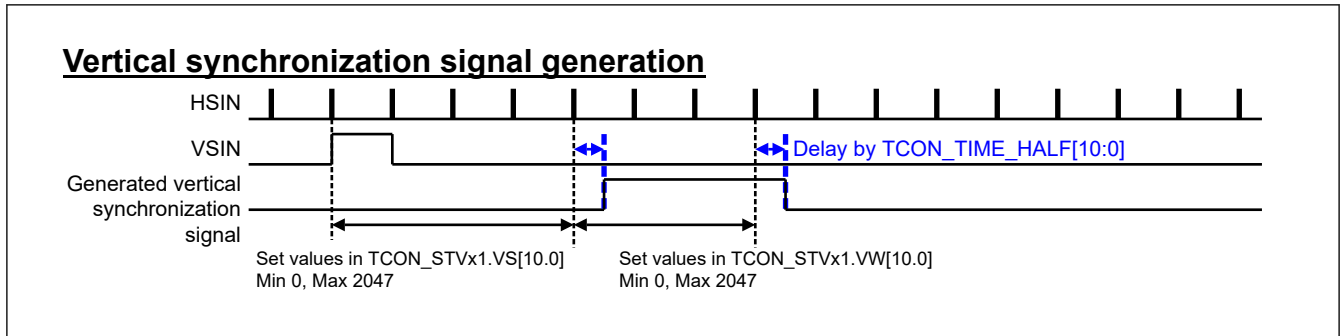

Figure 49.18 Generation of vertical synchronization signal

49.2.52 TCON_STVx2 : TCON Vertical Timing Setting Register x2 (x = A, B)

26:16	HS[10:0]	Horizontal Synchronization Signal STHx1 First Change Timing Signal delay in pixels. 0x000: 0 pixel (no delay) ⋮ 0x3FF: 1023 pixels Other settings are prohibited.	R/W
31:27	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

The horizontal timing setting registers (TCON_STHA1/TCON_STHB1 and TCON_STHA2/TCON_STHB2) have the same configuration, and x is either A or B in the descriptions.

HW[10:0] bits (Horizontal Synchronization Signal STHx1 Second Change Timing)

The HW[10:0] bits specify the second change (negation) timing of the horizontal synchronization signal STHx1, which is generated in the TCON. Set the second change timing as a distance from the first change point in terms of pixels.

HS[10:0] bits (Horizontal Synchronization Signal STHx1 First Change Timing)

The HS[10:0] bits specify the first change (assertion) timing of the horizontal synchronization signal STHx1, which is generated in the TCON. Set the change timing as a distance from the input horizontal synchronization signal (HSIN) or the reference timing based on the offset specified in the TCON_TIM.OFFSET[10:0] bit (horizontal synchronization signal generation reference timing) in terms of pixels.

Figure 49.20 shows the horizontal synchronization signal generation timing if the input horizontal synchronization signal (HSIN) is based on the negated edge reference of the HINT signal. Figure 49.21 shows the horizontal synchronization signal generation timing after offset. By setting the TCON_TIM.OFFSET[10:0] bit (horizontal synchronization generation reference timing) and these horizontal synchronization bits appropriately, it is possible to generate a signal that is asserted before HSIN and negated after HSIN, where HSIN is the horizontal synchronization signal input to the TCON.

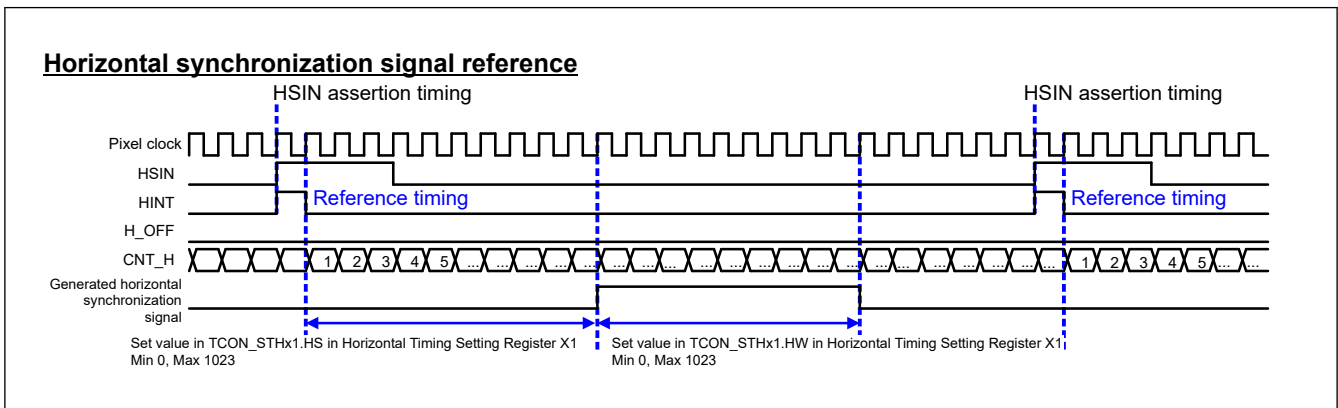

Figure 49.20 Signal generation based on input horizontal synchronization signal (HSIN)

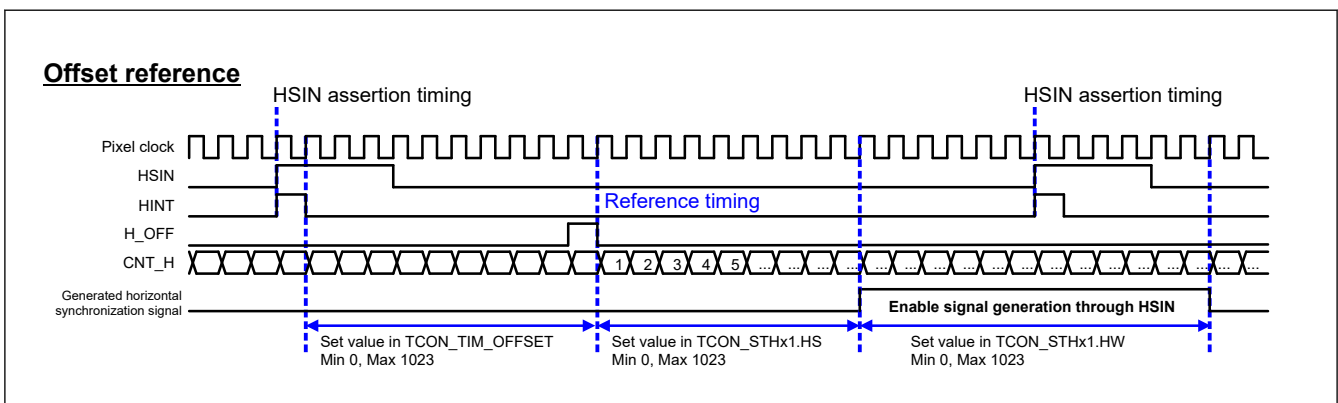

Figure 49.21 Horizontal synchronization signal generation based on offset

When generating the signal across HSIN on the offset reference, the horizontal synchronization signal of the last line of the frame spans the first line of the next frame. Even if the BG_EN.EN bit is cleared to 0 and the GLCDC operation is stopped, the horizontal synchronization signal across HSIN is not cleared at the frame end and retains the predetermined value until the second change timing set in the registers. If BG_EN.SWRST is cleared to 0, the signal returns to the initial state immediately.

49.2.54 TCON_STHx2 : TCON Horizontal Timing Setting Register x2 (x = A, B)

Base address: GLCDC = 0x4034_2000

3	—	This bit is read as 0. The write value should be 0.	R/W
4	INV	Horizontal Synchronization Signal STHx Polarity Inversion Control 0: Do not invert 1: Invert	R/W
7:5	—	These bits are read as 0. The write value should be 0.	R/W
8	HSSEL	Horizontal Synchronization Signal STHx Reference Timing Control 0: Select input horizontal synchronization signal (HSIN) as reference for signal generation 1: Select offset specified in TCON_TIM.OFFSET[10:0] (horizontal synchronization generation reference timing) as reference for signal generation	R/W
31:9	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note: Rewriting these bits is prohibited during operation. Set the required settings before enabling operation. Operation is not guaranteed if the bit is rewritten during operation.

The horizontal timing setting registers (TCON_STHA1/TCON_STHB1 and TCON_STHA2/TCON_STHB2) have the same configuration, and x is either A or B in the descriptions.

SEL[2:0] bits (Output Signal Select Control for LCD_TCON2/LCD_TCON3 Pin)

The SEL[2:0] bits control the output signal select for the LCD_TCON2/LCD_TCON3 pins.

INV bit (Horizontal Synchronization Signal STHx Polarity Inversion Control)

The INV bit controls polarity inversion of the horizontal synchronization signal (STHx).

HSSEL bit (Horizontal Synchronization Signal STHx Reference Timing Control)

The HSSEL bit selects the reference timing for generating the horizontal synchronization signal STHx. For details on the signal to be generated, see [Figure 49.20](#) and [Figure 49.21](#). For the configuration of the inversion control and output signal select, see [Figure 49.19](#).

VPOSDTC bit (Specified Line Detection Control)

The VPOSDTC bit enables or disables detection of the specified line. When this bit is set to 1, the associated bit in the SYSCNT_STMON register sets to 1 on event notification from graphics 2. When it is set to 0, the associated bit in the SYSCNT_STMON register does not set to 1 even on event notification from graphics 2.

L1UNDFDTC bit (Graphics 1 Underflow Detection Control)

The L1UNDFDTC bit enables or disables detection of the graphics 1 underflow. When this bit is set to 1, the associated bit in the SYSCNT_STMON register sets to 1 when an underflow occurs in graphics 1. When it is set to 0, the associated bit in the SYSCNT_STMON register does not set to 1 even when an underflow occurs in graphics 1. The underflow state in graphics 1 is automatically cleared on assertion of the vertical synchronization signal (VS) regardless of the value of this bit, and normal operation is recovered.

L2UNDFDTC bit (Graphics 2 Underflow Detection Control)

The L2UNDFDTC bit enables or disables detection of the graphics 2 underflow. When this bit is set to 1, the associated bit in the SYSCNT_STMON register sets to 1 when an underflow occurs in graphics 2. When it is set to 0, the associated bit in the SYSCNT_STMON register does not set to 1 even when an underflow occurs in graphics 2. The underflow state in graphics 2 is automatically cleared on assertion of the vertical synchronization signal (VS) regardless of the value of this bit, and normal operation is recovered.

49.2.57 SYSCNT_INTEN : System Control Block Interrupt Request Enable Control Register

Base address: GLCDC = 0x4034_2000
 GLCDC_NS = 0x5034_2000

Offset address: 0x1444

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	L2UNDFINTEN	L1UNDFINTEN	VPOSDTC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

31:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

VPOSDTC bit (Interrupt Request Signal GLCDC_VPOS Enable Control)

The VPOSDTC bit enables or disables the interrupt request signal GLCDC_VPOS. When this bit is set to 1, the interrupt request signal GLCDC_VPOS is asserted when the associated status monitor flag SYSCNT_STMON[0] sets. When it is cleared to 0, the interrupt request signal GLCDC_VPOS is not asserted even when the associated status monitor flag SYSCNT_STMON[0] sets. If this bit is cleared during GLCDC_VPOS assertion, the associated status monitor flag SYSCNT_STMON[0] does not change, but the interrupt request signal GLCDC_VPOS is negated.

L1UNDFINTEN bit (Interrupt Request Signal GLCDC_L1UNDF Enable Control)

The L1UNDFINTEN bit enables or disables the interrupt request signal GLCDC_L1UNDF. When this bit is set to 1, the interrupt request signal GLCDC_L1UNDF is asserted when the associated status monitor flag SYSCNT_STMON[1] sets. When it is cleared to 0, the interrupt request signal GLCDC_L1UNDF is not asserted even when the associated status monitor flag SYSCNT_STMON[1] sets. If this bit is cleared during GLCDC_L1UNDF assertion, the associated status monitor flag SYSCNT_STMON[1] does not change, but the interrupt request signal GLCDC_L1UNDF is negated.

L2UNDFINTEN bit (Interrupt Request Signal GLCDC_L2UNDF Enable Control)

The L2UNDFINTEN bit enables or disables the interrupt request signal GLCDC_L2UNDF. When this bit is set to 1, the interrupt request signal GLCDC_L2UNDF is asserted when the associated status monitor flag SYSCNT_STMON[2] sets. When it is cleared to 0, the interrupt request signal GLCDC_L2UNDF is not asserted even when the associated status monitor flag SYSCNT_STMON[2] sets. If this bit is cleared during GLCDC_L2UNDF assertion, the associated status monitor flag SYSCNT_STMON[2] does not change, but the interrupt request signal GLCDC_L2UNDF is negated.

49.2.58 SYSCNT_STCLR : System Control Block Status Clear Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1448

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

31:3	—	These bits are read as 0. The write value should be 0.	R/W

Note: S-TYPE-3, P-TYPE-3

Note 1. These bits are read as 0.

VPOSCLR bit (Graphics 2 Specified Line Detection Flag Clear)

Writing 1 to the VPOSCLR bit clears the graphics 2 specified line detection flag. Clearance of the flag by this bit is only valid for the associated flag, and does not directly affect the other states and interrupt request signals. However, an interrupt request signal might be negated by clearing the detection flag.

L1UNDFCLR bit (Graphics 1 Underflow Detection Flag Clear)

Writing 1 to the L1UNDFCLR bit clears the graphics 1 underflow detection flag. Clearance of the flag by this bit is only valid for the associated flag, and does not directly affect the other states and interrupt request signals. However, an interrupt request signal might be negated by clearing the detection flag.

L2UNDFCLR bit (Graphics 2 Underflow Detection Flag Clear)

Writing 1 to the L2UNDFCLR bit clears the graphics 2 underflow detection flag. Clearance of the flag by this bit is only valid for the associated flag, and does not directly affect the other states and interrupt request signals. However, an interrupt request signal might be negated by clearing the detection flag.

49.2.59 SYSCNT_STMON : System Control Block Status Monitor Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x144C

Bit position:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit position:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Bit field:	—	—	—	—	—	—	—	—	—	—	—	—	—	L2UNDF	L1UNDF	VPOS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Function	R/W
0	VPOS	Graphics 2 Specified Line Detection Flag 0: Specified line notification not detected in graphics 2 1: Specified line notification detected in graphics 2	R
1	L1UNDF	Graphics 1 Underflow Detection Flag 0: No underflow detected in graphics 1 1: Underflow detected in graphics 1	R
2	L2UNDF	Graphics 2 Underflow Detection Flag 0: No underflow detected in graphics 2 1: Underflow detected in graphics 2	R
31:3	—	These bits are read as 0.	R

Note: S-TYPE-3, P-TYPE-3

VPOS flag (Graphics 2 Specified Line Detection Flag)

The VPOS flag indicates that the specified line notification was detected in graphics 2. When this flag is 1, it indicates that the specified line notification was detected in graphics 2 at some time in the past. It does not necessarily mean that graphics 2 is currently processing the specified line. When this flag is 0, it indicates that no specified line notification was detected after the module operation was enabled. When the interrupt request signal is enabled and is cleared while this flag is 1, the associated interrupt request signal GLCDC_VPOS is negated, but this does not affect the state of graphics 2.

L1UNDF flag (Graphics 1 Underflow Detection Flag)

The L1UNDF flag indicates that an underflow was detected in graphics 1. When this flag is 1, it indicates that an underflow was detected in graphics 1 at some time in the past. It does not necessarily mean that graphics 1 is currently in the underflow state. When this flag is 0, it indicates that no underflow was detected after the module operation was enabled. When the interrupt request signal is enabled and is cleared while this flag is 1, the associated interrupt request signal GLCDC_L1UNDF is negated, but this does not affect the state of graphics 1.

Even if the current graphics data is not required (GR1_AB1.DISPSEL[1:0] = 0xb), if the SYSCNT_DTCTEN.L1UNDFDTC flag (graphics 1 underflow detection control) is 1 and detection is enabled, this flag is set to 1 at the start of the graphics image valid area. To avoid unnecessary detection flag settings or interrupt request signal assertions, when the display does not require the current graphics data, set the SYSCNT_DTCTEN.L1UNDFDTC flag and the SYSCNT_INTEN.L1UNDFINTEN bit (interrupt request signal GLCDC_L1UNDF enable control) to 0.

