

V850E2/ME3

User's Manual: Hardware

RENESAS MCU V850E2/ME3 Microcontrollers

μPD703500

μPD703590

All information contained in these materials, including products and product specifications, represents information on the product at the time of publication and is subject to change by Renesas Electronics Corp. without notice. Please review the latest information published by Renesas Electronics Corp. through various means, including the Renesas Electronics Corp. website (<http://www.renesas.com>).

Notice

1. All information included in this document is current as of the date this document is issued. Such information, however, is subject to change without any prior notice. Before purchasing or using any Renesas Electronics products listed herein, please confirm the latest product information with a Renesas Electronics sales office. Also, please pay regular and careful attention to additional and different information to be disclosed by Renesas Electronics such as that disclosed through our website.
2. Renesas Electronics does not assume any liability for infringement of patents, copyrights, or other intellectual property rights of third parties by or arising from the use of Renesas Electronics products or technical information described in this document. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
3. You should not alter, modify, copy, or otherwise misappropriate any Renesas Electronics product, whether in whole or in part.
4. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation of these circuits, software, and information in the design of your equipment. Renesas Electronics assumes no responsibility for any losses incurred by you or third parties arising from the use of these circuits, software, or information.
5. When exporting the products or technology described in this document, you should comply with the applicable export control laws and regulations and follow the procedures required by such laws and regulations. You should not use Renesas Electronics products or the technology described in this document for any purpose relating to military applications or use by the military, including but not limited to the development of weapons of mass destruction. Renesas Electronics products and technology may not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations.
6. Renesas Electronics has used reasonable care in preparing the information included in this document, but Renesas Electronics does not warrant that such information is error free. Renesas Electronics assumes no liability whatsoever for any damages incurred by you resulting from errors in or omissions from the information included herein.
7. Renesas Electronics products are classified according to the following three quality grades: “Standard”, “High Quality”, and “Specific”. The recommended applications for each Renesas Electronics product depends on the product’s quality grade, as indicated below. You must check the quality grade of each Renesas Electronics product before using it in a particular application. You may not use any Renesas Electronics product for any application categorized as “Specific” without the prior written consent of Renesas Electronics. Further, you may not use any Renesas Electronics product for any application for which it is not intended without the prior written consent of Renesas Electronics. Renesas Electronics shall not be in any way liable for any damages or losses incurred by you or third parties arising from the use of any Renesas Electronics product for an application categorized as “Specific” or for which the product is not intended where you have failed to obtain the prior written consent of Renesas Electronics. The quality grade of each Renesas Electronics product is “Standard” unless otherwise expressly specified in a Renesas Electronics data sheets or data books, etc.
 - “Standard”: Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; and industrial robots.
 - “High Quality”: Transportation equipment (automobiles, trains, ships, etc.); traffic control systems; anti-disaster systems; anti-crime systems; safety equipment; and medical equipment not specifically designed for life support.
 - “Specific”: Aircraft; aerospace equipment; submersible repeaters; nuclear reactor control systems; medical equipment or systems for life support (e.g. artificial life support devices or systems), surgical implantations, or healthcare intervention (e.g. excision, etc.), and any other applications or purposes that pose a direct threat to human life.
8. You should use the Renesas Electronics products described in this document within the range specified by Renesas Electronics, especially with respect to the maximum rating, operating supply voltage range, movement power voltage range, heat radiation characteristics, installation and other product characteristics. Renesas Electronics shall have no liability for malfunctions or damages arising out of the use of Renesas Electronics products beyond such specified ranges.
9. Although Renesas Electronics endeavors to improve the quality and reliability of its products, semiconductor products have specific characteristics such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Further, Renesas Electronics products are not subject to radiation resistance design. Please be sure to implement safety measures to guard them against the possibility of physical injury, and injury or damage caused by fire in the event of the failure of a Renesas Electronics product, such as safety design for hardware and software including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult, please evaluate the safety of the final products or system manufactured by you.
10. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. Please use Renesas Electronics products in compliance with all applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive. Renesas Electronics assumes no liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
11. This document may not be reproduced or duplicated, in any form, in whole or in part, without prior written consent of Renesas Electronics.
12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products, or if you have any other inquiries.

(Note 1) “Renesas Electronics” as used in this document means Renesas Electronics Corporation and also includes its majority-owned subsidiaries.

(Note 2) “Renesas Electronics product(s)” means any product developed or manufactured by or for Renesas Electronics.

NOTES FOR CMOS DEVICES

① VOLTAGE APPLICATION WAVEFORM AT INPUT PIN

Waveform distortion due to input noise or a reflected wave may cause malfunction. If the input of the CMOS device stays in the area between V_{IL} (MAX) and V_{IH} (MIN) due to noise, etc., the device may malfunction. Take care to prevent chattering noise from entering the device when the input level is fixed, and also in the transition period when the input level passes through the area between V_{IL} (MAX) and V_{IH} (MIN).

② HANDLING OF UNUSED INPUT PINS

Unconnected CMOS device inputs can be cause of malfunction. If an input pin is unconnected, it is possible that an internal input level may be generated due to noise, etc., causing malfunction. CMOS devices behave differently than Bipolar or NMOS devices. Input levels of CMOS devices must be fixed high or low by using pull-up or pull-down circuitry. Each unused pin should be connected to V_{DD} or GND via a resistor if there is a possibility that it will be an output pin. All handling related to unused pins must be judged separately for each device and according to related specifications governing the device.

③ PRECAUTION AGAINST ESD

A strong electric field, when exposed to a MOS device, can cause destruction of the gate oxide and ultimately degrade the device operation. Steps must be taken to stop generation of static electricity as much as possible, and quickly dissipate it when it has occurred. Environmental control must be adequate. When it is dry, a humidifier should be used. It is recommended to avoid using insulators that easily build up static electricity. Semiconductor devices must be stored and transported in an anti-static container, static shielding bag or conductive material. All test and measurement tools including work benches and floors should be grounded. The operator should be grounded using a wrist strap. Semiconductor devices must not be touched with bare hands. Similar precautions need to be taken for PW boards with mounted semiconductor devices.

④ STATUS BEFORE INITIALIZATION

Power-on does not necessarily define the initial status of a MOS device. Immediately after the power source is turned ON, devices with reset functions have not yet been initialized. Hence, power-on does not guarantee output pin levels, I/O settings or contents of registers. A device is not initialized until the reset signal is received. A reset operation must be executed immediately after power-on for devices with reset functions.

⑤ POWER ON/OFF SEQUENCE

In the case of a device that uses different power supplies for the internal operation and external interface, as a rule, switch on the external power supply after switching on the internal power supply. When switching the power supply off, as a rule, switch off the external power supply and then the internal power supply. Use of the reverse power on/off sequences may result in the application of an overvoltage to the internal elements of the device, causing malfunction and degradation of internal elements due to the passage of an abnormal current.

The correct power on/off sequence must be judged separately for each device and according to related specifications governing the device.

⑥ INPUT OF SIGNAL DURING POWER OFF STATE

Do not input signals or an I/O pull-up power supply while the device is not powered. The current injection that results from input of such a signal or I/O pull-up power supply may cause malfunction and the abnormal current that passes in the device at this time may cause degradation of internal elements. Input of signals during the power off state must be judged separately for each device and according to related specifications governing the device.

How to Use This Manual

- Readers** This manual is intended for users who wish to understand the functions of the V850E2/ME3 (μ PD703500, 703590) and design application systems using these products.
- Purpose** This manual is intended to give users an understanding of the hardware functions of the V850E2/ME3 shown in the **Organization** below.
- Organization** This manual is divided into two parts: Hardware (this manual) and Architecture (**V850E2 Architecture User's Manual**).

Hardware

- Pin functions
- CPU function
- On-chip peripheral functions
- Electrical specifications

Architecture

- Data types
- Register set
- Instruction format and instruction set
- Interrupts and exceptions
- Pipeline operation

How to Read This Manual It is assumed that the readers of this manual have general knowledge in the fields of electrical engineering, logic circuits, and microcontrollers.

To understand the overall functions of the V850E2/ME3
→ Read this manual according to the **CONTENTS**.

To find the details of a register where the name is known
→ Use **APPENDIX A REGISTER INDEX**.

Register format

→ The name of the bit whose number is in angle brackets (< >) in the figure of the register format of each register is defined as a reserved word in the device file.

To understand the details of an instruction function

→ Refer to the **V850E2 Architecture User's Manual** available separately.

To know the electrical specifications of the V850E2/ME3

→ See **CHAPTER 18 ELECTRICAL SPECIFICATIONS**

The “yyy bit of the xxx register” is described as the “xxx.yyy bit” in this manual. Note with caution that if “xxx.yyy” is described as is in a program, however, the compiler/assembler cannot recognize it correctly.

The mark <R> shows major revised points. The revised points can be easily searched by copying an “<R>” in the PDF file and specifying it in the “Find what:” field.

Conventions

Data significance:	Higher digits on the left and lower digits on the right
Active low representation:	\overline{xxx} (overscore over pin or signal name)
Memory map address:	Higher addresses on the top and lower addresses on the bottom
Note:	Footnote for item marked with Note in the text
Caution:	Information requiring particular attention
Remark:	Supplementary information
Numeric representation:	Binary ... xxxx or xxxxB Decimal ... xxxx Hexadecimal ... xxxxH
Prefix indicating power of 2 (address space, memory capacity):	K (kilo): $2^{10} = 1,024$ M (mega): $2^{20} = 1,024^2$ G (giga): $2^{30} = 1,024^3$

Related Documents

The related documents indicated in this publication may include preliminary versions. However, preliminary versions are not marked as such.

CHAPTER 6 MEMORY ACCESS CONTROL FUNCTION		185
6.1	SRAM, External ROM, External I/O Interface	185
6.1.1	Features	185
6.1.2	SRAM connection	186
6.1.3	SRAM, external ROM, external I/O access	188
6.2	Page ROM Controller (ROMC)	197
6.2.1	Features	197
6.2.2	Page ROM connection	198
6.2.3	On-page/off-page judgment	199
6.2.4	Page ROM configuration register (PRC)	200
6.2.5	Page ROM access	201
6.3	SDRAM Controller (SDRAMC)	205
6.3.1	Features	205
6.3.2	SDRAM connection	205
6.3.3	Address multiplex function	206
6.3.4	SDRAM configuration registers 1, 3, 4, 6 (SCR1, SCR3, SCR4, SCR6)	212
6.3.5	SDRAM access	215
6.3.6	Refresh control function	236
6.3.7	Self-refresh control function	241
6.3.8	SDRAM initialization sequence	243
6.4	Cautions	246
CHAPTER 7 DMA FUNCTIONS (DMA CONTROLLER)		247
7.1	Features	247
7.2	Configuration	248
7.3	Control Registers	249
7.3.1	DMA control register (DC)	249
7.3.2	DMA source address registers 0 to 3 (DSA0 to DSA3)	250
7.3.3	DMA destination address registers 0 to 3 (DDA0 to DDA3)	252
7.3.4	DMA transfer count registers 0 to 3 (DBC0 to DBC3)	254
7.3.5	DMA addressing control registers 0 to 3 (DADC0 to DADC3)	256
7.3.6	DMA channel control registers 0 to 3 (DCHC0 to DCHC3)	259
7.3.7	DMA restart register (DRST)	262
7.3.8	DMA terminal count output control register (DTC)	263
7.3.9	DMA trigger factor registers 0 to 3 (DTFR0 to DTFR3)	264
7.3.10	DMA interface control registers 0 to 3 (DIFC to DIFC3)	270
7.3.11	DMA single transfer mode control register (DSMC)	272
7.4	Transfer Modes	273
7.4.1	Single transfer mode	273
7.4.2	Single-step transfer mode	275
7.4.3	Block transfer mode	276
7.5	Transfer Types	277
7.5.1	2-cycle transfer	277

7.5.2	Flyby transfer	286
7.6	Transfer Target.....	298
7.6.1	Transfer type and transfer target.....	298
7.6.2	External bus cycles during DMA transfer	300
7.7	DMA Channel Priority Control	301
7.7.1	Fixed-priority mode	301
7.7.2	Round-robin mode	302
7.8	Next Address Setting Function	304
7.9	DMA Transfer Start Factors	305
7.10	Terminal Count Output upon DMA Transfer End	307
7.11	Forcible Interruption	308
7.12	Forcible Termination.....	309
7.13	Times Related to DMA Transfer.....	310
7.14	Maximum Response Time for DMA Transfer Request	311
7.15	Cautions	312
7.15.1	Interrupt factors.....	314
7.16	DMA Transfer End.....	314

CHAPTER 8 INTERRUPT/EXCEPTION PROCESSING FUNCTION..... 315

8.1	Features	315
8.2	Non-Maskable Interrupts.....	319
8.2.1	Operation	320
8.2.2	Restore	322
8.2.3	Non-maskable interrupt status flag (NP)	323
8.2.4	Edge detection function.....	323
8.3	Maskable Interrupts	324
8.3.1	Operation	324
8.3.2	Restore	326
8.3.3	Priorities of maskable interrupts.....	327
8.3.4	Interrupt control register (xxICn)	331
8.3.5	Interrupt mask registers 0 to 5 (IMR0 to IMR5).....	334
8.3.6	In-service priority register (ISPR)	336
8.3.7	Maskable interrupt status flag (ID)	336
8.3.8	Selecting interrupt trigger mode	337
8.4	Software Exception.....	352
8.4.1	Operation	352
8.4.2	Restore	353
8.4.3	Exception status flag (EP).....	354
8.5	Exception Trap	355
8.5.1	Illegal opcode definition.....	355
8.5.2	Debug trap	357
8.6	Multiple Interrupt Servicing Control.....	359
8.7	Periods in Which Interrupts Are Not Acknowledged by CPU	361
8.8	Cautions	361

CHAPTER 9 CLOCK GENERATION FUNCTION **362**

9.1	Features	362
9.2	Configuration	363
9.3	Control Registers	363
9.3.1	Clock control register (CKC)	363
9.3.2	Clock source select register (CKS)	368
9.3.3	VBCSEL pin function	370
9.3.4	SSCG control register (SSCGC).....	371
9.3.5	Lock register (LOCKR).....	373
9.4	Operation	374
9.4.1	Operation status of each clock.....	374
9.4.2	Setting of input clock (FX).....	374
9.5	Operating Clock Provisions	375
9.5.1	Calculating BUSCLK frequency	376
9.5.2	Calculating operating clock frequency of each on-chip peripheral function.....	376
9.6	Power-Save Control	379
9.6.1	Overview.....	379
9.6.2	Control registers.....	380
9.6.3	HALT mode.....	383
9.6.4	IDLE mode.....	387
9.7	Cautions	392

CHAPTER 10 TIMER/COUNTER FUNCTION **393**

10.1	Timer C	393
10.1.1	Features.....	393
10.1.2	Function overview	393
10.1.3	Basic configuration.....	394
10.1.4	Timer C	396
10.1.5	Control registers.....	400
10.1.6	Operation	408
10.1.7	Application examples	415
10.1.8	Cautions.....	422
10.2	Timer D	424
10.2.1	Features.....	424
10.2.2	Function overview	424
10.2.3	Basic configuration.....	424
10.2.4	Timer D	425
10.2.5	Control registers.....	428
10.2.6	Operation	430
10.2.7	Application examples	432
10.2.8	Cautions.....	432
10.3	16-Bit 2-Phase Encoder Input Up/Down Counter/General-Purpose Timer (Timer ENC1)	433
10.3.1	Functions	433
10.3.2	Features.....	433
10.3.3	Basic configuration.....	434
10.3.4	Timer ENC1	436

10.3.5 Control registers.....	438
10.3.6 Operation	452
10.3.7 Supplementary description of internal operation	463
10.3.8 Cautions.....	466
CHAPTER 11 SERIAL INTERFACE FUNCTION.....	467
11.1 Features	467
11.1.1 Switching between UARTB0 and CSI30 modes	467
11.2 Asynchronous Serial Interfaces B0, B1 (UARTB0, UARTB1).....	468
11.2.1 Features.....	468
11.2.2 Configuration.....	469
11.2.3 Control registers.....	473
11.2.4 Interrupt requests.....	490
11.2.5 Control method	493
11.2.6 Operation	496
11.2.7 Dedicated baud rate generators 0, 1 (BRG0, BRG1).....	507
11.2.8 Control flow.....	513
11.2.9 Cautions.....	524
11.3 Clocked Serial Interfaces 30, 31 (CSI30, CSI31).....	526
11.3.1 Features.....	526
11.3.2 Configuration.....	527
11.3.3 Control registers.....	529
11.3.4 Dedicated baud rate generators 0, 1 (BRG0, BRG1).....	541
11.3.5 Operation	543
11.3.6 Usage	561
11.3.7 Cautions.....	567
CHAPTER 12 USB FUNCTION CONTROLLER (USBF)	568
12.1 Overview	568
12.2 Configuration.....	569
12.3 Requests	570
12.3.1 Automatic requests	570
12.3.2 Other requests	578
12.4 Register Configuration	579
12.4.1 Control registers.....	579
12.4.2 Data hold registers.....	633
12.4.3 Request data register.....	658
12.4.4 Peripheral control registers	674
12.5 STALL Handshake or No Handshake.....	678
12.6 Register Values in Specific Status	679
12.7 FW Processing	681
12.7.1 Initialization processing.....	683
12.7.2 Interrupt servicing	686
12.7.3 USB main processing	687
12.7.4 Suspend/Resume processing	714

12.7.5 Processing after power application	717
12.7.6 Receiving data for bulk transfer (OUT) in DMA mode	720
12.7.7 Transmitting data for bulk transfer (IN) in DMA mode	724
12.7.8 USB connection example	729
CHAPTER 13 A/D CONVERTER	730
13.1 Features	730
13.2 Configuration	731
13.3 Control Registers	733
13.4 Operation	740
13.4.1 Basic operation	740
13.4.2 Operation mode and trigger mode	741
13.5 Operation in A/D Trigger Mode	746
13.5.1 Select mode operation	746
13.5.2 Scan mode operations	748
13.6 Operation in Timer Trigger Mode	749
13.6.1 Select mode operation	750
13.6.2 Scan mode operation	752
13.7 Operation in External Trigger Mode	753
13.7.1 Select mode operations	753
13.7.2 Scan mode operation	756
13.8 Cautions	757
13.9 How to Read A/D Converter Characteristics Table	760
CHAPTER 14 PWM UNIT	764
14.1 Features	764
14.2 Configuration	764
14.3 Control Registers	766
14.4 Operation	769
14.4.1 PWM basic operation	769
14.4.2 Starting/stopping PWM operation	772
14.4.3 Setting active level of PWM pulse	774
14.4.4 Specifying PWM pulse width rewrite period	775
14.4.5 Repeat cycle	776
Chapter 15 Port Functions	777
15.1 Features	777
15.2 Port Configuration	777
15.3 Port Pin Functions	806
15.3.1 Port 1	806
15.3.2 Port 2	811
15.3.3 Port 5	816
15.3.4 Port 6	821
15.3.5 Port 7	826

15.3.6	Port AL	829
15.3.7	Port AH	834
15.3.8	Port DH	836

CHAPTER 1 INTRODUCTION

The V850E2/ME3 is a product of the Renesas Electronics single-chip microcontroller “V850 microcontrollers”. This chapter gives a simple outline of the V850E2/ME3.

1.1 Outline

The V850E2/ME3 is a 32-bit single-chip microcontroller that integrates the V850E2 CPU, which the performance of the V850E1, a 32-bit RISC-type CPU core for ASIC, newly developed as the CPU core central to system LSI for the current age of system-on-chip, has been strengthened. This device incorporates cache, data RAM, instruction RAM, and various peripheral functions such as memory controllers, a DMA controller, timers/counters, serial interfaces, USB function controller (USBF), and an A/D converter for realizing high-capacity data processing and sophisticated real-time control.

(1) V850E2 CPU

The V850E2 CPU has further strengthened the performance of the V850E1 CPU.

Furthermore, the pipeline has been increased to 7-stages in order to raise the clock frequency of the CPU. To increase the throughput of the CPU, parallelization of pipeline processing has been performed, and the program area has been extended to 512 MB.

It is possible to use the software resources of the V850 CPU and V850E1 CPU integrated system since the instruction codes of the V850E2 are upwardly compatible at the object code level with those of the conventional core.

(2) External memory interface function

The V850E2/ME3 features various on-chip external memory interfaces including separately configured address (26 bits) and data (32 bits) buses, and SDRAM and ROM interfaces, as well as on-chip memory controllers that can be directly linked to page ROM, etc., thereby raising system performance and reducing the number of parts needed for application systems.

Also, through the DMA controller, CPU internal calculations and data transfers can be performed simultaneously with transfers to and from the external memory, so it is possible to process large volumes of image data or voice data, etc., and through high-speed execution of instructions using internal data RAM and instruction RAM, motor control, communications control and other real-time control tasks can be realized simultaneously.

(3) Internal instruction RAM

The instruction RAM can be accessed at high speed, in one clock, so that application programs can be executed in real time.

(4) A full range of middleware and development environment products

The V850E2/ME3 can execute middleware such as JPEG, JBIG, MH/MR/MMR, and TCP/IP at high speed. Also, middleware that enables speech recognition, voice synthesis, and other such processing is available, and by including these middleware programs, a multimedia system can be easily realized.

A development environment system that includes an optimized C compiler, debugger, in-circuit emulator, and other elements is also available.

1.2 Features

- Number of instructions: 89
- Minimum instruction execution time: 5.0 ns (at internal 200 MHz operation)
- General-purpose registers: 32 bits × 32
- Instruction set:
 - V850E2 CPU
 - Signed multiplication (16 bits × 16 bits → 32 bits or 32 bits × 32 bits → 64 bits): 1 clock
 - Saturated operation instructions (with overflow/underflow detection function)
 - 32-bit shift instructions: 1 clock
 - Bit manipulation instructions
 - Load/store instructions with long/short format
 - Signed load instructions
 - Sum-of-product instruction (MAC) (32 bits × 32 bits + 64 bits → 64 bits)
- Memory space:
 - 512 MB linear address space (common program/data use)
 - Chip select output function: 8 spaces
 - Memory block division function: 2, 64 MB/block
 - Programmable wait function
 - Idle state insertion function
- External bus interface:
 - 32-bit data bus (address/data separated)
 - 32-/16-/8-bit bus sizing function
 - External bus division function: 1/1, 1/2, 1/4 (66 MHz MAX.)
 - Bus hold function
 - External wait function
 - Address setup wait function
- <R> ○ Internal memory
 - Instruction RAM: 168 KB (μPD703500)
 - 192 KB (μPD703590)
 - Data RAM: 32 KB
- Instruction cache 8 KB 4-way set associative
- Data cache 8 KB 4-way set associative
- Interrupts/exceptions:
 - External interrupts: 40 (including NMI)
 - Internal interrupts: 59 sources
 - Exceptions: 2 sources
 - Eight levels of priorities can be set.
- Memory access controller
 - SDRAM controller (compatible with SDRAM)
 - Page ROM controller

- **DMA controller:**
 - 4 channels
 - Transfer unit: 8 bits/16 bits/32 bits
 - Maximum transfer count: 16,777,216 (2^{24})
 - Transfer type: Flyby (1-cycle)/2-cycle
 - Transfer mode: Single/Single step/Block
 - Transfer target: Memory ↔ memory, memory ↔ I/O
 - Transfer request: External request/On-chip peripheral I/O/Software
 - DMA transfer terminate (terminal count) output signal
 - Next address setting function
 - DMA channel priority: Fixed-priority mode/round-robin mode

- **I/O lines:**
 - Input ports: 1
 - I/O ports: 77

- **Timer functions:**
 - 16-bit timer/event counter: 6 channels (no capture operation for 2 channels)
 - 16-bit timers: 6
 - 16-bit capture/compare registers: 12
 - 16-bit interval timer: 4 channels
 - Up/down counter/timer for 16-bit 2-phase encoder input: 2 channels
 - 16-bit capture/compare registers: 4
 - 16-bit compare registers: 4

- **Serial interfaces:**
 - Asynchronous serial interface B (UARTB)
 - Clocked serial interface 3 (CSI3)
 - CSI3/UARTB: 1 channel
 - UARTB: 1 channel
 - CSI3: 1 channel
 - USB function controller (USBF): 1 channel
 - Full speed (12 Mbps)
 - Endpoint Control transfer: 64 bytes × 2
 - Interrupt transfer: 8 bytes × 2
 - Bulk transfer (IN): 64 bytes × 2 banks × 2
 - Bulk transfer (OUT): 64 bytes × 2 banks × 2

- **A/D converter:**
 - 10-bit resolution A/D converter: 8 channels

- **PWM (Pulse Width Modulation):**
 - 16-bit resolution PWM: 2 channels

- **Clock generator:**
 - ×20 function using SSCG

- **Power-save function:**
 - HALT/IDLE mode

- **Package:**
 - 176-pin plastic QFP (fine pitch) (24 × 24)

- **CMOS technology:**
 - All static circuits

1.3 Applications

Servo control, NC machine tools, ink-jet printers, facsimiles, DVD players, video printers, PPC, information equipment, etc.

1.4 Ordering Information

Part Number	Package	Maximum Operating Frequency	Internal Instruction RAM
μ PD703500GM-JEU-A	176-pin plastic QFP (fine pitch) (24 × 24)	200 MHz	168 KB
<R> μ PD703590GM-JEU-A	176-pin plastic QFP (fine pitch) (24 × 24)	200 MHz	192 KB

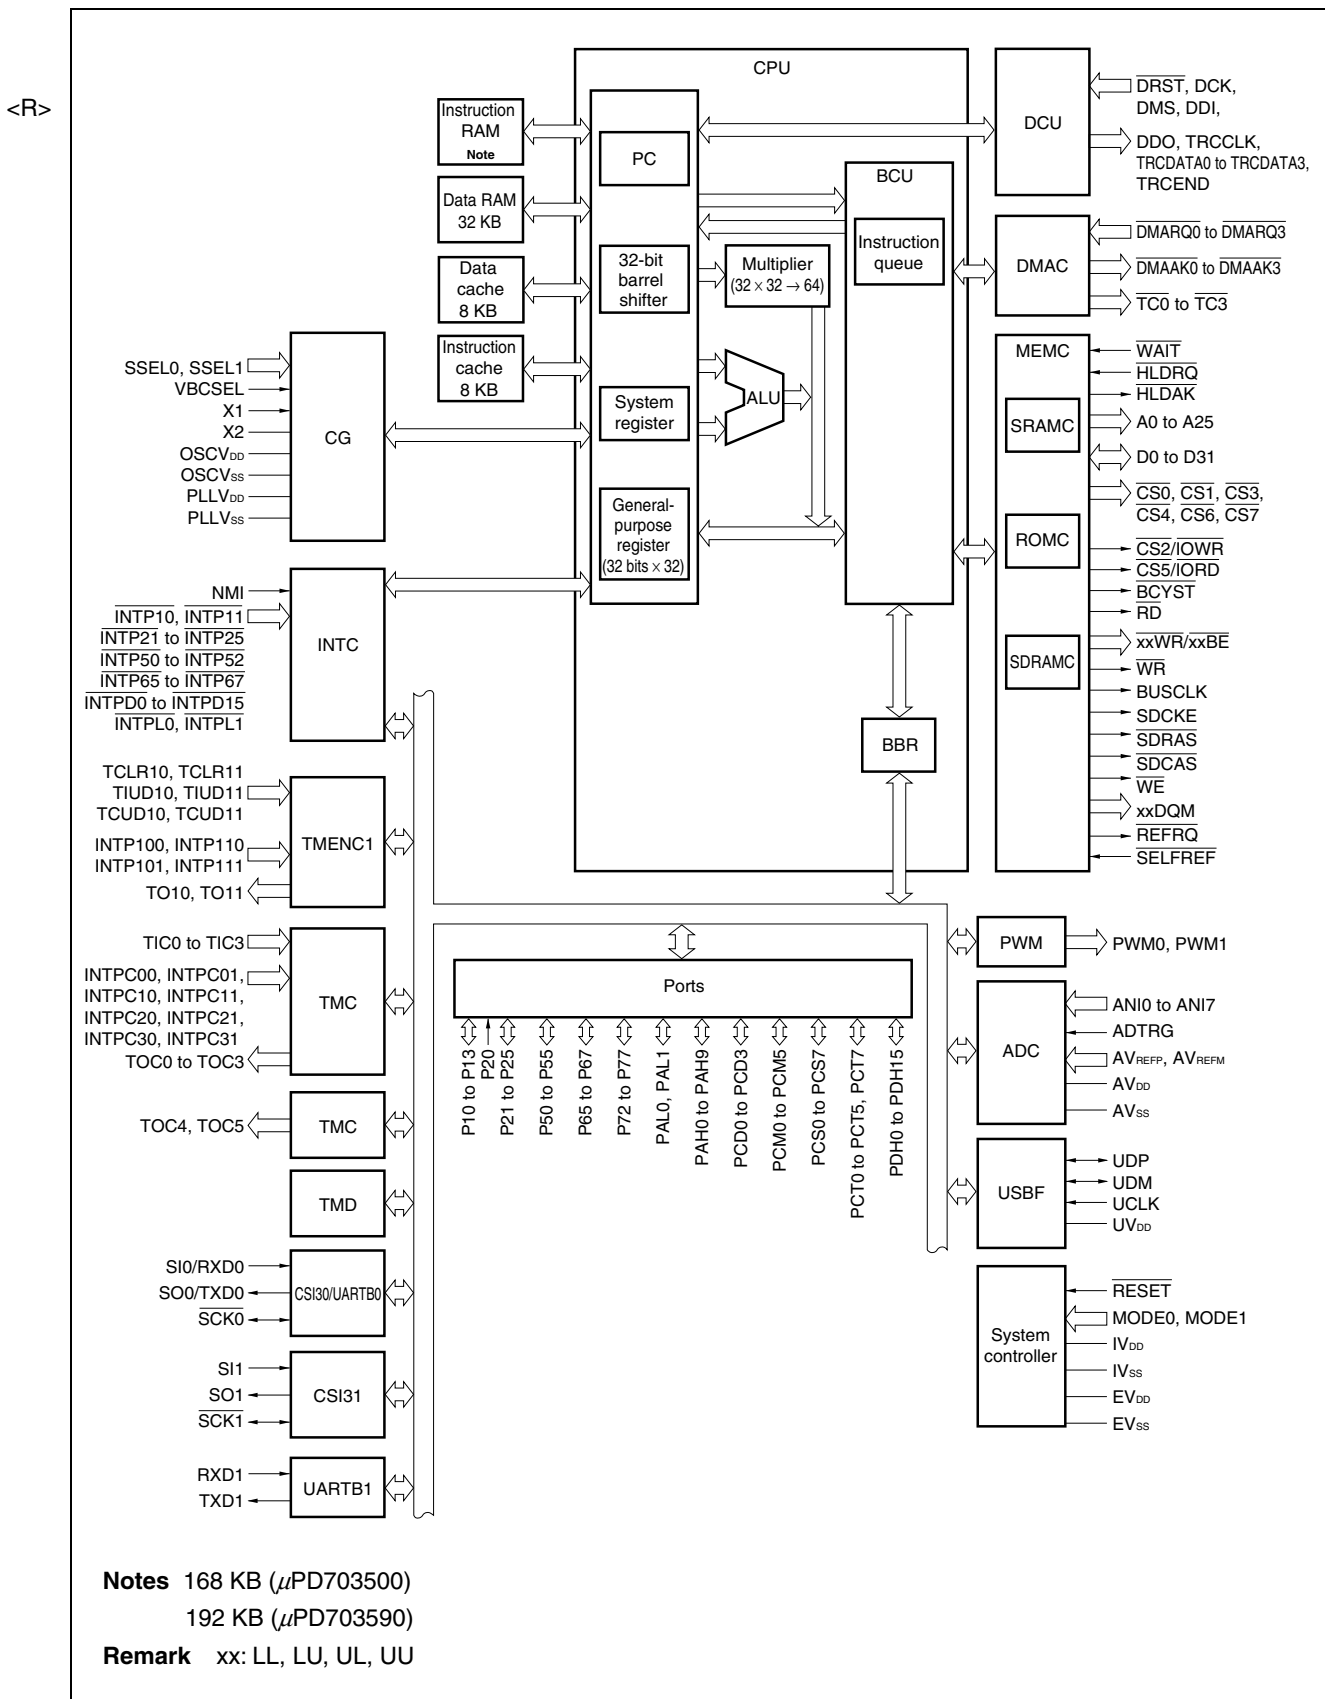

Remark Products with -A at the end of the part number are lead-free products.

Pin Identification

A0 to A25:	Address bus	PAH0 to PAH9:	Port AH
ADTRG:	A/D trigger input	PAL0, PAL1:	Port AL
ANI0 to ANI7:	Analog input	PCD0 to PCD3:	Port CD
AVDD:	Analog power supply	PCM0 to PCM5:	Port CM
AVREFM:	Analog reference voltage	PCS0 to PCS7:	Port CS
AVREFP:	Analog reference voltage	PCT0 to PCT5, PCT7:	Port CT
AVSS:	Analog ground	PDH0 to PDH15:	Port DH
BCYST:	Bus cycle start timing	PLLVD:	PLL power supply
BUSCLK:	Bus clock output	PLLVSS:	PLL ground
CS0 to CS7:	Chip select	PWM0, PWM1:	Pulse width modulation
D0 to D31:	Data bus	RD:	Read strobe
DCK:	Debug clock input	REFRQ:	Refresh request
DDI:	Debug data input	RESET:	Reset
DDO:	Debug data output	RXD0, RXD1:	Receive data
DRST:	Debug reset	SCK0, SCK1:	Serial clock
DMS:	Debug mode select	SDCAS:	SDRAM column address strobe
DMAAK0 to DMAAK3:	DMA acknowledge	SDCKE:	SDRAM clock enable
DMARQ0 to DMARQ3:	DMA request	SDRAS:	SDRAM row address strobe
EVDD:	Port power supply	SELFREF:	Self-refresh request
EVSS:	Port ground	SI0, SI1:	Serial input
HLDAK:	Hold acknowledge	SO0, SO1:	Serial output
HLDRQ:	Hold request	SSEL0, SSEL1:	Clock generator operating mode select
INTP10, INTP11, INTP21 to INTP25, INTP50 to INTP52, INTP65 to INTP67:	External interrupt input	TC0 to TC3:	Terminal count
INTP100, INTP101, INTP110, INTP111:	Timer capture trigger input	TCLR10, TCLR11:	Timer clear
INTPC00, INTPC01, INTPC10, INTPC11, INTPC20, INTPC21, INTPC30, INTPC31, INTPD0 to INTPD15,		TCUD10, TCUD11:	Timer control pulse input
INTPL0, INTPL1:	External interrupt input	TIC0 to TIC3:	Timer input
IORD:	I/O read strobe	TIUD10, TIUD11:	Timer count pulse input
IOWR:	I/O write strobe	TO10, TO11, TOC0 to TOC5 :	Timer output
IVDD:	Internal unit power supply	TRCCLK:	Trace clock
IVSS:	Internal unit ground	TRCDATA0 to TRCDATA3:	Trace data output
LLBE:	Lower lower byte enable (D0 to D7)	TRCEND:	Trace end status output
LLDQM:	Lower lower DQ mask enable (D0 to D7)	TXD0, TXD1:	Transmit data
LLWR:	Lower lower write strobe (D0 to D7)	UCLK:	USB external clock input
LUBE:	Lower upper byte enable (D8 to D15)	UDM:	USB data input & output (-)
LUDQM:	Lower upper DQ mask enable (D8 to D15)	UDP:	USB data input & output (+)
LUWR:	Lower upper write strobe (D8 to D15)	ULBE:	Upper lower byte enable (D16 to D23)
MODE0, MODE1:	Mode	ULDQM:	Upper lower DQ mask enable (D16 to D23)
NMI:	Non-maskable interrupt request	ULWR:	Upper lower write strobe (D16 to D23)
OSCVDD:	Clock generator power supply	UUBE:	Upper upper byte enable (D24 to D31)
OSCVSS:	Clock generator ground	UUDQM:	Upper upper DQ mask enable (D24 to D31)
P10 to P13:	Port 1	UUWR:	Upper upper write strobe (D24 to D31)
P20 to P25:	Port 2	UVDD:	USB power supply
P50 to P55:	Port 5	VBCSEL:	VB clock select
P65 to P67:	Port 6	WAIT:	Wait
P72 to P77:	Port 7	WE:	Write enable
		WR:	Write strobe
		X1, X2:	Crystal

1.6 Function Blocks

1.6.1 Internal block diagram

1.6.2 On-chip units

(1) CPU

The CPU uses seven-stage pipeline control to enable single-clock execution of address calculations, arithmetic logic operations, data transfers, and almost all other instruction processing.

Other dedicated on-chip hardware, such as a multiplier (16 bits × 16 bits → 32 bits or 32 bits × 32 bits → 64 bits) and a barrel shifter (32 bits), help accelerate processing of complex instructions.

(2) Bus control unit (BCU)

The BCU starts the required external bus cycle based on the physical address obtained by the CPU. When an instruction is fetched from external memory area and the CPU does not send a bus cycle start request, the BCU generates a prefetch address and prefetches the instruction code. The prefetched instruction code is stored in an instruction queue in the CPU.

The BCU controls an SDRAM controller (SDRAMC), SRAM controller (SRAMC), page ROM controller (ROMC), and DMA controller (DMAC) and performs external memory access and DMA transfer.

(a) SDRAM controller (SDRAMC)

The SDRAM controller generates the $\overline{\text{SDRAS}}$, $\overline{\text{SDCAS}}$, UUDQM, ULDQM, LUDQM, and LLDQM signals and performs access control for SDRAM.

CAS latency 1 (excluding flyby DMA transfer), 2, and 3 are supported, and the burst length is fixed to 1.

A refresh function that supports the CBR (automatic) refresh cycle and a dynamic self-refresh function based on an external input are also available.

(b) Page ROM controller (ROMC)

This controller supports accessing ROM that includes the page access function.

It performs address comparisons with the immediately preceding bus cycle and executes wait control for normal access (off-page)/page access (on-page). It can handle page widths of 8 to 128 bytes.

(c) DMA controller (DMAC)

This controller controls data transfer between memory and I/O instead of the CPU.

There are two address modes: flyby (1-cycle) transfer, and 2-cycle transfer. There are three bus modes, single transfer, single step transfer, and block transfer.

(3) RAM

Instruction RAM (168 KB) and data RAM (32 KB) are provided.

The instruction RAM can be accessed in one clock from the CPU when an instruction is fetched. It can be accessed in two clocks when writing. This RAM is mapped from address 00000000H.

The data RAM can be accessed in one clock from the CPU when its data is read/written. It is mapped from address 1FFF7000H.

(4) Cache

A 4-way set associative instruction cache (8 KB) and a data cache (8 KB) are provided.

(5) Interrupt controller (INTC)

This controller handles hardware interrupt requests (NMI, INTP_n) from on-chip peripheral I/O and external hardware. Eight levels of interrupt priorities can be specified for these interrupt requests, and multiple-interrupt servicing control can be performed for interrupt sources (n = 10, 11, 21 to 25, 50 to 52, 65 to 67, D0 to D15, L0, L1, C00, C01, C10, C11, C20, C21, C30, C31).

(6) Clock generator (CG)

This clock generator supplies frequencies which are 20 times the input clock (F_x) (using an on-chip PLL) as the internal system clock (f_{CLK}). As the input clock, an external oscillator is input from pins X1 and X2.

(7) Timer/counters

This unit incorporates a 6-channel 16-bit timer/event counter, 4-channel 16-bit interval timer, and 2-channel up/down counter/timer for 16-bit 2-phase encoder input and can measure pulse widths or frequency and output a programmable pulse.

(8) Serial interfaces

The serial interfaces consist of 3 channels divided between an asynchronous serial interface B (UARTB) and clocked serial interface 3 (CSI3). Of these 3 channels, one is alternative with UARTB and CSI3, one is fixed to CSI3, and one is fixed to UARTB.

UARTB transfers data by using the TXD_n and RXD_n pins (n = 0, 1).

CSI3 transfers data by using the SOn, SIn, and \overline{SCKn} pins (n = 0, 1).

In addition, a USB function controller (USBF) is also provided.

(9) A/D converter (ADC)

This high-speed, high-resolution 10-bit A/D converter includes 8 analog input pins. Conversion is performed using the successive approximation method.

(10) PWM

Two channels for PWM signal output of 16-bit resolution have been provided. By connecting an external low-pass filter, PWM output can be used as digital to analog conversion output. PWM is ideal for actuator control signals such as those in motors.

(11) Debug function (DCU)

An on-chip debug function via an on-chip debug emulator is provided.

(12) Ports

As shown below, the following ports have general-purpose port functions and control pin functions.

Port	I/O	Control Function
Port 1	4-bit I/O	Serial interface I/O, USB clock signal input, external interrupt input
Port 2	1-bit input, 5-bit I/O	NMI input, serial interface I/O, external interrupt input
Port 5	6-bit I/O	DMA controller I/O, external interrupt input, timer/counter I/O
Port 6	3-bit I/O	Timer/counter I/O, external interrupt input
Port 7	6-bit I/O	DMA controller I/O, timer/counter I/O, external interrupt input
Port AL	2-bit I/O	External address bus, external interrupt input
Port AH	10-bit I/O	External address bus
Port DH	16-bit I/O	External data bus, external interrupt input, PWM output, timer/counter I/O
Port CS	8-bit I/O	External bus interface control signal output
Port CT	7-bit I/O	External bus interface control signal output
Port CM	6-bit I/O	Wait insertion signal input, external bus interface control signal I/O, self-refresh request signal input, A/D converter external trigger input
Port CD	4-bit I/O	External bus interface control signal output, bus clock output

CHAPTER 2 PIN FUNCTIONS

The names and functions of the pins in the V850E2/ME3 are listed below. These pins can be divided into port pins and non-port pins according to their functions.

2.1 List of Pin Functions

(1) Port pins

(1/3)

Pin Name	Pin No.	I/O	Function	Alternate Function
P10	159	I/O	Port 1 4-bit I/O port Input data can be read/output data can be written in 1-bit units.	$\overline{\text{INTP10}}/\text{UCLK}$
P11	155			$\overline{\text{INTP11}}/\text{SCK0}$
P12	154			$\text{SI0}/\text{RXD0}$
P13	153			$\text{SO0}/\text{TXD0}$
P20	152	Input	Port 2 P20 is an input port dedicated to checking the NMI input status. If a valid edge is input, it operates as an NMI input. P21 to P25 are a 5-bit I/O port. Input data can be read/output data can be written in 1-bit units.	NMI
P21	149	I/O		$\overline{\text{INTP21}}/\text{RXD1}$
P22	148			$\overline{\text{INTP22}}/\text{TXD1}$
P23	147			$\overline{\text{INTP23}}/\text{SCK1}$
P24	146			$\overline{\text{INTP24}}/\text{SI1}$
P25	145			$\overline{\text{INTP25}}/\text{SO1}$
P50	25	I/O	Port 5 6-bit I/O port Input data can be read/output data can be written in 1-bit units.	$\overline{\text{INTP50}}/\text{DMARQ0}$
P51	24			$\overline{\text{INTP51}}/\text{DMAAK0}$
P52	23			$\overline{\text{INTP52}}/\text{TC0}$
P53	22			$\text{INTPC00}/\text{TIC0}/\text{DMARQ1}$
P54	21			$\text{INTPC01}/\text{DMAAK1}$
P55	20			$\text{TOC0}/\text{TC1}$
P65	19	I/O	Port 6 3-bit I/O port Input data can be read/output data can be written in 1-bit units.	$\overline{\text{INTP65}}/\text{INTPC10}/\text{TIC1}$
P66	18			$\overline{\text{INTP66}}/\text{INTPC11}$
P67	17			$\overline{\text{INTP67}}/\text{TOC1}$
P72	176	I/O	Port 7 6-bit I/O port Input data can be read/output data can be written in 1-bit units.	$\text{INTPC20}/\text{TIC2}/\text{DMARQ2}$
P73	175			$\text{INTPC21}/\text{DMAAK2}$
P74	174			$\text{TOC2}/\text{TC2}$
P75	173			$\text{INTPC30}/\text{TIC3}/\text{DMARQ3}$
P76	172			$\text{INTPC31}/\text{DMAAK3}$
P77	171			$\text{TOC3}/\text{TC3}$

(2/3)

2.2 Pin Status

The status of each pin after reset, in power-save mode (IDLE, HALT modes), and during DMA transfer, refresh, and bus hold (TH) is shown below.

Pin \ Operating Status	Reset	IDLE Mode	HALT Mode/During DMA Transfer, Refresh	Bus Hold (TH) ^{Note 1}
A0 to A1 (PAL0 to PAL1)	Hi-Z	Hi-Z	Operating	Hi-Z
A2 to A15	Hi-Z	Hi-Z	Operating	Hi-Z
A16 to A25 (PAH0 to PAH9)	Hi-Z	Hi-Z	Operating	Hi-Z
D0 to D15	Hi-Z	Hi-Z	Operating	Hi-Z
D16 to D31 (PDH to PDH15)	Hi-Z	Hi-Z	Operating	Hi-Z

$\overline{DMAAK2}$ (P73)	×	H	Operating	H
$\overline{DMAAK3}$ (P76)	×	H	Operating	H
MODE0, MODE1	MODE0, MODE1 inputs			
DDI, DMS, DCK	DDI, DMS, DCK inputs			
NMI (P20)	NMI input			
SSEL0, SSEL1	SSEL0, SSEL1 inputs			
Peripheral function input pin other than above	×	–	Operating	Operating
Peripheral function output pin other than above	×	Hold	Operating	Operating
Port input pin other than above	Hi-Z	–	–	Operating
Port output pin other than above	×	Hold	Hold	Operating

Remark Explanation on **Note** and **Remark** are given on the next page.

- Notes 1.** The pin set in the port mode holds the status immediately before.
2. High-level output when the SDRAM controller is not used
 3. Low-level output when the SDRAM controller is not used

Remark

Hi-Z:	High-impedance
H:	High-level output
L:	Low-level output
–:	No sampling of input
×:	No select function at reset
SELF:	Self-refresh state when pins are connected to SDRAM

Notes on turning on/off power

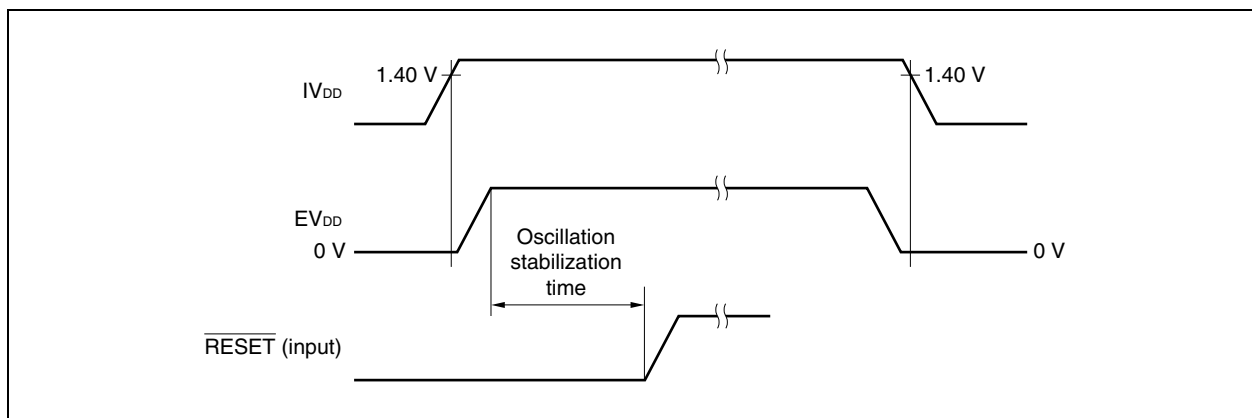

The V850E2/ME3 has two power supply pins: a power supply pin for internal units (IV_{DD}) and a power supply pin for external pins (EV_{DD}). The I/O status of an alternate-function I/O pin may be undefined outside the range in which the operation is guaranteed. If this undefined I/O status affects the system, the pin can be made to go into a high-impedance state using the following measure.

• When turning on power

Keep the voltage on the EV_{DD} pin at 0 V until the voltage on the IV_{DD} pin reaches the operation guaranteed range (1.40 to 1.65 V).

• When turning off power

Keep the voltage on the IV_{DD} pin to within the operation guaranteed range (1.40 to 1.65 V) until the voltage on the EV_{DD} pin drops to 0 V.

2.3 Description of Pin Functions

(1) P10 to P13 (Port 1) ... 3-state I/O

P10 to P13 function as a 4-bit I/O port that can read input data or write output data in 1-bit units.

Besides functioning as an I/O port, in the control mode, these pins operate as serial interface I/O (UARTB0, CSI30), USB clock signal input, and external interrupt request input.

The operation mode can be set to port or control mode in 1-bit units, specified by the PMC1 register.

(a) Port mode

P10 to P13 can be set to input or output in 1-bit units using the PM1 register.

(b) Control mode

P10 to P13 can be set to port/control mode in 1-bit units using the PMC1 register.

(i) $\overline{\text{INTP10}}$, $\overline{\text{INTP11}}$ (External interrupt input) ... input

These are external interrupt request input pins.

(ii) SO0 (Serial output) ... output

This is a serial transmit data output pin of CSI30.

(iii) SI0 (Serial input) ... input

This is a serial receive data input pin of CSI30.

(iv) $\overline{\text{SCK0}}$ (Serial clock) ... 3-state I/O

This is a CSI30 serial clock I/O pin.

(v) TXD0 (Transmit data) ... output

This is a serial transmit data output pin of UARTB0.

(vi) RXD0 (Receive data) ... input

This is a serial receive data input pin of UARTB0.

(vii) UCLK (USB external clock input) ... input

This is a clock input pin of the USB.

When using as the UCLK pin, be careful to avoid the input of a staircase waveform due to reflection, etc., or the input of noise.

(2) P20 to P25 (Port 2) ... 3-state I/O

Port 2, except P20, which is an input pin dedicated to checking the input status of NMI, is a 5-bit I/O port that can read input data or write output data in 1-bit units.

Besides functioning as an I/O port, in the control mode, these pins operate as serial interface I/O (UARTB1/CSI31) and external interrupt request input.

The operation mode can be set to port or control mode in 1-bit units, specified by the PMC2 register.

(a) Port mode

P21 to P25 can be set to input or output in 1-bit units using the PM2 register. P20 is an input port dedicated to checking the NMI input status, and if a valid edge is input, it operates as an NMI input.

(b) Control mode

P21 to P25 can be set to port/control mode in 1-bit units using the PMC2 register.

(i) NMI (Non-maskable interrupt request) ... input

This is the non-maskable interrupt request input pin.

(ii) $\overline{\text{INTP21}}$ to $\overline{\text{INTP25}}$ (External interrupt input) ... input

These are external interrupt request input pins.

(iii) SO1 (Serial output) ... output

This is a serial transmit data output pin of CSI31.

(iv) SI1 (Serial input) ... input

This is a serial receive data input pin of CSI31.

(v) $\overline{\text{SCK1}}$ (Serial clock) ... 3-state I/O

This is a CSI31 serial clock I/O pin.

(vi) TXD1 (Transmit data) ... output

This is a serial transmit data output pin of UARTB1.

(vii) RXD1 (Receive data) ... input

This is a serial receive data input pin of UARTB1.

(3) P50 to P55 (Port 5) ... 3-state I/O

P50 to P55 function as a 6-bit I/O port that can read input data or write output data in 1-bit units.

Besides functioning as an I/O port, in the control mode, these pins operate as DMA request input, DMA acknowledge output, DMA transfer termination output (terminal count), timer/counter I/O, and external interrupt request input.

The operation mode can be set to port or control mode in 1-bit units, specified by the PMC5 register.

(a) Port mode

P50 to P55 can be set to input or output in 1-bit units using the PM5 register.

(b) Control mode

P50 to P55 can be set to port/control mode in 1-bit units using the PMC5 register.

(i) $\overline{\text{DMARQ0}}$, $\overline{\text{DMARQ1}}$ (DMA request) ... input

These are DMA service request signal input pins. They correspond to DMA channels 0 and 1, respectively, and operate independently of each other. The priority order is fixed to $\overline{\text{DMARQ0}} > \overline{\text{DMARQ1}} > \overline{\text{DMARQ2}} > \overline{\text{DMARQ3}}$.

These signals are sampled at the rising edge of the BUSCLK signal. Maintain an active level until a DMA request is acknowledged.

(ii) $\overline{\text{DMAAK0}}$, $\overline{\text{DMAAK1}}$ (DMA acknowledge) ... output

These are acknowledge signal output pins that show a DMA service request was granted. They correspond to DMA channels 0 and 1, respectively, and operate independently of each other.

(iii) $\overline{\text{TC0}}$, $\overline{\text{TC1}}$ (Terminal count) ... output

These are terminal count signal output pins that show that the DMA transfer from the DMA controller is complete. These pins correspond to DMA channels 0 and 1 respectively, and operate independently of each other. The terminal count signals of DMA channels 0 to 3 can be commonly output from the $\overline{\text{TC0}}$ pin.

(iv) $\overline{\text{INTPC00}}$, $\overline{\text{INTPC01}}$ (External interrupt input) ... input

These are external interrupt request input pins and the external capture trigger input pins of timer C0.

(v) $\overline{\text{TIC0}}$ (Timer input) ... input

This is an external count clock input pin of timer C0.

(vi) $\overline{\text{TOC0}}$ (Timer output) ... output

This is a pulse signal output pin of timer C0.

(vii) $\overline{\text{INTP50}}$ to $\overline{\text{INTP52}}$ (External interrupt input) ... input

These are external interrupt request input pins.

(4) P65 to P67 (Port 6) ... 3-state I/O

P65 to P67 function as a 3-bit I/O port that can read input data or write output data in 1-bit units.

Besides functioning as an I/O port, in the control mode, these pins operate as timer/counter I/O and external interrupt request input.

The operation mode can be set to port or control mode in 1-bit units, specified by the PMC6 register.

(a) Port mode

P65 to P67 can be set to input or output in 1-bit units using the PM6 register.

(b) Control mode

P65 to P67 can be set to port/control mode in 1-bit units using the PMC6 register.

(i) TIC1 (Timer input) ... input

This is the external count clock input pin for timer C1.

(ii) TOC1 (Timer output) ... output

This is the pulse signal output pin for timer C1.

(iii) $\overline{\text{INTP65}}$ to $\overline{\text{INTP67}}$ (External interrupt input) ... input

These are external interrupt request input pins.

(iv) INTPC10, INTPC11 (External interrupt input) ... input

These are external interrupt request input pins and the external capture trigger input pins of timer C1.

(5) P72 to P77 (Port 7) ... 3-state I/O

P72 to P77 function as a 6-bit I/O port that can read input data or write output data in 1-bit units.

Besides functioning as an I/O port, in the control mode, these pins operate as DMA request input, DMA acknowledge output, DMA transfer termination output (terminal count), timer/counter I/O, and external interrupt request input.

The operation mode can be set to port or control mode in 1-bit units, specified by the PMC7 register.

(a) Port mode

P72 to P77 can be set to input or output in 1-bit units using the PM7 register.

(b) Control mode

P72 to P77 can be set to port/control mode in 1-bit units using the PMC7 register.

(i) $\overline{\text{DMARQ2}}$, $\overline{\text{DMARQ3}}$ (DMA request) ... input

These are DMA service request signal input pins. They correspond to DMA channels 2 and 3, respectively, and operate independently of each other. The priority order is fixed to $\overline{\text{DMARQ0}} > \overline{\text{DMARQ1}} > \overline{\text{DMARQ2}} > \overline{\text{DMARQ3}}$.

These signals are sampled at the rising edge of the BUSCLK signal. Maintain an active level until a DMA request is acknowledged.

(ii) $\overline{\text{DMAAK2}}$, $\overline{\text{DMAAK3}}$ (DMA acknowledge) ... output

These are acknowledge signal output pins that show a DMA service request was granted. They correspond to DMA channels 2 and 3, respectively, and operate independently of each other.

(iii) $\overline{\text{TC2}}$, $\overline{\text{TC3}}$ (Terminal count) ... output

These are terminal count signal output pins that show that DMA transfer from the DMA controller is complete. These pins correspond to DMA channels 2 and 3 respectively, and operate independently of each other. The terminal count signals of DMA channels 0 to 3 can be commonly output from the $\overline{\text{TC0}}$ pin.

(iv) $\overline{\text{INTPC20}}$, $\overline{\text{INTPC21}}$, $\overline{\text{INTPC30}}$, $\overline{\text{INTPC31}}$ (External interrupt input) ... input

These are external interrupt request input pins and the external capture trigger input pins of timers C2 and C3.

(v) $\overline{\text{TIC2}}$, $\overline{\text{TIC3}}$ (Timer input) ... input

These are external count clock input pins of timers C2 and C3.

(vi) $\overline{\text{TOC2}}$, $\overline{\text{TOC3}}$ (Timer output) ... output

These are pulse signal output pins of timers C2 and C3.

(6) PCM0 to PCM5 (Port CM) ... 3-state I/O

PCM0 to PCM5 function as a 6-bit I/O port that can read input data or write output data in 1-bit units.

Besides functioning as a port, in the control mode, these pins operate as wait insertion signal input, bus hold control signal, refresh request signal output for SDRAM, self-refresh request signal input, and A/D converter external trigger input.

The operation mode can be set to port or control in 1-bit units, specified by the PMCCM register.

(a) Port mode

PCM0 to PCM5 can be set to input or output in 1-bit units using the PMCM register.

(b) Control mode

PCM0 to PCM5 can be set to port/control mode in 1-bit units using the PMCCM register.

(i) $\overline{\text{WAIT}}$ (Wait) ... input

This is the control signal input pin at which a data wait is inserted in the bus cycle. The $\overline{\text{WAIT}}$ signal can be input asynchronously to the BUSCLK signal. When the BUSCLK signal falls, sampling is executed. When the set/hold time is not terminated within the sampling timing, wait insertion may not be executed.

Caution Input to the $\overline{\text{WAIT}}$ pin is valid immediately after reset release. If a low level is input to the $\overline{\text{WAIT}}$ pin because an external pull-down resistor is connected to it, the external bus is placed in the bus hold status.

(ii) $\overline{\text{HLD\!AK}}$ (Hold acknowledge) ... output

This is the acknowledge signal output pin that indicates the high impedance status for the address bus, data bus, and control bus when the V850E2/ME3 receives a bus hold request.

While this signal is active, the impedance of the address bus, data bus, and control bus becomes high and the bus mastership is transferred to the external bus master.

(iii) $\overline{\text{HLDRQ}}$ (Hold request) ... input

This is the input pin through which an external device requests the V850E2/ME3 to release the address bus, data bus, and control bus. The $\overline{\text{HLDRQ}}$ signal can be input asynchronously to the BUSCLK signal. When this pin is active, the address bus, data bus, and control bus are set to the high impedance status. This occurs either when the V850E2/ME3 completes execution of the current bus cycle or immediately if no bus cycle is being executed, then the $\overline{\text{HLD\!AK}}$ signal is set as active and the bus is released.

In order to make the bus hold state secure, keep the $\overline{\text{HLDRQ}}$ signal active until the $\overline{\text{HLD\!AK}}$ signal is output.

Caution Input to the $\overline{\text{HLDRQ}}$ pin is valid immediately after reset release. If a low level is input to the $\overline{\text{HLDRQ}}$ pin because an external pull-down resistor is connected to it, the external bus is placed in the bus hold status.

(iv) $\overline{\text{REFRQ}}$ (Refresh request) ... output

This is the refresh request signal output pin for SDRAM.

This signal becomes active during the refresh cycle. Also, during bus hold, it becomes active when a refresh request is generated and informs the external bus master that a refresh request was generated.

(v) $\overline{\text{SELFREF}}$ (Self-refresh request) ... input

This is a self-refresh request signal input pin for SDRAM.

The internal data RAM and internal instruction RAM (in the read mode) can be accessed even in the self-refresh cycle. However, access to a peripheral I/O register or external device is held pending until the self-refresh cycle is cancelled.

Caution Input to the $\overline{\text{SELFREF}}$ pin becomes valid immediately after the reset signal has been cleared. Consequently, if a low level is input to the $\overline{\text{SELFREF}}$ pin by an external pull-down resistor, self refreshing is started. Note that, at this time, the normal instruction fetch cycle does not occur.

(vi) ADTRG (A/D trigger input) ... input

This is an external trigger input pin of the A/D converter.

(7) PCT0 to PCT5, PCT7 (Port CT) ... 3-state I/O

PCT0 to PCT5 and PCT7 function as a 7-bit I/O port that can read input data or write output data in 1-bit units.

Besides functioning as a port, in the control mode, these pins operate as control signal outputs for when memory is expanded externally.

The operation mode can be set to port or control mode in 1-bit units, specified by the PMCCT register.

(a) Port mode

PCT0 to PCT5 and PCT7 can be set to input or output in 1-bit units using the PMCT register.

(b) Control mode

PCT0 to PCT5 and PCT7 can be set to port/control mode in 1-bit units using the PMCCT register.

(i) $\overline{\text{LLWR}}$ (Lower lower byte write strobe) ... 3-state output

This is a strobe signal output pin that shows whether the bus cycle currently being executed is a write cycle for the SRAM, external ROM, or external peripheral I/O area.

For the data bus, the lowest byte (D0 to D7) becomes valid. If the bus cycle is a lowest memory write, it becomes active at the falling edge of the BUSCLK signal in the T1 state and becomes inactive at the falling edge of the BUSCLK signal in the T2 state.

(ii) $\overline{\text{LUWR}}$ (Lower upper byte write strobe) ... 3-state output

This is a strobe signal output pin that shows whether the bus cycle currently being executed is a write cycle for the SRAM, external ROM, or external peripheral I/O area.

For the data bus, the third byte (D8 to D15) becomes valid. If the bus cycle is a third byte memory write, it becomes active at the falling edge of the BUSCLK signal in the T1 state and becomes inactive at the falling edge of the BUSCLK signal in the T2 state.

(iii) $\overline{\text{ULWR}}$ (Upper lower byte write strobe) ... 3-state output

This is a strobe signal output pin that shows whether the bus cycle currently being executed is a write cycle for the SRAM, external ROM, or external peripheral I/O area.

For the data bus, the second byte (D16 to D23) becomes valid. If the bus cycle is a second byte memory write, it becomes active at the falling edge of the BUSCLK signal in the T1 state and becomes inactive at the falling edge of the BUSCLK signal in the T2 state.

(iv) $\overline{\text{UUWR}}$ (Upper upper byte write strobe) ... 3-state output

This is a strobe signal output pin that shows whether the bus cycle currently being executed is a write cycle for the SRAM, external ROM, or external peripheral I/O area.

For the data bus, the highest byte (D24 to D31) becomes valid. If the bus cycle is a highest memory write, it becomes active at the falling edge of the BUSCLK signal in the T1 state and becomes inactive at the falling edge of the BUSCLK signal in the T2 state.

(v) $\overline{\text{LLBE}}$ (Lower lower byte enable) ... 3-state output

This is a signal output pin that enables the lowest byte (D0 to D7) of the external data bus.

(vi) $\overline{\text{LUBE}}$ (Lower upper byte enable) ... 3-state output

This is a signal output pin that enables the third byte (D8 to D15) of the external data bus.

(vii) $\overline{\text{ULBE}}$ (Upper lower byte enable) ... 3-state output

This is a signal output pin that enables the second byte (D16 to D23) of the external data bus.

(viii) $\overline{\text{UUBE}}$ (Upper upper byte enable) ... 3-state output

This is a signal output pin that enables the highest byte (D24 to D31) of the external data bus.

(ix) $\overline{\text{LLDQM}}$ (Lower lower DQ mask enable) ... 3-state output

This is a control signal output pin for the data bus to SDRAM. For the data bus, the lowest byte (D0 to D7) is valid. This signal carries out SDRAM output disable control during a read operation, and SDRAM byte mask control during a write operation.

(x) $\overline{\text{LUDQM}}$ (Lower upper DQ mask enable) ... 3-state output

This is a control signal output pin for the data bus to SDRAM. For the data bus, the third byte (D8 to D15) is valid. This signal carries out SDRAM output disable control during a read operation, and SDRAM byte mask control during a write operation.

(xi) $\overline{\text{ULDQM}}$ (Upper lower DQ mask enable) ... 3-state output

This is a control signal output pin for the data bus to SDRAM. For the data bus, the second byte (D16 to D23) is valid. This signal carries out SDRAM output disable control during a read operation, and SDRAM byte mask control during a write operation.

(xii) UUDQM (Upper upper DQ mask enable) ... 3-state output

This is a control signal output pin for the data bus to SDRAM. For the data bus, the highest byte (D24 to D31) is valid. This signal carries out SDRAM output disable control during a read operation, and SDRAM byte mask control during a write operation.

(xiii) \overline{RD} (Read strobe) ... 3-state output

This is a strobe signal output pin that shows the bus cycle currently being executed is a read cycle for the SRAM, external ROM, external peripheral I/O, or page ROM area. In the idle state (T1), it becomes inactive.

(xiv) \overline{WR} (Write strobe) ... 3-state output

This is a strobe signal output pin that shows the bus cycle currently being executed is a write cycle for the SRAM, external ROM, or external peripheral I/O area.

It becomes active at the falling edge of the BUSCLK signal in the T1 state and becomes inactive at the falling edge of the BUSCLK signal in the T2 state.

(xv) \overline{WE} (Write enable) ... 3-state output

This is a enable signal output pin that shows the bus cycle currently being executed is a write cycle for the SDRAM area. In the idle state (T1), it becomes inactive.

(xvi) \overline{BCYST} (Bus cycle start timing) ... 3-state output

This is a status signal output pin that shows the start of the bus cycle. It becomes active for 1-clock cycle from the start of each cycle.

(8) PCS0 to PCS7 (Port CS) ... 3-state I/O

PCS0 to PCS7 function as an 8-bit I/O port that can read input data or write output data in 1-bit units.

Besides functioning as a port, in the control mode, these pins operate as control signal outputs for when memory and peripheral I/O are expanded externally.

The operation mode can be set to port or control mode in 1-bit units, specified by the PMCCS register.

(a) Port mode

PCS0 to PCS7 can be set to input or output in 1-bit units using the PMCS register.

(b) Control mode

PCS0 to PCS7 can be set to port/control mode in 1-bit units using the PMCCS register.

(i) $\overline{CS0}$ to $\overline{CS7}$ (Chip select) ... 3-state output

These are the chip select signal output pins for the SRAM, external ROM, external peripheral I/O, and page ROM area.

The \overline{CSn} signal is assigned to area n (n = 0 to 7).

It becomes active while the bus cycle that accesses the corresponding memory block is activated.

In the idle state (TI), it becomes inactive.

(ii) \overline{IOWR} (I/O write strobe) ... 3-state output

This is a write strobe signal output pin for external I/O during DMA flyby transfer. It indicates whether the bus cycle currently being executed is a write cycle for external I/O during DMA flyby transfer, or a write cycle for the SRAM area.

Note that if the IOEN bit of the bus cycle period control register (BCP) is set (1), this signal can be output even in the normal SRAM, external ROM, or external I/O cycle.

(iii) \overline{IORD} (I/O read strobe) ... 3-state output

This is a read strobe signal output pin for external I/O during DMA flyby transfer. It indicates whether the bus cycle currently being executed is a read cycle for external I/O during DMA flyby transfer, or a read cycle for the SRAM area.

Note that if the IOEN bit of the BCP register is set (1), this signal can be output even in the normal SRAM, external ROM, or external I/O cycle.

(9) PCD0 to PCD3 (Port CD) ... 3-state I/O

PCD0 to PCD3 function as a 4-bit I/O port that can read input data or write output data in 1-bit units.

Besides functioning as a port, in control mode, these pins operate as control signal outputs for when the memory and peripheral I/O are expanded externally.

The operation mode can be set to port or control mode in 1-bit units, specified by the PMCCD register.

(a) Port mode

PCD0 to PCD3 can be set to input or output in 1-bit units using the PMCD register.

(b) Control mode

PCD0 to PCD3 can be set to port or control mode in 1-bit units using the PMCCD register.

(i) SDCKE (SDRAM clock enable) ... output

This is the SDRAM clock enable output signal. It becomes inactive in self-refresh and standby mode.

(ii) BUSCLK (Bus clock output) ... output

This is a clock output pin for SDRAM.

(iii) $\overline{\text{SDCAS}}$ (SDRAM column address strobe) ... 3-state output

This is a command output signal for SDRAM.

(iv) $\overline{\text{SDRAS}}$ (SDRAM row address strobe) ... 3-state output

This is a command output signal for SDRAM.

(10) PAH0 to PAH9 (Port AH) ... 3-state I/O

PAH0 to PAH9 function as an 8- or 10-bit I/O port that can read input data or write output data in 1-bit units.

Besides functioning as a port, in control mode, these pins operate as an address bus (A16 to A25) for when the memory is expanded externally.

The operation mode can be set to port or control mode in 1-bit units, specified by the PMCAH register.

(a) Port mode

PAH0 to PAH9 can be set to input or output in 1-bit units using the PMAH register.

(b) Control mode

PAH0 to PAH9 can be set to function alternately as A16 to A25 using the PMCAH register.

(i) A16 to A25 (Address bus) ... 3-state output

These are the address output pins of the higher 10 bits of the address bus's 26-bit address when the external memory is accessed.

The output changes in synchronization with the fall of the BUSCLK signal in the T1 state. In the idle state (TI), the address of the bus cycle immediately before is retained.

(11) PAL0, PAL1 (Port AL) ... 3-state I/O

PAL0 and PAL1 function as a 2-bit I/O port that can read input data or write output data in 1-bit units.

Besides functioning as a port, in control mode, these pins operate as an address bus (A0, A1) and external interrupt request input for when the memory is expanded externally.

The operation mode can be set to port or control mode in 1-bit units, specified by the PMCAL register.

(a) Port mode

PAL0 and PAL1 can be set to input or output in 1-bit units using the PMAL register.

(b) Control mode

PAL0 and PAL1 can be set to port or control mode in 1-bit units using the PMCAL register.

(i) A0, A1 (Address bus) ... 3-state output

These are the address output pins of the lower 2 bits of the address bus's 26-bit address when the external memory is accessed.

The output changes in synchronization with the fall of the BUSCLK signal in the T1 state. In the idle state (TI), the address of the bus cycle immediately before is retained.

(ii) $\overline{\text{INTPL0}}$, $\overline{\text{INTPL1}}$ (External interrupt input) ... input

These are external interrupt request input pins.

(12) PDH0 to PDH15 (Port DH) ... 3-state I/O

PDH0 to PDH15 function as an 8- or 16-bit I/O port that can read input data or write output data in 1-bit units.

Besides functioning as a port, in control mode, these pins operate as timer/counter I/O, PWM output, data bus (D16 to D31), and external interrupt request input.

The operation mode can be set to port or control mode in 1-bit units, specified by the PMCDH register.

(a) Port mode

PDH0 to PDH15 can be set to input or output in 1-bit units using the PMDH register.

(b) Control mode

PDH0 to PDH15 can be set to port or control mode in 1-bit units using the PMCDH register.

(i) $\overline{\text{INTPD0}}$ to $\overline{\text{INTPD15}}$ (External interrupt input) ... input

These are external interrupt request input pins.

(ii) TOC4, TOC5 (Timer output) ... output

These are pulse signal output pins of timers C4 and C5.

(iii) INTP100, INTP101, INTP110, INTP111 (Timer capture trigger input) ... input

These are external capture trigger input pins of timers ENC10 and ENC11.

(iv) TIUD10, TIUD11 (Timer count pulse input) ... input

These are external count clock input pins of timers ENC10 and ENC11.

(v) TCUD10, TCUD11 (Timer control pulse input) ... input

These are external count clock input pins of timers ENC10 and ENC11.

(vi) TCLR10, TCLR11 (Timer clear) ... input

These are clear signal input pins of timers ENC10 and ENC11.

(vii) TO10, TO11 (Timer output) ... output

These are pulse signal output pins of timers ENC10 and ENC11.

(viii) PWM0, PWM1 (Pulse width modulation) ... output

These pins output the PWM pulse signal.

(ix) D16 to D31 (Data bus) ... 3-state I/O

These pins constitute a data bus for when the external memory is accessed. These are the higher 16-bit I/O bus pins of the 32-bit data.

The output changes in synchronization with the rise of the BUSCLK signal in the T1 state.

(13) PLLV_{DD} (PLL power supply)

This is an 1.5 V positive power supply pin for PLL synthesizer.

(14) PLLV_{SS} (PLL ground)

This is a ground pin for PLL synthesizer.

(15) SSEL0, SSEL1 (Clock generator operating mode select) ... input

These are input pins used to specify the clock generator's operating mode. Fix the operating mode via a resistor.

(16) DCK (Debug clock input) ... input

This pin inputs a debug clock. At the rising edge of the DCK signal, the DMS and DDI signals are sampled, and data is output from the DDO pin at the falling edge of the DCK signal. Keep this pin high when the debug function is not used.

(17) DDI (Debug data input) ... input

This pin inputs debug data. This pin is sampled at the rising edge of the DCK signal when the debug serial interface is in the shift state. Data is input with the LSB first. Keep this pin high when the debug function is not used.

(18) DDO (Debug data output) ... 3-state output

This pin outputs debug data. It outputs data at the falling edge of the DCK signal when the debug serial interface is in the shift state. Data is output with the LSB first.

(19) DMS (Debug mode select) ... input

This input pin selects a debug mode. Depending on the level of the DMS signal, the state machine of the debug serial interface changes. This pin is sampled at the rising edge of the DCK signal. Keep this pin high when the debug function is not used.

(20) $\overline{\text{DRST}}$ (Debug reset) ... input

This pin inputs a debug reset signal that is a negative-logic signal to initialize the DCU asynchronously. When this signal goes low, the DCU is reset/invalidated. Keep this pin low when the debug function is not used.

(21) MODE0, MODE1 (Mode) ... input

These are input pins used to specify the operating mode. Fix the operating mode via a resistor.

(22) $\overline{\text{RESET}}$ (Reset) ... input

$\overline{\text{RESET}}$ is a signal that is input asynchronously and that has a constant low level width regardless of the operating clock's status. When this signal is input, a system reset is executed as the first priority ahead of all other operations.

In addition to being used for ordinary initialization/start operations, this pin can also be used to release a standby mode (HALT or IDLE).

(23) X1, X2 (Crystal)

These pins are used to connect the resonator that generates the system clock.

(24) ANI0 to ANI7 (Analog input) ... input

These are analog input pins for the A/D converter.

Connect a capacitor between these pins and AV_{SS} to prevent noise-related operation faults. Also, do not apply voltage that is outside the range for AV_{SS} and AV_{DD} to pins that are being used as inputs for the A/D converter. If it is possible for noise above the AV_{DD} range or below the AV_{SS} to enter, clamp these pins using a diode that has a small V_{F} value.

(25) AV_{REFM}, AV_{REFP} (Analog reference voltage) ... input

These are reference voltage supply pins for the A/D converter.

(26) AV_{DD} (Analog power supply)

This is a 3.3 V positive power supply pin for the A/D converter.

(27) AV_{SS} (Analog ground)

This is a ground pin for the A/D converter.

(28) EV_{DD} (Port power supply)

This is a 3.3 V positive power supply pin for port.

(29) EV_{SS} (Port ground)

This is a ground pin for port.

(30) OSCV_{DD} (Clock generator power supply)

This is a 3.3 V positive power supply pin for the clock generator.

(31) OSCV_{SS} (Clock generator ground)

This is a ground pin for the clock generator.

(32) UV_{DD} (USB power supply)

This is a 3.3 V positive power supply pin for the USB.

(33) UDP (USB data input & output (+)) ... I/O

This is a data I/O pin (+) of the USB.

(34) UDM (USB data input & output (-)) ... I/O

This is a data I/O pin (-) of the USB.

(35) IV_{DD} (Internal unit power supply)

These are 1.5 V positive power supply pins for each internal unit. All the IV_{DD} pins should be connected to a positive power supply.

(36) IV_{SS} (Internal unit ground)

These are ground pins. All the IV_{SS} pins should be grounded.

(37) A2 to A15 (Address bus) ... output

These are the address output pins of the lower 14 bits of the address bus's 26-bit address when the external memory is accessed.

(38) D0 to D15 (Data bus) ... 3-state I/O

These pins constitute a data bus for when the external memory is accessed. These are the lower 16-bit I/O bus pins of the 32-bit data.

The output changes in synchronization with the rise of the BUSCLK signal in the T1 state.

(39) TRCCLK (Trace clock) ... output

This is a trace clock output pin.

(40) TRCDATA0 to TRCDATA3 (Trace data output) ... output

These are trace data output (D0 to D3) pins.

(41) TRCEND (Trace end status output) ... output

This is a trace end status output pin.

(42) VBCSEL (VB clock select) ... input

This is an input pin used to specify the VBCLK frequency. Fix the operating mode via a resistor.

2.4 Pin I/O Circuits and Recommended Connection of Unused Pins

It is recommended that 1 to 10 kΩ resistors be used when connecting to V_{DD} or V_{SS} via resistors.

(1/5)

Pin Name	Alternate-Function Pin	Pin No.	I/O Circuit Type	Recommended Connection
P10	$\overline{\text{INTP10}}/\overline{\text{UCLK}}$	159	8-J	Input: Independently connect to EV _{DD} or EV _{SS} via a resistor. Output: Leave open.
P11	$\overline{\text{INTP11}}/\overline{\text{SCK0}}$	155		
P12	SI0/RXD0	154		
P13	SO0/TXD0	153	5	
P20	NMI	152	2	Connect to V _{SS} directly.
P21	$\overline{\text{INTP21}}/\overline{\text{RXD1}}$	149	8-J	Input: Independently connect to EV _{DD} or EV _{SS} via a resistor. Output: Leave open.
P22	$\overline{\text{INTP22}}/\overline{\text{TXD1}}$	148	5	
P23	$\overline{\text{INTP23}}/\overline{\text{SCK1}}$	147	8-J	
P24	$\overline{\text{INTP24}}/\overline{\text{SI1}}$	146		
P25	$\overline{\text{INTP25}}/\overline{\text{SO1}}$	145	5	
P50	$\overline{\text{INTP50}}/\overline{\text{DMARQ0}}$	25	5	Input: Independently connect to EV _{DD} via a resistor. Output: Leave open.
P51	$\overline{\text{INTP51}}/\overline{\text{DMAAK0}}$	24	5	Input: Independently connect to EV _{DD} or EV _{SS} via a resistor. Output: Leave open.
P52	$\overline{\text{INTP52}}/\overline{\text{TC0}}$	23		
P53	$\overline{\text{INTPC00}}/\overline{\text{TIC0}}/\overline{\text{DMARQ1}}$	22	5	Input: Independently connect to EV _{DD} via a resistor. Output: Leave open.

2.5 Pin I/O Circuits

CHAPTER 3 CPU FUNCTION

The CPU of the V850E2/ME3 is based on RISC architecture and executes almost all the instructions in one clock cycle using 7-stage pipeline control.

3.1 Features

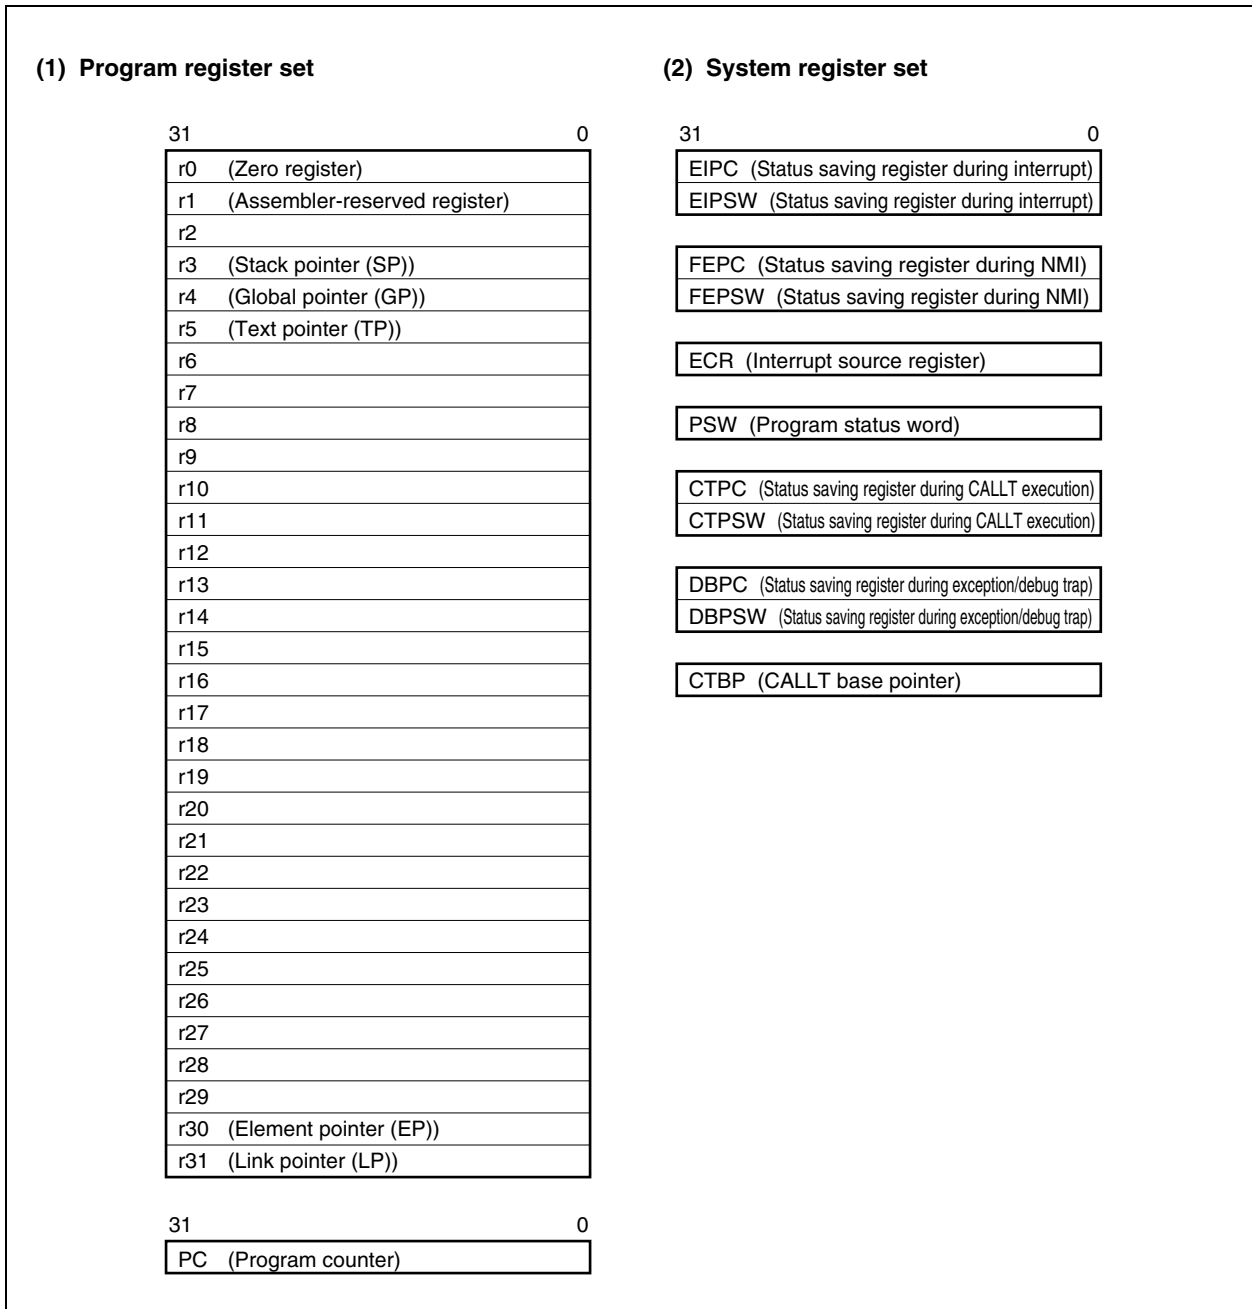

- Minimum instruction execution time: 5 ns (@200 MHz internal operation)
- High-performance 32-bit architecture for embedded control
 - Number of instructions: 89
 - 32-bit general-purpose registers: 32
 - Load/store instructions in long/short formats
 - 3-operand instructions
 - 7-stage pipeline of 1 clock cycle per stage
 - Hardware interlock on register/flag hazards
 - Memory space: 512 MB linear for program space
4 GB linear for data space
- Special instructions
 - Saturated operation instructions
 - Bit manipulation instructions (SET1, CLR1, NOT1, TST1)
 - Multiplication using on-chip hardware multiplier
 - 16 bits × 16 bits → 32 bits
 - 32 bits × 32 bits → 32 bits or 64 bits
 - MAC operation
 - 32 bits × 32 bits + 64 bits → 64 bits

3.2 CPU Register Set

The registers of the V850E2/ME3 can be classified into two categories: a general program register set and a dedicated system register set. All the registers have a 32-bit width.

Refer to **V850E2 Architecture User’s Manual** for details.

Figure 3-1. CPU Register Set

3.2.1 Program register set

The program register set includes general-purpose registers and a program counter.

Table 3-1. Program Registers

Name	Usage	Operation
r0	Zero register	Always holds 0
r1	Assembler-reserved register	Working register for generating 32-bit immediate data
r2	Address/data variable register (when r2 is not used by the real-time OS)	
r3	Stack pointer	Used to generate stack frame when function is called
r4	Global pointer	Used to access global variable in data area
r5	Text pointer	Register to indicate the start of the text area (where program code is located)
r6 to r29	Address/data variable registers	
r30	Element pointer	Base pointer when memory is accessed
r31	Link pointer	Used by compiler when calling function
PC	Program counter	Holds instruction address during program execution

Remark For detailed descriptions of r1, r3 to r5, and r31 used by an assembler or C compiler, refer to the **CA850 (C Compiler Package) Assembly Language User's Manual**.

(1) General-purpose registers (r0 to r31)

Thirty-two general-purpose registers, r0 to r31, are provided. All these registers can be used for data variables or address variables.

However, care must be exercised as follows in using the r0 to r5, r30, and r31 registers.

(a) r0, r30

r0 and r30 are implicitly used by instructions.

r0 is a register that always holds 0, and is used for operations using 0 and offset 0 addressing.

r30 is used as a base pointer when accessing memory using the SLD and SST instructions.

(b) r1, r3 to r5, r31

r1, r3 to r5, and r31 are implicitly used by the assembler and C compiler.

Therefore, their contents must be saved before using these registers so that they are not lost.

The contents must be restored to the registers after the registers have been used.

(c) r2

r2 is sometimes used by a real-time OS. When the real-time OS to be used is not using r2, r2 can be used as an address variable register or a data variable register.

(2) Program counter (PC)

This register holds the instruction address during program execution. The lower 29 bits of this register are valid, and bits 31 to 29 are reserved for future function expansion (fixed to 0). If a carry occurs from bit 28 to 29, it is ignored.

Bit 0 is fixed to 0, and branching to an odd address cannot be performed.

**3.2.2 System register set**

System registers control the status of the CPU and hold interrupt information.

To read/write these system registers, specify a system register number indicated below using the system register load/store instruction (LDSR or STSR instruction).

Table 3-2. System Register Numbers

No.	System Register Name	Operand Specification	
		LDSR Instruction	STSR Instruction
0	Status saving register during interrupt (EIPC) ^{Note 1}	○	○
1	Status saving register during interrupt (EIPSW) ^{Note 1}	○	○
2	Status saving register during NMI (FEPC)	○	○
3	Status saving register during NMI (FEPSW)	○	○
4	Interrupt source register (ECR)	×	○
5	Program status word (PSW)	○	○
6 to 15	Reserved for future function expansion (operations that access these register numbers cannot be guaranteed).	×	×
16	Status saving register during CALLT execution (CTPC)	○	○
17	Status saving register during CALLT execution (CTPSW)	○	○
18	Status saving register during exception/debug trap (DBPC)	○ ^{Note 2}	○ ^{Note 2}
19	Status saving register during exception/debug trap (DBPSW)	○ ^{Note 2}	○ ^{Note 2}
20	CALLT base pointer (CTBP)	○	○
21 to 31	Reserved for future function expansion (operations that access these register numbers cannot be guaranteed).	×	×

Notes 1. Because these registers have only one set, to enable multiple interrupts, it is necessary to save these registers by program.

2. These registers can be accessed only during the period between the execution of the DBTRAP instruction or illegal opcode and the DBRET instruction.

Caution Even if bit 0 of EIPC, FEPC, or CTPC is set to 1 by the LDSR instruction, bit 0 will be ignored when the program is returned by the RETI instruction after interrupt servicing (because bit 0 of the PC is fixed to 0). When setting the value of EIPC, FEPC, and CTPC, use an even value (bit 0 = 0) unless there is a special reason not to.

Remark ○: Access allowed
×: Access prohibited

(1) Interrupt status saving registers (EIPC and EIPSW)

EIPC and EIPSW are used to save the status when an interrupt occurs.

If a software exception or a maskable interrupt occurs, the contents of the program counter (PC) are saved to EIPC, and the contents of the program status word (PSW) are saved to EIPSW (these contents are saved to the NMI status saving registers (FEPC and FEPSW) if a non-maskable interrupt occurs).

The address of the instruction next to the instruction under execution, except some instructions (see **8.7 Periods in Which Interrupts Are Not Acknowledged by CPU**), is saved to EIPC when a software exception or a maskable interrupt occurs.

The current contents of the PSW are saved to EIPSW.

Because only one set of interrupt status saving registers is available, the contents of these registers must be saved by program when multiple interrupt servicing is enabled.

Bits 31 to 29 of EIPC and bits 31 to 8 of EIPSW are reserved for future function expansion (these bits are always fixed to 0).

(2) NMI status saving registers (FEPC and FEPSW)

FEPC and FEPSW are used to save the status when a non-maskable interrupt (NMI) occurs.

If an NMI occurs, the contents of the program counter (PC) are saved to FEPC, and those of the program status word (PSW) are saved to FEPSW.

The address of the instruction next to the instruction under execution, except some instructions, is saved to FEPC when an NMI occurs.

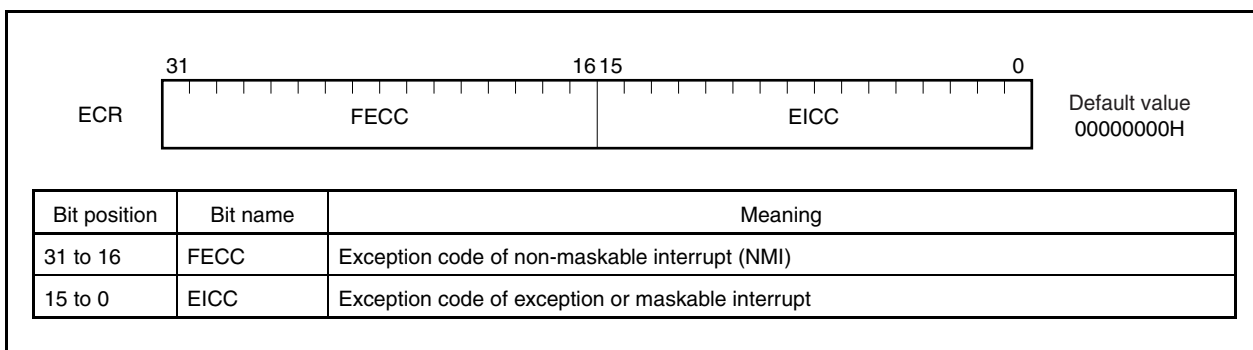

The current contents of the PSW are saved to FEPSW.

Bits 31 to 29 of FEPC and bits 31 to 8 of FEPSW are reserved for future function expansion (these bits are always fixed to 0).

(3) Interrupt source register (ECR)

The interrupt source register (ECR) holds the source of an exception or interrupt if an exception or interrupt occurs. This register holds the exception code of each interrupt source. Because this register is a read-only register, data cannot be written to this register using the LDSR instruction.

(4) Program status word (PSW)

The program status word (PSW) is a collection of flags that indicate the status of the program (result of instruction execution) and the status of the CPU.

If the contents of a bit of this register are changed by using the LDSR instruction, the new contents are validated immediately after completion of LDSR instruction execution. If the ID flag is set (= 1), however, acknowledgment of interrupt requests is prohibited during execution of the LDSR instruction.

Bits 31 to 8 of this register are reserved for future function expansion (these bits are fixed to 0).

(1/2)

Bit position	Flag name	Meaning
31 to 8	RFU	Reserved field. Fixed to 0.
7	NP	Indicates that a non-maskable interrupt (NMI) is being serviced. This bit is set to 1 when an NMI request is acknowledged, disabling multiple interrupt servicing. 0: NMI is not being serviced. 1: NMI is being serviced.
6	EP	Indicates that an exception is being processed. This bit is set to 1 when an exception occurs. Even if this bit is set, interrupt requests are acknowledged. 0: Exception is not being processed. 1: Exception is being processed.
5	ID	Indicates whether a maskable interrupt can be acknowledged. 0: Interrupt enabled (EI) 1: Interrupt disabled (DI)
4	SAT ^{Note}	Indicates that the result of a saturation operation has overflowed and is saturated. Because this is a cumulative flag, it is set to 1 when the result of a saturation operation instruction is saturated, and is not cleared to 0 even if the subsequent operation result is not saturated. Use the LDSR instruction to clear this bit. This flag is neither set to 1 nor cleared to 0 by execution of an arithmetic operation instruction. 0: Not saturated 1: Saturated
3	CY	Indicates whether a carry or a borrow occurred as a result of an operation (this flag is reset if a carry or a borrow did not occur). 0: Carry or borrow did not occur. 1: Carry or borrow occurred.
2	OV ^{Note}	Indicates whether an overflow occurred during operation (this flag is reset if an overflow did not occur). 0: Overflow did not occur. 1: Overflow occurred.
1	S ^{Note}	Indicates whether the result of an operation is negative (this flag is reset if the result is positive). 0: The result is positive or 0. 1: The result is negative.
0	Z	Indicates whether the result of an operation is 0 (this flag is reset if the result is not 0). 0: The result is not 0. 1: The result is 0.

Remark Also read **Note** on the next page.

(2/2)

Note The result of the operation that has performed saturation processing is determined by the contents of the OV and S flags. The SAT flag is set to 1 only when the OV flag is set to 1 when a saturation operation is performed.

Status of operation result	Flag status			Result of operation of saturation processing
	SAT	OV	S	
Maximum positive value is exceeded	1	1	0	7FFFFFFFH
Maximum negative value is exceeded	1	1	1	80000000H
Positive (maximum value is not exceeded)	Holds value before operation	0	0	Operation result itself
Negative (maximum value is not exceeded)			1	

(5) CALLT execution status saving registers (CTPC and CTPSW)

CTPC and CTPSW are CALLT execution status saving registers.

When the CALLT instruction is executed, the contents of the program counter (PC) are saved to CTPC, and those of the program status word (PSW) are saved to CTPSW.

The contents saved to CTPC are the address of the instruction next to CALLT.

The current contents of the PSW are saved to CTPSW.

Bits 31 to 29 of CTPC and bits 31 to 8 of CTPSW are reserved for future function expansion (fixed to 0).

(6) Exception/debug trap status saving registers (DBPC and DBPSW)

DBPC and DBPSW are exception/debug trap status registers.

If an exception trap or debug trap occurs, the contents of the program counter (PC) are saved to DBPC, and those of the program status word (PSW) are saved to DBPSW.

The contents to be saved to DBPC are the address of the instruction next to the one that is being executed when an exception trap or debug trap occurs.

The current contents of the PSW are saved to DBPSW.

These registers can be accessed only during the period between the execution of the DBTRAP instruction or illegal opcode and the DBRET instruction.

Bits 31 to 29 of DBPC and bits 31 to 8 of DBPSW are reserved for future function expansion (fixed to 0).

(7) CALLT base pointer (CTBP)

The CALLT base pointer (CTBP) is used to specify a table address or generate a target address (bit 0 is fixed to 0).

Bits 31 to 29 of this register are reserved for future function expansion (fixed to 0).

3.3 Operating Modes

3.3.1 Operating modes

The V850E2/ME3 has the following operating modes. Mode specification is carried out using the MODE0 and MODE1 pins.

(1) Normal operation mode

32-bit mode, 16-bit mode

After system reset is cleared, each pin related to the bus interface enters the control mode, the SRAM cycle branches to 0000000H (reset entry address) of the external device (memory), and instruction processing starts. After that, by activating the internal instruction RAM using the IRC register, the access for addresses 00000H to 7FFFFH is then handled as the access for the internal instruction RAM.

However, the internal instruction RAM is mounted at addresses 000000H to 029FFFFH. Therefore, do not access addresses 2A000H to 7FFFFH when access to the internal instruction RAM is enabled.

In the 32-bit mode, the bus interface functions as a 32-bit data bus; it functions as a 16-bit data bus in the 16-bit mode.

Caution Be sure to allocate external memory to address 0000000H for correct operation.

3.3.2 Operating mode specification

The operating mode is specified according to the status of the MODE0 and MODE1 pins. In an application system fix the specification of these pins and do not change them during operation. Operation is not guaranteed if these pins are changed during operation.

MODE1	MODE0	Operating Mode		Remarks
L	L	Normal operation mode	32-bit mode	32-bit data bus
L	H		16-bit mode	16-bit data bus
Other than above		Setting prohibited		

Remark L: Low-level input
H: High-level input

3.4 Address Space

The CPU of the V850E2/ME3 supports up to 4 GB of linear address space (data space). The memory and I/O are allocated in this address space (memory-mapped I/O mode).

Figure 3-2 shows the CPU address space.

Figure 3-2. CPU Address Space

In instruction address addressing, up to 512 MB of linear address space (program space) is supported.

In operand addressing (data access), up to 4 GB of linear address space (program space) is supported.

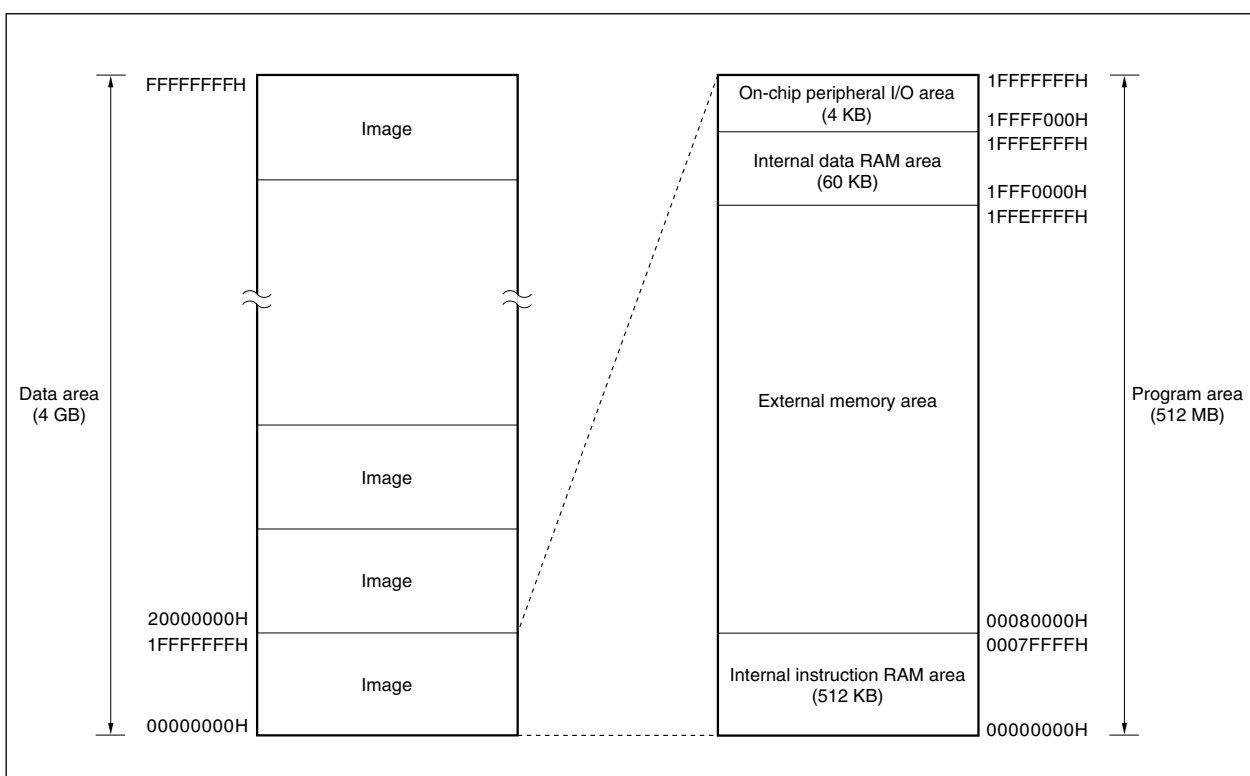

A 512 MB program area is seen as 8 images in the data area. In actuality, the same 512 MB linear address space is accessed regardless of the values of bits 31 to 29 of the CPU address.

The internal instruction RAM, internal data RAM, and on-chip peripheral I/O area are allocated to this 512 MB program area.

Caution Since the instruction prefetch buffer has the 48-byte configuration, instructions may be fetched from the area of the program counter value (PC value) + 48 bytes. In this case, instructions may be fetched from an area to which no memory is connected.

To avoid this operation, allocate a branch instruction at the lower 48 bytes or lower address from a boundary of the memory area (internal instruction RAM, internal data RAM, on-chip peripheral I/O area, and each external memory space), then shift the control to another area.

Figure 3-3. Data Area and Program Area

3.4.1 Wrap-around of CPU address space

(1) Program space

Of the 32 bits of the PC (program counter), the higher 3 bits are fixed to 0, and only the lower 29 bits are valid. Even if a carry or borrow occurs from bit 28 to 29 as a result of a branch address calculation, the higher 3 bits ignore the carry or borrow.

Therefore, the upper-limit address 1FFFFFFFH and the lower-limit address of the program space, address 0000000H, become contiguous addresses. Wrap-around refers to a situation like this whereby the upper-limit address and lower-limit address become contiguous.

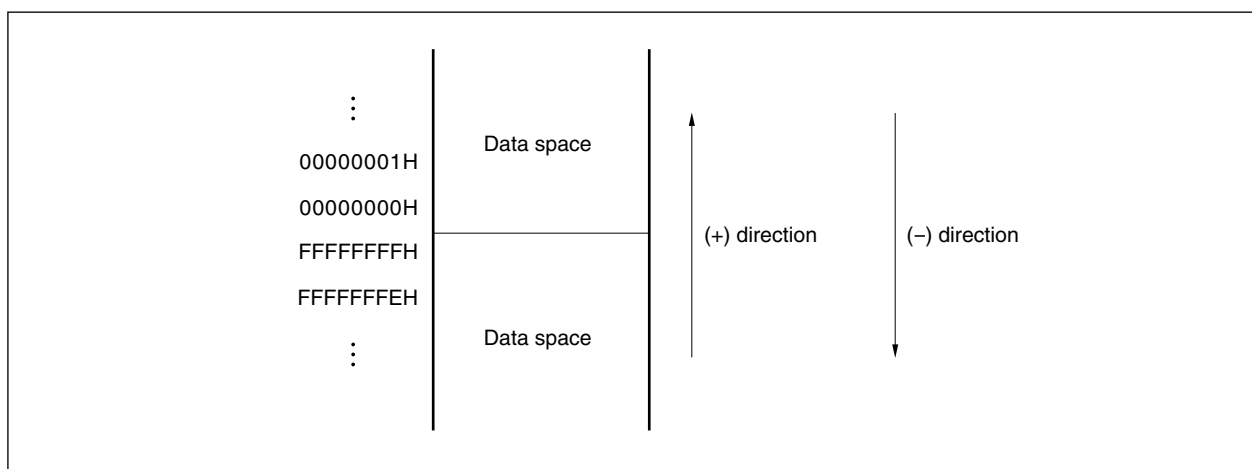

Caution The 64 KB area of 1FFF000H to 1FFFFFFFH can be seen as an image of FFFF000H to FFFFFFFFH. Instructions cannot be fetched from this area because it is an on-chip peripheral I/O area, internal data RAM area, or access-prohibited area. Therefore, do not execute any branch address calculation in which the result will reside in any part of this area.

(2) Data space

The result of an operand address calculation that exceeds 32 bits is ignored.

Therefore, the upper-limit address FFFFFFFFH, and the lower-limit address of the program space, address 0000000H are contiguous addresses, and the data space is wrapped around at the boundary of these addresses.

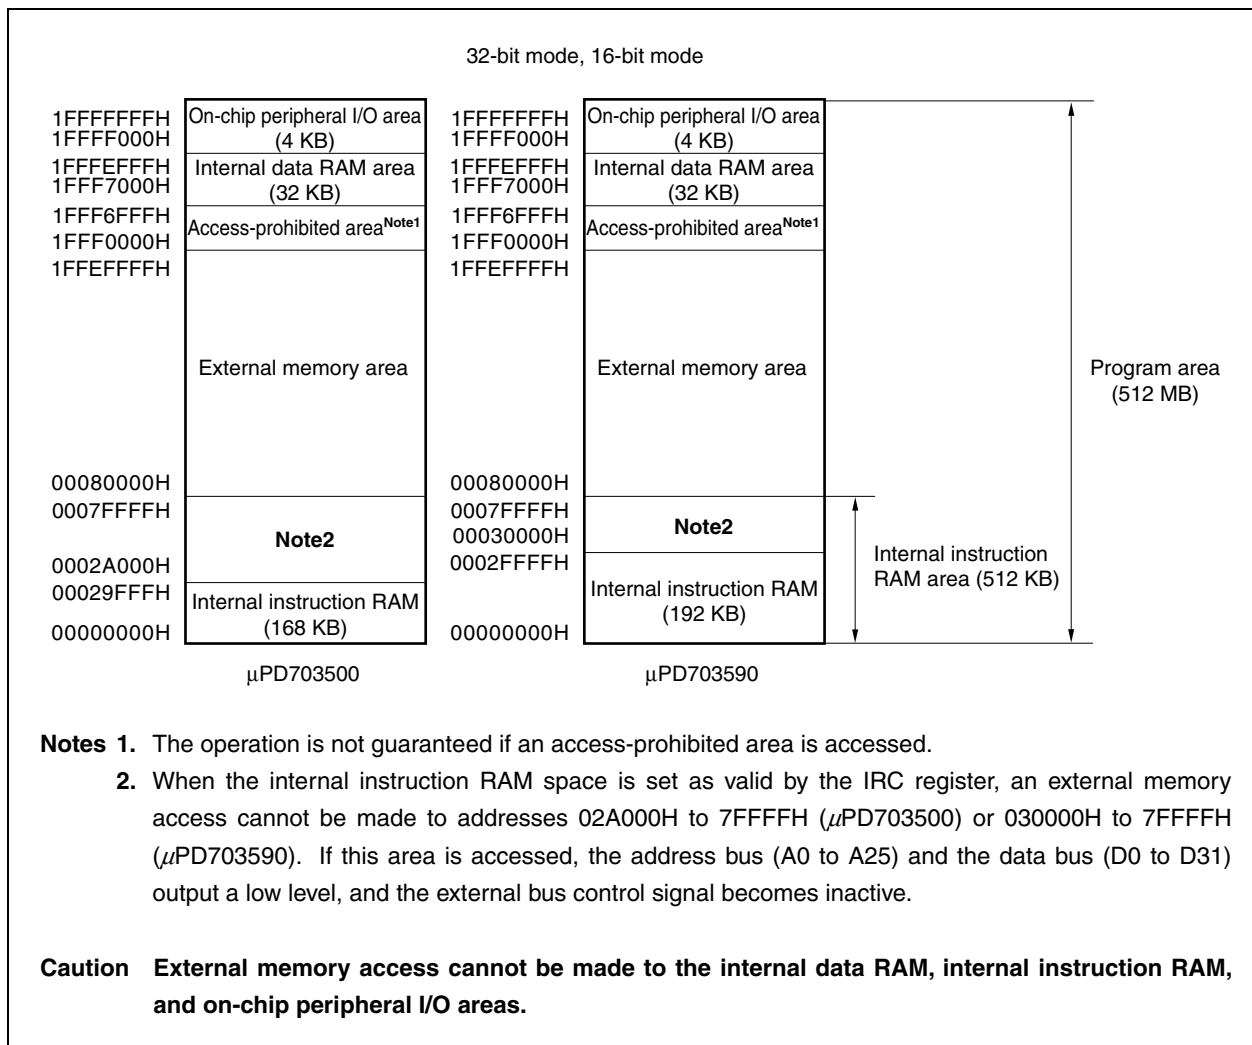

3.4.2 Memory map

Areas are reserved in the V850E2/ME3 as shown in Figure 3-4.

<R>

Figure 3-4. Memory Map

3.4.3 Area

(1) Internal instruction RAM area

(a) Memory map

512 KB of internal instruction RAM area, addresses 00000H to 7FFFFH, is reserved. 168 KB are provided at addresses 000000H to 029FFFH as physical instruction RAM.

<R>

Caution When the internal instruction RAM space is set as valid by the IRC register, an external memory access cannot be made to addresses 02A000H to 7FFFFH (μ PD703500) or 030000H to 7FFFFH (μ PD703590). If this area is accessed, the address bus (A0 to A25) and the data bus (D0 to D31) output a low level, and the external bus control signal becomes inactive.

(b) Interrupt/exception table

The V850E2/ME3 increases the interrupt response speed by assigning handler addresses corresponding to interrupts/exceptions.

The collection of these handler addresses is called an interrupt/exception table. When an interrupt/exception request is acknowledged, execution jumps to the handler address, and the program written in that memory is executed. Table 3-3 shows the sources of interrupts/exceptions, and the corresponding addresses.

Remark In order to operate the program normally even after a reset, allocate the handler address to the reset routine at address 0 in the external memory.

Table 3-3. Interrupt/Exception Table (1/2)

Start Address of Interrupt/Exception Table	Interrupt/Exception Source	Start Address of Interrupt/Exception Table	Interrupt/Exception Source
00000000H	RESET	00000140H	INTP67
00000010H	NMI0	00000150H	INTPD0
00000040H	TRAP0n (n = 0 to F)	00000160H	INTPD1
00000050H	TRAP1n (n = 0 to F)	00000170H	INTPD2
00000060H	ILGOP/DBG0	00000180H	INTPD3
00000080H	INTP10	00000190H	INTPD4
00000090H	INTP11	000001A0H	INTPD5
000000A0H	INTP21	000001B0H	INTPD6
000000B0H	INTP22	000001C0H	INTPD7
000000C0H	INTP23	000001D0H	INTPD8

(2) Internal data RAM area

The 32 KB area of addresses 1FFF7000H to 1FFFEFFFH is provided as the internal data RAM area.

Caution External memory access cannot be made to addresses 1FFF0000H to 1FFF6FFFH. The operation is not guaranteed if external memory access is performed.

**(3) On-chip peripheral I/O area**

4 KB of memory, addresses 1FFFF000H to 1FFFFFFFH, are provided as an on-chip peripheral I/O area.

Peripheral I/O registers associated with the operating mode specification and the state monitoring for the on-chip peripheral I/O are all memory-mapped to the on-chip peripheral I/O area. Program fetches cannot be executed from this area.

Cautions 1. For registers in which byte access is possible, if halfword access is executed, the higher 8 bits become undefined during a read operation, and the lower 8 bits of data are written to the register during a write operation.

Do not access an 8-bit register in halfword units.

2. Addresses that are not defined as registers are reserved for future expansion. If these addresses are accessed, the operation is undefined and not guaranteed.

(4) External memory area

512 MB are available for external memory area. The external memory area is addresses 00000000H to 1FFFEFFFH. The external memory area is allocated to addresses 00080000H to 1FFFEFFFH by setting the IREN0 bit of the IRC register to 1 after a program is transferred to the internal instruction RAM.

Access to the external memory area is performed using the chip select signal assigned to each area (which is carried out in the CS unit set by the CSC0 and CSC1 registers).

Note that the internal instruction RAM, internal data RAM, and on-chip peripheral I/O areas cannot be used as external memory areas.

3.4.4 Recommended use of address space

The architecture of the V850E2/ME3 requires that a register that serves as a pointer be secured for address generation in operand data accessing of data space. Operand data access from instruction can be directly executed at the address in this pointer register ± 32 KB. However, because the general-purpose registers that can be used as a pointer register are limited, by minimizing the deterioration of address calculation performance when changing the pointer value, the number of usable general-purpose registers for handling variables is maximized, and the program size can be saved.

In connection with the memory map of the V850E2/ME3, the following usage is recommended to enhance the efficiency of pointer operation.

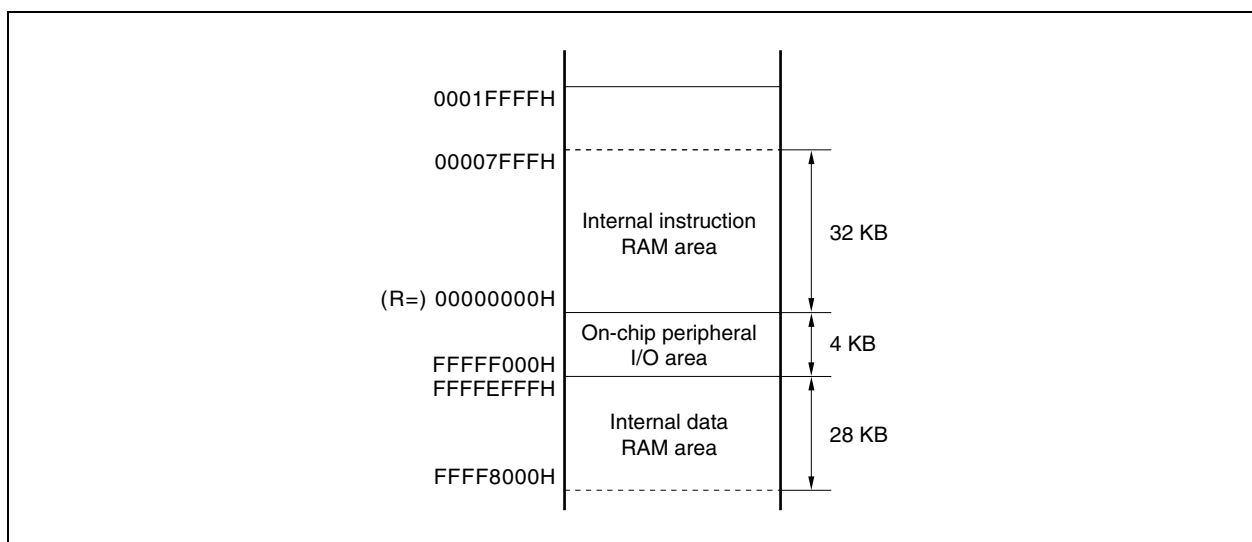

(1) Program space

Of the 32 bits of the program counter (PC), the higher 3 bits are fixed to 0, and only the lower 29 bits are valid. Therefore, a contiguous 512 MB space, starting from address 00000000H, unconditionally corresponds to the memory map of the program space.

(2) Data space

With the V850E2/ME3, a 512 MB physical address space is seen as 8 images in the 4 GB CPU address space. The highest bit (bit 28) of this 29-bit address is assigned as an address sign-extended to 32 bits.

Example Application of wrap-around is as shown below.

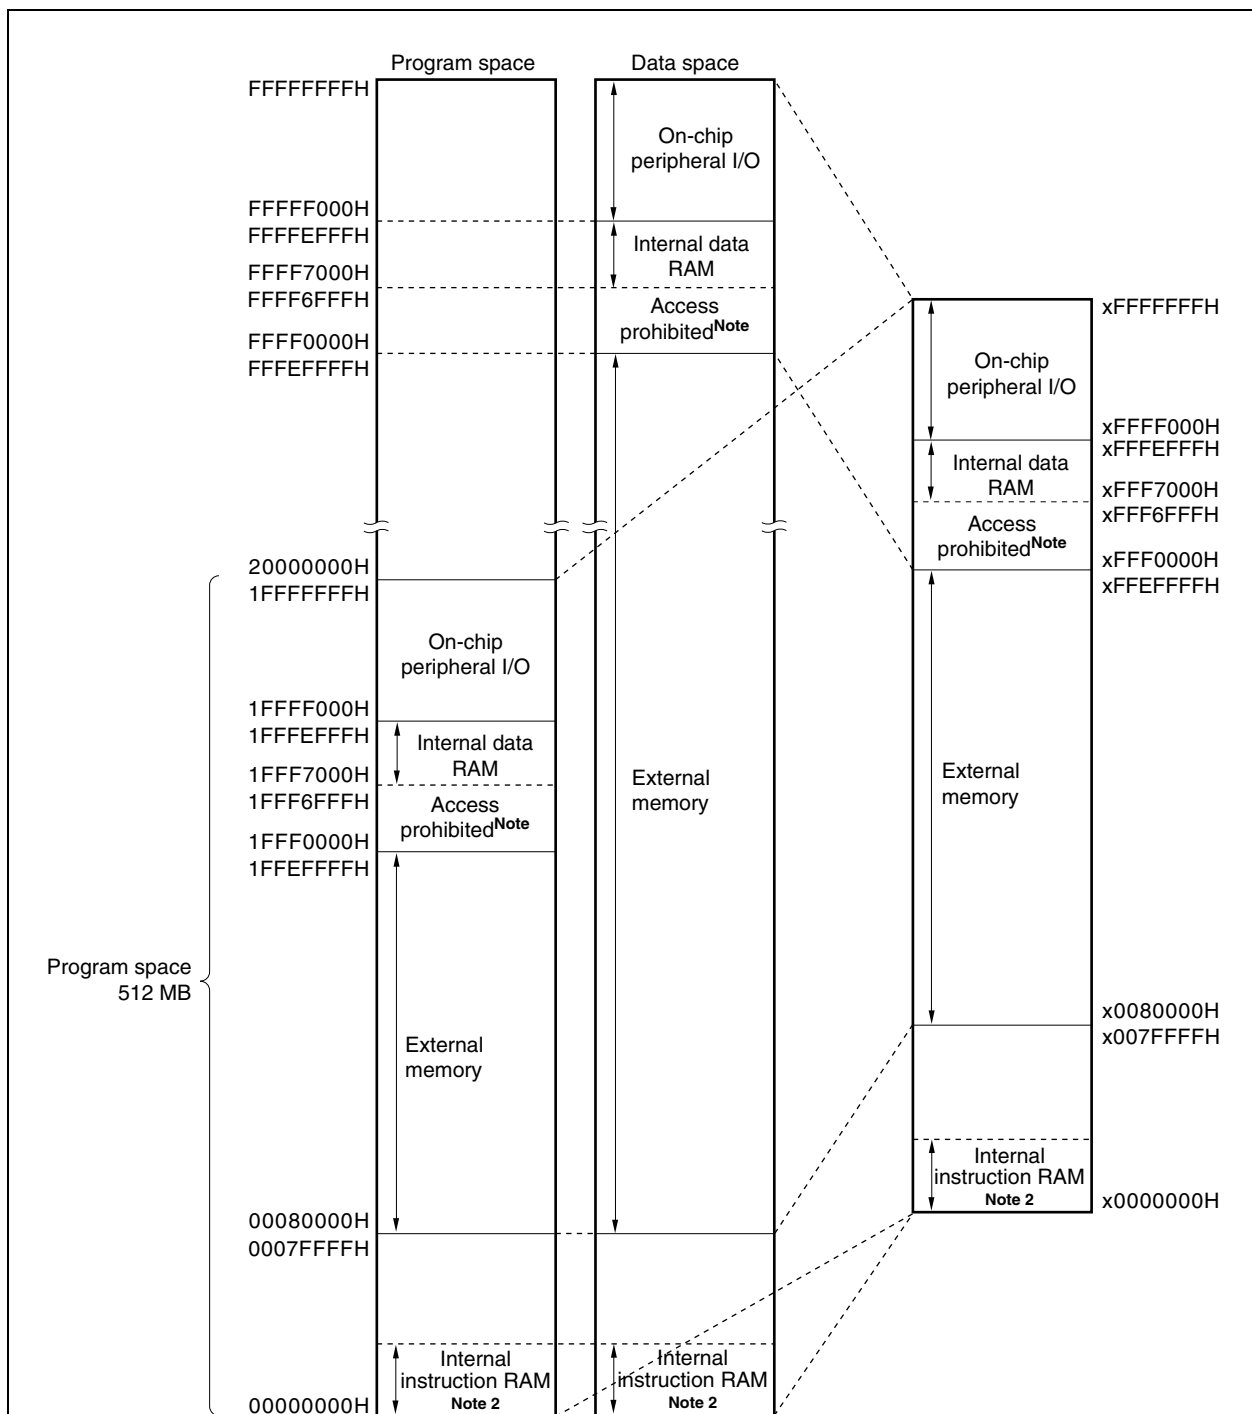

When R = r0 (zero register) is specified with the LD/ST disp16[R] instruction, an addressing range of 00000000H ± 32 KB can be referenced with the sign-extended disp16.

The zero register (r0) is a register fixed to 0 by the hardware, and eliminates the need for additional registers for the pointer.

<R>

Figure 3-5. Recommended Memory Map

- Notes**
1. The operation is not guaranteed if an access-prohibited area is accessed.
 2. μ PD703500: 168KB (00000000-00029FFFFH)
 μ PD703590: 192KB (00000000-0002FFFFH)

Remark The arrows indicate the recommended area.

3.4.6 Specific registers

Specific registers are registers that are protected from being written with illegal data due to erroneous program execution, etc. The V850E2/ME3 has four specific registers, the power-save control register (PSC) (see **9.6.2 (2) Power-save control register (PSC)**), clock control register (CKC) (see **9.3.1 Clock control register (CKC)**), clock source select register (CKS) (see **9.3.2 Clock source select register (CKS)**), and SSCG control register (SSCGC) (see **9.3.4 SSCG control register (SSCGC)**). Disable DMA transfer when writing to a specific register.

There is also the PRCMD register, a protection register supporting write operations for specific registers to avoid an unexpected stoppage of the application system due to erroneous program execution (see **9.6.2 (1) Command register (PRCMD)**).

3.4.7 System wait control register (VSWC)

The VSWC register is a register that controls the bus access wait for the on-chip peripheral I/O registers.

Access to on-chip peripheral I/O registers of the V850E2 CPU core basically is made in 3 clocks, however, in the V850E2/ME3 waits may be required in addition to the three clocks. Set the VSWC register to 0042H (setting wait to three clocks).

This register can be read or written in 16-bit units (address: 1FFFF06EH, initial value: 00CFH).

Operation Frequency (fx)	f_{VBCLK}	Number of Waits to Be Inserted	VSWC Setting Value
$100 \text{ MHz} \leq f_x \leq 200 \text{ MHz}$	$33.3 \text{ MHz} \leq f_{VBCLK} \leq 100 \text{ MHz}$	3	0042H

Caution When changing the VSWC register contents, insert at least 16 NOP instructions immediately after the instruction for changing the VSWC register setting (see 3.5 Cautions).

Remark If the timing of changing a count value contend with the timing of accessing a register when accessing a register having status flags that indicate the status of the on-chip peripheral functions (such as UBnSTR) or a register that indicates the count value of a timer (such as TMCn), the register access is retried. As a result, it may take a longer time to access an on-chip peripheral I/O register.

3.4.8 Initialization sequence

Initialize the V850E2/ME3 in the following sequence.

<1> Program execution started from external memory after reset is released

Set the following registers that affect the external bus access performance using the program located at address 000000H.

- VSWC register
Setting of a wait cycle for accessing the on-chip peripheral I/O
- DWC0 and DWC1 registers
Setting of a data wait cycle of the external bus
- ASC register
Setting of an address setup wait cycle of the external bus
- BCC register
Setting of an idle state of the external bus

As necessary, set the CSC0, CSC1, BCT0, BCT1, LBS, PRC, PFCDH, and PFCCS registers.

Cautions 1. Be sure to allocate the interrupt/exception table to the external memory at address 00000000H. In addition, in order to validate the internal instruction RAM, transfer the interrupt/exception table to the internal instruction RAM.

2. Set the SCR1, SCR3, SCR4, and SCR6 registers after the processing of step <2>.

<2> Checking LOCKR.LOCK bit

After setting the registers in <1> above, check whether the LOCKR.LOCK bit is cleared to 0 (PLL is locked), and set the registers as follows.

- (i) VSWC register
Set to 004FH
Because 0042H is set in <1>, set 004FH here.
- (ii) BMC register
Set the frequency division value of the external bus.
- (iii) VSWC register
Re-set the value set in <1>.
- (iv) CKC register
Set the internal system clock frequency division value.
- (v) CKS register
Switch from OSC output to SSCG output (switch the clock supply to the CPU from the input frequency to the X1 and X2 pins to the frequency multiplied by 20 by the PLL).

Remark The CKC and CKS registers must be rewritten in a special sequence because they are specific registers.

<3> Transferring program code to internal instruction RAM

Transfer the program code to the internal instruction RAM by program processing or using the DMA function.

Refer to **4.10 Allocation of Program to Internal Instruction RAM Area** for how to transfer the program code.

3.5 Cautions

Cautions on using CPU functions are shown below.

(1) Allocation to address 0000000H

To operate correctly, be sure to allocate the external memory to address 0000000H.

(2) Cautions on changing register settings

When changing the following registers, insert at least 16 NOP instructions immediately after the last instruction for changing the register.

- Chip area select control registers 0, 1 (CSC0, CSC1)
- Cache area specification register (BHC)
- Bus transaction control register (BTSC)
- Cache manipulation specification register (COPR)
- System wait control register (VSWC)

Do not allocate any of the following instructions between instructions that set registers.

- Instruction for accessing external memory space (LD, ST, SWITCH, CALLT, DISPOSE, PREPARE, PUSH, POP)
- Branch instruction (JARL, JMP, JR, Bcond)

[Description example]

```

:
:
ori    0x0005, r0, r20
st.h   r20, 0x1FFF070[r0]    -- Sets BTSC register

ori    0x00ff, r0, r20
st.h   r20, 0x1FFF06A[r0]    -- Sets BHC register

nop;nop;nop;nop;           -- Insert 16 NOP instructions
nop;nop;nop;nop;
nop;nop;nop;nop;
nop;nop;nop;nop;

jarl   _main, lp            -- Branches to main routine (cache area)

```

CHAPTER 4 BUS CONTROL FUNCTION

The V850E2/ME3 is provided with an external bus interface function by which external I/O and memories, such as ROM and RAM, can be connected.

4.1 Features

- 32-bit/16-bit/8-bit data bus sizing function
- 8-space chip select function
- Wait function
 - Programmable wait function, through which up to 7 wait states can be inserted for each area
 - External wait function via $\overline{\text{WAIT}}$ pin
- Idle state insertion function
- Bus mastership arbitration function
- Bus hold function
- External device connection enabled via bus control/port alternate function pins

4.2 Bus Control Pins

The following pins are used for connection to external devices.

Bus Control Pin (Function When in Control Mode)	Function When in Port Mode	Register for Port/Control Mode Switching
Data bus (D0 to D15)	–	–
Data bus (D16 to D31)	PDH0 to PDH15 (Port DH)	PMCDH
Address bus (A0, A1)	PAL0, PAL1 (Port AL)	PMCAL
Address bus (A16 to A25)	PAH0 to PAH9 (Port AH)	PMCAH
Chip select ($\overline{\text{CS}}0$ to $\overline{\text{CS}}7$, $\overline{\text{IOWR}}$, $\overline{\text{IORD}}$)	PCS0 to PCS7 (Port CS)	PMCCS
SDRAM sync control ($\overline{\text{SDCKE}}$)	PCD0 (Port CD)	PMCCD
Bus clock (BUSCLK)	PCD1 (Port CD)	
SDRAM control ($\overline{\text{SDCAS}}$, $\overline{\text{SDRAS}}$)	PCD2, PCD3 (Port CD)	
Read/write control ($\overline{\text{LLWR}}/\overline{\text{LLBE}}/\overline{\text{LLDQM}}$, $\overline{\text{LUWR}}/\overline{\text{LUBE}}/\overline{\text{LUDQM}}$, $\overline{\text{ULWR}}/\overline{\text{ULBE}}/\overline{\text{ULDQM}}$, $\overline{\text{UUDQM}}/\overline{\text{UUBE}}/\overline{\text{UUWR}}$, $\overline{\text{RD}}$, $\overline{\text{WE}}/\overline{\text{WR}}$)	PCT0 to PCT5 (Port CT)	PMCCCT
Bus cycle start ($\overline{\text{BCYST}}$)	PCT7 (Port CT)	
External wait control ($\overline{\text{WAIT}}$)	PCM0 (Port CM)	PMCCM
Bus hold control ($\overline{\text{HLDRQ}}$, $\overline{\text{HLDK}}$)	PCM2, PCM3 (Port CM)	
SDRAM refresh control ($\overline{\text{REFRQ}}$)	PCM4 (Port CM)	
Self-refresh control ($\overline{\text{SELFREF}}$)	PCM5 (Port CM)	

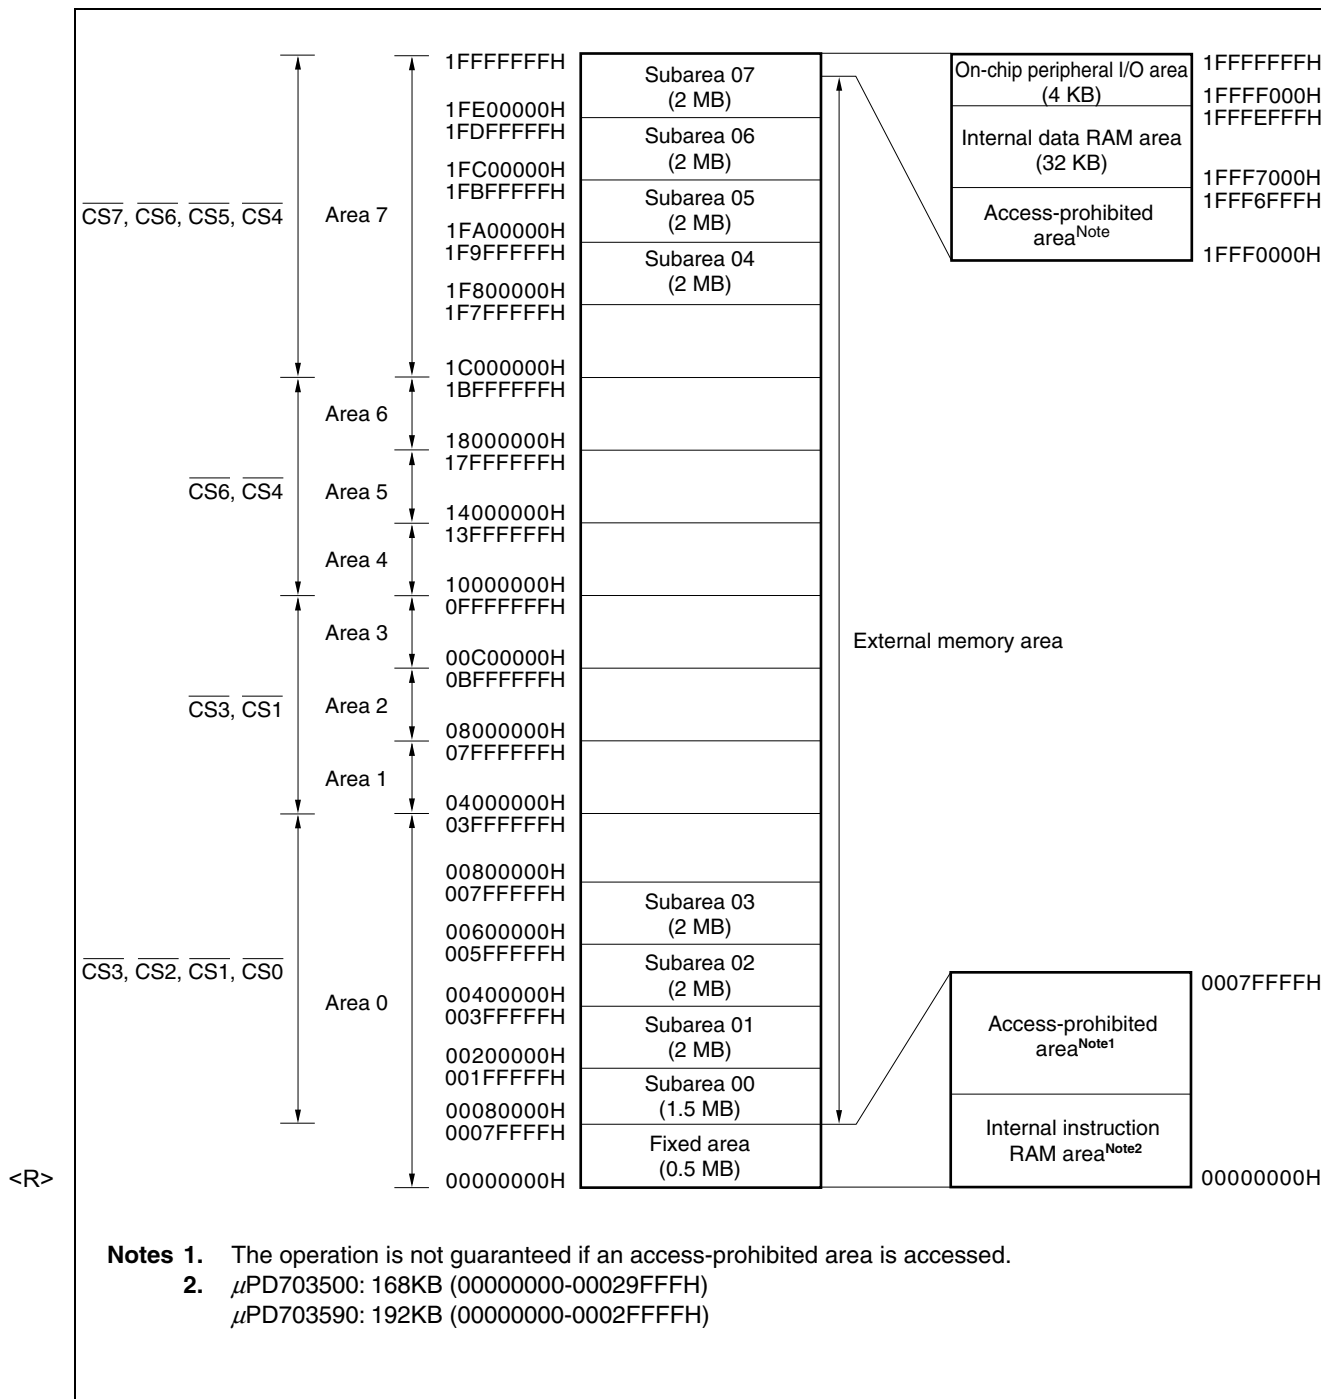

Remark When the system is reset, each bus control pin becomes unconditionally valid. (However, D16 to D31, $\overline{\text{ULWR}}/\overline{\text{ULBE}}/\overline{\text{ULDQM}}$, and $\overline{\text{UUWR}}/\overline{\text{UUBE}}/\overline{\text{UUDQM}}$ are valid only in 32-bit mode.)

4.2.1 Pin status when internal instruction RAM, internal data RAM, or on-chip peripheral I/O is accessed

The address bus and data bus output a low level when the internal instruction RAM, internal data RAM, or on-chip peripheral I/O is accessed. The external bus control signal is deasserted.

4.3 Memory Block Function

The 512 MB memory space is divided into eight areas including seven 2 MB subareas and one 1.5 MB subarea.

4.3.1 Chip select control function

Each area can be divided using the CSC0 and CSC1 registers to control the chip select signal.

The memory space can be effectively used by dividing it into areas using the chip select control function. The priority order is described below.

(1) Chip area select control registers 0, 1 (CSC0, CSC1)

These registers can be read or written in 16-bit units and become valid by setting each bit to 1.

If different chip select signal outputs are set to the same area, the priority order is controlled as follows.

CSC0: $\overline{CS0} > \overline{CS2} > \overline{CS1} > \overline{CS3}$

CSC1: $\overline{CS7} > \overline{CS5} > \overline{CS6} > \overline{CS4}$

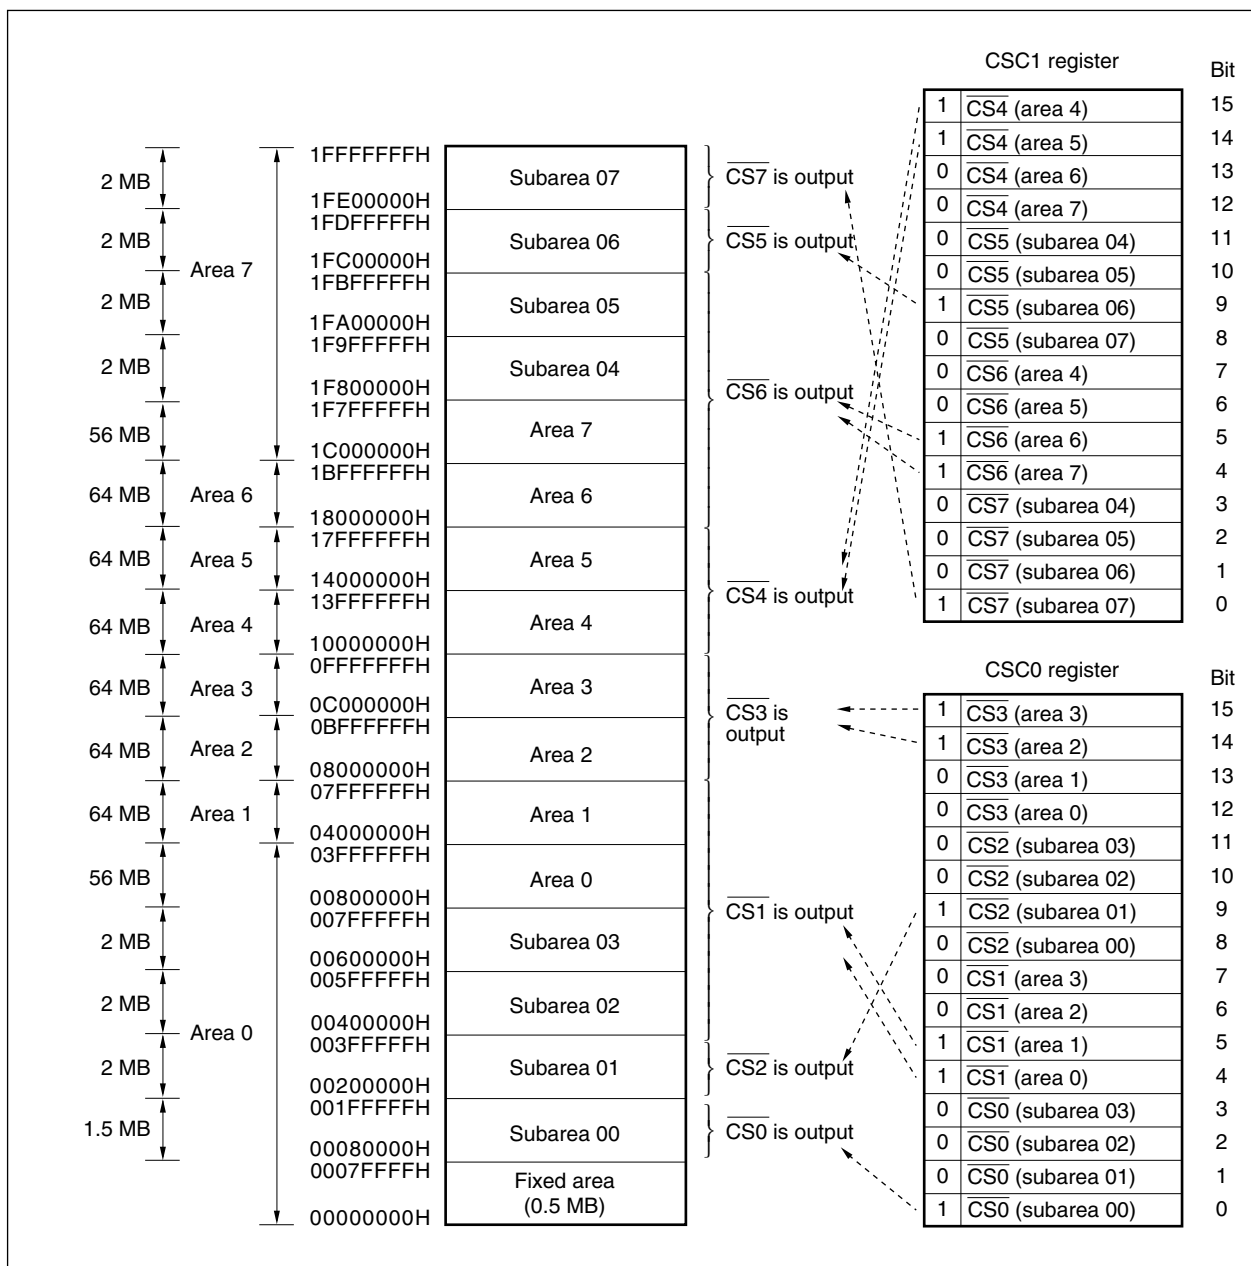

- Cautions**
1. Write to the CSC0 and CSC1 registers after reset, and then do not change the set value.
 2. When changing the CSC0 and CSC1 register contents, insert at least 16 NOP instructions immediately after the instruction for changing the CSC0 and CSC1 register setting (see 3.5 Cautions).
 3. The $\overline{CS0}$ signal is valid for address 0000H after the reset state is released.

CSC0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address FFFFFF060H	After reset C231H
	CS33	CS32	CS31	CS30	CS23	CS22	CS21	CS20	CS13	CS12	CS11	CS10	CS03	CS02	CS01	CS00		
CSC1	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address FFFFFF062H	After reset C231H
	CS43	CS42	CS41	CS40	CS53	CS52	CS51	CS50	CS63	CS62	CS61	CS60	CS73	CS72	CS71	CS70

Remark n = 0 to 7, m = 0 to 3

The CSC0 and CSC1 register settings and memory map in the initial status are shown below.

The following shows the memory map when the CSC0 register is set to FCC3H and the CSC1 register is set to E716H.

- Notes 1.** The settings to bits 10 and 9 are invalid because the CS7 signal, to which the higher priority is given by setting bits 2 and 1 of the CSC1 register, is output to subareas 05 and 06.
- 2.** The settings to subarea 05 to subarea 07, which are included in area 7, are invalid because the CS5 and CS7 signals, to which the higher priority is given by setting bits 8, 2, and 1 of the CSC1 register, are output to subarea 05 to subarea 07 (the setting to subarea 04 is valid because no CSn signal is output to this area).
- 3.** The settings to bits 15 and 14 are invalid because the CS1 signal, to which the higher priority is given by setting bits 7 and 6 of the CSC0 register, is output to area 2 and area 3.
- 4.** The settings to subarea 00 to subarea 03, which are included in area 0, are invalid because the CS0 and CS2 signals, to which the higher priority is given by setting bits 11, 10, 1, and 0 of the CSC0 register, are output to subarea 00 to subarea 03.

4.4 Bus Cycle Type Control Function

In the V850E2/ME3, the following external devices can be connected directly to each area.

- SRAM, external ROM, external I/O
- Page ROM
- SDRAM

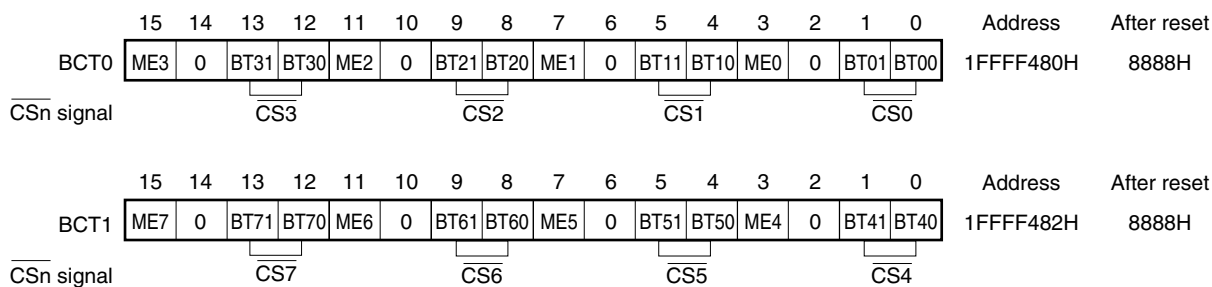

Connected external devices are specified using the BCT0 and BCT1 registers.

(1) Bus cycle type configuration registers 0, 1 (BCT0, BCT1)

These registers can be read or written in 16-bit units.

Be sure to clear bits 14, 10, 6, and 2 to 0. If they are set to 1, the operation is not guaranteed.

Caution Write to the BCT0 and BCT1 registers after reset, and then do not change the set value (however, the MEn bit value can be changed). Also, do not access an external memory area other than the one for this initialization routine until the initial setting of the BCT0 and BCT1 registers is complete. However, it is possible to access external memory areas whose initialization settings are complete.

Bit position	Bit name	Function															
15, 11, 7, 3	MEn	Sets memory controller operation enable for each chip select. 0: Operation disabled 1: Operation enabled															
13, 12, 9, 8, 5, 4, 1, 0	BTn1, BTn0	Specifies the device to be connected to the CSn signal. <table border="1" style="margin-left: 20px;"> <thead> <tr> <th>BTn1</th> <th>BTn0</th> <th>External device connected to CSn signal</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>SRAM, external I/O</td> </tr> <tr> <td>0</td> <td>1</td> <td>Page ROM</td> </tr> <tr> <td>1</td> <td>0</td> <td>Setting prohibited</td> </tr> <tr> <td>1</td> <td>1</td> <td>n = 1, 3, 4, 6: SDRAM n = 0, 2, 5, 7: Setting prohibited</td> </tr> </tbody> </table>	BTn1	BTn0	External device connected to CSn signal	0	0	SRAM, external I/O	0	1	Page ROM	1	0	Setting prohibited	1	1	n = 1, 3, 4, 6: SDRAM n = 0, 2, 5, 7: Setting prohibited

1	0	Setting prohibited															
1	1	n = 1, 3, 4, 6: SDRAM n = 0, 2, 5, 7: Setting prohibited															

Remark n = 0 to 7

4.5 Bus Access

4.5.1 Number of access clocks

The number of base clocks necessary for accessing each resource is as follows.

Resource (Bus Width)	Bus Cycle Configuration	Instruction Fetch	Operand Data Access	
			Read	Write
Internal instruction RAM (128 bits)		2 ^{Note 1}	2	
Internal data RAM (32 bits)		1 ^{Note 2}	1	

Notes 1. When random accessing: 2 clocks

2. Instructions are fetched from the internal instruction RAM in 4-word units, and in 1-word units from the internal data RAM.

Remark Unit: Clock/access

4.5.2 Bus sizing function

The bus sizing function controls the data bus width for each CS space. The data bus width is specified using the LBS register.

(1) Local bus sizing control register (LBS)

This register can be read or written in 16-bit units.

- Cautions**
1. Write to the LBS register after reset, then do not change the set value. Also, do not access an external memory area other than the one for this initialization routine until the initial setting of the LBS register is complete. However, it is possible to access external memory areas whose initialization settings are complete.
 2. When the data bus width is specified as 8 bits, only the signal shown below becomes active.
LLWR: When accessing SRAM, external ROM, or external I/O (write cycle)
 3. When the data bus width is specified as 16 bits, only the signals shown below become active.
LLWR, LUWR: When accessing SRAM, external ROM, or external I/O (write cycle)

Remark n = 0 to 7

4.5.3 Bus width

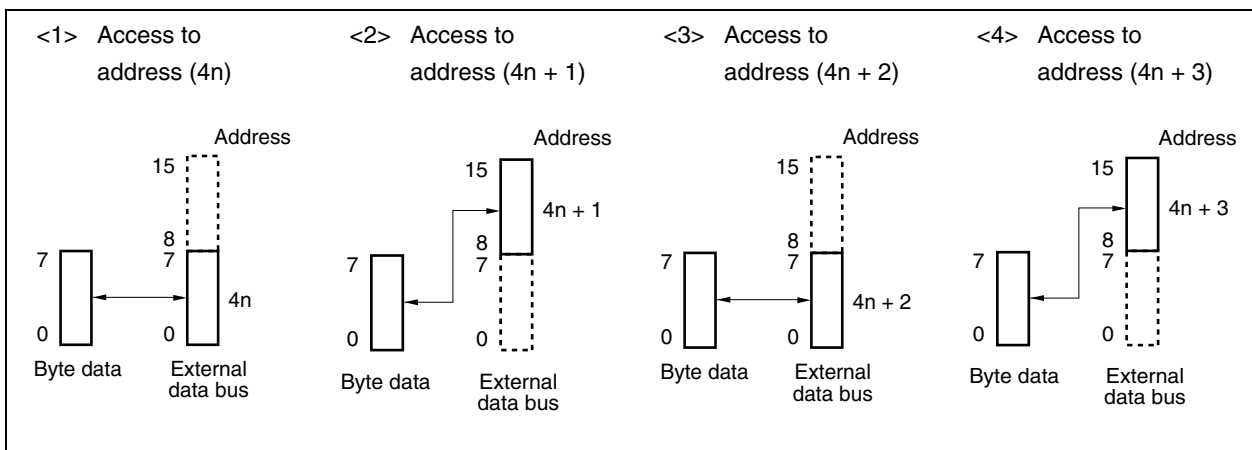

The V850E2/ME3 accesses on-chip peripheral I/O and external memory in 8-bit, 16-bit, or 32-bit units. The following shows the operation for each type of access. All data is accessed in order starting from the lower order side.

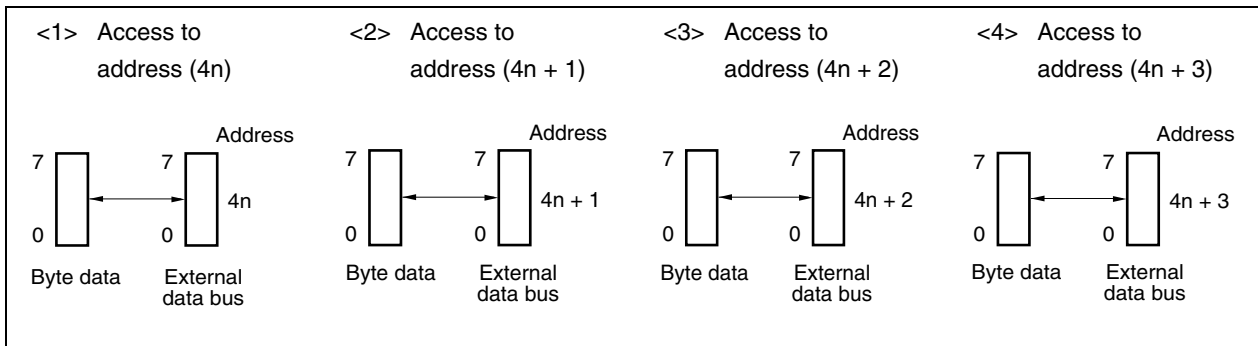

(1) Byte access (8 bits)

(a) When the data bus width is 32 bits

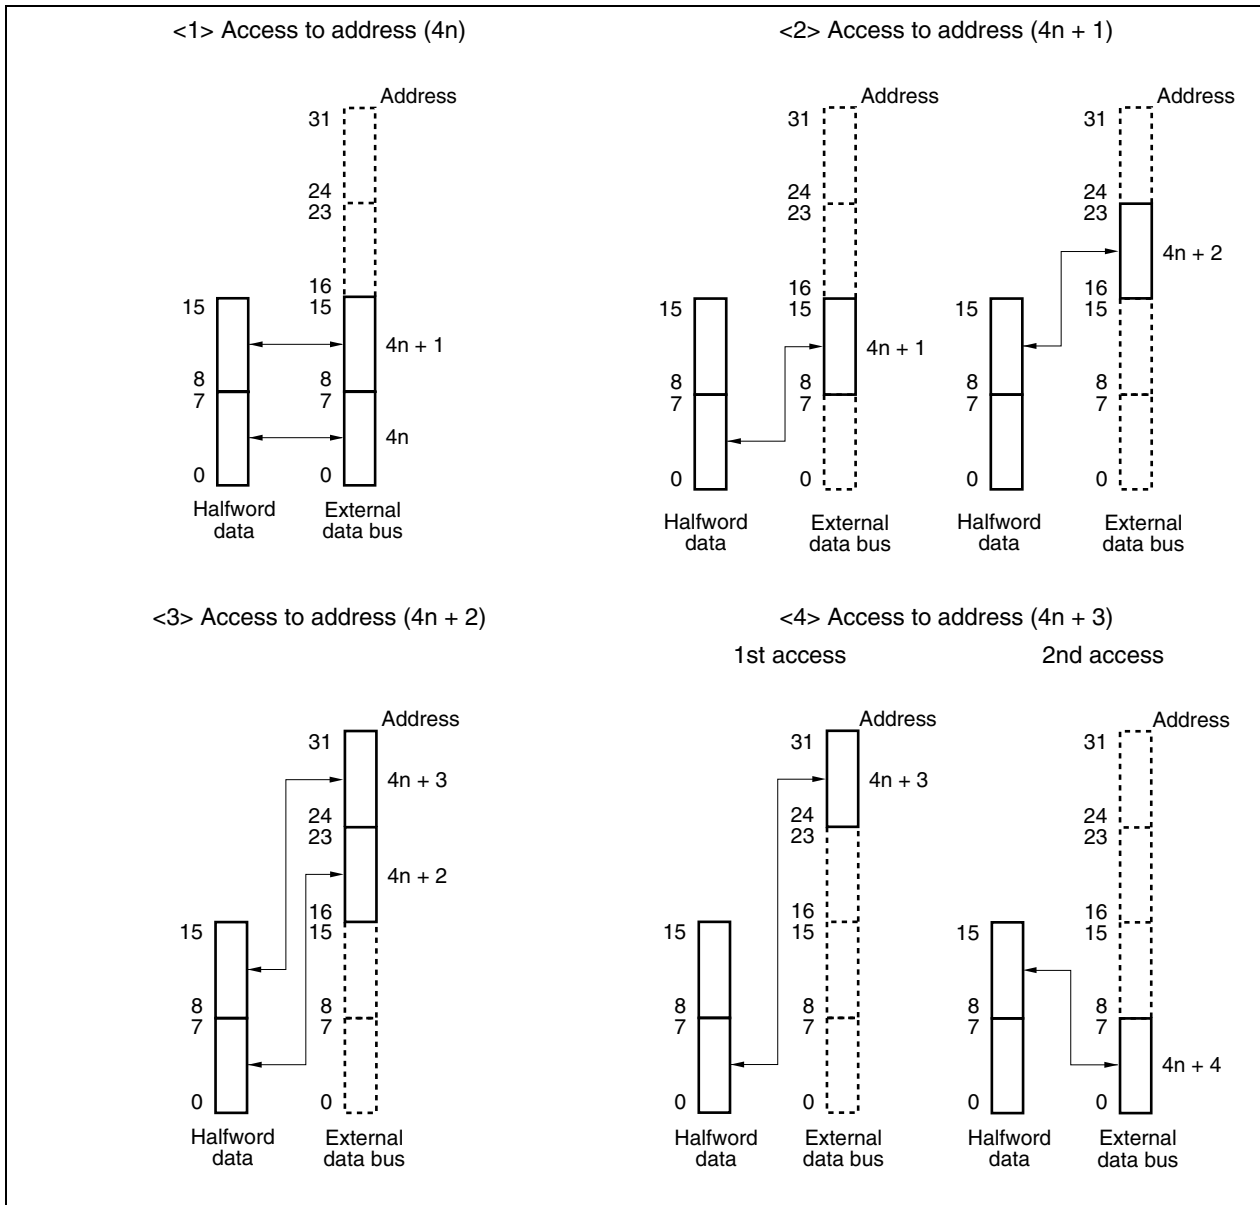

(b) When the data bus width is 16 bits

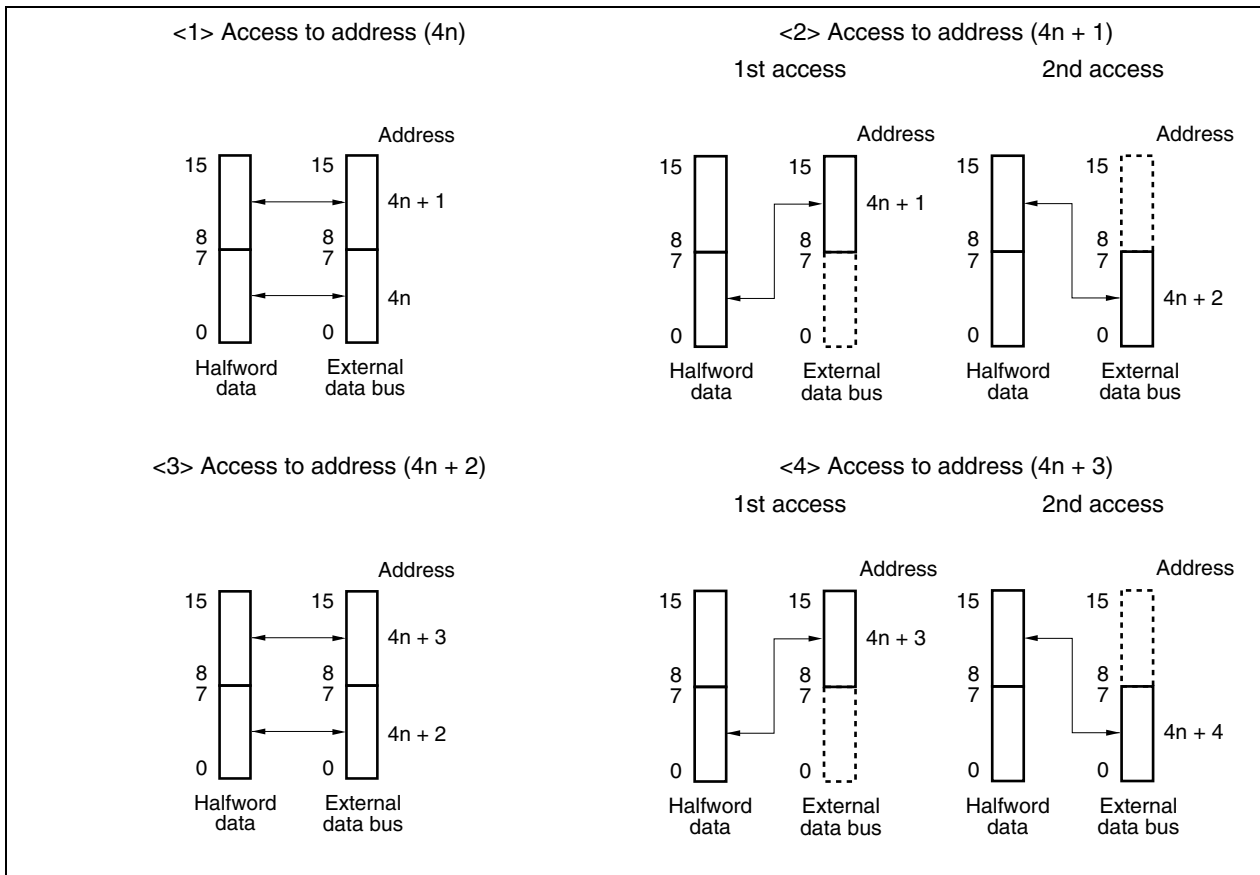

(c) When the data bus width is 8 bits

(2) Halfword access (16 bits)

(a) When the data bus width is 32 bits

(b) When the data bus width is 16 bits

(c) When the data bus width is 8 bits

(3) Word access (32 bits)

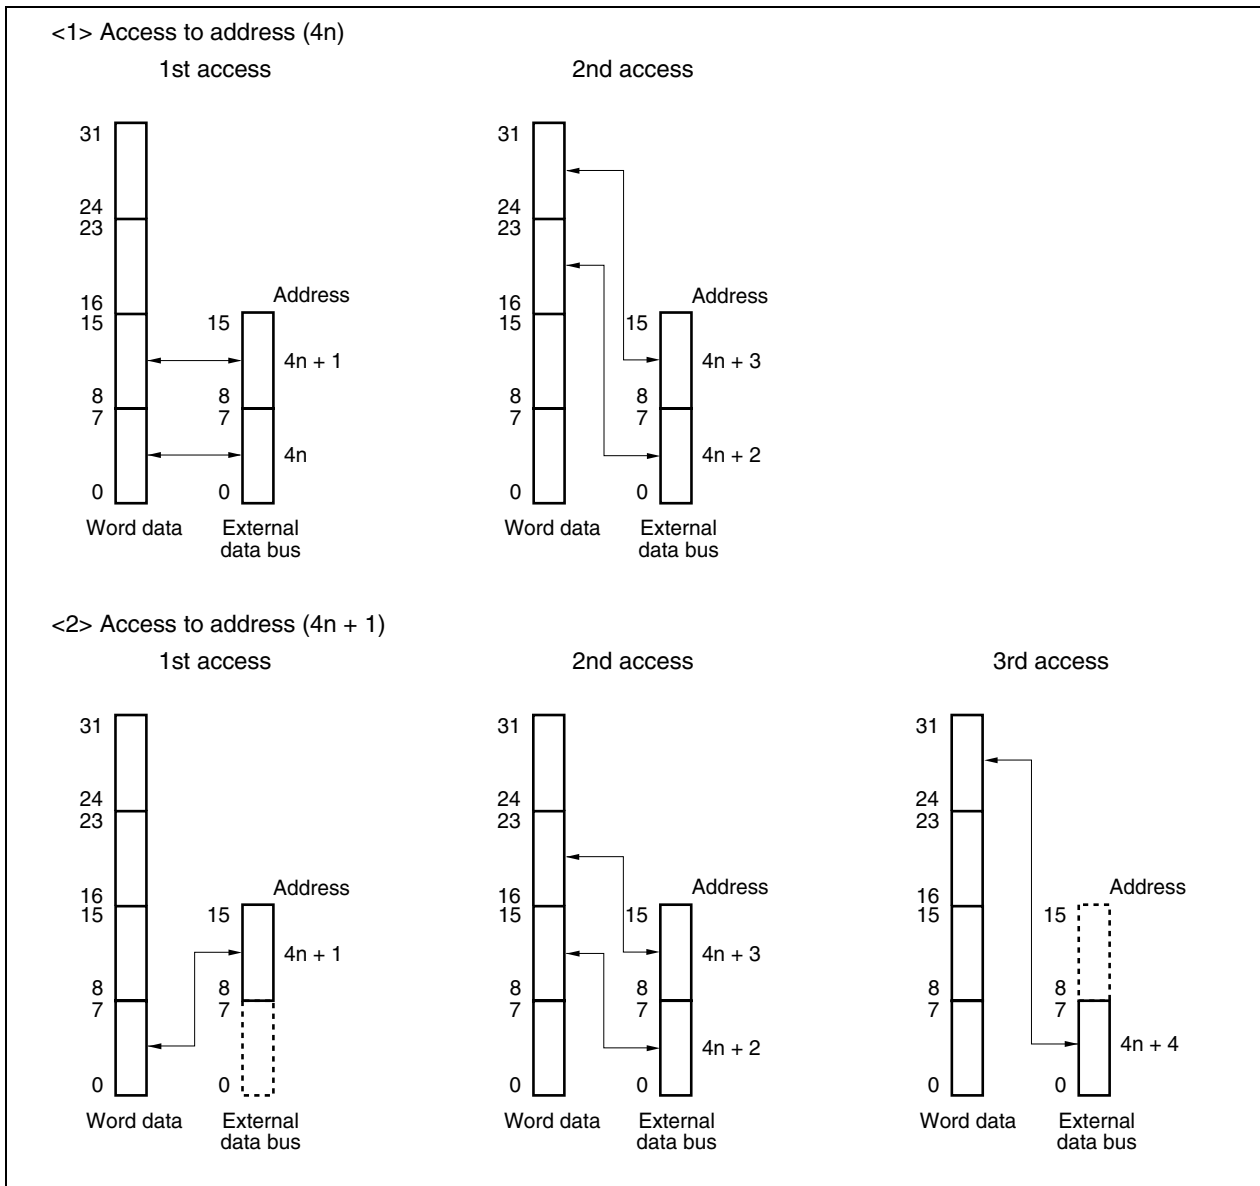

(a) When the data bus width is 32 bits (1/2)

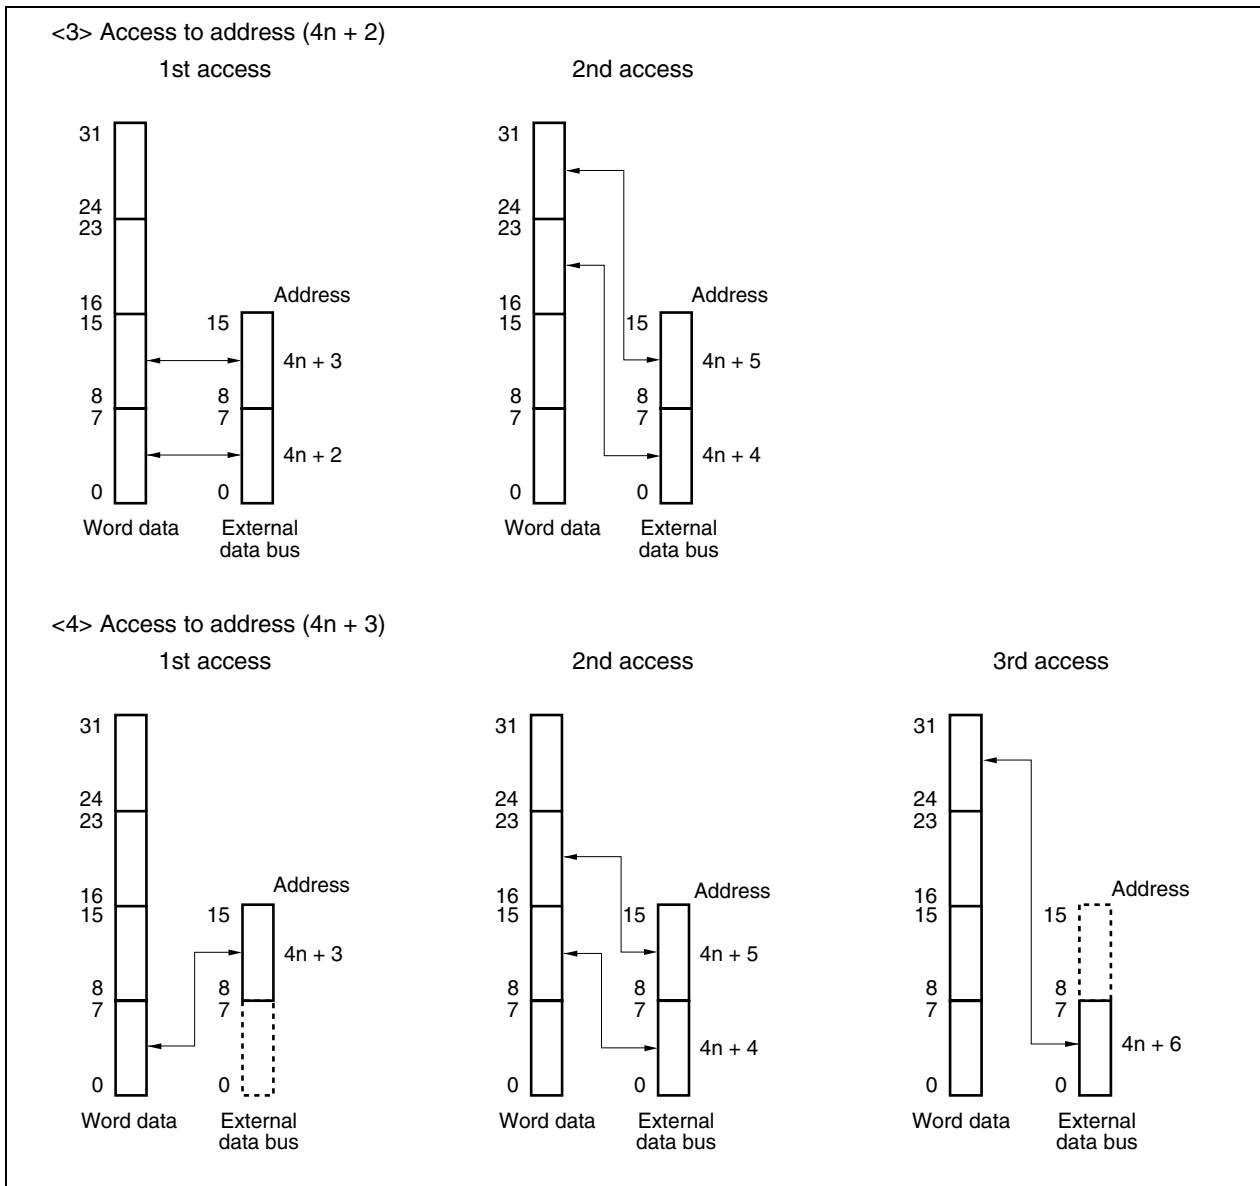

(a) When the data bus width is 32 bits (2/2)

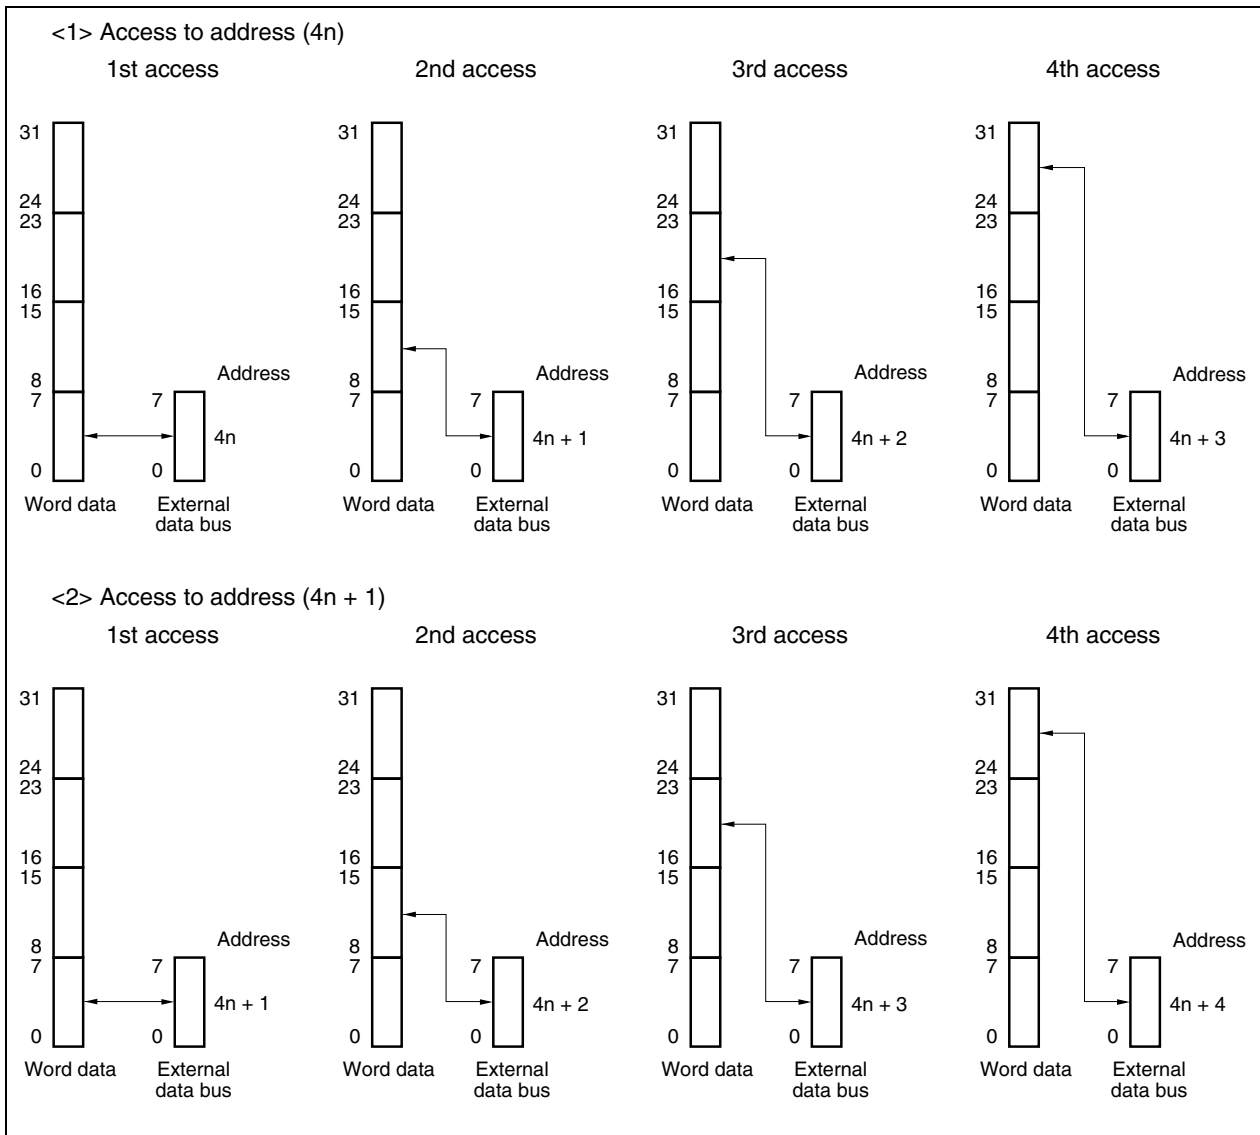

(b) When the data bus width is 16 bits (1/2)

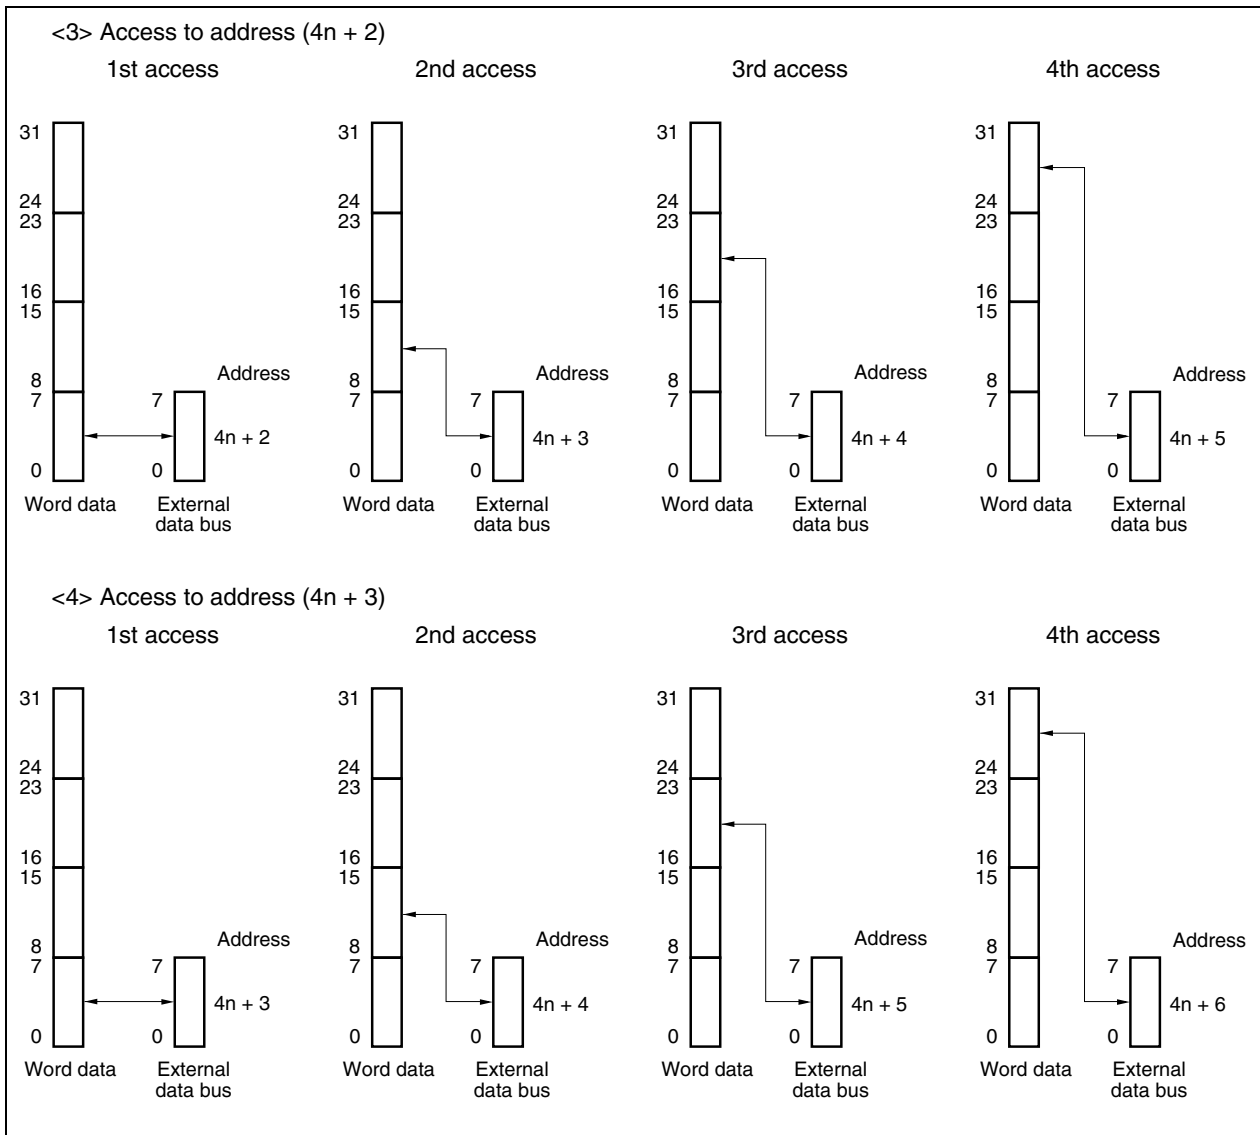

(b) When the data bus width is 16 bits (2/2)

(c) When the data bus width is 8 bits (1/2)

(c) When the data bus width is 8 bits (2/2)

4.5.4 Data control function

(1) Write buffer function

The V850E2/ME3 has an on-chip write buffer of 4 words (128 bits). The write buffer stores data if a write cycle cannot be executed while the external bus is occupied^{Note}. The next instructions are speculatively executed until the write buffer becomes full. The write buffer is valid for all the external memory areas. If a write request is generated while the write buffer is full, the next instruction execution is postponed until there is a vacancy in the write buffer.

While data is being stored in the write buffer (when a write operation to the external memory has not been completed), DMA flyby and bus hold requests are not acknowledged (DMA flyby and bus hold requests are acknowledged and an enable signal is generated after all the data of the write buffers has been written to the external memory).

Note The external bus is occupied when there is a bus cycle currently under execution. If instruction fetch cycles are successively executed, all write cycles for the write data stored in the write buffer are always generated after the bus cycle currently under execution (instruction fetch cycle) is completed.

- Cautions**
1. **Because the write buffer consists of four stages, the write buffer becomes full after 4 bytes (32 bits) when a byte write operation is executed (while a write operation to the external memory is standing by). Similarly, the conditions under which the write buffer becomes full vary due to an address miss-align access, etc.**
 2. **When data is written to an external device, the write operation to the external device may not be executed even when a CPU write operation has been completed by the write buffer. The CPU can access the on-chip peripheral I/O registers after the write operation has been completed, even if data exist in the write buffer. Therefore, if it is necessary to change the value of an on-chip peripheral I/O register after completion of execution of an external memory cycle, write 00H to the WAS register before writing the on-chip peripheral I/O register whose value is to be changed. When writing an on-chip peripheral I/O register other than the WAS register without writing 00H to the WAS register, the register value may be changed before completion of the external memory cycle.**
 3. **If a read access to the external device occurs when data exist in the write buffer, reading from the external device is executed after writing all the data in the write buffer to the external device.**
 4. **During 2-cycle transfer that writes data to the external device, the write operation to the external device may not be completed even if the DCHCn.TCn bit = 1 (DMA transfer completion) is read by the write buffer (n = 0 to 3). If it is necessary to change the value of an on-chip peripheral I/O register after completion of DMA transfer (completion of a write operation to the external device), perform either of the following operations.**
 - **Monitor the TCn signal (the TCn signal becomes active in synchronization with a write operation to the external device).**
 - **After detecting setting (to 1) of the TCn bit, write 00H to the WAS register, and then change the value of the on-chip peripheral I/O register. If the value of an on-chip peripheral I/O register other than the WAS register is changed without writing 00H to the WAS register, the value of the on-chip peripheral I/O register may be changed before completion of DMA transfer.**

(2) Write access synchronization control register (WAS)

When an external device is written, even if the write operation by the CPU via the write buffer is complete, writing to the external device may not be complete. The WAS register is used to complete writing all data in the write buffer to the external device. Refer to **4.5.4 (1) Write buffer function** for details.

This register is write-only, in 8-bit units.

Caution Be sure to write 00H to the WAS register. If the value other than 00H is written, operation is not guaranteed.

	7	6	5	4	3	2	1	0	Address	After reset
WAS	0	0	0	0	0	0	0	0	1FFFF49CH	Undefined

4.6 Bus Clock Control Function

(1) Bus mode control register (BMC)

This register sets the frequency (f_{BUSCLK}) of bus clock (BUSCLK).

Writing the BMC register stops BUSCLK once at low level. BUSCLK resumes operation with the set divided clock after it has been stopped. While BUSCLK is stopped, the operation of the RFSn register of SDRAM is also stopped (n = 1, 3, 4, 6).

This register can be read or written in 8-bit units.

Be sure to clear bits 7 to 2 to 0. If they are set to 1, the operation is not guaranteed.

- Cautions 1. Write the BMC register after reset, and then do not change the value that has been written.**
- 2. Before writing to the BMC register, be sure to set the VSWC register to 004FH. Even if the value of the VSWC register before the value of the BMC register is changed is 004FH, be sure to re-set the VSWC register to 004FH. After changing the set value of the BMC register, re-set the value of the VSWC register to the value before the set value of the BMC register was changed (see 3.4.8 Initialization sequence).**
- 3. The maximum operating frequency of BUSCLK is 66 MHz. Do not perform a setting that may exceed this frequency in the BMC register.**
- 4. If the CKM1 and CKM0 bits are cleared to 00 when a low level is input to the VBCSEL pin, operation is not guaranteed.**

Figure 4-1. BMC Register Switching Timing

4.7 Wait Function

4.7.1 Programmable wait function

(1) Data wait control registers 0, 1 (DWC0, DWC1)

To facilitate interfacing with low-speed memory and I/Os, it is possible to insert up to 7 data wait states in the starting bus cycle for each CS space.

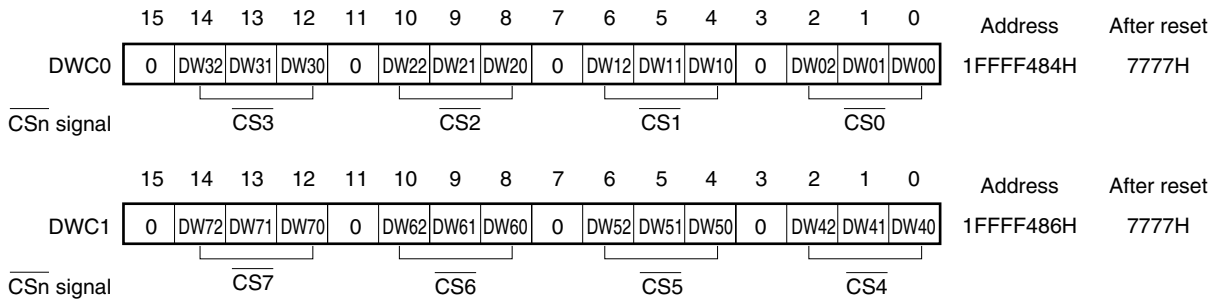

The number of wait states can be specified by program using DWC0 and DWC1 registers. Just after system reset, all blocks have 7 data wait states inserted.

These registers can be read or written in 16-bit units.

Cautions 1. The internal instruction RAM area and internal data RAM area are not subject to programmable waits and ordinarily no wait access is carried out.

The on-chip peripheral I/O area is not subject to programmable waits, with wait control performed by each peripheral function only.

2. In the following cases, the settings of the DWC0 and DWC1 registers are invalid (wait control is performed by each memory controller).
 - Page ROM on-page access
 - SDRAM access
3. Do not access an external memory area other than the one for this initialization routine until the initial setting of the DWC0 and DWC1 registers is complete. However, it is possible to access external memory areas whose initialization settings are complete.

Bit position	Bit name	Function																																				
14 to 12, 10 to 8, 6 to 4, 2 to 0	DWn2 to DWn0	Specifies the number of wait states inserted in the CSn space. <table border="1" style="margin-left: 20px;"> <thead> <tr> <th>DWn2</th> <th>DWn1</th> <th>DWn0</th> <th>Number of wait states inserted in CSn space</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>0</td> <td>Not inserted</td> </tr> <tr> <td>0</td> <td>0</td> <td>1</td> <td>1</td> </tr> <tr> <td>0</td> <td>1</td> <td>0</td> <td>2</td> </tr> <tr> <td>0</td> <td>1</td> <td>1</td> <td>3</td> </tr> <tr> <td>1</td> <td>0</td> <td>0</td> <td>4</td> </tr> <tr> <td>1</td> <td>0</td> <td>1</td> <td>5</td> </tr> <tr> <td>1</td> <td>1</td> <td>0</td> <td>6</td> </tr> <tr> <td>1</td> <td>1</td> <td>1</td> <td>7</td> </tr> </tbody> </table>	DWn2	DWn1	DWn0	Number of wait states inserted in CSn space	0	0	0	Not inserted	0	0	1	1	0	1	0	2	0	1	1	3	1	0	0	4	1	0	1	5	1	1	0	6	1	1	1	7

1	0	1	5																																			
1	1	0	6																																			
1	1	1	7																																			

Remark n = 0 to 7

(2) Address setup wait control register (ASC)

The V850E2/ME3 allows insertion of address setup wait states before the SRAM/page ROM cycle (the setting of the ASC register in the SDRAM cycle is invalid).

The number of address setup wait states can be set with the ASC register for each CS space.

This register can be read or written in 16-bit units.

- Cautions 1. The internal instruction RAM area, internal data RAM area, and on-chip peripheral I/O area are not subject to address setup wait insertion.**
- 2. During an address setup wait, the $\overline{\text{WAIT}}$ pin-based external wait function is disabled.**
- 3. Be sure to set the number of waits to 1 or more if the $\overline{\text{CSn}}$ signal is delayed using the PFCCS register.**
- 4. The address-setup wait set value is valid during a DMA flyby transfer.**

(3) Bus cycle period control register (BCP)

With the V850E2/ME3, the operations of $\overline{\text{IORD}}$ and $\overline{\text{IOWR}}$ can be enabled or disabled in the SRAM, external ROM, and external I/O cycles.

This register can be read or written in 8-bit or 1-bit units.

Be sure to clear bits 7 to 4 and 2 to 0 to 0. If they are set to 1, the operation is not guaranteed.

Cautions 1. During a flyby DMA transfer for SRAM, external ROM, or external I/O, the $\overline{\text{IORD}}$ and $\overline{\text{IOWR}}$ signals are always output, irrespective of the IOEN bit setting.

**Flyby transfer from external I/O to external memory: $\overline{\text{IORD}}$ and $\overline{\text{WR}}$ signals become active.
Flyby transfer from external memory to external I/O: $\overline{\text{IOWR}}$ and $\overline{\text{RD}}$ signals become active.**

In page ROM cycle, on the other hand, the IOEN bit setting has no meaning.

2. Write to the BCP register after reset, and then do not change the set values.
3. If the internal instruction RAM is accessed while the IOEN bit is set (1) (write mode), the $\overline{\text{IOWR}}$ signal becomes inactive.

	7	6	5	4	3	2	1	0

IOEN	Enable/disable $\overline{\text{IORD}}$ and $\overline{\text{IOWR}}$ operation							
0	Disables the operation of $\overline{\text{IORD}}$ and $\overline{\text{IOWR}}$ in SRAM, external ROM, and external I/O cycles.							
1	Enables the operation of $\overline{\text{IORD}}$ and $\overline{\text{IOWR}}$ in SRAM, external ROM, and external I/O cycles.							

(4) DMA flyby transfer wait control register (FWC)

The FWC register sets the number of data wait cycles during DMA flyby transfer for each channel n (see the timing chart in **7.5.2 Flyby transfer**) (n = 0 to 3).

The set value of this register is valid during DMA flyby transfer, and the set values of the DWC0, DWC1, and PRC registers are invalid.

This register can be read or written in 16-bit units.

Caution The internal instruction RAM area and internal data RAM area are not subject to the programmable wait operation and are always accessed with no wait cycle. The on-chip peripheral I/O area is also not subject to the programmable wait operation, and is subject only to wait control by each peripheral function.

Remark n = 0 to 3

4.7.2 External wait function

When an extremely slow memory, I/O, or asynchronous system is connected, an arbitrary number of wait states can be inserted in the bus cycle by the external wait pin ($\overline{\text{WAIT}}$) for synchronization with the external device.

Just as with programmable waits, accessing internal instruction RAM, internal data RAM, and on-chip peripheral I/O areas cannot be controlled by external waits.

The external $\overline{\text{WAIT}}$ signal can be input asynchronously to BUSCLK and is sampled at the rising edge of BUSCLK immediately after the T1 and TW states of a bus cycle. If the setup/hold time in the sampling timing is not satisfied, the wait state may or may not be inserted in the next state.

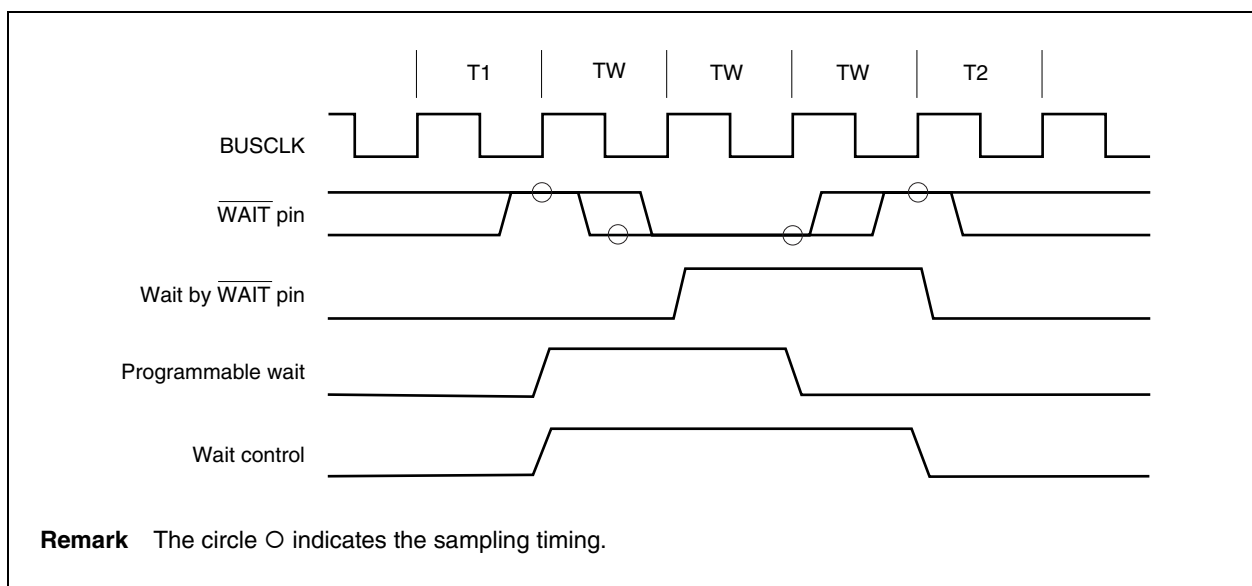

4.7.3 Relationship between programmable wait and external wait

A wait cycle is inserted as the result of an OR operation between the wait cycle specified by the set value of the programmable wait and the wait cycle controlled by the $\overline{\text{WAIT}}$ pin.

For example, if the timings of the programmable wait and the $\overline{\text{WAIT}}$ pin signal are as illustrated below, three wait states will be inserted in the bus cycle.

Figure 4-2. Example of Wait Insertion

4.7.4 Bus cycles in which wait function is valid

In the V850E2/ME3, the number of waits can be specified according to the memory type specified for each area. The following shows the bus cycles in which the wait function is valid and the registers used for wait setting.

Table 4-1. Bus Cycles in Which Wait Function Is Valid

Bus Cycle		Type of Wait	Programmable Wait Setting			Wait from $\overline{\text{WAIT}}$ pin	
			Register	Bit	Wait Count		
SRAM, external ROM, external I/O cycles		Address setup wait	ASC	ACn1, ACn0	0 to 3	– (invalid)	
		Data access wait	DWC0, DWC1	DWn2 to DWn0	0 to 7	√ (valid)	
Page ROM cycle		Address setup wait	ASC	ACn1, ACn0	0 to 3	– (invalid)	
		Off-page	Data access wait	DWC0, DWC1	DWn2 to DWn0	0 to 7	√ (valid)
		On-page	Data access wait	PRC	PRW2 to PRW0	0 to 7	√ (valid)
SDRAM cycle		Row address precharge	SCRm	BCWm1, BCWm0	1 to 3	– (invalid)	
DMA flyby transfer cycle	External I/O ↔ SRAM		Flyby transfer wait	FWC	FWa2 to FWa0	0 to 7	√ (valid)
			Address-setup wait	ASC	ACn1, ACn0	0 to 3	– (invalid)
	External I/O → SDRAM	Off-page	Row address precharge	SCRm	BCWm1, BCWm0	1 to 3	– (invalid)
			Flyby transfer wait	FWC	FWa2 to FWa0	1 to 8	– (invalid)
		On-page	Row address precharge	SCRm	BCWm1, BCWm0	1 to 3	– (invalid)
			Flyby transfer wait	FWC	FWa2 to FWa0	1 to 8	– (invalid)

Remark n = 0 to 7
m = 1, 3, 4, 6
a = 0 to 3

(2) DMA flyby transfer idle control register (FIC)

The FIC register sets the number of idle states during DMA flyby transfer for each DMA channel n (see the timing chart in **7.5.2 Flyby transfer**) (n = 0 to 3). The idle state is inserted at the end of DMA flyby transfer. During DMA flyby transfer, the set value of this register is valid, and the set value of the BCC register is invalid.

This register can be read or written in 16-bit units.

Caution The internal instruction RAM area, internal data RAM area, and on-chip peripheral I/O area are not subject to idle state insertion.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset

0	1	1															
1	0	2															
1	1	3															

Remark n = 0 to 3

4.9 Internal Instruction RAM Control Function

The V850E2/ME3 has 168 KB of instruction RAM.

Data after inputting to the $\overline{\text{RESET}}$ pin is not guaranteed.

Data can be written to the internal instruction RAM only by a word access.

Address miss-align access to the internal instruction RAM is prohibited. (If performed, the operation is not guaranteed.)

(1) Instruction RAM control register (IRC)

This register specifies enable/disable of the internal instruction RAM.

This register can be read or written in 8-bit or 1-bit units.

Be sure to set bits 7 to 1 to "0". If they are set to 1, operation is not guaranteed.

	7	6	5	4	3	2	1	0	Address	After reset
IRC	0	0	0	0	0	0	0	IREN0	1FFFF800H	00H

Bit position	Bit name	Function
0	IREN0	Specifies enable/disable of internal instruction RAM. 0: Internal instruction RAM area (00000000H to 0007FFFFH) disabled 1: Internal instruction RAM area (00000000H to 0007FFFFH) enabled

<R>

Caution When the setting of a mode is changed, the next access to the internal instruction RAM may be executed first because of the pipeline operation of the CPU. When the setting of the IRC register is changed from write-disable to write-enable, therefore, be sure to read the IRC register to confirm that writing has been executed, and then execute an access to the internal instruction RAM.

(2) Instruction RAM mode register (IRWE)

This register specifies a mode for accessing the internal instruction RAM.

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
IRWE	0	0	0	0	0	0	0	IRWEN	1FFFF80AH	00H

Bit position	Bit name	Function
0	IRWEN	Specifies the access control of internal instruction RAM. 0: Read/write access enabled 1: Read access enabled, write access disabled

Cautions 1. When the setting of a mode is changed, the next access to the internal instruction RAM may be executed first because of the pipeline operation of the CPU. When the setting of the IRWE register is changed from write-disable to write-enable, therefore, be sure to read the IRWE register to confirm that writing has been executed, and then execute an access to the internal instruction RAM.

2. Data can be written to the internal instruction RAM only by a word access.
3. Address miss-align access to the internal instruction RAM is prohibited.

4.10 Allocation of Program to Internal Instruction RAM Area

Program execution from the external memory is inefficient in fetching instructions compared to execution from the internal instruction RAM; furthermore, if a higher CPU operating clock is used to improve the fetch efficiency, waits should thus be inserted in the external memory, which rather degrades the efficiency.

The V850E2/ME3 makes it possible to fetch instructions from the internal instruction RAM, by copying the contents of the memory that is externally connected to the memory controller to the internal instruction RAM.

4.10.1 Procedure for copying external memory contents

Implement the procedure shown below after booting the program from the external memory; the external memory contents can then be copied to the internal instruction RAM and applications be executed.

[Procedure for copying external memory contents]

- <1> After a system reset is released, boot the program in the external memory that is assigned to the CS0 space.
- <2> Jump to the program that is allocated to addresses 0002A000H and later in the external memory
- <3> Transfer the instructions for setting DMA transfer and the IRC.IREN0 bit (1) to the internal data RAM area (see the program example below).
- <4> Jump to the internal data RAM area.
- <5> Transfer the contents subject to DMA transfer to addresses 00000000H to 00029FFFH in the internal instruction RAM area.
- <6> Change the PSW register setting to mask NMI processing.
- <7> Set the IREN0 bit (1) after the DMA transfer is complete
- <8> Jump to the instruction RAM and enable NMI processing.
- <9> Jump to the internal instruction RAM area and start the ordinary program.

