Indicate the number of empty transmit FIFO stages. By setting the SPCR.SPE bit to 0, the FREE[2:0] bits will be 100b.

41.2.18 RSPI Receive FIFO Status Register (SPRFSR)

Address(es): RSPIA0.SPRFSR 000E 285Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	FILL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	FILL[2:0]	Receive FIFO Fill Level	b2 b0 0 0 0: Number of stored stages 0 0 0 1: Number of stored stages 1 0 1 0: Number of stored stages 2 0 1 1: Number of stored stages 3 1 0 0: Number of stored stages 4	R
b7 to b3	—	Reserved	These bits are read as 0.	R

FILL[2:0] Bits (Receive FIFO Fill Level)

Indicate the number of stored receive FIFO stages. By setting the SPCR.SPE bit to 0, the FILL[2:0] bits will be 000b.

41.2.19 RSPI Status Clear Register (SPSCLR)

Address(es): RSPIA0.SPSCLR 000E 286Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SPRFC	SPCFC	SPTEFC	UDRFC	PERFC	MODFC	—	OVRFC	RRDYFC	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b7	RRDYFC	RSPI Receive Data Ready Flag Clear	By writing 1, the RSPI receive data ready flag can be cleared. The read value is always 0.	W
b8	OVRFC	Overrun Error Flag Clear	By writing 1, the overrun error flag can be cleared. The read value is always 0.	W
b9	—	Reserved	This bit is read as 0. The write value should be 0.	R
b10	MODFC	Mode Fault Error Flag Clear	By writing 1, the mode fault error flag can be cleared. The read value is always 0.	W*1
b11	PERFC	Parity Error Flag Clear	By writing 1, the parity error flag can be cleared. The read value is always 0.	W
b12	UDRFC	Underrun Error Flag Clear	By writing 1, the underrun error flag can be cleared. The read value is always 0.	W*1, *2
b13	SPTEFC	Transmit Buffer Empty Flag Clear	By writing 1, the transmit buffer empty flag can be cleared. The read value is always 0.	W
b14	SPCFC	Communication End Flag Clear	By writing 1, the communication end flag can be cleared. The read value is always 0.	W
b15	SPRFC	Receive Buffer Full Flag Clear	By writing 1, the receive buffer full flag can be cleared. The read value is always 0.	W

Note 1. Before setting the MODFC and UDRFC, make sure that the SPSR.MODF and UDRF flags are set to 1.
Note 2. When the UDRF flag is cleared, the MODF flag is cleared at the same time (MODFC = 1).

The SPSCLR register is used to clear the status flags in the SPSR register that indicates the operating status of RSPIA.

41.2.20 RSPI FIFO Clear Register (SPFCLR)

Address(es): RSPIA0.SPFCLR 000E 286Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	FCLR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	FCLR	FIFO Clear	By writing 1, the pointer in the FIFO and the stored data are initialized. The read value is always 0.	W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

The SPFCLR register is used to clear the FIFO. If the value of the SPFCLR register is changed while the SPCR.SPE bit is 1, the operation after the change is not guaranteed.

FCLR Bit (FIFO Clear)

Writing 1 to this bit initializes the pointer and stored data in the transmit/receive FIFO.

41.3 Operation

In this section, the serial transfer period means a period from the beginning of driving valid data to the fetching of the final valid data.

41.3.1 Overview of RSPI Operations

The RSPIA is capable of serial transfers in the following five modes.

(1) Slave mode (SPI operation)
(2) Single-master mode (SPI operation)
(3) Multi-master mode (SPI operation)
(4) Slave mode (clock synchronous operation)
(5) Master mode (clock synchronous operation).

A particular mode of the RSPIA can be selected by using the MSTR, MODFEN, SPMS, and FRFS bits in SPCR. Table 41.6 lists the relationship between RSPI modes and SPCR settings, and a description of each mode.

Table 41.6 Relationship between RSPI Modes and SPCR Settings and Description of Each Mode

	SPI Operation			Clock Synchronous Operation	
Mode	**Slave**	**Single-Master**	**Multi-Master**	**Slave**	**Master**
MSTR bit setting	0	1	1	0	1
MODFEN bit setting	0 or 1	0	1	0	0
SPMS bit setting	0	0	0	1	1
FRFS bit setting	Enabled	Enabled	Enabled	Disabled	Disabled
RSPCK0 signal	Input	Output	Output/Hi-Z*1	Input	Output
MOSI0 signal	Input	Output	Output/Hi-Z*1	Input	Output
MISO0 signal	Output/Hi-Z*2	Input	Input	Output	Input
SSL00 signal	Input	Output	Input	Hi-Z (not used)	Hi-Z (not used)
SSL01 to SSL03 signals	Hi-Z (not used)	Output	Output/Hi-Z*1	Hi-Z (not used)	Hi-Z (not used)
Output pin mode	CMOS/open-drain				
SSL polarity change function	Supported	Supported	Supported	—	—
Transfer rate	Up to PCLKA/2				
Clock source	RSPCK input	On-chip baud rate generator	On-chip baud rate generator	RSPCK input	On-chip baud rate generator
Clock polarity	Two				
Clock phase	Two*3	Two*3	Two*3	One (CPHA = 1)	Two
First transfer bit	MSB/LSB				
Transmit data length	4 to 32 bits				
Burst transfer	Possible (CPHA = 1)	Possible (CPHA = 0,1)	Possible (CPHA = 0,1)	—	—
RSPCK delay control	Not supported	Supported	Supported	Not supported	Supported
SSL negation delay control	Not supported*4	Supported	Supported	Not supported	Supported
Next-access delay control	Not supported	Supported	Supported	Not supported	Supported
Transfer activation method	SSL input active or RSPCK oscillation	Transmit buffer is written to when a transmit buffer empty interrupt request is generated or the SPTEF flag is 1	Transmit buffer is written to when a transmit buffer empty interrupt request is generated or the SPTEF flag is 1	RSPCK oscillation	Transmit buffer is written to when a transmit buffer empty interrupt request is generated or the SPTEF flag is 1
Sequence control	Not supported	Supported	Supported	Not supported	Supported
Transmit buffer empty detection	Supported*5	Supported	Supported	Supported*5	Supported
Receive buffer full detection	Supported*6				
Overrun error detection	Supported*6	Supported*6, *7	Supported*6, *7	Supported*6	Supported*6, *7
Parity error detection	Supported*6, *8				
Mode fault error detection	Supported (MODFEN = 1)	Not supported	Supported	Not supported	Not supported
Underrun error detection	Supported*5	Not supported	Not supported	Supported*5	Not supported

Note 1. Motorola SPI: When SSL00 is asserted by another master device, the pin becomes Hi-Z.
TI SSP: When the SPCR.SPE bit is 1, the pin becomes Hi-Z from the time SSL00 is asserted by another master device until the end of communication.

Note 2. Motorola SPI: When SSL00 is negated or the SPCR.SPE bit is 0, the pin becomes Hi-Z.
TI SSP: The pin becomes Hi-Z when the RSPIA is not communicating (from the end of communication to the next assertion of SSL00) or when the SPCR.SPE bit is 0.

Note 3. In TI SSP mode, setting the SPCMDm.CPHA bit to 0 is not effective.

Note 4. Available only in TI SSP mode.

Note 5. When RSPIA is receive-only slave mode (refer to Table 41.4 RSPI Communication Status), transmit buffer empty error detection and underrun error detection are not performed.

Note 6. When RSPIA is transmit-only master mode or transmit-only slave mode (refer to Table 41.4 RSPI Communication Status), receiver buffer full detection, overrun error detection, and parity error detection are not performed.

Note 7. When the SPCR.SCKASE bit is 1, overrun error detection does not proceed.

Note 8. When the SPCR.SPPE bit is 0, parity error detection is not performed.

41.3.2 Controlling RSPI Pins

The RSPIA in single-master mode (SPI operation) or multi-master mode (SPI operation) determines MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) according to MOIFE and MOIFV bit settings in SPPCR, as listed in Table 41.7.

Table 41.7 MOSI Signal Value Determination during SSL Negation Period

MOIFE Bit	MOIFV Bit	MOSI Signal Value during SSL Negation Period
0	0, 1	Final data from previous transfer
1	0	Low
1	1	High

41.3.3 RSPI System Configuration Examples

This configuration example describes that the low level of SSL0n signals is the active level.
When connecting and using in a multi-slave or multi-master mode, the transfer format of the connected device should be unified to either Motorola SPI or TI SSP.

41.3.3.1 Single Master/Single Slave (with This MCU Acting as Master)

Figure 41.5 shows a single-master/single-slave RSPI system configuration example when this MCU is used as a master. In the single-master/single-slave configuration, the SSL00 to SSL03 output of this MCU (master) are not used. The SSL input of the SPI slave is fixed to the low level, and the SPI slave is maintained in a select state. In the transfer format corresponding to the case where the SPCMDm.CPHA bit is 0, there are slave devices for which the SSL signal cannot be fixed to the active level. In situations where the SSL signal cannot be fixed, the SSL0n output of this MCU should be connected to the SSL input of the slave device.
This MCU (master) drives the RSPCK0 and MOSI0. The SPI slave drives the MISO.

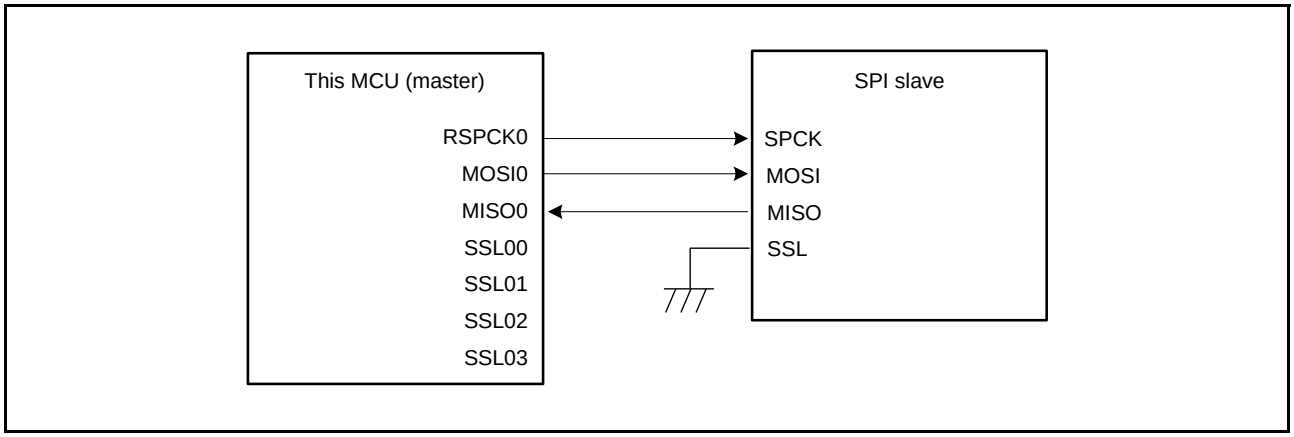

Figure 41.5 Single-Master/Single-Slave Configuration Example (This MCU = Master)

41.3.3.2 Single Master/Single Slave (with This MCU Acting as Slave)

Figure 41.6 shows a single-master/single-slave RSPI system configuration example when this MCU is used as a slave. When this MCU is to operate as a slave, the SSL00 pin is used as SSL input. The SPI master drives the SPCK and MOSI. This MCU (slave) drives the MISO0. When SSL00 is at the non-active level, the pin state is Hi-Z.
In the single-slave configuration in which the SPCMDm.CPHA bit is set to 1, set the SPCR.FRFS bit to 0, and set the SPCR.SPMS bit to 0, the SSL00 input of this MCU (slave) is fixed to the low level, this MCU (slave) is maintained in a select state, and in this manner it is possible to execute serial transfer (Figure 41.7). Note that the communication end event and the communication end interrupt do not output when SSL00 input was fixed as Figure 41.7.

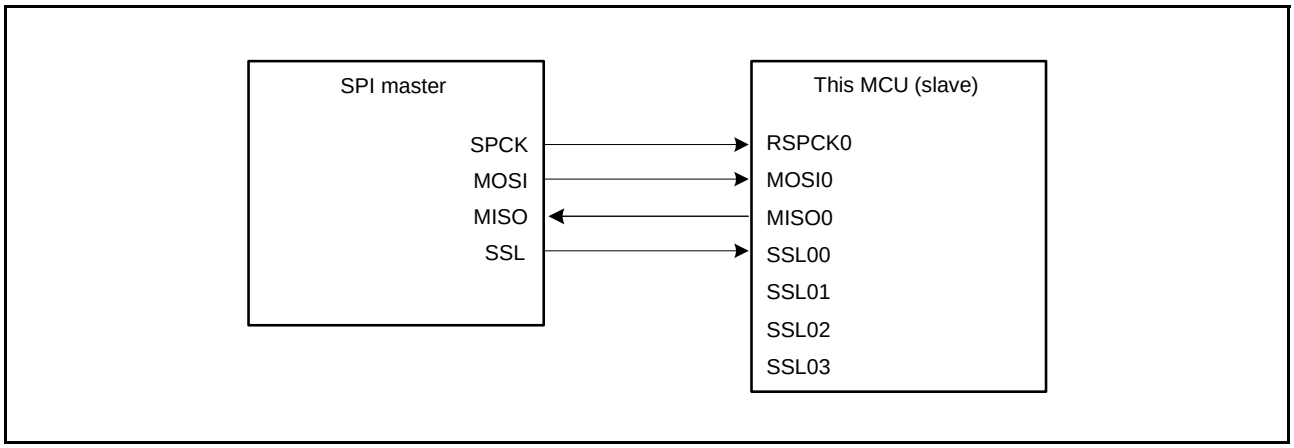

Figure 41.6 Single-Master/Single-Slave Configuration Example (This MCU = Slave, CPHA = 0)

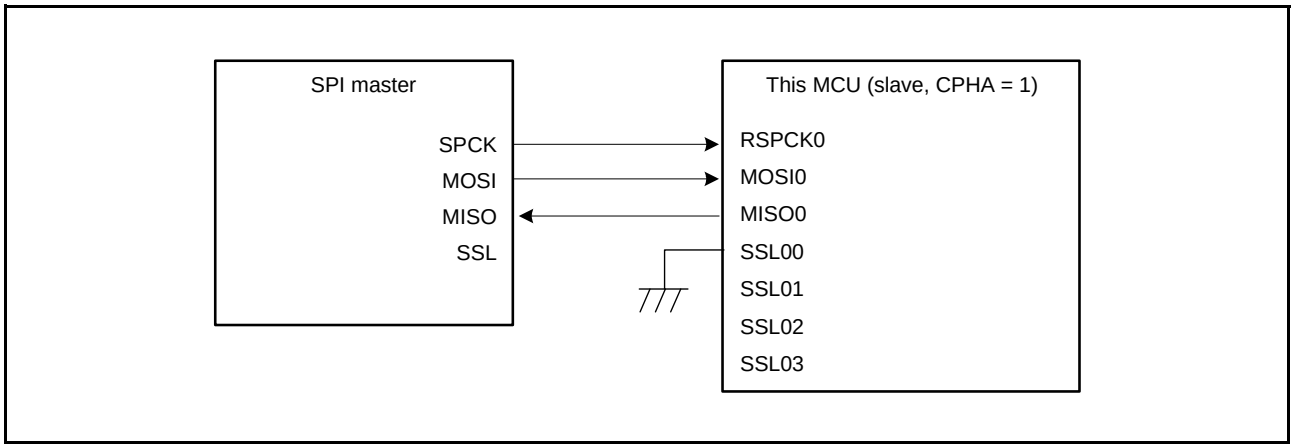

Figure 41.7 Single-Master/Single-Slave Configuration Example (This MCU = Slave, CPHA = 1)

41.3.3.3 Single Master/Multi-Slave (with This MCU Acting as Master)

Figure 41.8 shows a single-master/multi-slave RSPI system configuration example when this MCU is used as a master. In the example of Figure 41.8, the RSPI system is comprised of this MCU (master) and four slaves (SPI slave 0 to SPI slave 3).

The RSPCK0 and MOSI0 outputs of this MCU (master) are connected to the SPCK and MOSI inputs of SPI slave 0 to SPI slave 3. The MISO outputs of SPI slave 0 to SPI slave 3 are all connected to the MISO0 input of this MCU (master). SSL00 to SSL03 outputs of this MCU (master) are connected to the SSL inputs of SPI slave 0 to SPI slave 3, respectively.

This MCU (master) drives RSPCK0, MOSI0, and SSL00 to SSL03. Of the SPI slave 0 to SPI slave 3, the slave that receives low-level input into the SSL input drives MISO.

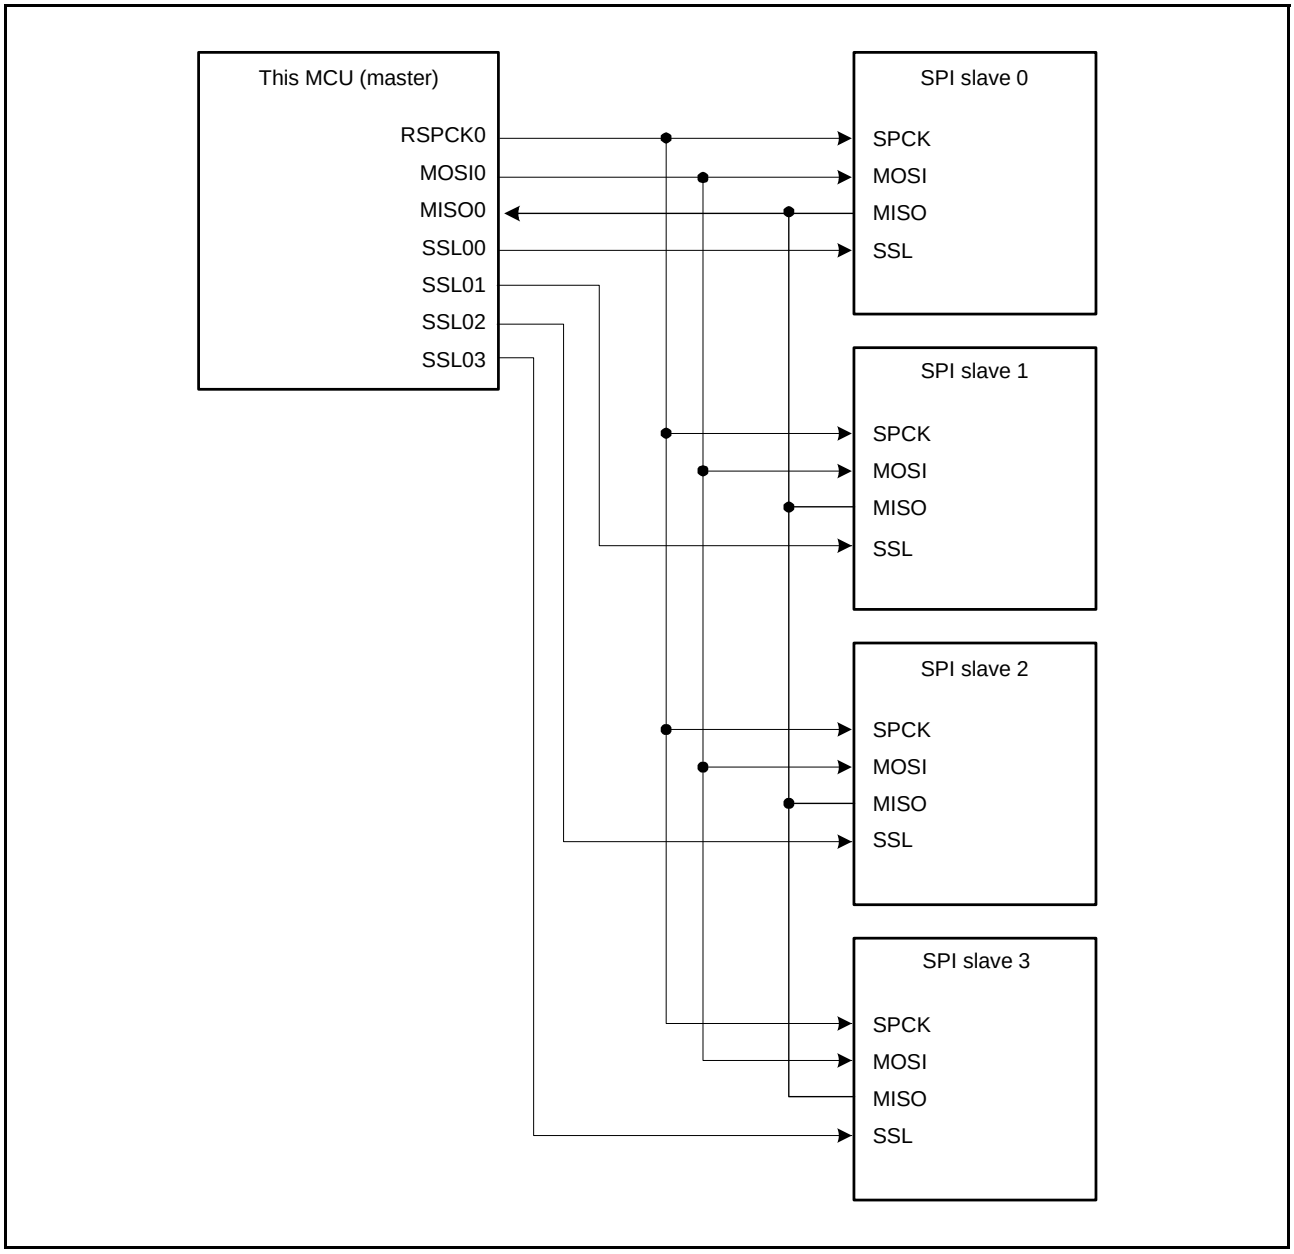

Figure 41.8 Single-Master/Multi-Slave Configuration Example (This MCU = Master)

41.3.3.4 Single Master/Multi-Slave (with This MCU Acting as Slave)

Figure 41.9 shows a single-master/multi-slave RSPI system configuration example when this MCU is used as a slave. In the example of Figure 41.9, the RSPI system is comprised of an SPI master and two MCUs (slave X and slave Y). The SPCK and MOSI outputs of the SPI master are connected to the RSPCK0 and MOSI0 inputs of the MCUs (slave X and slave Y). The MISO0 outputs of the MCUs (slave X and slave Y) are all connected to the MISO input of the SPI master. SSLX and SSLY outputs of the SPI master are connected to the SSL00 inputs of the MCUs (slave X and slave Y), respectively.

The SPI master always drives SPCK, MOSI, SSLX, and SSLY. Of the MCUs (slave X and slave Y), the slave that receives low-level input into the SSL00 input drives MISO0.

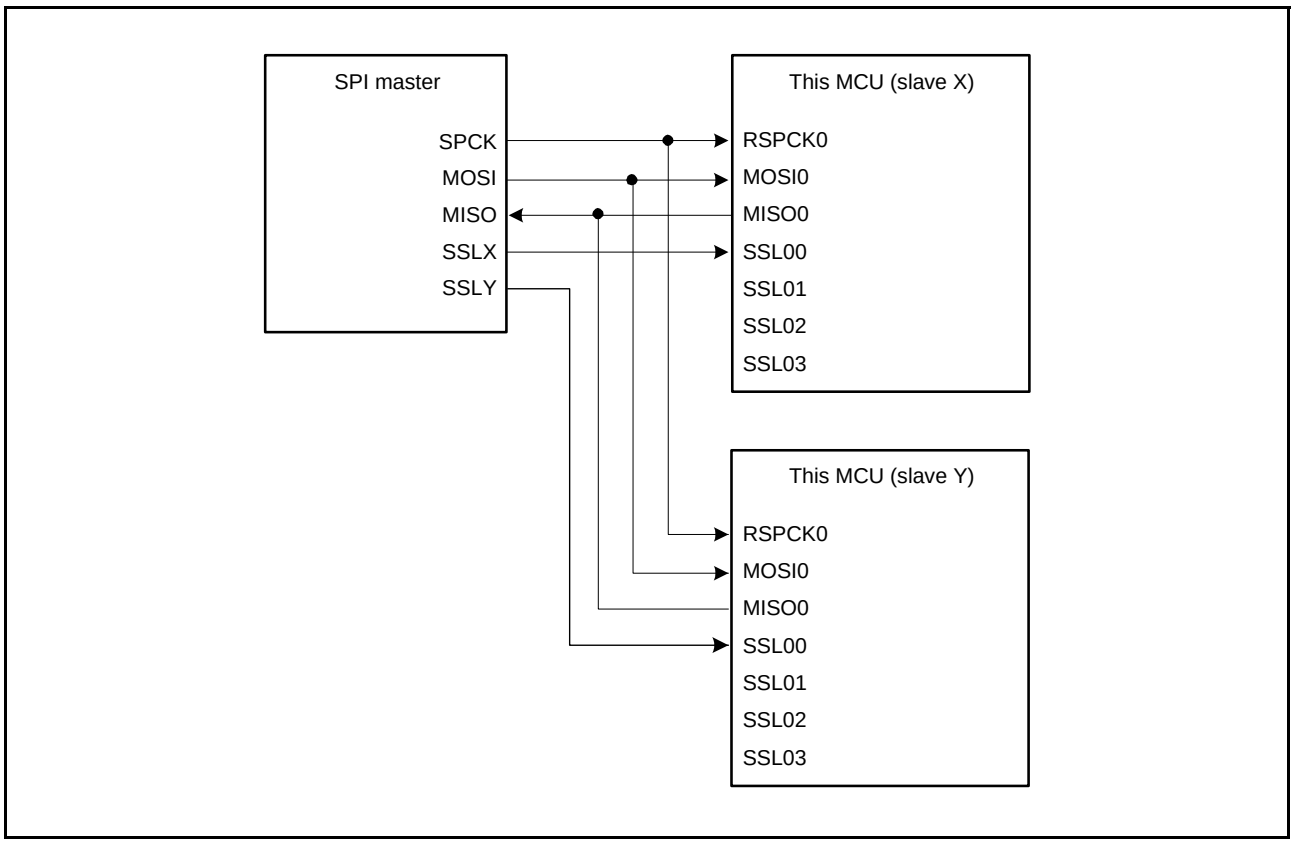

Figure 41.9 Single-Master/Multi-Slave Configuration Example (This MCU = Slave)

41.3.3.5 Multi-Master/Multi-Slave (with This MCU Acting as Master)

Figure 41.10 shows a multi-master/multi-slave RSPI system configuration example when this MCU is used as a master. In the example of Figure 41.10, the RSPI system is comprised of two MCUs (master X and master Y) and two SPI slaves (SPI slave 1 and SPI slave 2).

The RSPCK0 and MOSI0 outputs of the MCUs (master X and master Y) are connected to the SPCK and MOSI inputs of SPI slaves 1 and 2. The MISO outputs of SPI slaves 1 and 2 are connected to the MISO0 inputs of the MCUs (master X and master Y). Any generic port Y output from this MCU (master X) is connected to the SSL00 input of this MCU (master Y). Any generic port X output of this MCU (master Y) is connected to the SSL00 input of this MCU (master X). The SSL01 and SSL02 outputs of the MCUs (master X and master Y) are connected to the SSL inputs of the SPI slaves 1 and 2. In this configuration example, since the system can be comprised solely of SSL00 input, and SSL01 and SSL02 outputs for slave connections, the SSL03 output of this MCU is not required.

This MCU drives RSPCK0, MOSI0, SSL01, and SSL02 when the SSL00 input level is high. When the SSL00 input level is low, this MCU detects a mode fault error, sets RSPCK0, MOSI0, SSL01, and SSL02 to Hi-Z, and releases the RSPI bus right to the other master. Of the SPI slaves 1 and 2, the slave that receives low-level input into the SSL input drives MISO.

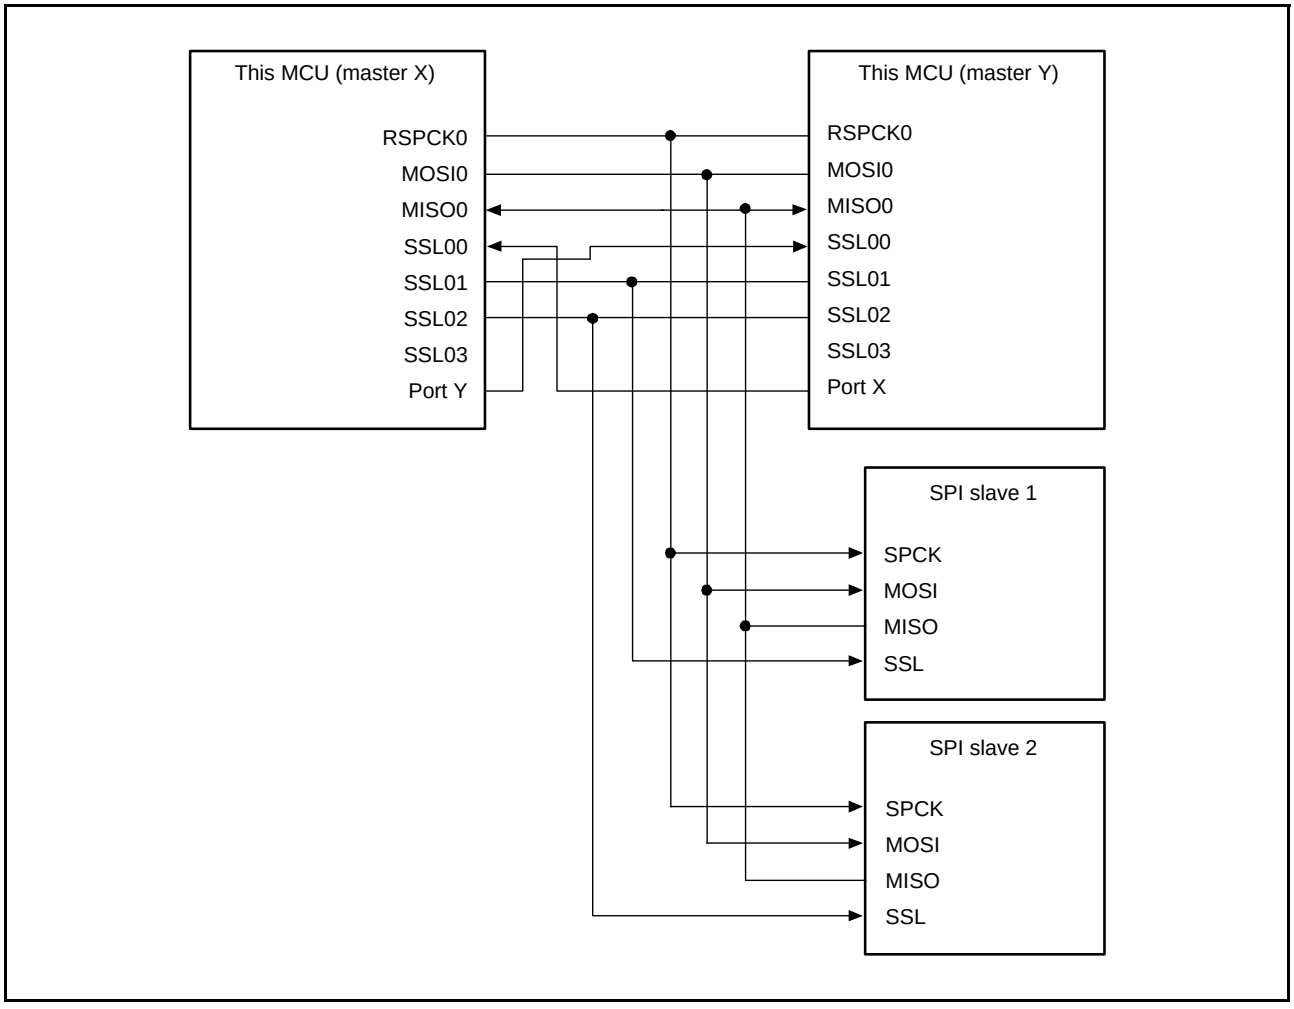

Figure 41.10 Multi-Master/Multi-Slave Configuration Example (This MCU = Master)

When setting TI SSP, enter the following levels for port X and port Y.

- Start of communication: the value of SSLP.SSL0P of the other master
- End of communication: the inverted value of SSLP.SSL0P of the other master

41.3.3.6 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (with This MCU Acting as Master)

Figure 41.11 shows a master (clock synchronous operation)/slave (clock synchronous operation) RSPI system configuration example when this MCU is used as a master. In the master (clock synchronous operation)/slave (clock synchronous operation) configuration, SSL00 to SSL03 of this MCU (master) are not used.
This MCU (master) drives the RSPCK0 and MOSI0. The SPI slave drives the MISO.

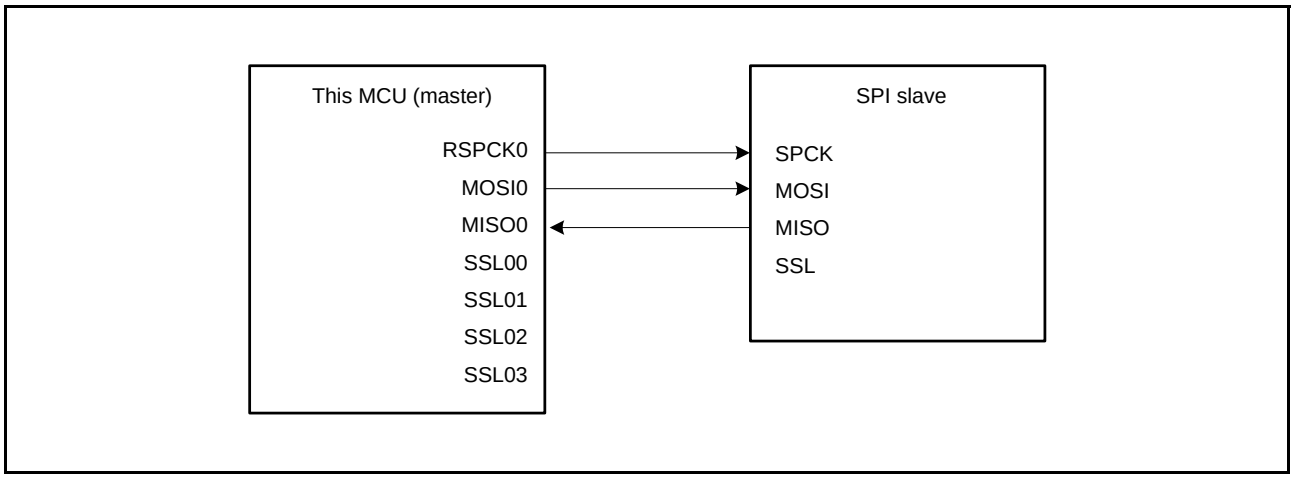

Figure 41.11 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) Configuration Example (This MCU = Master)

41.3.3.7 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (with This MCU Acting as Slave)

Figure 41.12 shows a master (clock synchronous operation)/slave (clock synchronous operation) RSPI system configuration example when this MCU is used as a slave. When this MCU is to operate as a slave (clock synchronous operation), this MCU (slave) drives the MISO0 and the SPI master drives the SPCK and MOSI. In addition, SSL00 to SSL03 of this MCU (slave) are not used.
Only in the single-slave configuration in which the SPCMDm.CPHA bit is set to 1, this MCU (slave) can execute serial transfer.

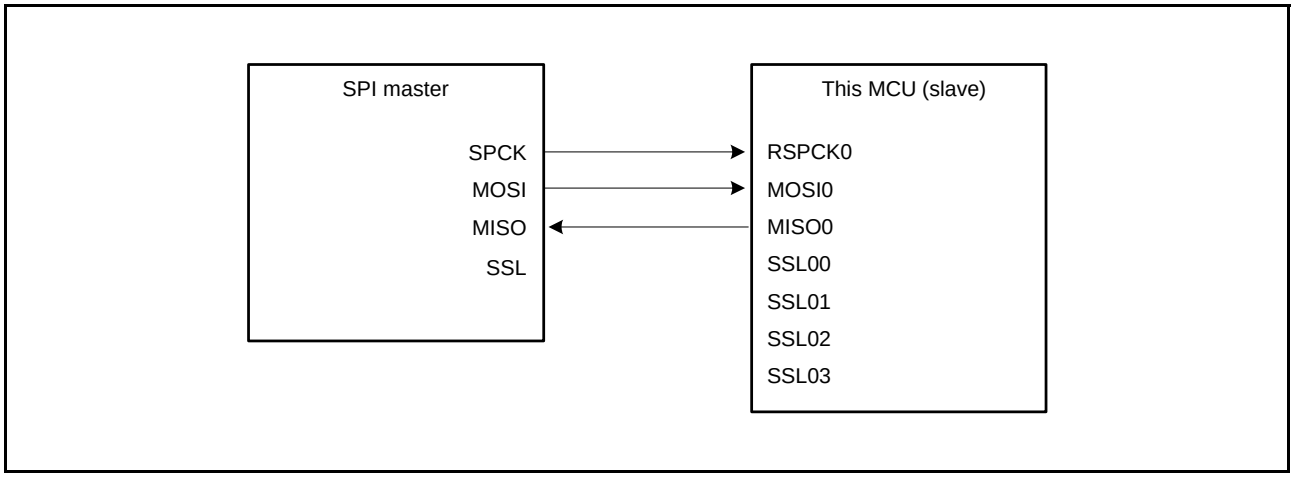

Figure 41.12 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) Configuration Example (This MCU = Slave, CPHA = 1)

41.3.4 Data Format

The RSPIA's data format depends on the settings in RSPI command register m (SPCMDm) (m = 0 to 7) and the parity enable bit in RSPI control register (SPCR.SPPE). Regardless of whether the MSB or LSB is first, the RSPIA treats the range from the LSB bit in the RSPI data register (SPDR) to the selected data length as transmit data.

41.3.4.1 Data Format of One Frame

The format of one frame of data before or after transfer is shown below.

(a) With Parity Disabled

When parity is disabled, transmission or reception of data proceeds with the length in bits selected in the RSPI data length setting bits in RSPI command register m (SPCMDm.SPB[4:0]).

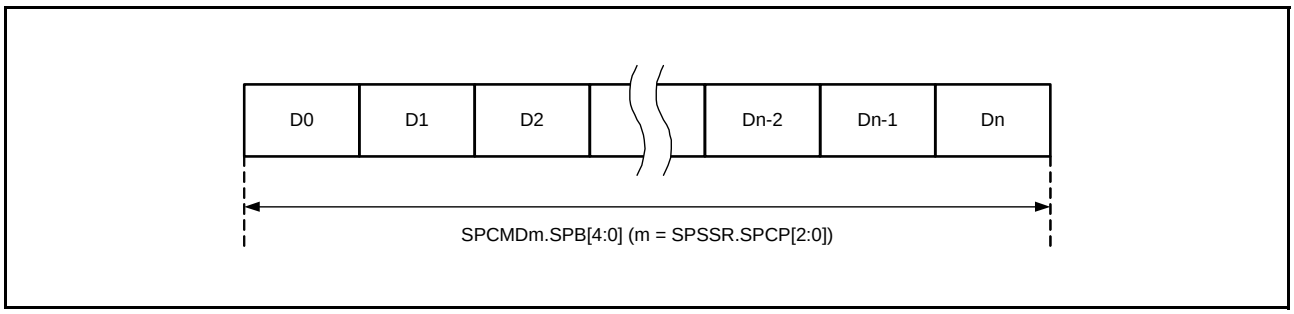

Figure 41.13 Outline of the Data Format (with Parity Disabled)

(b) With Parity Enabled

When parity is enabled, transmission or reception of data proceeds with the length in bits selected in the RSPI data length setting bits in RSPI command register m (SPCMDm.SPB[4:0]). In this case, however, the last bit is a parity bit.

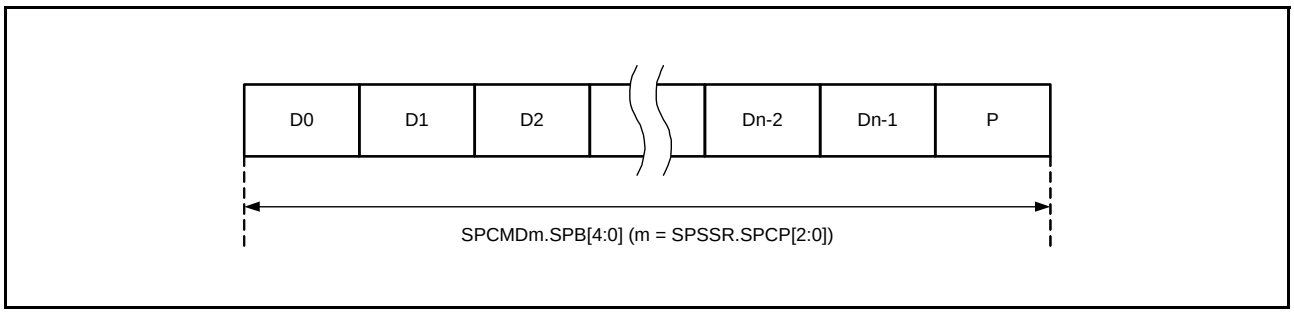

Figure 41.14 Outline of the Data Format (with Parity Enabled)

41.3.4.2 When Parity is Disabled (SPCR.SPPE = 0)

When parity is disabled, data for transmission are copied to the shift register with no prior processing. A description of the connection between the RSPI data register (SPDR) and the shift register in terms of the combination of MSB or LSB first and data length is given below.

(1) MSB First Transfer (32-Bit Data)

Figure 41.15 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, an RSPI data length of 32 bits, and MSB first selected.
In transmission, bits T31 to T00 from the current stage of the transmit buffer are copied to the shift register. Data for transmission are shifted out from the shift register in order from T31, through T30, and so on to T00.
In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R31 to R00 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer.

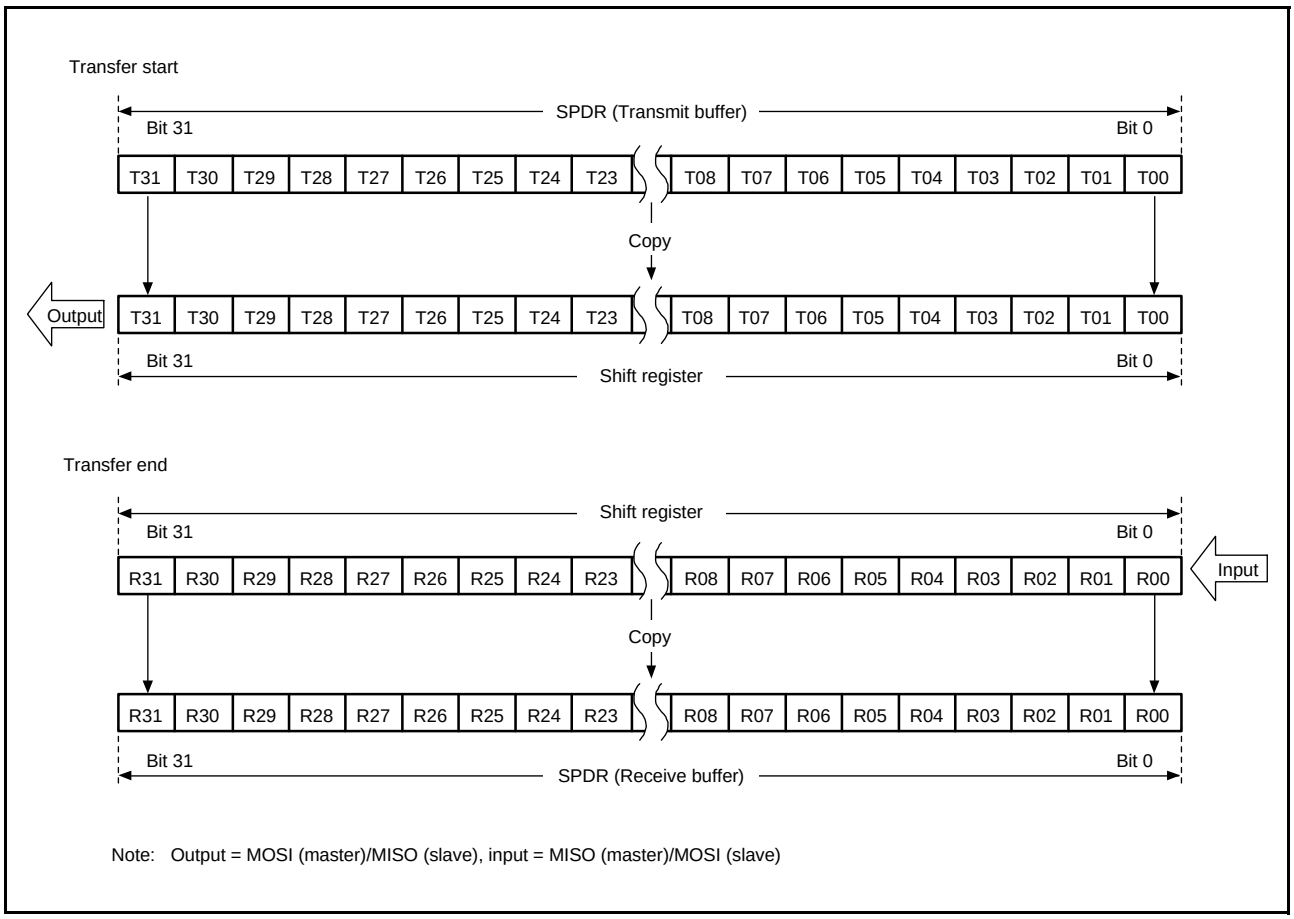

Figure 41.15 MSB First Transfer (32-Bit Data, Parity Disabled)

(2) MSB First Transfer (24-Bit Data)

Figure 41.16 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, 24 bits as the RSPI data length for an example that is not 32 bits, and MSB first selected.
In transmission, the lower-order 24 bits (T23 to T00) from the current stage of the transmit buffer are copied to the shift register. Data for transmission are shifted out from the shift register in order from T23, through T22, and so on to T00.
In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R23 to R00 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer.

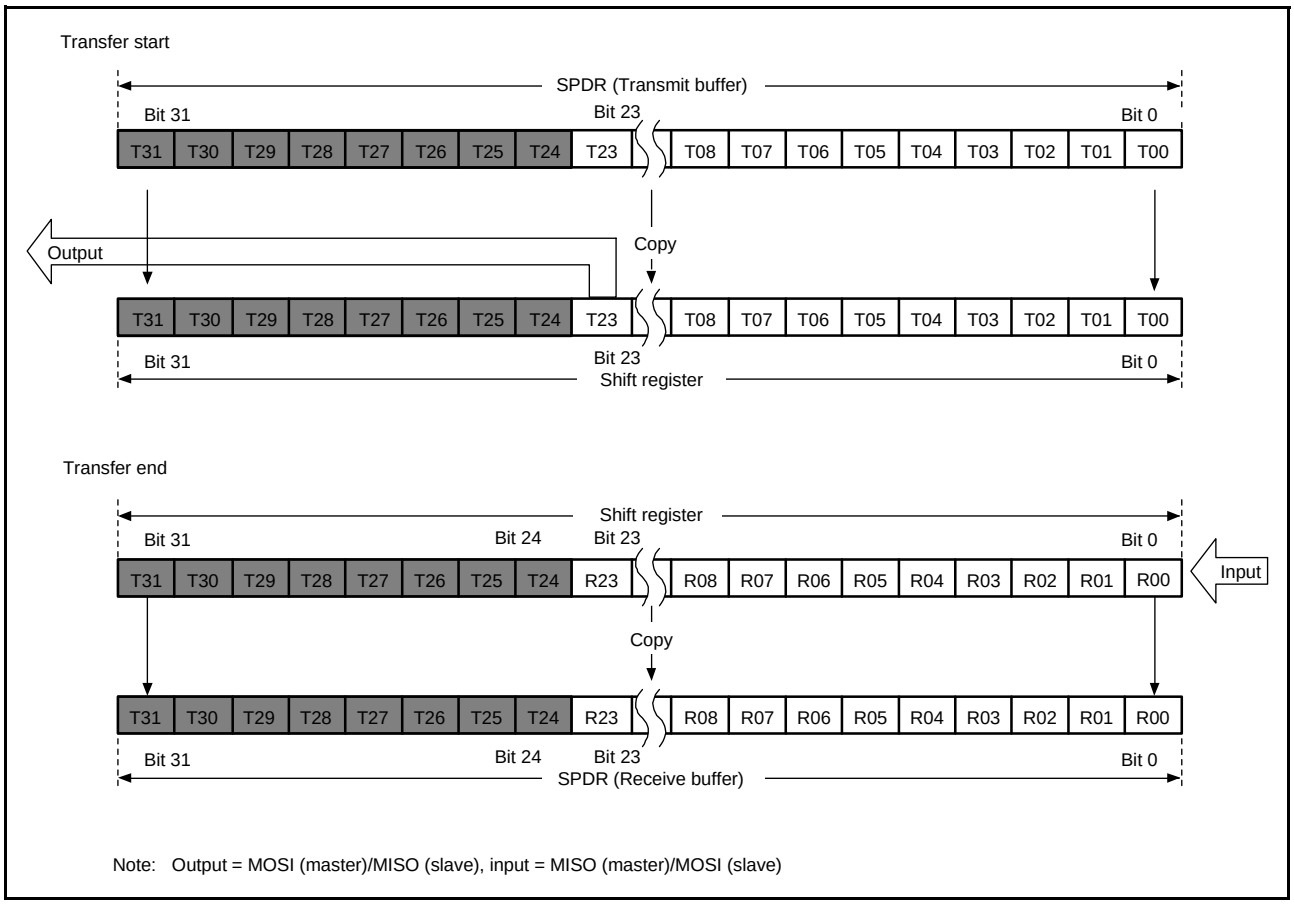

Figure 41.16 MSB First Transfer (24-Bit Data, Parity Disabled)

(3) LSB First Transfer (32-Bit Data)

Figure 41.17 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, an RSPI data length of 32 bits, and LSB first selected.

In transmission, bits T31 to T00 from the current stage of the transmit buffer are reordered bit by bit to obtain the order T00 to T31 for copying to the shift register. Data for transmission are shifted out from the shift register in order from T00, through T01, and so on to T31.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R00 to R31 have been collected after input of the required number of cycles of RSPCK, the values in the shift register are reordered bit by bit to obtain the order R31 to R00 for copying to the receive buffer.

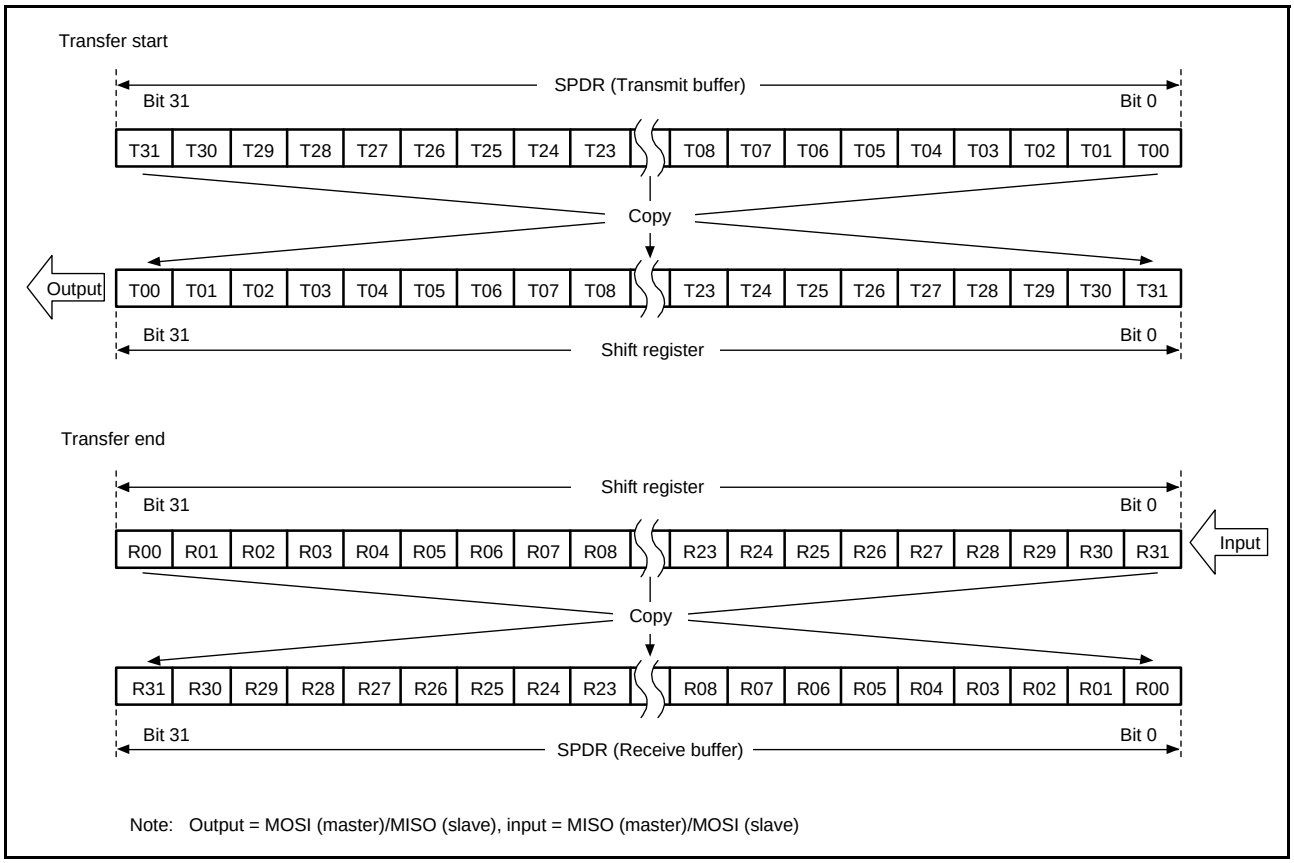

Figure 41.17 LSB First Transfer (32-Bit Data, Parity Disabled)

(4) LSB First Transfer (24-Bit Data)

Figure 41.18 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, 24 bits as the RSPI data length for an example that is not 32 bits, and LSB first selected.

In transmission, the lower-order 24 bits (T23 to T00) from the current stage of the transmit buffer are reordered bit by bit to obtain the order T00 to T23 for copying to the shift register. Data for transmission are shifted out from the shift register in order from T00, through T01, and so on to T23.

In reception, received data are shifted in bit by bit through bit 8 of the shift register. When bits R00 to R23 have been collected after input of the required number of cycles of RSPCK, the values in the shift register are reordered bit by bit to obtain the order R23 to R00 for copying to the receive buffer.

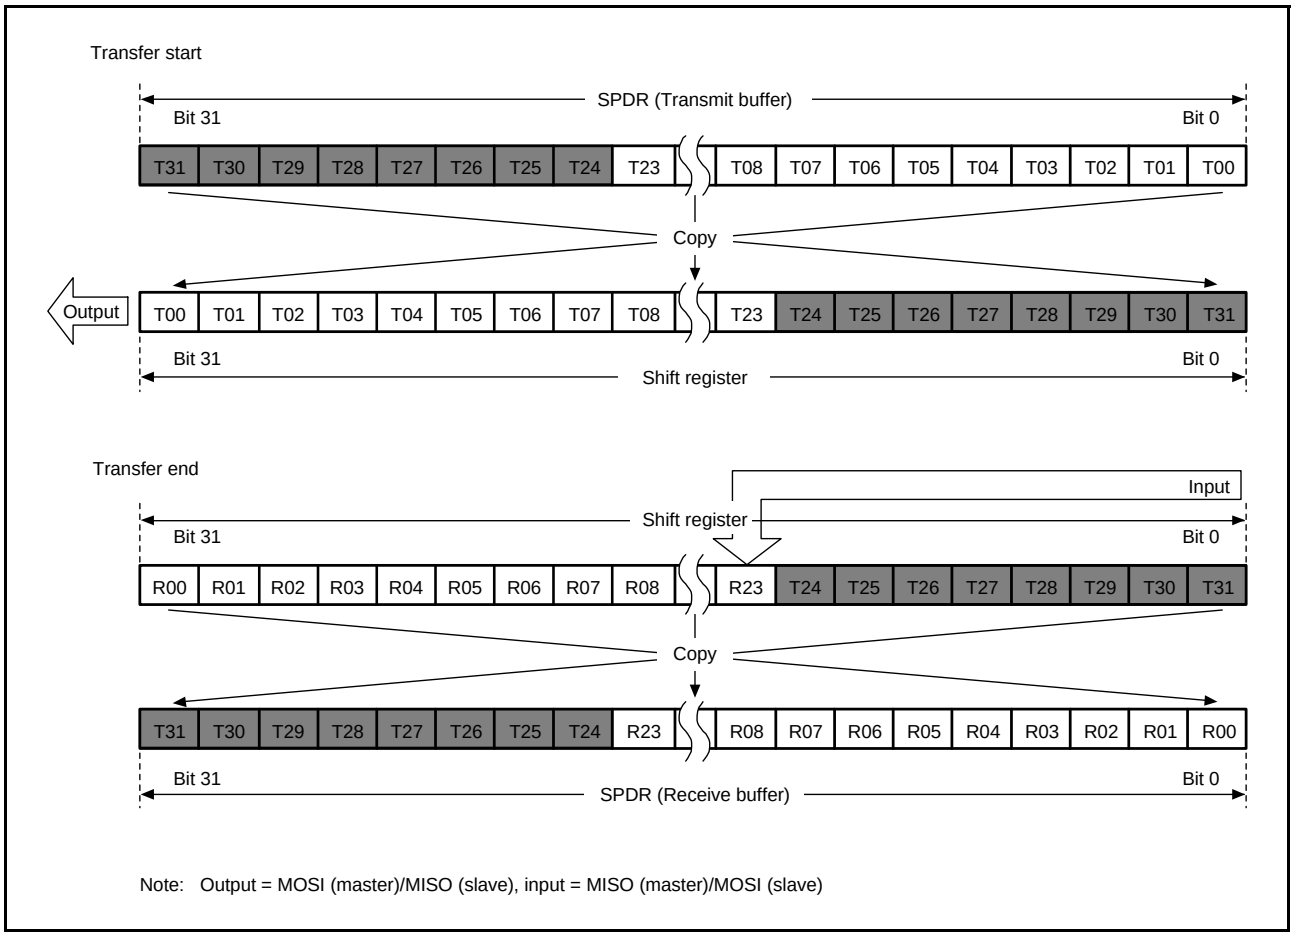

Figure 41.18 LSB First Transfer (24-Bit Data, Parity Disabled)

41.3.4.3 When Parity is Enabled (SPCR.SPPE = 1)

When parity is enabled, the lowest-order bit of the data for transmission becomes a parity bit. Hardware calculates the value of the parity bit.

(1) MSB First Transfer (32-Bit Data)

Figure 41.19 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, an RSPI data length of 32 bits, and MSB first selected.

In transmission, the value of the parity bit (P) is calculated from bits T31 to T01. This replaces the final bit, T00, and the whole is copied to the shift register. Data are transmitted in the order T31, T30, …, T01, and P.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R31 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. On copying of data to the receive buffer, the data from R31 to P are checked to judge the parity error.

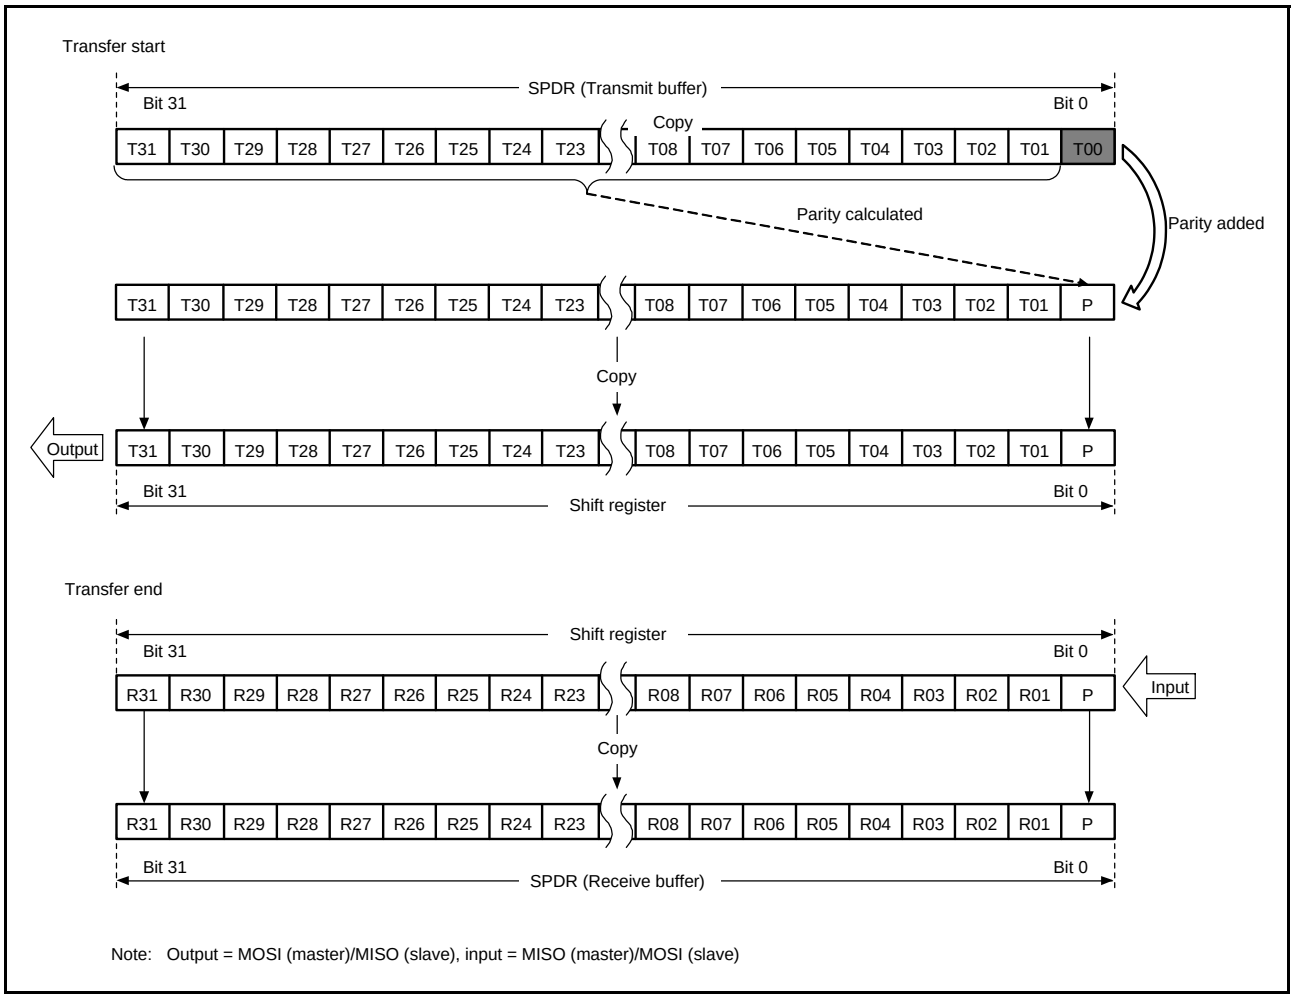

Figure 41.19 MSB First Transfer (32-Bit Data, Parity Enabled)

(2) MSB First Transfer (24-Bit Data)

Figure 41.20 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, 24 bits as the RSPI data length for an example that is not 32 bits, and MSB first selected.
In transmission, the value of the parity bit (P) is calculated from bits T23 to T01. This replaces the final bit, T00, and the whole is copied to the shift register. Data are transmitted in the order T23, T22, …, T01, and P.
In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R23 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the receive buffer. On copying of data to the receive buffer, the data from R23 to P are checked to judge the parity error.

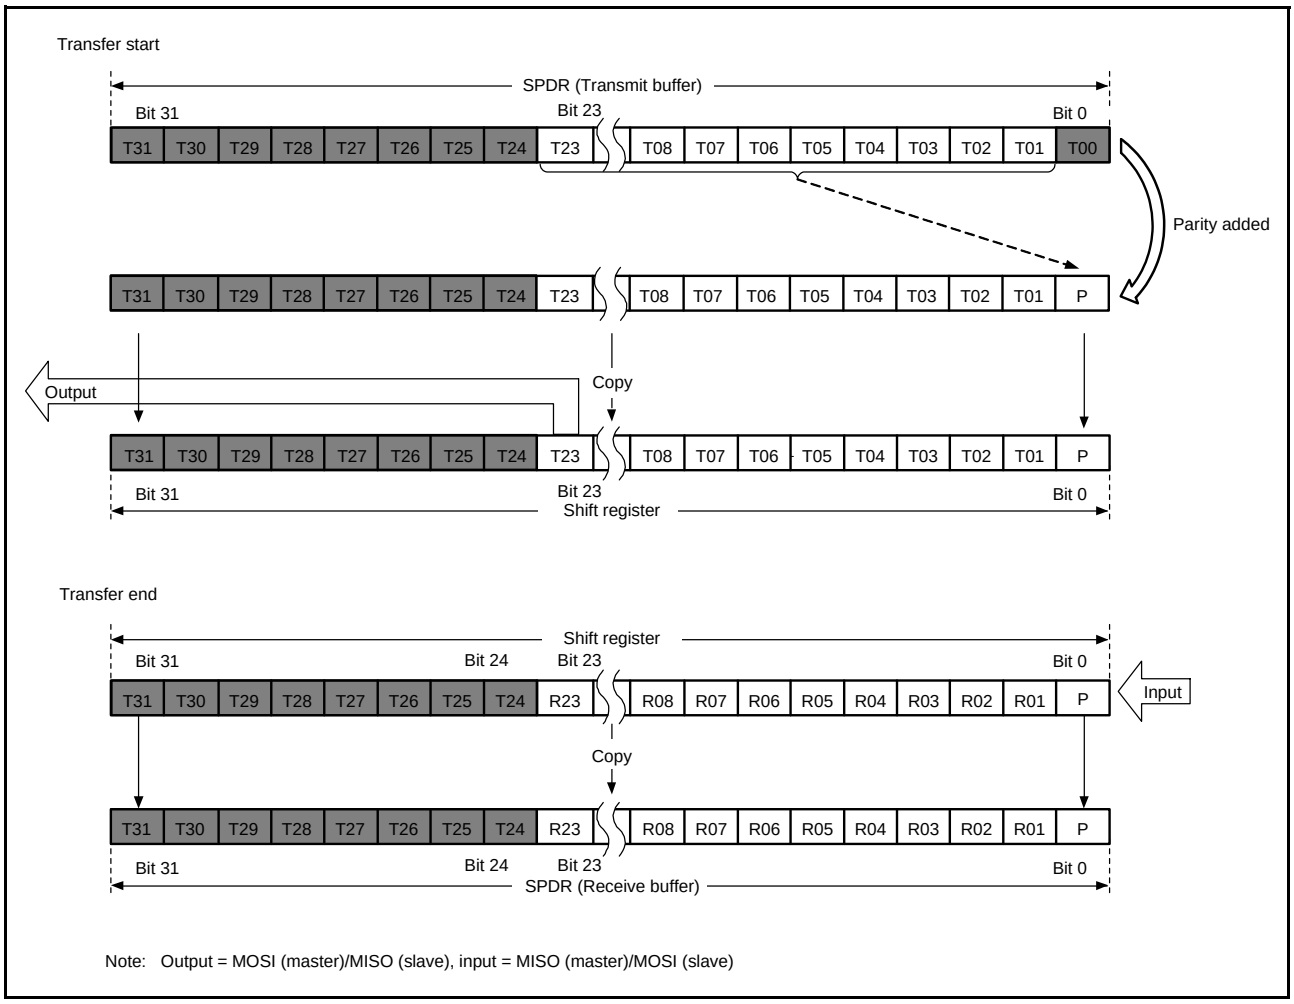

Figure 41.20 MSB First Transfer (24-Bit Data, Parity Enabled)

(3) LSB First Transfer (32-Bit Data)

Figure 41.21 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, an RSPI data length of 32 bits, and LSB first selected.

In transmission, the value of the parity bit (P) is calculated from bits T30 to T00. This replaces the final bit, T31, and the whole is copied to the shift register. Data are transmitted in the order T00, T01, …, T30, and P.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R00 to P have been collected after input of the required number of cycles of RSPCK, the values in the shift register are reordered bit by bit to obtain the order P to R00 for copying to the receive buffer. On copying of data to the receive buffer, the data from R00 to P are checked to judge the parity error.

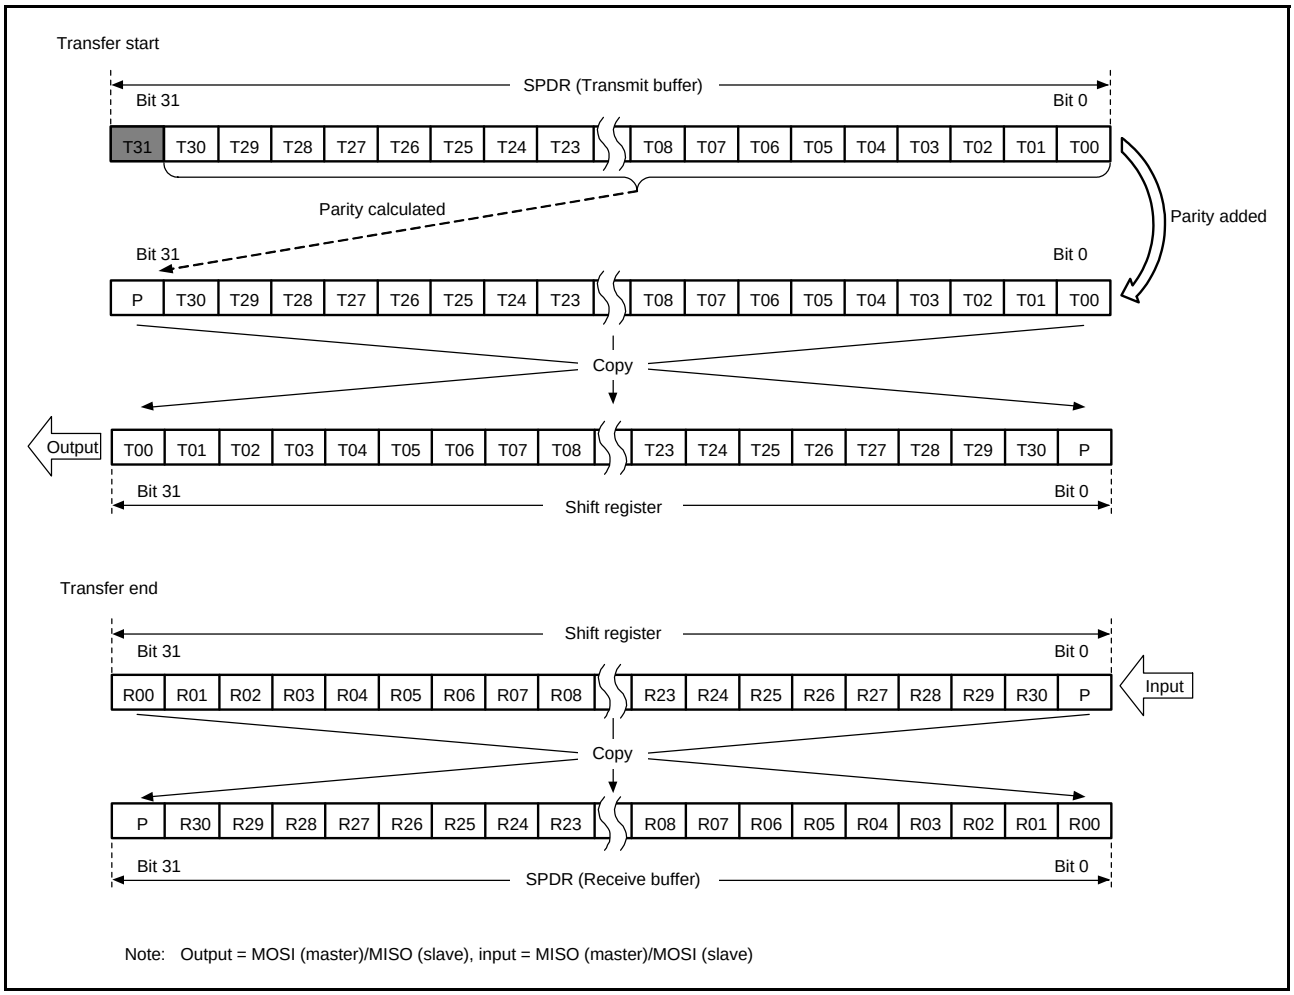

Figure 41.21 LSB First Transfer (32-Bit Data, Parity Enabled)

(4) LSB First Transfer (24-Bit Data)

Figure 41.22 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, 24 bits as the RSPI data length for an example that is not 32 bits, and LSB first selected.
In transmission, the value of the parity bit (P) is calculated from bits T22 to T00. This replaces the final bit, T23, and the whole is copied to the shift register. Data are transmitted in the order T00, T01, …, T22, and P.
In reception, received data are shifted in bit by bit through bit 8 of the shift register. When bits R00 to P have been collected after input of the required number of cycles of RSPCK, the values in the shift register are reordered bit by bit to obtain the order P (bit 23) to R00 (bit 0) for copying to the receive buffer. On copying of data to the receive buffer, the data from R00 to P are checked to judge the parity error.

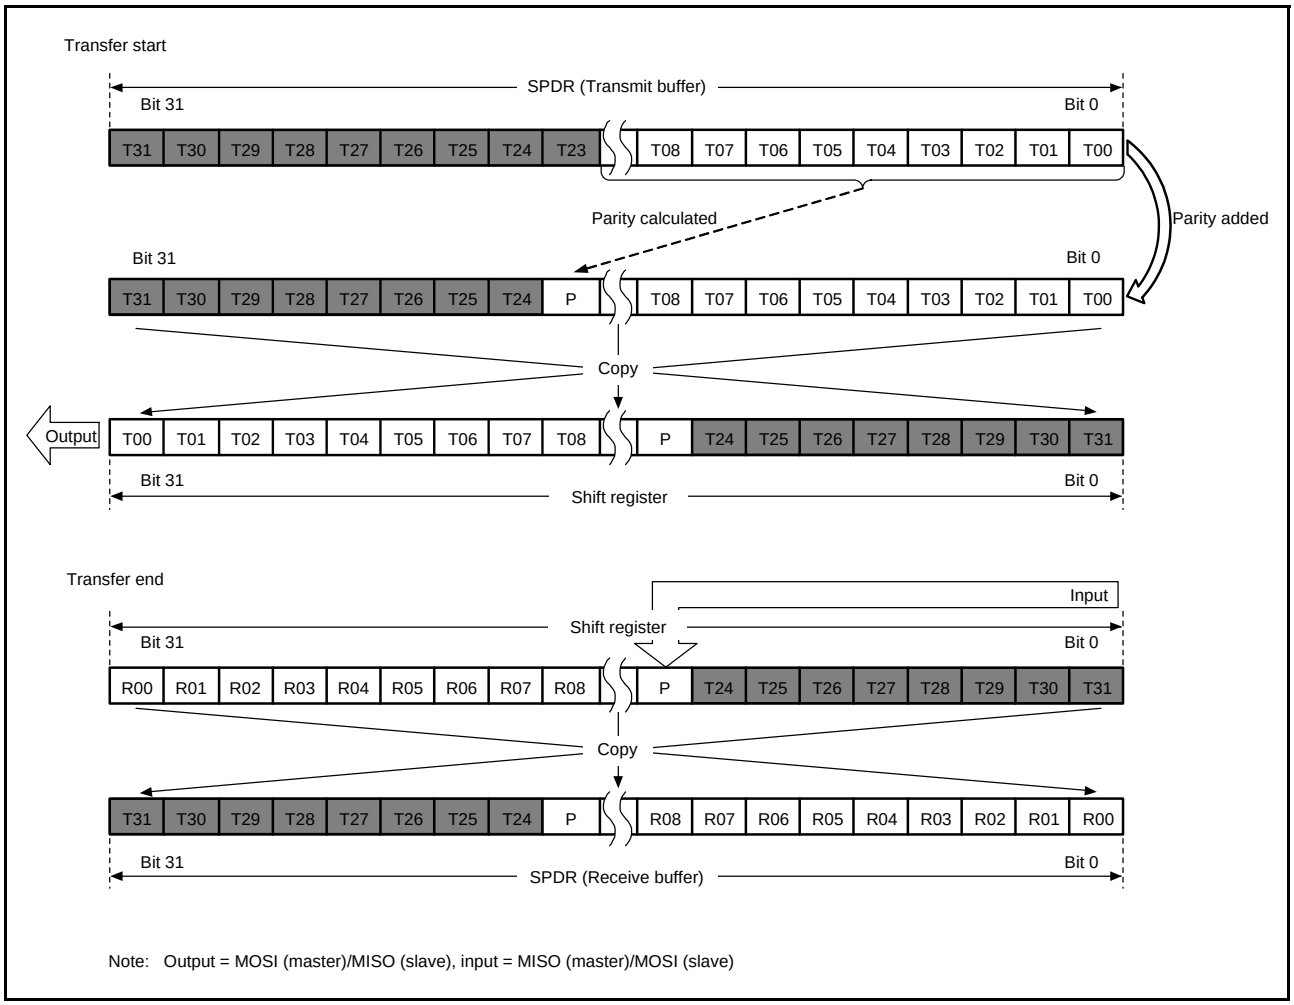

Figure 41.22 LSB First Transfer (24-Bit Data, Parity Enabled)

41.3.4.4 Byte Swap Transmission

When the SPDCR.BYSW bit is 1 (byte swapping of SPDR data enabled), data bytes written in the transmit buffer (SPDR) will be swapped (in 8 bit units) when the data is transferred to the shift register. Figure 41.23 shows data transfer between the SPDR register and the shift register when data length is 32 bits in combination of MSB/LSB first with byte swapping enabled/disabled.

(1) MSB first transfer (when the byte swap is disabled)
Data (Byte 3 [T31 to T24] to Byte 0 [T07 to T00]) in the transmit buffer are copied to the shift register. Bit values in the shift register are shifted and transmitted in the order of T31, T30, …, and T00 as transmit data.

(2) MSB first transfer (when the byte swap is enabled)
Byte values of the transmit buffer (Byte 3 [T31 to T24] to Byte 0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte 0 [T07 to T00] to Byte 3 [T31 to T24].
Bit values in the shift register are shifted and transmitted in the order of T07, T06, …, T00, T15, T14, …, T08, T23, T22, …, T16, T31, T30, …, and T24 as transmit data.

(3) LSB first transfer (when the byte swap is disabled)
Bit values of the transmit buffer (Byte 3 [T31 to T24] to Byte 0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte 0 [T00 to T07] to Byte 3 [T24 to T31].
Bit values in the shift register are shifted and transmitted in the order of T00, T01, …, and T31 as transmit data.

(4) LSB first transfer (when the byte swap is enabled)
Bit values of each byte of the transmit buffer (Byte 3 [T31 to T24] to Byte 0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte 3 [T24 to T31] to Byte 0 [T00 to T07].
Bit values in the shift register are shifted and transmitted in the order of T24, T25, …, T31, T16, T17, …, T23, T08, T09, …, T15, T00, T01, …, and T07 as transmit data.

32-bit Byte Swap Specifications	Byte Swap is Disabled (BYSW = 0)	Byte Swap is Enabled (BYSW = 1)
MSB-first (LSBF = 0)		LSB-first (LSBF = 1)		
Figure 41.23 Transmit Data Handling in MSB/LSB First with Byte Swapping Enabled/Disabled (Data Length = 32 bits)

Figure 41.24 shows data transfer between the SPDR register and the shift register when data length is 16 bits in combination of MSB/LSB first with byte swapping enabled/disabled.

(1) MSB first transfer (when the byte swap is disabled)
Data (Byte 1 [T15 to T08] to Byte 0 [T07 to T00]) in the transmit buffer are copied to the shift register in the order of Byte 1 [T15 to T08] to Byte 0 [T07 to T00]. Bit values in the shift register are shifted and transmitted in the order of T15, T14, …, and T00 as transmit data.

(2) MSB first transfer (when the byte swap is enabled)
Byte values of the transmit buffer (Byte 1 [T15 to T08] to Byte 0 [T07 to T00]) are reversed in byte units and are copied to the shift register in the order of Byte 0 [T07 to T00] to Byte 1 [T15 to T08]. Bit values in the shift register are shifted and transmitted in the order of T07, T06, …, T00, T15, T14, …, T08 as transmit data.

(3) LSB first transfer (when the byte swap is disabled)
Bit values of the transmit buffer (Byte 1 [T15 to T08] to Byte 0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte 0 [T00 to T07] to Byte 1 [T15 to T08]. Bit values in the shift register are shifted and transmitted in the order of T00, T01, …, and T15 as transmit data.

(4) LSB first transfer (when the byte swap is enabled)
Bit values of each byte of the transmit buffer (Byte 1 [T15 to T08] to Byte 0 [T07 to T00]) are reversed in bit units and are copied to the shift register in the order of Byte 1 [T08 to T15] to Byte 0 [T00 to T07].
Bit values in the shift register are shifted and transmitted in the order of T08, T09, …, T15, T00, T01, …, and T07 as transmit data.

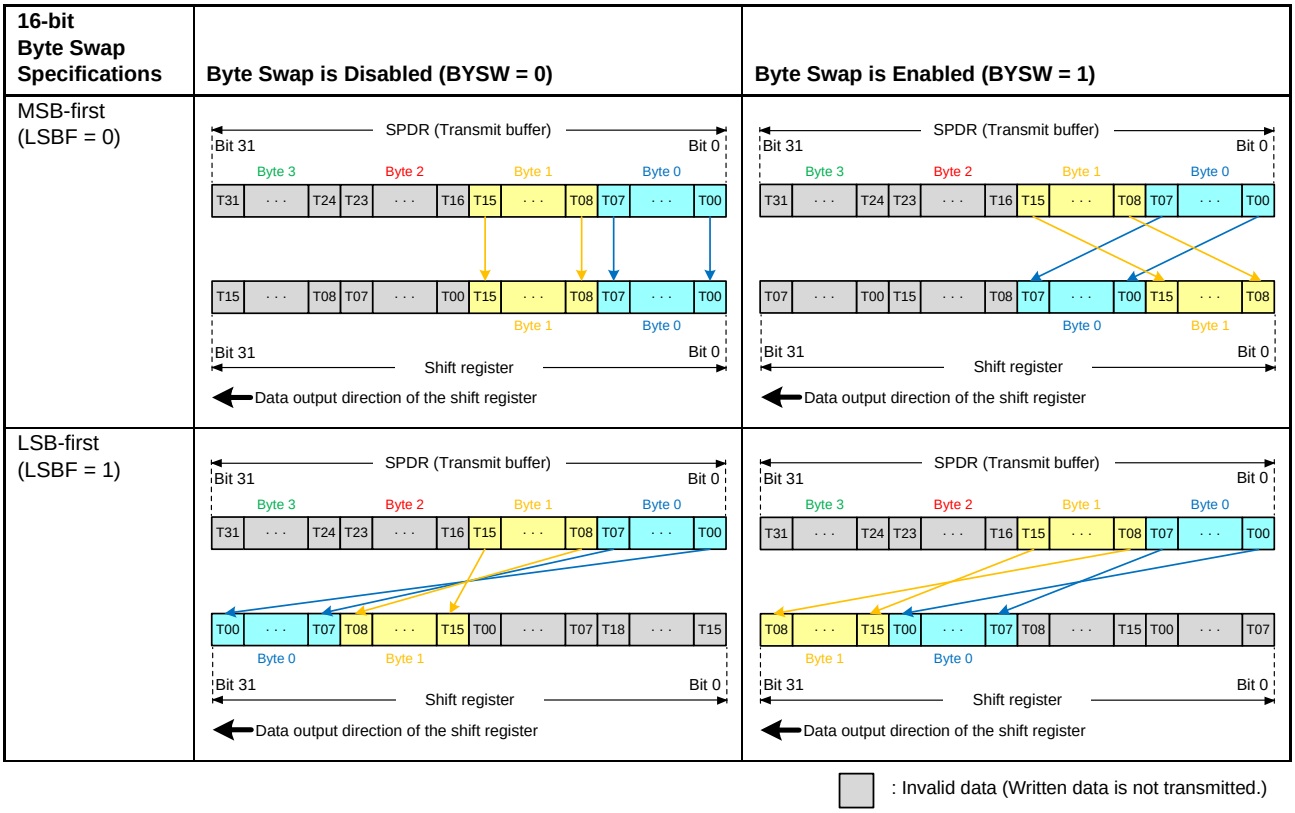

Figure 41.24 Transmit Data Handling in MSB/LSB First with Byte Swapping Enabled/Disabled (Data Length = 16 bits)

Note 1. When using the byte swap, set 16 bits or 32 bits to the data length (SPCMDm.SPB[4:0] setting). If setting the other length (4 to 15 or 17 to 31 bits), the operation is not guaranteed.

Note 2. When the byte swap is enabled, disable the parity function (SPCR.SPPE = 0). If the parity function is enabled (SPCR.SPPE = 1), the operation after the change is not guaranteed.
Note 3. Set the SPDCR.BYSW bit, while the SPCR.SPE bit is 0. If the value of the SPDCR.BYSW bit is changed while the SPCR.SPE bit is 1, the operation after the change is not guaranteed.

41.3.4.5 Byte Swap Reception

When the SPDCR.BYSW bit is 1 (byte swapping of SPDR data enabled), data bytes in the shift register will be swapped (in 8 bit units) when the data is transferred to the receive buffer (SPDR). Figure 41.25 shows data transfer between the shift register and the SPDR register when data length is 32 bits in combination of MSB/LSB first with byte swapping enabled/disabled.

(1) MSB first transfer (when the byte swap is disabled)
The first received data (R31) is stored in bit 0 of the shift register, and received data is shifted in the order of R31, R30, …, and R00. When necessary RSPCK cycles are input and data is stored from Byte 3 [R31 to R24] to Byte 0 [R07 to R00], the shift register value is copied to the receive buffer.

(2) MSB first transfer (when the byte swap is enabled)
The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07, R06, …, R00, R15, R14, …, R08, R23, R22, …, R16, R31, R30, …, and R24. When necessary RSPCK cycles are input and data is stored from Byte 0 [R07 to R00] to Byte 3 [R31 to R24], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte 3 [R31 to R24] to Byte 0 [R07 to R00].

(3) LSB first transfer (when the byte swap is disabled)
The first received data (R00) is stored in bit 0 of the shift register, and received data is shifted in the order of R00, R01, …, and R31. When necessary RSPCK cycles are input and data is stored from Byte 0 [R00 to R07] to Byte 3 [R24 to R31], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte 3 [R31 to R24] to Byte 0 [R07 to R00].

(4) LSB first transfer (when the byte swap is enabled)
The first received data (R24) is stored in bit 0 of the shift register, and received data is shifted in the order of R24, R25, …, R31, R16, R17, …, R23, R08, R09, …, R15, R00, R01, …, and R07. When necessary RSPCK cycles are input and data is stored from Byte 3 [R24 to R31] to Byte 0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte 3 [R31 to R24] to Byte 0 [R07 to R00].

32-bit Byte Swap Specifications	Byte Swap is Disabled (BYSW = 0)	Byte Swap is Enabled (BYSW = 1)
MSB-first (LSBF = 0)		LSB-first (LSBF = 1)		
Figure 41.25 Receive Data Handling in MSB/LSB First with Byte Swapping Enabled/Disabled (Data Length = 32 bits)

Figure 41.26 shows data transfer between the shift register and the SPDR register when data length is 16 bits in combination of MSB/LSB first with byte swapping enabled/disabled.

(1) MSB first transfer (when the byte swap is disabled)
The first received data (R15) is stored in bit 0 of the shift register, and received data is shifted in the order of R15, R14, …, and R00. When necessary RSPCK cycles are input and data is stored from Byte 3 [R31 to R24] to Byte 0 [R07 to R00], the shift register value is copied to the receive buffer.

(2) MSB first transfer (when the byte swap is enabled)
The first received data (R07) is stored in bit 0 of the shift register, and received data is shifted in the order of R07, R06, …, R00, R15, R14, …, and R08. When necessary RSPCK cycles are input and data is stored from Byte 0 [R07 to R00] to Byte 1 [R15 to R08], byte values in the shift register are reversed in byte units and are copied to the receive buffer in the order of Byte 3 [R31 to R24] to Byte 0 [R07 to R00].

(3) LSB first transfer (when the byte swap is disabled)
The first received data (R00) is stored in bit 15 of the shift register, and received data is shifted in the order of R00, R01, …, R07, R08, R09, …, and R15. When necessary RSPCK cycles are input and data is stored from Byte 0 [R00 to R07] to Byte 1 [R08 to R15], bit values in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte 3 [R31 to R24] to Byte 0 [R07 to R00].

(4) LSB first transfer (when the byte swap is enabled)
The first received data (R08) is stored in bit 15 of the shift register, and received data is shifted in the order of R08, R09, …, R15, R00, R01, …, and R15. When necessary RSPCK cycles are input and data is stored from Byte 1 [R08 to R15] to Byte 0 [R00 to R07], bit values of each byte in the shift register are reversed in bit units and are copied to the receive buffer in the order of Byte 3 [R31 to R24] to Byte 0 [R07 to R00].

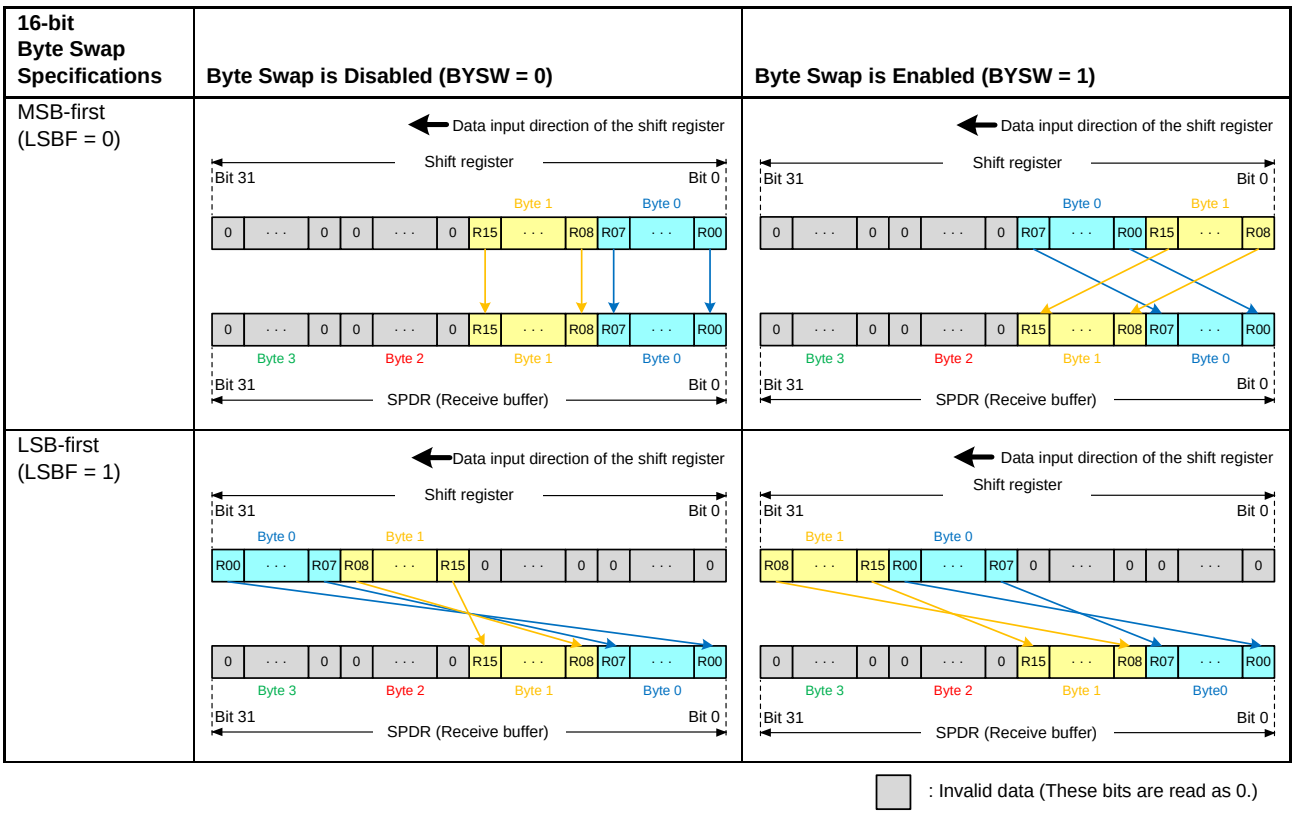

Figure 41.26 Receive Data Handling in MSB/LSB First with Byte Swapping Enabled/Disabled (Data Length = 16 bits)

Note 1. When using the byte swap, set 16 bits or 32 bits to the data length (SPCMDm.SPB[4:0] setting). If setting the other length (4 to 15 or 17 to 31 bits), the operation is not guaranteed.
Note 2. When the byte swap is enabled, disable the parity function (SPCR.SPPE = 0). If the parity function is enabled (SPCR.SPPE = 1), the operation after the change is not guaranteed.
Note 3. Set the SPDCR.BYSW bit, while the SPCR.SPE bit is 0. If the value of the SPDCR.BYSW bit is changed while the SPCR.SPE bit is 1, the operation after the change is not guaranteed.

41.3.5 Transfer Format (Frame Format)

41.3.5.1 CPHA = 0

Figure 41.27 shows a sample transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 0. Note that clock synchronous operation (the SPCR.SPMS bit is 1) should not performed when the RSPIA operates in slave mode (SPCR.MSTR = 0) and the CPHA bit is 0. In Figure 41.27, RSPCK0 (CPOL = 0) indicates the RSPCK0 signal waveform when the SPCMDm.CPOL bit is 0; RSPCK0 (CPOL = 1) indicates the RSPCK0 signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the RSPIA fetches serial transfer data into the shift register. The I/O directions of the signals depend on the RSPIA settings. For details, refer to section 41.3.2, Controlling RSPI Pins.

When the SPCMDm.CPHA bit is 0, the driving of valid data to the MOSI0 and MISO0 signals commences at an SSL0n signal assertion timing. The first RSPCK0 signal change timing that occurs after the SSL0n signal assertion becomes the first transfer data fetch timing. After this timing, data is sampled at every 1 RSPCK cycle. The change timing for MOSI0 and MISO0 signals is 1/2 RSPCK cycles after the transfer data fetch timing. The CPOL bit setting does not affect the RSPCK0 signal operation timing; it only affects the signal polarity.

t1 denotes a period from an SSL0n signal assertion to RSPCK0 oscillation (RSPCK delay). t2 denotes a period from the termination of RSPCK0 oscillation to an SSL0n signal negation (SSL negation delay). t3 denotes a period in which SSL0n signal assertion is suppressed for the next transfer after the end of serial transfer (next-access delay). t1, t2, and t3 are controlled by a master device running on the RSPI system. For a description of t1, t2, and t3 when the RSPIA of this MCU is in master mode, refer to section 41.3.13.1, Master Mode Operation.

[Motorola SPI]

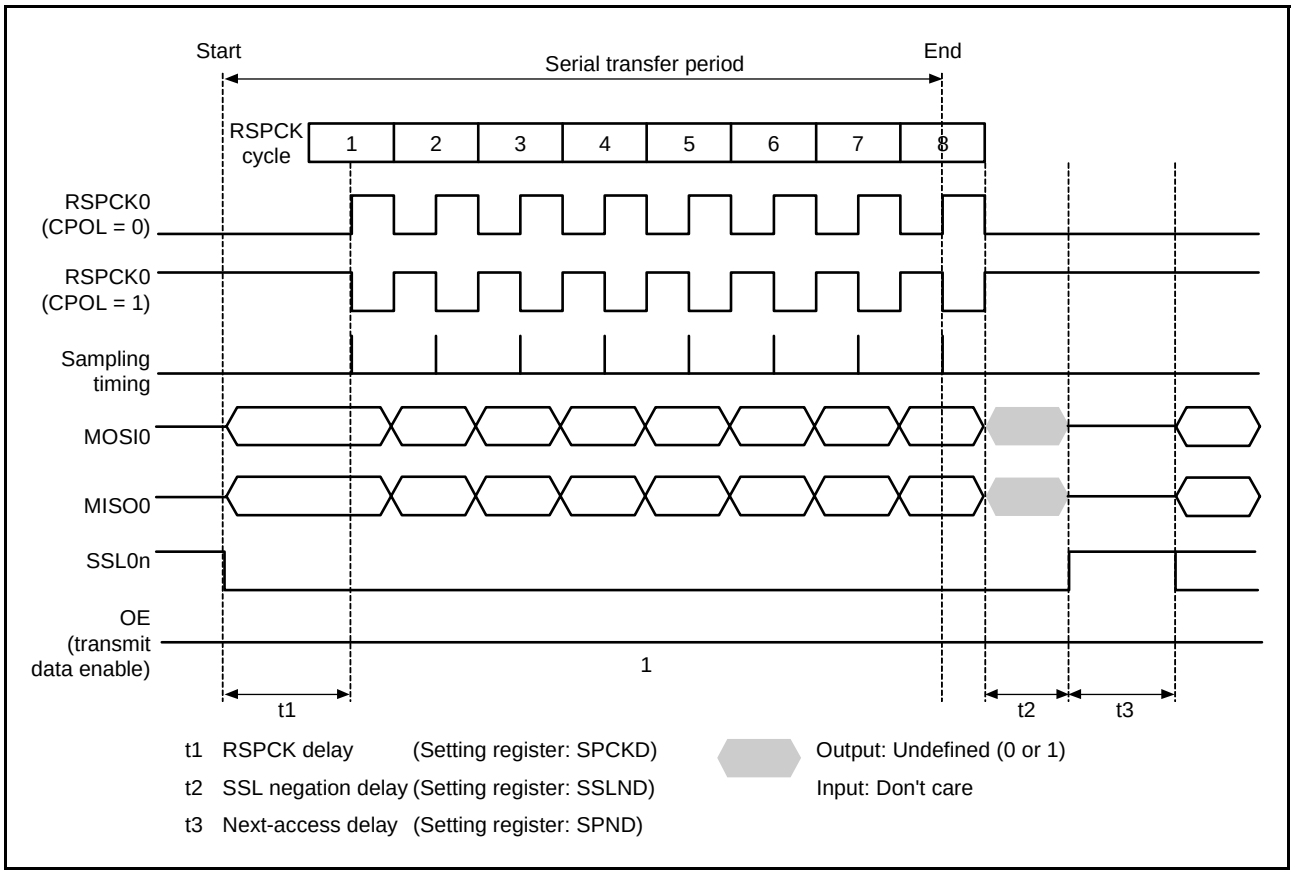

Figure 41.27 RSPI Transfer Format (CPHA = 0, FRFS = 0)

[TI SSP]

In TI SSP mode, setting the CPHA bit to 0 is not effective.

41.3.5.2 CPHA = 1

Figure 41.28 and Figure 41.29 show sample transfer formats for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 1. However, when the SPCR.SPMS bit is 1, the SSL0n signals are not used, and only the three signals RSPCK0, MOSI0, and MISO0 handle communications. In Figure 41.28, RSPCK0 (CPOL = 0) indicates the RSPCK0 signal waveform when the SPCMDm.CPOL bit is 0; RSPCK0 (CPOL = 1) indicates the RSPCK0 signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the RSPIA fetches serial transfer data into the shift register. The I/O directions of the signals depend on the RSPI mode (master or slave). For details, refer to section 41.3.2, Controlling RSPI Pins.

When the SPCMDm.CPHA bit is 1, the driving of invalid data to the MISO0 signal commences at an SSL0n signal assertion timing. The output of valid data to the MOSI0 and MISO0 signals commences at the first RSPCK0 signal change timing that occurs after the SSL0n signal assertion. After this timing, data is updated at every 1 RSPCK cycle. The transfer data fetch timing is 1/2 RSPCK cycles after the data update timing. The SPCMDm.CPOL bit setting does not affect the RSPCK0 signal operation timing; it only affects the signal polarity.

t1, t2, and t3 are the same as those in the case of CPHA = 0. For a description of t1, t2, and t3 when the RSPIA of this MCU is in master mode, refer to section 41.3.13.1, Master Mode Operation.

[Motorola SPI]

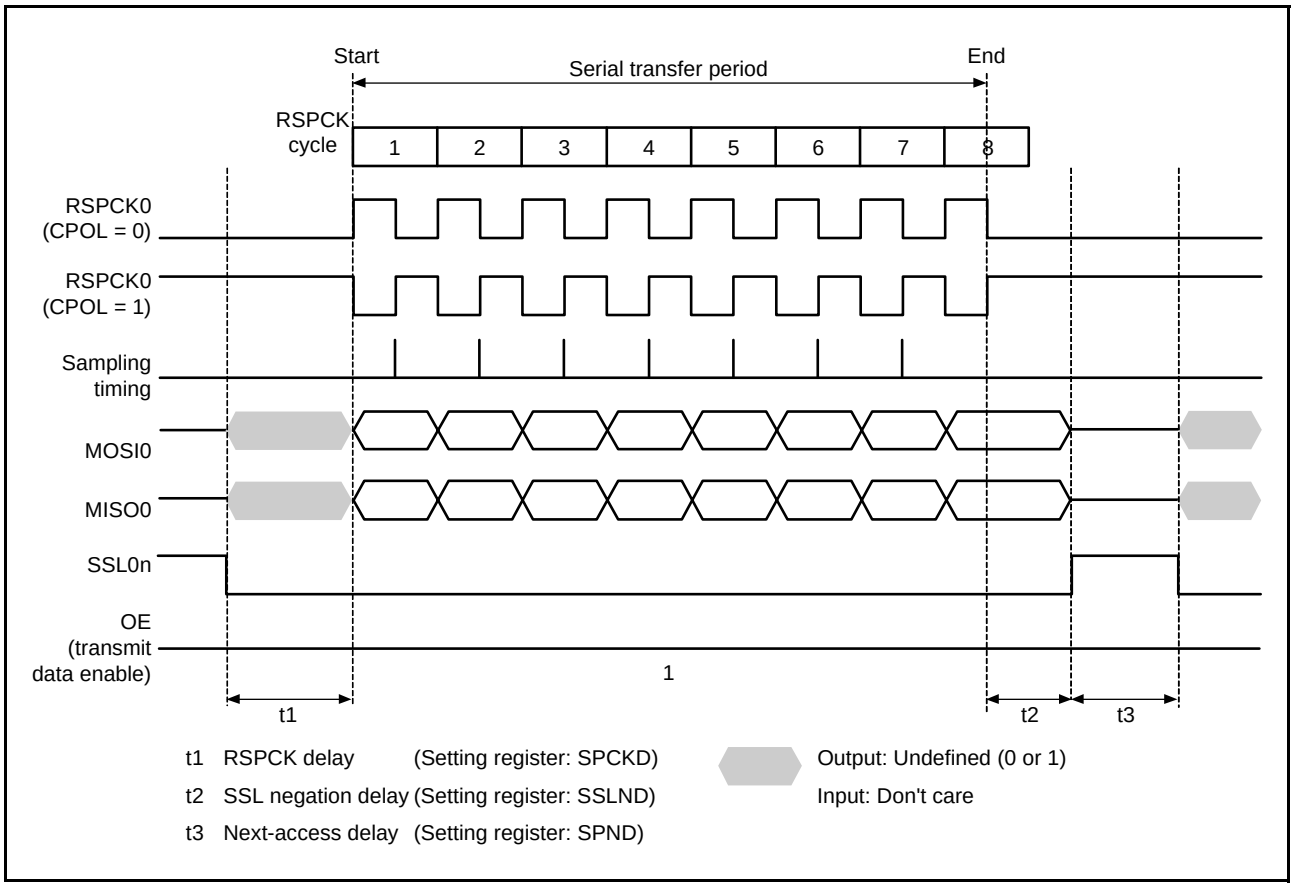

Figure 41.28 RSPI Transfer Format (CPHA = 1, FRFS = 0)

[TI SSP]

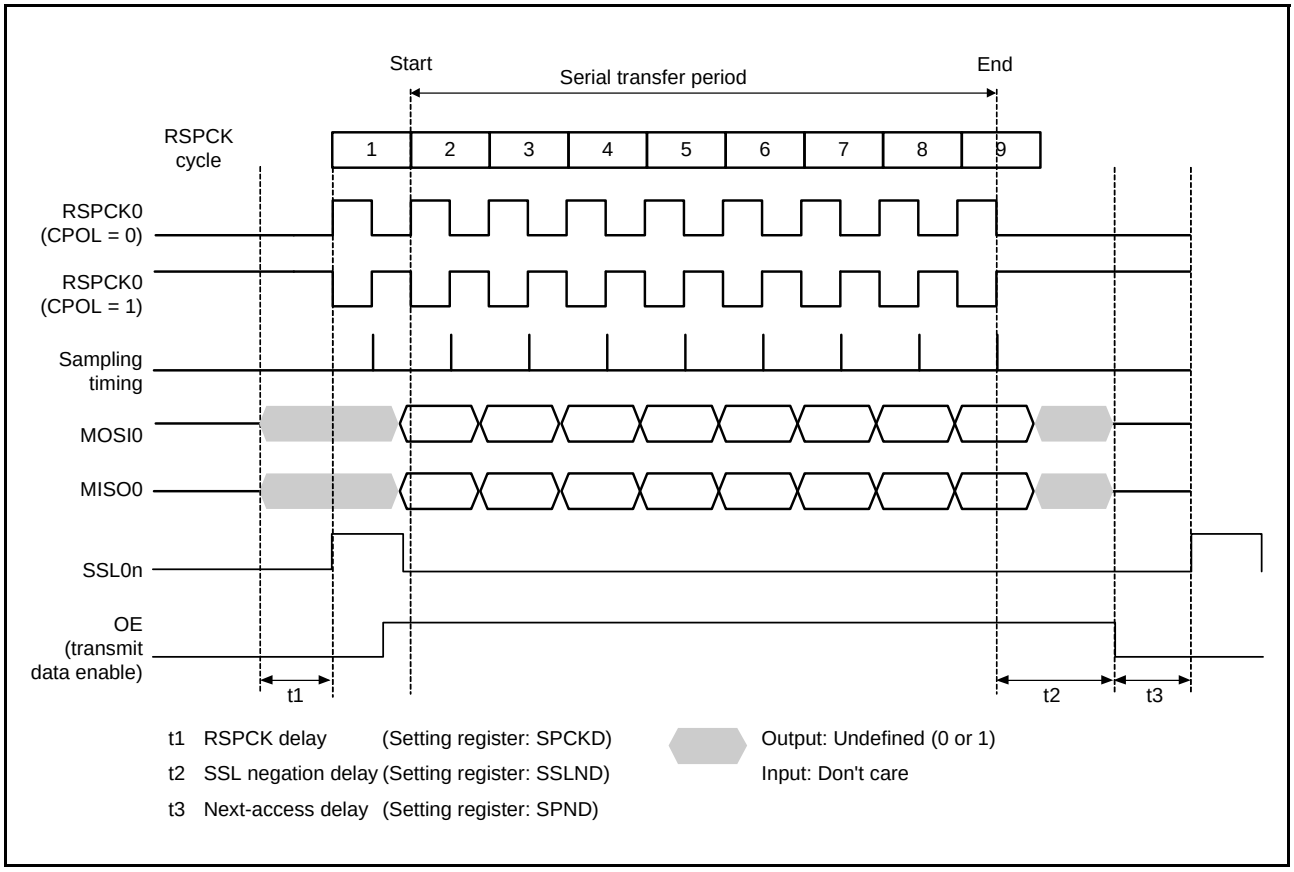

Figure 41.29 RSPI Transfer Format (CPHA = 1, FRFS = 1)

41.3.6 Communication Mode

Transmit-receive mode, transmit-only mode, and receive-only mode can be selected by the communication mode select bit (SPCR.CMMD[1:0]).

The SPDR access shown in Figure 41.30, Figure 41.31 and Figure 41.32 indicate the condition of access to the SPDR register, where W denotes a write cycle.

41.3.6.1 Transmit-Receive Mode (SPCR.CMMD[1:0] = 00b)

Figure 41.30 shows an example of operation when the communication mode select bits (SPCR.CMMD[1:0]) are set to 00b. In the example in Figure 41.30, the RSPIA performs an 8-bit serial transfer in which SPFCR.TTRG[1:0] = 00b, SPFCR.RTRG[1:0] = FIFO stage – 1, SPCMDm.CPHA = 1, and SPCMDm.CPOL = 0. The numbers given under the RSPCK0 waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

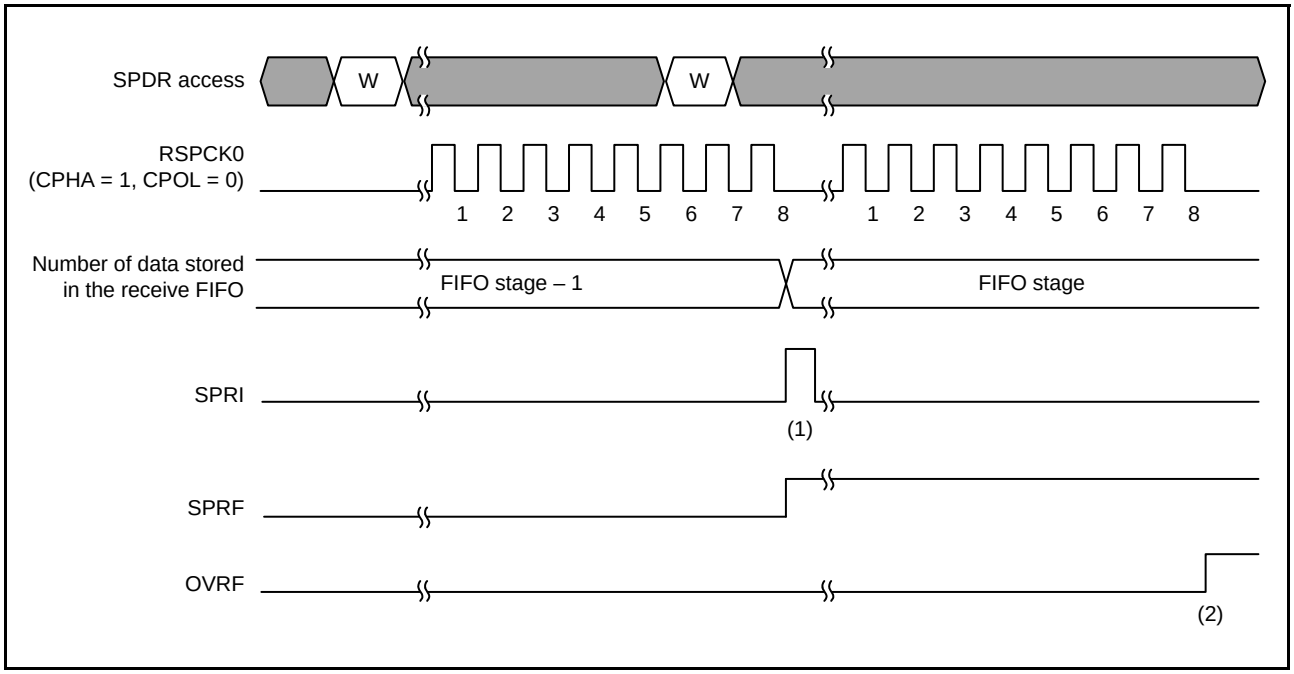

Figure 41.30 Operation Example of SPCR.CMMD[1:0] = 00b

The operation of the flags at timings shown in steps (1) and (2) in the figure is described below.

(1) When a serial transfer ends while the number of data stored in the SPDR receive buffer matches the number of frames set in SPFCR.RTRG[1:0] bits, the RSPIA generates a receive buffer full interrupt request (SPRI) (sets the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer.

(2) When a serial transfer ends with data for the number of FIFO stages is stored in the SPDR receive buffer, the RSPIA sets the SPSR.OVRF flag to 1 and discards the received data in the shift register.

When transmit-receive mode (CMMD[1:0] = 00b) is selected, reception occurs simultaneously with transmit operations. As such, the SPRF and OVRF flags in the SPSR register become 1 at the timing described in (1) and (2), respectively, according to the state of the receive buffer.

41.3.6.2 Transmit-Only Mode (SPCR.CMMD[1:0] = 01b)

Figure 41.31 shows an example of operation when the communication mode select bits (SPCR.CMMD[1:0]) are set to 01b. In the example in Figure 41.31, the RSPIA performs an 8-bit serial transfer in which SPFCR.TTRG[1:0] = 00b, SPFCR.RTRG[1:0] = 00b, SPCMDm.CPHA = 1, and SPCMDm.CPOL = 0. The numbers given under the RSPCK0 waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

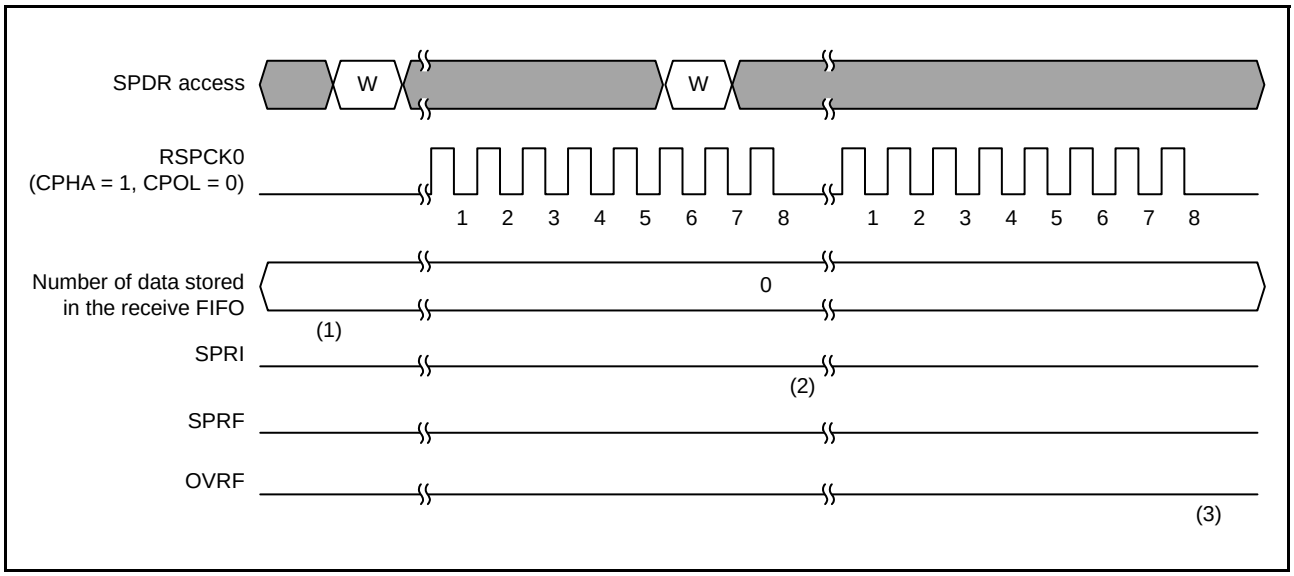

Figure 41.31 Operation Example of SPCR.CMMD[1:0] = 01b

The operation of the flags at timings shown in steps (1) to (3) in the figure is described below.

(1) Make sure there is no data left in the receive buffer and the SPSR.SPRF, OVRF flags are 0 before entering the mode of transmit operations only (SPCR.CMMD[1:0] = 01b).

(2) When a serial transfer ends without received data in the receive FIFO of SPDR, if transmit-only mode is selected (SPCR.CMMD[1:0] = 01b), the SPRF flag remains 0 and the RSPIA does not copy the data from the shift register to the receive buffer.

(3) Since the receive buffer of SPDR does not hold data that was received in the previous serial transfer, even when a serial transfer ends, the SPSR.OVRF flag retains the value of 0, and the data in the shift register is not copied to the receive buffer.

When transmit-only mode (SPCR.CMMD[1:0] = 01b) is selected, the RSPIA transmits data but does not receive data. Therefore, the SPSR.SPRF, OVRF flags remain 0 at the timings of (1) to (3).

41.3.6.3 Receive-Only Mode (SPCR.CMMD[1:0] = 10b)

Figure 41.32 shows an example of operation when the communication mode select bits (SPCR.CMMD[1:0]) are set to 10b. In the example in Figure 41.32, the RSPIA performs an 8-bit serial transfer in which SPFCR.TTRG[1:0] = 00b, SPFCR.RTRG[1:0] = FIFO stage – 1, SPCMDm.CPHA = 1, and SPCMDm.CPOL = 0. The numbers given under the RSPCK0 waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

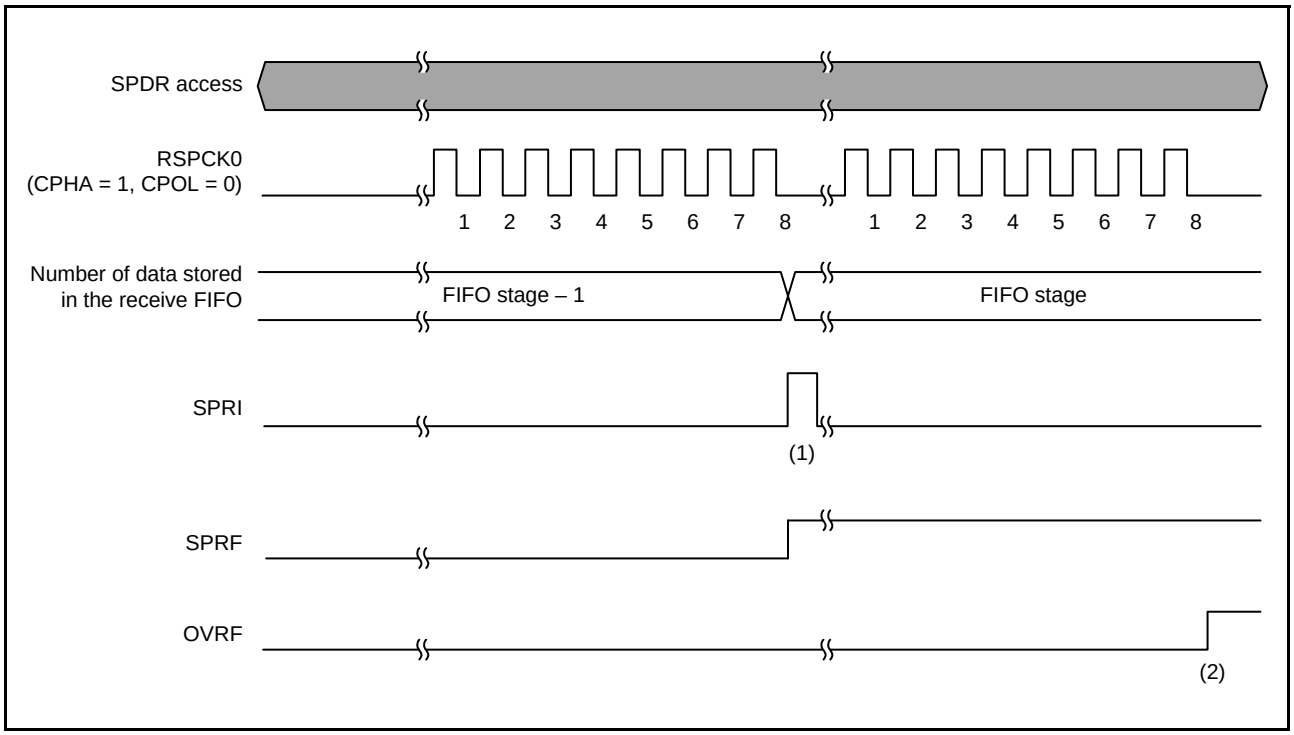

Figure 41.32 Operation Example of SPCR.CMMD[1:0] = 10b

The operation of the flags at timings shown in steps (1) to (2) in the figure is described below.

(1) When a serial transfer ends while the number of data stored in the SPDR receive buffer matches the number of frames set in SPFCR.RTRG[1:0] bits, the RSPIA generates a receive buffer full interrupt request (SPRI) (sets the SPSR.SPRF flag to 1) and copies the received data in the shift register to the receive buffer.

(2) When a serial transfer ends with data for the number of FIFO stages is stored in the SPDR receive buffer, the RSPIA sets the SPSR.OVRF flag to 1 and discards the received data in the shift register.

41.3.7 Transmit Buffer Empty/Receive Buffer Full Interrupts

Figure 41.33 shows an example of operation of the transmit buffer empty interrupt (SPTI) and the receive buffer full interrupt (SPRI). The SPDR register access shown in Figure 41.33 indicate the conditions of access to the SPDR register, where W denotes a write cycle, and R a read cycle. In the examples in Figure 41.33, the RSPIA performs an 8-bit serial transfer in which the SPCR.CMMD[1:0] bits are 00b, SPFCR.TTRG[1:0] bits are 00b, the SPFCR.RTRG[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCK0 waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

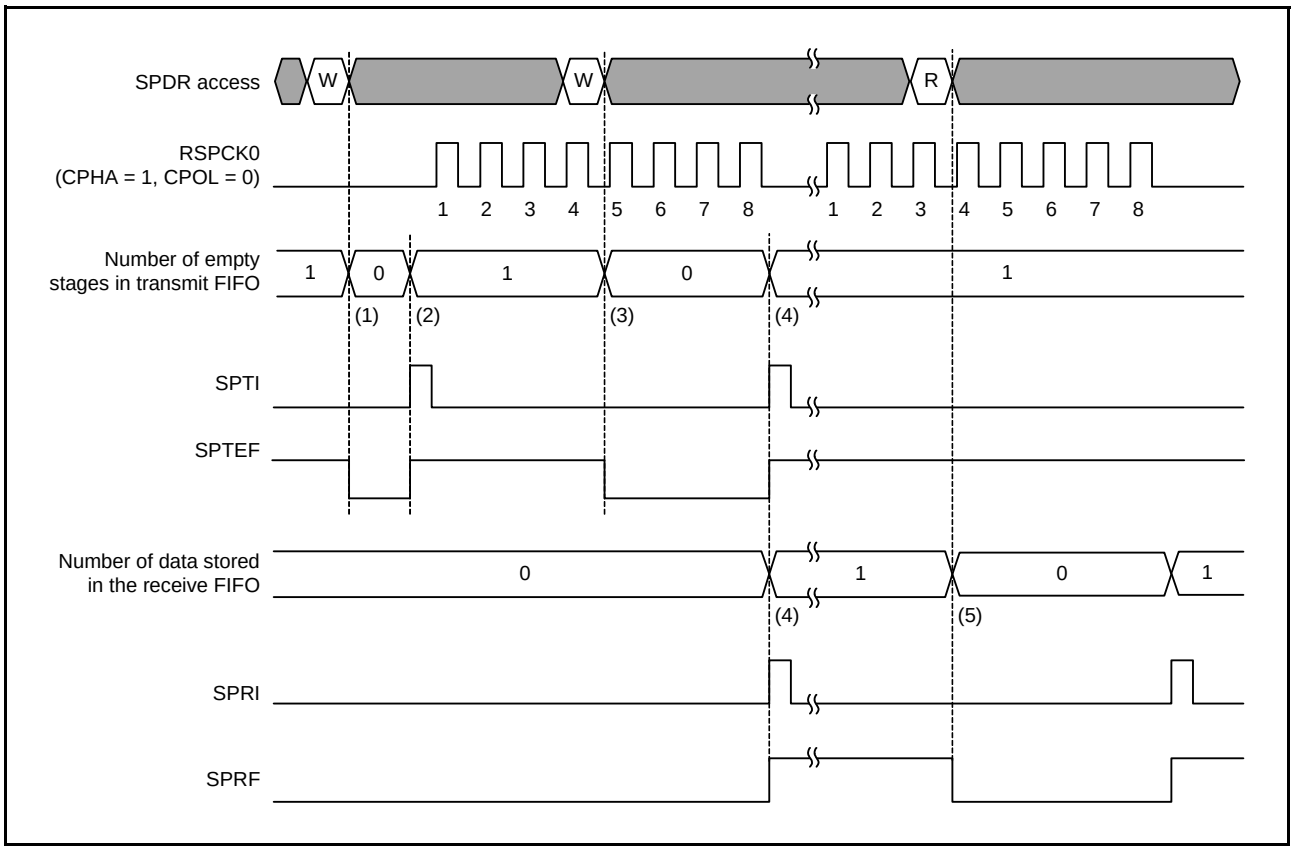

Figure 41.33 Operation Example of SPTI and SPRI Interrupts

The operation of the interrupts at timings shown in steps (1) to (5) in the figure is described below.

(1) If transmit data is written to SPDR when the next transmit data is not set in the transmit FIFO, the RSPIA writes data to the transmit buffer. When transmit data is written to SPDR in one processing routine using DTC/DMAC, the SPSR.SPTEF flag becomes 0 at the last access.

(2) If the shift register is empty, the RSPIA copies the data from the transmit buffer to the shift register. If the number of empty stage of the transmit FIFO is greater than the threshold value, the RSPIA generates a transmit buffer empty interrupt request (SPTI) and sets the SPSR.SPTEF flag to 1. How a serial transfer is started depends on the mode of the RSPIA. For details, refer to section 41.3.13, SPI Operation, and section 41.3.14, Clock Synchronous Operation.

(3) When transmit data is written to SPDR in the transmit buffer empty interrupt routine or in the transmit buffer empty detecting process by polling the SPTEF flag, the data is transferred to the transmit buffer. When transmit data is written to SPDR in one processing routine using DTC/DMAC, the SPSR.SPTEF flag becomes 0 at the last access. Because the data being transmitted is stored in the shift register, the RSPIA does not copy the data from the transmit buffer to the shift register.

(4) If the serial transfer ends (data sampling clock edge in the final bit is detected) when the data stored in the receive FIFO of SPDR < the number of FIFO stages, the RSPIA copies the receive data from the shift register to the receive buffer. At this time, if the data stored in the receive FIFO is greater than the threshold value, the RSPIA generates a

receive buffer full interrupt request (SPRI), and sets the SPSR.SPRF flag to 1. Since the shift register becomes empty upon completion of the serial transfer, when the next transmit data had been set in the transmit FIFO before the serial transfer ended, the RSPIA sets the SPSR.SPTEF flag to 1 and copies the data from the transmit buffer to the shift register. Even when received data is not copied from the shift register to the receive buffer in an overrun error status, upon completion of the serial transfer, the RSPIA determines that the shift register is empty, thus data transfer from the transmit buffer to the shift register is enabled.

(5) When SPDR is read in the receive buffer full interrupt (SPRI) routine or in the receive buffer full detecting process by polling the SPRF flag, the receive data can be read. If the received data is read from SPDR in one processing routine using DTC/DMAC, the SPRF flag becomes 0 at the last access.

If transmit data is written to SPDR while no empty stages in the transmit FIFO, the RSPIA does not update the data in the transmit buffer. Transmit data should be written to SPDR in the transmit buffer empty interrupt request routine or in the transmit buffer empty detecting process by polling the SPTEF flag.

When setting the SPCR.SPE bit to 0 (RSPI function disabled), if the SPCR.SPTIE is 1, a transmit buffer empty interrupt request will occur. However, transmit buffer empty interrupt is inhibited by disabling transmit buffer empty interrupt (the SPTIE bit is 0) at the same time as SPE bit setting.

When serial transfer ends while data is stored in the receive FIFO for the number of FIFO stages, the RSPIA does not copy data from the shift register to the receive buffer, and detects an overrun error (refer to section 41.3.10, Error Detection). To prevent a receive data overrun error, read the received data before the next serial transfer ends.

Transmit buffer empty interrupt and receive buffer full interrupt or the corresponding IRn.IR flags (where n is the interrupt vector number) in the ICU can be used to confirm the states of the transmit and receive buffers. The status of the transmit and receive buffers can be also confirmed by the SPTEF and SPRF flags.

41.3.8 Idle Interrupts

When the SPSSR.SPCP[2:0] bits becomes 000b, if the next transmit data is not set, the SPSR.IDLNF flag is set to 0 and an idle interrupt request is generated. An interrupt request is also made by setting the SPCR.SPE bit to 0.

[Motorola SPI]

Figure 41.34 shows an example of idle interrupt operation during normal operation.

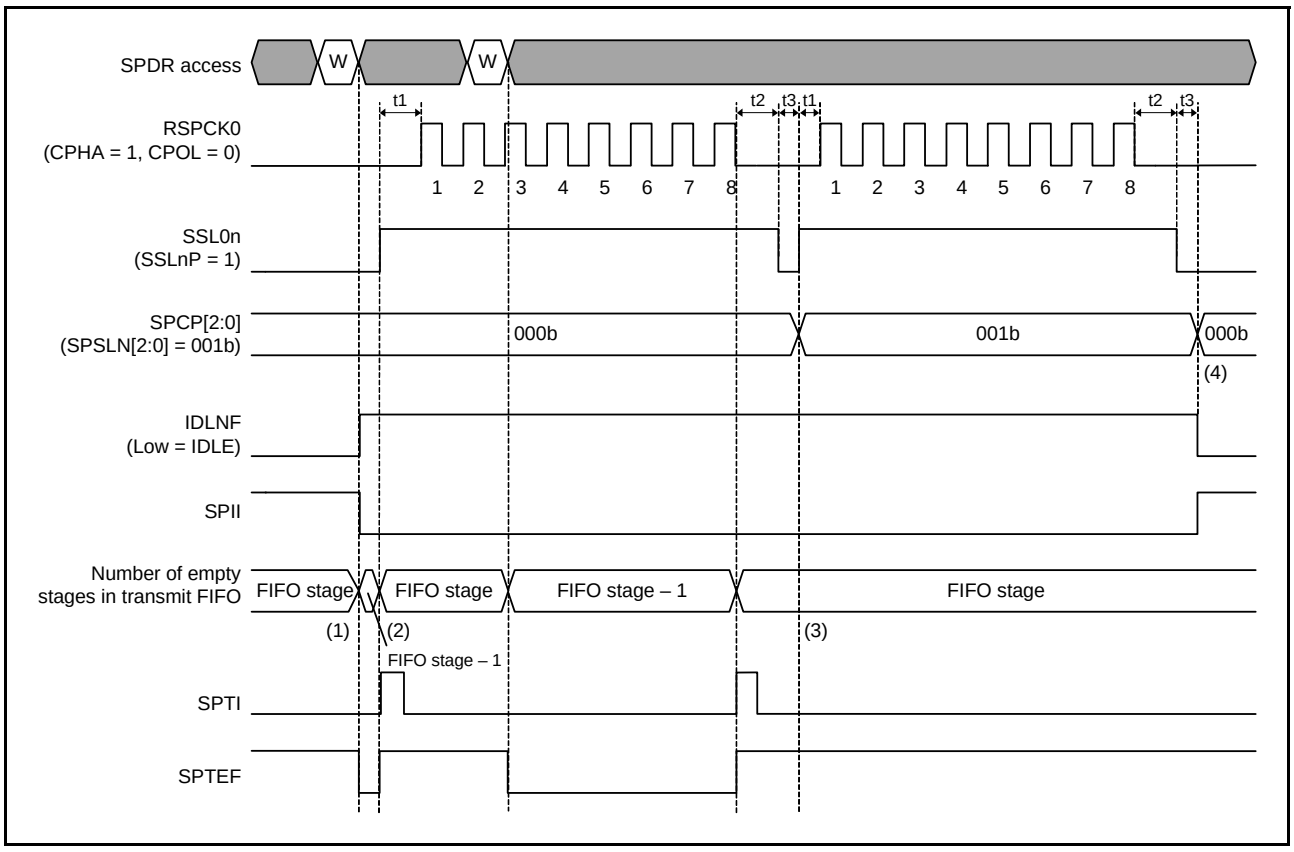

Figure 41.34 Operation Example of Idle Interrupts (Master Mode, Motorola SPI)

(1) At the start of transmission, if the next transmit data is not set in the transmission buffer, the SPSR.IDLNF flag becomes 0 (IDLE). Writing transmit data sets the SPSR.IDLNF flag to 1 (BUSY). When the SPCR.SPIIE bit is set to 1 before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPCR.SPIIE bit to 0 before starting transmission.

(2) After transmission has started, the SPSR.IDLNF flag remains 1 (BUSY) regardless of the transmit buffer state.

(3) The SPSSR.SPCP[2:0] bits change the command to the next one at the end of t3 cycle. When the next command is not 000b, the SPSR.IDLNF flag remains unchanged even when the next transmit data has not been written.

(4) The SPSR.IDLNF flag becomes 0 (IDLE) at the end of t3 cycle because the next command is 000b and the next transmit data is not present. When the SPCR.SPIIE bit is 1, an SPII interrupt is output.

[TI SSP]

Figure 41.35 shows an example of idle interrupt operation during normal operation.

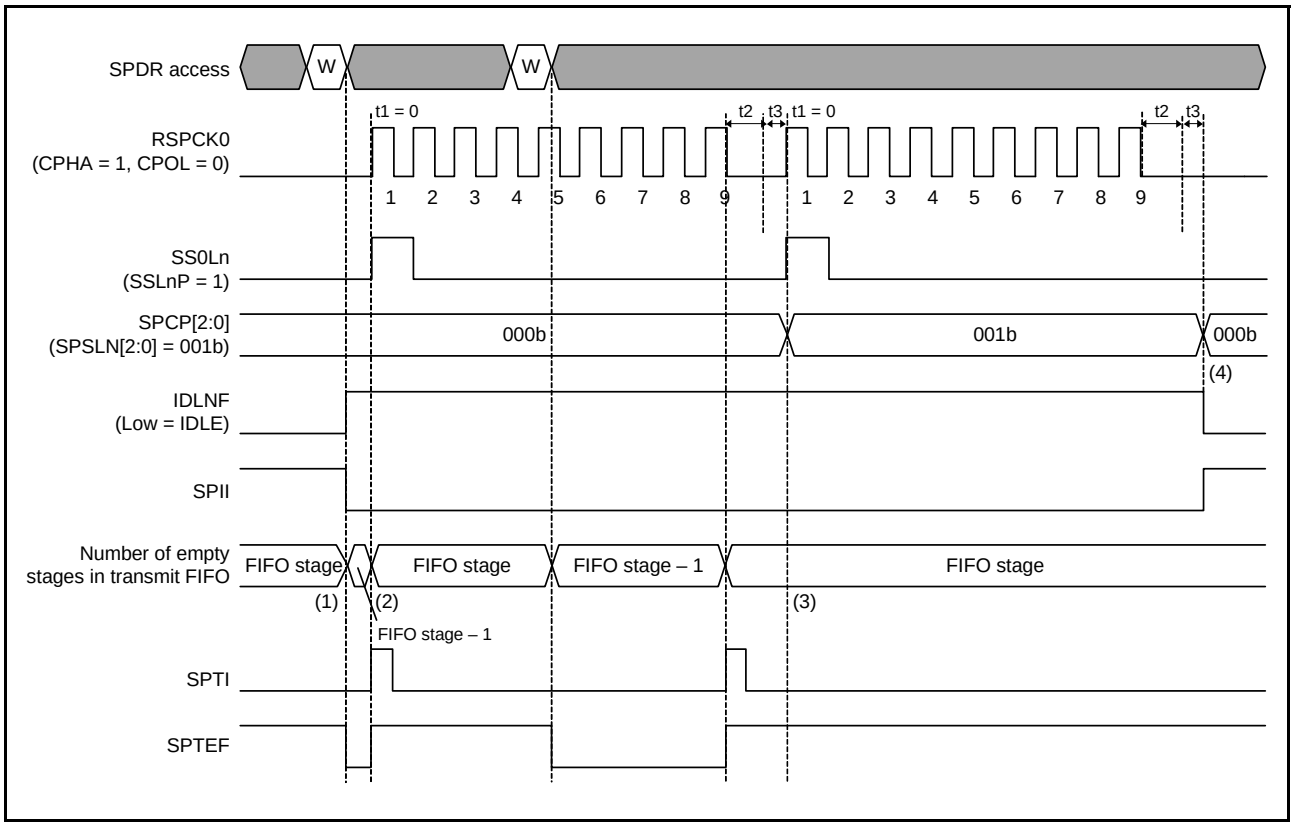

Figure 41.35 Operation Example of Idle Interrupts (Master Mode, TI SSP)

(1) At the start of transmission, if the next transmit data is not set in the transmission buffer, the SPSR.IDLNF flag becomes 0 (IDLE). Writing transmit data sets the SPSR.IDLNF flag to 1 (BUSY). When the SPCR.SPIIE bit is set to 1 before transmit data is written, interrupt processing is required before transmission start. For this reason, set the SPCR.SPIIE bit to 0 before starting transmission.

(2) After transmission has started, the SPSR.IDLNF flag remains 1 (BUSY) regardless of the transmit buffer state.

(3) The SPSSR.SPCP[2:0] bits change the command to the next one at the end of t3 cycle. When the next command is not 000b, the SPSR.IDLNF flag remains unchanged even when the next transmit data has not been written.

(4) The SPSR.IDLNF flag becomes 0 (IDLE) the end of t3 cycle because the next command is 000b and the next transmit data is not present. When the SPCR.SPIIE bit is 1, an SPII interrupt is output.

An idle interrupt during slave mode operation depends only on the value of the SPCR.SPE bit.

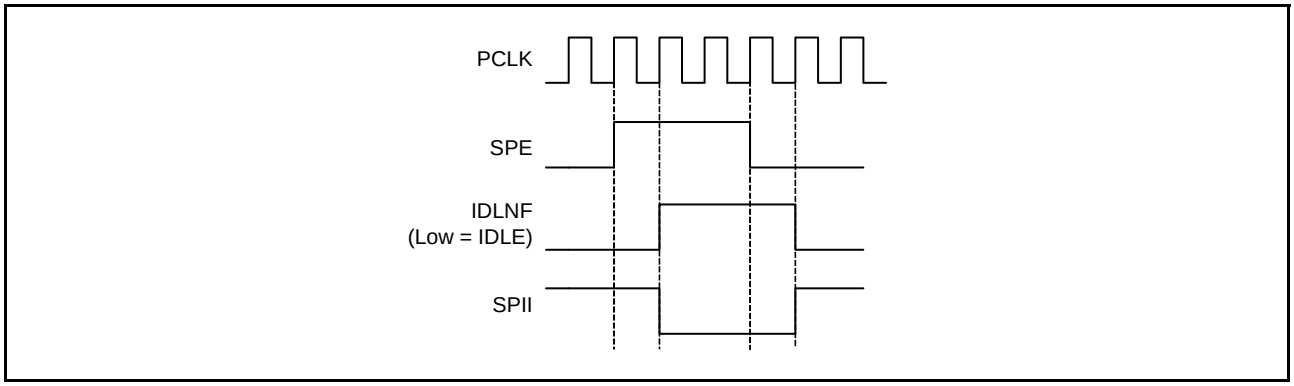

Figure 41.36 Operation Example of Idle Interrupts (Slave Mode)

41.3.9 Communication End Interrupts

41.3.9.1 Transmit-Receive Master Mode or Transmit-Only Master Mode

Refer to the description of the SPCF Flag (Communication End Flag) in section 41.2.16, RSPI Status Register (SPSR) for setting/clearing conditions of the communication end flag during transmit-receive master mode or transmit-only master mode.

[Motorola SPI]

Figure 41.37 shows an example of the SPCI interrupt operation during transmit-receive master mode/transmit-only master mode.

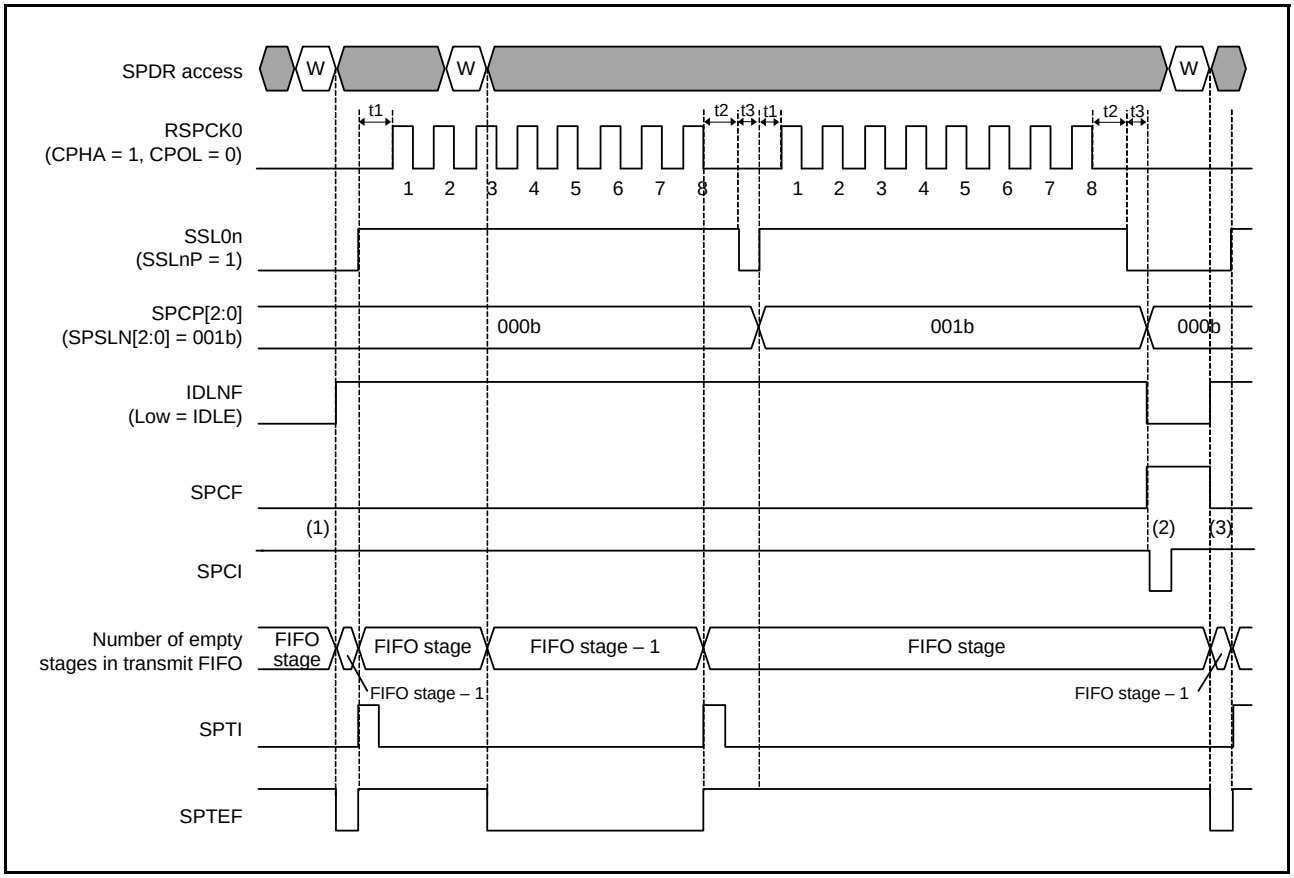

Figure 41.37 Operation Example of SPCI Interrupts (Transmit-Receive Master Mode/Transmit-Only Master Mode, Motorola SPI)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) at the end of t3 cycle, because the next command is 000b and there is no next transmit data. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when the next transmit data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

[TI SSP]

Figure 41.38 shows an example of the SPCI interrupt operation during transmit-receive master mode/transmit-only master mode.

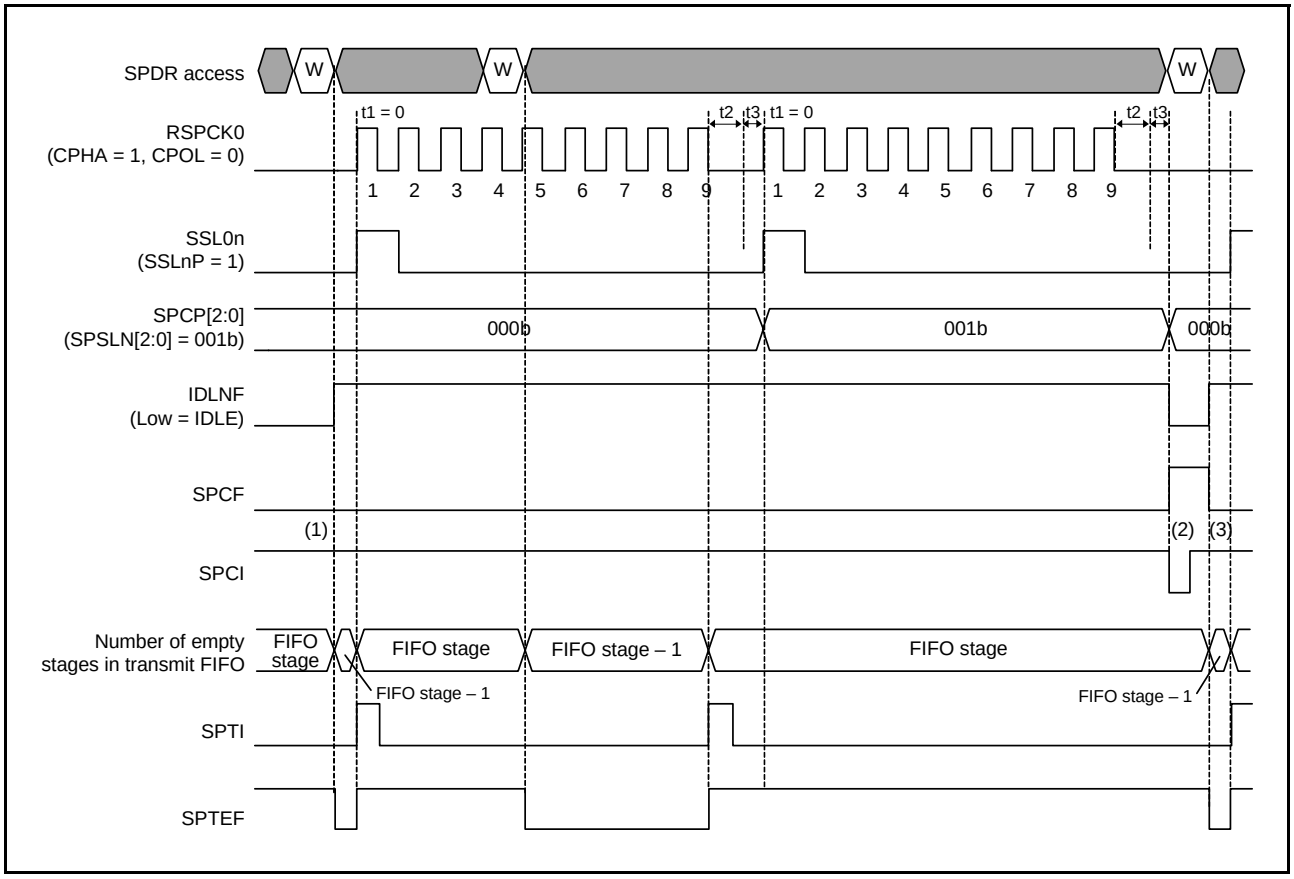

Figure 41.38 Operation Example of SPCI Interrupts (Transmit-Receive Master Mode/Transmit-Only Master Mode, TI SSP)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) at the end of t3 cycle, because the next command is 000b and there is no next transmit data. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when the next transmit data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

41.3.9.2 Receive-Only Master Mode

Refer to the description of the SPCF Flag (Communication End Flag) in section 41.2.16, RSPI Status Register (SPSR) for setting/clearing conditions of the communication end flag during receive-only master mode.

Figure 41.39 shows an example of the SPCI interrupt operation during receive-only master mode when the SPRMCR.RFC[4:0] bits are 00000b.

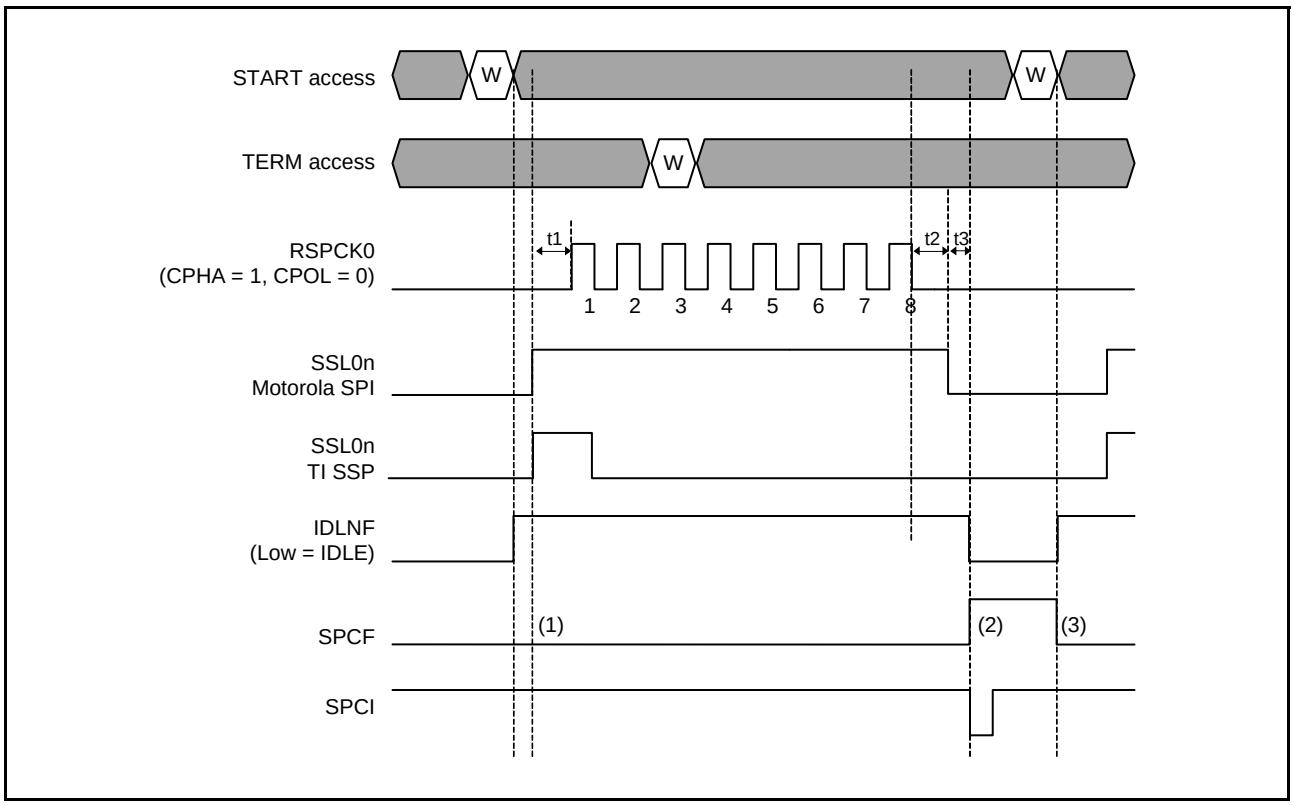

Figure 41.39 Operation Example of SPCI Interrupts (RFC[4:0] = 00000b) (Receive-Only Master Mode)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) When the SPRMCR.TERM bit is set to 1 during communication, the SPCF flag becomes 1 (communication end) at the end of t3 cycle. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when 1 is written to the SPRMCR.START bit. Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

Figure 41.40 shows an example of the SPCI interrupt operation during receive-only master mode when the SPRMCR.RFC[4:0] bits are not 00000b.

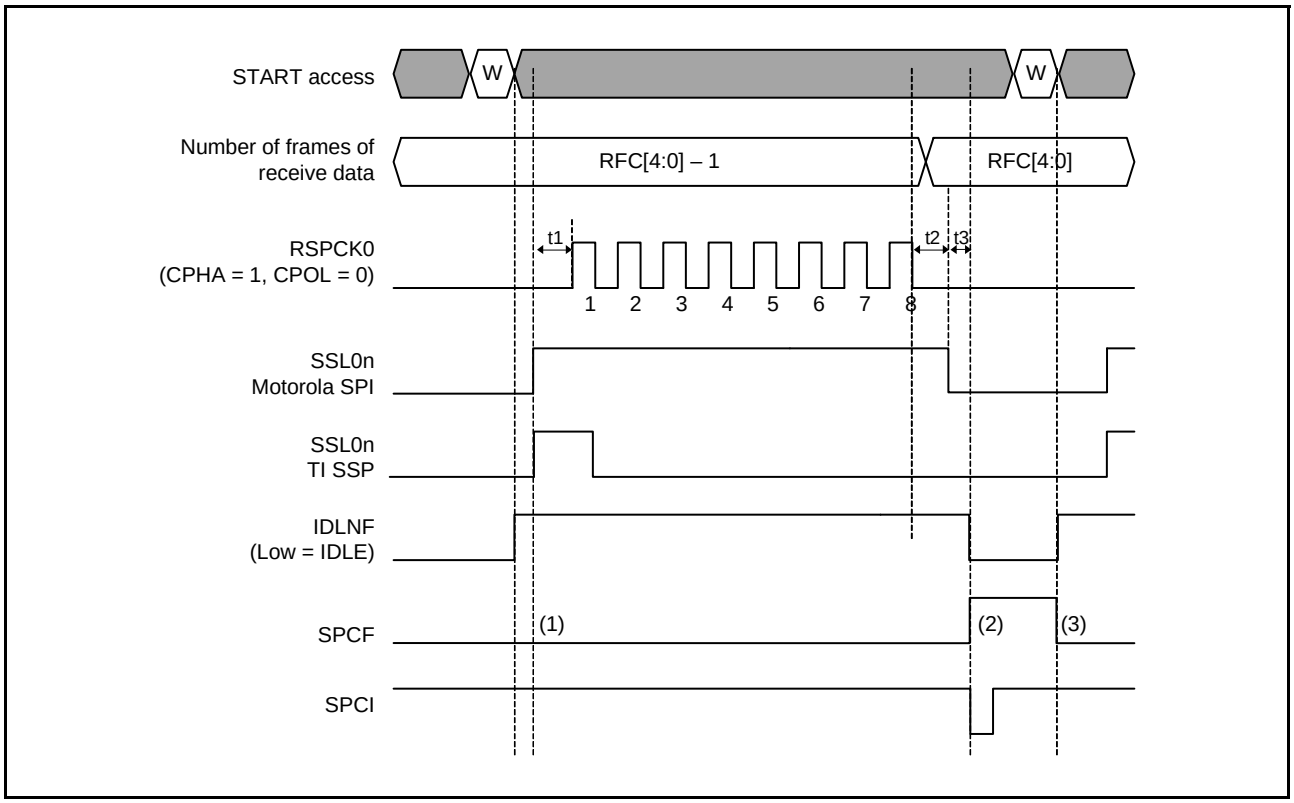

Figure 41.40 Operation Example of SPCI Interrupts (RFC[4:0] ≠ 00000b) (Receive-Only Master Mode)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) at the end of t3 cycle after receiving the number of frames set by the SPRMCR.RFC[4:0] bits. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when 1 is written to the SPRMCR.START bit. Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

In slave mode operation, the output timing of the SPCI interrupt is deferent due to the value of the SPCR.SPMS bit (RSPI mode select bit). And the clear timing of the communication end interrupt is deferent due to the communication mode (transmit-receive, transmit-only, or receive-only).

41.3.9.3 Transmit-Receive Slave Mode or Transmit-Only Slave Mode on SPI Operation (4-Wire Method)

Refer to the description of the SPCF Flag (Communication End Flag) in section 41.2.16, RSPI Status Register (SPSR) for setting/clearing conditions of the communication end flag during transmit-receive slave mode or transmit-only slave mode on SPI operation (4-wire method).

[Motorola SPI]

Figure 41.41 shows an example of the SPCI interrupt operation during transmit-receive slave mode/transmit-only slave mode on SPI operation.

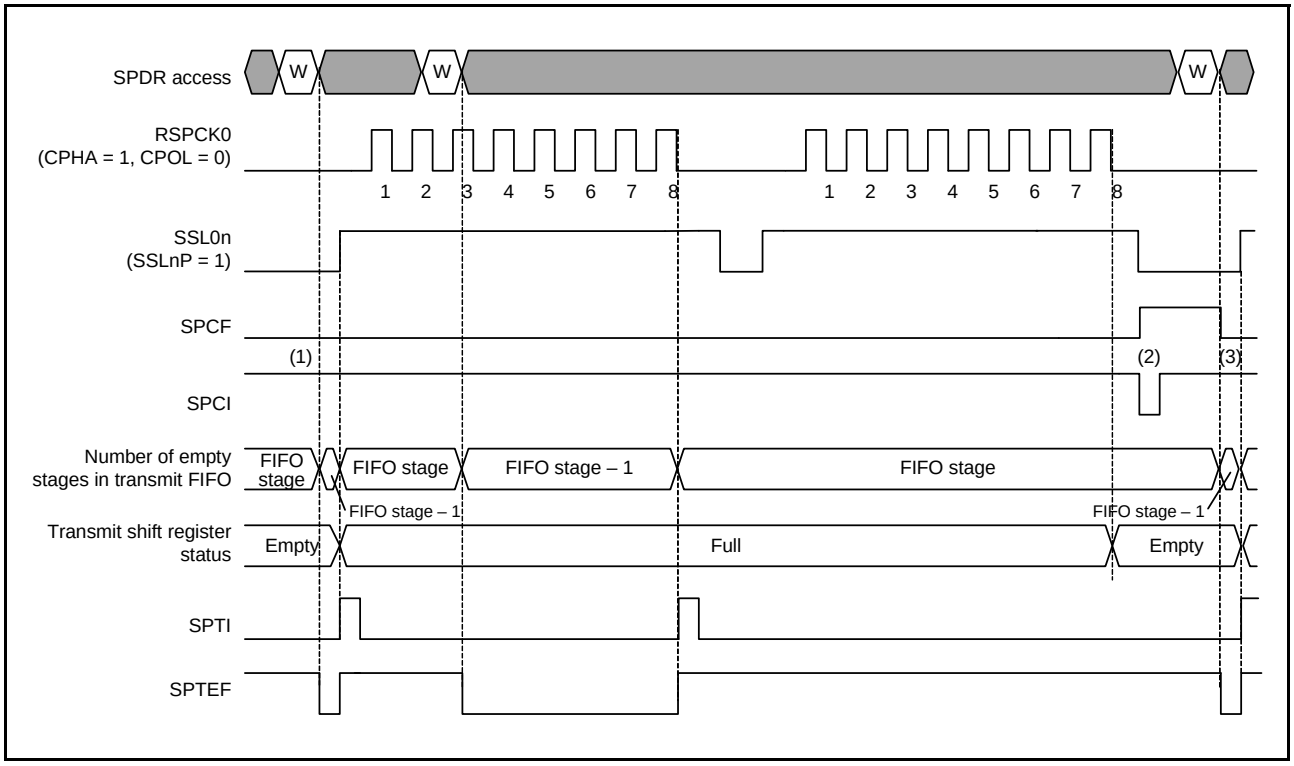

Figure 41.41 Operation Example of SPCI Interrupts (Transmit-Receive Slave Mode/Transmit-Only Slave Mode, Motorola SPI)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) at the timing of SSL0n negation, when the next transmit data is not set in the transmit FIFO and the transmit shift register is empty. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when the next transmit data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

[TI SSP]

Figure 41.42 shows an example of the SPCI interrupt operation during transmit-receive slave mode/transmit-only slave mode on SPI operation.

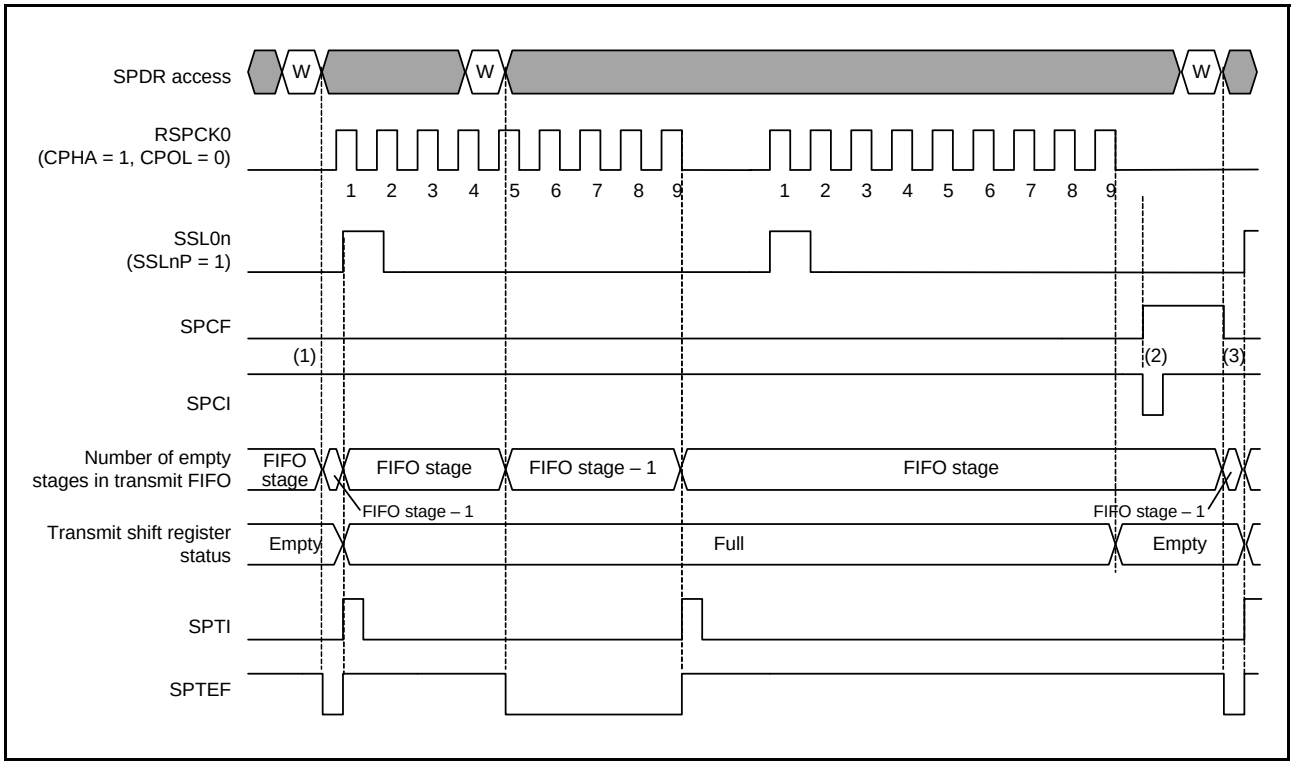

Figure 41.42 Operation Example of SPCI Interrupts (Transmit-Receive Slave Mode/Transmit-Only Slave Mode, TI SSP)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) when the next transmit data is not set in the transmit FIFO, the transmit shift register is empty, and SSL negation delay is completed. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when the next transmit data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

41.3.9.4 Receive-Only Slave Mode on SPI Operation (4-Wire Method)

Refer to the description of the SPCF Flag (Communication End Flag) in section 41.2.16, RSPI Status Register (SPSR) for setting/clearing conditions of the communication end flag during receive-only slave mode on SPI operation (4-wire method).

[Motorola SPI]

Figure 41.43 shows an example of the SPCI interrupt operation during receive-only slave mode on SPI operation.

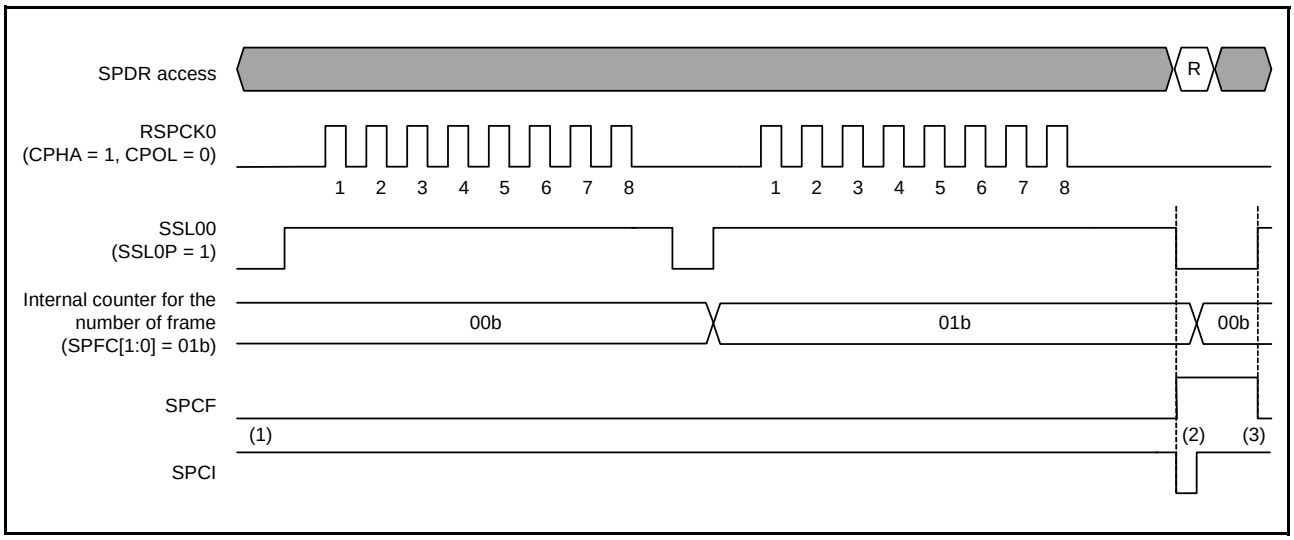

Figure 41.43 Operation Example of SPCI Interrupts (Receive-Only Slave Mode, Motorola SPI)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) After the frames of the value set in the SPDCR.SPFC[1:0] bits are stored in the receive buffer, the SPCF flag becomes 1 (communication end) at the timing of SSL00 negation. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCIE bit is 1.

(3) The SPCF flag becomes 0 at the SSL00 assertion when the next transmission start. Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

[TI SSP]

Figure 41.44 shows an example of the SPCI interrupt operation during receive-only slave mode on SPI operation.

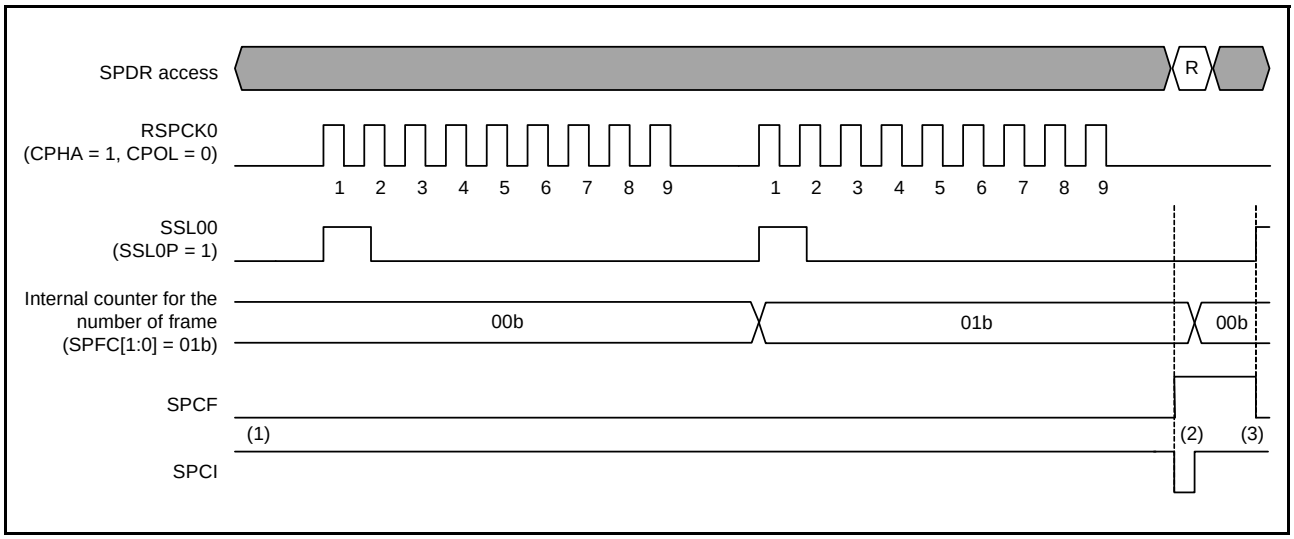

Figure 41.44 Operation Example of SPCI Interrupts (Receive-Only Slave Mode, TI SSP)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) After the frames of the value set in the SPDCR.SPFC[1:0] bits are stored in the receive buffer, the SPCF flag becomes 1 (communication end) at the timing when SSL00 negation delay is completed. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCIE bit is 1.

(3) The SPCF flag becomes 0 at the SSL00 assertion when the next transmission start. Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

41.3.9.5 Transmit-Receive Slave Mode or Transmit-Only Slave Mode on Clock Synchronous Operation (3-Wire Method)

Refer to the description of the SPCF Flag (Communication End Flag) in section 41.2.16, RSPI Status Register (SPSR) for setting/clearing conditions of the communication end flag during transmit-receive slave mode or transmit-only slave mode on clock synchronous operation (3-wire method).

Figure 41.45 shows an example of the SPCI interrupt operation during transmit-receive slave mode/transmit-only slave mode on clock synchronous operation.

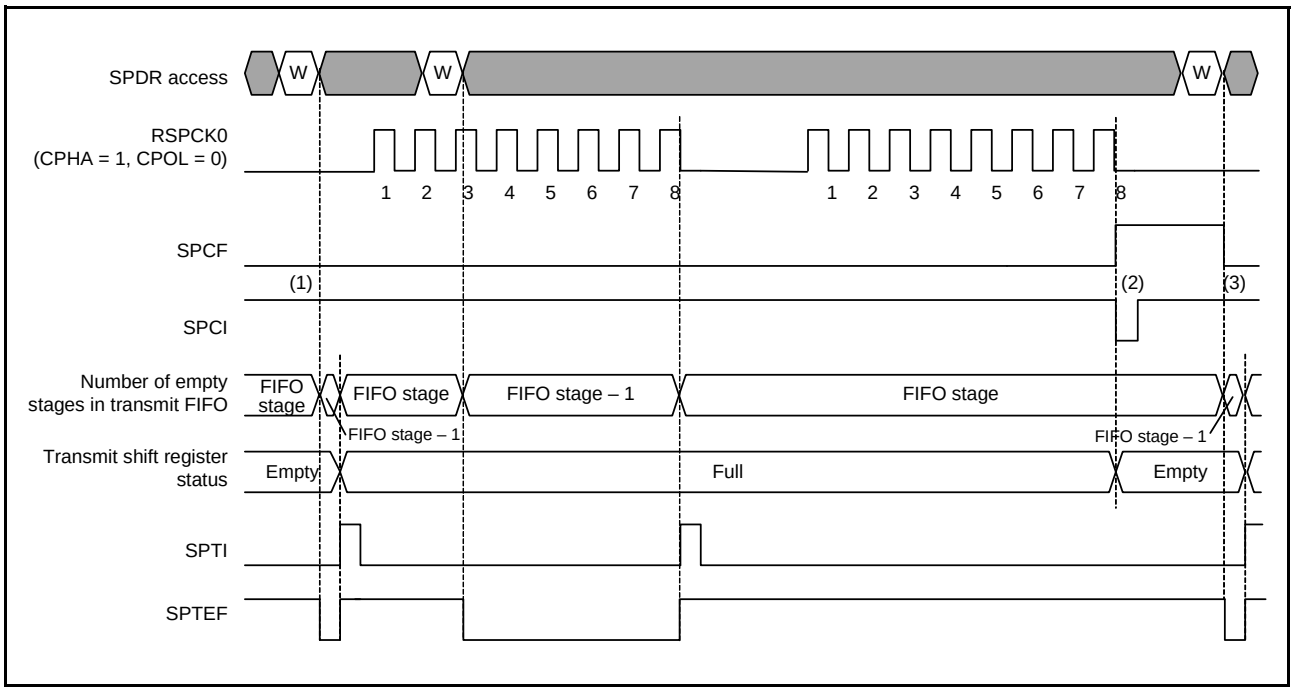

Figure 41.45 Operation Example of SPCI Interrupts (Transmit-Receive Slave Mode/Transmit-Only Slave Mode, Clock Synchronous Operation)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) at the sampling timing of the final data bit of RSPCK0, when the next transmit data is not set in the transmit buffer and the transmit shift register is empty. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 when the next transmit data is written to the transmit buffer (SPTX). Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

41.3.9.6 Receive-Only Slave Mode on Clock Synchronous Operation (3-Wire Method)

Refer to the description of the SPCF Flag (Communication End Flag) in section 41.2.16, RSPI Status Register (SPSR) for setting/clearing conditions of the communication end flag during receive-only slave mode on clock synchronous operation (3-wire method).

Figure 41.46 shows an example of the SPCI interrupt operation during receive-only slave mode on clock synchronous operation.

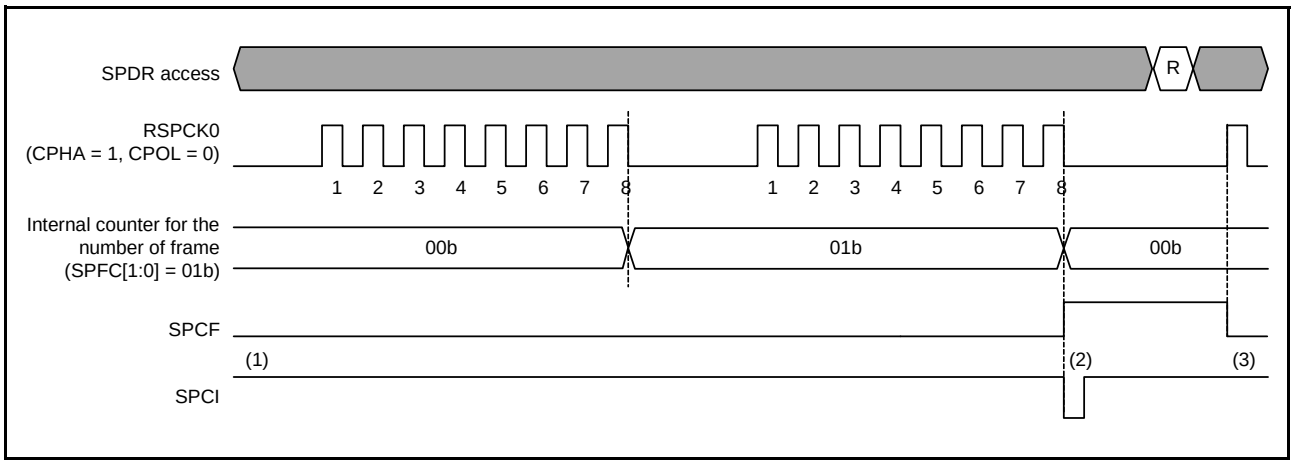

Figure 41.46 Operation Example of SPCI Interrupts (Receive-Only Slave Mode, Clock Synchronous Operation)

(1) The SPCF flag is 0 and the level of the SPCI interrupt is 1 before starting communication. And these have kept during communication.

(2) The SPCF flag becomes 1 (communication end) at the sampling timing of the final data bit of RSPCK0, when the final frame of the value set in the SPDCR.SPFC[1:0] bits is received. And then the SPCI interrupt outputs with PCLK 1 cycle width if the SPCR.SPCIE bit is 1.

(3) The SPCF flag becomes 0 at the first edge of RSPCK0 for the next transmission. Or when 1 is written to the SPSCLR.SPCFC bit, then the SPCF flag becomes 0.

41.3.10 Error Detection

In the normal serial transfer of the RSPIA, the data written to the transmit buffer of SPDR is transmitted, and the received data can be read from the receive buffer of SPDR. If access is made to SPDR, depending on the status of the transmit/receive buffer or the status of the RSPIA at the beginning or end of serial transfer, in some cases non-normal transfers can be executed.

If a non-normal transfer operation occurs, the RSPIA detects the event as an underrun error, overrun error, parity error, or mode fault error. Table 41.8 lists the relationship between non-normal transfer operations and the RSPIA's error detection function.

Table 41.8 Relationship between Non-Normal Transfer Operations and Error Detection Function of RSPIA

	Occurrence Condition	RSPI Operation	Error Detection
1	The SPDR register is written while no empty stages in the transmit FIFO.	• The contents of the transmit buffer are kept. • Missing write data.	None
2	The SPDR register is read while no empty stages in the receive FIFO.	If reception has completed, then the received data is output to the bus. Otherwise, data received previously is output instead.	None
3	Serial transfer is started in transmit-receive slave mode or transmit-only slave mode when transmit data is not ready to output.	• Serial transfer is suspended • Transmit/receive data is missing • The MISO0 output signal is disabled • RSPI function is disabled	Underrun error Refer to section 41.3.10.4, Underrun Error for underrun error.
4	Serial transfer terminates when data is stored in the receive FIFO with no empty FIFO stage.	• The contents of the receive FIFO are kept • Missing receive data	Overrun error Refer to section 41.3.10.1, Overrun Error for overrun error.
5	An incorrect parity bit is received with the parity function enabled in the transmit-receive mode or receive-only mode	The parity error flag is asserted.	Parity error Refer to section 41.3.10.2, Parity Error for parity error.
6	The SSL00 input signal is asserted when the serial transfer is idle in multi-master mode.	• Driving of the RSPCK0, MOSI0, SSL01 to SSL03 output signals is stopped. • RSPI function is disabled.	Mode fault error Refer to section 41.3.10.3, Mode Fault Error for mode fault error.
7	The SSL00 input signal is asserted during serial transfer in multi-master mode.	• Serial transfer is suspended. • Missing transmit/receive data. • Driving of the RSPCK0, MOSI0, SSL01 to SSL03 output signals is stopped. • RSPI function is disabled.	
8	The SSL00 input signal is negated during serial transfer in slave mode. [Motorola SPI]	• Serial transfer is suspended. • Missing transmit/receive data. • Driving of the MISO0 output signal is stopped. • RSPI function is disabled.	
9	The SSL00 input signal is asserted during serial transfer in slave mode. [TI SSP]	• Serial transfer is suspended. • Missing transmit/receive data. • Driving of the MISO0 output signal is stopped. • RSPI function is disabled.	
10	After data is stored in the receive FIFO with RDRIS = 1, the number of stored data is less than the threshold value and no receive data is written for the set value of the SPDRCSR register.	• The receive data ready flag is asserted.	Receive data ready Refer to section 41.3.11, Received Data Ready Detection for receive data ready

On operation 1 in Table 41.8, the RSPIA does not detect an error. To prevent data omission during the writing to SPDR, the SPDR register should be written when a transmit buffer empty interrupt request occurs or while the SPSR.SPTEF flag is 1.

Likewise, the RSPIA does not detect an error on operation 2. To prevent extraneous data from being read, the SPDR register should be read when a receive buffer full interrupt request occurs or while the SPSR.SPRF flag is 1.

For the transmit and receive interrupts, refer to section 41.3.7, Transmit Buffer Empty/Receive Buffer Full Interrupts.

41.3.10.1 Overrun Error

If a serial transfer ends while no empty stages in the receive FIFO, the RSPIA detects an overrun error, and sets the SPSR.OVRF flag to 1. When the OVRF flag is 1, the RSPIA does not copy data from the shift register to the receive buffer so that the data prior to the occurrence of the error is retained in the receive buffer. To set the SPSR.OVRF flag to 0, issue a system reset or write 1 to the SPSRC.OVRFC bit.

Figure 41.47 shows an example of operations of the SPSR.SPRF and OVRF flags. The SPSCLR and SPDR accesses shown in Figure 41.47 indicate the condition of accesses to SPSCLR and SPDR, respectively, where W denotes a write cycle, and R a read cycle. In the example in Figure 41.47, the RSPIA performs an 8-bit serial transfer in which the SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCK0 waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

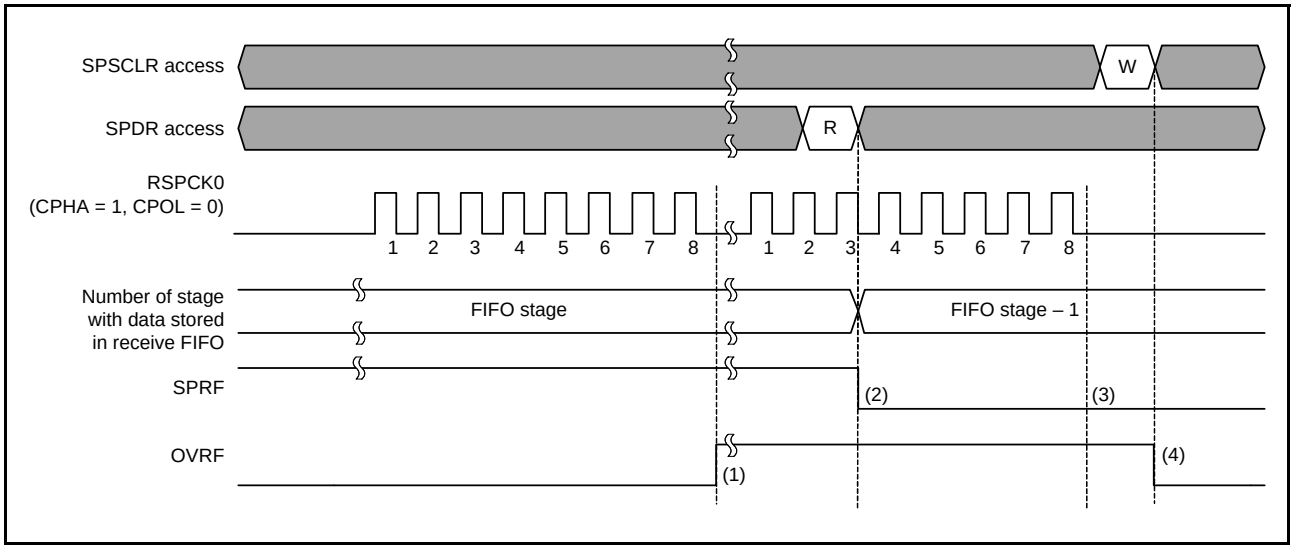

Figure 41.47 Operation Example of SPRF and OVRF Flags

The operation of the flags at the timing shown in steps (1) to (4) in the figure is described below.

(1) If a serial transfer terminates while no empty stages in the receive FIFO, the RSPIA detects an overrun error, and sets the OVRF flag to 1. The RSPIA does not copy the data in the shift register to the receive buffer. Even if the SPPE bit is 1, parity errors are not detected. In master mode, the RSPIA copies the pointer value to SPCMDm register to the SPSSR.SPECM[2:0] bits.

(2) When SPDR is read, the RSPIA outputs the data in the receive buffer. At this time the SPRF flag becomes 0 at the last access when the received data is read from the SPDR register in one processing routine using DTC/DMAC. Even if the receive buffer becomes empty, the OVRF flag does not become 0.

(3) If the serial transfer ends with the OVRF flag being 1 (an overrun error occurs), the RSPIA does not copy the data in the shift register to the receive buffer (the SPRF flag remains 0). A receive buffer full interrupt is not generated. Even if the SPPE bit is 1, parity errors are not detected. When in master mode, the RSPIA does not update the SPSSR.SPECM[2:0] bits. When in an overrun error state and the RSPIA does not copy the received data from the shift register to the receive buffer, upon termination of the serial transfer, the RSPIA determines that the shift register is empty; in this manner, data transfer from the transmit buffer to the shift register is enabled.

(4) When 1 is written to the SPSCLR.OVRFC bit, the OVRF flag is set to 0.

The occurrence of an overrun can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. When executing a serial transfer without using an error interrupt, measures should be taken to ensure the early detection of overrun errors, such as reading the SPSR register immediately after SPDR is read. When the RSPIA is used in master mode, the pointer value to the SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits. If an overrun error occurs and the OVRF flag is set to 1, normal reception operations cannot be performed until the OVRF flag is set to 0.

When the RSPCK auto-stop function is enabled in master mode, an overrun error does not occur. Figure 41.48 and Figure 41.49 show the clock stop waveform when a serial transfer continues while no empty stages in the receive FIFO in master mode.

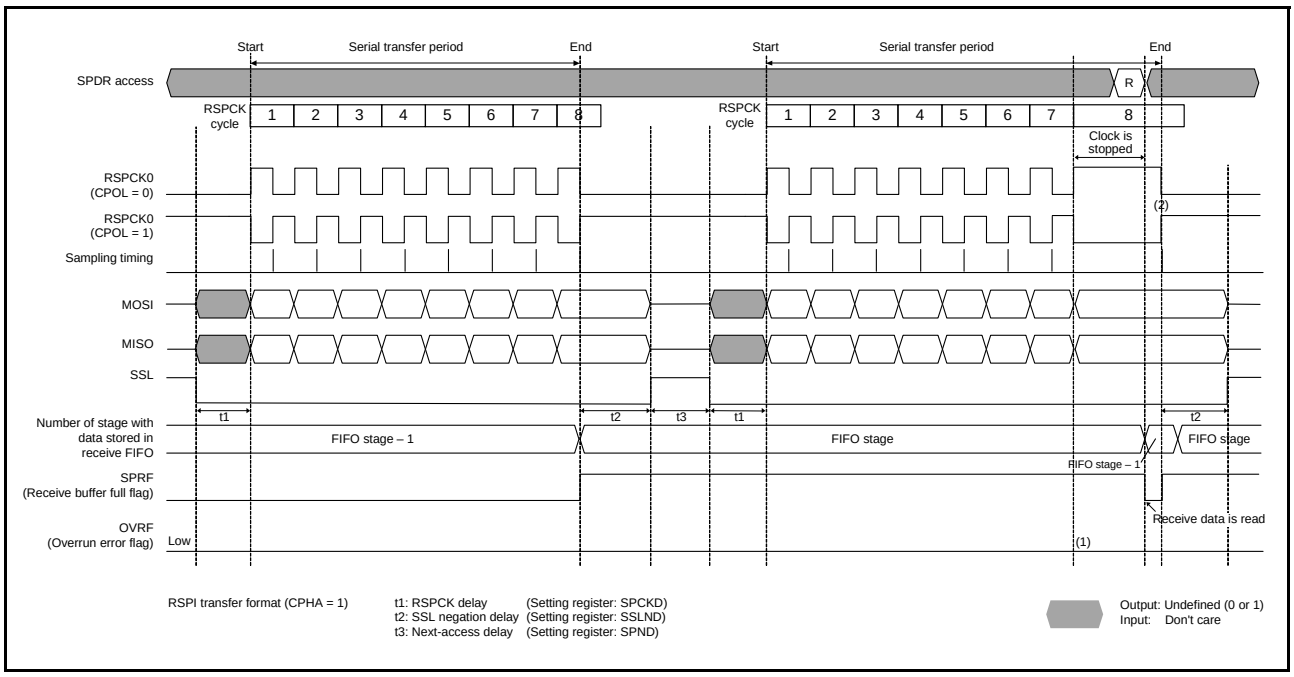

Figure 41.48 Clock Stop Waveform When a Serial Transfer Continues While No Empty Stages in the Receive FIFO in Master Mode (CPHA = 1)

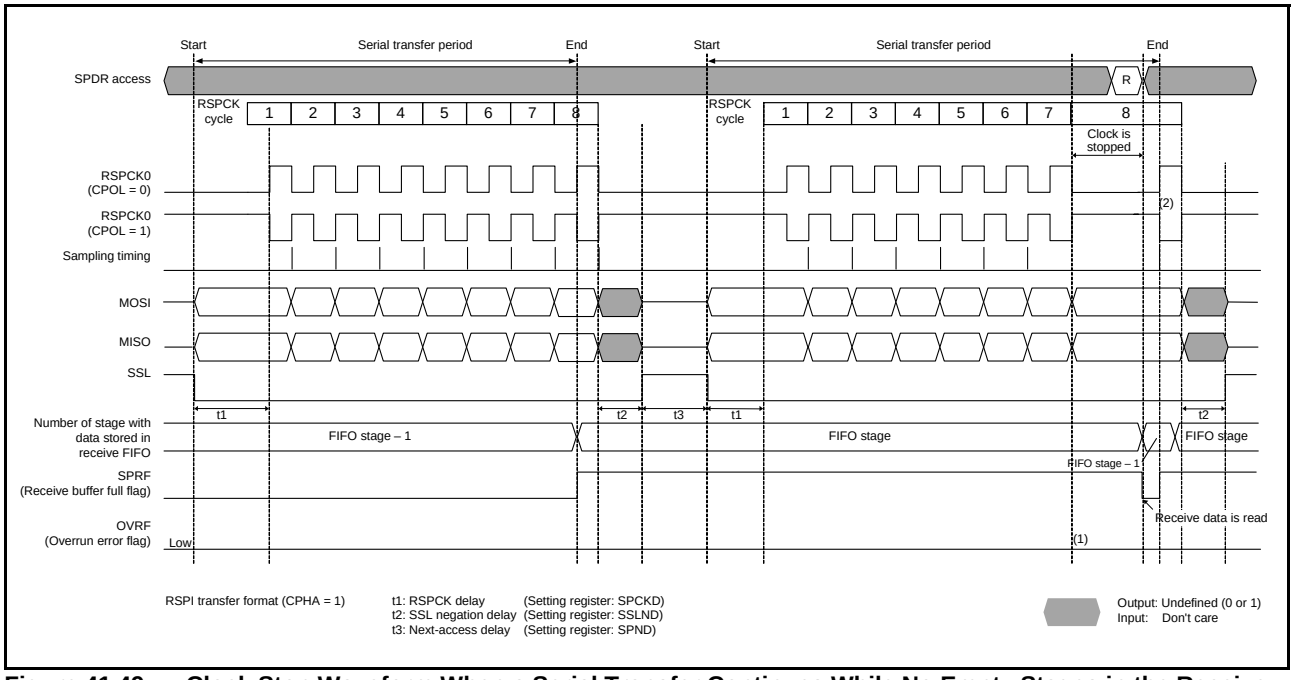

Figure 41.49 Clock Stop Waveform When a Serial Transfer Continues While No Empty Stages in the Receive FIFO in Master Mode (CPHA = 0)

The operation of the flags at the timings shown in steps (1) and (2) in the figure is described below.

(1) When no empty stages in the receive FIFO, an overrun error does not occur because the RSPCK0 is stopped.

(2) If SPDR is read while the clock is stopped, data in the receive buffer can be read. The RSPCK0 restarts after reading the receive buffer.

When the RSPCK auto-stop function is enabled for transfer with no delay of between frames during burst transfer in master mode, an overrun error does not occur. Figure 41.50 and Figure 41.51 show the clock stop waveform when there is no delay between frames during burst transfer and a serial transfer continues while no empty stages in the receive FIFO in master mode.

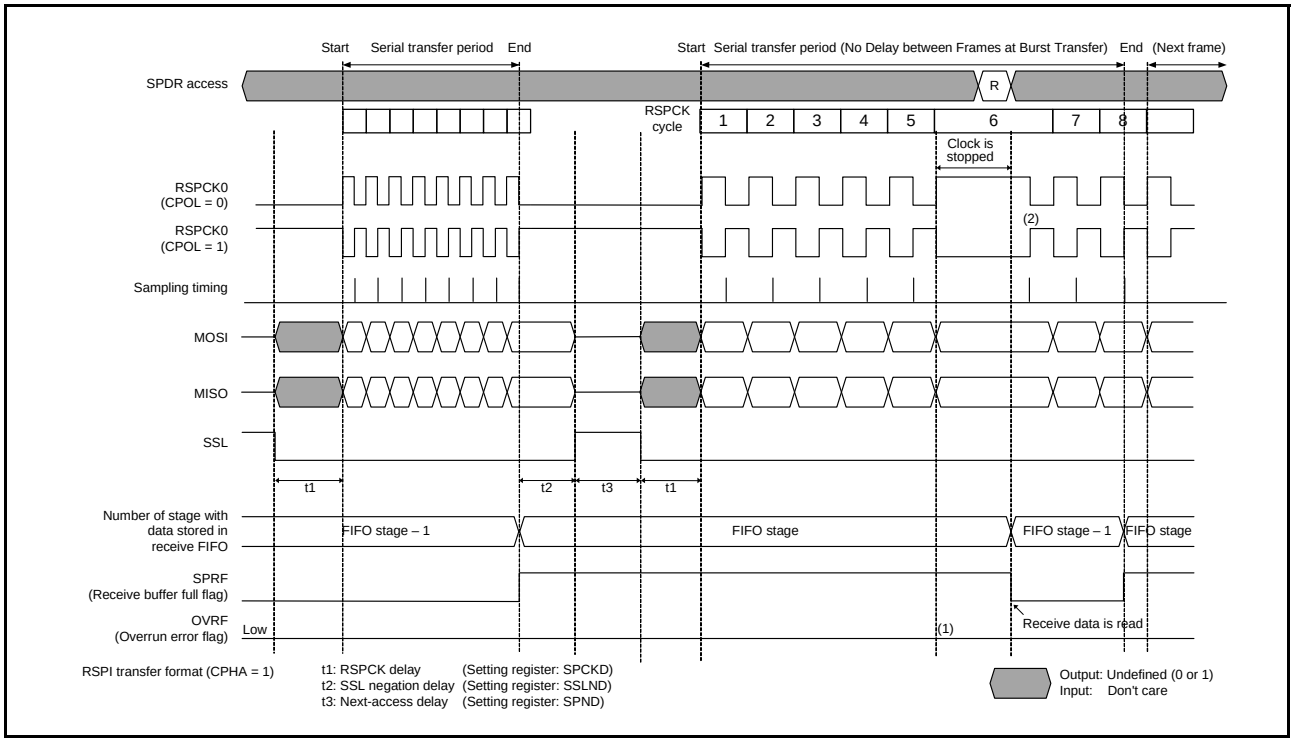

Figure 41.50 Clock Stop Waveform When a Serial Transfer Continues While No Empty Stages in the Receive FIFO in Master Mode (No Delay between Frames at Burst Transfer, CPHA = 1)

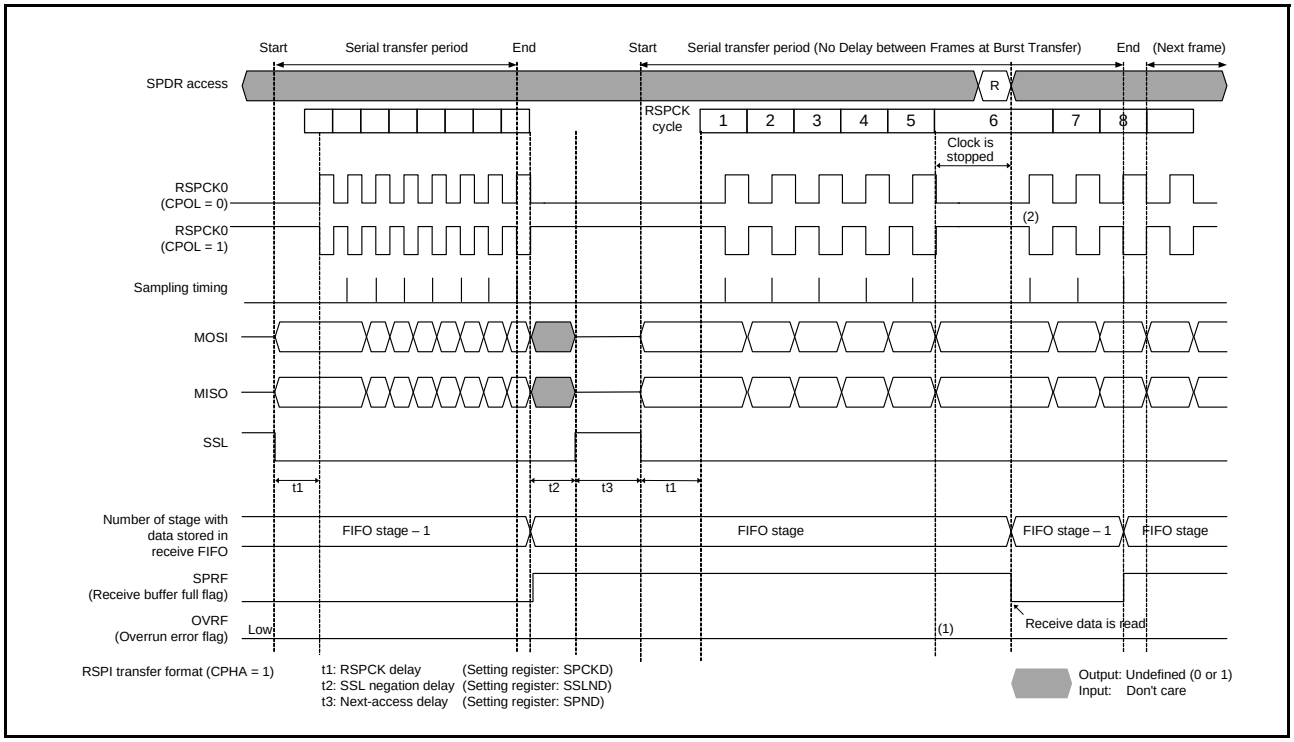

Figure 41.51 Clock Stop Waveform When a Serial Transfer Continues While No Empty Stages in the Receive FIFO in Master Mode (No Delay between Frames at Burst Transfer, CPHA = 0)

The operation of the flags at the timings shown in steps (1) and (2) in the figure is described below.

(1) When no empty stages in the receive FIFO, an overrun error does not occur because the RSPCK0 is stopped.

(2) If SPDR is read while the clock is stopped, data in the receive buffer can be read. The RSPCK0 restarts after reading the receive buffer.

41.3.10.2 Parity Error

If the SPCR.SPPE bit set to 1, when serial transfer in transmit-receive mode or receive-only mode terminates, the RSPIA checks whether there are parity errors. Upon detecting a parity error in the received data, the RSPIA sets the SPSR.PERF flag to 1. Since the RSPIA does not copy the data in the shift register to the receive buffer when the SPSR.OVRF flag is set to 1, parity error detection is not performed for the received data. To set the PERF flag to 0, issue a system reset or write 1 to the SPSCLR.PERFC bit.

Figure 41.52 shows an example of operation of the OVRF and PERF flags. The SPSR access shown in Figure 41.52 indicates the condition of access to SPSR register, where W denotes a write cycle, and R a read cycle. In the example of Figure 41.52, serial communications is performed while the SPCR.SPPE bit is 1. The RSPIA performs an 8-bit serial transfer in which the SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCK0 waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

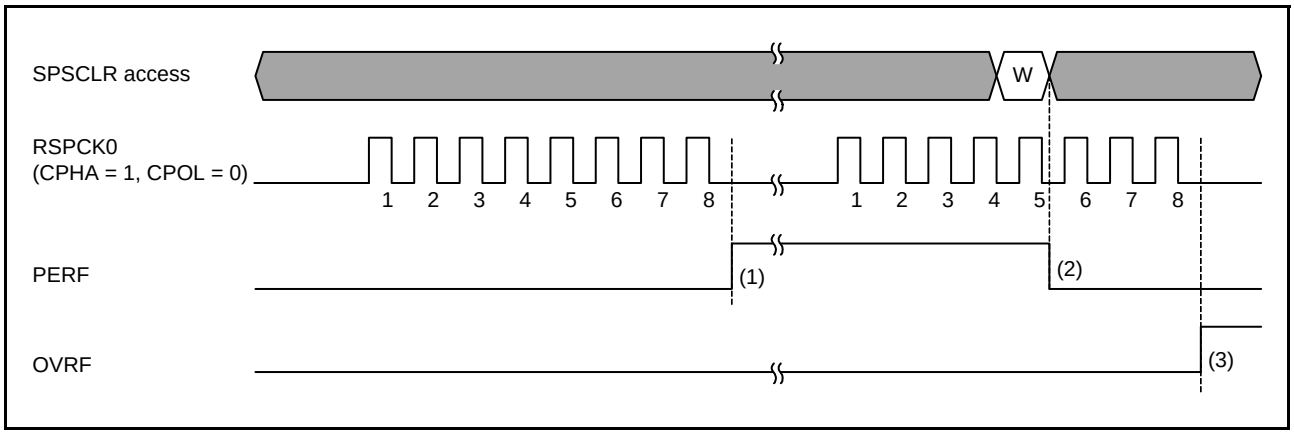

Figure 41.52 Operation Example of PERF Flag

The operation of the flags at the timing shown in steps (1) to (3) in the figure is described below.

(1) If a serial transfer terminates with the RSPIA not detecting an overrun error, the RSPIA copies the data in the shift register to the receive buffer. The RSPIA judges the received data at this timing, and sets the PERF flag to 1 if a parity error is detected. In master mode, the RSPIA copies the pointer value to SPCMDm register to the SPSSR.SPECM[2:0] bits.

(2) When 1 is written to the SPSCLR.PERFC bit, the PERF flag is set to 0.

(3) When the RSPIA detects an overrun error and serial transfer is terminated, the data in the shift register is not copied to the receive buffer. The RSPIA does not perform parity error detection at this timing.

The occurrence of a parity error can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. To use an error interrupt, set the SPCR.SPEIE bit to 1. When executing a serial transfer without using an error interrupt, measures should be taken to ensure the early detection of parity errors, such as reading the SPSR register. When the RSPIA is used in master mode, the pointer value to SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.

41.3.10.3 Mode Fault Error

The RSPIA operates in multi-master mode when the SPCR.MSTR bit is 1, the SPCR.SPMS bit is 0, and the SPCR.MODFEN bit is 1. If the active level is input with respect to the SSL00 input signal of the RSPIA in multi-master mode, the RSPIA detects a mode fault error irrespective of the status of the serial transfer, and sets the SPSR.MODF flag to 1. Upon detecting the mode fault error, the RSPIA copies the value of the pointer to SPCMDm to the SPSSR.SPECM[2:0] bits. The active level of the SSL00 signal is determined by the SSLP.SSL0P bit.
When the MSTR bit is 0, the RSPIA operates in slave mode. The RSPIA detects a mode fault error if the MODFEN bit of the RSPIA in slave mode is 1, and the SPMS bit is 0, and the following conditions are satisfied during the serial transfer period (from the time the driving of valid data is started to the time the final valid data is fetched).

- In the Motorola SPI mode, when the SSL00 input signal is negated during the serial transfer period
- In the TI SSP mode, when the SSL00 input signal is asserted during the serial transfer period
  However, during a burst transfer, no error is detected even if the SSL00 input signal is asserted during the last bit of frame.

Upon detecting a mode fault error, the RSPIA stops driving of the output signals and sets the SPCR.SPE bit to 0. When the SPE bit is cleared, the RSPI function is disabled (refer to section 41.3.12, Initializing RSPIA). In the case of multi-master configuration, detection of a mode fault error is used to stop driving of the output signals and the RSPI function, which allows the master right to be released.
The occurrence of a mode fault error can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. Detecting mode fault errors without utilizing the error interrupt requires polling of the SPSR register. When using the RSPIA in master mode, the pointer value to SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.
When the MODF flag is 1, writing of the value 1 to the SPE bit is ignored by the RSPIA. To enable the RSPI function after the detection of a mode fault error, set the MODF flag to 0.

41.3.10.4 Underrun Error

If RSPIA operates in slave mode (the SPCR.MSTR bit is 0) and the communication mode select bits (CMMD[1:0]) in the RSPI control register (SPCR) is set to 00b or 01b, when serial transfer is started before transmit data output is ready with the SPCR.SPE bit is 1 (RSPI function is enabled), the RSPIA detects an underrun error, and sets the SPSR.MODF and SPSR.UDRF flags to 1.
Upon detecting an underrun error, the RSPIA stops driving of the output signals and sets the SPCR.SPE bit to 0. Clearing of the SPE bit disables the RSPI function. (Refer to section 41.3.12, Initializing RSPIA).
The occurrence of an underrun error can be checked either by reading the SPSR register or by using an error interrupt and reading the SPSR register. Detecting underrun errors without utilizing the error interrupt requires polling of the SPSR register.
When the MODF flag is 1, writing of the value 1 to the SPE bit is ignored by the RSPIA. To enable the RSPI function after the detection of an underrun error, set the MODF flag to 0.

41.3.11 Received Data Ready Detection

When the SPCR.CMMD[1:0] bits are 00b, 01b or 11b, and the value of the SPDRCSR register is not 00h, after receiving data in the receive FIFO during communication (SPE = 1), the SPSR.RRDYF flag is set to 1 when the received data is not stored even after the number of received FIFOs is equal to or less than the threshold value and the value set in the SPDRCSR register has elapsed.

When the receive data ready is detected, the interrupt and event link output can be selected as SPRI or SPEI with the SPCR.RDRIS bit.

Figure 41.53 shows an example of received data ready detection operation.

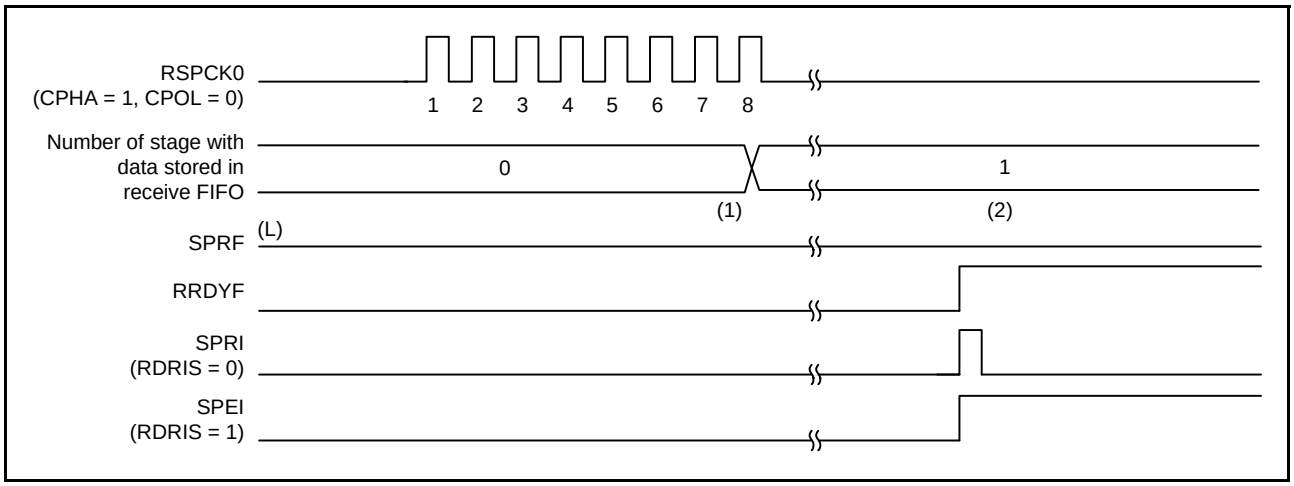

Figure 41.53 Received Data Ready Detection

The operation at the timing shown in steps (1) and (2) in the figure is described below.

(1) Store the received data to the receive FIFO. The SPSR.SPRF flag is 0, because the number of data stored in the receive FIFO is equal to or less than the value of the SPFCR.RTRG[1:0] bits.

(2) Set the RRDYF flag and assert SPRI or SPEI because data is not written to the receive FIFO for the value of the SPDRCSR register from (1).

41.3.12 Initializing RSPIA

If 0 is written to the SPCR.SPE bit or the RSPIA sets the SPE bit to 0 because of the detection of a mode fault error or an underrun error, the RSPIA disables the RSPI function, and initializes some of the module functions. When a system reset is generated, the RSPIA initializes all of the module functions. The following describes initialization by the clearing of the SPCR.SPE bit and initialization by a system reset.

41.3.12.1 Initialization by Clearing the SPE Bit

When the SPCR.SPE bit is set to 0, the RSPIA performs the following initialization:

- Suspending any serial transfer that is being executed
- Stopping the driving of output signals (Hi-Z) in slave mode
- Initializing the internal state of the RSPIA
- Set the SPSR.SPTEF flag to 1

Initialization by the clearing of the SPE bit does not initialize the control bits of the RSPIA. For this reason, the RSPIA can be started in the same transfer mode as prior to the initialization if the SPE bit is set to 1 again.
The SPSR.SPCF, SPRF, OVRF, MODF, PERF, and UDRF flags are not initialized, nor is the value of the RSPI sequence status register (SPSSR) initialized. For this reason, even after the RSPIA is initialized, data from the receive buffer, the communication end status, and the error status during RSPI transfer can be read to check them.
The SPSR.SPTEF flag is initialized to 1. Therefore, if the SPCR.SPTIE bit is set to 1 after RSPIA initialization, a transmit buffer empty interrupt is generated. When the CPU initializes the RSPIA, in order to disable any transmit buffer empty interrupt, 0 should be written to the SPTIE bit simultaneously with the writing of 0 to the SPE bit.

41.3.12.2 System Reset

The initialization by a system reset completely initializes the RSPIA through the initialization of all bits for controlling the RSPIA, initialization of the status bits, and initialization of data registers, in addition to the requirements described in section 41.3.12.1, Initialization by Clearing the SPE Bit.

41.3.13 SPI Operation

41.3.13.1 Master Mode Operation

The only difference between single-master mode operation and multi-master mode operation lies in mode fault error detection (refer to section 41.3.10, Error Detection). When operating in single-master mode, the RSPIA does not detect mode fault errors whereas the RSPIA running in multi-master mode does detect mode fault errors. This section explains operations that are common to single-master mode and multi-master mode.

(1) Starting a Serial Transfer

The RSPIA updates the data in the transmit buffer (SPTXn, n = 0 to 3) when data is written to the RSPI data register (SPDR) with the transmit buffer being empty (data for the next transfer is not set). When the shift register is empty the RSPIA copies data from the transmit buffer to the shift register and starts serial transfer. Upon copying transmit data to the shift register, the RSPIA changes the status of the shift register to “full”, and upon termination of serial transfer, it changes the status of the shift register to “empty”. The status of the shift register cannot be referenced.
For details on the RSPI transfer format, refer to section 41.3.5, Transfer Format (Frame Format). The polarity of the SSL0n output pins depends on the SSLP register settings.

(2) Terminating a Serial Transfer

[Except receive-only operation in master mode]
Irrespective of the SPCMDm.CPHA bit, the RSPIA terminates the serial transfer after transmitting an RSPCK0 edge corresponding to the final sampling timing. If the number of data stored in the receive FIFO is less than the number of FIFO stages, after the termination of serial transfer, the RSPIA copies data from the shift register to the receive buffer of the SPDR register.
It should be noted that the final sampling timing varies depending on the bit length of transmit data. In master mode, the RSPI data length depends on the SPCMDm.SPB[4:0] bits setting. The polarity of the SSL0n output pin depends on the SSLP register settings.
For details on the RSPI transfer format, refer to section 41.3.5, Transfer Format (Frame Format).

[Receive-only operation in master mode]
The RSPIA terminates the serial transfer when any of the following conditions is satisfied.

- After the RSPIA detects the RSPCK0 edge corresponding to the final sampling timing irrespective of the SPCMDm.CPHA bit
- When writing 1 to the SPRMCR.TERM bit during the serial transfer period

If the number of data stored in the receive FIFO is less the number of FIFO stages, after termination of serial transfer, the RSPIA copies data from the shift register to the receive buffer of the SPDR register.
It should be noted that the final sampling timing varies depending on the bit length of transmit data. In master mode, the RSPI data length depends on the SPCMDm.SPB[4:0] bits setting. The polarity of the SSL0n output pin depends on the SSLP register settings.
For details on the RSPI transfer format, refer to section 41.3.5, Transfer Format (Frame Format).

(3) Sequence Control

The transfer format that is employed in master mode is determined by the following registers.

- RSPI sequence control register (SPSCR)
- RSPI command register m (SPCMDm) (m = 0 to 7)
- RSPI bit rate register (SPBR)
- RSPI clock delay register (SPCKD)
- RSPI slave select negation delay register (SSLND)
- RSPI next-access delay register (SPND)

SPSCR is a register used to determine the sequence configuration for serial transfers that are executed by the RSPIA in master mode. The following items are set in the SPCMDm register: SSL0n pin output signal value, MSB/LSB first, data length, some of the bit rate settings, RSPCK polarity/phase, whether SPCKD is to be referenced, whether SSLND is to be referenced, and whether SPND is to be referenced. The SPBR register holds some of the bit rate settings; the SPCKD register, an RSPI clock delay value; the SSLND register, an SSL negation delay; and the SPND register, a next-access delay value.

According to the sequence length that is assigned to the SPSCR register, the RSPIA makes up a sequence comprised of a part or all of the SPCMDm register. The RSPIA contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the RSPI function is enabled, the RSPIA loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. The RSPIA increments the pointer each time the next-access delay period for a data transfer ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, the RSPIA sets the pointer in SPCMD0, and in this manner the sequence is executed repeatedly.

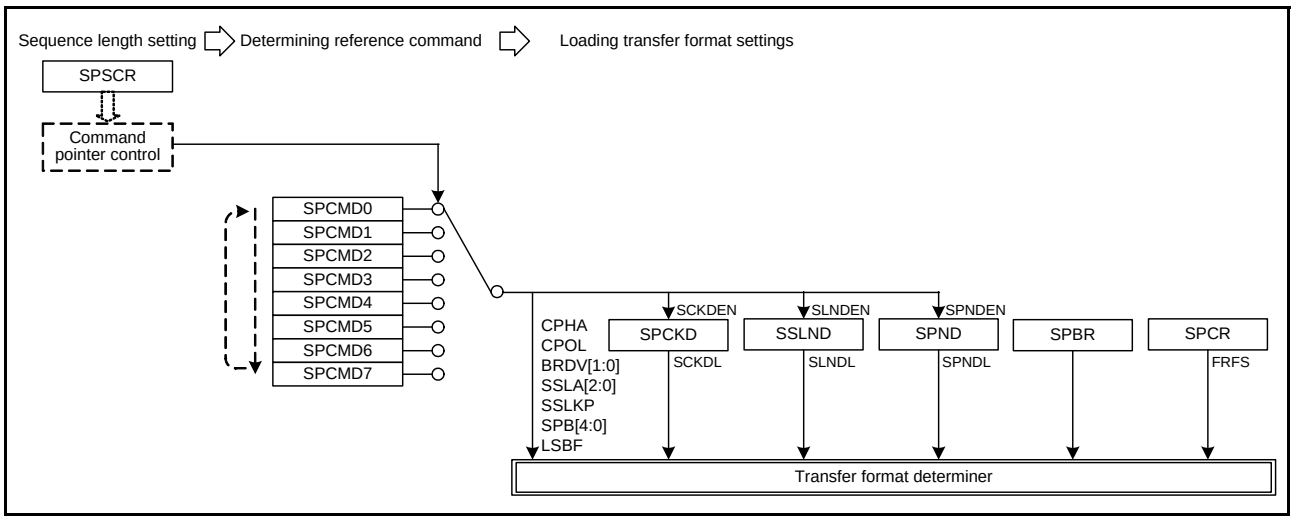

Figure 41.54 Procedure for Determining the Form of Serial Transfer in Master Mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm).

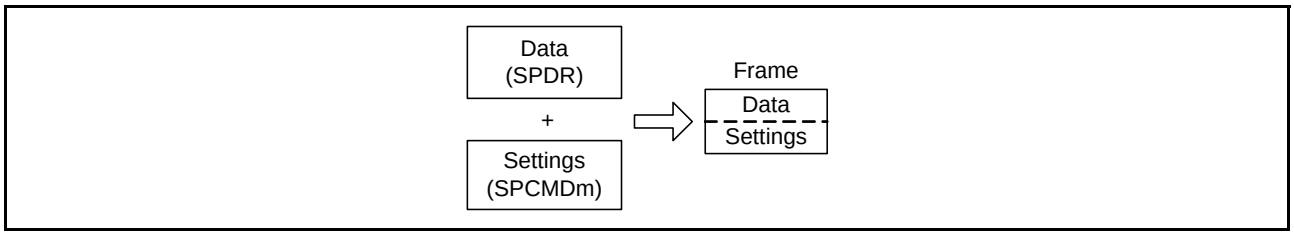

Figure 41.55 Concept of a Frame

Figure 41.56 shows the relationship between the command and the transmit buffer (SPTXn, n = 0 to 3) and receive buffer (SPRXn, n = 0 to 3) in sequence operations.

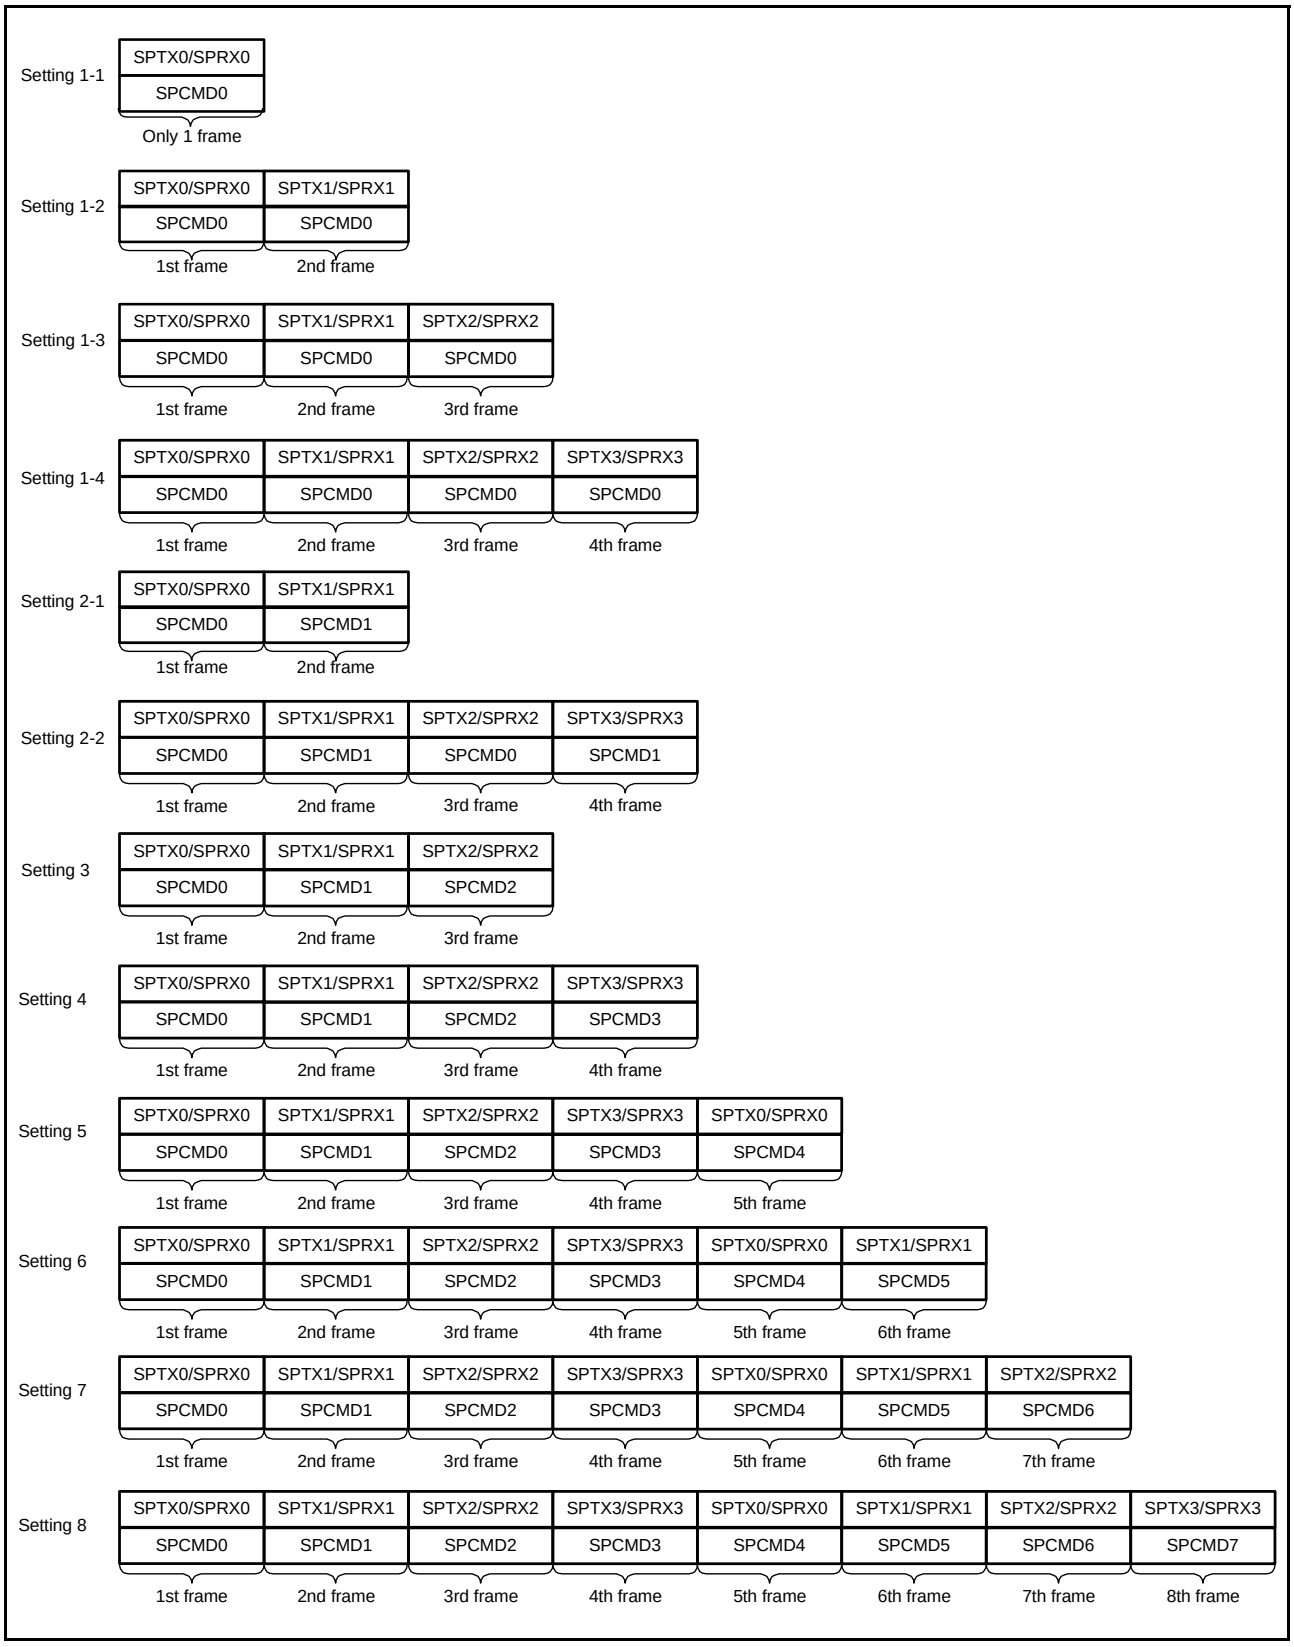

Figure 41.56 Correspondence between the RSPI Command Register m and Transmit/Receive Buffers in Sequence Operations

(4) Burst Transfer

[Motorola SPI]

If the SPCMDm.SSLKP bit that the RSPIA references during the current serial transfer is 1, the RSPIA keeps the SSL0n signal level during the serial transfer until the beginning of the SSL0n signal assertion for the next serial transfer. If the SSL0n signal level for the next serial transfer is the same as the SSL0n signal level for the current serial transfer, the RSPIA can execute continuous serial transfers while keeping the SSL0n signal assertion status (burst transfer).