L2UNDF flag (Graphics 2 Underflow Detection Flag)

The L2UNDF flag indicates that an underflow was detected in graphics 2. When this flag is 1, it indicates that an underflow was detected in graphics 2 at some time in the past. It does not necessarily mean that graphics 2 is currently in the

underflow state. When this flag is 0, it indicates that no underflow was detected after the module operation was enabled. When the interrupt request signal is enabled and is cleared while this flag is 1, the associated interrupt request signal GLCDC_L2UNDF is negated, but this does not affect the state of graphics 2.

Even if the current graphics data is not required (GR2_AB1.DISPSEL[1:0] = 0xb), if the SYSCNT_DTCTEN.L2UNDFDTC flag (graphics 2 underflow detection control) is 1 and detection is enabled, this flag is set to 1 at the start of the graphics image valid area. To avoid the unnecessary detection flag settings or interrupt request signal assertions, when the display does not require the current graphics data, set the SYSCNT_DTCTEN.L2UNDFDTC flag and the SYSCNT_INTEN.L2UNDFINTEN bit (interrupt request signal GLCDC_L2UNDF enable control) to 0.

49.2.60 SYSCNT_PANEL_CLK : System Control Block Version and Panel Clock Control Register

Base address: GLCDC = 0x4034_2000
GLCDC_NS = 0x5034_2000

Offset address: 0x1450

12	PIXSEL	Pixel Clock Select Control 0: Select no frequency division, parallel RGB 1: Select quarter frequency, serial RGB This setting must have the same value as OUT_SET.FRQSEL[1].	R/W
15:13	—	These bits are read as 0. The write value should be 0.	R/W
31:16	VER[15:0]	Version Information Version information of the GLCDC.	R

Note: S-TYPE-3, P-TYPE-3

The configuration of the pixel and panel clock generator circuits are shown in [section 8, Clock Generation Circuit](#).

DCDR[5:0] bits (Clock Division Ratio Setting Control)

The DCDR[5:0] bits control the setting of the panel clock division ratio. The division ratio bit can only be set to the values listed in [Table 49.9](#). Operation is not guaranteed for values not listed.

Table 49.9 Input clock division (1 of 2)

DCDR[5:0]	Clock division ratio	CLKSEL = 0, LCD_EXTCLK (≤ 60 MHz)	CLKSEL = 1, LCDCLK (Up to 240 MHz)
000000b	1/2	LCD_EXTCLK/2	LCDCLK/2 ^{*1}

Table 49.9 Input clock division (2 of 2)

DCDR[5:0]	Clock division ratio	CLKSEL = 0, LCD_EXTCLK (≤ 60 MHz)	CLKSEL = 1, LCDCLK (Up to 240 MHz)
000001b	1/1	LCD_EXTCLK*1	LCDCLK*1
000010b	1/2	LCD_EXTCLK/2	LCDCLK/2*1
000011b	1/3	LCD_EXTCLK/3	LCDCLK/3*1
000100b	1/4	LCD_EXTCLK/4	LCDCLK/4*1
000101b	1/5	LCD_EXTCLK/5	LCDCLK/5
000110b	1/6	LCD_EXTCLK/6	LCDCLK/6
000111b	1/7	LCD_EXTCLK/7	LCDCLK/7
001000b	1/8	LCD_EXTCLK/8	LCDCLK/8
001001b	1/9	LCD_EXTCLK/9	LCDCLK/9
001100b	1/12	LCD_EXTCLK/12	LCDCLK/12
010000b	1/16	LCD_EXTCLK/16	LCDCLK/16
011000b	1/24	LCD_EXTCLK/24	LCDCLK/24
100000b	1/32	LCD_EXTCLK/32	LCDCLK/32

Note 1. The panel clock is output as the LCD_CLK output clock. This setting may be prohibited because LCD_EXTCLK and LCD_CLK have limited frequencies. See [section 51, Electrical Characteristics](#).

To set the panel clock:

1. After setting the input source of the panel clock in the CLKSEL bit, set the division ratio in the DCDR[5:0] bits and the pixel clock selection.
2. Set the CLKEN bit to 1.

CLKEN bit (Panel Clock Output Enable Control)

The CLKEN bit enables or disables the panel clock output. When enabling the panel clock output and operating the panel clock block, set this bit to 1. When changing the PIXSEL, CLKSEL, or DCDR bit, you must set this bit to 0 once and stop the panel clock output. Operation is not guaranteed if any setting is changed while the panel clock is being output.

CLKSEL bit (Panel Clock Supply Source Control)

The CLKSEL bit controls the selection of the panel clock supply source from either the external clock pin (LCD_EXTCLK) or LCDCLK. When the external clock is selected, set this bit to 0. When LCDCLK is selected, set this bit to 1.

PIXSEL bit (Pixel Clock Select Control)

The PIXSEL bit controls the selection of the pixel clock output. When selecting parallel RGB, set this bit to 0 to output the same frequency as the panel clock (no frequency division). When selecting serial RGB, set this bit to 1 to output the quarter frequency of the panel clock as the pixel clock.

This bit must be synchronized with the OUT_SET.FRQSEL[1:0] setting. You must set the same value as in FRQSEL[1]. Otherwise, operation is not guaranteed.

VER[15:0] bits (Version Information)

The VER[15:0] bits provide GLCDC version information.

49.3 Operation

49.3.1 Overall Control

The GLCDC consists of six modules as shown in [Figure 49.22](#), each of which functions independently. The four modules handling image data are interconnected by the vertical and horizontal synchronization signals VS, HS, VE, and HE, and image data (RGB888), as shown in [Figure 49.23](#). The processing of image data is carried out with the pixel clock (PXCLK). LCD_CLK synchronizes with PXCLK (also in phase with each other), and has the same or quadruple frequency (for serial RGB888 output). The registers controlling operation and setting parameters are connected with the PABI and operate on PCLKA. The circuits, including the data buffer and the CLUT memory, operate on PCLKA to read graphics data from

the GLCDC0 and GLCDC1 bus, access the color palette (CLUT) memory, and expand graphics data into the ARGB8888 format.

Figure 49.22 GLCDC configuration

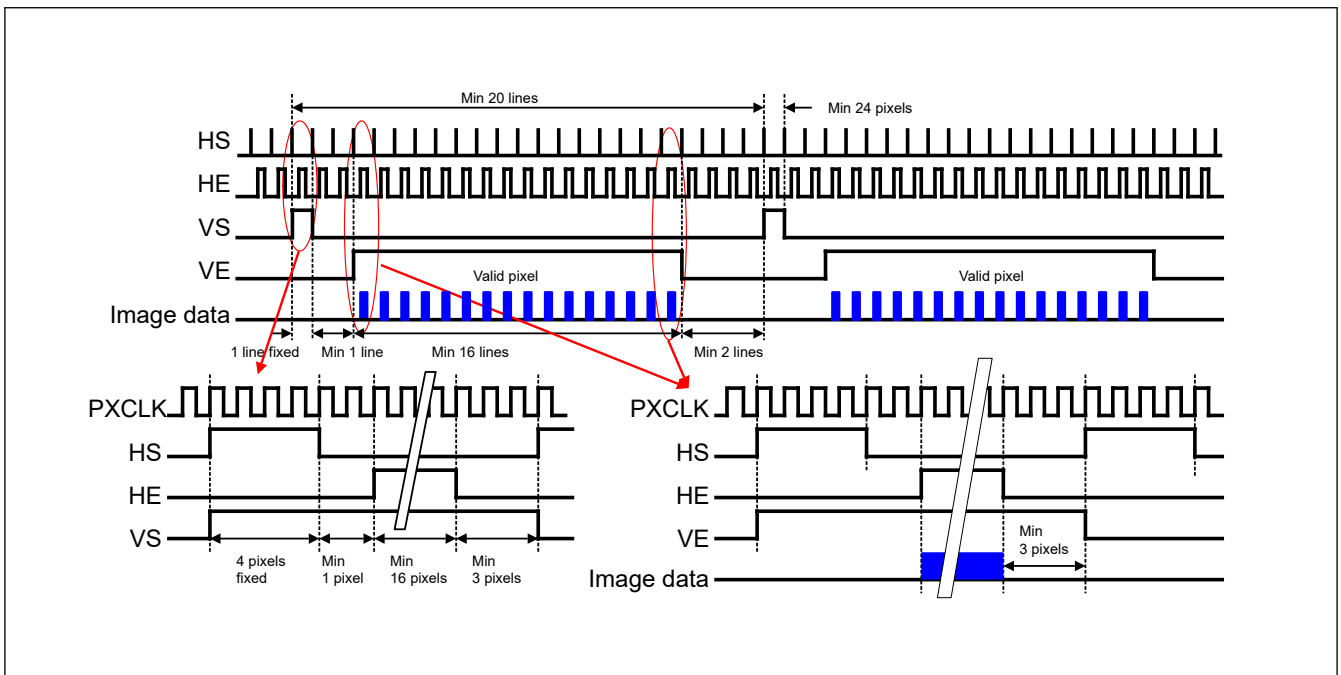

Figure 49.23 Image data carrier signals in the GLCDC

The graphics 1, graphics 2, and output control modules have no individual operation enable bits. By clearing the software reset state in the background screen generation module, these modules wait for vertical and horizontal synchronization

signals VS, HS, VE, and HE, and image data (RGB888) to be input, detect assertion of the vertical synchronization signal VS, and start operation for each frame based on the values preset in the registers. For the system control module, clearing the software reset state in the background screen generation module allows it to monitor the status of graphics 1 and 2 in accordance with the register settings and assert interrupt request signals. These status flags are intended for observing the internal status and exert no influence on the internal operation. The operation between startup and stop of the GLCDC is outlined in this section.

(1) Startup

To start GLCDC operation:

1. Confirm that PCLKA is supplied to the GLCDC and that the reset is negated. When setting LCD_CLK to the same frequency as PXCLK or LCD_CLK to the quadruple speed clock, the setting must be consistent with the value in the register specified in the subsequent stage. The quadruple speed clock is required only when the output format is serial RGB888. Operation is not guaranteed if the quadruple speed clock is supplied to LCD_CLK in other output formats than serial RGB888.
2. Set 1 to the BG_EN.SWRST bit to release the entire GLCDC from a software reset.
3. Set parameters necessary for operation in each register. Although registers of any module can be set first, while the BG_EN.VEN bit (control of GLCDC internal register value reflection to internal operations), BG_EN.EN bit (background plane operation enable) of the background screen generation module, and the VEN bit in the register update control register of each module remain cleared to 0, confirm that PCLKA and PXCLK/LCD_CLK are supplied and the BG_MON.SWRST bit (entire module software reset state monitor) is set to 1.
4. When displaying the graphics data read by graphics 1 and 2 through the GLCDC0 and GLCDC1 bus, set 1 to the GRn_FLMRD.RENB bit (graphics data read enable).
5. Write the color palette data of graphics 1 and 2 (0 and 1 planes) to the CLUT memory through the register access bus (PABI) as required. This is necessary for the LUT1, LUT4, LUT8, and ARGB1555 data formats. ARGB1555 uses addresses 0x80 and 0x00 on the two planes, LUT1 uses 0x01 and 0x00, LUT4 uses the addresses from 0x0F to 0x00, and LUT8 uses the addresses from 0xFF to 0x00.
6. Set 1 to the BG_EN.VEN bit (control of background plane register value reflection to internal operations) and the BG_EN.EN bit (background plane operation enable) of the background screen generation module at the same time. This setting allows output of the vertical and horizontal synchronization signals VS, HS, VE, and HE, and the image data (RGB888) from the background screen generation module. When the pixel data is valid (both VE and HE are 1), output from the background screen generation module uses the value in the BG_BGC register. The data value is 0x00000000 for pixels that are not valid.
7. Each module detects the assertion of the vertical synchronization signal (VS) output from its previous stage (background screen generation module for graphics 1, graphics 1 for graphics 2, and graphics 2 for the output control module) and starts operation in accordance with its register settings. All the modules control the operation in frame units. When the assertion of the vertical synchronization signal (VS) is detected, the current frame is taken as the frame head and the status is initialized. If necessary (when the VEN bits in the register update control registers are 1), the register values read through the register access bus are reflected to the internal operation.

(2) Changing parameters during operation

With the GLCDC, it is possible to update parameters of each module and reflect the updates to the internal operations during operation, without preventing graphics data to be read by the background screen generation module, graphics 1, or graphics 2. By setting 1 to the VEN bits of the modules, including the background screen generation module, almost all parameters are reflected to the internal operations at the start of the following frame (at the start of the control screen for the background screen generation module, and immediately after the VS assertion of the previous stage for the other modules). However, if the CLUT plane being used for internal operations (determined in the GRn_CLUTINT.SEL[1:0] bits) is modified, the updates are reflected to the internal operations immediately without waiting for the following VS assertion. To circumvent this immediate reflection of the CLUT plane modification to the internal operations, first write all the image data (ARGB8888) necessary for the CLUT plane that is not being used for internal operations, next modify the GRn_CLUTINT.SEL[1:0] bits, and finally set 1 to the VEN bit of the background screen generation module or the target module.

To modify parameters during operation:

1. Confirm that the VEN bit of each module is 0. Operation is not guaranteed if the target registers are modified when the VEN bit of the module to which the register values are to be reflected to the internal operations, or the VEN bit of the background screen generation module is 1.
2. Modify the value of the target registers.
3. If only a particular module is to be the target, set 1 to the VEN bit of the target module. If multiple modules or the background screen generation module are to be the targets, set 1 to the VEN bit of the background screen generation module. In this case, all the modules are included as targets, not only the background screen generation module.
4. Confirm that the VEN bit to which 1 was set is 0. If the bit is cleared to 0, the target register contents are reflected to the internal operations. If the bit remains 1, however, the target register contents might not yet be reflected to the internal operations. The VEN bit of each module is cleared to 0 immediately after the target register values are internally reflected. However, the VEN bit of the background screen generation module is not cleared to 0 until the module output VE is negated (with all the modules, sufficient delay is secured in reference to the VS assertion of the background screen generation module so that the register values are reflected to the internal operations for the same frame). Figure 49.24 shows the operation of the signals output by the background screen generation module and the monitor bits.

Figure 49.24 Control signals for register value reflection to internal operations

(3) Stopping and restarting in normal operation

To stop the GLCDC:

1. Confirm that the VEN bit of each module is cleared to 0.
2. Clear the BG_EN.EN bit (background plane operation enable) of the background screen generation module to 0.
3. Confirm that the BG_MON.EN bit (background plane operation monitor) of the background screen generation module has changed to 0. This bit is cleared to 0 only after operation has stopped. It is cleared at the frame end of the background screen generation module, not when the operations of all the modules are complete (not at the frame end of the output control module). If it is necessary to wait for all the modules to complete operations, a certain period (for example, a period equivalent to one line) is required.
4. Usually, a software reset can be safely applied (clearing of the BG_EN.SWRST bit) after confirming that the BG_MON.EN bit of the background screen generation module has changed to 0. (Even if the output signal returns to the initial value, no problems occur because the GLCDC has already entered the vertical blanking interval.)
5. When restarting the GLCDC by setting the relevant registers without applying a software reset, wait until sufficient time elapses after the BG_MON.EN bit becomes 0 (when the output control module output is the frame end) before starting the GLCDC. The GLCDC itself is not affected by this because the GLCDC starts operating after recognizing the assertion of the VS of the previous stage as the frame head. However, operation of some connected devices might be affected if a blanking interval or a period equivalent to one line is too short. For details, check the specifications of the connected device. When a software reset is applied, the register values are also initialized and almost all of the registers

must be set again. Only the color palette data (CLUT memory content) is retained (only for a software reset after normal end).

Figure 49.25 shows the changes in signal lines and bits for the stop and restart in normal operation. Even if the background screen generation module is stopped by a clearing of the BG_EN.EN bit to 0, the GLCDC stops because of an abnormal operation sequence, not normal operation, if the GLCDC0 and GLCDC1 bus access is not complete at the frame end because of an underflow in graphics 1 or 2, inappropriate setting of graphics data access, or other undesirable conditions.