[Program example]

The following shows an example of the program that writes 168 KB data to the RAM area via DMA channel 0.

```

ori      0x0001, r0, r20
st.b     r20, 0x1FFFF0B8[r0] ; Sets DC register

ori      0x1084, r0, r20
st.h     r20, 0x1FFFF0B0[r0] ; Sets DADC0 register (transfer destination: internal instruction RAM,
                               transfer mode: block transfer, write in word units)

st.w     r0, 0x1FFFF080[r0] ; Sets DSA0 register (start address: 00000000H)
st.w     r0, 0x1FFFF084[r0] ; Sets DDA0 register (start address: 00000000H)

ori      0xA800, r0, r20
st.w     r20, 0x1FFFF0A0[r0] ; Sets DBC0 register (transfer count: A800H)

ori      0x0003, r0, r20
st.b     r20, 0x1FFFF0BA[r0] ; Sets DCHC0 register (DMA transfer started by software trigger)

```

(After transfer is complete)

```

ldsr     r21, 0x5
ori      0xA0, r21, r20
stsr     0x5, r20 ; Sets PSW register (disables interrupts and masks non-maskable
                  interrupt servicing)

ori      0x0001, r0, r20
st.b     r20, 0x1FFFF800[r0] ; Sets IREN0 bit

```

(Jumps to instruction RAM area)

```

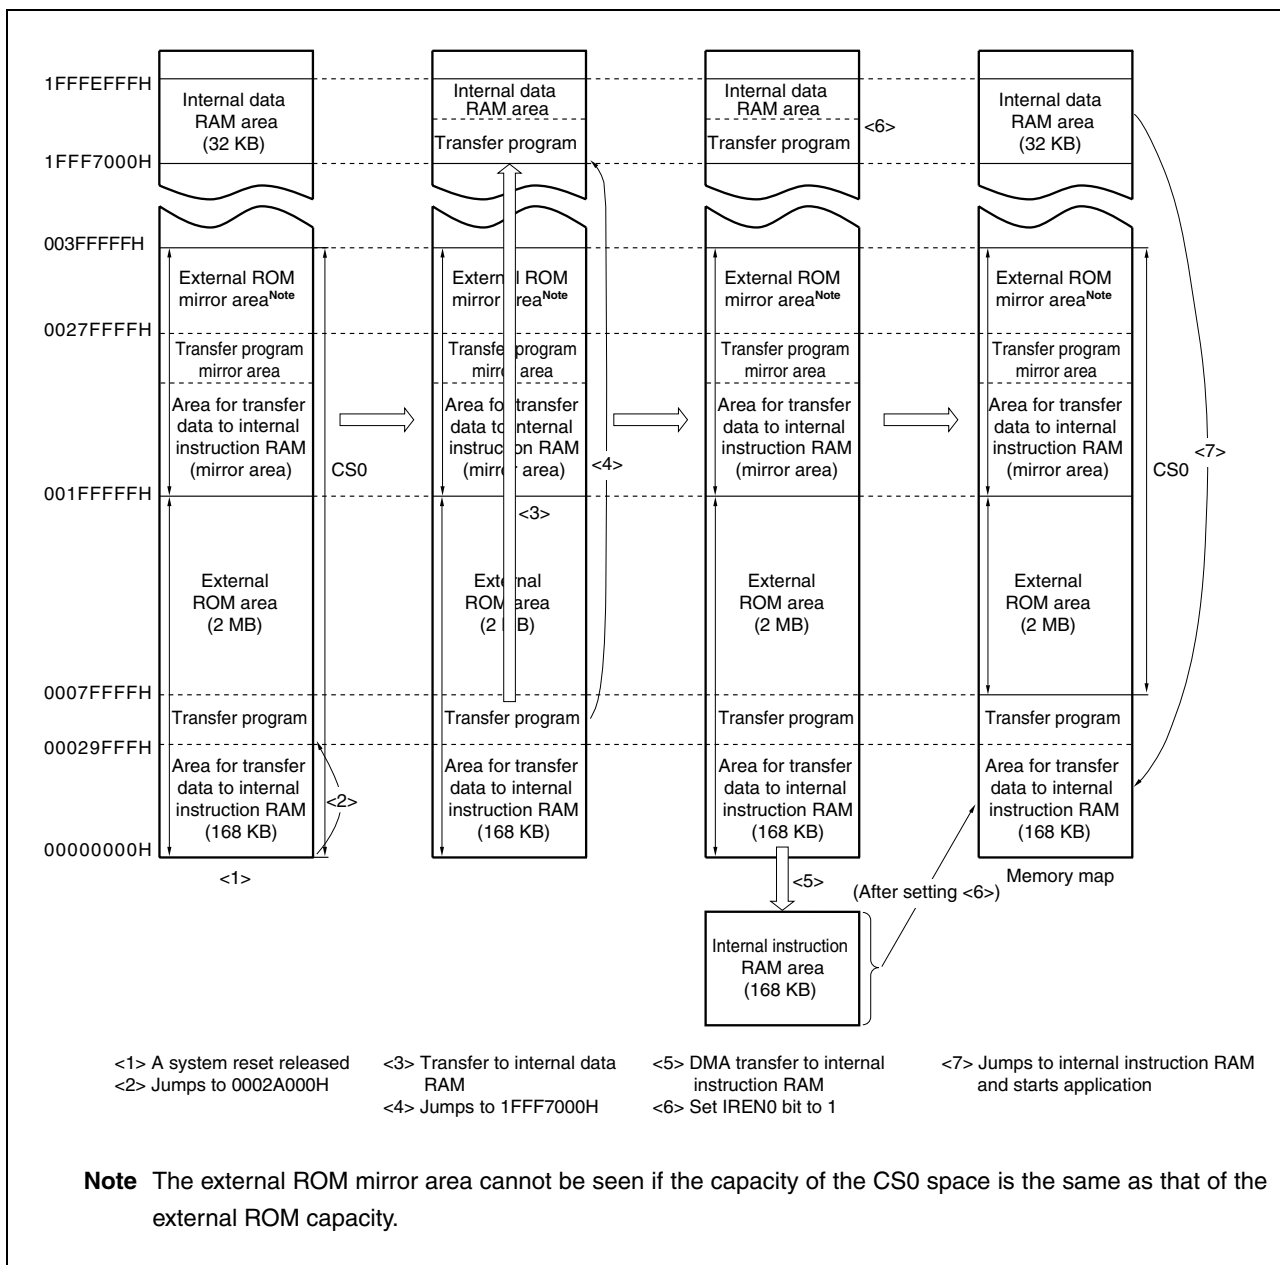

stsr     r21, 0x5 ; Sets PSW register (enables interrupts and non-maskable interrupt
                  servicing)

```

The following shows an example of processing that copies the external ROM contents to the internal instruction RAM (168 KB) when a 2 MB external ROM is assigned to the CS0 space to which subareas 00 and 01 (3.5 MB) are set.

Remark Refer to 4.3 Memory Block Function for subareas 00 and 01.

Figure 4-3. Example of Transfer from External ROM to Internal Instruction RAM

4.11 Bus Hold Function

4.11.1 Function outline

If the PCM2 and PCM3 pins are specified in the control mode, the $\overline{\text{HLDAK}}$ and $\overline{\text{HLDRQ}}$ functions become valid.

If it is determined that the $\overline{\text{HLDRQ}}$ pin has become active (low level) as a bus mastership request from another bus master, the external address/data bus and each strobe pin are shifted to high impedance and then released (bus hold state). If the $\overline{\text{HLDRQ}}$ pin becomes inactive (high level) and the bus mastership request is canceled, driving of these pins begins again.

During the bus hold period, the internal operations of the V850E2/ME3 continue until the external memory or a peripheral I/O register is accessed.

The bus hold state can be known by the $\overline{\text{HLDAK}}$ pin becoming active (low level). The period from when the $\overline{\text{HLDRQ}}$ pin becomes active (low level) to when the $\overline{\text{HLDAK}}$ pin becomes active (low level) is at least 2 clocks.

In a multiprocessor configuration, etc., a system with multiple bus masters can be configured.

State	Data Bus Width	Access Type	Timing at Which Bus Hold Request Cannot Be Acknowledged
CPU bus lock	32 bits	Word access for 4n+1 address	Between first and second accesses
			Between second and third accesses
		Word access for 4n+2 address	Between first and second accesses
		Word access for 4n+3 address	Between first and second accesses
	16 bits	Halfword access for odd address	Between second and third accesses
			Between first and second accesses
		Word access for even address	Between first and second accesses
		Word access for odd address	Between first and second accesses
	8 bits	Halfword access for odd address	Between second and third accesses
			Between first and second accesses
		Word access	Between first and second accesses
		Halfword access	Between first and second accesses
Read modify write access of bit manipulation instruction	–	–	Between read access and write access

Cautions 1. When an external bus master accesses SDRAM during a bus hold state, make sure that the external bus master executes the all-bank precharge command.

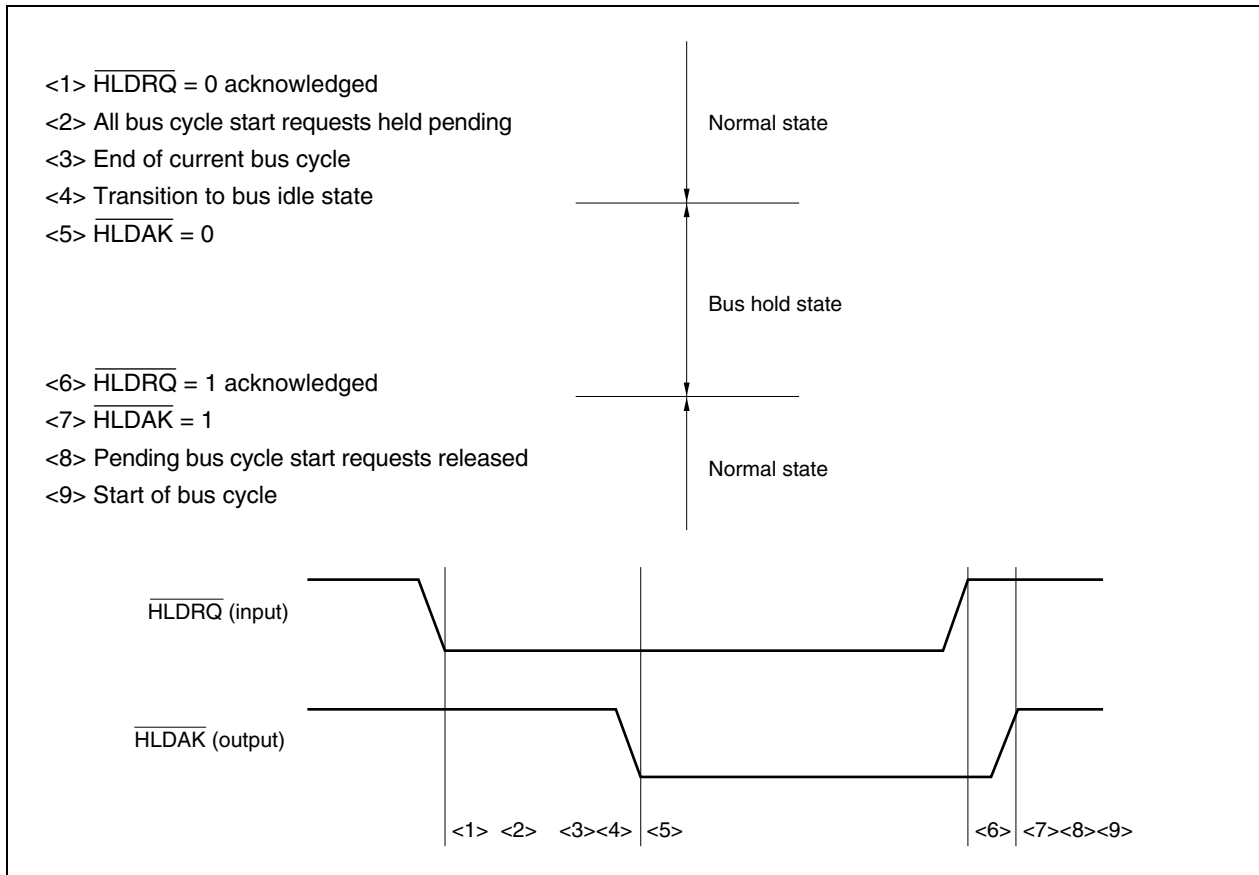

The CPU always executes the all-bank precharge command to release a bus hold state. In a bus hold state, do not allow an external bus master to change the SDRAM command register value.

2. The $\overline{\text{HLDRQ}}$ function is invalid during a reset period. The $\overline{\text{HLDAK}}$ pin becomes active either immediately after or after the insertion of a 1-clock address cycle from when the $\overline{\text{RESET}}$ pin is set to inactive following the simultaneous activation of the $\overline{\text{RESET}}$ and $\overline{\text{HLDRQ}}$ pins.

When a bus master other than the V850E2/ME3 is externally connected, use the $\overline{\text{RESET}}$ signal for bus arbitration at power-on.

4.11.2 Bus hold procedure

The procedure of the bus hold function is illustrated below.

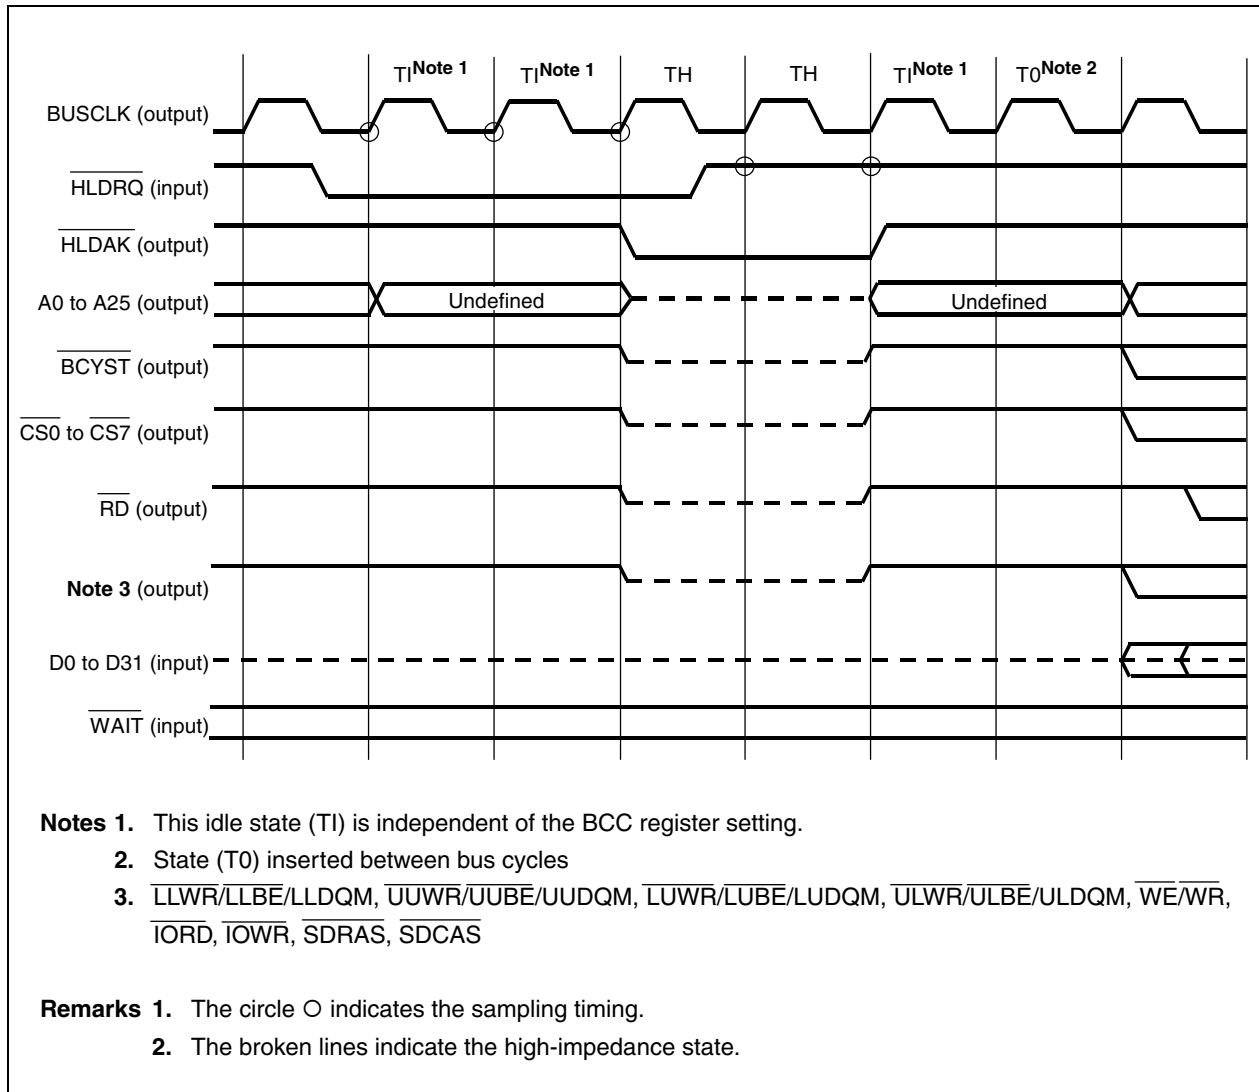

4.11.3 Operation in power-save mode

The internal system clock is stopped in IDLE mode. Consequently, the bus hold state is not set since the $\overline{\text{HLDQRQ}}$ pin cannot be acknowledged even if it becomes active.

In the HALT mode, the $\overline{\text{HLDARQ}}$ pin immediately becomes active when the $\overline{\text{HLDQRQ}}$ pin becomes active, and the bus hold state is set. When the $\overline{\text{HLDQRQ}}$ pin becomes inactive after that, the $\overline{\text{HLDARQ}}$ pin also becomes inactive. As a result, the bus hold state is cleared and the HALT mode is set again.

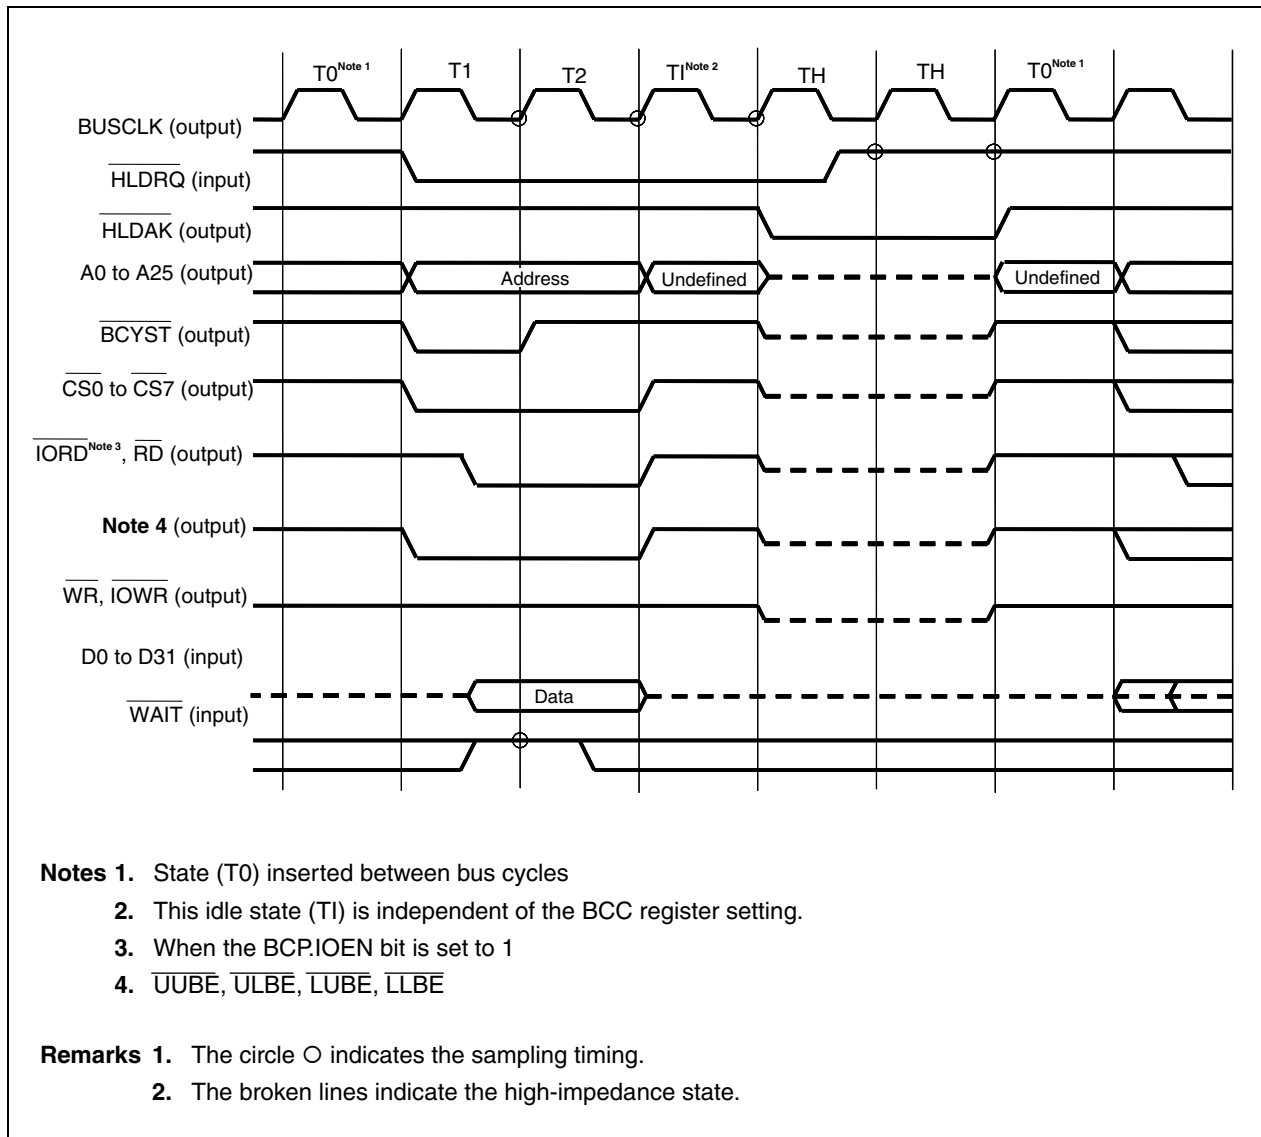

4.11.4 Bus hold timing

(1) If bus hold request is issued when bus cycle is not generated

4.11.5 Bus hold timing (SRAM)

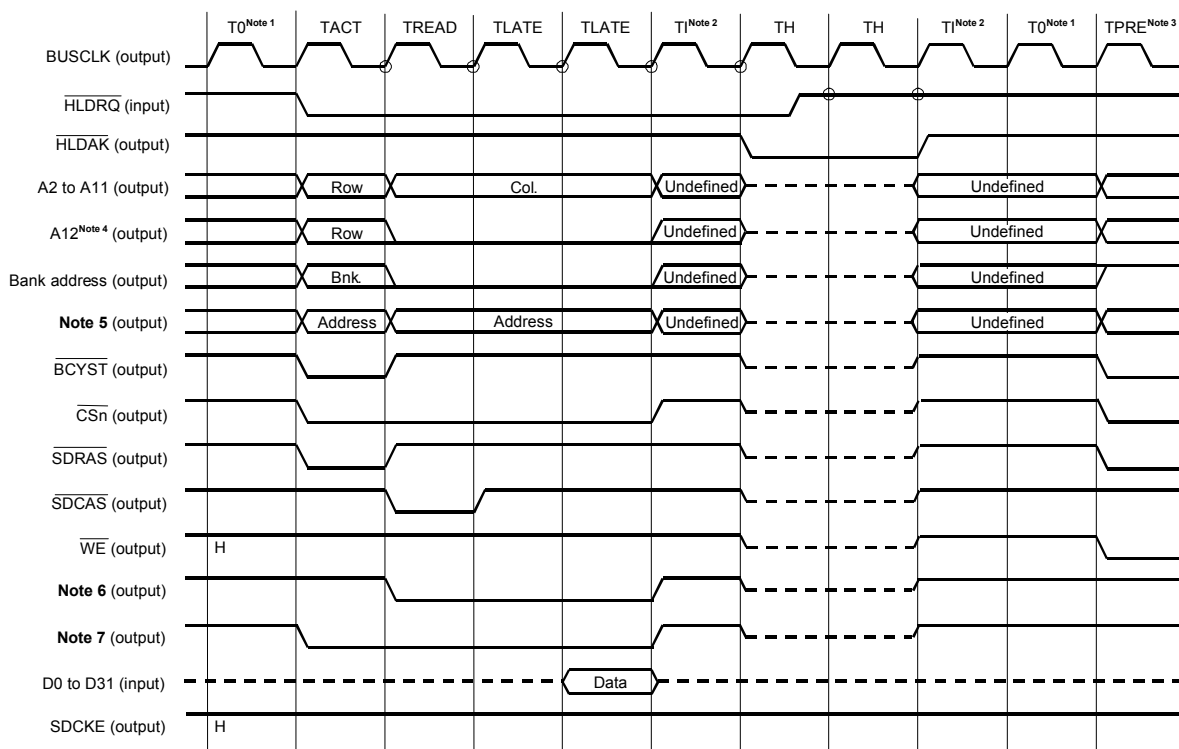

(1) SRAM (when read, no idle state insertion, $BUSCLK = fvBCLK/2$)

(2) SRAM (when written, two idle states inserted, $BUSCLK = f_{VBCLK}/2$)

4.11.6 Bus hold timing (SDRAM)

(1) SDRAM (when read, latency = 2, no idle state insertion)

- Notes**
1. State (T0) inserted between bus cycles
 2. This idle state (TI) is independent of the BCC register setting.
 3. The all-bank precharge command is always executed.
 4. This is the signal when the 32-bit external bus is used. Read it as A11 when the 16-bit bus is used, and A10 when the 8-bit bus is used.
 5. Addresses other than the bank address, A12, and A2 to A11.
 6. When \overline{xxWR} output mode/ \overline{xxDQM} output mode is set (PFCCT.PFCCTm bit = 0)
 7. When \overline{xxBE} output mode/ \overline{xxDQM} output mode is set (PFCCTm bit = 1)

- Remarks**
1. The circle ○ indicates the sampling timing.
 2. The broken lines indicate the high-impedance state.
 3. n = 1, 3, 4, 6
m = 0 to 3
xx = UU, UL, LU, LL
 4. Bnk.: Bank address
Col.: Column address
Row: Row address

(2) SDRAM (when read, latency = 2, two idle states inserted, 32-bit bus width)

**Notes** 1. State (T0) inserted between bus cycles

2. This idle state (TI) is inserted by means of a BCC register setting.
3. This idle state (TI) is independent of the BCC register setting.
4. The all-bank precharge command is always executed.
5. This is the signal when the 32-bit external bus is used. Read it as A11 when the 16-bit bus is used, and A10 when the 8-bit bus is used.
6. Addresses other than the bank address, A12, and A2 to A11.
7. When \overline{xxWR} output mode/ $xxDQM$ output mode is set (PFCCT.PFCCTm bit = 0)
8. When $xxBE$ output mode/ $xxDQM$ output mode is set (PFCCTm bit = 1)

Remarks 1. The circle ○ indicates the sampling timing.

2. The broken lines indicate the high-impedance state.
3. n = 1, 3, 4, 6
m = 0 to 3
xx = UU, UL, LU, LL
4. Bnk.: Bank address
Col.: Column address
Row: Row address

(3) SDRAM (when written)

4.12 Bus Priority Order

There are five external bus cycles: bus hold, instruction fetch, operand data access, DMA cycle, and refresh cycle.

In order of priority, bus hold is the highest, followed by the refresh cycle, DMA cycle, operand data access, and instruction fetch, in that order.

An instruction fetch may be inserted between a read access and write access during a read modify write access.

Also, an instruction fetch may be inserted between bus accesses when the CPU bus clock is used.

Table 4-2. Bus Priority Order

Priority Order	External Bus Cycle	Bus Master
High ↑ ↓ Low	Bus hold	External device
	Refresh cycle	SDRAM controller
	DMA cycle	DMA controller
	Operand data access	CPU
	Instruction fetch	CPU

4.13 Boundary Operation Conditions

4.13.1 Program space

Branching to the on-chip peripheral I/O area is prohibited. If the above is performed, undefined data is fetched, and fetching from the external memory is not performed.

4.13.2 Data space

The V850E2/ME3 is provided with an address misalign function.

Through this function, regardless of the data format (word or halfword), data can be allocated to all addresses. However, in the case of word data and halfword data, if the data is not subject to boundary alignment, the bus cycle will be generated at least 2 times and bus efficiency will drop.

(1) External bus width: 16 bits

(a) In the case of halfword-length data access

When the address's LSB is 1, a byte-length bus cycle will be generated 2 times.

(b) In the case of word-length data access

- (i) When the address's LSB is 1, bus cycles will be generated in the order of byte-length bus cycle, halfword-length bus cycle, and byte-length bus cycle.
- (ii) When the address's lower 2 bits are 10, a halfword-length bus cycle will be generated 2 times.

(2) External bus width: 32 bits

(a) In the case of halfword-length data access

When the address's lower 2 bits are 11, a byte-length bus cycle will be generated 2 times.

(b) In the case of word-length data access

When the address's lower 2 bits are 10, a halfword-length bus cycle will be generated 2 times.

4.14 Timing at Which T0 State Is Not Inserted

A T0 state is not inserted at the following timing.

(1) Read

- During a refill operation when instruction cache or data cache is used (in the second and subsequent cycles)
- If a read request (including a read request by instruction fetch or DMA) is generated before a write operation to the external device is completed when a read operation occurs immediately after a write operation
- If a read request (including a read request by instruction fetch or DMA) that is greater than the bus width of the external device is generated (in the second and subsequent cycles)

[Example]

- 32-bit read access with 16-bit external bus width
- 32-bit or 16-bit read access with 8-bit external bus width

(2) Write

- If a write request (including a write request by DMA) is generated before a write operation to the external device is completed when a write operation occurs immediately after a write operation, and data is stored in the write buffer (a cycle in which the data stored in the write buffer is written to the external device)
- If a write request (including a write request by DMA) greater than the bus width of the external bus is generated (after the second and subsequent cycles)

[Example]

- 32-bit write access with external 16-bit bus width
- 32-bit or 16-bit write access with external 8-bit bus

4.15 Cautions

Cautions concerning the bus control function are shown below.

(1) Write operation to external device

When data is written to an external device, the write operation to the external device may not be executed even when a CPU write operation has been completed by the write buffer. The CPU can access the on-chip peripheral I/O registers after the write operation has been completed even if data exist in the write buffer. Therefore, if it is necessary to change the value of an on-chip peripheral I/O register after completion of execution of an external memory cycle, write 00H to the WAS register before writing the on-chip peripheral I/O register whose value is to be changed. When writing an on-chip peripheral I/O register other than the WAS register without writing 00H to the WAS register, the register value may be changed before completion of the external memory cycle.

(2) 2-cycle transfer that writes data to external device

During 2-cycle transfer that writes data to the external device, the write operation to the external device may not be completed even if DCHCn.TCn bit = 1 (DMA transfer completion) is read by the write buffer (n = 0 to 3). If it is necessary to change the value of an on-chip peripheral I/O register after completion of DMA transfer (completion of a write operation to the external device), perform either of the following operations.

- Monitor the $\overline{\text{TCn}}$ signal (the $\overline{\text{TCn}}$ signal becomes active in synchronization with a write operation to the external device).
- After detecting setting (to 1) of the TCn bit, write 00H to the WAS register and then change the value of the on-chip peripheral I/O register. If the value of an on-chip peripheral I/O register other than the WAS register is changed without writing 00H to the WAS register, the value of the on-chip peripheral I/O register may be changed before completion of DMA transfer.

(3) Caution on setting ASC register

Be sure to set the number of address setup wait states to 1 or more if the $\overline{\text{CSn}}$ signal is delayed using the PFCCS register (n = 0 to 7).

(4) Caution on BCP register setting

If the internal instruction RAM is accessed while the IOEN bit of the BCP register is set (1) (in the write mode), the $\overline{\text{IOWR}}$ signal becomes inactive.

(5) Caution on setting BCC register

The $\overline{\text{CSn}}$ signal does not become active in the idle state (n = 0 to 7).

(6) Caution on setting IRWE register

- When the setting of a mode is changed, the next access to the internal instruction RAM may be executed first because of the pipeline operation of the CPU. When the setting of the IRWE register is changed from write-disable to write-enable, therefore, be sure to read the IRWE register to confirm that writing has been executed, and then execute an access to the internal instruction RAM.
- Data can be written to the internal instruction RAM only by a word access.
- Address miss-align access to the internal instruction RAM is prohibited.

CHAPTER 5 CACHE FUNCTION

5.1 Features

(1) Cache types

- Instruction cache
 - 8 KB 4-way set associative
 - (512 entries (128 indexes × 4 ways))
- Data cache
 - 8 KB 4-way set associative
 - (512 entries (128 indexes × 4 ways))

When the area is specified as cacheable, 4-word sequential burst read cycles are issued in external 32-bit bus mode, and 8 half-word burst read cycles in external 16-bit bus mode.

The “entry” is a caching unit that consists of a combination of the tag section, data section, valid flag, and dirty flag (only in the data cache). The entry for the number of ways can be cached per index.

(2) Operation mode of data cache

The data cache supports the two modes shown below, which have different coherency upon write operation and allocation (caching) procedure (refer to **5.6 Coherency in Cache System** for coherency).

- Write-through mode (WT)
 - Data transfer is performed for both the data cache and the external memory lines. The external memory always holds the latest data.
- Writeback allocate mode (WB-A)
 - Data transfer is performed only for a data cache line. Data in the data cache line in which data is changed is transferred to the external memory when the line is the target of replacement. When a cache miss occurs, data in the line is transferred from the external memory to the data cache.

(3) Cache operation

The following cache operations are supported.

(a) Operation in way units (operation for the specified ways)

- Clear function: Initializes entries.

(b) Operation in entry units (operation for the specified indexes)

- Clear function: Initializes entries.
- Sync function: Writes data in the instruction cache/data cache back to the memory to synchronize (keep coherency) with the memory.
- Fill function: Stores data in the memory in the instruction cache/data cache.

(4) Cache replace method

This method employs LRU (Least Recently Used) algorithm in index units.

When a cache hit occurs, the order of ways is changed by moving the hit entry to the lowest way so that the entry that has not been accessed for the longest time is moved to the highest way.

When a cache miss occurs, the highest way becomes the target of replacement.

5.2 Configuration

The data memory of the 4-way set associative cache has an 8 KB capacity, which consists of 4 ways, including a 4-word 128-entry block per line. When a cache miss occurs, a refill is performed in 1-line units.

Figure 5-1. Configuration of Instruction Cache

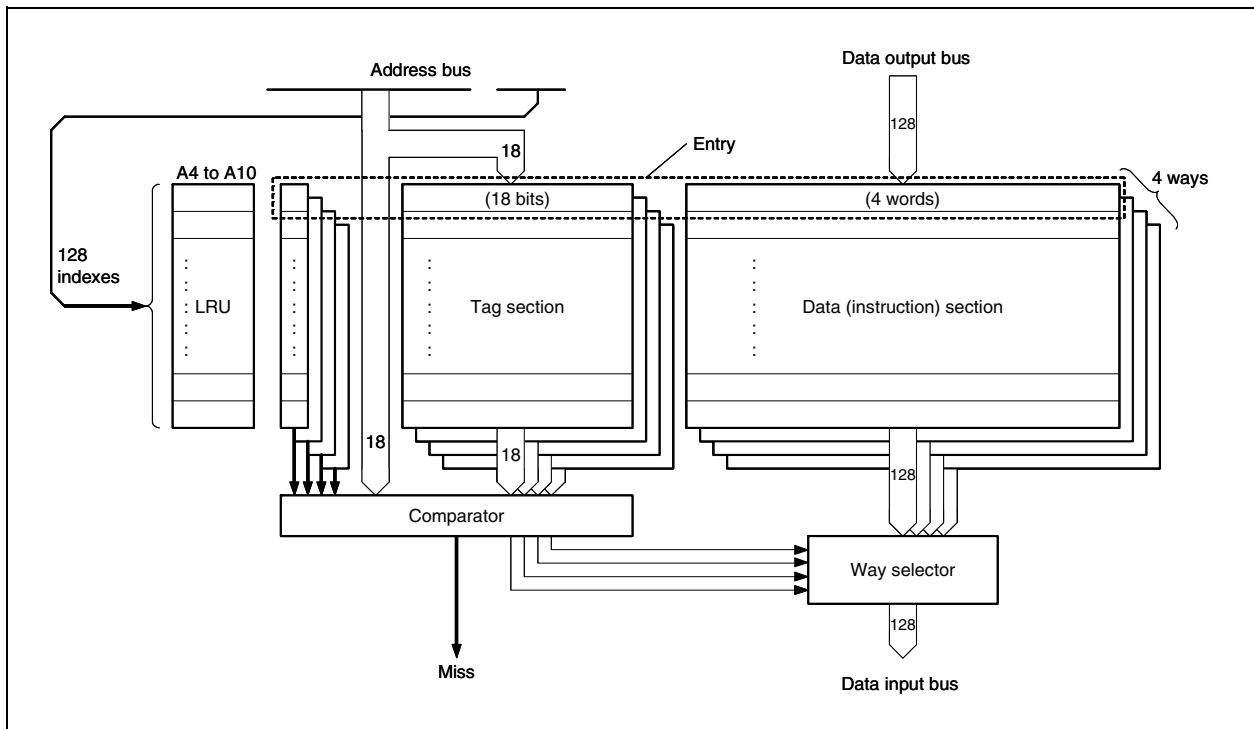

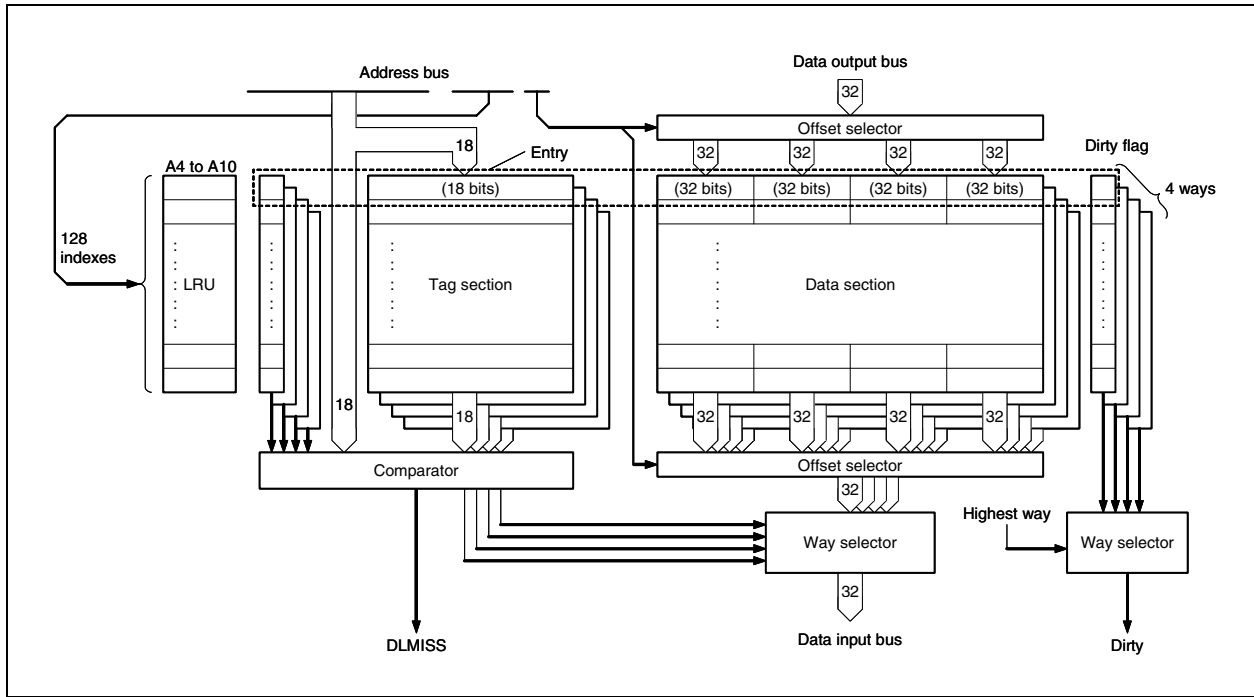

Figure 5-2. Configuration of Data Cache

5.3 Control Registers

The registers for controlling the cache are allocated to the on-chip peripheral I/O area. These registers are classified into the following two types.

(a) Registers for setting operating environment

- Bus transaction control register (BTSC)
- Cache area specification register (BHC)

(b) Registers for controlling operations

- Cache operation specification register (COPR)
- Cache operation start address H register (CADH)
- Cache operation start address L register (CADL)
- Cache operation count specification register (CCNT)

Caution Be sure to change the operation environment of the instruction cache or perform the instruction cache operations from an uncached area. If execution branches to the instruction cacheable area after setting the relevant register, insert at least 16 NOP instructions immediately after the instruction for setting the COPR.STRT bit, before the branch instruction.

- Remarks**
1. The following operations can be performed for the instruction cache by setting the above registers.
 - Clear
 - Fill
 - Way clear
 2. The following operations can be performed for the data cache by setting the above registers.
 - Clear
 - Fill
 - Way clear
 - Sync if dirty

(1) Bus transaction control register (BTSC)

The BTSC register sets the operation mode for the cache.

This register can be read or written in 16-bit units.

When using the higher 8 bits of the BTSC register as the BTSCH register and the lower 8 bits as the BTSC L register, they can be read or written in 8-bit or 1-bit units.

Be sure to clear bits 15 to 4 and 1 to “0”, and set bits 2 and 0 to “1”; otherwise the operation is not guaranteed.

- Cautions 1. When changing the BTSC register contents, insert at least 16 NOP instructions immediately after the instruction for changing the BTSC register setting (see 3.5 Cautions).**
- 2. Set the BTSC register in the uncached area.**
If execution branches to the instruction cache area after setting the BTSC register, insert at least 16 NOP instructions immediately before the branch instruction after setting the BTSC and BHC registers (refer to 3.5 Cautions).
- 3. Bit 3 of the BTSC register can be set only after the cache is initialized after a system reset and before the first cache access is performed. Do not change the set value after a cache access is performed; otherwise the operation is not guaranteed.**
- 4. Set the BTSC register before setting the BHC register.**

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
BTSC	0	0	0	0	0	0	0	0	0	0	0	0	DCM	1	0	1	Address	After reset
																	1FFFF070H	0005H

Bit position	Bit name	Function
3	DCM	Specifies the operation mode for the data cache. 0: Write-through mode 1: Writeback allocate mode

(2) Cache area specification register (BHC)

The BHC register sets the configuration of the instruction and data caches per the CSn area selected by the chip select signal (\overline{CSn}). (n = 7 to 0)

This register can be read or written in 16-bit units.

Cautions 1. The internal instruction RAM area, internal data RAM area, and on-chip peripheral I/O area are “uncached” regardless of the BHC register setting.

2. When using the instruction cache/data cache, set the BTSC register before setting the BHC register.

3. The location where an instruction for setting the BHC register is allocated cannot be changed from an uncached area to a cacheable area, or from a cacheable area to an uncached area; otherwise operation is not guaranteed. In this case, branch the execution to area 1, set area 0 in area 1 to a cacheable area using an instruction, and as necessary, branch the execution to area 0 again.

If the instruction is allocated in the internal instruction RAM area, uncached or cacheable settings can be made for either CS space.

(Example of prohibited setting)

- When an instruction for setting the BHC register is allocated in area 0

4. The BHC register is allocated at the same address as the cache configuration register (BHC) of the conventional product V850E/ME2, but register names, bit names, and bit arrangement differ.

5. When changing the BHC register contents, insert at least 16 NOP instructions immediately after the instruction for changing the BHC register setting (see 3.5 Cautions).

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset
BHC	BHD7	BHD6	BHD5	BHD4	BHD3	BHD2	BHD1	BHD0	BHI7	BHI6	BHI5	BHI4	BHI3	BHI2	BHI1	BHI0	1FFFF06AH	0000H

Bit position	Bit name	Function
15 to 8	BHD7 to BHD0	Sets the data cache allocated to the CSn area. 0: Uncached 1: Cacheable
7 to 0	BHI7 to BHI0	Sets the instruction cache allocated to the CSn area. 0: Uncached 1: Cacheable

(3) Cache manipulation specification register (COPR)

The COPR register sets control of access for the cache.

This register can be read or written in 16-bit units.

When using the higher 8 bits of the COPR register as the COPRH register and the lower 8 bits as the COPRL register, they can be read or written in 8-bit or 1-bit units.

Caution When changing the COPR register contents, insert at least 16 NOP instructions immediately after the instruction for changing the COPR register setting (see 3.5 Cautions).

COPR																Address	After reset
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	1FFFF07AH	0000H
0	CFC2	CFC1	CFC0	WSL1	WSL0	WSLE	LBSL	0	0	0	0	0	0	0	STRT		
Bit position	Bit name	Function															
14 to 12	CFC2 to CFC0	Set the operation to be performed on the cache.															
		CFC2	CFC1	CFC0	Operation to be performed on cache												
		0	0	0	Sync if dirty (initial value)												
		1	0	0	Way Clear												
		1	0	1	Fill												
		1	1	0	Clear												
		Other			Setting prohibited												
11, 10	WSL1, WSL0	Set the way subject to operation. The settings of these bits are valid only when the WSLE bit is 1.															
		WSL1	WSL0	Way Subject to Operation													
		0	0	Way 0													
		0	1	Way 1													
		1	0	Way 2													
		1	1	Way 3													
9	WSLE	Specifies the method to determine entries to be operated. 0: Address match specification method 1: Way/index specification method															
8	LBSL	Sets the cache to be accessed. 0: Instruction cache 1: Data cache															
0	STRT	When this bit is set (1), execution of the operation set by bits 14 to 8 is started. This bit is automatically cleared (0) when the execution is complete.															
Remark Refer to 5.4 Entry Specification Method for the address match and way/index specification methods.																	

(4) Cache manipulation start address H, L registers (CADH, CADL)

The CADH and CADL registers set the address of an access target set by the COPR register.

(a) Cache manipulation start address H register (CADH)

This register can be read or written in 16-bit units.

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset
CADH	0	0	0	CAD28	CAD27	CAD26	CAD25	CAD24	CAD23	CAD22	CAD21	CAD20	CAD19	CAD18	CAD17	CAD16	1FFF076H	0000H

Bit position	Bit name	Function
12 to 0	CAD28 to CAD16	Set bits 28 to 16 of the address of the access target specified by the COPR register.

(b) Cache manipulation start address L register (CADL)

This register can be read or written in 16-bit units.

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset
CADL	CAD15	CAD14	CAD13	CAD12	CAD11	CAD10	CAD9	CAD8	CAD7	CAD6	CAD5	CAD4	0	0	0	0	1FFF074H	0000H

Bit position	Bit name	Function
15 to 4	CAD15 to CAD4	Set bits 15 to 4 of the address of the access target specified by the COPR register.

(5) Cache manipulation count specification register (CCNT)

The CCNT register sets the count for accessing the access target set by the COPR register.

This register can be read or written in 16-bit units.

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset
CCNT	CT15	CT14	CT13	CT12	CT11	CT10	CT9	CT8	CT7	CT6	CT5	CT4	CT3	CT2	CT1	CT0	1FFFF078H	0000H

Bit position	Bit name	Function
15 to 0	CT15 to CT0	Specify the repeat count for the operation (other than Way clear) specified by the COPR register.

5.4 Entry Specification Method

In operations other than Way clear, an entry in the cache, which is the target of operations, is determined by the address (CAD) specified by the CADH and CADL registers.

At this time, the following two methods are available to specify the target entry.

(1) Way/index specification method

Operations are performed on entries of “CCNT register value + 1” starting from an index in an index field of the address (CAD) of the way specified by the COPR.WSL1 and COPR.WSL0 bits.

This method can be used in all operations. However, indexes CADH, CADL, and CCNT are invalid because the Way clear operation can be performed only in the way units.

Figure 5-3. Way/Index Specification Method (1)

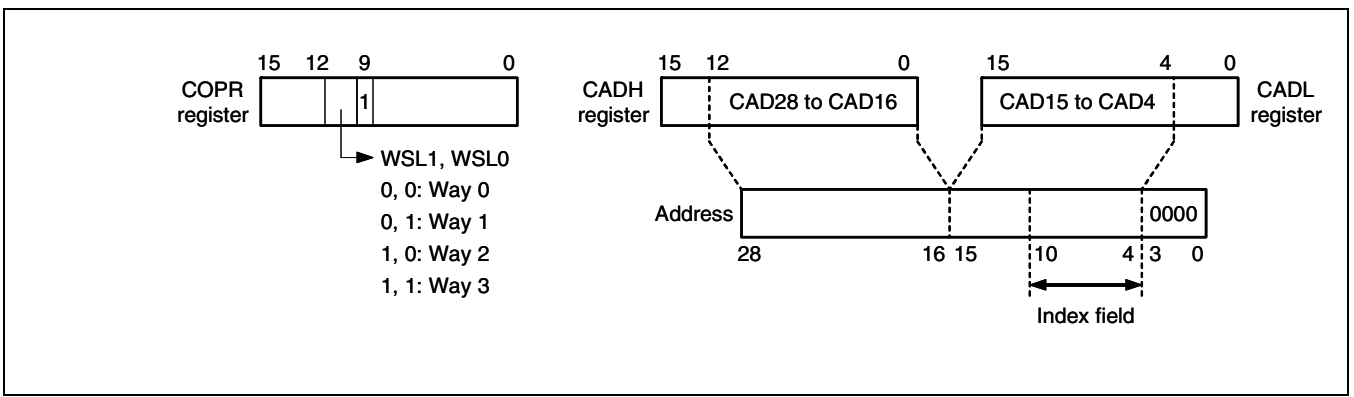

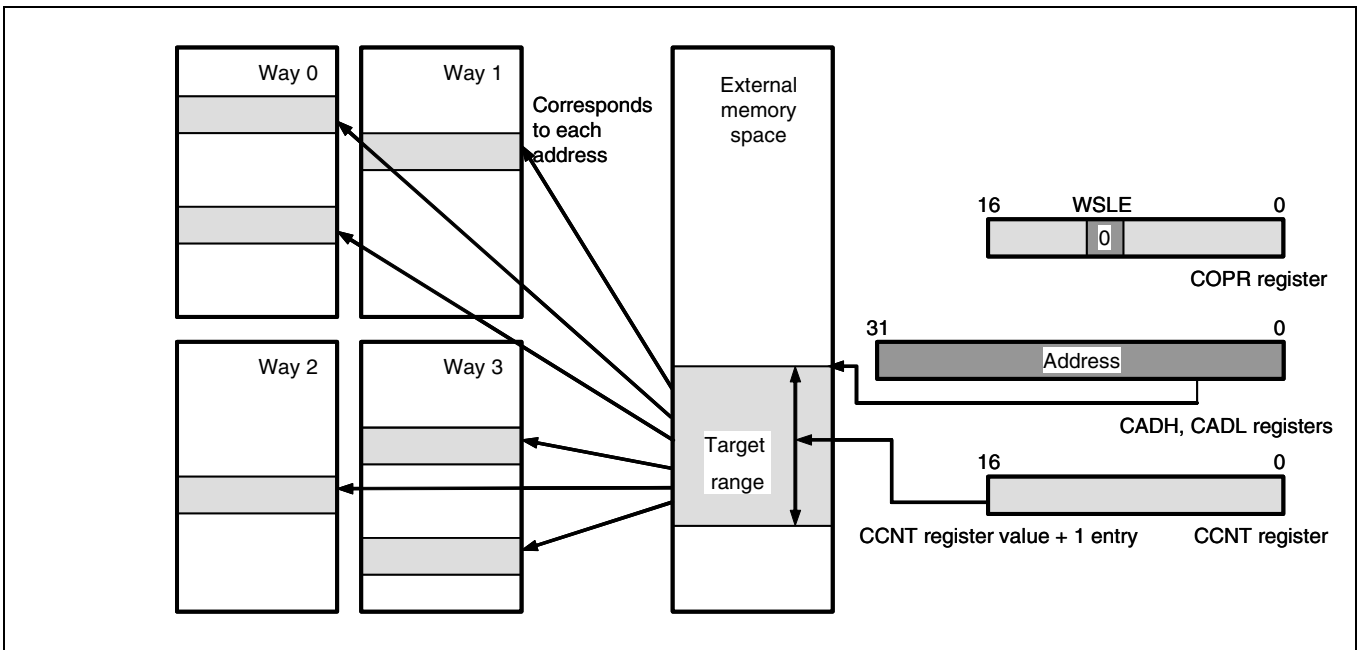

Figure 5-4. Way/Index Specification Method (2)

(2) Address match specification method

Operations are performed on an entry corresponding to the area of “CCNT register value + 1” × 10H that starts with the specified address (CAD). Operations are not performed if there is no entry that corresponds to the specified addresses, in the cache.

This method can be used for the Clear and Sync if dirty operations.

Figure 5-5. Address Match Specification Method (1)

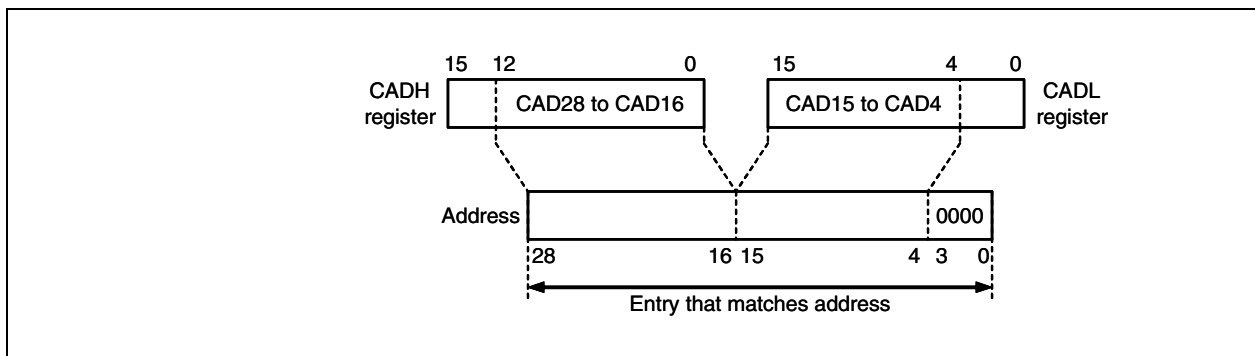

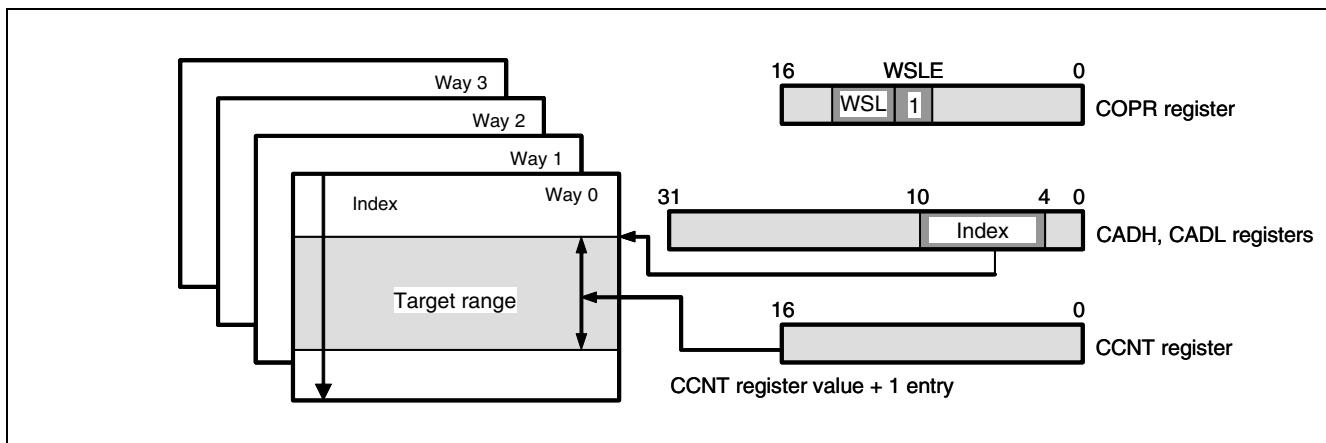

Figure 5-6. Address Match Specification Method (2)

5.5 Operation

5.5.1 Caching operation

Caching (allocation) performs processing to store memory data in the cache.

The operation varies depending on the result of accessing a cache.

- When a read miss occurs in the instruction cache/data cache: Caching is performed.
- When a write miss occurs in the data cache (WB-A mode): Caching is performed.
- When a write miss occurs in the data cache (WT mode): Caching is not performed.

The contents of a dirty entry are written back to the memory before caching is performed in the data cache. The contents of the clean entry are not written back to the memory.

Entries become dirty after the following access.

- When a write hit occurs in WB-A mode
- Caching in conjunction with a write miss in WB-A mode (write is bypassed)

Remark Dirty entry: The contents of the cache entry and the main memory (external memory) do not match
Clean entry: The contents of the cache entry and the main memory (external memory) match

5.5.2 LRU operation

The order of ways is “way 0, way 1, way 2, and way 3” from the higher order in the initial state.

The order of ways changes when a hit, miss, or clear occurs.

- When a hit occurs: The hit entry is moved to the lowest way.
- When a miss occurs: An entry in which caching is performed moves to the lowest way.
- When a clear occurs: The order of ways is reset to the initial state when all the 4 entries in an index are cleared.

Example When the caching operation is performed in the order of the following steps <1> to <4> in the initial order of ways, the order of ways changes as shown in square brackets.

- <1> A hit occurs in way 1
[0, 2, 3, 1]: The hit way (way 1) moves to the lowest way.
- <2> A miss occurs (caching is performed)
[2, 3, 1, 0]: The highest way (way 0) moves to the lowest way with caching operation
- <3> Access to uncached area
[2, 3, 1, 0]: The order of ways does not change if caching is not performed
- <4> All ways are cleared
[0, 1, 2, 3]: The order of ways is initialized.

5.6 Coherency in Cache System

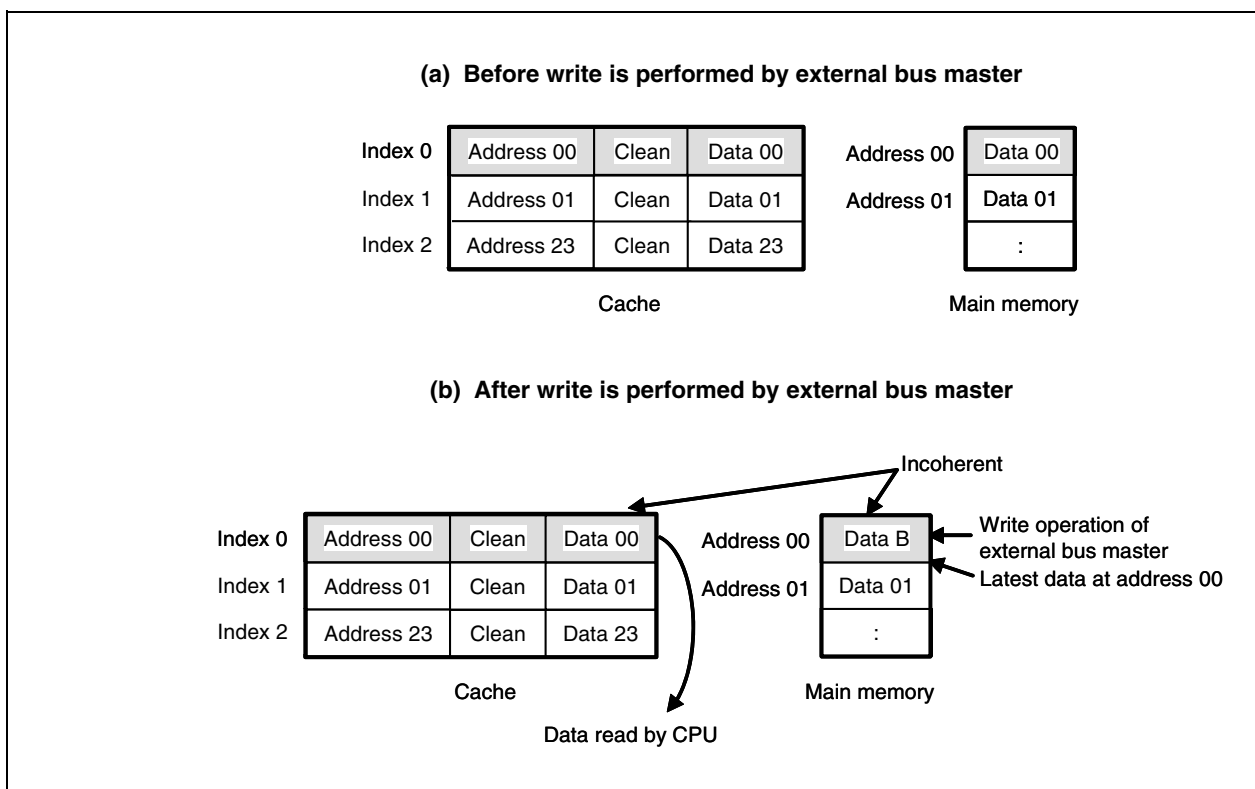

5.6.1 Coherency problem in cache system

The contents of the cache entry and the main memory (external memory) may differ in the cache system. In a system in which a bus master other than V850E2/ME3 is used, therefore, the coherency problems shown below may occur.

- (1) The external bus master writes data to an address in the main memory (external memory) that corresponds to the clean address in the cache.

The contents of the cache entry and the main memory do not match, and the old data in the cache is read by the CPU.

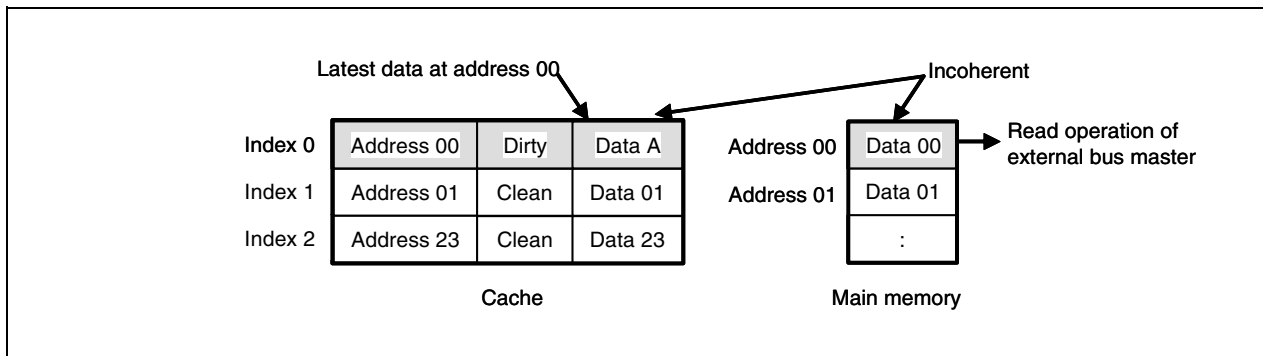

Figure 5-7. Write by External Bus Master

- (2) The external bus master reads data at an address in main memory (external memory) that corresponds to the dirty address in the cache.

The contents of the cache entry and a value read by the external bus master do not match, and the old data is read by the external bus master.

Figure 5-8. Read by External Bus Master

- (3) The external bus master writes data to an address in the main memory (external memory) that corresponds to the dirty address in the cache.

The contents of the cache entry and the main memory do not match, and the old data in the cache is read by the CPU.

When a sync operation (Sync if dirty) is performed on the contents of the cache entry and the main memory, the data written by the external bus master is lost.

Figure 5-9. Write by External Bus Master

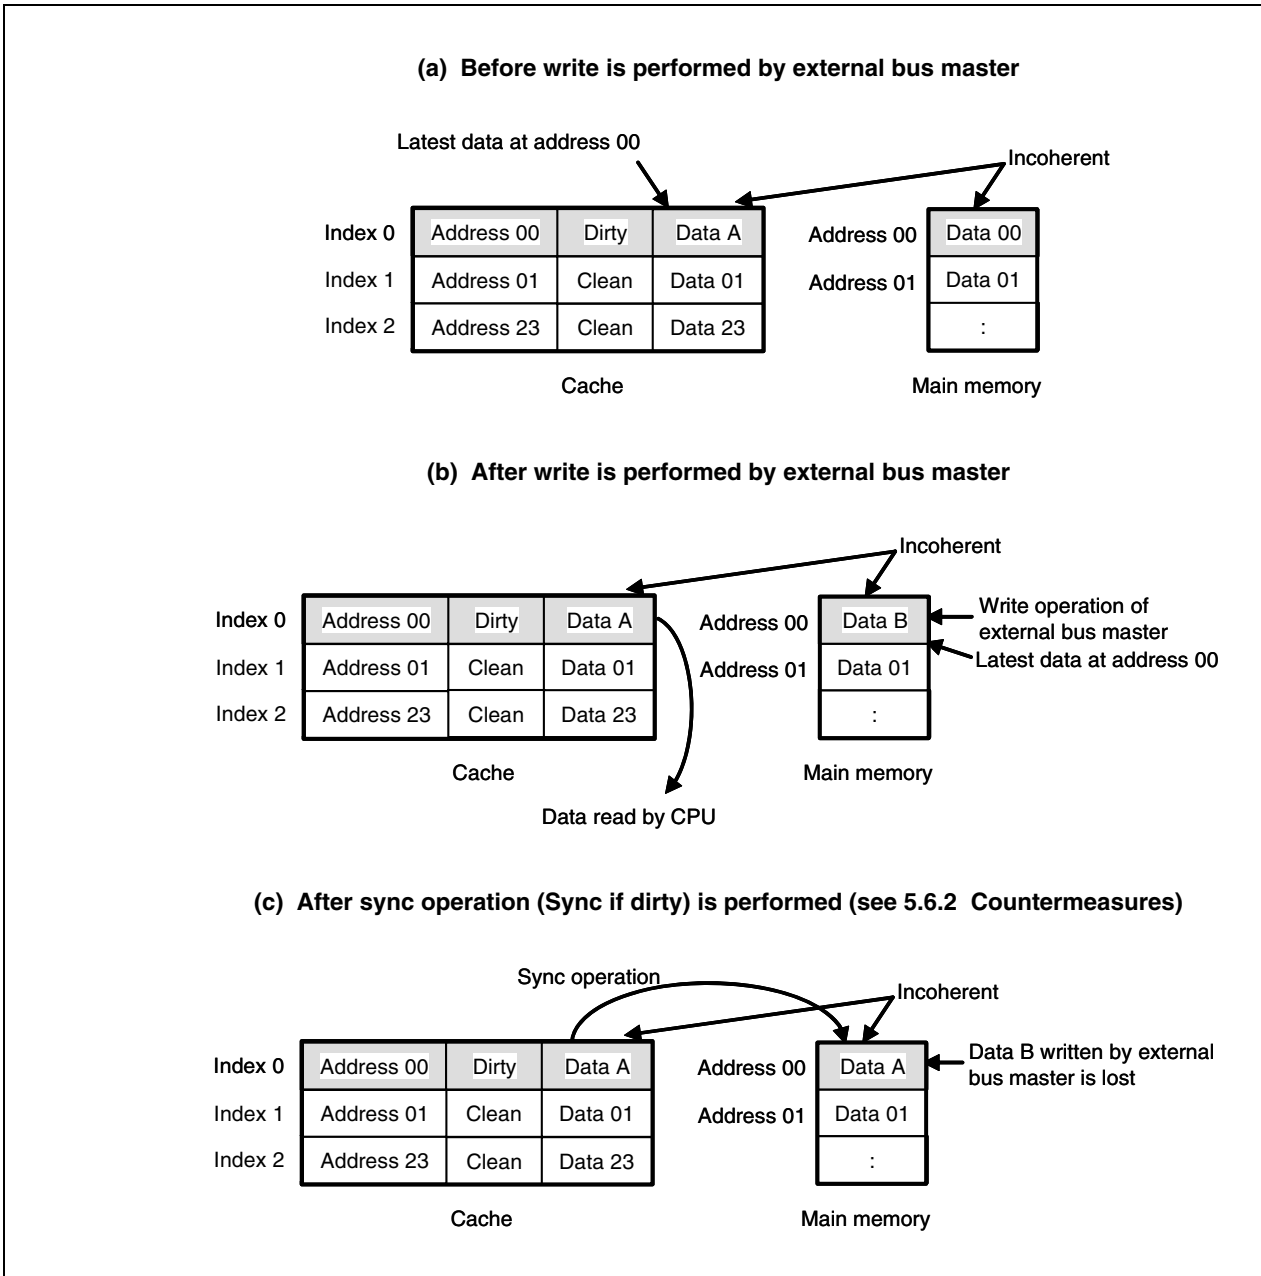

Table 5-1. Coherency Problem in Each Cache

Coherency Problem	Instruction Cache	Data Cache (WT Mode)	Data Cache (WB-A Mode)
(1)	Occurs	Occurs	Occurs
(2)	–	–	Occurs
(3)	–	–	Occurs

Remark (1) to (3) in the above table correspond to (1) to (3) in **5.6.1 Coherency problem in cache system**.

5.6.2 Countermeasures

The following operation functions are provided in the V850E2/ME3 to cope with the coherency problem.

- Sync if dirty: Synchronizes data in cache entry and main memory
(Writes a dirty entry in the cache to the main memory (external memory))
- Way clear: Erases the way in a specified cache at once
- Clear: Erases the cache entry

It is assumed that the examples for the above operations described on the following pages are performed with the address match specification method, but the way/index specification method can also be used. Refer to **5.4 Entry Specification Method** for the address match specification method and way/index specification method.

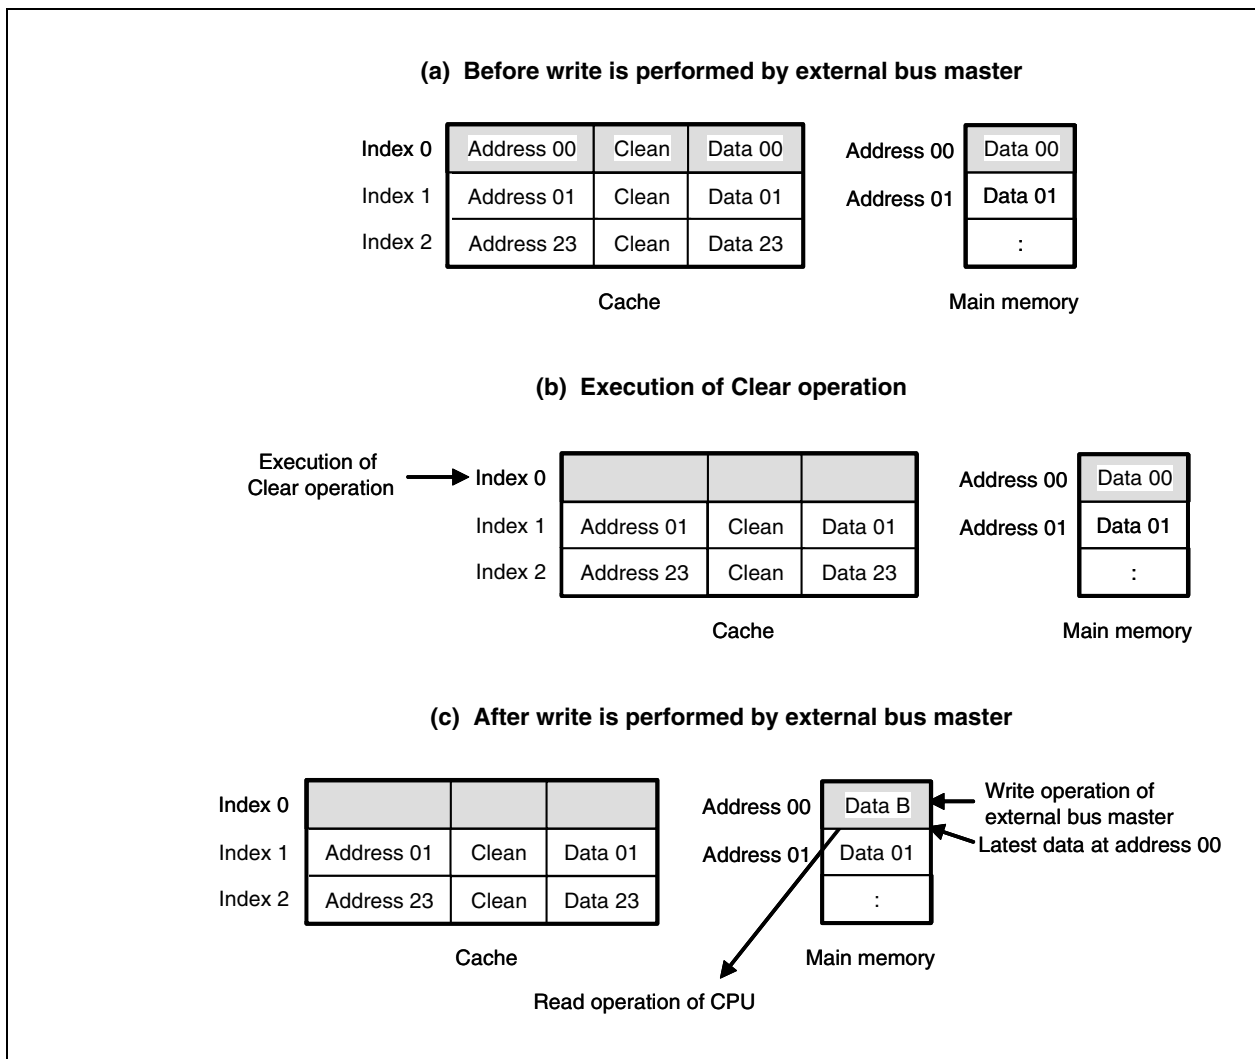

The Way clear operation can also be used for the Clear operation.

(1) Example for coping with coherency problem (1)

Erase the cache entry (Clear operation (address match specification method)) immediately before the external bus master writes data to the clean address (address 00 in Figure 5-7).

This case assumes that the CPU does not use the relevant address 00 in Figure 5-7) in the period from erasure of the cache entry to write by the external bus master.

Figure 5-10. Countermeasure Example (1)

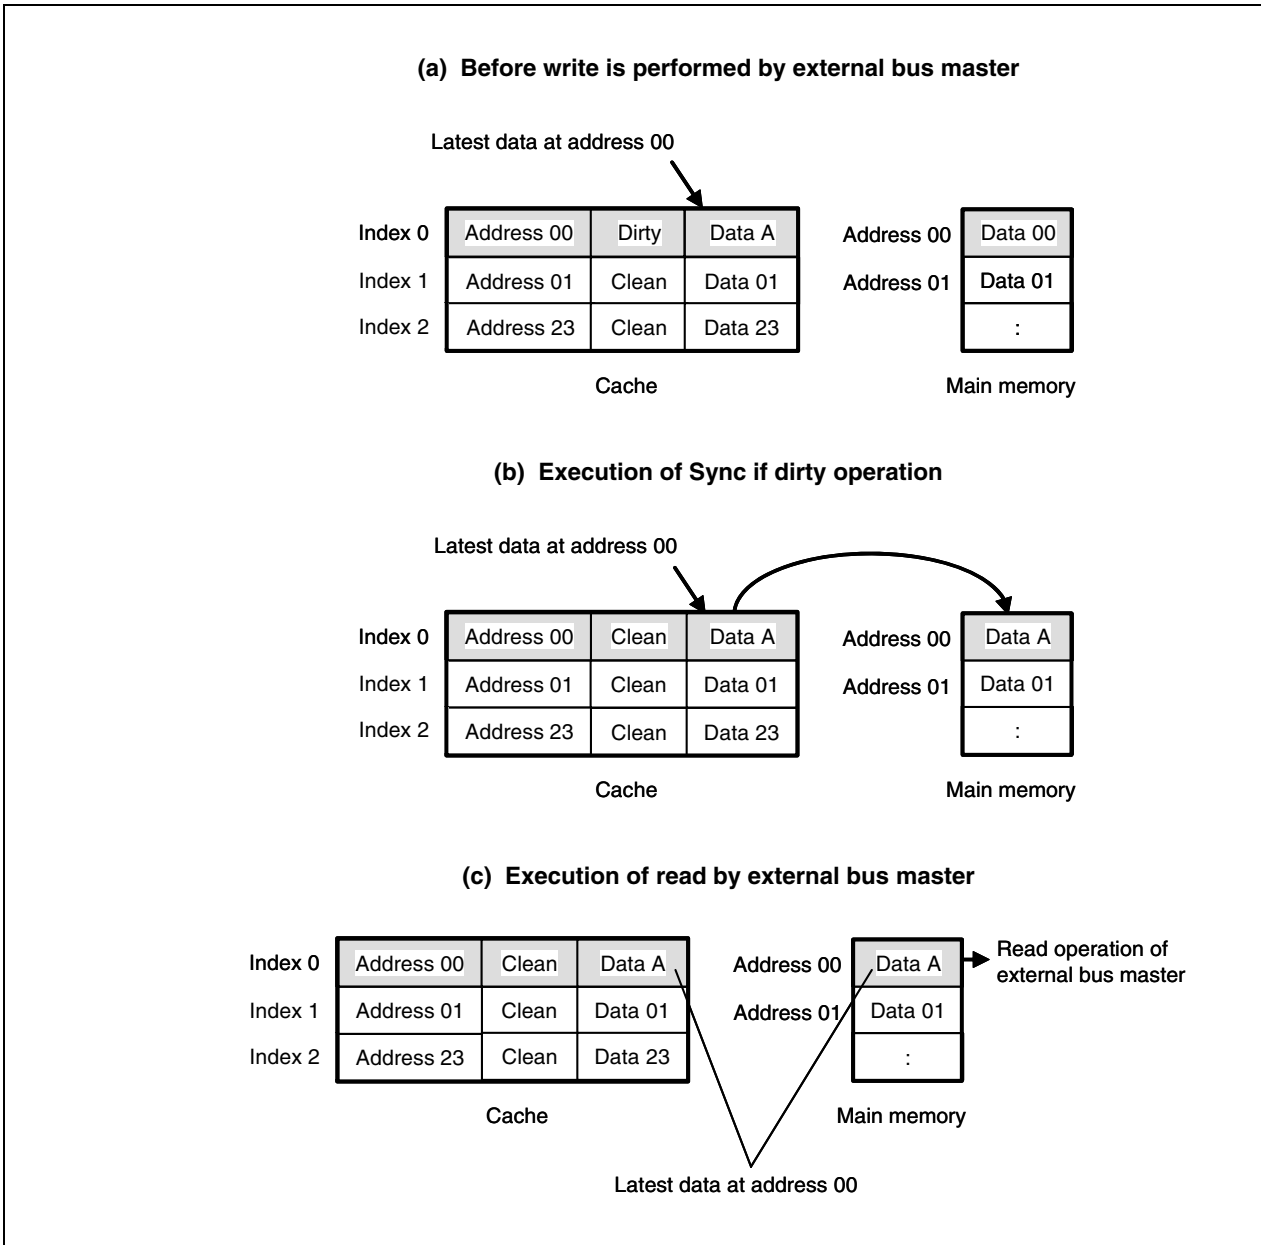

(2) Example for coping with coherency problem (2)

Perform a sync operation (Sync if dirty operation (address match specification method)) immediately before the external bus master read data from the dirty address (address 00 in Figure 5-8), and write data in the cache entry (latest data) to the main memory (external memory).

This case assumes that the CPU does not write data to the relevant address (address 00 in Figure 5-8) in the period from execution of synchronization to read by the external bus master.

Figure 5-11. Countermeasure Example (2)

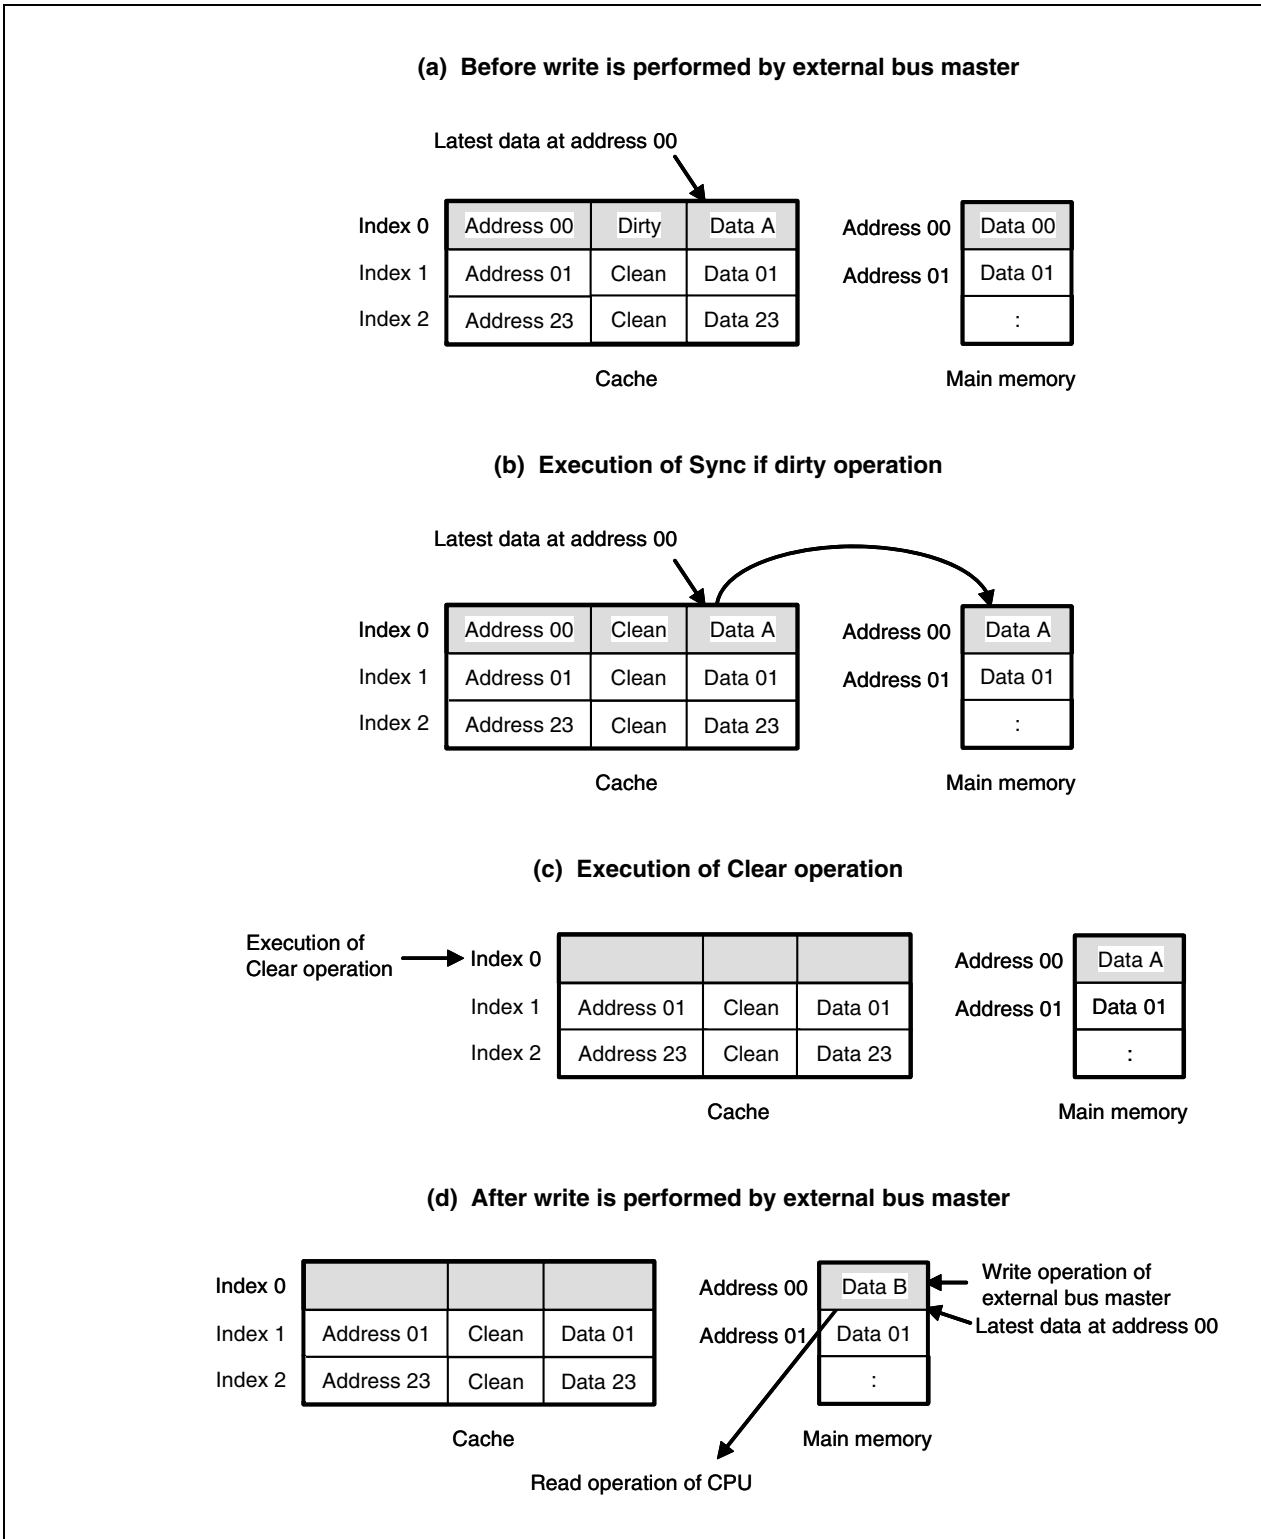

(3) Example for coping with coherency problem (3)

Perform a sync operation (Sync if dirty operation (address match specification method)) and erase the cache entry (Clear operation (address match specification method)) immediately before the external bus master writes data to the dirty address (address 00 in Figure 5-9).

This case assumes that the CPU does not use the relevant address (address 00 in Figure 5-9) in the period from erasure of the cache entry to write by the external bus master.

Figure 5-12. Countermeasure Example (3)

5.6.3 Functions of each operation

The types of operations and functions for the instruction and data caches are shown below.

Table 5-2. Types Operation for Instruction Cache and Data Cache

Operation	Description	Usable Cache
Sync if dirty	If data in the specified entry is dirty, the data is written to the external memory and the contents of the cache and external memory are synchronized.	Data cache
Way clear ^{Notes 1, 2}	The specified way (set by the COPR.WSL1 and COPR.WSL0 bits) are erased at once. The cache data can be erased faster than using the Clear command.	Instruction cache, data cache
Clear	Erases data in the specified entry.	Instruction cache, data cache
Fill ^{Note 1}	Load the data (4 words) in a specified address (CAD28 to CAD0) and stores it in a specified entry.	Instruction cache, data cache

Notes 1. The address match specification method cannot be used.

2. The way/index specification method can be used, but indexes CADH, CADL, and CCNT are invalid.

5.7 Cache Operation

Note the several cautions below when performing the cache operation, in order to guarantee consistency for the operation-target areas. If these cautions are not followed, the system may cause operational problems even if the CPU operates normally (as is described in the specifications).

(1) COPR register access for area to which program is allocated

- (a) Do not perform a cache operation for the area to which the program that performs a cache operation by the COPR register is allocated.
- (b) In principle, read the STRT bit immediately after execution of the cache operation by the COPR register, then execute a polling loop to confirm completion of the cache operation by the COPR register (clearing the STRT bit). (If multiple cache operations are successively performed by the COPR register, execute a polling loop immediately after the last cache operation by the COPR register).
- (c) Insert 16 NOP instructions immediately after the polling loop in the above (b).
- (d) Do not execute a branch instruction^{Note 2} in the section in which the register set value is changed^{Note 1}.
- (e) Disable interrupts in the section in which a cache operation by the COPR register is performed^{Note 1}.
- (f) Implement either <1> or <2> for non-maskable interrupts (NMI). Implement <i> if an operation is performed for the area that includes an NMI handler.

<i> Disable NMI inputs in the section in which the register set value is changed^{Note 1}, in the same way as disabling maskable interrupts.

<ii> Do not include the NMI handler routine in the cache operation target area. In addition, allocate a polling loop for the STRT bit in the interrupt handler routine.

- Notes**
1. The section starting from an instruction that performs cache operation by the COPR register to the 16th NOP instruction (refer to **5.7 (1) (c)**)
 2. JARL, JMP, JR, BCC, POPMHR, POPMLR, SWITCH, DISPOSE, TRAP, RETI, ASSERT, CALLT, CTRET, DBTRAP, DBRET

<Program example>

```
ori    0x0010, r0, r10

st.h   r0, CADL[r0] ( 0x1FFFF074 ) -- Sets CADL register
ori    0x0003, r0, r10
st.h   r10, CCNT[r0] ( 0x1FFFF078 ) -- Sets CCNT register
ori    0x6001, r0, r10
st.h   r10, COPR[r0] ( 0x1FFFF07A ) -- Sets COPR register
                                           (Clear [address match])

di
```

```
loop:
  tstl  0, COPR[r0] ( 0x1FFFF07A )
  bnz   loop -- Performs polling until STRT bit is cleared (0)
  nop; nop; nop; nop;
  nop; nop; nop; nop;
  nop; nop; nop; nop;
  nop; nop; nop; nop;
  ei
```

(2) Cache operation performed by COPR register for area to which data is allocated

- (a) In principle, read the STRT bit immediately after execution of the cache operation by the COPR register, then execute a polling loop to confirm completion of the cache operation by the COPR register (clearing the STRT bit). (If multiple cache operations are successively performed by the COPR register, execute a polling loop immediately after the last cache operation by the COPR register).
- (b) Implement either <i> or <ii> for non-maskable interrupts (NMI). Implement <i> if an operation is performed for the area that includes an NMI handler.

<i> Disable NMI inputs in the section in which the register set value is changed^{Note}, in the same way as disabling maskable interrupts.

<ii> Do not include the NMI handler routine in the cache operation target area. In addition, allocate a polling loop for the STRT bit in the interrupt handler routine.

Note The section starting from an instruction that performs cache operation by the COPR register to the 16th NOP instruction (refer to **5.7 (1) (c)**).

<Program example>

```

ori    0x0010, r0, r10

5.8 Program Examples

(1) When synchronizing data corresponding to the area of 256 bytes (16 entries) from address 003FFF00H in the data cache (execution of Sync if Dirty then Clear)

```

ori    0x000f, r0, r10
st.h   r10, CCNT[r0] ( 0x1FFFFF078 ) -- Sets CCNT register
ori    0x003f, r0, r10
st.h   r10, CADH[r0] ( 0x1FFFFF076 ) -- Sets CADH register
ori    0xff00, r0, r10
st.h   r10, CADL[r0] ( 0x1FFFFF074 ) -- Sets CADL register
di                                           -- Disables interrupts
ori    0x0101, r0, r10
st.h   r10, COPR[r0] ( 0x1FFFFF07A ) -- Sets COPR register (Sync if Dirty)
loop1:
tstl   0, COPR[r0] ( 0x1FFFFF07A )
bnz    loop1                               -- Performs polling until STRT bit is cleared (0)
ei                                           -- Enables interrupts

ori    0x000f, r0, r10
st.h   r10, CCNT[r0] ( 0x1FFFFF078 ) -- Sets CCNT register
ori    0x003f, r0, r10
st.h   r10, CADH[r0] ( 0x1FFFFF076 ) -- Sets CADH register
ori    0xff00, r0, r10
st.h   r10, CADL[r0] ( 0x1FFFFF074 ) -- Sets CADL register
di                                           -- Disables interrupts
ori    0x6101, r0, r10
st.h   r10, COPR[r0] ( 0x1FFFFF07A ) -- Sets COPR register (Clear)
loop2:
tstl   0, COPR[r0] ( 0x1FFFFF07A )
bnz    loop2                               -- Performs polling until STRT bit is cleared (0)
ei                                           -- Enables interrupts

```

Remark After execution of this program example, the values in the CCNT, CADH, CADL, and COPR registers are overwritten as shown below (value before execution → value after execution).

<Sync if Dirty>

CCNT register: 000FH → 000FH

CADH register: 003FH → 0040H (Higher 16 bits of "003FFF00H + 10H × 16")

CADL register: FF00H → 0000H (Lower 16 bits of "003FFF00H + 10H × 16")

COPR register: 0101H → 0100H (STRT bit is cleared to 0)

<Clear>

CCNT register: 000FH → 000FH

CADH register: 003FH → 0040H (Higher 16 bits of "003FFF00H + 10H × 16")

CADL register: FF00H → 0000H (Lower 16 bits of "003FFF00H + 10H × 16")

COPR register: 6101H → 6010H (STRT bit is cleared to 0)

(2) When filling data of 1 KB (64 entries) from address 0020100H in four times, 256 bytes (16 entries) for each, in way 1 in the instruction cache (Fill)

```

ori    0x000f, r0, r10
st.h   r10, CCNT[r0] ( 0x1FFFFF078 ) -- Sets CCNT register
ori    0x0020, r0, r10
st.h   r10, CADH[r0] ( 0x1FFFFF076 ) -- Sets CADH register
ori    0x0100, r0, r10
st.h   r10, CADL[r0] ( 0x1FFFFF074 ) -- Sets CADL register
ori    0x5600, r0, r10
st.h   r10, COPR[r0] ( 0x1FFFFF07A ) -- Sets COPR register (Fill)
di                                           -- Disables interrupts
loop:
tstl   0, COPR[r0] ( 0x1FFFFF07A )
bnz    loop                                -- Performs polling until STRT bit is cleared (0)
nop; nop; nop; nop;
nop; nop; nop; nop;
nop; nop; nop; nop;
nop; nop; nop; nop;
ei                                           -- Enables interrupts

```

After setting the Fill operation to the COPR register, execute the st.b instruction as shown below, which sets the STRT bit to 1, four times at any timing.

```

ori    0x0001, r0, r10
st.b r10, COPR[r0]

```

After executing the Fill operation, execute the ld instruction for address 0020100H.

```

movhi  0x20100, r10
ld.b   0x0[r10], r11

```

(3) When erasing data in way 3 in the data cache at once (Way Clear)