- When the SPCR.SCKDDIS bit (RSPCK delay between data bytes disable bit) is 0

Figure 41.57 shows an example of an SSL0n signal operation for the case where a burst transfer is implemented using SPCMD0 and SPCMD1 register settings. The text below explains the RSPI operations (1) to (8) as shown in Figure 41.57. It should be noted that the polarity of the SSL0n output signal depends on the SSLP register settings.

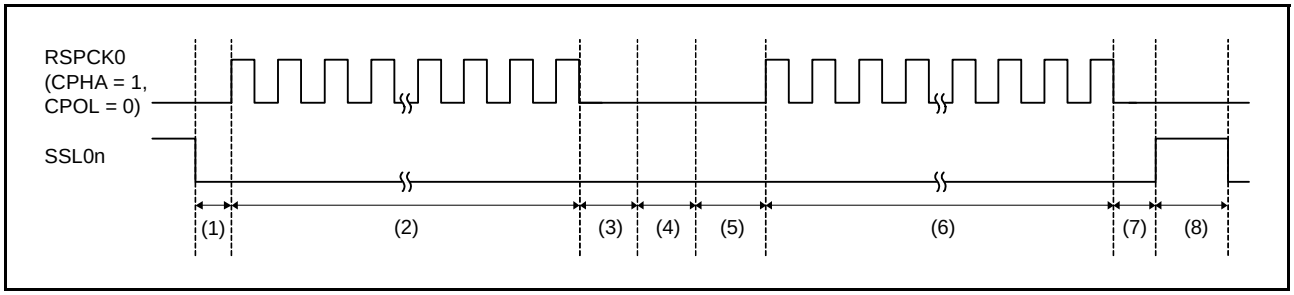

Figure 41.57 Example of Burst Transfer Operation Using SSLKP Bit (SCKDDIS = 0, FRFS = 0)

(1) Based on SPCMD0, the RSPIA asserts the SSL0n signal and inserts RSPCK delays.
(2) The RSPIA executes serial transfers according to SPCMD0.
(3) The RSPIA inserts SSL negation delays.
(4) In transmit-receive mode or transmit-only mode, since the SPCMD0.SSLKP bit is 1, the RSPIA keeps the SSL0n signal value on SPCMD0. This period is sustained, at the shortest, for a period equal to the next-access delay of SPCMD0 and additional 5 PCLKA cycles. If the shift register is empty after the passage of a minimum period, this period is sustained until the transmit data is stored in the shift register for the next transfer.
In receive-only mode, since the SPCMD0.SSLKP bit is 1, the RSPIA keeps the SSL0n signal value on SPCMD0. This period is sustained for a period equal to the next-access delay of SPCMD0 and additional 5 PCLKA cycles.
(5) Based on SPCMD1, the RSPIA asserts the SSL0n signal and inserts RSPCK delays.
(6) The RSPIA executes serial transfers according to SPCMD1.
(7) The RSPIA inserts SSL negation delays.
(8) Since the SPCMD1.SSLKP bit is 0, the RSPIA negates the SSL0n signal. In addition, a next-access delay is inserted according to SPCMD1.

Note: If the SSL0n signal output settings in the SPCMDm register in which 1 is assigned to the SSLKP bit (to use for burst transfer) are different from the SSL0n signal output settings in the SPCMDm register to be used in the next transfer, the RSPIA switches the SSL0n signal status to SSL0n signal assertion ((5) in Figure 41.57) corresponding to the command for the next transfer. Note that if such an SSL0n signal switching occurs, the slaves that drive the MISO0 signal compete, and collision of signal levels may occur.

The RSPIA in master mode references the SSL0n signal operation within the module for the case where the SSLKP bit is not used. Even when the SPCMDm.CPHA bit is 0, the RSPIA can accurately start serial transfers by using the SSL0n signal assertion for the next transfer that is detected internally. For this reason, burst transfer in master mode is enabled regardless of the CPHA bit setting. (Refer to section 41.3.13, SPI Operation.)

- When the SPCR.SCKDDIS bit (RSPCK delay between data bytes disable bit) is 1

Figure 41.58 shows an example of an SSL0n signal operation for the case where a burst transfer is implemented using SPCMD0 and SPCMD1 register settings. The text below explains the RSPI operations (1) to (6) as shown in Figure 41.58. It should be noted that the polarity of the SSL0n output signal depends on the SSLP register settings.

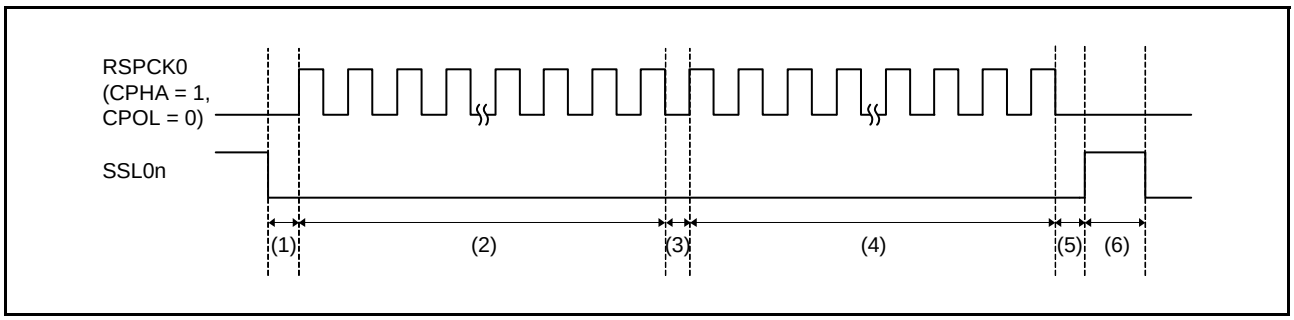

Figure 41.58 Example of Burst Transfer Operation Using SSLKP Bit (SCKDDIS = 1, FRFS = 0)

(1) Based on the SPCMD0 register, the RSPIA asserts the SSL0n signal and inserts RSPCK delays.
The RSPCK delay is inserted only the first frame of burst transfer.

(2) In transmit-receive mode or transmit-only mode, the RSPIA executes serial transfers according to the SPCMD0 register. The RSPIA waits for the last clock output until the next transmit data is stored in the shift register, if the shift register is empty during RSPCK negate period between frames.
In receive-only mode, the RSPIA executes serial transfers according to the SPCMD0 register.

(3) In transmit-receive mode or transmit-only mode, since the SPCMD0.SSLKP bit is 1, the RSPIA keeps the SSL0n signal value on the SPCMD0 register. If the shift register is not empty, RSPCK negate period between frames is 0.5 RSPCK.
In receive-only mode, since it is not the last frame*1, the RSPIA keeps the SSL0n signal value on the SPCMD0 register. RSPCK negate period between frames is 0.5 RSPCK.

(4) The RSPIA executes serial transfers according to the SPCMD1 register.

(5) The RSPIA inserts SSL negation delays.

(6) In transmit-receive mode or transmit-only mode, since the SPCMD1.SSLKP bit is 0, the RSPIA negates the SSL0n signal. In addition, a next-access delay is inserted according to the SPCMD1 register.
In receive-only mode, the RSPIA negates the SSL0n signal. In addition, a next-access delay is inserted according to the SPCMD1 register.

Note 1. In receive-only mode, the last frame is a frame set by the SPRMCR.RFC[4:0] bits when SPRMCR.RFC[4:0] ≠ 00000b or a frame in which SPRMCR.TERM = 1 has been accepted.

[TI SSP]
The RSPIA asserts the SSL0n signal for one cycle at the start of serial transfer.
The RSPIA can execute continuous serial transfers by asserting the SSL0n signal for one cycle at the start of serial transfer (burst transfer).

- When the SPCMDm.SSLKP bit (SSL signal level keeping bit) is 1, and the SPCR.SCKDDIS bit (RSPCK delay between data bytes disable bit) is 1

Figure 41.59 shows an example of an SSL0n signal operation and the serial data MISO0/MOSI0 for the case where a burst transfer is implemented using the SPCMD0 and SPCMD1 register settings. The text below explains the RSPI operations (1) to (6) as shown in Figure 41.59. It should be noted that the polarity of the SSL0n output signal depends on the SSLP register settings.

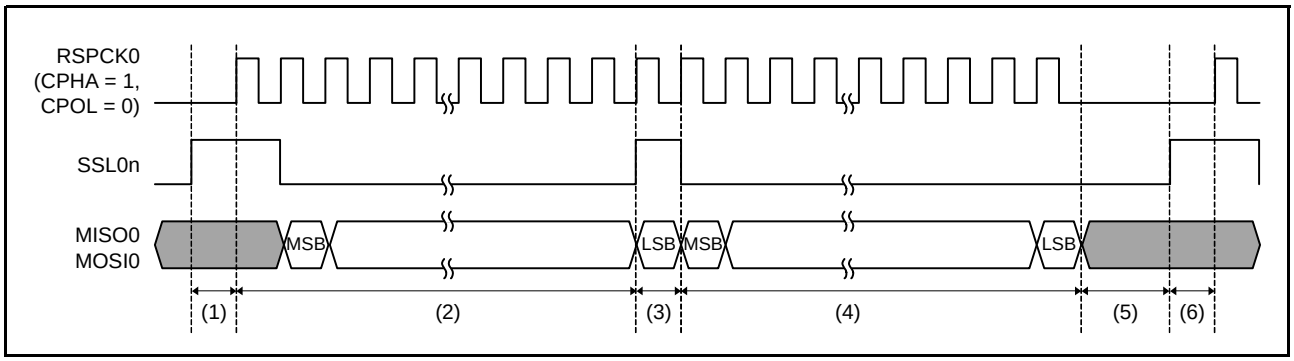

Figure 41.59 Example of Burst Transfer Operation (FRFS = 1)

(1) Based on the SPCMD0 register, the RSPIA asserts the SSL0n signal and inserts RSPCK delays.
The RSPCK delay is inserted only the first frame of burst transfer.
(2) The RSPIA executes serial transfers according to the SPCMD0 register.
(3) Final data transfer and the SSL0n assertion are performed simultaneously.
During transmit-receive/transmit-only operation, the RSPIA waits for the last clock output until the next transmit data is stored in the shift register, if the shift register is empty during RSPCK negate period between frames.
(4) The RSPIA executes serial transfers according to the SPCMD1 register.
(5) The RSPIA inserts SSL0n negation delays at the last frame*1.
(6) A next-access delay is inserted according to the SPCMD1 register.

Note 1. In receive-only mode, the last frame is a frame set by the SPRMCR.RFC[4:0] bits when SPRMCR.RFC[4:0] ≠ 00000b or a frame in which SPRMCR.TERM = 1 has been accepted.
Note: If the SSL0n signal output settings in the SPCMDm register in which 1 is assigned to the SSLKP bit are different from the SSL0n signal output settings in the SPCMDm register to be used in the next transfer, the RSPIA switches the SSL0n signal status to SSL0n signal assertion ((5) in Figure 41.59) corresponding to the command for the next transfer. Note that if such an SSL0n signal switching occurs, the slaves that drive the MISO0 signal compete, and collision of signal levels may occur.

(5) RSPCK Delay (t1)

The RSPCK delay value of the RSPIA in master mode depends on the SPCMDm.SCKDEN bit setting and the SPCKD register setting. The RSPIA determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines an RSPCK delay value during serial transfer by using the SPCMDm.SCKDEN bit and the SPCKD.SCKDL[2:0] bits, as listed in Table 41.9. For a definition of RSPCK delay, refer to section 41.3.5, Transfer Format (Frame Format).

The RSPCK delay is inserted only the first frame of burst transfer when data transfer is performed without delay between frames in burst transfer (SPCMDm.SSLKP = 1, SPCR.SCKDDIS = 1).

Table 41.9 Relationship among SCKDEN Bit, SCKDL[2:0] Bits, and RSPCK Delay Value

		RSPCK Delay Value	
SPCMDm.SCKDEN Bit	**SPCKD.SCKDL[2:0] Bits**	**Motorola SPI**	**TI SSP**
0	000b to 111b	1 RSPCK	0 RSPCK
1	000b	1 RSPCK	1 RSPCK
	001b	2 RSPCK	2 RSPCK
	010b	3 RSPCK	3 RSPCK
	011b	4 RSPCK	4 RSPCK
	100b	5 RSPCK	5 RSPCK
	101b	6 RSPCK	6 RSPCK
	110b	7 RSPCK	7 RSPCK
	111b	8 RSPCK	8 RSPCK

(6) SSL Negation Delay (t2)

The SSL negation delay value of the RSPIA in master mode depends on the SPCMDm.SLNDEN bit setting and the SSLND register setting. The RSPIA determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines an SSL negation delay value during serial transfer by using the SPCMDm.SLNDEN bit and SSLND.SLNDL[2:0] bits, as listed in Table 41.10. For a definition of SSL negation delay, refer to section 41.3.5, Transfer Format (Frame Format).

The SSL negation delay is inserted only the last frame of burst transfer when data transfer is performed without delay between frames in burst transfer (SPCMDm.SSLKP = 1, SPCR.SCKDDIS = 1).

Table 41.10 Relationship among SLNDEN Bit, SLNDL[2:0] Bits, and SSL Negation Delay Value

SPCMDm.SLNDEN Bit	**SSLND.SLNDL[2:0] Bits**	**SSL Negation Delay Value**
0	000b to 111b	1 RSPCK
1	000b	1 RSPCK
	001b	2 RSPCK
	010b	3 RSPCK
	011b	4 RSPCK
	100b	5 RSPCK
	101b	6 RSPCK
	110b	7 RSPCK
	111b	8 RSPCK

(7) Next-Access Delay (t3)

The next-access delay value of the RSPIA in master mode depends on the SPCMDm.SPNDEN bit setting and the SPND setting. The RSPIA determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines a next-access delay value during serial transfer by using the SPCMDm.SPNDEN bit and the SPND.SPNDL[2:0] bits, as listed in Table 41.11. For a definition of next-access delay, refer to section 41.3.5, Transfer Format (Frame Format).

The next-access delay is inserted only the last frame of burst transfer when data transfer is performed without delay between frames in burst transfer (SPCMDm.SSLKP = 1, SPCR.SCKDDIS = 1).

Table 41.11 Relationship among SPNDEN Bit, SPNDL[2:0], and Next-Access Delay Value

SPCMDm.SPNDEN Bit	SPND.SPNDL[2:0] Bits	Next-Access Delay Value
0	000b to 111b	1 RSPCK + 5 PCLKA
1	000b	1 RSPCK + 5 PCLKA
	001b	2 RSPCK + 5 PCLKA
	010b	3 RSPCK + 5 PCLKA
	011b	4 RSPCK + 5 PCLKA
	100b	5 RSPCK + 5 PCLKA
	101b	6 RSPCK + 5 PCLKA
	110b	7 RSPCK + 5 PCLKA
	111b	8 RSPCK + 5 PCLKA

(8) Initialization Flowchart

Figure 41.60 is a flowchart illustrating an example of initialization in SPI operation when the RSPIA is used in master mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

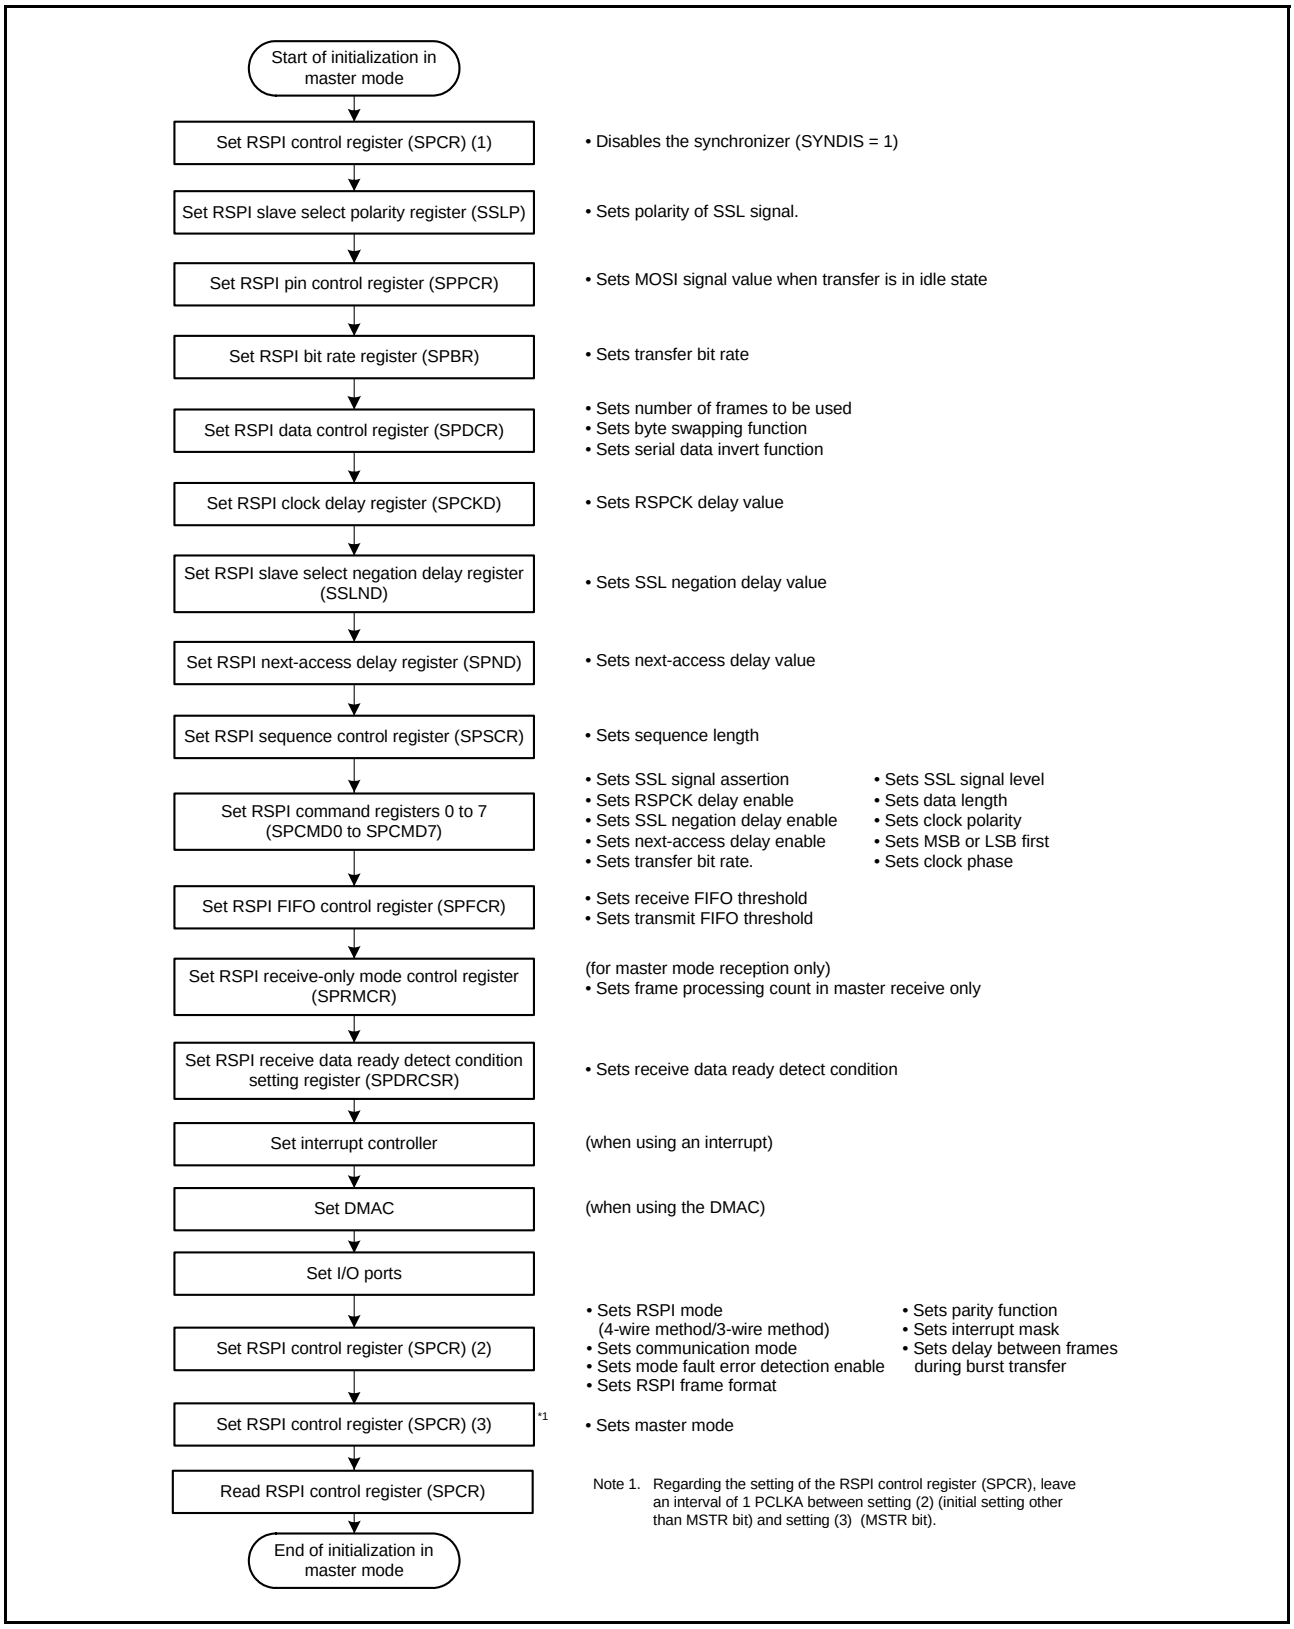

Figure 41.60 Example of Initialization Flowchart in Master Mode (SPI Operation)

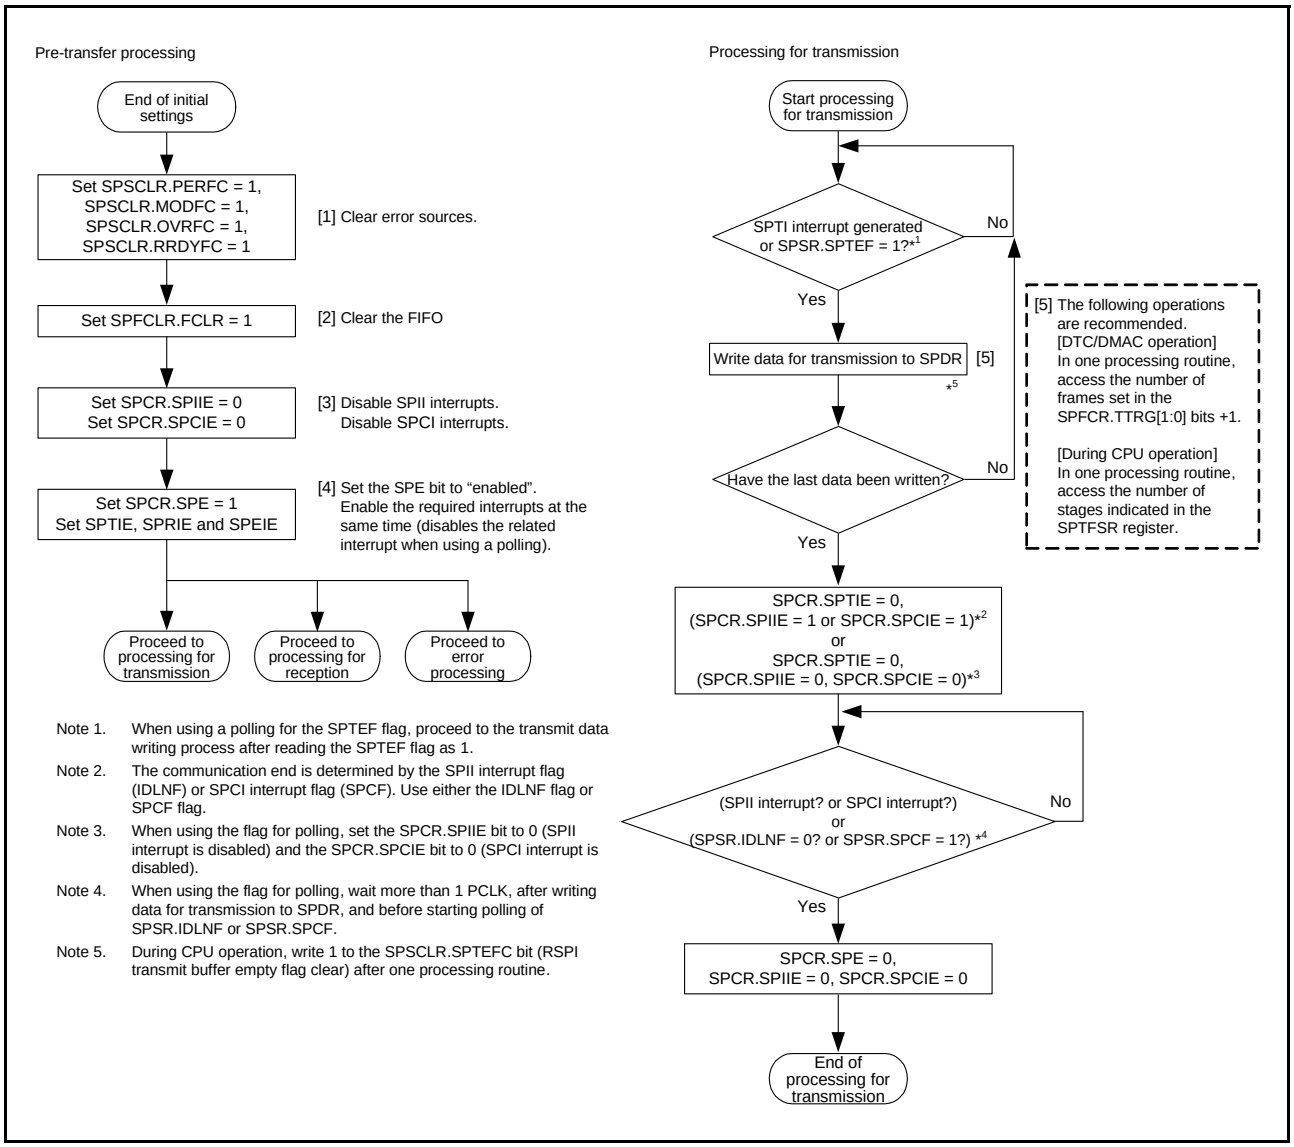
(9) Software Processing Flow

Figure 41.61 to Figure 41.63 show examples of the flow of software processing.

(a) Transmit Processing Flow

Enabling SPII or SPCI interrupt after final transmit data is written makes it possible to notify the CPU that transmission of all data has been completed.



Note 1. When using a polling for the SPTEF flag, proceed to the transmit data writing process after reading the SPTEF flag as 1.

Note 2. The communication end is determined by the SPII interrupt flag (IDLNF) or SPCI interrupt flag (SPCF). Use either the IDLNF flag or SPCF flag.

Note 3. When using the flag for polling, set the SPCR.SPIIE bit to 0 (SPII interrupt is disabled) and the SPCR.SPCIE bit to 0 (SPCI interrupt is disabled).

Note 4. When using the flag for polling, wait more than 1 PCLK, after writing data for transmission to SPDR, and before starting polling of SPSR.IDLNF or SPSR.SPCF.

Note 5. During CPU operation, write 1 to the SPSCLR.SPTEFC bit (RSPI transmit buffer empty flag clear) after one processing routine.

Figure 41.61 Flowchart in Master Mode (Transmission)

(b) Receive Processing Flow

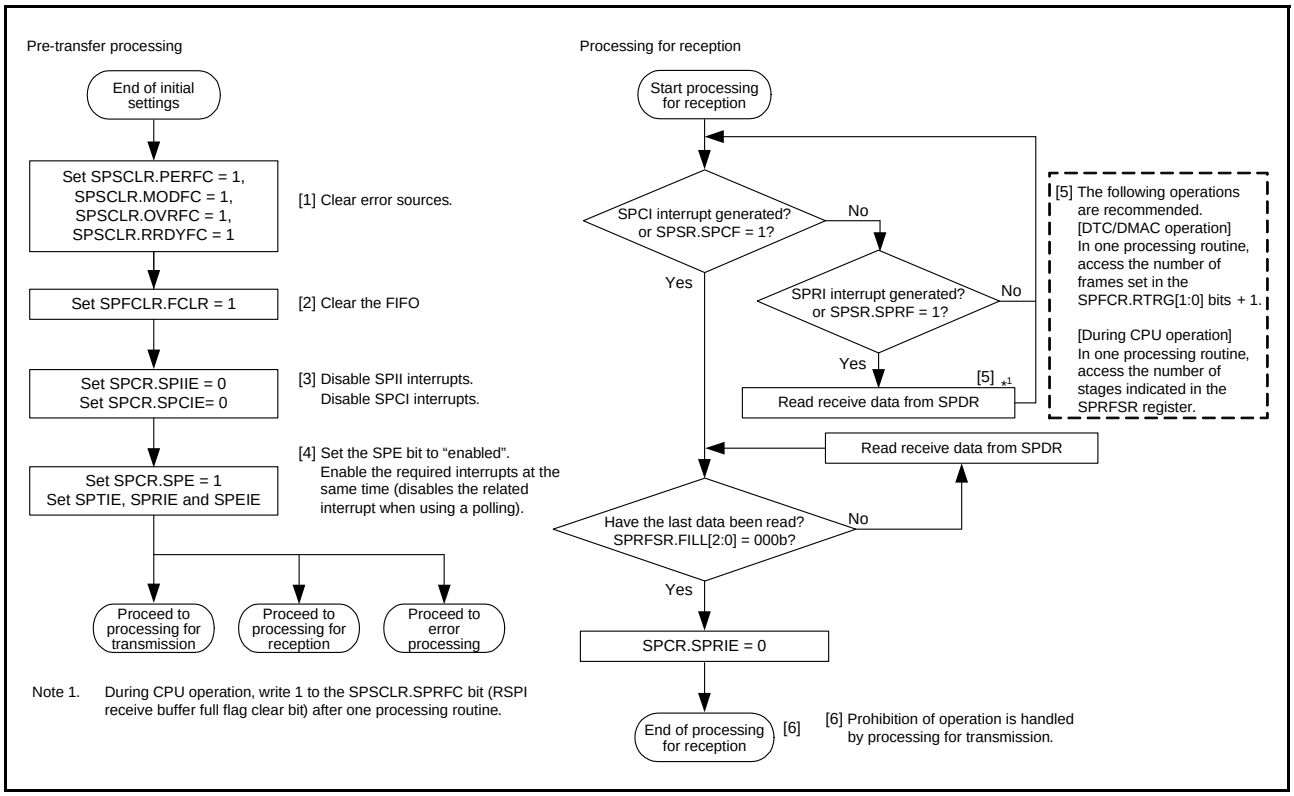


Figure 41.62 Flowchart in Master Mode (Reception)

(c) Receive-Only Processing Flow

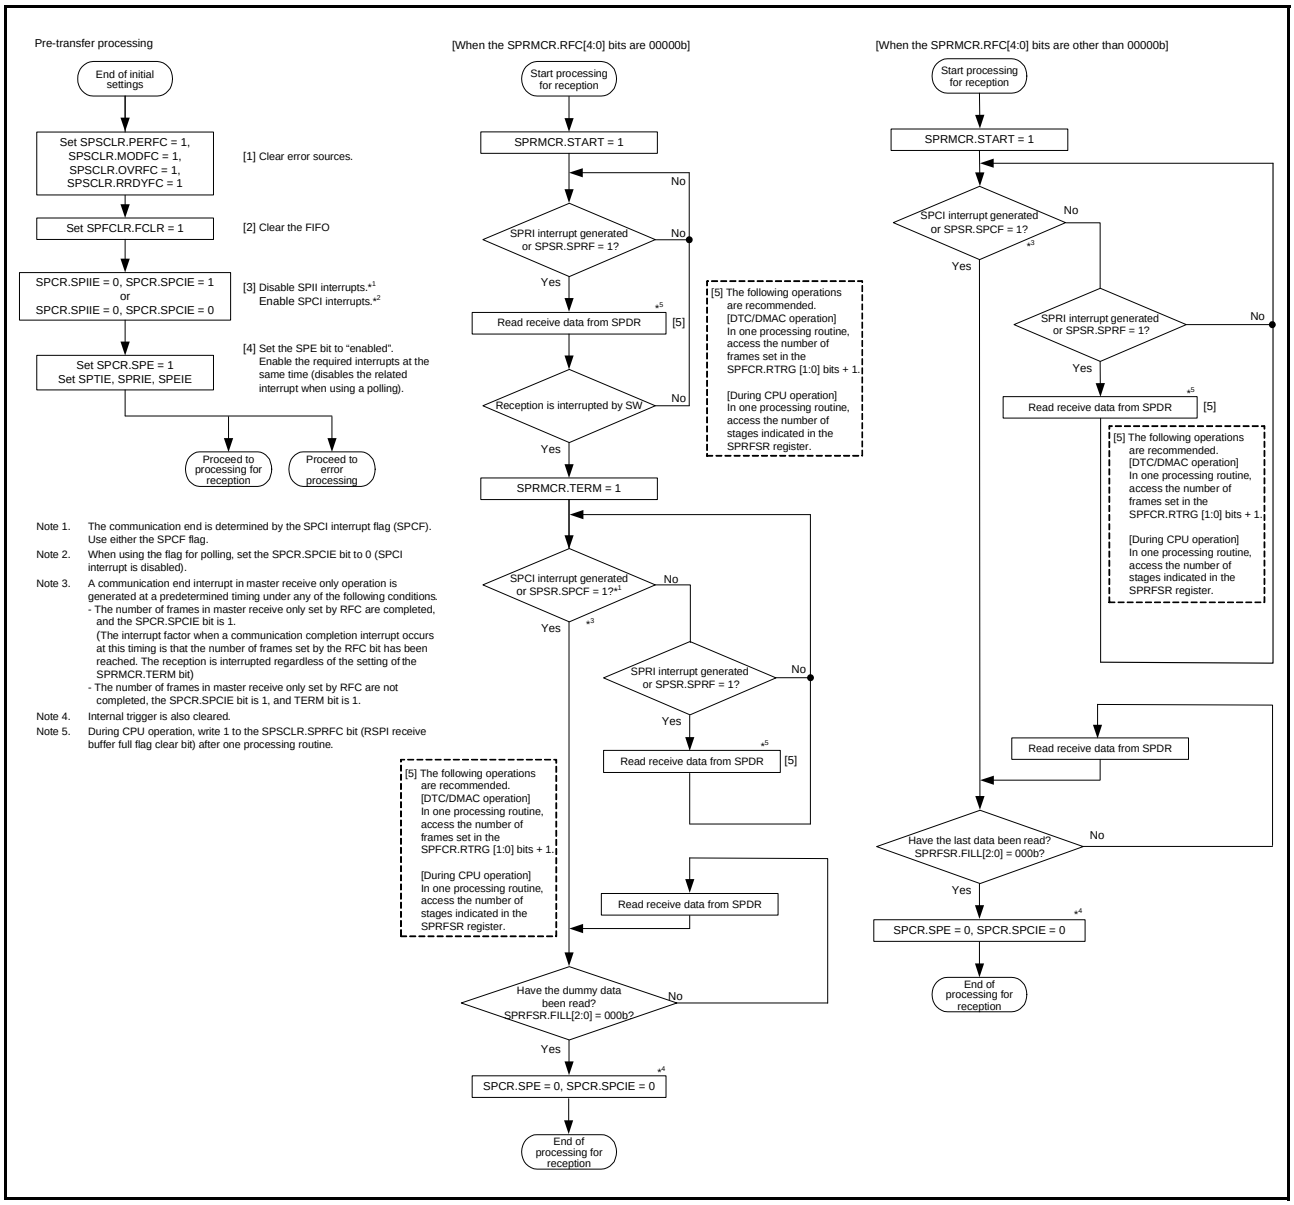

Figure 41.63 Flowchart in Master Mode (Receive-Only)

(d) Flow of Error Processing

When a mode fault error is generated, the SPCR.SPE bit is automatically cleared, stopping operations for transmission and reception. For errors from other sources, however, the SPCR.SPE bit is not cleared and operations for transmission and reception continue; accordingly, we recommend clearing of the SPCR.SPE bit to stop operations in the case of errors other than mode fault errors. Not doing so will lead to updating of the SPSSR.SPECM[2:0] bits.

When interrupts are used and an error occurs, if the ICU.IRn.IR flag for the SPTI or SPRI interrupt request is set to 1, clear the ICU.IRn.IR flag in the error processing routine. If the SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the RSPIA.

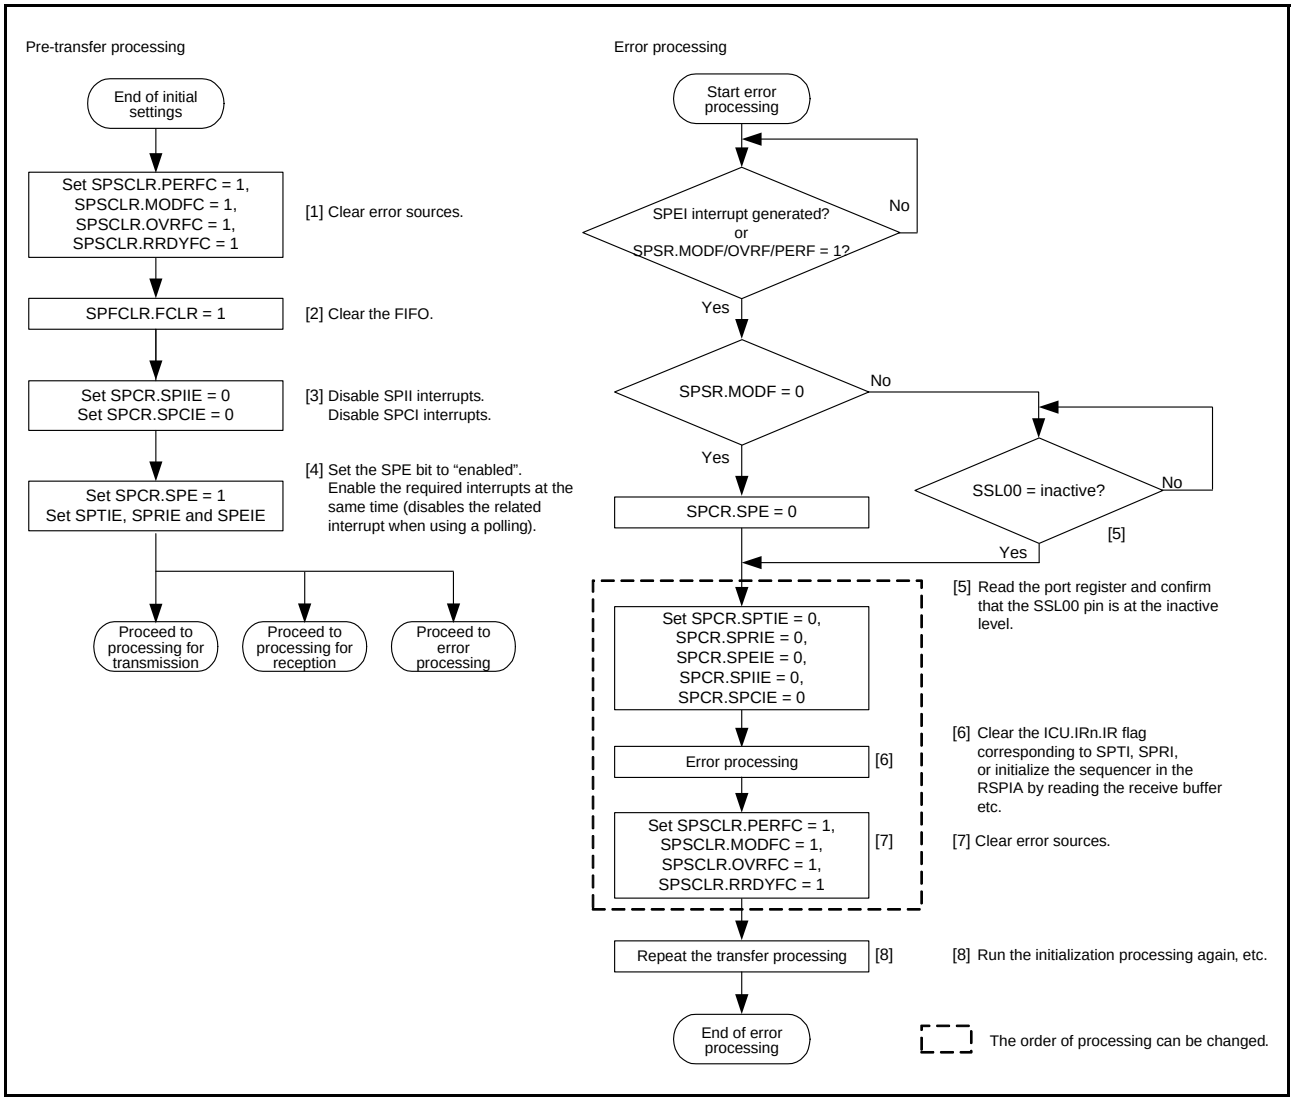

Figure 41.64 Flowchart for Master Mode (Error Processing)

41.3.13.2 Slave Mode Operation

(1) Starting a Serial Transfer

If the SPCMD0.CPHA bit is 0, when detecting an SSL00 input signal assertion, the RSPIA needs to start driving valid data to the MISO0 output signal. For this reason, when the CPHA bit is 0, the assertion of the SSL00 input signal triggers the start of a serial transfer.
If the CPHA bit is 1, when detecting the first RSPCK0 edge in an SSL00 signal asserted condition, the RSPIA needs to start driving valid data to the MISO0 output signal. For this reason, when the CPHA bit is 1, the first RSPCK0 edge in an SSL00 signal asserted condition triggers the start of a serial transfer.
Irrespective of the CPHA bit setting, the timing at which the RSPIA starts driving of the MISO0 output signal is the SSL00 signal assertion timing. The data which is output by the RSPIA is either valid or invalid, depending on the CPHA bit setting.
For details on the RSPI transfer format, refer to section 41.3.5, Transfer Format (Frame Format). The polarity of the SSL00 input signal depends on the setting of the SSLP.SSL0P bit.

(2) Terminating a Serial Transfer

Irrespective of the SPCMD0.CPHA bit, the RSPIA terminates the serial transfer after detecting an RSPCK0 edge corresponding to the final sampling timing. When the number of data stored in the receive FIFO is less than the number of FIFO stages, upon termination of serial transfer the RSPIA copies received data from the shift register to the receive buffer of the SPDR register. Upon termination of a serial transfer the RSPIA changes the status of the shift register to “empty”, regardless of the receive buffer state. A mode fault error occurs if the RSPIA detects an SSL00 input signal negation from the beginning of serial transfer to the end of serial transfer (refer to section 41.3.10, Error Detection).
The final sampling timing changes depending on the bit length of transmit data. In slave mode, the RSPI data length depends on the SPCMD0.SPB[4:0] bit setting. The polarity of the SSL00 input signal depends on the SSLP.SSL0P bit setting. For details on the RSPI transfer format, refer to section 41.3.5, Transfer Format (Frame Format).

(3) Notes on Single-Slave Operation

[Motorola SPI]
If the SPCMD0.CPHA bit is 0, when detecting an SSL00 input signal assertion edge, the RSPIA starts a serial transfer. Upon the SSL00 input signal is fixed to the active level when using the RSPIA in single slave mode in a configuration as shown in Figure 41.7, the RSPIA cannot start a serial transfer correctly while the CPHA bit is 0. To correctly perform transmission and reception of the RSPIA in slave mode in a configuration where the SSL00 input signal is fixed to the active level, set the CPHA bit to 1. If the CPHA bit must be set to 0, do not fix the SSL00 input signal to active level.

[TI SSP]
In the TI SSP mode, upon the SSL00 input signal is fixed to the inactive level when using the RSPIA in single slave mode in a configuration as shown in Figure 41.7, the RSPIA cannot start a serial transfer correctly.
When using the RSPIA in single slave mode, operate in a configuration as shown in Figure 41.6.

(4) Burst Transfer

[Motorola SPI]
When the SPCMD0.CPHA bit is 1, continuous serial transfer (burst transfer) is available while maintaining the SSL00 input signal assertion state. When the CPHA bit is 1, the period (from the first RSPCK0 edge in the SSL00 input signal active state until the sampling timing for receiving the final bit) corresponds to the serial transfer period. Even if the SSL00 input signal is always at the active level, start of an access can be detected, which allows burst transfer.
When the CPHA bit is 0, the second and subsequent serial burst transfers cannot be performed correctly for the same reason as (3).

[TI SSP]

In serial transfer, data transfer starts after the SSL0n input signal is asserted for RSPCK 1 cycle. Since frame transfer starts from the SSL0n input signal, SSL must be asserted between frames.

(5) Initialization Flowchart

Figure 41.65 shows an example of initialization flow when using the RSPIA in slave-mode SPI operation. For how to set the interrupt controller, DMAC, and input/output ports, see descriptions of each block.

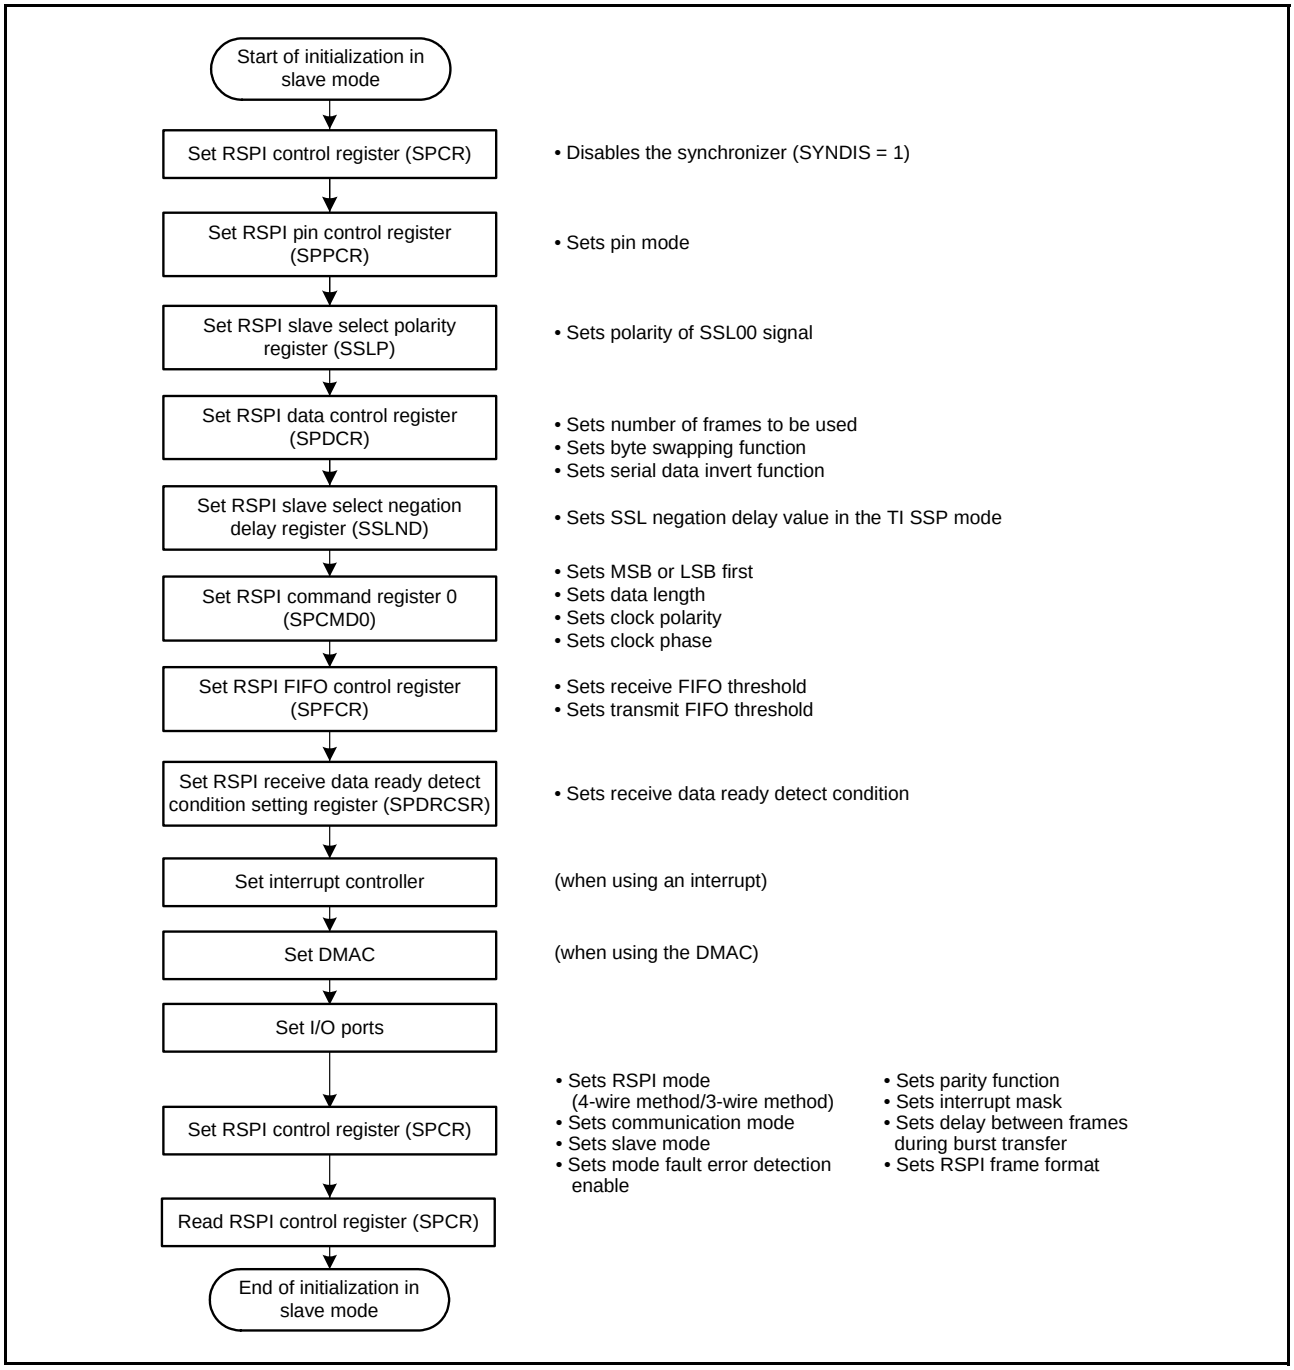

Figure 41.65 Example of Initialization Flow in Slave Mode

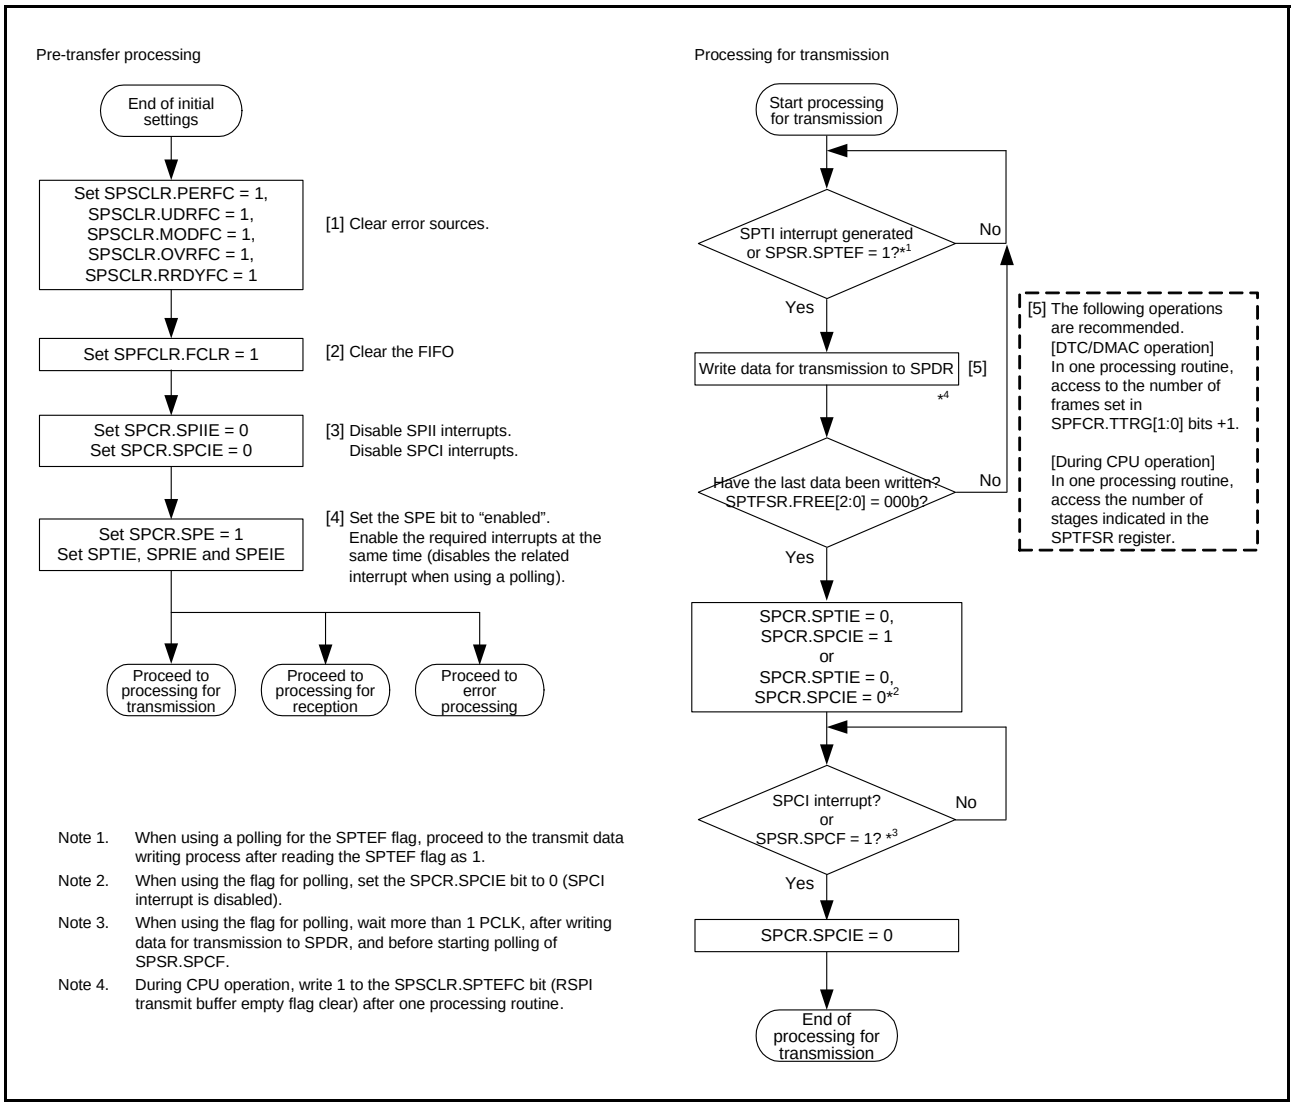
(6) Software Processing Flow

Figure 41.66 to Figure 41.69 show examples of the flow of software processing.

(a) Transmit Processing Flow



Note 1. When using a polling for the SPTEF flag, proceed to the transmit data writing process after reading the SPTEF flag as 1.

Note 2. When using the flag for polling, set the SPCR.SPCIE bit to 0 (SPCI interrupt is disabled).

Note 3. When using the flag for polling, wait more than 1 PCLK, after writing data for transmission to SPDR, and before starting polling of SPSR.SPCF.

Note 4. During CPU operation, write 1 to the SPSCLR.SPTEFC bit (RSPI transmit buffer empty flag clear) after one processing routine.

Figure 41.66 Flowchart in Slave Mode (Transmission)

(b) Receive Processing Flow

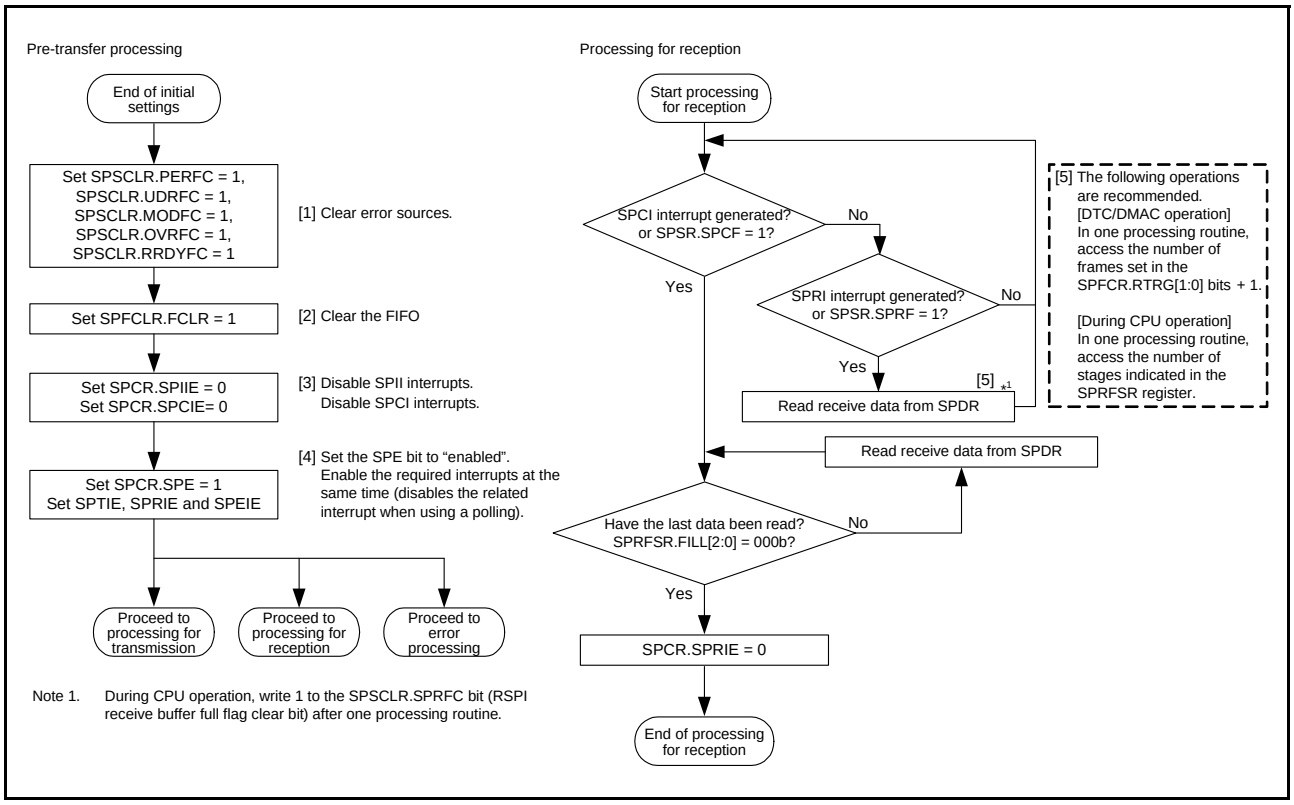


Figure 41.67 Flowchart in Slave Mode (Reception)

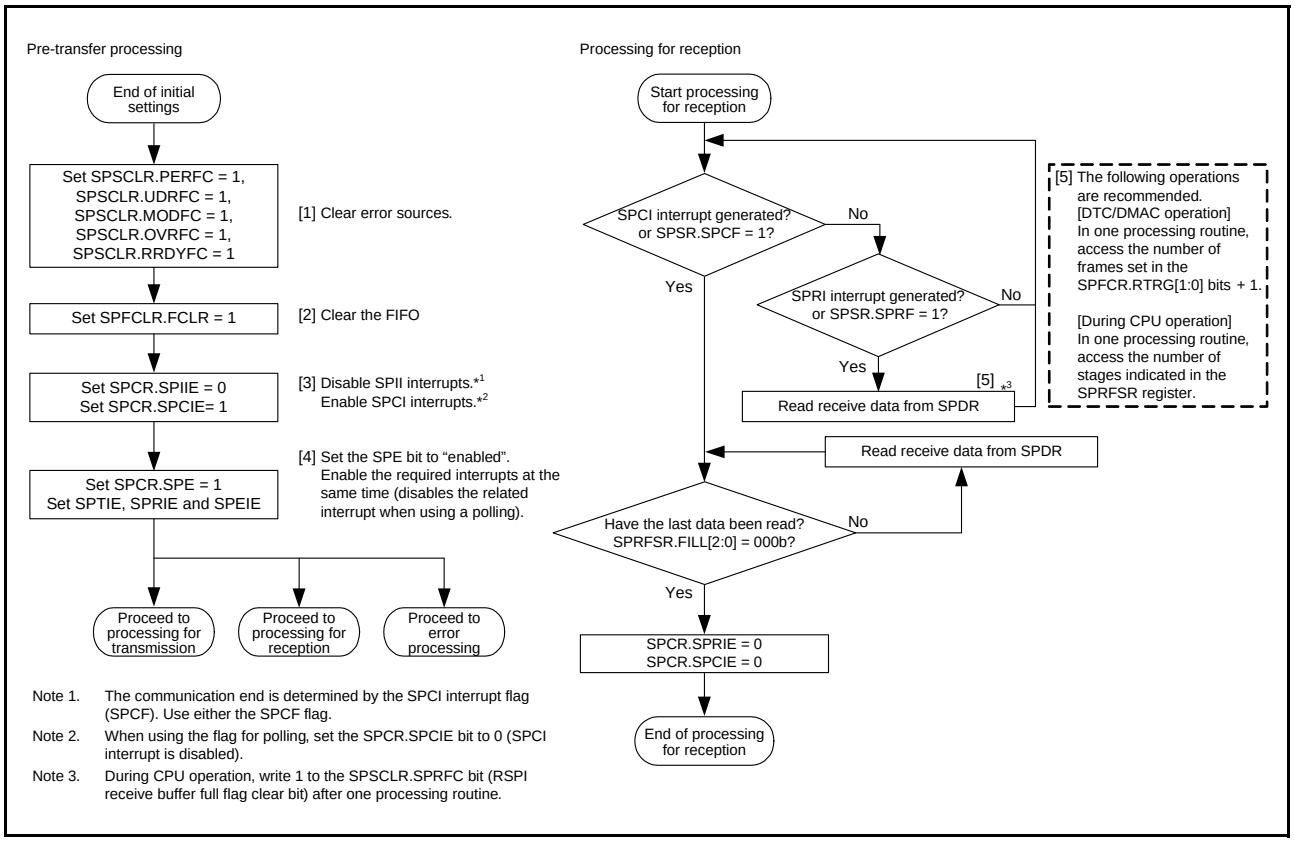
(c) Receive-Only Processing Flow



Note 1. The communication end is determined by the SPCI interrupt flag (SPCF). Use either the SPCF flag.
Note 2. When using the flag for polling, set the SPCR.SPCIE bit to 0 (SPCI interrupt is disabled).
Note 3. During CPU operation, write 1 to the SPSCLR.SPRFC bit (RSPI receive buffer full flag clear bit) after one processing routine.

Figure 41.68 Flowchart in Slave Mode (Receive-Only)

(d) Flow of Error Processing

In slave mode operation, the MODF flag can be cleared regardless of the SSL00 pin status even when a mode fault error is generated.

When interrupts are used and an error occurs, if the ICU.IRn.IR flag for the SPTI or SPRI interrupt request is set to 1, clear the ICU.IRn.IR flag in the error processing routine. If the SPRI interrupt request is indicated, read the receive buffer and initialize the sequencer in the RSPIA.

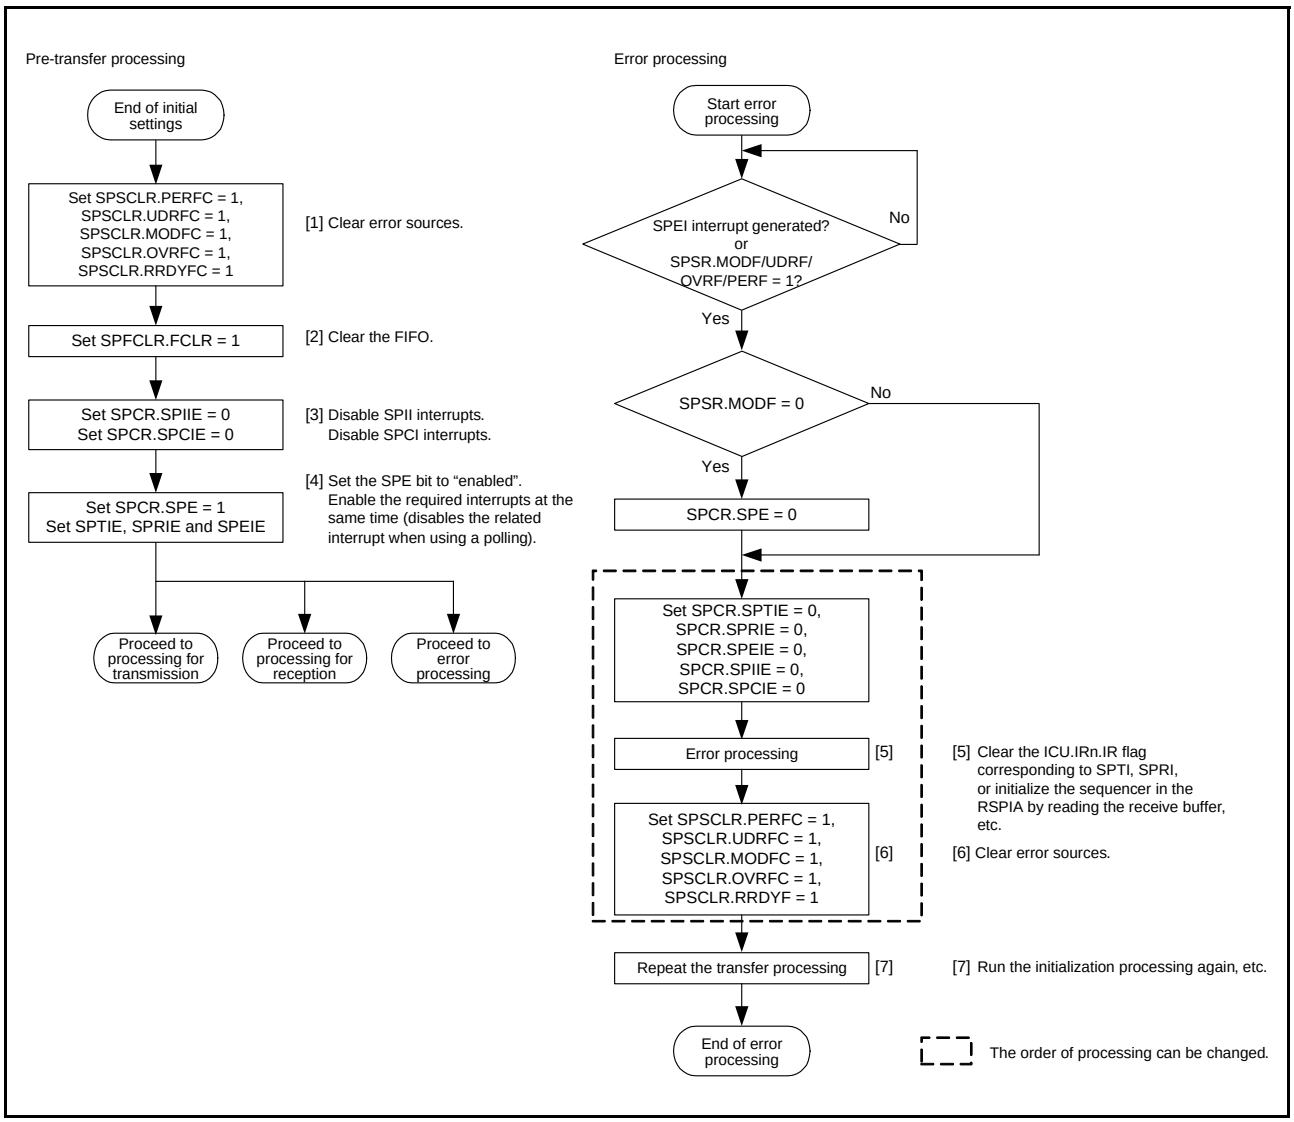


Figure 41.69 Flowchart in Slave Mode (Error Processing)

41.3.14 Clock Synchronous Operation

Setting the SPCR.SPMS bit to 1 selects clock synchronous operation of the RSPIA. In clock synchronous operation, the SSL0n pin is not used, and the three pins of RSPCK0, MOSI0, and MISO0 handle communications. The SSL0n pin is available as I/O port pins.
Although clock synchronous operation does not require use of the SSL0n pin, operation of the module is the same as in SPI operation. That is, in both master and slave mode operations, communications can be performed with the same flow as in SPI operation. However, mode fault errors are not detected because the SSL0n pin is not used.
Furthermore, do not set the SPCMDm.CPHA bit to 0 if clock synchronous operation is to proceed in slave mode (SPCR.MSTR = 0).

41.3.14.1 Master Mode Operation

(1) Starting a Serial Transfer

The RSPIA updates the data in the transmit buffer (SPTXn, n = 0 to 3) of the SPDR register when data is written to the SPDR register with the transmit buffer being empty (data for the next transfer is not set). When the shift register is empty, the RSPIA copies data from the transmit buffer to the shift register and starts serial transmission. Upon copying transmit data to the shift register, the RSPIA changes the status of the shift register to “full”, and upon termination of serial transfer, it changes the status of the shift register to “empty”. The status of the shift register cannot be referenced.
For details on the RSPI transfer format, refer to section 41.3.5, Transfer Format (Frame Format).
However, transfer in clock synchronous operation is conducted without the SSL0n output signal.

(2) Terminating a Serial Transfer

The RSPIA terminates the serial transfer after transmitting an RSPCK0 edge corresponding to the final sampling timing. If the number of data stored in the receive FIFO is less than the number of FIFO stages, upon termination of serial transfer, the RSPIA copies data from the shift register to the receive buffer of the RSPI data register (SPDR).
It should be noted that the final sampling timing varies depending on the bit length of transmit data. In master mode, the RSPI data length depends on the SPCMDm.SPB[4:0] bit setting. For details on the RSPI transfer format, refer to section 41.3.5, Transfer Format (Frame Format).
However, transfer in clock synchronous operation is conducted without the SSL0n output signal.

(3) Sequence Control

The transfer format employed in master mode is determined by the following registers:

- RSPI sequence control register (SPSCR)
- RSPI command register m (SPCMDm) (m = 0 to 7)
- RSPI bit rate register (SPBR)
- RSPI clock delay register (SPCKD)
- RSPI slave select negation delay register (SSLND)
- RSPI next-access delay register (SPND)

Although the SSL0n signals are not output in clock synchronous operation, these settings are valid.

The SPSCR register is a register used to determine the sequence configuration for serial transfers that are executed by the RSPIA in master mode. The following items are set in the SPCMDm register: MSB/LSB first, data length, some of the bit rate settings, RSPCK polarity/phase, whether the SPCKD register is to be referenced, whether the SSLND register is to be referenced, and whether the SPND register is to be referenced. The SPBR register holds some of the bit rate settings; the SPCKD register, an RSPI clock delay value; the SSLND register, an SSL negation delay; and the SPND register, a next-access delay value.
According to the sequence length that is assigned to the SPSCR register, the RSPIA makes up a sequence comprised of a part or all of the SPCMDm register. The RSPIA contains a pointer to the SPCMDm register that makes up the sequence.

The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the RSPI function is enabled, the RSPIA loads the pointer to the commands in the SPCMD0 register, and incorporates the SPCMD0 register setting into the transfer format at the beginning of serial transfer. The RSPIA increments the pointer each time the next-access delay period for a data transfer ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, the RSPIA sets the pointer in the SPCMD0 register, and in this manner the sequence is executed repeatedly.

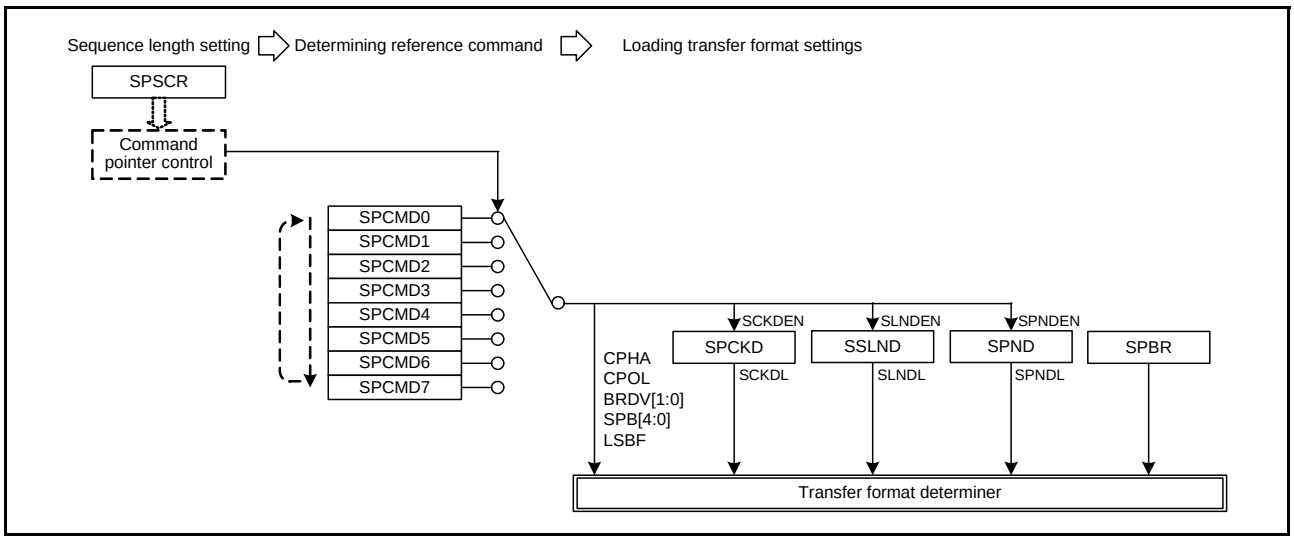

Figure 41.70 Procedure for Determining the Form of Serial Transfer in Master Mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm).

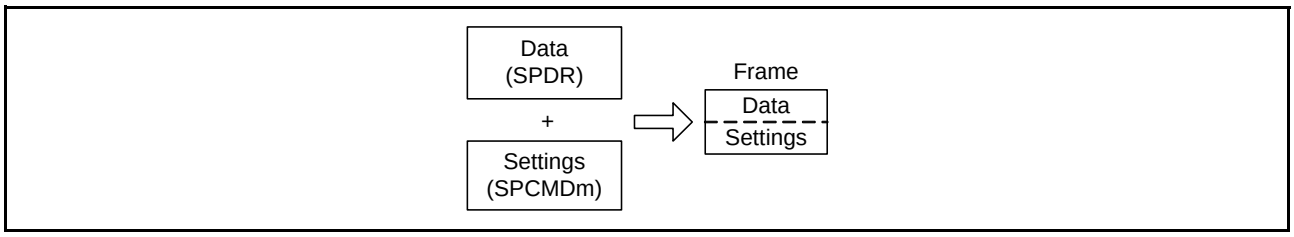

Figure 41.71 Concept of a Frame

Figure 41.72 shows the relationship between the command and the transmit buffer (SPTXn, n = 0 to 3) and receive buffer (SPRXn, n = 0 to 3) in the sequence of operations.

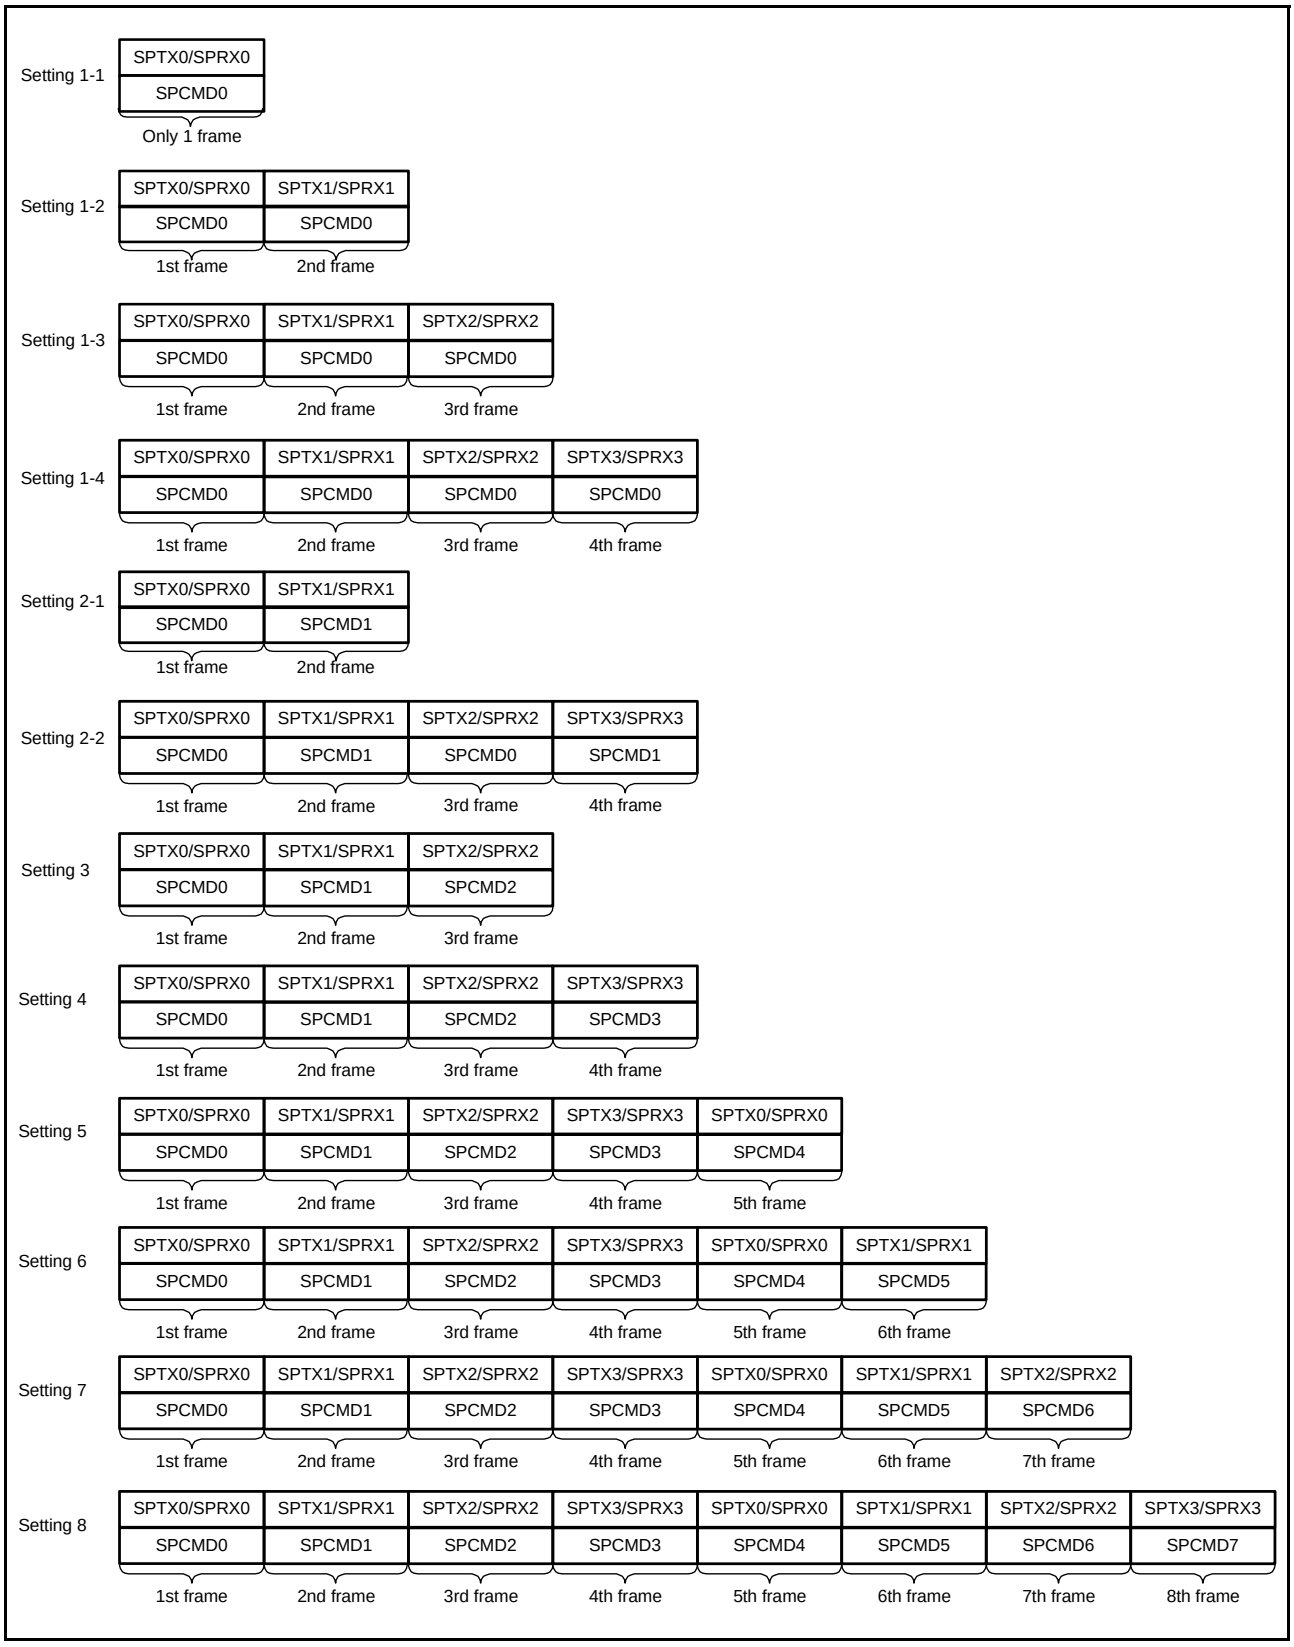

Figure 41.72 Correspondence between the RSPI Command Register m and Transmit/Receive Buffers in Sequence Operations

(4) Initialization Flowchart

Figure 41.73 is a flowchart illustrating an example of initialization in clock synchronous operation when the RSPIA is used in master mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

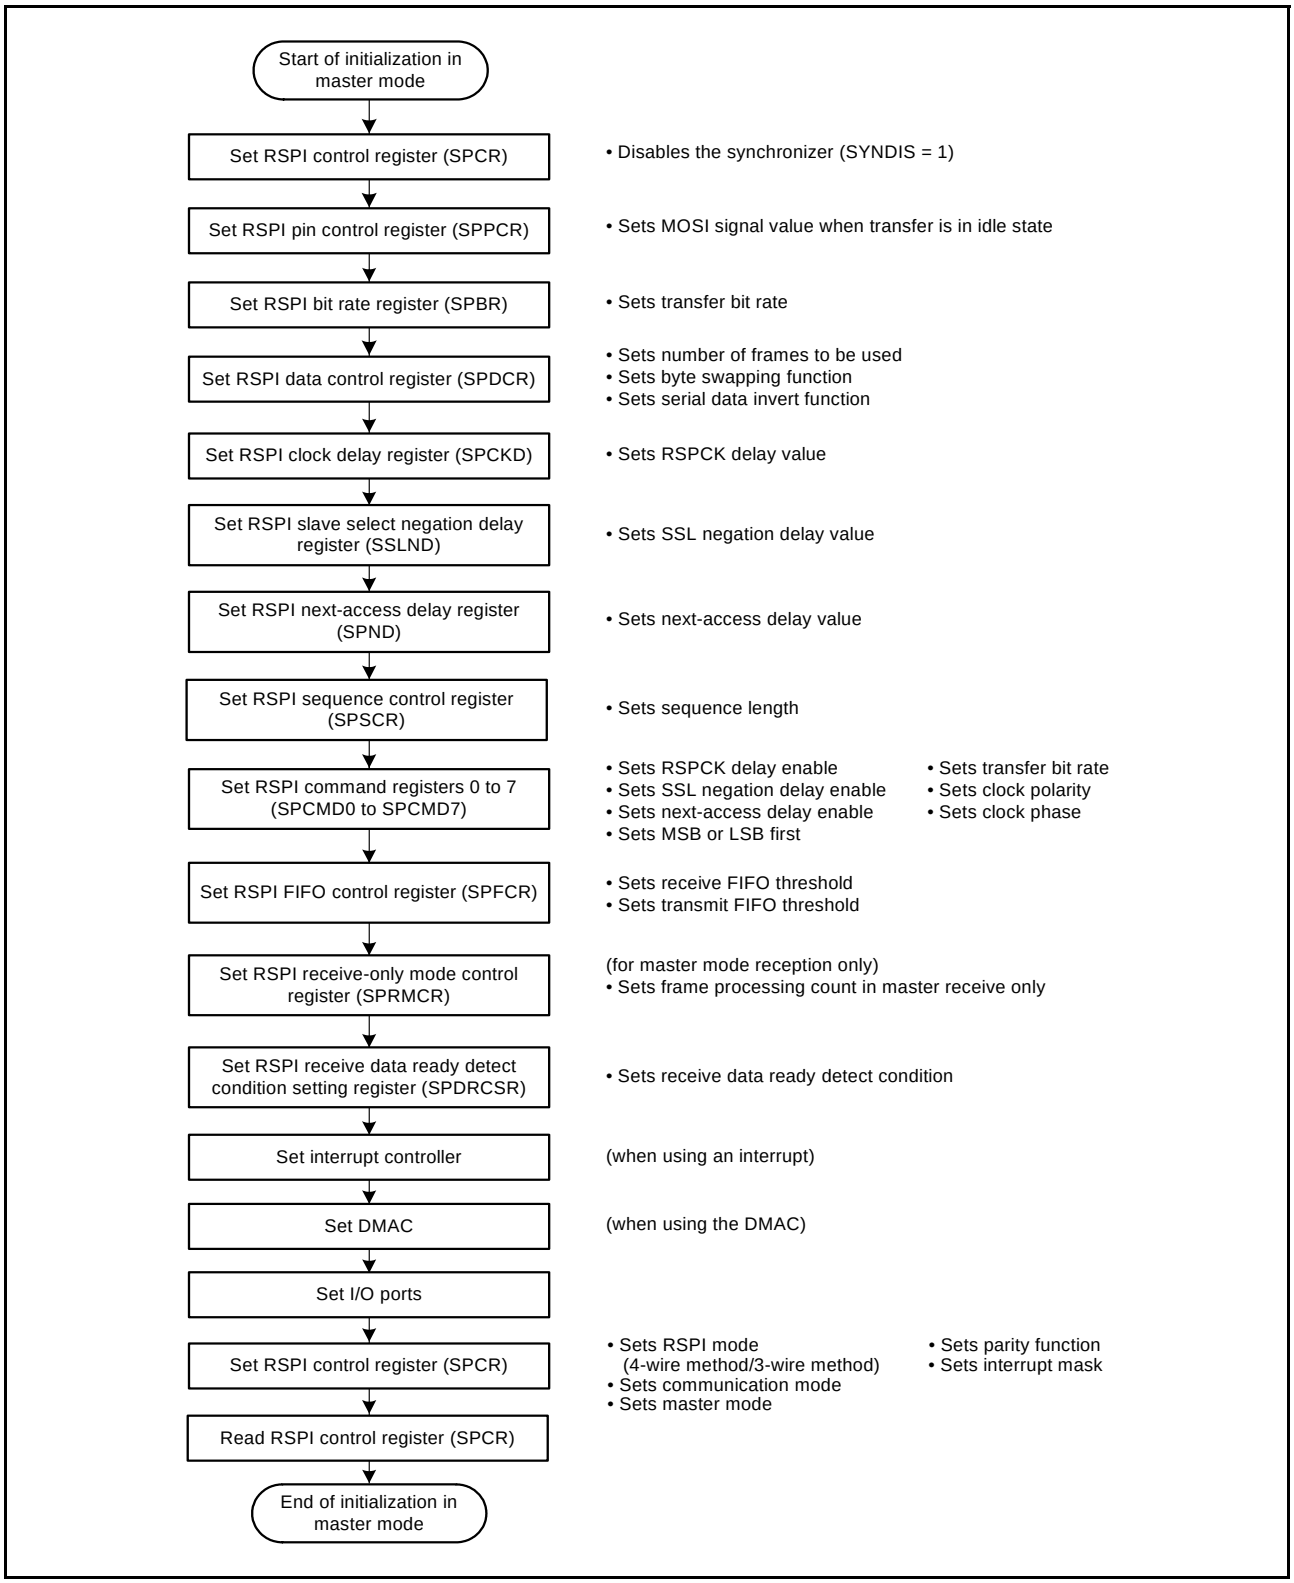

Figure 41.73 Example of Initialization Flowchart in Master Mode (Clock Synchronous Operation)

(5) Flow of Software Processing

Software processing during clock-synchronous operation when the RSPIA is used in master mode is the same as that for SPI master mode operation. For details, refer to section 41.3.13.1, (9) Software Processing Flow. Note that mode fault errors will not occur.

41.3.14.2 Slave Mode Operation

(1) Starting a Serial Transfer

When the SPCR.SPMS bit is 1, the first RSPCK0 edge triggers the start of a serial transfer in the RSPIA.
When the SPMS bit is 1, the RSPIA drives the MISO0 output signal.
For details on the RSPI transfer format, refer to section 41.3.5, Transfer Format (Frame Format).
It should be noted that the SSL00 input signal is not used in clock synchronous operation.

(2) Terminating a Serial Transfer

The RSPIA terminates the serial transfer after detecting an RSPCK0 edge corresponding to the final sampling timing. When the number of data stored in the receive FIFO is less than the number of FIFO stages, upon termination of serial transfer the RSPIA copies received data from the shift register to the receive buffer of the SPDR register. Upon termination of a serial transfer the RSPIA changes the status of the shift register to “empty” regardless of the receive buffer status. The final sampling timing changes depending on the bit length of transmit data. In slave mode, the RSPI data length depends on the SPCMD0.SPB[4:0] bit setting.
For details on the RSPI transfer format, refer to section 41.3.5, Transfer Format (Frame Format).

(3) Initialization Flowchart

Figure 41.74 is a flowchart illustrating an example of initialization in clock synchronous operation when the RSPIA is used in slave mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

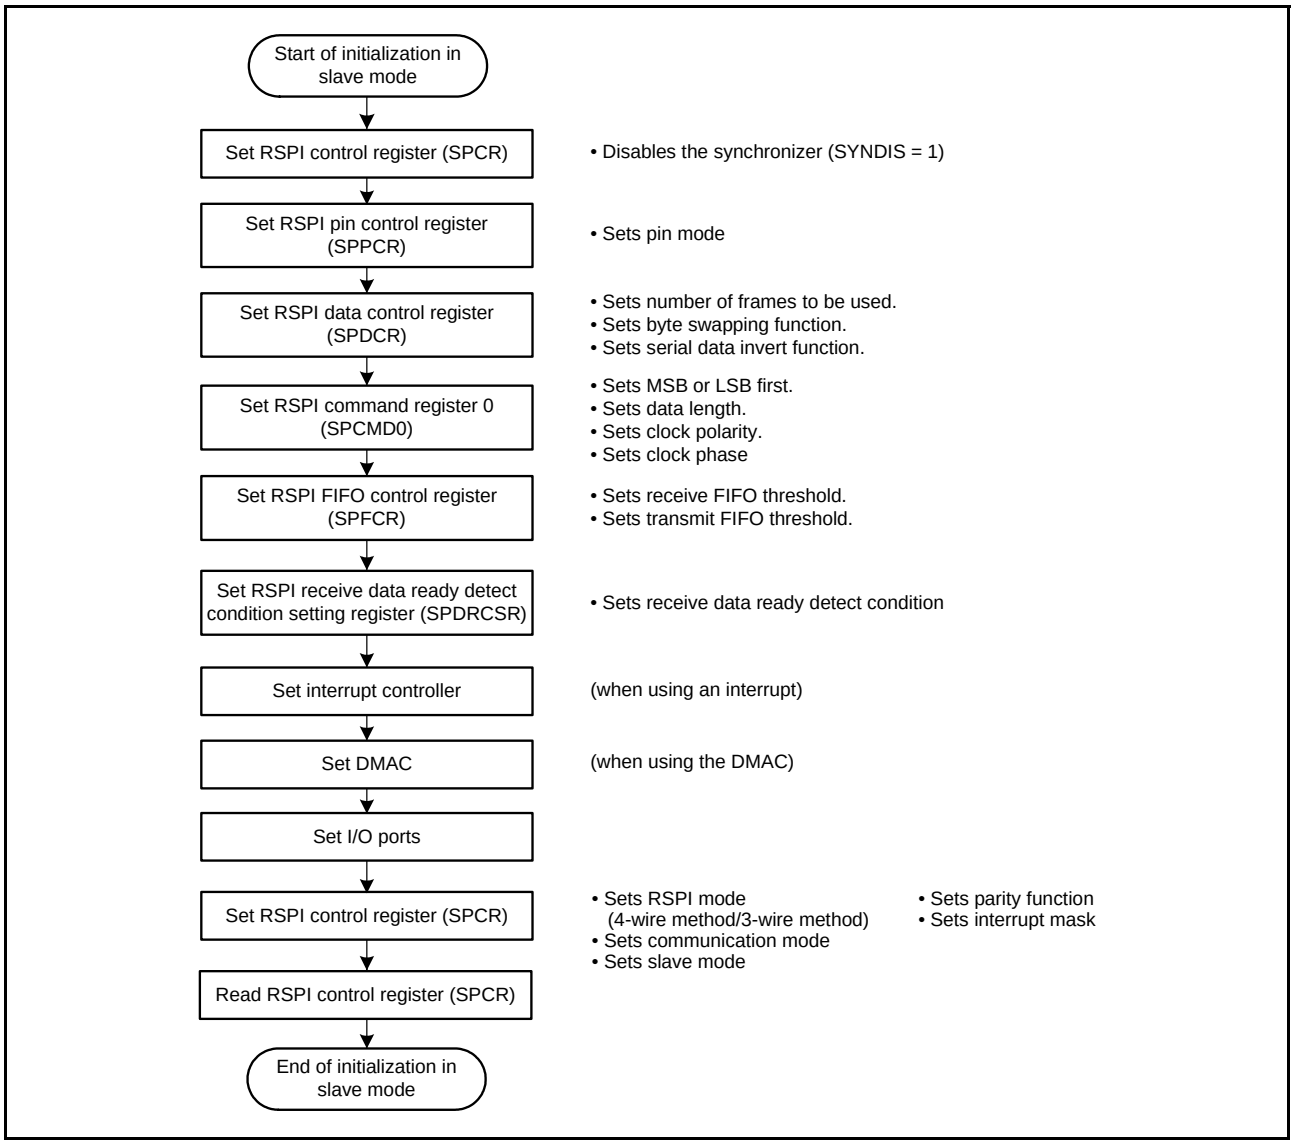

Figure 41.74 Example of Initialization Flowchart in Slave Mode (Clock Synchronous Operation)

(4) Flow of Software Processing

Software processing during clock-synchronous operation when the RSPIA is used in slave mode is the same as that for SPI slave mode operation. For details, refer to section 41.3.13.2, (6) Software Processing Flow. Note that mode fault errors will not occur.

41.3.15 Loopback Mode

When 1 is written to the SPPCR.SPLP2 bit or SPPCR.SPLP bit, the RSPIA shuts off the path between the MISO0 pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSI0 pin and the shift register if the SPCR.MSTR bit is 0, and connects the input path and output path of the shift register. The RSPIA does not shut off the path between the MOSI0 pin and the shift register if the SPCR.MSTR bit is 1, and between the MISO0 pin and the shift register if the SPCR.MSTR bit is 0. This is called loopback mode.
When a serial transfer is executed in loopback mode, the transmit data for the RSPIA or the reversed transmit data becomes the received data for the RSPIA.
Table 41.12 lists the relationship among the SPLP2 and SPLP bits and the received data.

Table 41.12 SPLP2 and SPLP Bit Settings and Received Data

SPPCR.SPLP2 Bit	SPPCR.SPLP Bit	Received Data
0	0	Input data from the MOSI0 pin or MISO0 pin
0	1	Inverted transmit data
1	x	Transmit data

x: Don’t care.

Figure 41.75 shows the configuration of the shift register I/O paths in loopback mode.

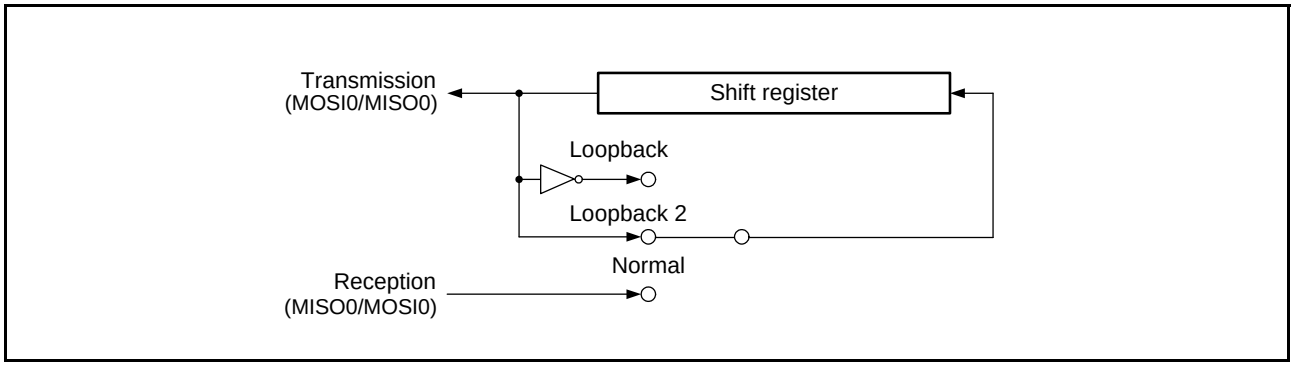

Figure 41.75 Configuration of Shift Register I/O Paths in Loopback Mode

41.3.16 Self-Diagnosis of Parity Bit Function

The parity circuit consists of a parity bit adding unit used for transmit data and an error detecting unit used for received data. In order to detect defects in the parity bit adding unit and error detecting unit of the parity circuit, self-diagnosis is executed for the parity circuit following the flowchart shown in Figure 41.76.

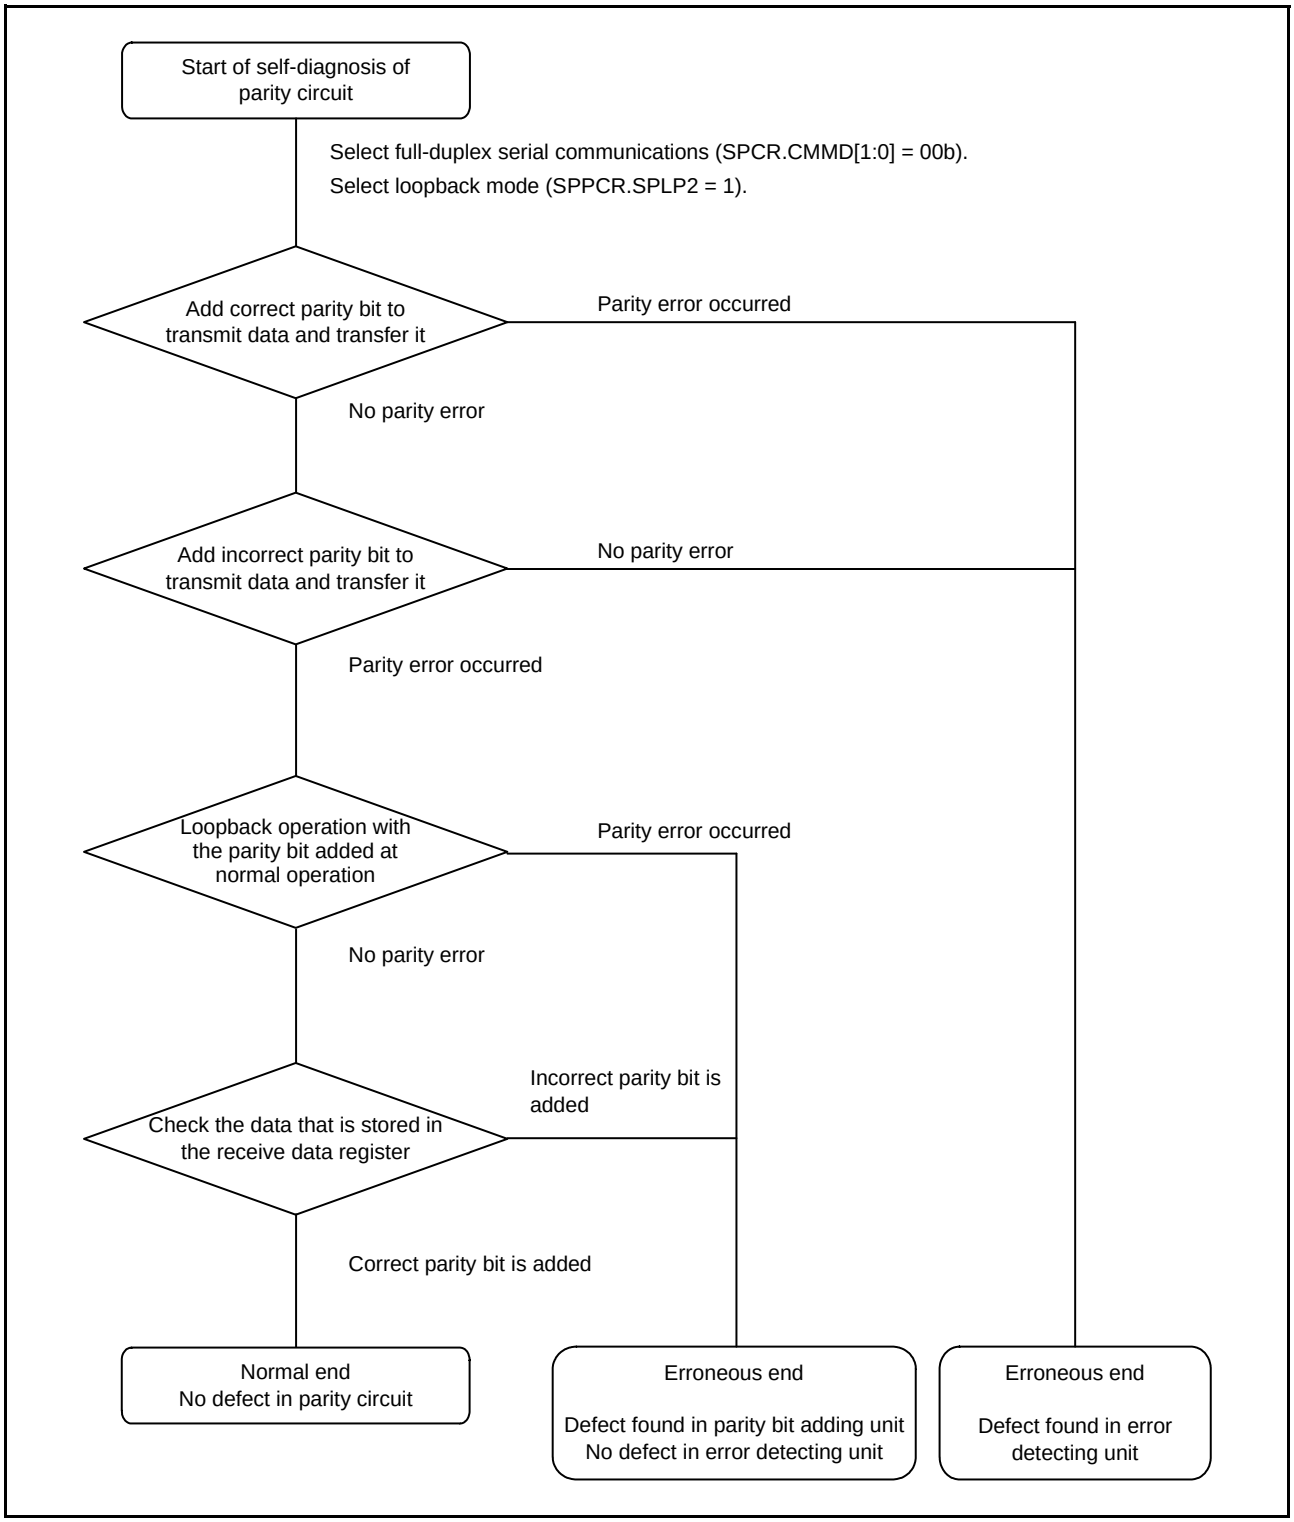

Figure 41.76 Flowchart for Self-Diagnosis of Parity Circuit

41.3.17 Interrupt Sources

The RSPIA has interrupt sources of receive buffer full, transmit buffer empty, error (mode fault, underrun, overrun, and parity error), idle, communication end, and receive data ready. In addition, the DTC or DMAC can be activated by the receive buffer full or transmit buffer empty interrupt to perform data transfer.

Since the vector address for SPEI is allocated to interrupt requests due to mode fault, underrun, overrun, parity errors, and receive data ready (only when the RDRIS bit is 1), the actual interrupt source must be determined from the flags.

Interrupt sources for the RSPIA are listed in Table 41.13. An interrupt is generated on satisfaction of an interrupt condition in Table 41.13. Clear the receive buffer full and transmit buffer empty sources through data transfer.

When using the DTC or DMAC to perform data transmission/reception, the DTC or DMAC must be set up first to be in a status in which transfer is enabled before making the RSPIA settings. For the method for setting the DTC or DMAC, refer to section 18, DMA Controller (DMACAb), or section 20, Data Transfer Controller (DTCb).

If the conditions for generating a transmit buffer empty or receive buffer full interrupt are generated while the ICU.IRn.IR flag is 1, the interrupt is not output as a request for ICU but is retained internally (the capacity for retention is one request per source). A retained interrupt request is output when the ICU.IRn.IR flag becomes 0. A retained interrupt request is automatically discarded once it is output as an actual interrupt request. The interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) for an internally retained interrupt request can also be cleared to 0.

Table 41.13 Interrupt Sources of RSPIA

Interrupt Source	Symbol	Interrupt Condition	DMAC/DTC Activation
Receive buffer full Receive data ready	SPRI	The SPSR.SPRF flag is set to 1 while the SPCR.SPRIE bit is 1, or the RRDYF flag is set to 1 while the SPEIE is 1 and RDRIS bit is 0.	Possible
Transmit buffer empty	SPTI	The SPSR.SPTEF flag is set to 1 while the SPCR.SPTIE bit is 1.	Possible
Mode fault error Underrun error Overrun error Parity error Receive data ready	SPEI	The SPSR.MODF, OVRF, or PERF flag is set to 1 while the SPCR.SPEIE bit is 1, or the RRDYF flag is set to 1 while the SPEIE and RDRIS bits are 1.	Impossible
Idle	SPII	The SPSR.IDLNF flag is set to 0 while the SPCR.SPIIE bit is 1.	Impossible
Communication end	SPCI	The SPSR.SPCF flag is set to 1 while the SPCR.SPCIE bit is 1.	Impossible

41.3.18 Link Operation by Event Linking

The RSPIA supports the following event output for the event link controller (ELC). The event link output signal is output regardless of the interrupt enable bit setting.

41.3.18.1 Receive Buffer Full Event Output

This event signal is output when the number of data stored in the receive FIFO is greater than the threshold value, or when the SPCR.RDRIS bit = 0 and after writing to the receive FIFO, and the number of data stored in the receive FIFO is equal to or less than the threshold value, the value set in the SPDRCSR register has elapsed.
A receive buffer full event is output at the timing shown in Figure 41.77.

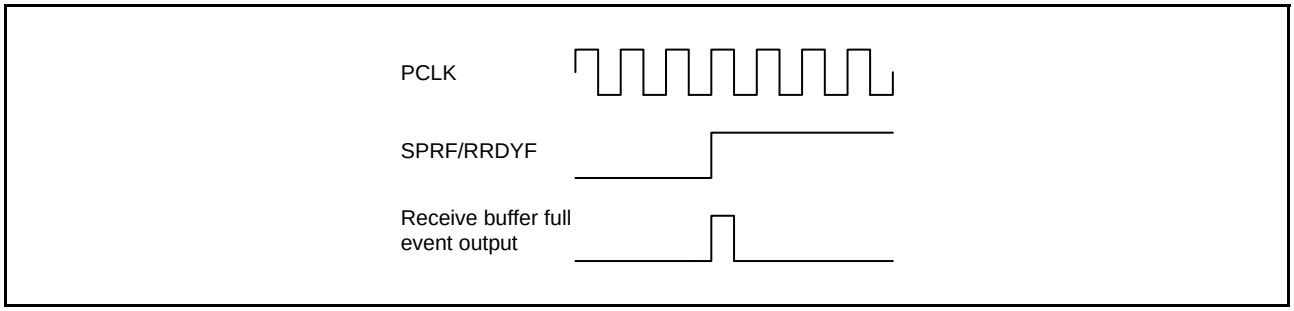

Figure 41.77 Event Output Timing of the Receive Buffer Full

41.3.18.2 Transmit Buffer Empty Event Output

This event signal is output when the number of empty stages in the transmit FIFO is greater than the threshold value or when the value of the SPCR.SPE bit has changed from 0 to 1.
A transmit buffer empty event is output at the timing shown in Figure 41.78.

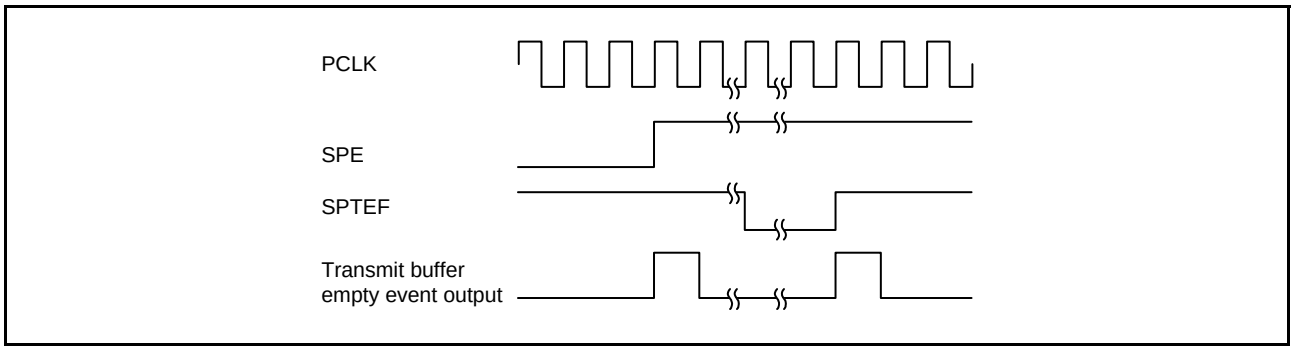

Figure 41.78 Event Output Timing of the Transmit Buffer Empty

41.3.18.3 Error Event Output

The error event signal is output due to five sources (mode fault, underrun, overrun, parity error, and receive data ready). For notes on error event output, see section 41.4.2, Note on Error Events Output.

(1) Mode Fault

A mode fault event occurs when all the following conditions are satisfied:

- SPI operation (SPCR.SPMS = 0)
- Slave mode (SPCR.MSTR = 0)
- The detection of mode fault error is enabled (SPCR.MODFEN = 1)
- Any of the following conditions are satisfied
  1. In the Motorola SPI mode, the SSL00 pin is deactivated during data transfer.
  2. In the TI SSP mode, the SSL00 pin is activated during data transfer.

(2) Underrun

The condition for this event signal being output in response to an underrun is the start of serial transfer while the value of the SPCR.MSTR bit is 0 (slave mode), the value of the SPCR.SPE bit is 1 (enables the RSPI function), and the transmit data are not ready for output.

(3) Overrun

The condition for this event signal being output in response to an overrun is completion of the serial transfer while the value of the SPCR.CMMD[1:0] bits are 00b or 10b, and the data is stored in the receive FIFO for the number of FIFO stages, in which case the SPSR.OVRF flag is set to 1.

(4) Parity Error

The condition for this event signal being output in response to a parity error is detection of a parity error on completion of the serial transfer while the value of the SPCR.CMMD[1:0] bits are 00b or 10b, and the value of the SPCR.SPE bit is 1.

(5) Receive Data Ready

The condition for this event signal being output in response to a receive data ready is elapsing of the value set by the SPDRSCR register when the number of data stored in the receive FIFO is less than or equal to the receive FIFO threshold value after the data has stored in the receive FIFO, while the value of the SPCR.CMMD[1:0] bits are 00b or 10b, the value of the SPCR.RDRIS bit is 1.

(6) Output Timing

Each error event signal is output at the timing shown in Figure 41.79.
Error event is output each time an error occurs.

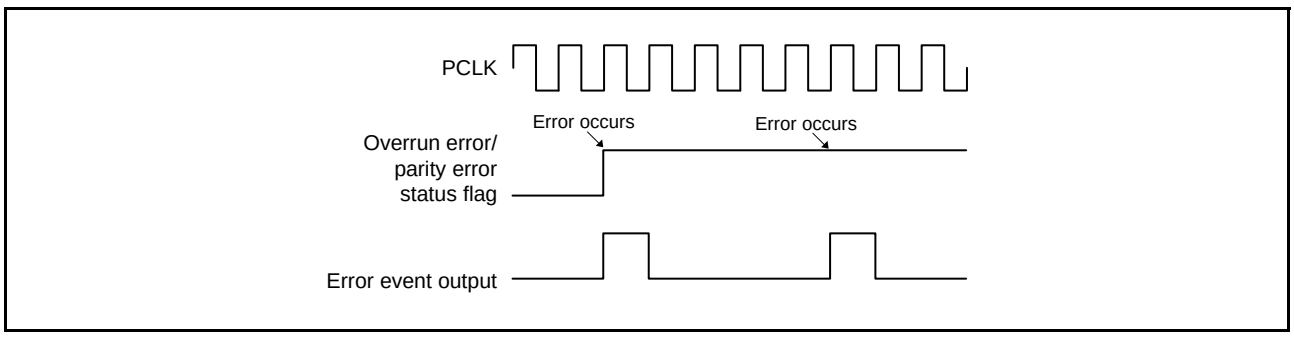

Figure 41.79 Error Event Output Timing

41.3.18.4 Idle Event Output

(1) In Master Mode

[Transmit-receive mode/transmit-only mode]

In transmit-receive master mode or transmit-only master mode, an event is output when the SPSR.IDLNF flag (idle flag) changes from 1 to 0.

The SPSR.IDLNF flag changes from 1 to 0 only when any of the following conditions are satisfied.

(a) The SPCR.SPE bit becomes 0 (RSPI is initialized) during transmission

(b) All the following conditions are satisfied:

- The next transmit data is not set in the transmission buffer (SPTXn, n = 0 to 3)
- The SPSSR.SPCP[2:0] bits are 000b (beginning of sequence control)
- The operations up to the next-access delay have finished (the master main state machine has entered the idle state)

[Receive-only mode]

In receive-only master mode, an event is output when any of the following conditions are satisfied.

(a) The SPCR.SPE bit is set to 0 (RSPI is initialized).

(b) Any the following conditions are satisfied:

- When the SPRMCR.RFC[4:0] bits are 00000b, after 1 is written to the SPRMCR.TERM bit, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)
- When the SPRMCR.RFC[4:0] bits are other than 00000b, after 1 is written to the SPRMCR.TERM bit, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)
- When the SPRMCR.RFC[4:0] bits are other than 00000b, after the operation is completed for the number of received frames set by the SPRMCR.RFC[4:0] bits, the operations up to the next-access delay have finished (the master main state machine has entered the idle state)

(2) In Slave Mode

In slave mode, an event is output when the SPCR.SPE bit is set to 0 (RSPI is initialized).

(3) Output Timing

An idle event is output at the timing shown in Figure 41.80.

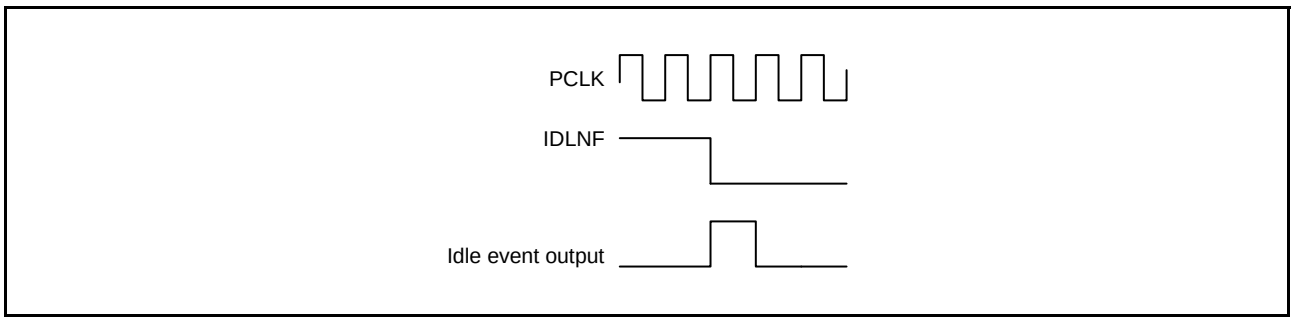

Figure 41.80 Idle Event Output Timing

41.3.18.5 Communication End Event Output

In master mode, an event is output under the condition for setting the SPSR.IDLNF flag (idle flag) from 1 to 0. In slave mode, an event is output under the conditions listed in Table 41.14 and Table 41.15.

Table 41.14 Generating Conditions of Communication End Event (Transmit-Receive Slave Mode/Transmit-Only Slave Mode)

RSPI Mode	Transmit Buffer State	Shift Register State	Others
SPI operation (SPMS = 0, FRFS = 0)	Empty	Empty	Negation of the SSL00 input
SPI operation (SPMS = 0, FRFS = 1)	Empty	Empty	Completion of the SSL negation delay
Clock synchronous operation (SPMS = 1)	Empty	Empty	Even edge detection of the last RSPCK0 for the last data

Table 41.15 Generating Conditions of Communication End Event (Receive-Only Slave Mode)

RSPI Mode	Condition
SPI operation (SPMS = 0, FRFS = 0)	Negation of the SSL00 input after storing the number of frames set by the SPDCR.SPFC[1:0] bits in the receive buffer
SPI operation (SPMS = 0, FRFS = 1)	Completion of the SSL negation delay after storing the number of frames set by the SPDCR.SPFC[1:0] bits in the receive buffer
Clock synchronous operation (SPMS = 1)	Even edge detection of the last RSPCK0 for the last frame set by the SPDCR.SPFC[1:0] bits

Whether the operation is in master mode or slave mode, an event is not output if 0 is written to the SPCR.SPE bit during communication or the SPCR.SPE bit is cleared by the mode fault error or underrun error.
A communication end event is output at timings shown in Figure 41.81 to Figure 41.86. The communication end event output timing in master operation is omitted because it is output at the same timing as an idle event.

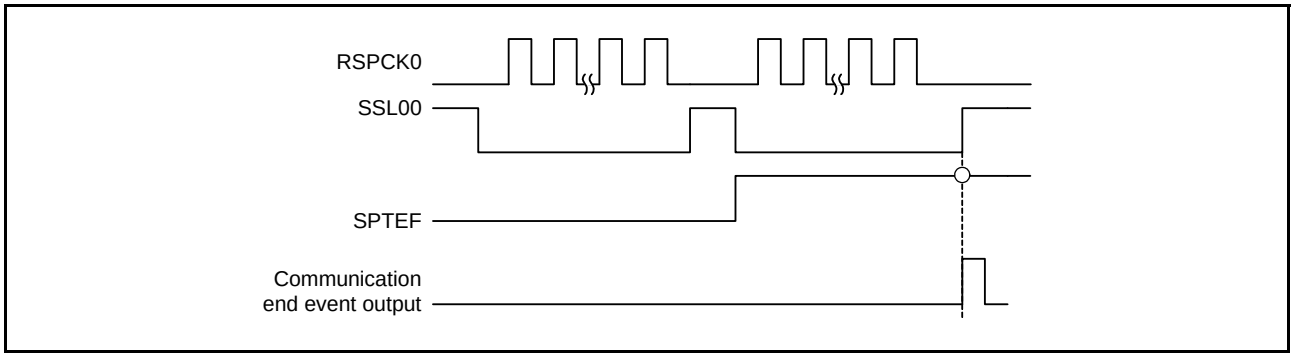

Figure 41.81 Communication End Event Output Timing (Transmit-Receive Slave Mode/Transmit-Only Slave Mode, Motorola SPI Operation)

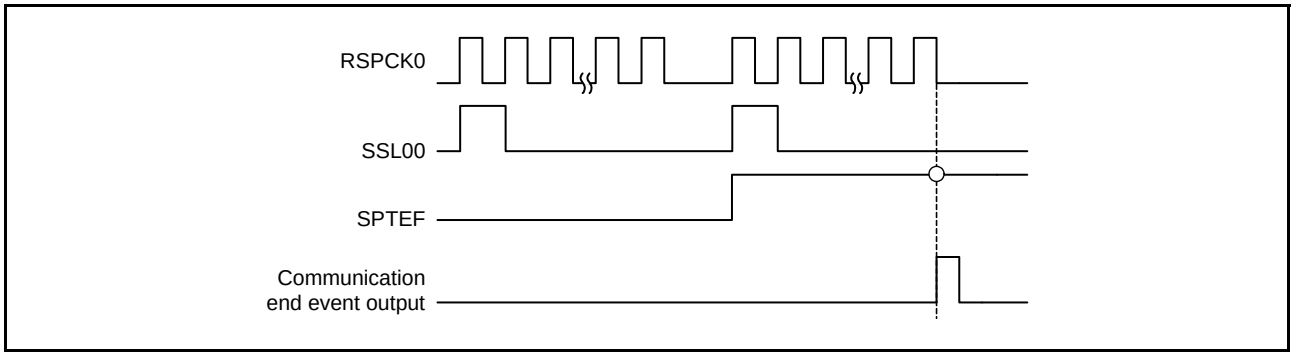

Figure 41.82 Communication End Event Output Timing (Transmit-Receive Slave Mode/Transmit-Only Slave Mode, TI SSP Operation)

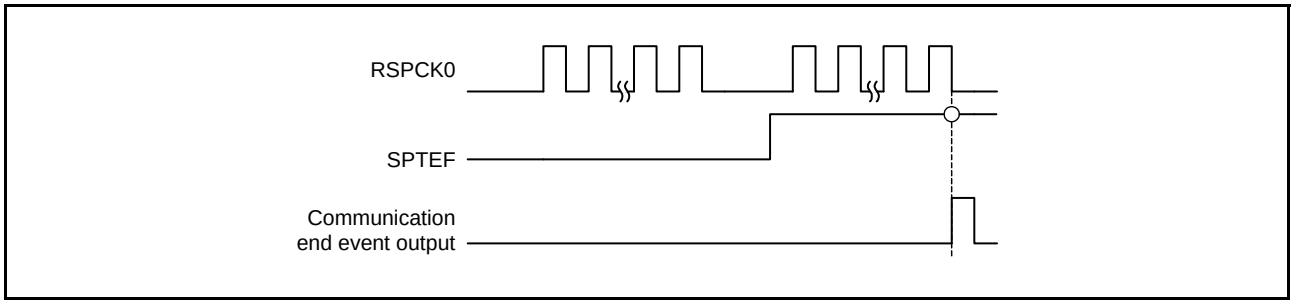

Figure 41.83 Communication End Event Output Timing (Transmit-Receive Slave Mode/Transmit-Only Slave Mode, Clock Synchronous Operation)

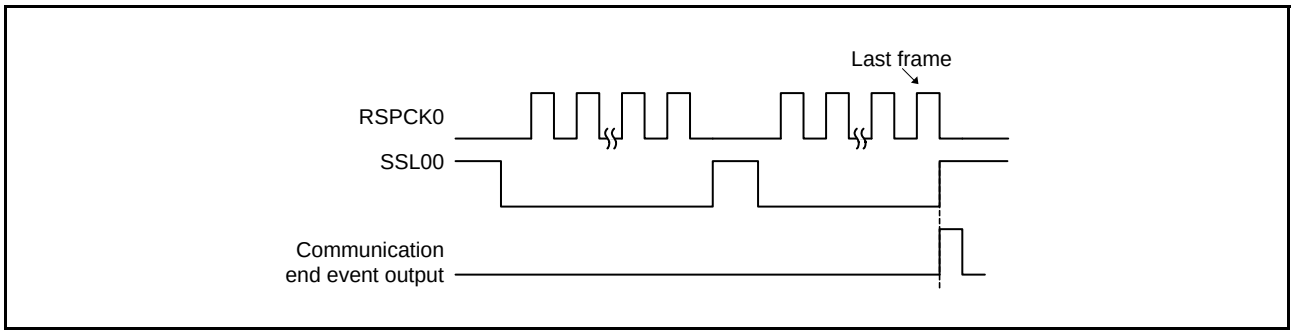

Figure 41.84 Communication End Event Output Timing (Receive-Only Slave Mode, Motorola SPI Operation)

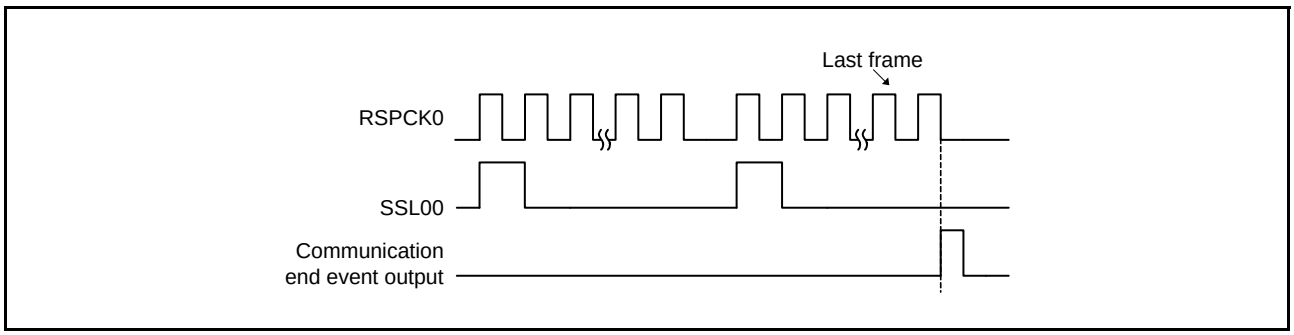

Figure 41.85 Communication End Event Output Timing (Receive-Only Slave Mode, TI SSP Operation)

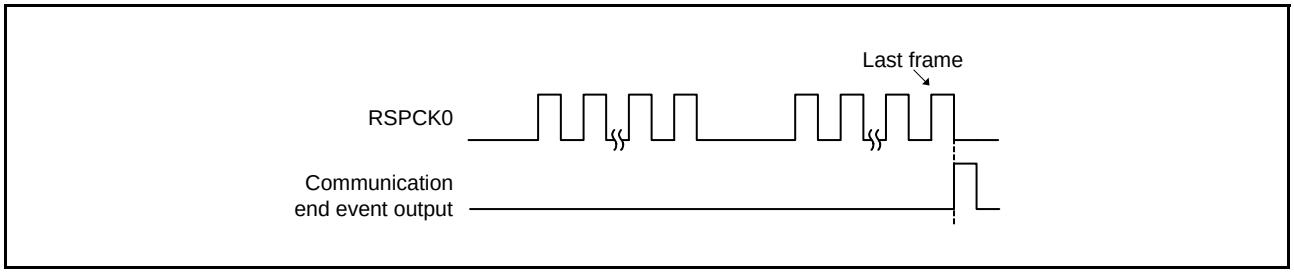

Figure 41.86 Communication End Event Output Timing (Receive-only slave mode, Clock Synchronous Operation)

41.4 Usage Notes

41.4.1 Notes on Starting Transfer

When the ICU.IRn.IR flag is 1 at the time transfer is to start, follow the procedure below to clear interrupt requests before enabling operations (by setting the SPCR.SPE bit to 1).

1. Confirm that transfer has stopped (i.e. that the SPCR.SPE bit is 0).
2. Set the relevant interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) to 0.
3. Read the relevant interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) and confirm that its value is 0.
4. Set the ICU.IRn.IR flag to 0.

41.4.2 Note on Error Events Output

To enable SPI operation of the RSPIA in master mode in the multi-master environment (SPCR.SPMS bit = 0, SPCR.MSTR bit = 1, and SPCR.MODFEN bit = 1), do not use any output of error events.

41.4.3 Note on Low Power Consumption Functions

To reduce power consumption of this module by using the low power consumption functions, set the SPCR.SPE bit to 0 to terminate communication, and then use the low power consumption functions.

41.4.4 Note on the SPRF and SPTEF flags

When polling the SPSR.SPRF flag and/or SPSR.SPTEF flag, set the SPCR.SPRIE bit and/or SPCR.SPTIE bit to 0.

41.4.5 Notes on Burst Transfer in Master Mode

During burst transfer, changing the following settings between the SPCMDm register with the SSLKP bit set to 1 and the SPCMDm register used in the next transfer is prohibited.

- SSL Signal Assertion setting (SSLA[2:0] bits)
- RSPCK output setting (CPHA, CPOL, BRDV[1:0] bits)

41.4.6 Notes on Operating in Slave, TI SSP Mode

In the slave TI SSP mode, the delay between frames must observe the following intervals. Secure the following intervals on the master side.

[Master side: interval from the RSPCK edge of last bit to the RSPCK edge of next SSL] > [Slave side: OE delay time = PCLKA * (1 to 2) + SLNDL[2:0] setting value]

41.4.7 Notes on the Data Length

Table 41.16 shows the relationship between the data length and operation of the RSPIA.

Table 41.16 Relationship between the Data Length and Operation of the RSPIA

Data Length										
4 bit	**5 bit**	**6 bit**	**7 bit**	**8 bit**	**9 bit**	**10 bit**	**11 bit**	**12 bit**	**13 bit**	**14 bit**
Conditionally possible	Conditionally possible	Conditionally possible	Possible	Possible	Possible	Possible	Possible	Possible	Possible	Possible

Possible: Operating possible
Conditionally possible: Operating possible when the SPCR.SCKASE or SCKDDIS bit is 0.

41.4.8 Notes when SPCR.SPE = 1

If the value of the registers listed below are changed while the SPCR.SPE bit is 1, the operation after the change is not guaranteed.

Table 41.17 List of Registers that Cannot Be Rewritten When SPCR.SPE = 1 (1/2)

Register	Bit
SPCKD	SCKDL[2:0]

Note 1. Rewriting prohibited in slave mode. In master mode, rewriting is available only when there is no next transmit data in the transmit FIFO.

42. Quad-SPI Memory Interface (QSPIX)

The Quad-SPI memory interface (QSPIX) module is a memory controller for connecting serial ROM (nonvolatile memory such as a serial flash memory, serial EEPROM, or serial FeRAM) that has an SPI-compatible interface.

42.1 Overview

Table 42.1 lists the QSPIX specifications, Figure 42.1 shows a block diagram, and Table 42.2 lists the I/O pins.

Table 42.1 QSPIX Specifications

Parameter	Specifications
Number of channels	1 channel
SPI	• Support for Single/Extended SPI, Dual SPI, and Quad SPI protocols • Configurable to SPI mode 0 and SPI mode 3 • Address size selectable to 8, 16, 24, or 32 bits
Timing adjustment function	Timing corresponding to various serial ROMs can be generated.
Memory mapped mode	The data in the serial ROM can be read by accessing the memory space of the MCU. • Support for Read, Fast Read, Fast Read Dual Output, Fast Read Dual I/O, Fast Read Quad Output, and Fast Read Quad I/O instructions • Substitutable instruction code • Adjustable number of dummy cycles • Prefetch function • Polling processing • SPI bus cycle extension function • XIP (execute in place) mode
Indirect access mode	The data in the serial ROM can be accessed by accessing the data register of the QSPIX. • Flexible support for various serial flash instructions and functions including erase, program, ID read, and power-down control by software control
Interrupt source	Error interrupt
Low power consumption function	Module-stop state can be set to reduce power consumption

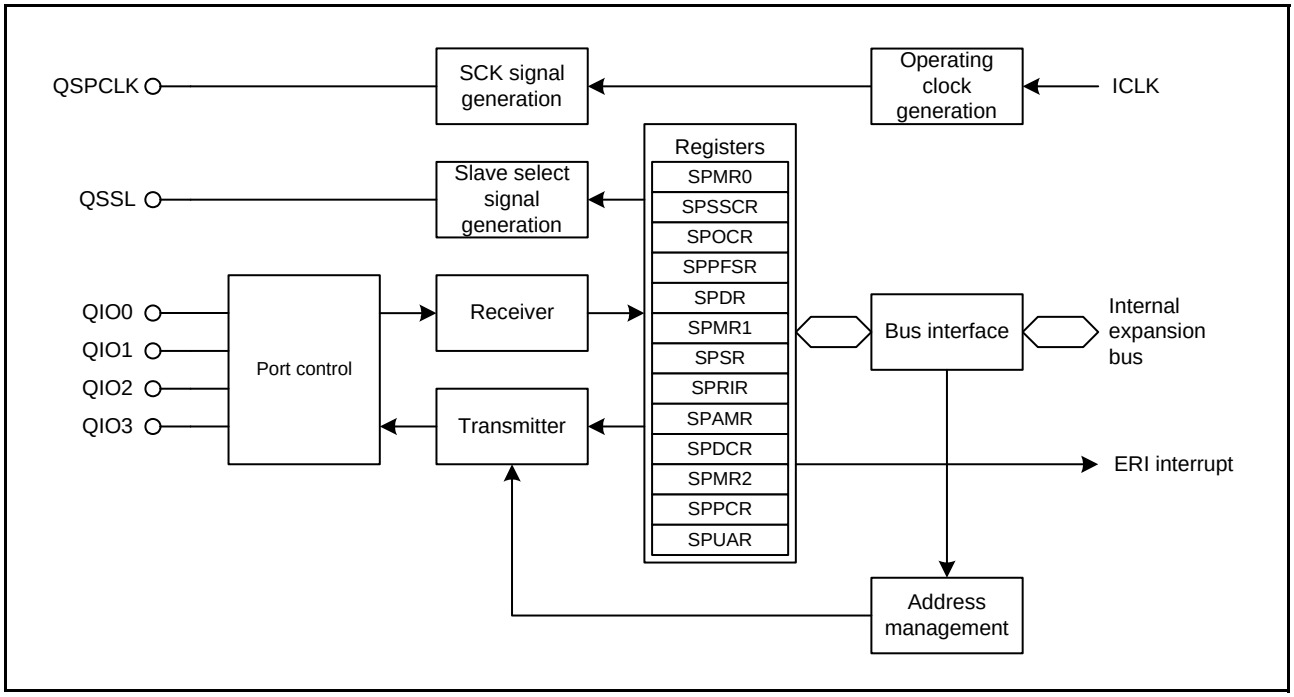

Figure 42.1 QSPIX Block Diagram

Table 42.2 QSPIX I/O Pins

Pin Name	I/O	Description
QSPCLK	Output	QSPIX clock output pin
QSSL	Output	QSPIX slave select pin
QIO0	I/O	Data 0 input/output pin
QIO1	I/O	Data 1 input/output pin
QIO2	I/O	Data 2 input/output pin or WP# signal output
QIO3	I/O	Data 3 input/output pin

42.2 Register Descriptions

42.2.1 Mode Register 0 (SPMR0)

Address(es): QSPIX.SPMR0 7400 0000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SRIS	—	—	—	—	—	DODE	CKMD	—	PFE	SSE[1:0]		—	RISEL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	RISEL[2:0]	Read Instruction Select	b2 b0 0 0 0: Read (03h*1/13h) 0 0 1: Fast Read (0Bh/0Ch) 0 1 0: Fast Read Dual Output (3Bh/3Ch) 0 1 1: Fast Read Dual I/O (BBh/BCh) 1 0 0: Fast Read Quad Output (6Bh/6Ch) 1 0 1: Fast Read Quad I/O (EBh/ECh) 1 1 0: Setting prohibited 1 1 1: Setting prohibited	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5, b4	SSE[1:0]	Slave Select Extension	b5 b4 0 0: Do not extend QSSL 0 1: Extend QSSL by 33 QSPCLK cycles 1 0: Extend QSSL by 129 QSPCLK cycles 1 1: Extend QSSL until a discontinuous address is detected	R/W
b6	PFE	Prefetch Function Enable	0: Disable function 1: Enable function	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b8	CKMD	Clock Mode Select	0: SPI mode 0 1: SPI mode 3	R/W
b9	DODE	Data Output Drive Time Extension	0: Do not extend 1: Extend by 1 QSPCLK cycle	R/W
b14 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	SRIS	Special Read Instruction Select	0: Use instruction code selected by RISEL[2:0] bits 1: Use instruction code set in the SPRIR register	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. When the SPAMR.SIZE[1:0] bits are 00b, code 0Bh may be sent because bit 8 of the address (A8) is assigned to bit 3 of the instruction code.

42.2.2 Slave Select Signal Control Register (SPSSCR)

Address(es): QSPIX.SPSSCR 7400 0004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	SSSU	SSHLD	SSHW[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	1	0	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	SSHW[3:0]	Slave Select High Width Setting	b3 b0 0 0 0 0: 1 cycle of operating clock 0 0 0 1: 2 cycles of operating clock 0 0 1 0: 3 cycles of operating clock 0 0 1 1: 4 cycles of operating clock 0 1 0 0: 5 cycles of operating clock 0 1 0 1: 6 cycles of operating clock 0 1 1 0: 7 cycles of operating clock 0 1 1 1: 8 cycles of operating clock 1 0 0 0: 9 cycles of operating clock 1 0 0 1: 10 cycles of operating clock 1 0 1 0: 11 cycles of operating clock 1 0 1 1: 12 cycles of operating clock 1 1 0 0: 13 cycles of operating clock 1 1 0 1: 14 cycles of operating clock 1 1 1 0: 15 cycles of operating clock 1 1 1 1: 16 cycles of operating clock	R/W
b4	SSHLD	Slave Select Hold Time Setting	0: Negate QSSL 0.5 cycles of operating clock after the last rising edge of QSPCLK 1: Negate QSSL 1.5 cycles of operating clock after the last rising edge of QSPCLK	R/W
b5	SSSU	Slave Select Setup Time Setting	0: Assert QSSL 0.5 cycles of operating clock before the first rising edge of QSPCLK 1: Assert QSSL 1.5 cycles of operating clock before the first rising edge of QSPCLK	R/W
b31 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to configure the timing of the slave select (QSSL) signal.

42.2.3 Clock Control Register (SPOCR)

Address(es): QSPIX.SPOCR 7400 0008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	DUTY	DIV[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	DIV[4:0]	Clock Divisor Select	b4 b0 0 0 0 0 0: ICLK divided by 2 0 0 0 0 1: ICLK divided by 3*1 0 0 0 1 0: ICLK divided by 4 0 0 0 1 1: ICLK divided by 5*1 0 0 1 0 0: ICLK divided by 6 0 0 1 0 1: ICLK divided by 7*1 0 0 1 1 0: ICLK divided by 8 0 0 1 1 1: ICLK divided by 9*1 0 1 0 0 0: ICLK divided by 10 0 1 0 0 1: ICLK divided by 11*1 0 1 0 1 0: ICLK divided by 12 0 1 0 1 1: ICLK divided by 13*1 0 1 1 0 0: ICLK divided by 14 0 1 1 0 1: ICLK divided by 15*1 0 1 1 1 0: ICLK divided by 16 0 1 1 1 1: ICLK divided by 17*1 1 0 0 0 0: ICLK divided by 18 1 0 0 0 1: ICLK divided by 20 1 0 0 1 0: ICLK divided by 22 1 0 0 1 1: ICLK divided by 24 1 0 1 0 0: ICLK divided by 26 1 0 1 0 1: ICLK divided by 28 1 0 1 1 0: ICLK divided by 30 1 0 1 1 1: ICLK divided by 32 1 1 0 0 0: ICLK divided by 34 1 1 0 0 1: ICLK divided by 36 1 1 0 1 0: ICLK divided by 38 1 1 0 1 1: ICLK divided by 40 1 1 1 0 0: ICLK divided by 42 1 1 1 0 1: ICLK divided by 44 1 1 1 1 0: ICLK divided by 46 1 1 1 1 1: ICLK divided by 48	R/W
b5	DUTY	Duty Cycle Correction	0: Make no correction 1: Correct the duty cycle when the divisor is odd number	R/W
b31 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Set the DUTY bit to 1

This register is used to configure the frequency and duty ratio of the operating clock (= QSPCLK).

42.2.4 Prefetch Status Register (SPPFSR)

Address(es): QSPIX.SPPFSR 7400 000Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b25 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b26	—	—	Set the missing upper 6 bits for the 26-bit offset address of the SPI space access window. These bits are effective in memory mapped mode.	R/W

42.3 Memory Map

Figure 42.2 shows the memory map in the QSPI area and the relation to the SPI space.

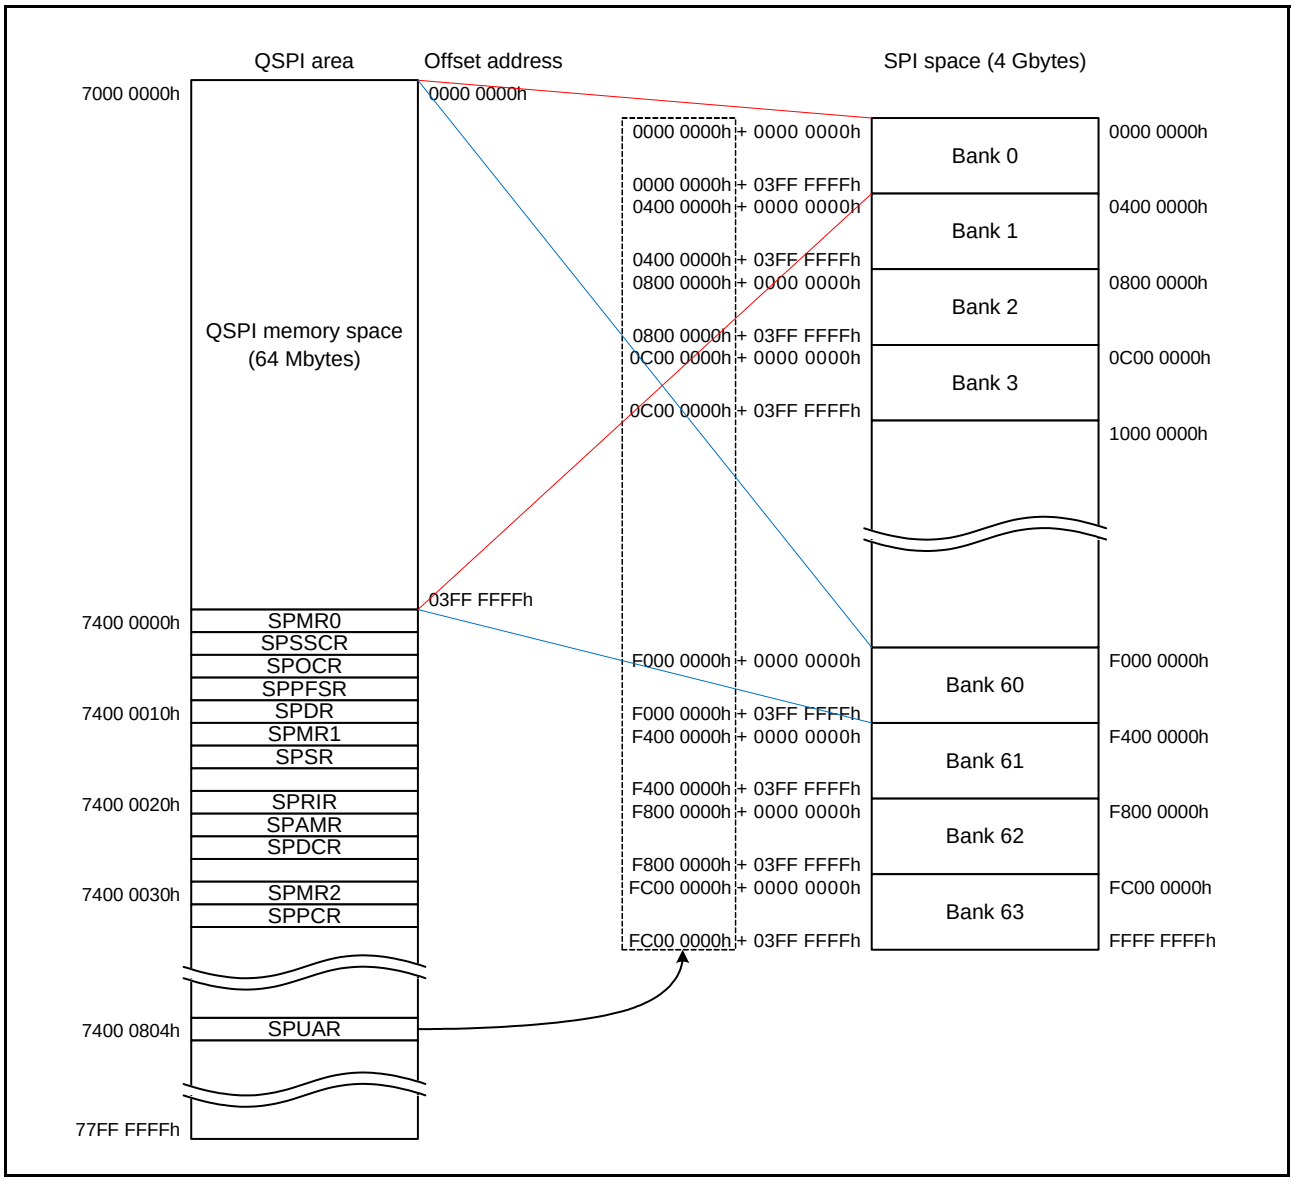

Figure 42.2 Memory Map in the QSPI Area and Relation to the SPI Space

When an address in the QSPI memory space is accessed for a read, an SPI bus cycle is automatically generated and data read from the serial ROM is returned.

The address to access the SPI space is generated from the upper 6 bits of the SPUAR register and the offset of the QSPI memory space. The address for the SPI space generated in this way has 32 bits, but the address sent to the SPI bus is selected from 8, 16, 24, and 32 bits by the SPAMR.SIZE[1:0] bits. When 8, 16, or 24 bits are selected, the lower bits of the address is sent to the SPI bus.

42.4 SPI Bus

42.4.1 SPI Protocol

The QSPIX supports the Single/Extended SPI, Dual SPI, and Quad SPI protocols. The initial state is Single/Extended SPI protocol. To change the protocol, set the SPMR2.IOMOD[1:0] bits.

42.4.1.1 Single/Extended SPI Protocol

The Single/Extended SPI protocol uses only the QIO0 pin to send instruction codes. Subsequent address and data I/O operations are performed using one to four pins, depending on the instruction code (setting of the SPMR0.RISEL[2:0] bits).

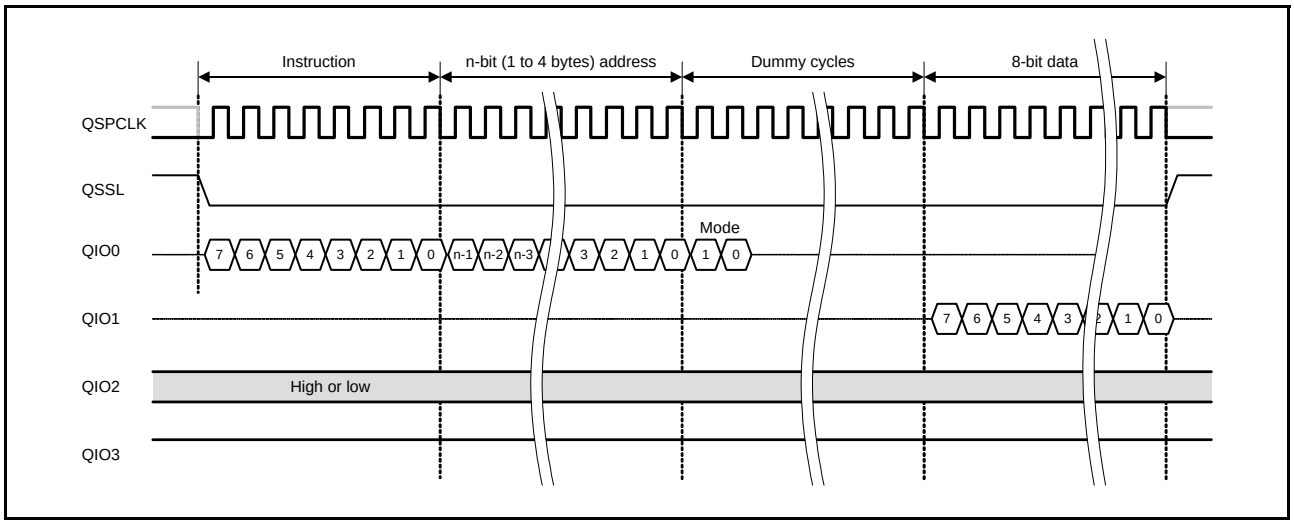

Figure 42.3 Single SPI Protocol Example for Fast Read

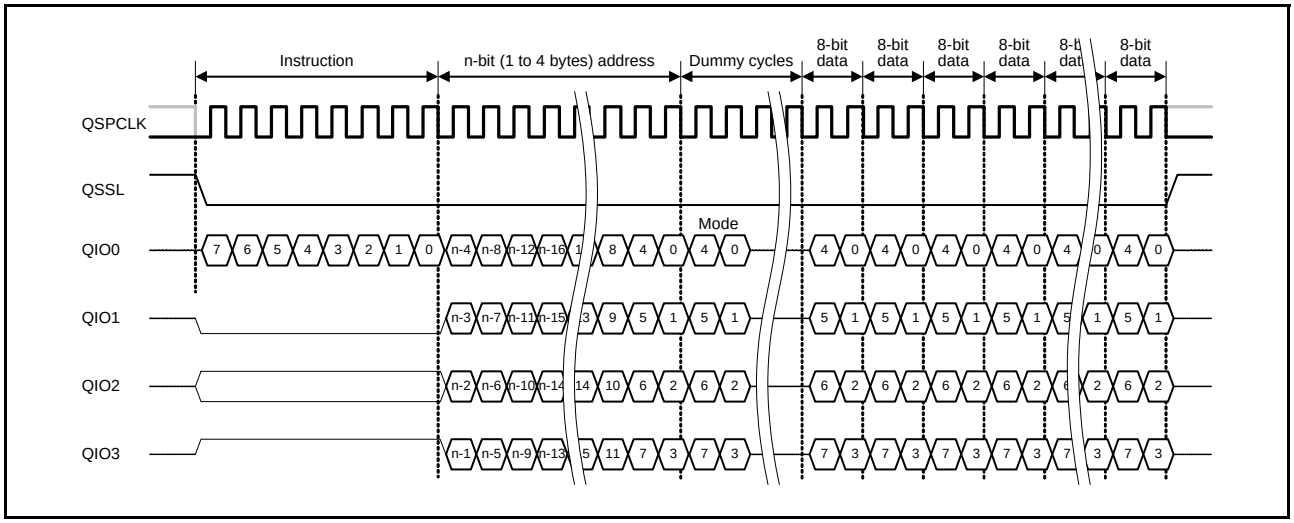

Figure 42.4 Extended SPI Protocol Example for Fast Read Quad I/O

42.4.1.2 Dual SPI Protocol

The Dual SPI protocol uses two pins, QIO0 and QIO1, to perform I/O operations for all signals such as instruction codes, addresses, and data.

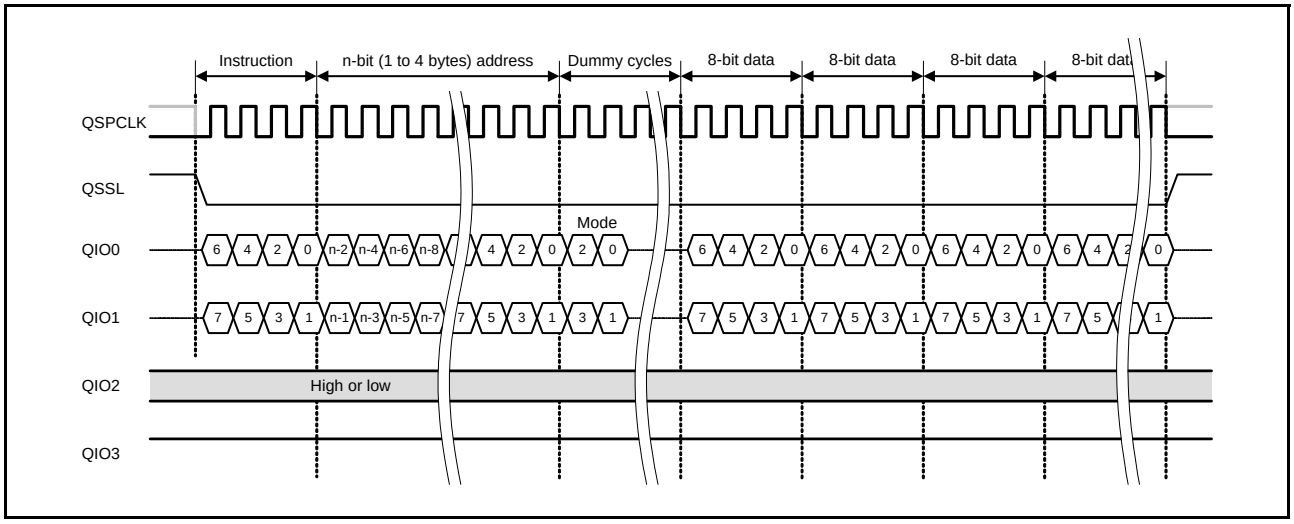

Figure 42.5 Dual SPI Protocol Example for Fast Read

42.4.1.3 Quad SPI Protocol

The Quad SPI protocol uses four pins, QIO0, QIO1, QIO2, and QIO3, to perform I/O operations for all signals such as instruction codes, addresses, and data.

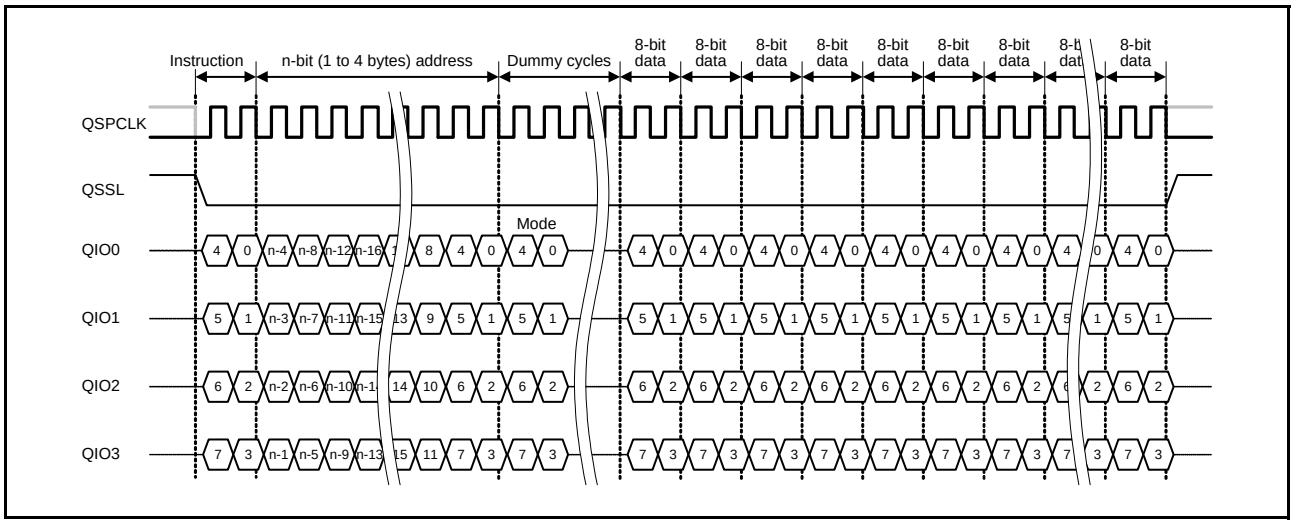

Figure 42.6 Quad SPI Protocol Example for Fast Read

42.4.2 SPI Mode

The SPI mode can be selected from either SPI mode 0 or SPI mode 3 by the SPMR0.CKMD bit. This can be switched by changing the register setting during operation. The difference between SPI modes 0 and SPI mode 3 is the level when the QSPCLK signal is stopped, which is low in SPI mode 0 and high in SPI mode 3.
Transmit data is output from the MCU at the falling edge of QSPCLK and read into the serial ROM at the rising edge of QSPCLK. Receive data is output from the serial ROM at the falling edge of QSPCLK and read into the MCU at the next falling edge of QSPCLK.

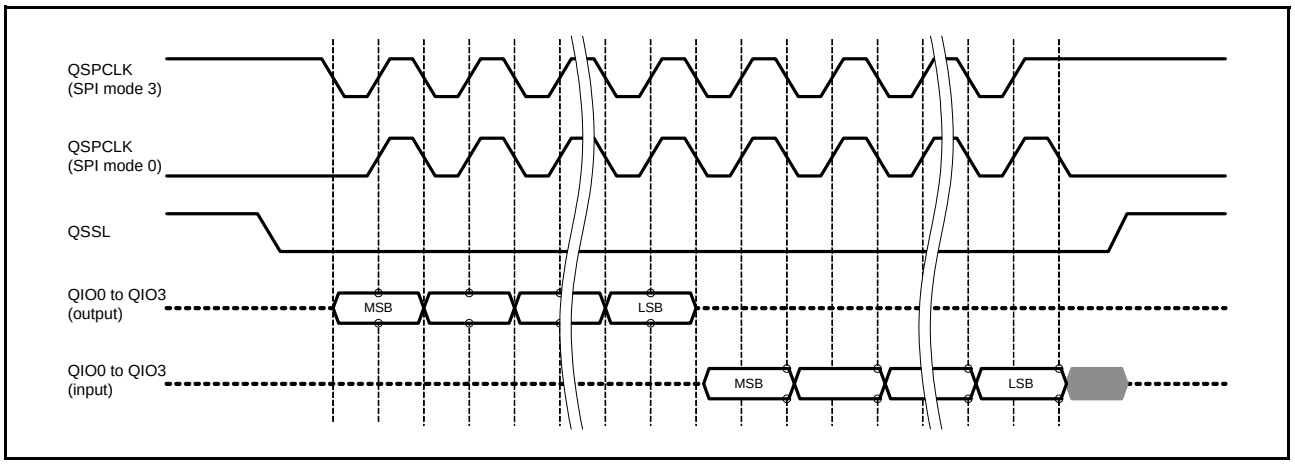

Figure 42.7 Basic Serial Interface Timing

42.5 SPI Bus Timing Adjustment

Various signal timings on the SPI bus can be adjusted by register settings. The configured timing applies to all SPI bus cycles, regardless of memory mapped or indirect access mode.

42.5.1 SPI Bus Operating Clock

The SPI bus operates according to the operating clock obtained by dividing ICLK. The operating clock frequency can be selected in the range of ICLK divided by 2 to 48 by the SPOCR.DIV[4:0] bits.

Table 42.3 Relationship among DIV[4:0] Bits, Frequency Divisor, and Operating Clock Frequencies when ICLK is 120 MHz

DIV[4:0]	Frequency divisor	Operating clock frequency (MHz)
11111b	48	2.50
11110b	46	2.61
11101b	44	2.73
11100b	42	2.86
11011b	40	3.00
11010b	38	3.16
11001b	36	3.33
11000b	34	3.53
10111b	32	3.75
10110b	30	4.00
10101b	28	4.29
10100b	26	4.62
10011b	24	5.00
10010b	22	5.45
10001b	20	6.00
10000b	18	6.67
01111b	17	7.06
01110b	16	7.50
01101b	15	8.00
01100b	14	8.57
01011b	13	9.23
01010b	12	10.00
01001b	11	10.91
01000b	10	12.00
00111b	9	13.33
00110b	8	15.00
00101b	7	17.14
00100b	6	20.00
00011b	5	24.00
00010b	4	30.00
00001b	3	40.00
00000b	2	60.00

42.5.2 QSPCLK Signal Duty Ratio

When the operating clock is configured as ICLK divided by an even number, the high and low widths of the QSPCLK signal match. However when it is configured as ICLK divided by an odd number, the high width is one ICLK cycle longer than the low width.

To bring the duty ratio of the QSPCLK signal closer to 50% when the operating clock is configured as ICLK divided by an odd number, set the SPOCR.DUTY bit to 1 to delay the rising edge of the QSPCLK output signal by 0.5 ICLK cycles. When the operating clock is configured as ICLK divided by an even number, the setting of the SPOCR.DUTY bit is ignored.

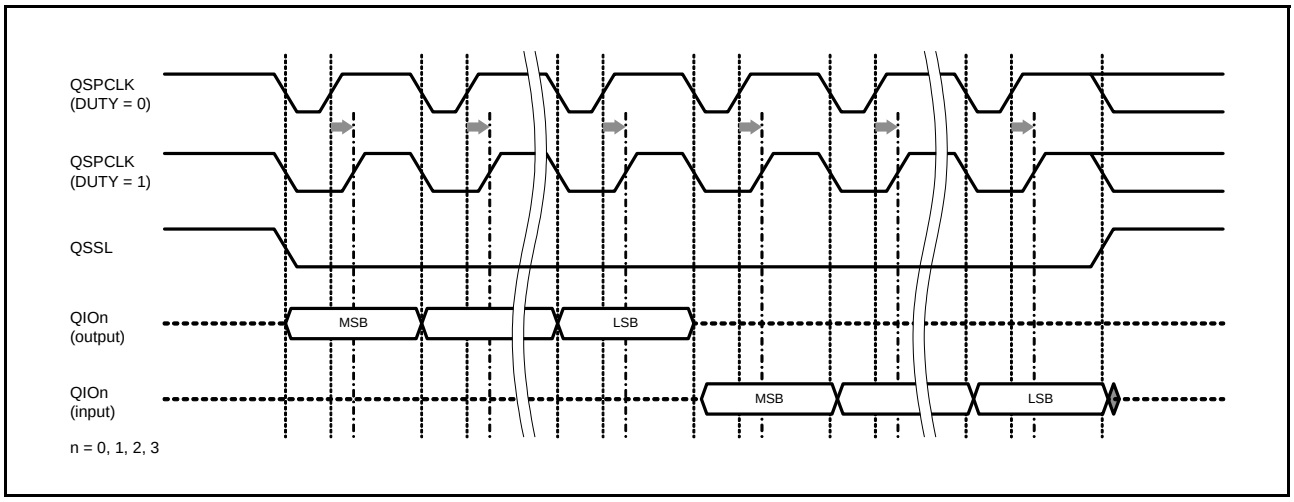

Figure 42.8 Example of Correction of the QSPCLK Signal Duty Ratio Using the DUTY Bit, When ICLK Is Divided by 3

42.5.3 Minimum High Width of the QSSL Signal

Between adjacent SPI bus cycles, the QSSL signal must be held high (inactive) for a sufficient time to ensure the deselect time required for serial ROM. The minimum high width of the QSSL signal can be selected from 1 to 16 cycles of the operating clock by the SPSSCR.SSHW[3:0] bits.

42.5.4 QSSL Signal Setup Time

The time from when the QSSL signal goes low to the first rising edge of QSPCLK signal (QSSL signal setup time) can be configured to satisfy the serial ROM requirements. The setup time can be selected from 0.5 or 1.5 cycles of the operating clock with the SPSSCR.SSSU bit.

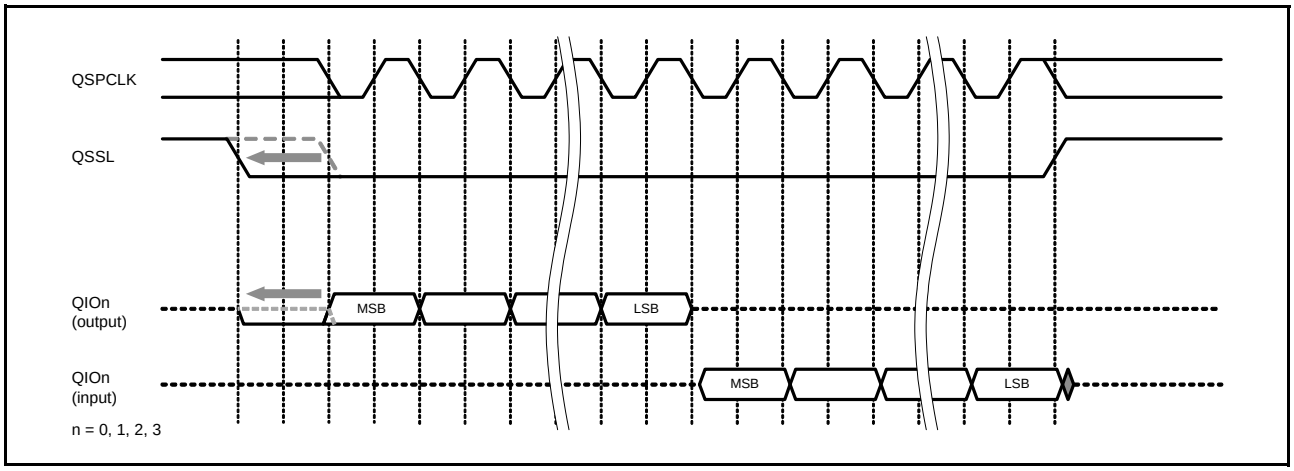

Figure 42.9 Setup Time Adjustment for the QSSL Signal Using the SSSU Bit

42.5.5 QSSL Signal Hold Time

The time from the last rising edge of QSPCLK signal until the QSSL signal goes high (QSSL signal hold time) can be configured to satisfy the serial ROM requirements. The hold time can be selected from 0.5 or 1.5 cycles of the operating clock with the SPSSCR.SSHLD bit.

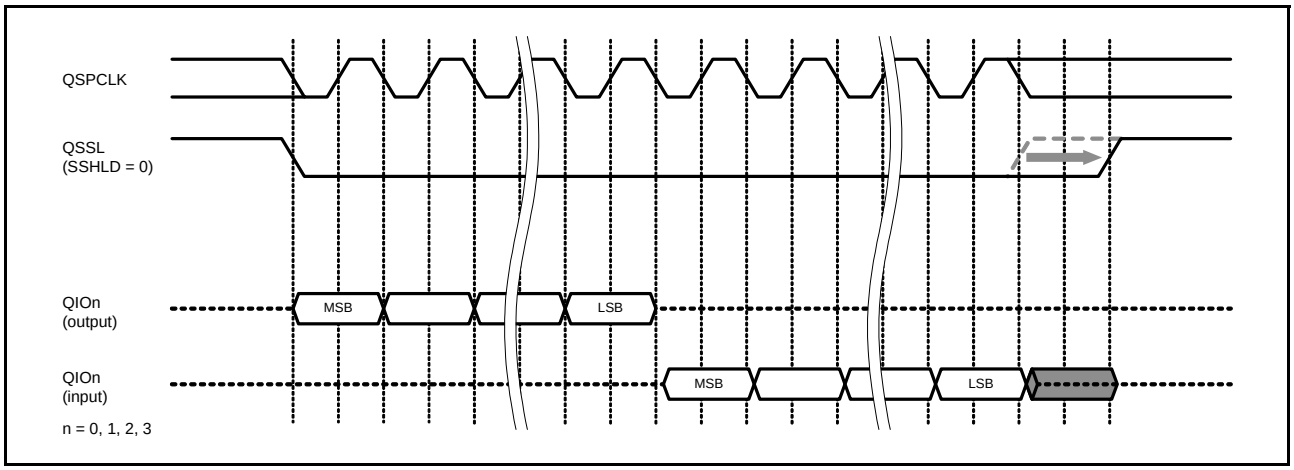

Figure 42.10 Hold Time Adjustment for the QSSL Signal Using the SSHLD Bit

42.5.6 Serial Data Output Drive Time

The output drive time of the QIO0 to QIO3 pins can be extended by one cycle of QSPCLK using the SPMR0.DODE bit. When the DODE bit is set to 1, the first cycle after the address output for the Read instruction and the third cycle of the dummy cycles for the other read instructions do not become high impedance.

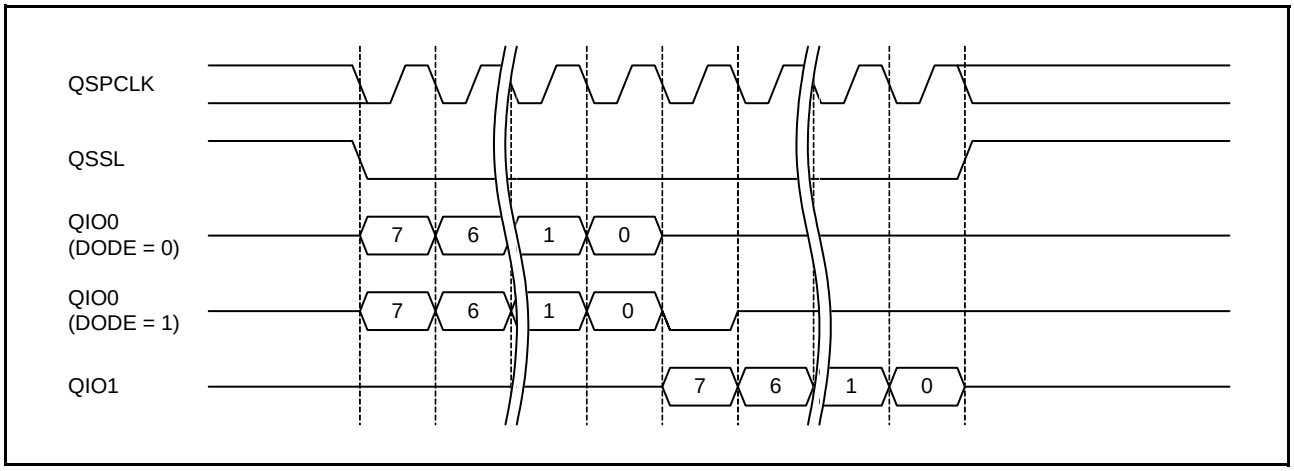

Figure 42.11 Data Output Drive Time Adjustment Using the DODE Bit (1) (Read)

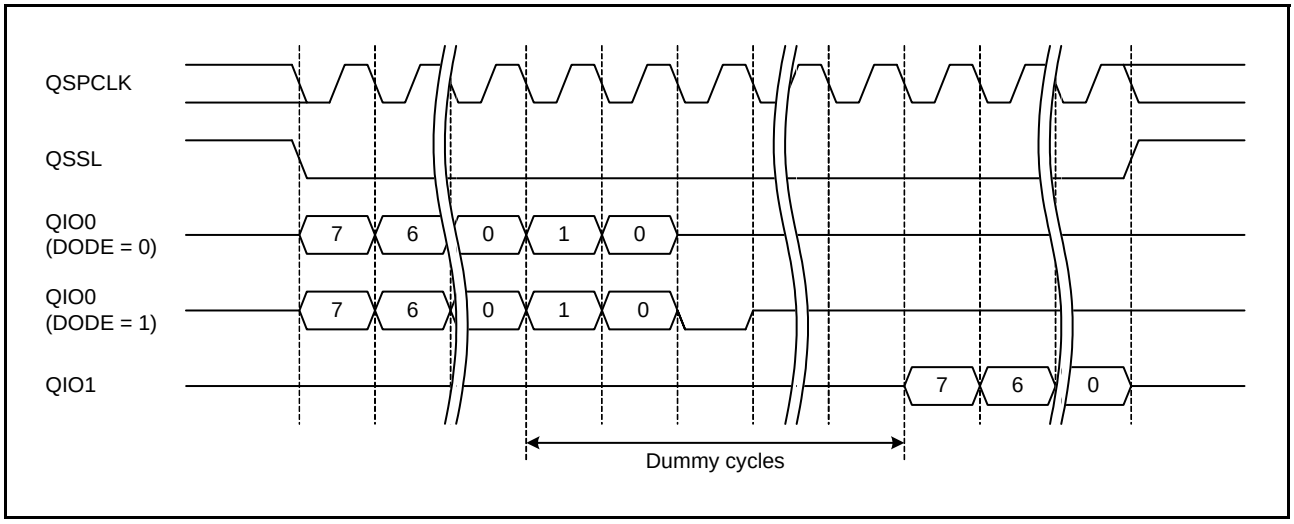

Figure 42.12 Data Output Drive Time Adjustment Using the DODE Bit (2) (Fast Read)

42.6 SPI Instruction Set Used for ROM Access

42.6.1 SPI Instructions That Are Automatically Generated

When QSPIX accesses the serial ROM, an SPI bus cycle using one of the instructions listed in Table 42.4 to Table 42.8 is automatically generated based on the settings in the SPAMR and SPMR0 registers. If the SPMR0.SRIS bit is 1, the setting value of the SPRIR register is used as the instruction code.

Table 42.4 SPI Instructions Automatically Generated When SPAMR.SIZE[1:0] = 00b

SPI Instruction	Instruction code	Address bytes	Dummy cycles	Data bytes	Remarks
Read	03h	1	—	1 to ∞	RISEL[2:0] = 000b, A8 = 0
	0Bh	1	—	1 to ∞	RISEL[2:0] = 000b, A8 = 1

Table 42.5 SPI Instructions Automatically Generated When SPAMR.SIZE[1:0] = 01b

SPI Instruction	Instruction code	Address bytes	Dummy cycles	Data bytes	Remarks
Read	03h	2	—	1 to ∞	RISEL[2:0] = 000b

Table 42.6 SPI Instructions Automatically Generated When SPAMR.SIZE[1:0] = 10b

SPI Instruction	Instruction code	Address bytes	Dummy cycles	Data bytes	Remarks
Read	03h	3	—	1 to ∞	RISEL[2:0] = 000b
Fast Read	0Bh	3	8*1	1 to ∞	RISEL[2:0] = 001b
Fast Read Dual Output	3Bh	3	8*1	1 to ∞	RISEL[2:0] = 010b
Fast Read Dual I/O	BBh	3	4*1	1 to ∞	RISEL[2:0] = 011b
Fast Read Quad Output	6Bh	3	8*1	1 to ∞	RISEL[2:0] = 100b
Fast Read Quad I/O	EBh	3	6*1	1 to ∞	RISEL[2:0] = 101b

Note 1. The number of dummy cycles is configurable in SPDCR.DCYC[3:0].

Table 42.7 SPI Instructions Automatically Generated When SPAMR.SIZE[1:0] = 11b and I4AE = 0

SPI Instruction	Instruction code	Address bytes	Dummy cycles	Data bytes	Remarks
Read	03h	4	—	1 to ∞	RISEL[2:0] = 000b
Fast Read	0Bh	4	8*1	1 to ∞	RISEL[2:0] = 001b
Fast Read Dual Output	3Bh	4	8*1	1 to ∞	RISEL[2:0] = 010b
Fast Read Dual I/O	BBh	4	4*1	1 to ∞	RISEL[2:0] = 011b
Fast Read Quad Output	6Bh	4	8*1	1 to ∞	RISEL[2:0] = 100b
Fast Read Quad I/O	EBh	4	6*1	1 to ∞	RISEL[2:0] = 101b

Note 1. The number of dummy cycles is configurable in SPDCR.DCYC[3:0].

Table 42.8 SPI Instructions Automatically Generated When SPAMR.SIZE[1:0] = 11b and I4AE = 1

SPI Instruction	Instruction code	Address bytes	Dummy cycles	Data bytes	Remarks
Read	13h	4	—	1 to ∞	RISEL[2:0] = 000b
Fast Read	0Ch	4	8*1	1 to ∞	RISEL[2:0] = 001b
Fast Read Dual Output	3Ch	4	8*1	1 to ∞	RISEL[2:0] = 010b
Fast Read Dual I/O	BCh	4	4*1	1 to ∞	RISEL[2:0] = 011b
Fast Read Quad Output	6Ch	4	8*1	1 to ∞	RISEL[2:0] = 100b
Fast Read Quad I/O	ECh	4	6*1	1 to ∞	RISEL[2:0] = 101b

Note 1. The number of dummy cycles is configurable in SPDCR.DCYC[3:0].

42.6.2 Read Instruction

Read instruction is a common read method supported by most serial ROMs.
When the SPI bus cycle is started, the QSSL signal is asserted and the instruction code (03h/13h)*1 and the one- to four-byte address specified by the SPAMR.SIZE[1:0] bits are transmitted from the QIO0 pin. After that, data is received from the QIO1 pin.

Note 1. Most 4K-bit serial ROMs have a 1-byte address field and assign the most significant bit (A8) of the address to bit 3 of the Read instruction code to minimize the overhead. To support these devices, when the SPAMR.SIZE[1:0] bits are 00b (8-bit address), QSPIX outputs A8 (address bit 8) to bit 3 of the Read instruction code. Therefore 0Bh may be output instead of 03h as the code of the Read instruction. This code (0Bh) overlaps with the code of the Fast Read instruction, but most serial ROMs of 2K-bit or less are designated to ignore bit 3 of the instruction code, so 0Bh is correctly recognized as the Read instruction. In rare cases, there are serial ROMs that allow bit 3 to be decoded, but when such a serial ROM is connected, avoid access that causes A8 to be 1.

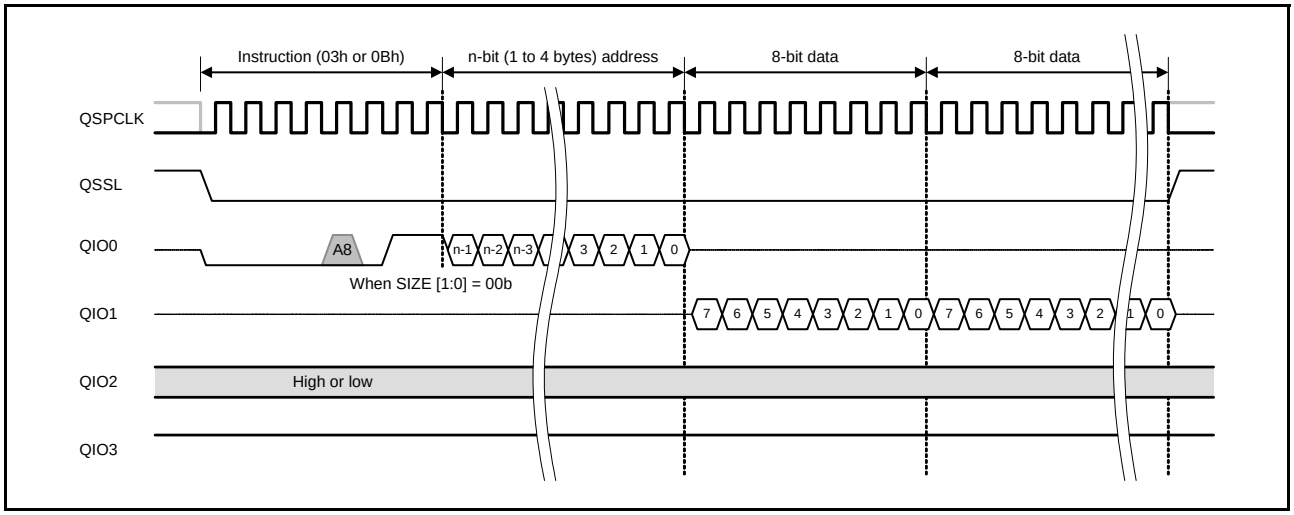

Figure 42.13 Read Instruction Bus Cycle

42.6.3 Fast Read Instruction

Fast Read instruction is a read method that supports a communication clock that is faster than the Read instruction.
When the SPI bus cycle is started, the QSSL signal is asserted, the instruction code (0Bh/0Ch) and the one- to four-byte address specified by the SPAMR.SIZE[1:0] bits are transmitted from the QIO0 pin, and the dummy cycles specified in the SPDCR.DCYC[3:0] bits are inserted. After that, data is received from the QIO1 pin.
The Dual SPI protocol uses the QIO0 and QIO1 pins, and the Quad SPI protocol uses the QIO0 to QIO3 pins to transmit and receive instruction codes, addresses, and data.
The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used in this SPI bus cycle is applied to the next SPI bus cycle, so the instruction code is omitted in the next SPI bus cycle. For details on the XIP mode, refer to section 42.8, XIP Mode.
Switching to the Fast Read instruction is controlled by the SPMR0 register.

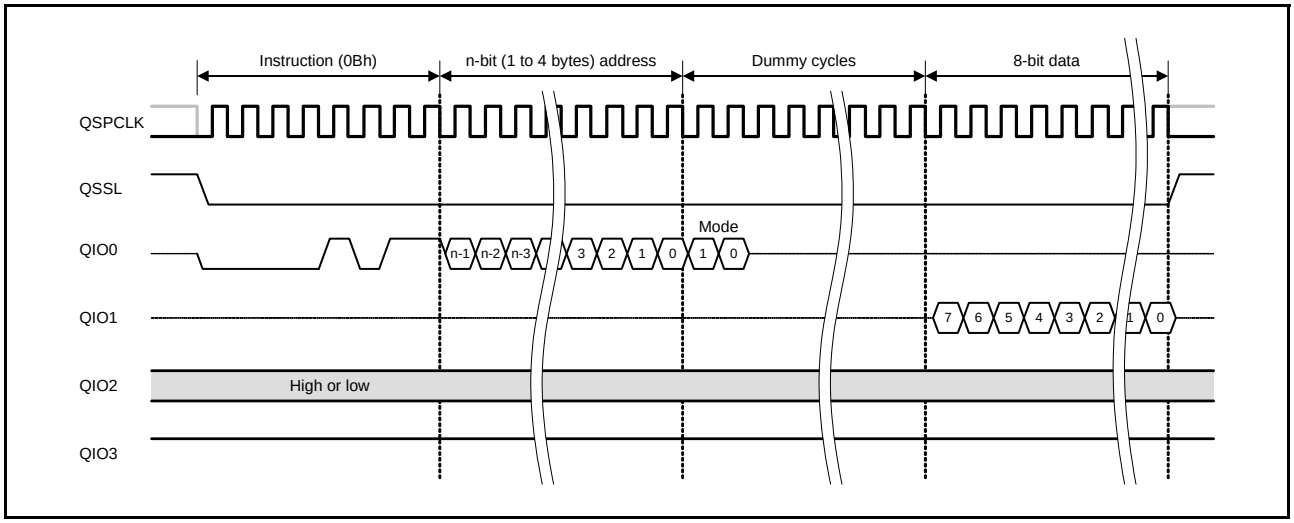

Figure 42.14 Fast Read Instruction Bus Cycle (Extended SPI Protocol)

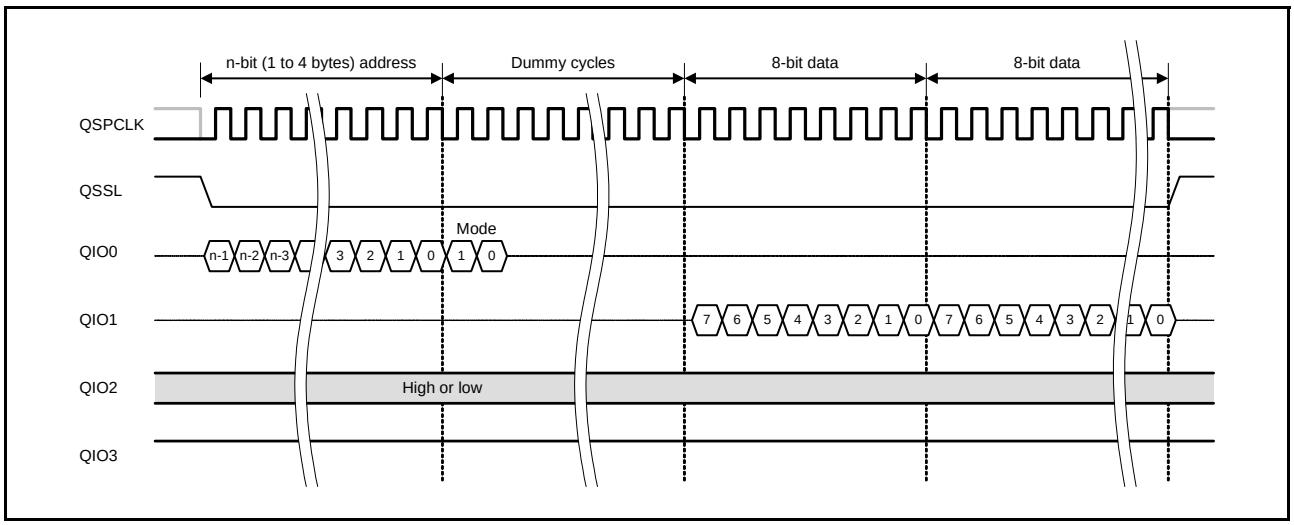

Figure 42.15 Fast Read Instruction Bus Cycle in XIP Mode (Extended SPI Protocol)

Note: To use the Fast Read instruction, a serial ROM that supports Fast Read transfers is required.

42.6.4 Fast Read Dual Output Instruction

The Fast Read Dual Output instruction is a read method that uses two signal lines to receive data.
When the SPI bus cycle is started, the QSSL signal is asserted, the instruction code (3Bh/3Ch) and the one- to four-byte address specified by the SPAMR.SIZE[1:0] bits are transmitted from the QIO0 pin (the QIO0 and QIO1 pins in Dual SPI protocol), and the dummy cycles specified in the SPDCR.DCYC[3:0] bits are inserted. After that, data is received form the QIO0 and QIO1 pins. Even bits of data are received from the QIO0 pin and odd bits are received from the QIO1 pin.
The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used in this SPI bus cycle is applied to the next SPI bus cycle, so the instruction code is omitted in the next SPI bus cycle. For details on the XIP mode, refer to section 42.8, XIP Mode.
Switching to Fast Read Dual Output instruction is controlled by the SPMR0 register.

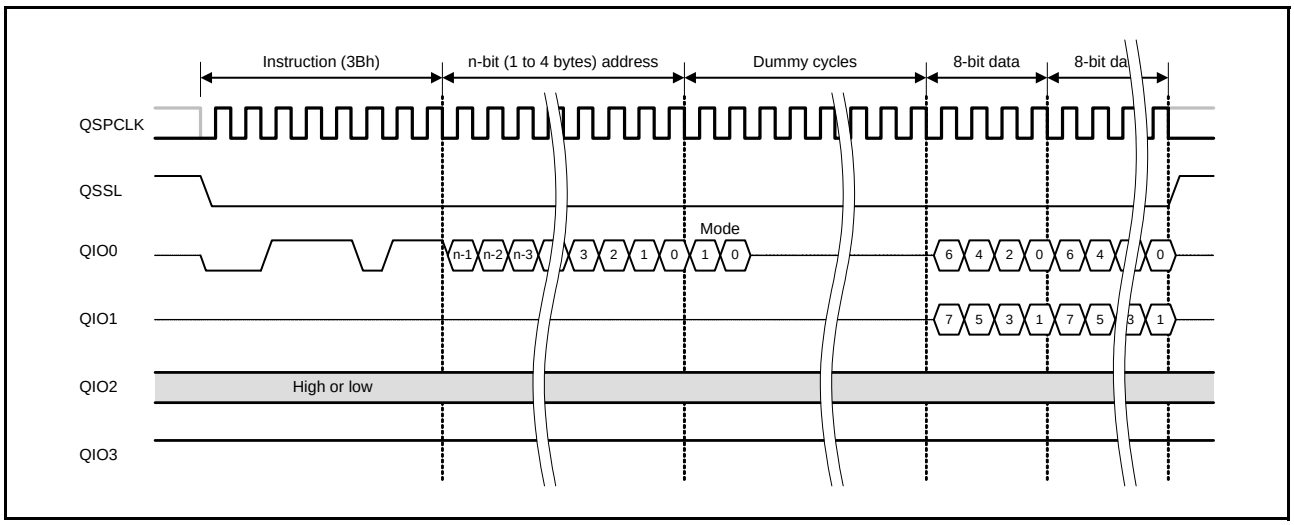

Figure 42.16 Fast Read Dual Output Instruction Bus Cycle (Extended SPI Protocol)

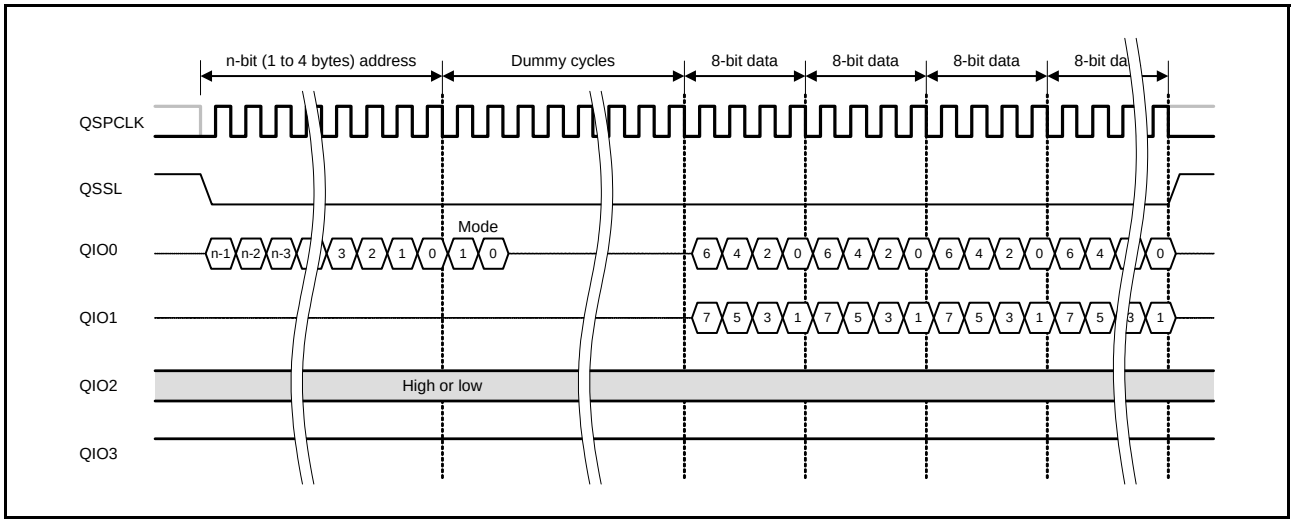

Figure 42.17 Fast Read Dual Output Instruction Bus Cycle in XIP Mode (Extended SPI Protocol)

Note: To use the Fast Read Dual Output instruction, a serial ROM that supports Fast Read Dual Output transfers is required.

42.6.5 Fast Read Dual I/O Instruction

The Fast Read Dual I/O instruction is a read method that uses two signal lines for address transmission and data reception.

When the SPI bus cycle is started, the QSSL signal is asserted, the instruction code (BBh/BCh) is transmitted from the QIO0 pin (the QIO0 and QIO1 pins in Dual SPI protocol), the one- to four-byte address specified by the SPAMR.SIZE[1:0] bits is transmitted from the QIO0 and QIO1 pins, and the dummy cycles specified in the SPDCR.DCYC[3:0] bits is inserted. After that, data is received from the QIO0 and QIO1 pins. The QIO0 pin is used for even bits of address, dummy byte, and data, and the QIO1 pin is used for odd bits.

The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used in this SPI bus cycle is applied to the next SPI bus cycle, so the instruction code is omitted in the next SPI bus cycle. For details on the XIP mode, refer to section 42.8, XIP Mode.

Switching to Fast Read Dual I/O instruction is controlled by the SPMR0 register.

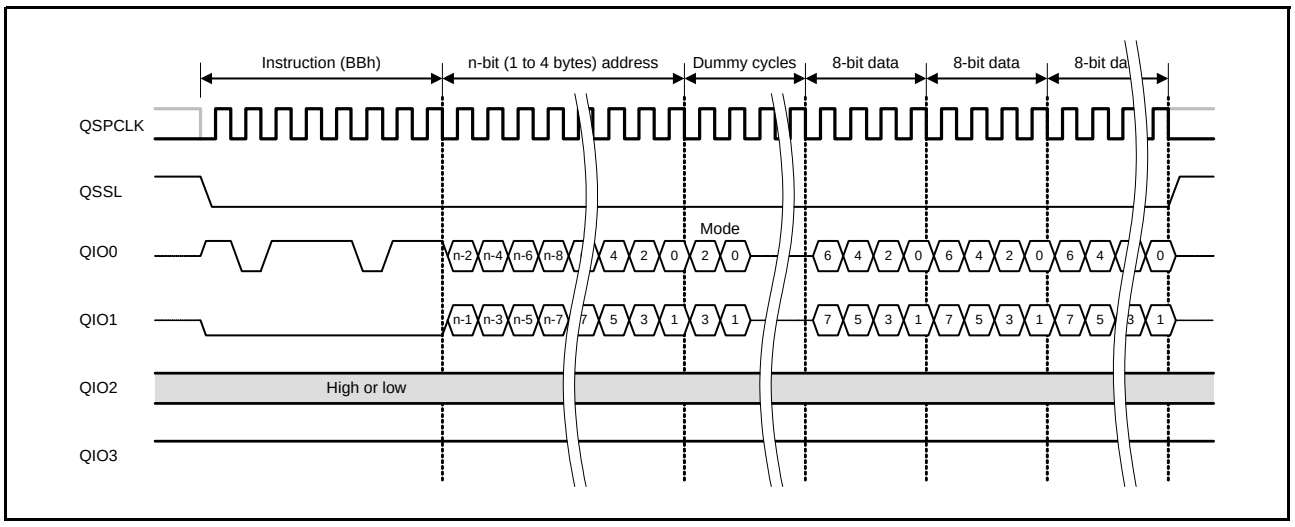

Figure 42.18 Fast Read Dual I/O Instruction Bus Cycle (Extended SPI Protocol)

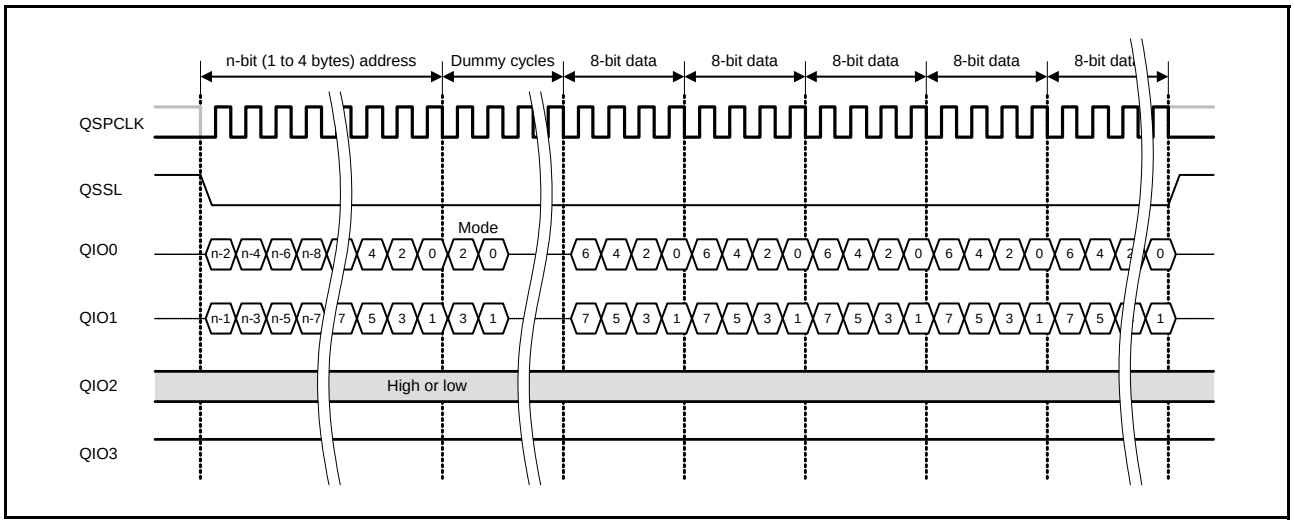

Figure 42.19 Fast Read Dual I/O Instruction Bus Cycle in XIP Mode

Note: To use the Fast Read Dual I/O instruction, a serial ROM that supports Fast Read Dual I/O transfers is required.

42.6.6 Fast Read Quad Output Instruction

The Fast Read Quad Output instruction is a read method that uses four signal lines to receive data.
When the SPI bus cycle is started, the QSSL signal is asserted, the instruction code (6Bh/6Ch) and the one- to four-byte address specified by the SPAMR.SIZE[1:0] bits are transmitted from the QIO0 pin (the QIO0 to QIO3 pins in Quad SPI protocol), and the dummy cycles specified in the SPDCR.DCYC[3:0] bits are inserted. After that, data is received form the QIO0 to QIO3 pins.
The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used in this SPI bus cycle is applied to the next SPI bus cycle, so the instruction code is omitted in the next SPI bus cycle. For details on the XIP mode, refer to section 42.8, XIP Mode.
Switching to Fast Read Quad Output instruction is controlled by the SPMR0 register.

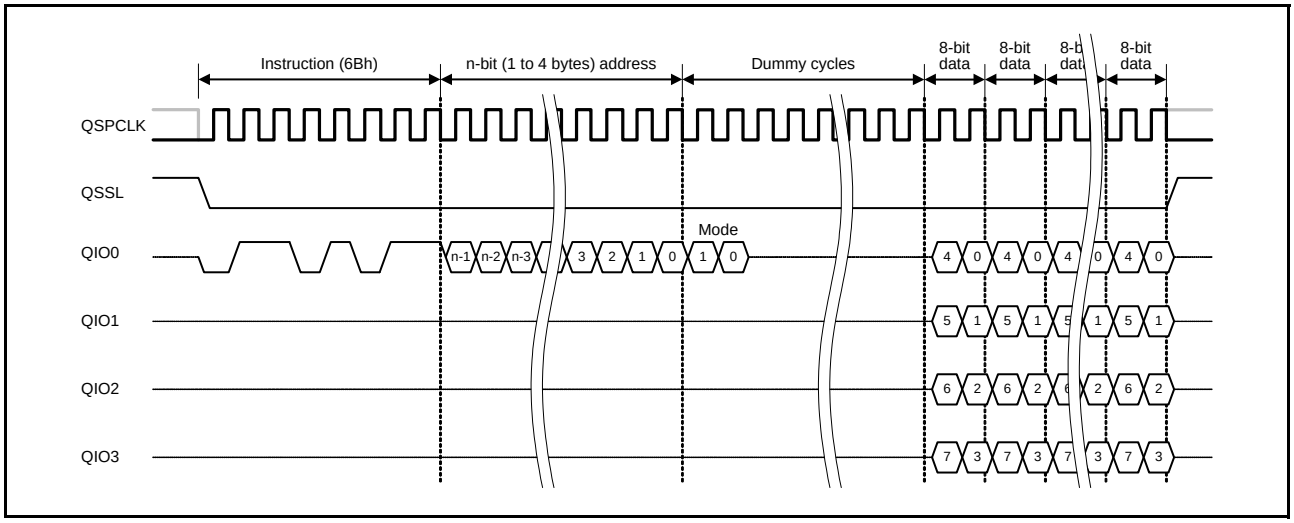

Figure 42.20 Fast Read Quad Output Instruction Bus Cycle (Extended SPI Protocol)

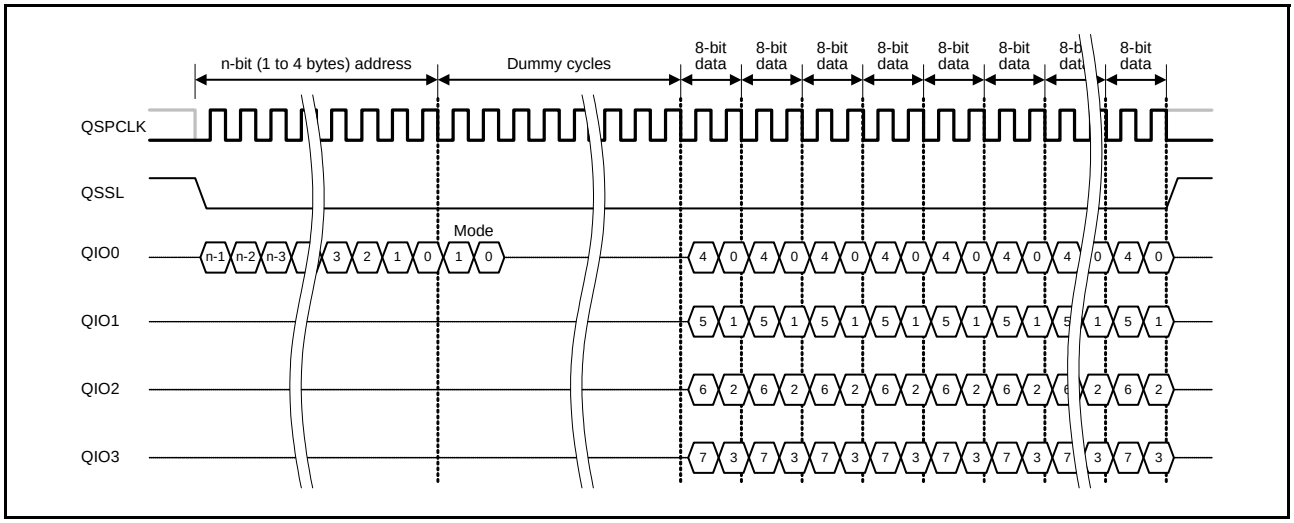

Figure 42.21 Fast Read Quad Output Instruction Bus Cycle in XIP Mode (Extended SPI Protocol)

Note: To use Fast Read Quad Output, a serial ROM that supports Fast Read Quad Output transfer is required.

42.6.7 Fast Read Quad I/O Instruction

The Fast Read Quad I/O instruction is a read method that uses four signal lines for address transmission and data reception.

When the SPI bus cycle is started, the QSSL signal is asserted, the instruction code (EBh/ECh) is transmitted from the QIO0 pin (the QIO0 to QIO3 pins in Quad SPI protocol), the one- to four-byte address specified by the SPAMR.SIZE[1:0] bits is transmitted from the QIO0 to QIO3 pins, and the dummy cycles specified in the SPDCR.DCYC[3:0] bits is inserted. After that, data is received from the QIO0 to QIO3 pins.

The first two dummy cycles are used to select the XIP mode. When the XIP mode is selected, the same instruction used in this SPI bus cycle is applied to the next SPI bus cycle, so the instruction code is omitted in the next SPI bus cycle. For details on the XIP mode, refer to section 42.8, XIP Mode.

Switching to Fast Read Quad I/O instruction is controlled by the SPMR0 register.

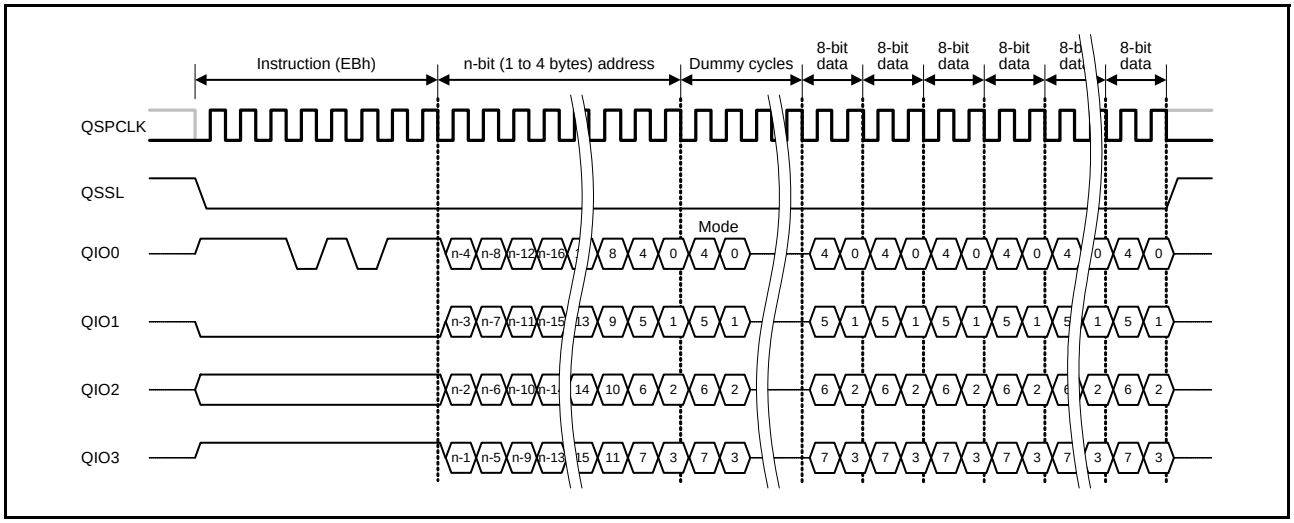

Figure 42.22 Fast Read Quad I/O Instruction Bus Cycle (Extended SPI Protocol)

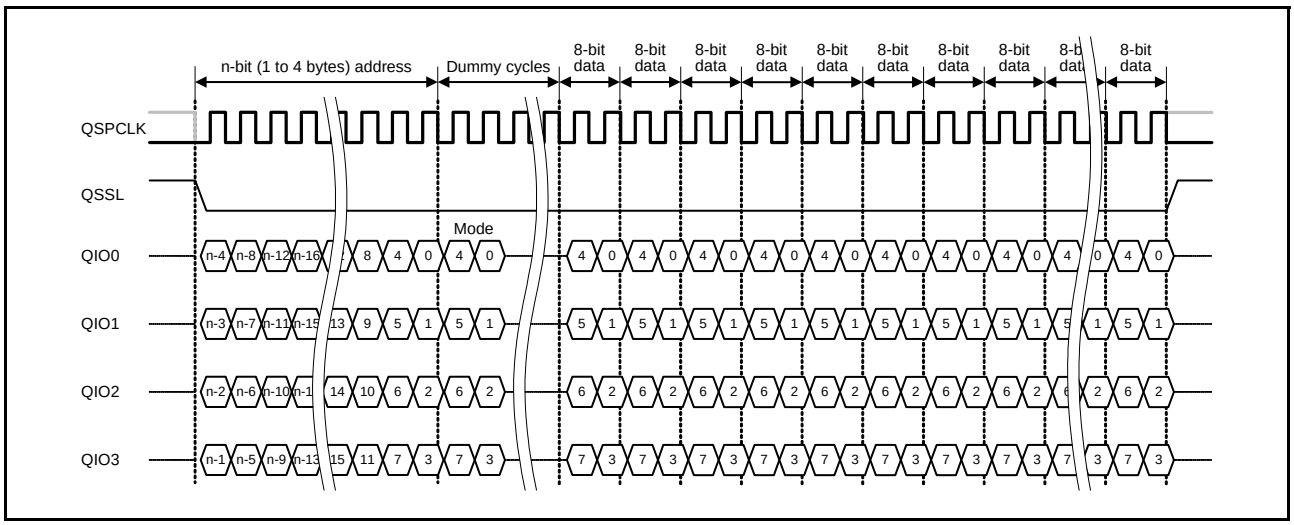

Figure 42.23 Fast Read Quad I/O Instruction Bus Cycle in XIP Mode

Note: To use the Fast Read Quad I/O instruction, a serial ROM that supports Fast Read Quad I/O transfers is required.

42.7 SPI Bus Cycle Generation

42.7.1 Standard ROM Read

Read access in memory-mapped mode is converted into single SPI bus cycle for each access.
When QSPIX detects a read access to QSPI memory space (address 7000 0000h to 73FF FFFFh), it asserts the QSSL signal and initiates the SPI bus cycle. When it receives the required number of data from the serial ROM, it negates the QSSL signal and terminates the SPI bus cycle.
When it detects the next read access, it secures the minimum high width of the QSSL signal and then start a new SPI bus cycle.

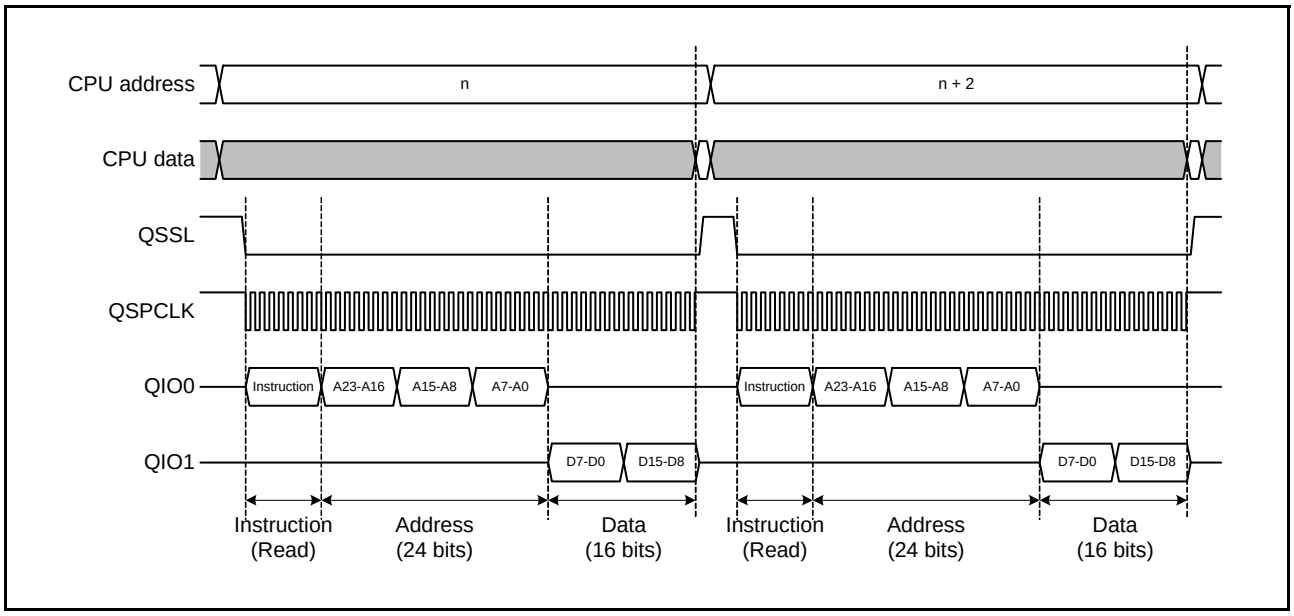

Figure 42.24 Successive Data Read Operations

42.7.2 ROM Read Using Prefetch Function

In many cases, such as CPU instruction execution and block data transfer, ROM data is read from consecutive addresses in ascending order.
The memory read command of the serial ROM can read data infinitely in a single SPI bus cycle. However, if the bus cycle issued by the CPU are individually converted to the SPI bus cycle, the SPI bus cycle is divided and this feature of the serial ROM cannot be utilized.
QSPIX has a prefetch function to take advantage of this feature.
The prefetch function is enabled when the SPMR0.PFE bit is set to 1. When the prefetch function is enabled, QSPIX continuously receives and buffers data without waiting for the next ROM read request. When the CPU reads the ROM, it compares the addresses and returns the data in the buffer to the CPU if the addresses match. If the addresses do not match, the data in the buffer is discarded and a new SPI bus cycle is generated.
The size of the prefetch buffer is 18 bytes. When this buffer is full, the SPI bus cycle ends. When the data in the buffer is read and the buffer becomes free, a new SPI bus cycle is automatically started to resume prefetching.
The prefetch function realizes efficient data transfer in situations where data is read in ascending order from consecutive addresses such as instruction fetch and block data transfer.

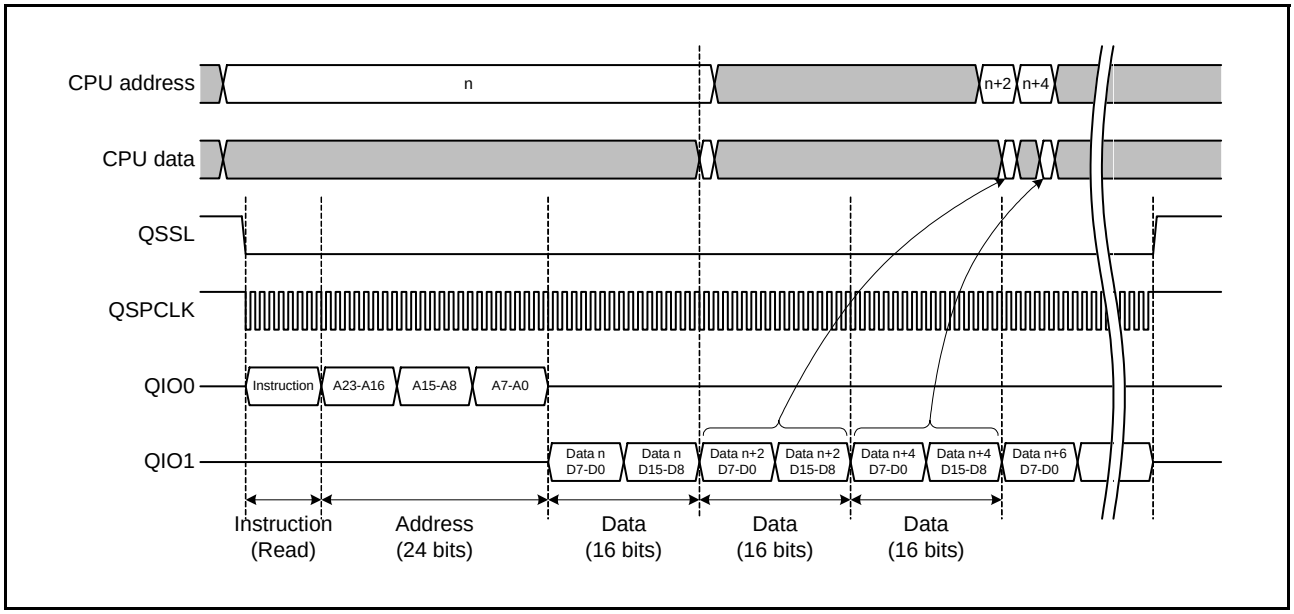

Figure 42.25 Continuous Data Read Using Prefetch Function

42.7.3 Termination of Prefetch

If a ROM read bus cycle to another address occurs while receiving data for prefetching, QSPIX terminates the current SPI bus cycle that is no longer needed and starts a new SPI bus cycle.

42.7.4 Specifying the Prefetch Address

When a write access to the QSPI memory space is detected while the PFE bit is 1, QSPIX obtains the current address as a prefetch address and starts prefetching. Write access to the QSPI memory space is only used to obtain the prefetch address, not to write to the serial ROM.
Combining this function with the prefetch status polling function described below can reduce the load on the internal bus when reading data from a low-speed serial ROM.

Note: When specifying the prefetch address, write to the QSPI memory space in byte size. Writing in word size or long word size causes a bus error.

42.7.5 Prefetch Status Polling

If a low-speed serial ROM is used, the read cycle from the QSPI memory space has to wait until the end of the SPI bus cycle, which increases the load on the internal bus.
The prefetch status polling function is provided to reduce this load.
Read the SPPFSR.PBLVL[4:0] bits to get the number of prefetched data and perform read access to the QSPI memory space if there is the required number of data.

```
//
// copy 1 Kbyte (32 bit x 256 word) data from serial ROM to SDRAM
//
unsigned long *sptr;                        // pointer for the serial ROM
unsigned long *dptr;                        // pointer for the SDRAM
int i;

SPMR0 |= 0x0040;                            // set PFE bit to enable prefetch
*( (volatile unsigned char *) sptr ) = 0;   // make the TAG valid to start prefetch

for ( i = 0 ; i < 256 ; i++ ) {
   while ( ( SPPFSR & 0x00FF ) < 0x04 ) {   // wait for 4-byte data to be received
   };
   *(dptr++) = *(sptr++);
}
```

Note: Place the polling program outside the QSPI memory space. If the polling program is placed on the serial ROM, the prefetch target is frequently switched to the instruction code, so the effect of polling is lost, the prefetch buffer may not be filled, and an infinite loop may occur.

42.7.6 ROM Read Using the Slave Select Extension Function

If the SPMR0.SSE[1:0] bits are set to a value other than 00b, QSPIX waits for the next ROM read without terminating the SPI bus cycle (while stopping the QSPCLK signal and holding the QSSL signal low) even after receiving data from the serial ROM.

If the address of the next ROM read is a continuation of the current address, the QSPCLK signal is resumed and subsequent data reception continues. If the address of the next ROM read is not a continuation of the current address, the QSSL signal is driven high to end the SPI bus cycle, and then a new SPI bus cycle is started.

This function eliminates the time to transmit instruction codes and addresses, when reading data intermittently from consecutive addresses, enabling efficient data transfer.

The extension time of the QSSL signal can be selected with the SPMR0.SSE[1:0] bits. When the specified time elapses, the QSSL signal goes high and the SPI bus cycle ends automatically. If the SSE[1:0] bits are set to 11b, the QSSL signal is extended infinitely, which increases the power consumption of the serial ROM.

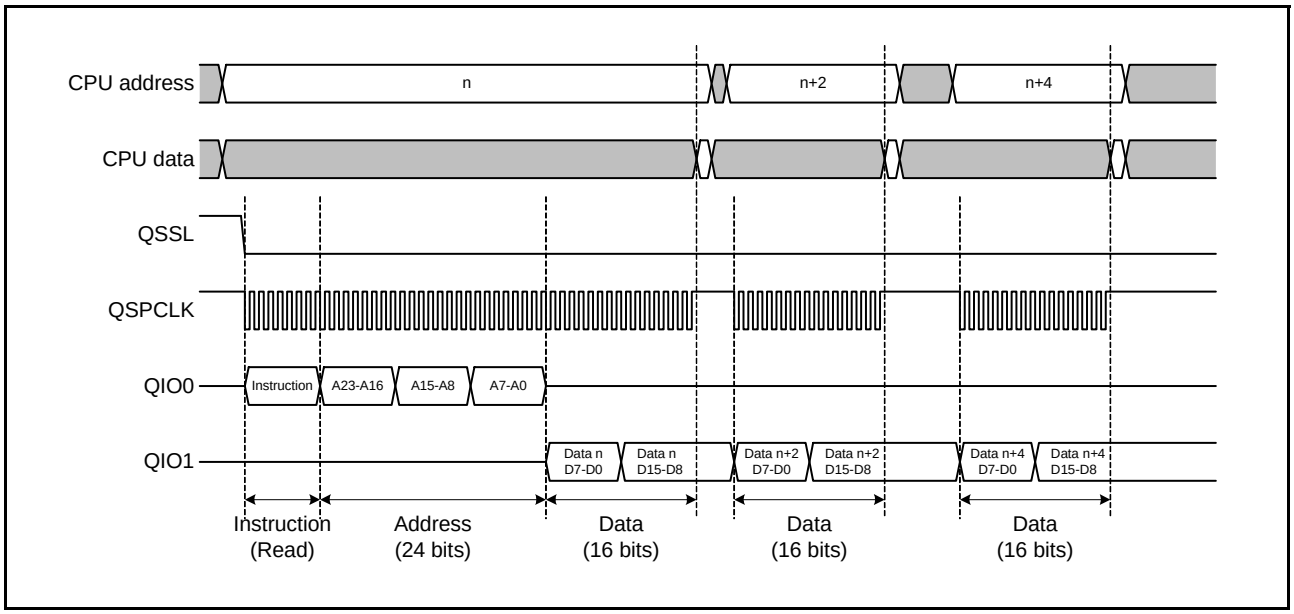

Figure 42.26 Successive Data Read Using the Slave Select Extension Function

42.8 XIP Mode

Some serial ROMs can reduce latency by omitting the instruction code reception for reading the ROM. This function is controlled by the mode data received during the dummy cycles in the previous SPI bus cycle.
In QSPIX, when the SPDCR.XIPE bit is set to 1, the data specified in the SPDCR.MODE[7:0] bits are transmitted during the first two cycles of the dummy cycles as shown in Figure 42.27.
The mode data to enable the XIP mode differs for each serial ROM, so set the MODE[7:0] bits properly according to the serial ROM to be used.

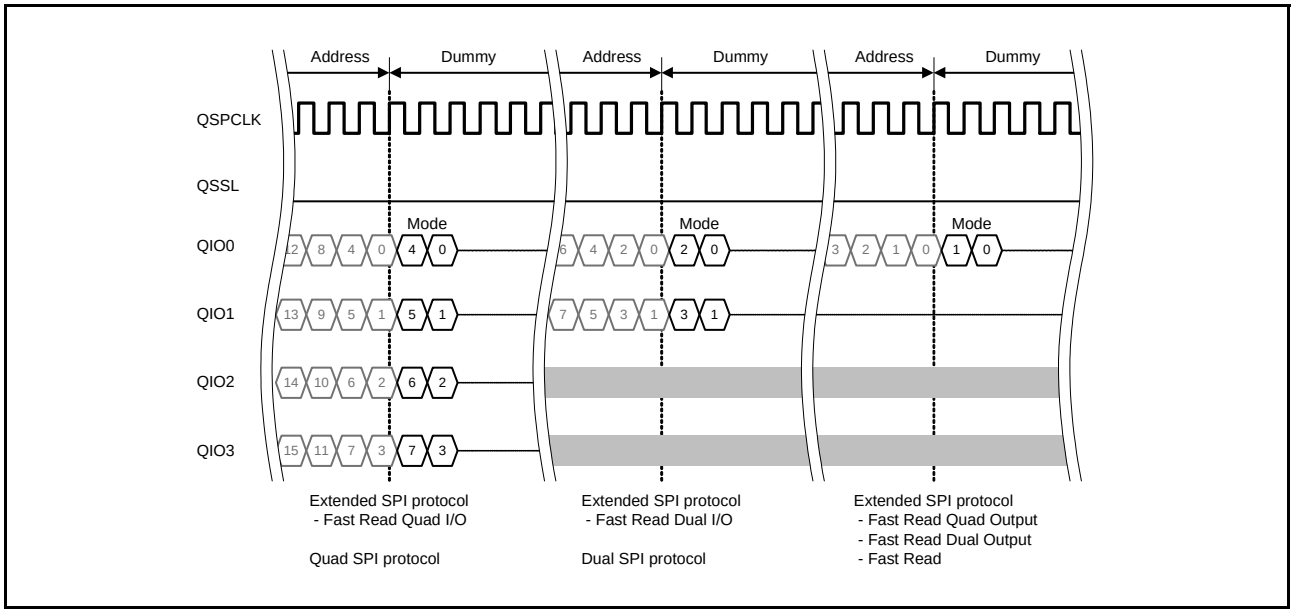

Figure 42.27 XIP Mode Control Data

42.8.1 Activation of the XIP Mode

To activate the XIP mode of the serial ROM, specify the value for activating the XIP mode of the serial ROM to be used in the SPDCR.MODE[7:0] bits, and set the XIPE bit to 1. The value specified in the MODE[7:0] bits is transmitted during the dummy cycles in the next SPI bus cycle. Read the SPDCR.XIPS flag to confirm if the XIP mode has been activated.