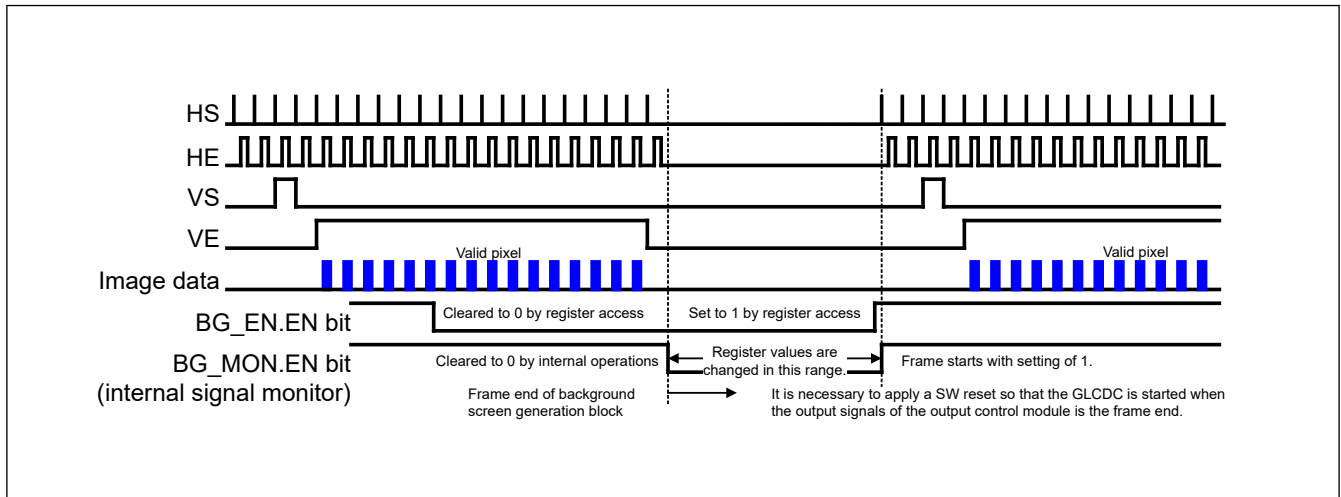

Figure 49.25 Stop and restart in normal operation

(4) Stopping and restarting in abnormal operation

Stop in abnormal operation occurs in the following cases:

- When during operation (BG_EN.EN or BG_MON.EN is set to 1), a software reset (BG_EN.SWRST bit is cleared to 0) or a reset is applied
- When unnecessary (unintended) access to the GLCDC0 and GLCDC1 bus occurs and a data cycle is not completed, even though the BG_EN.EN bit is cleared to 0 and so the BG_MON.EN bit is also cleared to 0

In both cases, the GLCDC is internally initialized and the register access bus can be accessed normally (except for a hardware reset). However, the GLCDC0 and GLCDC1 bus might write unintended graphics data to the GLCDC. Therefore, it is advisable to apply a software reset (clear the BG_EN.SWRST bit to 0) and confirm that there is no unintended access to the GLCDC0 and GLCDC1 bus, even after confirming that both the BG_EN.EN and BG_MON.EN bits are cleared to 0. Next release the GLCDC from the software reset (set the BG_EN.SWRST bit to 1), set the relevant registers, and set the BG_EN.En and BG_EN.VEN bits in the background screen generation module to 1 to restart the GLCDC. For the procedure for checking the GLCDC0 and GLCDC1 bus state, see the *ARM® AHB Specification*. Use this procedure even after a reset when the GLCDC0 and GLCDC1 bus, a target device, or a target controller is not initialized. If these are initialized on a reset assertion for the GLCDC, a normal startup procedure can be used without checking the GLCDC0 and GLCDC1 bus state.

49.3.2 Screen Definition

The essential signals for GLCDC operations are generated by the background screen generation module, and the graphics 1 and 2 modules and output control module operate based on the sequentially transferred vertical and horizontal synchronization signals (VS and HS) and vertical and horizontal pixel enable signals (VE and HE). The reference point (frame start point) of the background screen cannot be determined by the output signals. The point shown in the figures is virtual and provided only for register settings. The reference points (frame start points) of the graphics 1 and 2 modules and output control module are the assertion of the vertical synchronization signal (VS), which is input (output) from the previous stage. Each module defines the valid pixel display area and special processing area for pixel data (rectangular areas for graphics 1 and 2) according to the position and width based on this reference point. Figure 49.26 shows the definition of the background screen, and Figure 49.27 shows the definition of the graphics 1 and 2 screen. The output control module performs correction for the entire valid pixel area (when both VE and HE are 1) output from the previous stage (graphics 2). (No registers are provided in the output control module for setting the correction area.) TCON in the output control module

generates the control signals to be output based on the internal vertical and horizontal synchronization signals (VS and HS), and the change timing of the output signals can be freely modified within the valid setting range specifiable in the registers.

Figure 49.26 Definition of background screen

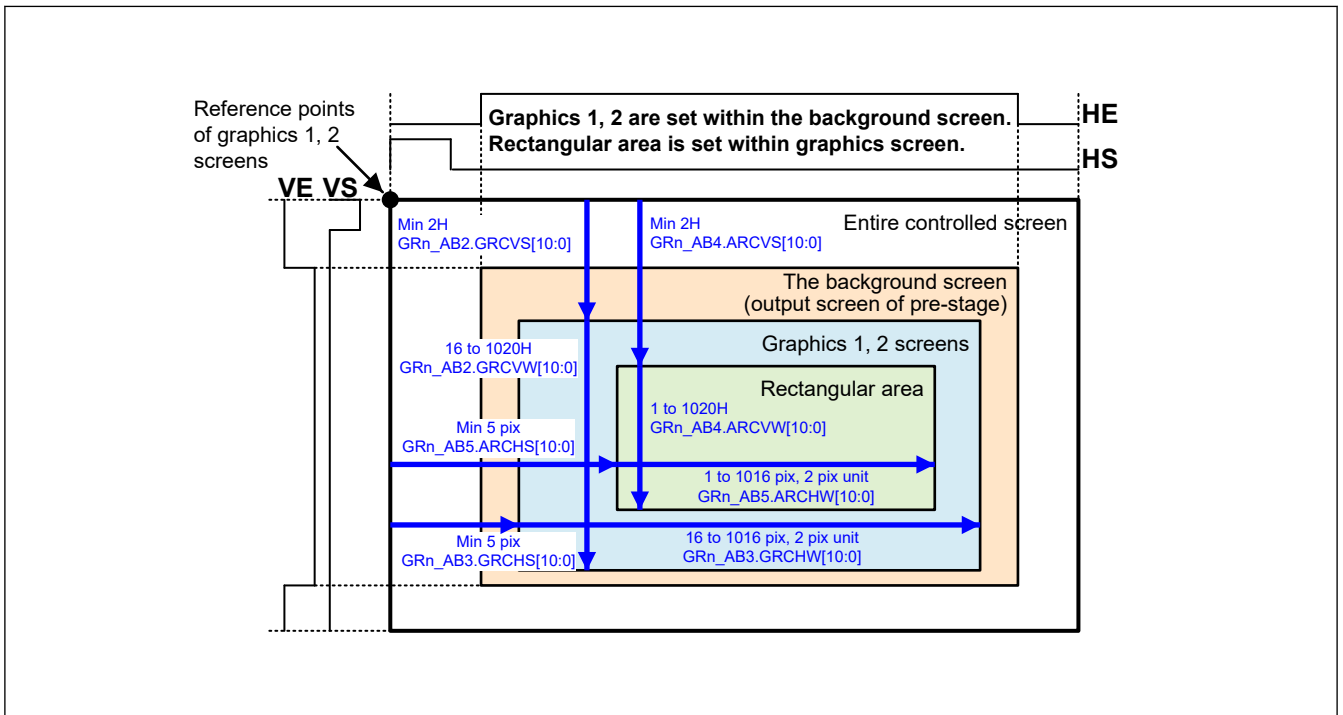

Figure 49.27 Definition of graphics 1 and 2 screens

49.3.3 Underflow and Interrupts

The GLCDC can detect the three types of status conditions described in this section. To detect each status condition, set the associated bit in the Status Detection Control Register (SYSCNT_DTCTEN) to 1.

49.3.3.1 Graphics 2 underflow detection

This function detects underflows in the graphics data interface block for graphics 2. The SYSCNT_STMON.L2UNDF flag sets to 1 if the graphics data cannot be read from the graphics data interface block (if valid data is not stored in the 4-stage ring buffer). The underflow is cleared as an internal state of graphics 2 on the VS (vertical synchronization) signal assertion of the previous stage. However, to clear the relevant bit in the Status Monitor Register of the system control block, the software must set the associated bit in the Status Clear Register to 1.

49.3.3.2 Graphics 1 underflow detection

This function detects underflows in the graphics data interface block for graphics 1. The SYSCNT_STMON.L1UNDF flag is set to 1 if the graphics data cannot be read from the graphics data interface block (if valid data is not stored in the 4-stage ring buffer). The underflow is cleared as an internal state of graphics 1 on the VS (vertical synchronization) signal assertion of the previous stage. However, to clear the relevant bit in the Status Monitor Register of the system control block, the software must set the associated bit in the Status Clear Register to 1.

49.3.3.3 Graphics 2 line detection

This function detects that the number of lines specified in the GR2_CLUTINT.LINE[10:0] bit was processed. The detection is performed on the HS (horizontal synchronization) signal assertion of the previous stage, not when valid pixels start to be processed. Each time the number of detected lines reach the value specified for graphics 2, the SYSCNT_STMON.VPOS flag sets to 1. As with underflow detection, to clear the relevant bit in the Status Monitor Register of the system control block, the software must set the associated bit in the Status Clear Register to 1.

49.3.3.4 Interrupts

The GLCDC provides three interrupt request output signals (GLCDC_L2UNDF, GLCDC_L1UNDF, and GLCDC_VPOS) that correspond to detection of the three status conditions. The GLCDC_L2UNDF, GLCDC_L1UNDF, and GLCDC_VPOS signals are associated with graphics 2 underflow detection, graphics 1 underflow detection, and graphics 2 line detection, respectively. Each of the interrupt request signals is asserted by setting the associated bit in the Interrupt Request Enable Register (SYSCNT_INTEN) to 1. Detecting the status and enabling the associated interrupt request can be controlled separately. Even if detection is enabled, the interrupt request signal is not asserted unless the interrupt request output signal is enabled. In addition, if the Status Monitor Register (SYSCNT_STMON) clears while the interrupt request output signal is asserted (the associated bit in the Status Clear Register (SYSCNT_STCLR) is set to 1), or if the associated bit in the Interrupt Request Enable Register (SYSCNT_INTEN) is cleared to 0, the interrupt request signal is negated. The interrupt request signal generation circuit is configured as shown in Figure 49.28. This circuit is glitch-free except for reset-induced glitches.

Figure 49.28 Interrupt request signal generation circuit

49.4 Usage notes

49.4.1 Module-stop function

GLCDC operation can be disabled or enabled using Module Stop Control Register C (MSTPCRC). The GLCDC module is initially stopped after reset. Releasing the module-stop state enables access to the registers. For details, see [section 10, Low Power Modes](#).

50. Internal Voltage Regulator

50.1 Overview

The MCU supports two power supply providing for core voltage (VDD):

- Switching regulator (DCDC)
- External power supply from external power device (External VDD)

Table 50.1 shows the specifications of Internal voltage regulator.

DCDC or External VDD is selected with the OFS setting.

- When OFS2.DCDCEN is 1, DCDC is selected (DCDC mode)
- When OFS2.DCDCEN is 0, External VDD is selected (External VDD mode)

Table 50.1 Power supply selection

OFS setting (OFS2.DCDCEN)	Power mode
1	DCDC mode
0	External VDD mode

50.2 Operation

50.2.1 DCDC mode

Table 50.2 lists the DCDC mode pin settings, and Figure 50.1 shows the DCDC mode settings.

In DCDC mode, VDD is supplied from VCL through VLO output and an external inductor and capacitor.

Table 50.2 DCDC mode pin settings

Pins	Setting descriptions
All VCC and VCC2 pins	<ul style="list-style-type: none"> • Connect each pin to the system power supply. • Connect each pin to VSS through a 0.1 μF multilayer ceramic capacitor. Place the capacitor close to the pin.
VCC_DCDC pins	<ul style="list-style-type: none"> • Connect the pin to the system power supply. • Connect the pin to VSS_DCDC through a 22 μF and 0.1-μF multilayer ceramic capacitor in parallel. Place the capacitor close to the pin.
VCL pins	<ul style="list-style-type: none"> • Connect each pin to VSS through a 0.22 μF multilayer ceramic capacitor. Place the capacitor close to the pin. • Connect each pin to an external inductor and capacitor. Place the inductor and capacitor close to the pin.(see Figure 50.1.)
All VLO pins	Connect each pin to an external inductor and capacitor. Place the 2.2- μ H inductor and 47 μ F capacitor close to the pin. This capacitor must be grounded to VSS_DCDC

Figure 50.1 DCDC mode setting

50.2.2 External VDD mode

Table 50.3 lists the external VDD mode pin settings, and Figure 50.2 shows the external VDD mode settings.

VDD is supplied from VCL pins.

Note: Low-speed mode, Software Standby mode, Deep Software Standby mode 1, 2, 3 and Battery Backup Function are not supported in this mode.

Table 50.3 Setting Descriptions for external VDD mode

Pins	Setting descriptions
All VCC and VCC2 pins	<ul style="list-style-type: none"> Connect each pin to the system power supply device for VCC. Connect each pin to VSS through a 0.1 μF multilayer ceramic capacitor. Place the capacitor close to the pin.
VCC_DCDC pins	<ul style="list-style-type: none"> Connect the pin to VSS_DCDC through 0.1 μF multilayer ceramic capacitor. Place the capacitor close to the pin.
VCL pins	<ul style="list-style-type: none"> Connect each pin to the system power supply device for VDD. Connect each pin to VSS through a 0.22 μF multilayer ceramic capacitor. Place the capacitor close to the pin.
All VLO pins	Keep pin open

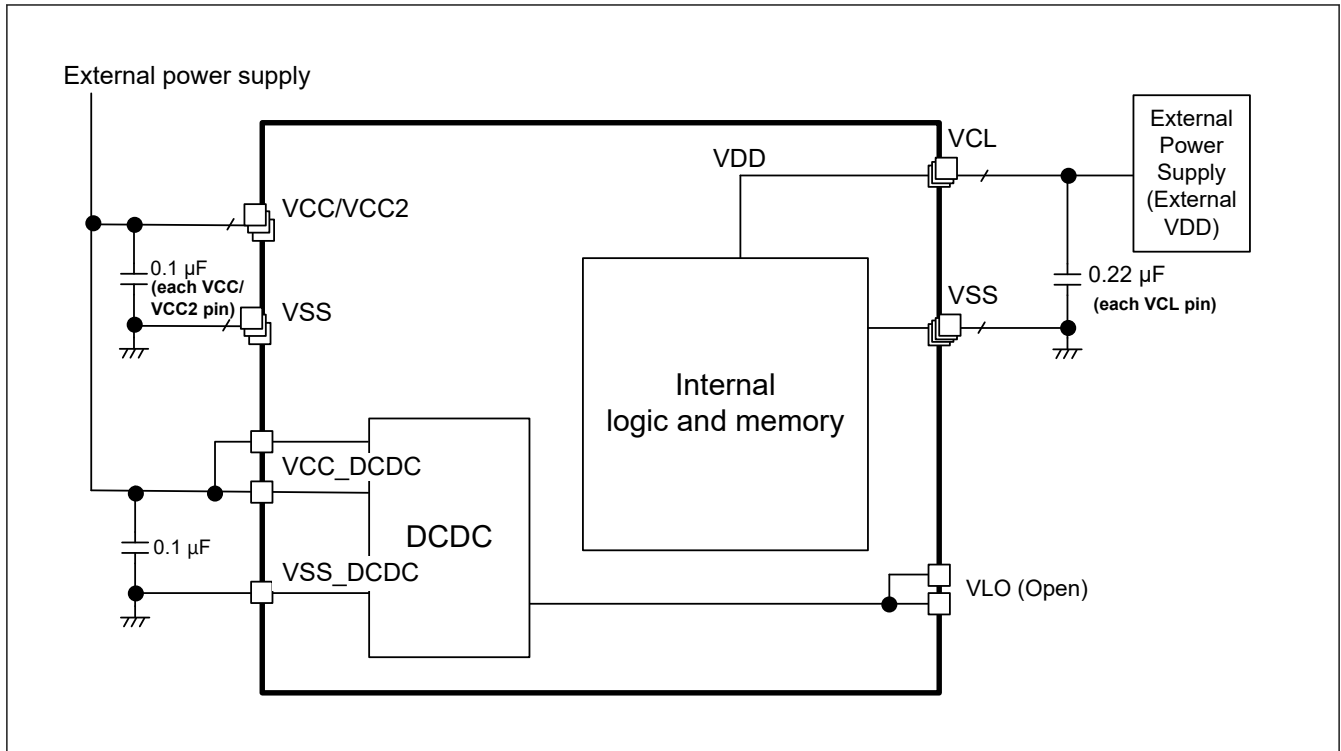

Figure 50.2 External VDD mode setting

In order to startup the device properly, use either of following procedure.