```

di                                           -- Disables interrupts
ori    0x4f01, r0, r10
st.h   r10, COPR[r0] ( 0x1FFFFF07A ) -- Sets COPR register(Way Clear)
loop:
tstl   0, COPR[r0] ( 0x1FFFFF07A )
bnz    loop                                -- Performs polling until STRT bit is cleared (0)
ei                                           -- Enables interrupts

```

5.9 Cautions

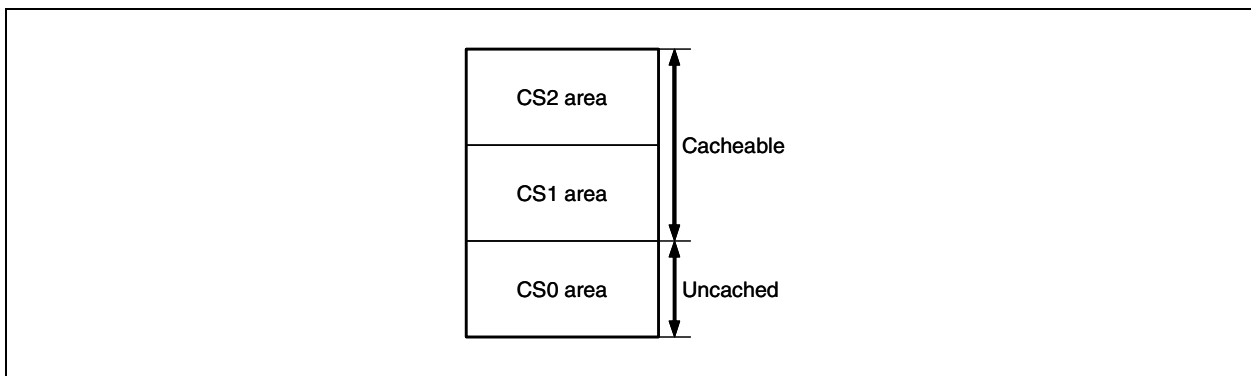

(1) Accessing the memory boundary of the cache area successively

When CSn areas are uncached and cacheable areas, only the branch instruction can be used for accessing the memory boundary successively (n = 0 to 7). The operation is not guaranteed if any other instruction is used. When a cached area is set as shown in Figure 5-13, for example, the memory area is accessed as follows.

- The CS2 area to the CS0 area can be accessed only by the branch instruction^{Note}
- The CS0 area to the CS1 area can be accessed successively

Note Allocate the branch instruction in the CS2 area away from the boundary of the CS2 and CS0 areas (because the CPU fetches instructions at up to 64-byte forward address when using the instruction cache).

Figure 5-13. Cache Area Setting Example

(2) DMA transfer to cache area

When performing DMA transfer for the cacheable area, be sure to perform a Sync if dirty operation for synchronization, and then execute the Way clear command, before the DMA transfer.

(3) Coherency problem in cache system

Refer to **5.6.1 Coherency problem in cache system** when using a system in which an external bus master other than the V850E2/ME3 is connected.

(4) Caution on using writeback mode

When a system which data is stored in the external memory when the power supply is shutdown is used in writeback mode, perform a Sync if dirty operation for synchronization before shutting down the power supply.

(5) Cautions on setting BHC register

- When using instruction cache or data cache, set the BHC register after setting the BTSC register.
- The area that includes the instruction that sets the BHC register cannot be set from an uncached area to a cacheable area, or from a cacheable area to an uncached area. (The operation is not guaranteed if changed.) In this case, branch to area 1 and then set area 0 to a cacheable area by an instruction in area 1. If necessary, branch to area 0 again.
An uncached area and a cacheable area can be set in any CS space in the internal instruction RAM area.
- Although the BHC register has an allocated address which is the same as the cache configuration register (BHC) of V850E/ME2, the name of the register names of the registers, the name of each bit, and bit arrays differ.

CHAPTER 6 MEMORY ACCESS CONTROL FUNCTION

6.1 SRAM, External ROM, External I/O Interface

6.1.1 Features

- SRAM is accessed in a minimum of 2 states.
- Up to 7 states of programmable data waits can be inserted by setting the DWC0 and DWC1 registers (DMA flyby transfer: FWC register).
- Data wait can be controlled via $\overline{\text{WAIT}}$ pin input.
- Up to 3 idle states can be inserted after a read/write cycle by setting the BCC register (DMA flyby transfer: FIC register).
- Up to 3 address setup wait states can be inserted by setting the ASC register.
- DMA flyby transfer can be activated (SRAM → external I/O, external I/O → SRAM)

6.1.2 SRAM connection

Examples of connection to SRAM are shown below.

Figure 6-1. Examples of Connection to SRAM (1/2)

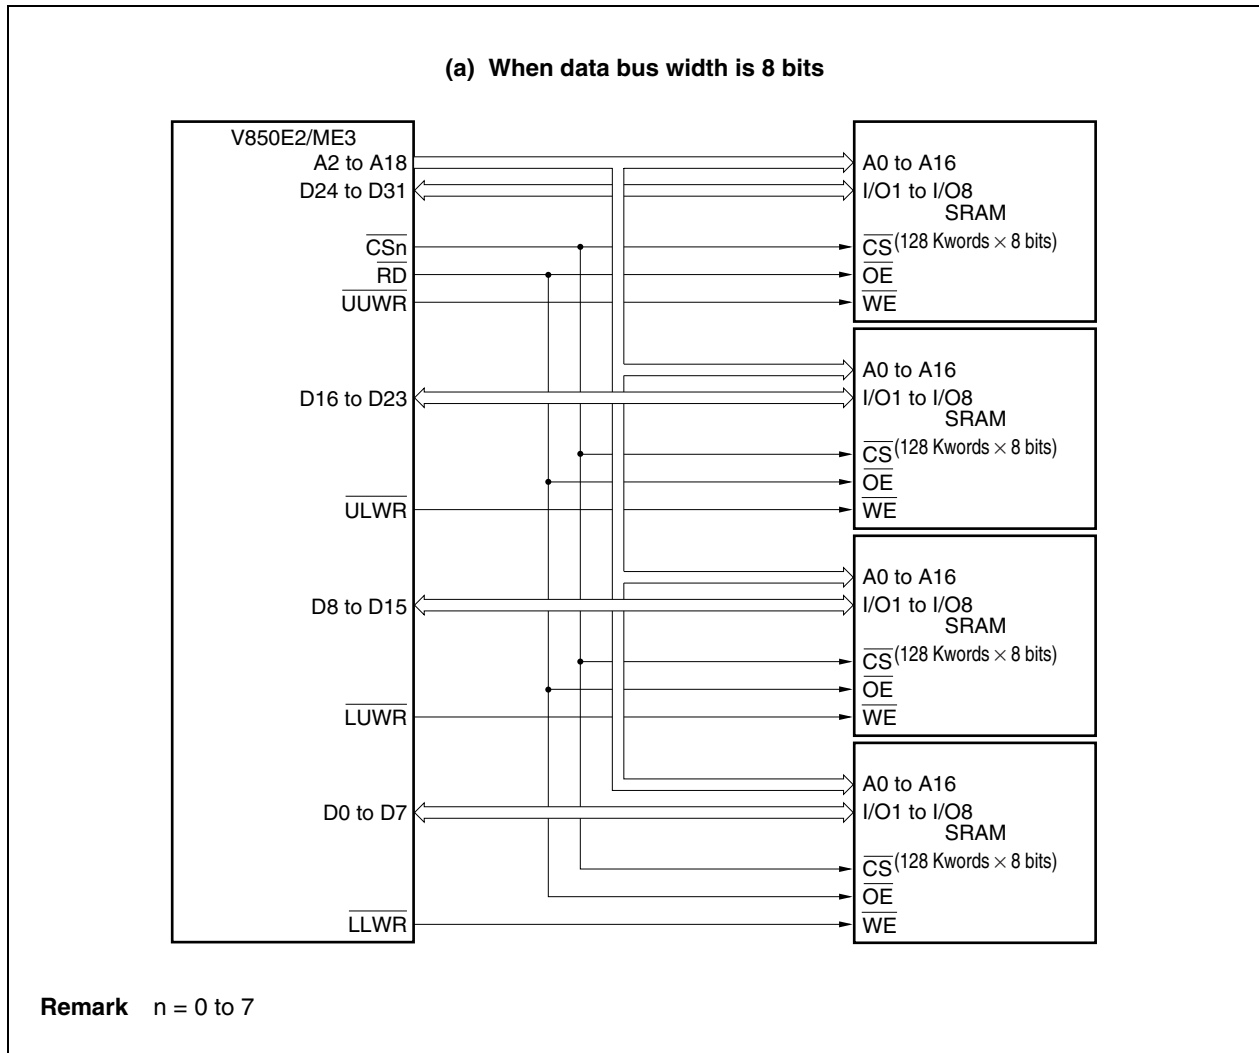

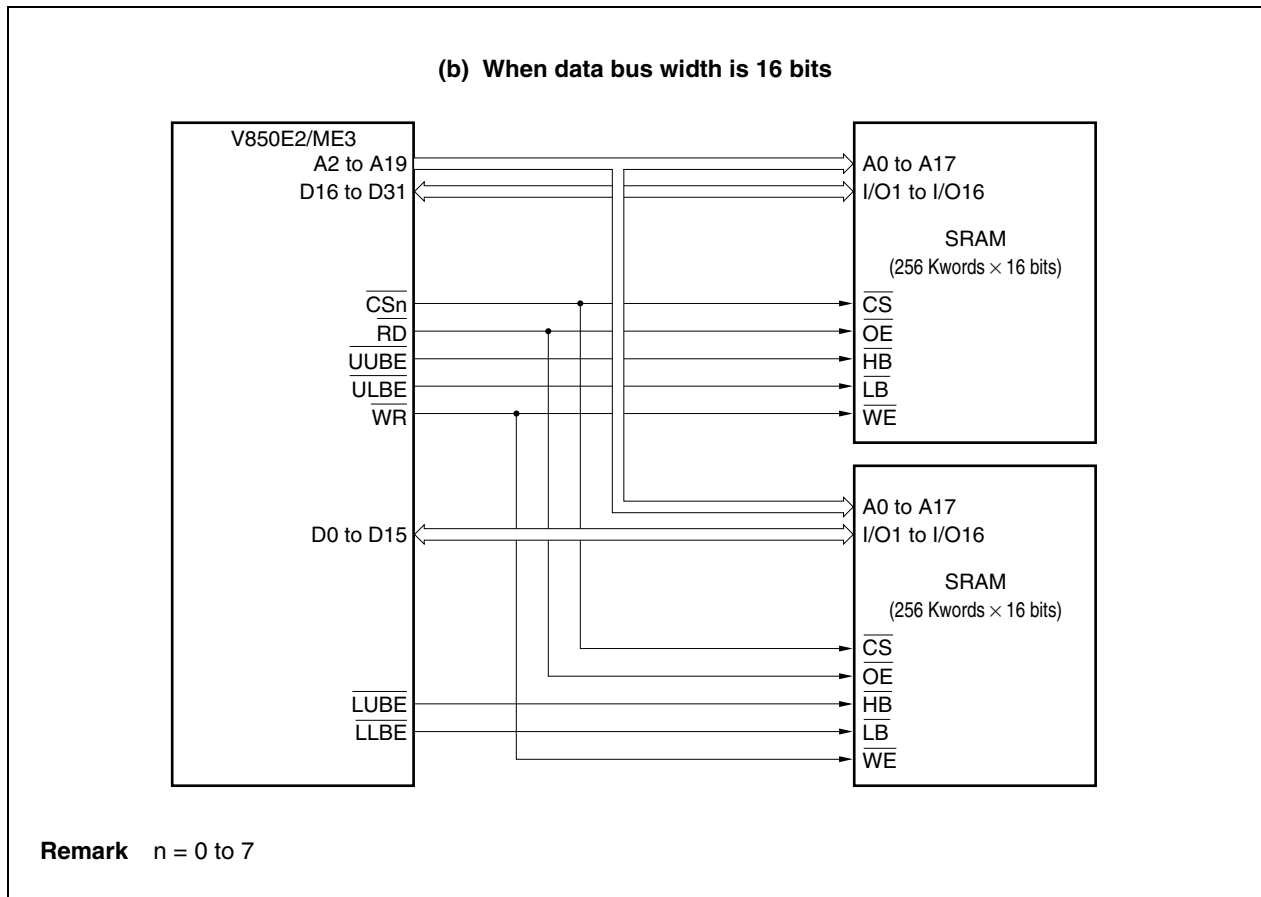

Figure 6-1. Examples of Connection to SRAM (2/2)

6.1.3 SRAM, external ROM, external I/O access

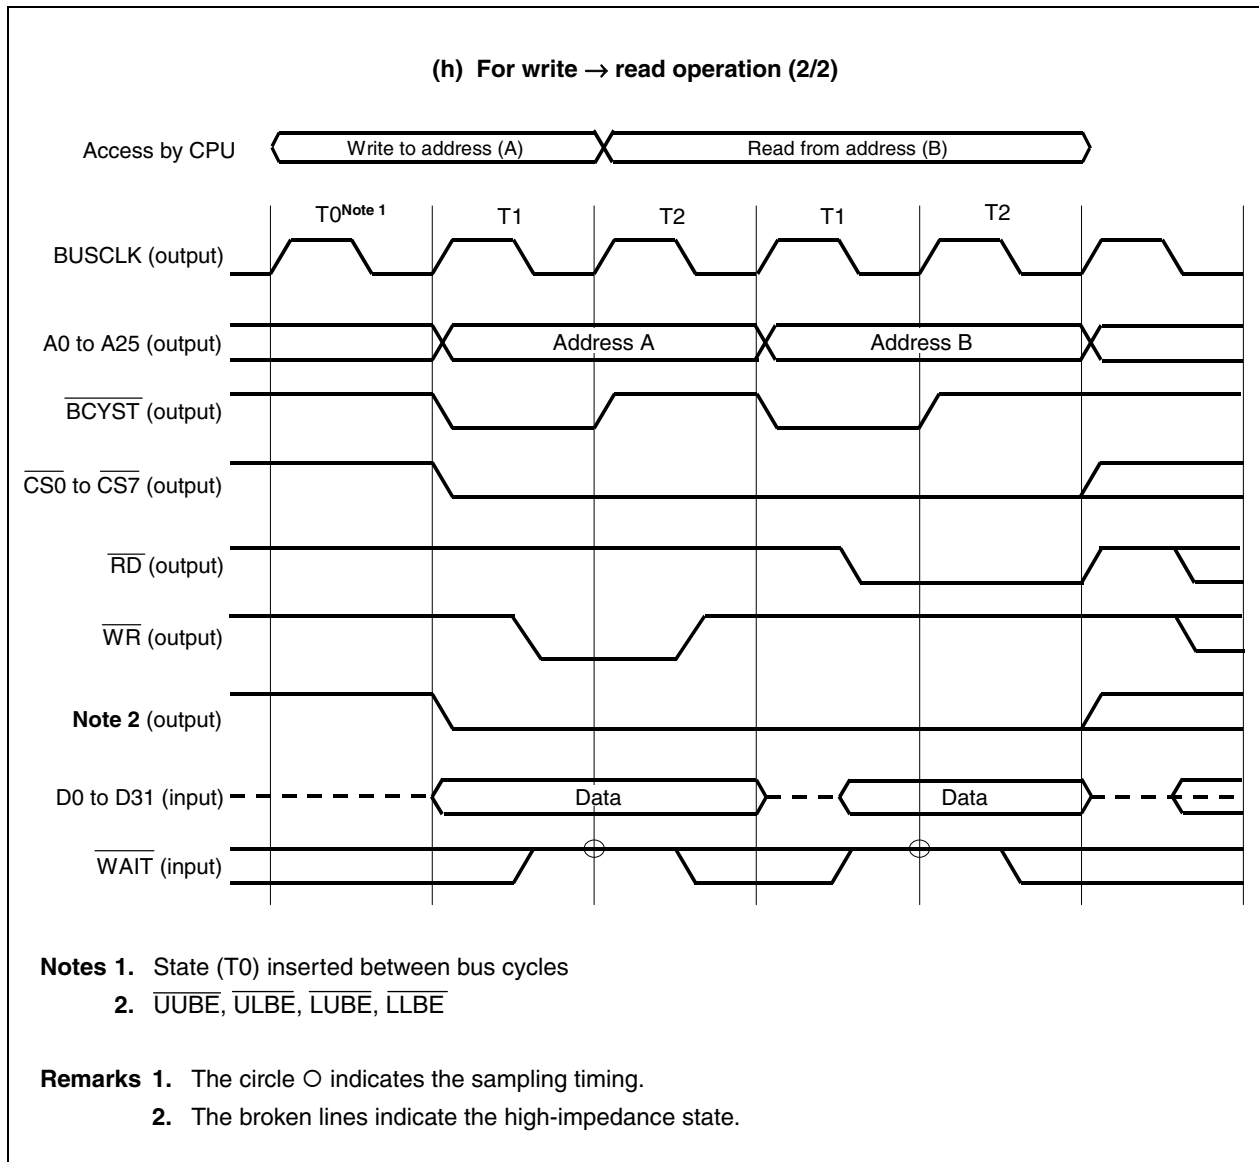

Figure 6-2. SRAM, External ROM, External I/O Access Timing (9/9)

6.2 Page ROM Controller (ROMC)

The page ROM controller (ROMC) is provided for accessing ROM (page ROM) with a page access function.

Addresses are compared with the immediately preceding bus cycle and wait control for normal access (off-page) and page access (on-page) is executed. This controller can handle page widths from 8 to 128 bytes.

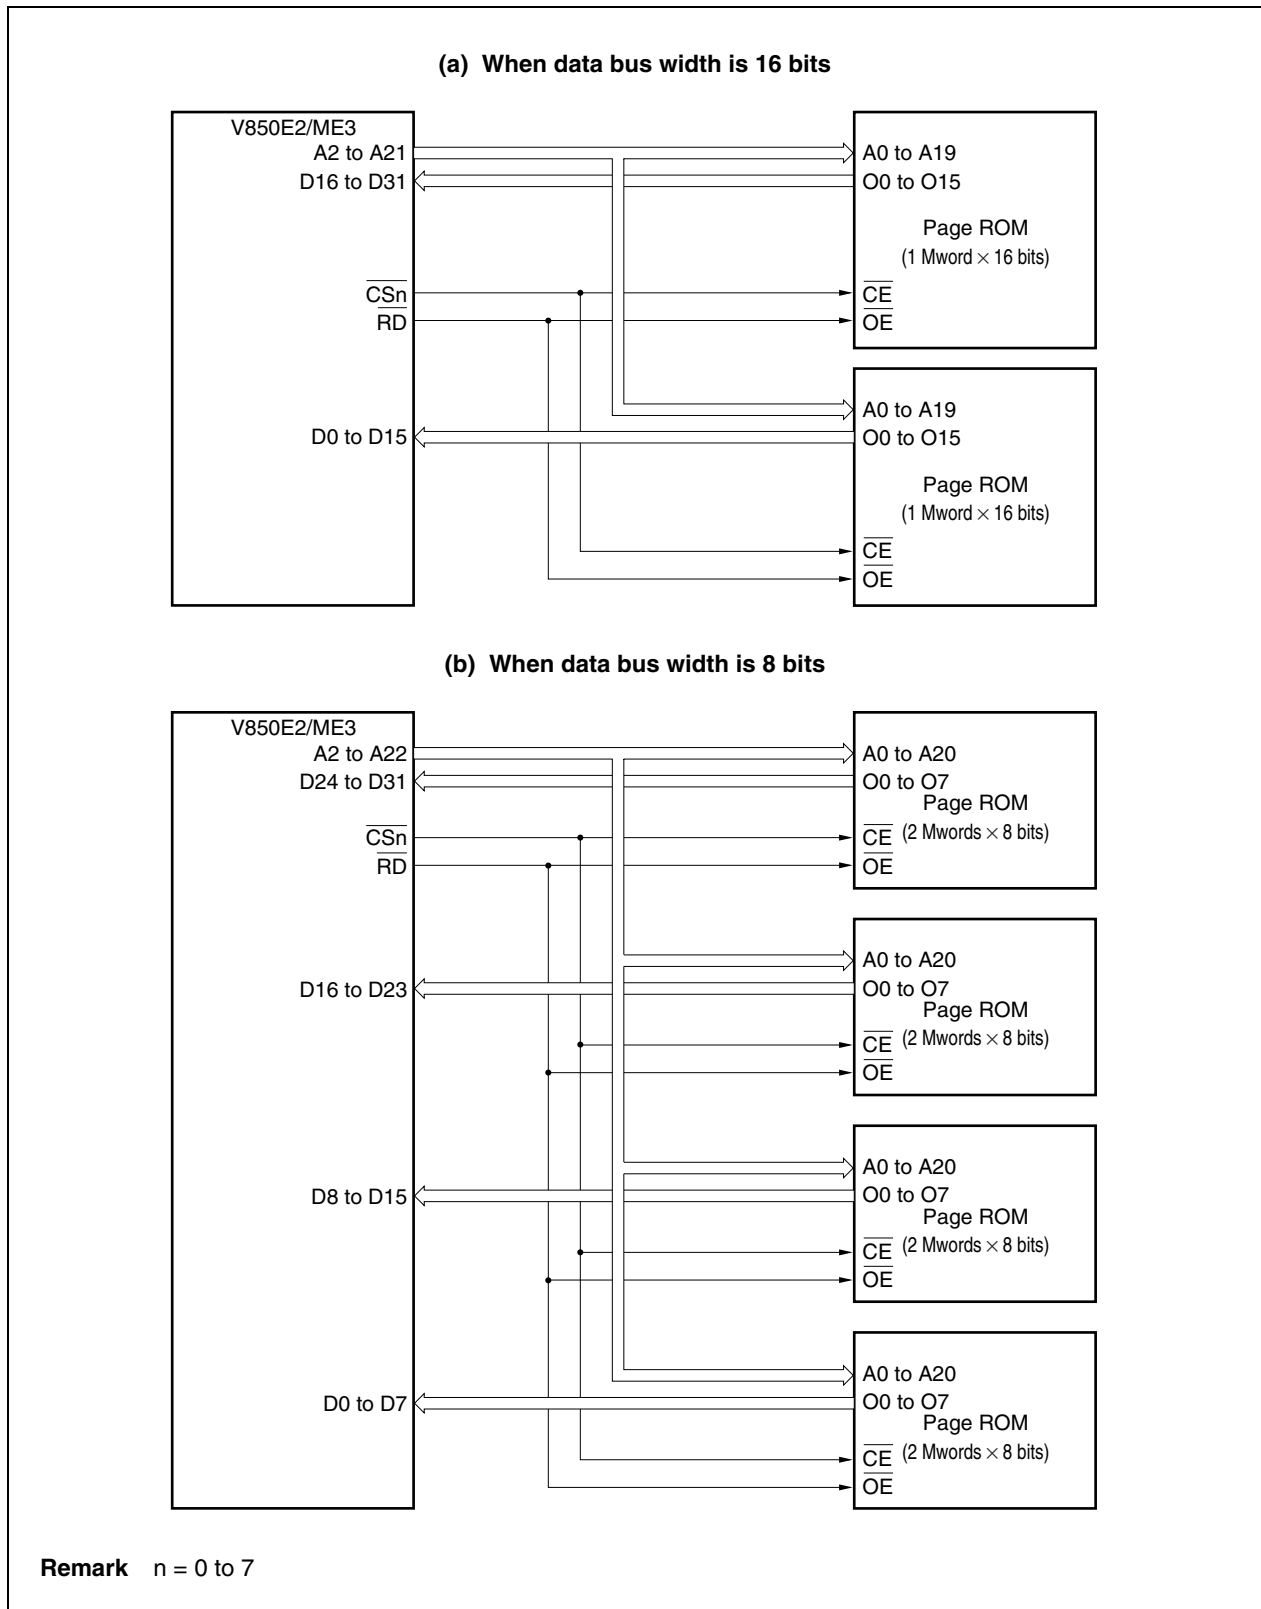

6.2.1 Features

- Direct connection to 8-bit/16-bit/32-bit page ROM supported
- For 32-bit bus width: 2/4/8/16/32-word page access supported
For 16-bit bus width: 4/8/16/32/64-word page access supported
For 8-bit bus width: 8/16/32/64/128-word page access supported
- Page ROM is accessed in a minimum of 2 states.
- On-page judgment function
- Addresses to be compared can be changed by setting the PRC register.
- Up to 7 states of programmable data waits can be inserted by setting the following registers.
 - During on-page cycle: PRC register
 - During off-page cycle: DWC0 and DWC1 registers
 - During DMA flyby cycle: FWC register
- Waits can be controlled via $\overline{\text{WAIT}}$ pin input.
- DMA flyby cycle can be activated (page ROM → external I/O)
- SRAM write cycle is started when a write cycle request is issued to a CSn space (n = 0 to 7) where page ROM is located

6.2.2 Page ROM connection

Examples of connection to page ROM are shown below.

Figure 6-3. Examples of Connection to Page ROM

6.2.3 On-page/off-page judgment

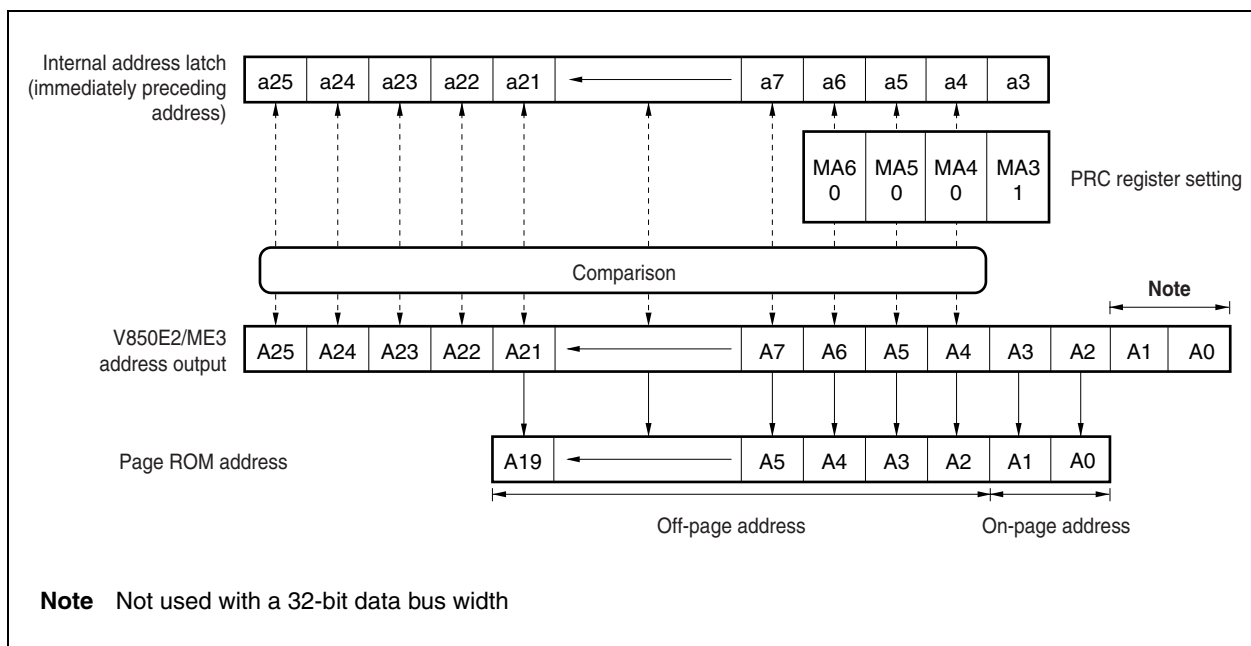

Whether a page ROM cycle is on-page or off-page is judged by latching the address of the previous cycle and comparing it with the address of the current cycle. If the use of the instruction cache is not specified, an off-page cycle is always started, except in the following cases (m = 0, 1, n = 0 to 7).

- 16/32-bit access to 8-bit bus
- 32-bit access to 16-bit bus

One of the addresses (A3 to A6) is set as the masking address (no comparison is made) according to the configuration of the connected page ROM and the number of continuously readable bits set by the PRC register.

An example of controlling address masking when four page ROMs of 1 Mword × 8 bits are connected is shown below.

Figure 6-4. Example of Control by MA6 to MA3 Bits of PRC Register

6.2.4 Page ROM configuration register (PRC)

The masking address (no comparison is made) out of the addresses (A3 to A6) corresponding to the configuration of the connected page ROM and the number of bits that can be read continuously, as well as the number of waits corresponding to f_{BUSCLK}, are set.

This register can be read or written in 16-bit units.

Caution Write to the PRC register after reset, and then do not change the set value. Also, do not access an external memory area other than the one for this initialization routine until the initial setting of the PRC register is complete. However, it is possible to access external memory areas whose initialization settings are complete.

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset

6.2.5 Page ROM access

Figure 6-5. Page ROM Access Timing (1/4)

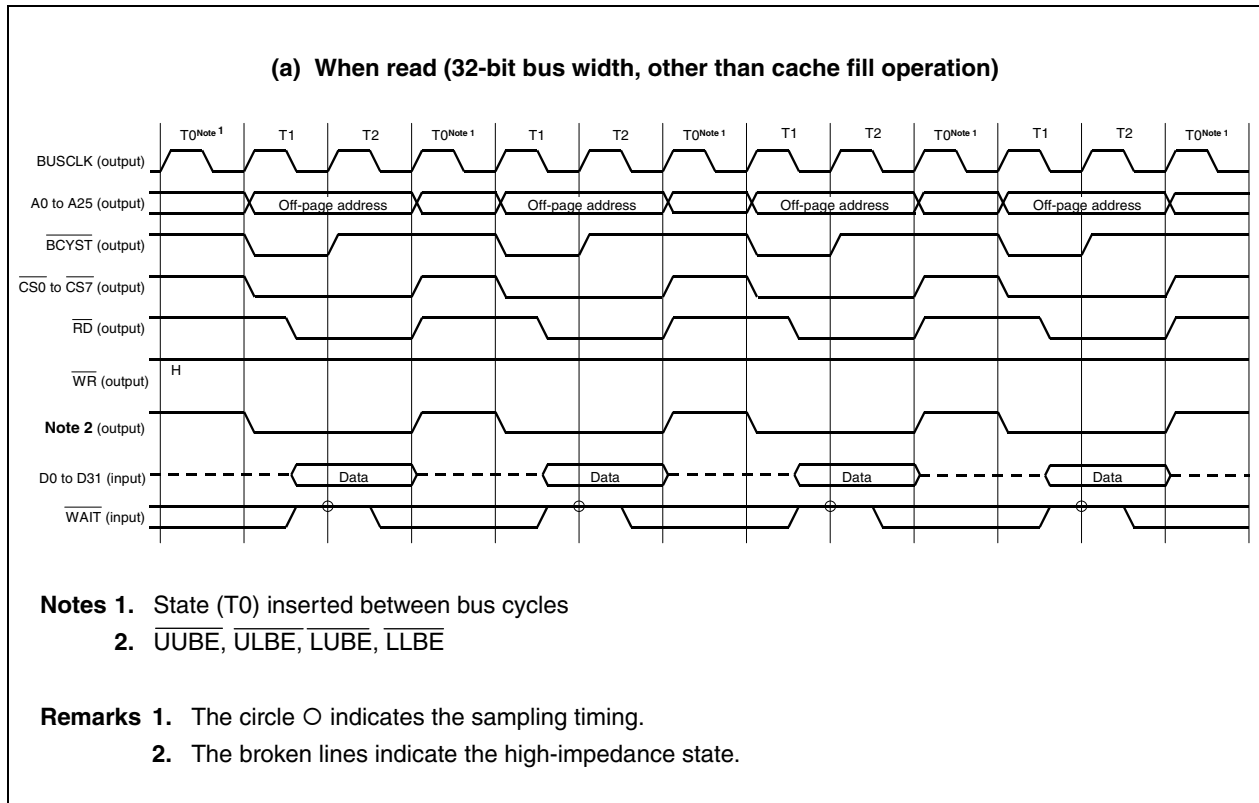

Figure 6-5. Page ROM Access Timing (2/4)

Figure 6-5. Page ROM Access Timing (3/4)

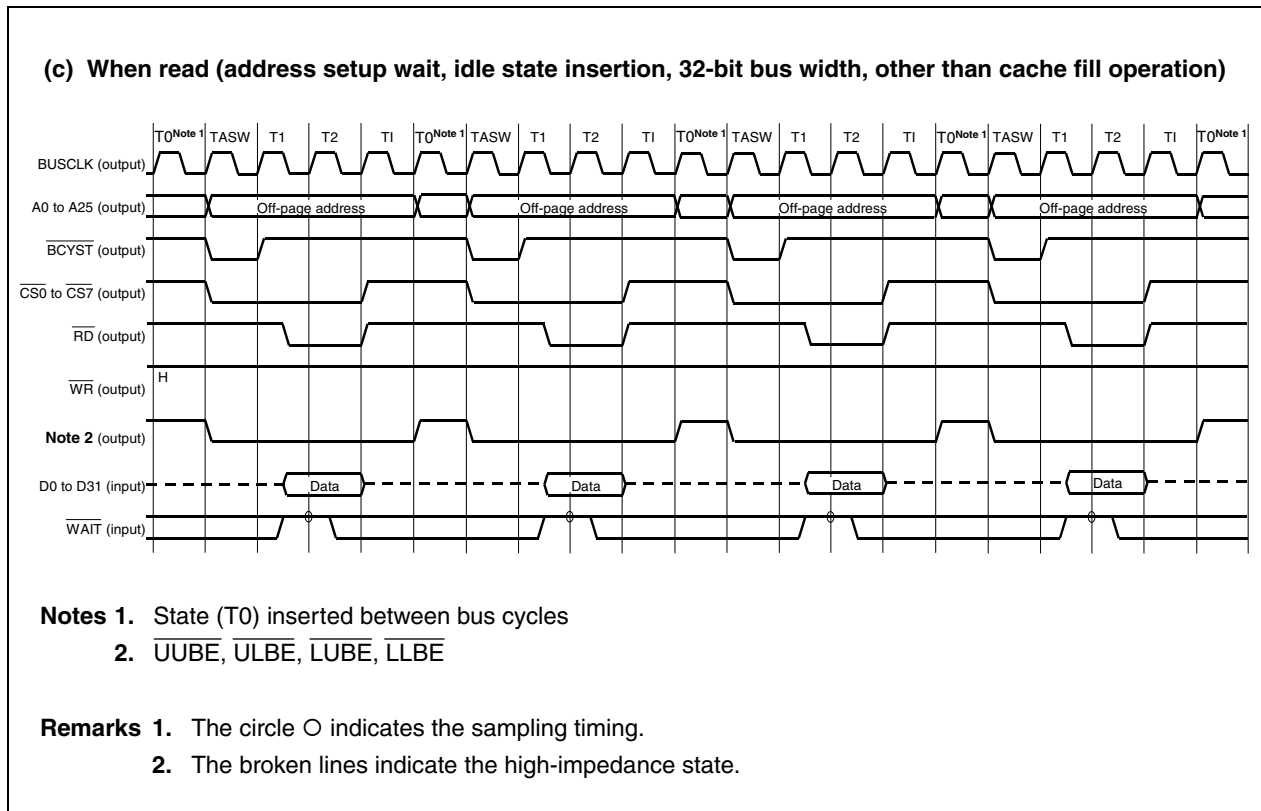

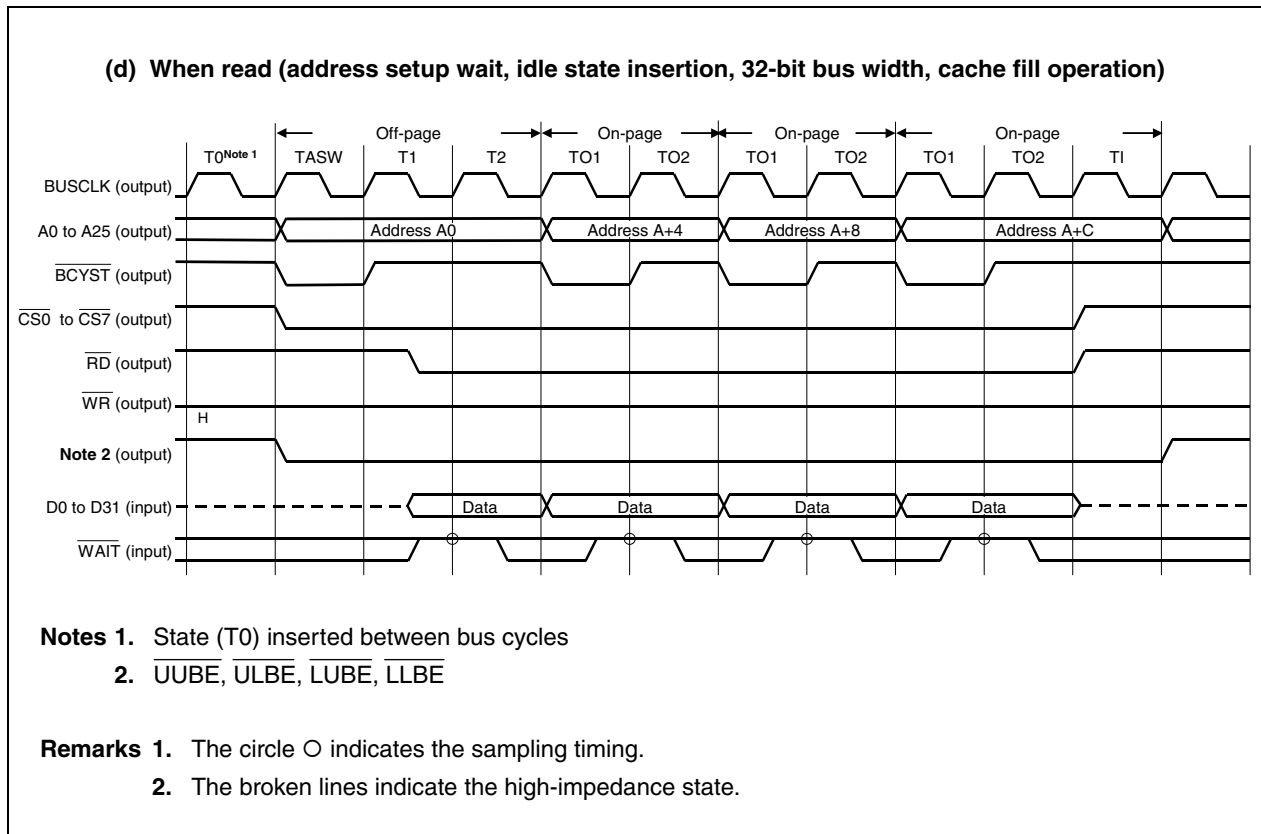

Figure 6-5. Page ROM Access Timing (4/4)

6.3 SDRAM Controller (SDRAMC)

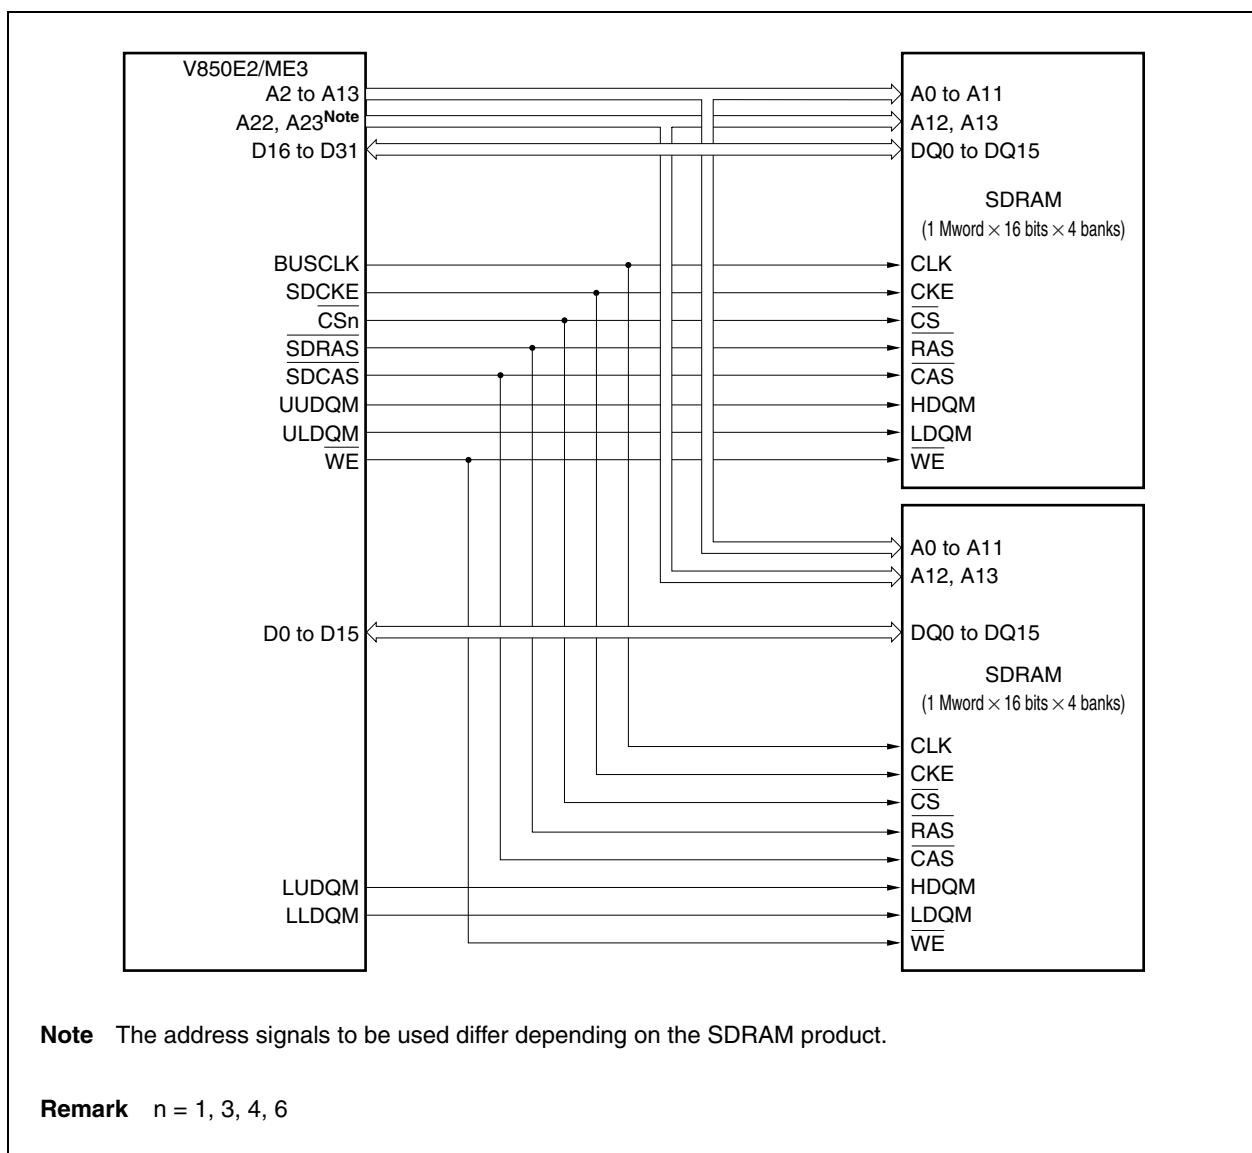

6.3.1 Features

- Burst length: 1
- Wrap type: Sequential
- CAS latency: 1, 2, and 3 supported (only 2 and 3 supported during DMA flyby transfer)
- 4 types of SDRAM can be assigned to 4 areas.
- Row and column address multiplex widths can be changed.
- Waits (0 to 3 waits) can be inserted between the bank active command and the read/write command.
- Supports CBR (automatic) refresh and self-refresh.
- DMA flyby cycle (from external I/O to SDRAM) can be activated.

6.3.2 SDRAM connection

An example of connection to SDRAM is shown below.

Figure 6-6. Example of Connection to SDRAM

6.3.3 Address multiplex function

Depending on the value of the SCRn.SAWn0 and SCRn.SAWn1 bits, the row address output in the SDRAM cycle is multiplexed as shown in Figure 6-7 (a) (n = 1, 3, 4, 6). Depending on the value of the SSOOn0 and SSOOn1 bits, the column address output in the SDRAM cycle is multiplexed as shown in Figure 6-7 (b) (n = 1, 3, 4, 6). In Figures 6-7 (a) and (b), a0 to a25 indicate the addresses output from the CPU, and A0 to A25 indicate the address pins of the V850E2/ME3.

Figure 6-7. Row Address/Column Address Output (1/2)

(1) Output of each address and connection of SDRAM

The set contents of the SCRn register, physical address, address output from the V850E2/ME3, and connection between the V850E2/ME3 and SDRAM at each data bus width (8 bits or 16 bits) are described below.

(a) At 8-bit data bus width

An example of connecting 64 Mb SDRAM (2 Mwords × 8 bits × 4 banks) at 8-bit data bus width is shown below.

- Set contents of SCRn register
 SSON1, SSON0 bits = 00: Data bus width = 8 bits
 RAWn1, RAWn0 bits = 01: Row address width = 12 bits
 SAWn1, SAWn0 bits = 01: Column address width = 9 bits
- Physical address
 A22, A21: Bank address
 A20 to A9: Row address
 A8 to A0: Column address
- Address output from V850E2/ME3
 A22, A21: Bank address
 A11 to A0: Row address (12 bits), column address (9 bits)

- Connection of V850E2/ME3 and SDRAM
 A22, A21 (V850E2/ME3) → BA0 (A13), BA1 (A12) (SDRAM)
 A11 to A0 (V850E2/ME3) → A11 to A0 (SDRAM)

(2) Bank address output

The V850E2/ME3 precharges a bank to access by using a bank precharge command when a row address is output immediately after page change. After bank change, it precharges the bank previously accessed when a column address is output. Therefore, a bank is precharged both when a row address is output and when a column address is output. To connect SDRAM with the contents described in **6.3.3 (1) (a) At 8-bit data bus width**, always connect the pins (A22 and A21) of the V850E2/ME3 that outputs bank addresses to the bank address pins (A13 and A12) of SDRAM.

An example of address output by the bank precharge command when the page or bank is changed if SDRAM is connected with the contents described in **6.3.3 (1) (a) At 8-bit data bus width** is shown below.

(a) When page is changed (at 8-bit data bus width)

When the page is changed, the precharge command outputs the physical addresses to be accessed (a20 and a18 to a9) to the A11 and A9 to A0 pins, and the bank addresses to be accessed (a22 and a21) to the A22 and A21 pins.

(b) When bank is changed (at 8-bit data bus width)

When the bank is changed, the bank precharge command outputs the physical addresses to be accessed (a8 to a0) to the A8 to A0 pins, and the bank addresses previously accessed (a22 and a21) to the A22 and A21 pins.

The bits that determine the precharge mode (A10: 8-bit data bus width, A11: 16-bit data bus width, A12: 32-bit data bus width) output a high level when the all bank precharge command is executed, and a low level when any other command is executed for precharging.

6.3.4 SDRAM configuration registers 1, 3, 4, 6 (SCR1, SCR3, SCR4, SCR6)

These registers specify the number of waits and the address multiplex width. The SCRn register corresponds to \overline{CSn} (n = 1, 3, 4, 6). For example, to connect SDRAM to $\overline{CS1}$, set SCR1. These registers can be read or written in 16-bit units.

- Cautions 1. An SDRAM read/write cycle is not generated prior to executing a register write operation. Access SDRAM after reading the value of the SCRn register and confirming that the WCFn bit is set to 1.**
- 2. To write to the SCRn register again following access to SDRAM, clear the MEn bit of the BCT0 and BCT1 registers to 0, and then set it to 1 again before performing access (n = 0 to 6).**
 - 3. Do not execute continuous instructions to write to the SCRn register. Be sure to insert another instruction between commands to write to the SCRn register.**
 - 4. Start accessing SDRAM after all the SCRn registers have been set. Set the RFSn register before setting the SCRn register (n = 1, 3, 4, 6).**

Remark n = 1, 3, 4, 6

6.3.5 SDRAM access

During power-on or a refresh operation, the all-bank precharge command is always issued for SDRAM. When accessing SDRAM after that, therefore, the active command and read/write command are issued in that order (see <1> in Figure 6-8).

If a page change occurs following this, the precharge command, active command, and read/write command are issued in that order (see <2> in Figure 6-8).

If a bank change occurs, the active command and read/write command for the bank to be accessed next are issued in that order. Following this read/write command, the precharge command for the bank that was accessed before the bank currently being accessed will be issued (see <3> in Figure 6-8).

Figure 6-8. State Transition of SDRAM Access

(1) SDRAM single read cycle

The SDRAM single read cycle is a cycle for reading from SDRAM by executing a load instruction (LD) for the SDRAM area, by fetching an instruction, or by 2-cycle DMA transfer.

In the SDRAM single read cycle, the active command (ACT) and read command (RD) are issued to SDRAM in that order. During on-page access, however, only the read command is issued and the precharge command and active command are not issued. When a page change occurs in the same bank, the precharge command (PRE) is issued before the active command.

A one-state T0 cycle is always inserted immediately before all read commands activated by the CPU.

The number of idle states (TI) set by the BCC register are inserted after the read cycle (no idle states are inserted, however, if the BCn1 and BCn0 bits are 00) (n = 1, 3, 4, 6). The timing charts of the SDRAM single read cycle are shown below.

Caution When executing a write access to SRAM or external I/O after read accessing SDRAM, data conflict may occur depending on the SDRAM data output float delay time. In such a case, avoid data conflict by inserting an idle state in the SDRAM space via a setting in the BCC register.

Figure 6-9. SDRAM Single Read Cycle (1/5)

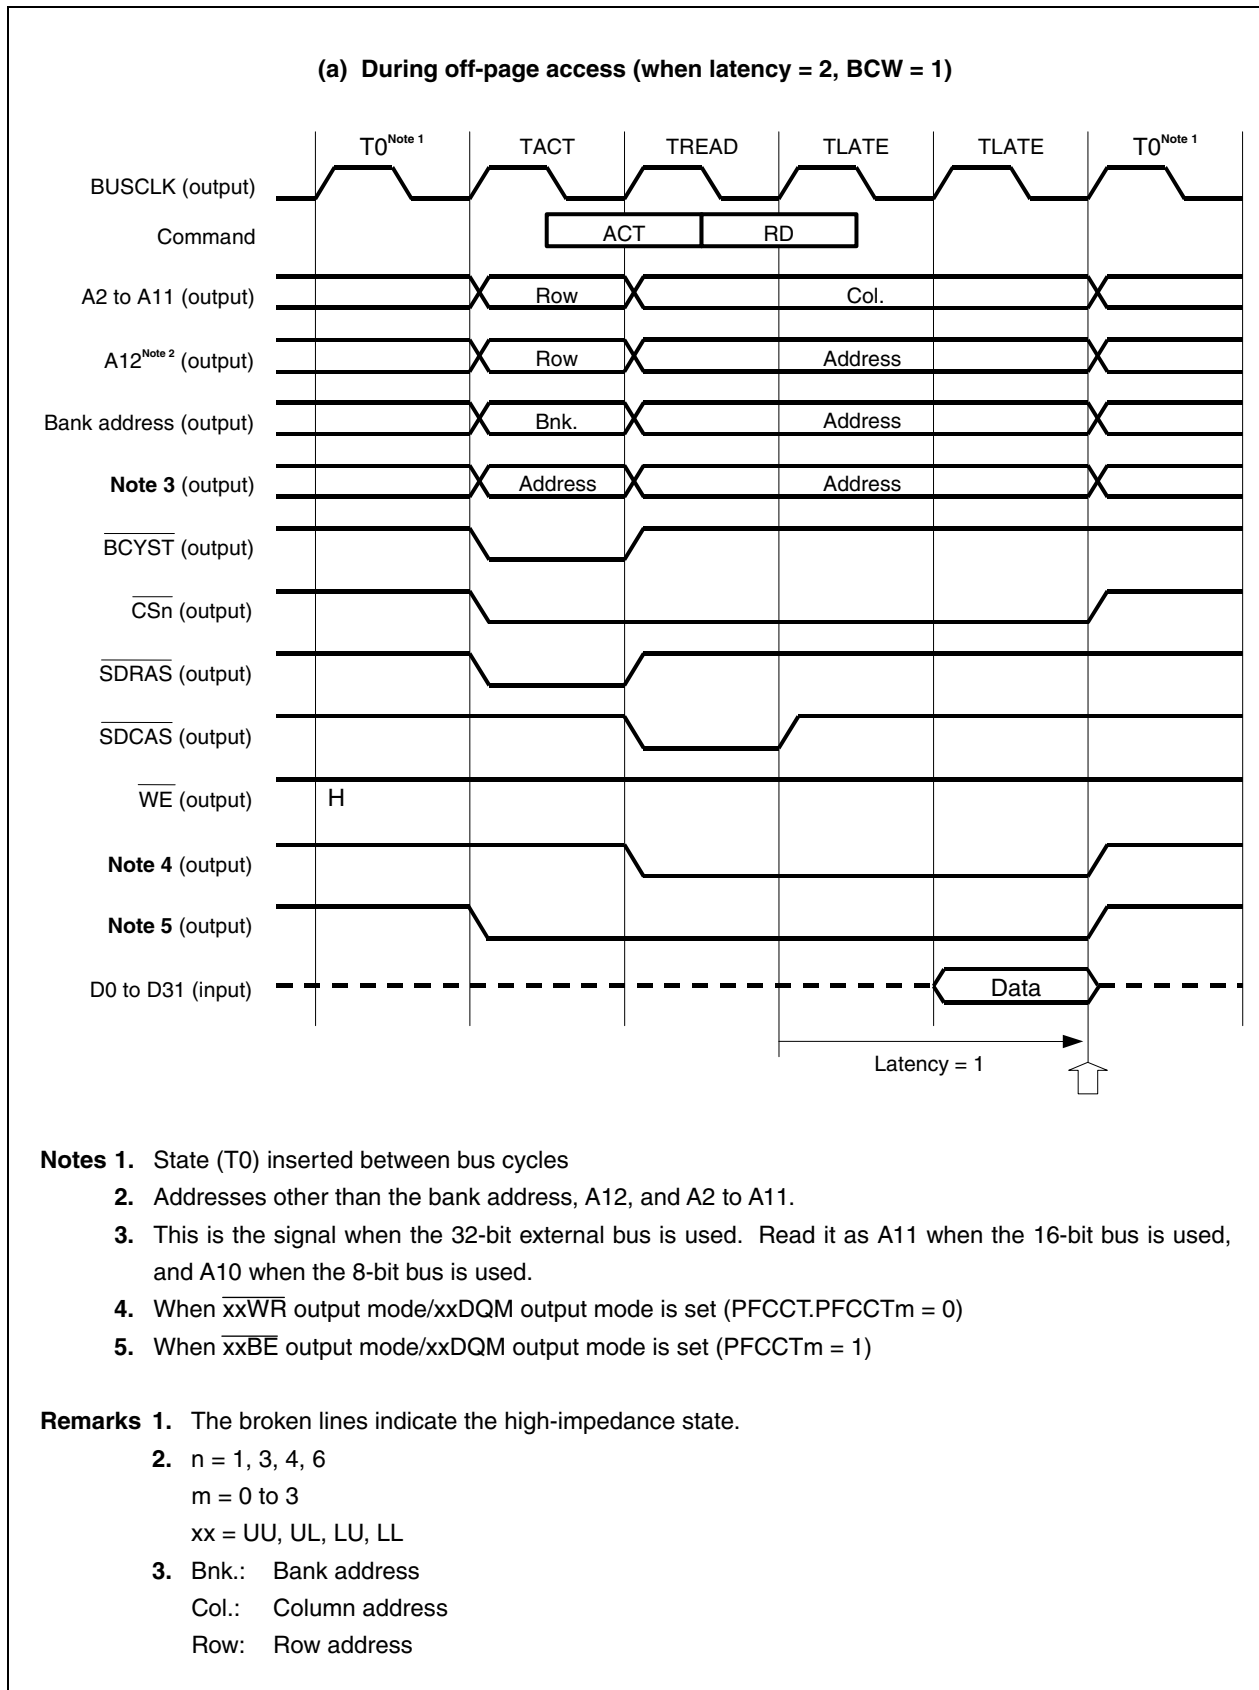

Figure 6-9. SDRAM Single Read Cycle (2/5)

Figure 6-9. SDRAM Single Read Cycle (3/5)

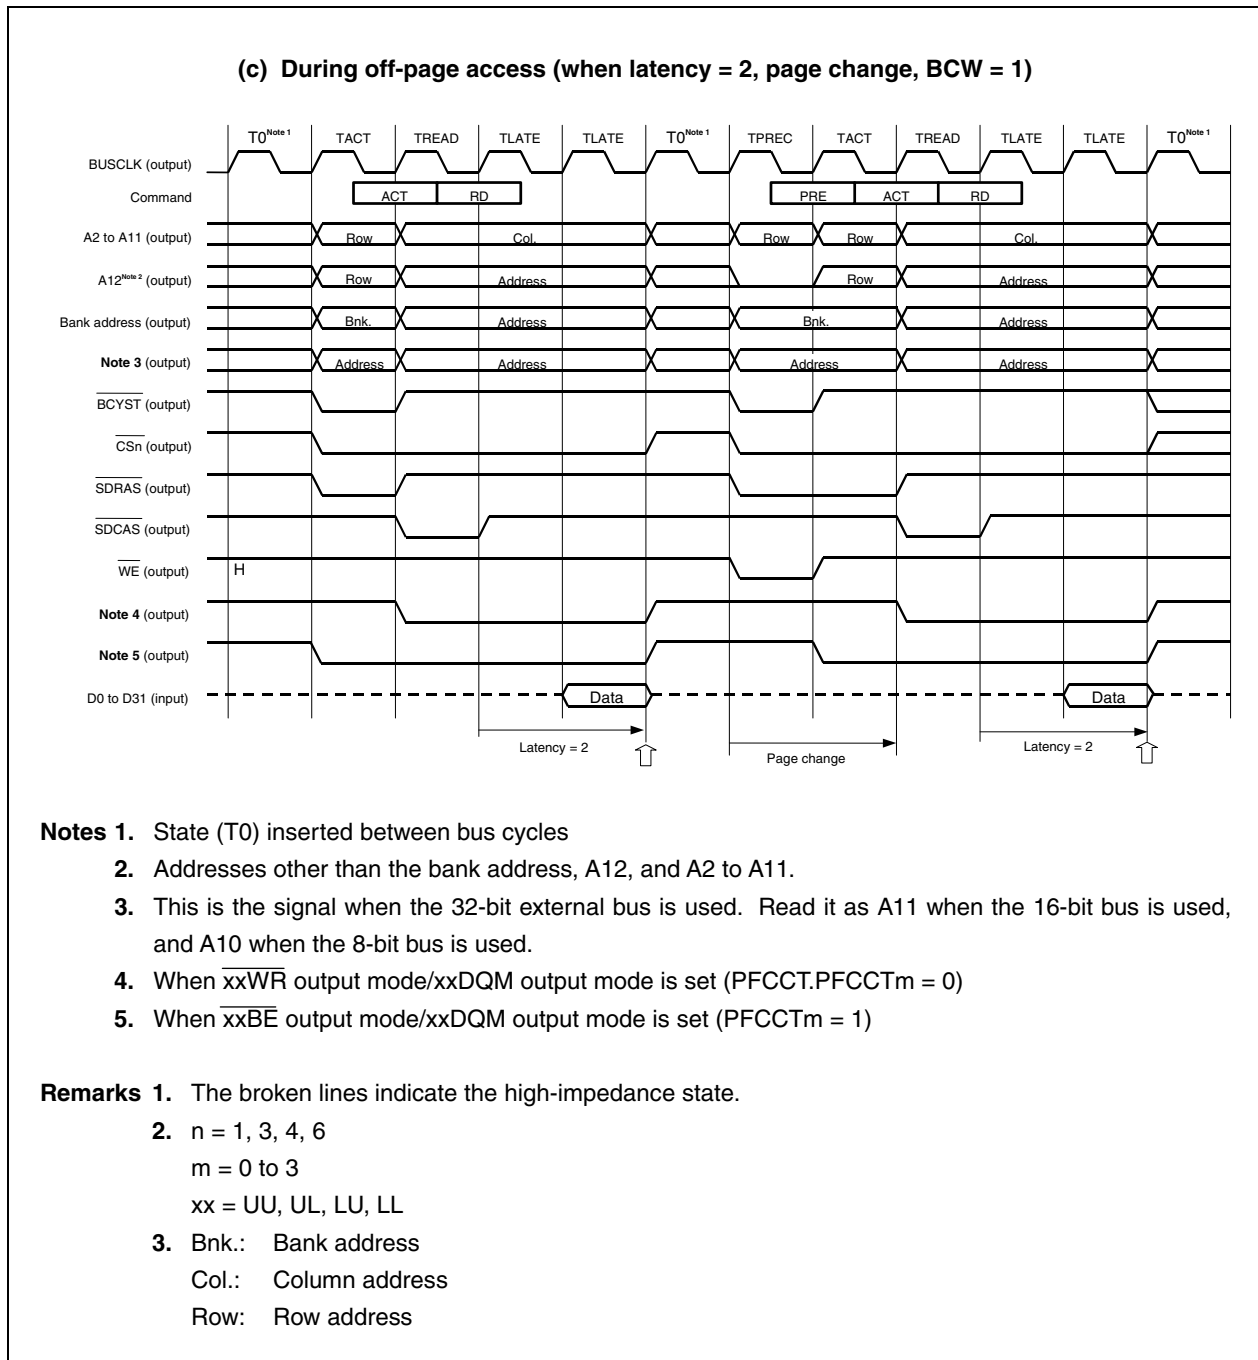

Figure 6-9. SDRAM Single Read Cycle (4/5)

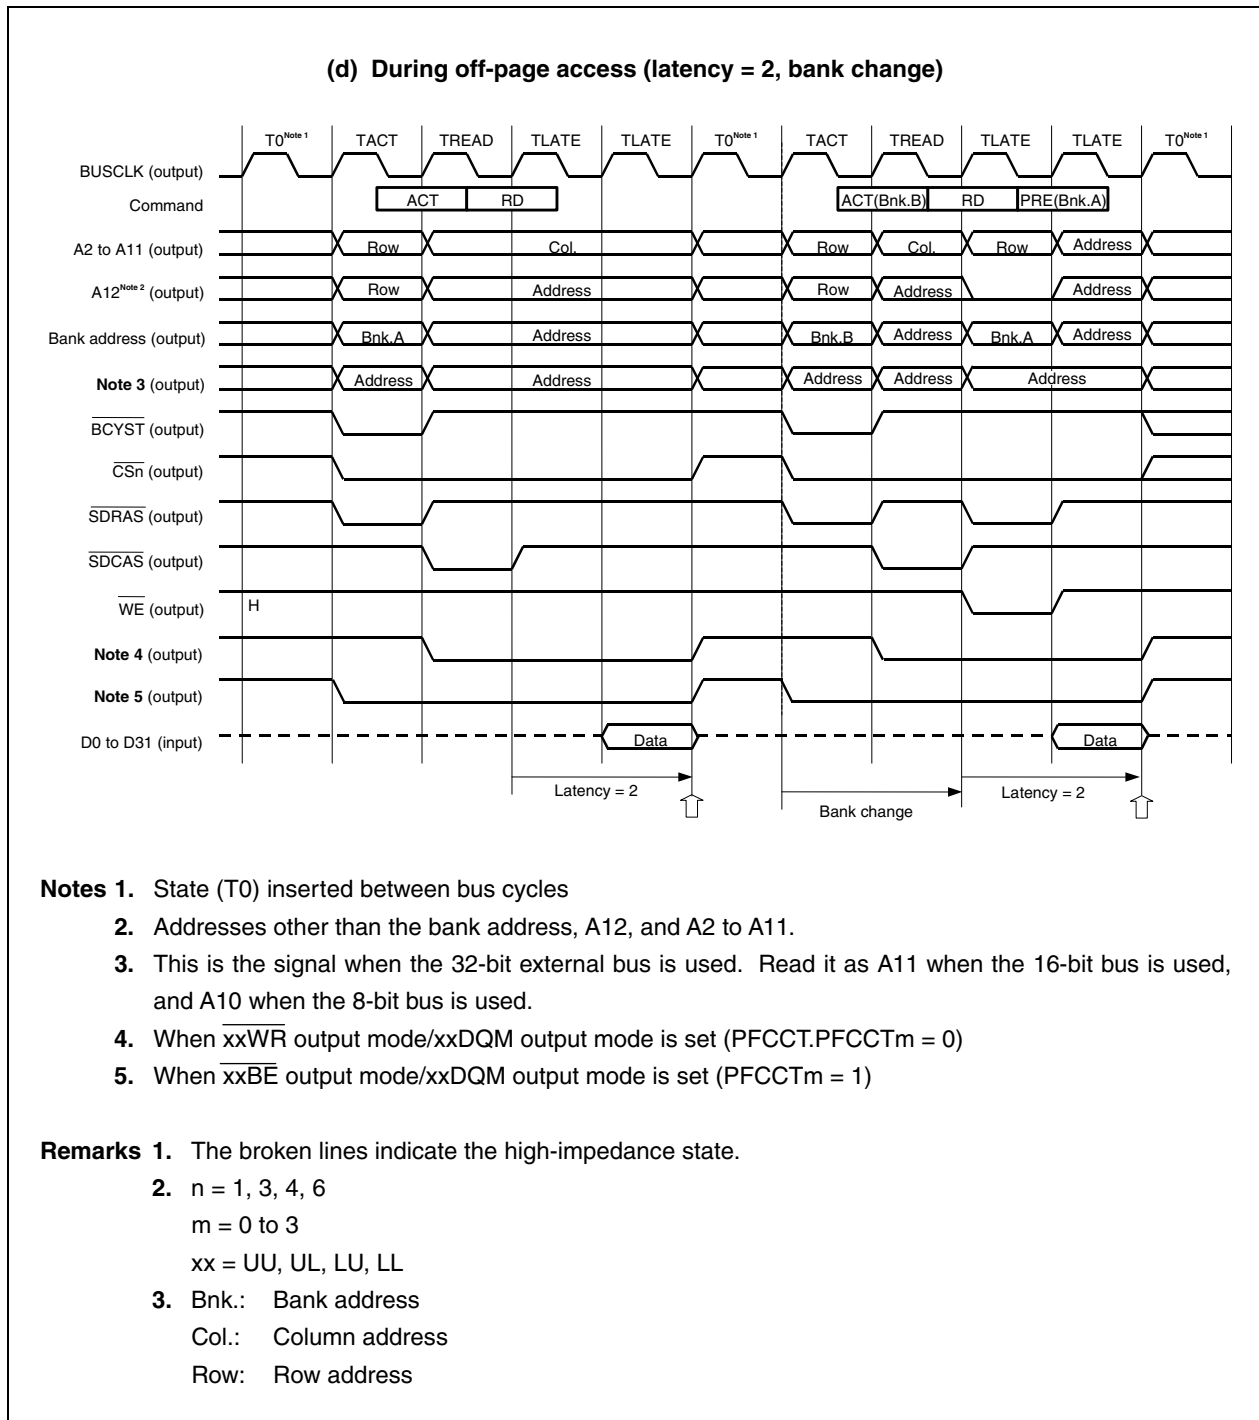

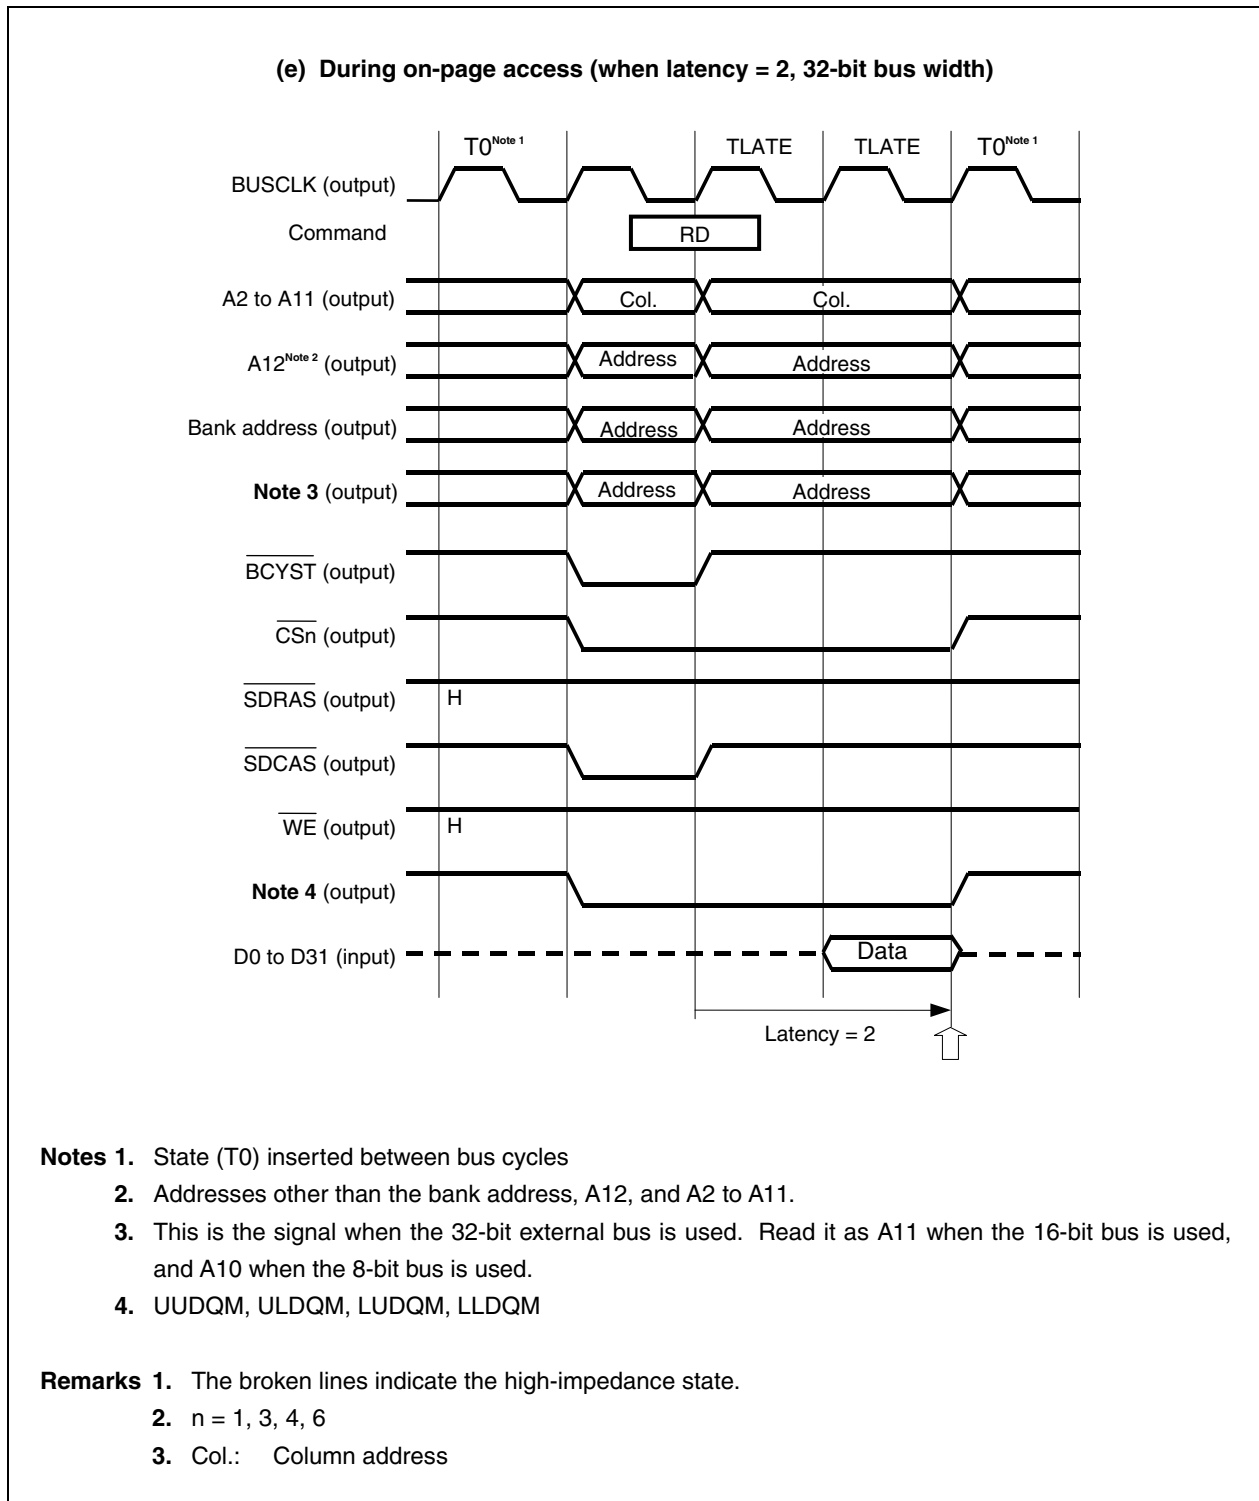

Figure 6-9. SDRAM Single Read Cycle (5/5)

(2) SDRAM single write cycle

The SDRAM single write cycle is a cycle for writing to SDRAM by executing a write instruction (ST) for the SDRAM area or by 2-cycle DMA transfer.

In the SDRAM single write cycle, the active command (ACT) and write command (WR) are issued to SDRAM in that order. During on-page access, however, only the write command is issued and the precharge command and active command are not issued. When a page change occurs in the same bank, the precharge command (PRE) is issued before the active command.

The timing charts of the SDRAM single write cycle are shown below.

Figure 6-10. SDRAM Single Write Cycle (1/6)

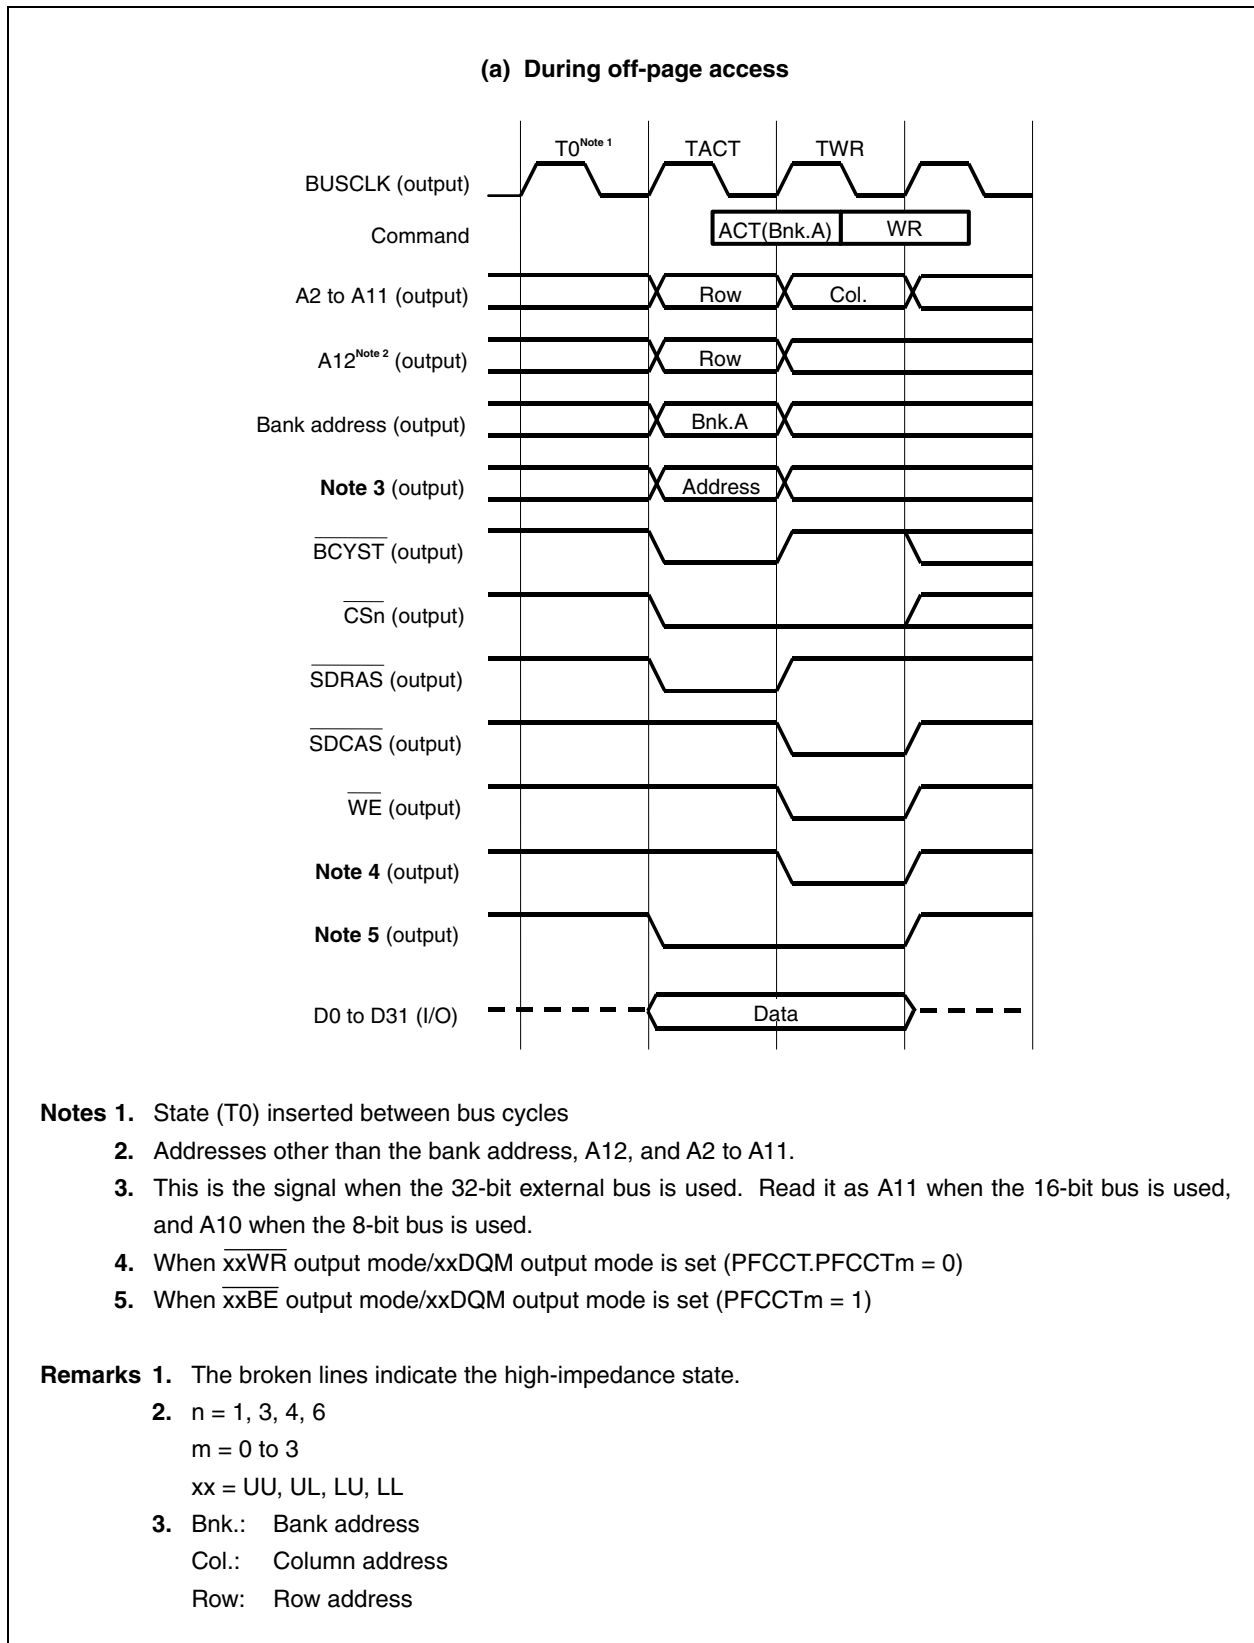

Figure 6-10. SDRAM Single Write Cycle (2/6)

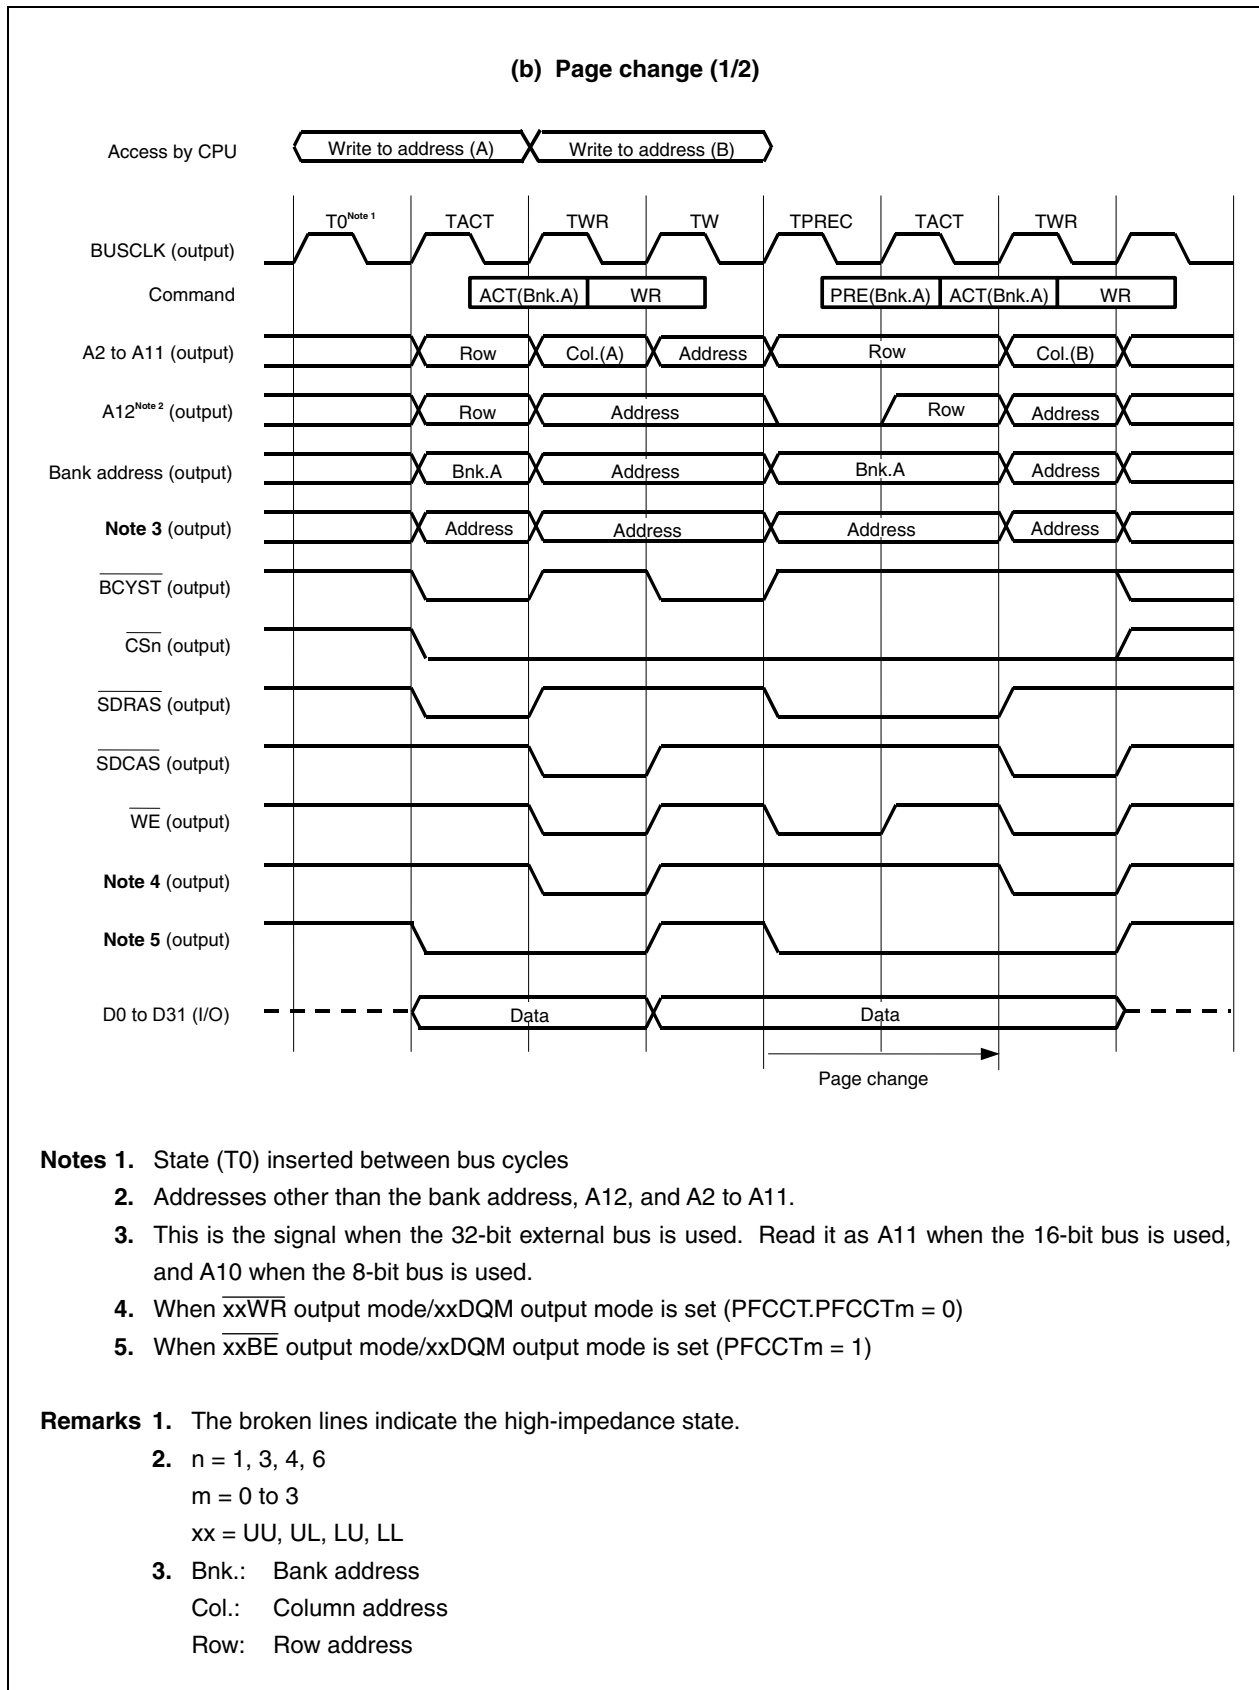

Figure 6-10. SDRAM Single Write Cycle (3/6)

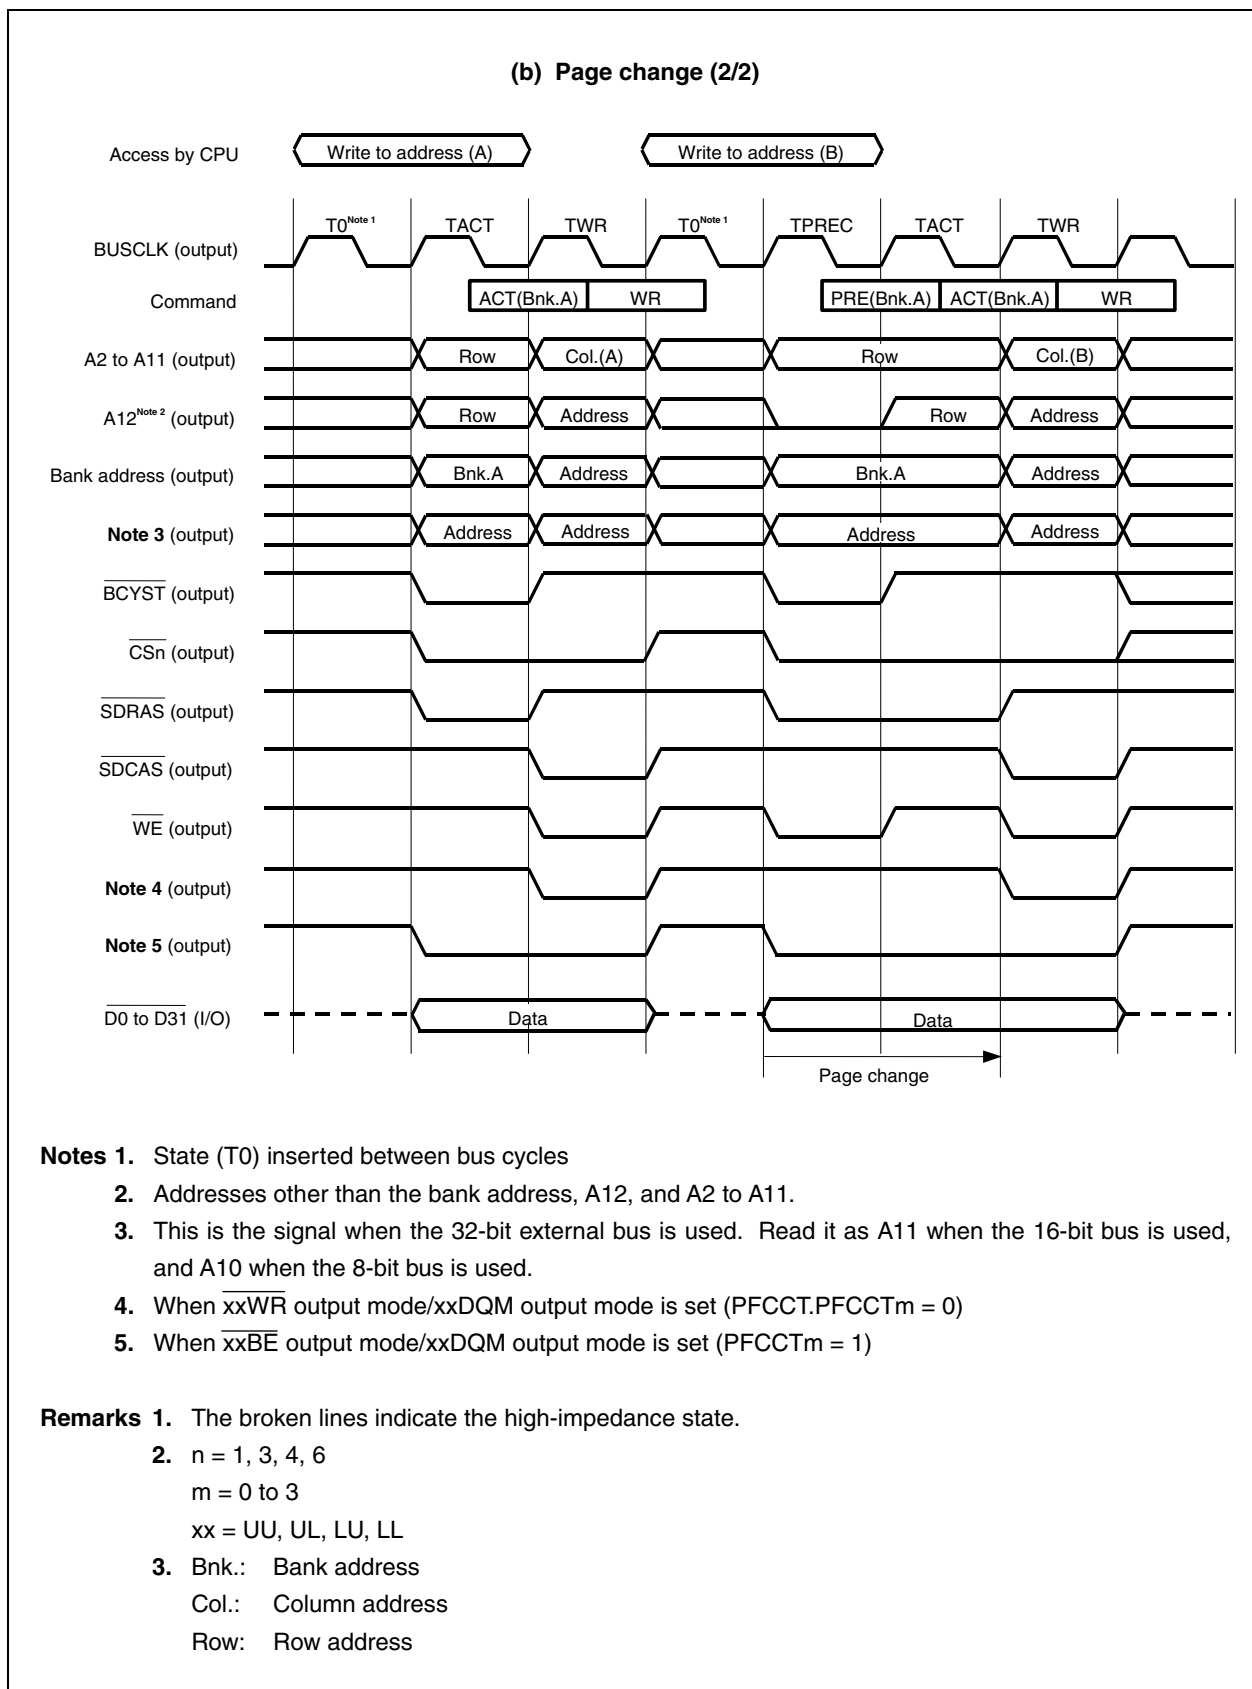

Figure 6-10. SDRAM Single Write Cycle (4/6)

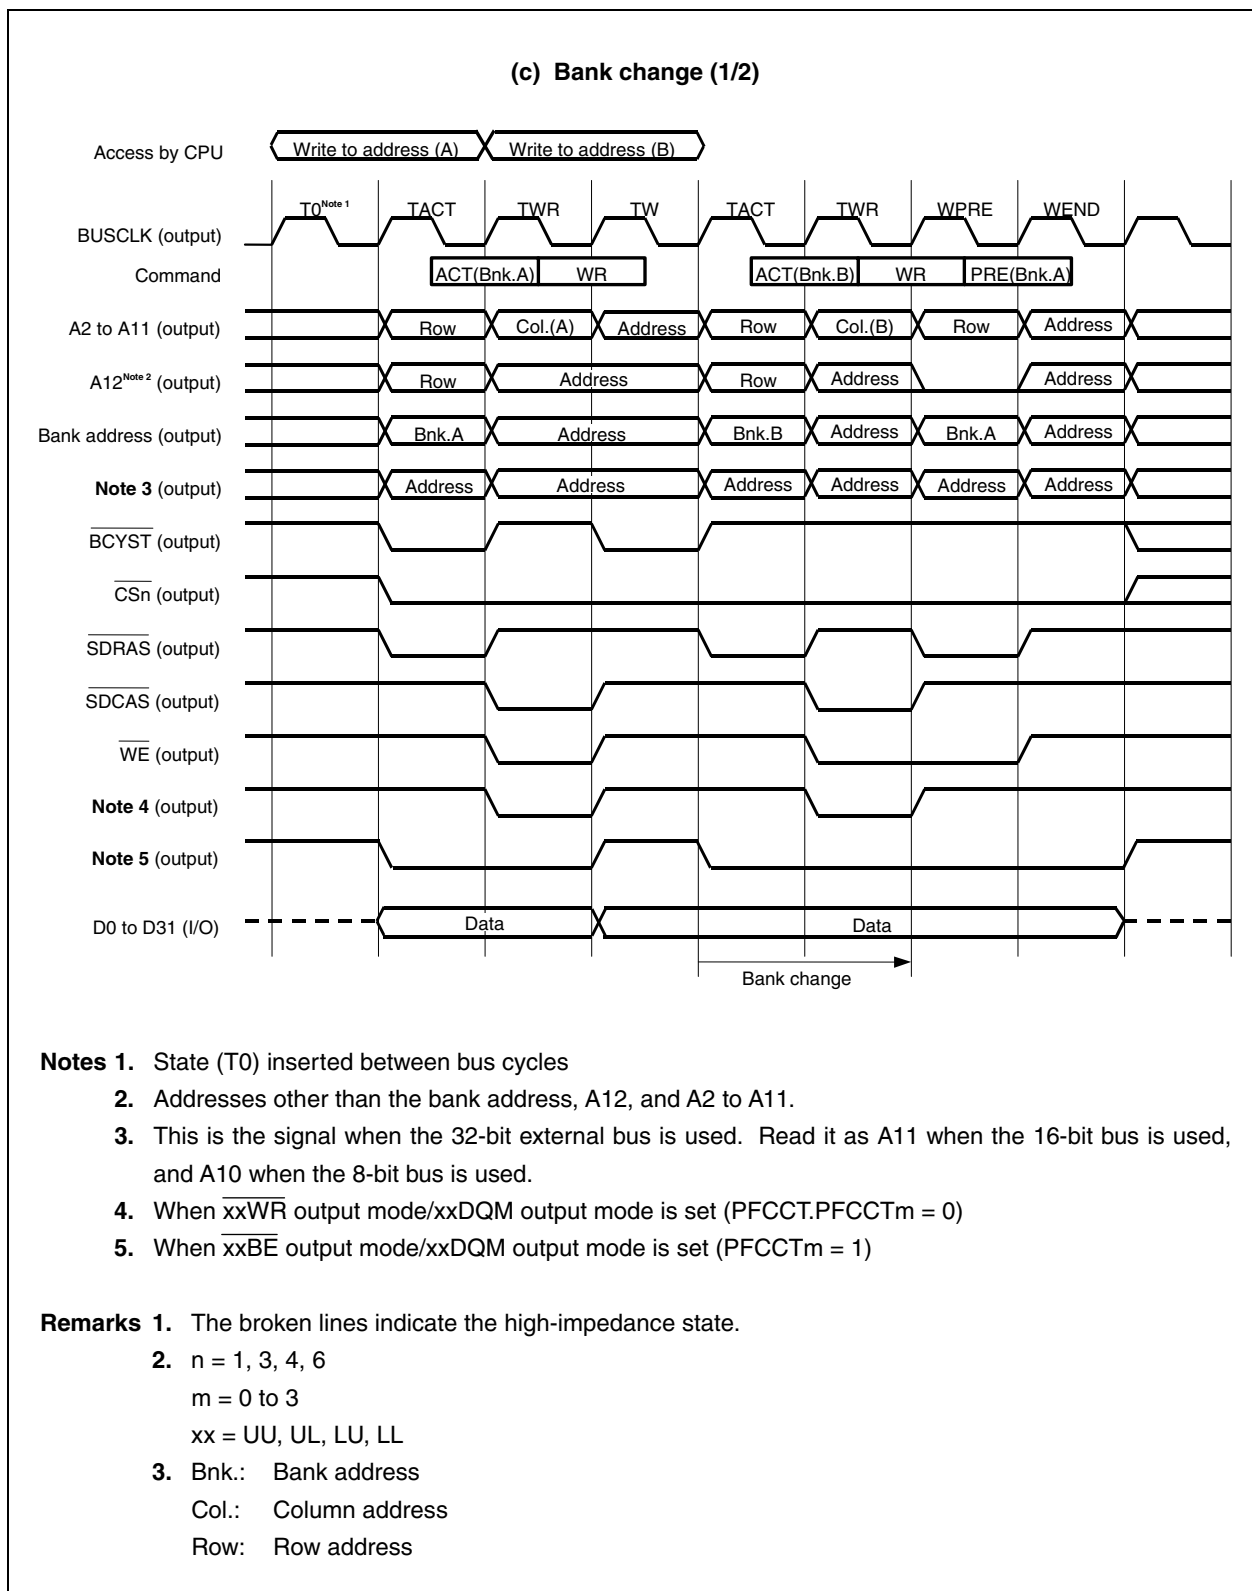

Figure 6-10. SDRAM Single Write Cycle (5/6)

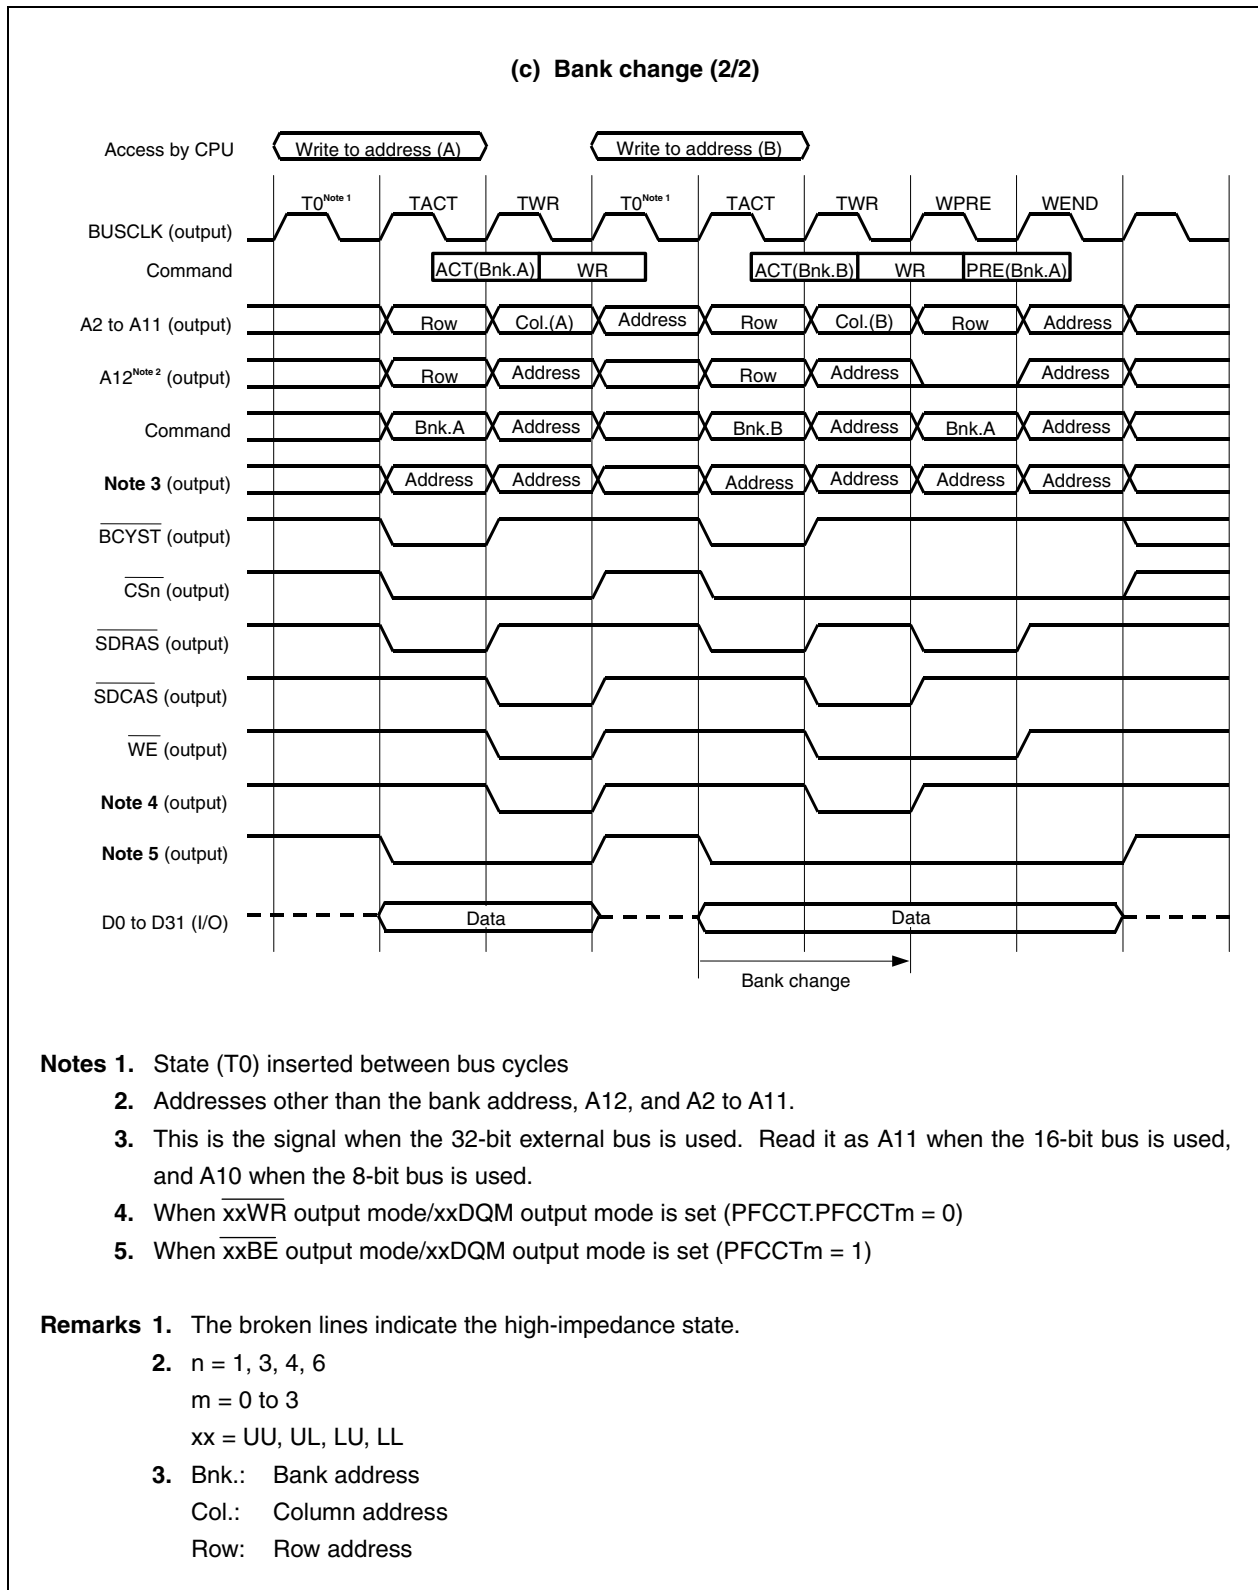

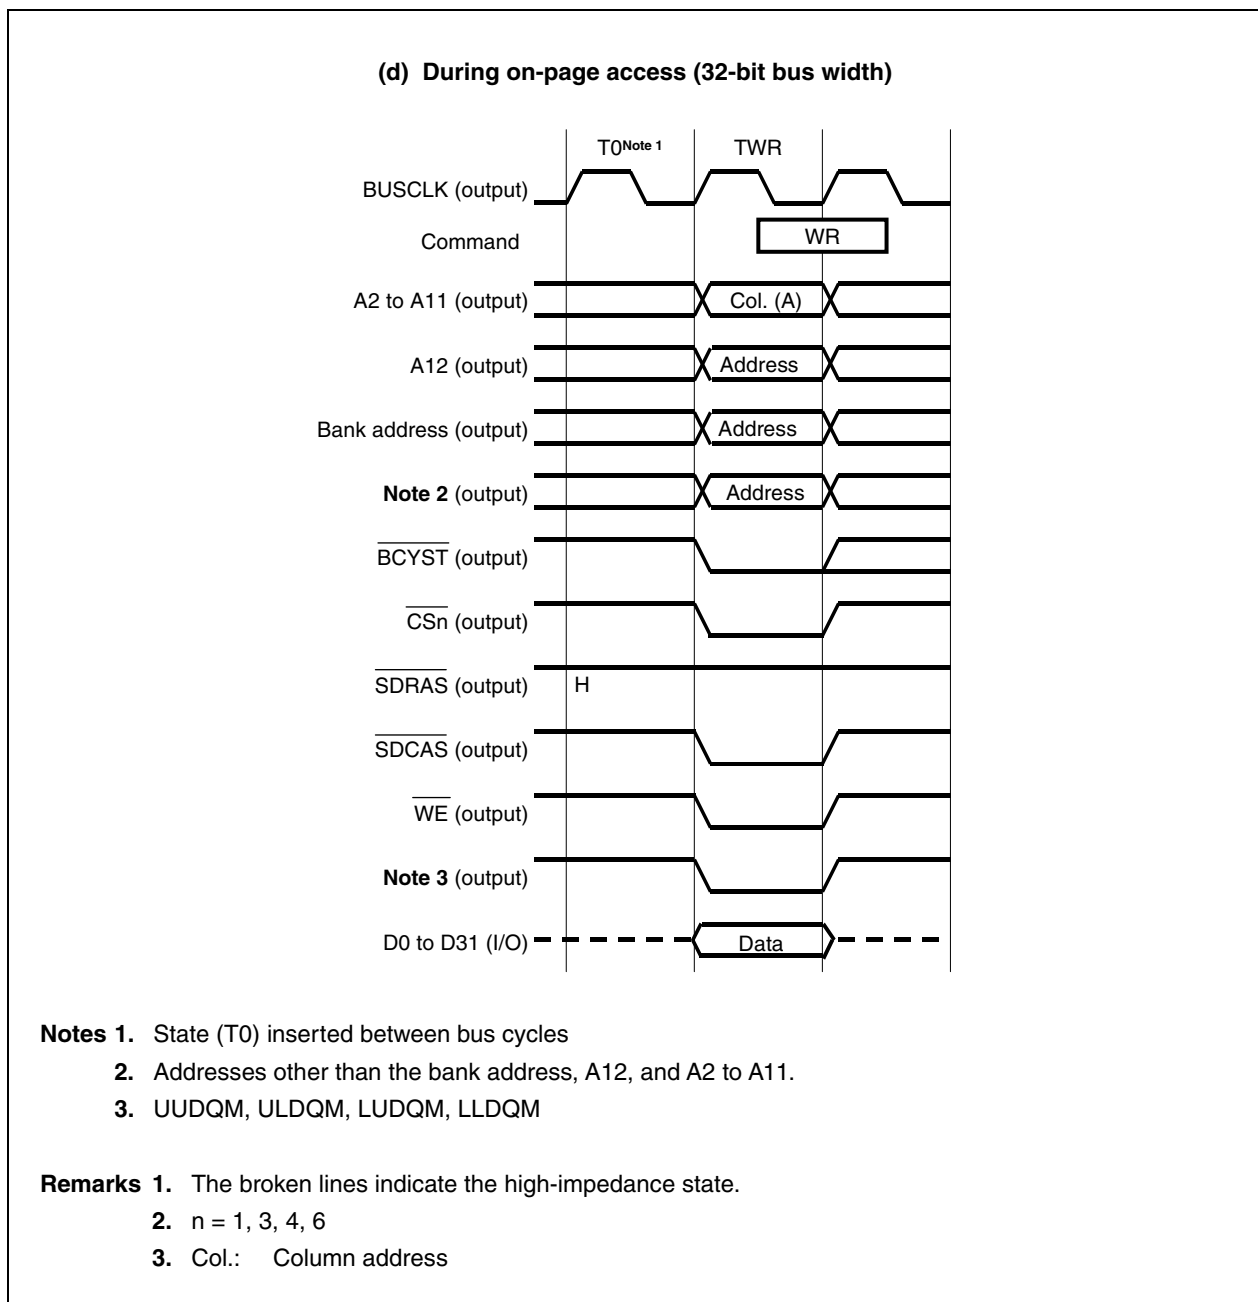

Figure 6-10. SDRAM Single Write Cycle (6/6)

(3) SDRAM access timing control

The SDRAM access timing can be controlled by the SCRn register (n = 1, 3, 4, 6). For details, see **6.3.4 SDRAM configuration registers 1, 3, 4, 6 (SCR1, SCR3, SCR4, SCR6)**.

Caution Wait control by the $\overline{\text{WAIT}}$ pin is not available during SDRAM access.

(a) Number of waits from bank active command to read/write command

The number of wait states from bank active command issue to read/write command issue can be set by setting the SCRn.BCWn1 and SCRn.BCWn0 bits.

BCWn1, BCWn0 bits = 01B: 1 wait

BCWn1, BCWn0 bits = 10B: 2 waits

BCWn1, BCWn0 bits = 11B: 3 waits

(b) Number of waits from precharge command to bank active command

The number of wait states from precharge command issue to bank active command issue can be set by setting the SCRn.BCWn1 and SCRn.BCWn0 bits.

BCWn1, BCWn0 bits = 01B: 1 wait

BCWn1, BCWn0 bits = 10B: 2 waits

BCWn1, BCWn0 bits = 11B: 3 waits

(c) CAS latency setting when read

The CAS latency during a read operation can be set by setting the SCRn.LTMn2 to SCRn.LTMn0 bits.

LTMn2 to LTMn0 bits = 001B: Latency = 1 (setting prohibited during DMA flyby transfer)

LTMn2 to LTMn0 bits = 010B: Latency = 2

LTMn2 to LTMn0 bits = 011B: Latency = 3

(d) Number of waits from refresh command to next command

The number of wait states from refresh command issue to next command issue can be set by setting the SCRn.BCWn1 and SCRn.BCWn0 bits. The number of wait states becomes four times the value set by BCWn1 and BCWn0 bits.

BCWn1, BCWn0 bits = 01B: 4 waits

BCWn1, BCWn0 bits = 10B: 8 waits

BCWn1, BCWn0 bits = 11B: 12 waits

Figure 6-11. SDRAM Access Timing (1/6)

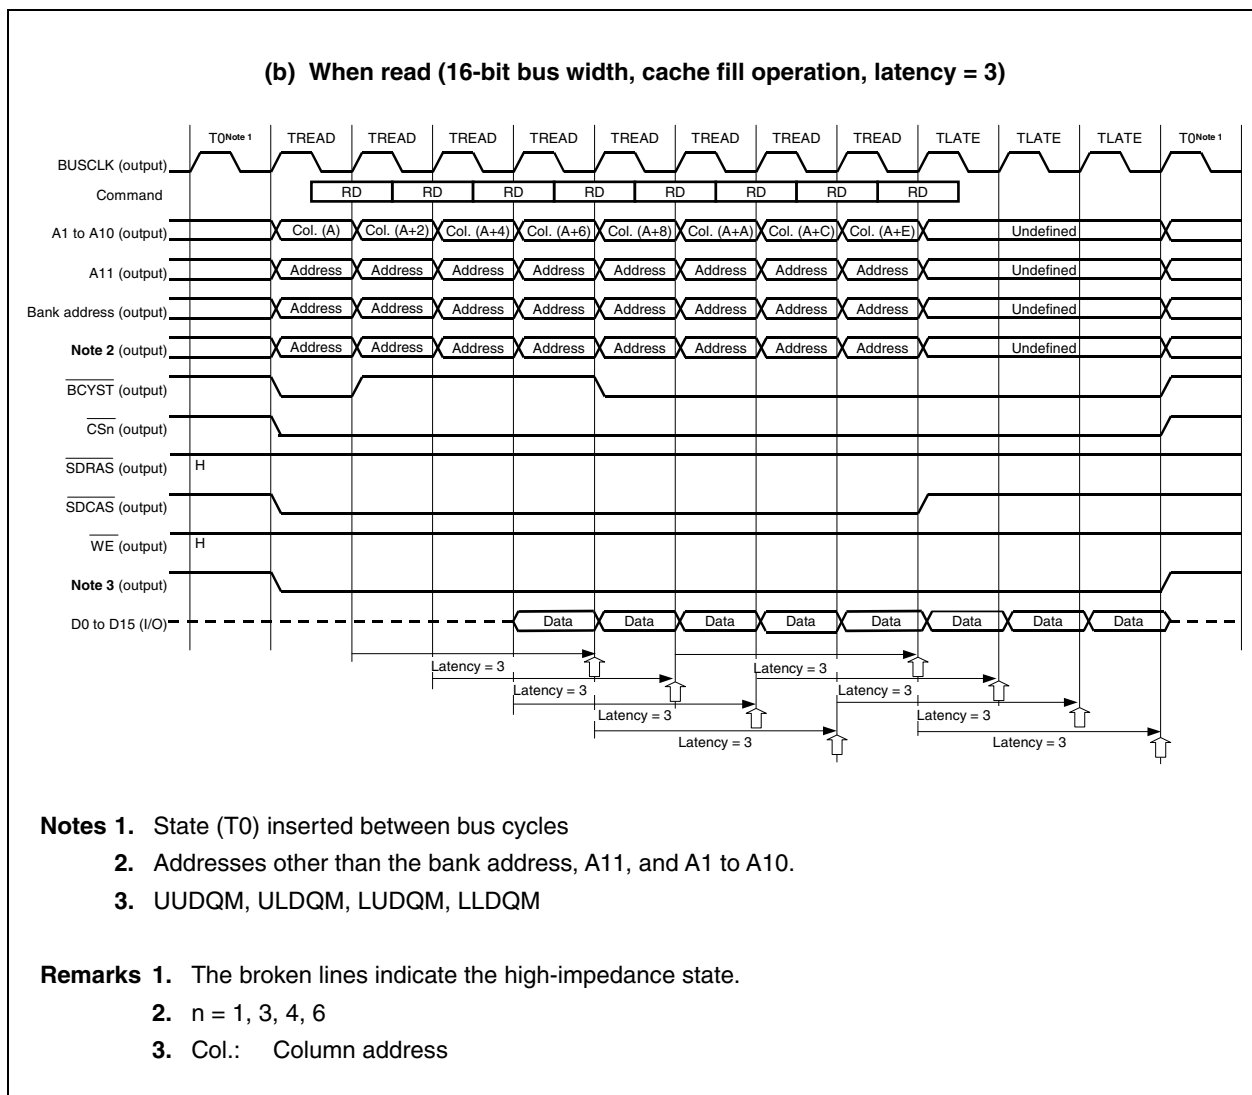

Figure 6-11. SDRAM Access Timing (3/6)

Figure 6-11. SDRAM Access Timing (4/6)

Figure 6-11. SDRAM Access Timing (5/6)

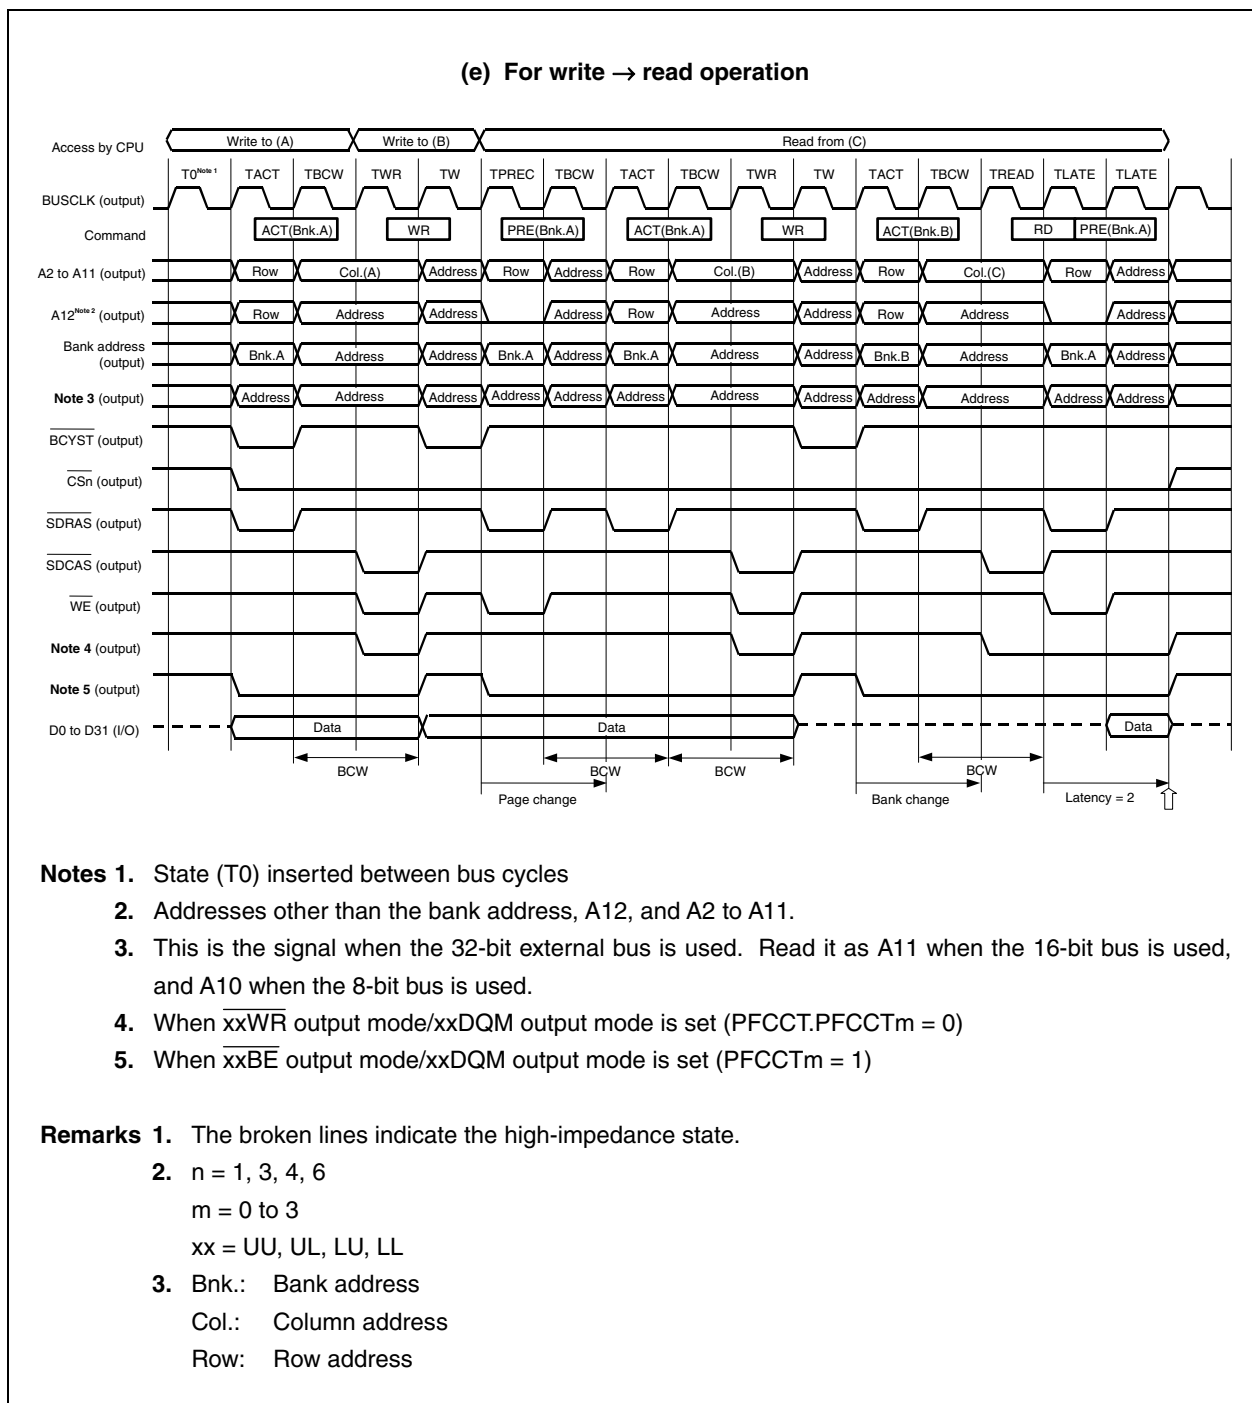

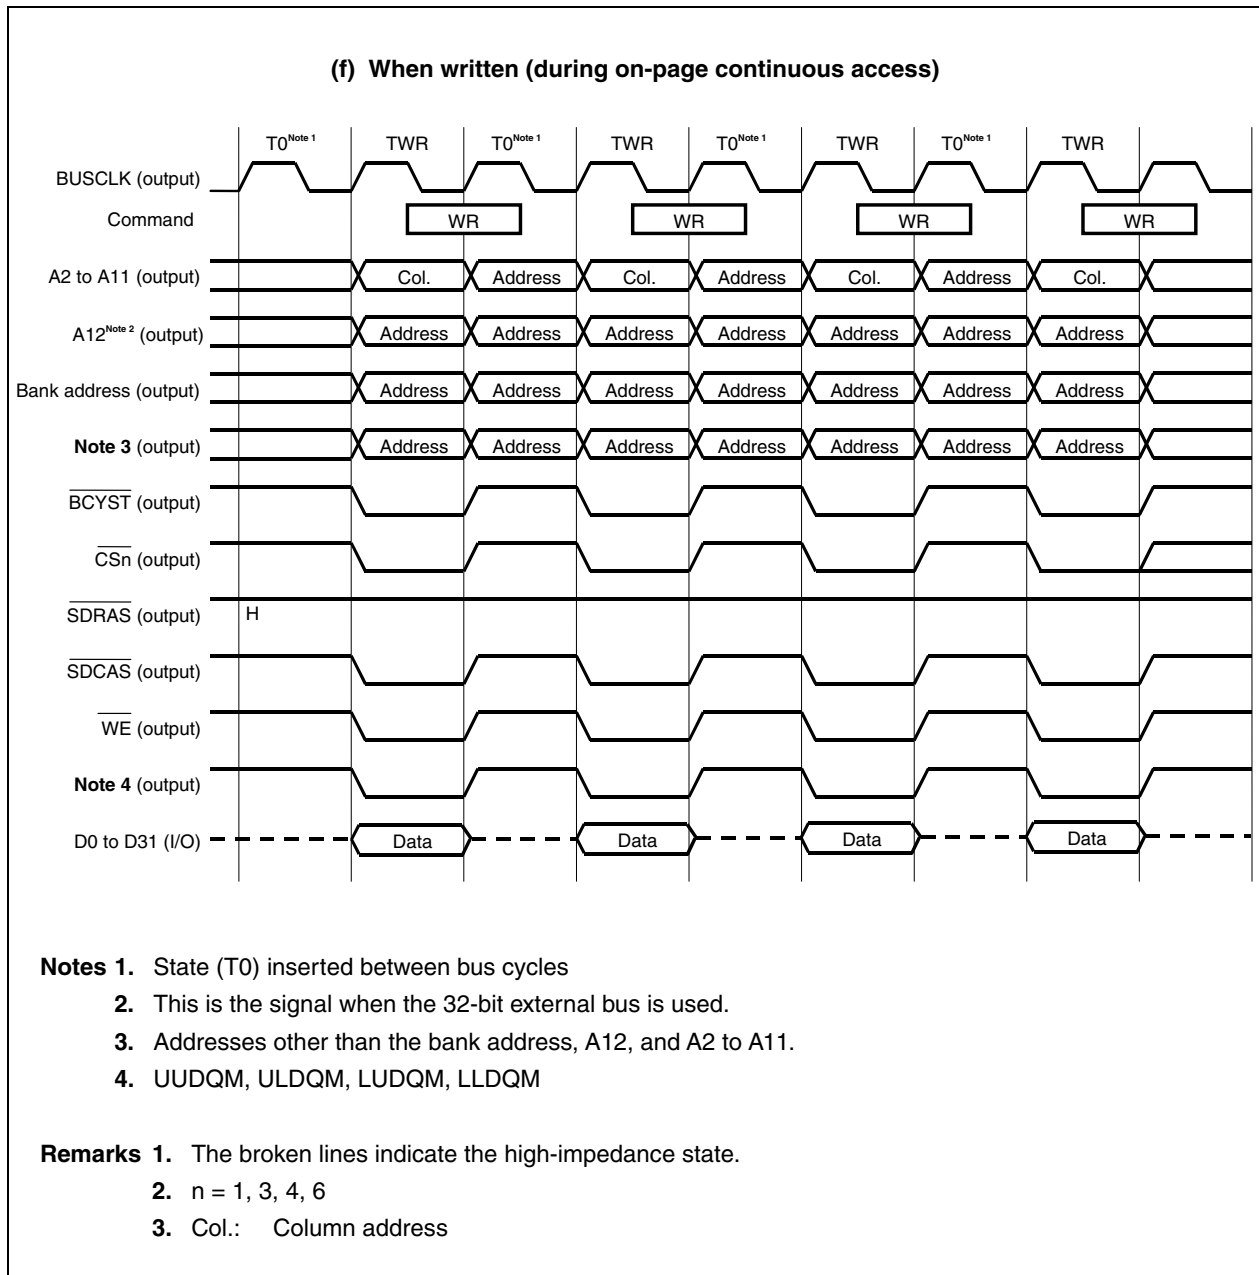

Figure 6-11. SDRAM Access Timing (6/6)

6.3.6 Refresh control function

The V850E2/ME3 can generate a refresh cycle. The refresh cycle is set with the RFS1, RFS3, RFS4, and RFS6 registers. The RFSn register corresponds to \overline{CSn} (n = 1, 3, 4, 6). For example, to connect SDRAM to $\overline{CS1}$, set the RFS1 register.

When another bus master occupies the external bus, the SDRAM controller cannot occupy the external bus. In this case, the SDRAM controller issues a refresh request to the bus master by changing the \overline{REFRQ} signal to active (low level). During a refresh operation, the address bus retains the state it was in just before the refresh cycle.

(1) SDRAM refresh control registers 1, 3, 4, 6 (RFS1, RFS3, RFS4, RFS6)

These registers are used to enable or disable a refresh and set the refresh interval. The refresh interval is determined by the following calculation formula.

$$\text{Refresh interval } (\mu\text{s}) = \text{Refresh count clock } (T_{RCY}) \times \text{Interval factor}$$

The refresh count clock and interval factor are determined by the RCCn1 and RCCn0 bits and RIN5n to RIN0n bits, respectively, of the RFSn register.

Note that n corresponds to the register number (1, 3, 4, 6) of the SCR1, SCR3, SCR4, and SCR6 registers.

These registers can be read or written in 16-bit units.

- Cautions**
1. **Write to the RFS1, RFS3, RFS4, and RFS6 registers after reset, and then do not change the set values. However, when the SDRAM refresh interval needs to be changed by changing the CKC register set value (internal system clock (f_{CLK})), the set value of the RFS1, RFS3, RFS4, and RFS6 registers can be changed. For details, refer to Caution 2 in 9.3.1 Clock control register (CKC). Also, do not access an external memory area other than the one for this initialization routine until the initial settings of the RFS1, RFS3, RFS4, and RFS6 registers are complete. However, it is possible to access external memory areas whose initialization settings are complete.**
 2. **To change the refresh interval, consider and set a value at which refreshing can be performed in time even while the refresh interval is changed. For details, see 9.3.1 (1) Notes on changing refresh interval.**

Table 6-1. Example of Interval Factor Settings

Specified Refresh Interval Value (μs)	Refresh Count Clock (T_{RCY})	Interval Factor Value ^{Notes 1, 2}	
		BUSCLK = 66 MHz	BUSCLK = 50 MHz
15.6	32/BUSCLK	32 (15.5)	24 (15.4)
	128/BUSCLK	8 (15.5)	6 (15.4)
	256/BUSCLK	4 (15.5)	3 (15.4)

- Notes 1.** The interval factor is set by the RINn0 to RINn5 bits ($n = 1, 3, 4, 6$).
- 2.** The values in parentheses are the calculated values for the refresh interval (μs).
- Refresh interval (μs) = Refresh count clock (T_{RCY}) \times Interval factor

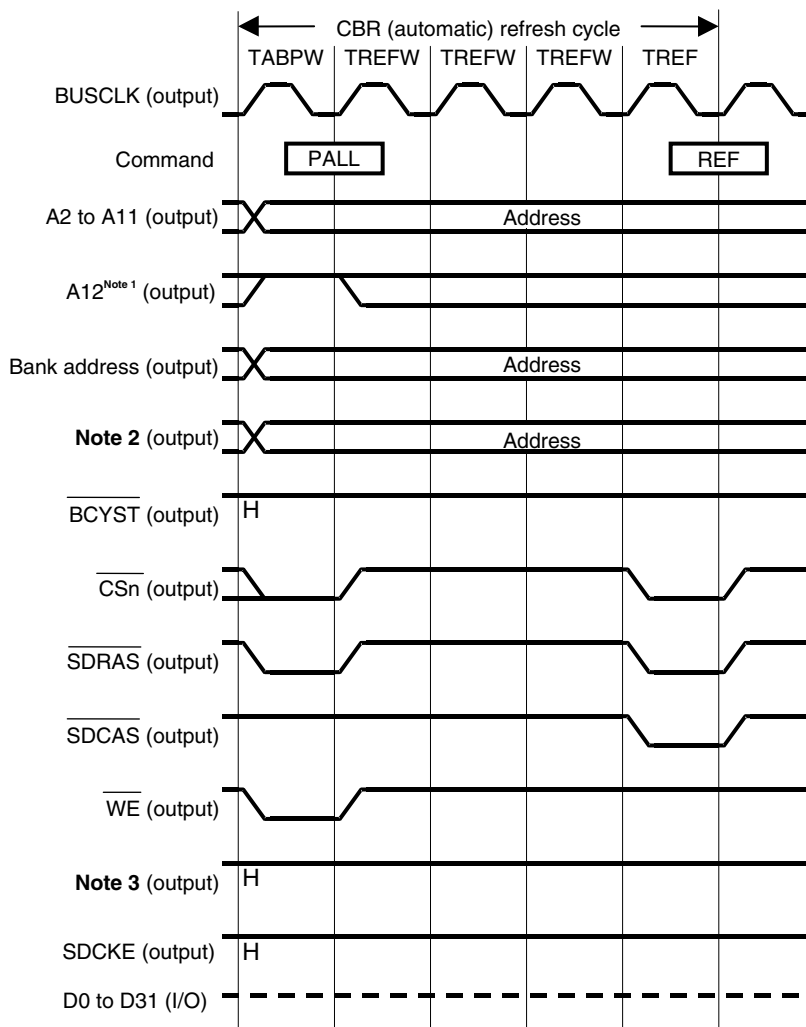

Caution Refresh requests are issued in the refresh interval set by the RFSn register; however, the actual refresh cycle may be kept waiting depending on the external bus state (under bus cycle execution or during bus hold).

The V850E2/ME3 can automatically generate a CBR (automatic) refresh cycle and a self-refresh cycle.

(2) CBR (automatic) refresh cycle

In the CBR (automatic) refresh cycle, the CBR (automatic) refresh command (REF) is issued four clocks after the precharge command for all banks (PALL) is issued.

Figure 6-12. CBR (Automatic) Refresh Cycle

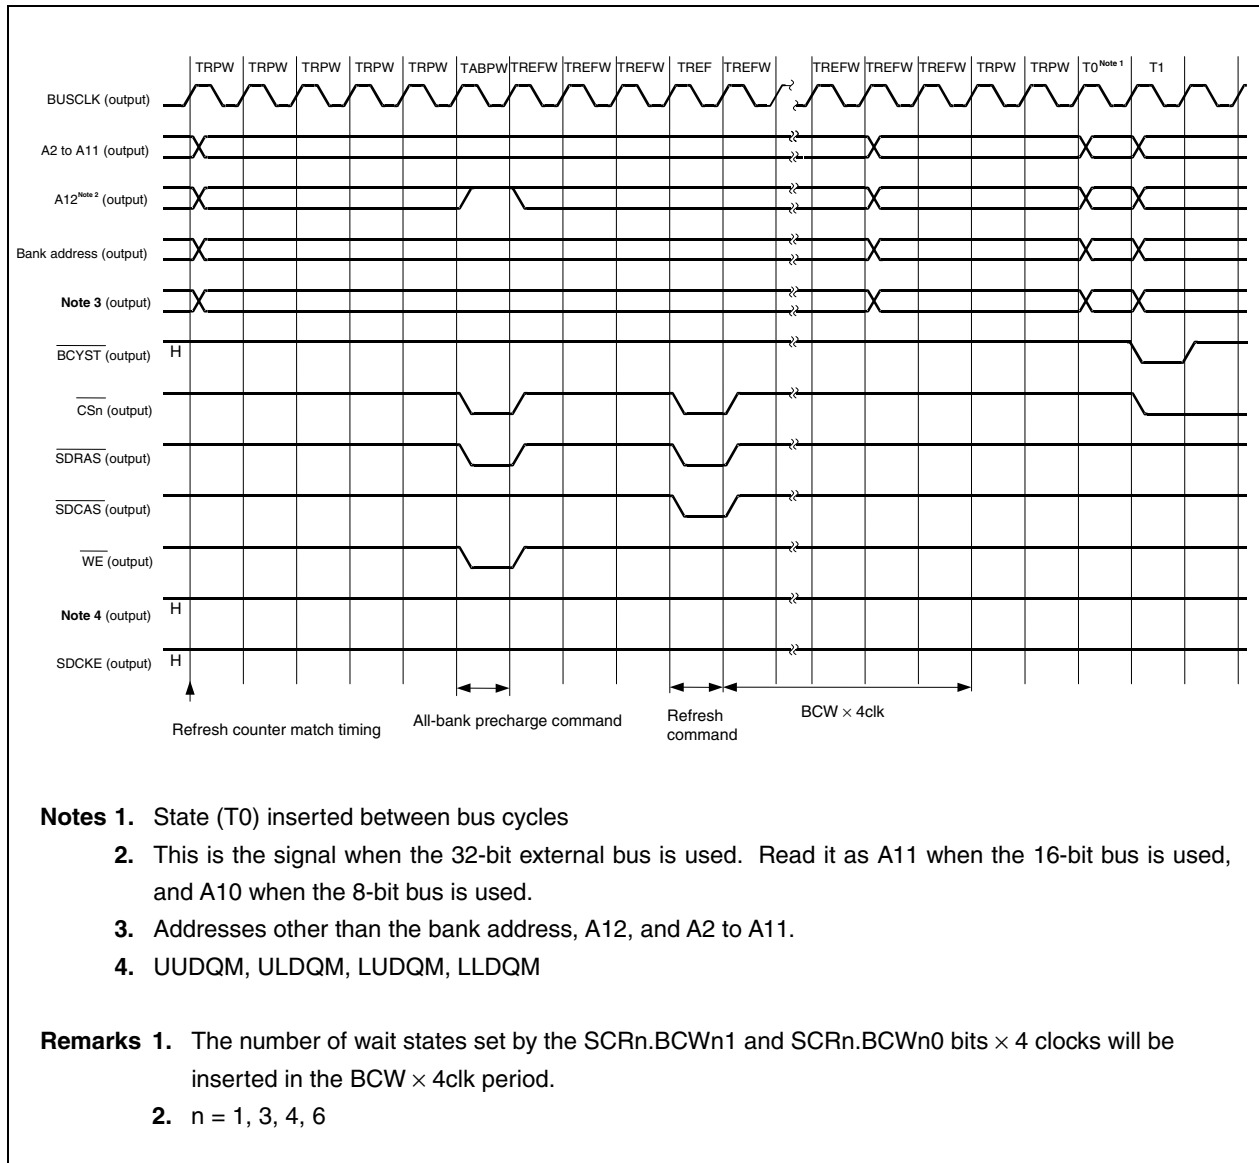

- Notes**
1. This is the signal when the 32-bit external bus is used. Read it as A11 when the 16-bit bus is used, and A10 when the 8-bit bus is used.
 2. Addresses other than the bank address, A12, and A2 to A11.
 3. UUDQM, ULDQM, LUDQM, LLDQM

- Remarks**
1. The broken lines indicate the high-impedance state.
 2. n = 1, 3, 4, 6

(3) CBR (automatic) refresh timing

Figure 6-13. CBR (Automatic) Refresh Timing (SDRAM)

6.3.7 Self-refresh control function

In the case of transition to the IDLE mode, or if the $\overline{\text{SELFREF}}$ signal becomes active, the DRAM controller generates the self-refresh cycle.

- Cautions 1.** When the transition to the self-refresh cycle is caused by $\overline{\text{SELFREF}}$ signal input, releasing the self-refresh cycle is only possible by inputting an inactive level to the $\overline{\text{SELFREF}}$ pin.
- 2.** The internal instruction RAM and internal data RAM can be accessed even in the self-refresh cycle. However, access to an on-chip peripheral I/O register or external device is held pending until the self-refresh cycle is cleared.

To release the self-refresh cycle, use one of the three methods below.

(1) Release by NMI input

In the case of self-refresh cycle in IDLE mode, make the $\overline{\text{SDRAS}}$ and $\overline{\text{SDCAS}}$ signals inactive immediately to release the self-refresh cycle.

(2) Release by INTP_n input (n = 10, 11, 21 to 25, 50 to 52, 65 to 67, D0 to D15, L0, L1)

In the case of self-refresh cycle in IDLE mode, make the $\overline{\text{SDRAS}}$ and $\overline{\text{SDCAS}}$ signals inactive immediately to release the self-refresh cycle.

(3) Release by $\overline{\text{RESET}}$ input

Figure 6-14. Self-Refresh Timing (SDRAM)

- Notes 1.** Shown above is the case when the self-refresh cycle is started in the IDLE mode. If the self-refresh cycle is started by inputting the active level of the SELFREF signal, BUSCLK does not stop (SDCKE goes low).
2. State (T0) inserted between bus cycles
 3. This is the signal when the 32-bit external bus is used. Read it as A11 when the 16-bit bus is used, and A10 when the 8-bit bus is used.
 4. Addresses other than the bank address, A12, and A2 to A11.
 5. UUDQM, ULDQM, LUDQM, LLDQM

- Remarks 1.** The number of wait states set by the SCRn.BCWn1 and SCRn.BCWn0 bits \times 4 clocks will be inserted in the BCW \times 4clk period.
2. n = 1, 3, 4, 6

6.3.8 SDRAM initialization sequence

Be sure to initialize SDRAM when applying power. Initialize SDRAM in the following procedure.

- (1) **Set the registers of SDRAM (other than SDRAM configuration register n (SCRn) and SDRAM refresh control register n (RFSn)).**
 - Bus cycle type configuration registers 0 and 1 (BCT0 and BCT1)
 - Bus cycle control register (BCC)
- (2) **Set other than the RENn bit of SDRAM refresh control registers 1, 3, 4, 6 (RFS1, RFS3, RFS4, RFS6). Clear the RENn bit to 0.**
- (3) **Set SDRAM configuration registers 1, 3, 4, 6 (SCR1, SCR3, SCR4, SCR6). When writing data to the SCRn register, the following commands are issued for SDRAM in the order shown below.**
 - All-bank precharge command
 - Refresh command (8 times)
 - Command that is used to set a mode register
- (4) **After confirming that all the SDRAM initialization steps have been completed using the SCRn.WCFn bit, set the RFSn.RENn bit to 1. Set the value set in step (2) to other bits than the RENn bit.**

- Cautions 1.** To set the SCR1, SCR3, SCR4, and SCR6 registers, confirm that the LOCKR.LOCK bit is set to 1, set the CKS.CKSSEL bit to 1, and change clock supply to the CPU to SSCG output (see 3.4.8 Initialization sequence).
- 2.** If it is necessary to make the input levels of the UUDQM, ULDQM, LUDQM, and LLDQM pins high until initialization of SDRAM is completed, do not change the set values of the PFCCT.PFCCT3 to PFCCT.PFCCT0 bits and do not write the external device until initialization of SDRAM is completed.

Figures 6-15 and 6-16 show examples of the SDRAM mode register setting timing.

Figure 6-15. SDRAM Mode Register Setting Cycle

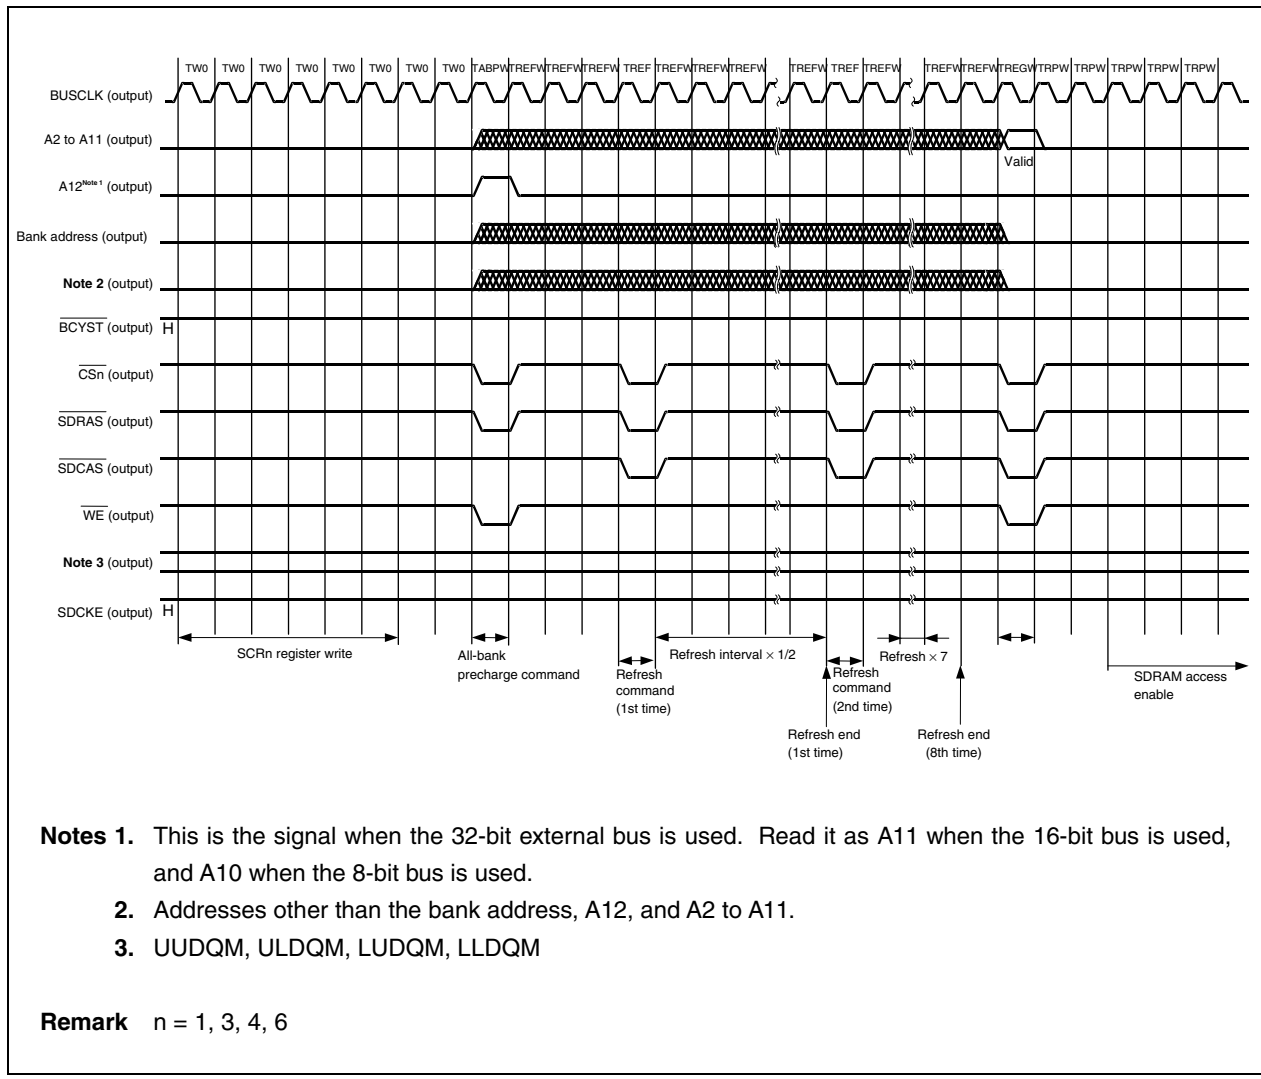

Figure 6-16. SDRAM Register Write Operation Timing

6.4 Cautions

Cautions concerning the memory access control function are shown below.

(1) Write access to SRAM or external I/O after read accessing SDRAM

When executing a write access to SRAM or external I/O after read accessing SDRAM, data conflict may occur depending on the SDRAM data output float delay time. In such a case, avoid data conflict by inserting an idle state in the SDRAM space via a setting in the BCC register.

(2) Caution on self-refresh control function

The internal instruction RAM and internal data RAM can be accessed even in the self-refresh cycle. However, access to an on-chip peripheral I/O register or external device is held pending until the self-refresh cycle is cleared.

CHAPTER 7 DMA FUNCTIONS (DMA CONTROLLER)

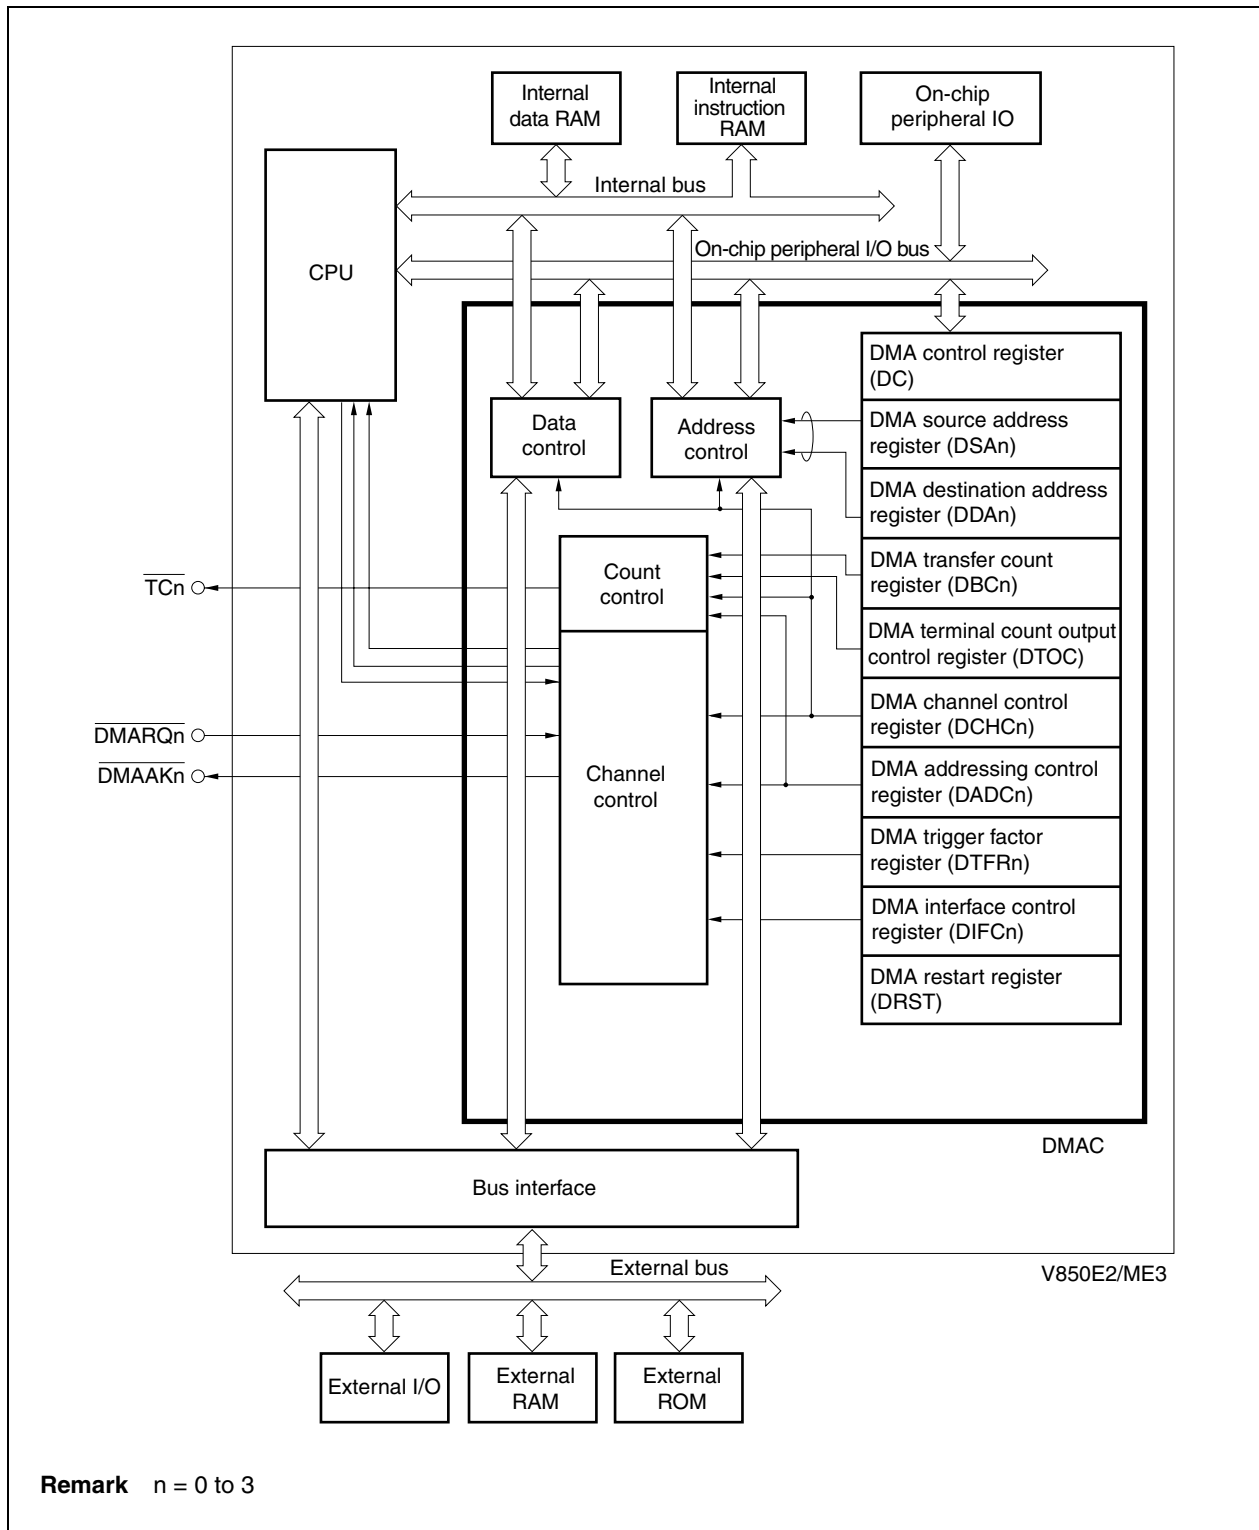

The V850E2/ME3 includes a direct memory access (DMA) controller (DMAC) that executes and controls DMA transfer.

The DMAC controls data transfer between memory and I/O, or among memories, based on requests by interrupts from on-chip peripheral I/O (serial interface, timer/counter, and A/D converter) or DMA requests issued by the $\overline{\text{DMARQ0}}$ to $\overline{\text{DMARQ3}}$ pins, software triggers, or USB. Memory refers to the internal instruction RAM, internal data RAM, or external memory. However, the internal instruction RAM can be used only as the transfer destination.

7.1 Features

- 4 independent DMA channels
- Transfer unit: 8/16/32 bits
- Maximum transfer count: 16,777,216 (2^{24})
- Two types of transfer
 - Flyby (1-cycle) transfer
 - 2-cycle transfer
- Three transfer modes
 - Single transfer mode
 - Single-step transfer mode
 - Block transfer mode
- Transfer requests
 - Request by interrupts from on-chip peripheral I/O (serial interface, timer/counter, A/D converter)
 - Requests via $\overline{\text{DMARQ0}}$ to $\overline{\text{DMARQ3}}$ pin input
 - Requests by software trigger
 - Requests by USB (only in the single-step transfer mode)
- Transfer targets
 - Memory \leftrightarrow I/O
 - Memory \leftrightarrow memory
- DMA transfer end output signals ($\overline{\text{TC0}}$ to $\overline{\text{TC3}}$)
- Next address setting function

7.2 Configuration

7.3 Control Registers

7.3.1 DMA control register (DC)

This register is used to control the clock supply and the transfer priority.

This register can be read or written in 8-bit or 1-bit units.

Caution If the **POWER** bit has been cleared (0), the DMA-related registers other than the DC register cannot be set.

Before using DMA, therefore, be sure to set the **POWER** bit (1) (the **POWER** and **PR** bits can be set (1) at the same time). When clearing the **POWER** bit (0), first clear the **ENn** bit of the **DCHCn** register (0) and set the **FCLRn** bit (1) (n = 0 to 3).

	7	6	5	4	3	2	1	0	Address	After reset
DC	0	0	0	0	0	0	PR	POWER	1FFF0B8H	00H

Bit position	Bit name	Function
1	PR	Specifies the mode for controlling the priority for each channel. Refer to 7.7 DMA Channel Priority Control for priority order control modes. 0: Fixed priority mode (initial value) 1: Round-robin mode
0	POWER	Sets the clock supply to DMA. Clock supply is started by setting this bit (1). Clock supply is stopped by clearing this bit (0), so the current consumption can be lowered. However, each control register (except for the DC register) and DMA are initialized. 0: Clock supply to DMA is stopped and DMA is initialized. (initial value) 1: Clock is supplied to DMA.

Remark Bits 7 to 2 are fixed to 0, so setting these bits to 1 is ignored.

7.3.2 DMA source address registers 0 to 3 (DSA0 to DSA3)

These registers are used to set the DMA transfer source address (28 bits) for DMA channel n ($n = 0$ to 3).

Since these registers are configured as 2-stage FIFO buffer registers, a new transfer source address for DMA transfer can be specified during DMA transfer (see **7.8 Next Address Setting Function**). In this case, the newly set value of the $DSAn$ register is transferred to the slave register and becomes valid only when DMA transfer has been completed normally and the $DCHCn.TCn$ bit is set to 1 ($n = 0$ to 3).

When flyby transfer is specified with the $DADCn.TTYPn$ bit, the external memory addresses are set by the $DSAn$ register, regardless of the transfer direction. At this time, the setting of the $DDAn$ register is ignored ($n = 0$ to 3).

These registers can be read or written in 32-bit units.

When using the higher 16 bits of the $DSAn$ register as the $DSAnH$ register and the lower 16 bits as the $DSAnL$ register, they can be read or written in 16-bit units.

- Cautions 1.** When the last transfer specified with the $DBCn$ register ends, the value of the $DSAn$ register of the corresponding channel is transferred from the master register to the slave register. To set the transfer source address for a new DMA transfer, therefore, set the address to the $DSAn$ register before the last transfer specified with the $DBCn$ register ends (it is recommended to use a 32-bit transfer instruction) ($n = 0$ to 3).
- 2.** It is recommended to access the $DSAn$ register for read in 32-bit units during DMA transfer. If it is accessed in 16-bit units, correct data cannot be read when a carry from bit 15 of the $DSAnL$ register to bit 0 of the $DSAnH$ register occurs, or when a borrow from bit 0 of the $DSAnH$ to bit 15 of the $DSAnL$ register occurs.

27 to 0	SA _n 27 to SA _n 0	Set the DMA transfer source address (A27 to A0). During DMA transfer, these bits store the next DMA transfer source address. During flyby transfer, these bits stores the external memory address.																																				

- Remarks**
1. Bit 28 is fixed to 0, so setting this bit to 1 is ignored.
 2. n = 0 to 3

7.3.3 DMA destination address registers 0 to 3 (DDA0 to DDA3)

These registers are used to set the DMA transfer destination address (28 bits) for DMA channel n (n = 0 to 3).

Since these registers are configured as 2-stage FIFO buffer registers, a new transfer destination address for DMA transfer can be specified during DMA transfer (see **7.8 Next Address Setting Function**). In this case, the newly set value of the DDAn register is transferred to the slave register and becomes valid only when DMA transfer has been completed normally and the DCHCn.TCn bit is set to 1 (n = 0 to 3).

When flyby transfer is specified with the DADCn.TTYPn bit, the setting of the DDAn register is ignored, regardless of the transfer direction.

These registers can be read or written in 32-bit units.

When using the higher 16 bits of the DDAn register as the DDAnH register and the lower 16 bits as the DDAnL register, they can be read or written in 16-bit units.

- Cautions**
- 1. When the last transfer specified with the DBCn register ends, the value of the DDAn register of the corresponding channel is transferred from the master register to the slave register. To set the transfer source address for a new DMA transfer, therefore, set the address to the DDAn register before the last transfer specified with the DBCn register ends (it is recommended to use a 32-bit transfer instruction) (n = 0 to 3).**
 - 2. It is recommended to access the DDAn register for read in 32-bit units during DMA transfer. If it is accessed in 16-bit units, correct data cannot be read when a carry from bit 15 of the DDAnL register to bit 0 of the DDAnH register occurs, or when a borrow from bit 0 of the DDAnH to bit 15 of the DDAnL register occurs.**

27 to 0	DAn27 to DAn0	Set the DMA transfer destination address (A27 to A0). During DMA transfer, these bits store the next DMA transfer destination address. This setting is ignored during flyby transfer.																																				

- Remarks**
1. Bit 28 is fixed to 0, so setting this bit to 1 is ignored.
 2. n = 0 to 3

7.3.4 DMA transfer count registers 0 to 3 (DBC0 to DBC3)

These 32-bit registers are used to set the byte transfer count for DMA channel n ($n = 0$ to 3). They store the remaining transfer count during DMA transfer.

Since these registers are configured as 2-stage FIFO buffer registers, a new DMA byte transfer count for DMA transfer can be specified during DMA transfer (see **7.8 Next Address Setting Function**). In this case, the newly set value of the DBC n register is transferred to the slave register and becomes valid only when DMA transfer has been completed normally and the DCHC n .TC n bit is set to 1 ($n = 0$ to 3).

These registers are decremented by 1 for each transfer, and transfer ends when a borrow occurs.

These registers can be read or written in 32-bit units.

When using the higher 16 bits of the DBC n register as the DBC n H register and lower 16 bits as the DBC n L register, they can be read or written in 16-bit units.

- Cautions**
1. When the last transfer specified with the DBC n register ends, the value of the DBC n register of the corresponding channel is transferred from the master register to the slave register. To set the transfer source address for a new DMA transfer, therefore, set the address to the DBC n register before the last transfer specified with the DBC n register ends (it is recommended to use a 32-bit transfer instruction) ($n = 0$ to 3).
 2. It is recommended to access the DBC n register for read in 32-bit units during DMA transfer. If it is accessed in 16-bit units, correct data cannot be read when a borrow from bit 0 of the DBC n H to bit 15 of the DBC n L register occurs.

- Remarks**
- Bits 30 to 24 are fixed to 0, so setting these bits to 1 is ignored.
 - n = 0 to 3

7.3.5 DMA addressing control registers 0 to 3 (DADC0 to DADC3)

These 16-bit registers are used to control the DMA transfer mode for DMA channel n (n = 0 to 3). These registers cannot be accessed during DMA operation.

These registers can be read or written in 16-bit units.

Be sure to clear bit 4 to 0. If it is set to 1, the operation is not guaranteed.

Cautions 1. The DS_n1 and DS_n0 bits set how many bits of data are to be transferred.

When 8-bit data is set (DS_n1 and DS_n0 bits = 00), the lower bytes of the data bus (D0 to D7) are not always used.

If the transfer data size is set to 16 bits, transfer is always started from an address with the lowest bit of the address aligned to "0". If the data size is set to 32 bits, transfer is started from an address with the lowest 2 bits of the address aligned to "0". In this case, transfer cannot be started from an odd address.

- 2. When the flyby transfer is set by setting the TTYP_n bit to 1, the address count direction of the external memory is set using the SAD_n1 and SAD_n0 bits regardless of the transfer direction (the settings of the DAD_n1 and DAD_n0 bits are ignored).**
- 3. This operation is not guaranteed if the set data is changed during DMA transfer (overwriting the same data causes no problem). Be sure to clear (0) the DCHC_n.ENN bit and set (1) the FCLR_n bit before changing data (n = 0 to 3).**

(1/2)

0	TDIRn	Sets the transfer direction during transfer between I/O and memory. The setting is valid during flyby transfer only and ignored during 2-cycle transfer. 0: Memory → I/O (read) 1: I/O → memory (write)															

Remark n = 0 to 3

7.3.6 DMA channel control registers 0 to 3 (DCHC0 to DCHC3)

These 8-bit registers are used to control the DMA transfer operating mode for DMA channel n (n = 0 to 3).

These registers can be read or written in 8-bit or 1-bit units. (However, bits 6 to 3 are read-only. If bits 2 and 1 are read, the read value is always 0.)

Be sure to clear bits 6, 4, and 3 to 0. If they are set to 1, the operation is not guaranteed.

Cautions 1. During a 2-cycle transfer that performs a write operation on the external device, the write operation on the external device may not be completed even if the TCn bit is set to 1 (DMA transfer completion) by the write buffer function. Recognize completion of the write operation on the external device as follows, if necessary.

- Monitor the signal of the \overline{TCn} pin (the \overline{TCn} pin becomes active in synchronization with a write operation to the external device).
 - After it has been detected that the TCn bit is set to 1, write 00H to the WAS register. When this write is completed, completion of an access from the write buffer to the external device can be recognized.
2. Do not set the STGn bit to 1 while DMA is suspended.
 3. Each bit is updated upon completion of DMA transfer (at terminal count) with the ENn bit cleared to 0 and the TCn bit set to 1 in that order. While the statuses of the TCn and ENn bits are being polled, therefore, values indicating the status of “transfer not completed and prohibited” (TCn bit = 0 and ENn bit = 0) may be read if the DCHCn register is read while each bit is being updated.
 4. Do not set (1) the ENn and FCLRn bits at the same time.
 5. When 2-cycle transfer is suspended by clearing the ENn bit to 0 or by detecting a valid edge of the NMI signal, confirm that the WSTn bit has been cleared to 0 then set the FCLRn bit to 1.

- Cautions 6.** Do not use the transfer request with the DMA transfer request pin ($\overline{\text{DMARQn}}$) input and the transfer request with software (by setting the STGn bit (1)) for the same channel, because which trigger source is valid cannot be identified.

If DMA transfer is started via software and if the software does not correctly detect whether the expected DMA transfer operation has been completed through manipulation (setting to 1) of the STGn bit, it cannot be guaranteed whether the next (second) manipulation of the STGn bit corresponds to the start of “the next DMA transfer expected by software”. For example, suppose single transfer is started by manipulating the STGn bit. Even if the STGn bit is manipulated next (the second time) without checking by software whether the single transfer has actually been executed, the next (second) DMA transfer is not always executed. This is because the STGn bit may be manipulated the second time before the first DMA transfer is started or completed because, for example, DMA transfer with a higher priority had already been started when the STGn bit was manipulated for the first time. It is therefore necessary to manipulate the STGn bit next time (the second time) after checking whether DMA transfer started by the first manipulation of the STGn bit has been completed.

Completion of DMA transfer can be confirmed by clearing the DTFRn.DFn bit.

7. Among channels for which the condition “ENn bit = 1 and DFn bit = 1” is satisfied, the DMA transfer request of a channel with the highest priority is acknowledged (setting (1) order of each bit does not affect the result).
8. When DMA transfer is triggered by an on-chip peripheral I/O interrupt request, confirm that the TCn bit has been set to 1 after completion of the DMA transfer, then follow the procedure below to clear the DMA transfer request.

- (1) Confirm that the TCn bit = 1 (DMA transfer complete).
- (2) Check whether the on-chip peripheral I/O function that triggered the DMA transfer is operating. For example, for UARTB transmission, confirm with the UBnSTR.UBnTSF bit that the transmission data no longer exists on the transmit shift register or UBnTX register.
- (3) Stop the on-chip peripheral I/O function that triggered the DMA transfer. For UARTB transmission, clear the UBnCTL0.UBnTXE bit (0) to prohibit transmission.
- (4) Clear the DTFRn.DFn bit to 0.
- (5) Set the FCLRn bit to 1 and clear the ENn bit to 0.
Also, before setting the FCLRn bit to 1, be sure to confirm that the WSTn bit is cleared to 0.

	<7>	6	5	4	3	<2>	<1>	<0>	Address	After reset
DCHC0	TC0	0	WST0	0	0	FCLR0	STG0	EN0	1FFFF0BAH	00H

DCHC2	TC2	0	WST2	0	0	FCLR2	STG2	EN2	1FFFF0BCH	00H
DCHC3	TC3	0	WST3	0	0	FCLR3	STG3	EN3	1FFFF0BDH	00H

Bit position	Bit name	Function
7	TCn	<p>This status bit indicates whether DMA transfer through DMA channel n is complete or not.</p> <p>0: DMA transfer is not complete. 1: DMA transfer is complete.</p> <p>Caution Clear the TCn bit (0) by writing “0” with the st.b instruction after reading “1” with the ld.b instruction, or by writing “0” after reading “1” with the clr1 and not1 instructions.</p>
5	WSTn	<p>This status bit indicates the transfer status of DMA channel n. To set the FCLRn bit (1) (forcibly terminates DMA transfer), confirm that the WSTn bit is cleared (0) and then set the FCLRn bit (1).</p>
2	FCLRn	<p>If this bit is set to 1, the DMA request held inside is cleared.</p> <p>Caution Clear the ENn bit (0) at the same time as setting the FCLRn bit (1).</p>
1	STGn	<p>If this bit is set to 1, DMA transfer by a software trigger is started.</p> <p>Caution When the FCLRn and STGn bits are set (1) at the same time, the setting of the FCLRn bit takes precedence.</p>
0	ENn	<p>Specifies whether DMA transfer through DMA channel n is to be enabled or disabled. This bit is cleared to 0 when DMA transfer ends.</p> <p>0: DMA transfer disabled (DMA transfer suspended) 1: DMA transfer enabled</p> <p>Cautions</p> <ol style="list-style-type: none"> 1. The ENn bit is cleared (0) when the DBCn.MLEn bit has been cleared (0) and the last transfer set with the DBCn register is completed. 2. When the DRST.STPDIS bit has been set (1), transfer is suspended even if the ENn bit is set (1). 3. To restart DMA transfer, write “0” with the st.b instruction after reading “1” with the ld.b instruction, or write “0” after reading “1” with the clr1 and not1 instructions, and then set the ENn bit (1).

Remark n = 0 to 3

7.3.7 DMA restart register (DRST)

This 8-bit register is used to control DMA transfer.

This register can be read only in 8-bit units. However, bit 7 can be read or written in 1-bit units.

Be sure to clear bit 6 to 0. If it is set to 1, the operation is not guaranteed.

	7	6	5	4	3	2	1	0	Address	After reset
DRST	STPDIS	0	0	0	EN13	EN12	EN11	EN10	1FFFF0BEH	00H

Bit position	Bit name	Function
7	STPDIS	Indicates whether or not DMA transfer has been suspended by an NMI input. Clear this bit (0) to resume the suspended DMA transfer. 0: DMA transfer has not been suspended. 1: DMA transfer has been suspended. Caution Clear the STPDIS bit (0) by writing "0" using the clr1 and not1 instructions.
3 to 0	EN13 to EN10	Indicate the state of the DCHCn.ENn bit. 0: DMA transfer disabled (DMA transfer suspended). 1: DMA transfer enabled.

Remarks 1. Bits 5 and 4 are fixed to 0, so setting these bits to 1 is ignored.

2. n = 0 to 3

7.3.8 DMA terminal count output control register (DTCO)

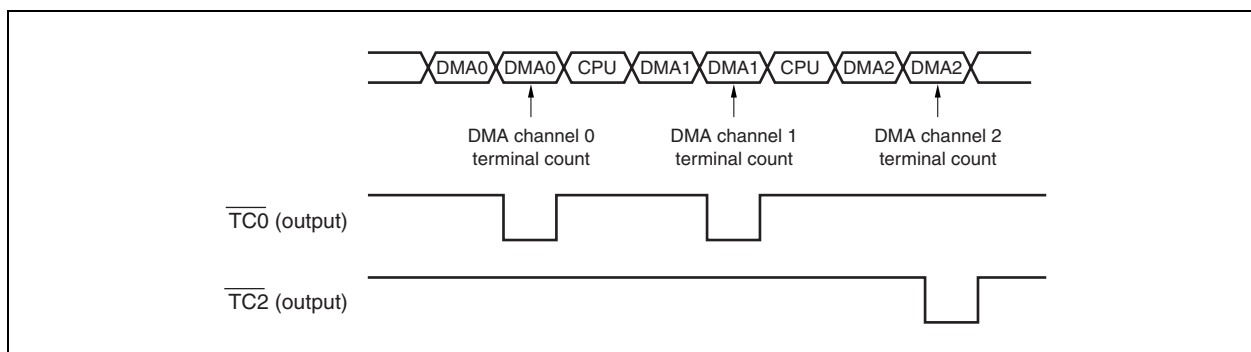

The DMA terminal count output control register (DTCO) is an 8-bit register that controls the terminal count output from each DMA channel and DMA transfer during NMI input. Terminal count signals from each DMA channel can be brought together and output from the $\overline{TC0}$ pin.

This register can be read or written in 8-bit or 1-bit units. However, bits 6 to 4 are read-only. Be sure to set bit 0 to "1". Otherwise, the operation is not guaranteed.

	7	6	5	4	<3>	<2>	<1>	0	Address	After reset
DTCO	DMSTPM	0	0	0	TCO3	TCO2	TCO1	1	1FFF8A0H	01H

Bit position	Bit name	Function
7	DMSTPM	<p>Controls DMA transfer when NMI is input.</p> <p>0: Forcibly suspends DMA transfer when NMI is input.</p> <p>1: Does not suspend DMA transfer when NMI is input.</p> <p>Cautions</p> <ol style="list-style-type: none"> 1. When DMSTPM bit = 0, NMI servicing can be executed immediately after completion of the DMA cycle currently under execution. Before executing the suspended DMA transfer, however, be sure to re-initialize it. 2. When DMSTPM bit = 1, NMI servicing is held pending in the block transfer mode until DMA transfer has been completed the preset number of times. In the single transfer mode and single-step transfer mode, NMI servicing is executed after the DMA cycle currently under execution is completed. As necessary, forcibly terminate DMA transfer by setting the INITn bit of the DCHCn register to 1 (n = 0 to 3). 3. Be sure to change the value of the DMSTPM bit when DMA is not used. The operation is not guaranteed if the value of the DMSTPM bit is changed after registers related to DMAC have been set or during DMA transfer.
3 to 1	TCO3 to TCO1	<p>Indicate the state of the $\overline{TC0}$ pin.</p> <p>0: Channel n terminal count signal not output from $\overline{TC0}$ pin.</p> <p>1: Channel n terminal count signal output from $\overline{TC0}$ pin.</p>

The following shows an example of the case when the DTCO register is set to 03H.

7.3.9 DMA trigger factor registers 0 to 3 (DTFR0 to DTFR3)

These 8-bit registers are used to control the DMA transfer start trigger through interrupt requests from on-chip peripheral I/O.

The interrupt requests set by these registers serve as DMA transfer startup factors.

These registers can be read or written in 8-bit units. However, only bit 7 (DFn) can be read or written in 1-bit units.

- Cautions**
1. Be sure to stop DMA operation of all channels before changing the DTFRn register setting.
 2. An interrupt request from the on-chip peripheral I/O is held pending as the DMA transfer start factor. The held DMA transfer start factor is executed after restoring to the normal operation mode.
 3. If the factor of starting DMA transfer is changed by using the IFCn6 to IFCn0 bits, be sure to clear the DFn bit of all channels to 0 using the instruction immediately after. When in single-step transfer, clear the DFn bit to 0 and then set the DCHCn.FCLRn bit of all channels to 1.
 4. When a transmission completion interrupt request signal (UBTIT0 or UBTIT1) of UARTB is used as the factor of starting DMA transfer, the factor of starting DMA transfer that is triggered by the interrupt request signal generated when the last transmission was completed is retained. In this case, clear the DFn bit to 0 to clear the DMA transfer request.
 5. Do not start two or more DMA channels with the same factor. If two or more DMA channels are started with the same factor, the DMA channel with the lower priority may be accepted before the DMA channel with the higher priority.
 6. Before starting DMA transfer by an interrupt request from the USB, set the DTFRn register to 7EH and set the single-step transfer mode.
 7. Use the edge detection mode for flyby transfer.

		Other than above								Setting prohibited
		Caution When using an external interrupt (when IFCn6 to IFCn0 bits = 0000010B to 0100000B) as a DMA trigger source, be sure to specify an edge (do not use level detection).								

Remark n = 0 to 3

The relationship between the $\overline{\text{DMARQn}}$ signal and the interrupt source that serves as a DMA transfer trigger is as follows ($n = 0$ to 3).

Remark The DMA is started by the interrupt source set with the IFCn6 to IFCn0 bits. To prevent an interrupt from being serviced, mask the interrupt by setting the interrupt control register. DMA transfer starts even if an interrupt is masked.

For the level detection mode (IFCn6 to IFCn0 bits = 0000000) and edge detection mode (IFCn6 to IFCn0 bits = 0000001) of the $\overline{\text{DMARQn}}$ pin input, see **Figures 7-8 to 7-10** ($n = 0$ to 3).

(1) DMA request detection function

The V850E2/ME3 has a level detection mode and an edge detection mode as functions to sample the $\overline{\text{DMARQn}}$ pin ($n = 0$ to 3). The level detection mode also has a mask mode in which sampling the DMA request is masked.

Caution Use the edge detection mode for flyby transfer.

(a) Level detection mode (IFCn6 to IFCn0 bits = 0000000)

In this mode, handshaking of the $\overline{\text{DMARQn}}$ and $\overline{\text{DMAAKn}}$ signals can be executed at high speeds. In the single transfer mode, assert the $\overline{\text{DMARQn}}$ signal for the duration of $1 \times f_{\text{BUSCLK}}$ from the rising edge of the $\overline{\text{DMAAKn}}$ signal, in order not to start the DMA transfer cycle next to that currently under execution. If the $\overline{\text{DMARQn}}$ signal is active for the duration of $1 \times f_{\text{BUSCLK}}$ or longer, the next DMA request is recognized. In the 2-cycle transfer mode, however, the active period of the $\overline{\text{DMAAKn}}$ signal may be shortened depending on the combination of the transfer source and transfer destination.

For the active width of the $\overline{\text{DMAAKn}}$ signal for 2-cycle transfer, refer to **Table 7-4 Minimum Value of Active Width of $\overline{\text{DMAAKn}}$ Signal for 2-Cycle Transfer**.

<1> Mask mode (IFCn6 to IFCn0 bits = 0000000 and DIFCn.DRMKn3 to DRMKn0 bits = other than 0000)

In this mode, the $\overline{\text{DMARQn}}$ signal sampling can be masked to the next DMA transfer cycle from the $\overline{\text{DMAAKn}}$ signal rise for the period set by the DIFCn register.

(b) Edge detection mode (IFCn6 to IFCn0 bits = 0000001)

This mode uses the falling edge input of the $\overline{\text{DMARQn}}$ signal as a DMA request. It achieves handshaking of the $\overline{\text{DMARQn}}$ and $\overline{\text{DMAAKn}}$ signals at a speed much lower than that when the level detection mode is used. However, if the falling edge of the $\overline{\text{DMARQn}}$ signal is input while the $\overline{\text{DMAAKn}}$ signal is active, the next DMA transfer cycle for single transfer is acknowledged.

For the detailed timing in each mode, refer to **CHAPTER 18 ELECTRICAL SPECIFICATIONS (TARGET)**.

7.3.10 DMA interface control registers 0 to 3 (DIFC to DIFC3)

These 8-bit registers control the active extension width of the $\overline{\text{DMAAKn}}$ signal of each DMA channel and control the mask function (DMA mask mode) of the $\overline{\text{DMARQn}}$ signal (n = 0 to 3).

These registers can be read or written in 8-bit or 1-bit units.

Caution Be sure to set the DIFCn register before the DMA operation starts. If setting is performed while the DMA is operating, operation is not guaranteed.

7.3.11 DMA single transfer mode control register (DSMC)

This 8-bit register is used to specify single or single-step transfers for each DMA channel.

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
DSMC	0	0	0	0	DSMC3	DSMC2	DSMC1	DSMC0	1FFF8ACH	00H

Bit position	Bit name	Function
3 to 0	DSMC3 to DSMC0	Set the transfer mode during DMA single transfer. 0: Single transfer mode 1: Single-step transfer mode

7.4 Transfer Modes

7.4.1 Single transfer mode

In single transfer mode, the DMAC releases the bus at each byte/halfword/word transfer. If there is a subsequent DMA transfer request, transfer is performed again once. This operation continues until a terminal count occurs.

When the DMAC has released the bus, if another higher priority DMA transfer request is issued, the higher priority DMA request always takes precedence. If other DMA transfer request with the lower priority occurs one clock after single transfer has been completed, however, this request does not take precedence even if the previous DMA transfer request signal with the higher priority remains active. DMA transfer with the lower priority newly request is executed after the CPU bus has been released.

Figures 7-1 to 7-4 show examples of single transfer.

Figure 7-1. Single Transfer Example 1

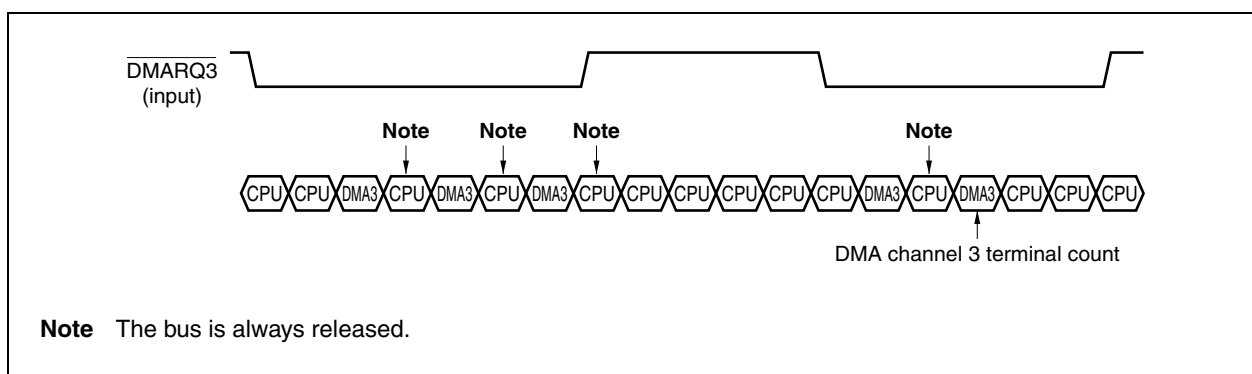

Figure 7-2 shows an example of a single transfer in which a higher priority DMA transfer request is issued. DMA channels 0 to 2 are in the block transfer mode and channel 3 is in the single transfer mode.

Figure 7-2. Single Transfer Example 2

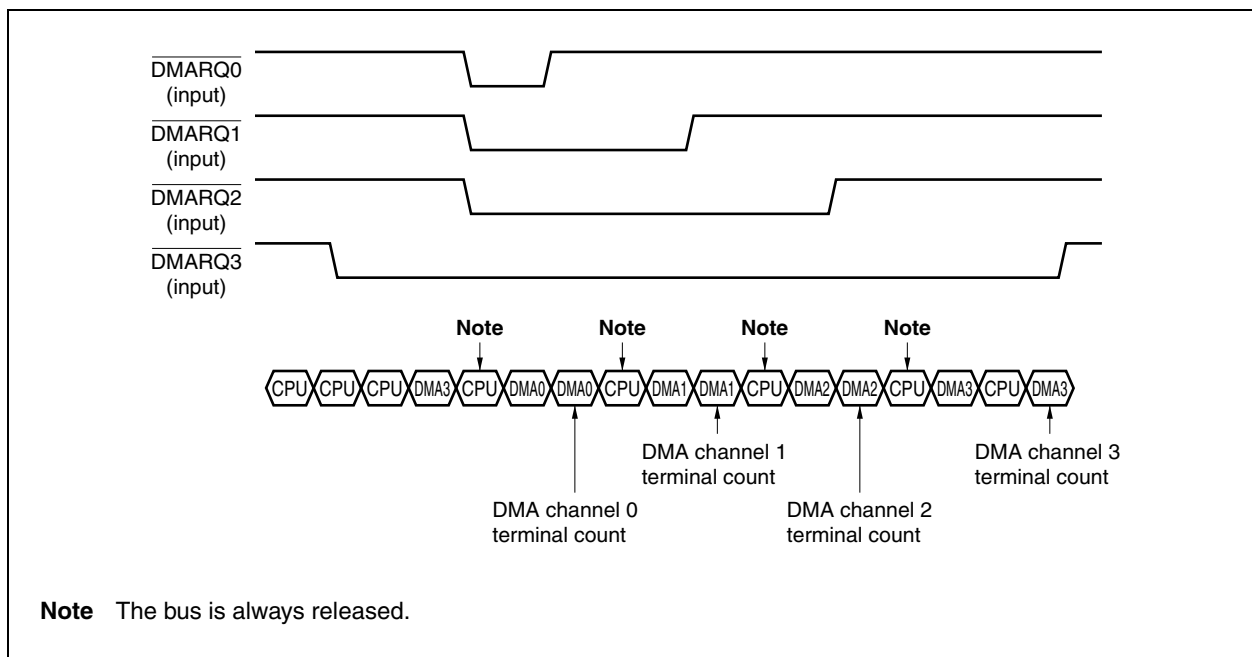

Figure 7-3 is an example of single transfer where a DMA transfer request with the lower priority is issued one clock after single transfer has been completed. DMA channels 0 and 3 are used for single transfer. If two DMA transfer request signals become active at the same time, two DMA transfer operations are alternately executed.

Figure 7-3. Single Transfer Example 3

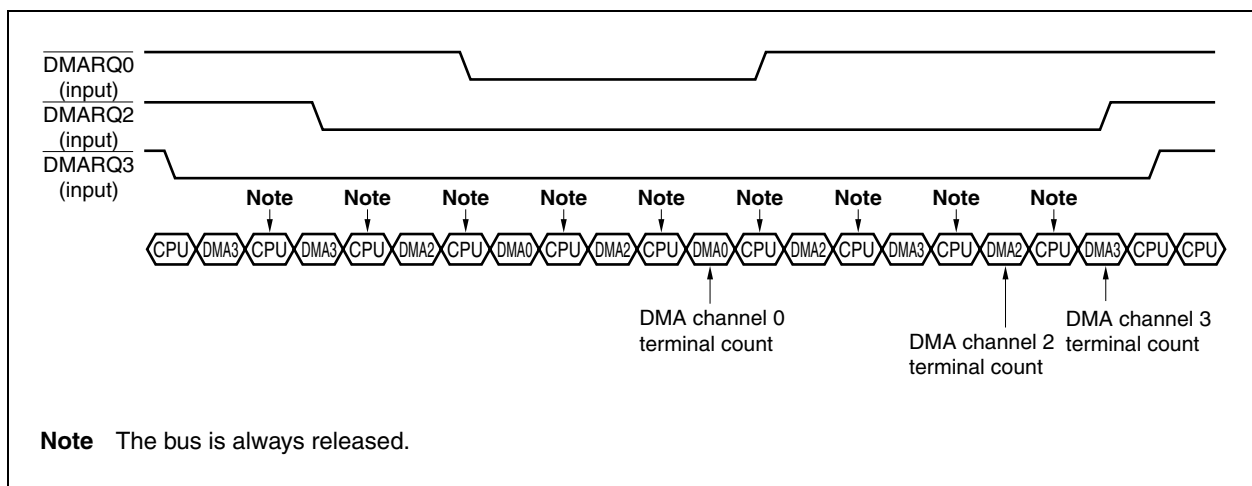

Figure 7-4 is an example of single transfer where two or more DMA transfer requests with the lower priority are issued one clock after single transfer has been completed. DMA channels 0, 2, and 3 are used for single transfer. If three DMA transfer request signals become active at the same time, two or three DMA transfers are executed alternately from the highest priority.

Figure 7-4. Single Transfer Example 4

7.4.2 Single-step transfer mode

In single-step transfer mode, the DMAC releases the bus at each byte/halfword/word transfer. If there is a subsequent DMA transfer request signal ($\overline{\text{DMARQ0}}$ to $\overline{\text{DMARQ3}}$), transfer is performed again. This operation continues until a terminal count occurs.

When the DMAC has released the bus, if another higher priority DMA transfer request is issued, the higher priority DMA request always takes precedence.

The following shows an example of a single-step transfer. Figure 7-6 shows an example of single-step transfer made in which a higher priority DMA request is issued. DMA channels 0 and 1 are in the single-step transfer mode.

Figure 7-5. Single-Step Transfer Example 1

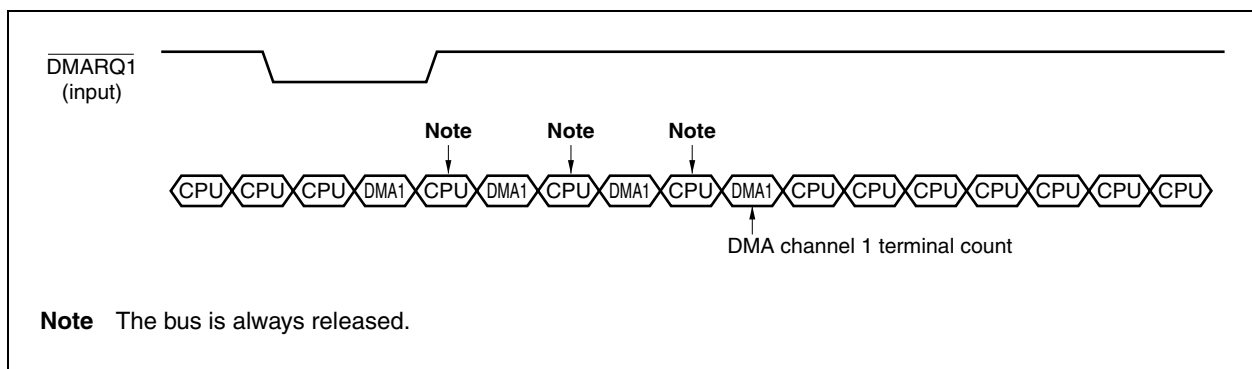

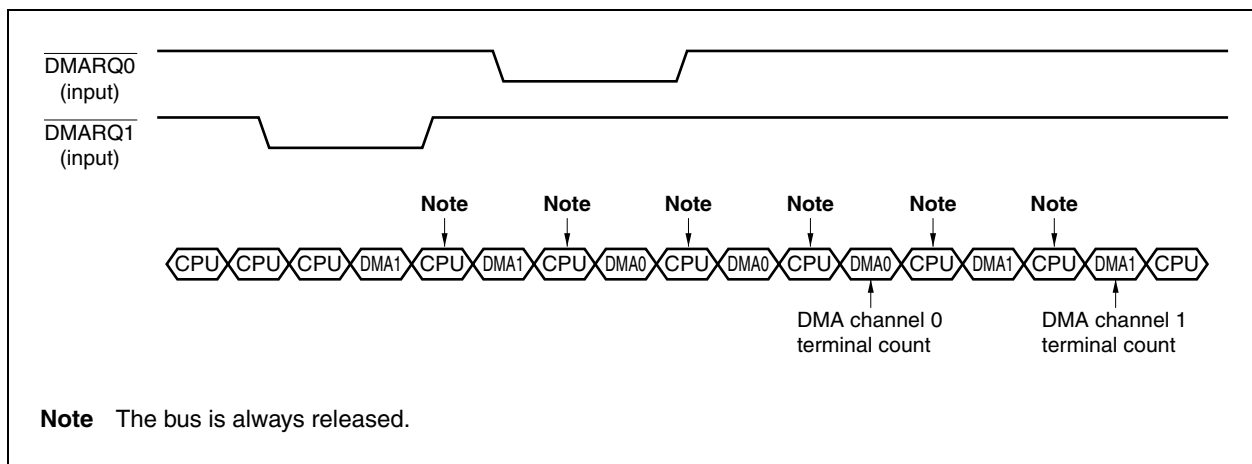

Figure 7-6. Single-Step Transfer Example 2

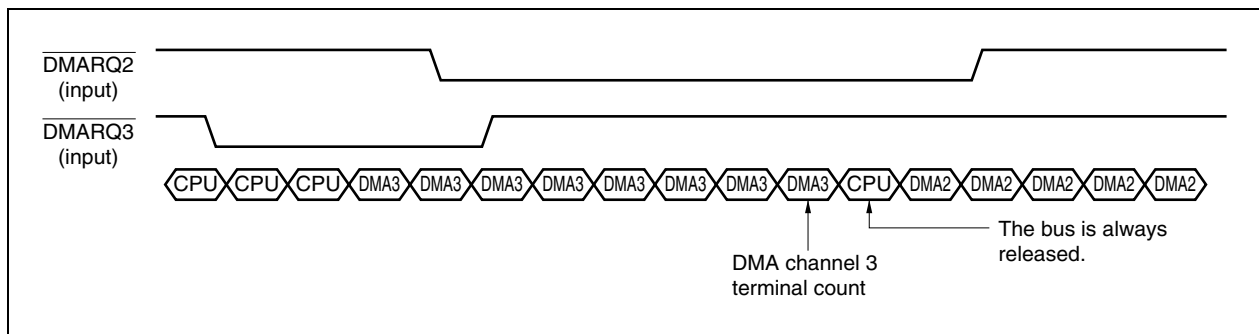

7.4.3 Block transfer mode

In the block transfer mode, once transfer starts, the DMAC continues the transfer operation without releasing the bus until a terminal count occurs. No other DMA requests are acknowledged during block transfer.

After the block transfer ends and the DMAC releases the bus, another DMA transfer can be acknowledged. The bus cycle of the CPU is not inserted during block transfer, but bus hold and refresh cycles are inserted in between DMA transfer operations.

The following shows an example of block transfer in which a higher priority DMA request is issued. DMA channels 2 and 3 are in the block transfer mode.

Figure 7-7. Block Transfer Example

7.5 Transfer Types

7.5.1 2-cycle transfer

In 2-cycle transfer, data transfer is performed in two cycles, a read cycle (source to DMAC) and a write cycle (DMAC to destination).

In the first cycle, the source address is output and reading is performed from the source to the DMAC. In the second cycle, the destination address is output and writing is performed from the DMAC to the destination.

Caution An idle cycle of 1 to 2 clocks is always inserted between a read cycle and a write cycle.

Figure 7-8. Timing of 2-Cycle DMA Transfer (SRAM → External I/O) (1/2)

Single Transfer Mode (SRAM Data 1 Wait, SDRAM Latency = 2,
BMC Register = 00H, Level Detection Mode)

**Figure 7-10. Timing of 2-Cycle DMA Transfer (SRAM → SDRAM):
Single Transfer Mode (SRAM Data 1 Wait, BMC Register = 00H,
Edge Detection Mode)**

Figure 7-11. Timing of 2-Cycle DMA Transfer (SRAM → External I/O)

Figure 7-12. Timing of 2-Cycle DMA Transfer (SDRAM → SRAM)

(1) Timing of $\overline{\text{DMARQn}}$ and $\overline{\text{DMAAKn}}$ signals for 2-cycle transfer

The targets of 2-cycle transfer are as follows.

Table 7-1. Targets of 2-Cycle Transfer

		Transfer Destination			
		External I/O/External Memory	On-Chip Peripheral I/O	Internal Data RAM	Internal Instruction RAM
Transfer source	External I/O/external memory	√	√	√	√
	On-chip peripheral I/O	√	√	√	√
	Internal data RAM	√	√	×	√

Remarks 1. √: Can be transferred, ×: Cannot be transferred

2. For details, refer to Table 7-4 Minimum Value of Active Width of $\overline{\text{DMAAKn}}$ Signal for 2-Cycle Transfer.

The bus configuration is as shown below.

Figure 7-13. Bus Configuration

The $\overline{\text{DMAAKn}}$ signal output by the DMA controller is asserted in a cycle used to write/read the external I/O or external memory ($n = 0$ to 3).

The data transfer path for 2-cycle transfer is shown below.

Table 7-2. Data Transfer Path for 2-Cycle Transfer

		Transfer Destination			
		External I/O/External Memory	On-Chip Peripheral I/O	Internal Data RAM	Internal Instruction RAM
Transfer source	External I/O/external memory	<6> → <1> → <5>	<6> → <1> → <4>	<6> → <1> → <3>	<6> → <1> → <2>
	On-chip peripheral I/O	<4> → <1> → <5>	<4> → <1> → <4>	<4> → <1> → <3>	<4> → <1> → <2>
	Internal data RAM	<3> → <1> → <5>	<3> → <1> → <4>	–	<3> → <1> → <2>

The correlation between external access during 2-cycle transfer (execution to external I/O/external memory) and the active width of the $\overline{\text{DMAAKn}}$ signal is as follows.

Table 7-3. Correlation Between External Access (Execution to External I/O/External Memory) and Active Width of $\overline{\text{DMAAKn}}$ Signal

		Transfer Destination			
		External I/O/External Memory	On-Chip Peripheral I/O	Internal Data RAM	Internal Instruction RAM
Transfer source	External I/O/external memory	√	√	√	√
	On-chip peripheral I/O	×	–	–	–
	Internal data RAM	×	–	–	–

Remarks √: The $\overline{\text{DMAAKn}}$ signal is asserted while DMA access to/from external I/O/external memory is being executed.

×: The $\overline{\text{DMAAKn}}$ signal may not be asserted while DMA access to/from external I/O/external memory is being executed.

Handshaking of the $\overline{\text{DMARQn}}$ and $\overline{\text{DMAAKn}}$ signals may be completed before a write operation to the external I/O or external memory is executed.

As soon as data has been transferred to the write buffer (<4> → <1> → <5> or <1> → <5>), assertion of the $\overline{\text{DMAAKn}}$ signal ends. Therefore, handshaking with the $\overline{\text{DMARQn/DMAAKn}}$ signal may be completed before a write operation to the external I/O or external memory is executed. If data of three buffers has already been stored in the write buffer separately, data transferred by DMA is stored in the fourth buffer, and the $\overline{\text{DMAAKn}}$ signal is then deasserted. Subsequently, when a write operation of the stored data has taken place three times, transfer to the external I/O or external memory targeted by the last $\overline{\text{DMAAKn}}$ signal (already deasserted) is executed (<5> → <6>).

(2) DMAAKn signal active width extension function

The DMAAKn signal is output in synchronization with the internal bus cycle during 2-cycle transfer, and is not synchronized with the external bus cycle ($n = 0$ to 3). The DMA cycle differs depending on the configuration subject to DMA transfer (refer to 7.5.1 (1) Timing of $\overline{\text{DMARQn}}$ and $\overline{\text{DMAAKn}}$ signals for 2-cycle transfer).

To sample assertion of the $\overline{\text{DMAAKn}}$ signal with BUSCLK, extend the active width of the $\overline{\text{DMAAKn}}$ signal by using the DIFCn.DAKEn3 to DIFCn.DAKEn0 bits.

The minimum value of the active width of the $\overline{\text{DMAAKn}}$ during 2-cycle transfer is shown in the table below.

Table 7-4. Minimum Value of Active Width of $\overline{\text{DMAAKn}}$ Signal During 2-Cycle Transfer**(a) $f_{\text{BUSCLK}} = 50 \text{ MHz}$ ($f_{\text{BUSCLK}} = f_{\text{VBCLK}}/2$)**

		Transfer Destination			
		External I/O/ External Memory	On-Chip Peripheral I/O	Internal Data RAM	Internal Instruction RAM
Transfer source	External I/O/external memory	$1 \times f_{\text{BUSCLK}}$ + Read cycle + $2 \times f_{\text{BUSCLK}}$	$0.5 \times f_{\text{BUSCLK}}$ + Read cycle + $4.5 \times f_{\text{BUSCLK}}$	$0.5 \times f_{\text{BUSCLK}}$ + Read cycle + $4 \times f_{\text{BUSCLK}}$	$0.5 \times f_{\text{BUSCLK}}$ + Read cycle + $4 \times f_{\text{BUSCLK}}$
	On-chip peripheral I/O	$1.5 \times f_{\text{BUSCLK}}$	–	–	–
	Internal data RAM	$1.5 \times f_{\text{BUSCLK}}$	–	–	–

(b) $f_{\text{BUSCLK}} = 66 \text{ MHz}$ ($f_{\text{BUSCLK}} = f_{\text{VBCLK}}$)

		Transfer Destination			
		External I/O/ External Memory	On-Chip Peripheral I/O	Internal Data RAM	Internal Instruction RAM
Transfer source	External I/O/external memory	$1 \times f_{\text{BUSCLK}}$ + Read cycle + $4 \times f_{\text{BUSCLK}}$	$1 \times f_{\text{BUSCLK}}$ + Read cycle + $9 \times f_{\text{BUSCLK}}$	$1 \times f_{\text{BUSCLK}}$ + Read cycle + $7 \times f_{\text{BUSCLK}}$	$1 \times f_{\text{BUSCLK}}$ + Read cycle + $7 \times f_{\text{BUSCLK}}$
	On-chip peripheral I/O	$3 \times f_{\text{BUSCLK}}$	–	–	–
	Internal data RAM	$3 \times f_{\text{BUSCLK}}$	–	–	–

Caution The function to extend the active width of the $\overline{\text{DMAAKn}}$ signal can be used only during 2-cycle transfer ($n = 0$ to 3). It cannot be used during flyby transfer. The operation is not guaranteed if it is used during flyby transfer. During flyby transfer, the $\overline{\text{DMAAKn}}$ signal synchronized with the bus cycle is output.

Remarks 1. i: Number of wait cycles set by VSWC register
2. f_{BUSCLK} : BUSCLK frequency

7.5.2 Flyby transfer

Since data is transferred in 1 cycle during a flyby transfer, a memory address is always output irrespective whether it is a source address or a destination address, and read/write signals of the memory and external I/O become active at the same time. Therefore, the external I/O is selected by the $\overline{\text{DMAAK0}}$ to $\overline{\text{DMAAK3}}$ signals.

To perform a normal access to the external I/O by means other than DMA transfer, externally AND the $\overline{\text{CSm}}$ and $\overline{\text{DMAAKx}}$ signals ($m = 0$ to 7 , $x = 0$ to 3), and connect the resultant signal to the chip select signal of the external I/O. A circuit example of a normal access, other than DMA transfer, to external I/O is shown below.

Caution Flyby transfer to SDRAM is possible only from external I/O.

Figure 7-14. Circuit Example When Flyby Transfer Is Performed Between External I/O and SRAM

7.6 Transfer Target

7.6.1 Transfer type and transfer target

Table 7-1 lists the relationships between transfer type and transfer target. The mark “√” means “transfer possible”, and the mark “×” means “transfer impossible”.

Table 7-5. Relationship Between Transfer Type and Transfer Target

		Transfer Destination									
		2-Cycle Transfer					Flyby Transfer				
		On-Chip Peripheral I/O ^{Note 1}	External I/O	Internal Data RAM	Internal Instruction RAM	External Memory	On-Chip Peripheral I/O	External I/O	Internal Data RAM	Internal Instruction RAM	External Memory
Transfer source	On-chip peripheral I/O ^{Note 1}	√	√	√	×	√	×	×	×	×	×
	External I/O	√	√	√	√	√	×	×	×	×	√
	Internal data RAM	√	√	×	√ ^{Note 2}	√	×	×	×	×	×
	External memory	√	√	√	√ ^{Note 2}	√	×	√ ^{Note 3}	×	×	×

- Notes 1.** If the transfer source is the on-chip peripheral I/O, only the single transfer mode can be used. However, if the start factor of the transfer is a request from the USB, only the single-step transfer mode can be used.
- 2.** These transfer areas are valid only when the internal instruction RAM is enabled to be write-accessed (IRWE.IRWEN bit = 0).
For details, refer to **4.9 (2) Instruction RAM mode register (IRWE)**.
- 3.** Flyby transfer to SDRAM is possible only from external I/O. The reverse direction is not possible.

- Cautions 1.** The operation is not guaranteed for combinations of transfer destination and source marked with “×” in Table 7-5.
- 2.** In the case of flyby transfer, make the data bus width the same for the source and destination.
- 3.** Do not use DMA transfer to set on-chip peripheral I/O registers and to read the set values.

- Remark 1.** During 2-cycle DMA transfer, if the data bus width of the transfer source and that of the transfer destination are different, the operation becomes as follows.
If DMA transfer is executed to transfer data of an on-chip peripheral I/O register (as a transfer source or destination), be sure to specify the same transfer size as the register size. For example, to execute DMA transfer of an 8-bit register, be sure to specify byte (8-bit) transfer.

<32-bit transfer>

- Transfer from a 32-bit bus to a 17-bit bus
A read cycle (32 bits) is generated and then a write cycle (16 bits) is generated twice consecutively.
- Transfer from a 32-bit bus to an 8-bit bus
A read cycle (32 bits) is generated and then a write cycle (8 bits) is generated 4 times consecutively.

- Transfer from a 16-bit bus to an 8-bit bus
A read cycle (16 bits) is generated twice consecutively and then a write cycle (8 bits) is generated 4 times consecutively.
- Transfer from a 16-bit bus to a 32-bit bus
A read cycle (16 bits) is generated twice consecutively and then a write cycle (32 bits) is generated. For how to write data to the transfer destination, see **Remark 2** below.
- Transfer from an 8-bit bus to a 32-bit bus
A read cycle (8 bits) is generated 4 times consecutively and then a write cycle (32 bits) is generated. For how to write data to the transfer destination, see **Remark 2** below.
- Transfer from an 8-bit bus to a 16-bit bus
A read cycle (8 bits) is generated 4 times consecutively and then a write cycle (16 bits) is generated twice consecutively. For how to write data to the transfer destination, see **Remark 2** below.

<16-bit transfer>

- Transfer from a 32-bit bus to a 16-bit bus
A read cycle (the higher 16 bits are high impedance) is generated and then a write cycle (16 bits) is generated.
- Transfer from a 32-bit bus to an 8-bit bus
A read cycle (the higher 16 bits are high impedance) is generated and then a write cycle (8 bits) is generated twice consecutively.
- Transfer from a 16-bit bus to an 8-bit bus
A read cycle (16 bits) is generated and then a write cycle (8 bits) is generated twice consecutively.
- Transfer from a 16-bit bus to a 32-bit bus
A read cycle (16 bits) is generated and then a write cycle (the higher 16 bits are high impedance) is generated. For how to write data to the transfer destination, see **Remark 2** below.
- Transfer from an 8-bit bus to a 32-bit bus
A read cycle (8 bits) is generated twice consecutively and then a write cycle (the higher 16 bits are high impedance) is generated. For how to write data to the transfer destination, see **Remark 2** below.
- Transfer from an 8-bit bus to a 16-bit bus
A read cycle (8 bits) is generated twice consecutively and then a write cycle (16 bits) is generated. For how to write data to the transfer destination, see **Remark 2** below.

<8-bit transfer>

- Transfer from a 32-bit bus to a 16-bit bus
A read cycle (the higher 24 bits are high impedance) is generated and then a write cycle (the higher 8 bits are high impedance) is generated.
- Transfer from a 32-bit bus to an 8-bit bus
A read cycle (the higher 24 bits are high impedance) is generated and then a write cycle (8 bits) is generated.
- Transfer from a 16-bit bus to an 8-bit bus
A read cycle (the higher 8 bits are high impedance) is generated and then a write cycle (8 bits) is generated.
- Transfer from a 16-bit bus to a 32-bit bus
A read cycle (the higher 8 bits are high impedance) is generated and then a write cycle (the higher 24 bits are high impedance) is generated. For how to write data to the transfer destination, see **Remark 2** below.

- Transfer from an 8-bit bus to a 32-bit bus
A read cycle (8 bits) is generated and then a write cycle (the higher 24 bits are high impedance) is generated. For how to write data to the transfer destination, see **Remark 2** below.
- Transfer from an 8-bit bus to a 16-bit bus
A read cycle (8 bits) is generated and then a write cycle (the higher 8 bits are high impedance) is generated. For how to write data to the transfer destination, see **Remark 2** below.

Remark 2. Under the following conditions, data is written to the lower byte and then the higher byte of the transfer destination.

- Transfer from a 16-bit bus to a 32-bit bus
- Transfer from an 8-bit bus to a 32-bit bus
- Transfer from an 8-bit bus to a 16-bit bus

7.6.2 External bus cycles during DMA transfer

The external bus cycles during DMA transfer are shown below.

Table 7-6. External Bus Cycles During DMA Transfer

Transfer Type	Transfer Target	External Bus Cycle	
2-cycle transfer	On-chip peripheral I/O, internal data RAM, internal instruction RAM	None	–
	External I/O	Yes	SRAM cycle
	External memory	Yes	Memory access cycle set by the BCT register
Flyby transfer	Between external memory and external I/O	Yes	DMA flyby transfer cycle accessing memory that is set as external memory by the BCT register

7.7 DMA Channel Priority Control

Priority control has two modes: Fixed-priority and round-robin modes. Selection of mode is performed using the DC.PR bit.

7.7.1 Fixed-priority mode

The DMA channel priorities are fixed as follows.

DMA channel 0 > DMA channel 1 > DMA channel 2 > DMA channel 3

In the block transfer mode, the channel used for transfer is never switched.

In the single-step transfer mode, if a higher priority DMA transfer request is issued while the bus is released, the higher priority DMA transfer request is acknowledged.

Caution If DMA is started by inputting the same signal to more than one $\overline{\text{DMARQ}}_n$ pin ($n = 0$ to 3), a DMA channel with a lower priority may be acknowledged before a DMA channel with a higher priority.

Figure 7-20. Example of DMA Transfer in Fixed-Priority Mode

7.7.2 Round-robin mode

In round-robin mode, the priority is changed each time a transfer request is acknowledged so that the channel with which the transfer is performed most recently is given the lowest priority.

The priority immediately after a reset is the same as that in fixed-priority mode, as shown below.

DMA channel 0 > DMA channel 1 > DMA channel 2 > DMA channel 3

The priority is also set as above when the DC.PR bit is cleared (0).

The following shows an example of a priority change when DMA transfer is performed with the priority immediately after reset.

Table 7-7. Example of Priority Change in DMA Channels 3 to 0 in Round-Robin Mode

Priority Before Transfer	DMA Channel Used for Transfer	Priority After Transfer	Remark
DMA0 > DMA1 > DMA2 > DMA3	DMA 3	DMA0 > DMA1 > DMA2 > DMA3 (Priority does not change.)	–
	DMA2	DMA3 > DMA0 > DMA1 > DMA2	The lowest priority is given to DMA2. At the same time, the priorities of DMA0 and DMA1, which have been higher than that of DMA2, are shifted.
	DMA1	DMA2 > DMA3 > DMA0 > DMA1	The lowest priority is given to DMA1. At the same time, the priority of DMA0, which has been higher than that of DMA1, are shifted.
	DMA0	DMA1 > DMA2 > DMA3 > DMA0	After transfer, lowest priority is given to DMA0.

Remark DMA_n: DMA channel n (n = 3 to 0)

The figure shown below illustrates an example when a DMA transfer request with a priority higher than that of DMA transfer currently being executed in round-robin mode is generated, thereby causing a priority change (DMA channels 3 and 0 (DMA3 and DMA0) are using single transfer, and DMA channels 2 and 1 (DMA2 and DMA1) are using block transfer).

Figure 7-21. Example of DMA Transfer in Round-Robin Mode

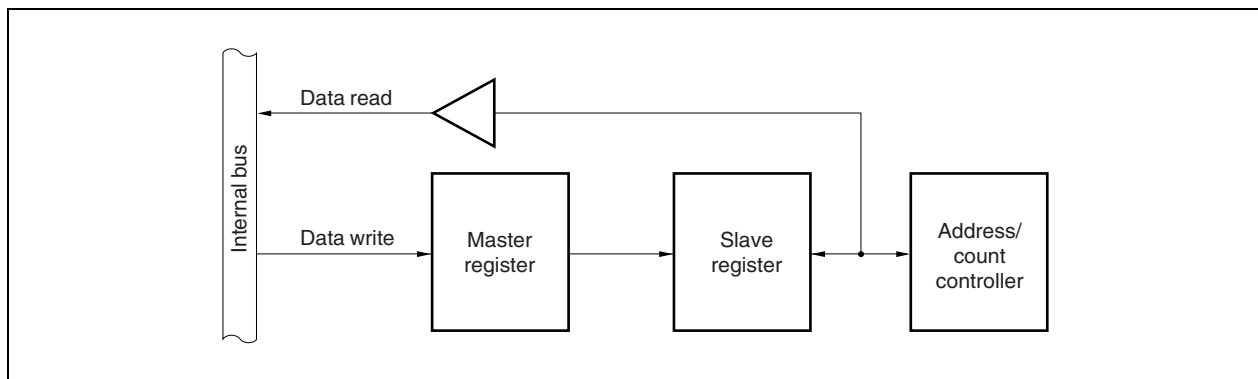

7.8 Next Address Setting Function

The DSA_n, DDA_n, and DBC_n registers are buffer registers with a 2-stage FIFO configuration ($n = 0$ to 3). When the terminal count is issued, these registers are automatically rewritten with the value that was set immediately before.

Therefore, during DMA transfer, transfer is automatically started when a new DMA transfer setting is made for these registers and the DCHC_n.EN_n bit, and MLE_n bit is set to 1 (however, the DMA transfer end interrupt may be issued even if DMA transfer is automatically started).

The configuration of the buffer register is shown below.

Figure 7-22. Buffer Register Configuration

The actual DMA transfer is executed in accordance with the contents of the slave register.

If data is written to the DSA_n, DDA_n, or DBC_n register when the DCHC_n.EN_n bit has been cleared (0), the data is written to both the master and slave registers. When the EN_n bit has been set (1), data is written to the master register only.

If the setting of a new DMA transfer is made using the DSA_n, DDA_n, and DBC_n registers during DMA transfer, the values of the registers are automatically updated after completion of transfer^{Note}.

Note Before setting a new DMA transfer, confirm the start of the preceding DMA transfer.

If the setting of the new DMA transfer is made before the start of the preceding DMA transfer, the new set value is overwritten to both the master register and slave register, and DMA transfer according to the preceding set value cannot be executed.

7.9 DMA Transfer Start Factors

There are 4 types of DMA transfer start factors, as shown below.

(1) Request from an external pin ($\overline{\text{DMARQn}}$)

Requests from the $\overline{\text{DMARQn}}$ pin are sampled each time the $\overline{\text{BUSCLK}}$ signal rises ($n = 0$ to 3).

Hold the request from $\overline{\text{DMARQn}}$ pin until the corresponding $\overline{\text{DMAAKn}}$ signal becomes active.

If a state whereby the DCHCn.TCn bit = 0 and the ENn bit = 1 is set, the $\overline{\text{DMARQn}}$ signal becomes valid. If the $\overline{\text{DMARQn}}$ signal set by the DTFRn register becomes active in this status, DMA transfer starts.

Remark Since the $\overline{\text{DMARQn}}$ signal is level-sampled and not edge-detected, to enable edge detection of a DMA request, set an external interrupt request for the DMA start trigger instead of using the $\overline{\text{DMARQn}}$ signal ($n = 0$ to 3).

(2) Request from software

If the DCHCn.TCn , DCHCn.ENn , and DCHCn.STGn bits are set as follows, DMA transfer starts ($n = 0$ to 3).

- TCn bit = 0
- ENn bit = 1
- STGn bit = 1

(3) Request from on-chip peripheral I/O

If, when the TCn and ENn bits are set as shown below, an interrupt request is issued from the on-chip peripheral I/O that is set in the DTFRn register, DMA transfer starts ($n = 0$ to 3).

- TCn bit = 0
- ENn bit = 1

(4) Request by USB (enabled only in single-step transfer mode)

If a request is generated from the USB set to the DTFRn register when the TCn and ENn bits are set as follows, DMA transfer starts ($n = 0$ to 3).

- TCn bit = 0
- ENn bit = 1

Cautions 1. Do not use two or more start factors ((1) to (4)) in combination for the same channel (if two or more start factors are generated at the same time, only one of them is valid, but the valid start factor cannot be identified).

The operation is not guaranteed if two or more start factors are used in combination.

2. If DMA transfer is started via software and if the software does not correctly detect whether the expected DMA transfer operation has been completed through manipulation (setting to 1) of the DCHCn.STGn bit, it cannot be guaranteed whether the next (second) manipulation of the STGn bit corresponds to the start of “the next DMA transfer expected by software” (n = 0 to 3).

For example, suppose single transfer is started by manipulating the STGn bit. Even if the STGn bit is manipulated next (the second time) without checking by software whether the single transfer has actually been executed, the next (second) DMA transfer is not always executed. This is because the STGn bit may be manipulated the second time before the first DMA transfer is started or completed because, for example, DMA transfer with a higher priority had already been started when the STGn bit was manipulated for the first time.

It is therefore necessary to manipulate the STGn bit next time (the second time) after checking whether DMA transfer started by the first manipulation of the STGn bit has been completed.

Completion of DMA transfer can be checked in the following ways.

- Detecting the acknowledge signal ($\overline{\text{DMAAKn}}$) or terminal count signal ($\overline{\text{TCn}}$) by using a peripheral port or interrupt
- Checking the contents of the DBCn register

7.10 Terminal Count Output upon DMA Transfer End

The terminal count signal (\overline{TCn}) becomes active for one clock of BUSCLK during the last DMA transfer cycle ($n = 3$ to 0).

Figure 7-23. Terminal Count Signal (\overline{TCn}) Timing Example (1)

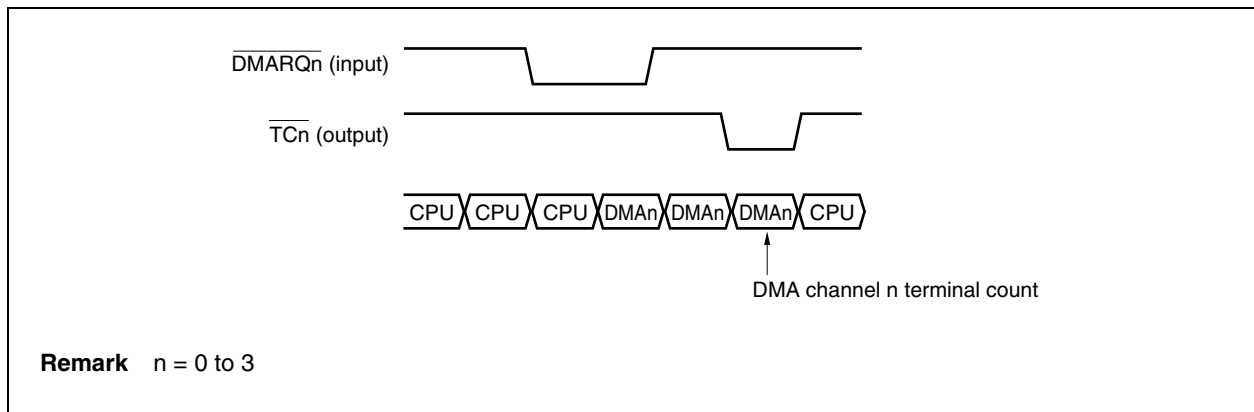

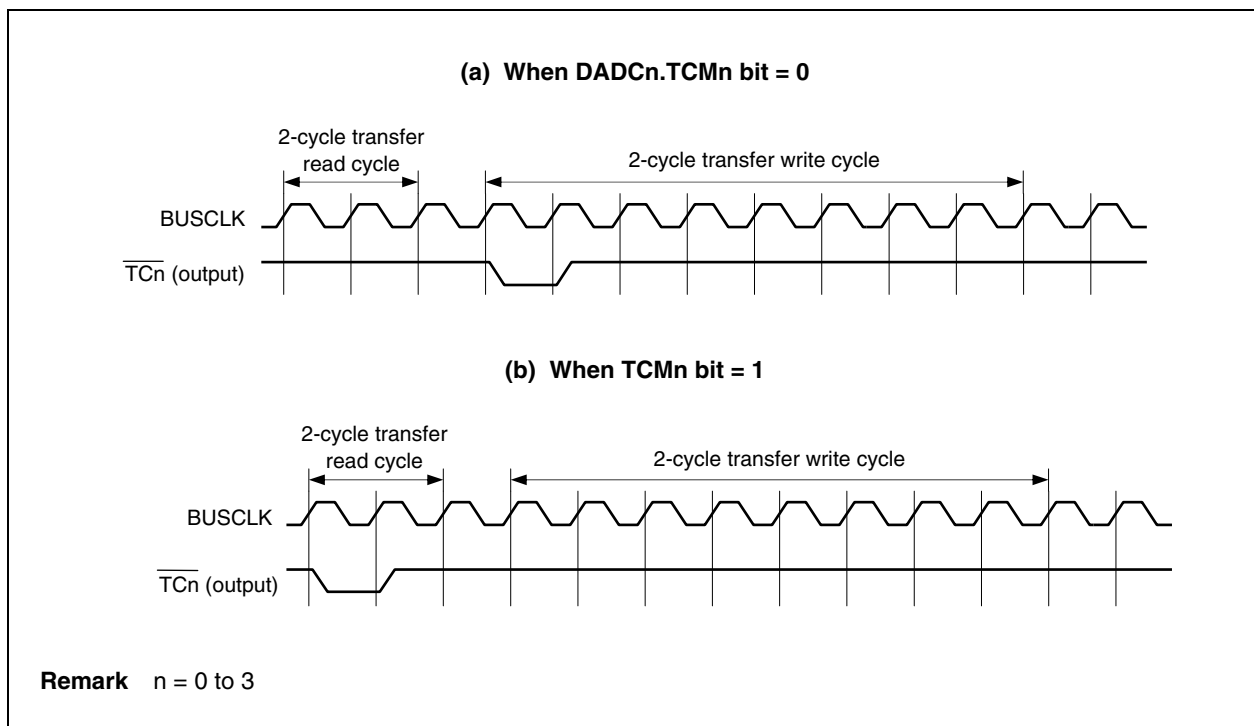

Figure 7-24. Terminal Count Signal (\overline{TCn}) Timing Example (2)

(2-Cycle Transfer from External Memory (32 Bits) to External Memory (8 Bits), Transfer Data Size: 32 Bits)

7.11 Forcible Interruption

DMA transfer can be forcibly interrupted by NMI input during DMA transfer.

When a valid edge is detected at the NMI input pin, the following processing is performed.

- <1> Transfer is interrupted after data of the size specified with the DADCn.DS1 and DADCn.DS0 bits has been transferred (only during DMA transfer).
- <2> The DRST.STPDIS bit is set (1).
- <3> DMA transfer of all channels is interrupted regardless of the DCHCn.ENn bit value.
- <4> An NMI request is acknowledged.

The STPDIS bit must be cleared (0) to resume the interrupted DMA transfer. When DMA transfer is resumed, transfer of a DMA channel that has been interrupted by NMI input before the transfer was started takes precedence over other channels.

If such an interrupted DMA channel does not take precedence when transfer is resumed, or if transfer is not resumed by a transfer request that has already been acknowledged, clear the ENn bit (0) set the DCHCn.FCLRn bit (1), then clear the STPDIS bit (0).

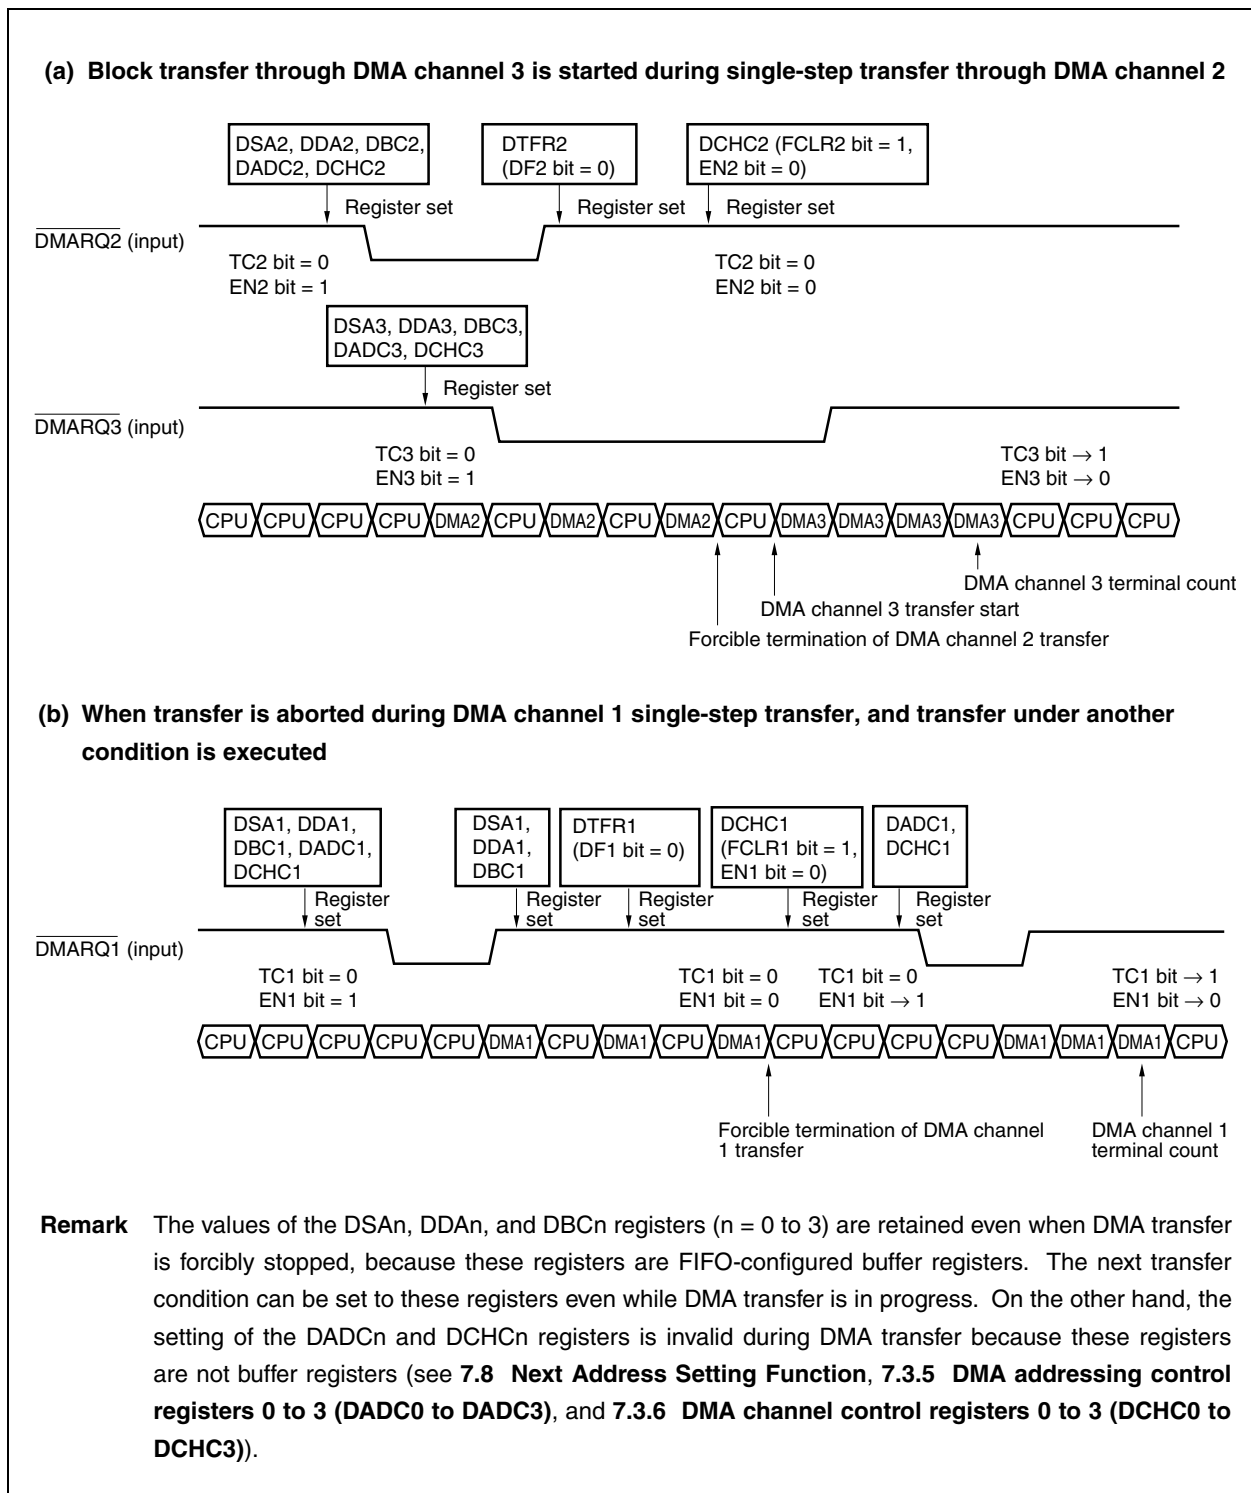

If the STPDIS bit is cleared (0) at the same time as an NMI input is detected, detection of the NMI input takes precedence. Therefore, design the system so that the timings for detecting NMI input and clearing the STPDIS bit (0) do not conflict.

7.12 Forcible Termination

DMA transfer can be forcibly terminated by the DTFRn.DFn, DCHCn.FCLRn, and DCHCn.ENn bits, in addition to the forcible interruption operation, by means of NMI input (n = 0 to 3).

Examples of forcible termination by the DFn, FCLRn, and ENn bits are illustrated below (n = 0 to 3).

Figure 7-25. Examples of Forcible Termination of DMA Transfer

7.13 Times Related to DMA Transfer

The overhead before and after DMA transfer and minimum execution clock for DMA transfer are shown below. In the case of external memory access, the time depends on the type of external memory connected.

Table 7-8. Number of Minimum Execution Clocks in DMA Cycle

DMA Cycle		Number of Minimum Execution Clocks
<1> Time to respond to DMA request		$6 \times f_{VBCLK}^{\text{Note}}$
<2> Memory access	External memory access	Differs depending on the memory connected
	Internal data RAM or internal instruction RAM access	Read operation: $7 \times f_{VBCLK}$, write operation: $6 \times f_{VBCLK}$
	On-chip peripheral I/O register access	$7 \times f_{VBCLK}$

Note If an external interrupt (INTPn) is specified as a factor of starting DMA transfer, noise elimination time is added ($n = 10, 11, 21$ to $25, 50$ to $52, 65$ to $67, D0$ to $D15, L0$, or $L1$).

The minimum execution clock in the DMA cycle in each transfer mode is as follows.

2-cycle transfer

- Single transfer: DMA response time (<1>) + Transfer source memory access (<2>) + 1^{Note} + Transfer destination memory access (<2>)
- Block transfer: DMA response time (<1>) + (Transfer source memory access (<2>) + 1^{Note} + Transfer destination memory access (<2>)) \times Number of transfers

Note One clock is always inserted between the read cycle and write cycle of DMA transfer. However, two clocks are inserted when the undivided external bus clock is used.

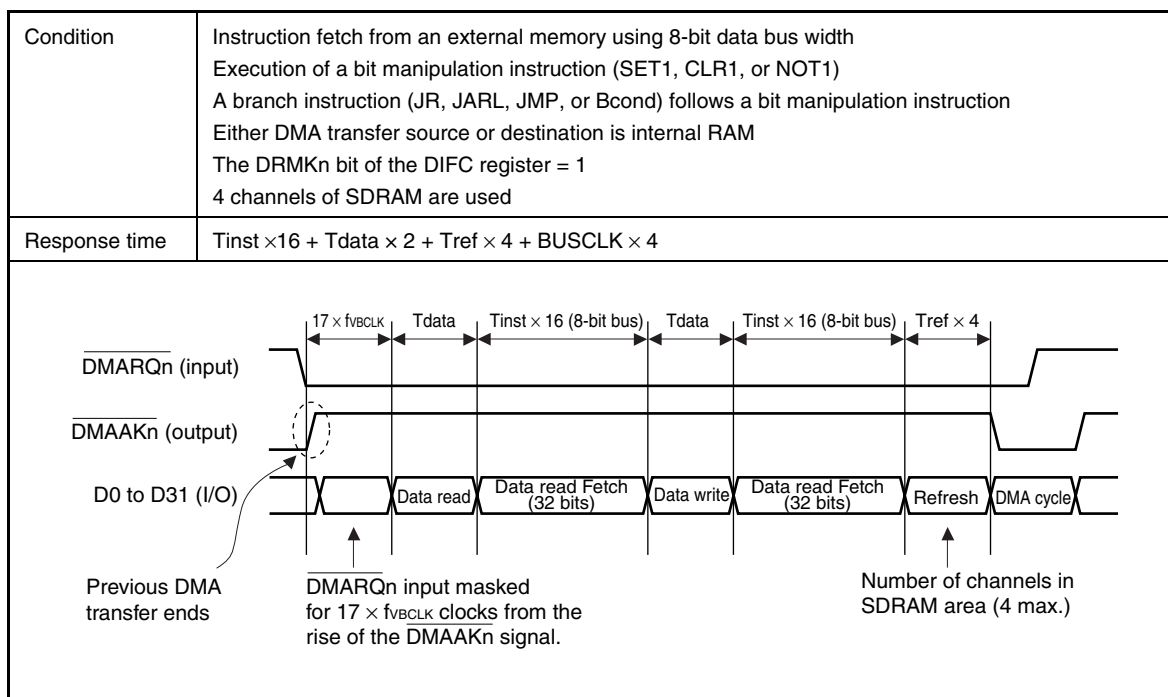

Flyby transfer: DMA response time (<1>) + External memory access (<2>)

7.14 Maximum Response Time for DMA Transfer Request

The response time for a DMA transfer request becomes the longest under the following conditions (state in which all the refresh cycles for the SDRAM are enabled).

Caution The wait time caused by the following conditions is not included.

- DMA with high priority occurs
- When DMA transfer triggered by other than the DMARQn pin input occurs
- External bus hold
- Cache miss-hit

- Remarks 1.** T_{inst} : Number of clocks per bus cycle during instruction fetch
 T_{data} : Number of clocks per bus cycle during data access
 T_{ref} : Number of clocks per refresh cycle
 $17 \times f_{VBCLK}$: Time for masking DMARQn input
- 2.** $n = 0$ to 3

7.15 Cautions

(1) Memory boundary

The transfer operation is not guaranteed if the source or the destination address exceeds the area of DMA objects (external memory, internal data RAM, internal instruction RAM, or on-chip peripheral I/O) during DMA transfer.

(2) Transfer of misaligned data

DMA transfer of 32-/16-bit bus width misaligned data is not supported. If the source or the destination address is set to an odd address, the LSB of the address is forcibly handled as "0".

(3) Bus arbitration for CPU

When DMA transfer is executed to transfer data to/from an external device, the CPU can access internal data RAM and internal instruction RAM not being used for DMA transfer.

Because the DMA controller has a priority higher than the CPU acquiring bus mastership, a CPU access that takes place during DMA transfer is kept waiting until the preceding DMA transfer is completed and the bus is released to the CPU. If DMA transfer is executed between the external memory and on-chip peripheral I/O, however, the CPU can access the internal data RAM and internal instruction RAM.

(4) Holding $\overline{\text{DMARQn}}$ signal

Be sure to keep the $\overline{\text{DMARQn}}$ signal active until the $\overline{\text{DMAAKn}}$ signal becomes active (n = 0 to 3).

(5) $\overline{\text{DMAAKn}}$ signal output

The $\overline{\text{DMAAKn}}$ signal keeps the active state in the TI state of flyby transfer.

(6) DMA start factors

Do not start two or more DMA channels with the same factor. If two or more DMA channels are started with the same factor, the DMA channel with the lower priority may be accepted before the DMA channel with the higher priority.

(7) Read values of DSAn and DDAn registers

If the values of the DSAn and DDAn registers are read during DMA transfer, the values in the middle of being updated may be read (n = 0 to 3).

For example, if the DSAnH register and the DSAnL register are read in that order when the value of the DMA transfer source address (DSAn register) is "0000FFFFH" and the counting direction is incremental (when the DADCn.SADn1 and DADCn.SADn0 bits = 00), the value of the DSAnL register differs as follows depending on whether DMA transfer is executed immediately after the DSAnH register has been read.

(a) If DMA transfer does not occur while the DSAn register is being read

<1> Reading DSAnH register: DSAnH = 0000H

<2> Reading DSAnL register: DSAnL = FFFFH

(b) If DMA transfer occurs while the DSAn register is being read

<1> Reading DSAnH register: DSAnH = 0000H

<2> Occurrence of DMA transfer

<3> Incrementing DSAn register : DSAn = 00010000H

<4> Reading DSAnL register: DSAnL = 0000H

(8) Cautions on setting DADCn register

If the set data is changed during a DMA transfer, operation is not guaranteed (re-setting the same value as already set value is enabled). Before changing data, clear the DCHCn.ENn bit to 0 and set the FCLRn bit to 1 (n = 0 to 3).

(9) Cautions on setting DCHCn register

During a 2-cycle transfer that performs a write operation to the external device, the write operation to the external device may not be completed even if the DCHCn.TCn bit is set to 1 (DMA transfer completion) by the write buffer function. Recognize completion of the write operation to the external device as follows, if necessary (n = 0 to 3).

(a) Monitor the signal of the \overline{TCn} pin (the \overline{TCn} pin becomes active in synchronization with a write operation to the external device).

(b) After it has been detected that the TCn bit is set to 1, write 00H to the WAS register. When this write is completed, completion of an access from the write buffer to the external device can be recognized.

(10) Caution on setting DTFRn register

An interrupt request from an on-chip peripheral I/O input in the IDLE mode is held pending as a DMA transfer start factor (n = 0 to 3). The held DMA start factor is executed after restoring to the normal operation mode.

(11) \overline{DMAAKn} signal active width extension function

The function to extend the active width of the \overline{DMAAKn} signal can be used only during 2-cycle transfer (n = 0 to 3). It cannot be used during flyby transfer. The operation is not guaranteed if it is used during flyby transfer. During flyby transfer, the \overline{DMAAKn} signal synchronized with the bus cycle is output.

(12) SDRAM flyby transfer

Flyby transfer to SDRAM is possible only from external I/O.

7.15.1 Interrupt factors

DMA transfer is interrupted if the following factors are issued.

- Bus hold
- Refresh cycle

If the factor that is interrupting DMA transfer disappears, DMA transfer promptly restarts.

7.16 DMA Transfer End

When DMA transfer ends and the DCHCn.TCn bit is set to 1, a DMA transfer end interrupt (INTDMA_n) is issued to the interrupt controller (INTC) (n = 0 to 3).

CHAPTER 8 INTERRUPT/EXCEPTION PROCESSING FUNCTION

The V850E2/ME3 is provided with a dedicated interrupt controller (INTC) for interrupt servicing and can process a total of 91 interrupt requests.

An interrupt is an event that occurs independently of program execution, and an exception is an event whose occurrence is dependent on program execution.

The V850E2/ME3 can process interrupt requests from the on-chip peripheral hardware and external sources. Moreover, exception processing can be started by the TRAP instruction (software exception) or by generation of an exception event (i.e. fetching of an illegal opcode) (exception trap).

8.1 Features

○ Interrupts

- Non-maskable interrupts: 1 source

Caution P20 is fixed to NMI input. The level of the NMI pin is read when the P20 bit of the P2 register is read, regardless of the value of the PM2 and PMC2 registers.

Set the valid edge of the NMI pin by using the NMIR0 bit of the INTR2 register and the NMIF0 bit of the INTF2 register (default value: both rising/falling edges detection).

- Maskable interrupt

External: 39 sources, Internal: 59 sources

- 8 levels of programmable priorities (maskable interrupts)
- Multiple interrupt control according to priority
- Masks can be specified for each maskable interrupt request.
- Noise elimination^{Note}, edge detection, and valid edge specification for external interrupt request signals.

Note See 15.6 Noise Eliminator for details of the noise eliminator.

○ Exceptions

- Software exceptions: 32 sources
- Exception traps: 2 sources (illegal opcode exception and debug trap)

Interrupt sources are listed in Table 8-1.

Table 8-1. Interrupt Source List (1/3)

Type	Classification	Interrupt/Exception Source				Default Priority	Exception Code	Handler Address	Restored PC
		Name	Controlling Register	Generating Source	Generating Unit				
Reset	Interrupt	RESET	–	Reset input	–	–	0000H	00000000H	Undefined
Non-maskable	Interrupt	NMI0	–	NMI input	–	–	0010H	00000010H	nextPC

Remarks 1. Default Priority: The priority order when two or more maskable interrupt requests occur at the same time. The highest priority is 0.

Restored PC: The value of the program counter (PC) saved to EIPC, FEPC, or DBPC of the CPU when interrupt servicing is started. Note, however, that the restored PC when a non-maskable or maskable interrupt is acknowledged while one of the following instructions is being executed does not become the nextPC. (If an interrupt is acknowledged during interrupt execution, execution stops, and then resumes after the interrupt servicing has finished. In this case, the address of the aborted instruction is the restore PC.)

- Division instructions (DIV, DIVH, DIVU, DIVHU)
- PREPARE, DISPOSE instructions (only if an interrupt is generated before the stack pointer is updated)

nextPC: The PC value that starts the processing following interrupt/exception processing.

2. The execution address of the illegal instruction when an illegal opcode exception occurs is calculated by (Restored PC – 4).

8.2 Non-Maskable Interrupts

A non-maskable interrupt request signal is acknowledged unconditionally, even when interrupts are in the interrupt disabled (DI) status. An NMI is not subject to priority control and takes precedence over all the other interrupts.

A non-maskable interrupt request signal is input from the NMI pin. When the valid edge specified by bit 0 (NMIR0) of external interrupt rising edge specification register 2 (INTR2) or bit 0 (NMIF0) of external interrupt falling edge specification register 2 (INTF2) is detected at the NMI pin, the interrupt occurs.

While the service program of the non-maskable interrupt is being executed, the acknowledgment of another non-maskable interrupt request signal is held pending. The pending NMI is acknowledged after the original service program of the non-maskable interrupt under execution has been terminated (by the RETI instruction). Note that if two or more NMI request signals are input during the execution of the service program for an NMI, the number of NMIs that will be acknowledged after the RETI instruction is executed is cleared to 0 is only one.

8.2.1 Operation

If a non-maskable interrupt is generated, the CPU performs the following processing, and transfers control to the handler routine:

- <1> Saves the restored PC to FEPC.
- <2> Saves the current PSW to FEPSW.
- <3> Writes exception code 0010H to the higher halfword (FECC) of ECR.
- <4> Sets the NP and ID bits of the PSW to 1 and clears the EP bit to 0.
- <5> Sets the handler address (00000010H) corresponding to the non-maskable interrupt to the PC, and transfers control.

The servicing configuration of a non-maskable interrupt is shown in Figure 8-1.

Figure 8-1. Servicing Configuration of Non-Maskable Interrupt

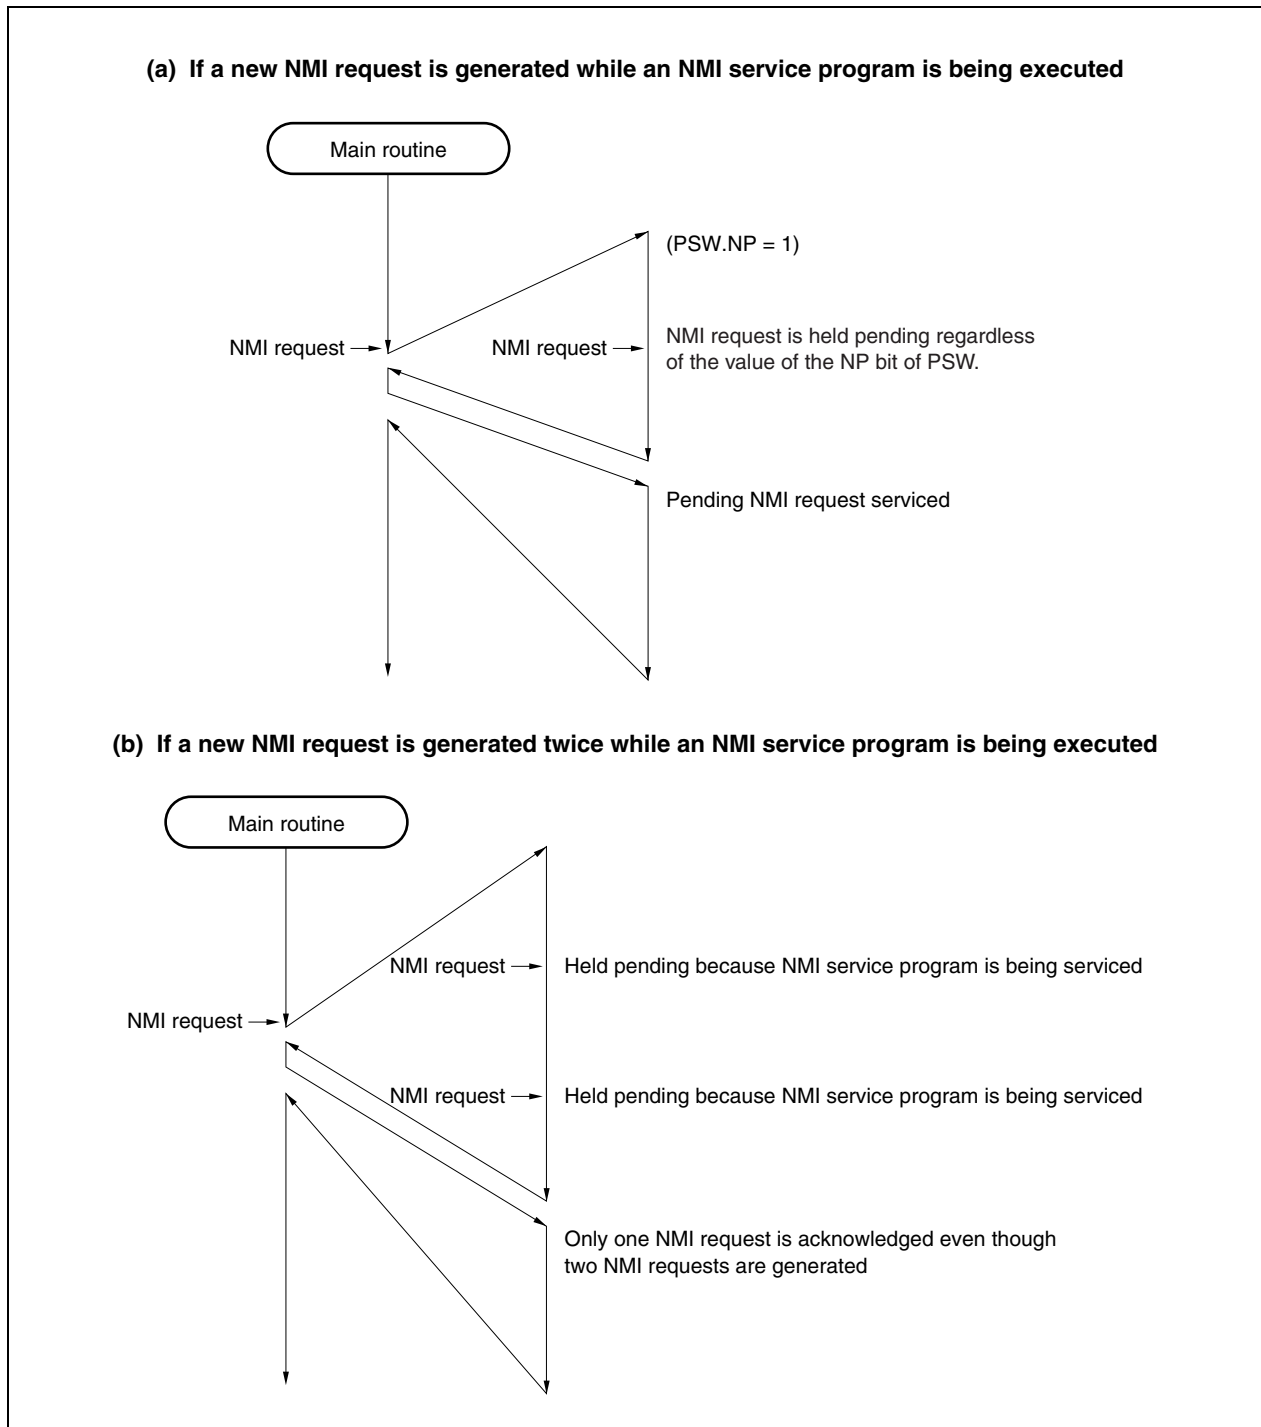

Figure 8-2. Acknowledging Non-Maskable Interrupt Request

8.2.2 Restore

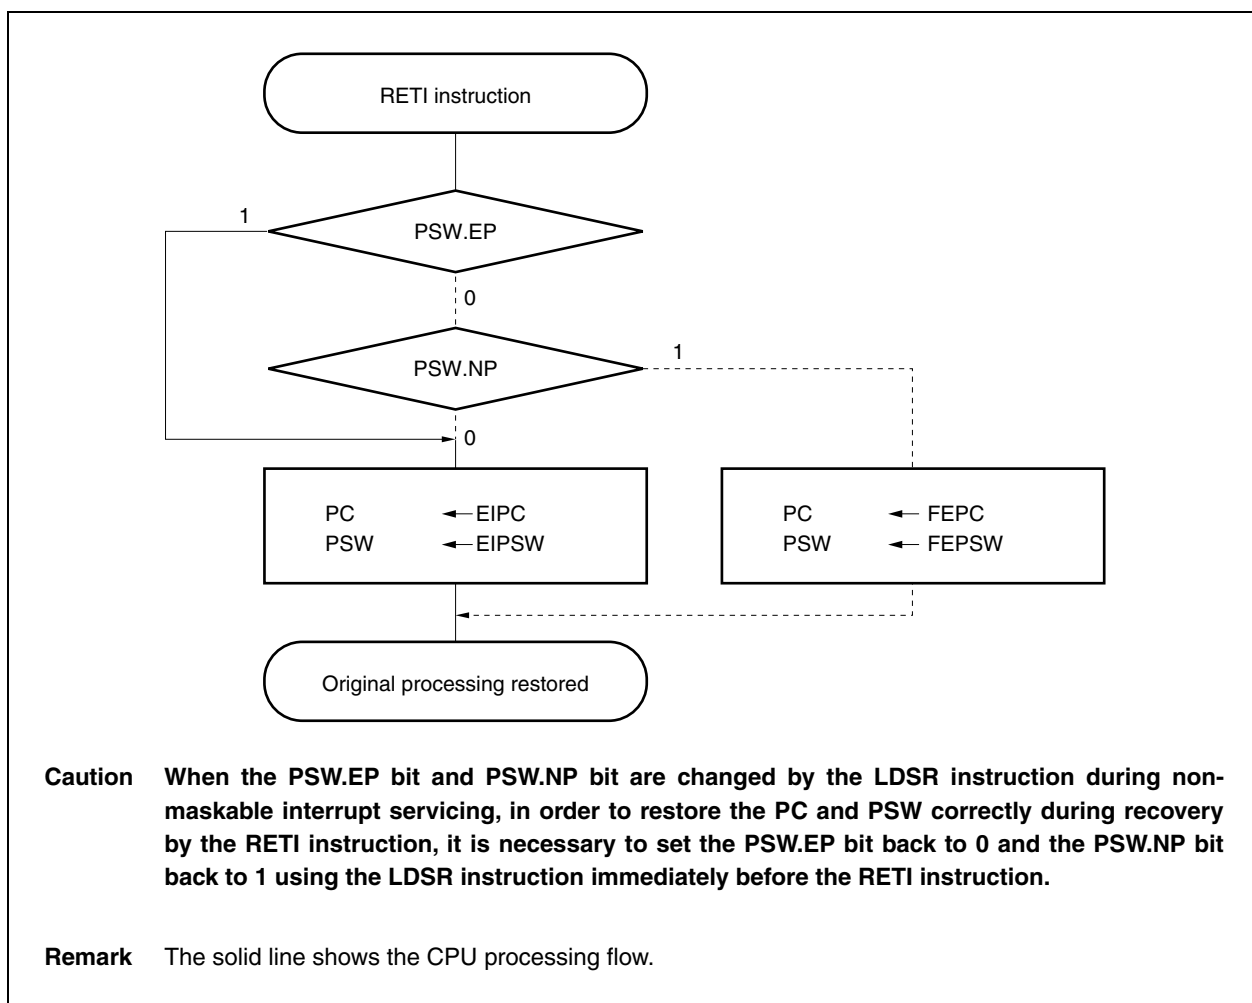

Execution is restored from the non-maskable interrupt servicing by the RETI instruction.

When the RETI instruction is executed, the CPU performs the following processing, and transfers control to the address of the restored PC.

- <1> Restores the values of the PC and the PSW from FEPC and FEPSW, respectively, because the EP bit of the PSW is 0 and the NP bit of the PSW is 1.
- <2> Transfers control back to the address of the restored PC and PSW.

Figure 8-3 illustrates how the RETI instruction is processed.

Figure 8-3. RETI Instruction Processing

8.3 Maskable Interrupts

Maskable interrupt request signals can be masked by interrupt control registers. The V850E2/ME3 has 90 maskable interrupt sources.

If two or more maskable interrupt request signals are generated at the same time, they are acknowledged according to the default priority. In addition to the default priority, eight levels of priorities can be specified by using the interrupt control registers (programmable priority control).

When an interrupt request signal has been acknowledged, the acknowledgment of other maskable interrupt request signals is disabled and the interrupt disabled (DI) status is set.

When the EI instruction is executed in an interrupt service routine, the interrupt enabled (EI) status is set, which enables servicing of interrupts having a higher priority than the interrupt request signal in progress (specified by the interrupt control register). Note that only interrupts with a higher priority will have this capability; interrupts with the same priority level cannot be nested.

However, when enabling multiple interrupts, save EIPC and EIPSW in memory or a register before executing the EI instruction, and execute the DI instruction before executing the RETI instruction to reset EIPC and EIPSW to the previous values.

8.3.1 Operation

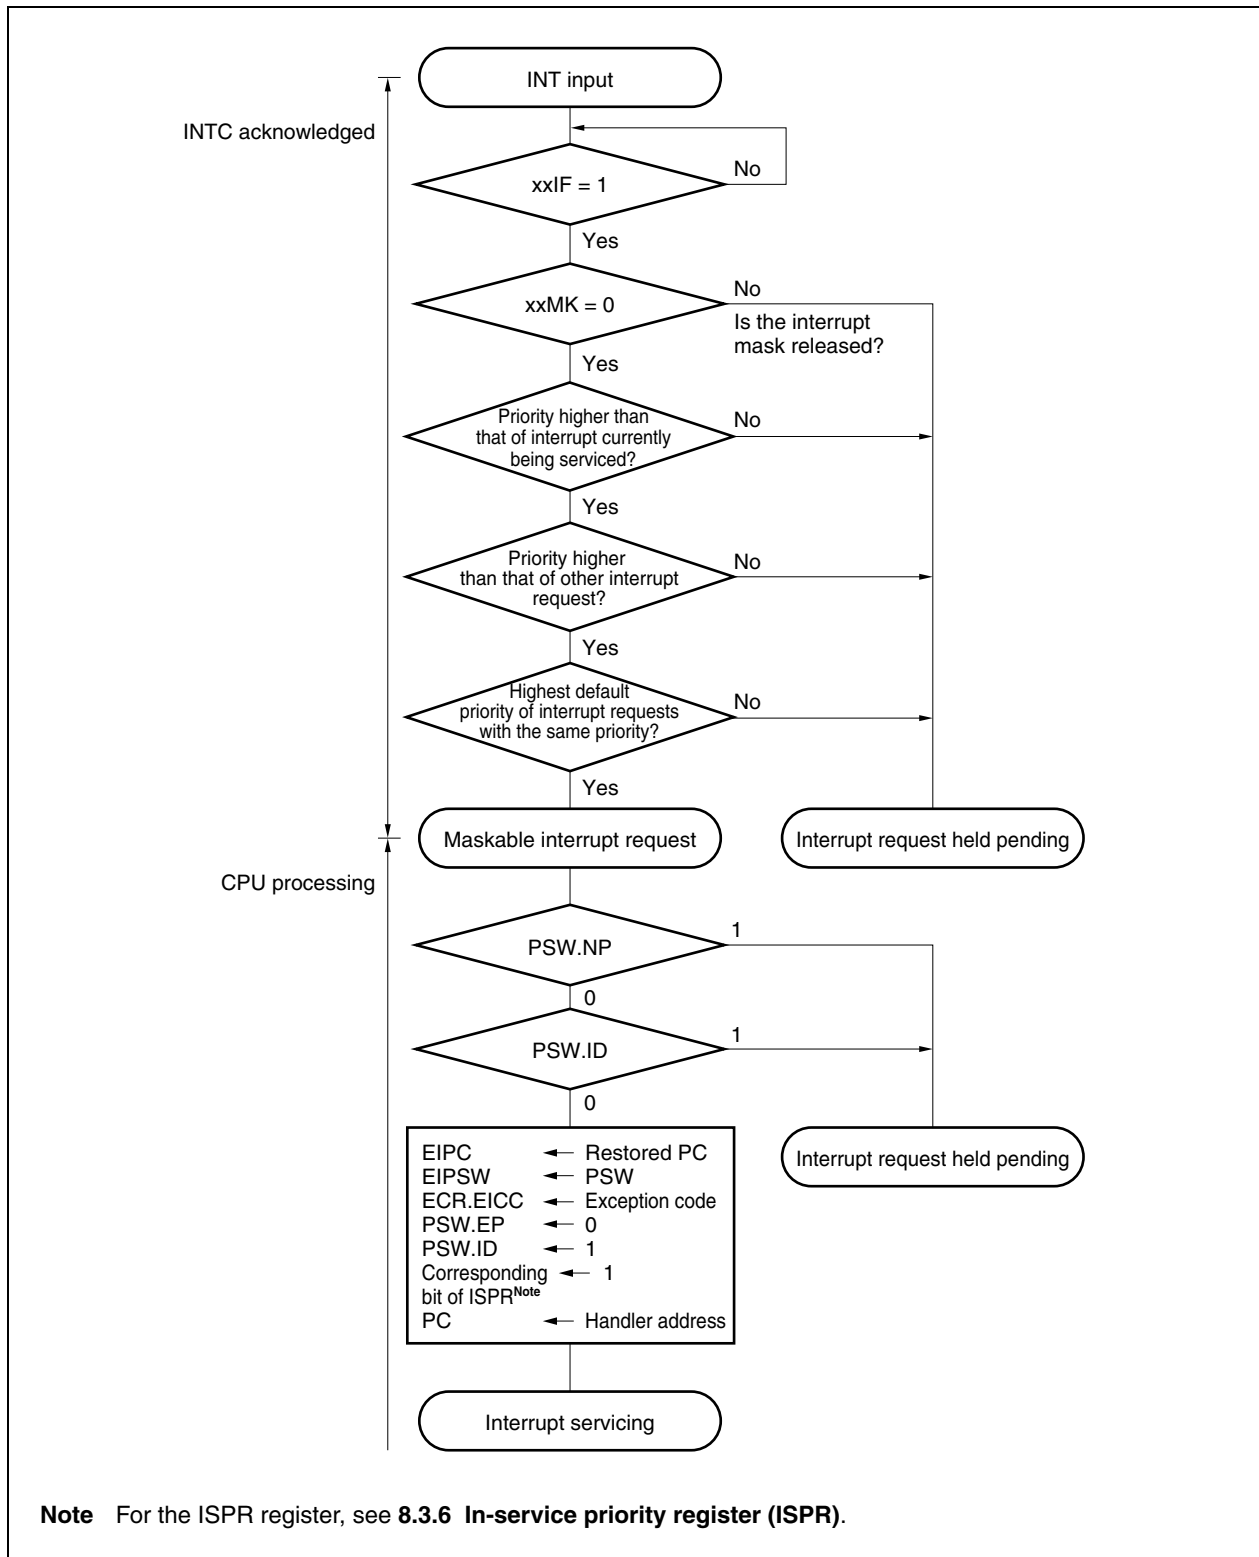

If a maskable interrupt occurs, the CPU performs the following processing, and transfers control to a handler routine:

- <1> Saves the restored PC to EIPC.
- <2> Saves the current PSW to EIPSW.
- <3> Writes an exception code to the lower halfword of ECR (EICC).
- <4> Sets the ID bit of the PSW to 1 and clears the EP bit to 0.
- <5> Sets the handler address corresponding to each interrupt to the PC, and transfers control.

The maskable interrupt request signal masked by the interrupt controllers (INTC) and the maskable interrupt request signal that occurs while another interrupt is being serviced (when the PSW.NP bit = 1 or PSW.ID bit = 1) are held pending internally by INTC. In such case, if the interrupts are unmasked, or when the NP bit = 0 and ID bit = 0 as set by the RETI and LDSR instructions, the new maskable interrupt servicing is started in accordance with the priority of the maskable interrupt request signal.

The servicing configuration of a maskable interrupt is shown in Figure 8-4.

Figure 8-4. Maskable Interrupt Servicing

8.3.2 Restore

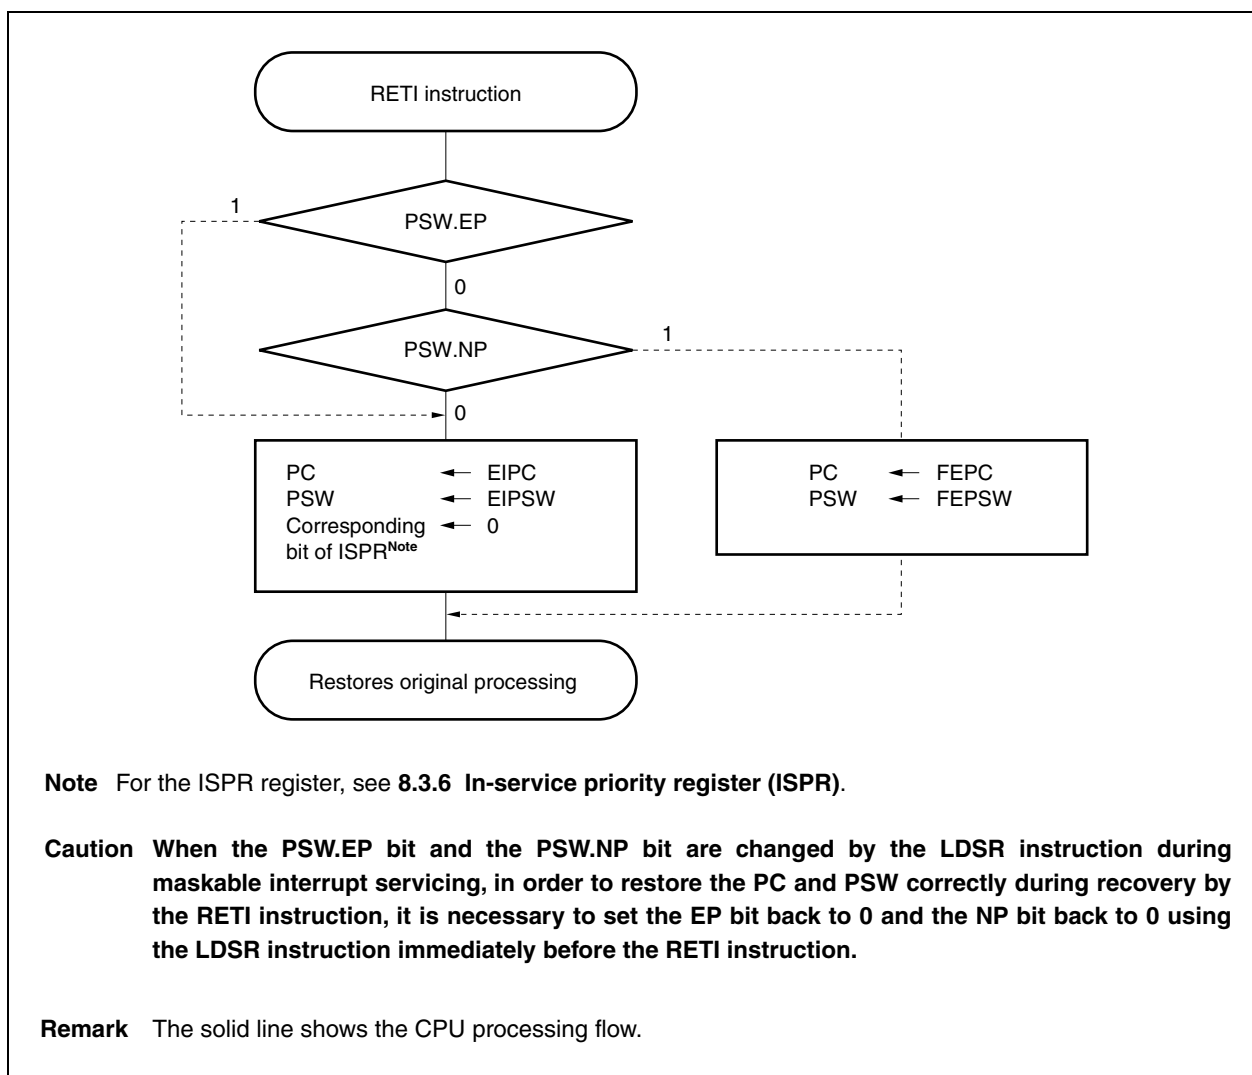

Recovery from maskable interrupt servicing is carried out by the RETI instruction.

When the RETI instruction is executed, the CPU performs the following steps, and transfers control to the address of the restored PC.

- <1> Restores the values of the PC and the PSW from EIPC and EIPSW because the EP bit of the PSW is 0 and the NP bit of the PSW is 0.
- <2> Transfers control to the address of the restored PC and PSW.

Figure 8-5 illustrates the processing of the RETI instruction.

Figure 8-5. RETI Instruction Processing

8.3.3 Priorities of maskable interrupts

The V850E2/ME3 provides multiple interrupt servicing in which an interrupt is acknowledged while another interrupt is being serviced. Multiple interrupts can be controlled by priority levels.

There are two types of priority level control: control based on the default priority levels, and control based on the programmable priority levels that are specified by the interrupt priority level specification bit (xxPRn) of the interrupt control register (xxICn). When two or more interrupts having the same priority level specified by the xxPRn bit are generated at the same time, interrupts are serviced in order depending on the priority level allocated to each interrupt request signal type (default priority level) beforehand. For more information, see **Table 8-1 Interrupt Source List**. The programmable priority control customizes interrupt request signals into eight levels by setting the priority level specification flag.

Note that when an interrupt request signal is acknowledged, the ID flag of PSW is automatically set to 1. Therefore, when multiple interrupts are to be used, clear the ID flag to 0 beforehand (for example, by placing the EI instruction in the interrupt service program) to set the interrupt enable mode.

Remark xx: Identification name of each peripheral unit (see **Table 8-2**)
n: Peripheral unit number (see **Table 8-2**)

Figure 8-6. Example of Processing in Which Another Interrupt Request Signal Is Generated While an Interrupt Is Being Serviced (1/2)

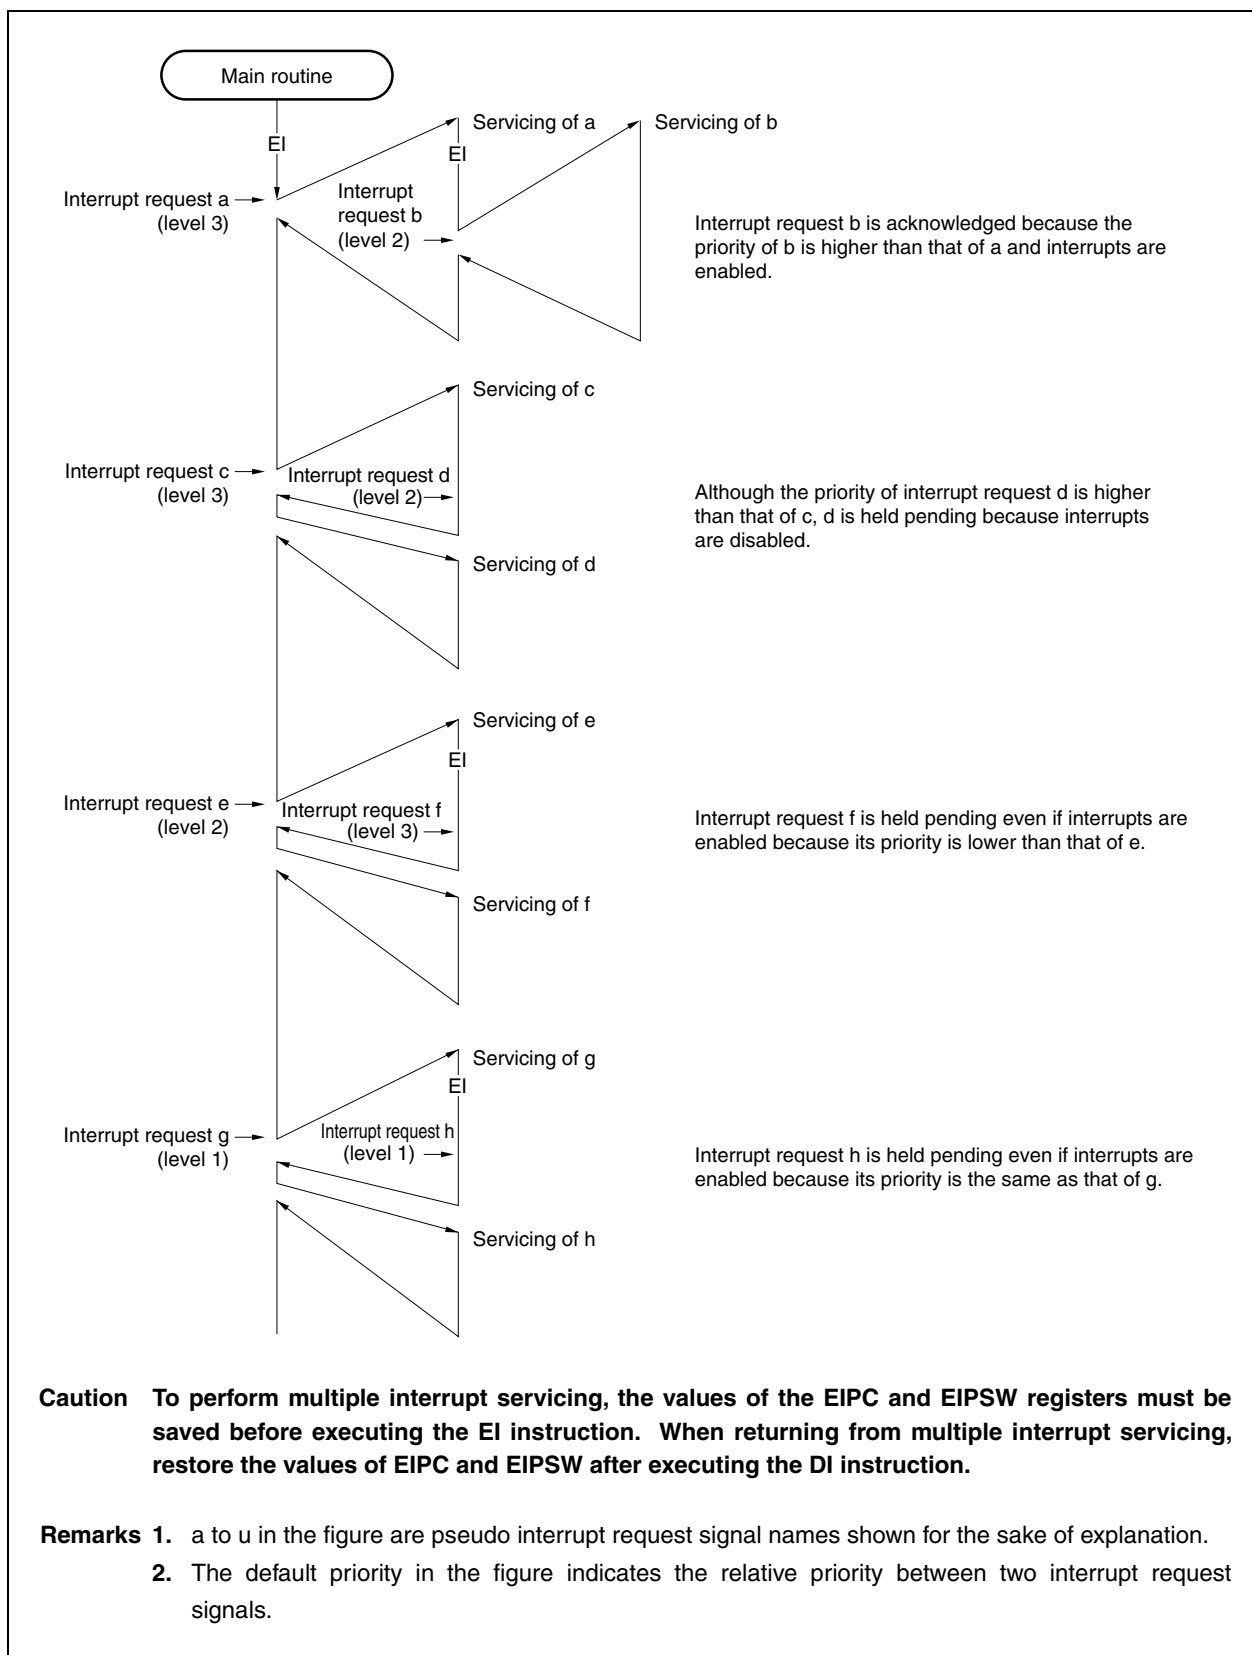

Figure 8-6. Example of Processing in Which Another Interrupt Request Signal Is Generated While an Interrupt Is Being Serviced (2/2)

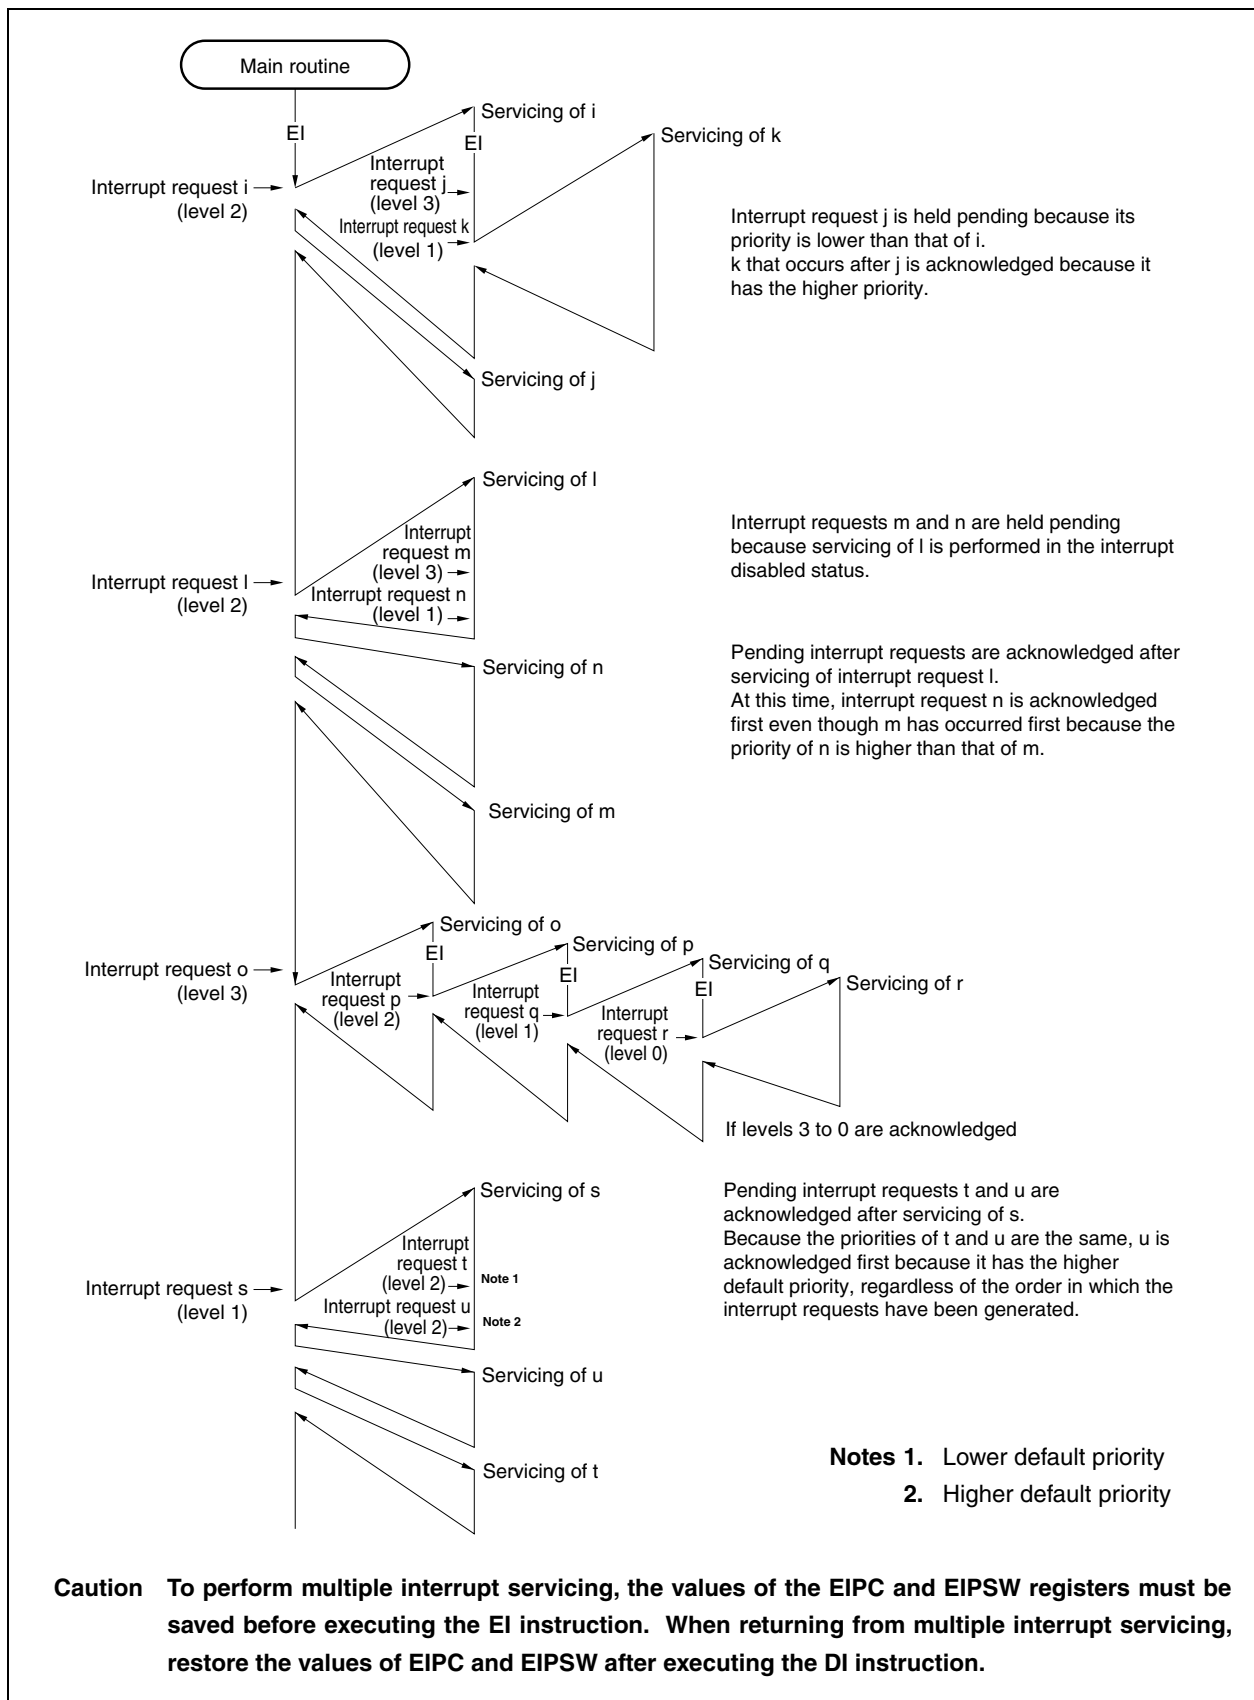

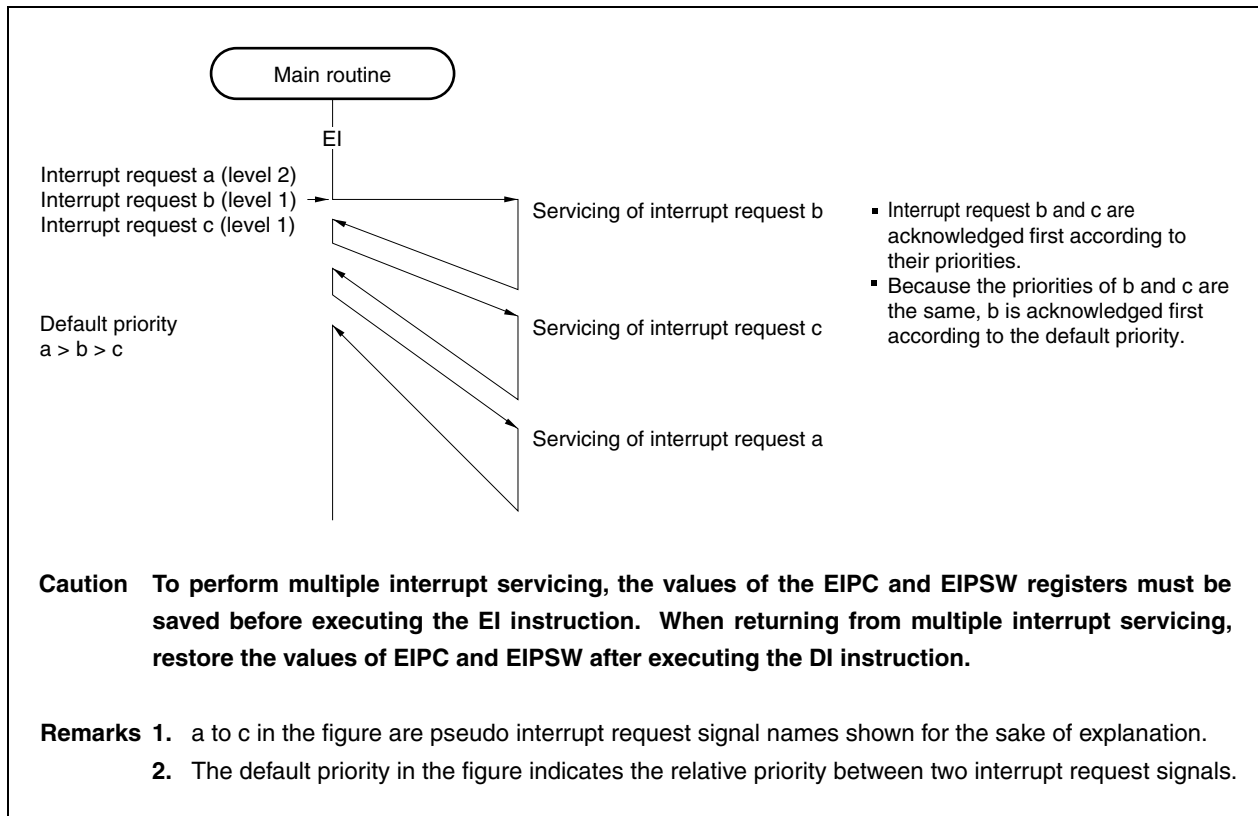

Figure 8-7. Example of Servicing Interrupt Request Signals Simultaneously Generated

8.3.4 Interrupt control register (xxICn)

An interrupt control register is assigned to each interrupt request signal (maskable interrupt) and sets the control conditions for each maskable interrupt request.

This register can be read or written in 8-bit or 1-bit units.

Caution 1. Disable interrupts (DI) to read the xxIFn bit of the xxICn register. If the xxIFn bit is read while interrupts are enabled (EI), the correct value may not be read if there is a conflict between acknowledging an interrupt and reading the bit.

2. When manipulating the xxICn.xxMKn bit with the state where an interrupt request can be generated (including an interrupt disable (DI) state), be sure to manipulate with a bit manipulation instruction or by using the IMRm.xxMKn bit (m = 0 to 5).

	<7>	<6>	5	4	3	2	1	0	Address	After reset

8.3.5 Interrupt mask registers 0 to 5 (IMR0 to IMR5)

These registers set the interrupt mask state for the maskable interrupts. The xxMKn bit of the IMR0 to IMR5 registers interlocks with the xxMKn bit of the xxICn register.

The IMRm register (m = 0 to 5) can be read or written in 16-bit units.

If the higher 8 bits of the IMRm register are used as an IMRmH register and the lower 8 bits as an IMRmL register, these registers can be read or written in 8-bit or 1-bit units.

Bits 15 to 10 of the IMR5 register (bits 7 to 2 of the IMR5H register) are fixed to 1. If these bits are not 1, the operation cannot be guaranteed.

Caution The device file defines the xxMKn bit of the xxICn register as a reserved word. If a bit is manipulated using the name of xxMKn, the contents of the xxICn register, instead of the IMRm register, are rewritten (as a result, the contents of the IMRm register are also rewritten).

IMR0	15	14	13	12	11	10	9	8	Address	After reset
	PDMK2	PDMK1	PDMK0	P6MK7	P6MK6	P6MK5	P5MK2	P5MK1

IMR5	15	14	13	12	11	10	9	8	Address	After reset
	1	1	1	1	1	1	RSUMMK	USP4MK		
	7	6	5	4	3	2	1	0		
	USP2MK	US2BMK	US1BMK	US0BMK	ADMK	UTOMK1	UIFMK1	UTMK1		

Bit position	Bit name	Function
15 to 0	xxMKn	Interrupt mask flag 0: Interrupt servicing enabled 1: Interrupt servicing disabled (pending)

Remark xx: Identification name of each peripheral unit (see **Table 8-2**)
n: Peripheral unit number (see **Table 8-2**)

8.3.6 In-service priority register (ISPR)

This register holds the priority level of the maskable interrupt currently acknowledged. When an interrupt request signal is acknowledged, the bit of this register corresponding to the priority level of that interrupt request signal is set to 1 and remains set while the interrupt is serviced.

When the RETI instruction is executed, the bit corresponding to the interrupt request signal having the highest priority is automatically cleared to 0 by hardware. However, it is not cleared to 0 when execution is returned from non-maskable interrupt servicing or exception processing.

This register is read-only, in 8-bit or 1-bit units.

Caution If an interrupt is acknowledged while the ISPR register is being read in the interrupt enabled (EI) status, the value of the ISPR register after the bits of the register have been set to 1 by acknowledging the interrupt may be read. To accurately read the value of the ISPR register before an interrupt is acknowledged, read the register while interrupts are disabled (DI status).

	<7>	<6>	<5>	<4>	<3>	<2>	<1>	<0>	Address	After reset
ISPR	ISPR7	ISPR6	ISPR5	ISPR4	ISPR3	ISPR2	ISPR1	ISPR0	1FFF1FAH	00H

Bit position	Bit name	Function
7 to 0	ISPR7 to ISPR0	Indicates priority of interrupt currently acknowledged 0: Interrupt request signal with priority n not acknowledged 1: Interrupt request signal with priority n acknowledged

Remark n = 0 to 7 (priority level)

8.3.7 Maskable interrupt status flag (ID)

The ID flag controls the maskable interrupt's operating state, and stores control information regarding enabling or disabling of interrupt requests. The ID flag is allocated to PSW.

	31		8	7	6	5	4	3	2	1	0																	
PSW	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	NP	EP	ID	SAT	CY	OV	S	Z	After reset 0000020H

Bit position	Bit name	Function
5	ID	Indicates whether maskable interrupt servicing is enabled or disabled. 0: Maskable interrupt request signal acknowledgment enabled 1: Maskable interrupt request signal acknowledgment disabled (pending) This bit is set to 1 by the DI instruction and cleared to 0 by the EI instruction. Its value is also modified by the RETI instruction or LDSR instruction when referencing the PSW. Non-maskable interrupt request signals and exceptions are acknowledged regardless of this flag. When a maskable interrupt is acknowledged, the ID flag is automatically set to 1 by hardware. The interrupt request signal generated during the acknowledgment disabled period (ID flag = 1) is acknowledged when the xxIFn bit of xxICn is set to 1, and the ID flag is cleared to 0.

8.3.8 Selecting interrupt trigger mode

The valid edge of the $\overline{\text{INTPn}}$, INTPCm , TIC0 to TIC3, INTPx , TIUD10, TIUD11, TCUD10, TCUD11, TCLR10, and TCLR11 pins can be selected by program ($n = 10, 11, 21$ to $25, 50$ to $52, 65$ to $67, L0, L1$, or $D0$ to $D15, m = 00, 01, 10, 11, 20, 21, 30$, or $31, x = 100, 101, 110$, or 111). A trigger level can also be selected for the $\overline{\text{INTPn}}$ pin. The following valid edges can be selected.

- Rising edge
- Falling edge
- Both rising and falling edges

The INTPn , INTPCm , TIC0 to TIC3, INTPx , TIUD10, TIUD11, TCUD10, TCUD11, TCLR10, and TCLR11 signals detected by the edge are used as interrupt sources, to input a capture trigger, or to input an external count signal to the timers.

The valid edge of these signals is specified by external interrupt rising edge specification registers 1, 2, 5, 6, AL, and DH (INTR1, INTR2, INTR5, INTR6, INTRAL, and INTRDH), external interrupt falling edge specification registers 1, 2, 5, 6, AL, and DH (INTF1, INTF2, INTF5, INTF6, INTFAL, and INTFDH), valid edge select registers C0 to C3 (SESC0 to SESC3), and valid edge select registers 10 and 11 (SESA10 and SESA11). The trigger level is specified by external interrupt rising edge specification registers 1, 2, 5, 6, AL, and DH (INTR1, INTR2, INTR5, INTR6, INTRAL, and INTRDH) and external interrupt falling edge specification registers 1, 2, 5, 6, AL, and DH (INTF1, INTF2, INTF5, INTF6, INTFAL, and INTFDH).

(1) External interrupt rising edge specification register 1 (INTR1), external interrupt falling edge specification register 1 (INTF1)

These registers are used to specify the trigger mode of the external interrupt requests (INTP10 and INTP11) input from external pins. The correspondence between each bit of this register and the external interrupt request controlled by that bit is as follows.

- INTF10 and INTR10 bits: INTP10
- INTF11 and INTR11 bits: INTP11

The rising edge, falling edge, or both the rising and falling edges can be independently specified as the valid edge. Each of these registers can be read or written in 8-bit or 1-bit units.

Caution Set the PMC1 register before setting the trigger mode of the $\overline{\text{INTP10}}$ and $\overline{\text{INTP11}}$ pins.

If the PMC1 register is set after the INTR1 and INTF1 registers have been set, an illegal interrupt may occur when the PMC1 register is set.

	7	6	5	4	3	2	1	0	Address	After reset
INTR1	0	0	0	0	0	0	INTR11	INTR10	1FFFFC22H	03H
INTF1	0	0	0	0	0	0	INTF11	INTF10	1FFFFC02H	00H

Bit position	Bit name	Function															
1, 0	INTF1n, INTR1n (n = 0, 1)	Specify the trigger mode of the $\overline{\text{INTP10}}$ and $\overline{\text{INTP11}}$ pins. <table border="1" style="margin-left: 20px;"> <thead> <tr> <th>INTF1n</th> <th>INTR1n</th> <th>Operation</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Falling edge</td> </tr> <tr> <td>0</td> <td>1</td> <td>Rising edge</td> </tr> <tr> <td>1</td> <td>0</td> <td>Level detection (low-level detection)^{Notes 1, 2}</td> </tr> <tr> <td>1</td> <td>1</td> <td>Both rising and falling edges</td> </tr> </tbody> </table>	INTF1n	INTR1n	Operation	0	0	Falling edge	0	1	Rising edge	1	0	Level detection (low-level detection) ^{Notes 1, 2}	1	1	Both rising and falling edges
INTF1n	INTR1n	Operation															
0	0	Falling edge															
0	1	Rising edge															
1	0	Level detection (low-level detection) ^{Notes 1, 2}															
1	1	Both rising and falling edges															

- Notes 1.** The level of the $\overline{\text{INTP1n}}$ pin is sampled each time the main clock (fx) is divided by four. When the low level of this pin is detected, an interrupt request is latched as the P1IFn bit (n = 0, 1). Consequently, even when the CPU acknowledges the interrupt and the P1IFn bit of the interrupt control register (P1ICn) is automatically cleared to 0, the P1IFn bit is immediately set to 1 and interrupts occur consecutively. To avoid this status, make the $\overline{\text{INTP1n}}$ pin of the external device inactive in the interrupt servicing routine, and forcibly clear the P1IFn bit to 0.
- 2.** If a level-detected interrupt request (INTP1n) with a lower priority occurs while an interrupt is being serviced and if this level-detected interrupt request (INTP1n) that has newly occurred becomes inactive before the current interrupt has been serviced, the interrupt request of the new interrupt (INTP1n) is held pending (n = 0, 1). To not acknowledge the interrupt request of INTP1n, clear the P1IFn bit of the interrupt control register.

(2) External interrupt rising edge specification register 2 (INTR2), external interrupt falling edge specification register 2 (INTF2)

These registers are used to specify the trigger mode of the external interrupt requests (INTP2n) input from external pins and the non-maskable interrupt (NMI) (n = 1 to 5). For the trigger mode of the NMI, see **8.2.4 (1) External interrupt rising edge specification register 2 (INTR2), external interrupt falling edge specification register 2 (INTF2)**.

The correspondence between each bit and the external interrupt request and non-maskable interrupt that are controlled by that bit is as follows.

- INTF21 and INTR21 bits: INTP21
- INTF22 and INTR22 bits: INTP22
- INTF23 and INTR23 bits: INTP23
- INTF24 and INTR24 bits: INTP24
- INTF25 and INTR25 bits: INTP25

The rising edge, falling edge, or both the rising and falling edges can be independently specified as the valid edge of the $\overline{\text{INTP2n}}$ pin.

Each of these registers can be read or written in 8-bit or 1-bit units.

Caution Set the PMC2 register before setting the trigger mode of the $\overline{\text{INTP2n}}$ pin (n = 1 to 5).
If the PMC2 register is set after the INTR2 and INTF2 registers have been set, an illegal interrupt may occur when the PMC2 register is set.

	7	6	5	4	3	2	1	0	Address	After reset
INTR2	0	0	INTR25	INTR24	INTR23	INTR22	INTR21	NMIR0	1FFFC24H	3FH
INTF2	0	0	INTF25	INTF24	INTF23	INTF22	INTF21	NMIF0	1FFFC04H	00H

Bit position	Bit name	Function															
5 to 1	INTF2n, INTR2n (n = 1 to 5)	Specify the trigger mode of the $\overline{\text{INTP2n}}$ pin. <table border="1"> <thead> <tr> <th>INTF2n</th> <th>INTR2n</th> <th>Operation</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Falling edge</td> </tr> <tr> <td>0</td> <td>1</td> <td>Rising edge</td> </tr> <tr> <td>1</td> <td>0</td> <td>Level detection (low-level detection)^{Notes 1, 2}</td> </tr> <tr> <td>1</td> <td>1</td> <td>Both rising and falling edges</td> </tr> </tbody> </table>	INTF2n	INTR2n	Operation	0	0	Falling edge	0	1	Rising edge	1	0	Level detection (low-level detection) ^{Notes 1, 2}	1	1	Both rising and falling edges
INTF2n	INTR2n	Operation															
0	0	Falling edge															
0	1	Rising edge															
1	0	Level detection (low-level detection) ^{Notes 1, 2}															
1	1	Both rising and falling edges															

- Notes 1.** The level of the $\overline{\text{INTP2n}}$ pin is sampled each time the main clock (fx) is divided by four. When the low level of this pin is detected, an interrupt request is latched as the P2IFn bit (n = 1 to 5). Consequently, even when the CPU acknowledges the interrupt and the P2IFn bit of the interrupt control register (P2ICn) is automatically cleared to 0, the P2IFn bit is immediately set to 1 and interrupts occur consecutively. To avoid this status, make the $\overline{\text{INTP2n}}$ pin of the external device inactive in the interrupt servicing routine, and forcibly clear the P2IFn bit to 0.
- 2.** If a level-detected interrupt request ($\overline{\text{INTP2n}}$) with a lower priority occurs while an interrupt is being serviced and if this level-detected interrupt request ($\overline{\text{INTP2n}}$) that has newly occurred becomes inactive before the current interrupt has been serviced, the interrupt request of the new interrupt ($\overline{\text{INTP2n}}$) is held pending (n = 1 to 5). To not acknowledge the interrupt request of $\overline{\text{INTP2n}}$, clear the P2IFn bit of the interrupt control register.

Remark For the bit 0 (NMIR0) of the INTR2 register and bit 0 (NMIF0) of the INTF2 register, see **8.2.4 (1) External interrupt rising edge specification register 2 (INTR2), external interrupt falling edge specification register 2 (INTF2)**.

(3) External interrupt rising edge specification register 5 (INTR5), external interrupt falling edge specification register 5 (INTF5)

These registers are used to specify the trigger mode of the external interrupt requests (INTP5n) input from external pins (n = 0 to 2). The correspondence between each bit of this register and the external interrupt request controlled by that bit is as follows.

- INTF50 and INTR50 bits: INTP50
- INTF51 and INTR51 bits: INTP51
- INTF52 and INTR52 bits: INTP52

The rising edge, falling edge, or both the rising and falling edges can be independently specified as the valid edge. Each of these registers can be read or written in 8-bit or 1-bit units.

Caution Set the PMC5 register before setting the trigger mode.

If the PMC5 register is set after the INTR5 and INTF5 registers have been set, an illegal interrupt may occur when the PMC5 register is set.

	7	6	5	4	3	2	1	0	Address	After reset
INTR5	0	0	0	0	0	INTR52	INTR51	INTR50	1FFFFC2AH	07H
INTF5	0	0	0	0	0	INTF52	INTF51	INTF50	1FFFFC0AH	00H

Bit position	Bit name	Function															
2 to 0	INTF5n, INTR5n (n = 0 to 2)	Specify the trigger mode of the $\overline{\text{INTP5n}}$ pin. <table border="1"> <thead> <tr> <th>INTF5n</th> <th>INTR5n</th> <th>Operation</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Falling edge</td> </tr> <tr> <td>0</td> <td>1</td> <td>Rising edge</td> </tr> <tr> <td>1</td> <td>0</td> <td>Level detection (low-level detection)^{Notes 1, 2}</td> </tr> <tr> <td>1</td> <td>1</td> <td>Both rising and falling edges</td> </tr> </tbody> </table>	INTF5n	INTR5n	Operation	0	0	Falling edge	0	1	Rising edge	1	0	Level detection (low-level detection) ^{Notes 1, 2}	1	1	Both rising and falling edges
INTF5n	INTR5n	Operation															
0	0	Falling edge															
0	1	Rising edge															
1	0	Level detection (low-level detection) ^{Notes 1, 2}															
1	1	Both rising and falling edges															

- Notes 1.** The level of the $\overline{\text{INTP5n}}$ pin is sampled each time the main clock (fx) is divided by four. When the low level of this pin is detected, an interrupt request is latched as the P5IFn bit (n = 0 to 2). Consequently, even when the CPU acknowledges the interrupt and the P5IFn bit of the interrupt control register (P5ICn) is automatically cleared to 0, the P5IFn bit is immediately set to 1 and interrupts occur consecutively. To avoid this status, make the $\overline{\text{INTP5n}}$ pin of the external device inactive in the interrupt servicing routine, and forcibly clear the P5IFn bit to 0.
- 2.** If a level-detected interrupt request (INTP5n) with a lower priority occurs while an interrupt is being serviced and if this level-detected interrupt request (INTP5n) that has newly occurred becomes inactive before the current interrupt has been serviced, the interrupt request of the new interrupt (INTP5n) is held pending (n = 0 to 2). To not acknowledge the interrupt request of INTP5n, clear the P5IFn bit of the interrupt control register.

(4) External interrupt rising edge specification register 6 (INTR6), external interrupt falling edge specification register 6 (INTF6)

These registers are used to specify the trigger mode of the external interrupt requests (INTP6n) input from external pins (n = 5 to 7). The correspondence between each bit of this register and the external interrupt request controlled by that bit is as follows.

- INTF65 and INTR65 bits: INTP65
- INTF66 and INTR66 bits: INTP66
- INTF67 and INTR67 bits: INTP67

The rising edge, falling edge, or both the rising and falling edges can be independently specified as the valid edge. Each of these registers can be read or written in 8-bit or 1-bit units.

Caution Set the PMC6 register before setting the trigger mode.

If the PMC6 register is set after the INTR6 and INTF6 registers have been set, an illegal interrupt may occur when the PMC6 register is set.

	7	6	5	4	3	2	1	0	Address	After reset
INTR6	INTR67	INTR66	INTR65	0	0	0	0	0	1FFFFC2CH	E0H
INTF6	INTF67	INTF66	INTF65	0	0	0	0	0	1FFFFC0CH	00H

Bit position	Bit name	Function															
7 to 5	INTF6n, INTR6n (n = 7 to 5)	Specify the trigger mode of the $\overline{\text{INTP6n}}$ pin. <table border="1"> <thead> <tr> <th>INTF6n</th> <th>INTR6n</th> <th>Operation</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Falling edge</td> </tr> <tr> <td>0</td> <td>1</td> <td>Rising edge</td> </tr> <tr> <td>1</td> <td>0</td> <td>Level detection (low-level detection)^{Notes 1, 2}</td> </tr> <tr> <td>1</td> <td>1</td> <td>Both rising and falling edges</td> </tr> </tbody> </table>	INTF6n	INTR6n	Operation	0	0	Falling edge	0	1	Rising edge	1	0	Level detection (low-level detection) ^{Notes 1, 2}	1	1	Both rising and falling edges
INTF6n	INTR6n	Operation															
0	0	Falling edge															
0	1	Rising edge															
1	0	Level detection (low-level detection) ^{Notes 1, 2}															
1	1	Both rising and falling edges															

- Notes 1.** The level of the $\overline{\text{INTP6n}}$ pin is sampled each time the main clock (fx) is divided by four. When the low level of this pin is detected, an interrupt request is latched as the P6IFn bit (n = 5 to 7). Consequently, even when the CPU acknowledges the interrupt and the P6IFn bit of the interrupt control register (P6ICn) is automatically cleared to 0, the P6IFn bit is immediately set to 1 and interrupts occur consecutively. To avoid this status, make the $\overline{\text{INTP6n}}$ pin of the external device inactive in the interrupt servicing routine, and forcibly clear the P6IFn bit to 0.
- 2.** If a level-detected interrupt request ($\overline{\text{INTP6n}}$) with a lower priority occurs while an interrupt is being serviced and if this level-detected interrupt request ($\overline{\text{INTP6n}}$) that has newly occurred becomes inactive before the current interrupt has been serviced, the interrupt request of the new interrupt ($\overline{\text{INTP6n}}$) is held pending (n = 5 to 7). To not acknowledge the interrupt request of $\overline{\text{INTP6n}}$, clear the P6IFn bit of the interrupt control register.

(5) External interrupt rising edge specification register AL (INTRAL), external interrupt falling edge specification register AL (INTFAL)

These registers are used to specify the trigger mode of the external interrupt requests (INTPL_n) input from external pins (n = 0, 1). The correspondence between each bit of this register and the external interrupt request controlled by that bit is as follows.

- INTFAL0 and INTRAL0 bits: INTPL0
- INTFAL1 and INTRAL1 bits: INTPL1

The rising edge, falling edge, or both the rising and falling edges can be independently specified as the valid edge. Each of these registers can be read or written in 8-bit or 1-bit units.

Caution Set the PMCAL register before setting the trigger mode.

If the PMCAL register is set after the INTRAL and INTFAL registers have been set, an illegal interrupt may occur when the PMCAL register is set.

	7	6	5	4	3	2	1	0	Address	After reset
INTRAL	0	0	0	0	0	0	INTRAL1	INTRAL0	1FFFFC30H	03H
INTFAL	0	0	0	0	0	0	INTFAL1	INTFAL0	1FFFFC10H	00H

Bit position	Bit name	Function															
1, 0	INTFAL _n , INTRAL _n (n = 0, 1)	Specify the trigger mode of the INTPL _n pin. <table border="1"> <thead> <tr> <th>INTFAL_n</th> <th>INTRAL_n</th> <th>Operation</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Falling edge</td> </tr> <tr> <td>0</td> <td>1</td> <td>Rising edge</td> </tr> <tr> <td>1</td> <td>0</td> <td>Level detection (low-level detection)^{Notes 1, 2}</td> </tr> <tr> <td>1</td> <td>1</td> <td>Both rising and falling edges</td> </tr> </tbody> </table>	INTFAL _n	INTRAL _n	Operation	0	0	Falling edge	0	1	Rising edge	1	0	Level detection (low-level detection) ^{Notes 1, 2}	1	1	Both rising and falling edges
INTFAL _n	INTRAL _n	Operation															
0	0	Falling edge															
0	1	Rising edge															
1	0	Level detection (low-level detection) ^{Notes 1, 2}															
1	1	Both rising and falling edges															

Notes 1. The level of the INTPL_n pin is sampled each time the main clock (fx) is divided by four. When the low level of this pin is detected, an interrupt request is latched as the PLIF_n bit (n = 0, 1). Consequently, even when the CPU acknowledges the interrupt and the PLIF_n bit of the interrupt control register (PLIC_n) is automatically cleared to 0, the PLIF_n bit is immediately set to 1 and interrupts occur consecutively. To avoid this status, make the INTPL_n pin of the external device inactive in the interrupt servicing routine, and forcibly clear the PLIF_n bit to 0.

2. If a level-detected interrupt request (INTPL_n) with a lower priority occurs while an interrupt is being serviced and if this level-detected interrupt request (INTPL_n) that has newly occurred becomes inactive before the current interrupt has been serviced, the interrupt request of the new interrupt (INTPL_n) is held pending (n = 0, 1). To not acknowledge the interrupt request of INTPL_n, clear the PLIF_n bit of the interrupt control register.

(6) External interrupt rising edge specification register DH (INTRDH), external interrupt falling edge specification register DH (INTFDH)

These registers are used to specify the trigger mode of the external interrupt requests (INTPD_n) input from external pins (n = 0 to 15). The correspondence between each bit of this register and the external interrupt request controlled by that bit is as follows.

- INTFDH0 and INTRDH0 bits: INTPD0
- INTFDH1 and INTRDH1 bits: INTPD1
- INTFDH2 and INTRDH2 bits: INTPD2
- INTFDH3 and INTRDH3 bits: INTPD3
- INTFDH4 and INTRDH4 bits: INTPD4
- INTFDH5 and INTRDH5 bits: INTPD5
- INTFDH6 and INTRDH6 bits: INTPD6
- INTFDH7 and INTRDH7 bits: INTPD7
- INTFDH8 and INTRDH8 bits: INTPD8
- INTFDH9 and INTRDH9 bits: INTPD9
- INTFDH10 and INTRDH10 bits: INTPD10
- INTFDH11 and INTRDH11 bits: INTPD11
- INTFDH12 and INTRDH12 bits: INTPD12
- INTFDH13 and INTRDH13 bits: INTPD13
- INTFDH14 and INTRDH14 bits: INTPD14
- INTFDH15 and INTRDH15 bits: INTPD15

The rising edge, falling edge, or both the rising and falling edges can be independently specified as the valid edge. The INTRDH and INTFDH registers can be read or written in 16-bit units.

If the higher 8 bits of the INTRDH and INTFDH registers are used as the INTRDHH and INTFDHH registers, and the lower 8 bits as the INTRDHL and INTFDHL registers, these registers can be read or written in 8-bit or 1-bit units.

Caution Set the PMCDH register before setting the trigger mode.

If the PMCDH register is set after the INTRDH and INTFDH registers have been set, an illegal interrupt may occur when the PMCDH register is set.

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset
INTRDH	INTR DH15	INTR DH14	INTR DH13	INTR DH12	INTR DH11	INTR DH10	INTR DH9	INTR DH8	INTR DH7	INTR DH6	INTR DH5	INTR DH4	INTR DH3	INTR DH2	INTR DH1	INTR DH0	1FFFFC36H	FFFFH
INTFDH	INTF DH15	INTF DH14	INTF DH13	INTF DH12	INTF DH11	INTF DH10	INTF DH9	INTF DH8	INTF DH7	INTF DH6	INTF DH5	INTF DH4	INTF DH3	INTF DH2	INTF DH1	INTF DH0	1FFFFC16H	0000H

Bit position	Bit name	Function															
15 to 0	INTFDHn, INTRDHn (n = 0 to 15)	Specify the trigger mode of the $\overline{\text{INTPDn}}$ pin. <table border="1" style="margin-left: 20px;"> <thead> <tr> <th>INTFDHn</th> <th>INTRDHn</th> <th>Operation</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Falling edge</td> </tr> <tr> <td>0</td> <td>1</td> <td>Rising edge</td> </tr> <tr> <td>1</td> <td>0</td> <td>Level detection (low-level detection)^{Notes 1, 2}</td> </tr> <tr> <td>1</td> <td>1</td> <td>Both rising and falling edges</td> </tr> </tbody> </table>	INTFDHn	INTRDHn	Operation	0	0	Falling edge	0	1	Rising edge	1	0	Level detection (low-level detection) ^{Notes 1, 2}	1	1	Both rising and falling edges

0	0	Falling edge															
0	1	Rising edge															
1	0	Level detection (low-level detection) ^{Notes 1, 2}															
1	1	Both rising and falling edges															

- Notes 1.** The level of the $\overline{\text{INTPDn}}$ pin is sampled each time the main clock (fx) is divided by four. When the low level of this pin is detected, an interrupt request is latched as the PDIFn bit (n = 0 to 15). Consequently, even when the CPU acknowledges the interrupt and the PDIFn bit of the interrupt control register (PDICn) is automatically cleared to 0, the PDIFn bit is immediately set to 1 and interrupts occur consecutively. To avoid this status, make the $\overline{\text{INTPDn}}$ pin of the external device inactive in the interrupt servicing routine, and forcibly clear the PDIFn bit to 0.
- 2.** If a level-detected interrupt request (INTPDn) with a lower priority occurs while an interrupt is being serviced and if this level-detected interrupt request (INTPDn) that has newly occurred becomes inactive before the current interrupt has been serviced, the interrupt request of the new interrupt (INTPDn) is held pending (n = 0 to 15). To not acknowledge the interrupt request of INTPDn, clear the PDIFn bit of the interrupt control register.

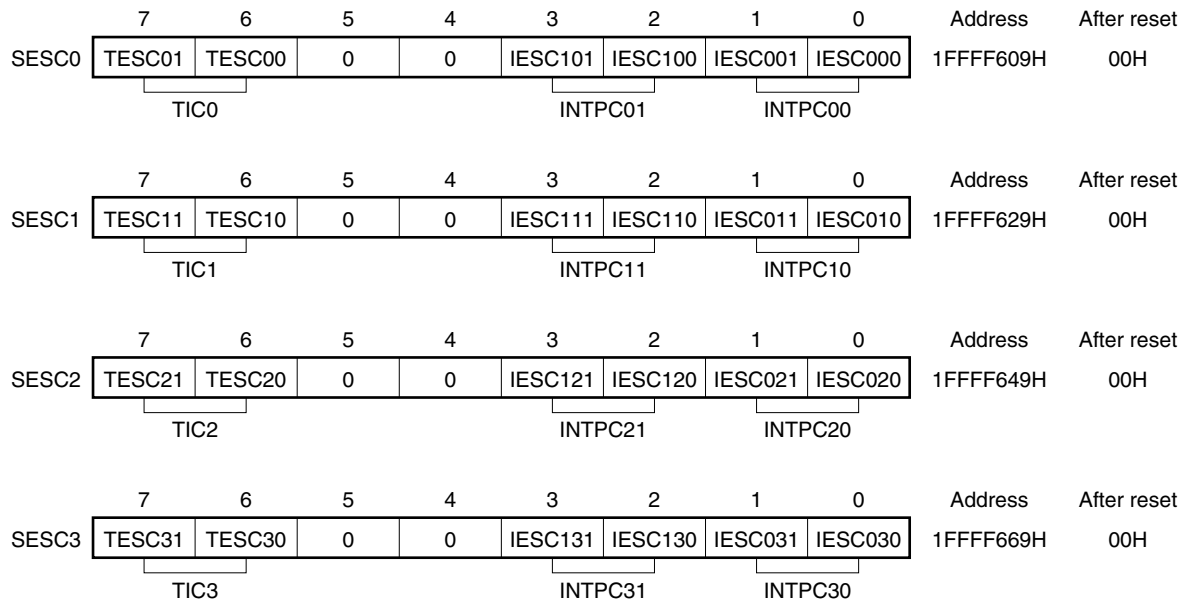

(7) Valid edge select registers C0 to C3 (SESC0 to SESC3)

These registers are used to specify the valid edge of the external interrupt requests (INTPC00, INTPC01, INTPC10, INTPC11, INTPC20, INTPC21, INTPC30, INTPC31, or TIC0 to TIC3) input from external pins to TMCn (n = 0 to 3).

The rising edge, falling edge, or both the rising and falling edges can be independently specified as the valid edge. Each of these registers can be read or written in 8-bit units.

Be sure to clear bits 5 and 4 to 0. If they are set to 1, the operation is not guaranteed.

- Cautions**
- 1. Do not change each bit of the SESCn register while the timer is operating (n = 0 to 3). To change a bit, clear the CECn bit of the TMCCn0 register to 0. The operation is not guaranteed if the SESCn register is rewritten during timer operation.**
 - 2. Even when the INTPC00/TIC0, INTPC10/TIC1, INTPC20/TIC2, and INTPC30/TIC3 pins are used as INTPC00, INTPC10, INTPC20, and INTPC30, respectively, without using timer C, be sure to set the CAECn and CECn bits of timer mode control registers C00 to C03 (TMCC00 to TMCC30) to 1.**
 - 3. When setting the trigger mode of the INTPC00, INTPC01, INTPC10, INTPC11, INTPC20, INTPC21, INTPC30, INTPC31, and TIC0 to TIC3 pins, set the PMCx register (x = 5 to 7), then, after setting the CAECn and CECn bits of the TMCCn0 register to 1 (n = 0 to 3), set the SESCn register. If the PMCx register is set after the SESCn register has been set, an illegal interrupt, incorrect count, or incorrect clear may occur depending on the timing of setting the PMCx register (n = 0 to 3, x = 5 to 7).**

Bit position	Bit name	Function															
7, 6	TESCn1, TESCn0 (n = 0 to 3)	Specify the valid edge of the INTPCm0, INTPCm1, and TICm pins (m = 0 to 3). <table border="1" style="margin-top: 10px;"> <thead> <tr> <th>xESCn1</th> <th>xESCn0</th> <th>Operation</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Falling edge</td> </tr> <tr> <td>0</td> <td>1</td> <td>Rising edge</td> </tr> <tr> <td>1</td> <td>0</td> <td>Setting prohibited</td> </tr> <tr> <td>1</td> <td>1</td> <td>Both rising and falling edges</td> </tr> </tbody> </table>	xESCn1	xESCn0	Operation	0	0	Falling edge	0	1	Rising edge	1	0	Setting prohibited	1	1	Both rising and falling edges
xESCn1	xESCn0		Operation

0	1		Rising edge														
1	0	Setting prohibited															
1	1	Both rising and falling edges															
3, 2	IESCn1, IESCn0 (n = 10 to 13)																
1, 0	IESCn1, IESCn0 (n = 00 to 03)																

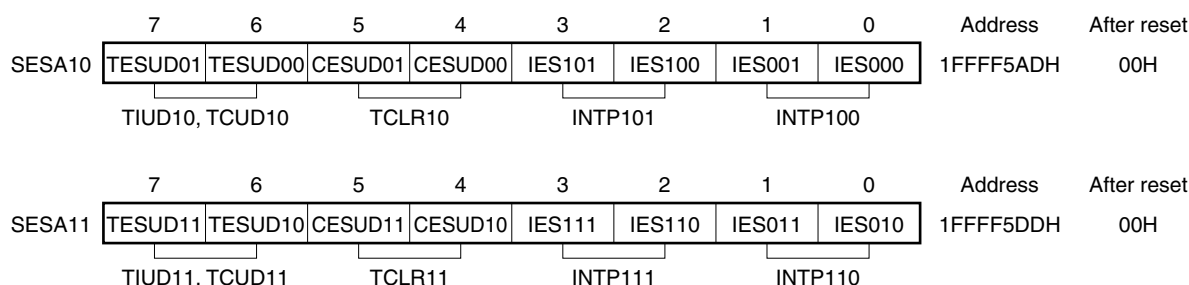

(8) Valid edge select registers 10, 11 (SESA10, SESA11)

These registers are used to specify the valid edge of the external interrupt requests (TIUD10, TIUD11, TCUD10, TCUD11, TCLR10, or TCLR11) input from external pins and the external capture trigger inputs to timer ENC1 (INTP100, INTP101, INTP110, or INTP111).

The rising edge, falling edge, or both the rising and falling edges can be independently specified as the valid edge. Each of these registers can be read or written in 8-bit or 1-bit units.

- Cautions 1. Changing each bit of the SESA1n register is prohibited while TMENC1n is operating (CE1n1 bit = 1).**
- 2. Set the PMCDH register before setting the trigger mode of the INTP100, INTP101, INTP110, INTP111, TIUD10, TIUD11, TCUD10, TCUD11, TCLR10, and TCLR11 pins. If the PMCDH register is set after the SESA1n register has been set, an illegal interrupt, incorrect count, or incorrect clear may occur depending on the timing of setting the PMCDH register.**

8.4 Software Exception

A software exception is generated when the CPU executes the TRAP instruction, and can always be acknowledged.

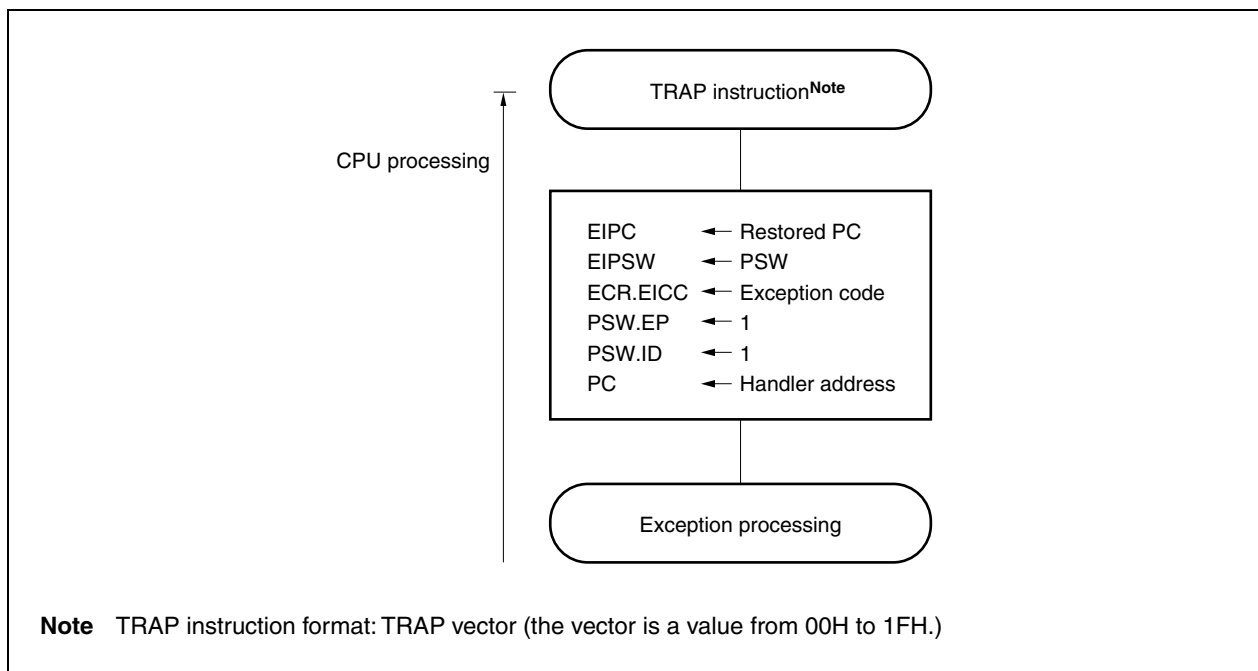

8.4.1 Operation

If a software exception occurs, the CPU performs the following processing, and transfers control to the handler routine:

- <1> Saves the restored PC to EIPC.
- <2> Saves the current PSW to EIPSW.
- <3> Writes an exception code to the lower 16 bits (EICC) of ECR (interrupt source).
- <4> Sets the EP and ID bits of the PSW to 1.
- <5> Sets the handler address (00000040H or 00000050H) corresponding to the software exception to the PC, and transfers control.

Figure 8-8 illustrates the processing of a software exception.

Figure 8-8. Software Exception Processing

The handler address is determined by the TRAP instruction's operand (vector). If the vector is 00H to 0FH, it becomes 00000040H, and if the vector is 10H to 1FH, it becomes 00000050H.

8.4.2 Restore

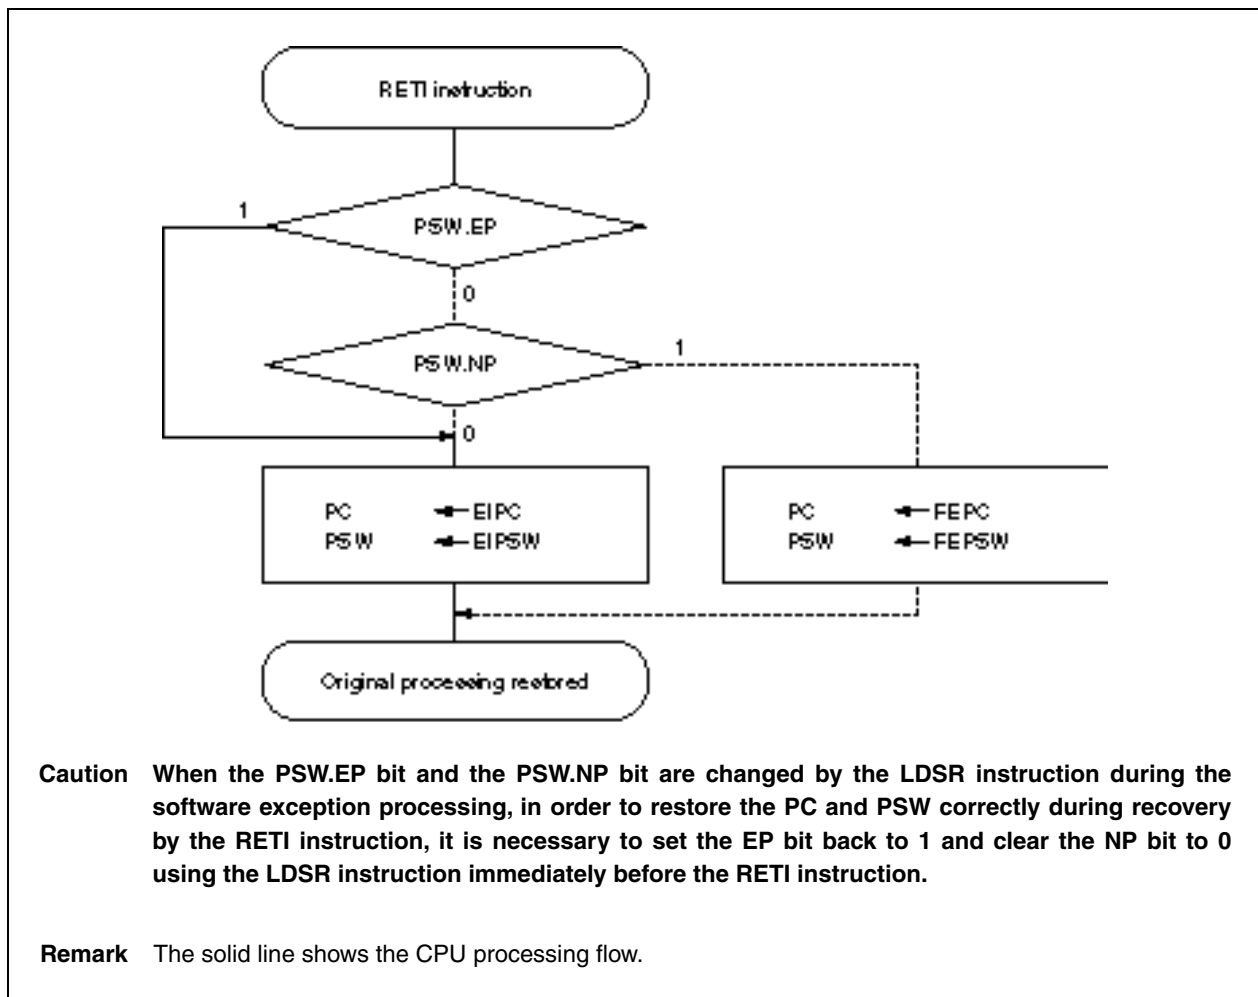

Recovery from software exception processing is carried out by the RETI instruction.

By executing the RETI instruction, the CPU carries out the following processing and shifts control to the restored PC's address.

- <1> Loads the restored PC and PSW from EIPC and EIPSW because the EP bit of the PSW is 1.
- <2> Transfers control to the address of the restored PC and PSW.

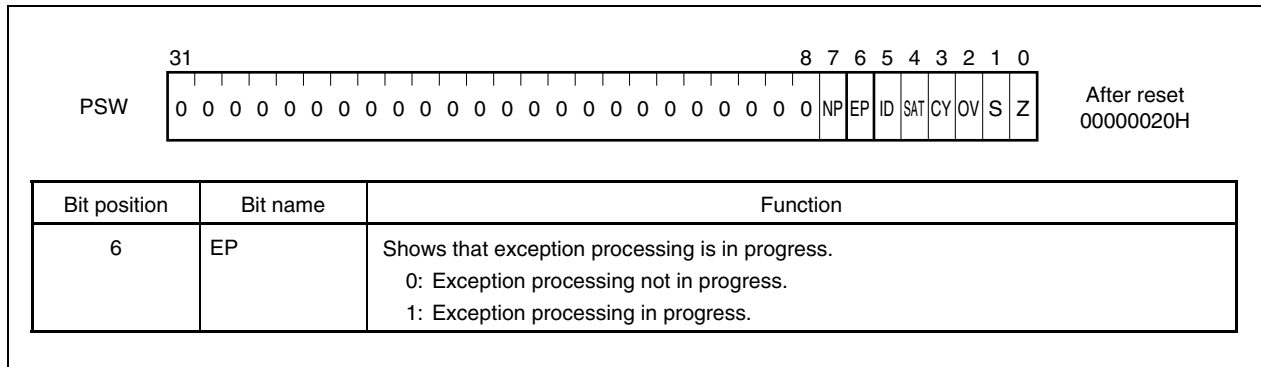

Figure 8-9 illustrates the processing of the RETI instruction.

Figure 8-9. RETI Instruction Processing

8.4.3 Exception status flag (EP)

The EP flag is a status flag used to indicate that exception processing is in progress. It is set to 1 when an exception occurs. The EP flag is allocated to PSW.

8.5 Exception Trap

An exception trap is an interrupt that is requested when the illegal execution of an instruction takes place. In the V850E2/ME3, an illegal opcode exception (ILGOP: Illegal Opcode Trap) is considered as an exception trap.

8.5.1 Illegal opcode definition

The illegal instruction has an opcode (bits 10 to 5) of 11111B, a sub-opcode (bits 26 to 23) of 0111B to 1111B, and a sub-opcode (bit 16) of 0B. An exception trap is generated when an instruction applicable to this illegal instruction is executed.

Caution Since it is possible to assign this instruction to an illegal opcode in the future, it is recommended that it not be used.

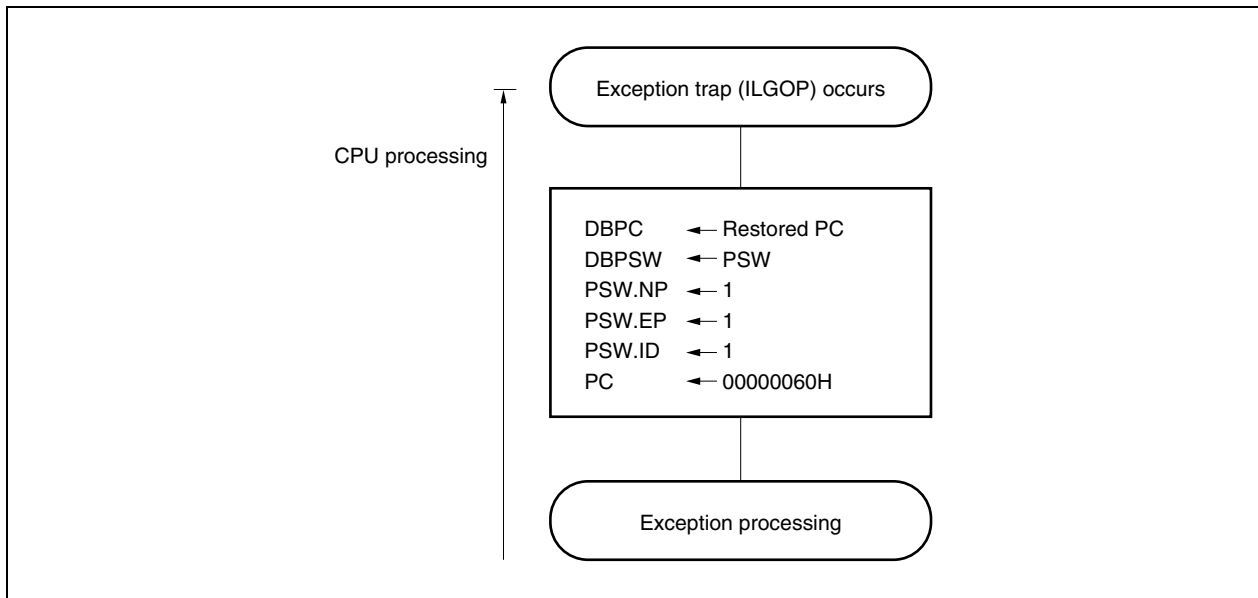

(1) Operation

If an exception trap occurs, the CPU performs the following processing, and transfers control to the handler routine:

- <1> Saves the restored PC to DBPC.
- <2> Saves the current PSW to DBPSW.
- <3> Sets the NP, EP, and ID bits of the PSW to 1.
- <4> Sets the handler address (00000060H) corresponding to the exception trap to the PC, and transfers control.

Figure 8-10 illustrates the processing of the exception trap.

Figure 8-10. Exception Trap Processing

(2) Restore

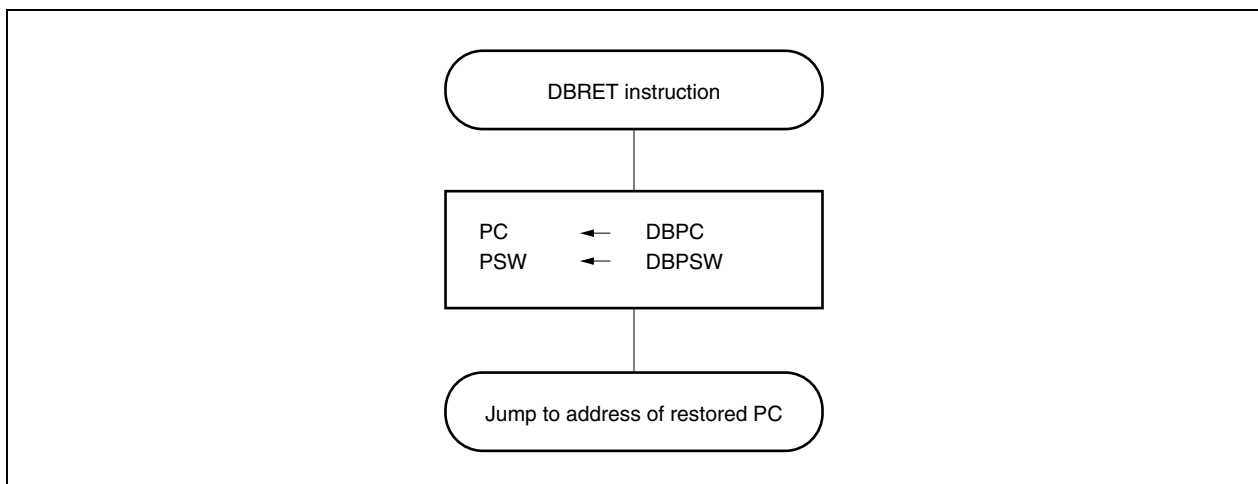

Execution is restored from an exception trap by the DBRET instruction. When the DBRET instruction is executed, the CPU carries out the following processing and controls the address of the restored PC.

- <1> Loads the restored PC and PSW from DBPC and DBPSW.
- <2> Transfers control to the address indicated by the restored PC and PSW.

Caution DBPC and DBPSW can be accessed only during the period between when the illegal opcode is executed and when the DBRET instruction is executed.

Figure 8-11 illustrates the processing for restoring from an exception trap.

Figure 8-11. Processing of Restoration from Exception Trap

8.5.2 Debug trap

The debug trap is an exception that can be acknowledged every time and is generated by execution of the DBTRAP instruction.

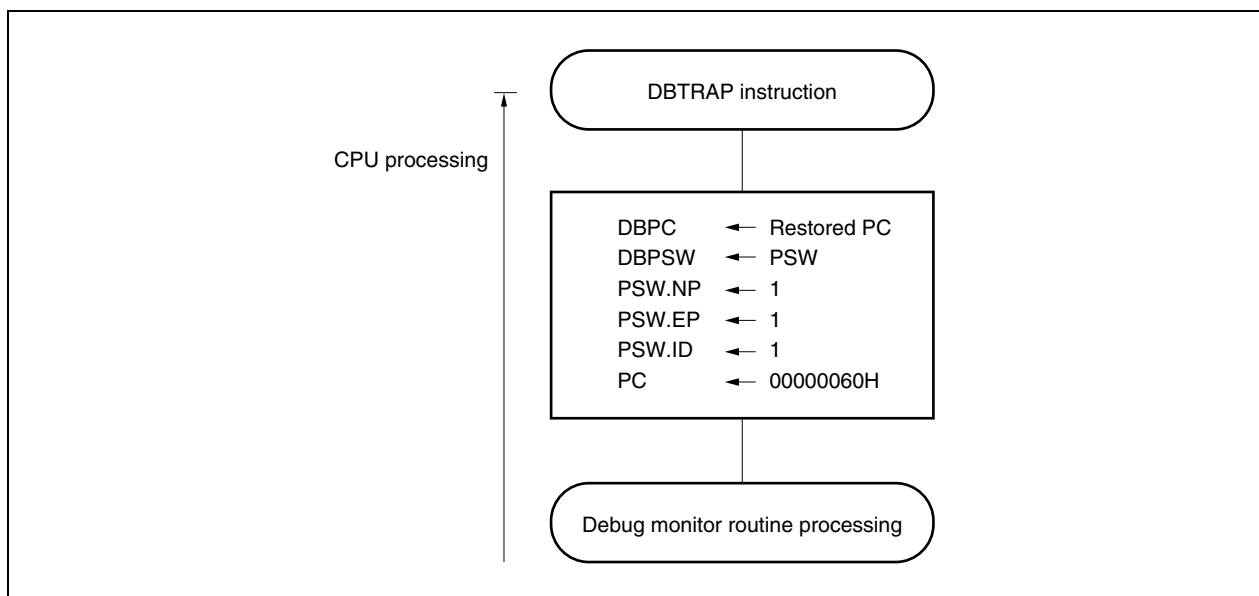

When the debug trap is generated, the CPU performs the following processing.

(1) Operation

- <1> Saves the restored PC to DBPC.
- <2> Saves the current PSW to DBPSW.
- <3> Sets the NP, EP and ID bits of the PSW to 1.
- <4> Sets the handler address (00000060H) corresponding to the debug trap to the PC and transfers control.

Figure 8-12 illustrates the processing of the debug trap.

Figure 8-12. Debug Trap Processing

(2) Restore

Execution is restored from a debug trap the DBRET instruction. When the DBRET instruction is executed, the CPU carries out the following processing and controls the address of the restored PC.

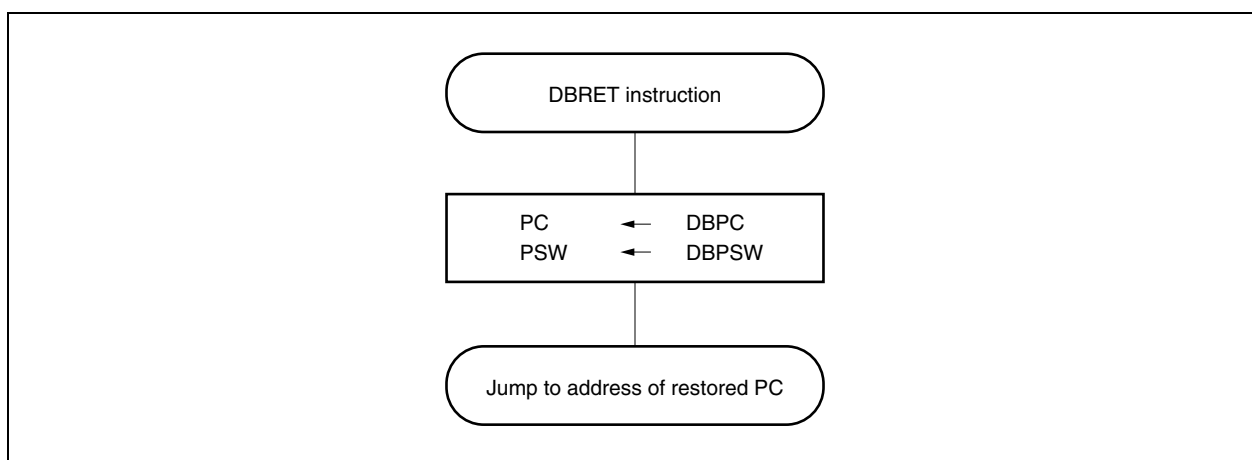

<1> Loads the restored PC and PSW from DBPC and DBPSW.

<2> Transfers control to the address indicated by the restored PC and PSW.

Caution DBPC and DBPSW can be accessed during the period between when the DBTRAP instruction is executed and when the DBRET instruction is executed.

Figure 8-13 illustrates the processing for restoring from a debug trap.

Figure 8-13. Processing of Restoration from Debug Trap

8.6 Multiple Interrupt Servicing Control

Multiple interrupt servicing control is a process by which an interrupt request that is currently being serviced can be interrupted during servicing if there is an interrupt request signal with a higher priority level, and the higher priority interrupt request signal is acknowledged and serviced first.

If there is an interrupt request signal with a lower priority level than the interrupt request signal currently being serviced, that interrupt request signal is held pending.

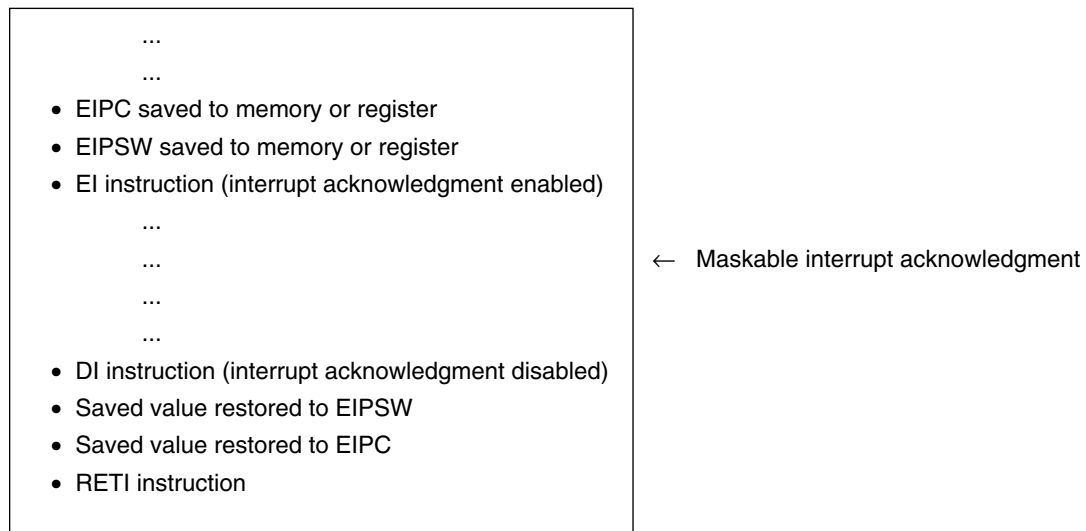

Multiple interrupt servicing control of maskable interrupts is executed when interrupts are enabled (PSW.ID bit = 0). Thus, to execute multiple interrupts, it is necessary to set the interrupt enabled state (ID bit = 0) even for an interrupt service routine.

If maskable interrupts are enabled or a software exception is generated in a maskable interrupt or software exception service program, it is necessary to save EIPC and EIPSW.

This is accomplished by the following procedure.

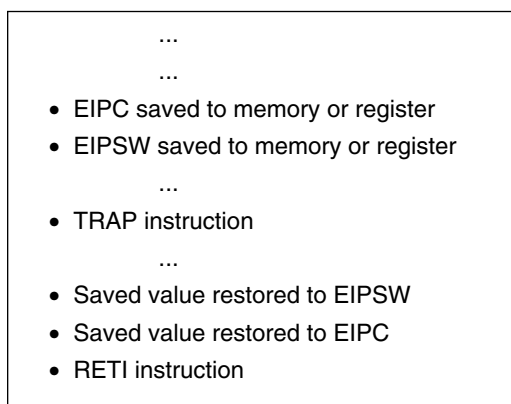

(1) Acknowledgment of maskable interrupt request signals in service program

Service program of maskable interrupt or exception

(2) Generation of exception in service program

Service program of maskable interrupt or exception

← Exception such as TRAP instruction acknowledged.

The priority order for multiple interrupt servicing control has 8 levels, from 0 to 7 for each maskable interrupt request signal (0 is the highest priority), but it can be set as desired via software. The priority order is set using the xxPRn0 to xxPRn2 bits of the interrupt control request register (xxICn), provided for each maskable interrupt request signal. After system reset, an interrupt request signal is masked by the xxMKn bit and the priority order is set to level 7 by the xxPRn0 to xxPRn2 bits.

The priority order of maskable interrupts is as follows.

(High) Level 0 > Level 1 > Level 2 > Level 3 > Level 4 > Level 5 > Level 6 > Level 7 (Low)

Interrupt servicing that has been suspended as a result of multiple servicing control is resumed after the servicing of the higher priority interrupt has been completed and the RETI instruction has been executed.

A pending interrupt request signal is acknowledged after the current interrupt servicing has been completed and the RETI instruction has been executed.

Caution In a non-maskable interrupt service routine (time until the RETI instruction is executed), maskable interrupts are suspended and not acknowledged.

Remark xx: Identification name of each peripheral unit (see **Table 8-2**)
n: Peripheral unit number (see **Table 8-2**)

8.7 Periods in Which Interrupts Are Not Acknowledged by CPU

An interrupt is acknowledged by CPU while an instruction is being executed. However, no interrupt will be acknowledged between an interrupt request non-sample instruction and the next instruction (interrupt is held pending).

The interrupt request non-sample instructions are as follows.

- The store instruction for the command register (PRCMD)
- The store, SET1, NOT1, or CLR1 instruction for the following registers.
 - Interrupt-related registers:
Interrupt control register (xxICn), interrupt mask registers 0 to 5 (IMR0 to IMR5)
 - Power-save control register (PSC)

Remark xx: Identification name of each peripheral unit (refer to **Table 8-2**)
n: Peripheral unit number (refer to **Table 8-2**)

8.8 Cautions

Cautions concerning the interrupt/exception processing function are shown below.

(1) Setting trigger mode of $\overline{\text{INTPn}}$ pin

Set the PMCM register before setting the trigger mode of the $\overline{\text{INTPn}}$ pin.

If the PMCM register is set after the INTRm and INTFm registers have been set, an illegal interrupt may occur when the PMCM register is set (n = 10, 11, 21 to 25, 50 to 52, 65 to 67, L0, L1, D0 to D15, m = 1, 2, 5, 6, AL, DH).

(2) Multiple interrupt servicing control

In a non-maskable interrupt servicing routine (time until the RETI instruction is executed), maskable interrupts are held pending and not acknowledged.

CHAPTER 9 CLOCK GENERATION FUNCTION

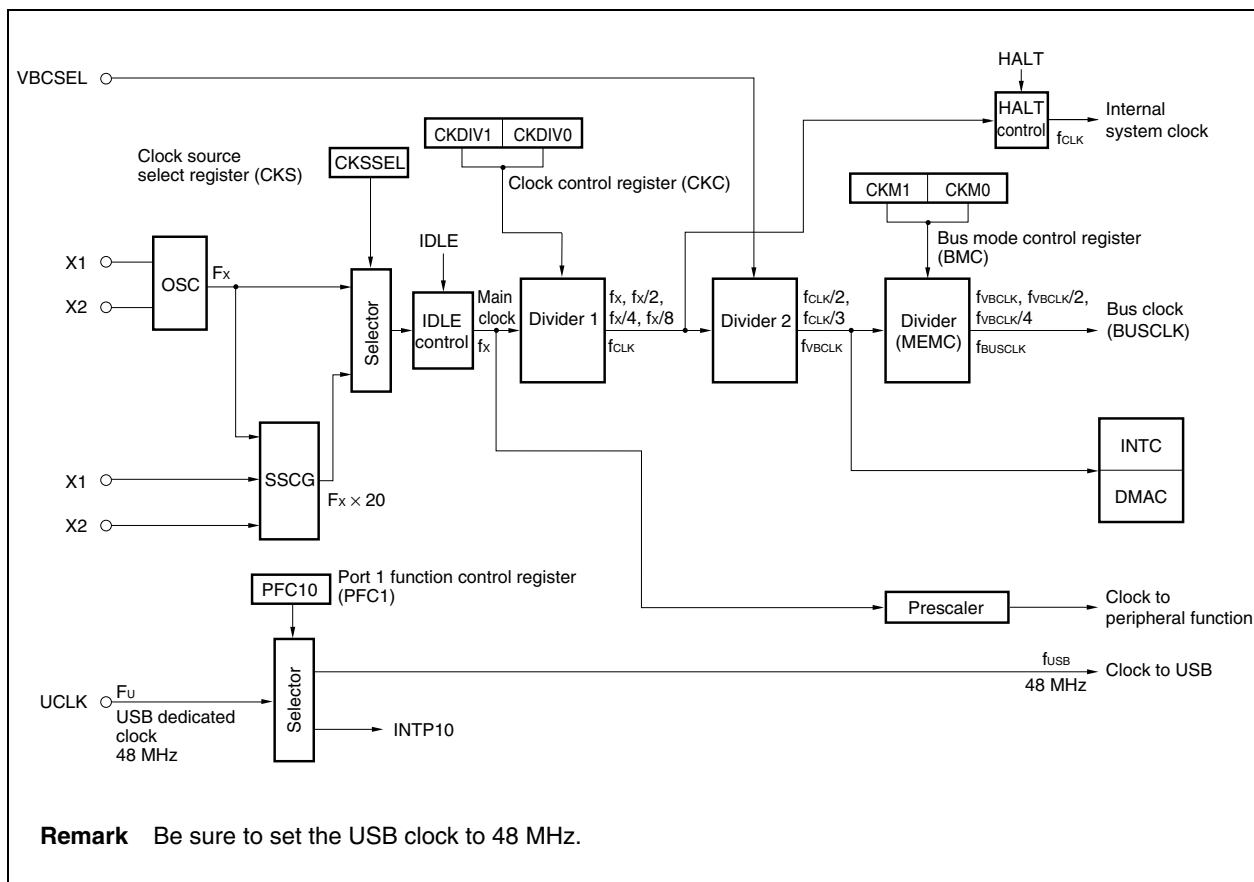

The clock generator (CG) consists of a spread spectrum frequency synthesizer phase locked loop (SSCG) and a divider circuit, and generates and controls the clock supplied to the internal units as well as the CPU.

The SSCG is a spread spectrum clock generator used to suppress noise, and is effective in reducing the peak value of electromagnetic interference (EMI) noise.

9.1 Features

- SSCG output is used fixed to $\times 20$.
- Selection of frequency modulation rate (f_{DM}) of SSCG output
 - Selection by SSCGC register (without modulation (frequency fixed), -0.5% , -1% , -2% , -3% , -4% , -5%)
- MDL-Selector Table (modulation period)
Selection by SSCGC register (13 to 27 kHz, 23 to 37 kHz, 32 to 48 kHz)
- Division function by register setting (1/1, 1/2, 1/4, 1/8)
- Clock sources
Oscillation by connecting a resonator
- Operation mode selection by register setting
The clock to be supplied to each unit is selected from the following by register setting.
 - Clock output by SSCG
 - Clock from OSC without passing through SSCG
- USB-dedicated clock input
- Power-save control
 - HALT mode
 - IDLE mode

9.2 Configuration

9.3 Control Registers

9.3.1 Clock control register (CKC)

The clock control register is an 8-bit register that controls the internal system clock (f_{CLK}) in PLL mode. It can be written to only by a specific sequence so that it cannot easily be overwritten by mistake due to an inadvertent program loop.

This register can be read or written in 8-bit units.

Be sure to clear bits 7 to 2 to "0". If they are set to 1, the operation is not guaranteed.

(1/2)

	7	6	5	4	3	2	1	0	Address	After reset
CKC	0	0	0	0	0	0	CKDIV1	CKDIV0	1FFFF822H	03H

Bit position	Bit name	Function															
1, 0	CKDIV1, CKDIV0	<p>Sets the internal system clock (f_{CLK}) when PLL mode is used.</p> <table border="1"> <thead> <tr> <th>CKDIV1</th> <th>CKDIV0</th> <th>Internal system clock (f_{CLK})</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>$f_x/8$</td> </tr> <tr> <td>0</td> <td>1</td> <td>$f_x/4$</td> </tr> <tr> <td>1</td> <td>0</td> <td>$f_x/2$</td> </tr> <tr> <td>1</td> <td>1</td> <td>f_x</td> </tr> </tbody> </table> <p>To change the internal system clock frequency in the middle of an operation, be sure to set it to f_x first, and then change the frequency as desired.</p>	CKDIV1	CKDIV0	Internal system clock (f_{CLK})	0	0	$f_x/8$	0	1	$f_x/4$	1	0	$f_x/2$	1	1	f_x
CKDIV1	CKDIV0	Internal system clock (f_{CLK})															
0	0	$f_x/8$															
0	1	$f_x/4$															
1	0	$f_x/2$															
1	1	f_x															

Cautions 1. Note that if the internal system clock (f_{CLK}) is changed, the frequency of the bus clock (BUSCLK) is also changed.

2. If it necessary to change the refresh interval of the SDRAM as a result of changing the internal system clock (f_{CLK}), follow this procedure.

<1> Mask all interrupts. Disable DMA operations.

For how to disable maskable interrupts, refer to the description of interrupt mask registers 0 to 5 (IMR0 to IMR5) (8.3.5 Interrupt mask registers 0 to 5 (IMR0 to IMR5)). For how to disable non-maskable interrupts, disable multiple interrupts by setting the NP bit of the PSW to 1 (refer to 3.2.2 (4) Program status word (PSW)).

<2> Clear the MEa bit of the BCTm register to 0.

<3> Clear the RENn bit of the RFSn register to 0 ($n = 1, 3, 4,$ or 6).

<4> Change the values of the CKDIV0 and CKDIV1 bits of the CKC register (refer to 9.3.1 (2) Setting data to clock control register (CKC) for how to change the values).

<5> Set the MEa bit of the BCTm register to 1.

<6> Set a new refresh interval to the RFSn register, and clear the RENn bit to 0 ($n = 1, 3, 4,$ or 6).

<7> Write the same value currently set to the SCRn register to the SCRn register ($n = 1, 3, 4,$ or 6).

<8> Confirm that the WCFn bit of the SCRn register is set to 1, then set the RENn bit of the RFSn register to 1. Do not change any other bits except for the RENn bit ($n = 1, 3, 4,$ or 6).

<9> Enable DMA operations as necessary.

<10> Access SDRAM.

Remarks 1. f_x : Main clock

2. $a = 0$ to 3 when $m = 0$

$a = 4$ to 7 when $m = 1$

(2/2)

To change the refresh interval, set a value at which refresh can be made in time even while the interval is changed (refer to 9.3.1 (1) Notes on changing refresh interval). If the refresh interval is correctly secured with the interrupt servicing time taken into consideration, the processing in <1> above may be skipped. The RFSn and BCTm registers are prohibited from being rewritten, but they can be rewritten when the refreshing interval is re-set by changing the value of the CKC register.

A register write cycle of SDRAM is generated as a result of rewriting the SCRn register (processing in <6> above), but the value of SDRAM before the RFSn and SCRn registers are re-set is retained.

(1) Notes on changing refresh interval

Figure 9-1 shows the internal state and the external bus state when the refresh interval is changed when the SDRAM is connected to the CS1 and CS3 areas. In such a case, the SDRAM that is connected to CS1 is not refreshed during a <1> and <3> period, and the SDRAM that is connected to CS3 is not refreshed during a <2> period.

The time for <1> may be increased or decreased depending on factors such as the use status of the internal system bus or a bus hold request from the external bus. Moreover, the time for <2> and <3> may be increased or decreased depending on the value set to the RFSn register.

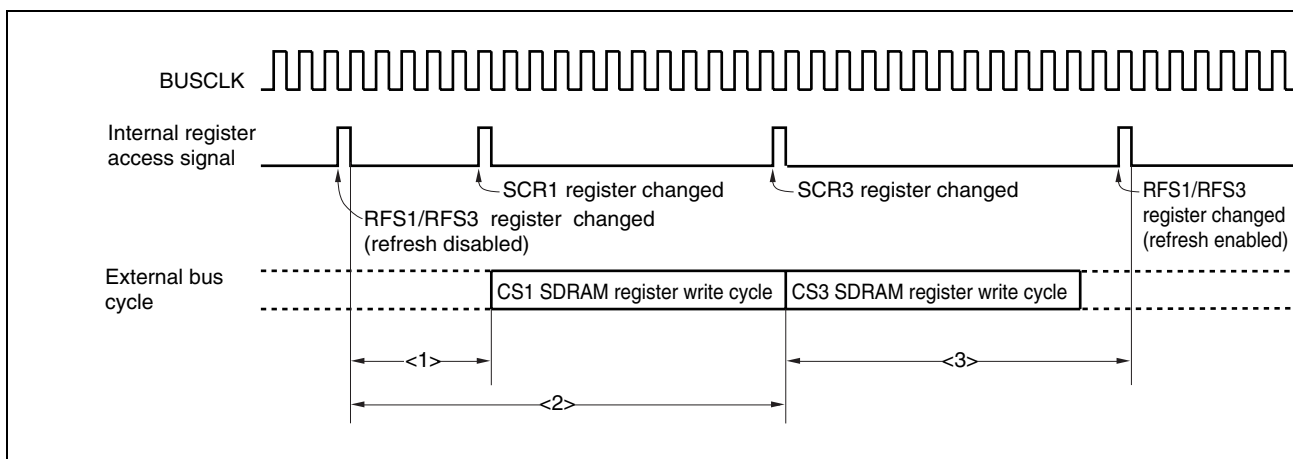

When changing the refresh interval, therefore, the value must be set by making allowances for periods <1> to <3> in which a refresh is not performed.

When the SDRAM is connected to only one CS area, the refresh interval value must be changed by making allowances for period <1>.

- Cautions 1.** The refresh command is issued eight times in the register write cycle regardless of the setting of the RENn bit of the RFSn register.
- 2.** The $\overline{\text{REFRQ}}$ signal does not operate while the RENn bit is set to 0, so care must be exercised when the external bus master references the $\overline{\text{REFRQ}}$ signal.
- 3.** Input to the $\overline{\text{SELFREF}}$ signal is ignored while the MEa bit of the BCTm register is set to 0, so the operation does not shift to the self-refresh state.

- Remarks 1.** n = 1, 3, 4, or 6
- 2.** a = 0 to 3 when m = 0
a = 4 to 7 when m = 1

Figure 9-1. Internal State and External Bus State When Refresh Interval Is Changed

(2) Setting data to clock control register (CKC)

Set data in the CKC register in the following sequence.

- <1> Prepare data in any one of the general-purpose registers to set in the specific register.
- <2> Write data to the command register (PRCMD).
- <3> Set the clock control register (CKC) (with the following instruction).
 - Store instruction (ST/SST instruction)
- <4> Insert the NOP instructions (16 instructions (<4> to <19>)).