42.8.2 Termination of the XIP Mode

To terminate the XIP mode of the serial ROM, specify the value for terminating the XIP mode of the serial ROM to be used in the SPDCR.MODE[7:0] bits, and set the XIPE bit to 0. The value specified in the MODE[7:0] bits is transmitted during the dummy cycles in the next SPI bus cycle. Read the SPDCR.XIPS flag to confirm if the XIP mode has been terminated.

42.9 QIO2 and QIO3 Pin States

The status of the QIO2 and QIO3 pins depend on the instruction selected by the SPMR0.RISEL[2:0] bits.

Table 42.9 QIO2 and QIO3 Pin States

SPMR0.RISEL[2:0] bits	Instruction	QIO2 pin state*1	QIO3 pin state*2
000b	Read	Output the level specified by SPPCR.WP bit (initial output is low)	Output high
001b	Fast Read		
010b	Fast Read Dual Output		
011b	Fast Read Dual I/O		
100b	Fast Read Quad Output	Serial data input or output (Hi-Z during standby)	Serial data input or output (Hi-Z during standby)
101b	Fast Read Quad I/O		
110b	Setting prohibited	—	—
111b			

Note 1. Some serial ROMs may share the QIO2 pin with the WP# pin.
Note 2. Some serial ROMs may share the QIO3 pin with the HOLD# or RESET# pin.

42.10 Indirect Access Mode

In addition to memory read command, the serial ROMs have various commands such as device ID read, erase, program, and status read. To use these commands, QSPIX provides a function to access the serial ROM via I/O register.

42.10.1 Using Indirect Access Mode

To send a commands to the serial ROM via the I/O register, set the SPMR1.AMOD bit to 1 (indirect access mode). Do not perform normal serial ROM reads via the QSPI memory space while the indirect access mode is selected. To return to normal serial ROM reading after using the indirect access mode, set the AMOD bit to 0 (memory mapped mode).

Note: If the XIP mode is activated, terminate the XIP mode before entering indirect access mode.

42.10.2 Generating SPI Bus Cycle during Indirect Access Mode

In indirect access mode, the first access to the SPDR register starts the SPI bus cycle and write to the SPMR1 register ends the SPI bus cycle. The QSSL signal goes low during the SPI bus cycle.
A write to the SPDR register during the SPI bus cycle is converted to one-byte transmission to the SPI bus, and a read from the SPDR register is converted to one-byte reception from the SPI bus.

Note: In indirect access mode, writing to registers other than the SPMR1 and SPDR registers (SPMR0, SPSSCR, SPOCR, SPPFSR, SPSR, SPRIR, SPAMR, SPDCR, SPMR2, SPPCR, and SPUAR) is prohibited.

The following is an example program for indirect access mode.

```
//### CAUTION! ### This code must be outside the serial ROM that is to be controlled.

// Define specific instruction codes of the target serial ROM.
#define Instruction_FREAD 0x0B          // Fast Read
#define Instruction_RDSR 0x05           // Read Status register
#define Instruction_RDID 0x9F           // Read Identification
#define Instruction_WREN 0x06           // Write Enable
#define Instruction_CERA 0xC7           // Chip Erase

unsigned char mfid, mtype, mcap, data, temp;

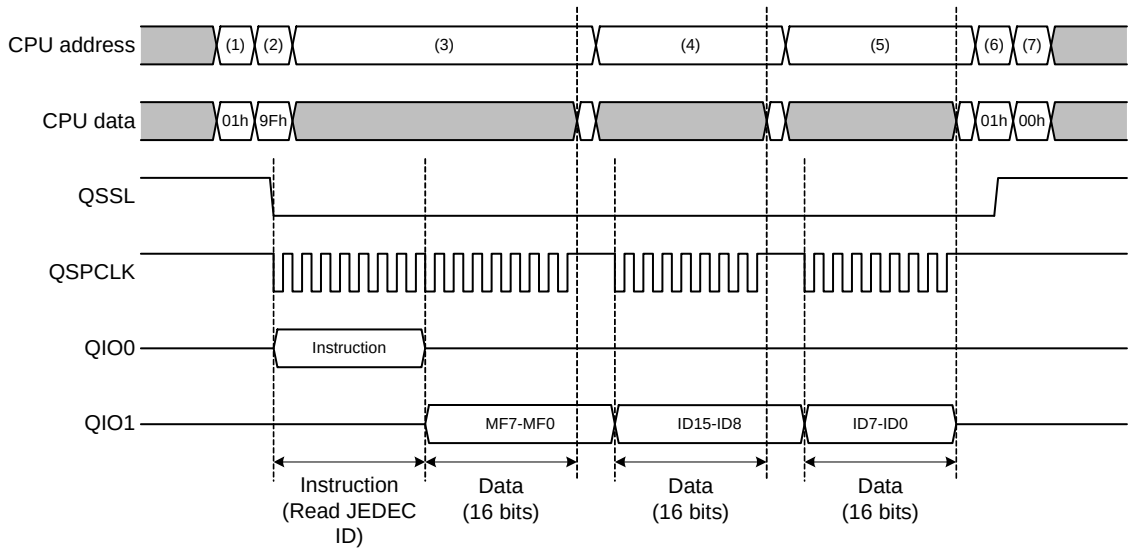
SPMR1 = 0x01;                           // Select indirect access mode

// Get the device identification assigned by JEDEC.
SPDR = Instruction_RDID;                // put “Read Identification” instruction (start SPI bus cycle)
mfid = (unsigned char) SPDR;            // get “Manufacturer Identification”
mtype = (unsigned char) SPDR;           // get “Memory Type”
mcap = (unsigned char) SPDR;            // get “Memory Capacity”
SPMR1 = 0x01;                           // end SPI bus cycle

// Get one byte from the address 0x012345.
SPDR = Instruction_FREAD;               // put “Fast Read” instruction (start SPI bus cycle)
SPDR = 0x01;                            // put upper byte of the address 0x012345
SPDR = 0x23;                            // put middle byte of the target address 0x012345
SPDR = 0x45;                            // put lower byte of the target address 0x012345
temp = (unsigned char) SPDR;            // get one byte dummy code for FAST READ transaction
data = (unsigned char) SPDR;            // get the data
SPMR1 = 0x01;                           // end SPI bus cycle

// Erase All contents.
SPDR = Instruction_WREN;                // put “Write Enable” instruction (start SPI bus cycle)
SPMR1 = 0x01;                           // end SPI bus cycle
SPDR = Instruction_CERA;                // put “Chip Erase” instruction (start SPI bus cycle)
SPMR1 = 0x01;                           // end SPI bus cycle
SPDR = Instruction_RDSR;                // put “Read Status Register” instruction (start SPI bus cycle)
while (SPDR & 0x01){};                  // polling “Write Progress Bit” until completion
SPMR1 = 0x01;                           // end SPI bus cycle

SPMR1 = 0x00;                           // Select memory mapped mode
```



(1)	SPMR1 = 01h;	// Select indirect access mode // Get the device identification assigned by JEDEC
(2)	SPDR = Instruction_RDID;	// Put “Read Identification” instruction (open the transaction)
(3)	mfid = (unsigned char) SPDR;	// Get ID byte-1 “Manufacturer Identification”
(4)	mtype = (unsigned char) SPDR;	// Get ID byte-2 “Memory Type”
(5)	mcap = (unsigned char) SPDR;	// Get ID byte-3 “Memory Capacity”
(6)	SPMR1 = 01h;	// Close the transaction
(7)	SPMR1 = 00h;	// Select memory mapped mode

Figure 42.28 Example of Timing in Indirect Access Mode (Read JEDEC ID)

Note: When Single/Extended SPI protocol is used in indirect access mode, the standard Read or Fast Read instruction must be used to reference the contents of the serial ROM. The QSPIX does not support Fast Read Dual Output, Fast Read Dual I/O, Fast Read Quad Output, or Fast Read Quad I/O instructions in this configuration. When these instructions are required, use memory mapped mode.

42.11 Interrupts

If read access is performed to the QSPI memory space during the indirect access mode, the ROMAE flag becomes 1 and a ROM access error interrupt request (ERI) is generated. The interrupt request is retained until the ROMAE flag is cleared. For details, refer to section 15., Interrupt Controller (ICUE).

42.12 Usage Notes

42.12.1 Settings of the Module Stop Function

QSPIX operation can be disabled or enabled by module stop control register D (MSTPCRD).
After a reset, the QSPIX is stopped. The registers become accessible when it is released from the module stop state. For details, refer to section 11., Low Power Consumption.

42.12.2 Procedure for Changing the Settings of Multiple Control Registers

The QSPIX registers can be changed during the SPI bus cycle. However, if the settings of multiple control registers are changed in succession, the SPI bus cycle may occur before all the settings are completed. Set the registers so that the SPI bus timing specifications can be satisfied at any stage of register setting.
The following is an example program for changing the QSPCLK frequency.

```
//
// Making QSPCLK faster
//
SPMR0 = 0x0041;             // PFE = 1, SSE = 00b, RISEL = 001b (prefetch enable fast read)
SPSSCR = 0x04;              // SSSU = 0, SSHLD = 0, SSHW = 4 (minimum QSSL high width = 5 cycles)
SPOCR = 0x00;               // DUTY = 0, DIV = 0 (1/2 mode)  ### switch clock speed last ###

//
// Making QSPCLK slower
//
SPOCR = 0x06;               // DUTY = 0, DIV = 6 (1/8 mode)  ### switch clock speed first ###
SPSSCR = 0x01;              // SSSU = 0, SSHLD = 0, SSHW = 1 (minimum QSSL high width = 2 cycles)
SPMR0 = 0x0040;             // PFE = 1, SSE = 00b, RISEL = 000b (prefetch enable, standard read)
```

42.12.3 Bus Timeout

When the bus timeout detection is enabled (BSC.BEREN.TOEN bit = 1), a bus timeout may occur if it takes a long time to acquire data from the serial ROM.
In such cases, disable the bus timeout detection or increase the frequency of the QSPIX operating clock.
For details on bus timeout, refer to section 16.7.1.2, Timeout.

42.12.4 Note on the Endian Setting of CPU

The internal expansion bus to which QSPIX is connected is fixed to little endian.
If the CPU is set to big endian (OFSM.MDE.MDE[2:0] bits are 000b), the data arrangement is reversed, so be careful with the data arrangement. Also, in this case, the CPU cannot execute the program directly on the serial ROM.
When executing the program directly on the serial ROM, set the CPU to little endian (OFSM.MDE.MDE[2:0] bits to 111b).

43. CRC Calculator (CRCA)

The CRC (Cyclic Redundancy Check) calculator generates CRC codes.

43.1 Overview

Table 43.1 lists the specifications of the CRC calculator, and Figure 43.1 shows a block diagram of the CRC calculator.

Table 43.1 CRC Specifications

Item	Description	
Data size	8 bits	32 bits
Data for CRC calculation*1	CRC codes are generated for any desired data in 8n-bit units (where n is a whole number)	CRC codes are generated for any desired data in 32n-bit units (where n is a whole number)
CRC processor unit	8-bit parallel processing	32-bit parallel processing
CRC generating polynomial	One of three generating polynomials is selectable • 8-bit CRC $X^8 + X^2 + X + 1$ • 16-bit CRC $X^{16} + X^{15} + X^2 + 1$ $X^{16} + X^{12} + X^5 + 1$	One of two generating polynomials is selectable • 32-bit CRC $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$ $X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$
CRC calculation switching	The order of the bits produced by CRC calculation can be switched for LSB first or MSB first communication	
Low power consumption	Module stop state can be set.	

Note 1. The circuit does not have a function to divide data for calculation into CRC calculation units. Write data in 8-bit or 32-bit units.

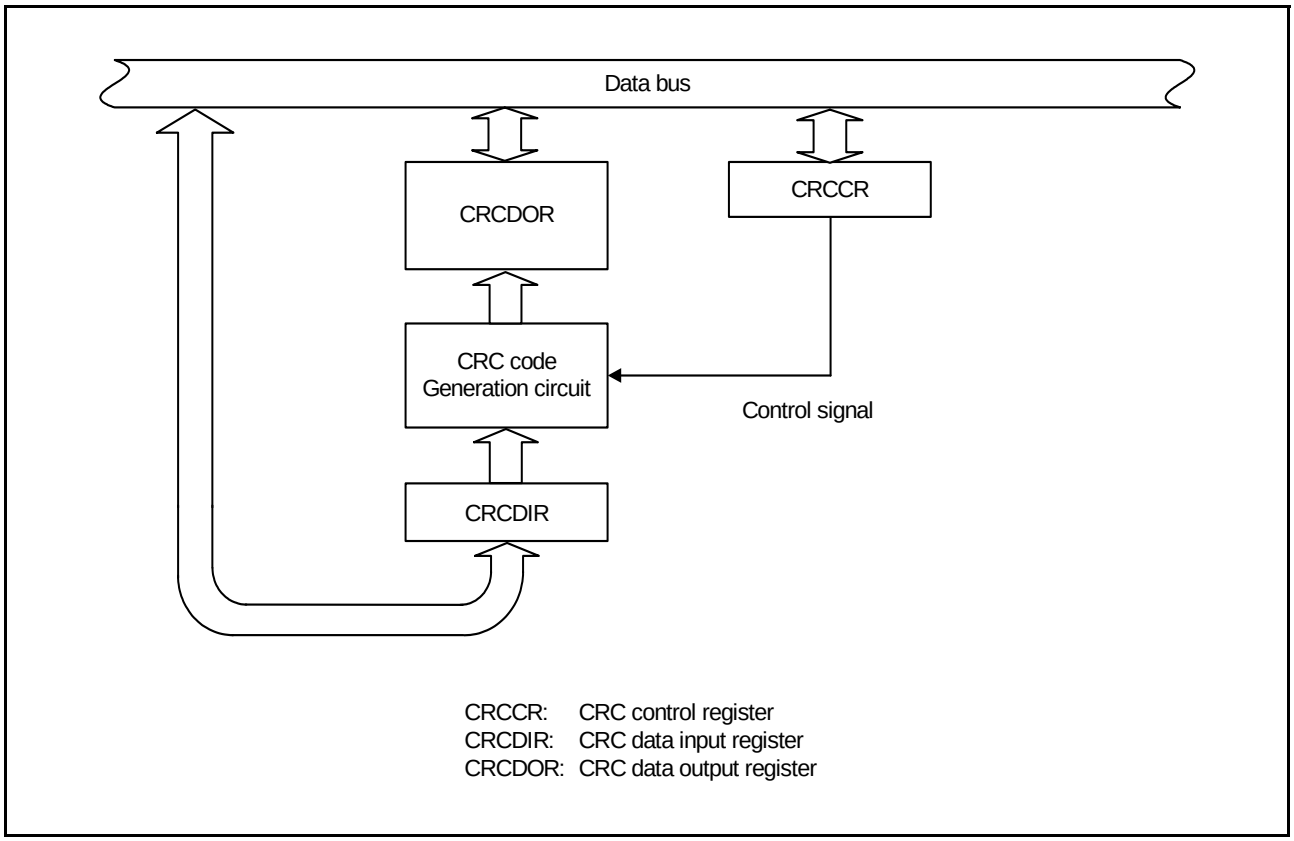


Figure 43.1 CRC Block Diagram

43.2 Register Descriptions

43.2.1 CRC Control Register (CRCCR)

Address(es): CRC.CRCCR 0008 8280h

	b7	b6	b5	b4	b3	b2	b1	b0
	DORCLR	LMS	—	—	—	GPS[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	GPS[2:0]	CRC Generating Polynomial Switching	b2 b1 b0 0 0 0: No calculation is executed. 0 0 1: 8-bit CRC ($X^8 + X^2 + X + 1$) 0 1 0: 16-bit CRC ($X^{16} + X^{15} + X^2 + 1$) 0 1 1: 16-bit CRC ($X^{16} + X^{12} + X^5 + 1$) 1 0 0: 32-bit CRC ($X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$) 1 0 1: 32-bit CRC ($X^{32} + X^{28} + X^{27} + X^{26} + X^{25} + X^{23} + X^{22} + X^{20} + X^{19} + X^{18} + X^{14} + X^{13} + X^{11} + X^{10} + X^9 + X^8 + X^6 + 1$) 1 1 0: No calculation is executed. 1 1 1: No calculation is executed.	R/W
b5 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	LMS	CRC Calculation Switching	0: Generates CRC for LSB first communication. 1: Generates CRC for MSB first communication.	R/W
b7	DORCLR	CRCDOR Register Clear	1: Clears the CRCDOR register. This bit is read as 0.	W*1

Note 1. Only 1 can be written.

LMS Bit (CRC Calculation Switching)

The setting this bit selects the order of the bits of generated CRC codes. The bit selects transmission of the lower-order byte of the CRC code first for LSB first communication, or the higher-order byte first for MSB first communication. For details on the transmission and reception of CRC codes, refer to section 43.3, Operation.

DORCLR Bit (CRCDOR Register Clear)

Write 1 to this bit so that the CRCDOR register is set to 0000 0000h.
This bit is read as 0. Writing 0 to this bit has no effect.

43.2.2 CRC Data Input Register (CRCDIR)

- When 32-bit CRC is selected

Address(es): CRC.CRCDIR 0008 8284h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- When 16-bit or 8-bit CRC is selected

Address(es): CRC.CRCDIR 0008 8284h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

The CRCDIR register is a readable and writable register. Write data for CRC calculation to this register.
When generating a 32-bit CRC, the CRCDIR register should be accessed in longword units. When generating a 8-bit or 16-bit CRC, the CRCDIR register should be accessed in byte units.

43.2.3 CRC Data Output Register (CRCDOR)

- When 32-bit CRC is selected

Address(es): CRC.CRCDOR 0008 8288h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- When 16-bit CRC is selected

Address(es): CRC.CRCDOR 0008 8288h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- When 8-bit CRC is selected

Address(es): CRC.CRCDOR 0008 8288h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

The CRCDOR register is a readable and writable register.
The value after a reset is 0000 0000h. When calculating with the initial value set to a value other than 0000 0000h, rewrite the CRCDOR register.
Writing data to the CRCDIR register stores result of calculation in the CRCDOR register. In addition, following communication data, when a CRC code is written to the CRCDIR register and if the calculation result is 0000 0000h, there is no error in the communication data.
When a 32-bit CRC is selected, the CRCDOR register should be accessed in longword units. When a 16-bit CRC is selected, the CRCDOR register should be accessed in word units. When an 8-bit CRC is selected, the CRCDOR register should be accessed in byte units.

43.3 Operation

The CRC calculator generates CRC codes for use in LSB first or MSB first communication.
The following shows examples of generating the CRC code for input data (F0h) using the 16-bit CRC generating polynomial ($X^{16} + X^{12} + X^5 + 1$). In these examples, the value of the CRC data output register (CRCDOR) is cleared by setting the DORCLR bit to 1 to set the initial value for CRC calculation to 0000 0000h.

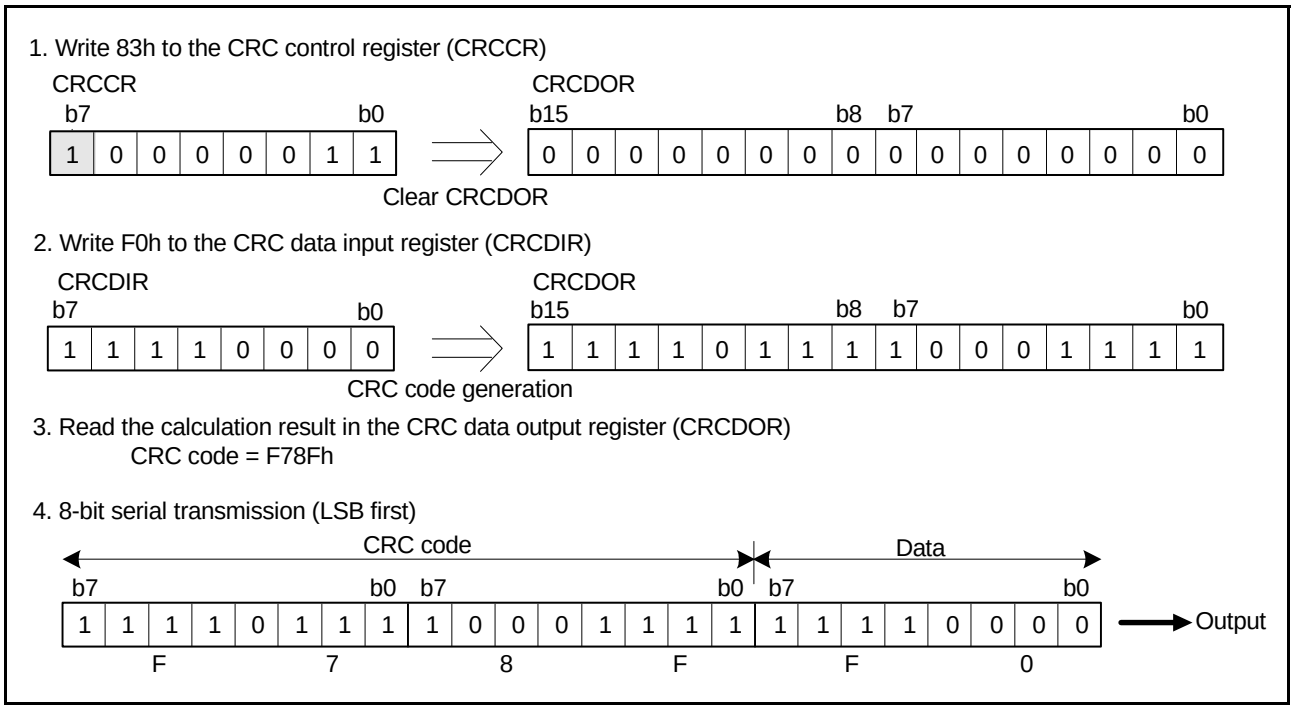

Figure 43.2 LSB First Data Transmission

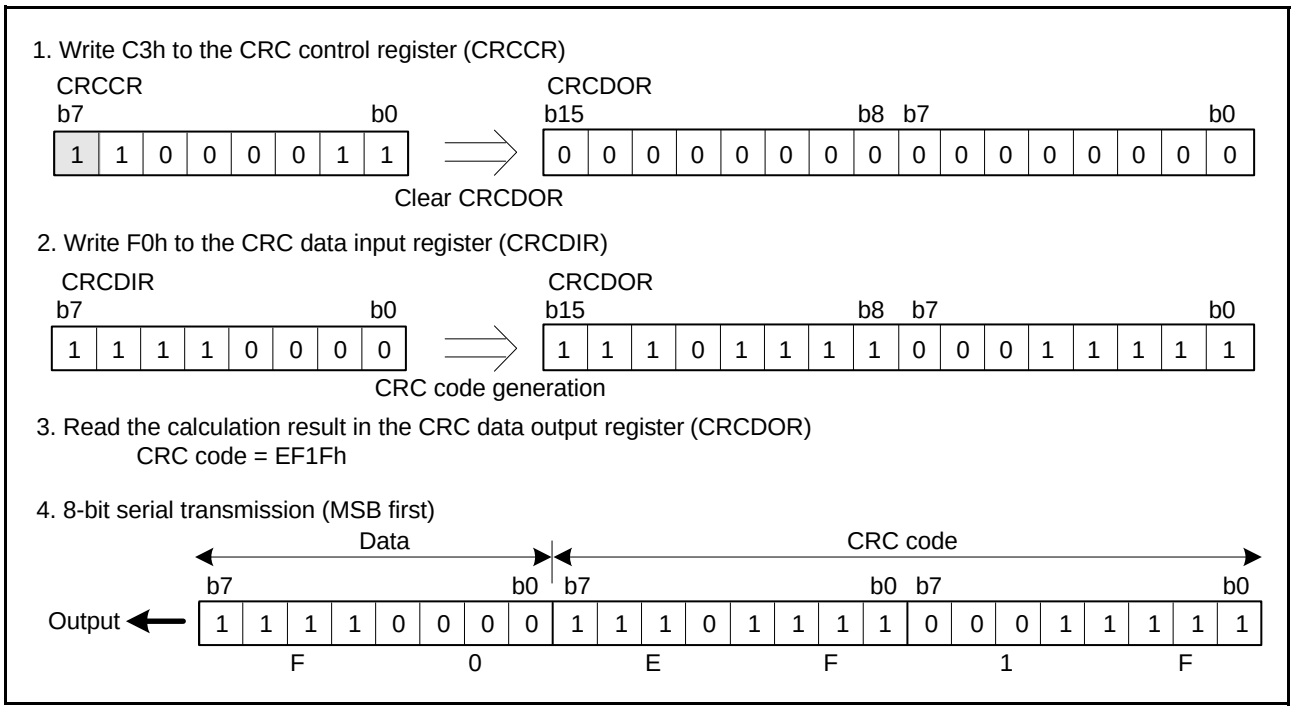

Figure 43.3 MSB First Data Transmission

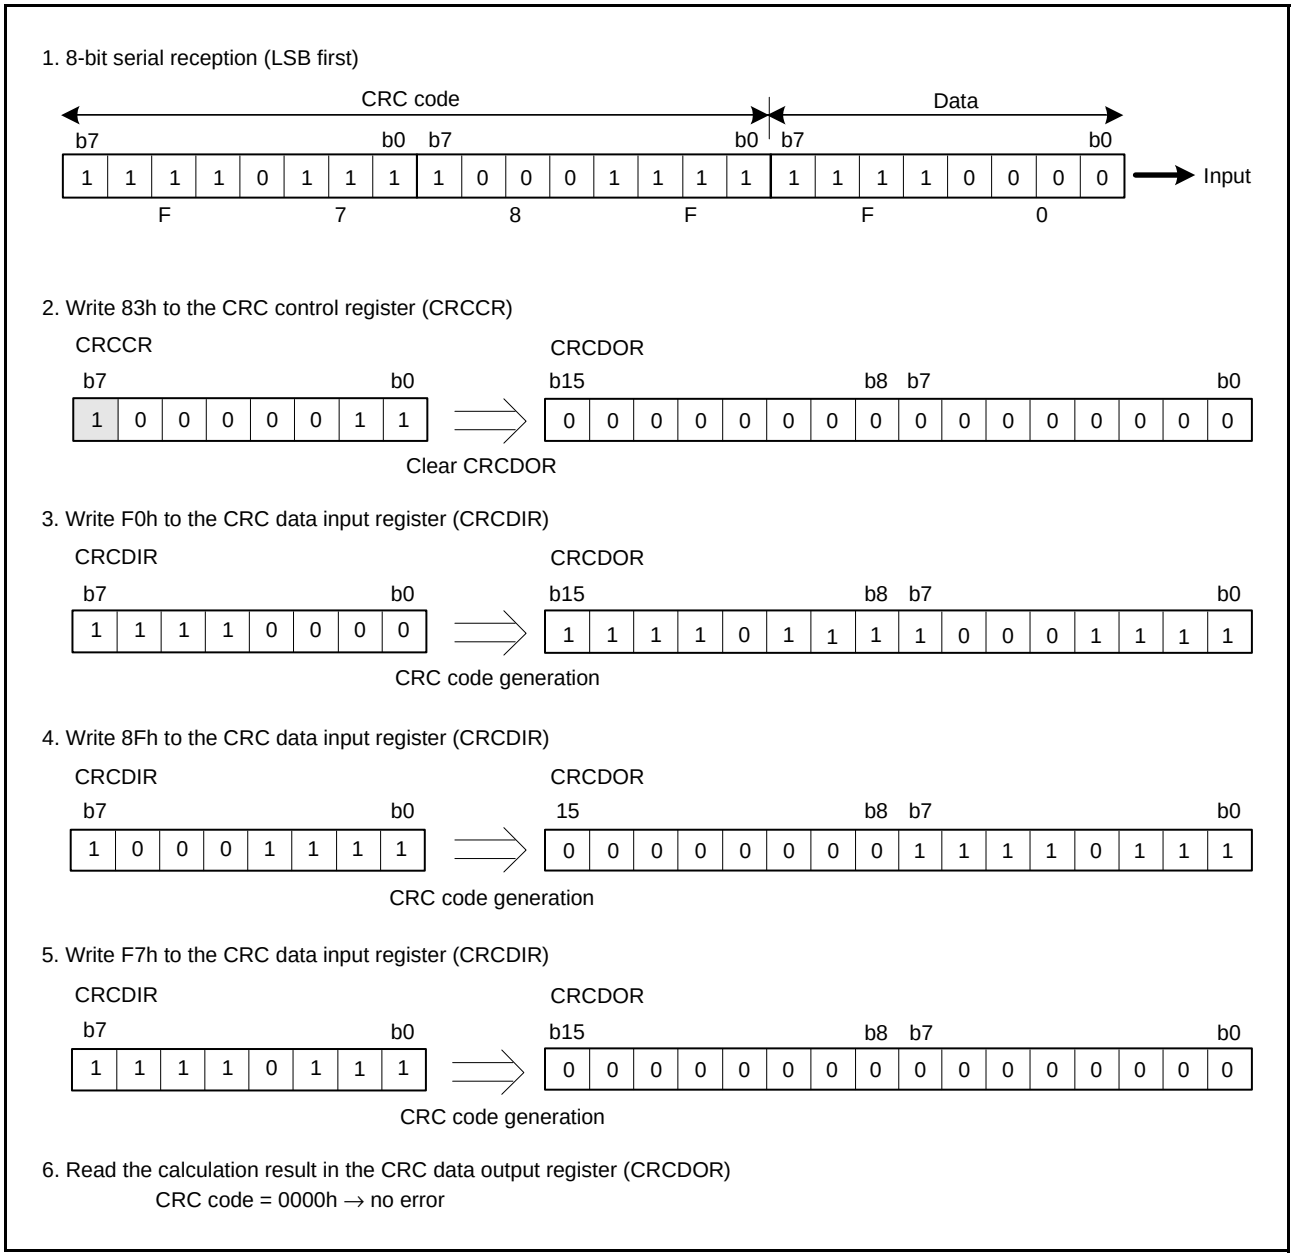

Figure 43.4 LSB First Data Reception

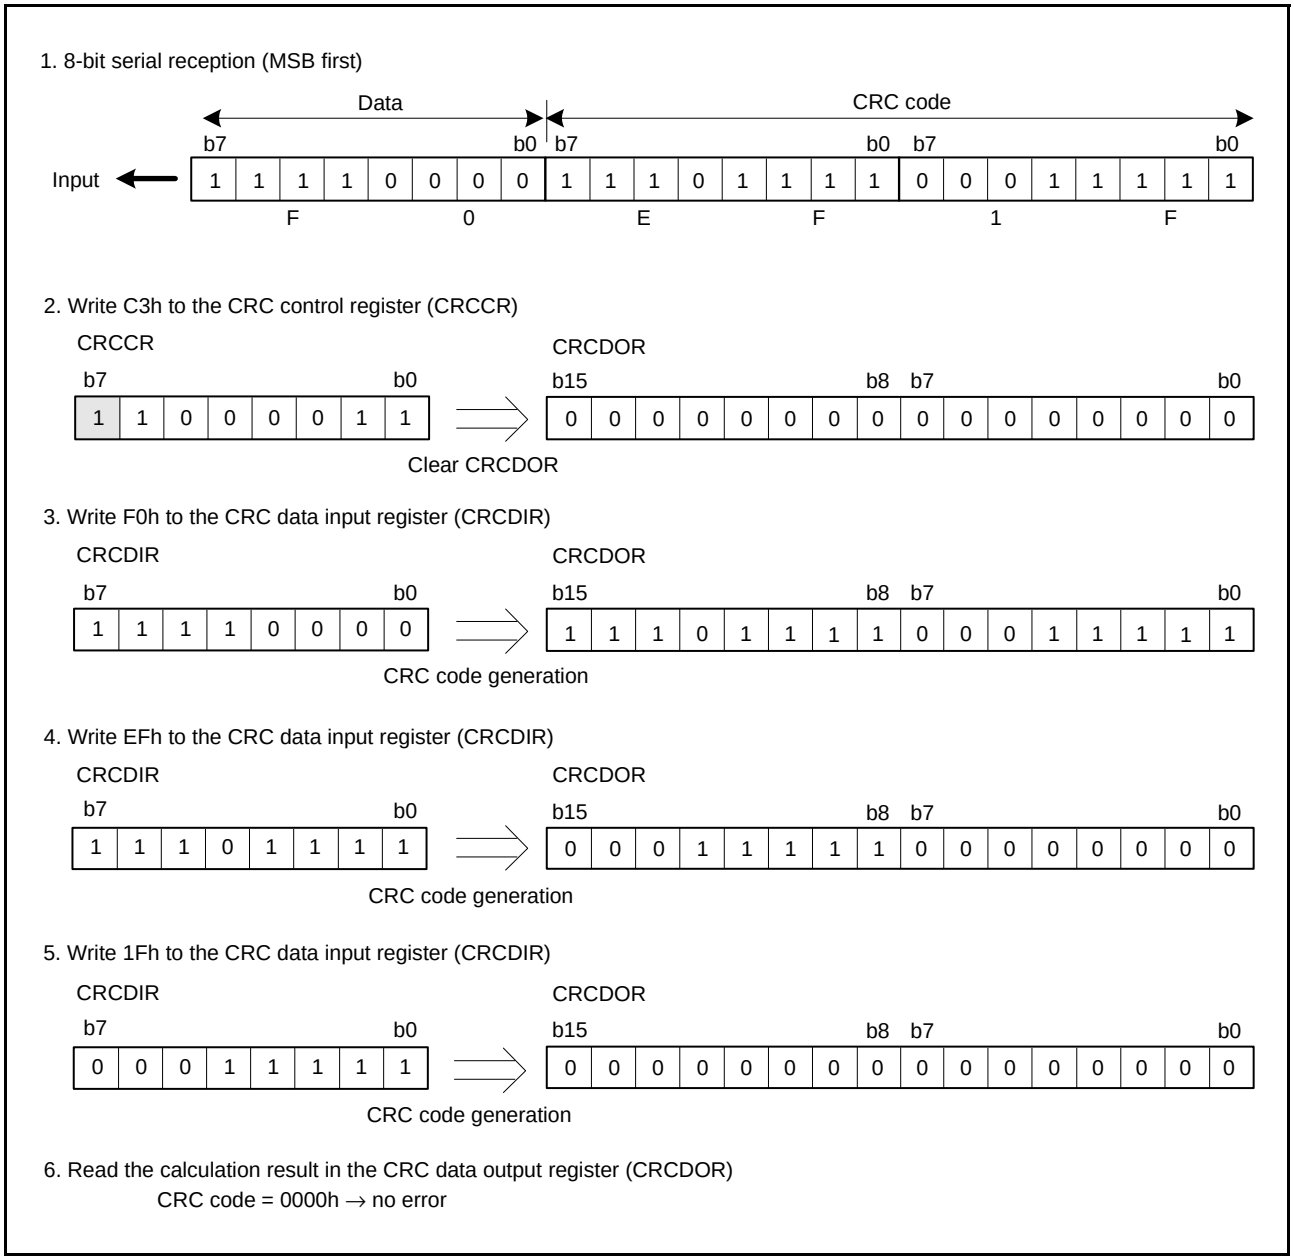

Figure 43.5 MSB First Data Reception

43.4 Usage Notes

43.4.1 Module Stop Function Setting

Operation of the CRC calculator can be disabled or enabled using the module stop control register B (MSTPCRB). After a reset, the CRC is in the module stop state. Register access is enabled by releasing the module stop state.
For details, refer to section 11, Low Power Consumption.

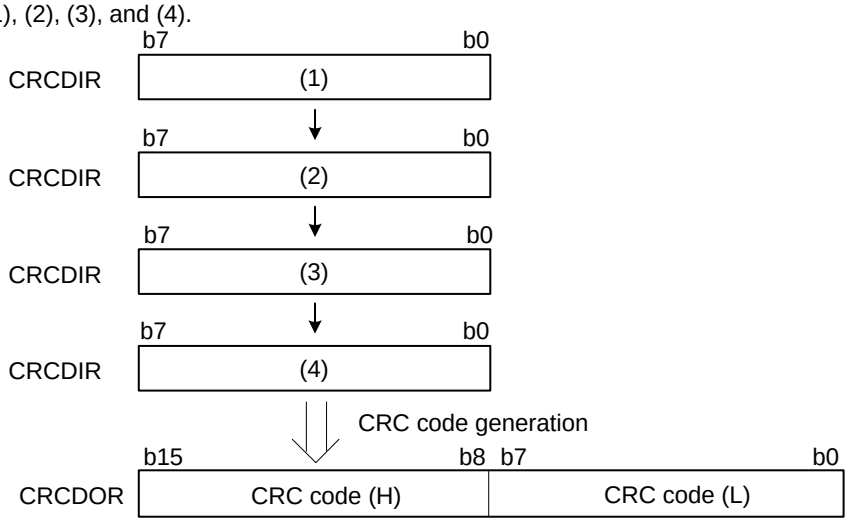
43.4.2 Note on Transmission

Note that the sequence of transmission for the CRC code differs according to whether transmission is LSB first or MSB first.

When transmitting 32-bit data

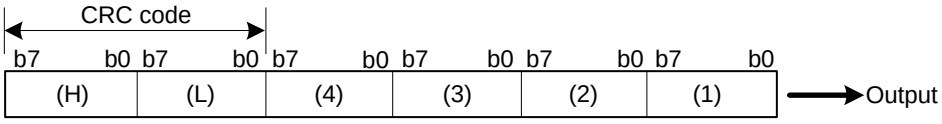
1. CRC code

After specifying the method for generation calculation, write data to the CRCDIR register in the order of (1), (2), (3), and (4).



2. Transmit data

(i) When transmission is LSB first



(ii) When transmission is MSB first

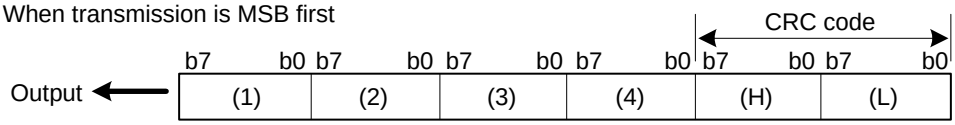


Figure 43.6 LSB First and MSB First Data Transmission

44. SD Host Interface (SDHI)

This MCU incorporates an SD host interface (SDHI) which is compliant with the SD Specifications. When developing host devices that are compliant with the SD Specifications, the user must enter into the SD Host/Ancillary Product License Agreement (SD HALA).

44.1 Overview

Table 44.1 lists the SDHI specifications.

Table 44.1 SDHI Specifications

Item	Description
SD bus interface	• Compatible with SD memory card and SDIO card (**NOT** compatible with the SPI bus interface, embedded SDIO shared bus, 8-bit SD bus, or SDIO suspend/resume functions) • Transfer bus mode selectable from 4-bit wide bus mode or 1-bit default bus mode • Compatible with SD, SDHC, and SDXC formats
Transfer modes	Selectable from high-speed mode or default speed mode
SDHI clock	The SDHI clock is generated by dividing peripheral module clock B (PCLKB) by *n*, where *n* = 1, 2, 4, 8, 16, 32, 64, 128, 256, or 512
Error check functions	• CRC7 (command/response) • CRC16 (transfer data)
Interrupt sources	• Card access interrupt (CACI) • SDIO access interrupt (SDACI) • Card detection interrupt (CDETI) • SD buffer access interrupt (SBFAI)
DMA transfer sources	• DMAC and DTC triggerable by the SBFAI interrupt • SD buffer is read and write accessible using the DMAC and DTC
Other functions	• Card detection • Write protection

Figure 44.1 shows a block diagram of the SDHI.

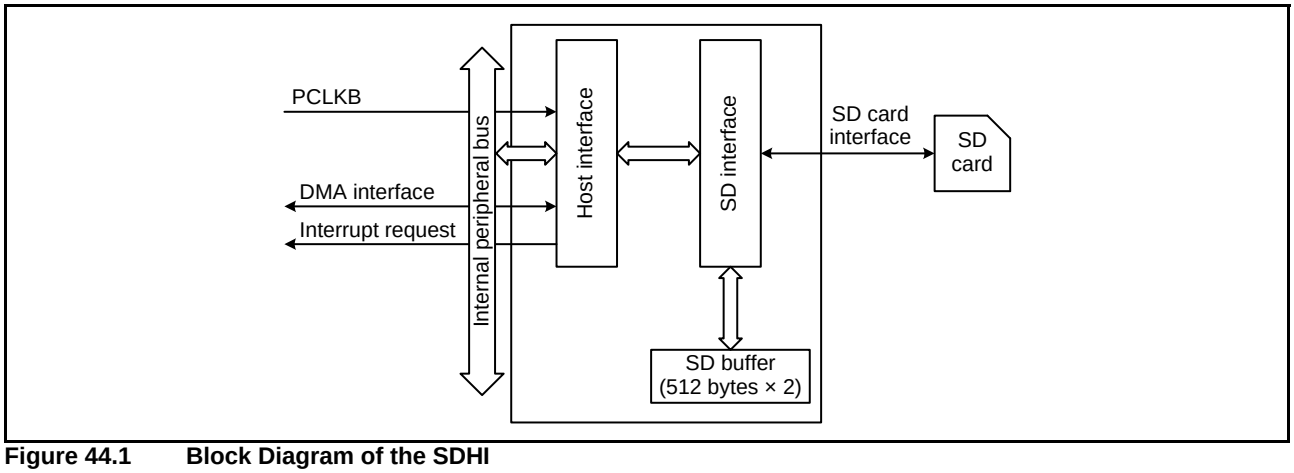

Figure 44.1 Block Diagram of the SDHI

Table 44.2 lists the pin configuration of the SDHI.

Table 44.2 Pin Configuration of the SDHI

Pin Name	I/O	Description
SDHI_CLK	Output	SDHI clock
SDHI_CMD	I/O	Command output, response input
SDHI_D0	I/O	Data 0 (DAT0)
SDHI_D1	I/O	Data 1 (DAT1), SDIO access interrupt
SDHI_D2	I/O	Data 2 (DAT2), read wait
SDHI_D3	I/O	Data 3 (DAT3), SD card detection
SDHI_CD	Input	SD card detection
SDHI_WP	Input	SD card write protection

44.2 Register Details

44.2.1 Command Register (SDCMD)

Address(es): SDHI.SDCMD 0008 AC00h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CMD12AT[1:0]		TRSTP	CMDRW	CMDTP	RSPTP[2:0]			ACMD[1:0]		CMDIDX[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	CMDIDX[5:0]	Command Index Field Value Select	These bits configure the command index field value. The examples below include the bit values for the ACMD[1:0] bits. b7 b0 0 0 0 0 0 1 1 0: CMD6 0 0 0 1 0 0 1 0: CMD18 0 1 0 0 1 1 0 1: ACMD13	R/W
b7, b6	ACMD[1:0]	Command Type Select	b7 b6 0 0: CMD 0 1: ACMD Only set the values listed above.	R/W
b10 to b8	RSPTP[2:0]	Response Type Select *1	b10 b8 0 0 0: Normal mode. Depending on the command, the response type and transfer method are selected by setting the ACMD[1:0] bits and CMDIDX[5:0] bits. At this time, the values for b15 to b11 in this register are invalid. 0 1 1: Expansion mode and no response 1 0 0: Expansion mode and R1, R5, R6, or R7 response 1 0 1: Expansion mode and R1b response 1 1 0: Expansion mode and R2 response 1 1 1: Expansion mode and R3 or R4 response Only set the values listed above.	R/W
b11	CMDTP	Data Transfer Select *2	0: Command does not include data transfer (bc, bcr, or ac) 1: Command includes data transfer (adtc)	R/W
b12	CMDRW	Data Transfer Direction Select *3	0: Write data to the SD card 1: Read data from the SD card	R/W
b13	TRSTP	Block Transfer Select *3	0: Single block transferred 1: Multiple blocks transferred	R/W
b15, b14	CMD12AT[1:0]	CMD12 Automatic Issue Select *4	b15 b14 0 0: CMD12 is automatically issued during multi-block transfer 0 1: CMD12 is not automatically issued during multi-block transfer Only set the values listed above.	R/W
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Some commands cannot be used in normal mode. Refer to Table 44.3 and set the RSPTP[2:0] bits.
Note 2. The CMDTP bit is valid only when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b.
Note 3. Bits CMDRW and TRSTP are valid only when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b, and the CMDTP bit is 1.
Note 4. The CMD12AT[1:0] bits are valid only when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b, and the TRSTP bit is 1.

The command type and response type are set in the SDCMD register. The command type and transfer mode must be set when the RSPTP[2:0] bits are 011b, 100b, 101b, 110b, or 111b. The sequence starts when a value is written to this register. Refer to Table 44.3 for setting examples. Do not write to the SDCMD register when the SDSTS2.CBSY flag is 1.

Table 44.3 lists examples of SDCMD register settings.

Table 44.3 Examples of SDCMD Register Settings

Type	Command Symbol	SDCMD Register Setting	Remarks
CMD	CMD0	0000 0000h	
	CMD2	0000 0002h	
	CMD3	0000 0003h	
	CMD4	0000 0004h	
	CMD5	0000 0705h or 0000 0005h	
	CMD6	0000 1C06h or 0000 0006h	
	CMD7	0000 0007h	When the card is deselected, the SD card does not return a response, so the SDSTS2.RSPTO flag becomes 1.
	CMD8	0000 0408h or 0000 0008h	
	CMD9	0000 0009h	
	CMD10	0000 000Ah	
	CMD11	0000 040Bh or 0000 000Bh	
	CMD12	0000 000Ch	
	CMD13	0000 000Dh	
	CMD15	0000 000Fh	
	CMD16	0000 0010h	
	CMD17	0000 0011h	
	CMD18	0000 0012h	
	CMD20	0000 0514h or 0000 0014h	
	CMD24	0000 0018h	
	CMD25	0000 0019h	
	CMD27	0000 001Bh	
	CMD28	0000 001Ch	
	CMD29	0000 001Dh	
	CMD30	0000 001Eh	
	CMD32	0000 0020h	
	CMD33	0000 0021h	
	CMD38	0000 0026h	
	CMD42	0000 002Ah	
	CMD52	0000 0434h or 0000 0034h	
	CMD53	0000 1C35h	Single block read
		0000 0C35h	Single block write
		0000 7C35h	Multi-block read
		0000 6C35h	Multi-block write
		0000 0035h	The setting to the left can be used regardless of the transfer being single block or multi-block. However, the MSB in the SDARG register (RW flag) must be set to 0 when reading and 1 when writing.
	CMD55	0000 0037h	
	CMD56	0000 0038h	
ACMD	ACMD6	0000 0046h	
	ACMD13	0000 004Dh	
	ACMD22	0000 0056h	
	ACMD23	0000 0057h	
	ACMD41	0000 0069h	
	ACMD42	0000 006Ah	
	ACMD51	0000 0073h	

44.2.2 Argument Register (SDARG)

Address(es): SDHI.SDARG 0008 AC08h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The SDARG register is used for setting the argument field value. Set the SDARG register before setting the SDCMD register. The argument field value of the automatically issued CMD12 is 0000 0000h regardless of the SDARG register value.

44.2.3 Data Stop Register (SDSTOP)

Address(es): SDSTOP 0008 AC10h

	b31	b30	b29	b28	b27	b26	b25	b24
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8
	—	—	—	—	—	—	—	SDBLKCNTEN
Value after reset:	0	0	0	0	0	0	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	STP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STP	Transfer Stop	Data transfer stops when this bit is set to 1.	R/W
b7 to b1	—	Reserved	These bits are 0 when read and cannot be modified.	R
b8	SDBLKCNTEN	Block Count Register Value Select *1	0: SDBLKCNT register value is invalid 1: SDBLKCNT register value is valid	R/W
b31 to b9	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Do not rewrite this bit when the SDSTS2.CBSY flag is 1.

The SDSTOP register stops data transfer. During a multi-block transfer sequence, the SDBLKCNT register value (number of blocks to be transferred) can be set to valid or invalid by setting the SDSTOP register.

STP Bit (Transfer Stop)

When setting the STP bit to 1, set it after the SDSTS1.RSPEND flag becomes 1; when setting the STP bit to 0, set it after the SDSTS1.ACEND flag becomes 1. After a command sequence is complete, the SDHI does not issue CMD12 and the SDSTS1.ACEND flag does not become 1 even if the STP bit is set to 1. When the SDHI is in the busy state after receiving the R1b response, the SDHI does not issue CMD12 even if the STP bit is 1, and after the SDHI is released from

the busy state, the SDSTS1.ACEND flag becomes 1.

- Performing a multi-block transfer
  When the STP bit is set to 1, the SDHI issues CMD12, and the command sequence is stopped. The SD buffer can be accessed even after the STP bit is set to 1, but a buffer access error occurs and the SDSTS2.ILW flag or SDSTS2.ILR flag becomes 1. If the command sequence stops due to a communication error or a timeout, the SDHI does not issue CMD12.
- Performing a single block transfer
  When the STP bit is set to 1 during a single block write access, if there is no data in the SD buffer, the SDSTS1.ACEND flag becomes 1. If there is data in the SD buffer, after the SDHI is released from the busy state, the SDSTS1.ACEND flag becomes 1. When the STP bit is set to 1 during a single block read access, the SDSTS1.ACEND flag becomes 1. Also, CMD12 is not issued even if the STP bit is set to 1 during a single block read access or single block write access.

SDBLKCNTEN Bit (Block Count Register Value Select)

If the SDBLKCNTEN bit is 1 during a multi-block transfer sequence, the SDHI automatically issues CMD12. When the SDCMD.RSPTP[2:0] bits are set to 000b and CMD18 or CMD25 is issued, or if the SDCMD.RSPTP[2:0] bits are set to 011b, 100b, 101b, 110b, or 111b and the SDCMD.TRSTP bit is 1 (multiple blocks transferred), if the SDCMD.CMD12AT[1:0] bits are 00b (CMD12 is automatically issued during multi-block transfer), and the number of transfer blocks reaches the value set in the SDBLKCNT register, the SDHI automatically issues CMD12.
If the command sequence is stopped by a communication error or a timeout, CMD12 is not automatically issued.

44.2.4 Block Count Register (SDBLKCNT)

Address(es): SDHI.SDBLKCNT 0008 AC14h

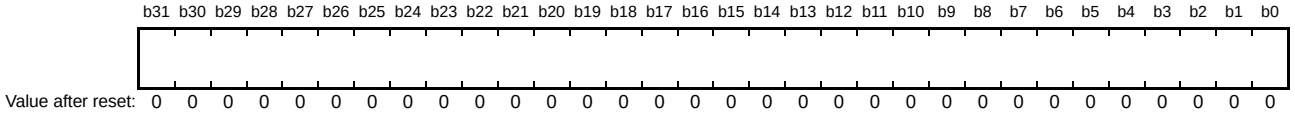
	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

When performing a multi-block transfer, SDBLKCNT is a readable/writable register used to set the number of blocks to be transferred. For example, when the register value is 0000 0001h, 1 block is transferred; when the register value is 0000 FFFFh, 65,535 blocks are transferred; and when the register value is FFFF FFFFh, 4,294,967,295 blocks are transferred. Do not set this register to 0000 0000h. Do not rewrite the SDBLKCNT register when the SDSTS2.CBSY flag is 1.

44.2.5 Response Register 10 (SDRSP10), Response Register 32 (SDRSP32), Response Register 54 (SDRSP54), Response Register 76 (SDRSP76)

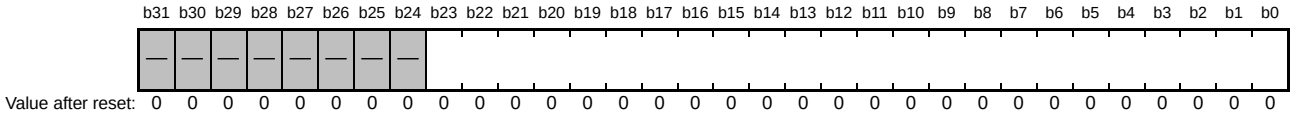
- SDRSP10, SDRSP32, SDRSP54

Address(es): SDHI.SDRSP10 0008 AC18h, SDHI.SDRSP32 0008 AC20h, SDHI.SDRSP54 0008 AC28h



- SDRSP76

Address(es): SDHI.SDRSP76 0008 AC30h



Bit	Symbol	Bit Name	Description	R/W
b23 to b0	—	—	This register stores the response from the SD card.	R
b31 to b24	—	Reserved	These bits are 0 when read.	R

Registers SDRSP10, SDRSP32, SDRSP54, and SDRSP76 are read-only registers that store the response from the SD card. Depending on the type of response from the SD card, the SDHI divides and stores the response among the four registers.

Table 44.4 lists the correspondence between the response type and its storage destination.

Table 44.4 Correspondence Between the Response Type and Its Storage Destination

Response Type	SDRSP10 Register	SDRSP32 Register	SDRSP54 Register	SDRSP76 Register
R1	[39:8]	—	[39:8] *1	—
R1b	[39:8]	—	[39:8] *1	—
R2	[39:8]	[71:40]	[103:72]	[127:104]
R3	[39:8]	—	—	—
R4	[39:8]	—	—	—
R5	[39:8]	—	—	—
R6	[39:8]	—	—	—
R7	[39:8]	—	—	—

Note 1. The response for CMD18 and CMD25 is stored in registers SDRSP10 and SDRSP54. Therefore, even if the SDRSP10 register is overwritten with the response for the automatically transmitted CMD12, the response for CMD18 or CMD25 can be confirmed by reading the SDRSP54 register.

44.2.6 SD Status Register 1 (SDSTS1)

Address(es): SDHI.SDSTS1 0008 AC38h

	b31	b30	b29	b28	b27	b26	b25	b24
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8
	—	—	—	—	—	SDD3MON	SDD3IN	SDD3RM
Value after reset:	0	0	0	0	0	x	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	SDWPMON	—	SDCDMON	SDCDIN	SDCDRM	ACEND	—	RSPEND
Value after reset:	x	0	x	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RSPEND	Response End Detection Flag	0: Response end is not detected 1: Response end is detected	R/(W) *1
b1	—	Reserved	This bit is 0 when read and cannot be modified.	R
b2	ACEND	Access End Detection Flag	0: Access end is not detected 1: Access end is detected	R/(W) *1
b3	SDCDRM	SDHI_CD Removal Flag	0: SD card removal not detected by the SDHI_CD pin 1: SD card removal detected by the SDHI_CD pin	R/(W) *1
b4	SDCDIN	SDHI_CD Insertion Flag	0: SD card insertion not detected by the SDHI_CD pin 1: SD card insertion detected by the SDHI_CD pin	R/(W) *1
b5	SDCDMON	SDHI_CD Pin Monitor Flag	0: SDHI_CD pin level is high *2 1: SDHI_CD pin level is low *2	R
b6	—	Reserved	This bit is 0 when read and cannot be modified.	R
b7	SDWPMON	SDHI_WP Pin Monitor Flag	0: SDHI_WP pin level is high 1: SDHI_WP pin level is low	R
b8	SDD3RM	SDHI_D3 Removal Flag	0: SD card removal not detected by the SDHI_D3 pin 1: SD card removal detected by the SDHI_D3 pin	R/(W) *1
b9	SDD3IN	SDHI_D3 Insertion Flag	0: SD card insertion not detected by the SDHI_D3 pin 1: SD card insertion detected by the SDHI_D3 pin	R/(W) *1
b10	SDD3MON	SDHI_D3 Pin Monitor Flag	0: SDHI_D3 pin level is low 1: SDHI_D3 pin level is high	R
b31 to b11	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. The flag does not change even if set to 1. Writing 0 changes the flag value to 0.
Note 2. The flag changes when the pin level continues for the period set in the SDOPT.CTOP[3:0] bits or longer.

The SDSTS1 register indicates the detection of a response end or access end for a command sequence. The SDSTS1 register also indicates the detection SD card insertion/removal, and indicates the write protection status.
During a multi-block transfer sequence, if CMD12 or CMD52 (SDIO abort) is issued, the ACEND flag becomes 1, but the RSPEND flag remains set to 0.
If the command sequence is stopped due to a communication error or timeout, the ACEND flag or RSPEND flag becomes 1.
After a reset is released, the SDD3MON flag, SDD3IN flag, and SDD3RM flag values are changed according to the status of the SDHI_D3 pin, and their values are changed when data is being transferred in wide bus mode.
Flags to be cleared should be set to 0; flags not being cleared should be set to 1.

RSPEND Flag (Response End Detection Flag)

— This flag becomes 1 under any of the following conditions:

- A response is received.
- A command that does not have a response is issued.
- After the R1b response is received, the SDHI is released from the busy state.
- During a multi-block transmission, after the SDIOMD.C52PUB bit is set to 1, the CMD52 response is received.
- A communication error or timeout causes the command sequence to abort.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

Note: When a command is issued that is absent of data transfer, the RSPEND flag becomes 1 after the command sequence ends.

ACEND Flag (Access End Detection Flag)

— This flag becomes 1 under any of the following conditions:

- During a single block read sequence, the SD buffer read access is completed.
- During a multi-block read sequence, the last block is read from the SD buffer.
- During a multi-block read sequence, if CMD12 is automatically issued, data is read from the SD buffer, and the response for CMD12 is received.
- During a single block write sequence, after a CRC status token is received, the SDHI is released from the busy state.
- During a multi-block write sequence, after a CRC status token is received for the last block, the SDHI is released from the busy state.
- During a multi-block write sequence, when CMD12 is automatically issued, a response busy of the automatically issued CMD12 is received.
- During a multi-block read sequence, when CMD12 is automatically issued, after setting the SDSTOP.STP bit to 1, a response of the automatically issued CMD12 is received.
- During a multi-block write sequence, when CMD12 is automatically issued, after setting the SDSTOP.STP bit to 1, a response busy of the automatically issued CMD12 is received.
- During a multi-block read sequence, after the SDIOMD.IOABT bit is set to 1, the response for CMD52 is received.
- During a multi-block write sequence, after the SDIOMD.IOABT bit is set to 1, the response for CMD52 is received.
- A communication error or timeout causes the command sequence to abort.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

Note: The ACEND flag becomes 1 after the command sequence ends.

SDCDRM Flag (SDHI_CD Removal Flag)

— This flag becomes 1 under the following condition:

- The SDHI_CD pin changes from low to high, and the high period is the period set in the SDOPT.CTOP[3:0] bits or longer.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

SDCDIN Flag (SDHI_CD Insertion Flag)

— This flag becomes 1 under the following condition:

- The SDHI_CD pin changes from high to low, and the low period is the period specified in the SDOPT.CTOP[3:0] bits or longer.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

SDD3RM Flag (SDHI_D3 Removal Flag)

— This flag becomes 1 under the following condition:

- The SDHI_D3 pin changes from high to low, and the low period is at least two PCLKB cycles.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

SDD3IN Flag (SDHI_D3 Insertion Flag)

— This flag becomes 1 under the following condition:

- The SDHI_D3 pin changes from low to high, and the high period is at least two PCLKB cycles.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

44.2.7 SD Status Register 2 (SDSTS2)

Address(es): SDHI.SDSTS2 0008 AC3Ch

	b31	b30	b29	b28	b27	b26	b25	b24
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8
	ILA	CBSY	SDCLKCREN	—	—	—	BWE	BRE
Value after reset:	0	0	1	0	0	0	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	SDD0MON	RSPTO	ILR	ILW	DTO	ENDE	CRCE	CMDE
Value after reset:	x	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMDE	Command Error Detection Flag	0: Command error not detected 1: Command error detected	R/(W) *1
b1	CRCE	CRC Error Detection Flag	0: CRC error not detected 1: CRC error detected	R/(W) *1
b2	ENDE	End Bit Error Detection Flag	0: End bit error not detected 1: End bit error detected	R/(W) *1
b3	DTO	Data Timeout Detection Flag	0: Data timeout not detected 1: Data timeout detected	R/(W) *1
b4	ILW	SDBUFR Illegal Write Access Detection Flag	0: Illegal write access to the SDBUFR register not detected 1: Illegal write access to the SDBUFR register detected	R/(W) *1
b5	ILR	SDBUFR Illegal Read Access Detection Flag	0: Illegal read access to the SDBUFR register not detected 1: Illegal read access to the SDBUFR register detected	R/(W) *1
b6	RSPTO	Response Timeout Detection Flag	0: Response timeout not detected 1: Response timeout detected	R/(W) *1
b7	SDD0MON	SDHI_D0 Pin Status Flag	0: SDHI_D0 pin is low 1: SDHI_D0 pin is high	R
b8	BRE	SDBUFR Read Enable Flag	0: Read access to the SDBUFR register disabled 1: Read access to the SDBUFR register enabled	R/(W) *1
b9	BWE	SDBUFR Write Enable Flag	0: Write access to the SDBUFR register disabled 1: Write access to the SDBUFR register enabled	R/(W) *1
b10	—	Reserved	This bit is 0 when read and cannot be modified.	R
b11	—	Reserved	This bit is 0 when read. Set it to 1 when writing.	R/W
b12	—	Reserved	This bit is 0 when read and cannot be modified.	R
b13	SDCLKCREN	SDCLKCR Write Enable Flag	0: SD bus (CMD and DAT lines) is busy, so write access to the SDCLKCR.CLKEN bit and CLKSEL[7:0] bits is disabled. 1: SD bus (CMD and DAT lines) is not busy, so write access to the SDCLKCR.CLKEN bit and CLKSEL[7:0] bits is enabled.	R
b14	CBSY	Command Sequence Status Flag	0: Command sequence completed 1: Command sequence in progress (busy)	R
b15	ILA	Illegal Access Error Detection Flag	0: Illegal access error not detected 1: Illegal access error detected	R/(W) *1
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. The flag does not change even if set to 1. Writing 0 changes the flag value to 0.

The SDSTS2 register indicates the status of the SD buffer and the status of the SD card. Flags to be cleared should be set to 0; flags not being cleared should be set to 1.

CMDE Flag (Command Error Detection Flag)

The command sequence is stopped when a command error occurs. When the SDIOMD.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence will not be completed. Perform the error processing shown in section 44.3.6.8 or section 44.3.6.9 and complete the command sequence.

— This flag becomes 1 under any of the following conditions:

- The command index field value for the command transmitted differs from the command index field value for the response received.
- The command index field value for the automatically issued CMD12 or CMD52 (which are the commands to stop transfer) differs from the command index field value for the response received.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

CRCE Flag (CRC Error Detection Flag)

The command sequence is stopped when a CRC error occurs. When the SDIOMD.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence will not be completed. Perform the error processing shown in section 44.3.6.8 or section 44.3.6.9 and complete the command sequence.

— This flag becomes 1 under any of the following conditions:

- The received CRC status token is in error (the value of the CRC status is a value other than 010b).
- The read data contains a CRC error.
- The response contains a CRC error.
- The response for the automatically issued CMD12 or CMD52 (which are the commands to stop transfer) contains a CRC error.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

ENDE Flag (End Bit Error Detection Flag)

The command sequence is stopped when an end bit error occurs. When the SDIOMD.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence will not be completed. Perform the error processing shown in section 44.3.6.8 or section 44.3.6.9 and complete the command sequence.

— This flag becomes 1 under any of the following conditions:

- The response length is in error (the end bit could not be detected).
- The read data length is in error (the end bit of the enabled bit could not be detected).
- The CRC status token length is in error (the end bit could not be detected).
- The response length for the automatically issued CMD12 or CMD52 (which are the commands to stop transfer) contains an error (the end bit could not be detected).

— This flag becomes 0 under the following condition:

- The flag is set to 0.

DTO Flag (Data Timeout Detection Flag)

This flag indicates that the data expected to be received during the period specified (set in the SDOPT.TOP[3:0] bits) was not received. However, response timeouts are excluded. The command sequence stops when a data timeout occurs.

— This flag becomes 1 under any of the following conditions:

- After the R1b response is received, the SDHI is busy for the period specified or longer.
- After the CRC status token is received, the SDHI is busy for the period specified or longer.
- After data is written, the CRC status token is not received even after the period specified elapsed.
- After a read command is issued, the read data is not received even after the period specified elapsed.
- After CMD12 is issued during a command sequence, the SDHI is busy for the period specified or longer.
- After the read data is received, the next read data is not received even after the period specified elapsed.
- After the SDHI exits the read wait state, the next read data is not received even after the period specified elapsed.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

ILW Flag (SDBUFR Illegal Write Access Detection Flag)

— This flag becomes 1 under any of the following conditions:

- A value is written to the SDBUFR register while the SDHI is not in the data read or data write command state.
- A value is written to the SDBUFR register while the SD buffer is full.
- A value is written to the SDBUFR register while the CRC status token or CRC status token length is in error.
- After the CRC status token is received, a value is written to the SDBUFR register if the SDHI is busy for the period set in bits SDOPT.TOP[3:0] or longer.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

ILR Flag (SDBUFR Illegal Read Access Detection Flag)

— This flag becomes 1 under any of the following conditions:

- The SDBUFR register is read while the SD buffer is empty.
- The value read from the SDBUFR register includes a CRC error or end bit error.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

RSPTO Flag (Response Timeout Detection Flag)

The command sequence is stopped when a response timeout occurs. When the SDIOMD.C52PUB bit is set to 1 and CMD52 is automatically issued, if a communication error or response timeout occurs, the command sequence will not be completed. Perform the error processing shown in section 44.3.6.8 or section 44.3.6.9 and complete the command sequence.

— This flag becomes 1 under the following condition:

- A response is not received even after 640 SDHI clock cycles or more have elapsed (including the response for the automatically issued CMD12 or CMD52 (which are the commands to stop transfer)).

— This flag becomes 0 under the following condition:

- The flag is set to 0.

SDD0MON Flag (SDHI_D0 Pin Status Flag)

This flag indicates the status of the SDHI_D0 pin. After an erase command is issued, if the DTO flag is 1 and the RSPTO flag is 0, polling can be used to monitor the SDD0MON flag change from 0 to 1, and check that the erase command sequence is complete. If a communication error or timeout occurs during the write sequence, the SDHI_D0 pin may remain low. When the SDHI clock is stopped, the value before the SDHI clock was stopped is retained.

BRE Flag (SDBUFR Read Enable Flag)

— This flag becomes 1 under any of the following conditions:

- During a single block transfer, the data size set in the SDSIZE.LEN[9:0] bits is stored in the SD buffer.
- During a multi-block transfer, the data size set in the SDSIZE.LEN[9:0] bits is stored in one of the two SD buffers.

— This flag becomes 0 under any of the following conditions:

- The bit is set to 0.
- DMA transfer is used to read 1 block of data from the SD buffer.

If the CPU is used to read data from the SDBUFR register, set the BRE flag to 0 before reading the data size *1 set in the SDSIZE.LEN[9:0] bits. Even if the block of data read contains a CRC error or end bit error, the data is stored in the SD buffer and the BRE flag becomes 1.

Note 1. If the transfer data size set in the SDSIZE.LEN[9:0] bits is an odd number, the odd numbered byte is ignored. Refer to section 44.5.2, SDBUFR Register Illegal Write Error for details.

BWE Flag (SDBUFR Write Enable Flag)

— This flag becomes 1 under any of the following conditions:

- During a single block transfer, the SD buffer is empty.
- During a multi-block transfer, bank 1 or bank 2 of the SD buffer is empty.

— This flag becomes 0 under any of the following conditions:

- The flag is set to 0.
- DMA transfer is used to write 1 block of data to the SD buffer.

If the CPU is used to write data to the SDBUFR register, set the BWE flag to 0 before writing the data size *1 set in the SDSIZE.LEN[9:0] bits.

Note 1. If the transfer data size set in the SDSIZE.LEN[9:0] bits is an odd number, the odd numbered byte is ignored. Refer to section 44.5.2, SDBUFR Register Illegal Write Error for details.

SDCLKCREN Flag (SDCLKCR Write Enable Flag)

When a value is written to the SDCMD register, the SDHI starts the command sequence, the SDSTS2.CBSY flag becomes 1, and the SDSTS2.SDCLKCREN flag becomes 0. When the command sequence is complete, after the SDSTS2.CBSY flag becomes 0, eight cycles of the SDHI clock elapse and then the SDSTS2.SDCLKCREN flag becomes 1.

ILA Flag (Illegal Access Error Detection Flag)

— This flag becomes 1 under any of the following conditions:

- A value is written to the SDCMD register when the SDSTS2.CBSY flag is 1.
- The SDCMD.CMDTP bit is set to 1 (command accompanying data transfer), the SDCMD.ACMD[1:0] bits are set to 00b, and the SDCMD.CMDIDX[5:0] bits are set to 001100b (CMD12).

— This flag becomes 0 under the following condition:

- The flag is set to 0.

44.2.8 SD Interrupt Mask Register 1 (SDIMSK1)

Address(es): SDHI.SDIMSK1 0008 AC40h

	b31	b30	b29	b28	b27	b26	b25	b24
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8
	—	—	—	—	—	—	SDD3INM	SDD3RMM
Value after reset:	0	0	0	0	0	0	1	1

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	SDCDINM	SDCDRMM	ACENDM	—	RSPENDM
Value after reset:	0	0	0	1	1	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	RSPENDM	Response End Interrupt Request Mask	0: Response end interrupt request is not masked 1: Response end interrupt request is masked	R/W
b1	—	Reserved	This bit is 0 when read and cannot be modified.	R
b2	ACENDM	Access End Interrupt Request Mask	0: Access end interrupt request is not masked 1: Access end interrupt request is masked	R/W
b3	SDCDRMM	SDHI_CD Removal Interrupt Request Mask	0: SD card removal interrupt request by the SDHI_CD pin not masked 1: SD card removal interrupt request by the SDHI_CD pin masked	R/W
b4	SDCDINM	SDHI_CD Insertion Interrupt Request Mask	0: SD card insertion interrupt request by the SDHI_CD pin not masked 1: SD card insertion interrupt request by the SDHI_CD pin masked	R/W
b7 to b5	—	Reserved	These bits are 0 when read and cannot be modified.	R
b8	SDD3RMM	SDHI_D3 Removal Interrupt Request Mask	0: SD card removal interrupt request by the SDHI_D3 pin not masked 1: SD card removal interrupt request by the SDHI_D3 pin masked	R/W
b9	SDD3INM	SDHI_D3 Insertion Interrupt Request Mask	0: SD card insertion interrupt request by the SDHI_D3 pin not masked 1: SD card insertion interrupt request by the SDHI_D3 pin masked	R/W
b31 to b10	—	Reserved	These bits are 0 when read and cannot be modified.	R

The SDIMSK1 register enables and disables the interrupt requests from the status flags in the SDSTS1 register. Refer to Table 44.8, Interrupt Sources for details on the relationship between the status flags and the requested interrupt source.

44.2.9 SD Interrupt Mask Register 2 (SDIMSK2)

Address(es): SDHI.SDIMSK2 0008 AC44h

	b31	b30	b29	b28	b27	b26	b25	b24
	—	—	—	—	—	—	—	—

Value after reset:	1	0	0	0	1	0	1	1

	b7	b6	b5	b4	b3	b2	b1	b0
	—	RSPTOM	ILRM	ILWM	DTTOM	ENDEM	CRCEM	CMDEM
Value after reset:	0	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	CMDEM	Command Error Interrupt Request Mask	0: Command error interrupt request not masked 1: Command error interrupt request masked	R/W
b1	CRCEM	CRC Error Interrupt Request Mask	0: CRC error interrupt request not masked 1: CRC error interrupt request masked	R/W
b2	ENDEM	End Bit Error Interrupt Request Mask	0: End bit detection error interrupt request not masked 1: End bit detection error interrupt request masked	R/W
b3	DTTOM	Data Timeout Interrupt Request Mask	0: Data timeout interrupt request not masked 1: Data timeout interrupt request masked	R/W
b4	ILWM	SDBUFR Register Illegal Write Interrupt Request Mask	0: Illegal write detection interrupt request for the SDBUFR register not masked 1: Illegal write detection interrupt request for the SDBUFR register masked	R/W
b5	ILRM	SDBUFR Register Illegal Read Interrupt Request Mask	0: Illegal read detection interrupt request for the SDBUFR register not masked 1: Illegal read detection interrupt request for the SDBUFR register masked	R/W
b6	RSPTOM	Response Timeout Interrupt Request Mask	0: Response timeout interrupt request not masked 1: Response timeout interrupt request masked	R/W
b7	—	Reserved	This bit is 0 when read and cannot be modified.	R
b8	BREM	BRE Interrupt Request Mask	0: Read enable interrupt request for the SDBUFR register not masked 1: Read enable interrupt request for the SDBUFR register masked	R/W
b9	BWEM	BWE Interrupt Request Mask	0: Write enable interrupt request for the SDBUFR register not masked 1: Write enable interrupt request for the SDBUFR register masked	R/W
b10	—	Reserved	This bit is 0 when read and cannot be modified.	R
b11	—	Reserved	This bit is 1 when read and cannot be modified.	R
b14 to b12	—	Reserved	These bits are 0 when read and cannot be modified.	R
b15	ILAM	Illegal Access Error Interrupt Request Mask	0: Illegal access error interrupt request not masked 1: Illegal access error interrupt request masked	R/W
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. When the SDIMSK2.BWEM bit is 0 or the SDIMSK2.BREM bit is 0, set the SDDMAEN.DMAEN bit to 0. When the SDDMAEN.DMAEN bit is 1, set the SDIMSK2.BWEM bit to 1 and the SDIMSK2.BREM bit to 1.

The SDIMSK2 register enables and disables the interrupt requests from the status flags in the SDSTS2 register. Refer to Table 44.8 for details on the relationship between the status flags and the requested interrupt source.

44.2.10 SDHI Clock Control Register (SDCLKCR)

Address(es): SDHI.SDCLKCR 0008 AC48h

	b31	b30	b29	b28	b27	b26	b25	b24
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8
	—	—	—	—	—	—	CLKCTRLEN	CLKEN
Value after reset:	0	0	0	0	0	0	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	CLKSEL[7:0]							
Value after reset:	0	0	1	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	CLKSEL[7:0]	SDHI Clock Frequency Select *1	b7 b0 0 0 0 0 0 0 0 0: PCLKB divided by 2 0 0 0 0 0 0 0 1: PCLKB divided by 4 0 0 0 0 0 0 1 0: PCLKB divided by 8 0 0 0 0 0 1 0 0: PCLKB divided by 16 0 0 0 0 1 0 0 0: PCLKB divided by 32 0 0 0 1 0 0 0 0: PCLKB divided by 64 0 0 1 0 0 0 0 0: PCLKB divided by 128 0 1 0 0 0 0 0 0: PCLKB divided by 256 1 0 0 0 0 0 0 0: PCLKB divided by 512 1 1 1 1 1 1 1 1: PCLKB *2 Only set the values listed above.	R/W
b8	CLKEN	SDHI Clock Output Control *1	0: SDHI clock output is disabled (SDHI_CLK signal fixed low) 1: SDHI clock output enabled	R/W
b9	CLKCTRLEN	SDHI Clock Output Automatic Control Select	0: Automatic control of SDHI clock output disabled 1: Automatic control of SDHI clock output enabled	R/W
b31 to b10	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Bits CLKSEL[7:0] and CLKEN cannot be write accessed when the SDSTS2.SDCLKCREN flag is 0.
Note 2. When setting the CLKSEL[7:0] bits to 11111111b or when changing the CLKSEL[7:0] bit values from 11111111b to another value, perform the following steps:
(1) Set the CLKEN bit to 0. Do not change the other bit values.
(2) Change the CLKSEL[7:0] bit values. Do not change the other bit values.
(3) Set the CLKEN bit to 1. Do not change the other bit values.

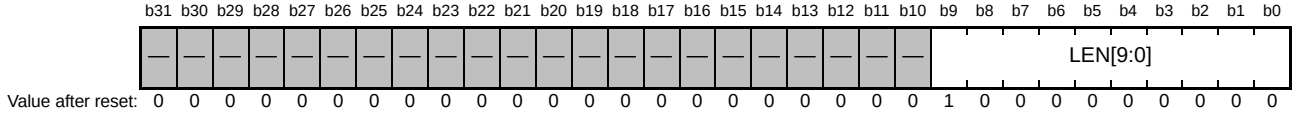
The SDCLKCR register controls the SDHI clock frequency settings and output. Set the CLKEN bit to 1 before writing to the SDCMD register to start a command sequence. Do not write access the SDCLKCR register when the SDSTS2.SDCLKCREN flag is 0.

CLKCTRLEN Bit (SDHI Clock Output Automatic Control Select)

The SDHI clock output automatic control is a function for starting and stopping SDHI clock output only during a command sequence. When this function is enabled, the SDHI starts outputting the SDHI clock after a value is set to the SDCMD register. After the command sequence is complete and eight cycles of the SDHI clock elapse, the SDHI stops outputting the SDHI clock. When the SDCLKCR.CLKEN bit is 0, output from the SDHI_CLK pin becomes low regardless of the CLKCTRLEN bit setting.

44.2.11 Transfer Data Size Register (SDSIZE)

Address(es): SDHI.SDSIZE 0008 AC4Ch



Bit	Symbol	Bit Name	Description	R/W
b9 to b0	LEN[9:0]	Transfer Data Size Setting	Set the transfer data size. *1	R/W
b11 to b10	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R
b31 to b12	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Do not rewrite these bits when the SDSTS2.CBSY flag is 1.

The SDSIZE register is used to set the transfer data size.

LEN[9:0] Bits (Transfer Data Size Setting)

When using single block transfer, the transfer data size can be set from 1 byte to 512 bytes. When CMD12 is automatically issued during a multi-block transfer sequence (CMD18 and CMD25), the transfer data size can only be set to 512 bytes. When CMD12 is not automatically issued during a multi-block transfer sequence, the transfer data size can be set to 32, 64, 128, 256, or 512 bytes. However, a 32-, 64-, 128-, or 256-byte multi-block read transfer can only be performed during an SDIO multi-block transfer (CMD53). Do not set these bits to 0 when using a command that includes data transfer.

44.2.12 Card Access Option Register (SDOPT)

Address SDHI.SDOPT 0008 AC50h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	WIDTH	—	—	—	—	—	—	—	TOP[3:0]				CTOP[3:0]			
Value after reset	0	1	0	0	0	0	0	0	1	1	1	0	1	1	1	0

Bit	Symbol	Bit Name	Description		R/W
b3 to b0	CTOP[3:0]	Card Detection Time Counter *1	b3 b0 0 0 0 0: PCLKB × 2^{10} 0 0 0 1: PCLKB × 2^{11} 0 0 1 0: PCLKB × 2^{12} 0 0 1 1: PCLKB × 2^{13} 0 1 0 0: PCLKB × 2^{14} 0 1 0 1: PCLKB × 2^{15} 0 1 1 0: PCLKB × 2^{16} 0 1 1 1: PCLKB × 2^{17}	b3 b0 1 0 0 0: PCLKB × 2^{18} 1 0 0 1: PCLKB × 2^{19} 1 0 1 0: PCLKB × 2^{20} 1 0 1 1: PCLKB × 2^{21} 1 1 0 0: PCLKB × 2^{22} 1 1 0 1: PCLKB × 2^{23} 1 1 1 0: PCLKB × 2^{24} 1 1 1 1: Do not set this value.	R/W
b7 to b4	TOP[3:0]	Timeout Counter *1	b7 b4 0 0 0 0: SDHI clock × 2^{13} 0 0 0 1: SDHI clock × 2^{14} 0 0 1 0: SDHI clock × 2^{15} 0 0 1 1: SDHI clock × 2^{16} 0 1 0 0: SDHI clock × 2^{17} 0 1 0 1: SDHI clock × 2^{18} 0 1 1 0: SDHI clock × 2^{19} 0 1 1 1: SDHI clock × 2^{20}	b7 b4 1 0 0 0: SDHI clock × 2^{21} 1 0 0 1: SDHI clock × 2^{22} 1 0 1 0: SDHI clock × 2^{23} 1 0 1 1: SDHI clock × 2^{24} 1 1 0 0: SDHI clock × 2^{25} 1 1 0 1: SDHI clock × 2^{26} 1 1 1 0: SDHI clock × 2^{27} 1 1 1 1: Do not set this value.	R/W
b8	—	Reserved	This bit is 0 when read. Set it to 0 when writing.		R/W
b12 to b9	—	Reserved	These bits are 0 when read and cannot be modified.		R
b13	—	Reserved	This bit is 0 when read. Set it to 0 when writing.		R/W
b14	—	Reserved	This bit is 1 when read and cannot be modified.		R
b15	WIDTH	SD Bus Width Select *1	0: Wide bus mode (4 bits) 1: Default bus mode (1 bit)		R/W
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.		R

Note 1. Do not rewrite these bits when the SDSTS2.CBSY flag is 1.

The SD bus width and timeout counter are set in the SDOPT register.

44.2.13 SD Error Status Register 1 (SDERSTS1)

Address(es): SDHI.SDERSTS1 0008 AC58h

	b31	b30	b29	b28	b27	b26	b25	b24
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	—	—	CRCLENE	RDLENE	RSPLENE1	RSPLENE0	CMDE1	CMDE0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMDE0	Command Error Flag 0	0: Command index field value for a command *1 response is error free 1: Command index field value for a command *1 response is in error	R
b1	CMDE1	Command Error Flag 1	0: Command index field value for a command *2 response is error free 1: Command index field value for a command *2 response is in error (by setting the SDCMD.CMDIDX[5:0] bits, the error that occurs by issuing CMD12 is indicated by the CMDE0 flag)	R
b2	RSPLENE0	Response Length Error Flag 0	0: Command *1 response length is error free 1: Command *1 response length is in error	R
b3	RSPLENE1	Response Length Error Flag 1	0: Command *2 response length is error free 1: Command *2 response length is in error (by setting the SDCMD.CMDIDX[5:0] bits, the error that occurs by issuing CMD12 is indicated by the RSPLENE0 flag)	R
b4	RDLENE	Read Data Length Error Flag	0: Read data length error did not occur 1: Read data length error occurred	R
b5	CRCLENE	CRC Status Token Length Error Flag	0: CRC status token length error did not occur 1: CRC status token length error occurred	R
b7, b6	—	Reserved	These bits are 0 when read.	R
b8	RSPCRCE0	Response CRC Error Flag 0	0: No CRC error detected in command *1 response 1: CRC error detected in command *1 response	R
b9	RSPCRCE1	Response CRC Error Flag 1	0: No CRC error detected in command *2 response 1: CRC error detected in command *2 response (the error that occurs for CMD12 with the setting of the SDCMD.CMDIDX[5:0] bits is indicated by the RSPCRCE0 flag)	R
b10	RDCRCE	Read Data CRC Error Flag	0: No CRC error detected in read data 1: CRC error detected in read data	R
b11	CRCTKE	CRC Status Token Error Flag	0: No error detected in CRC status token 1: Error detected in CRC status token	R
b14 to b12	CRCTK[2:0]	CRC Status Token	Store the CRC status token value (normal value is 010b)	R
b15	—	Reserved	This bit is 0 when read.	R
b31 to b16	—	Reserved	These bits are undefined when read.	R

Note 1. Command other than CMD12 or CMD52 which are automatically issued to stop data transfer.
Note 2. CMD12 or CMD52 which are automatically issued to stop data transfer.

The SDERSTS1 register indicates the CRC status token, CRC error, end bit error, and command error.

44.2.14 SD Error Status Register 2 (SDERSTS2)

Address(es): SDHI.SDERSTS2 0008 AC5Ch

	b31	b30	b29	b28	b27	b26	b25	b24

Bit	Symbol	Bit Name	Description	R/W
b0	RSPTO0	Response Timeout Flag 0	0: After a command *1 was issued, a response was received in less than 640 cycles of the SDHI clock. 1: After a command *1 was issued, a response was not received even after 640 cycles or more of the SDHI clock elapsed.	R
b1	RSPTO1	Response Timeout Flag 1	0: After a command *2 was issued, a response was received in less than 640 cycles of the SDHI clock. 1: After a command *2 was issued, a response was not received even after 640 cycles or more of the SDHI clock elapsed (by setting the SDCMD.CMDIDX[5:0] bits, the error that occurs by issuing CMD12 is indicated by the RSPTO0 flag).	R
b2	BSYTO0	Busy Timeout Flag 0	0: After the R1b response was received, the SDHI was released from the busy state during the specified period *3. 1: After the R1b response was received, the SDHI was in the busy state even after the specified period *3 elapsed.	R
b3	BSYTO1	Busy Timeout Flag 1	0: After CMD12 was automatically issued, the SDHI was released from the busy state during the specified period *3. 1: After CMD12 was automatically issued, the SDHI was in the busy state even after the specified period *3 elapsed (by setting the SDCMD.CMDIDX[5:0] bits, the error that occurs by issuing CMD12 is indicated by the BSYTO0 flag).	R
b4	RDTO	Read Data Timeout Flag	After a read command is issued, this flag becomes 1 when read data is not received even after the specified period *3 elapses. After read data is received, this flag becomes 1 when the next block of read data is not received even after the specified period *3 elapses. After the SDHI exits the read wait state, this flag becomes 1 when the next block of read data is not received even after the specified period *3 elapses.	R
b5	CRCTO	CRC Status Token Timeout Flag	0: After data was written to the SD card, a CRC status token was received during the specified period *3. 1: After CRC data was written to the SD card, a CRC status token was not received even after the specified period *3 elapsed.	R
b6	CRCBSYTO	CRC Status Token Busy Timeout Flag	0: After a CRC status token was received, the SDHI was released from the busy state during the specified period *3. 1: After a CRC status token was received, the SDHI is in the busy state even after the specified period *3 elapsed.	R
b31 to b7	—	Reserved	These bits are 0 when read.	R

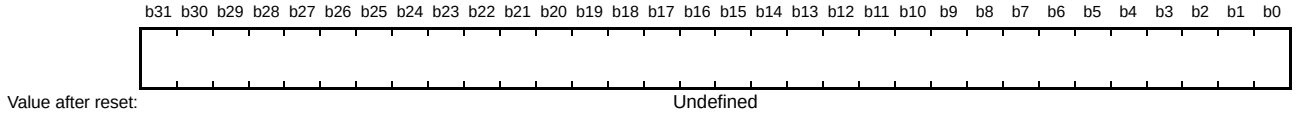
Note 1. Command other than CMD12 or CMD52 which are automatically issued to stop data transfer.
Note 2. CMD12 or CMD52 which are automatically issued to stop transfer.

Note 3. Set the SDOPT.TOP[3:0] bits to select the number of *n* cycles.

The SDERSTS2 register indicates the timeout status.

44.2.15 SD Buffer Register (SDBUFR)

Address(es): SDHI.SDBUFR 0008 AC60h



The SDBUFR register is used when writing data to the SD card and when reading data from the SD card. The SDBUFR register is connected to the SDHI's internal SD buffer. Refer to section 44.3.1, Data Block Format of the SD Card for details on the configuration of the SDBUFR register and the SD buffer.

44.2.16 SDIO Mode Control Register (SDIOMD)

Address(es): SDHI.SDIOMD 0008 AC68h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	C52PUB	IOABT	—	—	—	—	—	RWREQ	—	INTEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	INTEN	SDIO Interrupt Acceptance Enable *1	0: SDIO interrupt accept disabled 1: SDIO interrupt accept enabled	R/W
b1	—	Reserved	This bit is 0 when read and cannot be modified.	R
b2	RWREQ	Read Wait Request	0: SDHI exits read wait state 1: Request for SDHI to enter read wait state	R/W
b7 to b3	—	Reserved	These bits are 0 when read and cannot be modified.	R
b8	IOABT	SDIO Abort	If this bit is set to 1 during multi-block transfer triggered by CMD53, CMD52 is immediately issued, and the command sequence is aborted.	R/W
b9	C52PUB	SDIO None Abort	If this bit is set to 1 during multi-block transfer triggered by CMD53, CMD52 is issued before the transfer process is complete, and the command sequence is completed.	R/W
b31 to b10	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Do not rewrite this bit when the SDSTS2.CBSY flag is 1.

The SDIOMD register controls reception of the SDIO interrupt, controls CMD52 issuance during multi-block transfer, and controls the read wait request. Do not set bits C52PUB and IOABT to 1 at the same time.

RWREQ Bit (Read Wait Request)

If the RWREQ bit is set to 1 during a multi-block read sequence triggered by issuing CMD53, when the current block is done being read, the SDHI enters the read wait state. The method for exiting the read wait state is as follows.

- If the RWREQ bit is set to 0 while the SDHI is in the read wait state, the SDHI exits the read wait state.
- If the IOABT bit is set to 1 while the SDHI is in the read wait state, after CMD52 is issued, the RWREQ bit becomes 0 and the SDHI exits the read wait state.
- If bits C52PUB and RWREQ are simultaneously set to 1 during a multi-block read sequence triggered by issuing CMD53 *1, the SDHI does not automatically exit the read wait state, so after receiving the CMD52 response, set the RWREQ bit to 0.

Note 1. Set bits RWREQ and C52PUB to 1 simultaneously.

If the RWREQ bit is set to 1 while the last block is being transferred during a multi-block read sequence triggered by issuing CMD53, the SDHI will not enter the read wait state, the SDSTS1.ACEND flag becomes 1, and the RWREQ bit becomes 0. Set the RWREQ bit to 1 after the SDSTS1.RSPEND flag becomes 1.

IOABT Bit (SDIO Abort)

- If the IOABT bit is set to 1 during a multi-block transfer sequence triggered by issuing CMD53, the SDHI stops the CMD53 command sequence, and CMD52 is issued. If the command sequence is stopped due to a communication error or timeout, the SDHI does not issue CMD52. The SD buffer can be accessed even after the IOABT bit is set to 1, but the SDSTS2.ILR flag or ILW flag becomes 1, and a buffer access error occurs. Write a value to the SDARG register before setting the IOABT bit to 1.
- During a single block write, if there is no data in the SD buffer when the IOABT bit is set to 1, the SDHI does not issue CMD52, and the SDSTS1.ACEND flag becomes 1. If there is data in the SD buffer when the IOABT bit is set to 1, the SDHI does not issue CMD52, and after the SDHI exits the busy state, the SDSTS1.ACEND flag becomes 1.
- If the IOABT bit is set to 1 during a single block read, the SDHI does not issue CMD52, and the SDSTS1.ACEND flag immediately becomes 1.
- If the SDHI is in the busy state after the R1b response is received and the IOABT bit is set to 1, the SDHI does not issue CMD52, and after the SDHI exits the busy state, the SDSTS1.ACEND flag becomes 1.
- If the IOABT bit is set to 1 after the command sequence is completed, the SDHI does not issue CMD52, and the SDSTS1.ACEND flag does not become 1.
- Set the IOABT bit to 1 after the SDSTS1.RSPEND flag becomes 1.
- Set the IOABT bit to 0 after the SDSTS1.ACEND flag becomes 1.

C52PUB Bit (SDIO None Abort)

- If the C52PUB bit is set to 1 during a multi-block write sequence triggered by issuing CMD53, CMD52 is automatically issued when the SD buffer is empty and the current block write access is complete. The C52PUB bit becomes 0 after the response for CMD52 is received. If the C52PUB bit is 1 while the last block is being transferred, the SDHI does not issue CMD52, and after the SDSTS1.RSPEND flag becomes 1, the C52PUB bit is set to 0.
- If the C52PUB bit and RWREQ bit are set to 1 during a multi-block read sequence triggered by issuing CMD53, the SDHI enters the read wait state after the current block read access is complete, and the SDHI automatically issues CMD52. The C52PUB bit becomes 0 after the response for CMD52 is received. If the C52PUB bit is set to 1 while the last block is being transferred, the SDHI does not issue CMD52, and after the SDSTS1.RSPEND flag becomes 1, the C52PUB bit is set to 0.
- During a multi-block read sequence triggered by issuing CMD53, if the C52PUB bit is set to 1, also set the RWREQ bit to 1.
- Write a value to the SDARG register before setting the C52PUB bit to 1.
- Set the C52PUB bit to 1 after the SDSTS1.RSPEND flag becomes 1.

44.2.17 SDIO Status Register (SDIOSTS)

Address(es): SDHI.SDIOSTS 0008 AC6Ch

	b31	b30	b29	b28	b27	b26	b25	b24
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8
	EXWT	EXPUB52	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	IOIRQ
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IOIRQ	SDIO Interrupt Status Flag	0: SDIO interrupt not accepted 1: SDIO interrupt accepted	R/(W) *1
b2, b1	—	Reserved	These bits are undefined when read. Set them to 1 when writing.	R/W
b13 to b3	—	Reserved	These bits are 0 when read and cannot be modified.	R
b14	EXPUB52	EXPUB52 Status Flag	Indicates the status of the EXPUB52	R/(W) *1
b15	EXWT	EXWT Status Flag	Indicates the status of the EXWT	R/(W) *1
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. The flag value does not change even when set to 1. If 0 is written to this flag, it becomes 0.

The SDIOSTS register indicates the status of the SDIO card access. When clearing a flag, bits to be cleared should be set to 0; bits not being cleared should be set to 1.

IOIRQ Flag (SDIO Interrupt Status Flag)

— This flag becomes 1 under the following condition:

- The SDIO interrupt from the SDIO card is accepted while the SDIOMD.INTEN bit is 1.

— This flag becomes 0 under the following condition:

- The flag is set to 0. *1

Note 1. Access the SDIO card, negate the SDIO interrupt from the SDIO card, and then set the IOIRQ flag to 0. If the SDIO interrupt from the SDIO card is not negated, the IOIRQ flag might become 1 again.

EXPUB52 Flag (EXPUB52 Status Flag)

— This flag becomes 1 under any of the following conditions:

- When multi-block transfer is triggered by CMD53 being issued, the SDIOMD.C52PUB bit is set to 1 while the last block is being transferred.
- When multi-block write is triggered by CMD53 being issued, the SDIOMD.C52PUB bit remains set to 1 while the last block is being transferred.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

EXWT Flag (EXWT Status Flag)

— This flag becomes 1 under the following condition:

- During a multi-block read sequence triggered by CMD53 being issued, the SDIOMD.RWREQ bit is set to 1 while the last block is being transferred.

— This flag becomes 0 under the following condition:

- The flag is set to 0.

44.2.18 SDIO Interrupt Mask Register (SDIOIMSK)

Address(es): SDHI.SDIOIMSK 0008 AC70h

	b31	b30	b29	b28	b27	b26	b25	b24
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8
	EXWTM	EXPUB52M	—	—	—	—	—	—
Value after reset:	1	1	0	0	0	0	0	0

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	IOIRQM
Value after reset:	0	0	0	0	0	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	IOIRQM	IOIRQ Interrupt Mask Control	0: IOIRQ interrupt not masked 1: IOIRQ interrupt masked	R/W
b2, b1	—	Reserved	These bits are 1 when read. Set them to 1 when writing.	R/W
b13 to b3	—	Reserved	These bits are 0 when read and cannot be modified.	R
b14	EXPUB52M	EXPUB52 Interrupt Request Mask Control	0: EXPUB52 interrupt request not masked 1: EXPUB52 interrupt request masked	R/W
b15	EXWTM	EXWT Interrupt Request Mask Control	0: EXWT interrupt request not masked 1: EXWT interrupt request masked	R/W
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

The SDIOIMSK register enables and disables the interrupt requests from the status flags in the SDIOSTS register. Refer to Table 44.8, Interrupt Sources for details on the relationship between the status flags and the requested interrupt source.

44.2.19 DMA Transfer Enable Register (SDDMAEN)

Address(es): SDHI.SDDMAEN 0008 ADB0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DMAEN	—
Value after reset:	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b1	DMAEN	DMA Transfer Enable *1 *2	0: Using DMAC and DTC to access the SDBUFR register is disabled 1: Using DMAC and DTC to access the SDBUFR register is enabled	R/W
b3, b2	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R
b4	—	Reserved	This bit is 1 when read. Set it to 1 when writing.	R
b5	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b7, b6	—	Reserved	These bits are 0 when read and cannot be modified.	R
b9, b8	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b11, b10	—	Reserved	These bits are 0 when read and cannot be modified.	R
b12	—	Reserved	This bit is 1 when read. Set it to 1 when writing.	R
b31 to b13	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Do not rewrite this bit when the SDSTS2.CBSY bit is 1.
Note 2. When the SDIMSK2.BWEM bit is 0 or the SDIMSK2.BREM bit is 0, set the SDDMAEN.DMAEN bit to 0. When the SDDMAEN.DMAEN bit is 1, set the SDIMSK2.BWEM bit to 1 and the SDIMSK2.BREM bit to 1.

The SDDMAEN register enables and disables DMA transfer.

DMAEN Bit (DMA Transfer Enable)

When using DMA transfer to access the SD buffer, set the DMAEN bit to 1 before setting the SDCMD register.

44.2.20 SDHI Software Reset Register (SDRST)

Address(es): SDHI.SDRST 0008 ADC0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SDRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	SDRST	SDHI Software Reset Control	0: SDHI software reset 1: SDHI software reset released	R/W
b2, b1	—	Reserved	These bits are 1 when read. Set them to 1 when writing.	R
b31 to b3	—	Reserved	These bits are 0 when read and cannot be modified.	R

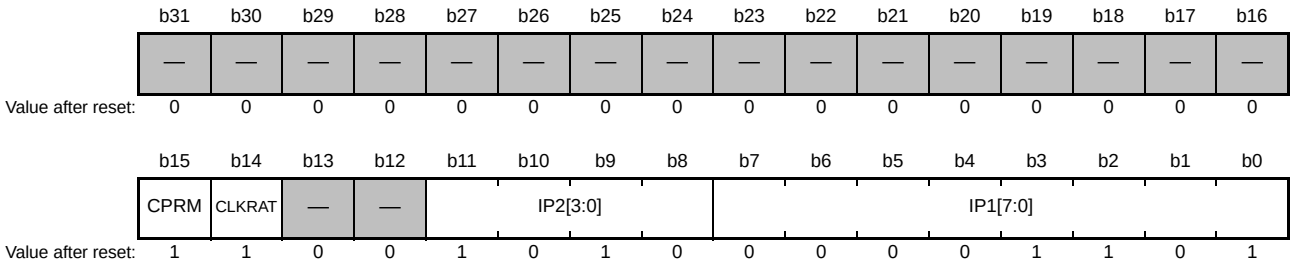
Table 44.5 lists the bits and flags initialized by the SDHI software reset.

Table 44.5 Bits and Flags Initialized by the SDHI Software Reset

Register	Bit/Flag
SDSTOP	SDBLKCNTEN
SDSTS1	RSPEND, ACEND
SDSTS2	CMDE, CRCE, ENDE, DTO, ILW, ILR, RSPTO, SDD0MON, BRE, BWE, SDCLKCREN, ILA
SDCLKCR	CLKEN
SDOPT	CTOP[3:0], TOP[3:0], WIDTH Bits b8 and b13 in the SDOPT register are also initialized by the SDHI software reset.
SDERSTS1	CMDE0, CMDE1, RSPLENE0, RSPLENE1, RDLENE, CRCLENE, RSPCRCE0, RSPCRCE1, RDCRCE, CRCTKE, CRCTK[2:0]
SDERSTS2	RSPTO0, RSPTO1, BSYTO0, BSYTO1, RDTO, CRCTO, CRCBSYTO
SDIOSTS	IOIRQ, EXPUB52, EXWT

44.2.21 Version Register (SDVER)

Address(es): SDHI.SDVER 0008 ADC4h



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	IP1[7:0]	IP Version 1	IP version 1	R
b11 to b8	IP2[3:0]	IP Version 2	IP version 2	R
b13, b12	—	Reserved	These bits are 0 when read.	R
b14	CLKRAT	Operating Clock Condition	0: SDHI clock frequency = PCLKB frequency not supported 1: SDHI clock frequency = PCLKB frequency supported	R
b15	CPRM	CPRM Function Select	0: CPRM function is enabled 1: CPRM function is disabled	R
b31 to b16	—	Reserved	These bits are 0 when read.	R

The SDVER register indicates the SDHI version.

44.2.22 Swap Control Register (SDSWAP)

Address(es): SDHI.SDSWAP 0008 ADE0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	BRSWP	BWSWP	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is 0 when read and cannot be modified.	R
b1	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b2	—	Reserved	This bit is 0 when read and cannot be modified.	R
b4, b3	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b5	—	Reserved	This bit is 0 when read and cannot be modified.	R
b6	BWSWP	SDBUFR Swap Write *1	0: Normal write operation 1: Swap the byte endian before writing to the SDBUFR register	R/W
b7	BRSWP	SDBUFR Swap Read *1	0: Normal read operation 1: Swap the byte endian before reading the SDBUFR register	R/W
b10 to b8	—	Reserved	These bits are 0 when read and cannot be modified.	R
b12, b11	—	Reserved	These bits are 0 when read. Set them to 0 when writing.	R/W
b14, b13	—	Reserved	These bits are 0 when read and cannot be modified.	R
b15	—	Reserved	This bit is 0 when read. Set it to 0 when writing.	R/W
b31 to b16	—	Reserved	These bits are 0 when read and cannot be modified.	R

Note 1. Do not rewrite this bit when the SDSTS2.CBSY flag is 1.

The SDSWAP register is used to select whether or not the byte endian is swapped when accessing the SDBUFR register. Refer to section 44.3.1 for details on the differences in accessing the SDBUFR register based on the SDSWAP register value.

44.3 SDHI Operation

44.3.1 Data Block Format of the SD Card

The SDHI has a default bus mode (1-bit width) that uses just the SDHI_D0 pin as a data line and a wide bus mode (4-bit width) that uses pins SDHI_D0 to SDHI_D3. Figure 44.2 shows the transfer format when the SDOPT.WIDTH bit is 1 (default bus mode), and Figure 44.3 shows the transfer format when the SDOPT.WIDTH bit is 0 (wide bus mode).

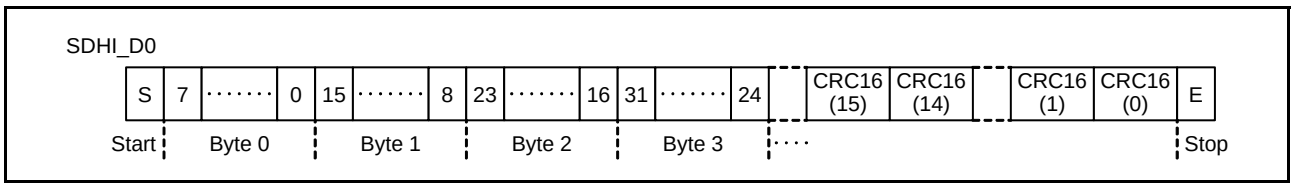


Figure 44.2 Transfer Format in Default Bus Mode

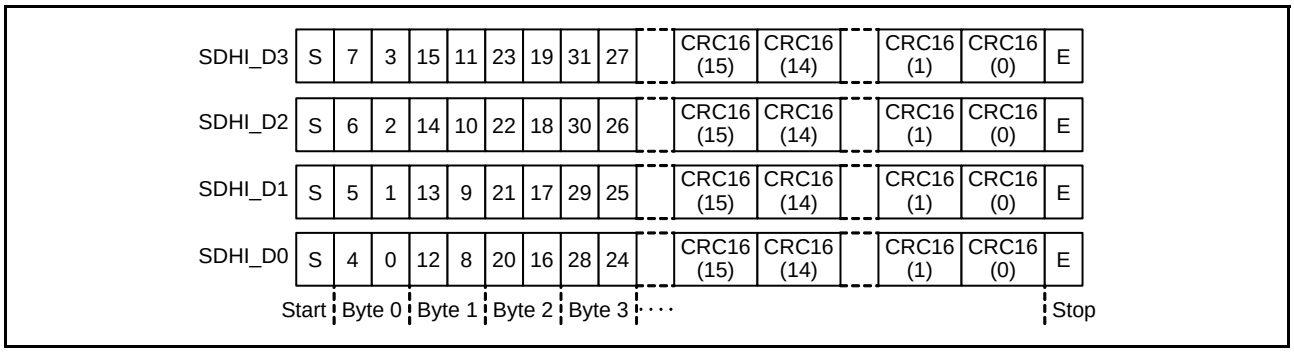

Figure 44.3 Transfer Format in Wide Bus Mode

44.3.2 SD Buffer and the SDBUFR Register

The SDHI transfers data to an SD card via its internal SD buffer. The SD buffer is comprised of a double buffer, and each buffer is 512 bytes. Figure 44.4 shows the data configuration of a single buffer of the SD buffer's double buffer.

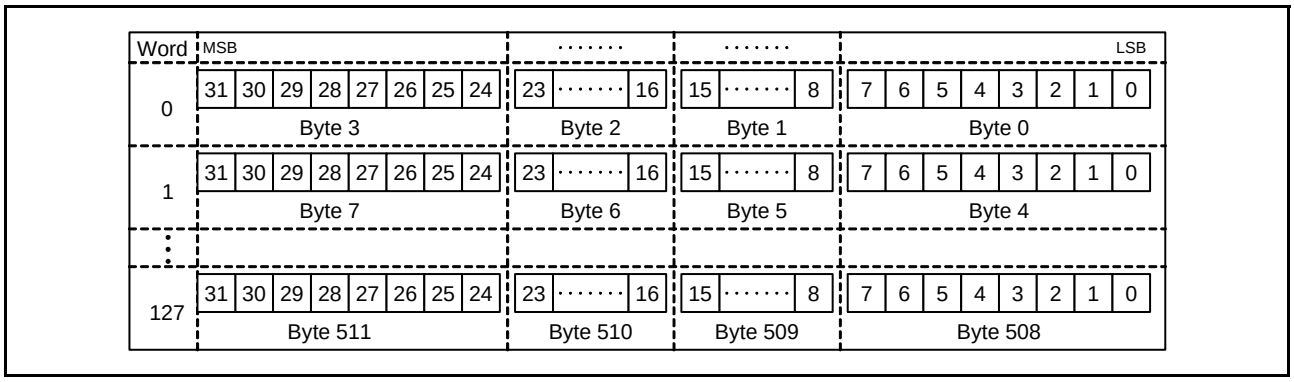

Figure 44.4 Data Configuration of Single Buffer in the SD Buffer

Access to the SD buffer is done via the SDBUFR register. If data is written to the SDBUFR register while the SDSWAP.BWSWP bit is 1, the SDHI swaps the endian for the byte, and stores the data in the SDBUFR register. If data is read from the SDBUFR register while the SDSWAP.BRSWP bit is 1, the data of the endian for the byte that was swapped can be read. Figure 44.5 shows the data alignment when reading the SDBUFR register.

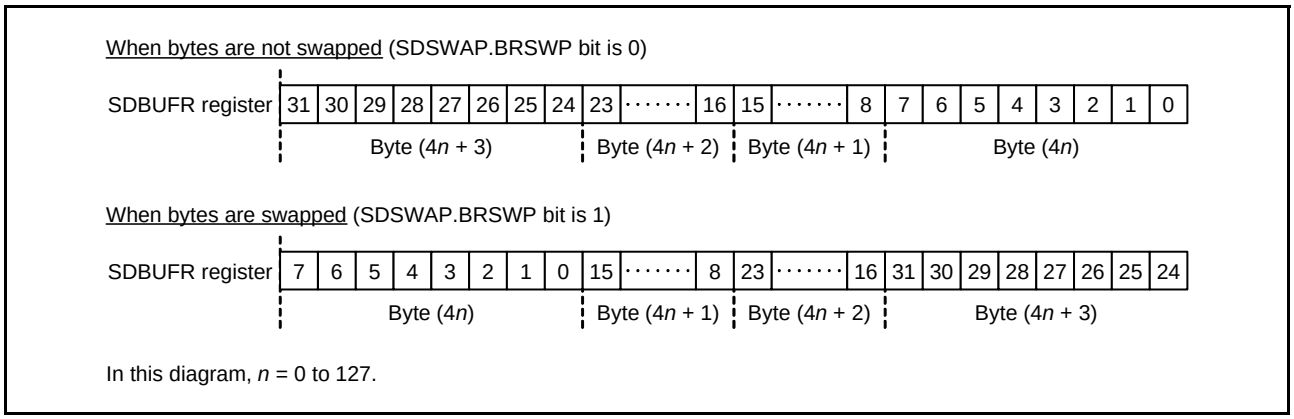

Figure 44.5 Data Alignment When Reading the SDBUFR Register

44.3.3 SD Card Detection

The SDHI can detect an SD card using either the SDHI_CD pin or SDHI_D3 pin.

44.3.3.1 Using the SDHI_CD Pin to Detect an SD Card

Figure 44.6 shows the timing chart for SD card detection using the SDHI_CD pin. The SDHI_CD pin is connected to the card detection switch of the SD card connector, and is pulled-up by the MCU. The pull-up resistance value is determined by the specifications of the host device. Note that there are some SD card sockets whose card detection switches become open when the SD card is inserted.

- Detecting SD card insertion
  The signal from the SDHI_CD pin becomes low when an SD card is inserted. This causes the SDSTS1.SDCDIN flag to become 1 if the SDHI_CD pin is low for the number of cycles set in the SDOPT.CTOP[3:0] bits. The SDSTS1.SDCDIN flag is cleared by setting it to 0.
- Detecting SD card removal
  The signal from the SDHI_CD pin becomes high when the SD card is removed. This causes the SDSTS1.SDCDRM flag to become 1 if the SDHI_CD pin is high for the number of cycles set in the SDOPT.CTOP[3:0] bits. The SDSTS1.SDCDRM flag is cleared by setting it to 0.

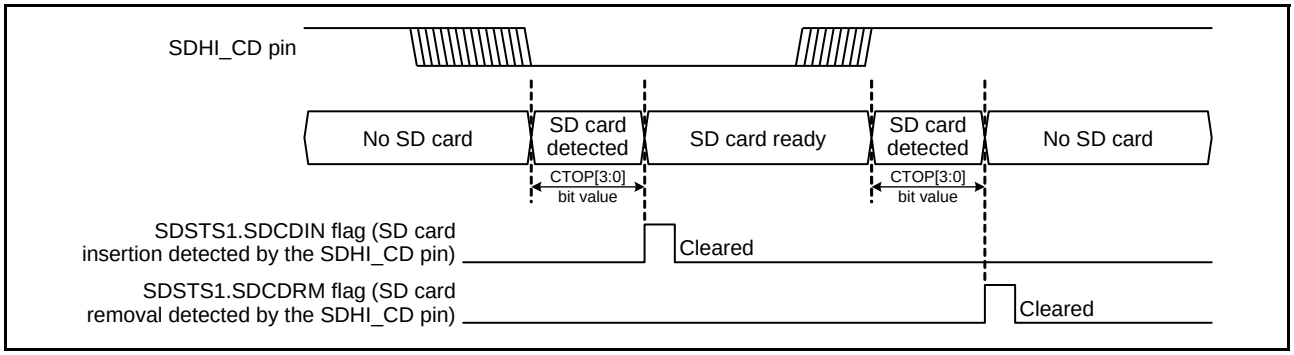

Figure 44.6 SD Card Detection Using the SDHI_CD Pin

44.3.3.2 Using the SDHI_D3 Pin to Detect an SD Card

Figure 44.7 shows the timing chart for SD card detection using the SDHI_D3 pin. The SDHI_D3 pin is pulled-down by the MCU. The pull-down resistance value is determined by the specifications of the host device.

- Detecting SD card insertion
  The signal from the SDHI_D3 pin becomes high when an SD card is inserted. This causes the SDSTS1.SDD3IN flag to become 1. The SDSTS1.SDD3IN flag is cleared by setting it to 0.
- Detecting SD card removal
  The signal from the SDHI_D3 pin becomes low when the SD card is removed. This causes the SDSTS1.SDD3RM flag to become 1. The SDSTS1.SDD3RM flag is cleared by setting it to 0.

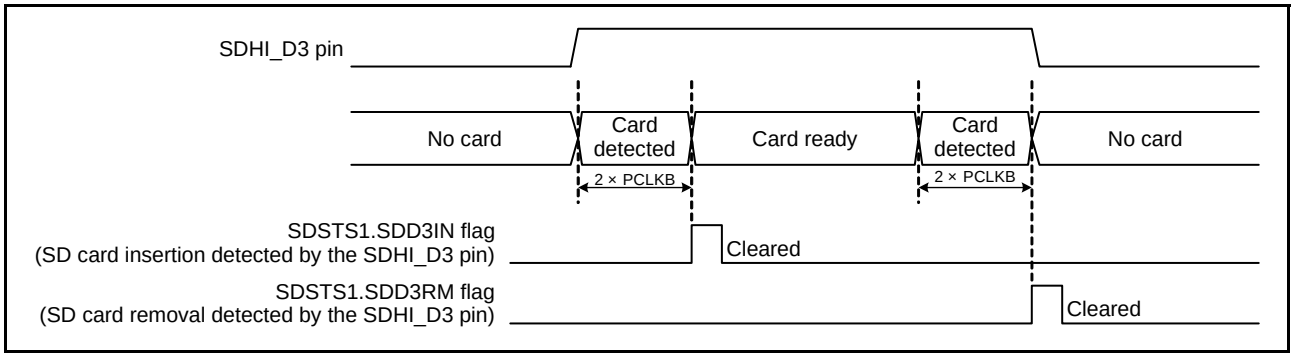

Figure 44.7 SD Card Detection Using the SDHI_D3 Pin

44.3.4 SD Card Write Protection

The SDHI can disable writing to an SD card via the SDHI_WP pin or a command.

44.3.4.1 Using the SDHI_WP Pin to Enable Write Protection

The SDHI_WP pin is connected to the WP detection switch of the SD card connector, and the SDHI_WP pin is pulled-down or pulled-up when an SD card is inserted. The resistance value and whether the SDHI_WP pin is pulled-up or pulled-down are determined by the specifications of the host device. The status of the SDHI_WP pin is reflected in the SDSTS1.SDWPMON flag. After an SD card is inserted, read the SDSTS1.SDWPMON flag to check if write protection is enabled or disabled.

44.3.4.2 Using a Command to Enable Write Protection

The SDHI uses the write protect command or the SD card lock command to disable writing to the SD card.

44.3.5 Communication Errors and Timeouts

When a communication error or timeout error occurs, depending on the type of error, the corresponding status flag in the SDSTS2 register becomes 1. Also, depending on the source of the error, the corresponding flag in the SDERSTS1 or SDERSTS2 register becomes 1.

The status flags in registers SDERSTS1 and SDERSTS2 become 0 by writing to the SDCMD register, or by setting the SDRST.SDRST bit to 0.

Table 44.6 Communication Errors

Communication Error	Interrupt Flag Register		Error Status Register		This Occurs When...
	Register symbol	Bit symbol	Register symbol	Bit symbol	
End bit error	SDSTS2	ENDE	SDERSTS1	CRCLENE	The CRC status token length is in error
				RDLENE	The read data length is in error
				RSPLENE1	The response length is in error *1
				RSPLENE0	The response length is in error *2
CRC error		CRCE		CRCTKE	The CRC status token is in error
				RDCRCE	There is a CRC error in the read data
				RSPCRCE1	There is a CRC error in the response *1
				RSPCRCE0	There is a CRC error in the response *2
Command error		CMDE		CMDE1	The command index field value for the transmitted command and received response do not match *1
				CMDE0	The command index field value for the transmitted command and received response do not match *2

Note 1. CMD12 or CMD52 which are automatically issued to stop transfer.
Note 2. A command other than CMD12 or CMD52 which are automatically issued to stop transfer.

Table 44.7 Timeouts

Timeout	Interrupt Flag Register		Error Status Register		This Occurs When...
	Register symbol	Bit symbol	Register symbol	Bit symbol	
Response timeout	SDSTS2	RSPTO	SDERSTS2	RSPTO1	A response is not received even after a minimum of 640 SDHI clock cycles elapse *1
				RSPTO0	A response is not received even after a minimum of 640 SDHI clock cycles elapse *2
Data timeout (excluding response timeout)		DTO		CRCBSYTO	After the CRC status token is received, the SDHI is busy for at least the period set *3
				CRCTO	After the write data is transmitted, the CRC status token is not received even after at least the period set *3 elapses
				RDTO	After the read command is issued, the read data is not received even after at least the period set *3 elapses
					After the read data is received, the next block read data is not received even after at least the period set *3 elapses
					After the SDHI exits the read wait state, the next block read data is not received even after at least the period set *3 elapses
				BSYTO1	After CMD12 is issued during the command sequence, the SDHI is busy for at least the period set *3
				BSYTO0	After the R1b response is received, the SDHI is busy for at least the period set *3 (a command other than CMD12 is issued during the command sequence)

Note 1. CMD12 or CMD52 which are automatically issued to stop transfer.
Note 2. A command other than CMD12 or CMD52 which are automatically issued to stop transfer.
Note 3. The period is set in the SDOPT.TOP[3:0] bits.

44.3.6 Examples of Issuing a Command

44.3.6.1 Command Absent of Response Reception and Data Transfer

Figure 44.8 shows an example of no response being received and no data being transferred after the SDHI issues a command.

1. Set the flags in registers SDSTS1 and SDSTS2 to 0.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 44.5.5 for details on setting the SDCLKCR register.
3. After setting the argument field value to the SDARG register, write the command information to be sent to the SDCMD register. The SDHI issues a command when a value is written to the SDCMD register.
4. After a command is issued, the SDSTS1.RSPEND flag becomes 1, and a response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0.

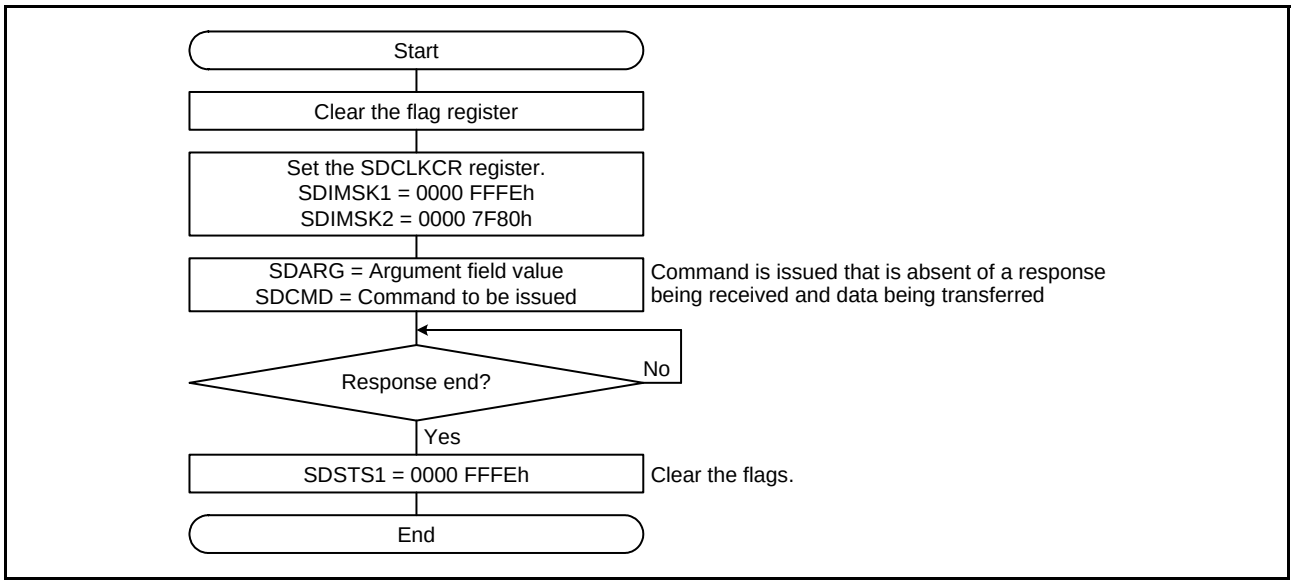

Figure 44.8 Command Issued That Is Absent of Response Reception and Data Transfer

44.3.6.2 Command Absent of Data Transfer

Figure 44.9 shows an example of no data being transferred after the SDHI issues a command.

1. Set the flags in registers SDSTS1 and SDSTS2 to 0.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 44.5.5 for details on setting the SDCLKCR register.
3. After setting the argument field value in the SDARG register, write the information of the command to be issued to the SDCMD register. The SDHI issues a command when a value is written to the SDCMD register.
4. After a response is received, the SDSTS1.RSPEND flag becomes 1, and a response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0, and read the response stored in the SDRSP10 register.

Perform error processing (clear the interrupt flag) if a communication error or timeout occurs.

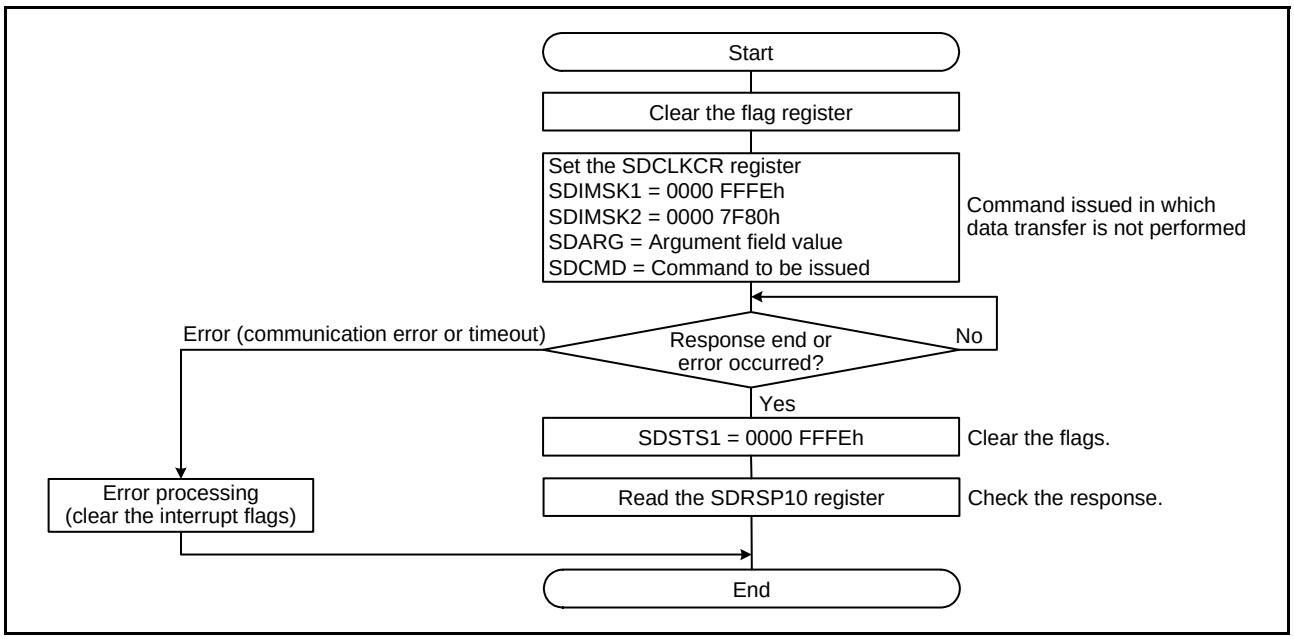

Figure 44.9 Command Issued That Is Absent of Data Transfer

44.3.6.3 Single Block Read Command (CMD17)

Figure 44.10 shows an example of issuing the single block read command (CMD17).

1. Set the flags in registers SDSTS1 and SDSTS2 to 0.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 44.5.5 for details on setting the SDCLKCR register.
3. After setting the argument field value for CMD17 to the SDARG register, write 0000 0011h to the SDCMD register. The SDHI issues CMD17 when a value is written to the SDCMD register.
4. When the response is received, the SDSTS1.RSPEND flag becomes 1, and a response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0, and read the response stored in the SDRSP10 register. If the response read is in error, set the SDSTOP.STP bit or SDIOMD.IOABT bit to 1, and the command sequence can be stopped. When the command sequence is stopped, the SDSTS1.ACEND flag becomes 1. Note that CMD12 and CMD52 are not automatically issued by stopping this command sequence.
6. After the response is received, set the SDIMSK1.ACENDM bit to 0 and set the SDIMSK2.BREM bit to 0.
7. After the amount of data set in the SDSIZE.LEN[9:0] bits is received from the SD card, the SDSTS2.BRE flag becomes 1, and the BRE interrupt request is generated.
8. Set the SDSTS2.BRE flag to 0, and read the amount of data set in the SDSIZE.LEN[9:0] bits from the SDBUFR register.
9. After data has been read from the SDBUFR register, the SDSTS1.ACEND flag becomes 1, and the access end interrupt request is generated.
10. Set the SDSTS1.ACEND flag to 0.

Perform error processing (clear the interrupt flag) if a communication error or timeout occurs.

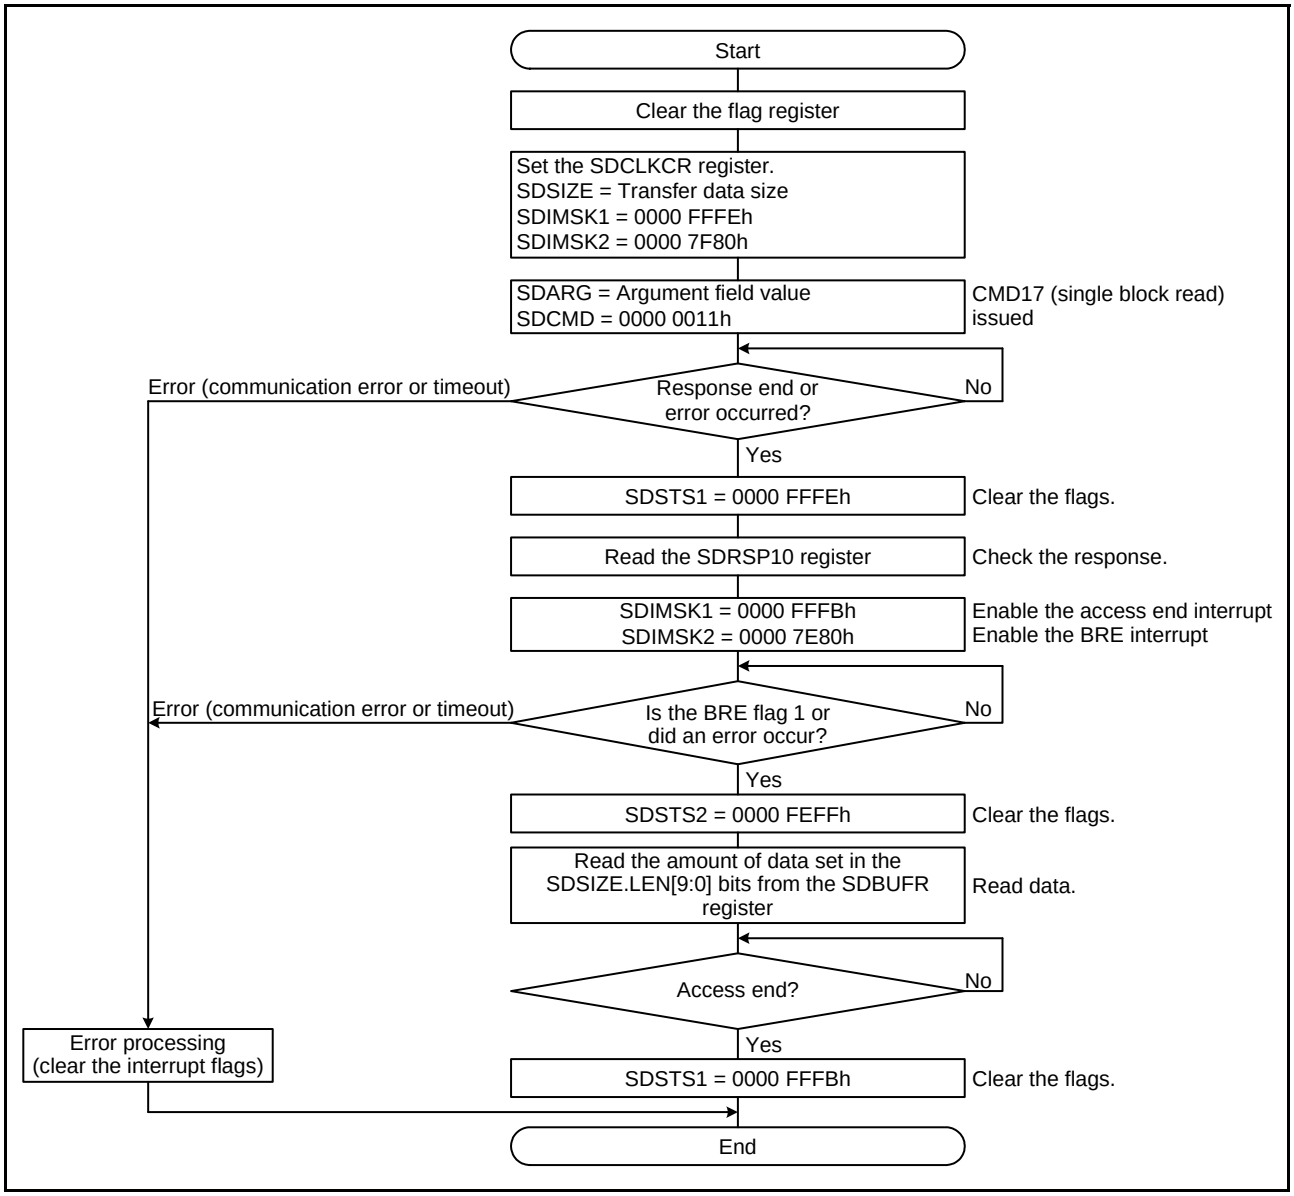

Figure 44.10 Issuing the Single Block Read Command

44.3.6.4 Single Block Write Command (CMD24)

Figure 44.11 shows an example of issuing the single block write command (CMD24).

1. Set the flags in registers SDSTS1 and SDSTS2 to 0.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 44.5.5 for details on setting the SDCLKCR register.
3. After setting the argument field value for CMD24 to the SDARG register, write 0000 0018h to the SDCMD register. The SDHI issues CMD24 when a value is written to the SDCMD register.
4. When the response is received, the SDSTS1.RSPEND flag becomes 1, and the response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0 and read the response stored in the SDRSP10 register. If the read response is in error, set the SDSTOP.STP bit or SDIOMD.IOABT bit to 1, and the command sequence can be stopped. When the command sequence is stopped, the SDSTS1.ACEND flag becomes 1. Note that when this command sequence is stopped, CMD12 and CMD52 are not automatically issued.
6. After the response is received, set the SDIMSK1.ACENDM bit to 0, and set the SDIMSK2.BWEM bit to 0.
7. When the SDBUFR register becomes write accessible, the SDSTS2.BWE flag becomes 1, and the BWE interrupt request is generated.
8. Set the SDSTS2.BWE flag to 0, and write the amount of data set in the SDSIZE.LEN[9:0] bits to the SDBUFR register. After writing to the SDBUFR register, the SDHI transmits write data to the SD card. Also, after writing to the SDBUFR register, data transmission may cause a communication error or timeout to occur.
9. After all data has been written to the SD card, the SDHI receives the CRC status token, and the SDHI_D0 pin line becomes busy (low). Then, when the SDHI exits the busy state, the SDSTS1.ACEND flag becomes 1, and the access end interrupt request is generated.
10. Set the SDSTS1.ACEND flag to 0.

Perform error processing (clear the interrupt flag) if a communication error or timeout occurs.

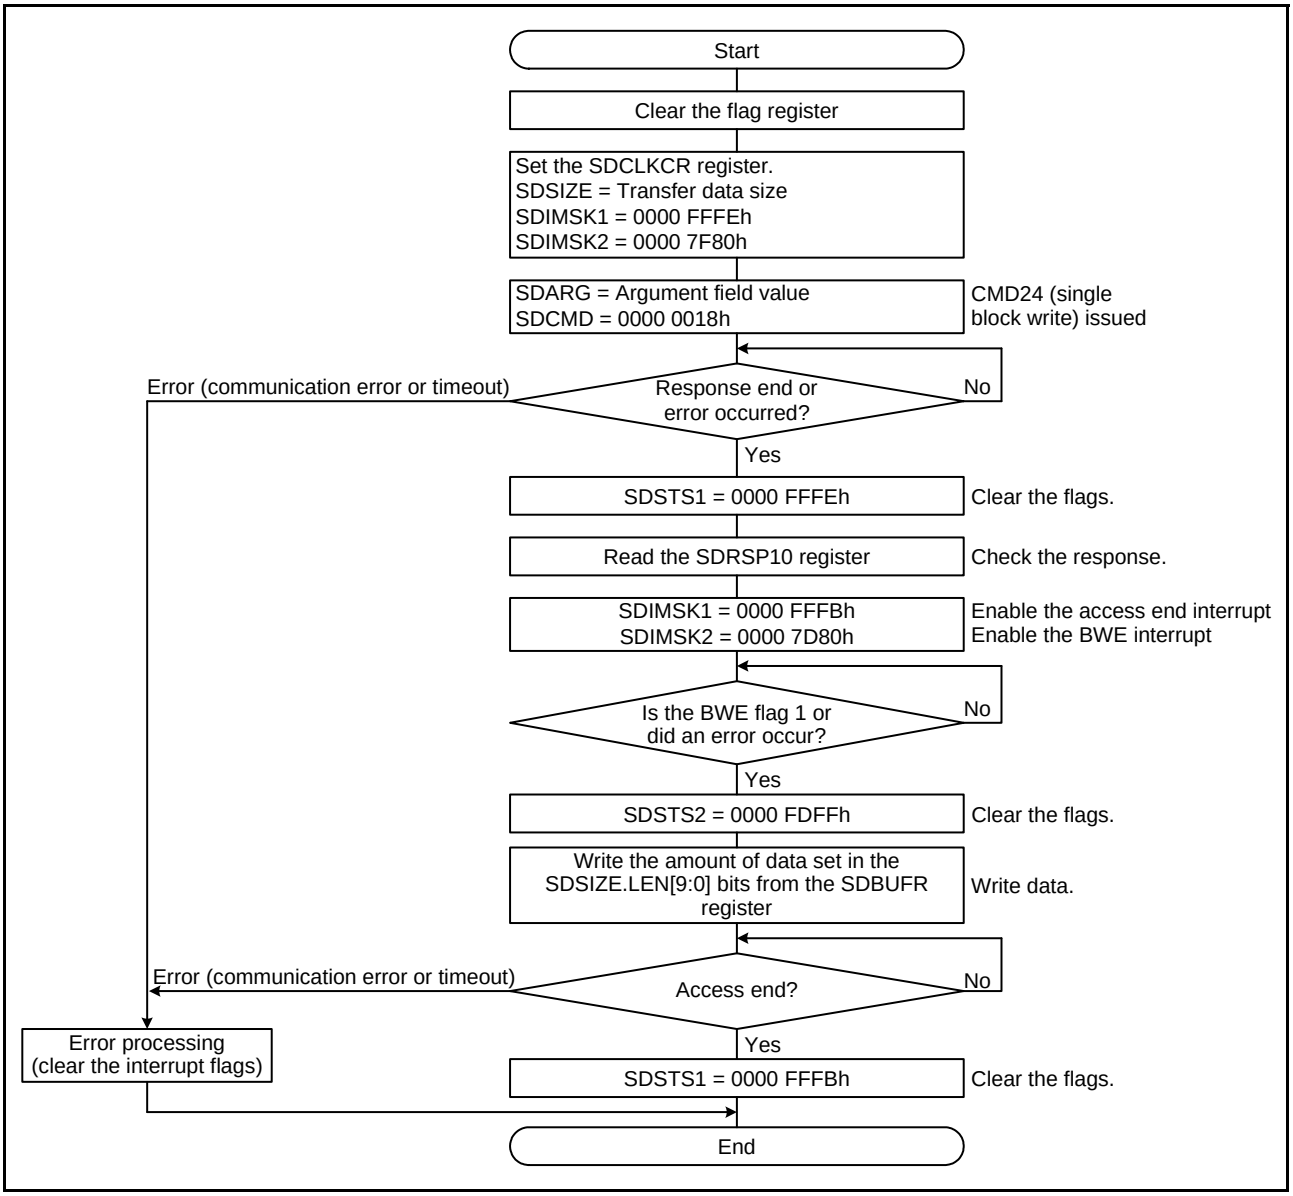

Figure 44.11 Issuing the Single Block Write Command

44.3.6.5 Multi-Block Read Command (CMD18)

Figure 44.12 shows an example of issuing the multi-block read command (CMD18).

1. Set the flags in registers SDSTS1 and SDSTS2 to 0.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 44.5.5 for details on setting the SDCLKCR register. Set the SDSTOP.SDBLKCNTEN bit to 1, and set the number of transfer blocks in the SDBLKCNT register.
3. After setting the argument field value for CMD18 to the SDARG register, write 0000 0012h to the SDCMD register. The SDHI issues CMD18 when a value is written to the SDCMD register.
4. When the response is received, the SDSTS1.RSPEND flag becomes 1, and the response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0 and read the response stored in the SDRSP54 register. If the read response is in error, set the SDSTOP.STP bit to 1, and the command sequence can be stopped. When the SDSTOP.STP bit is set to 1, the SDHI automatically issues CMD12, and the response is received. At this point, the SDSTS1.ACEND flag becomes 1, and if the access end interrupt request is enabled, the access end interrupt request is generated. Next, set the SDSTS1.ACEND flag to 0 and read the response.
6. After the response is received, set the SDIMSK1.ACENDM bit to 0, and set the SDIMSK2.BREM bit to 0.
7. After receiving one block of data from the SD card, the SDSTS2.BRE bit becomes 1, and the BRE interrupt request is generated.
8. Set the SDSTS2.BRE flag to 0, and read the amount of data set in the SDSIZE.LEN[9:0] bits from the SDBUFR register. The read access to the SDBUFR register repeats for the amount of transfer blocks set in the SDBLKCNT register. Also, while reading the SDBUFR register, data reception may cause a communication error or timeout to occur. After the amount of transfer blocks set in the SDBLKCNT register have been read, the SDHI automatically issues CMD12, and the response is received. At this time, the SDHI automatically writes 0000 0000h to the SDARG register.
9. When all blocks have been received and the CMD12 response is received, the SDSTS1.ACEND flag becomes 1 and the access end interrupt request is generated.
10. Set the SDSTS1.ACEND flag to 0 and read the response.

Perform error processing (clear the interrupt flag) if a communication error or timeout occurs.

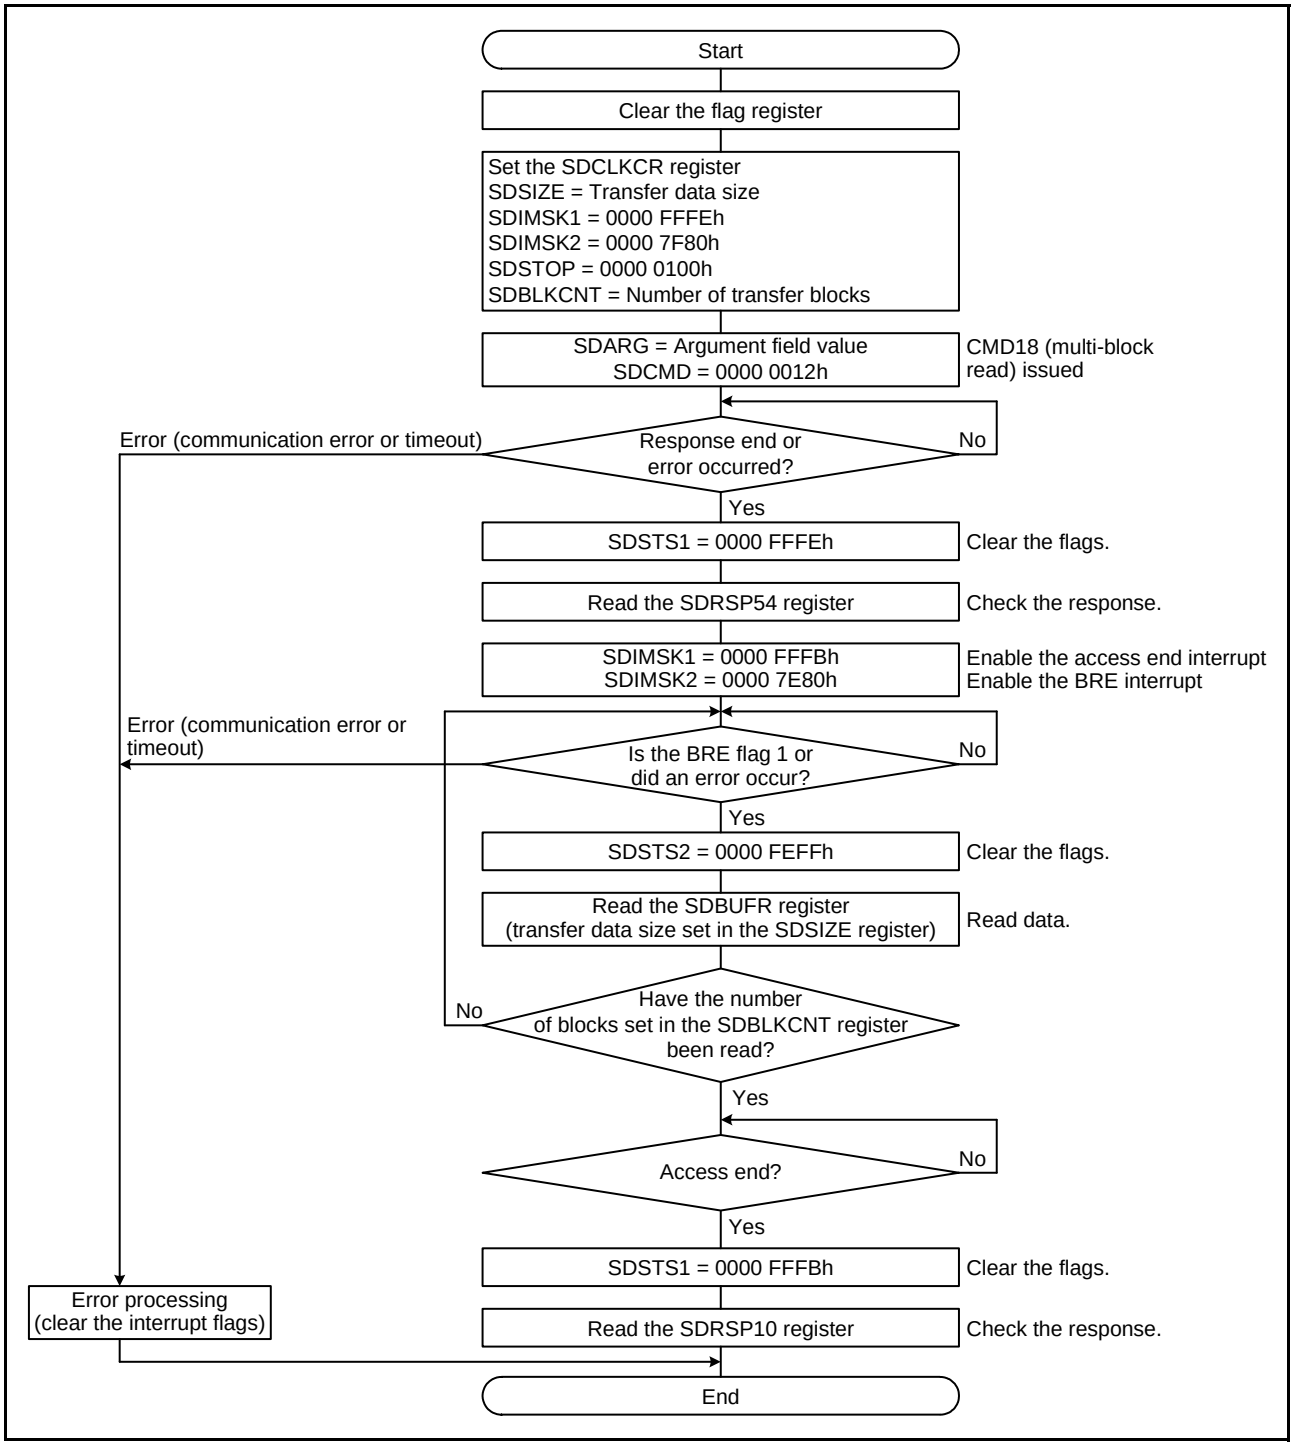

Figure 44.12 Issuing the Multi-Block Read Command

44.3.6.6 Multi-Block Write Command (CMD25)

Figure 44.13 shows an example of issuing the multi-block write command (CMD25).

1. Set the flags in registers SDSTS1 and SDSTS2 to 0.
2. Set the SDHI clock in the SDCLKCR register, and set the interrupt requests to be masked in registers SDIMSK1 and SDIMSK2. Refer to section 44.5.5 for details on setting the SDCLKCR register. Set the SDSTOP.SDBLKCNTEN bit to 1, and set the number of transfer blocks in the SDBLKCNT register.
3. After setting the argument field value for CMD25 to the SDARG register, write 0000 0019h to the SDCMD register. The SDHI issues CMD25 when a value is written to the SDCMD register.
4. When the response is received, the SDSTS1.RSPEND flag becomes 1, and the response end interrupt request is generated.
5. Set the SDSTS1.RSPEND flag to 0 and read the response stored in the SDRSP54 register. If the read response is in error, set the SDSTOP.STP bit to 1, and the command sequence can be stopped. When the SDSTOP.STP bit is set to 1, the SDHI automatically issues CMD12, and the response is received. At this point, the SDSTS1.ACEND flag becomes 1, and if the access end interrupt request is enabled, the access end interrupt request is generated. Next, set the SDSTS1.ACEND flag to 0 and read the response.
6. After the response is received, configure the SDIMSK1 register to enable the access end interrupt request, and configure the SDIMSK2 register to enable the BWE interrupt request.
7. When the SDBUFR register becomes write accessible, the SDSTS2.BWE flag becomes 1, and the BWE interrupt request is generated.
8. Set the SDSTS2.BWE flag to 0, and write the amount of data set in the SDSIZE.LEN[9:0] bits to the SDBUFR register. After writing to the SDBUFR register, and after the SDHI transmits write data to the SD card, the CRC status token is received, and the SDHI_D0 pin line becomes busy (low). The write access to the SDBUFR register and CRC status token reception repeat for the amount of transfer blocks set in the SDBLKCNT register. Also, after writing to the SDBUFR register, data transmission may cause a communication error or timeout to occur. After the amount of transfer blocks set in the SDBLKCNT register have been written, the SDHI automatically issues CMD12, and the response is received. At that time, the SDHI automatically writes 0000 0000h to the SDARG register.
9. When all blocks have been transmitted and the CRC status token is received, the SDHI exits the busy state, the SDSTS1.ACEND flag becomes 1, and the access end interrupt request is generated.
10. Set the SDSTS1.ACEND flag to 0 and read the response.

Perform error processing (clear the interrupt flag) if a communication error or timeout occurs.

44.3.6.10 DMA Transfer

Figure 44.21 shows an example of data being transferred from the SDBUFR register after the CMD18 multi-block read command is issued.

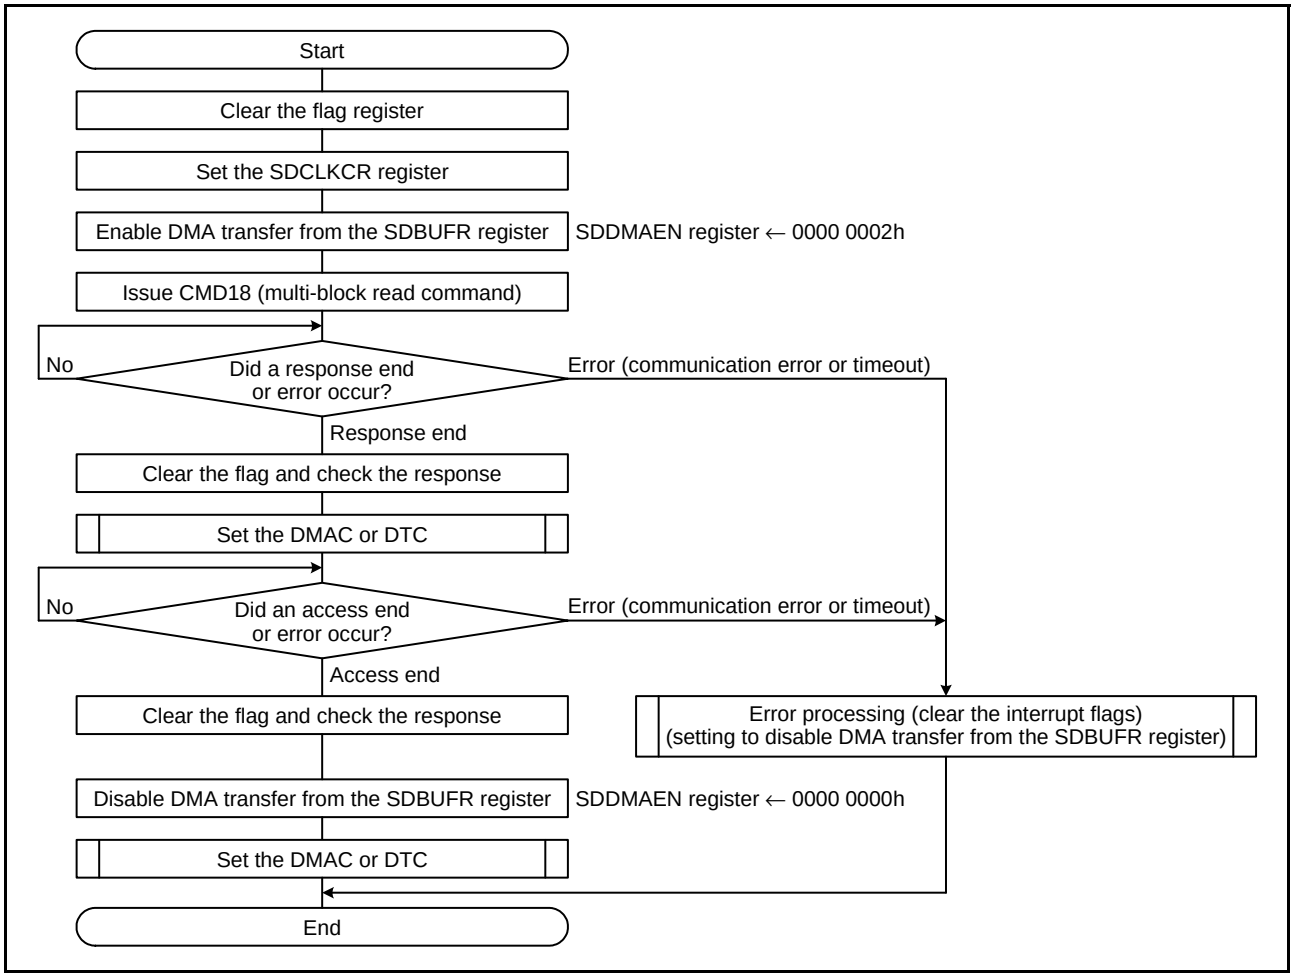

Figure 44.21 DMA Transfer After CMD18 is Issued

Figure 44.22 shows an example of data being DMA transferred to the SDBUFR register after the CMD25 multi-block write command is issued.

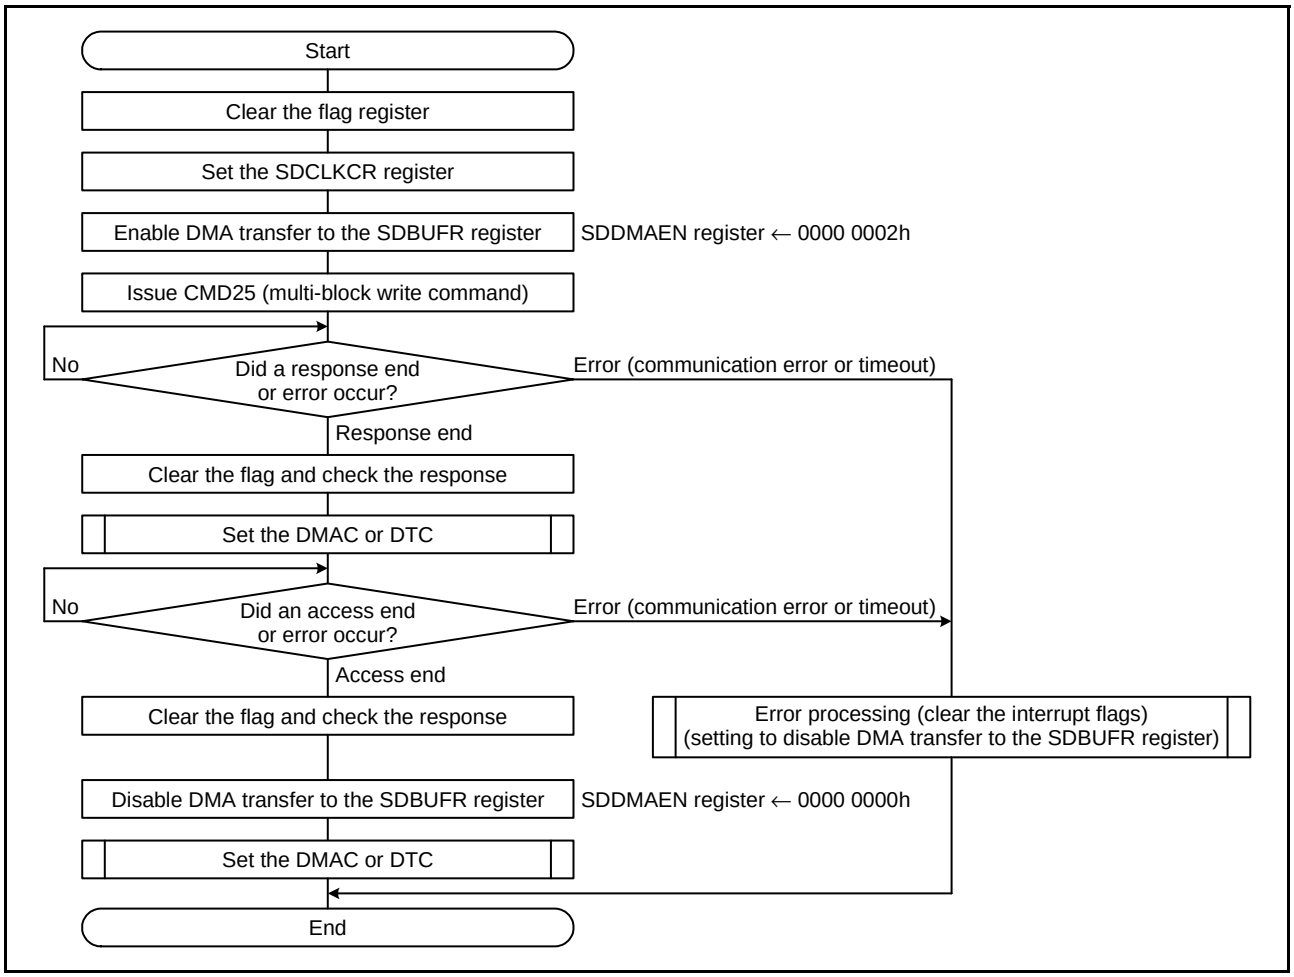

Figure 44.22 DMA Transfer After CMD25 is Issued

44.4 Interrupts

Table 44.8 lists the SDHI interrupt sources. When the status flags in registers SDSTS1, SDSTS2, and SDIOSTS become 1, if the corresponding bits in registers SDIMSK1, SDIMSK2, and SDIOIMSK are 0, the SDHI requests an interrupt. When clearing the status flags in registers SDSTS1, SDSTS2, and SDIOSTS, write 0 to the status flags to be cleared and write 1 to the states flags not being cleared.

Table 44.8 Interrupt Sources

Interrupt Source	Status Flag Register		Interrupt Mask/Enable Register		DMAC/DTC Triggerable
	Register symbol	Bit symbol	Register symbol	Bit symbol	
CACI	SDSTS1	ACEND	SDIMSK1	ACENDM	No
		RSPEND		RSPENDM	
	SDSTS2	ILA	SDIMSK2	ILAM	
		BWE		BWEM	
		BRE		BREM	
		RSPTO		RSPTOM	
		ILR		ILRM	
		ILW		ILWM	
		DTO		DTTOM	
		ENDE		ENDEM	
		CRCE		CRCEM	
		CMDE		CMDEM	
SDACI	SDIOSTS	EXWT	SDIOIMSK	EXWTM	No
		EXPUB52		EXPUB52M	
		IOIRQ		IOIRQM	
CDETI	SDSTS1	SDD3IN	SDIMSK1	SDD3INM	No
		SDD3RM		SDD3RMM	
		SDCDIN		SDCDINM	
		SDCDRM		SDCDRMM	
SBFAI	SDSTS2	BWE	SDDMAEN	DMAEN	Yes
		BRE			

44.4.1 DMA Transfer Triggered by Interrupt Requests

When the SBFAI interrupt is requested, DMA/DTC transfer can be used to write to or read the SDBUFR register. When using the SBFAI interrupt, set the SDDMAEN.DMAEN bit to 1, the SDIMSK2.BWEM bit to 1, and SDIMSK2.BREM bit to 1.

When the SDDMAEN.DMAEN bit is 1, if a write command is issued, the SDSTS2.BWE flag becomes 1; if a read command is issued, the SDSTS2.BRE flag becomes 1. At this point, the SBFAI interrupt request is output. When the last data of a block is transferred (one block is the transfer data size set in the SDSIZE.LEN[9:0] bits), the SBFAI interrupt request is cleared, and the SDSTS2.BWE flag or the SDSTS2.BRE flag becomes 0.

The SBFAI interrupt request is also cleared by following:

- The SDRST.SDRST bit is set to 0 (SDHI software reset).
- The SDSTOP.STP bit is set to 1.
- The SDIOMD.IOABT bit is set to 1.
- The SDDMAEN.DMAEN bit is set to 0.
  However, if the DMAEN bit is set to 1 again before the next command is written to the SDCMD register, the SBFAI interrupt request is output again.

The SBFAI interrupt request will not be cleared when a communication error or timeout occurs during DMA transfer. Perform error processing by software.

The SDSTS2.BWE flag and BRE flag will not become 0 when a communication error or timeout occurs, nor will they become 0 when the SDSTOP.STP bit and SDIOMD.IOABT bit are set to 1. If the SDSTS2.BWE flag or BRE flag remain set to 1, even if a write command or read command is issued, the SBFAI interrupt request will not be output, and the SDSTS2.BWE flag and BRE flag must be set to 0 before issuing the next command.

Table 44.9 lists the DMAC and DTC settings when performing DMA transfer.

Table 44.9 DMAC and DTC Settings When Performing DMA Transfer

Item		Setting Description
Transfer mode		Block transfer mode
Transfer data	1 data	32 bits
	Block size	Size set in the SDSIZE.LEN[9:0] bits divided by 4
Number of block transfers		Number of transfers set in the SDBLKCNT register

44.5 Notes on Using the SDHI

44.5.1 Illegal Read Access During a Multi-Block Read and How To Avoid It

When the multi-block read command (CMD18) is issued to read one or two blocks, if the response to CMD18 stored in the SDRSP10 register is read, the timing of the read access may cause the response to be read incorrectly.
Figure 44.23 shows examples of a normal read and an illegal read when using CMD18 to read two blocks.

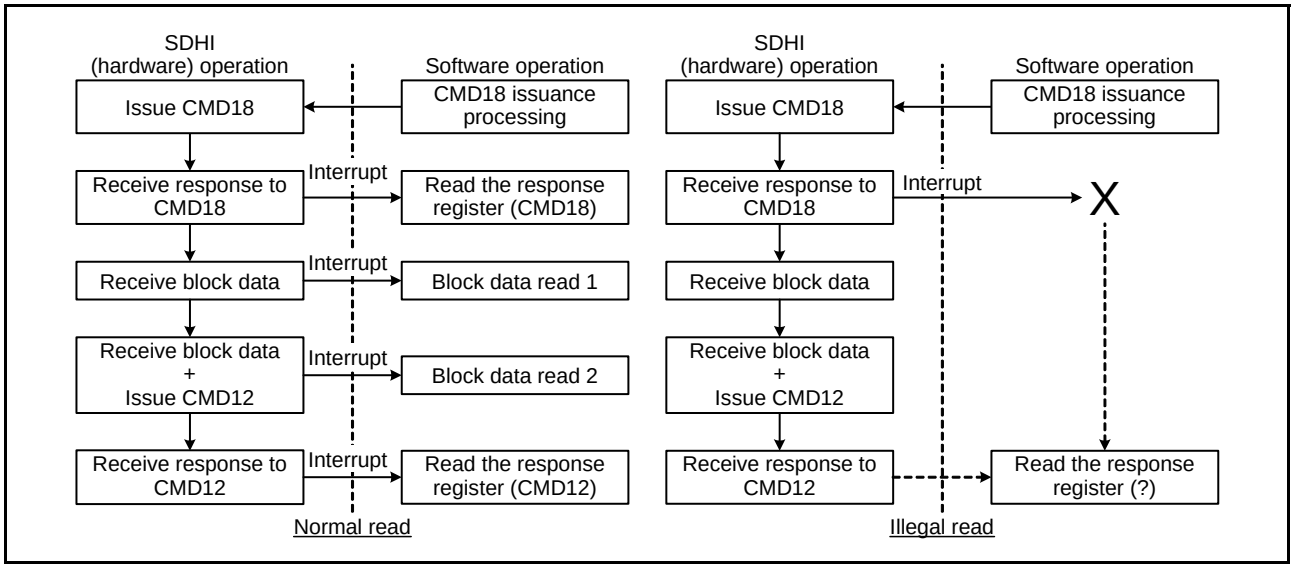

Figure 44.23 Multi-Block Read Processing When Reading Two Blocks

In the example of the illegal read, when the interrupt is generated by receiving the response to CMD18, the timing for reading the SDRSP10 register during the interrupt handling is delayed, and instead of the response for CMD18 being read, the response for CMD12 or the data during the response for CMD12 may be read.
This problem can be avoided by performing either of the following:

- When reading one block or two blocks, use a single block read command instead of a multi-block read command.
- When reading the response for CMD18, read the SDRSP54 register instead of the SDRSP10 register.

When using a multi-block read command to read three or more blocks, CMD12 will not be issued if no block data is read, which will prevent this problem from happening. Also, when using a multi-block write command, the above problem can be avoided by transmitting block data after reading the response to CMD25.

44.5.2 SDBUFR Register Illegal Write Error

When writing to the SDBUFR register after issuing a single block write command or a multi-block write command, write data for the size set by the SDSIZE.LEN[9:0] bits. If the amount of data written to the SDBUFR register is greater than the size set by the SDSIZE.LEN[9:0] bits, an illegal write error occurs in the SDBUFR register, and the SDSTS2.ILW flag becomes 1. However, the padding data included in the data being written to the SDBUFR register is ignored, so this error does not occur. For example, if the data size set by the SDSIZE.LEN[9:0] bits is an odd number, of the data written to the SDBUFR register, there is a remainder of 1 byte or 3 bytes. Although the extra data is written to the register, no error occurs. If the data size set by the SDSIZE.LEN[9:0] bits is an even number, and there is a remainder of 2 bytes, no error occurs even if these 2 bytes are written to the SDBUFR register.
If data written to the SDBUFR register is not transmitted, the SDSTS2.SDCLKCREN flag may remain set to 0. In this case, in order to set the SDSTS2.SDCLKCREN flag to 1, the SDRST.SDRST bit must be set to 0 and then set back to 1.

44.5.3 Automatic Control of the SDHI Clock Output

As per the SD card specifications, after MCU power-on, 74 cycles of the SDHI clock must be output from the host to the SD card before the card initialization command (CMD0) can be issued. Therefore, 74 cycles of the SDHI clock should be output from the SDHI to the SD card before enabling automatic control of the SDHI clock output.
When automatic control of the SDHI clock output is enabled, SDHI clock output stops if the command sequence is ended by a communication error or timeout. Therefore, if it is necessary to change the internal status of the SD card even after the command sequence ends, disable automatic control of the SDHI clock output and output the SDHI clock to the SD card.

44.5.4 Restrictions on Setting the C52PUB Bit During a Multi-Block Write Sequence

During a CMD53 multi-block write sequence, if the SDIOMD.C52PUB bit is set to 1, the SDHI issues CMD52 after the SD buffer becomes empty. To immediately issue CMD52, perform one of the procedures below to suspend writing to the SD buffer, and set the C52PUB bit to 1.

Procedure to suspend writing to the SD buffer when not performing DMA transfer (interrupt used)

1. Set the SDIMSK2.BWEM bit to 1 to disable the interrupt, and suspend writing to the SDBUFR register.
2. Set the SDIOMD.C52PUB bit to 1. Then, when the SD buffer becomes empty, the SDHI issues CMD52.
3. After receiving the response for CMD52, set the SDIMSK2.BWEM bit to 0 to enable the interrupt, and resume writing to the SDBUFR register.

Procedure to suspend writing to the SD buffer when performing DMA transfer

1. Configure settings to perform DMA transfer every [SDSIZE register setting value × *n* blocks], and suspend writing to the SDBUFR register before setting the SDIOMD.C52PUB bit (*n* = 1, 2, ...).
2. Set the SDIOMD.C52PUB bit to 1. Then, when the SD buffer becomes empty, the SDHI issues CMD52.
3. After receiving the response for CMD52, resume DMA transfer to the SDBUFR register.

44.5.5 Note on Setting the SDCLKCR Register

The SDCLKCR register cannot be written when the SDSTS2.SDCLKCREN flag is 0. Set the SDSTS2.SDCLKCREN flag to 1 before writing to the SDCLKCR register.

44.5.6 Writing to the SDSTOP Register During a Multi-Block Read Sequence

When the SDSTOP.SDBLKCNTEN bit is 1 during a multi-block read sequence, if the SDSTOP.STP bit is set to 1 and the command sequence is stopped, the command sequence may not be completed depending on when the SDSTOP.STP bit is set to 1. To avoid this problem, set the SDSTOP.STP bit and the SDSTOP.SDBLKCNTEN bit to 0 simultaneously. Note that at this time, the SDSTOP.SDBLKCNTEN bit should be set to 0 even if the SDSTS2.SDCLKCREN bit is 0.
If the SDSTOP.SDBLKCNTEN bit is not set to 0, the command sequence can be completed by setting the SDRST.SDRST bit to 0.
During a CMD53 multi-block transfer, when stopping data transfer by setting the SDIOMD.IOABT bit to 1, the SDSTOP.SDBLKCNTEN bit should remain set to 1.

44.5.7 Controlling Module Operation

SDHI operation is controlled by setting the MSTPCRD.MSTPD19 bit. Setting the MSTPD19 bit to 0 enables the SDHI; setting the MSTPD19 bit to 1 disables the SDHI. The SDHI is disabled after a reset. Registers in the SDHI can be accessed by setting the MSTPD19 bit to 0. Refer to section 11, Low Power Consumption for details.

45. Serial Sound Interface (SSIE)

45.1 Overview

This MCU has a serial sound interface (SSIE0). SSIE supports monaural and time-division multiplexed (TDM) formats in addition to standard audio data formats such as I^2S, left-justified, and right-justified.

Table 45.1 Features of SSIE

Item		Description
Number of channels		One channel, SSIE0
Transfer mode		• Master/slave • Transmission, reception, or transception
Data format		• I^2S format • Left-justified format • Right-justified format • Monaural format • TDM format
Serial data		• Fixed to MSB first • System word length: Selectable from among 8, 16, 24, 32, 48, 64, 128, or 256 bits • Data word length: Selectable from among 8, 16, 18, 20, 22, 24, or 32 bits • The level of padding bits is programmable. • Mute function
Bit clock (BCK)	In master mode	• Clock source: AUDIO_CLK • Frequency: Selectable from among 1/1, 1/2, 1/4, 1/6, 1/8, 1/12, 1/16, 1/24, 1/32, 1/48, 1/64, 1/96, or 1/128 of the AUDIO_CLK frequency • Continued supply or stopping while data transfer is halted is selectable.
	In master and slave modes	• Polarity is selectable as rising edges or falling edges.
LR clock (LRCK)		• Polarity is selectable as low or high. • Continued supply or stopping while data transfer is halted is selectable.
FIFO	Capacity	• Transmit FIFO: 4 bytes × 32 stages • Receive FIFO: 4 bytes × 32 stages
	Data alignment	• Alignment of data (left-justified or right-justified) in the FIFO is selectable.
Interrupts		• Data transfer error/idle state • Receive data full • Transmit data empty
Low power consumption function		• Module stop function • Master clock (MCK) supply stopping function

Table 45.2 lists and Figure 45.1 shows the terms and the definitions used in this chapter.

Table 45.2 Definitions of Terms

Term	Definition
Start trigger	First edge of the type specified by the SSICR.LRCKP bit of the signal on the SSILRCK pin after the start of data transfer
Frame boundary	Point where SSIE starts transferring the first data of a frame or the point where SSIE ends transferring the last data of the frame
Frame word length	Number of system words per frame (number of channels)
System word length	Number of transferred bits per channel
Data word length	Number of effective bits per channel
Master clock (MCK)	Clock for master mode input from the AUDIO_CLK pin

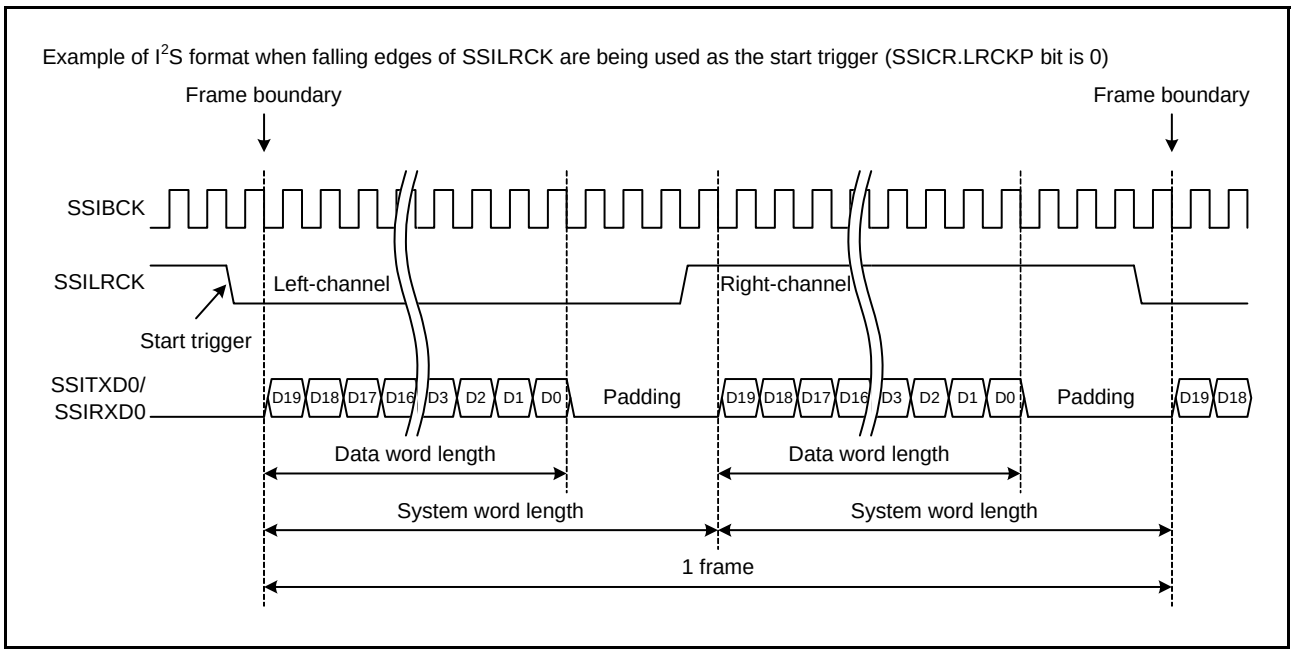

Figure 45.1 Definitions of Terms Related to Data Format

Figure 45.2 shows a block diagram of the SSIE0.

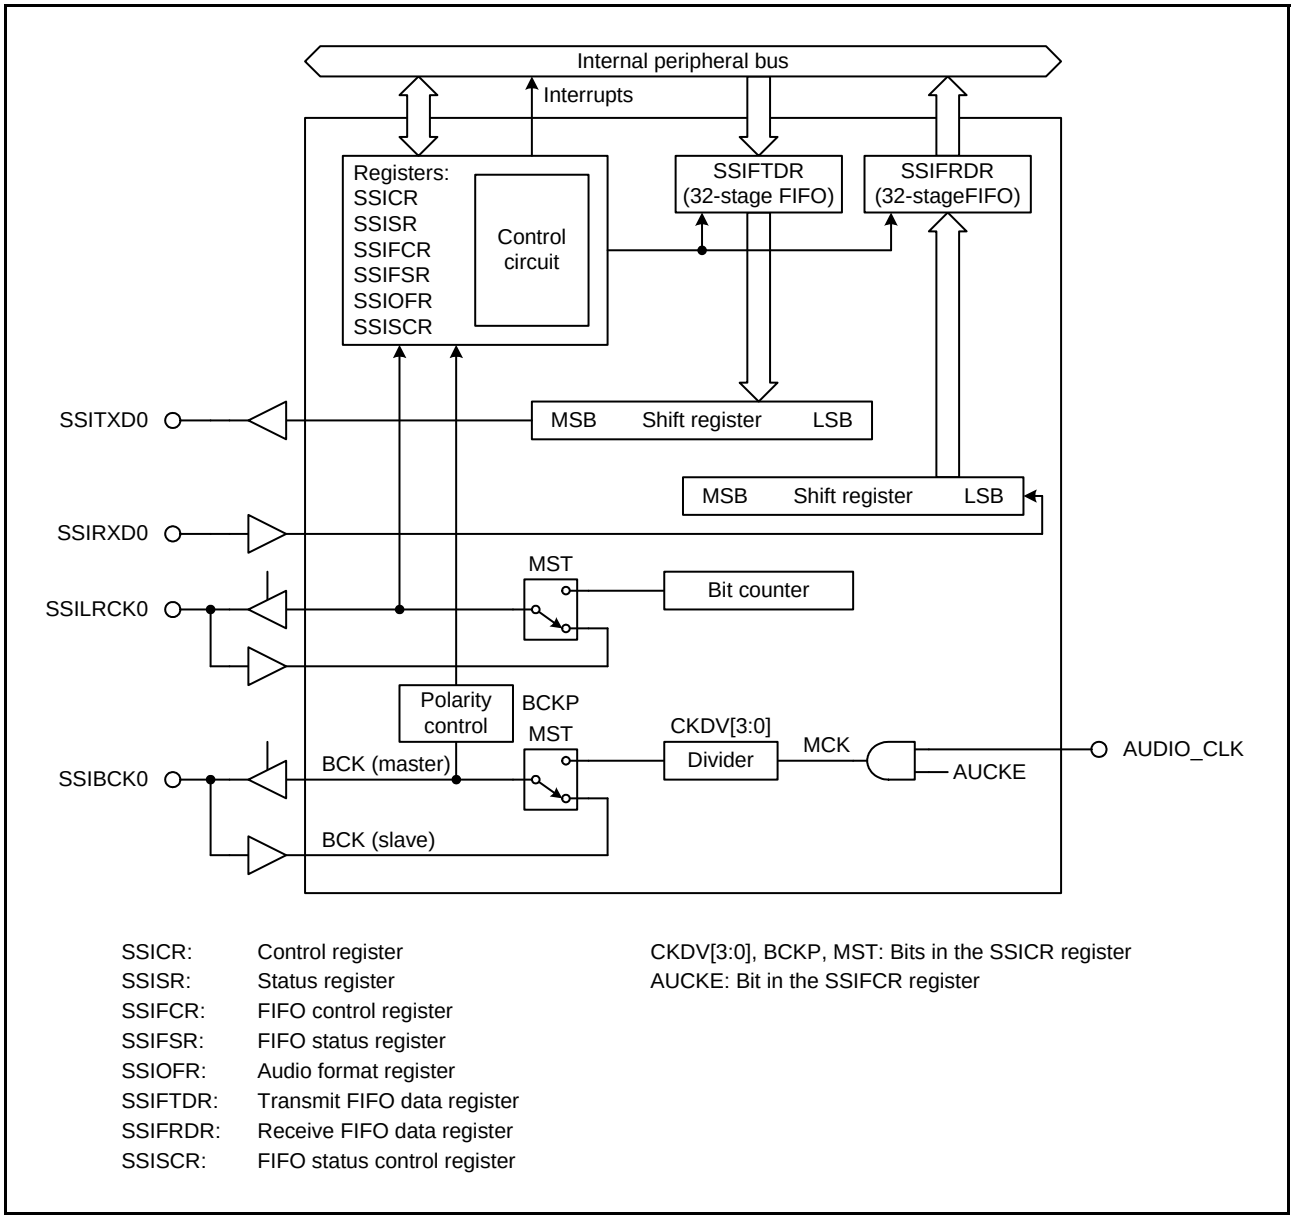

Figure 45.2 SSIE Block Diagram (SSIE0)

Table 45.3 lists the I/O pins of the SSIE.

Table 45.3 I/O pins of SSIE

Pin Name	I/O	Function
AUDIO_CLK	Input	Audio clock input
SSIBCK0	I/O	Channel 0 bit-clock input/output
SSILRCK0	I/O	Channel 0 LR clock input/output
SSITXD0	Output	Channel 0 data output
SSIRXD0	Input	Channel 0 data input

45.2 Register Descriptions

45.2.1 Control Register (SSICR)

Address(es): SSIE0.SSICR 0008 A500h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	REN	Reception Enable*1	0: Reception disabled 1: Reception enabled	R/W
b1	TEN	Transmission Enable*1	0: Transmission disabled 1: Transmission enabled	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3	MUEN	Mute	0: Unmute 1: Mute	R/W
b7 to b4	CKDV[3:0]	Bit Clock Division Ratio Select *2	Set the division ratio to generate a bit clock from MCK. b7 b4 0 0 0 0: No division 0 0 0 1: Divided by 2 0 0 1 0: Divided by 4 0 0 1 1: Divided by 8 0 1 0 0: Divided by 16 0 1 0 1: Divided by 32 0 1 1 0: Divided by 64 0 1 1 1: Divided by 128 1 0 0 0: Divided by 6 1 0 0 1: Divided by 12 1 0 1 0: Divided by 24 1 0 1 1: Divided by 48 1 1 0 0: Divided by 96 Settings other than above are prohibited.	R/W
b8	DEL	Serial Data Delay Select*2	Set the delay between the edges of SSILRCK and the input and output of data. 0: Delay of 1 cycle of SSIBCK 1: No delay	R/W
b9	PDTA	Data Alignment Select*2	Set the data alignment of the SSIFTDR and SSIFRDR registers. 0: Left-justified 1: Right-justified	R/W
b10	SDTA	Serial Data Alignment Select *2	0: I2S and left-justified format (data bits are transmitted and received before the padding bits) 1: Right-justified format (data bits are transmitted and received after the padding bits)	R/W
b11	SPDP	Padding Data Select*2	0: Padding bits are at the low level. 1: Padding bits are at the high level.	R/W
b12	LRCKP	LR Clock Polarity Select*2	0: SSILRCK is low for left channel. The frame boundary is a falling edge of SSILRCK. 1: SSILRCK is high for left channel. The frame boundary is a rising edge of SSILRCK.	R/W

Bit	Symbol	Bit Name	Description	R/W
b13	BCKP	Bit Clock Polarity Select*2	0: Output signals change at a falling edge of bit clock and input signals are sampled at a rising edge of bit clock. 1: Output signals change at a rising edge of bit clock and input signals are sampled at a falling edge of bit clock.	R/W
b14	MST	Master Mode*2	0: Slave mode 1: Master mode	R/W
b15	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b18 to b16	SWL[2:0]	System Word Length Select*2	b18 b16 0 0 0: 8 bits 0 0 1: 16 bits 0 1 0: 24 bits 0 1 1: 32 bits 1 0 0: 48 bits 1 0 1: 64 bits 1 1 0: 128 bits 1 1 1: 256 bits	R/W
b21 to b19	DWL[2:0]	Data Word Length Select*2	b21 b19 0 0 0: 8 bits 0 0 1: 16 bits 0 1 0: 18 bits 0 1 1: 20 bits 1 0 0: 22 bits 1 0 1: 24 bits 1 1 0: 32 bits 1 1 1: Setting prohibited.	R/W
b23, b22	FRM[1:0]	Frame Word Length Select*2	Set a number of system words per a frame. b23 b22 0 0: 2 system words (I^2S, left-justified, or right-justified) or 1 system word (monaural) 0 1: 4 system words (TDM format only) 1 0: 6 system words (TDM format only) 1 1: 8 system words (TDM format only)	R/W
b24	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b25	IIEN	Idle State Interrupt Enable	0: Idle state interrupt disabled 1: Idle state interrupt enabled	R/W
b26	ROIEN	Receive Overflow Interrupt Enable	0: Receive overflow interrupt disabled 1: Receive overflow interrupt enabled	R/W
b27	RUIEN	Receive Underflow Interrupt Enable	0: Receive underflow interrupt disabled 1: Receive underflow interrupt enabled	R/W
b28	TOIEN	Transmit Overflow Interrupt Enable	0: Transmit overflow interrupt disabled 1: Transmit overflow interrupt enabled	R/W
b29	TUIEN	Transmit Underflow Interrupt Enable	0: Transmit underflow interrupt disabled 1: Transmit underflow interrupt enabled	R/W
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. After the TEN or REN bit is rewritten, confirm that the SSISR.IIRQ flag is in the desired status (when transmission or reception is enabled, confirm that the IIRQ flag is 0; when transmission and reception are disabled, confirm that the IIRQ flag is 1).

Note 2. Rewrite these bits while SSIE is in idle state (SSISR.IIRQ flag = 1). If the value of these bits is changed while data transfer is in progress, the operation after the change is not guaranteed.

TEN Bit (Transmission Enable) and REN Bit (Reception Enable)

These bits enable/disable transmission and reception. When one of these bits is set to 1, the given type of data transfer starts in synchronization with a start trigger of the SSILRCK signal. When the bit is set to 0, the data transfer stops at the next frame boundary. To use an SSIE for both transmission and reception, set both the TEN and REN bits to 1 simultaneously. To stop the data transfer, set both the TEN and REN bits to 0 simultaneously.

To switch among transmission, reception, and transception, do so in the idle state.

MUEN Bit (Mute)

This bit is used to mute audio output by driving the SSITXD0 pin low. When this bit is changed during a frame, the setting takes effect at the next frame boundary.
The MUEN bit only controls fixing of the SSITXD0 pin. Status flags are set and interrupt signals are generated regardless of the setting of the MUEN bit.
Changing the value of this bit must be performed after setting the data format to be used.

CKDV[3:0] Bits (Bit Clock Division Ratio Select)

These bits specify the divisor for the generation of a bit clock (BCK) from the master clock (MCK). This bit is disabled in slave mode.
Set these bits while the SSIFCR.AUCKE bit is 0.

DEL Bit (Serial Data Delay Select)

When this bit is 0, a delay of one cycle of the bit clock is inserted between edges of SSILRCK0 and SSITXD0 and SSIRXD0. When 1, no delay is inserted.
Set this bit to 0 for the I^2S format and to 1 for the left-justified or right-justified format. Set this bit in conformance with the other party device for the monaural and TDM formats.When the monaural format is used, setting of this bit changes the high width of SSILRCK.

PDTA Bit (Data Alignment Select)

This bit specifies the alignment of the effective bits in the SSIFTDR and SSIFRDR registers. This bit is valid when the data word length 18 to 24 bits (the DWL[2:0] bits = 010b to 101b). Set this bit to 0, when the other data word length is selected.
Figure 45.3 shows the data alignment of the SSIFTDR and SSIFRDR registers.

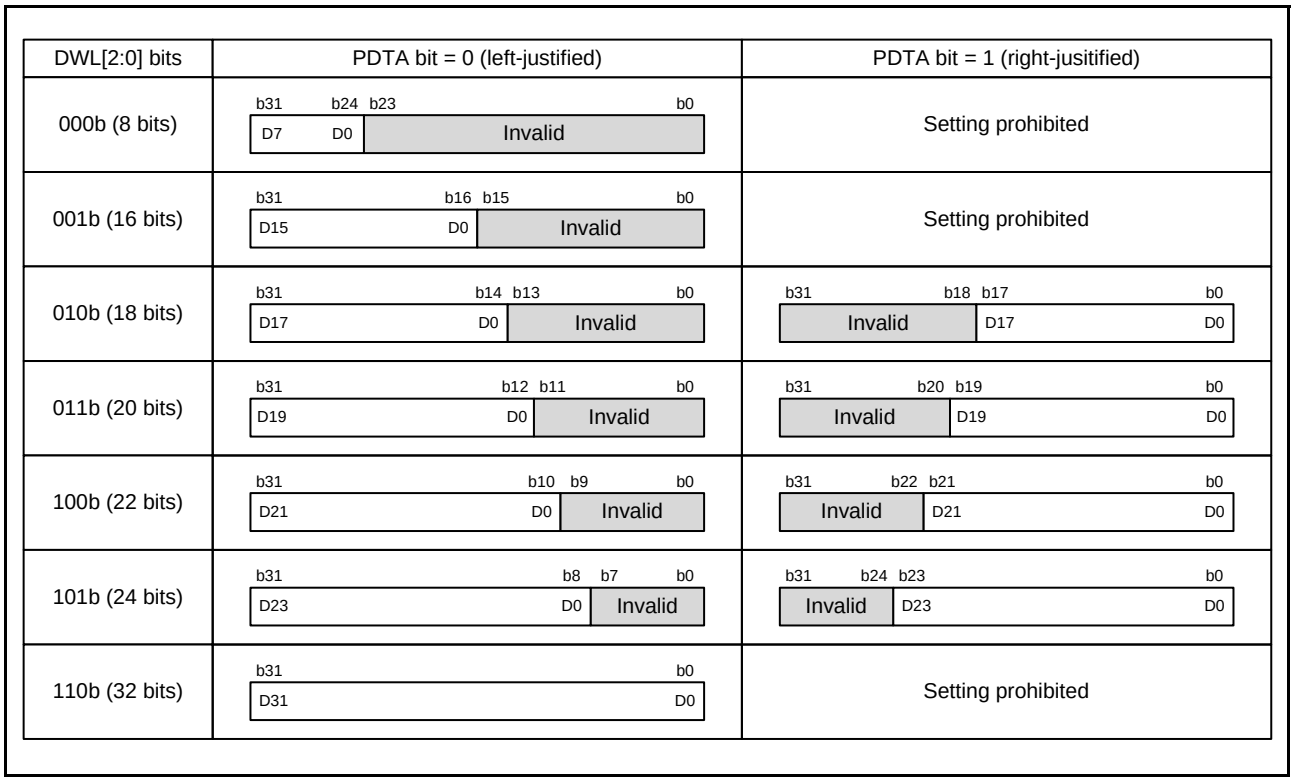

Figure 45.3 Data Alignment in the SSIFTDR and SSIFRDR Registers

SDTA Bit (Serial Data Alignment Select)

This bit specifies the order of data bits and padding bits for transception in system words. SSIE transmits and receives data bits first and then padding bits when this bit is 0 and padding bits first and then data bits when this bit is 1. This bit is invalid for data format without padding bits.

LRCKP Bit (LR Clock Polarity Select)

This bit specifies the initial status and polarity of the SSILRCK pin. Table 45.4 lists the settings of this bit and the corresponding states of the LR clock. SSIE uses the SSILRCK signal as a start trigger in slave mode.
Set this bit to 0 when the I^2S format is selected and 1 when the other data formats are selected.

Table 45.4 The Value of the LRCKP Bit and Responses to the States of the LR clock

LRCKP bit	Initial State	Left Channel	Right Channel	Frame Boundary
0	High	Low	High	Falling edge
1	Low	High	Low	Rising edge

BCKP Bit (Bit Clock Polarity Select)

This bit specifies the polarity of the bit clock. Table 45.5 lists the settings of this bit and the corresponding timings of the respective signals.
Set this bit while the SSIFCR.AUCKE bit is 0.

Table 45.5 The Value of the BCKP bit and the Bit Clock Polarity

BCKP bit	Output of SSILRCK and SSITXD0	Input of SSILRCK and SSIRXD0
0	The signals change on falling edges of SSIBCK.	The signals are sampled on rising edges of SSIBCK.
1	The signals change on rising edges of SSIBCK.	The signals are sampled on falling edges of SSIBCK.

SWL[2:0] Bits (System Word Length Select)

These bits specify the number of bits in a system word. The setting of these bits determines the frequency ratio of the bit clock to the LR clock. Then number of the padding bits is obtained from the difference in the SWL[2:0] and DWL[2:0] bits. Refer to Table 45.8 for details.

DWL[2:0] Bits (Data Word Length Select)

These bits specify the number of bits of valid data in a system word. The data word length must not exceed the system word length. For details, refer to Table 45.8.

FRM[1:0] Bits (Frame Word Length Select)

These bits specify the number of system words in a frame.

Set these bits to 00b when the I^{2}S, left-justified, right-justified, or monaural format is selected. Do not set these bits to 00b when the TDM format is selected.

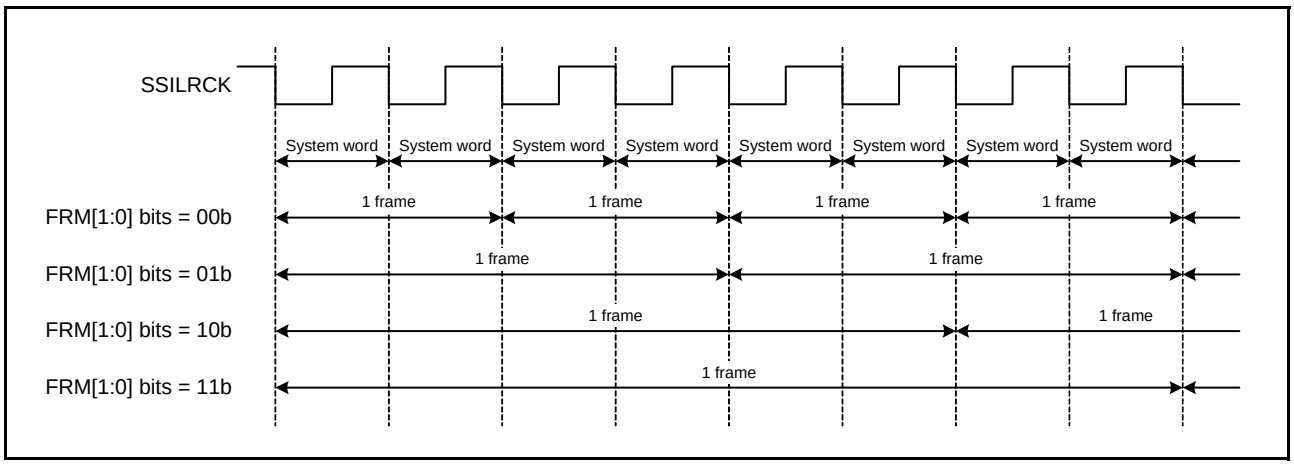

Figure 45.4 Frame Word Length

IIEN Bit (Idle State Interrupt Enable)

This bit enables or disables the idle state interrupts.

While this bit is 1, an interrupt request is output when the SSISR.IIRQ flag becomes 1. An interrupt request is also output when this bit is changed from 0 to 1 while the IIRQ flag is 1.

ROIEN Bit (Receive Overflow Interrupt Enable)

This bit enables or disables interrupts receive overflow interrupts.

While this bit is 1, an interrupt request is output when the SSISR.ROIRQ flag becomes 1. An interrupt request is also output when this bit is changed from 0 to 1 while the ROIRQ flag is 1.

RUIEN Bit (Receive Underflow Interrupt Enable)

This bit enables/disables the receive underflow interrupts.

While this bit is 1, an interrupt request is output when the SSISR.RUIRQ flag becomes 1. An interrupt request is also output when this bit is changed from 0 to 1 while the RUIRQ flag is 1.

TOIEN Bit (Transmit Overflow Interrupt Enable)

This bit enables/disables the transmit overflow interrupts.

While this bit is 1, an interrupt request is output when the SSISR.TOIRQ flag becomes 1. An interrupt request is also output when this bit is changed from 0 to 1 while the TOIRQ flag is 1.

TUIEN Bit (Transmit Underflow Interrupt Enable)

This bit enables/disables the transmit underflow interrupts.

While this bit is 1, an interrupt request is output when the SSISR.TUIRQ flag becomes 1. An interrupt request is also output when this bit is changed from 0 to 1 while the TUIRQ flag is 1.

45.2.2 Status Register (SSISR)

Address(es): SSIE0.SSISR 0008 A504h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	TUIRQ	TOIRQ	RUIRQ	ROIRQ	IIRQ	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b24 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b25	IIRQ	Idle State Flag	0: Transfer state 1: Idle state	R
b26	ROIRQ	Receive Overflow Flag	0: No receive overflows occurred. 1: A receive overflow has occurred.	R/W
b27	RUIRQ	Receive Underflow Flag	0: No receive underflows occurred. 1: A receive underflow has occurred.	R/W
b28	TOIRQ	Transmit Overflow Flag	0: No transmit overflows occurred. 1: A transmit overflow has occurred.	R/W
b29	TUIRQ	Transmit Underflow Flag	0: No transmit underflows occurred. 1: A transmit underflow has occurred.	R/W
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register indicates the SSIE status.

IIRQ Flag (Idle State Flag)

This flag indicates whether SSIE is in the idle state or transfer state.

[Setting condition]

- When a transmission of a frame is completed after changing the SSICR.TEN bit from 1 to 0.
- When a reception of a frame is completed after changing the SSICR.REN bit from 1 to 0.
- When a transmission of a frame is completed after changing the SSICR.TEN and SSICR.REN bits from 1 to 0.

[Clearing condition]

- When a start trigger is generated by writing a transmit data in the SSIFTDR register, while the SSICR.TEN bit is 1.
- When a start trigger is detected while the SSICR.REN bit is 1.
- When a start trigger is generated by writing a transmit data to the SSIFTDR register, while the SSICR.TEN and SSICR.REN bits are 1.

ROIRQ Flag (Receive Overflow Flag)

This flag indicates a receive overflow. This flag indicates that the data processing of the received data is delayed. The received data is not transferred to the receive FIFO if a receive overflow occurs. This flag is not cleared by resetting a receive FIFO.
[Priority order for setting and clearing]
Setting is prioritized.
[Setting condition]

- When a reception of the next data is completed while the receive FIFO is full.

[Clearing condition]

- When 0 is written to this flag after confirming this flag is 1.
- When the SSICR.REN bit is changed from 0 to 1.

RUIRQ Flag (Receive Underflow Flag)

This flag indicates a receive underflow. This flag indicates that the SSIFRDR register is read while the receive FIFO is empty. Data read from the SSIFRDR register is invalid if a receive underflow occurs. This flag is not cleared by resetting a receive FIFO. Reading the SSIFRDR register while resetting the receive FIFO does not lead to setting of this flag.
[Priority order for setting and clearing]
Setting is prioritized.
[Setting condition]

- When the SSIFRDR register is read while the receive FIFO is empty.

[Clearing condition]

- When 0 is written to this flag after confirming this flag is 1.
- When the SSICR.REN bit is changed from 0 to 1.

TOIRQ Flag (Transmit Overflow Flag)

This flag indicates a transmit overflow. This flag indicates that a data is written to the SSIFTDR register while the transmit FIFO is full. The written data is discarded. This flag is not cleared by resetting a transmit FIFO.
[Priority order for setting and clearing]
Setting is prioritized.
[Setting condition]

- When a data is written to the SSIFTDR register while the transmit FIFO is full.

[Clearing condition]

- When 0 is written to this flag after confirming this flag is 1.
- When the SSICR.TEN bit is changed from 0 to 1.

TUIRQ Flag (Transmit Underflow Flag)

This flag indicates a transmit underflow. This flag indicates that supply of the transmit data was not enough to the transmission of the frame. The SSITXD0 pin becomes low if a transmit underflow occurs, and remains low even if the flag is cleared. This flag is not cleared by resetting a transmit FIFO.
[Priority order for setting and clearing]
Setting is prioritized.
[Setting condition]

- When a data transfer to the transmit shift register occurs while the transmit FIFO is empty.

[Clearing condition]

- When 0 is written to this flag after confirming this flag is 1.
- When the SSICR.TEN bit is changed from 0 to 1.

45.2.3 FIFO Control Register (SSIFCR)

Address(es): SSIE0.SSIFCR 0008 A510h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	AUCKE	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SSIRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	BSW	—	—	—	—	—	—	—	TIE	RIE	TFRST	RFRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RFRST	Receive FIFO Reset*1	0: The receive FIFO is released from the reset state. 1: The receive FIFO is reset.	R/W
b1	TFRST	Transmit FIFO Reset*1	0: The transmit FIFO is released from the reset state. 1: The transmit FIFO is reset.	R/W
b2	RIE	Receive Data Full Interrupt Enable	0: Receive data full interrupt is disabled. 1: Receive data full interrupt is enabled.	R/W
b3	TIE	Transmit Data Empty Interrupt Enable	0: Transmit data empty interrupt is disabled. 1: Transmit data empty interrupt is enabled.	R/W
b10 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11	BSW	Byte Swap*1	0: Byte swapping is disabled 1: Byte swapping is enabled	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	SSIRST	Software Reset	0: The software reset is released. 1: A software reset is applied.	R/W
b30 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31	AUCKE	MCK Supply Enable*1	0: MCK is stopped. 1: MCK is supplied.	R/W

Note 1. Rewrite these bits while SSIE is in idle state (SSISR.IIRQ flag = 1). If the value of these bits is changed while data transfer is in progress, the operation after the change is not guaranteed.

RFRST Bit (Receive FIFO Reset)

This bit is used to reset the receive FIFO. Writing 1 to this bit resets the receive FIFO and initializes the RDC[5:0] bits and RDF flag in the SSIFSR register. Since this bit is not automatically cleared, write 0 to this bit to release from the reset state. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedure.
This bit is subject to the software reset by the SSIRST bit. Because the software reset by the SSIRST bit has priority over the reset by this bit, this bit cannot be set to 1 when the SSIRST bit is 1.

TFRST Bit (Transmit FIFO Reset)

This bit is used to reset the transmit FIFO. Writing 1 to this bit resets the transmit FIFO and initializes the TDC[5:0] bits and TDE flag in the SSIFSR register. Since this bit is not automatically cleared, write 0 to this bit to release from the reset state. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedure.
This bit is subject to the software reset by the SSIRST bit. Because the software reset by the SSIRST bit has priority over the reset by this bit, this bit cannot be set to 1 when the SSIRST bit is set.

RIE Bit (Receive Data Full Interrupt Enable)

This bit enables or disables a receive data full interrupt. Set this bit to 1 after specifying the condition for generating a receive data full interrupt in the SSISCR.RDFS[4:0] bits.

TIE Bit (Transmit Data Empty Interrupt Enable)

This bit enables or disables a transmit data empty interrupt. Set this bit to 1 after specifying the condition for generating a transmit data empty interrupt in the SSISCR.TDES[4:0] bits.

BSW Bit (Byte Swap)

The BSW bit enables or disables byte swapping when the SSIFTDR is written and the SSIFRDR register is read. This bit is valid only when the SSIFTDR and SSIFRDR register are accessed in 16-bit or 32-bit units. For details, refer to Figure 45.5.

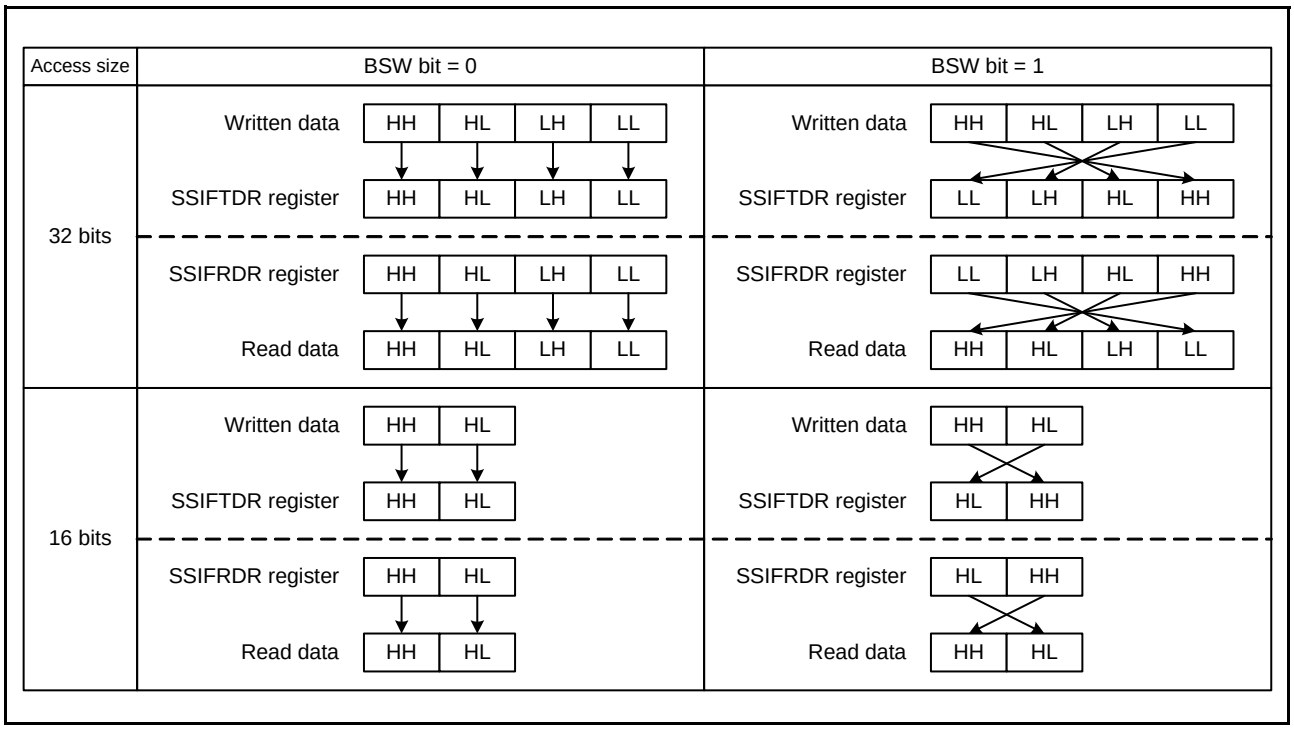

Figure 45.5 Examples of Byte-Swapping Operations

SSIRST Bit (Software Reset)

This bit is used to reset SSIE. Writing 1 to this bit initializes the internal state of SSIE. The registers and bits to be reset by setting this bit are listed below.

- SSICR.MUEN, TEN, and REN bits
- SSISR register
- SSIFCR.TFRST and RFRST bits
- SSIFSR register
- SSIFTDR register
- SSIFRDR register

Because this bit is not automatically cleared, write 0 to this bit to release from the reset state. After writing 0 to this bit, be sure to check that this bit is 0 before starting the next procedure.

Because writing 1 to this bit during data transfer leads to initialization by software reset regardless of the bit clock, be careful to stop data transfer by using this bit.

AUCKE Bit (MCK Supply Enable)

This bit enables/disables supply of MCK while in master-mode. The setting value of this bit is reflected at the timing shown in Figure 45.6.

Changes to settings related to MCK (the settings of the MST, BCKP, and CKDV[3:0] bits in the SSICR register) should only proceed while this bit is 0.

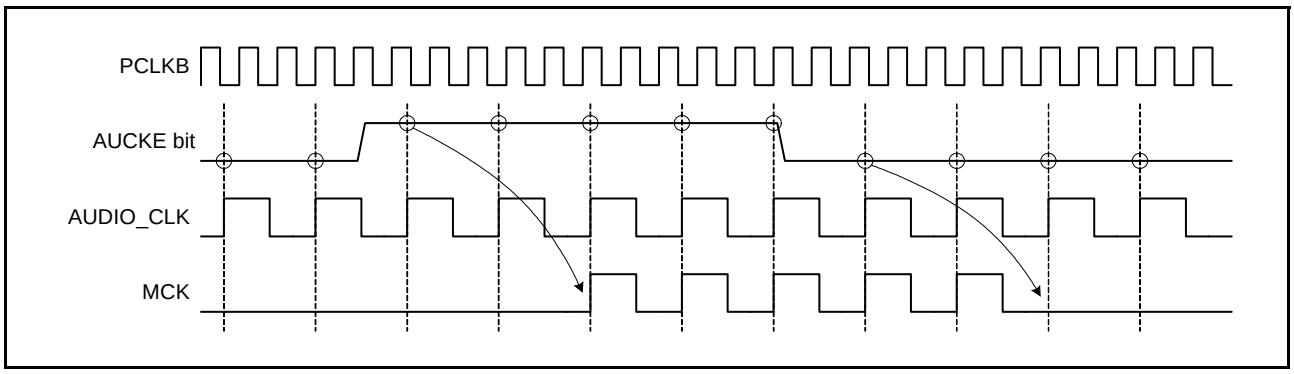

Figure 45.6 Supplying and Stopping MCK

45.2.4 FIFO Status Register (SSIFSR)

Address(es): SSIE0.SSIFSR 0008 A514h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	TDC[5:0]						—	—	—	—	—	—	—	TDE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	RDC[5:0]						—	—	—	—	—	—	—	RDF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RDF	Receive Data Full Flag	0: The number of received data stored in the receive FIFO does not exceed the value of the SSISCR.RDFS[4:0] bits. 1: The number of received data stored in the receive FIFO exceeds the value of the RDFS[4:0] bits.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13 to b8	RDC[5:0]	Receive FIFO Data Count	Number of data stored in the receive FIFO	R
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	TDE	Transmit Data Empty Flag	0: The number of spaces available in the transmit FIFO does not exceed the value of the SSISCR.TDES[4:0] bits 1: The number of spaces available in the transmit FIFO exceeds the value of TDES[4:0] bits.	R/W
b23 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b29 to b24	TDC[5:0]	Transmit FIFO Data Count	Number of data stored in the transmit FIFO	R
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register indicates the status of the transmit FIFO and the receive FIFO.

RDF Flag (Receive Data Full Flag)

This flag indicates that the number of unread data in the receive FIFO is more than the value of the SSISCR.RDFS[4:0] bits.

[Priority order for setting and clearing]

Clearing is prioritized.

[Setting condition]

- When the number of data stored in the receive FIFO exceeds the value of the SSISCR.RDFS[4:0] bits.

[Clearing condition]*1

- When 0 is written to this flag after confirming this flag is 1.
- When a received data is read from the SSIFRDR register by DMA/DTC transfer (the last transfer of the block if using block transfer).

Note 1. This flag is cleared by a software reset and receive FIFO reset.

RDC[5:0] Bits (Receive FIFO Data Count)

These bits indicate the number of valid data that are stored in the receive FIFO. When this bit is 00h, there is no received data. When 20h, the receive FIFO is full and there is no space available.

TDE Flag (Transmit Data Empty Flag)

This flag indicates that the number of spaces available in the transmit FIFO is more than the value of the SSISCR.TDES[4:0] bits.
[Priority order for setting and clearing]
Clearing is prioritized.
[Setting condition]

- When the number of spaces available in the transmit FIFO exceeds the value of the SSISCR.TDES[4:0] bits.

[Clearing condition]*1

- When 0 is written to this flag after confirming this flag is 1.
- When a transmit data is written to the SSIFTDR register by DMA/DTC transfer (the last transfer of the block if using block transfer).

Note 1. This flag is cleared by a software reset and transmit FIFO reset.

TDC[5:0] Bits (Transmit FIFO Data Count)

These bits indicate the number of valid data that are stored in the transmit FIFO. When this bit is 00h, there is no data to be transmitted. When 20h, the transmit FIFO is full and there is no space available.

45.2.5 Transmit FIFO Data Register (SSIFTDR)

- When accessing in longword size

Address(es): SSIE0.SSIFTDR 0008 A518h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- When accessing in word size

Address(es): SSIE0.SSIFTDR.H 0008 A518h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	H															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- When accessing in byte size

Address(es): SSIE0.SSIFTDR.HH 0008 A518h

	b7	b6	b5	b4	b3	b2	b1	b0
	HH							
Value after reset:	0	0	0	0	0	0	0	0

This register is a write-only register used to write a transmit data to the 32-stage and 4-byte-wide transmit FIFO. Access to this register according to the access size listed in Table 45.6.

Table 45.6 Access Size to the SSIFTDR and SSIFRDR Registers

		Access Size		
SSICR.DWL[2:0] Bits	**Data Word Length**	**Byte**	**Word**	**Longword**
000b	8	Available	Not available	Not available
001b	16	Not available	Available	Not available
010b	18	Not available	Not available	Available
011b	20	Not available	Not available	Available
100b	22	Not available	Not available	Available

45.2.6 Receive FIFO Data Register (SSIFRDR)

- When accessing in longword size

Address(es): SSIE0.SSIFRDR 0008 A51Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- When accessing in word size

Address(es): SSIE0.SSIFRDR.H 0008 A51Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	H															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- When accessing in byte size

Address(es): SSIE0.SSIFRDR.HH 0008 A51Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	HH							
Value after reset:	0	0	0	0	0	0	0	0

This register is a read-only register used to read a received data from the 32-stage and 4-byte-wide receive FIFO. Access to this register according to the access size listed in Table 45.6.

45.2.7 Audio Format Register (SSIOFR)

Address(es): SSIE0.SSIOFR 0008 A520h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	BCKASTP	LRCONT	—	—	—	—	—	—	OMOD[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	OMOD[1:0]	Data Format Select*1	b1 b0 0 0: I²S, left-justified, or right-justified format 0 1: TDM format 1 0: Monaural format 1 1: Setting prohibited	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	LRCONT	LRCK Continuous Output Enable*2, *3	0: LRCK stops in the idle state. 1: Output of LRCK continues in the idle state.	R/W
b9	BCKASTP	BCK Continuous Output Disable*2, *3	0: BCK is always output. 1: BCK stops in idle state.	R/W
b31 to b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Rewrite these bits while SSIE is in idle state (SSISR.IIRQ flag = 1). If the value of these bits is changed while data transfer is in progress, the operation after the change is not guaranteed.
Note 2. This bit is valid only in master-mode. The setting is invalid in slave-mode.
Note 3. Do not set both of the BCKASTP and LRCONT bits to 1.

This register is used to set an audio format (which includes the settings of data format, LR clock continuous output mode, and BCK continuous output disable).

LRCONT Bit (LRCK Continuous Output Enable)

This bit enables or disables the output from SSILRCK pin when SSIE is in the idle state. This bit is effective only in master mode.

BCKASTP Bit (BCK Continuous Output Disable)

This bit enables or disables the output from SSIBCK pin when SSIE is in the idle state. This bit is effective only in master mode.

Set this bit to 0 to output BCK from the SSIBCK pin before starting data transfer. If this bit is set to 1 during data transfer, BCK output from the SSIBCK pin stops when the SSIE enters the idle state.

Set this bit after the data format to be used is specified. Do not rewrite this bit while the supply of MCK stops.

45.2.8 FIFO Status Control Register (SSISCR)

Address(es): SSIE0.SSISCR 0008 A524h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	TDES[4:0]					—	—	—	RDFS[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	RDFS[4:0]	Receive Data Full Condition Setting*1	Specifies the condition for setting the RDF flag to 1. b4 b0 00000: When receive FIFO has unread received data. 00001: When receive FIFO has two or more unread received data. ... 11110: When receive FIFO has 31 or more unread received data. 11111: When receive FIFO is full.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12 to b8	TDES[4:0]	Transmit Data Empty Condition Setting*1	Specifies the condition for setting the TDE flag to 1. b12 b8 00000: When transmit FIFO has space available. 00001: When transmit FIFO has at least two stages available. ... 11110: When transmit FIFO has at least 31 stages available. 11111: When transmit FIFO is empty.	R/W
b31 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Rewrite these bits while SSIE is in idle state (SSISR.IIRQ flag = 1). If the value of these bits is changed while data transfer is in progress, the operation after the change is not guaranteed.

45.3 Operation

45.3.1 Data Formats

SSIE supports five data formats. Table 45.7 lists the supported data formats.

Table 45.7 Supported Data Formats and Bit Setting

Data Format	SSIOFR.OMOD[1:0] Bits	SSICR.DEL Bit	SSICR.LRCKP Bit	SSICR.SDTA Bit
I^2S format	00b	0	0	0
Left-justified format	00b	1	1	0
Right-justified format	00b	1	1	1
TDM format	01b	0 or 1	1	0 or 1
Monaural format	10b	0 or 1	1	0 or 1

The following describes the serial data structure shared by data formats.
A serial data structure is defined by the system word length (set in the SSICR.SWL[2:0] bits) and the data word length (set in the SSICR.DWL[2:0] bits). If the data word length is shorter than the system word length, padding bits are inserted (Figure 45.7).

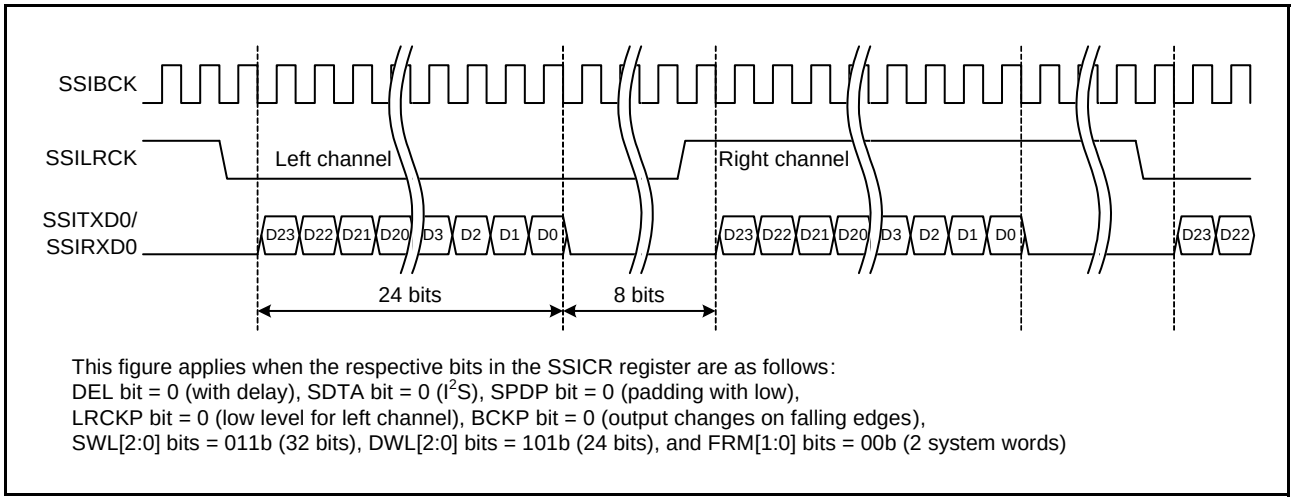

Figure 45.7 Example of Padding Bit Insertion (I^2S Format, System Word Length > Data Word Length)

The number of padding bits is calculated from the system word length minus the data word length.
Table 45.8 lists the number of padding bits to be inserted with each combination of system word length (SWL[2:0] bits) and data word length (DWL[2:0] bits).

Table 45.8 Number of Padding Bits

System Word Length (SSICR.SWL[2:0] Bits)	Data Word Length (SSICR.DWL[2:0] Bits)						
	8 (000b)	**16 (001b)**	**18 (010b)**	**20 (011b)**	**22 (100b)**	**24 (101b)**	**32 (110b)**
8 (000b)	0	Prohibited setting	Prohibited setting	Prohibited setting	Prohibited setting	Prohibited setting	Prohibited setting
16 (001b)	8	0	Prohibited setting	Prohibited setting	Prohibited setting	Prohibited setting	Prohibited setting
24 (010b)	16	8	6	4	2	0	Prohibited setting
32 (011b)	24	16	14	12	10	8	0
48 (100b)	40	32	30	28	26	24	16
64 (101b)	56	48	46	44	42	40	32
128 (110b)	120	112	110	108	106	104	96
256 (111b)	248	240	238	236	234	232	224

45.3.1.1 I²S Format

The I²S format configures a frame with two system words of left channel and right channel. The SSILRCK signals becomes low for left channel and high for right channel. The effective data are output one bit clock period after the SSILRCK changes and then the padding bits are output.
Figure 45.8 shows an example of I²S format.

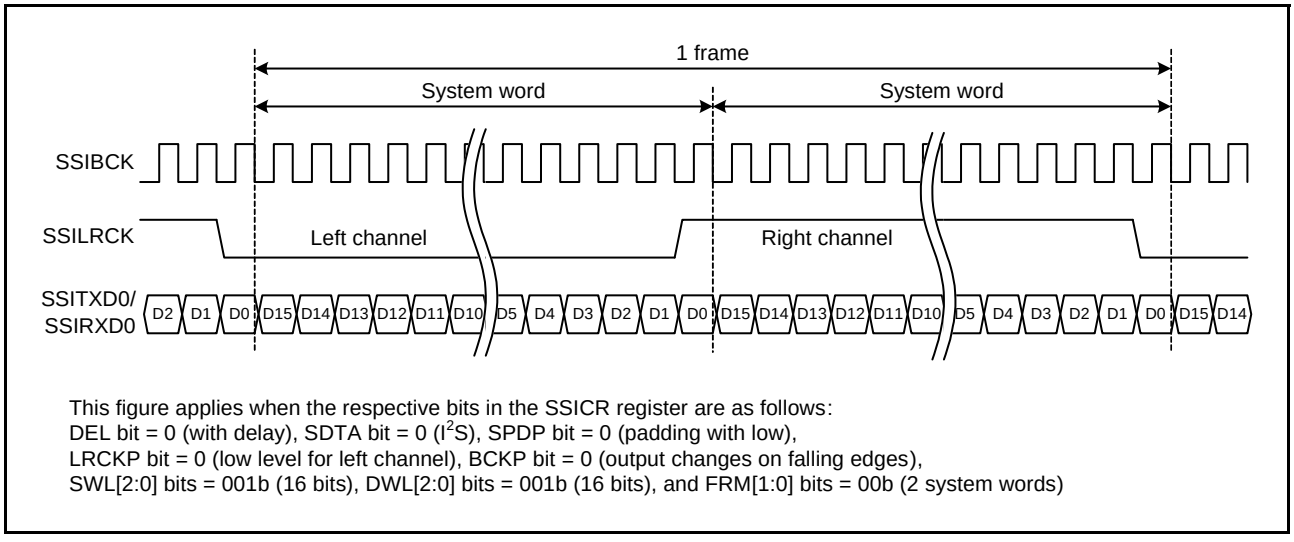

Figure 45.8 Example of I²S Format

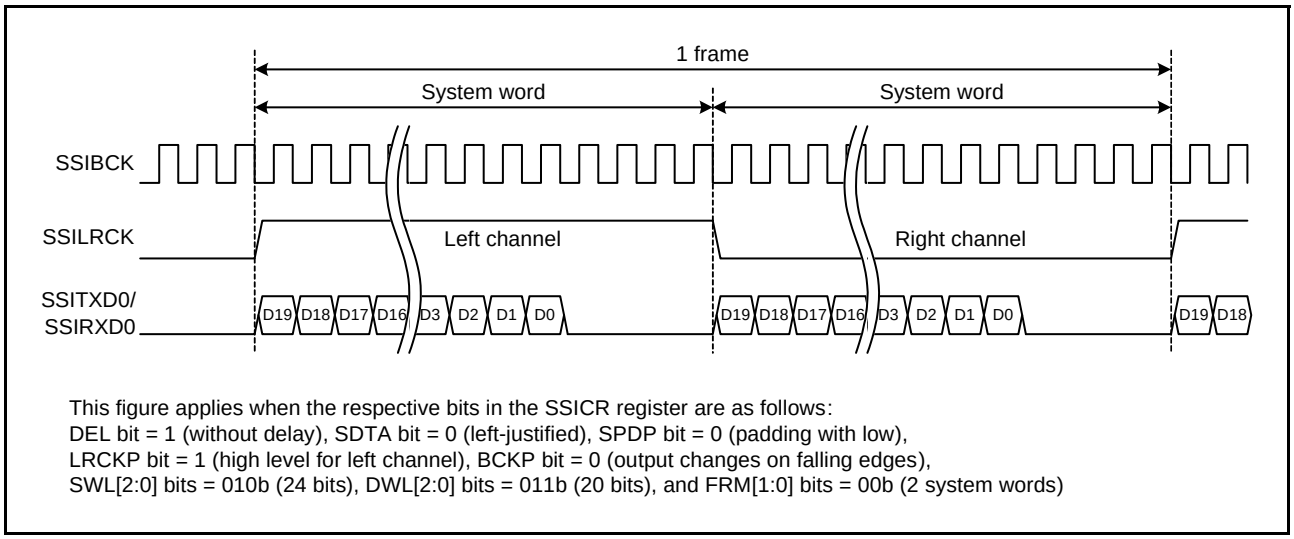
45.3.1.2 Left-Justified Format

The left-justified format configures a frame with two system words of left channel and right channel. The SSILRCK signals becomes high for left channel and low for right channel. The effective data are output at the same time as the SSILRCK changes and then the padding bits are output.
Figure 45.9 shows an example of left-justified format.