- VCL voltage must be raised 500 μs after VCC voltage is raised to minimum VCC voltage.
- Raise VCC voltage with RES pin is low, and release RES pin after 200 μs when VCL voltage is raised.

Figure 50.3 Power-up sequence of external VDD mode without using RES pin

Figure 50.4 Power-up sequence of external VDD mode with using RES pin

50.3 Usage Notes

In DCDC mode, to minimize power loss and maximize efficiency, Renesas recommends using a 2.2-μH inductor with a DC resistance of 100 mΩ or less. Short VCC and VCC_DCDC.

In external VDD mode, the voltage of VDD should always be below the voltage of VCC including the power-on and power-off sequence. Refer to the chapter of electrical characteristics for more information.

51. Electrical Characteristics

Unless otherwise specified, minimum and maximum values are guaranteed by either design simulation, characterization results or test in production.

Supported peripheral functions and pins differ from one product name to another.

Unless otherwise specified, the electrical characteristics of the MCU are defined under the following conditions:

- $VCC = VCC_DCDC = VCC_USB = VBATT = 1.68$ to 3.6 V
- $VCC2 = 1.65$ to 3.6 V
- $AVCC0 = 1.65$ to 3.6 V
- $VREFH0 = 2.7$ V to $AVCC0$
- $VREFH = 1.65$ V to $AVCC0$
- $VSS = VSS_DCDC = AVSS0 = VREFL0 / VREFL = VSS_USB = 0$ V
- VCC voltage is lower than 2.7 V : $LVOCR.LVO0E = 1$, otherwise $LVOCR.LVO0E = 0$
- $VCC2$ voltage is lower than 2.7 V : $LVOCR.LVO1E = 1$, otherwise $LVOCR.LVO1E = 0$
- $T_j = T_{opj}$

When not specified otherwise, typical values are measured at room temperature of 25 °C and $VCC = VCC_DCDC = VCC_USB = VBATT = AVCC0 = VREFH0 = VREFH = 3.3$ V.

Figure 51.1 shows the timing conditions.

Figure 51.1 Input or output timing measurement conditions

The recommended measurement conditions for the timing specification of each peripheral provided are for the best peripheral operation. Make sure to adjust the driving abilities of each pin to meet your conditions.

51.1 Absolute Maximum Ratings

Table 51.1 Absolute maximum ratings (1 of 2)

Parameter	Symbol	Value	Unit
Power supply voltage	$VCC, VCC2, VCC_DCDC, VCC_USB^{*2}$	-0.3 to +4.0	V
External power supply voltage	VCL	-0.3 to +1.6	V
VBATT power supply voltage	VBATT	-0.3 to +4.0	V

Table 51.1 Absolute maximum ratings (2 of 2)

Parameter	Symbol	Value	Unit
Input voltage (except for 5 V-tolerant ports*1)	V_{in}	-0.3 to VCC + 0.3 or -0.3 to VCC2 + 0.3	V
Input voltage (5 V-tolerant ports*1)	V_{in}	-0.3 to + VCC + 4.0 (max. 5.8)	V
Reference power supply voltage	VREFH/VREFH0	-0.3 to AVCC0 + 0.3	V
Analog power supply voltage	AVCC0	-0.3 to +4.0	V
Analog input voltage	V_{AN}	-0.3 to AVCC0 + 0.3	V
Operating junction temperature*3	T_{opj}	-40 to +105	°C
Storage temperature	T_{stg}	-55 to +125	°C

Note 1. Ports P205, P206, P402 to P404, P406 to P415, P511, P512, P709 to P715 and PB01 are 5 V tolerant.

Note 2. Connect VCC_DCDC and VCC_USB to VCC.

Note 3. See [section 51.2.1. Tj/Ta Definition](#).

Caution: Permanent damage to the MCU might result if absolute maximum ratings are exceeded.

Table 51.2 Recommended operating conditions

Parameter	Symbol	Min	Typ	Max	Unit	
Power supply voltages	VCC, VCC_DCDC	Other than the following	1.68	—	3.60	V
		When IIC Fast-mode+ is used	2.70	—	3.60	V
		When USB/SDRAM is used	3.00	—	3.60	V
	VCC2	1.65	—	3.60	V	
	VCL	When external VDD is used*2	1.20	—	1.25	V
		When DCDC is used (High-speed mode)	—	1.21	—	V
When DCDC is used (Low-speed mode or Software Standby mode)		—	1.18	—	V	
VSS, VSS_DCDC	—	0	—	V		
USB power supply voltages	VCC_USB	—	VCC	—	V	
	VSS_USB	—	0	—	V	
VBATT power supply voltage	VBATT	1.62	—	3.60	V	
Analog power supply voltages	AVCC0*1	When ADC is not used	1.65	—	3.60	V
		When ADC is used	2.70	—	3.60	V
	AVSS0	—	0	—	V	

Note 1. When the A/D converter, the D/A converter and the High-Speed Analog Comparator are not in use, do not leave the AVCC0, VREFH/VREFH0, AVSS0, and VREFL/VREFL0 pins open. Connect the AVCC0 and VREFH/VREFH0 pins to VCC, and the AVSS0 and VREFL/VREFL0 pins to VSS, respectively.

Note 2. VCL voltage must never be higher than VCC voltage.

51.2 DC Characteristics

51.2.1 Tj/Ta Definition

Table 51.3 DC characteristics

Parameter	Symbol	Typ	Max	Unit	Test conditions
Permissible operating junction temperature	T_j	—	105	°C	High-speed mode Low-speed mode

Note: Make sure that $T_j = T_a + \theta_{ja} \times \text{total power consumption (W)}$, where total power consumption = $(VCC - V_{OH}) \times \Sigma I_{OH} + V_{OL} \times \Sigma I_{OL} + (I_{CCmax} + I_{CC_DCDCmax}) \times VCC$.

Note: Minimum Ambient Temperature(T_a) is -40°C

51.2.2 I/O V_{IH} , V_{IL} Table 51.4 I/O V_{IH} , V_{IL} except for Schmitt trigger input pins

Parameter		VCC/VCC2/ AVCC0	Symbol	Min	Typ	Max	Unit
Peripheral function pins	EXTAL (external clock input), WAIT, SPI* ¹ (except RSPCK)	1.68 V or above	V_{IH}	$VCC \times 0.8$	—	—	V
			V_{IL}	—	—	$VCC \times 0.2$	
	SPI* ² (except RSPCKB_A)	1.65 V or above	V_{IH}	$VCC2 \times 0.8$	—	—	
			V_{IL}	—	—	$VCC2 \times 0.2$	
	OSPI (except OM_RSTO1 and OM_ECSINT1)	2.70 V or above	V_{IH}	$VCC2 \times 0.8$	—	—	
			V_{IL}	—	—	$VCC2 \times 0.2$	
		1.65 V or above	V_{IH}	$VCC2 \times 0.7$	—	$VCC2 + 0.3$	
			V_{IL}	$VSS - 0.3$	—	$VCC2 \times 0.3$	
	D00 to D15, TMS, TDI, TCK, SWDIO, SWCLK	1.68 V or above	V_{IH}	$VCC \times 0.7$	—	—	
			V_{IL}	—	—	$VCC \times 0.3$	
	DQ00 to DQ15	3.00 V or above	V_{IH}	$VCC \times 0.7$	—	—	
			V_{IL}	—	—	$VCC \times 0.3$	
	IIC (SMBus)	2.70 V or above	V_{IH}	2.1	—	$VCC + 3.6$ (max 5.8)	
			V_{IL}	—	—	0.8	
RTCIC0, RTCIC1, RTCIC2, EXCIN when VCC power supply is selected	1.68 V or above	V_{IH}	0.9	—	3.9		
		V_{IL}	—	—	0.3		
RTCIC0, RTCIC1, RTCIC2, EXCIN when VBATT power supply is selected	1.68 V or above	V_{IH}	0.9	—	3.9		
		V_{IL}	—	—	0.3		

Note 1. SPI0_A, SPI0_B, SPI0_C and SPI1_B

Note 2. SPI1_A

Note 3. RES and peripheral function pins associated with P205, P206, P402 to P404, P406 to P415, P511, P512, P709 to P715, PB01 (total 26 pins).

Note 4. All input pins except for the peripheral function pins already described in the table. There is an item for each power supply voltage for each port. Refer to the IO chapter for the power supply of the port.

Note 5. P205, P206, P402 to P404, P406 to P415, P511, P512, P709 to P715, PB01 (total 25 pins).

Note 6. All input pins except for the ports already described in the table. There is an item for each power supply voltage for each port. Refer to the IO chapter for the power supply of the port.

Note 7. When VCC is less than 1.68 V, the input voltage of 5 V-tolerant ports should be less than 3.6 V, otherwise breakdown may occur because 5 V-tolerant ports are electrically controlled so as not to violate the break down voltage.

Table 51.5 I/O V_{IH} , V_{IL} of Schmitt trigger input pins

Parameter		VCC/VCC2/ AVCC0	Symbol	Min	Typ	Max	Unit

		VCC and VCC2 I/O	1.65 V or above	ΣI _{OL} (max)	—	—	80	mA	
		AVCC0 I/O	1.65 V or above		—	—	33		

- Note 1. This is the value when low driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability except for 400 and P401 is retained in Deep Software Standby mode.
- Note 2. This is the value when middle driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability except for 400 and P401 is retained in Deep Software Standby mode.
- Note 3. This is the value when high driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability except for 400 and P401 is retained in Deep Software Standby mode.
- Note 4. This is the value when high-speed high driving ability is selected in the Port Drive Capability in the PmnPFS register. The selected driving ability is retained in Deep Software Standby mode.
- Note 5. Except for P200, which is an input port.

Caution: To protect the reliability of the MCU, the output current values should not exceed the values in this table. The average output current indicates the average value of current measured during 100 μs.

51.2.4 I/O V_{OH} , V_{OL} , and Other Characteristics

Table 51.7 I/O V_{OH} , V_{OL} , and other characteristics (1 of 2)

Parameter		VCC/VCC2/ AVCC0	Symbol	Min	Typ	Max	Unit	Test conditions
Output voltage	IIC	2.70 V or above	V_{OL}	—	—	0.4	V	$I_{OL} = 3.0 \text{ mA}$
			V_{OL}	—	—	0.6		$I_{OL} = 6.0 \text{ mA}$
		1.68 V or above	V_{OL}	—	—	$VCC \times 0.2$		$I_{OL} = 3.0 \text{ mA}$
			V_{OL}	—	—	0.6		$I_{OL} = 6.0 \text{ mA}$
	IIC*1	2.70 V or above	V_{OL}	—	—	0.4		$I_{OL} = 15.0 \text{ mA}$ (ICFER.FMPE = 1)
			V_{OL}	—	0.4	—		$I_{OL} = 20.0 \text{ mA}$ (ICFER.FMPE = 1)
	Ports P205, P206, P402 to P404, P406 to P415, P511, P512, P709 to P715, PA09, PB01 (total 26 pins)*2	—	V_{OH}	$VCC - 1.0$	—	—		$I_{OH} = -20 \text{ mA}$ $VCC = 3.3 \text{ V}$
		—	V_{OL}	—	—	1		$I_{OL} = 20 \text{ mA}$ $VCC = 3.3 \text{ V}$
	Other output pins	1.68 V or above	V_{OH}	$VCC - 0.5$	—	—		$I_{OH} = -1.0 \text{ mA}$
			V_{OL}	—	—	0.5		$I_{OL} = 1.0 \text{ mA}$
		1.65V or above	V_{OH}	$VCC2 - 0.5$	—	—		$I_{OH} = -1.0 \text{ mA}$
			V_{OL}	—	—	0.5		$I_{OL} = 1.0 \text{ mA}$
V_{OH}		$AVCC0 - 0.5$	—	—	—	$I_{OH} = -1.0 \text{ mA}$		
V_{OL}		—	—	—	0.5	$I_{OL} = 1.0 \text{ mA}$

		1.65 V or above		-300	—	-5		$VCC2, AVCC0 = 1.65 \text{ to } 3.6 \text{ V}$ $V_{in} = 0 \text{ V}$

Table 51.7 I/O V_{OH} , V_{OL} , and other characteristics (2 of 2)

Parameter		VCC/VCC2/ AVCC0	Symbol	Min	Typ	Max	Unit	Test conditions
Input capacitance	Ports P014, P015	—	C_{in}	—	—	16	pF	Vbias = 0 V Vamp = 20 mV f = 1 MHz Ta = 25°C
	Ports P814/ USB_DP, P815/ USB_DM	—		—	—	12		
	Ports P400, P401, P409, P410, P511, P512	—		—	—	10		
	Other input pins	—		—	—	8		

Note 1. SCL0_A, SDA0_A, SCL1_A, SDA1_A (total 4 pins).

Note 2. This is the value when high driving ability is selected in the Port Drive Capability bit in the PmnPFS register. The selected driving ability is retained in Deep Software Standby mode.

51.2.5 Operating and Standby Current

Figure 51.2 Consumption current measurement diagram

Table 51.8 Current of high-speed mode, maximum condition (MVE and peripheral operation) (DCDC mode)

Parameter		Symbol	Typ	Max	Unit	Test conditions			
Supply current *1*2	—	I_{CC}	2.8	7.05	mA				
	CPUCLK = 480 MHz	$V_{CC_DCDC} \geq 2.5\text{ V}$	$I_{CC_DCDC}^{*5}$	170	303	mA	$V_{CC_DCDC} = 3.3\text{ V}$ CPUCLK = 480 MHz, ICLK = 240 MHz, PCLKA = 120 MHz, PCLKB = 60 MHz, PCLKC = 60 MHz, PCLKD = 120 MHz, PCLKE = 240 MHz, FCLK = 60 MHz, BCLK = 120 MHz		
			I_{DD}^{*3}	398	624				
		$V_{CC_DCDC} < 2.5\text{ V}$	$I_{CC_DCDC}^{*5}$	311	320			mA	$V_{CC_DCDC} = 1.8\text{ V}$
			I_{DD}	398	400 ^{*4}				
	CPUCLK = 400 MHz	$V_{CC_DCDC} \geq 2.5\text{ V}$	$I_{CC_DCDC}^{*5}$	142	267	mA	$V_{CC_DCDC} = 3.3\text{ V}$ CPUCLK = 400 MHz, ICLK = 200 MHz, PCLKA = 100 MHz, PCLKB = 50 MHz, PCLKC = 50 MHz, PCLKD = 100 MHz, PCLKE = 100 MHz, FCLK = 50 MHz, BCLK = 100 MHz		
			I_{DD}^{*3}	333	550				
		$V_{CC_DCDC} < 2.5\text{ V}$	$I_{CC_DCDC}^{*5}$	260	320			mA	$V_{CC_DCDC} = 1.8\text{ V}$
			I_{DD}	333	400 ^{*4}				
	CPUCLK = 360 MHz	$V_{CC_DCDC} \geq 2.5\text{ V}$	$I_{CC_DCDC}^{*5}$	133	257	mA	$V_{CC_DCDC} = 3.3\text{ V}$ CPUCLK = 360 MHz, ICLK = 120 MHz, PCLKA = 120 MHz, PCLKB = 60 MHz, PCLKC = 60 MHz, PCLKD = 120 MHz, PCLKE = 120 MHz, FCLK = 60 MHz, BCLK = 120 MHz		
			I_{DD}^{*3}	311	530				
		$V_{CC_DCDC} < 2.5\text{ V}$	$I_{CC_DCDC}^{*5}$	243	320			mA	$V_{CC_DCDC} = 1.8\text{ V}$
I_{DD}			311	400 ^{*4}					
CPUCLK = 240 MHz	$V_{CC_DCDC} \geq 2.5\text{ V}$	$I_{CC_DCDC}^{*5}$	106	224	mA	$V_{CC_DCDC} = 3.3\text{ V}$ CPUCLK = 240 MHz, ICLK = 240 MHz, PCLKA = 120 MHz, PCLKB = 60 MHz, PCLKC = 60 MHz, PCLKD = 120 MHz, PCLKE = 120 MHz, FCLK = 60 MHz, BCLK = 120 MHz			
		I_{DD}^{*3}	248	460					
	$V_{CC_DCDC} < 2.5\text{ V}$	$I_{CC_DCDC}^{*5}$	194	320			mA	$V_{CC_DCDC} = 1.8\text{ V}$	
		I_{DD}	248	400 ^{*4}					

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. Measured with clocks supplied to the peripheral functions and peripherals being operated. This does not include the BGO operation.