```
[Sample coding]  <1> MOV    0x02, r10
                  <2> ST.B   r10, PRCMD[r0]
                  <3> ST.B   r10, CKC[r0]
                  <4> NOP
                  :
                  <19> NOP
```

No special sequence is required to read the specific register.

Cautions 1. Although the data written to the PRCMD register is dummy data, use the same register as the general-purpose register used in specific register setting (<3>) for writing to the PRCMD register (<2>). The same method should be applied when using a general-purpose register for addressing.

2. Be sure to terminate all DMA transfers prior to the execution of the above sequence.

9.3.2 Clock source select register (CKS)

This 8-bit register controls supply of the main clock (fx). It can be written to only by a specific sequence so that it cannot easily be overwritten by mistake due to an inadvertent program loop.

This register can be read or written in 8-bit or 1-bit units.

Be sure to clear bits 7 to 16 to "0". If they are set to 1, the operation is not guaranteed.

- Cautions 1. With the V850E2/ME3, it is not assumed that the CPU operates with the OSC output always supplied as the main clock (CKSSEL bit = 0). Therefore, be sure to confirm in the initialization sequence that the LOCK bit of the LOCKR register is 0, and then supply the main clock from the SSCG output (CKSSEL bit = 1); otherwise the operation will not be guaranteed.**
- 2. The CKS register can be changed only once after a reset release. Do not change it again.**

	7	6	5	4	3	2	1	<0>	Address	After reset
CKS	0	0	0	0	0	0	0	CKSSEL	1FFFF82CH	00H

Bit position	Bit name	Function
0	CKSSEL	Controls supply of the main clock (fx). 0: OSC output clock (Fx) 1: SSCG output clock (Fx × 20)

Set data in the clock source select register (CKS) in the following sequence.

- <1> Prepare data in any one of the general-purpose registers to set in the specific register.
- <2> Write data to the command register (PRCMD).
- <3> Set the clock source select register (CKS) (with the following instruction).
 - Store instruction (ST/SST instruction)
- <4> Insert the NOP instructions (16 instructions (<4> to <19>)).

```
[Sample coding]    <1> MOV    0x01, r10
                   <2> ST.B  r10, PRCMD[r0]
                   <3> ST.B  r10, CKS[r0]
                   <4> NOP
                   :
                   <19> NOP
```

No special sequence is required to read the specific register.

- Cautions**
1. Although the data written to the PRCMD register is dummy data, use the same register as the general-purpose register used in specific register setting (<3>) for writing to the PRCMD register (<2>). The same method should be applied when using a general-purpose register for addressing.
 2. Be sure to terminate all DMA transfers prior to the execution of the above sequence.

9.3.3 VBCSEL pin function

A division ratio can be set with the VBCSEL pin.

Table 9-1. Division Ratio Setting with VBCSEL Pin

VBCSEL Pin	Division Ratio	f _{VCLK} Output Frequency (MHz) (When f _{CLK} = 200 MHz)
0	f _{VCLK} = f _{CLK} /2	100 MHz
1	f _{VCLK} = f _{CLK} /3	66 MHz

Caution Specification of the VBCSEL pin should be fixed in the application system. If it is changed during operation, the operation is not guaranteed.

9.3.4 SSCG control register (SSCGC)

This is an 8-bit register that controls the frequency modulation rate and modulation period of SSCG output. It modulates the frequency by the frequency modulation rate (Down Spread) set by the ADJ2 to ADJ0 bits within the modulation period set by the SMDLn bit. This is effective in reducing the peak value of EMI noise. It can be written to only by a specific sequence so that it cannot easily be overwritten by mistake due to an inadvertent program loop.

This register can be read or written in 8-bit units.

Caution The SSCGC register can be set only when OSC output is supplied as the main clock (CKSSEL bit of CKS register = 0). If the setting of the SSCGC register is changed, the SSCG is unlocked (LOCK bit of LOCKR register = 1). Be sure to confirm that the LOCK bit = 0 before starting to supply SSCG output as the main clock (CKSSEL bit = 1); otherwise the operation will not be guaranteed.

(1/2)

	7	6	5	4	3	2	1	0	Address	After reset
SSCGC	0	0	SMDL1	SMDL0	ADJON	ADJ2	ADJ1	ADJ0	1FFFF836H	10H

Bit position	Bit name	Function															
5, 4	SMDL1, SMDL0	Set the modulation period of SSCG output. <table border="1" style="width: 100%; border-collapse: collapse; margin-top: 5px;"> <thead> <tr> <th style="width: 10%;">SMDL1</th> <th style="width: 10%;">SMDL0</th> <th style="width: 80%;">Modulation period of SSCG output</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> <td>13 to 27 kHz</td> </tr> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">1</td> <td>23 to 37 kHz</td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">0</td> <td>32 to 48 kHz</td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">1</td> <td>Setting prohibited</td> </tr> </tbody> </table>	SMDL1	SMDL0	Modulation period of SSCG output	0	0	13 to 27 kHz	0	1	23 to 37 kHz	1	0	32 to 48 kHz	1	1	Setting prohibited
SMDL1	SMDL0	Modulation period of SSCG output															
0	0	13 to 27 kHz															
0	1	23 to 37 kHz															
1	0	32 to 48 kHz															
1	1	Setting prohibited															

(2/2)

Bit position	Bit name	Function						
3 to 0	ADJON, ADJ2 to ADJ0	Set the frequency modulation rate of SSCG output.						
		ADJON	ADJ2	ADJ1	ADJ0	Frequency modulation rate of SSCG output		
						Min.	Typ.	Max.
		0	×	×	×	No modulation (frequency fixed)		
		1	0	0	0	-0.31%	-0.50%	-1.28%
		1	0	0	1	-0.67%	-1.00%	-1.75%
		1	0	1	0	-1.23%	-2.00%	-3.10%
		1	0	1	1	-1.74%	-3.00%	-4.33%
		1	1	0	0	-2.48%	-4.00%	-5.83%
		1	1	0	1	-3.27%	-5.00%	-7.28%
Other than above				Setting prohibited				
<p>Cautions 1. If the frequency modulation rate of SSCG output is set to other than “No modulation (frequency fixed)” (ADJON bit = 0), the internal system clock (f_{CLK}), bus clock (BUSCLK), and clock supplied to the on-chip peripheral functions all operate at the frequency that accords with the frequency modulation rate set by the ADJ2 to ADJ0 bits (see 9.5 Operating Clock Provisions). Therefore, thoroughly evaluate and confirm the system.</p> <p>2. An overshoot/undershoot of the frequency modulation rate occurs.</p>								

Set data in the SSCG control register (SSCGC) in the following sequence.

- <1> Prepare data in any one of the general-purpose registers to set in the specific register.
- <2> Write data to the command register (PRCMD).
- <3> Set the SSCG control register (SSCGC) (with the following instruction).
 - Store instruction (ST/SST instruction)
- <4> Insert the NOP instructions (16 instructions (<4> to <19>)).

```
[Sample coding]
<1> MOV  0x08, r10
<2> ST.B r10, PRCMD[r0]
<3> ST.B r10, SSCGC[r0]
<4> NOP
      ⋮
<19> NOP
```

No special sequence is required to read the specific register.

- Cautions**
1. Although the data written to the PRCMD register is dummy data, use the same register as the general-purpose register used in specific register setting (<3>) for writing to the PRCMD register (<2>). The same method should be applied when using a general-purpose register for addressing.
 2. Be sure to terminate all DMA transfers prior to the execution of the above sequence.

9.3.5 Lock register (LOCKR)

The lockup time (frequency stabilization time: approx. 2 ms) is the time from when the power is turned on until the phase locks at the prescribed frequency. The state until this stabilization occurs is called the lockup state, and the stabilized state is called the locked state.

The lock register (LOCKR) has a LOCK flag that indicates that the PLL is in the lock wait state.

This register is read-only, in 8-bit or 1-bit units.

Caution If the phase is locked, the LOCK flag is cleared to 0. If it is unlocked later because of a standby status, writing to SSCGC register, or $\overline{\text{RESET}}$ input, the LOCK flag is set to 1. If the phase is unlocked by a cause other than these, however, the LOCK flag is not affected (LOCK = 0).

	7	6	5	4	3	2	1	<0>	Address	After reset
LOCKR	0	0	0	0	0	0	0	LOCK	1FFFF824H	01H

Bit position	Bit name	Function
0	LOCK	This is a read-only flag that indicates the PLL lock wait state. This flag holds the value 0 as long as a lockup state is maintained. 0: Indicates that the PLL is locked. 1: Indicates that the PLL is waiting to be locked (unlock state).

If some other factor operates to cause an unlock state to occur, for control processing that depends on software execution speed, such as real-time processing, be sure to judge the LOCK flag by software immediately after operation begins and start processing after the PLL is locked.

On the other hand, static processing such as the setting of internal hardware or the initialization of register data or memory data can be executed without waiting for the LOCK flag to be reset to 0.

9.4 Operation

9.4.1 Operation status of each clock

The following table shows the operation status of each clock.

Table 9-2. Operation Status of Each Clock

Clock Source		OSC	PLL	Main Clock (fx)		USB Clock (f _{USB})	BUSCLK (f _{BUSCLK})
				Clock Supply to On-Chip Peripheral Function	Internal System Clock (f _{CLK})		
PLL mode	Normal operation	√	√	√	√	√	√
	HALT mode	√	√	√	×	√	√
	IDLE mode	√	√	×	×	√	×
	Reset period	√	×	×	√ ^{Note}	×	√ ^{Note}

Remark √: Operates
×: Stops

Note Operates on the OSC output clock.

9.4.2 Setting of input clock (Fx)

This table lists the frequencies supplied to the V850E2/ME3.

Table 9-3. Frequency List

Multiple	SSEL1 Pin	SSEL0 Pin	Input Frequency (MHz) (Target Values)	Main Clock (fx) Frequency (MHz)
20	0	0	6.00 to 7.24	120.00 to 144.80
	0	1	7.25 to 8.49	145.00 to 169.80
	1	0	8.50 to 10.00	170.00 to 200.00
	1	1	5.00 to 5.99	100.00 to 119.80

9.5 Operating Clock Provisions

SSCG consists of a multiplier that multiplies the OSC clock by 20 and a modulation circuit for frequency diffusion. The multiplier that multiplies the OSC clock generates an output error of up to ± 150 ps in the output period because of its circuit characteristics.

The modulation circuit adds the modulation error with respect to the set modulation rate, which varies depending on the modulation rate.

Therefore, the output frequency (f_{CLK}) of BUSCLK, which outputs a clock via SSCG, and the operating frequency of the on-chip peripheral I/O (main clock (f_x) of timers C, D, and ENC1, PWM unit, CSI3, UARTB, and A/D converter) are affected by this error. When calculating the frequency of each signal, therefore, be sure to take this error into consideration.

The methods of calculating the output period and output frequency at each modulation rate are shown below.

(1) Minimum value of operating frequency (f_{MIN})

Modulation Rate of SSCG Output (%)	Parameter	Output Period: T_{MAX} (ns)	Output Frequency (MHz)
No modulation	1.00000	$(1/f_x) \times 10^3 + 0.15$	$(1/T_{MAX}) \times 10^3$
-0.50	0.99110	$\{1/(0.99110 \times f_x)\} \times 10^3 + 0.15$	$(1/T_{MAX}) \times 10^3$
-1.00	0.98625	$\{1/(0.98625 \times f_x)\} \times 10^3 + 0.15$	$(1/T_{MAX}) \times 10^3$
-2.00	0.97450	$\{1/(0.97450 \times f_x)\} \times 10^3 + 0.15$	$(1/T_{MAX}) \times 10^3$
-3.00	0.96335	$\{1/(0.96335 \times f_x)\} \times 10^3 + 0.15$	$(1/T_{MAX}) \times 10^3$
-4.00	0.95085	$\{1/(0.95085 \times f_x)\} \times 10^3 + 0.15$	$(1/T_{MAX}) \times 10^3$
-5.00	0.93860	$\{1/(0.93860 \times f_x)\} \times 10^3 + 0.15$	$(1/T_{MAX}) \times 10^3$

(2) Maximum value of operating frequency (f_{MAX})

Modulation Rate of SSCG Output (%)	Parameter	Output Period: T_{MAX} (ns)	Output Frequency (MHz)
No modulation	1.00000	$(1/f_x) \times 10^3 - 0.15$	$(1/T_{MIN}) \times 10^3$
-0.50	1.00390	$\{1/(1.00390 \times f_x)\} \times 10^3 - 0.15$	$(1/T_{MIN}) \times 10^3$
-1.00	1.00375	$\{1/(1.00375 \times f_x)\} \times 10^3 - 0.15$	$(1/T_{MIN}) \times 10^3$
-2.00	1.00550	$\{1/(1.00550 \times f_x)\} \times 10^3 - 0.15$	$(1/T_{MIN}) \times 10^3$
-3.00	1.00665	$\{1/(1.00665 \times f_x)\} \times 10^3 - 0.15$	$(1/T_{MIN}) \times 10^3$
-4.00	1.00915	$\{1/(1.00915 \times f_x)\} \times 10^3 - 0.15$	$(1/T_{MIN}) \times 10^3$
-5.00	1.01140	$\{1/(1.01140 \times f_x)\} \times 10^3 - 0.15$	$(1/T_{MIN}) \times 10^3$

(3) Average operating frequency (f_{AVE})

The average operating frequency can be calculated by this expression.

$$\text{Average operating frequency } (f_{AVE}) = (f_{MIN} + f_{MAX})/2$$

The average operating frequency is in one period of the modulation period set by the SMDL1 and SMDL0 bits of the SSCGC register. The operating frequency in a period shorter than the modulation period may have a relatively larger error than the result of the above expression.

9.5.1 Calculating BUSCLK frequency

If the modulation function of SSCG is used, f_{VCLK} from which BUSCLK is generated fluctuates. Exercise care in calculating the frequency (f_{BUSCLK}) of BUSCLK.

The following table shows the frequency fluctuation of BUSCLK.

Table 9-4. Frequency Fluctuation of BUSCLK

BMC Register		BUSCLK Frequency (f_{BUSCLK}) (MHz)		
CKM1	CKM0	Min.	Typ.	Max.
0	0	f_{MIN}	f_{AVE}	f_{MAX}
0	1	$f_{MIN}/2$	$f_{AVE}/2$	$f_{MAX}/2$
1	0	Setting prohibited		
1	1	$f_{MIN}/4$	$f_{AVE}/4$	$f_{MAX}/4$

9.5.2 Calculating operating clock frequency of each on-chip peripheral function

When the modulation function of SSCG is used, the main clock (f_x) from which the operating clock of each on-chip peripheral function is generated fluctuates. Note (1) to (8) below.

(1) Count period of timer C:

Period of count clock frequency (set by the CSCn2 to CSCn0 bits of the TMCCn0 register) when input clock is specified (ETICn bit of the TMCCn1 register = 0) (n = 0 to 5)

The count period can be calculated from the average operating frequency.

However, the average operating frequency is in one period of the modulation period set by the SMDL1 and SMDL0 bits of the SSCGC register. Note that the average operating frequency may have a relatively larger error than the result of calculation during a count operation in a period shorter than the modulation period.

If it is necessary to guarantee an absolute value for the count operation, it is recommended to set appropriate counts during operation at f_{MIN} if the counting operation is performed within a specific time and during operation at f_{MAX} if the operation is performed for longer than a specific time.

Do not use the modulation function of SSCG if a high-accuracy count operation is necessary.

(2) Count period of timer D:

Period of count clock frequency (set by CSDn2 to CSDn0 bits of the TMCDn register) (n = 0 to 3)

The count period can be calculated from the average operating frequency.

However, the average operating frequency is in one period of the modulation period set by the SMDL1 and SMDL0 bits of the SSCGC register. Note that the average operating frequency may have a relatively larger error than the result of calculation during a count operation in a period shorter than the modulation period.

If it is necessary to guarantee an absolute value for the count operation, it is recommended to set appropriate counts during operation at f_{MIN} if the counting operation is performed within a specific time and during operation at f_{MAX} if the operation is performed for longer than a specific time.

Do not use the modulation function of SSCG if a high-accuracy count operation is necessary.

(3) Count period of timer ENC1:

Period of count clock frequency (set by PRM1n2 to PRM1n0 bits of the PRM1n register) when general-purpose timer mode is specified (T1CMDn bit of the TUM1n register = 0) (n = 0, 1)

The count period can be calculated from the average operating frequency.

However, the average operating frequency is in one period of the modulation period set by the SMDL1 and SMDL0 bits of the SSCGC register. Note that the average operating frequency may have a relatively larger error than the result of calculation during a count operation in a period shorter than the modulation period.

If it is necessary to guarantee an absolute value for the count operation, it is recommended to set appropriate counts during operation at f_{MIN} if the counting operation is performed within a specific time and during operation at f_{MAX} if the operation is performed for longer than a specific time. Duty setting is guaranteed during either high level output or low level output when timer output is performed.

Do not use the modulation function of SSCG if a high-accuracy count operation is necessary.

(4) Pulse output period of PWM unit:

Period of operating clock frequency (set by the CKSPn1 and CKSPn0 bits of the PWMCn register) (n = 0, 1)

The pulse output period can be calculated from the average operating frequency.

However, the average operating frequency is in one period of the modulation period set by the SMDL1 and SMDL0 bits of the SSCGC register. Note that the average operating frequency may have a relatively larger error than the result of calculation when a pulse with a period shorter than the modulation period is output.

If it is necessary to guarantee an absolute value for the pulse output, it is recommended to set appropriate counts during operation at f_{MIN} if the counting operation is performed within a specific time and during operation at f_{MAX} if the operation is performed for longer than a specific time. Duty setting is guaranteed during either high level output or low level output when PWM output is performed.

Do not use the modulation function of SSCG if a high-accuracy pulse output is necessary.

(5) Serial communication (transmission, reception, or transmission/reception) transfer rate of CSI3:

Period of base clock frequency (CKS3n2 to CKS3n0 of the CSIC3n register = other than 111) (n = 0, 1) with master mode specified

The transfer rate can be calculated from the average operating frequency.

However, the average operating frequency is in one period of the modulation period set by the SMDL1 and SMDL0 bits of the SSCGC register. Note that the average operating frequency may have a relatively larger error than the result of calculation at a transfer rate shorter than the modulation period.

If it is necessary to guarantee an absolute value for the transfer rate, it is recommended to set an appropriate transfer rate during operation at f_{MIN} for the minimum transfer rate and during operation at f_{MAX} for the maximum transfer rate.

(6) Serial communication (transmission or reception) transfer rate of UARTB:

Period of serial transfer speed (set by the UBnBRS15 to UBnBRS0 bits of the UBnCTL2 register) ($n = 0, 1$)

Set the value of the transfer rate (set value (k) of the UBnCTL2 register) so that the permissible maximum and minimum baud rate errors are satisfied at both f_{MIN} and f_{MAX} .

Here is a calculation example.

<1> Determine the set value (k) of the UBnCTL2 register from the calculation result of the expression $f_{AVE} \text{ (Hz)} / (8 \times \text{Target baud rate})$.

<2> Calculate the actual baud rate value at f_{MAX} and f_{MIN} , by using the set value (k) calculated in <1> above.

<3> Check that the result of calculation in <2> above satisfies the allowable maximum/minimum baud rate error.

<4> Calculate the set value of the transfer rate using <1> to <3> (set value (k) of the UBnCTL2 register).

Caution Change the modulation rate of SSCG if the set value (set value (k) of the UBnCTL2 register) of the transfer rate that satisfies the above calculation method cannot be obtained. The more the transfer rate is raised, the less selectable the modulation rate becomes.

Example:

$f_x = 200 \text{ MHz}$: Setting of modulation rates of 3%, 4%, and 5% is prohibited.

$f_x = 150 \text{ MHz}$: Setting of modulation rates of 4% and 5% is prohibited.

(7) A/D converter:

Conversion time

Calculate the set value (2 to 10 μs) of the A/D conversion time (set by the FR3 to FR0 bits of the ADM1 register) by f_{AVE} (calculation by f_{MIN} and f_{MAX} is not necessary).

(8) Digital noise elimination time

Calculate the minimum noise elimination time set by the NCWCn and NCW1m registers at f_{MAX} and the maximum noise elimination time at f_{MIN} ($n = 0$ to 3, $m = 0, 1$).

9.6 Power-Save Control

9.6.1 Overview

The power-save function has the following three modes.

(1) HALT mode

In this mode, the clock generator (oscillator (OSC, SSCG) and PLL synthesizer) continues to operate, but the CPU's operation clock stops. Since the supply of clocks to on-chip peripheral functions other than the CPU continues, operation continues. The power consumption of the overall system can be reduced by intermittent operation using a combination of the HALT mode and the normal operation mode.

The system is switched to HALT mode by a specific instruction (the HALT instruction).

(2) IDLE mode

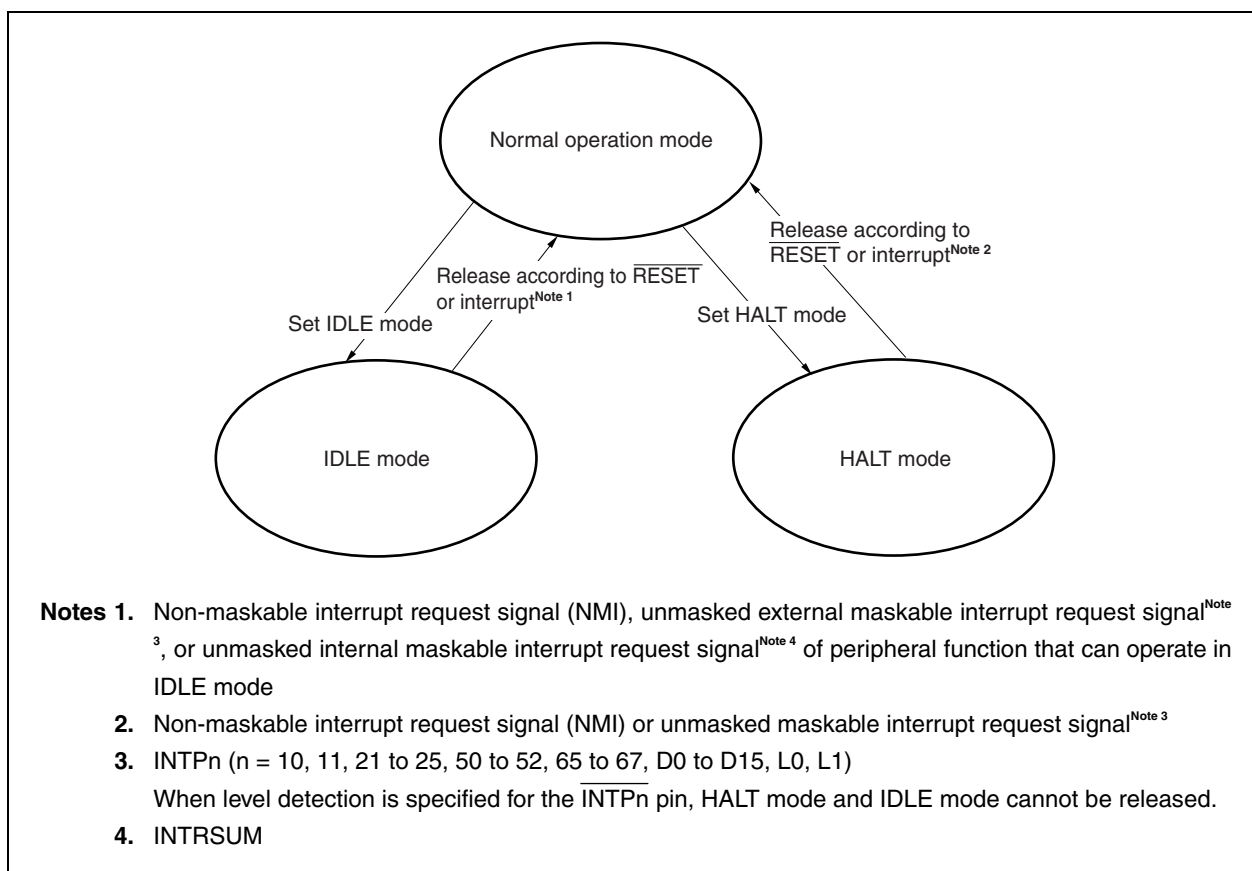

In this mode, the clock generator (oscillator (OSC, SSCG) and PLL synthesizer) continues to operate, but the supply of internal system clocks (f_{CLK}) is stopped, which causes the overall system to stop.

When the system is released from IDLE mode, it can be switched to normal operation mode quickly because the oscillator's oscillation stabilization time does not need to be secured.

Figure 9-2 shows the operation of the clock generator in normal operation mode, HALT mode, and IDLE mode.

An effective low power consumption system can be realized by combining these modes and switching modes according to the required use.

Figure 9-2. Power-Save Mode State Transition Diagram

9.6.2 Control registers

(1) Command register (PRCMD)

This is an 8-bit register that is used to set protection for write operations to registers that can significantly affect the system so that the application system is not halted unexpectedly due to an inadvertent program loop.

Writing to the first specific register (power-save control register (PSC), etc.) is only valid after first writing to the PRCMD register. Because of this, the register value can be overwritten only by the specified sequence, preventing an illegal write operation from being performed.

This register is write-only, in 8-bit units (when it is read, undefined data is read out).

	7	6	5	4	3	2	1	0	Address	After reset
PRCMD	RREG7	RREG6	RREG5	RREG4	RREG3	RREG2	RREG1	RREG0	1FFFF1FCH	Undefined

Bit position	Bit name	Function
7 to 0	RREG7 to RREG0	Registration code (arbitrary 8-bit data) The specific register targeted is as follows. <ul style="list-style-type: none"> • Power-save control register (PSC) • Clock control register (CKC) • Clock source select register (CKS) • SSCG control register (SSCGC)

(2) Power-save control register (PSC)

This is an 8-bit register that controls the power-save function.

If interrupts are enabled by the setting of the NMIM and INTM bits, the IDLE mode can be released by an interrupt request (except when interrupt servicing is disabled by the interrupt mask registers (IMR0 to IMR5)).

The IDLE mode is specified by the setting of the STP bit.

This register, which is one of the specific registers, is valid only when accessed in a specific sequence during a write operation.

This register can be read or written in 8-bit or 1-bit units.

Be sure to clear bits 7 and 6 to 0. If they are set to 1, the operation is not guaranteed.

Cautions 1. It is impossible to set the STP bit and the NMIM or INTM bit at the same time. Be sure to set the STP bit after setting the NMIM or INTM bit.

2. The IDLE mode is not released by a non-maskable interrupt request signal and an unmasked maskable interrupt request signal for which the NMIM and INTM bits are set to 1 because these interrupt requests are invalid (they are not held pending).

	7	6	<5>	<4>	3	2	<1>	0	Address	After reset
PSC	0	0	NMIM	INTM	0	0	STP	0	1FFFF1FEH	00H

Bit position	Bit name	Function
5	NMIM	This is the enable/disable setting bit for IDLE mode release using the valid edge input of NMI ^{Note} . 0: Release by NMI enabled 1: Release by NMI disabled
4	INTM	This is the enable/disable setting for IDLE mode release using an unmasked maskable interrupt (INTPn) (n = 10, 11, 21 to 25, 50 to 52, 65 to 67, D0 to D15, L0, L1) ^{Note} . 0: Release by maskable interrupt enabled 1: Release by maskable interrupt disabled
1	STP	Indicates the IDLE mode status. If 1 is written to this bit, the system enters IDLE mode. When IDLE mode is released, this bit is automatically reset to 0. 0: IDLE mode is released 1: IDLE by mode is in effect Caution When setting IDLE mode, first set the internal system clock to $f_x/8$ with the CKC register, then set the STP bit (1).

Note Setting is valid only in IDLE mode.

Set data in the power-save control register (PSC) in the following sequence.

- <1> Prepare data in any one of the general-purpose registers to set to the specific register.
- <2> Clear the clock control register (CKC) to 00H.
- <3> Write data to the command register (PRCMD).
- <4> Set the power-save control register (PSC) (with the following instructions).
 - Store instruction (ST/SST instruction)
 - Bit manipulation instruction (SET1/CLR1/NOT1 instruction)
- <5> Insert the NOP instructions (16 instructions (<22> to <37>).

Sample coding