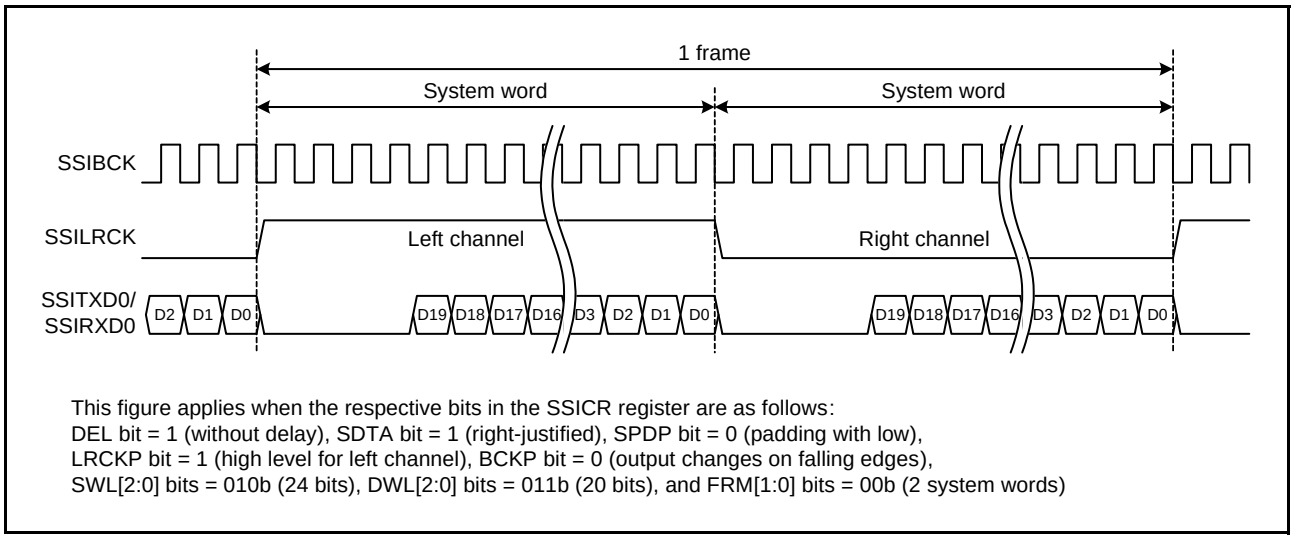


This figure applies when the respective bits in the SSICR register are as follows:
DEL bit = 1 (without delay), SDTA bit = 0 (left-justified), SPDP bit = 0 (padding with low),
LRCKP bit = 1 (high level for left channel), BCKP bit = 0 (output changes on falling edges),
SWL[2:0] bits = 010b (24 bits), DWL[2:0] bits = 011b (20 bits), and FRM[1:0] bits = 00b (2 system words)

Figure 45.9 Example of Left-Justified Format

45.3.1.3 Right-Justified Format

The right-justified format configures a frame with two system words of left channel and right channel. The SSILRCK signals becomes high for left channel and low for right channel. The padding bits are output at the same time as the SSILRCK changes and then the effective data are output.
Figure 45.10 shows an example of right-justified format.



This figure applies when the respective bits in the SSICR register are as follows:
DEL bit = 1 (without delay), SDTA bit = 1 (right-justified), SPDP bit = 0 (padding with low),
LRCKP bit = 1 (high level for left channel), BCKP bit = 0 (output changes on falling edges),
SWL[2:0] bits = 010b (24 bits), DWL[2:0] bits = 011b (20 bits), and FRM[1:0] bits = 00b (2 system words)

Figure 45.10 Example of Right-Justified Format

45.3.1.4 Monaural Format

The monaural format configures a frame with one system word. The SSILRCK signal is used as a transfer start trigger. Figure 45.11, Figure 45.12, and Figure 45.13 show examples of monaural formats with 0 as the value of the SSICR.DEL bit and no padding bits, with 0 as the value of the DEL bit and padding bits, and with 1 as the value of the DEL bit and no padding bits, respectively.

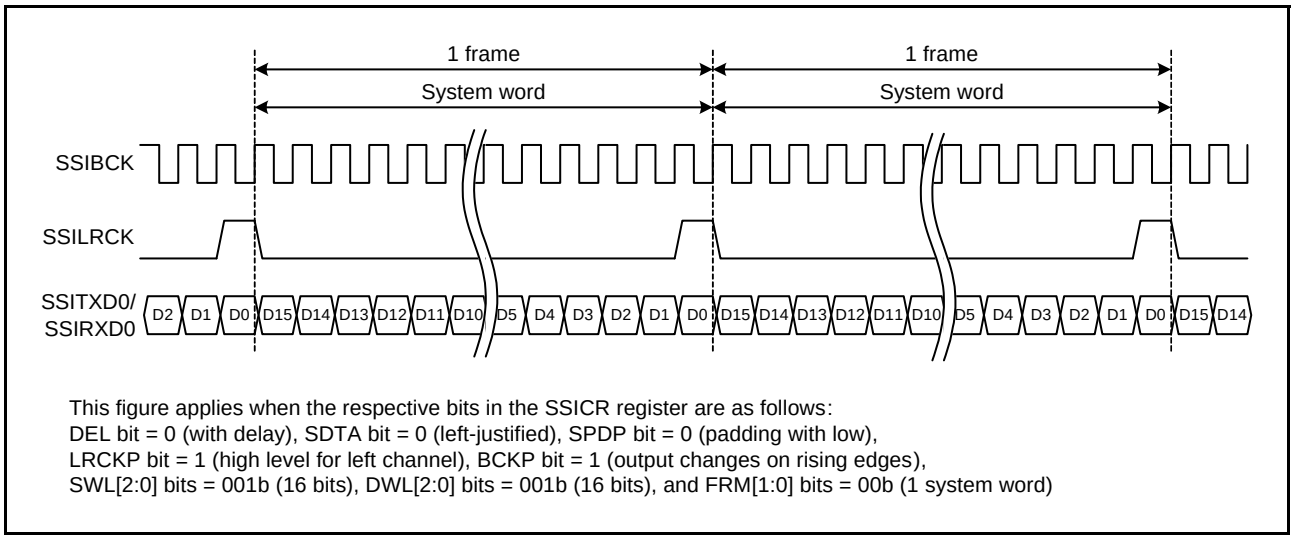


Figure 45.11 Example of Monaural Format (1): SSICR.DEL Bit = 0 and No Padding

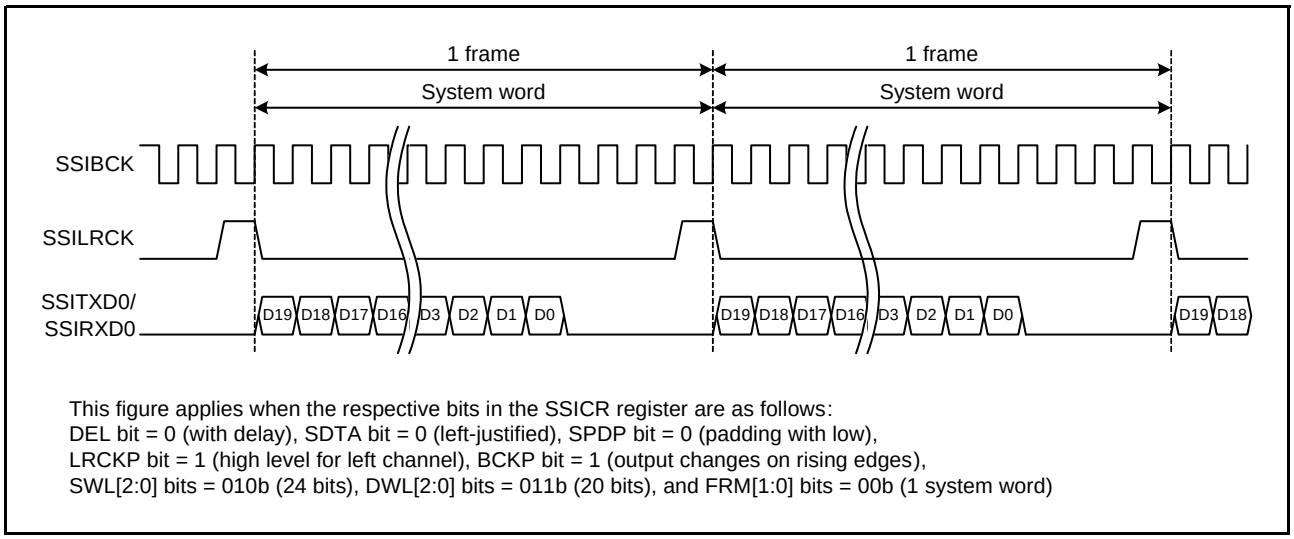

Figure 45.12 Example of Monaural Format (2): SSICR.DEL Bit = 0 and Padding Bits

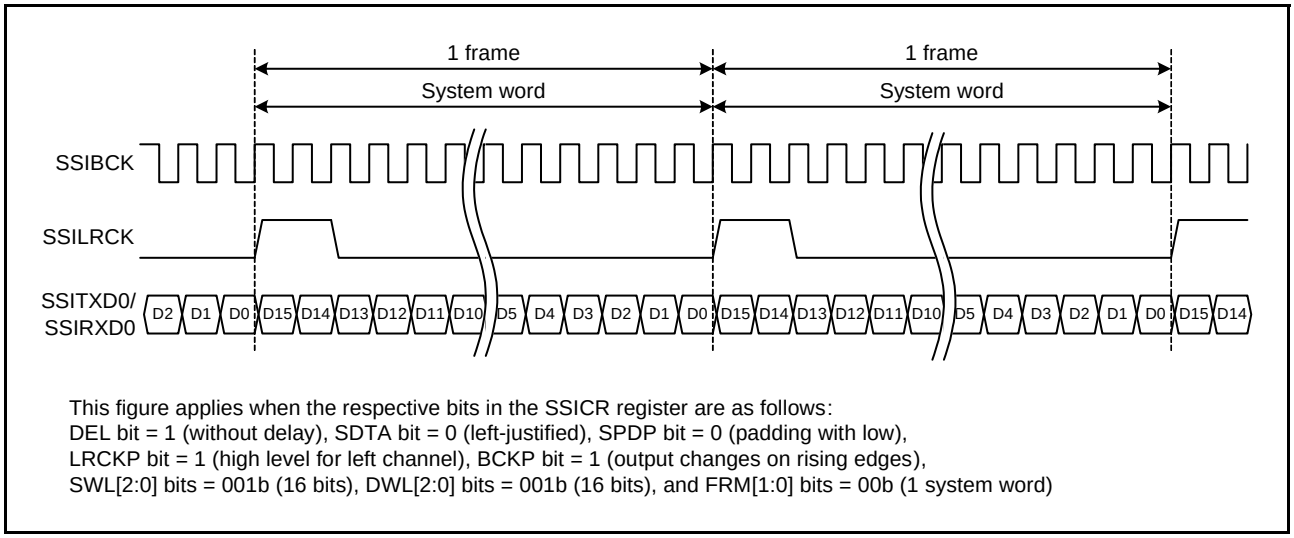

Figure 45.13 Example of Monaural Format (3): SSICR.DEL Bit = 1 and No Padding

45.3.1.5 TDM Format

The TDM format configures a frame with four to eight system words. The SSILRCK signals become high for the first system word and low for the other system words. The SSILRCK signal is defined as the synchronous pulse and its rising edge means a start of a frame.

Figure 45.14 and Figure 45.15 show examples of the TDM formats with 0 as the value of the SSICR.DEL bit and no padding bits, and with 1 as the value of the SSICR.DEL bit and padding bits, respectively.

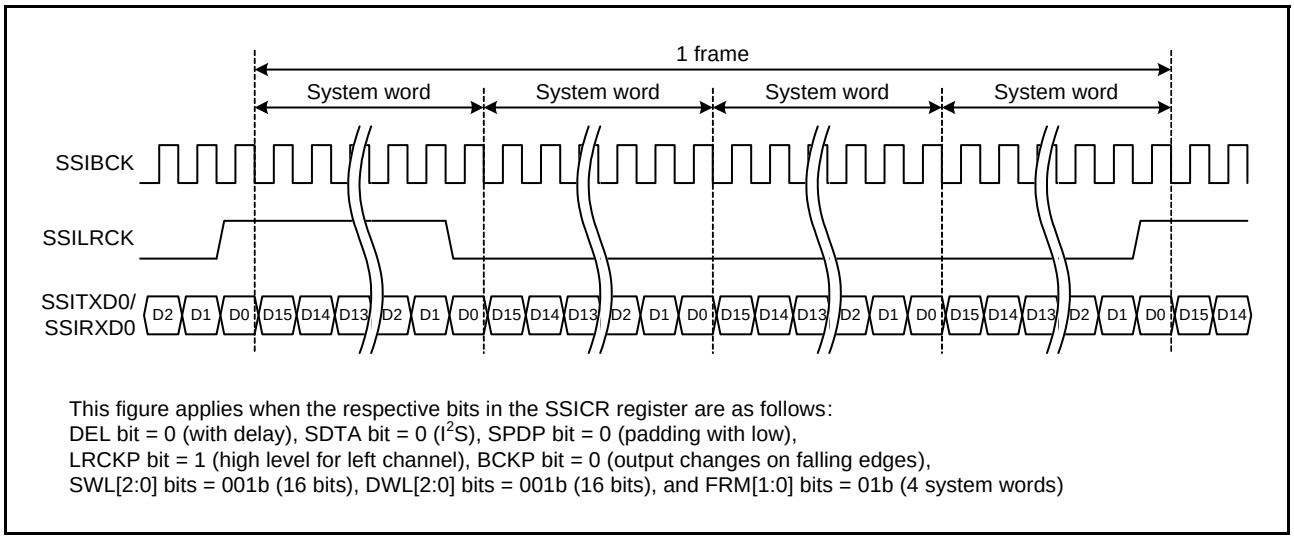

Figure 45.14 Example of TDM Format (1): SSICR.DEL Bit = 0 and No Padding

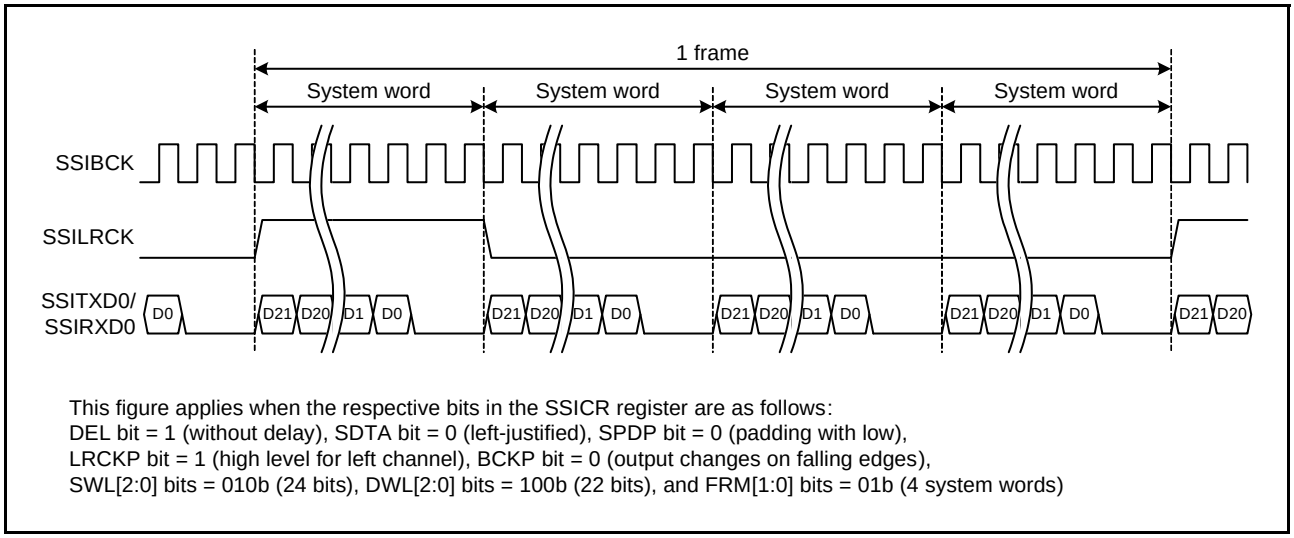


This figure applies when the respective bits in the SSICR register are as follows:
DEL bit = 1 (without delay), SDTA bit = 0 (left-justified), SPDP bit = 0 (padding with low),
LRCKP bit = 1 (high level for left channel), BCKP bit = 0 (output changes on falling edges),
SWL[2:0] bits = 010b (24 bits), DWL[2:0] bits = 100b (22 bits), and FRM[1:0] bits = 01b (4 system words)

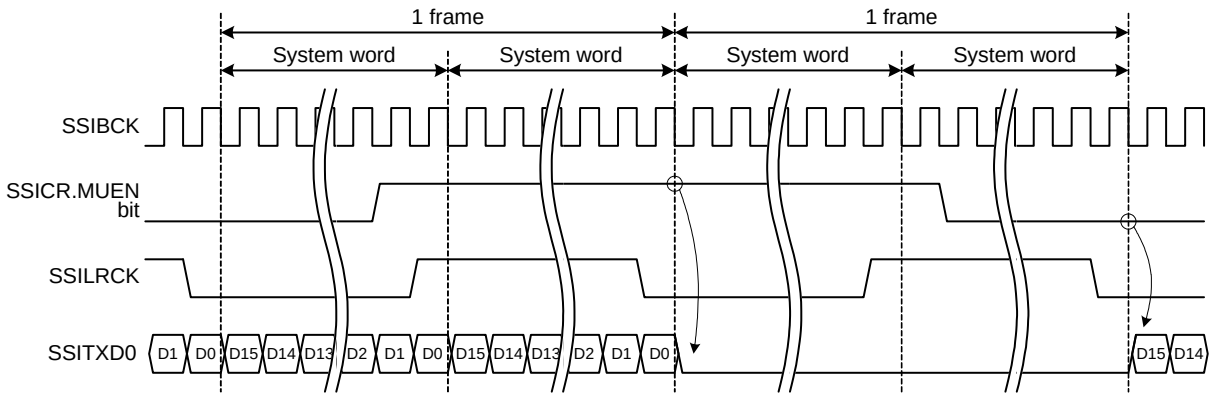
Figure 45.15 Example of TDM Format (2): SSICR.DEL Bit = 1 and Padding Bits

45.3.2 Output Control

SSIE has functions to control the outputs of data and clocks such as mute function, LRCK continuous output function, and BCK continuous output disable function.

45.3.2.1 Mute Function

The output from the SSITXD0 pin can be fixed to the low level by using the mute function. If the SSICR.MUEN bit is changed during a frame, the setting takes effect at the next frame boundary. Even while the MUEN bit is set to 1, status flags are updated and interrupt request signals are generated.
Figure 45.16 shows an example of the mute operation.



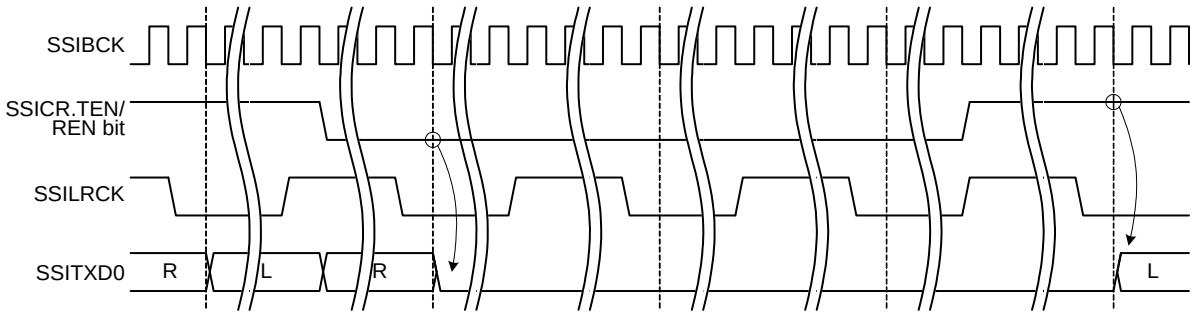
This figure applies when the respective bits in the SSICR register are as follows:
DEL bit = 0 (with delay), SDTA bit = 0 (I^2S), SPDP bit = 0 (padding with low),
LRCKP bit = 0 (low level for left channel), BCKP bit = 0 (output changes on falling edges),
SWL[2:0] bits = 001b (16 bits), DWL[2:0] bits = 001b (16 bits), and FRM[1:0] bits = 00b (2 system words)

Figure 45.16 Example of Mute Operation

45.3.2.2 LRCK Continuous Output Function

LRCK can be output from the SSILRCK pin even in the idle state by using the LRCK continuous output function. It is controlled by the SSIOFR.LRCONT bit.

Figure 45.17 shows an example of the operation with LRCK continuous output function.



This figure applies when the respective bits in the SSICR register are as follows:
DEL bit = 0 (with delay), SDTA bit = 0 (I^2S), SPDP bit = 0 (padding with low),
LRCKP bit = 0 (low level for left channel), BCKP bit = 0 (output changes on falling edges),
and FRM[1:0] bits = 00b (2 system words)

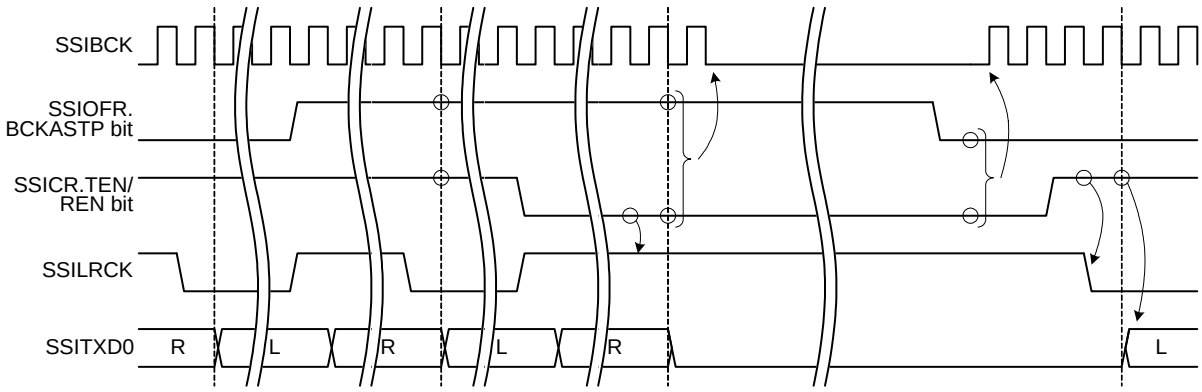
Figure 45.17 Example of Operation with LRCK Continuous Output Function

45.3.2.3 BCK Continuous Output Disable Function

BCK output from the SSIBCK pin can be stopped in the idle state by using the BCK continuous output disable function. It is controlled by the SSIOFR.BCKASTP bit. When the BCKASTP bit is set to 1, BCK stops in the idle state.

Set the BCKASTP bit to 0 and then start data transfer. If this bit is set to 1 during data transfer, BCK stops when SSIE enters the idle state. To resume the data transfer, set the BCKSTP bit to 0 to output BCK and then set the SSICR.TEN/REN bit to 1.

Figure 45.18 shows an example of the operation with BCK continuous output disable function.



This figure applies when the SSIOFR.LRCONT bit is 0 and the respective bits in the SSICR register are as follows:
DEL bit = 0 (with delay), SDTA bit = 0 (I^2S), SPDP bit = 0 (padding with low),
LRCKP bit = 0 (low level for left channel), BCKP bit = 0 (output changes on falling edges),
and FRM[1:0] bits = 00b (2 system words)

Figure 45.18 Example of Operation with BCK Continuous Output Disable Function

45.3.3 Transfer Modes

SSIE supports the transfer modes listed in Table 45.9. Table 45.10 lists the control bits valid in each transfer mode.

Table 45.9 Transfer Modes

Transfer Mode	SSICR.MST Bit	SSICR.REN Bit	SSICR.TEN Bit
Slave-mode transmission	0	0	1
Slave-mode reception	0	1	0
Slave-mode transception	0	1	1
Master-mode transmission	1	0	1
Master-mode reception	1	1	0
Master-mode transception	1	1	1

Table 45.10 Control Bits Valid in Each Transfer Mode*1

Control Bit		Transfer Mode					
Register	Bit	Slave-mode Reception	Slave-mode Transmission	Slave-mode Transception	Master-mode Reception	Master-mode Transmission	Master-mode Transception
SSICR	CKDV[3:0]	Ineffective	Ineffective	Ineffective	Effective	Effective	Effective
	MUEN	Ineffective	Effective	Effective	Ineffective	Effective	Effective
SSIFCR	AUCKEN	Ineffective	Ineffective	Ineffective	Effective	Effective	Effective
	TIE	Ineffective	Effective	Effective	Ineffective	Effective	Effective
	RIE	Effective	Ineffective	Effective	Effective	Ineffective	Effective
	TFRST	Ineffective	Effective	Effective	Ineffective	Effective	Effective
	RFRST	Effective	Ineffective	Effective	Effective	Ineffective	Effective
SSIOFR	BCKASTP	Ineffective	Ineffective	Ineffective	Effective	Effective	Effective
	LRCONT	Ineffective	Ineffective	Ineffective	Effective	Effective	Effective
	OMOD[1:0]	Effective	Effective	Effective	Effective	Effective	Effective
SSISCR	TDES[4:0]	Ineffective	Effective	Effective	Ineffective	Effective	Effective
	RDFS[4:0]	Effective	Ineffective	Effective	Effective	Ineffective	Effective

Note 1. “Ineffective” means that the setting of the bits does not affect operation.

45.3.3.1 Slave Mode

The SSIE operates in slave mode when the SSICR.MST bit is 0. The SSIBCK and SSILRCK signals must be supplied from an external device.

45.3.3.2 Master Mode

The SSIE operates in master mode when the SSICR.MST bit is 1. The SSIBCK and SSILRCK signals are internally generated from the audio clock (AUDIO_CLK).

45.3.3.3 Transmission

The SSIE operates as a transmitter when the SSICR.TEN bit is 1 and the SSICR.REN bit is 0. Receive circuits do not operate.

45.3.3.4 Reception

The SSIE operates as a receiver when the SSICR.TEN bit is 0 and the SSICR.REN bit is 1. Transmit circuits do not

operate.

45.3.3.5 Transception

The SSIE operates as a transceiver when both of the SSICR.TEN and SSICR.REN bits are 1.

45.3.4 State Transition

SSIE has the two main operation states: idle state and transfer state. The SSICR.TEN and SSICR.REN bits switch between these states. The SSISR.IIRQ flag can be used to confirm in which state SSIE is.
Figure 45.19 shows the state transition of the SSIE.

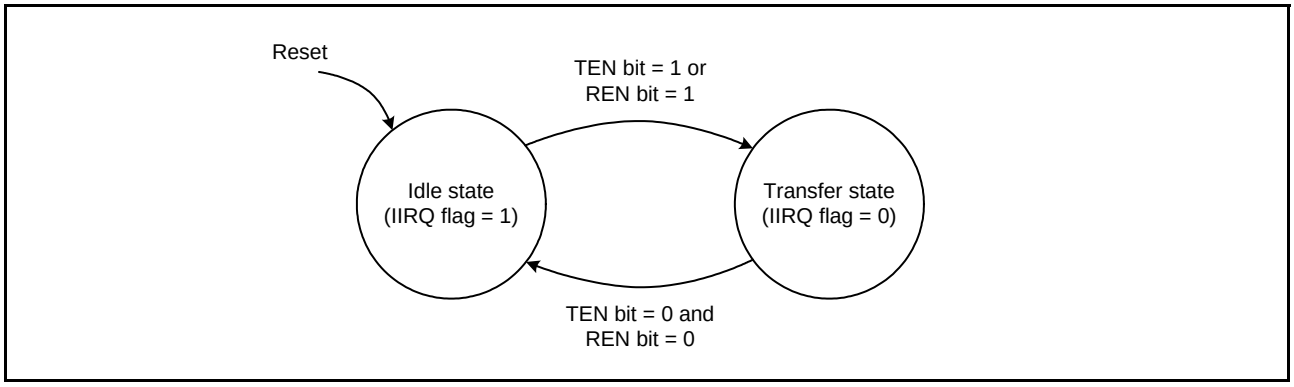


Figure 45.19 State Transition of the SSIE

45.3.4.1 Idle State

In the idle state, SSIE stops data transfer. When both or either of the SSICR.TEN and SSICR.REN bits are/is set to 1, the SSIE enters the transfer state.
Outputs of the BCK and LRCK in master mode can be controlled by the SSIOFR.BCKASTP and SSIOFR.LRCONT bits, respectively. For details, refer to Table 45.11.

Table 45.11 Output of Clock/Data in the Idle State

SSICR.MST Bit	SSIOFR.BCKASTP Bit	SSIOFR.LRCONT Bit	SSIBCK	SSILRCK	SSITXD0
0	Invalid	Invalid	— (input)	— (input)	Stop
1	0	0	Supply	Stop	Stop
1	0	1	Supply	Supply	Stop
1	1	0	Stop	Stop	Stop
1	1	1	Stop	Supply	Stop

45.3.4.2 Transfer States

In this state, SSIE continues data transfer. When the SSICR.TEN and SSICR.REN bit is set to 0, SSIE enters the idle state.

For details, refer to Figure 45.20.

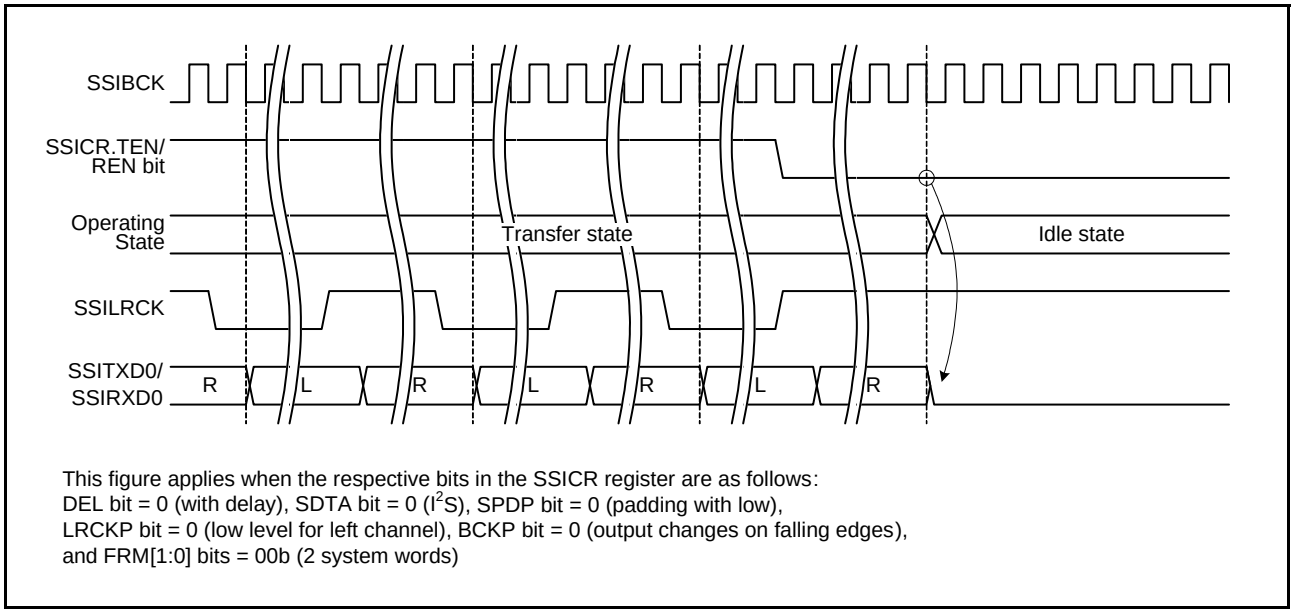

Figure 45.20 Transfer State and Transition to Idle State

45.3.5 SSIE Initialization

Figure 45.21 shows an example of the flow to initialize SSIE.

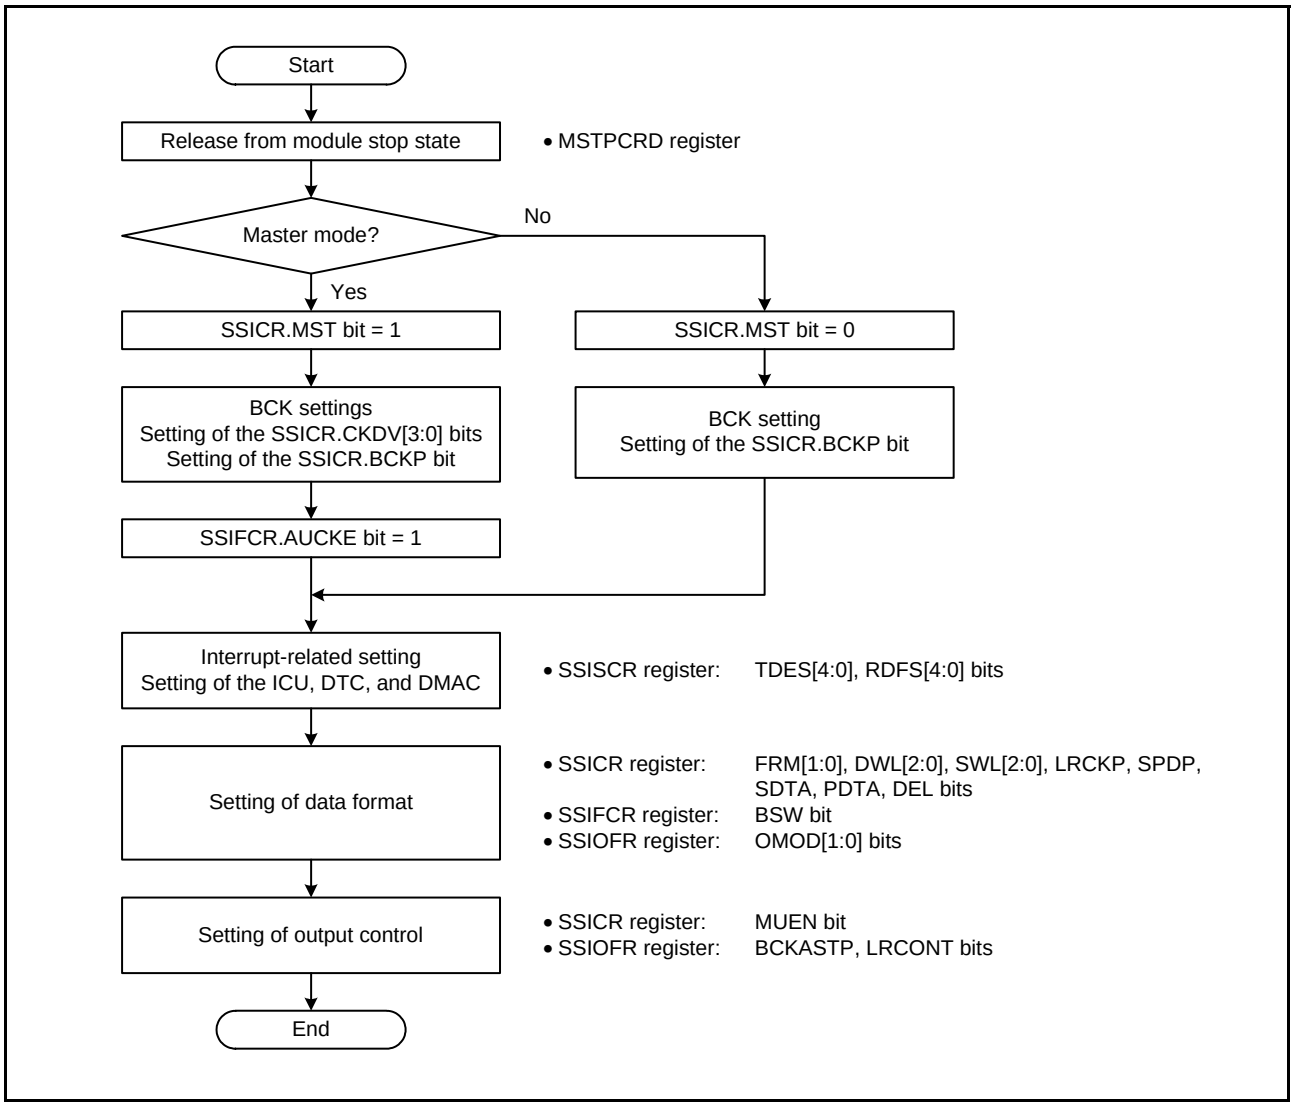

Figure 45.21 Example Flowchart of SSIE Initialization

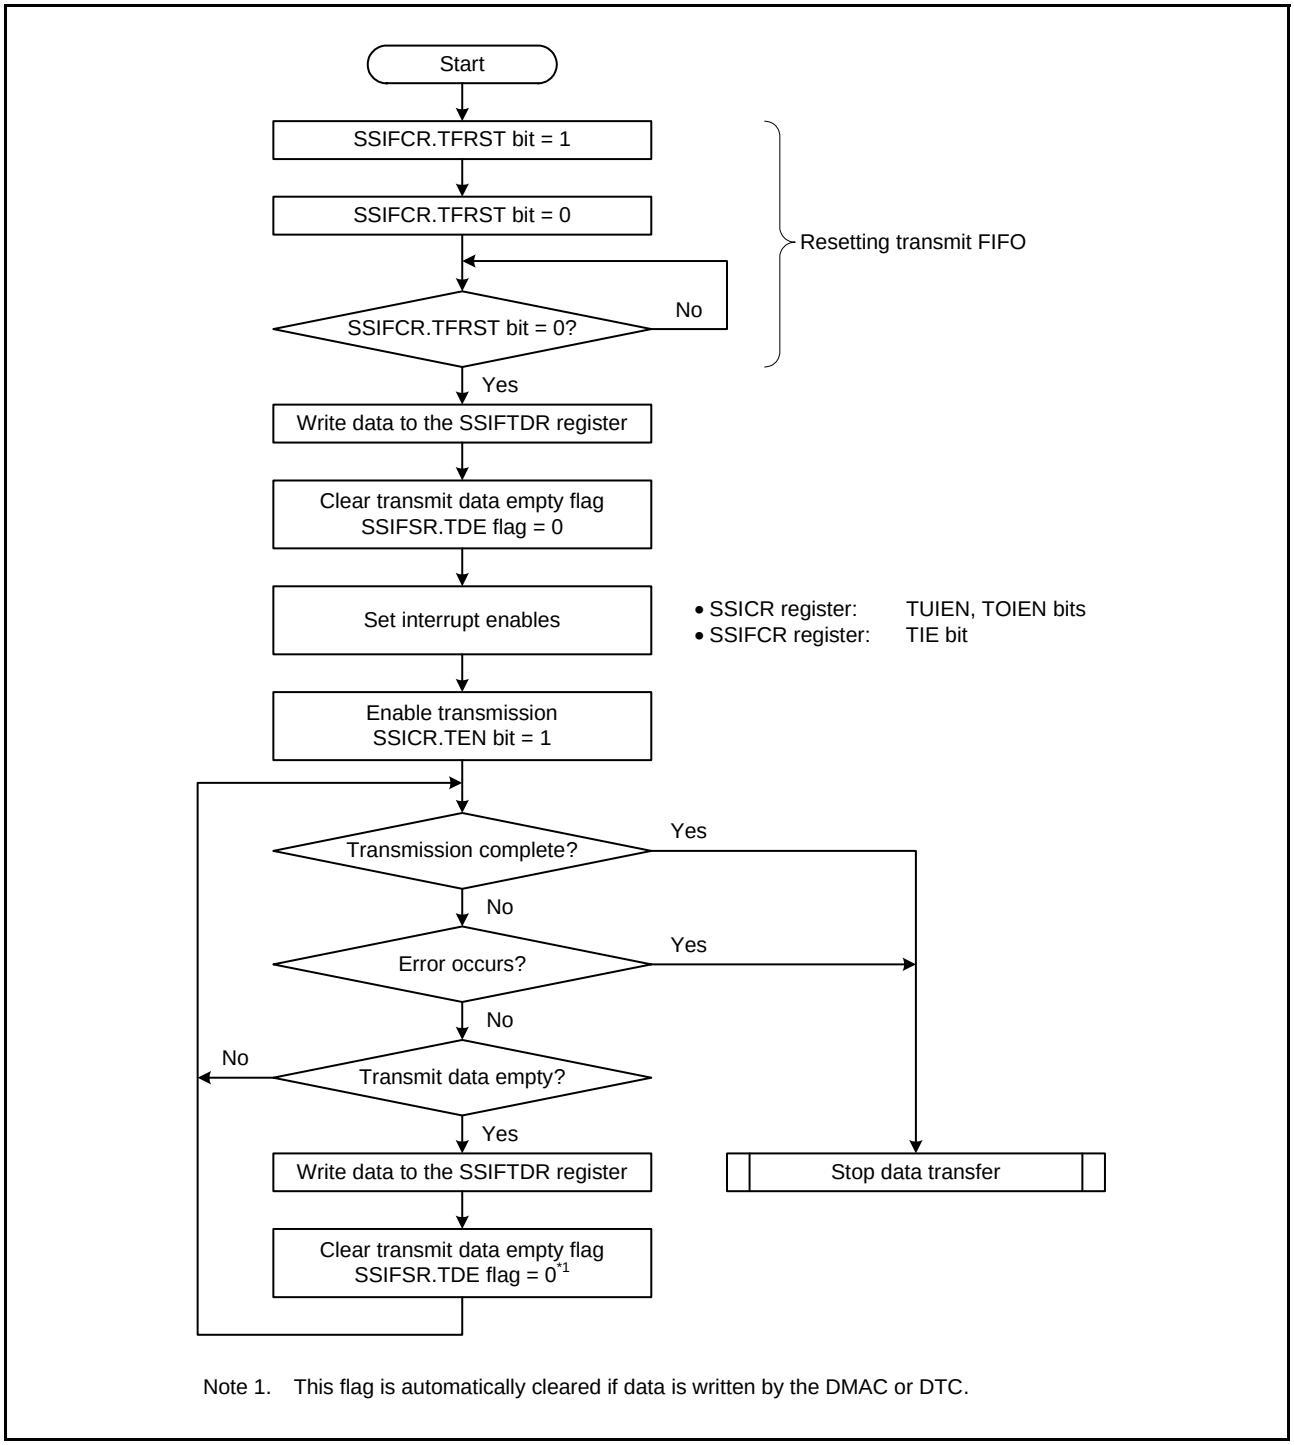
45.3.6 Transmission

Figure 45.22 shows an example of the flow to transmit data.
When the SSICR.TEN bit is set to 1 after setting the data for one frame in the SSIFTDR register, the SSIE starts transmission. When the number of spaces available in the transmit FIFO reaches the value specified by the SSISCR.TDES[4:0] bits while the SSIFCR.TIE bit is 1, a transmit data empty interrupt occurs. The number of data to be written to the SSIFTDR register should be determined in accordance with the space available in the transmit FIFO specified by the TDES[4:0] bits.

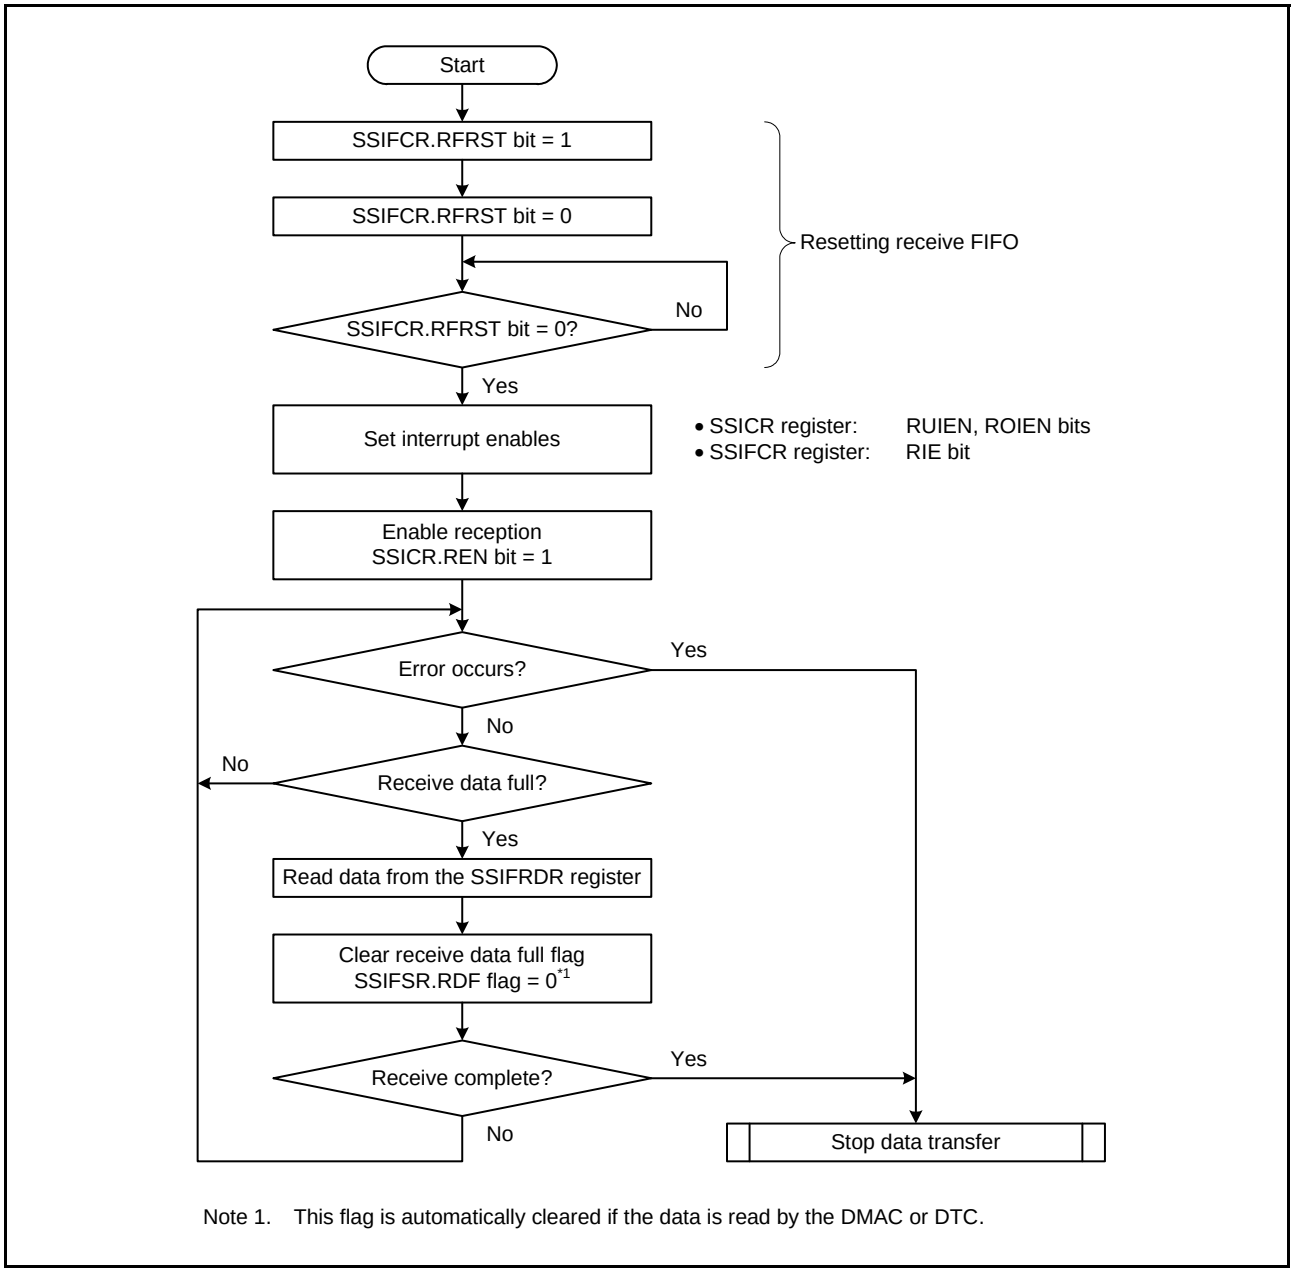


Note 1. This flag is automatically cleared if data is written by the DMAC or DTC.

Figure 45.22 Example Flowchart of Transmission

45.3.7 Reception

Figure 45.23 shows an example of the flow to receive data.
When the SSICR.REN bit is set to 1, SSIE starts reception. When the number of data stored in the receive FIFO reaches to the value specified by the SSISCR.RDFS[4:0] bits while the SSIFCR.RIE bit is 1, a receive data full interrupt occurs. The number of data to be read from the SSIFRDR register should be determined in accordance with the number of data stored in the receive FIFO specified by the RDFS[4:0] bits.



Note 1. This flag is automatically cleared if the data is read by the DMAC or DTC.

Figure 45.23 Example Flowchart of Reception

45.3.8 Stop Data Transfer

Figure 45.24 shows an example of the flow to stop data transfer.

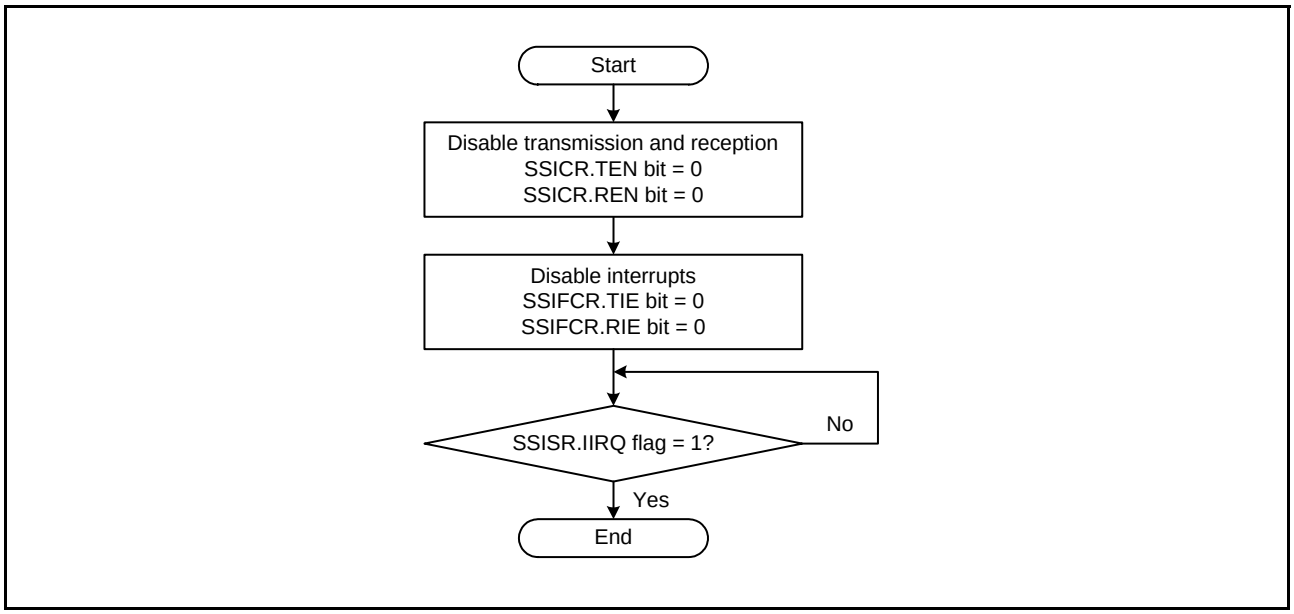


Figure 45.24 Example Flowchart of Stopping Data Transfer

To resume data transfer, conform with the example flowcharts of transmission and reception in Figure 45.22 and Figure 45.23, respectively. When changing the settings of clocks or switching a transfer mode between master and slave, start from initialization.

45.3.9 Error Processing

SSIE has the following four errors.

- Transmit underflow
- Transmit overflow
- Receive underflow
- Receive overflow

If an error has occurred, follow the procedure to stop data transfer shown in Figure 45.24 and then clear the corresponding flag. When an error has occurred while the corresponding interrupt enable bit in the SSICR register is 1, an interrupt is generated.

(1) Transmit Underflow

When a data transfer from the transmit FIFO to transmit shift register has performed while the transmit FIFO is empty, a transmit underflow is informed. If a transmit underflow has occurred, the SSITXD0 pin is driven low.

(2) Transmit Overflow

When a data is written to the SSIFTDR register while the transmit FIFO is full, a transmit overflow is informed. The data to be written is discarded.

(3) Receive Underflow

When a data is read from the SSIFRDR register while the receive FIFO is empty, a receive underflow is informed. The read data is undefined.

(4) Receive Overflow

When a data transfer from receive shift register to the receive FIFO has performed while the receive FIFO is full, a receive overflow is informed. The data to be transferred is discarded and is not stored in the receive FIFO.

45.4 Interrupts

Table 45.12 lists the interrupt sources. Figure 45.25 shows an block diagram for interrupts.

Table 45.12 SSIE Interrupt Sources

Channel	Name	Interrupt Source	Interrupt Request Flag	Interrupt Enable Bit	DMAC/DTC Triggerable
SSIE0	SSIF0	Transmit underflow interrupt Transmit overflow interrupt Receive underflow interrupt Receive overflow interrupt Idle state interrupt	SSISR.TUIRQ SSISR.TOIRQ SSISR.RUIRQ SSISR.ROIRQ SSISR.IIRQ	SSICR.TUIEN SSICR.TOIEN SSICR.RUIEN SSICR.ROIEN SSICR.IIEN	No
	SSIRXI0	Receive data full interrupt	SSIFSR.RDF	SSIFCR.RIE	Yes
	SSITXI0	Transmit data empty interrupt	SSIFSR.TDE	SSIFCR.TIE	Yes

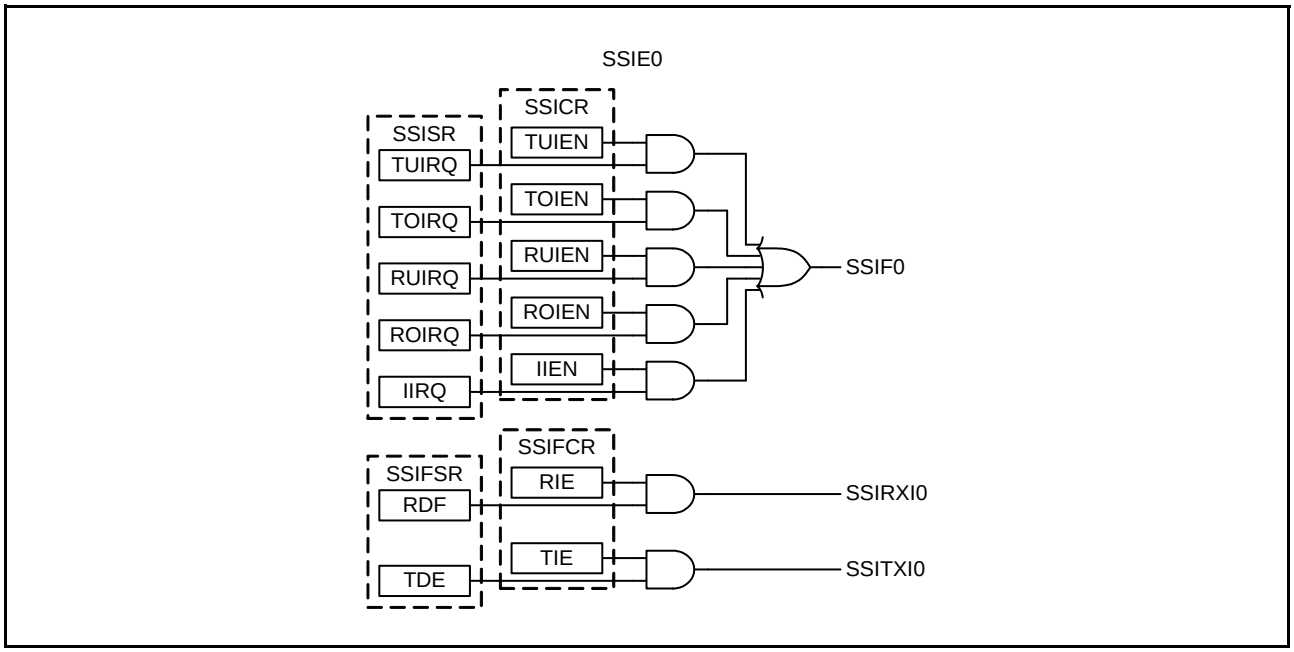

Figure 45.25 Interrupt System Block Diagram

45.4.1 SSIF0 Interrupt

The SSIF0 interrupt combines five interrupt sources. Each interrupt source has a status flag and an interrupt enable bit, so the interrupt can be enabled or disabled individually.

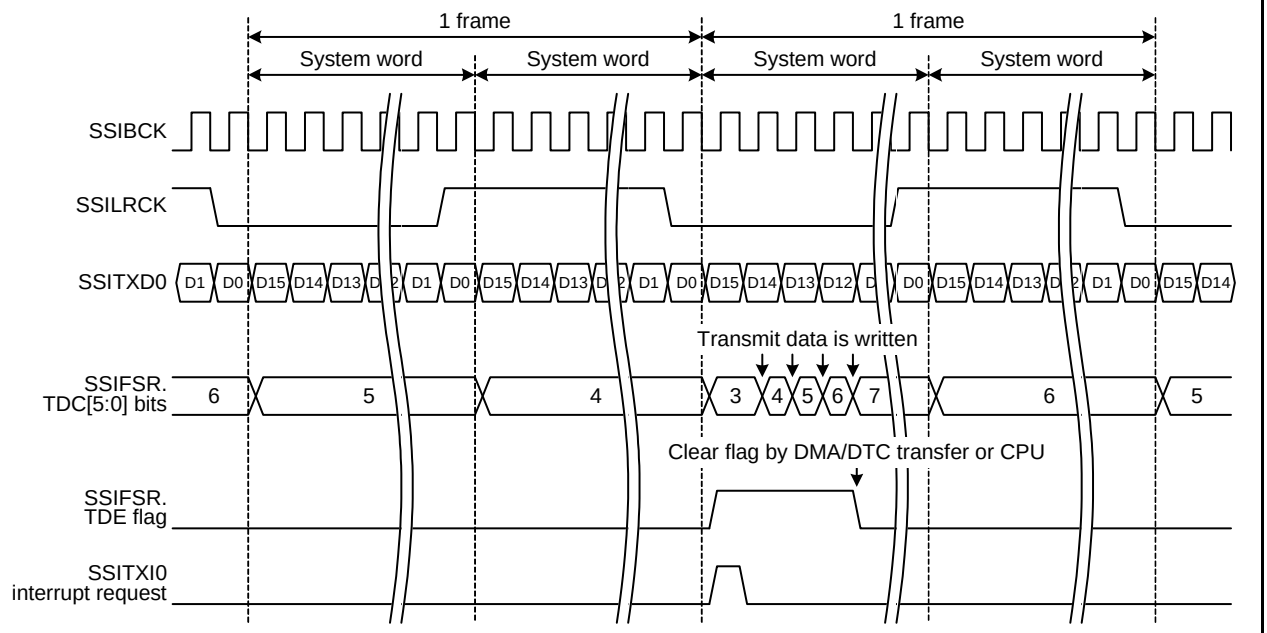
If an SSIF0 interrupt occurs, read the SSISR register in the interrupt handling routine to check the source of the interrupt request, and then perform proper operation. To clear the interrupt request, set the corresponding interrupt enable bit to 0 or clear the interrupt request flag.

45.4.2 SSITXI0 Interrupt

The SSITXI0 interrupt (channel 0 transmit data empty interrupt) is an edge detection interrupt. This interrupt request is generated when either of the following conditions is satisfied.

- The SSIFSR.TDE flag has changed from 0 to 1 while the SSIFCR.TIE bit is 1.
- The SSIFCR.TIE bit has been changed from 0 to 1 while the SSIFSR.TDE flag is 1.

Figure 45.26 shows a timing chart when an interrupt request is generated when the TDE flag changes.



This figure applies when the SSISCR.TDES[4:0] bits are 11100b (at least 29) and when the respective bits in the SSICR register are as follows:
DEL bit = 0 (with delay), SDTA bit = 0 (I^2S), SPDP bit = 0 (padding with low),
LRCKP bit = 0 (low level for left channel), BCKP bit = 0 (output changes on falling edges),
SWL[2:0] bits = 001b (16 bits), DWL[2:0] bits = 001b (16 bits), and FRM[1:0] bits = 00b (2 system words)

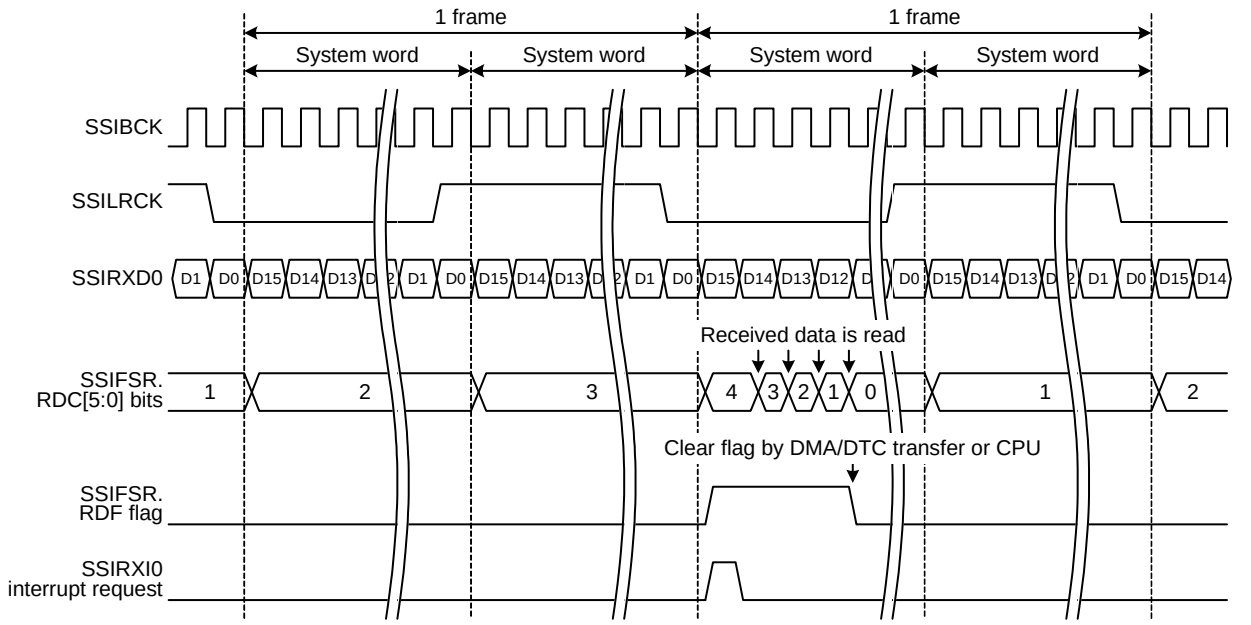
Figure 45.26 SSITXI0 Interrupt Timing Chart

45.4.3 SSIRXI0 Interrupt

The SSIRXI0 interrupt (channel 0 receive data full interrupt) is an edge detection interrupt. This interrupt request is generated when either of the following conditions is satisfied.

- The SSIFSR.RDF flag has changed from 0 to 1 while the SSIFCR.RIE bit is 1.
- The SSIFCR.RIE bit has been changed from 0 to 1 while the SSIFSR.RDF flag is 1.

Figure 45.27 shows a timing chart when an interrupt request is generated when the RDF flag changes.



This figure applies when the SSISCR.RDFS[4:0] bits are 00011b (at least 4) and when the respective bits in the SSICR register are as follows:
DEL bit = 0 (with delay), SDTA bit = 0 (I^2S), SPDP bit = 0 (padding with low),
LRCKP bit = 0 (low level for left channel), BCKP bit = 0 (output changes on falling edges),
SWL[2:0] bits = 001b (16 bits), DWL[2:0] bits = 001b (16 bits), and FRM[1:0] bits = 00b (2 system words)

Figure 45.27 SSIRXI0 Interrupt Timing Chart

45.5 Notes

45.5.1 Setting the Module Stop Function

Operation of the SSIE can be enabled or disabled by setting a bit in the module stop control register D (MSTPCRD). The SSIE is initially disabled after a reset. Registers in the SSIE only become accessible after it has been released from the module stop state. For details, refer to section 11, Low Power Consumption.

45.5.2 Note on LRCK in Slave Mode

The SSIE uses the SSILRCK signal as a start trigger in slave mode. Neither valid edges after the start trigger nor signal levels are used, so if a bit slippage occurs by a noise, the bit slippage cannot be repaired even at a frame boundary.

46. Remote Control Signal Receiver (REMCa)

This MCU has a remote control signal receiver (REMC0). The REMC can receive data by checking the width and period of an external pulse input signal.

46.1 Overview

Table 46.1 lists the REMC specifications. Figure 46.1 shows a block diagram of the REMC.

Table 46.1 REMC Specifications

Item	Description
External pulse input	PMC0
Operating clock sources*1	• Sub-clock • TMR compare match output (TMO0) • PCLKB
Detection patterns	• Header pattern • Data ‘0’ pattern • Data ‘1’ pattern • Special data pattern
Receive buffer	8 bytes (64 bits)
Interrupt request signal	REMCI0
Interrupt request source	• Compare match (Compare bit count: 1 to 16 bits) • Receive error • Data reception complete • Receive buffer full • Header pattern match • Data ‘0’ pattern or data ‘1’ pattern match • Special data pattern match
Interrupt mode	Either of the following two interrupt modes can be selected for the four interrupt sources of compare match, data reception complete, header pattern match, and special data pattern match. • Normal interrupt mode An interrupt request is generated when any of the interrupt request generation condition is met. • Sequential interrupt mode An interrupt request is generated when the interrupt request generation conditions are met for all the enabled interrupt request sources.
Selectable functions	• Input signal inversion • Digital filter (matching three or two times)*2 • Pattern end setting
Low power consumption	• Module stop state can be set. • Signal reception during low power consumption state and recovery from low power consumption state in response to the REMC interrupt request are available.

Note 1. Satisfy the frequency of the peripheral module clock (PCLKB) > the frequency of the REMC operating clock.
Note 2. The sampling clock of the digital filter is an operating clock selected by the REMCON1.CSRC[3:0] bits.

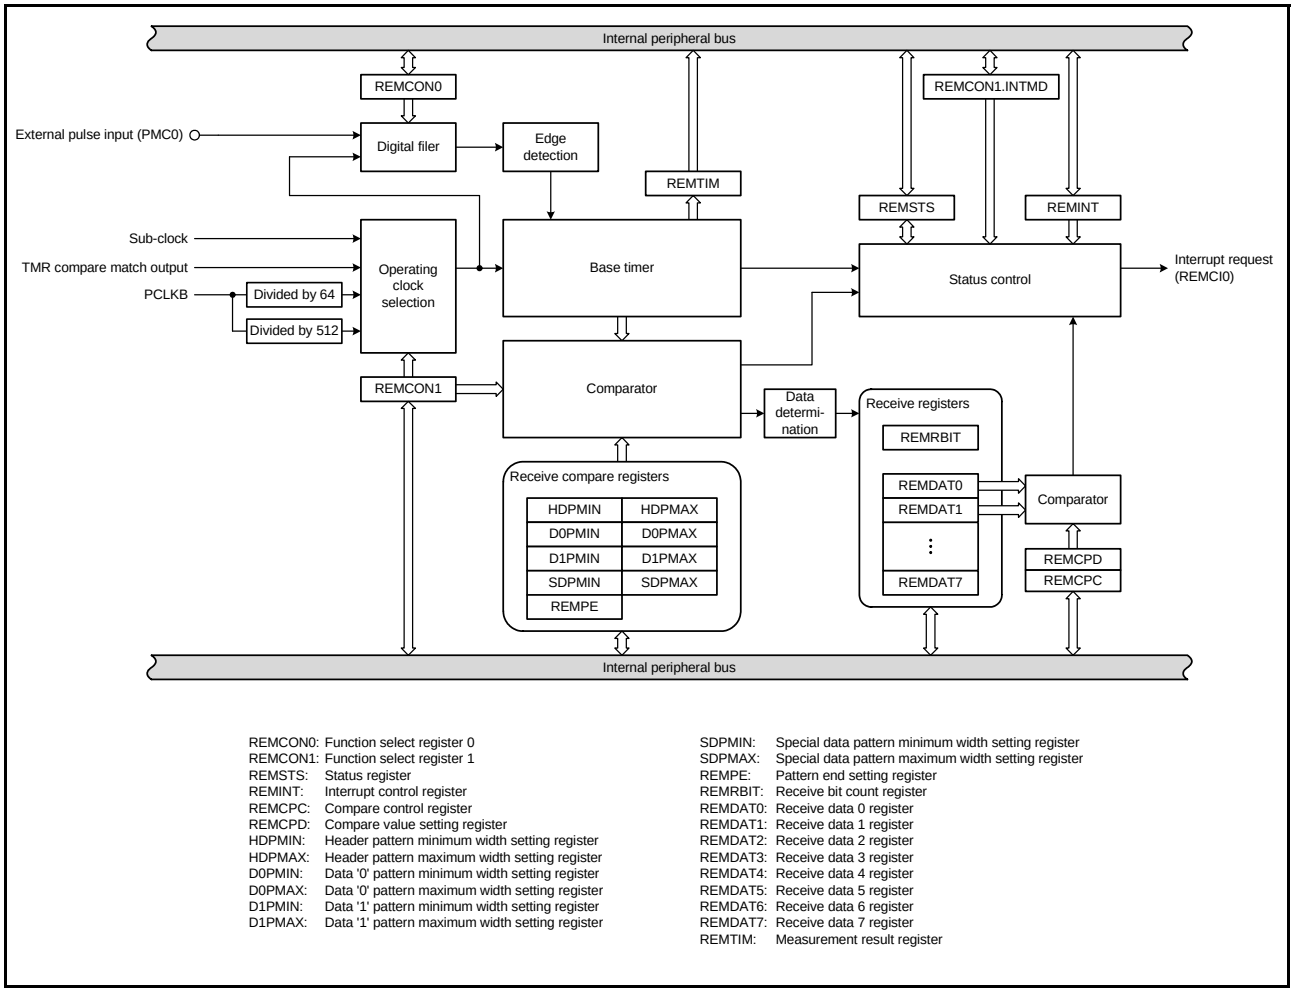


Figure 46.1 REMC Block Diagram

Table 46.2 lists the input pins used for the REMC.

Table 46.2 REMC Pin Configuration

Channel	Pin Name	I/O	Function
REMC0	PMC0	Input	External pulse signal input

46.2 Registers

46.2.1 Function Select Register 0 (REMCON0)

Address(es): REMC0.REMCON0 000A 0B00h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	FILSEL	—	EC	INFLG	FIL	INV	ENFLG
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ENFLG	Remote Control Status Flag*1	0: Stopped 1: Operating	R
b1	INV	Input Signal Inversion*2	0: Not inverted 1: Inverted	R/W
b2	FIL	Digital Filter Enable/Disable Setting*2	0: Disables the digital filter for matching three or two times. 1: Enables the digital filter for matching three or two times.	R/W
b3	INFLG	Input Signal Flag*1	0: The level of the internal input signal of the remote control signal receiver is low. 1: The level of the internal input signal of the remote control signal receiver is high.	R
b4	EC	Receive Error Capture Operation Select*2	0: Captures the data after an error pattern is received. 1: Does not capture the data after an error pattern is received.	R/W
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6	FILSEL	Digital Filter Function Select*2	0: Digital filter for matching three times 1: Digital filter for matching two times	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. These flags become 0 when the REMCON1.EN bit is set to 0.
Note 2. These bits can be rewritten when the REMCON1.EN bit and the REMCON0.ENFLG flag are both 0 (REMC is stopped).

ENFLG Flag (Remote Control Status Flag)

This flag can be used to confirm whether the remote control signal receiver is stopped or operating.
This flag changes after zero to one clock when a value is written to the REMCON1.EN bit.

FIL Bit (Digital Filter Enable/Disable Setting)

This bit enables or disables the digital filter.

INFLG Flag (Input Signal Flag)

This flag can be used to confirm the level of the internal input signal of the remote control signal receiver. The confirmed level is the result set by the INV and FIL bits.

EC Bit (Receive Error Capture Operation Select)

This bit can be used to set capture operation to the REMRBIT and REMDATj registers (j = 0 to 7) after an error pattern is received.

46.2.2 Function Select Register 1 (REMCON1)

Address(es): REMC0.REMCON1 000A 0B01h

	b7	b6	b5	b4	b3	b2	b1	b0
	INTMD	CSRC[3:0]				EN	TYP[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	TYP[1:0]	Receive Mode Select*1	These bits can be used to select the format for capturing the remote control signal waveform. b1 b0 0 0: Format A shown in section 46.3.3, Pattern Setting. 0 1: Format B shown in section 46.3.3, Pattern Setting. 1 0: Format C shown in section 46.3.3, Pattern Setting. 1 1: Setting prohibited	R/W
b2	EN	Remote Control	0: Operation disabled 1: Operation enabled	R/W
b6 to b3	CSRC[3:0]	Operating Clock Select*2	b6 b3 x 0 1 0: TMR compare match output x 1 0 0: Sub-clock 0 1 1 0: PCLKB/64 1 1 1 0: PCLKB/512 Settings other than those listed above are prohibited.	R/W
b7	INTMD	Interrupt Mode Select*2	0: Normal interrupt mode 1: Sequential interrupt mode	R/W

x: Don't care

Note 1. To rewrite the TYP[1:0] bits when the REMCON1.EN bit or REMCON0.ENFLG flag is 1 (REMC is operating), change the values of these bits one bit at a time.

Note 2. These bits can be rewritten when the REMCON1.EN bit and the REMCON0.ENFLG flag are both 0 (REMC is stopped).

EN Bit (Remote Control)

This bit enables or disables REMC operation.

Use the REMCON0.ENFLG flag to confirm whether operation has started or not.

CSRC[3:0] Bits (Operating Clock Select)

These bits select the operating clock for the REMC.

Satisfy the frequency of the operating clock < the frequency of the PCLKB.

INTMD Bit (Interrupt Mode Select)

This bit selects the interrupt mode.

In normal interrupt mode, an interrupt is generated when the result of the logical OR of the flags for interrupt sources that have been enabled (the corresponding bit set to 1) in the interrupt control register (REMINT) is "true".

In sequential interrupt mode, an interrupt is generated when the result of the logical AND of the flags for interrupt sources that have been enabled (the corresponding bit set to 1) in the REMINT register is "true".

For details on the available interrupt sources and operation in each interrupt mode, see section 46.3.12, Interrupts.

46.2.3 Status Register (REMSTS)

Address(es): REMC0.REMSTS 000A 0B02h

	b7	b6	b5	b4	b3	b2	b1	b0
	SDFLG	D1FLG	D0FLG	HDFLG	BFULFLG	DRFLG	REFLG	CPFLG
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CPFLG	Compare Match Flag	0: Mismatch 1: Match	R
b1	REFLG	Receive Error Flag	0: No error has occurred. 1: An error has occurred.	R
b2	DRFLG	Data Receiving Flag	0: Waiting for data reception. 1: Data is being received.	R
b3	BFULFLG	Receive Buffer Full Flag	0: Receive buffer is empty. 1: Receive buffer is full (64 bits received).	R/(W) *1
b4	HDFLG	Header Pattern Match Flag	0: Mismatch 1: Match	R
b5	D0FLG	Data ‘0’ Pattern Match Flag	0: Mismatch 1: Match	R
b6	D1FLG	Data ‘1’ Pattern Match Flag	0: Mismatch 1: Match	R
b7	SDFLG	Special Data Pattern Match Flag	0: Mismatch 1: Match	R

Note: If updating and reading data overlap, an undefined value may be read. For details on reading this register, see section 46.4.7, Reading Registers.

Note: This register becomes 00h when the REMCON1.EN bit is set to 0.

Note 1. Only 0 can be written to clear the flag. However, if this flag is written when changing the REMCON0.INFLG flag, the value read from this flag may become undefined.

CPFLG Flag (Compare Match Flag)

This flag indicates the comparison result between the value of the REMCPD register specified by the REMCPC.CPN[3:0] bits and the data to be stored in the REMDAT1 and REMDAT0 registers.

[Setting condition]

- When the value of the REMCPD register matches the value to be stored in the REMDAT1 and REMDAT0 registers (when the setting value of the REMCPC.CPN[3:0] bits is n, bits n to 0 in the REMCPD register match bits n to 0 in the REMDAT1 and REMDAT0 registers)

[Clearing conditions]

- When the DRFLG flag changes from 0 to 1 (next frame reception starts)
- When the HDFLG flag changes from 0 to 1

REFLG Flag (Receive Error Flag)

This flag indicates that a receive error has occurred. The setting conditions differ depending on the value of the REMCON1.TYP[1:0] bits.

[Setting condition]

When the REMCON1.TYP[1:0] bits are 00b (format A):

- The data ‘0’, data ‘1’, or special data pattern is detected prior to receiving the header pattern
- The width between a rising edge and the next rising edge of the input signal is not the header, data ‘0’, data ‘1’, or special data pattern (when the REMCON0.INV bit is 0)
- A conflict occurs between when data reception is completed (timing when the DRFLG flag changes from 1 to 0) and when the new input signal changes.

When the REMCON1.TYP[1:0] bits are 01b (format B):

- The data ‘0’, data ‘1’, or special data pattern is detected prior to receiving the header pattern
- The width between a falling edge and the next falling edge of the input signal is not the data ‘0’, data ‘1’, or special data pattern (when the REMCON0.INV bit is 0)
- A conflict occurs between when data reception is completed (timing when the DRFLG flag changes from 1 to 0) and when the new input signal changes.

When the REMCON1.TYP[1:0] bits are 10b (format C):

- The width between a rising edge and the next rising edge of the input signal is not the header, data ‘0’, data ‘1’, or special data pattern (when the REMCON0.INV bit is 0)
- A conflict occurs between when data reception is completed (timing when the DRFLG flag changes from 1 to 0) and when the new input signal changes.

[Clearing conditions]

- The header pattern is detected
- When the DRFLG flag changes from 0 to 1 (next frame reception starts).

DRFLG Flag (Data Receiving Flag)

This flag indicates the state of receiving the remote control signal.

[Setting condition]

- Rising edge of REMC internal input signal (when the REMCON0.INV bit is 0)

[Clearing condition]

- This flag becomes 0 after one cycle of the operating clock when the value of the base timer is greater than any value of the HDPMAX, D0PMAX, D1PMAX, SDPMAX, and REMPE registers.

BFULFLG Flag (Receive Buffer Full Flag)

[Setting condition]

- When the value of the REMRBIT register becomes 64

[Clearing conditions]

- When the HDFLG flag changes from 0 to 1
- When the DRFLG flag changes from 0 to 1 (next frame reception starts)
- This flag becomes 0 after one to two cycles when 0 is written to the BFULFLG flag.

HDFLG Flag (Header Pattern Match Flag)

[Setting condition]

- See Table 46.3, Measurement Results and Flags.

[Clearing conditions]

- When the DRFLG flag changes from 0 to 1 (next frame reception starts)
- When the REFLG flag changes from 0 to 1
- See Table 46.3, Measurement Results and Flags.

D0FLG Flag (Data '0' Pattern Match Flag)

[Setting condition]

- See Table 46.3, Measurement Results and Flags.

[Clearing conditions]

- When the DRFLG flag changes from 0 to 1 (next frame reception starts)
- When the REFLG flag changes from 0 to 1
- See Table 46.3, Measurement Results and Flags.

D1FLG Flag (Data '1' Pattern Match Flag)

[Setting condition]

- See Table 46.3, Measurement Results and Flags.

[Clearing conditions]

- When the DRFLG flag changes from 0 to 1 (next frame reception starts)
- When the REFLG flag changes from 0 to 1
- See Table 46.3, Measurement Results and Flags.

SDFLG Flag (Special Data Pattern Match Flag)

[Setting condition]

- See Table 46.3, Measurement Results and Flags.

[Clearing conditions]

- When the DRFLG flag changes from 0 to 1 (next frame reception starts)
- When the REFLG flag changes from 0 to 1
- See Table 46.3, Measurement Results and Flags.

Table 46.3 Measurement Results and Flags

Comparison Result between REMTIM Register Value (Measurement Result) and Each Register	Flag Value			
	HDFLG	D0FLG	D1FLG	SDFLG
Between HDPMIN and HDPMAX	1	0	0	0
Between D0PMIN and D0PMAX	0	1*1	0	0
Between D1PMIN and D1PMAX	0	0	1*1	0
Between SDPMIN and SDPMAX	0	0	0	1*1
Values not listed above	0	0	0	0

Note 1. When the REMCON1.TYP[1:0] bits are 00b or 01b, the D0FLG, D1FLG, and SDFLG flags remain unchanged until the header pattern is detected.

46.2.4 Interrupt Control Register (REMINT)

Address(es): REMC0.REMINT 000A 0B03h

	b7	b6	b5	b4	b3	b2	b1	b0
	SDINT	—	DINT	HDINT	BFULINT	DRINT	REINT	CPINT
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CPINT	Compare Match Interrupt Enable*1	0: Disabled 1: Enabled	R/W
b1	REINT	Receive Error Interrupt Enable*1	0: Disabled 1: Enabled	R/W
b2	DRINT	Data Reception Complete Interrupt Enable	0: Disabled 1: Enabled	R/W
b3	BFULINT	Receive Buffer Full Interrupt Enable*1	0: Disabled 1: Enabled	R/W
b4	HDINT	Header Pattern Match Interrupt Enable*1	0: Disabled 1: Enabled	R/W
b5	DINT	Data ‘0’ Pattern or Data ‘1’ Pattern Match Interrupt Enable	0: Disabled 1: Enabled	R/W
b6	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b7	SDINT	Special Data Pattern Match Interrupt Enable*1	0: Disabled 1: Enabled	R/W

Note 1. These bits can be rewritten when the REMCON1.EN bit and the REMCON0.ENFLG flag are both 0 (REMC is stopped).

46.2.5 Compare Control Register (REMCPC)

Address(es): REMC0.REMCPC 000A 0B05h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	CPN[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	CPN[3:0]	Compare Bit Count Specification*1	b3 b0 0 0 0 0: Bit 0 in the REMCPD register and bit 0 in the REMDAT0 register are compared. 0 0 0 1: Bit 1 and 0 in the REMCPD register and bit 1 and 0 in the REMDAT0 register are compared. : 0 1 1 1: Bit 7 to 0 in the REMCPD register and bit 7 to 0 in the REMDAT0 register are compared. : 1 0 0 1: Bit 9 to 0 in the REMCPD register and bit 1 and 0 in the REMDAT1 register, bit 7 to 0 in the REMDAT0 register are compared. : 1 1 1 1: Bit 15 to 0 in the REMCPD register and bit 7 to 0 in the REMDAT1 register, bit 7 to 0 in the REMDAT0 register are compared.	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. These bits can be rewritten when the REMCON1.EN bit and the REMCON0.ENFLG flag are both 0 (REMC is stopped).

46.2.6 Compare Value Setting Register (REMCPD)

Address(es): REMC0.REMCPD 000A 0B06h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CPD[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	CPD[15:0]	Compare Value Setting*1	Set the value to be compared with the data in the REMDAT1, REMDAT0 registers when the compare function is used. The REMCPC.CPN[3:0] bits can be used to set the number of bits to be compared.	R/W

Note 1. These bits can be rewritten when the REMCON1.EN bit and the REMCON0.ENFLG flag are both 0 (REMC is stopped).

46.2.7 Header Pattern Minimum Width Setting Register (HDPMIN)

Address(es): REMC0.HDPMIN 000A 0B08h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	HDPMIN[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b10 to b0	HDPMIN[10:0]	Header Pattern Minimum Width Setting*1	Set the minimum width of header pattern. Setting range: 000h to 7FFh	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. These bits can be rewritten when the REMCON1.EN bit and the REMCON0.ENFLG flag are both 0 (REMC is stopped).

46.2.8 Header Pattern Maximum Width Setting Register (HDPMAX)

Address(es): REMC0.HDPMAX 000A 0B0Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	HDPMAX[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b10 to b0	HDPMAX[10:0]	Header Pattern Maximum Width Setting*1	Set the maximum width of header pattern. Setting range: 000h to 7FFh	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. These bits can be rewritten when the REMCON1.EN bit and the REMCON0.ENFLG flag are both 0 (REMC is stopped).

46.2.9 Data ‘0’ Pattern Minimum Width Setting Register (D0PMIN)

Address(es): REMC0.D0PMIN 000A 0B0Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	D0PMIN[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	D0PMIN[7:0]	Data ‘0’ Pattern Minimum Width Setting *1	Set the minimum width of data ‘0’ pattern. Setting range: 00h to FFh	R/W

Note 1. These bits can be rewritten when the REMCON1.EN bit and the REMCON0.ENFLG flag are both 0 (REMC is stopped).

46.2.10 Data ‘0’ Pattern Maximum Width Setting Register (D0PMAX)

Address(es): REMC0.D0PMAX 000A 0B0Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	D0PMAX[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	D0PMAX[7:0]	Data ‘0’ Pattern Maximum Width Setting *1	Set the maximum width of data ‘0’ pattern. Setting range: 00h to FFh	R/W

Note 1. These bits can be rewritten when the REMCON1.EN bit and the REMCON0.ENFLG flag are both 0 (REMC is stopped).

46.2.11 Data ‘1’ Pattern Minimum Width Setting Register (D1PMIN)

Address(es): REMC0.D1PMIN 000A 0B0Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	D1PMIN[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	D1PMIN[7:0]	Data ‘1’ Pattern Minimum Width Setting *1	Set the minimum width of data ‘1’ pattern. Setting range: 00h to FFh	R/W

Note 1. These bits can be rewritten when the REMCON1.EN bit and the REMCON0.ENFLG flag are both 0 (REMC is stopped).

46.2.12 Data ‘1’ Pattern Maximum Width Setting Register (D1PMAX)

Address(es): REMC0.D1PMAX 000A 0B0Fh

	b7	b6	b5	b4	b3	b2	b1	b0
	D1PMAX[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	D1PMAX[7:0]	Data ‘1’ Pattern Maximum Width Setting *1	Set the maximum width of data ‘1’ pattern. Setting range: 00h to FFh	R/W

Note 1. These bits can be rewritten when the REMCON1.EN bit and the REMCON0.ENFLG flag are both 0 (REMC is stopped).

46.2.13 Special Data Pattern Minimum Width Setting Register (SDPMIN)

Address(es): REMC0.SDPMIN 000A 0B10h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SDPMIN[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b10 to b0	SDPMIN[10:0]	Special Data Pattern Minimum Width Setting*1	Set the minimum width of special data pattern. Setting range: 000h to 7FFh	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. These bits can be rewritten when the REMCON1.EN bit and the REMCON0.ENFLG flag are both 0 (REMC is stopped).

46.2.14 Special Data Pattern Maximum Width Setting Register (SDPMAX)

Address(es): REMC0.SDPMAX 000A 0B12h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SDPMAX[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b10 to b0	SDPMAX[10:0]	Special Data Pattern Maximum Width Setting*1	Set the maximum width of special data pattern. Setting range: 000h to 7FFh	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. These bits can be rewritten when the REMCON1.EN bit and the REMCON0.ENFLG flag are both 0 (REMC is stopped).

46.2.15 Pattern End Setting Register (REMPE)

Address(es): REMC0.REMPE 000A 0B14h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	PE[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b10 to b0	PE[10:0]	Pattern End Width Setting*1	Set the width of pattern end. Setting range: 000h to 7FFh These bits can be used to set the timing at which the REMSTS.DRFLG flag changes from 1 to 0.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. These bits can be rewritten when the REMCON1.EN bit and the REMCON0.ENFLG flag are both 0 (REMC is stopped).

46.2.16 Receive Bit Count Register (REMRBIT)

Address(es): REMC0.REMRBIT 000A 0B17h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	RBIT[6:1]						RBIT[0]
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RBIT[0]	Receive Bit Count Check 0	Receive bit count can be read. These bits indicate the bit position of the buffer to be stored by counting the detected data ‘0’ pattern or data ‘1’ pattern. • When the receive bit count exceeds 64 (40h), the value returns to 1. • The header pattern and special data pattern are not counted. • If an error is detected while the REMCON0.EC bit is 1, the value is not incremented even when the data ‘0’ pattern or data ‘1’ pattern is detected. • The REMRBIT register becomes 00h when the REMSTS.DRFLG flag changes from 0 to 1. • The REMRBIT register becomes 00h when the REMSTS.HDFLG flag changes from 0 to 1. When 0 is written to the REMRBIT.RBIT[0] bit, the value of the REMRBIT register becomes 00h after one to two cycles of the operating clock.	R/W
b6 to b1	RBIT[6:1]	Receive Bit Count Check 6 to 1		R
b7	—	Reserved	The read value is undefined. The write value should be 0.	R/W

Note: If updating and reading data overlap, an undefined value may be read. For details on reading this register, see section 46.4.7, Reading Registers.

Note: The values of this register are initialized when the REMCON1.EN bit is 0.

46.2.17 Receive Data 0 Register (REMDAT0)

Address(es): REMC0.REMDAT0 000A 0B18h

	b7	b6	b5	b4	b3	b2	b1	b0
	DAT0[7:1]							DAT0[0]
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DAT0[0]	Receive Data 0 Store Bit 0	Receive data is stored. The values of the REMDAT0 to REMDAT7 registers become all 00h after one to two cycles of the operating clock when 0 is written to bit 0 in the REMDAT0 register.	R/W
b7 to b1	DAT0[7:1]	Receive Data 0 Store Bits 7 to 1		R

Note: If updating and reading data overlap, an undefined value may be read. For details on reading this register, see section 46.4.7, Reading Registers.
Note: The values of this register are initialized when the REMCON1.EN bit is 0.

46.2.18 Receive Data j Register (REMDATj) (j = 1 to 7)

Address(es): REMC0.REMDAT1 000A 0B19h, REMC0.REMDAT2 000A 0B1Ah, REMC0.REMDAT3 000A 0B1Bh, REMC0.REMDAT4 000A 0B1Ch, REMC0.REMDAT5 000A 0B1Dh, REMC0.REMDAT6 000A 0B1Eh, REMC0.REMDAT7 000A 0B1Fh

	b7	b6	b5	b4	b3	b2	b1	b0
	DATj[7:0]							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	DATj[7:0]	Receive Data j Store	Receive data is stored.	R

Note: If updating and reading data overlap, an undefined value may be read. For details on reading this register, see section 46.4.7, Reading Registers.
Note: The values of this register are initialized when the REMCON1.EN bit is 0.

When data ‘0’ pattern or data ‘1’ pattern is detected, the result is stored bit by bit as received data. For details on storing received data, see section 46.3.8, Receive Data Buffer.

46.2.19 Measurement Result Register (REMTIM)

Address(es): REMC0.REMTIM 000A 0B20h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	TIM[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b10 to b0	TIM[10:0]	Measurement Result	The measurement result of each pattern width can be read. The value of the base timer is captured when one of the following patterns is detected. • Header pattern • Data ‘0’ pattern • Data ‘1’ pattern • Special data pattern • Data pattern other than the above (receive error)	R
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: If updating and reading data overlap, an undefined value may be read. For details on reading this register, see section 46.4.7, Reading Registers.

Note: The values of this register are initialized when the REMCON1.EN bit is 0.

46.2.20 Remote Control Signal Receive Pin Control Register (REMPC)

Address(es): REMC0.REMPC 0008 C29Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	PMC0S[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	PMC0S[2:0]	PMC0 Pin Select	b2 b0 0 0 0: The remote control signal is not received. 0 0 1: The PMC0 signal is input from the PC3 pin. 0 1 0: The PMC0 signal is input from the PB3 pin. 1 0 0: The PMC0 signal is input from the P53 pin. Settings other than those listed above are prohibited.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

46.3 Operation

46.3.1 Overview of REMC Operation

Figure 46.2 shows an example of the remote control signal. The signal begins with a header, followed by a sequence of data. This header differs from the subsequent sequence of data in waveform, allowing the header and the data to be distinguished. The sequence of data contains custom code and data code, and 0 or 1 is distinguished depending on the bit length. After a stop bit, there is an interval during which the signal does not change (frame space), thus constituting a frame.
The time between the edges of the external input signal is measured using the base timer in the REMC. The patterns of the remote control signal are detected and the data is captured according to the measurement results.

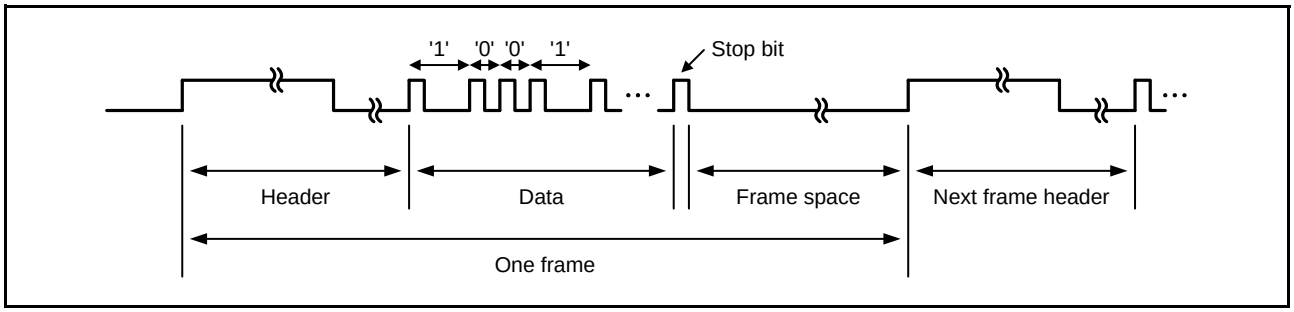

Figure 46.2 Example of Remote Control Signal

46.3.2 Initial Setting

Initialize the REMC according to the procedure shown in Figure 46.3 to receive the remote control signal.
Set the REMCON1.EN bit to 0 if the REMC is operating. Then the REMCON0.ENFLG flag becomes 0 and the REMC stops the operation.
Set the format for the remote control signal waveform by the REMCON1.TYP[1:0] bits; select the signal inversion or non-inversion by the REMCON0.INV bit; select the operating clock by the REMCON1.CSRC[3:0] bits; and set the digital filter by the REMCON0.FIL and REMCON0.FILSEL bits, while the REMCON0.ENFLG flag is 0. Set the detecting width for each data pattern into the HDPMIN, HDPMAX, D0PMIN, D0PMAX, D1PMIN, D1PMAX, SDPMIN, SDPMAX, and REMPE registers. Make any other settings such as enabling interrupts by the REMINT register and setting of the compare function by the REMCPC and REMCPD registers if required.
After all necessary register settings are completed, set the REMCON1.EN bit to 1 to start REMC operation.

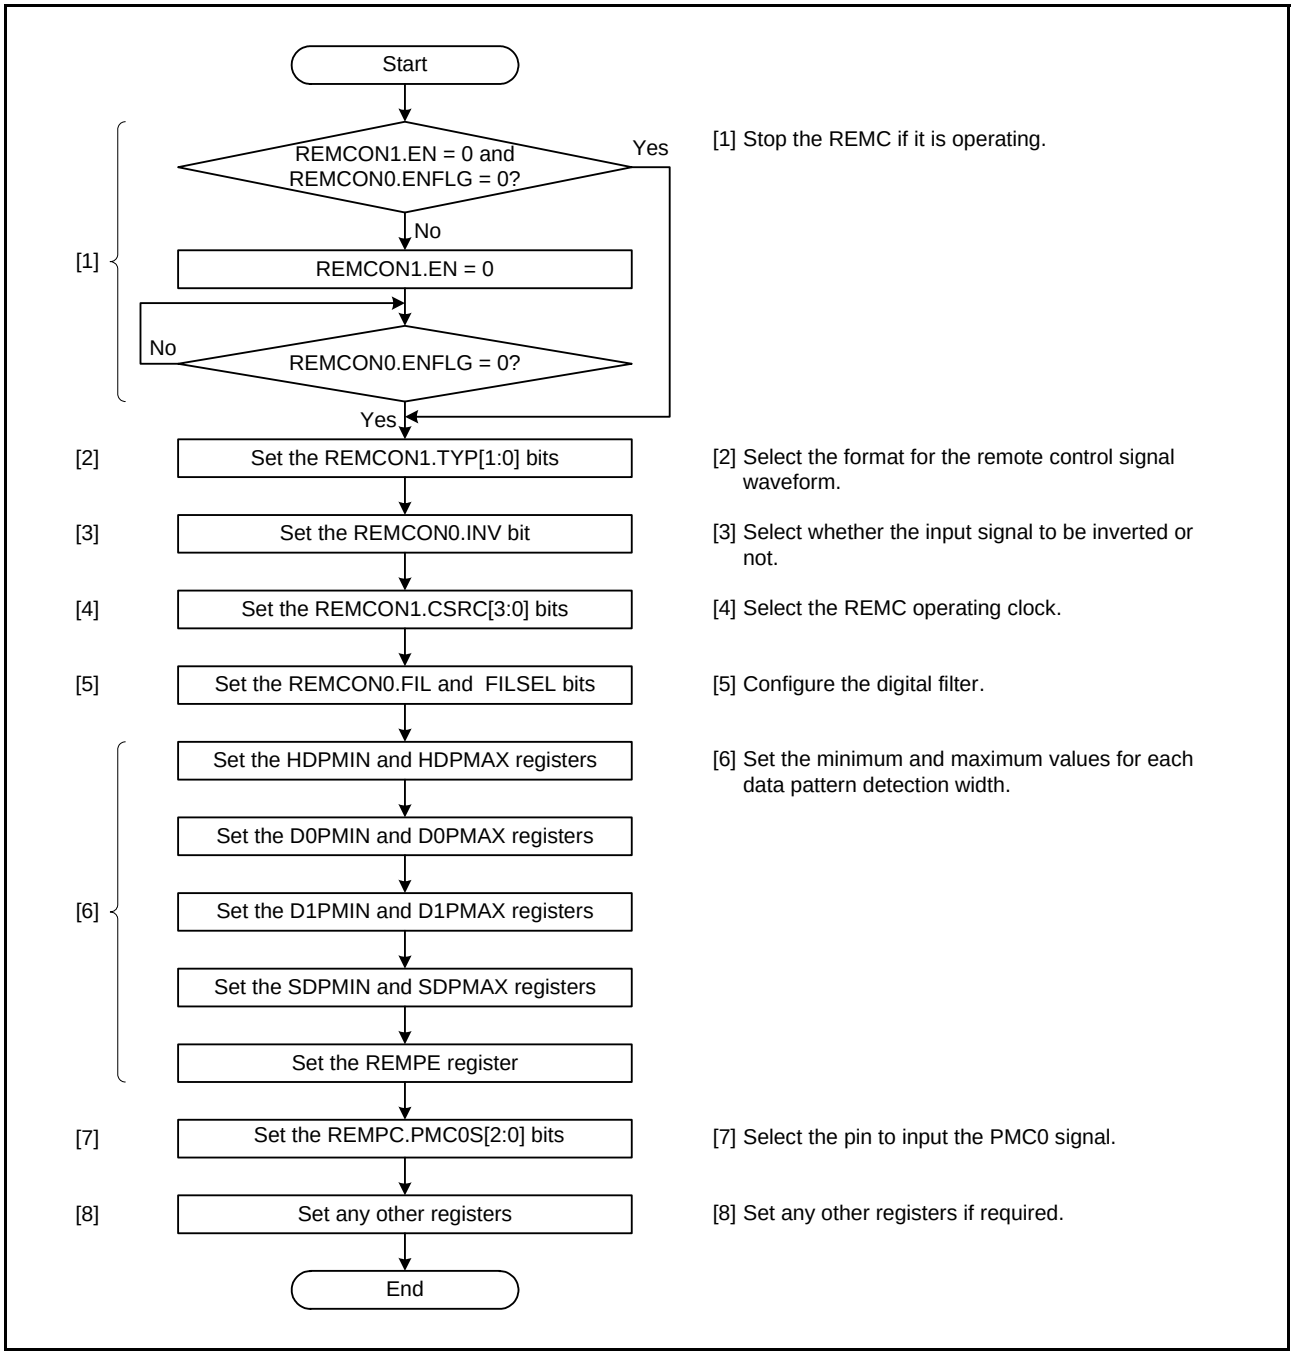

Figure 46.3 Example of Flowchart for Initial Settings of REMC

46.3.3 Pattern Setting

The format for capturing the remote control signal reception waveform can be set by setting the REMCON1.TYP[1:0] bits. Figure 46.4 and Figure 46.5 show examples of a remote control signal reception waveform captured by setting the REMCON1.TYP[1:0] bits.

When the REMCON1.TYP[1:0] bits are 00b (format A)

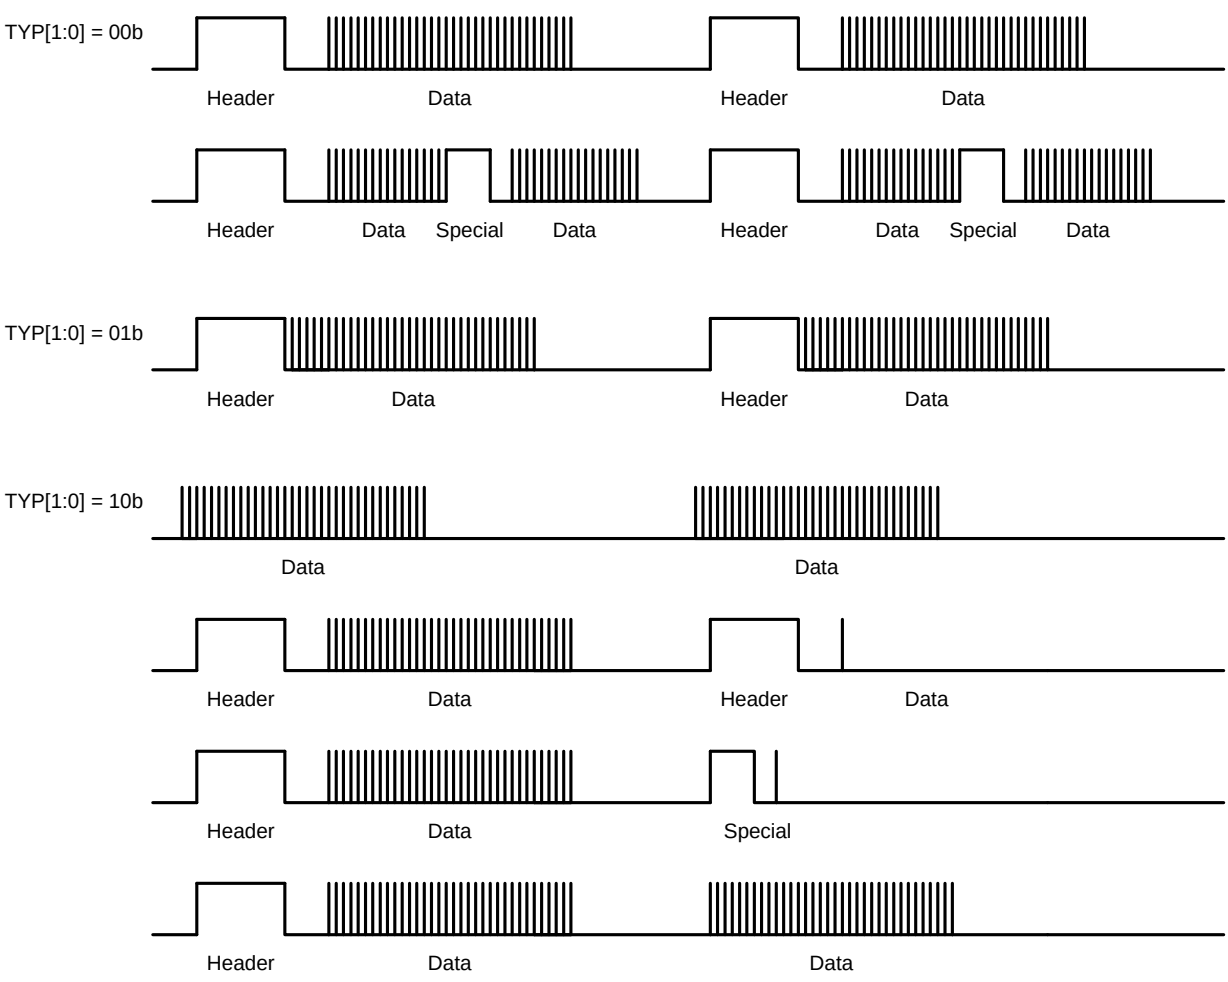
The measured result is determined from the setting value of the header pattern at the rising edge of the internal input signal.
When the header pattern is received, the measured result is determined from the setting values of the data ‘0’, data ‘1’ and special data patterns at the rising edge of the internal input signal.

When the REMCON1.TYP[1:0] bits are 01b (format B)

The measured result is determined from the setting value of the header pattern at the falling edge of the internal input signal.
When the header pattern is received, the measured result is determined from the setting values of the data ‘0’, data ‘1’ and special data patterns at the falling edge of the internal input signal.
The header pattern is detected once within one frame.

When the REMCON1.TYP[1:0] bits are 10b (format C)

The measured result is determined from the setting values of the header, data ‘0’, data ‘1’ and special data patterns at the rising edge of the internal input signal.



TYP[1:0]	Header Pattern	Data '0' Pattern	Data '1' Pattern	Special Data Pattern
TYP[1:0] = 00b				
TYP[1:0] = 01b				
TYP[1:0] = 10b				

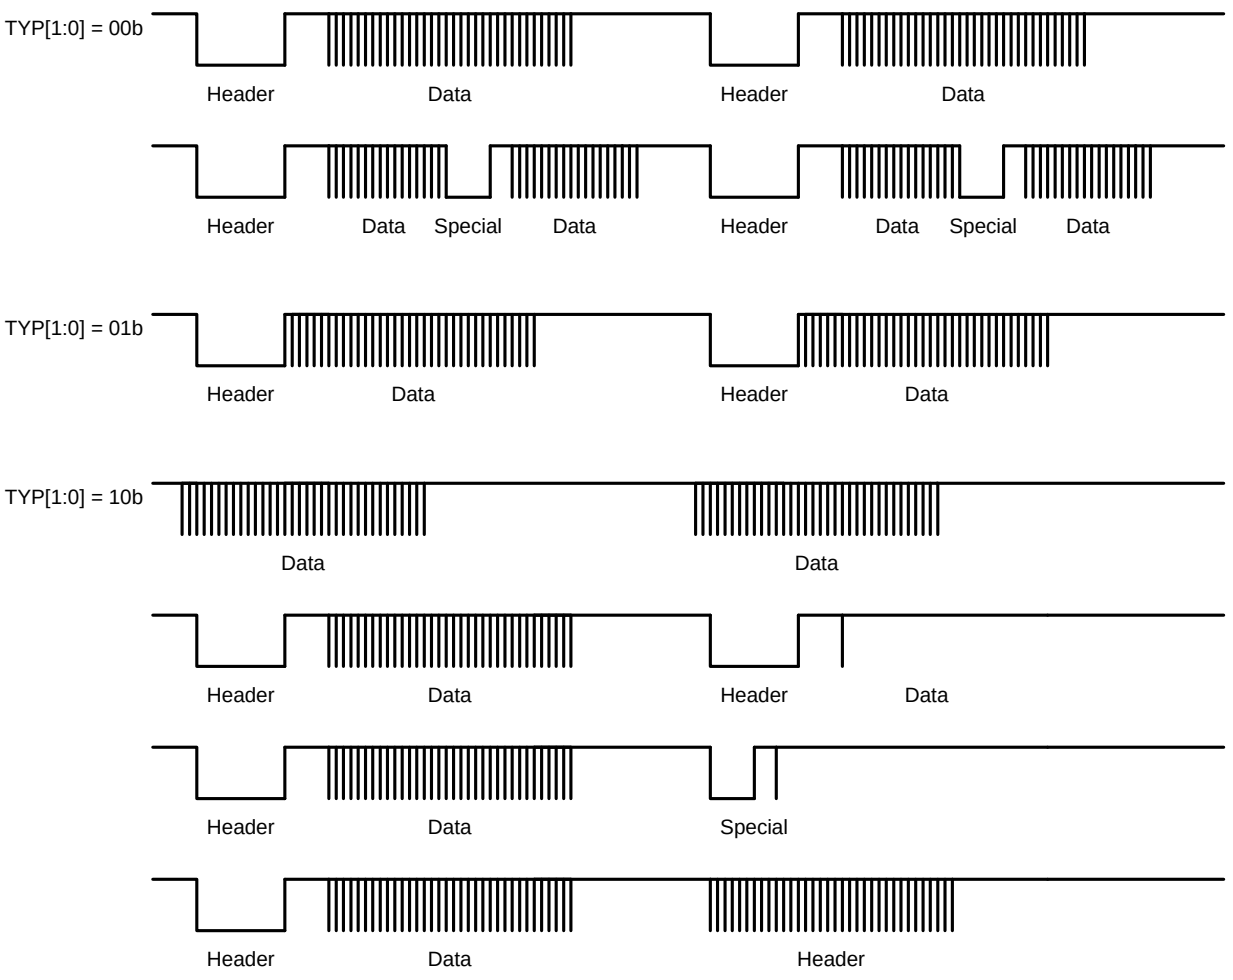
TYP[1:0]: Bits in the REMCON1 register

↑↓・・・Measurement starts

↑↓・・・Pattern measurement

When TYP[1:0] = 01b, the number of detecting the header pattern within the receive frame is one.
The above diagram applies when the REMCON0.INV bit is 0.

Figure 46.4 Example of Remote Control Signal Reception Waveform Captured by Setting REMCON1.TYP[1:0] Bits (REMCON0.INV = 0)



TYP[1:0]	Header Pattern	Data '0' Pattern	Data '1' Pattern	Special Data Pattern
TYP[1:0] = 00b				
TYP[1:0] = 01b				
TYP[1:0] = 10b				

TYP[1:0]: Bits in the REMCON1 register

↑↓ · · · Pattern measurement

When TYP[1:0] = 01b, the number of detecting the header pattern within the receive frame is one.
The above diagram applies when the REMCON0.INV bit is 1.

Figure 46.5 Example of Remote Control Signal Reception Waveform Captured by Setting REMCON1.TYP[1:0] Bits (REMCON0.INV = 1)

46.3.4 Operating Clocks

The REMC can use one of the following clocks as its operating clock: the divided clock of the peripheral module clock (PCLKB), the sub-clock supplied from the sub-clock oscillator, or TMR compare match output.
When supplying the sub-clock to the REMC, take note of the procedure for supplying the clock. The following describes how to supply these clocks.

46.3.4.1 When Using Sub-Clock as the REMC Operating Clock

The sub-clock can be used as the REMC operating clock. For the procedure to start the sub-clock oscillation, refer to section 9, Clock Generation Circuit. After the sub-clock oscillation is stabilized, set the REMCON1.CSRC[3:0] bits to x100b (sub-clock).

46.3.4.2 Using TMR Compare Match Output as REMC Operating Clock

The TMR compare match output can be supplied as the REMC operating clock. TMO0 can be supplied to the REMC0, respectively. For details on the TMR compare match output, refer to section 28, 8-Bit Timer (TMRb).

46.3.5 PMC0 Input

The options below can be selected in PMC0 input.

- Input polarity
- Digital filter

Figure 46.6 shows the configuration of PMC0 internal input signal generation.

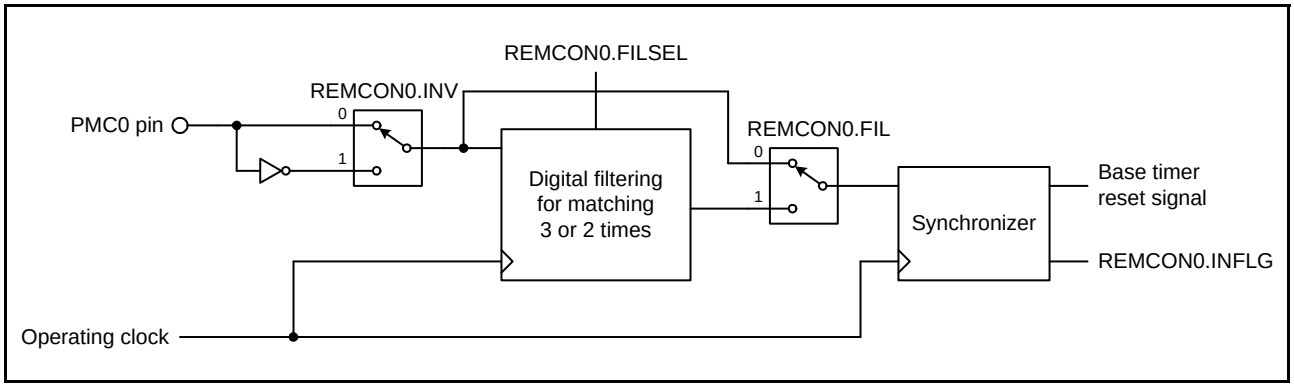

Figure 46.6 PMC0 Internal Input Signal Generation Configuration

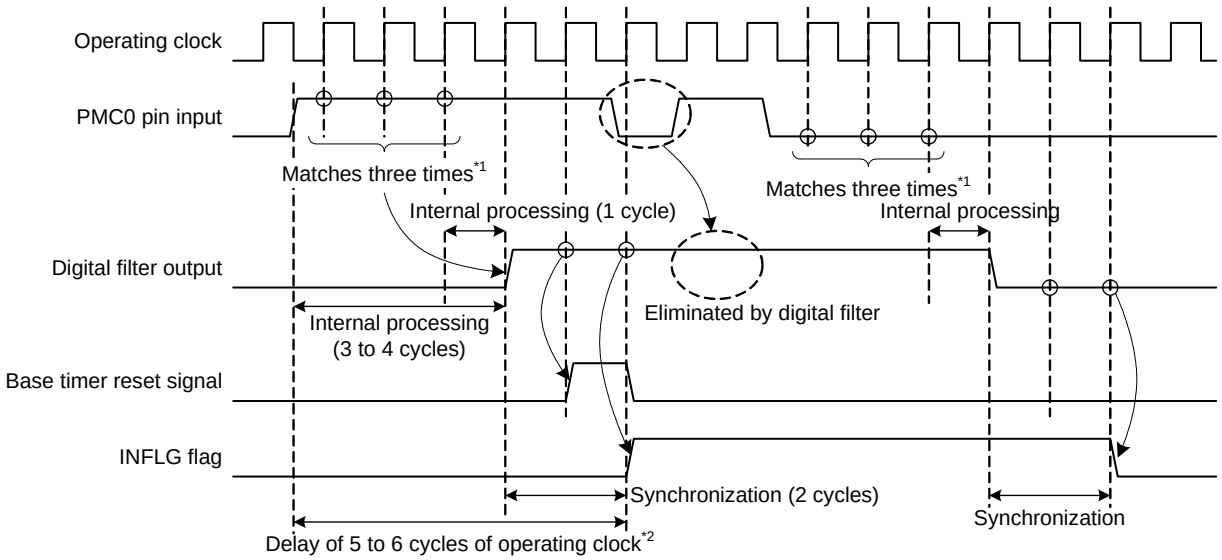
The input polarity of the PMC0 pin can be inverted. Whether to invert or not can be selected by the REMCON0.INV bit.
When the REMCON0.FIL bit is 1 (digital filter enabled), if the signal input to the PMC0 pin holds the same level for k sequential cycles (k = 3 or 2; value selected by the REMCON0.FILSEL bit), that level is transferred to the internal circuit. This enables noise to be eliminated from k cycles of the sampling clock.
Input to the PMC0 pin is transferred as the REMCON0.INFLG flag (input signal flag) and the base timer reset signal to the internal circuit in synchronization with the operating clock. The base timer reset signal is used to initialize the internal base timer to the pattern detection corresponding to the REMCON1.TYP[1:0] setting. There is a delay caused by internal processing after the input to the PMC0 pin is changed and before these signals are generated. Figure 46.7 shows digital filtering for PMC0 input.



Note 1. The above applies when the REMCON0.FIL bit is 1 (digital filter enabled) and the REMCON0.FILSEL bit is 0 (matches three times). When the FILSEL bit is 1 (matches twice), the signal is output earlier by one cycle of operating clock than that in this figure.

Note 2. When the FIL bit is 0 (digital filter disabled), a delay becomes one to two cycles of the operating clock for synchronization.

Figure 46.7 Digital Filtering for PMC0 Input

46.3.6 Pattern Detection

The REMC has a function that detects the following patterns.

- Header pattern
- Data ‘0’ pattern
- Data ‘1’ pattern
- Special data pattern

Using the base timer included in the REMC, the time between the edges of the external input signal is measured to determine which pattern matches the measurement result. This enables detection of the remote control signal and capturing the data. The width for determining each pattern can be set to any value using each pattern setting register. Figure 46.8 shows the waveform of REMC operation.

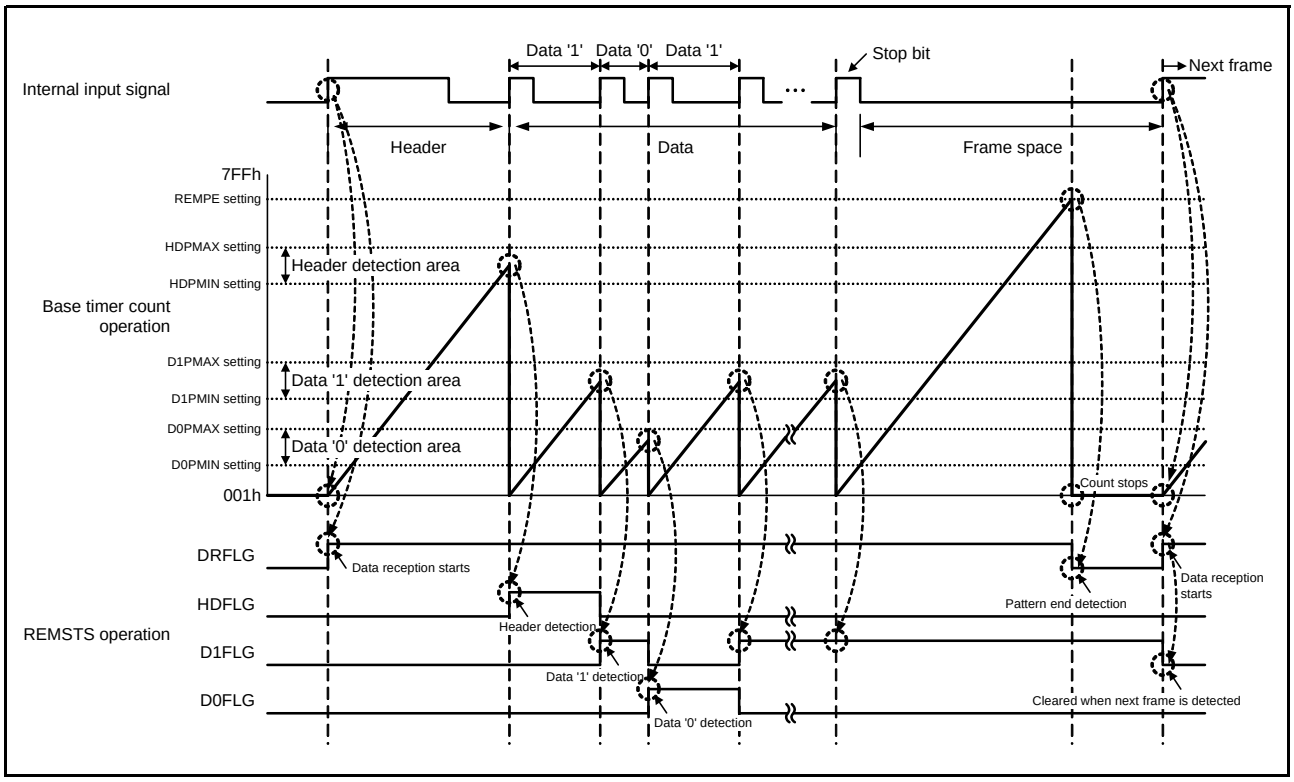


Figure 46.8 Waveform of REMC Operation

46.3.6.1 Header Pattern Detection

The header pattern can be detected by setting the minimum width of the header pattern in the HDPMIN register and the maximum width in the HDPMAX register.
The minimum and maximum widths of the header pattern must be “1 < HDPMIN register value ≤ HDPMAX register value”.

$$\text{Setting value n} = \frac{\text{Minimum width (maximum width) of header pattern}}{\text{Operating clock cycle time}}$$

When not using the header pattern, set the HDPMIN and HDPMAX registers to 000h.
Make sure that the setting value of the header pattern is different from the setting values of data ‘0’, data ‘1’, and special data patterns, and the setting ranges are not overlapped.

When the REMCON1.TYP[1:0] bits are 00b or 01b, if the data ‘0’, data ‘1’, or special data pattern is detected before the header pattern is detected, the following occur:

- The REMSTS.REFLG flag becomes 1 (an error has occurred).
- The REMSTS.D0FLG, REMSTS.D1FLG, and REMSTS.SDFLG flags remain unchanged.
- The REMDAT0 to REMDAT7 registers remain unchanged.

When the REMCON1.TYP[1:0] bits are 01b, the number of detecting the header pattern is one while the DRFLG flag is 1.

46.3.6.2 Data ‘0’ Pattern Detection

The data ‘0’ pattern can be detected by setting the minimum width of the data ‘0’ pattern in the D0PMIN register and the maximum width in the D0PMAX register.
The minimum and maximum widths of the data ‘0’ pattern must be “1 < D0PMIN register value ≤ D0PMAX register value”.

$$\text{Setting value n} = \frac{\text{Minimum width (maximum width) of data ′0′ pattern}}{\text{Operating clock cycle time}}$$

When not using the data ‘0’ pattern, set the D0PMIN and D0PMAX registers to 00h.
Make sure that the setting value of the data ‘0’ pattern is different from the setting values of the header, data ‘1’, and special data patterns, and the setting ranges are not overlapped.

When the REMCON1.TYP[1:0] bits are 00b or 01b, if the data ‘0’ pattern is detected before the header pattern is detected, the following occur:

- The REMSTS.REFLG flag becomes 1 (an error has occurred).
- The REMSTS.D0FLG, REMSTS.D1FLG, and REMSTS.SDFLG flags remain unchanged.
- The REMDAT0 to REMDAT7 registers remain unchanged.

46.3.6.3 Data ‘1’ Pattern Detection

The data ‘1’ pattern can be detected by setting the minimum width of the data ‘1’ pattern in the D1PMIN register and the maximum width in the D1PMAX register.
The minimum and maximum widths of the data ‘1’ pattern must be “1 < D1PMIN register value ≤ D1PMAX register value”.

$$\text{Setting value n} = \frac{\text{Minimum width (maximum width) of data ′1′ pattern}}{\text{Operating clock cycle time}}$$

When not using the data ‘1’ pattern, set the D1PMIN and D1PMAX registers to 00h.
Make sure that the setting value of the data ‘1’ pattern is different from the setting values of the header, data ‘0’, and special data patterns, and the setting ranges are not overlapped.

When the REMCON1.TYP[1:0] bits are 00b or 01b, if the data ‘1’ pattern is detected before the header pattern is detected, the following occur:

- The REMSTS.REFLG flag becomes 1 (an error has occurred).
- The REMSTS.D0FLG, REMSTS.D1FLG, and REMSTS.SDFLG flags remain unchanged.
- The REMDAT0 to REMDAT7 registers remain unchanged.

46.3.6.4 Special Data Pattern Detection

The special data pattern can be detected by setting the minimum width of the special data pattern in the SDPMIN register and the maximum width in the SDPMAX register.
The minimum and maximum widths of the special data pattern must be “1 < SDPMIN register value ≤ SDPMAX register value”.

$$\text{Setting value n} = \frac{\text{Minimum width (maximum width) of special data pattern}}{\text{Operating clock cycle time}}$$

When not using the special data pattern, set the SDPMIN and SDPMAX registers to 000h.
Make sure that the setting value of the special data pattern is different from the setting values of the header, data ‘0’, and data ‘1’ patterns, and the setting ranges are not overlapped.

When the REMCON1.TYP[1:0] bits are 00b or 01b, if the special data pattern is detected before the header pattern is detected, the following occur:

- The REMSTS.REFLG flag becomes 1 (an error has occurred).
- The REMSTS.D0FLG, REMSTS.D1FLG, and REMSTS.SDFLG flags remain unchanged.
- The REMDAT0 to REMDAT7 registers remain unchanged.

46.3.6.5 Examples of Setting Pattern Setting Registers

For the header, data ‘0’, data ‘1’, and special data setting registers, make sure that the minimum to maximum values of each pattern are different, and the setting ranges do not overlap as shown in Figure 46.9.

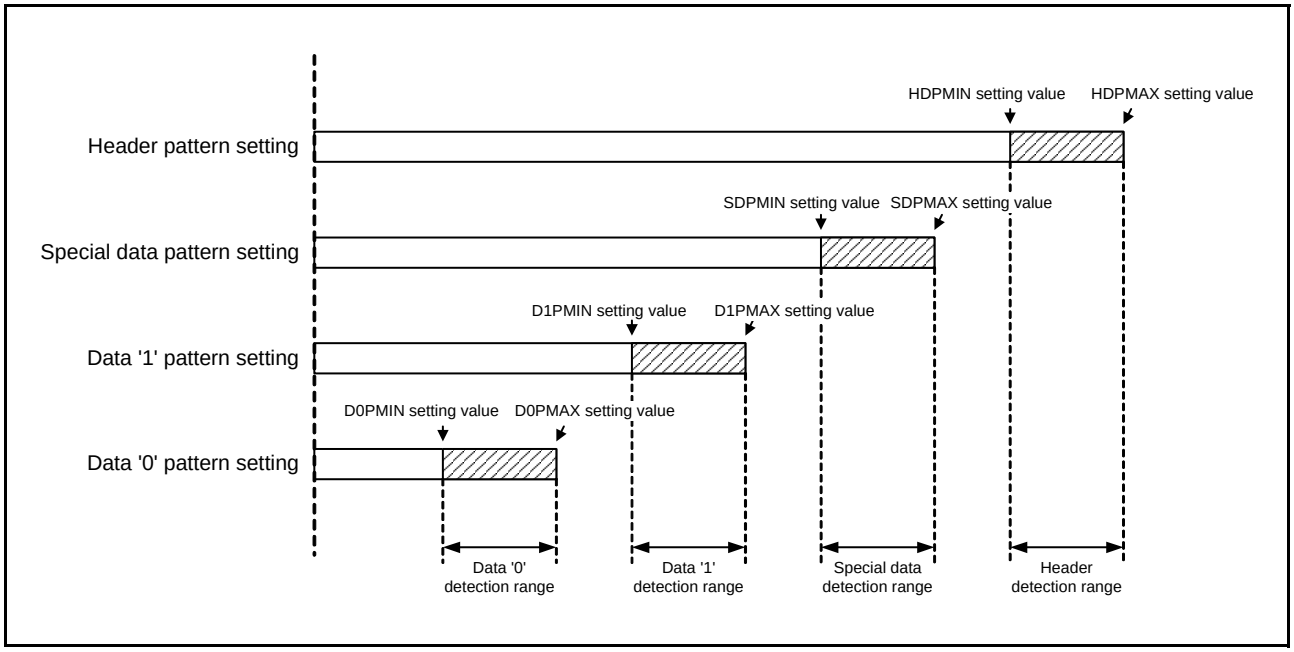

Figure 46.9 Examples of Setting Pattern Setting Registers

46.3.6.6 Updating Status Flags upon Pattern Detection

The detected patterns can be confirmed by reading the following flags: header pattern match flag (REMSTS.HDFLG), data ‘0’ pattern match flag (REMSTS.D0FLG), data ‘1’ pattern match flag (REMSTS.D1FLG), and special data pattern match flag (REMSTS.SDFLG). These flags are negated when a different pattern is detected. If a pattern other than the above patterns is detected, it is detected as an error pattern. This can be confirmed by reading the receive error flag (REMSTS.REFLG). This flag is negated when the next frame is received. Figure 46.10 shows pattern detection and an example of flag operation.

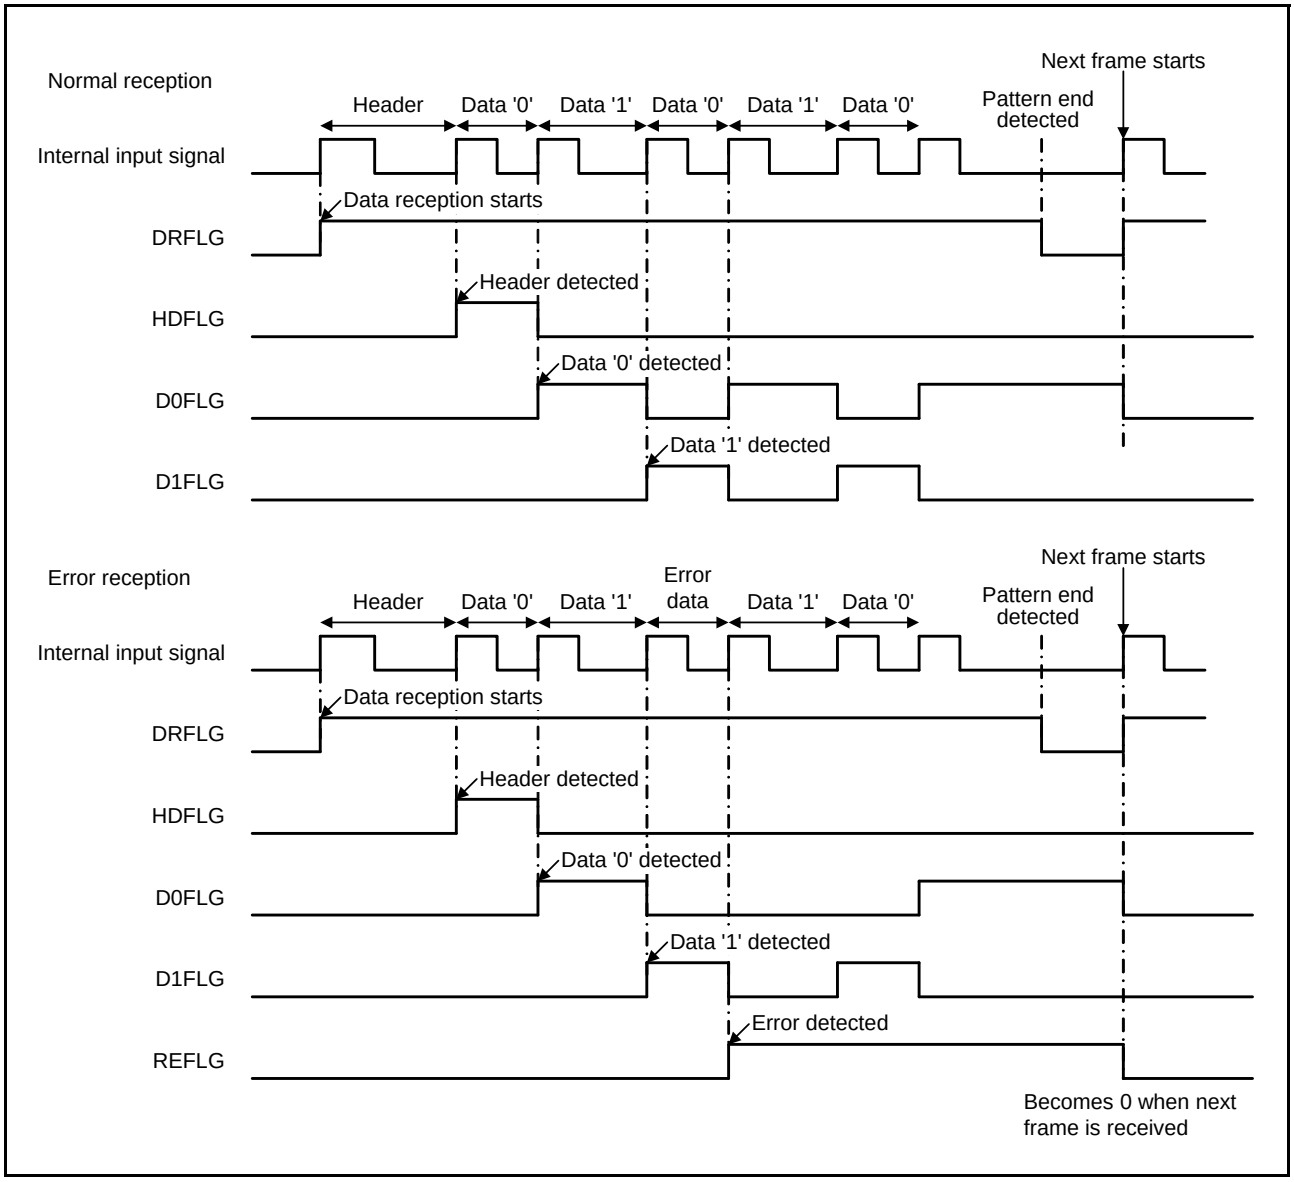

Figure 46.10 Example of Flag Operation

46.3.7 Pattern End

The timing when the REMSTS.DRFLG flag becomes 0 can be set.

When setting the REMPE register, be sure to set that the REMPE value > HDPMAX, D0PMAX, D1PMAX, or SDPMAX value.

When the REMPE value ≤ HDPMAX, D0PMAX, D1PMAX, or SDPMAX value, the REMPE register cannot be used to set the timing when the REMSTS.DRFLG flag becomes 0. In this case, data reception is completed according to the largest value from among the setting values of the HDPMAX, D0PMAX, D1PMAX, and SDPMAX registers. Figure 46.11 shows operation of the data reception complete flag for each pattern end setting.

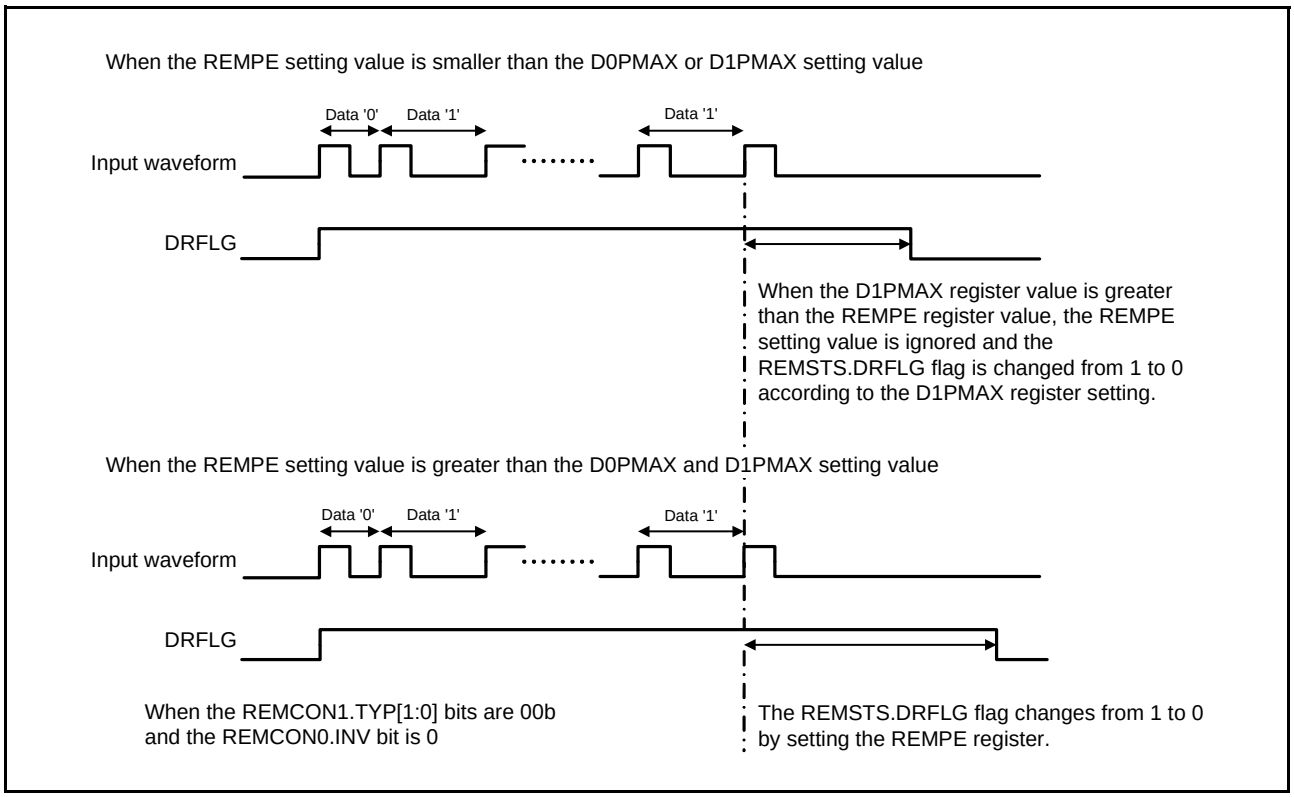

Figure 46.11 Operation of Data Reception Complete Flag for Each Pattern End Setting

46.3.8 Receive Data Buffer

The receive data j register (REMDATj) (j = 0 to 7) is an 8-byte (64-bit) buffer for storing received data. When data ‘0’ pattern or data ‘1’ pattern is detected, the detection result is sequentially stored starting from the REMDAT0.DAT0[0] bit as shown in Figure 46.12. The REMRBIT register is counted up at the same time, so the number of the current received bits can be checked by reading the REMRBIT register. See Table 46.4 for the relationship between the number of received bits and the location where data is stored. The values of the REMDATj and REMRBIT registers do not change even when the header pattern or special pattern is received. If the REMDATj or REMRBIT register is read while the data is being updated, the value read may be undefined.

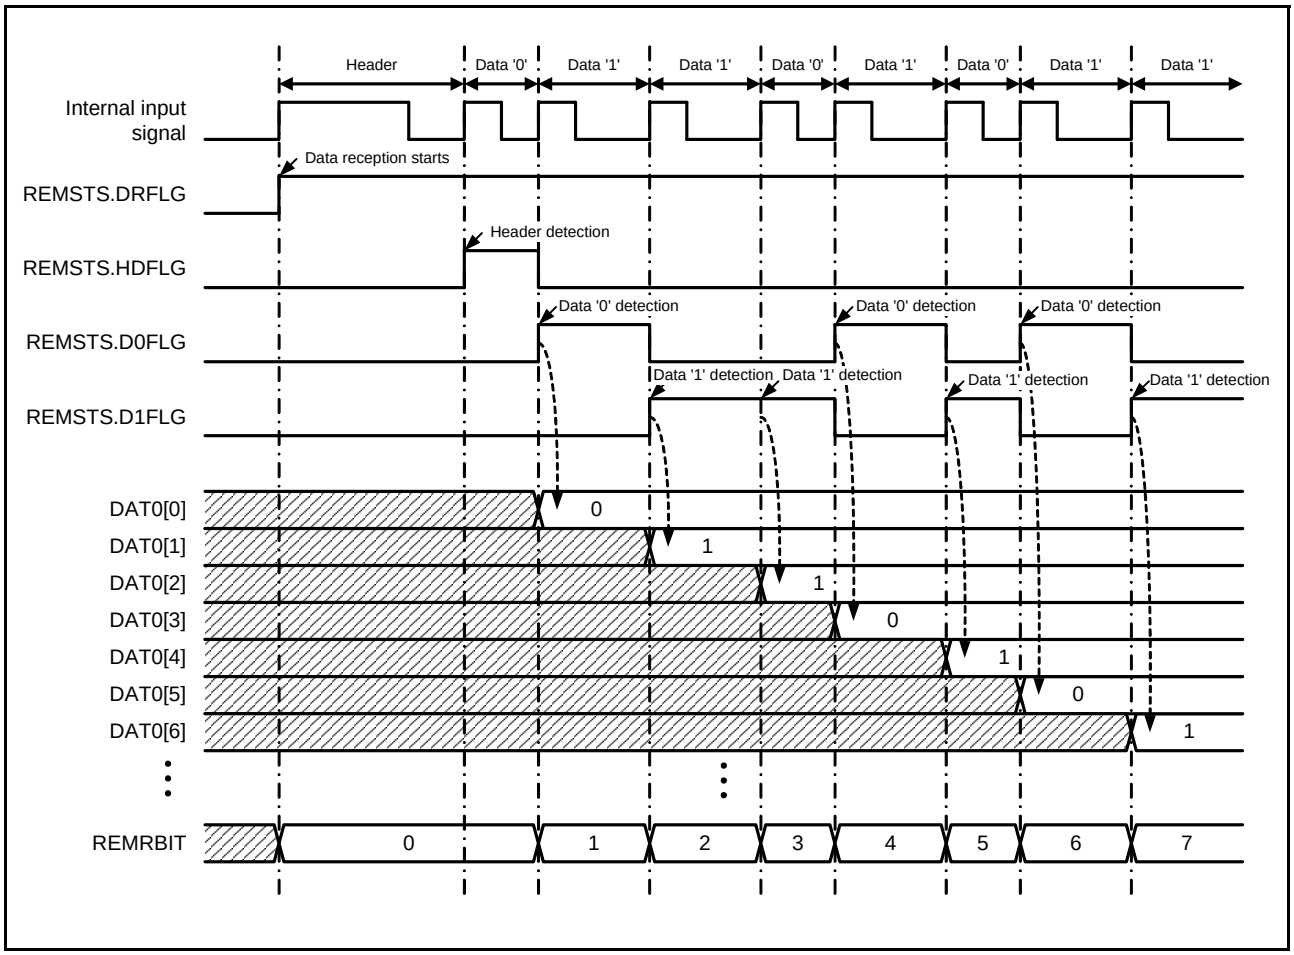

Figure 46.12 Operation of Receive Data Buffer

Table 46.4 Relationship between Number of Received Bits and Location Where Data is Stored

Note: When the data exceeds 64 bits, the REMDATj register is sequentially overwritten from the first bit.

When 0 is written to the REMDAT0.DAT0[0] bit, the values of the REMDAT0 to REMDAT7 registers become 00h after one to two cycles of the operating clock. Figure 46.13 shows the REMDATj/REMRBIT register operation when 00h is written to the REMDAT0 register.

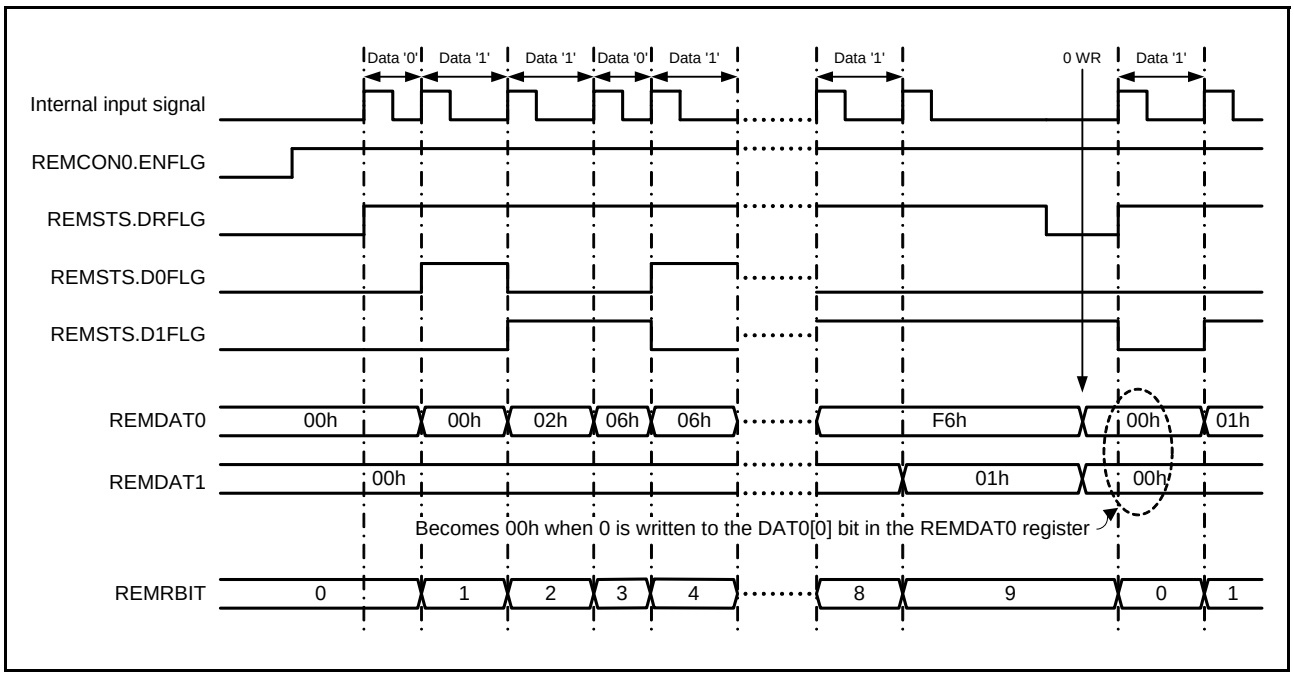

Figure 46.13 REMDATj/REMRBIT Register Operation (00h is Written to REMDAT0 Register)

When 0 is written to the REMRBIT.RBIT[0] bit, the value of the REMRBIT register becomes 00h after one to two cycles of the operating clock. When the REMCON1.TYP[1:0] bits are 00b or 10b, if the header pattern is detected during data reception, the value of the REMRBIT register is initialized to 00h and the received data is sequentially overwritten from the REMDAT0.DAT0[0] bit. Figure 46.14 shows operation of header pattern detection during data reception.

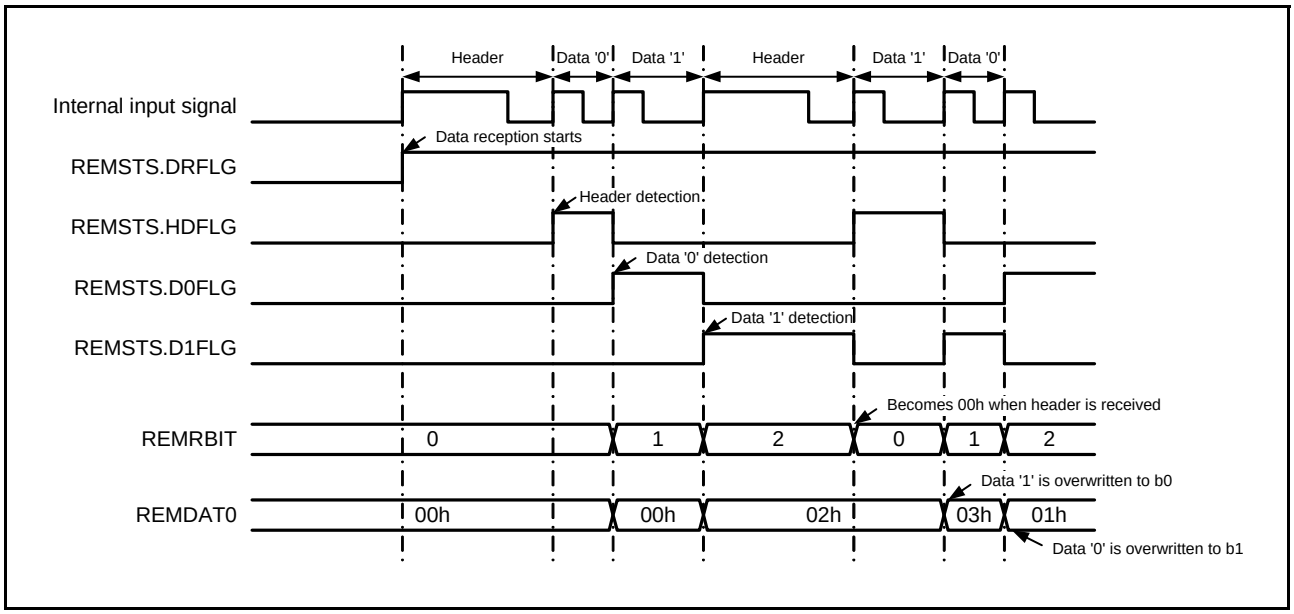

Figure 46.14 Operation of Header Pattern Detection during Data Reception

When the data exceeds 64 bits, the buffer is sequentially overwritten from the first bit. Figure 46.15 shows the REMRBIT register operation when the REMSTS.BFULFLG flag becomes 1.

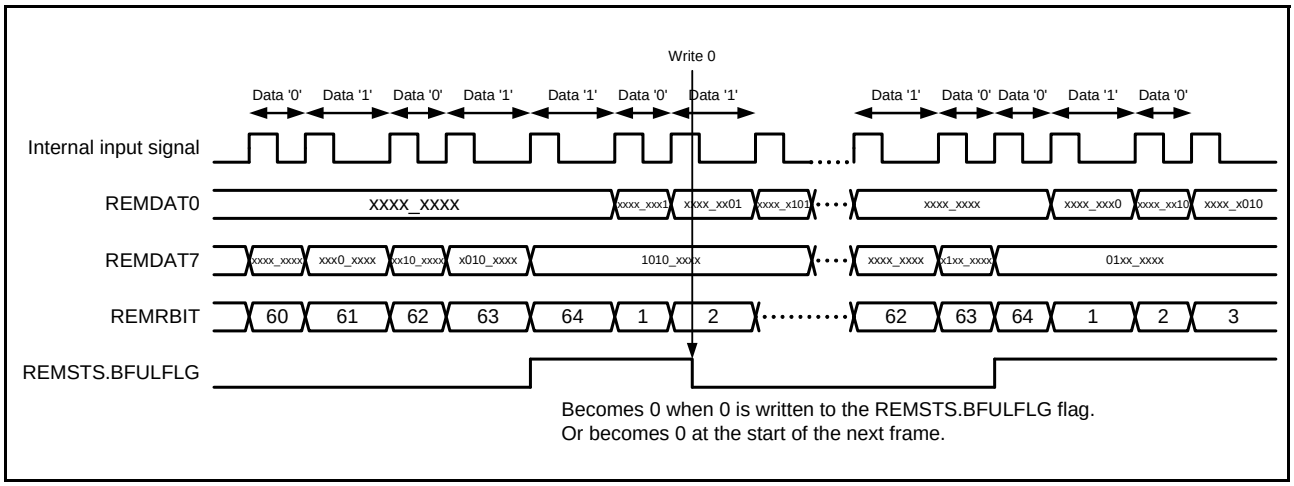

Figure 46.15 REMRBIT Register Operation (REMSTS.BFULFLG Flag = 1)

46.3.9 Compare Function

The REMC has a function to compare the value of the REMCPD register with the value of the REMDAT1 and REMDAT0 registers. As a result of comparison, it can be detected that the first 1 to 16 bits of the remote control signal are the specific values. Figure 46.16 shows the operation timing of the receive buffer and the compare function.

When using the compare function, set the following:

- Select bits to be compared by setting the REMCPC.CPN[3:0] bits (when the setting value is n, bits n to 0 are compared. n: 0 to 15).
- Set the compare data in the REMCPD register.
  When the value of the REMRBIT register becomes the bit count specified by the REMCPC.CPN[3:0] bits, if the stored comparison result between the REMCPD register and the REMDAT1 and REMDAT0 registers matches, the REMSTS.CPFLG flag becomes 1 (compare match).

When the value of the REMRBIT register matches the bit count specified by the REMCPC.CPN[3:0] bits during reception of 64 bits or more, even if the comparison result between the REMCPD register and the REMDAT1 and REMDAT0 registers matches, the REMSTS.CPFLG flag does not become 1 (compare match).

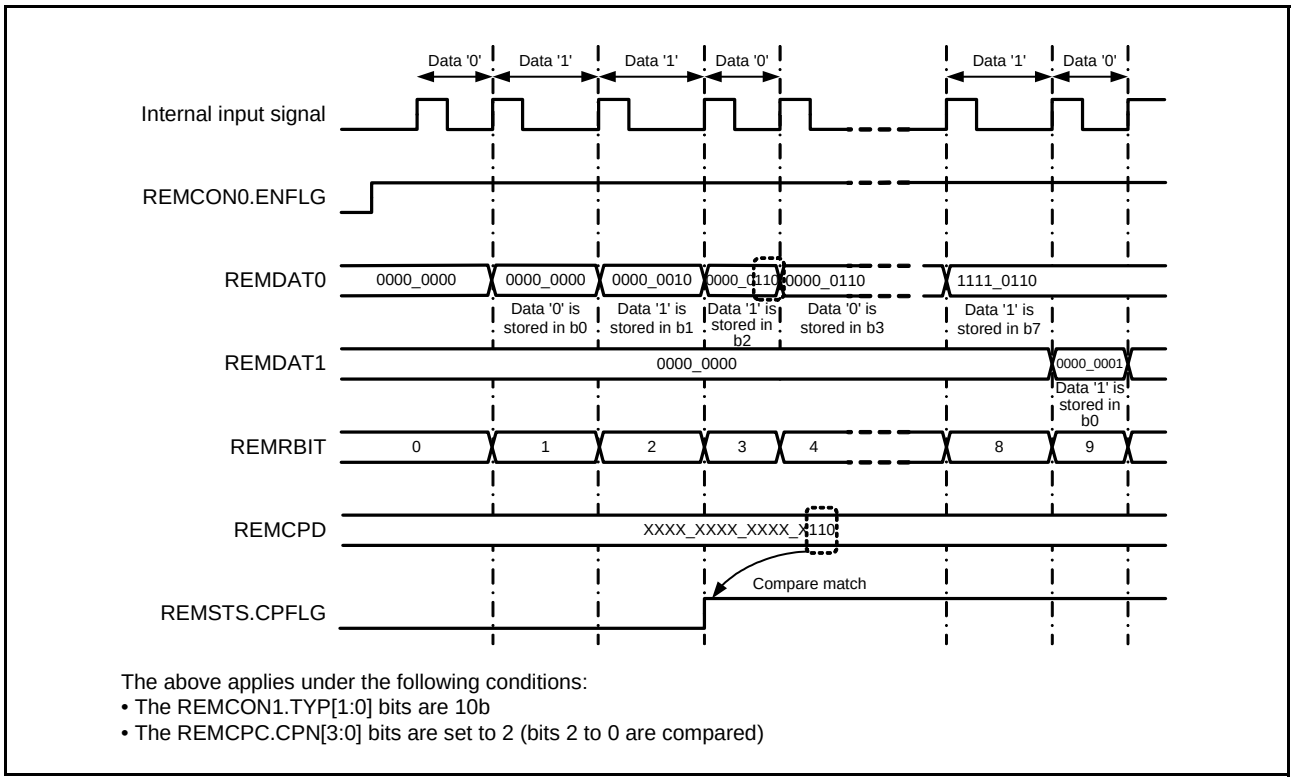

Figure 46.16 Receive Buffer and Compare Function

46.3.10 Error Pattern Reception

When the error pattern is detected during data reception, subsequent operation differs depending on the setting of the REMCON0.EC bit.

Figure 46.17 shows operation of the REMDAT0 and REMRBIT registers when the REMCON0.EC bits are set to 0. If an error is detected while the REMCON0.EC bit is 0, the data when the error is detected is not captured, but the data is captured when the data ‘0’ pattern or data ‘1’ pattern is detected later.

Figure 46.18 shows operation of the REMDAT0 and REMRBIT registers when the REMCON0.EC bits are set to 1. If an error is detected while the REMCON0.EC bit is 1, the values of the REMRBIT and REMDAT0 to REMDAT7 registers are not updated even when the data ‘0’ pattern or data ‘1’ pattern is detected later. Once the REMSTS.DRFLG flag is cleared and after data reception is completed, if data reception starts again, the REMSTS.REFLG flag is cleared and the data is captured.

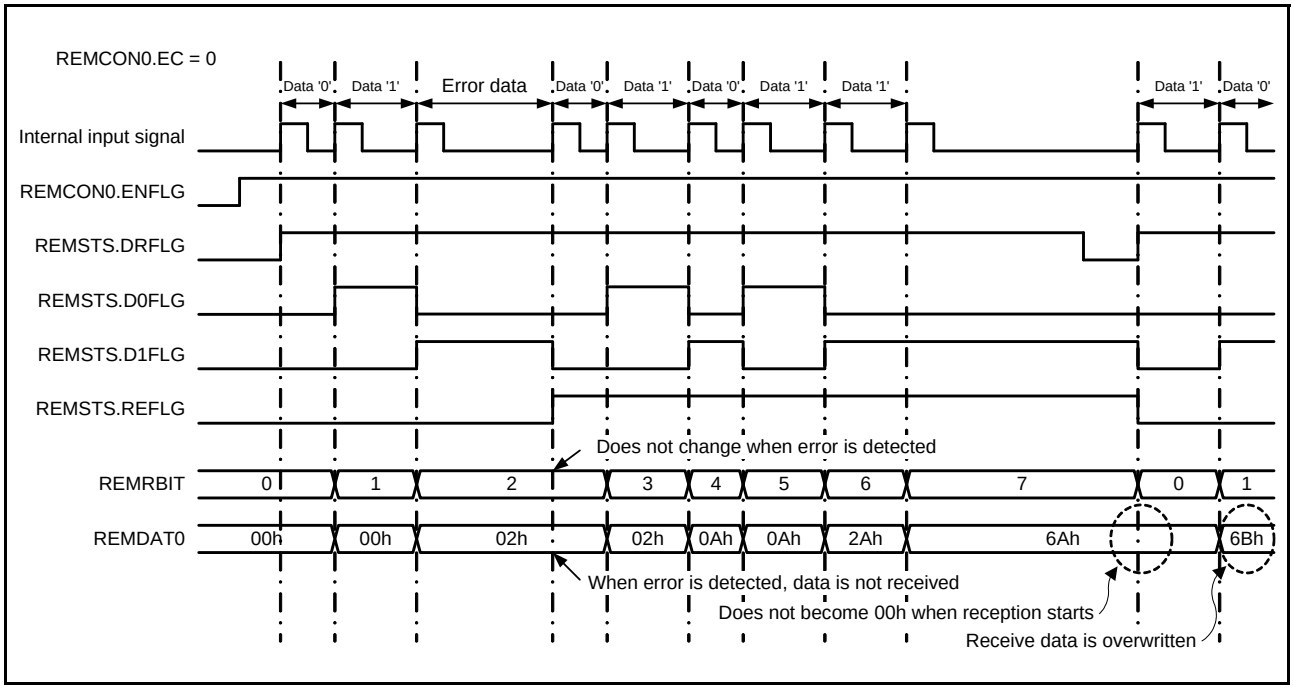

Figure 46.17 REMDAT0 and REMRBIT Registers Operation upon Error Detection (REMCON0.EC Bit = 0)

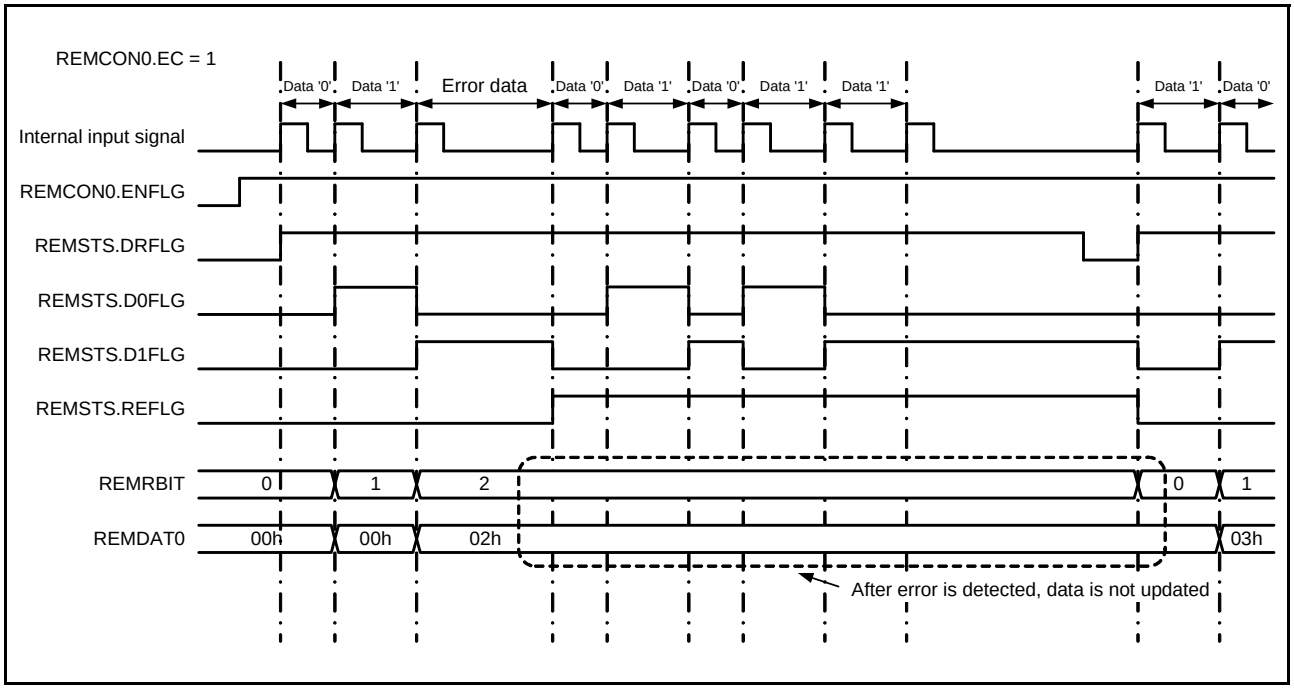

Figure 46.18 REMDAT0 and REMRBIT Registers Operation upon Error Detection (REMCON0.EC Bit = 1)

46.3.11 Storing Base Timer Value When Pattern is Detected

The measurement result register (REMTIM) stores the base timer value when one of the following patterns is detected. This makes it possible to measure each pattern width. Figure 46.19 shows an operation example of the measurement function.

- Header pattern
- Data ‘0’ pattern
- Data ‘1’ pattern
- Special data pattern
- Data pattern other than the above (receive error)

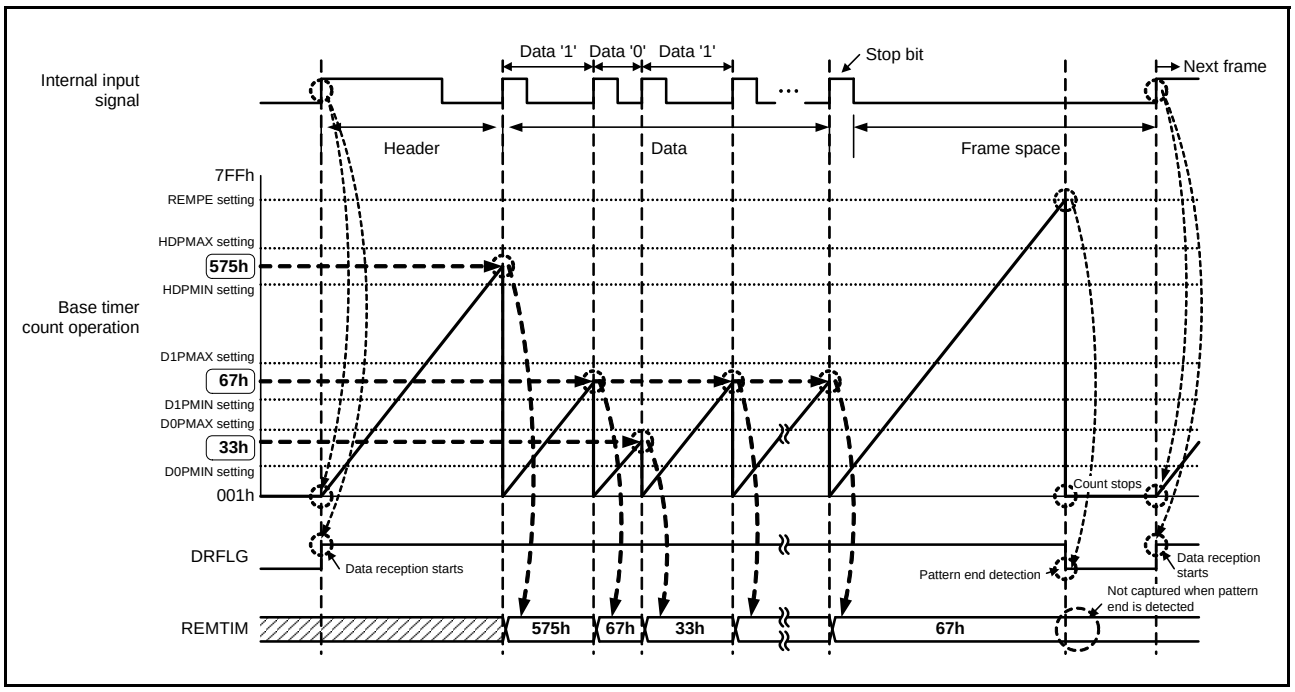

Figure 46.19 Operation Example of Measurement Function

46.3.12 Interrupts

The REMC has the following seven interrupt sources: compare match, receive error, data reception complete, receive buffer full, header pattern match, data ‘0’ pattern or data ‘1’ pattern match, and special data pattern match. All of these interrupt sources are assigned to a single vector number.

Table 46.5 lists the REMC interrupt sources, and Table 46.6 lists the interrupt modes and REMCI0 interrupt request generation conditions.

In normal interrupt mode, if the enable bit for an interrupt source in the REMINT register is set to 1 when the given interrupt request generation condition is satisfied, an REMCI0 interrupt request is output.

The condition for generating an interrupt request in sequential interrupt mode differs from that in normal interrupt mode. In sequential interrupt mode, an REMCI0 interrupt request is output when either of the following conditions is satisfied.

- If the enable bits for the generation of an interrupt request in response to the four interrupt sources: compare match, data reception complete, header pattern match, and special data pattern match are set to 1 by the corresponding bits in the REMINT register, the interrupt request is generated when the interrupt request generation conditions for all enabled interrupt sources among the four sources are satisfied.
- For any of the interrupt sources other than the four above, an interrupt is generated if this is enabled by the corresponding bit in the REMINT register.

Refer to section 15, Interrupt Controller (ICUE) for details on interrupt control.

Table 46.5 REMC Interrupt Sources

Interrupt Source	Status Flag	Interrupt Enable Bit	Each Interrupt Request Generation Condition
Compare match	REMSTS.CPFLG	REMINT.CPINT	When the REMSTS.CPFLG flag changes from 0 to 1
Receive error	REMSTS.REFLG	REMINT.REINT	When the REMSTS.REFLG flag changes from 0 to 1 (When a receive error is detected)
Data reception complete	REMSTS.DRFLG	REMINT.DRINT	When the REMSTS.DRFLG flag changes from 1 to 0
Receive buffer full	REMSTS.BFULFLG	REMINT.BFULINT	When the REMSTS.BFULFLG flag changes from 0 to 1
Header pattern match	REMSTS.HDFLG	REMINT.HDINT	When the REMSTS.HDFLG flag changes from 0 to 1 (When the header pattern is detected)
Data ‘0’ pattern or data ‘1’ pattern match	REMSTS.D0FLG, REMSTS.D1FLG	REMINT.DINT	• When the REMSTS.D0FLG flag changes from 0 to 1 (When the data ‘0’ pattern is detected) • When the REMSTS.D1FLG flag changes from 0 to 1 (When the data ‘1’ pattern is detected)
Special data pattern match	REMSTS.SDFLG	REMINT.SDINT	When the REMSTS.SDFLG flag changes from 0 to 1 (When the special data pattern is detected)

Table 46.6 Conditions for Generating an Interrupt Request for Each Interrupt Mode

	Interrupt Mode	
Item	**Normal Interrupt Mode**	**Sequential Interrupt Mode**
Bit setting	REMCON1.INTMD bit = 0	REMCON1.INTMD bit = 1
REMCI0 interrupt request generation condition	Satisfaction of any enabled interrupt source condition among the following seven leads to the generation of an interrupt request. • Compare match • Receive error • Data reception complete • Receive buffer full • Header pattern match • Data ‘0’ pattern or data ‘1’ pattern match • Special data pattern match	Satisfaction of all enabled interrupt source conditions among the following four leads to the generation of the interrupt request. • Compare match • Data reception complete • Header pattern match • Special data pattern match Satisfaction of any enabled interrupt source condition among the following three leads to the generation of an interrupt request. • Receive error • Receive buffer full • Data ‘0’ pattern or data ‘1’ pattern match

46.3.13 Data Reception in Low Power Consumption State

In this MCU, data can be received in a low power consumption state (sleep mode, all-module clock stop mode, software standby mode, or deep software standby mode).
To receive data in a low power consumption state, REMC communications should be set before transitioning to the state.

46.3.13.1 Using REMC Interrupt Request to Return from Low Power Consumption State

Power consumption while waiting for data reception can be reduced by using the REMC interrupt request to be output during data reception as the source for returning from the low power consumption state (see Figure 46.20). Pattern detection and compare function enable returning from the low power consumption state only when specified data is received.

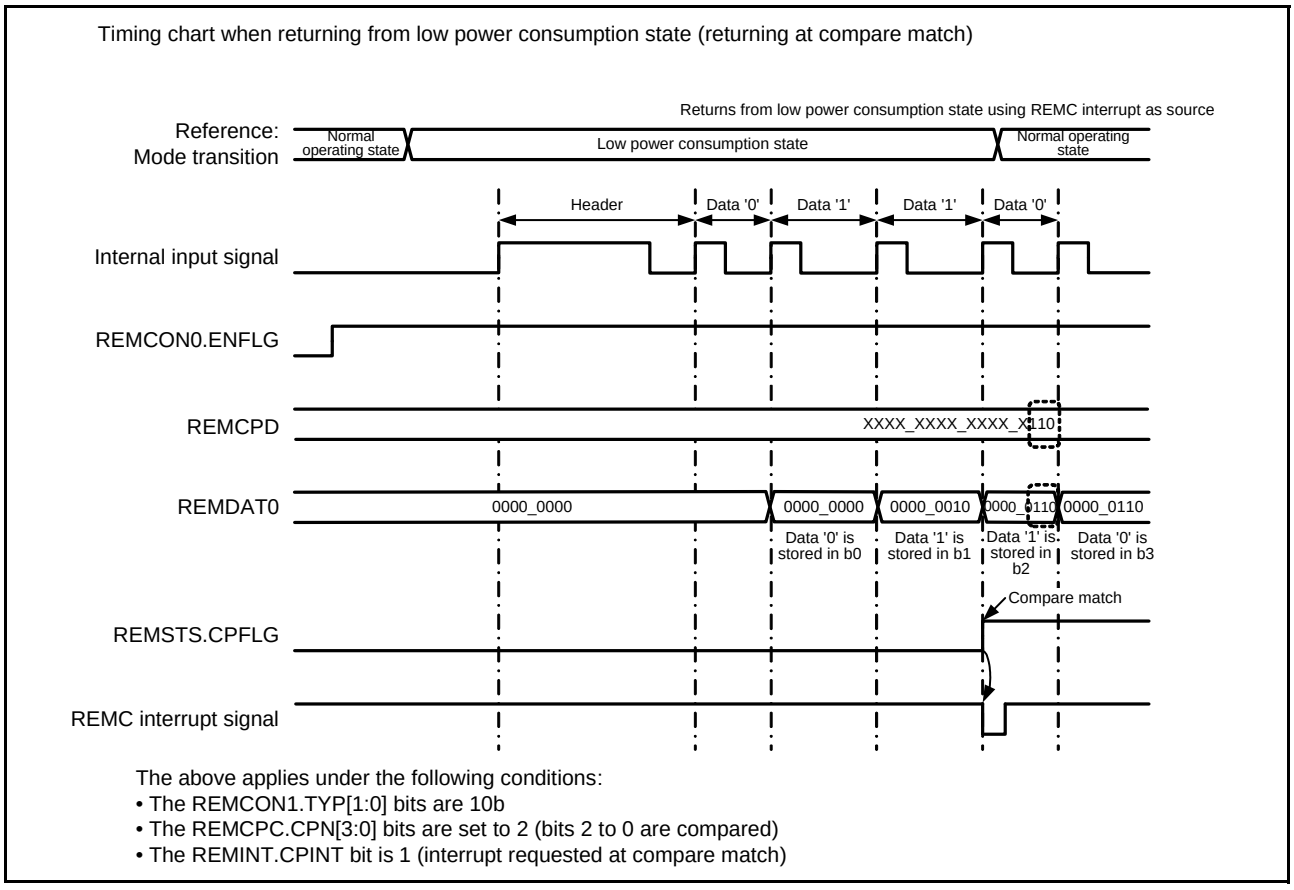

Figure 46.20 Using REMC Interrupt Request to Return from Low Power Consumption State (Normal Interrupt Mode)

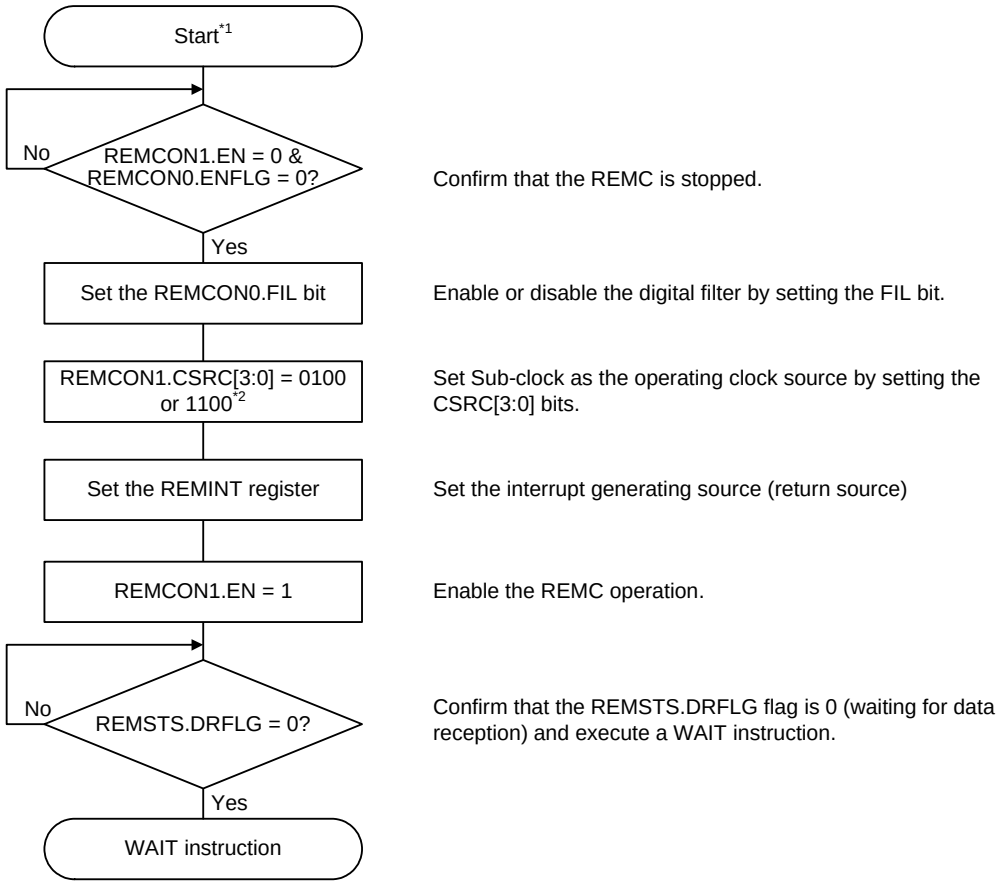
46.3.13.2 Data Reception in Software Standby Mode and Deep Software Standby Mode

Data can be received in software standby mode or deep software standby mode while the sub-clock is selected as the REMC operating clock.

When data is to be received in software standby mode or deep software standby mode, set the RCR3.RTCEN bit to 1 to select continuous supply of the sub-clock to the REMC as the operating clock in software standby mode or deep software standby mode. For details on how to supply the REMC operating clock, see section 46.3.4, Operating Clocks.

To return the chip from the software standby mode or deep software standby mode, select the conditions for generating REMC interrupt requests during data reception and the output conditions specified for the interrupt mode.

Pattern detection and comparison will only cause return from the software standby mode when the specified data is received. Figure 46.21 shows an example of a flowchart of the procedure for setting up data reception in software standby mode or deep software standby mode.



Note 1. Continuous supply of the sub-clock to the REMC is required in software standby mode or deep software standby mode. This is selected by setting the RCR3.RTCEN bit to 1.

Note 2. When the REMCON1.CSRC[3:0] bits are modified, re-setting of the REMCON0 register, REMCON1 register, REMCPC register, REMCPD register, REMPE register, and the respective data pattern width setting registers is required.

Figure 46.21 Flowchart for Setting Data Reception in Software Standby Mode or Deep Software Standby Mode

46.4 Usage Notes

46.4.1 Module Stop Function Setting

REMC operation can be disabled or enabled by setting the module stop control register. The REMC is stopped with the value after reset. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

46.4.2 Settings for Peripheral Module Clock and REMC Operating Clock

Set the peripheral module clock (PCLKB) frequency to higher than the REMC operating clock frequency.

46.4.3 Starting/Stopping Operation of Remote Control Signal Receiver

The REMCON1.EN bit controls starting/stopping of operation of the remote control signal receiver.
The REMCON0.ENFLG flag indicates that the operation is enabled or disabled. After the REMCON1.EN bit is set to 1 (operation enabled), it takes up to zero to one cycle of the operating clock before the REMC circuit starts operating and the REMCON0.ENFLG flag becomes 1. During this period, do not access the REMC related registers (listed in section 46.2.1 to section 46.2.20) except for the REMCON0.ENFLG flag.

46.4.4 Accessing Registers

Change the following registers only when the REMCON1.EN bit and REMCON0.ENFLG flag are both 0 (REMC is stopped)

- REMCON0 register
- REMCON1 register (except for bits 0 to 2)
- REMINT register (except for bits 2 and 5)
- REMCPC register
- REMCPD register
- Pattern width setting registers for header, data ‘0’, data ‘1’, and special data patterns
- Pattern end setting register

When rewriting the REMCON1.TYP[1:0] bits while the REMCON1.EN bit or REMCON0.ENFLG flag is 1 (REMC is operating), change the values of these bits one bit at a time. If the REMCON1.TYP[1:0] bits are rewritten when the REMCON0.INFLG flag changes, the signal captured into the remote control signal receiver may be undefined.
After 0 is written to bit 0 in the REMDAT0 or REMRBIT register or the REMSTS.BFULFLG flag, do not write 0 to the same bit again for two cycles of the operating clock. If 0 is written when the REMCON0.INFLG flag changes, the values of the REMDATj and REMRBIT registers and the REMSTS.BFULFLG flag may be undefined.

46.4.5 PMC0 Input Control

If the REMCON0.FILSEL, FIL, or INV bit is rewritten, the signal captured into the remote control signal receiver is undefined for three cycles of the digital filter sampling clock.

46.4.6 Notes on Changing the Operating Clock

When the REMCON1.CSRC[3:0] bits are rewritten, set the following registers again: REMCON0, REMCON1, REMINT, REMCPC, REMCPD, REMPE, and header, data ‘0’, data ‘1’, and special data pattern width setting registers.

46.4.7 Reading Registers

When the following registers are read while data changes, an undefined value may be read.

Flags in the REMCON0 and REMSTS registers (except for the REMSTS.DRFLG flag) and registers REMTIM, REMDAT0 to REMDAT7, and REMRBIT

Follow the procedures below to avoid reading an undefined value.

- Using an interrupt
  Set the REMINT.DRINT bit to 1 (data reception complete interrupt enabled) and read the registers within the REMC interrupt routine.
- Polling by a program 1
  Set the REMINT.DRINT bit to 1 (data reception complete interrupt enabled) and poll the ICU.IRn.IR flag by a program. Read the registers when the IF bit becomes 1 (interrupt request generated).
- Polling by a program 2
  (1) Poll the REMSTS.DRFLG flag.
  (2) When the REMSTS.DRFLG flag becomes 1, poll this flag until it becomes 0.
  (3) Read the necessary content of the registers when the REMSTS.DRFLG flag becomes 0.

47. Capacitive Touch Sensing Unit (CTSUa)

The capacitive touch sensing unit (CTSU) measures the electrostatic capacitance of the touch sensor. Changes in the electrostatic capacitance are determined by software, which enables the CTSU to detect whether a finger is in contact with the touch sensor. The electrode surface of the touch sensor is usually enclosed with a dielectric so that a finger does not come into contact with the electrode.

As shown in Figure 47.1, electrostatic capacitance (parasitic capacitance) exists between the electrode and the surrounding conductors. Because the human body is an electrical conductor, when a finger is placed close to the electrode, the value of electrostatic capacitance increases.

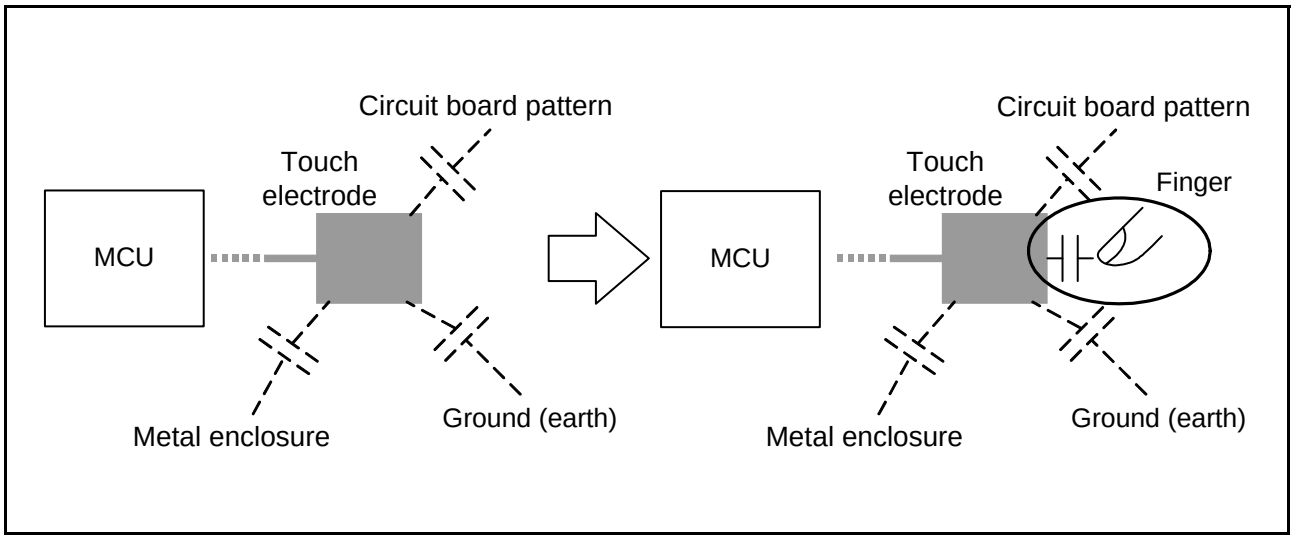


Figure 47.1 Increased Electrostatic Capacitance Due to Presence of Finger

Electrostatic capacitance is detected by the following methods: Self-capacitance and mutual capacitance.

In the self-capacitance method, the CTSU detects electrostatic capacitance generated between a finger and a single electrode. In the mutual capacitance method, two electrodes are used as a transmit electrode and a receive electrode, and the CTSU detects the change in the electrostatic capacitance generated between the two when a finger is placed close to them.

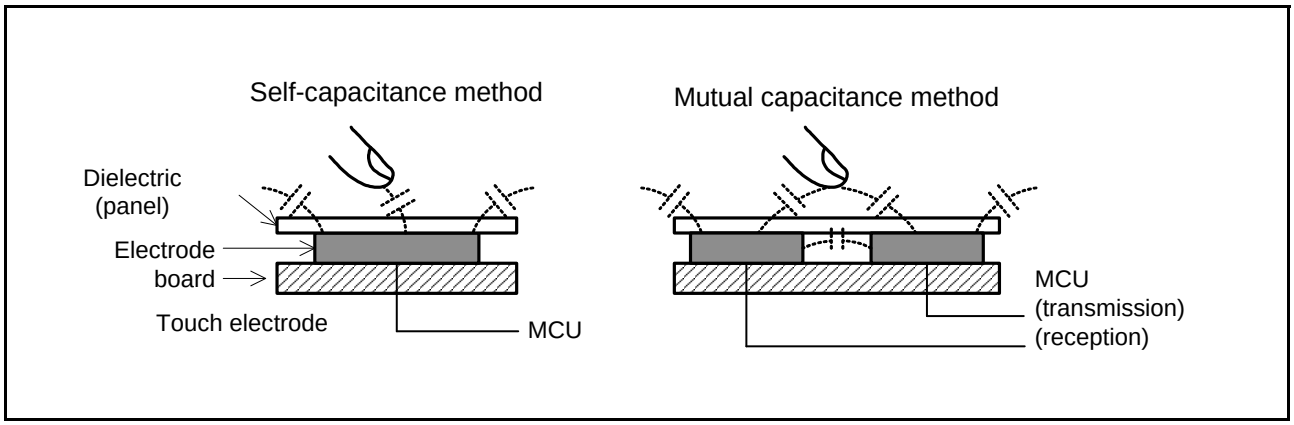

Figure 47.2 Self-Capacitance Method and Mutual Capacitance Method

Electrostatic capacitance is measured by counting a clock signal whose frequency changes according to the amount of charged/discharged current, for a specified period.

For details on the measurement principles of the CTSU, refer to section 47.3.1, Principles of Measurement Operation.

In this section, “PCLK” is used to refer to PCLKB.

47.1 Overview

Table 47.1 lists the specifications of the CTSU, and Figure 47.3 shows a block diagram of the CTSU.

Table 47.1 CTSU Specifications

Item		Description
Operating clock		PCLK, PCLK/2, or PCLK/4
Pins	TS0 to TS16	Electrostatic capacitance measurement pins (17 channels)
	TSCAP	LPF (low-pass filter) connection pin
Measurement modes	Self-capacitance single scan mode	Electrostatic capacitance on a channel is measured by the self-capacitance method.
	Self-capacitance multi-scan mode	Electrostatic capacitance on multiple channels is measured successively by the self-capacitance method.
	Mutual capacitance full scan mode	Electrostatic capacitance on multiple channels is measured successively by mutual capacitance.
Noise prevention		Synchronous noise prevention, high-pass noise prevention
Measurement start conditions		• Software trigger • External trigger (event input from the event link controller (ELC))

As shown in Figure 47.3, the CTSU consists of the status control block, trigger control block, clock control block, channel control block, port control block, sensor drive pulse generator, measurement block, interrupt block, and control registers.

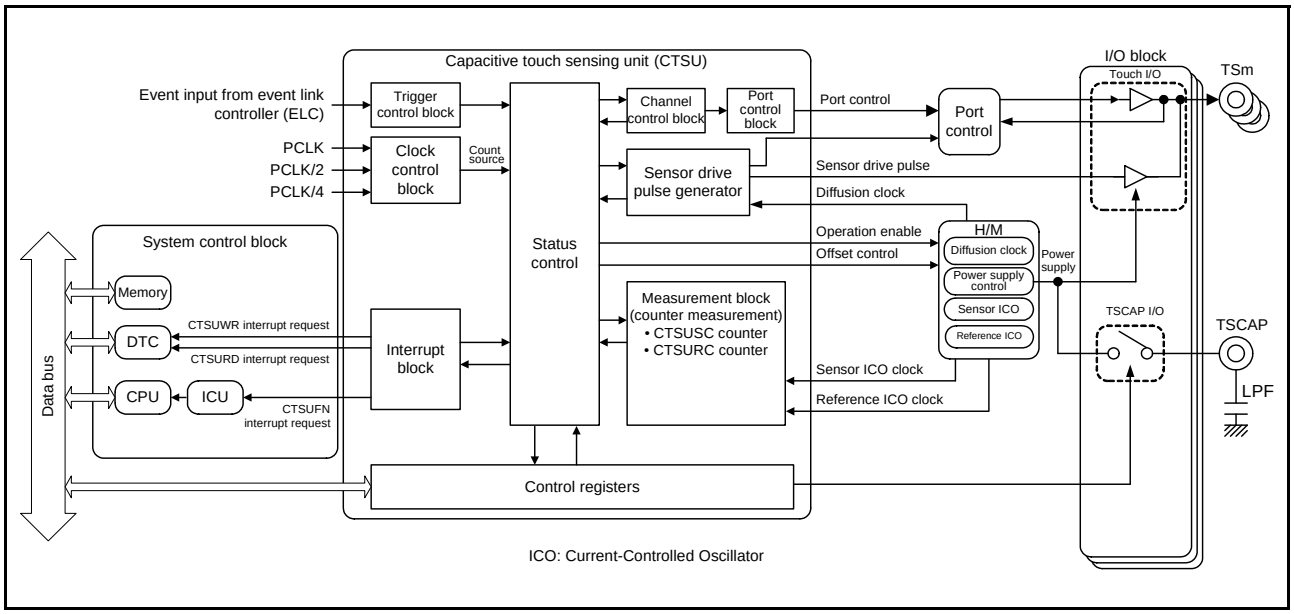

Figure 47.3 CTSU Block Diagram (m = 0 to 16)

Table 47.2 CTSU Pin Configuration

Pin Name	I/O	Function
TS0 to TS16	I/O	Electrostatic capacitive measurement pins (touch pins)
TSCAP	—	LPF connection pin

47.2 Register Descriptions

47.2.1 CTSU Control Register 0 (CTSUCR0)

Address(es): CTSU.CTSUCR0 000A 0900h

	b7	b6	b5	b4	b3	b2	b1	b0
	CTSUTXVSEL	—	—	CTSUINIT	CTSUIOC	CTSUSNZ	CTSUCAP	CTSUSTRT
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CTSUSTRT	CTSU Measurement Operation Start	0: Measurement operation stops 1: Measurement operation starts	R/W
b1	CTSUCAP	CTSU Measurement Operation Start Trigger Select	0: Software trigger 1: External trigger	R/W
b2	CTSUSNZ	CTSU Wait State Power-Saving Enable	0: Power-saving function during wait state is disabled 1: Power-saving function during wait state is enabled	R/W
b3	CTSUIOC	CTSU Transmit Pin Control	0: The TS pins are driven low 1: The TS pins are driven high	R/W
b4	CTSUINIT	CTSU Control Block Initialization	Writing 1 to this bit initializes the CTSU control block and registers*1. This bit is read as 0.	R/W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	CTSUTXVSEL	CTSU Transmission Power Supply Select*2	0: VCC selected 1: Internal logic power supply selected	R/W

Note 1. The CTSUSC, CTSURC, CTSUMCH0, CTSUMCH1, and CTSUST registers are initialized.
Note 2. This bit can be set to 1 only in mutual capacitance full scan mode. Otherwise (in self-capacitance single scan mode or self-capacitance multi-scan mode), set this bit to 0.

The CTSUCAP, CTSUSNZ and CTSUTXVSEL bits should be set when the CTSUSTRT bit is 0. These bits can be set at the same time as starting measurement operation.

CTSUSTRT Bit (CTSU Measurement Operation Start)

This bit specifies whether CTSU operation starts or stops.
When the CTSUCAP bit is 0 (software trigger), measurement is started by writing 1 to the CTSUSTRT bit, and the CTSUSTRT bit becomes 0 when measurement is finished.
When the CTSUCAP bit is 1 (external trigger), the CTSU waits for an external trigger by writing 1 to the CTSUSTRT bit, and measurement is started at the rising edge of the external trigger. When measurement is finished, the CTSU waits for the next external trigger and operation is continued.
Table 47.3 lists the CTSU states.

Table 47.3 CTSU States

CTSUSTRT Bit	CTSUCAP Bit	CTSU State
0	0	Stopped
0	1	Stopped
1	0	During measurement
1	1	During measurement/wait for an external trigger*1

Note 1. The state can be read from the CTSUST.CTSUSTC[2:0] flags.
During measurement: CTSUST.CTSUSTC[2:0] flags ≠ 000b
Wait for an external trigger: CTSUST.CTSUSTC[2:0] flags = 000b

If the CTSUSTRT bit is set to 1 when the CTSUSTRT bit is 1, writing is ignored and operation is continued.

To forcibly stop operation (forced stop) when the CTSUSTRT bit is 1, set the CTSUSTRT bit to 0 and the CTSUINIT bit to 1 simultaneously.

CTSUCAP Bit (CTSU Measurement Operation Start Trigger Select)

This bit specifies the measurement start condition. For details, see the description of the CTSUSTRT bit.

CTSUSNZ Bit (CTSU Wait State Power-Saving Enable)

This bit enables or disables power-saving operation during a wait state. This bit can also be used to suspend the CTSU power supply, which decreases power consumption during the wait state.
In the suspended state, the CTSU power supply is turned off while the external TSCAP is still charged after the CTSU power supply has been turned on and the TSCAP has been charged.

Table 47.4 CTSU Power Supply State Control

CTSUCR1.CTSUPON Bit	CTSUSNZ Bit	CTSUCAP Bit	CTSUSTRT Bit	CTSU Power Supply State
0	0	0	0	Stopped
1	0	—	—	Operating
1	1	0	0	Suspended

Note: Settings other than the above are prohibited.

To start measurement from the suspended state, set the CTSUSNZ bit to 0 and wait for 16 µs before setting the CTSUSTRT bit to 1. To set the suspended state after measurement is finished, set the CTSUSNZ bit to 1.

CTSUIOC Bit (CTSU Transmit Pin Control)

This bit selects the logic level of the TS pin when the CTSUERRS.CTSUTSOD bit is set to 1.
This bit setting is ignored when the CTSUTSOD bit is 0.

CTSUINIT Bit (CTSU Control Block Initialization)

The internal control registers can be initialized by writing 1 to this bit. To forcibly stop the current operation, set the CTSUSTRT bit to 0 and the CTSUINIT bit to 1 simultaneously. In this case, the operation is stopped and the internal control registers are initialized.
Do not write 1 to the CTSUINIT bit at the same time as setting the CTSUSTRT bit to 1 (CTSU operation starts).

CTSUTXVSEL Bit (CTSU Transmission Power Supply Select)

This bit is used to switch the power supply for the transmit buffer in mutual capacitance full scan mode. Set this bit to 0 for any other mode.
This bit switches the power supply for touch I/O which is set for transmission by the CTSUCHTRCn registers.
Table 47.5 lists the power supply for TSm pin.
When the VCC voltage fluctuates greatly due to the switching of the output buffer, switching to the internal logic power supply can reduce the effect on the voltage fluctuation.

Table 47.5 Power Supply for TSm Pin

Setting of CTSUCHTRCn Registers	CTSUTXVSEL Bit	Power Supply for TSm Pin
0 (reception)	0 (VCC)	VCC
	1 (internal logic power supply)	
1 (transmission)	0 (VCC)	
	1 (internal logic power supply)	Internal logic power supply

47.2.2 CTSU Control Register 1 (CTSUCR1)

Address(es): CTSU.CTSUCR1 000A 0901h

	b7	b6	b5	b4	b3	b2	b1	b0
	CTSUMD[1:0]		CTSUCLK[1:0]		CTSUATUNE1	—	CTSUCSW	CTSUPON
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CTSUPON	CTSU Power Supply Enable	0: Powered off 1: Powered on	R/W
b1	CTSUCSW	CTSU LPF Capacitance Charging Control	0: Capacitance switch turned off 1: Capacitance switch turned on	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3	CTSUATUNE1	CTSU Power Supply Capacity Adjustment	0: Normal output 1: High-current output	R/W
b5, b4	CTSUCLK[1:0]	CTSU Operating Clock Select	b5 b4 0 0: PCLK 0 1: PCLK/2 (PCLK divided by 2) 1 0: PCLK/4 (PCLK divided by 4) 1 1: Setting prohibited	R/W
b7, b6	CTSUMD[1:0]	CTSU Measurement Mode Select	b7 b6 0 0: Self-capacitance single scan mode 0 1: Self-capacitance multi-scan mode 1 0: Setting prohibited 1 1: Mutual capacitance full scan mode	R/W

The CTSUCR1 register should be set when the CTSUCR0.CTSUSTRT bit is 0.

CTSUPON Bit (CTSU Power Supply Enable)

This bit controls power supply to the CTSU. Set the CTSUPON and CTSUCSW bits to the same value at the same time.

CTSUCSW Bit (CTSU LPF Capacitance Charging Control)

This bit controls charging of the LPF capacitor connected to the TSCAP pin (turning on/off of the capacitance switch). After the capacitance switch is turned on, wait until the capacitance connected to the TSCAP pin is charged for the specified time before starting measurement (CTSUCR0.CTSUSTRT = 1). Prior to measurement, use an I/O port to output a low level to the TSCAP pin, and discharge the LPF capacitance that has been already charged. Set the CTSUPON and CTSUCSW bits to the same value at the same time.

CTSUATUNE1 Bit (CTSU Power Supply Capacity Adjustment)

This bit sets the capacity of the CTSU power supply. Normally, the value of this bit should be set to 0.

CTSUCLK[1:0] Bits (CTSU Operating Clock Select)

These bits select the operating clock.

CTSUMD[1:0] Bits (CTSU Measurement Mode Select)

These bits set the measurement mode. For details, refer to section 47.3.2, Measurement Modes.

47.2.3 CTSU Synchronous Noise Reduction Setting Register (CTSUSDPRS)

Address(es): CTSU.CTSUSDPRS 000A 0902h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	CTSUSOFF	CTSUPRMODE[1:0]		CTSUPRRATIO[3:0]			
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	CTSUPRRATIO[3:0]	CTSU Measurement Time and Pulse Count Adjustment	Recommended setting value: 3 (0011b)	R/W
b5, b4	CTSUPRMODE[1:0]	CTSU Base Period and Pulse Count Setting	b5 b4 0 0: 510 pulses 0 1: 126 pulses 1 0: 62 pulses (recommended setting value) 1 1: Setting prohibited	R/W
b6	CTSUSOFF	CTSU High-Pass Noise Reduction Function Off Setting	0: High-pass noise reduction function turned on 1: High-pass noise reduction function turned off	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

The CTSUSDPRS register should be set when the CTSUCR0.CTSUSTRT bit is 0.

CTSUPRRATIO[3:0] Bits (CTSU Measurement Time and Pulse Count Adjustment)

These bits are used to determine the measurement time and the number of measurement pulses. These are calculated by the following formula. The number of base pulses is determined by setting the CTSUPRMODE[1:0] bits.

Number of measurement pulses = number of base pulses × (CTSUPRRATIO[3:0] bits + 1)

Measurement time = (number of base pulses × (CTSUPRRATIO[3:0] bits + 1) + (number of base pulses – 2) × 0.25) × base clock cycle

Note: For details on the base clock cycle, refer to section 47.2.17, CTSU Sensor Offset Register 1 (CTSUSO1).

CTSUPRMODE[1:0] Bits (CTSU Base Period and Pulse Count Setting)

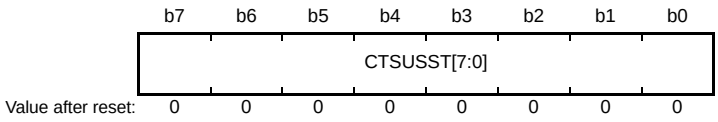
These bits select the number of base pulses during measurement.

CTSUSOFF Bit (CTSU High-Pass Noise Reduction Function Off Setting)

This bit turns on or off the function for reducing high-pass noise. Set this bit to 1 when turning off the high-pass noise reduction function.

47.2.4 CTSU Sensor Stabilization Wait Control Register (CTSUSST)

Address(es): CTSU.CTSUSST 000A 0903h



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	CTSUSST[7:0]	CTSU Sensor Stabilization Wait Control	The value of these bits should be fixed to 00010000b.	R/W

The CTSUSST register should be set when the CTSUCR0.CTSUSTRT bit is 0.

CTSUSST[7:0] Bits (CTSU Sensor Stabilization Wait Control)

These bits set the stabilization wait time for the TSCAP pin voltage. The value of these bits should be fixed to 00010000b. If these bits are not set, the TSCAP voltage becomes unstable at the start of measurement, and the CTSU is unable to obtain correct touch measurement results.

47.2.5 CTSU Measurement Channel Register 0 (CTSUMCH0)

Address(es): CTSU.CTSUMCH0 000A 0904h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	CTSUMCH0[4:0]				
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	CTSUMCH0[4:0]	CTSU Measurement Channel 0	• In self-capacitance single scan b4 b0 0 0 0 0 0: TS0 0 0 0 0 1: TS1 : : 0 1 1 1 1: TS15 1 0 0 0 0: TS16 Other than above: Starting measurement operation (CTSUCR0.CTSUSTRT bit = 1) is prohibited after these bits are set. • In other measurement modes b4 b0 0 0 0 0 0: TS0 0 0 0 0 1: TS1 : : 0 1 1 1 1: TS15 1 0 0 0 0: TS16 1 1 1 1 1: Measurement is stopped	R/W*1
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Writing to these bits is enabled only in self-capacitance single scan mode (CTSUCR1.CTSUMD[1:0] bits = 00b).

The CTSUMCH0 register should be set when the CTSUCR0.CTSUSTRT bit is 0.

CTSUMCH0[4:0] Bits (CTSU Measurement Channel 0)

These bits set the channel to be measured in self-capacitance single scan mode, and indicate the receive channel that is being measured in other modes.

Set only enabled channels (00000b to 10000b) when setting channels in self-capacitance single scan mode. In other modes, writing to these bits has no effect.

47.2.6 CTSU Measurement Channel Register 1 (CTSUMCH1)

Address(es): CTSU.CTSUMCH1 000A 0905h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	CTSUMCH1[4:0]				
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	CTSUMCH1[4:0]	CTSU Measurement Channel 1	b4 b0 0 0 0 0 0: TS0 0 0 0 0 1: TS1 0 0 0 1 0: TS2 0 0 0 1 1: TS3 0 0 1 0 0: TS4 0 0 1 0 1: TS5 0 0 1 1 0: TS6 0 0 1 1 1: TS7 0 1 0 0 0: TS8 0 1 0 0 1: TS9 0 1 0 1 0: TS10 0 1 0 1 1: TS11 0 1 1 0 0: TS12 0 1 1 0 1: TS13 0 1 1 1 0: TS14 0 1 1 1 1: TS15 1 0 0 0 0: TS16 1 1 1 1 1: Measurement is stopped	R
b7 to b5	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R

CTSUMCH1[4:0] Bits (CTSU Measurement Channel 1)

These bits indicate the transmit channel that is being measured in full scan mode. The value of these bits is 11111b while measurement is stopped or in self-capacitance single scan mode and multi-scan mode.

47.2.7 CTSU Channel Enable Control Register 0 (CTSUCHAC0)

Address(es): CTSU.CTSUCHAC0 000A 0906h

	b7	b6	b5	b4	b3	b2	b1	b0
	CTSUCHAC07	CTSUCHAC06	CTSUCHAC05	CTSUCHAC04	CTSUCHAC03	CTSUCHAC02	CTSUCHAC01	CTSUCHAC00
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CTSUCHAC00	CTSU Channel 0 Enable Control	0: Not measurement target 1: Measurement target	R/W
b1	CTSUCHAC01	CTSU Channel 1 Enable Control		R/W
b2	CTSUCHAC02	CTSU Channel 2 Enable Control		R/W
b3	CTSUCHAC03	CTSU Channel 3 Enable Control		R/W
b4	CTSUCHAC04	CTSU Channel 4 Enable Control		R/W
b5	CTSUCHAC05	CTSU Channel 5 Enable Control		R/W
b6	CTSUCHAC06	CTSU Channel 6 Enable Control		R/W
b7	CTSUCHAC07	CTSU Channel 7 Enable Control		R/W

The CTSUCHAC0 register should be set when the CTSUCR0.CTSUSTRT bit is 0.

CTSUCHAC0j Bit (CTSU Channel m Enable Control) (j = 0 to 7; m = 0 to 7)

This bit sets the pin (for receive and transmit) whose electrostatic capacitance is to be measured.

47.2.8 CTSU Channel Enable Control Register 1 (CTSUCHAC1)

Address(es): CTSU.CTSUCHAC1 000A 0907h

	b7	b6	b5	b4	b3	b2	b1	b0
	CTSUCHAC17	CTSUCHAC16	CTSUCHAC15	CTSUCHAC14	CTSUCHAC13	CTSUCHAC12	CTSUCHAC11	CTSUCHAC10
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CTSUCHAC10	CTSU Channel 8 Enable Control	0: Not measurement target 1: Measurement target	R/W
b1	CTSUCHAC11	CTSU Channel 9 Enable Control		R/W
b2	CTSUCHAC12	CTSU Channel 10 Enable Control		R/W
b3	CTSUCHAC13	CTSU Channel 11 Enable Control		R/W
b4	CTSUCHAC14	CTSU Channel 12 Enable Control		R/W
b5	CTSUCHAC15	CTSU Channel 13 Enable Control		R/W
b6	CTSUCHAC16	CTSU Channel 14 Enable Control		R/W
b7	CTSUCHAC17	CTSU Channel 15 Enable Control		R/W

The CTSUCHAC1 register should be set when the CTSUCR0.CTSUSTRT bit is 0.

CTSUCHAC1j Bit (CTSU Channel m Enable Control) (j = 0 to 7; m = 8 to 15)

This bit sets the pin (for receive and transmit) whose electrostatic capacitance is to be measured.

47.2.9 CTSU Channel Enable Control Register 2 (CTSUCHAC2)

Address(es): CTSU.CTSUCHAC2 000A 0908h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CTSUCHAC20
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CTSUCHAC20	CTSU Channel 16 Enable Control	0: Not measurement target 1: Measurement target	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The CTSUCHAC2 register should be set when the CTSUCR0.CTSUSTRT bit is 0.

CTSUCHAC20 Bit (CTSU Channel 16 Enable Control)

This bit sets the pin (for receive and transmit) whose electrostatic capacitance is to be measured.

47.2.10 CTSU Channel Transmit/Receive Control Register 0 (CTSUCHTRC0)

Address(es): CTSU.CTSUCHTRC0 000A 090Bh

	b7	b6	b5	b4	b3	b2	b1	b0
	CTSUCHTRC07	CTSUCHTRC06	CTSUCHTRC05	CTSUCHTRC04	CTSUCHTRC03	CTSUCHTRC02	CTSUCHTRC01	CTSUCHTRC00
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CTSUCHTRC00	CTSU Channel 0 Transmit/Receive Control	0: Reception 1: Transmission	R/W
b1	CTSUCHTRC01	CTSU Channel 1 Transmit/Receive Control		R/W
b2	CTSUCHTRC02	CTSU Channel 2 Transmit/Receive Control		R/W
b3	CTSUCHTRC03	CTSU Channel 3 Transmit/Receive Control		R/W
b4	CTSUCHTRC04	CTSU Channel 4 Transmit/Receive Control		R/W
b5	CTSUCHTRC05	CTSU Channel 5 Transmit/Receive Control		R/W
b6	CTSUCHTRC06	CTSU Channel 6 Transmit/Receive Control		R/W
b7	CTSUCHTRC07	CTSU Channel 7 Transmit/Receive Control		R/W

The CTSUCHTRC0 register should be set when the CTSUCR0.CTSUSTRT bit is 0.

CTSUCHTRC0j Bit (CTSU Channel m Transmit/Receive Control) (j = 0 to 7; m = 0 to 7)

This bit allocates reception or transmission to the corresponding TSm pin in full scan mode. Set this bit to 0 in self-capacitance single scan mode and multi-scan mode.

47.2.11 CTSU Channel Transmit/Receive Control Register 1 (CTSUCHTRC1)

Address(es): CTSU.CTSUCHTRC1 000A 090Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	CTSUCHTRC17	CTSUCHTRC16	CTSUCHTRC15	CTSUCHTRC14	CTSUCHTRC13	CTSUCHTRC12	CTSUCHTRC11	CTSUCHTRC10
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CTSUCHTRC10	CTSU Channel 8 Transmit/Receive Control	0: Reception 1: Transmission	R/W
b1	CTSUCHTRC11	CTSU Channel 9 Transmit/Receive Control		R/W
b2	CTSUCHTRC12	CTSU Channel 10 Transmit/Receive Control		R/W
b3	CTSUCHTRC13	CTSU Channel 11 Transmit/Receive Control		R/W
b4	CTSUCHTRC14	CTSU Channel 12 Transmit/Receive Control		R/W
b5	CTSUCHTRC15	CTSU Channel 13 Transmit/Receive Control		R/W
b6	CTSUCHTRC16	CTSU Channel 14 Transmit/Receive Control		R/W
b7	CTSUCHTRC17	CTSU Channel 15 Transmit/Receive Control		R/W

The CTSUCHTRC1 register should be set when the CTSUCR0.CTSUSTRT bit is 0.

CTSUCHTRC1j Bit (CTSU Channel m Transmit/Receive Control) (j = 0 to 7; m = 8 to 15)

This bit allocates reception or transmission to the corresponding TSm pin in full scan mode. Set this bit to 0 in self-capacitance single scan mode and multi-scan mode.

47.2.12 CTSU Channel Transmit/Receive Control Register 2 (CTSUCHTRC2)

Address(es): CTSU.CTSUCHTRC2 000A 090Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CTSUCHTRC20
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CTSUCHTRC20	CTSU Channel 16 Transmit/Receive Control	0: Reception 1: Transmission	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The CTSUCHTRC2 register should be set when the CTSUCR0.CTSUSTRT bit is 0.

CTSUCHTRC20 Bit (CTSU Channel 16 Transmit/Receive Control)

This bit allocates reception or transmission to the corresponding TS16 pin in full scan mode. Set this bit to 0 in self-capacitance single scan mode and multi-scan mode.

47.2.13 CTSU High-Pass Noise Reduction Control Register (CTSUDCLKC)

Address(es): CTSU.CTSUDCLKC 000A 0910h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	CTSUSSCNT[1:0]		—	—	CTSUSSMOD[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CTSUSSMOD[1:0]	CTSU Diffusion Clock Mode Select	These bits should be set to 00b.	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5, b4	CTSUSSCNT[1:0]	CTSU Diffusion Clock Control	These bits should be set to 11b.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The CTSUDCLKC register should be set when the CTSUCR0.CTSUSTRT bit is 0.

CTSUSSMOD[1:0] Bits (CTSU Diffusion Clock Mode Select)

These bits set the mode of the spectrum diffusion clock for high-pass noise reduction. When using the high-pass function, the value of these bits should be fixed to 00b. If these bits are not set, the effect of high-pass noise reduction cannot be correctly obtained.

CTSUSSCNT[1:0] Bits (CTSU Diffusion Clock Control)

These bits adjust the spectrum diffusion amount to reduce high-pass noise. When using the high-pass noise reduction function, the value of these bits should be fixed to 11b. If these bits are not set, touch measurement may not be correctly performed.

47.2.14 CTSU Status Register (CTSUST)

Address(es): CTSU.CTSUST 000A 0911h

	b7	b6	b5	b4	b3	b2	b1	b0
	CTSUPS	CTSUROVF	CTSUSOVF	CTSUDTSR	—	CTSUSTC[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	CTSUSTC[2:0]	CTSU Measurement Status Counter	b2 b0 0 0 0: Status 0 0 0 1: Status 1 0 1 0: Status 2 0 1 1: Status 3 1 0 0: Status 4 1 0 1: Status 5	R
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	CTSUDTSR	CTSU Data Transfer Status Flag	0: Measurement result has been read 1: Measurement result has not been read	R
b5	CTSUSOVF	CTSU Sensor Counter Overflow Flag	0: No overflow 1: An overflow	R/W
b6	CTSUROVF	CTSU Reference Counter Overflow Flag	0: No overflow 1: An overflow	R/W
b7	CTSUPS	CTSU Mutual Capacitance Status Flag	0: First measurement 1: Second measurement	R

When using the CTSUCR0.CTSUINIT bit to clear an overflow flag, make sure that the CTSUCR0.CTSUSTRT bit is 0.

CTSUSTC[2:0] Flags (CTSU Measurement Status Counter)

These counters indicate the current measurement status. For details on each status, refer to section 47.3.2.2, Status Counter.

CTSUDTSR Flag (CTSU Data Transfer Status Flag)

This flag indicates whether the measurement result stored in the sensor counter and the reference counter has been read. This flag is set to 1 when measurement is completed; 0 when the reference counter is read by software or the DTC. This flag is also cleared using the CTSUCR0.CTSUINIT bit.

CTSUSOVF Flag (CTSU Sensor Counter Overflow Flag)

This flag indicates whether the sensor counter has overflowed. FFFFh can be read as the measurement result (CTSUSC counter) when an overflow has occurred.

Even if an overflow occurs, measurement processing is continued until the set period.

No interrupt is generated even when an overflow occurs. To determine the channel on which the overflow has occurred, read the measurement result of each channel after measurement is completed (after a measurement end interrupt is generated).

This flag is cleared when 0 is written after 1 is read by software. This flag is also cleared using the CTSUCR0.CTSUINIT bit.

CTSUROVF Flag (CTSU Reference Counter Overflow Flag)

This flag indicates whether the reference counter has overflowed. FFFFh can be read as the measurement result (CTSURC counter) when an overflow has occurred.

Even if an overflow occurs, measurement processing is continued until the set period.

No interrupt is generated even when an overflow occurs. To determine the channel on which the overflow has occurred, read the measurement result of each channel after measurement is completed (after a measurement end interrupt is generated).
This flag is cleared when 0 is written after 1 is read by software. This flag is also cleared using the CTSUCR0.CTSUINIT bit.

CTSUPS Flag (CTSU Mutual Capacitance Status Flag)

This flag indicates whether the measurement is the first or second of two measurements for each channel in mutual capacitance full scan mode (CTSUCR1.CTSUMD[1:0] bits = 11b).
This flag indicates 0 while measurement is stopped or in other measurement modes.

47.2.15 CTSU High-Pass Noise Reduction Spectrum Diffusion Control Register (CTSUSSC)

Address(es): CTSU.CTSUSSC 000A 0912h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	CTSUSSDIV[3:0]				—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11 to b8	CTSUSSDIV[3:0]	CTSU Spectrum Diffusion Frequency Division Setting	These bits specify the spectrum diffusion frequency division setting according to the base clock frequency division setting.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

CTSUSSDIV[3:0] Bits (CTSU Spectrum Diffusion Frequency Division Setting)

These bits specify the spectrum diffusion frequency division setting according to the base clock frequency division setting. See the relationship between base clock frequencies and the CTSUSSDIV[3:0] bits settings in Table 47.6, for setting the value of these bits.

Table 47.6 Relationship between Base Clock Frequencies and the CTSUSSDIV[3:0] Bits Settings

Base Clock Frequency fb (MHz)	CTSUSSDIV[3:0] Bits Setting
4.00 ≤ fb	0000b
2.00 ≤ fb < 4.00	0001b
1.33 ≤ fb < 2.00	0010b
1.00 ≤ fb < 1.33	0011b
0.80 ≤ fb < 1.00	0100b
0.67 ≤ fb < 0.80	0101b

0.36 ≤ fb < 0.40	1010b
0.33 ≤ fb < 0.36	1011b
0.31 ≤ fb < 0.33	1100b
0.29 ≤ fb < 0.31	1101b
0.27 ≤ fb < 0.29	1110b
fb < 0.27	1111b

47.2.16 CTSU Sensor Offset Register 0 (CTSUSO0)

Address(es): CTSU.CTSUSO0 000A 0914h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CTSUSNUM[5:0]						CTSUSO[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	CTSUSO[9:0]	CTSU Sensor Offset Adjustment	b9 b0 0 0 0 0 0 0 0 0 0 0: Current offset amount is 0 0 0 0 0 0 0 0 0 0 1: Current offset amount is 1 0 0 0 0 0 0 0 0 1 0: Current offset amount is 2 : : 1 1 1 1 1 1 1 1 1 0: Current offset amount is 1022 1 1 1 1 1 1 1 1 1 1: Current offset amount is maximum	R/W
b15 to b10	CTSUSNUM[5:0]	CTSU Measurement Count Setting	These bits set the number of measurements.	R/W

CTSUSO[9:0] Bits (CTSU Sensor Offset Adjustment)

These control bits adjust the input current offset of the sensor ICO. These bits are used to offset the sensor ICO input current generated from electrostatic capacitance while the electrode is not being touched during touch measurement, thus preventing overflow of the CTSU sensor counter.

Make settings for the TS pin that is to be measured next after a CTSUWR interrupt is generated.

CTSUSNUM[5:0] Bits (CTSU Measurement Count Setting)

These bits set how many times the number of measurement pulses specified by the CTSUSDPRS.CTSUPRRATIO[3:0] and CTSUSDPRS.CTSUPRMODE[1:0] bits is repeated in the measurement time. The number of measurement pulses is repeated (CTSUSNUM[5:0] bits + 1) times.

Make settings for the TS pin that is to be measured next after a CTSUWR interrupt is generated.

47.2.17 CTSU Sensor Offset Register 1 (CTSUSO1)

Address(es): CTSU.CTSUSO1 000A 0916h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b14, b13	CTSUICOG[1:0]	CTSU ICO Gain Adjustment	b14 b13 0 0: 100% gain 0 1: 66% gain 1 0: 50% gain 1 1: 40% gain	R/W
b15	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. The CTSUSDPA[4:0] bits should not be set to 00000b while the high-pass noise reduction function is turned off (CTSUSDPRS.CTSUSOFF bit = 1) in mutual capacitance full scan mode (CTSUCR1.CTSUMD[1:0] bits = 11b).

Write first to the CTSUSSC register, then CTSUSO0 register, and then CTSUSO1 register after a CTSUWR interrupt is generated. Write operation to the CTSUSO1 register causes a transition to Status 3. Thus, set all the bits in a single setting when writing to the CTSUSO1 register.

CTSURICOA[7:0] Bits (CTSU Reference ICO Current Adjustment)

These bits adjust the oscillation frequency using the input current of the reference ICO.

CTSUSDPA[4:0] Bits (CTSU Base Clock Setting)

These bits are used to generate a base clock used as the source for the sensor drive pulse by dividing the operating clock. For details on the setting procedure, refer to section 47.3.2.1, Initial Setting Flowchart.

CTSUICOG[1:0] Bits (CTSU ICO Gain Adjustment)

These bits adjust the output frequency gain of the sensor ICO and the reference ICO. If changes in the capacitance between when the electrode is touched and when it is not touched greatly exceed the dynamic range of the sensor ICO, set the gain adjustment bits to adjust the gain appropriately.

47.2.18 CTSU Sensor Counter (CTSUSC)

Address(es): CTSU.CTSUSC 000A 0918h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CTSUSC[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	CTSUSC[15:0]	CTSU Sensor Counter	These bits indicate FFFFh when an overflow occurs.	R

Read first from the CTSUSC counter and then the CTSURC counter after a CTSURD interrupt is generated.

CTSUSC[15:0] Bits (CTSU Sensor Counter)

These bits are configured as an increment counter that counts the sensor ICO clock.
Read these bits after a CTSURD interrupt is generated. After the CTSURC counter is read, these bits are cleared immediately before the CTSU measurement status counter value changes to Status 4 (the CTSUST.CTSUSTC[2:0] flags changes to 100b) in the next measurement. These bits are also cleared using the CTSUCR0.CTSUINIT bit.

47.2.19 CTSU Reference Counter (CTSURC)

Address(es): CTSU.CTSURC 000A 091Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CTSURC[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	CTSURC[15:0]	CTSU Reference Counter	These bits indicate FFFFh when an overflow occurs.	R

Read first from the CTSUSC counter and then the CTSURC counter after a CTSURD interrupt is generated.
Even when the stabilization time specified for Status 3 has elapsed, if the CTSURC counter is not read, Status 3 continues until the counter is read.

CTSURC[15:0] Bits (CTSU Reference Counter)

These bits are configured as an increment counter that counts the reference ICO clock.
The reference ICO is used to optimize touch measurement performed using the sensor ICO. There is some deviation depending on the internal sensor ICO and the reference ICO in the CTSU, but both ICOs have almost the same characteristics, and the dynamic range and the current to frequency characteristics are almost the same. The range of current amount that can be set by the reference ICO current adjustment bits is about the same as the range of both ICOs, and the current amount input to the sensor ICO must be within this dynamic range. First, use the reference ICO to check the differences between the ICOs and measure the current to oscillation frequency characteristics. Since the reference ICO oscillation frequency can be obtained from the reference ICO counter, the ICO oscillation frequency (counter value/ measurement time) for the input current amount can be measured by setting the value in the reference ICO current adjustment bits and measuring the reference ICO counter. The reference ICO counter value measured using the maximum value of the reference ICO current adjustment bits is the maximum value of the ICO dynamic range. Therefore, the current amount of the sensor ICO needs to be offset by setting the offset adjustment bits so that the sensor ICO counter value does not exceed this value.
Read the CTSURC[15:0] bits after a CTSURD interrupt is generated. After these bits are read, they are cleared immediately before the CTSU measurement status counter value changes to Status 4 (the CTSUST.CTSUSTC[2:0] flags changes to 100b) in the next measurement. These bits are also cleared using the CTSUCR0.CTSUINIT bit.

47.2.20 CTSU Error Status Register (CTSUERRS)

Address(es): CTSU.CTSUERRS 000A 091Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CTSUICOMP	—	—	—	—	—	—	—	CTSUTSOC	—	—	—	CTSUDRV	CTSUTSOD	CTSUSPMD[1:0]	
Value after reset:	x	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CTSUSPMD[1:0]	Calibration Mode	b1 b0 0 0: Capacitance measurement mode 0 1: Setting prohibited 1 0: Calibration mode 1 1: Setting prohibited	R/W
b2	CTSUTSOD	TS Pin Fixed Output	0: Capacitance measurement mode 1: TS pins are forced to be high or low	R/W
b3	CTSUDRV	Calibration Setting 1	0: Capacitance measurement mode 1: Calibration setting 1	R/W
b6 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	CTSUTSOC	Calibration Setting 2	0: Capacitance measurement mode 1: Calibration setting 2	R/W
b14 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	CTSUICOMP	TSCAP Voltage Error Monitor	0: Normal TSCAP voltage 1: Abnormal TSCAP voltage	R

CTSUSPMD[1:0] Bit (Calibration Mode)

These bits are used to calibrate the CTSU.
When measuring the capacitance, set these bits to 00b.

CTSUTSOD Bit (TS Pin Fixed Output)

This bit is used to calibrate the CTSU. When setting this bit to 1, the TS pins are forced to the logic level specified by the CTSUCR0.CTSUIOC bit.
When measuring the capacitance, set this bit to 0.

CTSUDRV Bit (Calibration Setting 1)

This bit is used to calibrate the CTSU.
When measuring the capacitance, set this bit to 0.

CTSUTSOC Bit (Calibration Setting 2)

This bit is used to calibrate the CTSU.
When measuring the capacitance, set this bit to 0.

CTSUICOMP Bit (TSCAP Voltage Error Monitor)

If the offset current amount set by the CTSUSO0 register exceeds the sensor ICO input current during touch measurement, the TSCAP voltage becomes abnormal and touch measurement cannot be correctly performed. This bit monitors the TSCAP voltage and it is set to 1 if the voltage becomes abnormal. If the TSCAP voltage becomes abnormal, the sensor ICO counter value will be undefined, but touch measurement is normally completed, so it difficult to detect an abnormality by reading the sensor ICO counter value. If the CTSU reference ICO current adjustment bits (CTSURICOA[7:0]) in the CTSUSO1 register are set to a value other than 0, check this bit when touch measurement is completed.