Note 3. I_{DD} depends on f (CPUCLK and ICLK) as follows.

$$I_{DD} \text{ Max.} = 0.68 \times f \text{ CPUCLK} + 0.51 \times f \text{ ICLK} + 180 \text{ (unit : mA, fCPUCLK and fICLK are MHz)}$$

Note 4. Do not actual consumption current during operation exceed the current value described here in $V_{CC_DCDC} < 2.5\text{V}$.

Note 5. Typical DCDC efficiency is applied.

Table 51.9 Current of high-speed mode, maximum condition (MVE and peripheral operation) (External VDD mode)

Parameter	CPUCLK Frequency	Symbol	Typ	Max	Unit	Test conditions
Supply current ^{*1} ^{*2}	—	I _{CC}	2.8	7.05	mA	
	CPUCLK = 480 MHz	I _{DD} ^{*3}	398	624	mA	CPUCLK = 480 MHz, ICLK = 240 MHz, PCLKA = 120 MHz, PCLKB = 60 MHz, PCLKC = 60 MHz, PCLKD = 120 MHz, PCLKE = 240 MHz, FCLK = 60 MHz, BCLK = 120 MHz
	CPUCLK = 400 MHz	I _{DD} ^{*3}	333	550	mA	CPUCLK = 400 MHz, ICLK = 200 MHz, PCLKA = 100 MHz, PCLKB = 50 MHz, PCLKC = 50 MHz, PCLKD = 100 MHz, PCLKE = 100 MHz, FCLK = 50 MHz, BCLK = 100 MHz
	CPUCLK = 360 MHz	I _{DD} ^{*3}	311	530	mA	CPUCLK = 360 MHz, ICLK = 120 MHz, PCLKA = 120 MHz, PCLKB = 60 MHz, PCLKC = 60 MHz, PCLKD = 120 MHz, PCLKE = 120 MHz, FCLK = 60 MHz, BCLK = 120 MHz
	CPUCLK = 240 MHz	I _{DD} ^{*3}	248	460	mA	CPUCLK = 240 MHz, ICLK = 240 MHz, PCLKA = 120 MHz, PCLKB = 60 MHz, PCLKC = 60 MHz, PCLKD = 120 MHz, PCLKE = 120 MHz, FCLK = 60 MHz, BCLK = 120 MHz

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. Measured with clocks supplied to the peripheral functions and peripherals being operated. This does not include the BGO operation.

Note 3. I_{DD} depends on f (CPUCLK and ICLK) as follows.

$$I_{DD} \text{ Max.} = 0.68 \times f \text{ CPUCLK} + 0.51 \times f \text{ ICLK} + 180 \text{ (unit : mA, fCPUCLK and fICLK are MHz)}$$

Table 51.10 Current of high-speed mode, maximum data processing (MVE operation), peripheral clock ON (DCDC mode)

Parameter	CPUCLK	Symbol	Typ	Max	Unit	Test conditions
Supply current ^{*1} ^{*2}	CPUCLK = 480 MHz	I _{CC_DCDC} ^{*4}	156	276	mA	V _{CC_DCDC} = 3.3 V ^{*5}
		I _{DD} ^{*3}	366	568		
	CPUCLK = 400 MHz	I _{CC_DCDC} ^{*4}	131	246		
		I _{DD} ^{*3}	308	506		
	CPUCLK = 360 MHz	I _{CC_DCDC} ^{*4}	121	232		
		I _{DD} ^{*3}	283	478		
	CPUCLK = 240 MHz	I _{CC_DCDC} ^{*4}	94	198		
		I _{DD} ^{*3}	220	408		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. Measured with clocks supplied to the peripheral functions and peripherals being operated. This does not include the BGO operation.

Note 3. I_{DD} depends on f (CPUCLK and ICLK) as follows.

$$I_{DD} \text{ Max.} = 0.67 \times f \text{ CPUCLK} + 0.30 \times f \text{ ICLK} + 180 \text{ (unit : mA, fCPUCLK and fICLK are MHz)}$$

Note 4. Typical DCDC efficiency is applied.

Note 5. Same frequency condition is applied as in the maximum condition.

Table 51.11 Current of high-speed mode, maximum data processing (MVE operation), peripheral clock ON (External VDD mode)

Parameter	Symbol	Typ	Max	Unit	Test conditions	
Supply current ^{*1*2}	CPUCLK = 480 MHz	I_{DD}^{*3}	366	568	mA	*4
	CPUCLK = 400 MHz	I_{DD}^{*3}	308	506		
	CPUCLK = 360 MHz	I_{DD}^{*3}	283	478		
	CPUCLK = 240 MHz	I_{DD}^{*3}	220	408		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. Measured with clocks supplied to the peripheral functions and peripherals being operated. This does not include the BGO operation.

Note 3. I_{DD} depends on f (CPUCLK and ICLK) as follows.

$$I_{DD} \text{ Max.} = 0.67 \times f \text{ CPUCLK} + 0.30 \times f \text{ ICLK} + 180 \text{ (unit : mA, fCPUCLK and fICLK are MHz)}$$

Note 4. Same frequency condition is applied as in the maximum condition.

Table 51.12 Current of high-speed mode, maximum data processing (MVE operation), peripheral clock OFF (DCDC mode)

Parameter	Symbol	Typ	Max	Unit	Test conditions	
Supply current ^{*1*2}	CPUCLK = 480 MHz	$I_{CC_DCDC}^{*4}$	146	263	mA	VCC_DCDC = 3.3 V *5
		I_{DD}^{*3}	342	541		
	CPUCLK = 400 MHz	$I_{CC_DCDC}^{*4}$	123	235		
		I_{DD}^{*3}	289	483		
	CPUCLK = 360 MHz	$I_{CC_DCDC}^{*4}$	111	219		
		I_{DD}^{*3}	261	450		
	CPUCLK = 240 MHz	$I_{CC_DCDC}^{*4}$	83	184		
		I_{DD}^{*3}	194	378		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.

Note 3. I_{DD} depends on f (CPUCLK and ICLK) as follows.

$$I_{DD} \text{ Max.} = 0.68 \times f \text{ CPUCLK} + 0.17 \times f \text{ ICLK} + 180 \text{ (unit : mA, fCPUCLK and fICLK are MHz)}$$

Note 4. Typical DCDC efficiency is applied.

Note 5. Same frequency condition is applied as in the maximum condition.

Table 51.13 Current of high-speed mode, maximum data processing (MVE operation), peripheral clock OFF (External VDD mode)

Parameter	Symbol	Typ	Max	Unit	Test conditions	
Supply current ^{*1*2}	CPUCLK = 480 MHz	I_{DD}^{*3}	342	541	mA	*4
	CPUCLK = 400 MHz	I_{DD}^{*3}	289	483		
	CPUCLK = 360 MHz	I_{DD}^{*3}	261	450		
	CPUCLK = 240 MHz	I_{DD}^{*3}	194	378		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.

Note 3. I_{DD} depends on f (CPUCLK and ICLK) as follows.

$$I_{DD} \text{ Max.} = 0.68 \times f \text{ CPUCLK} + 0.17 \times f \text{ ICLK} + 180 \text{ (unit : mA, fCPUCLK and fICLK are MHz)}$$

Note 4. Same frequency condition is applied as in the maximum condition.

Table 51.14 Current of high-speed mode, CPU Sleep mode (DCDC mode and External VDD mode)

Parameter		Symbol	Typ	Max	Unit	Test conditions
Supply current ^{*1*3*4}	CPUCLK = 240 MHz	I_{DD}^{*2}	29	221	mA	—

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. I_{DD} depends on f (CPUCLK and ICLK) as follows.

I_{DD} Typ. (25°C) = $0.063 \times f \text{ CPUCLK} + 0.13 \times f \text{ ICLK} + 17.6$ (unit : mA, fCPUCLK and fICLK are MHz)

I_{DD} Max. = $0.063 \times f \text{ CPUCLK} + 0.13 \times f \text{ ICLK} + 180$ (unit : mA, fCPUCLK and fICLK are MHz)

Note 3. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.

Note 4. ICLK, FCLK, BCLK, PCLKA, PCLKB, PCLKC, PCLKD and PCLKE are set to divided by 64.

Table 51.15 Current of high-speed mode, CPU Deep Sleep mode (DCDC mode and External VDD mode)

Parameter		Symbol	Typ	Max	Unit	Test conditions
Supply current ^{*1*3*4}	CPUCLK = 240 MHz	I_{DD}^{*2}	12	90	mA	—

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. I_{DD} depends on f (ICLK) as follows.

I_{DD} Typ. (25°C) = $0.13 \times f \text{ ICLK} + 5.3$ (unit : mA, fCPUCLK and fICLK are MHz)

I_{DD} Max. = $0.13 \times f \text{ ICLK} + 72$ (unit : mA, fCPUCLK and fICLK are MHz)

Note 3. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.

Note 4. ICLK, FCLK, BCLK, PCLKA, PCLKB, PCLKC, PCLKD and PCLKE are set to divided by 64.

Table 51.16 Increase during BGO operation (DCDC mode and External VDD mode)

Parameter		Symbol	Typ	Max	Unit	Test conditions
Supply current ^{*1}	Data flash P/E	I_{CC}	6	—	mA	—
	Code flash P/E		8	—		

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Table 51.17 Current of Low-speed mode (DCDC mode)

Parameter	Symbol	Typ	Max	Unit	Test conditions
Supply current ^{*1*2*3}	I_{DD}	14.5	—	mA	CPUCLK = ICLK = 1MHz Graphics power domain is off

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.

Note 3. FCLK, BCLK, PCLKA, PCLKB, PCLKC, PCLKD and PCLKE are set to divided by 64 (15.6 kHz).

Table 51.18 Standby current (DCDC mode)

Parameter	Symbol	Typ	Max	Unit	Test conditions		
Supply current*1	Software Standby mode*2		I _{CC}	0.02	0.94	mA	—
	Data of SRAM and TCM is retained		I _{CC_DCDC}	0.88	28.29		VCC_DCDC = 3.3 V PDRAMSCR0.RKEEPn = 1 (n = 0 to 6) PDRAMSCR1.RKEEP0 = 1
	Data of SRAM and TCM is not retained		I _{CC_DCDC}	0.83	26.64		VCC_DCDC = 3.3 V PDRAMSCR0.RKEEPn = 0 (n = 0 to 6) PDRAMSCR1.RKEEP0 = 0
	Deep Software Standby mode 1		I _{CC}	5.21	148	μA	—
			I _{CC_DCDC}	0.57	5.50		—
	Increase when the function is activated	Data of Standby SRAM is retained	I _{CC}	0.12	2.60		—
		PVD0, PVD1,PVD2 or Battery power supply switch		See Table 51.20			—
		When the LOCO is in use		3.10	—		—
		Crystal oscillator and RTC		See Table 51.21			—
	Deep Software Standby mode 2		I _{CC}	1.68	43.99	μA	—
		I _{CC_DCDC}	0.57	5.50	—		
Increase when the function is activated	PVD0, PVD1,PVD2 or Battery power supply switch	I _{CC}	See Table 51.20		—		
	Crystal oscillator and RTC		See Table 51.21		—		
Deep Software Standby mode 3		I _{CC}	0.99	42.90	μA	—	
		I _{CC_DCDC}	0.57	5.50		—	
Increase when the function is activated	Crystal oscillator and RTC	See Table 51.21		—			
RTC operating while VCC is off (with the battery backup function, only the RTC operate)	When a crystal oscillator with low power mode 3 is in use	I _{VBAT}	0.52	—	VBATT=1.8 V, VCC=0 V		
			1.05	—	VBATT=3.3 V, VCC=0 V		
	When a crystal oscillator with low power mode 2 is in use		0.56	—	VBATT=1.8 V, VCC=0 V		
			1.10	—	VBATT=3.3 V, VCC=0 V		
	When a crystal oscillator with low power mode 1 is in use		0.62	—	VBATT=1.8 V, VCC=0V		
			1.17	—	VBATT=3.3 V, VCC=0 V		
	When a crystal oscillator with standard mode is in use		0.93	—	VBATT=1.8 V, VCC=0 V		
			1.50	—	VBATT=3.3 V, VCC=0 V		
	When EXCIN is in use		0.37	—	VBATT=1.8 V, VCC=0 V		
			0.86	—	VBATT=3.3 V, VCC=0 V		
Increase when the function is activated		Common circuit when using RTCICn (n = 0~2) input or EXCIN	0.04	—	VBATT=1.8 V, VCC=0 V		
		0.04	—	VBATT=3.3 V, VCC=0 V			
	RTCICn (n = 0~2) input is in use per channel	0.02	—	VBATT=1.8 V, VCC=0 V			
		0.02	—	VBATT=3.3 V, VCC=0 V			

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. When an external clock is used, EXTAL pin is pull-up or pull-down. In case clock is toggled, software standby mode current consumption is increased by 130μA at 48MHz under typical conditions.

Table 51.19 Coremark and normal mode current (DCDC and External power supply mode)

Parameter			Symbol	Typ	Max	Unit	Test conditions		
Supply current ^{*1*2}	Coremark	Cache on	I _{DD}	318	—	μA/MHz	CPUCLK = 480 MHz ICLK = 240 MHz PCLKA = 7.5 MHz PCLKB = 7.5 MHz PCLKC = 7.5 MHz PCLKD = 7.5 MHz PCLKE = 7.5 MHz FCLK = 7.5 MHz BCLK = 7.5 MHz		
		Cache off, executing from ITCM		281	—				
		Cache off, executing from SRAM		178	—				
		Cache off, executing from flash		169	—				
	Normal mode	All peripheral disabled, Cache on, while (1) code		223	—				
		All peripheral disabled, Cache off, while (1) code executing from flash		138	—				
	Coremark	Cache off, executing from flash		165	—			μA/MHz	CPUCLK = 360 MHz ICLK = 120 MHz PCLKA = 30 MHz PCLKB = 30 MHz PCLKC = 30 MHz PCLKD = 30 MHz PCLKE = 30 MHz FCLK = 30 MHz BCLK = 30 MHz
	Normal mode	All peripheral disabled, Cache off, while (1) code executing from flash		137	—				

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. Supply of the clock signal to peripherals is stopped in this state. This does not include the BGO operation.

Table 51.20 Increase when the PVD0, PVD1, PVD2 or Battery power supply switch is enabled in Deep Software Standby mode 1 and 2.