```

<1> MOV    0x02, r10
<2> ST.B   r10, PRCMD[r0]
<3> ST.B   r10, CKC[r0]
<4> NOP
    ⋮
<19> NOP
<20> ST.B   r10, PRCMD[r0]    ; Write PRCMD register
<21> ST.B   r10, PSC[r0]     ; Set PSC register
<22> NOP                               ; Dummy instruction
    ⋮
<37> NOP                               ; Dummy instruction
(next instruction)                ; Execution routine after IDLE mode release

```

No special sequence is required to read the specific register.

- Cautions 1. A store instruction for the command register does not acknowledge interrupts. This coding is made on assumption that <20> and <21> above are executed by the program with consecutive store instructions. If another instruction is set between <20> and <21>, the above sequence may become ineffective when the interrupt is acknowledged by that instruction, and a malfunction of the program may result.**
2. Although the data written to the PRCMD register is dummy data, use the same register as the general-purpose register used in specific register setting (<21>) for writing to the PRCMD register (<20>). The same method should be applied when using a general-purpose register for addressing.
 3. At least 16 NOP instructions must be inserted after executing a store instruction to the PSC register to set IDLE mode.
 4. Be sure to terminate all DMA transfers prior to the execution of the above sequence.

9.6.3 HALT mode

(1) Setting and operation status

In HALT mode, the clock generator (oscillator (OSC, SSCG) and PLL synthesizer) continues to operate, but the operation clock of the CPU is stopped. Since the supply of clocks to on-chip peripheral functions other than the CPU continues, operation continues. The power consumption of the overall system can be reduced by setting the system to HALT mode while the CPU is idle.

The system is switched to HALT mode by the HALT instruction.

Although program execution stops in HALT mode, the contents of all registers, internal data RAM, internal instruction RAM, and ports are maintained in the state they were in immediately before HALT mode began. Also, operation continues for all on-chip peripheral functions (other than ports) that do not depend on CPU instruction processing. The following shows the status of each hardware unit in HALT mode.

- Cautions**
- 1. If the HALT instruction is executed while an interrupt request signal is being held pending, the HALT mode is set once but it is immediately released by the pending interrupt request signal.**
 - 2. At least 16 NOP instructions must be inserted after executing a HALT instruction.**

Table 9-5. Operation Status in HALT Mode

Function	Operation Status
Clock generator	Operating
Main clock (fx)	Operating
CPU	Stopped
Internal data	All internal data such as CPU registers, statuses, data, and the contents of internal data RAM and internal instruction RAM are maintained in the state they were in immediately before HALT mode began.
DMAC	Operating
INTC	Operating
TMC0 to TMC5	Operating
TMD0 to TMD3	Operating
TMENC10, TMENC11	Operating
UARTB0, UARTB1	Operating
CSI30, CSI31	Operating
A/D converter	Operating
Ports	Maintained the state before HALT mode set
USB function controller	Operating
D0 to D31	Operating
A0 to A25	
\overline{RD} , $\overline{WE/WR}$, \overline{BCYST}	
\overline{ULWR} , \overline{UUWR} , \overline{LLWR} , \overline{LUWR} , \overline{IORD} , \overline{IOWR}	
\overline{LLDQM} , \overline{LUDQM} , \overline{ULDQM} , \overline{UUDQM}	
\overline{LLBE} , \overline{LUBE} , \overline{ULBE} , \overline{UUBE}	
$\overline{CS0}$ to $\overline{CS7}$	
\overline{SDRAS}	
\overline{SDCAS}	
\overline{REFRQ}	
\overline{HLDK}	
\overline{HLDRQ}	
\overline{WAIT}	
$\overline{SELFREF}$	
\overline{SDCKE}	
BUSCLK	Clock output

(2) Release of HALT mode

HALT mode is released by a non-maskable interrupt request signal, an unmasked maskable interrupt request signal (INTP_n), or $\overline{\text{RESET}}$ pin input. (n = 10, 11, 21 to 25, 50 to 52, 65 to 67, D0 to D15, L0, or L1)

(a) Release according to a non-maskable interrupt request signal or an unmasked maskable interrupt request signal

HALT mode is released by a non-maskable interrupt request signal or by an unmasked maskable interrupt request signal regardless of the priority. The operation after release is as follows.

Table 9-6. Operation After HALT Mode Is Released by Interrupt Request Signal

Release Source	Enable Interrupt (EI) Status	Disable Interrupt (DI) Status
Non-maskable interrupt request signal	Branch to handler address	
Unmasked maskable interrupt request signal	Branch to handler address or execute next instruction	Execute next instruction

However, if the system is set to HALT mode during an interrupt servicing routine, operation will differ as follows.

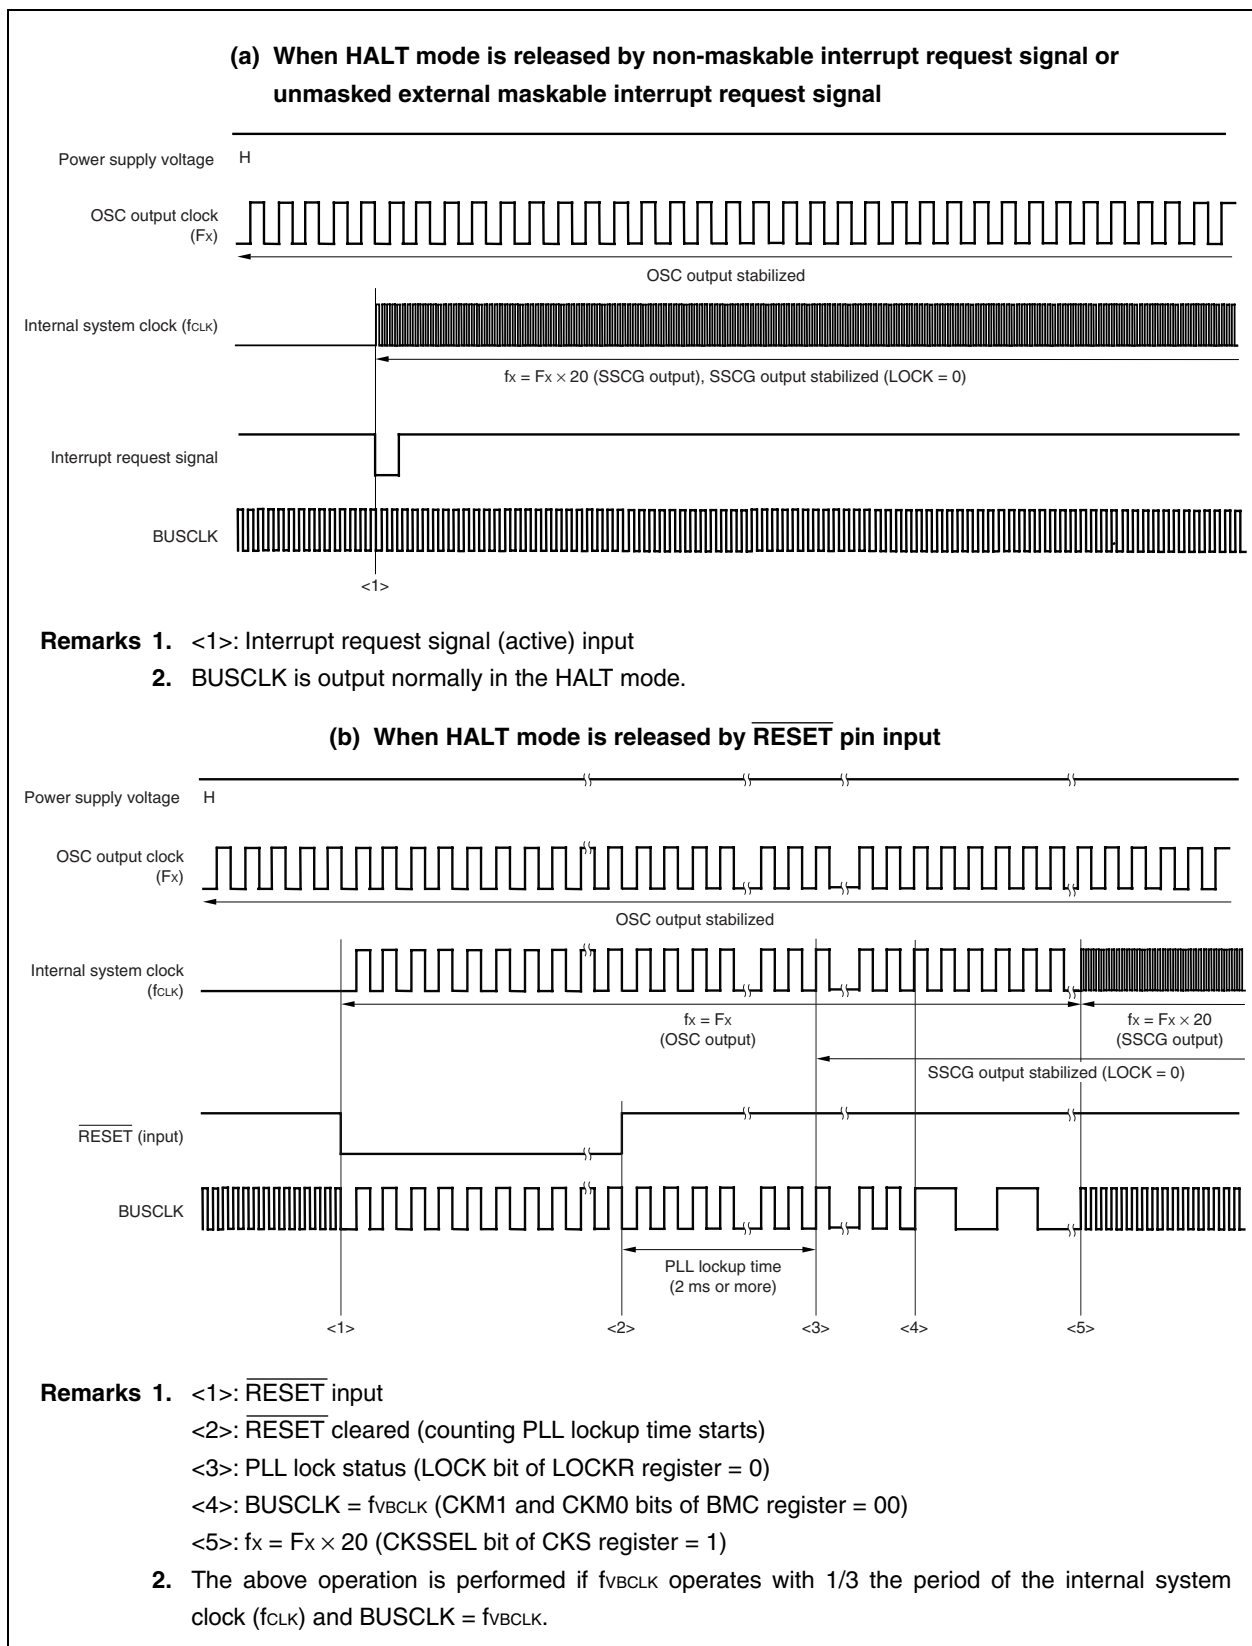

- (i) If an interrupt request signal is generated with a lower priority than that of the maskable interrupt request signal that is currently being serviced, HALT mode is released, but the newly generated interrupt request is not acknowledged. The new interrupt request signal is held pending.
- (ii) If an interrupt request (including non-maskable interrupt request signals) is generated with a higher priority than that of the maskable interrupt request signal that is currently being serviced, HALT mode is released and the newly generated interrupt request signal is acknowledged.

(b) Release according to $\overline{\text{RESET}}$ pin input

This is the same as a normal reset operation.

The BUSCLK operation when the HALT mode is released is illustrated below.

Figure 9-3. BUSCLK Operation When HALT Mode Is Released (When $f_{CLK} = f_x$)

9.6.4 IDLE mode

(1) Setting and operation status

In this mode, the entire system is stopped with the clock generator (oscillator (OSC, SSCG) and PLL synthesizer) continuing to operate and clock supply to the CPU and other on-chip peripheral functions stopped.

When IDLE mode is released, the system can be switched to normal operation mode quickly because the oscillator's oscillation stabilization time or the PLL lockup time does not need to be secured.

The system is switched to IDLE mode by setting the PSC register using a store instruction (ST or SST instruction) or a bit manipulation instruction (SET1, CLR1, or NOT1 instruction) (see **9.6.2 Control registers**).

In IDLE mode, program execution is stopped, and the contents of all registers, internal data RAM, internal instruction RAM, and ports are maintained in the state they were in immediately before execution stopped. The operation of CPU and other on-chip peripheral functions is stopped.

The following shows the status of each hardware unit in IDLE mode.

- Cautions**
- 1. Insert at least 16 NOP instructions after the instruction that stores data in the PSC register to set the IDLE mode.**
 - 2. Set the CKC register to 00H before setting the IDLE mode. To change the CKC register set value, also change the RFSa register set value because the self-refresh interval is changed by changing the CKC register set value (a = 1, 3, 4, 6).**

Table 9-7. Operation Status in IDLE Mode

Function	Operation Status
Clock generator	Operating
Main clock (fx)	Stopped
CPU	Stopped
Internal data	All internal data such as CPU registers, statuses, data, and the contents of internal data RAM and internal instruction RAM are maintained in the state they were in immediately before IDLE mode began.
DMAC	Stopped
INTC	Stopped
TMC0 to TMC5	Stopped
TMD0 to TMD3	Stopped
TMENC10, TMENC11	Stopped
UARTB0, UARTB1	Stopped
CSI30, CSI31	Stopped
A/D converter	Stopped
Ports	Maintained the state before IDLE mode set
USB function controller	Operating
D0 to D31	High impedance
A0 to A25	
\overline{RD} , $\overline{WE}/\overline{WR}$, \overline{BCYST}	High-level output
\overline{ULWR} , \overline{UUWR} , \overline{LLWR} , \overline{LUWR} , \overline{IORD} , \overline{IOWR}	
\overline{LLDQM} , \overline{LUDQM} , \overline{ULDQM} , \overline{UUDQM}	
\overline{LLBE} , \overline{LUBE} , \overline{ULBE} , \overline{UUBE}	
$\overline{CS0}$ to $\overline{CS7}$	
\overline{SDRAS}	
\overline{SDCAS}	Self-refresh status when connected to SDRAM
\overline{REFRQ}	
\overline{HLDK}	Operating (outputs high level when SDRAM controller is not used)
\overline{HLDRQ}	High-level output
\overline{WAIT}	
$\overline{SELFREF}$	
\overline{SDCKE}	
\overline{BUSCLK}	Input (no sampling)
\overline{SDCKE}	Low-level output (outputs high level when SDRAM controller is not used)
\overline{BUSCLK}	Low-level output

(2) Release of IDLE mode

The IDLE mode is released by a non-maskable interrupt request signal, an unmasked external maskable interrupt request (INTPn)^{Note}, an unmasked internal maskable interrupt request signal of a peripheral function that can operate in the IDLE mode (INTRSUM), and $\overline{\text{RESET}}$ pin input (n = 10, 11, 21 to 25, 50 to 52, 65 to 67, D0 to D15, L0, or L1).

Note When level detection is set, the IDLE mode cannot be released.

(a) Release according to a non-maskable interrupt request signal or an unmasked maskable interrupt request signal

IDLE mode can be released by an interrupt request signal only when it has been set with the INTM and NMIM bits of the PSC register cleared to 0.

IDLE mode is released by a non-maskable interrupt request, an unmasked external maskable interrupt request signal (INTPn), or an unmasked internal maskable interrupt request signal of a peripheral function that can operate in the IDLE mode (INTRSUM) regardless of the priority (n = 10, 11, 21 to 25, 50 to 52, 65 to 67, D0 to D15, L0, or L1). The operation after release is as follows.

Cautions 1. When the INTM bit of the PSC register = 1, the IDLE mode cannot be released by the unmasked maskable interrupt request signal.

2. Set the CKC register to an arbitrary value after the IDLE mode is released. To change the CKC register set value, also change the RFSa register set value because the self-refresh interval is changed by changing the CKC register set value (a = 1, 3, 4, 6).

Table 9-8. Operation After IDLE Mode Is Released by Interrupt Request

Release Source	Enable Interrupt (EI) Status	Disable Interrupt (DI) Status
Non-maskable interrupt request signal	Branch to handler address	
Unmasked maskable interrupt request signal	Branch to handler address or execute next instruction	Execute next instruction

However, if the system is set to IDLE mode during an interrupt servicing routine, operation will differ as follows.

(i) If an interrupt request signal is generated with a lower priority than that of the maskable interrupt request signal that is currently being serviced, IDLE mode is released, but the newly generated interrupt request signal is not acknowledged. The new interrupt request signal is held pending.

- (ii) If an interrupt request signal (including non-maskable interrupt request signals) is generated with a higher priority than that of the maskable interrupt request signal that is currently being serviced, IDLE mode is released and the newly generated interrupt request signal is acknowledged.

If the system is set to IDLE mode during an NMI servicing routine, IDLE mode is released, but the interrupt is not acknowledged (interrupt is held pending).

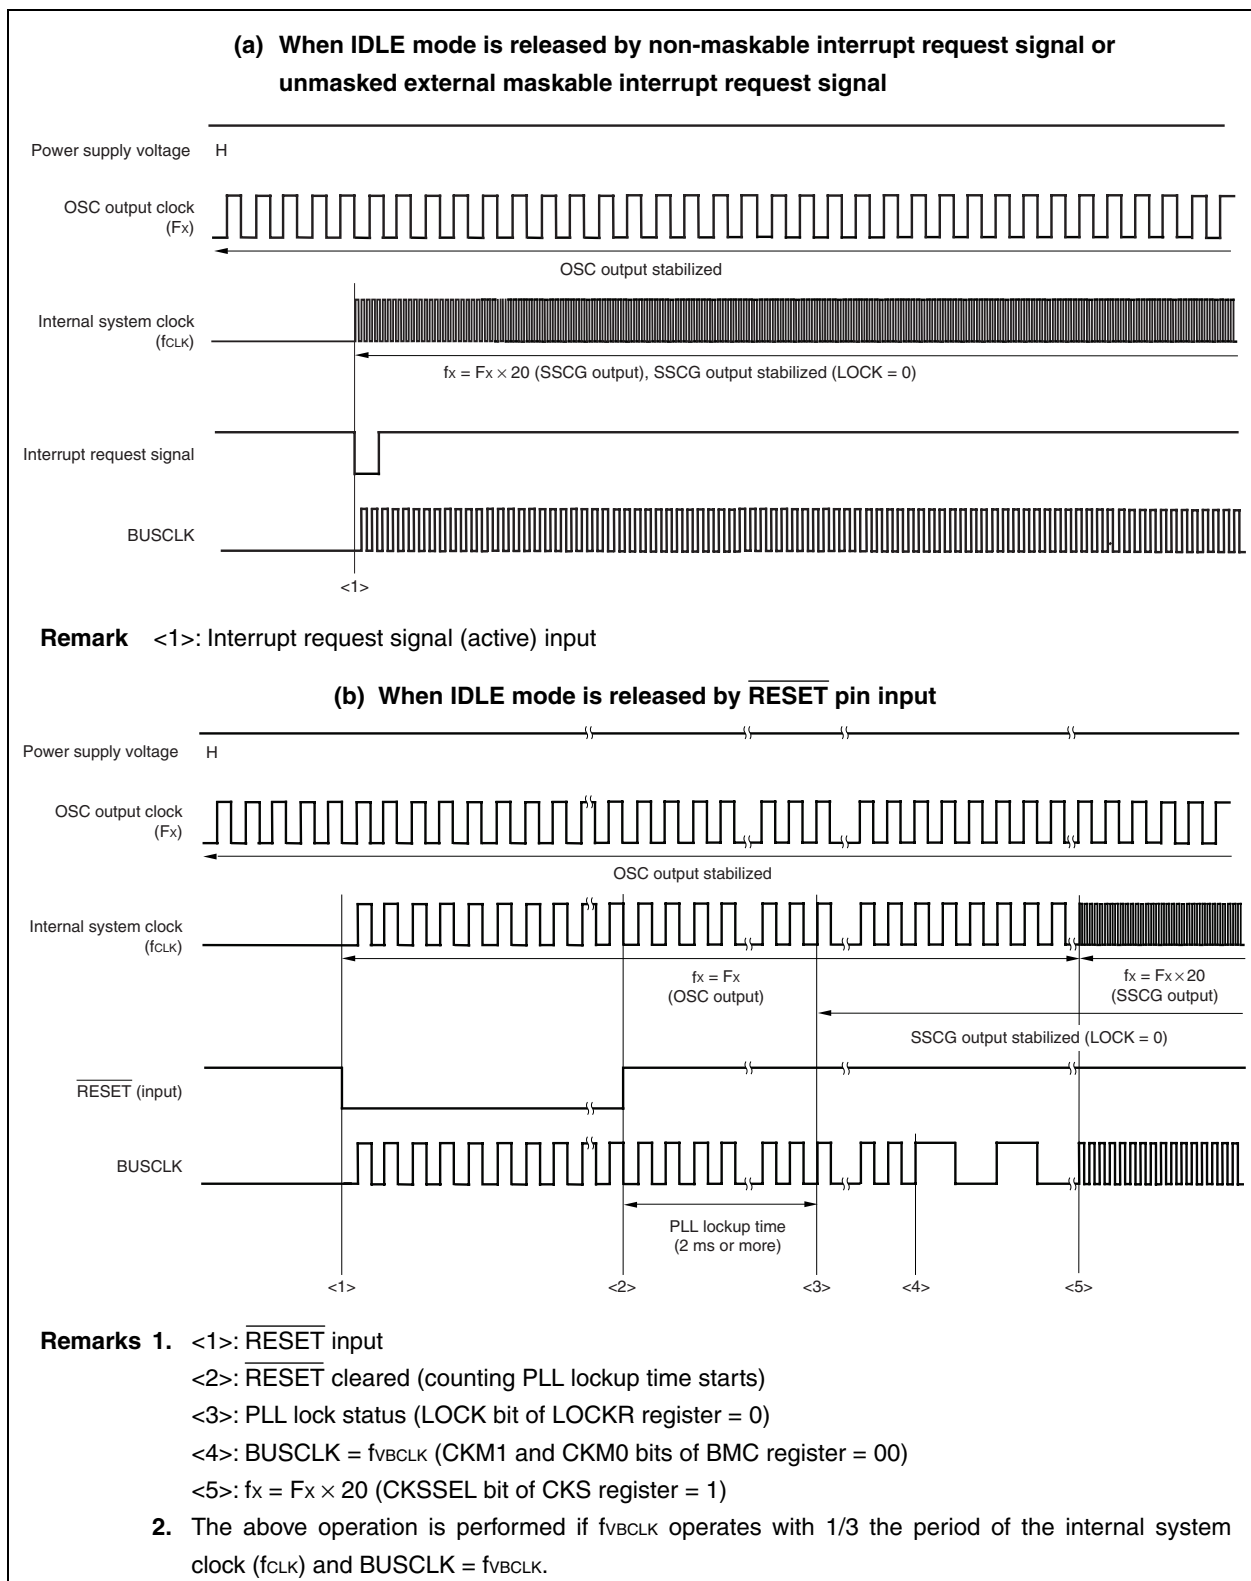

Interrupt servicing that is started when IDLE mode is released by NMI pin input is handled in the same way as normal NMI interrupt servicing that occurs during an emergency (because the NMI interrupt handler address is unique). Therefore, when a program must be able to distinguish between these two situations, a software status must be prepared in advance and that status must be set before setting the PSC register using a store instruction or a bit manipulation instruction. By checking for this status during NMI interrupt servicing, an ordinary NMI can be distinguished from the processing that is started when IDLE mode is released by NMI pin input.

(b) Release according to $\overline{\text{RESET}}$ pin input

This is the same as a normal reset operation.

The BUSCLK operation when the IDLE mode is released is illustrated below.

Figure 9-4. BUSCLK Operation When IDLE Mode Is Released (When $f_{CLK} = f_x$)

9.7 Cautions

Cautions concerning the clock generation function are shown below.

(1) Caution on setting CKC register

Note that if the internal system clock (f_{CLK}) is changed, the frequency (f_{BUSCLK}) of the bus clock (BUSCLK) is also changed.

(2) Caution on setting CKS register

With the V850E2/ME3, it is not assumed that the CPU operates with the OSC output always supplied as the main clock (CKSSEL bit of CKS register = 0). Therefore, be sure to confirm in the initialization sequence that the LOCK bit of the LOCKR register is 0, and then supply the main clock from the SSCG output (CKSSEL bit = 1); otherwise the operation will not be guaranteed.

(3) Caution on setting SSCGC register

The SSCGC register can be set only when OSC output is supplied as the main clock (CKSSEL bit of CKS register = 0). If the setting of the SSCGC register is changed, the SSCG is unlocked (LOCK bit of LOCKR register = 1). Be sure to confirm that the LOCK bit = 0 before starting to supply SSCG output as the main clock (CKSSEL bit = 1); otherwise the operation will not be guaranteed.

CHAPTER 10 TIMER/COUNTER FUNCTION

10.1 Timer C

10.1.1 Features

Timer C is a 16-bit timer/counter that can perform the following operations.

- Interval timer function
- PWM output
- External signal cycle measurement

10.1.2 Function overview

- 16-bit timer/counter: 6 channels (no capture operation for 2 channels)
- Capture/compare common registers: 12 sources
- Interrupt request sources
 - Capture/match interrupt requests: 12 sources
 - Capture register: Generates INTCCm0 or INTCCm1 at INTPCm0 or INTPCm1 input
 - Compare register: Generates INTCCn0 or INTCCn1 at match signal of CCCn0 or CCCn1
 - Overflow interrupt requests: 6 sources
- Timer/counter count clock sources: 2 types
(Selection of external pulse input or main clock division)
- Either free-running mode or overflow stop mode can be selected as the operation mode when the timer/counter overflows
- Timer/counter can be cleared by a match of the timer/counter and a compare register
- External pulse outputs: 6

Remark m = 0 to 3, n = 0 to 5

10.1.3 Basic configuration

Table 10-1. Timer C Configuration

Timer	Count Clock	Register	Read/Write	Generated Interrupt Signal	Capture Trigger	Timer Output S/R	Other Functions
Timer C	fx/8, fx/16, fx/32, fx/64, fx/128, fx/256, fx/512, fx/1,024	TMC0	Read	INTOVC0	–	–	
		CCC00	Read/write	INTCCC00	INTPC00	TOC0 (S)	
		CCC01	Read/write	INTCCC01	INTPC01	TOC0 (R)	
		TMC1	Read	INTOVC1	–	–	
		CCC10	Read/write	INTCCC10	INTPC10	TOC1 (S)	
		CCC11	Read/write	INTCCC11	INTPC11	TOC1 (R)	
		TMC2	Read	INTOVC2	–	–	
		CCC20	Read/write	INTCCC20	INTPC20	TOC2 (S)	
		CCC21	Read/write	INTCCC21	INTPC21	TOC2 (R)	
		TMC3	Read	INTOVC3	–	–	
		CCC30	Read/write	INTCCC30	INTPC30	TOC3 (S)	
		CCC31	Read/write	INTCCC31	INTPC31	TOC3 (R)	
		TMC4	Read	INTOVC4	–	–	
		CCC40	Read/write	INTCCC40	–	TOC4 (S)	A/D conversion start trigger
		CCC41	Read/write	INTCCC41	–	TOC4 (R)	A/D conversion start trigger
		TMC5	Read	INTOVC5	–	–	
		CCC50	Read/write	INTCCC50	–	TOC5 (S)	A/D conversion start trigger
		CCC51	Read/write	INTCCC51	–	TOC5 (R)	A/D conversion start trigger

Remark fx: Main clock
S/R: Set/reset

(1) Timer C (16-bit timer/counter)

Figure 10-1. Timer C Block Diagram

10.1.4 Timer C

(1) Timers C0 to C5 (TMC0 to TMC5)

TMCn functions as a 16-bit free-running timer or as an event counter for an external signal. Besides being mainly used for cycle measurement, TMCn can be used as pulse output (n = 0 to 5).

TMCn is read-only, in 16-bit units.

Cautions 1. The TMCn register can only be read. If the TMCn register is written, the subsequent operation is undefined.

2. If the CAECn bit of the TMCCn0 register is cleared to 0, a reset is performed asynchronously.

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset
TMC0																	1FFFF600H	0000H
TMC1																	1FFFF620H	0000H
TMC2																	1FFFF640H	0000H
TMC3																	1FFFF660H	0000H
TMC4																	1FFFF680H	0000H
TMC5																	1FFFF6A0H	0000H

TMCn performs the count-up operations of an internal count clock or external count clock. Timer start and stop are controlled by the CECn bit of timer mode control register Cn0 (TMCCn0) (n = 0 to 5).

The internal or external count clock is selected by the ETICn bit of timer mode control register Cn1 (TMCCn1) (n = 0 to 5).

(a) Selection of the external count clock

TMCn operates as an event counter.

When the ETICn bit of timer mode control register Cn1 (TMCCn1) is set to 1, TMCm counts the valid edges of the external clock input (TICm), synchronized with the internal count clock. The valid edge is specified by valid edge select register Cm (SESCm) (m = 0 to 3, n = 0 to 5).

Caution When the INTPCm0/TICm pin is used as TICm (external clock input pin), disable the INTPCm0 interrupt or set CCCm0 to compare mode (m = 0 to 3, n = 0 to 5).

(b) Selection of the internal count clock

TMCn operates as a free-running timer.

When an internal clock is specified as the count clock by timer mode control register Cn1 (TMCCn1), TMCn is counted up for each input clock cycle specified by the CSCn0 to CSCn2 bits of the TMCCn0 register (n = 0 to 5).

Division by the prescaler can be selected for the count clock from among $fx/8$, $fx/16$, $fx/32$, $fx/64$, $fx/128$, $fx/256$, $fx/512$, and $fx/1,024$ by the TMCCn0 register (fx: main clock).

An overflow interrupt can be generated if the timer overflows. Also, the timer can be stopped following an overflow by setting the OSTCn bit of the TMCCn1 register to 1.

Caution The count clock cannot be changed while the timer is operating.

The conditions when the TMCn register becomes 0000H are shown below.

(a) Asynchronous reset

- CAECn bit of TMCCn0 register = 0
- Reset input

(b) Synchronous reset

- CECn bit of TMCCn0 register = 0
- The CCCn0 register is used as a compare register, and the TMCn and CCCn0 registers match when clearing the TMCn register is enabled (CCLRCn bit of the TMCCn1 register = 1)

(2) Capture/compare registers Cn0 and Cn1 (CCcn0 and CCcn1) (n = 0 to 5)

These capture/compare registers (Cn0 and Cn1) are 16-bit registers.

They can be used as capture registers or compare registers according to the CMSCn0 and CMSCn1 bit specifications of timer mode control register Cn1 (TMCCn1) (n = 0 to 5).

These registers can be read or written in 16-bit units. (However, write operations can only be performed in compare mode.)

Caution The CCC40, CCC41, CCC50, and CCC51 registers can only be used as compare registers. They cannot be used as capture registers.

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset
CCC0n																	1FFFF602H, 1FFFF604H	0000H
CCC1n																	1FFFF622H, 1FFFF624H	0000H
CCC2n																	1FFFF642H, 1FFFF644H	0000H
CCC3n																	1FFFF662H, 1FFFF664H	0000H
CCC4n																	1FFFF682H, 1FFFF684H	0000H
CCC5n																	1FFFF6A2H, 1FFFF6A4H	0000H

Remark n = 0, 1

(a) Setting these registers as capture registers (CMSCn0 and CMSCn1 bits of TMCCn1 register = 0)

When these registers are set as capture registers, the valid edges of the corresponding external interrupt signals INTPCm0 and INTPCm1 are detected as capture triggers. The timer TMCm is synchronized with the capture trigger, and the value of TMCm is latched in the CCCm0 and CCCm1 registers (capture operation) (m = 0 to 3, n = 0 to 5).

The valid edge of the INTPCm0 pin is specified (rising edge, falling edge, or both rising and falling edges) according to the IESC0m1 and IESC0m0 bits of the SESCm register, and the valid edge of the INTPCm1 pin is specified according to the IESC1m1 and IESC1m0 bits of the SESCm register.

The capture operation is performed asynchronously to the count clock. The latched value is held in the capture register until another capture operation is performed.

When the CAECn bit of timer mode control register Cn0 (TMCCn0) is 0, 0000H is read.

If these registers are specified as capture registers, an interrupt is generated by detecting the valid edge of signals INTPCm0 and INTPCm1.

Caution If the capture operation contends with the timing of disabling the TMCm register from counting (when the CECn bit of the TMCCn0 register = 0), the captured data becomes undefined. In addition, the INTCCm0 and INTCCm1 interrupts do not occur (m = 0 to 3, n = 0 to 5).

(b) Setting these registers as compare registers (CMSCn0 and CMSCn1 bits of TMCCn1 register = 1)

When these registers are set as compare registers, the TMCn and register values are compared for each count clock, and an interrupt is generated by a match. If the CCLRCn bit of timer mode control register Cn1 (TMCCn1) is set to 1, the TMCn value is cleared to 0 at the same time as a match with the CCCn0 register (it is not cleared to 0 by a match with the CCCn1 register) (n = 0 to 5).

A compare register is equipped with a set/reset function. The corresponding timer output (TOCn) is set or reset, in synchronization with the generation of a match signal.

The interrupt selection source differs according to the function of the selected register.

Cautions 1. To write to capture/compare registers Cn0 and Cn1, always set the CAECn bit to 1 first. If the CAECn bit is 0, the data that is written will be invalid.

2. Write to capture/compare registers Cn0 and Cn1 after setting them as compare registers via TMCCn0 and TMCCn1 register settings. If they are set as capture registers (CMSCn0 and CMSCn1 bits of TMCCn1 register = 0), no data is written even if a write operation is performed to CCCm0 and CCCm1 (m = 0 to 3, n = 0 to 5).

3. When these registers are set as compare registers, INTPCn0 and INTPCn1 cannot be used (n = 0 to 5).

When using these registers as an external interrupt input pin, use the $\overline{\text{INTP65}}$ and $\overline{\text{INTP66}}$ pins.

10.1.5 Control registers

(1) Timer mode control registers C00 to C50 (TMCC00 to TMCC50)

The TMCCn0 registers control the operation of TMCn (n = 0 to 5).

These registers can be read or written in 8-bit or 1-bit units.

Be sure to clear bits 3 and 2 to "0". If they are set to "1", the operation is not guaranteed.

Cautions 1. The CAECn and other bits cannot be set at the same time. The other bits and the registers of the other TMCn unit should always be set after the CAECn bit has been set. Also, to use external pins related to the timer function when timer C is used, be sure to set the CAECn bit to 1 after setting the external pins to control mode.

2. When conflict occurs between an overflow and a TMCCn0 register write, the OVFCn bit value becomes the value written during the TMCCn0 register write (n = 0 to 5).

(1/2)

	<7>	6	5	4	3	2	<1>	<0>	Address	After reset
TMCC00	OVFC0	CSC02	CSC01	CSC00	0	0	CEC0	CAEC0	1FFFF606H	00H
TMCC10	OVFC1	CSC12	CSC11	CSC10	0	0	CEC1	CAEC1	1FFFF626H	00H
TMCC20	OVFC2	CSC22	CSC21	CSC20	0	0	CEC2	CAEC2	1FFFF646H	00H

Bit position	Bit name	Function
7	OVFCn	<p>This is a flag that indicates TMCn overflow.</p> <p>0: No overflow occurs 1: Overflow occurs</p> <p>When TMCn has counted up from FFFFH to 0000H, the OVFCn bit becomes 1 and an overflow interrupt request (INTOVFn) is generated at the same time. However, if TMCn is cleared to 0000H after a match at FFFFH when the CCCn0 register is set to compare mode (CMSCn0 bit of TMCCn1 register = 1) and clearing is enabled for a match when TMCn and CCCn0 are compared (CCLRCn bit of TMCCn1 register = 1), then TMCn is considered to be cleared and the OVFCn bit does not become 1. Also, no INTOVFn interrupt is generated.</p> <p>The OVFCn bit retains the value 1 until 0 is written directly or until an asynchronous reset is performed because the CAECn bit is 0. An interrupt operation due to an overflow is independent of the OVFCn bit, and the interrupt request flag (OVCFIn) for INTOVFn is not affected even if the OVFCn bit is manipulated. If an overflow occurs while the OVFCn bit is being read, the flag value changes, and the change is reflected when the next read operation occurs.</p>

When the CAECn bit is changed from 1 to 0, all registers of the TMCn unit are initialized. When CAECn is set to 1 again, the TMCn unit registers must be set again. 																																				

Remark n = 0 to 5

(2) Timer mode control registers C01 to C51 (TMCC01 to TMCC51)

The TMCCn1 registers control the operation of TMCn (n = 0 to 5).

These registers can be read or written in 8-bit units.

- Cautions**
1. The various bits of the TMCCn1 register must not be changed during timer operation. If they are to be changed, they must be changed after setting the CECn bit of the TMCCn0 register to 0. If these bits are overwritten during timer operation, operation cannot be guaranteed (n = 0 to 5).
 2. If the ENTOCn and ALVCn bits are changed at the same time, a glitch (spike shaped noise) may be generated in the TOCn pin output. Either create a circuit configuration that will not malfunction even if a glitch is generated or make sure that the ENTOCn and ALVCn bits do not change at the same time (n = 0 to 5).
 3. TOCn output is not changed by an external interrupt signal (INTPCm0 or INTPCm1). To use the TOCn signal, specify that the capture/compare registers are compare registers (CMSCn0 and CMSCn1 bits of TMCCn1 register = 1) (m = 0 to 3, n = 0 to 5).
 4. The TMCC41 and TMCC51 registers can be used only when the CCC40, CCC41, CCC50, and CCC51 registers are used as compare registers. They cannot be used when the CCC40, CCC41, CCC50, and CCC51 registers are used as capture registers.
 5. To clear the external interrupt signal by setting the ECLRCn bit, be sure to make the following setting.

Count clock period of TMD0 > Count clock period of TMCn

If this setting is not made, the falling edge of the INTCMD0 interrupt signal may not be detected.

Correct example (if count clock of TMD0 is slow)

CSD02 to CSD00 bits of TMCD0 register = 011: fx/64

CSCn2 to CSCn0 bits of TMCC0 register = 001: fx/16

Remark Resetting the flip-flop of the TOCn output takes precedence (n = 0 to 5).

Bit position	Bit name	Function
3	CCLRCn	Sets whether the clearing of TMCn is enabled or disabled during a compare operation. 0: Clearing is disabled 1: Clearing is enabled (if CCCn0 and TMCn match during a compare operation, TMCn is cleared)
2	ECLRCn	Enables/disables clearing TMCn by INTCMD0 (TMD0). 0: Disables clearing by INTCMD0. 1: Enables clearing by INTCMD0. After TMCn has been cleared, it resumes counting. Caution When ECLRCn bit = 1, unless a compare match interrupt (INTCMD0) is generated by TMD0, timer counting does not start (even if the CECn bit of the TMCCn0 register is set (1)).
1	CMSCn1	Selects the operation mode of the capture/compare register (CCcn1). 0: The register operates as a capture register (CCcm1) 1: The register operates as a compare register (CCcn1)
0	CMSCn0	Selects the operation mode of the capture/compare register (CCcn0). 0: The register operates as a capture register (CCcm0) 1: The register operates as a compare register (CCcn0)

Remark m = 0 to 3
n = 0 to 5

(3) Valid edge select registers C0 to C3 (SESC0 to SESC3)

These registers specify the valid edge of an external interrupt request (INTPC00, INTPC01, INTPC10, INTPC11, INTPC20, INTPC21, INTPC30, INTPC31, and TIC0 to TIC3) from an external pin of TMCn (n = 0 to 3).

The rising edge, the falling edge, or both rising and falling edges can be specified as the valid edge independently for each pin.

Each of these registers can be read or written in 8-bit units.

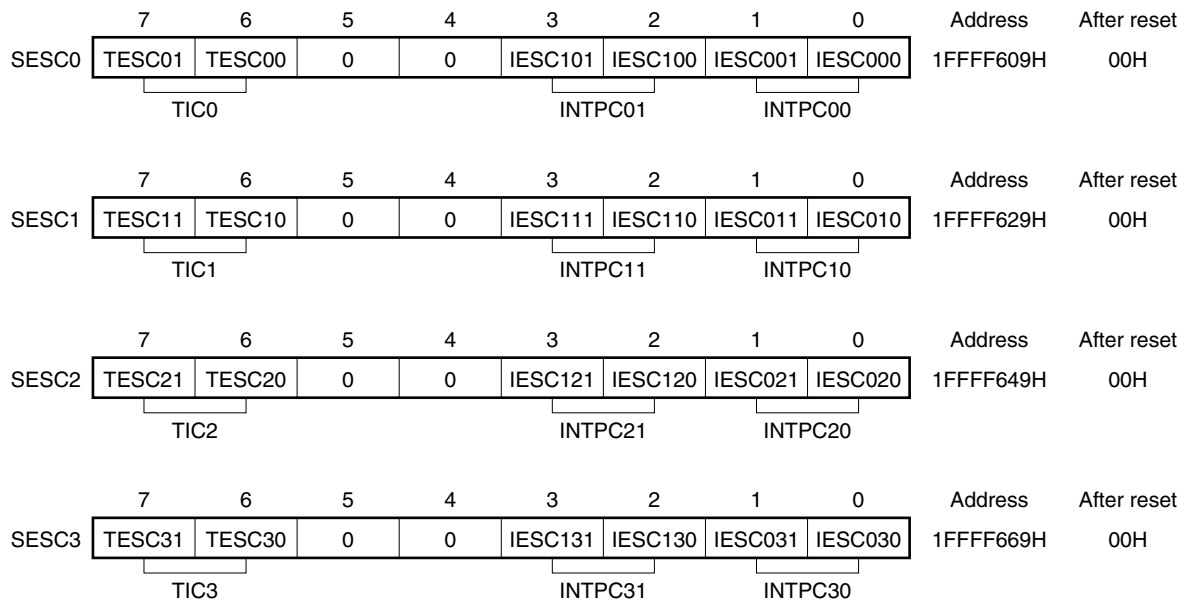

Be sure to clear bits 5 and 4 to "0". If they are set to "1", the operation is not guaranteed.

Cautions 1. The various bits of the SESCn register must not be changed during timer operation (n = 0 to 3). If they are to be changed, they must be changed after setting the CECn bit of the TMCCn0 register to 0. If the SESCn register is overwritten during timer operation, operation cannot be guaranteed.

2. Even when using the INTPC00/TIC0, INTPC10/TIC1, INTPC20/TIC2, and INTPC30/TIC3 pins as INTPC00, INTPC10, INTPC20, and INTPC30, respectively, without using timer C, be sure to set the CAECn and CECn bits of timer mode control registers C00 to C03 (TMCC00 to TMCC30) to 1.

3. When setting the trigger mode of the INTPC00, INTPC01, INTPC10, INTPC11, INTPC20, INTPC21, INTPC30, INTPC31, and TIC0 to TIC3 pins, set the PMCx register (x = 5 to 7), then, after setting the CAECn and CECn bits of the TMCCn0 register to 1 (n = 0 to 3), set the SESCn register.

If the PMCx register is set after the SESCn register has been set, an illegal interrupt, incorrect counting, and incorrect clearing may occur depending on the timing of setting the PMCx register (n = 0 to 3, x = 5 to 7).

(4) Noise elimination width setting registers C0 to C3 (NCWC0 to NCWC3)

The NCWCn registers are used to set the noise elimination width of the digital noise filter of the timer C input pin (n = 0 to 3).

These registers can be read or written in 8-bit units.

Be sure to clear bits 7 to 2 to “0”. If they are set to “1”, the operation is not guaranteed.

In addition, do not overwrite this register during timer operation.

10.1.6 Operation

(1) Count operation

Timer C can function as a 16-bit free-running timer or as an external signal event counter. The setting for the type of operation is specified by timer mode control registers Cn0 and Cn1 (TMCCn0 and TMCCn1) (n = 0 to 5). When it operates as a free-running timer, if the CCCn0 or CCCn1 register and the TMCn count value match, an interrupt signal is generated and the timer output signal (TOCn) can be set or reset. Also, a capture operation that holds the TMCm count value in the CCCm0 or CCCm1 register is performed, in synchronization with the valid edge that was detected from the external interrupt request input pin as an external trigger (m = 0 to 3). The capture value is held until the next capture trigger is generated.

Caution When using the INTPCm0/TICm pin as TICm (external clock input pin), be sure to disable the INTPCm0 interrupt or set the CCCm0 register to compare mode (m = 0 to 3).

Figure 10-2. Basic Operation of Timer C

(2) Overflow

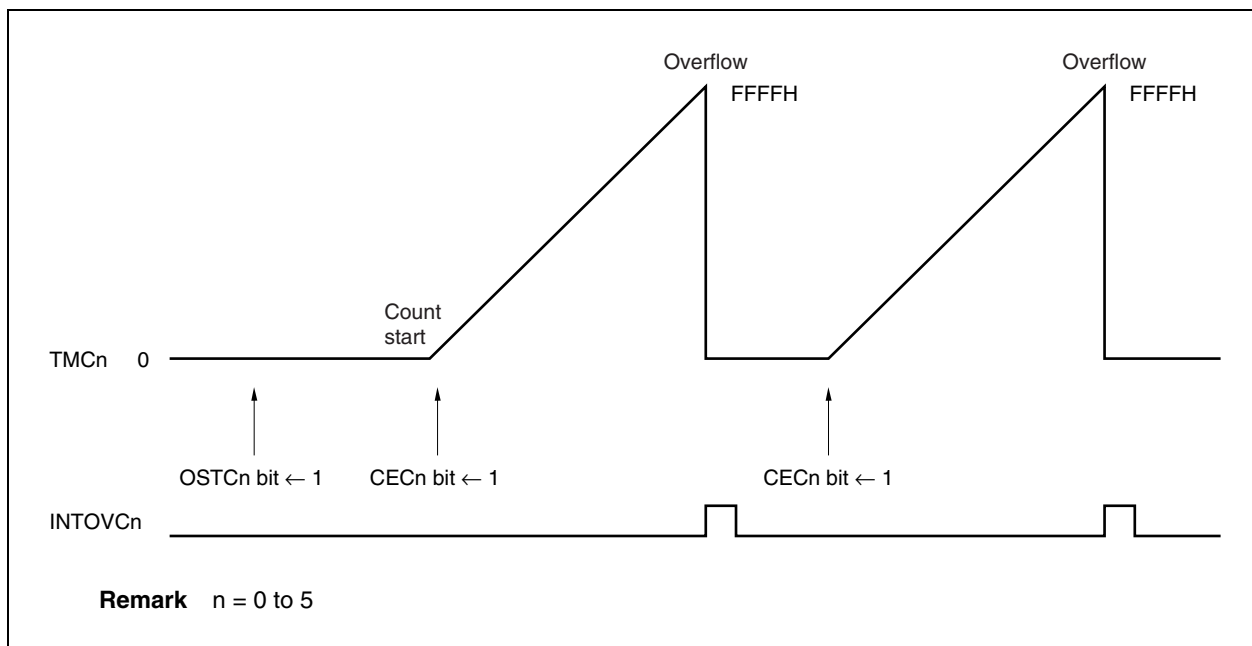

When the TMCn register has counted the count clock from FFFFH to 0000H, the OVFCn bit of the TMCCn0 register is set to 1, and an overflow interrupt (INTOVCn) is generated at the same time. However, if the CCCn0 register is set to compare mode (CMSCn0 bit of TMCCn1 register = 1) and to the value FFFFH when match clearing is enabled (CCLRCn bit of TMCCn1 register = 1), then the TMCn register is considered to be cleared and the OVFCn bit is not set to 1 when the TMCn register changes from FFFFH to 0000H. Also, the overflow interrupt (INTOVCn) is not generated.

When the TMCn register is changed from FFFFH to 0000H because the CECn bit of the TMCCn0 register changes from 1 to 0, the TMCn register is considered to be cleared, but the OVFCn bit is not set to 1 and no INTOVCn interrupt is generated.

Also, timer operation can be stopped after an overflow by setting the OSTCn bit of the TMCCn1 register to 1. When the timer is stopped due to an overflow, the count operation is not restarted until the CECn bit is set to 1. Operation is not affected even if the CECn bit is set to 1 during a count operation.

Remark n = 0 to 5

Figure 10-3. Operation After Overflow (When OSTCn Bit = 1)

(3) Capture operation

The TMCn register has two capture/compare registers. These are the CCCn0 register and the CCCn1 register. A capture operation or a compare operation is performed according to the settings of both the CMSCn1 and CMSCn0 bits of the TMCCn1 register. If the CMSCn1 and CMSCn0 bits of the TMCCn1 register are cleared to 0, the register operates as a capture register.

A capture operation that captures and holds the TMCm count value asynchronously relative to the count clock is performed in synchronization with an external trigger. The valid edge that is detected from an external interrupt request input pin (INTPCm0 or INTPCm1) is used as an external trigger (capture trigger). The TMCm count value during counting is captured and held in the capture register, in synchronization with that capture trigger signal. The capture register value is held until the next capture trigger is generated.

Also, an interrupt request (INTCCm0 or INTCCm1) is generated by INTPCm0 or INTPCm1 signal input.

The valid edge of the capture trigger is set by valid edge select register Cm (SESCm).

If both the rising and falling edges are set as capture triggers, the input pulse width from an external source can be measured. Also, if only one of the edges is set as the capture trigger, the input pulse cycle can be measured.

Remark m = 0 to 3
n = 0 to 5

Figure 10-4. Capture Operation Example

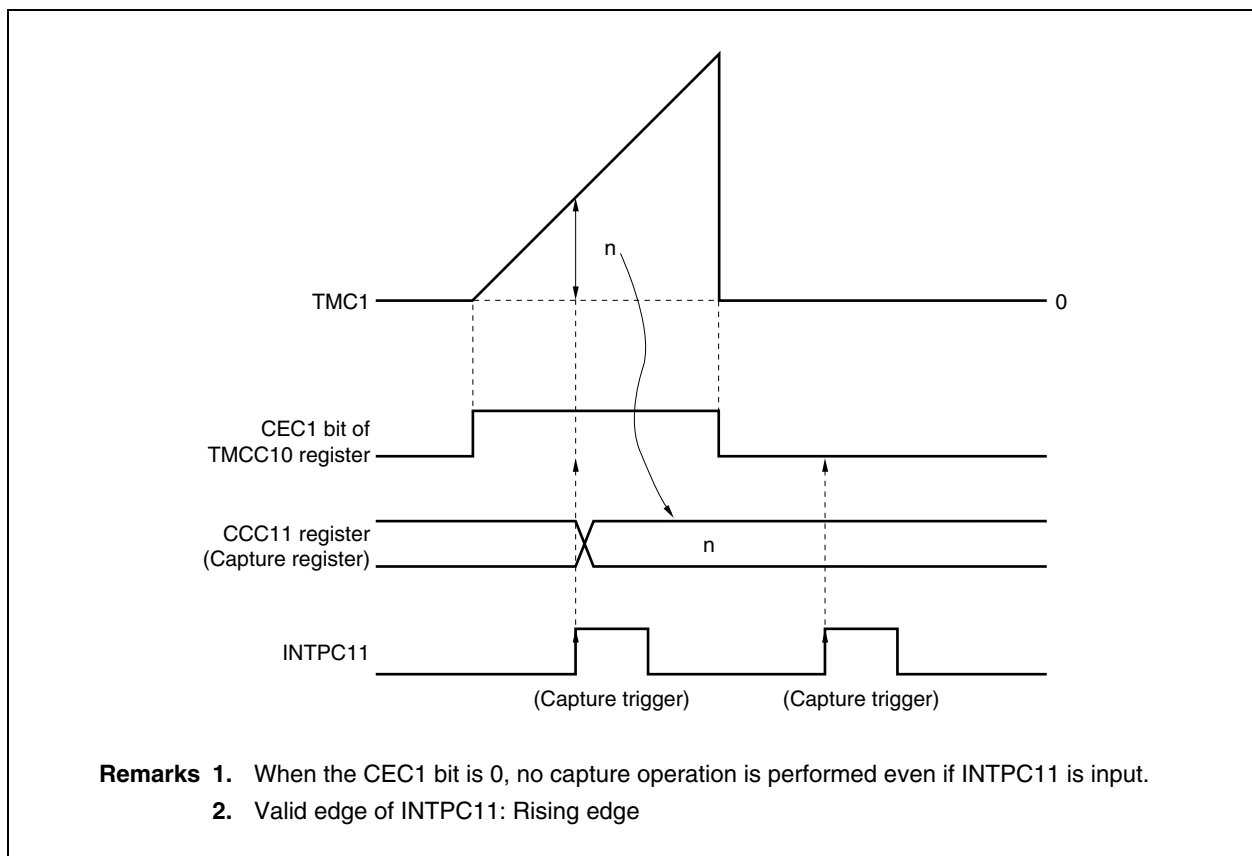

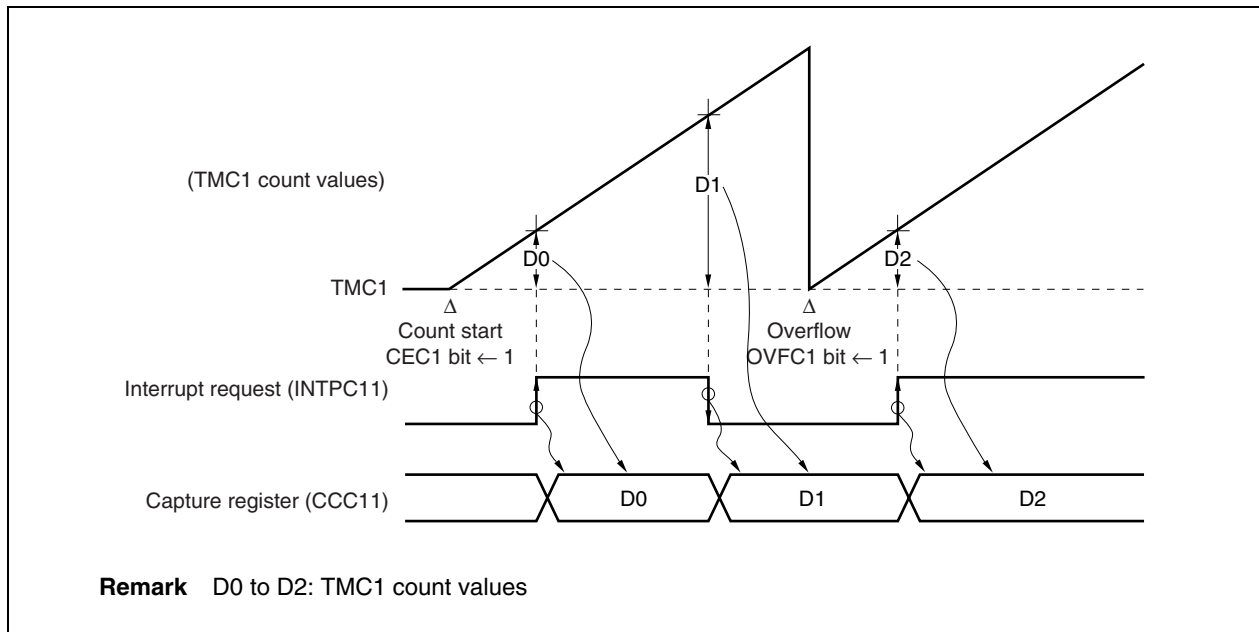

Figure 10-5. TMC1 Capture Operation Example (When Both Edges Are Specified)

(4) Compare operation

The TMCn register has two capture/compare registers. These are the CCCn0 register and the CCCn1 register. A capture operation or a compare operation is performed according to the settings of both the CMSCn1 and CMSCn0 bits of the TMCCn1 register. If the CMSCn1 and CMSCn0 bits of the TMCCn1 register are set to 1, the register operates as a compare register.

A compare operation that compares the value that was set in the compare register and the TMCn count value is performed.

If the TMCn count value matches the value of the compare register, which had been set in advance, a match signal is sent to the output controller. The match signal causes the timer output pin (TOCn) to change and an interrupt request signal (INTCCn0 or INTCCn1) to be generated at the same time.

If the CCCn0 or CCCn1 registers are cleared to 0000H, the 0000H after the TMCn register counts up from FFFFH to 0000H is judged as a match. In this case, the TMCn register value is cleared to 0 at the next count timing, however, this 0000H is not judged as a match. Also, the 0000H when the TMCn register begins counting is not judged as a match.

If match clearing is enabled (CCLRCn bit of TMCCn1 register = 1) for the CCCn0 register, the TMCn register is cleared when a match with the TMCn register occurs during a compare operation.

Remark n = 0 to 5

Figure 10-6. Compare Operation Example (1/2)

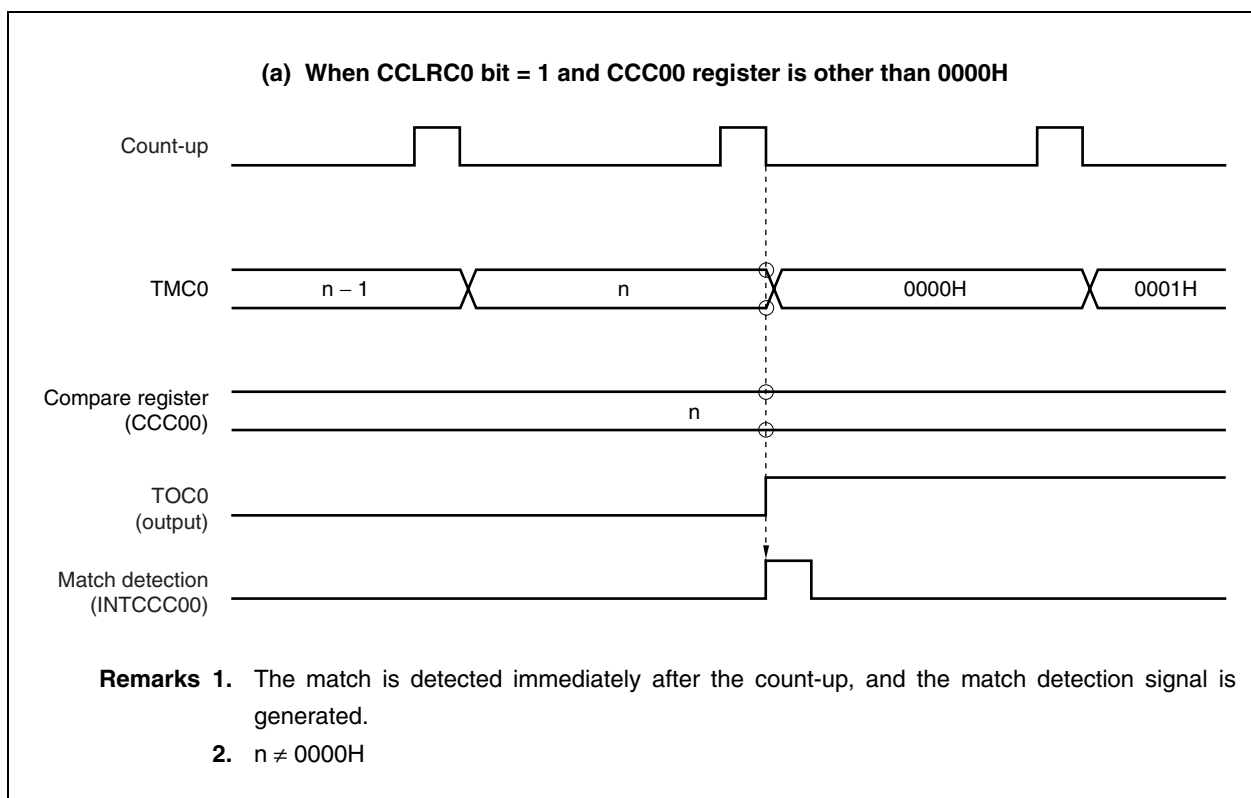

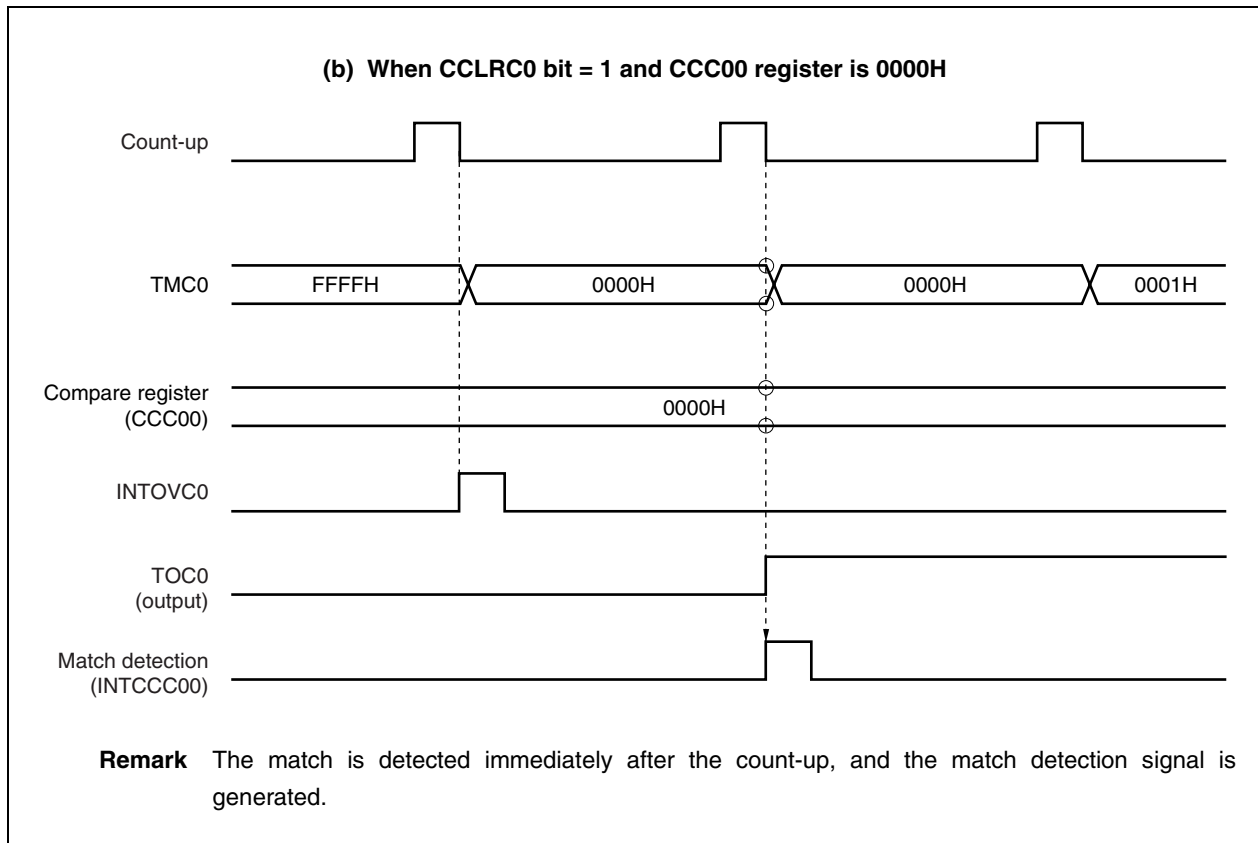

Figure 10-6. Compare Operation Example (2/2)

(5) External pulse output

Timer C has six timer output pins (TOCn).

An external pulse output (TOCn) is generated when a match of the two compare registers (CCCn0 and CCCn1) and the TMCn register is detected.

If a match is detected when the TMCn count value and the CCCn0 register value are compared, the output level of the TOCn pin is set. Also, if a match is detected when the TMCn count value and the CCCn1 register value are compared, the output level of the TOCn pin is reset.

The output level of the TOCn pin can be specified by the TMCCn1 register.

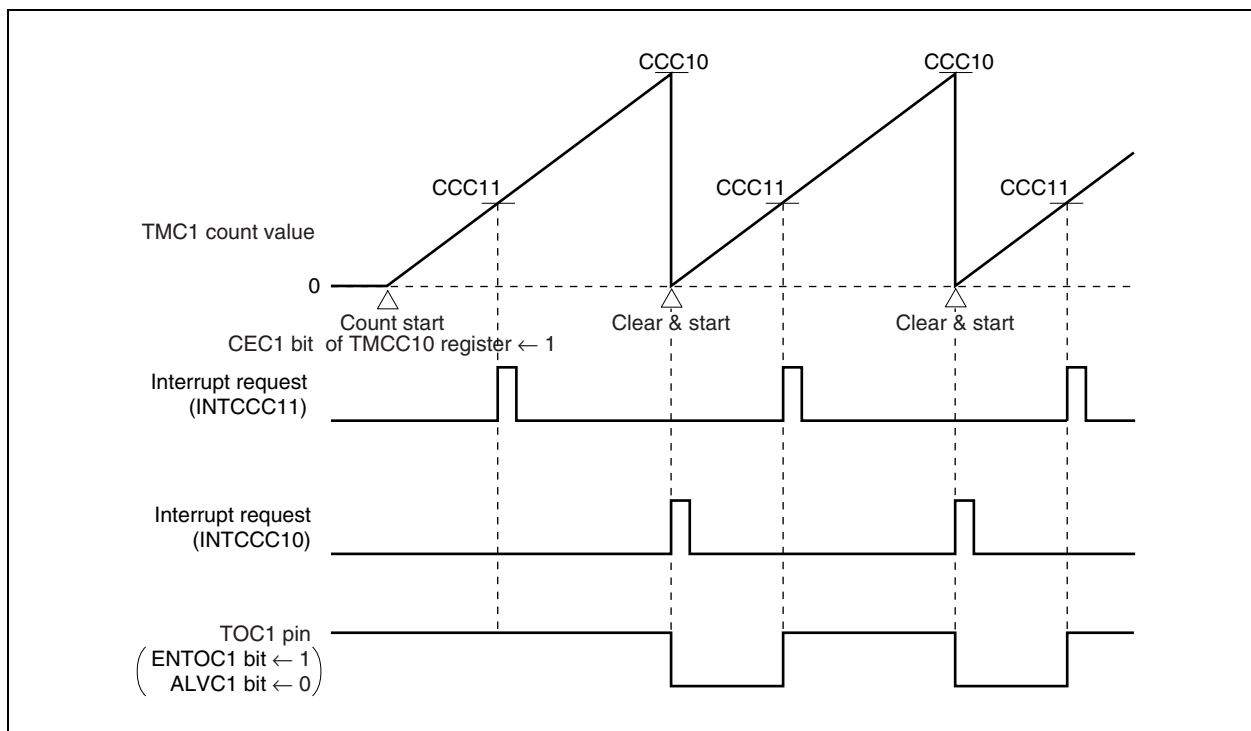

Remark n = 0 to 5

Table 10-2. TOCn Output Control

TMCCn1 Register		TOCn Output	
ENTOCn Bit	ALVCn Bit	External Pulse Output	Output Level
0	0	Disable	High level
0	1	Disable	Low level
1	0	Enable	When the CCCn0 register is matched: low level When the CCCn1 register is matched: high level
1	1	Enable	When the CCCn0 register is matched: high level When the CCCn1 register is matched: low level

Remark n = 0 to 5

Figure 10-7. TMC1 Compare Operation Example (Set/Reset Output Mode)

10.1.7 Application examples

(1) Interval timer

By setting the TMCCn0 and TMCCn1 registers as shown in Figure 10-8, timer C operates as an interval timer that repeatedly generates interrupt requests with the value that was preset in the CCCn0 register as the interval. When the counter value of the TMCn register matches the setting value of the CCCn0 register, the TMCn register is cleared to 0000H and an interrupt request signal (INTCCn0) is generated at the same time that the count operation resumes.

Remark n = 0 to 5

Figure 10-8. Contents of Register Settings When Timer C Is Used as Interval Timer

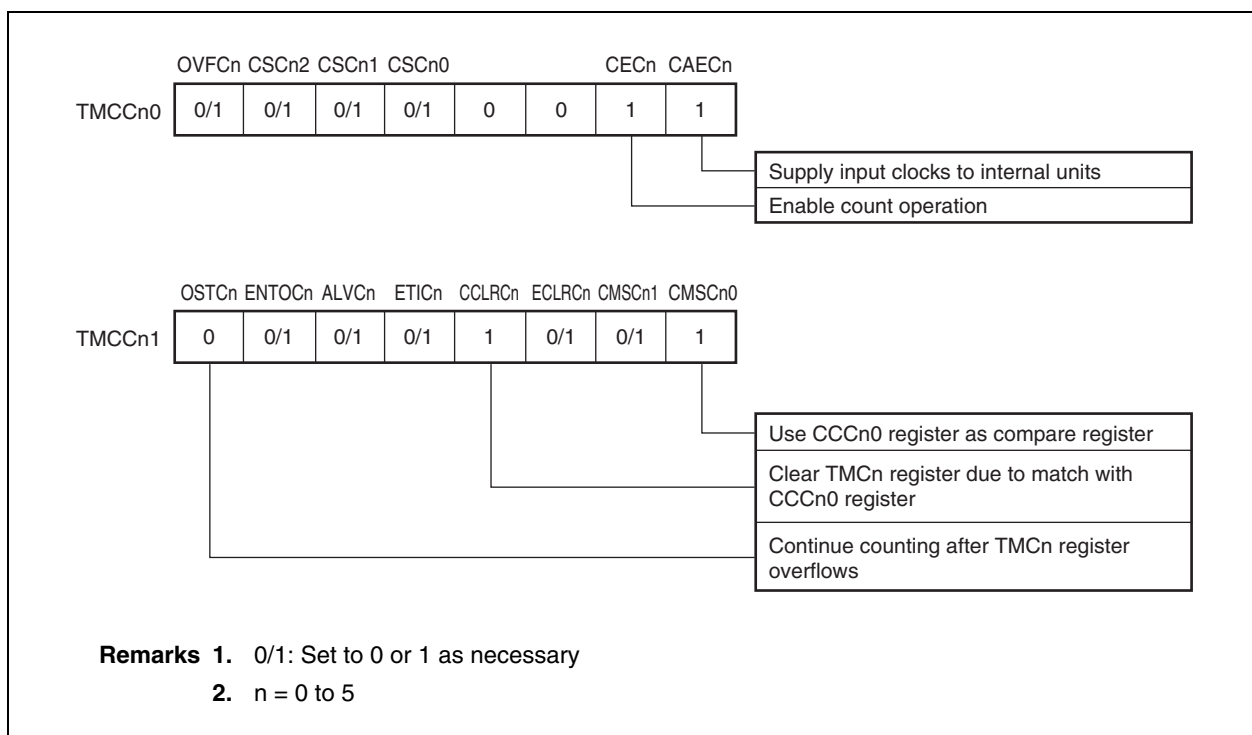

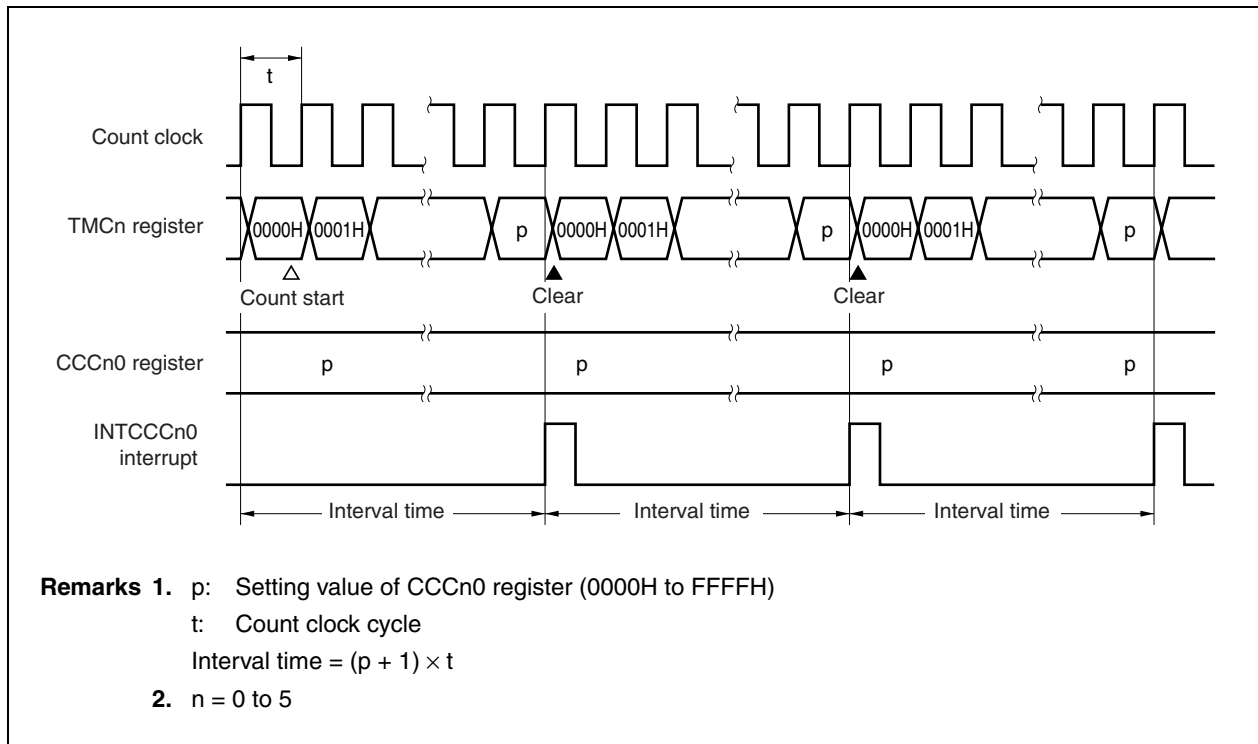

Figure 10-9. Interval Timer Operation Timing Example

(2) PWM output

By setting the TMCCn0 and TMCCn1 registers as shown in Figure 10-10, timer C can output a PWM signal, whose frequency is determined according to the setting of the CSCn2 to CSCn0 bits of the TMCCn0 register, with the values that were preset in the CCCn0 and CCCn1 registers determining the intervals.

When the counter value of the TMCn register matches the setting value of the CCCn0 register, the TOCn output becomes active. Then, when the counter value of the TMCn register matches the setting value of the CCCn1 register, the TOCn output becomes inactive. The TMCn register continues counting. When it overflows, its count value is cleared to 0000H, and the register continues counting. In this way, a PWM signal whose frequency is determined according to the setting of the CSCn2 to CSCn0 bits of the TMCCn0 register can be output. When the setting value of the CCCn0 register and the setting value of the CCCn1 register are the same, the TOCn output remains inactive and does not change.

The active level of the TOCn output can be set by the ALVCn bit of the TMCCn1 register.

Remark n = 0 to 5

Figure 10-10. Contents of Register Settings When Timer C Is Used for PWM Output

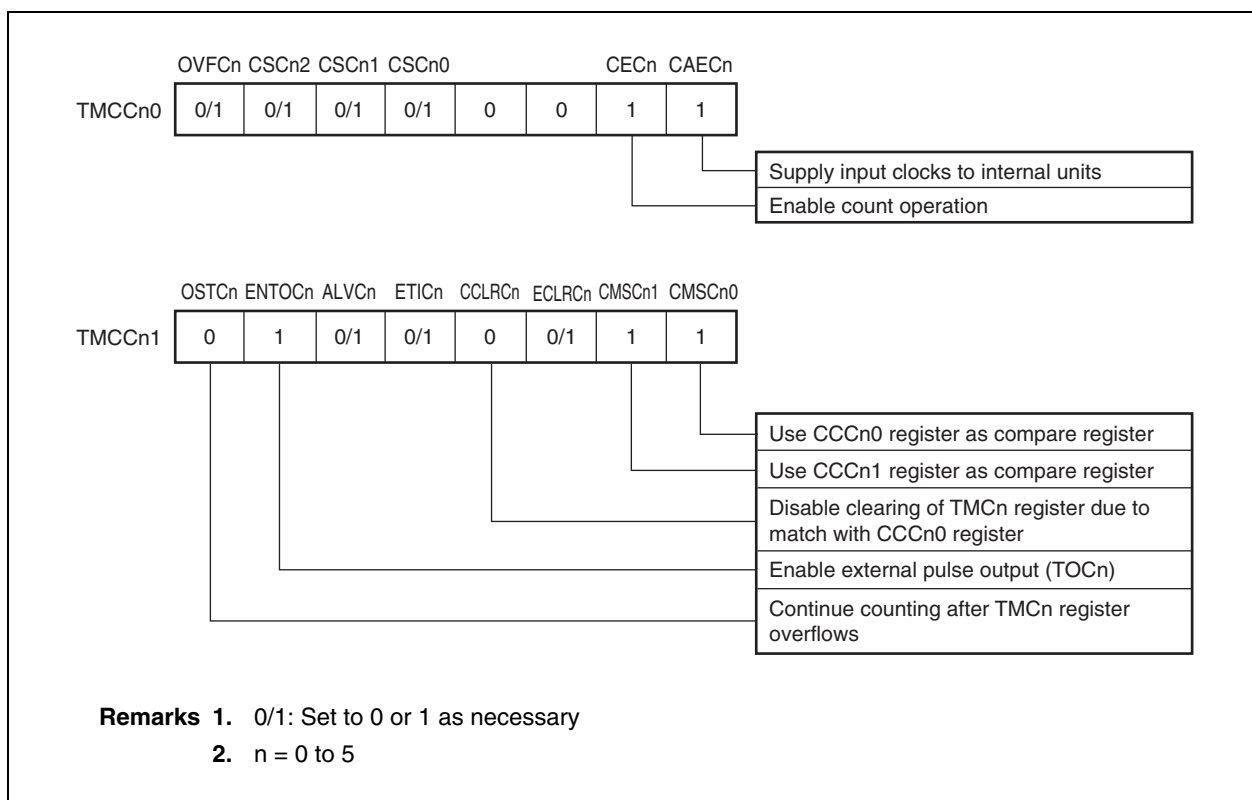

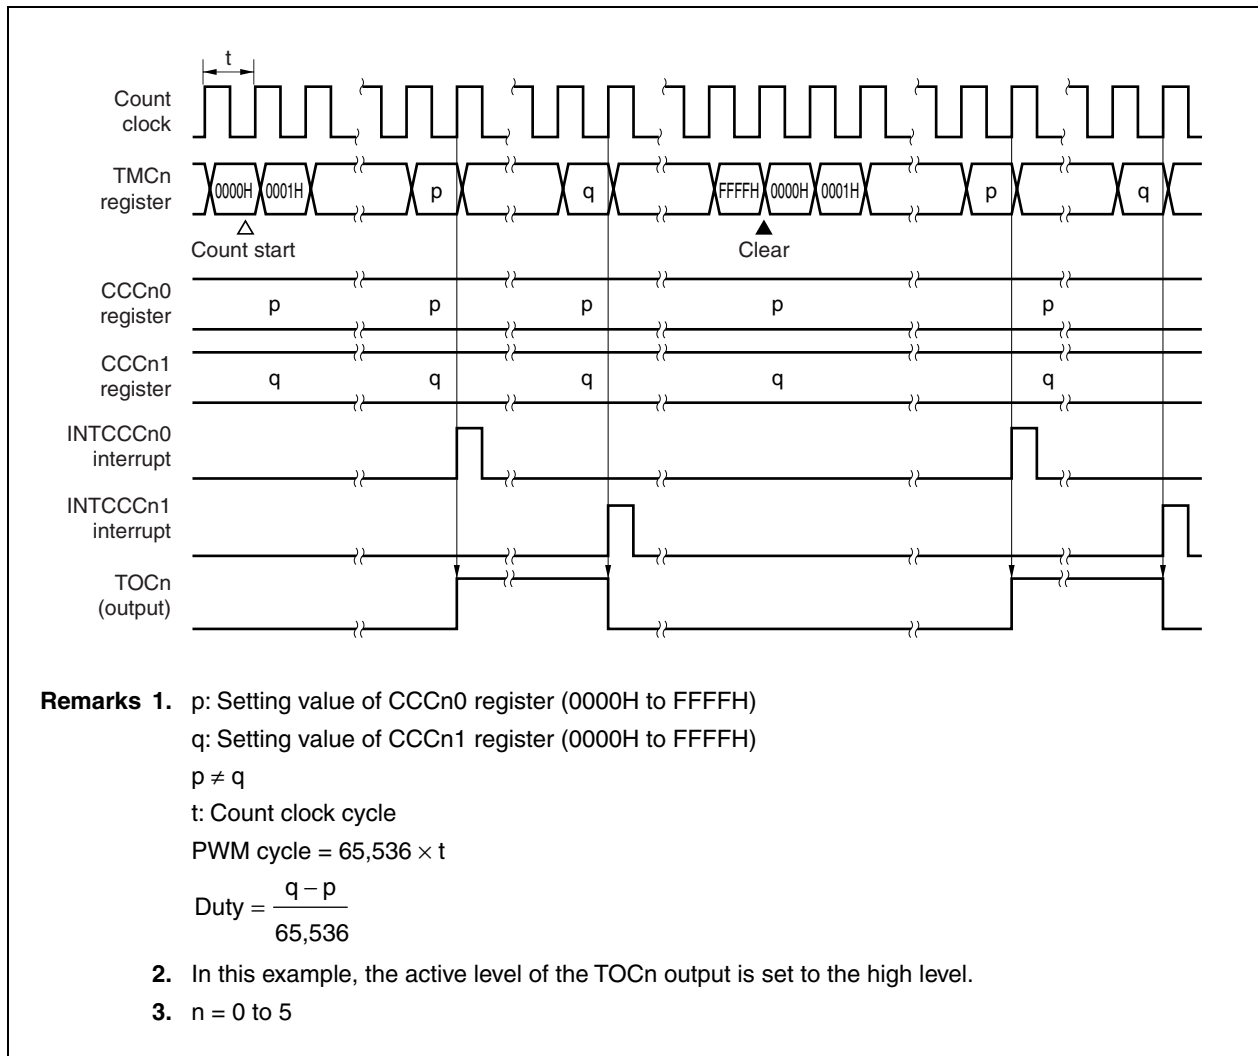

Figure 10-11. PWM Output Operation Timing Example

(3) Cycle measurement

By setting the TMCCn0 and TMCCn1 registers as shown in Figure 10-12, timer C can measure the cycle of signals input to the INTPCm0 or INTPCm1 pin.

The valid edge of the INTPCm0 pin is selected according to the IESC0m1 and IESC0m0 bits of the SESCm register, and the valid edge of the INTPCm1 pin is selected according to the IESC1m1 and IESC1m0 bits of the SESCm register. Either the rising edge, the falling edge, or both edges can be selected as the valid edges of both pins.

If the CCCm0 register is set as a capture register, the valid edge input of the INTPCm0 pin is set as the trigger for capturing the TMCm register value in the CCCm0 register. When this value is captured, an INTCCCM0 interrupt is generated.

Similarly, if the CCCm1 register is set as a capture register, the valid edge input of the INTPCm1 pin is set as the trigger for capturing the TMCm register value in the CCCm1 register. When this value is captured, an INTCCCM1 interrupt is generated.

The cycle of signals input to the INTPCm0 pin is calculated by obtaining the difference between the TMCm register's count value (D_x) that was captured in the CCCm0 register according to the x -th valid edge input of the INTPCm0 pin and the TMCm register's count value ($D_{(x+1)}$) that was captured in the CCCm0 register according to the $(x+1)$ -th valid edge input of the INTPCm0 pin and multiplying the value of this difference by the cycle of the clock control signal.

The cycle of signals input to the INTPCm1 pin is calculated by obtaining the difference between the TMCm register's count value (D_x) that was captured in the CCCm1 register according to the x -th valid edge input of the INTPCm1 pin and the TMCm register's count value ($D_{(x+1)}$) that was captured in the CCCm1 register according to the $(x+1)$ -th valid edge input of the INTPCm1 pin and multiplying the value of this difference by the cycle of the clock control signal.

Remark $m = 0$ to 3
 $n = 0$ to 5

Figure 10-12. Contents of Register Settings When Timer C Is Used for Cycle Measurement

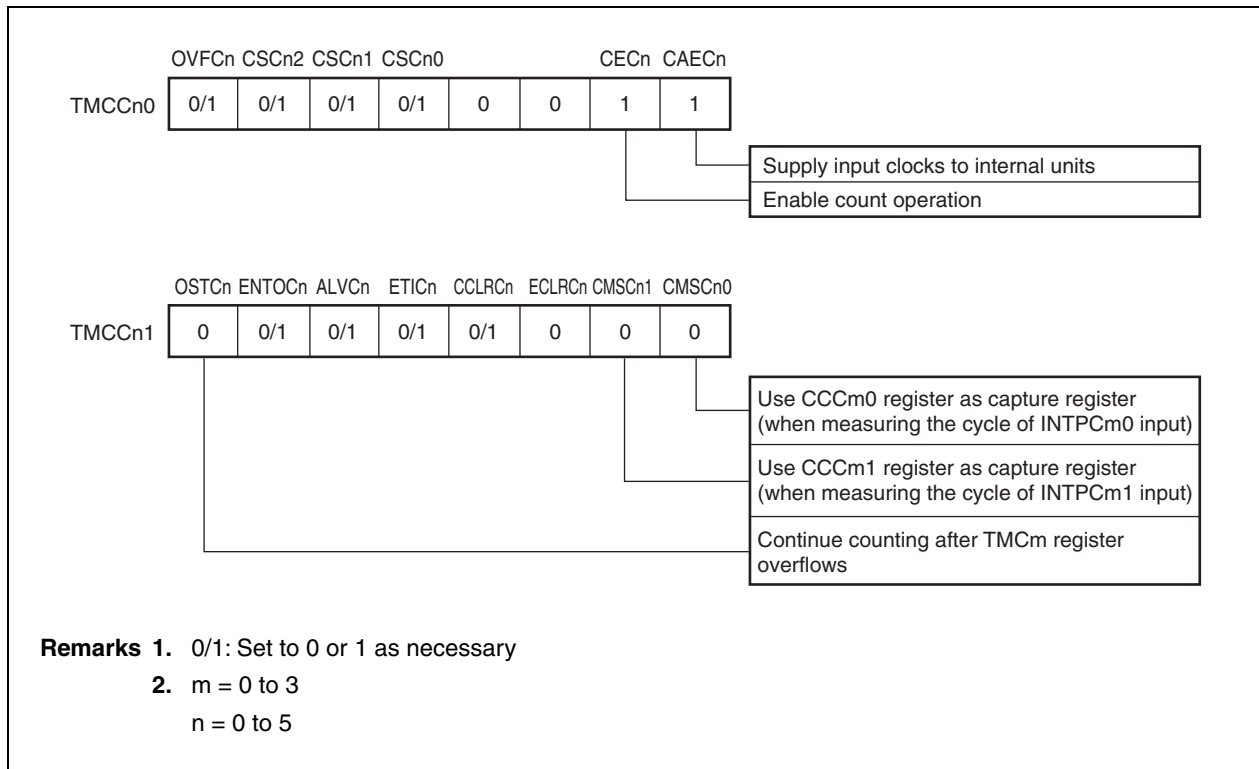

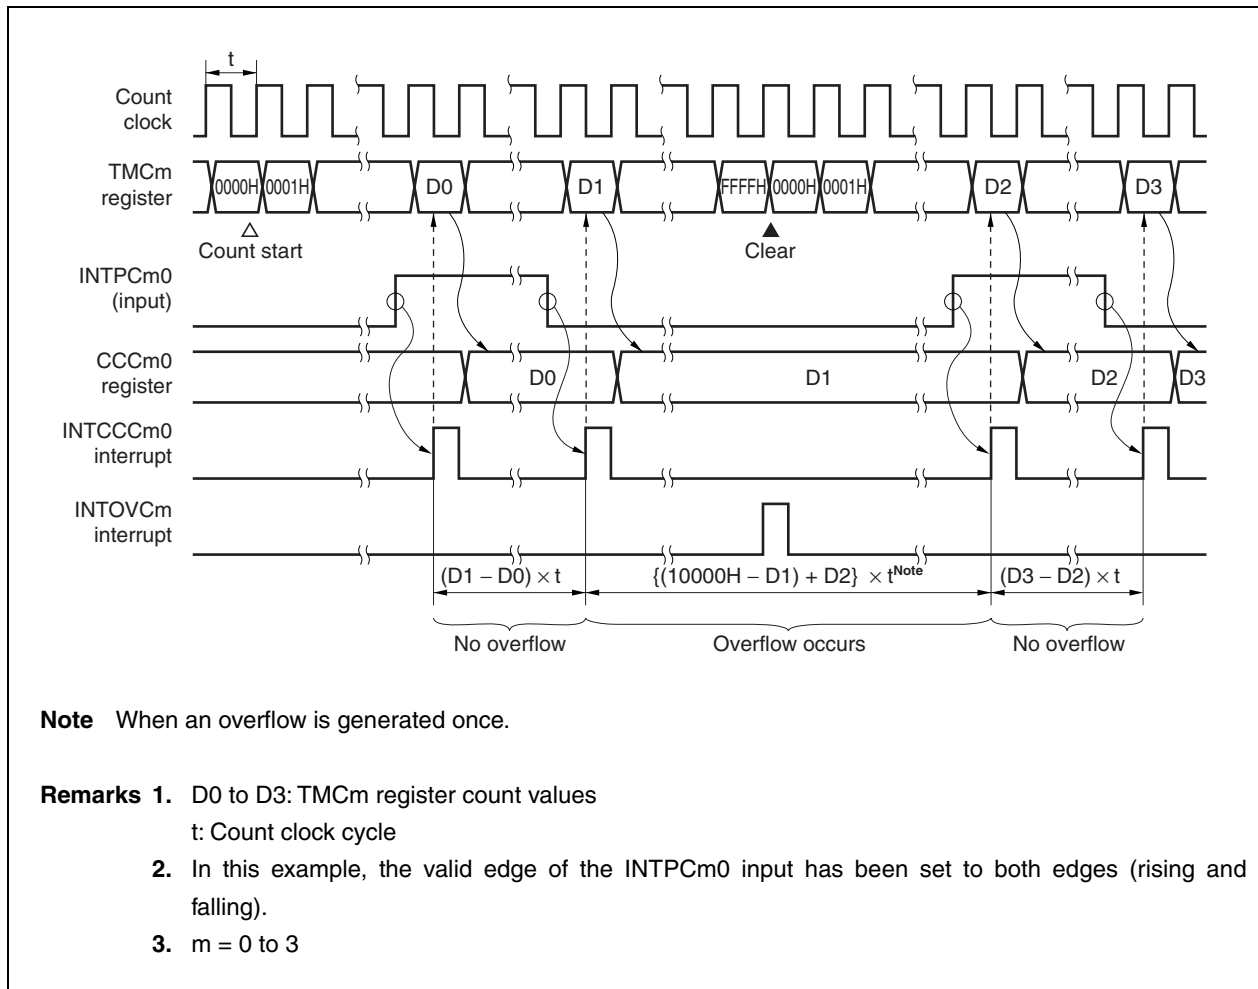

Figure 10-13. Cycle Measurement Operation Timing Example

10.1.8 Cautions

Cautions concerning the timer C are shown below.

(1) Conflict between reading CCCm0 register and capture operation

If a conflict occurs between the reading of the CCCm0 register and a capture operation when the CCCm0 register is used in capture mode, an external trigger (INTPCm0) valid edge is detected and an external interrupt request (INTCCm0) is generated, however, the timer value is not stored in the CCCm0 register.

(2) Conflict between reading CCCm1 register and capture operation

If a conflict occurs between the reading of the CCCm1 register and a capture operation when the CCCm1 register is used in capture mode, an external trigger (INTPCm1) valid edge is detected and an external interrupt request (INTCCm1) is generated, however, the timer value is not stored in the CCCm1 register.

(3) Rewriting during timer operation

The following bits and registers must not be rewritten during timer operation (CECn bit of TMCCn0 register = 1).

- CSCn2 to CSCn0 bits of TMCCn0 register
- TMCCn1 register
- SESCm register

(4) Register setting when Timer C used

The CAECn bit of the TMCCn0 register is a TMCn reset signal. To use TMCn, first set the CAECn bit to 1.

(5) Valid edge detection of external interrupt request signals (INTPCm0, INTPCm1), external clock input (TICm)

The digital noise elimination time $(0 \text{ to } 5) \times f_x/4$ are required to detect the valid edge of the external interrupt request signal (INTPCm0 or INTPCm1) or the external clock input (TICm). Therefore, edge detection will not be performed normally for changes that are less than the digital noise elimination time. For details of digital noise elimination, see 15.6.3 Timer C and timer ENC1 input pins.

(6) Operation of external interrupt request signals (INTCCn0, INTCCn1)

The operation of an external interrupt request signal (INTCCn0 or INTCCn1) is automatically determined according to the operating state of the capture/compare register. When the capture/compare register is used for a capture operation, the external interrupt request signal is used for valid edge detection. When the capture/compare register is used for a compare operation, the external interrupt request signal is used for an interrupt indicating a match with the TMCn register.

(7) Glitch generation

If the ENTOCn and ALVCn bits of the TMCCn1 register are changed at the same time, a glitch (spike shaped noise) may be generated in the TOCn pin output. Either create a circuit configuration that will not malfunction even if a glitch is generated or make sure that the ENTOCn and ALVCn bits are not changed at the same time.

(8) Alternate-function pins when timer C not used

Even when using the INTPC00/TIC0, INTPC10/TIC1, INTPC20/TIC2, and INTPC30/TIC3 pins as INTPC00, INTPC10, INTPC20, and INTPC30, respectively, without using timer C, be sure to set the CAECn and GECn bits of timer mode control registers C00 to C03 (TMCC00 to TMCC30) to 1.

(9) When used as TICm (external clock input pin)

When the INTPCm0/TICm pin is used as TICm (external clock input pin), disable the INTPCm0 interrupt or set CCCm0 to compare mode (m = 0 to 3).

(10) Count clock

The count clock cannot be changed while the timer is operating.

(11) CCC40, CCC41, CCC50, and CCC51 registers

The CCC40, CCC41, CCC50, and CCC51 registers can only be used as compare registers. They cannot be used as capture registers.

(12) INTPCn0 and INTPCn1 pins when CCCn0 and CCCn1 registers set as compare registers

When the CCCn0 and CCCn1 registers are set as compare registers, INTPCn0 and INTPCn1 cannot be used (n = 0 to 5).

When using these registers as an external interrupt input pin, use the $\overline{\text{INTP65}}$ and $\overline{\text{INTP66}}$ pins.

(13) Setting trigger mode

When setting the trigger mode of the INTPCm0, INTPCm1, and TICm pins, set the PMCx register (m = 0 to 3, x = 5 to 7), then, after set the CAECm and CECm bits of the TMCCm0 register to 1, set the SESCm register.

If the PMCx register is set after the SESCm register has been set, an illegal interrupt, incorrect counting, and incorrect clearing may occur depending on the timing of setting the PMCx register.

Remark m = 0 to 3
n = 0 to 5

10.2 Timer D

10.2.1 Features

Timer D functions as a 16-bit interval timer.

10.2.2 Function overview

- 16-bit interval timer: 4 channels
- Compare registers: 4
- Interrupt request sources: 4 sources
- Count clock selected from divisions of main clock

10.2.3 Basic configuration

(1) Timer D (16-bit timer/counter)

Figure 10-14. Timer D Block Diagram

10.2.4 Timer D

(1) Timers D0 to D3 (TMD0 to TMD3)

TMDn is a 16-bit timer. It is mainly used as an interval timer for software (n = 0 to 3).

Starting and stopping TMDn is controlled by the CEDn bit of the timer mode control register Dn (TMCDn) (n = 0 to 3).

Division by the prescaler can be selected for the count clock from among $fx/8$, $fx/16$, $fx/32$, $fx/64$, $fx/128$, $fx/256$, $fx/512$, and $fx/1,024$ by the CSDn0 to CSDn2 bits of the TMCDn register (fx: main clock).

TMDn is read-only, in 16-bit units.

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset
TMD0																	1FFFF540H	0000H
TMD1																	1FFFF550H	0000H
TMD2																	1FFFF560H	0000H
TMD3																	1FFFF570H	0000H

The conditions for which the TMDn register becomes 0000H are shown below (n = 0 to 3).

- Reset input
- CAEDn bit of TMCDn register = 0
- CEDn bit of TMCDn register = 0
- Match of TMDn register and CMDn register
- Overflow

- Cautions**
1. If the CAEDn bit of the TMCDn register is cleared to 0, a reset is performed asynchronously.
 2. If the CEDn bit of the TMCDn register is cleared to 0, a reset is performed, in synchronization with the internal clock. Similarly, a synchronized reset is performed after a match with the CMDn register and after an overflow.
 3. The count clock must not be changed during a timer operation. If it is to be overwritten, it should be overwritten after the CEDn bit is cleared to 0.
 4. Up to 8 main clocks are required after a value is set in the CEDn bit until the set value is transferred to internal units. When a count operation begins, the count cycle from 0000H to 0001H differs from subsequent cycles.
 5. After a compare match is generated, the timer is cleared at the next count clock. Therefore, if the division ratio is large, the timer value may not be zero even if the timer value is read immediately after a match interrupt is generated.
 6. To initialize the TMDn register and start counting again, set the CEDn bit of the TMCDn register to 1 after 8 main clocks.

(2) Compare registers D0 to D3 (CMD0 to CMD3)

The CMDn register and the TMDn register count values are compared, and an interrupt request signal (INTCMDn) is generated when a match occurs. TMDn is cleared, in synchronization with this match. If the CAEDn bit of the TMCDn register is cleared to 0, a reset is performed asynchronously, and the registers are initialized (n = 0 to 3).

The CMDn registers are configured with a master/slave configuration. When a CMDn register is written, data is first written to the master register and then the master register data is transferred to the slave register. In a compare operation, the slave register value is compared with the count value of the TMDn register. When the CMDn register is read, data in the master side is read out.

The CMDn register can be read or written in 16-bit units.

- Cautions 1.** A write operation to a CMDn register requires 8 main clocks until the value that was set in the CMDn register is transferred to internal units. When writing continuously to the CMDn register, be sure to reserve a time interval of at least 8 main clocks.
- 2.** The CMDn register can be overwritten only once in a single TMDn register cycle (from 0000H until an INTCMDn interrupt is generated due to a match of the TMDn register and CMDn register). If this cannot be secured by the application, make sure that the CMDn register is not overwritten during timer operation.
- 3.** Note that an INTCMDn interrupt will be generated after an overflow if a value less than the counter value is written in the CMDn register during TMDn register operation (Figure 10-15).

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset
CMD0																	1FFFF542H	0000H
CMD1																	1FFFF552H	0000H
CMD2																	1FFFF562H	0000H
CMD3																	1FFFF572H	0000H

Figure 10-15. Example of Timing During TMDn Operation

10.2.5 Control registers

(1) Timer mode control registers D0 to D3 (TMCD0 to TMCD3)

The TMCDn registers control the operation of timer Dn (n = 0 to 3).
 These registers can be read or written in 8-bit or 1-bit units.

Caution The CAEDn and other bits cannot be set at the same time. The other bits and the registers of the other TMDn units should always be set after the CAEDn bit has been set.

(2/2)

Bit position	Bit name	Function
0	CAEDn	<p>Controls the internal count clock.</p> <p>0: The entire TMDn unit is reset asynchronously. The supply of input clocks to the TMDn unit stops.</p> <p>1: Input clocks are supplied to the TMDn unit.</p> <p>Cautions</p> <ol style="list-style-type: none"> 1. When the CAEDn bit is cleared to 0, the TMDn unit can be asynchronously reset. 2. When the CAEDn bit = 0, the TMDn unit is in a reset state. Therefore, to operate TMDn, the CAEDn bit must be set to 1. 3. If the CAEDn bit is cleared to 0, all the registers of the TMDn unit are initialized. If the CAEDn bit is set to 1 again, be sure all the registers of the TMDn unit have been set again.

Remark n = 0 to 3

10.2.6 Operation

(1) Compare operation

TMDn can be used for a compare operation in which the value that was set in a compare register (CMDn) is compared with the TMDn count value (n = 0 to 3).

If a match is detected by the compare operation, an interrupt (INTCMDn) is generated. The generation of the interrupt causes TMDn to be cleared to 0 at the next count timing. This function enables timer D to be used as an interval timer.

The CMDn register can also be cleared to 0. In this case, when an overflow occurs and TMDn becomes 0, a match is detected and INTCMDn is generated. Although the TMDn value is cleared to 0 at the next count timing, INTCMDn is not generated by this match.

Figure 10-16. TMD0 Compare Operation Example (1/2)

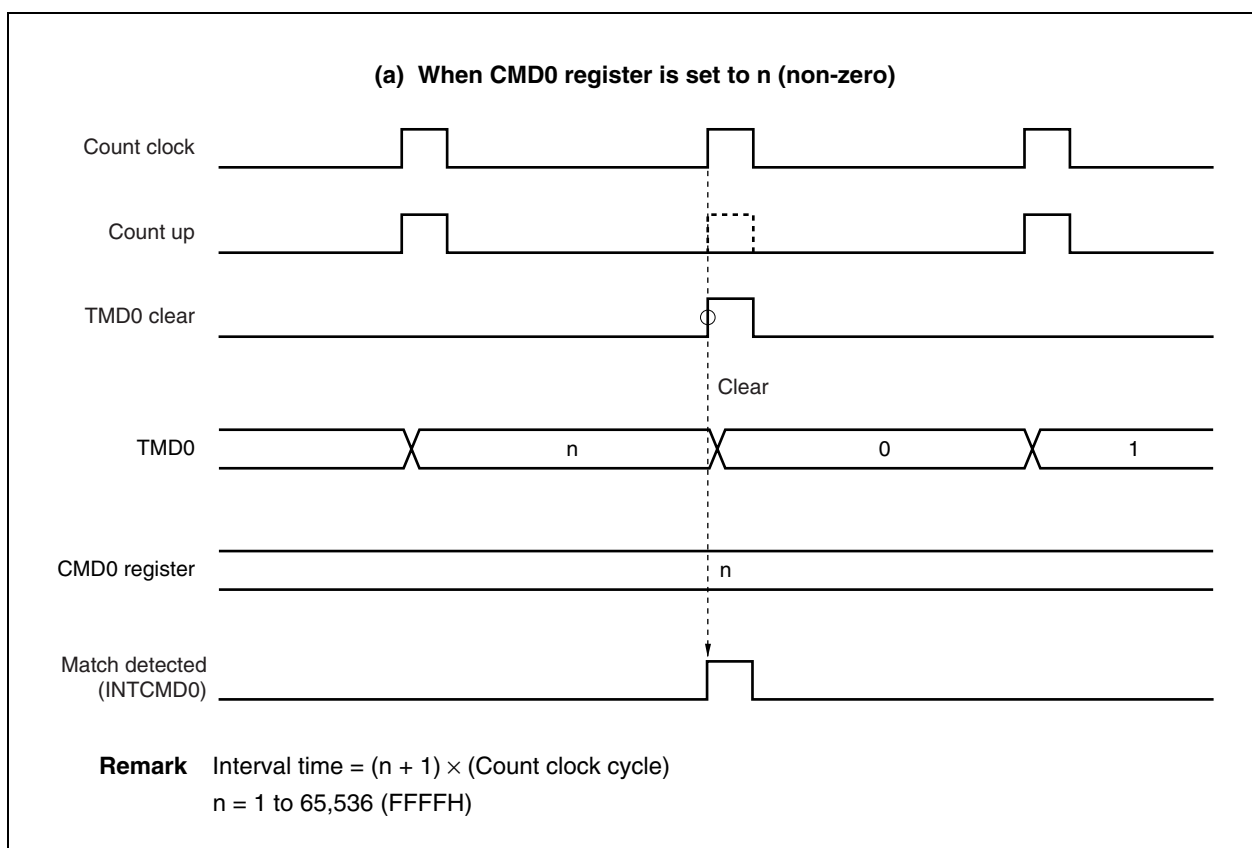

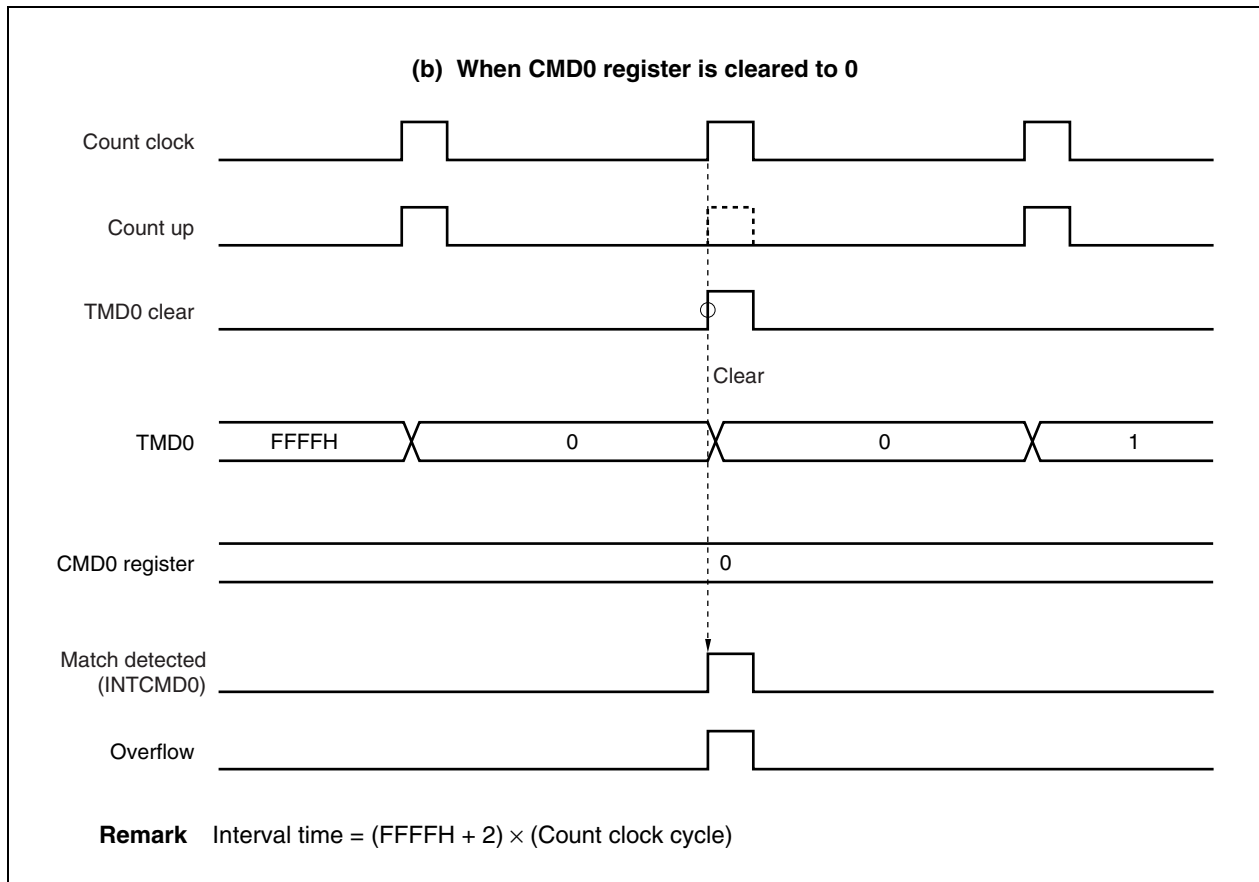

Figure 10-16. TMD0 Compare Operation Example (2/2)

10.2.7 Application examples

(1) Interval timer

This section explains an example in which timer D is used as an interval timer with 16-bit precision.

Interrupt requests (INTCMDn) are output at equal intervals (see **Figure 10-16 TMD0 Compare Operation Example**). The setup procedure is shown below (n = 0 to 3).

- <1> Set the CAEDn bit of the TMCDn register to 1.
- <2> Set each register.
 - Select the count clock using the CSDn0 to CSDn2 bits of the TMCDn register.
 - Set the compare value in the CMDn register.
- <3> Start counting by setting the CEDn bit of the TMCDn register to 1.
- <4> If the TMDn register and CMDn register values match, an INTCMDn interrupt is generated.
- <5> INTCMDn interrupts are generated thereafter at equal intervals.

Remark n = 0 to 3

10.2.8 Cautions

Cautions concerning the timer D are shown below.

(1) Starting timer D operation

To operate TMDn, first set the CAEDn bit of the TMCDn register to 1.

(2) Caution on setting TMCDn register

Up to 8 main clocks are required after a value is set in the CEDn bit until the set value is transferred to internal units. When a count operation begins, the count cycle from 0000H to 0001H differs from subsequent cycles.

(3) Recount after TMDn register initialization

To initialize the TMDn register status and start counting again, clear the CEDn bit to 0 and then set the CEDn bit to 1 after an interval of 8 main clocks has elapsed.

(4) Caution on setting CMDn register

- Up to 8 main locks are required until the value that was set in the CMDn register is transferred to internal units. When writing continuously to the CMDn register, be sure to secure a time interval of at least 8 main clocks.
- The CMDn register can be overwritten only once during a timer/counter operation (from 0000H until an INTCMDn interrupt is generated due to a match of the TMDn register and CMDn register). If this cannot be secured, make sure that the CMDn register is not overwritten during a timer/counter operation.

(5) Count clock

The count clock must not be changed during a timer operation. If it is to be overwritten, it should be overwritten after the CEDn bit is cleared to 0. If the count clock is overwritten during a timer operation, operation cannot be guaranteed.

(6) Writing to CMDn register

A match signal will be generated after an overflow if a value less than the counter value is written in the CMDn register during TMDn register operation.

Remark n = 0 to 3

10.3 16-Bit 2-Phase Encoder Input Up/Down Counter/General-Purpose Timer (Timer ENC1)

10.3.1 Functions

Timers ENC10 and ENC11 (TMENC10, TMENC11) perform the following operations.

- General-purpose timer mode (Refer to **10.3.6 (1) Operation in general-purpose timer mode.**)
 - Free-running timer
 - Timer output
- Up/down counter mode (Refer to **10.3.6 (2) Operation in UDC mode.**)
 - UDC mode A (mode 1, mode 2, mode 3, mode 4)
 - UDC mode B (mode 1, mode 2, mode 3, mode 4)

10.3.2 Features

- Timers ENC10 and ENC11: 2 channels
- Compare registers: 4
- Capture/compare registers: 4
- Interrupt request sources
 - Capture/compare match interrupt: 4 sources
 - Compare match interrupt request: 4 sources
- Capture request signal: 4 sources
 - The TMENC1n value can be latched using the valid edge of the INTP1n0 and INTP1n1 pins corresponding to the capture/compare register as the capture trigger.
- Count clock selectable through division by prescaler
- Timer output function

In the general-purpose timer mode, 16-bit resolution timer can be output from the TO1n pin.
- Timer clear

The following timer clear operations are performed according to the mode that is used.

 - (a) General-purpose timer mode: Timer clear operation is possible upon occurrence of match with the CM1n0 register set value.
 - (b) Up/down counter mode: The timer clear operation can be selected from among the following four conditions.
 - (i) Timer clear performed upon occurrence of match with the CM1n0 register set value during TMENC1n count-up operation, and timer clear performed upon occurrence of match with the CM1n1 register set value during TMENC1n count-down operation.
 - (ii) Timer clear performed only by external input.
 - (iii) Timer clear performed upon occurrence of match between the TMENC1n count value and the CM1n0 register set value.
 - (iv) Timer clear performed upon occurrence of external input and match between the TMENC1n count value and the CM1n0 register set value.
- External pulse output (TO1n): 2

10.3.3 Basic configuration

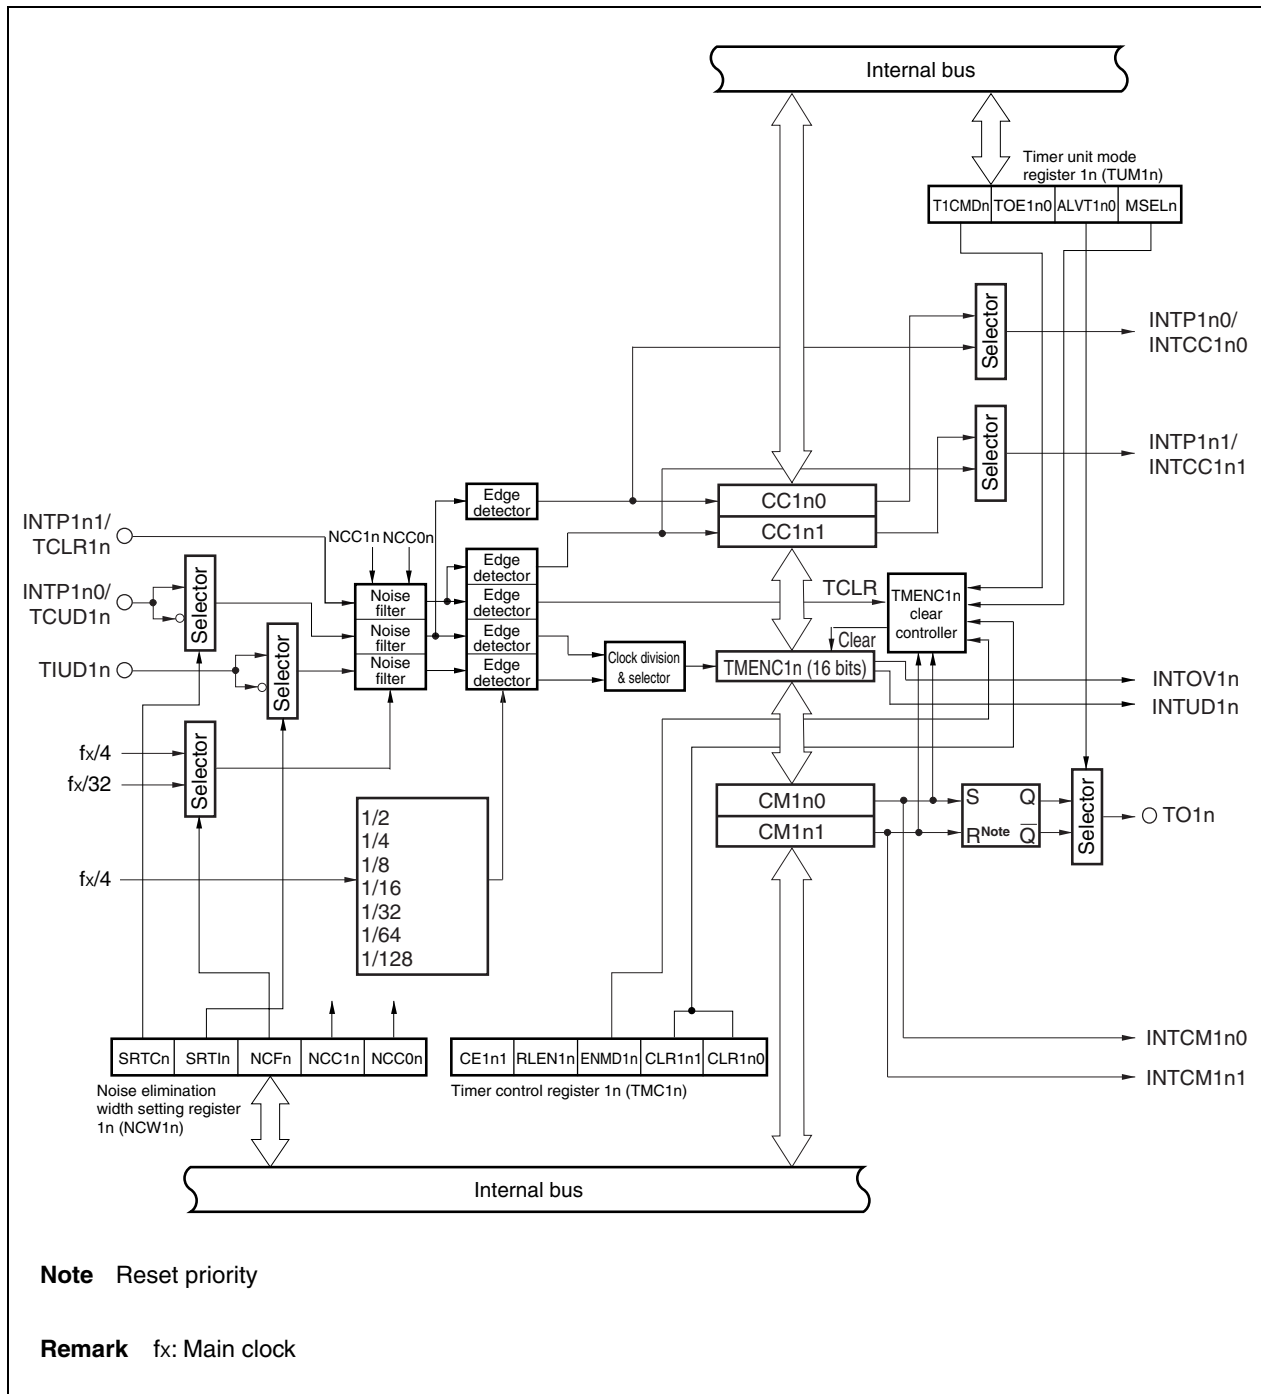

Table 10-4. Timer ENC1 Configuration

Timer	Count Clock	Register	Read/Write	Generated Interrupt Signal	Capture Trigger
Timer ENC1	fx/8, fx/16, fx/32, fx/64, fx/128, fx/256, fx/512	TMENC10	Read/write	–	–
		CM100	Read/write	INTCM100	–
		CM101	Read/write	INTCM101	–
		CC100	Read/write	INTCC100	INTP100
		CC101	Read/write	INTCC101	INTP101
		TMENC11	Read/write	–	–
		CM110	Read/write	INTCM110	–
		CM111	Read/write	INTCM111	–
		CC110	Read/write	INTCC110	INTP110
		CC111	Read/write	INTCC111	INTP111

Remark fx: Main clock

(1) Timer ENC1 (16-bit up/down counter)

Figure 10-17. Timer ENC1 Block Diagram

10.3.4 Timer ENC1

(1) Timers ENC10, ENC11 (TMENC10, TMENC11)

TMENC1n is a general-purpose timer (in general-purpose mode) and 2-phase encoder input up/down counter (in UDC mode).

This timer counts up in the general-purpose operation mode and counts up/down in the UDC mode.

It can be read or written in 16-bit units.

- Cautions 1. Writing to TMENC1n is enabled only when the CE1n1 bit of the TMC1n register is 0 (count operation disabled).**
- 2. Continuous reading of TMENC1n is prohibited. If TMENC1n is continuously read, the second read value may differ from the actual value. If TMENC1n must be read twice, be sure to read another register between the first and the second read operation.**
- 3. Writing the same value to the TMENC1n register is prohibited.**

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset
TMENC10																	1FFF5A0H	0000H
TMENC11																	1FFF5D0H	0000H

TMENC1n start and stop is controlled by the CE1n1 bit of timer control register 1n (TMC1n).

The TMENC1n operation consists of the following two modes.

(a) General-purpose timer mode

In the general-purpose timer mode, TMENC1n operates as a 16-bit interval timer, free-running timer, or timer output.

Counting is performed based on the count clock selected by software. Division by the prescaler can be selected for the count clock from among $fx/8$, $fx/16$, $fx/32$, $fx/64$, $fx/128$, $fx/256$, or $fx/512$ using the PRM1n2 to PRM1n0 bits of prescaler mode register 1n (PRM1n) (fx: main clock).

(b) Up/down counter mode (UDC mode)

In the UDC mode, TMENC1n functions as a 16-bit up/down counter that performs counting based on the TCUD1n and TIUD1n input signals. This mode is divided into the UDC A mode and UDC B mode, depending on the condition of clearing TMENC1n.

- Cautions 1.** The TCUD1n and INTP1n0 pins function alternately. Therefore, because the TCUD1n pin is used in the UDC mode, the external capture function of the INTP1n0 pin cannot be used.
- 2.** The TCLR1n and INTP1n1 pins function alternately. Therefore, when the TCLR1n input is used in UDC mode A, the external capture function of the INTP1n1 pin cannot be used.

The conditions for clearing TMENC1n are as follows, depending on the operation mode.

Table 10-5. Timer ENC1 (TMENC1n) Clear Conditions

Operation Mode	TUM1n Register		TMC1n Register			TMENC1n Clear
	T1CMDn Bit	MSELn Bit	ENMD1n Bit	CLR1n1 Bit	CLR1n0 Bit	
General-purpose timer mode	0	0	0	×	×	Clearing not performed (free-running timer)
			1	×	×	Cleared upon match with CM1n0 set value
UDC mode A	1	0	×	0	0	Cleared only by TCLR1n input
			×	0	1	Cleared upon match with CM1n0 set value during count-up operation
			×	1	0	Cleared by TCLR1n input or upon match with CM1n0 set value during count-up operation
			×	1	1	Clearing not performed
UDC mode B	1	1	×	×	×	Cleared upon match with CM1n0 set value during up-count operation or upon match with CM1n1 set value during count-down operation
Other than the above						Setting prohibited

Remark ×: Indicates that the set value of that bit is ignored.

10.3.5 Control registers

(1) Timer unit mode registers 10, 11 (TUM10, TUM11)

The TUM1n register is an 8-bit register used to specify the TMENC1n operation mode or to control the operation of the timer output pin.

TUM1n can be read or written in 8-bit or 1-bit units.

- Cautions**
1. Changing the value of the TUM1n register during TMENC1n operation (CE1n1 bit of TMC1n register = 1) is prohibited.
 2. It is prohibited to set the MSELn bit (UDC mode B) to 1 when the T1CMDn bit (general-purpose timer mode) is 0.
 3. Writing the same value to the TUM1n register is permitted (writing the same value is guaranteed even during a count operation).

	7	6	5	4	3	2	1	0	Address	After reset
TUM10	T1CMD0	0	0	0	TOE100	ALVT100	0	MSEL0	1FFFF5ABH	00H
TUM11	T1CMD1	0	0	0	TOE110	ALVT110	0	MSEL1	1FFFF5DBH	00H

Bit position	Bit name	Function
7	T1CMDn	Specifies TMENC1n operation mode. 0: General-purpose timer mode (count up) 1: UDC mode (count up/down)
3	TOE1n0	Specifies timer output (TO1n) enable. 0: Timer output disabled 1: Timer output enabled Caution When T1CMDn bit = 1 (UDC mode), timer output is not performed regardless of the setting of the TOE1n0 bit. At this time, timer output consists of the negative phase level of the level set by the ALVT1n0 bit.
2	ALVT1n0	Specifies active level of timer output (TO1n). 0: Active level is high level 1: Active level is low level Caution When T1CMDn bit = 1 (UDC mode), timer output is not performed regardless of the setting of the TOE1n0 bit. At this time, timer output consists of the negative phase level of the level set by the ALVT1n0 bit.
0	MSELn	Specifies operation in UDC mode (count up/down) 0: UDC mode A TMENC1n can be cleared by setting the CLR1n1 and CLR1n0 bits of the TMC1n register. 1: UDC mode B TMENC1n is cleared in the following cases. • Upon match with CM1n0 during TMENC1n count-up operation • Upon match with CM1n1 during TMENC1n count-down operation Caution When the T1CMDn bit = 0 (general-purpose timer mode), setting MSELn bit = 1 (UDC mode B) is prohibited. When UDC mode B is set, the ENMD1n, CLR1n1, and CLR1n0 bits of the TMC1n register become invalid.

Remark n = 0, 1

(2) Timer control registers 10, 11 (TMC10, TMC11)

The TMC1n register is used to enable/disable TMENC1n operation and to set transfer and timer clear operations. TMC1n can be read or written in 8-bit or 1-bit units.

- Cautions**
1. Changing the values of the TMC1n register bits other than the CE1n1 bit during TMENC1n operation (CE1n1 bit = 1) is prohibited.
 2. Writing the same value to the TMC1n register is permitted (writing the same value is guaranteed even during a count operation).

(1/2)

	7	<6>	5	4	3	2	1	0	Address	After reset
TMC10	0	CE101	0	0	RLEN10	ENMD10	CLR101	CLR100	1FFFF5ACH	00H
TMC11	0	CE111	0	0	RLEN11	ENMD11	CLR111	CLR110	1FFFF5DCH	00H

Bit position	Bit name	Function
6	CE1n1	Enables/disables TMENC1n operation. 0: TMENC1n count operation disabled 1: TMENC1n count operation enabled
3	RLEN1n	Enables/disables transfer from the CM1n0 register to TMENC1n in UDC mode A. 0: Transfer disabled 1: Transfer enabled Cautions 1. When the RLEN1n bit = 1, the value set to the CM1n0 register is transferred to TMENC1n upon occurrence of a TMENC1n underflow. 2. The RLEN1n bit is valid only in UDC mode A (TUM1n register's T1CMDn bit = 1, MSELn bit = 0). In the general-purpose timer mode (T1CMDn bit = 0) and in UDC mode B (T1CMDn bit = 1, MSELn bit = 1), a transfer operation is not performed even the RLEN1n bit is set to 1.
2	ENMD1n	Enables/disables clearing of TMENC1n in general-purpose timer mode (T1CMDn bit of TUM1n register = 0). 0: Clear disabled (free-running mode) Clearing is not performed even when TMENC1n and the CM1n0 register values match. 1: Clear enabled Clearing is performed when TMENC1n and the CM1n0 register values match. Caution The ENMD1n bit setting becomes invalid in UDC mode (T1CMDn bit of TUM1n register = 1).

Remark n = 0, 1

0	0	Cleared only by external input (TCLR1n)															
0	1	Cleared upon match of TMENC1n count value and the CM1n0 register set value															
1	0	Cleared by TCLR1n input or upon match of TMENC1n count value and the CM1n0 register set value															
1	1	Not cleared															

Remark n = 0, 1

(3) Capture/compare control registers 10, 11 (CCR10, CCR11)

The CCR1n register specifies the operation mode of the CC1n0 and CC1n1 registers.
CCR1n can be read or written in 8-bit or 1-bit units.

- Cautions 1. Overwriting the CCR1n register during TMENC1n operation (CE1n1 bit of TMC1n register = 1) is prohibited.**
- 2. The TCUD1n and INTP1n0 pins function alternately. Therefore, because the TCUD1n pin is used in the UDC mode, the external capture function of the INTP1n0 pin cannot be used.**
 - 3. The TCLR1n and INTP1n1 pins function alternately. Therefore, when the TCLR1n input is used in UDC mode A, the external capture function of the INTP1n1 pin cannot be used.**
 - 4. Writing the same value to the CCR1n register is permitted (writing the same value is guaranteed even during a count operation).**

	7	6	5	4	3	2	1	0	Address	After reset
CCR10	0	0	0	0	0	0	CMS01	CMS00	1FFFF5AAH	00H
CCR11	0	0	0	0	0	0	CMS11	CMS10	1FFFF5DAH	00H

Bit position	Bit name	Function
1	CMSn1	Specifies operation mode of the CC1n1 register. 0: Capture register 1: Compare register
0	CMSn0	Specifies operation mode of the CC1n0 register. 0: Capture register 1: Compare register

Remark n = 0, 1

(4) Valid edge select registers 10, 11 (SESA10, SESA11)

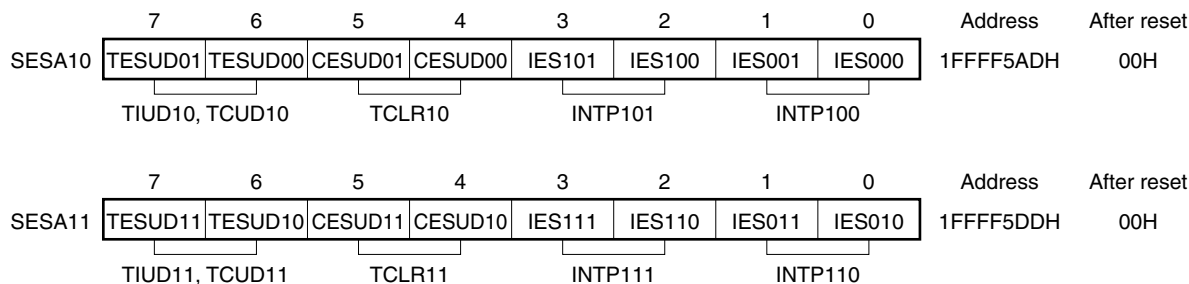

The SESA1n register is used to specify the valid edge of external interrupt requests from external pins (INTP100, INTP101, INTP110, INTP111, TIUD10, TIUD11, TCUD10, TCUD11, TCLR10, TCLR11).

The valid edge (rising edge, falling edge, or both rising and falling edges) can be specified independently for each pin.

SESA1n can be read or written in 8-bit or 1-bit units.

- Cautions 1.** Changing the values of the SESA1n register bits during TMENC1n operation (CE1n1 bit of TMC1n register = 1) is prohibited.
- 2.** Set the PMCDH register before setting the trigger mode of the INTP100, INTP101, INTP110, INTP111, TIUD10, TIUD11, TCUD10, TCUD11, TCLR10, and TCLR11 pins. If the PMCDH register is set after the SESA1n register has been set, an illegal interrupt, incorrect counting, and incorrect clearing may occur depending on the timing of setting the PMCDH register.
- 3.** Writing the same value to the SESA1n register is permitted (writing the same value is guaranteed even during a count operation).

Remark n = 0, 1

(5) Prescaler mode registers 10, 11 (PRM10, PRM11)

The PRM1n register is used to perform the following selections.

- Selection of count clock in general-purpose timer mode (T1CMDn bit of TUM1n register = 0)
- Selection of count operation mode in UDC mode (T1CMDn bit = 1)

PRM1n can be read or written in 8-bit or 1-bit units.

- Cautions 1. Overwriting the PRM1n register during TMENC1n operation (CE1n1 bit of TMC1n register = 1) is prohibited.**
- 2. Clearing the PRM1n2 bit to 0 is prohibited in UDC mode (T1CMDn bit of TUM1n register = 1).**
- 3. When TMENC1n is in mode 4, specification of the valid edge for the TIUD1n and TCUD1n pins is invalid.**
- 4. Writing the same value to the PRM1n register is permitted (writing the same value is guaranteed even during a count operation).**

Remark n = 0, 1

(a) In general-purpose timer mode (T1CMDn bit of TUM1n register = 0)

The count clock is specified by the PRM1n2 to PRM1n0 bits.

(b) UDC mode (T1CMDn bit of TUM1n register = 1)

The TMENC1n count triggers in the UDC mode are as follows.

Operation Mode	TMENC1n Operation
Mode 1	Count down upon detection of valid edge of TIUD1n input when TCUD1n = high level Count up upon detection of valid edge of TIUD1n input when TCUD1n = low level
Mode 2	Count up upon detection of valid edge of TIUD1n input Count down upon detection of valid edge of TCUD1n input
Mode 3	Count up upon detection of valid edge of TIUD1n input when TCUD1n = high level Count down upon detection of valid edge of TIUD1n input when TCUD1n = low level
Mode 4	Automatic judgment upon detection of both edges of TIUD1n input and both edges of TCUD1n input

(6) Status registers 10, 11 (STATUS10, STATUS11)

The STATUS1n register indicates the operating status of TMENC1n.

STATUS1n is read-only, in 8-bit or 1-bit units.

	7	6	5	4	3	<2>	<1>	<0>	Address	After reset
STATUS10	0	0	0	0	0	UDF10	OVF10	UBD10	1FFFF5AFH	00H

Bit position	Bit name	Function
2	UDF1n	TMENC1n underflow flag 0: No TMENC1n count underflow 1: TMENC1n count underflow Caution The UDF1n bit is cleared to 0 upon completion of a read access to the STATUS1n register from the CPU.
1	OVF1n	TMENC1n overflow flag 0: No TMENC1n count overflow 1: TMENC1n count overflow Caution The OVF1n bit is cleared to 0 upon completion of a read access to the STATUS1n register from the CPU.
0	UBD1n	Indicates the operating status of TMENC1n count up/down. 0: TMENC1n count up in progress 1: TMENC1n count down in progress Caution The state of the UBD1n bit differs according to the mode as follows. <ul style="list-style-type: none"> • The UBD1n bit is fixed to 0 in general-purpose timer mode (T1CMDn bit of TUM1n register = 0). • The UBD1n bit indicates the TMENC1n count-up/down status in UDC mode B (MSELn bit of TUM1n register = 1).

Remark n = 0, 1

(7) Noise elimination width setting registers 10, 11 (NCW10, NCW11)

The NCW1n register is used to set the noise elimination width of the digital noise filter of the timer ENC1 input pin. NCW1n can be read or written in 8-bit units.

- Cautions 1.** Whether the signal is input through or inverted can be specified for each of the INTp1n0/TCUD1n and TIUD1n pins. The setting of the noise elimination width by the NCFn, NCC1n, and NCC0n bits is for each timer and cannot be changed for each pin.
- 2.** The setting of the SRTCn bit is valid even when the INTp1n0/TCUD1n pin is used as a capture trigger (INTp1n0).

	7	6	5	4	3	2	1	0	Address	After reset

1	1	1	1,120	1,493.3	$(1/(f_x/32)) \times 7$

- Remarks**
1. $n = 0, 1$
 2. f_x : Main clock

(8) Compare registers 100, 110 (CM100, CM110)

The CM1n0 register is a 16-bit register that always compares its value with the value of TMENC1n. When the value of a compare register matches the value of TMENC1n, an interrupt request signal is generated. The CM1n0 register can be read or written in 16-bit units. The interrupt request signal generation timing in the various modes is described below.

- In the general-purpose timer mode (T1CMDn bit of TUM1n register = 0) and UDC mode A (MSELn bit of TUM1n register = 0), an interrupt request signal (INTCM1n0) is generated when a match is detected.
- In UDC mode B (MSELn bit of TUM1n register = 1), an interrupt request signal (INTCM1n0) is generated only upon occurrence of a match during a count-up operation.

- Cautions**
1. When the CE1n1 bit of the TMC1n register is 1, it is prohibited to overwrite the value of the CM1n0 register.
 2. Writing the same value to the CM1n0 register is permitted (writing the same value is guaranteed even during a count operation).

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset
CM100																	1FFFF5A2H	0000H
CM110																	1FFFF5D2H	0000H

(9) Compare registers 101, 111 (CM101, CM111)

The CM1n1 register is a 16-bit register that always compares its value with the value of TMENC1n. When the value of the compare register matches the value of TMENC1n, an interrupt request signal is generated. The CM1n1 register can be read or written in 16-bit units. The interrupt generation timing in the various modes is described below.

- In the general-purpose timer mode (T1CMDn bit of TUM1n register = 0) and UDC mode A (MSELn bit of TUM1n register = 0), an interrupt request signal (INTCM1n1) is generated when a match is detected.
- In UDC mode B (MSELn bit of TUM1n register = 1), an interrupt request signal (INTCM1n1) is generated only upon occurrence of a match during a count-down operation.

- Cautions**
1. When the CE1n1 bit of the TMC1n register is 1, it is prohibited to overwrite the value of the CM1n1 register.
 2. Writing the same value to the CM1n1 register is permitted (writing the same value is guaranteed even during a count operation).

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset
CM101																	1FFFF5A4H	0000H
CM111																	1FFFF5D4H	0000H

(10) Capture/compare registers 100, 110 (CC100, CC110)

The CC1n0 register is a 16-bit register. It can be specified as a capture register or as a compare register using the CCR1n register. The CC1n0 register can be read or written in 16-bit units.

- Cautions 1.** When used as a capture register (CMSn0 bit of CCR1n register = 0), write access is prohibited.
2. When used as a compare register (CMSn0 bit of CCR1n register = 1) during TMENC1n operation (CE1n1 bit of TMC1n register = 1), overwriting the CC1n0 register values is prohibited.
 3. When TMENC1n has been stopped (CE1n1 bit of TMC1n register = 0), the capture trigger is disabled.
 4. When the operation mode is changed from capture register to compare register, set a new compare value.
 5. Continuous reading of the CC1n0 register is prohibited. If the CC1n0 register is continuously read, the second read value may differ from the actual value. If the CC1n0 register must be read twice, be sure to read another register between the first and the second read operation.
 6. Writing the same value to the CC1n0 register is prohibited.

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset
CC100																	1FFFF5A6H	0000H
CC110																	1FFFF5D6H	0000H

(a) When set as a capture register

When CC1n0 is set as a capture register, the valid edge of the corresponding external interrupt request signal (INTP1n0) is detected as the capture trigger. TMENC1n latches the count value in synchronization with the capture trigger (capture operation). The latched value is held in the capture register until the next capture operation.

The valid edge of external interrupt request signals (rising edge, falling edge, both rising and falling edges) is selected by the SESA1n register.

When the CC1n0 register is specified as a capture register, interrupt request signals are generated upon detection of the valid edge of the INTP1n0 signal.

Caution The TCUD1n and INTP1n0 pins function alternately. Therefore, because the TCUD1n pin is used in the UDC mode, the external capture function of the INTP1n0 pin cannot be used.

(b) When set as a compare register

When the CC1n0 register is set as a compare register, it always compares its own value with the value of TMENC1n. If the value of CC1n0 matches the value of the TMENC1n, the CC1n0 register generates an interrupt request signal (INTCC1n0).

(11) Capture/compare registers 101, 111 (CC101, CC111)

The CC1n1 register is a 16-bit register. It can be specified as a capture register or as a compare register using the CCR1n register. The CC1n1 register can be read or written in 16-bit units.

- Cautions 1. When used as a capture register (CMSn1 bit of CCR1n register = 0), write access is prohibited.**
- 2. When used as a compare register (CMSn1 bit of CCR1n register = 1) during TMENC1n operation (CE1n1 bit of TMC1n register = 1), overwriting the CC1n1 register values is prohibited.**
 - 3. When TMENC1n has been stopped (CE1n1 bit of TMC1n register = 0), the capture trigger is disabled.**
 - 4. When the operation mode is changed from capture register to compare register, newly set a compare value.**
 - 5. Continuous reading of the CC1n1 register is prohibited. If the CC1n1 register is continuously read, the second read value may differ from the actual value. If the CC1n1 register must be read twice, be sure to read another register between the first and the second read operation.**
 - 6. Writing the same value to the CC1n1 register is prohibited.**

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset
CC101																	1FFFF5A8H	0000H
CC111																	1FFFF5D8H	0000H

(a) When set as a capture register

When CC1n1 is set as a capture register, the valid edge of the corresponding external interrupt request signal (INTP1n1) is detected as the capture trigger. TMENC1n latches the count value in synchronization with the capture trigger (capture operation). The latched value is held in the capture register until the next capture operation.

The valid edge of external interrupt request signal (rising edge, falling edge, both rising and falling edges) is selected by the SESA1n register.

When the CC1n1 register is specified as a capture register, interrupts are generated upon detection of the valid edge of the INTP1n1 signal.

Caution The TCLR1n and INTP1n1 pins function alternately. Therefore, when the TCLR1n input is used in UDC mode A, the external capture function of the INTP1n1 pin cannot be used.

(b) When set as a compare register

When the CC1n1 register is set as a compare register, it always compares its own value with the value of TMENC1n. If the value of the CC1n1 register matches the value of the TMENC1n, the CC1n1 register generates an interrupt request signal (INTCC1n1).

10.3.6 Operation

(1) Operation in general-purpose timer mode

TMENC1n can perform the following operations in the general-purpose timer mode.

(a) Interval operation (when TMC1n.ENMD1n0 bit = 1)

TMENC1n and the CM1n0 register always compare their values and the INTCM1n0 interrupt request signal is generated upon occurrence of a match.

TMENC1n is cleared to 0000H at the count clock following the match. Furthermore, when one more count clock is input, TMENC1n counts up to 0001H.

The interval time can be calculated with the following formula.

$$\text{Interval time} = (\text{CM1n0 register value} + 1) \times \text{TMENC1n count clock rate}$$

(b) Free-running operation (when TMC1n.ENMD1n0 bit = 0)

TMENC1n fully counts from 0000H to FFFFH, is cleared to 0000H at the next count clock after the STATUS1n.OVF1n bit has been set (1), and continues counting. The free-running cycle can be calculated by the following formula.

$$\text{Free-running cycle} = 65,536 \times \text{TMENC1n count clock rate}$$

(c) Compare function

TMENC1n connects two compare register (CM1n0, CM1n1) channels and two capture/compare register (CC1n0, CC1n1) channels.

When the TMENC1n count value and the set value of one of the compare registers match, a match interrupt request signal (INTCM1n0, INTCM1n1, INTCC1n0^{Note}, INTCC1n1^{Note}) is output. Particularly in the case of interval operation, TMENC1n is cleared upon generation of the INTCM1n0 interrupt.

Note This match interrupt request signal is generated when the CC1n0 and CC1n1 registers are set to the compare register mode.

(d) Capture function

TMENC1n connects two capture/compare register (CC1n0, CC1n1) channels. When the CC1n0 and CC1n1 registers are set to the capture register mode, the value of TMENC1n is captured in synchronization with the corresponding capture trigger signal (INTP1n0, INTP1n1). Furthermore, an interrupt request signal (INTCC1n0, INTCC1n1) is generated by the valid edge of the INTP1n0, INTP1n1 input signals specified as the capture trigger signals.

Table 10-7. Capture Trigger Signal (TMENC1n) to 16-Bit Capture Register

Capture Register	Capture Trigger Signal
CC1n0	INTP1n0
CC1n1	INTP1n1

Remark The CC1n0 and CC1n1 registers are capture/compare registers. Which of these registers is used is specified by the CCR1n register.

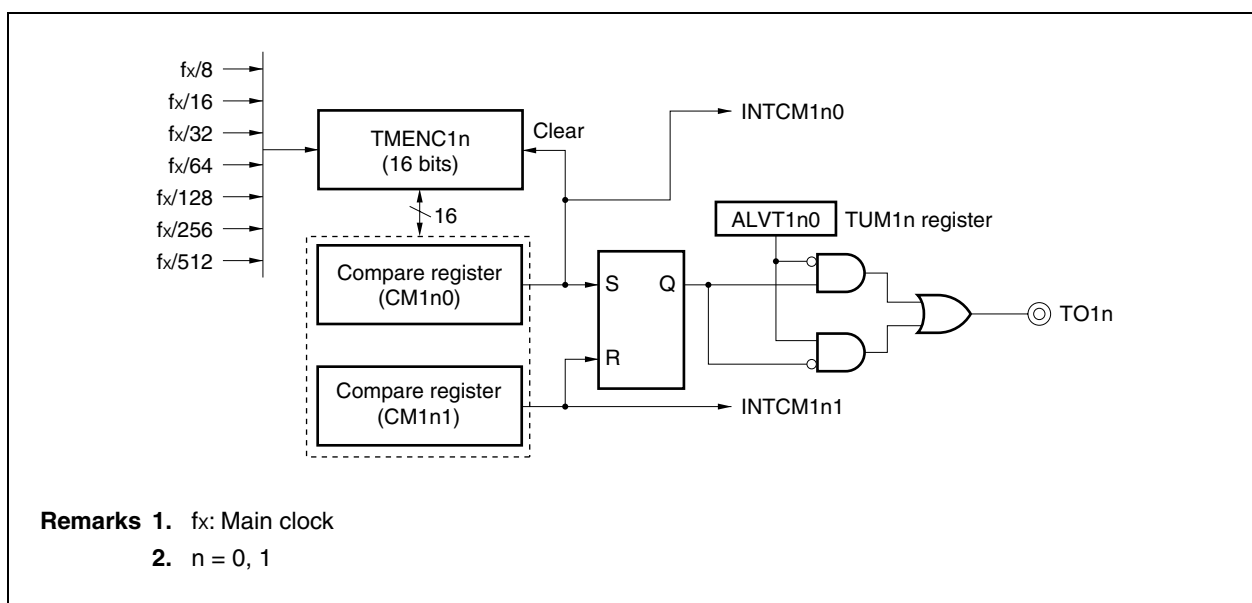

The valid edge of the capture trigger is specified by the SESA1n register. If both the rising edge and the falling edge are selected as the capture triggers, it is possible to measure the input pulse width externally. If a single edge is selected as the capture trigger, the input pulse cycle can be measured.

(e) Timer output operation

Timer output operation is performed from the TO1n pin by setting TMENC1n to the general-purpose timer mode (T1CMDn bit = 0) using the TUM1n register. During the timer output operation, the cycle and duty (CM1n0 and CM1n1 registers) cannot be rewritten. The resolution is 16 bits, and the count clock can be selected from among seven internal clocks (fx/8, fx/16, fx/32, fx/64, fx/128, fx/256, fx/512).

<R>

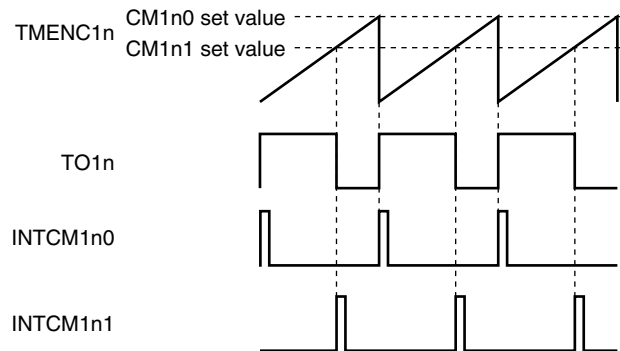

Figure 10-18. TMENC1n Block Diagram (During Timer Output Operation)

(i) Description of operation

The CM1n0 register is a compare register used to set the timer output cycle. When the value of this register matches the value of TMENC1n, the INTCM1n0 interrupt request signal is generated. The compare match is saved by hardware, and TMENC1n is cleared at the next count clock after the match. The CM1n1 register is a compare register used to set the timer output duty. Set the duty required for the timer cycle.

<R>

Figure 10-19. Timer Output Example (When ALVT1n0 Bit = 0 Is Set)

- Cautions**
1. Changing the values of the CM1n0 and CM1n1 registers is prohibited during TMENC1n operation (CE1n1 bit of TMC1n register = 1).
 2. Changing the value of the ALVT1n0 bit of the TUM1n register is prohibited during TMENC1n operation.
 3. Timer output is performed from the second timer cycle after the CE1n1 bit is set to 1.

Remark n = 0, 1

(2) Operation in UDC mode**(a) Overview of operation in UDC mode**

The count clock input to TMENC1n in the UDC mode (T1CMDn bit of TUM1n register = 1) can only be externally input from the TIUD1n and TCUD1n pins. Count-up/-down judgment in the UDC mode is determined based on the phase difference of the TIUD1n and TCUD1n pin inputs according to the PRM1n register setting (there is a total of four choices).

Table 10-8. List of Count Operations in UDC Mode

PRM1n Register			Operation Mode	TMENC1n Operation
PRM1n2	PRM1n1	PRM1n0		
1	0	0	Mode 1	Count down upon detection of valid edge of TIUD1n input when TCUD1n = high level Count up upon detection of valid edge of TIUD1n input when TCUD1n = low level
1	0	1	Mode 2	Count up upon detection of valid edge of TIUD1n input Count down upon detection of valid edge of TCUD1n input
1	1	0	Mode 3	Count up upon detection of valid edge of TIUD1n input when TCUD1n = high level Count down upon detection of valid edge of TIUD1n input when TCUD1n = low level
1	1	1	Mode 4	Automatic judgment upon detection of both edges of TIUD1n input and both edges of TCUD1n input

Remark n = 0, 1

The UDC mode is further divided into two modes according to the TMENC1n clear conditions (a count operation is performed only with TIUD1n and TCUD1n input in both modes).

- **UDC mode A (TUM1n.T1CMDn bit = 1, TUM1n.MSELn bit = 0)**

The TMENC1n clear source can be selected as only external clear input (TCLR1n), a match signal between the TMENC1n count value and the CM1n0 register set value during count-up operation, or the logical sum (OR) of the two signals, using bits CLR1n1 and CLR1n0 of the TMC1n register. TMENC1n can transfer the value of the CM1n0 register upon occurrence of a TMENC1n underflow.

- **UDC mode B (TUM1n.T1CMDn bit = 1, TUM1n.MSELn bit = 1)**

The status of TMENC1n after a match of the TMENC1n count value and the CM1n0 register set value is as follows.

<1> In the case of a count-up operation, TMENC1n is cleared to 0000H, and the INTCM1n0 interrupt request signal is generated.

<2> In the case of a count-down operation, the TMENC1n count value is decremented by 1.

The status of TMENC1n after a match of the TMENC1n count value and the CM1n1 register set value is as follows.

<1> In the case of a count-up operation, the TMENC1n count value is incremented by 1.

<2> In the case of a count-down operation, TMENC1n is cleared to 0000H, and the INTCM1n1 interrupt request signal is generated.

(b) Count-up/-down operation in UDC mode

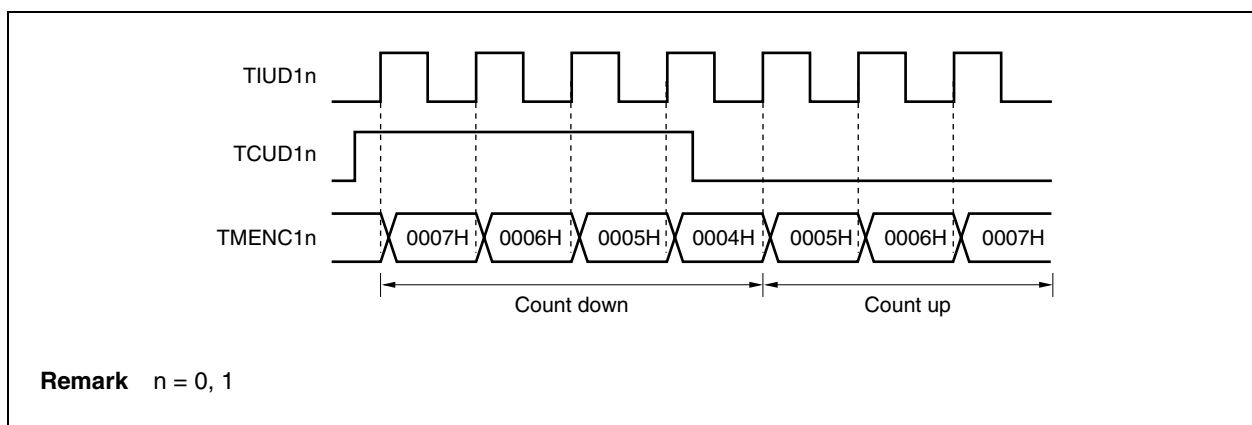

TMENC1n count-up/-down judgment in the UDC mode is determined based on the phase difference of the TIUD1n and TCUD1n pin inputs according to the PRM1n register setting.

(i) Mode 1 (PRM1n.PRM1n2 bit = 1, PRM1n.PRM1n1 bit = 0, PRM1n.PRM1n0 bit = 0)

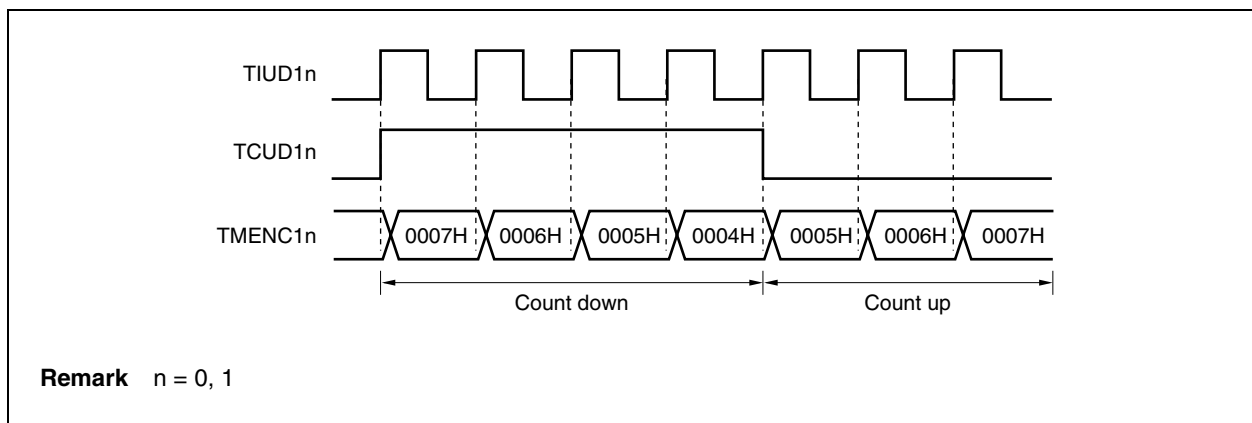

In mode 1, the following count operations are performed based on the level of the TCUD1n pin upon detection of the valid edge of the TIUD1n pin.

- TMENC1n count-down operation when TCUD1n pin = high level
- TMENC1n count-up operation when TCUD1n pin = low level

Figure 10-20. Mode 1 (When Rising Edge Is Specified as Valid Edge of TIUD1n Pin)

**Figure 10-21. Mode 1 (When Rising Edge Is Specified as Valid Edge of TIUD1n Pin):
In Case of Simultaneous TIUD1n, TCUD1n Pin Edge Timing**

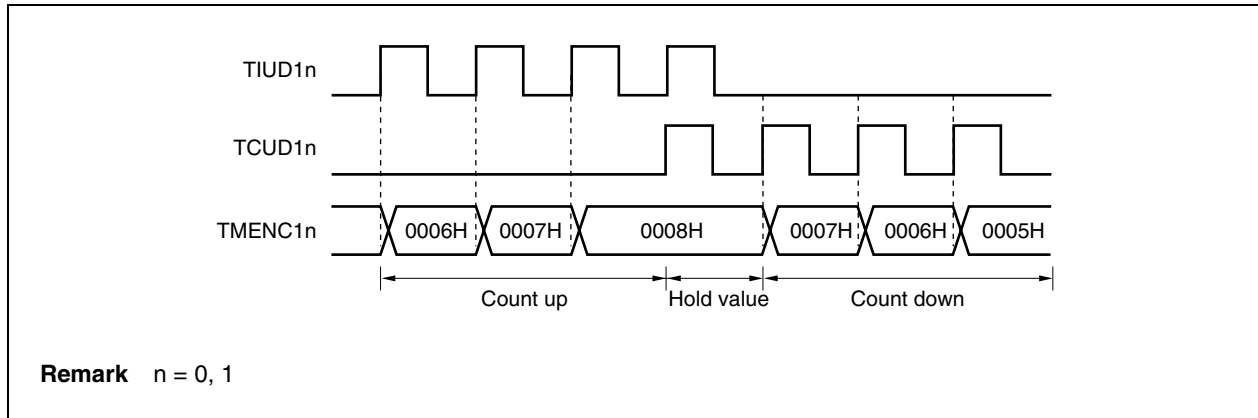

(ii) Mode 2 (PRM1n.PRM1n2 bit = 1, PRM1n.PRM1n1 bit = 0, PRM1n.PRM1n0 bit = 1)

The count conditions in mode 2 are as follows.

- TMENC1n count up upon detection of valid edge of TIUD1n pin
- TMENC1n count down upon detection of valid edge of TCUD1n pin

Caution If the count clock is simultaneously input to the TIUD1n pin and the TCUD1n pin, count operation is not performed and the immediately preceding value is held.

Figure 10-22. Mode 2 (When Rising Edge Is Specified as Valid Edge of TIUD1n, TCUD1n Pins)

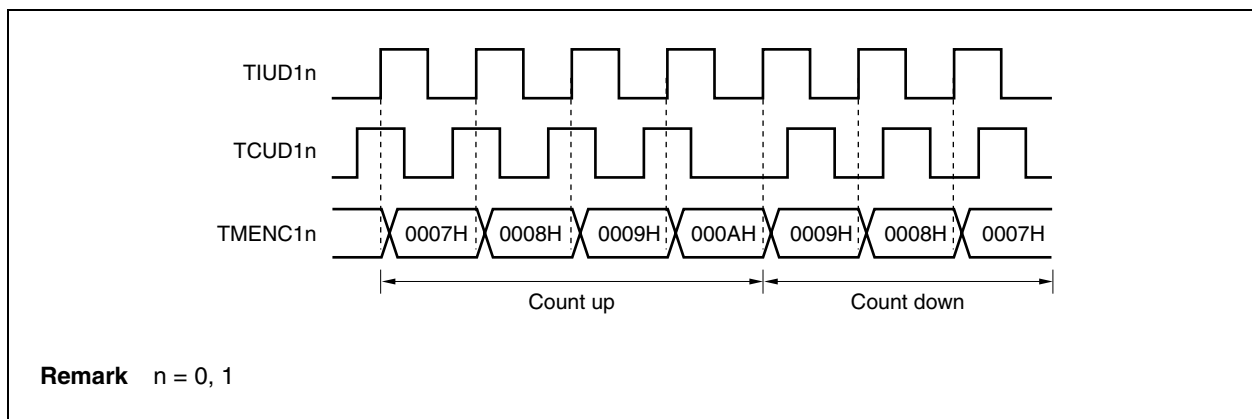

(iii) **Mode 3 (PRM1n.PRM1n2 = 1, PRM1n.PRM1n1 = 1, PRM1n.PRM1n0 = 0)**

In mode 3, when two signals 90 degrees out of phase are input to the TIUD1n and TCUD1n pins, the level of the TCUD1n pin is sampled at the input of the valid edge of the TIUD1n pin (see **Figure 10-23**).

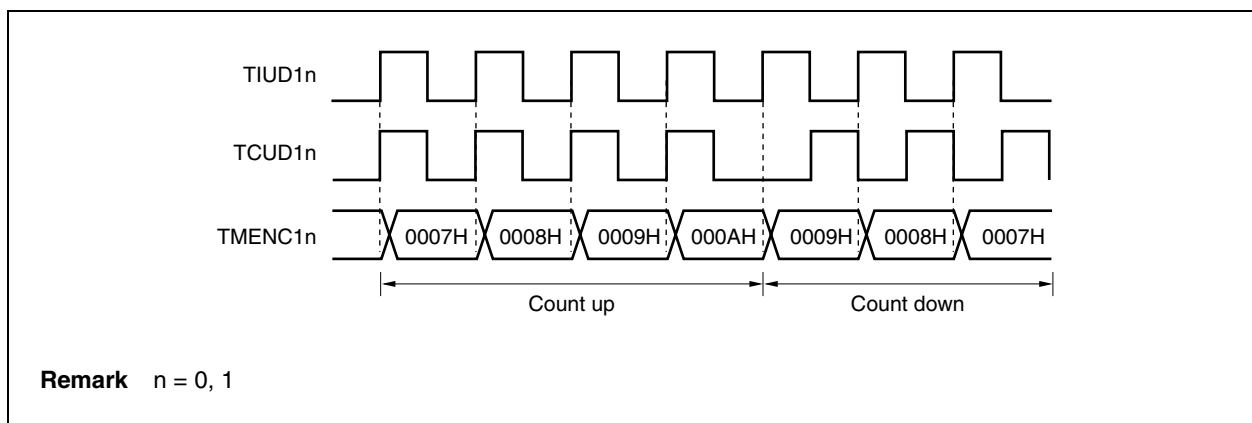

If the TCUD1n pin level sampled at the valid edge input to the TIUD1n pin is low, TMENC1n counts down when the valid edge is input to the TIUD1n pin.

If the TCUD1n pin level sampled at the valid edge input to the TIUD1n pin is high, TMENC1n counts up when the valid edge is input to the TIUD1n pin.

Figure 10-23. Mode 3 (When Rising Edge Is Specified as Valid Edge of TIUD1n pin)

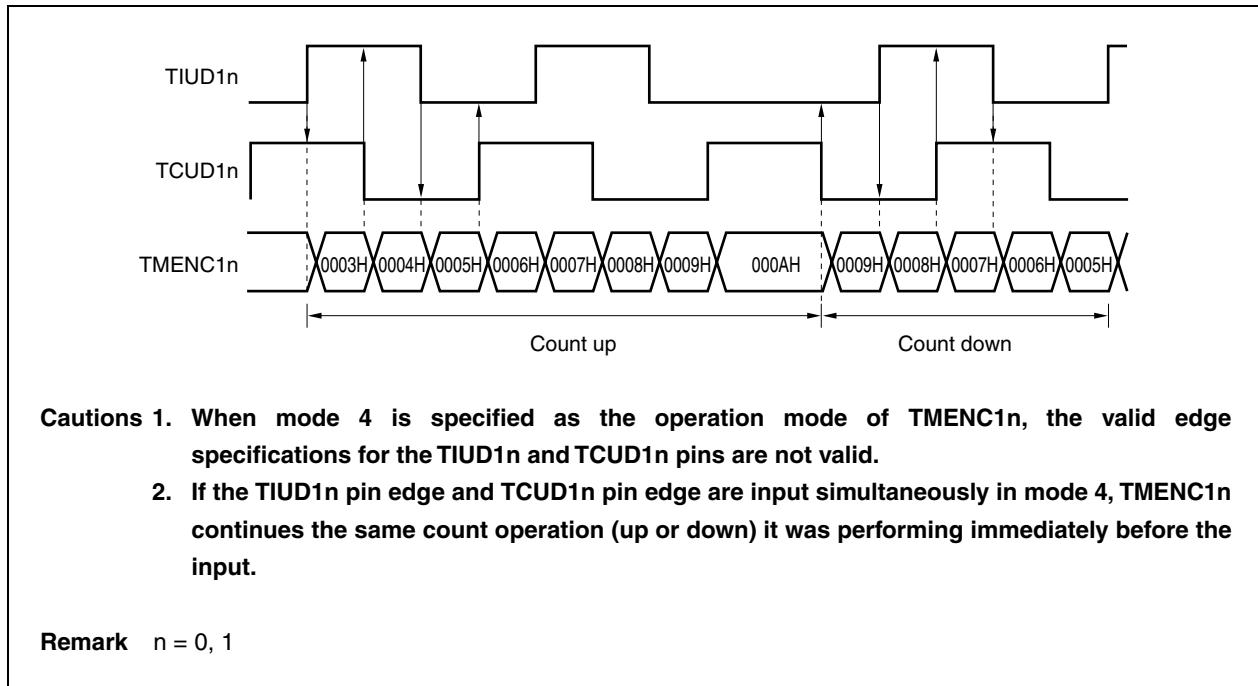

**Figure 10-24. Mode 3 (When Rising Edge Is Specified as Valid Edge of TIUD1n Pin):
In Case of Simultaneous TIUD1n, TCUD1n Pin Edge Timing**

(iv) Mode 4 (PRM1n.PRM1n2 = 1, PRM1n.PRM1n1 = 1, PRM1n.PRM1n0 = 1)

In mode 4, when two signals out of phase are input to the TIUD1n and TCUD1n pins, up/down operation is automatically judged and counting is performed according to the timing shown in **Figure 10-25**.

In mode 4, counting is executed at both the rising and falling edges of the two signals input to the TIUD1n and TCUD1n pins. Therefore, TMENC1n counts four times per cycle of an input signal ($\times 4$ count).

Figure 10-25. Mode 4

(c) Operation in UDC mode A**(i) Interval operation**

The operations at the count clock following a match of the TMENC1n count value and the CM1n0 register set value are as follows.

- In case of count-up operation: TMENC1n is cleared to 0000H and the INTCM1n0 interrupt request signal is generated.
- In case of count-down operation: The TMENC1n count value is decremented by 1 and the INTCM1n0 interrupt request signal is generated.

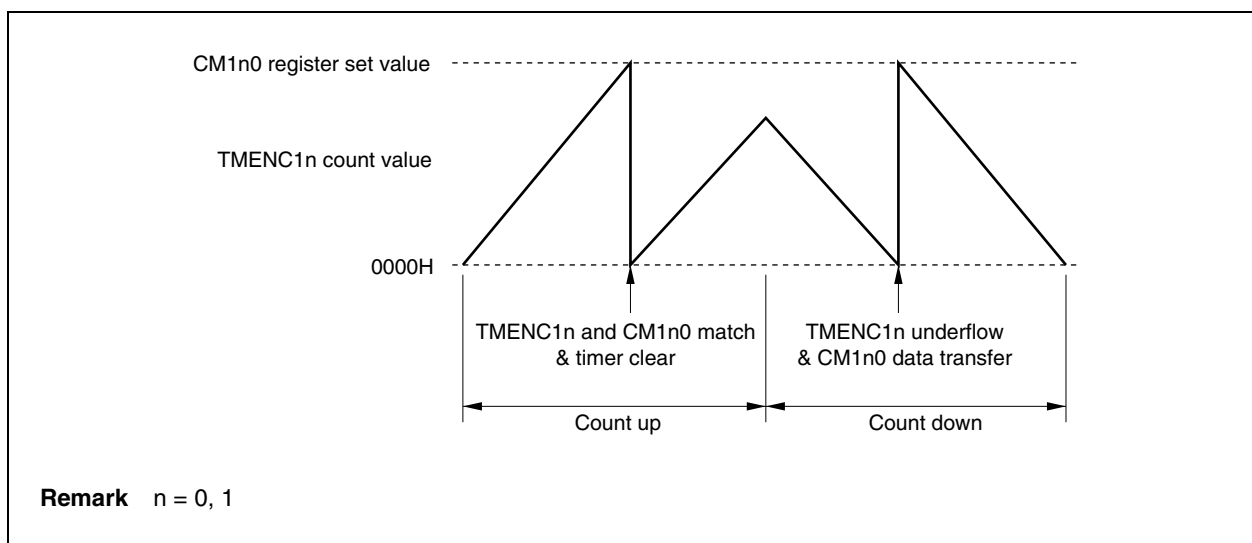

Remark The interval operation can be combined with the transfer operation.

(ii) Transfer operation

If TMENC1n = 0000H during counting down when the TMC1n.RLEN1n bit = 1, the set value of the CM1n0 register is transferred to TMENC1n at the next count clock.

- Remarks**
1. Transfer enable/disable can be set using the RLEN1n bit of the TMC1n register.
 2. The transfer operation can be combined with the interval operation.

Figure 10-26. Example of TMENC1n Operation When Interval Operation and Transfer Operation Are Combined

**(iii) Compare function**

TMENC1n connects two compare register (CM1n0, CM1n1) channels and two capture/compare register (CC1n0, CC1n1) channels.

When the TMENC1n count value and the set value of one of the compare registers match, a match interrupt request signal (INTCM1n0, INTCM1n1, INTCC1n0^{Note}, INTCC1n1^{Note}) is output.

Note This match interrupt request signal is generated when CC1n0 and CC1n1 are set to the compare register mode.

(iv) Capture function

TMENC1n connects two capture/compare register (CC1n0, CC1n1) channels.

When the CC1n0 and CC1n1 registers are set to the capture register mode, the value of TMENC1n is captured in synchronization with the corresponding capture trigger signal.

A capture interrupt request signal (INTCC1n0, INTCC1n1) is generated upon detection of the valid edge.

(d) Operation in UDC mode B**(i) Basic operation**

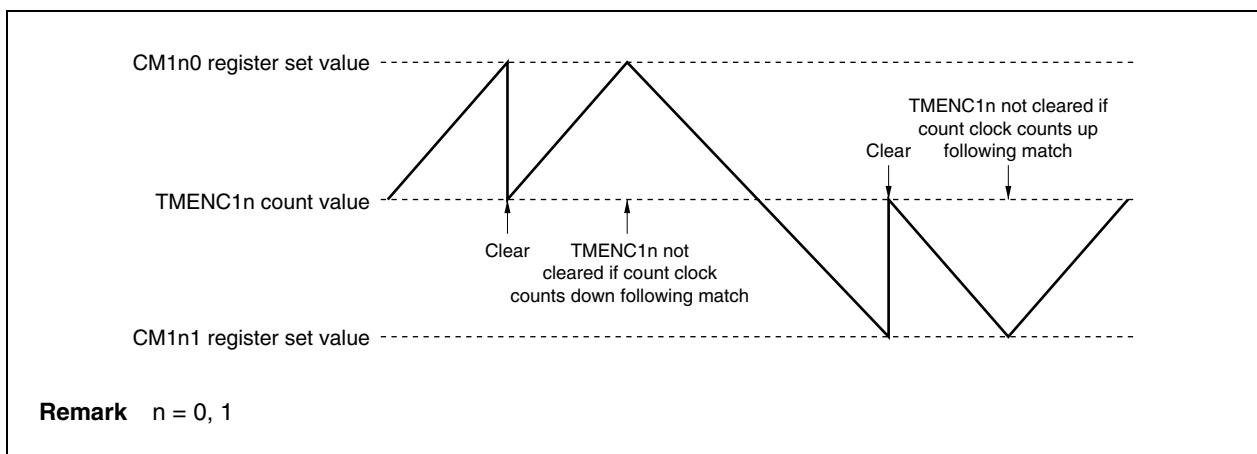

The operations at the next count clock after the count value of TMENC1n and the CM1n0 register set value match when TMENC1n is in UDC mode B are as follows.

- In case of count-up operation: TMENC1n is cleared to 0000H and the INTCM1n0 interrupt request signal is generated.
- In case of count-down operation: The TMENC1n count value is decremented by 1.

The operations at the next count clock after the count value of TMENC1n and the CM1n1 register set value match when TMENC1n is in UDC mode B are as follows.

- In case of count-up operation: The TMENC1n count value is incremented by 1.
- In case of count-down operation: TMENC1n is cleared to 0000H and the INTCM1n1 interrupt request signal is generated.

Figure 10-27. Example of TMENC1n Operation in UDC Mode

**(ii) Compare function**

TMENC1n connects two compare register (CM1n0, CM1n1) channels and two capture/compare register (CC1n0, CC1n1) channels.

When the TMENC1n count value and the set value of one of the compare registers match, a match interrupt request signal (INTCM1n0 (only during count-up operation), INTCM1n1 (only during count-down operation), INTCC1n0^{Note}, INTCC1n1^{Note}) is output.

Note This match interrupt request signal is generated when the CC1n0 and CC1n1 registers are set to the compare register mode.

(iii) Capture function

TMENC1n connects two capture/compare register (CC1n0, CC1n1) channels.

When the CC1n0 and CC1n1 registers are set to the capture register mode, the value of TMENC1n is captured in synchronization with the corresponding capture trigger signal. A capture interrupt request signal (INTCC1n0, INTCC1n1) is generated upon detection of the valid edge.

10.3.7 Supplementary description of internal operation

(1) Clearing of count value in UDC mode B

When TMENC1n is in UDC mode B, the conditions to clear the count value are as follows.

- In case of TMENC1n count up operation: TMENC1n count value is cleared upon match with the CM1n0 register
- In case of TMENC1n count down operation: TMENC1n count value is cleared upon match with the CM1n1 register

Figure 10-28. Clear Operation After Match of CM1n0 Register Set Value and TMENC1n Count Value

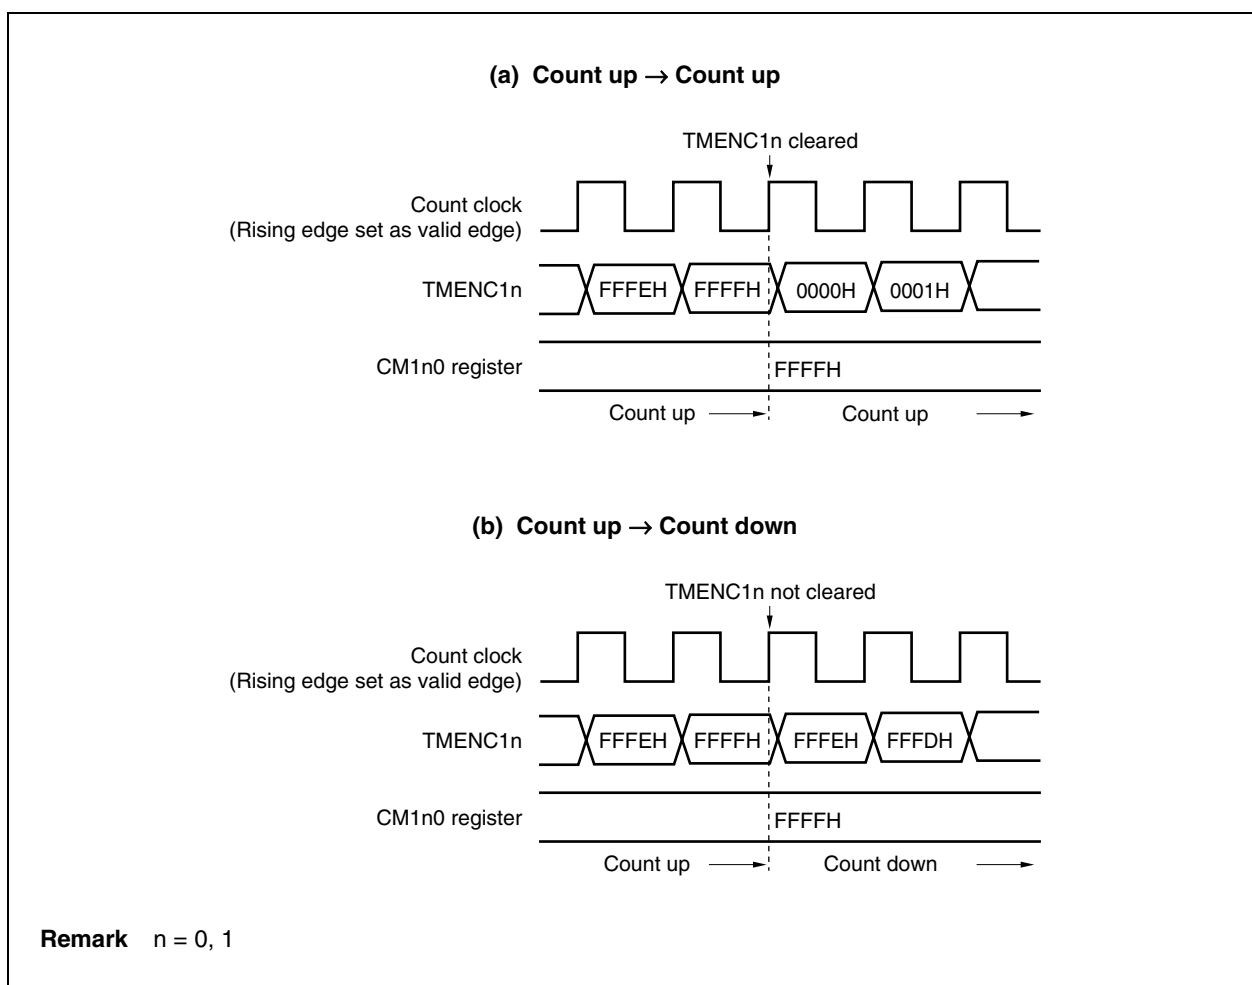

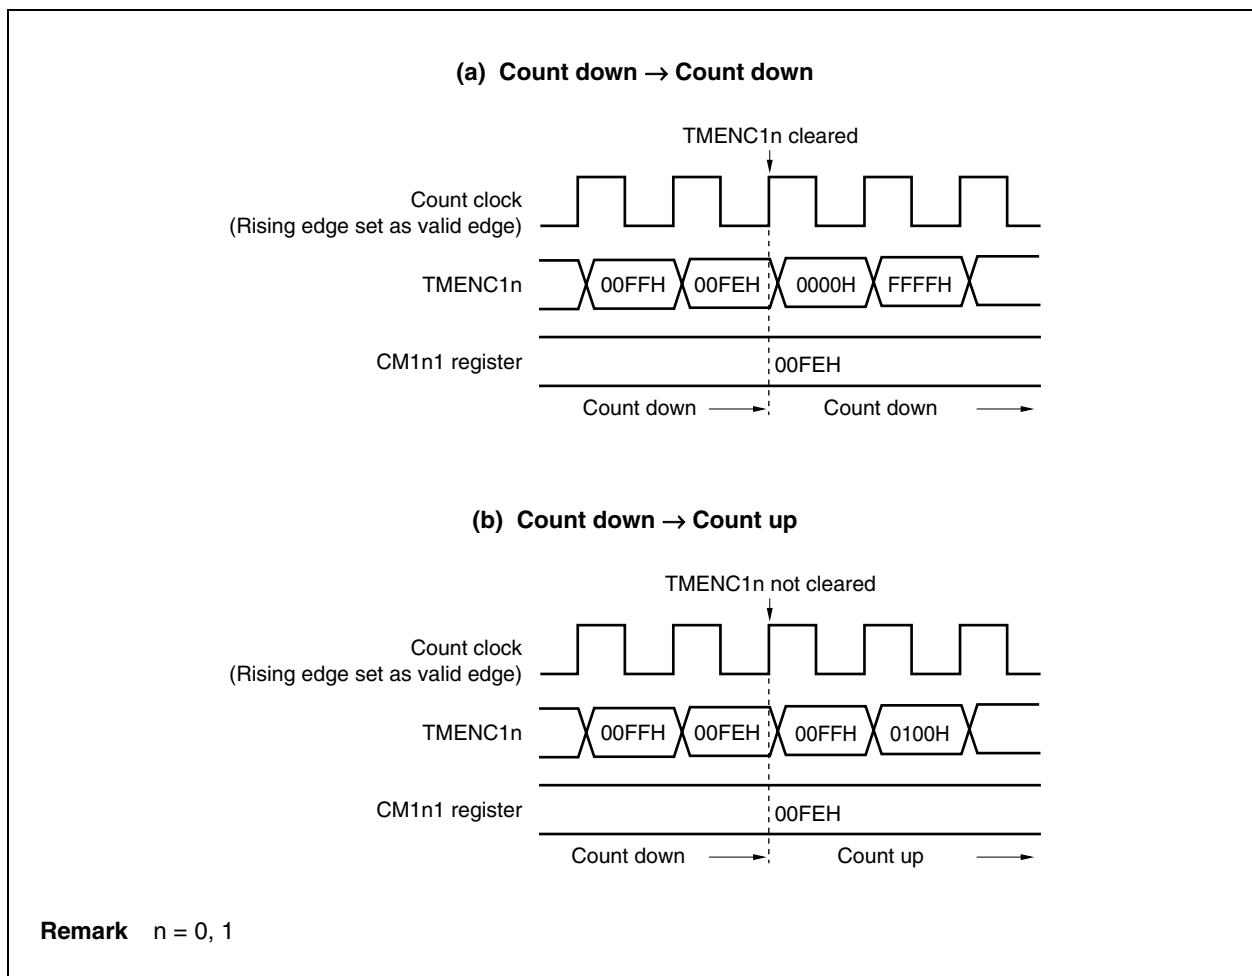

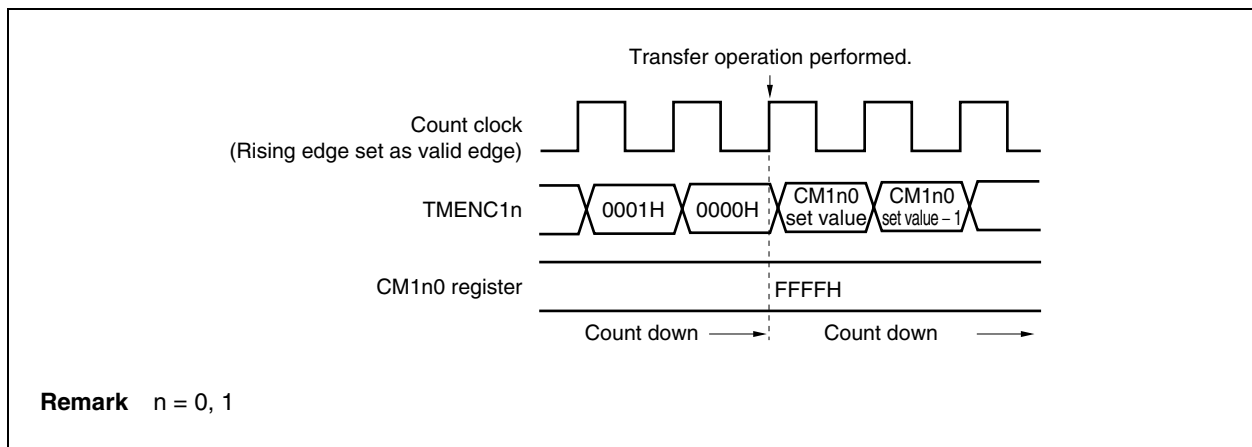

Figure 10-29. Clear Operation After Match of CM1n1 Register Set Value and TMENC1n Count Value

(2) Transfer operation

If TMENC1n = 0000H during counting down when the TMC1n.RLEN1n bit = 1 in UDC mode A, the set value of the CM1n0 register is transferred to TMENC1n at the next count clock. The transfer operation is not performed during counting up.

Figure 10-30. Internal Operation During Transfer Operation

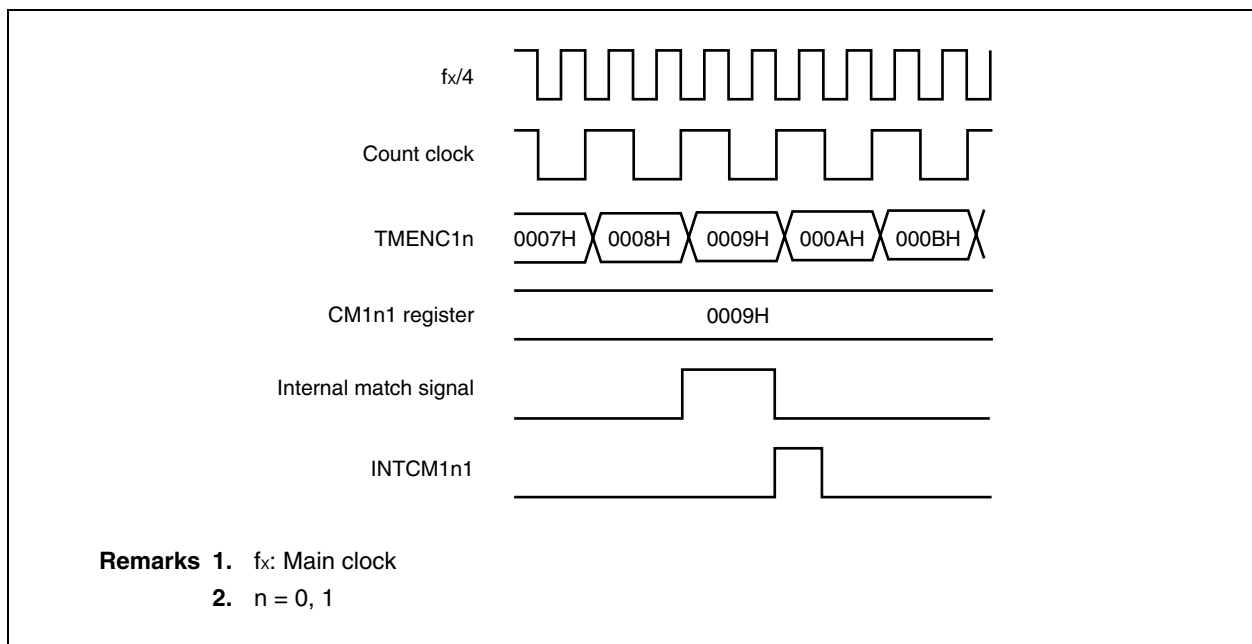

(3) Interrupt request signal output upon compare match

An interrupt request signal is output when the count value of TMENC1n matches the set value of the CM1n0, CM1n1, CC1n0^{Note}, or CC1n1^{Note} register. The interrupt generation timing is as follows.

Note When the CC1n0 and CC1n1 registers are set to the compare register mode.

Figure 10-31. Interrupt Request Signal Output upon Compare Match (CM1n1 with Operation Mode Set to General-Purpose Timer Mode and Count Clock Set to $f_x/8$)

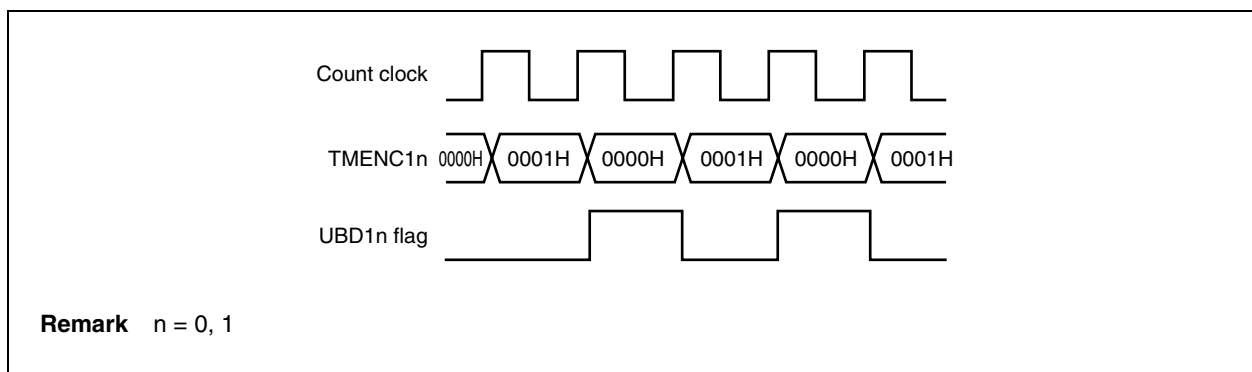

An interrupt request signal such as the one illustrated in Figure 10-31 is output at the next count clock following a match of the TMENC1n count value and the set value of the corresponding compare register.

(4) UBD1n flag (bit 0 of STATUS1n register) operation

In the UDC mode (T1CMDn bit of TUM1n register = 1), the UBD1n flag changes as follows during TMENC1n count-up/-down operation at every internal operation clock.

Figure 10-32. UBD1n Flag Operation

(5) Overflow interrupt request signal (INTOV1n) and underflow interrupt request signal (INTUD1n)

- (a) The overflow interrupt request signal (INTOV1n) is generated when the count value of TMENC1n has reached FFFFH and the next count operation is a count-up.
- (b) The underflow interrupt request signal (INTUD1n) is generated when the count value of TMENC1n has reached 0000H and the next count operation is a count-down.
- (c) TMENC1n continues counting even after occurrence of an overflow or underflow, if a count edge is detected. If the condition of the underflow (0000H → FFFFH) is satisfied when the RLEN1n bit of the TMC1n register is 1 (enabling transfer), however, the set value of the CM1n0 register is transferred.
- (d) If the condition of the underflow (0000H → FFFFH) is satisfied with the set value of the CM1n0 register = FFFFH when the RLEN1n bit of the TMC1n register is cleared to 0 (disabling transfer), the INTCM1n0 interrupt and INTUD1n interrupt occur simultaneously.

10.3.8 Cautions

Cautions concerning the timer ENC1 are shown below.

(1) INTP1n0 pin in UDC mode

The TCUD1n and INTP1n0 pins function alternately. Therefore, because the TCUD1n pin is used in the UDC mode, the external capture function of the INTP1n0 pin cannot be used.

(2) INTP1n1 pin in UDC mode A

The TCLR1n and INTP1n1 pins function alternately. Therefore, when the TCLR1n input is used in UDC mode A, the external capture function of the INTP1n1 pin cannot be used.

(3) Setting trigger mode

Set the PMCDH register before setting the trigger mode of the INTP1n0, INTP1n1, TIUD1n, TCUD1n, and TCLR1n pins. If the PMCDH register is set after the SESA1n register has been set, an illegal interrupt, incorrect counting, and incorrect clearing may occur depending on the timing of setting the PMCDH register.

(4) Caution on setting NCW1n register

Whether the signal is input through or inverted can be specified for each of the INTP1n0/TCUD1n and TIUD1n pins by the SRTCn and SRTIn bits of the NCW1n register. The setting of the noise elimination width by the NCFn, NCC1n, and NCC0n bits is for each timer and cannot be changed for each pin.

CHAPTER 11 SERIAL INTERFACE FUNCTION

11.1 Features

The serial interface function provides three types of serial interfaces equipped with five transmit/receive channels of which four channels can be used simultaneously.

The following three interface formats are available.

- (1) Asynchronous serial interfaces B0 and B1 (UARTB0 and UARTB1): 2 channels
- (2) Clocked serial interfaces 30 and 31 (CSI30 and CSI31): 2 channels
- (3) USB function controller (USBF): 1 channel

Remark For details of the USB function, see **CHAPTER 12 USB FUNCTION CONTROLLER (USBF)**.

UARTB0 and UARTB1, which use the method of transmitting/receiving one byte of serial data following a start bit, enable full-duplex communication to be performed.

CSI30 and CSI31 transfer data according to three types of signals (3-wire serial I/O). These signals are the serial clock ($\overline{SCK0}$ and $\overline{SCK1}$), serial input (SI0 and SI1), and serial output (SO0 and SO1) signals.

The USB supports full-speed transfer of 12 Mbps and consists of seven endpoints.

11.1.1 Switching between UARTB0 and CSI30 modes

In the V850E2/ME3, since UARTB0 and CSI30 are alternate function pins, they cannot be used at the same time. The registers must be set in advance.

11.2 Asynchronous Serial Interfaces B0, B1 (UARTB0, UARTB1)

11.2.1 Features

- Transfer rate: Maximum 1.5 Mbps (using a dedicated baud rate generator)
- Full-duplex communications
- Single mode and FIFO mode selectable
 - Single mode: 8-bit \times 1-stage data register (UBnTX register or UBnRX register) is used for each of transmission and reception.
 - FIFO mode
 - Transmit FIFO: UBnTX register (8 bits \times 16 stages).
 - Receive FIFO: UBnRXAP register (16 bits \times 16 stages)
 - The error information of the received data is stored in the higher 8 bits of the UBnRXAP register.
- Two-pin configuration
 - TXDn: Transmit data output pin
 - RXDn: Receive data input pin
- Reception error detection function
 - Overflow error (FIFO mode only)
 - Parity error
 - Framing error
 - Overrun error (single mode only)
- Interrupt sources: 5 types
 - Reception error interrupt (UBTIREn)
 - Reception completion interrupt (UBTIRn)
 - Transmission completion interrupt (UBTITn)
 - FIFO transmission completion interrupt (UBTIFn) (FIFO mode only)
 - Reception timeout interrupt (UBTITOn) (FIFO mode only)
- The character length of transmit/receive data is specified according to the UBnCTL0 register
- Character length: 7 or 8 bits
- Parity functions: Odd, even, 0, or none
- Transmission stop bits: 1 or 2 bits
- MSB first/LSB first selectable for transfer data
- On-chip dedicated baud rate generator

Remark n = 0, 1

11.2.2 Configuration

UARTBn is controlled by UARTBn control register 0 (UBnCTL0), the UARTBn status register (UBnSTR), UARTBn control register 2 (UBnCTL2), UARTBn FIFO control register 0 (UBnFIC0), UARTBn FIFO control register 1 (UBnFIC1), UARTBn FIFO control register 2 (UBnFIC2), UARTBn FIFO status register 0 (UBnFIS0), and UARTBn FIFO status register 1 (UBnFIS1) (n = 0, 1). Receive data is stored in a receive data register (the UBnRX register in the single mode or receive FIFO in the FIFO mode (the UBnRXAP register)) and transmit data is written to a transmit data register (the UBnTX register in the single mode or transmit FIFO in the FIFO mode). If a reception error (such as a parity error or a framing error) occurs in the FIFO mode, the error data can be identified by reading UARTBn receive data register AP (UBnRXAP) in 16-bit (halfword) units.

Figure 11-1 shows the configuration of the asynchronous serial interface.

(1) UARTBn control register 0 (UBnCTL0) (n = 0, 1)

This register controls the transfer operation of UARTBn.

(2) UARTBn status register (UBnSTR) (n = 0, 1)

This register indicates the transfer status during transmission and the contents of a reception error. The status flag of this register, which indicates the transfer status during transmission, indicates the data retention status of transmit shift register n and transmit data register n (the UBnTX register in the single mode or transmit FIFO in the FIFO mode). Each reception error flag is set to 1 when a reception error occurs, and cleared to 0 when 0 is written to the UBnSTR register.

(3) UARTBn control register 2 (UBnCTL2) (n = 0, 1)

This register is used to specify the division ratio by which to control the baud rate (serial transfer speed) of UARTBn.

(4) UARTBn FIFO control register 0 (UBnFIC0) (n = 0, 1)

This register is used to select the operation mode of UARTBn, clear the transmit FIFO/receive FIFO that becomes valid in the FIFO mode, and specify the timing mode in which the transmission completion interrupt (UBTITn)/reception completion interrupt (UBTIRn) occurs.

(5) UARTBn FIFO control register 1 (UBnFIC1) (n = 0, 1)

This register is valid in the FIFO mode. It generates a reception timeout interrupt request (UBTITOn) if data is stored in the receive FIFO when the next data does not come (start bit is not detected) even after the reception wait time of the next data has elapsed.

(6) UARTBn FIFO control register 2 (UBnFIC2) (n = 0, 1)

This register is valid in the FIFO mode. It is used to set the timing to generate the transmission completion interrupt (UBTITn)/reception completion interrupt (UBTIRn), using the number of data transmitted or received as a trigger.

(7) UARTBn FIFO status register 0 (UBnFIS0) (n = 0, 1)

This register is valid in the FIFO mode. The number of bytes of data stored in the receive FIFO can be read from this register.

(8) UARTBn FIFO status register 1 (UBnFIS1) (n = 0, 1)

This register is valid in the FIFO mode. The number of vacant bytes of the transmit FIFO can be read from this register.

(9) Receive shift register n (n = 0, 1)

This is a shift register that converts the serial data that was input to the RXDn pin into parallel data. One byte of data is received, and if a stop bit is detected, the received data is transferred to receive data register n.

This register cannot be directly manipulated.

(10) UARTBn receive data register AP (UBnRXAP), UARTBn receive data register (UBnRX) (n = 0, 1)

Receive data register n holds receive data. In the single mode, the 8-bit × 1-stage UBnRX register is used. The 16-bit × 16-stage receive FIFO (UBnRXAP register) is used in the FIFO mode.

The receive data is stored in the lower 8 bits of the receive FIFO (UBnRXAP register) and the error information of the received data is stored in the higher 8 bits (bit 8 and bit 9). If a reception error (such as a parity error or a framing error) occurs in the FIFO mode, the error data can be identified by reading the UBnRXAP register in 16-bit (halfword) units (error information is appended as UBnPEF bit = 1 or UBnFEF bit = 1). When the lower 8 bits of the UBnRXAP register are read in 8-bit (byte) units, the higher 8 bits are discarded. Therefore, if no error has occurred, the receive data of the UBnRXAP register can be read consecutively by being read in 8-bit (byte) units in the same way as the UBnRX register.

When 7-bit length data is received with the LSB first, the received data is transferred to bits 6 to 0 of receive data register n from the LSB (bit 0), with the MSB (bit 7) always being 0. When data is received with the MSB first, the received data is transferred to bits 7 to 1 of receive data register n from the MSB (bit 7), with the LSB (bit 0) always being 0. If an overrun error occurs, the receive data at that time is not transferred to receive data register n.

While reception is enabled, the received data is transferred from receive shift register n to receive data register n, in synchronization with the shift-in processing of one frame.

A reception completion interrupt request (UBTIRn) is generated by transferring the data to the UBnRX register in the single mode, or transferring the number of receive data set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register to receive FIFO in the FIFO mode. If data is stored in receive FIFO when the next data does not come (start bit is not detected) after the next data reception wait time specified by the UBnTC4 to UBnTC0 bits of the UBnFIC1 register has elapsed in the FIFO mode, a reception timeout interrupt request (UBTITOn) is generated.

(11) Transmit shift register n (n = 0, 1)

This is a shift register that converts the parallel data that was transferred from transmit data register n into serial data.

When one byte of data is transferred from transmit data register n, transmit shift register n data is output from the TXDn pin.

This register cannot be directly manipulated.

(12) UARTBn transmit data register n (UBnTX) (n = 0, 1)

Transmit data register n is a buffer for transmit data. The 8-bit × 1-stage UBnTX register is used as this buffer in the single mode. In the FIFO mode, the 8-bit × 16-stage transmit FIFO is used.

When 7-bit length data is transmitted with the LSB first, bits 6 to 0 of transmit data register n are transmitted as the transmit data from the LSB (bit 0) with the MSB (bit 7) always being 0. When data is transmitted with the MSB first, bits 7 to 1 of transmit data register n are transmitted as the transmit data from the MSB (bit 7) with the LSB (bit 0) always being 0.

In the single mode, transmission is started by writing transmit data to the UBnTX register while transmission is enabled (UBnTXE bit = 1 in the UBnCTL0 register). When writing the transmit data to the UBnTX register is enabled (when 1-byte data is transferred from the UBnTX register to transmit shift register n), a transmission completion interrupt request (UBTITn) is generated.

In the FIFO mode, transmission is started by writing at least the number of transmit data set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register and 16 bytes or less to transmit FIFO and then enabling transmission (UBnTXE bit = 1). When the number of transmit data set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register have been transferred from transmit FIFO to transmit shift register n (transmit data of the number set as the trigger can be written), a transmission completion interrupt request (UBTITn) is generated. In the FIFO mode, a FIFO transmission completion interrupt request (UBTIFn) is generated when there is no more data in transmit FIFO and transmit shift register n (when FIFO and the register become empty).

(13) Timeout counter

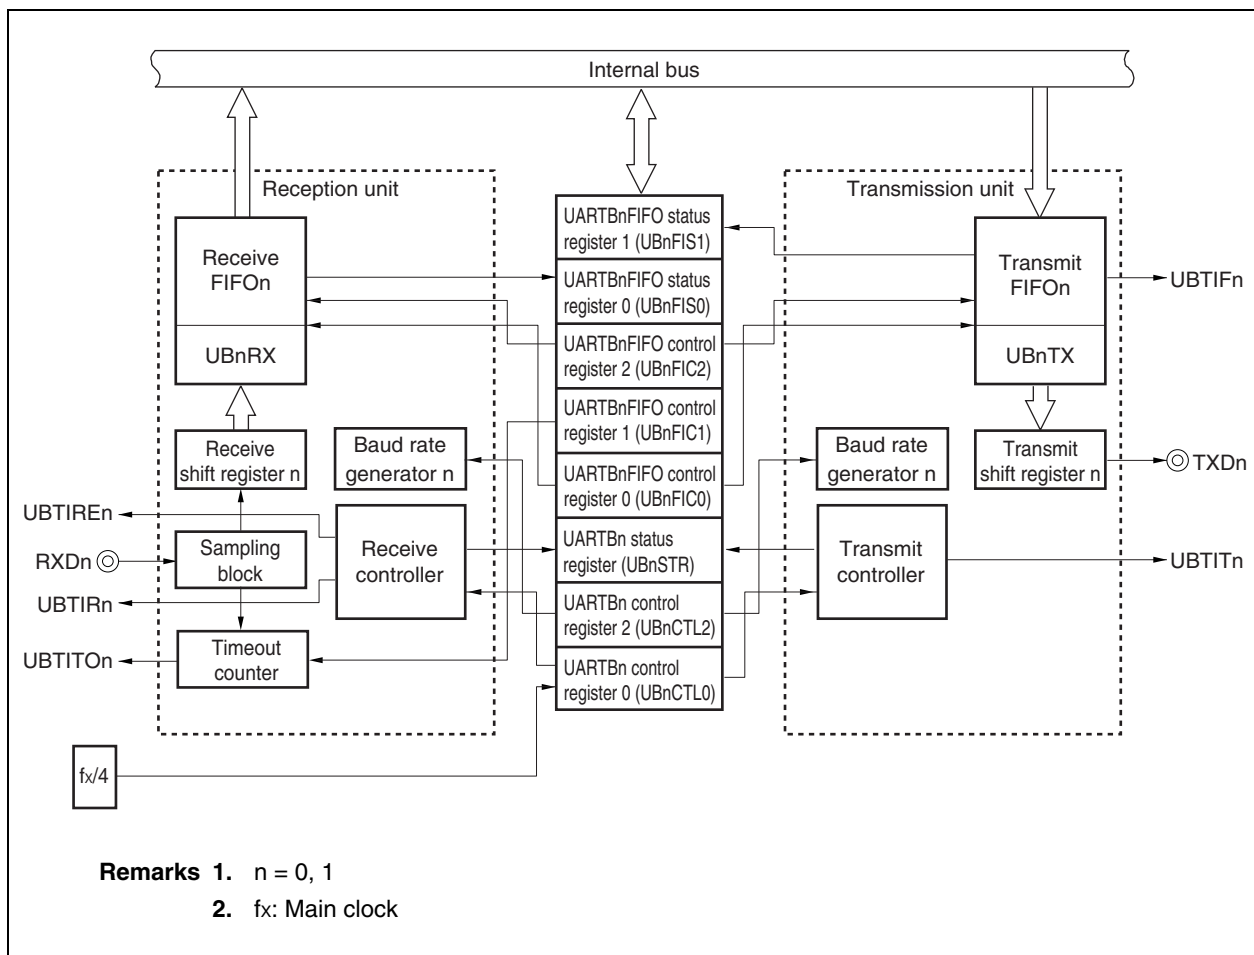

This counter is used to recognize that data exists (remains) in receive FIFO when the number of received data does not reach the number set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register, and is valid only in the FIFO mode.

If data is stored in receive FIFO when the next data does not come (start bit is not detected) after the next data reception wait time specified by the UBnTC4 to UBnTC0 bits of the UBnFIC1 register has elapsed after the stop bit has been received, a reception timeout interrupt request (UBTITOn) is generated.

(14) Sampling block

This block samples the RXDn signal at the rising edge of the input clock ($f_x/4$) (f_x : main clock). If the same sampling value is detected two times, output of the match detector changes, and the value is sampled as input data. Data of less than one clock width is judged as noise and is not transmitted to the internal circuitry.

Figure 11-1. Block Diagram of Asynchronous Serial Interfaces B0 and B1

11.2.3 Control registers

(1) UARTBn control register 0 (UBnCTL0) (n = 0, 1)

The UBnCTL0 register controls the transfer operations of UARTBn.

This register can be read or written in 8-bit or 1-bit units.

Cautions 1. When using UARTBn, set the external pins related to the UARTBn function in the control mode, set UARTBn control register 2 (UBnCTL2). Then set the UBnPWR bit to 1 before setting the other bits.

2. Be sure to input a high level to the RXDn pin when setting the external pins related to the UARTBn function in the control mode. If a low level is input, it is judged that a falling edge is input after the UBnRXE bit has been set to 1, and reception may be started.

When the reception unit status is to be initialized, the reception status may not be able to be initialized unless the UBnRXE bit is set to 1 again after an interval of two cycles of $f_x/4$ (f_x: main clock) has elapsed since the UBnRXE bit was cleared to 0. 																				
4	UBnDIR	<p>Specifies the transfer direction mode (MSB/LSB).</p> <p>0: The first bit of transfer data is the MSB. 1: The first bit of transfer data is the LSB.</p> <p>Caution Clear the UBnPWR bit or UBnTXE and UBnRXE bits to 0 before changing the setting of the UBnDIR bit.</p>																				
3, 2	UBnPS1, UBnPS0	<p>Controls the parity bit.</p> <table border="1"> <thead> <tr> <th>UBnPS1</th> <th>UBnPS0</th> <th>Transmit operation</th> <th>Receive operation</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Do not output a parity bit</td> <td>Receive with no parity</td> </tr> <tr> <td>0</td> <td>1</td> <td>Output 0 parity</td> <td>Receive as 0 parity</td> </tr> <tr> <td>1</td> <td>0</td> <td>Output odd parity</td> <td>Judge as odd parity</td> </tr> <tr> <td>1</td> <td>1</td> <td>Output even parity</td> <td>Judge as even parity</td> </tr> </tbody> </table> <p>Cautions</p> <ol style="list-style-type: none"> 1. Clear the UBnTXE and UBnRXE bits to 0 before overwriting the UBnPS1 and UBnPS0 bits. 2. If "0 parity" is selected for reception, no parity judgment is made. Therefore, no error interrupt is generated because the UBnPE bit of the UBnSTR register is not set to 1. <ul style="list-style-type: none"> • Even parity If the transmit data contains an odd number of bits with the value "1", the parity bit is set to 1. If it contains an even number of bits with the value "1", the parity bit is cleared to 0. This controls the number of bits with the value "1" contained in the transmit data and the parity bit so that it is an even number. During reception, the number of bits with the value "1" contained in the receive data and the parity bit is counted, and if the number is odd, a parity error is generated. • Odd parity In contrast to even parity, odd parity controls the number of bits with the value "1" contained in the transmit data and the parity bit so that it is an odd number. During reception, the number of bits with the value "1" contained in the receive data and the parity bit is counted, and if the number is even, a parity error is generated. 	UBnPS1	UBnPS0	Transmit operation	Receive operation	0	0	Do not output a parity bit	Receive with no parity	0	1	Output 0 parity	Receive as 0 parity	1	0	Output odd parity	Judge as odd parity	1	1	Output even parity	Judge as even parity
UBnPS1	UBnPS0	Transmit operation	Receive operation																			
0	0	Do not output a parity bit	Receive with no parity																			
0	1	Output 0 parity	Receive as 0 parity																			
1	0	Output odd parity	Judge as odd parity																			
1	1	Output even parity	Judge as even parity																			

Remark n = 0, 1

(3/3)

Bit position	Bit name	Function
3, 2	UBnPS1, UBnPS0	<ul style="list-style-type: none"> • 0 parity During transmission, the parity bit is cleared to 0 regardless of the transmit data. During reception, no parity error is generated because no parity bit is checked. • No parity No parity bit is added to transmit data. During reception, the receive data is considered to have no parity bit. No parity error is generated because there is no parity bit.
1	UBnCL	Specifies the character length of the transmit/receive data. 0: 7 bits 1: 8 bits Caution Clear the UBnTXE and UBnRXE bits to 0 before overwriting the UBnCL bit.
0	UBnSL	Specifies the stop bit length of the transmit data. 0: 1 bit 1: 2 bits Cautions 1. Clear the UBnTXE bit to 0 before overwriting the UBnSL bit. 2. Since reception always operates by using a single stop bit length, the UBnSL bit setting does not affect receive operations.

Remarks 1. When reception is disabled, receive shift register n does not detect a start bit. No shift-in processing or transfer processing to receive data register n is performed, and the contents of receive data register n are retained.

When reception is enabled, the receive shift operation starts, in synchronization with the detection of the start bit, and when the reception of one frame is completed, the contents of receive shift register n are transferred to receive data register n. A reception completion interrupt (UBTIRn) is also generated, in synchronization with the transfer to receive data register n (in FIFO mode, transfer triggered by reaching set number of receive data).

If data is stored in receive FIFO when the next data does not come (start bit is not detected) after the next data reception wait time specified by the UBnTC4 to UBnTC0 bits of the UBnFIC1 register has elapsed in the FIFO mode, a reception timeout interrupt request (UBTITOn) is generated.

2. n = 0, 1

(2) UARTBn status register (UBnSTR) (n = 0, 1)

The UBnSTR register indicates the transfer status and reception error contents while UARTBn is transmitting data. The status flag that indicates the transfer status during transmission indicates the data retention status of transmit shift register n and transmit data register n (the UBnTX register in the single mode or transmit FIFO in the FIFO mode). The status flag that indicates a reception error holds its status until it is cleared to 0. This register can be read or written in 8-bit or 1-bit units.

Caution When the UBnPWR bit or UBnRXE bit of the UBnCTL0 register is cleared to 0, or when 0 is written to the UBnSTR register, the UBnOVF, UBnPE, UBnFE, and UBnOVE bits of the UBnSTR register are cleared to 0.

 3. x: Don't care

(4) UARTBn transmit data register (UBnTX) (n = 0, 1)

The UBnTX register is used to set transmit data. It functions as the 8-bit × 1-stage UBnTX register, in the single mode (UBnMOD bit = 0 in the UBnFIC0 register), and as the 8-bit × 16-stage transmit FIFO in the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register).

In the single mode, transmission is started by writing transmit data to the UBnTX register when transmission is enabled (the UBnTXE bit = 1 in the UBnCTL0 register). When data can be written to the UBnTX register (when 1 byte of data is transferred from the UBnTX register to transmit shift register n), a transmission completion interrupt request (UBTITn) is generated.

In the FIFO mode, transmission is started by enabling transmission (UBnTXE bit = 1) after writing at least the number of transmit data set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register and 16 bytes or less to transmit FIFO. When the number of transmit data set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register have been transferred from transmit FIFO to transmit shift register n (transmit data of the number set as the trigger can be written to transmit FIFO), a transmission completion interrupt request (UBTITn) is generated. In the FIFO mode, a FIFO transmission completion interrupt request (UBTIFn) is generated when there is no more data in transmit FIFO and transmit shift register n (when the FIFO and register become empty).

For the generation timing of the interrupt, see **11.2.4 Interrupt requests**.

When 7-bit length data is transmitted with the LSB first, bits 6 to 0 of transmit data register n are transmitted as the transmit data from the LSB (bit 0) with the MSB (bit 7) always being 0. When data is transmitted with the MSB first, bits 7 to 1 of transmit data register n are transmitted as the transmit data from the MSB (bit 7) with the LSB (bit 0) always being 0.

This register is write-only, in 8-bit units. Data is written to transmit data register n.

Bit position	Bit name	Function
7 to 0	UBnTD7 to UBnTD0	Write transmit data.

Remark n = 0, 1

(5) UARTBn receive data register AP (UBnRXAP), UARTBn receive data register (UBnRX) (n = 0, 1)

These registers store parallel data converted by receive shift register n. They function as the 8-bit × 1-stage UBnRX register, in the single mode (UBnMOD bit = 0 in the UBnFIC0 register), and as the 16-bit × 16-stage receive FIFO (UBnRXAP register) in the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register).

The receive data is stored in the lower 8 bits of the receive FIFO (UBnRXAP register) and the error information of the received data is stored in the higher 8 bits (bit 8 and bit 9). If a reception error (such as a parity error or a framing error) occurs in the FIFO mode, the UBnRXAP register is read in 16-bit (halfword) units. In this way, the flag of the data stored in receive FIFO can be checked (error information is appended as UBnPEF bit = 1 or UBnFEF bit = 1), so that the error data can be recognized (when the lower 8 bits of the UBnRXAP register are read in 8-bit (byte) units, the higher 8 bits are discarded). Therefore, if no error has occurred, the receive data of the UBnRXAP register can be read consecutively by being read in 8-bit (byte) units in the same way as the UBnRX register).

If reception is enabled (UBnRXE bit = 1 in the UBnCTL0 register), the receive data is transferred from receive shift register n to receive data register n, in synchronization with the completion of the shift-in processing of one frame.

By transferring the receive data to the UBnRX register in the single mode or by transferring the number of receive data set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register to the receive FIFO in the FIFO mode, a reception completion interrupt request (UBTIRn) is generated. If data is stored in receive FIFO when the next data does not come (start bit is not detected) even after the next data reception wait time specified by the UBnTC4 to UBnTC0 bits of the UBnFIC1 register has elapsed in the FIFO mode, a reception timeout interrupt request (UBTITOn) is generated.

For information about the timing for generating these interrupt requests, see **11.2.4 Interrupt requests**.

If data is received with the LSB first when the data length is specified as 7 bits, the received data is transferred to bits 6 to 0 of receive data register n from the LSB (bit 0), with the MSB (bit 7) always being 0. If data is received with the MSB first, it is transferred to bits 7 to 1 of receive data register n from the MSB (bit 7) with the LSB (bit 0) always being 0. However, if an overrun error occurs, the receive data at that time is not transferred to receive data register n.

The UBnRXAP register is read-only, in 16-bit units. However, the lower 8 bits of the UBnRXAP register are read-only, in 8-bit units.

The UBnRX register is read-only, in 8-bit units.

In addition to reset input, the value of these registers can be set to FFH in the single mode or to 00FFH in the FIFO mode, by clearing the UBnPWR bit of the UBnCTL0 register to 0.

- Cautions 1. The UBnPEF and UBnFEF bits cannot be read because these registers serve as 8-bit registers in the single mode.**
- 2. When no reception error has occurred in the FIFO mode, the receive data of the UBnRXAP register can be read consecutively by reading the lower 8 bits of the UBnRXAP register in 8-bit (byte) units. An 8-bit access to the higher 8 bits is prohibited. If they are accessed, the operation is not guaranteed.**

Cautions 3. Do not perform the following operations when debugging a system that uses the single mode.

- Setting a break for an instruction immediately after the UBnRX register is read
- Setting a break before DMA transfer with the UBnRX register specified as the transfer source is completed
- Setting a break before completion of reception of the next data after reception of data and reading the UBnRX register, and checking the UBnRX register in the I/O register window of the debugger

If any of these operations is performed, an overrun error may occur during the subsequent reception.

Bit position	Bit name	Function
9 (UBnRXAP)	UBnPEF	This is a status flag that indicates a parity error. Status is valid only in the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register), and is invalid in the single mode (UBnMOD bit = 0 in the UBnFIC0 register). 0: No parity error 1: Parity error occurs (during reception). Caution The operation of the UBnPEF bit differs depending on the set values of the UBnPS1 and UBnPS0 bits of the UBnCTL0 register.
8 (UBnRXAP)	UBnFEF	This is a status flag indicating a framing error. Status is valid only in the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register), and is invalid in the single mode (UBnMOD bit = 0 in the UBnFIC0 register). 0: No framing error 1: Framing error occurs (during reception). Caution Only the first bit of the stop bits of the receive data is checked, regardless of the stop bit length.
7 to 0	UBnRD7 to UBnRD0	Stores receive data.

Remark n = 0, 1

(6) UARTBn FIFO control register 0 (UBnFIC0) (n = 0, 1)

The UBnFIC0 register is used to select the operation mode of UARTBn and the functions that become valid in the FIFO mode (UBnMOD bit = 1). In the FIFO mode, it clears transmit FIFO/receive FIFO and specifies the timing mode in which the transmission completion interrupt (UBTITn)/reception completion interrupt (UBTIRn) is generated.

This register can be read or written in 8-bit or 1-bit units.

Remark n = 0, 1

(8) UARTBn FIFO control register 2 (UBnFIC2) (n = 0, 1)

The UBnFIC2 register is valid in the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register). It sets the timing of generating an interrupt, using the number of transmit/receive data as a trigger. When data is transmitted, the number of data transferred from transmit FIFO is specified as the condition of generating the interrupt. When data is received, the number of data stored in receive FIFO is specified as the interrupt generation condition. This register can be read or written in 16-bit units.

When the higher 8 bits of the UBnFIC2 register can be used as the UBnFIC2H register and the lower 8 bits, as the UBnFIC2L register, these registers can be read or written in 8-bit units.

Caution Be sure to clear the UBnTXE bit (to disable transmission) and UBnRXE bit (to disable reception) of the UBnCTL0 register to 0 before writing data to the UBnFIC2 register. If data is written to the UBnFIC2 register with the UBnTXE or UBnRXE bit set to 1, the operation is not guaranteed.

(10) UARTBn FIFO status register 1 (UBnFIS1) (n = 0, 1)

The UBnFIS1 register is valid in the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register). This register can be used to read the number of vacant bytes of transmit FIFO.

This register is read-only, in 8-bit units.

Caution 1. The values of the UBnTB4 to UBnTB0 bits are reflected after transmit data has been written to the UBnTX register and then time of two cycles of $f_x/4$ (f_x : main clock) has passed. Therefore, care must be exercised when referencing the UBnFIS1 register after transmit data has been written to the UBnTX register.

2. The UBnFIS1 register is set to 10H by setting the UBnPWR bit of the UBnCTL0 register to 1.

11.2.4 Interrupt requests

The following five types of interrupt requests are generated from UARTBn (n = 0, 1).

- Reception error interrupt (UBTIREn)
- Reception completion interrupt (UBTIRn)
- Transmission completion interrupt (UBTITn)
- FIFO transmission completion interrupt (UBTIFn)
- Reception timeout interrupt (UBTITOn)

The default priorities among these five types of interrupt requests is, from high to low, reception error interrupt, reception completion interrupt, transmission completion interrupt, FIFO transmission completion interrupt, and reception timeout interrupt.

Table 11-2. Generated Interrupts and Default Priorities

Interrupt	Priority
Reception error	1
Reception completion	2
Transmission completion	3
FIFO transmission completion	4
Reception timeout	5

(1) Reception error interrupt (UBTIREn)

(a) Single mode

When reception is enabled, a reception error interrupt is generated according to the logical OR of the three types of reception errors (parity error, framing error, overrun error) explained for the UBnSTR register.

When reception is disabled, no reception error interrupt is generated.

(b) FIFO mode

When reception is enabled, a reception error interrupt is generated according to the logical OR of the three types of reception errors (parity error, framing error, overflow error) explained for the UBnSTR register.

When reception is disabled, no reception error interrupt is generated.

(2) Reception completion interrupt (UBTIRn)**(a) Single mode**

When reception is enabled, a reception completion interrupt is generated if data is shifted into receive shift register n and stored in the UBnRX register (if the receive data can be read).

When reception is disabled, no reception completion interrupt is generated.

(b) FIFO mode

When reception is enabled, a reception completion interrupt is generated if data is shifted into receive shift register n and receive data of the number set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register is transferred to receive FIFO n (if receive data of the specified number can be read).

When reception is disabled, no reception completion interrupt is generated.

(3) Transmission completion interrupt (UBTITn)**(a) Single mode**

The transmission completion interrupt is generated if transmit data of one frame, including 7 or 8 bits of characters, is shifted out from transmit shift register n and the UBnTX register becomes vacant (if transmit data can be written).

(b) FIFO mode

The transmission completion interrupt is generated if transmit data of the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register is transferred to transmit shift register n from transmit FIFO n (if transmit data of the specified number can be written).

(4) FIFO transmission completion interrupt (UBTIFn)**(a) Single mode**

Cannot be used.

(b) FIFO mode

The FIFO transmission completion interrupt is generated when no more data is in transmit FIFO n and transmit shift register n (when the FIFO and register become empty). After the FIFO transmission completion interrupt has occurred, clear the interrupt held pending (UBTITn) in the pending mode (UBnITM bit = 0 in the UBnFIC0 register) by clearing the FIFO (UBnTFC bit = 1 in the UBnFIC0 register).

Caution If the FIFO transmission completion interrupt is generated (all transmit data are not transmitted) because writing the next transmit data to transmit FIFO n is delayed, do not clear the FIFO.

(5) Reception timeout interrupt (UBTITOn)**(a) Single mode**

Cannot be used.

(b) FIFO mode

The reception timeout interrupt is generated if data is stored in receive FIFO when the next data does not come (start bit is not detected) even after the next data reception wait time specified by the UBnTC4 to UBnTC0 bits of the UBnFIC1 register has elapsed, when the timeout counter function is used (UBnTCE bit = 1 in the UBnFIC1 register).

The reception timeout interrupt is not generated while reception is disabled.

If receive data of the number set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register is not received, the timing of reading the number of receive data less than the specified number can be set by the reception timeout interrupt.

Since the timeout counter starts counting at start bit detection, a receive timeout interrupt does not occur if data of 1 character has not been received.

11.2.5 Control method

(1) Single mode/FIFO mode

The single mode or FIFO mode can be selected by using the UBnMOD bit of the UBnFIC0 register.

(a) Single mode

- Each of the UBnRX and UBnTX registers consists of 8 bits \times 1 stage.
- When 1 byte of data is received, the UBTIRn interrupt is generated.
- If the next reception operation of UARTBn is completed before the receive data of the UBnRX register is read after the UBTIRn interrupt has been generated, the UBTIREn interrupt is generated and an overrun error occurs.

(b) FIFO mode

- Receive FIFO (UBnRXAP register) consists of 16 bits \times 16 stages and transmit FIFO consists of 8 bits \times 16 stages.
- Receive FIFO can recognize error data by reading the 16-bit UBnRXAP register only when a reception error (parity error or framing error) occurs.
- Transmission is started when transmission is enabled (UBnTXE bit = 1 in the UBnCTL0 register) after transmit data of at least the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register and 16 bytes or less are written to transmit FIFO.
- The pending mode or pointer mode can be selected for the generation timing of the UBTITn and UBTIRn interrupts.

(2) Pending mode/pointer mode

The pending mode or pointer mode can be selected by using the UBnITM and UBnIRM bits of the UBnFIC0 register in the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register).

If transmission is started by writing data of more than double the amount set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register to transmit FIFO, the transmission completion interrupt (UBTITn) may occur more than once. The reception completion interrupt (UBTIRn) may also occur more than once if the number of receive data set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register is 8 bytes or less in receive FIFO. In the pending or pointer mode, it can be specified how an interrupt is handled after it has been held pending.

(a) Pending mode**(i) During transmission (writing to transmit FIFO)**

- If the data of the first transmission completion interrupt (UBTITn) is not written to transmit FIFO after the interrupt has occurred, the second UBTITn interrupt does not occur (is held pending) even if the generation condition of the second UBTITn interrupt is satisfied (when transmit data of the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register is transferred from transmit FIFO to the transmit shift register).

When data for the first UBTITn interrupt is later written to transmit FIFO, the pending UBTITn interrupt is generated^{Note}.

Note The number of pending interrupts is as follows.

When trigger is set to 1 byte (UBnTT3 to UBnTT0 bits of UBnFIC2 register = 0000): 15 times max.

When trigger is set to 2 bytes (UBnTT3 to UBnTT0 bits of UBnFIC2 register = 0001): 7 times max.

:

When trigger is set to 6 bytes (UBnTT3 to UBnTT0 bits of UBnFIC2 register = 0101): 1 time max.

When trigger is set to 7 bytes (UBnTT3 to UBnTT0 bits of UBnFIC2 register = 0110): 1 time max.

When trigger is set to 8 bytes (UBnTT3 to UBnTT0 bits of UBnFIC2 register = 0111): 1 time max.

- In the pending mode, transmit data of the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register is always written to transmit FIFO when the transmission completion interrupt (UBTITn) occurs. Writing data to transmit FIFO is prohibited if the data is more or less than the specified number. If data more or less than the specified number is written, the operation is not guaranteed.
- Fix the UBnTT3 to UBnTT0 bits of the UBnFIC2 register to 0000 (set number of transmit data: 1 byte) to write transmit data to transmit FIFO by DMA. If any other setting is made, the operation is not guaranteed.

(ii) During reception (reading from receive FIFO)

- If data for the first reception completion interrupt (UBTIRn) is not read from receive FIFO, the second UBTIRn interrupt does not occur (is held pending) even if the generation condition of the second UBTIRn is satisfied (if receive data of the number set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register can be read from receive FIFO). When data for the first UBTIRn interrupt is later read from the receive FIFO, the pending UBTIRn interrupt is generated^{Note}.

Note The number of pending interrupts is as follows.

When trigger is set to 1 byte (UBnRT3 to UBnRT0 bits of UBnFIC2 register = 0000): 15 times max.

When trigger is set to 2 bytes (UBnRT3 to UBnRT0 bits of UBnFIC2 register = 0001): 7 times max.

:

When trigger is set to 6 bytes (UBnRT3 to UBnRT0 bits of UBnFIC2 register = 0101): 1 time max.

When trigger is set to 7 bytes (UBnRT3 to UBnRT0 bits of UBnFIC2 register = 0110): 1 time max.

When trigger is set to 8 bytes (UBnRT3 to UBnRT0 bits of UBnFIC2 register = 0111): 1 time max.

- In the pending mode, receive data of the number set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register is always read from receive FIFO when the reception completion interrupt (UBTIRn) occurs. Reading data from receive FIFO is prohibited if the data is more or less than the specified number. If data more or less than the specified number is read, the operation is not guaranteed.
- Fix the UBnRT3 to UBnRT0 bits of the UBnFIC2 register to 0000 (set number of receive data: 1 byte) to read receive data from receive FIFO by DMA. If any other setting is made, the operation is not guaranteed.

(b) Pointer mode**(i) During transmission (writing to transmit FIFO)**

- Each time the data of 1 byte is transferred to transmit shift register n from transmit FIFO, a transmission completion interrupt (UBTITn) occurs.
- In the pointer mode, be sure to fix the UBnTT3 to UBnTT0 bits of the UBnFIC2 register to 0000 (set number of transmit data: 1 byte) as the number of transmit data set as the trigger for transmit FIFO when the transmission completion interrupt (UBTITn) occurs. If any other setting is made, the operation is not guaranteed.