This bit is cleared by writing 0 to the CTSUCR1.CTSUPON bit and turning off the power supply.

47.2.21 CTSU Reference Current Calibration Register (CTSUTRMR)

Address(es): CTSU.CTSUTRMR 007F B0ECh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	CAL[7:0]							
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 1. The write value should be 1.	R/W
b23 to b16	CAL[7:0]	Reference Current Calibration	These bits calibrate the reference current used as the reference for measurement.	R/W
b31 to b24	—	Reserved	These bits are read as 1. The write value should be 1.	R/W

The CTSUTRMR register stores a reference current value calibrated under the specified condition for each chip at factory shipment.
When rewriting this register, set the CTSUERRS.CTSUSPMD[1:0] bits to 10b (calibration mode). When resetting the MCU, the value returns to the factory setting value.
Do not rewrite this register when the CTSUSPMD[1:0] bits are 00b (capacitance measurement mode).

47.3 Operation

47.3.1 Principles of Measurement Operation

Figure 47.4 shows the measurement circuit.

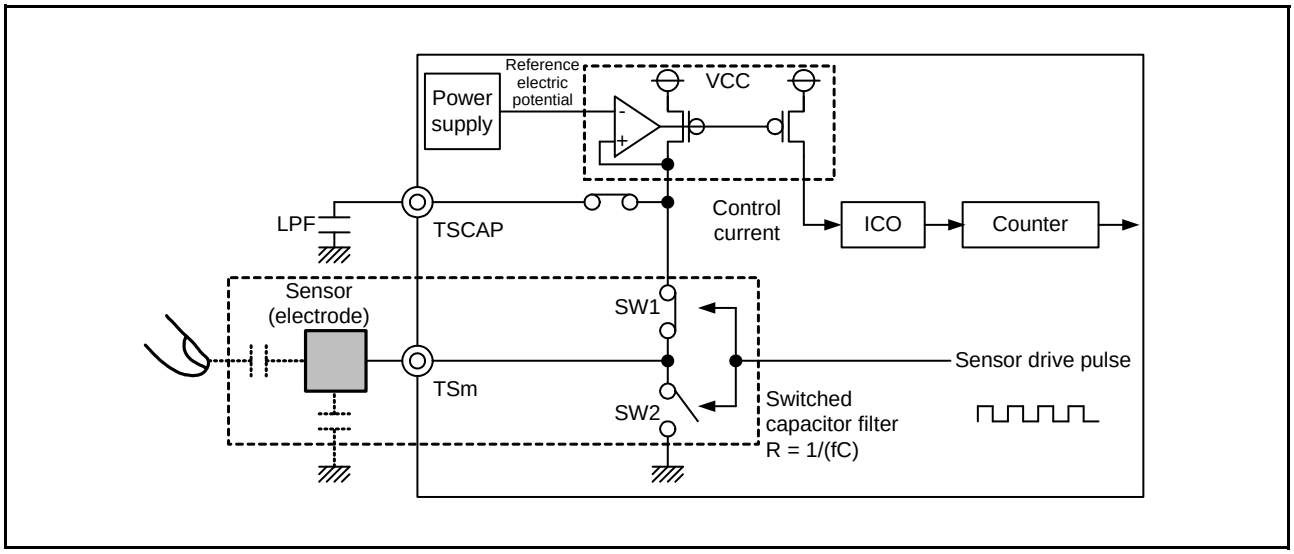

Figure 47.4 Measurement Circuit (m = 0 to 16)

The electrostatic capacitance measurement operation principles of the CTSU current frequency conversion method are explained using Figure 47.5 to Figure 47.7.

(1) The electrostatic capacitance of the electrode is charged by turning SW1 on and SW2 off (Figure 47.5).

(2) The charged capacitance is discharged by turning SW1 off and SW2 on (Figure 47.6).

Current flows to the switched capacitor filter by switching between charging and discharging in steps (1) and (2). At this time, the value of electrostatic capacitance varies depending on whether a finger is in close proximity, so the flowing current changes. A clock is generated by supplying the control current, which is proportional to the amount of the current flowing through the switched capacitor filter, from the circuit that generates the TSCAP power supply to the ICO. The counter is used to measure the clock frequency which changes depending on whether a finger is in close proximity, and the value read from the counter is used by software to determine contact with a finger (Figure 47.7).

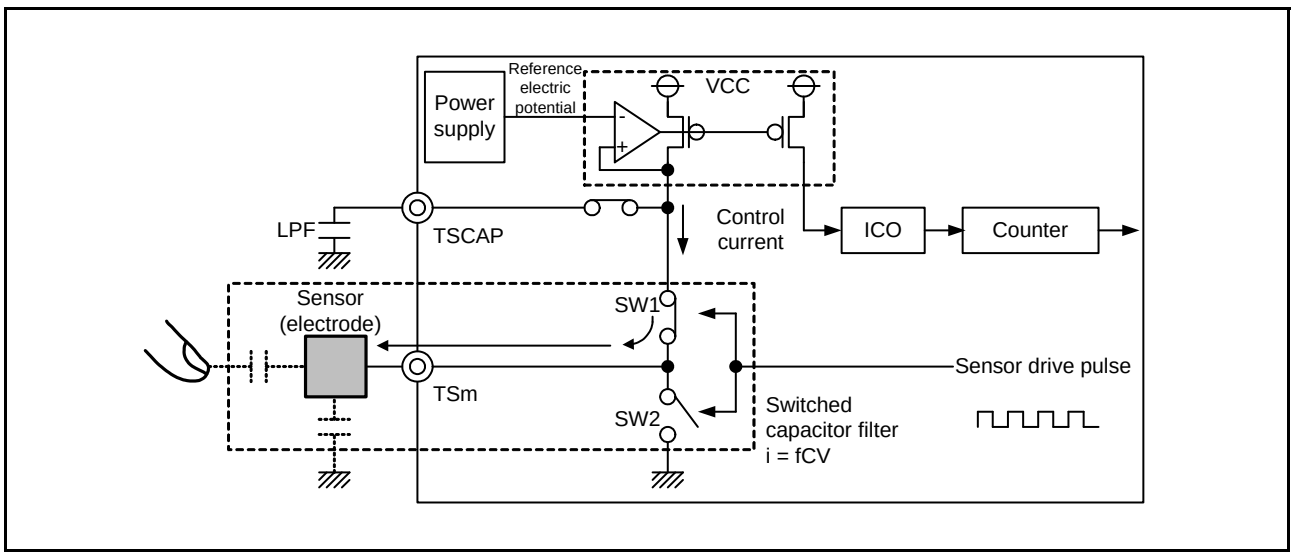

Figure 47.5 Charging Operation (m = 0 to 16)

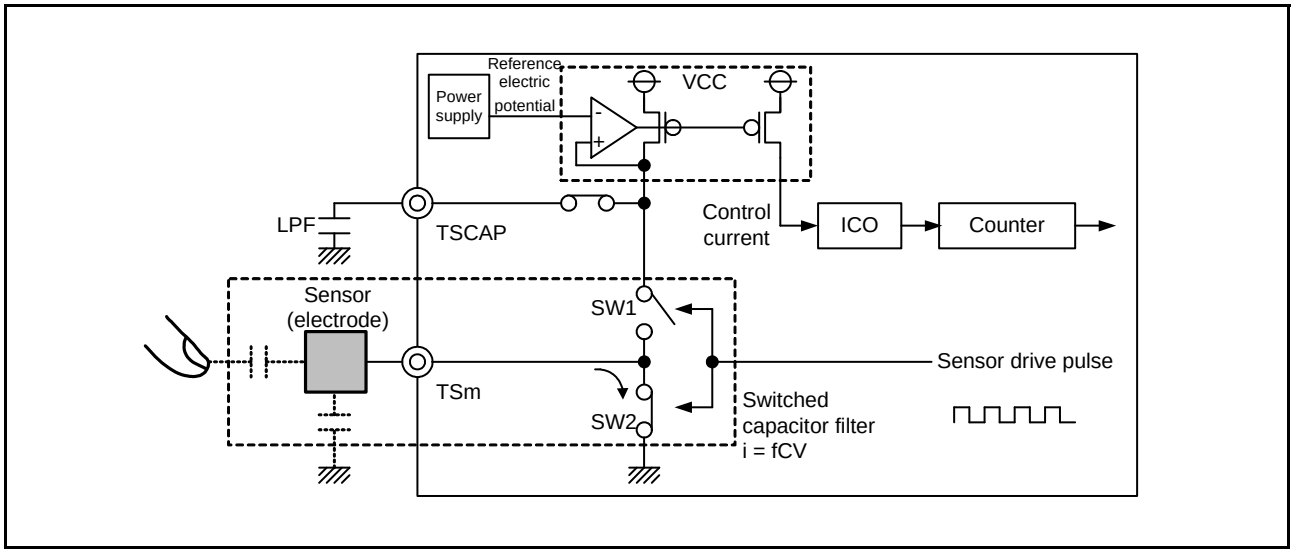

Figure 47.6 Discharging Operation (m = 0 to 16)

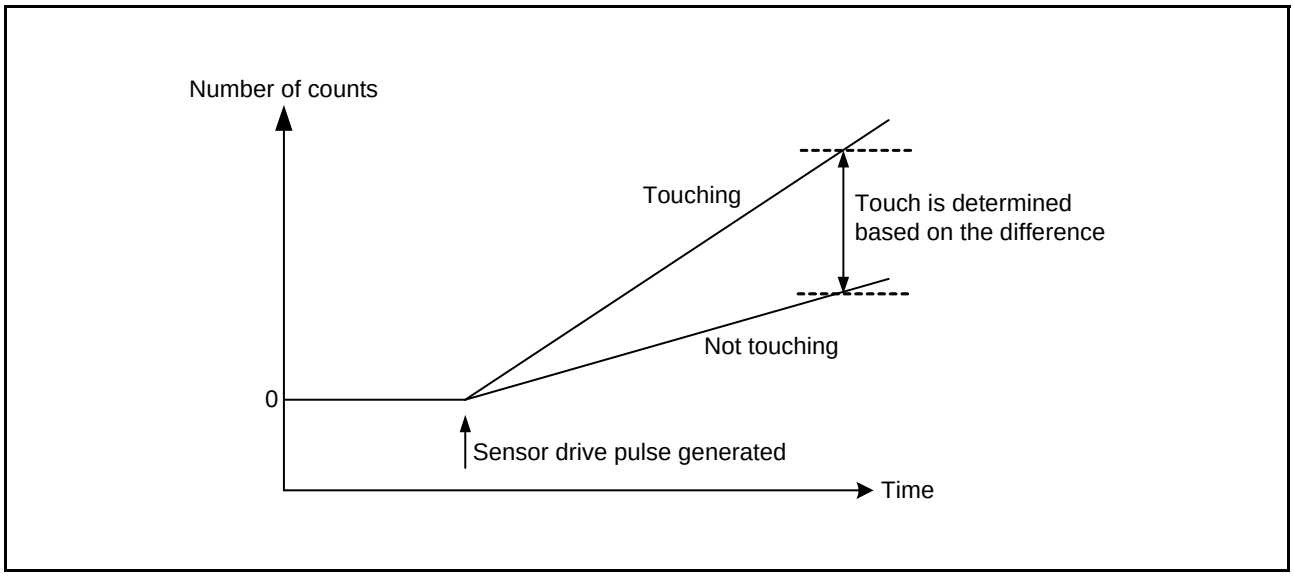

Figure 47.7 Change in Measured Value When Finger is Touching and Not Touching

47.3.2 Measurement Modes

The CTSU supports self-capacitance and mutual capacitance methods. Figure 47.8 illustrates these methods.

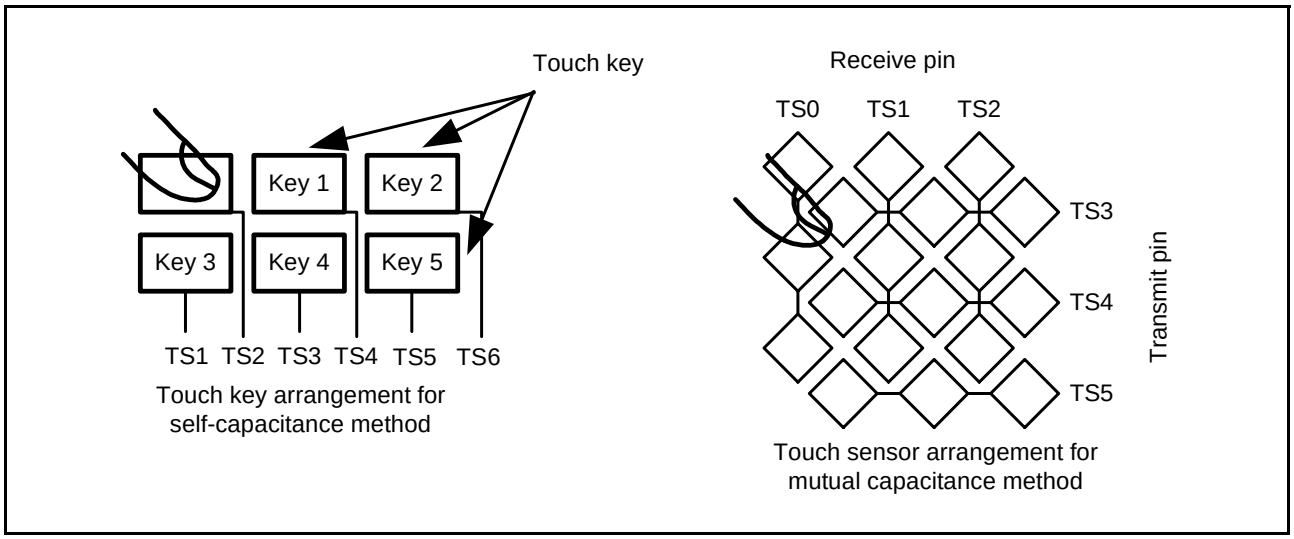

Figure 47.8 Overview of Self-Capacitance Method and Mutual Capacitance Method

In the self-capacitance method, a single touch pin is allocated to a single touch key to measure individual electrostatic capacitance when a finger is in close proximity. In this method, single scan and multi-scan can be used as measurement modes.

In the mutual capacitance method, the capacitance between two opposite electrodes (transmit and receive pins) is measured.

47.3.2.1 Initial Setting Flowchart

Figure 47.9 shows the flowchart for CTSU initial setting.

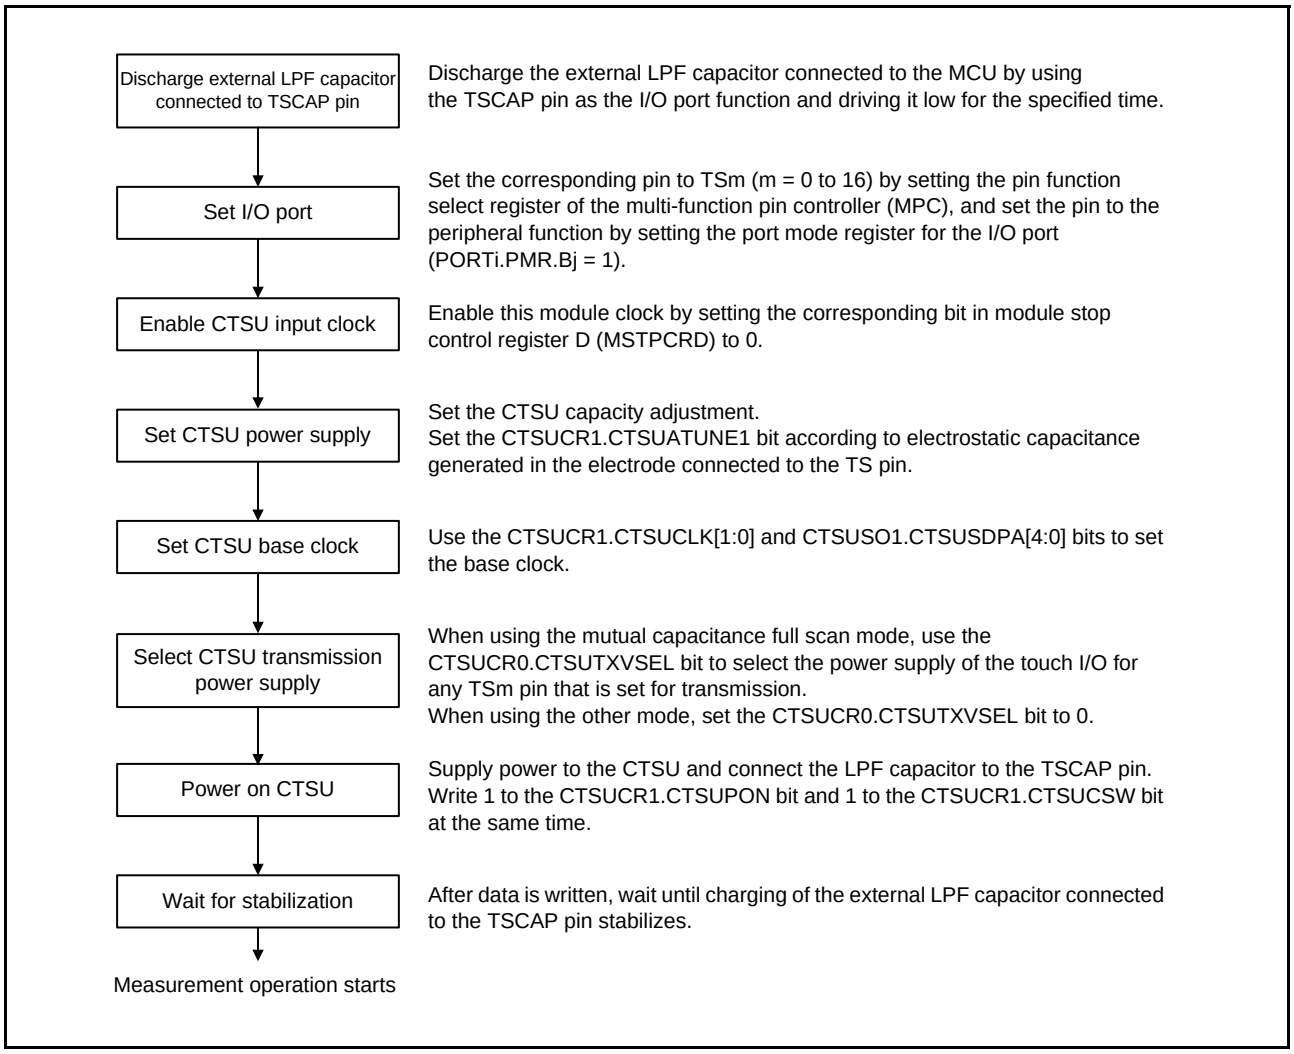

Figure 47.9 CTSU Initial Setting Flowchart

Figure 47.10 shows the flowchart for stopping CTSU operation and setting to the standby state.

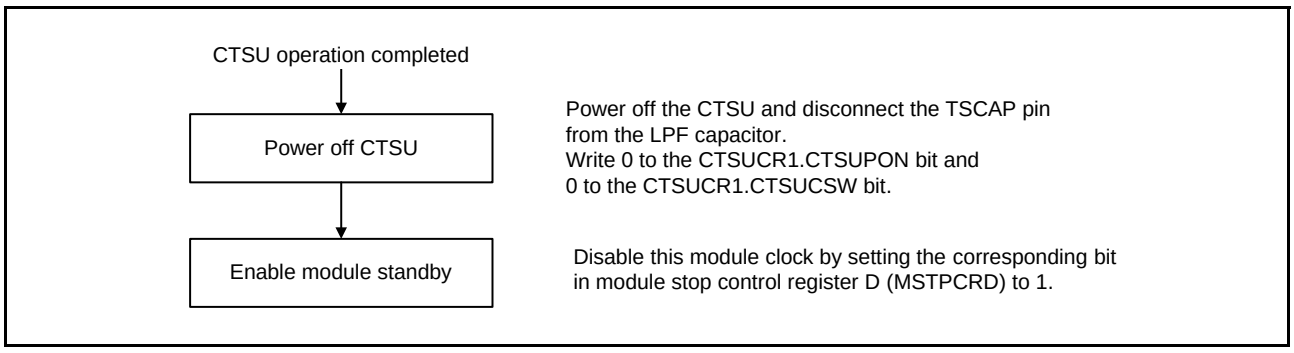

Figure 47.10 CTSU Stopping Flowchart

When restarting operation after it has been stopped, follow the initial setting flowchart shown in Figure 47.9.

47.3.2.2 Status Counter

The measurement status counter of the CTSU status register (CTSUST) indicates the current measurement status. The measurement status is common to all four modes. Figure 47.11 shows status operation transitions.

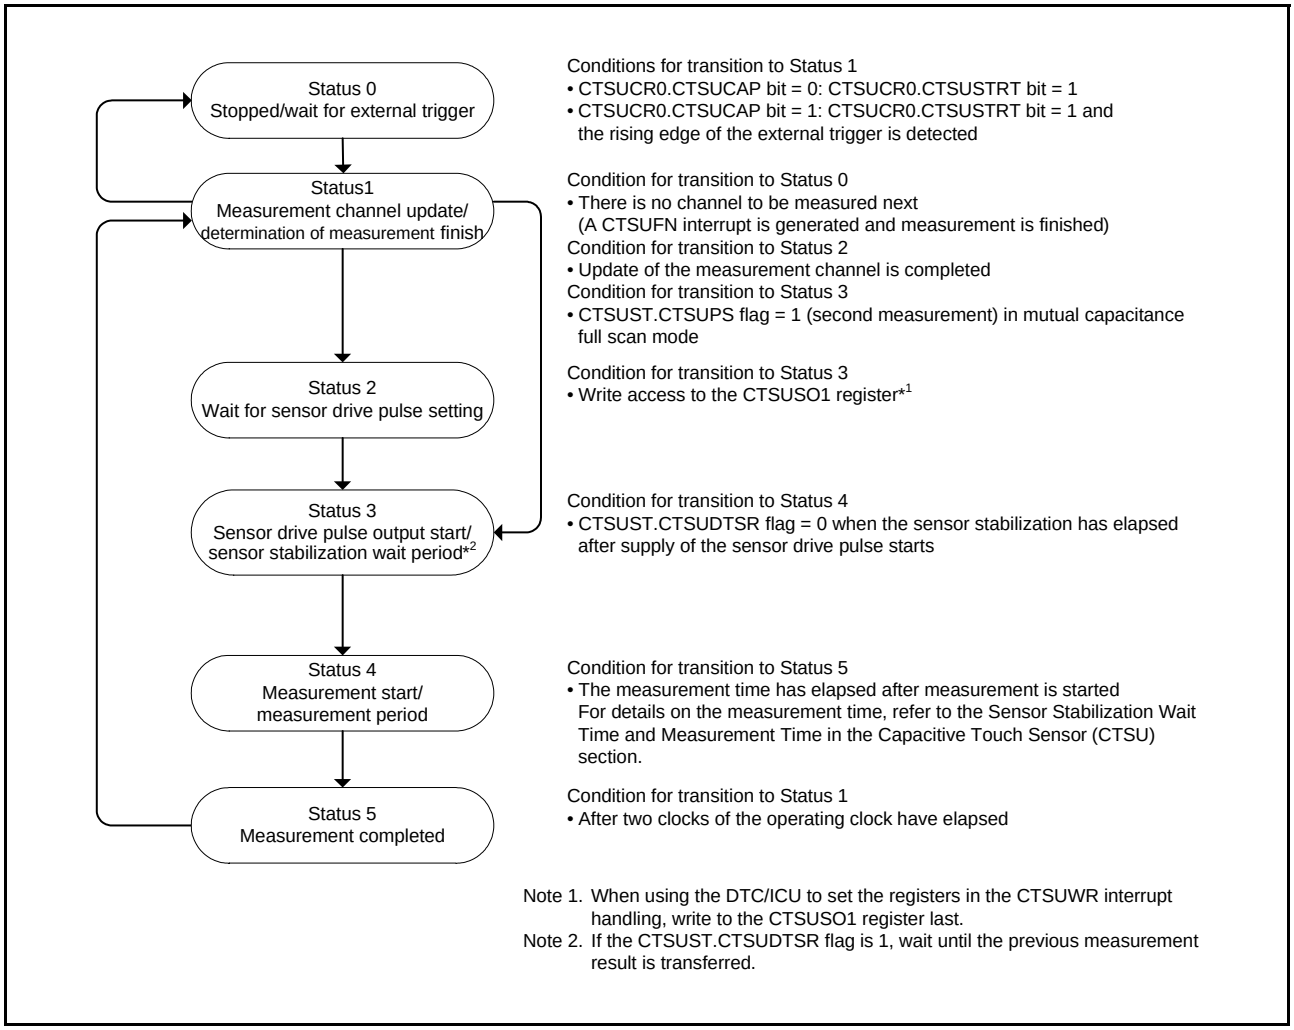

Figure 47.11 Status Operation Transitions

The status of the status counter transitions to Status 0 when all of the specified measurement channels are measured. The CTSUCR0.CTSUSTRT bit is cleared to 0 by hardware when a software trigger is used. When an external trigger is used, the value 1 is retained, and the CTSU waits for the next trigger.

When operation is forcibly stopped (by writing 0 to the CTSUCR0.CTSUSTRT bit and 1 to the CTSUCR0.CTSUINIT bit at the same time) during measurement or the wait state for the trigger, the status transitions to Status 0 and measurement is stopped forcibly.

If there is no channel to be measured by setting the CTSUMCH0, CTSUCHACn, and CTSUCHTRCn registers (n = 0 to 2), a CTSUFN interrupt is generated immediately after a transition to Status 1, and then the status transitions to Status 0. The following are the cases when there is no channel to be measured.

- A measurement target channel is not specified by the CTSUCHACn registers.
- In self-capacitance single scan mode, the channel specified in the CTSUMCH0 register is not a measurement target in the CTSUCHACn registers.
- In full scan mode, there is no transmit channel or receive channel to be measured by combining the CTSUCHACn and CTSUCHTRCn registers.

47.3.2.3 Self-Capacitance Single Scan Mode Operation

In self-capacitance single scan mode, electrostatic capacitance on a channel is measured. Figure 47.12 shows the software flowchart and an operation example, and Figure 47.13 shows the timing chart.

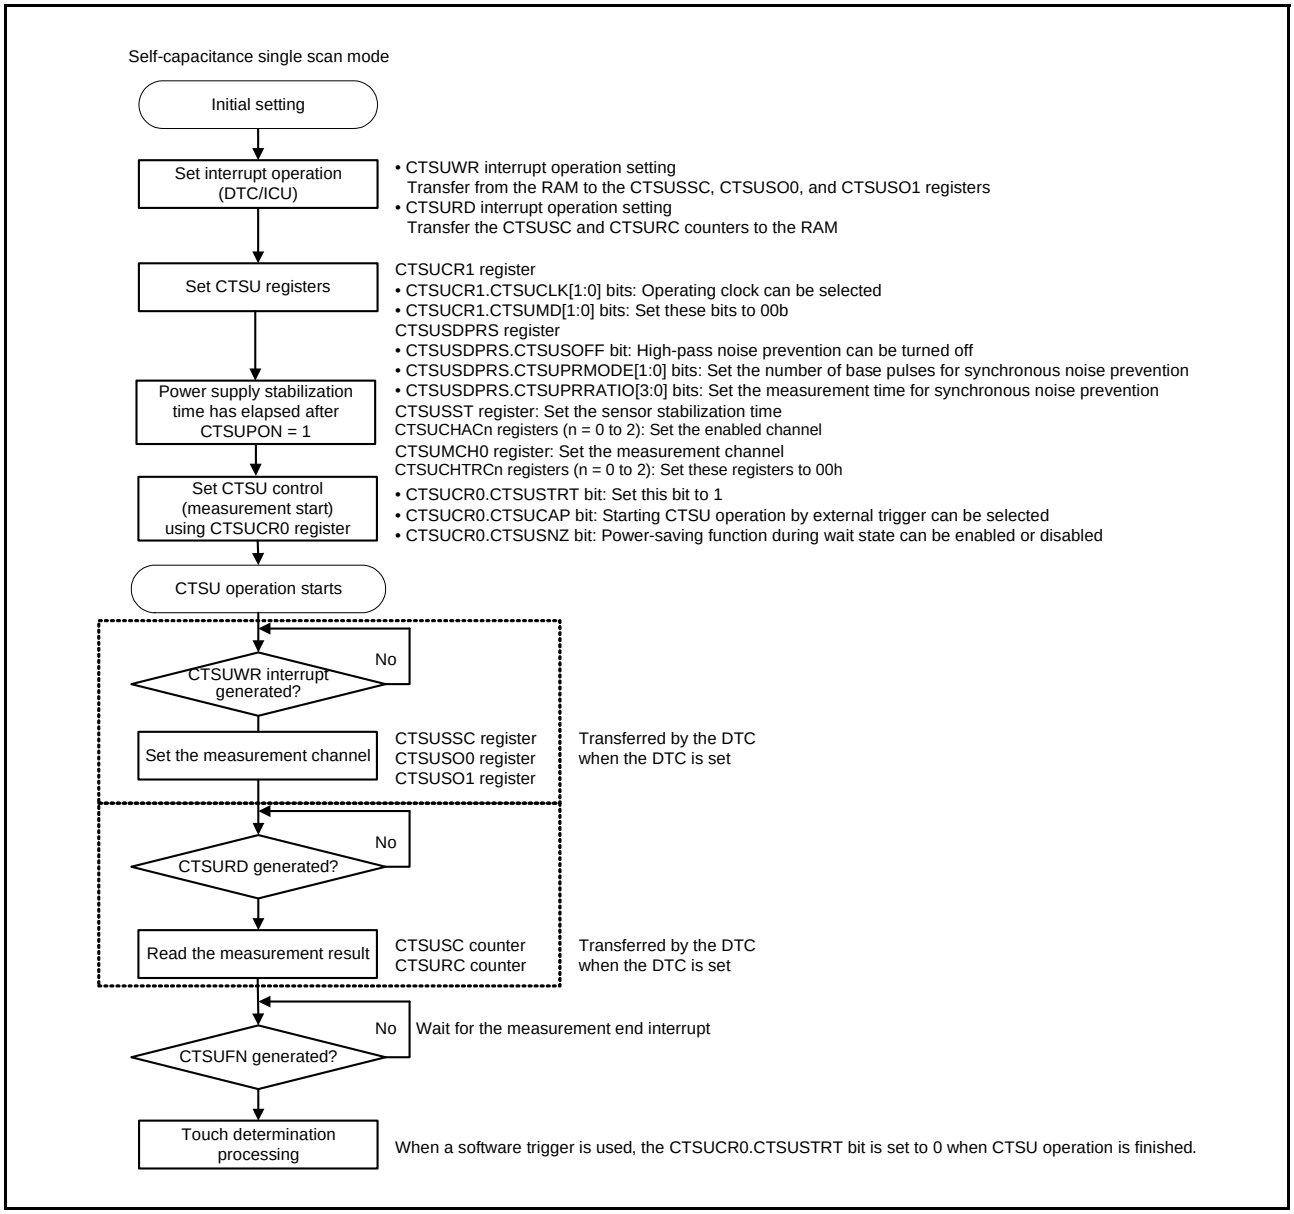

Figure 47.12 Software Flowchart and Operation Example of Self-Capacitance Single Scan Mode

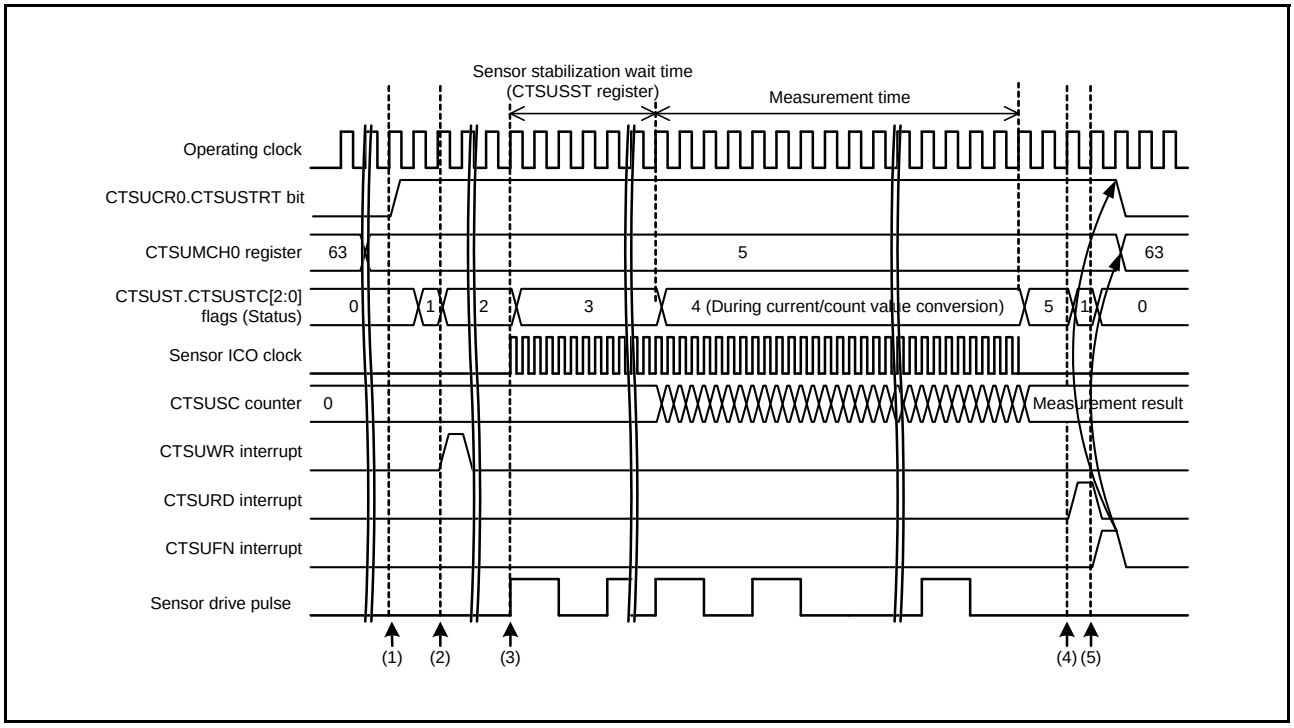

Figure 47.13 Timing Chart of Self-Capacitance Single Scan Mode (Measurement Start Condition is Software Trigger)

The following describes operation shown in the timing chart in Figure 47.13.

(1) After various settings are made, operation is started by writing 1 to the CTSUCR0.CTSUSTRT bit.

(2) After a channel to be measured is determined according to the preset conditions, a request for setting the corresponding channel (CTSUWR) is output.

(3) Upon completion of writing the measurement channel settings (CTSUSSC, CTSUSO0, and CTSUSO1 registers), the sensor drive pulse is output and the sensor ICO clock and the reference ICO clock operate.

(4) After the sensor stabilization wait time and the measurement time have elapsed and measurement is finished, a measurement result read request (CTSURD) is output.

(5) A measurement end interrupt (CTSUFN) is output and measurement is finished (transition to Status 0).

Table 47.7 lists the touch pin states in self-capacitance single scan mode.

Table 47.7 Touch Pin States in Self-Capacitance Single Scan Mode

	Touch Pin	
Status	**Measurement Channel**	**Non-Measurement Channel**
0	Low	Low
1	Low	Low
2	Low	Low
3	Pulse	Low
4	Pulse	Low
5	Low	Low

47.3.2.4 Self-Capacitance Multi-Scan Mode Operation

In self-capacitance multi-scan mode, electrostatic capacitance on all channels that are specified as measurement targets by setting the CTSUCHACn registers (n = 0 to 2) are measured sequentially in ascending order. Figure 47.14 shows the software flowchart and an operation example, and Figure 47.15 shows the timing chart.

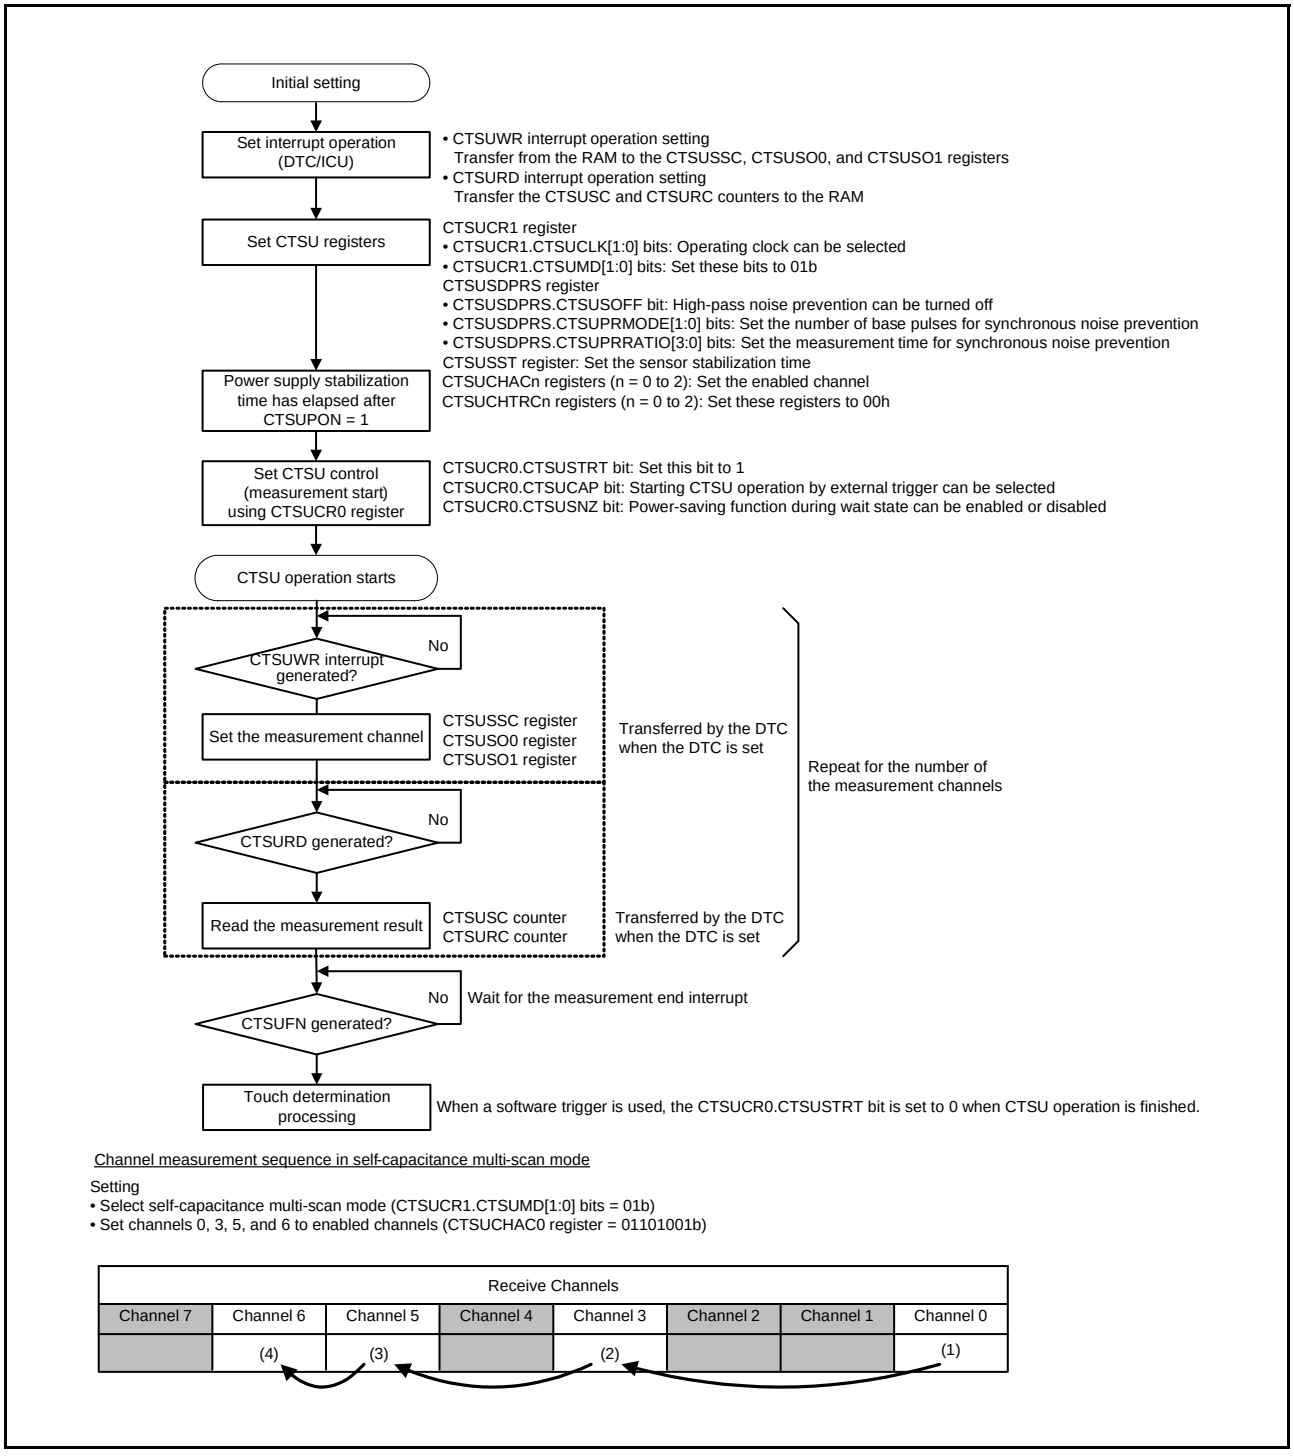

Figure 47.14 Software Flow and Operation Example of Self-Capacitance Multi-Scan Mode

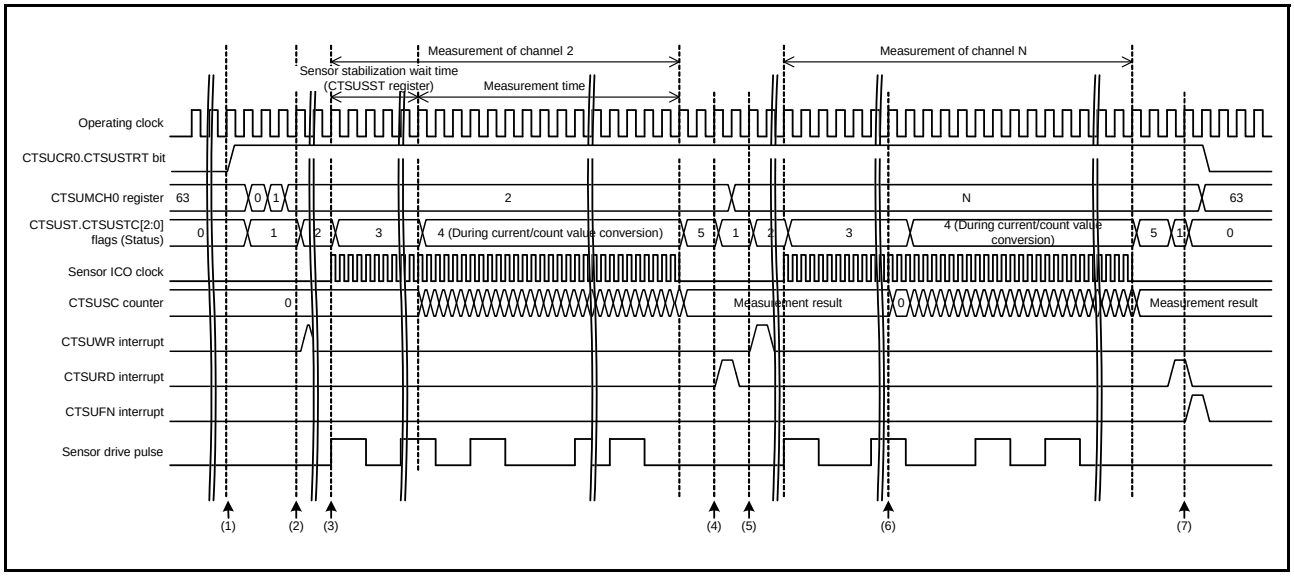

Figure 47.15 Timing Chart of Self-Capacitance Multi-Scan Mode (Measurement Start Condition is Software Trigger)

The following describes operation shown in the timing chart in Figure 47.15.

(1) After various settings are made, operation is started by writing 1 to the CTSUCR0.CTSUSTRT bit.

(2) After a channel to be measured is determined according to the preset conditions, a request for setting the corresponding channel (CTSUWR) is output.

(3) Upon completion of writing the measurement channel settings (CTSUSSC, CTSUSO0, and CTSUSO1 registers), the sensor drive pulse is output and the sensor ICO clock and the reference ICO clock operate.

(4) After the sensor stabilization wait time and the measurement time have elapsed and measurement is finished, a measurement result read request (CTSURD) is output.

(5) After a channel to be measured next is determined, a measurement channel setting request (CTSUWR) is output.

(6) After the stabilization wait time has elapsed and when the previous measurement is read, the result is cleared and measurement is started.

(7) Upon completion of all measurement channels, a measurement end interrupt (CTSUFN) is output and measurement is finished (transition to Status 0).

Table 47.8 lists the touch pin states in self-capacitance multi-scan mode.

Table 47.8 Touch Pin States in Self-Capacitance Multi-Scan Mode

	Touch Pin	
Status	**Measurement Channel**	**Non-Measurement Channel**
0	Low	Low
1	Low	Low
2	Low	Low
3	Pulse	Low
4	Pulse	Low
5	Low	Low

47.3.2.5 Mutual Capacitance Full Scan Mode Operation

In mutual capacitance full scan mode, measurement is performed during the high-level period of the sensor drive pulse on the receive channel by applying the edge to the target transmit channel to be measured. A single measurement target is measured twice, at the rising and falling edges. The difference between the data of these two measurements is used to determine whether or not the electrode is touched, thus achieving higher touch sensitivity.
Electrostatic capacitance is measured sequentially on channels set to transmission or reception specified by the CTSUCHTRCn registers (n = 0 to 2), and measurement targets specified by the CTSUCHACn registers. Electrostatic capacitance is measured by combining signals from the measurement target pins that are allocated to transmission or reception. Figure 47.16 shows the software flowchart and an operation example, and Figure 47.17 shows the timing chart.

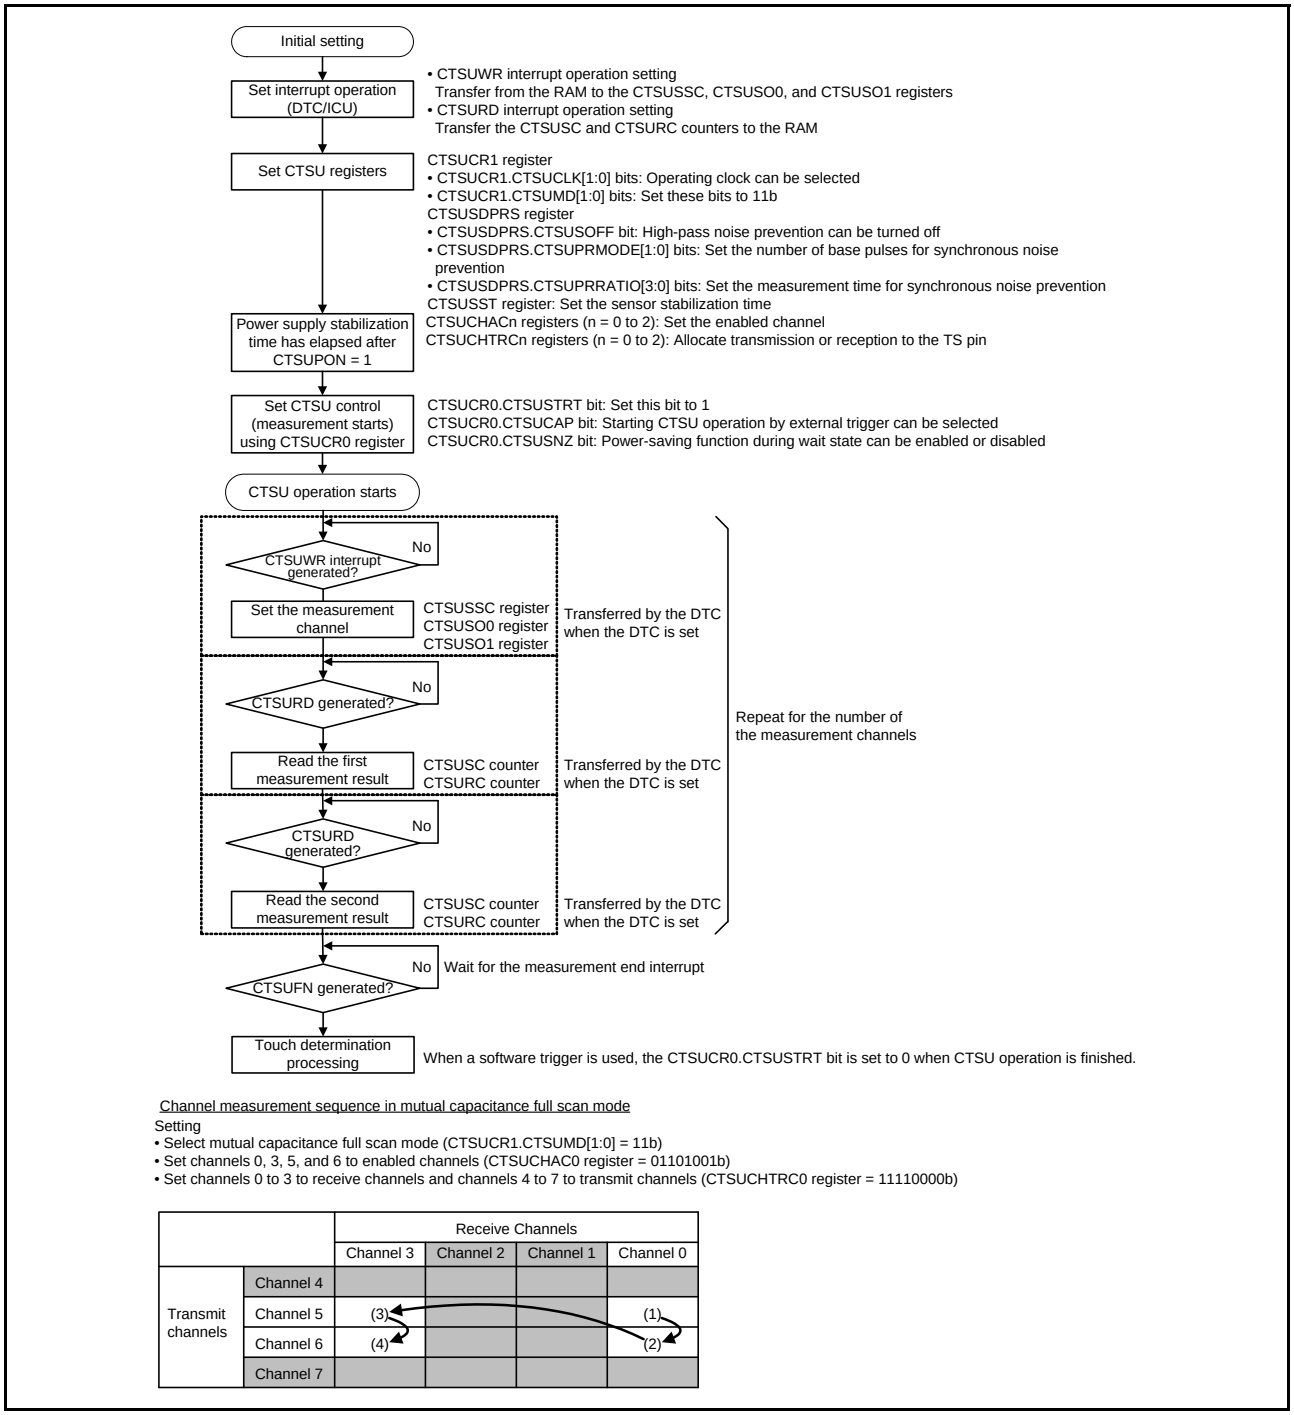

Figure 47.16 Software Flowchart and Operation Example of Mutual Capacitance Full Scan Mode

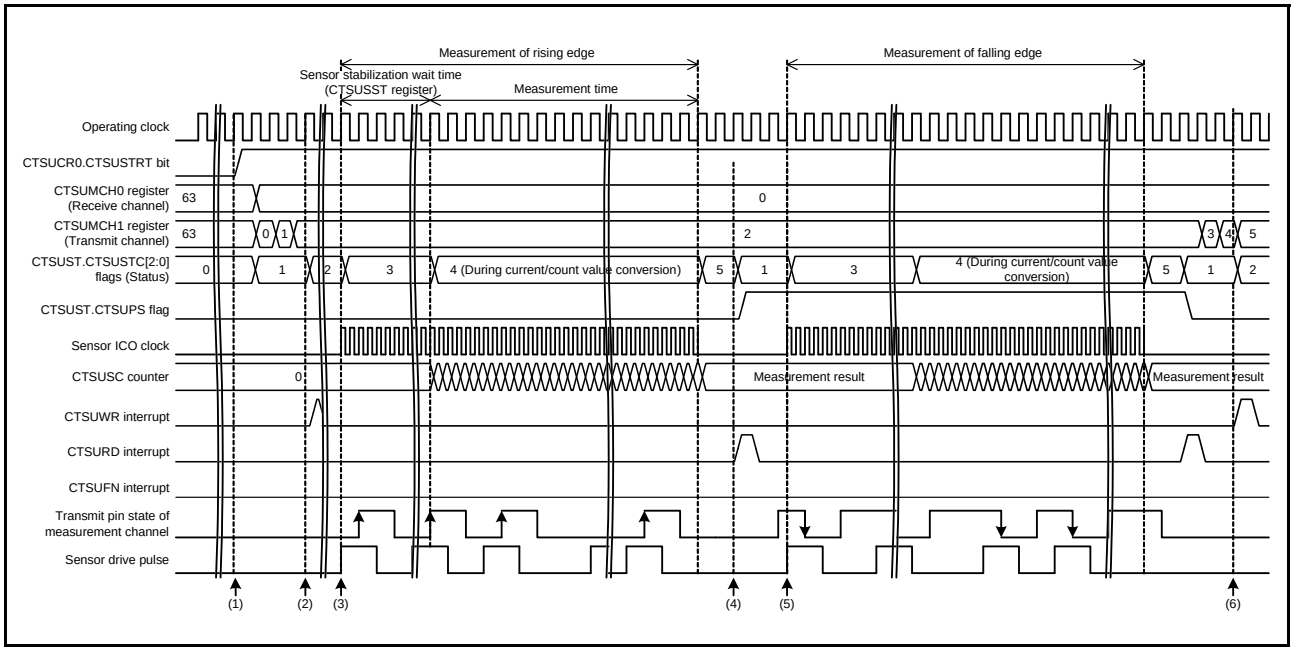

Figure 47.17 Timing Chart of Mutual Capacitance Full Scan Mode (Measurement Start Condition is Software Trigger)

The following describes operation shown in the timing chart in Figure 47.17.

(1) After various settings are made, operation is started by writing 1 to the CTSUCR0.CTSUSTRT bit.

(2) After a channel to be measured is determined according to the preset conditions, a request for setting the corresponding channel (CTSUWR) is output.

(3) Upon completion of writing the measurement channel settings (CTSUSSC, CTSUSO0, and CTSUSO1 registers), the sensor drive pulse is output and the sensor ICO clock and the reference ICO clock operate.
At the same time, a pulse which is handled as the rising edge is output to the transmit pin on the measurement channel during the high-level period of the sensor drive pulse.

(4) After the sensor stabilization wait time and the measurement time have elapsed and measurement is finished, a measurement result read request (CTSURD) is output.

(5) The same channel is measured by outputting a pulse that is handled as the falling edge during the high-level period of the sensor drive pulse.

(6) After the same channel is measured twice, a channel to be measured next is determined and measured in the similar way.

(7) Upon completion of all measurement channels, a measurement end interrupt (CTSUFN) is output and measurement is finished (transition to Status 0).

The mutual capacitance measurement status flag (CTSUST.CTSUPS flag) is changed when Status 5 transitions to Status 1.

Table 47.9 lists the touch pin states in mutual capacitance full scan mode.

Table 47.9 Touch Pin States in Mutual Capacitance Full Scan Mode

	Touch Pin of Receive Channel		Touch Pin of Transmit Channel		
Status	Measurement Channel	Non-Measurement Channel	Measurement Channel	Non-Measurement Channel	Remarks
0	Low	Low	Low	Low	—
1	Low	Low	Low/High	Low	—
2	Low	Low	Low	Low	—
3	Pulse	Low	Pulse	Low	Pulse of the phase same as that of the receive channel at the first measurement Pulse of the phase opposite to that of the receive channel at the second measurement
4	Pulse	Low	Pulse	Low	—
5	Low	Low	Low	Low	—

47.3.3 Items Common to Multiple Modes

47.3.3.1 Sensor Stabilization Wait Time and Measurement Time

Figure 47.18 shows the timing chart of the sensor stabilization wait time and measurement time.

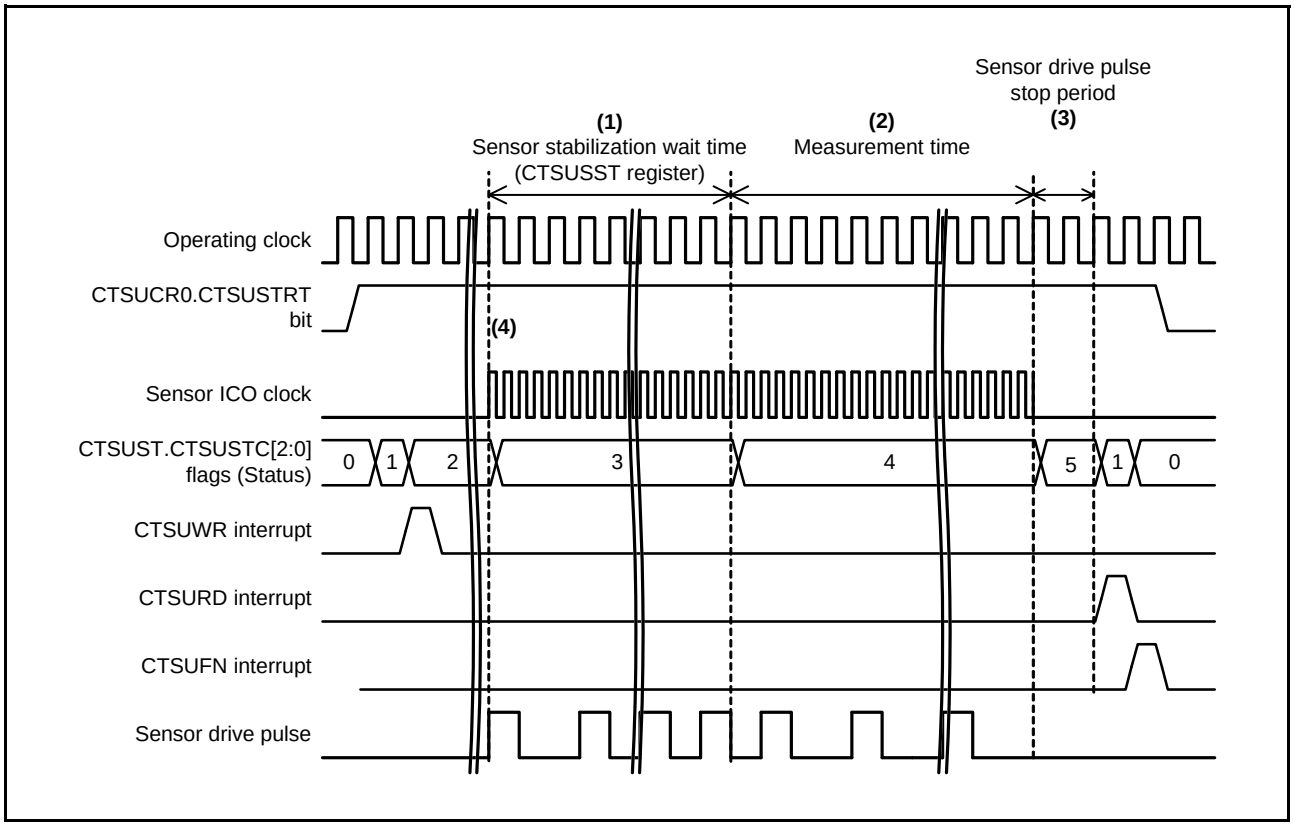

Figure 47.18 Sensor Stabilization Wait Time and Measurement Time

(1) In response to the CTSUWR interrupt request, output of the sensor drive pulse is started by write access to the CTSUSO1 register. Then, wait for the stabilization time set in the CTSUSST register.

(2) When the sensor stabilization time has elapsed and the CTSUST.CTSUDTSR flag is set to 0, measurement is started at transition to Status 4. The measurement time is determined by setting the base clock cycle and the CTSUSDPRS.CTSUPRMODE[1:0], CTSUPRRATIO[3:0], and CTSUSO0.CTSUSNUM[5:0] bits. When the measurement time has elapsed, measurement of the corresponding channel is finished.

(3) After the measurement time has elapsed, the status transitions to Status 1 after two operating clock cycles and a CTSURD interrupt is generated, so read the data from the CTSUSC and CTSURC counters.
At this time, the sensor drive pulse is output at the low level. When measurement of all specified channels is completed, the CTSUCR0.CTSUSTRT bit becomes 0.

(4) The sensor ICO clock oscillates while the CTSUSTC[2:0] flags are 011b (Status 3) or 100b (Status 4).

47.3.3.2 Interrupts

There are three types of interrupts for the CTSU:

- Write request interrupt for setting registers for each channel (CTSUWR)
- Measurement data transfer request interrupt (CTSURD)
- Measurement end interrupt (CTSUFN)

(1) Write request interrupt for setting registers for each channel (CTSUWR)

Store the setting data for each measurement channel in the RAM, and set the DTC or ICU transfer corresponding to the CTSUWR interrupt in advance. The CTSUWR interrupt is output when Status 1 transitions to Status 2. Write the setting data of the corresponding channel from the RAM to the CTSUSSC, CTSUSO0, and CTSUSO1 registers (Figure 47.19). Since write access to the CTSUSO1 register controls a transition to the next status, be sure to set this register last.

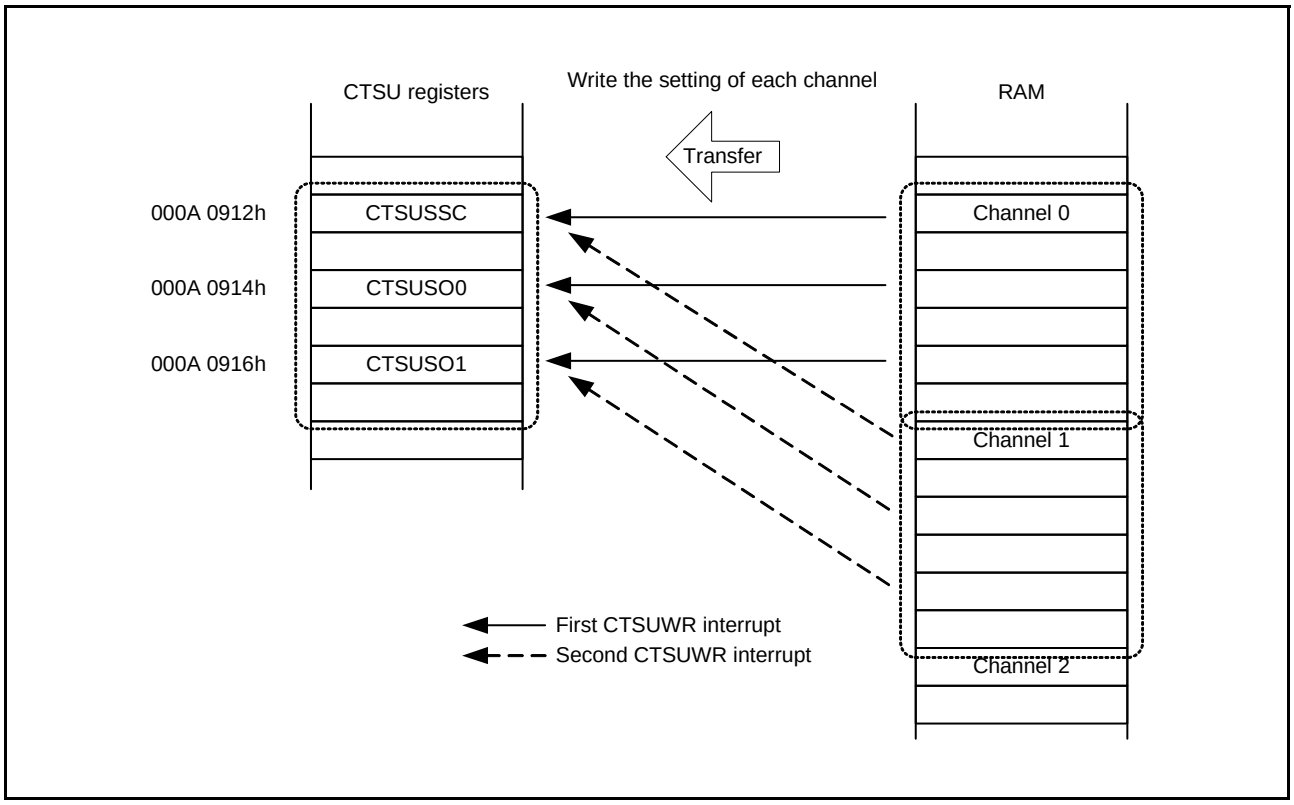

Figure 47.19 Example of DTC Transfer Operation Using CTSUWR Interrupt

The registers (CTSUSSC, CTSUSO0, and CTSUSO1 registers) to be set are allocated at sequential addresses. Set the operation at interrupt generation as shown below:

- Transfer destination address: Address of the CTSUSSC register
- Handling at the transfer destination address: Transfer 2-byte data three times by a single interrupt. (The address of the start byte is fixed.)
- Transfer source address: CTSUSSC register data storage address for the minimum channel in the setting data stored in the RAM
- Handling at the transfer source address: Transfer 2-byte data three times by a single interrupt. (The address of the first byte is continued from the previous interrupt handling.)
- Number of transfers by an interrupt: Specify the number of measurements.

(2) Measurement data transfer request interrupt (CTSURD)

Set DTC or ICU transfer corresponding to the CTSURD interrupt in advance. The CTSURD interrupt is output when Status 5 transitions to Status 1. Read the measurement result from the CTSUSC and CTSURC counters (Figure 47.20).

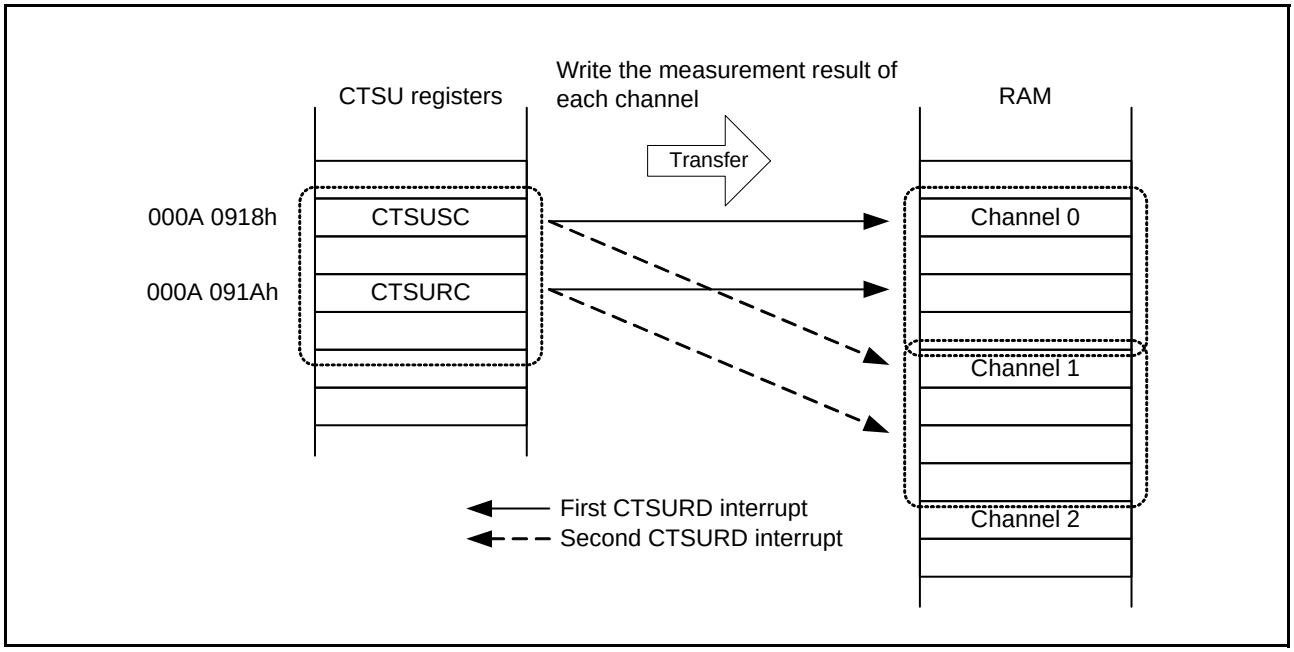

Figure 47.20 Example of DTC Transfer Operation Using CTSURD Interrupt

The measurement result registers (CTSUSC and CTSURC counters) used as transfer sources are allocated at sequential addresses. Set the operation at interrupt generation as shown below:

- Transfer source address: Address of the CTSUSC counter
- Handling at the transfer source address: Transfer 2-byte data twice by a single interrupt. (The start address is fixed.)
- Transfer destination address: CTSUSC counter data storage address for the minimum channel in the setting data stored in the RAM.
- Handling at the transfer destination address: Transfer 2-byte data twice by a single interrupt. (The start address is continued from the previous interrupt handling.)
- Number of transfers by an interrupt: Specify the number of measurements.

(3) Measurement end interrupt (CTSUFN)

When all channels are measured, an interrupt is generated when Status 1 transitions to Status 0. Use software to confirm the overflow flags (CTSUST.CTSUSOVF and CTSUROVF flags) and read the measurement results to determine whether or not the electrode is touched.

Interrupt requests are accepted or disabled in the interrupt control block.

47.4 Usage Notes

47.4.1 Measurement Result Data (CTSUSC and CTSURC Counters)

Read access during measurement is prohibited. If the measurement result data is accessed, an incorrect value may be read due to asynchronous operation.

47.4.2 Software Trigger

When 10b (PCLK/4) is selected by the CTSUCR1.CTSUCLK[1:0] bits, to restart measurement by writing 1 to the CTSUCR0.CTSUSTRT bit after measurement has been completed, wait for at least three cycles to elapse after an interrupt is generated, and then write to the CTSUCR0.CTSUSTRT bit.

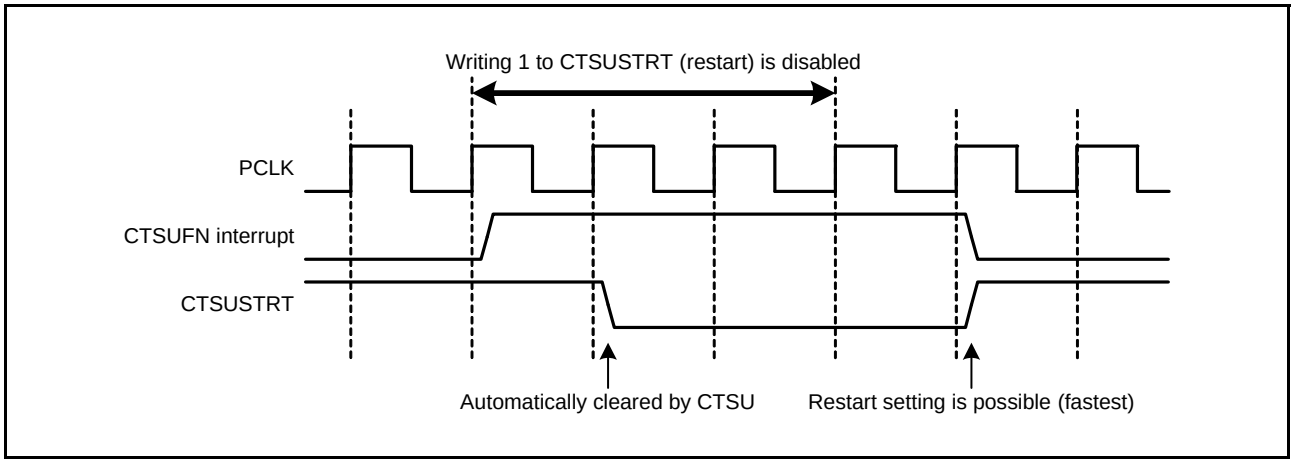

Figure 47.21 Notes on Restarting Measurement

47.4.3 External Trigger

- If an external trigger is input during the measurement time, measurement is not started. The next external event is enabled after one cycle of the operating clock when a CTSUFN interrupt is generated.
- To stop external trigger mode, write 0 to the CTSUCR0.CTSUSTRT bit and 1 to the CTSUCR0.CTSUINIT bit at the same time (forced stop).

47.4.4 Notes on Forcibly Stopping Operation

To forcibly stop the current operation, write 0 to the CTSUCR0.CTSUSTRT bit and 1 to the CTSUCR0.CTSUINIT bit at the same time. After this setting, the operation is stopped and the internal control registers are initialized.
When the CTSUCR0.CTSUINIT bit is used for initialization, the following registers are initialized in addition to the initialization of the internal measurement state.

- CTSUMCH0 register
- CTSUMCH1 register
- CTSUST register
- CTSUSC counter
- CTSURC counter

If operation is forcibly stopped, an interrupt request may be generated depending on the internal state. After operation is forcibly stopped, perform the processing for stopping/disabling the DTC or ICU.

If DTC transfer is stopped in the mounted system for some reason, also perform the processing for forcibly stopping and initializing the CTSU.

47.4.5 TSCAP Pin

The TSCAP pin requires an external decoupling capacitor to stabilize CTSU internal voltage. The traces between the TSCAP pin and the capacitor, and the capacitor and ground should be as short and wide as physically possible.
The capacitor connected to the TSCAP pin should be fully discharged using I/O port control to output a low level, before turning on the switch (CTSUCR1.CTSUCSW bit = 1) to establish a connection.

47.4.6 Notes during Measurement Operation (CTSUCR0.CTSUSTRT Bit = 1)

During measurement operation (CTSUCR0.CTSUSTRT bit = 1), do not use settings such as “stop the peripheral module clock” or “change the port settings related to the touch pins (TS and TSCAP pins)” in the higher layers of the system.
If control settings non-compliant to these restrictions are made, after operation is forcibly stopped (CTSUCR0.CTSUSTRT bit = 0 and CTSUCR0.CTSUINIT bit = 1), write 0 to the CTSUCR1.CTSUPON bit and 0 to the CTSUCR1.CTSUCSW bit at the same time, and set the CTSUCR0.CTSUSNZ bit to 0. Then, restart from the initial setting flow shown in Figure 47.9.

48. Boundary Scan

This MCU has boundary scan function.
The boundary scan is a serial I/O interface based on the JTAG (Joint Test Action Group, IEEE Std.1149.1 and IEEE Standard Test Access Port and Boundary-Scan Architecture).

48.1 Overview

Table 48.1 lists the specifications of boundary scan.
Figure 48.1 shows a block diagram of the boundary scan function.

Table 48.1 Specifications of Boundary Scan

Item	Description
Boundary scan enabled/disabled	Boundary scan is enabled when the RES# pin and the BSCANP pin are driven high and the EMLE pin is driven low.
Dedicated boundary scan pins	The following pins are dedicated for the JTAG, when boundary scan function is enabled (TDO/TCK/TDI/TMS/TRST#). 145-pin TFLGA/64-pin TFBGA: P26/P27/P30/P31/P34
Six test modes	• BYPASS mode • EXTEST mode • SAMPLE/PRELOAD mode • CLAMP mode • HIGHZ mode • IDCODE mode

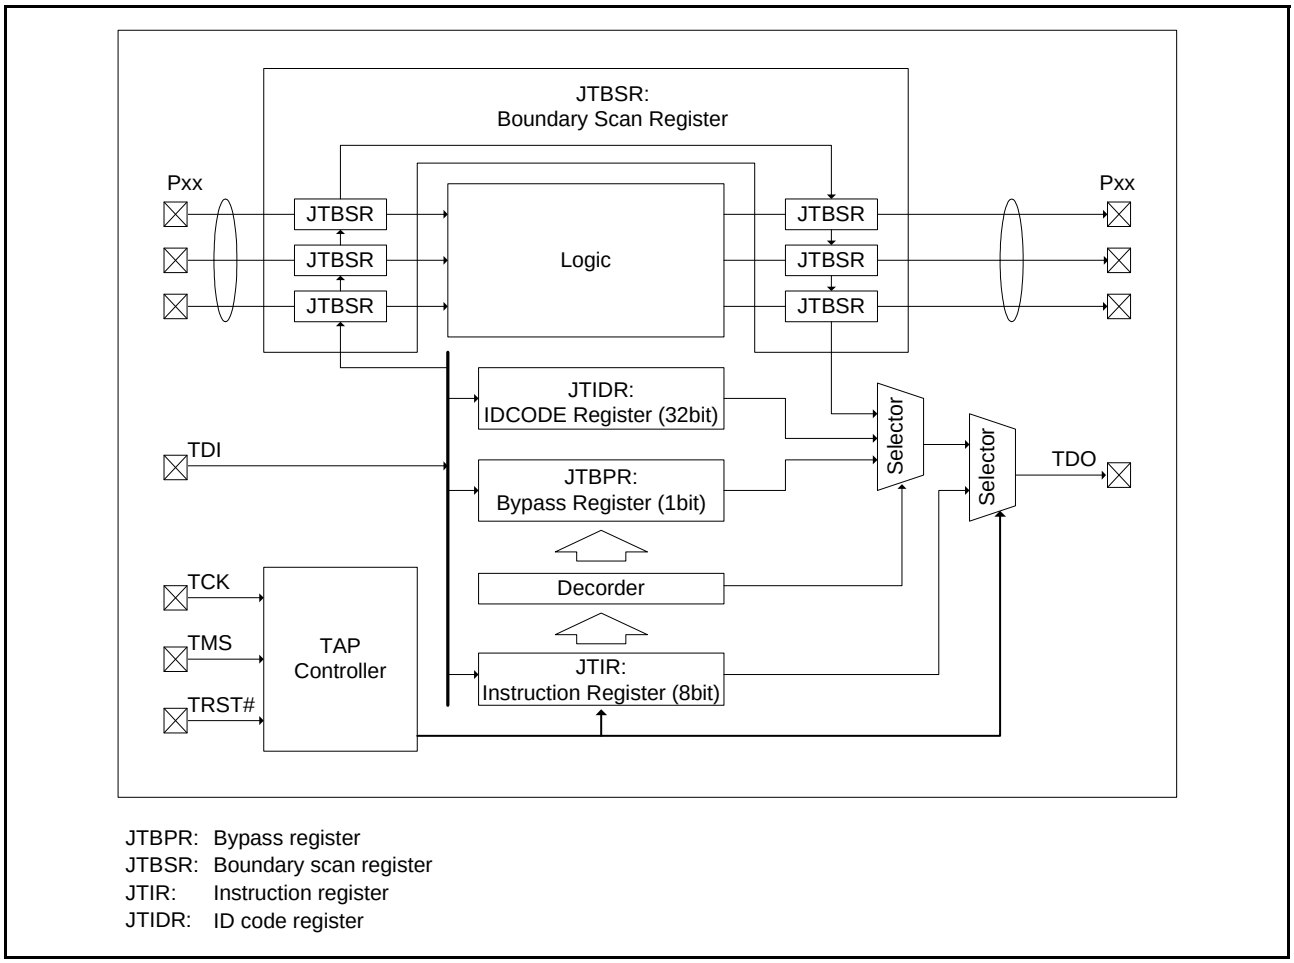

Figure 48.1 Block Diagram of JTAG

Table 48.2 shows the I/O pins used in the boundary scan function.

Table 48.2 Pin Configuration

Pin Name	I/O	Description
TCK	Input	Test clock input pin Clock signal for boundary scan. Input the clock the duty cycle of which is 50 percent when boundary scan function is used.
TMS	Input	Test mode select pin
TDI	Input	Test data input pin
TDO	Output	Test data output pin
TRST#	Input	Test reset input pin

48.2 Register Descriptions

Table 48.3 lists the boundary scan registers.

Table 48.3 List of Boundary Scan Registers

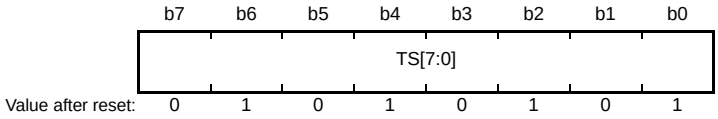
Register Name	Symbol	Value after Reset
Instruction register	JTIR	55h
ID code register	JTIDR	0841 8447h
Bypass register	JTBPR	Undefined
Boundary scan register	JTBSR	Undefined

Instructions can be input to the JTIR register via the TDI pin by serial transfer.
The JTBPR register, which is a 1-bit register, is connected between the TDI and TDO pins in BYPASS mode.
The JTBSR register, which is configured according to Table 48.6 to Table 48.8, is connected between the TDI and TDO pins when test data are being shifted in.
None of the registers is accessible from the CPU.
Table 48.4 shows the availability of serial transfer for the registers.

Table 48.4 Serial Transfer for the Registers

Register Name	Serial Input	Serial Output
Instruction register (JTIR)	Available	Available
ID code register (JTIDR)	Available	Available
Bypass register (JTBPR)	Available	Available
Boundary scan register (JTBSR)	Available	Available

48.2.1 Instruction Register (JTIR)



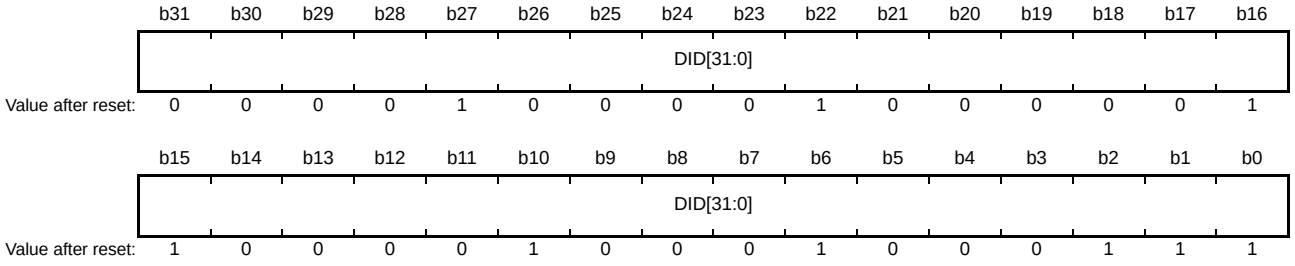
Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TS[7:0]	Test Bit Set	The command configuration is as shown in Table 48.5.	—

Table 48.5 Command Configuration

TS7	TS6	TS5	TS4	TS3	TS2	TS1	TS0	Instruction
0	0	0	0	0	0	0	0	EXTEST
0	1	0	0	0	0	0	0	SAMPLE/PRELOAD
0	1	0	1	0	1	0	1	IDCODE (initial value)
1	1	0	1	0	0	0	0	CLAMP
1	0	0	0	0	0	0	0	HIGHZ
1	1	1	1	1	1	1	1	BYPASS
Other than above								Reserved

JTAG instructions can be transferred to the JTIR register by serial input from the TDI pin.
The JTIR register is initialized when the TRST# pin is driven low, or when the TAP controller is in the Test-Logic-Reset state.

48.2.2 ID Code Register (JTIDR)



Bit	Symbol	Bit Name	Description	R/W
b31 to b0	DID[31:0]	Reserved	JTIDR is a register with the fixed value that indicates the device IDCODE.	—

JTIDR data is output from the TDO pin when the IDCODE instruction has been executed.

48.2.3 Bypass Register (JTBPR)

The JTBPR register is a 1-bit register and is connected between the TDI and TDO pins when the JTIR register is set to BYPASS mode.
The JTBPR register cannot be read from or written to by the CPU.

48.2.4 Boundary Scan Register (JTBSR)

The JTBSR register is a shift register to control the external input and output pins of this MCU and is distributed across the pads.
The EXTEST, SAMPLE/PRELOAD, CLAMP, and HIGHZ instructions are issued to apply the JTBSR register in boundary-scan testing.
Table 48.6 to Table 48.8 show the correspondence between the JTBSR bits and the pins of this MCU.
The value after reset is undefined.

48.3 Operations

The boundary scan functionality is valid when the RES# pin is driven high, the EMLE pin is driven low, and the BSCANP pin is driven high.

48.3.1 TAP Controller

Figure 48.2 shows the state transition diagram of the TAP controller.

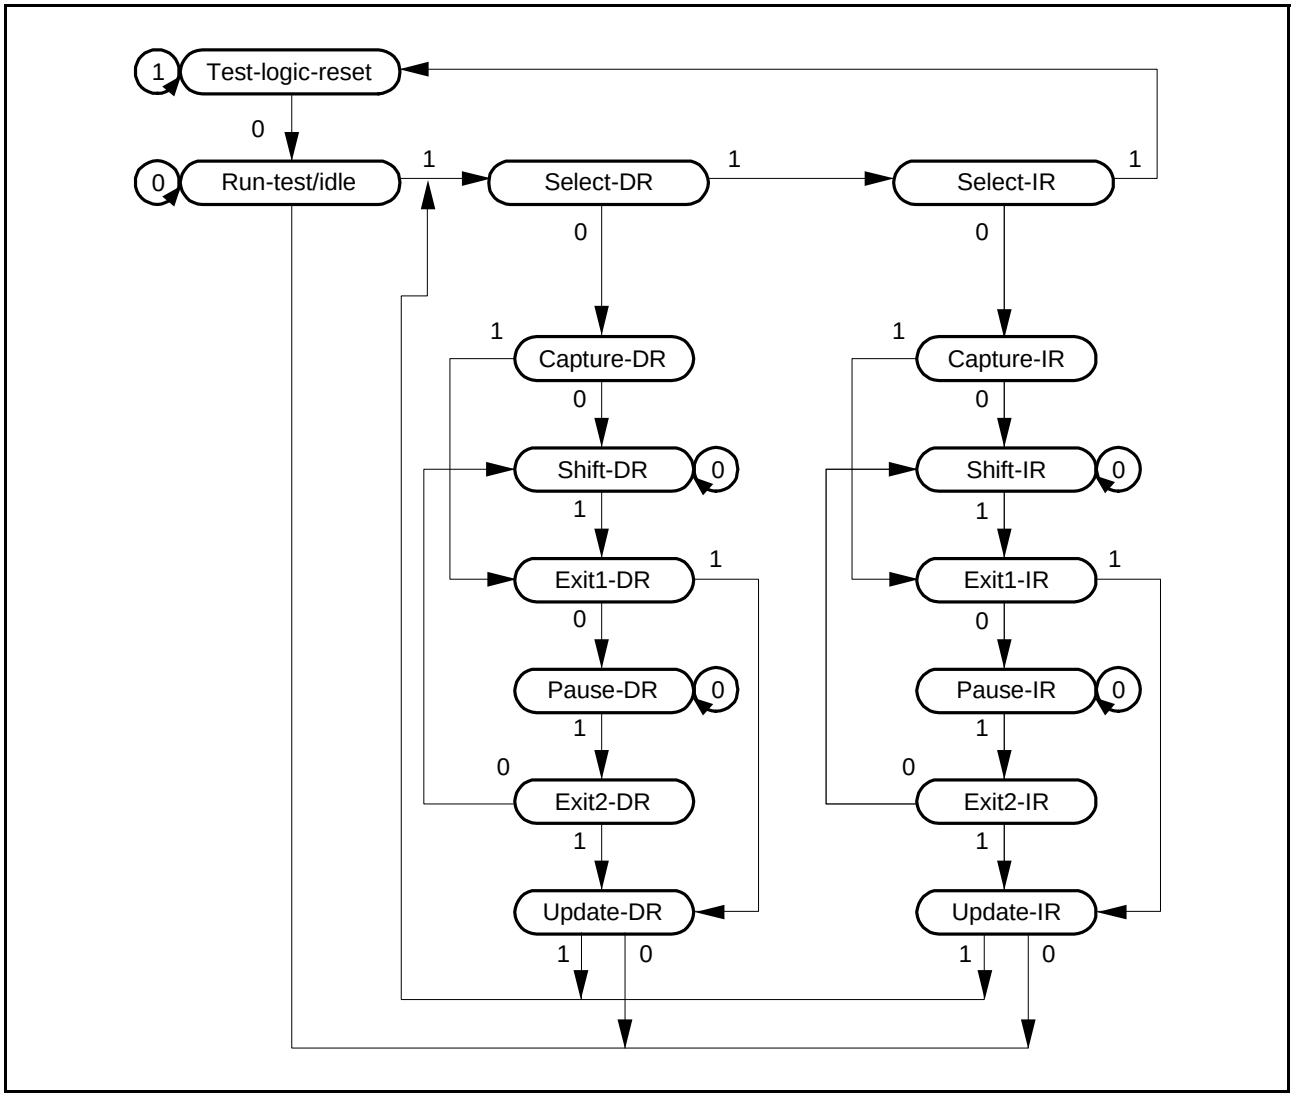

Figure 48.2 State Transition Diagram of TAP Controller

48.3.2 List of Commands

(1) BYPASS [Instruction Code: 1111 1111b]

The BYPASS instruction is an instruction that drives the bypass register (JTBPR). This instruction shortens the shift path, facilitating the transfer of serial data to other LSIs on a printed-circuit board at higher speeds. While this instruction is being executed, the test circuit has no effect on the system circuits.
The bypass register (JTBPR) is connected between the TDI and TDO pins. Bypass operation is initiated from shift-DR operation. The TDO is low in the first clock cycle in the shift-DR state; in the subsequent clock cycles, the TDI signal is output on the TDO pin.

(2) EXTEST [Instruction Code: 0000 0000b]

The EXTEST instruction is used to test external circuits when this LSI is installed on the printed circuit board. If this instruction is executed, output pins are used to output test data (specified by the SAMPLE/PRELOAD instruction) from the boundary scan register to the print circuit board, and input pins are used to input test result.

(3) SAMPLE/PRELOAD [Instruction Code: 0100 0000b]

The SAMPLE/PRELOAD instruction is used to input data from the LSI internal circuits to the boundary scan register, output data from scan path, and reload the data to the scan path. While this instruction is executed, input signals are directly input to the LSI and output signals are also directly output to the external circuits. The LSI system circuit is not affected by this instruction.
In SAMPLE operation, the boundary scan register latches the snap shot of data transferred from input pins to internal circuit or data transferred from internal circuit to output pins. The latched data is read from the scan path. The scan register latches the snap data at the rising edge of the TCK in Capture-DR state. The scan register latches snap shot without affecting the LSI normal operation.
In PRELOAD operation, initial value is written from the scan path to the parallel output latch of the boundary scan register prior to the EXTEST instruction execution. If the EXTEST is executed without executing this PRELOAD operation, undefined values are output from the beginning to the end (transfer to the output latch) of the EXTEST sequence. (In EXTEST instruction, output parallel latches are always output to the output pins.)

(4) IDCODE [Instruction Code: 0101 0101b]

When the IDCODE instruction is selected, IDCODE register value is output to the TDO in Shift-DR state of the TAP controller. In this case, IDCODE register value is output from the LSB. During this instruction execution, test circuit does not affect the system circuit. JTIR is initialized by the IDCODE instruction in Test-Logic-Reset state of the TAP controller.

(5) CLAMP [Instruction Code: 1101 0000b]

When the CLAMP instruction is selected, output pins output the boundary scan register value which was specified by the SAMPLE/PRELOAD instruction in advance. While the CLAMP instruction is selected, the status of boundary scan register is maintained regardless of the TAP controller state.
BYPASS is connected between TDI and TDO, the same operation as BYPASS instruction can be achieved.

(6) HIGHZ [Instruction Code: 1000 0000b]

When the HIGHZ instruction is selected, all output pins enter high-impedance state. While the HIGHZ instruction is selected, the status of boundary scan register is maintained regardless of the state of the TAP controller.
BYPASS is connected between TDI and TDO pins, leading to the same operation as when the BYPASS instruction has been selected.

48.4 Usage Notes

(1) Pin serial transfer, data are input or output in LSB order (refer to Figure 48.3).

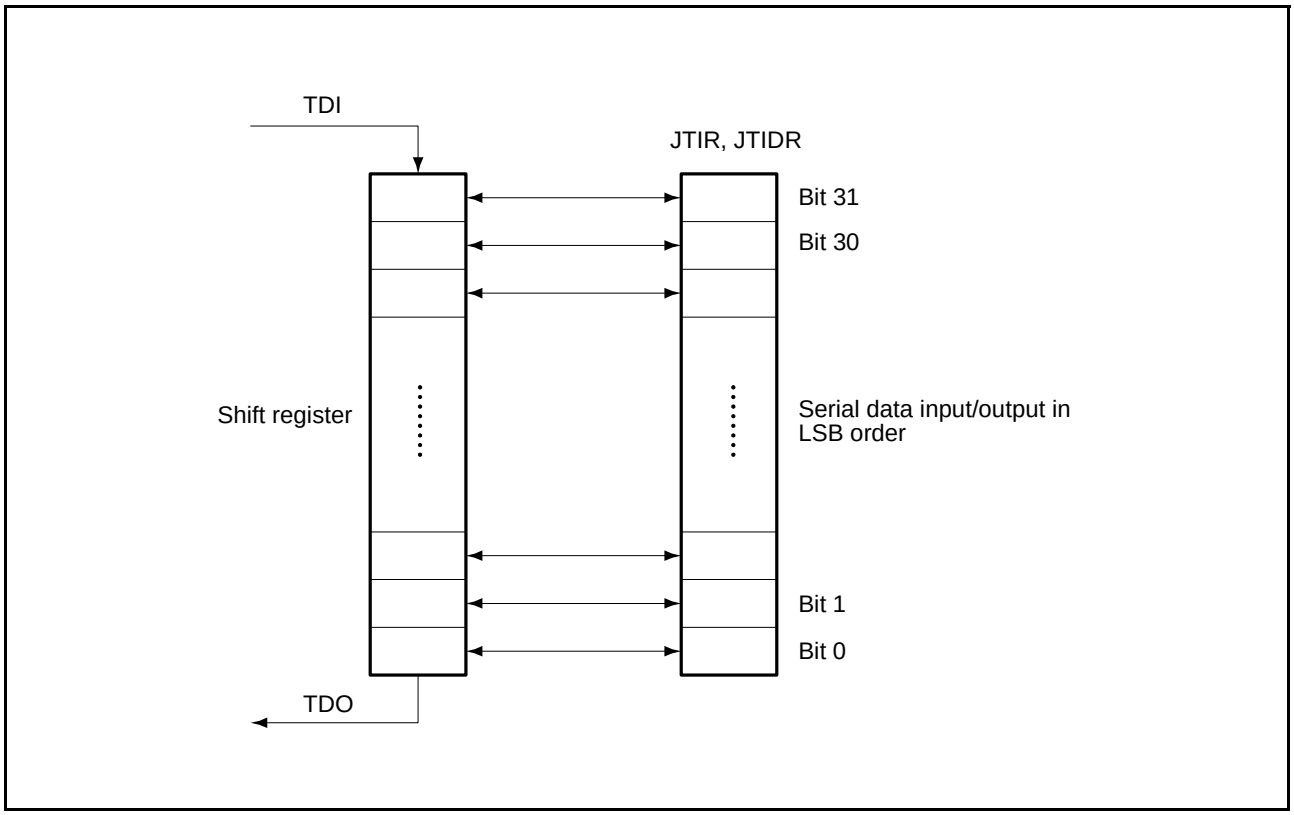

Figure 48.3 Serial Data Input/Output

(2) Pins of the boundary scan (TCK, TDI, TMS, and TRST#) have to be pulled up by pull-up resistors.
However, handle the TRST# pin in the way described in the manual for the given on-chip emulator if an on-chip emulator is in use.
If the TRST# pin is pulled down but a boundary scan is to proceed, ensure that the TRST# pin is also controllable.

(3) Power supply pins (VCC, VCL, VSS, AVCC0, AVCC1, AVSS0, AVSS1, VCC_USB, VSS_USB, VBATT) cannot be boundary-scanned.

(4) Analog reference pins (VREFH0, VREFL0) cannot be boundary-scanned.

(5) Clock pins (EXTAL, XTAL, XCIN, and XCOUT) cannot be boundary-scanned.

(6) Reset signal (RES#) cannot be boundary-scanned.

(7) USB dedicated pins (USB1_DP, USB1_DM) cannot be boundary-scanned.

(8) The on-chip emulator enable pin (EMLE) cannot be boundary-scanned.

(9) The boundary-scan pin (BSCANP) cannot be boundary-scanned.

(10) The boundary-scan pins (TCK, TMS, TRST#, TDI, and TDO) cannot be boundary-scanned.

(11) The boundary-scan facility is not available when the chip is in the states below.

- Reset state
- Software standby or deep software standby

(12) For a pin that incorporates open-drain functionality and for which the open-drain function is enabled, if the boundary-scan function sets the corresponding bit in the output scan register and output enable register to 1, executing an EXTEST, CLAMP, or SAMPLE/PRELOAD instruction makes the pin output the high level rather than placing it in the high-impedance state.

(13) Be sure to satisfy the standards for the boundary scan function when multiplex ports are used. Figure 48.4 (1) shows the pin configuration of the port pins on which the RIIC and TSCAP pin functions (P16, P17, P20, P21, and

PC4) are multiplexed. When the boundary scan function is to be used while pins P16, P17, P20, and P21 are in use as the RIIC pins (SCL1, SCL2, SDA1, and SDA2) or the PC4 pin is in use as a CTSU pin (TSCAP), contention with the open-drain outputs or sneak current might be generated.

(14) Figure 48.4 (2) shows the pin configuration of the pins P00 to P02, P40 to P47, P90, PD0 to PD7, PE0, and PE1. When the boundary scan function is used with pins P00 to P02, P40 to P47, P90, PD0 to PD7, PE0, and PE1 to be used as AD input pins (AN000 to AN007, ANEX0, ANEX1, and AN100 to AN111), the conflict with the AD input or sneak current might be generated.

(15) As the TS pins are multiplexed with port pin functions, make sure the standards for the boundary scan function are satisfied. Figure 48.4 (3) shows the pin configuration of the port pins on which the TS pin functions are multiplexed (P2[7:0], P14, P15, P33, P34, P53, PC0, PC1, PC5, and PC6). When the boundary scan function is to be used while pins P2[7:0], P14, P15, P33, P34, P53, PC0, PC1, PC5 and PC6 are in use as the TS pins (TS0 to TS16), the conflict with the TS outputs or sneak current might be generated.

(16) As the USB0 pins are multiplexed with port pin functions, make sure the standards for the boundary scan function are satisfied. Figure 48.4 (4) shows the pin configuration of the port pins on which the USB0 pin functions are multiplexed (PH1 and PH2). When the boundary scan function is to be used while pins PH1 and PH2 are in use as the USB0 pins (USB0_DP and USB0_DM), the conflict with the USB0 output signals or sneak current might be generated.

(17) The HIGHZ mode option of the MD pin is not available.

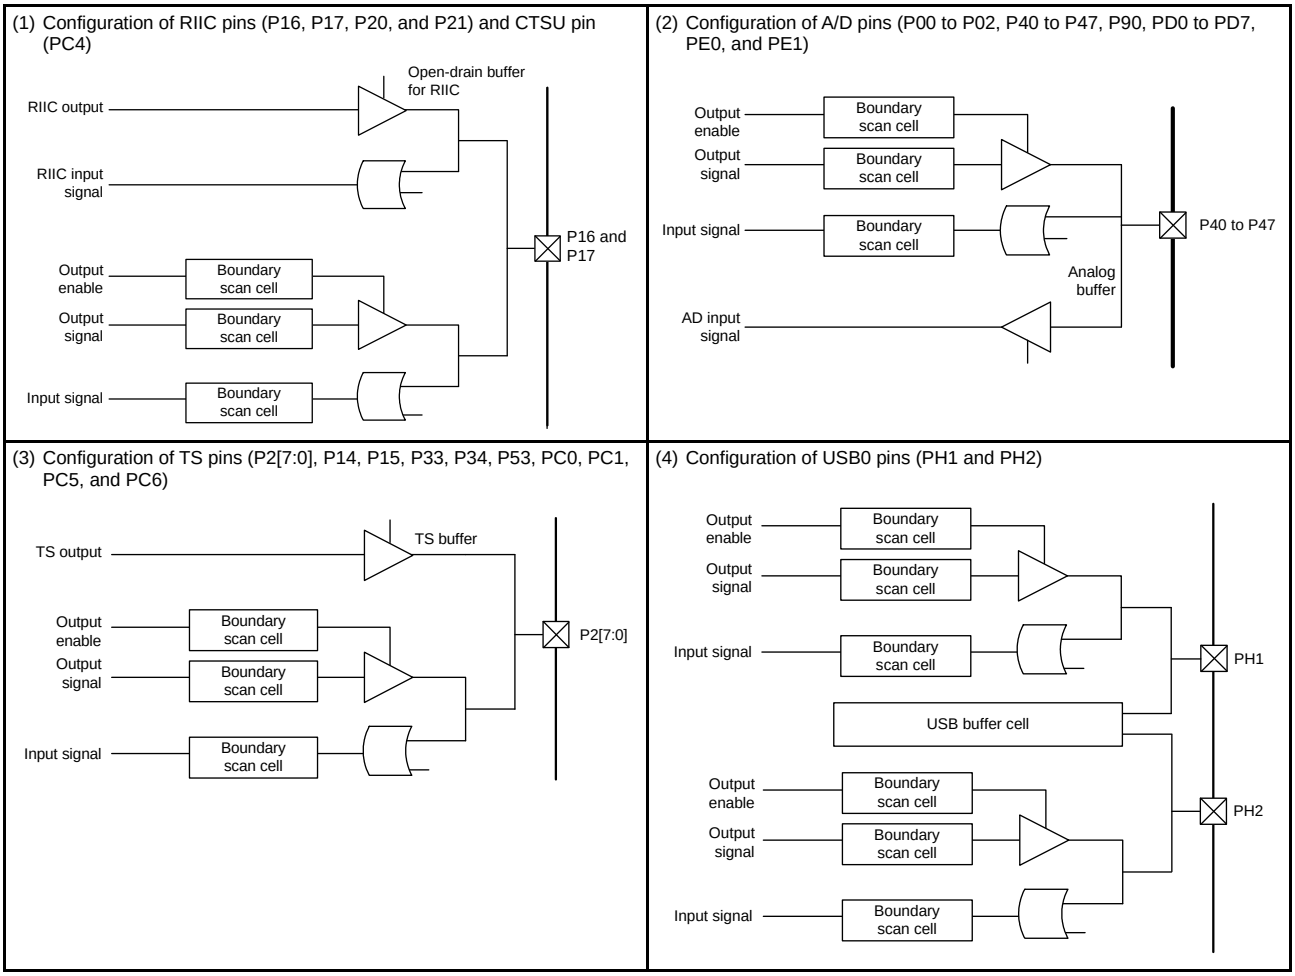

Figure 48.4 Pin Configuration

49. Trusted Secure IP (TSIP)

This MCU incorporates a Trusted Secure IP module to provide security functions. The module consists of an access management circuit, encryption engine, and random number generator. In combination with the Trusted Secure IP library, the Trusted Secure IP can prevent eavesdropping (confidentiality), falsification of information (integrity), and impersonation (authenticity).
Key information to be used in encrypting and decrypting data is only stored within the Trusted Secure IP, and any external access can be shut out to obtain a system with strong security.

49.1 Overview

Table 49.1 summarizes the specifications of the Trusted Secure IP. Figure 49.1 shows a block diagram of the Trusted Secure IP.

Table 49.1 Specifications of Trusted Secure IP (1/2)

Item	Description
Access control	Access management circuit • In case of irregular access to the Trusted Secure IP due to a falsified program or runaway execution of a program, this circuit blocks all subsequent access and stops the output of data from the Trusted Secure IP.
Encryption engine	AES: Compliant with NIST FIPS PUB 197 algorithm • Key sizes: 128, 192, or 256 bits • Block sizes: 128 bits • Block cipher mode of operation ECB, CBC, CTR: Compliant with NIST SP 800-38A CMAC: Compliant with NIST SP 800-38B CCM: Compliant with NIST SP 800-38C GCM: Compliant with NIST SP 800-38D XTS: Compliant with NIST SP 800-38E GCTR • Number of cycles for execution*1 ECB, CBC, CTR, CMAC, GCTR, XTS: 11 cycles of PCLKB for 128-bit keys, 13 cycles of PCLKB for 192-bit keys, 15 cycles of PCLKB for 256-bit keys CCM: 22 cycles of PCLKB for 128-bit keys, 26 cycles of PCLKB for 192-bit keys, 30 cycles of PCLKB for 256-bit keys AES-GCM • AES-GCM is realized by combining AES-GCTR and GHASH. RSA • Key sizes: Up to 2048 bits • Block sizes: Up to 2048 bits • Number of cycles for execution: Approximately 1,300,000 cycles of PCLKB when the CRT is used*1 TDES • Key sizes: 56 bits, 2 × 56 bits, or 3 × 56 bits • Block sizes: 64 bits • Block cipher mode of operation: ECB, CBC • Number of cycles for execution*1 16 cycles of PCLKB for 56-bit keys, 32 cycles of PCLKB for 2 × 56-bit keys, 48 cycles of PCLKB for 3 × 56-bit keys ARC4 • Key sizes: 2048 bits • Block sizes: 128 bits • Number of cycles for execution: 16 cycles of PCLKB*1 ECC • Key sizes: Up to 256 bits • Block sizes: 256 bits HASH Support for SHA1, SHA224/SHA256/MD5, GHASH • Block sizes: 512bits • Number of cycles for execution*1 SHA1: 80 cycles of PCLKB SHA224/SHA256/MD5: 64 cycles of PCLKB GHASH: 9 cycles of PCLKB

Table 49.1 Specifications of Trusted Secure IP (2/2)

Item	Description
Encryption engine	Key management • Keys are only valid within the Trusted Secure IP. • Only key generation information is output from the Trusted Secure IP. • Keys can be regenerated by the input of key generation information to the Trusted Secure IP. Endian • Big or little
Generation of random numbers	32-bit true random number generator • The Trusted Secure IP library can assemble 32-bit true random numbers to generate 128- or 256-bit true random numbers. • The generated 128-bit and 256-bit true random numbers are used as keys in encrypting and decrypting data.
Protection against illicit key copying	• An ID unique to the MCU (unique ID) is accessible from the access management circuit through the dedicated bus. • Combining the unique ID with the key generation information prevents the illicit copying of the key to another MCU.
Supervisor mode	• The supervisor mode signal is connected to the access management circuit and is used to limit control of the Trusted Secure IP module to supervisor mode only.
Interrupt sources	11
Low power consumption	Setting of the module stop state is possible.

Note 1. This does not include the overhead for calling functions of the Trusted Secure IP library.

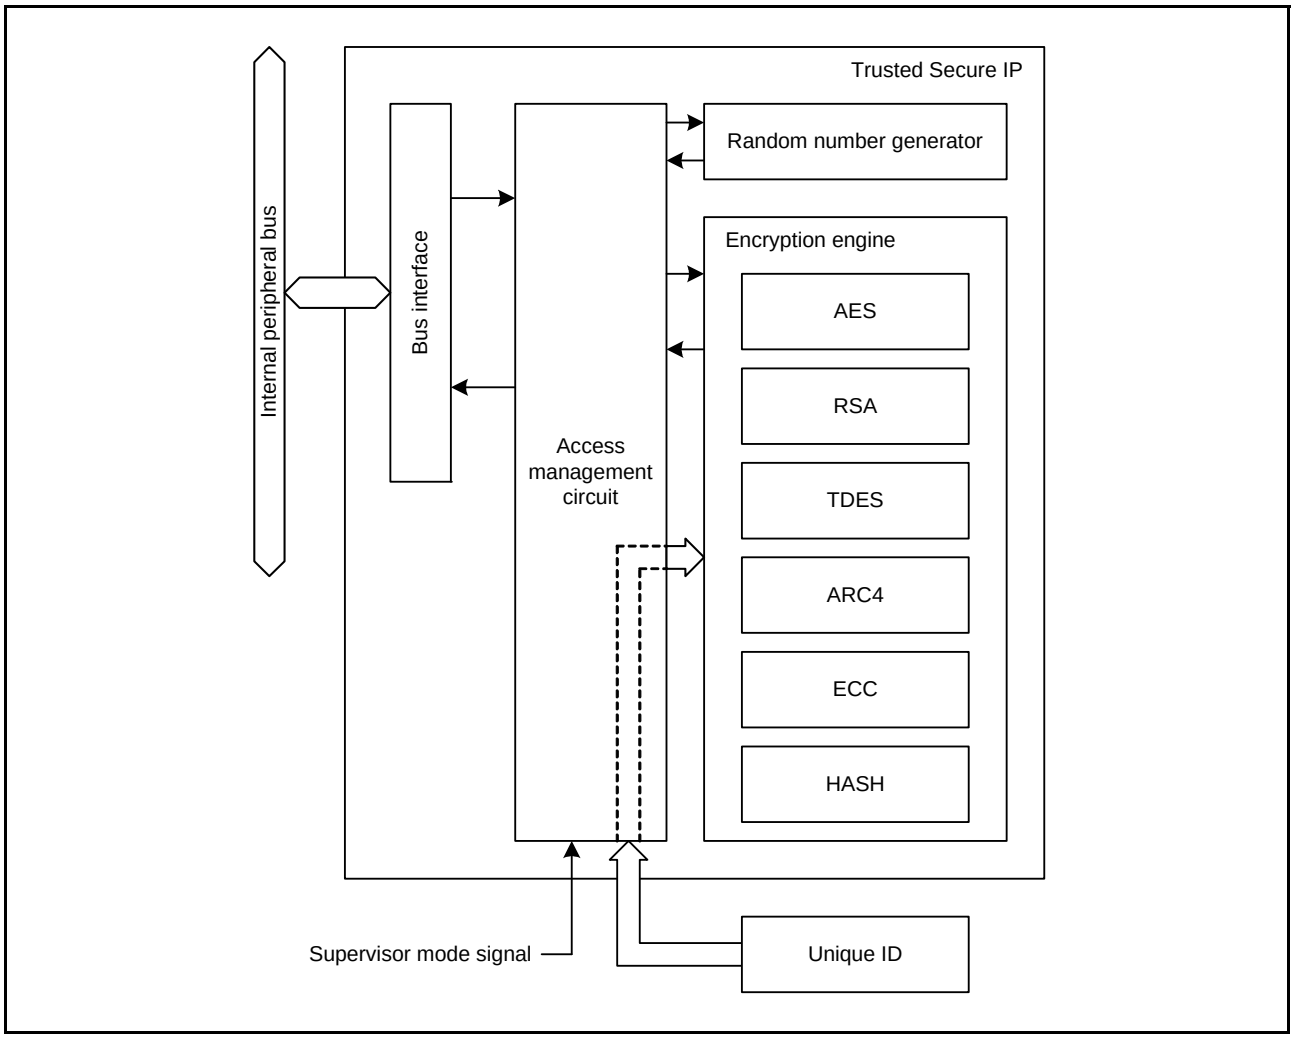

Figure 49.1 Trusted Secure IP Block Diagram

49.2 Operation

49.2.1 Operating Modes and State Transitions

Figure 49.2 shows the state transitions of the Trusted Secure IP.
Use of the Trusted Secure IP security functions is only possible through use of the Trusted Secure IP library provided by Renesas Electronics, in accordance with the state transitions as shown in the figure below.
When irregular access to the Trusted Secure IP (access that violates the defined procedure) due to a falsified program or a program entering runaway execution, etc. is attempted, the access management circuit does not accept any subsequent access and stops the output of any data from the Trusted Secure IP.

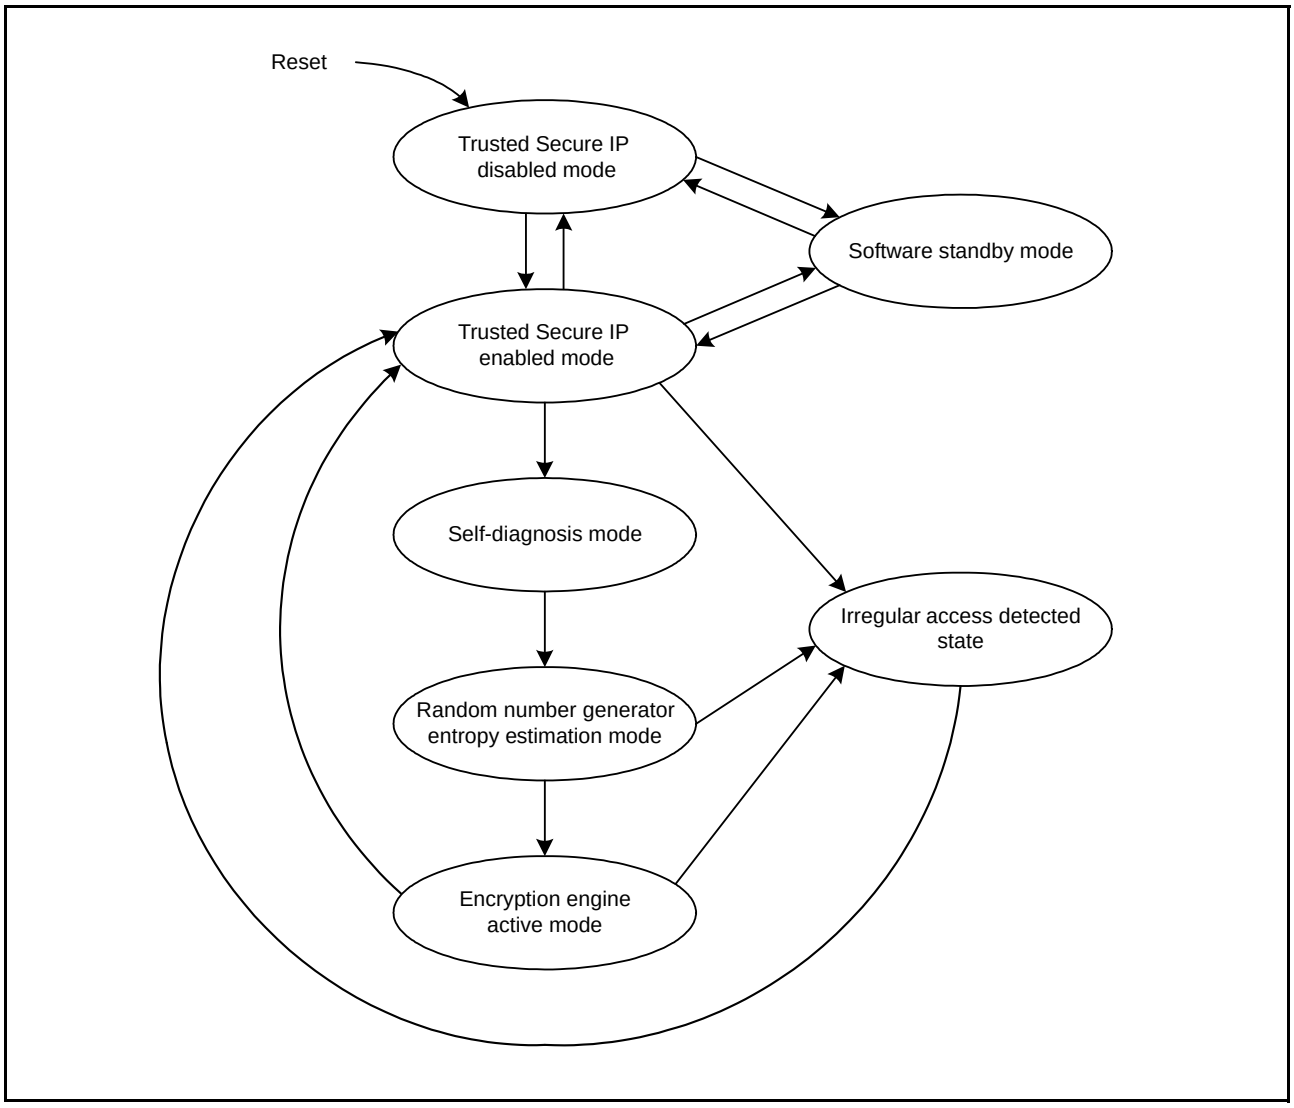

Figure 49.2 Trusted Secure IP Operating Modes and State Transitions

Many of the security functions that the Trusted Secure IP offers are applicable only in the encryption engine active mode. The operations that can be performed in this mode are given below.

(1) Key Installation
(2) Encryption and decryption
(3) Key generation
(4) Random number generation

49.2.2 Encryption Engine

Figure 49.3 shows processes of the encryption engine integrated in the Trusted Secure IP.
The encryption engine, using the key generation information, performs plaintext to ciphertext encryption and ciphertext to plaintext decryption by hardware.
In no part of the encryption or decryption process, is key data or intermediate data ever exposed outside of the Trusted Secure IP.

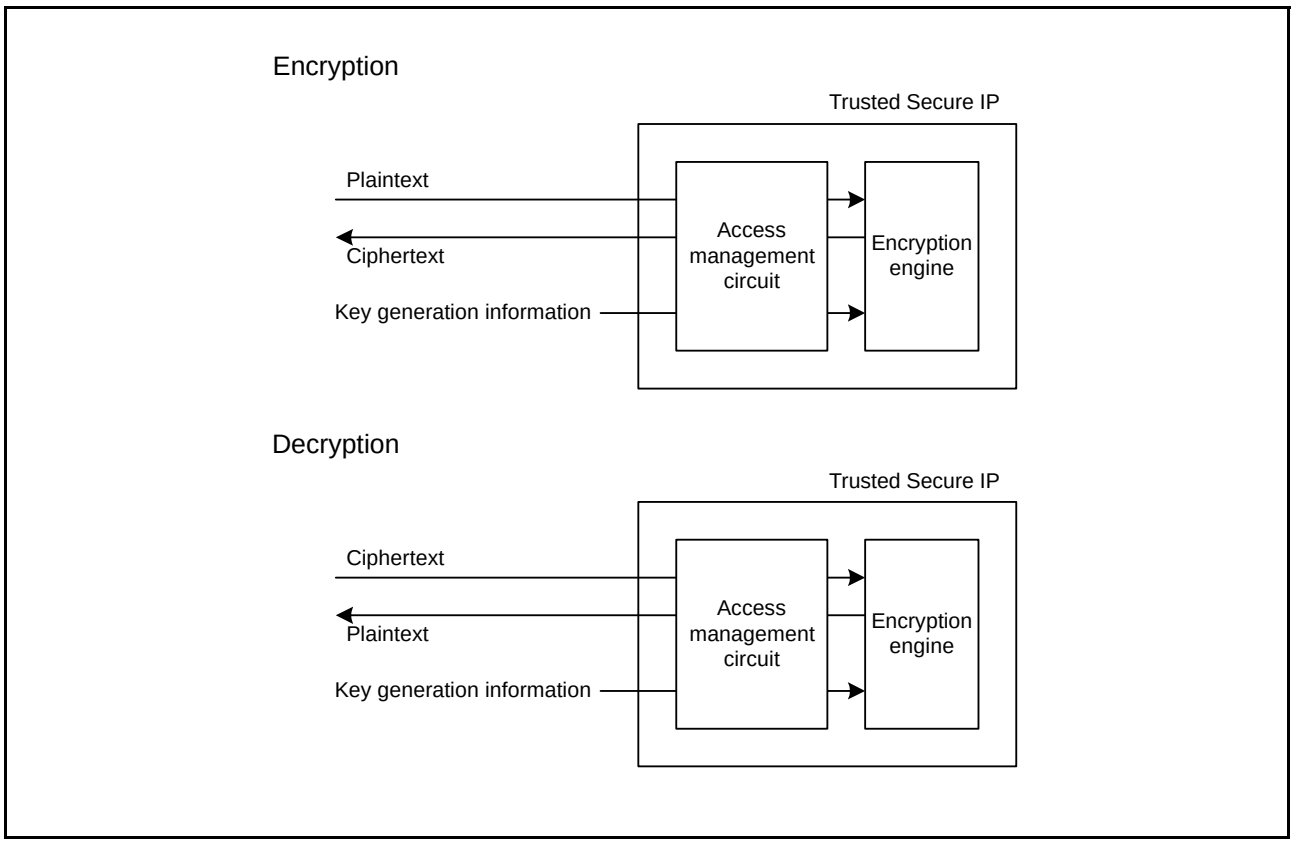

Figure 49.3 Encryption and Decryption processes by Encryption Engine

49.2.3 Key Installation

The key installation is the operation that safely converts the user key to the key generation information and stores it in flash memory. The procedure for installing the key data are given below.

(1) The user uses the key (Key-2) used for encrypting the user key to encrypt the user key (Key-1) producing eKey-1.
(2) The user sends the encrypted user key (eKey-1) to the Trusted Secure IP over the serial interface.
(3) The key generation information of the Key-2 (Index-2) contained in the Trusted Secure IP library is used to recover the Key-2, which is then used to decrypt the user key.
(4) The user key is converted to user key generation information (Index-1) using the unique ID and a random number, and stored in flash memory.

The installation process and flow chart are given in Figure 49.4 and Figure 49.5, respectively.
Once the key data is installed, the user key generation information (Index-1) can then be used to perform encryption or decryption.

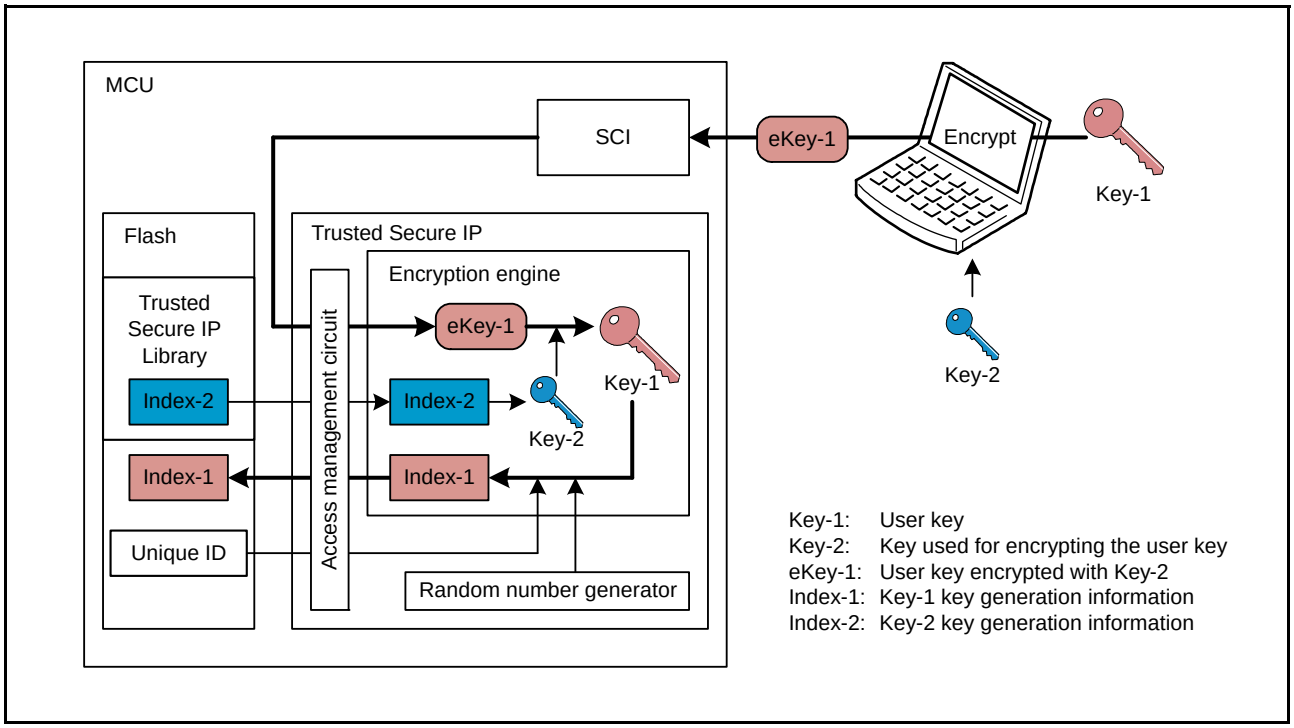

Figure 49.4 Key Installation Process

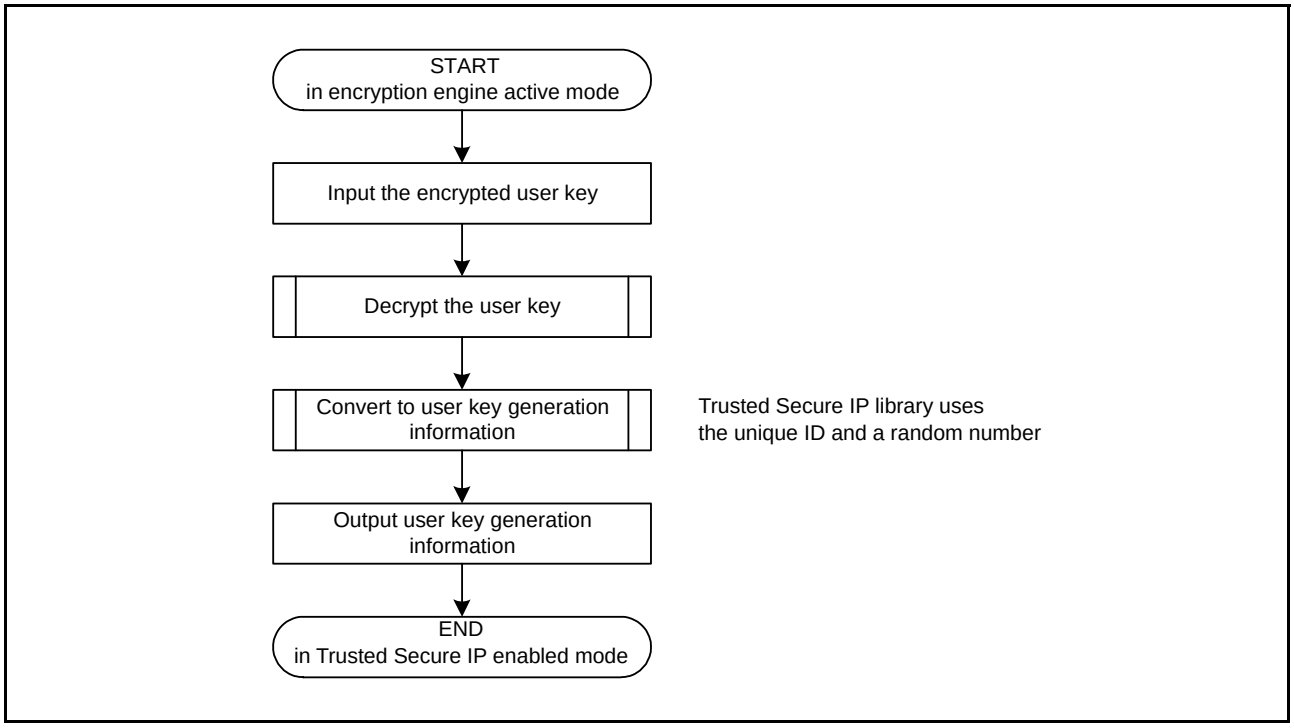

Figure 49.5 Key Installation Flow Chart

49.2.4 Encryption and Decryption

The procedures for encrypting and decrypting data are given below.

(1) Input the key generation information into the Trusted Secure IP, and recover the key data.
(2) Input the data to encrypt or decrypt into the Trusted Secure IP. This converts plaintext into ciphertext, and ciphertext into plaintext.
(3) Read the converted data.

The encryption engine has an input buffer and an output buffer, enabling encryption/decryption to proceed in parallel with data input/output.
Figure 49.6, Figure 49.7, and Figure 49.8 show the timing diagram, encryption flow, and decryption flow, respectively.

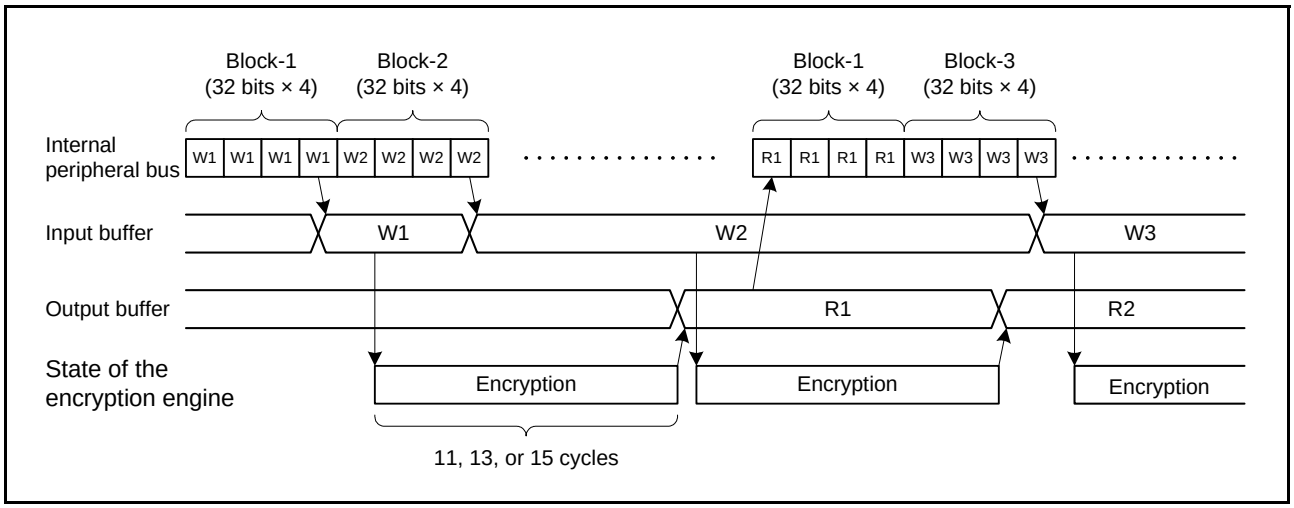

Figure 49.6 Encryption and Decryption Timing Diagram

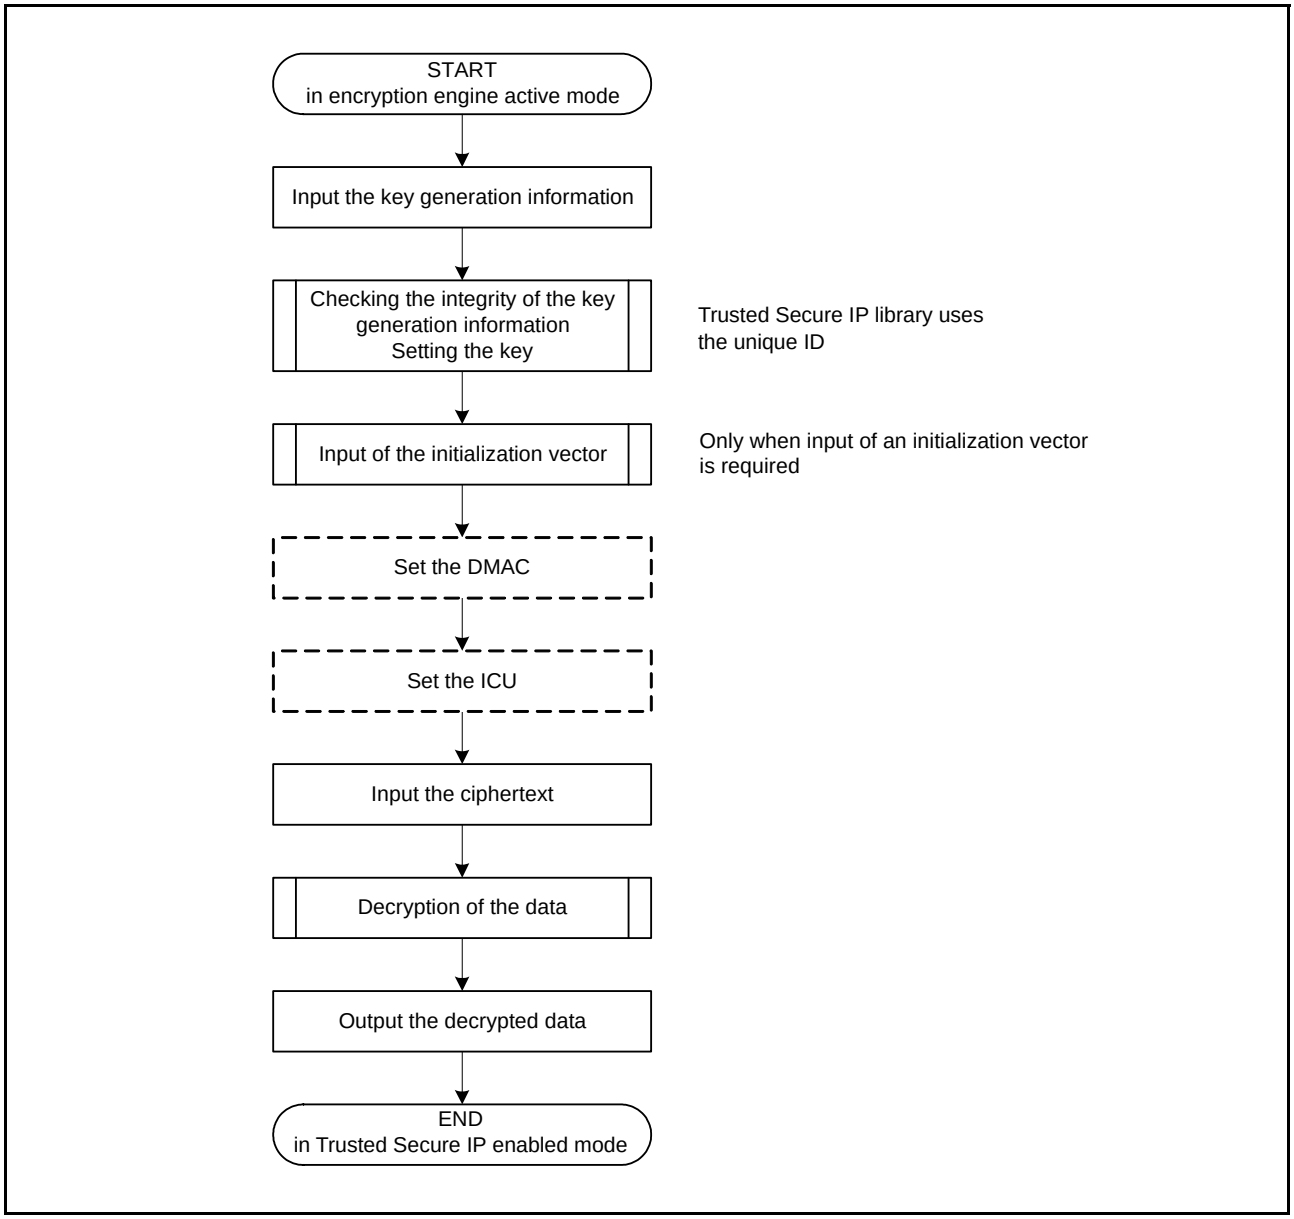

Figure 49.8 Decryption Flow Chart

49.2.5 Generating Key Generation Information (by Using Random Numbers)

Figure 49.9 shows the generating flow for the key generation information by using random numbers.

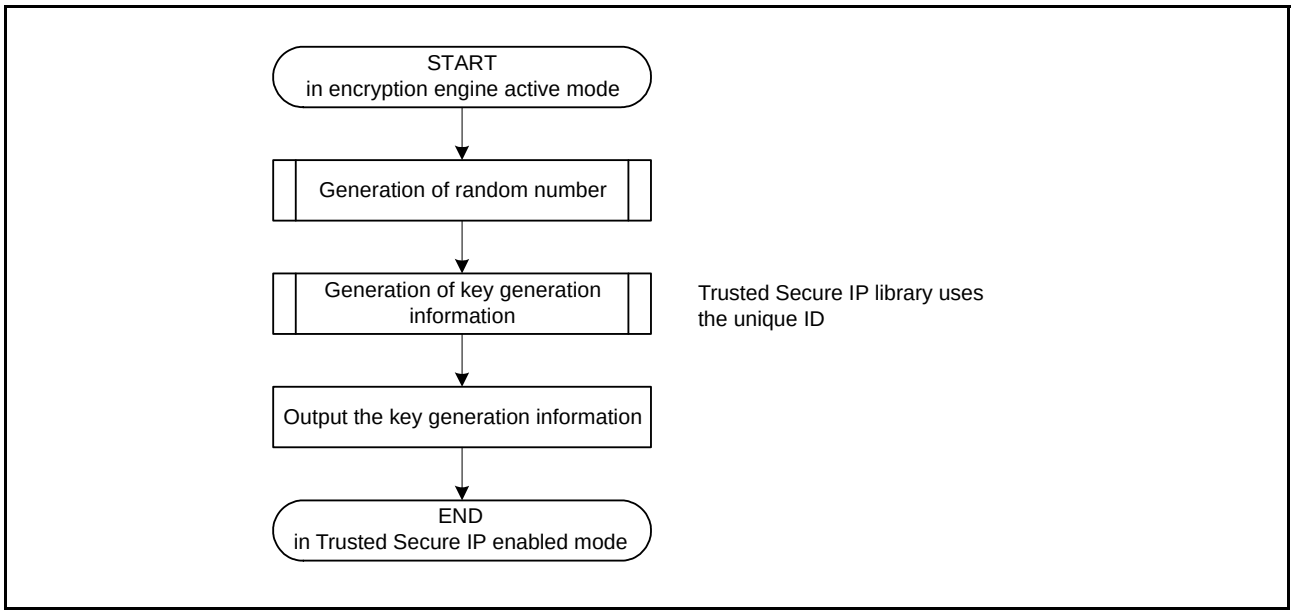

Figure 49.9 Key Generation Information Generating Flow Chart (Using Random Numbers)

49.2.6 Random Number Generation

Figure 49.10 shows the random number generation flow.

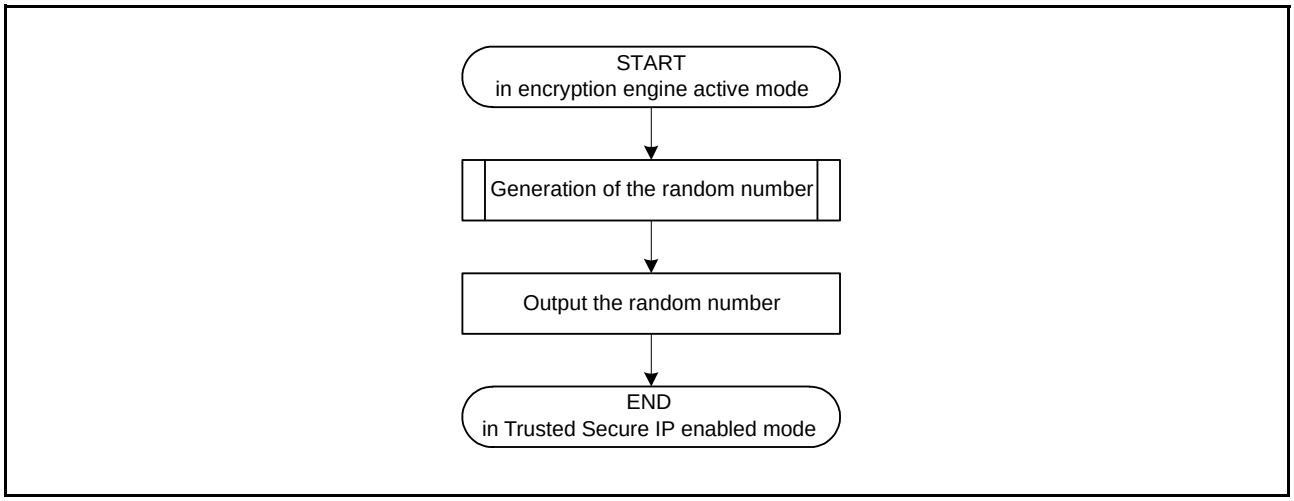

Figure 49.10 Random Number Generation Flow Chart

49.3 Interrupt

Table 49.2 lists the interrupt sources.
Trusted Secure IP library uses interrupts caused by these interrupt sources. Do not set the ICU.IERm.IENj bits corresponding to these interrupt sources to 0.

Table 49.2 Trusted Secure IP Interrupt Sources

Name	Interrupt Source
PROC_BUSY	Procedure completion interrupt
ROMOK	Falsification detection interrupt
LONG_PLG	Calculation completion interrupt
TEST_BUSY	Test busy
WRRDY0	Write ready 0
WRRDY1	Write ready 1
WRRDY4	Write ready 4
RDRDY0	Read ready 0
RDRDY1	Read ready 1
INTEGRATE_WRRDY	Integration write ready
INTEGRATE_RDRDY	Integration read ready

49.4 Usage Notes

49.4.1 Standby Mode

When standby mode is entered while the encryption engine is in processing, proper processing cannot be resumed after standby mode is exited. Standby mode should therefore be entered only after first entering Trusted Secure IP disabled mode or Trusted Secure IP enabled mode.

49.4.2 Setting the Module Stop Function

The module stop control register D (MSTPCRD) enables or disables operation of the Trusted Secure IP. After a reset, the Trusted Secure IP is stopped. After exiting the module stop state, the Trusted Secure IP can be accessed. Refer to section 11, Low Power Consumption for details.

49.4.3 Trusted Secure IP Library

Use of the Trusted Secure IP requires the Trusted Secure IP library provided by Renesas Electronics. Please contact our sales office for information regarding the Trusted Secure IP library.

50. 12-Bit A/D Converter (S12ADFa)

In this section, “PCLK” is used to refer to PCLKB.

50.1 Overview

This MCU incorporates two units of a 12-bit successive approximation A/D converter. Unit 0 for high-speed conversion can select analog input of up to 8 channels. Unit 1 for middle-speed conversion can select analog input of up to 12 channels, temperature sensor output, and internal reference voltage.

The 12-bit A/D converter converts analog input of up to 8 selected channels (unit 0) or up to 12 channels (unit 1), temperature sensor output, or internal reference voltage into a 12-bit digital value through successive approximation.

The A/D converter has three operating modes: single scan mode in which the analog inputs of eight arbitrarily selected channels (unit 0) and 12 channels (unit 1) are converted in ascending channel order; continuous scan mode in which the analog inputs of eight arbitrarily selected channels (unit 0) and 12 channels (unit 1) are continuously converted in ascending channel order; and group scan mode in which eight arbitrarily selected channels (unit 0) and 12 channels (unit 1) are arbitrarily divided into two groups (groups A and B) or three groups (groups A, B, and C) and converted in ascending channel order in each group.

In group scan mode, either two groups (groups A and B) or three groups (groups A, B, and C) is selected.

The conditions for scanning start of each group (A and B or A, B, and C) (synchronous trigger) can be independently selected, thus allowing A/D conversion of each group to be started independently.

During group priority operation, in addition to the above-mentioned operation, a trigger to start scanning for the priority group is accepted during scan for the low-priority group, and scan for the priority group is started after scan for the low-priority group was discontinued. The priority order is group A > group B > group C. Accordingly, as priority operation, when a trigger to start scanning for group B is accepted during scan for group C, group C scan is discontinued, and scan for group B is started. Likewise, when a trigger to start scanning for group A is accepted during scan for group C, group C scan is discontinued and scan for group A is started. In the same way, when a trigger to start scanning for group A is accepted during scan for group B, group B scan is discontinued and scan for group A is started.

The discontinued scan operation can be restarted after the scanning of the priority group is completed.

In double trigger mode, one analog input channel arbitrarily selected is converted in single scan mode or group scan mode (group A), and the resulting data of A/D conversion started by the first and second synchronous triggers are stored into different registers (duplication of A/D conversion data).

Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages internally generated in the 12-bit A/D converter is converted.

The temperature sensor output and internal reference voltage can be selected with analog input of the channels, and A/D conversion is performed in the order of the analog input of the channels, temperature sensor output, and internal reference voltage. A/D conversion of the extended analog input is independently performed.

The MCU incorporates the comparison function (with windows A and B). In addition, the value of A/D conversion and the reference value of the low side can be compared by a comparator.

Table 50.1 lists the specifications of the 12-bit A/D converter and Table 50.2 lists the functions of the 12-bit A/D converter. Figure 50.1 and Figure 50.2 show block diagrams of the 12-bit A/D converter.

Table 50.1 Specifications of 12-Bit A/D Converter (1/2)

Item	Description
Number of units	Two units (S12AD and S12AD1)
Input channels	Eight channels for S12AD and 12 channels for S12AD1 + 1 extension
Extended analog function	Temperature sensor output, internal reference voltage
A/D conversion method	Successive approximation method
Resolution	12 bits
Conversion time	0.48 µs per channel (12-bit conversion mode) 0.45 µs per channel (10-bit conversion mode) 0.42 µs per channel (8-bit conversion mode) (A/D conversion clock: when ADCLK operates at 60 MHz)
A/D conversion clock	Peripheral module clock PCLK*1 and A/D conversion clock ADCLK*1 can be set so that the frequency ratio should be one of the following. PCLK to ADCLK frequency ratio = 1:1, 2:1, 4:1, 8:1 ADCLK is set using the clock generation circuit.
Data registers	• 20 registers for analog input (eight for S12AD and 12 for S12AD1), 1 for A/D-converted data duplication in double trigger mode per unit, and 2 for A/D-converted data duplication during extended operation in double trigger mode per unit. • One register for temperature sensor (S12AD1) • One register for internal reference (S12AD1) • One register for self-diagnosis per unit • The results of A/D conversion are stored in 12-bit A/D data registers. • 8-, 10-, and 12-bit accuracy output for the results of A/D conversion • The value obtained by adding up A/D-converted results is stored as a value in the number of bit for conversion accuracy + 2 bits/4 bits*2 in the A/D data registers in A/D-converted value addition mode. • Double trigger mode (selectable in single scan and group scan modes): The first piece of A/D-converted analog-input data on one selected channel is stored in the data register for the channel, and the second piece is stored in the duplication register. • Extended operation in double trigger mode (available for specific triggers): A/D-converted analog-input data on one selected channel is stored in the duplication register that is prepared for each type of trigger.
Operating modes	Operating modes can be set independently for two units. • Single scan mode: A/D conversion is performed only once on the analog inputs arbitrarily selected. A/D conversion is performed only once on the temperature sensor output (S12AD1). A/D conversion is performed only once on the internal reference voltage (S12AD1). A/D conversion is performed only once on the extended analog input (S12AD1). • Continuous scan mode: A/D conversion is performed repeatedly on the analog input, temperature sensor output (S12AD1), and internal reference voltage (S12AD1) of the arbitrarily selected channel. A/D conversion is performed repeatedly on the extended analog input (S12AD1). • Group scan mode: Two (groups A and B) or three (groups A, B, and C) can be selected as the number of the groups to be used. Only the combination of groups A and B can be selected when the number of the groups is two. Analog inputs, temperature sensor output (S12AD1), and internal reference voltage (S12AD1) that are arbitrarily selected are divided into two groups (group A and B) or three groups (group A, B, and C), and A/D conversion of the analog input selected on a group basis is performed only once. The conditions for scanning start of groups A, B, and C (synchronous trigger) can be independently selected, thus allowing A/D conversion of each group to be started independently. • Group scan mode (when group priority control selected): If a priority-group trigger is input during scanning of the low-priority group, scan of the low-priority group is stopped and scan of the priority group is started. The priority order is group A (highest) > group B > group C (lowest). Whether or not to restart scanning of the low-priority group after processing for the high-priority group completes, is selectable. Rescan can also be set to start either from the beginning of the selected channel or the channel on which A/D conversion is not completed.

Table 50.1 Specifications of 12-Bit A/D Converter (2/2)

Item	Description
Conditions for A/D conversion start	• Software trigger • Synchronous trigger Trigger by the multi-function timer pulse unit (MTU), 8-bit timer (TMR), 16-bit timer pulse unit (TPU), or event link controller (ELC). • Asynchronous trigger A/D conversion can be triggered by the external trigger ADTRG0# (S12AD) or ADTRG1# (S12AD1) pin (independently for two units).
Functions	• Variable sampling state count (settable for each channel) • Self-diagnosis of 12-bit A/D converter • Selectable A/D-converted value addition mode or average mode • Analog input disconnection detection assist function (discharge function/precharge function) • Double trigger mode (duplication of A/D conversion data) • 12-/10-/8-bit conversion switching • Automatic clear function of A/D data registers • Extended analog input • Comparison function (windows A and B)
Interrupt sources	• In the modes except double trigger mode and group scan mode, a scan end interrupt request (S12ADI or S12ADI1) can be generated on completion of single scan (independently for two units). • In double trigger mode, a scan end interrupt request (S12ADI or S12ADI1) can be generated on completion of double scan (independently for two units). • In group scan mode, a scan end interrupt request (S12ADI or S12ADI1) can be generated on completion of group A scan, whereas a scan end interrupt request (S12GBADI or S12GBADI1) for group B can be generated on completion of group B scan, and a group C scan end interrupt request (S12GCADI or S12GCADI1) can be generated on completion of group C scan. • When double trigger mode is selected in group scan mode, an A/D scan end interrupt request (S12ADI or S12ADI1) can be generated on completion of double scan of group A, and the corresponding scan end interrupt request (S12GBADI/S12GCADI or S12GBADI1/S12GCADI1) can be generated on completion of group B and group C scan. • A compare interrupt request (S12CMPAI, S12CMPAI1, S12CMPBI, or S12CMPBI1) can be generated upon a match with the comparison condition for the digital compare function. • The S12ADI/S12ADI1, S12GBADI/S12GBADI1, and S12GCADI/S12GCADI1 interrupts can activate the DMA controller (DMAC) and data transfer controller (DTC).
Event link	• An ELC event is generated upon completion of all scans • Able to start scanning by a trigger from the ELC
Low power consumption function	• Module stop state can be set.*3, *4

Note 1. The frequency of PCLK, the peripheral module clock, becomes that set in the SCKCR.PCKB[3:0] bits, and that of ADCLK, the A/D conversion clock, becomes the frequency set in the SCKCR.PCKC[3:0] bits for unit 0 (S12AD), and that set in the SCKCR.PCKD[3:0] bits for unit 1 (S12AD1).
Note 2. The number of extended bits during addition differs depending on the addition count.
2-bit extension: 1-time to 4-time conversion (add zero to three times)
4-bit extension: 16-time conversion (add 15 times)
Note 3. See section 11, Low Power Consumption for details.
Note 4. Wait for 1 µs or longer to start A/D conversion after release from the module stop state.

Table 50.2 Functions of 12-Bit A/D Converter

Item			Pin Name, Abbreviation	
			Unit 0 (S12AD)	Unit 1 (S12AD1)
Analog input channels			AN000 to AN007	AN100 to AN111, internal reference voltage, temperature sensor output, extended input
Conditions for A/D conversion start	Software	Software trigger	Enabled	
	Asynchronous trigger	Trigger input pin	ADTRG0#	ADTRG1#
	Synchronous trigger	Compare match/input capture from MTU0.TGRA	TRGA0N	
		Compare match/input capture from MTU1.TGRA	TRGA1N	
		Compare match/input capture from MTU2.TGRA	TRGA2N	
		Compare match/input capture from MTU3.TGRA	TRGA3N	
		Compare match/input capture from MTU4.TGRA or underflow (trough) of MTU4.TCNT in complementary PWM mode	TRGA4N	
		Compare match/input capture from MTU6.TGRA	TRGA6N	
		Compare match/input capture from MTU7.TGRA or underflow (trough) of MTU7.TCNT in complementary PWM mode	TRGA7N	
		Compare match from MTU0.TGRE	TRG0N	
		Compare match between MTU4.TADCORA and MTU4.TCNT	TRG4AN	
		Compare match between MTU4.TADCORB and MTU4.TCNT	TRG4BN	
		Compare match between MTU4.TADCORA and MTU4.TCNT, or compare match between MTU4.TADCORB and MTU4.TCNT	TRG4AN or TRG4BN	
		Compare match between MTU4.TADCORA and MTU4.TCNT, and compare match between MTU4.TADCORB and MTU4.TCNT (when interrupt skipping function 2 is used)	TRG4ABN	
		Compare match between MTU7.TADCORA and MTU7.TCNT	TRG7AN	
		Compare match between MTU7.TADCORB and MTU7.TCNT	TRG7BN	
		Compare match between MTU7.TADCORA and MTU7.TCNT, or compare match between MTU7.TADCORB and MTU7.TCNT	TRG7AN or TRG7BN	
		Compare match between MTU7.TADCORA and MTU7.TCNT, and compare match between MTU7.TADCORB and MTU7.TCNT (when interrupt skipping function 2 is used)	TRG7ABN	
		Compare match between TMR0.TCORA and TMR0.TCNT	TMTRG0AN_0	
		Compare match between TMR2.TCORA and TMR2.TCNT	TMTRG0AN_1	
		Compare match/input capture from TPU0.TGRA or compare match/input capture from TPU1.TGRA or compare match/input capture from TPU2.TGRA or compare match/input capture from TPU3.TGRA or compare match/input capture from TPU4.TGRA	TPTRGAN	
		Compare match/input capture from TPU0.TGRA0	TPTRG0AN	
		ELC trigger	ELCTRG0N	ELCTRG1N
Interrupts			S12ADI, S12GBADI, S12GCADI, S12CMPAI, S12CMPBI interrupt	S12ADI1, S12GBADI1, S12GCADI1, S12CMPAI1, S12CMPBI1 interrupt
Setting of module stop function*1, *2			MSTPCRA.MSTPA17 bit	MSTPCRA.MSTPA16 bit

Note: When setting an A/D conversion start trigger to ADTRG0# or ADTRG1#, set the pin mode control bit in the port mode register for the corresponding pin to 1 (peripheral functions), and set the pin function select bit in the pin function control register to ADTRG0# or ADTRG1#. See section 22, I/O Ports for details.

Note 1. See section 11, Low Power Consumption for details.

Note 2. Wait for 1 µs or longer to start A/D conversion after release from the module stop state.

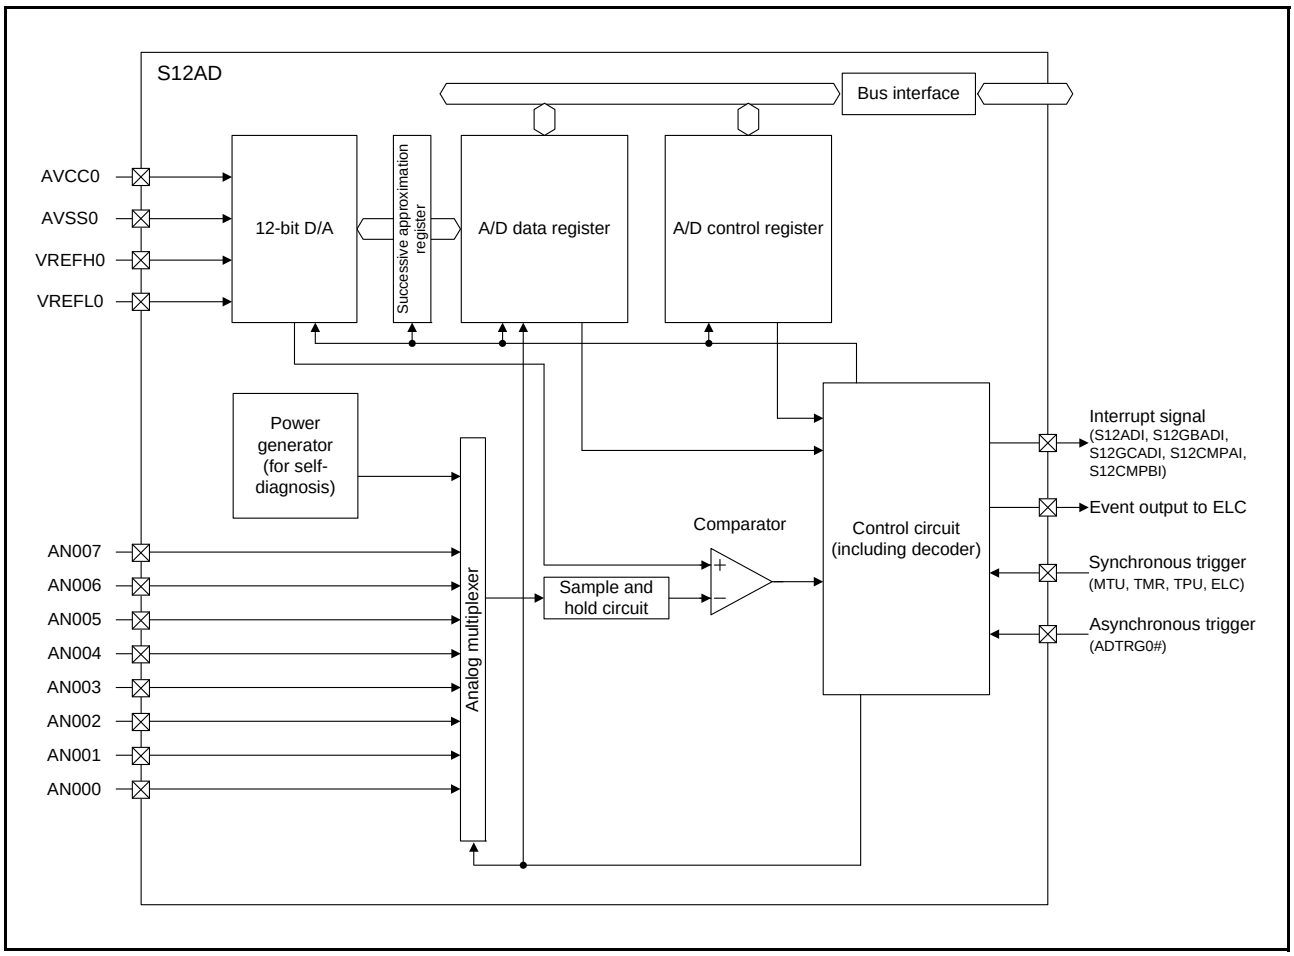

Figure 50.1 Block Diagram of 12-Bit A/D Converter (Unit 0)

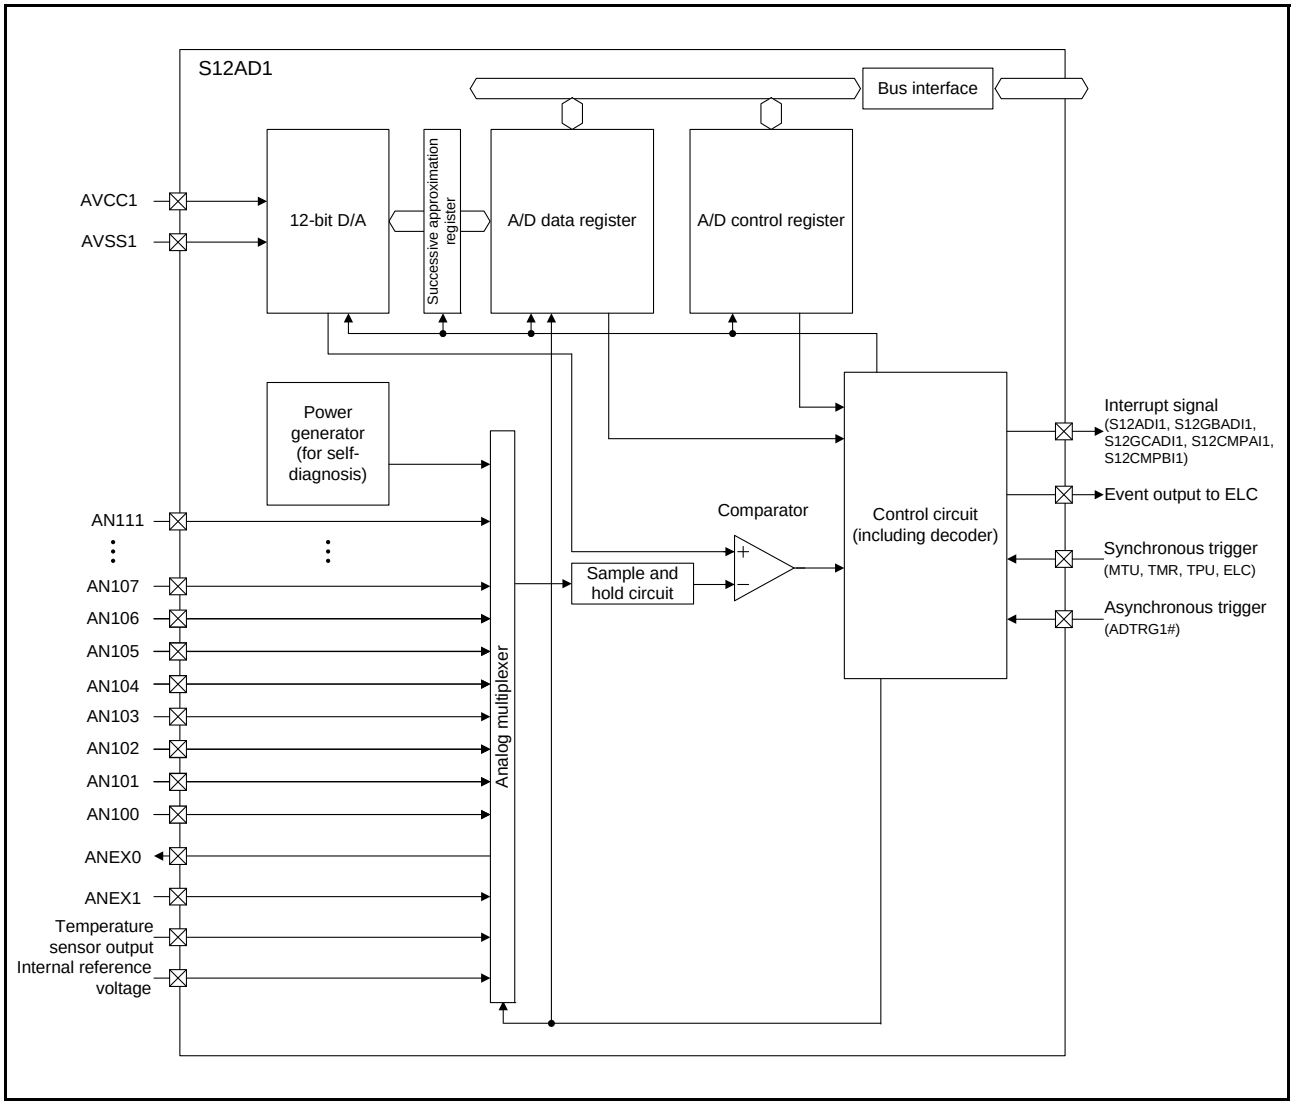

Figure 50.2 Block Diagram of 12-Bit A/D Converter (Unit 1)

Table 50.3 lists the input/output pins of the 12-bit A/D converter.

The 12-bit A/D converter consists of two units, unit 0 (S12AD) and unit 1 (S12AD1). These units can be operated independently. The input channels of S12AD and S12AD1 can be divided into three groups for operation.

Table 50.3 Input/Output Pins of 12-Bit A/D Converter

Unit	Pin Name	I/O	Function
Unit 0 (S12AD)	AVCC0	—	Analog block power supply pin
	AVSS0	—	Analog block ground pin
	VREFH0	Input	Reference power supply pin
	VREFL0	Input	Reference power supply ground pin
	AN000 to AN007	Input	Analog input pins
	ADTRG0#	Input	External trigger input pin for starting A/D conversion
Unit 1 (S12AD1)	AVCC1	—	Multiplexed analog block power supply and reference power supply pin functions
	AVSS1	—	Multiplexed analog block ground and reference power supply ground pin functions
	AN100 to AN111	Input	Analog input pins
	ANEX0	Output	Extended analog output pin
	ANEX1	Input	Extended analog input pin
	ADTRG1#	Input	External trigger input pin for starting A/D conversion

50.2 Register Descriptions

50.2.1 A/D Data Registers y (ADDRy) (y = 0 to 11), A/D Data Duplication Register (ADDBLDR), A/D Data Duplication Register A (ADDBLDRA), A/D Data Duplication Register B (ADDBLDRB), A/D Temperature Sensor Data Register (ADTSDR), A/D Internal Reference Voltage Data Register (ADOCDR)

Address(es): S12AD.ADDR0 0008 9020h, S12AD.ADDR1 0008 9022h, S12AD.ADDR2 0008 9024h, S12AD.ADDR3 0008 9026h, S12AD.ADDR4 0008 9028h, S12AD.ADDR5 0008 902Ah, S12AD.ADDR6 0008 902Ch, S12AD.ADDR7 0008 902Eh, S12AD.ADDBLDR 0008 9018h, S12AD.ADDBLDRA 0008 9084h, S12AD.ADDBLDRB 0008 9086h, S12AD1.ADDR0 0008 9120h, S12AD1.ADDR1 0008 9122h, S12AD1.ADDR2 0008 9124h, S12AD1.ADDR3 0008 9126h, S12AD1.ADDR4 0008 9128h, S12AD1.ADDR5 0008 912Ah, S12AD1.ADDR6 0008 912Ch, S12AD1.ADDR7 0008 912Eh, S12AD1.ADDR8 0008 9130h, S12AD1.ADDR9 0008 9132h, S12AD1.ADDR10 0008 9134h, S12AD1.ADDR11 0008 9136h, S12AD1.ADDBLDR 0008 9118h, S12AD1.ADDBLDRA 0008 9184h, S12AD1.ADDBLDRB 0008 9186h, S12AD1.ADTSDR 0008 911Ah, S12AD1.ADOCDR 0008 911Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The ADDRy registers (y = 0 to 7 for S12AD; y = 0 to 11 for S12AD1) are 16-bit read-only registers which store the A/D conversion results.
The ADDBLDR register is a 16-bit read-only register used in double trigger mode. The ADDBLDR register stores the results of A/D conversion when the conversion is started by the second trigger.
The ADDBLDRA and ADDBLDRB registers are 16-bit read-only registers that store the A/D conversion results in response to the respective triggers during extended operation in double trigger mode.
The ADTSDR register is a 16-bit read-only register that stores the A/D converted value of the temperature sensor output.
The ADOCDR register is a 16-bit read-only register that stores the A/D conversion results of the internal reference voltage.
The format of each register differs depending on the conditions below.

- Settings of the A/D data register format select bit (ADCER.ADRFMT) (flush-right or flush-left)
- Settings of the A/D data register bit resolution setting bits (ADCER.ADPRC[1:0]) (12-, 10-, or 8-bit)
- Settings of the addition count select bits (ADADC.ADC[2:0]) (2-, 3-, 4-, or 16-time conversion)
- Settings of the average mode enable bit (ADADC.AVEE) (add or average)

The data formats for each given condition are shown below.

(1) When A/D-Converted Value Addition/Average Mode is Not Selected

- Flush-right format with setting of 12-bit resolution
  The A/D-converted value is stored in bits 11 to 0. Bits 15 to 12 are read as 0.
- Flush-right format with setting of 10-bit resolution
  The A/D-converted value is stored in bits 9 to 0. Bits 15 to 10 are read as 0.
- Flush-right format with setting of 8-bit resolution
  The A/D-converted value is stored in bits 7 to 0. Bits 15 to 8 are read as 0.
- Flush-left format with setting of 12-bit resolution
  The A/D-converted value is stored in bits 15 to 4. Bits 3 to 0 are read as 0.
- Flush-left format with setting of 10-bit resolution
  The A/D-converted value is stored in bits 15 to 6. Bits 5 to 0 are read as 0.
- Flush-left format with setting of 8-bit resolution

The A/D-converted value is stored in bits 15 to 8. Bits 7 to 0 are read as 0.

(2) When A/D-Converted Average Mode is Selected

- Flush-right format with setting of 12-bit resolution
  The mean value of the A/D-converted results of the same channel is stored in bits 11 to 0.
  Bits 15 to 12 are read as 0.
- Flush-right format with setting of 10-bit resolution
  The mean value of the A/D-converted results of the same channel is stored in bits 9 to 0.
  Bits 15 to 10 are read as 0.
- Flush-right format with setting of 8-bit resolution
  The mean value of the A/D-converted results of the same channel is stored in bits 7 to 0.
  Bits 15 to 8 are read as 0.
- Flush-left format with setting of 12-bit resolution
  The mean value of the A/D-converted results of the same channel is stored in bits 15 to 4.
  Bits 3 to 0 are read as 0.
- Flush-left format with setting of 10-bit resolution
  The mean value of the A/D-converted results of the same channel is stored in bits 15 to 6.
  Bits 5 to 0 are read as 0.
- Flush-left format with setting of 8-bit resolution
  The mean value of the A/D-converted results of the same channel is stored in bits 15 to 8.
  Bits 7 to 0 are read as 0.

A/D-converted value average mode can be set only when 2- or 4-time conversion is selected in A/D-converted value addition mode.

(3) When A/D-Converted Value Addition Mode is Selected

- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 12-bit resolution
  The value added by the A/D-converted value of the same channel is stored in bits 13 to 0.
  Bits 15 and 14 are read as 0.
- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 10-bit resolution
  The value added by the A/D-converted value of the same channel is stored in bits 11 to 0.
  Bits 15 to 12 are read as 0.
- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 8-bit resolution
  The value added by the A/D-converted value of the same channel is stored in bits 9 to 0.
  Bits 15 to 10 are read as 0.
- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 16 times) with setting of 12-bit resolution
  The value added by the A/D-converted value of the same channel is stored in bits 15 to 0.
  When the 16-time conversion is selected, setting with 10- or 8-bit resolution is prohibited.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 12-bit resolution
  The value added by the A/D-converted value of the same channel is stored in bits 15 to 2.
  Bits 1 and 0 are read as 0.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 10-bit resolution
  The value added by the A/D-converted value of the same channel is stored in bits 15 to 4.
  Bits 3 to 0 are read as 0.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4

times) with setting of 8-bit resolution
The value added by the A/D-converted value of the same channel is stored in bits 15 to 6.
Bits 5 to 0 are read as 0.

- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 16 times) with setting of 12-bit resolution
  The value added by the A/D-converted value of the same channel is stored in bits 15 to 0.
  When the 16-time conversion is selected, setting with 10- or 8-bit resolution is prohibited.

When A/D-converted addition mode is selected, the value added by the A/D-converted value of the same channel is indicated. The number of A/D conversions can be set to 1, 2, 3, 4, or 16 times. If A/D-converted addition mode is selected, when the conversion count is set to 1 to 4 times, the value added by the A/D conversion result is retained in the A/D data register as 2-bit extended data of the conversion accuracy bits; when the conversion count is set to 16 times, the value added by the A/D conversion result is retained in the A/D data register as 4-bit extended data of the conversion accuracy bits. Even if A/D-converted value addition mode is selected, the value is stored in the A/D data register according to the settings of the A/D data register format select bits. When the 16-time conversion is selected, setting with 10- or 8-bit resolution is prohibited.

50.2.2 A/D Self-Diagnosis Data Register (ADRD)

Address(es): S12AD.ADRD 0008 901Eh, S12AD1.ADRD 0008 911Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ADRD is a 16-bit read-only register that stores the A/D conversion results based on the 12-bit A/D converter's self-diagnosis. In addition to the A/D-converted value, the self-diagnosis status is included in. In the ADRD register, the different formats are used depending on the conditions below.

- Settings of the A/D data register format select bit (ADCER.ADRFMT) (flush-right or flush-left)
- Settings of the A/D data register bit resolution setting bits (ADCER.ADPRC[1:0]) (12-, 10-, or 8-bit)

The A/D-converted value addition mode and A/D-converted value average mode cannot be applied to the A/D self-diagnosis function. For details of self-diagnosis, see section 50.2.9, A/D Control Extended Register (ADCER).

The data formats for each given condition are shown below.

- Flush-right format with setting of 12-bit resolution
  The A/D-converted value is stored in bits 11 to 0. The self-diagnosis status is stored in bits 15 and 14. Bits 13 and 12 are read as 0.
- Flush-right format with setting of 10-bit resolution
  The A/D-converted value is stored in bits 9 to 0. The self-diagnosis status is stored in bits 15 and 14. Bits 13 to 10 are read as 0.
- Flush-right format with setting of 8-bit resolution
  The A/D-converted value is stored in bits 7 to 0. The self-diagnosis status is stored in bits 15 and 14. Bits 13 to 8 are read as 0.
- Flush-left format with setting of 12-bit resolution
  The A/D-converted value is stored in bits 15 to 4. The self-diagnosis status is stored in bits 1 and 0. Bits 3 and 2 are read as 0.
- Flush-left format with setting of 10-bit resolution
  The A/D-converted value is stored in bits 15 to 6. The self-diagnosis status is stored in bits 1 and 0. Bits 5 to 2 are read as 0.
- Flush-left format with setting of 8-bit resolution
  The A/D-converted value is stored in bits 15 to 8. The self-diagnosis status is stored in bits 1 and 0. Bits 7 to 2 are read as 0.

Table 50.4 Self-Diagnosis Status Description

Bits 15 and 14 for flush-right format setting Bits 1 and 0 for flush-left format setting	Self-diagnosis status
00b	Self-diagnosis has never been executed since power-on.
01b	Self-diagnosis using the voltage of 0 V has been executed.
10b	Self-diagnosis using the voltage of reference power supply × 1/2 has been executed.
11b	Self-diagnosis using the voltage of reference power supply has been executed.

Note: For details of self-diagnosis, see section 50.2.9, A/D Control Extended Register (ADCER).

50.2.3 A/D Control Register (ADCSR)

Address(es): S12AD.ADCSR 0008 9000h, S12AD1.ADCSR 0008 9100h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	DBLANS[4:0]	Double Trigger Channel Select	These bits select one analog input channel for double triggered operation. The setting is only effective while double trigger mode is selected.	R/W
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6	GBADIE	Group B Scan End Interrupt Enable	0: Disables interrupt generation upon group B scan completion. 1: Enables interrupt generation upon group B scan completion.	R/W
b7	DBLE	Double Trigger Mode Select	0: Deselects double trigger mode. 1: Selects double trigger mode.	R/W
b8	EXTRG	Trigger Select*1	0: A/D conversion is started by synchronous trigger. 1: A/D conversion is started by asynchronous trigger.	R/W
b9	TRGE	Trigger Start Enable	0: Disables A/D conversion to be started by synchronous or asynchronous trigger. 1: Enables A/D conversion to be started by synchronous or asynchronous trigger.	R/W
b11, b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12	ADIE	Scan End Interrupt Enable	0: Disables interrupt generation upon scan completion. 1: Enables interrupt generation upon scan completion.	R/W
b14, b13	ADCS[1:0]	Scan Mode Select	b14 b13 0 0: Single scan mode 0 1: Group scan mode 1 0: Continuous scan mode 1 1: Setting prohibited	R/W
b15	ADST	A/D Conversion Start	0: Stops A/D conversion process. 1: Starts A/D conversion process.	R/W

Note 1. Starting A/D conversion using an external pin (asynchronous trigger)
Set the ADCSR.TRGE and EXTRG bits to 1 while a high-level signal is input to the external pin (ADTRG0# or ADTRG1#). Then, if the ADTRG0# or ADTRG1# signal is changed to low, the falling edge is detected and the scan process is started. In this case, the pulse width of the low-level input must be at least 1.5 clock cycles of PCLK.
The relationship between each unit and the external pin (asynchronous trigger) is shown below.

Unit	External pin (asynchronous trigger)
S12AD	ADTRG0#
S12AD1	ADTRG1#

ADCSR sets double trigger mode, A/D conversion start trigger; enables/disables scan end interrupt; selects the scan mode; and starts or stops A/D conversion.

DBLANS[4:0] Bits (Double Trigger Channel Select)

The DBLANS[4:0] bits select one of the channels for A/D conversion data duplication in double trigger mode. The A/D conversion results of the analog input of the channel selected by the DBLANS[4:0] bits are stored into the A/D data register y when conversion is started by the first trigger, and into the A/D data duplication register when started by the second trigger. Table 50.5 shows selection of the channel for double triggered operation.
When double trigger mode is selected, the channels selected by the ADANSA0 register are invalid, and the channel selected by the DBLANS[4:0] bits is subjected to A/D conversion instead.
When double trigger mode is selected in group scan mode, double trigger mode operation is performed for group A only

and not performed for group B or C. Also, in double trigger mode, the analog inputs of multiple channels, temperature sensor outputs, or internal reference voltage cannot be selected for group A, but can be selected for groups B and C.
The DBLANS[4:0] bits should be set while the ADST bit is 0. They should not be set simultaneously when 1 is written to the ADST bit.

Table 50.5 Relationship between DBLANS[4:0] Bits Settings and Double Trigger Enabled Channels

S12AD (Unit 0)		S12AD1 (Unit 1)			
DBLANS[4:0]	Duplication Channel	DBLANS[4:0]	Duplication Channel	DBLANS[4:0]	Duplication Channel
00000b	AN000	00000b	AN100	01000b	AN108
00001b	AN001	00001b	AN101	01001b	AN109

00011b	AN003	00011b	AN103	01011b	AN111
00100b	AN004	00100b	AN104		
00101b	AN005	00101b	AN105		
00110b	AN006	00110b	AN106		
00111b	AN007	00111b	AN107		

Note: Duplication cannot be selected for the A/D conversion data of self-diagnosis, temperature sensor output, and internal reference voltage.

GBADIE Bit (Group B Scan End Interrupt Enable)

The GBADIE bit enables or disables group B scan end interrupt in group scan mode.
A scan end interrupt for group B is provided individually for each unit. Table 50.6 shows the relationship between each unit and the scan end interrupt for group B.

Table 50.6 Relationship between Each Unit and Group B Scan End Interrupt

Unit	Group B Scan End Interrupt
S12AD	S12GBADI
S12AD1	S12GBADI1

DBLE Bit (Double Trigger Mode Select)

Double trigger mode has a function to store the resulting data of A/D conversion started by the first and second synchronous triggers into separate registers.
When double trigger mode is selected, the channels specified in the ADANSA0 register are invalid and the channel selected by the DBLANS[4:0] bits is effective instead. Double trigger mode can be only operated by the synchronous trigger selected by the ADSTRGR.TRSA[5:0] bits. Do not generate an asynchronous or software trigger. The A/D conversion results started by the first trigger are stored into the A/D data register y and those started by the second trigger are stored into the A/D data duplication register. In this case, if the ADIE bit is set to 1, the interrupt is generated not upon completion of the first conversion but upon completion of the second conversion.
In continuous scan mode, double trigger mode should not be selected. In addition, double trigger mode should not be used for self-diagnosis, or conversion of the temperature sensor output and internal reference voltage. When using double trigger mode in group scan mode, A/D conversion of the internal reference voltage should not be selected for group A.
The DBLE bit should be set after the ADST bit has been set to 0.

EXTRG Bit (Trigger Select)

The EXTRG bit selects the synchronous trigger or the asynchronous trigger as the trigger for starting A/D conversion. In group scan mode, the setting of this bit is valid for the selected trigger of group A.
For groups B and C, A/D conversion is started by the selected synchronous trigger regardless of this bit setting.

TRGE Bit (Trigger Start Enable)

The TRGE bit enables or disables A/D conversion by the synchronous trigger and the asynchronous trigger.
This bit should be set to 1 in group scan mode.

ADIE Bit (Scan End Interrupt Enable)

The ADIE bit enables or disables the A/D scan end interrupt (S12ADI) in scans except for groups B and C scan in group scan mode.
With double trigger mode deselected, the A/D scan conversion end is generated after the first scan is completed if the ADIE bit is set to 1.
When the extended analog input is selected also, if the ADIE bit is set to 1 when A/D conversion is completed, an A/D scan conversion end interrupt is generated.
With double trigger mode selected, the A/D scan conversion end is generated after the second scan is completed if the ADIE bit is set to 1 as long as the scan is started by the synchronous trigger selected by the ADSTRGR.TRSA[5:0] bits.
When scan is started by a software trigger, even with double trigger mode selected, the A/D scan conversion end interrupt is generated if the ADIE bit is set to 1 when the scan is completed. The A/D scan conversion end interrupt is provided individually for each unit. Table 50.7 shows the relationship between each unit and the A/D scan conversion end interrupt.

Table 50.7 Relationship between Each Unit and A/D scan conversion end Interrupt

Unit	A/D scan conversion end interrupt
S12AD	S12ADI
S12AD1	S12ADI1

ADCS[1:0] Bits (Scan Mode Select)

The ADCS[1:0] bits select the scan mode.
In single scan mode, A/D conversion is performed for the analog inputs selected with the ADANSA0 register in the ascending order of the channel number, and when one cycle of A/D conversion is completed for all the selected channels, the scan conversion is stopped.*1
In continuous scan mode, while the ADCSR.ADST bit is 1, A/D conversion is performed for the analog inputs selected with the ADANSA0 register in the ascending order of the channel number, and when one cycle of A/D conversion is completed for all the selected channels, A/D conversion is repeated from the first channel. If the ADCSR.ADST bit is set to 0 during continuous scan, A/D conversion is stopped even if scanning is in progress.*1
In group scan mode, A/D conversion is performed for the analog inputs (group A) selected with the ADANSA0 register in the ascending order of the channel number after scanning is started by the synchronous trigger selected by the ADSTRGR.TRSA[5:0] bits, and when one cycle of A/D conversion is completed for all the selected channels, A/D conversion is stopped.*1 A/D conversion is also performed for the analog inputs (group B or C) selected with the ADANSB0 register and the ADANSC0 register in the ascending order of the channel number after A/D conversion is started by the synchronous trigger selected by the ADSTRGR.TRSB[5:0] bits and ADGCTRGR.TRSC[5:0] bits, and when A/D conversion is completed for all the selected channels, A/D conversion is stopped.*1
When selecting group scan mode, different channels and triggers should be selected for groups A, B, and C.
When using two groups while group scan mode is set, use groups A and B (ADGCTRGR.GRCE bit = 0). When using three groups, use groups A, B, and C (ADGCTRGR.GRCE bit = 1).
When selecting the extended analog input, select single scan mode or sequence scan mode.
The ADCS[1:0] bits should be set while the ADST bit is 0. They should not be set simultaneously when 1 is written to the ADST bit.

Note 1. When the temperature sensor output or internal reference voltage is selected, after A/D conversion of the analog input, A/D conversion is performed on the temperature sensor output and internal reference voltage in this order.

Table 50.8 Selection of Scan Mode, Double Trigger Mode, and Targets for A/D Conversion

Scan Mode Setup	Double Trigger Mode Setting	Targets for A/D Conversion					
		Self-diagnosis	Analogue Input (Including Group A)	Analogue Input (Group B and Group C)	Temperature Sensor Output	Internal Reference Voltage	Extended Analog Input
Single scan	DBLE = 0	✓	✓	×	✓	✓	✓
	DBLE = 1	×	✓ (1 channel only)	×	×	×	×
Sequence scan	DBLE = 0	✓	✓	×	✓	✓	✓
	DBLE = 1	×	×	×	×	×	×
Group scan	DBLE = 0	✓	✓	✓	✓	✓	×
	DBLE = 1	×	✓ (1 channel only)	✓	✓ (Group B and Group C)	✓ (Group B and Group C)	×

✓: Selectable, ×: Not selectable

Note: When selecting the extended analog input, deselect other targets for A/D conversion.

ADST Bit (A/D Conversion Start)

The ADST bit starts or stops A/D conversion process.

Before the ADST bit is set to 1, set the A/D conversion clock, the conversion mode, and conversion target analog input.

[Setting conditions]

- 1 is written by software.
- The synchronous trigger selected by the ADSTRGR.TRSA[5:0] bits is detected with ADCSR.EXTRG and ADCSR.TRGE bits being set to 0 and 1, respectively.
- The synchronous trigger selected by the ADSTRGR.TRSB[5:0] bits is detected with the ADCSR.TRGE bit being set to 1 in group scan mode.
- The asynchronous trigger is detected with the ADCSR.TRGE and ADCSR.EXTRG bits being set to 1 and the ADSTRGR.TRSA[5:0] bits being set to 000000b.
- With group priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), a group B or C trigger is detected and A/D conversion of group B or C is started.
- With group priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADGSPCR.GBRSCN bit is set to 1 and A/D conversion of group B or C is restarted.
- With group priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADGSPCR.GBRP bit is set to 1 and A/D conversion of the lowest-priority group is started.

[Clearing conditions]

- 0 is written by software.
- The A/D conversion of all the selected channels, temperature sensor output, or the internal reference voltage (for S12AD1 only) is completed in single scan mode.
- A/D conversion of extended analog inputs is completed in single scan mode.
- Group A scan is completed in group scan mode.
- Group B scan is completed in group scan mode.
- Group C scan is completed in group scan mode.
- With group priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADGSPCR.GBRSCN bit is set to 1 and the scanning of the low-priority group started by a trigger is stopped.

Note: When group priority control operation mode has been enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), do not set the ADST bit to 1.

Note: When group priority control operation mode has been enabled (ADCSR.ADCS[1:0] bits = 01b and

ADGSPCR.PGS bit = 1) and ADGSPCR.GBRP = 1, do not set the ADST bit to 0. When forcibly terminating A/D conversion, follow the procedure for clearing the ADST bit.

Note: When the single-scan continuous function is used (ADGSPCR.GBRP bit = 1) with group priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADST bit remains as 1.

50.2.4 A/D Channel Select Register A0 (ADANSA0)

(1) S12AD.ADANSA0

Address(es): 0008 9004h

S12AD.ADANSC0 selects analog input channels for A/D conversion from among AN000 to AN007 in group C when group scan mode is selected. The S12AD.ADANSC0 register is not used in any scan mode other than group scan mode.

ANSC0n Bit (n = 00 to 07) (A/D Conversion Channel Select)

The ANSC0n bit select analog input channels for A/D conversion from among AN000 to AN007 in group C when group scan mode is selected. The S12AD.ADANSC0 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the channels corresponding to group A, selected with the S12AD.ADANSA0 register and the S12AD.ADCSR.DBLANS[4:0] bits in double trigger mode) should be excluded as the channels to be selected and the number of channels to be set.

The ANSC000 bit corresponds to AN000 and the ANSC007 bit corresponds to AN007.

The ANSC0n bit should be set while the S12AD.ADCSR.ADST bit is 0.

S12AD1.ADANSC0 selects analog input channels for A/D conversion from among AN100 to AN111 in group C when group scan mode is selected. The S12AD1.ADANSC0 register is not used in any scan mode other than group scan mode.

ANSC0n Bit (n = 00 to 11) (A/D Conversion Channel Select)

The ANSC0n bit select analog input channels for A/D conversion from among AN100 to AN111 in group C when group scan mode is selected. The S12AD1.ADANSC0 register is used for group scan mode only; not used for any other modes. The channels specified in group A (the channels corresponding to group A, selected with the S12AD1.ADANSA0 register and the S12AD1.ADCSR.DBLANS[4:0] bits in double trigger mode) should be excluded as the channels to be selected and the number of channels to be set.

The ANSC000 bit corresponds to AN100 and the ANSC011 bit corresponds to AN111.

The ANSC0n bit should be set while the S12AD1.ADCSR.ADST bit is 0.

50.2.7 A/D-Converted Value Addition/Average Function Channel Select Register 0 (ADADS0)

(1) S12AD.ADADS0

Address(es): 0008 9008h

b7	ADS007			R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

S12AD.ADADS0 selects channels AN000 to AN007 on which A/D conversion is performed successively 2, 3, 4, or 16 times and then converted values are added (integrated) or averaged.

ADS0n Bit (n = 00 to 07) (A/D-Converted Value Addition/Average Channel Select)

When the ADS0n bit of the number that is the same as that of A/D-converted channel selected by the S12AD.ADANSA0.ANSA0n bit (n = 00 to 07) or S12AD.ADCSR.DBLANS[4:0] bits and S12AD.ADANSB0.ANSB0n bit is set to 1, A/D conversion of analog input of the selected channels is performed successively 2, 3, 4, or 16 times that is set with the S12AD.ADADC.ADC[2:0] bits.

When the S12AD.ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D data register.

When the S12AD.ADADC.AVEE bit is 1, the mean value of the results obtained by addition (integration) is stored in the A/D data register.

As for the channel on which the A/D conversion is performed and addition/average mode is not selected, a normal one-time conversion is executed and the conversion result is stored to the A/D data register.

The ADS0n bit should be set while the S12AD.ADCSR.ADST bit is 0.

S12AD1.ADADS0 selects channels AN100 to AN111 on which A/D conversion is performed successively 2, 3, 4, or 16 times and then converted values are added (integrated) or averaged.

ADS0n Bit (n = 00 to 11) (A/D-Converted Value Addition/Average Channel Select)

When the ADS0n bit of the number that is the same as that of A/D-converted channel selected by the S12AD1.ADANSA0.ANSA0n bit (n = 00 to 11) or S12AD1.ADCSR.DBLANS[4:0] bits and S12AD1.ADANSB0.ANSB0n bit and S12AD1.ADANSC0.ANSC0n bit is set to 1, A/D conversion of analog input of the selected channels is performed successively 2, 3, 4, or 16 times that is set with the S12AD1.ADADC.ADC[2:0] bits.
When the S12AD1.ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D data register.
When the S12AD1.ADADC.AVEE bit is 1, the mean value of the results obtained by addition (integration) is stored in the A/D data register.
As for the channel on which the A/D conversion is performed and addition/average mode is not selected, a normal one-time conversion is executed and the conversion result is stored to the A/D data register.
The ADS0n bit should be set while the S12AD1.ADCSR.ADST bit is 0.

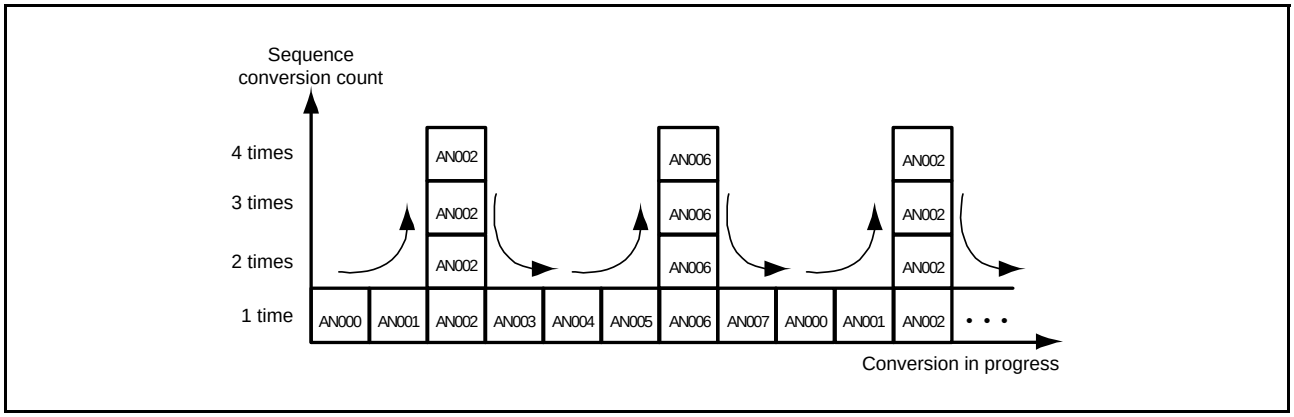

Figure 50.3 Scan Conversion Sequence with S12AD.ADADC.ADC[2:0] = 011b, S12AD.ADADC.AVEE = 0, S12AD.ADADS0.ADS002 = 1, and S12AD.ADADS0.ADS006 = 1

50.2.8 A/D-Converted Value Addition/Average Count Select Register (ADADC)

Address(es): S12AD.ADADC 0008 900Ch, S12AD1.ADADC 0008 910Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	AVEE	—	—	—	—	ADC[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	ADC[2:0]	Addition Count Select	b2 b0 0 0 0: 1-time conversion (no addition; same as normal conversion) 0 0 1: 2-time conversion (addition once) 0 1 0: 3-time conversion (addition twice)*1 0 1 1: 4-time conversion (addition three times) 1 0 1: 16-time conversion (addition 15 times)*1 Settings other than above are prohibited.	R/W
b6 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	AVEE	Average Mode Enable	0: Addition mode is selected. 1: Average mode is selected.	R/W

Note 1. The AVEE bit is enabled only when 2-time or 4-time conversion is selected. When average mode is selected (ADADC.AVEE bit = 1), do not set 3-time conversion (ADADC.ADC[2:0] = 010b) nor 16-time conversion (ADADC.ADC[2:0] = 101b).

ADADC sets the addition count for A/D conversion of the channel, temperature sensor output, and internal reference voltage for which A/D-converted value addition/average mode is selected, and selects either addition or average mode.

ADC[2:0] Bits (Addition Count Select)

The ADC[2:0] bits set the addition count common to the channels for which A/D conversion and A/D-converted value addition/average mode is selected, including the channels selected in double trigger mode (by ADCSR.DBLANS[4:0] bits), and to A/D conversion of temperature sensor output or internal reference voltage.
When average mode is selected by setting the ADADC.AVEE bit to 1, do not set the addition count to one time (ADADC.ADC[2:0] = 000b), three times (ADADC.ADC[2:0] = 010b), or 16 times (ADADC.ADC[2:0] = 101b).
The ADC[2:0] bits should be set while the ADCSR.ADST bit is 0.

AVEE Bit (Average Mode Enable)

The AVEE bit selects addition or average mode for A/D conversion of the channel for which A/D conversion and A/D-converted value addition/average mode is selected, including the channels selected in double trigger mode (by ADCSR.DBLANS[4:0] bits), temperature sensor output, and internal reference voltage.
When average mode is selected by setting the ADADC.AVEE bit to 1, do not set the addition count to one time (ADADC.ADC[2:0] = 000b), three times (ADADC.ADC[2:0] = 010b), or 16 times (ADADC.ADC[2:0] = 101b). The mean value of 1-time, 3-time, and 16-time conversion cannot be obtained.
The AVEE bit should be set while the ADCSR.ADST bit is 0.

50.2.9 A/D Control Extended Register (ADCER)

Address(es): S12AD.ADCER 0008 900Eh, S12AD1.ADCER 0008 910Eh

b11	DIAGM	Self-Diagnosis Enable	0: Disables self-diagnosis of 12-bit A/D converter. 1: Enables self-diagnosis of 12-bit A/D converter.	R/W
b14 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	ADRFMT	A/D Data Register Format Select	0: Flush-right is selected for the A/D data register format. 1: Flush-left is selected for the A/D data register format.	R/W

ADCER sets self-diagnosis mode, format of A/D data registers y (ADDRy), and automatic clearing of A/D data registers.

ADPRC[1:0] Bits (A/D Conversion Resolution Setting)

The ADPRC[1:0] bits select whether A/D conversion is performed with setting for 8-, 10-, or 12-bit resolution.
When the resolution of the A/D conversion is changed, the bit width of the valid data to be stored in the result register and time for A/D conversion are also changed. For details, refer to section 50.3.7, Analog Input Sampling Time and Scan Conversion Time.
The ADPRC[1:0] bits should be set while the ADCSR.ADST bit is 0.

ACE Bit (A/D Data Register Automatic Clearing Enable)

The ACE bit enables or disables automatic clearing (all 0) of ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, or ADOCDR after any of these registers have been read by the CPU and DTC. Automatic clearing of the A/D data register is enabled to detect a failure which has not been updated in the A/D data register.

DIAGVAL[1:0] Bits (Self-Diagnosis Conversion Voltage Select)

The DIAGVAL[1:0] bits select the voltage value used in self-diagnosis voltage fixed mode. For details, refer to the descriptions of the ADCER.DIAGLD bit.
Self-diagnosis should not be executed by setting the ADCER.DIAGLD bit to 1 when the ADCER.DIAGVAL[1:0] bits are set to 00b.

DIAGLD Bit (Self-Diagnosis Mode Select)

The DIAGLD bit selects whether the three voltage values are rotated or the fixed voltage is used in self-diagnosis. Setting this bit (ADCER.DIAGLD) to 0 allows conversion of the voltages in rotation mode where 0, the reference power supply × 1/2, and the reference power supply are converted in this order. When self-diagnosis rotation mode is selected after a reset, self-diagnosis is performed from 0 V. When self-diagnosis voltage fixed mode is selected, the fixed voltage specified by the ADCER.DIAGVAL[1:0] bits is converted. In self-diagnosis voltage rotation mode, the self-diagnosis voltage value does not return to 0 when scan conversion is completed. When scan conversion is restarted, therefore, rotation starts at the voltage value following the previous value. If fixed mode is switched to rotation mode, rotation starts at the fixed voltage value.
The DIAGLD bit should be set while the ADCSR.ADST bit is 0.

DIAGM Bit (Self-Diagnosis Enable)

The DIAGM bit enables or disables self-diagnosis.
Self-diagnosis is used to detect a failure of the 12-bit A/D converter. Specifically, one of the internally generated voltage values 0, the reference power supply × 1/2, and the reference power supply is converted. When conversion is completed, information on the converted voltage and the conversion result is stored into the self-diagnosis data register (ADRD). ADRD can then be read out by software to determine whether the conversion result falls within the normal range (normal) or not (abnormal). Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages is converted. When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed in groups A, B, and C.
The DIAGM bit should be set while the ADCSR.ADST bit is 0.

ADRFMT Bit (A/D Data Register Format Select)

The ADRFMT bit specifies flush-right or flush-left for the data to be stored in ADDRy, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADOCDR, ADRD, ADCMPDR0, ADCMPDR1, ADWINLLB, or ADWINULB.
The ADRFMT bit should be set while the ADCSR.ADST bit is 0.

For details on the format of each data register, see section 50.2.1, A/D Data Registers y (ADDRy) (y = 0 to 11), A/D Data Duplication Register (ADDBLDR), A/D Data Duplication Register A (ADDBLDRA), A/D Data Duplication Register B (ADDBLDRB), A/D Temperature Sensor Data Register (ADTSDR), A/D Internal Reference Voltage Data Register (ADOCDR), section 50.2.2, A/D Self-Diagnosis Data Register (ADRD), section 50.2.22, A/D Comparison Function Window A Lower Level Setting Register (ADCMPDR0), section 50.2.23, A/D Comparison Function Window A Upper Level Setting Register (ADCMPDR1), section 50.2.28, A/D Comparison Function Window B Lower Level Setting Register (ADWINLLB), and section 50.2.29, A/D Comparison Function Window B Upper Level Setting Register (ADWINULB).

50.2.10 A/D Conversion Start Trigger Select Register (ADSTRGR)

Address(es): S12AD.ADSTRGR 0008 9010h, S12AD1.ADSTRGR 0008 9110h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	TRSA[5:0]						—	—	TRSB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	TRSB[5:0]	A/D Conversion Start Trigger Select for Group B	Select the A/D conversion start trigger for group B in group scan mode.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13 to b8	TRSA[5:0]	A/D Conversion Start Trigger Select	Select the A/D conversion start trigger in single scan mode and continuous scan mode. In group scan mode, the A/D conversion start trigger for group A is selected.	R/W
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ADSTRGR selects the A/D conversion start trigger.

TRSB[5:0] Bits (A/D Conversion Start Trigger Select for Group B)

The TRSB[5:0] bits select the trigger to start scanning of the analog input selected in group B. The TRSB[5:0] bits require to be set only in group scan mode and are not used in any other scan mode. For the scan conversion start trigger for group B, setting a software trigger or an asynchronous trigger is prohibited. Therefore, the TRSB[5:0] bits should be set to the value other than 000000b and the ADCSR.TRGE bit should be set to 1 in group scan mode.

When two groups are selected (ADGCTRGR.GRCE = 0) during group priority operation in group scan mode, setting the ADGSPCR.GBRP bit to 1 allows group B to continuously operate in single scan mode. When setting the ADGSPCR.GBRP bit to 1, set the TRSB[5:0] bits to 3Fh. Note that the issuance period of trigger for A/D conversion must be more than or equal to the actual scan conversion time (t_{SCAN}). If the issuance period is less than t_{SCAN}, A/D conversion by the trigger may have no effect.

When the trigger from the module (MTU) operated in 120 MHz is selected as an A/D conversion start trigger, a delay of the period for synchronization processing occurs. See section 50.3.7, Analog Input Sampling Time and Scan Conversion Time for details.

Table 50.9 lists the A/D conversion startup sources selected by the TRSB[5:0] bits.

TRSA[5:0] Bits (A/D Conversion Start Trigger Select)

The TRSA[5:0] bits select the trigger to start A/D conversion in single scan mode and continuous scan mode. In group scan mode, the trigger to start scanning of the analog input selected in group A is selected. When scanning is executed in group scan mode or double trigger mode, set the ADCSR.TRGE bit to 1.

- When using the A/D conversion startup source of a synchronous trigger, set the ADCSR.TRGE bit to 1 and set the ADCSR.EXTRG bit to 0.
- When using the asynchronous trigger, set the ADCSR.TRGE bit to 1 and set the ADCSR.EXTRG bit to 1.
- Software trigger (ADCSR.ADST) is enabled regardless of the settings of the ADCSR.TRGE bit, the ADCSR.EXTRG bit, and the TRSA[5:0] bits.

Note that the issuance period of trigger for A/D conversion must be more than or equal to the actual scan conversion time (t_{SCAN}). If the issuance period is less than t_{SCAN}, A/D conversion by a trigger may have no effect. When the trigger from the module (MTU) operated in 120 MHz is selected as an A/D conversion start trigger, a delay of the period for synchronization processing occurs. See section 50.3.7, Analog Input Sampling Time and Scan Conversion Time

for details.

Table 50.10 lists the selection of A/D conversion start sources selected by the TRSA[5:0] bits.

b15	EXOEN	Extended Analog Output Control	0: Output disabled 1: Output enabled	R/W

ADEXICR specifies the settings of A/D conversion of the temperature sensor output, internal reference voltage, or extended analog input.

TSSAD Bit (Temperature Sensor Output A/D-Converted Value Addition/Average Mode Select)

When A/D conversion of the temperature sensor output is selected and the TSSAD bit is set to 1, A/D conversion of the temperature sensor output is performed in sequence for the count set in the ADADC.ADC[1:0] bits (2, 3, 4, or 16 times). The added (accumulated) total value is returned to the A/D temperature sensor data register (ADTSDR) when the ADADC.AVEE bit is 0 and the average is returned to ADTSDR when the ADADC.AVEE bit is 1. The TSSAD bit should be set while the ADCSR.ADST bit is 0.

OCSAD Bit (Internal Reference Voltage A/D-Converted Value Addition/Average Mode Select)

When the OCSAD bit is set to 1, A/D conversion of the internal reference voltage is selected and performed successively 2, 3, 4, or 16 times that is set with the ADADC.ADC[2:0] bits. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D internal reference voltage data register (ADOCDR). When the ADADC.AVEE bit is 1, the mean value is stored in ADOCDR.
The OCSAD bit should be set while the ADCSR.ADST bit is 0.

TSSA Bit (Temperature Sensor Output A/D Conversion Select)

This bit selects A/D conversion of the temperature sensor output for group A in single scan mode, sequence scan mode, or group scan mode. When A/D conversion of the temperature sensor output is performed, set the ADCSR.DBLE bit to 0.
The TSSA bit should be set while the ADCSR.ADST bit is 0.

OCSA Bit (Internal Reference Voltage A/D Conversion Select)

This bit selects A/D conversion of the internal reference voltage for group A in single scan mode, sequence scan mode, or group scan mode. When A/D conversion of the internal reference voltage is performed, set the ADCSR.DBLE bit to 0.
The OCSA bit should be set while the ADCSR.ADST bit is 0. Wait for at least 400 ns after setting the OCSA bit to 1 to start A/D conversion.

TSSB Bit (Temperature Sensor Output A/D Conversion Select)

This bit selects A/D conversion of the temperature sensor output for group B in group scan mode.
This bit should be set while the ADCSR.ADST bit is 0. When the TSSA bit is 1, do not set the TSSB bit to 1.

OCSB Bit (Internal Reference Voltage A/D Conversion Select)

This bit selects A/D conversion of the internal reference voltage for group B in group scan mode.
This bit should be set while the ADCSR.ADST bit is 0. When the OCSA bit is 1, do not set the OCSB bit to 1. Wait for at least 400 ns after setting the OCSB bit to 1 to start A/D conversion.

EXSEL[1:0] Bits (Extended Analog Input Select)

These bits can select extended analog input ANEX1 besides analog input channels (ANn).
When ANEX1 is selected, ANEX0 should be input to ANEX1 through an external operational amplifier. In addition, only analog input channels AN100 to AN107 are selectable. Do not select channels AN108 to AN111. For details, refer to section 50.3.5.1, Usage of ANEX1.

EXOEN Bit (Extended Analog Output Control)

This bit controls the extended analog output (ANEX0). When the output is enabled, the multiplexed value of AN100 to AN107 among the analog input channels of unit 1. Do not enable output while the EXSEL[1:0] bits are 00b.

50.2.12 A/D Group C Extended Input Control Register (ADGCEXCR)

Address(es): S12AD1.ADGCEXCR 0008 91D8h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	OCSC	TSSC
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TSSC	Group C Temperature Sensor Output A/D Conversion Select	0: Temperature sensor output is not A/D converted 1: Temperature sensor output is A/D converted	R/W
b1	OCSC	Group C Internal Reference Voltage A/D Conversion Select	0: Internal reference voltage is not A/D converted 1: Internal reference voltage is A/D converted	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

The ADGCEXCR register specifies extended input for group C.

TSSC Bit (Group C Temperature Sensor Output A/D Conversion Select)

This bit selects A/D conversion of the temperature sensor output for group C in group scan mode.

The TSSC bit should be set while the ADCSR.ADST bit is 0. The TSSC bit should not be set to 1 while the TSSA or TSSB bit is 1.

OCSC Bit (Group C Internal Reference Voltage A/D Conversion Select)

This bit selects A/D conversion of the internal reference voltage for group C in group scan mode.

The OCSC bit should be set while the ADCSR.ADST bit is 0. The OCSC bit should not be set while the OCSA or OCSB bit is 1. Wait for at least 400 ns after setting the OCSC bit to 1 to start A/D conversion.

50.2.13 A/D Group C Trigger Select Register (ADGCTRGR)

Address(es): S12AD.ADGCTRGR 0008 90D9h, S12AD1.ADGCTRGR 0008 91D9h

	b7	b6	b5	b4	b3	b2	b1	b0
	GRCE	GCADIE	TRSC[5:0]					
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	TRSC[5:0]	Group C A/D Conversion Start Trigger Select	Select the A/D conversion start trigger for group C in group scan mode.	R/W
b6	GCADIE	Group C Scan End Interrupt Enable	0: Disables interrupt generation after completion of group C scan 1: Enables interrupt generation after completion of group C scan	R/W
b7	GRCE	Group C A/D Conversion Operation Enable	Enables A/D conversion operation for group C. 0: Group C is not used 1: Group C is used	R/W

ADGCTRGR enables operation for group C and selects the A/D conversion start trigger. For details on group priority operation, see Table 50.16 and Table 50.17.

TRSC[5:0] Bits (Group C A/D Conversion Start Trigger Select)

These bits select the trigger to start scanning of the analog input selected in group C. These bits are used for group scan mode only; not used for any other modes. Software trigger or asynchronous trigger cannot be set as the scan conversion trigger for group C. When using group C in group scan mode, set the TRSC[5:0] bits to a value other than 000000b, set the ADCSR.TRGE bit to 1, and set the GRCE bit to 1.

When group C is used during group priority control in group scan mode and the ADGSPCR.GBRP bit is set to 1, group C can be continuously operated in single scan mode. When continuously operating group C in single scan mode, set the TRSC[5:0] bits to 3Fh and disable trigger selection.

Note that the issuance period of trigger for A/D conversion must be more than or equal to the actual scan conversion time (t_{SCAN}). If the issuance period is less than tSCAN, A/D conversion by a trigger may have no effect.

When the trigger from the module (MTU) operated in 120 MHz is selected as an A/D conversion start trigger, a delay of the period for synchronization processing occurs. See section 50.3.7, Analog Input Sampling Time and Scan Conversion Time for details.

Table 50.11 lists the selection of A/D conversion start sources selected by the TRSA[5:0] bits for group C.

Table 50.11 Selection of A/D Activation Sources by the TRSC[5:0] Bits

Module	Source	Remarks	TRSC[5]	TRSC[4]	TRSC[3]	TRSC[2]	TRSC[1]	TRSC[0]
Trigger source deselection state			1	1	1	1	1	1

ELC	ELCTRG0N /ELCTRG1N	A/D start source from the ELC	1	1	0	0	0	0

GCADIE Bit (Group C Scan End Interrupt Enable)

This bit enables or disables scan end interrupt generation for group C. A scan end interrupt for group C is provided individually for each unit. Table 50.12 shows the relationship between each unit and the scan end interrupt for group C.

Table 50.12 Relationship between Each Unit and Group C Scan End Interrupt

Unit	Group C Scan End Interrupt
S12AD	S12GCADI
S12AD1	S12GCADI1

GRCE Bit (Group C A/D Conversion Operation Enable)

When using group C in group scan mode, set the GRCE bit to 1.

When the GRCE bit is 0, trigger input for group C is disabled.

During group priority operation (the ADGSPCR.PGS bit is 1) with group C used, when the ADGSPCR.GBRP bit is set to 1, single scan for group C is continuously operated. When the GRCE bit is set to 1, single scan for group B is not continuously operated.

The GRCE bit should be set while the ADCSR.ADST bit is 0.

50.2.14 A/D Sampling State Register n (ADSSTRn) (n = 0 to 11, T, O)

Address(es): S12AD.ADSSTR0 0008 90E0h, S12AD.ADSSTR1 0008 90E1h, S12AD.ADSSTR2 0008 90E2h, S12AD.ADSSTR3 0008 90E3h, S12AD.ADSSTR4 0008 90E4h, S12AD.ADSSTR5 0008 90E5h, S12AD.ADSSTR6 0008 90E6h, S12AD.ADSSTR7 0008 90E7h, S12AD1.ADSSTRT 0008 91DEh, S12AD1.ADSSTRO 0008 91DFh, S12AD1.ADSSTR0 0008 91E0h, S12AD1.ADSSTR1 0008 91E1h, S12AD1.ADSSTR2 0008 91E2h, S12AD1.ADSSTR3 0008 91E3h, S12AD1.ADSSTR4 0008 91E4h, S12AD1.ADSSTR5 0008 91E5h, S12AD1.ADSSTR6 0008 91E6h, S12AD1.ADSSTR7 0008 91E7h, S12AD1.ADSSTR8 0008 91E8h, S12AD1.ADSSTR9 0008 91E9h, S12AD1.ADSSTR10 0008 91EAh, S12AD1.ADSSTR11 0008 91EBh

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	1	0	1	1

The ADSSTRn register sets the sampling time for analog input.
If one state is one ADCLK (A/D conversion clock) cycle and the ADCLK clock is 60 MHz, one state is 16.7 ns. The initial value is 11 states. If the impedance of analog input signal source is too high to secure sufficient sampling time or if the ADCLK clock is slow, the sampling time can be adjusted. The ADSSTRn register should be set while the ADCSR.ADST bit is 0. The lower-limit value for sampling time differs depending on the PCLK to ADCLK frequency ratio.
Set a value that is 5 states or more when PCLK to ADCLK frequency ratio = 1:1, 2:1, 4:1, or 8:1.

Table 50.13 shows the relationship between the A/D sampling state register and the relevant channels.
For details, refer to section 50.3.7, Analog Input Sampling Time and Scan Conversion Time.

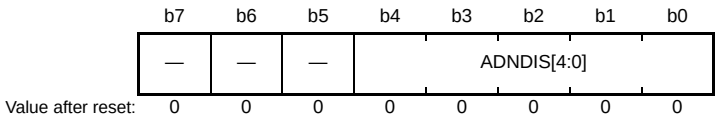
Table 50.13 Relationship between A/D Sampling State Register and Relevant Channels

Unit	Register Name	Relevant Channels
S12AD	ADSSTR0 register	AN000, Self-Diagnosis
	ADSSTR1 register	AN001
	ADSSTR2 register	AN002
	ADSSTR3 register	AN003
	ADSSTR4 register	AN004
	ADSSTR5 register	AN005
	ADSSTR6 register	AN006
	ADSSTR7 register	AN007
S12AD1	ADSSTR0 register	AN100, Self-Diagnosis
	ADSSTR1 register	AN101
	ADSSTR2 register	AN102
	ADSSTR3 register	AN103
	ADSSTR4 register	AN104
	ADSSTR5 register	AN105
	ADSSTR6 register	AN106
	ADSSTR7 register	AN107
	ADSSTR8 register	AN108
	ADSSTR9 register	AN109
	ADSSTR10 register	AN110
	ADSSTR11 register	AN111
	ADSSTRT register	Temperature sensor output
	ADSSTRO register	Internal reference voltage

Note 1. When performing A/D conversion of the temperature sensor output or internal reference voltage, the sampling time should be 5 µs or longer.

50.2.15 A/D Disconnection Detection Control Register (ADDISCR)

Address(es): S12AD.ADDISCR 0008 907Ah, S12AD1.ADDISCR 0008 917Ah



Bit	Symbol	Bit Name	Description	R/W
b4 to b0	ADNDIS[4:0]	A/D Disconnection Detection Assist Setting	b4 ADNDIS[4]: Discharge/precharge selected 0: Discharge 1: Precharge b3 to b0 ADNDIS[3:0]: Discharge/precharge period	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ADDISCR sets the disconnection detection assist function.

ADNDIS[4:0] Bits (A/D Disconnection Detection Assist Setting)

These bits select either precharge or discharge and the period of precharge/discharge for the A/D disconnection detection assist function. Setting the ADNDIS[4] bit = 1 allows to select precharge and setting the ADNDIS[4] bit = 0 allows to select discharge. The period of precharge/discharge can be set with the ADNDIS[3:0] bits. When the ADNDIS[3:0] bits = 0000b, the disconnection detection assist function is not effective. Setting of the ADNDIS[3:0] bits to 0001b is prohibited. Except for the case of ADNDIS[3:0] = 0000b or 0001b, the specified value indicates the number of states for the period of precharge/discharge. The ADNDIS[4:0] bits should be set when the ADCSR.ADST bit is 0.
The disconnection detection assist function cannot be used when the temperature sensor output or internal reference voltage is converted or when the self-diagnosis function is used.

50.2.16 A/D Group Scan Priority Control Register (ADGSPCR)

Address(es): S12AD.ADGSPCR 0008 9080h, S12AD1.ADGSPCR 0008 9180h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	GBRP	LGRRS	—	—	—	—	—	—	—	—	—	—	—	—	GBRSCN	PGS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PGS	Group Priority Control Setting*1	0: Operation is without group priority control 1: Operation is with group priority control	R/W
b1	GBRSCN	Low-Priority Group Restart Setting*2	(Enabled only when PGS = 1. Reserved when PGS = 0.) 0: Scanning for the group is not restarted after having been discontinued due to group priority control. 1: Scanning for the group is restarted after having been discontinued due to group priority control.	R/W
b13 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14	LGRRS	Restart Channel Select	(Enabled when PGS = 1 and GBRSCN = 1. Reserved when PGS = 0 or GBRSCN = 0.) 0: Scanning is restarted from the scan start channel. 1: Scanning is restarted from the channel on which A/D conversion is not completed.	R/W
b15	GBRP	Single Scan Continuous Start*3	(Enabled only when PGS = 1. Reserved when PGS = 0.) 0: Single scan is not continuously activated. 1: Single scan for the lowest-priority group is continuously activated.	R/W

Note 1. When the PGS bit is to be set to 1, the ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode). If the bits are set to any other values, proper operation is not guaranteed.
Note 2. When the GBRSCN bit is to be set to 1, the frequency ratio of peripheral module clock PCLK to A/D conversion clock ADCLK should be set to 1:1.
Note 3. When the GBRP bit has been set to 1, single scan is performed continuously for the lowest-priority group regardless of the setting of the GBRSCN bit.

ADGSPCR is used to discontinue scanning of the low-priority group and make settings for priority control of scanning for the priority group in group scan mode.
For the settings on group priority operation, see Table 50.16 and Table 50.17.

PGS Bit (Group Priority Control Setting)

This bit sets the priority of operation in group scan mode. Set this bit to 1 when giving priority to operation on the group. When the PGS bit is to be set to 1, the ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode).
During group priority operation, a trigger to start scanning for the priority group is accepted during scan for the low-priority group, and scan for the priority group is started after scan for the low-priority group was discontinued. The priority order is group A > group B > group C.
When a trigger to start scanning for group B is accepted during scan for group C, group C scan is discontinued, and scan for group B is started. When a trigger to start scanning for group A is accepted during scan for group C, group C scan is discontinued, and scan for group A is started.
Likewise, when a trigger to start scanning for group A is accepted during scan for group B, group B scan is discontinued and scan for group A is started.
When setting the PGS bit to 0, clearing should be performed by software according to section 50.6.2, Notes on Stopping A/D Conversion. When setting the PGS bit to 1, follow the procedure described in section 50.3.4.3, Operation under Group Priority Control.

GBRSCN Bit (Low-Priority Group Restart Setting)

This bit controls the restarting of scan operation during group priority control.
If a scan operation on the low-priority group has been stopped by a priority group trigger input with the GBRSCN bit set to 1, the scan operation is restarted after the scanning of the priority group is completed. Also, if a low-priority trigger is input during scan for the priority group, the scan operation on the low-priority group is restarted after the scan for the priority group is completed.
If the GBRSCN bit has been set to 0, triggers that are input during A/D conversion are ignored. Also, the ADCSR.ADST bit must be 0 when the GBRSCN bit is to be set.
The setting of the GBRSCN bit is enabled when the PGS bit is set to 1.

LGRRS Bit (Restart Channel Select)

This bit sets the channel on which scan is restarted during group priority control. The setting of the LGRRS bit is enabled when the PGS and GBRSCN bits are set to 1.
If a scan operation on the low-priority group has been stopped due to group priority operation with the LGRRS bit set to 0, the scan operation is restarted from the start channel after the scan for the priority group is completed.
If a scan operation on the low-priority group has been stopped due to group priority operation with the LGRRS bit set to 1, the scan operation is restarted*1 on the channel on which A/D conversion is not competed after the scan for the priority group is completed.
The LGRRS bit should be set while the ADCSR.ADST bit is 0.

Note 1. If A/D conversion on the addition set channel is not completed for the set number of times when scanning is stopped, A/D conversion on the channel is restarted for the set number of times when scanning is restarted.

GBRP Bit (Single Scan Continuous Start)

This bit is set when the lowest-priority group is continuously operated in single scan mode while group priority operation is set. The lowest-priority group is group C when groups A, B, and C are used; group B when groups A and B are used.
Setting the GBRP bit to 1 starts a single scan on the lowest-priority group. On completion of the scan, another single scan on the lowest-priority group is automatically started.
If scanning has been stopped due to group priority operation, single scan on the lowest-priority group is automatically restarted on completion of the A/D conversion on the priority group.
Disable the trigger input for the lowest-priority group before setting the GBRP bit to 1. When the GBRP bit is set to 1, only the lowest-priority group is scanned again even if the GBRSCN bit is 0.
The ADCSR.ADST bit must be 0 when the GBRP bit is to be set.
The setting of the GBRP bit is enabled when the PGS bit is 1.

50.2.17 A/D Comparison Function Control Register (ADCMPCR)

Address(es): S12AD.ADCMPCR 0008 9090h, S12AD1.ADCMPCR 0008 9190h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b14	WCMPE	Window Function Setting	0: The window function is disabled Window A or B operates as a comparator for comparing between one value on the low side and the A/D converted value 1: The window function is enabled Window A or B operates as a window comparator for comparing between two values on the high and low sides and the A/D converted value	R/W
b15	CMPAIE	Comparison Window A Interrupt Enable	0: Comparison interrupt by a match with the comparison condition (window A) is disabled 1: Comparison interrupt by a match with the comparison condition (window A) is enabled	R/W

The ADCMPCR register is used to set the settings for the comparison window function (windows A and B).

CMPAB[1:0] Bits (Window A/B Complex Conditions Setting)

The CMPAB[1:0] bits are enabled when single scan mode and window A/B are both enabled (CMPAE bit = 1 and CMPBE bit = 1). These bits specify the monitor conditions of the ADWINMON.MONCOMB bits. The CMPAB[1:0] bits should be set when the ADCSR.ADST bit is 0.

CMPBE Bit (Comparison Window B Enable)

This bit is used to disable or enable comparison window B. The CMPBE bit should be set when the ADCSR.ADST bit is 0.

To set the following registers, set this bit to 0.

- A/D channel select registers A0/B0 (ADANSA0 and ADANSB0)
- Bits OCSB, TSSB, OCSA, and TSSA in the A/D conversion extended input control register (ADEXICR.OCSB, TSSB, OCSA, and TSSA)

- Bits OCSC and TSSC in the A/D group C extended input control register (ADGCEXCR.OCSC and TSSC)
- The CMPCHB[5:0] bits in the window B channel select register (ADCMPBNSR.CMPCHB[5:0])

CMPAE Bit (Comparison Window A Enable)

This bit is used to disable or enable comparison window A. The CMPAE bit should be set when the ADCSR.ADST bit is 0.

To set the following registers, set this bit to 0.

- A/D channel select registers A0/B0 (ADANSA0 and ADANSB0)
- Bits OCSB, TSSB, OCSA, and TSSA in the A/D conversion extended input control register (ADEXICR.OCSB, TSSB, OCSA, and TSSA)
- Bits OCSC and TSSC in the A/D group C extended input control register (ADGCEXCR.OCSC and TSSC)
- Window A channel select registers 0 (ADCMPANSR0)
- Window A extended input select register (ADCMPANSER)

CMPBIE Bit (Comparison Window B Interrupt Enable)

Enables or disables comparison interrupts by a window B comparison condition match. A single comparison interrupt exists for each unit. Table 50.14 lists the relationship between each unit and its comparison interrupt.

WCMPE Bit (Window Function Setting)

This bit is used to disable or enable the window function. The WCMPE bit should be set when the ADCSR.ADST bit is 0.

CMPAIE Bit (Comparison Window A Interrupt Enable)

Enables or disables comparison interrupts by a window A comparison condition match. A single comparison interrupt exists for each unit. Table 50.14 lists the relationship between each unit and its comparison interrupt.