Parameter		Symbol	Typ	Max	Unit	Test conditions
Supply current	Common circuit when enabling PVDn (n = 0 to 2) or Battery power supply switch in Deep Software Standby mode 1	I _{CC}	4.51	—	μA	—
	Common circuit when enabling PVDn (n = 0 to 2) or Battery power supply switch in Deep Software Standby mode 2		4.97	—		—
	PVD0 enabled with OFS1(_SEC).PVDLPSEL = 1		2.16	—		—
	PVD1 enabled		2.16	—		—
	PVD2 enabled		2.16	—		—
	Battery power supply switch enabled with following conditions.*1		2.16	—		—

Note 1. Consumption current is not increased in other condition.

Table 51.21 Increase when the sub-clock oscillator and RTC are enabled in Deep Software Standby mode 1, 2 and 3.

Parameter			Symbol	Typ	Max	Unit	Test conditions
Supply current	When a crystal oscillator is in use	Low Power mode 3	I _{CC}	0.22	—	μA	—
		Low Power mode 2		0.27	—		—

Figure 51.4 Temperature dependency in Software Standby mode (I_{cc_DcDc}) (reference data)

Figure 51.5 Temperature dependency in Deep Software Standby mode 1 (reference data)

Figure 51.6 Temperature dependency in Deep Software Standby mode 2 (reference data)

Figure 51.7 Temperature dependency in Deep Software Standby mode 3 (reference data)

Figure 51.8 Software Standby current per SRAM state (reference data)

The more practical I_{CC_DCDC} value can be obtained with the following formula.

$$I_{CC_DCDC} = I_{DD} \times (V_{CL} \div V_{CC}) \div \text{efficiency}$$

Where: V_{CL} and V_{CC} are the voltage of V_{CL} pin and V_{CC} pin respectively, and efficiency is shown in the following figures.

Figure 51.9 Typical DCDC efficiency (%) vs load current (A) in High-speed mode , Tj = 25°C

Figure 51.10 Typical DCDC efficiency (%) vs load current (A) in High-speed mode , Tj = 105°C

Figure 51.11 Typical DCDC efficiency (%) vs load current (A) in Low-speed mode and Software Standby mode, Tj = 25°C

Figure 51.12 Typical DCDC efficiency (%) vs load current (A) in Low-speed mode and Software Standby mode, Tj = 105°C

Note: DCDC efficiency is obtained based on the VCC_DCDC current.

51.2.6 VCC Rise and Fall Gradient and Ripple Frequency

Table 51.24 VCC rise and fall gradient characteristics at power on/off

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions	
VCC rising gradient at power on ^{*1}	SrVCC	0.0084	—	20	ms/V	—	
VCC falling gradient at power off	VBATT function is disabled ^{*1}	SfVCC1	0.0084	—	—	ms/V	—
	VBATT function is enabled	SfVCC2	1.0000	—	—	—	—

Note 1. In case the VCC voltage crosses V_{POR1} .

Table 51.25 VCC ripple frequency and gradient characteristics during operation

The ripple voltage must meet the allowable ripple frequency $f_{r(VCC)}$ within the range between the VCC upper limit (3.6 V) and lower limit (1.68 V). When the VCC change exceeds $VCC \pm 10\%$, the allowable voltage change rising and falling gradient $dt/dVCC$ must be met.

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions
Allowable ripple frequency	$f_{r(VCC)}$	—	—	10.0	kHz	Figure 51.13 $V_{r(VCC)} \leq VCC \times 0.2$
		—	—	1.0	MHz	Figure 51.13 $V_{r(VCC)} \leq VCC \times 0.08$
		—	—	10.0	MHz	Figure 51.13 $V_{r(VCC)} \leq VCC \times 0.06$
Allowable voltage change rising and falling gradient	$dt/dVCC^{*1}$	1.0	—	—	ms/V	When VCC change exceeds $VCC \pm 10\%$

Note 1. In case the VCC voltage does not cross V_{POR1} .

Figure 51.13 Ripple waveform

Figure 51.14 VCC rising and falling waveform

51.2.7 Thermal Characteristics

Maximum value of junction temperature (T_j) must not exceed the value of [section 51.2.1. \$T_j/T_a\$ Definition.](#)

T_j is calculated by either of the following equations.

- $T_j = T_a + \theta_{ja} \times \text{Total power consumption}$
- $T_j = T_t + \Psi_{jt} \times \text{Total power consumption}$
 - T_j : Junction Temperature ($^{\circ}\text{C}$)
 - T_a : Ambient Temperature ($^{\circ}\text{C}$)
 - T_t : Top Center Case Temperature ($^{\circ}\text{C}$)
 - θ_{ja} : Thermal Resistance of “Junction”-to-“Ambient” ($^{\circ}\text{C}/\text{W}$)
 - Ψ_{jt} : Thermal Resistance of “Junction”-to-“Top Center Case” ($^{\circ}\text{C}/\text{W}$)
- Total power consumption = Voltage \times (Leakage current + Dynamic current)
- Leakage current of IO = $\sum (I_{OL} \times V_{OL}) / \text{Voltage} + \sum (|I_{OH}| \times |V_{CC} - V_{OH}|) / \text{Voltage}$
- Dynamic current of IO = $\sum IO (C_{in} + C_{load}) \times \text{IO switching frequency} \times \text{Voltage}$
 - C_{in} : Input capacitance
 - C_{load} : Output capacitance

Regarding θ_{ja} and Ψ_{jt} , see [Table 51.26](#).

Table 51.26 Thermal Resistance

Parameter	Package	Symbol	Value*1	Unit	Test conditions
Thermal Resistance	224-pin BGA (PLBG0224GD-A)	θ_{ja}	21.5	$^{\circ}\text{C}/\text{W}$	JESD 51-2 and 51-9 compliant
	224-pin BGA (PLBG0224GD-A)	Ψ_{jt}	0.24	$^{\circ}\text{C}/\text{W}$	JESD 51-2 and 51-9 compliant

Note 1. The values are reference values when the 4-layer board is used. Thermal resistance depends on the number of layers or size of the board. For details, see the JEDEC standards.

51.2.7.1 Calculation guide of maximum current

Table 51.27 Power consumption of each unit (1 of 2)

Dynamic current/ Leakage current	MCU Domain	Category	Item	Symbol	Frequency [MHz]	Current [μ A/MHz]	Current*1 [mA]	Condition		
Leakage current	Analog	Regulator and Leak*1	Tj = 95°C	I _{CC}	—	—	0.54	—

			DOC	120	0.427	0.051				
		System	CAC	60	0.738	0.044	—			
		DMA	DMAC (per 1ch)	240	9.012	2.163	—			
			DTC	240	11.175	2.682				
		FSBL operation					240	—	93.4	—
							120	—	72.9	—

Note 1. Regulator and Leak are Internal voltage regulator's current and MCU's leakage current. It is selected according to the temperature of T_j.

Note 2. To determine the current consumption per channel or unit, divide Current [mA] by the number of channels, groups or units.

Table 51.28 Outline of operation for each unit (1 of 2)

Peripheral	Outline of operation
RTC	RTC is operating with LOCO.
GPT	Operating modes is set to saw-wave PWM mode.
POEG	Only clear module stop bit.
AGT	AGT is operating with PCLKB.
ULPT	ULPT is operating with LOCO.
WDT	WDT is operating with PCLKB.
IWDT	IWDT is operating with IWDTCLK.
USBFS	Transfer types is set to bulk transfer. USBFS is operating using Full-speed transfer (12 Mbps).
SCI	SCI is transmitting data in clock synchronous mode.
IIC	Communication format is set to I2C-bus format. IIC is transmitting data in master mode.
CANFD	CANFD is transmitting and receiving data in self-test mode 1.

Table 51.28 Outline of operation for each unit (2 of 2)

Peripheral	Outline of operation
SPI	SPI mode is set to SPI operation (4-wire method). SPI master/slave mode is set to master mode. SPI is transmitting 32-bit width data.
OSPI	OSPI is issuing memory write command to HyperRAM.
SSIE	Communication mode is set to Master. System word length is set to 32 bits. Data word length is set to 20 bits. SSIE is transmitting data using I2S format.
ADC	Resolution is set to 12-bit accuracy. Data registers is set to A/D-converted value addition mode. ADC12 is converting the analog input in continuous scan mode.
DAC12	DAC12 is outputting the conversion result while updating the value of data register.
TSN	TSN is operating.
ACMPHS	ACMPHS is operating.
GLCDC	GLCDC is operating after writing data to CLUT.
DRW	DRW is doing rendering operation after sending data from SDRAM.
ELC	Only clear module stop bit.
RSIP-E51A	RSIP is doing self-test operation.
CRC	CRC is generating CRC code using 32-bit CRC32-C polynomial.
DOC	DOC is operating in data comparison mode.
CAC	Measurement target clocks is set to PCLKB. Measurement reference clocks is set to PCLKB. CAC is measuring the clock frequency accuracy.
DMAC	Bit length of transfer data is set to 32 bits. Transfer mode is set to block transfer mode. DMAC is transferring data from SRAM0 to SRAM0.
DTC	Bit length of transfer data is set to 32 bits. Transfer mode is set to block transfer mode. DTC is transferring data from SRAM0 to SRAM0.

51.2.7.2 Example of Tj calculation

Assumption :

- Package 224-pin BGA : $\theta_{ja} = 21.5 \text{ } ^\circ\text{C/W}$
- $T_a = 80 \text{ } ^\circ\text{C}$
- $I_{CC} + I_{CC_DCDC} = 240 \text{ mA}$
- $V_{CC} = 3.5 \text{ V}$ ($V_{CC} = V_{CC2} = AV_{CC0} = V_{CC_USB}$)
- $I_{OH} = 1 \text{ mA}$, $V_{OH} = V_{CC} - 0.5 \text{ V}$, 12 Outputs
- $I_{OL} = 20 \text{ mA}$, $V_{OL} = 1.0 \text{ V}$, 8 Outputs
- $I_{OL} = 1 \text{ mA}$, $V_{OL} = 0.5 \text{ V}$, 12 Outputs
- $C_{in} = 8 \text{ pF}$, 32 pins, Input frequency = 10 MHz
- $C_{load} = 30 \text{ pF}$, 32 pins, Output frequency = 10 MHz

Static current of IO = $\Sigma (V_{OL} \times I_{OL}) / \text{Voltage} + \Sigma ((V_{CC} - V_{OH}) \times I_{OH}) / \text{Voltage}$

$$\begin{aligned}
 &= (20 \text{ mA} \times 1 \text{ V}) \times 8 / 3.5 \text{ V} + (1 \text{ mA} \times 0.5 \text{ V}) \times 12 / 3.5 \text{ V} + ((V_{CC} - (V_{CC} - 0.5 \text{ V})) \times 1 \text{ mA}) \times 12 / 3.5 \text{ V} \\
 &= 45.7 \text{ mA} + 1.71 \text{ mA} + 1.71 \text{ mA} \\
 &= 49.1 \text{ mA}
 \end{aligned}$$

Dynamic current of IO = $\Sigma IO (C_{in} + C_{load}) \times IO \text{ switching frequency} \times \text{Voltage}$

$$\begin{aligned}
 &= ((8 \text{ pF} \times 32) \times 10 \text{ MHz} + (30 \text{ pF} \times 32) \times 10 \text{ MHz}) \times 3.5 \text{ V} \\
 &= 42.6 \text{ mA}
 \end{aligned}$$

Total power consumption = Voltage \times (Static current + Dynamic current)

$$= (240 \text{ mA} \times 3.5 \text{ V}) + (49.1 \text{ mA} + 42.6 \text{ mA}) \times 3.5 \text{ V}$$

$$= 1161 \text{ mW (1.161 W)}$$

$$T_j = T_a + \theta_{ja} \times \text{Total power consumption}$$

$$= 80 \text{ }^\circ\text{C} + 21.5 \text{ }^\circ\text{C/W} \times 1.161 \text{ W}$$

$$= 105.0 \text{ }^\circ\text{C}$$

51.3 AC Characteristics

51.3.1 Frequency

Table 51.29 Operation frequency value in high-speed mode

Parameter	Symbol	Min	Typ	Max	Unit
Operation frequency	CPU clock (CPUCLK) ^{*2} DCDC, BGA package, T _j ≤ 105°C ^{*4}	—	—	480	MHz
		—	—	480	
	External VDD, BGA package, T _j ≤ 105°C	—	—	480	
	System clock (ICLK) ^{*2}	—	—	240	
	Peripheral module clock (PCLKA) ^{*2}	—	—	120	
	Peripheral module clock (PCLKB) ^{*2}	—	—	60	
	Peripheral module clock (PCLKC) ^{*2}	— ^{*3}	—	60	
	Peripheral module clock (PCLKD) ^{*2}	—	—	120	
	Peripheral module clock (PCLKE) ^{*2}	—	—	240	
	Flash interface clock (FCLK) ^{*2}	— ^{*1}	—	60	
External bus clock (BCLK) ^{*2}	VCC ≥ 2.7 V	—	—	120	
	VCC ≥ 1.68 V	—	—	60	
EBCLK pin output	VCC ≥ 2.7 V	—	—	60	
	VCC ≥ 1.68 V	—	—	30	
SDCLK pin output	VCC ≥ 3.0 V	—	—	120	
	SCI clock (SCICLK)	—	—	120	
	SPI clock (SPICLK)	—	—	120	
	Octal SPI clock (OCTACLK)	—	—	200	
	CANFD core clock (CANFDCLK)	—	—	80	
	LCD clock (LCDCLK)	—	—	240	
	USB clock (USBCLK)	—	—	48	

Note 1. FCLK must run at a frequency of at least 4 MHz when programming or erasing the flash memory.

Note 2. See [section 8, Clock Generation Circuit](#) for the relationship between the CPUCLK, ICLK, PCLKA, PCLKB, PCLKC, PCLKD, PCLKE, FCLK, and BCLK frequencies.

Note 3. When the ADC12 is used, the PCLKC frequency must be at least 1 MHz.

Note 4. When DCDC is used with VCC_DCDC < 2.5V, I_{DD} current must be less than the value specified in operating current.

Please see [Table 51.8](#).

Table 51.30 Operation frequency value in low-speed mode

Parameter		Symbol	Min	Typ	Max	Unit	
Operation frequency	CPU clock (CPUCLK)* ²	f	—	—	1	MHz	
	System clock (ICLK)* ²		—	—	1		
	Peripheral module clock (PCLKA)* ²		—	—	1		
	Peripheral module clock (PCLKB)* ²		—	—	1		
	Peripheral module clock (PCLKC)* ²		—* ³	—	1		
	Peripheral module clock (PCLKD)* ²		—	—	1		
	Peripheral module clock (PCLKE)* ²		—	—	1		
	Flash interface clock (FCLK) * ²		—* ¹	—	1		
	External bus clock (BCLK)* ²		—	—	1		
	EBCLK pin output		—	—	1		
	SDCLK pin output	VCC ≥ 3.0 V		—	—		1
	SCI clock (SCICLK)		—	—	1		
	SPI clock (SPICLK)		—	—	1		
	Octal SPI clock (OCTACLK)		—	—	1		
	CANFD core clock (CANFDCLK)		—	—	1		
LCD clock (LCDCLK)		—	—	1			
USB clock (USBCLK)		—	—	1			

Note 1. Programming or erasing the flash memory is disabled in low-speed mode.

Note 2. See [section 8, Clock Generation Circuit](#) for the relationship between the CPUCLK, ICLK, PCLKA, PCLKB, PCLKC, PCLKD, PCLKE, FCLK, and BCLK frequencies.

Note 3. When the ADC12 is used, the PCLKC frequency must be at least 1 MHz.

51.3.2 Clock Timing

Table 51.31 Clock timing except for sub-clock oscillator (1 of 2)

Parameter		Symbol	Min	Typ	Max	Unit	Test conditions
EBCLK pin output cycle time	VCC = 2.70 V or above	t_{Bcyc}	16.6	—	—	ns	Figure 51.15
	VCC = 1.68 V or above		33.3	—	—

PLL1/PLL2 long term jitter	—	—	± 300	—	ps	Term: 1 μ s, 10 μ s	

Note 1. When setting up the main clock oscillator, ask the oscillator manufacturer for an oscillation evaluation, and use the results as the recommended oscillation stabilization time. Set the MOSCWTCR register to a value equal to or greater than the recommended value.

After changing the setting in the MOSCCR.MOSTP bit to start main clock operation, read the OSCSF.MOSCSF flag to confirm that it is 1, and then start using the main clock oscillator.