- Writing transmit data to transmit FIFO by DMA is prohibited. The operation is not guaranteed if DMA control is used.
- After the transmission completion interrupt (UBTITn) has been acknowledged, data of the number of vacant bytes of transmit FIFO can be written to transmit FIFO by referencing the UBnFIS1 register.

(ii) During reception (reading from receive FIFO)

- Each time the data of 1 byte is transferred to receive FIFO from receive shift register n, a reception completion interrupt (UBTIRn) occurs.
- In the pointer mode, be sure to fix the UBnRT3 to UBnRT0 bits of the UBnFIC2 register to 0000 (set number of receive data: 1 byte) as the number of receive data set as the trigger for receive FIFO when the reception completion interrupt (UBTIRn) occurs. If any other setting is made, the operation is not guaranteed.
- Reading receive data from receive FIFO by DMA is prohibited. The operation is not guaranteed if DMA control is used.
- After the reception completion interrupt (UBTIRn) has been acknowledged, data of the number of bytes stored in receive FIFO can be read from receive FIFO by referencing the UBnFIS0 register. In some cases, however, data is not stored in receive FIFO even though the UBTIRn interrupt is generated (UBnRB4 to UBnRB0 bits = 00000 in the UBnFIS0 register). In these cases, do not read data from receive FIFO. Always read data from receive FIFO when the number of bytes stored in receive FIFO is 1 byte or more (UBnRB4 to UBnRB0 bits = other than 00000).

11.2.6 Operation**(1) Data format**

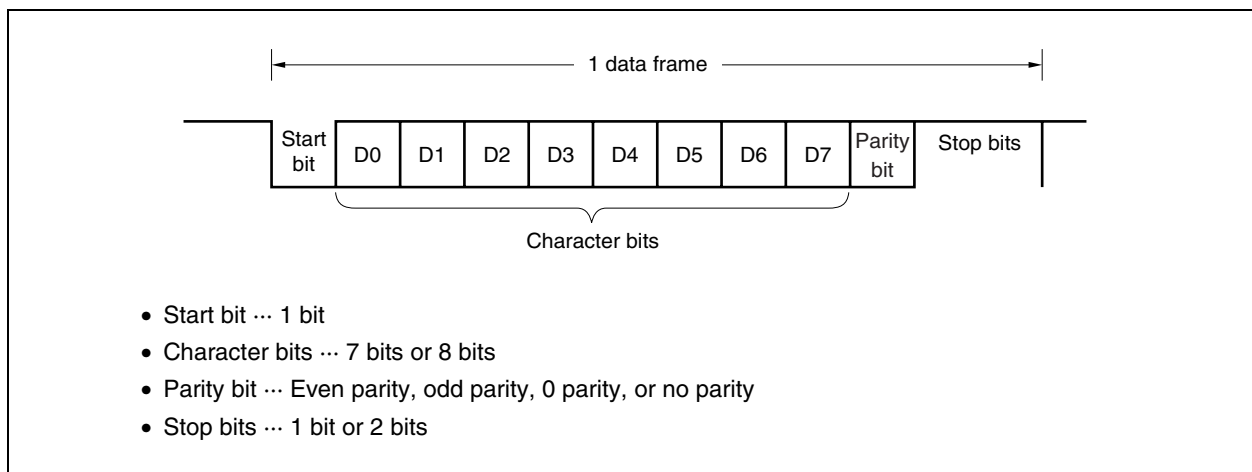

Full-duplex serial data transmission and reception can be performed.

The transmit/receive data format consists of one data frame containing a start bit, character bits, a parity bit, and stop bits as shown in Figure 11-2.

The character bit length within one data frame, the type of parity, and the stop bit length are specified by the UARTBn control register 0 (UBnCTL0) (n = 0, 1).

Also, data is transferred with LSB first/MSB first.

Figure 11-2. Asynchronous Serial Interface Transmit/Receive Data Format (LSB-First Transfer)

(2) Transmit operation

In the single mode (UBnMOD bit = 0 in the UBnFIC0 register), transmission is enabled when the UBnTXE bit of the UBnCTL0 register is set to 1, and transmission is started when transmit data is written to the UBnTX register (n = 0, 1).

In the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register), transmission is started when transmit data of at least the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register and 16 bytes or less is written to transmit FIFO and then the UBnTXE bit is set to 1.

Caution Setting the UBnTXE bit of the UBnCTL0 register to 1 before writing transmit data to transmit FIFO in the FIFO mode is prohibited. The operation is not guaranteed if this setting is made.

(a) Transmission enabled state

This state is set by the UBnTXE bit in the UBnCTL0 register (n = 0, 1).

- UBnTXE = 1: Transmission enabled state
- UBnTXE = 0: Transmission disabled state

However, when the transmission enabled state is set, to use UARTB0, which shares pins with clocked serial interface 30 (CSI30), the CSICAE0 bit of clocked serial interface mode register 30 (CSIM30) should be cleared to 0.

Since UARTBn does not have a CTS (transmission enabled signal) input pin, a port should be used to confirm whether the destination is in the reception enabled state.

(b) Starting a transmit operation

• In single mode (UBnMOD bit = 0 in UBnFIC0 register)

In the single mode, transmission is started when transmit data is written to the UBnTX register while transmission is enabled (n = 0, 1).

• In FIFO mode (UBnMOD bit = 1 in UBnFIC0 register)

In the FIFO mode, transmission is started when transmit data of at least the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register and 16 bytes or less is written to transmit FIFO and then transmission is enabled (UBnTXE bit = 1).

Data in transmit data register n (UBnTX register in single mode or transmit FIFO in the FIFO mode) is transferred to transmit shift register n when transmission is started. Then, transmit shift register n outputs data to the TXDn pin sequentially beginning with the LSB (the transmit data is transferred sequentially starting with the start bit). The start bit, parity bit, and stop bits are added automatically (n = 0, 1).

(c) Transmission interrupt request**(i) Transmission completion interrupt (UBTITn)**

- **In single mode (UBnMOD bit = 0 in UBnFIC0 register)**

In the single mode, the transmission completion interrupt (UBTITn) occurs when transmit data can be written to the UBnTX register (when 1 byte of data is transferred from the UBnTX register to transmit shift register n) (n = 0, 1).

- **In FIFO mode (UBnMOD bit = 1 in UBnFIC0 register)**

In the FIFO mode, the UBTITn interrupt occurs when transmit data of the number set as the trigger specified by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register is transferred from transmit FIFO to transmit shift register n (if transmit data of the number set as the trigger can be written) (n = 0, 1).

- **If pending mode is specified (UBnITM bit = 0 in UBnFIC0 register) in FIFO mode**

If the pending mode is specified in the FIFO mode, the second UBTITn interrupt is held pending after the first UBTITn interrupt has occurred, until as many transmit data as the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register are written to transmit FIFO, even if the generation condition of the second UBTITn interrupt is satisfied. When as many transmit data as the number set as the trigger are written to transmit FIFO in response to the first UBTITn interrupt, the second pending UBTITn interrupt is generated (n = 0, 1).

- **If pointer mode is specified (UBnITM bit = 1 in UBnFIC0 register) in FIFO mode**

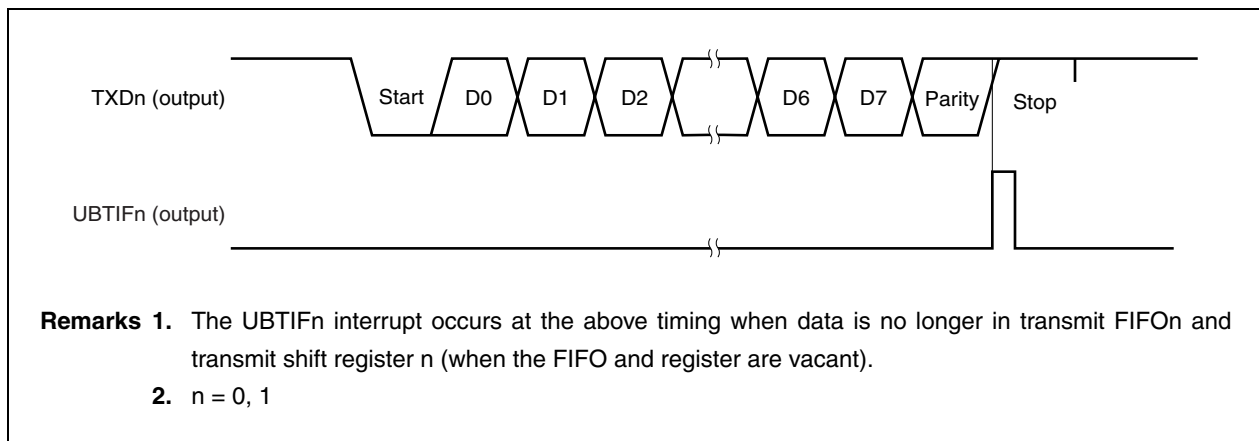

If the pointer mode is specified in the FIFO mode, the second UBTITn interrupt occurs when the generation condition of the second UBTITn interrupt is satisfied even if as many transmit data as the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register are not written to transmit FIFO when the first UBTITn interrupt occurs (n = 0, 1).

(ii) FIFO transmission completion interrupt (UBTIFn)

The FIFO transmission completion interrupt (UBTIFn) occurs when no more data is in transmit FIFO and transmit shift register n in the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register) (n = 0, 1). After the UBTIFn interrupt has occurred, clear the pending UBTITn interrupt in the pending mode (UBnITM bit = 0 in the UBnFIC0 register) by clearing the FIFO (UBnTFC bit = 1 in the UBnFIC0 register). If the UBTIFn interrupt occurs because writing the next transmit data to transmit FIFO is delayed (if all transmit data have not been transmitted), do not clear the FIFO.

If the data to be transmitted next has not been written to transmit data register n, the transmit operation is suspended.

Caution In the single mode, the transmission completion interrupt (UBTITn) occurs when the UBnTX register becomes empty (when 1 byte of data is transferred from the UBnTX register to transmit shift register n). In the FIFO mode, the FIFO transmission completion interrupt (UBTIFn) occurs when data is no longer in transmit FIFO and transmit shift register n (when the FIFO and register are vacant). However, the UBTITn interrupt or UBTIFn interrupt is not generated if transmit data register n becomes empty due to $\overline{\text{RESET}}$ input.

Figure 11-3. Timing of Asynchronous Serial Interface Transmission Completion Interrupt (UBTITn)**Figure 11-4. Timing of Asynchronous Serial Interface FIFO Transmission Completion Interrupt (UBTIFn)**

(3) Continuous transmission operation

- **In single mode (UBnMOD bit = 0 in UBnFIC0 register)**

In the single mode, the next data can be written to the UBnTX register as soon as transmit shift register n has started a shift operation ($n = 0, 1$). The timing of transfer can be identified by the transmission completion interrupt (UBTITn). By writing the next transmit data to the UBnTX register via the UBTITn interrupt within one data frame transmission period, data can be transmitted without an interval and an efficient communication rate can be realized.

Caution Confirm that the UBnTSF bit of the UBnSTR register is 0 before executing initialization during transmission processing. If initialization is executed while the UBnTSF bit is 1, the transmit data is not guaranteed.

- **If pending mode is specified (UBnITM bit = 0 in UBnFIC0 register) in FIFO mode**

If transmit data of at least the number set as the transmit trigger by UBnTT3 to UBnTT0 bits of the UBnFIC2 register and 16 bytes or less is written to transmit FIFO_n, transmission starts.

If the pending mode is specified in the FIFO mode, as many of the next transmit data as the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register can be written to transmit FIFO_n as soon as transmit shift register n has started shifting the last data of the specified number of data. The timing of transfer can be identified by the UBTITn interrupt. By writing as many of the next transmit data as the number set as the trigger to transmit FIFO_n or writing the data to the FIFO within the transmission period of the data in transmit FIFO_n via the UBTITn interrupt, data can be transmitted without an interval and an efficient communication rate can be realized.

Caution Confirm that the UBnTSF bit of the UBnSTR register is 0 before executing initialization during transmission processing (this can also be done by the FIFO transmission completion interrupt (UBTIFn)). If initialization is executed while the UBnTSF bit is 1, the transmit data is not guaranteed. To write transmit data to transmit FIFO_n by DMA, set the number of transmit data specified as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register to 1 byte; otherwise the operation will not be guaranteed.

- **If pointer mode is specified (UBnITM bit = 1 in UBnFIC0 register) in FIFO mode**

If the pointer mode is specified in the FIFO mode, a UBTITn interrupt occurs and the next data can be written to transmit FIFO_n as soon as transmit shift register n has started shifting the number of transmit data set as the trigger. At this time, as many data as the number of vacant bytes of transmit FIFO_n can be written by referencing the UBnFIS1 register. The timing of transfer can be identified by the UBTITn interrupt. By writing as many of the next transmit data as the number specified as the trigger to transmit FIFO_n (= 1 byte) or writing the data to the FIFO within the transmission period of the data in transmit FIFO_n via the UBTITn interrupt, data can be transmitted without an interval and an efficient communication rate can be realized.

Caution Confirm that the UBnTSF bit of the UBnSTR register is 0 before executing initialization during transmission processing (this can also be done by the FIFO transmission completion interrupt (UBTIFn)). If initialization is executed while the UBnTSF bit is 1, the transmit data is not guaranteed.

(4) Receive operation

The awaiting reception state is set by setting the UBnPWR bit to 1 in the UBnCTL0 register and then setting the UBnRXE bit to 1 in the UBnCTL0 register (n = 0, 1). RXDn pin sampling begins and a start bit is detected. When the start bit is detected, the receive operation begins, and data is stored sequentially in receive shift register n according to the baud rate that was set.

In the single mode (UBnMOD bit = 0 in the UBnFIC0 register), a reception completion interrupt (UBTIRn) is generated each time the reception of one frame of data is completed. Normally, the receive data is transferred from the UBnRX register to memory by this interrupt servicing.

In the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register), the UBTIRn interrupt occurs when as many receive data as the number set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register are transferred to receive FIFO n.

If the pending mode is specified (UBnIRM bit = 0 in the UBnFIC0 register) in the FIFO mode, as many receive data as the number set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register can be read from receive FIFO n.

If the pointer mode is specified (UBnIRM bit = 1 in the UBnFIC0 register) in the FIFO mode, as many data as the number of bytes stored in receive FIFO n (0 bytes or more) can be read from receive FIFO n by referencing the number of receive data specified as the trigger by the UBnRT3 to UBnRT0 bits (1 byte) or the UBnFIS0 register.

Caution If the pointer mode is specified in the FIFO mode and if as many data as the number of bytes stored in receive FIFO n are read by referencing the UBnFIS0 register, no data may be stored in receive FIFO n (UBnRB4 to UBnRB0 bits = 00000 in the UBnFIS0 register) even though the reception completion interrupt (UBTIRn) has occurred. In this case, do not read data from receive FIFO n. Be sure to read data from receive FIFO n after confirming that the number of bytes stored in receive FIFO n = 1 byte or more (UBnRB4 to UBnRB0 bits = other than 00000).

(a) Reception enabled state

This state is set by the UBnRXE bit in the UBnCTL0 register (n = 0, 1).

- UBnRXE = 1: Reception enabled state
- UBnRXE = 0: Reception disabled state

However, when the reception enabled state is set, to use UARTB0, which shares pins with clocked serial interface 30 (CSI30), the operation of CSI30 must be disabled by clearing the CSICAE0 bit of clocked serial interface mode register 30 (CSIM30) to 0 (n = 0, 1).

In the reception disabled state, the reception hardware stands by in the initial state. At this time, the reception completion interrupt or reception error interrupt does not occur, and the contents of receive data register n (UBnRX register in the single mode or receive FIFO n in the FIFO mode (UBnRXAP register)) are retained.

(b) Starting a receive operation

A receive operation is started by the detection of a start bit.

The RXDn pin is sampled using the serial clock from UARTBn control register 2 (UBnCTL2) (n = 0, 1).

(c) Reception completion interrupt**(i) Reception completion interrupt (UBTIRn)****• In single mode (UBnMOD bit = 0 in UBnFIC0 register)**

When UBnRXE bit = 1 in the UBnCTL0 register and the reception of one frame of data is completed (the stop bit is detected) in the single mode, a reception completion interrupt request (UBTIRn) is generated and the receive data in receive shift register n is transferred to the UBnRX register at the same time (n = 0, 1).

Also, if an overrun error occurs, the receive data at that time is not transferred to the UBnRX register, and a reception error interrupt (UBTIREn) is generated.

If a parity error or framing error occurs during the reception operation, the reception operation continues up to the position at which the stop bit is received. After completion of reception, an UBTIREn interrupt occurs (the receive data in receive shift register n is transferred to the UBnRX register).

If the UBnRXE bit is reset (0) during a receive operation, the receive operation is immediately stopped. At this time, the contents of the UBnRX register remain unchanged, the contents of the UARTBn status register (UBnSTR) are cleared, and the UBTIRn and UBTIREn interrupts do not occur.

No UBTIRn interrupt is generated when the UBnRXE bit = 0 (reception is disabled).

• In FIFO mode (UBnMOD bit = 1 in UBnFIC0 register)

In the FIFO mode, the reception completion interrupt (UBTIRn) occurs when data of one frame has been received (stop bit is detected) and when as many receive data as the number specified as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register are transferred from receive shift register n to receive FIFO n (n = 0, 1). If an overflow error occurs, the receive data is not transferred to receive FIFO n and the reception error interrupt (UBTIREn) occurs.

If a parity error or framing error occurs during reception, reception continues up to the reception position of the stop bit. After reception has been completed, the UBTIREn interrupt occurs and the receive data in receive shift register n is transferred to receive FIFO n. At this time, error information is appended as the UBnPEF or UBnFEF bit = 1 in the UBnRXAP register. If the UBTIREn interrupt occurs, the error data can be recognized by reading receive FIFO n as a 16-bit register, UBnRXAP.

(ii) Reception timeout interrupt (UBTITOn) (in FIFO mode only)

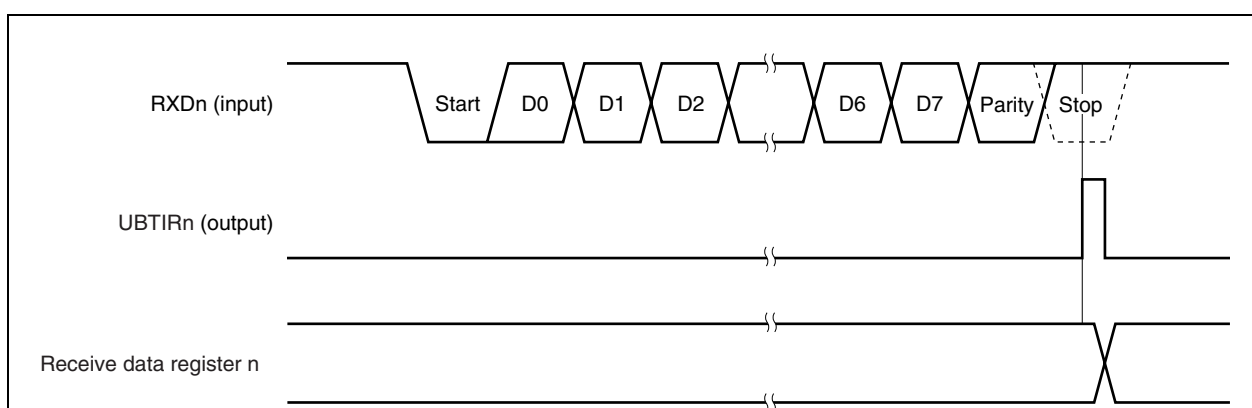

When the timeout counter function (UBnTCE bit = 1 in the UBnFIC1 register) is used in the FIFO mode, the reception timeout interrupt (UBTITOn) occurs if the next data does not come even after the next data reception wait time specified by the UBnTC4 to UBnTC0 bits of the UBnFIC1 register has elapsed and if data is stored in receive FIFO_n (n = 0, 1).

The UBTITOn interrupt does not occur while reception is disabled.

If as many receive data as the number set as the trigger by the UBnRT3 to UBnRT0 bits of the UBnFIC2 register are not received, the timing of reading less receive data than the specified number can be set by the UBTITOn interrupt.

Since the timeout counter starts counting at start bit detection, a receive timeout interrupt does not occur if data of 1 character has not been received.

Figure 11-5. Timing of Asynchronous Serial Interface Reception Completion Interrupt (UBTIRn)

Cautions 1. Be sure to read all the data (the number of data indicated by the UBnRB4 to UBnRB0 bits of the UBnFIS0 register) stored in receive data register n (UBnRX register in the single mode or receive FIFO_n in the FIFO mode (UBnRXAP register)) even when a reception error occurs.

Unless receive data register n is read, an overrun error occurs when the next data is received, causing the reception error status to persist.

If the pending mode is specified in the FIFO mode, however, be sure to clear the FIFO (UBnRFC bit = 1 in the UBnFIC0 register) after reading the data stored in receive FIFO_n.

In the FIFO mode, the FIFO can be cleared even without reading the data stored in receive FIFO_n.

If a parity error or framing error occurs in the FIFO mode, the UBnRXAP register can be read in 16-bit (halfword) units.

2. Data is always received with one stop bit.

A second stop bit is ignored.

Remark n = 0, 1

(5) Reception error

In the single mode (UBnMOD bit = 0 in the UBnFIC0 register), the three types of errors that can occur during a receive operation are a parity error, framing error, and overrun error. In the FIFO mode (UBnMOD bit = 1 in the UBnFIC0 register), the three types of errors that can occur during a receive operation are a parity error, framing error, and overflow error.

As a result of data reception, the UBnPE, UBnFE, or UBnOVE bit of the UBnSTR register is set to 1 if a parity error, framing error, or overrun error occurs in the single mode. The UBnOVF bit of the UBnSTR register is set to 1 if an overflow error occurs in the FIFO mode. The UBnPEF or UBnFEF bit of the UBnRXAP register is set to 1 if a parity error or framing error occurs in the FIFO mode. At the same time, a reception error interrupt (UBTIREn) occurs. The contents of the error can be detected by reading the contents of the UBnSTR or UBnRXAP register. The contents of the UBnSTR register are reset when 0 is written to the UBnOVF, UBnPE, UBnFE, or UBnOVE bit, or the UBnPWR or UBnRXE bit of the UBnCTL0 register. The contents of the UBnRXAP register are reset when 0 is written to the UBnPWR bit of the UBnCTL0 register.

Table 11-3. Reception Error Causes

Error Flag	Valid Operation Mode	Error Flag	Reception Error	Cause
UBnPE	Single mode	UBnPE	Parity error	The parity specification during transmission does not match the parity of the receive data
UBnFE		UBnFE	Framing error	No stop bit detected
UBnOVE		UBnOVE	Overrun error	The reception of the next data is completed before data is read from the UBnRX register
UBnOVF	FIFO mode	UBnOVF	Overflow error	The reception of the next data is completed while receive FIFO is full and before data is read.
UBnPEF		UBnPEF	Parity error	The parity specification during transmission does not match the parity of the data to be received.
UBnFEF		UBnFEF	Framing error	The stop bit is not detected when the target data is loaded.

Remark n = 0, 1

(6) Parity types and corresponding operation

A parity bit is used to detect a bit error in communication data. Normally, the same type of parity bit is used at the transmission and reception sides.

(a) Even parity**(i) During transmission**

The parity bit is controlled so that the number of bits with the value "1" within the transmit data including the parity bit is even. The parity bit value is as follows.

- If the number of bits with the value "1" within the transmit data is odd: 1
- If the number of bits with the value "1" within the transmit data is even: 0

(ii) During reception

The number of bits with the value "1" within the receive data including the parity bit is counted, and a parity error is generated if this number is odd.

(b) Odd parity**(i) During transmission**

In contrast to even parity, the parity bit is controlled so that the number of bits with the value "1" within the transmit data including the parity bit is odd. The parity bit value is as follows.

- If the number of bits with the value "1" within the transmit data is odd: 0
- If the number of bits with the value "1" within the transmit data is even: 1

(ii) During reception

The number of bits with the value "1" within the receive data including the parity bit is counted, and a parity error is generated if this number is even.

(c) 0 parity

During transmission the parity bit is set to "0" regardless of the transmit data.

During reception, no parity bit check is performed. Therefore, no parity error is generated regardless of whether the parity bit is "0" or "1".

(d) No parity

No parity bit is added to the transmit data.

During reception, the receive operation is performed as if there were no parity bit. Since there is no parity bit, no parity error is generated.

(7) Receive data noise filter

The RXDn signal is sampled at the rising edge of the input clock ($f_x/4$) (f_x : main clock). If the same sampling value is obtained twice, the match detector output changes, and this output is sampled as input data. Therefore, data not exceeding one clock width is judged to be noise and is not delivered to the internal circuit (see **Figure 11-7**).

Also, since the circuit is configured as shown in Figure 11-6, internal processing during a receive operation is delayed by up to 2 clocks according to the external signal status.

Figure 11-6. Noise Filter Circuit

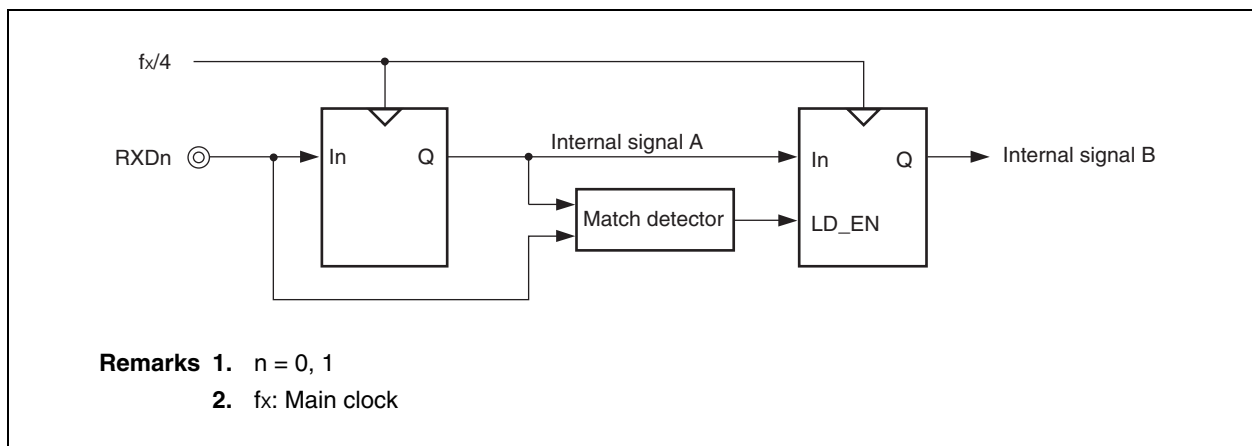

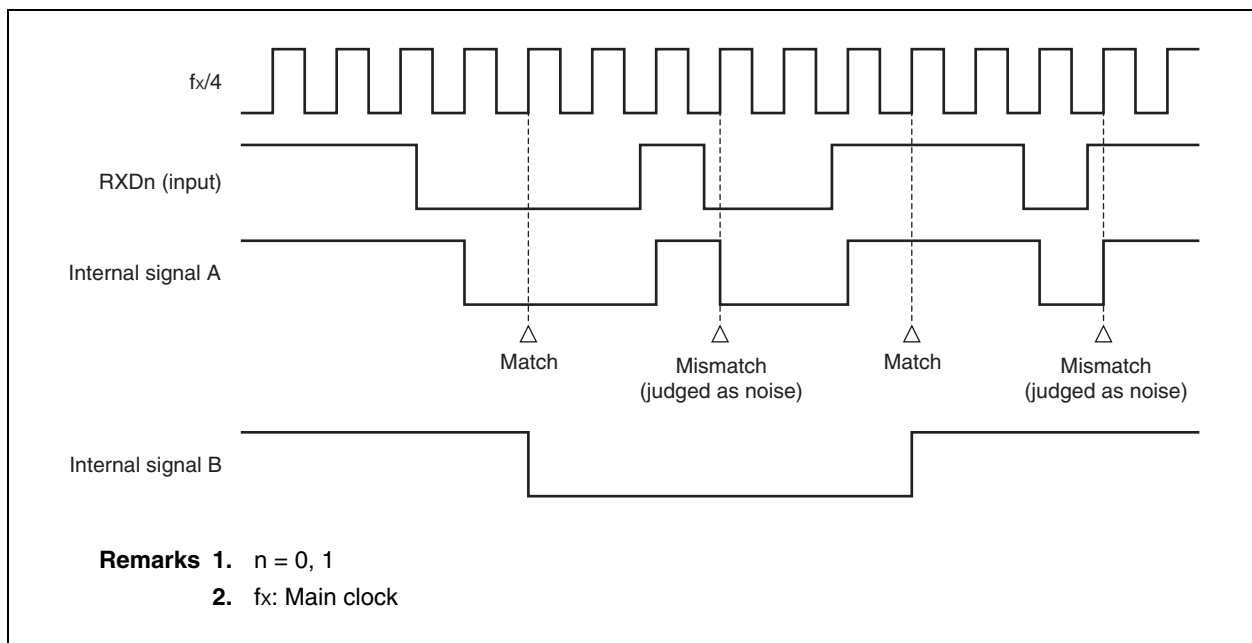

Figure 11-7. Timing of RXDn Signal Judged as Noise

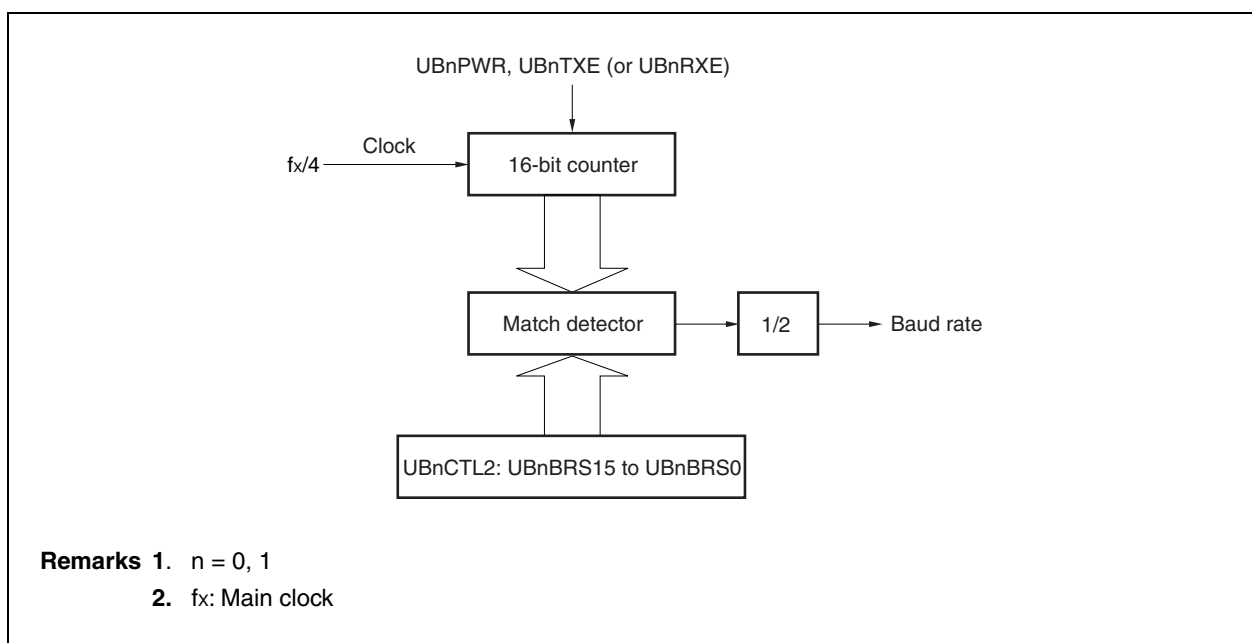

11.2.7 Dedicated baud rate generators 0, 1 (BRG0, BRG1)

A dedicated baud rate generator, which consists of a 16-bit programmable counter, generates serial clocks during transmission/reception in UARTBn. The dedicated baud rate generator output can be selected as the serial clock for each channel.

Separate 16-bit counters exist for transmission and for reception. The baud rate for transmission/reception is the same at the same channel.

(1) Baud rate generator configuration

Figure 11-8. Baud Rate Generator Configuration

(a) Base clock (Clock)

When $UBnPWR$ bit = 1 in the $UBnCTL0$ register, the input clock ($f_x/4$) is supplied to the transmission/reception unit (f_x : main clock). This clock is called the base clock. When the $UBnPWR$ bit = 0, the clock signal is fixed at low level.

(2) Serial clock generation

A serial clock can be generated according to the settings of the UBnCTL2 register (n = 0, 1).

The 16-bit counter divisor value can be selected according to the UBnBRS15 to UBnBRS0 bits of the UBnCTL2 register.

(a) Baud rate

The baud rate is the value obtained according to the following formula.

$$\text{Baud rate} = \frac{\text{Base clock frequency}}{2 \times k} \text{ [bps]}$$

Base clock frequency = $f_x/4$ (f_x : main clock)

k = Value set according to UBnBRS15 to UBnBRS0 bits of UBnCTL2 register (k = 4, 5, 6, ..., 65,535)

(b) Baud rate error

The baud rate error is obtained according to the following formula.

$$\text{Error (\%)} = \left(\frac{\text{Actual baud rate (baud rate with error)}}{\text{Desired baud rate (normal baud rate)}} - 1 \right) \times 100 \text{ [\%]}$$

Cautions 1. Make sure that the baud rate error during transmission does not exceed the allowable error of the reception destination.

2. Make sure that the baud rate error during reception is within the allowable baud rate range during reception, which is described in paragraph (4).

Example: Main clock (f_x) = 200 MHz = 200,000,000 Hz

Settings of UBnBRS15 to UBnBRS0 bits in UBnCTL2 register = 0000000010100011B

(k = 163)

Target baud rate = 153,600 bps

Baud rate = $200 \text{ M}/4/(2 \times 163)$

= $200,000,000/4/(2 \times 163) = 153,374 \text{ [bps]}$

Error = $(153,374/153,600 - 1) \times 100$

= -0.147 [%]

(3) Baud rate setting example**Table 11-4. Baud Rate Generator Setting Data**

Baud Rate (bps)	fx = 200 MHz		fx = 150 MHz	
	k	ERR	k	ERR
300	–	–	62,500	0.000
600	41,667	–0.001	31,250	0.000
1,200	20,833	0.002	15,625	0.000
2,400	10,417	–0.003	7,813	–0.006
4,800	5,208	0.006	3,906	0.006
9,600	2,604	0.006	1,953	0.006
19,200	1,302	0.006	977	–0.045
31,250	800	0.000	600	0.000
38,400	651	0.006	488	0.058
76,800	326	–0.147	244	0.058
153,600	163	–0.147	122	0.058
312,500	80	0.000	60	0.000

Caution The maximum allowable frequency of the main clock (fx) is 200 MHz.

Remark fx: Main clock
k: Settings of UBnBRS15 to UBnBRS0 bits in UBnCTL2 register (n = 0, 1)
ERR: Baud rate error [%]

(4) Allowable baud rate range during reception

The degree to which a discrepancy from the transmission destination's baud rate is allowed during reception is shown below.

Caution The equations described below should be used to set the baud rate error during reception so that it always is within the allowable error range.

Figure 11-9. Allowable Baud Rate Range During Reception

As shown in Figure 11-9, after the start bit is detected, the receive data latch timing is determined according to the counter that was set by the UBnCTL2 register. If all data up to the final data (stop bit) is in time for this latch timing, the data can be received normally.

Applying this to 11-bit reception is, theoretically, as follows.

$$FL = (\text{Brate})^{-1}$$

Brate: UARTBn baud rate ($n = 0, 1$)

k: UBnCTL2 setting value ($n = 0, 1$)

FL: 1-bit data length

Latch timing margin: 2 clocks

$$\text{Minimum allowable value: } FL_{\min} = 11 \times FL - \frac{k - 2}{2k} \times FL = \frac{21k + 2}{2k} FL$$

Therefore, the maximum baud rate that can be received at the transfer destination is as follows.

$$BR_{\max} = (FL_{\min}/11)^{-1} = \frac{22k}{21k + 2} \text{ Brate}$$

Similarly, the maximum allowable value can be obtained as follows.

$$\begin{aligned} \frac{10}{11} \times FL_{\max} &= 11 \times FL - \frac{k + 2}{2 \times k} \times FL = \frac{21k - 2}{2 \times k} FL \\ FL_{\max} &= \frac{21k - 2}{20k} FL \times 11 \end{aligned}$$

Therefore, the minimum baud rate that can be received at the transfer destination is as follows.

$$BR_{\min} = (FL_{\max}/11)^{-1} = \frac{20k}{21k - 2} \text{ Brate}$$

The allowable baud rate error of UARTB_n and the transfer destination can be obtained as follows from the expressions described above for computing the minimum and maximum baud rate values.

Table 11-5. Maximum and Minimum Allowable Baud Rate Error

Division Ratio (k)	Maximum Allowable Baud Rate Error	Minimum Allowable Baud Rate Error
4	+2.33 %	-2.44
8	+3.53 %	-3.61
16	+4.14 %	-4.19
32	+4.45 %	-4.48
64	+4.61 %	-4.62
128	+4.68 %	-4.69
256	+4.72 %	-4.73
512	+4.74 %	-4.74
1,024	+4.75 %	-4.75
2,048	+4.76 %	-4.76
4,096	+4.76 %	-4.76
8,192	+4.76 %	-4.76
16,384	+4.76 %	-4.76
32,768	+4.76 %	-4.76
65,535	+4.76 %	-4.76

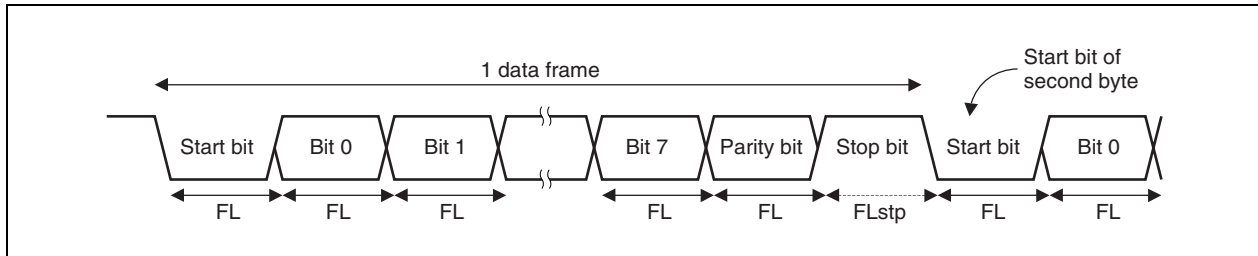

Remarks 1. The reception precision depends on the number of bits in one frame, the base clock frequency, and the division ratio (k). The higher the base clock frequency and the larger the division ratio (k), the higher the precision.

2. k: UB_nCTL2 setting value (n = 0, 1)

(5) Transfer rate during continuous transmission

During continuous transmission, the transfer rate from a stop bit to the next start bit is extended two clocks longer than normal. However, on the reception side, the transfer result is not affected since the timing is initialized by the detection of the start bit.

Figure 11-10. Transfer Rate During Continuous Transmission

Representing the 1-bit data length by FL, the stop bit length by FLstp, and the base clock frequency by $f_x/4$ (f_x : main clock) yields the following equation.

$$FL_{stp} = FL + 2/(f_x/4)$$

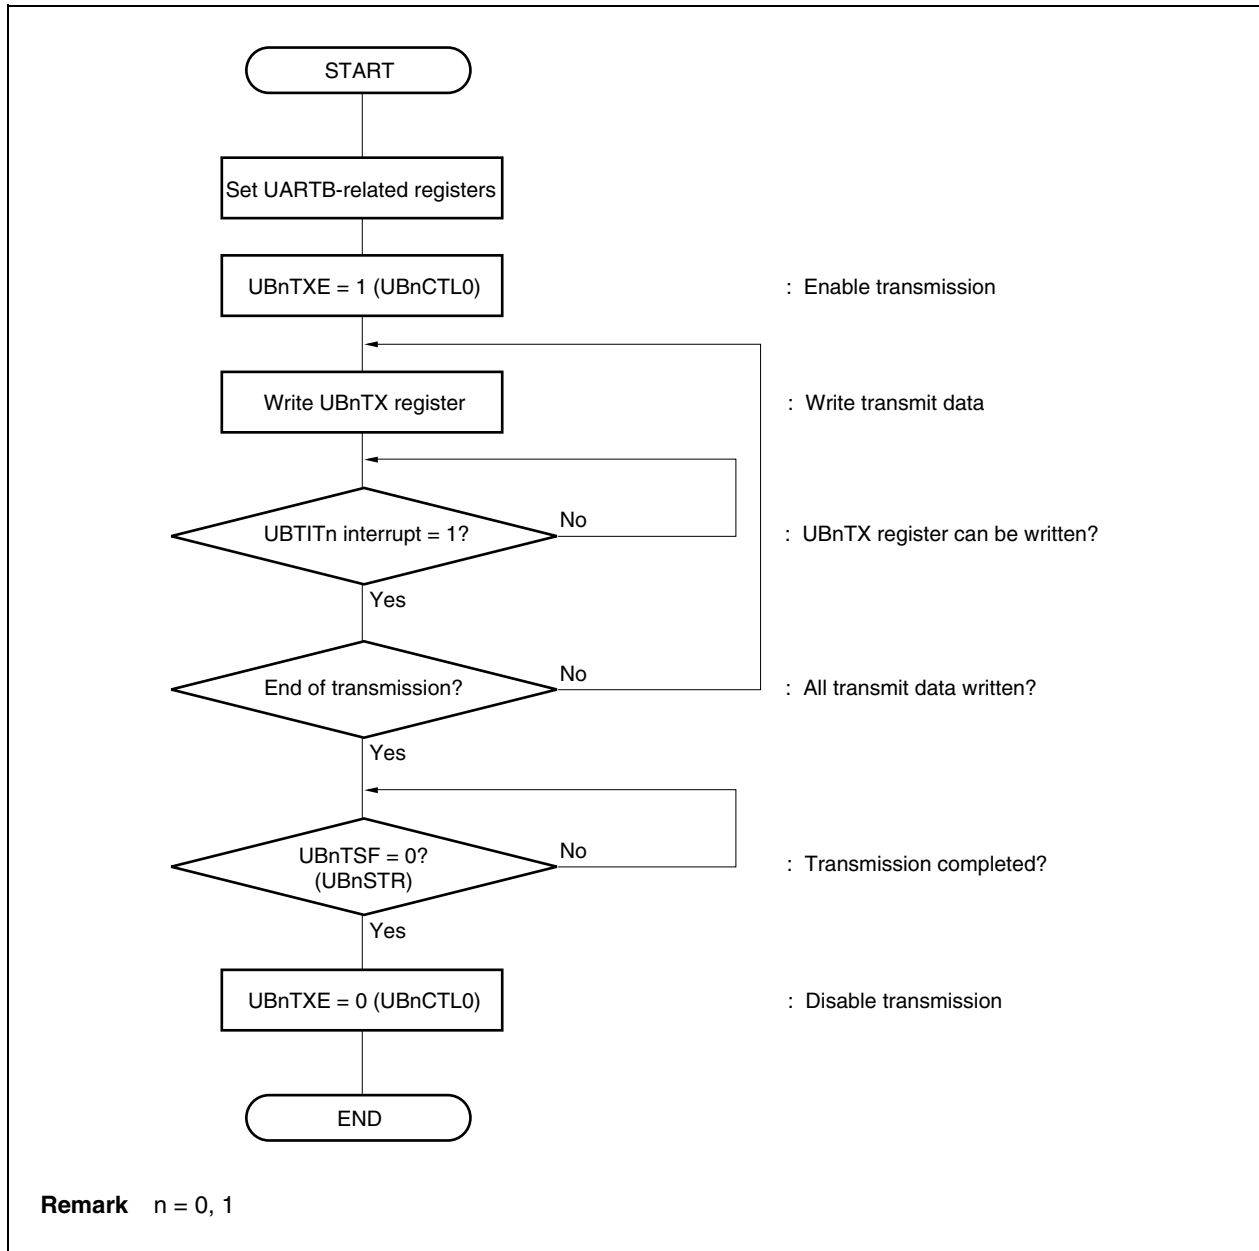

Therefore, the transfer rate during continuous transmission is as follows.

$$\text{Transfer rate} = 11 \times FL + 2/(f_x/4)$$

11.2.8 Control flow

(5) Example of continuous transmission processing flow in FIFO mode (CPU control)

Figure 11-15. Example of Continuous Transmission Processing Flow in FIFO Mode (CPU Control)

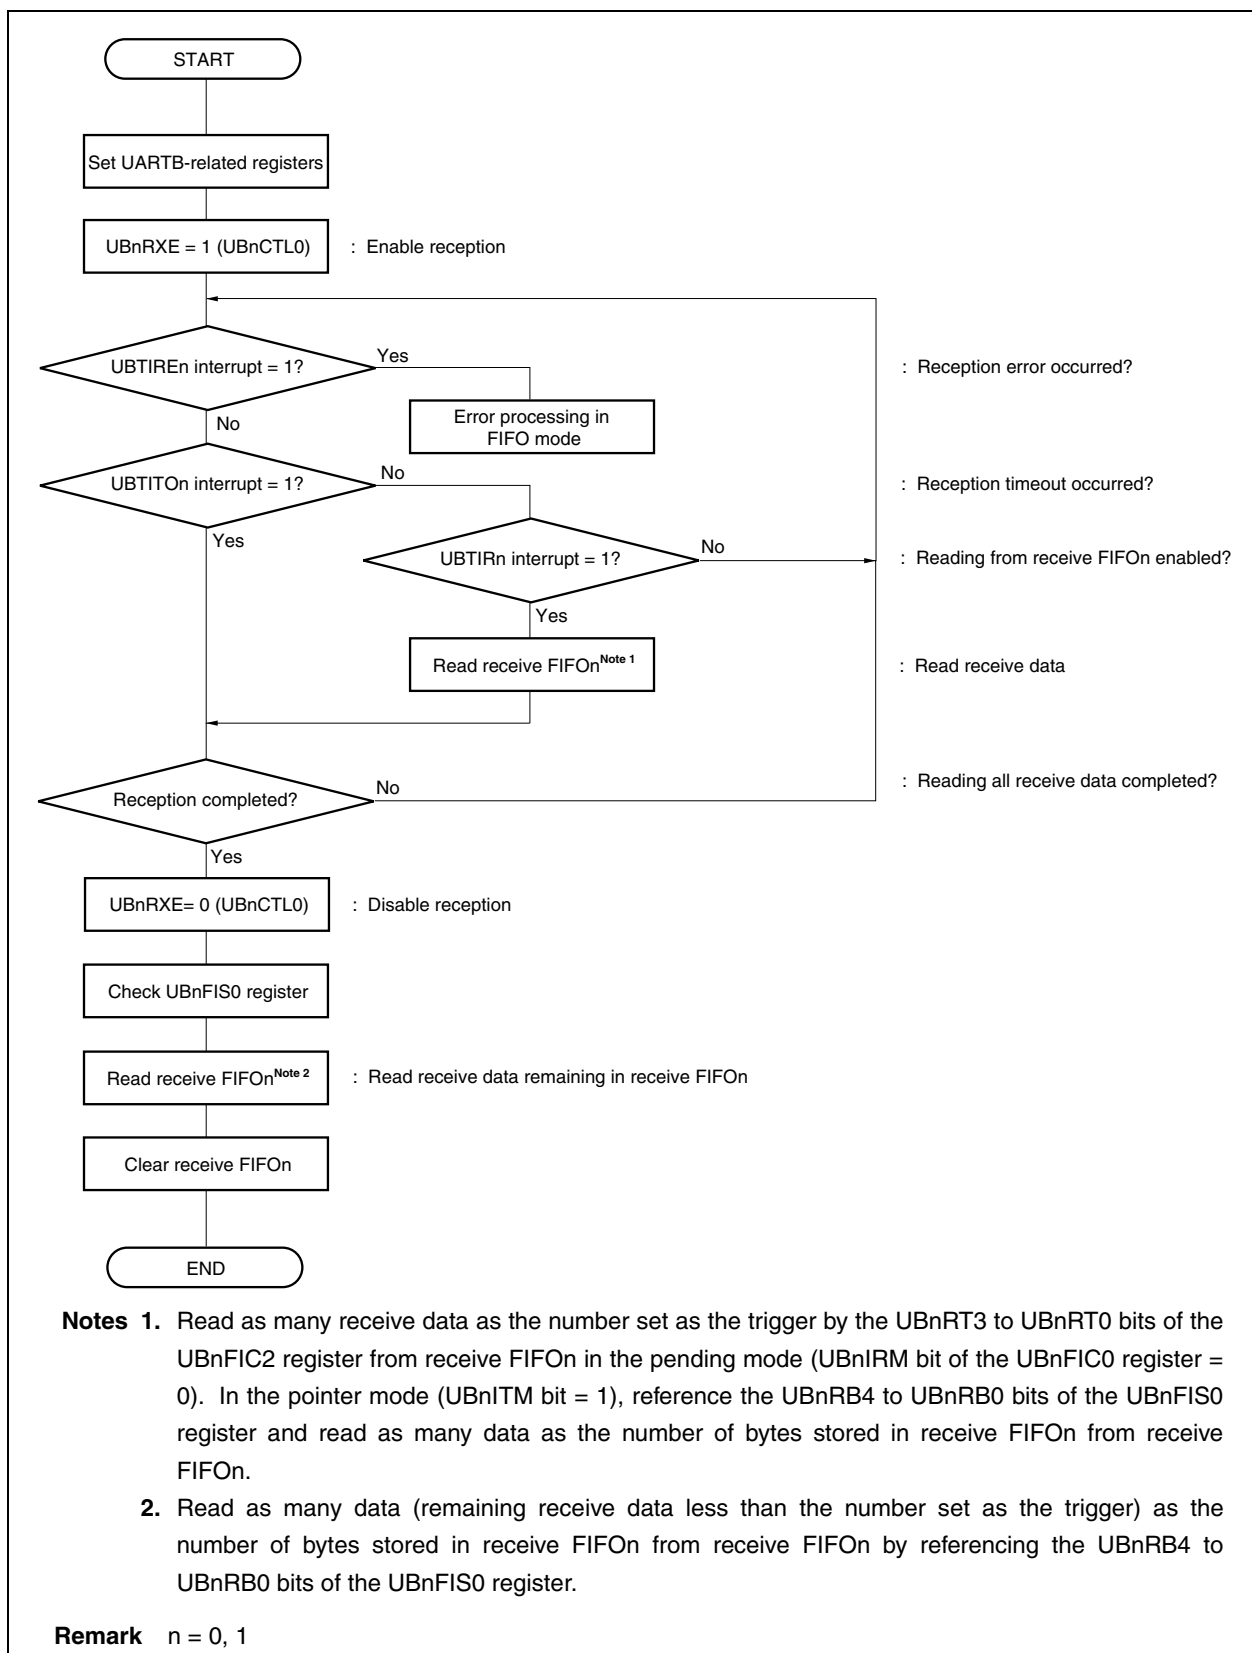

- Notes**
1. Write more transmit data than the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register to transmit FIFO n.
 2. This is the case where transmission is completed (transmit FIFO n and transmit shift register n become empty) before the next transmit data is written. To continue data transmission, clear the UBTIFn and UBTITn interrupts and write the next data to transmit FIFO n.
 3. In the pending mode (UBnITM bit of the UBnFIC0 register = 0), write as many transmit data as the number set as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register to transmit FIFO n. In the pointer mode (UBnITM bit = 1), reference the UBnTB4 to UBnTB0 bits of the UBnFIS1 register and write as many data as the number of vacant bytes in transmit FIFO n to transmit FIFO n. Write 16-byte data to fully use the 8-bit × 16-stage FIFO function.

Remark n = 0, 1

Figure 11-21. Example of Reception Error Processing Flow in FIFO Mode (2)

11.2.9 Cautions

Cautions concerning UARTB are shown below.

(1) When supply clock to UARTBn is stopped

When the supply of clocks to UARTBn is stopped (for example, IDLE mode), operation stops with each register retaining the value it had immediately before the supply of clocks was stopped. The TXDn pin output also holds and outputs the value it had immediately before the supply of clocks was stopped. However, operation is not guaranteed after the supply of clocks is restarted. Therefore, after the supply of clocks is restarted, the circuits should be initialized by setting the UBnPWR bit = 0, UBnRXE bit = 0, and UBnTXE bit = 0.

(2) Caution on setting UBnCTL0 register

- When using UARTBn, set the external pins related to the UARTBn function to the control mode and set the UBnCTL2 register. Then set the UBnPWR bit of the UBnCTL0 register to 1 before setting the other bits.
- Be sure to input a high level to the RXDn pin when setting the external pins related to the UARTBn function to the control mode. If a low level is input, it is judged that a falling edge is input after the UBnRXE bit of the UBnCTL0 register has been set to 1, and reception may be started.

(3) Caution on setting UBnFIC2 register

Be sure to clear the UBnTXE bit (to disable transmission) and UBnRXE bit (to disable reception) of the UBnCTL0 register to 0 before writing data to the UBnFIC2 register. If data is written to the UBnFIC2 register with the UBnTXE or UBnRXE bit set to 1, the operation is not guaranteed.

(4) Transmission interrupt request signal

In the single mode, the transmission completion interrupt (UBTITn) occurs when the UBnTX register becomes empty (when 1 byte of data is transferred from the UBnTX register to transmit shift register n). In the FIFO mode, the FIFO transmission completion interrupt (UBTIFn) occurs when data is no longer in transmit FIFO n and transmit shift register n (when the FIFO and register are vacant). However, the UBTITn interrupt or UBTIFn interrupt does not occur if transmit data register n becomes empty due to $\overline{\text{RESET}}$ input.

(5) Initialization during continuous transmission in single mode

Confirm that the UBnTSF bit of the UBnSTR register is 0 before executing initialization during transmission processing. If initialization is executed while the UBnTSF bit is 1, the transmit data is not guaranteed.

(6) Initialization during continuous transmission (pending mode) in FIFO mode

Confirm that the UBnTSF bit of the UBnSTR register is 0 before executing initialization during transmission processing (this can also be done by checking the FIFO transmission completion interrupt (UBTIFn)). If initialization is executed while the UBnTSF bit is 1, the transmit data is not guaranteed.

To write transmit data to transmit FIFO n by DMA control, set the number of transmit data specified as the trigger by the UBnTT3 to UBnTT0 bits of the UBnFIC2 register to 1 byte; otherwise the operation will not be guaranteed.

(7) Initialization during continuous transmission (pointer mode) in FIFO mode

Confirm that the UBnTSF bit of the UBnSTR register is 0 before executing initialization during transmission processing (this can also be done by checking the FIFO transmission completion interrupt (UBTIFn)). If initialization is executed while the UBnTSF bit is 1, the transmit data is not guaranteed.

(8) Receive operation in FIFO mode (pointer mode specified)

If the pointer mode is specified in the FIFO mode and if as many data as the number of bytes stored in receive FIFO_n are read by referencing the UBnFIS0 register, no data may be stored in receive FIFO_n (UBnRB4 to UBnRB0 bits = 00000 in the UBnFIS0 register) even though the reception completion interrupt (UBTIR_n) has occurred. In this case, do not read data from receive FIFO_n. Be sure to read data from receive FIFO_n after confirming that the number of bytes stored in receive FIFO_n = 1 byte or more (UBnRB4 to UBnRB0 bits = other than 00000).

11.3 Clocked Serial Interfaces 30, 31 (CSI30, CSI31)

11.3.1 Features

- Transfer rate: Master mode/slave mode: Maximum 6.25 Mbps
- Full-duplex communications
Transmission and reception cannot be operated independently (transmission/reception simultaneous operation).
- Master mode and slave mode can be selected
- Transmission data length: 8 to 16 bits (selectable in 1-bit units)
- Transfer data direction can be switched between MSB first and LSB first
- 3-wire mode
 SOn: Serial data output
 SIn: Serial data input
 SCKn: Serial clock I/O
- Bit rate
 In master mode: BRG output (selected by the CKS3n2 to CKS3n0 bits and MDLn2 to MDLn0 bits of clocked serial interface clock select register n (CSIC3n))
 In slave mode: Clock input from master (when CKS3n2 to CKS3n0 bits = 111 in the CSIC3n register)
- Interrupt sources: 2 types
 - Transmission/reception completion interrupt (INTCSI3n)
 - CSIBUFn overflow interrupt (INTCOVF3n)
- Transmission mode, reception mode, or transmission/reception mode can be selected
 - Transmission mode: Transmission is started by writing transmit data to transmit data CSI buffer register 3n (SFDB3n) while transmission is enabled (refer to **11.3.5 (11) Transmission mode**).
 - Reception mode: Reception is started by using processing that writes dummy data to transmit data CSI buffer register 3n (SFDB3n) as a trigger while reception is enabled (refer to **11.3.5 (12) Reception mode**).
 - Transmission/reception mode: Transmission/reception is started by using processing that writes transmit data to transmit data CSI buffer register 3n (SFDB3n) while transmission/reception is enabled (refer to **11.3.5 (13) Transmission/reception mode**).
- Sixteen on-chip 16-bit transmit/receive buffers (CSIBUFn)
- On-chip dedicated baud rate generator

Remark n = 0, 1

11.3.2 Configuration

CSI3n is controlled by the clocked serial interface mode register 3n (CSIM3n) (n = 0, 1).

(1) Clocked serial interface mode registers 30, 31 (CSIM30, CSIM31)

The CSIM3n register is an 8-bit register for specifying the operation of CSI3n.

(2) Clocked serial interface clock select registers 30, 31 (CSIC30, CSIC31)

The CSIC3n register is an 8-bit register for controlling the operation clock and operating mode of CSI3n.

(3) Serial I/O shift registers 0, 1 (SIO0, SIO1)

The SIO_n register is an 8-bit register for converting between serial data and parallel data. SIO_n is used for both transmission and reception.

Data is shifted in (reception) or shifted out (transmission) beginning at either the MSB side or the LSB side.

(4) Receive data buffer registers 30, 31 (SIRB30, SIRB31)

The SIRB3n register is a 16-bit buffer register that stores receive data. This register is also divided into two registers: the higher 8 bits (SIRB3nH) and lower 8 bits (SIRB3nL).

(5) Transmit data CSI buffer registers 30, 31 (SFDB30, SFDB31)

The SFDB3n register is a 16-bit buffer register that stores transmit data. This register is also divided into two registers: the higher 8 bits (SFDB3nH) and lower 8 bits (SFDB3nL).

(6) CSIBUF status registers 30, 31 (SFA30, SFA31)

The SFA3n register is an 8-bit register that indicates the status of CSI data buffer register n (CSIBUF_n) or the transfer status.

(7) Transfer data length select registers 30, 31 (CSIL30, CSIL31)

The CSIL3n register is an 8-bit register that selects the CSI3n transfer data length.

(8) Transfer data number specification registers 30, 31 (SFN30, SFN31)

The SFN3n register is an 8-bit register that sets the number of CSI3n transfer data in continuous mode.

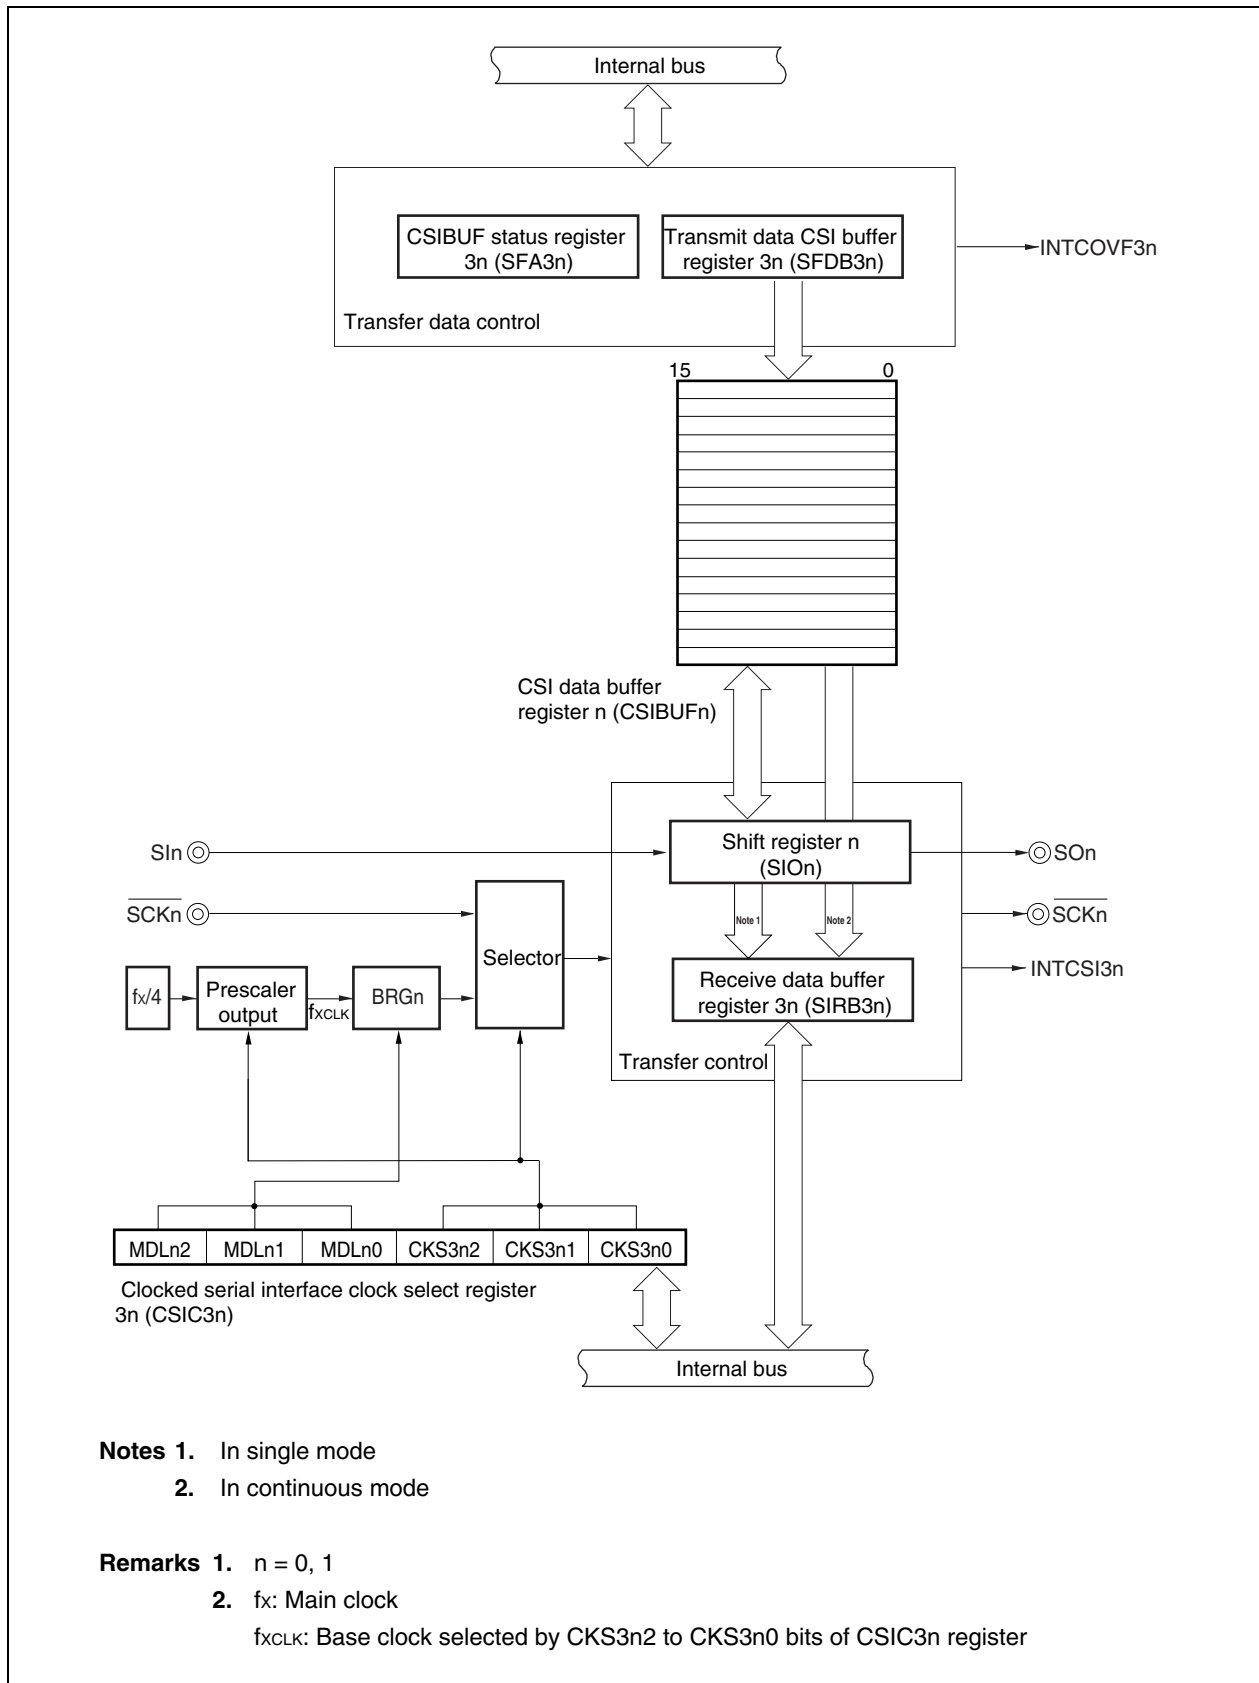

(9) CSI data buffer registers 0, 1 (CSIBUF0, CSIBUF1)

By consecutively writing transmit data to the SFDB3n register from where it is transferred, the data can be stored in the CSIBUF_n register while the CSIBUF_n pointer for writing is automatically incremented (CSIBUF_n).

The CSIBUF_n is a 16-bit buffer register.

In the continuous mode, the data received in the CSIBUF_n register can be sequentially read while the read CSIBUF_n pointer is automatically incremented, by continuously reading the receive data from the SIRB3n register.

Figure 11-22. Block Diagram of Clocked Serial Interfaces 30 and 31

11.3.3 Control registers

Because CSI30 shares pins with UARTB0, the CSI30 mode must be set in advance by using the PMC1 and PFC1 registers (see 11.1.1 **Switching between UARTB0 and CSI30 modes**).

(1) Clocked serial interface mode registers 30, 31 (CSIM30, CSIM31)

The CSIM3n register controls the operation of CSI3n (n = 0, 1).

These registers can be read or written in 8-bit or 1-bit units.

Be sure to clear bit 0 to "0". If it is set to "1", the operation is not guaranteed.

Cautions 1. Writing the TRMDn, DIRn, CSITn, and CSWEn bits is enabled only when CTXEn bit = 0 and CRXEn bit = 0.

2 Be sure to set the external pins related to the CSI3n function to control the mode before using CSI3n. Then set the CSICAEn bit to 1 before setting the other bits.

(1/2)

	7	6	5	4	3	2	1	0	Address	After reset
CSIM30	CSICAE0	CTXE0	CRXE0	TRMD0	DIR0	CSIT0	CSWE0	0	1FFFFD00H	00H
CSIM31	CSICAE1	CTXE1	CRXE1	TRMD1	DIR1	CSIT1	CSWE1	0	1FFFFD20H	00H

Bit position	Bit name	Function
7	CSICAE _n	Controls the operating clock. 0: Stop clock supply to CSI3 _n . 1: Supply clock to CSI3 _n . Cautions 1. The CSI3_n unit is reset when the CSICAE_n bit = 0, and CSI3_n is stopped. To operate CSI3_n, first set the CSICAE_n bit to 1. 2. When rewriting the CSICAE_n bit from 0 to 1 or from 1 to 0, simultaneously rewriting the bits other than the CSICAE_n bit of the CSIM3_n register is prohibited. When the CSICAE_n bit = 0, rewriting the bits other than the CSICAE_n bit of the CSIM3_n register, and the SFDB3_n, SFDB3_nL, and SFA3_n registers is prohibited.
6	CTXE _n	Enables or disables transmission. 1: Disables transmission. 0: Enables transmission. Cautions 1 The CTXE_n bit is reset when the CSICAE_n bit is cleared to 0. 2. Set the SFA3_n.FPCLR_n bit to 1 and clear the CSIBUF_n pointer to 0 before clearing the CTXE_n bit to 0.

Remark n = 0, 1

(2/2)

Bit position	Bit name	Function
5	CRXEn	Enables or disables reception. 1: Disables reception. 0: Enables reception. Caution The CRXEn bit is reset when the CSICAEn bit is cleared to 0.
4	TRMDn	Specifies the transfer mode. 0: Single mode 1: Continuous mode
3	DIRn	Specifies the transfer direction when data is written from the SFDB3n register to the CSIBUFn register or read from the SIRB3n and CSIBUFn registers. 0: The first bit of transfer data is the MSB. 1: The first bit of transfer data is the LSB.
2	CSITn	Controls delay of the transmission completion interrupt signal (INTCSI3n) (see 11.3.5 (14) Delay control of transmission/reception completion interrupt (INTCSI3n)). 0: No delay 1: Delay mode (In the continuous mode (TRMDn = 1), the next data transfer is delayed half a cycle because a delay of half a cycle is inserted when transfer of 1-bit data is complete.) Cautions 1. The delay mode (CSIT bit = 1) is valid only in the master mode (when the CKS3n2 to CKS3n0 bits of the CSIC3n register are other than 111). In the slave mode (when the CKS3n2 to CKS3n0 bits are 111), do not set the delay mode. Even if the delay mode is set, INTCSI3n is not affected by the CSITn bit. 2. If the CSITn bit is set to 1 in the continuous mode (TRMDn bit = 1), the INTCSI3n interrupt is not output except when the last data set by the SFNn3 to SFNn0 bits of the SFN3n register is transferred, but a delay of half a clock can be inserted between each data transfer.
1	CSWEn	Enables or disables transfer wait. 0: Disables transfer wait (1 wait cycle not inserted on starting transfer). 1: Enables transfer wait (1 wait cycle inserted on starting transfer). Caution Inserting a transfer wait cycle (CSWEn bit = 1) is valid only in the master mode (CKS3n2 to CKS3n0 bits = other than 111 in the CSIC3n register). In the slave mode (CKS3n2 to CKS3n0 bits = 111), do not insert a transfer wait cycle. Even if set, a transfer wait cycle is not inserted.

Remark n = 0, 1

(2) Clocked serial interface clock select registers 30, 31 (CSIC30, CSIC31)

The CSIC3n register is an 8-bit register that controls the operation clock and operating mode of CSI3n. These registers can be read or written in 8-bit or 1-bit units.

Caution Data can be written to the CSIC3n register only when the CTXEn bit = 0 and CRXEn bit = 0 in the CSIM3n register.

Remark n = 0, 1

(2/3)

Bit position	Bit name	Function															
4, 3	CKPn, DAPn	Specify the data transmission/reception timing for \overline{SCKn} . <table border="1" style="margin-left: 20px;"> <thead> <tr> <th>CKPn</th> <th>DAPn</th> <th>Operation mode</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td> </td> </tr> <tr> <td>0</td> <td>1</td> <td> </td> </tr> <tr> <td>1^{Note}</td> <td>0</td> <td> </td> </tr> <tr> <td>1^{Note}</td> <td>1</td> <td> </td> </tr> </tbody> </table>	CKPn	DAPn	Operation mode	0	0		0	1		1 ^{Note}	0		1 ^{Note}	1	
CKPn	DAPn	Operation mode															
0	0																
0	1																
1 ^{Note}	0																
1 ^{Note}	1																

Note If the CKPn bit is set to 1 in the master mode (CKS3n2 to CKS3n0 bits are other than 111), the \overline{SCKn} pin outputs a low level when it is inactive. If the CTXEn bit of the CSIM3n register is cleared to 0 (disabling transmission) and CRXEn bit is cleared to 0 (disabling reception), the \overline{SCKn} pin outputs a high level. Therefore, take the following measures to fix the \overline{SCKn} pin to low level when CSI3n is not used.

[$\overline{SCK0}$ pin ($\overline{SCK1}$ pin)]

- <1> Clearing the P11 bit of the P1 register to 0 (clearing the P23 bit of the P2 register to 0):
The port output level is set to low.
- <2> Clearing the PM11 bit of the PM1 register to 0 (clearing the PM23 bit of the PM2 register to 0):
The port is set in the output mode.
- <3> Clearing the PMC11 bit of the PMC1 register to 0 (clearing the PMC23 bit of the PMC2 register to 0):
The pin is set in the port mode (fixed to low-level output).
- <4> Clearing the CTXE0 and CRXE0 bits of the CSIM30 register to 0 (clearing the CTXE1 and CRXE1 bits of the CSIM31 register to 0):
Transmission and reception are disabled.
- <5> Setting the CTXE0 or CRXE0 bit of the CSIM30 register to 1 (setting the CTXE1 or CRXE1 bit of the CSIM31 register to 1):
Transmission or reception is enabled (both transmission and reception can also be enabled).
- <6> Setting the PMC11 bit of the PMC1 register to 1 (setting the PMC23 bit of the PMC2 register to 1):
The pin is set in the control mode ($\overline{SCK0}$ and $\overline{SCK1}$ pin output).

Because the register set values <1> and <2> are retained, control can be performed only by <3> to <6> once they have been set.

Remark n = 0, 1

(3/3)

Bit position	Bit name	Function					
2 to 0	CKS3n2 to CSK3n0	Specify the base clock (prescaler output).

Remark n = 0, 1

(3) Receive data buffer registers 30, 31 (SIRB30, SIRB31)

The SIRB3n register is a 16-bit buffer register that stores receive data.

By consecutively reading this register in the continuous mode (TRMDn bit = 1 in the CSIM3n register), the received data in the CSIBUFn register can be sequentially read while the CSIBUFn pointer for reading is incremented.

In the single mode (TRMDn bit = 0 in the CSIM3n register), received data is read by reading the SIRB3n register and it is judged that the SIRB3n register has become empty.

The SIRB3n register is read-only, in 16-bit units.

When the higher 8 bits of the SIRB3n register are used as the SIRB3nH register and the lower 8 bits as the SIRB3nL register, these registers are read-only, in 8-bit units. When reading in 8-bit units, be sure to read the SIRB3nH register and SIRB3nL register in that order.

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset ^{Note}

Note In continuous mode (TRMDn bit = 1 in the CSIM3n register): Undefined

Bit position	Bit name	Function
15 to 0	SIRBn15 to SIRBn0	Store receive data.

- Remarks**
- n = 0, 1
 - The SIRB3n register is cleared to 0000H when the CSICAEn bit of the CSIM3n register is cleared to 0.

(4) Transmit data CSI buffer registers 30, 31 (SFDB30, SFDB31)

The SFDB3n register is a 16-bit buffer register that stores transmit data.

When transmit data is written to this register, the data is sequentially stored in the CSIBUFn register while the CSIBUFn pointer for writing is incremented.

When the data of this register is read, the value of the transmit data written last is read.

The SFDB3n register can be read or written in 16-bit units.

When the higher 8 bits of the SFDB3n register are used as the SFDB3nH register, and the lower 8 bits as the SFDB3nL register, these registers can be read or written in 8-bit units. When reading in 8-bit units, be sure to read the SFDB3nH register and SFDB3nL register in that order.

Bit position	Bit name	Function
15 to 0	SFDBn15 to SFDBn0	Store transmit data.

Remark n = 0, 1

(5) CSIBUF status registers 30, 31 (SFA30, SFA31)

These registers indicate the status of the CSIBUFn register or the transfer status.

These registers can be read or written in 8-bit or 1-bit units (however, bits 6 to 0 can only be read. They do not change even if they are written).

- Cautions**
1. Reading the SFA3n register is prohibited when the CSICAEn bit of the CSIM3n register is 1 and when the main clock (fx) is stopped.
 2. Because the values of the SFFULn, SFEMPn, CSOTn, and SFPn3 to SFPn0 bits may change at any time during transfer, their values during transfer may differ from the actual values. Especially, use the CSOTn bit independently (do not use this bit in relation with the other bits). To detect the end of transfer by the SFA3n register, check to see if the SFEMPn bit is 1 after the data to be transferred has been written to the CSIBUFn register.
 3. If the SFA3n register is read immediately after data has been written to the SFDB3n and SFDB3nL registers when the main clock (fx) is 84 MHz or lower, the values of the SFFULn, SFEMPn, and SFPn3 to SFPn0 bits do not change in time.
 4. If the SFA3n register is read before the SFFULn bit is set to 1 and the 17th data is written, the CSIBUFn overflow interrupt (INTCOVF3n) is generated.

(1/3)

	7	6	5	4	3	2	1	0	Address	After reset
SFA30	FPCLR0	SFFUL0	SFEMP0	CSOT0	SFP03	SFP02	SFP01	SFP00	1FFFFD08H	20H
SFA31	FPCLR1	SFFUL1	SFEMP1	CSOT1	SFP13	SFP12	SFP11	SFP10	1FFFFD28H	20H

Bit position	Bit name	Function
7	FPCLRn	Specifies clearing of the CSIBUFn pointer. 0: No operation 1: Clear all CSIBUFn pointers to 0. Cautions 1. This bit is always 0 when it is read. 2. If 1 is written to the FPCLRn bit in the middle of transfer, transfer is aborted. Because all the CSIBUFn pointers are cleared to 0, the remaining data in the CSIBUFn register is ignored. If 1 is written to the FPCLRn bit, be sure to read the SFA3n register to check to see if all the CSIBUFn pointers have been correctly cleared to 0 (SFFULn bit = 0, SFEMPn bit = 1, SFPn3 to SFPn0 bits = 0000). Nothing happens even if 0 is written to the FPCLRn bit.

- Remarks**
1. n = 0, 1
 2. The SFA3n register is set to 20H when the CSICAEn bit of the CSIM3n register is cleared to 0.

(2/3)

Bit position	Bit name	Function
6	SFFULn	<p>This flag indicates the full status of the CSIBUFn register.</p> <p>0: CSIBUFn register has a vacancy. 1: CSIBUFn register is full.</p> <p>Cautions</p> <ol style="list-style-type: none"> 1. This bit is cleared to 0 when the CSICAEn bit of the CSIM3n register is cleared to 0 and the FPCLR bit is set to 1. 2. If transfer of 16 data is specified in the continuous mode (TRMDn bit = 1 in the CSIM3n register) (SFNn3 to SFNn0 bits = 0000 in the SFN3n register), the SFFULn bit is set to 1 in the same way as in the single mode (TRMDn bit = 0 in the CSIM3n register) when 16 data are in the CSIBUFn register. If even one of the data has been completely transferred, the SFFULn bit is cleared to 0. However, this does not mean that the CSIBUFn register has a vacancy.
5	SFEMPn	<p>This flag indicates the empty status of the CSIBUFn register.</p> <p>0: Data is in CSIBUFn register. 1: CSIBUFn register is empty.</p> <p>Cautions</p> <ol style="list-style-type: none"> 1. This flag is set to 1 when the CSICAEn bit of the CSIM3n register is cleared to 0 and the FPCLR bit is set to 1. 2. If the data written to the CSIBUFn register has been transferred, the SFEMPn bit is set to 1 (even if receive data is stored in the CSIBUFn register).
4	CSOTn	<p>This flag indicates transfer status.</p> <p>0: Idle status 1: Transfer or transfer start processing in progress</p> <p>Cautions</p> <ol style="list-style-type: none"> 1. Remark n = 0, 1

11.3.4 Dedicated baud rate generators 0, 1 (BRG0, BRG1)

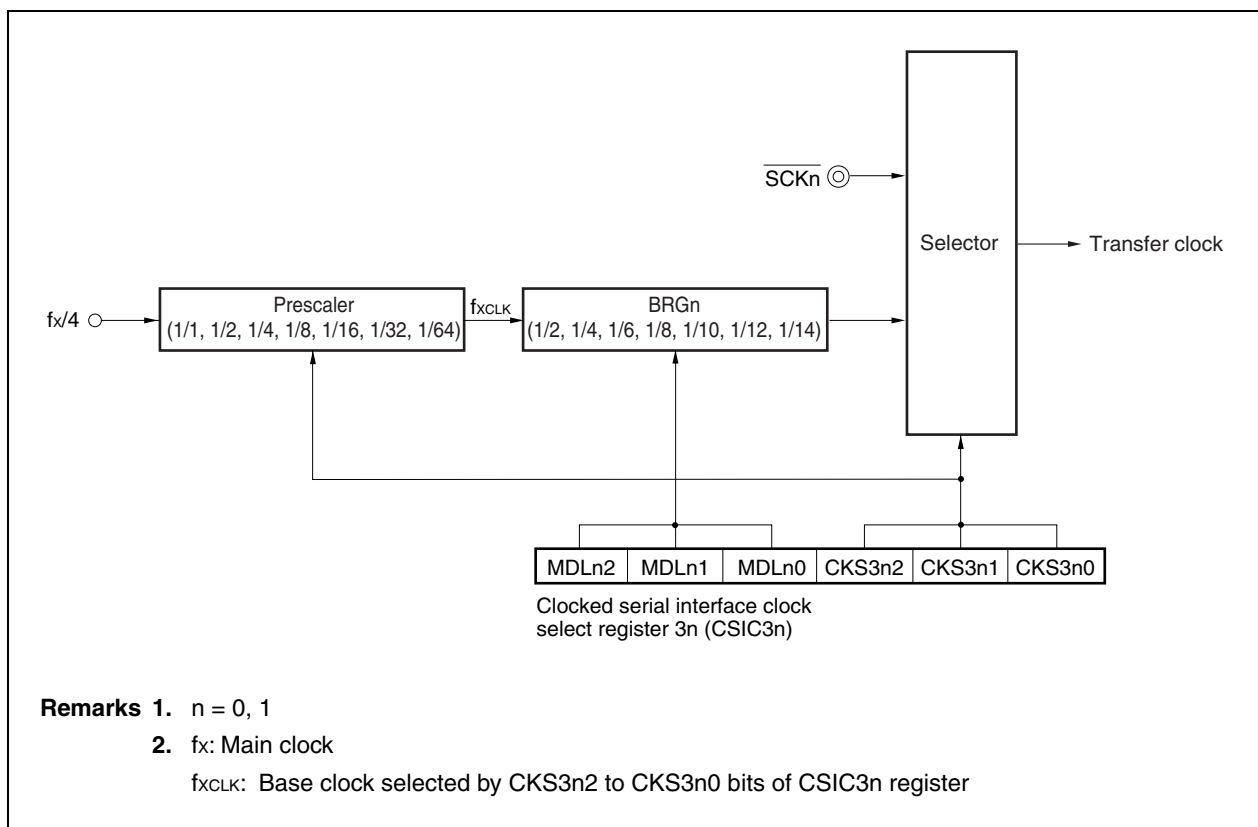

The transfer clock of CSI3n can be selected from the output of a dedicated baud rate generator or external clock (n = 0, 1).

The serial clock source is specified by the CSIC3n register.

In the master mode (CKS3n2 to CKS3n0 bits = other than 111 in the CSIC3n register), BRGn is selected as the clock source.

(1) Transfer clock

Figure 11-23. Transfer Clock of CSI3n

(2) Baud rate

The baud rate is calculated by the following expression.

$$\text{Baud rate} = \frac{F}{N \times 2^{(K+1)}} \text{ [bps]}$$

F = fx/4 (fx: main clock)

K = Value set by CKS3n2 to CKS3n0 bits of CSIC3n register (K = 0, 1, 2, ..., 6)

N = Value set by MDLn2 to MDLn0 bits of CSIC3n register (N = 1, 2, 3, ..., 7)

Cautions 1. If the CKS3n2 to CKS3n0 bits of the CSIC3n register are cleared to 000, setting the MDLn2 to MDLn0 bits of the CSIC3n register to 001 is prohibited.

2. Because the maximum transfer rate in the master mode (CKS3n2 to CKS3n0 bits = other than 111 in the CSIC3n register) is 6.25 Mbps, do not exceed this value.

Example: When CSI3n operates at 200 MHz, the maximum transfer rate is set when the CKS3n2 to CKS3n0 bits = 000 and the MDLn2 to MDLn0 bits = 100 in the CSIC3n register.

11.3.5 Operation

(1) Operation modes

Table 11-6. Operation Modes

TRMDn Bit	CKS3n2 to CKS3n0 Bits	CTXEn and CRXEn Bits	DIRn Bit	CSITn Bit	CSWEn Bit
Single mode	Master mode	Transmission/reception/ transmission and reception	MSB/LSB first	Enables/disables INTCSI3n delay mode	Disables transfer wait
	Slave mode			–	Enables transfer wait
Consecutive mode	Master mode			Enables/disables INTCSI3n delay mode	Disables transfer wait
	Slave mode			–	Enables transfer wait

- Remarks 1.** CTXEn bit: Bit 6 of CSIM3n register
 CRXEn bit: Bit 5 of CSIM3n register
 TRMDn bit: Bit 4 of CSIM3n register
 DIRn bit: Bit 3 of CSIM3n register
 CSITn bit: Bit 2 of CSIM3n register
 CSWEn bit: Bit 1 of CSIM3n register
 CKS3n2 to CKS3n0 bits: Bits 2 to 0 of CSIC3n register
- 2.** n = 0, 1

(2) Function of CSI data buffer registers 0, 1 (CSIBUF0, CSIBUF1)

By consecutively writing the transmit data to the SFDB3n register from where it is transferred, the data can be stored in the CSIBUFn register while the CSIBUFn pointer for writing is automatically incremented (the CSIBUFn register size is 16 bits × 16) (n = 0, 1).

The condition under which transfer is to be started (SFEMPn bit = 0 in the SFA3n register) is satisfied when data is written to the lower 8 bits (SFDB3nL register) of the SFDB3n register. If a transfer data length of 9 bits or more is specified (CCLn3 to CCLn0 bits = 0000 or 1001 to 1111 in the CSIL3n register), data must be written to the SFDB3n register in 16-bit units or to the SFDB3nH and SFDB3nL registers, in that order, in 8-bit units. If the transfer data length is set to 8 bits (CCLn3 to CCLn0 bits = 1000 in the CSIL3n register), data must be written to the SFDB3nL register in 8-bit units or to the SFDB3n register in 16-bit units. (If data is written to the SFDB3nL register in 16-bit units, however, the higher 8 bits of the data (of the SFDB3nH register) are ignored and not transferred).

The SFFULn bit of the SFA3n register is set to 1 when 16 data exist in the CSIBUFn register and outputs a CSIBUFn overflow interrupt (INTCOVF3n) when the SFFULn bit = 1 and when the 17th transfer data is written (17th transfer data is not written and ignored).

Sixteen data exist in the CSIBUFn register in the single mode (TRMDn bit = 0 in the CSIM3n register) when “CSIBUFn pointer value for writing = CSIBUFn pointer value for SIO loading, and SFFULn bit = 1 in the SFA3n register”. When the CSIBUFn pointer for SIO loading is incremented after completion of transfer, the CSIBUFn register has a vacancy of one data (in the continuous mode (TRMDn bit = 1 in the CSIM3n register), the CSIBUFn register does not have a vacancy even if one data has been transferred).

Figure 11-24. Function of CSI Data Buffer Register n (CSIBUFn)

(3) Data transfer direction specification function

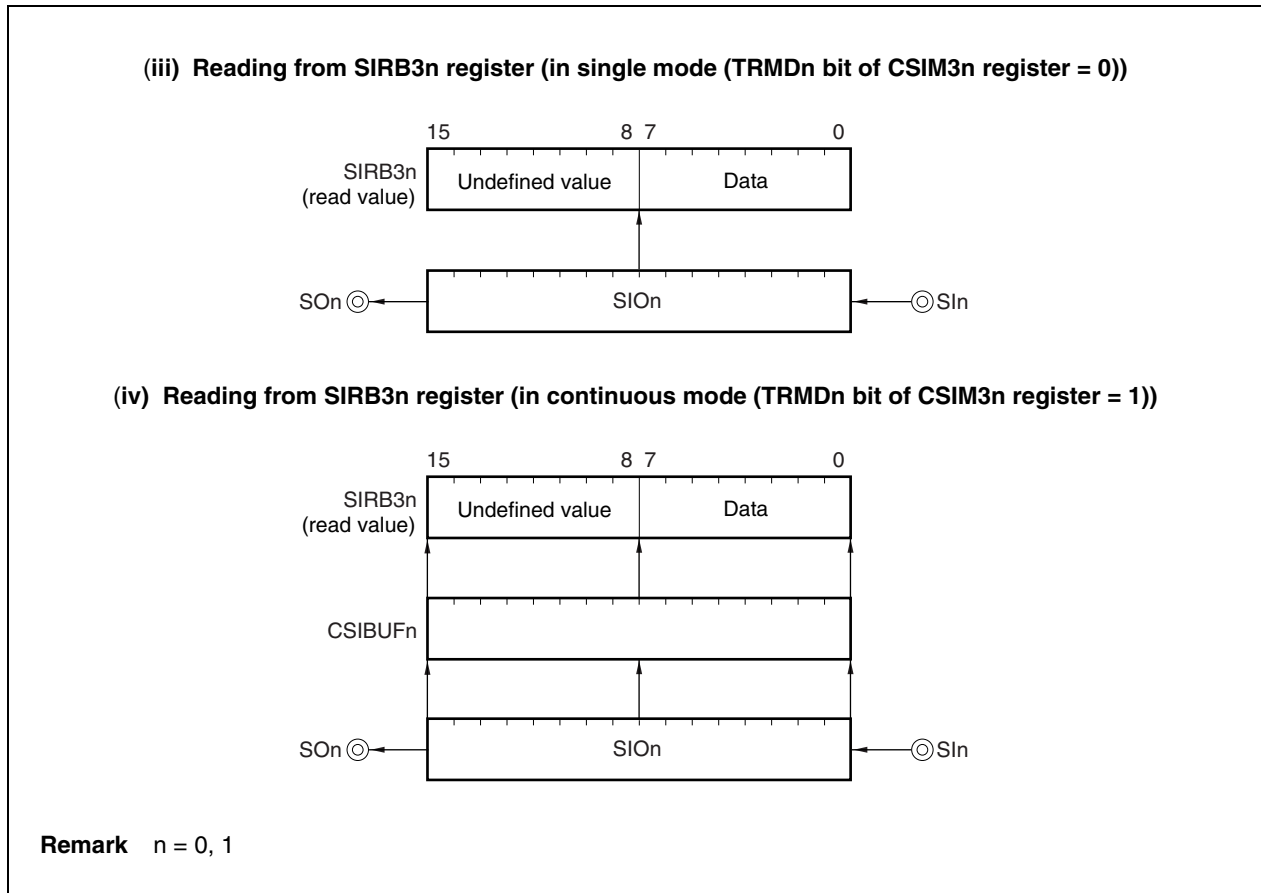

The data transfer direction can be changed by using the DIRn bit of the CSIM3n register (n = 0, 1).

(a) MSB first (DIRn bit = 0)

**Figure 11-25. Transfer Data Length: 8 Bits (CCLn3 to CCLn0 Bits = 1000 in CSIL3n Register),
Transfer Direction: MSB First (DIRn Bit = 0 in CSIM3n Register) (1/2)**

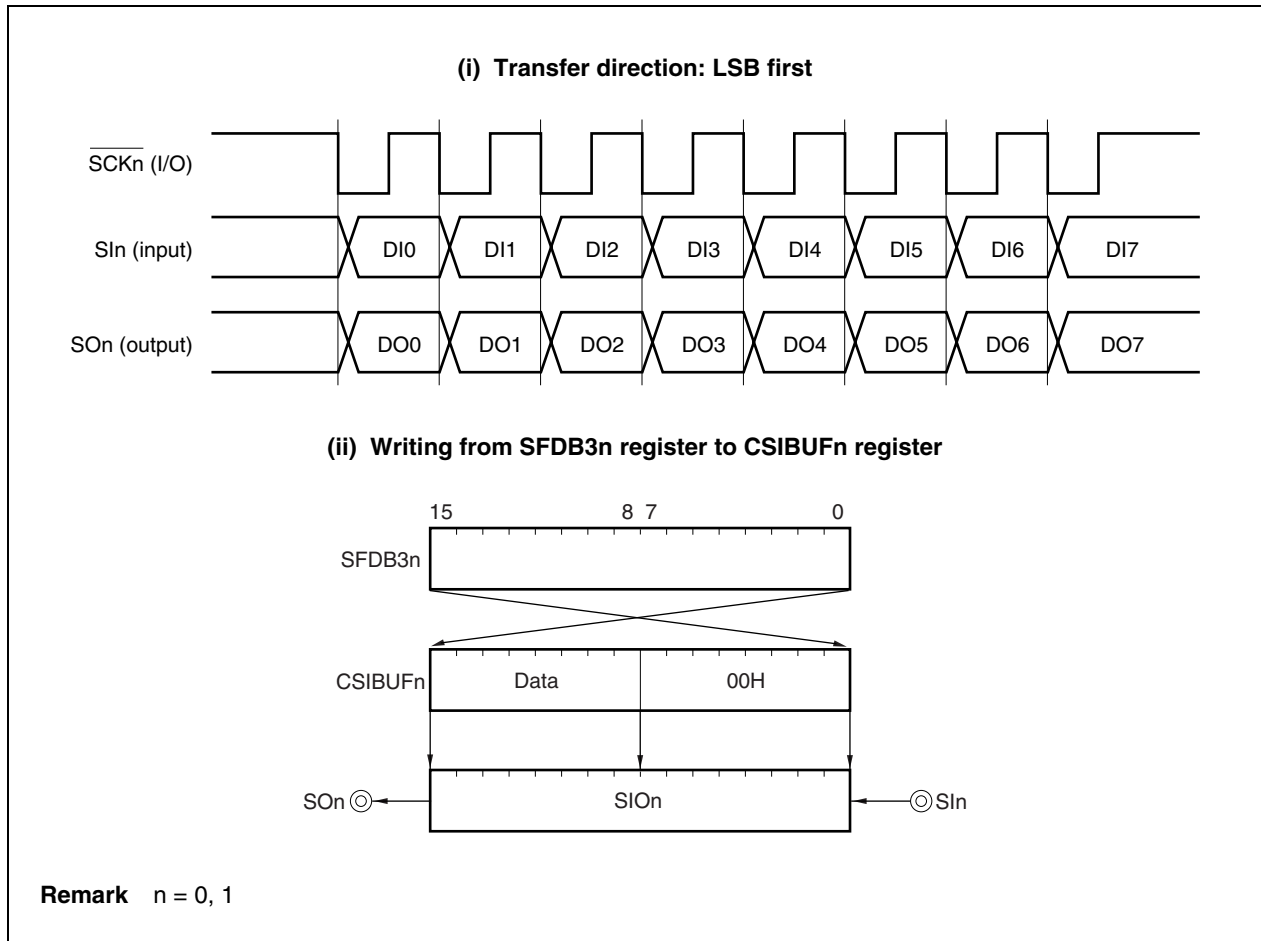

**Figure 11-25. Transfer Data Length: 8 Bits (CCLn3 to CCLn0 Bits = 1000 in CSIL3n Register),
Transfer Direction: MSB First (DIRn Bit = 0 in CSIM3n Register) (2/2)**

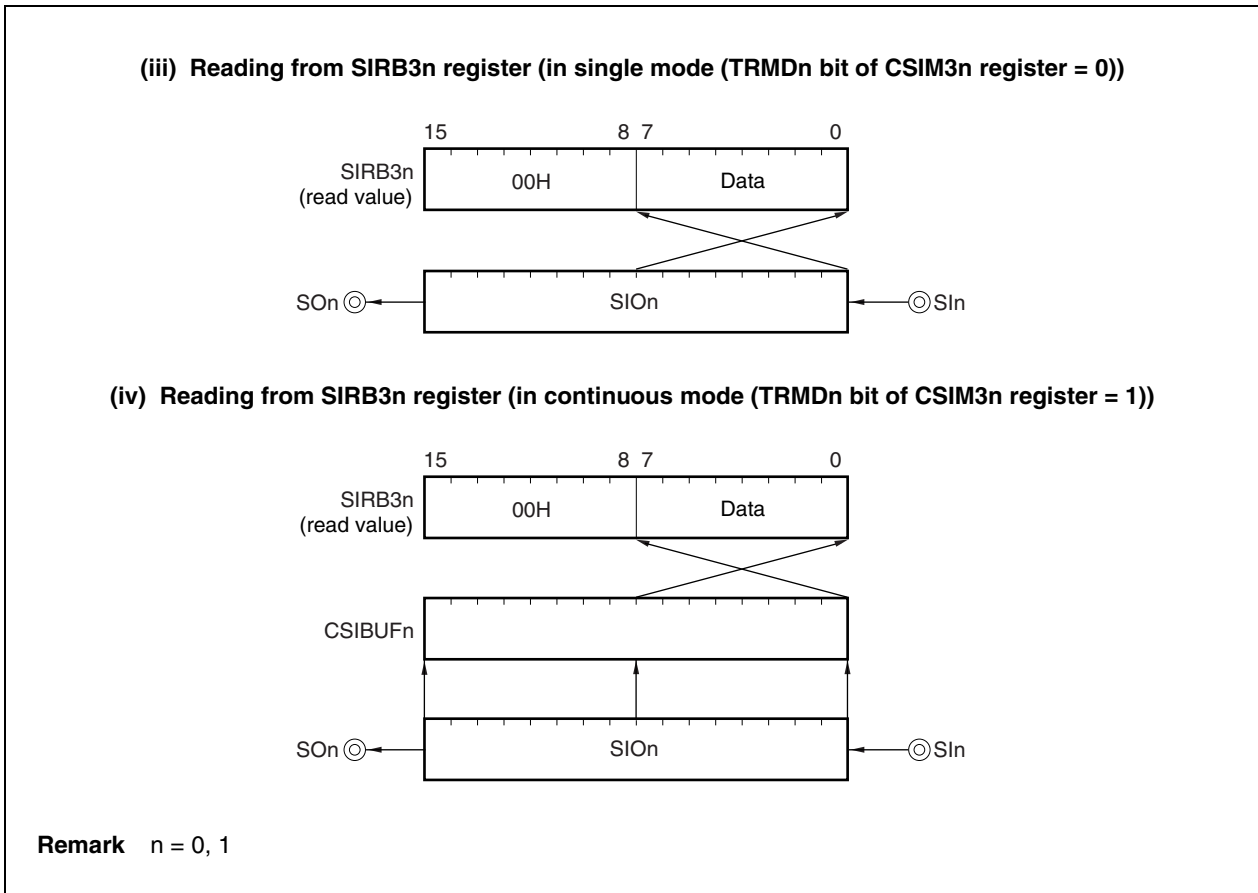

(b) LSB first (DIRn bit = 1)

Figure 11-26. Transfer Data Length: 8 Bits (CCLn3 to CCLn0 Bits = 1000 in CSIL3n Register),
Transfer Direction: LSB First (DIRn Bit = 1 in CSIM3n Register) (1/2)

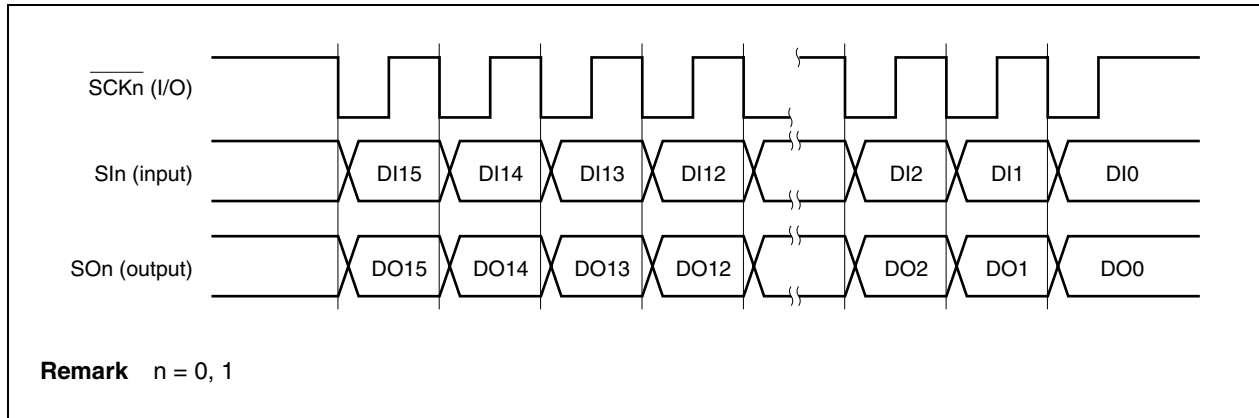

**Figure 11-26. Transfer Data Length: 8 Bits (CCLn3 to CCLn0 Bits = 1000 in CSIL3n Register),
Transfer Direction: LSB First (DIRn Bit = 1 in CSIM3n Register) (2/2)**

(4) Transfer data length changing function

The transfer data length can be set from 8 to 16 bits in 1-bit units, by using the CCLn3 to CCLn0 bits of the CSIL3n register (n = 1, 0).

**Figure 11-27. Transfer Data Length: 16 Bits (CCLn3 to CCLn0 Bits = 0000 in CSIL3n Register),
Transfer Direction: MSB First (DIRn Bit = 0 in CSIM3n Register)**

(5) Function to select serial clock and data phase

The serial clock and data phase can be changed by using the CKPn and DAPn bits of the CSIC3n register (n = 0, 1).

Figure 11-28. Clock Timing

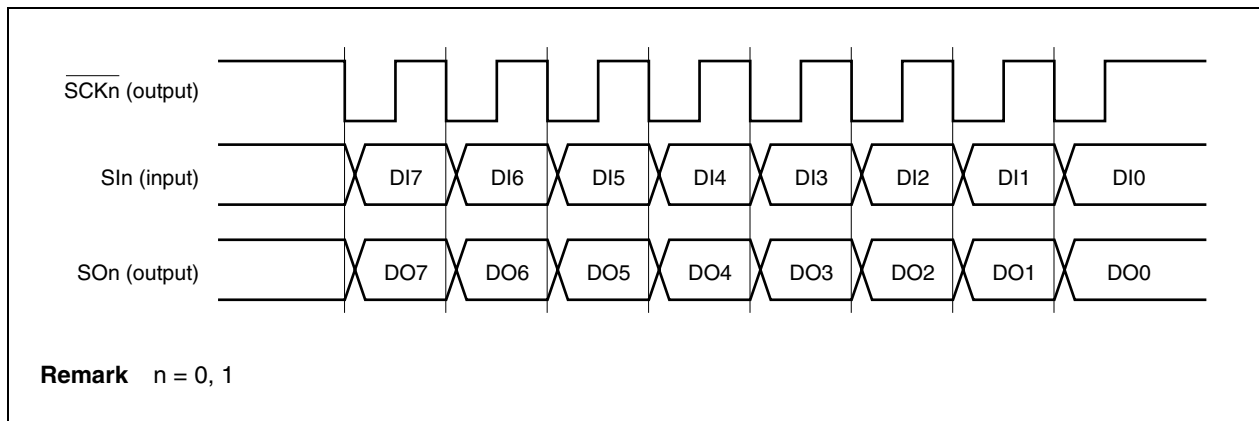

(6) Master mode

The master mode is set and data is transferred with the transfer clock output to the $\overline{\text{SCKn}}$ pin when the $\overline{\text{CKSn2}}$ to $\overline{\text{CKSn0}}$ bits of the $\overline{\text{CSIC3n}}$ register are set to a value other than 111 ($\overline{\text{SCKn}}$ pin input is invalid) ($n = 0, 1$).

The default output level of the $\overline{\text{SCKn}}$ pin is high when the $\overline{\text{CKPn}}$ bit of the $\overline{\text{CSIC3n}}$ register is 0, and low when the $\overline{\text{CKPn}}$ bit is 1.

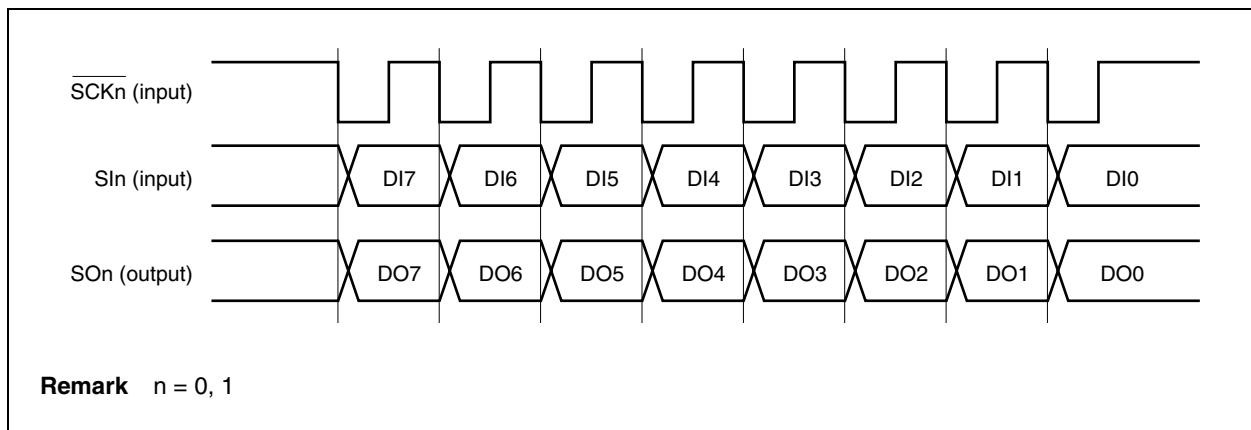

Figure 11-29. Master Mode ($\overline{\text{CKPn}}$ and $\overline{\text{DAPn}}$ Bits = 00 in $\overline{\text{CSIC3n}}$ Register, $\overline{\text{CCLn3}}$ to $\overline{\text{CCLn0}}$ Bits = 1000 in $\overline{\text{CSIL3n}}$ Register (Transfer Data Length: 8 Bits))

(7) Slave mode

The slave mode is set when the CKS3n2 to CKS3n0 bits of the CSIC3n register are set to 111, and data is transferred with the transfer clock input to the $\overline{\text{SCKn}}$ pin (in the slave mode, it is recommended to set the MDLn2 to MDLn0 bits of the CSIC3n register to 000 and set the BRGn stop mode) (n = 0, 1).

Figure 11-30. Slave Mode (CKPn and DAPn Bits = 00 in CSIC3n Register, CCLn3 to CCLn0 Bits = 1000 in CSIL3n Register (Transfer Data Length: 8 Bits))

The conditions under which data can be transferred in the slave mode are listed in the table below.

Table 11-7. Conditions Under Which Data Can Be Transferred in Slave Mode

Transfer Mode		CTXEn Bit	CRXEn Bit	CSIBUFn Register	SIRB3n Register and SIO _n Register
Single mode	Transmission mode	1	0	Data is in CSIBUFn register (SFEMPn bit = 0).	–
	Reception mode	0	1	Dummy data is in CSIBUFn register (SFEMPn bit = 0).	SIRB3n register or SIO _n register is empty.
	Transmission/reception mode	1	1	Data is in CSIBUFn register (SFEMPn bit = 0).	
Consecutive mode	Transmission mode	1	0	Data is in CSIBUFn register (SFEMPn bit = 0).	–
	Reception mode	0	1	Dummy data is in CSIBUFn register (SFEMPn bit = 0).	–
	Transmission/reception mode	1	1	Data is in CSIBUFn register (SFEMPn bit = 0).	–

Caution Transfer is not performed normally while data transfer is not enabled, even if the transfer clock is input from the master.

- Remarks**
- CTXEn bit: Bit 6 of CSIM3n register
 CRXEn bit: Bit 5 of CSIM3n register
 SFEMPn bit: Bit 5 of SFA3n register
 - n = 0, 1

(8) Transfer clock selection function

In the master mode (CKS3n2 to CKS3n0 bits = other than 111 in the CSIC3n register), the bit transfer rate can be selected by setting the CKS3n2 to CKS3n0 and MDLn2 to MDLn0 bits of the CSIC3n register (see **11.3.3 (2) Clocked serial interface clock select registers 30, 31 (CSIC30, CSIC31)**).

(9) Single mode

The single mode is set when the TRMDn bit of the CSIM3n register is 0 (n = 0, 1).

In this mode, transfer is started when the CTXEn bit or CRXEn bit is set to 1 and when data is in the CSIBUFn register (SFEMPn bit = 0 in the SFA3n register).

If no data is in the CSIBUFn register (SFEMPn bit = 1), transfer is kept waiting until transmit data or dummy data is written to the SFDB3n register.

When data is transferred to the CSIBUFn register while transmission or reception is enabled (CTXEn or CRXEn bit is 1), the CSOTn bit of the SFA3n register (transfer status flag) is set to 1. If transfer is not in the wait status, the transfer data indicated by the SIOOn load CSIBUFn pointer is loaded from the CSIBUFn register to the SIOOn register, and transfer processing is started.

If the SIRB3n register is empty when one data has been transferred in the reception mode or transmission/reception mode, the received data is stored from the SIOOn register to the SIRB3n register, the transmission/reception completion interrupt (INTCSI3n) is output, and the SIOOn load CSIBUFn pointer is incremented. If transmit data or dummy data is stored in the CSIBUFn register, the next transfer processing is started. However, storing the receive data in the SIRB3n register, outputting the INTCSI3n interrupt, and incrementing the SIOOn load CSIBUFn pointer are held pending, until the previously received data is read from the SIRB3n register and the SIRB3n register becomes empty.

In the transmission mode, the INTCSI3n interrupt is output and the SIOOn load pointer is incremented when transfer processing of one data has been completed (the SIRB3n register is always empty because no data is stored from the SIOOn register to the SIRB3n register).

In all modes (transmission, reception, and transmission/reception modes), if the CSIBUFn register is empty (write CSIBUFn pointer value = SIOOn load CSIBUFn pointer value) when transfer processing of one data has been completed, the CSOTn bit is cleared to 0. The value of the "number of remaining data in the CSIBUFn register (write CSIBUFn pointer – SIOOn load pointer)" can always be read from the SFPn3 to SFPn0 bits of the SFA3n register.

Caution Be sure to confirm that the SFFULn bit of the SFA3n register is 0 when writing data to the SFDB3n register. Even if data is written to this register when SFFULn bit is 1, the CSIBUFn overflow interrupt (INTCOVF3n) is output, and the written data is ignored.

Figure 11-31. Single Mode

(10) Continuous mode

The continuous mode is set when the TRMDn bit of the CSIM3n register is 1 (n = 0, 1).

In this mode, transfer is started when the CTXEn bit or CRXEn bit is 1 and when data is in the CSIBUFn register (SFEMPn bit = 0 in the SFA3n register). At this time, set the number of transfer data in advance by using the SFNn3 to SFNn0 bits of the SFN3n register. If data exceeding the number of transfer data specified by the SFNn3 to SFNn0 bits of the SFN3n register are written to the CSIBUFn register, the excess data are ignored and not transferred.

If no data is in the CSIBUFn register (SFEMPn bit = 1), transfer is kept waiting until transmit data or dummy data is written to the SFDB3n register.

If data is transferred to the CSIBUFn register when transmission or reception is enabled (CTXEn or CRXEn bit is 1), the CSOTn bit (transfer status flag) of the SFA3n register is set to 1 and the transfer data indicated by the SIOn load/store CSIBUFn pointer is loaded from the CSIBUFn register to SIOn register. Then transfer processing is started.

When transfer processing of one data is completed in the reception mode or transmission/reception mode, the received data is overwritten from the SIOn register to the transfer data in the CSIBUFn register indicated by the SIOn load/store CSIBUFn pointer, and then the pointer is incremented. By consecutively reading the transfer data from the SIRB3n register after all data in the CSIBUFn register have been transferred (when the INTCSI3n interrupt has occurred), the receive data can be sequentially read while the read CSIBUFn pointer is incremented. In the transmission mode, the SIOn load/store CSIBUFn pointer is incremented when transfer processing of one data has been completed.

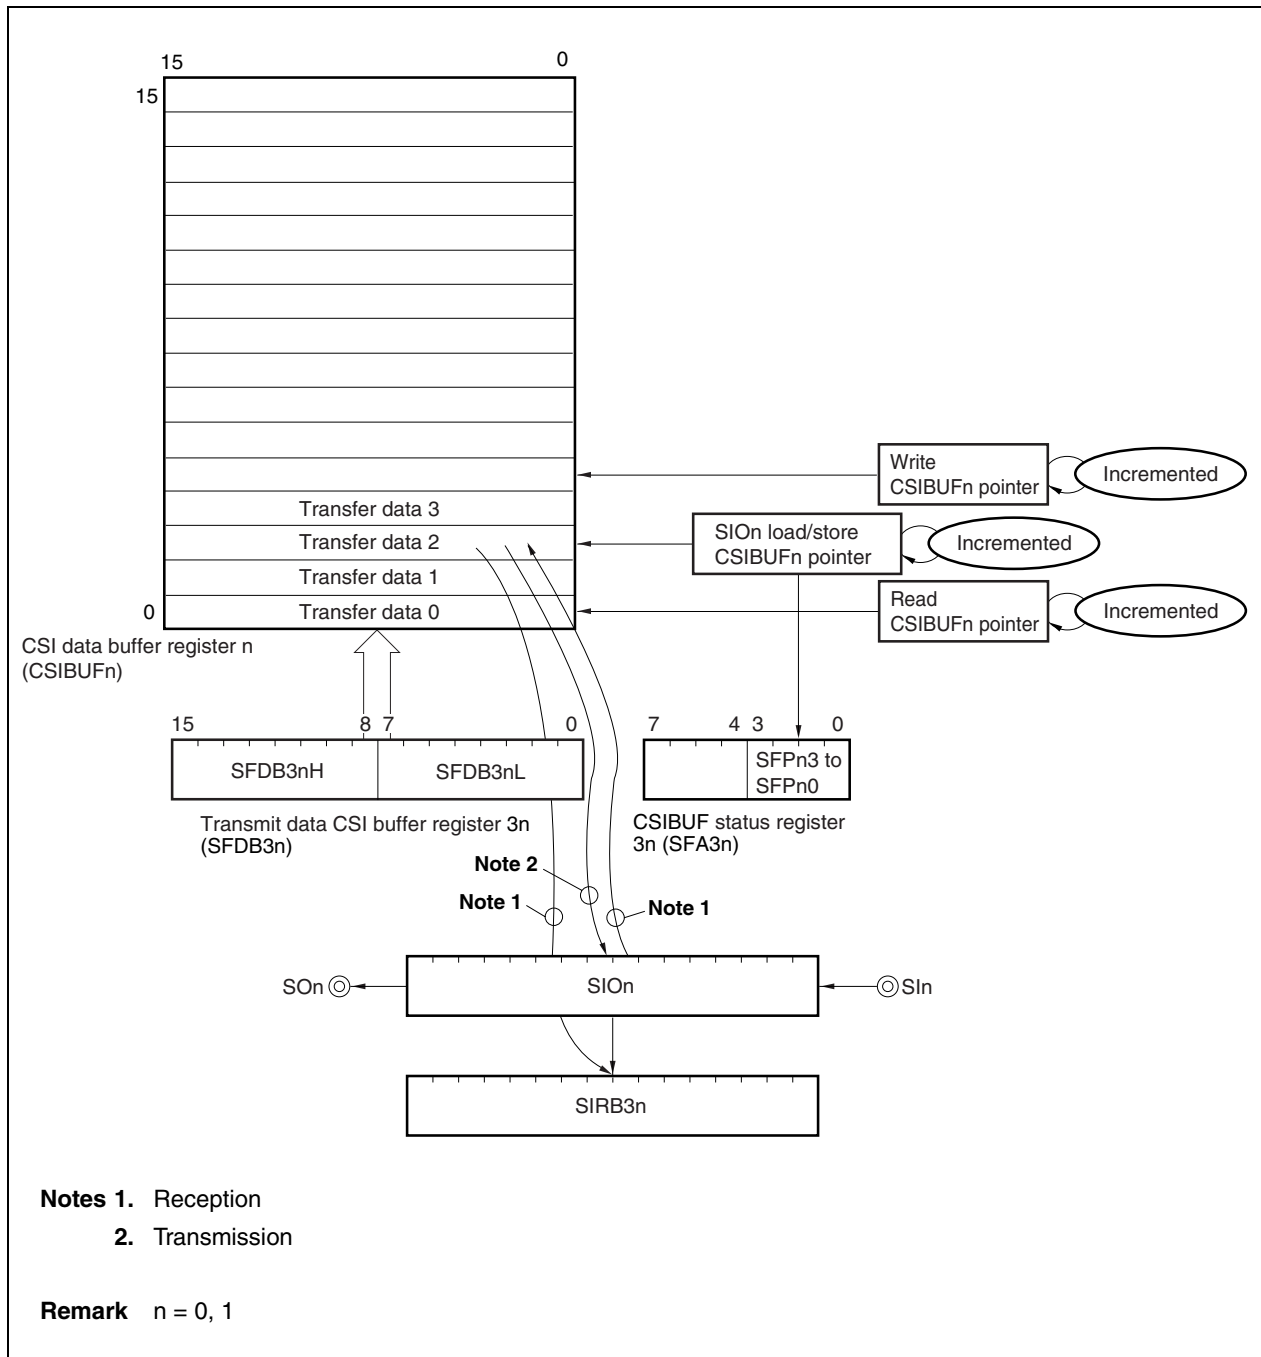

In all modes (transmission, reception, and transmission/reception modes), when data has been transferred by the value set by the SFNn3 to SFNn0 bits of the SFN3n register, the CSOTn bit is cleared to 0 and the transmission/reception completion interrupt (INTCSI3n) is output.

To transfer the next data, be sure to write 1 to the FPCLRn bit of the SFA3n register and clear all the CSIBUFn pointers to 0.

The “number of transferred data (SIOn load/store CSIBUFn pointer value)” can always be read from the SFPn3 to SFPn0 bits of the SFA3n register.

Caution The SFA3n register is in the same status when transfer data is written (before start of transfer) after the CSIBUFn pointer is cleared (FPCLRn bit = 1 in the SFA3n register) and when 16 data have been transferred (SFFULn bit = 0, SFEMPn bit = 1, SFPn3 to SFPn0 bits = 0000 in the SFA3n register).

Figure 11-32. Continuous Mode

(11) Transmission mode

The transmission mode is set when the CTXEn bit of the CSIM3n register is set to 1 and the CRXEn bit is cleared to 0. In this mode, transmission is started by a trigger that writes transmit data to the SFDB3n register or sets the CTXEn bit to 1 when transmit data is in the CSIBUFn register (n = 0, 1). Even in the single mode (TRMDn bit = 0 in the CSIM3n register), whether the SIRB3n or SIO n register is empty has nothing to do with starting transmission. The value input to the SIn pin during transmission is latched in the shift register (SIO n) but is not transferred to the SIRB3n and CSIBUFn registers at the end of transmission.

The transmission/reception completion interrupt (INTCSI3n) occurs immediately after data is sent out from the SIO n register.

(12) Reception mode

The reception mode is set when the CTXEn bit of the CSIM3n register is cleared to 0 and CRXEn bit is set to 1. In this mode, reception is started by using the processing of writing dummy data to the SFDB3n register as a trigger (n = 0, 1). In the single mode (TRMDn bit = 0 in the CSIM3n register), however, the condition of starting reception includes that the SIRB3n or SIO n register is empty. (If reception to the SIO n register is completed when the previously received data is held in the SIRB3n register without being read, the previously received data is read from the SIRB3n register and the wait status continues until the SIRB3n register becomes empty.) In the continuous mode, reception starts by writing dummy data of the number of receive data to the SFDB3n register with the first dummy data write processing taken as a trigger.

The SOn pin outputs a low level.

The transmission/reception completion interrupt (INTCSI3n) occurs immediately after receive data is transferred from the SIO n register to the SIRB3n register.

(13) Transmission/reception mode

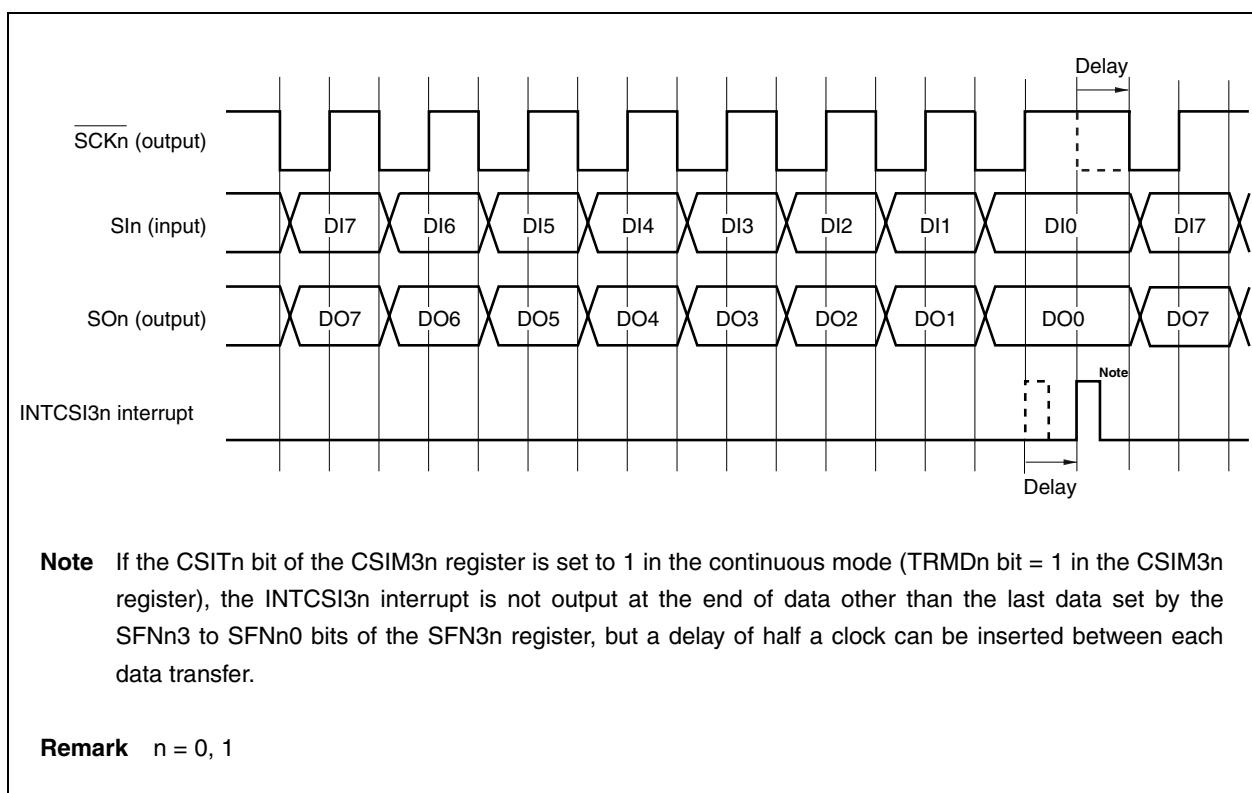

The transmission/reception mode is set when both the CTXEn and CRXEn bits of the CSIM3n register are set to 1. In this mode, transmission/reception is started by using the processing to write transmit data to the SFDB3n register as a trigger (n = 0, 1). In the single mode (TRMDn bit = 0 in the CSIM3n register), however, the condition of starting transmission/reception includes that the SIRB3n or SIO n register is empty. (If reception to the SIO n register is completed when the previously received data is held in the SIRB3n register without being read, the previously received data is read from the SIRB3n register and the wait status continues until the SIRB3n register becomes empty.)

(14) Delay control of transmission/reception completion interrupt (INTCSI3n)

In the master mode (CKS3n2 to CKS3n0 bits = other than 111 in the CSIC3n register), occurrence of the transmission/reception completion interrupt (INTCSI3n) can be delayed by half a clock (1/2 serial clock), depending on the setting (1) of the CSITn bit of the CSIM3n register. The CSITn bit is valid only in the master mode. In the slave mode (CKS3n2 to CKS3n0 bits = 111 in the CSIC3n register), setting the CSITn bit to 1 is prohibited (even if set, the INTCSI3n interrupt is not affected).

Caution If the CSITn bit of the CSIM3n register is set to 1 in the continuous mode (TRMDn bit = 1 in the CSIM3n register), the INTCSI3n interrupt is not output at the end of data other than the last data set by the SFNn3 to SFNn0 bits of the SFN3n register, but a delay of half a clock can be inserted between each data transfer.

Figure 11-33. Delay Control of Transmission/Reception Completion Interrupt (INTCSI3n):
CSITn Bit = 1 in CSIC3n Register, CSWEn Bit = 0, CKPn and DAPn Bits = 00,
CCLn3 to CCLn0 Bits = 1000 in CSIL3n Register (Transfer Data Length: 8 Bits)

(15) Enabling/disabling transfer wait

In the master mode (CKS3n2 to CKS3n0 bits = other than 111 in the CSIC3n register), starting transfer can be delayed by one clock for each time 1-bit data transfer is started, depending on the setting (1) of the CSWEn bit of the CSIM3n register (CSWEn bit = 1 (transfer wait inserted)). The CSWEn bit is valid only in the master mode. In the slave mode (CKS3n2 to CKS3n0 bits = 111 in the CSIC3n register), setting the CSWEn bit to 1 is prohibited (even if set, transfer wait is not inserted).

Figure 11-34. Enabling/Disabling Transfer Wait

(16) Output pins**(a) $\overline{\text{SCKn}}$ pin**

The $\overline{\text{SCKn}}$ pin outputs a high level when both the CTXEn and CRXEn bits of the CSIM3n register are 0 ($n = 0, 1$).

In the master mode (CKS3n2 to CKS3n0 bits = other than 111 in the CSIC3n register), this pin outputs the default level when the FPCLRn bit of the SFA3n register is set to 1.

Table 11-8. Default Output Level of $\overline{\text{SCKn}}$ Pin

CKPn Bit	CKS3n2 to CKS3n0 Bits	Default Output Level of $\overline{\text{SCKn}}$ Pin
0	111 (slave mode)	High level ^{Note}
	Other than 111 (master mode)	High level
1	111 (slave mode)	– (input)
	Other than 111 (master mode)	Low level

Note Default value after reset or value when CSICAEn bit = 0 in the CSIM3n register

Remarks 1. The output of the $\overline{\text{SCKn}}$ pin changes if the CKPn bit is rewritten in the master mode.

2. $n = 0, 1$

(b) SOn pin

The SOn pin outputs a low level when both the CTXEn and CRXEn bits of the CSIM3n register are 0 ($n = 0, 1$).

This pin outputs a low level when the FPCLRn bit of the SFA3n register is 1 (the previous value is retained only in the slave mode (CKS3n2 to CKS3n0 bits = 111 in the CSIC3n register) and when the DAPn bit = 0 in the CSIC3n register).

Table 11-9. Default Output Level of SOn Pin

Default Output Level of SOn Pin
Low level ^{Note}

Note Default value after reset or value when CSICAEn bit = 0 in the CSIM3n register

Remark $n = 0, 1$

(17) CSIBUFn overflow interrupt signal (INTCOVF3n)

The INTCOVF3n interrupt is output when 16 data exist in the CSIBUFn register and when the 17th data is written (to the SFDB3n or SFDB3nL register) (the 17th data is not written but ignored).

In the single mode (TRMDn bit = 0 in the CSIM3n register), 16 data exist in the CSIBUFn register when “write CSIBUFn pointer value = SIOOn load CSIBUFn pointer value and SFFULn bit = 1 in the SFA3n register”. When transfer is completed and the SIOOn load CSIBUFn pointer is incremented, the CSIBUFn register has one vacancy (the CSIBUFn register has no vacancy even when transfer of one data has been completed in the continuous mode (TRMDn bit = 1 in the CSIM3n register)).

11.3.6 Usage

(1) Single mode (in master mode and transmission mode)

- <1> Set the external pins related to the CSI3n function to control mode.
- <2> When the CSICAEn bit of the CSIM3n register is set to 1, supplying the operating clock is enabled.
- <3> Specify the transfer mode by setting the CSIC3n and CSIL3n registers.
- <4> Write 1 to the FPCLRn bit of the SFA3n register to clear all the CSIBUFn pointers to 0.
- <5> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <6> Specify the transfer mode by using the TRMDn, DIRn, CSITn, and CSWEn bits of the CSIM3n register and, at the same time, enable transmission by setting the CTXEn bit to 1.
- <7> Confirm that the SFFULn bit of the SFA3n register is 0, and then write transfer data to the SFDB3n register. If it is clearly known that the SFFULn bit is 0 because transfer data is written to that bit by the interrupt servicing routine of INTCSI3n, it is not always necessary to confirm that the SFFULn bit is 0.
- <8> Confirm that the INTCSI3n interrupt has occurred and the SFEMPn bit of the SFA3n register is 1, and disable transmission by clearing the CTXEn bit of the CSIM3n register to 0 (end of transmission).

Caution To execute further transfer, repeat <7> before <8>.

(2) Single mode (in master mode and reception mode)

- <1> Set the external pins related to the CSI3n function to control mode.
- <2> When the CSICAEn bit of the CSIM3n register is set to 1, supplying the operating clock is enabled.
- <3> Specify the transfer mode by setting the CSIC3n and CSIL3n registers.
- <4> Write 1 to the FPCLRn bit of the SFA3n register to clear all the CSIBUFn pointers to 0.
- <5> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <6> Specify the transfer mode by using the TRMDn, DIRn, CSITn, and CSWEn bits of the CSIM3n register and, at the same time, enable reception by setting the CRXEn bit to 1.
- <7> Confirm that the SFFULn bit of the SFA3n register is 0, and then write dummy transfer data to the SFDB3n register (reception start trigger). If it is clearly known that the SFFULn bit is 0 because dummy transfer data is written to that bit by the interrupt servicing routine of INTCSI3n, it is not always necessary to confirm that the SFFULn bit is 0.
- <8> Confirm that the INTCSI3n interrupt has occurred, and then read the SIRB3n register.
- <9> Confirm that the INTCSI3n interrupt has occurred and the SFEMPn bit is 1, and disable reception by clearing the CRXEn bit of the CSIM3n register to 0 (end of reception).

Cautions 1. To execute further transfer, repeat <7> and <8> before <9>.

2. The SOn pin outputs a low level but this is invalid.

(3) Single mode (in master mode and transmission/reception mode)

- <1> Set the external pins related to the CSI3n function to control mode.
- <2> When the CSICAEn bit of the CSIM3n register is set to 1, supplying the operating clock is enabled.
- <3> Specify the transfer mode by setting the CSIC3n and CSIL3n registers.
- <4> Write 1 to the FPCLRn bit of the SFA3n register to clear all the CSIBUFn pointers to 0.
- <5> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <6> Specify the transfer mode by using the TRMDn, DIRn, CSITn, and CSWEn bits of the CSIM3n register and, at the same time, enable transmission/reception by setting the CTXEn and CRXEn bits to 1.
- <7> Confirm that the SFFULn bit of the SFA3n register is 0, and then write transfer data to the SFDB3n register. If it is clearly known that the SFFULn bit is 0 because transfer data is written to that bit by the interrupt servicing routine of INTCSI3n, it is not always necessary to confirm that the SFFULn bit is 0.
- <8> Confirm that the INTCSI3n interrupt has occurred, and then read the SIRB3n register.
- <9> Confirm that the INTCSI3n interrupt has occurred and the SFEMPn bit is 1, and disable transmission/reception by clearing the CTXEn and CRXEn bits of the CSIM3n register to 0 (end of transmission/reception).

Caution To execute further transfer, repeat <7> and <8> before <9>.

(4) Single mode (in slave mode and transmission mode)

- <1> Set the external pins related to the CSI3n function to control mode.
- <2> When the CSICAEn bit of the CSIM3n register is set to 1, supplying the operating clock is enabled.
- <3> Specify the transfer mode by setting the CSIC3n and CSIL3n registers.
- <4> Write 1 to the FPCLRn bit of the SFA3n register to clear all the CSIBUFn pointers to 0.
- <5> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <6> Specify the transfer mode by using the TRMDn, DIRn, CSITn, and CSWEn bits of the CSIM3n register and, at the same time, enable transmission by setting the CTXEn bit to 1.
- <7> Confirm that the SFFULn bit of the SFA3n register is 0, and then write transfer data to the SFDB3n register. If it is clearly known that the SFFULn bit is 0 because transfer data is written to that bit by the interrupt servicing routine of INTCSI3n, it is not always necessary to confirm that the SFFULn bit is 0.
- <8> Confirm that the INTCSI3n interrupt has occurred and the SFEMPn bit is 1, and disable transmission by clearing the CTXEn bit of the CSIM3n register to 0 (end of transmission).

Caution To execute further transfer, repeat <7> before <8>.

(5) Single mode (in slave mode and reception mode)

- <1> Set the external pins related to the CSI3n function to control mode.
- <2> When the CSICAEn bit of the CSIM3n register is set to 1, supplying the operating clock is enabled.
- <3> Specify the transfer mode by setting the CSIC3n and CSIL3n registers.
- <4> Write 1 to the FPCLRn bit of the SFA3n register to clear all the CSIBUFn pointers to 0.
- <5> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <6> Specify the transfer mode by using the TRMDn, DIRn, CSITn, and CSWEn bits of the CSIM3n register and, at the same time, enable reception by setting the CRXEn bit to 1.
- <7> Confirm that the SFFULn bit of the SFA3n register is 0, and then write dummy transfer data to the SFDB3n register (reception start trigger). If it is clearly known that the SFFULn bit is 0 because dummy transfer data is written to that bit by the interrupt servicing routine of INTCSI3n, it is not always necessary to confirm that the SFFULn bit is 0.
- <8> Confirm that the INTCSI3n interrupt has occurred, and then read the SIRB3n register.
- <9> Confirm that the INTCSI3n interrupt has occurred and the SFEMPn bit is 1, and disable reception by clearing the CRXEn bit of the CSIM3n register to 0 (end of reception).

- Cautions** 1. To execute further transfer, repeat <7> and <8> before <9>.
2. The SOn pin outputs a low level but this is invalid.

(6) Single mode (in slave mode and transmission/reception mode)

- <1> Set the external pins related to the CSI3n function to control mode.
- <2> When the CSICAEn bit of the CSIM3n register is set to 1, supplying the operating clock is enabled.
- <3> Specify the transfer mode by setting the CSIC3n and CSIL3n registers.
- <4> Write 1 to the FPCLRn bit of the SFA3n register to clear all the CSIBUFn pointers to 0.
- <5> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <6> Specify the transfer mode by using the TRMDn, DIRn, CSITn, and CSWEn bits of the CSIM3n register and, at the same time, enable transmission/reception by setting the CTXEn and CRXEn bits to 1.
- <7> Confirm that the SFFULn bit of the SFA3n register is 0, and then write transfer data to the SFDB3n register. If it is clearly known that the SFFULn bit is 0 because transfer data is written to that bit by the interrupt servicing routine of INTCSI3n, it is not always necessary to confirm that the SFFULn bit is 0.
- <8> Confirm that the INTCSI3n interrupt has occurred, and then read the SIRB3n register.
- <9> Confirm that the INTCSI3n interrupt has occurred and the SFEMPn bit is 1, and disable transmission/reception by clearing the CTXEn and CRXEn bits of the CSIM3n register to 0 (end of transmission/reception).

- Caution** To execute further transfer, repeat <7> and <8> before <9>.

(7) Continuous mode (in master mode and transmission mode)

- <1> Set the external pins related to the CSI3n function to control mode.
- <2> When the CSICAEn bit of the CSIM3n register is set to 1, supplying the operating clock is enabled.
- <3> Specify the transfer mode by setting the CSIC3n and CSIL3n registers.
- <4> Write 1 to the FPCLRn bit of the SFA3n register to clear all the CSIBUFn pointers to 0.
- <5> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <6> Specify the transfer mode by using the TRMDn, DIRn, CSITn, and CSWEn bits of the CSIM3n register and, at the same time, enable transmission by setting the CTXEn bit to 1.
- <7> Set the amount of data to be transmitted by using the SFNn3 to SFNn0 bits of the SFN3n register.
- <8> Write the amount of data to be transmitted to the SFDB3n register as transfer data. Writing data exceeding the set value of the SFN3n register is prohibited.
- <9> Confirm that the INTCSI3n interrupt has occurred and the SFEMPn bit is 1. Then write 1 to the FPCLRn bit of the SFA3n register, and clear all the CSIBUFn pointers to 0 in preparation for the next transfer.
- <10> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <11> Disable transmission by clearing the CTXEn bit of the CSIM3n register to 0 (end of transmission).

Caution To execute further transfer, repeat <7> to <10> before <11>.

(8) Continuous mode (in master mode and reception mode)

- <1> Set the external pins related to the CSI3n function to control mode.
- <2> When the CSICAEn bit of the CSIM3n register is set to 1, supplying the operating clock is enabled.
- <3> Specify the transfer mode by setting the CSIC3n and CSIL3n registers.
- <4> Write 1 to the FPCLRn bit of the SFA3n register to clear all the CSIBUFn pointers to 0.
- <5> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <6> Specify the transfer mode by using the TRMDn, DIRn, CSITn, and CSWEn bits of the CSIM3n register and, at the same time, enable reception by setting the CRXEn bit to 1.
- <7> Set the amount of data to be received by using the SFNn3 to SFNn0 bits of the SFN3n register.
- <8> Write dummy transfer data of the number of receive data to the SFDB3n register. The first dummy transfer data write is the trigger to start reception. Writing dummy data exceeding the set value of the SFN3n register is prohibited.
- <9> Confirm that the INTCSI3n interrupt has occurred and the SFEMPn bit is 1. Then read the receive data from the SIRB3n register (sequentially read the receive data stored in the CSIBUFn register).
- <10> Write 1 to the FPCLRn bit of the SFA3n register, and clear all the CSIBUFn pointers to 0 in preparation for the next transfer.
- <11> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <12> Disable reception by clearing the CRXEn bit of the CSIM3n register to 0 (end of reception).

Cautions 1. To execute further transfer, repeat <7> to <11> before <12>.
2. The SOn pin outputs a low level.

(9) Continuous mode (in master mode and transmission/reception mode)

- <1> Set the external pins related to the CSI3n function to control mode.
- <2> When the CSICAEn bit of the CSIM3n register is set to 1, supplying the operating clock is enabled.
- <3> Specify the transfer mode by setting the CSIC3n and CSIL3n registers.
- <4> Write 1 to the FPCLRn bit of the SFA3n register to clear all the CSIBUFn pointers to 0.
- <5> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <6> Specify the transfer mode by using the TRMDn, DIRn, CSITn, and CSWEn bits of the CSIM3n register and, at the same time, enable transmission/reception by setting both the CTXEn and CRXEn bits to 1.
- <7> Set the amount of data to be transmitted/received by using the SFNn3 to SFNn0 bits of the SFN3n register.
- <8> Write the amount of data to be transmitted to the SFDB3n register as transfer data. Writing data exceeding the set value of the SFN3n register is prohibited.
- <9> Confirm that the INTCSI3n interrupt has occurred and the SFEMPn bit is 1. Then read the receive data from the SIRB3n register (sequentially read the receive data stored in the CSIBUFn register).
- <10> Write 1 to the FPCLRn bit of the SFA3n register, and clear all the CSIBUFn pointers to 0 in preparation for the next transfer.
- <11> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <12> Disable transmission/reception by clearing the CTXEn and CRXEn bits of the CSIM3n register to 0 (end of transmission/reception).

Caution To execute further transfer, repeat <7> to <11> before <12>.

(10) Continuous mode (in slave mode and transmission mode)

- <1> Set the external pins related to the CSI3n function to control mode.
- <2> When the CSICAEn bit of the CSIM3n register is set to 1, supplying the operating clock is enabled.
- <3> Specify the transfer mode by setting the CSIC3n and CSIL3n registers.
- <4> Write 1 to the FPCLRn bit of the SFA3n register to clear all the CSIBUFn pointers to 0.
- <5> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <6> Specify the transfer mode by using the TRMDn, DIRn, CSITn, and CSWEn bits of the CSIM3n register and, at the same time, enable transmission by setting the CTXEn bit to 1.
- <7> Set the amount of data to be transmitted by using the SFNn3 to SFNn0 bits of the SFN3n register.
- <8> Write the amount of data to be transmitted to the SFDB3n register as transfer data. Writing data exceeding the set value of the SFN3n register is prohibited.
- <9> Confirm that the INTCSI3n interrupt has occurred and the SFEMPn bit is 1. Then write 1 to the FPCLRn bit of the SFA3n register, and clear all the CSIBUFn pointers to 0 in preparation for the next transfer.
- <10> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <11> Disable transmission by clearing the CTXEn bit of the CSIM3n register to 0 (end of transmission).

Caution To execute further transfer, repeat <7> to <10> before <11>.

(11) Continuous mode (in slave mode and reception mode)

- <1> Set the external pins related to the CSI3n function to control mode.
- <2> When the CSICAEn bit of the CSIM3n register is set to 1, supplying the operating clock is enabled.
- <3> Specify the transfer mode by setting the CSIC3n and CSIL3n registers.
- <4> Write 1 to the FPCLRn bit of the SFA3n register to clear all the CSIBUFn pointers to 0.
- <5> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <6> Specify the transfer mode by using the TRMDn, DIRn, CSITn, and CSWEn bits of the CSIM3n register and, at the same time, enable reception by setting the CRXEn bit to 1.
- <7> Set the amount of data to be received by using the SFNn3 to SFNn0 bits of the SFN3n register.
- <8> Write dummy transfer data of the number of receive data to the SFDB3n register. The first dummy transfer data write is the trigger to start reception. Writing dummy data exceeding the set value of the SFN3n register is prohibited.
- <9> Confirm that the INTCSI3n interrupt has occurred and the SFEMPn bit is 1. Then read the receive data from the SIRB3n register (sequentially read the receive data stored in the CSIBUFn register).
- <10> Write 1 to the FPCLRn bit of the SFA3n register, and clear all the CSIBUFn pointers to 0 in preparation for the next transfer.
- <11> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <12> Disable reception by clearing the CRXEn bit of the CSIM3n register to 0 (end of reception).

- Cautions**
1. To execute further transfer, repeat <7> to <11> before <12>.
 2. The SOn pin outputs a low level.

(12) Continuous mode (in slave mode and transmission/reception mode)

- <1> Set the external pins related to the CSI3n function to control mode.
- <2> When the CSICAEn bit of the CSIM3n register is set to 1, supplying the operating clock is enabled.
- <3> Specify the transfer mode by setting the CSIC3n and CSIL3n registers.
- <4> Write 1 to the FPCLRn bit of the SFA3n register to clear all the CSIBUFn pointers to 0.
- <5> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <6> Specify the transfer mode by using the TRMDn, DIRn, CSITn, and CSWEn bits of the CSIM3n register and, at the same time, enable transmission/reception by setting both the CTXEn and CRXEn bits to 1.
- <7> Set the number of data to be transmitted/received by using the SFNn3 to SFNn0 bits of the SFN3n register.
- <8> Write the amount of data to be transmitted to the SFDB3n register as transfer data. Writing data exceeding the set value of the SFN3n register is prohibited.
- <9> Confirm that the INTCSI3n interrupt has occurred and the SFEMPn bit is 1. Then read the receive data from the SIRB3n register (sequentially read the receive data stored in the CSIBUFn register).
- <10> Write 1 to the FPCLRn bit of the SFA3n register, and clear all the CSIBUFn pointers to 0 in preparation for the next transfer.
- <11> Confirm that the SFFULn bit = 0, SFEMPn bit = 1, and SFPn3 to SFPn0 bits = 0000 in the SFA3n register.
- <12> Disable transmission/reception by clearing the CTXEn and CRXEn bits of the CSIM3n register to 0 (end of transmission/reception).

- Caution** To execute further transfer, repeat <7> to <11> before <12>.

11.3.7 Cautions

Cautions concerning CSI3n are shown below (n = 0, 1).

(1) Stopping CSI3n

The CSI3n unit is reset and CSI3n is stopped when the CSICAEn bit of the CSIM3n register is cleared to 0. To operate CSI3n, first set the CSICAEn bit to 1.

Usually, before clearing the CSICAEn bit to 0, clear both the CTXEn and CRXEn bits to 0 (after the end of transfer).

(2) Enabling transfer

Be sure to write 1 to the FPCLRn bit of the SFA3n register to clear all the CSIBUFn pointers to 0 before enabling transfer by setting the CTXEn or CRXEn bit of the CSIM3n register to 1. If the CTXEn or CRXEn bit is set to 1 without clearing the pointers, and if the previously transferred data remains in the CSIBUFn register, transferring that data is immediately started.

If transfer data is set to the CSIBUFn register before transfer is enabled, transfer is started as soon as the CTXEn or CRXEn bit is set to 1.

(3) Caution on setting SFA3n register

If the SFA3n register is read immediately after data has been written to the SFDB3n and SFDB3nL registers when the main clock (fx) is used at 84 MHz or lower, the SFFULn, SFEMPn, and SFPn3 to SFPn0 bits of the SFA3n register may not change their values in time.

If the SFA3n register is read before the SFFULn bit is set to 1 and the 17th data is written, the CSIBUFn overflow interrupt (INTCOVF3n) occurs.

(4) Caution on setting CSIM3n register

Be sure to set the external pins related to the CSI3n function to the control mode before using CSI3n. Then set the CSICAEn bit to 1 before setting the other bits.

(5) Maximum transfer rate in master mode

Because the maximum transfer rate in the master mode (CKS3n2 to CKS3n0 bits = other than 111 in the CSIC3n register) is 6.25 Mbps, do not exceed this value.

(6) Writing data to SFDB3n register in single mode

Be sure to confirm that the SFFULn bit of the SFA3n register is 0 when writing data to the SFDB3n register. Even if data is written to this register when SFFULn bit is 1, the CSIBUFn overflow interrupt (INTCOVF3n) is issued, and the written data is ignored.

(7) SFA3n register status in continuous mode

The SFA3n register is in the same status when transfer data is written (before start of transfer) after the CSIBUFn pointer is cleared (FPCLRn bit = 1 in the SFA3n register) and when 16 data have been transferred (SFFULn bit = 0, SFEMPn bit = 1, SFPn3 to SFPn0 bits = 0000 in the SFA3n register).

CHAPTER 12 USB FUNCTION CONTROLLER (USBF)

The V850E2/ME3 has an internal USB function controller (USBF) conforming to the Universal Serial Bus Specification.

12.1 Overview

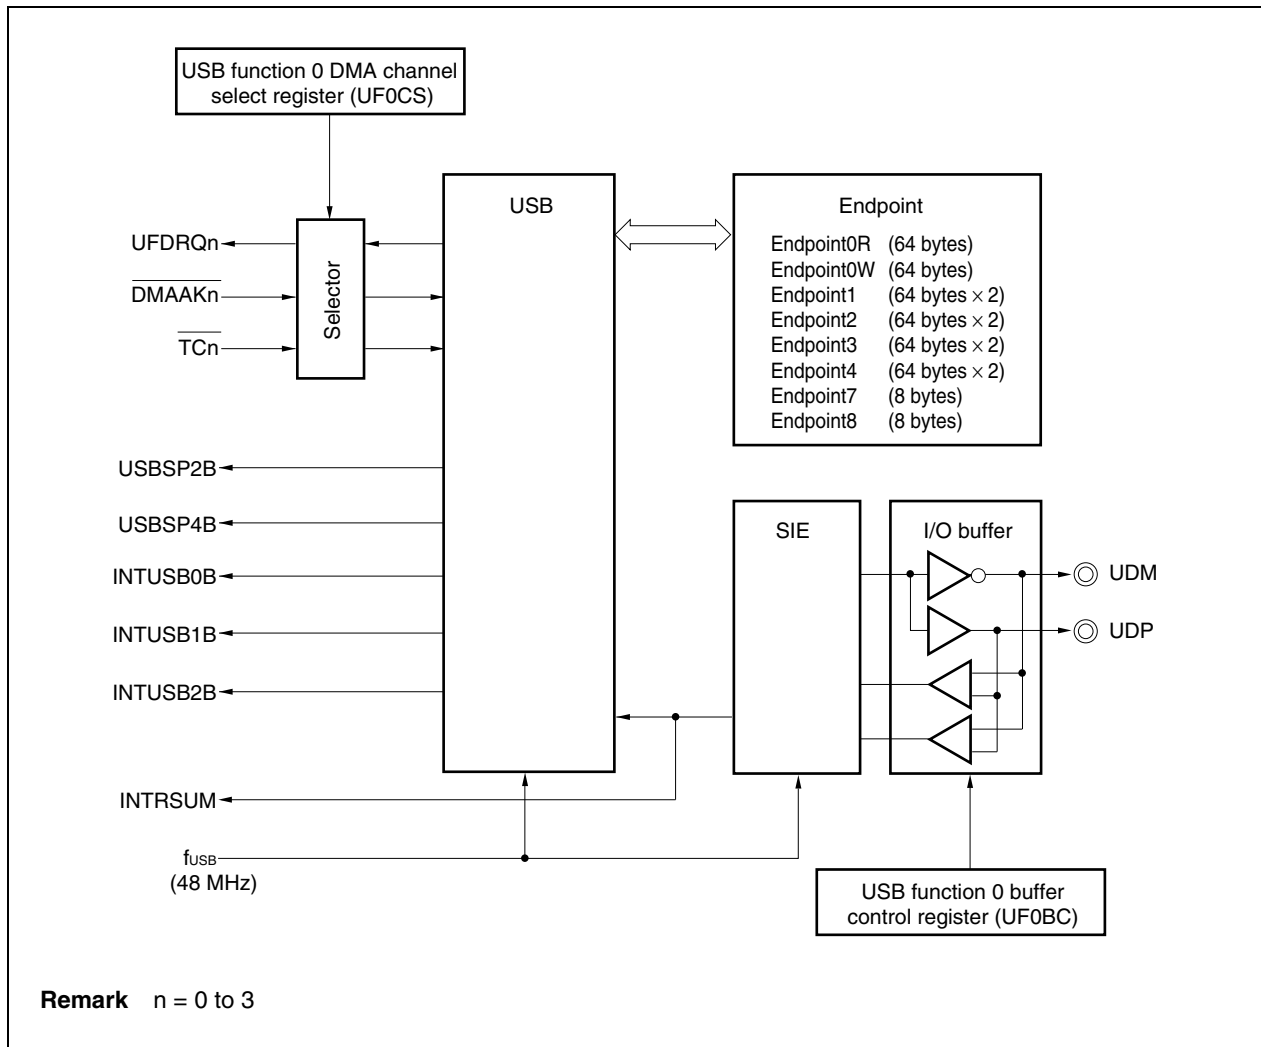

- Conforms to the Universal Serial Bus Specification.
- Supports 12 Mbps (full-speed) transfer
- Endpoint for transfer incorporated

Endpoint Name	FIFO Size (Bytes)	Transfer Type	Remark
Endpoint0 Read	64	Control transfer	–
Endpoint0 Write	64	Control transfer	–
Endpoint1	64 × 2	Bulk 1 transfer (IN)	2-buffer configuration
Endpoint2	64 × 2	Bulk 1 transfer (OUT)	2-buffer configuration
Endpoint3	64 × 2	Bulk 2 transfer (IN)	2-buffer configuration
Endpoint4	64 × 2	Bulk 2 transfer (OUT)	2-buffer configuration
Endpoint7	8	Interrupt 1 transfer	–
Endpoint8	8	Interrupt 2 transfer	–

- Clock: Clock input from UCLK pin ($f_{USB} = 48$ MHz)

Caution When using the USB function, connect UCLK by setting the PFC10 bit of the PFC1 register to 1 and then set the PMC10 bit of the PMC1 register to 1. When UCLK is not connected, do not access the USB-related registers.

12.2 Configuration

12.3 Requests

12.3.1 Automatic requests

(1) Decode

The following tables show the request formats and correspondence between requests and decoded values.

Table 12-1. Request Format

Offset	Field Name	
0	bmRequestType	
1	bRequest	
2	wValue	Lower side
3		Higher side
4	wIndex	Lower side
5		Higher side
6	wLength	Lower side
7		Higher side

Table 12-2. Correspondence Between Requests and Decoded Values

Request	Offset	Decoded Value							Response			Data Stage	
		bmRequestType	bRequest	wValue		wIndex		wLength		Df	Ad		Cf
		0	1	3	2	5	4	7	6				
GET_INTERFACE	81H	0AH	00H	00H	00H	0nH	00H	01H	STALL	STALL	ACK NAK	√	
GET_CONFIGURATION	80H	08H	00H	00H	00H	00H	00H	01H	ACK NAK	ACK NAK	ACK NAK	√

SET_ADDRESS	00H	05H	XXH	XXH	00H	00H	00H	00H	ACK NAK	ACK NAK	ACK NAK	×	

Remark √: Data stage is provided
 ×: Data stage is not provided

- Notes 1.** If the wLength value is less than the prepared value, the wLength value is returned; if the wLength value is greater than the prepared value, the prepared value is returned.
- 2.** The CLEAR_FEATURE request clears UF0 device status register L (UF0DSTL) and UF0 EPn status register L (UF0EnSL) (n = 0 to 4, 7, 8) when ACK is received in the status stage.

- Notes 3.** The SET_FEATURE request sets the UF0 device status register L (UF0DSTL) and UF0 EPn status register L (UF0EnSL) (n = 0 to 4, 7, 8) when ACK is received in the status stage. If the E0HALT bit of the UF0E0SL register is set, a STALL response is made in the status stage or data stage of control transfer for a request other than the GET_STATUS Endpoint0 request, SET_FEATURE Endpoint0 request, and a request generated by the CPUDEC interrupt request, until the CLEAR_FEATURE Endpoint0 request is received. A STALL response to an unsupported request does not set the E0HALT bit of the UF0E0SL register to 1, and the STALL response is cleared as soon as the next SETUP token has been received.
4. If the wValue is not the default value, an automatic STALL response is made.

Cautions 1. The sequence of control transfer defined by the Universal Serial Bus Specification is not satisfied under the following conditions. The operation is not guaranteed under these conditions.

- If an IN/OUT token is suddenly received without a SETUP stage
 - If DATA PID1 is sent in the data phase of the SETUP stage
 - If a token of 128 addresses or more is received
 - If the request data transmitted in the SETUP stage is of less than 8 bytes
2. An ACK response is made even when the host transmits data other than a Null packet in the status stage.
3. If the wLength value is 00H during control transfer (read) of FW processing, a Null packet is automatically transmitted for control transfer (without data). The FW request does not automatically transmit a Null packet.

Remarks 1. Df: Default state, Ad: Addressed state, Cf: Configured state

2. n = 0 to 4

It is determined by the setting of the UF0 active interface number register (UF0AIFN) whether a request with Interface number 1 to 4 is correctly responded to, depending on whether the Interface number of the target is valid or not.

3. \$\$: Valid endpoint number including transfer direction

The valid endpoint is determined by the currently set Alternate Setting number (see 12.4.1 (36) UF0 active alternative setting register (UF0AAS), (38) UF0 endpoint 1 interface mapping register (UF0E1IM) to (43) UF0 endpoint 8 interface mapping register (UF0E8IM)).

4. ? and #: Value transmitted from host (information on Interface numbers 0 to 4)

It is determined by the UF0 active interface number register (UF0AIFN) and UF0 active alternative setting register (UF0AAS) whether an Alternate Setting request corresponding to each Interface number is correctly responded to or not, depending on whether the Interface number and Alternate Setting of the target are valid or not.

(2) Processing

The processing of an automatic request in the Default state, Addressed state, and Configured state is described below.

Remark Default state: State in which an operation is performed with the Default address
Addressed state: State after an address has been allocated
Configured state: State after SET_CONFIGURATION wValue = 1 has been correctly received

(a) CLEAR_FEATURE() request

A STALL response is made in the status stage if the CLEAR_FEATURE() request cannot be cleared, if FEATURE does not exist, or if the target is an interface or an endpoint that does not exist. A STALL response is also made if the wLength value is other than 0.

- Default state: The correct response is made when the CLEAR_FEATURE() request has been received only if the target is a device or a request for Endpoint0; otherwise a STALL response is made in the status stage.
- Addressed state: The correct response is made when the CLEAR_FEATURE() request has been received only if the target is a device or a request for Endpoint0; otherwise a STALL response is made in the status stage.
- Configured state: The correct response is made when the CLEAR_FEATURE() request has been received only if the target is a device or a request for an endpoint that exists; otherwise a STALL response is made in the status stage.

When the CLEAR_FEATURE() request has been correctly processed, the corresponding bit of the UF0 CLR request register (UF0CLR) is set to 1, the EnHALT bit of the UF0 EPn status register L (UF0EnSL) is cleared to 0, and an interrupt is issued (n = 0 to 4, 7, 8). If the CLEAR_FEATURE() request is received when the subject is an endpoint, the toggle bit (that controls switching between DATA0 and DATA1) of the corresponding endpoint is always re-set to DATA0.

(b) GET_CONFIGURATION() request

A STALL response is made in the data stage if any of wValue, wIndex, or wLength is other than the values shown in Table 12-2.

- Default state: The value stored in the UF0 configuration register (UF0CNF) is returned when the GET_CONFIGURATION() request has been received.
- Addressed state: The value stored in the UF0CNF register is returned when the GET_CONFIGURATION() request has been received.
- Configured state: The value stored in the UF0CNF register is returned when the GET_CONFIGURATION() request has been received.

(c) GET_DESCRIPTOR() request

If the subject descriptor has a length that is a multiple of `wMaxPacketSize`, a Null packet is returned to indicate the end of the data stage. If the length of the descriptor at this time is less than the `wLength` value, the entire descriptor is returned; if the length of the descriptor is greater than the `wLength` value, the descriptor up to the `wLength` value is returned.

- **Default state:** The value stored in UF0 device descriptor register `n` (`UF0DDn`) and UF0 configuration/interface/endpoint descriptor register `m` (`UF0CIEm`) is returned ($n = 0$ to 17, $m = 0$ to 255) when the `GET_DESCRIPTOR()` request has been received.
- **Addressed state:** The value stored in the `UF0DDn` register and `UF0CIEm` register is returned when the `GET_DESCRIPTOR()` request has been received.
- **Configured state:** The value stored in the `UF0DDn` register and `UF0CIEm` register is returned when the `GET_DESCRIPTOR()` request has been received.

A descriptor of up to 256 bytes can be stored in the `UF0CIEm` register. To return a descriptor of more than 256 bytes, set the `CDCGDST` bit of the `UF0MODC` register to 1 and process the `GET_DESCRIPTOR()` request by FW.

Store the value of the total number of bytes of the descriptor set by the `UF0CIEm` register – 1 in the UF0 descriptor length register (`UF0DSCL`). The transfer data is controlled by the value of this data + 1 and `wLength`.

(d) GET_INTERFACE() request

If either of `wValue` and `wLength` is other than that shown in Table 12-2, or if `wIndex` is other than that set by the UF0 active interface number register (`UF0AIFN`), a STALL response is made in the data stage.

- **Default state:** A STALL response is made in the data stage when the `GET_INTERFACE()` request has been received.
- **Addressed state:** A STALL response is made in the data stage when the `GET_INTERFACE()` request has been received.
- **Configured state:** The value stored in the UF0 interface `n` register (`UF0IFn`) corresponding to the `wIndex` value is returned ($n = 0$ to 4) when the `GET_INTERFACE()` request has been received.

(e) GET_STATUS() request

A STALL response is made in the data stage if any of wValue, wIndex, or wLength is other than the values shown in Table 12-2. A STALL response is also made in the data stage if the target is an interface or an endpoint that does not exist.

- **Default state:** The value stored in the target status register^{Note} is returned only when the GET_STATUS() request has been received and when the request is for a device or Endpoint0; otherwise a STALL response is made in the data stage.
- **Addressed state:** The value stored in the target status register^{Note} is returned only when the GET_STATUS() request has been received and when the request is for a device or Endpoint0; otherwise a STALL response is made in the data stage.
- **Configured state:** The value stored in the target status register^{Note} is returned only when the GET_STATUS() request has been received and when the request is for a device or an endpoint that exists; otherwise a STALL response is made in the data stage.

Note The target status register is as follows.

- If the target is a device: UF0 device status register L (UF0DSTL)
- If the target is endpoint 0: UF0 EP0 status register L (UF0E0SL)
- If the target is endpoint n: UF0 EPn status register L (UF0EnSL) (n = 1 to 4, 7, 8)

(f) SET_ADDRESS() request

A STALL response is made in the status stage if either of wIndex or wLength is other than the values shown in Table 12-2. A STALL response is also made if the specified device address is greater than 127.

- **Default state:** The device enters the Addressed state and changes the USB Address value to be input to SIE into a specified address value if the specified address is other than 0 when the SET_ADDRESS() request has been received. If the specified address is 0, the device remains in the Default state.
- **Addressed state:** The device enters the Default state and returns the USB Address value to be input to SIE to the default address if the specified address is 0 when the SET_ADDRESS() request has been received. If the specified address is other than 0, the device remains in the Addressed state, and changes the USB Address value to be input to SIE into a specified new address value.
- **Configured state:** The device remains in the Configured state and returns the USB Address value to be input to SIE to the default address if the specified address is 0 when the SET_ADDRESS() request has been received. In this case, the endpoints other than endpoint 0 remain valid, and control transfer (IN), control transfer (OUT), bulk transfer and interrupt transfer for an endpoint other than endpoint 0 are also acknowledged. If the specified address is other than 0, the device remains in the Configured state and changes the USB Address value to be input to SIE into a specified new address value.

(g) SET_CONFIGURATION() request

If any of wValue, wIndex, or wLength is other than the values shown in Table 12-2, a STALL response is made in the status stage.

- **Default state:** The CONF bit of the UF0 mode status register (UF0MODS) and the UF0 configuration register (UF0CNF) are set to 1 if the specified configuration value is 1 when the SET_CONFIGURATION() request has been received. If the specified configuration value is 0, the CONF bit of the UF0MODS register and UF0CNF register are cleared to 0. In other words, the device skips the Addressed state and moves to the Configured state in which it responds to the Default address.
- **Addressed state:** The CONF bit of the UF0MODS register and UF0CNF register are set to 1 and the device enters the Configured state if the specified configuration value is 1 when the SET_CONFIGURATION() request has been received. If the specified configuration value is 0, the device remains in the Addressed state.
- **Configured state:** The CONF bit of the UF0MODS register and UF0CNF register are set to 1 and the device returns to the Addressed state if the specified configuration value is 0 when the SET_CONFIGURATION() request has been received. If the specified configuration value is 1, the device remains in the Configured state.

If the SET_CONFIGURATION() request has been correctly processed, the target bit of the UF0 SET request register (UF0SET) is set to 1, and an interrupt is issued. All Halt Features are cleared after the SET_CONFIGURATION() request has been completed even if the specified configuration value is the same as the current configuration value. If the SET_CONFIGURATION() request has been correctly processed, the data toggle of all endpoints is always initialized to DATA0 again (it is defined that the default status, Alternative Setting 0, is set from when the SET_CONFIGURATION request is received to when the SET_INTERFACE request is received).

(h) SET_FEATURE() request

A STALL response is made in the status stage if the SET_FEATURE() request is for a Feature that cannot be set or does not exist, or if the target is an interface or an endpoint that does not exist. A STALL response is also made if the wLength value is other than 0.

- **Default state:** The correct response is made when the SET_FEATURE() request has been received, only if the request is for a device or Endpoint0; otherwise a STALL response is made in the status stage.
- **Addressed state:** The correct response is made when the SET_FEATURE() request has been received, only if the request is for a device or Endpoint0; otherwise a STALL response is made in the status stage.
- **Configured state:** The correct response is made when the SET_FEATURE() request has been received, only if the request is for a device or an endpoint that exists; otherwise a STALL response is made in the status stage.

When the SET_FEATURE() request has been correctly processed, the target bit of the UF0 SET request register (UF0SET) and the EnHALT bit of the UF0 EPn status register L (UF0EnSL) are set to 1, and an interrupt is issued (n = 0 to 4, 7, 8).

(i) SET_INTERFACE() request

If wLength is other than the values shown in Table 12-2, if wIndex is other than the value set to the UF0 active interface number register (UF0AIFN), or if wValue is other than the value set to the UF0 active alternative setting register (UF0AAS), a STALL response is made in the status stage.

- Default state: A STALL response is made in the status stage when the SET_INTERFACE() request has been received.
- Addressed state: A STALL response is made in the status stage when the SET_INTERFACE() request has been received.
- Configured state: Null packet is transmitted in the status stage when the SET_INTERFACE() request has been received.

When the SET_INTERFACE() request has been correctly processed, an interrupt is issued. All the Halt Features of the endpoint linked to the target Interface are cleared after the SET_INTERFACE() request has been cleared. The data toggle of all the endpoints related to the target Interface number is always initialized again to DATA0. When the currently selected Alternative Setting is to be changed by correctly processing the SET_INTERFACE() request, the FIFO of the endpoint that is affected is completely cleared, and all the related interrupt sources are also initialized.

When the SET_INTERFACE() request has been completed, the FIFO of all the endpoints linked to the target Interface are cleared. At the same time, Halt Feature and Data PID are initialized, and the related UF0 INT status n register (UF0ISn) is cleared to 0 (n = 0 to 4). (Only Halt Feature and Data PID are cleared when the SET_CONFIGURATION request has been completed.)

If the target Endpoint is not supported by the SET_INTERFACE() request during DMA transfer, the DMA request signal is immediately deasserted, and the FIFO of the Endpoint that has been linked when the SET_INTERFACE() request has been completed is completely cleared. As a result of this clearing of the FIFO, data transferred by DMA is not correctly processed.

12.3.2 Other requests

(1) Response and processing

The following table shows how other requests are responded to and processed.

Table 12-3. Response and Processing of Other Requests

Request	Response and Processing
GET_DESCRIPTOR String	Generation of CPUDEC interrupt request
GET_STATUS Interface	Automatic STALL response
CLEAR_FEATURE Interface	Automatic STALL response
SET_FEATURE Interface	Automatic STALL response
all SET_DESCRIPTOR	Generation of CPUDEC interrupt request
All other requests	Generation of CPUDEC interrupt request

12.4 Register Configuration

12.4.1 Control registers

(1) UF0 EP0NAK register (UF0E0N)

This register controls NAK of Endpoint0 (except an automatically executed request).

This register can be read or written in 8-bit units (however, bit 0 can only be read).

It takes five USB clocks to reflect the status on this register after the UF0FIC0 and UF0FIC1 registers have been set. If it is necessary to read the status correctly, therefore, separate a write signal that accesses the UF0FIC0 and UF0FIC1 registers from a read signal that accesses the UF0EPS0, UF0EPS1, UF0EPS2, UF0E0N, and UF0EN registers by at least four USB clocks.

While NAK is being transmitted to Endpoint0 Read, Endpoint2, and Endpoint4, a write access to the EP0NKR bit is ignored.

Bit position	Bit name	Function
1	EP0NKR	This bit controls NAK to the OUT token to Endpoint0 (except an automatically executed request). It is automatically set to 1 by hardware when Endpoint0 has correctly received data. It is also cleared to 0 by hardware when the data of the UF0E0R register has been read by FW (counter value = 0). 1: Transmit NAK. 0: Do not transmit NAK (default value). Set this bit to 1 by FW when data should not be received from the USB bus for some reason even when USBF is ready for receiving data. In this case, USBF continues transmitting NAK until this bit is cleared to 0 by FW. This bit is also cleared to 0 as soon as the UF0E0R register has been cleared.
0	EP0NKW	This bit indicates how NAK to the IN token to Endpoint0 is controlled (except an automatically executed request). This bit is automatically cleared to 0 by hardware when the data of Endpoint0 is transmitted and the host correctly receives the transmitted data. The data of the UF0E0W register is retained until this bit is cleared. Therefore, it is not necessary to rewrite this bit even in the case of a retransmission request that is made if the host could not receive data correctly. To send a short packet, be sure to set the E0DED bit of the UF0DEND register to 1. This bit is automatically set to 1 when the FIFO is full. As soon as the E0DED bit of the UF0DEND register is set to 1, the EP0NKW bit is automatically set to 1 at the same time. 1: Do not transmit NAK. 0: Transmit NAK (default value). If control transfer enters the status stage while ACK cannot be correctly received in the data stage, this bit is cleared to 0 as soon as the UF0E0W register is cleared. This bit is also cleared to 0 when UF0E0W is cleared by FW.

Next, the procedure of a SETUP transaction that uses IN/OUT tokens is explained below.

(a) When IN token is used (except a request automatically executed by hardware)

FW should be used to clear the PROT bit of the UF0IS1 register to 0 after receiving the CPUDEC interrupt and before reading data from the UF0E0ST register. Next, perform processing in accordance with the request and, if it is necessary to return data by an IN token, write data to the UF0E0W register. Confirm that the PROT bit of the UF0IS1 register is 0 after writing has been completed, and set the E0DED bit of the UF0DEND register to 1. The hardware sends out data at the first IN token after the EP0NKW bit has been set to 1. If the PROT bit of the UF0IS1 register is 1, it indicates that a SETUP transaction has occurred again before completion of control transfer. In this case, clear the PROT bit of the UF0IS1 register to 0 by clearing the PROTC bit of the UF0IC1 register to 0, and then read data from the UF0E0ST register again. A request received can be read later.

(b) When OUT token is used (except a request automatically executed by hardware)

FW should be used to clear the PROT bit of the UF0IS1 register after receiving the CPUDEC interrupt and before reading data from the UF0E0ST register. Confirm that the PROT bit of the UF0IS1 register is 0 before reading data from the UF0E0R register. If the PROT bit is 1, it means that invalid data is retained. Clear the FIFO by FW (the EP0NKR bit is automatically cleared to 0). If the PROT bit of the UF0IS1 register is 0, read the data of the UF0E0L register and read as many data from the UF0E0R register as set. When reading data from the UF0E0R register has been completed (when the counter of the UF0E0R register has been cleared to 0), the hardware automatically clears the EP0NKR bit to 0.

(2) UF0 EP0NAKALL register (UF0E0NA)

This register controls NAK to all the requests of Endpoint0. It is also valid for automatically executed requests. This register can be read or written in 8-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
UF0E0NA	0	0	0	0	0	0	0	EP0NKA	1FFFFE01H	00H

Bit position	Bit name	Function
0	EP0NKA	<p>This bit controls NAK to a transaction other than a SETUP transaction to Endpoint0 (including an automatically executed request). This bit is manipulated by FW.</p> <p>1: Transmit NAK. 0: Do not transmit NAK (default value).</p> <p>This register is used to prevent a conflict between a write access by FW and a read access from SIE when the data used for an automatically executed request is to be changed. It postpones reflecting a write access on this bit from FW while an access from SIE is being made. Before rewriting the request data register from FW, confirm that this bit has been correctly set to 1.</p> <p>Setting this bit to 1 is reflected only in the following cases.</p> <ul style="list-style-type: none"> • Immediately after USBF has been reset and a SETUP token has never been received • Immediately after reception of Bus Reset and a SETUP token has never been received • PID of a SETUP token has been detected • The stage has been changed to the status stage <p>Clearing this bit to 0 is reflected immediately, except while an IN token is being received and a NAK response is being made.</p> <p>Setting the EP0NKA bit to 1 is reflected in the above four cases during Endpoint0 transfer, but it is reflected immediately after data has been written to the bit while Endpoint0 is transferring no data.</p>

(3) UF0 EPNAK register (UF0EN)

This register controls NAK of endpoints other than Endpoint0.

This register can be read or written in 8-bit units (however, bits 5, 4, 1, and 0 can only be read).

The BKO2NK bit can be written only when the BKO2NKM bit of the UF0ENM register is 1 and the BKO1NK bit can be written only when the BKO1NKM bit of the UF0ENM register is 1.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register (n = 1 to 4, 7, 8) and the current setting of the interface.

It takes five USB clocks to reflect the status on this register after the UF0FIC0 and UF0FIC1 registers have been set. If it is necessary to read the status correctly, therefore, separate a write signal that accesses the UF0FIC0 and UF0FIC1 registers from a read signal that accesses the UF0EPS0, UF0EPS1, UF0EPS2, UF0E0N, and UF0EN registers by at least four USB clocks.

While NAK is being transmitted to Endpoint0 Read, Endpoint2, and Endpoint4, a write access to the BKO1NK and BKO2NK bits is ignored.

Be sure to clear bits 7 and 6 to "0". If it is set to "1", the operation is not guaranteed.

(1/4)

Bit position	Bit name	Function
5	IT2NK	This bit controls NAK to Endpoint8 (interrupt 2 transfer). It is automatically set to 1 and transmission is started when the UF0INT2 register has become full as a result of writing data to it. To send a short packet that does not make the FIFO full, set the IT2DEND bit of the UF0DEND register to 1. As soon as the IT2DEND bit has been set to 1, this bit is automatically set to 1. 1: Do not transmit NAK. 0: Transmit NAK (default value). This bit is also cleared to 0 when the UF0INT2 register has been cleared.
4	IT1NK	This bit controls NAK to Endpoint7 (interrupt 1 transfer). It is automatically set to 1 and transmission is started when the UF0INT1 register has become full as a result of writing data to it. To send a short packet that does not make the FIFO full, set the IT1DEND bit of the UF0DEND register to 1. As soon as the IT1DEND bit has been set to 1, this bit is automatically set to 1. 1: Do not transmit NAK. 0: Transmit NAK (default value). This bit is also cleared to 0 when the UF0INT1 register has been cleared.

UF0EN	7	6	5	4	3	2	1	0	Address	After reset
	0	0	IT2NK	IT1NK	BKO2NK	BKO1NK	BKI2NK	BKI1NK	1FFFFE02H	00H

(2/4)

Bit position	Bit name	Function
3	BKO2NK	<p>This bit controls NAK to Endpoint4 (bulk 2 transfer (OUT)).</p> <p>1: Transmit NAK. 0: Do not transmit NAK (default value).</p> <p>This bit is set to 1 only when the FIFO connected to the SIE side of the UF0BO2 register (64-byte FIFO of bank configuration) cannot receive data. It is cleared to 0 when a toggle operation is performed. The bank is changed (toggle operation) when the following conditions are satisfied.</p> <ul style="list-style-type: none"> • Data correctly received is stored in the FIFO connected to the SIE side. • The value of the FIFO counter connected to the CPU side is 0 (completion of reading). <p>FW should be used to read data of the UF0BO2L register when it has received the BLKO2DT interrupt request and read as many data from the UF0BO2 register as the value of that data. To not receive data from the USB bus for some reason even if USBF is ready to receive data, set this bit to 1 by FW. In this case, USBF keeps transmitting NAK until the FW clears this bit to 0. This bit is also cleared to 0 as soon as the UF0BO2 register has been cleared.</p>
2	BKO1NK	<p>This bit controls NAK to Endpoint2 (bulk 1 transfer (OUT)).</p> <p>1: Transmit NAK. 0: Do not transmit NAK (default value).</p> <p>This bit is set to 1 only when the FIFO connected to the SIE side of the UF0BO1 register (64-byte FIFO of bank configuration) cannot receive data. It is cleared to 0 when a toggle operation is performed. The bank is changed (toggle operation) when the following conditions are satisfied.</p> <ul style="list-style-type: none"> • Data correctly received is stored in the FIFO connected to the SIE side. • The value of the FIFO counter connected to the CPU side is 0 (completion of reading). <p>FW should be used to read data of the UF0BO1L register when it has received the BLKO1DT interrupt request and read as many data from the UF0BO1 register as the value of that data. To not receive data from the USB bus for some reason even if USBF is ready to receive data, set this bit to 1 by FW. In this case, USBF keeps transmitting NAK until the FW clears this bit to 0. This bit is also cleared to 0 as soon as the UF0BO1 register has been cleared.</p>

- Cautions**
1. If DMA is enabled while data is being read from the UF0BO2 register in the PIO mode, a DMA request is immediately issued.
 2. If the last data of the FIFO on the CPU side is read in the DMA transfer mode, the DMA request signal becomes inactive.
 3. If the TC signal is received in the DMA transfer mode, the DMA request signal becomes inactive.

Bit position	Bit name	Function
1	BKI2NK	<p>This bit controls NAK to Endpoint3 (bulk 2 transfer (IN)).</p> <p>1: Do not transmit NAK. 0: Transmit NAK (default value).</p> <p>This bit is cleared to 0 only when the FIFO connected to the SIE side of the UF0BI2 register (64-byte FIFO of bank configuration) cannot receive data. It is set to 1 when a toggle operation is performed (the data of the UF0BI2 register is retained until transmission has been correctly completed). The bank is changed (toggle operation) when the following conditions are satisfied.</p> <ul style="list-style-type: none"> • Data is correctly written to the FIFO connected to the CPU bus side (writing has been completed and the FIFO is full or the UF0DEND register is set). • The value of the FIFO counter connected to the SIE side is 0. <p>This bit is automatically set to 1 and data transmission is started when the FIFO on the CPU side becomes full and a FIFO toggle operation is performed as a result of writing data to the FIFO. However, if the FIFO on the CPU side becomes full as a result of writing data to it by DMA while the BKI2T bit of the UF0DEND register is cleared to 0, the toggle operation is not performed because the condition of the toggle operation is not satisfied until the BKI2DED bit of the UF0DEND register is set to 1. To send a short packet that does not make the FIFO on the CPU side full, set the BKI2DED bit to 1 after completing writing data. When the BKI2DED bit is set to 1, a toggle operation is performed and at the same time, this bit is automatically set to 1. This bit is also cleared to 0 as soon as the UF0BI2 register has been cleared.</p>

- Cautions**
1. If DMA is enabled while data is being written to the UF0BI2 register in the PIO mode, a DMA request is immediately issued.
 2. If 64-byte data is written in the DMA transfer mode, the DMA request signal becomes inactive. If the BKI2NK bit is then set to 1, data is transmitted in synchronization with an IN token. The DMA request signal becomes active again as long as the DMA request is not masked as soon as the FIFO is toggled. If the BKI2NK bit is not set, data is not transmitted even if an IN token has been received. In this case, set the BKI2DED bit of the UF0DEND register to 1.
 3. If the TC signal is received in the DMA transfer mode, the DMA request signal becomes inactive. At the same time, the DMA request is masked. If the BKI2NK bit is not set to 1, data is not transmitted even if an IN token is received. When the BKI2DED bit of the UF0DEND register is set to 1 by FW, data is transmitted in synchronization with the IN token. To execute DMA transfer again, unmask the DMA request.

(4/4)

Bit position	Bit name	Function
0	BK11NK	<p>This bit controls NAK to Endpoint1 (bulk 1 transfer (IN)).</p> <p>1: Do not transmit NAK. 0: Transmit NAK (default value).</p> <p>This bit is cleared to 0 only when the FIFO connected to the SIE side of the UF0B11 register (64-byte FIFO of bank configuration) cannot receive data. It is set to 1 when a toggle operation is performed (the data of the UF0B11 register is retained until transmission has been correctly completed). The bank is changed (toggle operation) when the following conditions are satisfied.</p> <ul style="list-style-type: none"> • Data is correctly written to the FIFO connected to the CPU bus side (writing has been completed and the FIFO is full or the UF0DEND register is set). • The value of the FIFO counter connected to the SIE side is 0. <p>This bit is automatically set to 1 and data transmission is started when the FIFO on the CPU side becomes full and a FIFO toggle operation is performed as a result of writing data to the FIFO. However, if the FIFO on the CPU side becomes full as a result of writing data to it by DMA while the BK11T bit of the UF0DEND register is cleared to 0, the toggle operation is not performed because the condition of the toggle operation is not satisfied until the BK11DED bit of the UF0DEND register is set to 1. To send a short packet that does not make the FIFO on the CPU side full, set the BK11DED bit to 1 after completing writing data. When the BK11DED bit is set to 1, a toggle operation is performed and at the same time, this bit is automatically set to 1. This bit is also cleared to 0 as soon as the UF0B11 register has been cleared.</p>

- Cautions**
1. If DMA is enabled while data is being written to the UF0B11 register in the PIO mode, a DMA request is immediately issued.
 2. If 64-byte data is written in the DMA transfer mode, the DMA request signal becomes inactive. If the BK11NK bit is then set to 1, data is transmitted in synchronization with an IN token. The DMA request signal becomes active again as long as the DMA request is not masked as soon as the FIFO is toggled. If the BK11NK bit is not set, data is not transmitted even if an IN token has been received. In this case, set the BK11DED bit of the UF0DEND register to 1.
 3. If the TC signal is received in the DMA transfer mode, the DMA request signal becomes inactive. At the same time, the DMA request is masked. If the BK11NK bit is not set to 1, data is not transmitted even if an IN token is received. When the BK11DED bit of the UF0DEND register is set to 1 by FW, data is transmitted in synchronization with the IN token. To execute DMA transfer again, unmask the DMA request.

(4) UF0 EPNAK mask register (UF0ENM)

This register controls masking a write access to the UF0EN register.

This register can be read or written in 8-bit units.

Be sure to clear bits 7 to 4, 1, and 0 to "0". If it is set to "1", the operation is not guaranteed.

	7	6	5	4	3	2	1	0	Address	After reset
UF0ENM	0	0	0	0	BKO2NKM	BKO1NKM	0	0	1FFFFE03H	00H

Bit position	Bit name	Function
3	BKO2NKM	This bit specifies whether a write access to bit 3 (BKO2NK) of the UF0EN register is masked or not. 1: Do not mask. 0: Mask (default value).
2	BKO1NKM	This bit specifies whether a write access to bit 2 (BKO1NK) of the UF0EN register is masked or not. 1: Do not mask. 0: Mask (default value).

(5) UF0 SNDSIE register (UF0SDS)

This register performs manipulation such as no handshake. It can directly manipulate the pins of SIE.

This register can be read or written in 8-bit units.

Be sure to clear bit 2 to "0". If it is set to "1", the operation is not guaranteed.

	7	6	5	4	3	2	1	0	Address	After reset
UF0SDS	0	0	0	0	SNDSTL	0	0	RSUMIN	1FFFFE04H	00H

Bit position	Bit name	Function
3	SNDSTL	<p>This bit makes Endpoint0 issue a STALL handshake. Setting this bit to 1 if a request for CPUDEC processing is not supported by the system results in a STALL handshake response. If an unsupported wValue is sent by the SET_CONFIGURATION or SET_INTERFACE request, the hardware sets this bit to 1. If a problem occurs in Endpoint0 due to overrun of an automatically executed request, this bit is also set to 1. However, the E0HALT bit of the UF0E0SL register is not set to 1.</p> <p>1: Respond with STALL handshake. 0: Do not respond with STALL handshake (default value).</p> <p>This bit is cleared to 0 and the handshake response to the bus is other than STALL when the next SETUP token is received. To set the SNDSTL bit to 1 by FW, do not write data to the UF0E0W register. Depending on the timing of setting this bit, the STALL response is not made in time, and it may be made to the next transfer after a NAK response has been made.</p> <p>Setting this bit is valid only while an FW-executed request is under execution when this bit is set to 1. It is automatically cleared to 0 when the next SETUP token is received.</p> <p>Remark The SNDSTL bit is valid only for an FW-executed request.</p>
0	RSUMIN	<p>This bit outputs the Resume signal onto the USB bus. Writing this bit is invalid unless the RMWK bit of the UF0DSTL register is set to 1.</p> <p>1: Generate the Resume signal. 0: Do not generate the Resume signal (default value).</p> <p>While this bit is set to 1, the Resume signal continues to be generated. Clear this bit to 0 by FW after a specific time has elapsed. Because the signal is internally sampled at the clock, the operation is guaranteed only while CLK is supplied. Care must be exercised when CLK of the system is stopped.</p>

(6) UF0 CLR request register (UF0CLR)

This register indicates the target of the received CLEAR_FEATURE request.

This register is read-only, in 8-bit units.

This register is meaningful only when an interrupt request is generated. Each bit is set to 1 after completion of the status stage, and automatically cleared to 0 when this register is read.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register ($n = 1$ to 4, 7, 8) and the current setting of the interface.

								Address	After reset
	7	6	5	4	3	2	1	0	
UF0CLR	CLREP8	CLREP7	CLREP4	CLREP3	CLREP2	CLREP1	CLREP0	CLRDEV	1FFFFE05H 00H

Bit position	Bit name	Function
7 to 1	CLREPN	These bits indicate that a CLEAR_FEATURE Endpoint n request is received and automatically processed. 1: Automatically processed 0: Not automatically processed (default value)
0	CLRDEV	This bit indicates that a CLEAR_FEATURE Device request is received and automatically processed. 1: Automatically processed 0: Not automatically processed (default value)

Remark $n = 0$ to 4, 7, 8

(7) UF0 SET request register (UF0SET)

This register indicates the target of the automatically processed SET_XXXX (except SET_INTERFACE) request.

This register is read-only, in 8-bit units.

This register is meaningful only when an interrupt request is generated. Each bit is set to 1 after completion of the status stage, and automatically cleared to 0 when this register is read.

	7	6	5	4	3	2	1	0	Address	After reset
UF0SET	SETCON	0	0	0	0	SETEP	0	SETDEV	1FFFFE06H	00H

Bit position	Bit name	Function
7	SETCON	This bit indicates that a SET_CONFIGURATION request is received and automatically processed. 1: Automatically processed 0: Not automatically processed (default value)
2	SETEP	This bit indicates that a SET_FEATURE Endpoint n request (n = 0 to 4, 7, 8) is received and automatically processed. 1: Automatically processed 0: Not automatically processed (default value)
0	SETDEV	This bit indicates that a SET_FEATURE Device request is received and automatically processed. 1: Automatically processed 0: Not automatically processed (default value)

(8) UF0 EP status 0 register (UF0EPS0)

This register indicates the USB bus status and the presence or absence of register data.

This register is read-only, in 8-bit units.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register (n = 1 to 4, 7, 8) and the current setting of the interface.

It takes five USB clocks to reflect the status on this register after the UF0FIC0 and UF0FIC1 registers have been set. If it is necessary to read the status correctly, therefore, separate writing to the UF0FIC0 and UF0FIC1 registers from reading from the UF0EPS0, UF0EPS1, UF0EPS2, UF0E0N, and UF0EN registers by at least four USB clocks.

(1/2)

	7	6	5	4	3	2	1	0	Address	After reset
UF0EPS0	IT2	IT1	BKOUT2	BKOUT1	BKIN2	BKIN1	EP0W	EP0R	1FFFFE07H	00H

Bit position	Bit name	Function