Table 50.14 Relationship Between Each Unit and its Comparison Interrupt Unit

	Comparison Interrupt	
Unit	**When Window A Comparison Condition is Met**	**When Window B Comparison Condition is Met**
S12AD	S12CMPAI	S12CMPBI
S12AD1	S12CMPAI1	S12CMPBI1

50.2.18 A/D Comparison Function Window A Channel Select Register 0 (ADCMPANSR0)

(1) S12AD.ADCMPANSR0

Address(es): 0008 9094h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b5	CMPCHA005			R/W
b6	CMPCHA006			R/W
b7	CMPCHA007			R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register selects analog inputs AN000 to AN007 of the channels that perform comparison with the conditions of comparison window A.

CMPCHA0n Bit (n = 00 to 07) (Comparison Window A Channel Select)

The comparison function is enabled when the CMPCHA0n bit with the same index number as the A/D conversion channel selected by the ADANSA0.ANSA0n bit (n = 00 to 07), ADANSB0.ANSB0n bit, and ADANSC0.ANSC0n bit is set to 1.

The CMPCHA0n bit should be set to 1 while the ADCSR.ADST bit is 0.

b10	CMPCHA010			R/W
b11	CMPCHA011			R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register selects analog inputs AN100 to AN111 of the channels that perform comparison with the conditions of comparison window A.

CMPCHA0n Bit (n = 00 to 11) (Comparison Window A Channel Select)

The comparison function is enabled when the CMPCHA0n bit with the same index number as the A/D conversion channel selected by the ADANSA0.ANSA0n bit (n = 00 to 11), ADANSB0.ANSB0n bit, and ADANSC0.ANSC0n bit is set to 1.

The CMPCHA0n bit should be set while the ADCSR.ADST bit is 0.

50.2.19 A/D Comparison Function Window A Extended Input Select Register (ADCMPANSER)

Address(es): S12AD1.ADCMPANSER 0008 9192h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	CMPSOC	CMPSTS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPSTS	Temperature Sensor Output Comparison Select	0: Temperature sensor output is excluded from the targets for comparison window A 1: Temperature sensor output is included as the targets for comparison window A	R/W
b1	CMPSOC	Internal Reference Voltage Compare Select	0: Internal reference voltage is excluded from the targets for comparison window A 1: Internal reference voltage is included as the targets for comparison window A	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register selects whether the temperature sensor output or internal reference voltage is compared under the conditions of comparison window A.

CMPSTS Bit (Temperature Sensor Output Comparison Select)

The comparison window A is enabled when the CMPSTS bit is set to 1 while the ADEXICR.TSSA, ADEXICR.TSSB, or ADGCEXCR.TSSC bit is 1. The CMPSTS bit should be set while the ADCSR.ADST bit is 0.

CMPSOC Bit (Internal Reference Voltage Compare Select)

The comparison window A function is enabled when the ADEXICR.OCSA, ADEXICR.OCSB, or ADGCEXCR.OCSC bit is 1. The CMPSOC bit should be set while the ADCSR.ADST bit is 0.

50.2.20 A/D Comparison Function Window A Comparison Condition Setting Register 0 (ADCMPLR0)

(1) S12AD.ADCMPLR0

Address(es): 0008 9098h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b6	CMPLCHA006			R/W
b7	CMPLCHA007			R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register specifies the conditions for comparison of the values in the S12AD.ADCMPDR0/ADCMPDR1 register and the value of A/D conversion. The S12AD.ADCSR.ADST bit is 0.

CMPLCHA0n Bit (n = 00 to 07) (Comparison Window A Comparison Condition Select)

This bit specifies the comparison conditions of the channels (AN000 to AN007) targeted for the window A comparison conditions. The condition can be specified for each analog input for comparison. The CMPLCHA000 bit corresponds to AN000 and the CMPLCHA007 bit corresponds to AN007.

(2) S12AD1.ADCMPLR0

Address(es): 0008 9198h

b11	CMPLCHA011			R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register specifies the conditions for comparing between the values of the S12AD1.ADCMPDR0/ADCMPDR1 registers and the result of A/D conversion. The S12AD1.ADCMPLR0 register should be set while the S12AD1.ADCSR.ADST bit is 0.

CMPLCHA0n Bit (n = 00 to 11) (Comparison Window A Comparison Condition Select)

This bit specifies the conditions for comparison with the target channels for window A (AN100 to AN111). The conditions can be specified for each analog input for comparison. The CMPLCHA000 bit corresponds to AN100 and the CMPLCHA011 bit corresponds to AN111.

When the result of comparison of each analog input matches with the pre-set condition, the S12AD1.ADCMPSR0.CMPSTCHA0n flag (n = 00 to 11) is set to 1 and a comparison interrupt (S12CMPAI1) is generated. The conditions for comparison are shown in Figure 50.4.

(1) Comparison condition when the window function is disabled

CMPLCHA0n = 0

ADCMPDR0 register value ≤ A/D converted value	Not matched
ADCMPDR0 register value > A/D converted value	Matched

CMPLCHA0n = 1

ADCMPDR0 register value < A/D converted value	Matched
ADCMPDR0 register value ≥ A/D converted value	Not matched

(2) Comparison condition when the window function is enabled

CMPLCHA0n = 0

ADCMPDR1 register value < A/D converted value	Matched
ADCMPDR0 register value ≤ A/D converted value ≤ ADCMPDR1 register value	Not matched
A/D converted value < ADCMPDR0 register value	Matched

CMPLCHA0n = 1

ADCMPDR1 register value ≤ A/D converted value	Not matched
ADCMPDR0 register value < A/D converted value < ADCMPDR1 register value	Matched
A/D converted value ≤ ADCMPDR0 register value	Not matched

Figure 50.4 Details of Comparison Condition: Comparison Function Window A

50.2.21 A/D Comparison Function Window A Extended Input Comparison Condition Setting Register (ADCMPLER)

Address(es): S12AD1.ADCMPLER 0008 9193h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	CMPLOC	CMPLTS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPLTS	Comparison Window A Temperature Sensor Output Comparison Condition Select	When the window A function is disabled (the ADCMPCR.WCMPE bit is 0) 0: ADCMPDR0 register value > A/D converted value 1: ADCMPDR0 register value < A/D converted value When the window A function is enabled (the ADCMPCR.WCMPE bit is 1) 0: A/D converted value < ADCMPDR0 register value or A/D converted value > ADCMPDR1 register value 1: ADCMPDR0 register value < A/D converted value < ADCMPDR1 register value	R/W
b1	CMPLOC	Comparison Window A Internal Reference Voltage Comparison Condition Select	When the window A function is disabled (the ADCMPCR.WCMPE bit is 0) 0: ADCMPDR0 register value > A/D converted value 1: ADCMPDR0 register value < A/D converted value When the window A function is enabled (the ADCMPCR.WCMPE bit is 1) 0: A/D converted value < ADCMPDR0 register value or A/D converted value > ADCMPDR1 register value 1: ADCMPDR0 register value < A/D converted value < ADCMPDR1 register value	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register specifies the conditions for comparison of the value of the ADCMPDR0/ADCMPDR1 register and the result of A/D conversion. The ADCMPLER register should be set while the ADCSR.ADST bit is 0.

CMPLTS Bit (Comparison Window A Temperature Sensor Output Comparison Condition Select)

This bit selects the comparison conditions of temperature sensor output targeted for window A.
When the result of comparison of temperature sensor output matches with the pre-set condition, the ADCMPSER.CMPFTS flag is set to 1. A comparison interrupt (S12CMPAI1) is generated.
Figure 50.4 shows the conditions for comparison.

CMPLOC Bit (Comparison Window A Internal Reference Voltage Comparison Condition Select)

This bit selects the comparison conditions of the internal reference voltage targeted for window A.
When the result of comparison of the internal reference voltage matches with the pre-set condition, the ADCMPSER.CMPFOC flag is set to 1. A comparison interrupt (S12CMPAI1) is generated.
Figure 50.4 shows the conditions for comparison.

50.2.22 A/D Comparison Function Window A Lower Level Setting Register (ADCMPDR0)

Address(es): S12AD.ADCMPDR0 0008 909Ch, S12AD1.ADCMPDR0 0008 919Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This is a readable and writable register that specifies the reference data when the comparison window A function is used. The ADCMPDR0 register specifies the lower level of window A.
Writing to the ADCMPDR0 register is enabled even when A/D conversion is in progress. Rewriting the register value during the A/D conversion dynamically changes the reference data.
Satisfy the condition of [Upper limit level ≥ Lower limit level (ADCMPDR1 setting value ≥ ADCMPDR0 setting value)] when setting.

The data formats of the register for each given condition are shown below.

- Setting of the A/D data register format select bit (flush-right or -left format)
- Setting of the A/D conversion resolution setting bit (12, 10, or 8 bits)
- Setting of the A/D converted value addition/averaging function channel select register (when A/D converted value average mode is selected or not selected)
- Setting of the A/D converted value addition/average count select register (when addition/averaging mode is selected and addition count is selected)

Note: When the comparison values are set in a different format from that of the A/D data register y (ADDRy), correct result of comparison cannot be obtained.

(1) When A/D converted value addition/averaging mode is not selected

- Flush-right format with setting for 12-bit resolution
  The comparison level (lower) to be compared is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Flush-right format with setting for 10-bit resolution
  The comparison level (lower) to be compared is set in bits 9 to 0. Write 0 to bits 15 to 10.
- Flush-right format with setting for 8-bit resolution
  The comparison level (lower) to be compared is set in bits 7 to 0. Write 0 to bits 15 to 8.
- Flush-left format with setting for 12-bit resolution
  The comparison level (lower) to be compared is set in bits 15 to 4. Write 0 to bits 3 to 0.
- Flush-left format with setting for 10-bit resolution
  The comparison level (lower) to be compared is set in bits 15 to 6. Write 0 to bits 5 to 0.
- Flush-left format with setting for 8-bit resolution
  The comparison level (lower) to be compared is set in bits 15 to 8. Write 0 to bits 7 to 0.

(2) When A/D converted value addition/averaging mode is selected

- Flush-right format with setting for 12-bit resolution
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Flush-right format with setting for 10-bit resolution
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 9 to 0. Write 0 to bits 15 to 10.

- Flush-right format with setting for 8-bit resolution
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 7 to 0. Write 0 to bits 15 to 8.
- Flush-left format with setting for 12-bit resolution
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 15 to 4. Write 0 to bits 3 to 0.
- Flush-left format with setting for 10-bit resolution
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 15 to 6. Write 0 to bits 5 to 0.
- Flush-left format with setting for 8-bit resolution
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 15 to 8. Write 0 to bits 7 to 0.

A/D-converted value average mode can be set only when 2- or 4-time conversion is selected in A/D-converted value addition mode.

(3) When A/D converted value averaging mode is selected

- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 12-bit resolution
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 13 to 0. Write 0 to bits 15 and 14.
- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 10-bit resolution
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 11 to 0. Write 0 to bits 15 and 12.
- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 8-bit resolution
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 9 to 0. Write 0 to bits 15 and 10.
- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 16 times) with setting of 12-bit resolution
  The comparison level (lower) to be compared with the value of A/D conversion of the same channel is set in bits 15 to 0.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 12-bit resolution
  The comparison level (lower) to be compared with the A/D converted value of the same channel is set in bits 15 to 2. Write 0 to bits 1 and 0.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 10-bit resolution
  The comparison level (lower) to be compared with the A/D converted value of the same channel is set in bits 15 to 4. Write 0 to bits 3 to 0.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 8-bit resolution
  The comparison level (lower) to be compared with the A/D converted value of the same channel is set in bits 15 to 6. Write 0 to bits 5 to 0.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 16 times) with setting of 12-bit resolution
  The comparison level (lower) to be compared with the A/D converted value of the same channel is set in bits 15 to 0.

When A/D converted value addition mode is selected, the value for comparison with the result of cumulative A/D converted value of the same channel is specified. Conversion 1, 2, 3, 4, or 16 times is selectable. When A/D converted value addition mode is selected and if conversion 1 to 4 is selected, the resolution of the results of conversion will be extended by 2 bits and so set a value for comparison with the results in the ADCMPDR0 register. When conversion 16 times is selected, the resolution of the results of conversion will be extended by 4 bits and so set a value for comparison with the results in the ADCMPDR0 register.
Even when A/D converted value addition mode is selected, set the value for reference based on the setting of the A/D data register format select bit.

50.2.23 A/D Comparison Function Window A Upper Level Setting Register (ADCMPDR1)

Address(es): S12AD.ADCMPDR1 0008 909Eh, S12AD1.ADCMPDR1 0008 919Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This is a readable and writable register that specifies the data for reference when the comparison window A function is used. The register specifies the upper level of window A.
A write operation to the ADCMPDR1 register is enabled even during A/D conversion. Rewriting the value of the register during A/D conversion dynamically changes the reference data.
Satisfy the condition of [upper limit level ≥ lower limit level (ADCMPDR1 setting value ≥ ADCMPDR0 setting value)] when setting.
The ADCMPDR1 register is not used when the window function is disabled.

The data formats of the register for each given condition are shown below.

- Setting of the A/D data register format select bit (flush-right or -left format)
- Setting of the A/D conversion resolution setting bit (12, 10, or 8 bits)
- Setting of the A/D converted value addition/averaging function channel select register (when A/D converted value averaging mode is selected or not selected)
- Setting of the A/D converted value addition/averaging time select register (when addition/averaging mode is select and addition count is selected)

Note: When the comparison values are set in a different format from that of the A/D data register y (ADDRy), correct result of comparison cannot be obtained.

(1) When A/D-converted value addition/averaging mode is not selected

- Flush-right format with the setting for 12-bit resolution
  The comparison level (upper) is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Flush-right format with the setting for 10-bit resolution
  The comparison level (upper) is set in bits 9 to 0. Write 0 to bits 15 to 10.
- Flush-right format with the setting for 8-bit resolution
  The comparison level (upper) is set in bits 7 to 0. Write 0 to bits 15 to 8.
- Flush-left format with the setting for 12-bit resolution
  The comparison level (upper) is set in bits 15 to 4. Write 0 to bits 3 to 0.
- Flush-left format with the setting for 10-bit resolution
  The comparison level (upper) is set in bits 15 to 6. Write 0 to bits 5 to 0.
- Flush-left format with the setting for 8-bit resolution
  The comparison level (upper) is set in bits 15 to 8. Write 0 to bits 7 to 0.

(2) When A/D-converted averaging mode is selected

- Flush-right format with the setting for 12-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Flush-right format with the setting for 10-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 9 to

0. Write 0 to bits 15 to 10.

- Flush-right format with the setting for 8-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 7 to 0. Write 0 to bits 15 to 8.
- Flush-left format with the setting for 12-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 15 to 4. Write 0 to bits 3 to 0.
- Flush-left format with the setting for 10-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 15 to 6. Write 0 to bits 5 to 0.
- Flush-left format with the setting for 8-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 15 to 8. Write 0 to bits 7 to 0.

A/D-converted value average mode can be set only when 2- or 4-time conversion is selected in A/D-converted value addition mode.

(3) When A/D converted value averaging mode is selected

- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 12-bit resolution
  The comparison level (upper) to be compared with the A/D converted value of the same channel is set bits 13 to 0. Write 0 to bits 15 to 14.
- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 10-bit resolution
  The comparison level (upper) to be compared with the A/D converted value of the same channel is set bits 11 to 0. Write 0 to bits 15 to 12.
- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 8-bit resolution
  The comparison level (upper) to be compared with the A/D converted value of the same channel is set bits 9 to 0. Write 0 to bits 15 to 10.
- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 16 times) with setting of 12-bit resolution
  The comparison level (upper) to be compared with the A/D converted value of the same channel is set bits 15 to 0.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 12-bit resolution
  The comparison level (upper) to be compared with the A/D converted value of the same channel is set in bits 15 to 2. Write 0 to bits 1 and 0.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 10-bit resolution
  The comparison level (upper) to be compared with the A/D converted value of the same channel is set in bits 15 to 4. Write 0 to bits 3 to 0.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 8-bit resolution
  The comparison level (upper) to be compared with the A/D converted value of the same channel is set in bits 15 to 6. Write 0 to bits 5 to 0.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 16 times) with setting of 12-bit resolution
  The comparison level (upper) to be compared with the A/D converted value of the same channel is set in bits 15 to 0.

When A/D converted value addition mode is selected, the value for comparison with the result of cumulative A/D converted value of the same channel is specified. Conversion 1, 2, 3, 4, or 16 times is selectable. When A/D converted value addition mode is selected and if conversion 1 to 4 is selected, the resolution of the results of conversion will be extended by 2 bits and so set a value for comparison with the results in the ADCMPDR1 register. When conversion 16 times is selected, the resolution of the results of conversion will be extended by 4 bits and so set a value for comparison with the results in the ADCMPDR1 register.
Even when A/D converted value addition mode is selected, set the value for reference based on the setting of the A/D data register format select bit.

50.2.24 A/D Comparison Function Window A Channel Status Register 0 (ADCMPSR0)

(1) S12AD.ADCMPSR0

Address(es): 0008 90A0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	CMPST CHA007	CMPST CHA006	CMPST CHA005	CMPST CHA004	CMPST CHA003	CMPST CHA002	CMPST CHA001	CMPST CHA000
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPSTCHA000	Comparison Window A Flag	When window A operation is enabled (ADCMPCR.CMPAE = 1) These bits indicate the comparison result of the channels (AN000 to AN007) for the window A comparison condition 0: Comparison condition is not satisfied. 1: Comparison condition is satisfied.	R/W
b1	CMPSTCHA001			R/W
b2	CMPSTCHA002			R/W
b3	CMPSTCHA003			R/W
b4	CMPSTCHA004			R/W
b5	CMPSTCHA005			R/W
b6	CMPSTCHA006			R/W
b7	CMPSTCHA007			R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This is a register that stores the result of comparison by the comparison window A function.

CMPSTCHA0n Flag (n = 00 to 07) (Comparison Window A Flag)

These are status flags that indicate the result of comparison of the channels for the window A comparison conditions. When the conversion result matches with the comparison condition that is set in the ADCMPLR0.CMPLCHA0n bit (n = 00 to 07) upon completion of A/D conversion, these flags are set to 1. When the ADCMPCR.CMPIE bit is 1, a comparison interrupt request (S12CMPAI) is generated upon the setting of the flag.
The CMPSTCHA000 flag corresponds to AN000 and the CMPSTCHA007 flag corresponds to AN007.
1 cannot be written to the CMPSTCHA0n flag.
[Setting condition]

- When ADCMPCR.CMPAE = 1 and the condition set in the ADCMPLR0.CMPLCHA0n bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

(2) S12AD1.ADCMPSR0

b11	CMPSTCHA011			R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This is a register that stores the result of comparison of comparison window A.

CMPSTCHA0n Flag (n = 00 to 11) (Comparison Window A Flag)

These are status flags that indicate the result of comparison of the channels (AN100 to AN111) of the comparison condition for window A. When the conversion result matches with the comparison condition specified in the ADCMPLR0.CMPLCHA0n bit (n = 00 to 11) upon completion of A/D conversion, this flag is set to 1. When the ADCMPCR.CMPIE bit is 1, a comparison interrupt request (S12CMPAI1) is generated upon the setting of the flag. The CMPSTCHA000 flag corresponds to AN100 and the CMPSTCHA011 flag corresponds to AN111.
1 cannot be written to the CMPSTCHA0n flag.
[Setting condition]

- When ADCMPCR.CMPAE = 1, the condition set in the ADCMPLR0.CMPLCHA0n bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

50.2.25 A/D Comparison Function Window A Extended Input Channel Status Register (ADCMPSER)

Address(es): S12AD1.ADCMPSER 0008 91A4h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	CMPFOC	CMPFTS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPFTS	Comparison Window A Temperature Sensor Output Comparison Flag	When window A operation is enabled (ADCMPCR.CMPAE = 1) This bit indicates the comparison result of the temperature sensor output 0: The comparison condition is not satisfied. 1: The comparison condition is satisfied.	R/W
b1	CMPFOC	Comparison Window A Internal Reference Voltage Comparison Flag	When window A operation is enabled (ADCMPCR.CMPAE = 1) This bit indicates the comparison result of the internal reference voltage 0: The comparison condition is not satisfied. 1: The comparison condition is satisfied.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This is a register that stores the result of the comparison of the comparison window A function.

CMPFTS Flag (Comparison Window A Temperature Sensor Output Comparison Flag)

This is a status flag that indicates the result of comparison of the temperature sensor output. When the conversion result matches with the comparison condition specified in the ADCMPLER.CMPLTS bit upon completion of A/D conversion, this flag is set to 1. When the ADCMPCR.CMPIE bit is 1, a comparison interrupt request (S12CMPAI1) is generated upon the setting of the flag.

1 cannot be written to the CMPFTS flag.

[Setting condition]

- When ADCMPCR.CMPAE = 1, the condition set in the ADCMPLER.CMPLTS bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

CMPFOC Flag (Comparison Window A Internal Reference Voltage Comparison Flag)

This is a status flag that indicates the result of comparison of the internal reference voltage. When the conversion result matches with the comparison condition specified in the ADCMPLER.CMPLOC bit upon completion of A/D conversion, this flag is set to 1. When the ADCMPCR.CMPIE bit is 1, a comparison interrupt request (S12CMPAI1) is generated upon the setting of the flag.

1 cannot be written to the CMPFOC flag.

[Setting condition]

- When ADCMPCR.CMPAE = 1, the condition set in the ADCMPLER.CMPLOC bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

50.2.26 A/D Comparison Function Window A/B Status Monitoring Register (ADWINMON)

Address(es): S12AD.ADWINMON 0008 908Ch, S12AD1.ADWINMON 0008 918Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	MONCMPB	MONCMPA	—	—	—	MONCOMB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MONCOMB	Combination Result Monitoring	When window A operation is enabled (ADCMPCR.CMPAE = 1) These bits indicate the comparison result of the internal reference voltage 0: The comparison condition is not satisfied. 1: The comparison condition is satisfied.	R
b3 to b1	—	Reserved	These bits are read as 0.	R
b4	MONCMPA	Comparison Result Monitor A	0: The comparison condition for window A is not satisfied. 1: The comparison condition for window A is satisfied.	R
b5	MONCMPB	Comparison Result Monitor B	0: The comparison condition for window B is not satisfied. 1: The comparison condition for window B is satisfied.	R
b7, b6	—	Reserved	These bits are read as 0.	R

This register can monitor the results of comparison and the combined result.

MONCOMB Bit (Combination Result Monitoring)

This is a dedicated bit for reading the combined result of comparison condition A and B that were set in the ADCMPCR.CMPAB[1:0] bits as a combined condition.

[Setting condition]

- When ADCMPCR.CMPAE = 1 and ADCMPCR.CMPBE = 1, the condition set in the ADCMPCR.CMPAB[1:0] bits is satisfied.

[Clearing condition]

- No match with the combined condition set in the ADCMPCR.CMPAB[1:0] bits
- When ADCMPCR.CMPAE = 0 or ADCMPCR.CMPBE = 0

MONCMPA Bit (Comparison Result Monitor A)

This is a dedicated bit for reading 1 when the condition set in the ADCMPLR0 or ADCMPLER matches with the A/D converted value of the channel targeted for window A and for reading 0 when such condition is not satisfied.

[Setting condition]

- When ADCMPCR.CMPAE = 1, the condition set in the ADCMPLR0.CMPLCHA0n bit is satisfied.

[Clearing condition]

- When ADCMPCR.CMPAE = 1, the condition set in the ADCMPLR0.CMPLCHA0n bit is not satisfied.
- When ADCMPCR.CMPAE = 0, (ADCMPCR.CMPAE is automatically cleared to 0)

MONCMPB Bit (Comparison Result Monitor B)

This is a dedicated bit for reading 1 when the condition set in the ADCMPBNSR.CMPLB matches with the A/D converted value of the channel targeted for window B and for reading 0 when such condition is not satisfied.

[Setting condition]

- When ADCMPCR.CMPBE = 1, the condition set in the ADCMPBNSR.CMPLB bit is satisfied.

[Clearing condition]

- When ADCMPCR.CMPBE = 1, the condition set in the ADCMPBNSR.CMPLB bit is not satisfied.
- When ADCMPCR.CMPBE = 0, (ADCMPCR.CMPBE is automatically cleared to 0)

50.2.27 A/D Comparison Function Window B Channel Select Register (ADCMPBNSR)

(1) S12AD.ADCMPBNSR

Address(es): 0008 90A6h

	b7	b6	b5	b4	b3	b2	b1	b0
	CMPLB	—	CMPCHB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	CMPCHB[5:0]	Comparison Window B Channel Select	Select the channel that compares with the condition of comparison window B b5 b0 0 0 0 0 0 0: AN000 0 0 0 0 0 1: AN001 0 0 0 0 1 0: AN002 : : 0 0 0 1 1 0: AN006 0 0 0 1 1 1: AN007 Settings other than above are prohibited.	R/W
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	CMPLB	Comparison Window B Comparison Condition Setting	When the window function is disabled (the ADCMPCR.WCMPE bit is 0) 0: ADWINLLB register value > A/D converted value 1: ADWINLLB register value < A/D converted value When the window function is enabled (the ADCMPCR.WCMPE bit is 1) 0: A/D converted value < ADWINLLB register value or ADWINULB register value < A/D converted value 1: ADWINLLB register value < A/D converted value < ADWINULB register value	R/W

This register is used to specify the comparison window B function.

CMPCHB[5:0] Bits (Comparison Window B Channel Select)

These bits select the channel to be compared with the comparison window B from AN000 to AN007.
When the number of the A/D conversion channel selected in the ADANSAy.ANSAyn bit (y = 0, n = 00 to 07) and ADANSBy.ANSByn bit, the comparison window B function is enabled.
The CMPCHB[5:0] bits should be set while the ADCSR.ADST bit is 0.

CMPLB Bit (Comparison Window B Comparison Condition Setting)

This bit specifies the condition for comparison of the channels for window B. When the comparison result of each analog input matches the pre-set condition, the ADCMPBSR.CMPSTB flag is set to 1, a comparison interrupt request (S12CMPBI) is generated. Figure 50.5 shows the conditions for comparison.

(2) S12AD1.ADCMPBNSR

Address(es): 0008 91A6h

	b7	b6	b5	b4	b3	b2	b1	b0
	CMPLB	—	CMPCHB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	CMPCHB[5:0]	Comparison Window B Channel Select	Select the channel that compares with the condition of comparison window B b5 b0 0 0 0 0 0 0: AN100 0 0 0 0 0 1: AN101 0 0 0 0 1 0: AN102 : : 0 0 0 1 1 0: AN106 0 0 0 1 1 1: AN107 : : 0 0 1 0 1 1: AN111 1 0 0 0 0 0: Temperature sensor 1 0 0 0 0 1: Internal reference voltage Settings other than above are prohibited.	R/W
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	CMPLB	Comparison Window B Comparison Condition Setting	When window function is disabled (the ADCMPCR.WCMPE bit is 0) 0: ADWINLLB register value > A/D converted value 1: ADWINLLB register value < A/D converted value When window function is enabled (the ADCMPCR.WCMPE bit is 1) 0: A/D converted value < ADWINLLB register value or ADWINULB register value < A/D converted value 1: ADWINLLB register value < A/D converted value < ADWINULB register value	R/W

This register is used to specify the compare window B function.

CMPCHB[5:0] Bits (Comparison Window B Channel Select)

These bits select the channels to be compared under the comparison window B condition from AN100 to AN111, temperature sensor, internal reference voltage.

When the number of the A/D conversion channel selected in the ADANSAy.ANSAyn bit (y = 0, n = 00 to 11) and ADANSBy.ANSByn bit is specified, the comparison window B function is enabled.

The CMPCHB[5:0] bits should be set while the ADCSR.ADST bit is 0.

CMPLB Bit (Comparison Window B Comparison Condition Setting)

This bit specifies the condition for comparison of the channels for window B. When the comparison result of each analog input matches the pre-set condition, the ADCMPBSR.CMPSTB flag is set to 1, a comparison interrupt request (S12CMPBI1) is generated. Figure 50.5 shows the conditions for comparison.

(1) Comparison condition when the window function is disabled

CMPLB = 0

ADWINLLB register value ≤ A/D converted value	Not matched
ADWINLLB register value > A/D converted value	Matched

CMPLB = 1

ADWINLLB register value < A/D converted value	Matched
ADWINLLB register value ≥ A/D converted value	Not matched

(2) Comparison condition when the window function is enabled

CMPLB = 0

AD converted value > ADWINULB register value	Matched
ADWINLLB register value ≤ AD converted value ≤ ADWINULB register value	Not matched
AD converted value < ADWINLLB register value	Matched

CMPLB = 1

AD converted value ≥ ADWINULB register value	Not matched
ADWINLLB register value < A/D converted value < ADWINULB register value	Matched
AD converted value ≤ ADWINLLB register value	Not matched

Figure 50.5 Details of Comparison Condition: Comparison Function Window B

50.2.28 A/D Comparison Function Window B Lower Level Setting Register (ADWINLLB)

Address(es): S12AD.ADWINLLB 0008 90A8h, S12AD1.ADWINLLB 0008 91A8h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This is a readable and writable register that specifies reference data when comparison window B is in use. The register specifies the lower level of window B.
A write operation to the ADCMPDR1 register is enabled even during A/D conversion. Rewriting the value of the register during A/D conversion dynamically changes the reference data.
Satisfy the condition of [upper limit level ≥ lower limit level (ADWINULB setting value ≥ ADWINLLB setting value)] when setting.

The data formats of the register for each given condition are shown below.

- Setting of the A/D data register format select bit (flush-right or -left format)
- Setting of the A/D conversion resolution setting bit (12, 10, or 8 bits)
- Setting of the A/D converted value addition/averaging function channel select register (A/D converted value averaging mode: selected or not selected)
- Setting of the A/D converted value addition/averaging count select register (addition/averaging mode selected, addition count selected)

Note: When the comparison values are set in a different format from that of the A/D data register y (ADDRy), correct result of comparison cannot be obtained.

(1) When A/D-converted value addition/averaging mode is not selected

- Flush-right format with the setting for 12-bit resolution
  The comparison level (lower) is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Flush-right format with the setting for 10-bit resolution
  The comparison level (lower) is set in bits 9 to 0. Write 0 to bits 15 to 10.
- Flush-right format with the setting for 8-bit resolution
  The comparison level (lower) is set in bits 7 to 0. Write 0 to bits 15 to 8.
- Flush-left format with the setting for 12-bit resolution
  The comparison level (lower) is set in bits 15 to 4. Write 0 to bits 3 to 0.
- Flush-left format with the setting for 10-bit resolution
  The comparison level (lower) is set in bits 15 to 6. Write 0 to bits 5 to 0.
- Flush-left format with the setting for 8-bit resolution
  The comparison level (lower) is set in bits 15 to 8. Write 0 to bits 7 to 0.

(2) When A/D-converted averaging mode is selected

- Flush-right format with the setting for 12-bit resolution
  The comparison level (lower) to be compared with the A/D-converted results of the same channel is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Flush-right format with the setting for 10-bit resolution
  The comparison level (lower) to be compared with the A/D-converted results of the same channel is set in bits 9 to 0. Write 0 to bits 15 to 10.

- Flush-right format with the setting for 8-bit resolution
  The comparison level (lower) to be compared with the A/D-converted results of the same channel is set in bits 7 to 0. Write 0 to bits 15 to 8.
- Flush-left format with the setting for 12-bit resolution
  The comparison level (lower) to be compared with the A/D-converted results of the same channel is set in bits 15 to 4. Write 0 to bits 3 to 0.
- Flush-left format with the setting for 10-bit resolution
  The comparison level (lower) to be compared with the A/D-converted results of the same channel is set in bits 15 to 6. Write 0 to bits 5 to 0.
- Flush-left format with the setting for 8-bit resolution
  The comparison level (lower) to be compared with the A/D-converted results of the same channel is set in bits 15 to 8. Write 0 to bits 7 to 0.

A/D-converted value average mode can be set only when 2- or 4-time conversion is selected in A/D-converted value addition mode.

(3) When A/D-converted addition mode is selected

- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 12-bit resolution
  The comparison level (lower) to be compared with the A/D-converted results of the same channel is set in bits 13 to 0. Write 0 to bits 15 and 14.
- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 10-bit resolution
  The comparison level (lower) to be compared with the A/D-converted results of the same channel is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 8-bit resolution
  The comparison level (lower) to be compared with the A/D-converted results of the same channel is set in bits 9 to 0. Write 0 to bits 15 and 10.
- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 16 times) with setting of 12-bit resolution
  The comparison level (lower) to be compared with the A/D-converted results of the same channel is set in bits 15 to 0.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 12-bit resolution
  The comparison level (lower) to be compared with the A/D-converted results of the same channel is set in bits 15 to 2. Write 0 to bits 1 and 0.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 10-bit resolution
  The comparison level (lower) to be compared with the A/D-converted results of the same channel is set in bits 15 to 4. Write 0 to bits 3 to 0.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 8-bit resolution
  The comparison level (lower) to be compared with the A/D-converted results of the same channel is set in bits 15 to 6. Write 0 to bits 5 to 0.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 16 times) with setting of 12-bit resolution
  The comparison level (lower) to be compared with the A/D-converted results of the same channel is set in bits 15 to 0.

When A/D converted value addition mode is selected, the value for comparison with the result of cumulative A/D converted value of the same channel is specified. Conversion 1, 2, 3, 4, or 16 times is selectable. When A/D converted value addition mode is selected and if conversion 1 to 4 is selected, the resolution of the results of conversion will be extended by 2 bits and so set a value for comparison with the results in the ADWINLLB register. When conversion 16 times is selected, the resolution of the results of conversion will be extended by 4 bits and so set a value for comparison with the results in the ADWINLLB register.
Even when A/D converted value addition mode is selected, set the value for reference based on the setting of the A/D data register format select bit.

50.2.29 A/D Comparison Function Window B Upper Level Setting Register (ADWINULB)

Address(es): S12AD.ADWINULB 0008 90AAh, S12AD1.ADWINULB 0008 91AAh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

This is a readable and writable register that specifies the data for reference when the comparison window B function is used. The register specifies the upper level of window B.
A write operation to the register is enabled even during A/D conversion. Rewriting the value of the register during A/D conversion dynamically changes the reference data.
Satisfy the condition of [upper limit level ≥ lower limit level (ADWINULB setting value ≥ ADWINLLB setting value)] when setting.
The register is not used when the window function is disabled.

The format of the register differs depending on the conditions below.

- Setting of the A/D data register format select bit (flush-right or -left format)
- Setting of the A/D conversion resolution setting bit (12, 10, or 8 bits)
- Setting of the A/D-converted value addition/averaging function channel select register (when A/D converted value averaging mode is selected or not selected)
- Setting of the A/D converted value addition/averaging count select register (when addition/averaging mode is selected and addition count is selected)

Note: When the comparison values are set in a different format from that of the A/D data register y (ADDRy), correct result of comparison cannot be obtained.

(1) When A/D-converted value addition/averaging mode is not selected

- Flush-right format with the setting for 12-bit resolution
  The comparison level (upper) is set in bits 11 to 0. Write 0 to bits 15 to b12.
- Flush-right format with the setting for 10-bit resolution
  The comparison level (upper) is set in bits 9 to 0. Write 0 to bits 15 to b10.
- Flush-right format with the setting for 8-bit resolution
  The comparison level (upper) is set in bits 7 to 0. Write 0 to bits 15 to b8.
- Flush-left format with the setting for 12-bit resolution
  The comparison level (upper) is set in bits 15 to 4. Write 0 to bits 3 to 0.
- Flush-left format with the setting for 10-bit resolution
  The comparison level (upper) is set in bits 15 to 6. Write 0 to bits 5 to 0.
- Flush-left format with the setting for 8-bit resolution
  The comparison level (upper) is set in bits 15 to 8. Write 0 to bits 7 to 0.

(2) When A/D-converted averaging mode is selected

- Flush-right format with the setting for 12-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Flush-right format with the setting for 10-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 9 to

0. Write 0 to bits 15 to 10.

- Flush-right format with the setting for 8-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 7 to 0. Write 0 to bits 15 to 8.
- Flush-left format with the setting for 12-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 15 to 4. Write 0 to bits 3 to 0.
- Flush-left format with the setting for 10-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 15 to 6. Write 0 to bits 5 to 0.
- Flush-left format with the setting for 8-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 15 to 8. Write 0 to bits 7 to 0.

A/D-converted value average mode can be set only when 2- or 4-time conversion is selected in A/D-converted value addition mode.

(3) When A/D-converted addition mode is selected

- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 12-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 13 to 0. Write 0 to bits 15 and 14.
- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 10-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 11 to 0. Write 0 to bits 15 to 12.
- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 8-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 9 to 0. Write 0 to bits 15 to 10.
- Flush-right format (in A/D-converted value addition mode and when number of conversions is selected for 16 times) with setting of 12-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 13 to 0.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 12-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 15 to 2. Write 0 to bits 1 and 0.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 10-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 15 to 4. Write 0 to bits 3 to 0.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 1 to 4 times) with setting of 8-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 15 to 6. Write 0 to bits 5 to 0.
- Flush-left format (in A/D-converted value addition mode and when number of conversions is selected for 16 times) with setting of 12-bit resolution
  The comparison level (upper) to be compared with the A/D-converted results of the same channel is set in bits 15 to 0.

When A/D converted value addition mode is selected, the value for comparison with the result of cumulative A/D converted value of the same channel is specified. Conversion 1, 2, 3, 4, or 16 times is selectable. When A/D converted value addition mode is selected and if conversion 1 to 4 is selected, the resolution of the results of conversion will be extended by 2 bits and so set a value for comparison with the results in the ADWINLLB register. When conversion 16 times is selected, the resolution of the results of conversion will be extended by 4 bits and so set a value for comparison with the results in the ADWINLLB register.
Even when A/D converted value addition mode is selected, set the value for reference based on the setting of the A/D data register format select bit.

50.2.30 A/D Comparison Function Window B Channel Status Register (ADCMPBSR)

(1) S12AD.ADCMPBSR

Address(es): 0008 90ACh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CMPSTB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPSTB	Comparison Window B Flag	0: The comparison condition is not satisfied. 1: The comparison condition is satisfied.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is used to store results of comparison of the comparison window B function.

CMPSTB Flag (Comparison Window B Flag)

This is a status flag that indicates the result of comparison of the channels for window B comparison conditions (AN000 to AN007.
When the conversion result matches with the comparison condition that is set in the ADCMPBNSR.CMPCHB[5:0] bits upon completion of A/D conversion, this flag is set to 1. When the ADCMPCR.CMPIE bit is 1, a comparison interrupt request (S12CMPBI) is generated upon the setting of the flag.
1 cannot be written to the CMPSTB flag.
[Setting condition]

- When ADCMPCR.CMPBE = 1 and the condition set in the ADCMPBNSR.CMPLB bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

(2) S12AD1.ADCMPBSR

Address(es): 0008 91ACh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CMPSTB
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPSTB	Comparison Window B Flag	0: The comparison condition is not satisfied. 1: The comparison condition is satisfied.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This is a register that stores the result of comparison by comparison window B function.

CMPSTB Flag (Comparison Window B Flag)

This is a status flag that indicates the result of comparison of the channels for window B comparison conditions (AN100 to AN111, temperature sensor, internal reference voltage).
When the comparison condition that is set in the ADCMPBNSR.CMPCHB[5:0] bits is a match upon completion of A/D conversion, this flag is set to 1. When the ADCMPCR.CMPIE bit is 1, a comparison interrupt request (S12CMPBI1) is generated upon the setting of the flag.
1 cannot be written to the CMPSTB flag.
[Setting condition]

- When ADCMPCR.CMPBE = 1 and the condition set in the ADCMPBNSR.CMPLB bit is satisfied.

[Clearing condition]

- When 0 is written after reading the state of 1.

50.2.31 A/D Conversion Time Setting Register (ADSAM)

Address(es): S12AD.ADSAM 0008 906Eh, S12AD1.ADSAM 0008 916Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	SAM	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R
b5	SAM	Conversion Time Setting	0: Sets conversion time for high-speed. 1: Sets conversion time for middle-speed.	R/W
b15 to b6	—	Reserved	These bits are read as 0. The write value should be 0.	R

This register specifies conversion time for unit 0 (high-speed) and unit 1 (middle-speed).
Set the PSW.I bit to 0 (interrupt disabled) and the ADSAMPR.PRO[1:0] bits to 11 (writing enabled) before rewriting the register. Furthermore, disable writing to the register by setting the ADSAMPR.PRO[1:0] bits to 10 immediately after rewriting the register.

SAM Bit (Conversion Time Setting)

Set this bit to 0 for unit 0 which is a high-speed A/D converter. Setting this bit to 0 sets conversion time 13 states for 12-bit resolution, 11 states for 10-bit resolution, or 9 states for 8-bit resolution.
Set this bit to 1 for unit 1 which is a middle-speed A/D converter. Setting this bit to 1 sets conversion time 15 states for 12-bit resolution, 13 states for 10-bit resolution, or 11 states for 8-bit resolution.
Set the bit while the ADCSR.ADST bit is 0.
Note that the electrical characteristics cannot be satisfied when any setting other than the above is made to the respective units.

50.2.32 A/D Conversion Time Setting Protection Release Register (ADSAMPR)

Address(es): S12AD.ADSAMPR 0008 9063h, S12AD1.ADSAMPR 0008 9163h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PRO[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	PRO[1:0]	A/D Conversion Time Setting Register Protection	b1 b0 0 0: Writing to or reading from the A/D conversion time setting register is disabled (initial value. The value is read as 00b). 1 0: Writing to or reading from the A/D conversion time setting register is disabled (The value is read as 00b). 1 1: Writing to or reading from the A/D conversion time setting register is enabled (The value is read as 01b). Settings other than above are prohibited.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R

This register enables accesses to the A/D conversion time setting register (ADSAM).

Set the PRO[1:0] bits to 10b (writing disabled) after setting the A/D conversion time setting register (ADSAM).
The PRO[1:0] bits are read as 00b while writing to the bits is disabled, and 01b while writing to the bits is enabled.

50.3 Operation

50.3.1 Scanning Operation

In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.
A scan conversion is performed in three operating modes: single scan mode, continuous scan mode, and group scan mode. In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until the ADCSR.ADST bit is cleared to 0 from 1 by software. In group scan mode, the selected channels of groups A, B, and C are scanned once after starting to be scanned according to the respective synchronous trigger.
In single scan mode and continuous scan mode, A/D conversion is performed for ANn channels selected by the ADANSA0 register, starting from the channel with the smallest number n. In group scan mode, A/D conversion is performed for ANn channels of groups A, B, and C selected by the ADANSA0 register, ADANSB0 register, and ADANSC0 register, respectively, starting from the channel with the smallest number n.
When self-diagnosis is selected, it is executed once at the beginning of each scan and one of the three voltages internally generated in the 12-bit A/D converter is converted.
The temperature sensor output and internal reference voltage can be selected with analog input of the channels, and A/D conversion is performed in the order of the analog input of the channels, temperature sensor output, and internal reference voltage. When the extended analog is selected, perform A/D conversion in single scan mode or sequence scan mode.
Double trigger mode is to be used with single scan mode or group scan mode. With double trigger mode being enabled, A/D conversion data of a channel selected by the ADCSR.DBLANS[4:0] bits is duplicated only if the conversion is started by the synchronous trigger selected by the ADSTRGR.TRSA[5:0] bits. In group scan mode, the double trigger function can be used only for group A.
Extended double trigger mode indicates a state when the following synchronous trigger (two synchronous trigger sources enabled) is selected by the TRSA[5:0] bits in the A/D conversion start trigger select register (ADSTRGR) in double trigger mode.

- TRG4AN or TRG4BN (the ADSTRGR.TRSA[5:0] bits are set to 001011b)
- TRG7AN or TRG7BN (the ADSTRGR.TRSA[5:0] bits are set to 001111b)

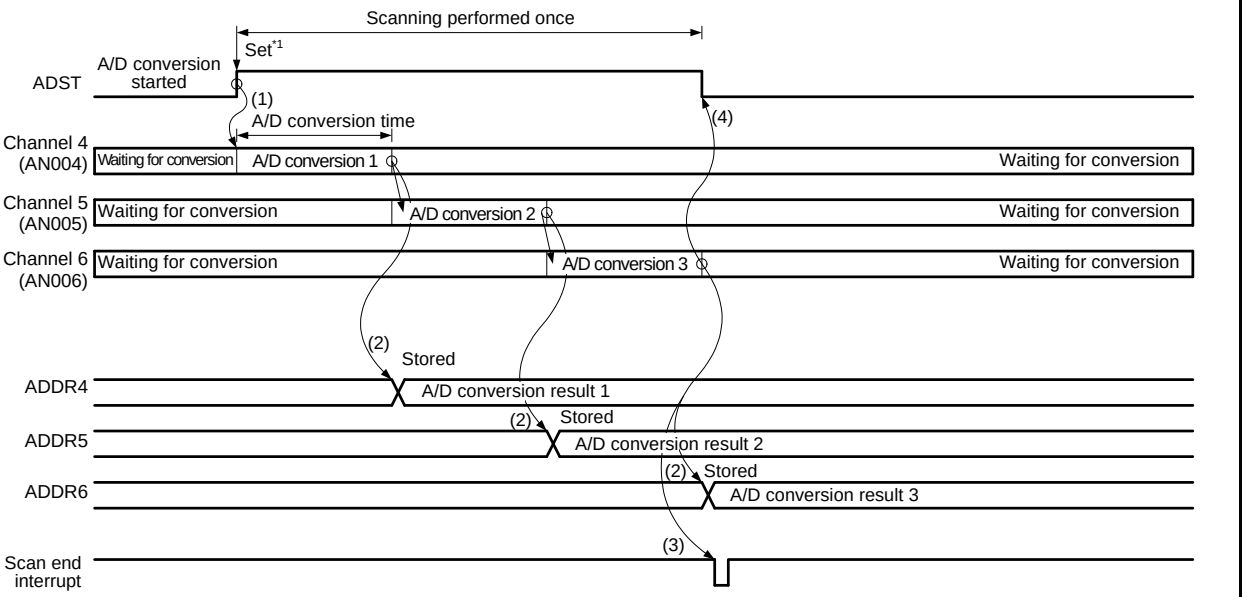
In extended double trigger mode, in addition to normal operations in double trigger mode, A/D conversion data is stored in A/D data duplication register A (ADDBLDRA) or A/D data duplication register B (ADDBLDRB) depending on the trigger type. If two types of triggers have occurred simultaneously in this mode, A/D conversion data is not sorted by the trigger sources and is stored in data duplication register B (ADDBLDRB).
Note that if a new trigger is input during A/D conversion caused by another trigger, the new trigger is ignored.

50.3.2 Single Scan Mode

50.3.2.1 Basic Operation

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels as below.

(1) When the ADCSR.ADST bit is set to 1 (A/D conversion start) by software, or synchronous or asynchronous trigger input, A/D conversion is performed for ANn channels selected by the ADANSA0 register, starting from the channel with the smallest number n.
(2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(3) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (interrupt generation upon scanning completion enabled).
(4) The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a wait state.



Note 1. ↓ indicates the instruction is executed by software.

Figure 50.6 Example of Operation in Single Scan Mode (Basic Operation: AN004, AN005, AN006 Selected)

50.3.2.2 Channel Selection and Self-Diagnosis

When channels and self-diagnosis are selected, A/D conversion is performed once for the reference voltage supplied to the 12-bit A/D converter as below. After that, A/D conversion is performed only once on the analog input of the selected channels.

(1) A/D conversion for self-diagnosis is started when the ADCSR.ADST bit is set to 1 (A/D conversion start) by software, or synchronous or asynchronous trigger input.
(2) When A/D conversion for self-diagnosis is completed, A/D conversion result is stored into the A/D self-diagnosis data register (ADRD), and A/D conversion is performed for ANn channels selected by the ADANSA0 register, starting from the channel with the smallest number n.
(3) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(4) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (interrupt generation upon scanning completion enabled).
(5) The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a wait state.

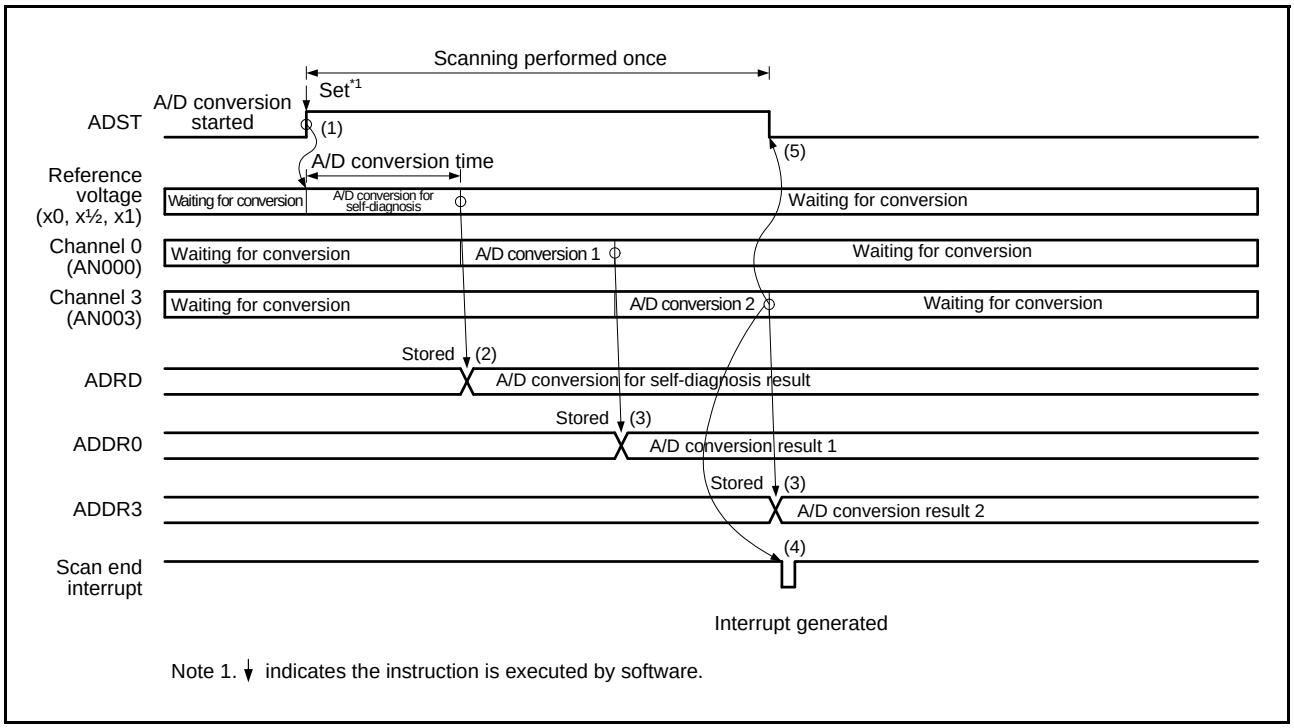


Figure 50.7 Example of Operation in Single Scan Mode (Basic Operation: AN000, AN003 Selected + Self-Diagnosis)

50.3.2.3 A/D Conversion With Temperature Sensor Output/Internal Reference Voltage Selected

When temperature sensor output or internal reference voltage is selected with channels, A/D conversion of analog input of the channels is performed as described below. After that, A/D conversion is performed only once for the temperature sensor output or internal reference voltage. When temperature sensor output and internal reference voltage are both selected, A/D conversion is performed for the temperature sensor output first and then internal reference voltage. Deselecting channels and selecting only one of temperature sensor output and internal reference voltage is possible.

(1) When the ADCSR.ADST bit is set to 1 (A/D conversion start) by software, or synchronous or asynchronous trigger input, and A/D conversion is performed for ANn channels selected by the ADANSA0 register, starting from the channel with the smallest number n.
(2) Each time A/D conversion of a single channel is completed, the A/D converted value is stored in the corresponding A/D data register (ADDRy), and then A/D conversion for temperature sensor output is started.
(3) When A/D conversion of the temperature sensor output is completed, the A/D converted value is stored in the corresponding A/D temperature sensor data register (ADTSDR), and then A/D conversion for internal reference voltage is started.
(4) After completion of A/D conversion of the internal reference voltage, the A/D converted value is stored in the corresponding A/D internal reference voltage data register (ADOCDR), and if the ADCSR.ADIE bit is set to 1 (when the generation of an interrupt after scanning is enabled), a scan end interrupt request is generated.
(5) The ADCSR.ADST bit holds 1 (A/D conversion start) during A/D conversion, and the bit is automatically cleared upon completion of the A/D conversion. The 12-bit A/D converter enters into a wait state.

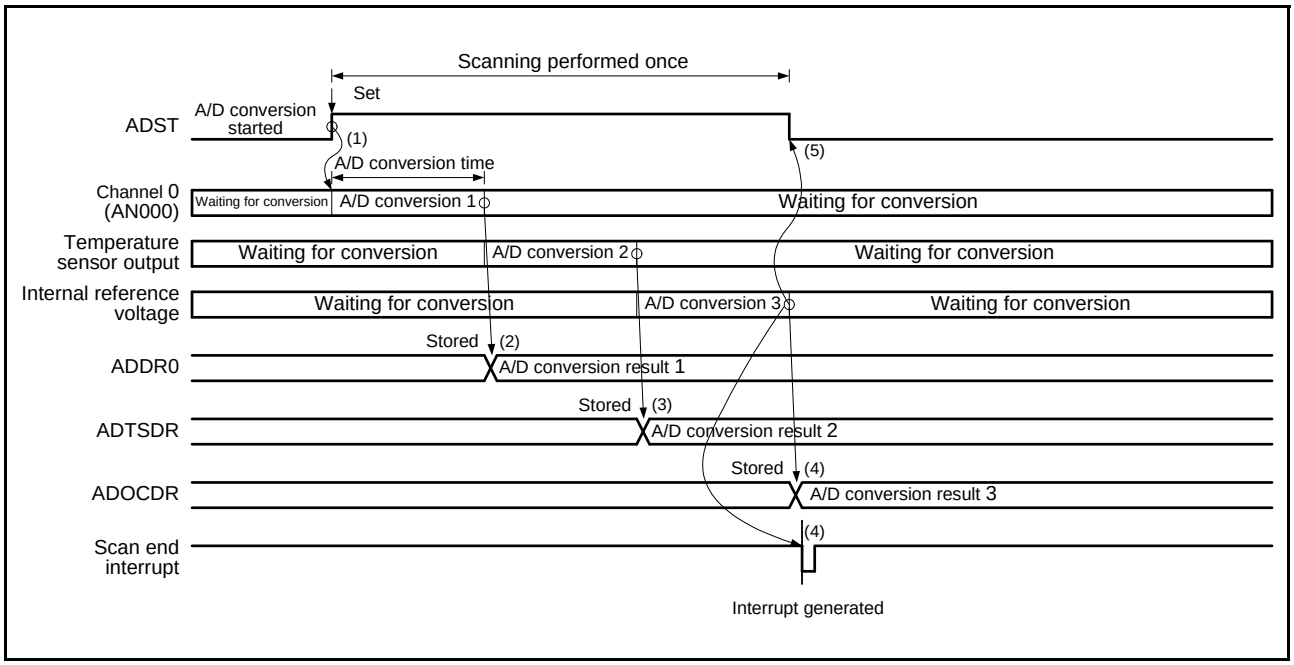

Figure 50.8 Example of Operation in Single Scan Mode (Basic Operation: AN000, Temperature Sensor Output, and Internal Reference Voltage Selected)

50.3.2.4 A/D Conversion in Double Trigger Mode

In single scan mode with double trigger mode, single scan operation started by synchronous trigger is performed twice as below.

Deselect self-diagnosis and set the temperature sensor A/D conversion select bit (ADEXICR.TSSA, ADEXICR.TSSB) and internal reference voltage A/D conversion select bit (ADEXICR.OCSA, ADEXICR.OCSB) to 0.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 register is invalid. In double trigger mode, synchronous triggers should be selected using the ADSTRGR.TRSA[5:0] bits, the ADCSR.EXTRG bit should be set to 0, and the ADCSR.TRGE bit should be set to 1. Software trigger should not be used.

(1) When the ADCSR.ADST bit is set to 1 (A/D conversion start) by synchronous trigger input, A/D conversion is started on the single channel selected by the ADCSR.DBLANS[4:0] bits.
(2) When A/D conversion is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(3) The ADCSR.ADST bit is automatically cleared to 0 and the 12-bit A/D converter enters a wait state. Here, a scan end interrupt request is not generated irrespective of the ADCSR.ADIE bit setting (interrupt generation upon scanning completion enabled).
(4) When the ADCSR.ADST bit is set to 1 (A/D conversion start) by the second trigger input, A/D conversion is started on the single channel selected by the ADCSR.DBLANS[4:0] bits.
(5) When A/D conversion is completed, the A/D conversion result is stored into the A/D data duplication register (ADDBLDR), which is exclusively used in double trigger mode.
(6) If the ADCSR.ADIE bit is 1 (interrupt generation upon scanning completion enabled), a scan end interrupt request is generated.
(7) The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion is completed. Then the 12-bit A/D converter enters a wait state.

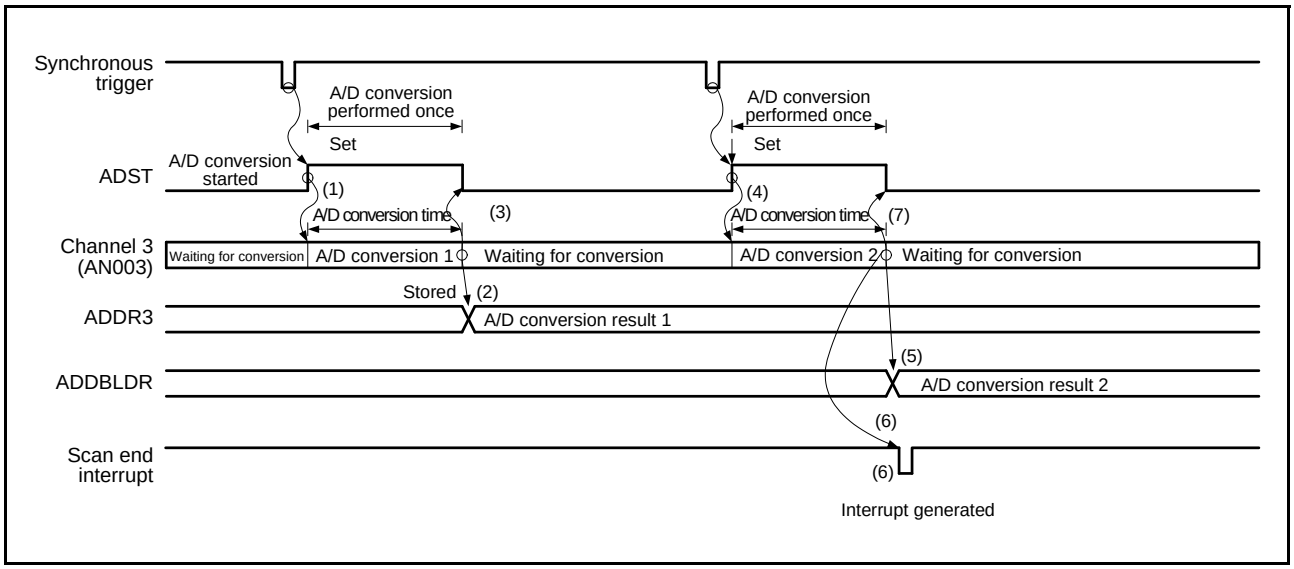

Figure 50.9 Example of Operation in Single Scan Mode (Double Trigger Mode Selected; AN003 Duplicated)

50.3.2.5 A/D Conversion in Extended Double Trigger Mode

When the double-trigger mode is selected in single-scanning mode, with TRG4AN or TRG4BN, TRG7AN or TRG7BN selected in the TRSA[5:0] bits of the A/D conversion start trigger select register (ADSTRGR), proceed with single scanning twice as follows.
Deselect self-diagnosis and set the temperature sensor A/D conversion select bit (ADEXICR.TSSA, ADEXICR.TSSB) and internal reference voltage A/D conversion select bit (ADEXICR.OCSA, ADEXICR.OCSB) to 0.
Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1. When the ADCSR.DBLE bit is set to 1, channel selection using the ADANSA0 register is invalid. In extended double trigger mode, the ADCSR.EXTRG bit should be set to 0, and the ADCSR.TRGE bit should be set to 1. Software trigger should not be used.

(1) When the ADCSR.ADST bit is set to 1 (A/D conversion start) by TRG4AN input, A/D conversion is started on the single channel selected by the ADCSR.DBLANS[4:0] bits.
(2) When A/D conversion is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy) and A/D data-duplication register A (ADDBLDRA).
(3) The ADCSR.ADST bit is automatically cleared to 0 and the 12-bit A/D converter enters a wait state. Here, a scan end interrupt request is not generated irrespective of the ADCSR.ADIE bit setting (interrupt generation upon scanning completion enabled).
(4) When the ADCSR.ADST bit is set to 1 (A/D conversion start) by TRG4BN input, A/D conversion is started on the single channel selected by the ADCSR.DBLANS[4:0] bits.
(5) When A/D conversion is completed, the A/D conversion result is stored into A/D data duplication register (ADDBLDR) and A/D data duplication register B (ADDBLDRB).
(6) If the ADCSR.ADIE bit is 1 (interrupt generation upon scanning completion enabled), a scan end interrupt request is generated.
(7) The ADCSR.ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion is completed. Then the 12-bit A/D converter enters a wait state.

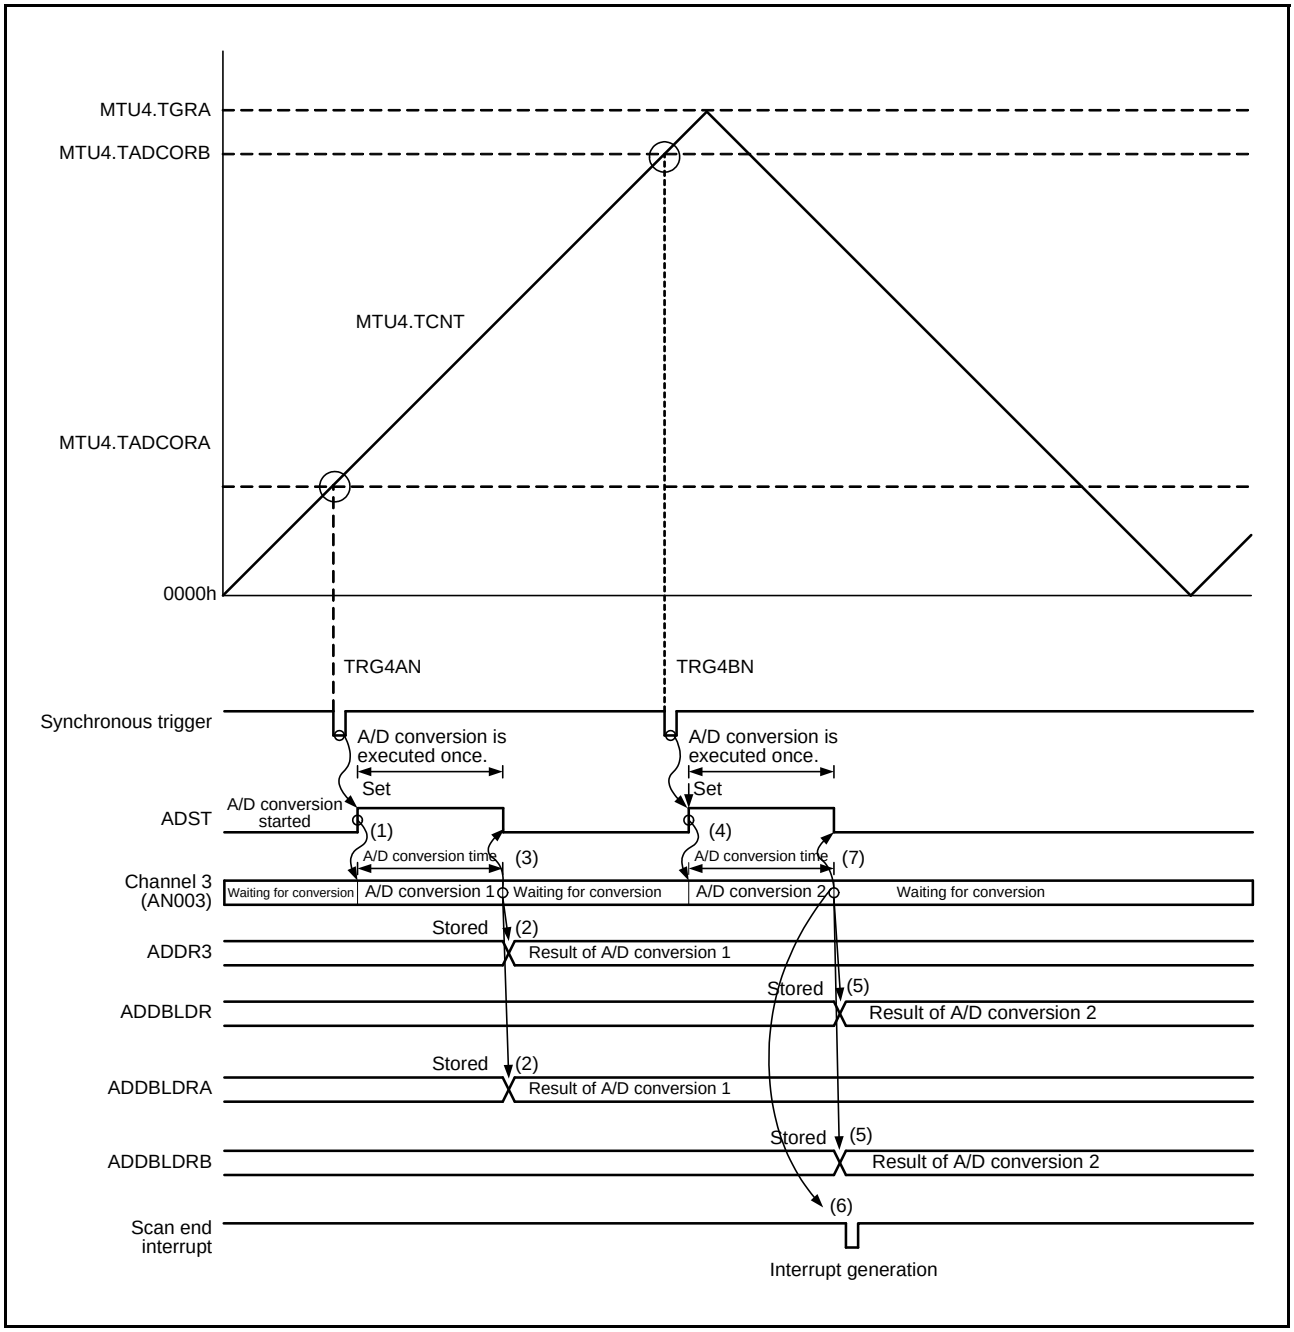

Figure 50.10 Example of Extended Operation in Double Trigger Mode (1)
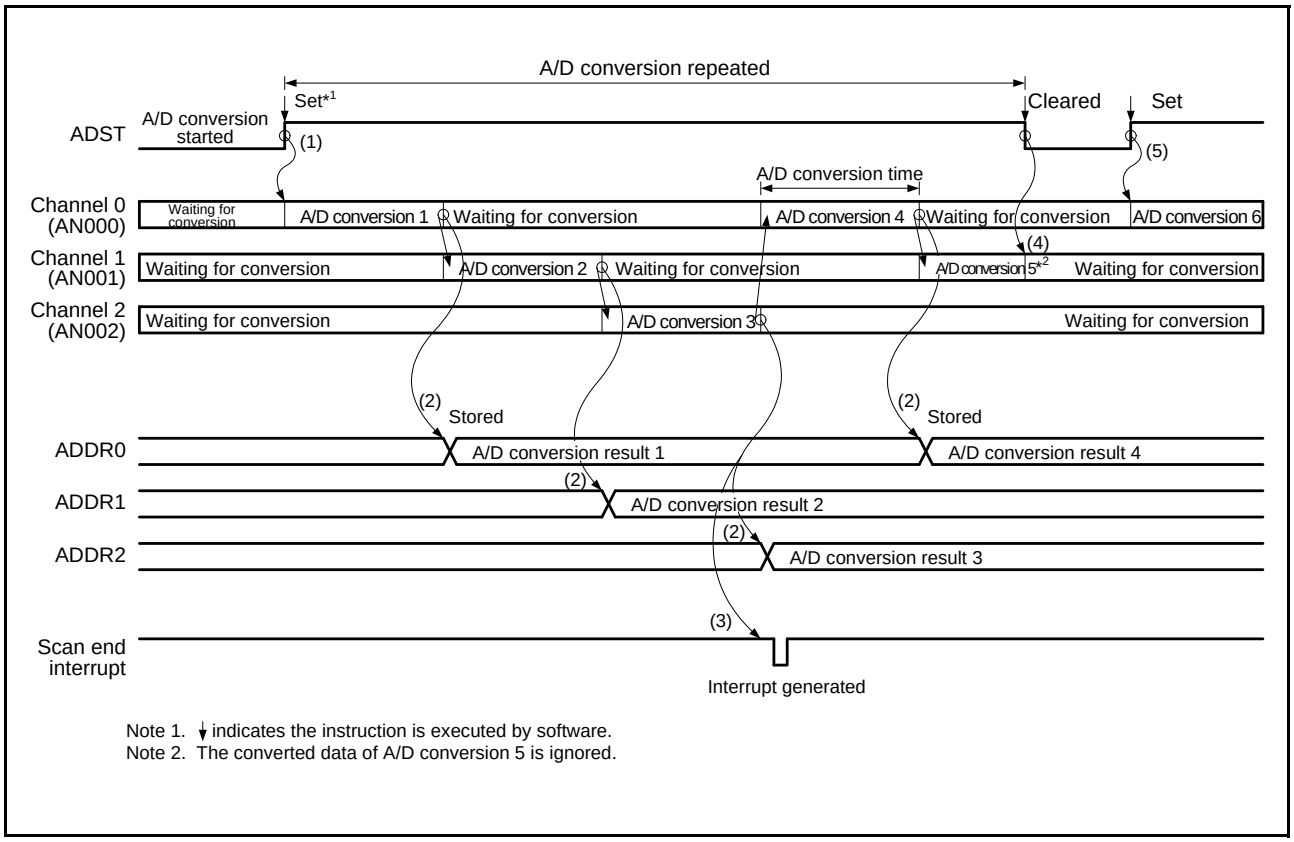
(Duplication Selected for AN003, TRG4AN or TRG4BN Selected, First Trigger is TRG4AN)

50.3.3 Continuous Scan Mode

50.3.3.1 Basic Operation

In basic operation of continuous scan mode, A/D conversion is performed repeatedly on the analog input of the specified channels as below.

(1) When the ADCSR.ADST bit is set to 1 (A/D conversion start) by software, or synchronous or asynchronous trigger input, A/D conversion is performed for ANn channels selected by the ADANSA0 register, starting from the channel with the smallest number n.
(2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(3) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (interrupt generation upon scanning completion enabled).
The 12-bit A/D converter sequentially starts A/D conversion for ANn channels selected by the ADANSA0 register, starting from the channel with the smallest number n.
(4) The ADCSR.ADST bit is not automatically cleared to 0 and steps 2 and 3 are repeated as long as the bit remains 1 (A/D conversion start). When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the 12-bit A/D converter enters a wait state.
(5) When the ADST bit is later set to 1 (A/D conversion start), A/D conversion is started again for ANn channels selected by the ADANSA0 register, starting from the channel with the smallest number n.



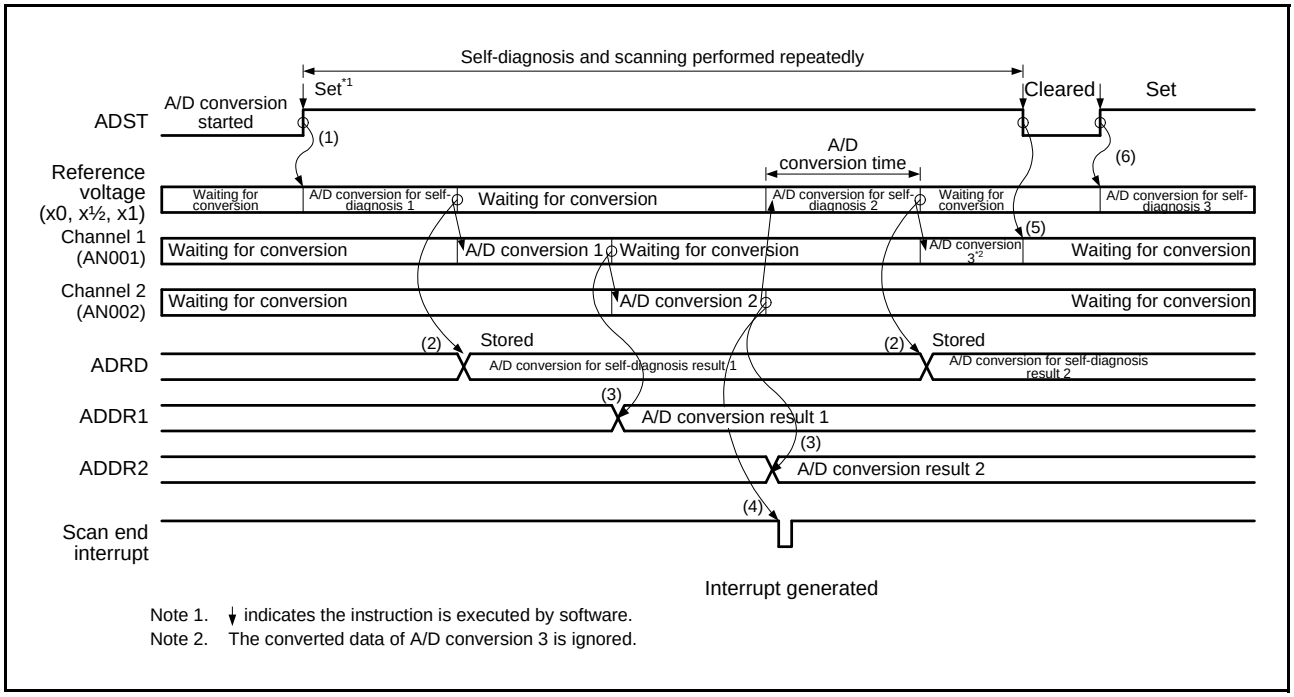
Note 1. ↓ indicates the instruction is executed by software.
Note 2. The converted data of A/D conversion 5 is ignored.

Figure 50.11 Example of Operation in Continuous Scan Mode (Basic Operation: AN000 to AN002 Selected)

50.3.3.2 Channel Selection and Self-Diagnosis

When channels and self-diagnosis are selected at the same time, A/D conversion is first performed for the reference voltage supplied to the 12-bit A/D converter, and then A/D conversion is performed on the analog input of the selected channels, which sequence is repeated as below.

(1) When the ADCSR.ADST bit is set to 1 (A/D conversion start) by software, or synchronous or asynchronous trigger input, A/D conversion for self-diagnosis is started first.
(2) When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored into the A/D self-diagnosis data register (ADRD). A/D conversion is then performed for ANn channels selected by the ADANSA0 register, starting from the channel with the smallest number n.
(3) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(4) When A/D conversion of all the selected channels is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (interrupt generation upon scanning completion enabled). At the same time, the 12-bit A/D converter starts A/D conversion for self-diagnosis and then starts A/D conversion on ANn channels selected by the ADANSA0 register, starting from the channel with the smallest number n.
(5) The ADCSR.ADST bit is not automatically cleared and steps 2 to 4 are repeated as long as the bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the 12-bit A/D converter enters a wait state.
(6) When the ADCSR.ADST bit is later set to 1 (A/D conversion start), the A/D conversion for self-diagnosis is started again.



Note 1. ↓ indicates the instruction is executed by software.
Note 2. The converted data of A/D conversion 3 is ignored.

Figure 50.12 Example of Operation in Continuous Scan Mode (Basic Operation; AN001 and AN002 Selected + Self-Diagnosis)

50.3.3.3 A/D Conversion With Temperature Sensor Output/Internal Reference Voltage Selected

When temperature sensor output or internal reference voltage are selected with channels, A/D conversion of analog input of the channels is performed, after that A/D conversion is performed for the temperature sensor output or internal reference voltage as described below. After that, A/D conversion is performed repeatedly on the analog input of the selected channels. When temperature sensor output and internal reference voltage are both selected, A/D conversion is performed temperature sensor output first and then internal reference voltage.
Deselecting channels and selecting only one of temperature sensor output and internal reference voltage is possible.

(1) When the ADCSR.ADST bit is set to 1 (A/D conversion start) by software, or synchronous or asynchronous trigger input, and A/D conversion is performed for ANn channels selected by the ADANSA0 register, starting from the channel with the smallest number n.
(2) Each time A/D conversion of a single channel is completed, the A/D converted value is stored in the corresponding A/D data register (ADDRy), and then A/D conversion for temperature sensor output is started.
(3) When A/D conversion of the temperature sensor output is completed, the A/D converted value is stored in the corresponding A/D temperature sensor data register (ADTSDR), and then A/D conversion for internal reference voltage is started.
(4) After completion of A/D conversion of the internal reference voltage, the A/D converted value is stored in the corresponding A/D internal reference voltage data register (ADOCDR), and if the ADCSR.ADIE bit is set to 1 (when interrupt generation after scanning is enabled), a scan end interrupt request is generated. The 12-bit A/D converter sequentially starts A/D conversion for ANn channels selected by the ADANSA0 register, starting from the channel with the smallest number n.
(5) While the ADCSR.ADST bit holds 1 without being automatically cleared, steps 2 to 4 above are repeated. When the ADCSR.ADST bit is cleared to 0 (A/D conversion stop), A/D conversion is stopped and the 12-bit A/D converter enters into a wait state.
(6) After that, when the ADSHMSR.SHMD bit is set to 1 (A/D conversion start), A/D conversion is performed for ANn channels selected in the ADANSA0 register starting from the channel with the smallest number n.

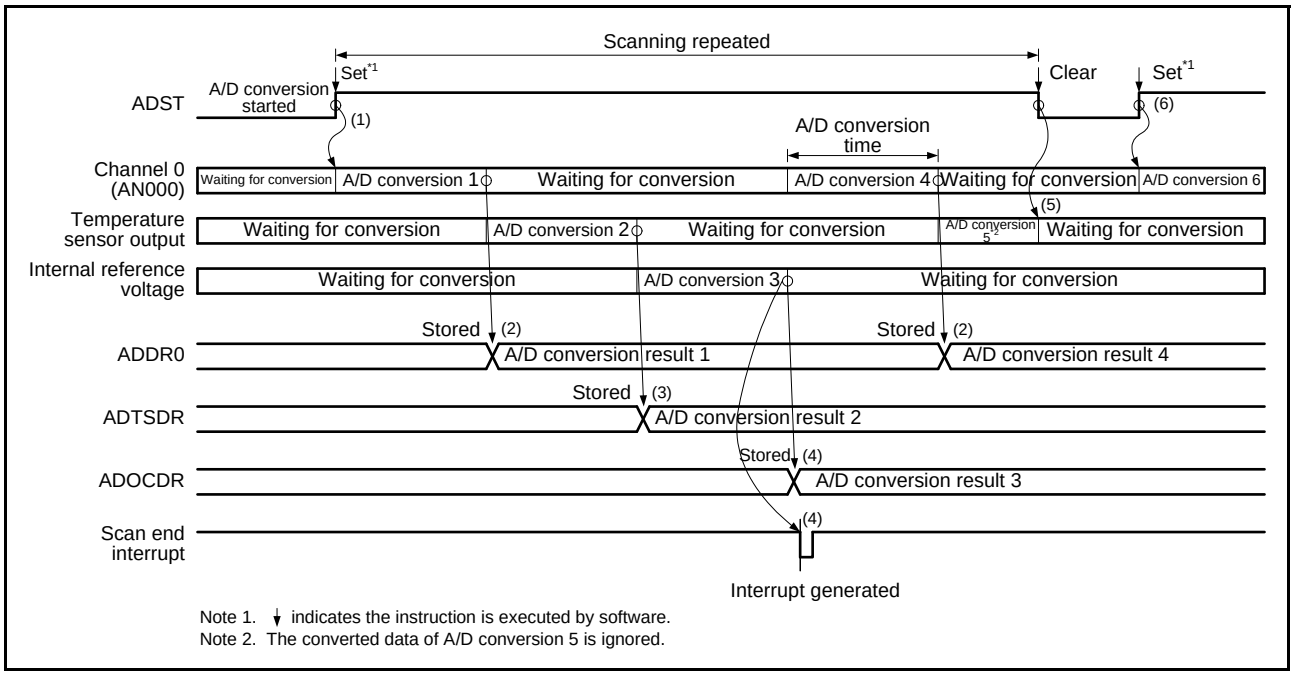


Figure 50.13 Example of Operation in Sequence Scan Mode (Basic Operation: AN000, Temperature Sensor Output and Internal Reference Voltage Selected)

50.3.4 Group Scan Mode

50.3.4.1 Basic Operation

Either two (groups A and B) or three (groups A, B, and C) can be selected as the number of the groups to be used in group scan mode.
In basic operation of group scan mode, A/D conversion is performed once on the analog inputs of all the specified channels in groups A and B, or groups A, B, and C after scan is started by a synchronous trigger as below. Scan operation of each group is similar to the scan operation in single scan mode.
The synchronous triggers of groups A and B, or groups A, B, and C can be selected using the TRSA[5:0], TRSB[5:0], and TRSC[5:0] bits in ADSTRGR, respectively. Different triggers should be used for each group A, B, and C so that scanning of groups A, B, and C does not occur simultaneously. Software trigger should not be used.
The channels to be scanned are selected using register ADANSA0 and bits TSSA and OCSA in register ADEXICR for group A, register ADANSB0 and bits TSSB and OCSB in register ADEXICR for group B, and register ADANSC0 and bits TSSC and OCSC in register ADGCEXCR for group C.
When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed for groups A and B, or groups A, B, and C.
The following describes operation in group scan mode using a trigger from the MTU. The TRG4AN, TRG4BN, and TRG4ABN triggers from the MTU are assumed to be used to start conversion of groups A, B and C, respectively.

(1) Scanning of group A is started by the TRG4AN trigger from the MTU.
(2) When group A scanning is completed, a scan end interrupt is generated if the ADCSR.ADIE bit is 1 (interrupt generation upon scanning completion enabled).
(3) Scanning of group B is started by the TRG4BN trigger from the MTU.
(4) When group B scanning is completed, a group B scan end interrupt is generated if the ADCSR.GBADIE bit is 1 (interrupt generation upon group B scan completion enabled).
(5) Scanning of group C is started by the TRG4ABN trigger from the MTU.
(6) When group C scanning is completed, a group C scan end interrupt is generated if the ADGCTRGR.GCADIE bit is 1 (interrupt generation upon group C scan completion enabled).

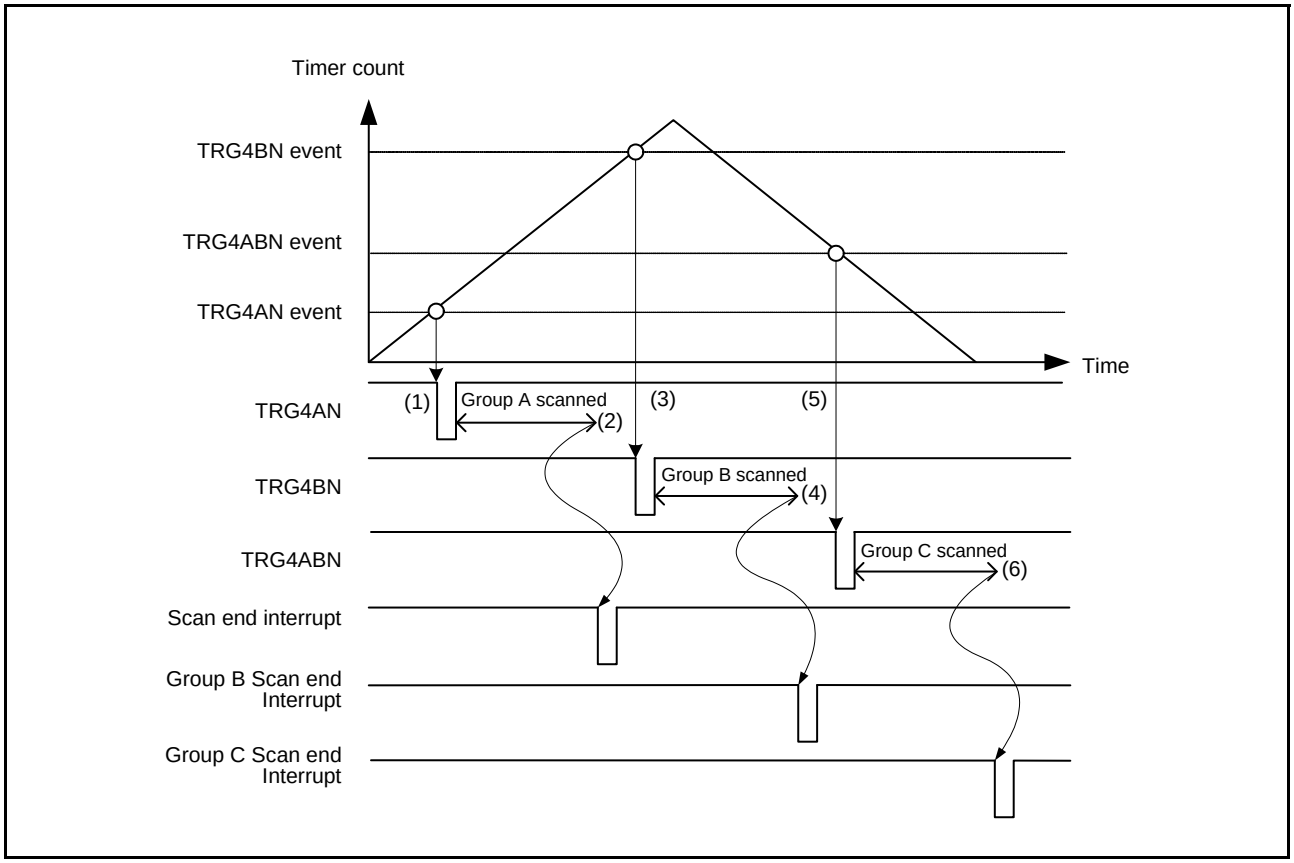

Figure 50.14 Example of Operation in Group Scan Mode (Basic Operation: Synchronous Triggers from MTU Used)

50.3.4.2 A/D Conversion in Double Trigger Mode

When double trigger mode is selected in group scan mode, two rounds of single scan operation started by a synchronous trigger are performed as a sequence for group A. For groups B and C, single scan operation started by a synchronous trigger is performed once.

In group scan mode, the synchronous triggers of groups A and B, or groups A, B, and C can be selected using the TRSA[5:0], TRSB[5:0], and TRSC[5:0] bits in ADSTRGR, respectively. Different triggers should be used for each group A, B, and C so that scanning of groups A, B, and C does not occur simultaneously. Software trigger and asynchronous trigger should not be used. When the TRG4AN or TRG4BN, TRG7AN or TRG7BN is selected in the ADSTRGR.TRSA[5:0] bits as the synchronous trigger of the group A, operation is in the extended double trigger mode. The channels to be scanned are selected using bits ADCSR.DBLANS[4:0] for group A, register ADANSB0 for group B, and register ADANSC0 for group C.

When double trigger mode is selected in group scan mode, the temperature sensor A/D conversion select bit (ADEXICR.TSSA) and internal reference voltage A/D conversion select bit (ADEXICR.OCSA) are set to 0 (not selected).

When double trigger mode is selected in group scan mode, self-diagnosis cannot be selected.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated to the ADCSR.DBLANS[4:0] bits and setting the ADCSR.DBLE bit to 1.

The following describes operation in group scan mode with double trigger mode using a synchronous trigger from the MTU. The TRG4ABN, TRGA0N, and TRGA1N triggers from the MTU are assumed to be used to start conversion of groups A, B, and C, respectively.

(1) Scanning of group C is started by the TRGA1N trigger from the MTU.
(2) When group C scanning is completed, a group C scan interrupt is generated if the ADGCTRGR.GCADIE bit is 1 (interrupt generation upon group C scan completion enabled).
(3) Scanning of group B is started by the TRGA0N trigger from the MTU.
(4) When group B scanning is completed, a group B scan end interrupt is generated if the ADCSR.GBADIE bit is 1 (interrupt generation upon group B scan enabled).
(5) The first scanning of group A is started by the first TRG4ABN trigger from the MTU.
(6) When the first scanning of group A is completed, the conversion result is stored into the corresponding A/D data register (ADDRy); a scan end interrupt request is not generated irrespective of the ADIE bit setting in ADCSR.
(7) The second scanning of group A is started by the second TRG4ABN trigger from the MTU.
(8) When the second scanning of group A is completed, the conversion result is stored into ADDBLDR. a scan end interrupt is generated if the ADCSR.ADIE bit is 1 (interrupt generation upon scanning completion enabled).
(9) The second scanning of group B is started by the second TRGA0N trigger from the MTU.
(10) When the second scanning of group B is completed, a group B scan interrupt is generated if the ADCSR.GBADIE bit is 1 (interrupt generation upon group B scan completion enabled).
(11) The second scanning of group C is started by the second TRGA1N trigger from the MTU.
(12) When the second scanning of group C is completed, a group C scan interrupt is generated if the ADGCTRGR.GCADIE bit is 1 (interrupt generation upon group C scan completion enabled).

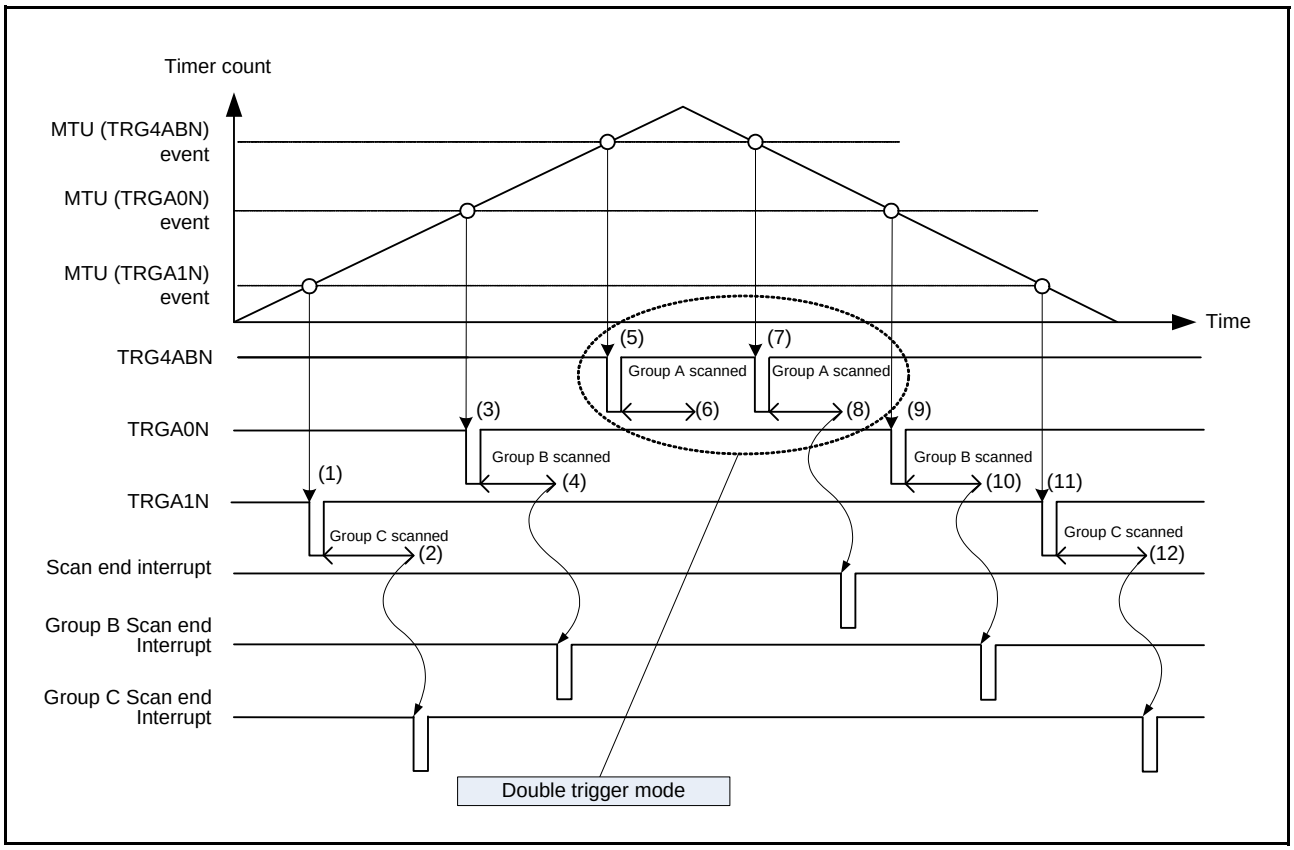

Figure 50.15 Example of Operation in Group Scan Mode with Double Trigger Mode (Basic Operation: Synchronous Triggers from MTU Used)

50.3.4.3 Operation under Group Priority Control

Setting the ADGSPCR.PGS bit to 1 in group scan mode makes operation proceed under group priority control. The group priority order is group A > group B > group C. Either two (groups A and B) or three (groups A, B, and C) can be selected as the number of the groups to be used in group scan mode. When setting the ADGSPCR.PGS bit to 1, follow the procedure described in Figure 50.16. If the procedure is not followed, proper scanning operation and data storage are not guaranteed.

In basic operation of group scan mode, if group A, B, or C is scanning, all other trigger inputs are ignored. Under group priority control, if a priority group trigger is input during A/D conversion for the low-priority group, A/D conversion for the low-priority group is discontinued and A/D conversion for the priority group proceeds.

If the ADGSPCR.GBRSCN bit is 0, the converter enters a wait state for the low-priority group on completion of the A/D conversion for the priority group.

The trigger input for the low-priority group during scanning is ignored.

If the ADGSPCR.GBRSCN bit is 1, the converter automatically restarts scanning for the low-priority group from the head of the group after A/D conversion for the priority group.

Also, the trigger input for the low-priority group generated during scanning for the priority group is enabled, and the converter automatically restarts scanning for the low-priority group after scanning for the priority group.

When the ADGSPCR.LGRRS bit is 0 while the ADGSPCR.GBRSCN bit is 1, the converter restarts scanning for the low-priority group from the head of the group. When the ADGSPCR.LGRRS bit is 1, the converter restarts scanning for the low-priority group from the channel on which scanning is discontinued.

However, when self-diagnosis is used, the converter restarts scanning from the channel on which scanning is discontinued after self-diagnosis is completed.

Table 50.15 summarizes operations in response to the input of a trigger during scanning with the settings of the ADGSPCR.GBRSCN bit.

When the ADGSPCR.GBRP bit is set to 1, scan operations in the lowest-priority group are continuously performed.

For the trigger settings in group scan mode, select a synchronous trigger for group A using the ADSTRGR.TRSA[5:0] bits, select a synchronous trigger different from that of group A for group B using the ADSTRGR.TRSB[5:0] bits, and select a synchronous trigger different from those of groups A and B for group C using the ADGCTRGR.TRSC[5:0] bits.

Set the ADSTRGR.TRSB[5:0] bits to 3Fh when setting group scan mode for two groups (the ADGCTRGR.GRCE bit to 0) and setting the ADGSPCR.GBRP bit to 1.

Set the ADGCTRGR.TRSC[5:0] bits to 3Fh when setting group scan mode for three groups (the ADGCTRGR.GRCE bit to 1) and setting the ADGSPCR.GBRP bit to 1.

Furthermore, as targets for scanning, select channels for group A by using the ADANSA0 register, and ADEXICR.TSSA and ADEXICR.OCSA bits; select the group B channels by using ADANSB0 register, and ADEXICR.TSSB and ADEXICR.OCSB bits; and select the group c by using ADANSC0 register, and ADGCEXCR.TSSC and ADGCEXCR.OCSC bits respectively.

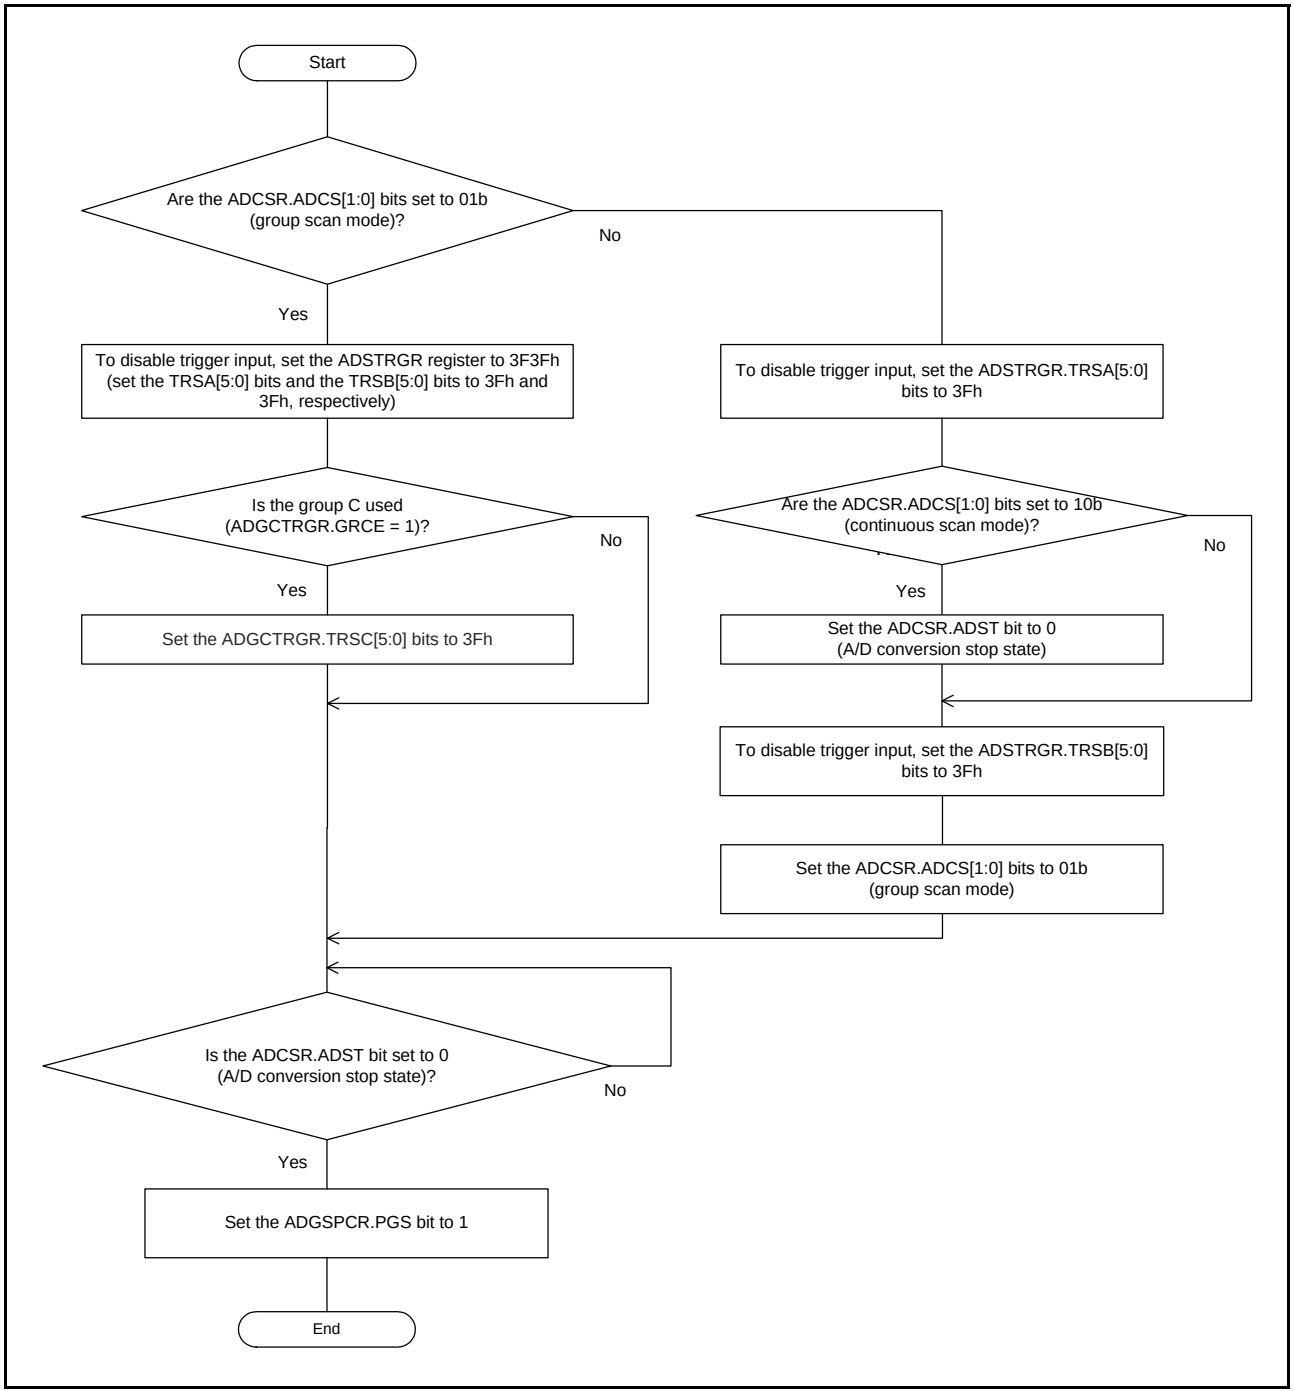

Figure 50.16 Flow of Setting the ADGSPCR.PGS Bit

Table 50.15 Control of Scanning Operations According to the Settings of the ADGSPCR.GBRSCN Bit

Scanning Operation	Trigger Input	ADGSPCR.GBRSCN = 0	ADGSPCR.GBRSCN = 1
When A/D conversion for group A is in progress	Input of trigger for group A	Trigger input is ineffective.	Trigger input is ineffective.
	Input of trigger for group B	Trigger input is ineffective.	A/D conversion is performed on group B after A/D conversion on group A is completed.
	Input of trigger for group C	Trigger input is ineffective.	A/D conversion is performed on group C after A/D conversion on group A is completed.
When A/D conversion for group B is in progress	Input of trigger for group A	A/D conversion in progress for group B discontinued and conversion for group A starts.	• A/D conversion in progress for group B is discontinued and conversion for group A starts. • A/D conversion for group B starts after conversion for group A is completed.
	Input of trigger for group B	Trigger input is ineffective.	Trigger input is ineffective.
	Input of trigger for group C	Trigger input is ineffective.	A/D conversion is performed on group C after A/D conversion on group B is completed.
When A/D conversion for group C is in progress	Input of trigger for group A	A/D conversion in progress for group C discontinued and conversion for group A starts.	• A/D conversion in progress for group C is discontinued and conversion for group A starts. • A/D conversion for group C starts after conversion for group A is completed.
	Input of trigger for group B	A/D conversion in progress for group C is discontinued and conversion for group B starts.	• A/D conversion in progress for group C is discontinued and conversion for group B starts. • A/D conversion for group C starts after conversion for group B is completed.
	Input of trigger for group C	Trigger input is ineffective.	Trigger input is ineffective.

When using group priority operation mode, refer to the following tables to select the desirable operating mode and set the registers.

Table 50.16 Group Priority Operation Setting and Operating Mode for Two Groups (ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 0)

ADGSPCR			
GBRSCN	**LGRRS**	**GBRP**	**Operation**
0	x	0	Group priority operation for two groups (groups A and B) • When a group A trigger is input, group B scan is completed (not restarted)
1	0	0	Group priority operation for two groups (groups A and B) • After group B scan is discontinued, group B scan is restarted from the head of the channel selected with the ADANSB0 register after group A scan is completed.
1	1	0	Group priority operation for two groups (groups A and B) • After group B scan is discontinued, group B scan is restarted from the channel on which scan was discontinued*1, among the channels selected with the ADANSB0 register after group A scan is completed.
x	0	1	Group priority operation for two groups (groups A and B) • Single scan for group B is started continuously without start trigger input. After group B scan is discontinued, single scan is restarted from the head of the channel selected with the ADANSB0 register after scan for group A is completed.
1	1	1	Group priority operation for two groups (groups A and B) • Single scan for group B is started continuously without start trigger input. After group B scan was discontinued, single scan is restarted from the channel on which scan was discontinued*1, among the channels selected with the ADANSB0 register after group A scan is completed.

x = Don't care

Note 1. When self-diagnosis is used (ADCER.DIAGM = 1), A/D conversion of the discontinued channel is started after self-diagnosis.

Table 50.17 Group Priority Operation Setting and Operating Mode for Three Groups (ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 1)

ADGSPCR			
GBRSCN	**LGRRS**	**GBRP**	**Operation**
0	x	0	Group priority operation for three groups (groups A, B, and C) • When a group A trigger is input, group B scan is completed (not restarted) • When a trigger for group A or B is input, group C scan is not completed (not restarted).
0	x	1	Group priority operation for three groups (groups A, B, and C) • When a group A trigger is input, group B scan is completed (not restarted) • Single scan for group C is started continuously without start trigger input. After group C scan is discontinued, scan is restarted from the head of the channel selected with the ADANSC0 register after scan for groups A and B is completed.
1	0	0	Group priority operation for three groups (groups A, B, and C) • After group B scan is discontinued, scan is restarted from the head of the channel selected with the ADANSB0 register after group A scan is completed. • After group C scan is discontinued, scan is restarted from the head of the channel selected with the ADANSC0 register after scan for groups A and B is completed.
1	1	0	Group priority operation for three groups (groups A, B, and C) • After group B scan is discontinued, scan is restarted from the head of the channel selected with the ADANSB0 register after group A scan is completed. • After group C scan is discontinued, scan is restarted from the channel on which scan was discontinued*1, among the channels selected with the ADANSC0 register after scan for groups A and B is completed.
1	0	1	Group priority operation for three groups (groups A, B, and C) • After group B scan is discontinued, scan is restarted from the head of the channel selected with the ADANSB0 register after group A scan is completed. • Single scan for group C is started continuously without start trigger input. After group C scan is discontinued, single scan is restarted from the head of the channel selected with the ADANSC0 register after scan for groups A and B is completed.
1	1	1	Group priority operation for three groups (groups A, B, and C) • After scanning for group B is discontinued, once scanning for group A completes, scanning is resumed starting from the channel on which scanning was discontinued*1, among those channels selected with the ADANSB0 register. • Single scan for group C is started continuously without start trigger input. After group C scan is discontinued, single scan is restarted from the channel on which scan was discontinued*1, among the channels selected with the ADANSC0 register after scan for groups A and B is completed.

x = Don’t care

Note 1. When self-diagnosis is used (ADCER.DIAGM = 1), A/D conversion of the discontinued channel is started after self-diagnosis.

(1) Group Priority Operation for Two Groups (ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 0)

The following examples 1 to 5 show group priority operation in group scan mode (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0) when channel 0 is selected for group A and channels 1 to 3 are selected for group B.

Operation example 1: Group A trigger input during group B scan, with rescan setting

(1) When a group B trigger input sets the ADCSR.ADST bit to 1 (A/D conversion start), scan for the ANn channels selected in the ADANSB0 register, starts from the channel with the smallest number n.
(2) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(3) If a group A trigger is input during scan for group B, group B scan is discontinued while the ADCSR.ADST bit remains 1, and scan for the ANn channels of group A selected in the ADANSA0 register, starts from the channel with the smallest number n.
If A/D conversion is not completed when scan was discontinued, the result is not stored in the corresponding A/D data register (ADDRy).
(4) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(5) A scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (interrupt generation upon scanning completion enabled).
(6) If the ADGSPCR.GBRSCN bit is 1 (scan for the group is restarted after having been discontinued due to group priority operation), scan for the ANn channels of group B selected in the ADANSB0 register, restarts from the channel with the smallest number n while the ADCSR.ADST bit remains 1.
(7) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(8) A group B scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (interrupt generation upon group B scan completion enabled).
(9) The ADCSR.ADST bit is automatically cleared to 0 when scan of all selected channels is completed, and the 12-bit A/D converter enters a wait state.

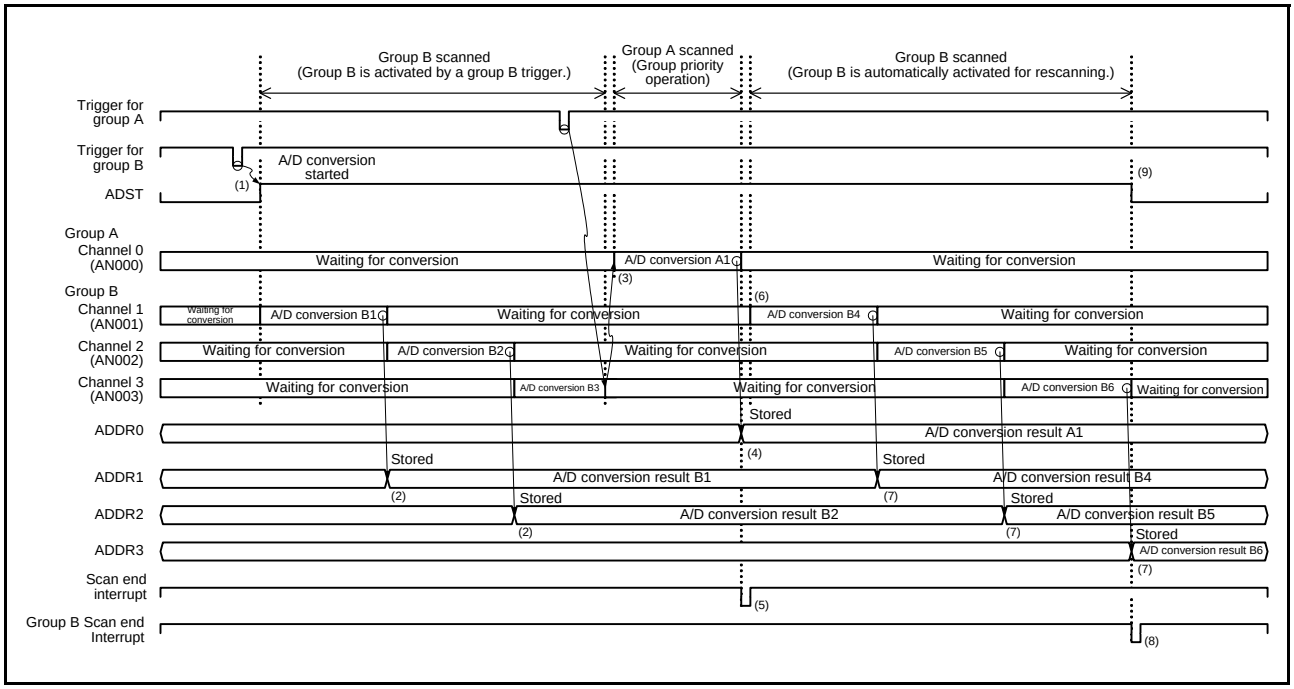

Figure 50.17 Example 1 of Group Priority Operation: Group A Trigger Input during Group B Scan, With Rescan Setting (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0)

Operation example 2: Group A trigger input during group B rescan, with rescan setting

Figure 50.18 shows an example when a group A trigger is input during rescan operation on group B.

If a group A trigger is input, scan for group A starts even while rescan operation is in progress. Scan for group B starts after scan for group A is completed.

Operations of the ADCSR.ADST bit, storing to the A/D conversion result in the A/D data register (ADDRy), and interrupt requests are the same as example 1.

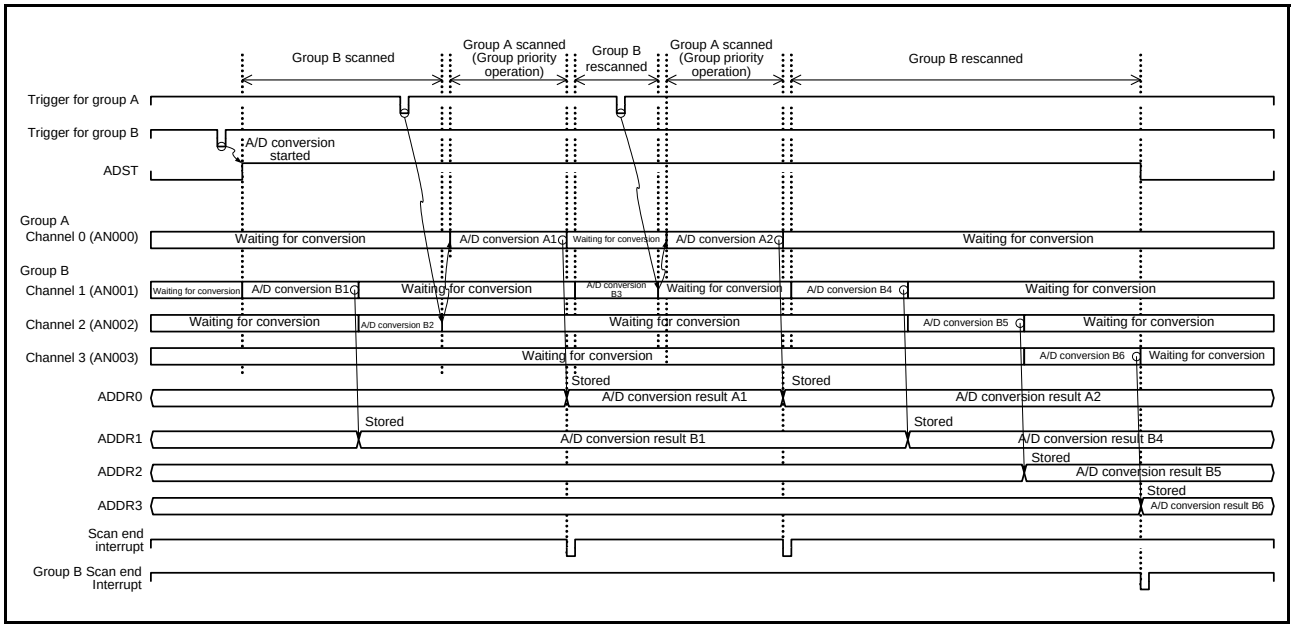

Figure 50.18 Example 2 of Group Priority Operation: Group A Trigger Input during Group B Rescan, With Rescan Setting (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0)

Operation example 3: Group B trigger input during group A scan, with rescan setting

The following describes an example when a group B trigger is input during scan operation on group A when the ADGPSCR.GBRSCN bit is 1 (scan for the group is restarted after having been discontinued due to group priority operation).

If the ADGPSCR.GBRSCN bit is 0, all group B triggers that are input during scan operation on group A are disabled.

(1) When a group A trigger input sets the ADCSR.ADST bit to 1 (A/D conversion start), scan for the ANn channels of group A selected in the ADANSA0 register, starts from the channel with the smallest number n.
(2) If a group B trigger is input during scan for group A, scan for group B can be started.
(3) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(4) After scan for group A is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (interrupt generation upon scanning completion enabled).
(5) After scan for group A is completed, scan for the ANn channels of group B selected in the ADANSB0 register, starts from the channel with the smallest number n while the ADCSR.ADST bit remains 1. When a group A trigger is input during scan for group B, group A scan starts as in example 1, and group B scan starts after group A scan is completed.
(6) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(7) After scan for group B is completed, a group B scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (interrupt generation upon group B scan completion enabled).
(8) The ADCSR.ADST bit is automatically cleared to 0 when scan of all selected channels is completed, and the 12-bit A/D converter enters a wait state.

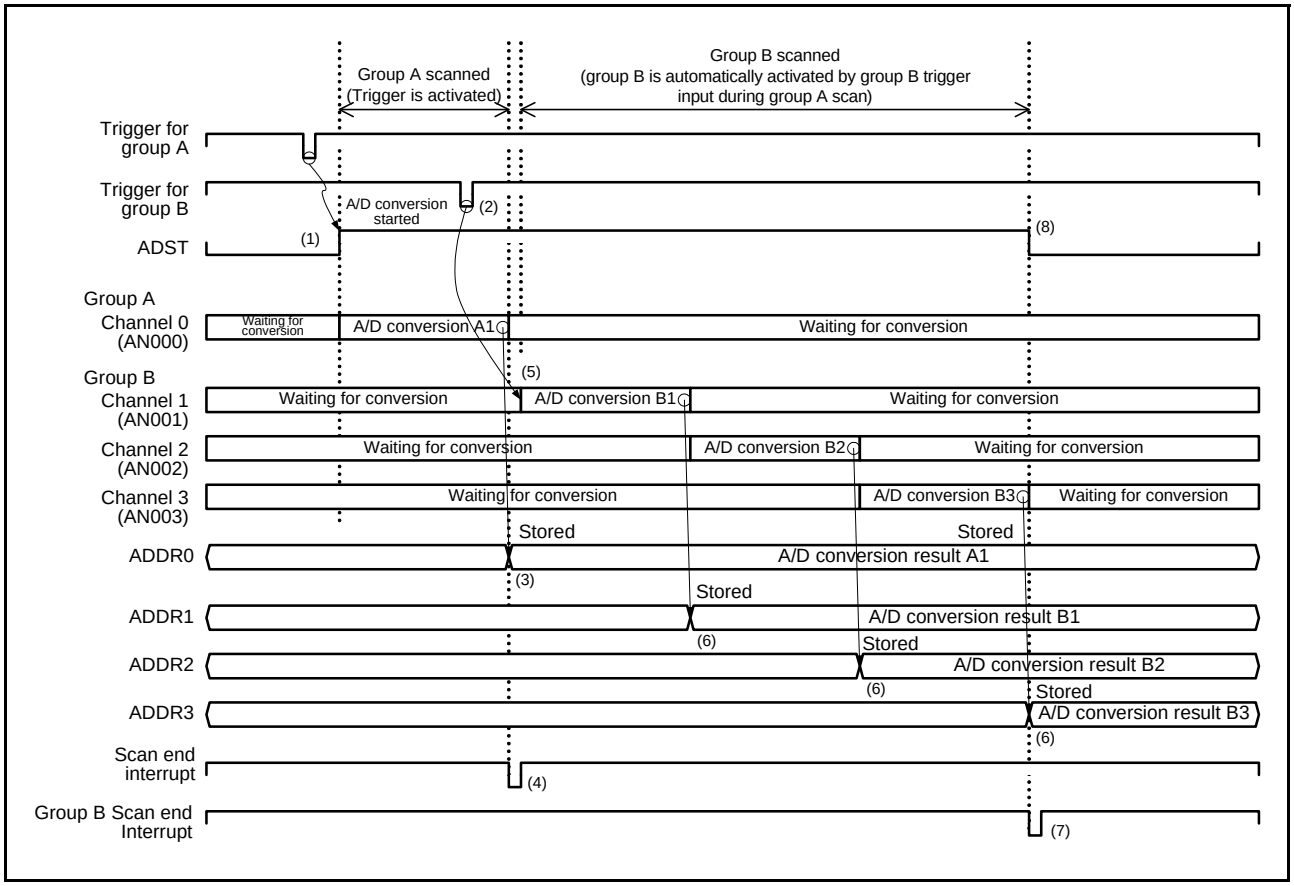

Figure 50.19 Example 3 of Group Priority Operation: Group B Trigger Input during Group A Scan, With Rescan Setting (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0)

Operation example 4 shows group priority operation in group scan mode (ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0) when channel 0 is selected for group A and channels 1 to 3 are selected for group B.

Operation example 4: Group A trigger input during group B scan, without rescan setting

(1) When a group B trigger input sets the ADCSR.ADST bit to 1 (A/D conversion start), scan for the ANn channels of group B selected in the ADANSB0 register, starts from the channel with the smallest number n.

(2) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).

(3) If a group A trigger is input during scan for group B, group B scan is discontinued while the ADCSR.ADST bit remains 1, and scan for the ANn channels of group A selected in the ADANSA0 register, starts from the channel with the smallest number n.
If A/D conversion is not completed when scan was discontinued, the result is not stored in the corresponding A/D data register (ADDRy).

(4) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).

(5) After scan for group A is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (interrupt generation upon scanning completion enabled).

(6) The ADST bit is automatically cleared to 0 when scan for group A is completed, and the 12-bit A/D converter enters a wait state. Scan for group B is not started until the next group B trigger is input.

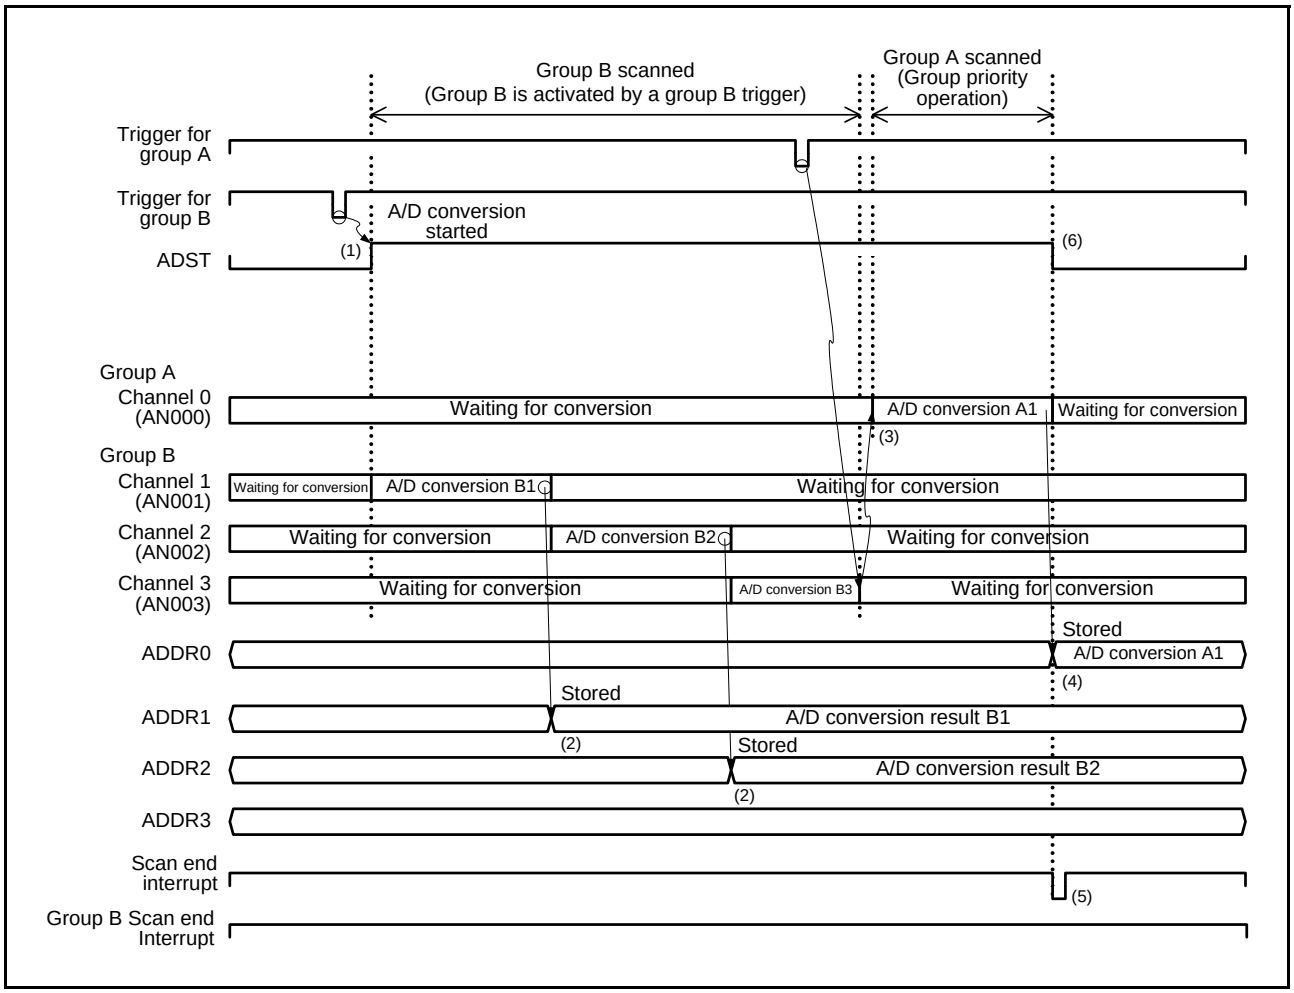

Figure 50.20 Example 4 of Group Priority Operation: Group A Trigger Input during Group B Scan, Without Rescan Setting (ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0)

Operation example 5 shows group priority operation in group scan mode (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 1, ADGSPCR.LGRRS = 0) when channel 0 is selected for group A and channels 1 and 2 are selected for group B. When the ADGCTRGR.GRCE bit is set to 1, single scan mode is continuously operated on group C and scan for group B is started by trigger input.

Operation example 5: Continuous single scan operation on group B

(1) When setting ADGSPCR.GBRP to 1 sets the ADCSR.ADST bit to 1 (A/D conversion start), scan for the ANn channels selected in the ADANSB0 register, starts from the channel with the smallest number n.
(2) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(3) If a group A trigger is input during scan for group B, group B scan is discontinued while the ADCSR.ADST bit remains 1, and scan for the ANn channels of group A selected in the ADANSA0 register, starts from the channel with the smallest number n. If A/D conversion is not completed when scan was discontinued, the result is not stored in the corresponding A/D data register (ADDRy).
(4) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(5) After scan for group A is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (interrupt generation upon scanning completion enabled).
(6) If the ADGSPCR.GBRP bit is set to 1 (single scan is continuously operated), scan for the ANn channels of group B selected in the ADANSB0 register, restarts from the channel with the smallest number n while the ADCSR.ADST bit remains 1.
(7) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(8) A group B scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (interrupt generation upon group B scan completion enabled).
(9) If the ADGSPCR.GBRP bit is set to 1 (single scan is continuously operated), scan for the ANn channels of group B selected in the ADANSB0 register, restarts from the channel with the smallest number n while the ADCSR.ADST bit remains 1.

To continuously operate single scan for group B, disable trigger input for group B.
Steps 6 to 9 are repeated as long as the ADGSPCR.GBRP bit remains 1. Clearing of the ADCSR.ADST bit to 0 is prohibited while the ADGSPCR.GBRP bit is set to 1. To forcibly stop scanning when ADGSPCR.GBRP = 1, follow the procedures for clear operation by software through the ADCSR.ADST bit shown in section 50.6.2, Notes on Stopping A/D Conversion.

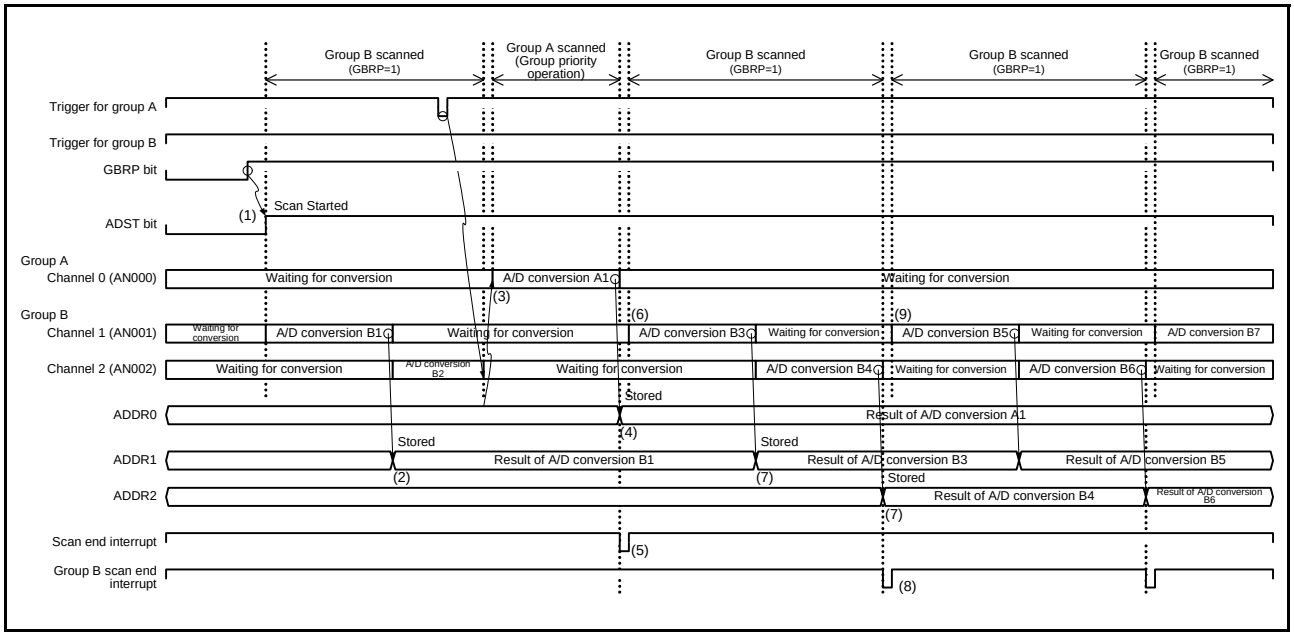

Figure 50.21 Example 5 for Group Priority Operation: Continuous Single Scan Operation on Group B (ADGSPCR.GBRP = 1, ADGSPCR.LGRRS = 1, ADGCTRGR.GRCE = 0)

(2) Group Priority Operation for Three Groups (ADGSPCR.PGS = 1, ADGCTRGR.GRCE = 1)

The following examples 1 to 5 show group priority operation in group scan mode (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1) when channel 0 is selected for group A, channels 1 and 2 are selected for group B, and channels 3 and 4 are selected for group C.
The priority groups mean groups A and B for group C and group A for group B.

Operation example 1: Priority group trigger input during low-priority group scan, with rescan setting

(1) When a group C trigger input sets the ADCSR.ADST bit to 1 (A/D conversion start), scan for the ANn channels selected in the ADANSC0 register, starts from the channel with the smallest number n.
(2) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy)
(3) If a group B trigger is input during scan for group C, group C scan is discontinued while the ADCSR.ADST bit remains 1, and scan for the ANn channels of group B selected in the ADANSB0 register, starts from the channel with the smallest number n. On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy)
(4) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy)
(5) If a group A trigger is input during scan for group B, group B scan is discontinued while the ADCSR.ADST bit remains 1, and scan for the ANn channels of group A selected in the ADANSA0 register, starts from the channel with the smallest number n. If A/D conversion is not completed when scan was discontinued, the result is not stored in the corresponding A/D data register (ADDRy).
(6) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy)
(7) A scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (interrupt generation upon scanning completion enabled).
(8) If the ADGSPCR.GBRSCN bit is 1 (scan for the group is restarted after having been discontinued due to group priority operation), scan for the ANn channels of group B selected in the ADANSB0 register, restarts from the channel with the smallest number n while the ADCSR.ADST bit remains 1. If the ADGSPCR.LGRRS bit is set to 1 at this time, scan for group B starts from the channel on which A/D conversion was discontinued.
(9) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy)
(10) A group B scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (interrupt generation upon group B scan completion enabled).
(11) If the ADGSPCR.GBRSCN bit is 1, scan for the ANn channels of group C selected in the ADANSC0 register, restarts from the channel with the smallest number n while the ADCSR.ADST bit remains 1. If the ADGSPCR.LGRRS bit is set to 1 at this time, scan for group C starts from the channel on which A/D conversion was discontinued.
(12) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy)
(13) A group C scan end interrupt is generated if the ADGCTRGR.GCADIE bit is 1 (interrupt generation upon group C scan completion enabled).
(14) The ADST bit is automatically cleared to 0 when scan for group A is completed, and the 12-bit A/D converter enters a wait state.

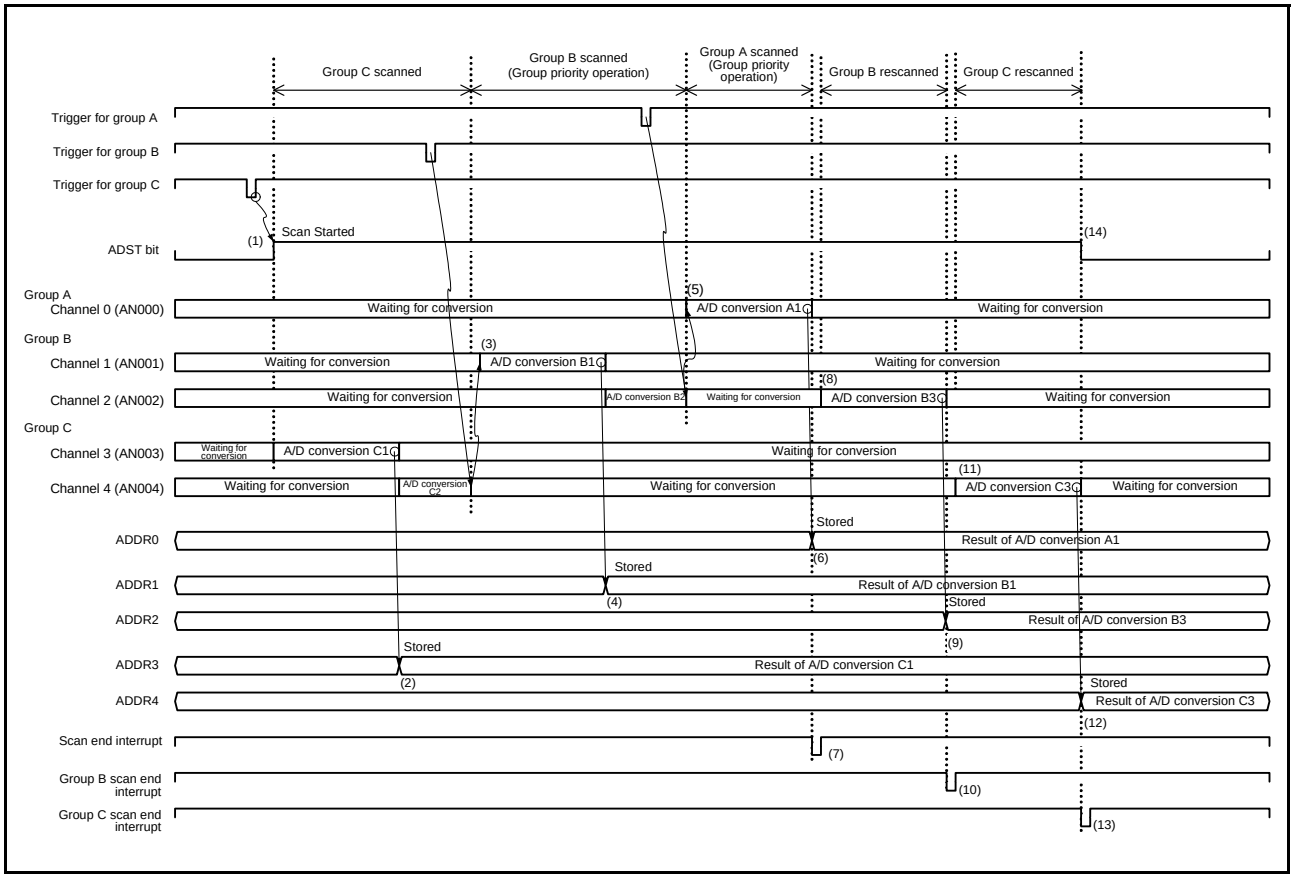

Figure 50.22 Example 1 of Group Priority Operation: Priority Group Trigger Input during Low-Priority Group Scan, With Rescan Setting (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1)

Operation example 2: Priority group trigger input during low-priority group rescan, with rescan setting

Figure 50.23 shows an example when a group A trigger is input during rescan operation on group B.

If a trigger for the priority groups (groups A and B for group C and group A for group B) is input, scan for the priority group starts even while rescan operation on the low-priority group is in progress. After scan for the priority group is completed, scan for the low-priority group is restarted after having been discontinued.

Operations of the ADCSR.ADST bit, storing to the A/D conversion result in the A/D data register (ADDRy), and interrupt requests are the same as example 1.

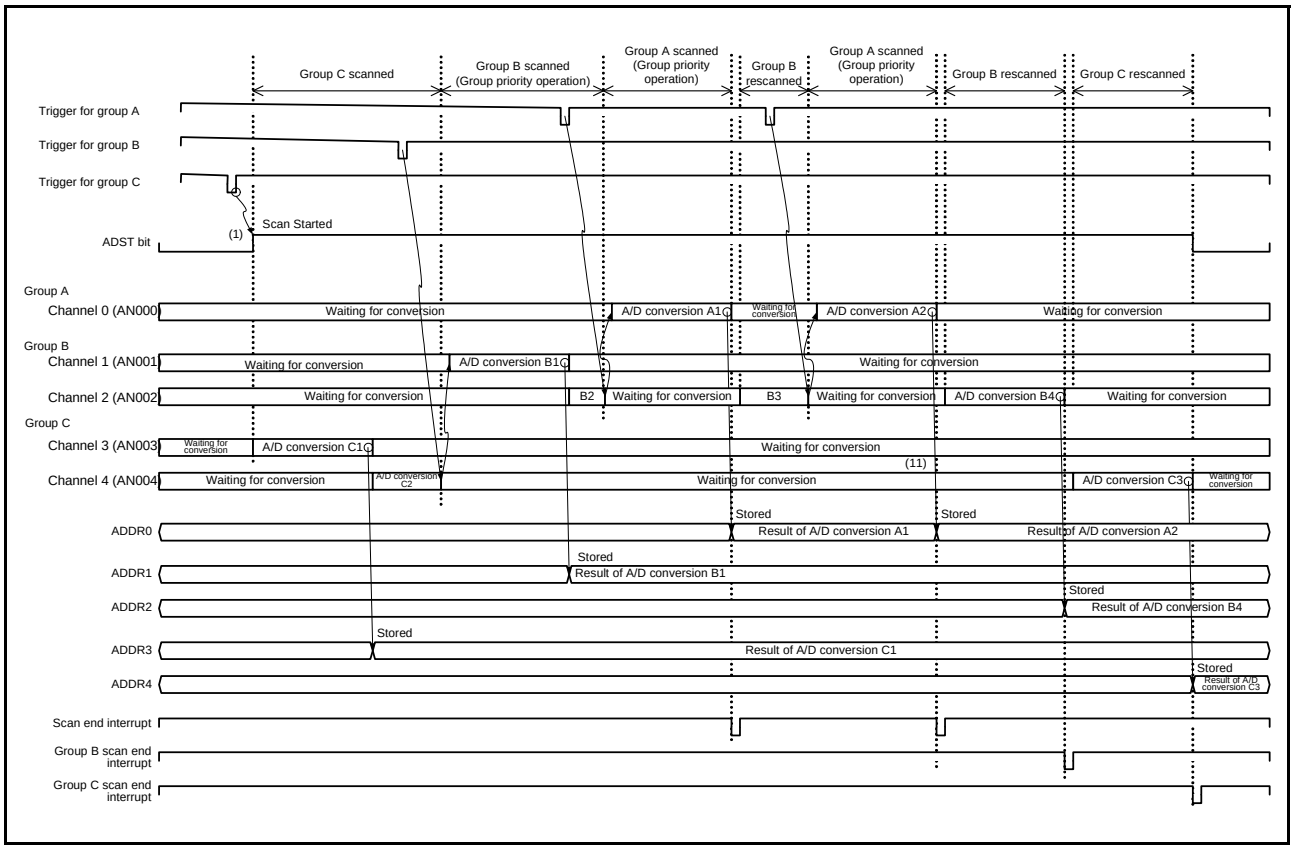

Figure 50.23 Example 2 of Group Priority Operation: Priority Group Trigger Input during Low-Priority Group Rescan, With Rescan Setting (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1)

Operation example 3: Low-priority group trigger input during priority group scan, with rescan setting

The following describes an example when a trigger for the low-priority group is input during scan operation on the priority group when the ADGPSCR.GBRSCN bit is 1 (scan for the group is restarted after having been discontinued due to group priority operation). If the ADGPSCR.GBRSCN bit is 0, all triggers for the low-priority group that are input during scan operation on the priority group are disabled.

(1) When a group A trigger input sets the ADCSR.ADST bit to 1 (A/D conversion start), scan for the ANn channels of group A selected in the ADANSA0 register, starts from the channel with the smallest number n.
(2) If a group B trigger is input during scan for group A, scan for group B can be started.
(3) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy)
(4) After scan for group A is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (interrupt generation upon scanning completion enabled).
(5) After scan for group A is completed, scan for the ANn channels of group B selected in the ADANSB0 register, starts from the channel with the smallest number n while the ADCSR.ADST bit remains 1. If the ADGSPCR.LGRRS bit is set to 1 at this time, scan for group B starts from the channel on which A/D conversion was discontinued.
When a group A trigger is input during scan for group B, group A scan starts as in example 1, and group B scan starts after group A scan is completed.
(6) If a group C trigger is input during scan for group B, scan for group C can be started.
(7) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy)
(8) After scan for group B is completed, a group B scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (interrupt generation upon group B scan completion enabled).
(9) After scan for group B is completed, scan for the ANn channels of group C selected in the ADANSC0 register, starts from the channel with the smallest number n while the ADCSR.ADST bit remains 1. If the ADGSPCR.LGRRS bit is set to 1 at this time, scan for group C starts from the channel on which A/D conversion was discontinued.
When a group A or B trigger is input during scan for group C, group A or B scan starts as in example 1, and group C scan starts after group A or B scan is completed.
(10) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy)
(11) After scan for group C is completed, a group C scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (interrupt generation upon group C scan completion enabled).
(12) The ADCSR.ADST bit is automatically cleared to 0 when scan of all selected channels is completed, and the 12-bit A/D converter enters a wait state.

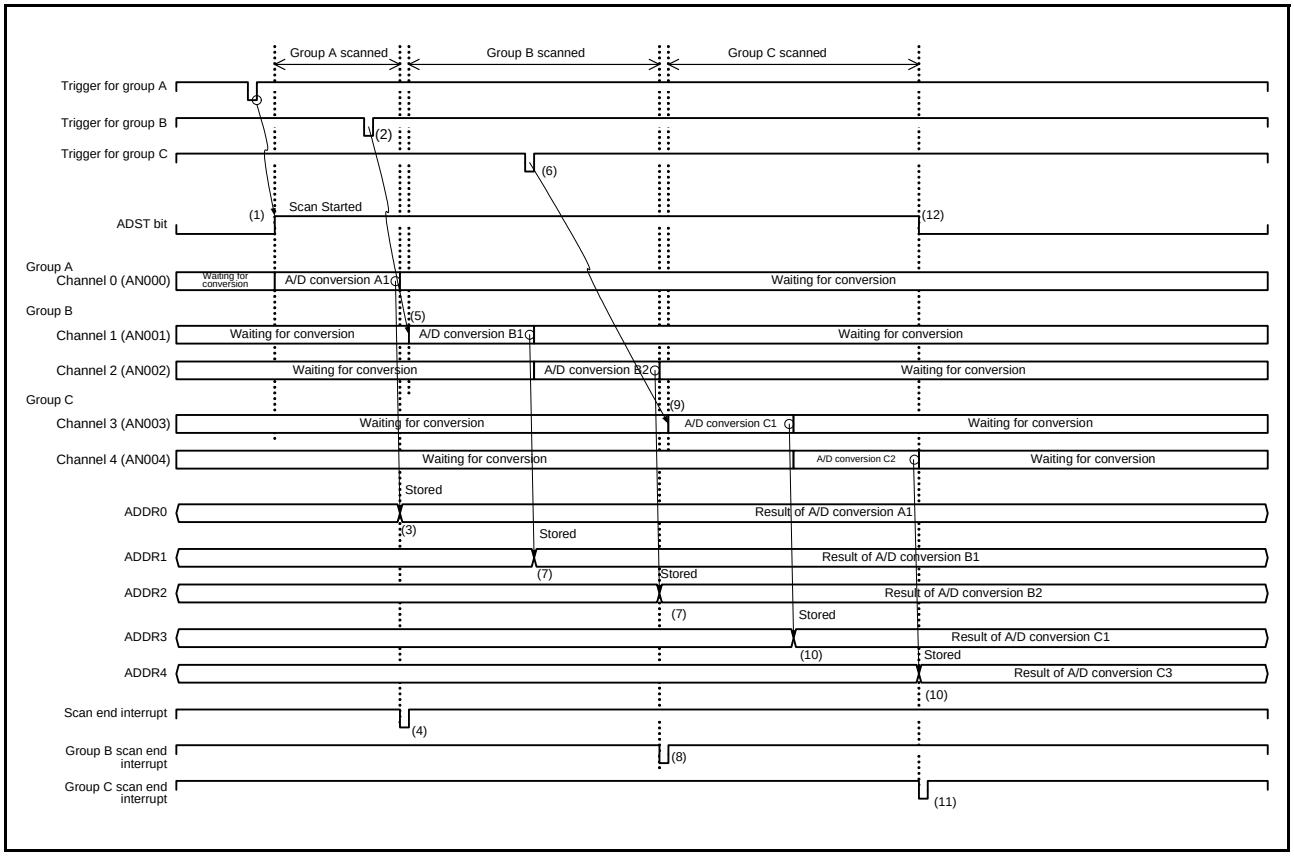

Figure 50.24 Example 3 of Group Priority Operation: Low-Priority Group Trigger Input during Priority Group Scan, With Rescan Setting (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1, ADGCTRGR.GRCE = 1)

Operation example 4 shows group priority operation in group scan mode (ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 0) when channel 0 is selected for group A, channels 1 and 2 are selected for group B, and channels 3 and 4 are selected for group C.

Operation example 4: Priority group trigger input during low-priority group scan, without rescan setting

(1) When a group C trigger input sets the ADCSR.ADST bit to 1 (A/D conversion start), scan for the ANn channels selected in the ADANSC0 register, starts from the channel with the smallest number n.

(2) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy)

(3) If a group B trigger is input during scan for group C, group C scan is discontinued while the ADCSR.ADST bit remains 1, and scan for the ANn channels of group B selected in the ADANSB0 register, starts from the channel with the smallest number n. If A/D conversion is not completed when scan was discontinued, the result is not stored in the corresponding A/D data register (ADDRy).

(4) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy)

(5) If a group A trigger is input during scan for group B, group B scan is discontinued while the ADCSR.ADST bit remains 1, and scan for the ANn channels of group A selected in the ADANSB0 register, starts from the channel with the smallest number n. If A/D conversion is not completed when scan was discontinued, the result is not stored in the corresponding A/D data register (ADDRy).

(6) After scan for group A is completed, a scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (interrupt generation upon scanning completion enabled).

(7) The ADST bit is automatically cleared to 0 when scan for group A is completed, and the 12-bit A/D converter enters a wait state. Scan for groups C and B is not started until the next trigger corresponding to the group is input.

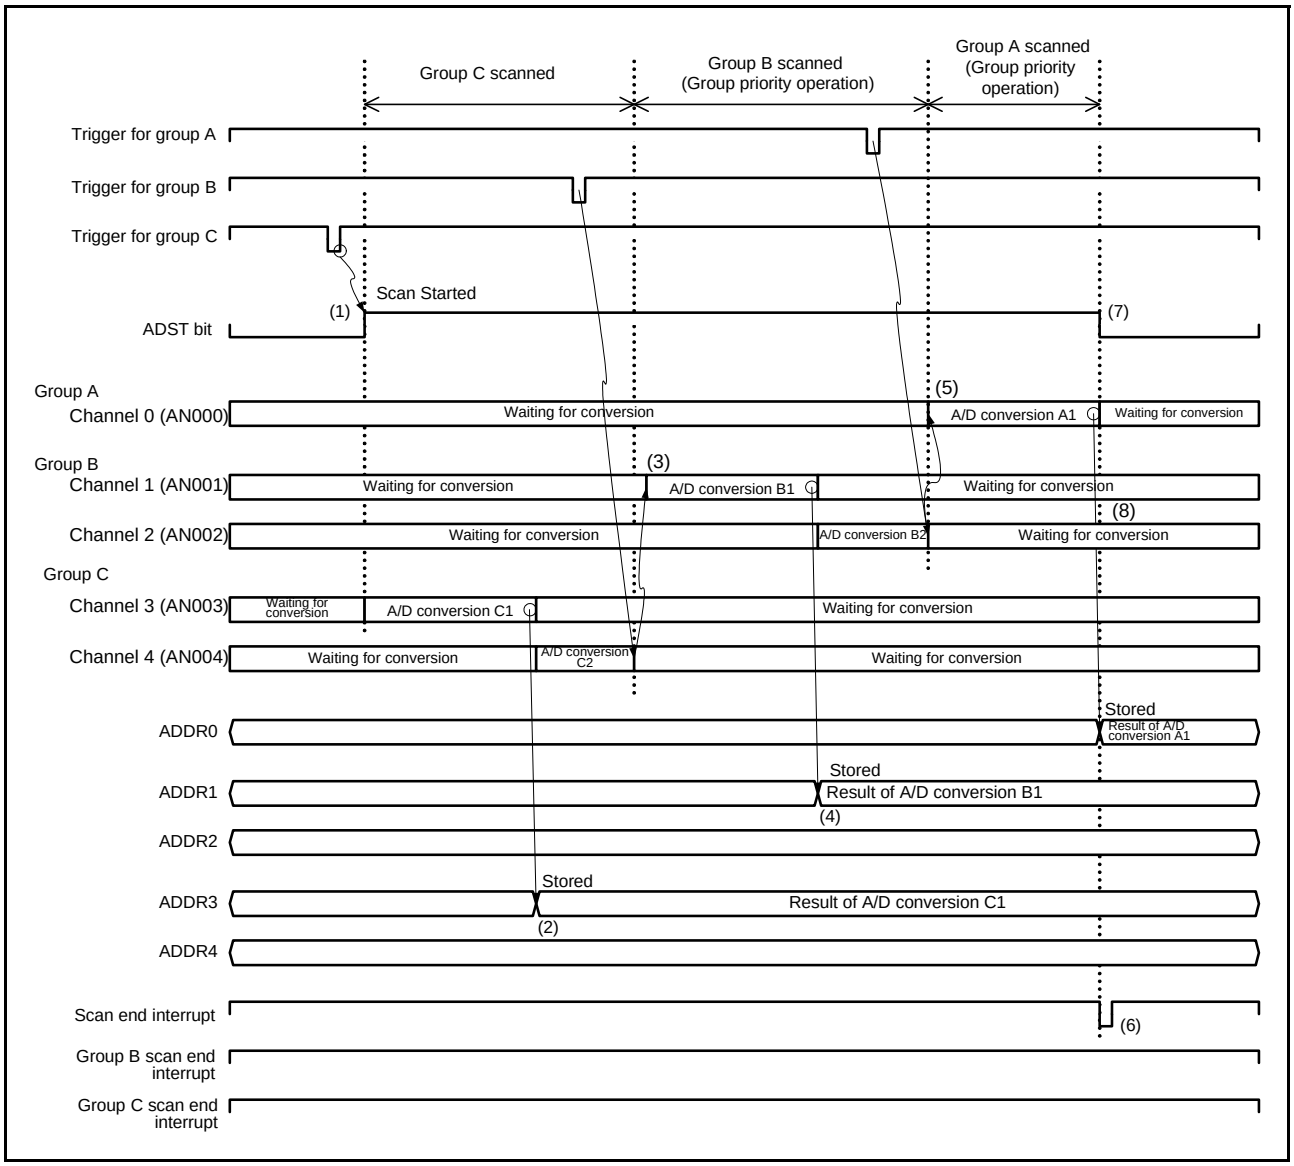

Figure 50.25 Example 4 of Group Priority Operation: Priority Group Trigger Input during Low-Priority Group Scan, Without Rescan Setting (ADGSPCR.GBRSCN = 0, ADGSPCR.GBRP = 0, ADGSPCR.LGRRS = 1)

Operation example 5 shows group priority operation in group scan mode (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 1, ADGSPCR.LGRRS = 1) when channel 0 is selected for group A, channel 1 is selected for group B, and channels 2 and 3 are selected for group C.
When the ADGCTRGR.GRCE bit is set to 1, single scan mode is continuously operated on group B and trigger input for group C is disabled.

Operation example 5: Continuous single scan operation on group C

(1) When setting ADGSPCR.GBRP to 1 sets the ADCSR.ADST bit to 1 (A/D conversion start), scan for the ANn channels selected in the ADANSC0 register, starts from the channel with the smallest number n.
(2) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy)
(3) If a group B trigger is input during scan for group C, group C scan is discontinued while the ADCSR.ADST bit remains 1, and scan for the ANn channels of group B selected in the ADANSB0 register, starts from the channel with the smallest number n. If A/D conversion is not completed when scan was discontinued, the result is not stored in the corresponding A/D data register (ADDRy).
(4) If a group A trigger is input during scan for group B, group B scan is discontinued while the ADCSR.ADST bit remains 1, and scan for the ANn channels of group A selected in the ADANSA0 register, starts from the channel with the smallest number n. If A/D conversion is not completed when scan was discontinued, the result is not stored in the corresponding A/D data register (ADDRy).
(5) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy)
(6) A scan end interrupt request is generated if the ADCSR.ADIE bit is 1 (interrupt generation upon scanning completion enabled).
(7) If the ADGSPCR.GBRSCN bit is 1 (scan for the group is restarted after having been discontinued due to group priority operation), scan for the ANn channels of group B selected in the ADANSB0 register, restarts from the channel with the smallest number n while the ADCSR.ADST bit remains 1. If the ADGSPCR.LGRRS bit is set to 1 at this time, scan for group B starts from the channel on which A/D conversion was discontinued.
(8) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy)
(9) A group B scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (interrupt generation upon group B scan completion enabled).
(10) If the ADGSPCR.GBRSCN bit is 1 (scan for the group is restarted after having been discontinued due to group priority operation), scan for the ANn channels of group C selected in the ADANSC0 register, restarts from the channel with the smallest number n while the ADCSR.ADST bit remains 1. If the ADGSPCR.LGRRS bit is set to 1 at this time, scan for group C starts from the channel on which A/D conversion was discontinued.
(11) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy)
(12) A group C scan end interrupt request is generated if the ADCSR.GBADIE bit is 1 (interrupt generation upon group C scan completion enabled).
(13) If the ADGSPCR.GBRP bit is set to 1 (single scan is continuously operated), scan for the ANn channels of group C selected in the ADANSC0 register, restarts from the channel with the smallest number n while the ADCSR.ADST bit remains 1.

To continuously operate single scan for group C, disable trigger input for group B.
Steps 13, 11, 12, and then 13 are repeated as long as the ADGSPCR.GBRP bit remains 1.
Clearing of the ADCSR.ADST bit to 0 is prohibited while the ADGSPCR.GBRP bit is set to 1.
To forcibly stop scanning when ADGSPCR.GBRP = 1, follow the procedures for clear operation by software through the ADCSR.ADST bit shown in section 50.6.2, Notes on Stopping A/D Conversion.

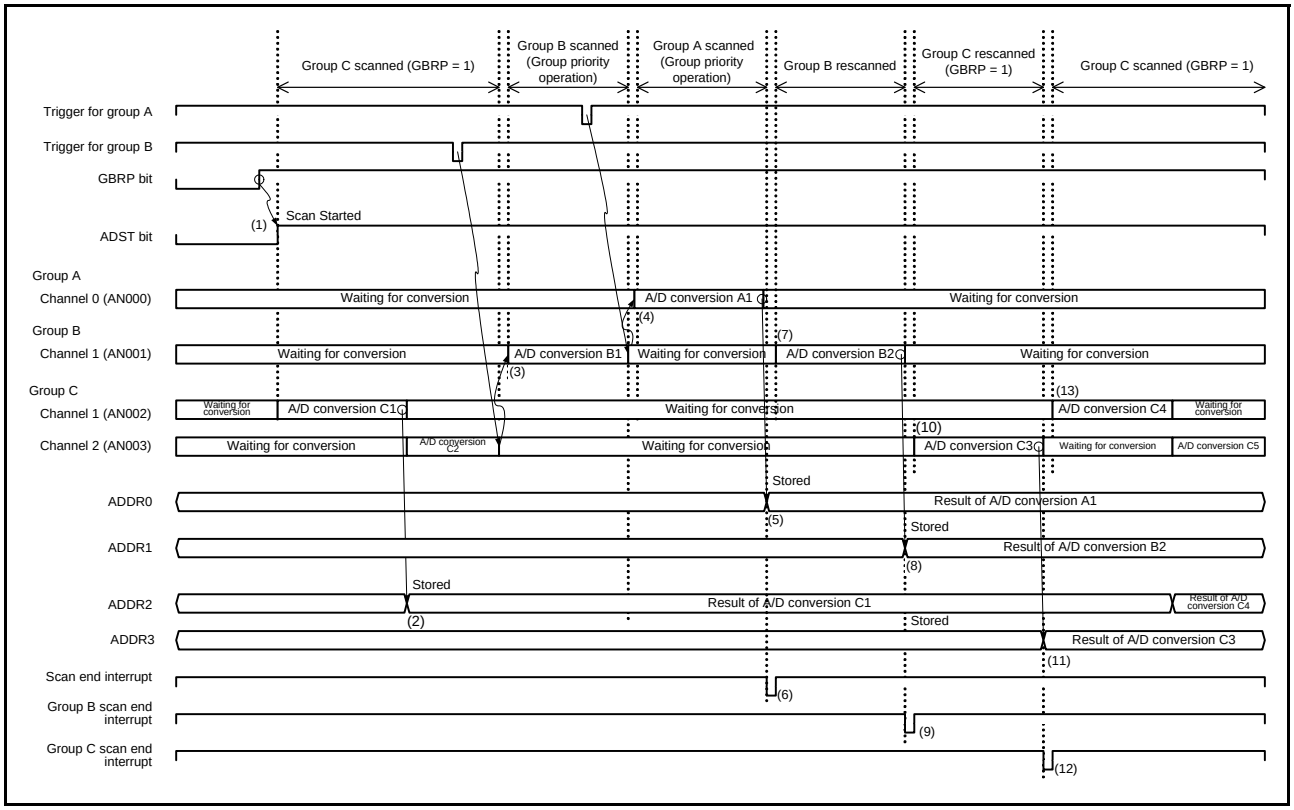

Figure 50.26 Example 5 for Group Priority Operation: Continuous Single Scan Operation on Group C (ADGSPCR.GBRP = 1, ADGSPCR.LGRRS = 1)

50.3.5 Extended Analog Input

Extended Analog Input (ANEX1) is used when an external operational amplifier is connected to the MCU and multiple analog values are A/D converted. When the extended analog input is selected, only AN100 to AN107 are selectable. Do not select AN108 to AN111, temperature sensor output, or internal reference voltage. Also, when the extended analog input is selected, self-diagnosis or disconnection detection assist function cannot be used.

50.3.5.1 Usage of ANEX1

To perform A/D conversion of multiple analog values through an operational amplifier, analog values are input by using analog input channels of the MCU (AN100 to AN107), the time-divided analog values are retrieved, and an operational amplifier is connected between ANEX0 and ANEX1.
When ANEX1 is connected, set the ADEXICR.EXSEL[1:0] bits to 01b (ANEX1 selected) and ADEXICR.EXOEN bit to 1 (ANEX0: output enabled) and then select single scan mode or sequence scan mode.
Do not set in group scan mode. Figure 50.27 shows an example of structure of the extended analog input when ANEX1 is in use, and Figure 50.28 shows operation when three channels (AN100, AN101, AN102) are selected and single scan mode is selected.

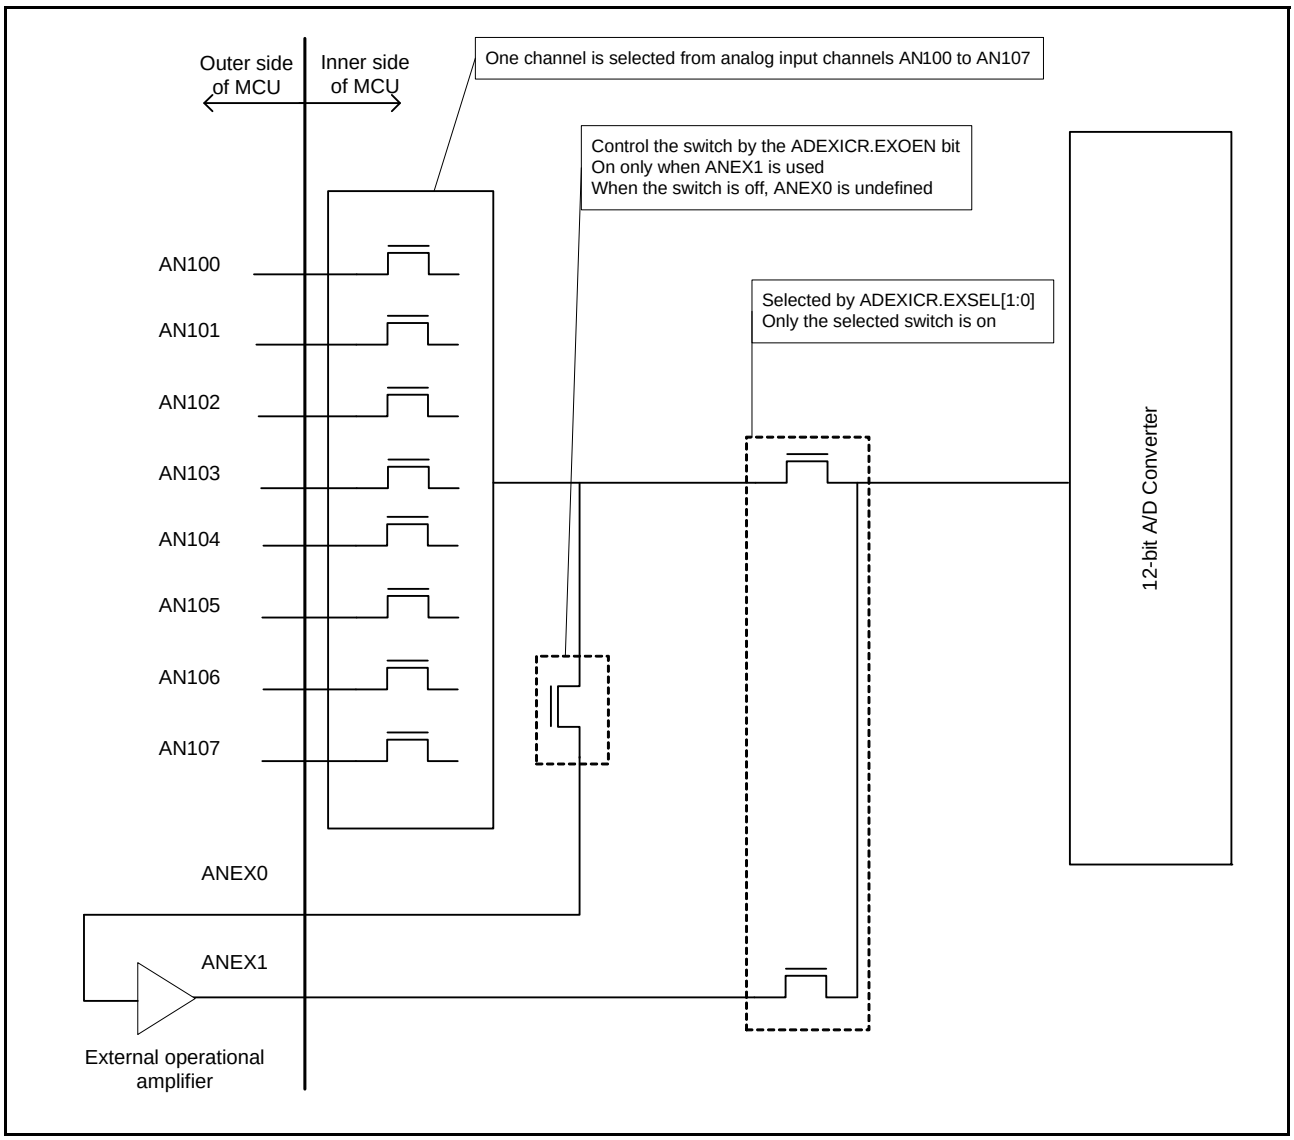

Figure 50.27 Example of Configuration of Extended Analog Input When ANEX1 is Used

(1) When the ADCSR.ADST bit is set to 1 (A/D conversion start) by software, or synchronous or asynchronous trigger input, A/D conversion is performed for the selected channels starting from the channel with the smallest number.
(2) Each time A/D conversion of a single channels is completed, the A/D converted value is stored in the corresponding A/D data register (ADDRy).
(3) After completion of A/D conversion of all selected channels, if the ADCSR.ADIE bit is set to 1 (when interrupt generation after scanning is enabled), a scan end interrupt request is generated.
(4) The ADCSR.ADST bit holds 1 during A/D conversion and is automatically cleared upon completion of A/D conversion of all selected channels, and the 12-bit A/D converter enters into a wait state.

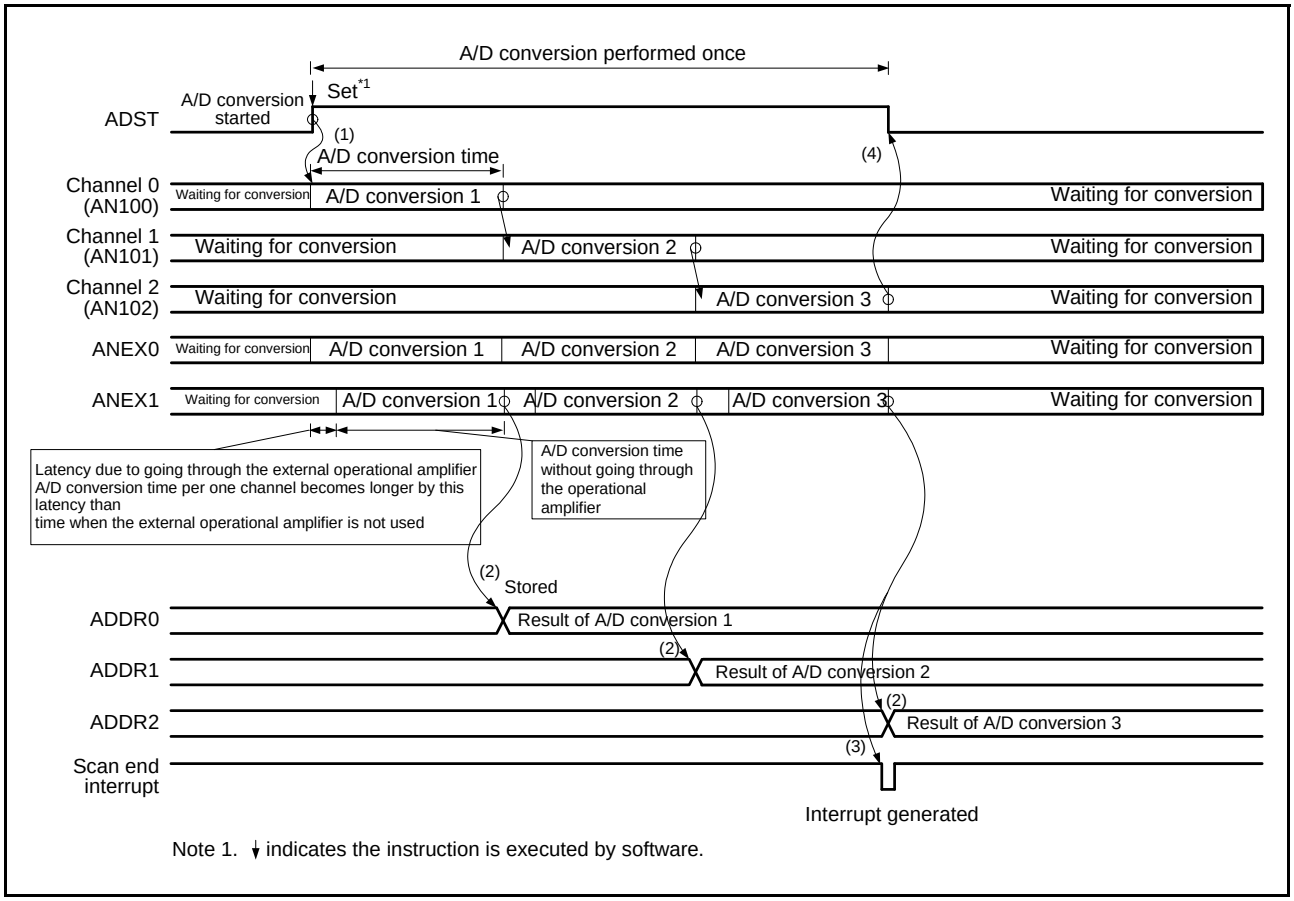

Figure 50.28 Example of Operation of ANEX1 Input (Single Scan Mode)

When the extended analog input is selected, each period for A/D conversion will be relatively longer than that of the case when analog input channels are directly A/D converted due to latency of the operational amplifier.

50.3.6 Comparison Function (Windows A/B)

50.3.6.1 Comparison Function Windows A/B

The comparison function compares the reference values set in registers ADCMPDR0, ADCMPDR1, ADWINLLB, and ADWINULB with the A/D conversion results. When this function is used, self-diagnosis or double trigger mode cannot be used. A window comparison function can also be used (when ADCMPCR.WCMPE = 1), enabling comparison of two values. Two sets of voltage level ranges can be set in the window comparison function, one for window A and one for window B.

Operation when window comparison is enabled (ADCMPCR.WCMPE = 1) in combination with continuous scan mode is described below.

(1) When the ADCSR.ADST bit is set to 1 (A/D conversion start) by software, or synchronous or asynchronous trigger input, A/D conversion is performed for selected channels, temperature sensor output, and internal reference voltage in this order.

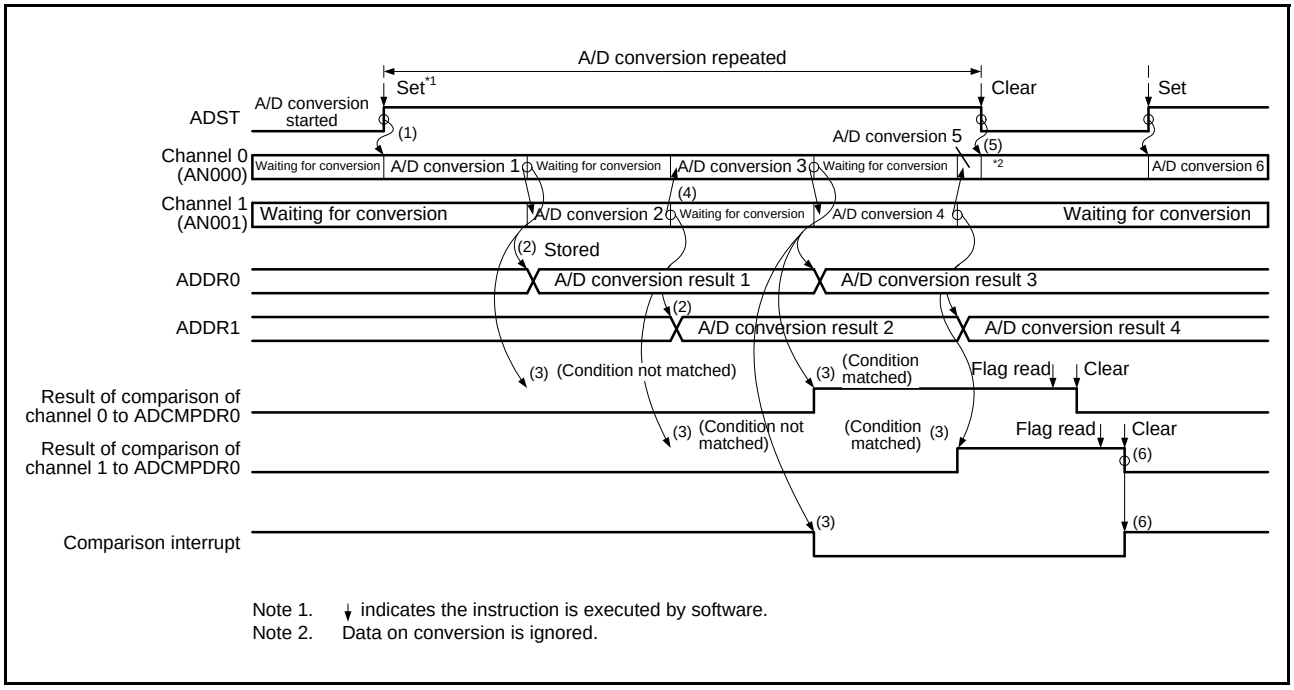
(2) Each time A/D conversion of a single channels is completed, the A/D converted value is stored in the corresponding A/D data register (ADDRy, ADTSDR, or ADOCDR). When ADCMPCR.CMPAE = 1 and window A is selected in the ADCMPANSRy and ADCMPANSER registers, the A/D converted value is compared with the setting values of the ADCMPDR0 and ADCMPDR1 registers.
When ADCMPCR.CMPBE = 1 and window B is selected in the ADCMPBNSR register, the A/D converted value is compare with the setting values of the ADWINULB and ADWINLLB registers.

(3) Upon a comparison match with the conditions specified in the ADCMPLR0 and ADCMPLER registers, the flags of the comparison window A (ADCMPSR0.CMPSTCHA0n, ADCMPSER.CMPFTS, and ADCMPSER.CMPFOC) are set to 1 for window A.
In this case, if the ADCMPCR.CMPAIE bit is set to 1, an interrupt request S12CMPAI is generated.
Similarly, for window B, upon a match with the conditions set in the ADCMPBNSR.CMPLB register, the comparison window B flag (ADCMPBSR.CMPSTB) is set to 1. In this case, if the ADCMPCR.CMPBIE bit is set to 1, an interrupt request S12CMPBI is generated.

(4) When all selected A/D conversion and comparison are completed, scanning is performed again.

(5) Set the ADCSR.ADST to 0 (A/D conversion stop) and execute the processing for the channels in which the comparison flag is 1.

(6) After the processing above, clear all comparison flags. When comparison is re-executed, start A/D conversion again.



Note 1. ↓ indicates the instruction is executed by software.
Note 2. Data on conversion is ignored.

Figure 50.29 Example of Operation of Comparison (AN000 and AN001 for Targets for Comparison)

50.3.6.2 Restrictions on Comparison Function

The Comparison function has the following restrictions.

1. Use of self-diagnosis and double trigger mode is prohibited.
   (ADRD and ADDBLDR are not targeted for the comparison function)
2. When temperature sensor or internal reference voltage is selected for window A, operation of window B is prohibited.
3. When temperature sensor or internal reference voltage is selected for window B, operation of window A is prohibited.
4. The same channel cannot be set for window A and window B.
5. Satisfy the condition of [reference value (high side) ≥ reference value (low side)].

50.3.7 Analog Input Sampling Time and Scan Conversion Time

Figure 50.30 shows the scan conversion timing in single scan mode, in which scan conversion is activated by software or a synchronous trigger. Figure 50.31 shows the scan conversion timing in single scan mode, in which scan conversion is activated by an asynchronous trigger. The scan conversion time (t_{SCAN}) includes the start-of-scanning-delay time (t_D), disconnection detection assistance processing time (t_{DIS})*1, self-diagnosis A/D conversion processing time (t_{DIAG})*2, A/D conversion processing time (t_{CONV}), and end-of-scanning-delay time (t_{ED}).
The A/D conversion processing time (t_{CONV}) consists of sampling time (t_{SPL}) and time for conversion by successive approximation (t_{SAM}). The sampling time (t_{SPL}) is used to charge sample-and-hold circuits in the A/D converter. If there is not sufficient sampling time due to the high impedance of an analog input signal source, or if the A/D conversion clock (ADCLK) is slow, sampling time can be adjusted using the ADSSTR register.
The time for conversion by successive approximation (t_{SAM}) for unit 0 is at 13 states (ADCLK) with 12-bit resolution selected, 11 states (ADCLK) with 10-bit resolution selected, and 9 states (ADCLK) with 8-bit resolution selected; and for unit 1, 15 states (ADCLK) with 12-bit resolution selected, 13 states (ADCLK) with 10-bit resolution selected, and 11 states (ADCLK) with 8-bit resolution selected. Table 50.18 shows the scan conversion time.

The scan conversion time (t_{SCAN}) in single scan mode for which the number of selected channels is n can be determined as follows:

$$t_{SCAN} = t_D + (t_{DIS} \times n) + t_{DIAG} + (t_{CONV} \times n)^{*3} + t_{ED}$$

The scan conversion time for the first cycle in continuous scan mode is t_{SCAN} for single scan minus t_{ED}.
The scan conversion time for the second and subsequent cycles in continuous scan mode is fixed to $(t_{DIS} \times n) + t_{DIAG} + t_{DSD} + (t_{CONV} \times n)^{*3}$.

Note 1. When disconnection detection assistance is not selected, $t_{DIS} = 0$.
Note 2. When the self-diagnosis function is not used, $t_{DIAG} = 0$, $t_{DSD} = 0$.
Note 3. $t_{CONV} \times n$ when the sampling time (t_{SPL}) of selected channels is the same, but it is the total of the sampling time of each channel and time for conversion by successive approximation (t_{SAM}).

Table 50.18 Times for Conversion during Scanning (in Numbers of Cycles of ADCLK and PCLK)

Item			Symbol		Type/Conditions: Synchronous Trigger (MTU)	Type/Conditions: Synchronous Trigger (TMR, TPU, ELC)	Type/Conditions: Asynchronous Trigger	Type/Conditions: Software Trigger	Unit
Scan start processing time*1, *2	A/D conversion on group under group priority control.	The low-priority group is to be stopped. (The priority group is activated after low-priority group B is stopped due to an A/D conversion source of the priority group.)	t_D		1 PCLKA + 4 PCLKB + 6 ADCLK	2PCLKB + 6 ADCLK	—	—	Cycle
		The low-priority group is not to be stopped. (Activation by an A/D conversion source of the priority group.)			1 PCLKA + 3 PCLKB + 4 ADCLK	2 PCLKB + 4 ADCLK	—	—	
	A/D conversion when self-diagnosis is enabled	A/D conversion for self-diagnosis is to be started.			1 PCLKA + 3 PCLKB + 6 ADCLK	2 PCLKB + 6 ADCLK	4 PCLKB+ 6 ADCLK	6 ADCLK	
	Other than above				1 PCLKA + 3 PCLKB + 4 ADCLK	2 PCLKB + 4 ADCLK	2 PCLKB + 4 ADCLK	4 ADCLK	
Disconnection detection assistance processing time			t_{DIS}		The setting of ADNDIS[3:0] (initial value = 00h) × ADCLK				
Self-diagnosis conversion processing time*1	Sampling time		t_{DIAG}	t_{SPL}	The setting of ADSSTR0 (initial value = 0Bh) × ADCLK				
	Time for conversion by successive approximation			t_{SAM}	Unit 0		Unit 1		
					13 ADCLK (12-bit conversion resolution) 11 ADCLK (10-bit conversion resolution) 9 ADCLK (8-bit conversion resolution)		15 ADCLK (12-bit conversion resolution) 13 ADCLK (10-bit conversion resolution) 11 ADCLK (8-bit conversion resolution)		
	Normal A/D conversion is to be started after completion of self-diagnosis conversion.		t_{DED}		2 ADCLK				
	A/D conversion for self-diagnosis is to be started after completion of conversion for continuous scan on the last channel specified.		t_{DSD}		2 ADCLK				
A/D conversion processing time*1	Sampling time		t_{CONV}	t_{SPL}	The setting of ADSSTRn (n = 0 to 11, T, O) (initial value = 0Bh) × ADCLK				
	Time for conversion by successive approximation			t_{SAM}	Unit 0		Unit 1		
					13 ADCLK (12-bit conversion resolution) 11 ADCLK (10-bit conversion resolution) 9 ADCLK (8-bit conversion resolution)		15 ADCLK (12-bit conversion resolution) 13 ADCLK (10-bit conversion resolution) 11 ADCLK (8-bit conversion resolution)		
Scan end processing time*1			t_{ED}		1 PCLKB + 3 ADCLK				

Note 1. For t_D, t_{DIAG}, t_{CONV}, and t_{ED}, see Figure 50.30 and Figure 50.31.
Note 2. This is the maximum time required from software writing or trigger input to A/D conversion start.

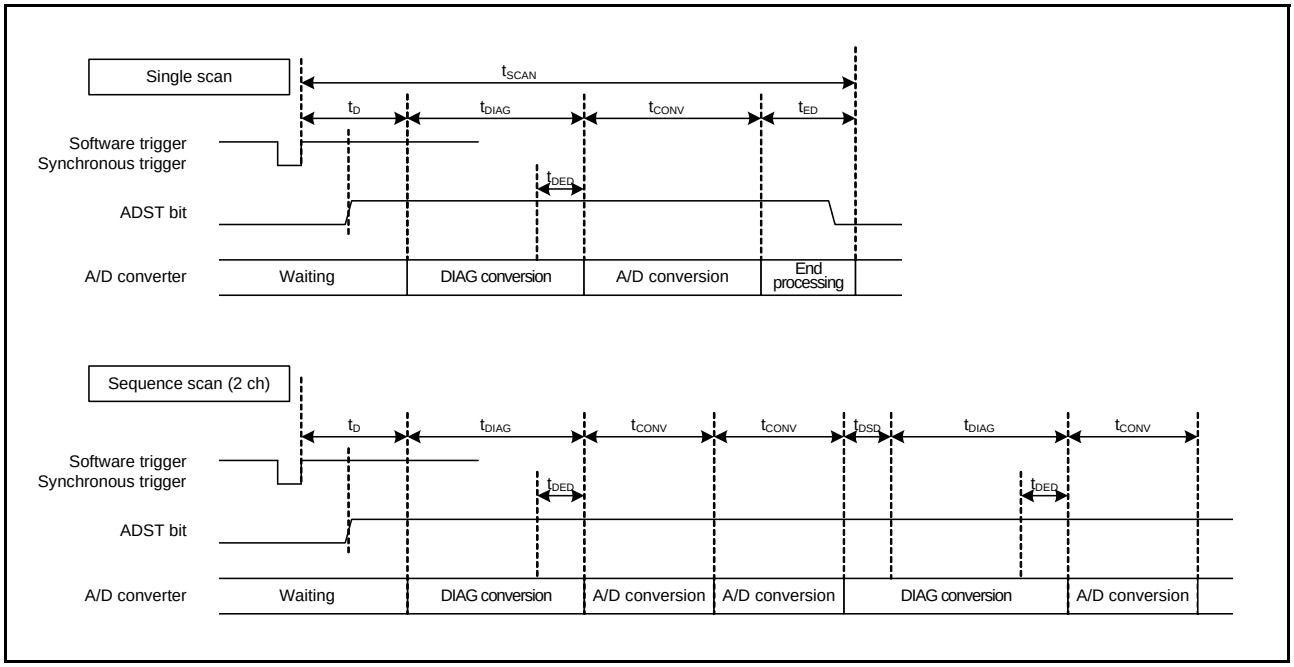


Figure 50.30 Scan Conversion Timing (Activated by Software or Synchronous Trigger)

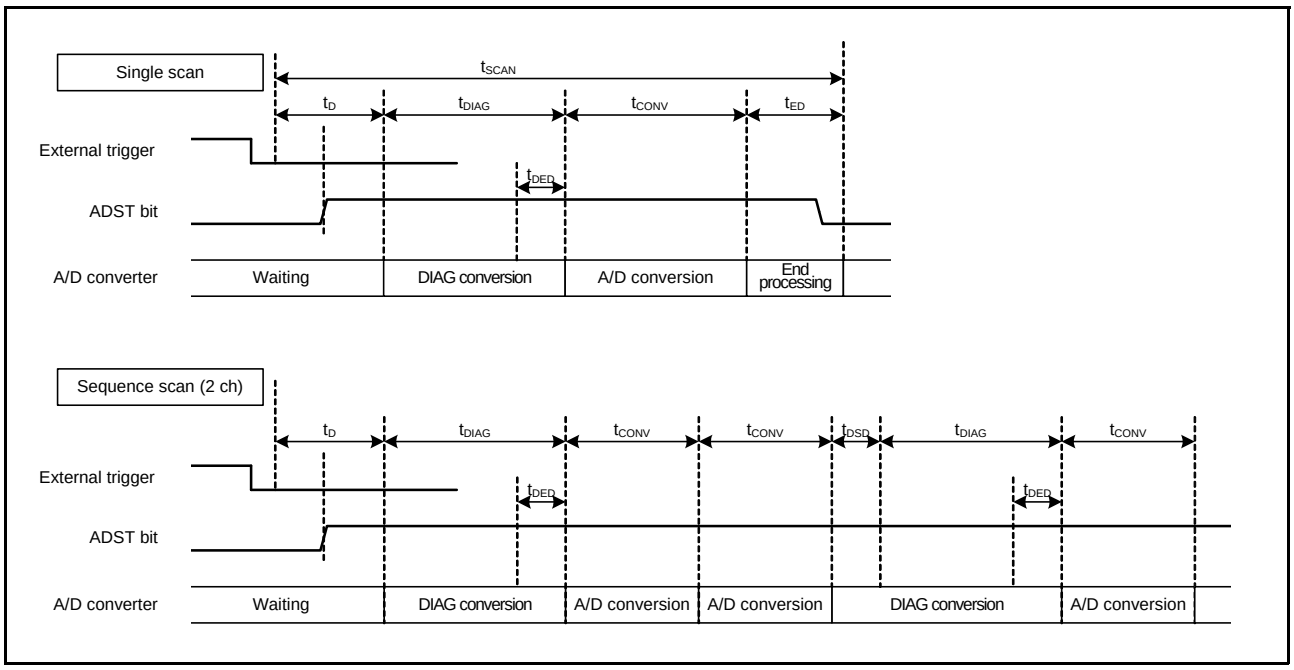

Figure 50.31 Scan Conversion Timing (Activated by Asynchronous Trigger)

50.3.7.1 Timing of Suspension and Starting of Scanning in Operation under Group Priority Control

The timings for suspension and starting of scanning in operation under group priority control that must considered are listed below.

1. The timing for suspending a scan of a group with a lower-priority and the timing for starting a scan of a group with a higher-priority.
2. The time at which scanning by the group with a lower-priority is resumed on completion of scanning by the higher-priority group when the trigger for scanning by the lower-priority group is accepted during scanning by the higher-priority group.
3. The timing for performing sequential single scans by a lower-priority group.

Figure 50.32 shows the timing diagram of each of the above cases.
The times at which scanning by group A is completed and scanning by group C resumes or scanning by group B is completed and scanning by group C resumes are the same as those for group A and group B in Figure 50.32.
The timing for consecutive single scans is the same for group B and group C.

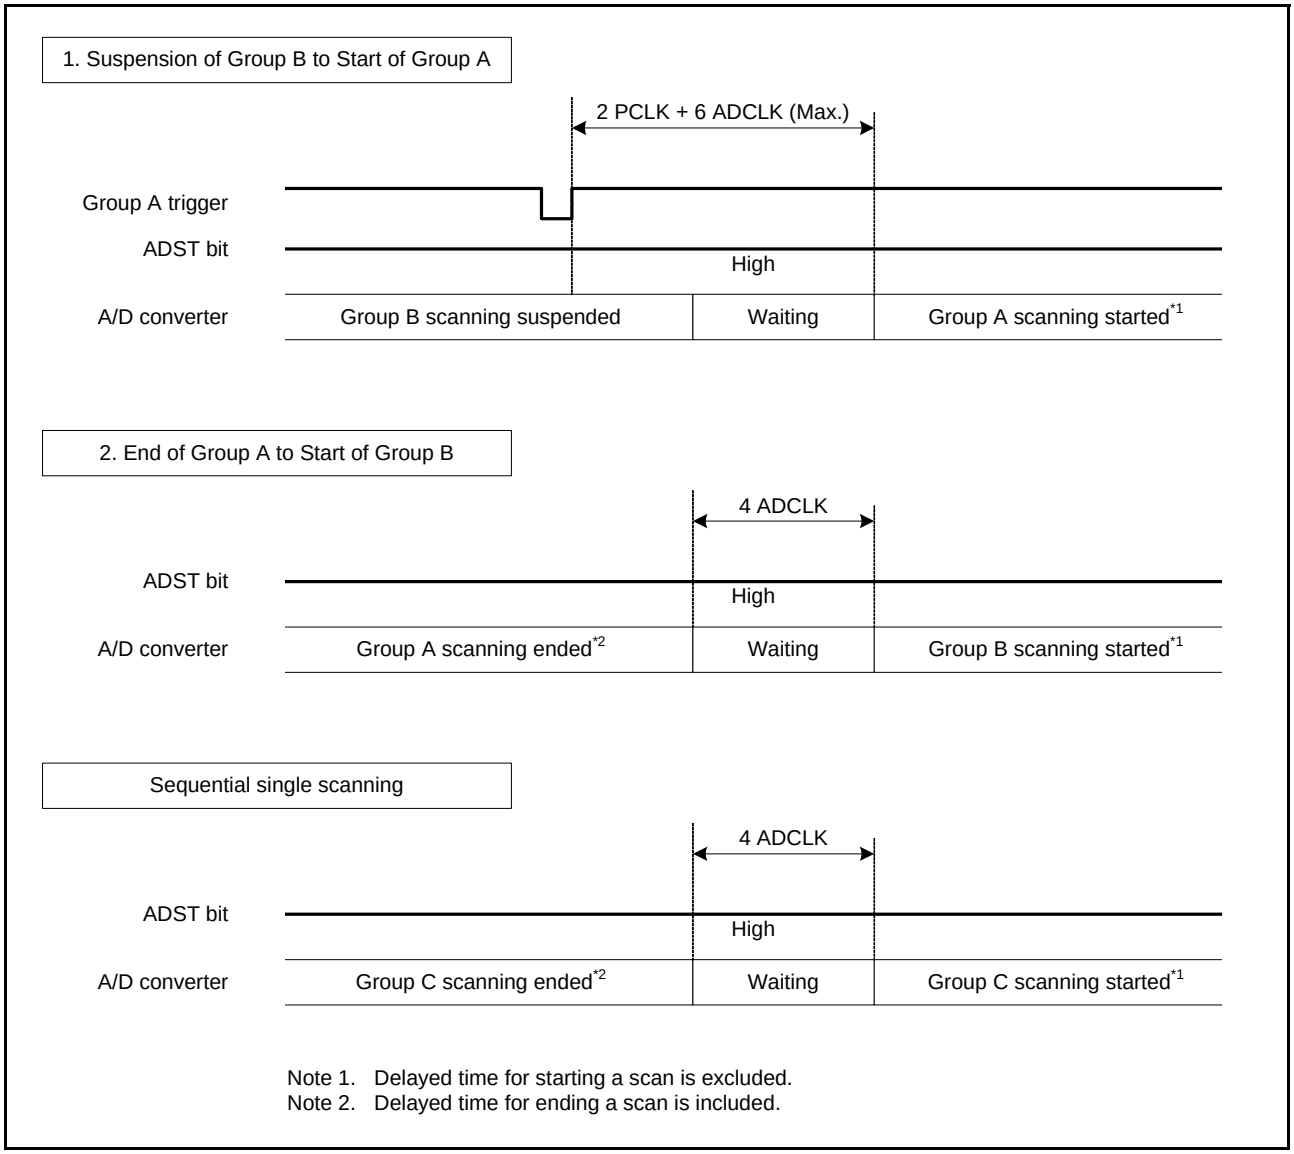

Figure 50.32 Timing of Stop/Start of Scanning in Group Priority Mode

50.3.8 Usage Example of A/D Data Register Automatic Clearing Function

Setting the ADCER.ACE bit to 1 automatically clears the A/D data registers (ADDRy, ADRD, ADTSDR, ADOCDR, ADDBLDR, ADDBLDRA, ADDBLDRB) to 0000h when the A/D data registers (ADDRy, ADRD, ADTSDR, ADOCDR, ADDBLDR, ADDBLDRA, ADDBLDRB) are read by the CPU, DTC, or DMAC.
This function enables detection of update failures of the A/D data registers (ADDRy, ADRD, ADTSDR, ADOCDR, ADDBLDR, ADDBLDRA, ADDBLDRB). The following describes the examples in which the function to automatically clear the ADDRy register is enabled and disabled.
In a case where the ADCER.ACE bit is 0 (automatic clearing disabled), if the A/D conversion result (0222h) is not written to the ADDRy register for some reason, the old data (0111h) will be the ADDRy value. Furthermore, if this ADDRy value is read into a general register using an A/D scan end interrupt, the old data (0111h) can be saved in the general register. When checking whether there is an update failure, it is necessary to frequently save the old data in the RAM or a general register.
In a case where the ADCER.ACE bit is 1 (automatic clearing enabled), when ADDRy = 0111h is read by the CPU, DTC, or DMAC, ADDRy is automatically cleared to 0000h. After that, if the A/D conversion result 0222h cannot be transferred to ADDRy for some reason, the cleared data (0000h) remains as the ADDRy value. If this ADDRy value is read into a general register using an A/D scan end interrupt at this point, 0000h will be saved in the general register. Occurrence of an ADDRy update failure can be determined by simply checking that the read data value is 0000h.

50.3.9 A/D-Converted Value Addition/Average Mode

In A/D-converted value addition mode, the same channel is A/D-converted 2, 3, 4, or 16 consecutive times and the sum of the converted values is stored in the data register. In A/D-converted value average mode, the same channel is A/D-converted two or four consecutive times and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that are present. This function, however, cannot always guarantee an improvement in A/D conversion accuracy.
The A/D-converted value addition/average mode can be used when A/D conversion of the channel select analog input, temperature sensor output (for S12AD1 only), or internal reference voltage (for S12AD1 only) is selected.

50.3.10 Disconnection Detection Assist Function

This converter incorporates the function to fix the charge for sampling capacitance to the specified state before start of A/D conversion. This function enables disconnection detection in wiring of analog inputs.
Figure 50.33 illustrates the A/D conversion operation when the disconnection detection assist function is used. Figure 50.34 shows an example of disconnection detection when precharge is selected. Figure 50.35 shows an example of disconnection detection when discharge is selected.

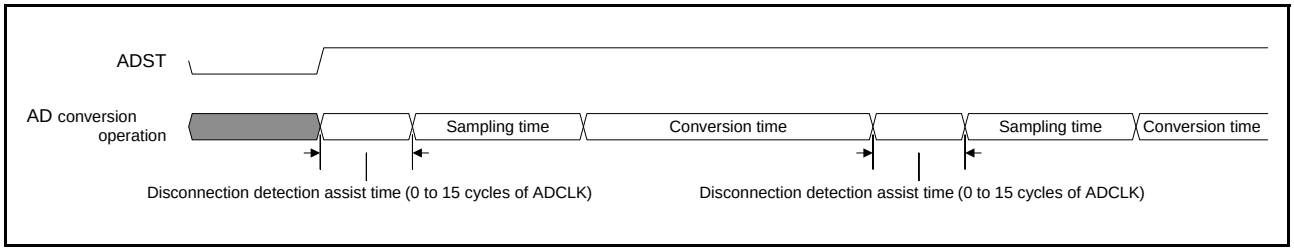

Figure 50.33 Operation of A/D Conversion When the Disconnection Detection Assist Function is Used

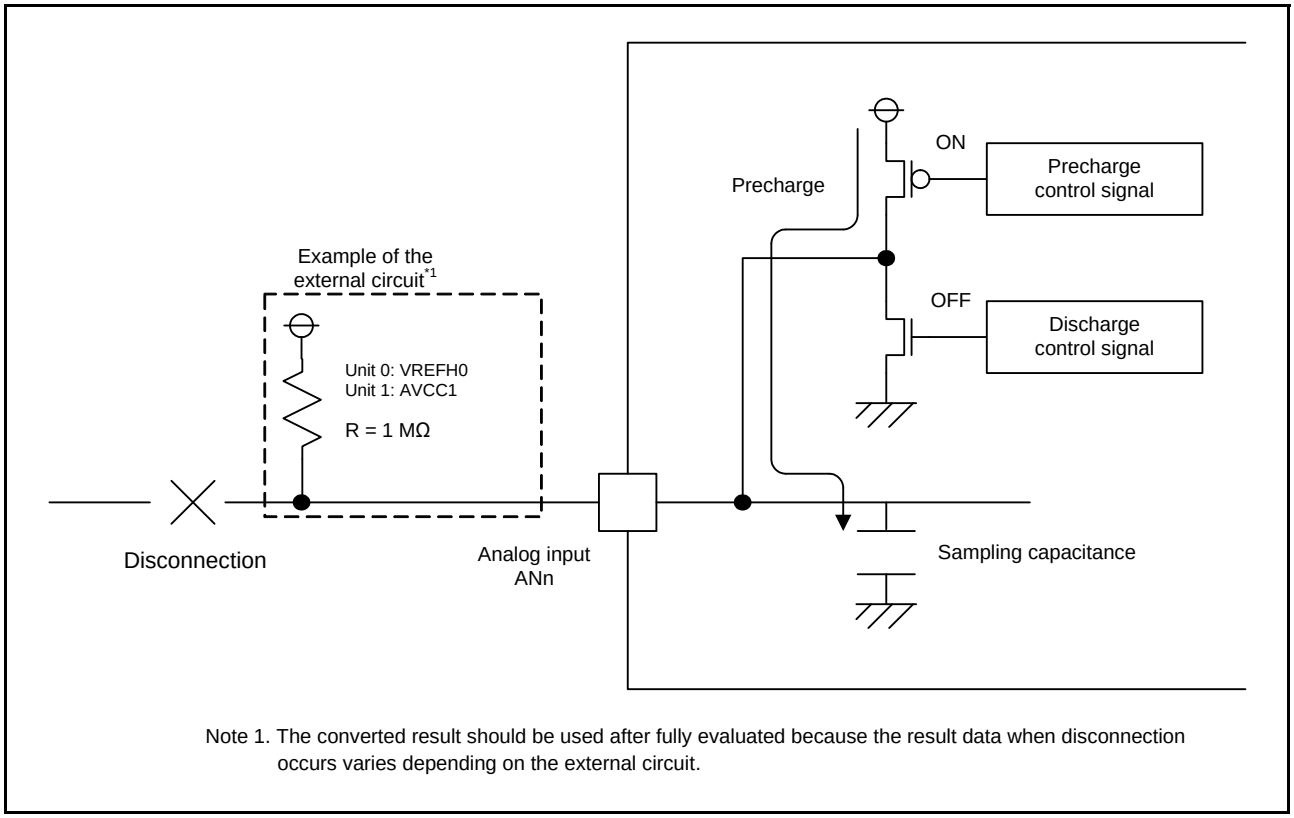
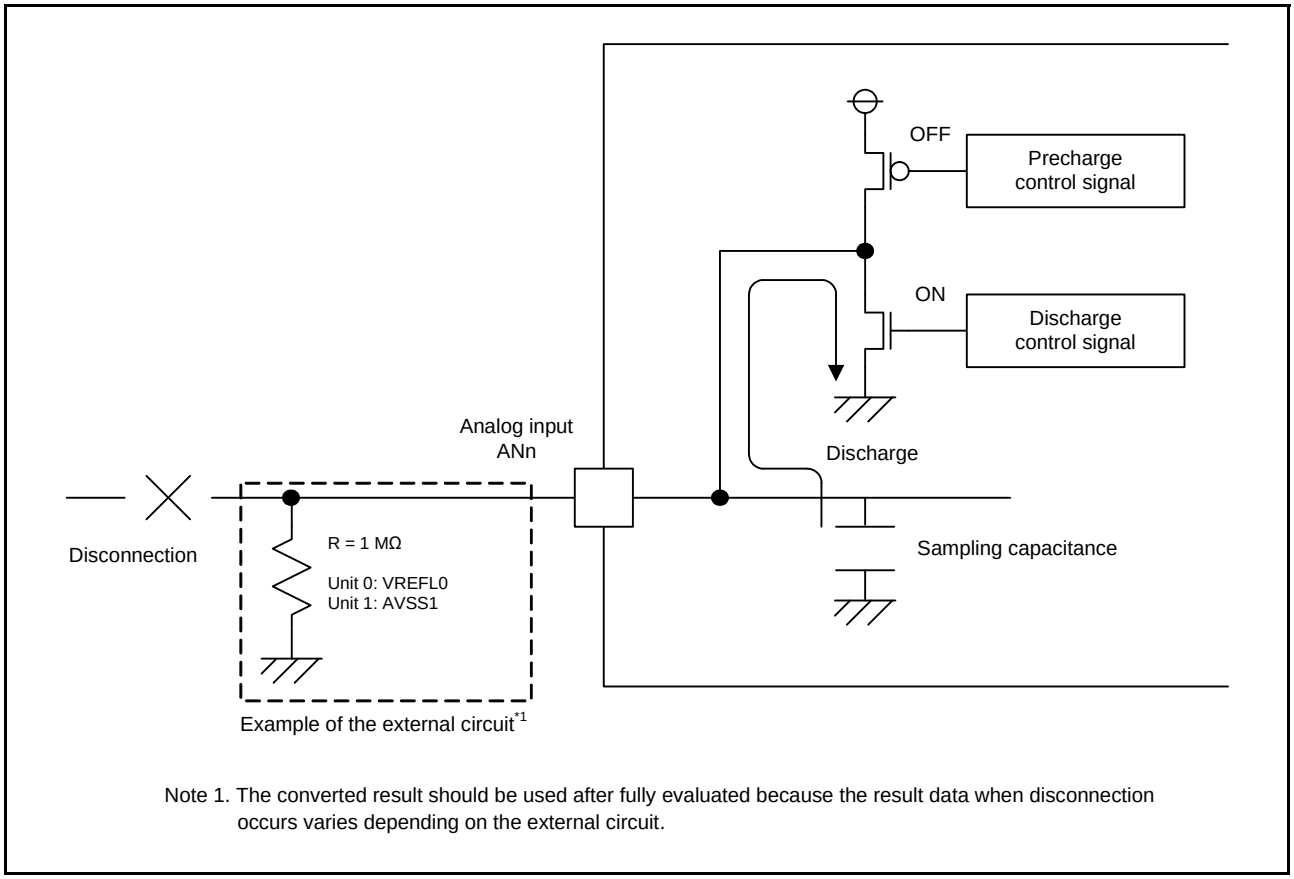


Note 1. The converted result should be used after fully evaluated because the result data when disconnection occurs varies depending on the external circuit.

Figure 50.34 Example of Disconnection Detection When Precharge is Selected



Note 1. The converted result should be used after fully evaluated because the result data when disconnection occurs varies depending on the external circuit.

Figure 50.35 Example of Disconnection Detection When Discharge is Selected

50.3.11 Starting A/D Conversion with Asynchronous Trigger

The A/D conversion can be started by the input of an asynchronous trigger. To start up the A/D converter by an asynchronous trigger, the A/D conversion start trigger select bits (ADSTRGR.TRSA[5:0]) should be set to 000000b, and a high-level signal should be input to the asynchronous trigger (ADTRG0# pin). Then, the ADCSR.TRGE and ADCSR.EXTRG bits should be set to 1. Figure 50.36 shows a timing of the asynchronous trigger input.
For the time from when the ADST bit is set to 1 until conversion starts, refer to section 50.6.3, A/D Conversion Restarting Timing and Termination Timing. An asynchronous trigger cannot be selected for group B or group C in group scan mode.

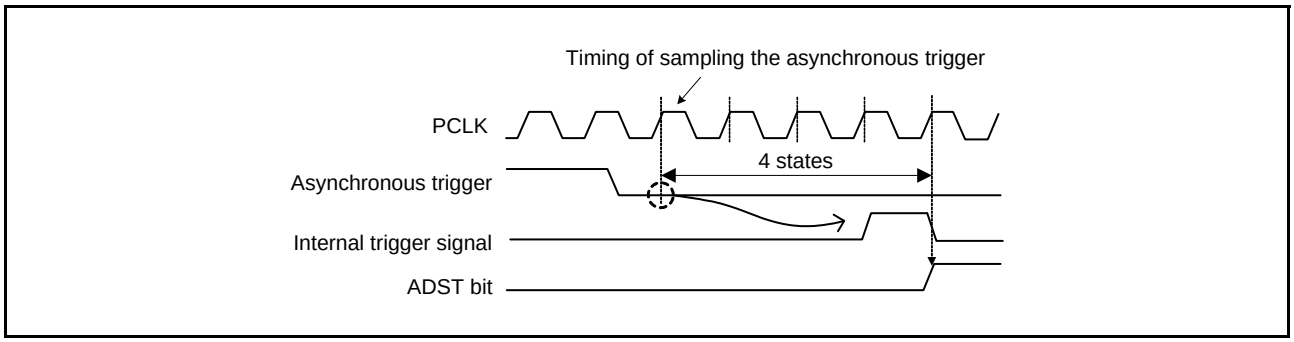


Figure 50.36 Timing of Sampling Asynchronous Trigger

50.3.12 Starting A/D Conversion with Synchronous Trigger from Peripheral Module

The A/D conversion can be started by a synchronous trigger. To start the A/D conversion by a synchronous trigger, the ADCSR.TRGE bit should be set to 1, the ADCSR.EXTRG bit should be cleared to 0, and the relevant sources should be selected by the ADSTRGR.TRSA[5:0] and ADSTRGR.TRSB[5:0] bits.

50.4 Interrupt Sources and DTC/DMAC Transfer Requests

50.4.1 Interrupt Requests

The 12-bit A/D converter can send scan end interrupt requests S12ADI/S12ADI1, S12GBADI/S12GBADI1, and S12GCADI/S12GCADI1 to the CPU.
This module can also generate interrupt requests S12CMPAI/S12CMPAI1 and S12CMPBI/S12CMPBI1 to the CPU in response to matches with a condition for comparison.
Setting the ADCSR.ADIE bit to 1 and 0 enables and disables an S12ADI/S12ADI1 interrupt, respectively; similarly, setting the ADCSR.GBADIE bit to 1 and 0 enables and disables a S12GBADI/S12GBADI1 interrupt, respectively; similarly, setting the ADGCTRGR.GCADIE bit to 1 and 0 enables and disables a S12GCADI/S12GCADI1 interrupt, respectively.
Setting the ADCMPCR.CMPAIE bit to 1 enables an S12CMPAI interrupt and setting the ADCMPCR.CMPAIE bit to 0 disables an S12CMPAI interrupt.
Setting the ADCMPCR.CMPBIE bit to 1 enables an S12CMPBI interrupt and setting the ADCMPCR.CMPBIE bit to 0 disables an S12CMPBI interrupt.
In addition, the DTC or DMAC can be activated when an S12ADI/S12ADI1, a S12GBADI/S12GBADI1, or S12GCADI/S12GCADI1 interrupt is generated. Using an S12ADI/S12ADI1, a S12GBADI/S12GBADI1, or S12GCADI/S12GCADI1 interrupt to allow the DTC or DMAC to read the converted data enables sequence conversion without burden on software.
For details on DTC and DMAC settings, see section 20, Data Transfer Controller (DTCb) and section 18, DMA Controller (DMACAb).

50.4.2 Scan Complete Event Output to ELC

The ELC can set up linked operation of a module specified in advance by using the S12ADI or S12ADI1 interrupt request signal as an event signal.
The S12GBADI or S12GBADI1 interrupt, S12GCADI or S12GCADI1 interrupt, S12CMPAI or S12CMPAI1 interrupt, and S12CMPBI or S12CMPBI1 interrupt request signals cannot be used as event signals. An event signal is output regardless of the setting of the corresponding interrupt request enable bit. The 12-bit A/D converter outputs the A/D conversion completed signals as event signals.

50.5 Allowable Impedance of Signal Source

To achieve high-speed conversion of 0.48 µs, the analog input pins of this MCU are designed so that the conversion accuracy is guaranteed if the impedance of the input signal source is 1.0 kΩ or less. If an external capacitor of large capacitance is attached in the application in which only a single pin input is converted in single scan mode, the only load on input is virtually 1.2 kΩ of the internal input resistor; therefore, the impedance of the signal source can be ignored. Being a low-pass filter, however, an analog input circuit may not follow the analog signal with a large differential coefficient. When high-speed analog signals are to be converted or multiple pins are to be converted in scan mode, a low-impedance buffer should be used.
Figure 50.37 shows an equivalent circuit of an analog input pin and an external sensor.
To perform A/D conversion accurately, charging of the internal capacitor C shown in Figure 50.37 must be completed within the specified period of time. This specified period is referred to as sampling time.

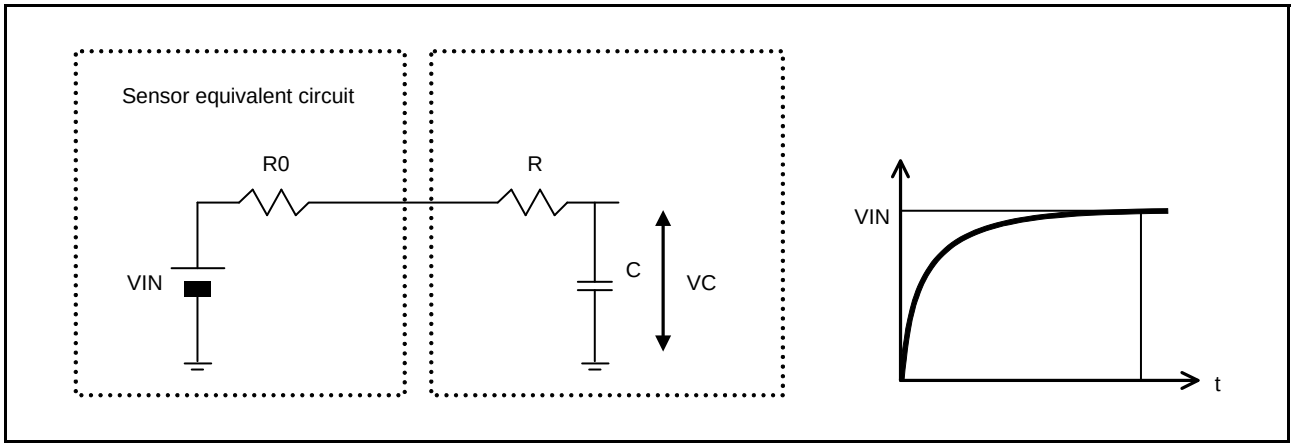

Figure 50.37 Equivalent Circuit of Analog Input Pin and External Sensor

50.6 Usage Notes

50.6.1 Notes on Reading Data Registers

The A/D data registers, A/D data duplication registers, A/D data duplication register A, A/D data duplication register B, A/D temperature sensor data register, A/D internal reference voltage data register, and A/D self-diagnosis data register should be read in 16-bit units. If a register is read twice in 8-bit units, that is, the higher-order byte and lower-order byte are separately read, the A/D-converted value having been read first may disagree with the A/D-converted value having been read for the second time. To prevent this, the data registers should never be read in 8-bit units.

50.6.2 Notes on Stopping A/D Conversion

50.6.2.1 Procedure of Stopping A/D Conversion

To stop A/D conversion when an asynchronous trigger or a synchronous trigger has been selected as the condition for starting A/D conversion, follow the procedure in Figure 50.38.

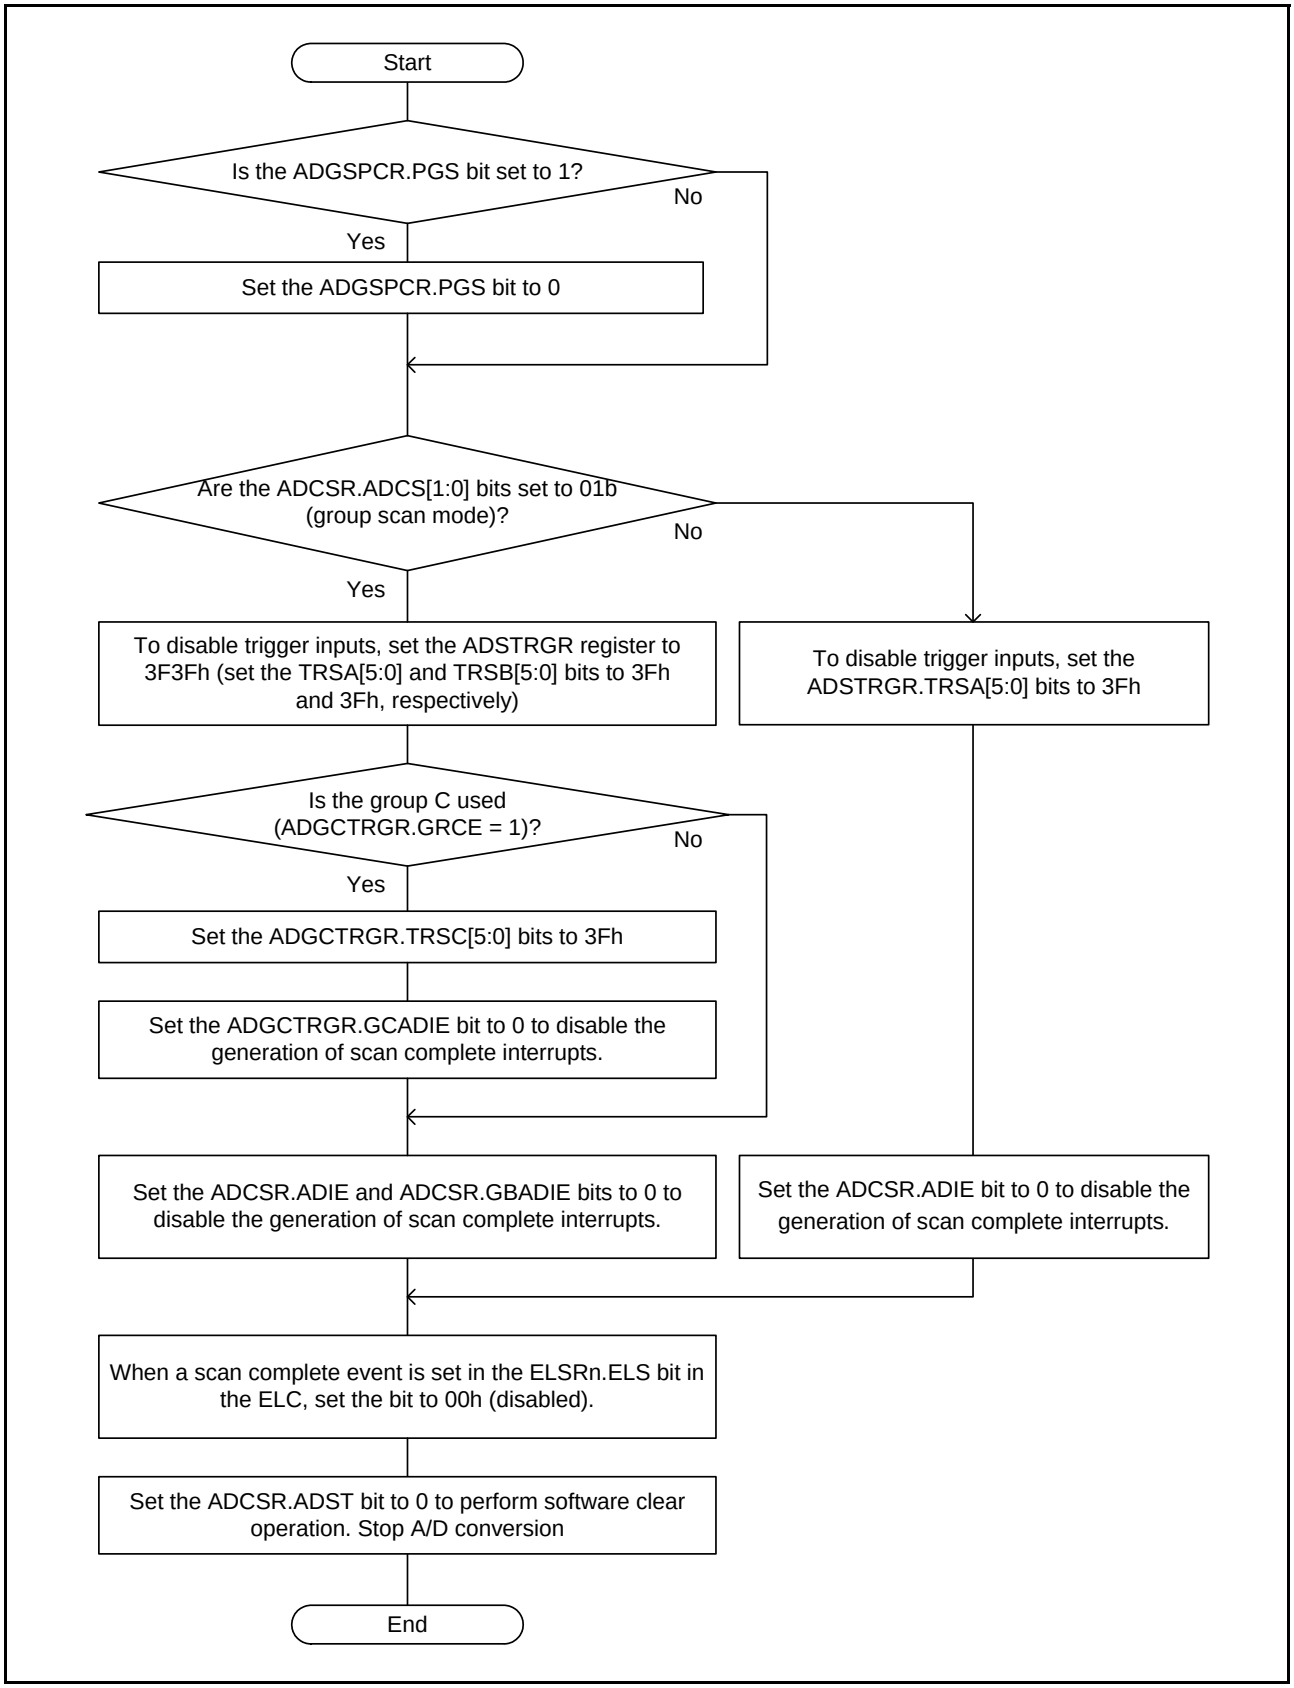

Figure 50.38 Procedure for Clear Operation by Software through the ADCSR.ADST Bit

50.6.2.2 Notes on Modes and Status Bits

The following values may be cleared or reset as described below: the voltage status used in self-diagnosis, the odd-even determination for the double-trigger mode, the bits for monitoring comparison for the comparison function.

- Re-set the settings for the voltage for use in self-diagnosis by setting the ADCER.DIAGLD bit to 1 and setting the ADCER.DIAGVAL[1:0] bits.
- Make double-trigger mode effective starting from the first scan by changing the setting of the ADCSR.DBLE bit from 0 to 1.
- Set the ADCMPCR.CMPAE and ADCMPCR.CMPBE bits to 0, which initializes the bits for monitoring comparison (MONCMPA, MONCMPB, MONCOMB).

50.6.3 A/D Conversion Restarting Timing and Termination Timing

It takes a maximum of six ADCLK cycles for the idle analog unit of the 12-bit A/D converter to be restarted by setting the ADCSR.ADST bit to 1. It takes a maximum of two ADCLK cycles for the operating analog unit of the 12-bit A/D converter to be terminated by setting the ADCSR.ADST bit to 0.

50.6.4 Notes on Scan End Interrupt Handling

When scanning the same analog input twice using any trigger, the first A/D-converted data is overwritten with the second A/D-converted data in the case that the CPU does not complete reading the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated.

50.6.5 Module Stop Function Setting

Operation of the 12-bit A/D converter can be disabled or enabled by setting module stop control register. The initial setting is for operation of the 12-bit A/D converter to be halted. Register access is enabled by releasing the module stop state.
After the module stop state is released, wait for 1 µs to start A/D conversion. For details, refer to section 11, Low Power Consumption.

50.6.6 Notes on Entering Low Power Consumption States

Before entering the module stop state or software standby mode, make sure to stop A/D conversion. Here, set the ADCSR.ADST bit to 0, and secure certain period of time until the analog unit of the 12-bit A/D converter is stopped. Follow the procedure given below to secure this time.
Set the ADCSR.ADST bit to 0 by following the procedure in Figure 50.38 Procedure for Clear Operation by Software through the ADCSR.ADST Bit. Then wait for two clock cycles of ADCLK before entering the module stop mode or software standby mode.

50.6.7 Notes on Canceling Software Standby Mode

After software standby mode is canceled, wait until the crystal oscillation stabilization time or the PLL circuit stabilization time elapses, and then wait for 1 µs before starting A/D conversion. For details, refer to section 11, Low Power Consumption.

50.6.8 Pin Setting When Using the 12-bit A/D Converter

When using the 12-bit A/D converter unit 0, do not use the P40 to P47, P03, P05, and P07 pins as output pins. We also recommend not using the P00 to P02, P90, PD0 to PD7, PE0, and PE1 pins as output pins. If any of the P00 to P02, P90, PD0 to PD7, PE0, and PE1 pins is used for an output pin, perform A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results.
When using the 12-bit A/D converter unit 1, we recommend not using the P00 to P02, P90, PD0 to PD7, PE0, and PE1 pins as output pins. If any of the P00 to P02, P90, PD0 to PD7, PE0, and PE1 pins is used for an output pins, perform A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results.

50.6.9 Caution When Using an External Bus

A/D conversion at the same time as access to an external bus may produce poor results.
In this case, use a software approach, such as performing A/D conversion several times, then obtaining the average after excluding the highest and lowest values.
Deterioration in A/D conversion resolution can be reduced by changing the assignment of the external data bus. For details of the setting, refer to section 23, Multi-Function Pin Controller (MPC).

50.6.10 Error in Absolute Accuracy When Disconnection Detection Assistance is in Use

Using disconnection detection assistance leads to an error in absolute accuracy of the A/D converter. This is because an error voltage is input to the analog input pins due to the resistive voltage division between the pull-up or pull-down resistor (Rp) and the resistance of the signal source (Rs). This error in absolute accuracy is calculated from the following formula. Only use disconnection detection assistance after thorough evaluation.

Maximum error in absolute accuracy (LSB) = 4095 × Rs / Rp

50.6.11 Voltage Range of Analog Power Supply Pins

If this MCU is used with the voltages outside the following ranges, the reliability of the MCU may be affected.