Note 2. This is the time from release from reset state until the HOCO oscillation frequency (f_{HOCO}) reaches the range for guaranteed operation.

Table 51.32 Clock timing for the sub-clock oscillator

Parameter	Symbol	Min	Typ	Max	Unit	Test conditions
Sub-clock frequency	f_{SUB}	—	32.768	—	kHz	—
Sub-clock oscillation stabilization wait time	$t_{SUBOSCWT}$	—	—	—*1	s	Figure 51.20

Note 1. When setting up the sub-clock oscillator, ask the oscillator manufacturer for an oscillation evaluation and use the results as the recommended oscillation stabilization time. After changing the setting in the SOSCCR.SOSTP bit to start sub-clock operation, only start using the sub-clock oscillator after the sub-clock oscillation stabilization time elapses with an adequate margin. A value that is two times the value shown is recommended.

		DPSWCR.WSTS = 0x9A	Standard		—	1.60	2.00	ms	
			Fast		—	1.20	1.50	ms	
	Deep Software Standby mode 3	Standard			—	2.10	3.50	ms	
		Fast			—	1.70	2.90	ms	
Wait time after cancellation of Deep Software Standby mode			—	t_{DSBYWT}	47.7	—	64.6	μ s	

- Note 1. When the frequency of the crystal is 48 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05) and the greatest value of the internal clock division setting is 1.
- Note 2. When the frequency of PLL1P is 480 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x05) and the greatest value of the internal clock division setting is 8.
- Note 3. When the frequency of the external clock is 48 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00) and the greatest value of the internal clock division setting is 1.
- Note 4. When the frequency of PLL1P is 480 MHz (Main Clock Oscillator Wait Control Register (MOSCWTCR) is set to 0x00) and the greatest value of the internal clock division setting is 8.
- Note 5. The Sub-clock oscillator frequency is 32.768 kHz and the greatest value of the internal clock division setting is 1.
- Note 6. The HOCO frequency is 20 MHz and the greatest value of the internal clock division setting is 1.
- Note 7. The PLL frequency is 480 MHz and the greatest value of the internal clock division setting is 8.
- Note 8. The MOCO frequency is 8 MHz and the greatest value of the internal clock division setting is 1.
- Note 9. For details, see SSCR1.SS1FR, DPSBYCR.DCSSMODE bits in the [section 10, Low Power Modes](#).
- Note 10. The recovery time can be calculated with the equation of $t_{Common} + \max(t_{OSCSTB}, t_{PG1}, t_{PGCK}) + \max(t_{PG2}, t_{LPW})$. And they can be determined with the following values and equations. For n, the greatest value is selected from among the internal clock(CPUCLK, ICLK, PCLKm, FCLK, BCLK and EBCLK) division settings (m = A to E). t_{OSCSTB} in the table below means the time when each oscillator is active. When multiple oscillators are active, t_{OSCSTB} is determined by the longest t_{OSCSTB} among the active oscillators.
- Note 11. The ICLK frequency is 240 MHz. This recovery time corresponds to t_{PG2} .

Table 51.35 Each element of recovery time

51.3.6 Bus Timing

Table 51.37 Bus timing (1 of 2)

Condition 1: When using the CS area controller (CSC).
 VCC = VCC_DCDC = VCC_USB = VBATT = 1.68 V to 3.6 V, VCC2 = 1.65 V to 3.6 V
 BCLK = 8 to 120 MHz, EBCLK = 8 to 60 MHz (When VCC = VCC_USB = VBATT = 2.70 to 3.6 V)
 BCLK = 8 to 60 MHz, EBCLK = 8 to 30 MHz (When VCC = VCC_USB = VBATT = 1.68 to 3.6 V)
 Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 30 pF
 EBCLK: High drive output is selected in the port drive capability bit in the PmnPFS register.
 Others: Middle drive output is selected in the port drive capability bit in the PmnPFS register.

Condition 2: When using the SDRAM area controller (SDRAMC).
 BCLK = SDCLK = 8 to 120 MHz
 VCC = VCC2 = VCC_DCDC = VCC_USB = VBATT = 3.0 to 3.6 V
 Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 15 pF
 SDCLK: High-speed high drive output is selected in the port drive capability bit in the PmnPFS register.
 Others: High drive output is selected in the port drive capability bit in the PmnPFS register.

Condition 3: When using the SDRAM area controller (SDRAMC) and CS area controller (CSC) simultaneously.
 BCLK = SDCLK = 8 to 60 MHz
 VCC = VCC2 = VCC_DCDC = VCC_USB = VBATT = 3.0 to 3.6 V
 Output load conditions: VOH = VCC × 0.5, VOL = VCC × 0.5, C = 15 pF
 EBCLK/SDCLK: High drive output is selected in the port drive capability bit in the PmnPFS register.
 Others: Middle drive output is selected in the port drive capability bit in the PmnPFS register.

Parameter		Symbol	Min	Max	Unit	Test conditions

51.3.7 I/O Ports, POEG, GPT, AGT, ULPT and ADC12 Trigger Timing

Table 51.38 I/O ports, POEG, GPT, AGT, ULPT and ADC12 trigger timing (1 of 3)

GPT Conditions:

Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

If GPT pins are specified across the VCC I/O and VCC2 I/O, characteristics below is guaranteed only when VCC = VCC2.

AGT Conditions:

Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

Parameter	Symbol	Min	Max	Unit	Test conditions	
I/O ports	Input data pulse width	t_{PRW}	5.5	—	t_{Icyc}	Figure 51.42
	EXCIN input frequency	t_{EXCIN}	—	36	kHz	
	RTCICn (n = 0 to 2) input pulse width	t_{RTCICW}	13.89	—	μs	Figure 51.43
POEG	POEG input trigger pulse width	t_{POEW}	3	—	t_{Pcyc}	Figure 51.44

Table 51.38 I/O ports, POEG, GPT, AGT, ULPT and ADC12 trigger timing (2 of 3)

GPT Conditions:

Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

If GPT pins are specified across the VCC I/O and VCC2 I/O, characteristics below is guaranteed only when VCC = VCC2.

AGT Conditions:

Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	Min	Max	Unit	Test conditions		
GPT	Input capture pulse width (Cycle)	Single edge	t_{GTICW}^{*1}	1.5	—	t_{pDcyc}	Figure 51.45	
		Dual edge		2.5	—			
	Input capture pulse width (Time)	2.70V or above	t_{GTICW}^{*1}	12.5	—	ns		
		1.68V or above (VCC)		25.0	—			
		1.65V or above (VCC2)						
	GTIOCxY output skew (x = 0 to 5, Y = A or B)	2.70V or above	t_{GTISK}	—	4	ns		Figure 51.46
		1.68V or above (VCC)		—	5			
	GTIOCxY output skew (x = 10 to 13, Y = A or B)	2.70V or above	t_{GTISK}	—	4	ns		
		1.68V or above (VCC)		—	5			
	GTIOCxY output skew (x = 0 to 5, 10 to 13, Y = A or B)	2.70V or above	t_{GTISK}	—	6	ns		
1.68V or above (VCC)		—		7				
AGT	AGTIO, AGTEE input cycle	2.70V or above	t_{ACYC}^{*2}	100	—	ns	Figure 51.47	
		1.68V or above (VCC)		100	—			
	AGTIO, AGTEE input high width, low width	2.70V or above	t_{ACKWH}, t_{ACKWL}	40	—	ns		
		1.68V or above (VCC)		40	—			
	AGTIO, AGTO, AGTOA, AGTOB output cycle	2.70V or above	t_{ACYC2}	62.5	—	ns		
		1.68V or above (VCC)		62.5	—			
	1.65V or above (VCC2)							

Table 51.38 I/O ports, POEG, GPT, AGT, ULPT and ADC12 trigger timing (3 of 3)

GPT Conditions:

Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

If GPT pins are specified across the VCC I/O and VCC2 I/O, characteristics below is guaranteed only when VCC = VCC2.

AGT Conditions:

Middle drive output is selected in the Port Drive Capability bit in the PmnPFS register.

Parameter		Symbol	Min	Max	Unit	Test conditions	
ULPT	ULPTEE, ULPTEVI input cycle	2.70V or above	32	-	μs	Figure 51.48	
		1.68V or above (VCC) 1.65V or above (VCC2)	32	-			
	ULPTEE, ULPTVI input high width, low width	2.70V or above	t _{ULCKWH} , t _{ULCKWL}	12	-		μs
		1.68V or above (VCC) 1.65V or above (VCC2)		12	-		
	ULPTO, ULPTOA, ULPTOB output cycle	2.70V or above	t _{ULCYC2}	64	-		μs
		1.68V or above (VCC) 1.65V or above (VCC2)		64	-		
ADC12	ADC12 trigger input pulse width	2.70V or above	t _{TRGW}	1.5	—	t _{Pcyc}	Figure 51.49
		1.68V or above (VCC) 1.65V or above (VCC2)		3.0	—		

Note: t_{Icyc}: ICLK cycle, t_{Pcyc}: PCLKB cycle, t_{PDcyc}: PCLKD cycle, t_{ULPTLCLK}: ULPTLCLK cycle..

Note 1. For Cycle and Time, the longer time characteristics is applied.

Note 2. Constraints on input cycle:

When not switching the source clock: t_{Pcyc} × 2 < t_{ACYC} should be satisfied.

When switching the source clock: t_{Pcyc} × 6 < t_{ACYC} should be satisfied.

Note 3. Constraints on input cycle:

ULPTEVI : t_{Pcyc} × 2 < t_{ULCYC} should be satisfied.

ULPTEE: t_{ULPTLCLK} × 2 < t_{ULCYC} should be satisfied.

51.3.12 IIC Timing

Table 51.46 IIC timing (1) (1 of 2)

(1) Conditions: Middle drive output is selected when VCC is 2.70 V or above, High drive output is selected when VCC is 1.68 to 1.95 V in the port drive capability bit in the PmnPFS register for the following pins: SDA0_B, SCL0_B, SDA1_B, SCL1_B

(2) The following pins do not require setting: SCL0_A, SDA0_A, SCL1_A, SDA1_A

(3) Use pins that have a letter appended to their names, for instance “_A” or “_B”, to indicate group membership.

For the IIC interface, the AC portion of the electrical characteristics is measured for each group.

Parameter	Symbol	VCC	Min	Max	Unit	Test conditions	
IIC (Standard mode, SMBus) ICFER.FMPE = 0 when VCC is 2.70 V or above, ICFER.FMPE = 1 when VCC is 1.68 to 1.95 V	SCL input cycle time	t_{SCL}	2.70 V or above 1.68 to 1.95 V	$6 (12) \times t_{IICcyc} + 1300$	—	ns	Figure 51.70
	SCL input high pulse width	t_{SCLH}	2.70 V or above 1.68 to 1.95 V	$3 (6) \times t_{IICcyc} + 300$	—	ns	
	SCL input low pulse width	t_{SCLL}	2.70 V or above 1.68 to 1.95 V	$3 (6) \times t_{IICcyc} + 300$	—	ns	
	SCL, SDA rise time	t_{Sr}	2.70 V or above 1.68 to 1.95 V	—	1000	ns	
	SCL, SDA fall time	t_{Sf}	2.70 V or above 1.68 to 1.95 V	—	300	ns	
	SCL, SDA input spike pulse removal time	t_{SP}	2.70 V or above 1.68 to 1.95 V	0	$1 (4) \times t_{IICcyc}$	ns	
	SDA input bus free time when wakeup function is disabled	t_{BUF}	2.70 V or above 1.68 to 1.95 V	$3 (6) \times t_{IICcyc} + 300$	—	ns	
	SDA input bus free time when wakeup function is enabled	t_{BUF}	2.70 V or above 1.68 to 1.95 V	$3 (6) \times t_{IICcyc} + 4 \times t_{Pcyc} + 300$	—	ns	
	START condition input hold time when wakeup function is disabled	t_{STAH}	2.70 V or above 1.68 to 1.95 V	$t_{IICcyc} + 300$	—	ns	
	START condition input hold time when wakeup function is enabled	t_{STAH}	2.70 V or above 1.68 to 1.95 V	$1 (5) \times t_{IICcyc} + t_{Pcyc} + 300$	—	ns	
	Repeated START condition input setup time	t_{STAS}	2.70 V or above 1.68 to 1.95 V	1000	—	ns	
	STOP condition input setup time	t_{STOS}	2.70 V or above 1.68 to 1.95 V	1000	—	ns	
	Data input setup time	t_{SDAS}	2.70 V or above 1.68 to 1.95 V	$t_{IICcyc} + 50$	—	ns	
	Data input hold time	t_{SDAH}	2.70 V or above 1.68 to 1.95 V	0	—	ns	
	SCL, SDA capacitive load	C_b	2.70 V or above 1.68 to 1.95 V	—	400	pF	

Table 51.46 IIC timing (1) (2 of 2)

(1) Conditions: Middle drive output is selected when VCC is 2.70 V or above, High drive output is selected when VCC is 1.68 to 1.95 V in the port drive capability bit in the PmnPFS register for the following pins: SDA0_B, SCL0_B, SDA1_B, SCL1_B

(2) The following pins do not require setting: SCL0_A, SDA0_A, SCL1_A, SDA1_A

(3) Use pins that have a letter appended to their names, for instance "_A" or "_B", to indicate group membership.

For the IIC interface, the AC portion of the electrical characteristics is measured for each group.

Parameter	Symbol	VCC	Min	Max	Unit	Test conditions	
IIC (Fast mode) ICFER.FMPE = 0 when VCC is 2.70 V or above, ICFER.FMPE = 1 when VCC is 1.68 to 1.95 V	SCL input cycle time	t _{SCL}	2.70 V or above	6 (12) × t _{IICcyc} + 600	—	ns	Figure 51.70
		1.68 to 1.95 V					
	SCL input high pulse width	t _{SCLH}	2.70 V or above	3 (6) × t _{IICcyc} + 300	—	ns	
			1.68 to 1.95 V				
	SCL input low pulse width	t _{SCLL}	2.70 V or above	3 (6) × t _{IICcyc} + 300	—	ns	
			1.68 to 1.95 V				
	SCL, SDA rise time	t _{Sr}	2.70 V or above	20	300	ns	
			1.68 to 1.95 V				
	SCL, SDA fall time	t _{Sf}	2.70 V or above	20 × (external pullup voltage/5.5 V) ^{*1}	300	ns	
			1.68 to 1.95 V				
	SCL, SDA input spike pulse removal time	t _{SP}	2.70 V or above	0	1 (4) × t _{IICcyc}	ns	
			1.68 to 1.95 V				
	SDA input bus free time when wakeup function is disabled	t _{BUF}	2.70 V or above	3 (6) × t _{IICcyc} + 300	—	ns	
			1.68 to 1.95 V				
	SDA input bus free time when wakeup function is enabled	t _{BUF}	2.70 V or above	3 (6) × t _{IICcyc} + 4 × t _{Pcyc} + 300	—	ns	
			1.68 to 1.95 V				
START condition input hold time when wakeup function is disabled	t _{STAH}	2.70 V or above	t _{IICcyc} + 300	—	ns		
		1.68 to 1.95 V					
START condition input hold time when wakeup function is enabled	t _{STAH}	2.70 V or above	1 (5) × t _{IICcyc} + t _{Pcyc} + 300	—	ns		
		1.68 to 1.95 V					
Repeated START condition input setup time	t _{STAS}	2.70 V or above	300	—	ns		
		1.68 to 1.95 V					
STOP condition input setup time	t _{STOS}	2.70 V or above	300	—	ns		
		1.68 to 1.95 V					
Data input setup time	t _{SDAS}	2.70 V or above	t _{IICcyc} + 50	—	ns		
		1.68 to 1.95 V					
Data input hold time	t _{SDAH}	2.70 V or above	0	—	ns		
		1.68 to 1.95 V					
SCL, SDA capacitive load	C _b	2.70 V or above	—	400	pF		
		1.68 to 1.95 V					

Note: t_{IICcyc}: IIC internal reference clock (IICφ) cycle, t_{Pcyc}: PCLKB cycle.

Note: Values in parentheses apply when ICMR3.NF[1:0] is set to 11b while the digital filter is enabled with ICFER.NFE set to 1.