7, 6	ITn	These bits indicate that data is in the UF0INTn register (FIFO). By setting the ITnDED bit of the UF0DEND register to 1, the status in which data is in the UF0INTn register can be created even if data is not written to the register (Null data transmission). As soon as the ITnDED bit of the UF0DEND register is set to 1 even when the counter of the UF0INTn register is 0, this bit is set to 1 by hardware. It is cleared to 0 after correct transmission. 1: Data is in the register. 0: No data is in the register (default value).
5, 4	BKOUTn	These bits indicate that data is in the UF0BOn register (FIFO) connected to the CPU side. When the FIFO configuring the UF0BOn register is toggled, this bit is automatically set to 1 by hardware. It is automatically cleared to 0 by hardware when reading the UF0BOn register (FIFO) connected to the CPU side has been completed (counter value = 0). It is not set to 1 when Null data is received (toggling the FIFO does not take place either). 1: Data is in the register. 0: No data is in the register (default value).
3, 2	BKINn	These bits indicate that data is in the UF0BIn register (FIFO) connected to the CPU side. By setting the BKInDED bit of the UF0DEND register to 1, the status in which data is in the UF0BIn register can be created even if data is not written to the register (Null data transmission). As soon as the BKInDED bit of the UF0DEND register has been set to 1 while the counter of the UF0BIn register is 0, this bit is set to 1 by hardware. It is cleared to 0 when a toggle operation is performed. 1: Data is in the register. 0: No data is in the register (default value).

Remark n = 1, 2

(2/2)

Bit position	Bit name	Function
1	EPOW	This bit indicates that data is in the UF0E0W register (FIFO). By setting the E0DED bit of the UF0DEND register to 1, the status in which data is in the UF0E0W register can be created even if data is not written to the register (Null data transmission). As soon as the E0DED bit of the UF0DEND register is set to 1 even when the counter of the UF0E0W register is 0, this bit is set to 1 by hardware. It is cleared to 0 after correct transmission. 1: Data is in the register. 0: No data is in the register (default value).
0	EP0R	This bit indicates that data is in the UF0E0R register (FIFO). It is automatically cleared to 0 by hardware when reading the UF0E0R register (FIFO) has been completed (counter value = 0). It is not set to 1 if Null data is received. 1: Data is in the register. 0: No data is in the register (default value).

(9) UF0 EP status 1 register (UF0EPS1)

This register indicates the USB bus status and the presence or absence of register data.

This register is read-only, in 8-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
UF0EPS1	RSUM	0	0	0	0	0	0	0	1FFFE08H	00H

Bit position	Bit name	Function
7	RSUM	<p>This bit indicates that the USB bus is in the Resume status. This bit is meaningful only when an interrupt request is generated.</p> <p>1: Suspend status 0: Resume status (default value)</p> <p>Because sampling is internally performed with the clock, the operation is guaranteed only when CLK is supplied. Care must be exercised when CLK of the system is stopped. The INTRSUM signal of SIE operates even when CLK is stopped. It can therefore be supported by making the interrupt control register (RSUMIC) valid or lowering the frequency of CLK to the USBF.</p> <p>This bit is automatically cleared to 0 when it is read.</p>

(10) UF0 EP status 2 register (UF0EPS2)

This register indicates the USB bus status and the presence or absence of register data.

This register is read-only, in 8-bit units.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register (n = 1 to 4, 7, 8) and the current setting of the interface.

	7	6	5	4	3	2	1	0	Address	After reset
UF0EPS2	0	HALT8	HALT7	HALT4	HALT3	HALT2	HALT1	HALT0	1FFF09H	00H

Bit position	Bit name	Function
6 to 0	HALTn	<p>These bits indicate that Endpoint n is currently stalled. They are set to 1 when a stall condition, such as occurrence of an overrun and reception of an undefined request, is satisfied. These bits are automatically set to 1 by hardware.</p> <p>1: Endpoint is stalled. 0: Endpoint is not stalled (default value).</p> <p>The SNDSTL bit is set to 1 as soon as the HALT0 bit has been set to 1 as a result of occurrence of an overrun or reception of an undefined request. If the next SETUP token is received in this status, the SNDSTL bit is cleared to 0 and, therefore, the HALT0 bit is also cleared to 0. If Endpoint0 is stalled by the SET_FEATURE Endpoint0 request, this bit is not cleared to 0 until the CLEAR_FEATURE Endpoint0 request is received or Halt Feature is cleared by FW. If the GET_STATUS Endpoint0, CLEAR_FEATURE Endpoint0, or SET_FEATURE Endpoint0 request is received, or if a request to be processed by FW is received due to the CPUDEC interrupt request, the HALT0 bit is masked and cleared to 0, until the next SETUP token is received.</p> <p>The HALTn bit is not cleared to 0 until Endpoint n receives the CLEAR_FEATURE Endpoint request, Halt Feature is cleared by the SET_INTERFACE or SET_CONFIGURATION request to the interface to which the endpoint is linked, or Halt Feature is cleared by FW. When the SET_INTERFACE or SET_CONFIGURATION request is correctly processed, the Halt Feature of all the target endpoints, except Endpoint0, is cleared after the request has been processed, even if the wValue is the same as the currently set value, and these bits are also cleared to 0. Halt Feature of Endpoint0 cannot be cleared if it is set because the STALL response is made in response to the SET_INTERFACE and SET_CONFIGURATION requests.</p>

Remark n = 0 to 4, 7, 8

(11) UF0 INT status 0 register (UF0IS0)

This register indicates the interrupt source. If the contents of this register are changed, the INTUSB0B signal becomes active.

This register is read-only, in 8-bit units.

If an interrupt request (INTUSB0B) is generated from USBF, the FW must read this register to identify the interrupt source.

Each bit of this register is forcibly cleared to 0 when 0 is written to the corresponding bit of the UF0IC0 register.

Caution In the USBF, multiple interrupt sources, such as Bus Reset, Resume, and Short, are ORed internally and are issued as a single interrupt request (INTUSB0B). Therefore, in the case of the occurrence of multiple interrupt sources, they are ORed and issued as an INTUSB0B interrupt request.

For example, if a Bus Reset interrupt source and Resume interrupt source are issued, the two sources are ORed and an INTUSB0B interrupt request is issued.

Under these conditions, if the Bus Reset interrupt source is cleared to 0 (BUSRSTC bit of UF0IC0 register = 0), the V850E2/ME3 internal INTUSB0B interrupt request may remain set to 1 since the Resume interrupt source will still be remaining. The new interrupt request flag (US0BIF bit of US0BIC register), therefore, might not be set to 1.

In this case, after performing clear processing for each interrupt request with the INTUSB0B interrupt servicing routine, confirm the flag status for the UF0IS0 and UF0IS1 registers again, and if there are any interrupt sources with flags set to 1, perform flag clearing (only the applicable bits need to be cleared (do not perform a batch clearing)).

(1/2)

	7	6	5	4	3	2	1	0	Address	After reset
UF0IS0	BUSRST	RSUSPD	0	SHORT	DMAED	SETRQ	CLRRQ	EPHALT	1FFFFE10H	00H

Bit position	Bit name	Function
7	BUSRST	This bit indicates that Bus Reset has occurred. 1: Bus Reset has occurred (interrupt request is generated). 0: Not Bus Reset status (default value)
6	RSUSPD	This bit indicates that the Resume or Suspend status has occurred. Reference bit 7 of the UF0EPS1 register by FW. 1: Resume or Suspend status has occurred (interrupt request is generated). 0: Resume or Suspend status has not occurred (default value).
4	SHORT	This bit indicates that data is read from the FIFO of either the UF0BO1 or UF0BO2 register and that the USBSPnB signal (n = 2, 4) is active. It is valid only when the FIFO is full in the DMA mode. 1: USBSPnB signal is active (interrupt request is generated). 0: USBSPnB signal is not active (default value). Identify on which endpoint the operation is performed, by using the UF0DMS1 register. This bit is not automatically cleared to 0 even when the UF0DMS1 register is read by FW.

(2/2)

Bit position	Bit name	Function
3	DMAED	<p>This bit indicates that the DMA end (TC) signal for Endpoint n (n = 1 to 4, 7, 8) is active.</p> <p>1: DMA end signal for Endpoint n has been input (interrupt request is generated).</p> <p>0: DMA end signal for Endpoint n has not been input (default value).</p> <p>When this bit is set to 1, the DMA request signal for Endpoint n becomes inactive. The DMA request signal for Endpoint n does not become active unless FW enables DMA transfer.</p> <p>Use the UF0DMS0 register to confirm on which endpoint the operation is actually performed. However, this bit is not automatically cleared to 0 even if the UF0DMS0 register is read by FW.</p>
2	SETRQ	<p>This bit indicates that the SET_XXXX request to be automatically processed has been received and automatically processed (XXXX = CONFIGURATION or FEATURE).</p> <p>1: SET_XXXX request to be automatically processed has been received (interrupt request is generated).</p> <p>0: SET_XXXX request to be automatically processed has not been received (default value).</p> <p>This bit is set to 1 after completion of the status stage. Upon occurrence of an interrupt due to reception of the SET_xxxx request, be sure to read the UF0SET register and check the request target. If the UF0SET register is not read, the interrupt may not occur even when the SET_xxxx request is automatically responded since then. This bit is not automatically cleared to 0 even if the UF0SET register is read by FW.</p> <p>The EPHALT bit is also set to 1 when the SET_FEATURE Endpoint request has been received.</p>
1	CLRRQ	<p>This bit indicates that the CLEAR_FEATURE request has been received and automatically processed.</p> <p>1: CLEAR_FEATURE request has been received (interrupt request is generated).</p> <p>0: CLEAR_FEATURE request has not been received (default value).</p> <p>This bit is set to 1 after completion of the status stage. Reference the UF0CLR register to identify what is the target of the request. This bit is not automatically cleared to 0 even if the UF0CLR register is read by FW.</p>
0	EPHALT	<p>This bit indicates that an endpoint has stalled.</p> <p>1: Endpoint has stalled (interrupt request is generated).</p> <p>0: Endpoint has not stalled (default value).</p> <p>This bit is also set to 1 when an endpoint has stalled by setting FW.</p> <p>Identify the endpoint that has stalled, by referencing the UF0EPS2 register. This bit is not automatically cleared to 0 even when the CLEAR_FEATURE Endpoint, SET_INTERFACE, or SET_CONFIGURATION request is received. It is not automatically cleared to 0, either, if the next SETUP token is received in case of overrun of Endpoint0.</p> <p>Caution Even if Halt Feature of Endpoint0 is set and this interrupt request is generated, bit 0 of the UF0EPS2 register is masked and cleared to 0 between when a SET_FEATURE Endpoint0, CLEAR_FEATURE Endpoint0, or GET_STATUS Endpoint0 request, or FW-processed request is received and when a SETUP token other than the above is received.</p>

<R>

(12) UF0 INT status 1 register (UF0IS1)

This register indicates the interrupt source. If the contents of this register are changed, the INTUSB0B signal becomes active.

This register is read-only, in 8-bit units.

If an interrupt request (INTUSB0B) is generated from USBF, the FW must read this register to identify the interrupt source.

Each bit of this register is forcibly cleared to 0 when 0 is written to the corresponding bit of the UF0IC1 register. However, the SUCES and STG bits of the UF0IS1 register are automatically cleared to 0 when the next SETUP token has been received.

Caution In the USBF, multiple interrupt sources, such as Bus Reset, Resume, and Short, are ORed internally and are issued as a single interrupt request (INTUSB0B). Therefore, in the case of the occurrence of multiple interrupt sources, they are ORed and issued as an INTUSB0B interrupt request.

For example, if a Bus Reset interrupt source and Resume interrupt source are issued, the two sources are ORed and an INTUSB0B interrupt request is issued.

Under these conditions, if the Bus Reset interrupt source is cleared to 0 (BUSRSTC bit of UF0IC0 register = 0), the V850E2/ME3 internal INTUSB0B interrupt request may remain set to 1 since the Resume interrupt source will still be remaining. The new interrupt request flag (US0BIF bit of US0BIC register), therefore, might not be set to 1.

In this case, after performing clear processing for each interrupt request with the INTUSB0B interrupt servicing routine, confirm the flag status for the UF0IS0 and UF0IS1 registers again, and if there are any interrupt sources with flags set to 1, perform flag clearing (only the applicable bits need to be cleared (do not perform a batch clearing)).

(1/2)

7	6	5	4	3	2	1	0	Address	After reset
0	E0IN	E0INDT	E0ODT	SUCES	STG	PROT	CPU DEC	1FFFFE11H	00H

Bit position	Bit name	Function
6	E0IN	This bit indicates that an IN token for Endpoint0 has been received and that the hardware has automatically transmitted NAK. 1: IN token is received and NAK is transmitted (interrupt request is generated). 0: IN token is not received (default value).
5	E0INDT	This bit indicates that data has been correctly transmitted from the UF0E0W register. 1: Transmission from UF0E0W register is completed (interrupt request is generated). 0: Transmission from UF0E0W register is not completed (default value). Data is transmitted in synchronization with the IN token next to the one that set the EP0NKW bit of the UF0E0N register to 1. This bit is automatically set to 1 by hardware when the host correctly receives that data. It is also set to 1 even if the data is a Null packet. This bit is automatically cleared to 0 by hardware when the first write access is made to the UF0E0W register.
4	E0ODT	This bit indicates that data has been correctly received in the UF0E0R register. 1: Data is in UF0E0R register (interrupt request is generated). 0: Data is not in UF0E0R register (default value). This bit is automatically set to 1 by hardware when data has been correctly received. At the same time, the EP0R bit of the UF0EPS0 register is also set to 1. If a Null packet has been received, this bit is not set to 1. It is automatically cleared to 0 by hardware when the FW reads the UF0E0R register and the value of the UF0E0L register becomes 0.
3	SUCES	This bit indicates that either an FW-processed or hardware-processed request has been received and that the status stage has been correctly completed. 1: Control transfer has been correctly processed (interrupt request is generated). 0: Control transfer has not been processed correctly (default value). This bit is set to 1 upon completion of the status stage. It is automatically cleared to 0 by hardware when the next SETUP token is received. This bit is also set to 1 when data with Data PID of 0 (Null data) is received in the status stage of control transfer.
2	STG	This bit is set to 1 when the stage of control transfer has changed to the status stage. It is valid for both FW-processed and hardware-processed requests. This bit is also set to 1 when the stage of control transfer (without data) has changed to the status stage. 1: Status stage (interrupt request is generated) 0: Not status stage (default value) This bit is automatically cleared to 0 by hardware when the next SETUP token is received. It is also set to 1 when the stage of control transfer has changed to the status stage while ACK cannot be correctly received in the data stage. In this case, the EP0NKW bit of the UF0E0N register is also cleared to 0 as soon as the UF0E0W register has been cleared, if the FW is processing control transfer (read).

(2/2)

Bit position	Bit name	Function
1	PROT	<p>This bit indicates that a SETUP token has been received. It is valid for both FW-processed and hardware-processed requests.</p> <p>1: SETUP token is correctly received (interrupt request is generated).</p> <p>0: SETUP token is not received (default value).</p> <p>This bit is set to 1 when data has been correctly received in the UF0E0ST register. Clear this bit to 0 by FW when the first read access is made to the UF0E0ST register. If it is not cleared to 0 by FW, reception of the next SETUP token cannot be correctly recognized.</p> <p>This bit is used to accurately recognize that a SETUP transaction has been executed again during control transfer. If the SETUP transaction is re-executed during control transfer and if a second request is executed by hardware, the CPUDEC bit is not set to 1, but the PROT bit can be used for recognition of the re-execution.</p>
0	CPUDEC	<p>This bit indicates that the UF0E0ST register has a request that is to be decoded by FW.</p> <p>1: Data is in UF0E0ST register (interrupt request is generated).</p> <p>0: Data is not in UF0E0ST register (default value).</p> <p>This bit is automatically cleared to 0 by hardware when all the data of the UF0E0ST register is read.</p>

(13) UF0 INT status 2 register (UF0IS2)

This register indicates the interrupt source. If the contents of this register are changed, the INTUSB1B signal becomes active.

This register is read-only, in 8-bit units.

If an interrupt request (INTUSB1B) is generated from USBF, the FW must read this register to identify the interrupt source.

Each bit of this register is forcibly cleared to 0 when 0 is written to the corresponding bit of the UF0IC2 register.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register ($n = 1, 3, 7, 8$) and the current setting of the interface.

	7	6	5	4	3	2	1	0	Address	After reset
UF0IS2	BKI2IN	BKI2DT	BKI1IN	BKI1DT	0	0	IT2DT	IT1DT	1FFFE12H	00H

Bit position	Bit name	Function
7, 5	BKInIN	These bits indicate that an IN token has been received in the UF0BIn register (Endpoint m) and that NAK has been returned. 1: IN token is received and NAK is transmitted (interrupt request is generated). 0: IN token is not received (default value).
6, 4	BKInDT	These bits indicate that the FIFO of the UF0BIn register (Endpoint m) has been toggled. This means that data can be written to Endpoint m. 1: FIFO has been toggled (interrupt request is generated). 0: FIFO has not been toggled (default value). The data written to Endpoint m is transmitted in synchronization with the IN token next to the one that set the BKInNK bit of the UF0EN register to 1. When the FIFO has been toggled and then data can be written from the CPU, this bit is automatically set to 1 by hardware. It is also set to 1 when the FIFO has been toggled, even if the data is a Null packet. This bit is automatically cleared to 0 by hardware when the first write access is made to the UF0BIn register.
1, 0	ITnDT	These bits indicate that data has been correctly received from the UF0INTn register (Endpoint x). 1: Transmission is completed (interrupt request is generated). 0: Transmission is not completed (default value). Data is transmitted in synchronization with the IN token next to the one that set the ITnNK bit of the UF0EN register to 1. This bit is automatically set to 1 by hardware when the host has correctly received that data. It is automatically cleared to 0 by hardware when the first write access is made to the UF0INTn register. This bit is also set to 1 even when the data is a Null packet.

Remark $n = 1, 2$

$m = 1$ and $x = 7$ where $n = 1$

$m = 3$ and $x = 8$ where $n = 2$

(14) UF0 INT status 3 register (UF0IS3)

This register indicates the interrupt source. If the contents of this register are changed, the INTUSB1B signal becomes active.

This register is read-only, in 8-bit units.

If an interrupt request (INTUSB1B) is generated from USBF, the FW must read this register to identify the interrupt source.

Each bit of this register is forcibly cleared to 0 when 0 is written to the corresponding bit of the UF0IC3 register.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register ($n = 2, 4$) and the current setting of the interface.

(1/2)

	7	6	5	4	3	2	1	0	Address	After reset
UF0IS3	BKO2FL	BKO2NL	BKO2 NAK	BKO2DT	BKO1FL	BKO1NL	BKO1 NAK	BKO1DT	1FFFFE13H	00H

Bit position	Bit name	Function
7, 3	BKOnFL	These bits indicate that data has been correctly received in the UF0BOn register (Endpoint m) and that both the FIFOs of the CPU and SIE hold the data. 1: Received data is in both the FIFOs of the UF0BOn register (interrupt request is generated). 0: Received data is not in the FIFO on the SIE side of the UF0BOn register (default value). If data is held in both the FIFOs of the CPU and SIE, these bits are automatically set to 1 by hardware. They are automatically cleared to 0 by hardware when the FIFO is toggled.
6, 2	BKOnNL	These bits indicate that a Null packet (packet with a length of 0) has been received in the UF0BOn register (Endpoint m). 1: Null packet is received (interrupt request is generated). 0: Null packet is not received (default value). These bits are set to 1 immediately after reception of a Null packet when the FIFO is empty. They are set to 1 when the FIFO on the CPU side has been completely read if data is in that FIFO.
5, 1	BKOnNAK	These bits indicate that an OUT token has been received to the UF0BOn register (Endpoint m) and that NAK has been returned. 1: OUT token is received and NAK is transmitted (interrupt request is generated). 0: OUT token is not received (default value).

Remark $n = 1, 2$
 $m = 2$ where $n = 1$
 $m = 4$ where $n = 2$

(2/2)

Bit position	Bit name	Function
4, 0	BKOnDT	<p>These bits indicate that data has been correctly received in the UF0BOn register (Endpoint m).</p> <p>1: Reception has been completed correctly (interrupt request is generated). 0: Reception has not been completed (default value).</p> <p>These bits are automatically set to 1 by hardware when data has been correctly received and the FIFO has been toggled. At the same time, the corresponding bits of the UF0EPS0 register are also set to 1. They are not set to 1 when the data is a Null packet. These bits are automatically cleared to 0 by hardware when the value of the UF0BOnL register becomes 0 as a result of reading the UF0BOn register by FW.</p> <p>These bits are automatically cleared to 0 when all the contents of the FIFO on the CPU side have been read. However, the interrupt request is not cleared if data is in the FIFO on the SIE side at this time, and the INTUSB1B signal does not become inactive. The signal is kept active if data is successively received.</p>

Remark n = 1, 2
m = 2 where n = 1
m = 4 where n = 2

(15) UF0 INT status 4 register (UF0IS4)

This register indicates the interrupt source. If the contents of this register are changed, the INTUSB2B signal becomes active.

This register is read-only, in 8-bit units.

If an interrupt request (INTUSB2B) is generated from USBF, the FW must read this register to identify the interrupt source.

Each bit of this register is forcibly cleared to 0 when 0 is written to the corresponding bit of the UF0IC4 register.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register (n = 1 to 4, 7, 8) and the current setting of the interface.

	7	6	5	4	3	2	1	0	Address	After reset

(16) UF0 INT mask 0 register (UF0IM0)

This register controls masking of the interrupt sources indicated by the UF0IS0 register.

This register can be read or written in 8-bit units.

FW can mask occurrence of an interrupt request from USBF (INTUSB0B) by writing 1 to the corresponding bit of this register.

								Address	After reset

Bit position	Bit name	Function								
5	SETINTC	This bit clears the SET_INT interrupt. 0: Clear								

(26) UF0 INT & DMARQ register (UF0IDR)

This register selects reporting via an interrupt request or starting DMA.

This register can be read or written in 8-bit units.

If data exists in either the UF0BO1 or UF0BO1 register, or if data can be written to the UF0BI1 or UF0BI2 register, this register selects whether it is reported to the FW by an interrupt request, or whether starting DMA is requested. If starting DMA is requested, the DMA transfer mode can be selected according to the setting of bits 0 and 1.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register (n = 1 to 4) and the current setting of the interface.

Be sure to clear bits 3 and 2 to "0". If they are set to "1", the operation is not guaranteed.

Caution If the target endpoint is not supported by the SET_INTERFACE request under DMA transfer, the DMA request signal becomes inactive immediately, and the corresponding bit is automatically cleared to 0 by hardware.

(1/2)

Bit position	Bit name	Function
7, 6	DQBInMS	These bits enable (mask) a write DMA transfer request (DMA request signal for Endpoint m) to the UF0BIn register. When these bits are set to 1, the DMA request signal for Endpoint m becomes active while writing data can be acknowledged. If the DMA end signal for Endpoint m is input (if the DMA controller issues TC), these bits are automatically cleared to 0 by hardware. To continue DMA transfer, re-set these bits to 1 by FW. 1: Enables active DMA request signal for Endpoint m (masks BKInDT interrupt). 0: Disables active DMA request signal for Endpoint m (default value).
5, 4	DQBOxMS	These bits enable (mask) a read DMA transfer request (DMA request signal for Endpoint x) to the UF0BOx register. When these bits are set to 1, the DMA request signal for Endpoint x becomes active if the data to be read is prepared in the UF0BOx register. If the DMA end signal for Endpoint x is input (if the DMA controller issues TC), these bits are automatically cleared to 0 by hardware. They are also cleared to 0 when the USBSPxB signal is active. To continue DMA transfer, re-set these bits to 1 by FW. 1: Enables active DMA request signal for Endpoint x (masks BKOnDT interrupt). 0: Disables active DMA request signal for Endpoint x (default value).

Remark n = 1, 2
 m = 1 and x = 2 where n = 1
 m = 3 and x = 4 where n = 2

(2/2)

Bit position	Bit name	Function			
1, 0	MODE1, MODE0	These bits select the DMA transfer mode.			
		MODE1	MODE2	Mode	Remark
		1	1	Setting prohibited	Operation cannot be guaranteed.
		1	0	Demand mode	DMA request signal becomes active as long as there is data. It becomes inactive if there is no more data.
		0	X	Single mode	DMA request signal becomes inactive each time DMA transfer has been executed.
		<p>Remarks</p> <p>1. X: Don't care</p> <p>2. When performing a DMA transfer using USB, transfer is possible only in the single-step transfer mode. Therefore, operation does not differ regardless whether the MODE1 and MODE2 bits are set to the demand mode or single mode.</p>			

(27) UF0 DMA status 0 register (UF0DMS0)

This register indicates the DMA status of Endpoint1 to Endpoint4.

This register is read-only, in 8-bit units.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register (n = 1 to 4) and the current setting of the interface.

	7	6	5	4	3	2	1	0	Address	After reset
UF0DMS0	0	0	DQE4	DQE3	DQE2	DQE1	0	0	1FFFE27H	00H

Bit position	Bit name	Function
5	DQE4	This bit indicates that a DMA read request is being issued from Endpoint4 to memory. 1: DMA read request from Endpoint4 is being issued. 0: DMA read request from Endpoint4 is not being issued (default value).
4	DQE3	This bit indicates that a DMA write request is being issued from memory to Endpoint3. Note that, even if data is in Endpoint3 (when the FIFO is not full and after the BK12DED bit has been set to 1), the DMA request signal becomes active immediately and DMA transfer is started when the DQB12MS bit of the UF0IDR register is set to 1. 1: DMA write request for Endpoint3 is being issued. 0: DMA write request for Endpoint3 is not being issued (default value).
3	DQE2	This bit indicates that a DMA read request is being issued from Endpoint2 to memory. 1: DMA read request from Endpoint2 is being issued. 0: DMA read request from Endpoint2 is not being issued (default value).
2	DQE1	This bit indicates that a DMA write request is being issued from memory to Endpoint1. Note that, even if data is in Endpoint1 (when the FIFO is not full and after the BK11DED bit has been set to 1), the DMA request signal becomes active immediately and DMA transfer is started when the DQB11MS bit of the UF0IDR register is set to 1. 1: DMA write request for Endpoint1 is being issued. 0: DMA write request for Endpoint1 is not being issued (default value).

(28) UF0 DMA status 1 register (UF0DMS1)

This register indicates the DMA status of Endpoint1 to Endpoint4.

This register is read-only, in 8-bit units.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register ($n = 1$ to 4) and the current setting of the interface.

Each bit is automatically cleared to 0 when this register is read. Even when this register is read, however, bits 4 and 3 of the UF0IS0 register are not cleared to 0. If the target endpoint is no longer supported by the SET_INTERFACE request, each bit is automatically cleared to 0 by hardware (however, the DMA_END interrupt request and Short interrupt request are not cleared).

								7	6	5	4	3	2	1	0	Address	After reset
UF0DMS1								DEDE4	DSPE4	DEDE3	DEDE2	DSPE2	DEDE1	0	0	1FFFFE28H	00H

Bit position	Bit name	Function
7, 5, 4, 2	DEDE _n	These bits indicate that the DMA end (TC) signal for Endpoint n becomes active and DMA is stopped while a DMA read request is being issued from Endpoint n to memory. 1: DMA end signal for Endpoint n is active. 0: DMA end signal for Endpoint n is inactive (default value).
6, 3	DSPE _m	These bits indicate that, although a DMA read request was being issued from Endpoint m to memory, DMA has been stopped because the received data is a short packet and there is no more data to be transferred. 1: USBSPmB signal is active. 0: USBSPmB signal is inactive (default value).

Remark $n = 1$ to 4
 $m = 2, 4$

(29) UF0 FIFO clear 0 register (UF0FIC0)

This register clears each FIFO.

This register is write-only, in 8-bit units. If this register is read, 00H is read.

FW can clear the target FIFO by writing 1 to the corresponding bit of this register. The bit to which 1 has been written is automatically cleared to 0. Writing 0 to the bit is invalid.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register ($n = 1, 3, 7, 8$) and the current setting of the interface.

	7	6	5	4	3	2	1	0	Address	After reset
UF0FIC0	BKl2SC	BKl2CC	BKl1SC	BKl1CC	ITR2C	ITR1C	EP0WC	EP0RC	1FFFFE30H	00H

Bit position	Bit name	Function
7, 5	BKlInSC	These bits clear only the FIFO on the SIE side of the UF0BIn register (reset the counter). 1: Clear Writing these bits is invalid while an IN token for Endpoint m is being processed with the BKlInNK bit set to 1. The BKlInNK bit is automatically cleared to 0 by clearing the FIFO. Make sure that the FIFO on the CPU side is empty when these bits are used.
6, 4	BKlInCC	These bits clear only the FIFO on the CPU side of the UF0BIn register (reset the counter). 1: Clear
3, 2	ITRnC	These bits clear the UF0INTn register (reset the counter). 1: Clear Writing these bits is invalid while an IN token for Endpoint x is being processed with the ITnNK bit set to 1. The ITnNK bit is automatically cleared to 0 by clearing the FIFO.
1	EP0WC	This bit clears the UF0E0W register (resets the counter). 1: Clear Writing this bit is invalid while an IN token for Endpoint0 is being processed with the EP0NKW bit set to 1. The EP0NKW bit is automatically cleared to 0 by clearing the FIFO.
0	EP0RC	This bit clears the UF0E0R register (resets the counter). 1: Clear When the EP0NKR bit is set to 1 (except when it has been set by FW), the EP0NKR bit is automatically cleared to 0 by clearing the FIFO.

Remark $n = 1, 2$
 $m = 1$ and $x = 7$ where $n = 1$
 $m = 3$ and $x = 8$ where $n = 2$

(30) UF0 FIFO clear 1 register (UF0FIC1)

This register clears each FIFO.

This register is write-only, in 8-bit units. If this register is read, 00H is read.

FW can clear the target FIFO by writing 1 to the corresponding bit of this register. The bit to which 1 has been written is automatically cleared to 0. Writing 0 to the bit is invalid.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register ($n = 2, 4$) and the current setting of the interface.

	7	6	5	4	3	2	1	0	Address	After reset
UF0FIC1	0	0	0	0	BKOnC	BKOnCC	BKOnC	BKOnCC	1FFFFE31H	00H

Bit position	Bit name	Function
3, 1	BKOnC	These bits clear the FIFOs on both the SIE and CPU sides of the UF0BOn register (reset the counter). 1: Clear When the BKOnNK bit is set to 1 (except when it has been set by FW), the BKOnNK bit is automatically cleared to 0 by clearing the FIFO.
2, 0	BKOnCC	These bits clear only the FIFO on the CPU side of the UF0BOn register (reset the counter). 1: Clear When the BKOnNK bit is set to 1 (except when it has been set by FW), the BKOnNK bit is automatically cleared to 0 by clearing the FIFO.

Remark $n = 1, 2$

(31) UF0 data end register (UF0DEND)

This register reports the end of writing to the transmission system.

This register is write-only, in 8-bit units (however, bits 7 and 6 can be read and written). If this register is read, 00H is read.

FW can start data transfer of the target endpoint by writing 1 to the corresponding bit of this register. The bit to which 1 has been written is automatically cleared to 0. Writing 0 to the bit is invalid.

The related bits are invalid if each endpoint is not supported by the setting of the UF0EnIM register (n = 1, 3, 7, 8) and the current setting of the interface.

(1/2)

	7	6	5	4	3	2	1	0	Address	After reset
UF0DEND	BKl2T	BKl1T	0	IT2DEND	IT1DEND	BKl2DED	BKl1DED	E0DED	1FFF3E35H	00H

Bit position	Bit name	Function
7, 6	BKInT	These bits specify whether toggling the FIFO is automatically executed if the FIFO on the CPU side of the UF0BIn register becomes full as a result of DMA. 1: Automatically execute a toggle operation of the FIFO as soon as the FIFO has become full. 0: Do not automatically execute a toggle operation of the FIFO even if the FIFO becomes full (default value).
4, 3	ITnDEND	Set these bits to 1 to transmit the data of the UF0INTn register. When these bits are set to 1, the ITnNK bit is set to 1 and data transfer is executed. 1: Transmit a short packet. 0: Do not transmit a short packet (default value). If the ITRnC bit of the UF0FIC0 register is set to 1 and then these bits are set to 1 (counter of UF0INTn register = 0 and the corresponding bit of the UF0EPS0 register = 1), a Null packet (with a data length of 0) is transmitted. If data exists in the UF0INTn register and if these bits are set to 1 (counter of UF0INTn register ≠ 0 and the corresponding bit of the UF0EPS0 register = 1), a short packet is transmitted. These bits are automatically controlled by hardware when the FIFO is full.

Remark n = 1, 2

(2/2)

Bit position	Bit name	Function
2, 1	BKInDED	<p>Set these bits to 1 when writing transmit data to the UF0BIn register has been completed. When these bits are set to 1, the FIFO is toggled as soon as possible, the BKInNK bit is set to 1, and data is transferred.</p> <p>1: Transmit a short packet. 0: Do not transmit a short packet (default value).</p> <p>These bits control the FIFO on the CPU side.</p> <p>If the BKInCC bit of the UF0FIC0 register is set to 1 and then these bits are set to 1 (counter of UF0BIn register = 0), a Null packet (with a data length of 0) is transmitted.</p> <p>If data exists in the UF0BIn register and if these bits are set to 1 (counter of UF0BIn register ≠ 0), and if the FIFO is not full, a short packet is transmitted.</p> <p>If the FIFO on the CPU side of the UF0BIn register becomes full as a result of DMA, with the PIO or BKInT bit set to 1, the hardware starts data transmission even if these bits are not set to 1.</p> <p>If the FIFO on the CPU side of the UF0BIn register becomes full as a result of DMA, with the BKInT bit cleared to 0, be sure to set these bits to 1 (see 12.4.1 (3) UF0 EPNAK register (UF0EN)).</p>
0	EODED	<p>Set this bit to 1 to transmit data of the UF0E0W register. When this bit is set to 1, the EP0NKW bit is set to 1 and data is transferred.</p> <p>1: Transmit a short packet. 0: Do not transmit a short packet (default value).</p> <p>If the EP0WC bit of the UF0FIC0 register is set to 1 and if this bit is set to 1 (counter of UF0E0W register = 0 and bit 1 of UF0EPS0 register = 1), a Null packet (with a data length of 0) is transmitted.</p> <p>If data exists in the UF0E0W register and if this bit is set to 1 (counter of UF0E0W register ≠ 0 and bit 1 of the UF0EPS0 register = 1), and if the FIFO is not full, a short packet is transmitted.</p>

Remark n = 1, 2

(32) UF0 GPR register (UF0GPR)

This register controls USBF and the USB interface.

This register is write-only, in 8-bit units. If this register is read, 00H is read. Be sure to clear bits 7 to 1 to "0".

FW can reset the USBF by writing 1 to bit 0 of this register. This bit is automatically cleared to 0 after 1 has been written to it. Writing 0 to this bit is invalid.

	7	6	5	4	3	2	1	0	Address	After reset
UF0GPR	0	0	0	0	0	0	0	MRST	1FFFFE37H	00H

Bit position	Bit name	Function
0	MRST	Set this bit to 1 to reset USBF. 1: Reset Actually, USBF is reset two USB clocks after this bit has been set to 1 by FW and the write signal has become inactive. Resetting USBF by the MRST bit while the system clock is operating has the same result as resetting by the RESET pin (hardware reset) (register value back to default value). However, the UF0CS and UF0BC registers are not reset by the MRST bit.

(33) UF0 mode control register (UF0MODC)

This register controls CPUDEC processing.

This register can be read or written in 8-bit units.

By setting each bit of this register, the setting of the UF0MODS register can be changed. The bit of this register is automatically cleared to 0 only at hardware reset and when the MRST bit of the UF0GRP register has been set to 1.

Even if the bit of this register has automatically been set to 1 by hardware, the setting by FW takes precedence.

Be sure to clear bits 7 and 5 to 2 to "0". If they are set to "1", the operation is not guaranteed.

Caution This register is provided for debugging purposes. Usually, do not set this register except for verifying the operation or when a special mode is used.

	7	6	5	4	3	2	1	0	Address	After reset
UF0MODC	0	CDC GDST	0	0	0	0	0	0	1FFF3E3AH	00H

Bit position	Bit name	Function
6	CDCGDST	Set this bit to 1 to switch the GET_DESCRIPTOR Configuration request to CPUDEC processing. By setting this bit to 1, the CDCGD bit of the UF0MODS register can be forcibly set to 1. <ul style="list-style-type: none"> 1: Forcibly change the GET_DESCRIPTOR Configuration request to CPUDEC processing (sets the CDCGD bit of the UF0MODS register to 1). 0: Automatically process the GET_DESCRIPTOR Configuration request (default value).

(34) UF0 mode status register (UF0MODS)

This register indicates the configuration status.

This register is read-only, in 8-bit units.

7	6	5	4	3	2	1	0	Address	After reset
UF0AIFN	ADDIF	0	0	0	0	0	IFNO1 IFNO0	1FFFFE40H	00H

Bit position	Bit name	Function
6	CDCGD	This bit specifies whether CPUDEC processing is performed for the GET_DESCRIPTOR Configuration request. 1: Forcibly change the GET_DESCRIPTOR Configuration request to CPUDEC processing. 0: Automatically process the GET_DESCRIPTOR Configuration request (default value).
4	MPACK	This bit indicates the transmit packet size of Endpoint0. 1: Transmit a packet of other than 8 bytes. 0: Transmit a packet of 8 bytes (default value). This bit is automatically set to 1 by hardware after the GET_DESCRIPTOR Device request has been processed (on normal completion of the status stage). It is not cleared to 0 until the USBF has been reset (it is not cleared to 0 by Bus Reset). If this bit is not set to 1, the hardware transfers only the automatically-executed request in 8-byte units. Therefore, even if data of more than 8 bytes is sent by the OUT token to be processed by FW before completion of the GET_DESCRIPTOR Device request, the data is correctly received. This bit is ignored if the size of Endpoint0 is 8 bytes.
3	DFLT	This bit indicates the default status (DFLT bit = 1). 1: Enables response. 0: Disables response (always no response) (default value). This bit is automatically set to 1 by Bus Reset. The transaction for all the endpoints is not responded to until this bit is set to 1.
2	CONF	This bit indicates whether the SET_CONFIGURATION request has been completed. 1: SET_CONFIGURATION request has been completed. 0: SET_CONFIGURATION request has not been completed (default value). This bit is set to 1 when Configuration value = 1 is received by the SET_CONFIGURATION request. Unless this bit is set to 1, access to an endpoint other than Endpoint0 is ignored. This bit is cleared to 0 when Configuration value = 0 is received by the SET_CONFIGURATION request. It is also cleared to 0 when Bus Reset is detected.

(35) UF0 active interface number register (UF0AIFN)

This register sets the valid Interface number that correctly responds to the GET/SET_INTERFACE request. Because Interface 0 is always valid, Interfaces 1 to 4 can be selected.

This register can be read or written in 8-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
UF0AIFN	ADDIF	0	0	0	0	0	IFNO1	IFNO0	1FFFFFFE40H	00H

Bit position	Bit name	Function															
7	ADDIF	This bit allows use of Interfaces numbered other than 0. 1: Support up to the Interface number specified by the IFNO1 and IFNO0 bits. 0: Support only Interface 0 (default value). Setting bits 1 and 0 of this register is invalid when this bit is not set to 1.															
1, 0	IFNO1, IFNO0	These bits specify the range of Interface numbers to be supported. <table border="1" style="width: 100%; border-collapse: collapse; margin-top: 5px;"> <thead> <tr> <th style="width: 10%;">IFNO1</th> <th style="width: 10%;">IFNO0</th> <th style="width: 80%;">Valid Interface No.</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">1</td> <td style="text-align: center;">0, 1, 2, 3, 4</td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">0</td> <td style="text-align: center;">0, 1, 2, 3</td> </tr> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">1</td> <td style="text-align: center;">0, 1, 2</td> </tr> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> <td style="text-align: center;">0, 1</td> </tr> </tbody> </table>	IFNO1	IFNO0	Valid Interface No.	1	1	0, 1, 2, 3, 4	1	0	0, 1, 2, 3	0	1	0, 1, 2	0	0	0, 1
IFNO1	IFNO0	Valid Interface No.															
1	1	0, 1, 2, 3, 4															
1	0	0, 1, 2, 3															
0	1	0, 1, 2															
0	0	0, 1															

(36) UF0 active alternative setting register (UF0AAS)

This register specifies a link between the Interface number and Alternative Setting.

This register can be read or written in 8-bit units.

USBF of the V850E2/ME3 can set a five-series Alternative Setting (Alternate Setting 0, 1, 2, 3, and 4 can be defined) and a two-series Alternative Setting (Alternative Setting 0 and 1 can be defined) for one Interface.

	7	6	5	4	3	2	1	0	Address	After reset
UF0AAS	ALT2	IFAL21	IFAL20	ALT2EN	ALT5	IFAL51	IFAL50	ALT5EN	1FFFFE41H	00H

Bit position	Bit name	Function															
7, 3	ALTn	These bits specify whether an n-series Alternative Setting is linked with Interface 0. When these bits are set to 1, the setting of the IFALn1 and IFALn0 bits is invalid. 1: Link n-series Alternative Setting with Interface 0. 0: Do not link n-series Alternative Setting with Interface 0 (default value).															
6, 5, 2, 1	IFALn1, IFALn0	These bits specify the Interface number to be linked with the n-series Alternative Setting. If the linked Interface number is outside the range specified by the UF0AIFN register, the n-series Alternative Setting is invalid (ALTnEN bit = 0). <table border="1" style="width: 100%; border-collapse: collapse; margin-top: 10px;"> <thead> <tr> <th style="width: 10%;">IFALn1</th> <th style="width: 10%;">IFALn0</th> <th style="width: 80%;">Interface number to be linked</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">1</td> <td>Links Interface 4.</td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">0</td> <td>Links Interface 3.</td> </tr> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">1</td> <td>Links Interface 2.</td> </tr> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> <td>Links Interface 1.</td> </tr> </tbody> </table> Do not link a five-series Alternative Setting and a two-series Alternative Setting with the same Interface number.	IFALn1	IFALn0	Interface number to be linked	1	1	Links Interface 4.	1	0	Links Interface 3.	0	1	Links Interface 2.	0	0	Links Interface 1.
IFALn1	IFALn0	Interface number to be linked															
1	1	Links Interface 4.															
1	0	Links Interface 3.															
0	1	Links Interface 2.															
0	0	Links Interface 1.															
4, 0	ALTnEN	These bits validate the n-series Alternative Setting. Unless these bits are set to 1, the setting of the ALTn, IFALn1, and IFALn0 bits is invalid. 1: Validate the n-series Alternative Setting. 0: Do not validate the n-series Alternative Setting (default value).															

Remark n = 2, 5

For example, when the UF0AIFN register is set to 82H and the UF0AAS register is set to 15H, Interfaces 0, 1, 2, and 3 are valid. Interfaces 0 and 2 support only Alternative Setting 0. Interface 1 supports Alternative Setting 0 and 1, and Interface 3 supports Alternative Setting 0, 1, 2, 3, and 4. With this setting, requests GET_INTERFACE wIndex = 0/1/2/3, SET_INTERFACE wValue = 0 & wIndex = 0/2, SET_INTERFACE wValue = 0/1 & wIndex = 1, and SET_INTERFACE wValue = 0/1/2/3/4 & wIndex = 3 are automatically responded to, and a STALL response is made to the other GET/SET_INTERFACE requests.

(37) UF0 alternative setting status register (UF0ASS)

This register indicates the current status of the Alternative Setting.

This register is read-only, in 8-bit units.

Check this register when the SET_INT interrupt request has been issued. The value received by the SET_INTERFACE request is reflected on the UF0IFn register (n = 0 to 4) as well as on this register.

	7	6	5	4	3	2	1	0	Address	After reset

(38) UF0 endpoint 1 interface mapping register (UF0E1IM)

This register specifies for which Interface and Alternative Setting Endpoint1 is valid.

This register can be read or written in 8-bit units.

The setting of this register and the Alternative Setting selected by the SET_INTERFACE request indicate whether Endpoint1 is currently valid, and the hardware determines how the GET_STATUS/CLEAR_FEATURE/SET_FEATURE Endpoint1 request and the IN transaction to Endpoint1 are responded to, and whether the related bits are valid or invalid.

	7	6	5	4	3	2	1	0		
UF0E1IM	E1EN2	E1EN1	E1EN0	E12AL1	E15AL4	E15AL3	E15AL2	E15AL1	1FFFFE43H	00H

Remark n = 1 to 4

12.4.2 Data hold registers

(1) UF0 EP0 read register (UF0E0R)

The UF0E0R register is a 64-byte FIFO that stores the OUT data sent from the host in the data stage of control transfer to/from Endpoint0.

This register is read-only, in 8-bit units. A write access to this register is ignored.

The hardware automatically transfers data to the UF0E0R register when it has received the data from the host. When the data has been correctly received, the E0ODT bit of the UF0IS1 register is set to 1. The UF0E0L register holds the quantity of the received data, and an interrupt request (INTUSB0B) is issued. The UF0E0L register always updates the length of the received data while it is receiving data. If the final transfer is correct reception, the interrupt request is generated. If the reception is abnormal, the UF0E0L register is cleared to 0 and the interrupt request is not generated.

The data held by the UF0E0R register must be read by FW up to the value of the amount of data read by the UF0E0L register. Check that all data has been read by using the EP0R bit of the UF0EPS0 register (the EP0R bit = 0 when all data has been read). If the value of the UF0E0L register is 0, the EP0NKR bit of the UF0E0N register is cleared to 0, and the UF0E0R register is ready for reception. The UF0E0R register is cleared when the next SETUP token has been received.

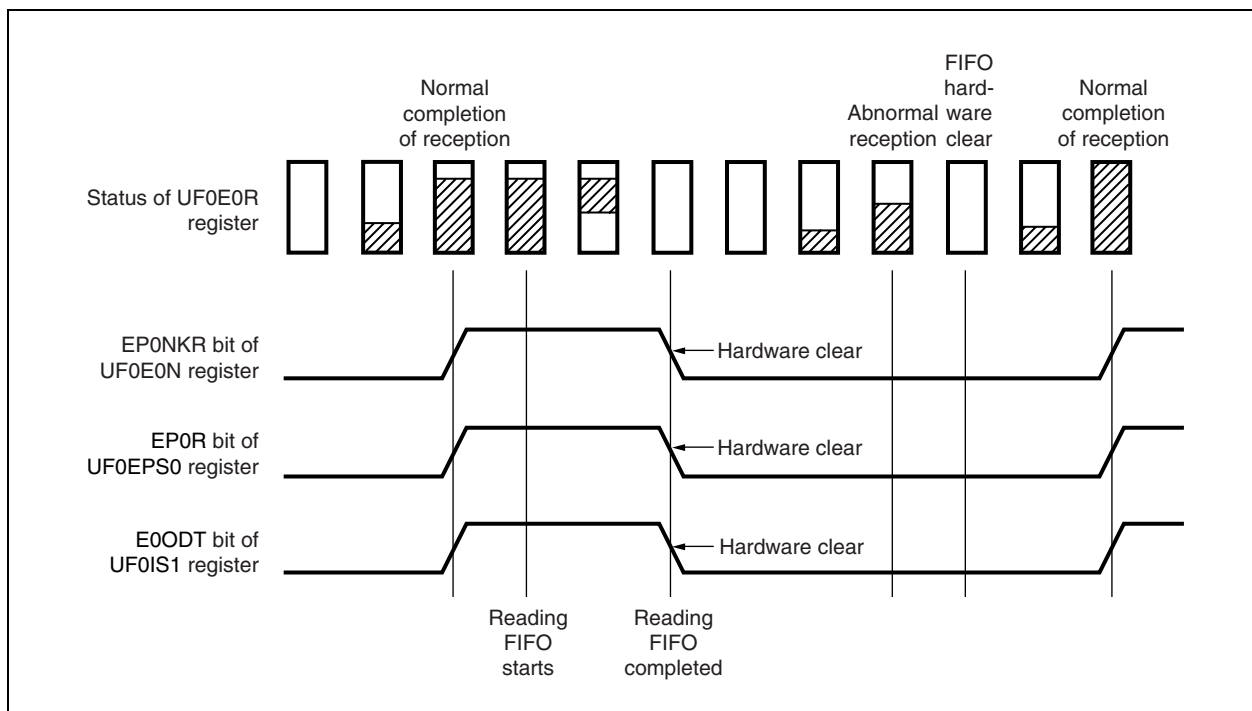

Caution Read all the data stored. Clear the FIFO to discard some data.

UF0E0R	E0R7	E0R6	E0R5	E0R4	E0R3	E0R2	E0R1	E0R0	1FFFFE80H	Undefined

Bit position	Bit name	Function
7 to 0	E0R7 to E0R0	These bits store the OUT data sent from the host in the data stage of control transfer to/from Endpoint0.

The operation of the UF0E0R register is illustrated below.

Figure 12-1. Operation of UF0E0R Register

(2) UF0 EP0 length register (UF0E0L)

The UF0E0L register stores the data length held by the UF0E0R register.

This register is read-only, in 8-bit units. A write access to this register is ignored.

The UF0E0L register always updates the length of the received data while it is receiving data. If the final transfer is abnormal reception, the UF0E0L register is cleared to 0 and the interrupt request is not generated. The interrupt request is generated only when the reception is normal, and the FW can read as many data from the UF0E0R register as the value read from the UF0E0L register. The value of the UF0E0L register is decremented each time the UF0E0R register has been read.

	7	6	5	4	3	2	1	0	Address	After reset
UF0E0L	E0L7	E0L6	E0L5	E0L4	E0L3	E0L2	E0L1	E0L0	1FFFFE81H	00H

Bit position	Bit name	Function
7 to 0	E0L7 to E0L0	These bits store the data length held by the UF0E0R register.

(3) UF0 EP0 setup register (UF0E0ST)

The UF0E0ST register holds the SETUP data sent from the host.

This register is read-only, in 8-bit units. A write access to this register is ignored.

The UF0E0ST register always writes data when a SETUP transaction has been received. The hardware sets the PROT bit of the UF0IS1 register when it has correctly received the SETUP transaction. It sets the CPUDEC bit of the UF0IS1 register in the case of an FW-processed request. Then an interrupt request (INTUSB0B) is issued. In the case of an FW-processed request, be sure to read the request in 8-byte units. If it is not read in 8-byte units, the subsequent requests cannot be correctly decoded. The read counter of the UF0E0ST register is not cleared even when Bus Reset is received. Always read this counter in 8-byte units regardless of whether Bus Reset is received or not.

Because the UF0E0ST register always enables writing, the hardware overwrites data to this register even if a SETUP transaction is received while the data of the register is being read. Even if the SETUP transaction cannot be correctly received, the CPUDEC interrupt request and Protect interrupt request are not generated, but the previous data is discarded. If a SETUP token of less than 8 bytes is received, however, the received SETUP token is discarded, and the previously received SETUP data is retained. If the SETUP token is received more than once when control transfer is executed once, be sure to check the PROT bit of the UF0IS1 register under the conditions below. If PROT bit = 1, read the UF0E0ST register again because the SETUP transaction has been received more than once.

<1> If a request is decoded by FW and the UF0E0R register is read or the UF0E0W register is written

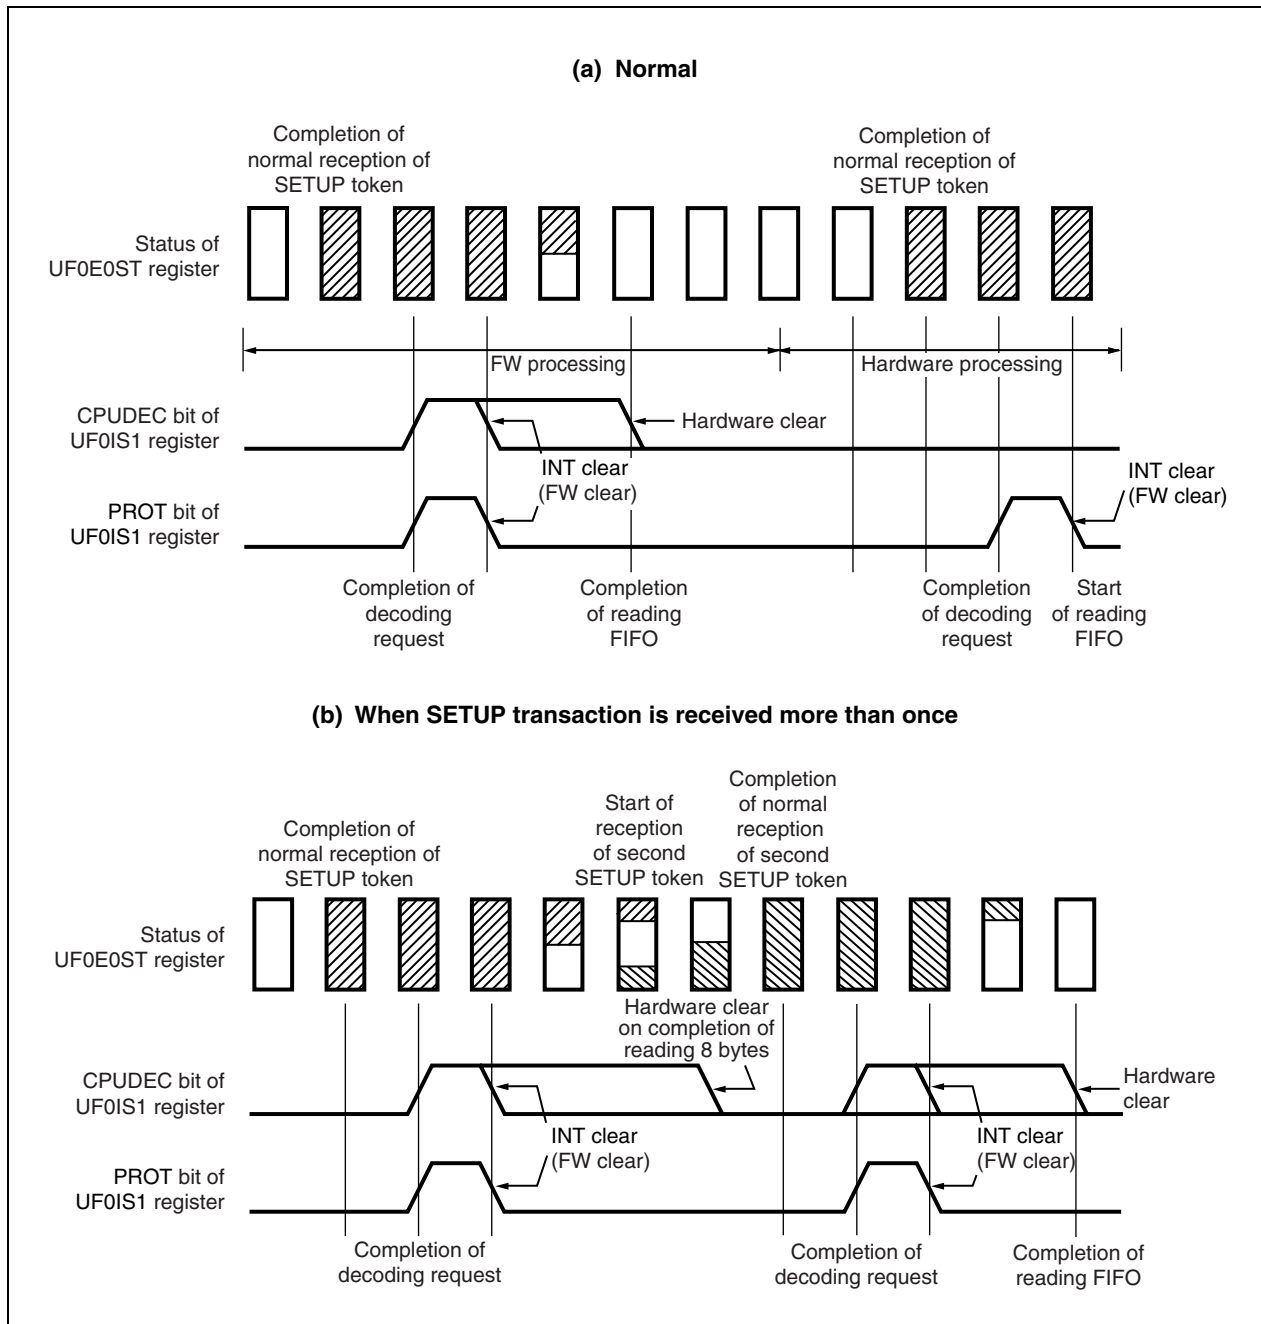

<2> When preparing for a STALL response for the request to which the decode result does not correspond

Caution Be sure to read all the stored data. The UF0E0ST register is always updated by the request in the SETUP transaction.

7 to 0	E0S7 to E0S0	These bits hold the SETUP data sent from the host.								

The operation of the UF0E0ST register is illustrated below.

Figure 12-2. Operation of UF0E0ST Register

(4) UF0E0W write register (UF0E0W)

The UF0E0W register is a 64-byte FIFO that stores the IN data (passes it to SIE) sent to the host in the data stage to Endpoint0.

This register is write-only, in 8-bit units. When this register is read, 00H is read.

The hardware transmits data to the USB bus in synchronization with an IN token only when the EP0NKW bit of the UF0E0N register is set to 1 (when NAK is not transmitted). When data is transmitted and when the host correctly receives the data, the EP0NKW bit of the UF0E0N register is automatically cleared to 0 by hardware. A short packet is transmitted when data is written to the UF0E0W register and the E0DED bit of the UF0DEND register is set to 1 (EP0W bit of the UF0EPS0 register = 1 (data exists)). A Null packet is transmitted when the UF0E0W register is cleared and the E0DED bit of the UF0DEND register is set to 1 (EP0W bit of the UF0EPS0 register = 1 (data exists)).

The UF0E0W register is cleared to 0 when the next SETUP token is received while transmission has not been completed yet. If the stage of control transfer (read) changes to the status stage while ACK has not been correctly received in the data stage, the UF0E0W register is automatically cleared to 0. At the same time, it is also cleared to 0 if the EP0NKW bit of the UF0E0N register is 1.

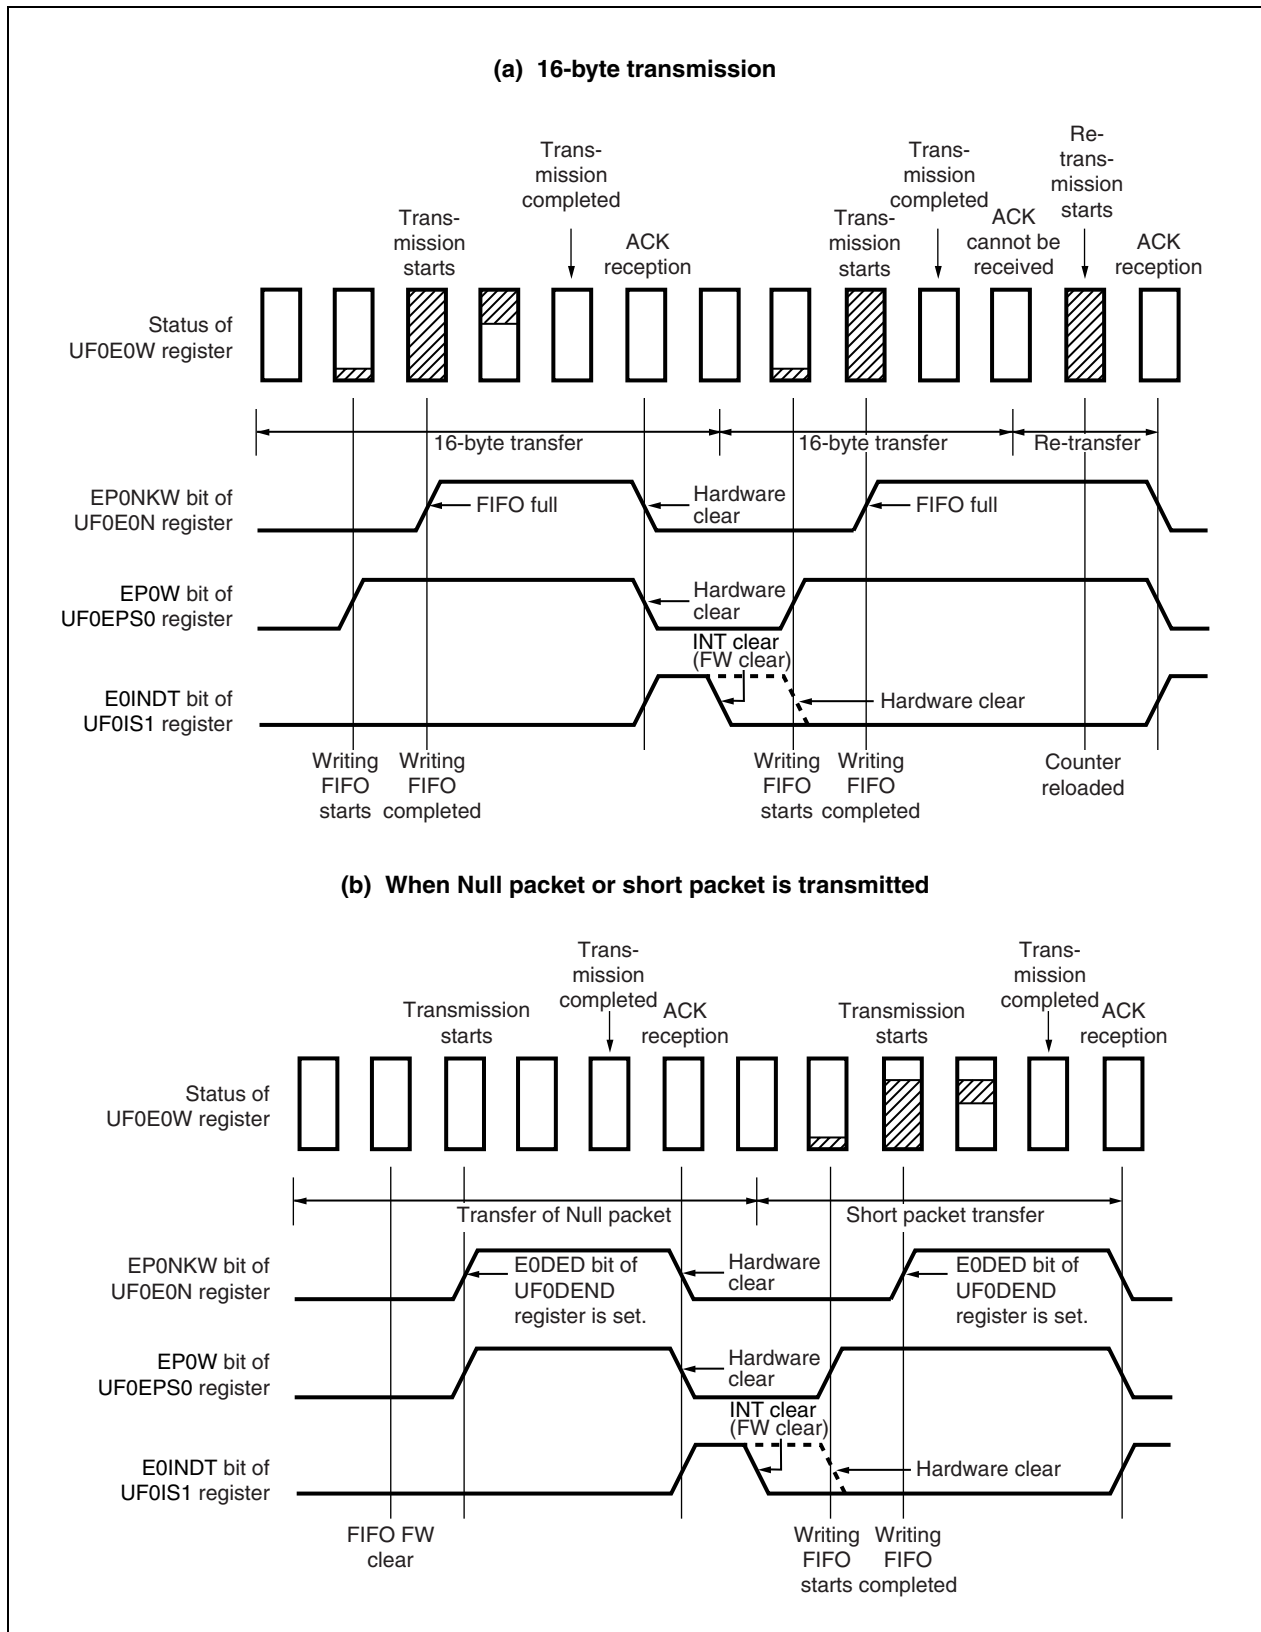

If the UF0E0W register is read while no data is in it, 00H is read.

Bit position	Bit name	Function
7 to 0	E0W7 to E0W0	These bits store the IN data sent to the host in the data stage to Endpoint0.

The operation of the UF0E0W register is illustrated below.

Figure 12-3. Operation of UF0E0W Register

(5) UF0 bulk out 1 register (UF0BO1)

The UF0BO1 register is a 64-byte × 2 FIFO that stores data for Endpoint2. This register consists of two banks of 64-byte FIFOs each of which performs a toggle operation and repeatedly connects the buses on the SIE and CPU sides. The toggle operation takes place when data is in the FIFO on the SIE side and when no data is in the FIFO on the CPU side (counter value = 0).

This register is read-only, in 8-bit units. A write access to this register is ignored.

When the hardware receives data for Endpoint2 from the host, it automatically transfers the data to the UF0BO1 register. When the register correctly receives the data, a FIFO toggle operation occurs. As a result, the BKO1DT bit of the UF0IS3 register is set to 1, the quantity of the received data is held by the UF0BO1L register, and an interrupt request or DMA request is issued to the CPU. Whether the interrupt request or DMA request is issued can be selected by using the DQBO1MS bit of the UF0IDR register.

Read the data held by the UF0BO1 register by FW, up to the value of the amount of data read by the UF0BO1L register. When the correct received data is held by the FIFO connected to the SIE side and the value of the UF0BO1L register reaches 0, the toggle operation of the FIFO occurs, and the BKO1NK bit of the UF0EN register is automatically cleared to 0. If data greater than the value of the UF0BO1L register is read and if the FIFO toggle condition is satisfied, the toggle operation of the FIFO occurs. As a result, the next packet may be read by mistake. Note that, if the toggle condition is not satisfied, the first data is repeatedly read.

If overrun data is received while data is held by the FIFO connected to the CPU side, Endpoint2 stalls, and the FIFO on the CPU side is cleared.

When the UF0BO1 register is read while no data is in it, an undefined value is read.

Caution Be sure to read all the data stored in this register.

	7	6	5	4	3	2	1	0	Address	After reset

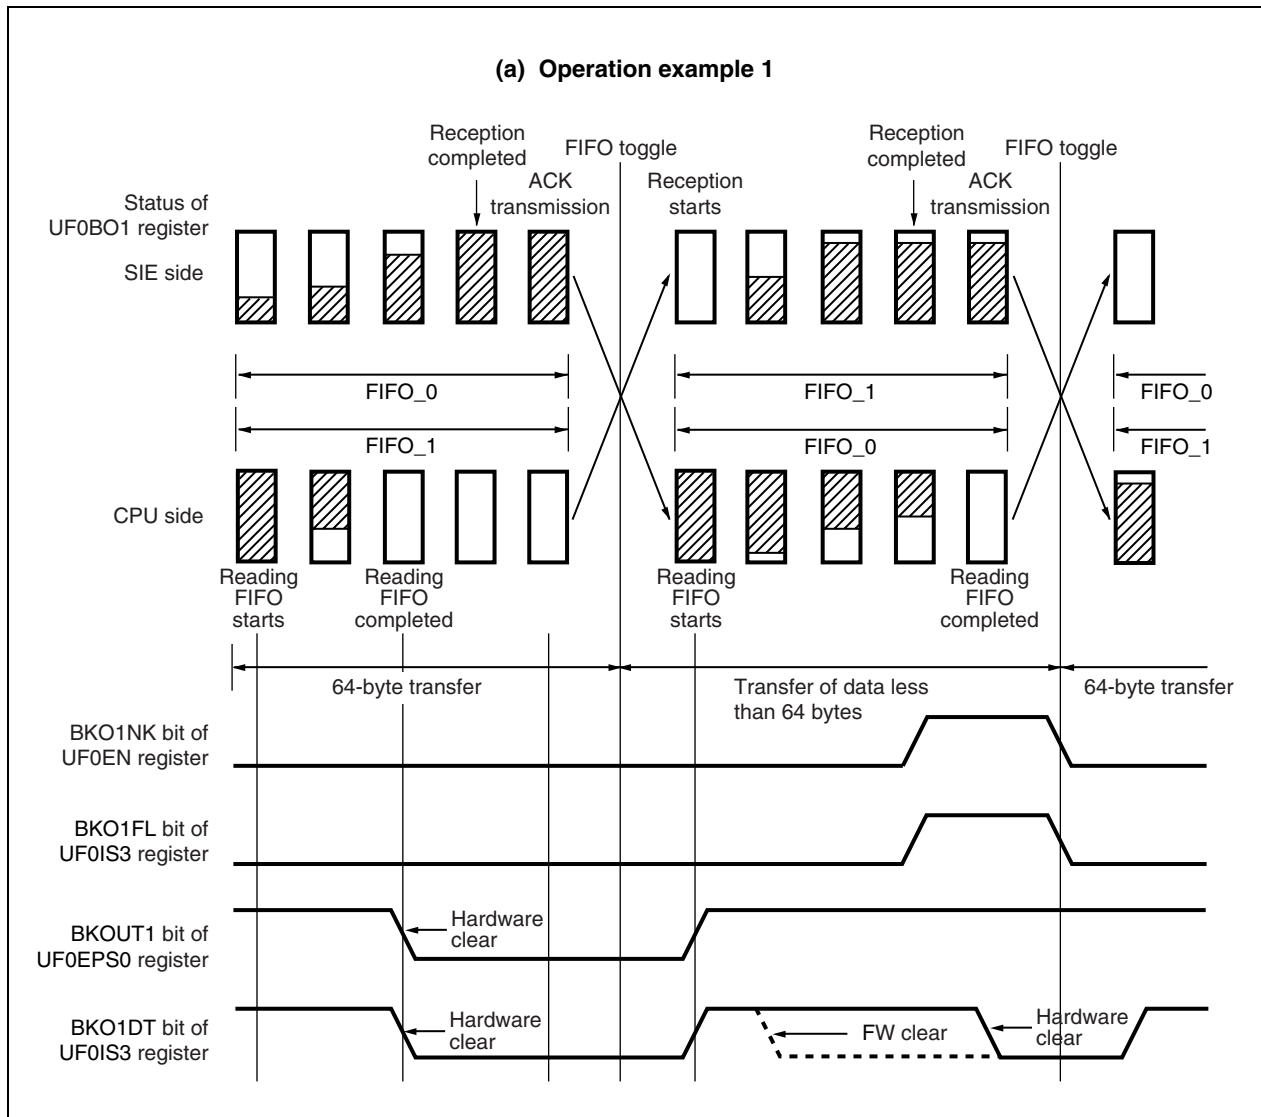

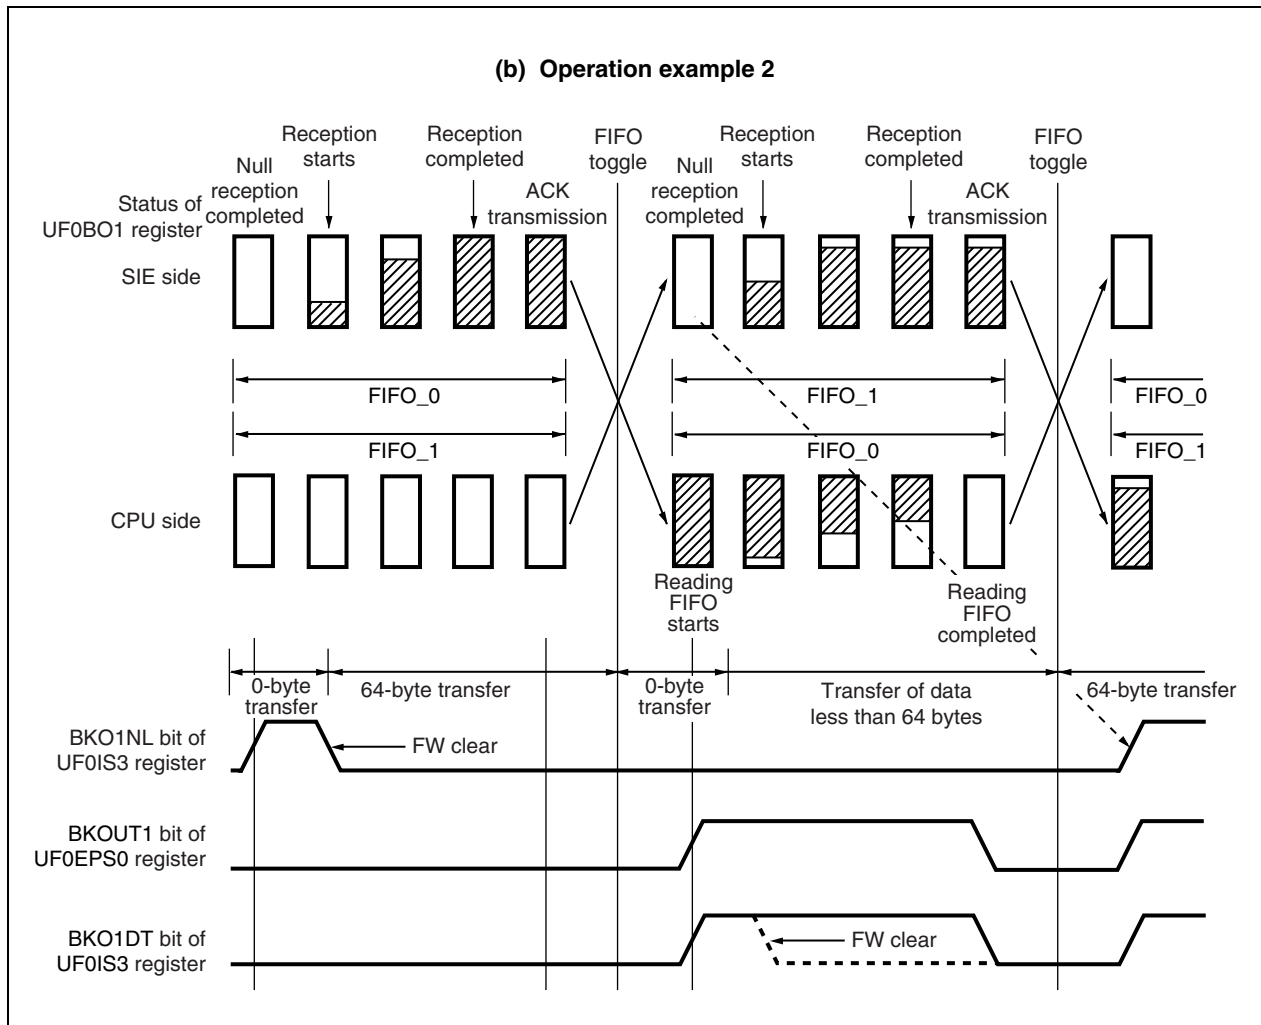

Figure 12-4. Operation of UF0BO1 Register (2/2)

(6) UF0 bulk out 1 length register (UF0BO1L)

The UF0BO1L register stores the length of the data held by the UF0BO1 register.

This register is read-only, in 8-bit units. A write access to this register is ignored.

The UF0BO1L register always updates the received data length while it is receiving data. If the final transfer is abnormal reception, the UF0BO1L register is cleared to 00H, and an interrupt request is not generated. Only if the reception is normal, the interrupt request is generated, and FW can read as much data from the UF0BO1 register as the value read from the UF0BO1L register. The value of the UF0BO1L register is decremented each time the UF0BO1 register has been read.

Bit position	Bit name	Function								
7 to 0	BKO1L7 to BKO1L0	These bits store the length of the data held by the UF0BO1 register.								

(7) UF0 bulk out 2 register (UF0BO2)

The UF0BO2 register is a 64-byte × 2 FIFO that stores data for Endpoint4. This register consists of two banks of 64-byte FIFOs each of which performs a toggle operation and repeatedly connects the buses on the SIE and CPU sides. The toggle operation takes place when data is in the FIFO on the SIE side and when no data is in the FIFO on the CPU side (counter value = 0).

This register is read-only, in 8-bit units. A write access to this register is ignored.

When the hardware receives data for Endpoint4 from the host, it automatically transfers the data to the UF0BO2 register. When the register correctly receives the data, a FIFO toggle operation occurs. As a result, the BKO2DT bit of the UF0IS3 register is set to 1, the quantity of the received data is held by the UF0BO2L register, and an interrupt request or DMA request is issued to the CPU. Whether the interrupt request or DMA request is issued can be selected by using the DQBO2MS bit of the UF0IDR register.

Read the data held by the UF0BO2 register by FW, up to the value of the amount of data read by the UF0BO2L register. When the correct received data is held by the FIFO connected to the SIE side and the value of the UF0BO2L register reaches 0, the toggle operation of the FIFO occurs, and the BKO2NK bit of the UF0EN register is automatically cleared to 0. If data greater than the value of the UF0BO2L register is read and if the FIFO toggle condition is satisfied, the toggle operation of the FIFO occurs. As a result, the next packet may be read by mistake. Note that, if the toggle condition is not satisfied, the first data is repeatedly read.

If overrun data is received while data is held by the FIFO connected to the CPU side, Endpoint4 stalls, and the FIFO on the CPU side is cleared.

When the UF0BO2 register is read while no data is in it, an undefined value is read.

Caution Be sure to read all the data stored in this register.

	7	6	5	4	3	2	1	0	Address	After reset

The operation of the UF0BO2 register is illustrated below.

Figure 12-5. Operation of UF0BO2 Register (1/2)

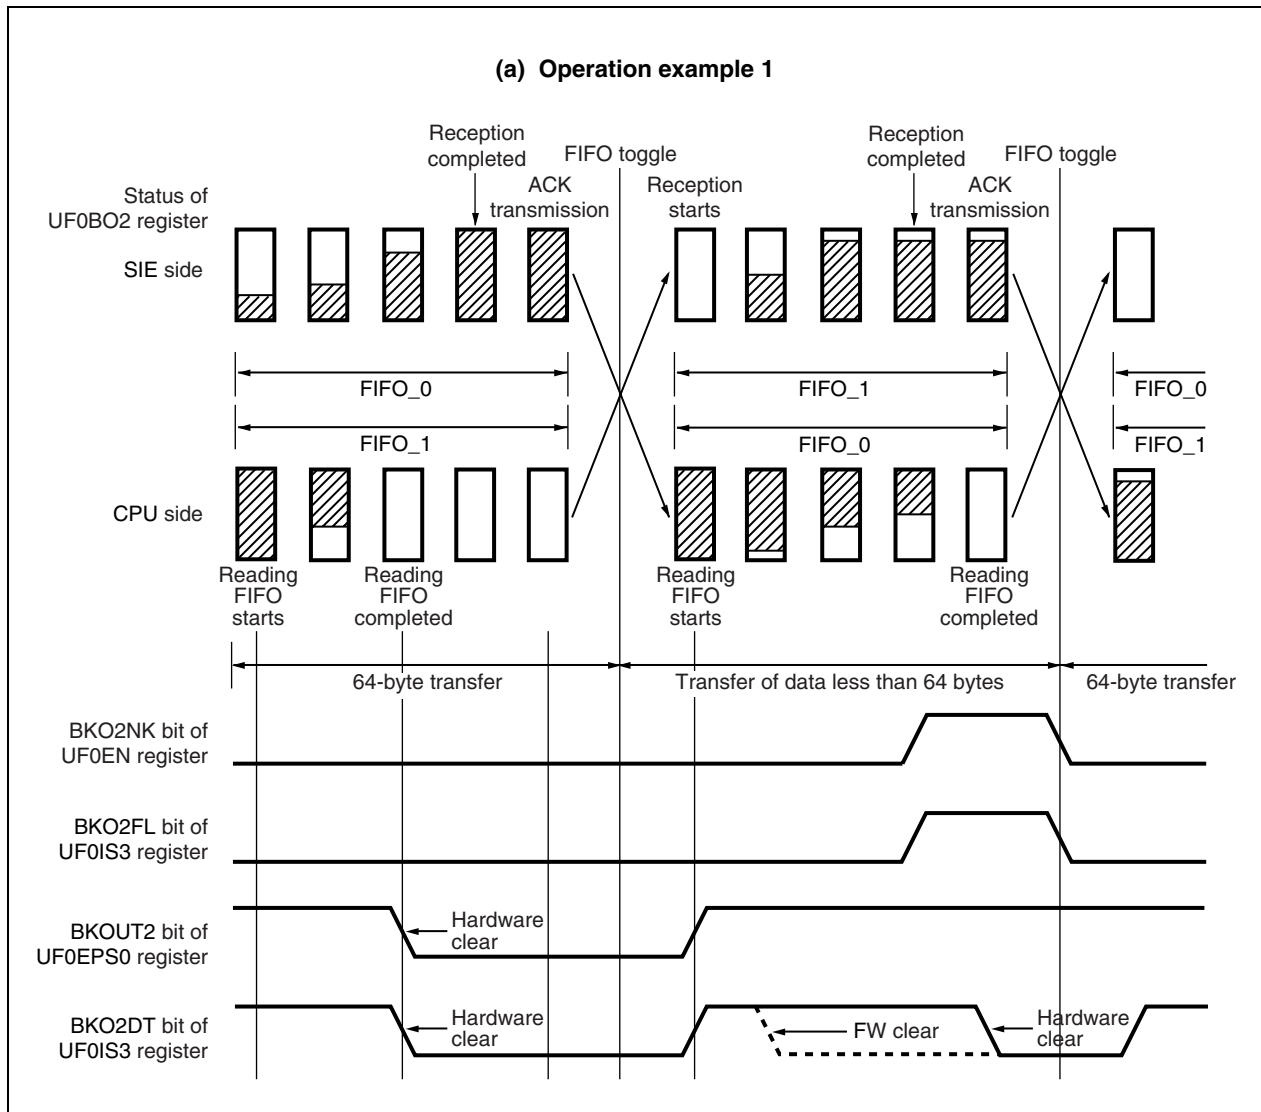

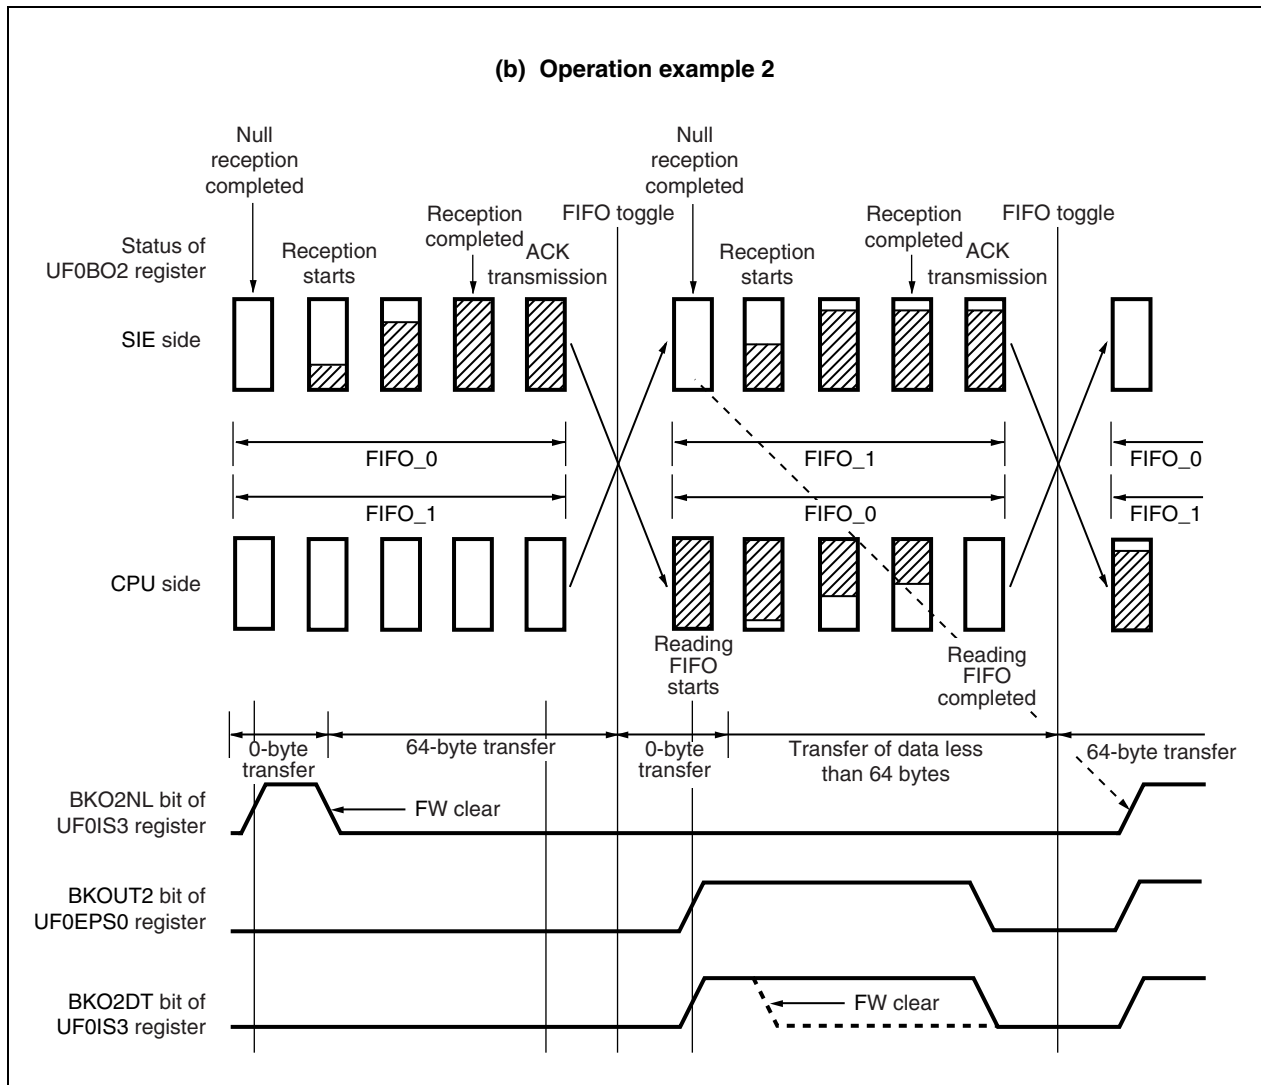

Figure 12-5. Operation of UF0BO2 Register (2/2)

(8) UF0BO2L bulk out 2 length register (UF0BO2L)

The UF0BO2L register stores the length of the data held by the UF0BO2 register.

This register is read-only, in 8-bit units. A write access to this register is ignored.

The UF0BO2L register always updates the received data length while it is receiving data. If the final transfer is abnormal reception, the UF0BO2L register is cleared to 00H, and an interrupt request is not generated. Only if the reception is normal, the interrupt request is generated, and FW can read as much data from the UF0BO2 register as the value read from the UF0BO2L register. The value of the UF0BO2L register is decremented each time the UF0BO2 register has been read.

Bit position	Bit name		Function							
7 to 0	BKO2L7 to BKO2L0		These bits store the length of the data held by the UF0BO2 register.							

(9) UF0BI1 bulk in 1 register (UF0BI1)

The UF0BI1 register is a 64-byte × 2 FIFO that stores data for Endpoint1. This register consists of two banks of 64-byte FIFOs each of which performs a toggle operation and repeatedly connects the buses on the SIE and CPU sides. The toggle operation takes place when no data is in the FIFO on the SIE side (counter value = 0) and when the FIFO on the CPU side is correctly written (FIFO full or BKI1DED bit = 1).

This register is write-only, in 8-bit units. When this register is read, 00H is read.

The hardware transmits data to the USB bus in synchronization with the IN token for Endpoint1 only when the BKI1NK bit of the UF0EN register is set to 1 (when NAK is not transmitted). The address at which data is to be written or read is managed by the hardware. Therefore, FW can transmit data to the host only by writing the data to the UF0BI1 register sequentially. A short packet is transmitted when data is written to the UF0BI1 register and the BKI1DED bit of the UF0DEND register is set to 1 (BKIN1 bit of UF0EPS0 register = 1 (data exists)). A Null packet is transmitted when the UF0BI1 register is cleared and the BKI1DED bit of the UF0DEND register is set to 1 (BKIN1 bit of the UF0EPS0 register = 1 (data exists)). After data is transmitted normally, FIFO toggle operation is started, the BKI1DT bit of the UF0IS2 register is set to 1, and an interrupt request is issued to the CPU. An interrupt request or DMA request can be selected by using the DQBI1MS bit of the UF0IDR register.

Caution To execute DMA transfer to or from the UF0BI1 register, not to perform block transfer. If block transfer is performed, the transferred data cannot be guaranteed.

	7	6	5	4	3	2	1	0	Address	After reset

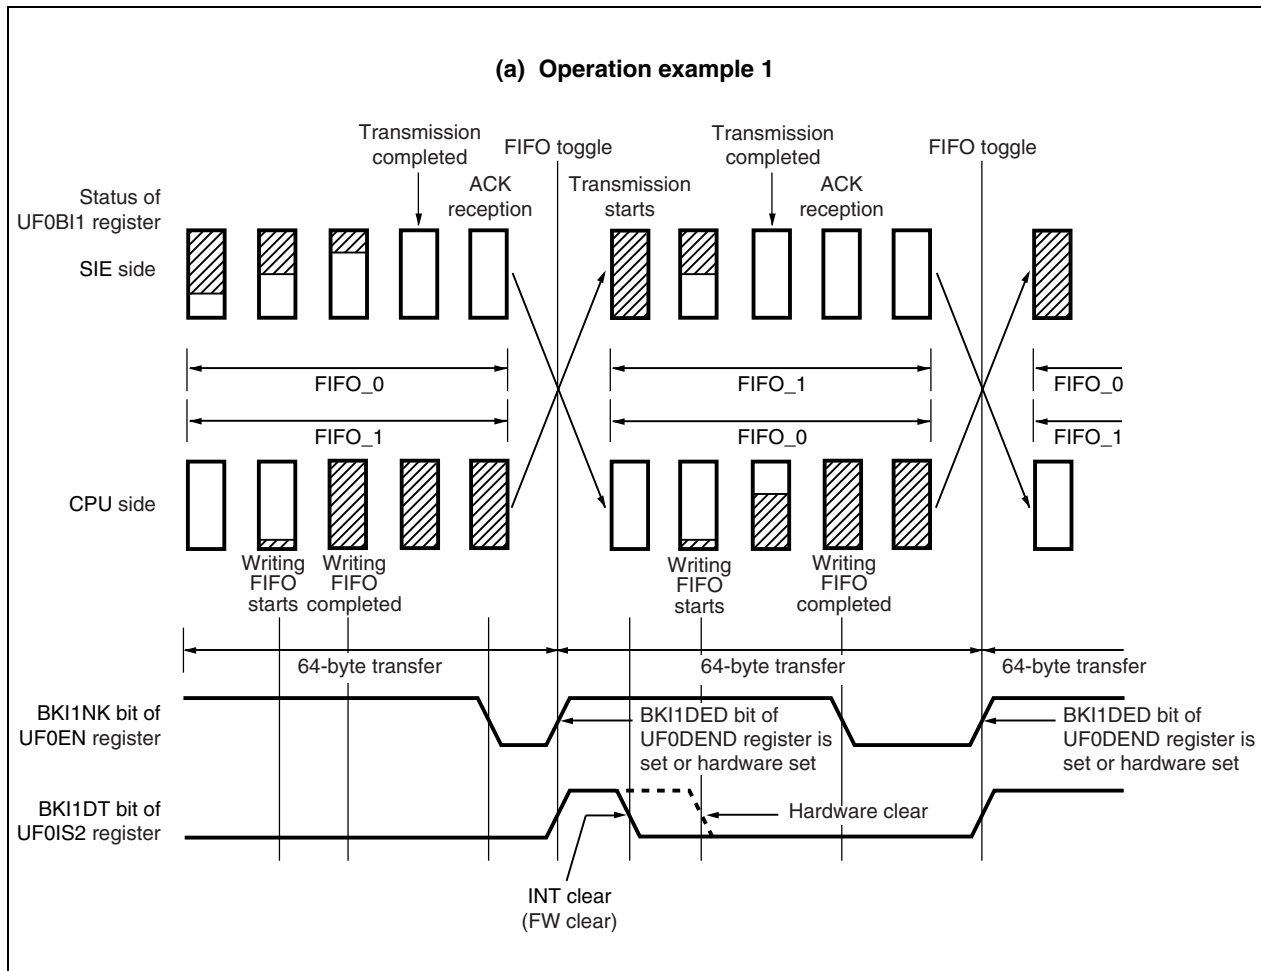

Figure 12-6. Operation of UF0BI1 Register (2/3)

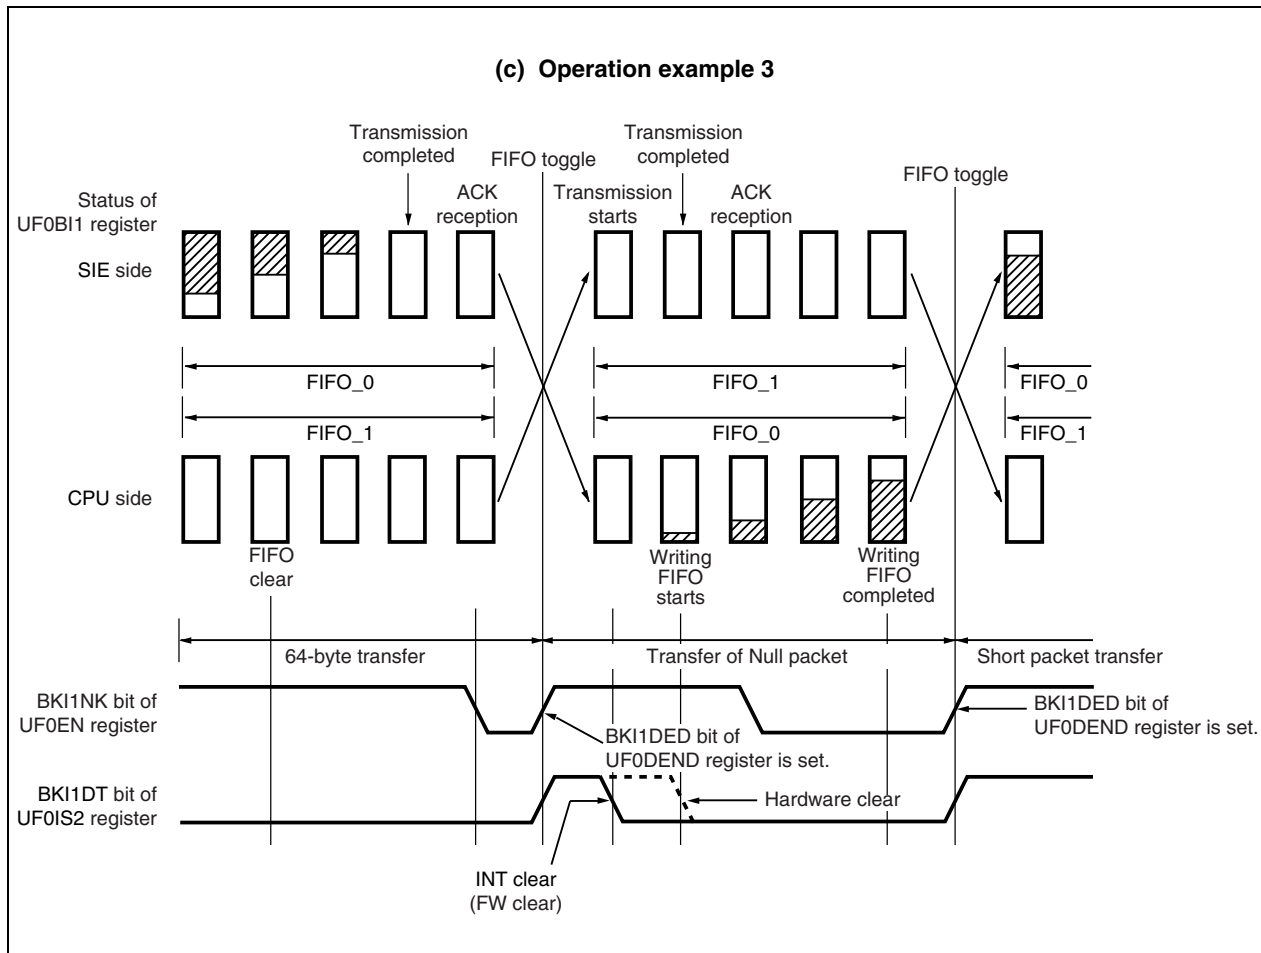

Figure 12-6. Operation of UF0B11 Register (3/3)

(10) UF0 bulk in 2 register (UF0BI2)

The UF0BI2 register is a 64-byte × 2 FIFO that stores data for Endpoint3. This register consists of two banks of 64-byte FIFOs each of which performs a toggle operation and repeatedly connects the buses on the SIE and CPU sides. The toggle operation takes place when no data is in the FIFO on the SIE side (counter value = 0) and when the FIFO on the CPU side is correctly written (FIFO full or BKI2DED bit = 1).

This register is write-only, in 8-bit units. When this register is read, 00H is read.

The hardware transmits data to the USB bus in synchronization with the IN token for Endpoint3 only when the BKI2NK bit of the UF0EN register is set to 1 (when NAK is not transmitted). The address at which data is to be written or read is managed by the hardware. Therefore, FW can transmit data to the host only by writing the data to the UF0BI2 register sequentially. A short packet is transmitted when data is written to the UF0BI2 register and the BKI2DED bit of the UF0DEND register is set to 1 (BKIN2 bit of UF0EPS0 register = 1 (data exists)). A Null packet is transmitted when the UF0BI2 register is cleared and the BKI2DED bit of the UF0DEND register is set to 1 (BKIN2 bit of the UF0EPS0 register = 1 (data exists)). After data is transmitted normally, FIFO toggle operation is started, the BKI2DT bit of the UF0IS2 register is set to 1, and an interrupt request is issued to the CPU. An interrupt request or DMA request can be selected by using the DQBI2MS bit of the UF0IDR register.

Caution To execute a DMA transfer to or from the UF0BI2 register, not to perform block transfer. If block transfer is performed, the transferred data cannot be guaranteed.

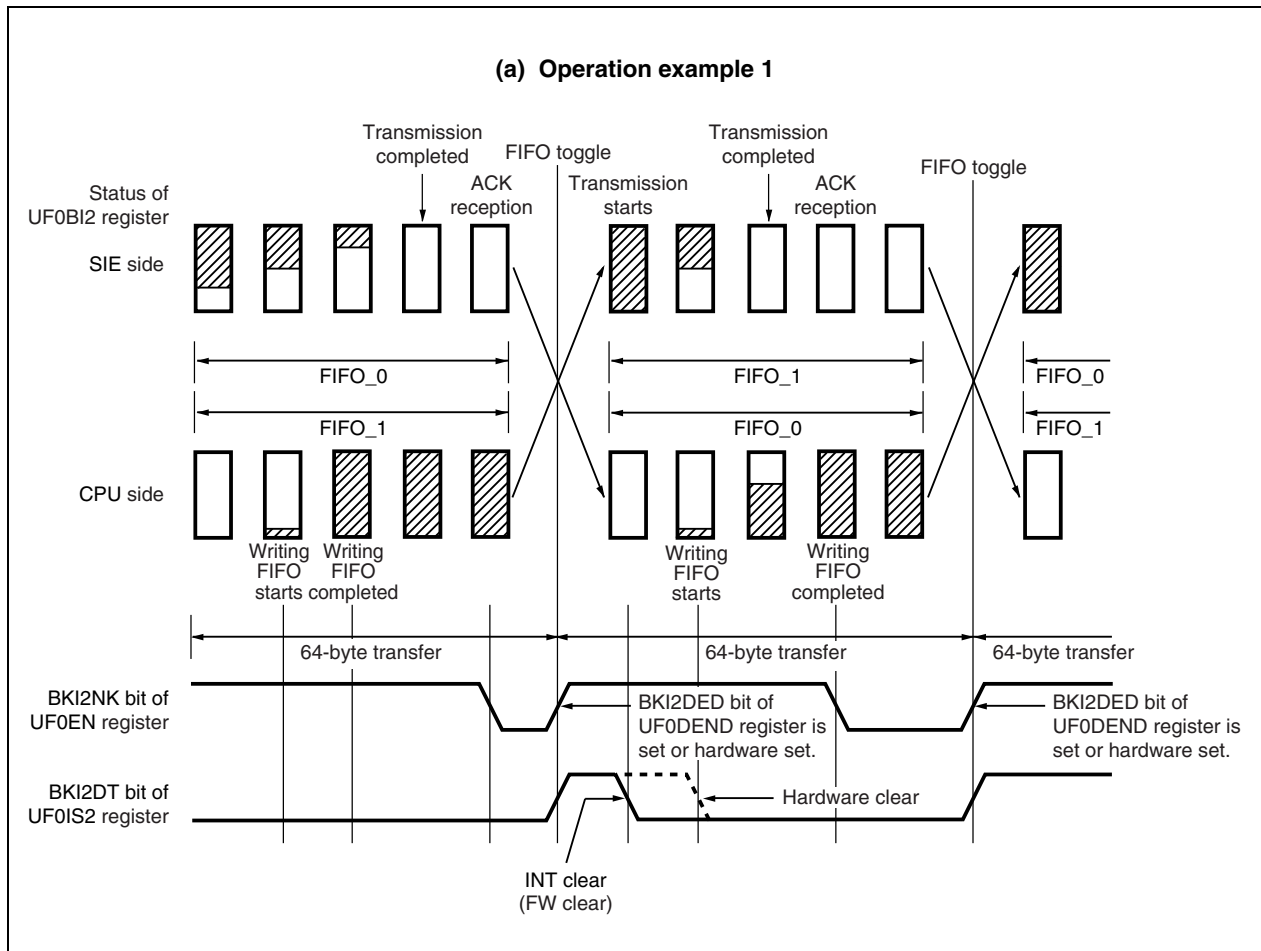

Figure 12-7. Operation of UF0BI2 Register (2/3)

Figure 12-7. Operation of UF0BI2 Register (3/3)

(11) UF0 interrupt 1 register (UF0INT1)

The UF0INT1 register is an 8-byte FIFO that stores data for Endpoint7 (to be passed to SIE).

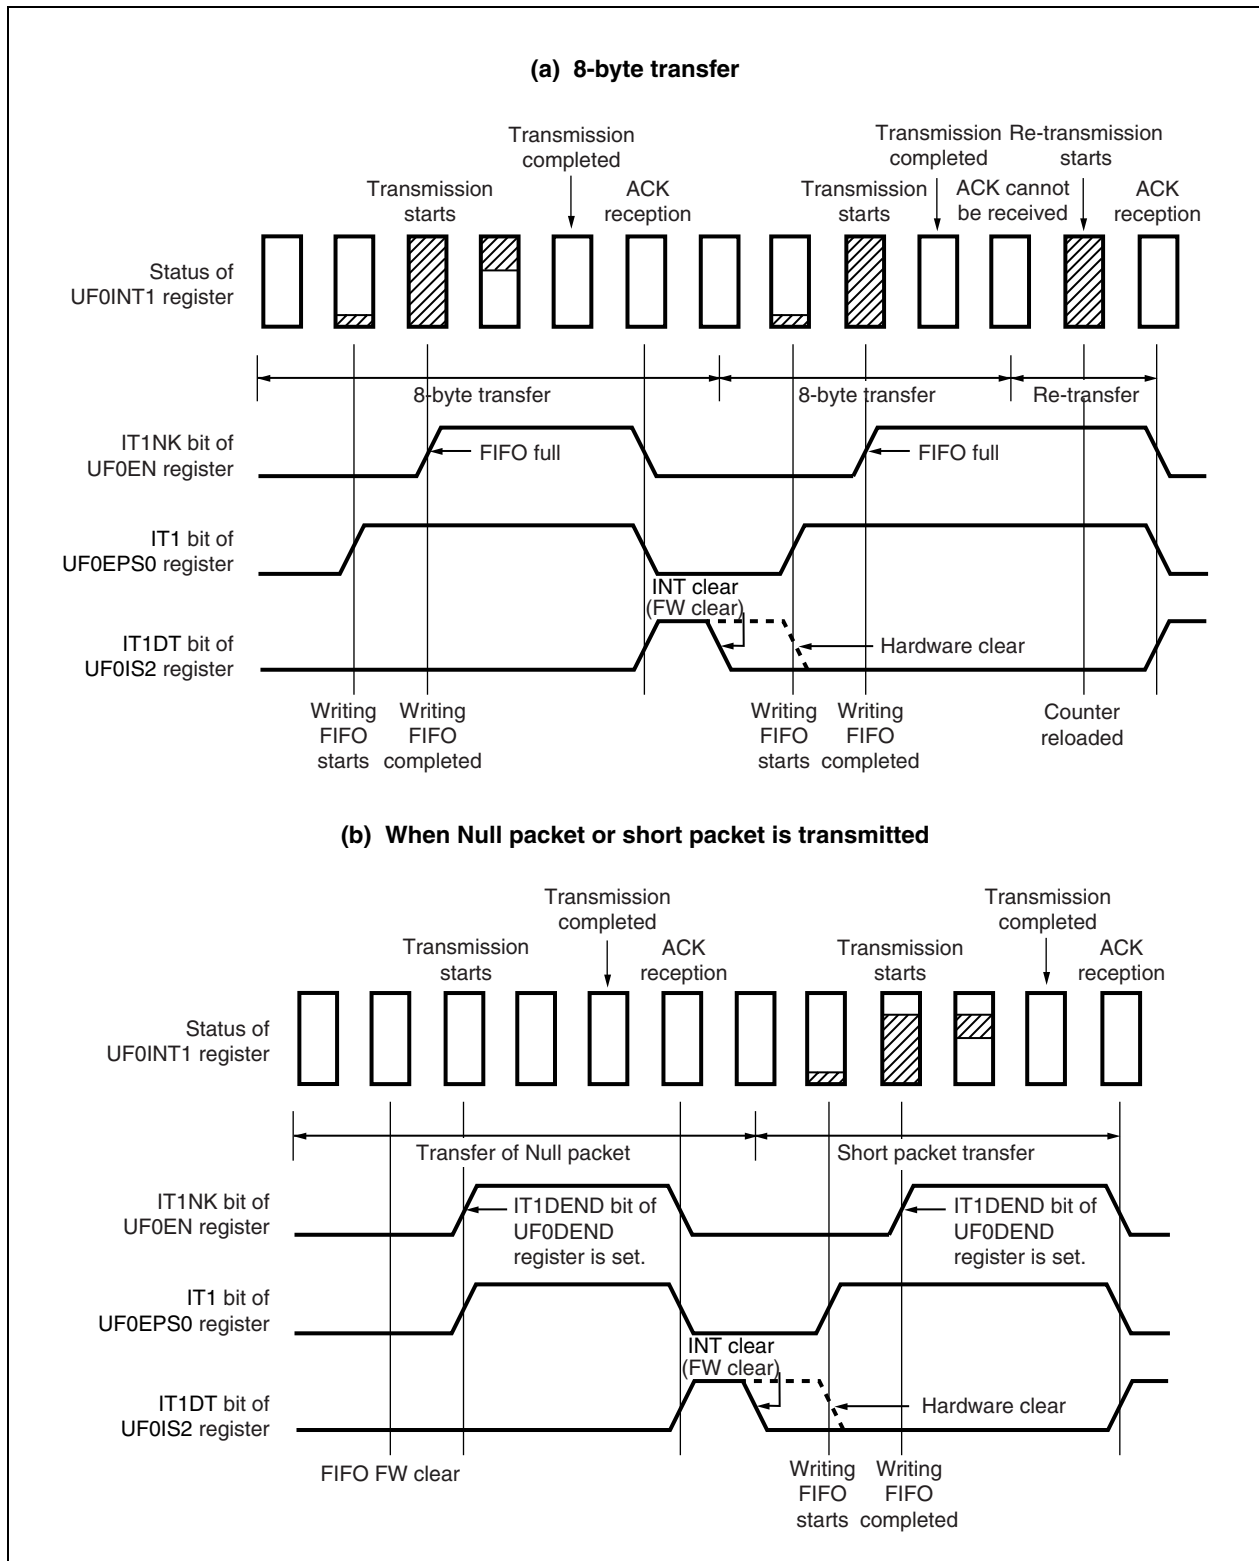

This register is write-only, in 8-bit units. When this register is read, 00H is read.

The hardware transmits data to the USB bus in synchronization with the IN token for Endpoint7 only when the IT1NK bit of the UF0EN register is set to 1 (when NAK is not transmitted). When the data is transmitted and the host correctly receives it, the IT1NK bit of the UF0EN register is automatically cleared to 0 by hardware. A short packet is transmitted when data is written to the UF0INT1 register and the IT1DEND bit of the UF0DEND register is set to 1 (IT1 bit of the UF0EPS0 register = 1 (data exists)). A Null packet is transmitted when the UF0INT1 register is cleared and the IT1DEND bit of the UF0DEND register is set to 1 (IT1 bit of the UF0EPS0 register = 1 (data exists)).

The operation of the UF0INT1 register is illustrated below.

Figure 12-8. Operation of UF0INT1 Register

(12) UF0 interrupt 2 register (UF0INT2)

The UF0INT2 register is an 8-byte FIFO that stores data for Endpoint8 (to be passed to SIE).

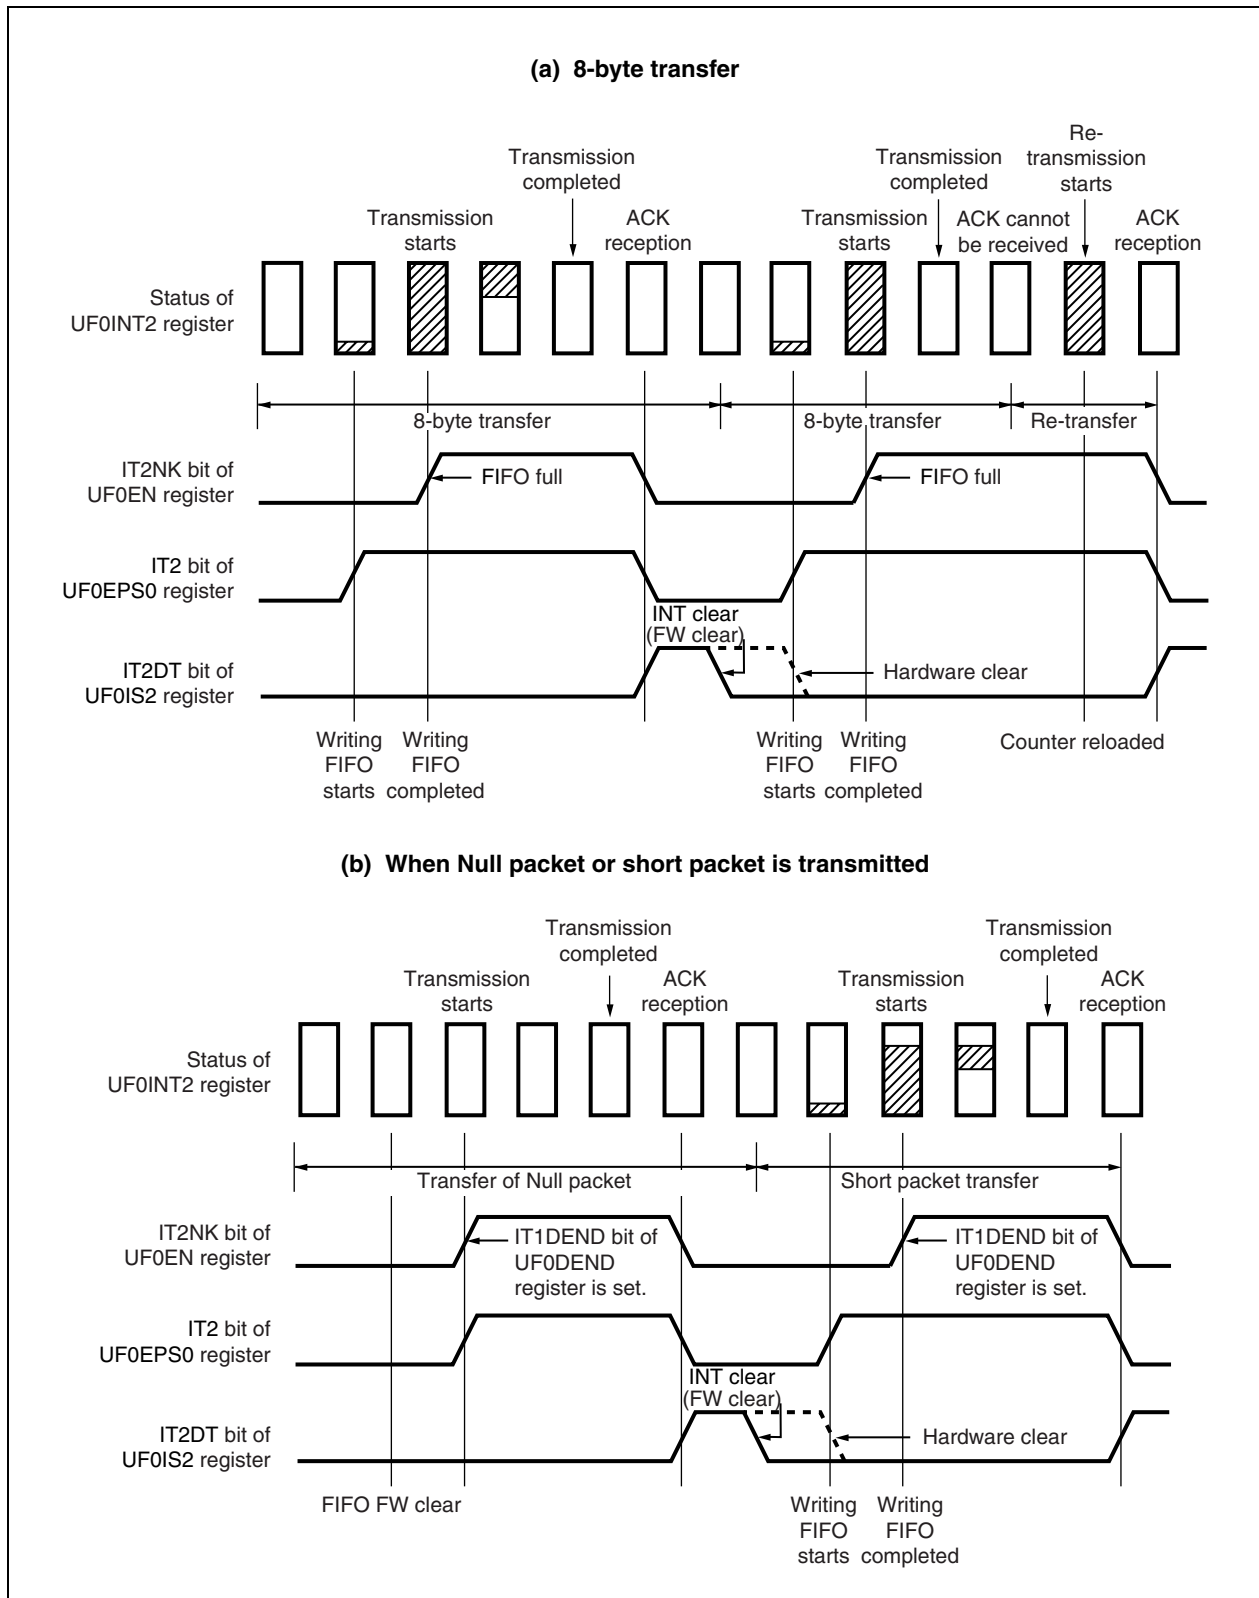

This register is write-only, in 8-bit units. When this register is read, 00H is read.

The hardware transmits data to the USB bus in synchronization with the IN token for Endpoint8 only when the IT2NK bit of the UF0EN register is set to 1 (when NAK is not transmitted). When the data is transmitted and the host correctly receives it, the IT2NK bit of the UF0EN register is automatically cleared to 0 by hardware. A short packet is transmitted when data is written to the UF0INT2 register and the IT2DEND bit of the UF0DEND register is set to 1 (IT2 bit of the UF0EPS0 register = 1 (data exists)). A Null packet is transmitted when the UF0INT2 register is cleared and the IT2DEND bit of the UF0DEND register is set to 1 (IT2 bit of the UF0EPS0 register = 1 (data exists)).

	7	6	5	4	3	2	1	0	Address	After reset
UF0INT2	IT27	IT26	IT25	IT24	IT23	IT22	IT21	IT20	1FFFFE8BH	Undefined
Bit position	Bit name	Function								
7 to 0	IT27 to IT20	These bits store data for Endpoint8.								

The operation of the UF0INT2 register is illustrated below.

Figure 12-9. Operation of UF0INT2 Register

12.4.3 Request data register

(1) UF0 device status register L (UF0DSTL)

This register stores the value that is to be returned in response to the GET_STATUS Device request.

This register can be read or written in 8-bit units.

The hardware automatically transmits the contents of this register to the host when it has received the GET_STATUS Device request.

Caution To rewrite this register, set the EP0NKA bit to 1 before reading the register contents, and rewrite the register contents after confirming that the bit has been set, in order to prevent conflict between a read access and a write access.

	7	6	5	4	3	2	1	0	Address	After reset
UF0DSTL	0	0	0	0	0	0	RMWK	SFPW	1FFFFEA2H	00H

Bit position	Bit name	Function
1	RMWK	This bit specifies whether the remote wakeup function of the device is used. 1: Enabled 0: Disabled If the device supports a remote wakeup function, this bit is set to 1 by hardware when the SET_FEATURE Device request has been received, and is cleared to 0 by hardware when the CLEAR_FEATURE Device request has been received. If the device does not support a remote wakeup function, make sure that the SET_FEATURE Device request is not issued from the host.
0	SFPW	This bit indicates whether the device is self-powered or bus-powered. 1: Self-powered 0: Bus-powered

(2) UF0 EP0 status register L (UF0E0SL)

This register stores the value that is to be returned in response to the GET_STATUS Endpoint0 request.

This register can be read or written in 8-bit units. Note, however, that data can be written to this register only when the EP0NKA bit is set to 1.

If an error occurs in USBF, the E0HALT bit is set to 1 by FW. A write access to this register is ignored while a USB-side access to Endpoint0 is being received.

When the E0HALT bit is set to 1 by FW, it is not reflected until the next SETUP token is received if the control transfer immediately before is for the SET_FEATURE Endpoint0, CLEAR_FEATURE Endpoint0, GET_STATUS Endpoint0 request, or an FW-processed request.

The hardware automatically transmits the contents of this register to the host when it has received the GET_STATUS Endpoint0 request. If Endpoint0 has stalled, the UF0E0W and UF0E0R registers are cleared, and the EP0NKW and EP0NKR bits of the UF0E0N register are cleared to 0.

Caution To rewrite this register, set the EP0NKA bit to 1 before reading the register contents, and rewrite the register contents after confirming that the bit has been set, in order to prevent conflict between a read access and a write access.

	7	6	5	4	3	2	1	0	Address	After reset
UF0E1SL	0	0	0	0	0	0	0	E1HALT	1FFFEEA8H	00H

Bit position	Bit name	Function
0	E0HALT	This bit indicates the status of Endpoint0. 1: Stalled 0: Not stalled This bit is set to 1 by hardware when the SET_FEATURE Endpoint0 request has been received, and cleared to 0 by hardware when the CLEAR_FEATURE Endpoint0 request has been received. DATA PID is initialized to DATA0.

(3) UF0 EP1 status register L (UF0E1SL)

This register stores the value that is to be returned in response to the GET_STATUS Endpoint1 request.

This register can be read or written in 8-bit units. Note, however, that data can be written to this register only when the EPONKA bit is set to 1.

If an error occurs in Endpoint1, the E1HALT bit is set to 1. A write access to this register is ignored while a USB-side access to Endpoint1 is being received.

The hardware automatically transmits the contents of this register to the host when it has received the GET_STATUS Endpoint1 request. If Endpoint1 has stalled, the UF0B11 register is cleared and the BK11NK bit is cleared to 0.

Because writing this register is always masked when transfer to Endpoint1, rather than control transfer, is executed, be sure to check this register to see if data has been correctly written to it.

Caution To rewrite this register, set the EPONKA bit to 1 before reading the register contents, and rewrite the register contents after confirming that the bit has been set, in order to prevent conflict between a read access and a write access.

	7	6	5	4	3	2	1	0	Address	After reset
UF0E1SL	0	0	0	0	0	0	0	E1HALT	1FFFFEA8H	00H

Bit position	Bit name	Function
0	E1HALT	<p>This bit indicates the status of Endpoint1.</p> <p>1: Stalled 0: Not stalled</p> <p>This bit is set to 1 by hardware when the SET_FEATURE Endpoint1 request has been received. It is cleared to 0 by hardware when the CLEAR_FEATURE Endpoint1 request, SET_CONFIGURATION request, or the SET_INTERFACE request for the Interface to which Endpoint1 is linked has correctly been received. DATA PID is initialized to DATA0.</p>

(4) UF0 EP2 status register L (UF0E2SL)

This register stores the value that is to be returned in response to the GET_STATUS Endpoint2 request.

This register can be read or written in 8-bit units. Note, however, that data can be written to this register only when the EPONKA bit is set to 1.

If an error occurs in Endpoint2, the E2HALT bit is set to 1. A write access to this register is ignored while a USB-side access to Endpoint2 is being received.

The hardware automatically transmits the contents of this register to the host when it has received the GET_STATUS Endpoint2 request. If Endpoint2 has stalled, the UF0BO1 register is cleared and the BKO1NK bit is cleared to 0.

Because writing this register is always masked when transfer to Endpoint2, rather than control transfer, is executed, be sure to check this register to see if data has been correctly written to it.

Caution To rewrite this register, set the EPONKA bit to 1 before reading the register contents, and rewrite the register contents after confirming that the bit has been set, in order to prevent conflict between a read access and a write access.

	7	6	5	4	3	2	1	0	Address	After reset
UF0E2SL	0	0	0	0	0	0	0	E2HALT	1FFFFEAAH	00H

Bit position	Bit name	Function
0	E2HALT	This bit indicates the status of Endpoint2. 1: Stalled 0: Not stalled This bit is set to 1 by hardware when the SET_FEATURE Endpoint2 request has been received. It is cleared to 0 by hardware when the CLEAR_FEATURE Endpoint2 request, SET_CONFIGURATION request, or the SET_INTERFACE request for the Interface to which Endpoint2 is linked has correctly been received. DATA PID is initialized to DATA0.

(5) UF0 EP3 status register L (UF0E3SL)

This register stores the value that is to be returned in response to the GET_STATUS Endpoint3 request.

This register can be read or written in 8-bit units. Note, however, that data can be written to this register only when the EPONKA bit is set to 1.

If an error occurs in Endpoint3, the E3HALT bit is set to 1. A write access to this register is ignored while a USB-side access to Endpoint3 is being received.

The hardware automatically transmits the contents of this register to the host when it has received the GET_STATUS Endpoint3 request. If Endpoint3 has stalled, the UF0BI2 register is cleared and the BKI2NK bit is cleared to 0.

Because writing this register is always masked when transfer to Endpoint3, rather than control transfer, is executed, be sure to check this register to see if data has been correctly written to it.

Caution To rewrite this register, set the EPONKA bit to 1 before reading the register contents, and rewrite the register contents after confirming that the bit has been set, in order to prevent conflict between a read access and a write access.

	7	6	5	4	3	2	1	0	Address	After reset
UF0E3SL	0	0	0	0	0	0	0	E3HALT	1FFFFEACH	00H

Bit position	Bit name	Function
0	E3HALT	<p>This bit indicates the status of Endpoint3.</p> <p>1: Stalled 0: Not stalled</p> <p>This bit is set to 1 by hardware when the SET_FEATURE Endpoint3 request has been received. It is cleared to 0 by hardware when the CLEAR_FEATURE Endpoint3 request, SET_CONFIGURATION request, or the SET_INTERFACE request for the Interface to which Endpoint3 is linked has correctly been received. DATA PID is initialized to DATA0.</p>

(6) UF0 EP4 status register L (UF0E4SL)

This register stores the value that is to be returned in response to the GET_STATUS Endpoint4 request.

This register can be read or written in 8-bit units. Note, however, that data can be written to this register only when the EPONKA bit is set to 1.

If an error occurs in Endpoint4, the E4HALT bit is set to 1. A write access to this register is ignored while a USB-side access to Endpoint4 is being received.

The hardware automatically transmits the contents of this register to the host when it has received the GET_STATUS Endpoint4 request. If Endpoint4 has stalled, the UF0BO2 register is cleared and the BKO2NK bit is cleared to 0.

Because writing this register is always masked when transfer to Endpoint4, rather than control transfer, is executed, be sure to check this register to see if data has been correctly written to it.

Caution To rewrite this register, set the EPONKA bit to 1 before reading the register contents, and rewrite the register contents after confirming that the bit has been set, in order to prevent conflict between a read access and a write access.

	7	6	5	4	3	2	1	0	Address	After reset
UF0E4SL	0	0	0	0	0	0	0	E4HALT	1FFFFEAEH	00H

Bit position	Bit name	Function
0	E4HALT	This bit indicates the status of Endpoint4. 1: Stalled 0: Not stalled This bit is set to 1 by hardware when the SET_FEATURE Endpoint4 request has been received. It is cleared to 0 by hardware when the CLEAR_FEATURE Endpoint4 request, SET_CONFIGURATION request, or the SET_INTERFACE request for the Interface to which Endpoint4 is linked has correctly been received. DATA PID is initialized to DATA0.

(7) UF0 EP7 status register L (UF0E7SL)

This register stores the value that is to be returned in response to the GET_STATUS Endpoint7 request.

This register can be read or written in 8-bit units. Note, however, that data can be written to this register only when the EPONKA bit is set to 1.

If an error occurs in Endpoint7, the E7HALT bit is set to 1. A write access to this register is ignored while a USB-side access to Endpoint7 is being received.

The hardware automatically transmits the contents of this register to the host when it has received the GET_STATUS Endpoint7 request. If Endpoint7 has stalled, the UF0INT1 register is cleared and the IT1NK bit is cleared to 0.

Because writing this register is always masked when transfer to Endpoint7, rather than control transfer, is executed, be sure to check this register to see if data has been correctly written to it.

Caution To rewrite this register, set the EPONKA bit to 1 before reading the register contents, and rewrite the register contents after confirming that the bit has been set, in order to prevent conflict between a read access and a write access.

	7	6	5	4	3	2	1	0	Address	After reset
UF0E7SL	0	0	0	0	0	0	0	E7HALT	1FFFFEB4H	00H

Bit position	Bit name	Function
0	E7HALT	<p>This bit indicates the status of Endpoint7.</p> <p>1: Stalled 0: Not stalled</p> <p>This bit is set to 1 by hardware when the SET_FEATURE Endpoint7 request has been received. It is cleared to 0 by hardware when the CLEAR_FEATURE Endpoint7 request, SET_CONFIGURATION request, or the SET_INTERFACE request for the Interface to which Endpoint7 is linked has correctly been received. DATA PID is initialized to DATA0.</p>

(8) UF0 EP8 status register L (UF0E8SL)

This register stores the value that is to be returned in response to the GET_STATUS Endpoint8 request.

This register can be read or written in 8-bit units. Note, however, that data can be written to this register only when the EPONKA bit is set to 1.

If an error occurs in Endpoint8, the E8HALT bit is set to 1. A write access to this register is ignored while a USB-side access to Endpoint8 is being received.

The hardware automatically transmits the contents of this register to the host when it has received the GET_STATUS Endpoint8 request. If Endpoint8 has stalled, the UF0INT2 register is cleared and the IT2NK bit is cleared to 0.

Because writing this register is always masked when transfer to Endpoint8, rather than control transfer, is executed, be sure to check this register to see if data has been correctly written to it.

Caution To rewrite this register, set the EPONKA bit to 1 before reading the register contents, and rewrite the register contents after confirming that the bit has been set, in order to prevent conflict between a read access and a write access.

	7	6	5	4	3	2	1	0	Address	After reset
UF0E8SL	0	0	0	0	0	0	0	E8HALT	1FFFFEB6H	00H

Bit position	Bit name	Function
0	E8HALT	<p>This bit indicates the status of Endpoint8.</p> <p>1: Stalled 0: Not stalled</p> <p>This bit is set to 1 by hardware when the SET_FEATURE Endpoint8 request has been received. It is cleared to 0 by hardware when the CLEAR_FEATURE Endpoint8 request, SET_CONFIGURATION request, or the SET_INTERFACE request for the Interface to which Endpoint8 is linked has correctly been received. DATA PID is initialized to DATA0.</p>

(9) UF0 address register (UF0ADRS)

This register stores the device address.

This register is read-only, in 8-bit units.

The device address sent by the SET_ADDRESS request is analyzed and the resultant value is automatically written to this register. If the SET_ADDRESS request is processed by FW, the value of this register is reflected as the device address when the SUCCESS signal is received in the status stage.

Caution Do not write to this register. Operation is not guaranteed if writing to this register is performed.

	7	6	5	4	3	2	1	0	Address	After reset
UF0ADRS	0	ADRS6	ADRS5	ADRS4	ADRS3	ADRS2	ADRS1	ADRS0	1FFFEC0H	00H
	Bit position	Bit name	Function							
	6 to 0	ADRS6 to ADRS0	These bits hold the device address of SIE.							

(10) UF0 configuration register (UF0CNF)

This register stores the value that is to be returned in response to the GET_CONFIGURATION request.

This register is read-only, in 8-bit units.

When the SET_CONFIGURATION request is received, its wValue is automatically written to this register.

When a change of the value of this register from 00H to other than 00H is detected, the CONF bits of the UF0MODS register are set to 1. If the SET_CONFIGURATION request is processed by FW, the status of this register is immediately reflected on the UF0MODS register as soon as data has been written to this register (CONF bits = 1 before completion of the status stage).

Caution Do not write to this register. Operation is not guaranteed if writing to this register is performed.

	7	6	5	4	3	2	1	0	Address	After reset
UF0CNF	0	0	0	0	0	0	CONF1	CONF0	1FFFFEC1H	00H

Bit position	Bit name	Function
1, 0	CONF1, CONF0	These bits hold the data to be returned in response to the GET_CONFIGURATION request.

(11) UF0 interface 0 register (UF0IF0)

This register stores the value that is to be returned in response to the GET_INTERFACE wIndex = 0 request.

This register is read-only, in 8-bit units.

When the SET_INTERFACE request is received, its wValue is automatically written to this register.

If the SET_INTERFACE request is processed by FW, wIndex and wValue are decoded, and the setting of endpoint is automatically changed. At this time, the status bit of the target endpoint and DPID are automatically cleared to 0, depending on the setting. The FIFO is not cleared automatically.

Caution Do not write to this register. Operation is not guaranteed if writing to this register is performed.

	7	6	5	4	3	2	1	0	Address	After reset
UF0IF0	0	0	0	0	0	IF02	IF01	IF00	1FFFEC2H	00H

Bit position	Bit name	Function
2 to 0	IF02 to IF00	These bits hold the data to be returned in response to GET_INTERFACE wIndex = 0 request.

(12) UF0 interface 1 to 4 registers (UF0IF1 to UF0IF4)

These registers store the value that is to be returned in response to the GET_INTERFACE wIndex = n request (n = 1 to 4).

These registers are read-only, in 8-bit units.

When the SET_INTERFACE request is received, its wValue is automatically written to these registers.

These registers are invalidated according to the setting of the UF0AIFN and UF0AAS registers.

If the SET_INTERFACE request is processed by FW, wIndex and wValue are decoded, and the setting of endpoint is automatically changed. At this time, the status bit of the target endpoint and DPID are automatically cleared to 0, depending on the setting. The FIFO is not cleared automatically.

Caution Do not write to this register. Operation is not guaranteed if writing to this register is performed.

	7	6	5	4	3	2	1	0	Address	After reset
UF0IF1	0	0	0	0	0	IF12	IF11	IF10	1FFFFEC3H	00H
UF0IF2	0	0	0	0	0	IF22	IF21	IF20	1FFFFEC4H	00H
UF0IF3	0	0	0	0	0	IF32	IF31	IF30	1FFFFEC5H	00H
UF0IF4	0	0	0	0	0	IF42	IF41	IF40	1FFFFEC6H	00H

Bit position	Bit name	Function
2 to 0	IFn2 to IFn0	These bits hold the data to be returned in response to GET_INTERFACE wIndex = n request.

Remark n = 1 to 4

(13) UF0 descriptor length register (UF0DSCL)

This register stores the length of the value that is to be returned in response to the GET_DESCRIPTOR Configuration request. The value of this register is the number of bytes of all the descriptors set by the UF0CIEN register minus 1 (n = 0 to 255). The total descriptor length that is to be returned in response to the GET_DESCRIPTOR Configuration request is determined according to the value of this register.

This register can be read or written in 8-bit units. However, data can be written to this register only when the EPONKA bit is set to 1.

Processing of wLength is automatically controlled. If this register is set to 00H, it means that the descriptor to be returned is 1 byte long. If the register is set to FFH, a descriptor length of 256 bytes is returned. When a descriptor exceeding 256 bytes in length is used, set the CDCGDST bit of the UF0MODC register to 1 and process the GET_DESCRIPTOR request by FW (at this time, the CDCGD bit of the UF0MODS register is also set to 1).

Caution To rewrite this register, set the EPONKA bit to 1 before reading the register contents, and rewrite the register contents after confirming that the bit has been set, in order to prevent conflict between a read access and a write access.

	7	6	5	4	3	2	1	0	Address	After reset
UF0DSCL	DPL7	DPL6	DPL5	DPL4	DPL3	DPL2	DPL1	DPL0	1FFFFED0H	00H

Bit position	Bit name	Function
7 to 0	DPL7 to DPL0	These bits set the value of the number of bytes of all the descriptors to be returned in response to the GET_DESCRIPTOR Configuration request minus 1.

(14) UF0 device descriptor registers 0 to 17 (UF0DD0 to UF0DD17)

These registers store the value to be returned in response to the GET_DESCRIPTOR Device request.

These registers can be read or written in 8-bit units. However, data can be written to these registers only when the EP0NKA bit is set to 1.

Cautions 1. To rewrite these registers, set the EP0NKA bit to 1 before reading the register contents, and rewrite the register contents after confirming that the bit has been set, in order to prevent conflict between a read access and a write access.

2. Use the value defined by USB Specification Ver. 2.0 and the latest Class Specification as the set value.

Table 12-4. Mapping and Data of UF0 Device Descriptor Registers

Symbol	Address	Field Name	Contents
UF0DD0	FFFFFFED1H	bLength	Size of this descriptor
UF0DD1	FFFFFFED2H	bDescriptorType	Device descriptor type
UF0DD2	FFFFFFED3H	bcdUSB	Value below decimal point of Rev. number of USB specification
UF0DD3	FFFFFFED4H		Value above decimal point of Rev. number of USB specification
UF0DD4	FFFFFFED5H	bDeviceClass	Class code
UF0DD5	FFFFFFED6H	bDeviceSubClass	Subclass code
UF0DD6	FFFFFFED7H	bDeviceProtocol	Protocol code
UF0DD7	FFFFFFED8H	bMaxPacketSize0	Maximum packet size of Endpoint0
UF0DD8	FFFFFFED9H	idVendor	Lower value of vendor ID
UF0DD9	FFFFFFEDA H		Higher value of vendor ID
UF0DD10	FFFFFFEDBH	idProduct	Lower value of product ID
UF0DD11	FFFFFFEDCH		Higher value of product ID
UF0DD12	FFFFFFEDDH	bcdDevice	Lower value of device release number
UF0DD13	FFFFFFEDEH		Higher value of device release number
UF0DD14	FFFFFFEDFH	iManufacturer	Index of string descriptor describing manufacturer
UF0DD15	FFFFFFEE0H	iProduct	Index of string descriptor describing product
UF0DD16	FFFFFFEE1H	iSerialNumber	Index of string descriptor describing device serial number
UF0DD17	FFFFFFEE2H	BNumConfigurations	Number of settable configurations

(15) UF0 configuration/interface/endpoint descriptor registers 0 to 255 (UF0CIE0 to UF0CIE255)

These registers store the value to be returned in response to the GET_DESCRIPTOR Configuration request. These registers can be read or written in 8-bit units. However, data can be written to these registers only when the EP0NKA bit is set to 1.

Descriptor information of up to 256 bytes can be stored in these registers. Store each descriptor in the order of Configuration, Interface, and Endpoint (see **Table 12-5**). If there are two or more Interfaces, repeatedly store the data following the Interface descriptor.

Table 12-5. Mapping of UF0CIEn Register

Address	Descriptor Stored
FFFFFFE3H	Configuration descriptor (9 bytes)
FFFFFFE4H	Interface descriptor (9 bytes)
FFFFFFE5H	Endpoint1 descriptor (7 bytes)
FFFFFFE6H	Endpoint2 descriptor (7 bytes)
FFFFFFE7H	Endpoint3 descriptor (7 bytes)
:	:
FFFFFFxxH	Interface descriptor (9 bytes)
FFFFFFxxH+9	Endpoint1 descriptor (7 bytes)
FFFFFFxxH+16	Endpoint2 descriptor (7 bytes)
FFFFFFxxH+23	Endpoint3 descriptor (7 bytes)
:	:

The range of the valid data that can be set to these registers varies according to the setting of the UF0DSCLE register. In addition to the descriptors listed in Table 12-6, descriptors peculiar to classes and vendors can also be stored.

If all the values are fixed, they can be stored in ROM.

- Cautions 1.** To rewrite these registers, set the EP0NKA bit to 1 before reading the register contents, and rewrite the register contents after confirming that the bit has been set, in order to prevent conflict between a read access and a write access.
- 2.** Use the value defined by USB Specification Ver. 2.0 and the latest Class Specification as the set value.

Table 12-6. Data of UF0CIEn Register**(a) Configuration descriptor (9 bytes)**

Offset	Field Name	Contents
0	bLength	Size of this descriptor
1	bDescriptorType	Descriptor type
2	wTotalLength	Lower value of the total number of bytes of Configuration, all Interface, and all Endpoint descriptors
3		Higher value of the total number of bytes of Configuration, all Interface, and all Endpoint descriptors
4	bNumInterface	Number of Interfaces
5	bConfigurationValue	Value to select this Configuration
6	iConfiguration	Index of string descriptor describing this Configuration
7	bmAttributes	Features of this Configuration (self-powered, without remote wakeup)
8	MaxPower	Maximum power consumption of this Configuration (unit: mA)

(b) Interface descriptor (9 bytes)

Offset	Field Name	Contents
0	bLength	Size of this descriptor
1	bDescriptorType	Descriptor type
2	bInterfaceNumber	Value of this Interface
3	bAlternateSetting	Value to select alternative setting of Interface
4	bNumEndpoints	Number of usable Endpoints
5	bInterfaceClass	Class code
6	bInterfaceSubClass	Subclass code
7	bInterfaceProtocol	Protocol code
8	Interface	Index of string descriptor describing this Interface

(c) Endpoint descriptor (7 bytes)

Offset	Field Name	Contents
0	bLength	Size of this descriptor
1	bDescriptorType	Descriptor type
2	bEndpointAddress	Address/transfer direction of this Endpoint
3	bmAttributes	Transfer type
4	wMaxPaketSize	Lower value of maximum number of transfer data
5		Higher value of maximum number of transfer data
6	bInterval	Transfer interval

12.4.4 Peripheral control registers

(1) USB function 0 DMA channel select register (UF0CS)

This register allocates each DMA service of the USB function to a DMA channel.

This register can be read or written in 16-bit units.

To allocate the service of a USB function to a DMA channel by using this register, set this register in advance, set the DTFRn register (n = 0 to 3) of the DMA controller to 7EH, and enable USB_DMA in advance.

Cautions 1. Setting the same DMA service to different DMA channels and setting different DMA services to the same DMA channel are prohibited.

2. When setting 7EH to the DTFRn register of the DMA controller, be sure to set 7EH to only one channel (n = 0 to 3). Do not set 7EH to two or more DMA channels. For example, when performing a DMA transfer for DMA channel 0 and DMA channel 1 using USB, set the DTFR0 register to other than 7EH after the DMA transfer for DMA channel 0 is complete, and then set the DTFR1 register to 7EH.

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset
UF0CS	0	UFD	UFD	UFD	0	UFD	UFD	UFD	0	UFD	UFD	UFD	0	UFD	UFD	UFD	1FFFFDF0H	0000H
		C32	C31	C30		C22	C21	C20		C12	C11	C10		C02	C01	C00		

Bit position	Bit name	Function																								
14 to 12, 10 to 8, 6 to 4, 2 to 0	UFDCn2 to UFDCn0	These bits set the DMA service of a USB function to be allocated to DMA channel n.																								
		<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="width: 15%;">UFDCn2</th> <th style="width: 15%;">UFDCn1</th> <th style="width: 15%;">UFDCn0</th> <th style="width: 55%;">Service to be allocated</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">1</td> <td style="text-align: center;">1</td> <td>EP4_DMA</td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">1</td> <td style="text-align: center;">0</td> <td>EP3_DMA</td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">0</td> <td style="text-align: center;">1</td> <td>EP2_DMA</td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">0</td> <td style="text-align: center;">0</td> <td>EP1_DMA</td> </tr> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">X</td> <td style="text-align: center;">X</td> <td>No allocation (DMA not used)</td> </tr> </tbody> </table>	UFDCn2	UFDCn1	UFDCn0	Service to be allocated	1	1	1	EP4_DMA	1	1	0	EP3_DMA	1	0	1	EP2_DMA	1	0	0	EP1_DMA	0	X	X	No allocation (DMA not used)
		UFDCn2	UFDCn1	UFDCn0	Service to be allocated																					
		1	1	1	EP4_DMA																					
		1	1	0	EP3_DMA																					
		1	0	1	EP2_DMA																					
1	0	0	EP1_DMA																							
0	X	X	No allocation (DMA not used)																							
Remark X: Don't care																										

Remark n = 0 to 3

(2) USB function 0 buffer control register (UF0BC)

This register performs enable control and floating control on the input buffer of the USB function.

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
UF0BC	0	0	0	0	0	0	UBFIEN	UBFIOR	1FFFFDF2H	00H

Bit position	Bit name	Function
1	UBFIEN	<p>This bit controls use of the USB buffer.</p> <p>1: Buffer valid 0: Buffer invalid</p> <p>Caution Clear this bit to 0 when the USB is not used. If this bit is set to 1, a current of 3 mA (TYP.) constantly flows, regardless of whether the USB is used or not.</p>
0	UBFIOR	<p>This bit controls use of floating measures of the USB buffer.</p> <p>1: Disables floating measures 0: Enables floating measures</p> <p>This bit prevents erroneous recognition of Bus Reset, Suspend, and Resume due to an undefined value when a cable is not connected (when data input is floated). When this bit is set to 1, control the processing for floating by the VBUS signal (which recognizes cable connection).</p>

The following flowcharts illustrate the program execution when the host is disconnected and then reconnected, and the program execution when power is supplied.

Figure 12-10. Flowchart of Program When Host Is Disconnected and Then Reconnected

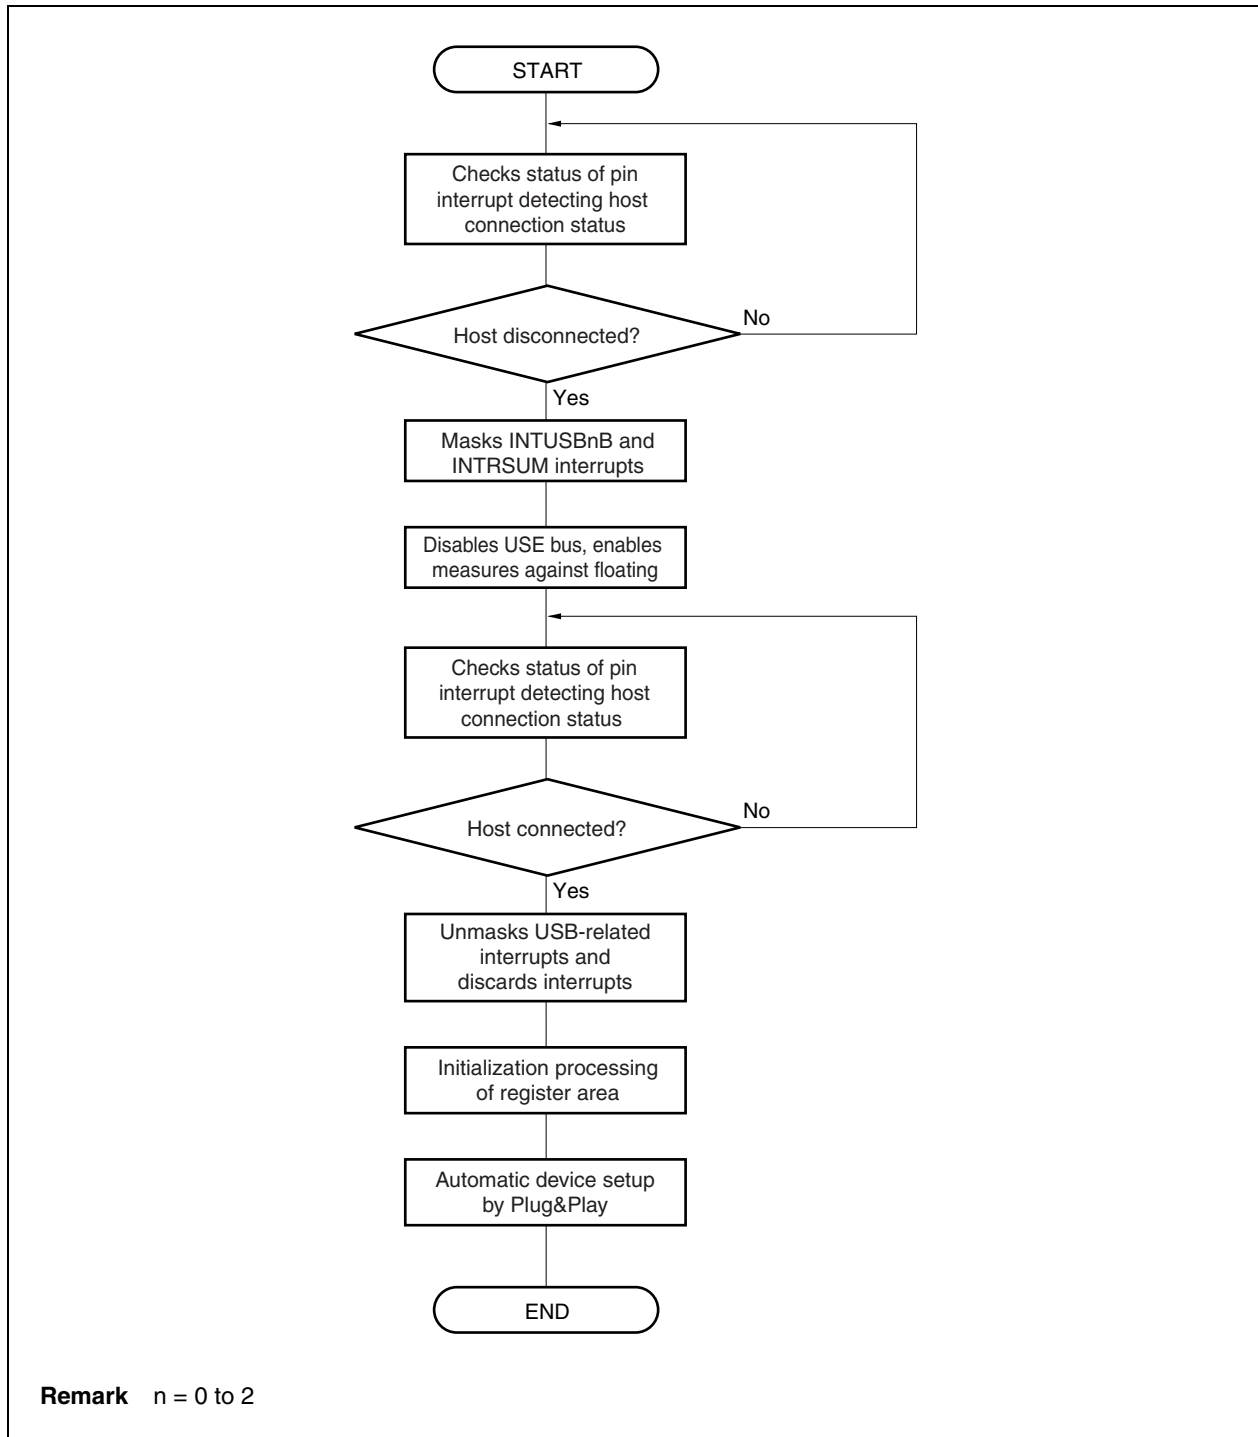

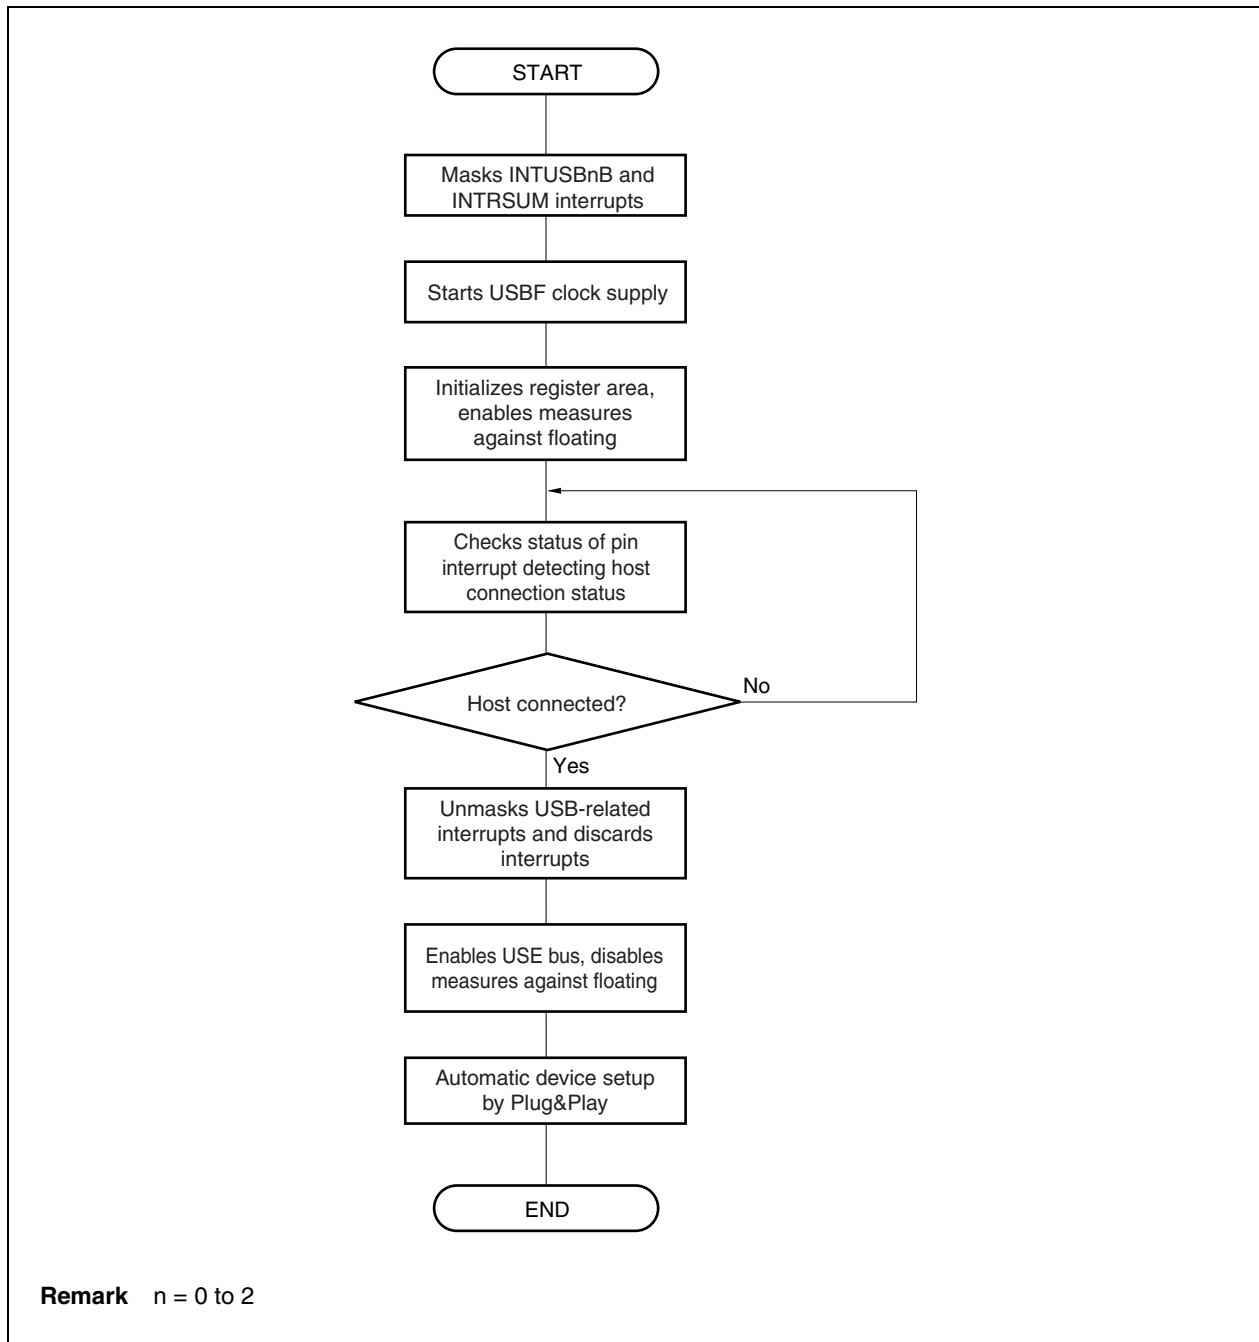

Figure 12-11. Flowchart of Program When Power Is Supplied

12.5 STALL Handshake or No Handshake

Errors of USBF are defined to be handled as follows.

Transfer Type	Transaction	Target Packet	Error Type	Function Response	Processing
Control transfer/ bulk transfer/ interrupt transfer	IN/OUT/SETUP	Token	Endpoint not supported	No response	None
			Endpoint transfer direction mismatch	No response	None
			CRC error	No response	None
			Bit stuffing error	No response	None
Control transfer/ bulk transfer	OUT/SETUP	Data	Timeout	No response	None
			PID check error	No response	None
			Unsupported PID (other than Data PID)	No response	None
			CRC error	No response	Discard received data
	Bit stuffing error	No response	Discard received data		
	OUT	Data	Data PID mismatch	ACK	Discard received data
Control transfer (SETUP stage)	SETUP	Data	Overrun	No response	Discard received data
Control transfer (data stage)	OUT	Data	Overrun	No response ^{Note 1}	Set SNDSTL bit of UF0SDS register to 1 and discard received data
Control transfer (status stage)	OUT	Data	Overrun	ACK or no response ^{Note 2}	Set SNDSTL bit of UF0SDS register to 1 and discard received data
Bulk transfer	OUT	Data	Overrun	No response ^{Note 1}	Set EnHALT bit of UF0EnSL register (n = 0 to 4, 7, 8) to 1
Control transfer/ bulk transfer/ interrupt transfer	IN	Handshake	PID check error	–	Hold transferred data and re-transfer data ^{Note 3}
			Unsupported PID (other than ACK PID)	–	Hold transferred data and re-transfer data ^{Note 3}
			Timeout	–	Hold transferred data and re-transfer data ^{Note 3}

Notes 1. A STALL response is made to re-transfer by the host.

2. An ACK response is made if the transfer data is of less than MaxPacketSize and the data received in the status stage is discarded. If MaxPacketSize is exceeded, no response is made, the SNDSTL bit of the UF0SDS register is set to 1, and the received data is discarded.

3. If an OUT transaction indicating a change from the data stage to the status stage is received during control transfer, an error is not handled and it is assumed that reception has been correctly completed.

Cautions 1. It is judged by the Alternative Setting number currently set whether the target Endpoint is valid or invalid.

2. For the response to the request included in control transfer to/from Endpoint0, see 12.3 Requests.

12.6 Register Values in Specific Status

Table 12-7. Register Values in Specific Status (1/2)

Register Name	After CPU Reset ($\overline{\text{RESET}}$)	After Bus Reset
UF0E0N register	00H	Value is held.
UF0E0NA register	00H	Value is held.
UF0EN register	00H	Value is held.

UF0CNF register	00H	00H
UF0IF0 register	00H	00H
UF0IF1 register	00H	00H
UF0IF2 register	00H	00H
UF0IF3 register	00H	00H
UF0IF4 register	00H	00H
UF0DSCL register	00H	Value is held.
UF0DDn register (n = 0 to 17)	Note 2	Note 2
UF0CIEn register (n = 0 to 255)	Note 2	Note 2

- Notes 1.** This register can be cleared to 0 by the $\overline{\text{RESET}}$ signal because its write pointer, counter, and read pointer are cleared to 0 when the $\overline{\text{RESET}}$ signal becomes active, in the same manner as clearing by the UF0FICn register, as the register is controlled by FIFO.
- 2.** This register cannot be cleared to 0. Because data can be written to it by FW, however, any value can be written to the register (before doing so, however, be sure to set the EPONKA bit of the UF0E0NA register to 1).

12.7 FW Processing

The following FW processing is performed.

- Setting processing on device side for the SET_CONFIGURATION, SET_INTERFACE, SET_FEATURE, and CLEAR_FEATURE requests during enumeration processing
- Analysis and processing of XXXXStandard, XXXXClass, and XXXXVendor requests not subject to automatic processing
- Reading data following bulk-transferred OUT token from receive buffer
- Writing data to be returned in response to bulk-transferred IN token
- Writing data to be returned in response to interrupt-transferred token

The following table lists the requests supported by FW.

Table 12-8. FW-Supported Standard Requests

Request	Reception Side	Processing/ Frequency	Explanation
CLEAR_FEATURE	Interface	Automatic STALL response	It is considered that this request does not come to Interface because there is no function selector value, though it is reserved for bmRequestType. When this request is received, the hardware makes an automatic STALL response.
SET_FEATURE	Interface	Automatic STALL response	It is considered that this request does not come to Interface because there is no function selector value, though it is reserved for bmRequestType. When this request is received, the hardware makes an automatic STALL response.
GET_DESCRIPTOR	String	FW	Returns the string descriptor. When this request is received by the SETUP token, the hardware generates the CPUDEC interrupt request for FW. FW decodes the contents of the request from the CPUDEC interrupt request, and writes the data to be returned to the host, to the UF0E0W register.
SET_DESCRIPTOR	Device	FW	Rewrites the device descriptor. When this request is received by the SETUP token, the hardware generates the CPUDEC interrupt request for FW. FW decodes the contents of the request from the CPUDEC interrupt request, and the writes the data for the next control transfer (OUT) to the UF0DDn register (n = 0 to 17).
SET_DESCRIPTOR	Configuration	FW	Rewrites the configuration descriptor. When this request is received by the SETUP token, the hardware generates the CPUDEC interrupt request for FW. FW decodes the contents of the request from the CPUDEC interrupt request, and the writes the data for the next control transfer (OUT) to the UF0CIEn register (n = 0 to 255).
SET_DESCRIPTOR	String	FW	Rewrites the string descriptor. When this request is received by the SETUP token, the hardware generates the CPUDEC interrupt request for FW. FW decodes the contents of the request from the CPUDEC interrupt request, and loads the data for the next control transfer (OUT).
Other	NA	FW	When this request is received by the SETUP token, the hardware generates the CPUDEC interrupt request for FW. FW decodes the contents of the request from the CPUDEC interrupt request, and performs the necessary processing.

12.7.1 Initialization processing

Initialization processing is executed in the following two ways.

- Initialization of request data register
- Setting of interrupt

When the request data register is initialized, data for the GET_XXXX request to which a value is to be automatically returned is written and an endpoint is allocated to an interface. In the interrupt settings, the interrupt sources that do not have to be checked can be masked by using the UF0IMn register (n = 0 to 4).

The following flowcharts illustrate the above processing.

Figure 12-12. Initializing Request Data Register

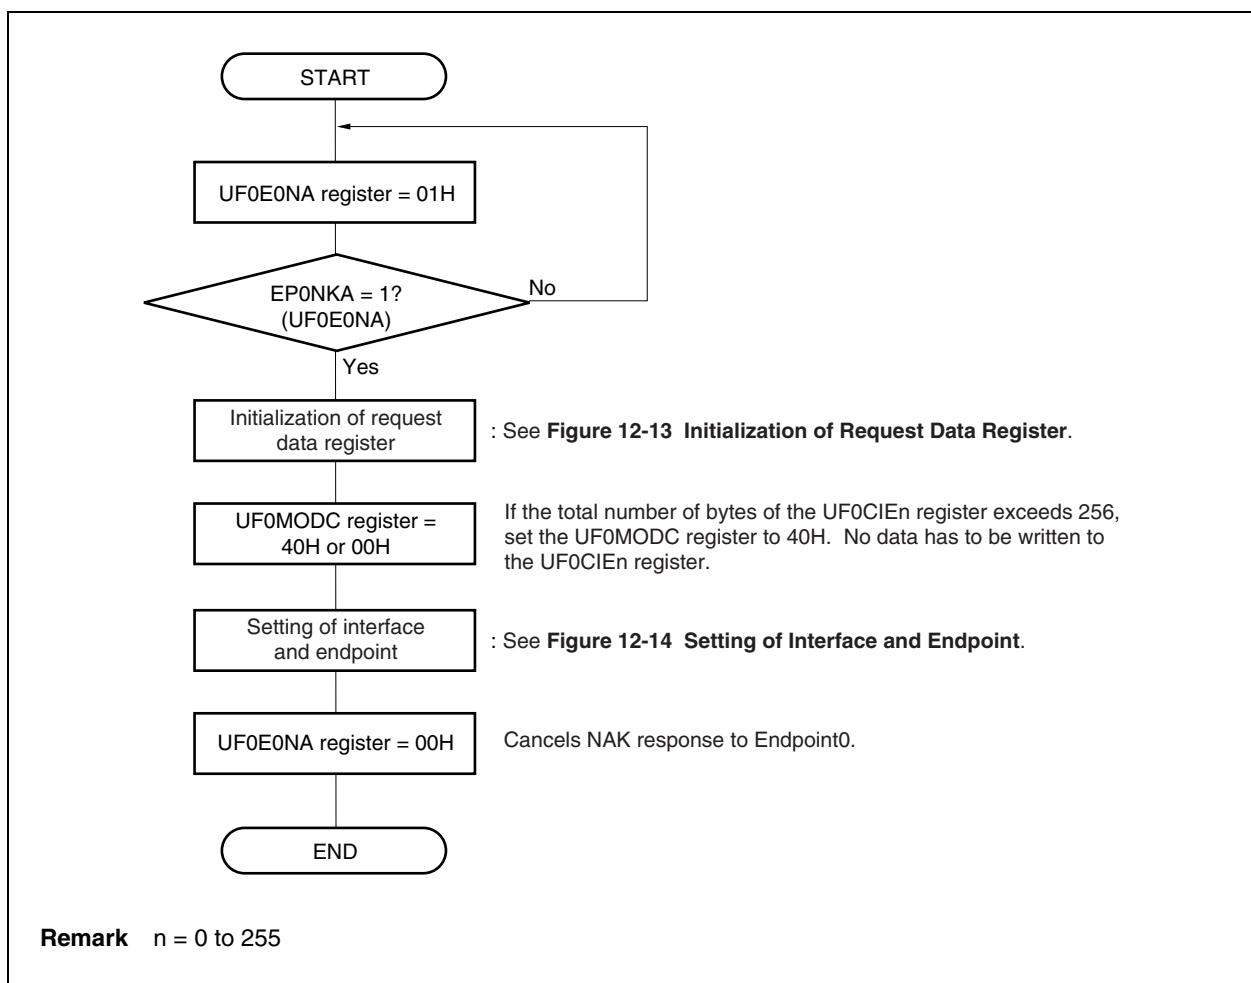

Figure 12-13. Initialization of Request Data Register

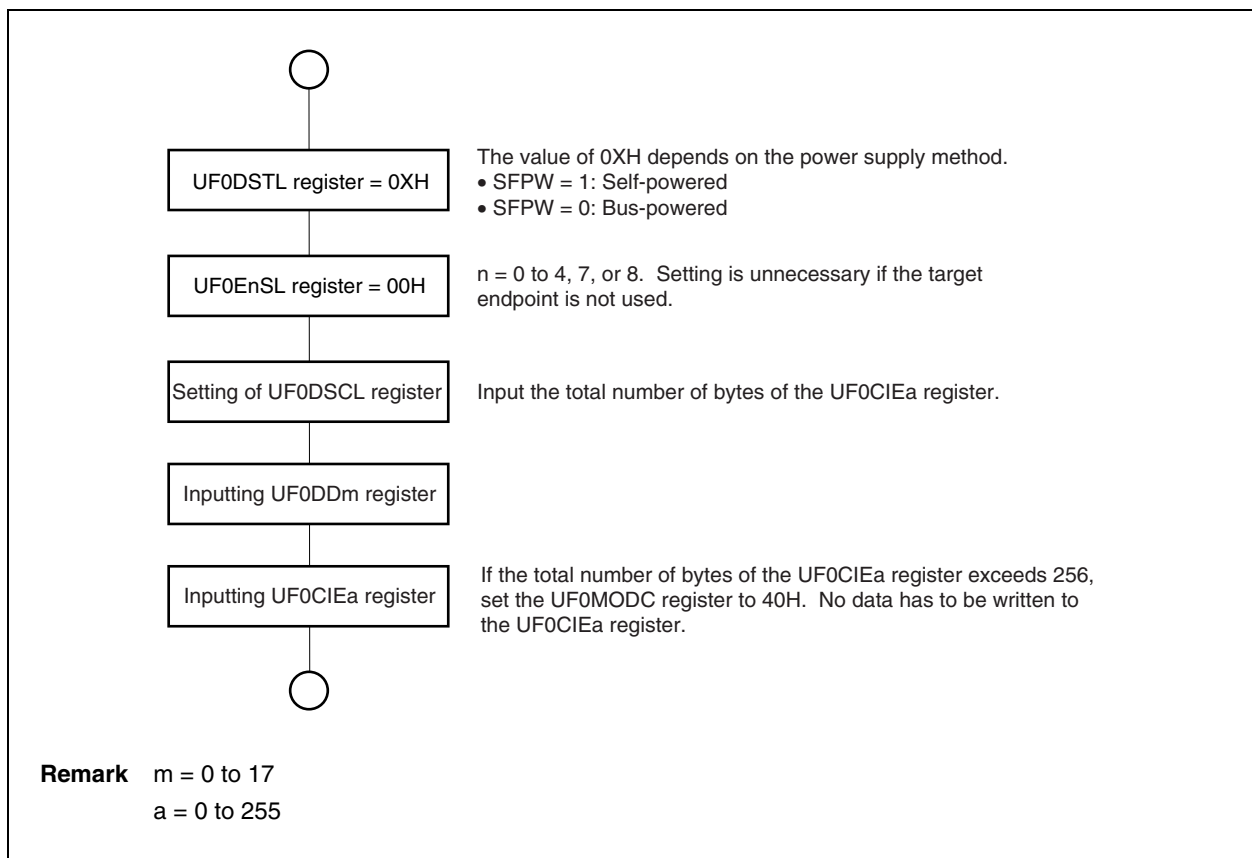

Figure 12-14. Setting of Interface and Endpoint

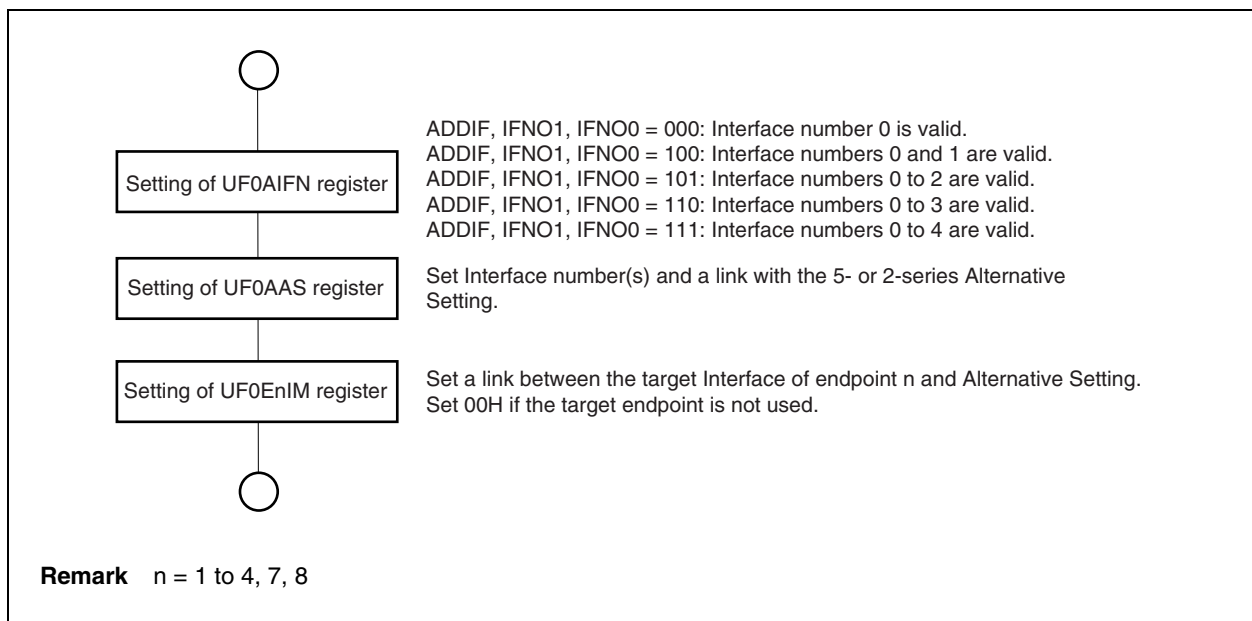

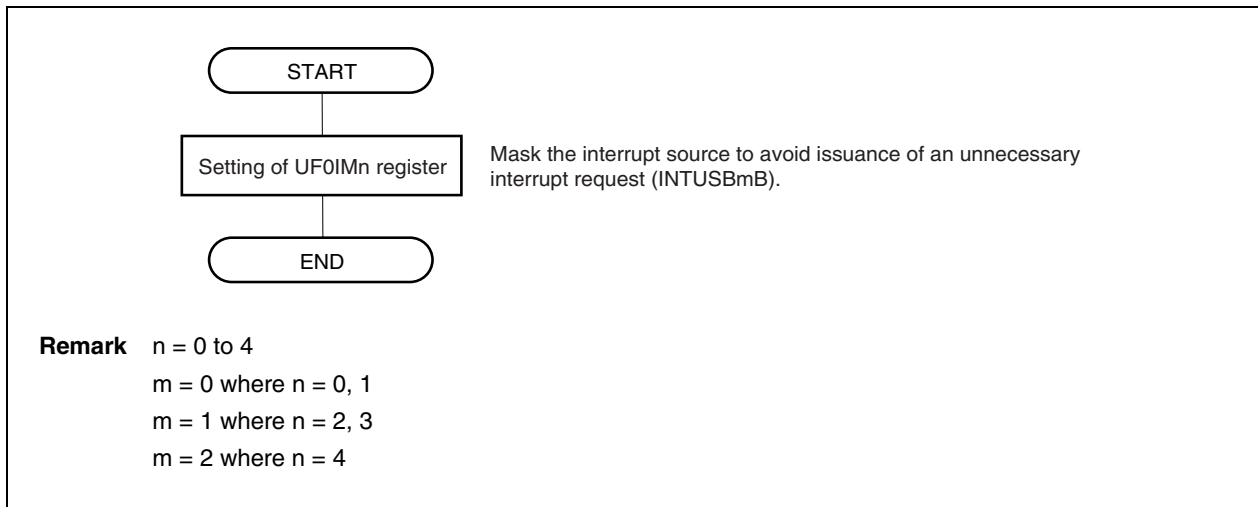

Figure 12-15. Setting of Interrupt

12.7.2 Interrupt servicing

The following flowchart illustrates how an interrupt is serviced.

Figure 12-16. Interrupt Servicing

The following bits of the UF0ISn register are automatically cleared by hardware when a given condition is satisfied (n = 1 to 4).

- E0INDT, E0ODT, SUCES, STG, and CPUDEC bits of UF0IS1 register
- BKI2DT, BKI1DT, IT2DT, and IT1DT bits of UF0IS2 register
- BKO2FL, BKO2DT, BKO1FL, and BKO1DT bits of UF0IS3 register

Because clearing an interrupt source by the UF0ICn register is given a lower priority than setting an interrupt source by hardware, the interrupt source may not be cleared depending on the timing (n = 0 to 4).

12.7.3 USB main processing

USB main processing involves processing USB transactions. The types of transactions to be processed are as follows.

- Fully automatically processed request for control transfer
- Automatically processed requests for control transfer
(SET_CONFIGURATION, SET_INTERFACE, SET_FEATURE, CLEAR_FEATURE)
- CPUDEC request for control transfer
- Processing for bulk transfer (IN)
- Processing for bulk transfer (OUT)
- Processing for interrupt transfer (IN)

Processing for endpoint n involves writing or reading for data transfer. The flowchart shown below is for PIO.

(1) Fully automatically processed request for control transfer

Because the fully automatically processed request for control transfer is executed by hardware, it cannot be referenced by FW. Therefore, FW does not have to perform any special processing for this request.

(2) Automatically processed requests for control transfer

(SET_CONFIGURATION, SET_INTERFACE, SET_FEATURE, CLEAR_FEATURE)

Processing to write a register for automatically processed requests for control transfer, such as SET_CONFIGURATION, SET_INTERFACE, SET_FEATURE, and CLEAR_FEATURE requests, is automatically executed by hardware, but an interrupt request is issued for recognition on the device side. This processing may be ignored if there is no special processing to be executed.

The flowcharts are shown below.

Figure 12-17. Automatically Processed Requests for Control Transfer

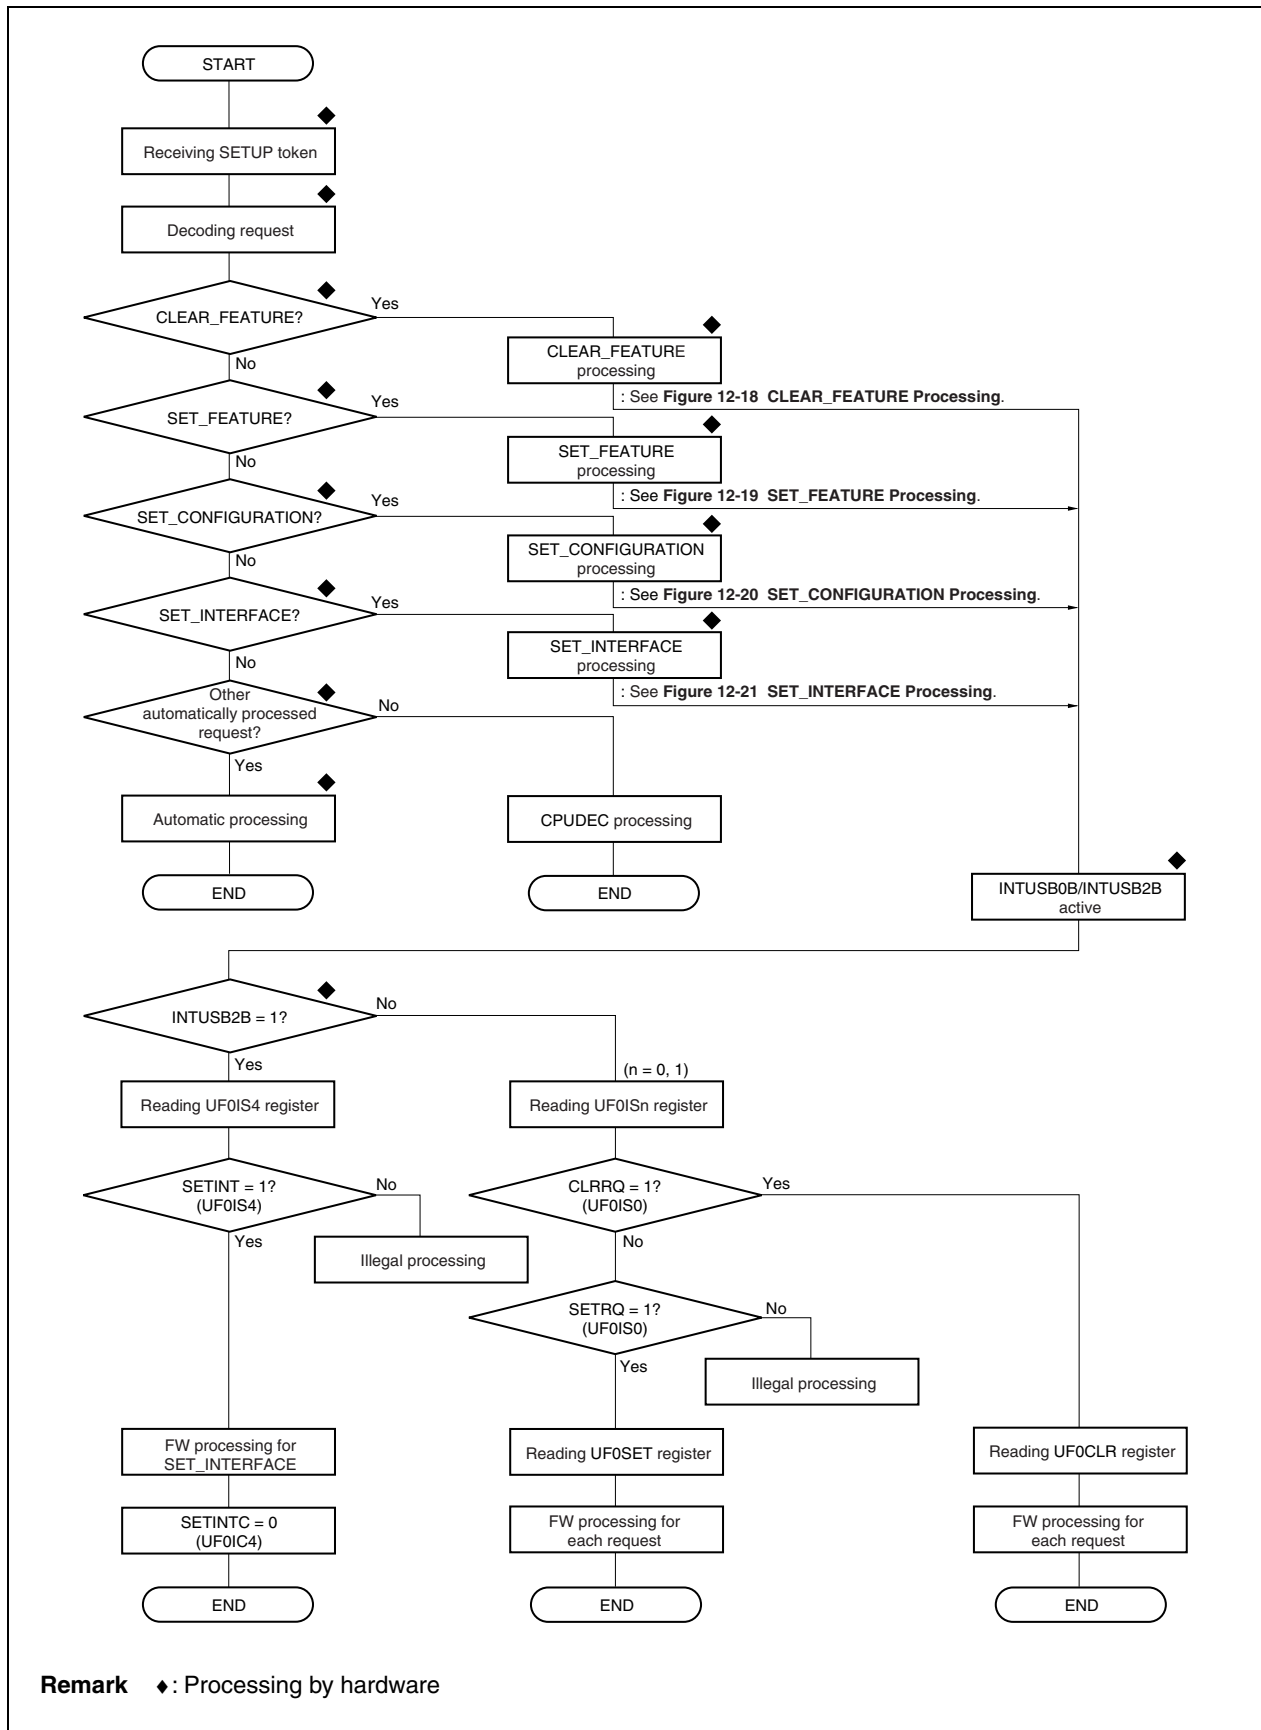

Figure 12-18. CLEAR_FEATURE Processing

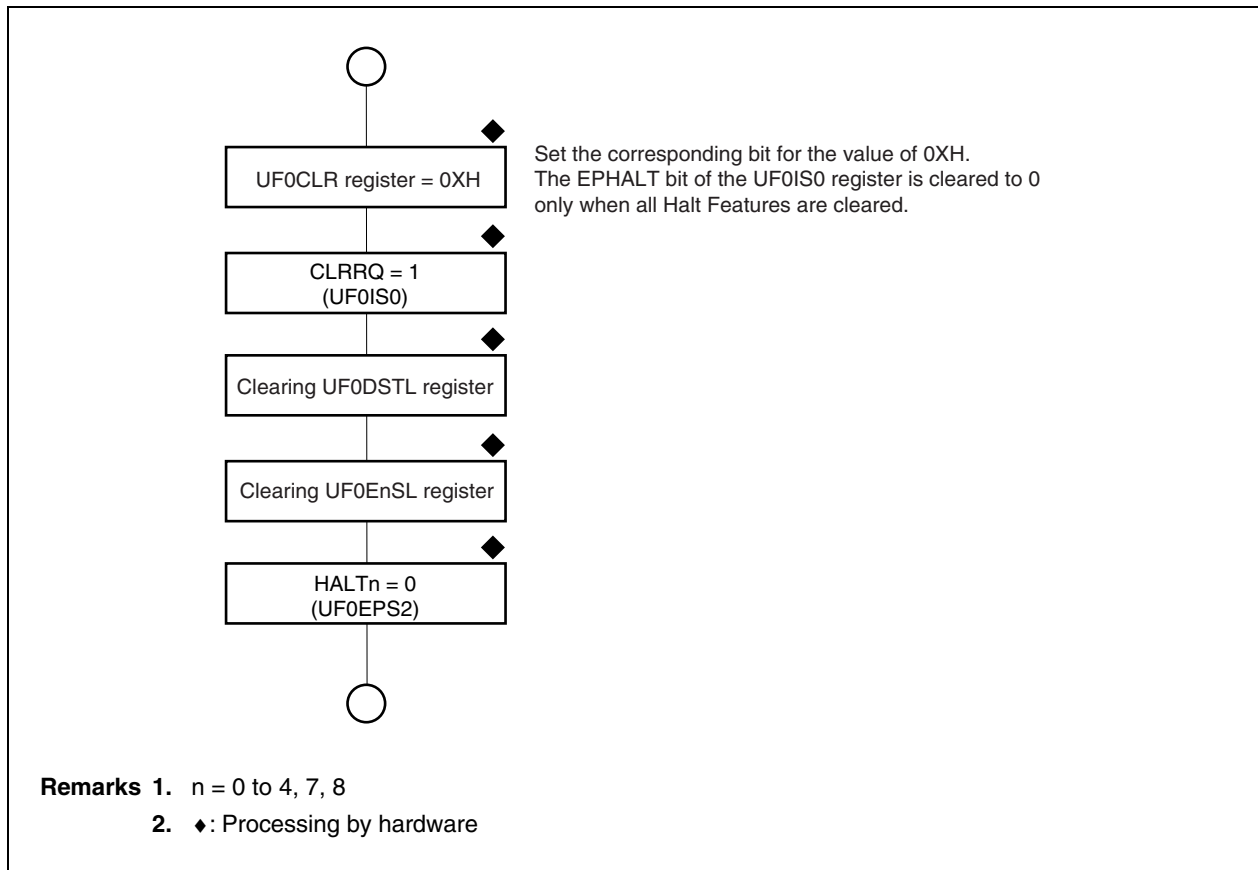

Figure 12-19. SET_FEATURE Processing

Figure 12-20. SET_CONFIGURATION Processing

Figure 12-21. SET_INTERFACE Processing

(3) CPUDEC request for control transfer

The CPUDEC request can be classified into three types of processing: control transfer (write), control transfer (read), and control transfer (without data). Control transfer (write) indicates a request that uses the OUT transaction in the data stage (e.g., SET_DESCRIPTOR), and control transfer (read) indicates a request that uses the IN transaction in the data stage (e.g., GET_DESCRIPTOR). Control transfer (without data) indicates a request that has no data stage (e.g., SET_CONFIGURATION).

The flowcharts are shown below.

Figure 12-22. CPUDEC Request for Control Transfer (1/12)

Figure 12-22. CPUDEC Request for Control Transfer (2/12)

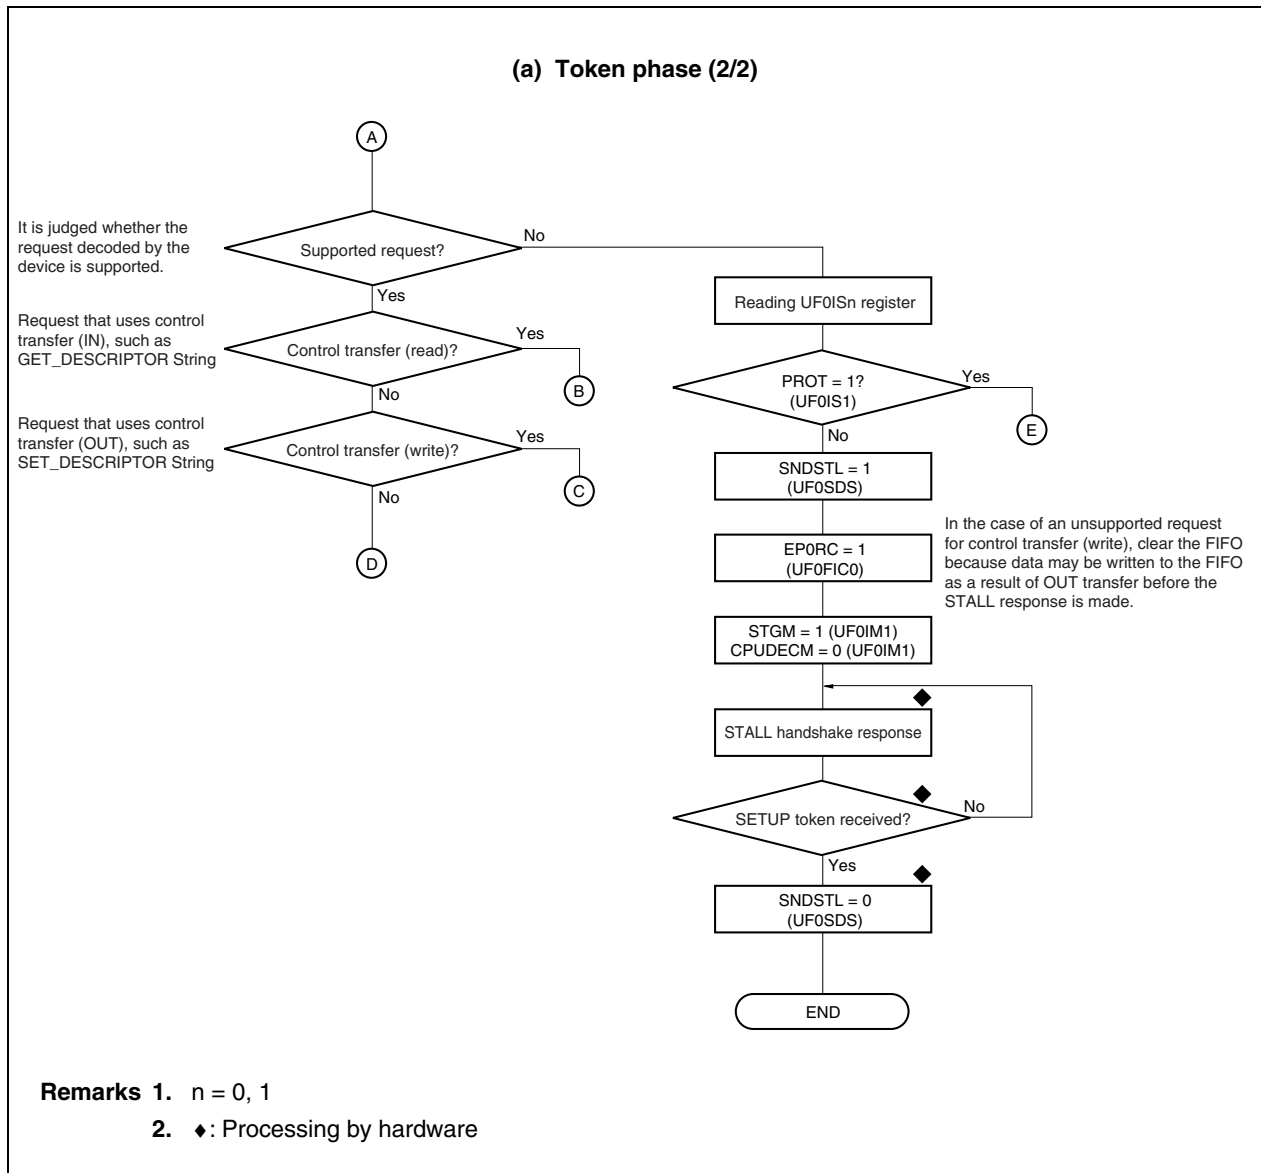

Figure 12-22. CPUDEC Request for Control Transfer (3/12)

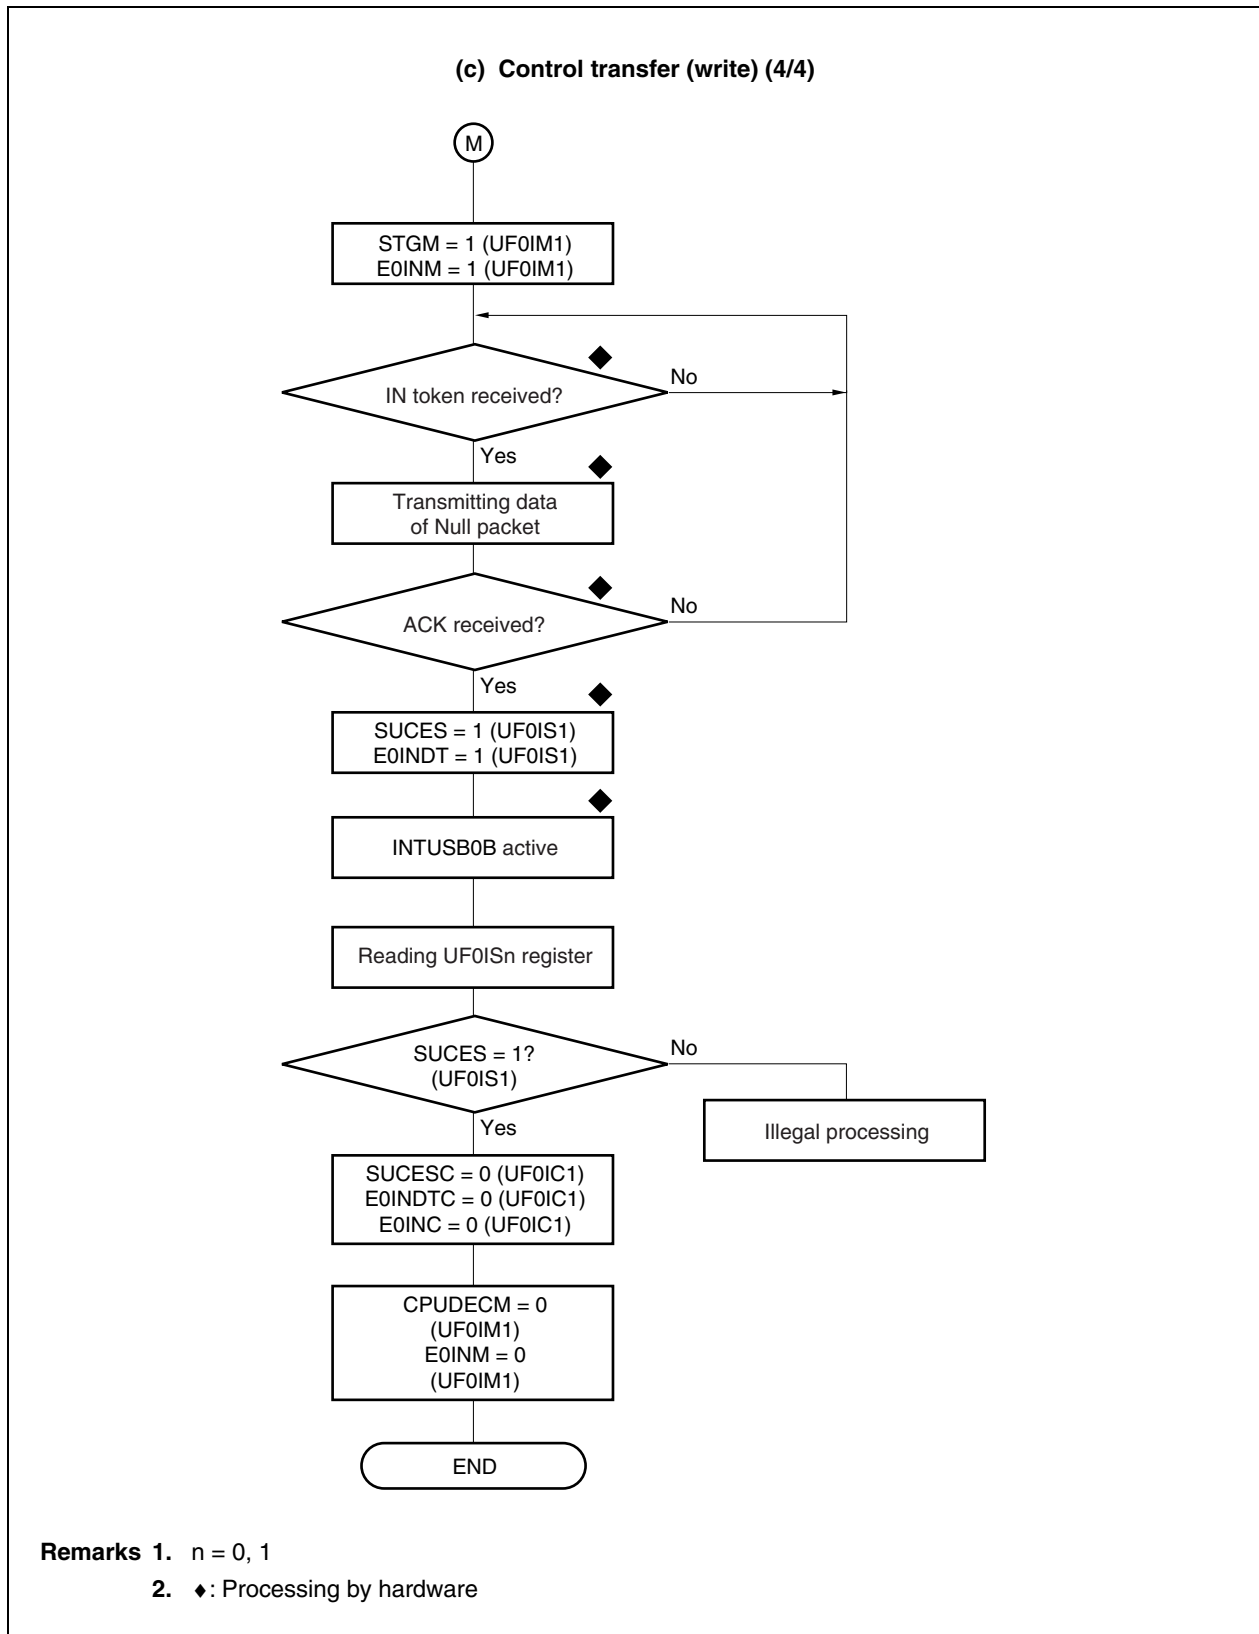

Figure 12-22. CPUDEC Request for Control Transfer (11/12)

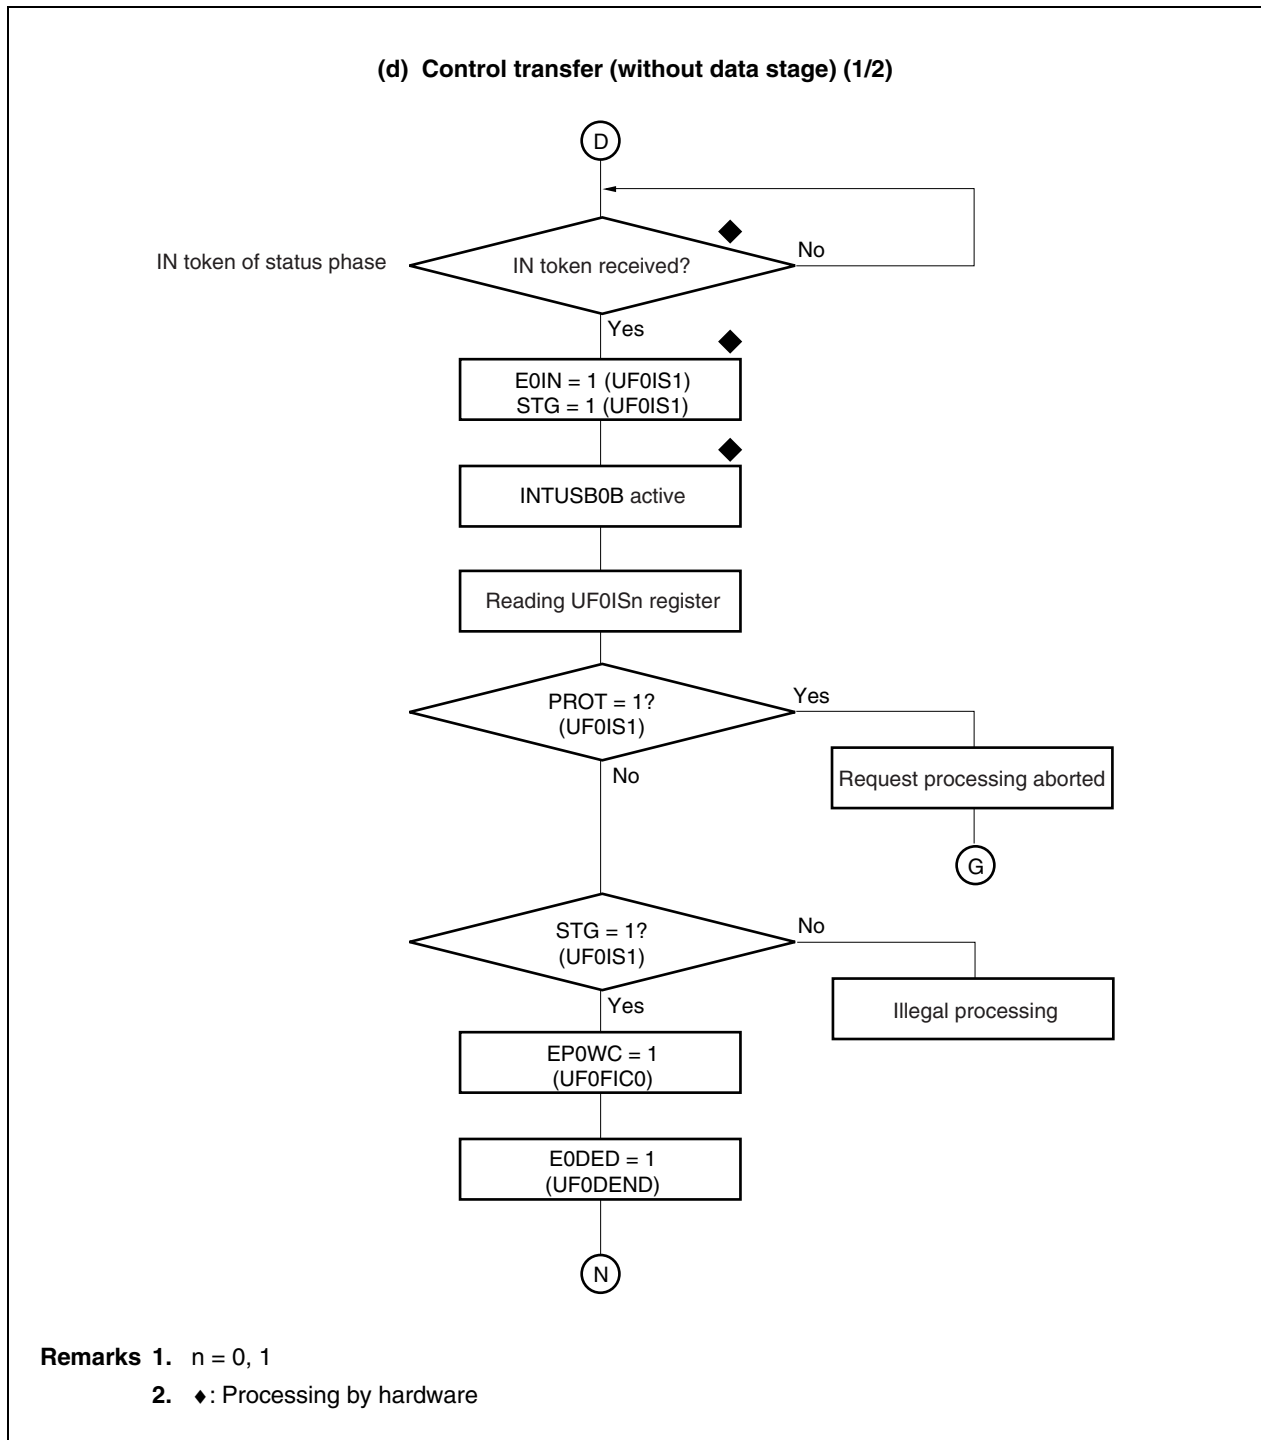

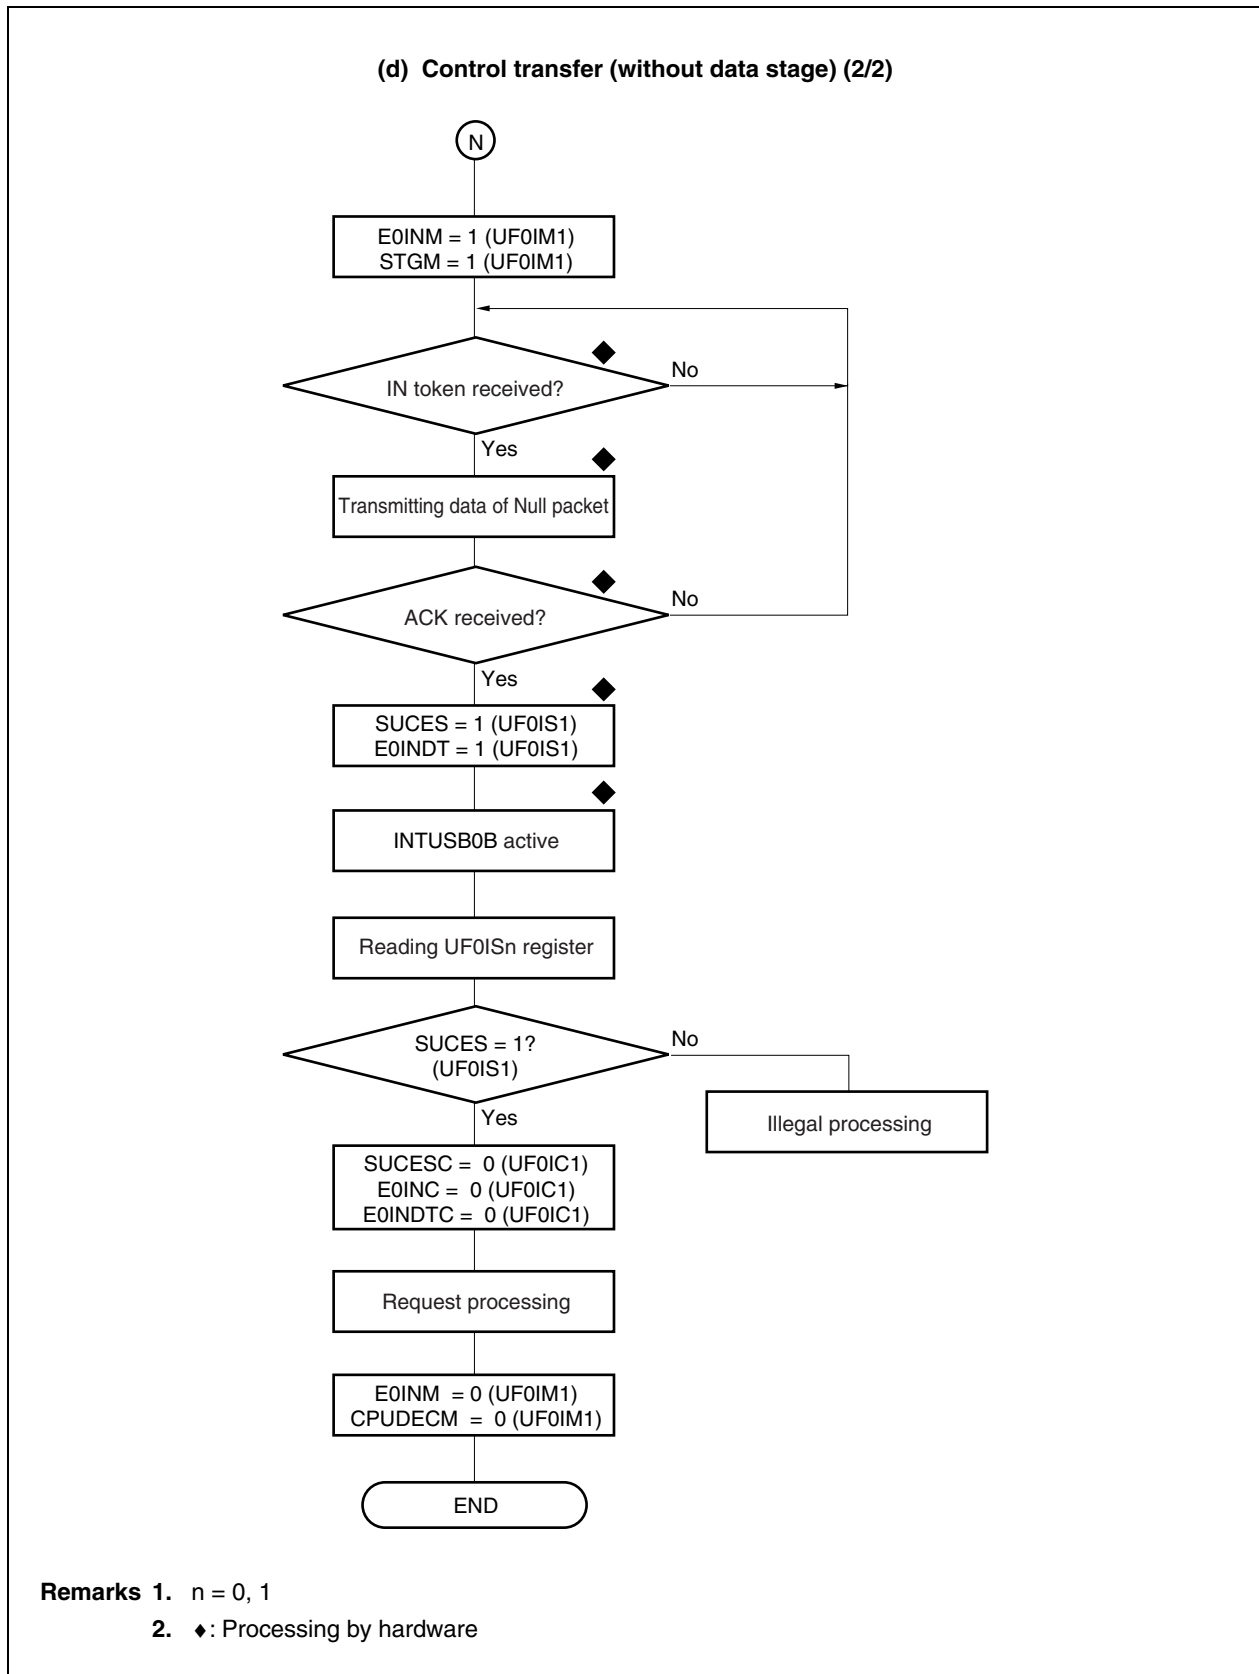

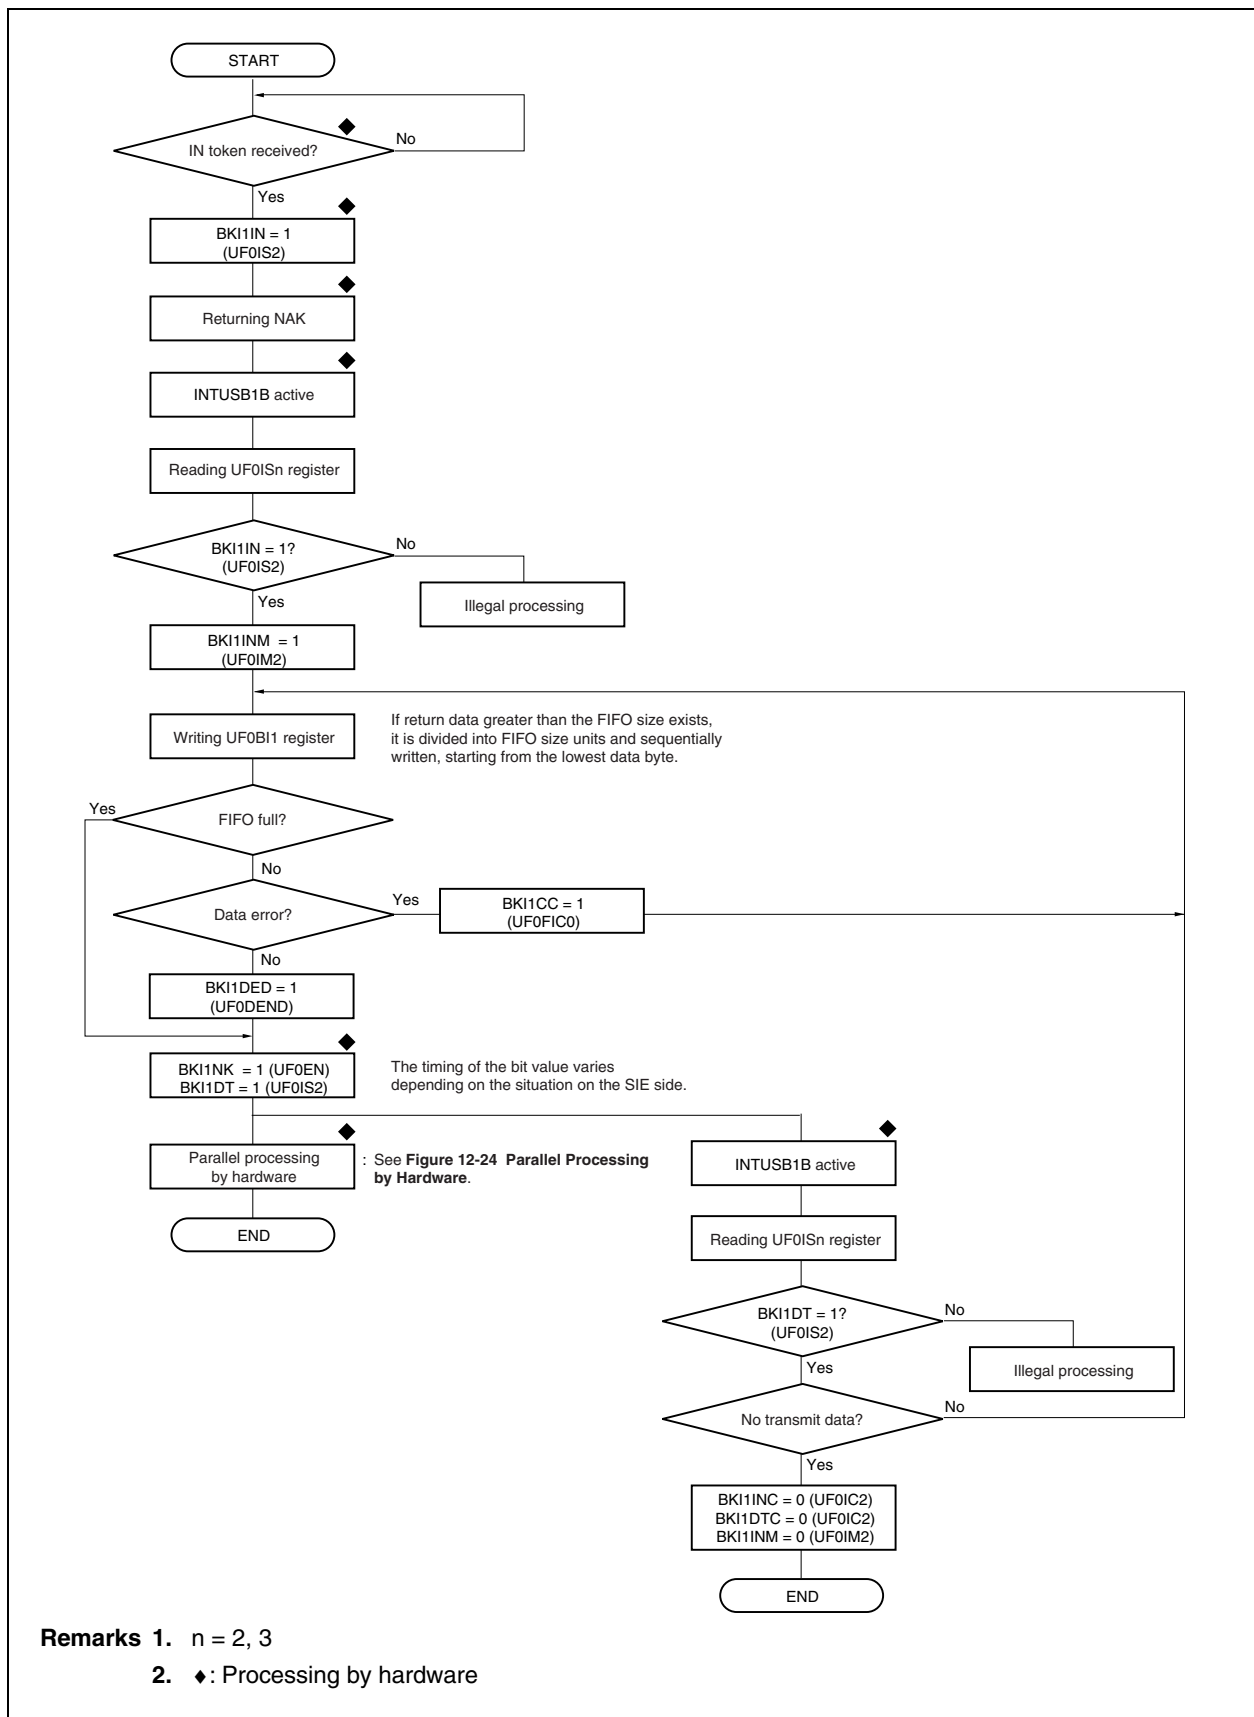

Figure 12-22. CPUDEC Request for Control Transfer (12/12)

(4) Processing for bulk transfer (IN)

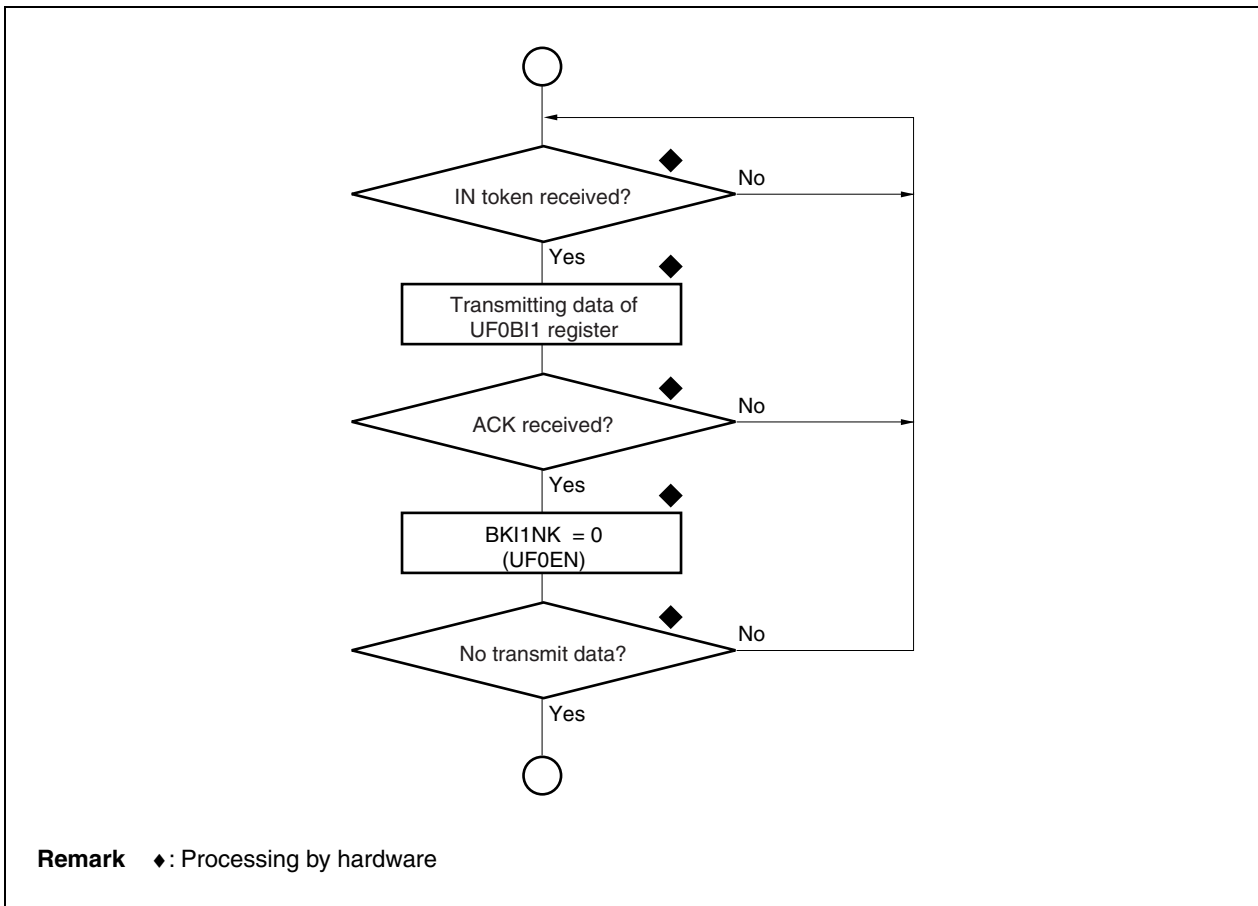

Bulk transfer (IN) is allocated to Endpoint1 and Endpoint3. The flowchart shown below illustrates how Endpoint1 is controlled. Endpoint3 can also be controlled in the same sequence. To use this flowchart as the control flow of Endpoint3, therefore, read the bit names of Endpoint1 in the flowchart as those of Endpoint3.

Figure 12-23. Processing for Bulk Transfer (IN) (Endpoint1)

- Remarks 1. n = 2, 3
 2. ♦: Processing by hardware

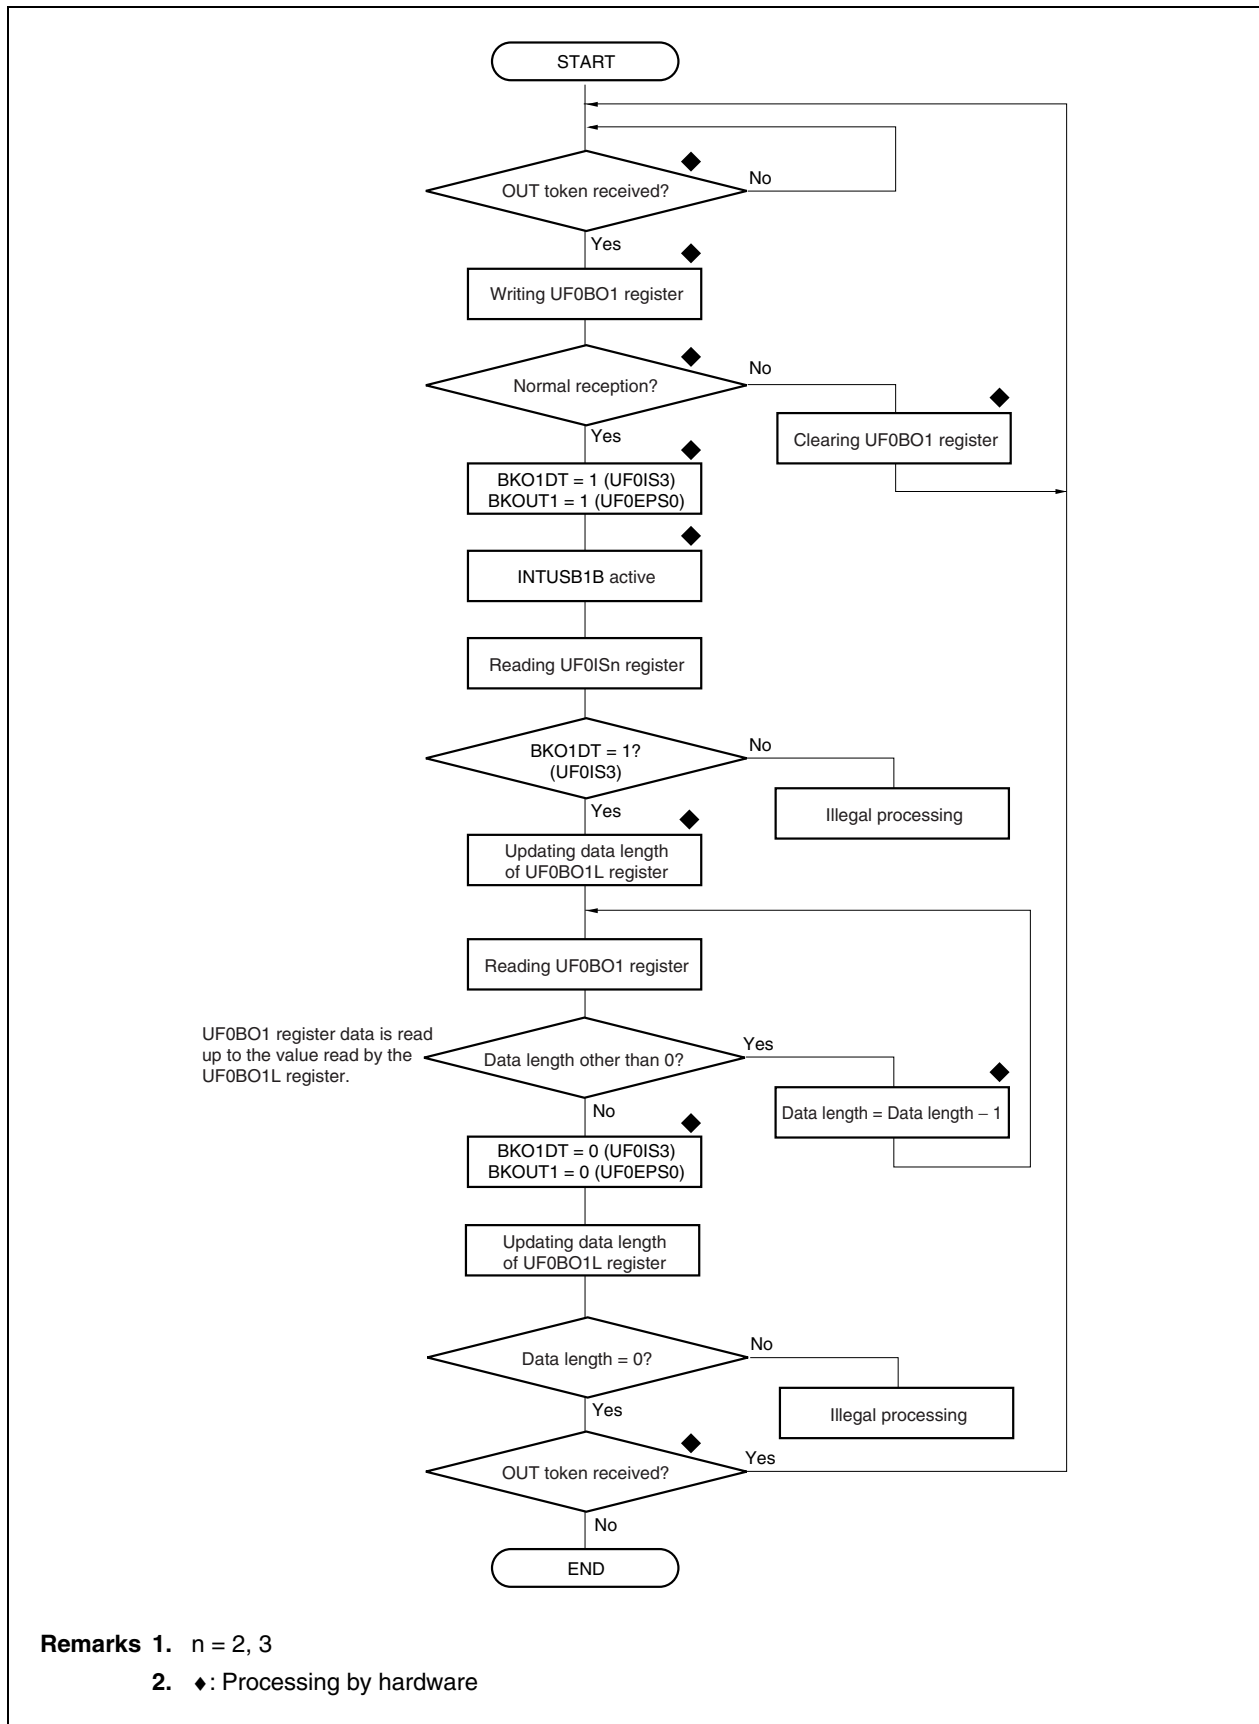

Figure 12-24. Parallel Processing by Hardware

(5) Processing for bulk transfer (OUT)

Bulk transfer (OUT) is allocated to Endpoint2 and Endpoint4. The flowchart shown below illustrates how Endpoint2 is controlled. Endpoint4 can also be controlled in the same sequence. To use this flowchart as the control flow of Endpoint4, therefore, read the bit names of Endpoint2 in the flowchart as those of Endpoint4.

Figure 12-25. Normal Processing for Bulk Transfer (OUT) (Endpoint2)

During bulk transfer (OUT), more data may be transmitted from the host than expected by the system. Endpoint2 and Endpoint4 for bulk transfer (OUT) of the V850E2/ME3 consist of two 64-byte buffers so that NAK responses are suppressed as much as possible and data can be read from the CPU side even while the bus side is being accessed as the transfer rate of the USB bus increases. Consequently, if the host sends more data than expected by the system, up to 128 bytes of extra data may be automatically received in the worst case. In this case, change the control flow from that of the normal processing of Endpoint2 and Endpoint4 to the flow illustrated below when the quantity of data expected by the system has decreased to two packets. This flowchart illustrates how Endpoint2 is controlled. Endpoint4 can also be controlled in the same sequence. To use this flowchart as the control flow of Endpoint4, therefore, read the bit names of Endpoint2 in the flowchart as those of Endpoint4.

Figure 12-26. Processing If More Data Than Expected by System Is Transmitted (Endpoint2) (1/2)

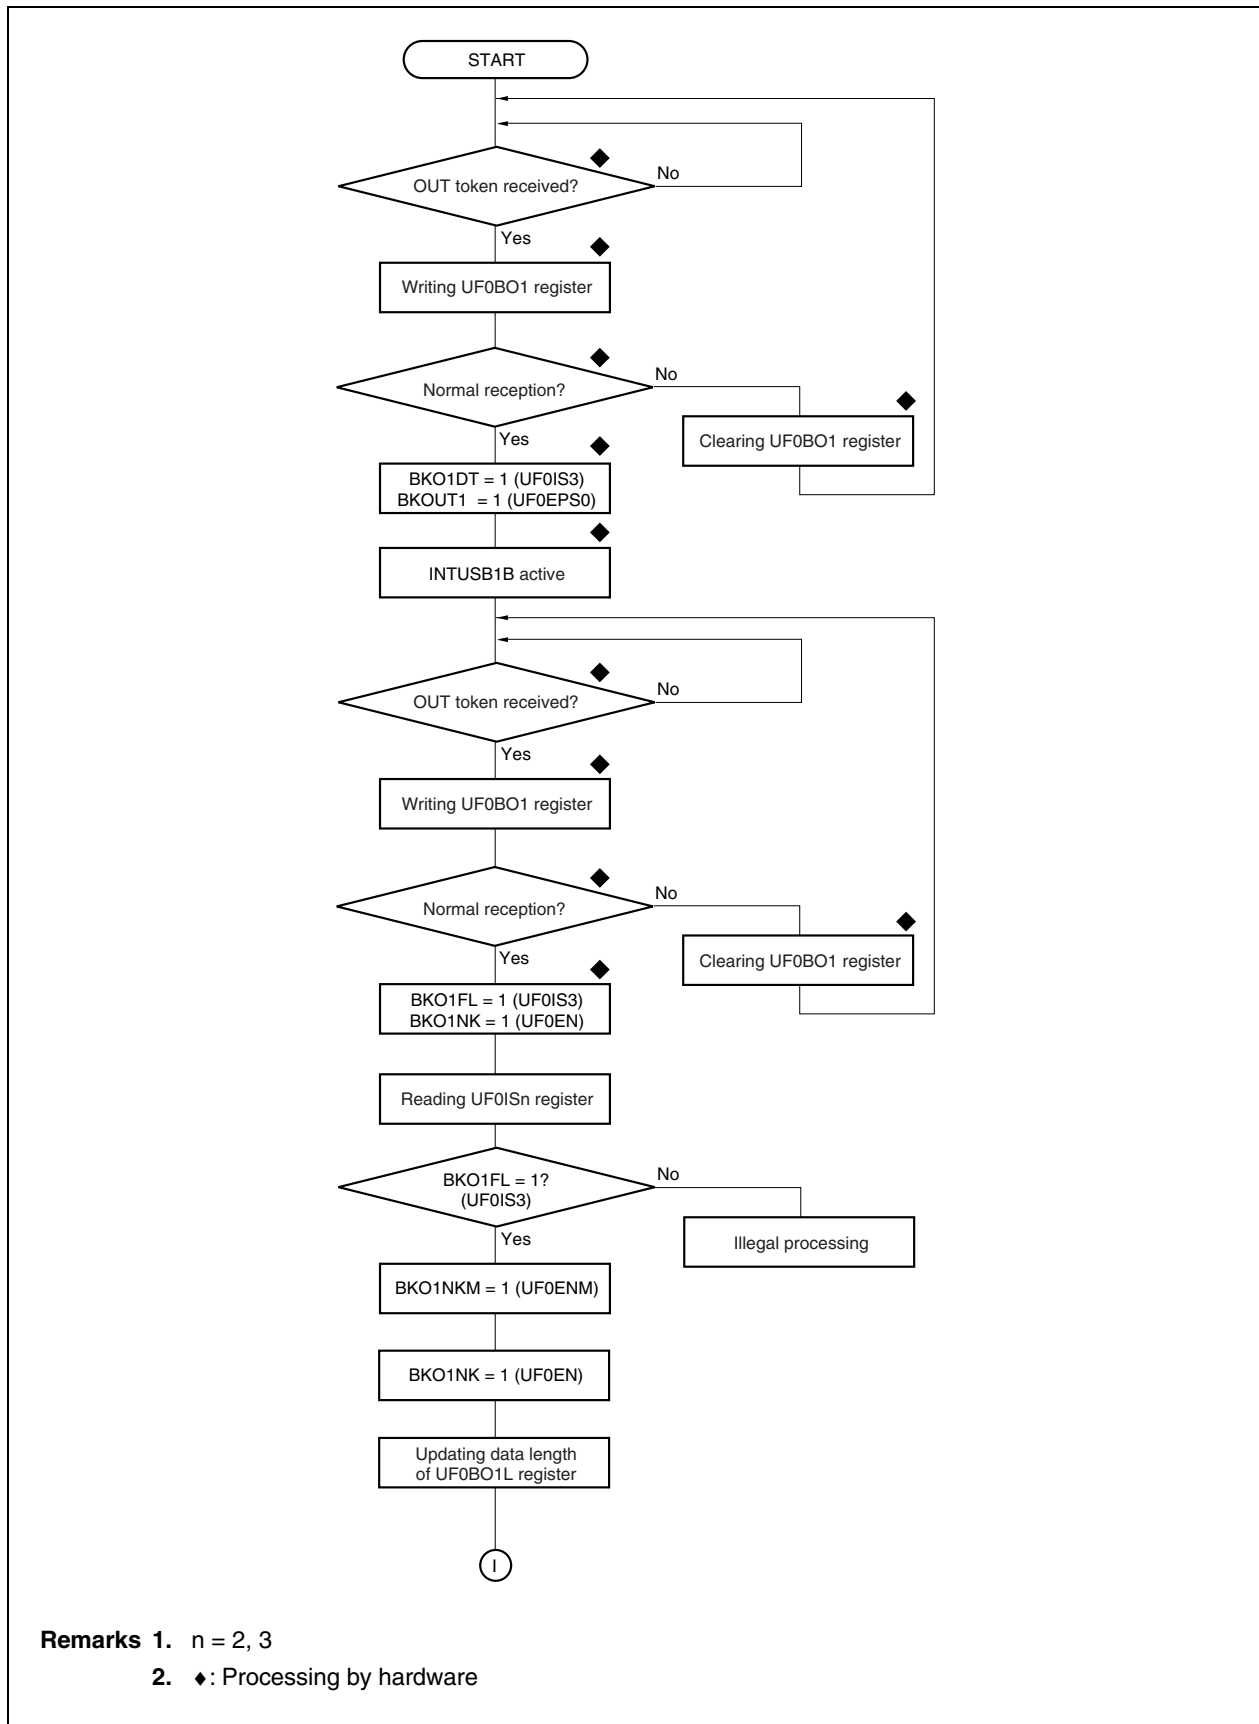

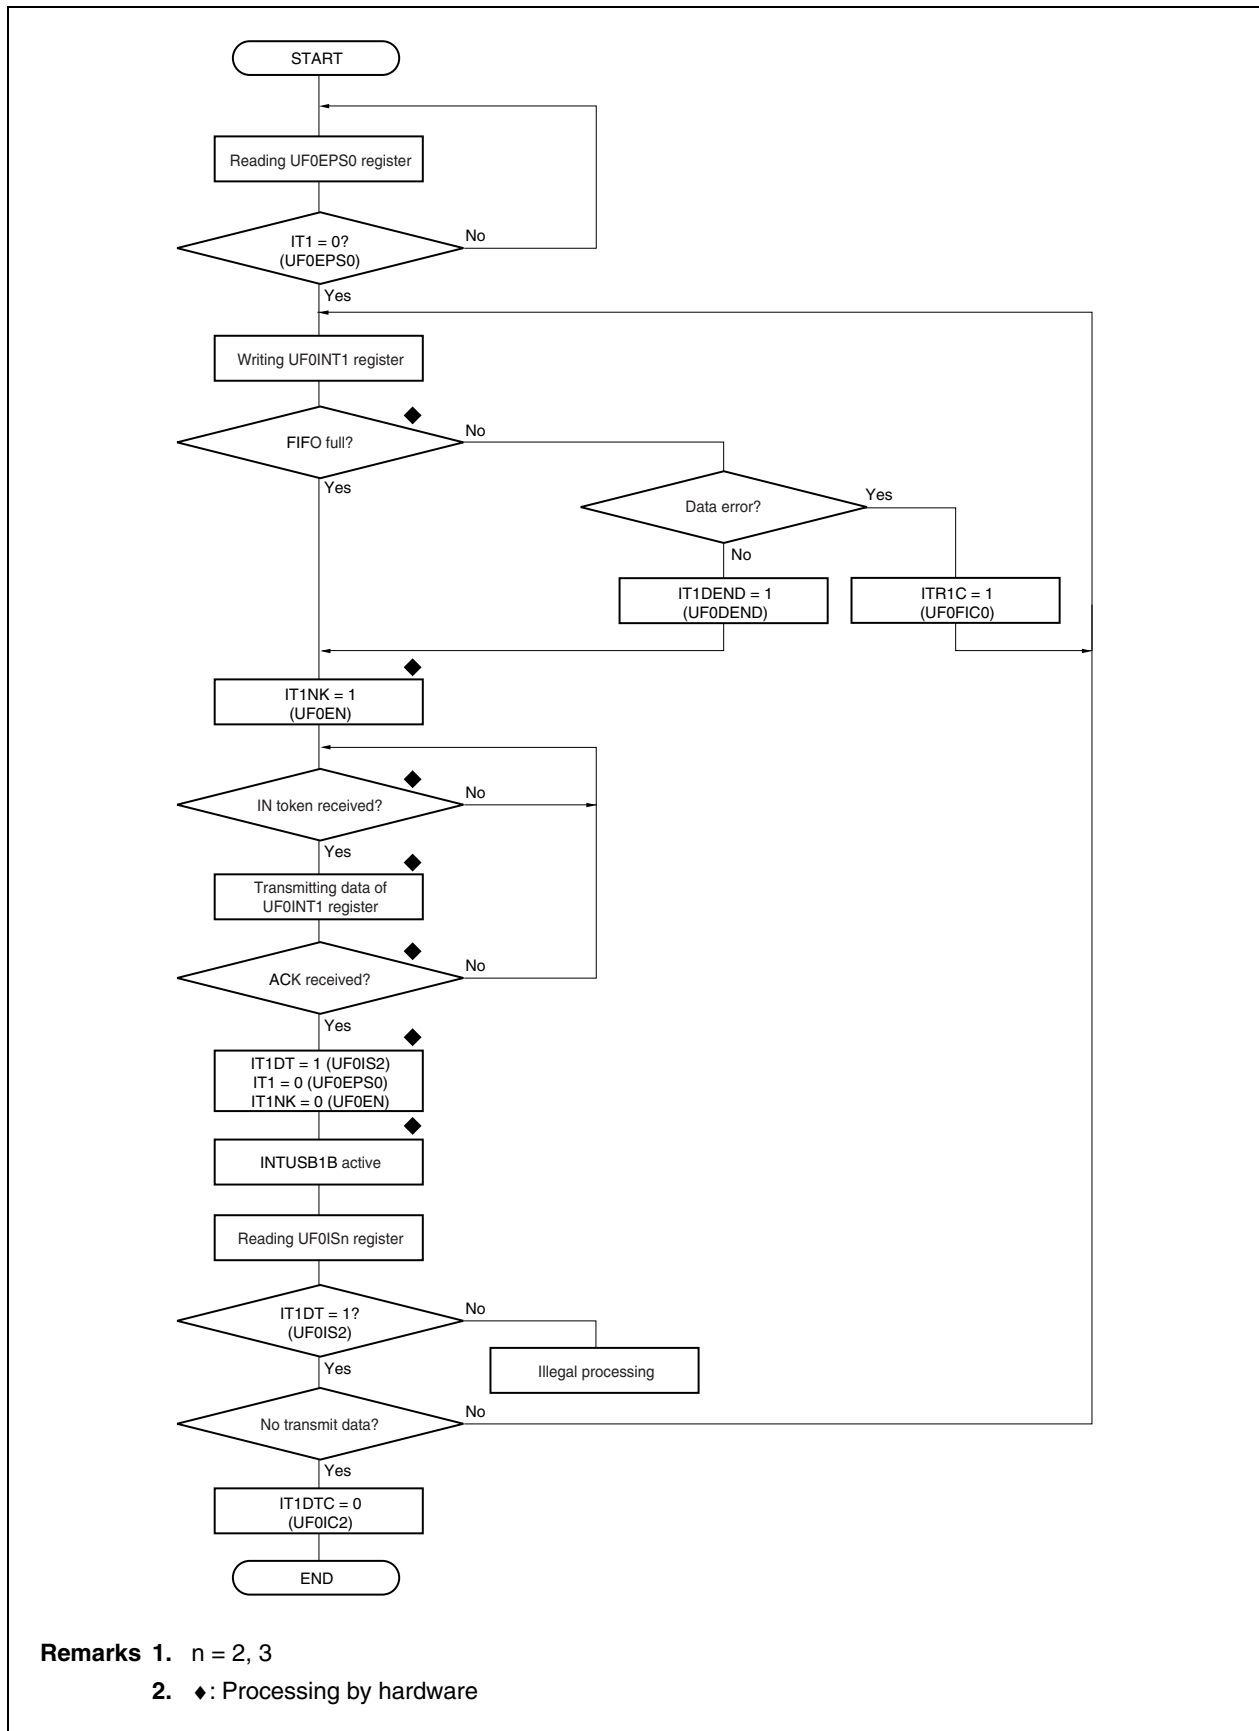

Figure 12-26. Processing If More Data Than Expected by System Is Transmitted (Endpoint2) (2/2)

(6) Processing for interrupt transfer (IN)

Interrupt transfer (IN) is allocated to Endpoint7 and Endpoint8. The flowchart shown below illustrates how Endpoint7 is controlled. Endpoint8 can also be controlled in the same sequence. To use this flowchart as the control flow of Endpoint8, therefore, read the bit names of Endpoint7 in the flowchart as those of Endpoint8.

Figure 12-27. Processing for Interrupt Transfer (IN) (Endpoint7)

12.7.4 Suspend/Resume processing

How Suspend/Resume processing is performed differs depending on the configuration of the system. One example is given below.

Figure 12-28. Example of Suspend/Resume Processing (1/3)

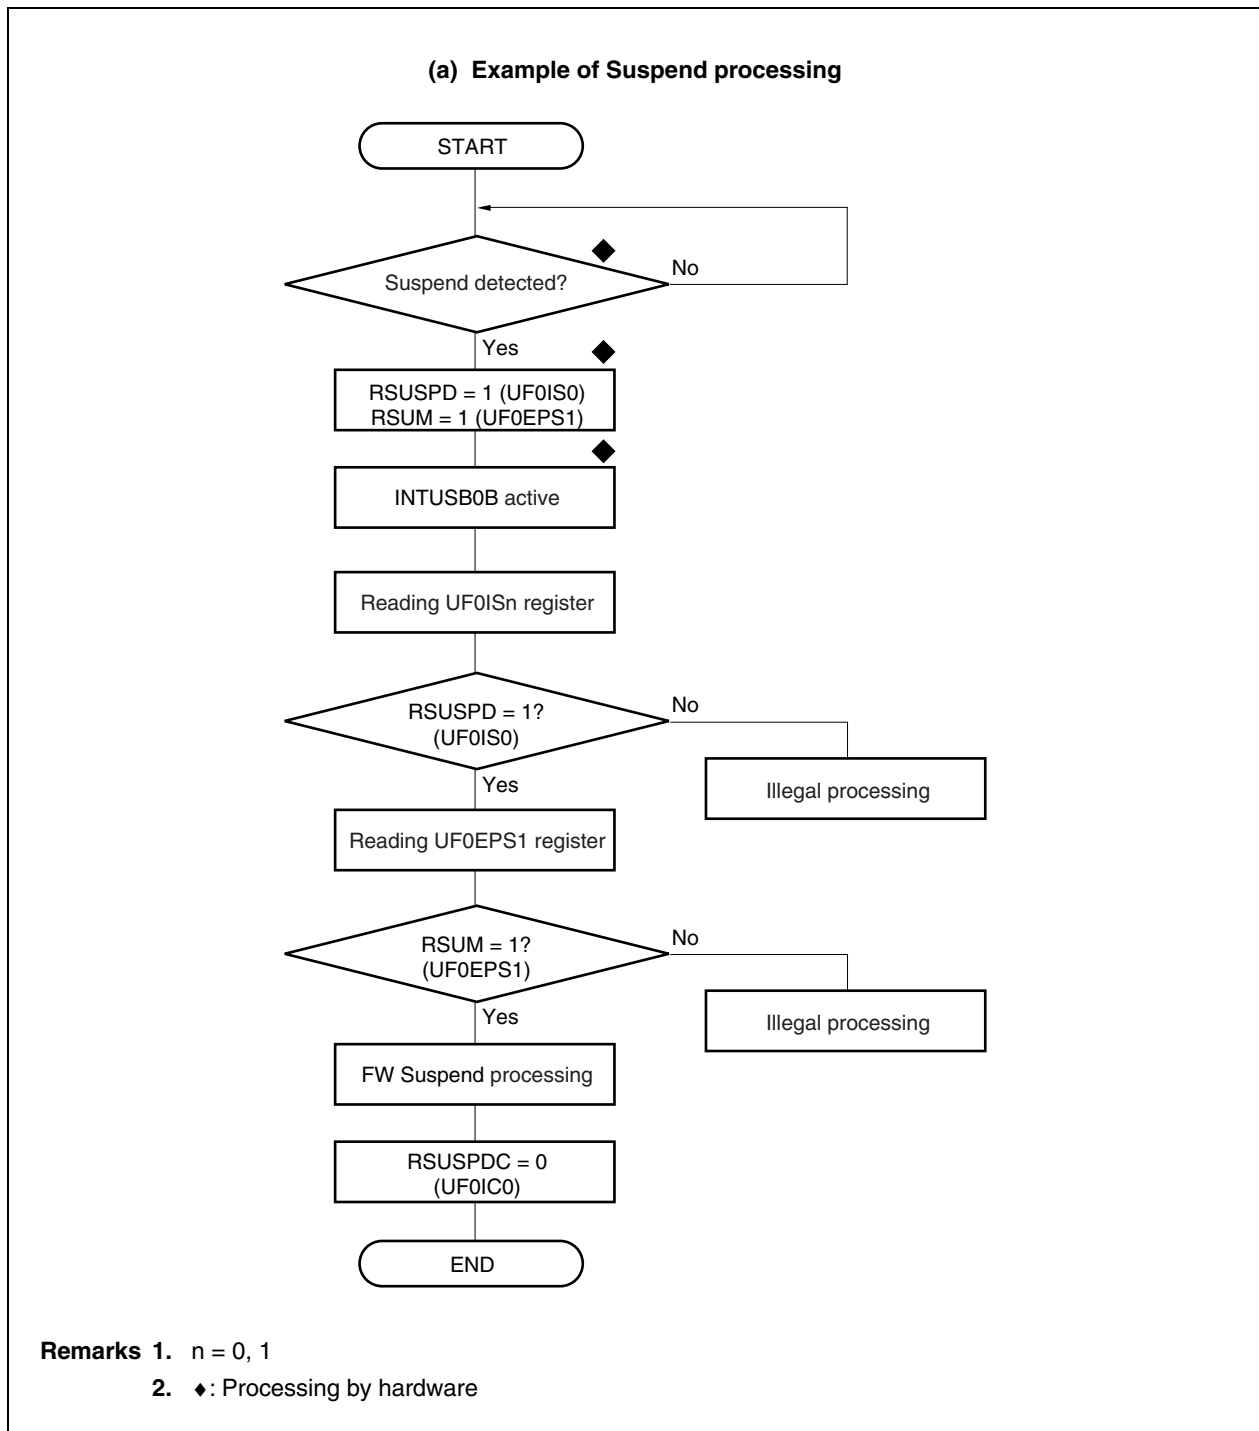

Figure 12-28. Example of Suspend/Resume Processing (2/3)

Figure 12-28. Example of Suspend/Resume Processing (3/3)

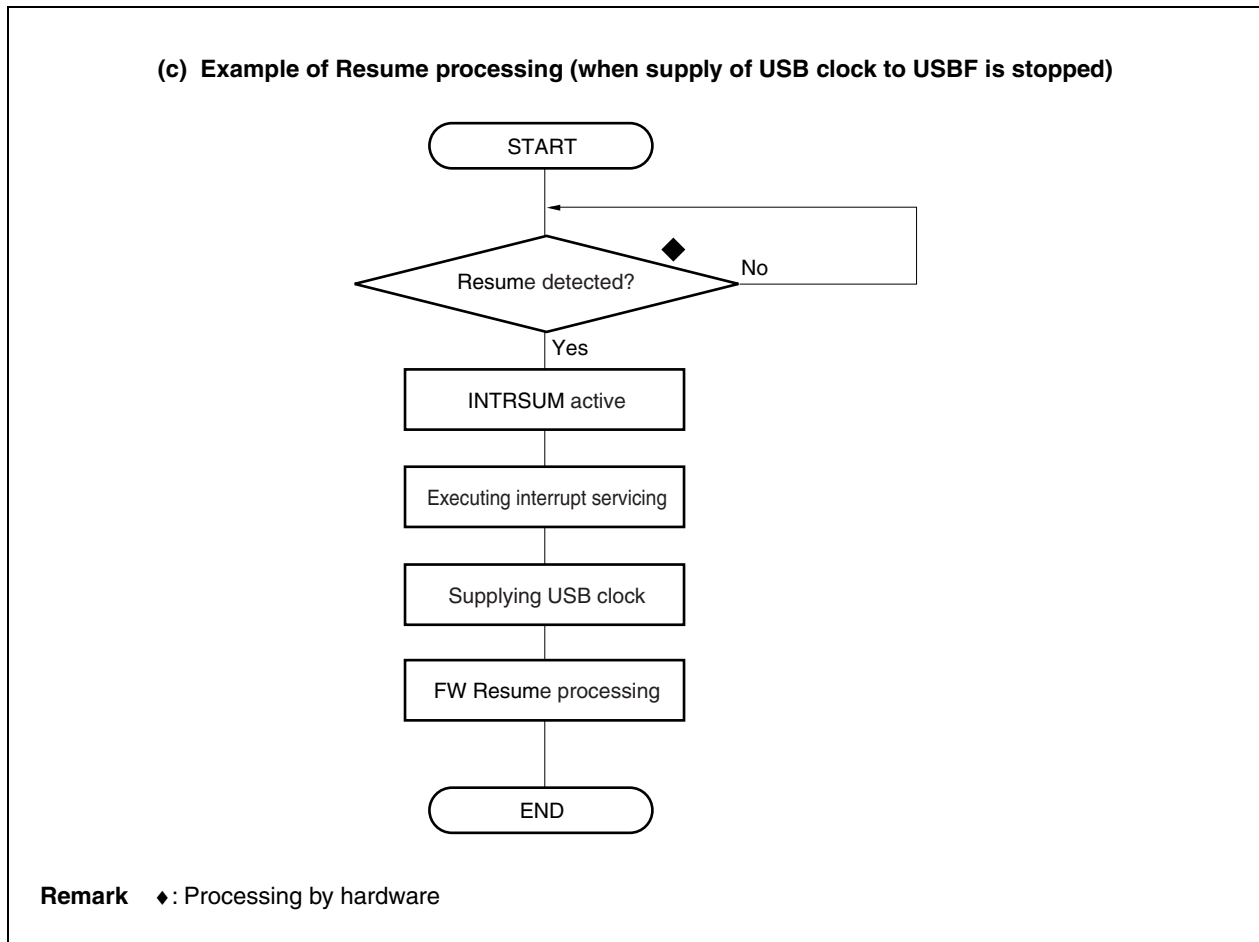

Figure 12-29. Example of Processing After Power Application/Power Failure (2/3)

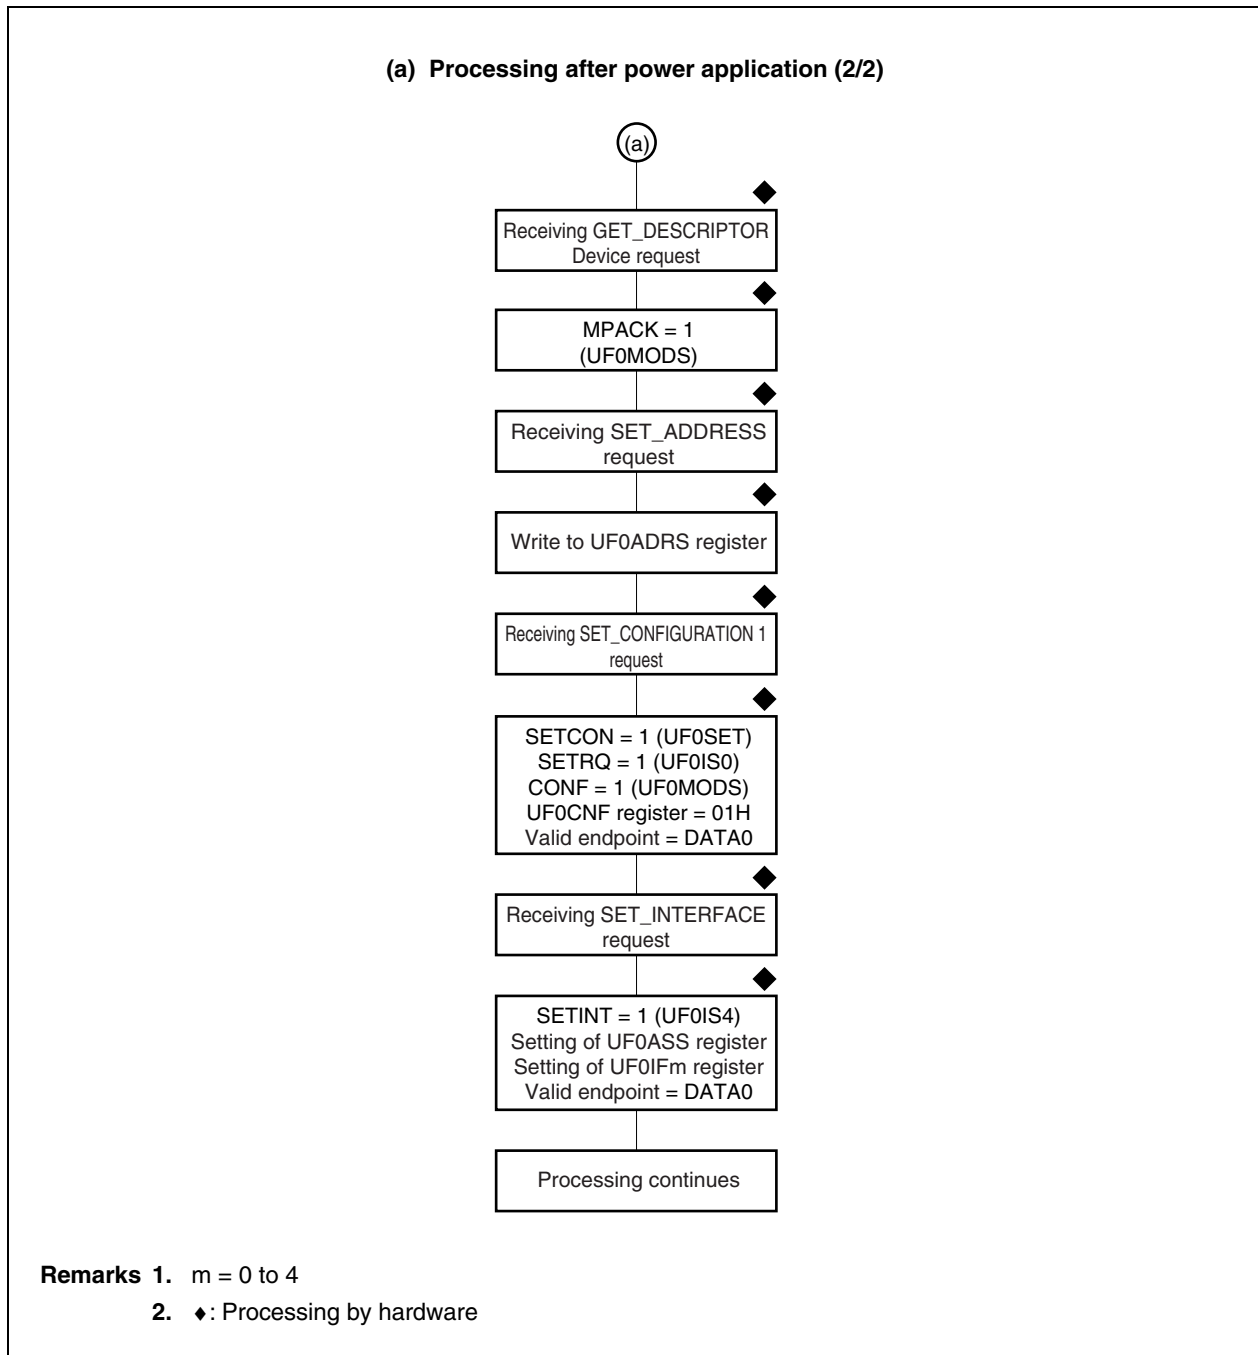

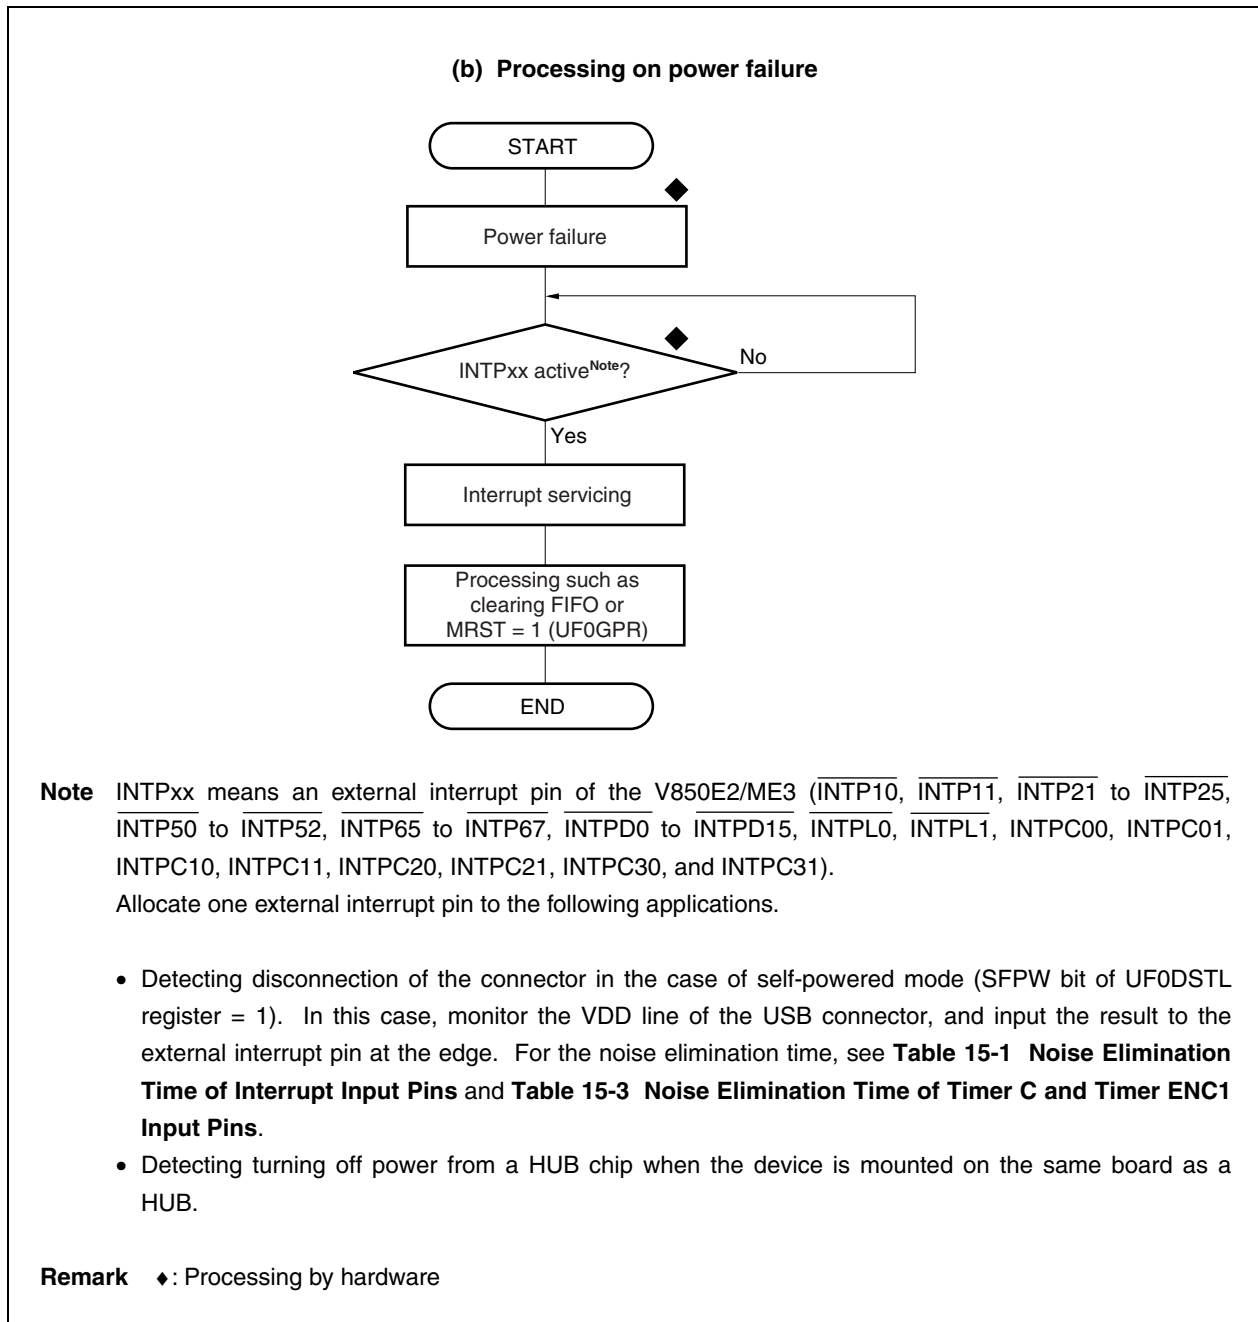

Figure 12-29. Example of Processing After Power Application/Power Failure (3/3)

12.7.6 Receiving data for bulk transfer (OUT) in DMA mode

Bulk transfer (OUT) is allocated to Endpoint2 and Endpoint4. The flowchart shown below illustrates how Endpoint2 is controlled when DMA is used. Endpoint4 can also be controlled in the same sequence. To use this flowchart as the control flow of Endpoint4, therefore, read the bit names of Endpoint2 in the flowchart as those of Endpoint4. The control flowchart shown below illustrates how remaining data is read by the CPU.

If data for bulk transfer (OUT) has been correctly received by setting the DQBO1MS bit of the UF0IDR register to 1, the DMA request signal for Endpoint2, instead of an interrupt request (INTUSB1B), becomes active. This DMA request signal for Endpoint2 operates according to the setting of the MODEn bit of the UF0IDR register (n = 0, 1). If all the data stored in the UF0BO1 register has been read by DMA, the DMA request signal for Endpoint2 becomes inactive. In this status, if data for the next bulk transfer (OUT) has been correctly received, the DMA request signal for Endpoint2 becomes active again. If the data for bulk transfer (OUT) that has been received is equal to or less than the FIFO size, a Short interrupt request is issued and the USBSP2B signal becomes active, as soon as reading the data by DMA is completed. As a result, the DQBO1MS bit of the UF0IDR register is cleared to 0, and the DMA request signal for Endpoint2 becomes inactive. To read data by DMA again, set the DQBO1MS bit to 1 again. If DMA is completed by the DMA end signal for Endpoint2, the DQBO1MS bit of the UF0IDR register is cleared to 0, and the DMA request signal for Endpoint2 becomes inactive. At the same time, the DMA_END interrupt request is issued. If data remains in the UF0BO1 register at this time, DMA can be started again by setting the DQBO1MS bit of the UF0IDR register again. However, the data for bulk transfer (OUT) is always equal to or less than the FIFO size. Consequently, a Short interrupt request is issued, the USBSP2B signal becomes active, the DQBO1MS bit is cleared, and the DMA request signal for Endpoint2 becomes inactive, as soon as the data is read by DMA.

- Cautions 1. The DMA request signal for Endpoint n (n = 2, 4) becomes active in the demand mode (MODE1 and MODE0 bits of the UF0IDR register = 10), as long as there is data to be transferred.**
- 2. The DMA request signal for Endpoint n (n = 2, 4) becomes active in the single mode (MODE1 and MODE0 bits of the UF0IDR register = 0X (X: don't care)) if there is data to be transferred, but this signal becomes inactive each time one byte has been transferred. This operation is repeated until there is no more data to be transferred.**

Figure 12-30. DMA Processing by Bulk Transfer (OUT) (1/3)

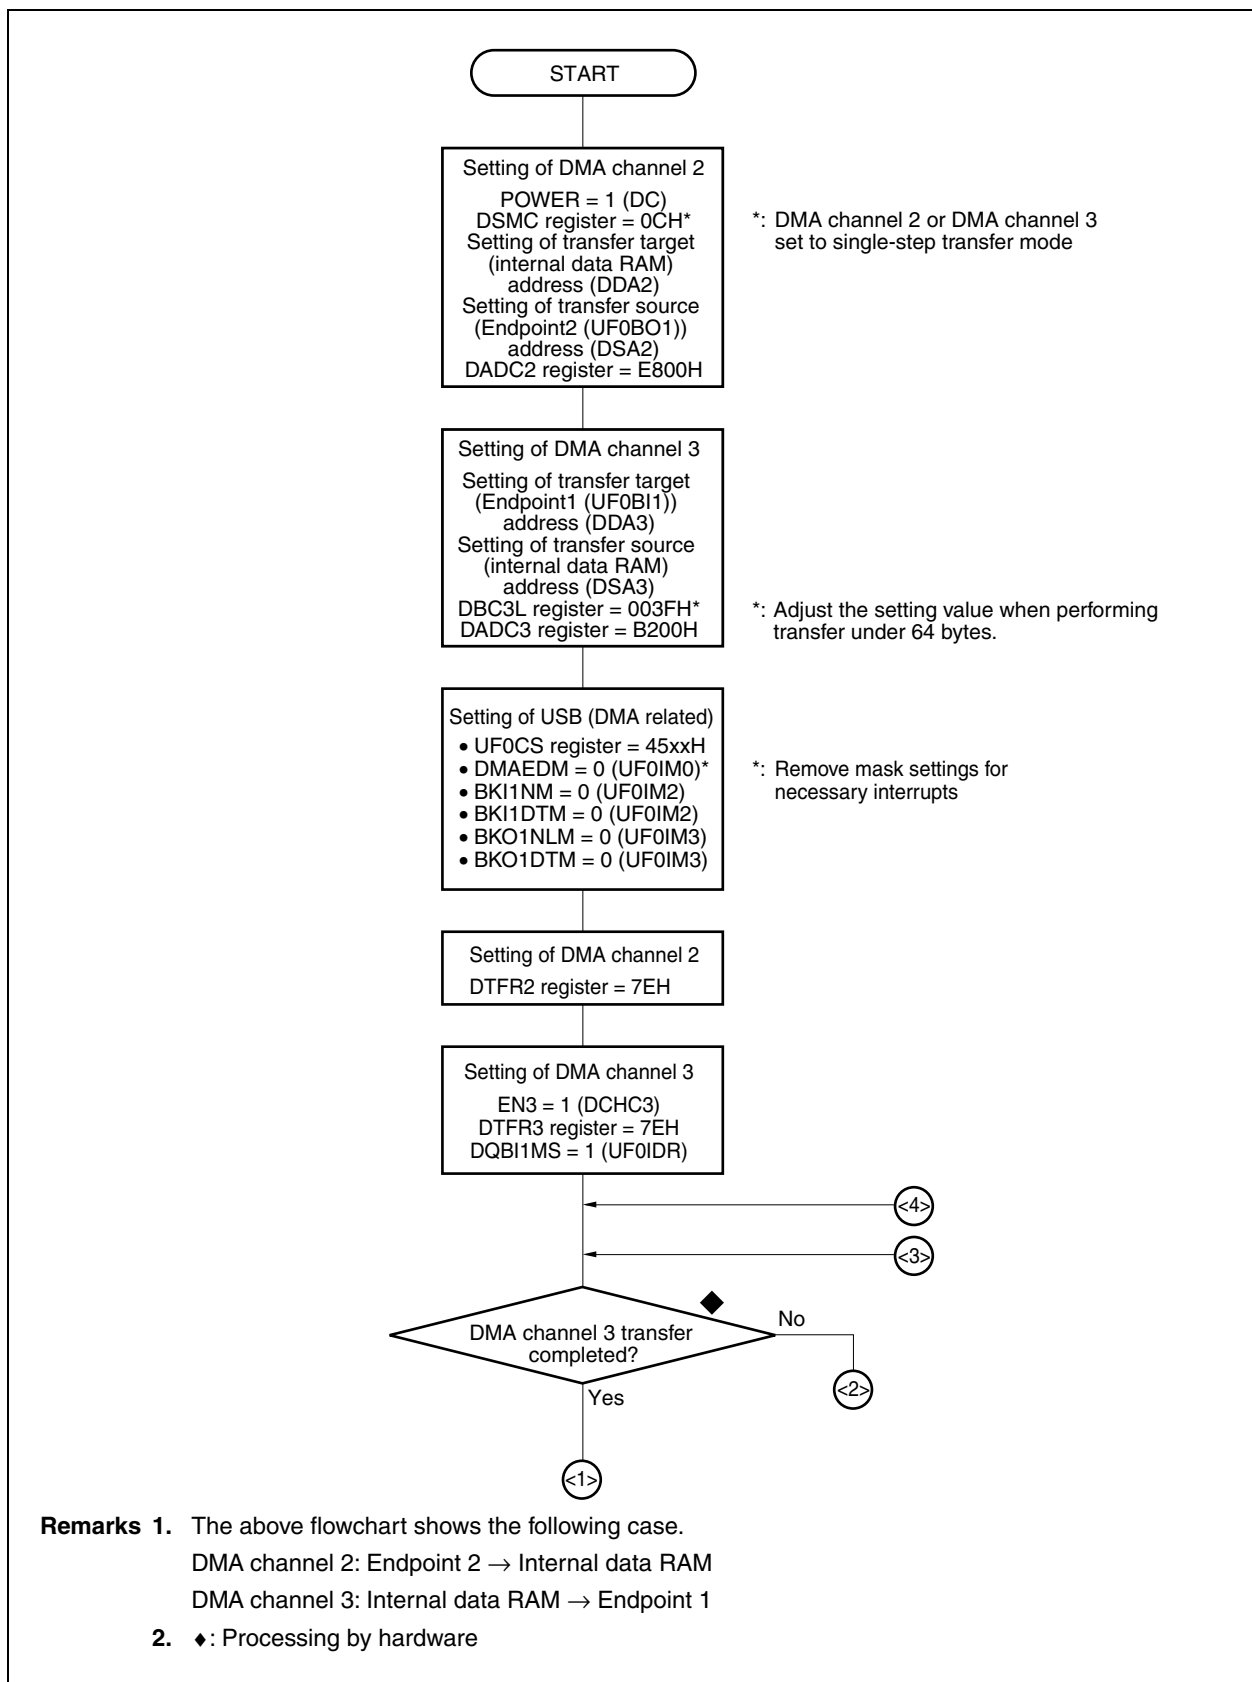

Figure 12-30. DMA Processing by Bulk Transfer (OUT) (2/3)

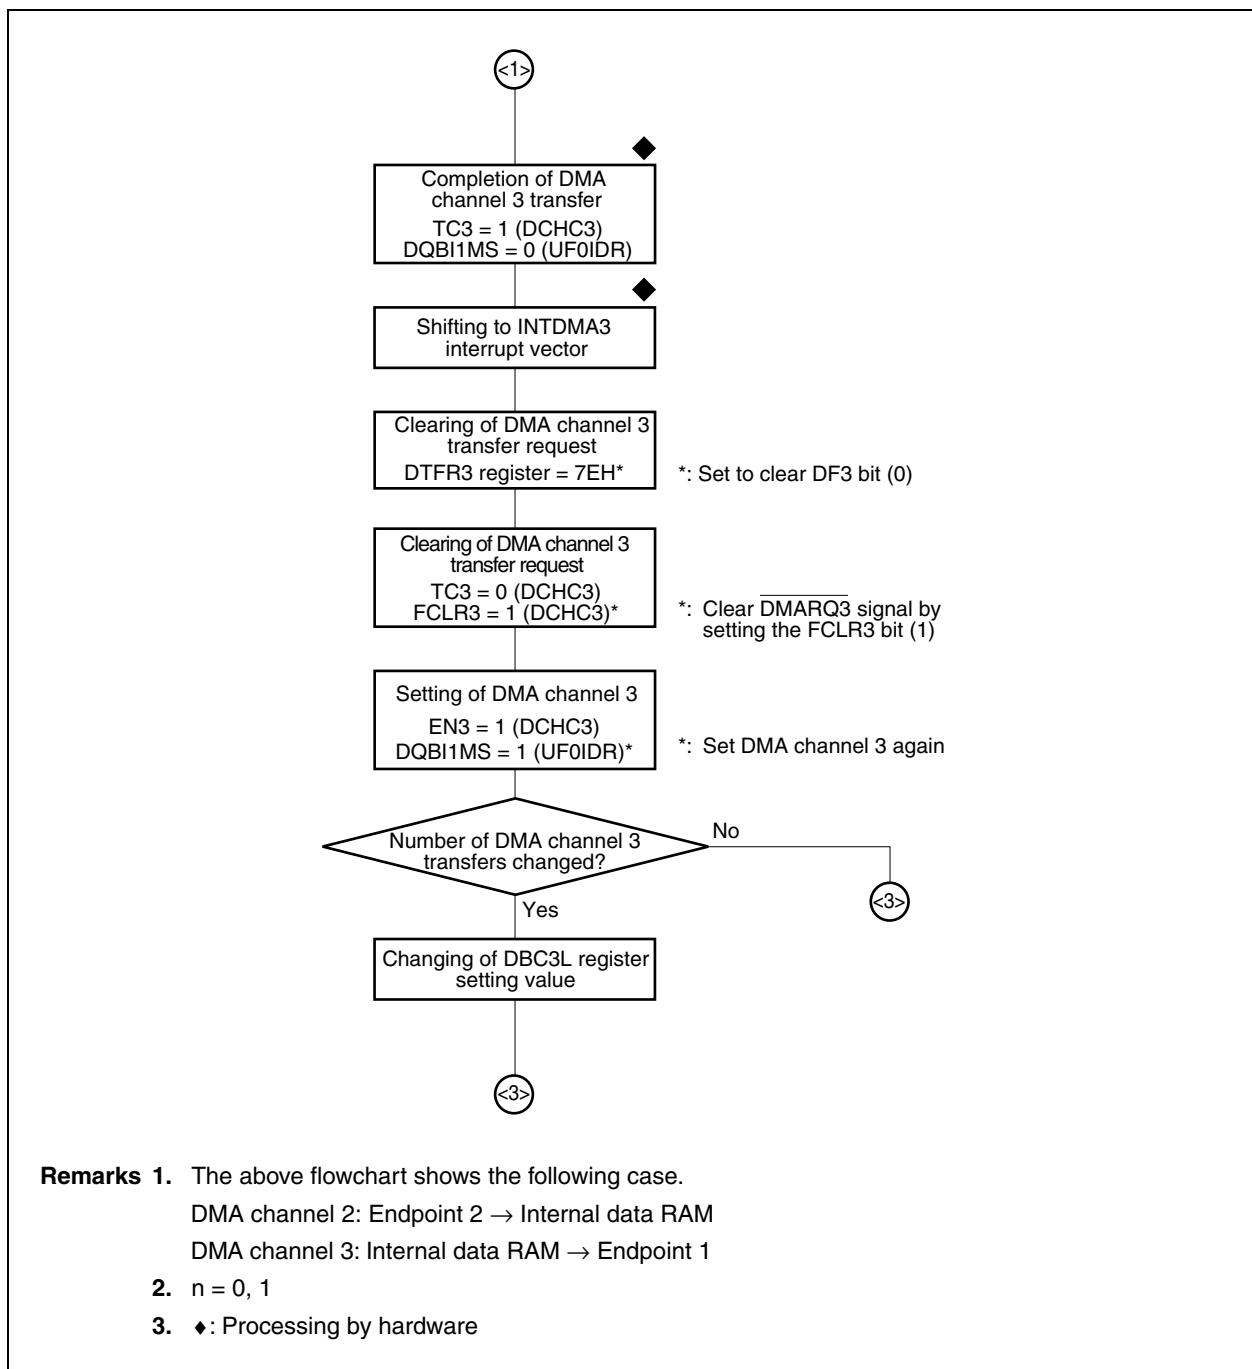

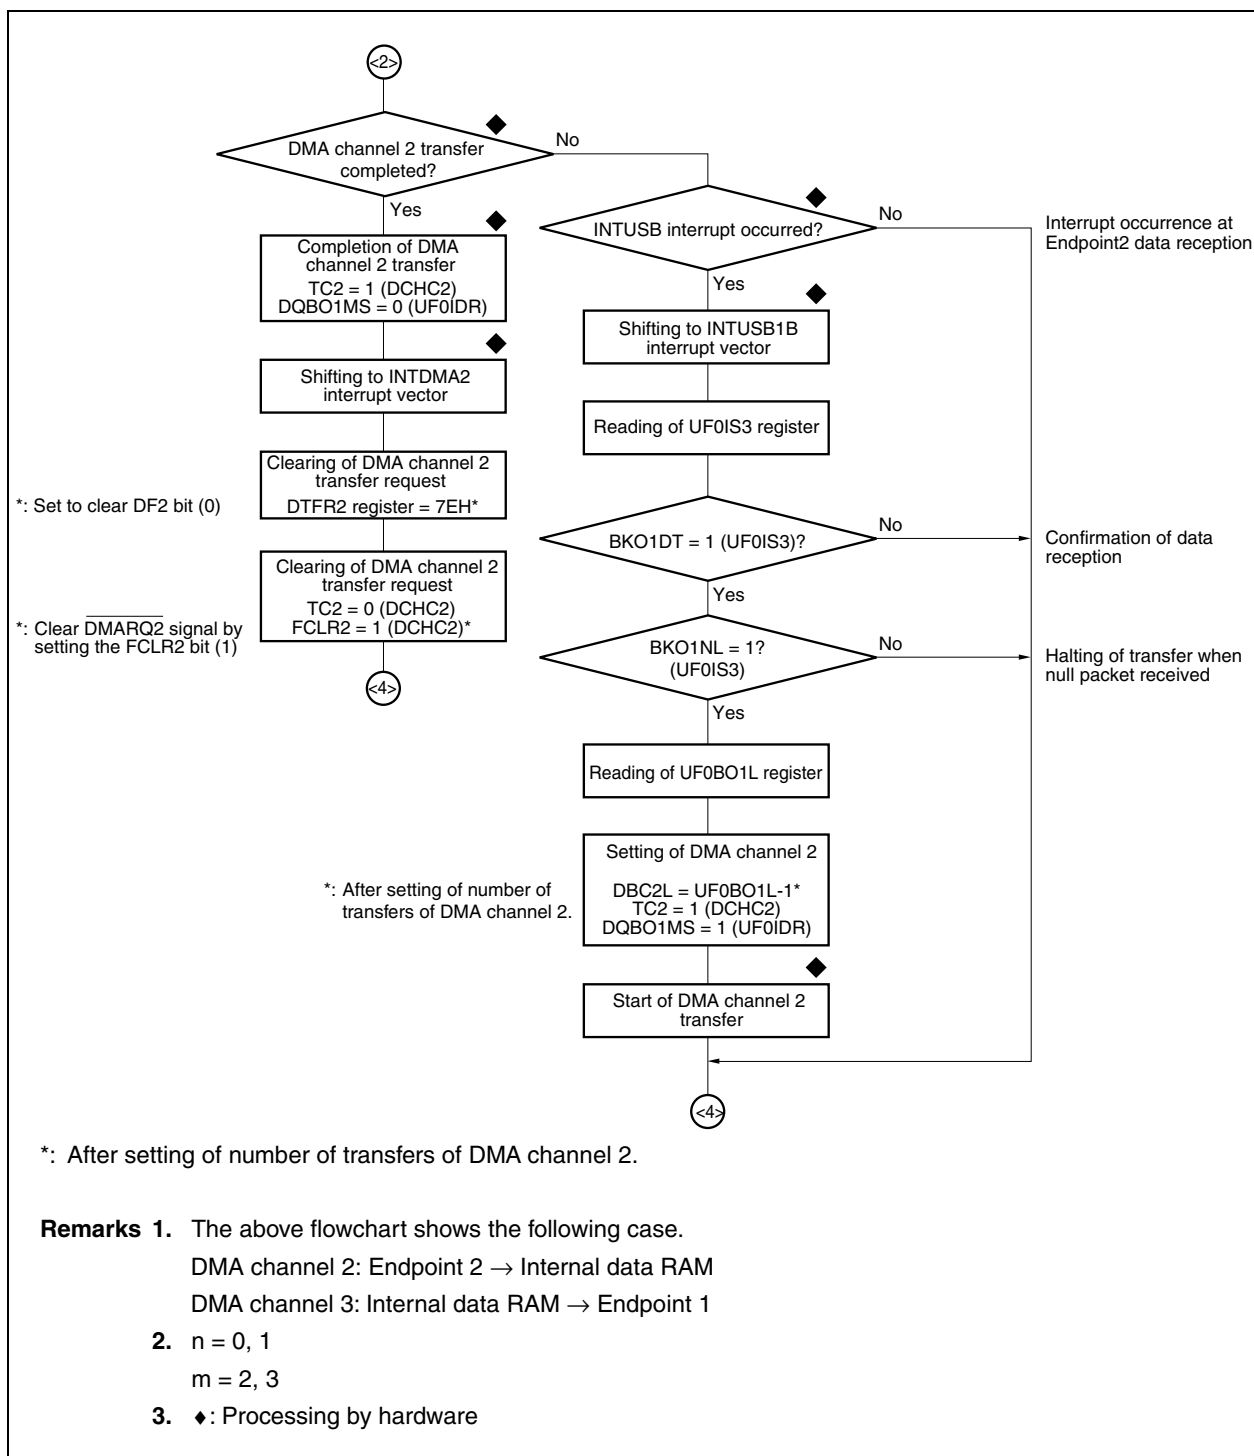

Figure 12-30. DMA Processing by Bulk Transfer (OUT) (3/3)

12.7.7 Transmitting data for bulk transfer (IN) in DMA mode

Bulk transfer (IN) is allocated to Endpoint1 and Endpoint3. The flowchart shown below illustrates how Endpoint1 is controlled when DMA is used. Endpoint3 can also be controlled in the same sequence. To use this flowchart as the control flow of Endpoint3, therefore, read the bit names of Endpoint1 in the flowchart as those of Endpoint3.

If data for bulk transfer (IN) can be written by setting the DQBI1MS bit of the UF0IDR register to 1, the DMA request signal for Endpoint1, instead of an interrupt request (INTUSB1B), becomes active. This DMA request signal for Endpoint1 operates according to the setting of the MODEn bit of the UF0IDR register (n = 0, 1). If all the data that can be written to the UF0B11 register has been written by DMA, the DMA request signal for Endpoint1 becomes inactive. In this status, the toggle operation of the FIFO takes place and, if data for bulk transfer (IN) can be written, the DMA request signal for Endpoint1 becomes active again. The automatic toggle operation of the FIFO is not executed even if the FIFO has become full as a result of DMA transfer, unless the BK11T bit of the UF0DEND register is set to 1. Therefore, be sure to set the BK11DED bit of the UF0DEND register to 1 to transfer data. If DMA is completed by the DMA end signal for Endpoint1, the DQBI1MS bit of the UF0IDR register is cleared to 0, and the DMA request signal for Endpoint1 becomes inactive. At the same time, the DMA_END interrupt request is issued. To transmit a short packet at this time when the FIFO is not full, set the BK11DED bit of the UF0DEND register to 1.

- Cautions 1. The DMA request signal for Endpoint n (n = 1, 3) becomes active in the demand mode (MODE1 and MODE0 bits of the UF0IDR register = 10), as long as data can be transferred.**
- 2. The DMA request signal for Endpoint n (n = 1, 3) becomes active in the single mode (MODE1 and MODE0 bits of the UF0IDR register = 0X (X: don't care)) if data can be transferred, but this signal becomes inactive each time one byte has been transferred. This operation is repeated until there is no more data to be transferred.**

12.7.8 USB connection example

Figure 12-32. USB Connection Example

**(1) Pull-up control of D+**

To prohibit connection report (D+ pull-up) to the USB host/HUB (such as while higher priority processing or initialization processing is under execution), the system must control pulling up of D+ via a general-purpose port. As shown in the circuit example in Figure 12-32, control the pull-up control signal of D+ and VBUS input signal by using a general-purpose port and USB cable VBUS (AND circuit). In Figure 12-32, pulling up D+ is prohibited when the general-purpose port is high level (secure the high level of the general-purpose port pin by pulling it up because the port pin is in the input mode by default). Use an IC to which power can be applied when the system power supply is off as IC2.

(2) Detecting USB cable connection/disconnection

The USB function controller (USBF) requires a VBUS input signal that recognizes connection and disconnection, because the state of USBF is managed by hardware. Voltage (5 V) is applied from the USB host/HUB as the VBUS input signal if the USB cable VBUS is connected to the USB host/HUB when power to the USBF is turned off. Therefore, use an IC to which power can be applied when the system power supply is off as IC1 shown in Figure 12-32. When disconnecting the USB cable in the circuit example in Figure 12-32, a signal input to INT P51 may be unstable while the VBUS voltage is dropping. Therefore, it is recommended to use a Schmitt buffer for IC1 shown in Figure 12-32.

CHAPTER 13 A/D CONVERTER

13.1 Features

- Analog input: 8 channels
- 10-bit A/D converter
- On-chip A/D conversion result register (ADCR0 to ADCR7)
10 bits × 8
- A/D conversion trigger mode
 - A/D trigger mode
 - Timer trigger mode
 - External trigger mode
- Successive approximation method

13.2 Configuration

The A/D converter of the V850E2/ME3 adopts the successive approximation method, and uses A/D converter mode registers 0, 1, 2 (ADM0, ADM1, ADM2), and the A/D conversion result register (ADCR0 to ADCR7) to perform A/D conversion operations.

(1) Input circuit

The input circuit selects the analog input (ANI0 to ANI7) according to the mode set by the ADM0, ADM1, and ADM2 registers.

(2) C-Array

Holds the charge of the differential voltage between the voltage input from the analog input pins (ANI0 to ANI7) and the reference voltage ($1/2 AV_{DD}$), and redistributes the sampled charges.

(3) C-Dummy

This block holds the reference voltage ($1/2 AV_{DD}$) and assigns the reference of the comparator input.

(4) Voltage comparator

The voltage comparator compares the C-Array comparison potential with the C-Dummy reference potential.

(5) A/D conversion result register n (ADCRn), A/D conversion result register nH (ADCRnH)

ADCRn is a 10-bit register that holds A/D conversion results. Each time A/D conversion is completed, the conversion results are loaded from the successive approximation register (SAR).

$\overline{\text{RESET}}$ input makes this register undefined.

(6) ANI0 to ANI7 pins

These are 8-channel analog input pins for the A/D converter. They input the analog signals to be A/D converted.

Caution Make sure that the voltages input to ANI0 to ANI7 do not exceed the rated values. If a voltage higher than AV_{DD} or lower than AV_{SS} (even within the range of the absolute maximum ratings) is input to a channel, the conversion value of the channel is undefined, and the conversion values of the other channels may also be affected.

(7) AV_{REFM} and AV_{REFP} pins

This is the pin for inputting the reference voltage of the A/D converter. It converts signals input to the ANI0 to ANI7 pins to digital signals based on the voltage applied between AV_{REFM} and AV_{REFP} .

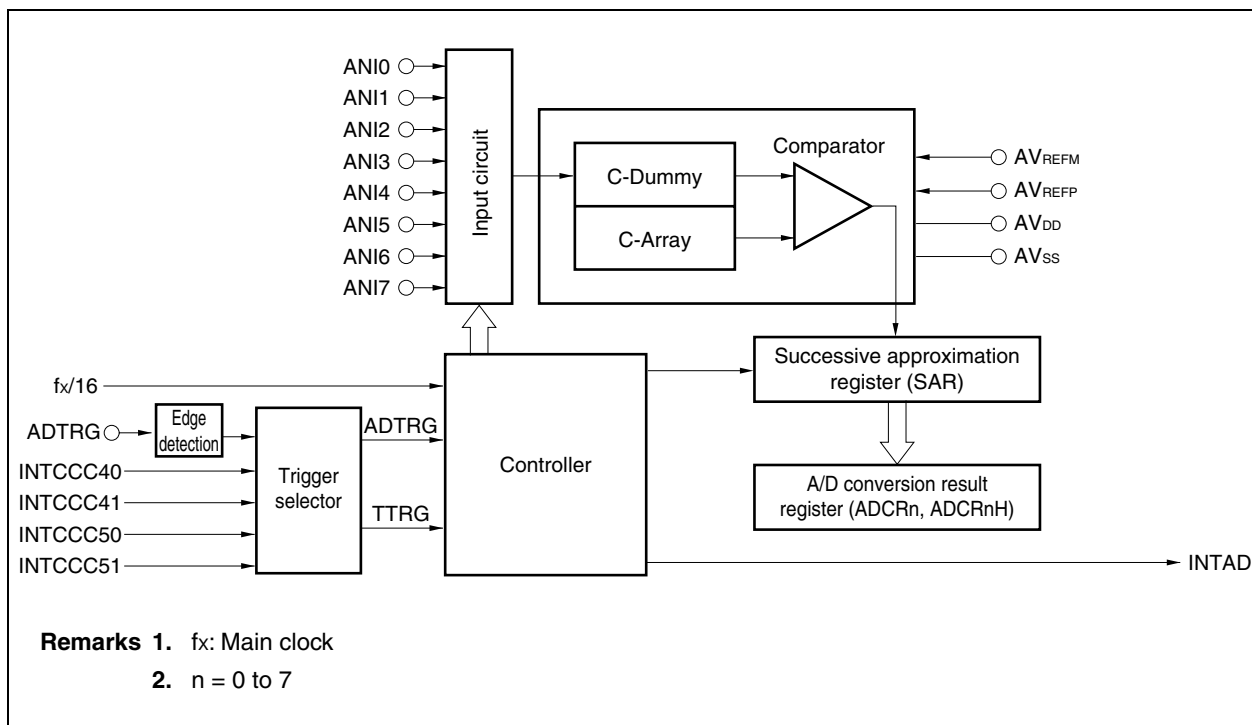

(8) AV_{SS} pin

This is the ground pin of the A/D converter. Always use this pin at the same potential as that of the EV_{SS} pin even when the A/D converter is not used.

(9) AV_{DD} pin

This is the analog power supply pin of the A/D converter. Always use this pin at the same potential as that of the EV_{DD} pin even when the A/D converter is not used.

Figure 13-1. Block Diagram of A/D Converter

Cautions 1. If there is noise at the analog input pins (ANI0 to ANI7) or at the reference voltage input pin (AVREFP, AVREFM), that noise may generate an illegal conversion result.

Software processing will be needed to avoid a negative effect on the system from this illegal conversion result.

An example of this software processing is shown below.

- Take the average result of a number of A/D conversions and use that as the A/D conversion result.
 - Execute a number of A/D conversions consecutively and use those results, omitting any exceptional results that may have been obtained.
 - If an A/D conversion result which can be judged that a system abnormality has occurred is obtained, do not attempt to overcome the abnormality right away, but handle the abnormality after checking the abnormality occurrence again.
2. Do not apply a voltage outside the AVREFM to AVREFP range to the pins that are used as A/D converter input pins.

13.3 Control Registers

(1) A/D converter mode register 0 (ADM0)

The ADM0 register is an 8-bit register that specifies the operation mode, and executes conversion operations. This register can be read or written in 8-bit or 1-bit units. However, bit 6 can only be read. Writing this bit is ignored.

Cautions 1. When the ADCE bit is 1 in the timer trigger mode and external trigger mode, the trigger signal standby state is set. To clear the ADCE bit, write 0 or reset.

In the A/D trigger mode, the conversion trigger is set by writing 1 to the ADCE bit. After the operation, when the mode is changed to the timer trigger mode or external trigger mode without clearing the ADCE bit, the trigger input standby state is set immediately after changing the register.

2. Changing the setting of the BS and MS bits is prohibited while A/D conversion is enabled (ADCE bit = 1).
3. When data is written to the ADM0 register during an A/D conversion operation, the conversion operation is initialized and conversion is executed from the beginning.

Bit position	Bit name	Function
7	ADCE	Enables or disables A/D conversion operation. 0: Disabled 1: Enabled
6	ADCS	Indicates the status of A/D converter. This bit is read only. 0: Stopped 1: Operating
5	BS	Specifies buffer mode in the select mode. 0: 1-buffer mode 1: 4-buffer mode
4	MS	Specifies operation mode of A/D converter. 0: Scan mode 1: Select mode

Bit position	Bit name	Bit value	Address	After reset
<7>	ADCE	0	1FFFF200H	00H
<6>	ADCS	0		
5	BS	0		
4	MS	0		
3		0		
2		0		
1		0		
0		0		

(2) A/D converter mode register 1 (ADM1)

The ADM1 register is an 8-bit register that specifies the conversion operation time and trigger mode. This register can be read or written in 8-bit or 1-bit units.

- Cautions 1. Changing the setting of the EGA1, EGA0, and FR3 to FR0 bits is prohibited while A/D conversion is enabled (ADCE bit = 1 in the ADM0 register).**
- 2. When data is written to the ADM1 register during an A/D conversion operation, the conversion operation is initialized and conversion is executed from the beginning.**

	7	6	5	4	3	2	1	0	Address	After reset
ADM1	EGA1	EGA0	TRG1	TRG0	FR3	FR2	FR1	FR0	1FFFF201H	00H

1	1	Setting prohibited															

Remark Sets A/D conversion operation time by using bits FR3 to FR0. For details, see **Table 13-1**.

Table 13-1. Setting of A/D Conversion Operation Time

FR3	FR2	FR1	FR0	Number of Conversion Clocks	Conversion Operation Time ^{Note 1}			
					$f_x = 200 \text{ MHz}$	$f_x = 150 \text{ MHz}$	$f_x = 100 \text{ MHz}$	A/D Stabilization Time ^{Note 2}
0	0	0	0	256	Setting prohibited	Setting prohibited	2.56 μs	64/ f_x
0	0	0	1	512	2.56 μs	3.41 μs	5.12 μs	128/ f_x
0	0	1	0	768	3.84 μs	5.12 μs	7.68 μs	160/ f_x
0	0	1	1	1024	5.12 μs	6.83 μs	Setting prohibited	160/ f_x
0	1	0	0	1280	6.40 μs	8.53 μs	Setting prohibited	160/ f_x
0	1	0	1	1536	7.68 μs	Setting prohibited	Setting prohibited	160/ f_x
0	1	1	0	1792	8.96 μs	Setting prohibited	Setting prohibited	160/ f_x
0	1	1	1	2048	Setting prohibited	Setting prohibited	Setting prohibited	160/ f_x
1	0	0	0	2304	Setting prohibited	Setting prohibited	Setting prohibited	160/ f_x
1	0	0	1	2560	Setting prohibited	Setting prohibited	Setting prohibited	160/ f_x
1	0	1	0	2816	Setting prohibited	Setting prohibited	Setting prohibited	160/ f_x
1	0	1	1	3072	Setting prohibited	Setting prohibited	Setting prohibited	160/ f_x
1	1	0	0	3328	Setting prohibited	Setting prohibited	Setting prohibited	160/ f_x
1	1	0	1	3584	Setting prohibited	Setting prohibited	Setting prohibited	160/ f_x
1	1	1	0	3840	Setting prohibited	Setting prohibited	Setting prohibited	160/ f_x
1	1	1	1	4096	Setting prohibited	Setting prohibited	Setting prohibited	160/ f_x

Notes 1. Set the conversion operation time in the range of 2 to 10 μs (target value).

2. After the ADCE bit is set to "1" from "0" to secure the stabilization time of the A/D converter, conversion is started after the A/D stabilization time has elapsed only before the first A/D conversion is executed.

Cautions 1. Do not change the set value of the A/D conversion time (FR3 to FR0 bits) during an A/D conversion operation (ADCE bit = 1). To change the value, clear the ADCE bit to 0.

2. When the trigger mode (TRG1 and TGR0 bits) is changed midway, A/D conversion can be started immediately without having to secure the A/D stabilization time by re-setting the ADCE bit to "1".

Remark f_x : Main clock

(3) A/D converter mode register 2 (ADM2)

The ADM2 register is an 8-bit register that specifies the analog input pin of the A/D converter.

This register can be read or written in 8-bit or 1-bit units.

- Cautions 1.** If a channel for which no analog input pin exists is specified, the result of A/D conversion is undefined.
- 2.** Changing the setting of the ANIS2 to ANIS0 bits is prohibited while A/D conversion is enabled (ADCE bit = 1 in the ADM0 register).
- 3.** When data is written to the ADM2 register during an A/D conversion operation, the conversion operation is initialized and conversion is executed from the beginning.

	7	6	5	4	3	2	1	0	Address	After reset
ADM2	0	0	0	0	0	ANIS2	ANIS1	ANIS0	1FFFF202H	00H

Bit position	Bit name	Function		
2 to 0	ANIS2 to ANIS0	Specify the analog input pin for A/D conversion.		
		ANIS2	ANIS1	ANIS0
		Specification of pin for A/D conversion		
			Select mode	Scan mode
		0	0	0
		0	0	1
		0	1	0
		0	1	1
		1	0	0
		1	0	1
		1	1	0
		1	1	1
			ANI0	ANI0
			ANI1	ANI0, ANI1
			ANI2	ANI0 to ANI2
			ANI3	ANI0 to ANI3
			ANI4	ANI0 to ANI4
			ANI5	ANI0 to ANI5
			ANI6	ANI0 to ANI6
			ANI7	ANI0 to ANI7

(4) ADC trigger select register (ADTS)

This is an 8-bit register that specifies the timer trigger signal in the timer trigger mode.

This register can be read or written in 8-bit units.

Be sure to clear bits 7 to 4 to "0". If they are set to "1", the operation is not guaranteed.

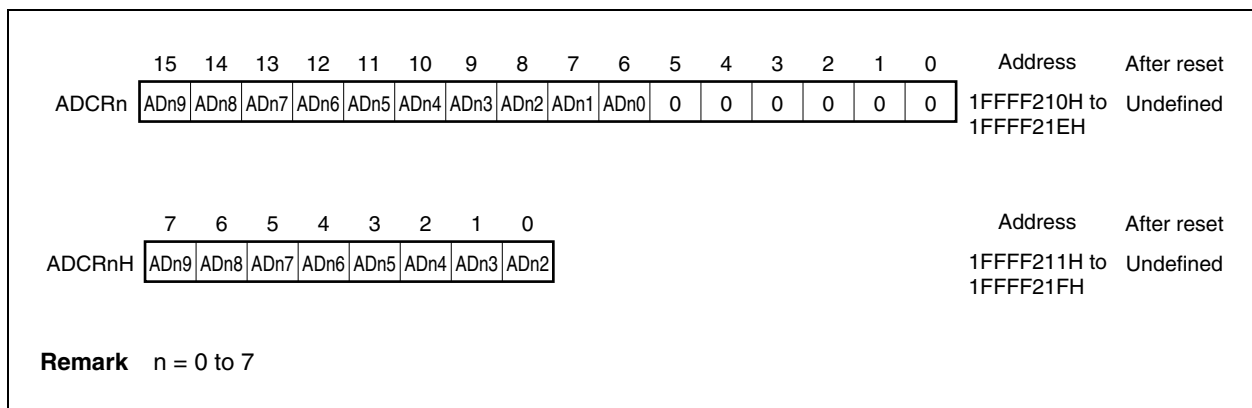

Caution Stop the A/D conversion operation (by clearing the ADCE bit of the ADM0 register to 0) before changing the setting of the ADTS register. The operation is not guaranteed if the setting of the ADTS register is changed while A/D conversion is enabled (ADCE bit = 1).

	7	6	5	4	<3>	<2>	<1>	<0>	Address	After reset
ADTS	0	0	0	0	TMS3	TMS2	TMS1	TMS0	1FFFF220H	00H

Bit position	Bit name	Function
3	TMS3	Controls connection of a timer trigger signal (INTCCC51). 0: Timer trigger of ADC is invalid. 1: Timer trigger of ADC is valid.
2	TMS2	Controls connection of a timer trigger signal (INTCCC50). 0: Timer trigger of ADC is invalid. 1: Timer trigger of ADC is valid.
1	TMS1	Controls connection of a timer trigger signal (INTCCC41). 0: Timer trigger of ADC is invalid. 1: Timer trigger of ADC is valid.
0	TMS0	Controls connection of a timer trigger signal (INTCCC40). 0: Timer trigger of ADC is invalid. 1: Timer trigger of ADC is valid.

(5) A/D conversion result registers 0 to 7, 0H to 7H (ADCR0 to ADCR7, ADCR0H to ADCR7H)

The ADCRn register is a 10-bit register holding the A/D conversion results. There are eight 10-bit registers. These registers are read-only, in 16-bit or 8-bit units. During 16-bit access, the ADCRn register is specified, and during higher 8-bit access, the ADCRnH register is specified (n = 0 to 7). When reading the 10-bit data of the A/D conversion results from the ADCRn register, only the higher 10 bits are valid and the lower 6 bits are always read as 0.

The correspondence between each analog input pin and the ADCRn register is shown below.

Analog Input Pin	ADCRn Register	
	Select 1 Buffer Mode/ Scan Mode	Select 4 Buffer Mode
ANI0	ADCR0, ADCR0H	ADCR0 to ADCR3, ADCR0H to ADCR3H
ANI1	ADCR1, ADCR1H	
ANI2	ADCR2, ADCR2H	
ANI3	ADCR3, ADCR3H	
ANI4	ADCR4, ADCR4H	ADCR4 to ADCR7, ADCR4H to ADCR7H
ANI5	ADCR5, ADCR5H	
ANI6	ADCR6, ADCR6H	
ANI7	ADCR7, ADCR7H	

The relationship between the analog voltage input to the analog input pins (ANI0 to ANI7) and the A/D conversion result (of the A/D conversion result register n (ADCRn)) is as follows:

$$SAR = INT \left(\frac{V_{IN}}{AV_{REF}} \times 1,024 + 0.5 \right)$$

$$ADCR^{Note} = SAR \times 64$$

or,

$$(SAR - 0.5) \times \frac{AV_{REF}}{1,024} \leq V_{IN} < (SAR + 0.5) \times \frac{AV_{REF}}{1,024}$$

INT(): Function that returns the integer of the value in ()

V_{IN}: Analog input voltage

AV_{REF}: AV_{REFM}, AV_{REFP} pin voltage

ADCR: Value of A/D conversion result register n (ADCRn)

Note The lower 6 bits of the ADCRn registers are fixed to 0.

Figure 13-2 shows the relationship between the analog input voltage and the A/D conversion results.

Figure 13-2. Relationship Between Analog Input Voltage and A/D Conversion Results

13.4 Operation

13.4.1 Basic operation

A/D conversion is executed by the following procedure.

- (1) The selection of the analog input and specification of the operation mode, trigger mode, etc. should be specified using the ADMn register^{Note 1} (n = 0 to 2).
When the ADCE bit of the ADM0 register is set to 1, A/D conversion starts in the A/D trigger mode. In the timer trigger mode and external trigger mode, the trigger standby state^{Note 2} is set.
- (2) When A/D conversion is started, the C array voltage on the analog input side and the C array voltage on the reference side are compared by the comparator.
- (3) When the comparison of the 10 bits ends, the conversion results are stored in the ADCRn register. When A/D conversion has been performed the specified number of times, the A/D conversion end interrupt (INTAD) is generated (n = 0 to 7).

Notes 1. If the setting of the ADMn register (n = 0 to 2) is changed during A/D conversion, the operation immediately before is stopped, and the result of the conversion is not stored in the ADCRn register (n = 0 to 7). The A/D conversion operation is then initialized, and conversion is executed from the beginning again.

2. During the timer trigger mode and external trigger mode, if the ADCE bit of the ADM0 register is set to 1, the mode changes to the trigger standby state. The A/D conversion operation is started by the trigger signal (ADCS bit = 1 in the ADM0 register), and the trigger standby state (ADCS bit = 0) is returned when the A/D conversion operation ends.

13.4.2 Operation mode and trigger mode

Various conversion operations can be specified for the A/D converter by specifying the operation mode and trigger mode. The operation mode and trigger mode are set by the ADM0 to ADM2 registers.

The following shows the relationship between the operation mode and trigger mode.

Table 13-2. Relationship Between Operation Mode and Trigger Mode

Trigger Mode	Operation Mode		Set Value			Analog Input
			ADM0	ADM1	ADM2	
A/D trigger	Select	1 buffer	xx010000B	00000xxxB	00000xxxB	ANI0 to ANI7
		4 buffers	xx110000B		00000xxxB	ANI0 to ANI7
	Scan		xxx00000B		00000xxxB	ANI0 to ANI7
Timer trigger	Select	1 buffer	xx010000B	00001xxxB	00000xxxB	ANI0 to ANI7
		4 buffers	xx110000B		00000xxxB	ANI0 to ANI7
	Scan		xxx00000B		00000xxxB	ANI0 to ANI7
External trigger	Select	1 buffer	xx010000B	xx10xxxxB	00000xxxB	ANI0 to ANI7
		4 buffers	xx110000B		00000xxxB	ANI0 to ANI7
	Scan		xxx00000B		00000xxxB	ANI0 to ANI7

(1) Trigger mode

There are three types of trigger modes that serve as the start timing of A/D conversion processing: A/D trigger mode, timer trigger mode, and external trigger mode. These trigger modes are set by the TRG1 and TRG0 bits of the ADM1 register.

(a) A/D trigger mode

This mode starts the conversion timing of the analog input set to the ANI0 to ANI7 pins, and by setting the ADCE bit of the ADM0 register to 1, starts A/D conversion. Unless the ADCE bit is cleared to 0 after conversion, the next conversion operation is repeated. If data is written to the ADM0 to ADM2 registers during conversion, conversion is stopped and then executed from the beginning again.

(b) Timer trigger mode

This mode specifies the conversion timing of the analog input set for the ANI0 to ANI7 pins using the values set to the timer C capture/compare register.

This register creates the analog input conversion timing by generating the compare match interrupts of the four capture/compare registers (CCC40, CCC41, CCC50, CCC51) connected to the 16-bit timer C (TMC4, TMC5).

If the ADCE bit of the ADM0 register is set to 1, the A/D converter waits for an interrupt (INTCCC40, INTCCC41, INTCCC50, or INTCCC51), and starts conversion when INTCCC40, INTCCC41, INTCCC50, or INTCCC51 occurs (ADCS bit = 1 in the ADM0 register). When conversion has finished, the converter waits for an interrupt again (ADCS = 0). If data is written to the ADM0 to ADM2 registers during conversion, conversion is stopped and then executed from the beginning again.

(c) External trigger mode

This mode specifies the conversion timing of the analog input to the ANI0 to ANI7 pins using the ADTRG pin. The EGA1 and EGA0 bits of the ADM1 register are used to specify the valid edge to be input to the ADTRG pin.