- Analog input voltage range
  Voltage applied to analog input pins AN000 to AN007, AN100 to AN111: AVSSn ≤ VANn ≤ AVCCn (n = 0, 1)
- Relationship between power supply pin pairs (AVCCn–AVSSn, VCC–VSS)

  A 0.1-µF capacitor should be connected between each pair of power supply pins to create a closed loop with the shortest route possible as shown in Figure 50.39, and connection should be made so that the following condition is satisfied at the supply side: AVSSn = VSS
  When the 12-bit A/D converter is not used, the following conditions should be satisfied:
  AVCCn = VCC and AVSSn = VSS

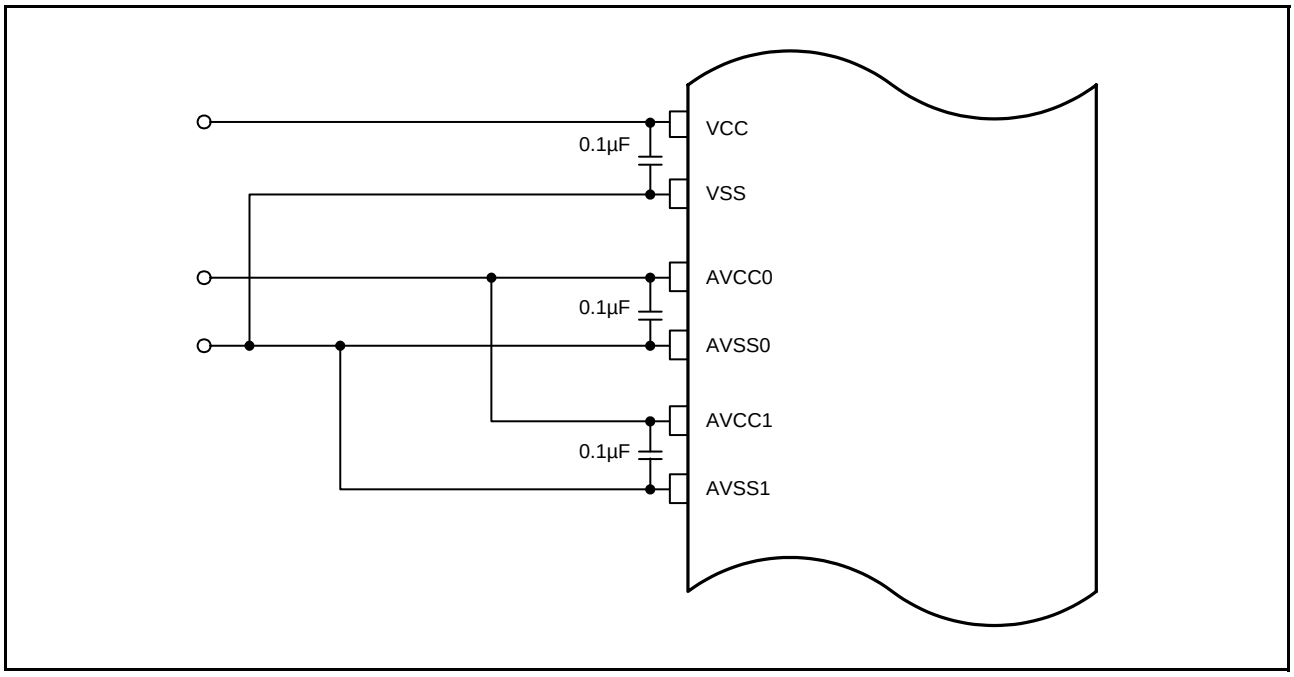

Figure 50.39 Power Supply Pin Connection Example

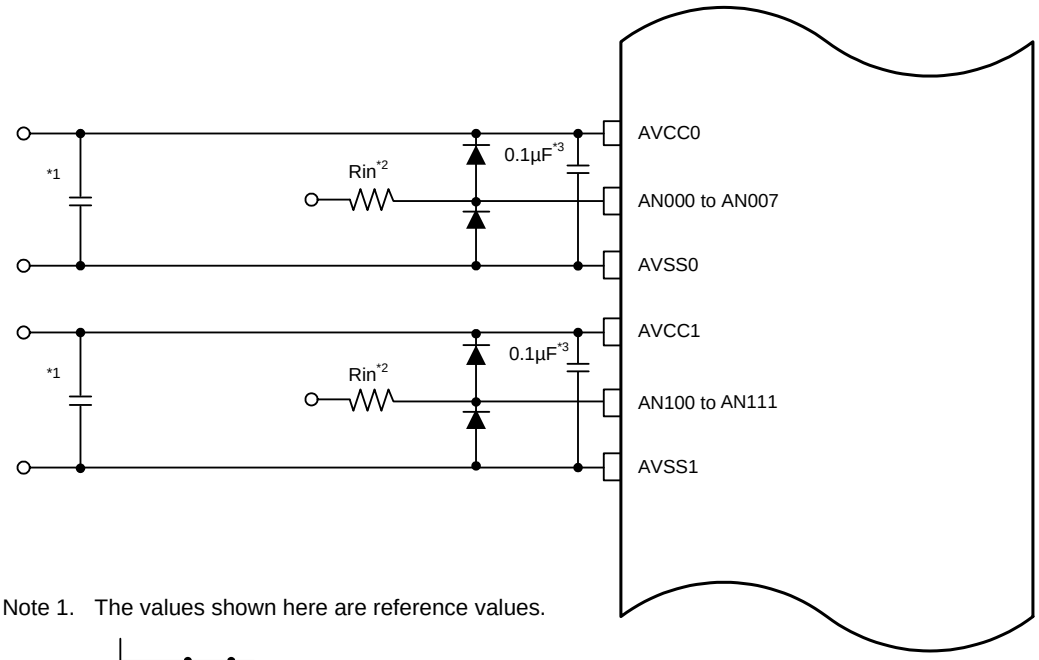
50.6.12 Notes on Board Design

The board should be designed so that digital circuits and analog circuits are separated from each other as far as possible. In addition, digital circuit signal lines and analog circuit signal lines should not intersect or placed near each other. If these rules are not followed, noise will be produced on analog signals and A/D conversion accuracy will be affected. The analog input pins (AN000 to AN007, AN100 to AN111), and analog power supply (AVCCn) should be separated from digital circuits using the analog ground (AVSSn). The analog ground (AVSSn) should be connected to a stable digital ground (VSS) on the board (single-point ground plane connection).

50.6.13 Notes on Noise Prevention

To prevent the analog input pins (AN000 to AN007, AN100 to AN111) from being destroyed by abnormal voltage such as excessive surge, a capacitor should be inserted between AVCCn and AVSSn, and a protection circuit should be connected to protect the above analog input pins as shown Figure 50.40.



Note 1. The values shown here are reference values.

Note 2. Rin: Signal source impedance

Note 3. Place capacitors to be inserted between the power source of AVCC0, AVSS0, AVCC1, and AVSS1 as close as possible to the power supply pins to prevent deterioration in A/D conversion resolution.

Figure 50.40 Sample Protection Circuit for Analog Inputs

51. Temperature Sensor (TEMPS)

51.1 Overview

This MCU includes a temperature sensor. The temperature sensor outputs a voltage which varies with the temperature. The 12-bit A/D converter unit 1 can convert the voltage from the sensor into a digital value. The temperature around the MCU can be obtained by converting the value into the temperature.

Table 51.1 lists the specifications of the temperature sensor, and Figure 51.1 shows a block diagram of the temperature sensor.

Table 51.1 Specifications of Temperature Sensor

Item	Description
Temperature sensor voltage output	Temperature sensor outputs a voltage to the 12-bit A/D converter unit 1.
Low-power consumption function	Module stop state can be set.
Temperature Sensor Calibration Data	Reference data measured for each chip at factory shipment is stored.

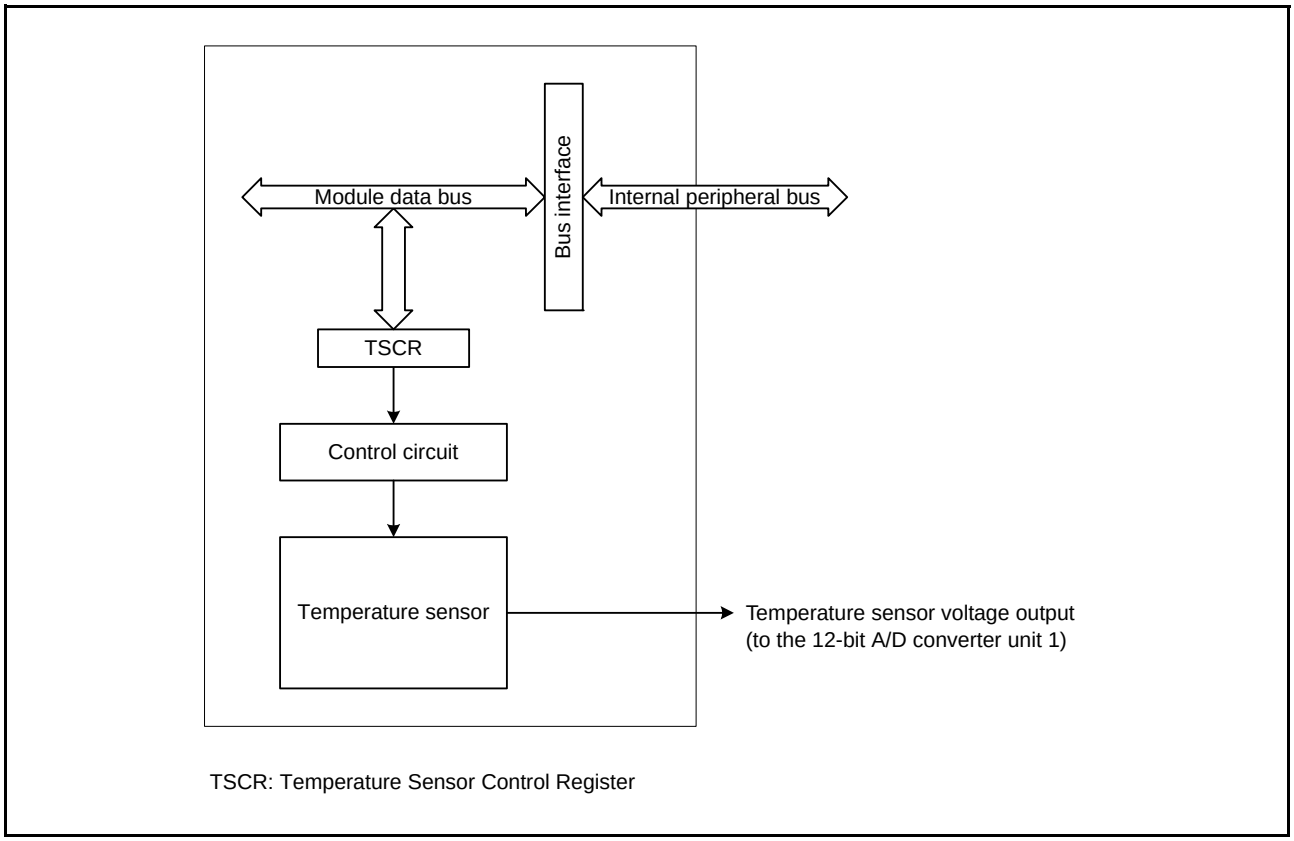


Figure 51.1 Block Diagram of Temperature Sensor

51.2 Register Descriptions

51.2.1 Temperature Sensor Control Register (TSCR)

Address(es): TEMPS.TSCR 0008 C500h

	b7	b6	b5	b4	b3	b2	b1	b0
	TSEN	—	—	TSOE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	TSOE	Temperature Sensor Output Enable	0: Disables output from the temperature sensor to the 12-bit A/D converter unit 1. 1: Enables output from the temperature sensor to the 12-bit A/D converter unit 1.	R/W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	TSEN	Temperature Sensor Enable	0: Stops the temperature sensor. 1: Starts the temperature sensor.	R/W

The settings of TSCR register have the timing restrictions shown in Figure 51.4.

51.2.2 Temperature Sensor Calibration Data Register (TSCDR)

Address(es): TEMPSCONST.TSCDR FE7F 7D7Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—												
Value after reset:	0	0	0	0	Unique value for each chip											

Note: This register is only readable when the SYSCR0.ROME bit is 1 (the on-chip ROM is enabled).

The TSCDR register stores temperature sensor calibration data measured for each chip at factory shipment. The TSCDR register is a 32-bit read-only register and should be read in 32-bit units.
Temperature sensor calibration data is a digital value obtained using the 12-bit A/D converter unit 1 to convert the voltage output by the temperature sensor under the condition of Ta = Tj = 128°C and AVCC1 = 3.3 V.
The voltage V1 output by the temperature sensor under the condition of Ta = Tj = 128°C can be calculated from the value of the TSCDR register according to the formula below.

V1 = 3.3 × value of the TSCDR register/4096 [V]

Note that the AVCC1 voltage does not affect voltage V1.

51.3 Using the Temperature Sensor

The temperature sensor outputs a voltage which varies with the temperature.
This voltage is converted to a digital value by the 12-bit A/D converter unit 1. The temperature around the MCU can be obtained by converting the value into the temperature.

51.3.1 Preparation for Using the Temperature Sensor

Perform a calibration of the temperature sensor as shown below. The voltage output by the temperature sensor is proportional to temperature, which can be calculated according to the following formula.

Formula for the temperature characteristic:
T = (Vs – V1)/Slope + T1

T: Measured temperature (°C)
Vs: Voltage output by the temperature sensor when the temperature is measured (V)
T1: Sample temperature measurement at first point (°C)
V1: Voltage output by the temperature sensor when T1 is measured (V)
T2: Sample temperature measurement at second point (°C)
V2: Voltage output by the temperature sensor when T2 is measured (V)
Slope: Temperature slope of the temperature sensor (V/°C); Slope = (V2 – V1)/(T2 – T1)

Characteristics of the temperature sensor vary from MCU to MCU. Therefore, a two-point calibration (the following experimental measurement at two different temperatures) is recommended.
Use the 12-bit A/D converter unit 1 to measure the voltage V1 output by the temperature sensor at temperature T1. Again, using the 12-bit A/D converter unit 1, measure the voltage V2 output by the temperature sensor at a different temperature T2. Obtain the temperature slope (Slope = (V2 – V1)/(T2 – T1)) from these results.
Subsequently, obtain temperatures by substituting the slope into the formula for the temperature characteristic (T = (Vs – V1)/Slope + T1).

If you are using the temperature slope given in Table 56.56 of section 56, Electrical Characteristics, use the 12-bit A/D converter unit 1 to measure the voltage V1 output by the temperature sensor at temperature T1, and then calculate the temperature characteristic by using the formula below.
However, this calibration gives less accurate temperatures than two-point calibration.

T = (Vs – V1)/Slope + T1

T: Measured temperature (°C)
Vs: Voltage output by the temperature sensor when the temperature is measured (V)
T1: Sample temperature measurement at first point (°C)
V1: Voltage output by the temperature sensor when T1 is measured (V)
Slope: Temperature slope given in Table 56.56 ÷ 1000 (V/°C)

In this MCU, the TSCDR register stores the temperature value (CAL_{128}) of the temperature sensor measured under the condition of Ta = Tj = 128°C and AVCC1 = 3.3 V. By using this value as the sample measurement result at the first point, preparation before using the temperature sensor can be omitted.
If V1 is calculated from CAL_{128},

$V1 = 3.3 \times CAL_{128}/4096$ [V]
Using this, the measured temperature can be calculated according to the formula below.

T = (Vs – V1)/Slope + 128 [°C]

T: Measured temperature (°C)
Vs: Voltage output by the temperature sensor when the temperature is measured (V)
V1: Voltage output by the temperature sensor when Ta = Tj = 128°C and AVCC1 = 3.3 V (V)
Slope: Temperature slope given in Table 56.56 ÷ 1000 (V/°C)

Error in the measured temperature (the range of variation is 3σ) is shown in Figure 51.2.

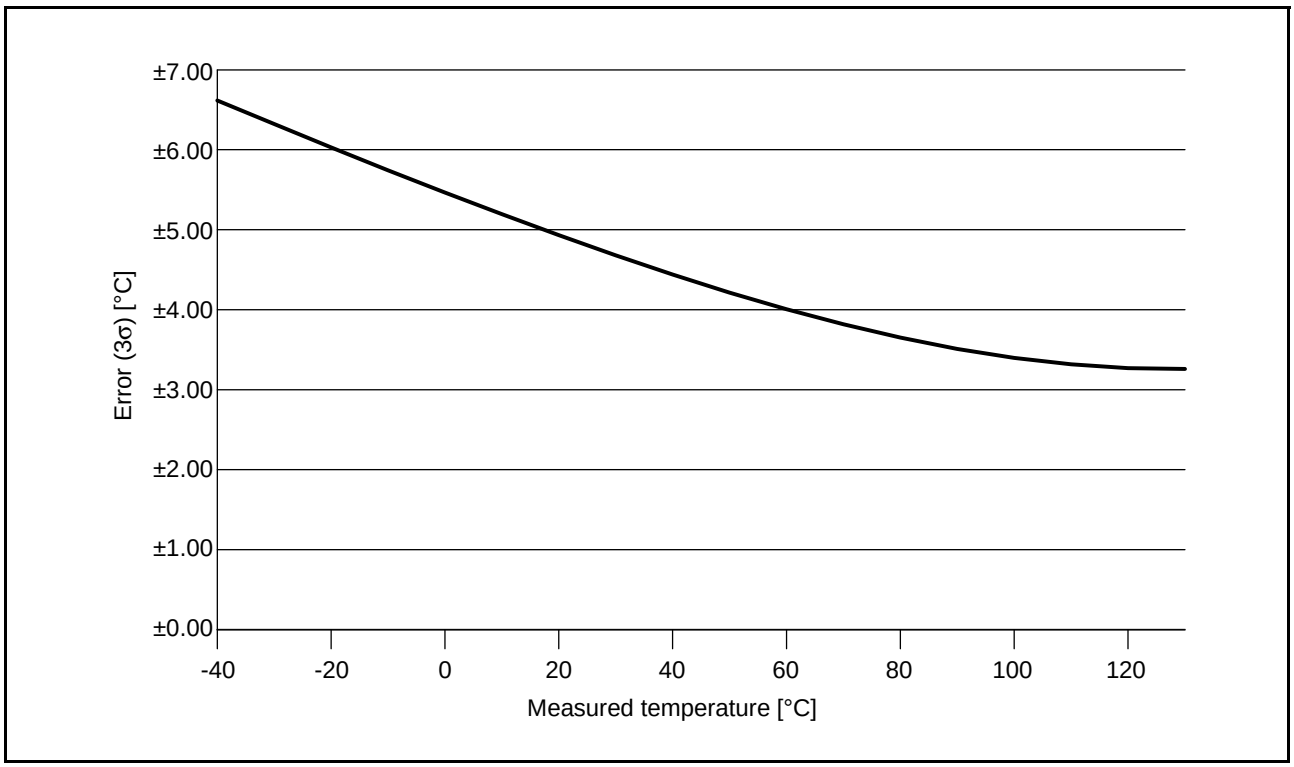

Figure 51.2 Error in the Measured Temperature

51.3.2 Setting of 12-Bit A/D Converter Unit 1

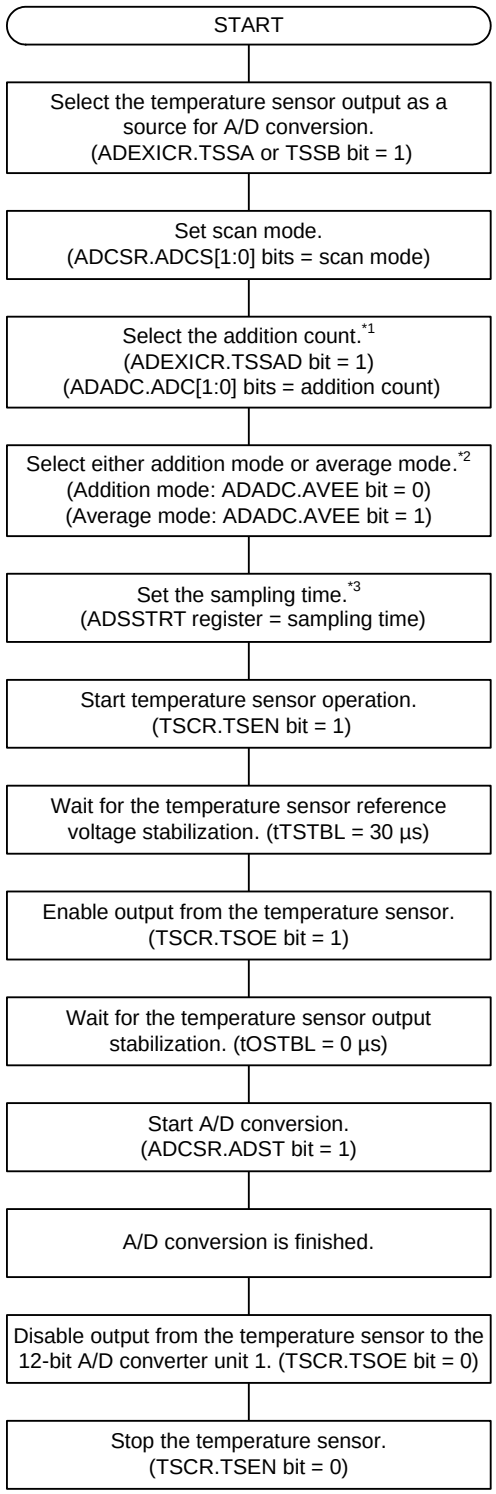
For A/D conversion of temperature sensor output voltages, 12-bit A/D converter unit 1 registers should be set as follows.

- Selecting the Temperature Sensor Voltage as a Source for A/D Conversion
  Select the temperature sensor voltage as a source for A/D conversion by setting the temperature sensor output A/D conversion select bit in the A/D conversion extended input control register (TSSA or TSSB in the ADEXICR register) to 1.
- Setting Scan Mode
  Select scan mode by setting the scan mode select bits in the A/D control register (ADCSR.ADCS[1:0]).
- Setting Addition/Average Mode
  For A/D conversion of the temperature sensor output, additional or average mode is selectable. To use either additional or average mode, set the temperature sensor output A/D converted value addition mode select bit in the A/D conversion extended input control register (ADEXICR.TSSAD) to 1, and the addition count select bits in the A/D converted value addition count select register (ADADC.ADC[1:0]) to the desired number of addition. Furthermore, clear the AVEE bit in ADADC to 0 to select addition mode; set the AVEE bit in ADADC to 1 to select average mode. In average mode, however, the ADC[1:0] bits in ADADC should not be set to 10b.
- Setting the Sampling Time of the 12-bit A/D converter Unit 1
  The sampling time of the 12-bit A/D converter can be changed at converting the output from the temperature sensor. The initial sampling time is 11 cycles of ADCLK. To change the setting of sampling time from 11 cycles of ADCLK, set the A/D sampling state register T (ADSSTRT) while the ADCSR.ADST bit is 0.

Setting the A/D conversion start bit in the A/D control register (ADCSR.ADST) to 1 starts A/D conversion, and the result is stored in the A/D temperature sensor data register (ADTSDR). If you will be using A/D conversion of the output from the temperature sensor, do so in accord with section 51.3.3, Procedure for Using the Temperature Sensor.

51.3.3 Procedure for Using the Temperature Sensor

Figure 51.3 shows the procedure for using the temperature sensor.



Note 1. When not using the addition/average mode, this setting is not required. To select average mode, do not set the ADADC.ADC[1:0] bits to 10b.
Note 2. When not using the addition/average mode, this setting is not required.
Note 3. The initial sampling time is 11 cycles of ADCLK. If the sampling time is not to be changed, this setting is not required.

Figure 51.3 Procedure for Using the Temperature Sensor

51.3.4 Timing of A/D Conversion of Temperature Sensor Output

Figure 51.4 shows the timing from the start of temperature-sensor operation until the completion of A/D conversion when only the output from the temperature sensor is to be A/D converted and conversion is in single-scan mode. The times shown in the figure are described in Table 51.2.

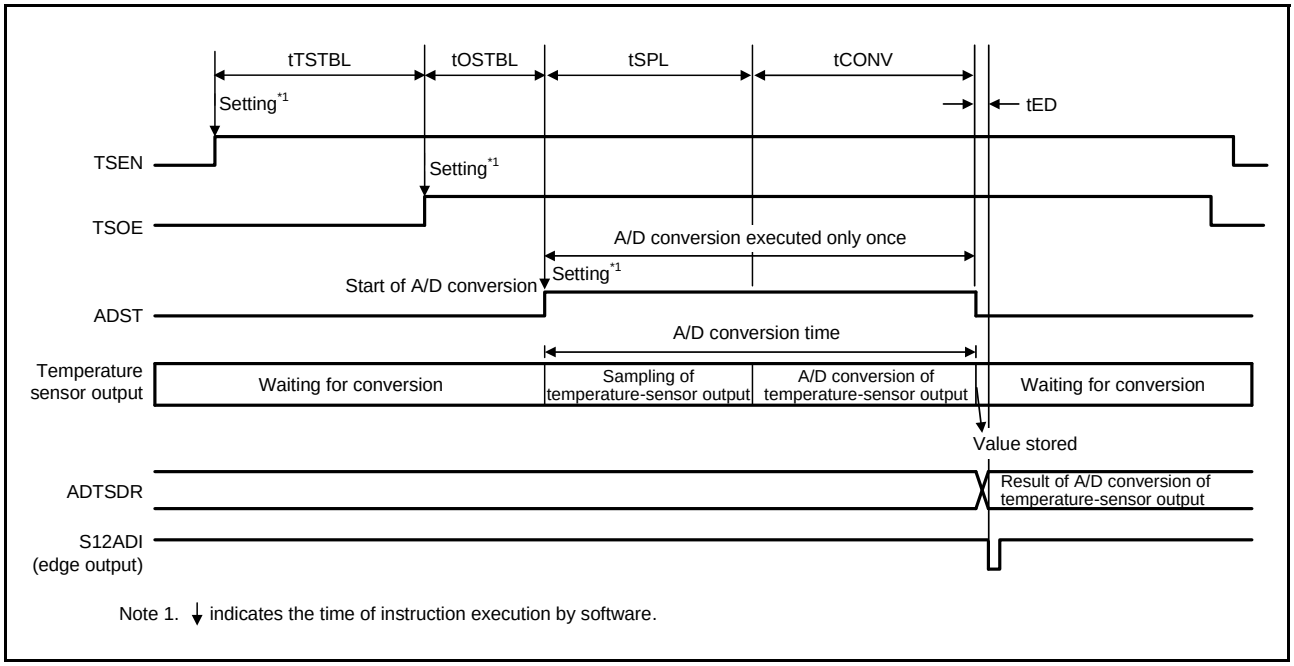


Figure 51.4 Timing from the Start of Temperature-Sensor Operation until Completion of A/D Conversion

Table 51.2 Time until Completion of A/D Conversion after the Start of Temperature-Sensor Operation

Item	Symbol	Time
Temperature-sensor reference-voltage stabilization wait time	tTSTBL	30 µs (min)
Temperature-sensor output stabilization wait time	tOSTBL	0 µs (min)
12-bit A/D converter unit 1 input sampling time	tSPL	ADSSTRT setting × tC(ADCLK)
A/D conversion time	tCONV	Refer to Table 50.18, Times for Conversion during Scanning (in Numbers of Cycles of ADCLK and PCLK) in section 50.3.7, Analog Input Sampling Time and Scan Conversion Time.
Scan conversion end delay time	tED	Refer to Table 50.18, Times for Conversion during Scanning (in Numbers of Cycles of ADCLK and PCLK) in section 50.3.7, Analog Input Sampling Time and Scan Conversion Time.

51.4 Usage Note

51.4.1 Module-Stop Function Setting

The corresponding bit in module stop control register B (MSTPCRB) can be used to enable and disable the temperature sensor. The initial setting is for the temperature sensor to be stopped. The register becomes accessible by releasing from the module-stop state. For details, refer to section 11, Low Power Consumption.

52. Data Operation Circuit (DOCA)

52.1 Overview

The data operation circuit (DOC) is used to compare, add, or subtract 16- or 32-bit values.

Table 52.1 lists the specifications of the DOC and Figure 52.1 is a block diagram of the DOC.

An interrupt can be generated if the result of 16- or 32-bit comparison meets one of the set interrupt conditions or if the result of the addition or subtraction result of 16- or 32-bit values is an overflow or underflow.

Table 52.1 DOC Specifications

Item	Description
Data operation function	• Comparison of 16- or 32-bit values (equal or not equal, greater or less than, or within or beyond a range) • Addition or subtraction of 16- or 32-bit values
Lower power consumption function	The DOC can be placed in a module-stop state.
Interrupts	• The result of data comparison meets the detection condition. • The result of data addition is greater than FFFFh (DOCR.DOPSZ = 0) or FFFF FFFFh (DOCR.DOPSZ = 1), which is an overflow. • The result of data subtraction is less than 0000h (DOCR.DOPSZ = 0) or 0000 0000h (DOCR.DOPSZ = 1), which is an underflow.
Event link function (output)	• The result of data comparison meets the detection condition. • The result of data addition is greater than FFFFh (DOCR.DOPSZ = 0) or FFFF FFFFh (DOCR.DOPSZ = 1), which is an overflow. • The result of data subtraction is less than 0000h (DOCR.DOPSZ = 0) or 0000 0000h (DOCR.DOPSZ = 1), which is an underflow.

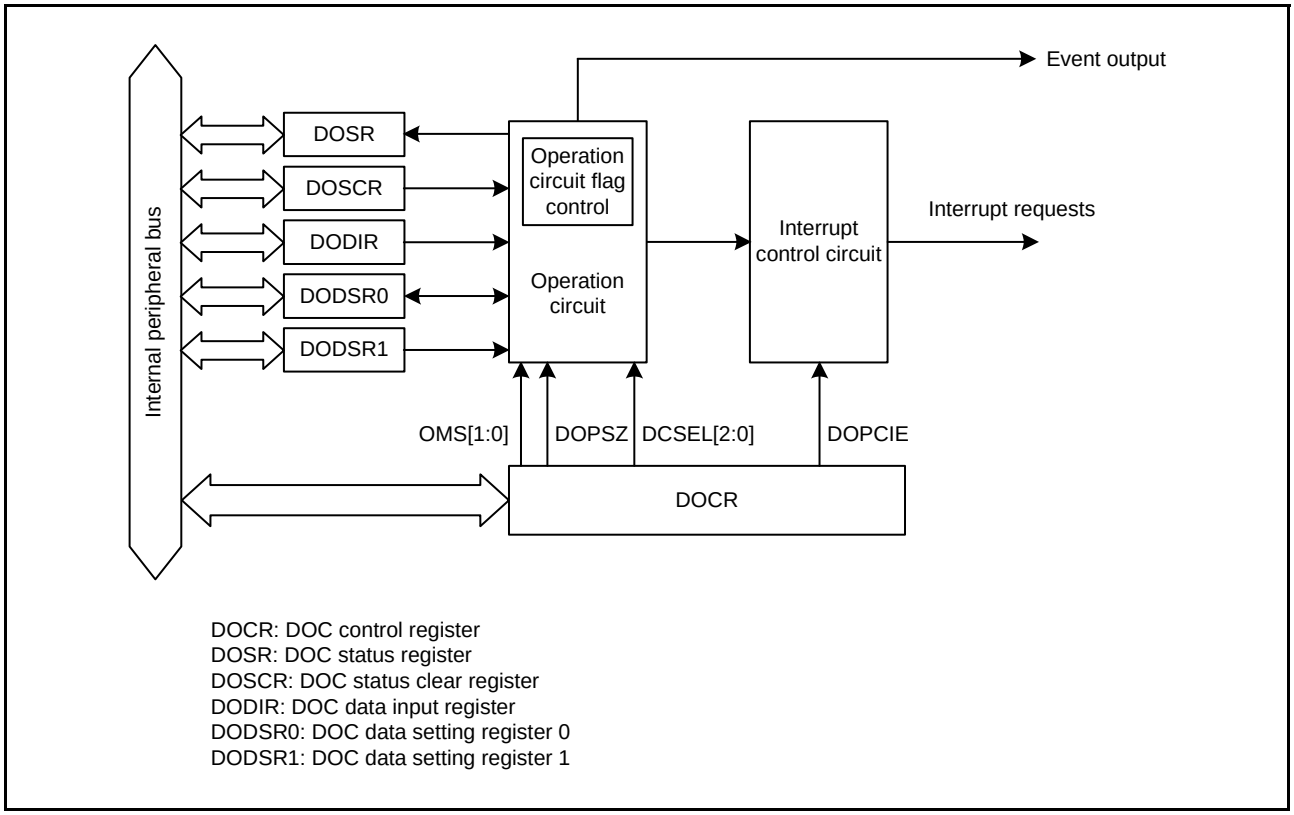

Figure 52.1 DOC Block Diagram

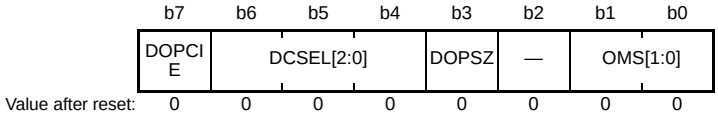
52.2 Register Descriptions

52.2.1 DOC Control Register (DOCR)

Address(es): DOC.DOCR 000A 0580h



Bit	Symbol	Bit Name	Description	R/W
b1, b0	OMS[1:0]	Operating Mode Select	b1 b0 0 0: Data comparison mode 0 1: Data addition mode 1 0: Data subtraction mode 1 1: Setting prohibited	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3	DOPSZ	Data Operation Size Select	0: 16-bit width 1: 32-bit width	R/W
b6-b4	DCSEL[2:0]	Detection Condition Select*1	b6 b4 0 0 0: Not equal to (DODIR ≠ DODSR0) 0 0 1: Equal to (DODIR = DODSR0) 0 1 0: Less than (DODIR < DODSR0) 0 1 1: Greater than (DODIR > DODSR0) 1 0 0: Within the range (DODSR0 < DODIR < DODSR1) 1 0 1: Beyond the range (DODIR < DODSR0, DODSR1 < DODIR) Settings other than above are prohibited.	R/W
b7	DOPCIE	Data Operation Circuit Interrupt Enable	0: Interrupt disabled 1: Interrupt enabled	R/W

Note 1. Valid only when data comparison mode is selected.

The DOCR register specifies the operation of DOC, or enabling or disabling of the interrupt.

OMS[1:0] Bits (Operating Mode Select)

These bits select the operating mode of the DOC.

DOPSZ Bit (Data Operation Size Select)

This bit selects the size of the data operation.

DCSEL[2:0] Bits (Detection Condition Select)

This bit is valid only when data comparison mode is selected.
This bit selects the condition for detection in data comparison mode.

DOPCIE Bit (Data Operation Circuit Interrupt Enable)

Setting this bit to 1 enables interrupts from the DOC.

52.2.2 DOC Status Register (DOSR)

Address(es): DOC.DOSR 000A 0584h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	DOPCF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DOPCF	Data Operation Result Flag	Indicates the result of an operation.	R
b7-b1	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

The DOSR register indicates the results of data operation.

DOPCF Flag (Data Operation Result Flag)

[Setting conditions]

- The setting of the DOCR.OMS[1:0] bits is 00b (data comparison mode) and the result of data comparison meets the condition selected by the DOCR.DCSEL[2:0] bits.
- The setting of the DOCR.OMS[1:0] bits is 01b (data addition mode) and the result of addition was greater than FFFFh (DOCR.DOPSZ = 0) or FFFF FFFFh (DOCR.DOPSZ = 1).
- The setting of the DOCR.OMS[1:0] bits is 10b (data subtraction mode) and the result of subtraction is below 0000h (DOCR.DOPSZ = 0) or 0000 0000h (DOCR.DOPSZ = 1).

[Clearing condition]

- Writing 1 to the DOSCR.DOPCFCL bit

52.2.3 DOC Status Clear Register (DOSCR)

Address(es): DOC.DOSCR 000A 0588h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	DOPCFCL
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DOPCFCL	Data Operation Result Clear	0: Retain the value of the DOPCF flag. 1: Clears the DOPCF flag.	W
b7-b1	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

The DOSCR register is for clearing the DOPCF flag. It is always read as 00h.

DOPCFCL Bit (Data Operation Result Clear)

Writing 1 to this bit clears the DOSR.DOPCF flag.

52.2.4 DOC Data Input Register (DODIR)

Address(es): DOC.DODIR 000A 058Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DODIR register is a readable and writable register that holds values for use in operations.
Access the DODIR register with the data operation size selected by the DOCR.DOPSZ bit.

52.2.5 DOC Data Setting Register 0 (DODSR0)

Address(es): DOC.DODSR0 000A 0590h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DODSR0 register is a readable and writable register that holds values for use in comparison or the results of other operations.
Access the DODSR0 register with the data operation size selected by the DOCR.DOPSZ bit.
In data comparison mode, store the standard value for use in comparison in this register. When either ‘within the range’ (DOCR.DCSEL[2:0] = 100b) or ‘beyond the range’ (DOCR.DCSEL[2:0] = 101b) is selected, specify the lower boundary of the range.
In data addition or data subtraction mode, this register holds the results of operations.

52.2.6 DOC Data Setting Register 1 (DODSR1)

Address(es): DOC.DODSR1 000A 0594h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DODSR1 register is a readable and writable register that holds a value for use in range comparison.
Access the DODSR1 register with the data operation size selected by the DOCR.DOPSZ bit.
When either ‘within the range’ (DOCR.DCSEL[2:0] = 100b) or ‘beyond the range’ (DOCR.DCSEL[2:0] = 101b) is selected in data comparison mode, specify the upper boundary of the range.
This register is only used when either ‘within the range’ or ‘beyond the range’ is selected.

52.3 Operation

52.3.1 Data Comparison Mode

Figure 52.2 to Figure 52.7 show an example of the steps involved in data comparison mode operation by the DOC*1. An example of operation with the operation size of 32 bits is shown below.

(1) Writing 00b to the DOCR.OMS[1:0] bits places the DOC in the data comparison mode. At the same time, write to the DOCR.DCSEL[2:0] bits to select the condition to be detected.
(2) Specify the standard values for comparison in the DODSR0 and DODSR1 registers.*2
(3) Write the value for comparison in the DODIR register.
(4) If the value written to the DODIR register satisfies the condition set in the DOCR.DCSEL[2:0] bits, the DOSR.DOPCF flag becomes 1, and an ELC event is generated. If the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also issued.

Note 1. Comparison is made to proceed at the same time a value is written to the DODIR register. Writing values to the DODSR0 and DODSR1 registers does not make comparison proceed.
Note 2. Setting of the DODSR1 register is only required when either ‘within the range’ or ‘beyond the range’ is selected. Set a greater value for the DODSR1 register than that of the DODSR0 register.

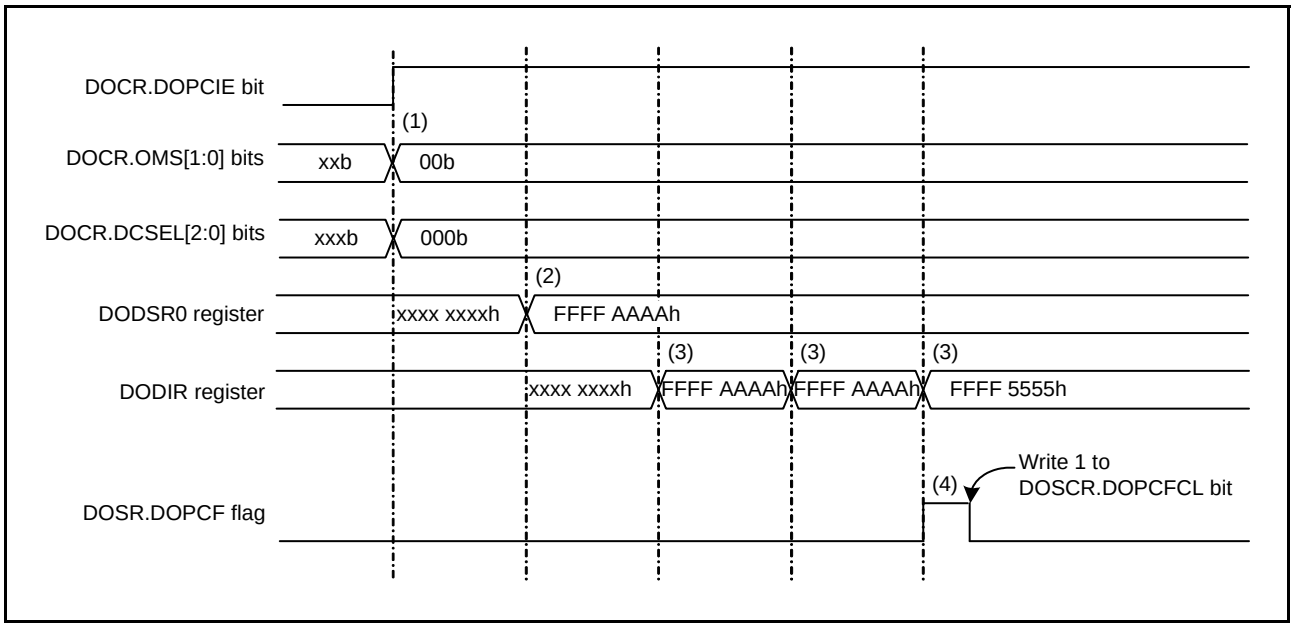


Figure 52.2 Example of the Operation of ‘Not Equal to’ as the Detection Condition in Data Comparison Mode

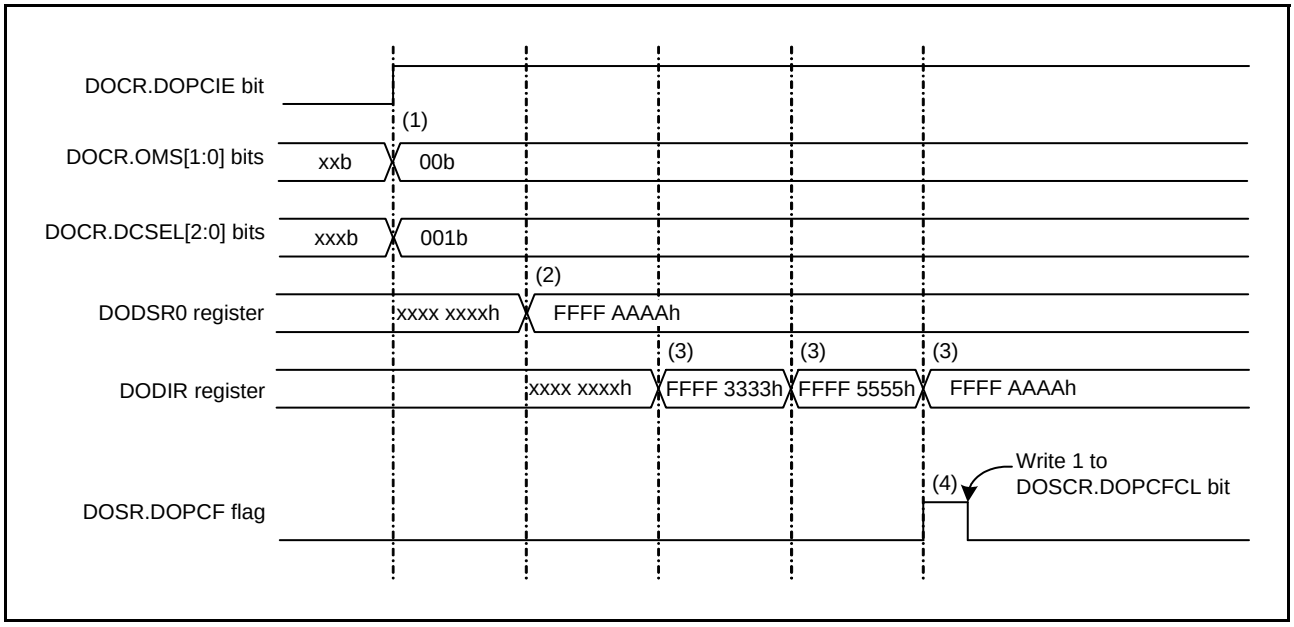

Figure 52.3 Example of the Operation of 'Equal to' as the Detection Condition in Data Comparison Mode

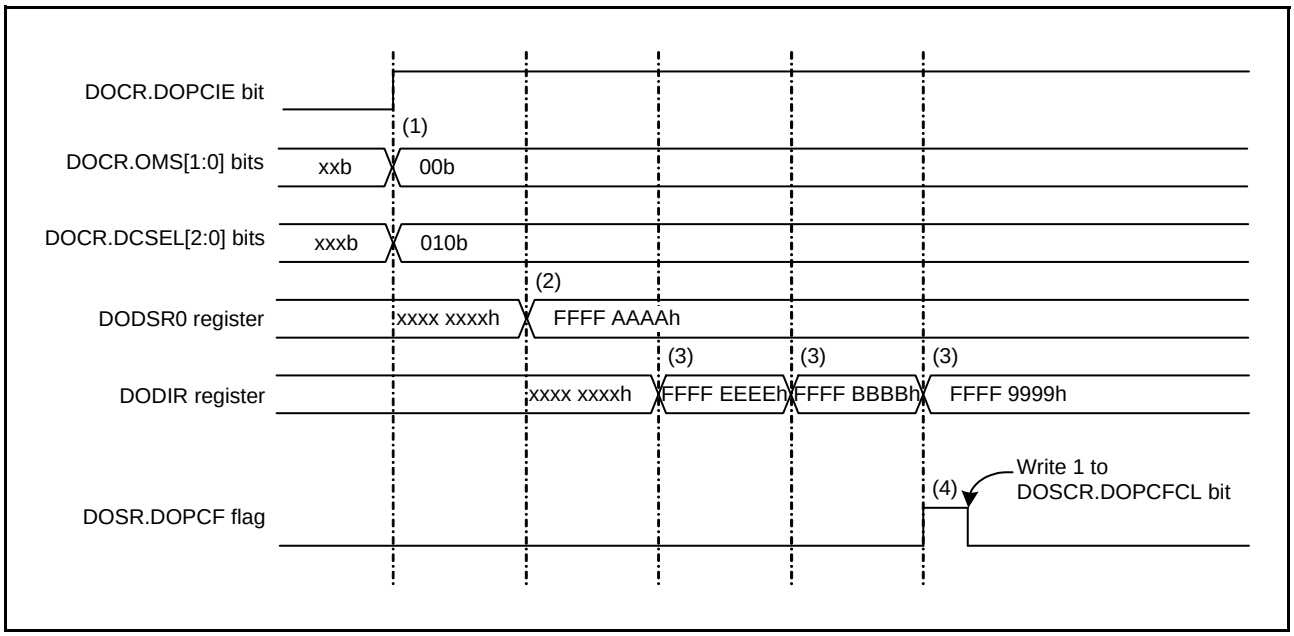

Figure 52.4 Example of the Operation of 'Less Than' as the Detection Condition in Data Comparison Mode

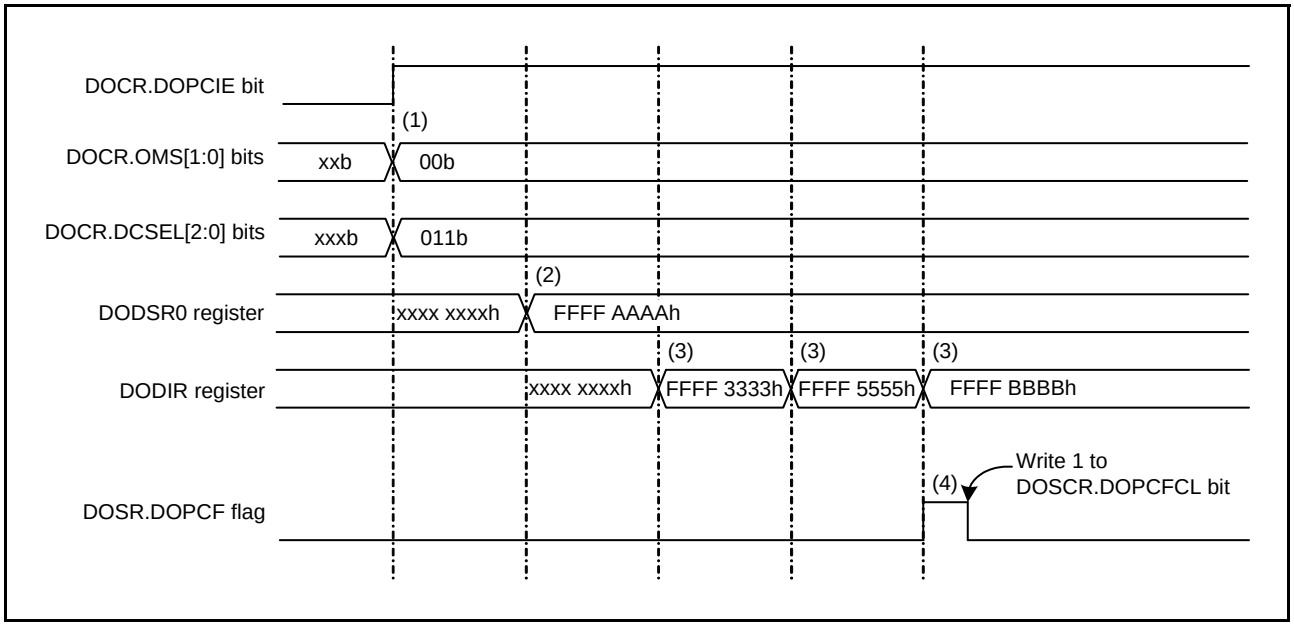

Figure 52.5 Example of the Operation of 'Greater Than' as the Detection Condition in Data Comparison Mode

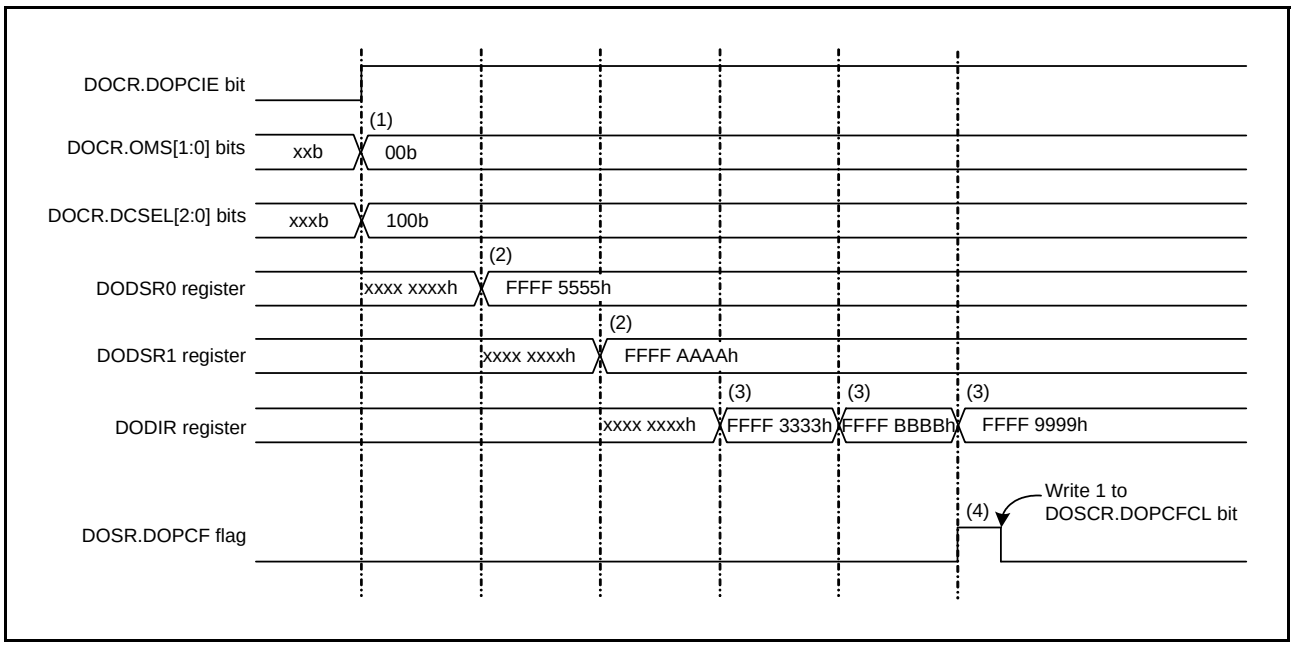

Figure 52.6 Example of the Operation of 'Within the Range' as the Detection Condition in Data Comparison Mode

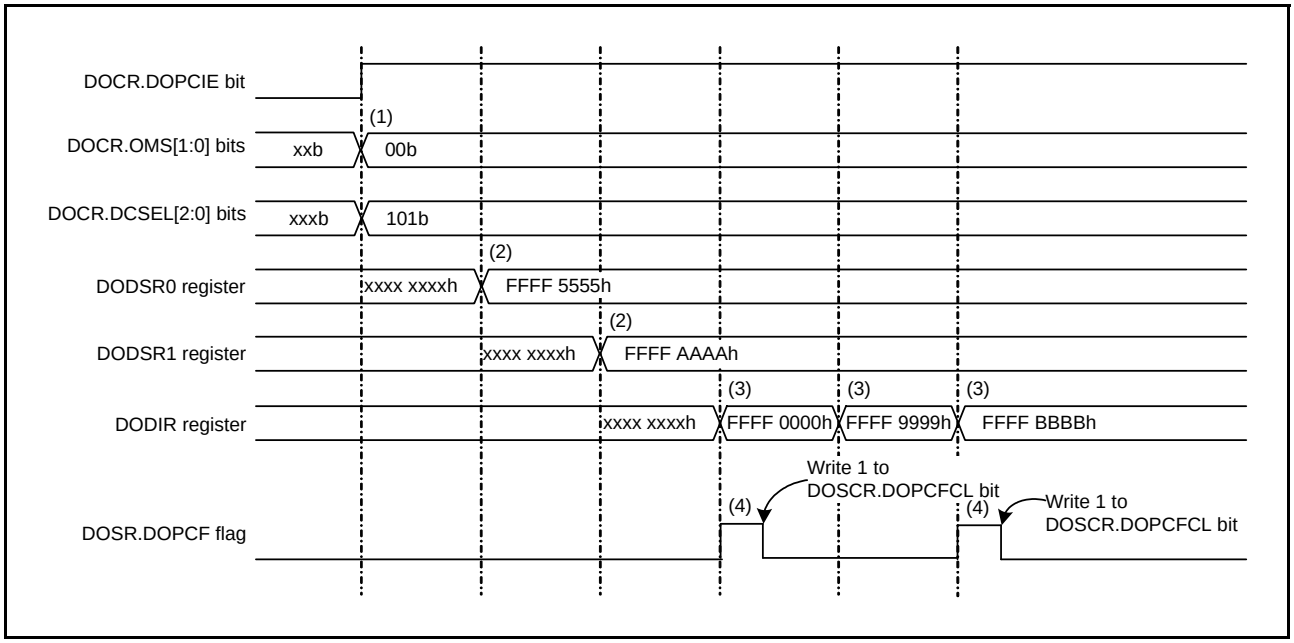

Figure 52.7 Example of the Operation of 'Beyond the Range' as the Detection Condition in Data Comparison Mode

52.3.2 Data Addition Mode

Figure 52.8 shows an example of the steps involved in data addition mode operation*1 by the DOC.
An example of operation when the data operation size is 32 bits is shown below.

(1) Writing 01b to the DOCR.OMS[1:0] bits selects data addition mode.
(2) Set the initial value in the DODSR0 register.
(3) Write the value for addition in the DODIR register. The result of the operation is stored in DODSR0.
(4) Write all values for use in addition to the DODIR register.
(5) If the result of the operation is greater than FFFF FFFFh, the DOSR.DOPCF flag becomes 1, and an ELC event is generated. If the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also issued.

Note 1. Addition is made to proceed at the same time as a value is written to the DODIR register. Writing a value to the DODSR0 register does not make addition proceed.

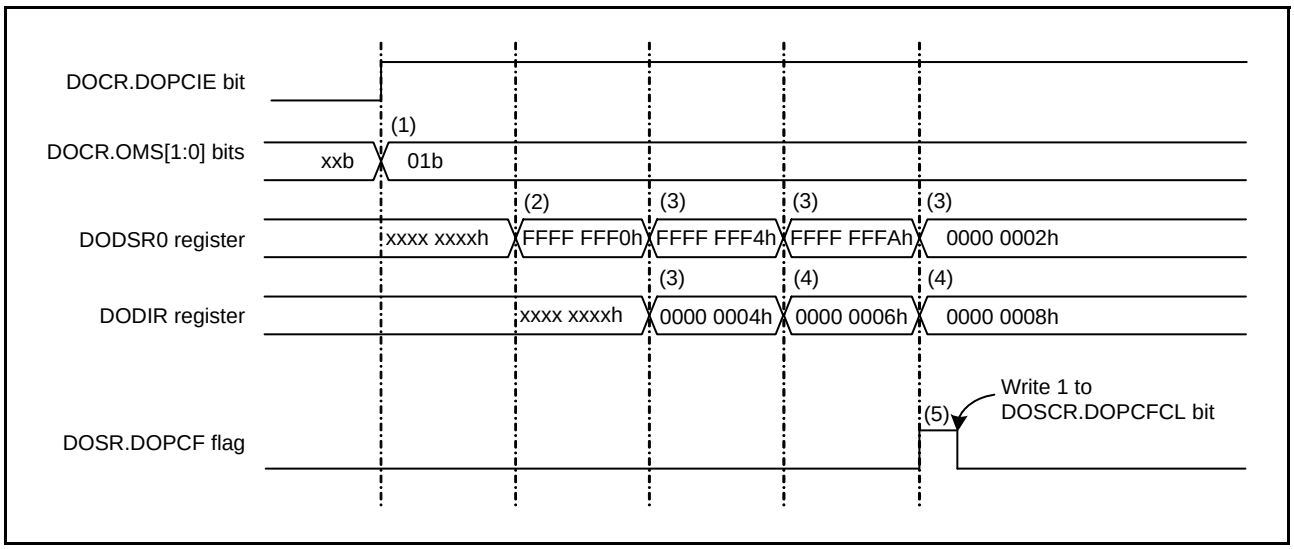

Figure 52.8 Example of Operation in Data Addition Mode

52.3.3 Data Subtraction Mode

Figure 52.9 shows an example of the steps involved in data subtraction mode operation*1 by the DOC.
An example of operation when the data operation size is 32 bits is shown below.

(1) Writing 10b to the DOCR.OMS[1:0] bits selects data subtraction mode.
(2) Set the initial value in the DODSR0 register.
(3) Write the value for subtraction in the DODIR register. The result of the operation is stored in DODSR0.
(4) Write all values for use in subtraction to the DODIR register.
(5) If the result of the operation is less than 0000 0000h, the DOSR.DOPCF flag becomes 1, and an ELC event is generated. If the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also issued.

Note 1. Subtraction is made to proceed at the same time a value is written to the DODIR register. Writing a value to the DODSR0 register does not make subtraction proceed.

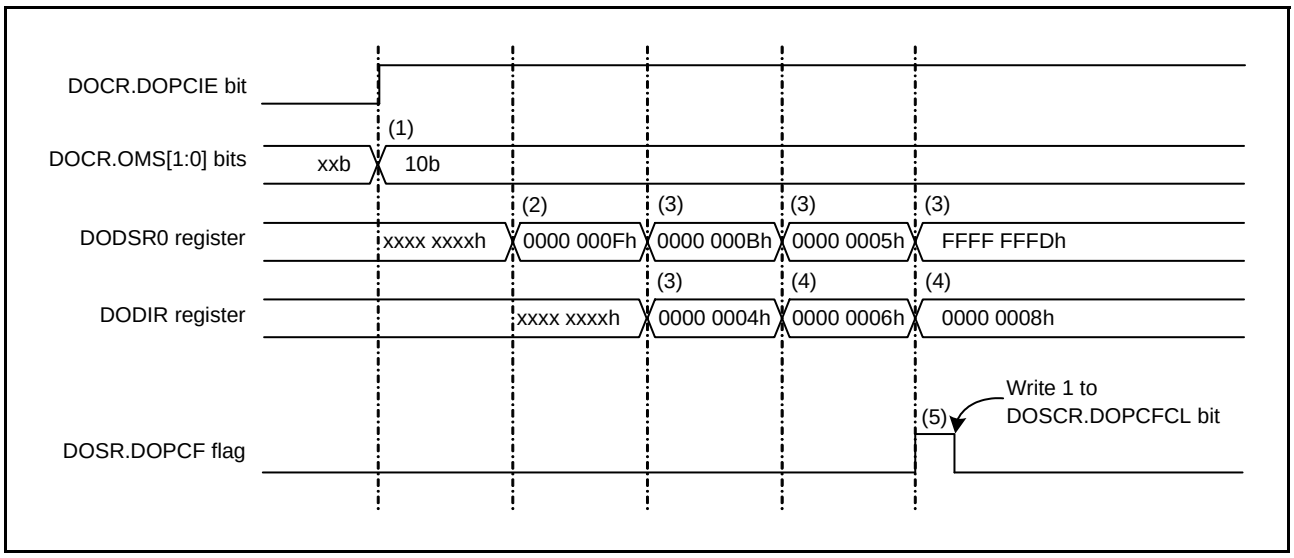

Figure 52.9 Example of Operation in Data Subtraction Mode

52.4 Interrupt Requests

The data operation circuit interrupt (DOPCI) is the interrupt request generated by the DOC. The DOSR.DOPCF flag becomes 1 when the interrupt source condition is satisfied, and an interrupt request is also issued if the DOCR.DOPCIE bit is 1.
Table 52.2 lists the details of the interrupt request.

Table 52.2 Interrupt Request from DOC

Interrupt Request	Data Operation Result Flag	Interrupt Generation Timing
Data operation circuit interrupt (DOPCI)	DOPCF	• The result of data comparison meets the detection condition. • The result of data addition is greater than FFFFh (DOCR.DOPSZ = 0) or FFFF FFFFh (DOCR.DOPSZ = 1). • The result of data subtraction is less than 0000h (DOCR.DOPSZ = 0) or 0000 0000h (DOCR.DOPSZ = 1).

52.5 Event Link Output

The DOC outputs event signals for the event link controller (ELC) under the following conditions, and these can be used to initiate operations by other modules selected in advance.

- The result of data comparison meets the detection condition.
- The result of data addition is greater than FFFFh (DOCR.DOPSZ = 0) or FFFF FFFFh (DOCR.DOPSZ = 1).
- The result of data subtraction is less than 0000h (DOCR.DOPSZ = 0) or 0000 0000h (DOCR.DOPSZ = 1).

52.5.1 Interrupt Handling and Event Linking

The DOC has a bit to enable or disable interrupts. When an interrupt source condition is satisfied while the interrupt is enabled, the interrupt request signal is issued to the CPU.
In contrast, an event link output signal is sent to other modules as an event signal via the ELC when an interrupt source is generated, regardless of the setting of the corresponding interrupt enable bit.

52.6 Usage Note

52.6.1 Module Stop Function Setting

Operation of the DOC can be enabled or disabled by setting the MSTPB6 bit in module stop control register B (MSTPCRB). The DOC is initially disabled after a reset. Register access is enabled by releasing the module stop state. For details, refer to section 11, Low Power Consumption.

53. RAM

This MCU has a 384-Kbyte high-speed static RAM (RAM), which runs at the frequency of 120 MHz in the no-wait state.

53.1 Overview

Table 53.1 lists the specifications of the RAM.

Table 53.1 Specifications of RAM

Item	RAM
Capacity	384 Kbytes
Address	0000 0000h to 0005 FFFFh
Memory bus	Memory bus 1
Access	• Single-cycle access is possible for both reading and writing.*1 • Enabling or disabling of the RAM is selectable.*2
Data retention function	Not available in deep software standby mode
Low power consumption function	Transitions to the module stop state are possible.
Error checking	• Parity check: Detection of 1-bit errors • A non-maskable interrupt or interrupt is generated in response to an error.

Note 1. When accessing across the 8-byte boundary, the number of cycles is doubled.
Note 2. Selectable by the RAME bit in SYSCR1. For details on SYSCR1, refer to section 3.2.3, System Control Register 1 (SYSCR1).

53.2 Register Descriptions

53.2.1 RAM Operating Mode Control Register (RAMMODE)

Address(es): 0008 1200h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	RAMMODE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	RAMMODE[1:0]	RAM Operating Mode Select	b1 b0 0 0: Parity checking is disabled. 0 1: Parity checking is enabled. Settings other than above are prohibited.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R

The RAMMODE register is write-protected by the RAM protection register (RAMPRCR). Before writing to the RAMMODE register, set the RAMPRCR.RAMPRCR bit to 1 to enable writing to it. Set the RAMMODE register before starting access to the RAM. If this register is modified after accessing to the RAM, RAM operation is not guaranteed.

53.2.2 RAM Error Status Register (RAMSTS)

Address(es): 0008 1201h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	RAMERR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RAMERR	RAM Error Status Flag	0: A parity check error has not occurred. 1: A parity check error has occurred.	R/(W)*1
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R

Note 1. Only 0 can be written to clear the flag.

When parity checking is enabled, the RAMERR flag is set to 1 if a parity check error is detected. The RAM error interrupt request is also generated at this time.
When parity checking is disabled, the RAMERR flag is not set to 1 because no parity check error is detected.
Writing 0 to the RAMERR flag clears the RAM error interrupt request corresponding to the parity check error.

53.2.3 RAM Error Address Capture Register (RAMECAD)

Address(es): 0008 1208h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	READ		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	READ													—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b18 to b3	READ	Error Address	The address where an error is found is read.	R
b31 to b19	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

When parity checking is enabled, this register will hold the address where a parity check error was found.
The address of the 8-byte boundary below the location where the error was found is stored in this register at the same time the RAMSTS.RAMERR flag is set to 1.
The error address is not updated when the RAMERR flag is 1 (error has occurred). Its value does not change when parity checking is disabled because no parity check error is detected.
The RAMECAD register is initialized only by a reset.

53.2.4 RAM Protection Register (RAMPRCR)

Address(es): 0008 1204h

	b7	b6	b5	b4	b3	b2	b1	b0
	KW[6:0]							RAMP RCR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RAMPRCR	RAMMODE Register Write Control	0: Disables writing to the RAMMODE register. 1: Enables writing to the RAMMODE register.	R/W
b7 to b1	KW[6:0]	Write Key Word	Enables or disables the rewriting of the RAMPRCR register. When rewriting the RAMPRCR register, write 1111000b to the KW[6:0] bits.	R/W

Writing 1 to the RAMPRCR bit is possible when KW[6:0] = 1111000b. Otherwise writing to RAMPRCR clears the bit to 0. The value of KW[6:0] is read as 0000000b.
The targets for write protection by the RAMPRCR register is the RAM operating mode control register (RAMMODE). Once the RAMPRCR bit is set to 1, writing to RAMMODE register is enabled until the RAMPRCR bit is cleared to 0. Clear the RAMPRCR bit to 0 after writing to RAMMODE register.

53.3 Operation

53.3.1 Parity Checking

Enabling and disabling of parity checking for the RAM can be selected through the RAMMODE register setting. In the initial state, parity checking is disabled. Even parity checking is used in this device.
1-bit parity check code is added to each 1-byte data for writing, and the parity is checked for reading.
If a 1-bit error is detected in the 1 byte when the parity is checked for reading, a RAM error interrupt can be generated. If a 2-bit error or more is detected in the 1 byte, errors cannot be correctly detected.
After power-on, parity check code is undefined until data is written. To use parity checking, write the initial value to all areas while parity checking is enabled before accessing to the RAM immediately after a reset.
Operation cannot be guaranteed if access is made to an area where the initial value is not written.

53.3.2 RAM Error Interrupt Function

A RAM error interrupt is generated when the RAMSTS.RAMERR bit that indicates a parity check error has been changed to 1 while parity checking is enabled.
Writing 0 to the bit clears the RAM interrupt.

53.3.3 Interrupt Source

Of the RAM interrupt sources, that due to the detection of an error through parity checking can be used as either a non-maskable interrupt or a maskable interrupt. For details, refer to section 15, Interrupt Controller (ICUE).

Table 53.2 RAM Interrupt Source

Name	Interrupt Source	DTC Activation	DMAC Activation
RAMERR	RAM error	Not possible	Not possible

53.4 Usage Notes

53.4.1 Low Power Consumption Function

Power consumption can be reduced by setting module stop control register C (MSTPCRC) to stop supply of the clock signal to the RAM.
Setting the MSTPCRC.MSTPC0 bit to 1 stops supply of the clock signal to the RAM.
Stopping supply of the clock signal places the RAM in the module stop state.
The RAM operates after a reset.
The RAM is not accessible in the module stop state.
Do not allow transitions to the module stop state while accessing to the RAM.
Access to the RAM in the module stop state is prohibited. If access is attempted, correct operation is not guaranteed.
For details on the MSTPCRC register, refer to section 11, Low Power Consumption.

53.4.2 Notes on Using Error Checking of RAM

Data in RAM are undefined when the power is turned on. Therefore, parity check errors occur if the data are read before initialization. The RAM is read in 8-byte (64-bit) units. Initialize it on 8-byte boundaries.
When a program is executed in the RAM with the parity check enabled, initialize the RAM in consideration of possible instruction prefetching by the CPU. Instruction prefetching can be performed up to 32 bytes. The initialization must thus cover extra 24 to 31 bytes from the last address of the program.

53.4.3 Notes on Self-Diagnosis of the RAM

A write buffer is mounted for the RAM. When the same address is read after a write operation, data in the write buffer, rather than in the memory cell of the RAM may be read. When the RAM is self-diagnosed, confirm that the data have been written by following the procedure below so that data will not be read from the write buffer.

(1) Write data to the address targeted for diagnosis.
(2) Write data to an address which is at least 4 addresses away from the that in (1).
(3) Read the data from the address in (1).

54. Standby RAM

This MCU provides an on-chip static RAM that can retain data in deep software standby (standby RAM).

54.1 Overview

Table 54.1 lists the specifications of the standby RAM.

Table 54.1 Specifications of Standby RAM

Item	Description
RAM capacity	4 Kbytes
RAM address	000A 4000h to 000A 4FFFh
Access	• Both read and write operations take 2 or 3 cycles of PCLKB when ICLK ≥ PCLKB; two cycles of ICLK are needed when ICLK < PCLKB. • Enabling or disabling of RAM access is selectable.*1 • Endian conforms to the endian setting of the chip. • Non-aligned access is prohibited. If non-aligned access is attempted, correct operation is not guaranteed.
Data retention function	Data can be retained in deep software standby mode
Low-power consumption function	The module-stop state is selectable.

Note 1. Selectable by the SBYRAME bit in SYSCR1. For details on SYSCR1, refer to section 3.2.3, System Control Register 1 (SYSCR1).

54.2 Operation

54.2.1 Data Retention

Whether or not the supply of internal power to the standby RAM continues in deep software standby mode is selectable by the DPSBYCR.DEEPCUT[1:0] bits.

If continuation of the supply of internal power is selected, data in the standby RAM are retained in deep software standby mode.

Refer to section 11, Low Power Consumption, for details on the DPSBYCR.DEEPCUT[1:0] bits.

54.2.2 Low Power Consumption Function

Power consumption can be reduced by setting module stop control register C (MSTPCRC) to stop supply of the clock signal to the standby RAM.

If the MSTPC7 bit in MSTPCRC is set to 1, supply of the clock signal to the standby RAM is stopped.

The standby RAM is thus placed in the module-stop state by stopping supply of the clock signals. The standby RAM operates after a reset.

The standby RAM is not accessible if it is in the module-stop state. A transition to the module-stop state should not be made while access to the standby RAM is in progress.

For details on the MSTPCRC register, refer to section 11, Low Power Consumption.

55. Flash Memory (FLASH)

This MCU incorporates code flash memory, data flash memory, and option-setting memory. The code flash memory stores instructions and operands, and the data flash memory stores only data. For option-setting memory, refer to section 7, Option-Setting Memory (OFSM).

55.1 Overview

Table 55.1 lists the specifications of the flash memory, and Figure 55.1 is a block diagram of the flash memory related modules.
The I/O pins used in boot mode, see Table 55.17.
The FCU (flash control unit) controls programming and erasure of the flash memory. The FACI (flash application command interface) controls the FCU according to the specified FACI commands.
Regarding the configuration of the code flash memory, see Figure 55.2 to Figure 55.5, and for the configuration of the data flash memory, see Figure 55.6.

Table 55.1 Specifications of Flash Memory (1/2)

Item	Code Flash Memory	Data Flash Memory
Memory capacity	• User area: 2 Mbytes max.	Data area: 8 Kbytes
ROM cache	• Capacity: 8 Kbytes • Mapping method: direct mapping • Line size: 16 bytes	Not available
Read cycle	• While ROM cache operation is enabled: When the cache is hit, one cycle; When the cache is missed, one to two cycles if ICLK ≤ 60 MHz, two to three cycles if ICLK > 60 MHz.*1 • When ROM cache operation is disabled: One cycle if ICLK ≤ 60 MHz Two cycles if ICLK > 60 MHz*1	Reading proceeds in every cycle of FCLK*2
Value after erasure	FFh	Undefined
Programming/erasing method	• Programming and erasing the code flash memory and data flash memory, and programming the option-setting memory are handled by the FACI commands specified in the FACI command issuing area (007E 0000h) (self-programming). • Programming/erasure through transfer by a serial-programmer via a serial interface (serial programming)	
Security function	Protects against illicit tampering with or reading out of data in flash memory	
Protection	Protects against erroneous rewriting of the flash memory	
Dual bank function	The dual-bank structure makes a safe update possible in cases where programming is suspended. • Linear mode: the code flash memory is used as one area • Dual mode: the code flash memory is divided into two areas	Not available
Trusted memory (TM) function	Protects against illicit reading of the code flash memory • Linear mode: blocks 8 and 9 • Dual mode: blocks 8, 9, 46, and 47	Not available
Background operations (BGOs)	• The code flash memory can be read while the code flash memory is being programmed or erased.*3 • The data flash memory can be read while the code flash memory is being programmed or erased. • The code flash memory can be read while the data flash memory is being programmed or erased.	

Table 55.1 Specifications of Flash Memory (2/2)

Item	Code Flash Memory	Data Flash Memory
Units of programming and erasure	• Units of programming for the user area: 128 bytes • Units of erasure for the user area: Block units	• Unit of programming for the data area: 4 bytes • Unit of erasure for the data area: 64/128/256 bytes
Other functions	Interrupts can be accepted during self-programming.	
	In the initial settings of this MCU, an expansion area of the option-setting memory can be set.	
On-board programming (Serial programming/Self-programming)	Programming/erasure in boot mode (SCI interface) • The asynchronous serial interface (SCI1) is used. • The transfer rate is adjusted automatically. Programming/erasure in boot mode (USB interface) • USB0 is used. • Dedicated hardware is not required, so direct connection to a PC is possible. Programming/erasure in boot mode (FINE interface) • FINE is used Programming/erasure in single-chip mode or on-chip ROM enabled extended mode • Programming or erasure by a routine for writing to code flash memory or data flash memory within the user program is possible.	
Off-board programming	Programming and erasure of the code flash memory and option-setting memory by using a parallel programmer is possible.	Programming or erasure of the data flash memory by a parallel programmer is not possible.
Unique ID	A 16-byte ID code provided for each MCU	

Note 1. If the frequency of ICLK is above 60 MHz, the setting of the ROMWT register must be changed. For details, see section 9.2.2, ROM Wait Cycle Setting Register (ROMWT).
Note 2. The required number of cycles for access must be set according to the FCLK frequency. For details, refer to section 55.4.22, Data Flash Memory Access Frequency Setting Register (EEPFCLK).
Note 3. Limitations apply to the combinations of the address ranges for programming/erasure process and reading process: see Table 55.25.

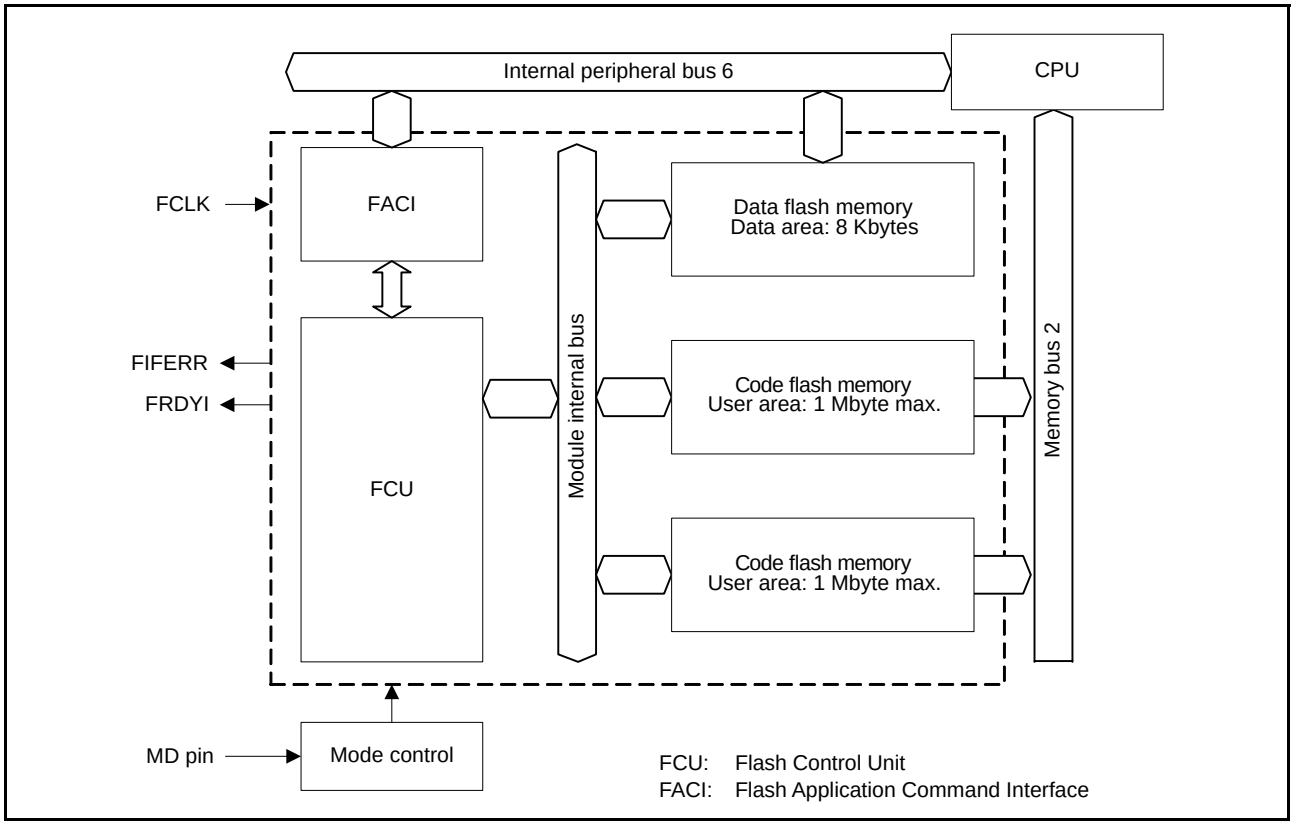

Figure 55.1 Block Diagram of Flash Memory Related Modules

55.2 Hardware Interface Area

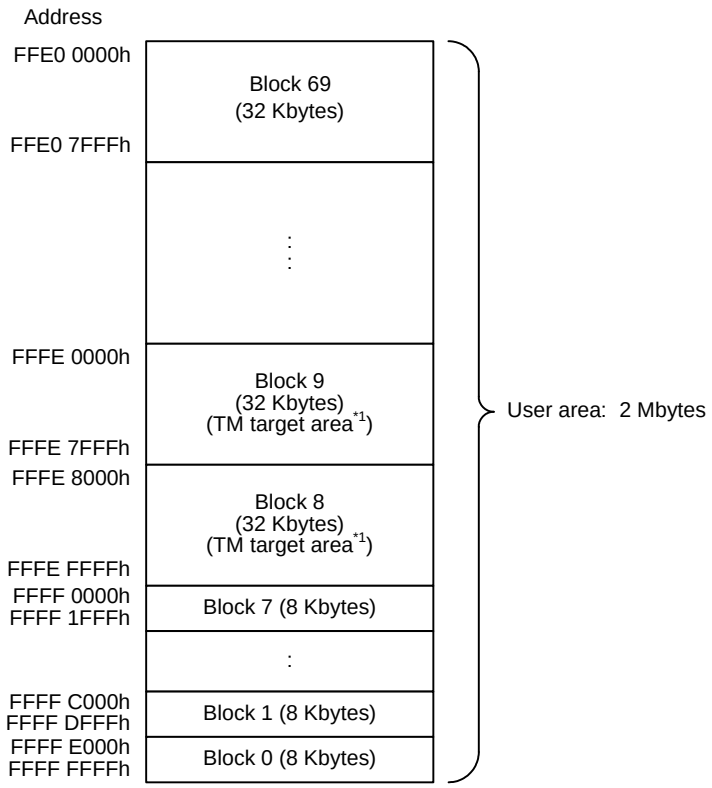
Using the hardware interface with the flash memory requires accessing to the area containing registers of the hardware, that for the issuing of FACI commands. Table 55.2 summarizes information on all of these areas.

Table 55.2 Information on the Hardware Interface Area

Area	Address	Capacity
Area containing the various registers of the hardware	See section 55.4, Register Descriptions.	See section 55.4, Register Descriptions.
FACI command-issuing area	007E 0000h	4 bytes
Option-setting memory (configuration setting area)	FE7F 5D00h to FE7F 5D7Fh	128 bytes

55.3 Structure of Memory

Figure 55.2 shows the memory map of code flash memory in linear mode. Figure 55.3 to Figure 55.5 show the memory map of code flash memory in dual mode. The code flash memory can be used as 2 bank areas by using the dual bank function. This dual-bank structure allows a safe update of a program while a user program is running.
The user area of the code flash memory in this MCU is divided into 8- and 32-Kbyte blocks, which serve as the units of erasure.
When the TM function is enabled in linear mode, blocks 8 and 9 are the TM target areas. The user area is available as areas for storing the user program.

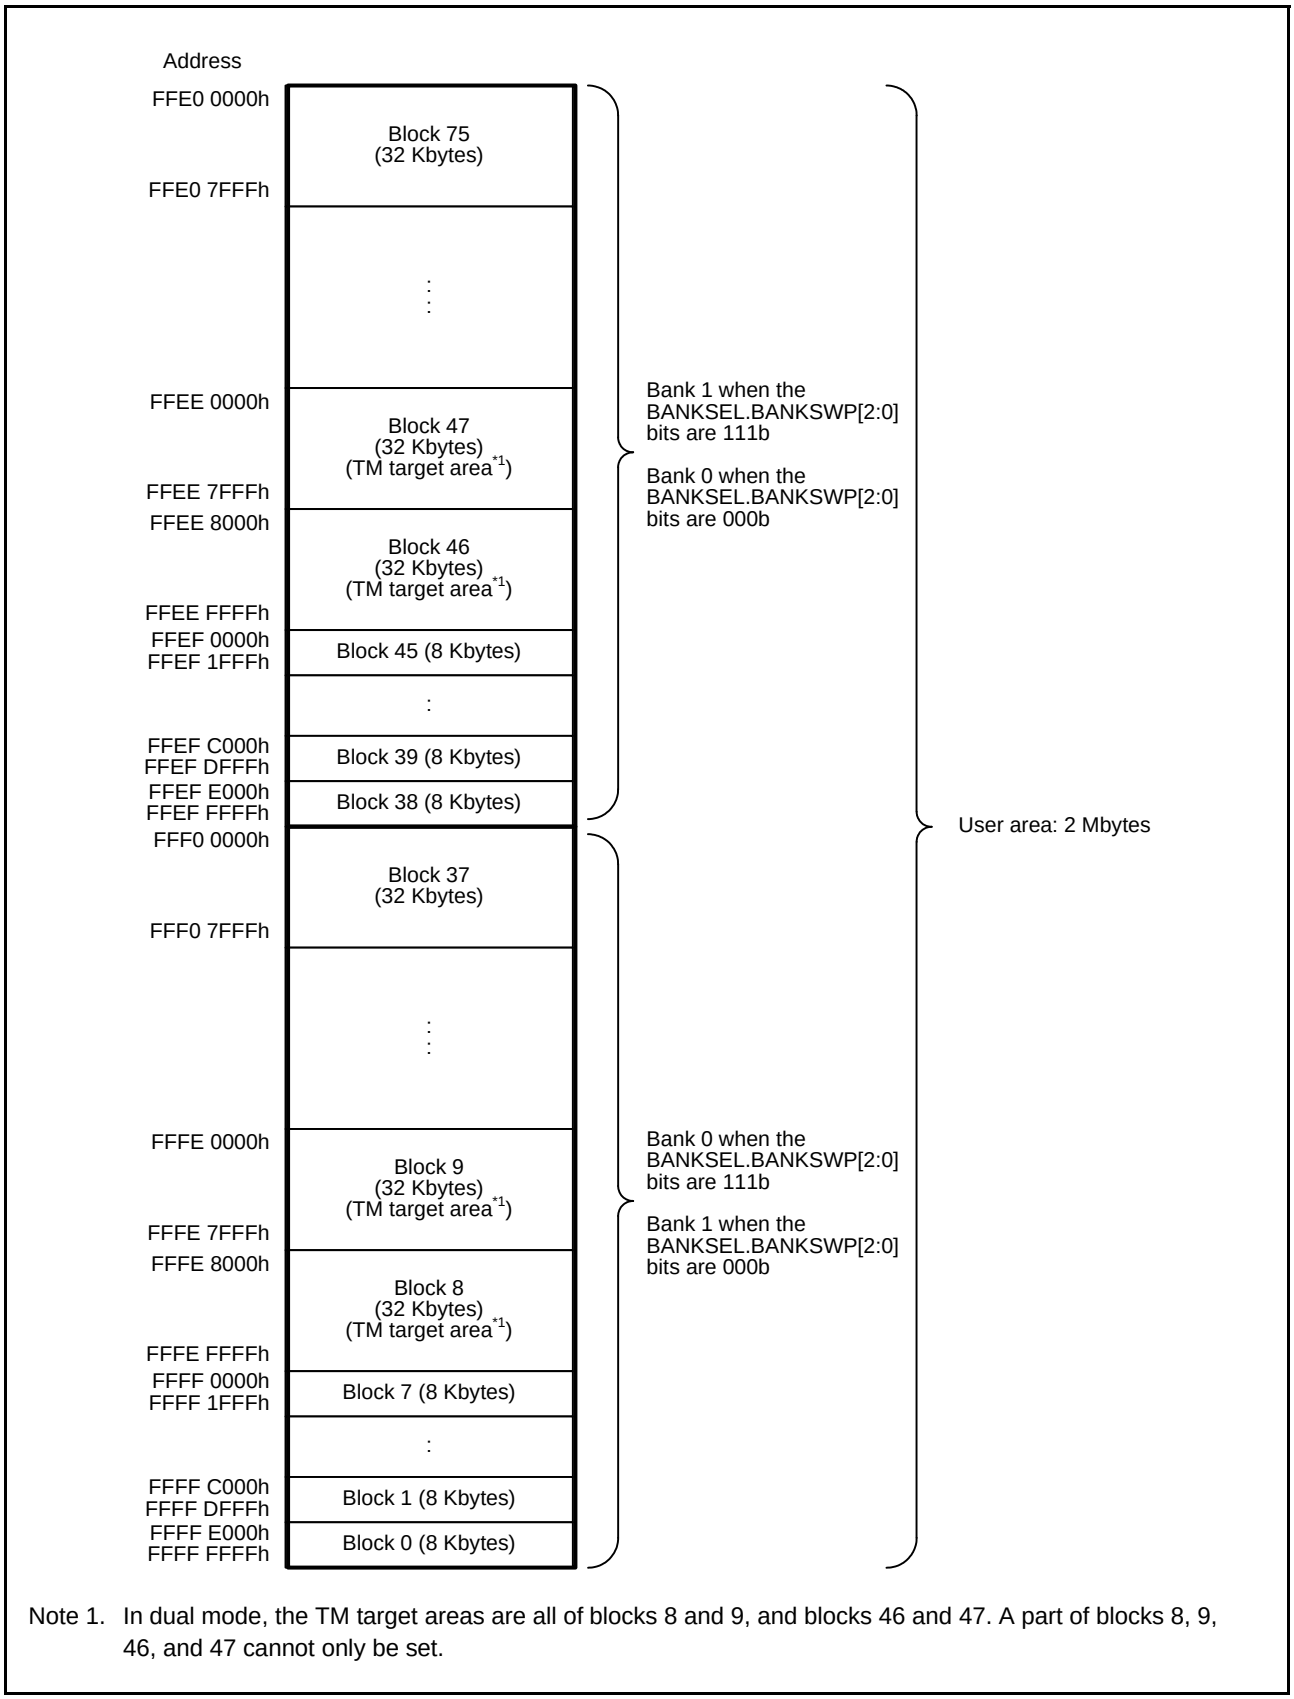


Code Flash Memory Capacity	Address	Number of Blocks
2 Mbytes	FFE0 0000h to FFFF FFFFh	0 to 69
1.5 Mbytes	FFE8 0000h to FFFF FFFFh	0 to 53
1 Mbyte	FFF0 0000h to FFFF FFFFh	0 to 37

Note 1. Both blocks 8 and 9 are the target areas for handling as TM. Setting only block 8 or only block 9 is not allowed.

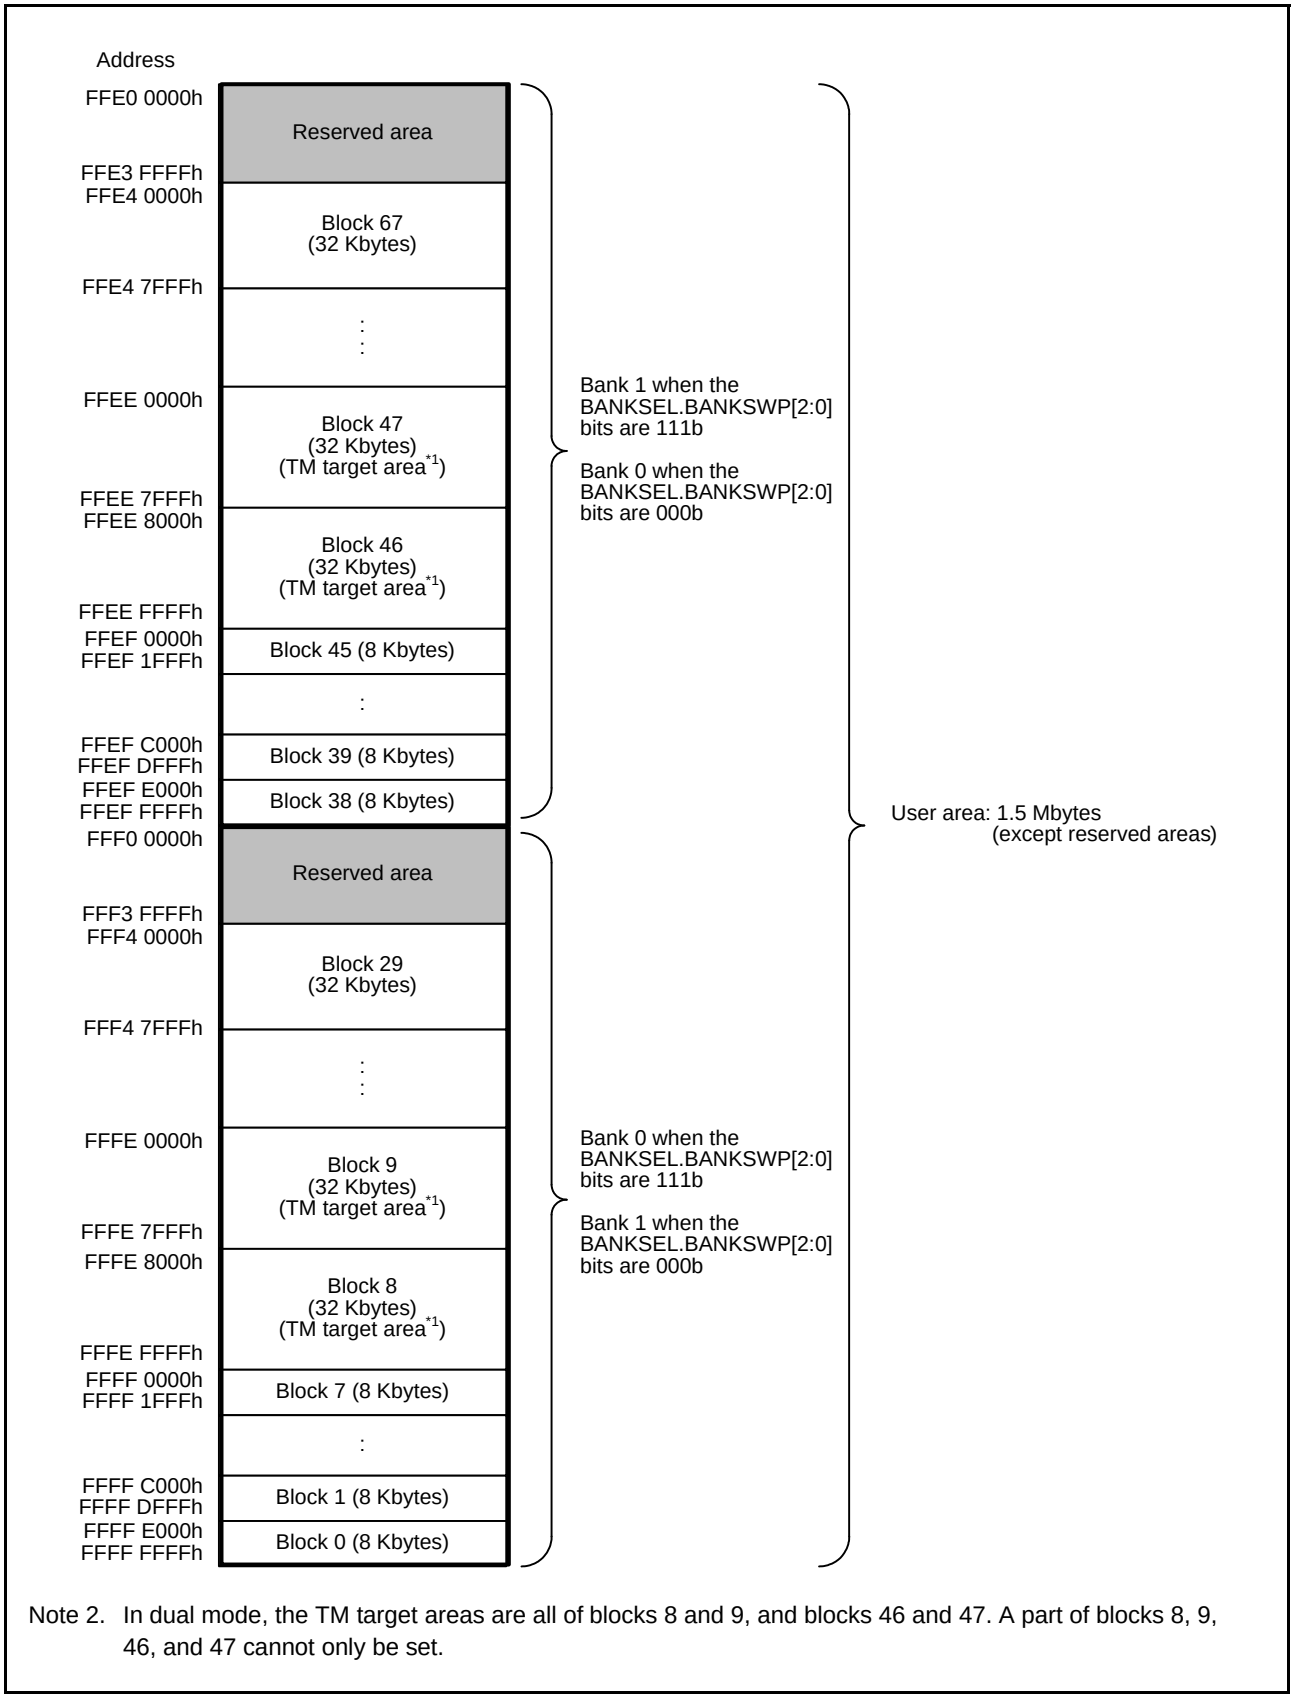
Figure 55.2 Map of the Code Flash Memory in Linear Mode

When the TM function is enabled in dual mode, blocks 8 and 9, and blocks 46 and 47 are the TM target areas. The user area can be used as storage area of the user program.



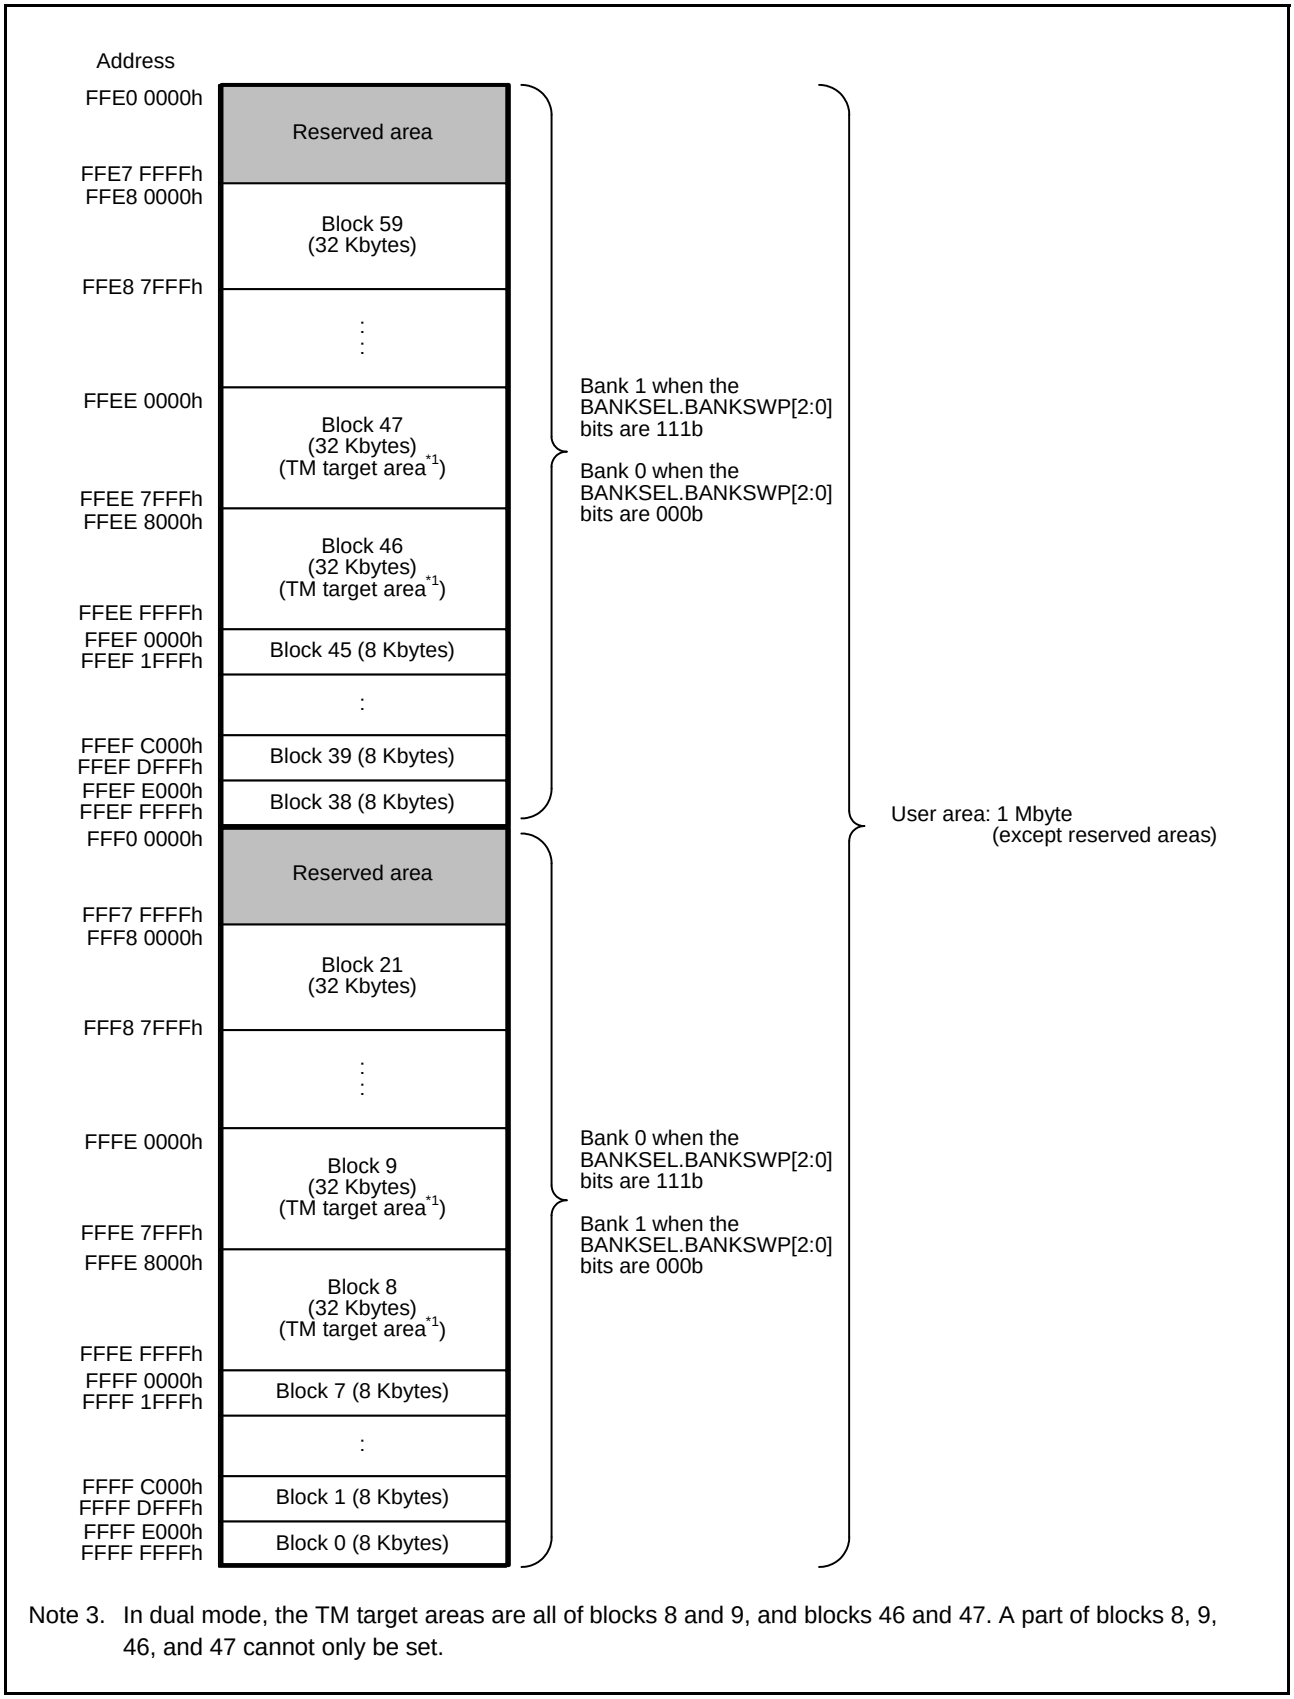
Note 1. In dual mode, the TM target areas are all of blocks 8 and 9, and blocks 46 and 47. A part of blocks 8, 9, 46, and 47 cannot only be set.

Figure 55.3 Map of the Code Flash Memory in Dual Mode (Products with 2 Mbytes of code flash memory)



Note 2. In dual mode, the TM target areas are all of blocks 8 and 9, and blocks 46 and 47. A part of blocks 8, 9, 46, and 47 cannot only be set.

Figure 55.4 Map of the Code Flash Memory in Dual Mode (Products with 1.5 Mbytes of code flash memory)



Note 3. In dual mode, the TM target areas are all of blocks 8 and 9, and blocks 46 and 47. A part of blocks 8, 9, 46, and 47 cannot only be set.

Figure 55.5 Map of the Code Flash Memory in Dual Mode (Products with 1 Mbyte of code flash memory)

The data area of the data flash memory in this MCU is divided into 64-byte blocks, with each being a unit for erasure. Figure 55.6 shows the mapping of the data flash memory.

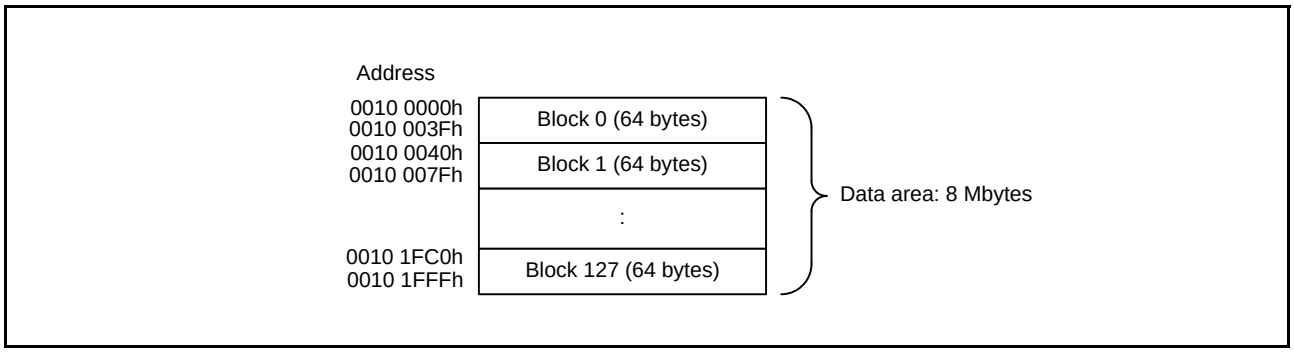


Figure 55.6 Map of the Data Flash Memory

55.4 Register Descriptions

55.4.1 ROM Cache Enable Register (ROMCE)

Address(es): FLASH.ROMCE 0008 1000h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ROMCEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ROMCEN	ROM Cache Enable	0: ROM cache is disabled. 1: ROM cache is enabled.	R/W
b15 to b1	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R

ROMCEN Bit (ROM Cache Enable)

When setting the ROMCEN bit to 1, the ROM cache starts operation. While ROM cache is enabled, the data is served from the cache when a cache hit occurs. Using ROM caching helps to reduce power consumption by the MCU.
Set a non-cacheable area while the ROMCEN bit is 0.

55.4.2 ROM Cache Invalidate Register (ROMCIV)

Address(es): FLASH.ROMCIV 0008 1004h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ROMCIV
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ROMCIV	ROM Cache Invalidate	When reading 0: Invalidation is not started/Invalidation is completed. 1: Invalidation is in progress. When writing Writing 1 invalidates the cache line. Writing 0 has no effect.	R/W
b15 to b1	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R

ROMCIV Bit (ROM Cache Invalidate)

When writing 1 to the ROMCIV bit, the ROM cache invalidation is performed.

55.4.3 Non-Cacheable Area n Address Register (NCRGn) (n = 0, 1)

Address(es): FLASH.NCRG0 0008 1040h, FLASH.NCRG1 0008 1048h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	1	1	1	1	1	1	1	1	1	1	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NCRGn register specifies the address where an area in which caching is disabled starts (non-cacheable area).
The higher-order 10 bits (b31 to b22), which are fixed to 1 and the lower-order 4 bits (b3 to b0), which are fixed to 0, are reserved. When writing, write 1 and 0 to the respective sets of bits.
Set the NCRGn register while the ROMCE.ROMCEN bit is 0.

55.4.4 Non-Cacheable Area n Setting Register (NCRCn) (n = 0, 1)

Address(es): FLASH.NCRC0 0008 1044h, FLASH.NCRC1 0008 104Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	NCSZ[16:12]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	NCSZ[11:0]												NC3E	NC2E	NC1E	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b1	NC1E	IF Non-Cacheable Area Specification Enable	This bit selects whether an area of memory is non-cacheable by the IF cache. 0: Disabled 1: Enabled	R/W
b2	NC2E	OA Non-Cacheable Area Specification Enable	This bit selects whether an area of memory is non-cacheable by the OA cache. 0: Disabled 1: Enabled	R/W
b3	NC3E	DM Non-Cacheable Area Specification Enable	This bit selects whether an area of memory is non-cacheable by the DM cache. 0: Disabled 1: Enabled	R/W
b20 to b4	NCSZ[16:0]	Non-Cacheable Area Size Specification	These bits specify the size of the given non-cacheable area. b20 b4 0 0000 0000 0000 0000: 16 bytes 0 0000 0000 0000 0001: 32 bytes 0 0000 0000 0000 0011: 64 bytes 0 0000 0000 0000 0111: 128 bytes 0 0000 0000 0000 1111: 256 bytes 0 0000 0000 0001 1111: 512 bytes 0 0000 0000 0011 1111: 1 Kbyte 0 0000 0000 0111 1111: 2 Kbytes 0 0000 0000 1111 1111: 4 Kbytes 0 0000 0001 1111 1111: 8 Kbytes 0 0000 0011 1111 1111: 16 Kbytes 0 0000 0111 1111 1111: 32 Kbytes 0 0000 1111 1111 1111: 64 Kbytes 0 0001 1111 1111 1111: 128 Kbytes 0 0011 1111 1111 1111: 256 Kbytes 0 0111 1111 1111 1111: 512 Kbytes 0 1111 1111 1111 1111: 1 Mbyte Settings other than above are prohibited.	R/W
b31 to b21	—	Reserved	These bits are read as 0. The write value should be 0.	R

The NCRCn register specifies enabling or disabling of non-cacheable areas n (n = 0, 1) and the size of the area. Write to the register while the ROMCE.ROMCEN bit is 0.

NC1E Bit (IF Non-Cacheable Area Specification Enable)

The NC1E bit enables or disables the settings of the non-cacheable area in the cache (IF cache) used for fast instruction fetching (IF) by the CPU.

NC2E Bit (OA Non-Cacheable Area Specification Enable)

The NC2E bit enables or disables the settings of the non-cacheable area in the cache (OA cache) used for fast operand access (OA) by the CPU.

NC3E Bit (DM Non-Cacheable Area Specification Enable)

The NC3E bit enables or disables the settings of the non-cacheable area in the cache (DM cache) used for fast access to data by bus masters other than the CPU.

NCSZ[16:0] Bit (Non-Cacheable Area Size Specification)

The NCSZ[16:0] bits specify the size of the non-cacheable area. They are used to mask address bits 4 to 20.
When an address generated by the bus master is compared to the value of the NCRGn register, bits corresponding to NCSZ[16:0] bits with the value 1 are ignored.

55.4.5 Flash P/E Protect Register (FWEPROR)

Address(es): FLASH.FWEPROR 0008 C296h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	FLWE[1:0]	
Value after reset:	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	FLWE[1:0]	Flash Programming and Erasure Enabling	b1 b0 0 0: Prohibits programming/erasure, and blank checking. 0 1: Permits programming/erasure, and blank checking. 1 0: Prohibits programming/erasure, and blank checking. 1 1: Prohibits programming/erasure, and blank checking.	R/W
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Programming/erasure of the flash memory, and blank checking are prohibited or permitted by hardware.
FWEPROR is initialized by a reset due to the signal on the RES# pin, a power-on reset, a voltage-monitoring 0 reset, an independent watchdog timer reset, a watchdog timer reset, a voltage-monitoring 1 reset, a voltage-monitoring 2 reset, and a software reset, and by transitions to software standby and deep software standby.

55.4.6 Flash Access Status Register (FASTAT)

Address(es): FLASH.FASTAT 007F E010h

	b7	b6	b5	b4	b3	b2	b1	b0
	CFAE	—	—	CMDLK	DFAE	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b3	DFAE	Data Flash Memory Access Violation Flag	0: No data flash memory access violation has occurred. 1: A data flash memory access violation has occurred.	R/W*1
b4	CMDLK	Command Lock Flag	0: The flash sequencer is not in the command-locked state. 1: The flash sequencer is in the command-locked state.	R
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	CFAE	Code Flash Memory Access Violation Flag	0: No code flash memory access violation has occurred. 1: A code flash memory access violation has occurred.	R/W*1

Note 1. Only 0 can be written to clear the flag after 1 is read.

This register indicates whether a code flash memory or data flash memory access violation has occurred. If either of the CFAE, and DFAE flags is 1, the CMDLK flag is set to 1 and the flash sequencer enters the command-locked state (see section 55.10.2, Error Protection). To release it from the command-locked state, a status clear command or forced stop command must be issued by the FACI.

DFAE Flag (Data Flash Memory Access Violation Flag)

This flag indicates whether a data flash memory access violation has occurred. If this flag is set to 1, the FSTATR.ILGLERR flag is set to 1, placing the flash sequencer in the command-locked state.

[Setting Condition]

- See Table 55.16, Error Protection Type

[Clearing Condition]

- When 0 is written after reading of 1
- When a status clear command or forced stop command is issued

CMDLK Flag (Command Lock Flag)

This flag indicates that the flash sequencer is in the command-locked state.

[Setting Condition]

- When the flash sequencer detects any of errors listed in Table 55.16, Error Protection Type and transitions to the command-locked state

[Clearing Condition]

- When the flash sequencer starting to process a status clear or forced stop command

CFAE Flag (Code Flash Memory Access Violation Flag)

This flag indicates whether a code flash memory access violation has occurred. If this flag is set to 1, the FSTATR.ILGLERR flag is set to 1, placing the flash sequencer in the command-locked state.

[Setting Conditions]

- See Table 55.16, Error Protection Type

[Clearing Condition]

- When 0 is written after reading of 1

- When a status clear command or forced stop command is issued

55.4.7 Flash Access Error Interrupt Enable Register (FAEINT)

Address(es): FLASH.FAEINT 007F E014h

	b7	b6	b5	b4	b3	b2	b1	b0
	CFAEIE	—	—	CMDLKIE	DFAEIE	—	—	—
Value after reset:	1	0	0	1	1	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b3	DFAEIE	Data Flash Memory Access Violation Interrupt Enable	0: Generation of an FIFERR interrupt request is disabled when FASTAT.DFAE is set to 1. 1: Generation of an FIFERR interrupt request is enabled when FASTAT.DFAE is set to 1.	R/W
b4	CMDLKIE	Command Lock Interrupt Enable	0: Generation of an FIFERR interrupt request is disabled when FASTAT.CMDLK is set to 1. 1: Generation of an FIFERR interrupt request is enabled when FASTAT.CMDLK is set to 1.	R/W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	CFAEIE	Code Flash Memory Access Violation Interrupt Enable	0: Generation of an FIFERR interrupt request is disabled when FASTAT.CFAE is set to 1. 1: Generation of an FIFERR interrupt request is enabled when FASTAT.CFAE is set to 1.	R/W

This register enables or disables generation of a flash access error (FIFERR) interrupt request.

DFAEIE Bit (Data Flash Memory Access Violation Interrupt Enable)

This bit enables or disables generation of an FIFERR interrupt request when a data flash memory access violation occurs and the FASTAT.DFAE flag is set to 1.

CMDLKIE Bit (Command Lock Interrupt Enable)

This bit enables or disables generation of an FIFERR interrupt request when the flash sequencer enters the command-locked state and the FASTAT.CMDLK flag is set to 1.

CFAEIE Bit (Code Flash Memory Access Violation Interrupt Enable)

This bit enables or disables generation of an FIFERR interrupt request when a code flash memory access violation occurs and the FASTAT.CFAE flag is set to 1.

55.4.8 Flash Ready Interrupt Enable Register (FRDYIE)

Address(es): FLASH.FRDYIE 007F E018h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	FRDYIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	FRDYIE	Flash Ready Interrupt Enable	0: Generation of an FRDY interrupt request is disabled. 1: Generation of an FRDY interrupt request is enabled.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register enables or disables generation of a flash ready (FRDY) interrupt request.

FRDYIE Bit (Flash Ready Interrupt Enable)

This bit is used to enable or disable generation of an FRDY interrupt request when the FASTAT.FRDY flag is changed from 0 to 1 upon completion of processing by the flash sequencer of programming, erasure, and blank checking command.

55.4.9 FACI Command Start Address Register (FSADDR)

Address(es): FLASH.FSADDR 007F E030h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	FSADDR[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	FSADDR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	FSADDR[31:0]	Start Address for FACI Command Processing	Start Address for FACI Command Processing	R/W*1

Note 1. Writing to these bits is possible only when the FSTATR.FRDY flag is 1. Writing to these bits while the FSTATR.FRDY flag = 0 is ignored. Note that b0 and b1 are read-only.

This register specifies the address where the target area for command processing starts when the FACI command for programming, block erasure, multi-block erasure, blank checking, or configuration setting is issued.
The FSADDR register is initialized when the FSUINITR.SUINIT bit is set to 1. It is also initialized by a reset.

FSADDR[31:0] Bits (Start Address for FACI Command Processing)

These bits specify the start address for FACI command processing. Bits 31 to 24 are ignored in FACI command processing for the code flash memory. Bits 31 to 17 are ignored in FACI command processing for the data flash memory. Bits 31 to 10 are ignored in processing of the FACI command for the option-setting memory. Bits that do not reach the address boundaries are also ignored. Table 55.3 shows the address boundary for each command.

Table 55.3 Address Boundary for Each of the Commands

Command	Address Boundary
Programming (code flash memory)	128-byte
Programming (data flash memory)	4-byte
Block erase (code flash memory)	8-Kbyte or 32-Kbyte
Block erase (data flash memory)	64-byte
Multi-block erase (data flash memory)	64-, 128-, or 256-byte
Blank check (data flash memory)	4-byte
Configuration setting	16-byte

See Table 55.15, Address Used by Configuration Set Command for the start address of the option-setting memory (configuration setting area).

55.4.10 FACI Command End Address Register (FEADDR)

Address(es): FLASH.FEADDR 007F E034h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	FEADDR[31:16]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	FEADDR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	FEADDR[31:0]	End Address for FACI Command Processing	The end address for FACI command processing	R/W*1

Note 1. Writing to these bits is possible only when the FSTATR.FRDY flag is 1. Writing to these bits while the FSTATR.FRDY flag = 0 is ignored. Note that b0 and b1 are read-only.

This register is used to specify the end address of the area targeted for the multi-block erase command and blank checking command handling. When executing the multi-block erase command, the setting value of the register must be the setting of the FEADDR register or lower. If the setting value of the FSADDR register is larger than the FEADDR register setting value, the flash sequencer enters the command locked state.
When the FBCCNT.BCDIR bit is 0, the value of the FSADDR register must be that of this register or less. When the FBCCNT.BCDIR bit is 1, the value of the FSADDR register must be at least that of this register. If the settings of the FBCCNT.BCDIR bit and the FSADDR and FEADDR registers are inconsistent with the above rules, the flash sequencer enters the command-locked state (see section 55.10.2, Error Protection).
The FEADDR register is initialized when the FSUINITR.SUINIT bit is set to 1. It is also initialized by a reset.

FEADDR[31:0] Bits (End Address for FACI Command Processing)

These bits are used to specify the end address for handling of the multi-block erase command and blank checking command. In command processing, bits 31 to 17 and any bits that do not reach the address boundaries listed in Table 55.3, Address Boundary for Each of the Commands are ignored.

55.4.11 Flash Status Register (FSTATR)

Address(es): FLASH.FSTATR 007F E080h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	ILGCOMERR	FESETERR	SECERR	OTERR	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	FRDY	ILGLERR	ERSERR	PRGERR	SUSRDY	DBFULL	ERSSPD	PRGSPD	—	FLWEERR	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	FLWEERR	Flash Write/Erase Protect Error Flag	0: An error has not occurred. 1: An error has occurred.	R
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b8	PRGSPD	Programming Suspend Status Flag	0: The flash sequencer is in a state other than those corresponding to the value 1. 1: The flash sequencer is in the programming suspension processing state or the programming suspended state.	R
b9	ERSSPD	Erasure Suspend Status Flag	0: The flash sequencer is in a state other than those corresponding to the value 1. 1: The flash sequencer is in the erasure suspension processing state or the erasure-suspended state.	R
b10	DBFULL	Data Buffer Full Flag	0: The data buffer is empty. 1: The data buffer is full.	R
b11	SUSRDY	Suspend Ready Flag	0: The flash sequencer cannot receive P/E suspend commands. 1: The flash sequencer can receive P/E suspend commands.	R
b12	PRGERR	Programming Error Flag	0: Programming has been completed successfully. 1: An error has occurred during programming.	R
b13	ERSERR	Erasure Error Flag	0: Erasure has been completed successfully. 1: An error has occurred during erasure.	R
b14	ILGLERR	Illegal Error Flag	0: The flash sequencer has not detected an illegal FACI command or illegal flash memory access. 1: The flash sequencer has detected an illegal FACI command or illegal flash memory access.	R
b15	FRDY	Flash Ready Flag	0: Programming, block erase, multi-block erase, P/E suspend, P/E resume, forced stop, blank check, or configuration setting command processing is in progress. 1: None of the above is in progress.	R
b19 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b20	OTERR	Other Error Flag	0: An error has not occurred. 1: An error has occurred.	R
b21	SECERR	Security Error Flag	0: Write protection by the FAW.FSPR bit is not violated 1: Write protection by the FAW.FSPR bit is violated	R
b22	FESETERR	FENTRY Setting Error Flag	0: A setting error in the FENTRYR register has not been detected. 1: A setting error in the FENTRYR register has been detected.	R
b23	ILGCOMERR	Illegal Command Error Flag	0: The flash sequencer has not detected an illegal FACI command error. 1: The flash sequencer has detected an illegal FACI command error.	R
b31 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register indicates the state of the flash sequencer.

FLWEERR Flag (Flash Write/Erase Protect Error Flag)

This flag indicates a violation of the flash memory overwrite protection setting in the FWEPROR register. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting Condition]

- See Table 55.16, Error Protection Type

[Clearing Condition]

- When the flash sequencer starts processing of a forced stop command

PRGSPD Flag (Programming Suspend Status Flag)

This flag indicates that the flash sequencer is in the processing of suspension of programming or has transitioned to the programming suspended state.

[Setting Condition]

- When the flash sequencer starts processing in response to a programming suspend command

[Clearing Conditions]

- When the flash sequencer has received a P/E resume command
  (after write access to the FACI command-issuing area is completed)
- When the flash sequencer starts processing of a forced stop command

ERSSPD Flag (Erasure Suspend Status Flag)

This flag indicates that the flash sequencer is the processing of erasure suspension or has transitioned to the erasure suspended state.

[Setting Condition]

- When the flash sequencer starts processing in response to an erasure suspend command

[Clearing Conditions]

- Reception of the P/E resume command by the flash sequencer
  (after write access to the FACI command-issuing area is completed)
- When the flash sequencer starts processing of a forced stop command

DBFULL Flag (Data Buffer Full Flag)

This flag indicates the state of the data buffer when a programming command or configuration setting command is issued. The FACI incorporates a buffer for write data (data buffer). When data for writing to the flash memory are issued to the FACI command-issuing area while the data buffer is full, the FACI inserts a wait cycle in the peripheral bus 6.

[Setting Condition]

- When the data buffer becomes full while a programming command or configuration setting command is being issued

[Clearing Condition]

- When the data buffer becomes empty

SUSRDY Flag (Suspend Ready Flag)

This flag indicates whether the flash sequencer can receive a P/E suspend command.

[Setting Condition]

- After starting programming/erasure processing and when the flash sequencer enters a state in which P/E suspend commands can be received

[Clearing Conditions]

- When the flash sequencer has accepted the P/E suspend command or forced stop command (after write access to the

FACI command-issuing area is completed)

- When the flash sequencer enters the command-locked state during programming or erasure
- When programming or erasure has been completed

PRGERR Flag (Programming Error Flag)

This flag indicates the result of programming of the flash memory. If this flag is 1, the flash sequencer is in the command-locked state.

[Setting Condition]

- See Table 55.16, Error Protection Type

[Clearing Condition]

- When the flash sequencer starts processing of a status clear or forced stop command

ERSERR Flag (Erasure Error Flag)

This flag indicates the result of erasure of the flash memory. If this flag is 1, the flash sequencer is in the command-locked state.

[Setting Condition]

- See Table 55.16, Error Protection Type

[Clearing Condition]

- When the flash sequencer starts processing of a status clear or forced stop command

ILGLERR Flag (Illegal Error Flag)

This flag indicates that the flash sequencer has detected an illegal FACI command or flash memory access. When this flag is 1, the flash sequencer is in the command-locked state.

[Setting Condition]

- See Table 55.16, Error Protection Type

[Clearing Condition]

- When the flash sequencer starts processing of a status clear or forced stop command.

FRDY Flag (Flash Ready Flag)

This flag indicates the command processing state of the flash sequencer.

[Setting Conditions]

- When the flash sequencer completes command processing
- When the flash sequencer receives a P/E suspend command and suspends programming or erasure of the flash memory
- When the flash sequencer has received a forced stop command and ended command processing

[Clearing Conditions]

- When the flash sequencer receives the FACI command of the setting of the program and configuration and after the first write access is made to the FACI command-issuing area
- When the flash sequencer receives any FACI command other than of the setting of the program and configuration and after the last write access is made to the FACI command issuing area

OTERR Flag (Other Error Flag)

This flag indicates that an FACI command has been issued when the condition of accepting commands is not satisfied. The OTERR flag is 1, the flash sequencer is in the command-locked state.

[Setting Condition]

- See Table 55.16, Error Protection Type

[Clearing Condition]

- When the flash sequencer starts processing of a status clear or forced stop command

SECERR Flag (Security Error Flag)

This flag indicates that write protection by the FAW.FSPR bit is violated. When the SECERR flag is 1, the flash sequencer is in the command-locked state.

[Setting Condition]

- See Table 55.16, Error Protection Type

[Clearing Condition]

- When the flash sequencer starts processing of a status clear or forced stop command

FESETERR Flag (FENTRY Setting Error Flag)

This flag indicates that a value of AA81h is written in the FENTRYR register or the value in the FENTRYR register differs when P/E is suspended and resumed. When the FESETERR flag is 1, the flash sequencer is in the command-locked state.

[Setting Condition]

- See Table 55.16, Error Protection Type

[Clearing Condition]

- When the flash sequencer starts processing of a status clear or forced stop command

ILGCOMERR Flag (Illegal Command Error Flag)

This flag indicates that the flash sequencer has detected an illegal FACI command. When the ILGCOMERR flag is 1, the flash sequencer is in the command-locked state.

[Setting Condition]

- See Table 55.16, Error Protection Type

[Clearing Condition]

- When the flash sequencer starts processing of a status clear or forced stop command

55.4.12 Flash P/E Mode Entry Register (FENTRYR)

Address(es): FLASH.FENTRYR 007F E084h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								FENTRYD	—	—	—	—	—	—	FENTRYC
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	FENTRYC	Code Flash Memory P/E Mode Entry	0: Code flash memory is in read mode. 1: Code flash memory is in P/E mode.	R/W*1, *2
b6 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	FENTRYD	Data Flash Memory P/E Mode Entry	0: Data flash memory is in read mode. 1: Data flash memory is in P/E mode.	R/W*1, *2
b15 to b8	KEY[7:0]	Key Code	Key code	R/W*3

Note 1. Writing to these bits is possible only when the FSTATR.FRDY flag is 1. Writing to these bits while the FSTATR.FRDY flag = 0 is ignored.
Note 2. Writing to this bit is possible only when AAh is written to the KEY bits in 16-bit units.
Note 3. Written values are not retained by these bits. These bits are read as 0.

This register is used to specify code flash memory P/E mode and data flash memory P/E mode. To specify code flash memory P/E mode or data flash memory P/E mode so that the flash sequencer can receive FACI commands, set either the FENTRYD or FENTRYC bit to 1 to place the flash sequencer in P/E mode.
Note that writing AA81h in this register causes the FSTATR.ILGLERR and FSTATR.FESETERR flags to be set to 1, and the flash sequencer to enter the command-locked state.
The FENTRYR register is initialized when the FSUINITR.SUINIT bit is set to 1. It is also initialized by a reset.

FENTRYC Bit (Code Flash Memory P/E Mode Entry)

This bit specifies the P/E mode for code flash memory.
[Setting Condition]

- When 1 is written to the FENTRYC bit while writing to the FENTRYR register is enabled and the FENTRYR register is 0000h

[Clearing Conditions]

- When the FENTRYR register is accessed in 8-bit units while the FSTATR.FRDY flag is 1
- When a value other than AAh is specified in the KEY bits and the FENTRYR register is accessed in 16-bit units while the FSTATR.FRDY flag is 1
- When 0 is written to the FENTRYC bit while writing to the FENTRYR register is enabled
- When the FENTRYR register is written while writing to the FENTRYR register is enabled and the value of the FENTRYR register is other than 0000h

FENTRYD Bit (Data Flash Memory P/E Mode Entry)

This bit specifies the P/E mode for data flash memory.
[Setting Condition]

- When 1 is written to the FENTRYR.FENTRYD bit while writing to the FENTRYR register is enabled and the FENTRYR register is 0000h

[Clearing Conditions]

- When the FENTRYR register is written in 8-bit units while the FSTATR.FRDY flag is 1
- When a value other than AAh is specified for the KEY bits while the FSTATR.FRDY flag is 1, and the FENTRYR register is written in 16-bit units

- When 0 is written to the FENTRYD bit while writing to the FENTRYR register is enabled
- When the FENTRYR register is written while writing to FENTRYR register is enabled and the value of the FENTRYR register is other than 0000h

KEY[7:0] Bits (Key Code)

These bits control permission and prohibition of writing to the FENTRYD and FENTRYC bits.

55.4.13 Flash Sequencer Set-Up Initialization Register (FSUINITR)

Address(es): FLASH.FSUINITR 007F E08Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	—	SUINIT
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SUINIT	Set-Up Initialization	0: The FEADDR, FCPSR, FSADDR, FENTRYR, and FBCCNT flash sequencer set-up registers keep their current values. 1: The FEADDR, FCPSR, FSADDR, FENTRYR, and FBCCNT flash sequencer set-up registers are initialized.	R/W*1, *2
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	Key code	R/W*3

Note 1. Writing to these bits is possible only when the FSTATR.FRDY flag is 1. Writing to these bits while the FSTATR.FRDY flag = 0 is ignored.
Note 2. Writing to these bits is possible only when 2Dh is written to the KEY bits in 16-bit units.
Note 3. Written values are not retained by these bits. This bit is read as 0.

This register is used for initialization of the flash sequencer set-up.

SUINIT Bit (Set-Up Initialization)

This bit initializes the following flash sequencer set-up registers.

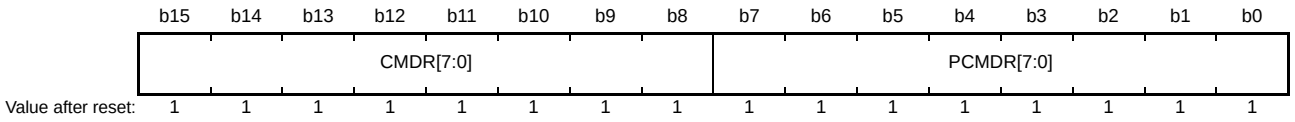
- FEADDR
- FCPSR
- FSADDR
- FENTRYR
- FBCCNT

KEY[7:0] Bits (Key Code)

These bits control permission and prohibition of writing to the SUINIT bit.

55.4.14 FACI Command Register (FCMDR)

Address(es): FLASH.FCMDR 007F E0A0h



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	PCMDR[7:0]	Precommand Flag	The command immediately before the latest command is stored.	R
b15 to b8	CMDR[7:0]	Command Flag	The latest command is stored.	R

This register records the two most recent commands accepted by the FACI.

PCMDR[7:0] Flags (Precommand Flag)

These flags indicate the command received immediately before the last command received by the FACI.

CMDR[7:0] Flags (Command Flag)

These flags indicate the latest command received by the FACI.

Table 55.4 States of FCMDR after Receiving Commands

Command	CMDR	PCMDR
Programming	E8h	Previous command
Block erase	D0h	20h
Multi-block erase	D0h	21h
P/E suspend	B0h	Previous command
P/E resume	D0h	Previous command
Status clear	50h	Previous command
Forced stop	B3h	Previous command
Blank check	D0h	71h
Configuration setting	40h	Previous command

55.4.15 Data Flash Blank Check Control Register (FBCCNT)

Address(es): FLASH.FBCCNT 007F E0D0h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	BCDIR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BCDIR	Blank Check Direction	0: Blank checking is executed from lower addresses to higher addresses (incremental mode). 1: Blank checking is executed from higher addresses to lower addresses (decremental mode).	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register specifies the addressing mode in processing of a blank check command. The register is initialized when the FSUINITR.SUINIT bit is set to 1. It is also initialized by a reset.

BCDIR Bit (Blank Check Direction)

This bit specifies the addressing mode for blank checking.

55.4.16 Data Flash Blank Check Status Register (FBCSTAT)

Address(es): FLASH.FBCSTAT 007F E0D4h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	BCST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	BCST	Blank Check Status Flag	0: The target area is in the non-programmed state (i.e. is blank; the area has been erased but has not yet been re-programmed). 1: The target area has been programmed with 0s or 1s.	R
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register stores the results of checking in response to a blank check command.

BCST Flag (Blank Check Status Flag)

This flag indicates the results of checking in response to a blank check command.

[Setting condition]

- When the blank checking command is issued and data of 0 or 1 is written to the target area

[Clearing condition]

- When the blank checking command is executed and the target area is blank

55.4.17 Data Flash Programming Start Address Register (FPSADDR)

Address(es): FLASH.FPSADDR 007F E0D8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PSADR[16]
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PSADR[15:0]															
Value after reset:	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b16 to b0	PSADR[16:0]	Programmed Area Start Address	The starting address of the programmed area to be found firstly	R
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register indicates the starting address of the programmed area to be found firstly in processing of a blank check command.

PSADR[16:0] Bits (Programmed Area Start Address)

These bits indicate the starting address of the programmed area to be found firstly in processing of a blank check command. The offset value is stored from the first address of the data flash memory. The value of the bits is valid only while the FBCSTAT.BCST bit is 1.

55.4.18 Flash Sequencer Processing Switching Register (FCPSR)

Address(es): FLASH.FCPSR 007F E0E0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ESUSPMD
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ESUSPMD	Erasure Suspend Mode	0: Suspension priority mode 1: Erasure priority mode	R/W
b15 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

This register is for selecting the erasure suspension mode.
The register is initialized when the FSUINITR.SUINIT bit is set to 1. It is also initialized by a reset.

ESUSPMD Bit (Erasure Suspend Mode)

This bit is for selecting the erasure suspension mode when a P/E suspend command is issued while the flash sequencer is executing erasure processing (see section 55.8.3.9, P/E Suspend Command). This bit should be set before issuing a block erase command.

55.4.19 Flash Sequencer Processing Clock Frequency Notification Register (FPCKAR)

Address(es): FLASH.FPCKAR 007F E0E4h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								PCKA[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0/1	0/1	0/1	0/1	0/1	0/1	0/1	0/1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	PCKA[7:0]	Flash Sequencer Processing Clock Frequency Notification	These bits are used to set the frequency of the FlashIF clock (FCLK) and notify the flash sequencer of the frequency used	R/W*1, *2
b15 to b8	KEY[7:0]	Key Code	Key code	R/W*3

Note 1. Writing to these bits is possible only when the FSTATR.FRDY flag is 1. Writing to these bits while the FSTATR.FRDY flag = 0 is ignored.
Note 2. Writing to these bits is possible only when 1Eh is written to the KEY[7:0] bits in 16-bit units.
Note 3. Written values are not retained by these bits. These bits are read as 0.

This register specifies the frequency of the FlashIF clock (FCLK) generated in the clock generator and notifies the flash sequencer of the frequency used. The flash sequencer determines the FACI command processing time based on the frequency notified by the FPCKAR register. The initial value is set to the maximum operating frequency of the FCLK.

PCKA[7:0] Bits (Flash Sequencer Processing Clock Frequency Notification)

These bits are used to specify the frequency of the FCLK generated in the clock generator and to notify the flash sequencer of the frequency used. Set the desired frequency in these bits before issuing an FACI command. Specifically, convert the frequency represented in MHz into a binary number and set it in these bits.

Example: When frequency is 35.9 MHz (PCKA[7:0] = 24h)
Round up the first decimal place of 35.9 MHz to a whole number (= 36) and convert it into a binary number.

If the value set in these bits is smaller than the frequency of the FCLK, the rewriting characteristics of the flash memory cannot be guaranteed. Conversely, if the value set in these bits is greater than the frequency of the FCLK, the rewriting characteristics of the flash memory can be guaranteed although the FACI command processing time such as time for rewriting will increase (the FACI command processing time becomes the shortest when the frequency of the FCLK is the same as the value set in the bits).

KEY[7:0] Bits (Key Code)

These bits control permission and prohibition of writing to the PCKA[7:0] bits.

55.4.20 Flash Access Window Monitor Register (FAWMON)

Address(es): FLASH.FAWMON 007F E0DCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	BTFLG	—	—	—	FAWE[11:0]											
Value after reset:	The value set by the user*1															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	FSPR	—	—	—	FAWS[11:0]											
Value after reset:	The value set by the user*1															

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	FAWS[11:0]	Flash Access Window Start Address	Flash access window start address	R
b14 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	FSPR	Access Window Protection Flag	0: With protection (P/E disabled) 1: Without protection (P/E enabled)	R
b27 to b16	FAWE[11:0]	Flash Access Window End Address	Flash access window end address	R
b30 to b28	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31	BTFLG	Start-Up Area Select Flag*2	0: Startup area 0 is in the range from FFFF C000h to FFFF DFFFh, startup area 1 is in the range from FFFF E000h to FFFF FFFFh. 1: Startup area 1 is in the range from FFFF C000h to FFFF DFFFh, startup area 0 is in the range from FFFF E000h to FFFF FFFFh.	R

Note 1. For products in which the option-setting memory has not been specifically set, the value is FFFF FFFFh. The value will be set by the user.

Note 2. When the FSUACR.SAS[1:0] bits are changed to 1xb, the startup area is dependent on the setting of the FSUACR.SAS[1:0] bits regardless of the setting of the FAW.BTFLG bit.

This register indicates the values of the write protection flag and start-up area select flag for setting the flash access window start/end address, and the access window. When a reset or configuration setting command is executed, the FACI transfers data from the option-setting memory to this register and the setting of the option-setting memory is enabled.

FAWS[11:0] Bits (Flash Access Window Start Address)

These bits are used to verify the access window start address setting value.

FSPR Flag (Access Window Protection Flag)

This flag indicates whether or not protection for a configuration setting command for the access window setting, for a configuration clear command, or for writing to the FSUACR register is available.

FAWE[11:0] Bits (Flash Access Window End Address)

These bits are used to verify the access window end address setting value. The value of these bits indicates the first address of the next P/E-enabled block as configured in the access window.

BTFLG Flag (Start-Up Area Select Flag)

This flag indicates whether the start-up area is switched by using start-up program protection.

55.4.21 Start-Up Area Control Register (FSUACR)

Address(es): FLASH.FSUACR 007F E0E8h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	KEY[7:0]								—	—	—	—	—	—	SAS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	SAS[1:0]	Start-Up Area Select	b1 b0 0 x: A start-up area is selected based on the setting of the FAW.BTFLG bit. 1 0: The area from FFFF E000h to FFFF FFFFh is selected as the address range for startup area 0, and the area from FFFF C000h to FFFF DFFFh is selected as the address range for startup area 1, regardless of the setting of the FAW.BTFLG bit. 1 1: The area from FFFF E000h to FFFF FFFFh is selected as the address range for startup area 1, and the area from FFFF C000h to FFFF DFFFh is selected as the address range for startup area 0, regardless of the setting of the FAW.BTFLG bit.	R/W*1, *2
b7 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15 to b8	KEY[7:0]	Key Code	Key codes	R/W*3

x: Don’t care

Note 1. Writable only when the FAW.FSPR bit is 1. When the FAW.FSPR bit is 0, writing to these bits are ignored.

Note 2. Writing to these bits is possible only when 66h is written to the KEY bit in 16-bit units.

Note 3. Written values are not retained by these bits. These bits are read as 0.

This register is used to switch startup areas 0 and 1 by startup program protection.

Do not use this register in dual mode (the MDE.BANKMD[2:0] bits are 000b). In dual mode, starting up proceeds from startup area 0.

SAS[1:0]Bits (Start-Up Area Select)

These bits are used to switch startup areas 0 and 1.

KEY[7:0] Bits (Key Code)

These bits enables or disable overwriting to the SAS[1:0] bits.

55.4.22 Data Flash Memory Access Frequency Setting Register (EEPFCLK)

Address(es): FLASH.EEPFCLK 007F C040h

	b7	b6	b5	b4	b3	b2	b1	b0
	EEPFCLK[7:0]							
Value after reset:	0	0	1	1	1	1	0	0

This register optimizes the speed of reading the data flash memory.
Set the frequency of the peripheral module clock (FCLK) of internal peripheral bus 6 which is the clock for access to the data flash memory, in MHz units. For example, 35.9 MHz should be rounded up and set the frequency to 36. Number of cycles required for access to the data flash memory are inserted according to the frequency.
When changing the frequency of the FCLK, follow the procedure below to modify the value of the data flash memory access frequency setting register (EEPFCLK) in either of the following ways according to whether operation is at a lower frequency before or after the change.

- When changing the speed from low to high: Modify EEPFCLK. After confirming the change by reading EEPFCLK, change the frequency.
- When changing the speed from high to low: Change the frequency. After the frequency is changed, modify EEPCFLK.

55.4.23 Unique ID Register n (UIDRn) (n = 0 to 3)

Address(es): FLASHCONST.UIDR0 FE7F 7D90h, FLASHCONST.UIDR1 FE7F 7D94h, FLASHCONST.UIDR2 FE7F 7D98h, FLASHCONST.UIDR3 FE7F 7D9Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	Unique value for each chip															

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	Unique value for each chip															

Note: These registers are only readable when the SYSCR0.ROME bit is 1 (the on-chip ROM is enabled).

The UIDRn is a read-only register that stores a 16-byte ID code (unique ID) for identifying the individual MCU. The UIDRn register should be read in 32-bit units.

55.5 Operating Modes Associated with Flash Memory

Figure 55.7 is a diagram of the mode transitions associated with the flash memory. For the procedures for setting the modes, refer to section 3, Operating Modes.

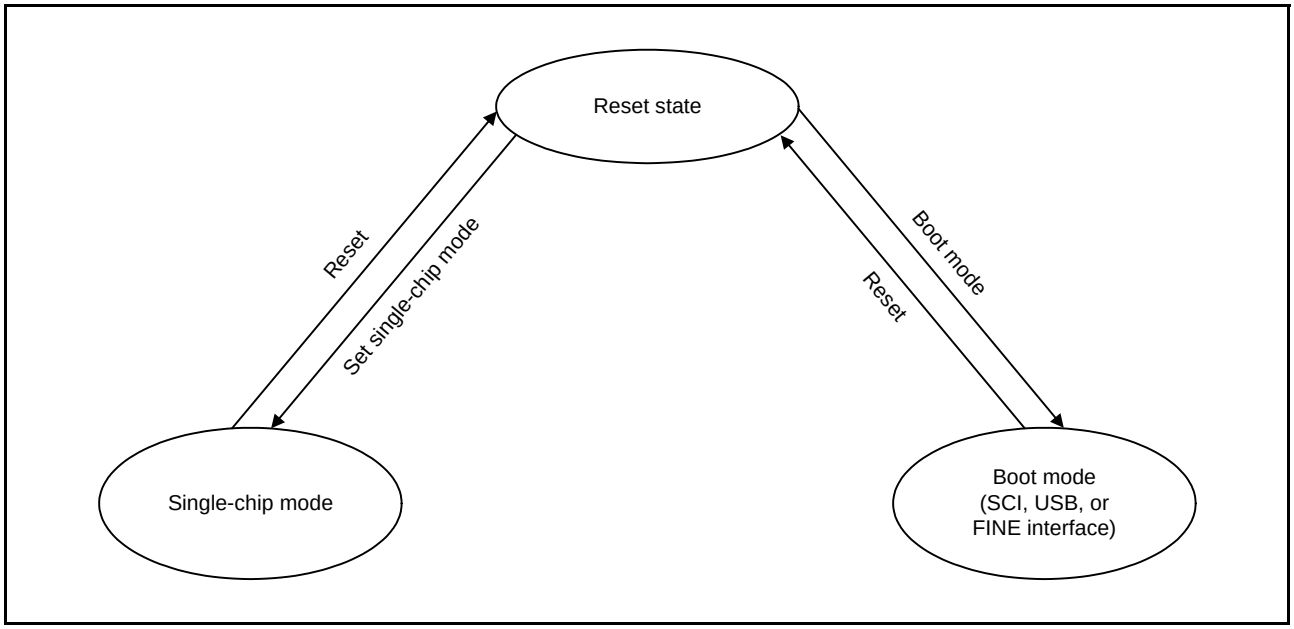


Figure 55.7 Mode Transitions Associated with Flash Memory

The flash memory area where programming and erasure are permitted and the boot program after a reset are different according to each mode. The differences between modes are listed in Table 55.5.

Table 55.5 Differences between Modes

Item	Single-chip Mode or On-chip ROM Enabled Extended Mode	Boot Mode (SCI, USB, or FINE Interface)
Programmable and erasable area	Code flash memory Data flash memory Option-setting memory (programming only)	Code flash memory Data flash memory Option-setting memory
Boot program at a reset	Program of the code flash memory	Boot program

55.6 Operating Modes of the Flash Sequencer

The flash sequencer has three operating modes as shown in Figure 55.8. Transitions between modes are initiated by changing the value of the FENTRYR register.

When the value of the FENTRYR register is 0000h, the flash sequencer is in read mode. In this mode, it does not receive FACI commands. The code flash memory and data flash memory are readable.

When the value of the FENTRYR register is 0001h, the flash sequencer is in code flash memory P/E mode where the code flash memory can be programmed or erased by FACI commands. In this mode, reading from the code flash memory is disabled under the conditions where BGO cannot be used. Under the conditions where BGO can be used, reading from the code flash memory is enabled.

When the value of the FENTRYR register is 0080h, the flash sequencer is in data flash memory P/E mode where the data flash memory can be programmed or erased by FACI commands. In this mode, the data flash memory is not readable. However, the code flash memory is readable.

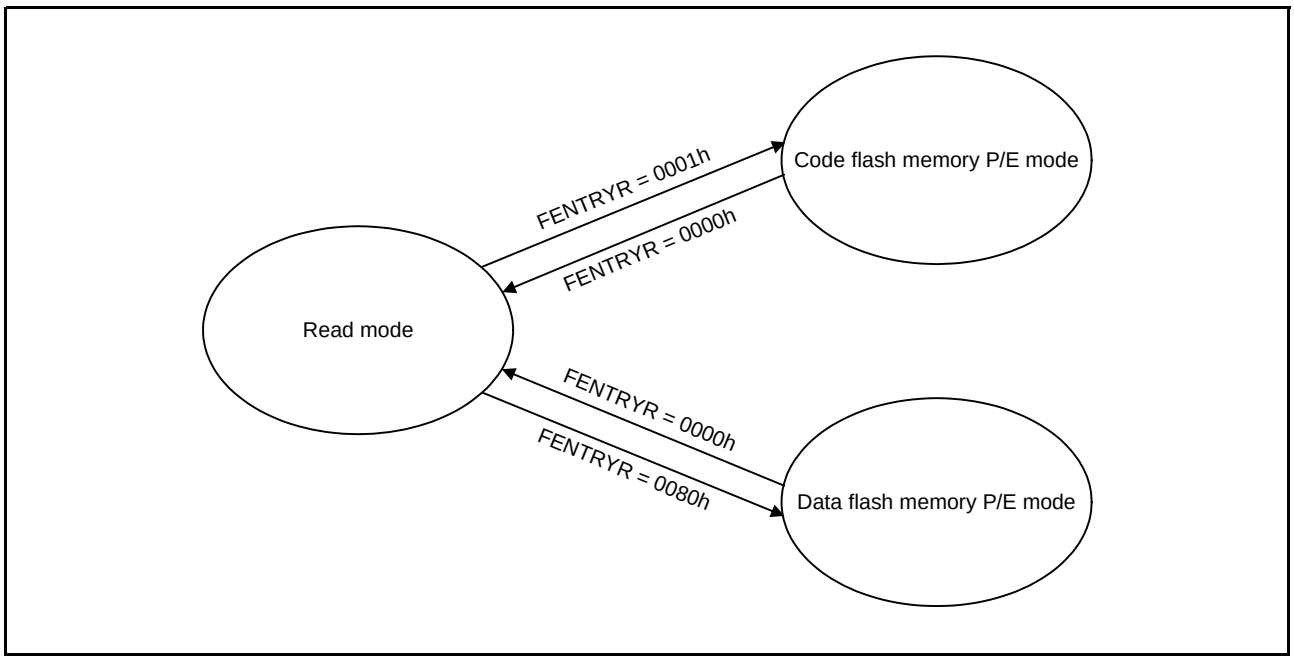

Figure 55.8 Modes of the Flash Sequencer

55.7 Overview of Functions

55.7.1 ROM Cache

This MCU has three types of cache as listed below.

- Instruction fetching cache (IF cache): 8 Kbytes
- Data cache (OA cache): 16 bytes
- Data cache (DM cache): 16 bytes

The IF cache and OA cache are for the CPU, and the DM cache is for bus masters other than the CPU, such as the DMAC and DTC.

After release from a reset, the caches are automatically invalidated following programming and erasure of the flash memory.

The area subject to caching is the 2-Mbyte address range from FFE0 0000h through FFFF FFFFh, in which up to two areas can be set as not within the scope of caching (non-cacheable areas).

55.7.1.1 Setting Non-Cacheable Area

Parts of the flash memory of this MCU that are within the cacheable areas can be set as not in the scope of caching by setting the NCRGn and NCRCn registers (n = 0, 1). Figure 55.9 shows the settings of each register and the non-cacheable areas.

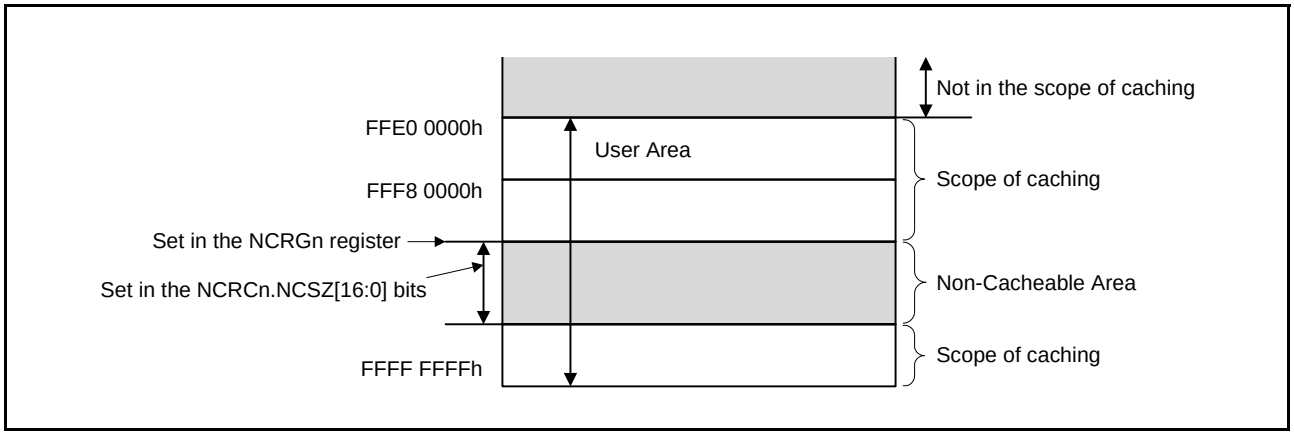

Figure 55.9 Specifying a Non-Cacheable Area (n = 0, 1)

The restrictions shown below in Table 55.6 apply to the settings of the NCRCn.NCSZ[16:0] bits and of the NCRGn register.

Table 55.6 Restrictions Applying to the Settings of the NCRCn.NCSZ[16:0] Bits and of the NCRGn Register

Settings of the NCRCn.NCSZ[16:0] Bits	Restrictions Applying to the Settings of the NCRGn Register
0 0000 0000 0000 0000: 16 bytes	No restriction
0 0000 0000 0000 0001: 32 bytes	Bit 4 in the NCRGn register is ignored.
0 0000 0000 0000 0011: 64 bytes	Bits 5 and 4 in the NCRGn register are ignored.
0 0000 0000 0000 0111: 128 bytes	Bits 6 to 4 in the NCRGn register are ignored.
0 0000 0000 0000 1111: 256 bytes	Bits 7 to 4 in the NCRGn register are ignored.
0 0000 0000 0001 1111: 512 bytes	Bits 8 to 4 in the NCRGn register are ignored.
0 0000 0000 0011 1111: 1 Kbyte	Bits 9 to 4 in the NCRGn register are ignored.
0 0000 0000 0111 1111: 2 Kbytes	Bits 10 to 4 in the NCRGn register are ignored.
0 0000 0000 1111 1111: 4 Kbytes	Bits 11 to 4 in the NCRGn register are ignored.
0 0000 0001 1111 1111: 8 Kbytes	Bits 12 to 4 in the NCRGn register are ignored.
0 0000 0011 1111 1111: 16 Kbytes	Bits 13 to 4 in the NCRGn register are ignored.
0 0000 0111 1111 1111: 32 Kbytes	Bits 14 to 4 in the NCRGn register are ignored.
0 0000 1111 1111 1111: 64 Kbytes	Bits 15 to 4 in the NCRGn register are ignored.
0 0001 1111 1111 1111: 128 Kbytes	Bits 16 to 4 in the NCRGn register are ignored.
0 0011 1111 1111 1111: 256 Kbytes	Bits 17 to 4 in the NCRGn register are ignored.
0 0111 1111 1111 1111: 512 Kbytes	Bits 18 to 4 in the NCRGn register are ignored.
0 1111 1111 1111 1111: 1 Mbyte	Bits 19 to 4 in the NCRGn register are ignored.

55.7.2 Methods of Programming/Erasure

By using a dedicated flash-memory programmer to program the flash memory of this MCU, the device can be rewritten regardless of whether this is before or after it is mounted on the target system.
Furthermore, security functions to prohibit rewriting or reading of the user program written to the flash memory are incorporated, and this can prevent falsification and illicit reading of the programs by third parties. TM target areas of the code flash memory can also be protected against reading by using the TM function.
Programming by the user program (self-programming) is available to suit applications where the application on the target system may require updating after manufacturing or shipment. Protection features for the safe rewriting of the flash memory are also incorporated. Furthermore, interrupt processing during self-programming is supported, so programming can proceed at the same time as processing for external communications, etc., and this is the case in various situations.
Table 55.7 lists the overview of the methods of programming and the corresponding operating modes.

Table 55.7 Methods of Programming

Method of Programming	Functional Overview	Operating Mode
Programming by a flash-memory programmer	A serial programmer is capable of on-board programming of the flash memory after the device is mounted on the target system. The TM function can be in enabled or disabled at this time.	Boot mode
	A parallel programmer and dedicated programming adapter board allow off-board programming of the flash memory, i.e. programming of the device before it is mounted on the target system.	
Self-programming	The execution of the user program that is written to code flash memory in advance by serial programming executing is also capable of programming the flash memory. The TM function can be in the enabled state at this time. The background operation capability makes it possible to fetch instructions or otherwise read data from code flash memory while the data flash memory is being programmed. Therefore, the data flash memory can be rewritten by executing a program for writing contained by the code flash memory. Furthermore, background operation can also be used for reading and writing to code flash memory alone, but only when the address range of code flash memory that is the target for programming and the address range of code flash memory that is the target for reading satisfy particular conditions (see Table 55.25). When this is the case, at the time of self-programming, a program for programming that is in the code flash memory can be executed to rewrite the code flash memory. In cases where background operation is not possible, instructions in the code flash memory cannot be fetched and data cannot be accessed while code flash memory is being re-written by self-programming. In such cases, a program for programming must be transferred to the internal RAM or external memory in advance and executed.	Single-chip mode On-chip ROM enabled extended mode

Table 55.8 lists the functions of the flash memory. Serial programmer commands realize each function of serial programming, while reading of the flash memory by an FACI command or the user program realizes each function of self-programming.
For security function settings, see section 7.2.1, Serial Programmer Command Control Register (SPCC), in section 7, Option-Setting Memory (OFSM).

Table 55.8 List of Basic Functions

Function	Functional Overview	Support Status	
		Serial Programming	Self-programming
Blank check	This is used to check a specified block to ensure that writing to it has not already proceeded. Results of reading from data flash memory to which nothing has been written after erasure are not guaranteed, so use blank checking to confirm that programming to memory has not proceeded after erasure.	Supported	Supported
Block erasure	Erases the memory contents in the specified block.	Supported	Supported
Multi-block erasure	Erases the contents of the specified block of the data flash memory.	Not supported	Supported
Programming	Write to the specified address.	Supported	Supported
Verify/Checksum	Compares the data read from flash memory and the data transferred from a serial programmer.	Supported	Not supported (read by user program is possible)
Read	Read data programmed to flash memory.	Supported	Supported
Setting of control or ID codes	Sets the OSIS register.	Supported	Supported
Prohibition of serial programmer connection	Sets the permission/prohibition of serial programmer connection.	Supported	Supported with conditions (Only switching the configuration from enabled to disabled is possible)
Prohibition of on-chip debugger connection	Sets the permission/prohibition of on-chip debugger connection.	Supported	Supported with conditions (Only switching the configuration from enabled to disabled is possible)
Area protection and start-up program protection functions	Configures the area protection and start-up program protection functions.	Supported	Supported
Option function selection	Selects the option function, and modifies the initial settings of this MCU.	Supported	Supported
Configuration clearing	Erases the option-setting memory and the TM target areas.	Supported	Not supported
Dual bank function	Switches different modes (linear or dual).	Supported	Supported
Setting the TM function	Sets the TM function.	Supported	Supported with conditions (Only switching the configuration from disabled to enabled is possible)

55.7.3 Security Functions

The flash memory supports various security functions.
The security function includes serial programmer ID code protection, prohibition of serial programmer connection, on-chip debugger ID code protection, prohibition of on-chip debugger connection, and the ROM code protection.
In serial programming, serial programmer ID code protection and prohibition of serial programmer connection can be used. On-chip debugger ID code protection and prohibition of on-chip debugger connection can be used during connection of the on-chip debugger. In off-board programming, ROM code protection can be used.
Table 55.9 lists the security functions supported by the flash memory.

Table 55.9 Lists of Security Functions

Function	Description
Serial programmer ID code protection	Connection of a serial programmer can be controlled by judging the control code or ID code.
Prohibition of serial programmer connection	The connection of a serial programmer for serial programming is prohibited. Since execution of the configuration clearing command is also prohibited when the connection of a serial programmer is prohibited, changing a security setting from “disabled” to “enabled” is not possible.
On-chip debugger ID code protection	Connection of an on-chip debugger can be controlled by judging the ID code.
Prohibition of on-chip debugger connection	The connection of an on-chip debugger is prohibited regardless of the ID code setting.
ROM code protection	This function is to prohibit reading, programming, and erasure of the flash memory when a parallel programmer is in use.

55.8 FACI Commands

55.8.1 List of FACI Commands

Table 55.10 List of FACI Commands

FACI Command	Description
Programming	This is used to program the code or data flash memory. Units of programming are 128 bytes for the code flash memory and 4 bytes for the data flash memory.
Block erase	This is used to erase the code or data flash memory. The unit of erasure is one block. (code flash memory: 8 K or 32 Kbytes, data flash memory: 64 bytes)
Multi-block erase	This is used to erase the data flash memory. The unit of erasure is 64, 128, 256 bytes
P/E suspend	This suspends programming or erasure processing.
P/E resume	This resumes suspended programming or erasure processing.
Status clear	This initializes the ILGLERR, ERSERR, PRGERR, ILGCOMERR, FESETERR, SECERR, and OTERR flags in the FSTATR register and the CMDLK, CFAE, and DFAE flags in the FASTAT releases the flash sequencer from the command-locked state.
Forced stop	This forcibly stops processing of FACI commands and initializes the FASTAT and FSTATR registers.
Blank check	This is used to blank-check the data flash memory. Range of checking: 4 bytes to 8 Kbytes (specified in 4-byte units).
Configuration setting	This is used to set the option-setting memory (configuration setting area). Units of setting: 16 bytes.

The FACI commands are issued by writing to the FACI command-issuing area (see Table 55.2). When write access as shown in Table 55.11 proceeds in the specified state, the flash sequencer executes the processing corresponding to the given command (see section 55.8.2, Relationship between the Flash Sequencer State and FACI Commands).

Table 55.11 FACI Command Formats

FACI Commands	Number of Write Access	Data to be Written to the FACI Command-Issuing Area			
		1st Access	2nd Access	3rd to (N+2)th Access	(N+3)th Access
Programming (code flash memory) 128-byte programming, N = 64	67	E8h	40h (= N)	WD_1 to WD_{64}	D0h
Programming (data flash memory) 4-byte programming, N = 2	5	E8h	02h (= N)	WD_1 to WD_2	D0h
Block erase (code flash memory)	2	20h	D0h	—	—
Block erase (data flash memory 64-byte)	2	20h	D0h	—	—
Multi-block erase (data flash memory 64-byte/128-byte/256-byte)	2	21h	D0h	—	—
P/E suspend	1	B0h	—	—	—
P/E resume	1	D0h	—	—	—
Status clear	1	50h	—	—	—
Forced stop	1	B3h	—	—	—
Blank check	2	71h	D0h	—	—
Configuration setting N = 8	11	40h	08h (= N)	WD_1 to WD_8	D0h

Note: WD_N (N = 1, 2,…): Nth 16-bit data to be programmed.

The flash sequencer clears the FSTATR.FRDY flag to 0 at the start of processing of a command other than the status clear command and sets this bit to 1 upon completion of command processing.
When the setting of the FRDYIE.FRDYIE bit is 1 and when the FSTATR.FRDY flag is set to 1, a flash ready (FRDY) interrupt is generated.

55.8.2 Relationship between the Flash Sequencer State and FACI Commands

Each FACI command can be accepted in a specific mode or state of the flash sequencer. FACI commands should be issued after the transition of the flash sequencer to the code flash memory P/E mode or data flash memory P/E mode and checking of the state of the flash sequencer. Use the FSTATR and FASTAT registers to check the state of the flash sequencer. The value of the FASTAT.CMDLK flag is the logical OR of values of the ILGLERR, ILGCOMERR, FESETERR, SECERR, OTERR, ERSERR, PRGERR, and FLWEERR flags in the FSTATR register. Therefore, the occurrence of errors can be checked by reading the value of the FASTAT.CMDLK flag.

Table 55.12 lists the available commands in each operating mode.

Table 55.12 Operating Mode and Available Commands

Operating Mode	FENTRYR Register Value	Available Commands
Read mode	0000h	None
Code flash memory P/E mode	0001h	Programming Block erase P/E suspend P/E resume Status clear Forced stop Configuration setting
Data flash memory P/E mode	0080h	Programming Block erase Multi-block erase P/E suspend P/E resume Status clear Forced stop Blank check

Table 55.13 shows the state of the flash sequencer and acceptable FACI commands. An appropriate mode is assumed to be set before the commands are executed.

Table 55.13 Acceptable FACI Commands and the State of the Flash Sequencer

	Processing of Programming or Erasure	Processing of Configuration Setting	Processing to Suspend Programming or Erasure	Processing of Blank Checking	Programming Suspended	Erasure Suspended	Programming while Erasure is Suspended	Command-Locked State (FRDY = 1)	Command-Locked State (FRDY = 0)	Processing of Forced Stop Command	Other State
FRDY flag	0	0	0	0	1	1	0	1	0	0	1
SUSRDY flag	1	0	0	0	0	0	0	0	0	0	0
ERSSPD flag	0	0	0/1	0/1	0	1	1	0/1	0/1	0	0
PRGSPD flag	0	0	0/1	0/1	1	0	0	0/1	0/1	0	0
CMDLK flag	0	0	0	0	0	0	0	1	1	0	0
Programming	×	×*4	×	×	×	✓*3	×	×	×	×	✓
Block erase	×	×*4	×	×	×	×	×	×	×	×	✓
Multi-block erase	×	×*4	×	×	×	×	×	×	×	×	✓
P/E suspend	✓	×*4	×	×	×	×	×	—	×	×	—
P/E resume	×	×*4	×	×	✓	✓	×	×	×	×	×
Status clear	×	×*4	×	×	✓	✓	×	✓	×	×	✓
Forced stop	✓	✓*4	✓	✓	✓	✓	✓	✓	✓	✓	✓
Blank check	×	×	×	×	✓*1	✓*1	×	×	×	×	✓*1
Configuration setting	×	×*4	×	×	×	×	×	×	×	×	✓*2

✓: Acceptable
×: Not acceptable (the sequencer in the command-locked state)
—: Ignored
Note 1. Acceptable only in data flash memory P/E mode
Note 2. Acceptable only in code flash memory P/E mode
Note 3. Programming is acceptable only for blocks other than blocks where erasure has been suspended.
Note 4. Do not issue a FACI command when configuration setting is being processed and the FSTATR.DBFULL bit is 1.

55.8.3 Usage of FACI Commands

This section gives an overview of the usage of FACI commands.

55.8.3.1 Transition to Code Flash Memory P/E Mode

To use the FACI commands for the code flash memory, a transition to code flash memory P/E mode is required. To cause shift to code flash memory P/E mode, set the FENTRYR.FENTRYC bit to 1.

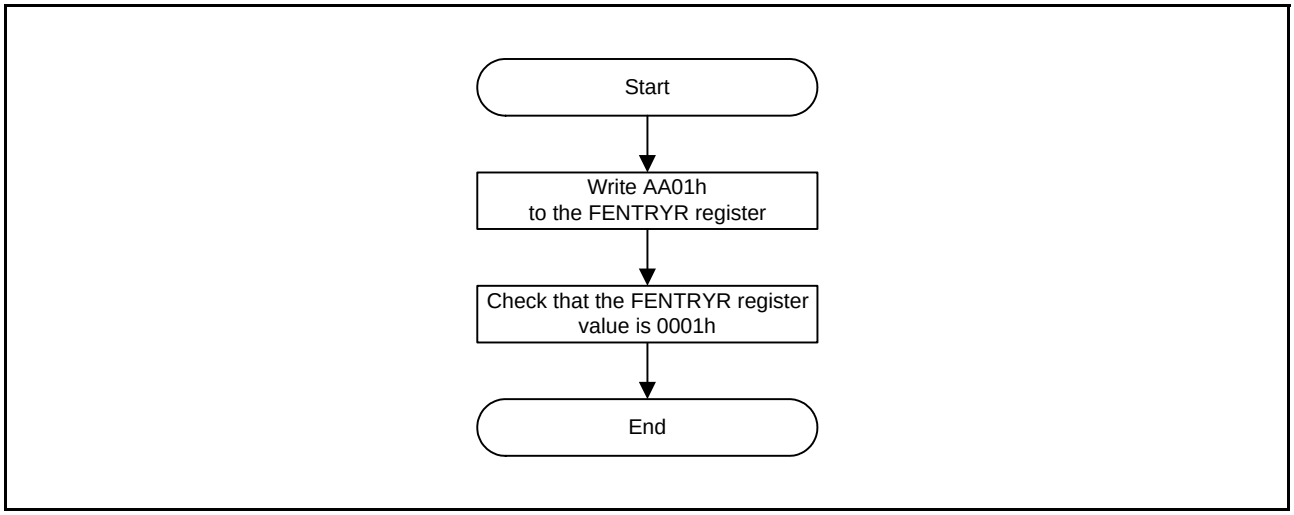

Figure 55.10 Procedure for Transition to Code Flash Memory P/E Mode

55.8.3.2 Transition to Data Flash Memory P/E Mode

To use the FACI commands for the data flash memory, a transition to data flash memory P/E mode is required. To shift to data flash memory P/E mode, set the FENTRYR.FENTRYRD bit to 1.

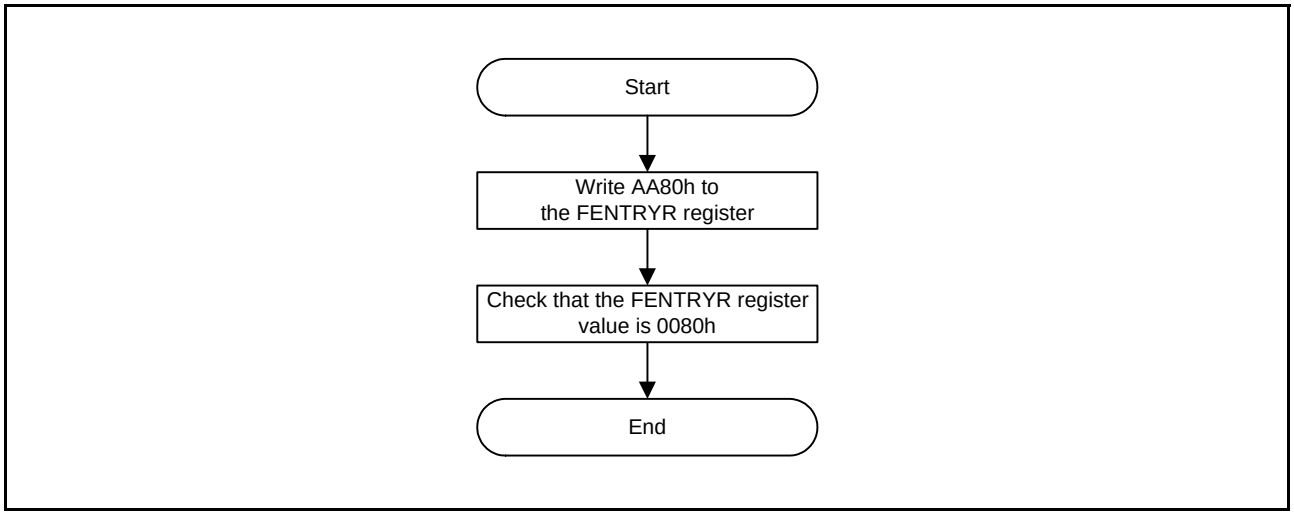

Figure 55.11 Procedure for Transition to Data Flash Memory P/E Mode

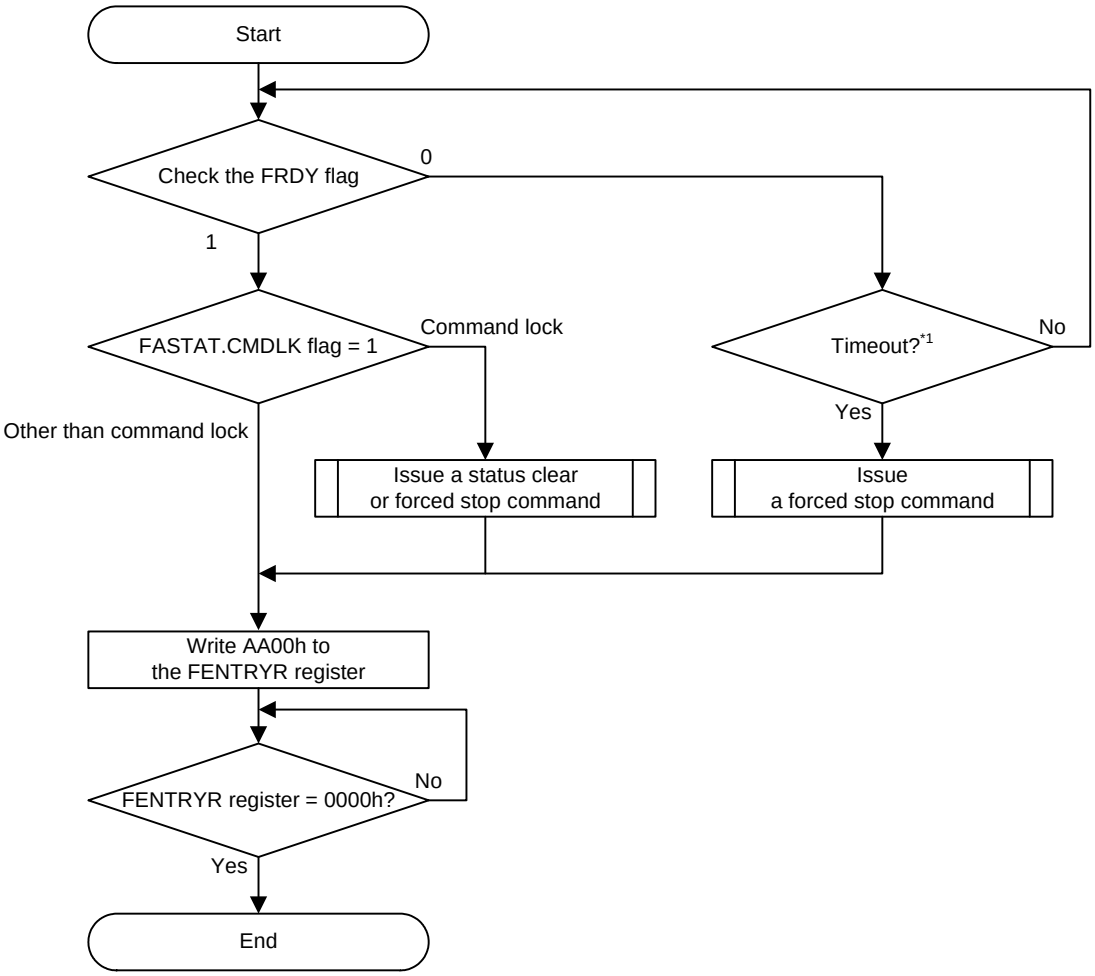
55.8.3.3 Transition to Read Mode

To read the flash memory without using the BGO function, a transition to read mode is required. To shift to read mode, set the FENTRYR register to 0000h. The transition to read mode should be made after processing by the flash sequencer is completed and while operation is in other than in the command-locked state. In addition, operation is started in read mode after release from the reset state.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for processing of the FACI command that is in progress (refer to the Electrical Characteristics chapter).

Figure 55.12 Procedure for Transition to Read Mode

55.8.3.4 Overview Flow when FACI Command is Used

Figure 55.13 shows an overview flow when the FACI command is used.
If BGO is enabled, the jump to the internal RAM or external area (other than code flash memory) is not required because an FACI command can be issued for the code or data flash memory by using the rewriting program in the code flash memory.
When the FCLK is changed, changing the FPCKAR register shortens time for processing the FACI command. For details, refer to section 55.4.19, Flash Sequencer Processing Clock Frequency Notification Register (FPCKAR).

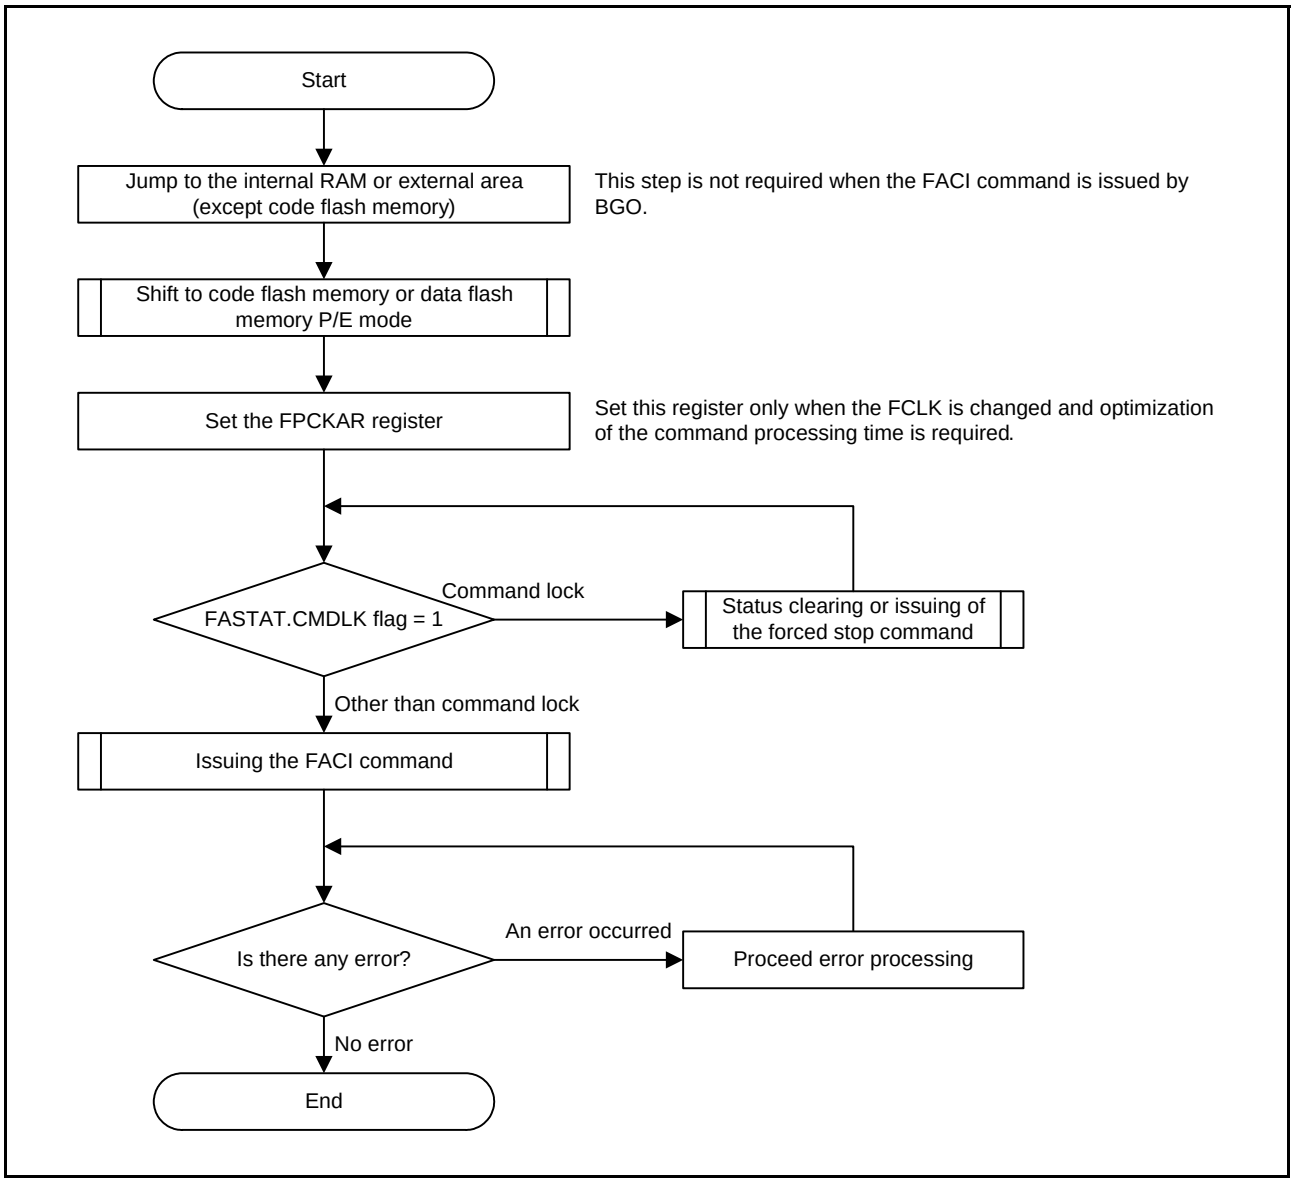


Figure 55.13 Overview Flow when FACI Command is Used

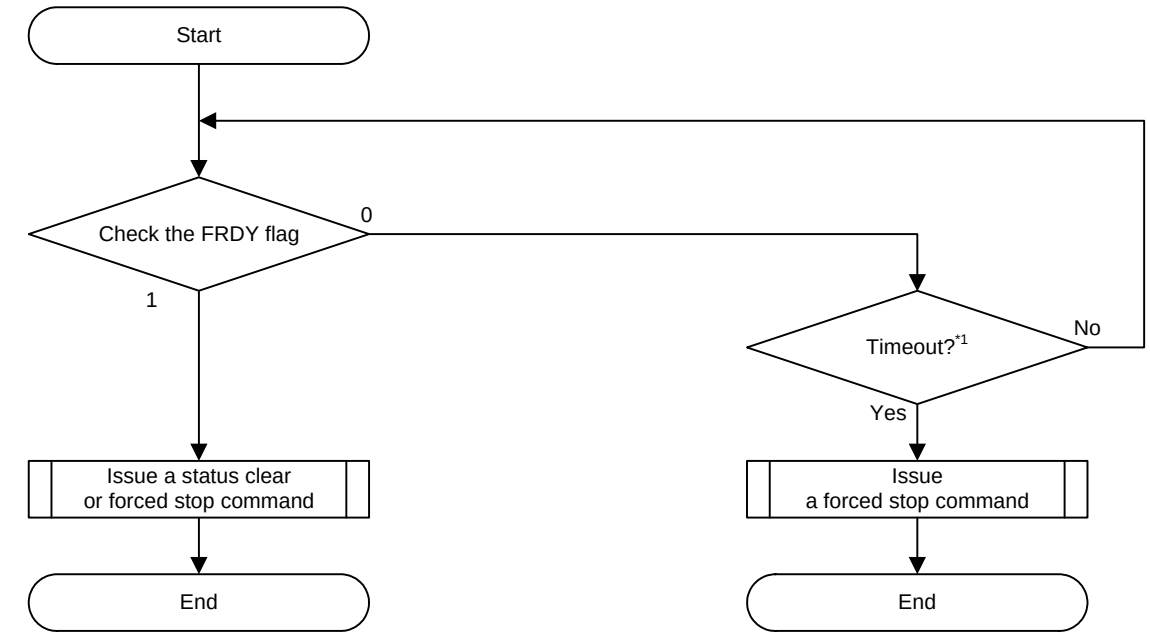
55.8.3.5 Recovery from the Command-Locked State

When the flash sequencer enters the command-locked state, FACI commands cannot be accepted. To release the sequencer from the command-locked state, use the status clear command, or forced stop command.
When the command-locked state is detected by checking for an error before issuing the P/E suspend command, the FSTATR.FRDY flag may hold 0 as the command processing has not been completed. When the processing is not completed even after time equal to the maximum programming or erasure time specified in the section 56, Electrical Characteristics times 1.1 has elapsed, this is considered a time-out and the flash sequencer should be stopped by the forced stop command.

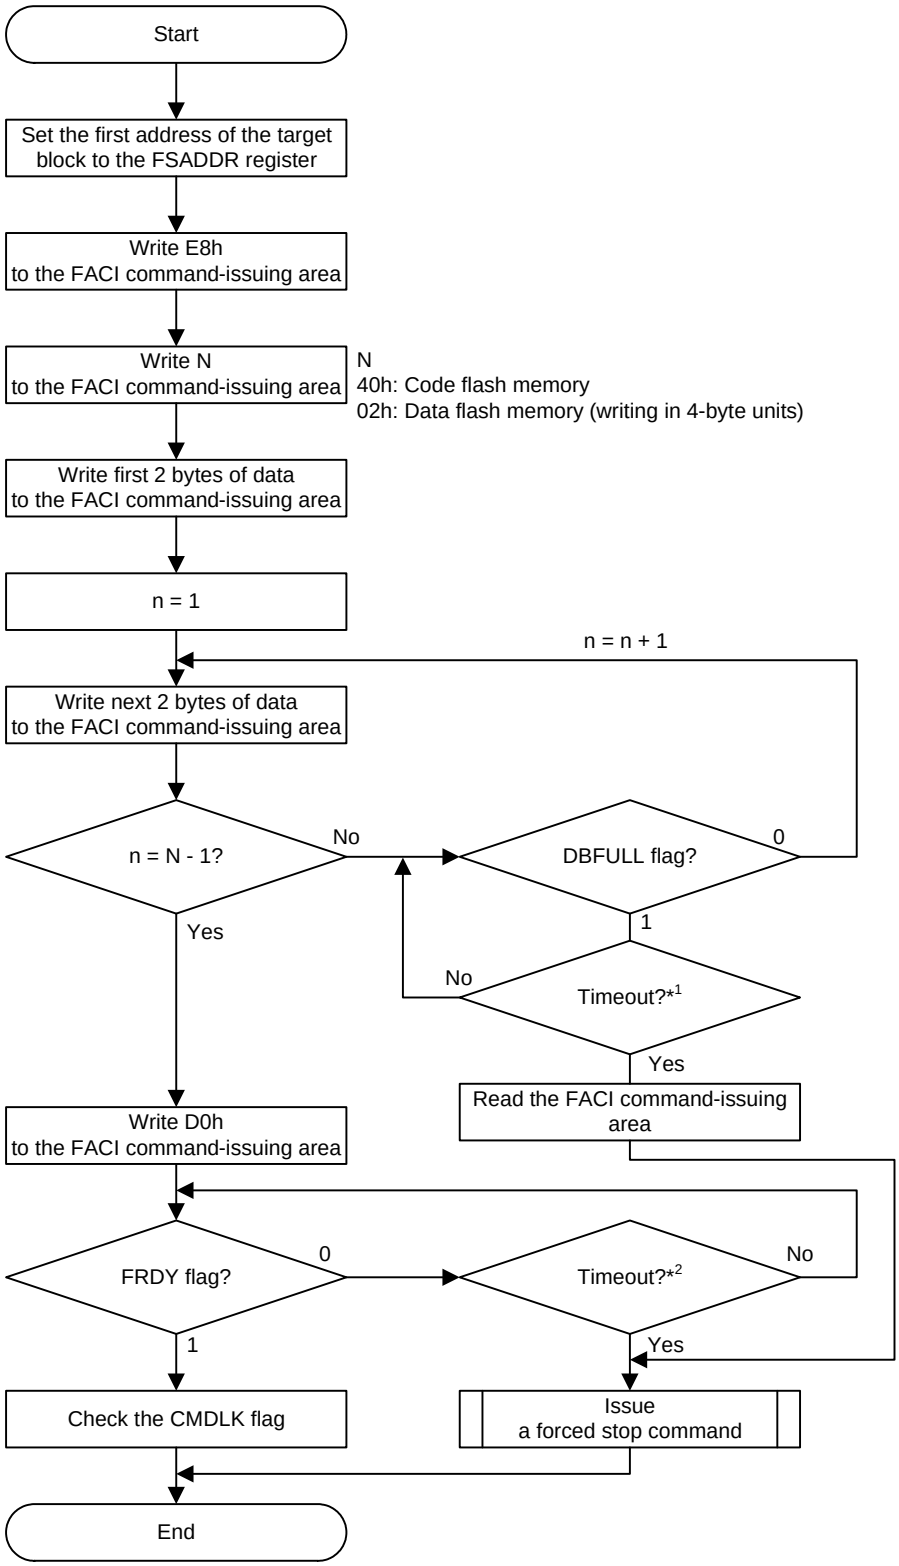


Note 1. Judgment of the timeout is based on 1.1 times the maximum time for processing of the FACI command that is in progress (refer to the Electrical Characteristics chapter).

Figure 55.14 Recovery from the Command-Locked State

55.8.3.6 Programming Command

A programming command is used for programming the code or data flash memory.
Before issuing a programming command, set the first address of the target block in the FSADDR register.
Writing D0h to the FACI command-issuing area at the final access of the FACI command-issuing starts the programming command processing. Completion of command processing can be checked by reading the FSTATR.FRDY flag. If the target area of programming command processing contains the area not for writing, write FFFFh to the corresponding area.
Issuing a programming command consecutively while the FACI internal data buffer is full leads to a wait on the peripheral bus 6 and this may affect on the bus accesses of the other peripheral IP modules. To avoid the generation of such a wait, issue an FACI command while the FSTATR.DBFULL flag is 0.
In addition, the data buffer never becomes full during programming of the data flash memory.

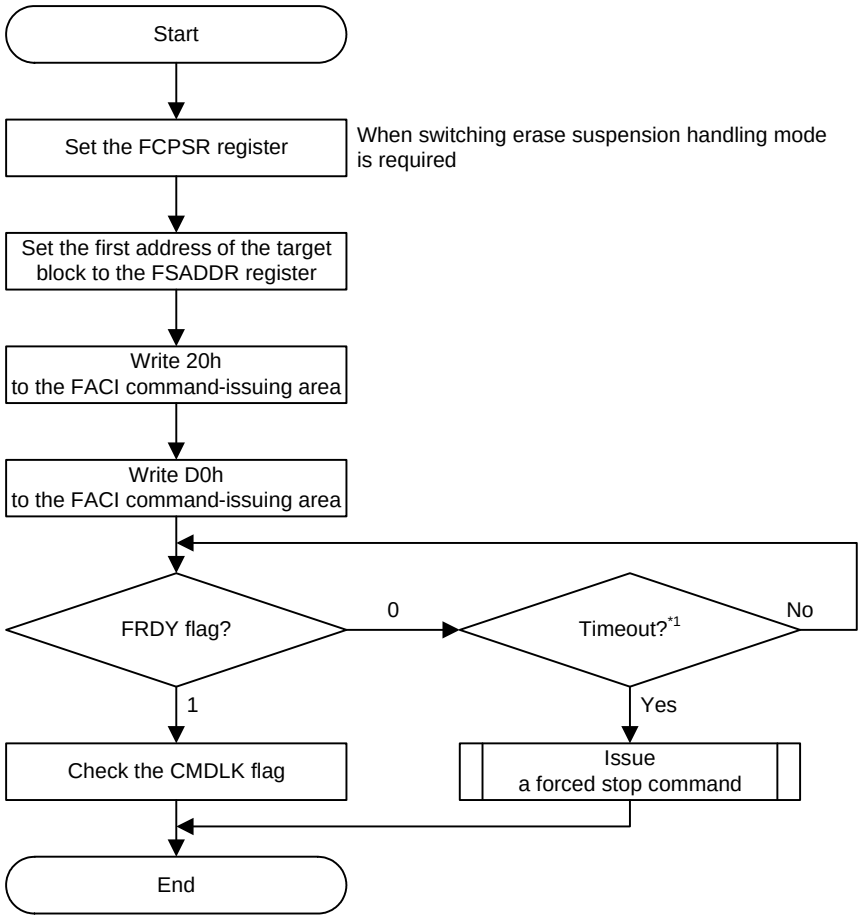


Note 1. Judgment of the timeout is based on 1.4 µs elapsing (when FCLK ≥ 20 MHz)
Note 2. Judgment of the timeout is based on 1.1 times 128-byte programming time (max) for code flash memory. For data flash memory, judgment is based on 1.1 times 4-byte programming time (max). For the 128-byte programming time and 4-byte programming time, refer to the Electrical Characteristics chapter.

Figure 55.15 Usage of the Programming Command

55.8.3.7 Block Erase Command

A block erase command is used to erase the code or data flash memory in single-block units.
Before issuing a block erase command, set the first address of the target block in the FSADDR register. Writing 20h and D0h to the FACI command-issuing area starts processing of a block erase command. Completion of command processing can be confirmed by reading the FSTATR.FRDY flag.
The FCPSR register must be set before issuing the block erase command. The setting of the FCPSR register must be changed to switch the suspending method (suspension priority mode/erasure priority mode) by the P/E suspend command.



Note 1. Judgment of the timeout is based on 1.1 times 32-Kbyte erasure time (max) for code flash memory.
For data flash memory, judgment is based on 1.1 times 64-byte erasure time (max).
For the 32-Kbyte erasure time and 64-byte erasure time, refer to the Electrical Characteristics chapter.

Figure 55.16 Usage of the Block Erase Command

55.8.3.8 Multi-Block Erase Command

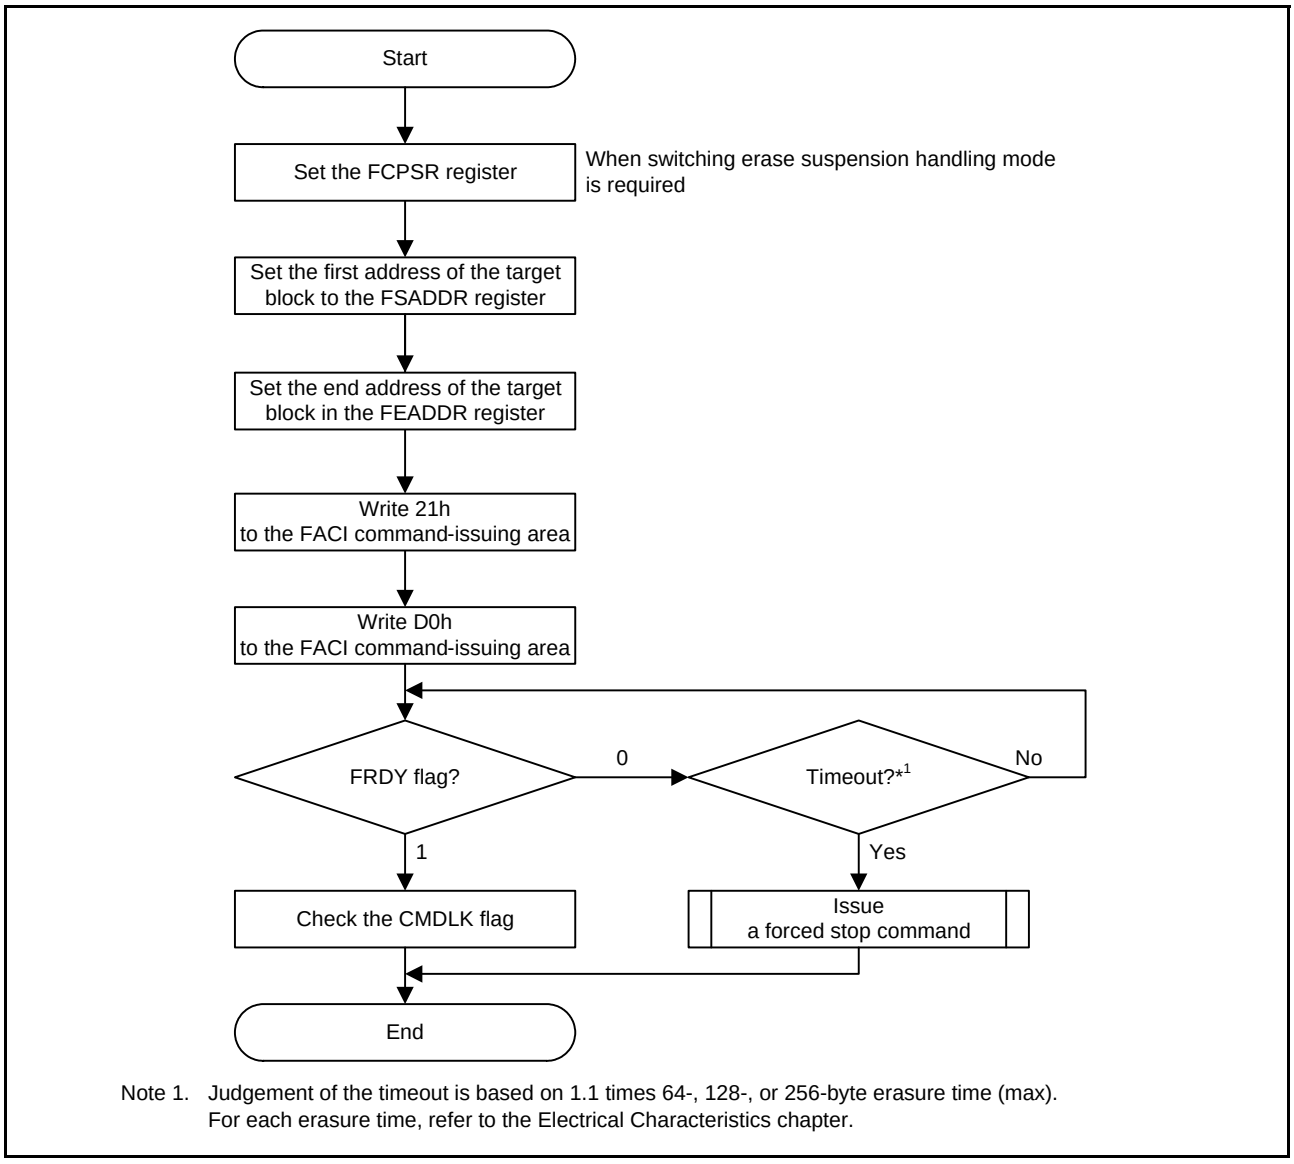
The multi-block erase command can also be issued to erase data in the data flash memory. The unit for erasure is 64, 128, or 256 bytes.

Set the first address of the target area for erasure to the FSADDR register and the end address to the FEADDR register before issuing a multi-block erase command. When 21h and D0h are written to the FACI command issuing area, the process of the multi-block erase command proceeds. The end of command processing can be confirmed by the FSTATR.FRDY flag.

The FCPSR register must be set before issuing the multi-block erase command. The setting of the FCPSR register must be changed when P/E suspension command is used to switch the handling of suspension of erasure (between suspension priority and erasure priority).

Table 55.14 Size Setting for Erasure

Erasure Size	FSADDR	FEADDR
64 bytes	FSA0 to FSA5 = 0 (64-byte boundary)	FSADDR + 3Ch
128 bytes	FSA0 to FSA6 = 0 (128-byte boundary)	FSADDR + 7Ch
256 bytes	FSA0 to FSA7 = 0 (256-byte boundary)	FSADDR + FCh



Note 1. Judgement of the timeout is based on 1.1 times 64-, 128-, or 256-byte erasure time (max). For each erasure time, refer to the Electrical Characteristics chapter.

Figure 55.17 Usage of the Multi-Block Erase Command

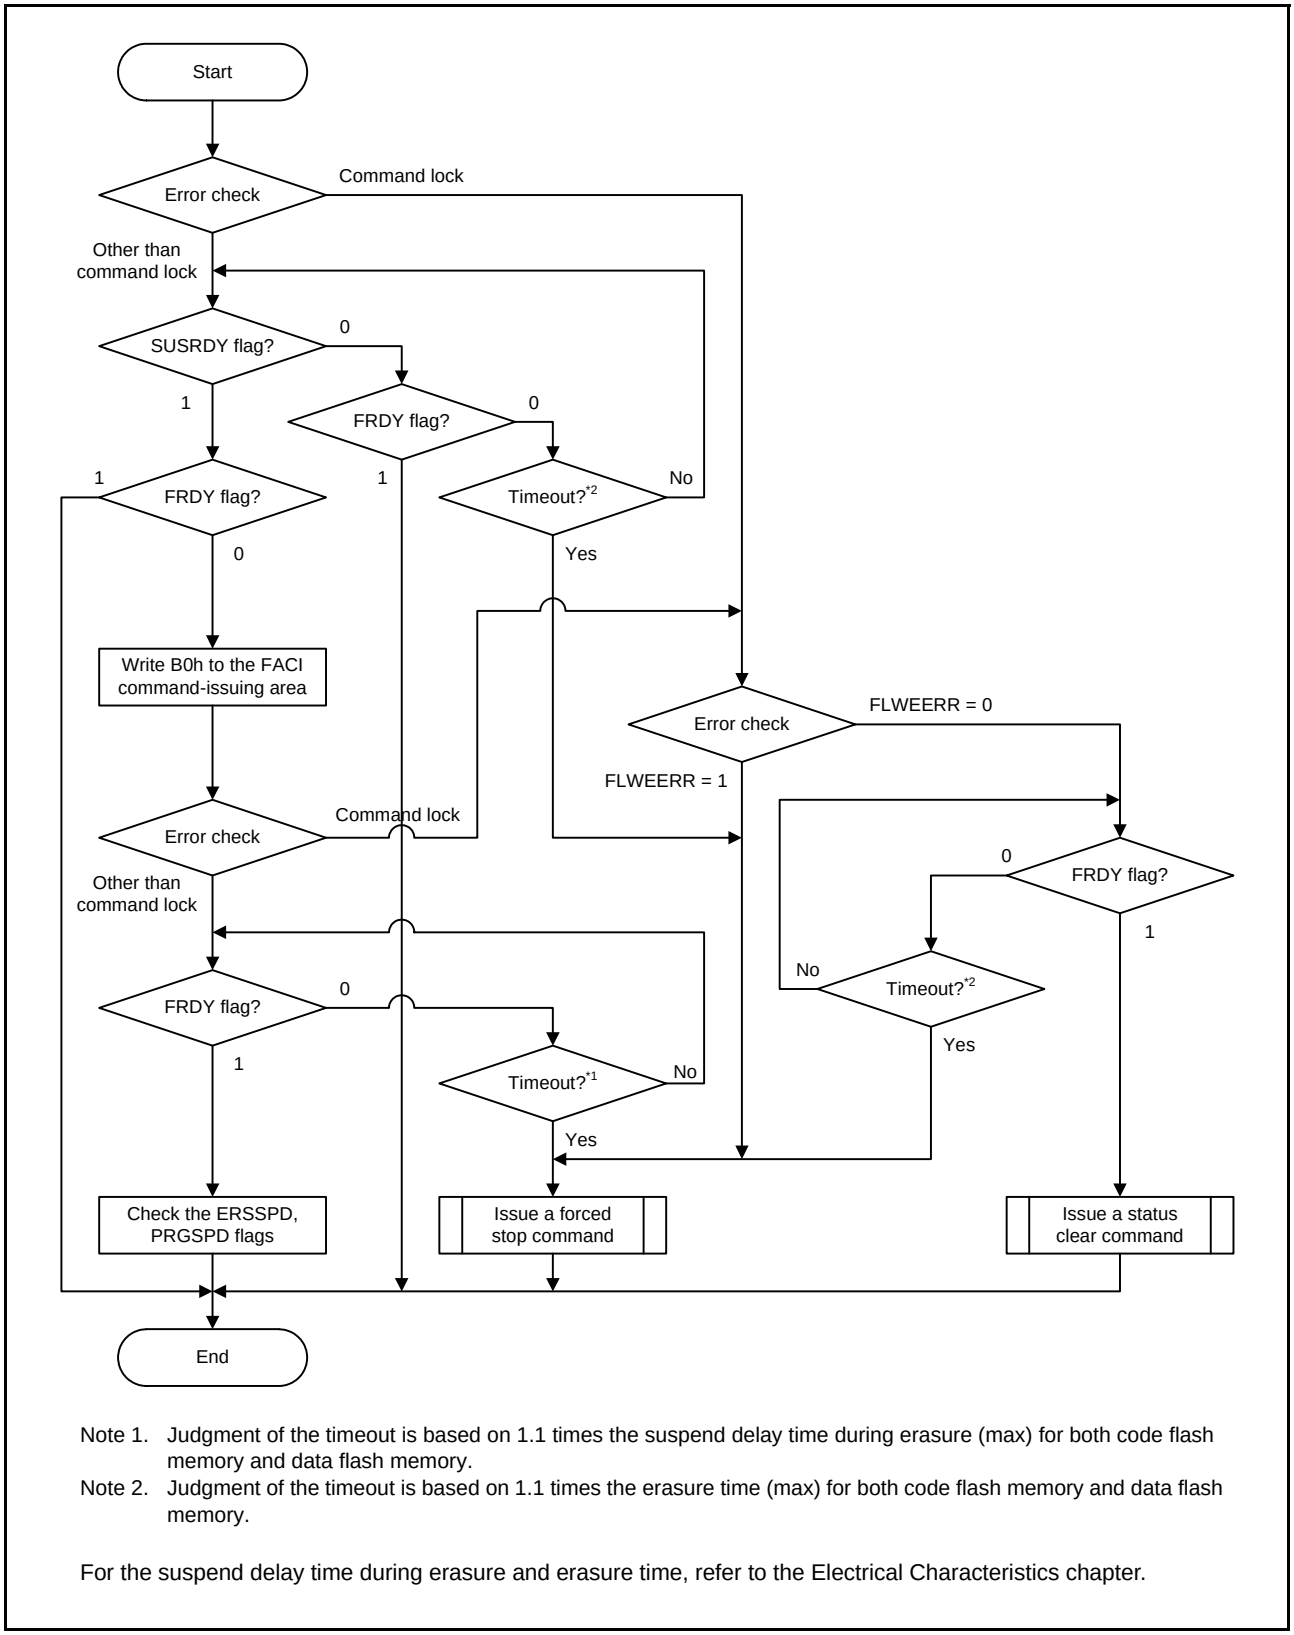
55.8.3.9 P/E Suspend Command

The P/E suspend command is used to suspend programming or erasure. Before issuing a P/E suspend command, check that the FASTAT.CMDLK flag is 0, and the execution of programming/erasure is normally performed. To confirm that the P/E suspend command can be received, also check that the FSTATR.SUSRDY flag is 1. After issuing a P/E suspend command, read the FASTAT.CMDLK flag to confirm that its value is not 1 (the flash sequencer is not in the command-locked state).

If an error occurs during programming or erasure processing, the FASTAT.CMDLK flag is set to 1. When P/E processing is completed between the FSTATR.SUSRDY flag having been confirmed to be 1 and acceptance of the P/E suspension command, the P/E suspension command is ignored and the flash sequencer does not enter the suspended state (the FSTATR.FRDY flag is 1 and the ERSSPD and PRGSPD flags in the FSTATR register are 0).

When a P/E suspend command is received and then the programming/erasure suspend processing finishes normally, the flash sequencer enters the suspended state, the FSTATR.FRDY flag is set to 1, and the ERSSPD or PRGSPD flag in the FSTATR register is 1. After issuing a P/E suspend command, check that the ERSSPD or PRGSPD flag in the FSTATR register is 1 and the suspended state is entered, and then decide the subsequent flow. If a P/E resume command is issued in the subsequent flow although the suspended state is not entered, an illegal command error occurs and the flash sequencer shifts to the command-locked state (see section 55.10.2, Error Protection).

If the erasure suspended state is entered, programming to blocks targeted for other than erasure can be performed. Additionally, the programming and erasure suspended states can shift to read mode by clearing the FENTRYR register.



Note 1. Judgment of the timeout is based on 1.1 times the suspend delay time during erasure (max) for both code flash memory and data flash memory.
Note 2. Judgment of the timeout is based on 1.1 times the erasure time (max) for both code flash memory and data flash memory.

For the suspend delay time during erasure and erasure time, refer to the Electrical Characteristics chapter.

Figure 55.18 Usage of the P/E Suspend Command

(1) Suspension during Programming

When issuing a P/E suspend command during the flash memory programming, the flash sequencer suspends programming processing. Figure 55.19 shows the suspend operation of programming. When receiving a programming-related command, the flash sequencer clears the FSTATR.FRDY flag to 0 to start programming. When the flash sequencer enters the state in which the P/E suspend command can be received after starting programming, it sets the FSTATR.SUSRDY flag to 1. When a P/E suspend command is issued, the flash sequencer receives the command and clears the FSTATR.SUSRDY flag to 0. When the flash sequencer receives a P/E suspend command while a programming pulse is being applied, the flash sequencer continues applying the pulse. After the specified pulse application time, the flash sequencer finishes pulse application, and starts the programming suspend processing and sets the FSTATR.PRGSPD flag to 1.

When the suspend processing finishes, the flash sequencer sets the FSTATR.FRDY flag to 1 to enter the programming suspended state. When receiving a P/E resume command in the programming suspended state, the flash sequencer clears the FSTATR.FRDY and FSTATR.PRGSPD flags to 0 and resumes programming.

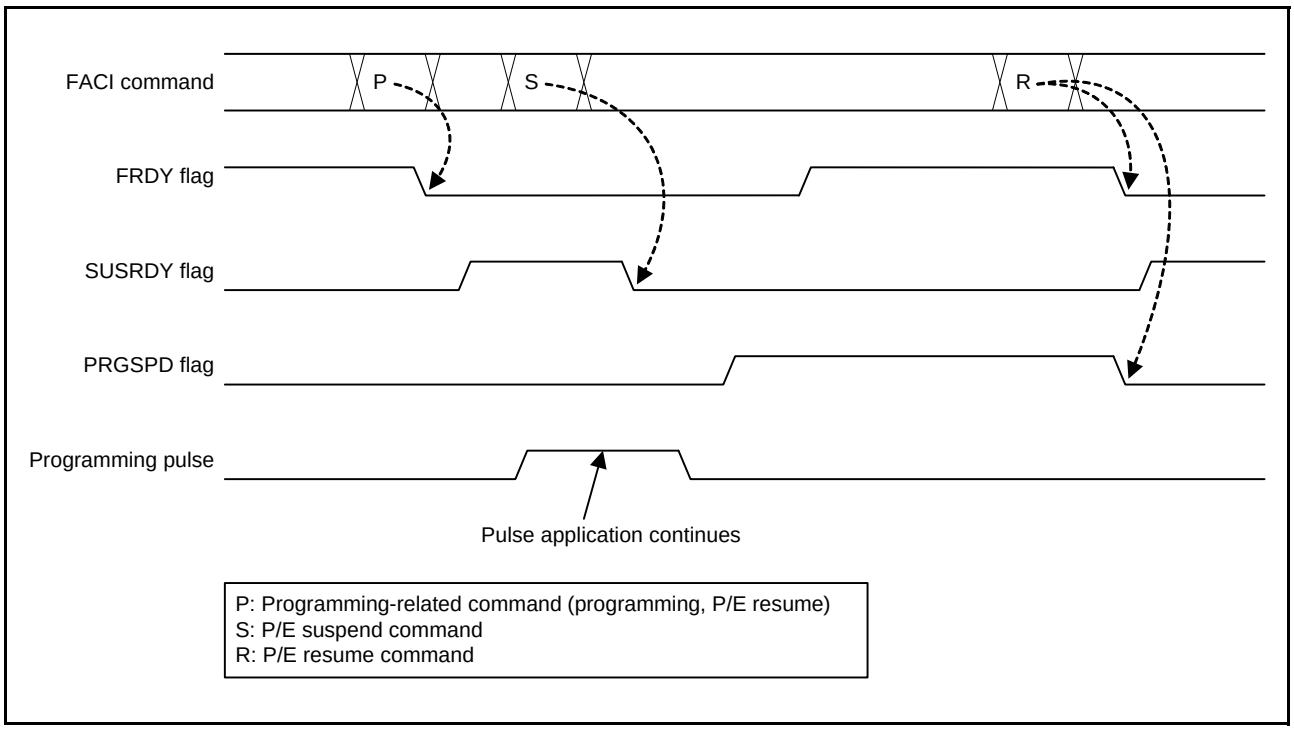


Figure 55.19 Suspension during Programming

(2) Suspension during Erasure (Suspension Priority Mode)

This MCU has a suspension priority mode for the suspension of erasure. Figure 55.20 shows the suspend operation of erasure in suspension priority mode (the FCPSR.ESUSPMD bit is 0).

When receiving an erasure-related command, the flash sequencer clears the FSTATR.FRDY flag to 0 to start erasure. When the flash sequencer enters the state in which the P/E suspend command can be received after starting erasure, it sets the FSTATR.SUSRDY flag to 1. When a P/E suspend command is issued, the flash sequencer receives the command and clears the FSTATR.SUSRDY flag to 0. When receiving a suspend command during erasure, the flash sequencer starts the suspend processing and sets the FSTATR.ERSSPD flag to 1 even if it is applying an erasure pulse. When the suspend processing is completed, the flash sequencer sets the FSTATR.FRDY flag to 1 to enter the erasure suspended state. When receiving a P/E resume command in the erasure suspended state, the flash sequencer clears the FRDY and ERSSPD flags in the FSTATR register to 0 and resumes erasure. Operations of the FRDY, SUSRDY, and ERSSPD flags in the FSTATR register at the suspension and resumption of erasure are the same, regardless of the erasure suspend mode.

The setting of the erasure suspend mode affects the control method of erasure pulses. In suspension priority mode, when receiving a P/E suspend command while erasure pulse A that has never been suspended in the past is being applied, the flash sequencer suspends the application of erasure pulse A and enters the erasure suspended state. When receiving a P/E suspend command while reapplying erasure pulse A after erasure is resumed by a P/E resume command, the flash sequencer continues applying erasure pulse A. After the specified pulse application time, the flash sequencer finishes erasure pulse application and enters the erasure suspended state. When the flash sequencer receives a P/E resume command next and erasure pulse B starts to be newly applied, and then the flash sequencer receives a P/E suspend command again, the application of erasure pulse B is suspended. In suspension priority mode, delay due to suspension can be minimized because the application of an erasure pulse is suspended one time per pulse and priority is given to the suspend processing.

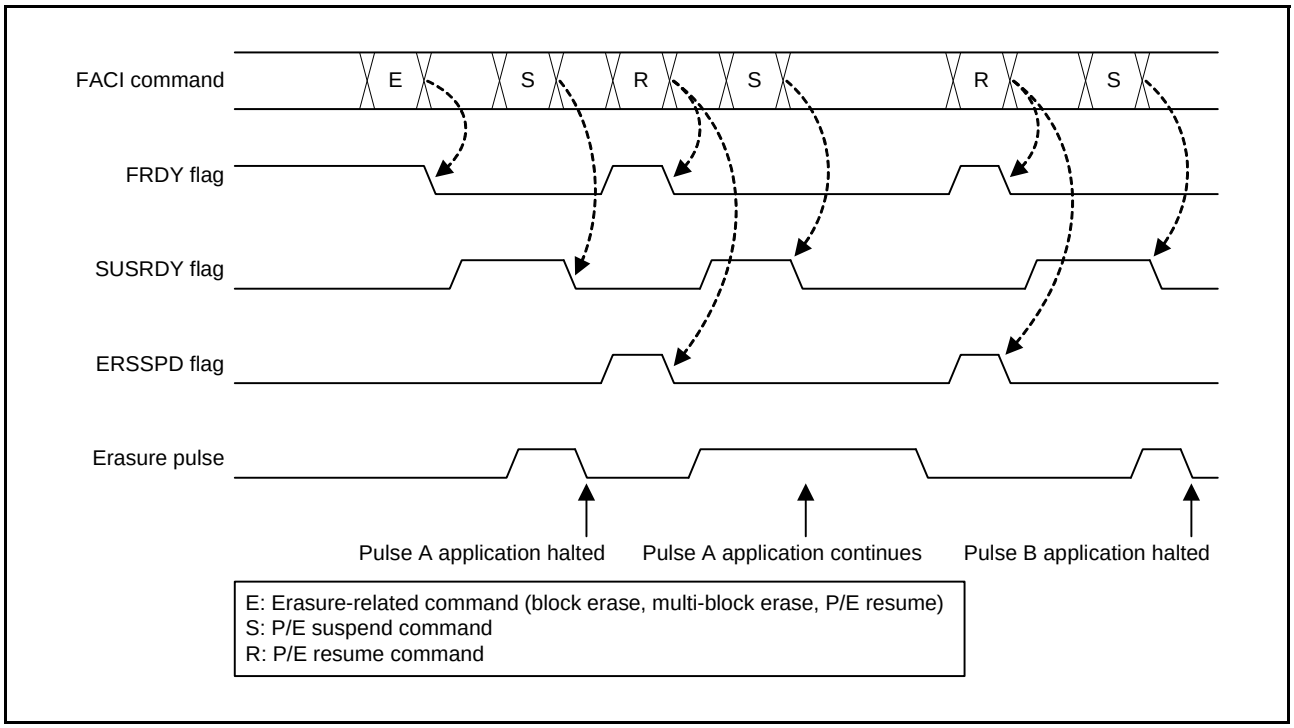

Figure 55.20 Suspension during Erasure (Suspension Priority Mode)

(3) Suspension during Erasure (Erasure Priority Mode)

This MCU has an erasure priority mode for the suspension of erasure.

Figure 55.21 shows the suspend operation of erasure when the erasure suspend mode is set to the erasure priority mode (the FCPSR.ESUSPMD bit is 1). The control method of erasure pulses in erasure priority mode is the same as that of programming pulses for the programming suspend processing.

When the flash sequencer receives a P/E suspend command while an erasure pulse is being applied, the flash sequencer definitely continues applying the pulse. In this mode, the required time for the whole erasure processing can be reduced as compared with the suspension priority mode because the reapplication of erasure pulses does not occur when a P/E resume command is issued.

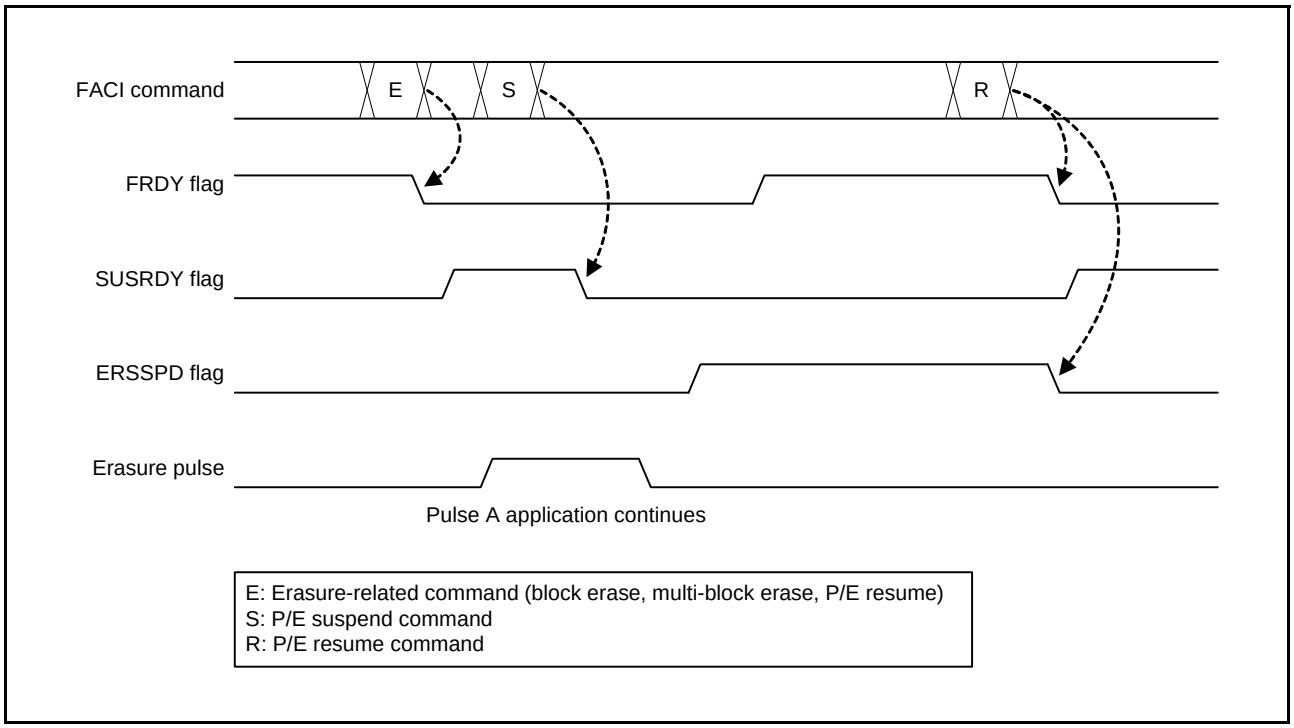

Figure 55.21 Suspension during Erasure (Erasure Priority Mode)

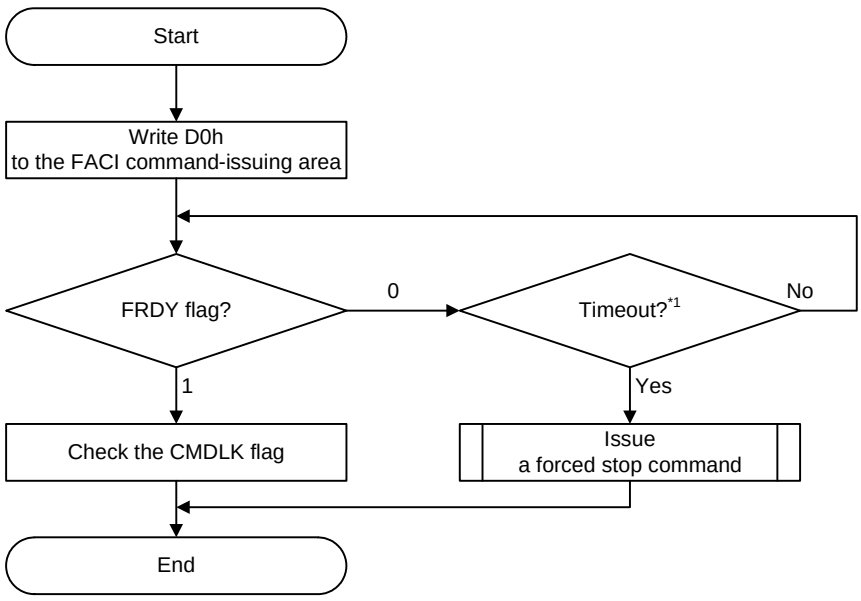
55.8.3.10 P/E Resume Command

To resume suspended programming or erasure, use the P/E resume command. When the settings of the FENTRYR register are changed during suspension, reset the setting of the FENTRYR register to the value immediately before the P/E suspend command was issued, and then issue a P/E resume command. Completion of processing of the resumed command can be confirmed by reading the FSTATR.FRDY flag.



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for halted processing of the FACI command (refer to the Electrical Characteristics chapter).

Figure 55.22 Usage of the P/E Resume Command

55.8.3.11 Status Clear Command

When one of the ILGLERR, ILGCOMERR, FESETERR, SECERR, OTERR, ERSERR, PRGERR, and FLWEERR flag bits in the FSTATR register is set to 1, the flash sequencer enters the command-locked state. When one of the CFAE and DFAE flags in the FASTAT register is set to 1, the flash sequencer also enters the command lock state. In the command-locked state, the flash sequencer can accept only status clearing command or forced end command.
The status clear command is used to clear the command-locked state (see section 55.8.3.5, Recovery from the Command-Locked State). To clear the CFAE, DFAE, and CMDLK flags in the FASTAT register, and the ILGLERR, ILGCOMERR, FESETERR, SECERR, OTEERR, ERSERR, and PRGERR flags in the FSTATR register in the command-locked state, the status clear command is available.
The FLWEERR flag cannot only be cleared by the status clearing command, but can only be cleared by the forced end command.