Note: Must use pins that have a letter appended to their name, for instance "_A", "_B", to indicate group membership. For the IIC interface, the AC portion of the electrical characteristics is measured for each group.

Note 1. Only supported for SCL0_A, SDA0_A, SCL1_A, and SDA1_A.

Table 51.47 IIC timing (2)

Setting of the SCL0_A, SDA0_A, SCL1_A, SDA1_A pins are not required with the port drive capability bit in the PmnPFS register.

	SCL, SDA input spike pulse removal time	t_{SP}	2.70 V or above	0	$1 (4) \times t_{IICcyc}$	ns	
	SDA input bus free time when wakeup function is disabled	t_{BUF}	2.70 V or above	$3 (6) \times t_{IICcyc} + 120$	—	ns	
	SDA input bus free time when wakeup function is enabled	t_{BUF}	2.70 V or above	$3 (6) \times t_{IICcyc} + 4 \times t_{Pcyc} + 120$	—	ns	
	Start condition input hold time when wakeup function is disabled	t_{STAH}	2.70 V or above	$t_{IICcyc} + 120$	—	ns	
	START condition input hold time when wakeup function is enabled	t_{STAH}	2.70 V or above	$1 (5) \times t_{IICcyc} + t_{Pcyc} + 120$	—	ns	
	Restart condition input setup time	t_{STAS}	2.70 V or above	120	—	ns	
	Stop condition input setup time	t_{STOS}	2.70 V or above	120	—	ns	
	Data input setup time	t_{SDAS}	2.70 V or above	$t_{IICcyc} + 30$	—	ns	
	Data input hold time	t_{SDAH}	2.70 V or above	0	—	ns	
SCL, SDA capacitive load	C_b^{*1}	2.70 V or above	—	550	pF		

Note: t_{IICcyc} : IIC internal reference clock (IIC ϕ) cycle, t_{Pcyc} : PCLKB cycle.

Note: Values in parentheses apply when ICMR3.NF[1:0] is set to 11b while the digital filter is enabled with ICFER.NFE set to 1.

Note 1. C_b indicates the total capacity of the bus line.

Figure 51.70 I²C bus interface input/output timing

51.3.13 SSIE Timing

Table 51.48 SSIE timing (1 of 2)

(1) High drive output is selected with the Port Drive Capability bit in the PmnPFS register.
 (2) Use pins that have a letter appended to their names, for instance “_A”, “_B” or “_C” to indicate group membership. For the SSIE interface, the AC portion of the electrical characteristics is measured for each group.

Parameter			Symbol	VCC	Min.	Max.	Unit	Comments
SSIBCK	Cycle	Master	t _O	2.70V or above	80	—	ns	Figure 51.71
				1.68V or above	80	—		
		Slave	t _I	2.70V or above	80	—	ns	
				1.68V or above	80	—		
	High level/low level	Master	t _{HC} /t _{LC}	2.70V or above	0.35	—	t _O	
				1.68V or above	0.35	—		
		Slave		2.70V or above	0.35	—	t _I

Figure 51.84 Illustration of ADC12 characteristic terms

Absolute accuracy

Absolute accuracy is the difference between output code based on the theoretical A/D conversion characteristics, and the actual A/D conversion result. When measuring absolute accuracy, the voltage at the midpoint of the width of the analog input voltage (1-LSB width), which can meet the expectation of outputting an equal code based on the theoretical A/D conversion characteristics, is used as an analog input voltage. For example, if 12-bit resolution is used and the reference voltage $V_{REFH0} = 3.072$ V, then the 1-LSB width becomes 0.75 mV, and 0 mV, 0.75 mV, and 1.5 mV are used as the analog input voltages. If the analog input voltage is 6 mV, an absolute accuracy of ± 5 LSB means that the actual A/D conversion result is in the range of 0x003 to 0x00D, though an output code of 0x008 can be expected from the theoretical A/D conversion characteristics.

Integral nonlinearity error (INL)

Integral nonlinearity error is the maximum deviation between the ideal line when the measured offset and full-scale errors are zeroed, and the actual output code.

Differential nonlinearity error (DNL)

Differential nonlinearity error is the difference between the 1-LSB width based on the ideal A/D conversion characteristics and the width of the actual output code.

Offset error

Offset error is the difference between the transition point of the ideal first output code and the actual first output code.

Full-scale error

Full-scale error is the difference between the transition point of the ideal last output code and the actual last output code.

	V _{DETBATT_5}	1.690	1.750	1.860		
VCC drop detection stabilization wait time*2	t _{DETWT}	—	—	20	μs	
Lower-limit VBATT voltage for power supply switching caused by VCC voltage drop	V _{BATTSW}	2.0	—	—	V	Figure 51.89
VCC-off period for starting power supply switching*1 (OFS1(_SEC).PVDAS and PVDLPSEL are 0 in Deep Software Standby mode 1, 2)	t _{VOFFBATT}	400	—	—	μs	
VCC-off period for starting power supply switching*1 (Other than above)		200	—	—		
Backup domain power-down detection level	V _{PDR} (BATR)	1.45	1.50	1.60	V	Figure 51.90
Time delay in assertion of the reset signal for the backup domain*3	t _p (PDRL)	—	—	2000	μs	
Time delay in negation of the reset signal for the backup domain	t _p (PDRH)	—	—	3000		
VBATT monitor operation stabilization time (after VBATTMNSLR.VBTMNSLR is changed to 1)	t _{MONWT}	—	—	4.2	μs	—
VBATT voltage monitor level	V _{MONBATT}	—	VBATT / 3	—	V	—
VBATT current increase (when VBATTMNSLR.VBTMNSLR is 1 compared to the case that VBATTMNSLR.VBTMNSLR is 0)	I _{VBATTSELB}	—	1.50	2.35	μA	—
VCC current increase (when VBATTMNSLR.VBTMNSLR is 1 compared to the case that VBATTMNSLR.VBTMNSLR is 0)	I _{VBATTSELC}	—	330	577	μA	—

Note 1. The VCC-off period for starting power supply switching indicates the period in which VCC is below the minimum value of the voltage level for switching to battery backup (V_{DETBATT}).

In addition, this period indicates the time t_{VOFFP} when VCC is below the minimum value of voltage detection levels V_{POR1}.

Note 2. Stable time when VBTBPCR2.VDETLVL is changed or VBTBPCR2.VDETLVL is changed from 0 to 1.

Note 3. When the VBATT_R recovers within this period, the backup domain reset signal may not be generated.

	32-KB	t _{E32K}	—	341	1040	—	189	576	ms	
Reprogramming/erasure cycle* ⁴	N _{PEC}	10000* ¹	—	—	—	10000* ¹	—	—	Times	
Suspend delay during programming	t _{SPD}	—	—	264	—	—	120	μs		
Programming resume time	t _{PRT}	—	—	110	—	—	50	μs		
First suspend delay during erasure in suspend priority mode	t _{SESD1}	—	—	216	—	—	120	μs		
Second suspend delay during erasure in suspend priority mode	t _{SESD2}	—	—	1.7	—	—	1.7	ms		
Suspend delay during erasure in erasure priority mode	t _{SEED}	—	—	1.7	—	—	1.7	ms		
First erasing resume time during erasure in suspend priority mode* ⁵	t _{REST1}	—	—	1.7	—	—	1.7	ms		
Second erasing resume time during erasure in suspend priority mode	t _{REST2}	—	—	144	—	—	80	μs		
Erasing resume time during erasure in erasure priority mode	t _{REET}	—	—	144	—	—	80	μs		
Forced stop command	t _{FD}	—	—	32	—	—	20	μs		
Data hold time* ²	t _{DRP}	20* ² * ³	—	—	—	20* ² * ³	—	—	Years	T _j = +105°C
		30* ² * ³	—	—	—	30* ² * ³	—	—		T _j = +85°C

Note 1. This is the minimum number of times to guarantee all the characteristics after reprogramming. The guaranteed range is from 1 to the minimum value.

Note 2. This indicates the minimum value of the characteristic when reprogramming is performed within the specified range.

Note 3. This result is obtained from reliability testing.

Note 4. The reprogram/erase cycle is the number of erasures for each block. When the reprogram/erase cycle is n times (n = 10,000), erasing can be performed n times for each block. For example, when 128-byte programming is performed 64 times for different addresses in 8-KB blocks, and then the entire block is erased, the reprogram/erase cycle is counted as one. However, programming the same address several times as one erasure is not enabled. Overwriting is prohibited.

Note 5. Time for resumption includes time for reapplying the erasing pulse (up to one full pulse) that was cut off at the time of suspension.

Note 6. The reference value at VCC = 3.3V and room temperature.

Figure 51.91 Suspension and forced stop timing for flash memory programming and erasure

51.12.2 Data Flash Memory Characteristics

Table 51.65 Data flash memory characteristics (1 of 2)

Conditions: Program or erase: FCLK = 4 to 60 MHz

Others	—	Hi-Z	Keep-O		Keep		Hi-Z	Keep

Note: Hi-Z: High-impedance

Keep-O: Output pins retain their previous values. Input pins go to high-impedance.

Keep-I: Pin states are retained same as during periods in Normal mode.

Keep: Pin states are retained same as during periods in Software Standby mode.

Note 1. Retains the I/O port state until the DPSBYCR.IOKEEP bit is cleared to 0.

Note 2. Input is enabled if the pin is specified as the Software Standby canceling source while it is used as an external interrupt pin.

Note 3. Input is enabled if the pin is specified as the Deep Software Standby canceling source.

Note 4. Input is enabled while the pin is used as an input pin.

Appendix 2. Package Dimensions

Information on the latest version of the package dimensions or mountings is displayed in “Packages” on the Renesas Electronics Corporation website.

Note: Name = Peripheral name
Description = Peripheral functionality
Base address = Lowest reserved address or address used by the peripheral

3.2 Access Cycles

This section provides access cycle information for the I/O registers described in this manual.

- Registers are grouped by associated module.
- The number of access cycles indicates the number of cycles based on the specified reference clock.
- In the internal I/O area, reserved addresses that are not allocated to registers must not be accessed, otherwise operations cannot be guaranteed.
- The number of I/O access cycles depends on bus cycles of the internal peripheral bus, divided clock synchronization cycles, and wait cycles of each module. Divided clock synchronization cycles differ depending on the frequency ratio between ICLK and PCLK.
- When the frequency of ICLK is equal to that of PCLK, the number of divided clock synchronization cycles is always constant.
- When the frequency of ICLK is greater than that of PCLK, at least 1 PCLK cycle is added to the number of divided clock synchronization cycles.
- The number of write access cycles indicates the number of cycles obtained by non-bufferable write access.

Note: This applies to the number of cycles when access from the CPU does not conflict with the instruction fetching to the external memory or bus access from other bus masters such as DTC or DMAC.

Table 3.2 Access cycles (1 of 3)

Peripheral base address symbol	Address ^{*1}		Number of access cycles					Cycle Unit	Related function
			ICLK = PCLK		ICLK > PCLK ^{*2}				
	From	To	Read	Write	Read	Write			
RMPU, SRAM, BUS, ICU_COMMON, CPSCU, DMAC0n, DMA0, DTC0, ICU, CPU_CTRL	0x4000_0000	0x4001_CFFF	3	2	3	2	ICLK	Renesas Memory Protection Unit, SRAM Control, BUS Control, Common Interrupt Controller, CPU System Security Control Unit, Direct memory access controller 0 n, DMAC Module Activation 0, Data Transfer Controller 0, Interrupt Controller, CPU Control Registers	
CPU_OCD	0x4001_1004	0x4001_1FFF	7	2	7	2	ICLK	On-Chip Debug

Table 3.2 Access cycles (2 of 3)

Peripheral base address symbol	Address* ¹		Number of access cycles					Cycle Unit	Related function
			ICLK = PCLK		ICLK > PCLK* ²				
	From	To	Read	Write	Read	Write			
RSIP-E51A	—	—	1 to 3	2	1 to 3	1 to 2	PCLK A	Renesas Security IP	

Table 3.2 Access cycles (3 of 3)

Peripheral base address symbol	Address* ¹		Number of access cycles				Cycle Unit	Related function
			ICLK = FCLK		ICLK > FCLK* ²			
	From	To	Read	Write	Read	Write		
FLAD, FACL	0x4011_C040	0x4011_EFFF	4	3	4	3	FCLK	Data Flash, Flash Application Command Interface

Note 1. This table only shows secure address. Access cycle of the non-secure address is the same as its secure address.

Note 2. If the number of PCLK or FCLK cycles is non-integer (for example 1.5), the minimum value is without the decimal point, and the maximum value is rounded up to the decimal point. For example, 1.5 to 2.5 is 1 to 3.

Appendix 4. Note for Register R/W

- A secure bus master issues a "secure access" using an address marked as secure by IDAU/SAU or MSAU.
- A secure bus master issues a "non-secure access" using an address marked as non-secure by IDAU/SAU or MSAU.
- A non-secure bus master issues a "non-secure access" using an address marked as non-secure by IDAU/SAU or MSAU.

Table 4.1 Type of Register Notes(S-TYPE)

TYPE	UM Description
S-TYPE-1	Only Secure access can write to this register. Read access is always allowed. Non-secure write access is ignored, but TrustZone access error is not generated.
S-TYPE-2	Read access is always allowed If the security attribution is configured as Secure, <ul style="list-style-type: none"> • Secure write access is allowed. • Non-secure write access is ignored, but TrustZone access error is not generated.
	If the security attribution is configured as Non-secure, <ul style="list-style-type: none"> • Secure write access is ignored, but TrustZone access error is not generated. • Non-secure access is allowed.
S-TYPE-3	If the security attribution is configured as Secure, <ul style="list-style-type: none"> • Secure access is allowed. • Non-secure write access is ignored and Non-secure read access is read as 0, TrustZone access error is generated
	If the security attribution is configured as Non-secure, <ul style="list-style-type: none"> • Secure write access is ignored and Secure read access is read as 0, TrustZone access error is generated. • Non-secure access is allowed
S-TYPE-4	If the security attribution is configured as Secure, <ul style="list-style-type: none"> • Secure access is allowed • Non-secure write access is ignored and Non-secure read access is read as 0, but TrustZone access error is not generated.
	If the security attribution is configured as Non-secure, <ul style="list-style-type: none"> • Secure write access is ignored and Secure read access is read as 0, but TrustZone access error is not generated. • Non-secure access is allowed.
S-TYPE-5	No note required.
S-TYPE-6	Secure access is allowed. Non-secure write access is ignored, and Non-secure read access is read as 0, TrustZone access error is generated.
S-TYPE-7	Secure write access is ignored, and Secure read access is read as 0, TrustZone access error is generated. Non-secure access is allowed.

Note: A non-secure bus master does NOT issue any access using an address marked as secure by IDAU/SAU or MSAU.

Table 4.2 Type of Register Notes(P-TYPE)

TYPE	UM Description
P-TYPE-1	Privileged write access is allowed. Read access is always allowed. Unprivileged write access is ignored, but TrustZone access error is not generated.
P-TYPE-2	Privileged access is allowed. Unprivileged write access is ignored, and Unprivileged read access is read as 0, TrustZone access error is generated.
P-TYPE-3	If the privilege attribution is configured as Privileged, <ul style="list-style-type: none"> • Privileged access is allowed. • Unprivileged write access is ignored and Unprivileged read access is read as 0, TrustZone access error is generated.
	If the privilege attribution is configured as Unprivilege, <ul style="list-style-type: none"> • Privileged access and Unprivileged access are allowed.
P-TYPE-4	If the privilege attribution is configured as Privileged, <ul style="list-style-type: none"> • Privileged access is allowed. • Unprivileged write access is ignored and Unprivileged read access is read as 0, TrustZone access error is not generated.
	If the privilege attribution is configured as Unprivilege, <ul style="list-style-type: none"> • Privileged access and Unprivileged access are allowed.
P-TYPE-5	No note required.

Appendix 5. Peripheral Variant

Table 5.1 shows the correspondence between the module name used in this manual and the Peripheral Variant.

Table 5.1 Module name vs Peripheral Variant

Module name	Peripheral variant
SCI	SCI_B
SPI	SPI_B
OSPI	OSPI_B