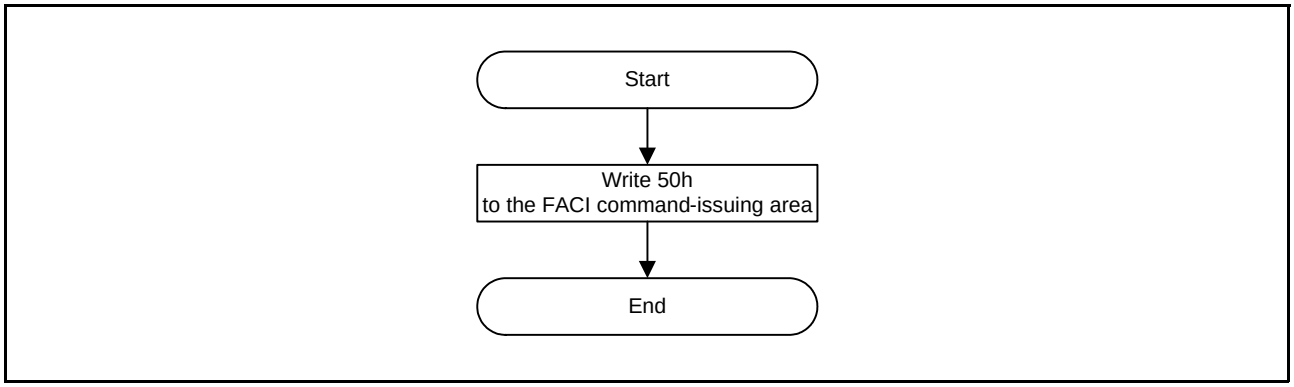


Figure 55.23 Usage of the Status Clear Command

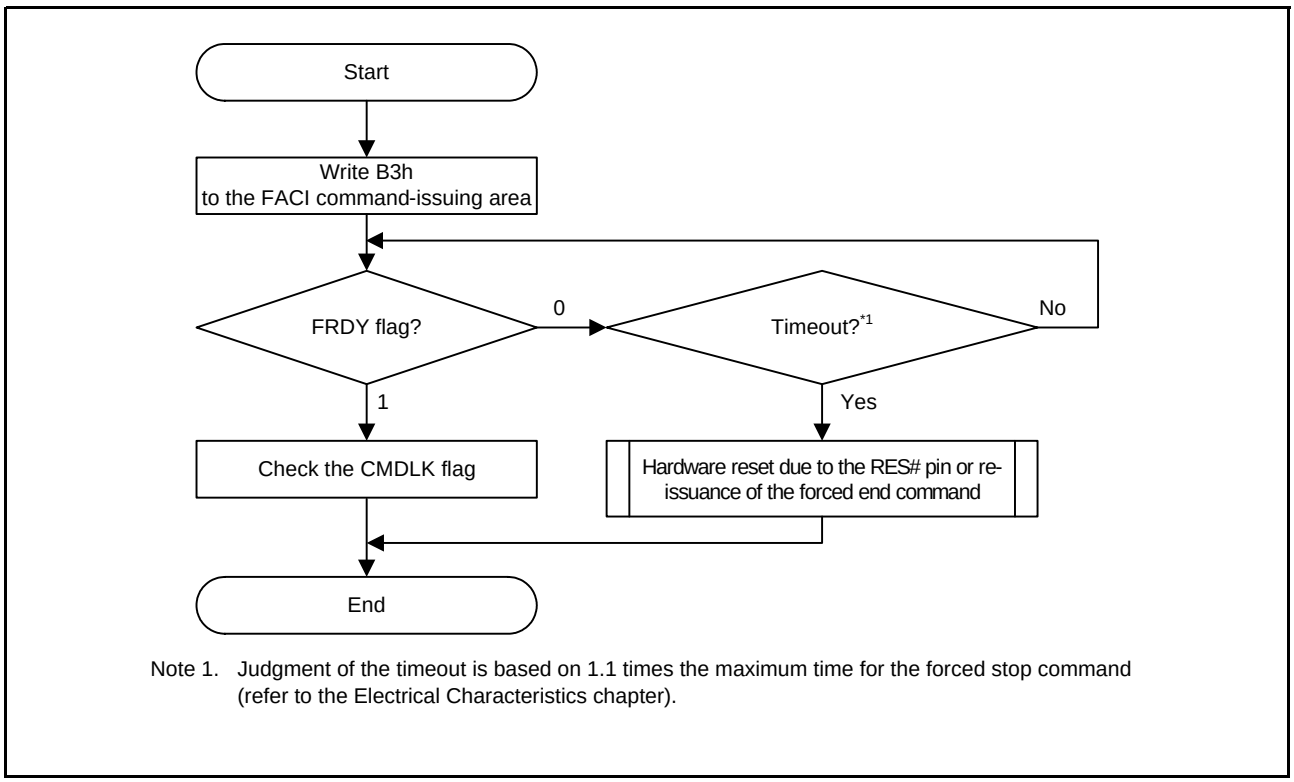
55.8.3.12 Forced Stop Command

The forced stop command forcibly ends command processing by the flash sequencer. Although this command halts command processing in higher speed than the P/E suspension command, values from the area where programming or erasure was in progress are not guaranteed. Furthermore, resumption of processing is not possible. Processing of programming or erasure that was terminated by the forced stop command is also defined as one round of programming. Executing a forced stop command also initializes the whole FCU and a part of the FACI, and the FASTAT and FSTATR registers. Accordingly, this command can be used in the procedure for recovery from the command-locked state and in processing in response to a time-out of the flash sequencer (see section 55.8.3.5, Recovery from the Command-Locked State).



Note 1. Judgment of the timeout is based on 1.1 times the maximum time for the forced stop command (refer to the Electrical Characteristics chapter).

Figure 55.24 Usage of the Forced Stop Command

How to Use the Forced Stop Command when a Command is being issued

When processing is terminated by the forced stop command while a timeout is generated based on the DBFULL bit judgment of the program command, writing to the FACI command issuing area may be handled as the data written by the program command. In this case, read the FACI command issuing area and generate a command lock intentionally, then issue the forced stop command according to the method of returning from the command lock state. A command lock can be generated although the access size for reading the FACI command issuing area is in 8-, 16-, or 32-bit units.

55.8.3.13 Blank Check Command

Values read from data flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state) are undefined. Use the blank check command when you need to confirm that an area is in the non-programmed state.

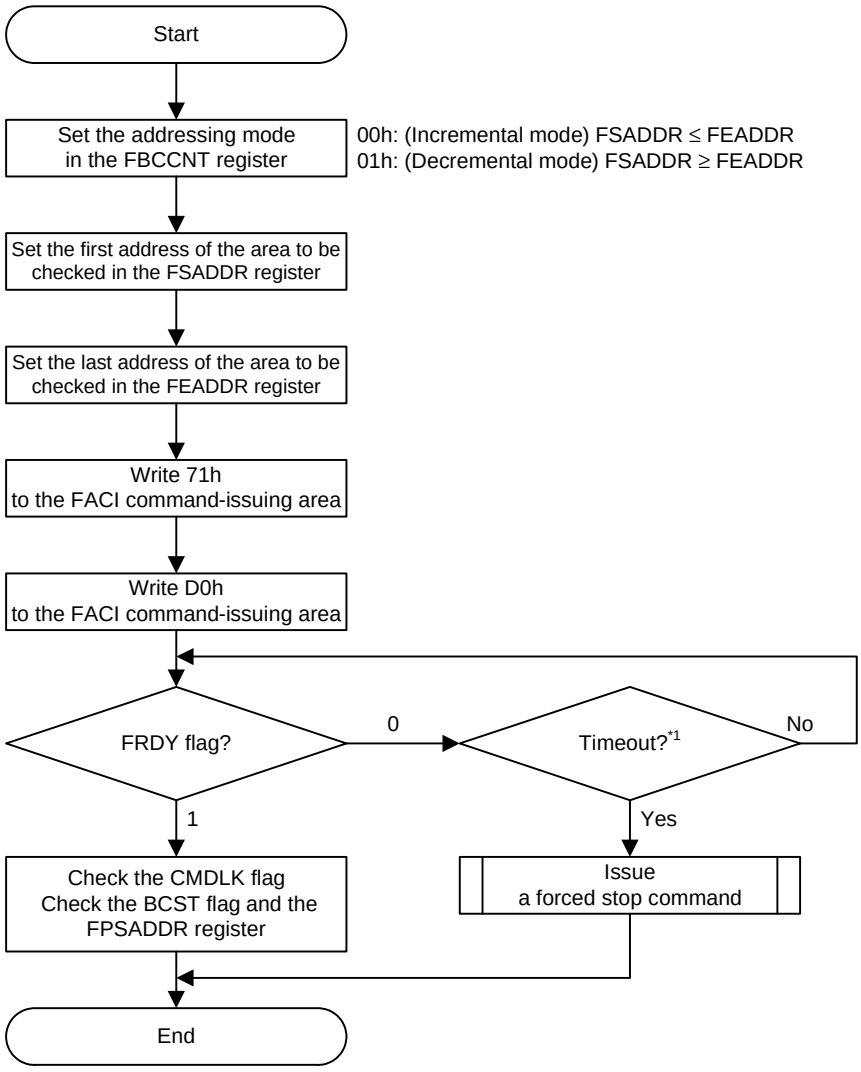
Before issuing a blank check command, set addressing mode, start and end addresses of the target area for blank checking to the FBCCNT, FSADDR, and FEADDR registers.

When the FBCCNT.BCDIR bit is 1, the value specified in the FSADDR register must be set at least the value specified in the FEADDR register.

When the FBCCNT.BCDIR bit is 0, the value specified in the FSADDR register must be the value specified in the FEADDR register or less.

When the settings of the FBCCNT.BCDIR bit, FSADDR register, and FEADDR register are inconsistent, the flash sequencer enters the command-locked state. The size of the target area for blank checking is in the range from 4 bytes to 8 Kbytes and is set in units of 4 bytes.

Write 71h and D0h to the FACI command-issuing area to start blank checking. Completion of processing can be confirmed by the FSTATR.FRDY flag. At the end of processing, the result of blank checking is stored in the FBCSTAT.BCST flag. If the target area for blank checking includes areas where programming has been completed, the flash sequencer stores the address of the programmed data that it first detected in the FPSADDR register.

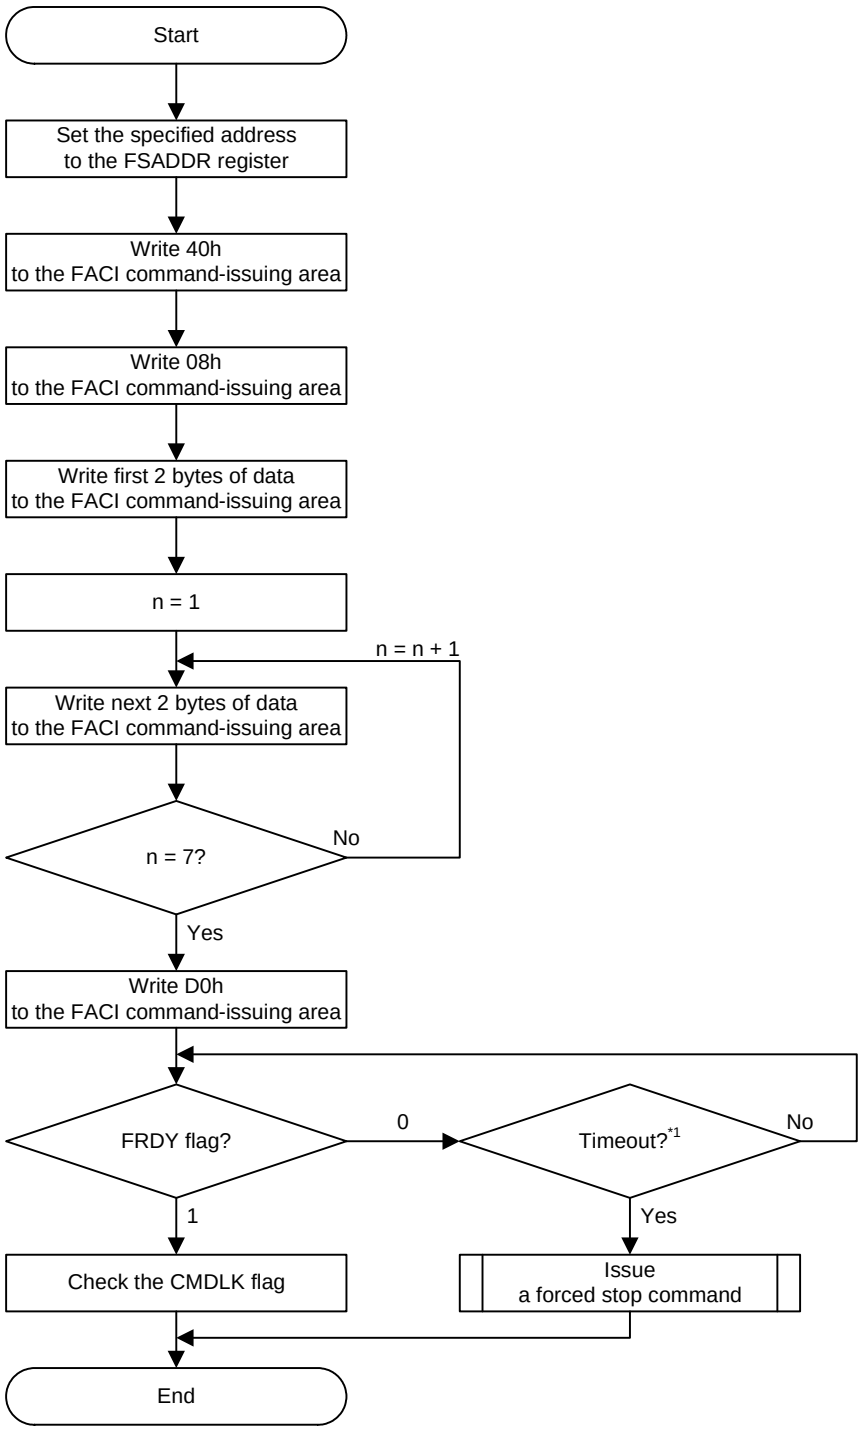


Note 1. Judgment of the timeout is based on 1.1 times the blank checking time (max.) for the entire target area. For the blank checking time, refer to the Electrical Characteristics chapter.

Figure 55.25 Usage of the Blank Check Command

55.8.3.14 Configuration Set Command

The configuration set command is used to set the option-setting memory (configuration setting area).
Before issuing a configuration set command, set the specified address (shown in Table 55.15) in the FSADDR register.
Writing D0h to the FACI command-issuing area in the final access for issuing the FACI command starts processing of the configuration set command.



Note 1. Timeout is judged to be after 185 ms (when FCLK ≥ 20 MHz), 205 ms (when FCLK = 15 MHz), or 340 ms (when FCLK = 4 MHz).

Figure 55.26 Usage of the Configuration Set Command

The correspondence between the possible target data for configuration setting and the address value set in the FSADDR register is shown in Table 55.15. For details on the FSADDR register, see section 55.4.9, FACI Command Start Address Register (FSADDR).

Table 55.15 Address Used by Configuration Set Command

Address	FSADDR Register Value	Setting Data	Operation of additional writing		Timing when the Setting is Enabled
			FAW.FSPR bit is 1	FAW.FSPR bit is 0	
FE7F 5D00h	00FF 5D00h	Option function select register 0 (OFS0), option function select register 1 (OFS1), endian select register (MDE)	Writable	Writable	At a reset
FE7F 5D10h	00FF 5D10h	TM identification data register (TMINF)	Writable	Writable	At a reset
FE7F 5D20h	00FF 5D20h	Bank select register (BANKSEL)	Writable	Writable	At a reset
FE7F 5D40h	00FF 5D40h	Serial programmer command control register (SPCC), TM enable flag register (TMEF)	Writable*1 (from 1 to 0 only)	Writable*1 (from 1 to 0 only)	When a reset or command is executed*3
FE7F 5D50h	00FF 5D50h	OCD/serial programmer ID setting register (OSIS)	Writable	Writable	At a reset
FE7F 5D64h	00FF 5D60h	Flash access window setting register (FAW)*2	Writable	Not writable*2	When a reset or command is executed
FE7F 5D70h	00FF 5D70h	ROM code protect register (ROMCODE)	Writable	Writable	At a reset

Note 1. Once these bits are set to 0, the bits cannot be restored to 1 by using the configuration setting command.
Note 2. The FAW.FSPR bit cannot be restored to 1 by using the configuration setting command once it is set to 0. Therefore, setting the access window and start-up area select flags again becomes impossible. (when the configuration setting command is issued to the address of FE7F 5D64h, the command is locked.) Exercise extra caution when handling the FAW.FSPR bit.
Note 3. The setting in the serial programmer command control register (SPCC) is enabled after a reset. The setting of the TM enable flag register (TMEF) is enabled when a reset or command is executed.

55.9 Suspend Operation

Reading from the flash memory is not possible during programming or erasure if the conditions for background operation given in Table 55.25 are not satisfied. When a P/E suspend command is issued to suspend the programming or erasure of the flash memory, reading from the flash memory is enabled. Regarding P/E suspend commands, there are one suspend command mode for programming and two suspend command modes for erasure (suspension priority mode and erasure priority mode). To resume suspended programming or erasure, the P/E resume command is available.

55.10 Protection Functions

55.10.1 Software Protection

Software protection disables programming and erasure for the flash memory through the settings of control registers. If an attempt is made to issue an FACI command against software protection, the flash sequencer enters the command-locked state.

55.10.1.1 Protection through FWEPROR

Programming cannot proceed in any mode unless the FWEPROR.FLWE[1:0] bits are set to 01b.

55.10.1.2 Protection through FENTRYR

When the FENTRYR register is set to 0000h, the flash sequencer enters read mode. In read mode, FACI commands cannot be accepted. If an attempt is made to issue an FACI command in read mode, the flash sequencer enters the command-locked state.

55.10.2 Error Protection

Error protection detects erroneous issuance of FACI commands, unauthorized access, and flash sequencer malfunction. FACI command acceptance is disabled (command-locked state) in response to the detection of these errors. The flash memory cannot be programmed or erased while the flash sequencer is in the command-locked state. For release from the command-locked state, issue a status clear or forced stop command. The status clear command can only be used while the FSTATR.FRDY flag is 1. The forced stop command can be used regardless of the value of the FSTATR.FRDY flag. Generation of a flash access error (FIFERR) interrupt detects malfunction. An FIFERR interrupt is generated under any of the following conditions.

- When the flash sequencer enters the command lock state (when the FASTAT.CMDLK flag is 1) while the FAEINT.CMDLKIE bit is 1
- When violation in access to the data flash memory occurred (the FASTAT.DFAE flag is 1) while the FAEINT.DFAEIE bit is 1
- When violation in access to the code flash memory occurred (when the FASTAT.CFAE flag is 1) while the FAEINT.CFAEIE bit is 1

When the flash sequencer enters the command-locked state in response to a command other than the P/E suspend command during programming or erasure processing, the flash sequencer continues the processing for programming or erasure. In this state, the P/E suspend command cannot be used to suspend the processing for programming or erasure. If a command is issued in the command-locked state, the ILGLERR and ILGCOMERR flags in the FSTATR register becomes 1 and the other flags retain the values set due to previous error detection.
Table 55.16 shows error protection types and status bit values after error detection.

Table 55.16 Error Protection Type (1/2)

Error Type	Description	ILGCOMERR	FESETERR	SECERR	OTERR	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE
FENTRYR setting error	The FENTRYR setting is AA81h	0	1	0	0	1	0	0	0	0	0
	The FENTRYR setting at suspension disagrees with that at resumption	0	1	0	0	1	0	0	0	0	0
Illegal command error	Access with an undefined unit was attempted in the first access by the FACI command (not writing of a byte)	1	0	0	0	1	0	0	0	0	0
	Access with an undefined code was attempted in the first access by the FACI command	1	0	0	0	1	0	0	0	0	0
	The value specified in the last access of the multiple-access FACI command is not D0h.	1	0	0	0	1	0	0	0	0	0
	The value “N” (see Table 55.11) specified in the second write access of an FACI command in the programming or configuration setting command is wrong.	1	0	0	0	1	0	0	0	0	0
	When a blank check command has been issued under one of the following conditions • When the FBCCNT.BCDIR bit is 0, and the value in FSADDR > that in FEADDR • When the FBCCNT.BCDIR bit is 1, and the value in FEADDR > that in FSADDR • The setting range of bits 16 to 0 in FEADDR is between 0 2000h and 1 FFFFh	1	0	0	0	1	0	0	0	0	0/1 *1
	When a multi-block erase command has been issued under one of the following settings. • The value in FSADDR > that in FEADDR • The setting range of bits 16 to 0 in FEADDR is between 0 2000h and 1 FFFFh	1	0	0	0	1	0	0	0	0	0/1 *1
	An FACI command not acceptable in each mode has been issued (see Table 55.12)	1	0	0	0	1	0	0	0	0	0
	Program or block erase command has been issued to the area protected by the area protection	1	0	0	0	1	0	0	0	0	0
	A program command has been issued to the area where the erasure has been suspended during the processing of erase suspension	1	0	0	0	1	0	0	0	0	0
	An FACI command has been issued when command acceptance conditions are not satisfied (see Table 55.13)	0/1 *2	0/1 *2	0/1 *2	0/1 *2	1	0/1 *2	0/1 *2	0/1 *2	0/1 *2	0/1 *2
Erasure error	An error occurs during erasure	0	0	0	0	0	1	0	0	0	0
Programming error	An error occurs during programming	0	0	0	0	0	0	1	0	0	0
Code flash memory access violation	When a program command or block erase command has been issued under the following settings in code flash memory P/E mode • The setting value of bits 23 to 0 in FSADDR is within the range from 00 0000h to DF FFFFh	0	0	0	0	1	0	0	0	1	0
	When a configuration program command has been issued under the following settings in code flash memory P/E mode • The setting value of bits 9 to 0 in the FSADDR register ranges from 000h to 0FFh, or from 180h to 3FFh	0	0	0	0	1	0	0	0	1	0

Table 55.16 Error Protection Type (2/2)

Error Type	Description	ILGCOMERR	FESETERR	SECERR	OTERR	ILGLERR	ERSERR	PRGERR	FLWEERR	CFAE	DFAE
Data flash memory access violation	When a program command or block erase command has been issued under the following settings in data flash memory P/E mode • The setting value of bits 16 to 0 in FSADDR is within the range from 0 2000h to 1 FFFFh	0	0	0	0	1	0	0	0	0	1
	When a multi-block erase command or blank check command has been issued under the following settings in data flash memory P/E mode • The setting value of bits 16 to 0 in FSADDR is within the range from 0 2000h to 1 FFFFh	1	0	0	0	1	0	0	0	0	1
Security error	When the FAW.FSPR bit is 0, a configuration setting command is issued for the settings of access window and the FAW.BTFLG bit	0	0	1	0	1	0	0	0	0	0
Others	The FACI command-issuing area has been accessed in read mode	0	0	0	1	1	0	0	0	0	0
	The FACI command-issuing area has been read in code flash memory P/E mode or data flash memory P/E mode	0	0	0	1	1	0	0	0	0	0
FLWE error	When the FACI command is processed, disable programming or erasure by using the FWEPROR register*3	0	0	0	0	0	0/1	0/1	1	0	0

Note 1. If the setting value in the FSADDR register matches the condition for violations in access to the data flash memory, the FASTAT.DFAE bit is set to 1.
Note 2. This is the value when a command is executed.
Note 3. For details on the FWEPROR register, see section 55.4.5, Flash P/E Protect Register (FWEPROR).

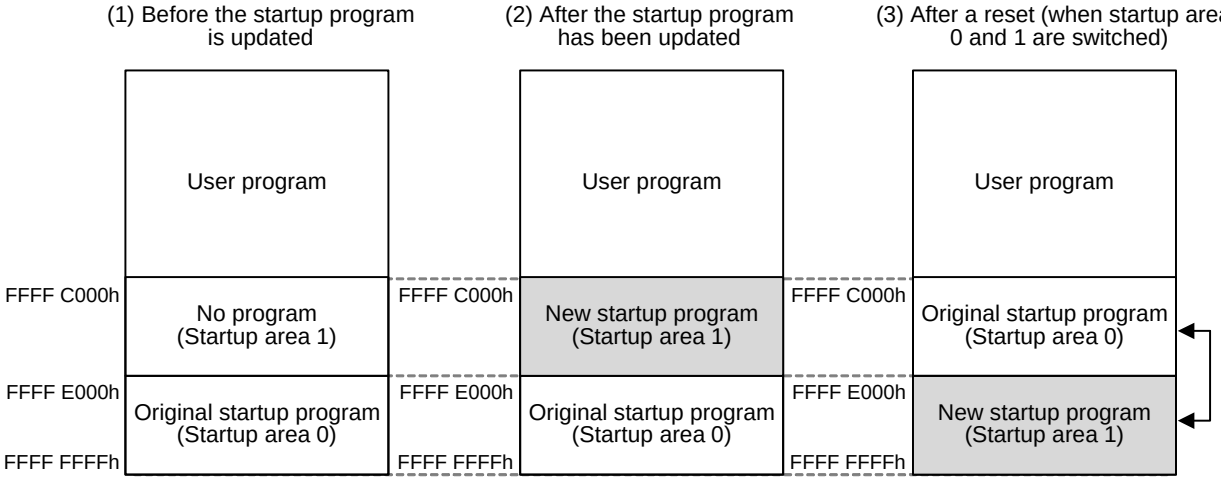
55.10.3 Start-Up Program Protection

Protection of the startup program is for protection of the program to be started after a reset (the startup program). This function provides a way to safely update the startup program when rewriting is suspended during a reset.

The startup area is 8 Kbytes in size and is assigned to the user area in the code flash memory. This function uses the values of the FAW.BTFLG bit and the FSUACR.SAS[1:0] bits to change the area where the startup program is stored in block units (see Figure 55.27 to Figure 55.30).

In protection of the startup program, the state of the selection of the startup area can be fixed by the access window protection bit (FAW.FSPR). However, the FAW.FSPR bit never be restored to 1 once the flag is set to 0. Exercise extra caution when handling the FAW.FSPR bit.

In addition, this protection cannot be used when dual mode is selected by the bank mode switching function (when the MDE.BANKMD[2:0] bits are 000b).



Note: The addresses are used for reading, programming, and erasure. Startup area 0 is erased when a block erase command is issued for the address FFFF C000h with allocation shown under (3).

(1) Before the startup program is updated
When the FAW.BTFLG bit is 1 and the SAS[1:0] bits are 0xb, the address range from FFFF C000h to FFFF DFFFh is selected as startup area 1 and the address range from FFFF E000h to FFFF FFFFh is selected as startup area 0.

(2) After the startup program has been updated
A new startup program can be written to startup area 1. At this time, startup area 0 will still contain the previous startup program, so rewriting by starting up from startup area 0 remains possible if rewriting to the startup area 1 fails.

(3) After a reset (when startup areas 0 and 1 are switched)
When rewriting startup area 1 is successfully completed, switch the assignment of startup areas 0 and 1 by rewriting the startup area selection bit (the FAW.BTFLG bit) with the configuration setting command. Afterwards, the program is started up from startup area 1 after a reset.

Figure 55.27 Concept of Protection of the Startup Program

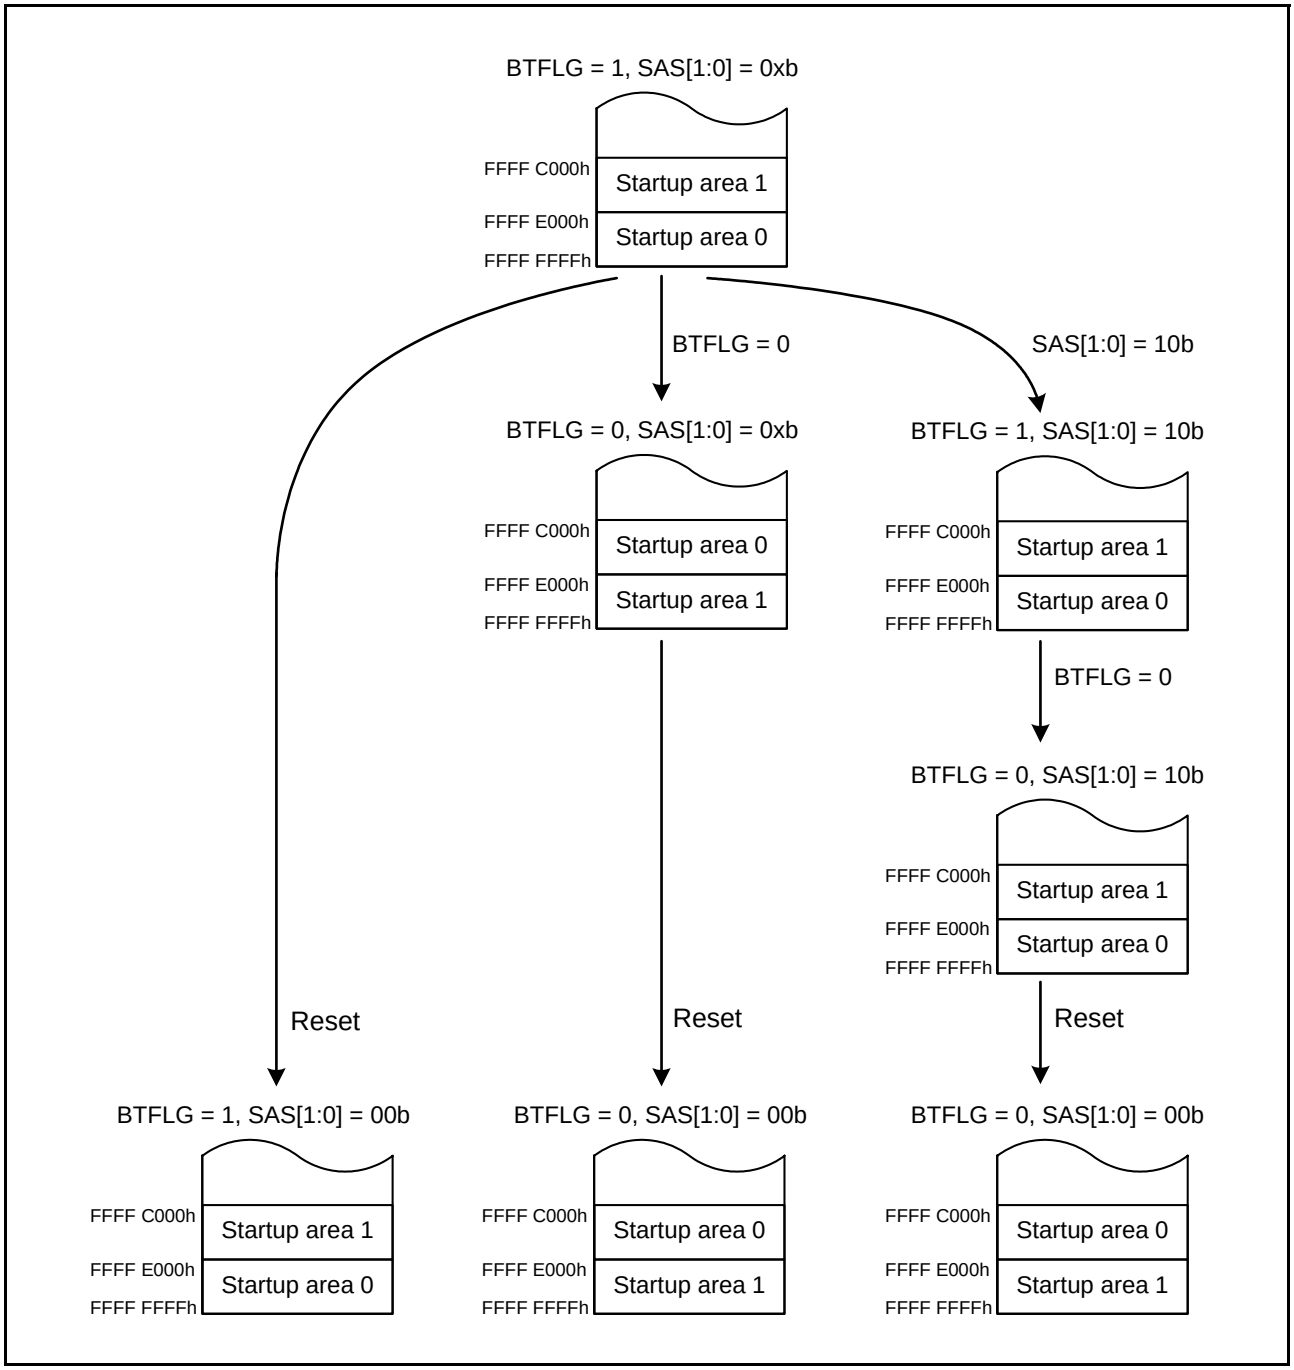


Figure 55.28 Example 1 of Transitions for Startup Program Protection Settings

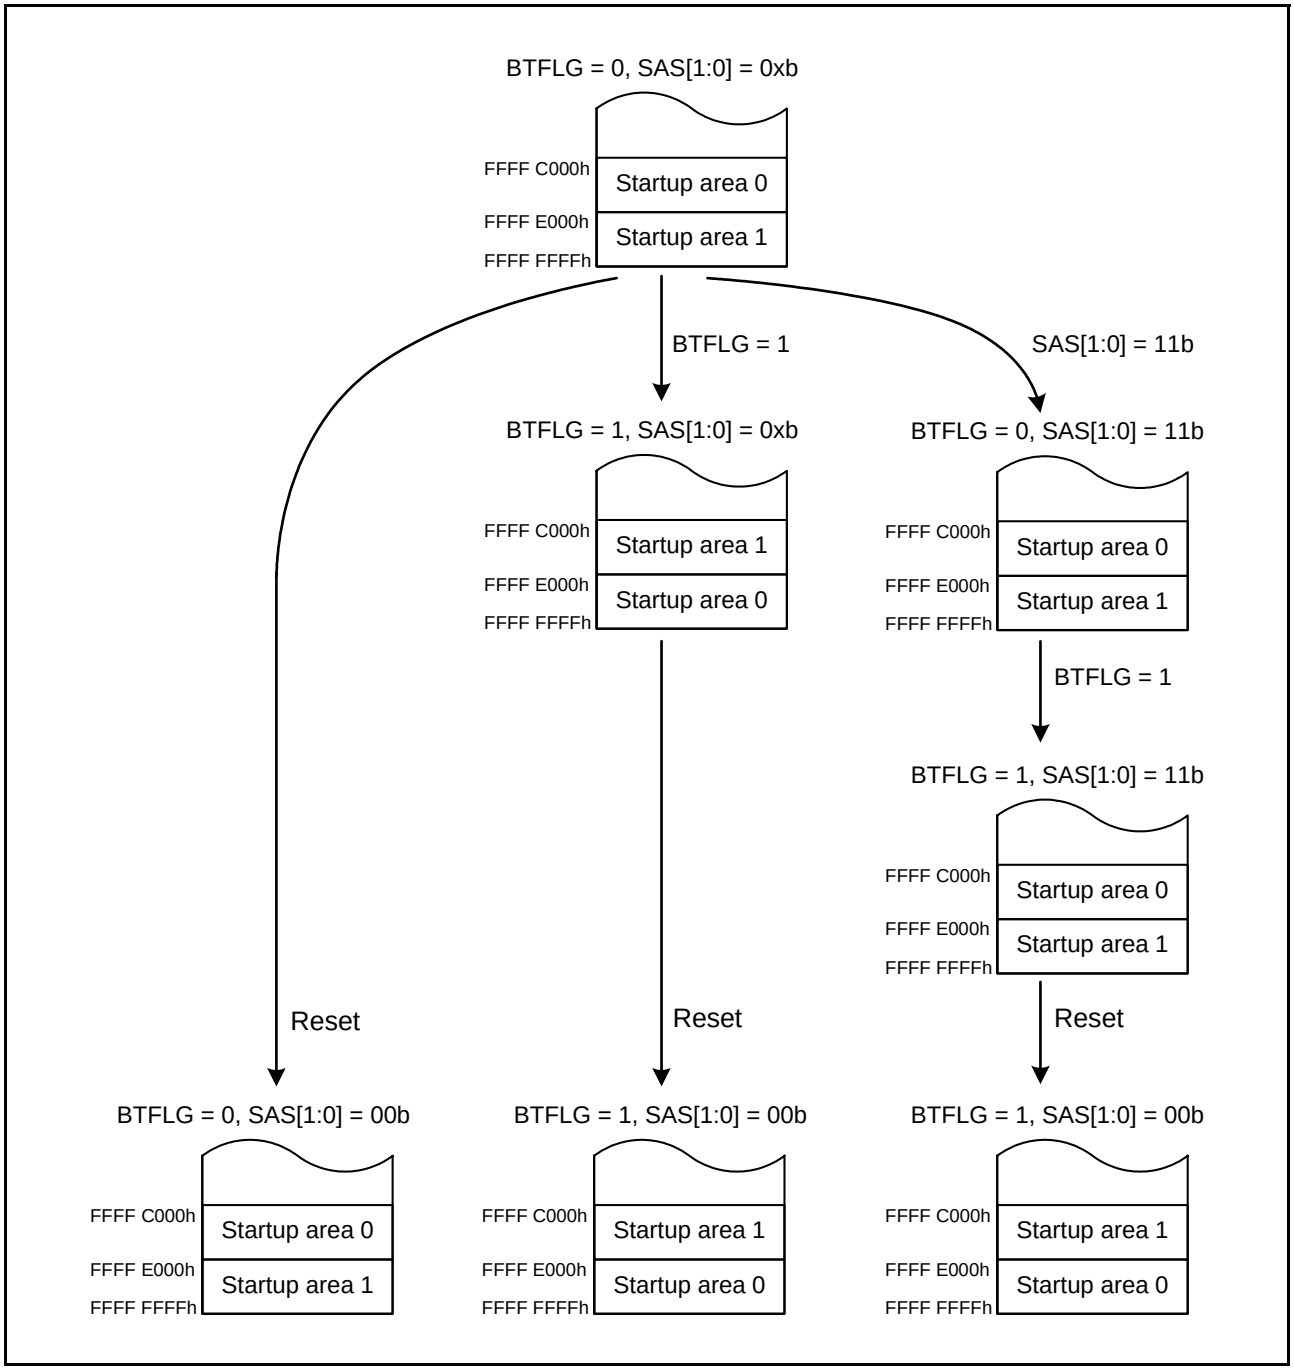

Figure 55.29 Example 2 of Transitions for Startup Program Protection Settings

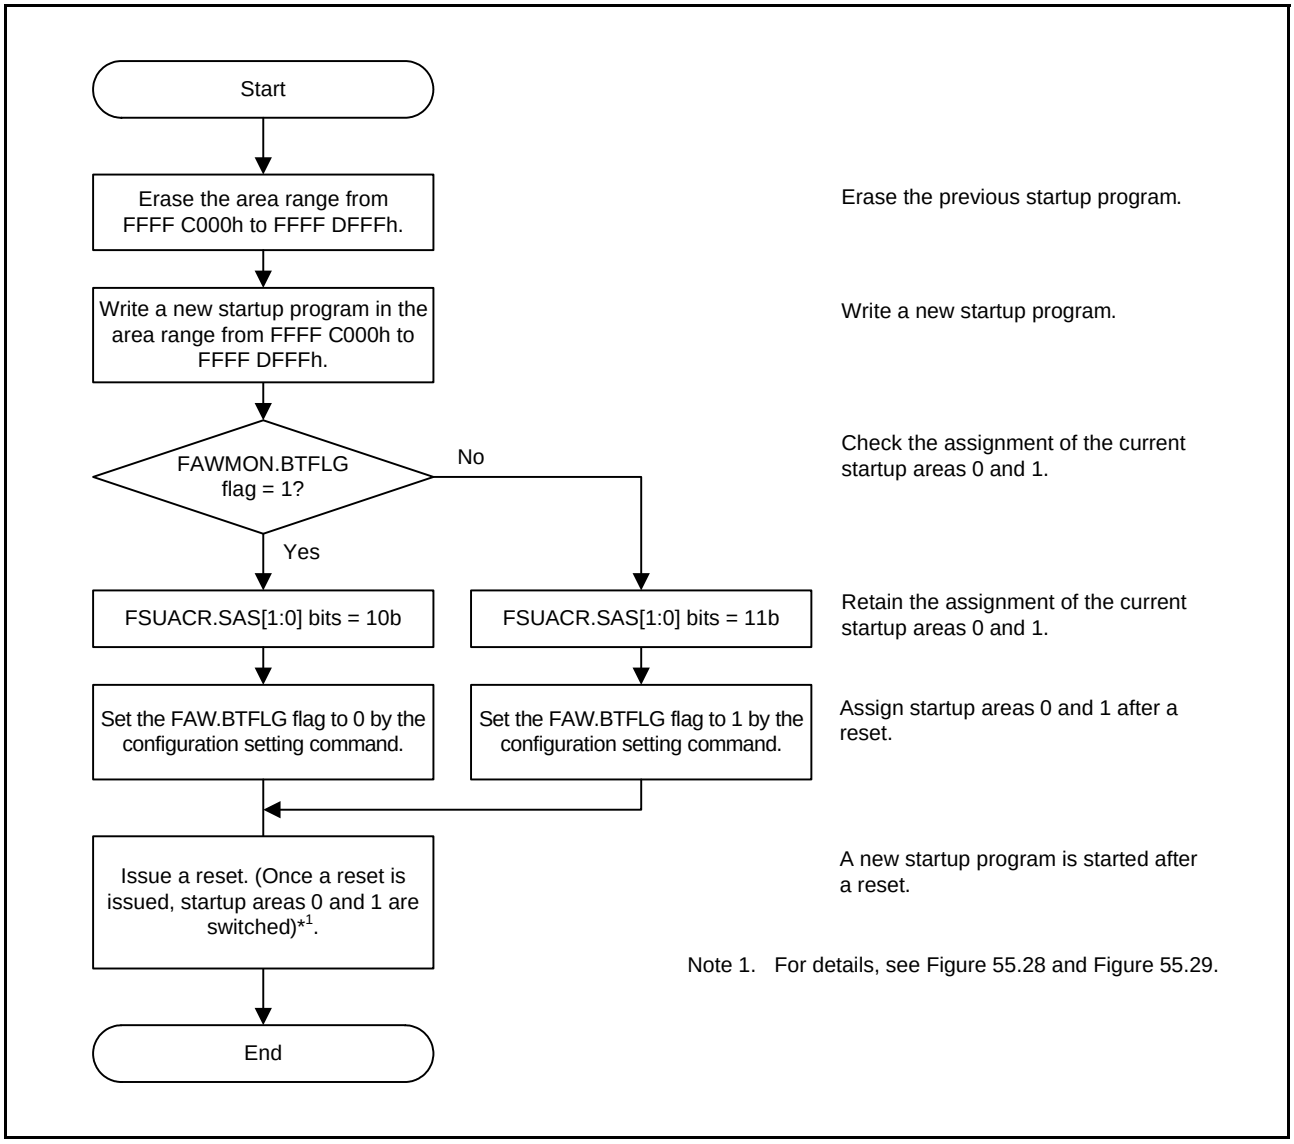

Figure 55.30 Example of Flowchart for Selecting Startup Area

55.10.4 Protection by Area Protection

Issuing an FACI command that programs or erases the area set outside the access window leads to the command-locked state. The access window is valid only in the user area of the code flash memory. The access window is valid in self-programming mode or serial programming mode.
The access window can be set in block units.
Figure 55.31 shows the Area Protection Overview.

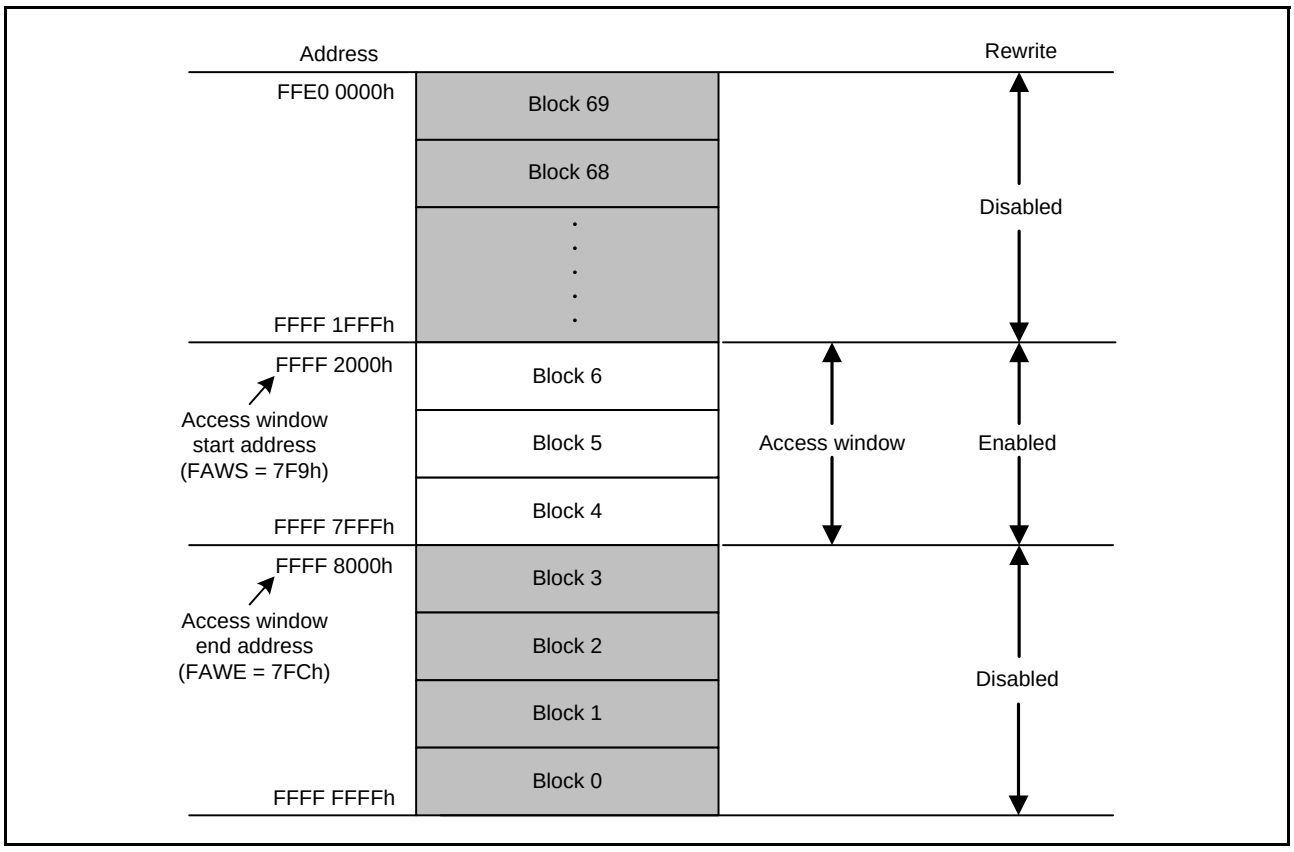

Figure 55.31 Area Protection Overview (When Blocks 4 to 6 are Set as the Access Window in Products with 2 Mbytes of Code Flash Memory)

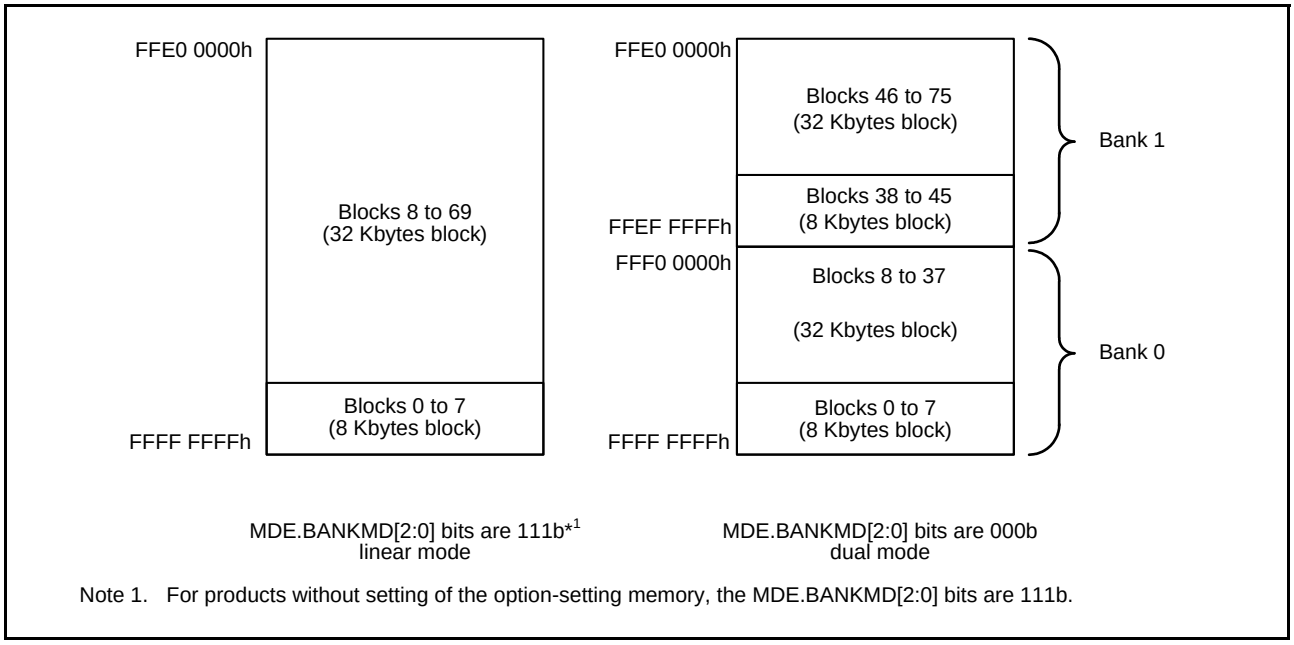
55.10.5 Dual Bank Function

This protection uses the functions of bank mode switching and startup bank selection to update a program while a user program is running and to provide a safe method of updating in cases where programming is suspended during a reset.

55.10.5.1 Switching Bank Modes

The bank mode switching function selects either linear mode in which the user area in the code flash memory is used as one area, or dual mode in which the user area is divided into two bank areas. Figure 55.32 shows an example of flow of switching bank modes. A reset after setting the MDE.BANKMD[2:0] bits in the option setting memory determines the mode of the bank mode switching function. Selecting dual mode enables the startup bank selection function.
When dual mode is selected by bank mode switching function (the MDE.BANKMD[2:0] bits are 000b), start-up program protection function cannot be used.

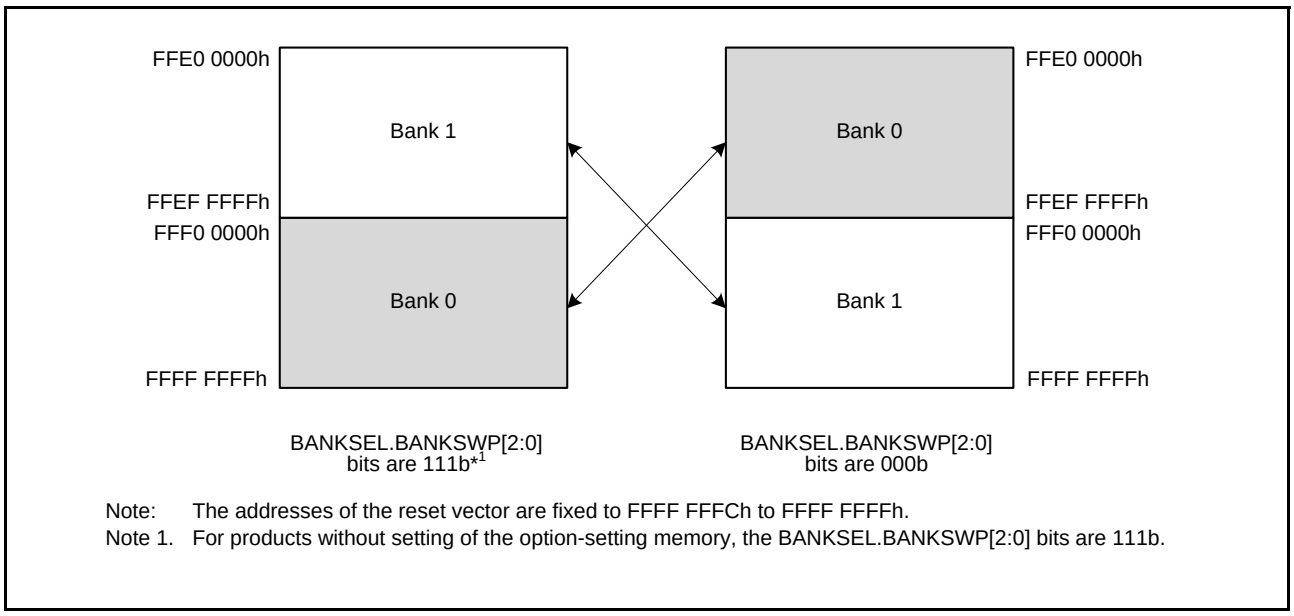


Note 1. For products without setting of the option-setting memory, the MDE.BANKMD[2:0] bits are 111b.

Figure 55.32 Example of Flow of Switching Bank Modes (For Products with 2 Mbytes of Code Flash Memory)

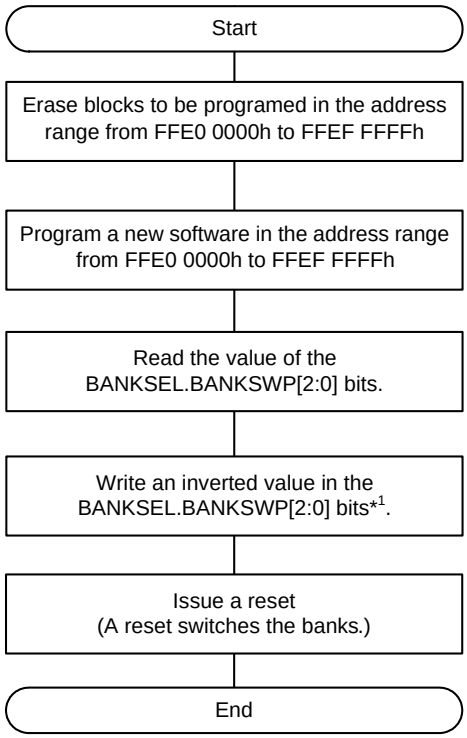
55.10.5.2 Selecting the Startup Bank

Startup bank selection provides a way to safely update the program by selecting a bank area to be started in dual mode (when the MDE.BANKMD[2:0] bits are 000b) when programming is suspended during a reset. Figure 55.33 is a schematic view of startup bank selection and Figure 55.34 shows an example of the flow of startup bank selection. A reset after setting the value of the BANKSEL.BANKSWP[2:0] bits in the option-setting memory changes the addresses of banks 0 and 1 and booting up a program proceeds from the updated area. When the address is switched by using startup bank selection, the P/E target for the FACI commands is also switched. This function is invalid in linear mode.



Note: The addresses of the reset vector are fixed to FFFF FFFCh to FFFF FFFFh.
Note 1. For products without setting of the option-setting memory, the BANKSEL.BANKSWP[2:0] bits are 111b.

Figure 55.33 Example of Startup Bank Selection (For Products with 2 Mbytes of Code Flash Memory)



Note 1. Set the inverse of the read value of the BANKSEL.BANKSWP[2:0] bits (000b or 111b).

Figure 55.34 Example of Startup Bank Selection Flow (For Products with 2 Mbytes of Code Flash Memory)

55.11 Boot Mode

There are three serial programming modes; the boot mode (SCI interface) with SCI, the boot mode (USB interface) with USB, and the boot mode (FINE interface) with FINE. Table 55.17 lists the I/O pins used in boot mode.

Table 55.17 I/O Pins Used in Boot Mode

Pin Name	I/O	Mode to be Used	Use
MD	Input	Boot mode (SCI interface) Boot mode (USB interface)	Selection of operating mode
PC7/UB	Input		Selection of boot mode (SCI interface) or boot mode (USB interface)
P30/RXD1	Input	Boot mode (SCI interface)	For host communication (to receive data through SCI)
P26/TXD1	Output		For host communication (to transmit data through SCI)
USB0_DP, USB0_DM	I/O	Boot mode (USB interface)	Data input/output of USB
P16/USB0_VBUS	Input		Detection of connection and disconnection of USB cables
P35/UPSEL	Input		Selection of USB bus-powered mode or self-powered mode
MD/FINED	I/O	Boot mode (FINE interface)	Selection of operating mode, FINE data I/O

55.11.1 Boot Mode (SCI Interface)

In boot mode (SCI interface), the host sends control commands and data for programming, and the flash memory is programmed or erased accordingly. An on-chip SCI handles transfer between the host and this MCU in asynchronous mode. Tools for transmission of control commands and the data for programming must be prepared in the host.
When this MCU is activated in boot mode (SCI interface), the program on the dedicated area the MCU is executed. The boot program automatically adjusts the bit rate of the SCI and controls programming/erasure by receiving control commands from the host.
Figure 55.35 shows the system configuration for operations in boot mode (SCI interface).

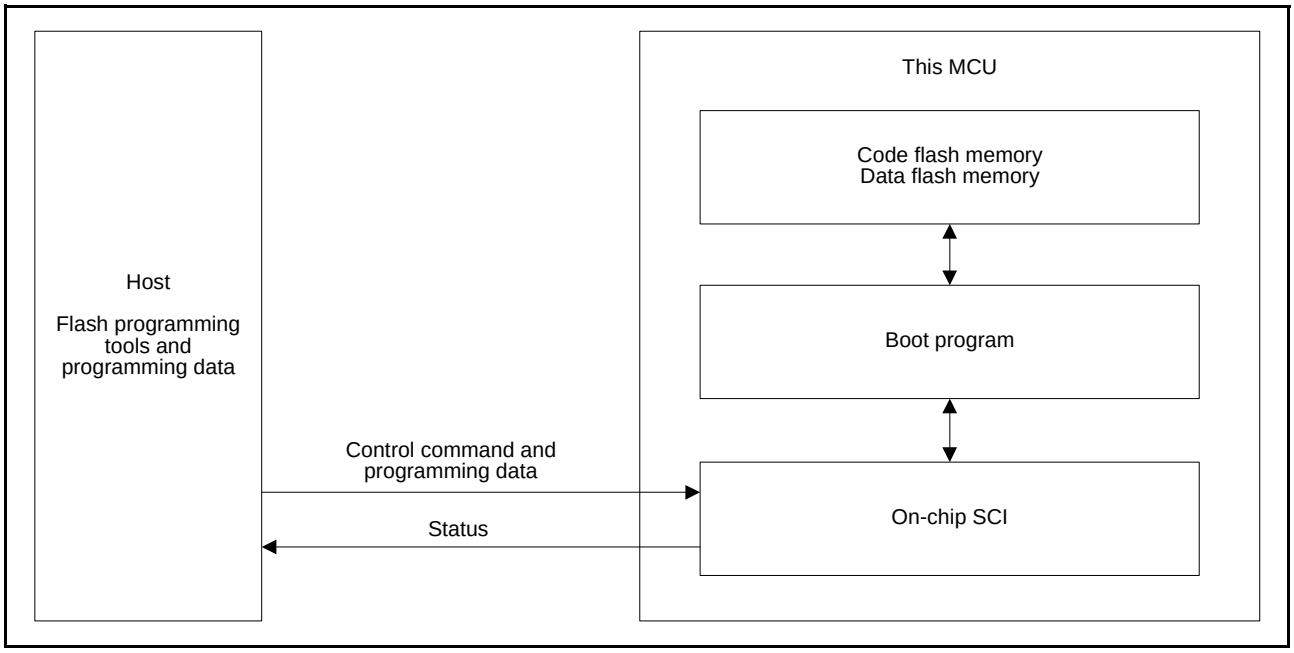


Figure 55.35 System Configuration for Operations in Boot Mode (SCI Interface)

55.11.2 Boot Mode (USB Interface)

In boot mode (USB interface), the flash memory can be programmed or erased by sending control commands and program data from the host. An on-chip USB is used for communications between the host and this MCU. The host requires tools for sending control commands and data for programming. Figure 55.36 shows the configuration of a system for use in boot mode (USB interface).

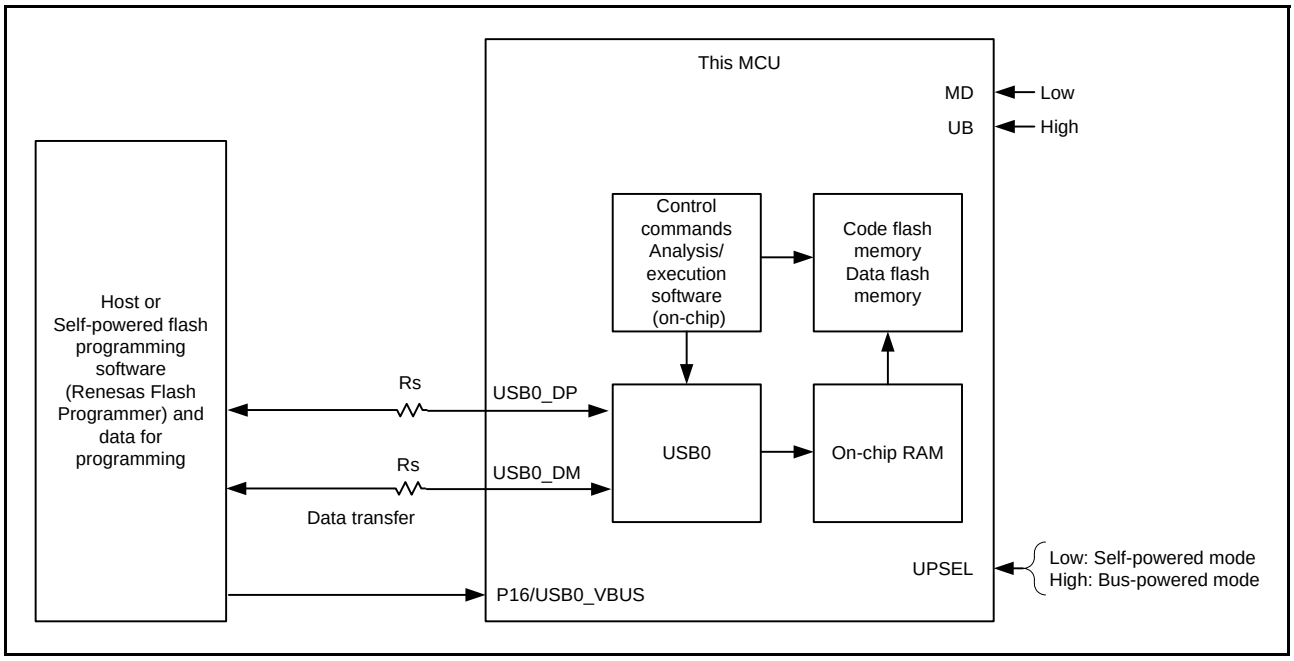

Figure 55.36 System Configuration in Boot Mode (USB Interface)

In boot mode (USB interface), self-powered mode or bus-powered mode is selected for operation. Release from the reset state while the low level is being applied to the MD and UPSEL pins and the high level is being applied to the UB pin selects self-powered mode. Release from the reset state while the low is being applied to the MD pin and the high level is being applied to the UB and UPSEL pins are high selects bus-powered mode.
Table 55.18 shows the enumeration information for each mode, and Table 55.19 shows the device class information.

Table 55.18 Enumeration Information

USB Specification	Ver.2.0 (Full-Speed)	
Maximum current	Self-powered mode (pins P35 and UPSEL = Low)	100 mA
	Bus-powered mode (pins P35 and UPSEL = High)	500 mA

Table 55.19 Device Class Information

Device Class	Communication Device Class (CDC)
Sub class	Abstract Control Model (ACM)

55.11.3 Boot Mode (FINE Interface)

The flash memory can be programmed and erased using the FINE in boot mode (FINE interface). The flash memory can be rewritten.

55.11.3.1 Operating Conditions in Boot Mode (FINE Interface)

FINE is used to communicate with the serial programmer in boot mode (FINE Interface).
Figure 55.37 shows an Example of Pin Connections in Boot Mode (FINE Interface). Table 55.20 lists Pin Handling in Boot Mode (FINE Interface).
The example of pin connections shown in Figure 55.37 is a simplified circuit. Operations are not guaranteed in all systems.

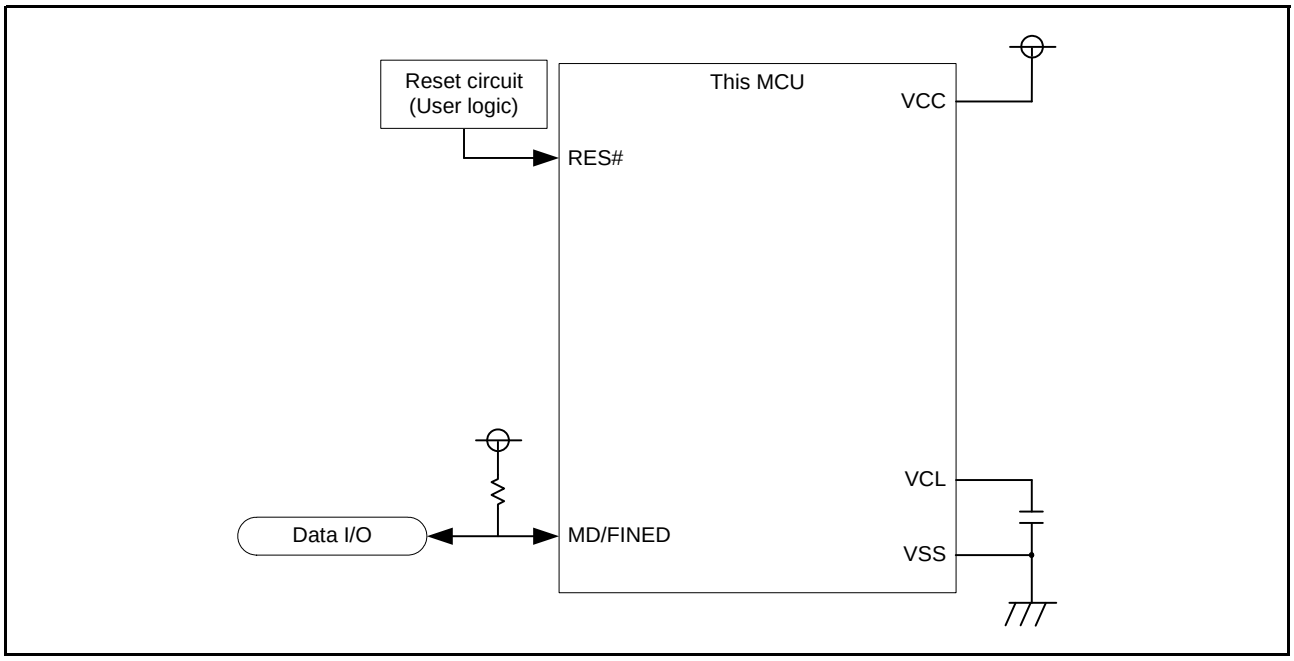

Figure 55.37 Example of Pin Connections in Boot Mode (FINE Interface)

Table 55.20 Pin Handling in Boot Mode (FINE Interface)

Pin Name	Name	I/O	Function
VCC, VSS	Power supply input	Input	Input 2.7 V or higher to the VCC pin. Input 0 V to the VSS pin.
VCL	Decoupling capacitor connect pin	—	Connect to the VSS pin via a 0.22-µF multilayer ceramic capacitor for stabilizing the internal voltage.
MD	Operating mode control/ data I/O	I/O	Connect the VCC pin via a resistor (pull up).
RES#	Reset input	Input	Reset pin. Connect to the reset circuit.

55.12 On-Chip Debugger ID Code Protection

This function is used to prohibit connection with the on-chip debugger (OCD). When an OCD is connected, the ID code of the OSIS register, which is written on the option-setting memory, is used for judging the ID codes.
The ID code sent from the OCD is judged if it matches the ID code in the OSIS register. If the codes match, connection with the OCD proceeds. If they do not match, the OCD cannot be connected.

55.13 Serial Programmer ID Code Protection

This function is used to prohibit connection with the serial programmer. When a serial programmer is connected, the control and ID codes of the OSIS register, which are written on the option-setting memory, are used for judgment of the ID codes.
Control or ID codes sent from serial programmers are checked to see if they match the control or ID code in the OSIS register. If the codes match, connection to the serial programmer proceeds. If they do not match, connection with the serial programmer does not proceed. If the control code is 45h and the codes do not match three times in a row, all data in the flash memory are erased.*1

Note 1. When the FAW.FSPR bit is 0, data in the flash memory are not erased.

55.14 ROM Code Protection

ROM code protection is a function to prohibit reading from or programming/erasure to the flash memory when the parallel programmer is used.
For details, see section 7.2.10, ROM Code Protection Register (ROMCODE).

55.15 Boot Mode Communications Protocol

This section describes the communications protocol for use in boot mode. When developing a serial programmer, use this communications protocol to control it.

55.15.1 How to Start the Chip Up in Boot Mode

(1) How to Start the Chip Up in Boot Mode (SCI Interface)

The chip starts up in boot mode (SCI interface) if both the MD and UB pins are at the low level on release from the reset state (i.e. when the level on the RES# pin changes from low to high). A waiting time of at least 400 ms is required while the RES# pin is held at the high level after the chip starts up in boot mode (SCI interface) until communications with the MCU can proceed.

Figure 55.38 shows the states of pins up to communications in boot mode (SCI interface) becoming possible.

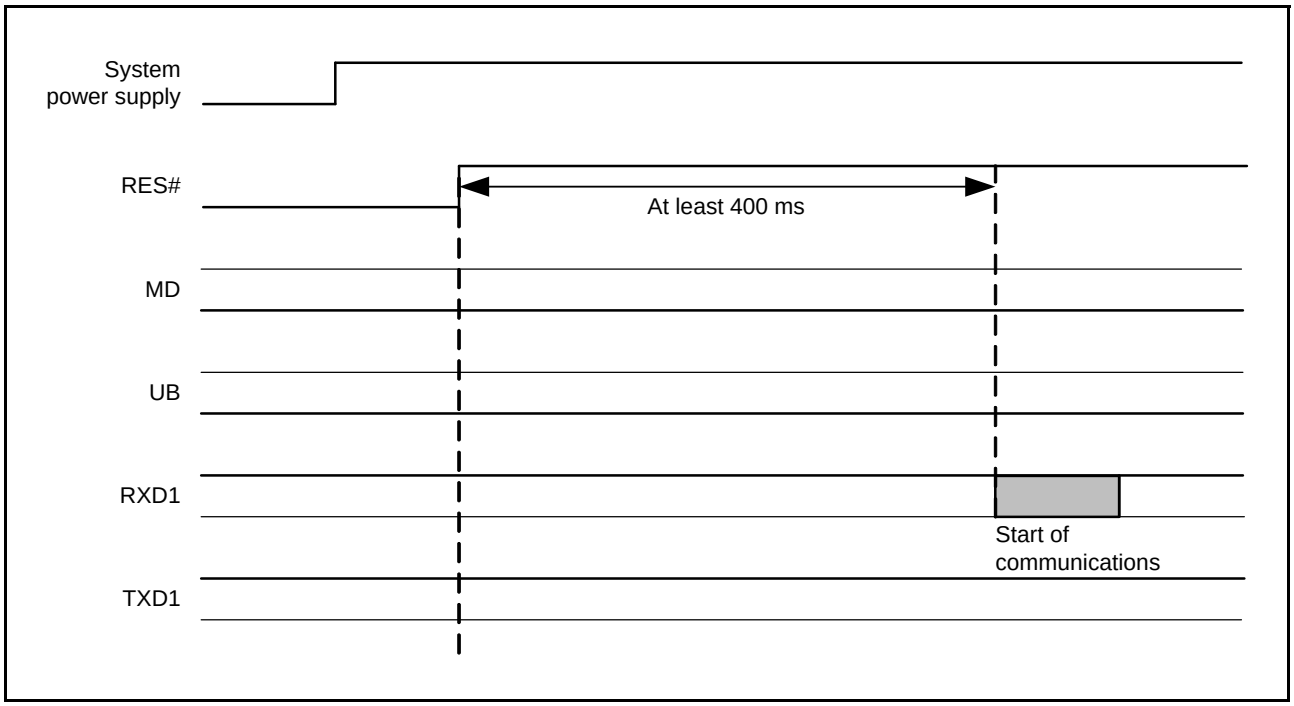

Figure 55.38 States of Pins Up to Communications in Boot Mode (SCI Interface) Becoming Possible

(2) How to Start the Chip Up in Boot Mode (USB Interface)

The chip starts up in boot mode (USB interface) if the MD pin is at the low level and UB pin is at the high level on release from the reset state (i.e. when the level on the RES# pin changes from low to high).

55.15.2 State Transitions in Boot Mode

55.15.2.1 State Transitions in Boot Mode (SCI Interface)

Figure 55.39 shows a flowchart for transition to boot mode (SCI interface).

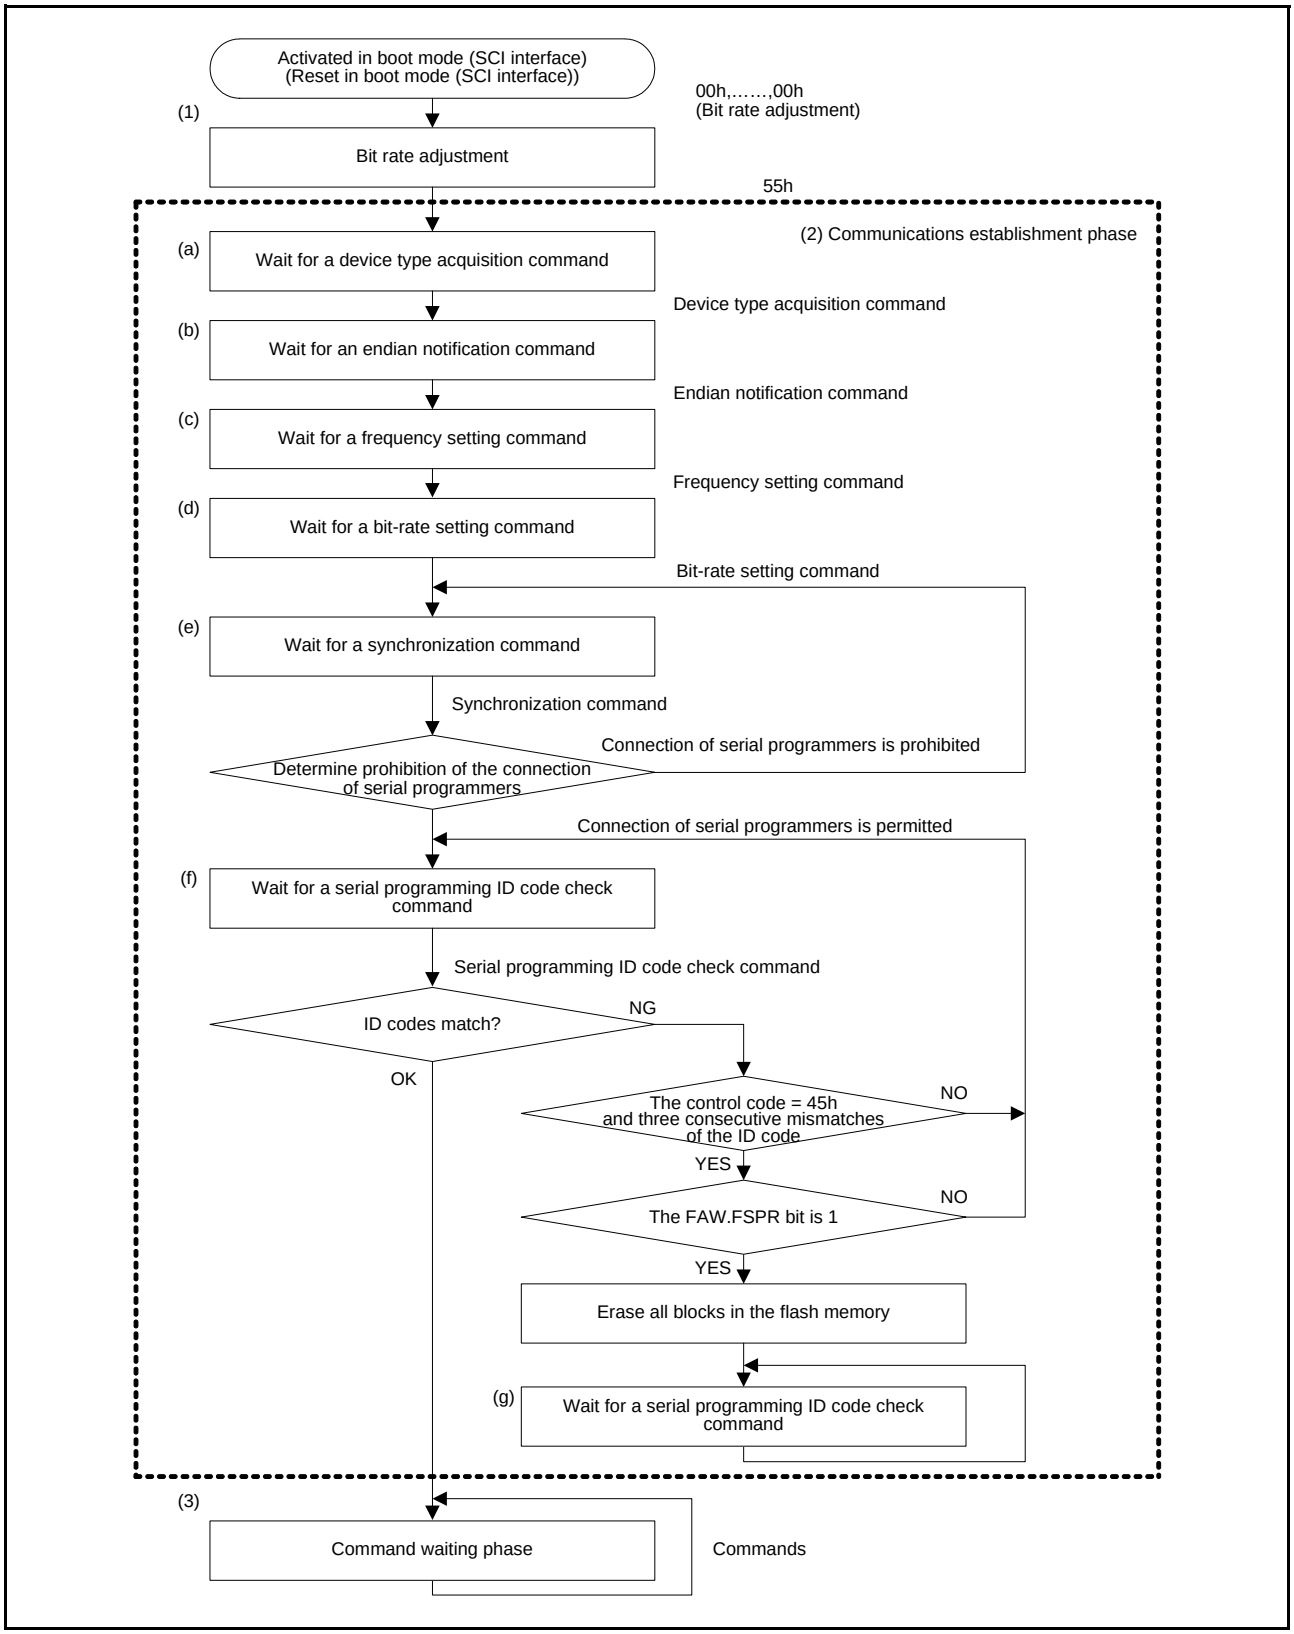

Figure 55.39 Flowchart for Transition to Boot Mode (SCI Interface)

(1) Matching the bit rates

When this MCU is activated in boot mode, the bit rate of the SCI is automatically adjusted to match that of the host. On completion of this automatic bit rate adjustment, this MCU transmits the value 00h to the host. On subsequent correct reception of the value 55h sent from the host, this MCU enters the communications establishment phase. For details on matching of the bit rates, see section 55.15.3, Automatic Adjustment of the Bit Rate.

(2) Communications establishment phase

The device, endian, frequency, and bit rate are selected in this phase. In this phase, the serial programmer ID code protection is judged. For the commands to use in the communications establishment phase, see section 55.15.5, Communications Establishment Phase.

(a) Waiting for a device type acquisition command

In this state, the MCU is waiting for a device type acquisition command to be sent from the host. When it receives a device type acquisition command, the state shifts to waiting for an endian notification command. For details of the device type acquisition command, see section 55.15.9, Device Type Acquisition Command.

(b) Waiting for an endian notification command

In this state, the MCU is waiting for an endian notification command to be sent from the host. When it receives an endian notification command, the state shifts to waiting for a frequency setting command. For details of the endian notification command, see section 55.15.10, Endian Notification Command.

(c) Waiting for a frequency setting command

In this state, the MCU is waiting for a frequency setting command to be sent from the host. When it receives a frequency setting command, the state shifts to waiting for a bit-rate setting command. For details of the frequency setting command, see section 55.15.11, Frequency Setting Command.

(d) Waiting for a bit-rate setting command

In this state, the MCU is waiting for a bit-rate setting command to be sent from the host. When it receives a bit-rate setting command, the state shifts to waiting for a synchronization command. For details of the bit-rate setting command, see section 55.15.12, Bit-Rate Setting Command.

(e) Waiting for a synchronization command

In this state, the MCU is waiting for a synchronization command to be sent from the host. When it receives a synchronization command, it transitions to the waiting state of the serial programming ID code check command. If the MCU has been set to prohibit the connection of a serial programmer, this MCU transmits an error code to indicate that connecting a serial programmer is prohibited and remains in the state of waiting for a synchronization command. For details of the synchronization command, see section 55.15.13, Synchronization Command.

(f) Waiting for a serial programming ID code check command

Wait for the serial programming ID code check command to be sent from the host. The control code or ID code that was sent is compared with the control code or ID code in the OSIS register. The device enters the command waiting phase if they match. If they do not match, the next transition is back to the state of waiting for a serial programming ID code check command.
If the control code is 45h and the codes do not match three times in a row, all data in the flash memory are erased.*1
For details of the ID code check command, see section 55.15.15, Serial Programming ID Code Check Command.

Note 1. When the FAW.FSPR bit is 0, the blocks in those areas are not erased.

(g) Waiting for a serial programming ID code check command (after erasure)

After all blocks in the flash memory are erased, reboot the MCU in boot mode.

(3) Phase of waiting for commands

In this state, programming and erasure proceed in accord with commands from the host. For details of the commands that can be issued in the command waiting phase, see section 55.15.6, Command Waiting Phase.

55.15.2.2 State Transitions in Boot Mode (USB Interface)

Figure 55.40 shows a flowchart for transition to boot mode (USB interface).

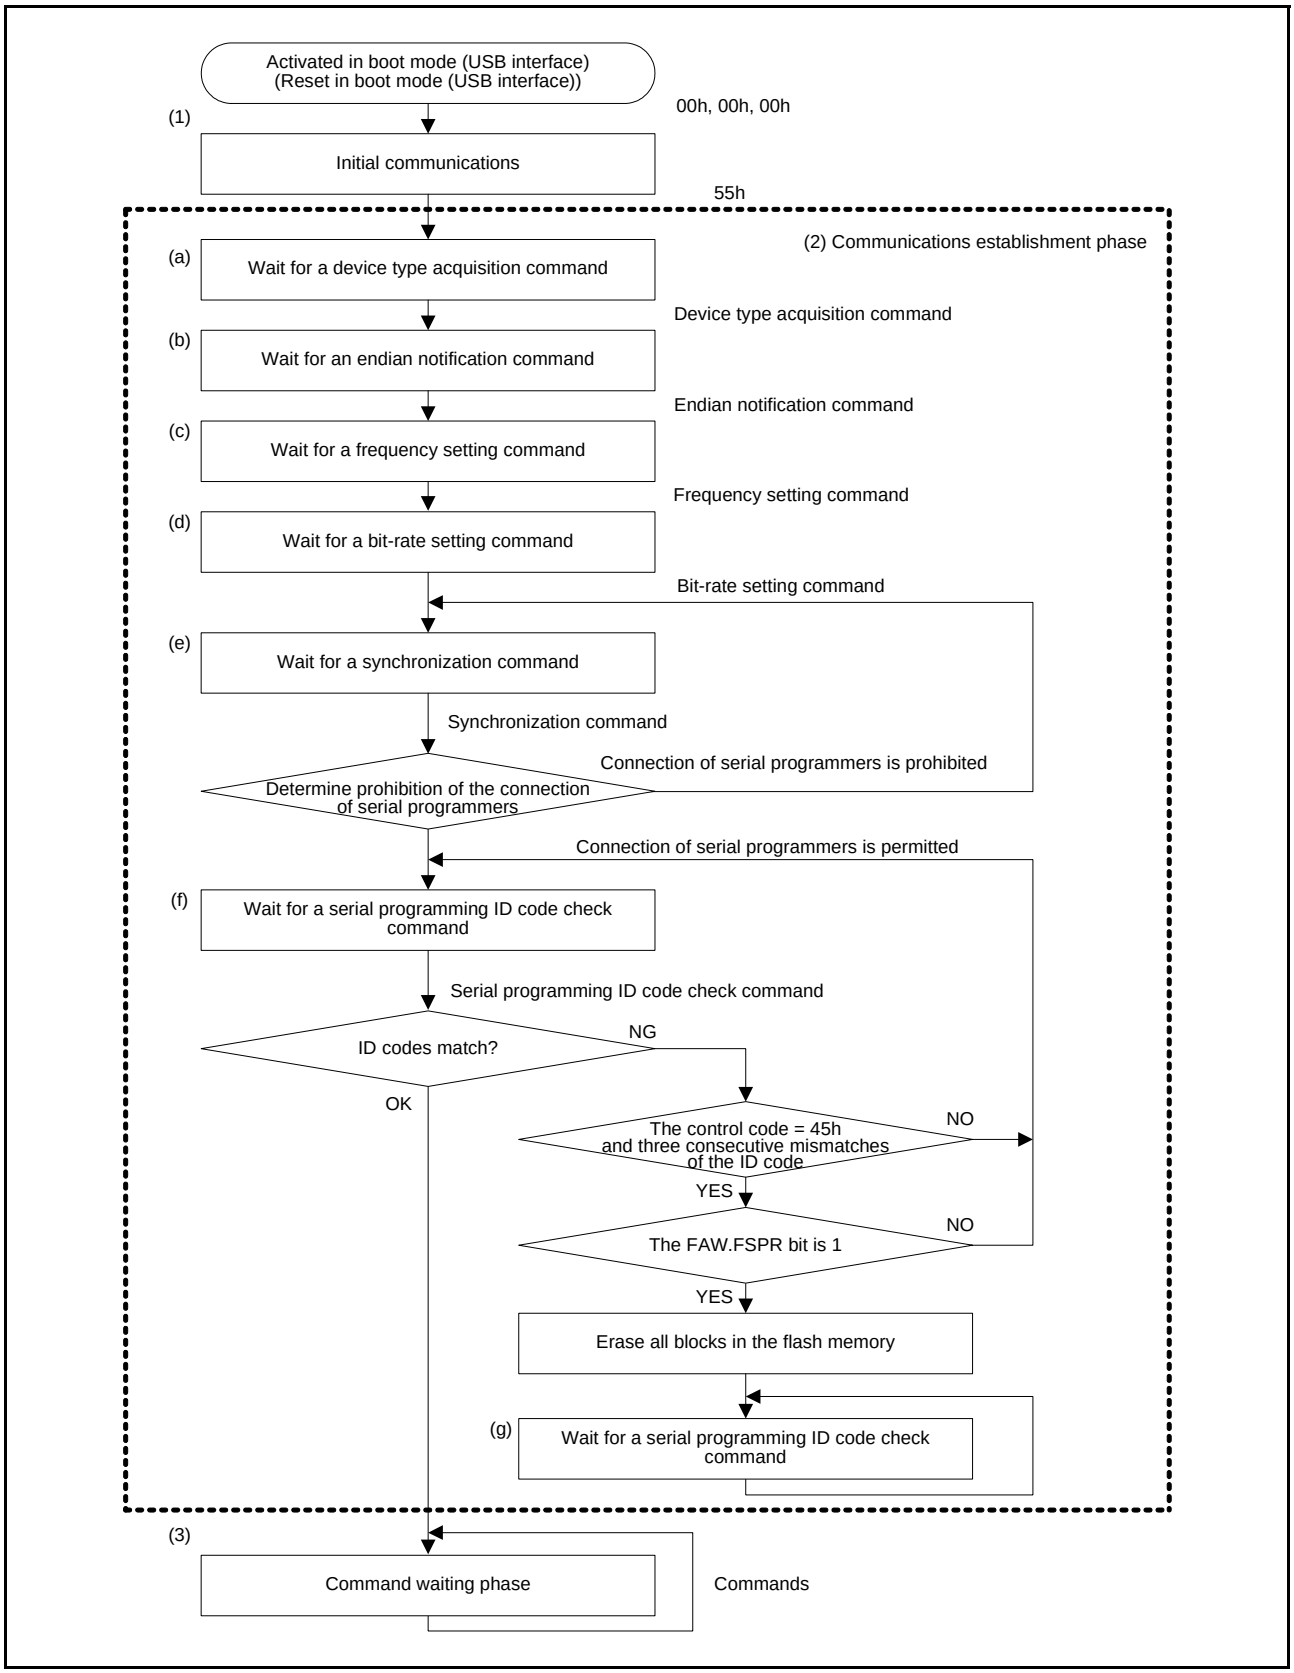

Figure 55.40 Flowchart for Transition to Boot Mode (USB Interface)

(1) Initial Communications

Enumeration starts when this MCU is activated in boot mode (USB interface).
Once the process of enumeration between the host and this MCU is completed, send the value 00h from the host to this MCU three times.
This MCU ignores transmission of the value 00h from the host from the fourth time and onward.
This MCU returns 00h to the host when receiving the value 00h three times. On subsequent correct reception of the value 55h sent from the host, this MCU enters the communications establishment phase.

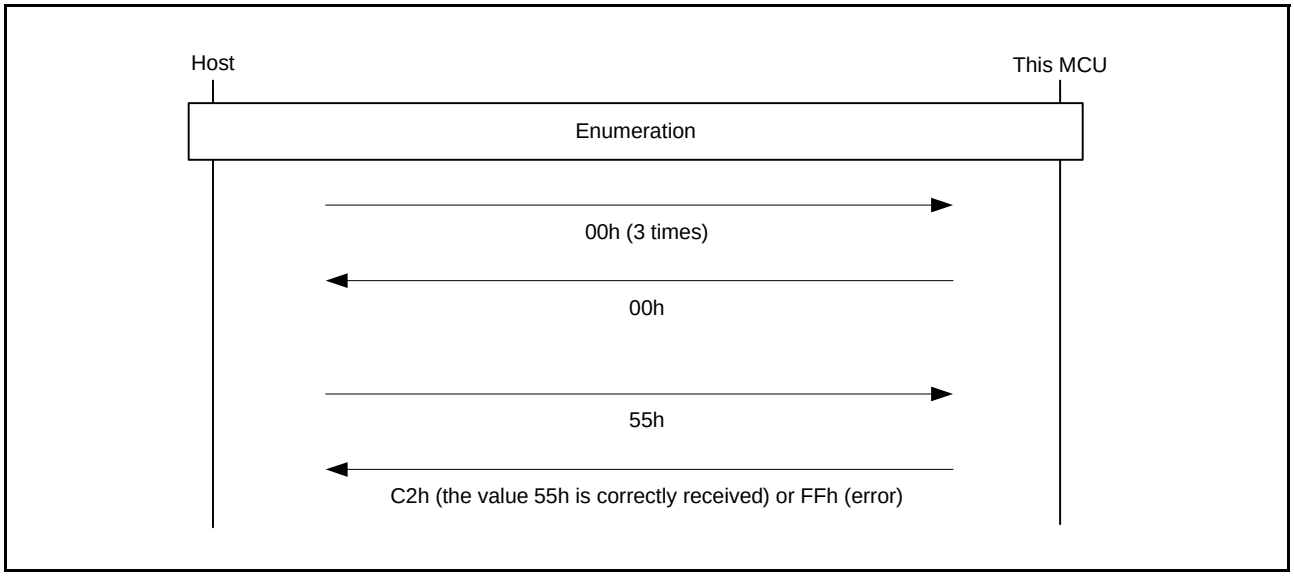

Figure 55.41 Initial Communications Between the Host and This MCU

(2) Communications establishment phase

The device, endian, frequency, and bit rate are selected in this phase. In this phase, the serial programmer ID code protection is judged. For the commands to use in the communications establishment phase, see section 55.15.5, Communications Establishment Phase.

(a) Waiting for a device type acquisition command

In this state, the MCU is waiting for a device type acquisition command to be sent from the host. When it receives a device type acquisition command, the state shifts to waiting for an endian notification command. For details of the device type acquisition command, see section 55.15.9, Device Type Acquisition Command.

(b) Waiting for an endian notification command

In this state, the MCU is waiting for an endian notification command to be sent from the host. When it receives an endian notification command, the state shifts to waiting for a frequency setting command. For details of the endian notification command, see section 55.15.10, Endian Notification Command.

(c) Waiting for a frequency setting command

In this state, the MCU is waiting for a frequency setting command to be sent from the host. When it receives a frequency setting command, the state shifts to waiting for a bit-rate setting command. For details of the frequency setting command, see section 55.15.11, Frequency Setting Command.

(d) Waiting for a bit-rate setting command

In this state, the MCU is waiting for a bit-rate setting command to be sent from the host. When it receives a bit-rate setting command, the state shifts to waiting for a synchronization command. For details of the bit-rate setting command, see section 55.15.12, Bit-Rate Setting Command.

(e) Waiting for a synchronization command

In this state, the MCU is waiting for a synchronization command to be sent from the host. When it receives a synchronization command, it transitions to the waiting state of the serial programming ID code check command. If the MCU has been set to prohibit the connection of a serial programmer, this MCU transmits an error code to indicate that connecting a serial programmer is prohibited and remains in the state of waiting for a synchronization command. For details of the synchronization command, see section 55.15.13, Synchronization Command.

(f) Waiting for a serial programming ID code check command

In this state, the MCU is waiting for a serial programming ID code check command to be sent from the host. The control code or ID code that was sent is compared with the control code or ID code in the OSIS register. The device enters the command waiting phase if they match. If they do not match, the next transition is back to the state of waiting for a serial programming ID code check command.
If the control code is 45h and the codes do not match three times in a row, all data in the flash memory are erased.*1
For details of the ID code check command, see section 55.15.15, Serial Programming ID Code Check Command.

Note 1. When the FAW.FSPR bit is 0, the blocks in those areas are not erased.

(g) Waiting for a serial programming ID code check command (after erasure)

After all blocks in the flash memory are erased, reboot the MCU in boot mode.

(3) Phase of waiting for commands

In this state, programming and erasure proceed in accord with commands from the host. For details of the commands that can be issued in the command waiting phase, see section 55.15.6, Command Waiting Phase.

55.15.3 Automatic Adjustment of the Bit Rate

When this MCU is booted up in boot mode (SCI interface), asynchronous transfer by the SCI is used to measure the periods at low level of consecutive bytes with value 00h that are sent from the host. While the period at low level is being measured, set the host's SCI transfer format to 8-bit data, one stop bit, no parity, and a transfer rate of 9,600 bps. This MCU measures the periods at low level in the signal from the host, adjusts the bit rate of its SCI, and then sends the value 00h to the host.

If reception of the value 00h by the host is successful, the host responds by sending the value 55h to this MCU. If successful reception of 00h by the host is not possible, reboot this MCU in boot mode, and then repeat the process of automatically adjusting the bit rate. If reception of the value 55h by this MCU is successful, it responds by sending C2h to the host, and if successful reception of 55h by this MCU is not possible, it responds by sending FFh to the host.

If this MCU is started up in boot mode (USB interface), the bit rate is not automatically adjusted.

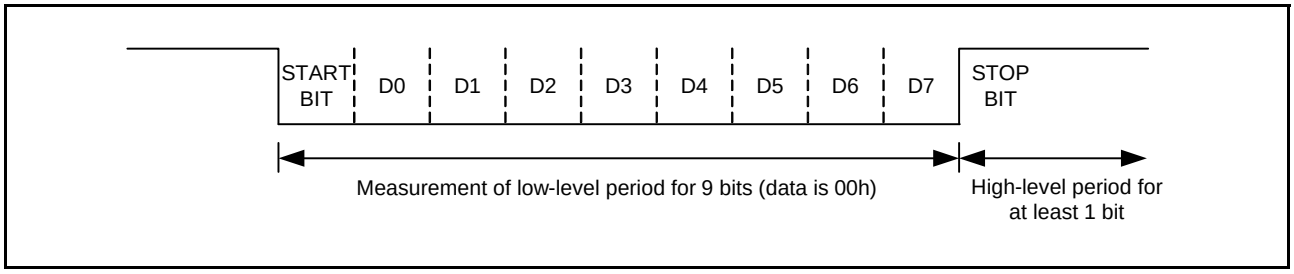

Figure 55.42 Transfer Format Used by SCI in Automatic Adjustment of Bit Rate

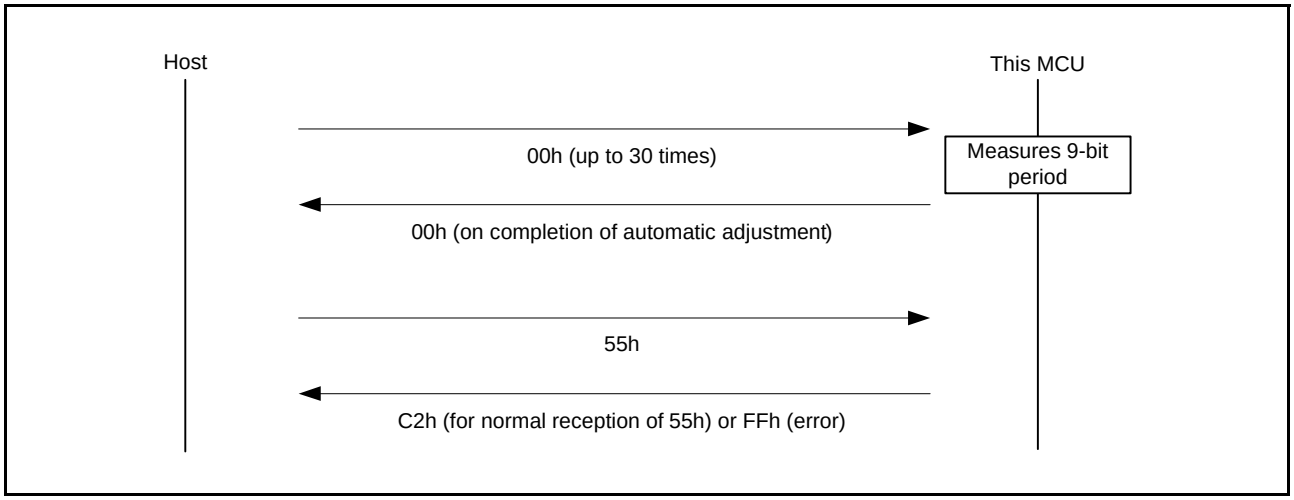

Figure 55.43 Sequence of Transfer between Host and This MCU

For the host's SCI bit rate, ensure that SCI communications proceed under the conditions given in Table 55.21.

Table 55.21 Conditions for Automatic Bit-Rate Adjustment

Bit Rate of SCI in Host
9,600 bps

55.15.4 Packet Format

(1) Command packet

The host sends commands to this MCU in the format below.

SOH	LNH	LNL	COM	Command information (variable length) (up to 255 bytes)	SUM	ETX

Symbol	Code	Description
SOH	01h	Start of a packet (1 byte)
LNH	—	Packet length (length of COM and the command information) (8 to 15 bits) (1 byte)
LNL	—	Packet length (length of COM and the command information) (0 to 7 bits) (1 byte)
COM	—	Command code (1 byte)
Command information	—	Command information (up to 255 bytes)
SUM*1	—	Two's complement of the sum of values of LNH, LNL, COM, and the command information (1 byte)
ETX	03h	End of a packet (1 byte)

Note 1. SUM indicates the 1 byte of data that produces 00h as the result of adding LNH, LNL, COM, the command information, and SUM itself.

(2) Status packet and data packet

Data transmission proceeds between the host and this MCU in the format below.

SOD	LNH	LNL	RES	Data (variable length) (up to 1024 bytes)	SUM	ETB or ETX

Symbol	Code	Description
SOD	81h	Start of a packet (1 byte)
LNH	—	Packet length (length of RES and the data) (8 to 15 bits) (1 byte)
LNL	—	Packet length (length of RES and the data) (0 to 7 bits) (1 byte)
RES	—	Response code (1 byte)
Data	—	Data (up to 1024 bytes)
SUM*1	—	Two's complement of the sum of values of LNH, LNL, RES, and the data (1 byte)
ETB	17h	End of a packet (1 byte)
ETX	03h	End of the last packet (1 byte)

Note 1. SUM indicates the 1 byte of data that produces 00h as the result of adding LNH, LNL, RES, the data, and SUM itself.

55.15.5 Communications Establishment Phase

Table 55.22 lists the commands available in the commands establishment phase.
The synchronization command and ID authentication mode acquisition command can also be used in the command waiting phase.

Table 55.22 Commands Available in the Communications Establishment Phase

Command Name	Function
Device type acquisition	Transmits the oscillation frequency and CPU operating frequency (in Hz) supported by boot mode to the host.
Endian notification	Indicates whether big-endian or little-endian is to be used.
Frequency setting	Sets the values of the oscillation frequency and CPU operating frequency (in Hz).
Bit-rate setting	Changes the bit rate.
Synchronization	This command is used in processing for communications synchronization. It is also used when confirming whether the MCU can accept commands.
ID authentication mode acquisition	This command sends the enabled state of serial programmer ID code protection to the host.
Serial programming ID code check	Determines whether the control code and ID code written in the option-setting memory matches the control code and ID code sent by the host.

In the communications establishment phase, send commands from the host in the order of the device type acquisition, endian notification, frequency setting, bit-rate setting, and synchronization commands according to the responses to commands. Send the ID authentication mode acquisition or serial programming ID code check command following the synchronization command.
If commands are issued in an incorrect order or other commands are issued, this MCU returns a response indicating a flow error.

55.15.6 Command Waiting Phase

Table 55.23 lists the commands available in the command waiting phase.
The synchronization command and ID authentication mode acquisition command can also be used in the communications establishment phase.

Table 55.23 Commands Available in the Command Waiting Phase

Command Name	Function
Synchronization	See Table 55.22.
Blank check	Check that a selected area is blank.
Block erase	Erases a selected single block.
Area erase	Erases the specified area.
Programming	Programs the selected area.
Read	Reads data from a selected area.
ID authentication mode acquisition	See Table 55.22.
Simple addition checksum	Calculates the sum of values in a selected area.
Configuration clearing	Erases the set value of the option-setting memory and the TM target areas.
Configuration programming	Programs the set value in the option-setting memory.
Configuration reading	Reads the set value of the option-setting memory.
Acquisition of the number of the area information	Obtains the number of area information of the flash memory.
Acquisition of the area information	Obtains the area information of the flash memory.

If the host has sent an undefined command, this MCU returns a response indicating an error in the form of a non-supported command.

55.15.7 Command Transfer Sequence

Though the sequence of transfer differs from command to command, common transfer sequences are used for the commands that only make settings for this MCU and for the commands that obtain information on the settings in this MCU. However, as the contents of the command packet, status packet, and data packet differ for each command, see the sections on the individual commands for details.

(1) Common transfer sequence for the commands that only make settings

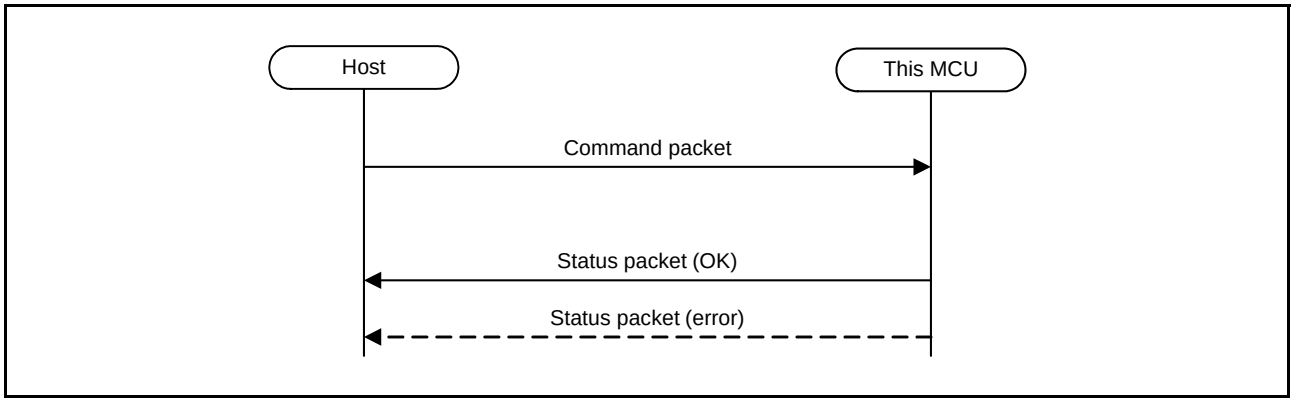

Figure 55.44 Common Transfer Sequence for the Commands that Only Make Settings

(2) Common transfer sequence for the commands that obtain information on settings

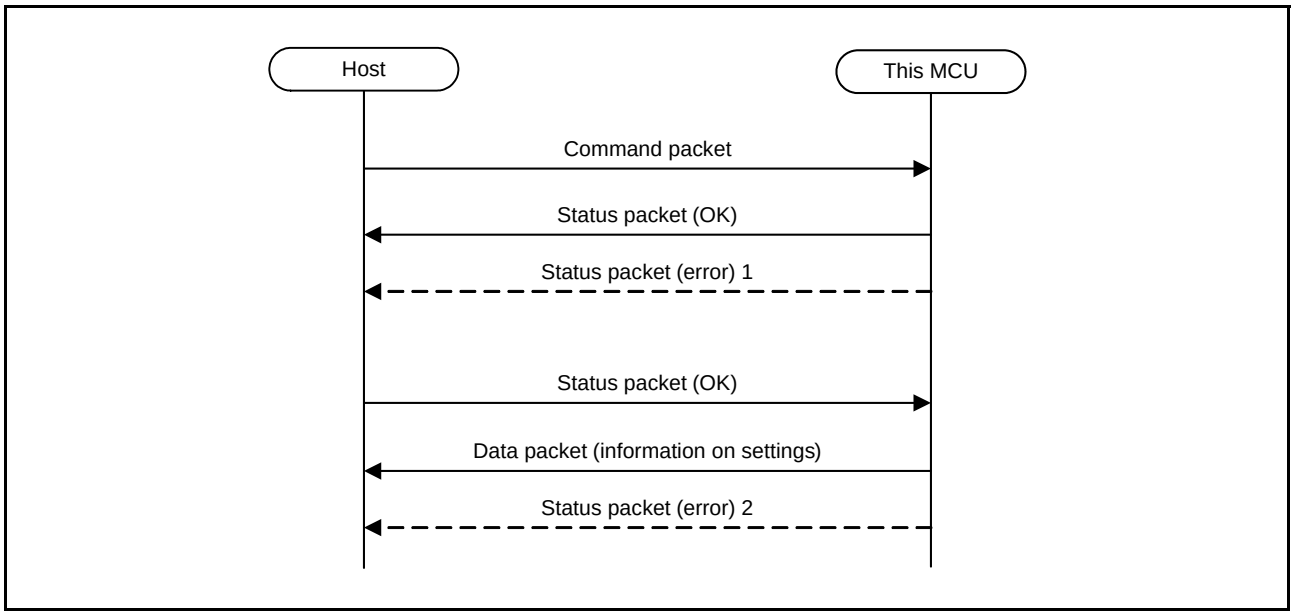

Figure 55.45 Common Transfer Sequence for the Commands that Obtain Information on Settings

Table 55.24 Common Transfer Sequence

Command Name	Common Transfer Sequence Type
Device type acquisition	Command that obtains information on settings
Endian notification	Command that only makes a setting
Frequency setting	Command that obtains information on settings
Bit rate setting	Not in a common transfer sequence
Synchronization	Command that only makes a setting
ID authentication mode acquisition	Command that obtains information on settings
Serial programming ID code check	Command that only makes a setting
Blank check	Command that only makes a setting
Block erase	Command that only makes a setting
Area erase	Command that only makes a setting
Programming	Not in a common transfer sequence
Read	Not in a common transfer sequence
Simple addition checksum	Command that obtains information on settings
Configuration clearing	Command that only makes a setting
Configuration programming	Not in a common transfer sequence
Configuration reading	Command that obtains information on settings
Acquisition of the number of the area information	Command that obtains information on settings
Acquisition of the area information	Command that obtains information on settings

For the command transfer sequences that are not in a common transfer sequence, see the sections on the individual commands.

55.15.8 Non-supported Commands

When this MCU receives an undefined command packet, it returns an unsupported error (C0h) and enters the command waiting state.

(1) Command packet structure

SOH	LNH	LNL	COM	SUM	ETX

SOH: 01h
LNH: Packet length (8 to 15 bits)
LNL: Packet length (0 to 7 bits)
COM: Command code*1
SUM: Sum of values
ETX: 03h

Note 1. Command code other than those specified in Table 55.23.

(2) Status packet structure

SOD	LNH	LNL	RES	ERR	SUM	ETX

SOD: 81h
LNH: 00h
LNL: 02h
RES: 80h | COM (command code)
ERR: Error code
C0h (“non-supported” error)
C1h (packet error)
C2h (checksum error)
C3h (flow error)
SUM: Sum of values
ETX: 03h

55.15.9 Device Type Acquisition Command

This command is used to make the MCU send the input frequency and system clock frequency (in Hz) supported by boot mode (SCI interface).
This command can only be accepted in the communications establishment phase.

(1) Command packet structure

SOH	LNH	LNL	COM	SUM	ETX

SOH: 01h
LNH: 00h
LNL: 01h
COM: 38h
SUM: C7h
ETX: 03h

(2) Data packet structure

SOD	LNH	LNL	RES	TYP	OSA	OSI	CPA	CPI	SUM	ETX

SOD: 81h
LNH: 00h
LNL: 19h
RES: 38h (OK)
TYP: Type code (8 bytes)*1
OSA: Maximum input frequency (4 bytes)
OSI: Minimum input frequency (4 bytes)
CPA: Maximum system clock frequency (4 bytes)
CPI: Minimum system clock frequency (4 bytes)
SUM: Sum of values
ETX: 03h

An example of the values sent is given below.

Maximum input frequency = 16,000,000 Hz
- OSA (1st byte): 00h
- OSA (2nd byte): F4h
- OSA (3rd byte): 24h
- OSA (4th byte): 00h

Minimum input frequency = 16,000,000 Hz
- OSI (1st byte): 00h
- OSI (2nd byte): F4h
- OSI (3rd byte): 24h
- OSI (4th byte): 00h

Maximum system clock (ICLK) = 120,000,000 Hz
- CPA (1st byte): 07h
- CPA (2nd byte): 27h
- CPA (3rd byte): 0Eh
- CPA (4th byte): 00h

Minimum system clock: (ICLK) = 120,000,000 Hz
- CPI (1st byte): 07h
- CPI (2nd byte): 27h
- CPI (3rd byte): 0Eh
- CPI (4th byte): 00h

In boot mode (USB interface), transfer is at the input frequency when the value of OSA or OSI is in use (20 MHz or 24 MHz).

Note 1. Reserved data

(3) Status packet structure, normal termination

SOD	LNH	LNL	RES	SUM	ETX

SOD: 81h
LNH: 00h
LNL: 01h
RES: 38h (OK)
SUM: C7h
ETX: 03h

(4) Status packet structure, error occurrence 1

SOD	LNH	LNL	RES	ERR	SUM	ETX

SOD: 81h
LNH: 00h
LNL: 02h
RES: B8h (error)
ERR: Error code
C1h (packet error)
C2h (checksum error)
C3h (flow error)
SUM: Sum of values
ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

(5) Status packet structure, error occurrence 2

SOD	LNH	LNL	RES	ERR	SUM	ETX

SOD: 81h
LNH: 00h
LNL: 02h
RES: B8h (error)
ERR: Error code
C1h (packet error)
C2h (checksum error)
SUM: Sum of values
ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

55.15.10 Endian Notification Command

This command is used to inform the MCU of the endian (big or little).
Specify either endian as the endian information according to the data to be programmed.
This command can only be accepted in the communications establishment phase.

(1) Command packet structure

SOH	LNH	LNL	COM	END	SUM	ETX

SOH: 01h
LNH: 00h
LNL: 02h
COM: 36h
END: Endian information
00h (big-endian)
01h (little-endian)
SUM: Sum of values
ETX: 03h

(2) Status packet structure, normal termination

SOD	LNH	LNL	RES	SUM	ETX

SOD: 81h
LNH: 00h
LNL: 01h
RES: 36h (OK)
SUM: C9h
ETX: 03h

(3) Status packet structure, error occurrence

SOD	LNH	LNL	RES	ERR	SUM	ETX

SOD: 81h
LNH: 00h
LNL: 02h
RES: B6h (error)
ERR: Error code
C1h (packet error)
C2h (checksum error)
C3h (flow error)
D7h (endian error)
SUM: Sum of values
ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

55.15.11 Frequency Setting Command

This command is used to set the values of oscillation frequency and CPU operating frequency (in Hz).
In boot mode (SCI or FINE interface), the HOCO runs at 16 MHz and the ICLK runs at 120 MHz, so set the input frequency to 16 MHz and the system clock frequency to 120 MHz. Additionally, in boot mode (SCI or FINE interface), the FCLK and PCLKB run at 60 MHz, so the MCU returns the hexadecimal value corresponding to 60,000,000 to indicate the frequency of the peripheral module clock.
In boot mode (USB interface), the input frequency in use is 20 MHz or 24 MHz and the ICLK runs at 120 MHz, so set the input frequency to 20 MHz or 24 MHz and the system clock frequency to 120 MHz. Additionally, in boot mode (USB interface), the FCLK runs at 60 MHz and the UCLK runs at 48 MHz, so the MCU returns the hexadecimal value corresponding to 48,000,000 to indicate the frequency of the peripheral module clock.
This command can only be accepted in the communications establishment phase.

(1) Command packet structure

SOH	LNH	LNL	COM	OC1	OC2	OC3	OC4	CC1	CC2	CC3	CC4	SUM	ETX

SOH: 01h

C2h (checksum error)
C3h (flow error)
D1h (input frequency error)
D2h (system clock (ICLK) frequency error)
SUM: Sum of values
ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

55.15.12 Bit-Rate Setting Command

This command is used to change the bit rate after receiving bit rate data (in bps).
If an error occurs, the bit rate is not changed.
This command can only be accepted in the communications establishment phase.
In boot mode (USB or FINE interface), the bit rate is not changed. The bit rate should be any desired value.

(1) Procedure

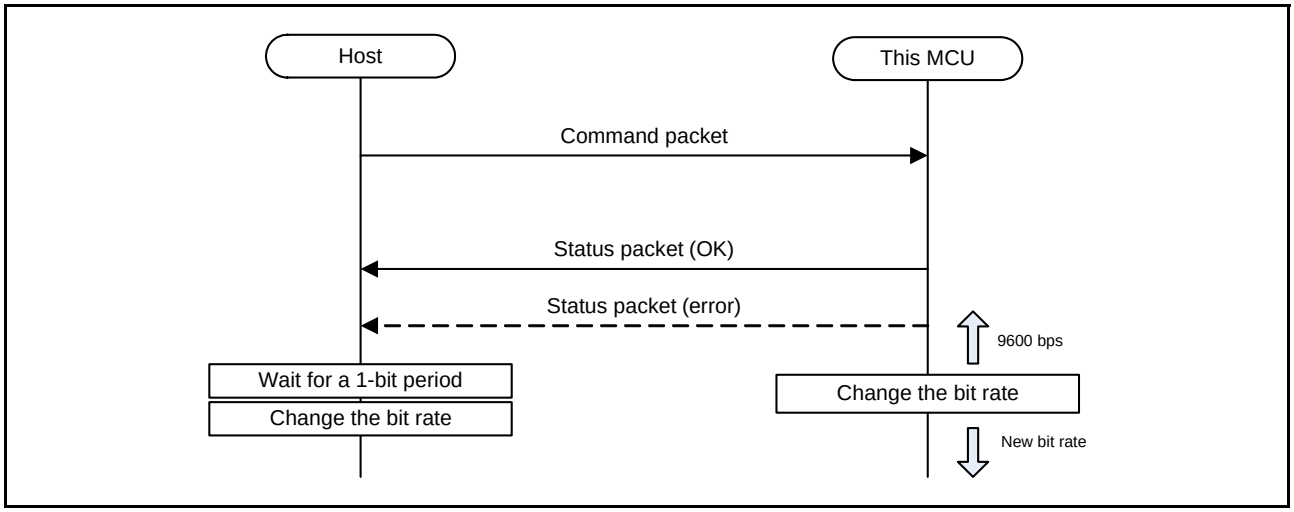

Figure 55.46 Bit-Rate Setting Command Transfer Sequence

(2) Command packet structure

SOH	LNH	LNL	COM	BR1	BR2	BR3	BR4	SUM	ETX

When the bit rate is 2,000,000 bps, send the values as below.
BR1: 00h
BR2: 1Eh
BR3: 84h
BR4: 80h

SOH: 01h
LNH: 00h

SUM: Sum of values
ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

55.15.13 Synchronization Command

This command is used in processing to synchronize communications.
It is also used when checking whether the MCU is ready to accept commands. If a serial programmer connection is prohibited, a serial programmer connection prohibition error is returned.
This command can be accepted in both the communications establishment and command waiting phases.

(1) Command packet structure

SOH	LNH	LNL	COM	SUM	ETX

SOH: 01h
LNH: 00h
LNL: 01h

C2h (checksum error)
SUM: Sum of values
ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

55.15.15 Serial Programming ID Code Check Command

This command sends the result when the control and ID codes set in the OSIS register match those received from the host.

This command can be accepted in the communications establishment phase. When the serial programmer ID code protection is enabled, the MCU does not enter the command waiting phase unless processing in response to this command ends normally.

If the control code is 45h, the codes do not match three times in a row, all data in the flash memory are erased.*1

Note 1. When the FAW.FSPR bit is 0, data in the flash memory are not erased.

(1) Command packet structure

SUM: Sum of values
ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

55.15.16 Blank Check Command

This command checks whether the specified area is blank.
Specify addresses aligned with 128-byte boundaries for the code flash memory and with 4-byte boundaries for the data flash memory. The option-setting memory cannot be specified. When trusted memory (TM) is enabled, an error occurs if the area for blank-checking include any part of the area being handled as TM.
This command can only be accepted in the command waiting phase.

(1) Command packet structure

SOH	LNH	LNL	COM	SHH	SHL	SLH	SLL	EHH	EHL	ELH	ELL	SUM	ETX

After the error code is returned, the chip returns to the command waiting state.

55.15.17 Block Erase Command

This command is used to erase a specified single block.
Specify the block for erasure as the first address in the block.
When the TM function is enabled, blocks targeted for TM target area cannot be erased. The option-setting memory cannot be erased.
This command can only be accepted in the command waiting phase.

(1) Command packet structure

SOH	LNH	LNL	COM	SHH	SHL	SLH	SLL	SUM	ETX

SUM: Sum of values
ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

55.15.18 Area Erase Command

The area erase command erases the specified area successively, block by block, in ascending order of addresses.
The target area can be selected from the code flash memory or data flash memory.
When the TM function is enabled, blocks other than those being handled as TM are erased.
This command can only be accepted in the command waiting phase.

SUM: Sum of values
ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

55.15.19 Programming Command

This command sets up the MCU for data to be programmed to its flash memory and specifies the area where the data are to be programmed.
Specify the data length in 128-byte units for the code flash memory and 4-byte units for the data flash memory. In addition, the program start address must be specified in 128-byte aligned for the code flash memory and 4-byte aligned for data flash memory. When the TM function is enabled, areas including the TM target area cannot be programmed.
This command can only be accepted in the command waiting phase.

ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

55.15.21 Configuration Clearing Command

This command is used to clear the option-setting memory (configuration setting area).
This command also erases the TM target areas. Therefore, when this command is in use, do not set the TM target areas outside the access window when setting an access window. The TM function is disabled after a reset.
While the FAW.FSPR bit is valid, a protection error occurs.
This command can only be accepted in the command waiting phase.

SUM: Sum of values
ETX: 03h

After the error code is returned, the chip returns to the command waiting state.

55.15.22 Simple Addition Checksum Command

This command is used to calculate the sum of values in the specified area and send the result to the host. While the TM function is enabled, however, the values in the TM target areas are not included in the calculation.
The target area of this command can be selected from the code flash memory or data flash memory. Calculation is by simple addition. If the size of each area is less than 8×2^n Kbytes, the area range from the final address of each area to 8×2^n Kbyte area is supplemented by FFh. The initial value is 0 and the sum of values in the specified area is obtained by adding the values of all bytes. If this command is issued for the data flash memory that includes erased blocks, the result is undefined. When a simple addition checksum is to be executed for the data flash memory, make sure that data have been written throughout the specified area.
This command can only be accepted in the command waiting phase.

55.15.23 Configuration Programming Command

This command is used to receive data to be written to the option-setting memory and to program the data in the specified area.
Programming must be specified in the unit acquired by using the area information acquisition command.
This command can only be accepted in the command waiting phase.
Programming in the area including the FAW register while the FAW.FSPR bit is enabled leads to a protection error.
Once the FAW.FSPR bit has been enabled, the bit cannot be disabled.
For details of the FAW.FSPR bit, refer to section 7.2.9, Flash Access Window Setting Register (FAW) in section 7, Option-Setting Memory (OFSM).
Rewriting the SPCC.SPE bit while the connection of serial programmer is prohibited leads to normal termination, but programming does not proceed.
In addition, this MCU cannot be connected to a serial programmer at a reset while connection to a serial programmer is disabled.
Writing to the TMEF.TMEF[2:0] bits, TMINF register, and MDE.BANKMD[2:0] bits while the TMEF.TMEF[2:0] bits are 000b in linear mode leads to normal termination, but programming does not proceed.
Writing to the TMEF.TMEF[2:0] bits, TMINF register, and MDE.BANKMD[2:0] bits while the TMEF.TMEF[2:0] bits or the TMEF.TMEFDB[2:0] bits are 000b in dual mode leads to normal termination, but programming does not proceed.

55.15.27 Usage Example

(1) Example of the Procedure for Reprogramming

Figure 55.50 shows an example of the procedure for reprogramming. Figure 55.51 shows an example of the method of changing to dual mode.

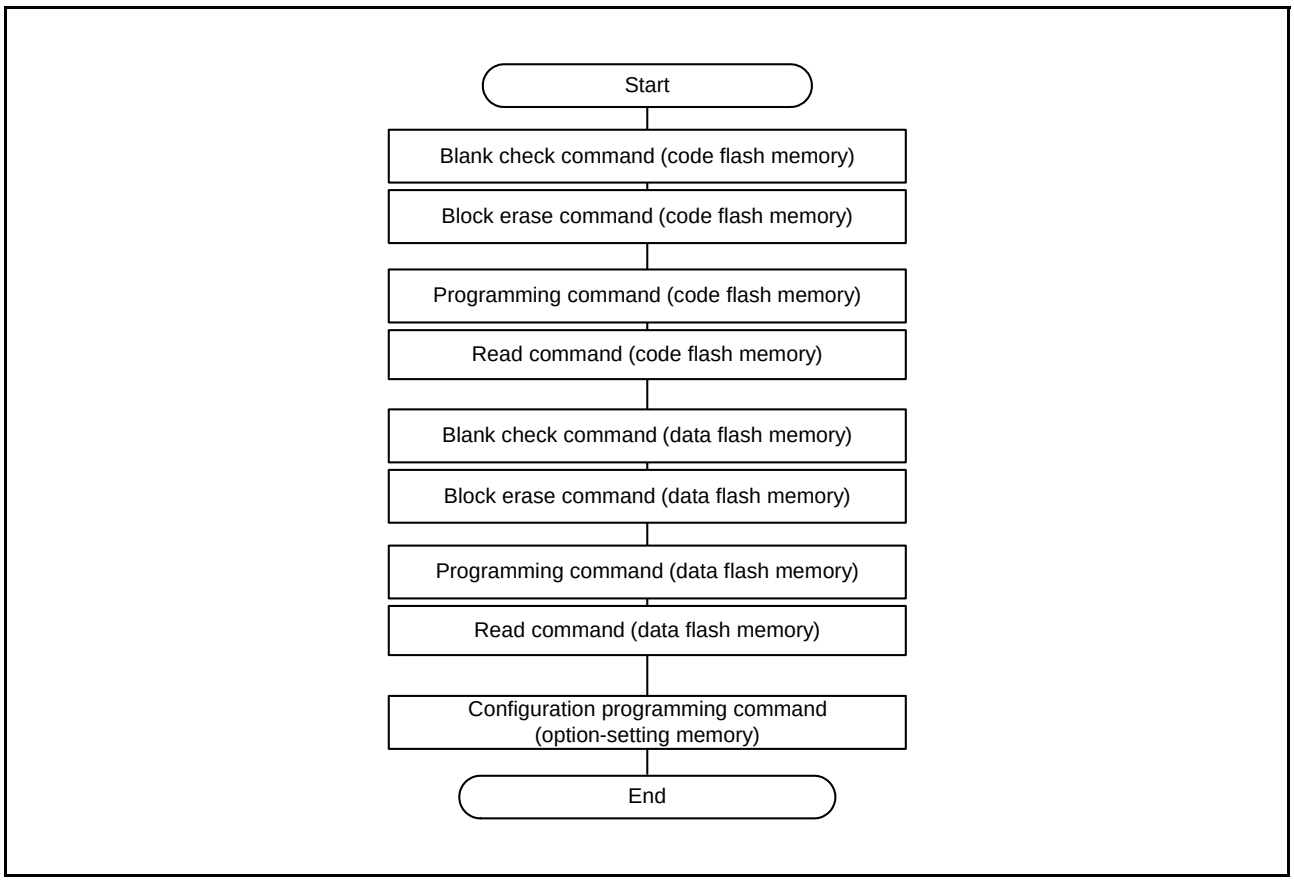

Figure 55.50 Example of Reprogramming Procedure

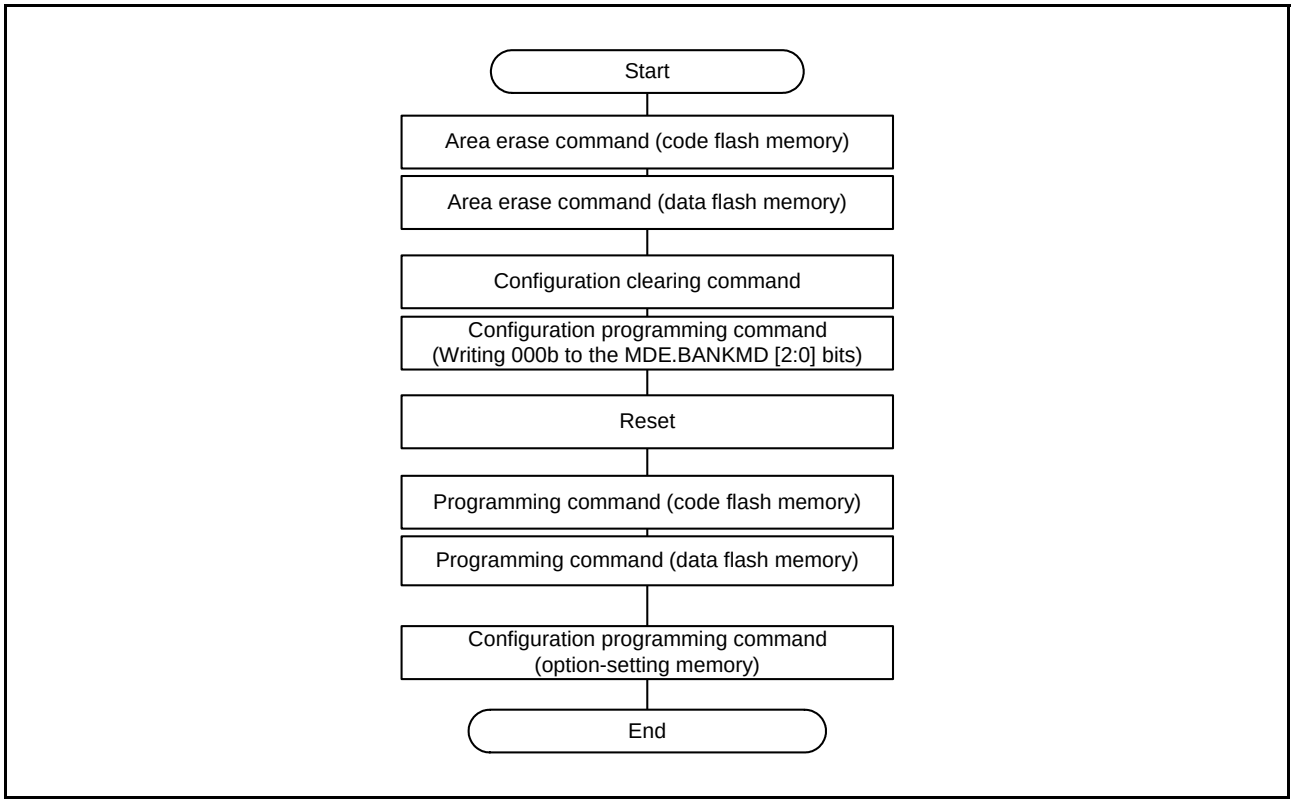

Figure 55.51 Rewriting when Switching Between Different Modes (from Linear to Dual)

55.16 Using the Serial Programmer for Rewriting

A dedicated serial programmer can be used to rewrite flash memory in boot mode.

(1) Serial Programming

By providing a connector on the board, it is possible to program the MCU with a serial programmer while the MCU is mounted on the board.

55.16.1 Environments for Serial Programming

The recommended environments for rewriting the flash memory of the MCU are described below.

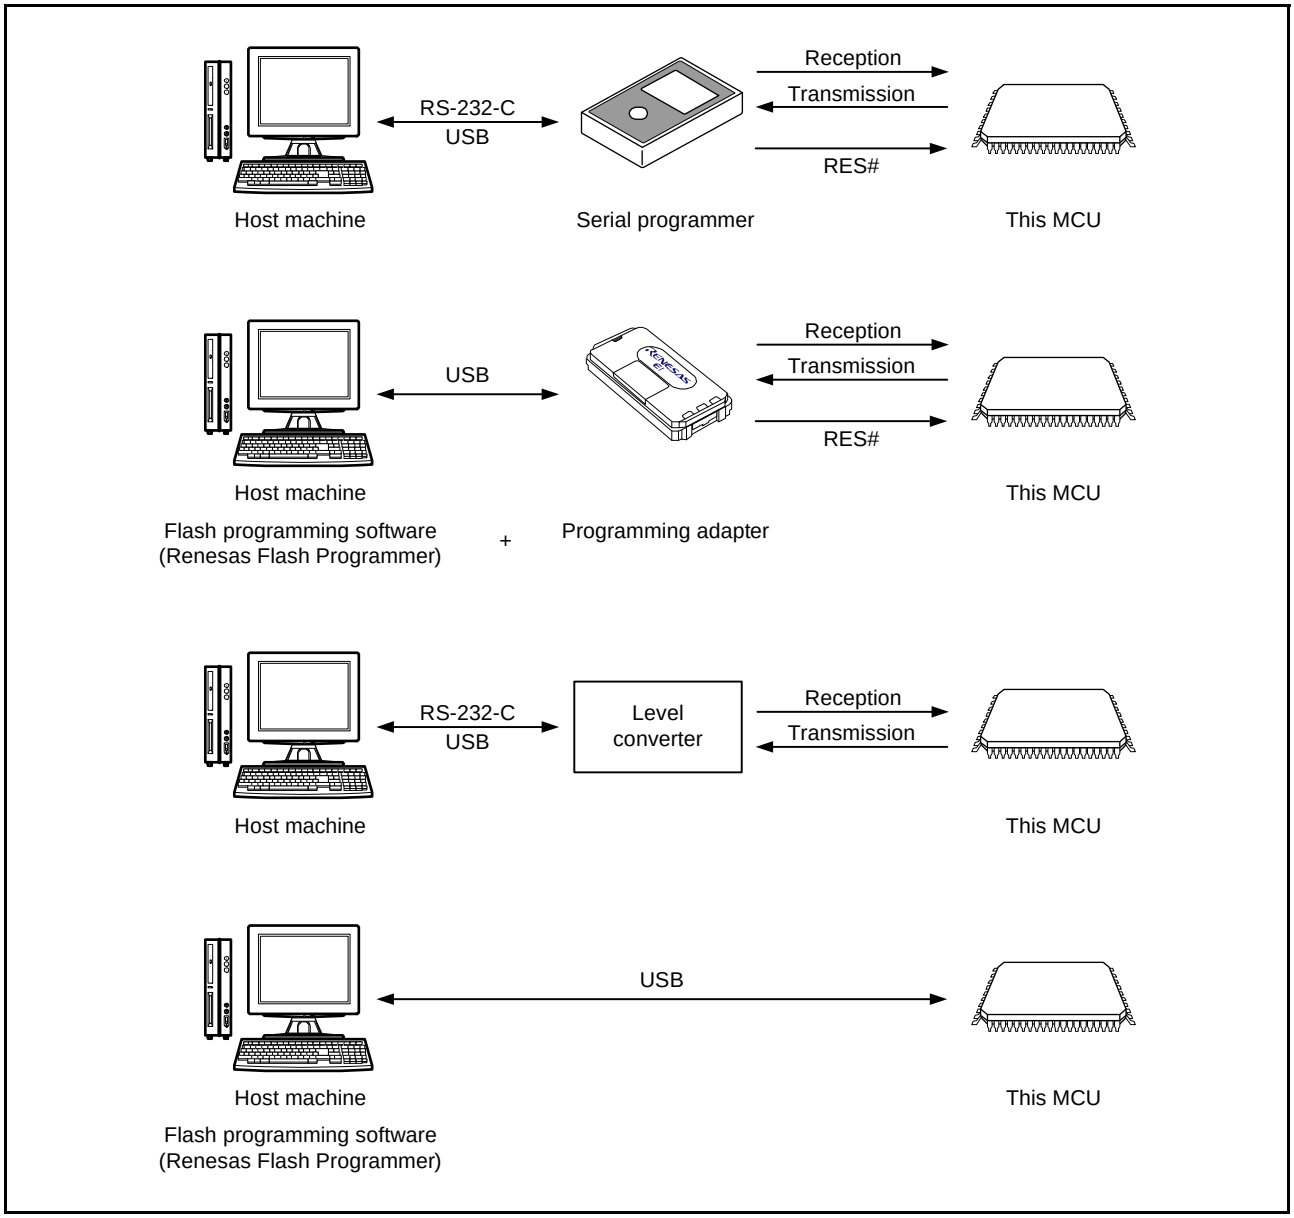

Figure 55.52 Environments for Rewriting the Flash Memory

Note: For details of the serial programmers, refer to the manual of each serial programmer; for details of the Renesas Flash Programmer flash programming software, refer to the Renesas Flash Programmer Flash Programming Software User's Manual.

55.17 Programming through Self-Programming

55.17.1 Overview

This MCU supports programming of the flash memory by the user program itself. The FACI commands can be used with user programs for writing to the flash memory. This allows upgrading of user programs and rewriting of constant data fields.

When the data flash memory is programmed, the background operation facility makes it possible to execute a programming program from the code flash memory to program the data flash memory. Furthermore, the programming program can be copied to internal RAM or external memory in advance of the programming operation, and executed from the given destination to program the data flash memory.

Background operation is also available for use when the address ranges of the area of code flash memory to be programmed and the area of code flash memory to be read satisfy particular conditions (see Table 55.25). At the time of self-programming in this case, a programming program in code flash memory can be used to program the code flash memory. Also, the programming program can be copied to internal RAM or external memory in advance of the programming operation, and executed from the given destination to program the code flash memory. This is useful when the address ranges do not satisfy the conditions for background operation.

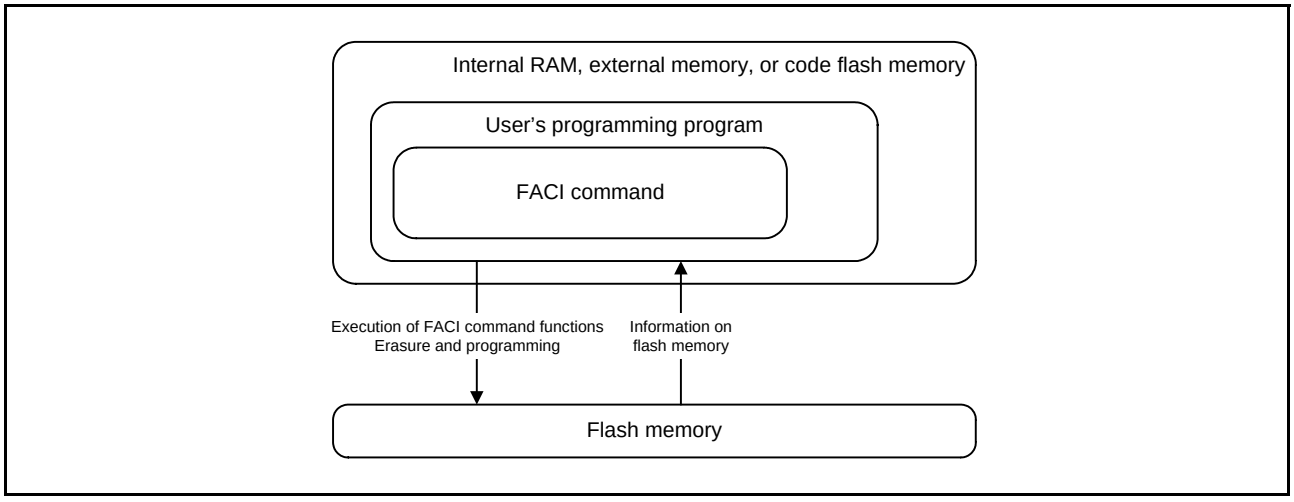

Figure 55.53 Schematic View of Self-Programming

55.17.2 Background Operation

The BGO is can be used to execute the flash rewrite routine on the code flash memory when the data flash memory or other area of code flash memory is rewritten.
Background operations can be used when the combination of the flash memory for rewriting and the flash memory for reading is any of those listed below.

Table 55.25 Conditions under which Background Operation is Usable

		Range for Rewriting	Range for Reading
Common to linear and dual modes		Data flash memory	Code flash memory
Linear mode	Products with 2 Mbytes of code flash memory	First half (1.0 Mbyte) of the code flash memory (addresses FFE0 0000h to FFEF FFFFh)	Second half (1.0 Mbyte) of the code flash memory (addresses FFF0 0000h to FFFF FFFFh) Data flash memory
		Second half (1.0 Mbyte) of the code flash memory (addresses FFF0 0000h to FFFF FFFFh)	First half (1.0 Mbyte) of the code flash memory (addresses FFE0 0000h to FFEF FFFFh) Data flash memory
	Products with 1.5 Mbytes of code flash memory	First half (0.5 Mbytes) of the code flash memory (addresses FFE8 0000h to FFEF FFFFh)	Second half (1.0 Mbyte) of the code flash memory (addresses FFF0 0000h to FFFF FFFFh) Data flash memory
		Second half (1.0 Mbyte) of the code flash memory (addresses FFF0 0000h to FFFF FFFFh)	First half (0.5 Mbytes) of the code flash memory (addresses FFE8 0000h to FFEF FFFFh) Data flash memory
Dual mode	When the BANKSEL.BANKSWP[2:0] bits are 111b:	Bank 1 area of the code flash memory	Bank 0 area of the code flash memory Data flash memory
	When the BANKSEL.BANKSWP[2:0] bits are 000b:	Bank 0 area of the code flash memory	Bank 1 area of the code flash memory Data flash memory

55.18 Reading Flash Memory

55.18.1 Reading Code Flash Memory

Special settings are not required to read code flash memory after release from the reset state. Data can simply be read out through access to addresses in the code flash memory.
When reading code flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state), all bits are read as 1.

55.18.2 Reading Data Flash Memory

Special settings are not required to read data flash memory after release from the reset state. Data can simply be read out through access to addresses in the data flash memory.
Values read from data flash memory that has been erased but not yet been programming again (i.e. that is in the non-programmed state) are undefined. Use blank checking when you need to confirm that an area is in the non-programmed state.

55.19 Trusted Memory

This MCU has a trusted memory (hereafter called TM) facility to prevent the reading of blocks 8 and 9 and blocks 46 and 47 (in dual mode) in the code flash memory by third party software. When set as trusted memory, these areas are suitable for storing software that handles processing for encryption algorithms, device control software that is associated with proprietary or confidential know-how, purchased middleware, and so on.
Table 55.26 lists the specifications of the TM function, Table 55.27 lists access restrictions within the TM target area when the TM function is enabled, and Figure 55.54 shows the cases where the CPU is able to operate in relation to the TM target area.

Table 55.26 TM Specifications

Item	Description
TM target area	Linear mode: Blocks 8 and 9 in the code flash memory (64 Kbytes in total) Dual mode: Blocks 8 and 9 in the code flash memory (64 Kbytes in total) and blocks 46 and 47 (64 Kbytes in total)
Access restrictions when TM is enabled	See Table 55.27, Restrictions on Access to the TM Target Area while the TM function is Enabled.
How to run program code when the TM function is enabled	When the TM function is enabled, starting to run program code in an area being handled as TM is only possible with a branch instruction from program code outside the areas being handled as TM.
Interrupt processing during the execution of program code in an area being handled as TM while the TM function is enabled	Both the acceptance of requests for interrupt processing and return from interrupt processing are possible.
Security function	Enabling the TM function restricts access to program code in the areas for handling as TM to instruction fetching only
Protection functions	• Restrictions on data access to the TM target area when the TM function is enabled*1 • Once enabled, the TM function prevents its own disabling until the areas being handled as TM are erased. • Once enabled, the TM function prevents further writing to the areas being handled as TM.

Note 1. Access to data in operations that include the borders of the TM target areas is also not allowed.

Table 55.27 Restrictions on Access to the TM Target Area while the TM function is Enabled

Type of Access	CPU	DMAC/DTC/EXDMAC
Instruction fetching	Yes	—
Access to data	No*1	No

Note: The same restrictions apply to on-chip debuggers as to the DMAC in the table above. For the operation of the OCD you are using in relation to the TM target area, see the manual of the given OCD.
Note 1. Place data to which access will be required in areas other than the TM target areas.

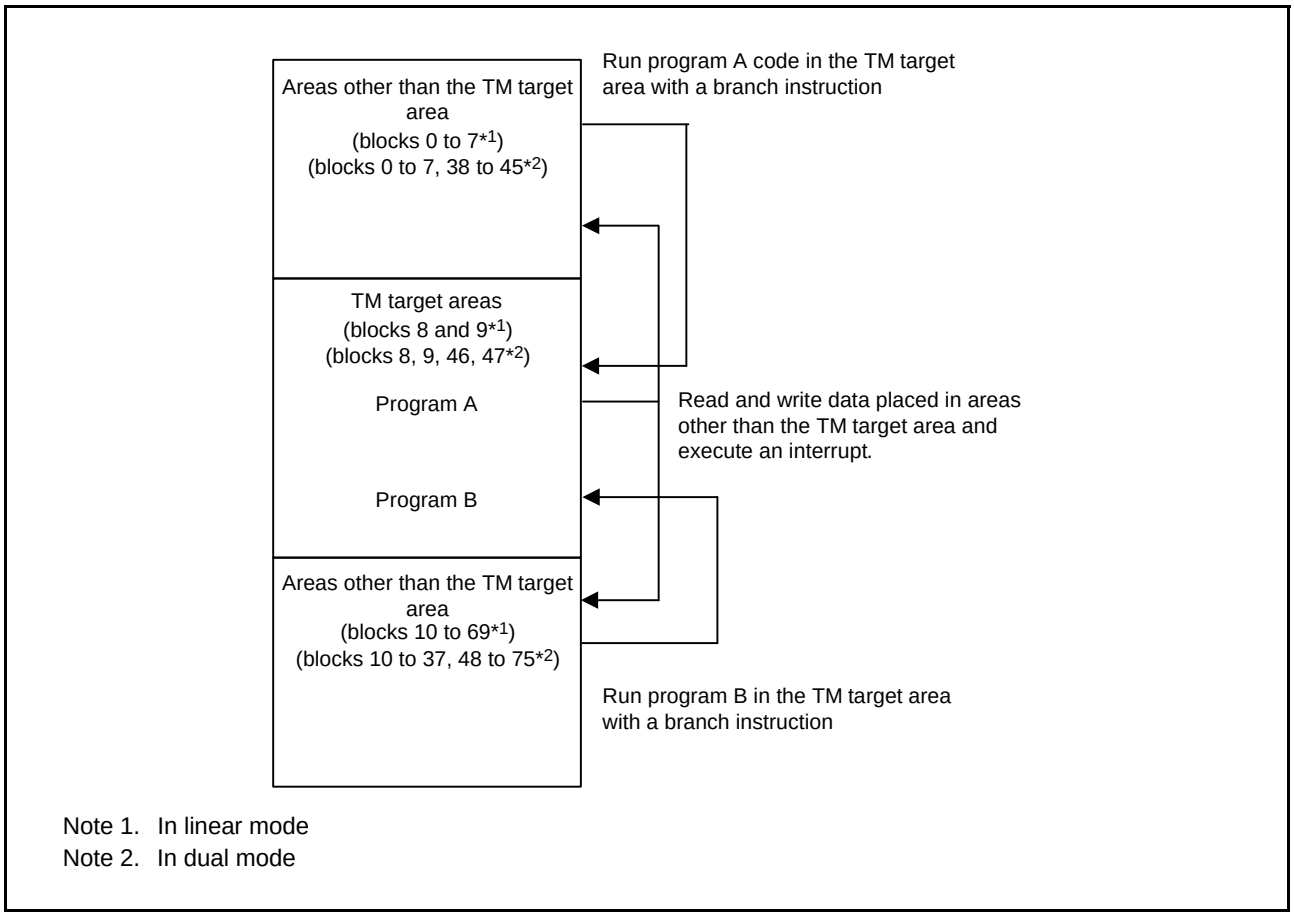

Figure 55.54 Cases where CPU is Allowed to Operate in Relation to the TM Target Area when the TM Function is Enabled

55.19.1 Allocating Program Code to the TM Target Area

When the TM function is enabled, implement countermeasures in the form of software for the TM target area as required as further measures to prevent the running of programs for access to consecutive addresses in the TM target areas from areas outside the TM target areas.

55.19.2 How to Enable the TM Function

55.19.2.1 By Self-Programming

After writing to blocks 8 and 9 of the code flash memory, i.e. the TM target areas (after programming blocks 8, 9, 46, and 47 in dual mode), use the configuration setting command of the FACI to enable the TM function.
Figure 55.55 is a flowchart of the procedure for enabling the TM function by self-programming.

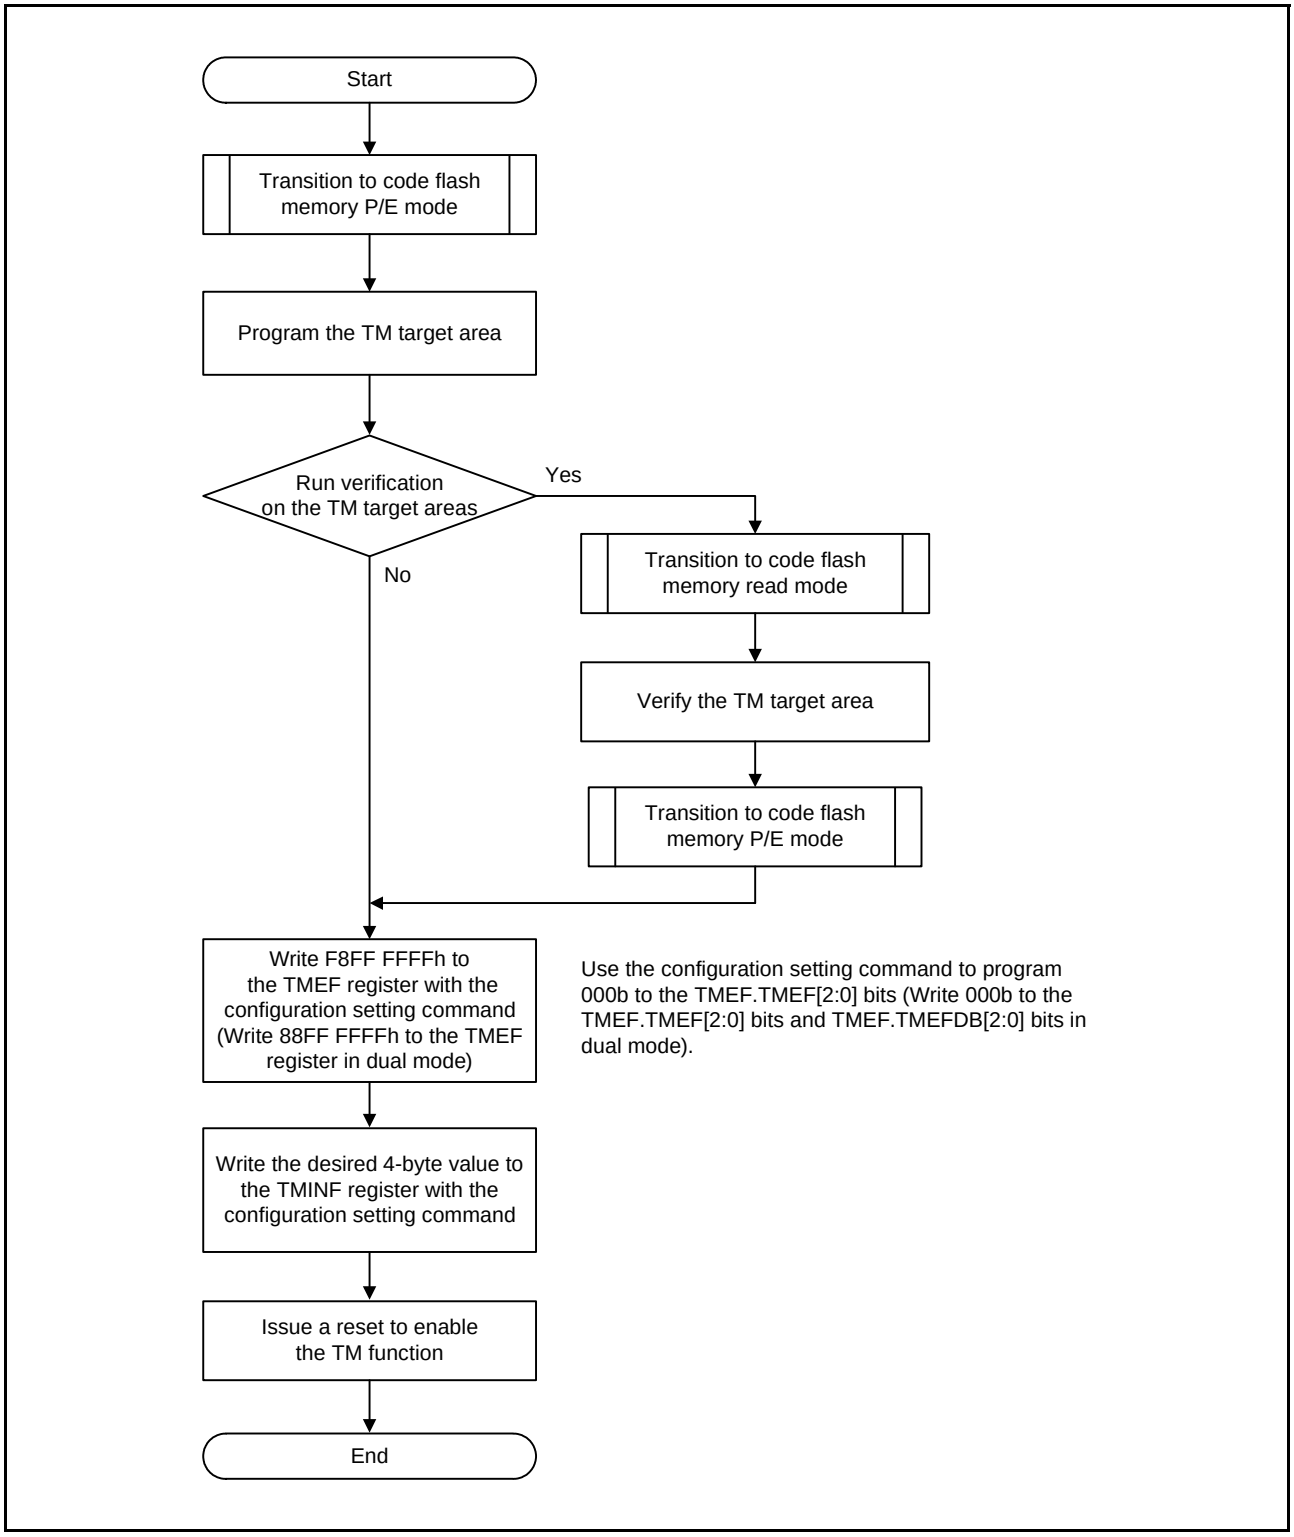

Figure 55.55 Flowchart for Enabling the TM Function by Self-Programming

55.19.2.2 By Using Boot Mode

In boot mode, use the configuration program command among the boot commands to enable the TM function after writing to blocks 8 and 9 of the code flash memory (or after writing to blocks 8, 9, 46, and 47 in dual mode).
For the configuration program command among the boot commands, see section 55.15.23, Configuration Programming Command.
Figure 55.56 is a flowchart of enabling the TM function in boot mode.

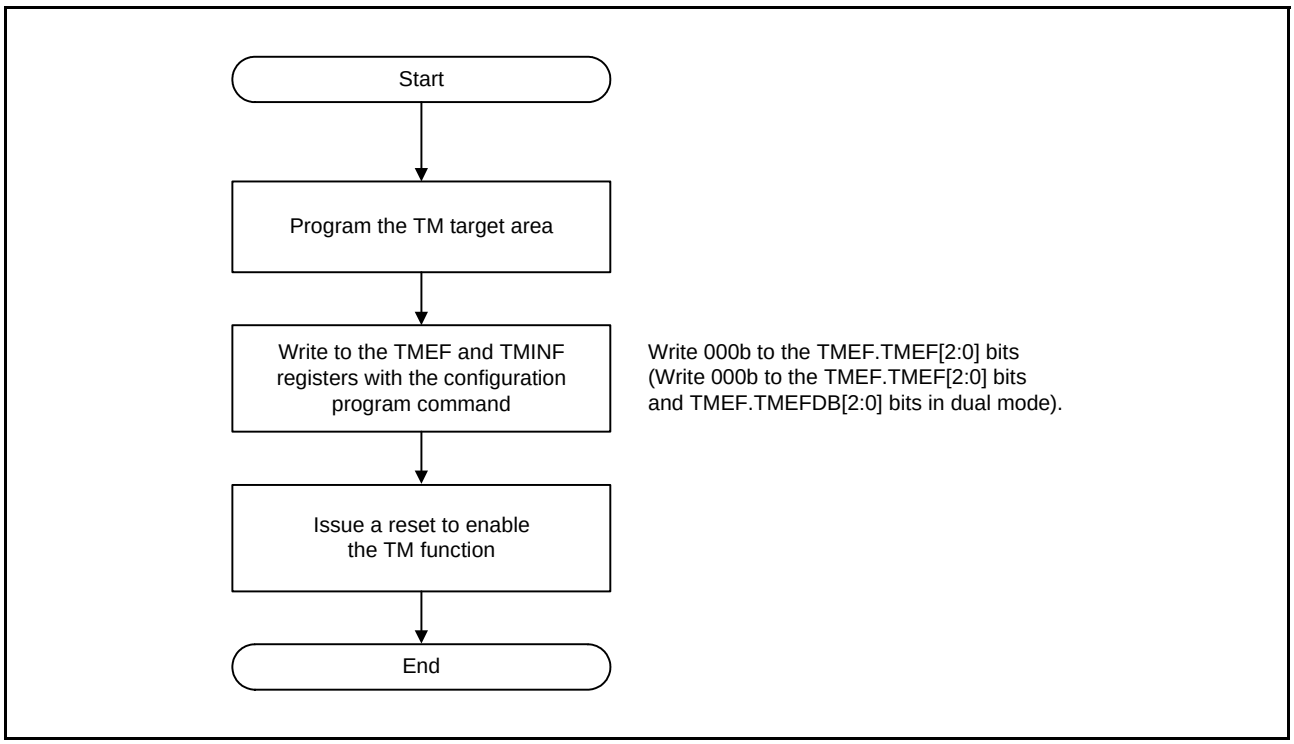

Figure 55.56 Flowchart for Enabling the TM Function by Using Boot Mode

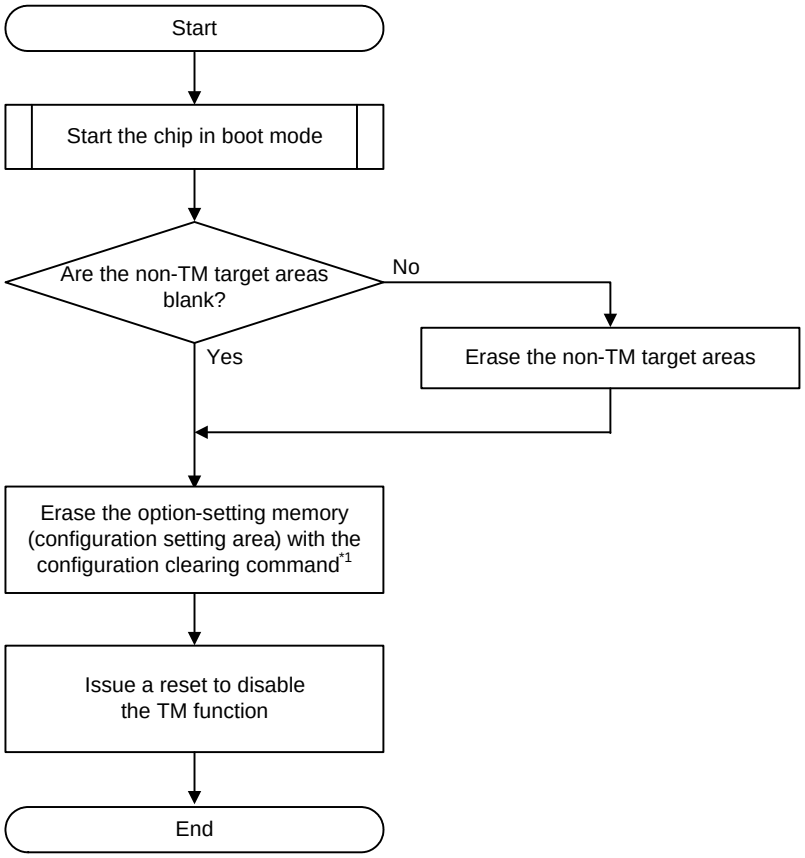
55.19.3 How to Disable the TM function

The TM function cannot be disabled unless the TM target areas are first erased with the configuration clearing command. Do not use the configuration clearing command for this purpose unless the TM function is to be disabled.
Figure 55.57 is a flowchart of disabling the TM function in boot mode.



Note 1. The TM target area and the option-setting memory are erased by issuing the configuration clearing command.

Figure 55.57 Flowchart for Disabling the TM Function in Boot Mode

55.19.4 Notes on Enabling the TM function

55.19.4.1 Protection against Access to the TM Target Areas

While the TM function is enabled, the only type of access to the TM target areas is instruction fetching by the CPU, so do not allocate data to the TM target areas.
If the CPU, DMAC, DTC, or EXDMAC, or OCD attempt access to data in the TM target areas while the TM function is enabled, values are always read as 0 instead of the actual values.

55.19.4.2 Further Writing to the TM Target Areas

Further writing to the TM target areas is not allowed as long as the TM function is enabled.
If you do need to write further data, follow the procedure described in section 55.19.3, How to Disable the TM function, to disable the TM function, write the modified or extended data to blocks 8 and 9 of the code flash memory (blocks 8, 9, 46, and 47 in dual mode), and then follow the procedure described in section 55.19.2, How to Enable the TM Function, to enable the TM function.

55.19.4.3 Executing the Configuration Clearing Command

Follow the procedure in section 55.19.3, How to Disable the TM function, before issuing the configuration clearing command.

55.19.4.4 When the MPU Setting is for Access to the TM Target Areas

When the TM function is enabled, even if the MPU is set to allow access to the TM target areas, the TM function takes priority.

55.19.4.5 FACI Block Erase Command for the TM Target Areas

There are no special restrictions on block erasure of the TM target areas with the FACI block erase command.
Accordingly, since each area corresponds to an erase block, the areas can be erased by issuing the block erase command.

55.19.4.6 Conditions for Correct Operation of the TM Function

The TM function operates normally under the conditions prescribed in section 56, Electrical Characteristics.

55.20 Usage Notes

(1) Reading Area Where Programming/Erasure was Interrupted and Area Targeted for Suspension

The data stored in the area where programming or erasure has been suspended or the area where programming or erasure has been suspended by using the suspend command are undefined. To avoid faulty operation caused by reading undefined data, take care not to fetch instructions or read data from areas where programming or erasure was suspended and where programming or erasure was suspended by using the suspend command.

(2) Suspension During Programming/Erasure

When processing of programming/erasure is stopped by issuing the P/E suspend command, the programming/erasure processing can be resumed by issuing the P/E resume command. If the flash sequencer enters the command-locked state for any reason and issues the forced stop command after the suspended processing is normally completed and the ERSSPD flag or PRGSPD flag is set to 1, the suspended processing cannot be resumed. In addition, the values in the area where the processing was suspended are not guaranteed. Erase that area.

(3) Prohibition of Additional Programming

Programming a given area of the code flash memory or data flash memory twice is not possible. To program the code flash memory or data flash memory where has been programed, erase the target area. Programming can be added to the option-setting memory.

(4) Resets During Programming/Erasure, or Blank Checking

In the case of a reset due to the signal on the RES# pin during programming/erasure, or blank checking of the flash memory, wait for at least t_{RESWF} (see section 56, Electrical Characteristics) of the reset input period once the operating voltage is within the range stipulated in the electrical characteristics, then release the device from the reset state.

(5) Allocation of Vectors for Interrupts and Other Exceptions During Programming/Erasure

Generation of an interrupt or other exception during programming/erasure may lead to fetching of the vector from the code flash memory. Under conditions where BGO cannot be used, set the address of the vector to an address that is not in the code flash memory. Alternatively, make sure that no handling of interrupts or exceptions proceeds during programming/erasure.

(6) Items Prohibited During Programming/Erasure, or Blank Checking

High voltage is applied to the flash memory during programming/erasure, or blank checking. To prevent damage to the flash memory, do not perform the following operations.

- Have the operating voltage from the power supply go beyond the permitted range.
- Change the FWEPROR.FLWE[1:0] bits.
- Change the SYSCR0.ROME bit.
- Change the OPCCR.OPCM[2:0] bits.
- Change the SCKCR.FCK[3:0] and PCLKB[3:0] bits.
- Change the SCKCR3.CKSEL[2:0] bits.
- Change the RSTCKCR.RSTCKEN bit.
- Transition to the all module clock stop mode, software standby mode, or deep software standby mode.

(7) Notes on Program Execution in Boot Mode (USB Interface)

- An oscillator is usable in boot mode (USB interface) when its frequency is 20 or 24 MHz and when the setting value of the main clock oscillator driving ability 2 switching bits (MOFCR.MODRV2[1:0]) are 00b in the result of the matching test conducted by the oscillator manufacturer (the recommended setting value).

- To ensure that the power supply is stable during programming/erasure of flash memory, do not connect a cable via a bus-powered HUB.

(8) Programming/Erasure in Low-Speed Operating Modes 1 and 2

Do not programming/erasure the flash memory when low-speed operating mode 1 or 2 is selected with the operating power control register (OPCCR).

56. Electrical Characteristics

56.1 Absolute Maximum Ratings

Table 56.1 Absolute Maximum Rating

Conditions: VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V

Item		Symbol	Value	Unit
Power supply voltage		VCC, VCC_USB	–0.3 to +4.0	V
V_{BATT} power supply voltage		V_{BATT}	–0.3 to +4.0	V
Analog power supply voltage		AVCC0, AVCC1*1	–0.3 to +4.0	V
Reference power supply voltage		VREFH0	–0.3 to AVCC0 + 0.3 (up to 4.0)	V
Input voltage	Ports for 5 V tolerant: P12 to P17, P20, P21, P30 to P33, P67, P73, PC0 to PC3, and PJ3	V_{in}	–0.3 to VCC + 4.0 (up to 5.8)	V
	TAMPI0 to TAMPI2, RTCIC0 to RTCIC2, EXCIN*2		–0.3 to +4.0	
	Port for 5 V tolerant: P07		–0.3 to AVCC0 + 4.0 (up to 5.8)	
	P03, P05, P40 to P47		–0.3 to AVCC0 + 0.3 (up to 4.0)	
	Other than above		–0.3 to VCC + 0.3 (up to 4.0)	
Junction temperature		T_j	–40 to +125	°C
Storage temperature		T_{stg}	–55 to +125	°C

Caution: Permanent damage to the LSI may result if absolute maximum ratings are exceeded.

Note 1. Connect the AVCC0, AVCC1, and VCC_USB pins to VCC, and the AVSS0, AVSS1, and VSS_USB pins to VSS. When the A/D converter unit 0 is not to be used, connect the VREFH0 pin to VCC and the VREFL0 pin to VSS, respectively. Do not leave these pins open. Insert capacitors of high frequency characteristics between the AVCC0 and AVSS0 pins, or AVCC1 and AVSS1 pins. Place capacitors of about 0.1 µF as close as possible to every power supply pin and use the shortest and heaviest possible traces.

Note 2. The listed values apply when pins P30, P31, and P32 are set for the TAMPIn or RTCICn (n = 0 to 2) functions, and pin PJ3 is set for the EXCIN function.

56.2 Recommended Operating Conditions

Table 56.2 Recommended Operating Conditions (1)

Item		Symbol	Min.	Typ.	Max.	Unit
Power supply voltage*1		VCC	2.7	—	3.6	V
		VSS	—	0	—	
V_{BATT} power supply voltage		V_{BATT}	1.62*2	—	3.6	V
USB power supply voltage		VCC_USB	—	VCC	—	V
		VSS_USB	—	0	—	
Analog power supply voltage*1, *3		AVCC0	—	VCC	—	V
		AVSS0	—	0	—	
		AVCC1	—	VCC	—	
		AVSS1	—	0	—	
		VREFH0	2.7	—	AVCC0	
		VREFL0	—	0	—	
Input voltage	Ports for 5 V tolerant: P12 to P17, P20, P21, P30 to P33, P67, P73, PC0 to PC3, and PJ3	V_{in}	–0.3	—	VCC + 3.6 (up to 5.5)	V
	TAMPI0 to TAMPI2, RTCIC0 to RTCIC2, EXCIN*4		–0.3	—	3.9	
	SCLHS0, SDAHS0*5		–0.3	—	VCC + 0.3	
	Port for 5 V tolerant: P07		–0.3	—	AVCC0 + 3.6 (up to 5.5)	
	P03, P05, P40 to P47		–0.3	—	AVCC0 + 0.3	
	Other than above		–0.3	—	VCC + 0.3	
Operating temperature	D version	T_{opr}	–40	—	85	°C
	G version		–40	—	105	
Junction temperature	D version	T_j	–40	—	105	°C
	G version		–40	—	125	

Note 1. Comply with the following potential condition: VCC = AVCC0 = AVCC1 = VCC_USB
Note 2. The low CL crystal unit cannot be used when the V_{BATT} voltage is less than 2.0 V.
Note 3. For details, see section 50.6.11, Voltage Range of Analog Power Supply Pins.
Note 4. The listed values apply when pins P30, P31, and P32 are set for the TAMPIn or RTCICn (n = 0 to 2) functions, and pin PJ3 is set for the EXCIN function.
Note 5. The listed values apply when pins P12 and P13 are respectively set for the SCLHS0 and SDAHS0 functions in Hs-mode of the RIICHS.

Table 56.3 Recommended Operating Conditions (2)

Item	Symbol	Value
Decoupling capacitance to stabilize the internal voltage	C_{VCL}	0.22 µF ± 30%*1

Note 1. Use a multilayer ceramic capacitor whose nominal capacitance is 0.22 µF and a capacitance tolerance is ±30% or better.

56.3 DC Characteristics

Table 56.4 DC Characteristics (1)

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
$T_a = T_{opr}$

Item		Symbol	Min.	Typ.	Max.	Unit	Test Conditions

Note 1. The input leakage current value at the EMLE and BSCANP pins are only when V_{in} = 0 V.

Table 56.6 DC Characteristics (3)

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
$T_a = T_{opr}$

Item				Symbol	D version		G version		Unit	Test Conditions
					Typ.	Max.	Typ.	Max.		
Supply current*1	High-speed operating mode	Full operation*2		I_{CC}*3	—	55	—	68	mA	ICLK = 120 MHz, PCLKA = 120 MHz, PCLKB = 60 MHz, PCLKC = 60 MHz, PCLKD = 60 MHz, FCLK = 60 MHz, BCLK = 120 MHz, BCLK pin = 60 MHz
		Normal operation	Peripheral module clocks are supplied *4		23	—	23	—		
			Peripheral module clocks are stopped *4, *5		13	—	13	—		
		Core Mark	Peripheral module clocks are stopped *4, *5		14.5	—	14.5	—		
		Sleep mode: Peripheral module clocks are supplied*4			20	38	20	51		
		All module clock stop mode (reference value)			9	26	9	39		
		Increased by BGO operation*8	Reading from the code flash memory while the data flash memory is being programmed		6	—	6	—		
			Reading from the code flash memory while the code flash memory is being programmed		7	—	7	—		
		Increased by Trusted Secure IP operation			—	15	—	15		
	Low-speed operating mode 1: Peripheral module clocks are stopped*4				1.6	—	1.6	—		All clocks 1 MHz
	Low-speed operating mode 2: Peripheral module clocks are stopped*4				1.6	—	1.6	—		All clocks 32.768 kHz
	Software standby mode				1.1	18	1.1	27		
	Deep software standby mode	Power is supplied to the standby RAM, USB resume detecting unit (USB0 only) and REMC			15.5	69	15.5	85	µA	
		Power is not supplied to the standby RAM, USB resume detecting unit (USB0 only) and REMC	Low power consumption function of the power-on reset circuit is disabled*6		11.5	42	11.5	54		
			Low power consumption function of the power-on reset circuit is enabled*7		4.9	32	4.9	47		
		Increase current by operating RTC	When a low C_L crystal is in use		1	—	1	—		
			When a standard C_L crystal is in use		2	—	2	—		
		Increase current by operating REMC	External clock (32 kHz) input		0.1	—	0.1	—		
			When a standard C_L crystal is in use		1.4	—	1.4	—		
	When the RTC is operating while VCC is not supplied (Only the RTC and sub-clock oscillator operate with the battery backup function)		When a low C_L crystal is in use		0.9	—	0.9	—		V_{BATT} = 2.0 V, VCC = 0 V
					1.6	—	1.6	—		V_{BATT} = 3.3 V, VCC = 0 V
			When a standard C_L crystal is in use		1.6	—	1.6	—		V_{BATT} = 1.62 V, VCC = 0 V
					1.7	—	1.7	—		V_{BATT} = 2.0 V, VCC = 0 V
					3.3	—	3.3	—		V_{BATT} = 3.3 V, VCC = 0 V
	Inrush current on release from deep software standby mode		Inrush current*9	I_{RUSH}	—	130	—	130	mA	
			Total inrush current*9	E_{RUSH}	—	1	—	1	µC	

Note 1. Supply current values are measured when all output pins are unloaded and all input pull-up resistors are disabled.

Note 2. Peripheral module clocks are supplied.
Note 3. I_{CC} depends on the f (ICLK) as follows (when ICLK/PCLKA : PCLKB/PCLKC/PCLKD : BCLK : BCLK pin = 2 : 1 : 2 : 1 and EXTAL = 12 MHz).
- D version
  I_{CC} max = 0.28 × f + 21.0 (full operation in high-speed operating mode)
  I_{CC} typ = 0.16 × f + 3.5 (normal operation in high-speed operating mode)
  I_{CC} typ = 0.20 × f + 1.4 (ICLK 1 MHz max) (low-speed operating mode 1)
  I_{CC} max = 0.14 × f + 21.0 (sleep mode)
- G version
  I_{CC} max = 0.31 × f + 30.0 (full operation in high-speed operating mode)
  I_{CC} typ = 0.16 × f + 3.5 (normal operation in high-speed operating mode)
  I_{CC} typ = 0.20 × f + 1.4 (ICLK 1 MHz max) (low-speed operating mode 1)
  I_{CC} max = 0.17 × f + 30.0 (sleep mode)

Note 4. Whether the peripheral module clocks are supplied or stopped is controlled only by the bit settings in the module stop control registers A to D.
Note 5. When the peripheral module clock is stopped, the settings of the clock frequency are as follows:
ICLK = 120 MHz and PCLKA = PCLKB = PCLKC = PCLKD = FCLK = BCLK = BCLK pin = 3.75 MHz (divided by 64).
Note 6. When the low power consumption function is disabled, the DEEPCUT[1:0] bits are set to 01b.
Note 7. When the low power consumption function is enabled, the DEEPCUT[1:0] bits are set to 11b.
Note 8. These are the increases during programming of the code flash memory after the code flash memory (limitations apply to the combinations of address ranges of the program area and the readable area) or the data flash memory has been programmed or erased.
Note 9. Reference value

Table 56.7 DC Characteristics (4)

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
$T_a = T_{opr}$

Item			Symbol	D version			G version			Unit	Test Conditions
				Min.	Typ.	Max.	Min.	Typ.	Max.		
Analog power supply current*1, *2	During 12-bit A/D conversion (unit 0)		I_{AVCC0}	—	0.8	1	—	0.8	1	mA	
	During 12-bit A/D conversion (unit 1)		I_{AVCC1}	—	0.6	1	—	0.6	1	mA	
	During 12-bit A/D conversion (unit 1) + temperature sensor			—	0.7	1.1	—	0.7	1.1		
	Waiting for A/D and temperature sensor conversion (all units)		I_{AVCC}	—	0.9	1.4	—	0.9	1.4	mA	$I_{AVCC} = I_{AVCC0} + I_{AVCC1}$
	A/D and temperature sensor are in standby mode (all units)			—	1.4	6.7	—	1.4	9.0	µA	
Reference power supply current	During 12-bit A/D conversion (unit 0)		I_{VREFH0}	—	38	60	—	38	60	µA	
	Waiting for 12-bit A/D conversion (unit 0)			—	0.07	0.5	—	0.07	0.6		
	12-bit A/D converter in module stop status (unit 0)			—	0.07	0.4	—	0.07	0.5		
USB operating current (increase per channel)		Low speed	$I_{CCUSBLS}$	—	3.7	6.5	—	3.7	6.5	mA	
		Full speed	$I_{CCUSBFS}$	—	4.2	10	—	4.2	10	mA	
CTSU operating current			I_{CTSU}	—	100	—	—	100	—	µA	
RAM retension voltage			V_{RAM}	2.7	—	—	2.7	—	—	V	
VCC rising gradient			SrVCC	8.4	—	20000	8.4	—	20000	µs/V	
VCC falling gradient*3			SfVCC	8.4	—	—	8.4	—	—	µs/V	

Note 1. The reference power supply current is included in the power supply current value for 12-bit A/D converter (unit 1).
Note 2. The analog power supply current cannot be separated into I_{AVCC0} and I_{AVCC1} in the 48-pin products because AVCC0 and AVCC1 share the same pin.
Note 3. This applies when V_{BATT} is used.

Table 56.8 Permissible Output Currents

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
$T_a = T_{opr}$

Item			Symbol	Min.	Typ.	Max.	Unit

Permissible output high current (average value per pin)	All output pins*1	Normal drive	I_{OH}	—	—	–2.0	mA
	All output pins*2	High drive		—	—	–3.8	
	All output pins*3	High-speed interface high-drive		—	—	–7.5	
Permissible output high current (max. value per pin)	All output pins*1	Normal drive	I_{OH}	—	—	–4.0	mA
	All output pins*2	High drive		—	—	–7.6	
	All output pins*3	High-speed interface high-drive		—	—	–15	
Permissible output high current (total)	Total of all output pins		ΣI_{OH}	—	—	–80	mA

Caution: To protect the LSI's reliability, the output current values should not exceed the values in this table.

Note 1. This is the value when normal driving ability is set with a pin for which normal driving ability is selectable.

Note 2. This is the value when high driving ability is set with a pin for which normal driving ability is selectable or the value of the pin to which high driving ability is fixed.

Note 3. This is the value when high-speed interface high-driving ability is set with a pin for which high-speed interface high-driving ability is selectable.

Table 56.9 Normal Output Characteristics

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V, T_a = 25°C

Item		Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Output high level voltage	Normal drive (P00 to P02, P12 to P14, P27, P36, P40 to P47, P50 to P52, P54 to P56, P72, P74 to P77, P80 to P83, P90 to P93, PA0 to PA7, PB0 to PB7, PC0 to PC7, PD0 to PD7, PE0 to PE7, PH1, PH2)	V_{OH}	—	3.26	—	V	I_{OH} = –0.5 mA
			—	3.22	—		I_{OH} = –1.0 mA

Table 56.10 Thermal Resistance Value (Reference)

Item	Package	Symbol	Max.	Unit	Test Conditions
Thermal resistance	144-pin LFQFP (PLQP0144KA-B)	θ_{ja}	48.4	°C/W	JESD51-2 and JESD51-7 compliant
	100-pin LFQFP (PLQP0100KB-B)		51.7		
	64-pin LFQFP (PLQP0064KB-C)		51.2		
	48-pin HWQFN (PWQN0048KC-A)		19.1*1		
	145-pin TFLGA (PTLG0145JC-A)		30.9		JESD51-2 and JESD51-9 compliant
	145-pin TFLGA (PTLG0145KB-A)		30.6		
	100-pin TFLGA (PTLG0100JB-A)		30.9		
	64-pin TFBGA (PTBG0064KB-A)		32.0		
	144-pin LFQFP (PLQP0144KA-B)	Ψ_{jt}	1.2	°C/W	JESD51-2 and JESD51-7 compliant
	100-pin LFQFP (PLQP0100KB-B)		1.2		
	64-pin LFQFP (PLQP0064KB-C)		1.2		
	48-pin HWQFN (PWQN0048KC-A)		0.1*1		
	145-pin TFLGA (PTLG0145JC-A)		0.4		JESD51-2 and JESD51-9 compliant
	145-pin TFLGA (PTLG0145KB-A)		0.4		
	100-pin TFLGA (PTLG0100JB-A)		0.4		
	64-pin TFBGA (PTBG0064KB-A)		0.4		

Note: The values are reference values when the 4-layer board is used. Thermal resistance depends on the number of layers or size of the board. For details, refer to the JEDEC standards.

Note 1. This value applies when the exposed die pad for this purpose is connected to VSS.

56.4 AC Characteristics

Table 56.11 Operating Frequency (High-Speed Operating Mode)

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
$T_a = T_{opr}$

Item			Symbol	Min.	Typ.	Max.	Unit
Operating frequency	System clock (ICLK)		f	—	—	120	MHz
	Peripheral module clock (PCLKA)			—	—	120	
	Peripheral module clock (PCLKB)			—	—	60	
	Peripheral module clock (PCLKC)			—	—	60	
	Peripheral module clock (PCLKD)			—	—	60	
	Flash-IF clock (FCLK)			—*1	—	60	
	External bus clock (BCLK)	Package of 144 pins or more		—	—	120	
		100-pin package		—	—	60	
	BCLK pin output	Package of 144 pins or more		—	—	60	
		100-pin package		—	—	30	
	SDRAM clock (SDCLK)	Package of 144 pins or more		—	—	60	
	SDCLK pin output	Package of 144 pins or more		—	—	60	

Note 1. The FCLK must run at a frequency of at least 4 MHz when changing the flash memory contents.

Table 56.12 Operating Frequency (Low-Speed Operating Mode 1)

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
$T_a = T_{opr}$

Item			Symbol	Min.	Typ.	Max.	Unit
Operating frequency	System clock (ICLK)		f	—	—	1	MHz
	Peripheral module clock (PCLKA)			—	—	1	
	Peripheral module clock (PCLKB)			—	—	1	
	Peripheral module clock (PCLKC)*1			—	—	1	
	Peripheral module clock (PCLKD)*1			—	—	1	
	Flash-IF clock (FCLK)			—	—	1	
	External bus clock (BCLK)	Package of 144 pins or more		—	—	1

Table 56.19 HOCO Clock Timing

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
$T_a = T_{opr}$

Item		Symbol	Min.	Typ.	Max.	Unit	Test Conditions
HOCO clock oscillation frequency	FLL not in use	f_{HOCO}	15.616 (–2.40%)	16	16.384 (+2.40%)	MHz	–20°C ≤ T_a
			17.568 (–2.40%)	18	18.432 (+2.40%)		
			19.520 (–2.40%)	20	20.480 (+2.40%)		
			15.520 (–3.00%)	16	16.480 (+3.00%)		T_a < –20°C
			17.460 (–3.00%)	18	18.540 (+3.00%)		
			19.400 (–3.00%)	20	20.600 (+3.00%)		
	FLL in use	f_{HOCO}	15.960 (–0.25%)	16	16.040 (+0.25%)	MHz	Sub-clock frequency precision: ±50 ppm
			17.955 (–0.25%)	18	18.045 (+0.25%)		
			19.950 (–0.25%)	20	20.050 (+0.25%)		
HOCO clock oscillation stabilization waiting time		t_{HOCOWT}	—	105	149	µs	Figure 56.8
HOCO clock power supply stabilization time		t_{HOCOP}	—	—	150	µs	Figure 56.9
FLL stabilization waiting time		t_{FLLWT}	—	—	1.8	ms	

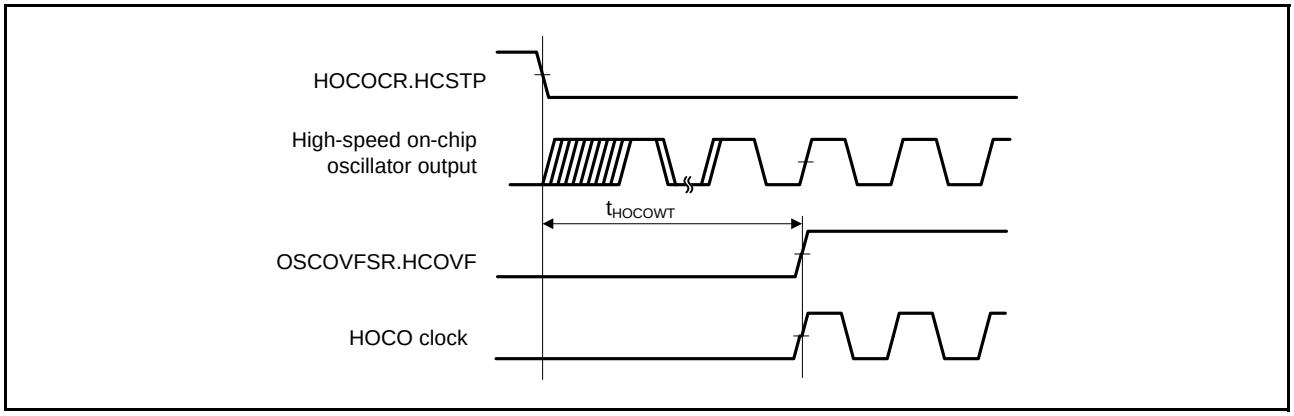

Figure 56.8 HOCO Clock Oscillation Start Timing (Oscillation is Started by Setting the HOCOCR.HCSTP Bit)

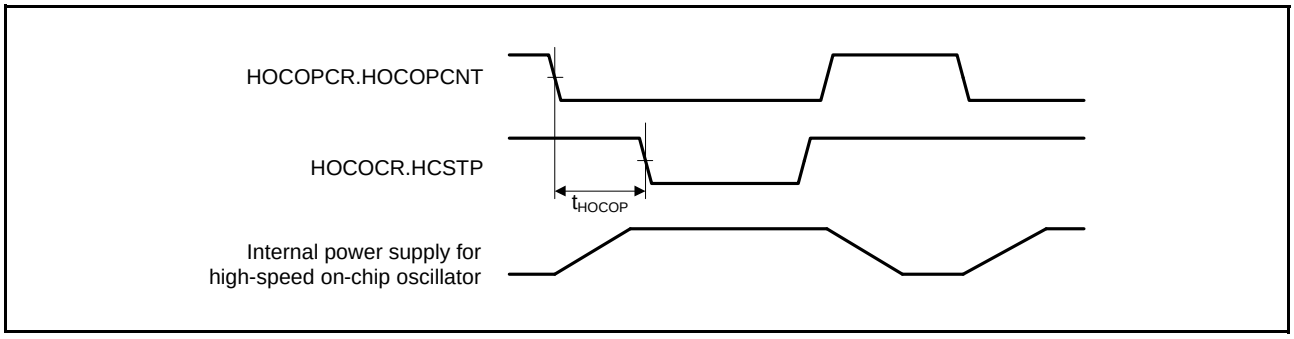

Figure 56.9 High-Speed On-Chip Oscillator Power Supply Control Timing

Table 56.20 PLL Clock Timing

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
$T_a = T_{opr}$

Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
PLL clock oscillation frequency	f_{PLL}	120	—	240	MHz	
PLL clock oscillation stabilization waiting time	t_{PLLWT}	—	259	320	µs	Figure 56.10

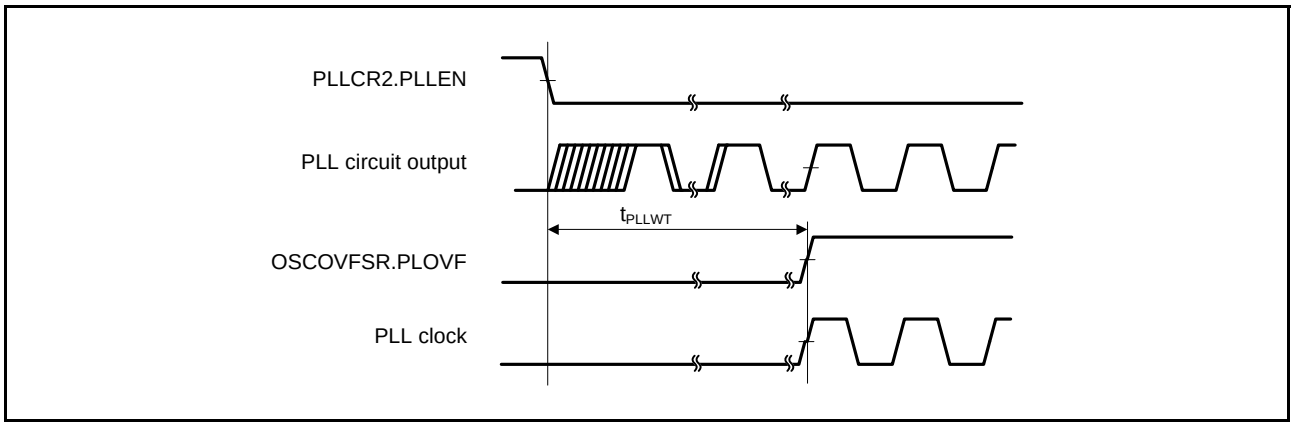

Figure 56.10 PLL Clock Oscillation Start Timing

Table 56.21 Sub-Clock Timing

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
When a low C_L crystal resonator is in use: V_{BATT} = 2.0 to 3.6 V,
When a standard C_L crystal resonator is in use: V_{BATT} = 1.62 to 3.6 V, $T_a = T_{opr}$

Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Sub-clock oscillation frequency	f_{SUB}	—	32.768	—	kHz	
Sub-clock oscillation stabilization time	t_{SUBOSC}	—	—	*1	s	Figure 56.11
Sub-clock oscillation stabilization waiting time	$t_{SUBOSCWT}$	—	—	*2	s	

Note 1. When using a sub-clock, ask the manufacturer of the oscillator to evaluate its oscillation. Refer to the results of evaluation provided by the manufacturer for the oscillation stabilization time.

Note 2. The number of cycles selected by the value of the SOSCWTCR.SSTS[7:0] bits determines the sub-clock oscillation stabilization waiting time in accord with the formula below.
$t_{SUBOSCWT}$ = [(SSTS[7:0] bits × 16384) + 10] / f_{LOCO}

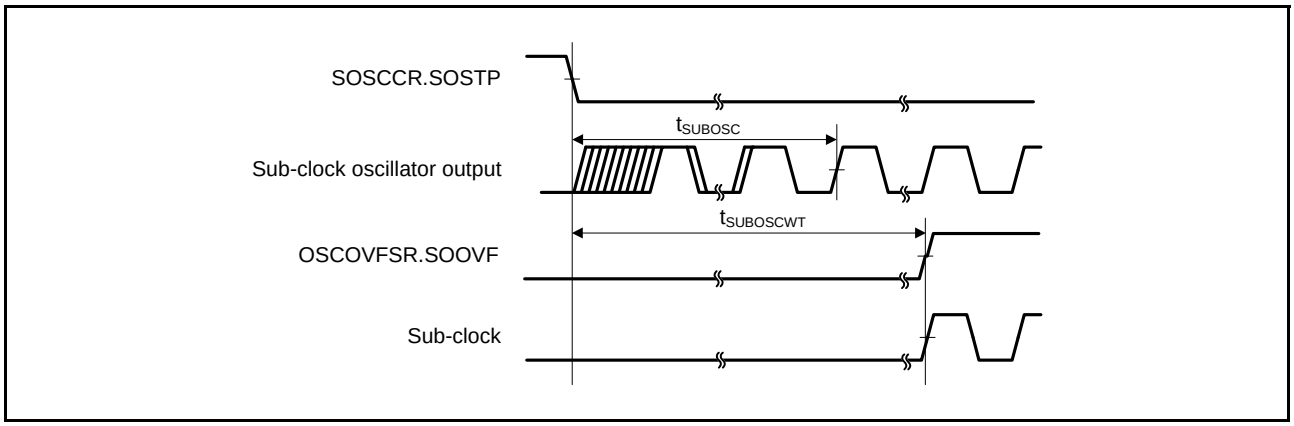

Figure 56.11 Sub-Clock Oscillation Start Timing

Table 56.22 CLKOUT Pin Output Timing

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
$T_a = T_{opr}$,
High-drive output is selected by the drive capacity control register

Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
CLKOUT pin output cycle time	t_{Ccyc}	25	—	—	ns	Figure 56.12 t_{Ccyc} = 25 ns
CLKOUT pin output high pulse width*1	t_{CH}	5	—	—	ns	
CLKOUT pin output low pulse width*1	t_{CL}	5	—	—	ns	
CLKOUT pin output rising time	t_{Cr}	—	—	5	ns	
CLKOUT pin output falling time	t_{Cf}	—	—	5	ns	

Note 1. If the main clock oscillator is selected by the CLKOUT output source select bit (CKOCR.CKOSEL[2:0]) and the external clock input is selected by the main clock oscillator switching bit (MOFCR.MOSEL), the pulse width depends on the input clock wave form.

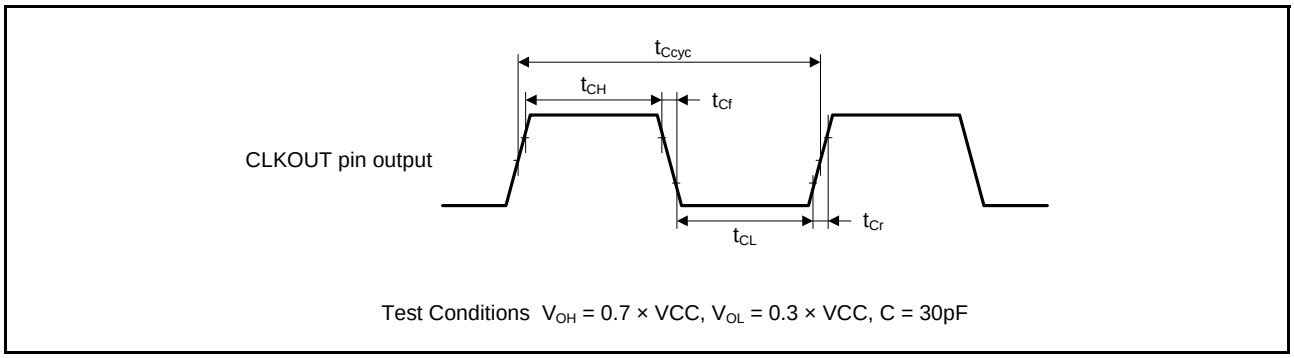

Figure 56.12 CLKOUT Pin Output Timing

56.4.3 Timing of Recovery from Low Power Consumption Modes

Table 56.23 Timing of Recovery from Low Power Consumption Modes (1)

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
$T_a = T_{opr}$

Item			Symbol	Min.	Typ.	Max.		Unit	Test Conditions
						$t_{SBYOSCWT}$*2	t_{SBYSEQ}*3		
Recovery time from software standby mode *1	Crystal resonator connected to main clock oscillator	Main clock oscillator operating	t_{SBYMC}	—	—	{(MSTS[7:0] bit × 32) + 76} / 0.216	100 + 7 / f_{ICLK} + 2n / f_{MAIN}	µs	Figure 56.13
		Main clock oscillator and PLL circuit operating	t_{SBYPC}			{(MSTS[7:0] bit × 32) + 138} / 0.216	100 + 7 / f_{ICLK} + 2n / f_{PLL}		
	External clock input to main clock oscillator	Main clock oscillator operating	t_{SBYEX}			352	100 + 7 / f_{ICLK} + 2n / f_{EXMAIN}		
		Main clock oscillator and PLL circuit operating	t_{SBYPE}			639	100 + 7 / f_{ICLK} + 2n / f_{PLL}		
	Sub-clock oscillator operating		t_{SBYSC}			{(SSTS[7:0] bit × 16384) + 13} / 0.216 + 10 / f_{FCLK}	100 + 4 / f_{ICLK} + 2n / f_{SUE}		
	High-speed on-chip oscillator operating	High-speed on-chip oscillator operating	t_{SBYHO}			454	100 + 7 / f_{ICLK} + 2n / f_{HOCO}		
		High-speed on-chip oscillator operating and PLL circuit operating	t_{SBYPH}			741	100 + 7 / f_{ICLK} + 2n / f_{PLL}		
	Low-speed on-chip oscillator operating*4		t_{SBYLO}			338	100 + 7 / f_{ICLK} + 2n / f_{LOCO}		

Note 1. The time for recovery from software standby mode is determined by the value obtained by adding the oscillation stabilization waiting time ($t_{SBYOSCWT}$) and the time required for operations by the software standby release sequencer (t_{SBYSEQ}).
Note 2. When several oscillators were running before the transition to software standby, the greatest value of the oscillation stabilization waiting time $t_{SBYOSCWT}$ is selected.
Note 3. For n, the greatest value is selected from among the internal clock division settings.
Note 4. This condition applies when f_{ICLK}:f_{FCLK} = 1:1, 2:1, or 4:1.

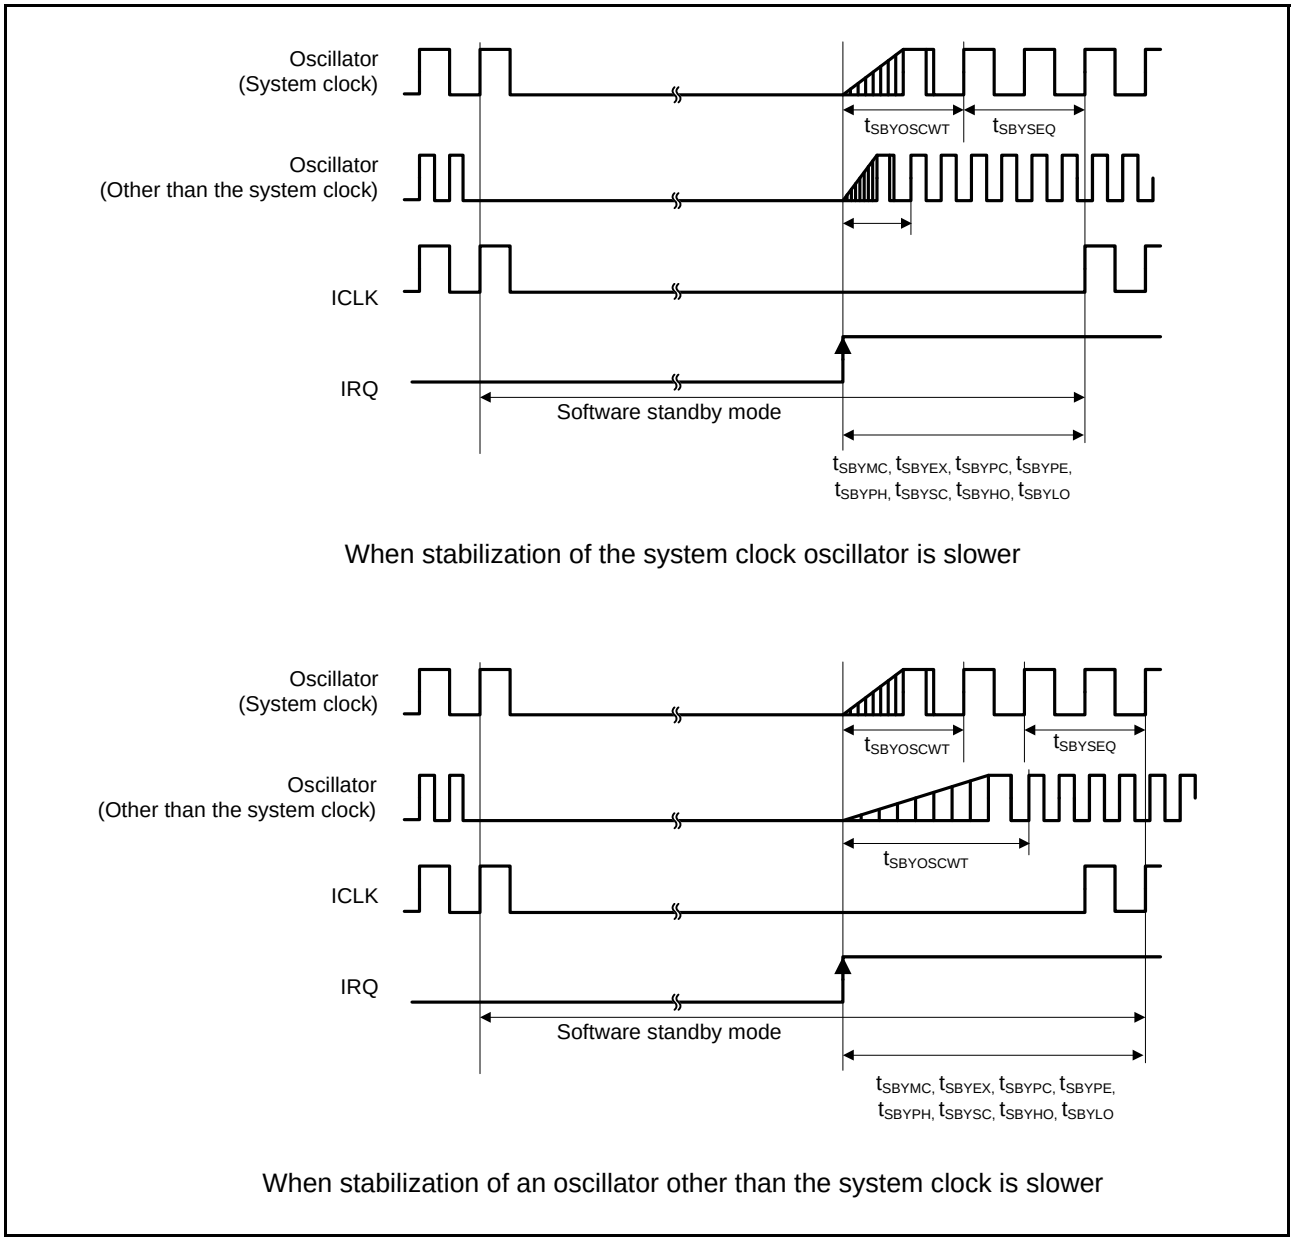

Figure 56.13 Software Standby Mode Recovery Timing

Table 56.24 Timing of Recovery from Low Power Consumption Modes (2)

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
$T_a = T_{opr}$

Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Recovery time from deep software standby mode	t_{DSBY}	—	—	0.9	ms	Figure 56.14

56.6 A/D Conversion Characteristics

Table 56.53 12-Bit A/D (Unit 0) Conversion Characteristics

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
PCLKB = PCLKC = 1 MHz to 60 MHz, $T_a = T_{opr}$,
Source impedance = 1.0 kΩ

Item	Min.	Typ.	Max.	Unit	Test Conditions
Resolution	8	—	12	Bit	
Analog input capacitance	—	—	30	pF	
Conversion time*1 (Operation at PCLKC = 60 MHz)	0.48 (0.267)*2	—	—	µs	Sampling in 16 states
Offset error	—	±1.0	±2.5	LSB	
Full-scale error	—	±1.0	±2.5	LSB	
Quantization error	—	±0.5	—	LSB	
Absolute accuracy	—	±2.5	±4.5	LSB	
DNL differential nonlinearity error	—	±0.5	±1.5	LSB	
INL integral nonlinearity error	—	±1.0	±2.5	LSB	

Note: The above specification values apply when there is no access to the external bus during A/D conversion. If access proceeds during A/D conversion, values may not fall within the above ranges.
Note 1. The conversion time includes the sampling time and the comparison time. As the test conditions, the number of sampling states is indicated.
Note 2. The value in parentheses indicates the sampling time.

Table 56.54 12-Bit A/D (Unit 1) Conversion Characteristics

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
PCLKB = PCLKD = 1 MHz to 60 MHz, $T_a = T_{opr}$,
Source impedance = 1.0 kΩ

Item	Min.	Typ.	Max.	Unit	Test Conditions
Resolution	8	—	12	Bit	
Conversion time*1 (Operation at PCLKD = 60 MHz)	0.88 (0.633)*2	—	—	µs	Sampling in 38 states (ADSAM.SAM = 1)
Conversion time*1 (Operation at PCLKD = 30 MHz)	1 (0.500)*2	—	—	µs	Sampling in 15 states (ADSAM.SAM = 1)
Analog input capacitance	—	—	30	pF	
Offset error	—	±2.0	±3.5	LSB	
Full-scale error	—	±2.0	±3.5	LSB	
Quantization error	—	±0.5	—	LSB	
Absolute accuracy	—	±4.0	±6.0	LSB	
DNL differential nonlinearity error (Operation at PCLKD = 60 MHz)	—	±1.5	±4.0	LSB	
DNL differential nonlinearity error (Operation at PCLKD = 30 MHz)	—	±1.5	±2.5	LSB	
INL integral nonlinearity error (Operation at PCLKD = 60 MHz)	—	±2.0	±4.0	LSB	
INL integral nonlinearity error (Operation at PCLKD = 30 MHz)	—	±2.0	±3.5	LSB	

Note: The above specification values apply when there is no access to the external bus during A/D conversion. If access proceeds during A/D conversion, values may not fall within the above ranges.
Note 1. The conversion time includes the sampling time and the comparison time. As the test conditions, the number of sampling states is indicated.
Note 2. The value in parentheses indicates the sampling time.

Table 56.55 A/D Internal Reference Voltage Characteristics

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
PCLKB = PCLKD = 60 MHz, $T_a = T_{opr}$

Item	Min.	Typ.	Max.	Unit	Test Conditions
A/D internal reference voltage	1.13	1.18	1.23	V	

56.7 Temperature Sensor Characteristics

Table 56.56 Temperature Sensor Characteristics

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
$T_a = T_{opr}$

Item	Min.	Typ.	Max.	Unit	Test Conditions
Relative accuracy	—	±1	—	°C	
Temperature slope	—	4	—	mV/°C	
Output voltage	—	1.21	—	V	T_a = 25°C
Temperature sensor start time	—	—	30	µs	
Sampling time*1	4.15	—	—	µs	

Note 1. Set the S12AD1.ADSSTRT register such that the sampling time of the 12-bit A/D converter satisfies this specification.

56.8 CTSU Characteristics

Table 56.57 CTSU Characteristics

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
$T_a = T_{opr}$

Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
External capacitance connected to TSCAP pin	C_{tscap}	9	10	11	nF	
TS pin capacitive load	C_{base}	—	—	50	pF	
Total sum of the high-level output current*1	ΣI_{OH}	—	—	–40*2	mA	The mutual capacitance method is in use.

Note 1. Total sum of I_{OH} of the pins other than TSCAP, and TS0 to TS16

Note 2. In the mutual capacitance method, when the amount of current output from the I/O pins other than those of the CTSU is relatively large, the VCC voltage largely drops, affecting measurement by the CTSU. Accordingly, the total sum of I_{OH} of the other pins should be no more than the listed value when the CTSU is in use.

56.9 Power-on Reset Circuit and Voltage Detection Circuit Characteristics

Table 56.58 Power-on Reset Circuit and Voltage Detection Circuit Characteristics

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
$T_a = T_{opr}$

Item			Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Voltage detection level	Power-on reset (POR)	Low power consumption function disabled*1	V_{POR}	2.5	2.6	2.7	V	Figure 56.93
		Low power consumption function enabled*2		1.8	2.25	2.7

56.10 Oscillation Stop Detection Timing

Table 56.59 Oscillation Stop Detection Circuit Characteristics

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
$T_a = T_{opr}$

Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Detection time	t_{dr}	—	—	1	ms	Figure 56.97

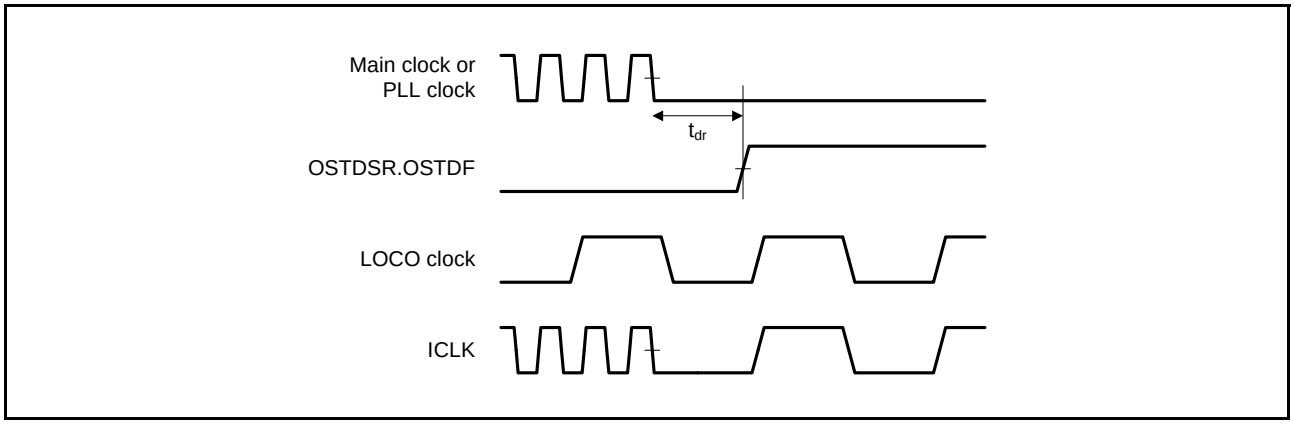

Figure 56.97 Oscillation Stop Detection Timing

56.11 Battery Backup Function Characteristics

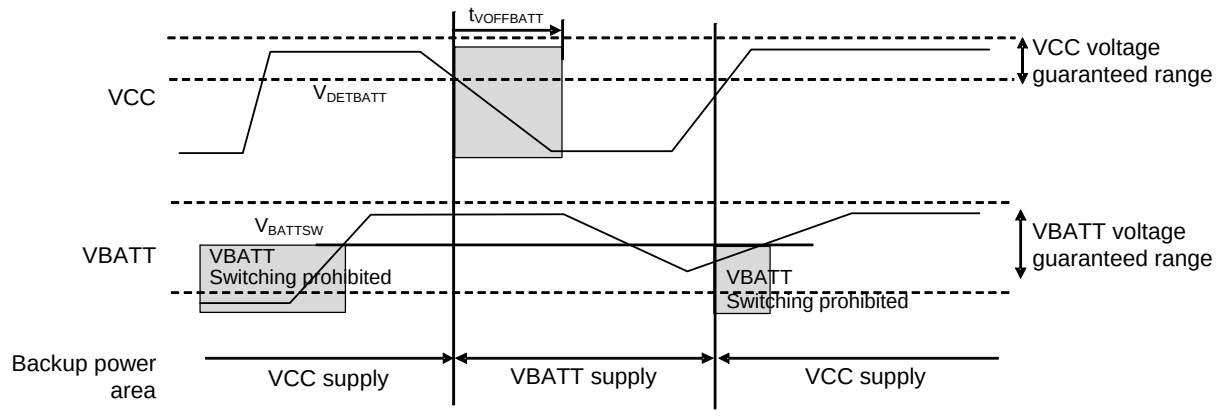
Table 56.60 Battery Backup Function Characteristics

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
V_{BATT} = 1.62 to 3.6 V, $T_a = T_{opr}$

Item	Symbol	Min.	Typ.	Max.	Unit	Test Conditions
Voltage level for switching to battery backup	$V_{DETBATT}$	2.50	2.60	2.70	V	Figure 56.98
Lower-limit V_{BATT} voltage for power supply switching due to VCC voltage drop	V_{BATTSW}	2.00	—	—	V	
VCC-off period for starting power supply switching*1	$t_{VOFFBATT}$	200	—	—	µs	
Backup domain power-down detection level	$V_{PDR(BKP)}$	1.45	1.5	1.55	V	Figure 56.99
Time delay in assertion of the reset signal for the backup domain*2	$t_{p(PDRL)}$	—	—	2000	µs	
Time delay in negation of the reset signal for the backup domain	$t_{p(PDRH)}$	—	—	1000	µs	
Temper input pulse width	$t_{w(TAMPI)}$	200	—	—	ns	Figure 56.100

Note 1. The VCC-off period for switching power supply indicates the period from VCC falling below the minimum value of the battery backup switching threshold voltage ($V_{DETBATT}$) until the source of supply is switched to VBATT. When the VCC recovers within this period, the source may not be switched to VBATT and supply from VCC is continued.

Note 2. When the V_{BKP} recovers within this period, the backup domain reset signal may not be generated.



Note. The VBATT voltage when the supplied power source switches from VCC to VBATT should not be lower than V_{BATTSW}, the lower-limit VBATT voltage for switching between power supplies due to a drop in the VCC voltage.

			10	—	—	10	—	—	10	—	—		T_a ≤ 105°C

Note 1. Definition of program/erase cycle:
The program/erase cycle is the number of erasing for each block. When the number of program/erase cycles is n, each block can be erased n times. For instance, when 128-byte program is performed 64 times for different addresses in 8-Kbyte block and then the block is erased, the program/erase cycle is counted as one. However, the same address cannot be programmed more than once before the next erase cycle (overwriting is prohibited).

Note 2. Characteristics are degraded as the number of program/erase increases. This is the minimum value of program/erase cycles to guarantee all characteristics listed in this table.

Note 3. This shows the characteristic when the flash memory writer or self-programming library from Renesas Electronics is in use, and the number of times programming and erasure proceed does not exceed the specified value.

Note 4. These values are based on the results of reliability testing.

Table 56.62 Data Flash Memory Characteristics

Conditions: VCC = AVCC0 = AVCC1 = VCC_USB = V_{BATT} = 2.7 to 3.6 V, 2.7 V ≤ VREFH0 ≤ AVCC0,
VSS = AVSS0 = AVSS1 = VREFL0 = VSS_USB = 0 V,
Temperature range for programming/erasure: $T_a = T_{opr}$

Suspend delay time during erasing (in erasure priority mode)	64 bytes	—	—	—	300	—	—	300	—	—	300	µs	
	128 bytes	—	—	—	390	—	—	390	—	—	390	µs	
	256 bytes	—	—	—	570	—	—	570	—	—	570	µs	
Forced stop command		t_{FD}	—	—	32	—	—	22	—	—	20	µs	
Data hold time*3, *4		t_{DDRP}	20	—	—	20	—	—	20	—	—	Year	$T_a \leq 85°C$
			10	—	—	10	—	—	10	—	—		$T_a \leq 105°C$

Note 1. Definition of program/erase cycle:
The program/erase cycle is the number of erasing for each block. When the number of program/erase cycles is n, each block can be erased n times. For instance, when 4-byte program is performed 512 times for different addresses in 2-Kbyte block and then the block is erased, the program/erase cycle is counted as one. However, the same address cannot be programmed more than once before the next erase cycle (overwriting is prohibited).

Note 2. Characteristics are degraded as the number of program/erase increases. This is the minimum value of program/erase cycles to guarantee all characteristics listed in this table.

Note 3. This shows the characteristic when the flash memory writer or self-programming library from Renesas Electronics is in use, and the number of times programming and erasure proceed does not exceed the specified value.

Note 4. These values are based on the results of reliability testing.

Table 1.1 Port States in Each Processing State (5 / 5)

Port Name Pin Name	Operating Mode According to Registers Setting		Reset	Software Standby Mode		Deep Software Standby Mode	After Deep Software Standby Mode is Canceled (Return to Start-up Mode)	
				OPE = 1	OPE = 0	IOKEEP = 1/0	IOKEEP = 1*1	IOKEEP = 0
PE0/IRQ8, PE1/IRQ9, PE2/IRQ7-DS, PE3/IRQ11, PE4/IRQ12, PE5/IRQ5, PE6/IRQ6, PE7/IRQ7	Single-chip mode (EXBE = 0)		Hi-Z	Keep-O*2		Keep-O*3	Keep	Hi-Z
	On-chip ROM enabled/ disabled extended (EXBE = 1)	8 bits in width of bus		[Data output] Hi-Z [Other than the above] Keep-O*2				
		16 bits in width of bus		[Data output] Hi-Z				
PF5/IRQ4	All		Hi-Z	Keep-O*2		Keep	Keep	Hi-Z
PJ3/IRQ11, PJ5/IRQ13	All		Hi-Z	Keep-O*2		Keep	Keep	Hi-Z
PH1/USB0_DP/ IRQ0	All		Hi-Z	Keep-O*2, *4		Hi-Z*3	Hi-Z	
PH2/USB0_DM/ IRQ1	All		Hi-Z	Keep-O*2, *4		Hi-Z*3	Hi-Z	
USB1_DM	All		Hi-Z	Keep-O*4		Hi-Z	Hi-Z	
USB1_DP	All		Hi-Z	Keep-O*4		Hi-Z	Hi-Z	

H: High-level

L: Low-level

Keep-O: Output pins retain their previous values, and input pins become high-impedance.

Keep: Pin states are retained during periods on software standby.

Hi-Z: High-impedance

Note 1. The I/O port state is retained until the DPSBYCR.IOKEEP bit is cleared to 0.
Note 2. Input is enabled if the pin is specified as the software standby cancelling source while it is used as an external interrupt pin.
Note 3. Input is enabled if the pin is specified as the deep software standby cancelling source.
Note 4. Input is possible, but only when the pin is in use as a USB input pin.

Appendix 2. Package Dimensions

Information on the latest version of the package dimensions or mountings has been displayed in “Packages” on Renesas Electronics Corporation website.

JEITA Package Code	RENESAS Code	Previous Code	MASS (Typ) [g]
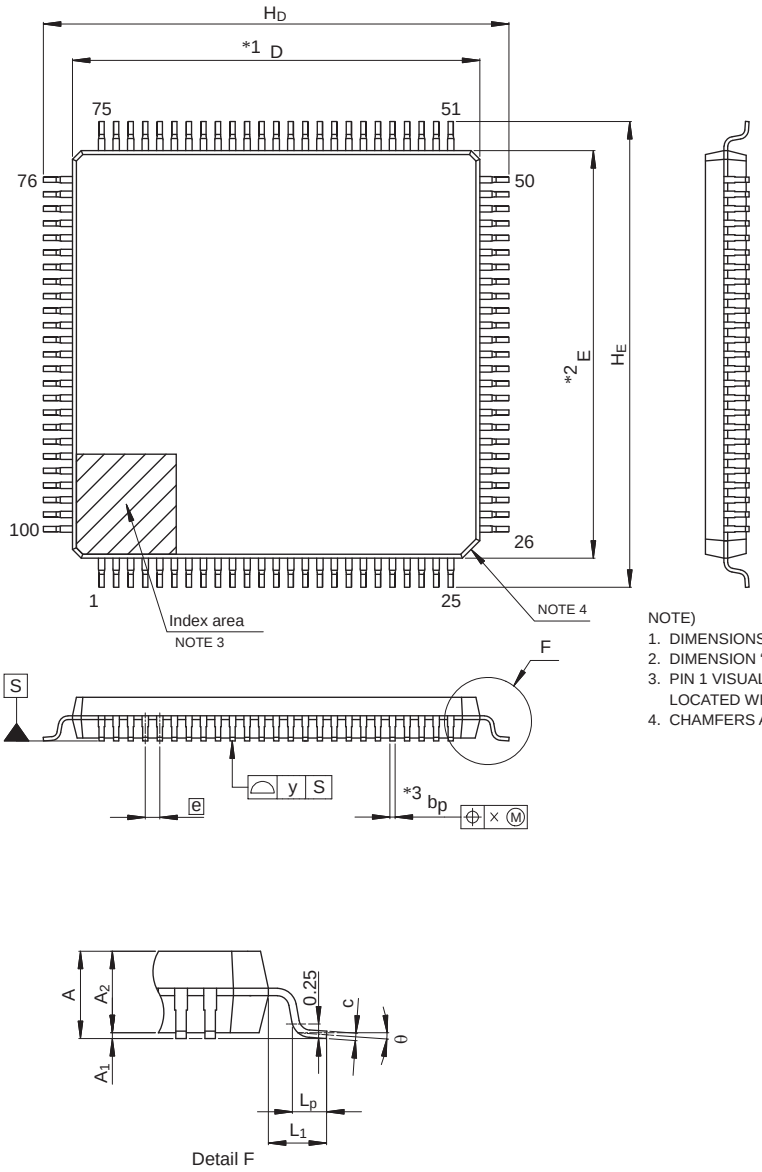
P-LFQFP100-14x14-0.50	PLQP0100KB-B	—	0.6

Unit: mm



NOTE)
1. DIMENSIONS "*1" AND "*2" DO NOT INCLUDE MOLD FLASH.
2. DIMENSION "*3" DOES NOT INCLUDE TRIM OFFSET.
3. PIN 1 VISUAL INDEX FEATURE MAY VARY, BUT MUST BE LOCATED WITHIN THE HATCHED AREA.
4. CHAMFERS AT CORNERS ARE OPTIONAL, SIZE MAY VARY.

REVISION HISTORY	RX671 Group User's Manual: Hardware

Classifications

- Items with Technical Update document number: Changes according to the corresponding issued Technical Update
- Items without Technical Update document number: Minor changes that do not require Technical Update to be issued

Rev.	Date	Description		Classification
		Page	Summary	
1.00	Mar 31, 2021	—	First edition, issued	
1.10	Apr 15, 2022	Features		
		69	Coremark value, changed	
		69	Useful functions for IEC60730 compliance, changed	
		1. Overview		
		76	Table 1.1 Outline of Specifications (7/10), changed	
		79	Table 1.1 Outline of Specifications (10/10), changed	
		82 to 84	Table 1.3 List of Products, changed	
		85	Figure 1.1 How to Read the Product Part Number, changed	
		86	Figure 1.2 Block Diagram, changed	
		91	Table 1.4 Pin Functions (5/8), changed	
		92	Table 1.4 Pin Functions (6/8), changed	
		94	Table 1.4 Pin Functions, Note changed	
		7. Option-Setting Memory (OFSM)		
		—	7.5.2 Setting Data for Programming the Option-Setting Memory, deleted	
		9. Clock Generation Circuit		
		319	9.2.5 PLL Control Register (PLLCR), changed	
		341	9.2.24 Sub-Clock Oscillator Control Register 2 (SOSCCR2), changed	
		343	9.2.26 High-Speed On-Chip Oscillator Trimming Registers n (HOCOTRRn) (n = 0 to 2), changed, Note added	
		360	Figure 9.15 Example Flowchart of Initialization when the Sub-Clock is to be Used as the Source to Drive Counting by the Realtime Clock, changed	TN-RX*-A0257A/E
		361	Figure 9.16 Example Flowchart for Initialization when the Sub-Clock is to be Used only as the System Clock, changed	
		362	Figure 9.17 Example Flowchart for when the Sub-Clock is not to be Used, Note 1 added	
		15. Interrupt Controller (ICUE)		
		453, 454	15.2.1 Interrupt Request Register n (IRn) (n = 016 to 255), changed	
		23. Multi-Function Pin Controller (MPC)		
		915	23.2.26 External Bus Control Register 1 (PFBCR1), changed	
		36. Serial Communications Interface (RSCI)		
		1770	Table 36.9 Relationship between N Setting in BRR[7:0] Bits and Bit Rate B, Explanatory notes, changed	
		1805 to 1810	36.2.17 Status Register (SSR), changed	
		38. High-Speed I^{2}C-bus Interface (RIICHS)		
		2085	38.2.22 Communication Status Interrupt Enable Register (ICCSIER), changed	
		2120	38.7.4 Hs-Mode Master Code Detection, added	
		2139	38.13 Interrupt Sources, added	
		2140	38.14 Event Link Function, added	
		55. Flash Memory (FLASH)		
		2844	Table 55.7 Methods of Programming, changed	
		2845	Table 55.8 List of Basic Functions, changed	
		2846	55.7.3 Security Functions, changed	
		2846	Table 55.9 Lists of Security Functions, changed	
		2932	55.17.1 Overview, changed	
		56. Electrical Characteristics		
		2949	Table 56.9 Normal Output Characteristics, added	
		2950	Table 56.10 Thermal Resistance Value (Reference), changed	

Rev.	Date	Description		Classification
		Page	Summary	
1.10	Apr 15, 2022	Appendix 2. Package Dimensions		
		3035	Figure A 145-Pin TFLGA (PTLG0145JC-A), added	
		3036	Figure B 145-Pin TFLGA (PTLG0145KB-A), added	
		3038	Figure D 100-Pin TFLGA (PTLG0100JB-A), added	
		3040	Figure F 64-Pin TFBGA (PTBG0064KB-A), added	
		3042	Figure H 48-Pin HWQFN (PWQN0048KC-A), added