When the ADCE bit of the ADM0 register is set to 1, the A/D converter waits for an external trigger (ADTRG), and starts conversion when the valid edge of ADTRG is detected (ADCS bit = 1 in the ADM0 register). When the converter has completed its conversion operation, it waits for an external trigger again (ADCS bit = 0).

If the valid edge is detected at the ADTRG pin during conversion, conversion is executed from the beginning again.

If data is written to the ADM0 to ADM2 registers during conversion, conversion is stopped and then executed from the beginning again.

(2) Operation mode

There are two operation modes that set the ANI0 to ANI7 pins: select mode and scan mode. The select mode has sub-modes that consist of 1-buffer mode and 4-buffer mode. These modes are set by the BS and MS bits of the ADM0 register.

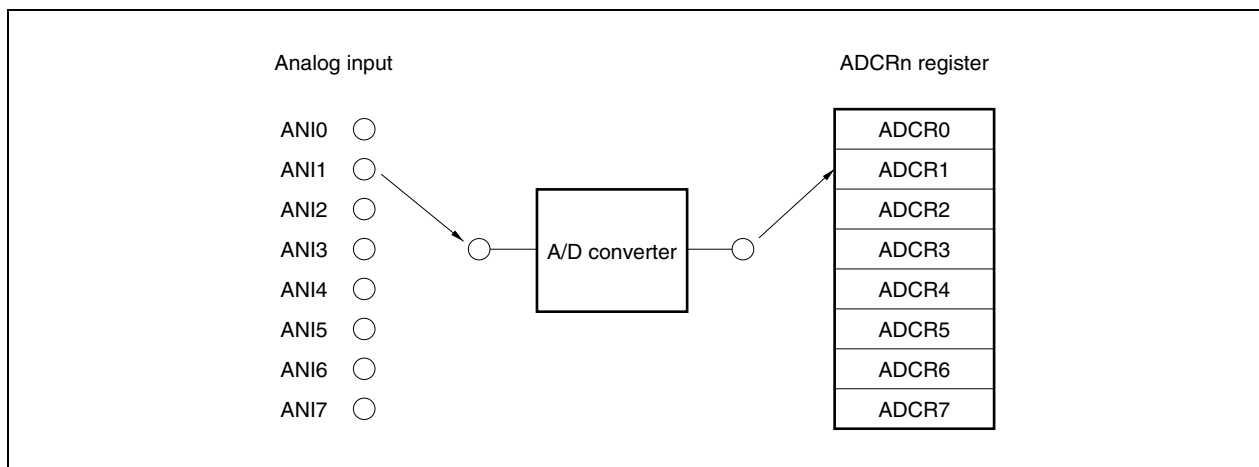

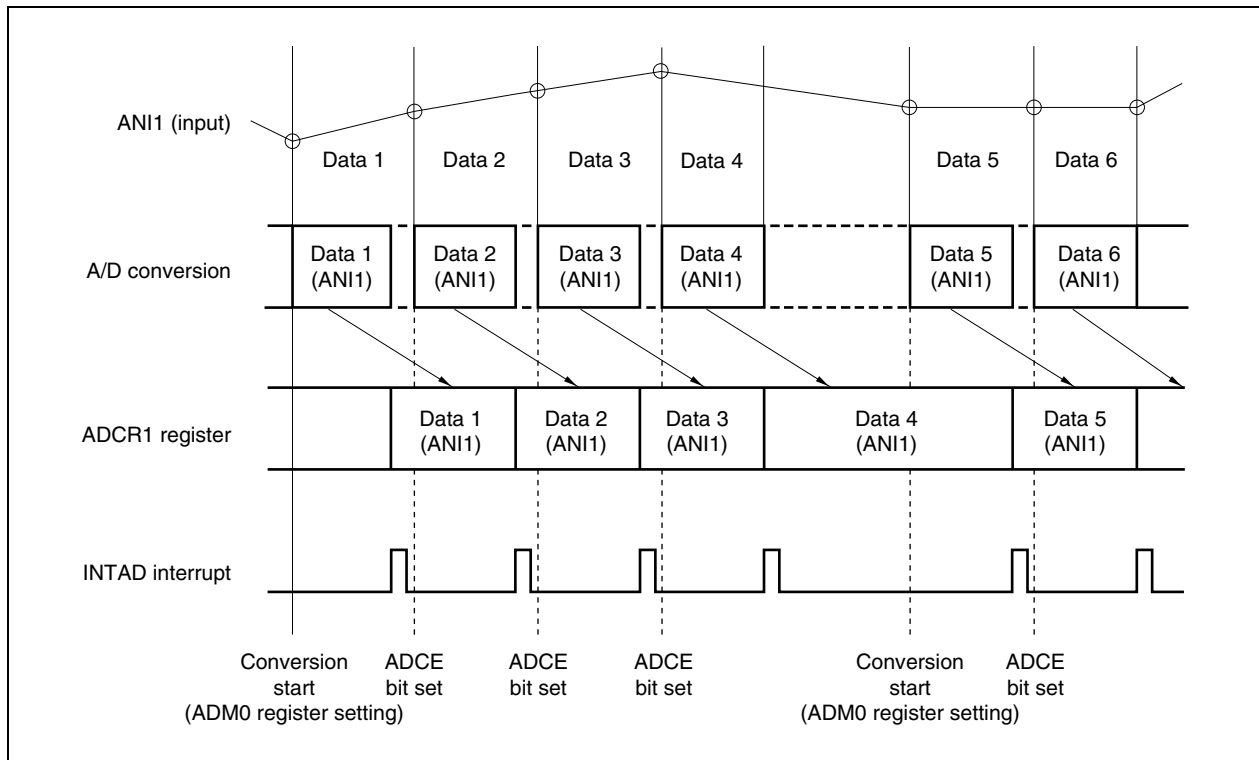

(a) Select mode

In this mode, one analog input specified by the ADM2 register is A/D converted. The conversion results are stored in the ADCRn register corresponding to the analog input (ANIn). For this mode, the 1-buffer mode and 4-buffer mode are provided for storing the A/D conversion results (n = 0 to 7).

• 1-buffer mode

In this mode, one analog input specified by the ADM2 register is A/D converted. The conversion results are stored in the ADCRn register corresponding to the analog input (ANIn) (n = 0 to 7). The ANIn and ADCRn register correspond one to one, and an A/D conversion end interrupt (INTAD) is generated each time one A/D conversion ends. After conversion has finished, the next conversion operation is repeated, unless the ADCE bit of the ADM0 register is cleared to 0.

Figure 13-3. Select Mode Operation Timing: 1-Buffer Mode (ANI1)

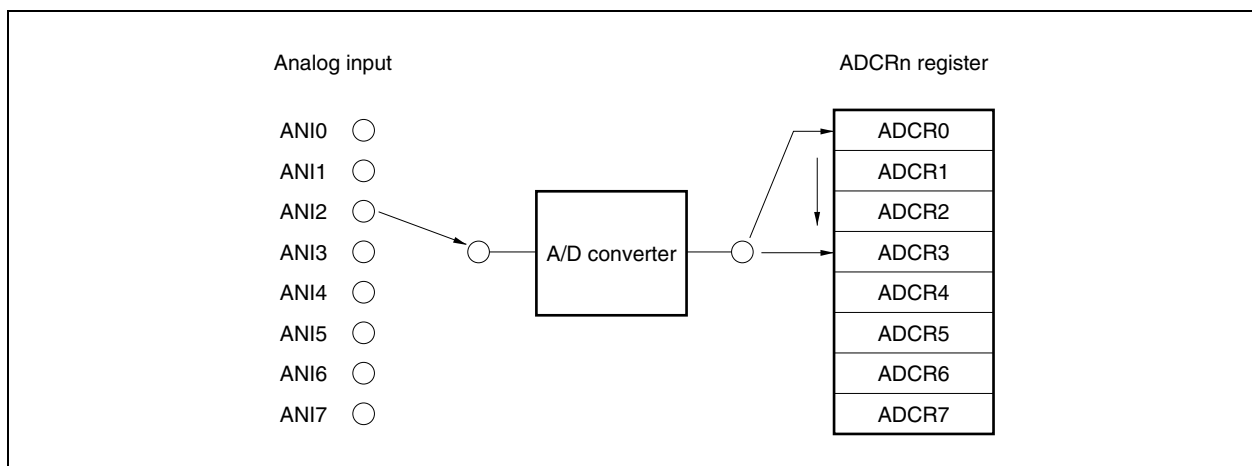

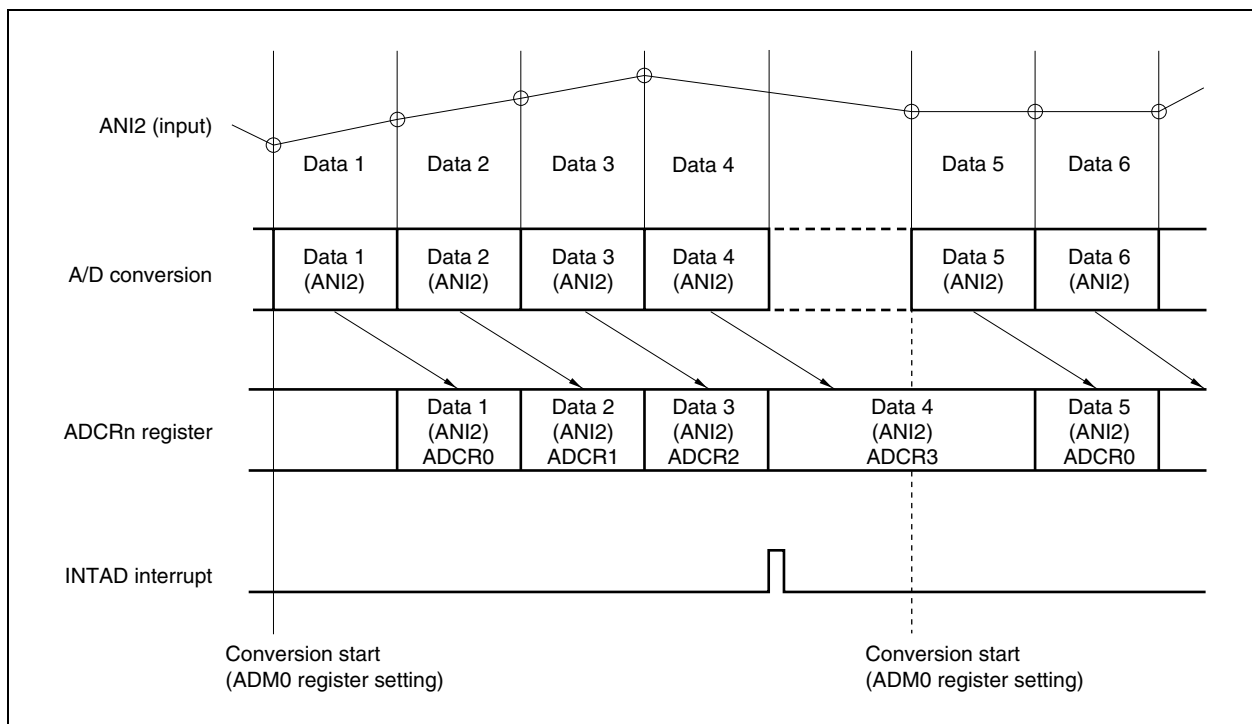

• **4-buffer mode**

In this mode, one analog input is A/D converted four times and the results are stored in the ADCRn register. The A/D conversion end interrupt (INTAD) is generated when the four A/D conversions end (n = 0 to 3 when the lower analog input channel is specified and n = 4 to 7 when the higher analog input channel is specified).

After conversion has finished, the next conversion operation is repeated, unless the ADCE bit of the ADM0 register is cleared to 0.

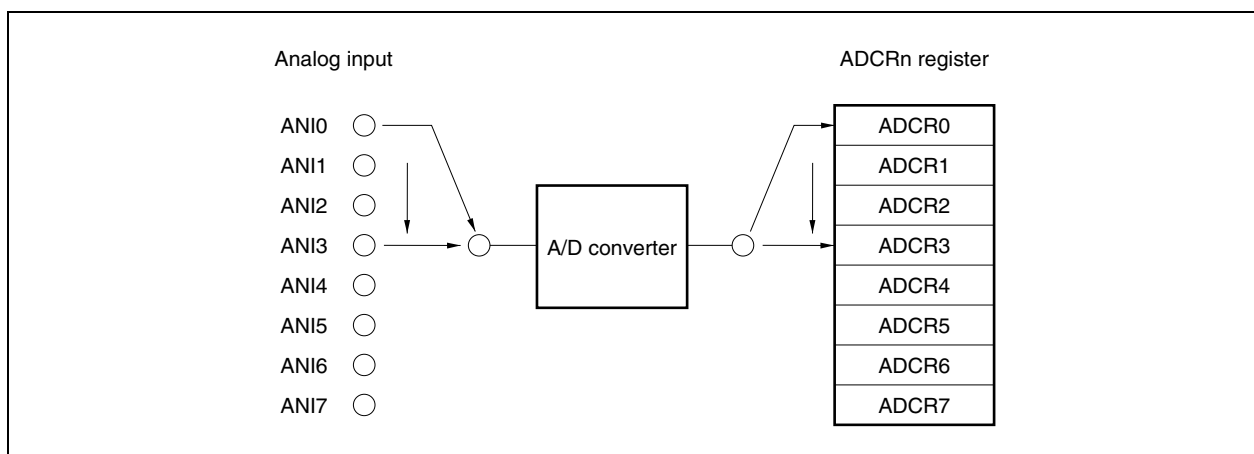

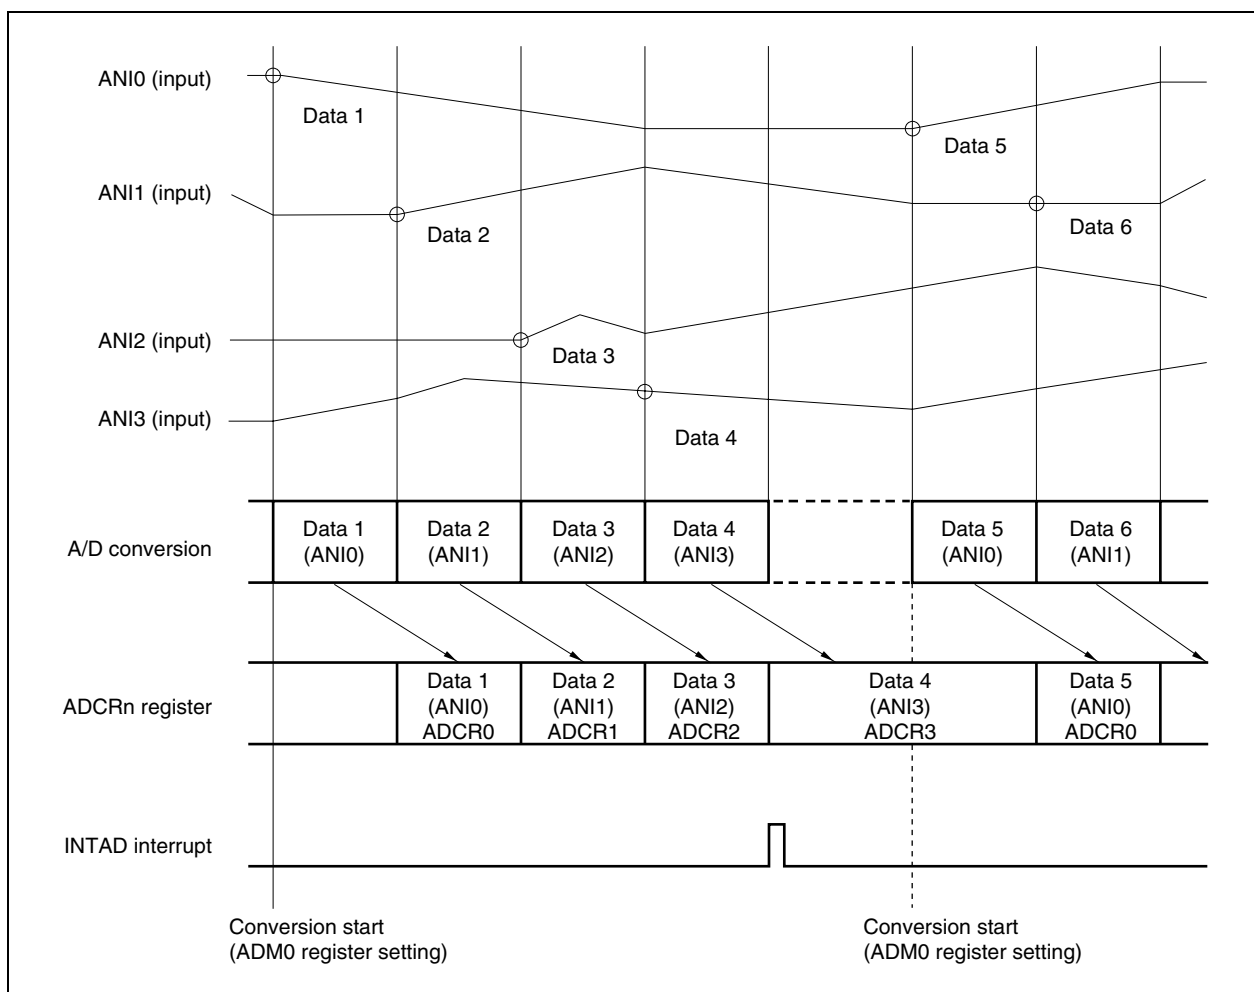

Figure 13-4. Select Mode Operation Timing: 4-Buffer Mode (ANI2)

(b) Scan mode

In this mode, the analog inputs specified by the ADM2 register are selected sequentially from the ANI0 pin, and A/D conversion is executed. The A/D conversion results are stored in the ADCRn register corresponding to the analog input (n = 0 to 7). When the conversion of the specified analog input ends, the A/D conversion end interrupt (INTAD) is generated. After conversion has finished, the next conversion operation is repeated, unless the ADCE bit of the ADM0 register is cleared to 0.

Figure 13-5. Scan Mode Operation Timing: 4-Channel Scan (ANI0 to ANI3)

13.5 Operation in A/D Trigger Mode

When the ADCE bit of the ADM0 register is set to 1, A/D conversion is started.

13.5.1 Select mode operation

In this mode, the analog input specified by the ADM2 register is A/D converted. The conversion results are stored in the ADCRn register corresponding to the analog input. In the select mode, the 1-buffer mode and 4-buffer mode are supported according to the storing method of the A/D conversion results (n = 0 to 7).

(1) 1-buffer mode (A/D trigger select: 1 buffer)

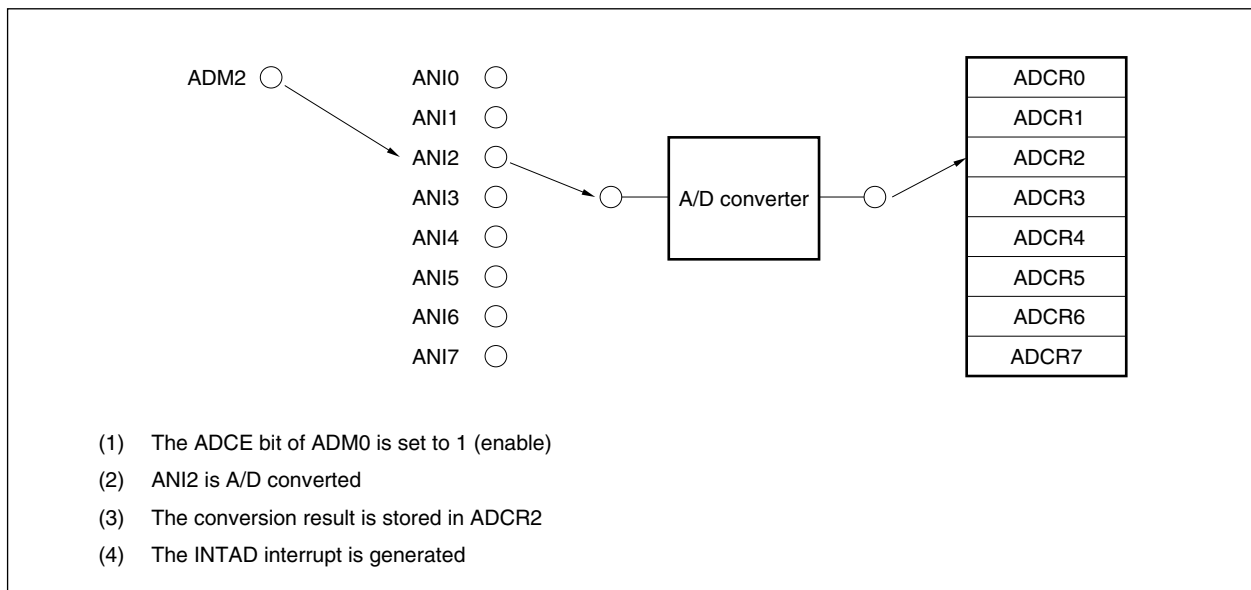

In this mode, one analog input is A/D converted once. The conversion results are stored in one ADCRn register. The analog input and ADCRn register correspond one to one.

Each time an A/D conversion is executed, an A/D conversion end interrupt (INTAD) is generated and A/D conversion ends. The next conversion operation is repeated, unless the ADCE bit of the ADM0 register is cleared to 0.

Analog Input	A/D Conversion Result Register
ANIn	ADCRn

This mode is most appropriate for applications in which the results of each first-time A/D conversion are read.

Figure 13-6. Example of 1-Buffer Mode Operation (A/D Trigger Select: 1 Buffer)

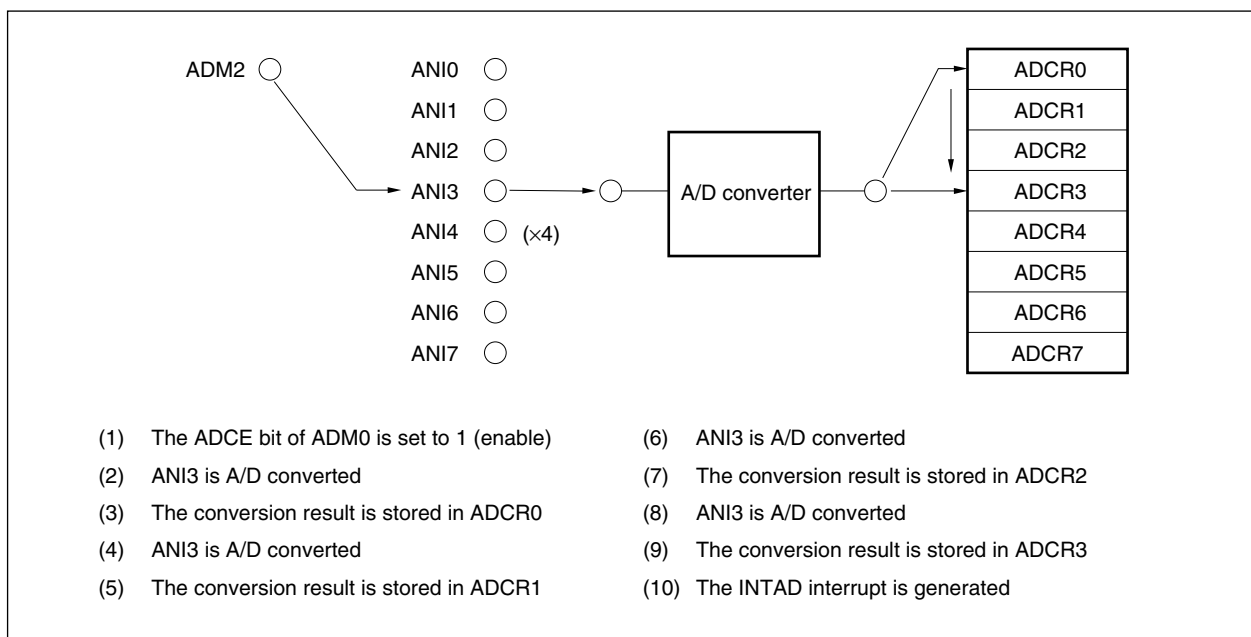

(2) 4-buffer mode (A/D trigger select: 4 buffers)

In this mode, one analog input is A/D converted four times and the results are stored in the ADCRn register. When the 4th A/D conversion ends, an A/D conversion end interrupt (INTAD) is generated and the A/D conversion is stopped. The next conversion operation is repeated, unless the ADCE bit of the ADM0 register is cleared to 0.

Analog Input	A/D Conversion Result Register
ANI0 to ANI3	ADCR0 (1st time)
	ADCR1 (2nd time)
	ADCR2 (3rd time)
	ADCR3 (4th time)
ANI4 to ANI7	ADCR4 (1st time)
	ADCR5 (2nd time)
	ADCR6 (3rd time)
	ADCR7 (4th time)

This mode is suitable for applications in which the average of the A/D conversion results is calculated.

Figure 13-7. Example of 4-Buffer Mode Operation (A/D Trigger Select: 4 Buffers)

13.5.2 Scan mode operations

In this mode, the analog inputs specified by the ADM2 register are selected sequentially from the ANI0 pin, and A/D conversion is executed. The A/D conversion results are stored in the ADCRn register corresponding to the analog input (n = 0 to 7).

When conversion of all the specified analog input ends, the A/D conversion end interrupt (INTAD) is generated, and A/D conversion is stopped. The next conversion operation is repeated, unless the ADCE bit of the ADM0 register is cleared to 0.

Analog Input	A/D Conversion Result Register
ANI0	ADCR0
⋮	⋮
ANIn ^{Note}	ADCRn

Note Set by the ANIS2 to ANIS0 bits of the ADM2 register.

This mode is most appropriate for applications in which multiple analog inputs are constantly monitored.

Figure 13-8. Example of Scan Mode Operation (A/D Trigger Scan)

13.6 Operation in Timer Trigger Mode

In this mode, the conversion timing of the analog input signal set by the ANI0 to ANI7 pins is defined by the value set to the capture/compare registers of timers C4 and C5.

The analog input conversion timing is generated when a compare match interrupt (INTCCC40, INTCCC41, INTCCC50, or INTCCC51) is generated by the capture/compare register connected to 16-bit timer C4 or C5 (TMC4 or TMC5).

When the ADCE bit of the ADM0 register is set to 1, the A/D converter waits for the interrupt (INTCCC40, INTCCC41, INTCCC50, or INTCCC51), and starts conversion when INTCCC40, INTCCC41, INTCCC50, or INTCCC51 occurs (ADCS bit = 1 in the ADM0 register). When conversion is finished, the converter waits for an interrupt again (ADCS bit = 0).

If INTCCC40, INTCCC41, INTCCC50, or INTCCC51 occurs during conversion, the conversion operation is executed from the beginning again.

If data is written to the ADM0 to ADM2 registers during conversion, the conversion operation is stopped and executed from the beginning again.

13.6.1 Select mode operation

In this mode, an analog input (ANI0 to ANI7) specified by the ADM2 register is A/D converted. The conversion results are stored in the ADCRn register corresponding to the analog input. In the select mode, the 1-buffer mode and 4-buffer mode are provided according to the storing method of the A/D conversion results.

(1) 1-buffer mode (timer trigger select: 1 buffer)

In this mode, one analog input is A/D converted once and the conversion results are stored in one ADCRn register.

One analog input is A/D converted once using the trigger of the match interrupt signals (INTCCC40, INTCCC41, INTCCC50, INTCCC51) and the results are stored in one ADCRn register. An A/D conversion end interrupt (INTAD) is generated for each A/D conversion.

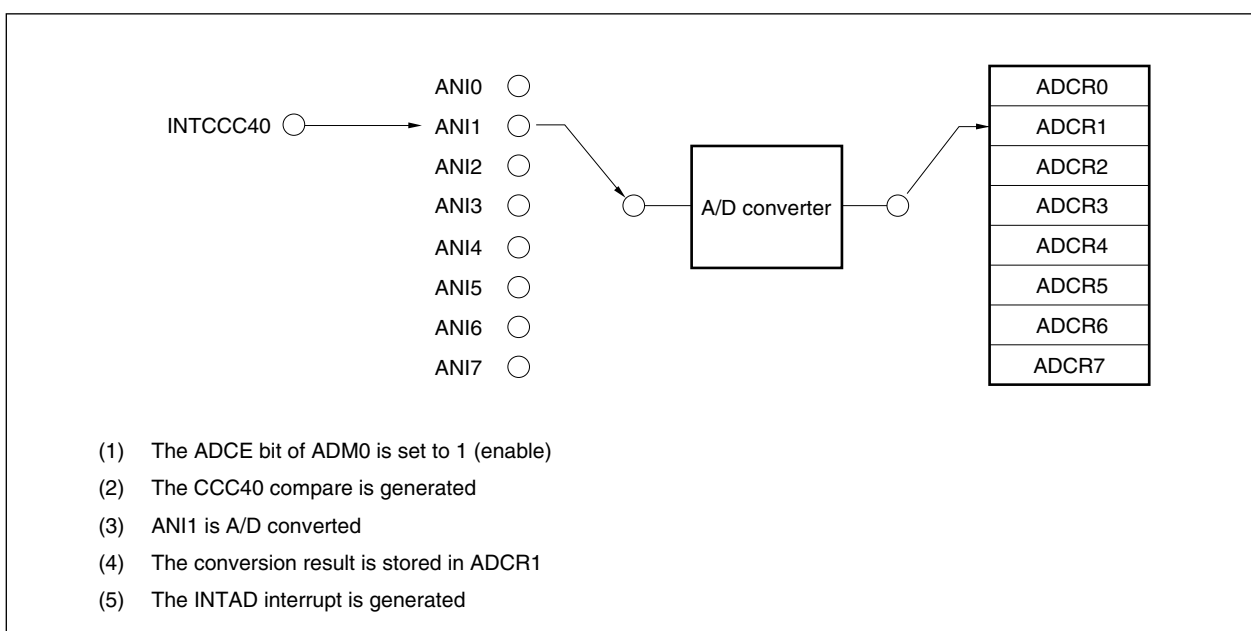

Unless the ADCE bit of the ADM0 register is cleared to 0, A/D conversion is repeated each time a timer match interrupt is generated.

**Table 13-3. Correspondence Between Analog Input Pins and ADCRn Register
(1-Buffer Mode (Timer Trigger Select: 1 Buffer))**

Trigger	Analog Input	A/D Conversion Result Register
INTCCCn interrupt	ANI0	ADCR0
INTCCCn interrupt	ANI1	ADCR1
INTCCCn interrupt	ANI2	ADCR2
INTCCCn interrupt	ANI3	ADCR3
INTCCCn interrupt	ANI4	ADCR4
INTCCCn interrupt	ANI5	ADCR5
INTCCCn interrupt	ANI6	ADCR6
INTCCCn interrupt	ANI7	ADCR7

Remark n = 40, 41, 50, 51

Figure 13-9. Example of 1-Buffer Mode Operation (Timer Trigger Select: 1 Buffer) (ANI1)

(2) 4-buffer mode (timer trigger select: 4 buffers)

In this mode, A/D conversion of one analog input is executed four times, and the results are stored in the ADCRn register.

One analog input is A/D converted four times using the match interrupt signals (INTCCC40, INTCCC41, INTCCC50, INTCCC51) as a trigger, and the results are stored in four ADCRn registers. The A/D conversion end interrupt (INTAD) is generated when the four A/D conversions end.

After conversion has finished, the next conversion is repeated, unless the ADCE bit of the ADM0 register is cleared to 0.

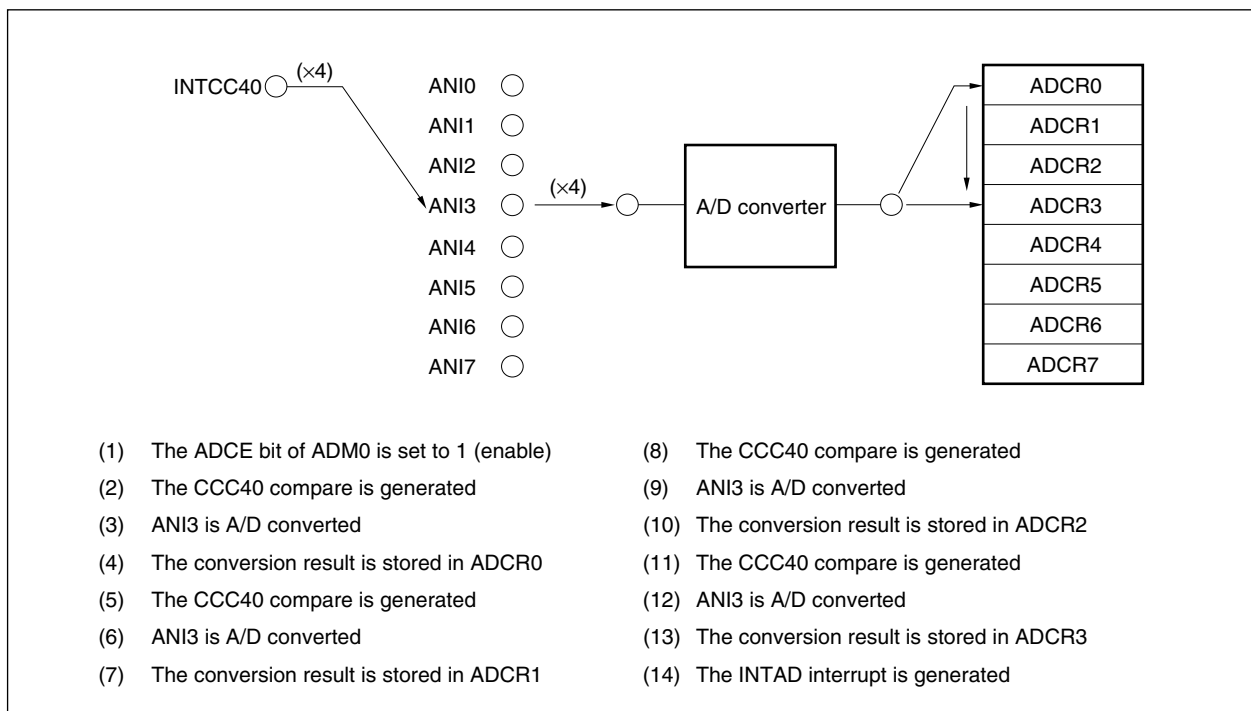

This mode is suitable for applications in which the average of the A/D conversion results is calculated.

Table 13-4. Correspondence Between Analog Input Pins and ADCRn Register (4-Buffer Mode (Timer Trigger Select: 4 Buffers))

Trigger	Analog Input	A/D Conversion Result Register
INTCCcn interrupt	ANI0 to ANI3	ADCR0 (1st time) ADCR1 (2nd time) ADCR2 (3rd time) ADCR3 (4th time)
	ANI4 to ANI7	ADCR4 (1st time) ADCR5 (2nd time) ADCR6 (3rd time) ADCR7 (4th time)

Remark n = 40, 41, 50, 51

Figure 13-10. Example of 4-Buffer Mode Operation (Timer Trigger Select: 4 Buffers) (ANI3)

13.6.2 Scan mode operation

In this mode, the analog inputs specified by the ADM2 register are selected sequentially from the ANI0 pin and are A/D converted the specified number of times using the timer match interrupt signal as a trigger.

The result of conversion is stored in the ADCRn register corresponding to the analog input. When all the specified analog input signals have been converted, an A/D conversion end interrupt (INTAD) occurs.

After conversion has finished, the A/D converter waits for a trigger unless the ADCE bit of the ADM0 register is cleared to 0. When a timer match interrupt occurs again, the converter starts A/D conversion again, starting from the ANI0 input.

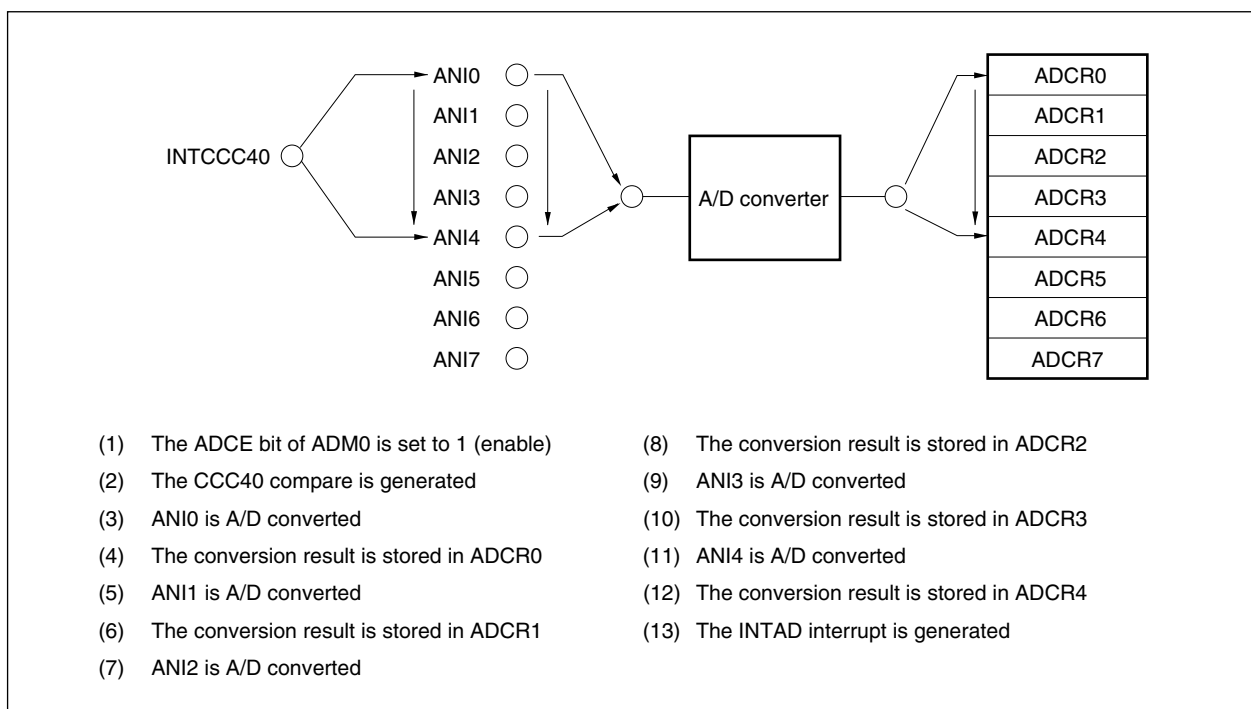

This mode is most appropriate for applications in which multiple analog inputs are constantly monitored.

Table 13-5. Correspondence Between Analog Input Pins and ADCRn Register (Scan Mode (Timer Trigger Scan))

Trigger	Analog Input	A/D Conversion Result Register
INTCCcn interrupt	ANI0	ADCR0
	ANI1	ADCR1
	ANI2	ADCR2
	ANI3	ADCR3
	ANI4	ADCR4
	ANI5	ADCR5
	ANI6	ADCR6
	ANI7	ADCR7

Remark n = 40, 41, 50, 51

Figure 13-11. Example of Scan Mode Operation (Timer Trigger Scan) (ANI0 to ANI4)

13.7 Operation in External Trigger Mode

In this mode, the conversion timing of the analog signals input to the ANI0 to ANI7 pins is specified by the ADTRG pin.

Detection of the valid edge at the ADTRG input pin is specified by using the EGA1 and EGA0 bits of the ADM1 register.

When the ADCE bit of the ADM0 register is set to 1, the A/D converter waits for an external trigger (ADTRG), and starts conversion when the valid edge of ADTRG is detected (ADCS bit = 1 in the ADM0 register). When the converter has ended conversion, it waits for the external trigger again (ADCS bit = 0).

If the valid edge is detected at the ADTRG pin during conversion, conversion is executed from the beginning again.

If data is written to the ADM0 to ADM2 registers during conversion, conversion is stopped and executed from the beginning again.

13.7.1 Select mode operations

In this mode, one analog input (ANI0 to ANI7) specified by the ADM2 register is A/D converted. The conversion results are stored in the ADCRn register corresponding to the analog input. In the select mode, there are two select modes: 1-buffer mode and 4-buffer mode, according to the storing method of the conversion results.

(1) 1-buffer mode (external trigger select: 1-buffer)

In this mode, one analog input is A/D converted using the ADTRG signal as a trigger. The conversion results are stored in one ADCRn register. The analog input and the A/D conversion results register correspond one to one. The A/D conversion end interrupt (INTAD) is generated for each A/D conversion, and A/D conversion is stopped.

Trigger	Analog Input	A/D Conversion Result Register
ADTRG signal	ANIn	ADCRn

While the ADCE bit of the ADM0 register is 1, A/D conversion is repeated every time a trigger is input from the ADTRG pin.

This mode is most appropriate for applications in which the results are read after each A/D conversion.

Figure 13-12. Example of 1-Buffer Mode Operation (External Trigger Select: 1 Buffer) (ANI1)

(2) 4-buffer mode (external trigger select: 4 buffers)

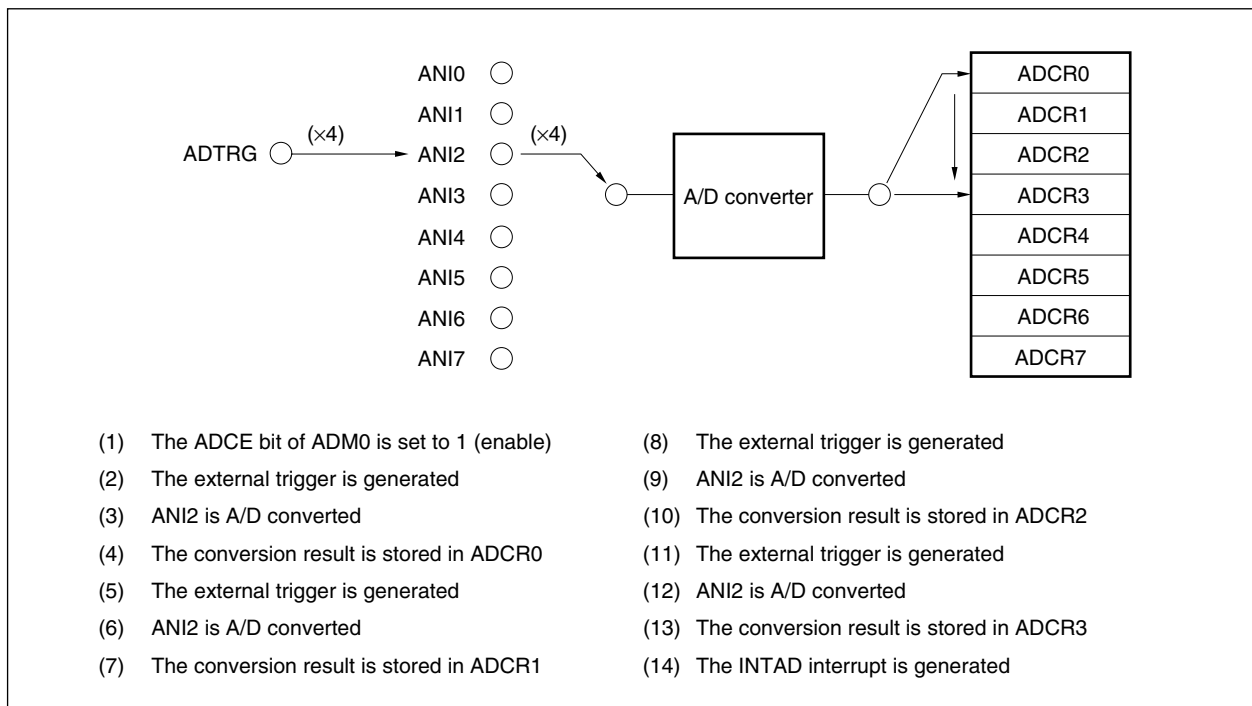

In this mode, one analog input is A/D converted four times using the ADTRG signal as a trigger and the results are stored in the ADCRn register. The A/D conversion end interrupt (INTAD) is generated and A/D conversion is stopped after the 4th A/D conversion.

Trigger	Analog Input	A/D Conversion Result Register
ADTRG signal	ANI0 to ANI3	ADCR0 (1st time)
		ADCR1 (2nd time)
		ADCR2 (3rd time)
		ADCR3 (4th time)
	ANI4 to ANI7	ADCR4 (1st time)
		ADCR5 (2nd time)
		ADCR6 (3rd time)
		ADCR7 (4th time)

While the ADCE bit of the ADM0 register is 1, A/D conversion is repeated every time a trigger is input from the ADTRG pin.

This mode is suitable for applications in which the average of the A/D conversion results is calculated.

Figure 13-13. Example of 4-Buffer Mode Operation (External Trigger Select: 4 Buffers) (ANI2)

13.7.2 Scan mode operation

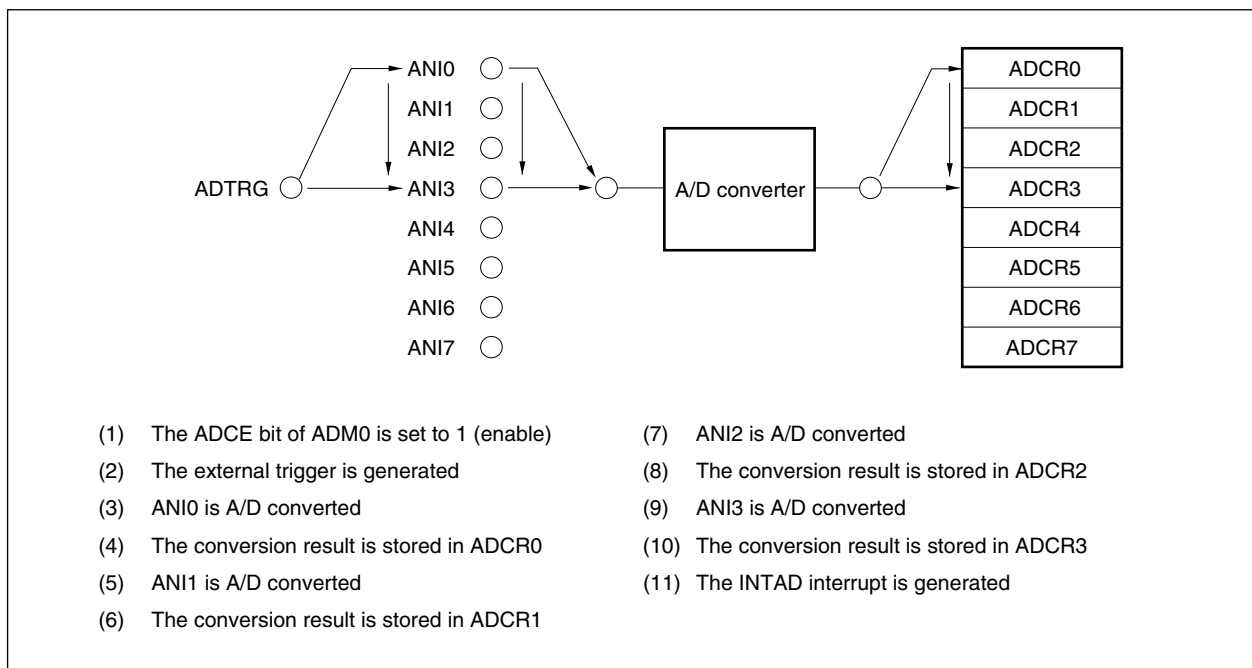

In this mode, the analog inputs specified by the ADM2 register are selected sequentially from the ANI0 pin using the ADTRG signal as a trigger, and A/D converted. The A/D conversion results are stored in the ADCRn register corresponding to the analog input (n = 0 to 7).

When conversion of all the specified analog inputs has ended, the A/D conversion end interrupt (INTAD) is generated. Unless the ADCE bit of the ADM0 register is cleared to 0 after end of conversion, the A/D converter waits for a trigger. The converter starts A/D conversion from the ANI0 input when a trigger is input to the ADTRG pin again.

Trigger	Analog Input	A/D Conversion Result Register
ADTRG signal	ANI0	ADCR0
	ANI1	ADCR1
	ANI2	ADCR2
	ANI3	ADCR3
	ANI4	ADCR4
	ANI5	ADCR5
	ANI6	ADCR6
	ANI7	ADCR7

When a trigger is input to the ADTRG pin while the ADCE bit of the ADM0 register is 1, A/D conversion is started again. This is most appropriate for applications in which multiple analog inputs are constantly monitored.

Figure 13-14. Example of Scan Mode Operation (External Trigger Scan) (ANI0 to ANI3)

13.8 Cautions

Cautions on using the A/D converter are shown below.

(1) Stopping conversion operation

When the ADCE bit of the ADM0 register is cleared to 0 during a conversion operation, the conversion operation stops and the conversion results are not stored in the ADCRn register (n = 0 to 7).

(2) External/timer trigger interval

Set the interval (input time interval) of the trigger in the external or timer trigger mode longer than the conversion time specified by the FR3 to FR0 bits of the ADM1 register.

When $0 < \text{interval} \leq \text{conversion operation time}$

When the following external trigger or timer trigger is input during a conversion operation, the conversion operation is aborted and the conversion starts according to the last external trigger input or timer trigger input. When conversion operations are aborted, the conversion results are not stored in the ADCRn register (n = 0 to 7). However, the number of times the trigger has been input is counted. When an interrupt occurs, the values that have been converted are stored in the ADCRn register.

(3) Operation in standby mode

<1> HALT mode

In this mode, A/D conversion continues. When this mode is released by NMI input or unmasked maskable interrupt input (see 9.6.3 (2) Release of HALT mode), the ADM0, ADM1, and ADM2 registers and ADCRn register hold the value (n = 0 to 7).

<2> IDLE mode

As clock supply to the A/D converter is stopped, no conversion operations are performed. When these modes are released by NMI input, the ADM0, ADM1, and ADM2 registers and the ADCRn register hold the value (n = 0 to 7). However, when the IDLE mode is set during a conversion operation, the conversion operation is stopped. At this time, if the mode released by NMI input or unmasked maskable interrupt input (see 9.6.4 (2) Release of IDLE mode), the conversion operation resumes, but the conversion result written to the ADCRn register will become undefined.

(4) Compare match interrupt in timer trigger mode

The compare register's match interrupt becomes an A/D conversion start trigger and starts the conversion operation. When this happens, the compare register's match interrupt also functions as a compare register match interrupt for the CPU. In order to prevent match interrupts from the compare register for the CPU, disable interrupts using the interrupt mask bits (CCC4MK0, CCC4MK1, CCC5MK0, CCC5MK1) of the interrupt control register (CCC4IC0, CCC4IC1, CCC5IC0, CCC5IC1).

(5) Input range of ANI0 to ANI7

Use the input voltage at ANI0 to ANI7 within the specified range. If a voltage outside the range of AV_{REFP} and AV_{REFM} is input to any of these pins (even within the absolute maximum rating range), the converted value of the channel is undefined. In addition, the converted value of the other channels may also be affected.

(6) Conflict**<1> Conflict between writing A/D conversion result registers (ADCRn, ADCRnH) at end of conversion and reading ADCRn and ADCRnH registers by instruction**

Reading the ADCRn and ADCRnH registers takes precedence. After these registers have been read, the new conversion result is written to the ADCRn and ADCRnH registers.

<2> Conflict between writing ADCRn and ADCRnH at end of conversion and input of external trigger signal

The external trigger signal is not accepted during A/D conversion. Therefore, it is not accepted while ADCRn and ADCRnH are being written.

<3> Conflict between writing ADCRn and ADCRnH at end of conversion and writing A/D converter mode register 1 (ADM1) or A/D converter mode register 2 (ADM2)

If ADM1 or ADM2 is written immediately after ADCRn and ADCRnH have been written on completion of A/D conversion, the conversion result is written to the ADCRn and ADCRnH registers, but the A/D conversion end interrupt (INTAD) may not occur depending on the timing.

(7) Absolute precision

The specified value of absolute precision is an attribute of microcontroller units, and is a value which is not effected by the setup environment (e.g., effects of noise, board wiring). In order to suppress degradation of absolute precision due to the setup environment, sufficient attention should be paid to board layouts, such as by isolating AV_{DD} and AV_{SS} from digital power supplies and by ensuring that the analog input pins (ANI0 to ANI7) are not effected by digital signals.

(8) Conversion results when a fixed A/D converter input voltage is subjected to A/D conversion more than once in the same channel

When a fixed A/D converter input voltage is subjected to A/D conversion more than once in the same channel, although the same conversion results can theoretically be obtained in an ideal environment (in which the power supply voltage, analog input voltage, ambient temperature, etc. are stable), in reality, since there are influences such as changes in the power supply voltage, analog input voltage, ambient temperature, etc. due to noise, conversion results are not the same.

This phenomenon is particularly appeared due to extremely minute environment influences occurring when an analog input voltage is near the change point of a digital value.

(9) Noise countermeasures

If there is noise at the analog input pins (ANI0 to ANI7) or at the reference voltage input pins (AV_{REFP}, AV_{REFM}), an illegal conversion result may be generated due to that noise.

Software processing will be needed to avoid a negative effect on the system from this illegal conversion result.

An example of this software processing is shown below.

- Take the average value of multiple A/D conversion results and use this value as the A/D conversion result.
- If exceptional results are obtained after the continuous multiple A/D conversions, use the conversion results omitting these exceptional results.
- If an A/D conversion result which can be judged that a system abnormality has occurred is obtained, do not attempt to overcome the abnormality right away, but handle the abnormality after checking the abnormality occurrence again.

(10) Coupling noise

When digital pulses are applied to the pins or pins are used as digital buffer output pins during A/D conversion, A/D conversion values may not be obtained as expected, due to coupling noise.

(11) Cautions on board design

As a constraint derived from electric potential fluctuations due to common impedance and inductance, digital and analog signals should be isolated as much as possible as the circuit board design. Crossing and bringing into close proximity of digital and analog signals should also be avoided as much as possible.

Connect the AV_{SS} pin at one point to a stable ground.

(12) AV_{REFP} and AV_{REFM} pins

When the impedance of the unit supplying power to the AV_{REFP} and AV_{REFM} pins is high or the capacity to supply current from the power supply is low, there is a risk of the reference voltage changing and the conversion accuracy deteriorating. Connecting a capacitor between the AV_{REFP} and AV_{SS} pins and between the AV_{REFM} and AV_{SS} pins is recommended to avoid this problem.

(13) Bypass capacitor connection

The bypass capacitor to be connected to the AV_{DD}, AV_{REFP}, and AV_{REFM} pins should be connected as closely as possible to the device, using a capacitor with high-frequency characteristics, such as a chip capacitor.

(14) Stabilization time for re-conversion operations

If the A/D control register is written or the external/timer trigger is input during A/D stabilization, the time needed for re-conversion operations to stabilize may increase.

(15) Re-conversion start trigger input during stabilization time

If the stabilization time end timing and the register writing conflict or the stabilization time end timing and the trigger input conflict, the stabilization time is inserted again.

(16) Variation of A/D conversion results

The results of the A/D conversion may vary depending on the fluctuation of the supply voltage, or may be affected by noise. To reduce the variation, take counteractive measures with the program, such as by averaging the A/D conversion results.

(17) A/D conversion result hysteresis characteristics

Successive comparison type A/D converters hold an analog input voltage in an internal sample & hold capacitor and then perform A/D conversion. After the A/D conversion has finished, the analog input voltage remains in the internal sample & hold capacitor. As a result, the following phenomena may occur if the output impedance of the analog input source is high.

- When the same channel is used for A/D conversions, if the voltage is higher or lower than the previous A/D conversion, then hysteresis characteristics may appear where the conversion result is affected by the previous value. Even if the conversion were to be performed at the same potential, the results may thus vary.
- When switching the analog input channel, hysteresis characteristics may appear where the conversion result is affected by the previous channel value. This is because one A/D converter is used for the A/D conversions. Even if the conversion were to be performed at the same potential, the results may thus vary.

To obtain more accurate conversion results, lower the output impedance of the analog input source, or execute A/D conversion twice consecutively on the same channel and discard the first conversion result.

13.9 How to Read A/D Converter Characteristics Table

Here, special terms unique to the A/D converter are explained.

(1) Resolution

This is the minimum analog input voltage that can be identified. That is, the percentage of the analog input voltage per bit of digital output is called 1LSB (Least Significant Bit). The percentage of 1LSB with respect to the full scale is expressed by %FSR (Full Scale Range). %FSR indicates the ratio of analog input voltage that can be converted as a percentage, and is always represented by the following formula regardless of the resolution.

$$\begin{aligned} 1\%FSR &= (\text{Max. value of analog input voltage that can be converted} - \text{Min. value of analog input voltage that can be converted})/100 \\ &= (AV_{REFP} - AV_{REFM})/100 \end{aligned}$$

1LSB is as follows when the resolution is 10 bits.

$$\begin{aligned} 1LSB &= 1/2^{10} = 1/1024 \\ &= 0.098\%FSR \end{aligned}$$

Accuracy has no relation to resolution, but is determined by overall error.

(2) Overall error

This shows the maximum error value between the actual measured value and the theoretical value.

Zero-scale error, full-scale error, linearity error and errors that are combinations of these express the overall error.

Note that the quantization error is not included in the overall error in the characteristics table.

Figure 13-15. Overall Error

(3) Quantization error

When analog values are converted to digital values, a $\pm 1/2\text{LSB}$ error naturally occurs. In an A/D converter, an analog input voltage in a range of $\pm 1/2\text{LSB}$ is converted to the same digital code, so a quantization error cannot be avoided.

Note that the quantization error is not included in the overall error, zero-scale error, full-scale error, integral linearity error, and differential linearity error in the characteristics table.

Figure 13-16. Quantization Error

(4) Zero-scale error

This shows the difference between the actual measurement value of the analog input voltage and the theoretical value ($1/2\text{ LSB}$) when the digital output changes from 0.....000 to 0.....001.

Figure 13-17. Zero-Scale Error

(5) Full-scale error

This shows the difference between the actual measurement value of the analog input voltage and the theoretical value ($3/2\text{LSB}$) when the digital output changes from 1.....110 to 1.....111.

Figure 13-18. Full-Scale Error

(6) Differential linearity error

While the ideal width of code output is 1LSB, this indicates the difference between the actual measurement value and the ideal value.

Figure 13-19. Differential Linearity Error

(7) Integral linearity error

This shows the degree to which the conversion characteristics deviate from the ideal linear relationship. It expresses the maximum value of the difference between the actual measurement value and the ideal straight line when the zero-scale error and full-scale error are 0.

Figure 13-20. Integral Linearity Error**(8) Conversion time**

This expresses the time from when a trigger was generated to the time when the digital output was obtained. The sampling time is included in the conversion time in the characteristics table.

(9) Sampling time

This is the time the analog switch is turned on for the analog voltage to be sampled by the sample & hold circuit.

Figure 13-21. Sampling Time

CHAPTER 14 PWM UNIT

14.1 Features

- PWMn: 2 channels
- 12- to 16-bit accuracy selectable
- Minimization of low-pass filter size due to main pulse + ancillary pulse configuration
 - Main pulse 4/5/6/7/8 bits
 - Ancillary pulse 8 bits
- Repeat frequency: 129 kHz to 2 MHz ($f_{PWMC} = 33$ MHz)
- Selecting pulse width rewrite period: Every 1 pulse/256 pulses
- Active level of PWM output pulse selectable
- PWM operating clock (f_{PWMC}): $f_x/4$, $f_x/8$, $f_x/16$, or $f_x/32$ selectable

- Remarks**
1. $n = 0, 1$
 2. f_{PWMC} : PWM operating clock
 f_x : Main clock

14.2 Configuration

PWMn has a PWM output configuration of 256 main pulses and sets the active-level width using modulo H register n.

(1) Prescaler

The prescaler divides f_x to generate the PWM operating clock (f_{PWMC}). The output frequency of the prescaler can be selected from $f_x/4$, $f_x/8$, $f_x/16$, and $f_x/32$, by using the CKSPn1 and CKSPn0 bits of the PWMCn register ($n = 0, 1$).

(2) Reload controller

The reload controller controls reloading of the modulo register value.

The reload timing (PWM pulse width rewrite period) can be selected from $2^x/f_{PWMC}$ or $2^{x+8}/f_{PWMC}$ by using the SYNn bit of the PWMCn register ($n = 0, 1$, $x = 4$ to 8 (main pulse bit length)).

(3) Main pulse generator/output controller

This circuit controls the output timing of the main pulse.

It generates the main pulse from the reload signal generated by the reload controller, according to the value of modulo H register n ($n = 0, 1$).

(4) Ancillary pulse generator/output controller

This circuit controls the output timing of the ancillary pulse.

It generates an ancillary pulse from the reload signal generated by the reload controller, according to the value of modulo L register n ($n = 0, 1$).

(5) Pulse synthesizer/output controller

This circuit controls the timing of the PWM pulse signal output by synthesizing the main pulse and ancillary pulse.

Figure 14-1. Block Diagram of PWM Unit

14.3 Control Registers

(1) PWM control registers 0 and 1 (PWMC0 and PWMC1)

PWMCn is a register that controls PWMn (n = 0, 1).

These registers can be read or written in 8-bit or 1-bit units.

- Cautions**
1. Do not change the setting of the PMPn2 to PMPn0, SYNn, CKSPn1, and CKSPn0 bits during PWM operation (when PWME_n bit = 1); otherwise the operation cannot be guaranteed.
 2. Note that, if the setting of the ALVn bit is changed during PWM operation (when PWME_n bit = 1), noise may be generated.

	7	6	5	4	3	2	1	0	Address	After reset
PWMC0	PWME0	PMP02	PMP01	PMP00	ALV0	SYN0	CKSP01	CKSP00	1FFFFB00H	08H

- Remarks 1.** n = 0, 1
x = 4 to 8 (specified by PMP_{n2} to PMP_{n0} bits)
- 2.** f_x: Main clock

(2) PWM modulo registers 0 and 1 (PWM0 and PWM1)

These 16-bit registers determine the pulse width of the PWM pulse.

These registers can be read or written in 16-bit units.

If the higher 8 bits of the PWMn register are used as a PWMHn register and the lower 8 bits are used as a PWMLn register, these registers can be read or written in 8-bit units.

<1> Modulo H register n (PWMHn): Bits 15 to 8

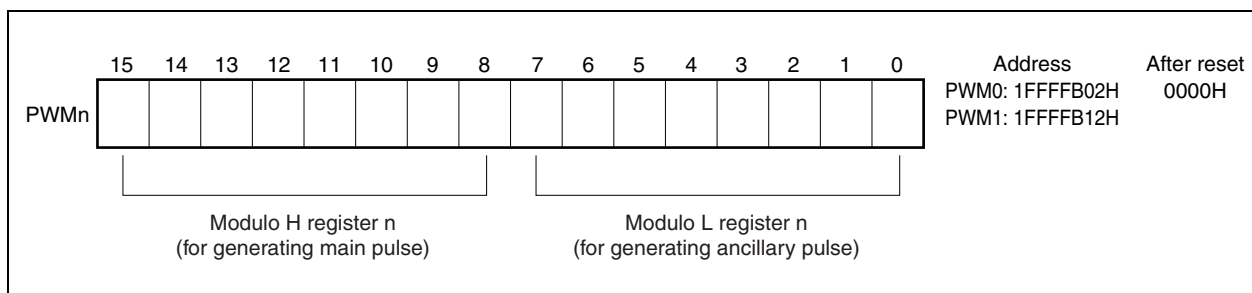

This register specifies the active level of the main pulse.

The data of the active level width of only the bit length specified by the PMPn2 to PMPn0 bits of the PWMCn register is valid. If the counter length is set to 4 to 7 bits by the PMPn2 to PMPn0 bits, data input to the higher bits is invalid.

<2> Modulo L register n (PWMLn): Bits 7 to 0

This register adjusts the timing of the ancillary pulse for fine tuning (see **Figure 14-2**).

A value of 0000H to FFFFH can be set to the PWMn register, and the PWM output changed linearly. If a value of 0000H is set, the inactive level is held. If the value is FFFFH, the PWM output becomes inactive for one ancillary pulse ($1/f_{PWM}$) in one rewrite cycle ($2^{16}/f_{PWM}$) (see **Figure 14-3**).

14.4 Operation

14.4.1 PWM basic operation

PWMn is divided into 256 parts, each of which is called a main pulse. Each main pulse has 4- to 8-bit accuracy. PWMn realizes a signal with an accuracy of 12 to 16 bits by synthesizing the required number of main pulses and an ancillary pulse with a pulse width of one clock.

The main pulse is set by the PMPn2 to PMPn0 bits of PWM control register n (PWMCn), and the pulse width is determined by the value of modulo H register n (valid number of bits). The repeat cycle of the PWM pulse output is the operating clock cycle (f_{PWMC}) of PWMn specified by the CKSPn1 and CKSPn0 bits of the PWMCn register divided by 2^x ($f_{\text{PWMC}}/2^x$).

Of the 256 main pulses, the ancillary pulses are generated only for the main pulses of the set number specified by modulo L register n. The pulse width is $1/f_{\text{PWMC}}$.

The logical sum of the main pulse and the ancillary pulse is output as the PWM pulse signal. Therefore, the average value of 256 PWM pulse signals is the PWM pulse signal with a resolution of 12 to 16 bits.

The duty factor of the output PWM pulse is determined as follows, by the value set to modulo H register n of PWM modulo register n (PWM0 or PWM1).

(1) If ancillary pulse is not generated

$$\text{Duty of output PWM pulse} = \frac{(\text{Value of modulo H register n})}{2^x}$$

(2) If ancillary pulse is generated

$$\text{Duty of output PWM pulse} = \frac{(\text{Value of modulo H register n}) + 1}{2^x}$$

Remark x = 4 to 8 (bit length of main pulse)

Figure 14-2. Example of PWM Output with Main Pulse and Ancillary Pulse

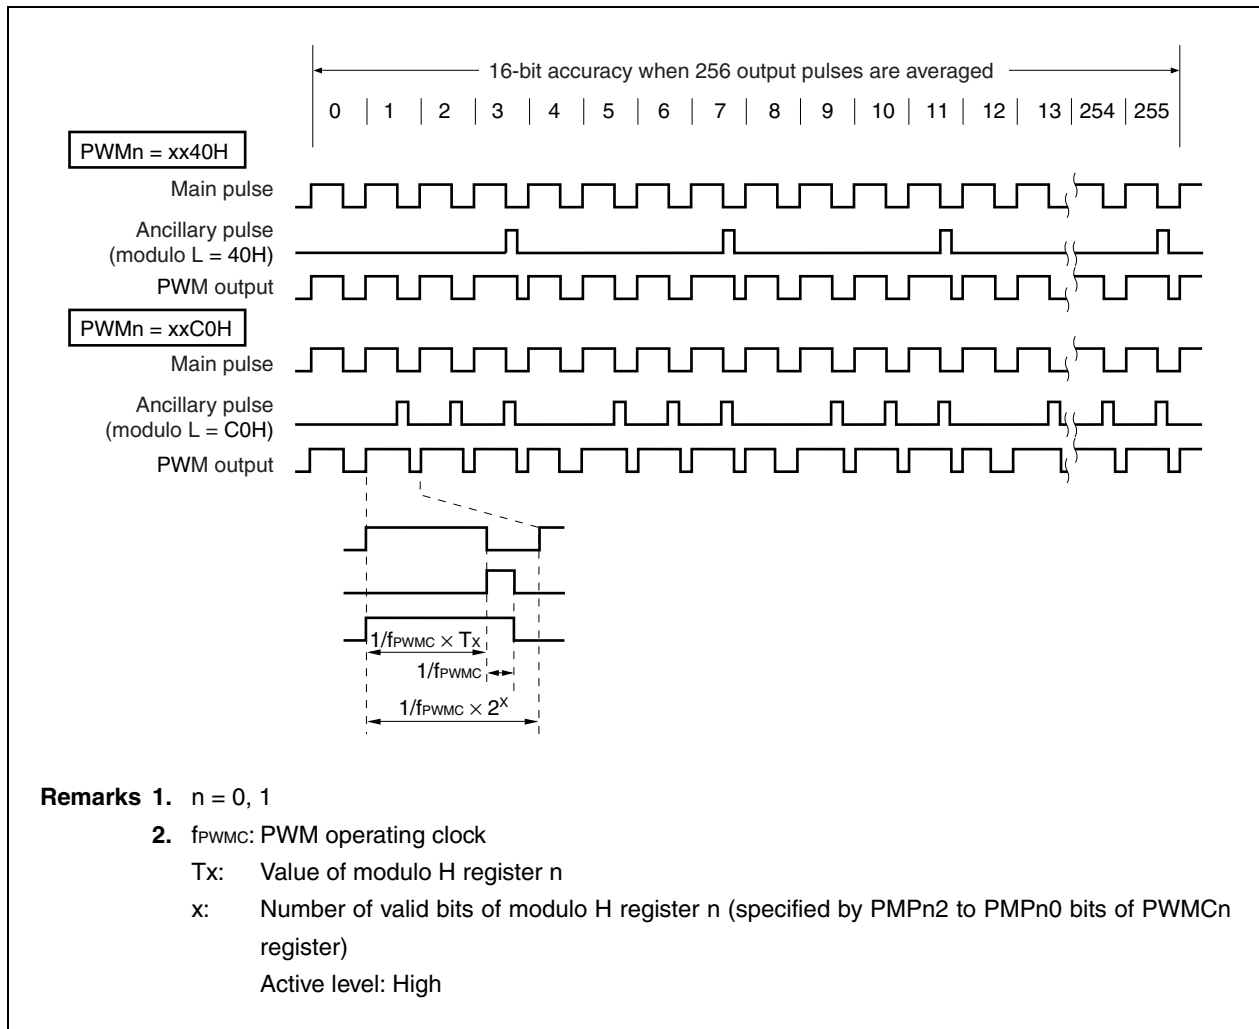

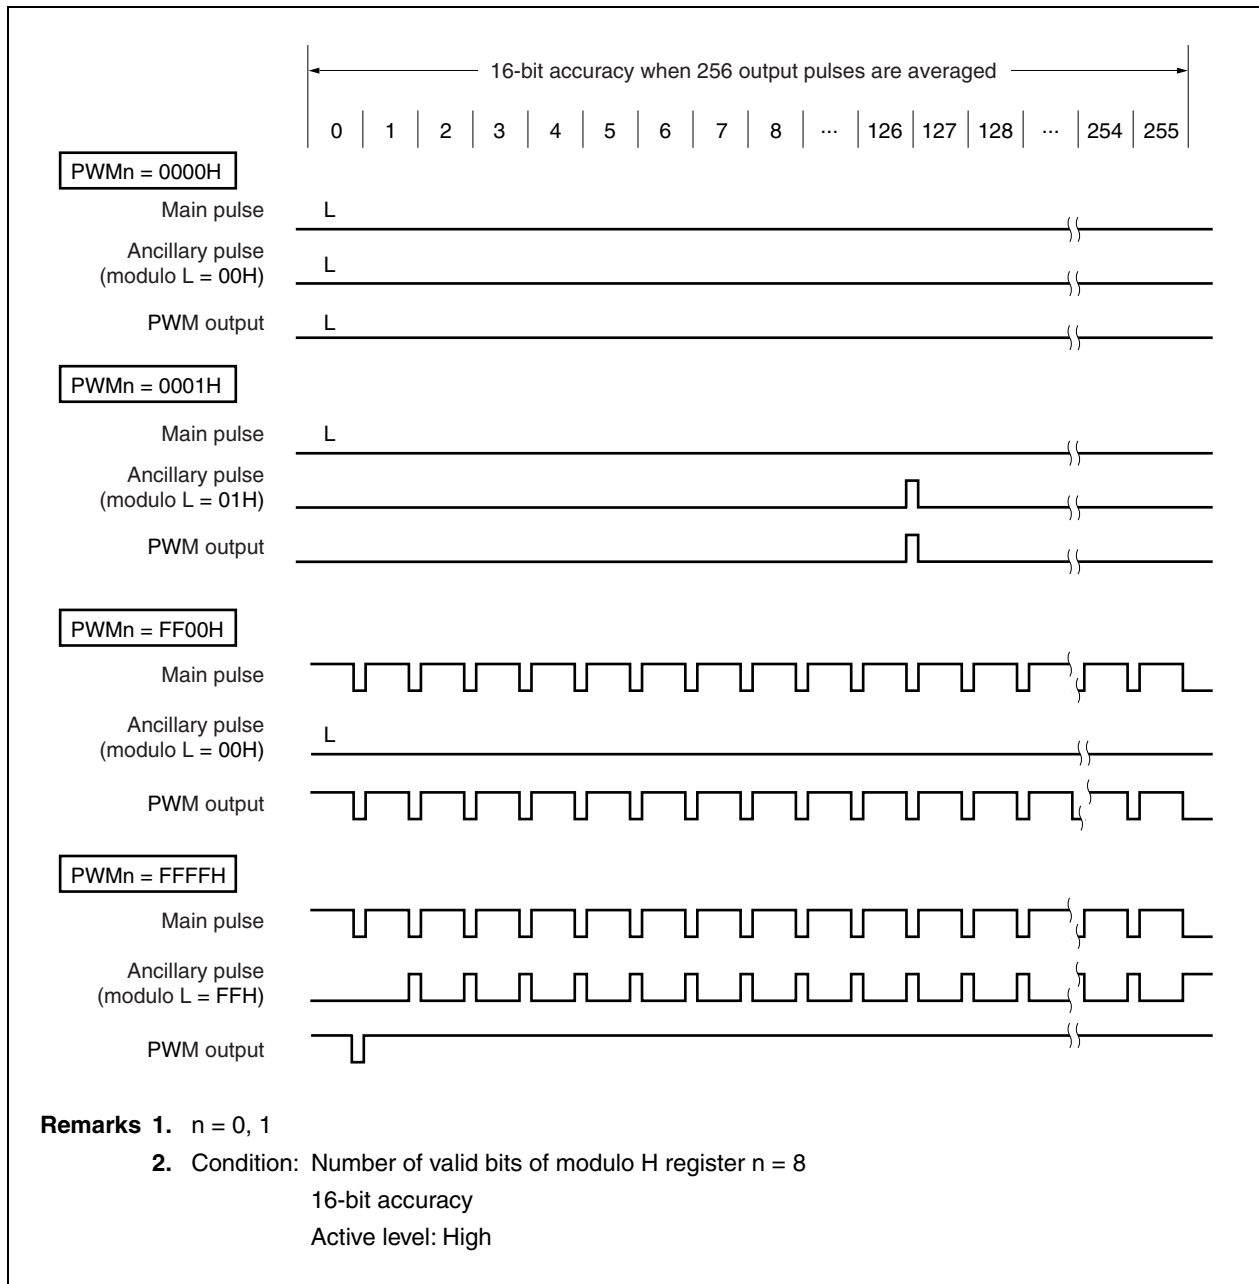

Figure 14-3. Example of PWM Output Operation

14.4.2 Starting/stopping PWM operation

To output a PWM pulse, set data to PWM modulo register n (PWMn) and then set the PWME_n bit of PWM control register n (PWMC_n) to 1 (n = 0, 1).

As a result, the PWM output pin outputs a PWM pulse of the active level specified by the ALV_n bit of the PWMC_n register.

When the PWME_n bit of the PWMC_n register is cleared to 0, the PWM output unit immediately stops the PWM output operation, and the PWM output pin becomes inactive.

(1) Setting for starting PWM operation

Before starting the operation of PWM_n (when PWME_n bit of PWMC_n register = 0), be sure to initialize the following registers.

- PMCDH, PFCDH registers: Set the control mode.
- PWM_n register: Set the pulse width.
- PWMC_n register:
 - CKSP_{n1} and CKSP_{n0} bits: Specify the operating clock (f_{PWC}) ($f_x/4$, $f_x/8$, $f_x/16$, $f_x/32$)
 - PMP_{n2} to PMP_{n0} bits: Specify the bit length (x) of the main pulse.
 - ALV_n bit: Specify the active level of the PWM pulse.
 - SYN_n bit: Specify the PWM pulse width rewrite period.

Cautions 1. Do not change the setting of the PMP_{n2} to PMP_{n0}, SYN_n, CKSP_{n1}, and CKSP_{n0} bits when PWME_n bit of the PWMC_n register = 1; otherwise the operation cannot be guaranteed.

2. Note that, if the setting of the ALV_n bit is changed during PWM operation (when PWME_n bit = 1), noise may be generated.

Remark n = 0, 1

When the PWME_n bit of the PWMC_n register is set, PWM_n starts operating. Immediately after PWM_n has started operating, however, the PWM pin maintains the status of the port mode (inactive level) until the reload signal of the PWM_n register is generated. After the operation has been started, the PWM output becomes active when the reload signal is generated, regardless of the setting of the SYN_n bit (PWM_n = other than 00xxH). If the timing of rewriting the pulse width is set to 2^{x+8} (long period: SYN_n bit = 0), the operation is started up to $2^{x+8}/f_{PWC}$ after the PWME_n bit has been set. The PWM_n register can be rewritten even during PWM output.

(2) Setting for stopping PWM operation

When the PWME_n bit of the PWMC_n register (n = 0, 1) is cleared to 0, the PWM operation is immediately stopped, and the PWM output becomes inactive immediately.

Figure 14-4. PWM Operation Timing

14.4.3 Setting active level of PWM pulse

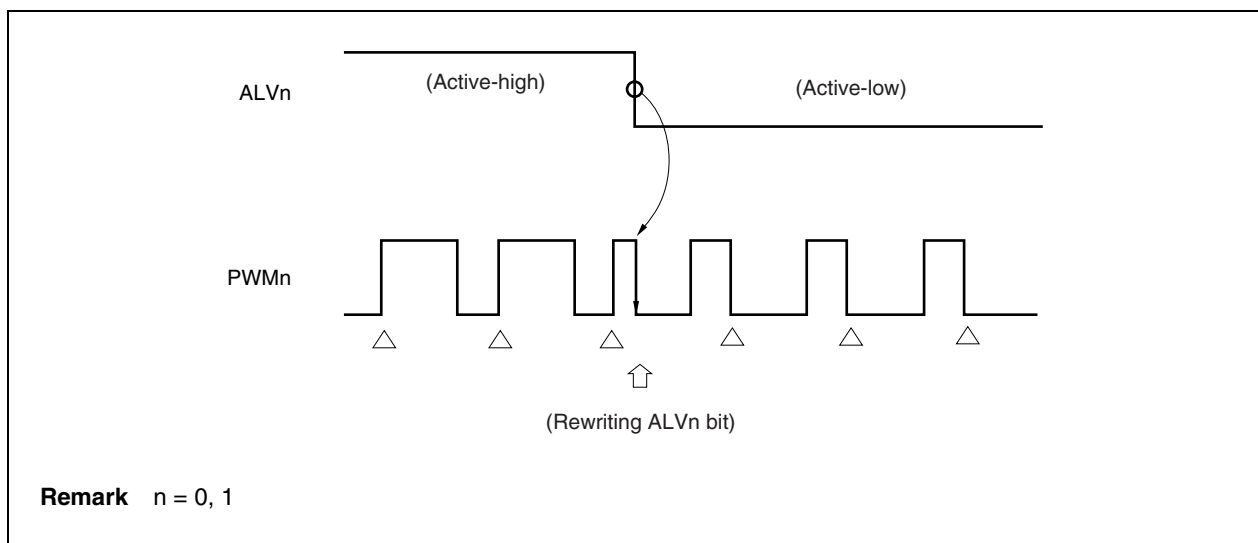

The ALVn bit of PWM control register n (PWMCn) specifies the active level of the PWM pulse output from the PWM output pin ($n = 0, 1$).

If the ALVn bit is set to 1, an active-high pulse is output; if it is cleared to 0, an active-low pulse is output.

If the ALVn bit is rewritten, the active level of PWM output is immediately changed. The figure below shows the setting of the active level of PWM output and pin status.

Regardless of the setting of the PWME_n bit (which enables or disables PWM), the active level of PWM output can be changed by manipulating the ALVn bit.

Figure 14-5. Setting Active Level of PWM Output

14.4.4 Specifying PWM pulse width rewrite period

PWM output is started and the pulse width is changed every 256 cycles of the PWM pulse ($2^{x+8}/f_{PWM}$) or every one PWM cycle ($2^x/f_{PWM}$). This PWM pulse width rewrite period is specified by the SYNn bit of the PWMCn register (n = 0, 1).

When the SYNn bit is cleared to 0, the pulse width is changed every 256 PWM pulse cycles ($2^{x+8}/f_{PWM}$) (long period). Therefore, it takes up to 2^{x+8} clocks to output a pulse of the width corresponding to the data written to the PWMn register.

An example of the PWM output timing at this time is shown in Figure 14-6.

When the SYNn bit is set to 1, the pulse width is changed every one PWM pulse cycle ($2^x/f_{PWM}$) (short period). In this case, it takes up to 2^x clocks to output a pulse of the width corresponding to the data written to the PWMn register.

If the PWM pulse rewrite period is specified to be every $2^x/f_{PWM}$ (if the SYNn bit is set to 1), the accuracy of the PWM pulse is x bits or more and (x+8) bits or less, or is lower than the accuracy when the rewrite cycle is set to $2^{x+8}/f_{PWM}$. However, the response speed improves because the repeat cycle increases.

Figure 14-7 shows an example of the PWM output timing where the rewrite timing is $2^x/f_{PWM}$.

Figure 14-6. PWM Output Timing Example 1 (PWM Pulse Width Rewrite Period: $2^{x+8}/f_{PWM}$)

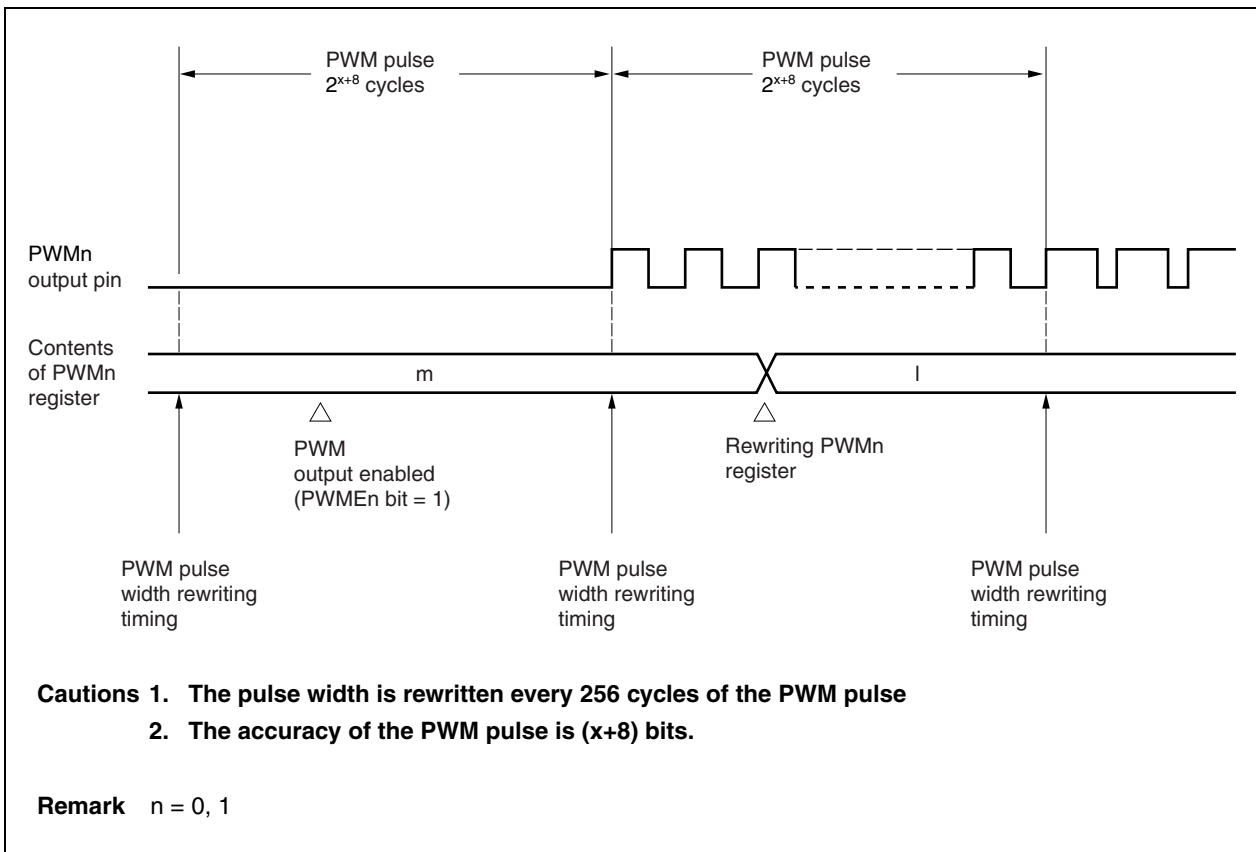

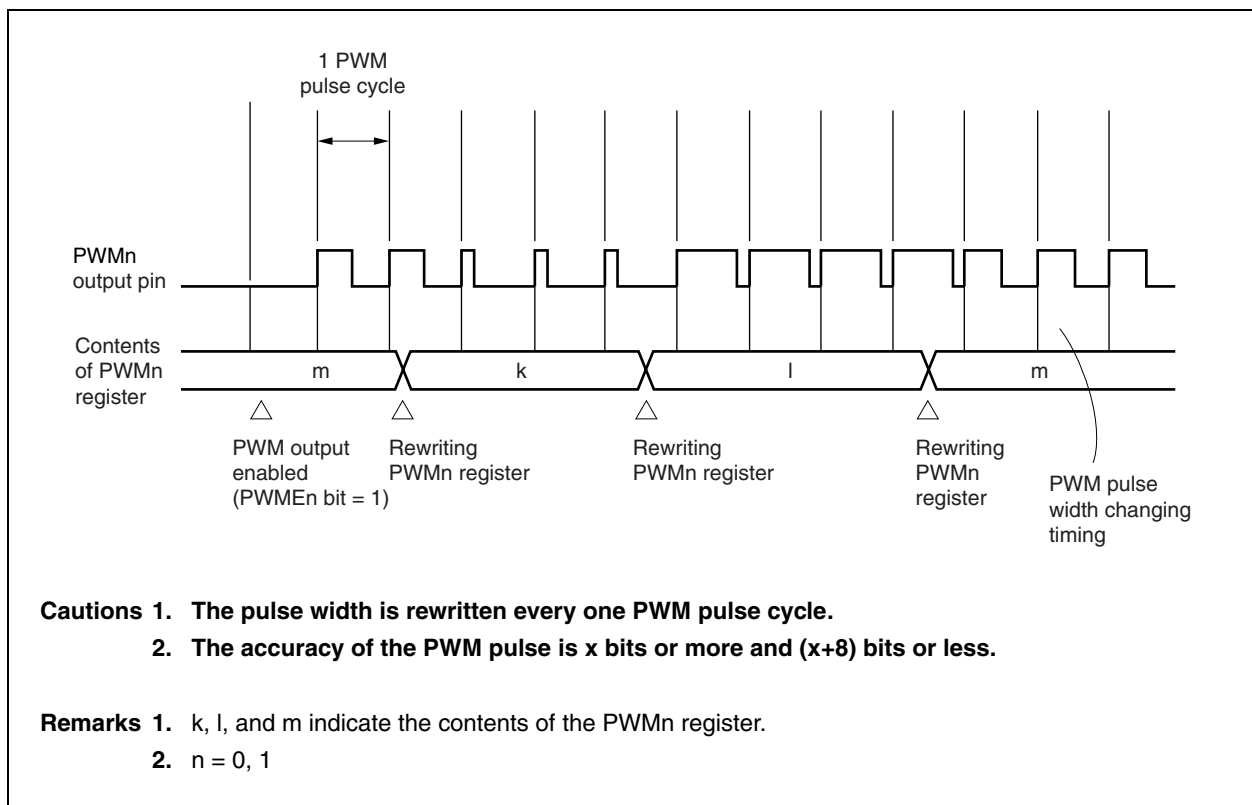

Figure 14-7. PWM Output Timing Example 2 (PWM Pulse Width Rewrite Period: $2^x/f_{PWMC}$)

14.4.5 Repeat cycle

The following table shows the repeat cycle of PWMn (n = 0, 1).

Table 14-1. Repeat Cycle of PWMn

Main Pulse Accuracy	Ancillary Pulse Accuracy	Repeat Cycle	Pulse Width Rewrite Period	
			Long Period (SYNn Bit = 0)	Short Period (SYNn Bit = 1)
4 bits	8 bits	$16/f_{PWMC}$	$2^{12}/f_{PWMC}$	$2^4/f_{PWMC}$
5 bits	8 bits	$32/f_{PWMC}$	$2^{13}/f_{PWMC}$	$2^5/f_{PWMC}$
6 bits	8 bits	$64/f_{PWMC}$	$2^{14}/f_{PWMC}$	$2^6/f_{PWMC}$
7 bits	8 bits	$128/f_{PWMC}$	$2^{15}/f_{PWMC}$	$2^7/f_{PWMC}$
8 bits	8 bits	$256/f_{PWMC}$	$2^{16}/f_{PWMC}$	$2^8/f_{PWMC}$

- Remarks**
1. n = 0, 1
 2. f_{PWMC} : PWM operating clock

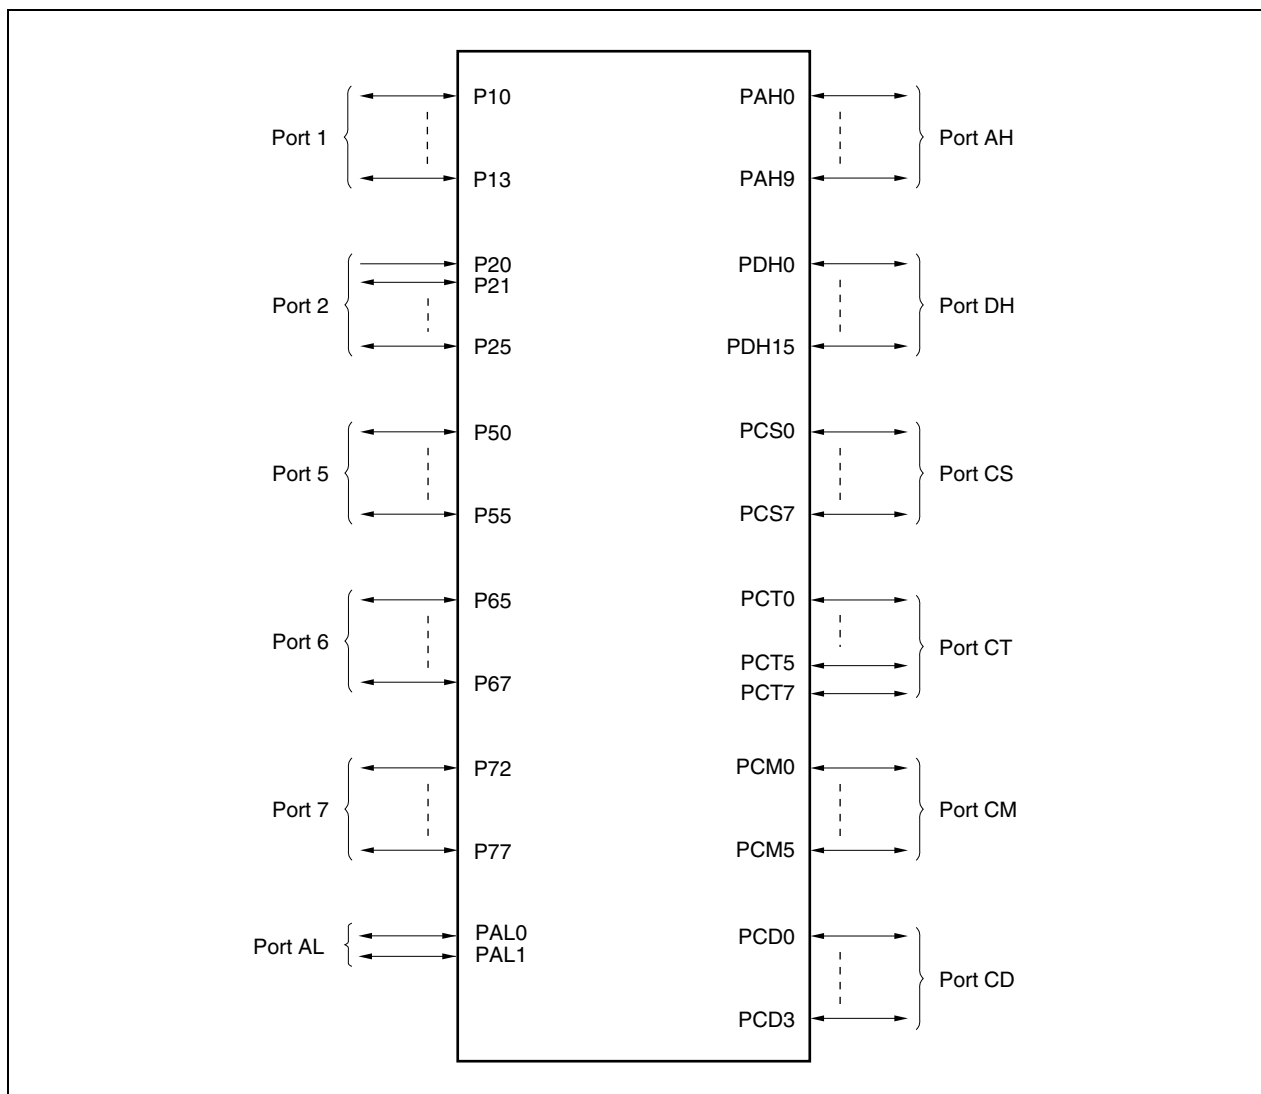

CHAPTER 15 PORT FUNCTIONS

15.1 Features

- Input-only ports: 1
I/O ports: 77
- Function alternately as other peripheral I/O pins.
- It is possible to specify input and output in 1-bit units.

15.2 Port Configuration

The V850E2/ME3 incorporates a total of 78 input/output ports (including 1 input-only port) labeled ports 1, 2, 5 to 7, AL, AH, DH, CS, CT, CM, and CD. The port configuration is shown below.

(1) Function of each port

The port functions of this product are shown below.

8-bit and 1-bit operations are possible on all ports, allowing various kinds of control to be performed. In addition to their port functions, these pins also function as on-chip peripheral I/O input/output pins in the control mode. For the block types of each port, see **(3) Block diagram of port**.

Port Name	Pin Name	Port Function	Function in Control Mode	Block Type
Port 1	P10 to P13	4-bit I/O	Serial interface I/O (CSI30, UARTB0) External interrupt input USB clock signal input	F-1, F-3, H-1, J-1
Port 2	P20 to P25	1-bit input, 5-bit I/O	NMI input Serial interface I/O (CSI31, UARTB1) External interrupt input	A-1, F-4, G-2, H-1
Port 5	P50 to P55	6-bit I/O	DMA controller I/O External interrupt input Timer/counter I/O	F-2, F-3, G-1, G-2, J-1
Port 6	P65 to P67	3-bit I/O	Timer/counter I/O External interrupt input	L-3, L-5
Port 7	P72 to P77	6-bit I/O	DMA controller I/O Timer/counter I/O External interrupt input	L-1, L-2, L-4
Port AL	PAL0, PAL1	2-bit I/O	External address bus (A0, A1) External interrupt input	G-3
Port AH	PAH0 to PAH9	10-bit input	External address bus (A16 to A25)	D-2
Port DH	PDH0 to PDH15	16-bit I/O	External data bus (D16 to D31) External interrupt input PWM output Timer/counter I/O	M-1, M-2, M-3
Port CS	PCS0 to PCS7	8-bit I/O	External bus interface control signal output	D-2, J-2
Port CT	PCT0 to PCT5, PCT7	7-bit I/O	External bus interface control signal output	D-2, J-3
Port CM	PCM0 to PCM5	6-bit I/O	Wait insertion signal input External bus interface control signal I/O Self-refresh request signal input A/D converter external trigger input	C-1, D-1, D-2, F-5
Port CD	PCD0 to PCD3	4-bit I/O	External bus interface control signal output Bus clock output	D-1, D-2

Cautions 1. When switching the mode of a port that functions as an output or I/O pin to control mode, be sure to follow the procedure below.

<1> Set the inactive level of the signals output in control mode to the appropriate bits in port n (n = 1, 2, 5 to 7, AL, AH, DH, CS, CT, CM, and CD).

<2> The mode is switched to control mode by the port n mode control register (PMCN).

If <1> above is not performed, the contents of port n may be output for a moment when the mode is switched from port mode to control mode.

2. To manipulate a port by using a bit manipulation instruction (SET1, CLR1, or NOT1), read the port in byte units, process the data of only the bit to be manipulated, and then write back the byte data to the port after conversion. In the case of a port having a mixture of input and output pins, the contents of the output latch are written over bits other than the bit to be manipulated. Consequently, the output latch of the input pin is undefined (in the input mode, however, the pin status does not change because the output buffer is turned off).

To change the port mode from the input to the output mode, therefore, set an expected output value to the corresponding bits, and then change the mode to the output mode. The same applies to a port that has both a control mode and an output mode.

(2) Function when each port's pins are reset and registers that set the port/control mode

15.3 Port Pin Functions

15.3.1 Port 1

Port 1 is a 4-bit I/O port that can be set to the input or output mode in 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
P1	0	0	0	0	P13	P12	P11	P10	1FFFF402H	Undefined

Bit position	Bit name	Function
3 to 0	P1n (n = 3 to 0)	I/O port

Remark For reading/writing of the I/O port, see **15.5 Operation of Port Function**.

In addition to their function as port pins, the port 1 pins can also operate as serial interface I/O (CSI30, UARTB0), USB clock signal input, and external interrupt request input in the control mode.

(1) Operation in control mode

Pin Name	Pin No.	Alternate Function	Remark	Block Type
P10	159	$\overline{\text{INTP10}}/\text{UCLK}$	External interrupt input/USB clock signal input	F-3
P11	155	$\overline{\text{INTP11}}/\text{SCK0}$	External interrupt request input/ serial interface (CSI30) I/O	H-1
P12	154	SI0/RXD0	Serial interface (CSI30) I/O/ serial interface (UARTB0) I/O	F-1
P13	153	SO0/TXD0		J-1

(2) I/O mode/control mode setting

The port 1 I/O mode setting is performed by the port 1 mode register (PM1), and the control mode setting is performed by the port 1 mode control register (PMC1) and port 1 function control register (PFC1).

(a) Port 1 mode register (PM1)

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PM1	1	1	1	1	PM13	PM12	PM11	PM10	1FFFF422H	FFH

Bit position	Bit name	Function
3 to 0	PM1n (n = 3 to 0)	Specifies input/output mode for P1n pin. 0: Output mode (output buffer on) 1: Input mode (output buffer off)

(b) Port 1 mode control register (PMC1)

This register can be read or written in 8-bit or 1-bit units.

Caution When using the USB function, connect UCLK by setting the PFC10 bit of the PFC1 register to 1 and then set the PMC10 bit of the PMC1 register to 1. When UCLK is not connected, do not access the USB-related registers.

	7	6	5	4	3	2	1	0	Address	After reset
PMC1	0	0	0	0	PMC13	PMC12	PMC11	PMC10	1FFFF442H	00H

Bit position	Bit name	Function
3	PMC13	Specifies operation mode of P13 pin in combination with the PFC1 register. 0: I/O port mode 1: SO0 output mode/TXD0 output mode
2	PMC12	Specifies operation mode of P12 pin in combination with the PFC1 register. 0: I/O port mode 1: SI0 input mode/RXD0 input mode
1	PMC11	Specifies operation mode of P11 pin in combination with the PFC1 register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTP11}}$) input mode/ $\overline{\text{SCK0}}$ I/O mode
0	PMC10	Specifies operation mode of P10 pin in combination with the PFC1 register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTP10}}$) input mode/UCLK input mode

(c) Port 1 function control register (PFC1)

This register can be read or written in 8-bit or 1-bit units.

- Cautions 1.** When the port mode is specified by the port 1 mode control register (PMC1), the setting of this register becomes invalid.
- 2.** When using the USB function, connect UCLK by setting the PFC10 bit of the PFC1 register to 1 and then set the PMC10 bit of the PMC1 register to 1. When UCLK is not connected, do not access the USB-related registers.

	7	6	5	4	3	2	1	0	Address	After reset
PFC1	0	0	0	0	PFC13	PFC12	PFC11	PFC10	1FFFF462H	00H

Bit position	Bit name	Function
3	PFC13	Specifies operation mode of P13 pin in control mode. 0: SO0 output mode 1: TXD0 output mode
2	PFC12	Specifies operation mode of P12 pin in control mode. 0: SI0 input mode 1: RXD0 input mode
1	PFC11	Specifies operation mode of P11 pin in control mode. 0: External interrupt request ($\overline{\text{INPT11}}$) input mode 1: SCK0 I/O mode
0	PFC10	Specifies operation mode of P10 pin in control mode. 0: External interrupt request ($\overline{\text{INPT10}}$) input mode 1: UCLK input mode

(3) Selecting interrupt trigger mode

The valid edges of the $\overline{\text{INTP10}}$ and $\overline{\text{INTP11}}$ pins can be selected by program. The levels to be detected can also be selected.

External interrupt rising edge specification register 1 (INTR1) and external interrupt falling edge specification register 1 (INTF1) are used to specify the valid edge and level detection.

(a) External interrupt rising edge specification register 1 (INTR1) and external interrupt falling edge specification register 1 (INTF1)

These registers are used to specify the trigger mode of the external interrupt requests (INTP10 and INTP11) from external pins.

The correspondence between each bit of this register and the external interrupt request controlled by that bit is as follows.

- INTF10 and INTR10 bits: INTP10
- INTF11 and INTR11 bits: INTP11

The valid edge can be independently selected from the rising edge, falling edge, and both rising and falling edges.

Both the registers can be read or written in 8-bit or 1-bit units.

Caution Set the PMC1 register before setting the trigger mode of the $\overline{\text{INTP10}}$ and $\overline{\text{INTP11}}$ pins. If the PMC1 register is set after the INTR1 and INTF1 registers have been set, an illegal interrupt may occur when the PMC1 register is set.

	7	6	5	4	3	2	1	0	Address	After reset
INTR1	0	0	0	0	0	0	INTR11	INTR10	1FFFFC22H	03H
INTF1	0	0	0	0	0	0	INTF11	INTF10	1FFFFC02H	00H

Bit position	Bit name	Function															
1, 0	INTF1n, INTR1n (n = 0, 1)	Specify trigger mode of $\overline{\text{INTP10}}$ and $\overline{\text{INTP11}}$ pins. <table border="1" style="margin-left: 20px;"> <thead> <tr> <th>INTF1n</th> <th>INTR1n</th> <th>Operation</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Falling edge</td> </tr> <tr> <td>0</td> <td>1</td> <td>Rising edge</td> </tr> <tr> <td>1</td> <td>0</td> <td>Level detection (low-level detection)^{Notes 1, 2}</td> </tr> <tr> <td>1</td> <td>1</td> <td>Both rising and falling edges</td> </tr> </tbody> </table>	INTF1n	INTR1n	Operation	0	0	Falling edge	0	1	Rising edge	1	0	Level detection (low-level detection) ^{Notes 1, 2}	1	1	Both rising and falling edges
INTF1n	INTR1n	Operation															
0	0	Falling edge															
0	1	Rising edge															
1	0	Level detection (low-level detection) ^{Notes 1, 2}															
1	1	Both rising and falling edges															

- Notes 1.** The level of the $\overline{\text{INTP1n}}$ pin is sampled each time the main clock (fx) is divided by four. When the low level of this pin is detected, an interrupt request is latched as the P1IFn bit (n = 0, 1). Consequently, even when the CPU acknowledges the interrupt and the P1IFn bit of the interrupt control register (P1ICn) is automatically cleared to 0, the P1IFn bit is immediately set to 1 and interrupts occur consecutively. To avoid this status, make the $\overline{\text{INTP1n}}$ pin of the external device inactive in the interrupt servicing routine, and forcibly clear the P1IFn bit to 0.
- 2.** If a level-detected interrupt request ($\overline{\text{INTP1n}}$) with a lower priority occurs while an interrupt is being serviced and if this level-detected interrupt request ($\overline{\text{INTP1n}}$) that has newly occurred becomes inactive before the current interrupt has been serviced, the interrupt request of the new interrupt ($\overline{\text{INTP1n}}$) is held pending (n = 0, 1). To not acknowledge the interrupt request of $\overline{\text{INTP1n}}$, clear the P1IFn bit of the interrupt control register.

15.3.2 Port 2

Port 2 is an I/O port that can be set to the input or output mode in 1-bit units except for P20, which is an input-only pin. P20 always functions as an NMI pin. By reading the P20 bit of the P2 register, the NMI pin level is read.

	7	6	5	4	3	2	1	0	Address	After reset
P2	0	0	P25	P24	P23	P22	P21	P20	1FFFF404H	Undefined

Bit position	Bit name	Function
5 to 0	P2n (n = 5 to 0)	I/O port

Remark For reading/writing of the I/O port, see 15.5 Operation of Port Function.

In addition to their function as port pins, the port 2 pins can also operate as the serial interface (CSI31, UARTB1) I/O and external interrupt request input in the control mode.

(1) Operation in control mode

Pin Name	Pin No.	Alternate Function	Remark	Block Type
P20	152	NMI	Non-maskable interrupt request input	A-1
P21	149	$\overline{\text{INTP21}}/\text{RXD1}$	External interrupt request input/ serial interface (UARTB1) I/O	F-4
P22	148	$\overline{\text{INTP22}}/\text{TXD1}$		G-2
P23	147	$\overline{\text{INTP23}}/\text{SCK1}$	External interrupt request input/ serial interface (CSI31) I/O	H-1
P24	146	$\overline{\text{INTP24}}/\text{SI1}$		F-4
P25	145	$\overline{\text{INTP25}}/\text{SO1}$		G-2

(2) I/O mode/control mode setting

The port 2 I/O mode setting is performed by the port 2 mode register (PM2), and the control mode setting is performed by the port 2 mode control register (PMC2) and the port 2 function control register (PFC2).

(a) Port 2 mode register (PM2)

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PM2	1	1	PM25	PM24	PM23	PM22	PM21	1	1FFFF424H	FFH

Bit position	Bit name	Function
5 to 1	PM2n (n = 5 to 1)	Specifies input/output mode for P2n pin. 0: Output mode (output buffer on) 1: Input mode (output buffer off)

(b) Port 2 mode control register (PMC2)

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PMC2	0	0	PMC25	PMC24	PMC23	PMC22	PMC21	1	1FFFF444H	01H

Bit position	Bit name	Function
5	PMC25	Specifies operation mode of P25 pin in combination with the PFC2 register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTP25}}$) input mode/SO1 output mode
4	PMC24	Specifies operation mode of P24 pin in combination with the PFC2 register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTP24}}$) input mode/SI1 input mode
3	PMC23	Specifies operation mode of P23 pin in combination with the PFC2 register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTP23}}$) input mode/ $\overline{\text{SCK1}}$ I/O mode
2	PMC22	Specifies operation mode of P22 pin in combination with the PFC2 register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTP22}}$) input mode/TXD1 output mode
1	PMC21	Specifies operation mode of P21 pin in combination with the PFC2 register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTP21}}$) input mode/RXD1 input mode

(c) Port 2 function control register (PFC2)

This register can be read or written in 8-bit or 1-bit units.

Caution When the port mode is specified by the port 2 mode control register (PMC2), the PFC2 setting becomes invalid.

	7	6	5	4	3	2	1	0	Address	After reset
PFC2	0	0	PFC25	PFC24	PFC23	PFC22	PFC21	0	1FFFF464H	00H

Bit position	Bit name	Function
5	PFC25	Specifies operation mode of P25 pin in control mode. 0: External interrupt request ($\overline{\text{INTP25}}$) input mode 1: SO1 output mode
4	PFC24	Specifies operation mode of P24 pin in control mode. 0: External interrupt request ($\overline{\text{INTP24}}$) input mode 1: SI1 input mode
3	PFC23	Specifies operation mode of P23 pin in control mode. 0: External interrupt request ($\overline{\text{INTP23}}$) input mode 1: $\overline{\text{SCK1}}$ I/O mode
2	PFC22	Specifies operation mode of P22 pin in control mode. 0: External interrupt request ($\overline{\text{INTP22}}$) input mode 1: TXD1 output mode
1	PFC21	Specifies operation mode of P21 pin in control mode. 0: External interrupt request ($\overline{\text{INTP21}}$) input mode 1: RXD1 input mode

(3) Selecting interrupt trigger mode

The valid edges of the $\overline{\text{INTP2n}}$ and NMI pins can be selected by program (n = 1 to 5). The level detection of the $\overline{\text{INTP2n}}$ pin can also be selected.

External interrupt rising edge specification register 2 (INTR2) and external interrupt falling edge specification register 2 (INTF2) are used to specify the valid edge and level detection.

(a) External interrupt rising edge specification register 2 (INTR2) and external interrupt falling edge specification register 2 (INTF2)

These registers are used to specify the trigger mode of an external interrupt request (INTP2n) from an external pin and the non-maskable interrupt (NMI) (n = 1 to 5). The correspondence between each bit of this register and the external interrupt request and non-maskable interrupt controlled by that bit is as follows.

- NMIF0 and NMIR0 bits: NMI
- INTF21 and INTR21 bits: INTP21
- INTF22 and INTR22 bits: INTP22
- INTF23 and INTR23 bits: INTP23
- INTF24 and INTR24 bits: INTP24
- INTF25 and INTR25 bits: INTP25

The rising edge, falling edge, or both the rising and falling edges can be specified as the valid edge of the $\overline{\text{INTP2n}}$ pin and the rising or falling edge can be specified as the valid edge of the NMI pin, independently for each pin.

Both the registers can be read or written in 8-bit or 1-bit units.

Caution Set the PMC2 register before setting the trigger mode of the $\overline{\text{INTP2n}}$ pin (n = 1 to 5).
If the PMC2 register is set after the INTR2 and INTF2 registers have been set, an illegal interrupt may occur when the PMC2 register is set.

	7	6	5	4	3	2	1	0	Address	After reset
INTR2	0	0	INTR25	INTR24	INTR23	INTR22	INTR21	NMIR0	1FFFFC24H	3FH
INTF2	0	0	INTF25	INTF24	INTF23	INTF22	INTF21	NMIF0	1FFFFC04H	00H

Bit position	Bit name	Function															
5 to 1	INTF2n, INTR2n (n = 1 to 5)	Specify trigger mode of $\overline{\text{INTP2n}}$ pin. <table border="1"> <thead> <tr> <th>INTF2n</th> <th>INTR2n</th> <th>Operation</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Falling edge</td> </tr> <tr> <td>0</td> <td>1</td> <td>Rising edge</td> </tr> <tr> <td>1</td> <td>0</td> <td>Level detection (low-level detection)^{Notes 1, 2}</td> </tr> <tr> <td>1</td> <td>1</td> <td>Both rising and falling edges</td> </tr> </tbody> </table>	INTF2n	INTR2n	Operation	0	0	Falling edge	0	1	Rising edge	1	0	Level detection (low-level detection) ^{Notes 1, 2}	1	1	Both rising and falling edges
INTF2n	INTR2n	Operation															
0	0	Falling edge															
0	1	Rising edge															
1	0	Level detection (low-level detection) ^{Notes 1, 2}															
1	1	Both rising and falling edges															
0	NMIF0, NMIR0	Specify trigger mode of NMI pin. <table border="1"> <thead> <tr> <th>NMIF0</th> <th>NMIR0</th> <th>Operation</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Falling edge</td> </tr> <tr> <td>0</td> <td>1</td> <td>Rising edge</td> </tr> <tr> <td>1</td> <td>0</td> <td>Setting prohibited</td> </tr> <tr> <td>1</td> <td>1</td> <td>Both rising and falling edges</td> </tr> </tbody> </table>	NMIF0	NMIR0	Operation	0	0	Falling edge	0	1	Rising edge	1	0	Setting prohibited	1	1	Both rising and falling edges
NMIF0	NMIR0	Operation															
0	0	Falling edge															
0	1	Rising edge															
1	0	Setting prohibited															
1	1	Both rising and falling edges															

- Notes 1.** The level of the $\overline{\text{INTP2n}}$ pin is sampled each time the main clock (fx) is divided by four. When the low level of this pin is detected, an interrupt request is latched as the P2IFn bit (n = 1 to 5). Consequently, even when the CPU acknowledges the interrupt and the P2IFn bit of the interrupt control register (P2ICn) is automatically cleared to 0, the P2IFn bit is immediately set to 1 and interrupts occur consecutively. To avoid this status, make the $\overline{\text{INTP2n}}$ pin of the external device inactive in the interrupt servicing routine, and forcibly clear the P2IFn bit to 0.
- 2.** If a level-detected interrupt request ($\overline{\text{INTP2n}}$) with a lower priority occurs while an interrupt is being serviced and if this level-detected interrupt request ($\overline{\text{INTP2n}}$) that has newly occurred becomes inactive before the current interrupt has been serviced, the interrupt request of the new interrupt ($\overline{\text{INTP2n}}$) is held pending (n = 1 to 5). To not acknowledge the interrupt request of $\overline{\text{INTP2n}}$, clear the P2IFn bit of the interrupt control register.

15.3.3 Port 5

Port 5 is a 6-bit I/O port that can be set to the input or output mode in 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
P5	0	0	P55	P54	P53	P52	P51	P50	1FFFF40AH	Undefined

Bit position	Bit name	Function
5 to 0	P5n (n = 5 to 0)	I/O port

Remark For reading/writing of the I/O port, see **15.5 Operation of Port Function**.

In addition to their function as port pins, the port 5 pins can also operate as the DMA controller I/O, timer/counter I/O, and external interrupt request input in the control mode.

(1) Operation in control mode

Pin Name	Pin No.	Alternate Function	Remark	Block Type
P50	25	$\overline{\text{INTP50}}/\overline{\text{DMARQ0}}$	External interrupt request input/DMA request input	F-3
P51	24	$\overline{\text{INTP51}}/\overline{\text{DMAAK0}}$	External interrupt request input/ DMA acknowledge signal output	G-2
P52	23	$\overline{\text{INTP52}}/\overline{\text{TC0}}$	External interrupt request input/DMA end signal output	
P53	22	$\overline{\text{INTPC00}}/\overline{\text{TIC0}}/\overline{\text{DMARQ1}}$	External interrupt request and timer C0 external capture trigger input/ timer/counter input/ DMA request input	F-2
P54	21	$\overline{\text{INTPC01}}/\overline{\text{DMAAK1}}$	External interrupt request and timer C0 external capture trigger input/DMA acknowledge signal output	G-1
P55	20	$\overline{\text{TOC0}}/\overline{\text{TC1}}$	Timer/counter output/DMA end signal output	J-1

(2) I/O mode/control mode setting

The port 5 I/O mode setting is performed by the port 5 mode register (PM5), and the control mode setting is performed by the port 5 mode control register (PMC5) and port 5 function control register (PFC5).

(a) Port 5 mode register (PM5)

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PM5	1	1	PM55	PM54	PM53	PM52	PM51	PM50	1FFFF42AH	FFH

Bit position	Bit name	Function
5 to 0	PM5n (n = 5 to 0)	Specifies input/output mode for P5n pin. 0: Output mode (output buffer on) 1: Input mode (output buffer off)

(b) Port 5 mode control register (PMC5)

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PMC5	0	0	PMC55	PMC54	PMC53	PMC52	PMC51	PMC50	1FFFF44AH	00H

Bit position	Bit name	Function
5	PMC55	Specifies operation mode of P55 pin in combination with the PFC5 register. 0: I/O port mode 1: TOC0 output mode/DMA end signal ($\overline{TC1}$) output mode
4	PMC54	Specifies operation mode of P54 pin in combination with the PFC5 register. 0: I/O port mode 1: External interrupt request and timer C0 external capture trigger (INTPC01) input mode/DMA acknowledge signal ($\overline{DMAAK1}$) output mode
3	PMC53	Specifies operation mode of P53 pin in combination with the PFC5 register. 0: I/O port mode 1: External interrupt request and timer C0 external capture trigger (INTPC00) input mode/TIC0 input mode/DMA request ($\overline{DMARQ1}$) input mode
2	PMC52	Specifies operation mode of P52 pin in combination with the PFC5 register. 0: I/O port mode 1: External interrupt request ($\overline{INTP52}$) input mode/DMA end signal ($\overline{TC0}$) output mode
1	PMC51	Specifies operation mode of P51 pin in combination with the PFC5 register. 0: I/O port mode 1: External interrupt request ($\overline{INTP51}$) input mode/DMA acknowledge signal ($\overline{DMAAK0}$) output mode
0	PMC50	Specifies operation mode of P50 pin in combination with the PFC5 register. 0: I/O port mode 1: External interrupt request ($\overline{INTP50}$) input mode/DMA request ($\overline{DMARQ0}$) input mode

(c) Port 5 function control register (PFC5)

This register can be read or written in 8-bit or 1-bit units.

Caution When the port mode is specified by the port 5 mode control register (PMC5), the setting of this register becomes invalid.

	7	6	5	4	3	2	1	0	Address	After reset
PFC5	0	0	PFC55	PFC54	PFC53	PFC52	PFC51	PFC50	1FFFF46AH	00H

Bit position	Bit name	Function
5	PFC55	Specifies operation mode of P55 pin in control mode. 0: TOC0 output mode 1: DMA end signal ($\overline{TC1}$) output mode
4	PFC54	Specifies operation mode of P54 pin in control mode. 0: External interrupt request and timer C0 external capture trigger (INTPC01) input mode 1: DMA acknowledge signal ($\overline{DMAAK1}$) output
3	PFC53	Specifies operation mode of P53 pin in control mode. 0: External interrupt request and timer C0 external capture trigger (INTPC01) input mode/TIC0 input mode 1: DMA request ($\overline{DMARQ1}$) input mode There is no register that selects an external interrupt request and timer C0 external capture trigger (INTPC00) input mode or TIC0 input mode. <ul style="list-style-type: none"> To use TIC0 input mode: Mask the external interrupt request and external capture trigger (INTPC00) of timer C0, or use the CCC00 register as a compare register. To use external interrupt request and external capture trigger (INTPC00) of timer C0: Clear the ETIC0 bit of the TMCC01 register to 0.
2	PFC52	Specifies operation mode of P52 pin. 0: External interrupt request ($\overline{INTP52}$) input mode 1: DMA end signal ($\overline{TC0}$) output mode
1	PFC51	Specifies operation mode of P51 pin. 0: External interrupt request ($\overline{INTP51}$) input mode 1: DMA acknowledge signal ($\overline{DMAAK0}$) output
0	PFC50	Specifies operation mode of P50 pin in control mode. 0: External interrupt request ($\overline{INTP50}$) input mode 1: DMA request ($\overline{DMARQ0}$) input mode

(3) Selecting interrupt trigger mode

The valid edges of the $\overline{\text{INTP5n}}$ pin can be selected by program ($n = 0$ to 2). The level detection of the $\overline{\text{INTP5n}}$ pin can also be selected.

External interrupt rising edge specification register 5 (INTR5) and external interrupt falling edge specification register 5 (INTF5) are used to specify the valid edge and level detection.

(a) External interrupt rising edge specification register 5 (INTR5) and external interrupt falling edge specification register 5 (INTF5)

These registers are used to specify the trigger mode of an external interrupt request (INTP5n) from an external pin ($n = 0$ to 2). The correspondence between each bit of this register and the external interrupt request controlled by that bit is as follows.

- INTF50 and INTR50 bits: INTP50
- INTF51 and INTR51 bits: INTP51
- INTF52 and INTR52 bits: INTP52

The rising edge, falling edge, or both the rising and falling edges can be specified as the valid edge of the $\overline{\text{INTP5n}}$ pin, independently for each pin.

Both the registers can be read or written in 8-bit or 1-bit units.

Caution Set the PMC5 register before setting the trigger mode.

If the PMC5 register is set after the INTR5 and INTF5 registers have been set, an illegal interrupt may occur when the PMC5 register is set.

	7	6	5	4	3	2	1	0	Address	After reset
INTR5	0	0	0	0	0	INTR52	INTR51	INTR50	1FFFFC2AH	07H
INTF5	0	0	0	0	0	INTF52	INTF51	INTF50	1FFFFC0AH	00H

Bit position	Bit name	Function															
2 to 0	INTF5n, INTR5n (n = 0 to 2)	Specify trigger mode of $\overline{\text{INTP5n}}$ pin. <table border="1"> <thead> <tr> <th>INTF5n</th> <th>INTR5n</th> <th>Operation</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Falling edge</td> </tr> <tr> <td>0</td> <td>1</td> <td>Rising edge</td> </tr> <tr> <td>1</td> <td>0</td> <td>Level detection (low-level detection)^{Notes 1, 2}</td> </tr> <tr> <td>1</td> <td>1</td> <td>Both rising and falling edges</td> </tr> </tbody> </table>	INTF5n	INTR5n	Operation	0	0	Falling edge	0	1	Rising edge	1	0	Level detection (low-level detection) ^{Notes 1, 2}	1	1	Both rising and falling edges
INTF5n	INTR5n	Operation															
0	0	Falling edge															
0	1	Rising edge															
1	0	Level detection (low-level detection) ^{Notes 1, 2}															
1	1	Both rising and falling edges															

- Notes 1.** The level of the $\overline{\text{INTP5n}}$ pin is sampled each time the main clock (fx) is divided by four. When the low level of this pin is detected, an interrupt request is latched as the P5IFn bit (n = 0 to 2). Consequently, even when the CPU acknowledges the interrupt and the P5IFn bit of the interrupt control register (P5ICn) is automatically cleared to 0, the P5IFn bit is immediately set to 1 and interrupts occur consecutively. To avoid this status, make the $\overline{\text{INTP5n}}$ pin of the external device inactive in the interrupt servicing routine, and forcibly clear the P5IFn bit to 0.
- 2.** If a level-detected interrupt request ($\overline{\text{INTP5n}}$) with a lower priority occurs while an interrupt is being serviced and if this level-detected interrupt request ($\overline{\text{INTP5n}}$) that has newly occurred becomes inactive before the current interrupt has been serviced, the interrupt request of the new interrupt ($\overline{\text{INTP5n}}$) is held pending (n = 0 to 2). To not acknowledge the interrupt request of $\overline{\text{INTP5n}}$, clear the P5IFn bit of the interrupt control register.

15.3.4 Port 6

Port 6 is a 3-bit I/O port that can be set to the input or output mode in 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
P6	P67	P66	P65	0	0	0	0	0	1FFFF40CH	Undefined

Bit position	Bit name	Function
7 to 5	P6n (n = 7 to 5)	I/O port

Remark For reading/writing of the I/O port, see **15.5 Operation of Port Function**.

In addition to their function as port pins, the port 6 pins can also operate as the timer/counter I/O and external interrupt request input in the control mode.

(1) Operation in control mode

Pin Name	Pin No.	Alternate Function	Remark	Block Type
P65	19	$\overline{\text{INTP65}}/\text{INTPC10}/\text{TIC1}$	External interrupt request and timer C1 external capture trigger input/ timer/counter input	L-5
P66	18	$\overline{\text{INTP66}}/\text{INTPC11}$	External interrupt request and timer C1 external capture trigger input	
P67	17	$\overline{\text{INTP67}}/\text{TOC1}$	External interrupt request input or timer/counter output	L-3

(2) I/O mode/control mode setting

The port 6 I/O mode setting is performed by the port 6 mode register (PM6), and the control mode setting is performed by the port 6 mode control register (PMC6) and port 6 function control register (PFC6).

(a) Port 6 mode register (PM6)

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PM6	PM67	PM66	PM65	1	1	1	1	1	1FFFF42CH	FFH

Bit position	Bit name	Function
7 to 5	PM6n (n = 7 to 5)	Specifies input/output mode for P6n pin. 0: Output mode (output buffer on) 1: Input mode (output buffer off)

(b) Port 6 mode control register (PMC6)

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PMC6	PMC67	PMC66	PMC65	0	0	0	0	0	1FFFF44CH	00H

Bit position	Bit name	Function
7	PMC67	Specifies operation mode of P67 pin. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTP67}}$) input mode/TOC1 output mode
6	PMC66	Specifies operation mode of P66 pin. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTP66}}$) input mode/external interrupt request and timer C1 external capture trigger (INTPC11) input mode
5	PMC65	Specifies operation mode of P65 pin. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTP65}}$) input mode/external interrupt request and timer C1 external capture trigger (INTPC10) input mode/TIC1 input mode

(c) Port 6 function control register (PFC6)

This register can be read or written in 8-bit or 1-bit units.

Caution When the port mode is specified by the port 6 mode control register (PMC6), the setting of this register becomes invalid.

	7	6	5	4	3	2	1	0	Address	After reset
PFC6	PFC67	PFC66	PFC65	0	0	0	0	0	1FFFF46CH	00H

Bit position	Bit name	Function
7	PFC67	Specifies operation mode of P67 pin in control mode. 0: External interrupt request (INTP67) input mode 1: TOC1 output mode
6	PFC66	Specifies operation mode of P66 pin in control mode. 0: External interrupt request ($\overline{\text{INTP66}}$) input mode 1: External interrupt request and timer C1 external capture trigger (INTPC11) input mode
5	PFC65	Specifies operation mode of P65 pin in control mode. 0: External interrupt request (INTP65) input mode 1: External interrupt request and timer C1 external capture trigger (INTPC10) input mode/TIC1 input mode There is no register that selects an external interrupt request and timer C1 external capture trigger (INTPC10) input mode or TIC1 input mode. <ul style="list-style-type: none"> To use TIC1 input mode: Mask the external interrupt request and external capture trigger (INTPC10) of timer C1, or use the CCC10 register as a compare register. To use external interrupt request and external capture trigger (INTPC10) of timer C1: Clear the ETIC1 bit of the TMCC11 register to 0.

(3) Selecting interrupt trigger mode

The valid edges of the $\overline{\text{INTP6n}}$ pin can be selected by program ($n = 5$ to 7). The level detection of the $\overline{\text{INTP6n}}$ pin can also be selected.

External interrupt rising edge specification register 6 (INTR6) and external interrupt falling edge specification register 6 (INTF6) are used to specify the valid edge and level detection.

(a) External interrupt rising edge specification register 6 (INTR6) and external interrupt falling edge specification register 6 (INTF6)

These registers are used to specify the trigger mode of an external interrupt request (INTP6n) from an external pin ($n = 5$ to 7). The correspondence between each bit of this register and the external interrupt request controlled by that bit is as follows.

- INTF65 and INTR65 bits: INTP65
- INTF66 and INTR66 bits: INTP66
- INTF67 and INTR67 bits: INTP67

The rising edge, falling edge, or both the rising and falling edges can be specified as the valid edge of the $\overline{\text{INTP6n}}$ pin, independently for each pin.

Both the registers can be read or written in 8-bit or 1-bit units.

Caution Set the PMC6 register before setting the trigger mode.

If the PMC6 register is set after the INTR6 and INTF6 registers have been set, an illegal interrupt may occur when the PMC6 register is set.

	7	6	5	4	3	2	1	0	Address	After reset
INTR6	INTR67	INTR66	INTR65	0	0	0	0	0	1FFFFC2CH	E0H
INTF6	INTF67	INTF66	INTF65	0	0	0	0	0	1FFFFC0CH	00H

Bit position	Bit name	Function															
7 to 5	INTF6n, INTR6n (n = 7 to 5)	Specify trigger mode of $\overline{\text{INTP6n}}$ pin. <table border="1" style="margin-left: 20px;"> <thead> <tr> <th>INTF6n</th> <th>INTR6n</th> <th>Operation</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Falling edge</td> </tr> <tr> <td>0</td> <td>1</td> <td>Rising edge</td> </tr> <tr> <td>1</td> <td>0</td> <td>Level detection (low-level detection)^{Notes 1, 2}</td> </tr> <tr> <td>1</td> <td>1</td> <td>Both rising and falling edges</td> </tr> </tbody> </table>	INTF6n	INTR6n	Operation	0	0	Falling edge	0	1	Rising edge	1	0	Level detection (low-level detection) ^{Notes 1, 2}	1	1	Both rising and falling edges
INTF6n	INTR6n	Operation															
0	0	Falling edge															
0	1	Rising edge															
1	0	Level detection (low-level detection) ^{Notes 1, 2}															
1	1	Both rising and falling edges															

- Notes 1.** The level of the $\overline{\text{INTP6n}}$ pin is sampled each time the main clock (fx) is divided by four. When the low level of this pin is detected, an interrupt request is latched as the P6IFn bit (n = 5 to 7). Consequently, even when the CPU acknowledges the interrupt and the P6IFn bit of the interrupt control register (P6ICn) is automatically cleared to 0, the P6IFn bit is immediately set to 1 and interrupts occur consecutively. To avoid this status, make the $\overline{\text{INTP6n}}$ pin of the external device inactive in the interrupt servicing routine, and forcibly clear the P6IFn bit to 0.
- 2.** If a level-detected interrupt request ($\overline{\text{INTP6n}}$) with a lower priority occurs while an interrupt is being serviced and if this level-detected interrupt request ($\overline{\text{INTP6n}}$) that has newly occurred becomes inactive before the current interrupt has been serviced, the interrupt request of the new interrupt ($\overline{\text{INTP6n}}$) is held pending (n = 5 to 7). To not acknowledge the interrupt request of $\overline{\text{INTP6n}}$, clear the P6IFn bit of the interrupt control register.

15.3.5 Port 7

Port 7 is a 6-bit I/O port that can be set to the input or output mode in 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
P7	P77	P76	P75	P74	P73	P72	0	0	1FFFF40EH	Undefined

Bit position	Bit name	Function
7 to 2	P7n (n = 7 to 2)	I/O port

Remark For reading/writing of the I/O port, see **15.5 Operation of Port Function**.

In addition to their function as port pins, the port 7 pins can also operate as the DMA controller I/O, timer/counter I/O, and external interrupt request input in the control mode.

(1) Operation in control mode

Pin Name	Pin No.	Alternate Function	Remark	Block Type
P72	176	INTPC20/TIC2/ DMARQ2	External interrupt request and timer C2 external capture trigger input/ timer/counter input/ DMA request input	L-4
P73	175	INTPC21/DMAAK2	External interrupt request and timer C2 external capture trigger input/DMA acknowledge signal output	L-2
P74	174	TOC2/TC2	Timer/counter output/DMA end signal output	L-1
P75	173	INTPC30/TIC3/ DMARQ3	External interrupt request and timer C3 external capture trigger input/ timer/counter input/ DMA request input	L-4
P76	172	INTPC31/DMAAK3	External interrupt request and timer C3 external capture trigger input/DMA acknowledge signal output	L-2
P77	171	TOC3/TC3	Timer/counter output/DMA end signal output	L-1

(2) I/O mode/control mode setting

The port 7 I/O mode setting is performed by the port 7 mode register (PM7), and the control mode setting is performed by the port 7 mode control register (PMC7) and port 7 function control register (PFC7).

(a) Port 7 mode register (PM7)

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PM7	PM77	PM76	PM75	PM74	PM73	PM72	1	1	1FFFF42EH	FFH

Bit position	Bit name	Function
7 to 2	PM7n (n = 7 to 2)	Specifies input/output mode for P7n pin. 0: Output mode (output buffer on) 1: Input mode (output buffer off)

(b) Port 7 mode control register (PMC7)

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PMC7	PMC77	PMC76	PMC75	PMC74	PMC73	PMC72	0	0	1FFFF44EH	00H

Bit position	Bit name	Function
7	PMC77	Specifies operation mode of P77 pin in combination with the PFC7 register. 0: I/O port mode 1: TOC3 output mode/DMA end signal ($\overline{TC3}$) output mode
6	PMC76	Specifies operation mode of P76 pin in combination with the PFC7 register. 0: I/O port mode 1: External interrupt request and time C3 external capture trigger (INTPC31) input mode/DMA acknowledge signal ($\overline{DMAAK3}$) output mode
5	PMC75	Specifies operation mode of P75 pin in combination with the PFC7 register. 0: I/O port mode 1: External interrupt request and timer C3 external capture trigger (INTPC30) input mode/TIC3 input mode/DMA request ($\overline{DMARQ3}$) input mode
4	PMC74	Specifies operation mode of P74 pin in combination with the PFC7 register. 0: I/O port mode 1: TOC2 output mode/DMA end signal ($\overline{TC2}$) output mode
3	PMC73	Specifies operation mode of P73 pin in combination with the PFC7 register. 0: I/O port mode 1: External interrupt request and time C2 external capture trigger (INTPC21) input mode/DMA acknowledge signal ($\overline{DMAAK2}$) output mode
2	PMC72	Specifies operation mode of P72 pin in combination with the PFC7 register. 0: I/O port mode 1: External interrupt request and timer C2 external capture trigger (INTPC20) input mode/TIC2 input mode/DMA request ($\overline{DMARQ2}$) input mode

(c) Port 7 function control register (PFC7)

This register can be read or written in 8-bit or 1-bit units.

Caution When the port mode is specified by the port 7 mode control register (PMC7), the setting of this register becomes invalid.

	7	6	5	4	3	2	1	0	Address	After reset
PFC7	PFC77	PFC76	PFC75	PFC74	PFC73	PFC72	0	0	1FFFF46EH	00H

Bit position	Bit name	Function
7	PFC77	Specifies operation mode of P77 pin in control mode. 0: TOC3 output mode 1: DMA end signal ($\overline{TC3}$) output mode
6	PFC76	Specifies operation mode of P76 pin in control mode. 0: External interrupt request and timer C3 external capture trigger (INTPC31) input mode 1: DMA acknowledge signal ($\overline{DMAAK3}$) output
5	PFC75	Specifies operation mode of P75 pin in control mode. 0: External interrupt request and timer C3 external capture trigger (INTPC30) input mode/TIC3 input mode 1: DMA request ($\overline{DMARQ3}$) input mode There is no register that selects an external interrupt request and timer C3 external capture trigger (INTPC30) input mode or TIC3 input mode. <ul style="list-style-type: none"> To use TIC3 input mode: Mask the external interrupt request and external capture trigger (INTPC30) of timer C3, or use the CCC30 register as a compare register. To use external interrupt request and external capture trigger (INTPC30) of timer C3: Clear the ETIC3 bit of the TMCC31 register to 0.
4	PFC74	Specifies operation mode of P74 pin. 0: TOC2 output mode 1: DMA end signal ($\overline{TC2}$) output mode
3	PFC73	Specifies operation mode of P73 pin. 0: External interrupt request and timer C2 external capture trigger (INTPC21) input mode 1: DMA acknowledge signal ($\overline{DMAAK2}$) output
2	PFC72	Specifies operation mode of P72 pin in control mode. 0: External interrupt request and timer C2 external capture trigger (INTPC20) input mode/TIC2 input mode 1: DMA request ($\overline{DMARQ2}$) input mode There is no register that selects an external interrupt request and timer C2 external capture trigger (INTPC20) input mode or TIC2 input mode. <ul style="list-style-type: none"> To use TIC2 input mode: Mask the external interrupt request and external capture trigger (INTPC20) of timer C2, or use the CCC20 register as a compare register. To use external interrupt request and external capture trigger (INTPC20) of timer C2: Clear the ETIC2 bit of the TMCC21 register to 0.

15.3.6 Port AL

Port AL (PAL) is a 16-bit I/O port that can be set to the input or output mode in 1-bit units.

When the higher 8 bits of port AL are used as port ALH (PALH) and the lower 8 bits as port ALL (PALL), port AL becomes two 8-bit ports that can be set in the input or output mode in 1-bit units.

	15	14	13	12	11	10	9	8	Address	After reset
PAL	0	0	0	0	0	0	0	0	1FFFF001H	Undefined
	7	6	5	4	3	2	1	0	Address	
	0	0	0	0	0	0	PAL1	PAL0	1FFFF000H	

Bit position	Bit name	Function
1, 0	PALn (n = 1, 0)	I/O port

Remark For reading/writing of the I/O port, see 15.5 Operation of Port Function.

In addition to their functions as port pins, in the control mode, the port AL pins operate as an address bus for when the memory is externally expanded and external interrupt request input.

(1) Operation in control mode

Pin Name	Pin No.	Alternate Function	Remark	Block Type
PAL0	76	$\overline{\text{INTPL0}}/\text{A0}$	Address bus when memory expanded/ external interrupt request input	G-3
PAL1	75	$\overline{\text{INTPL1}}/\text{A1}$		

(2) I/O mode/control mode setting

The port AL I/O mode setting is performed by the port AL mode register (PMAL), and control mode setting is performed by port AL mode control register L (PMCALL) and the port AL function control register (PFCAL).

(a) Port AL mode register (PMAL)

The port AL mode register (PMAL) can be read or written in 16-bit units.

When using the higher 8 bits of PMAL as port AL mode register H (PMALH) and the lower 8 bits as port AL mode register L (PMALL), the PMALH register is read-only, in 8-bit or 1-bit units, and the PMALL register can be read or written in 8-bit or 1-bit units.

	15	14	13	12	11	10	9	8	Address	After reset
PMAL	1	1	1	1	1	1	1	1	1FFFF021H	FFFFH
	7	6	5	4	3	2	1	0	Address	
	1	1	1	1	1	1	PMAL1	PMAL0	1FFFF020H	

Bit position	Bit name	Function
1, 0	PMALn (n = 1, 0)	Specifies input/output mode for PALn pin. 0: Output mode (output buffer on) 1: Input mode (output buffer off)

(b) Port AL mode control register (PMCAL)

The port AL mode control register (PMCAL) can be read or written in 16-bit units.

When using the higher 8 bits of PMCAL as port AL mode control register H (PMCALH) and the lower 8 bits as port AL mode control register L (PMCALL), the PMCALH register is read-only, in 8-bit or 1-bit units, and the PMCALL register can be read or written in 8-bit or 1-bit units.

	15	14	13	12	11	10	9	8	Address	After reset
PMCAL	0	0	0	0	0	0	0	0	1FFFF041H	0002H
	7	6	5	4	3	2	1	0	Address	
	0	0	0	0	0	0	PMCAL1	PMCAL0	1FFFF040H	

Bit position	Bit name	Function
1	PMCAL1	Specifies operation mode of PAL1 pin. 0: I/O port mode 1: $\overline{\text{INTPL1}}$ input mode/A1 output mode
0	PMCAL0	Specifies operation mode of PAL0 pin. 0: I/O port mode 1: $\overline{\text{INTPL0}}$ input mode/A0 output mode

(c) Port AL function control register L (PFCALL)

This register can be read or written in 8-bit or 1-bit units.

Caution When the port mode is specified by the port AL mode control register (PMCAL), the setting of this register becomes invalid.

	7	6	5	4	3	2	1	0	Address	After reset
PFCALL	0	0	0	0	0	0	PFCAL1	PFCAL0	1FFFF058H	03H

Bit position	Bit name	Function
1	PFCAL1	Specifies operation mode of PAL1 pin in control mode. 0: External interrupt request (INTPL1) input mode 1: A1 output mode
0	PFCAL0	Specifies operation mode of PAL0 pin in control mode. 0: External interrupt request (INTPL0) input mode 1: A0 output mode

(3) Selecting interrupt trigger mode

The valid edges of the $\overline{\text{INTPLn}}$ pin can be selected by program ($n = 0, 1$). The level detection of the $\overline{\text{INTPLn}}$ pin can also be selected.

External interrupt rising edge specification register AL (INTRAL) and external interrupt falling edge specification register AL (INTFAL) are used to specify the valid edge and level detection.

(a) External interrupt rising edge specification register AL (INTRAL) and external interrupt falling edge specification register AL (INTFAL)

These registers are used to specify the trigger mode of an external interrupt request (INTPLn) from an external pin ($n = 0, 1$). The correspondence between each bit of this register and the external interrupt request controlled by that bit is as follows.

- INTFAL0 and INTRAL0 bits: INTPAL0
- INTFAL1 and INTRAL1 bits: INTPAL1

The rising edge, falling edge, or both the rising and falling edges can be specified as the valid edge of the $\overline{\text{INTPLn}}$ pin, independently for each pin.

Both the registers can be read or written in 8-bit or 1-bit units.

Caution Before setting the trigger mode, set the PMCAL register.

If the PMCAL register is set after the INTRAL and INTFAL registers have been set, an illegal interrupt may occur when the PMCAL register is set.

	7	6	5	4	3	2	1	0	Address	After reset
INTRAL	0	0	0	0	0	0	INTRAL1	INTRAL0	1FFFC30H	03H
INTFAL	0	0	0	0	0	0	INTFAL1	INTFAL0	1FFFC10H	00H

Bit position	Bit name	Function															
1, 0	INTFALn, INTRALn (n = 0, 1)	Specify trigger mode of $\overline{\text{INTPLn}}$ pin. <table border="1"> <thead> <tr> <th>INTFALn</th> <th>INTRALn</th> <th>Operation</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Falling edge</td> </tr> <tr> <td>0</td> <td>1</td> <td>Rising edge</td> </tr> <tr> <td>1</td> <td>0</td> <td>Level detection (low-level detection)^{Notes 1, 2}</td> </tr> <tr> <td>1</td> <td>1</td> <td>Both rising and falling edges</td> </tr> </tbody> </table>	INTFALn	INTRALn	Operation	0	0	Falling edge	0	1	Rising edge	1	0	Level detection (low-level detection) ^{Notes 1, 2}	1	1	Both rising and falling edges
INTFALn	INTRALn	Operation															
0	0	Falling edge															
0	1	Rising edge															
1	0	Level detection (low-level detection) ^{Notes 1, 2}															
1	1	Both rising and falling edges															

- Notes 1.** The level of the $\overline{\text{INTPLn}}$ pin is sampled each time the main clock (fx) is divided by four. When the low level of this pin is detected, an interrupt request is latched as the PLIFn bit (n = 0, 1). Consequently, even when the CPU acknowledges the interrupt and the PLIFn bit of the interrupt control register (PLICn) is automatically cleared to 0, the PLIFn bit is immediately set to 1 and interrupts occur consecutively. To avoid this status, make the $\overline{\text{INTPLn}}$ pin of the external device inactive in the interrupt servicing routine, and forcibly clear the PLIFn bit to 0.
- 2.** If a level-detected interrupt request ($\overline{\text{INTPLn}}$) with a lower priority occurs while an interrupt is being serviced and if this level-detected interrupt request ($\overline{\text{INTPLn}}$) that has newly occurred becomes inactive before the current interrupt has been serviced, the interrupt request of the new interrupt ($\overline{\text{INTPLn}}$) is held pending (n = 0, 1). To not acknowledge the interrupt request of $\overline{\text{INTPLn}}$, clear the PLIFn bit of the interrupt control register.

15.3.7 Port AH

Port AH (PAH) is a 10-bit I/O port that can be set in the input or output mode in 1-bit units.

When the higher 8 bits of port AH are used as port AHH (PAHH) and the lower 8 bits as port AHL (PAHL), port AH becomes two 8-bit ports that can be set in the input or output mode in 1-bit units.

	15	14	13	12	11	10	9	8	Address	After reset
PAH	0	0	0	0	0	0	PAH9	PAH8	1FFFF003H	Undefined
	7	6	5	4	3	2	1	0	Address	
	PAH7	PAH6	PAH5	PAH4	PAH3	PAH2	PAH1	PAH0	1FFFF002H	

Bit position	Bit name	Function
9 to 0	PAHn (n = 9 to 0)	I/O port

Remark For reading/writing of the I/O port, see 15.5 Operation of Port Function.

In addition to their functions as port pins, in the control mode, the port AH pins operate as an address bus for when the memory is externally expanded.

(1) Operation in control mode

Pin Name	Pin No.	Alternate Function	Remark	Block Type
PAH0	58	A16	Address bus when memory expanded	D-2
PAH1	57	A17		
PAH2	52	A18		
PAH3	51	A19		
PAH4	50	A20		
PAH5	49	A21		
PAH6	48	A22		
PAH7	47	A23		
PAH8	46	A24		
PAH9	45	A25		

(2) I/O mode/control mode setting

The port AH I/O mode setting is performed by the port AH mode register (PMAH), and the control mode setting is performed by the port AH mode control register (PMCAH).

(a) Port AH mode register (PMAH)

The port AH mode register (PMAH) can be read or written in 16-bit units.

If the higher 8 bits of PMAH are used as port AH mode register H (PMAHH), and the lower 8 bits as port AH mode register L (PMAHL), these two 8-bit port mode registers can be read or written in 8-bit or 1-bit units.

	15	14	13	12	11	10	9	8	Address	After reset
PMAH	1	1	1	1	1	1	PMAH9	PMAH8	1FFFF023H	FFFFH
	7	6	5	4	3	2	1	0	Address	
	PMAH7	PMAH6	PMAH5	PMAH4	PMAH3	PMAH2	PMAH1	PMAH0	1FFFF022H	

Bit position	Bit name	Function
9 to 0	PMAHn (n = 9 to 0)	Specifies input/output mode for PAHn pin. 0: Output mode (output buffer on) 1: Input mode (output buffer off)

(b) Port AH mode control register (PMCAH)

The port AH mode control register (PMCAH) can be read or written in 16-bit units.

If the higher 8 bits of PMCAH are used as port AH mode control register H (PMCAHH), and the lower 8 bits as port AH mode control register L (PMCAHL), these two 8-bit port mode registers can be read or written in 8-bit or 1-bit units.

	15	14	13	12	11	10	9	8	Address	After reset
PMCAH	0	0	0	0	0	0	PMCAH9	PMCAH8	1FFFF043H	03FFH
	7	6	5	4	3	2	1	0	Address	
	PMCAH7	PMCAH6	PMCAH5	PMCAH4	PMCAH3	PMCAH2	PMCAH1	PMCAH0	1FFFF042H	

Bit position	Bit name	Function
9 to 0	PMCAHn (n = 9 to 0)	Specifies operation mode of PAHn pin. 0: I/O port mode 1: A25 to A16 output mode

15.3.8 Port DH

Port DH (PDH) is a 16-bit I/O port that can be set in the input or output mode in 1-bit units.

When the higher 8 bits of port DH are used as port DHH (PDHH), and the lower 8 bits as port DHL (PDHL), port DH becomes two 8-bit ports that can be set in the input or output mode in 1-bit units.

Caution In the 32-bit mode (MODE1 and MODE0 pins = 00) and when the BMODCN bit of the PFCDH register is set, all the register functions of port DH (see 15.3.8) become invalid.

	15	14	13	12	11	10	9	8	Address	After reset
PDH	PDH15	PDH14	PDH13	PDH12	PDH11	PDH10	PDH9	PDH8	1FFFF007H	Undefined
	7	6	5	4	3	2	1	0	Address	
	PDH7	PDH6	PDH5	PDH4	PDH3	PDH2	PDH1	PDH0	1FFFF006H	

Bit position	Bit name	Function
15 to 0	PDHn (n = 15 to 0)	I/O port

Remark For reading/writing of the I/O port, see 15.5 Operation of Port Function.

In addition to their functions as port pins, in the control mode, the port DH pins operate as a data bus for when the memory is externally expanded, timer/counter I/O, PWM output, and external interrupt request input.

(1) Operation in control mode

Pin Name	Pin No.	Alternate Function	Remark	Block Type
PDH0	112	D16/ $\overline{\text{INTPD0}}$	Data bus when memory expanded/ external interrupt request input	M-1
PDH1	113	D17/ $\overline{\text{INTPD1}}$	Data bus when memory expanded/ external interrupt request input	
PDH2	114	D18/ $\overline{\text{INTPD2}}$ /TOC4	Data bus when memory expanded/ external interrupt request input/ timer/counter output	M-2
PDH3	117	D19/ $\overline{\text{INTPD3}}$	Data bus when memory expanded/ external interrupt request input	M-1
PDH4	118	D20/ $\overline{\text{INTPD4}}$	Data bus when memory expanded/ external interrupt request input	
PDH5	119	D21/ $\overline{\text{INTPD5}}$ /TOC5	Data bus when memory expanded/ external interrupt request input/ timer/counter output	M-2
PDH6	120	D22/ $\overline{\text{INTPD6}}$ / INTP100/TCUD10	Data bus when memory expanded/ external interrupt request input/ timer ENC10 external capture trigger input/ timer/counter input	M-3
PDH7	121	D23/ $\overline{\text{INTPD7}}$ / INTP101/TCLR10	Data bus when memory expanded/ external interrupt request input/ timer ENC10 external capture trigger input/ timer/counter input	
PDH8	122	D24/ $\overline{\text{INTPD8}}$ /TO10	Data bus when memory expanded/ external interrupt request input/ timer/counter output	M-2
PDH9	123	D25/ $\overline{\text{INTPD9}}$ / TIUD10	Data bus when memory expanded/ external interrupt request input/ timer/counter input	M-3
PDH10	124	D26/ $\overline{\text{INTPD10}}$ / INTP110/TCUD11	Data bus when memory expanded/ external interrupt request input/ timer ENC11 external capture trigger input/ timer/counter input	
PDH11	125	D27/ $\overline{\text{INTPD11}}$ / INTP111/TCLR11	Data bus when memory expanded/ external interrupt request input/ timer ENC11 external capture trigger input/ timer/counter input	
PDH12	126	D28/ $\overline{\text{INTPD12}}$ /TO11	Data bus when memory expanded/ external interrupt request input/ timer/counter output	M-2
PDH13	127	D29/ $\overline{\text{INTPD13}}$ / TIUD11	Data bus when memory expanded/ external interrupt request input/ timer/counter input	M-3
PDH14	130	D30/ $\overline{\text{INTPD14}}$ / PWM0	Data bus when memory expanded/ external interrupt request input/PWM output	M-2
PDH15	131	D31/ $\overline{\text{INTPD15}}$ / PWM1	Data bus when memory expanded/ external interrupt request input/PWM output	

(2) I/O mode/control mode setting

The port DH I/O mode setting is performed by the port DH mode register (PMDH), and the control mode setting is performed by the port DH mode control register (PMCDH) and port DH function control register (PFCDH).

(a) Port DH mode register (PMDH)

The port DH mode register (PMDH) can be read or written in 16-bit units.

If the higher 8 bits of PMDH are used as port DH mode register H (PMDHH), and the lower 8 bits as port DH mode register L (PMDHL), these two 8-bit port mode registers can be read or written in 8-bit or 1-bit units.

	15	14	13	12	11	10	9	8	Address	After reset
PMDH	PMDH15	PMDH14	PMDH13	PMDH12	PMDH11	PMDH10	PMDH9	PMDH8	1FFFF027H	FFFFH
	7	6	5	4	3	2	1	0	Address	
	PMDH7	PMDH6	PMDH5	PMDH4	PMDH3	PMDH2	PMDH1	PMDH0	1FFFF026H	

Bit position	Bit name	Function
15 to 0	PMDHn (n = 15 to 0)	Specifies input/output mode for PDHn pin. 0: Output mode (output buffer on) 1: Input mode (output buffer off)

(b) Port DH mode control register (PMCDH)

The port DH mode control register (PMCDH) can be read or written in 16-bit units.

If the higher 8 bits of PMCDH are used as port DH mode control register H (PMCDHH), and the lower 8 bits as port DH mode control register L (PMCDHL), these two 8-bit port mode registers can be read or written in 8-bit or 1-bit units.

(1/2)

	15	14	13	12	11	10	9	8	Address	After reset
PMCDH	PMCDH15	PMCDH14	PMCDH13	PMCDH12	PMCDH11	PMCDH10	PMCDH9	PMCDH8	1FFFF047H	0000H

	PMCDH7	PMCDH6	PMCDH5	PMCDH4	PMCDH3	PMCDH2	PMCDH1	PMCDH0	1FFFF046H	

Bit position	Bit name	Function
15	PMCDH15	Specifies operation mode of PDH15 pin in combination with the PFCDH register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTPD15}}$) input mode/PWM1 output mode
14	PMCDH14	Specifies operation mode of PDH14 pin in combination with the PFCDH register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTPD14}}$) input mode/PWM0 output mode
13	PMCDH13	Specifies operation mode of PDH13 pin in combination with the PFCDH register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTPD13}}$) input mode/TIUD11 input mode

(2/2)

Bit position	Bit name	Function
12	PMCDH12	Specifies operation mode of PDH12 pin in combination with the PFCDH register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTPD12}}$) input mode/TO11 output mode
11	PMCDH11	Specifies operation mode of PDH11 pin in combination with the PFCDH register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTPD11}}$) input mode/timer ENC11 external capture trigger (INTP111) input mode/TCLR11 input mode
10	PMCDH10	Specifies operation mode of PDH10 pin in combination with the PFCDH register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTPD10}}$) input mode/timer ENC11 external capture trigger (INTP110) input mode/TCUD11 input mode
9	PMCDH9	Specifies operation mode of PDH9 pin in combination with the PFCDH register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTPD9}}$) input mode/TIUD10 input mode
8	PMCDH8	Specifies operation mode of PDH8 pin in combination with the PFCDH register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTPD8}}$) input mode/TO10 output mode
7	PMCDH7	Specifies operation mode of PDH7 pin in combination with the PFCDH register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTPD7}}$) input mode/timer ENC10 external capture trigger (INTP101) input mode/TCLR10 input mode
6	PMCDH6	Specifies operation mode of PDH6 pin in combination with the PFCDH register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTPD6}}$) input mode/timer ENC10 external capture trigger (INTP100) input mode/TCUD10 input mode
5	PMCDH5	Specifies operation mode of PDH5 pin in combination with the PFCDH register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTPD5}}$) input mode/TOC5 output mode
4	PMCDH4	Specifies operation mode of PDH4 pin in combination with the PFCDH register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTPD4}}$) input mode
3	PMCDH3	Specifies operation mode of PDH3 pin in combination with the PFCDH register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTPD3}}$) input mode
2	PMCDH2	Specifies operation mode of PDH2 pin in combination with the PFCDH register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTPD2}}$) input mode/TOC4 output mode
1	PMCDH1	Specifies operation mode of PDH1 pin in combination with the PFCDH register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTPD1}}$) input mode
0	PMCDH0	Specifies operation mode of PDH0 pin in combination with the PFCDH register. 0: I/O port mode 1: External interrupt request ($\overline{\text{INTPD0}}$) input mode

(c) Port DH function control register (PFCDH)

This register can be read or written in 8-bit or 1-bit units.

If the higher 8 bits of the PFCDH are used as port DH function control register H (PFCDHH), and the lower 8 bits as port DH function control register L (PFCDHL), these registers can be read or written in 8-bit or 1-bit units.

Caution When the port mode is specified by the port DH mode control register (PMCDH), the setting of this register becomes invalid. However, bit 0 is independent of the setting of the PMCDH0 bit of the PMCDH register.

(1/3)

	15	14	13	12	11	10	9	8	Address	After reset
PFCDH	PFCDH15	PFCDH14	PFCDH13	PFCDH12	PFCDH11	PFCDH10	PFCDH9	PFCDH8	1FFFF057H	0000H

6	PFCDH6	<p>Specifies operation mode of PDH6 pin in control mode.</p> <p>0: External interrupt request ($\overline{\text{INTPD6}}$) input mode 1: Timer ENC10 external capture trigger (INTP100) input mode/TCUD10 input mode</p> <p>There is no register that selects a timer ENC10 external capture trigger (INTP100) input mode or TCUD10 input mode.</p> <ul style="list-style-type: none"> To use TUCD10 input mode: Mask the external capture trigger (INTP100) of timer ENC10, or use the CC100 register as a compare register. To use external capture trigger (INTP100) of timer ENC10: Set the T1CMD0 bit of the TUM10 register to 0.
5	PFCDH5	<p>Specifies operation mode of PDH5 pin in control mode.</p> <p>0: External interrupt request ($\overline{\text{INTPD5}}$) input mode 1: TOC5 output mode</p>
2	PFCDH2	<p>Specifies operation mode of PDH2 pin in control mode.</p> <p>0: External interrupt request ($\overline{\text{INTPD2}}$) input mode 1: TOC4 output mode</p>

(3/3)

Bit position	Bit name	Function
0	BMODCN	<p>Specifies the operation mode of the D16 to D31 pins in the 16-bit mode (16-bit data bus). However, changing the value of the BMODCN bit from 0 to 1 is not reflected in the LBS register.</p> <p>0: The D16 to D31 pins are not used for starting in the 16-bit mode (data bus width: 16/8 bits).</p> <p>1: The D16 to D31 pins are not used for starting in the 16-bit mode (data bus width: 32/16/8 bits).</p> <p>Caution The BMODCN bit is valid only when the 16-bit mode is specified in accordance with the status of the MODE0 and MODE1 pins. This bit is invalid if the 32-bit mode is specified.</p> <p>The BMODCN bit can be rewritten only once. If it is rewritten twice or more, the operation is not guaranteed.</p> <p>When the BMODCN bit = 1, the operation is the same as when the 32-bit mode is specified in accordance with the status of the MODE0 and MODE1 pins.</p>

(3) Selecting interrupt trigger mode

The valid edges of the $\overline{\text{INTPDn}}$ pin can be selected by program ($n = 0$ to 15). The level detection of the $\overline{\text{INTPDn}}$ pin can also be selected.

External interrupt rising edge specification register DH (INTRDH) and external interrupt falling edge specification register DH (INTFDH) are used to specify the valid edge and level detection.

(a) External interrupt rising edge specification register DH (INTRDH) and external interrupt falling edge specification register DH (INTFDH)

These registers are used to specify the trigger mode of an external interrupt request (INTPDn) from an external pin ($n = 0$ to 15). The correspondence between each bit of this register and the external interrupt request controlled by that bit is as follows.

- INTFDH0 and INTRDH0 bits: INTPD0
- INTFDH1 and INTRDH1 bits: INTPD1
- INTFDH2 and INTRDH2 bits: INTPD2
- INTFDH3 and INTRDH3 bits: INTPD3
- INTFDH4 and INTRDH4 bits: INTPD4
- INTFDH5 and INTRDH5 bits: INTPD5
- INTFDH6 and INTRDH6 bits: INTPD6
- INTFDH7 and INTRDH7 bits: INTPD7
- INTFDH8 and INTRDH8 bits: INTPD8
- INTFDH9 and INTRDH9 bits: INTPD9
- INTFDH10 and INTRDH10 bits: INTPD10
- INTFDH11 and INTRDH11 bits: INTPD11
- INTFDH12 and INTRDH12 bits: INTPD12
- INTFDH13 and INTRDH13 bits: INTPD13
- INTFDH14 and INTRDH14 bits: INTPD14
- INTFDH15 and INTRDH15 bits: INTPD15

The rising edge, falling edge, or both the rising and falling edges can be specified as the valid edge of the $\overline{\text{INTPDn}}$ pin, independently for each pin.

INTRDH and INTFDH registers can be read or written in 16-bit units.

When the higher 8 bits of the INTRDH and INTFDH registers are used as INTRDHH and INTFDHH registers, and the lower 8 bits as INTRDHL and INTFDHL registers, these registers can be read or written in 8-bit or 1-bit units.

Caution Set the PMCDH register before setting the trigger mode.

If the PMCDH register is set after the INTRDH and INTFDH registers have been set, an illegal interrupt may occur when the PMCDH register is set.

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	Address	After reset
INTRDH	INTR DH15	INTR DH14	INTR DH13	INTR DH12	INTR DH11	INTR DH10	INTR DH9	INTR DH8	INTR DH7	INTR DH6	INTR DH5	INTR DH4	INTR DH3	INTR DH2	INTR DH1	INTR DH0	1FFFFC36H	FFFFH
INTFDH	INTF DH15	INTF DH14	INTF DH13	INTF DH12	INTF DH11	INTF DH10	INTF DH9	INTF DH8	INTF DH7	INTF DH6	INTF DH5	INTF DH4	INTF DH3	INTF DH2	INTF DH1	INTF DH0	1FFFFC16H	0000H

Bit position	Bit name	Function															
15 to 0	INTFDHn, INTRDHn (n = 0 to 15)	Specify trigger mode of $\overline{\text{INTPDn}}$ pin. <table border="1" style="margin-left: 20px;"> <thead> <tr> <th>INTFDHn</th> <th>INTRDHn</th> <th>Operation</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Falling edge</td> </tr> <tr> <td>0</td> <td>1</td> <td>Rising edge</td> </tr> <tr> <td>1</td> <td>0</td> <td>Level detection (low-level detection)^{Notes 1, 2}</td> </tr> <tr> <td>1</td> <td>1</td> <td>Both rising and falling edges</td> </tr> </tbody> </table>	INTFDHn	INTRDHn	Operation	0	0	Falling edge	0	1	Rising edge	1	0	Level detection (low-level detection) ^{Notes 1, 2}	1	1	Both rising and falling edges
INTFDHn	INTRDHn	Operation															
0	0	Falling edge															
0	1	Rising edge															
1	0	Level detection (low-level detection) ^{Notes 1, 2}															
1	1	Both rising and falling edges															

- Notes 1.** The level of the $\overline{\text{INTPDn}}$ pin is sampled each time the main clock (fx) is divided by four. When the low level of this pin is detected, an interrupt request is latched as the PDIFn bit (n = 0 to 15). Consequently, even when the CPU acknowledges the interrupt and the PDIFn bit of the interrupt control register (PDICn) is automatically cleared to 0, the PDIFn bit is immediately set to 1 and interrupts occur consecutively. To avoid this status, make the $\overline{\text{INTPDn}}$ pin of the external device inactive in the interrupt servicing routine, and forcibly clear the PDIFn bit to 0.
- 2.** If a level-detected interrupt request (INTPDn) with a lower priority occurs while an interrupt is being serviced and if this level-detected interrupt request (INTPDn) that has newly occurred becomes inactive before the current interrupt has been serviced, the interrupt request of the new interrupt (INTPDn) is held pending (n = 0 to 15). To not acknowledge the interrupt request of INTPDn, clear the PDIFn bit of the interrupt control register.

15.3.9 Port CS

Port CS (PCS) is an 8-bit I/O port that can be set to the input or output mode in 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PCS	PCS7	PCS6	PCS5	PCS4	PCS3	PCS2	PCS1	PCS0	1FFFF008H	Undefined

Bit position	Bit name	Function
7 to 0	PCS _n (n = 7 to 0)	I/O port

Remark For reading/writing of the I/O port, see **15.5 Operation of Port Function**.

In addition to their function as port pins, in the control mode, the port pins can also operate as the chip select signal outputs when memory is externally expanded and the read/write strobe signal output to an external I/O.

(1) Operation in control mode

Pin Name	Pin No.	Alternate Function	Remark	Block Type
PCS0	44	$\overline{CS0}$	Chip select signal output	D-2
PCS1	43	$\overline{CS1}$	Chip select signal output	
PCS2	42	$\overline{CS2}/\overline{IOWR}$	Chip select signal output/write strobe signal output	J-2
PCS3	41	$\overline{CS3}$	Chip select signal output	D-2
PCS4	40	$\overline{CS4}$	Chip select signal output	
PCS5	37	$\overline{CS5}/\overline{IORD}$	Chip select signal output/read strobe signal output	J-2
PCS6	36	$\overline{CS6}$	Chip select signal output	D-2
PCS7	35	$\overline{CS7}$	Chip select signal output	

(2) I/O mode/control mode setting

The port CS I/O mode setting is performed by the port CS mode register (PMCS), and the control mode setting is performed by the port CS mode control register (PMCCS) and the port CS function control register (PFCCS).

(a) Port CS mode register (PMCS)

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PMCS	PMCS7	PMCS6	PMCS5	PMCS4	PMCS3	PMCS2	PMCS1	PMCS0	1FFFF028H	FFH
Bit position	Bit name	Function								
7 to 0	PMCSn (n = 7 to 0)	Specifies input/output mode for PCSn pin. 0: Output mode (output buffer on) 1: Input mode (output buffer off)								

(b) Port CS mode control register (PMCCS)

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PMCCS	PMCCS7	PMCCS6	PMCCS5	PMCCS4	PMCCS3	PMCCS2	PMCCS1	PMCCS0	1FFFF048H	FFH
Bit position	Bit name	Function								
7	PMCCS7	Specifies operation mode of PCS7 pin. 0: I/O port mode 1: CS7 output mode								
6	PMCCS6	Specifies operation mode of PCS6 pin. 0: I/O port mode 1: CS6 output mode								
5	PMCCS5	Specifies operation mode of PCS5 pin. 0: I/O port mode 1: CS5 output mode/ \overline{IORD} output mode								
4	PMCCS4	Specifies operation mode of PCS4 pin. 0: I/O port mode 1: CS4 output mode								
3	PMCCS3	Specifies operation mode of PCS3 pin. 0: I/O port mode 1: CS3 output mode								
2	PMCCS2	Specifies operation mode of PCS2 pin. 0: I/O port mode 1: CS2 output mode/ \overline{IOWR} output mode								
1	PMCCS1	Specifies operation mode of PCS1 pin. 0: I/O port mode 1: CS1 output mode								
0	PMCCS0	Specifies operation mode of PCS0 pin. 0: I/O port mode 1: CS0 output mode								

(c) Port CS function control register (PFCCS)

This register can be read or written in 8-bit or 1-bit units.

The $\overline{\text{LLWR}}$, $\overline{\text{LUWR}}$, $\overline{\text{ULWR}}$ and $\overline{\text{UUWR}}$ signals (hereafter referred to as the $\overline{\text{xxWR}}$ signal) and LLDQM, LUDQM, ULDQM, and UUDQM signals (hereafter referred to as the $\overline{\text{xxDQM}}$ signal) are alternate-function pins ($\overline{\text{xxWR}}/\overline{\text{xxDQM}}$), and the $\overline{\text{WR}}$ signal and $\overline{\text{WE}}$ signal are alternate-function pins ($\overline{\text{WR}}/\overline{\text{WE}}$). When an access to the SRAM interface device occurs immediately after an access to the SDRAM occurs, the rise of the $\overline{\text{xxDQM}}$ ($\overline{\text{xxWR}}$) signal or the rise (inactive timing) of the $\overline{\text{WE}}$ ($\overline{\text{WR}}$) signal overlaps the SRAM interface device cycle, which may cause erroneous write. To prevent this, set the CSDCn bit to 1 to delay the timing at which the $\overline{\text{CSn}}$ signal falls by one clock.

Caution When the port mode is specified by the port CS mode control register (PMCCS), the PFCCS setting becomes invalid.

	7	6	5	4	3	2	1	0	Address	After reset
PFCCS	CSDC7	CSDC6	PFCCS5	CSDC4	0 ^{Note 1}	PFCCS2	0 ^{Note 1}	CSDC0	1FFFF049H	00H

Bit position	Bit name	Function
7, 6, 4, 0	CSDCn ^{Notes 2, 3, 4, 5}	Specifies chip select signal ($\overline{\text{CSn}}$) output timing. 0: No delay function 1: Delay function When this bit is set (1), the timing at which the corresponding chip select signal ($\overline{\text{CSn}}$) falls is delayed by one clock. The output timing of signals other than $\overline{\text{CSn}}$ is not affected.
5	PFCCS5	Specifies operation mode of PCS5 pin in control mode. 0: $\overline{\text{CS5}}$ output mode 1: $\overline{\text{IORD}}$ output mode ^{Note 6}
2	PFCCS2	Specifies operation mode of PCS2 pin in control mode. 0: $\overline{\text{CS2}}$ output mode 1: $\overline{\text{IOWR}}$ output mode ^{Note 6}

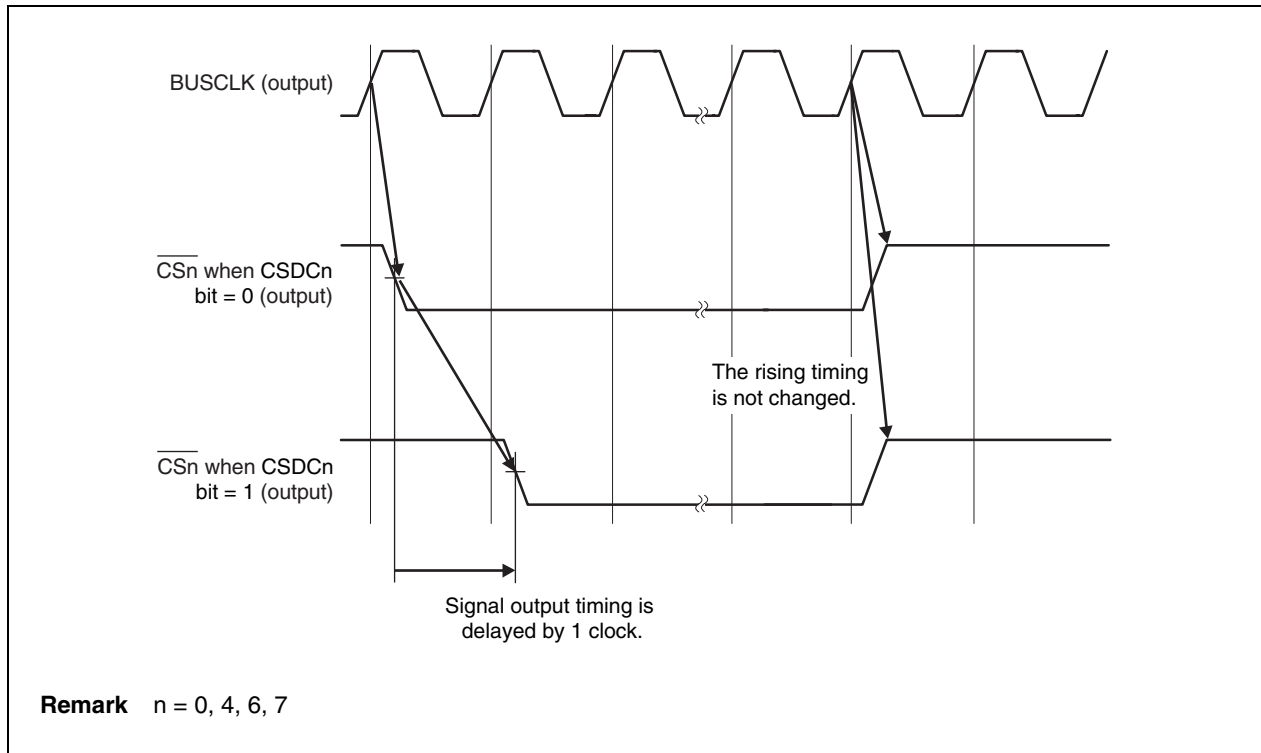

Notes

- Be sure to clear bits 3 and 1 to 0.
- Be sure to set the BTn0 and BTn1 bits of the BCT0 and BCT1 registers to 00 or 01 so that the device to which erroneous write may occur is connected to the CS space to which the CSDCn bit is set to 1.
- Do not change the value of the CSDCn bit for the CS space where the program under execution is allocated.
- Be sure to insert one or more address setup waits (required number of waits + 1) in the CS space for which the CSDCn bit is set to 1 using the ASC register.
- The CSDCn bit can be set to 1 only in the initialization sequence.
- To output the $\overline{\text{IORD}}$ and $\overline{\text{IOWR}}$ signals during access to the external I/O other than by a DMA flyby transfer, the IOEN bit of the BCP register must be set.

Remark n = 0, 4, 6, 7

An example of a timing chart where the CSDCn bit is set to 1 is shown below.

Figure 15-25. Timing When CSDCn Bit Is Set to 1

15.3.10 Port CT

Port CT (PCT) is a 6-bit I/O port that can be set to input or output mode in 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PCT	PCT7	0	PCT5	PCT4	PCT3	PCT2	PCT1	PCT0	1FFFF00AH	Undefined

Bit position	Bit name	Function
7, 5 to 0	PCTn (n = 7, 5 to 0)	I/O port

Remark For reading/writing of the I/O port, see **15.5 Operation of Port Function**.

In addition to the port function, this port outputs, in the control mode, control signals to externally expand the memory and byte enable signals when SDRAM is accessed in byte units.

(1) Operation in control mode

Pin Name	Pin No.	Alternate Function	Remark	Block Type
PCT0	83	$\overline{\text{LLWR}}/\overline{\text{LLBE}}/\overline{\text{LLDQM}}$	Write strobe signal output/byte enable signal output/ output disable/write mask signal	J-3
PCT1	82	$\overline{\text{LUWR}}/\overline{\text{LUBE}}/\overline{\text{LUDQM}}$	Write strobe signal output/byte enable signal output/ output disable/write mask signal	
PCT2	81	$\overline{\text{ULWR}}/\overline{\text{ULBE}}/\overline{\text{ULDQM}}$	Write strobe signal output/byte enable signal output/ output disable/write mask signal	
PCT3	80	$\overline{\text{UUWR}}/\overline{\text{UUBE}}/\overline{\text{UUDQM}}$	Write strobe signal output/byte enable signal output/ output disable/write mask signal	
PCT4	79	$\overline{\text{RD}}$	Read strobe signal output	D-2
PCT5	78	$\overline{\text{WE}}/\overline{\text{WR}}$	Write enable signal output/write strobe signal output	
PCT7	77	$\overline{\text{BCYST}}$	Bus cycle status signal output	

(2) I/O mode/control mode setting

The port CT I/O mode setting is performed by the port CT mode register (PMCT), and the control mode setting is performed by the port CT mode control register (PMCCT) and port CT function control register (PFCCT).

(a) Port CT mode register (PMCT)

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PMCT	PMCT7	1	PMCT5	PMCT4	PMCT3	PMCT2	PMCT1	PMCT0	1FFFF02AH	FFH
Bit position	Bit name	Function								
7, 5 to 0	PMCTn (n = 7, 5 to 0)	Specifies input/output mode for PCTn pin. 0: Output mode (output buffer on) 1: Input mode (output buffer off)								

(b) Port CT mode control register (PMCCT)

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PMCCT	PMCCT7	0	PMCCT5	PMCCT4	PMCCT3	PMCCT2	PMCCT1	PMCCT0	1FFFF04AH	BFH
Bit position	Bit name	Function								
7	PMCCT7	Specifies operation mode of PCT7 pin. 0: I/O port mode 1: BCYST output mode								
5	PMCCT5	Specifies operation mode of PCT5 pin. 0: I/O port mode 1: $\overline{WE}/\overline{WR}$ output mode The \overline{WE} output mode and \overline{WR} output mode are automatically selected by accessing the memory for which each mode is targeted.								
4	PMCCT4	Specifies operation mode of PCT4 pin. 0: I/O port mode 1: \overline{RD} output mode								
3	PMCCT3	Specifies operation mode of PCT3 pin. 0: I/O port mode 1: \overline{UUWR} output mode/ \overline{UUBE} output mode/ \overline{UUDQM} output mode								
2	PMCCT2	Specifies operation mode of PCT2 pin. 0: I/O port mode 1: \overline{ULWR} output mode/ \overline{ULBE} output mode/ \overline{ULDQM} output mode								
1	PMCCT1	Specifies operation mode of PCT1 pin. 0: I/O port mode 1: \overline{LUWR} output mode/ \overline{LUBE} output mode/ \overline{LUDQM} output mode								
0	PMCCT0	Specifies operation mode of PCT0 pin. 0: I/O port mode 1: \overline{LLWR} output mode/ \overline{LLBE} output mode/ \overline{LLDQM} output mode								

(c) Port CT function control register (PFCCT)

This register can be read or written in 8-bit or 1-bit units.

- Cautions**
1. When the port mode is specified by the port CT mode control register (PMCCT), the setting of this register becomes invalid.
 2. The timing of the $\overline{\text{xxDQM}}$ signal differs between when the $\overline{\text{xxWR}}$ output mode/ $\overline{\text{xxDQM}}$ output mode is selected and when the $\overline{\text{xxBE}}$ output mode/ $\overline{\text{xxDQM}}$ output mode is selected. However, if either mode is selected, no problems occur when connecting to SDRAM. For the output timing of the $\overline{\text{xxDQM}}$ signal, refer to the timing diagrams (Figures 6-9 to 6-11) in 6.3.5 SDRAM access ($\text{xx} = \text{UU}, \text{UL}, \text{LU}, \text{LL}$).

								Address	After reset
	7	6	5	4	3	2	1	0	
PFCCT	0	0	0	0	PFCCT3	PFCCT2	PFCCT1	PFCCT0	1FFF04BH 00H

Bit position	Bit name	Function
3	PFCCT3	Specifies operation mode of PCT3 pin in control mode. 0: $\overline{\text{UUWR}}$ output mode/UUDQM output mode 1: $\overline{\text{UUBE}}$ output mode/UUDQM output mode The $\overline{\text{UUWR}}$ output mode and UUDQM output mode, and the $\overline{\text{UUBE}}$ output mode and UUDQM output mode are automatically selected by accessing the memory for which each mode is targeted.
2	PFCCT2	Specifies operation mode of PCT2 pin in control mode. 0: $\overline{\text{ULWR}}$ output mode/ULDQM output mode 1: $\overline{\text{ULBE}}$ output mode/ULDQM output mode The $\overline{\text{ULWR}}$ output mode and ULDQM output mode, and the $\overline{\text{ULBE}}$ output mode and ULDQM output mode are automatically selected by accessing the memory for which each mode is targeted.
1	PFCCT1	Specifies operation mode of PCT1 pin in control mode. 0: $\overline{\text{LUWR}}$ output mode/LUDQM output mode 1: $\overline{\text{LUBE}}$ output mode/LUDQM output mode The $\overline{\text{LUWR}}$ output mode and LUDQM output mode, and the $\overline{\text{LUBE}}$ output mode and LUDQM output mode are automatically selected by accessing the memory for which each mode is targeted.
0	PFCCT0	Specifies operation mode of PCT0 pin in control mode. 0: $\overline{\text{LLWR}}$ output mode/LLDQM output mode 1: $\overline{\text{LLBE}}$ output mode/LUDQM output mode The $\overline{\text{LLWR}}$ output mode and LLDQM output mode, and the $\overline{\text{LLBE}}$ output mode and LUDQM output mode are automatically selected by accessing the memory for which each mode is targeted.

15.3.11 Port CM

Port CM (PCM) is a 6-bit I/O port that can be set to the input or output mode in 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PCM	0	0	PCM5	PCM4	PCM3	PCM2	PCM1	PCM0	1FFFF00CH	Undefined

Bit position	Bit name	Function
5 to 0	PCMn (n = 5 to 0)	I/O port

Remark For reading/writing of the I/O port, see **15.5 Operation of Port Function**.

In addition to their function as port pins, in the control mode, the port CM pins operate as the wait insertion signal input, bus hold control signal output, refresh request signal output from SDRAM, and A/D converter external trigger input.

(1) Operation in control mode

Pin Name	Pin No.	Alternate Function	Remark	Block Type
PCM0	34	$\overline{\text{WAIT}}$	Wait insertion signal input	C-1
PCM1	33	–	–	D-1
PCM2	32	$\overline{\text{HLDAK}}$	Bus hold acknowledge signal output	D-2
PCM3	31	$\overline{\text{HLDRQ}}$	Bus hold request signal input	C-1
PCM4	30	$\overline{\text{REFRQ}}$	Refresh request signal output	D-2
PCM5	29	$\overline{\text{SELFREF/ADTRG}}$	Self-refresh request signal input	F-5

(2) I/O mode/control mode setting

The port CM I/O mode setting is performed by the port CM mode register (PMCM), and the control mode setting is performed by the port CM mode control register (PMCCM) and the port CM function control register (PFCCM).

(a) Port CM mode register (PMCM)

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PMCM	1	1	PMCM5	PMCM4	PMCM3	PMCM2	PMCM1	PMCM0	1FFFF02CH	FFH

Bit position	Bit name	Function
5 to 0	PMCMn (n = 5 to 0)	Specifies input/output mode for PCMn pin. 0: Output mode (output buffer on) 1: Input mode (output buffer off)

(b) Port CM mode control register (PMCCM)

This register can be read or written in 8-bit or 1-bit units.

Be sure to clear bit 1 to "0". If it is set to "1", the operation is not guaranteed.

	7	6	5	4	3	2	1	0	Address	After reset
PMCCM	0	0	PMCCM5	PMCCM4	PMCCM3	PMCCM2	0	PMCCM0	1FFFF04CH	3DH

Bit position	Bit name	Function
5	PMCCM5	Specifies operation mode of PCM5 pin. 0: I/O port mode 1: $\overline{\text{SELFREF}}$ input mode/A/D converter external trigger (ADTRG) input mode
4	PMCCM4	Specifies operation mode of PCM4 pin. 0: I/O port mode 1: $\overline{\text{REFRQ}}$ output mode
3	PMCCM3	Specifies operation mode of PCM3 pin. 0: I/O port mode 1: $\overline{\text{HLDRQ}}$ input mode
2	PMCCM2	Specifies operation mode of PCM2 pin. 0: I/O port mode 1: $\overline{\text{HLDK}}$ output mode
0	PMCCM0	Specifies operation mode of PCM0 pin. 0: I/O port mode 1: $\overline{\text{WAIT}}$ input mode

(c) Port CM function control register (PFCCM)

This register can be read or written in 8-bit or 1-bit units.

Caution When the port mode is specified by the port CM mode control register (PMCCM), the PFCCM setting becomes invalid.

	7	6	5	4	3	2	1	0	Address	After reset
PFCCM	0	0	PFCCM5	0	0	0	0	0	1FFFF04DH	00H

Bit position	Bit name	Function
5	PFCCM5	Specifies operation mode of PCM5 pin in control mode. 0: $\overline{\text{SELFREF}}$ input mode 1: A/D converter external trigger (ADTRG) input mode

15.3.12 Port CD

Port CD (PCD) is a 4-bit I/O port that can be set to the input or output mode in 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PCD	0	0	0	0	PCD3	PCD2	PCD1	PCD0	1FFFF00EH	Undefined

Bit position	Bit name	Function
3 to 0	PCDn (n = 3 to 0)	I/O port

Remark For reading/writing of the I/O port, see **15.5 Operation of Port Function**.

In addition to their function as port pins, the port CD pins operate as the clock enable signal output, bus clock output, column address strobe signal output, and row address strobe signal output in the control mode.

(1) Operation in control mode

Pin Name	Pin No.	Alternate Function	Remark	Block Type
PCD0	91	SDCKE	Clock enable signal output	D-2
PCD1	88	BUSCLK	Bus clock output	D-1
PCD2	87	SDCAS	Column address strobe signal output	D-2
PCD3	86	SDRAS	Row address strobe signal output	

(2) I/O mode/control mode setting

The port CD I/O mode setting is performed by the port CD mode register (PMCD), and the control mode setting is performed by the port CD mode control register (PMCCD).

(a) Port CD mode register (PMCD)

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PMCD	1	1	1	1	PMCD3	PMCD2	PMCD1	PMCD0	1FFFF02EH	FFH

Bit position	Bit name	Function
3 to 0	PMCDn (n = 3 to 0)	Specifies input/output mode for PCDn pin. 0: Output mode (output buffer on) 1: Input mode (output buffer off)

(b) Port CD mode control register (PMCCD)

This register can be read or written in 8-bit or 1-bit units.

	7	6	5	4	3	2	1	0	Address	After reset
PMCCD	0	0	0	0	PMCCD3	PMCCD2	PMCCD1	PMCCD0	1FFFF04EH	0FH

Bit position	Bit name	Function
3	PMCCD3	Specifies operation mode of PCD3 pin. 0: I/O port mode 1: SDRAS output mode
2	PMCCD2	Specifies operation mode of PCD2 pin. 0: I/O port mode 1: $\overline{\text{SDCAS}}$ output mode
1	PMCCD1	Specifies operation mode of PCD1 pin. 0: I/O port mode 1: BUSCLK output mode
0	PMCCD0	Specifies operation mode of PCD0 pin. 0: I/O port mode 1: SDCKE output mode

15.4 Configuration of $\overline{\text{RESET}}$, A2 to A15, and D0 to D15 Pins

The $\overline{\text{RESET}}$, A2 to A15, and D0 to D15 pins are not alternative function pins. Their configuration is as follows.

(1) Configuration of $\overline{\text{RESET}}$, A2 to A15, and D0 to D15 pins

Pin Function	Remark	Block Type
$\overline{\text{RESET}}$	Schmitt buffer	N-1
A2 to A15	Output buffer off control	N-2
D0 to D15	Output buffer off control and DIR control	N-3

(2) Block diagram of $\overline{\text{RESET}}$, A2 to A15, and D0 to D15 pins

Figure 15-26. Block Diagram of Type N-1

Figure 15-27. Block Diagram of Type N-2

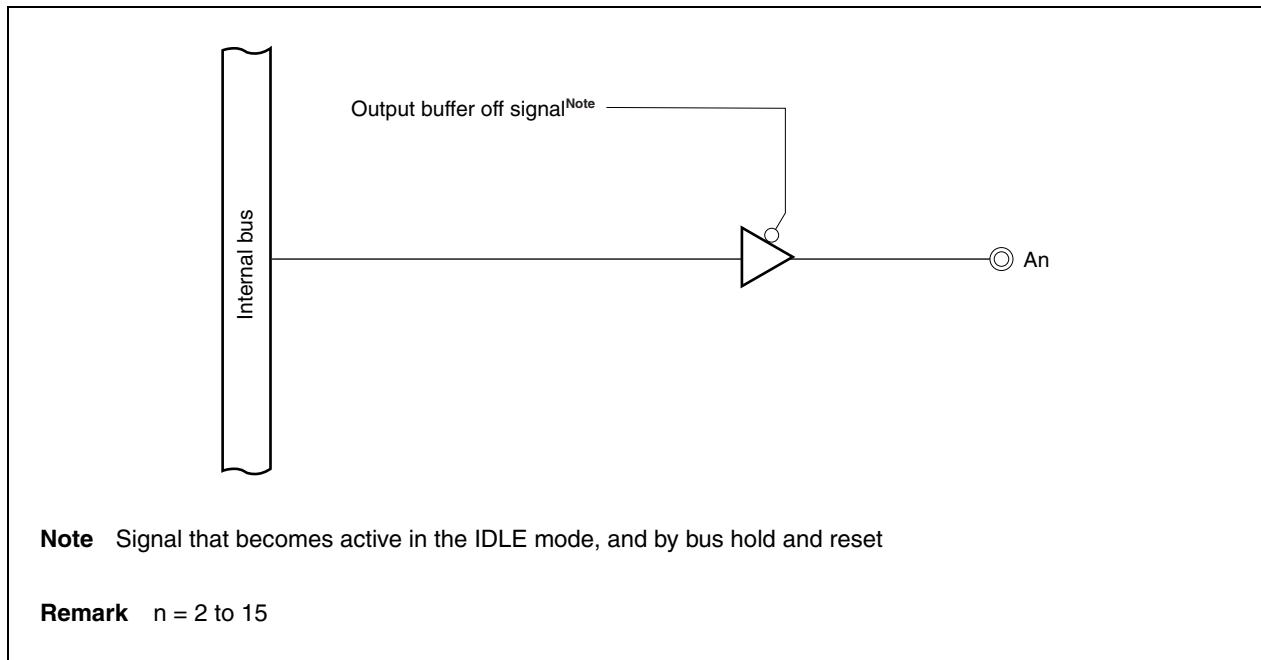

Figure 15-28. Block Diagram of Type N-3

15.5 Operation of Port Function

The operation of a port differs depending on whether it is set in the input or output mode, as follows.

15.5.1 Writing to I/O port

(1) In output mode

A value can be written to the output latch (Pn) by writing it to the port n register (Pn). The contents of the output latch are output from the pin.

Once data is written to the output latch, it is held until new data is written to the output latch.

(2) In input mode

A value can be written to the output latch (Pn) by writing it to the port n register (Pn). However, the status of the pin does not change because the output buffer is off.

Once data is written to the output latch, it is held until new data is written to the output latch.

Caution A bit manipulation instruction (CLR1, SET1, NOT1) manipulates 1 bit but accesses a port in 8-bit units. If this instruction is executed to manipulate a port with a mixture of input and output bits, the contents of the output latch of a pin set in the input mode, in addition to the bit to be manipulated, are overwritten to the current input pin status and become undefined.

15.5.2 Reading from I/O port

(1) In output mode

The contents of the output latch (Pn) can be read by reading the port n register (Pn). The contents of the output latch do not change.

(2) In input mode

The status of the pin can be read by reading the port n register (Pn). The contents of the output latch (Pn) do not change.

15.5.3 Output status of alternate function in control mode

The status of a port pin is not dependent upon the setting of the PMCn register and can be read by setting the port n mode register (PMn) to the input mode. If the PMn register is set to the output mode, the value of the port n register (Pn) can be read in the port mode, and the output status of the alternate function can be read in the control mode.

15.6 Noise Eliminator

15.6.1 Interrupt input pin

The following timing controller used to secure the noise elimination time is provided for the NMI and port pins that operate in the control mode when the valid edge is input. Input signals that change within the noise elimination time are not internally acknowledged.

Table 15-1. Noise Elimination Time of Interrupt Input Pins

Pin	Noise Elimination Time
NMI	Analog delay (80 ns typ.)
$\overline{\text{INTP10}}$	
$\overline{\text{INTP11}}$	
$\overline{\text{INTP21}}$	
$\overline{\text{INTP22}}$	
$\overline{\text{INTP23}}$	
$\overline{\text{INTP24}}$	
$\overline{\text{INTP25}}$	
$\overline{\text{INTP50}}$	
$\overline{\text{INTP51}}$	
$\overline{\text{INTP52}}$	
$\overline{\text{INTP65}}$	
$\overline{\text{INTP66}}$	
$\overline{\text{INTP67}}$	
$\overline{\text{INTPL0}}$	
$\overline{\text{INTPL1}}$	
$\overline{\text{INTPD0}}$	
$\overline{\text{INTPD1}}$	
$\overline{\text{INTPD2}}$	
$\overline{\text{INTPD3}}$	
$\overline{\text{INTPD4}}$	
$\overline{\text{INTPD5}}$	
$\overline{\text{INTPD6}}$	
$\overline{\text{INTPD7}}$	
$\overline{\text{INTPD8}}$	
$\overline{\text{INTPD9}}$	
$\overline{\text{INTPD10}}$	
$\overline{\text{INTPD11}}$	
$\overline{\text{INTPD12}}$	
$\overline{\text{INTPD13}}$	
$\overline{\text{INTPD14}}$	
$\overline{\text{INTPD15}}$	

- Cautions**
1. The above non-maskable and maskable interrupt pins are used to release the standby mode. A timing circuit that controls the clock is not employed because the internal system clock (f_{CLK}) is stopped in the standby mode.
 2. The noise eliminator is valid only in the control mode.

15.6.2 A/D converter input pin

The following timing controller used to secure the noise elimination time is provided for the ADTRG pin. An input signal that changes within the noise elimination time is not internally acknowledged.

Table 15-2. Noise Elimination Time of A/D Converter Input Pin

Pin	Noise Elimination Time
PCM5/ADTRG/ $\overline{\text{SELFREF}}$	Analog delay (80 ns typ.)

Caution The noise eliminator is valid only in the control mode.

15.6.3 Timer C and timer ENC1 input pins

The following noise filter that operates via clock sampling is provided for the pins of timers C and ENC1 that operate when the valid edge is input. Input signals that change within the noise elimination time are not internally acknowledged.

Table 15-3. Noise Elimination Time of Timer C and Timer ENC1 Input Pins

Pin	Noise Elimination Time
INTPC00/TIC0 INTPC01 INTPC10/TIC1 INTPC11 INTPC20/TIC2 INTPC21 INTPC30/TIC3 INTPC31	Selected from 0, 2, 3, or 5 clocks
INTP100/TCUD10 INTP101/TCLR10 TIUD10 INTP110/TCUD11 INTP111/TCLR11 TIUD11	Selected from 0, 2, 3, or 7 clocks

- Cautions**
1. The noise filter of the above pins cannot acknowledge an input signal when the CPU clock is stopped because it uses clock sampling.
 2. The noise eliminator is valid only in the control mode.

(1) Noise elimination width setting registers C0 to C3 (NCWC0 to NCWC3)

These registers are used to set the noise elimination width of the digital noise filter of the timer C input pins. These registers can be read or written in 8-bit units. Be sure to clear bits 7 to 2 to “0”. If they are set to “1”, the operation is not guaranteed. Do not overwrite this register during a count operation.

	7	6	5	4	3	2	1	0	Address	After reset
NCWC0	0	0	0	0	0	0	NCCC01	NCCC00	1FFFF610H	02H
NCWC1	0	0	0	0	0	0	NCCC11	NCCC10	1FFFF630H	02H
NCWC2	0	0	0	0	0	0	NCCC21	NCCC20	1FFFF650H	02H
NCWC3	0	0	0	0	0	0	NCCC31	NCCC30	1FFFF670H	02H

Bit position	Bit name	Function															
1, 0	NCCcn1, NCCcn0	Specify number of clocks from which noise is to be eliminated.															
		<table border="1"> <thead> <tr> <th>NCCcn1</th> <th>NCCcn0</th> <th>Number of clocks from which noise is to be eliminated</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>0 (through input)</td> </tr> <tr> <td>0</td> <td>1</td> <td>2</td> </tr> <tr> <td>1</td> <td>0</td> <td>3</td> </tr> <tr> <td>1</td> <td>1</td> <td>5</td> </tr> </tbody> </table>	NCCcn1	NCCcn0	Number of clocks from which noise is to be eliminated	0	0	0 (through input)	0	1	2	1	0	3	1	1	5
NCCcn1	NCCcn0	Number of clocks from which noise is to be eliminated															
0	0	0 (through input)															
0	1	2															
1	0	3															
1	1	5															
		Remark 1 clock = $f_x/4$ f_x : Main clock															

Remark n = 0 to 3

(2) Noise elimination width setting registers 10, 11 (NCW10, NCW11)

These registers are used to set the noise elimination width of the digital noise filter of the timer ENC1 input pins. These registers can be read or written in 8-bit units.

- Cautions**
- Whether the signal is input through or inverted can be specified for each of the INTP1n0/TCUD1n and TIUD1n pins. The noise elimination width set by the NCFn, NCC1n, and NCC0n bits is for each timer and cannot be changed for each pin.
 - The setting of the SRTCn bit is valid even when the INTP1n0/TCUD1n pin is used as a capture trigger (INTP1n0).

	7	6	5	4	3	2	1	0	Address	After reset
NCW10	0	0	SRTC0	SRTI0	0	NCF0	NCC10	NCC00	1FFFF5C0H	02H
NCW11	0	0	SRTC1	SRTI1	0	NCF1	NCC11	NCC01	1FFFF5F0H	02H

Bit position	Bit name	Function															
5	SRTCn	Specifies the input mode of the INTP1n0/TCUD1n pin. 0: Through input 1: Inverted This bit specifies whether the signal input from the INTP1n0/TCUD1n pin is input through to TMENC1n, or inverted.															
4	SRTIn	Specifies the input mode of the TIUD1n pin. 0: Through input 1: Inverted This bit specifies whether the signal input from the TIUD1n pin is input through to TMENC1n, or inverted.															
2	NCFn	Specifies the clock frequency for noise elimination. 0: $f_x/4$ 1: $f_x/32$ This bit selects a clock source for the noise filter.															
1, 0	NCC1n, NCC0n	Specify the number of clocks from which noise is to be eliminated. <table border="1"> <thead> <tr> <th>NCC1n^{Note 1}</th> <th>NCC0n^{Note 1}</th> <th>Number of clocks from which noise is to be eliminated</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>0 (through input)^{Note 2}</td> </tr> <tr> <td>0</td> <td>1</td> <td>2</td> </tr> <tr> <td>1</td> <td>0</td> <td>3</td> </tr> <tr> <td>1</td> <td>1</td> <td>7</td> </tr> </tbody> </table> <p>Notes</p> <ol style="list-style-type: none"> Do not overwrite this bit during a count operation. Clear the NCFn bit to 0 to input the signal through. <p>These bits are used to select the number of clocks from which noise is to be eliminated.</p>	NCC1n ^{Note 1}	NCC0n ^{Note 1}	Number of clocks from which noise is to be eliminated	0	0	0 (through input) ^{Note 2}	0	1	2	1	0	3	1	1	7

2. f_x : Main clock

15.7 Cautions

15.7.1 Cautions on setting port pins

(1) Procedure to change mode from port mode to control mode

Change the mode of a port pin that functions as an output or I/O pin in the control mode to the control mode using the following procedure.

- <1> Set the inactive level of the signal to be output in the control mode to the corresponding bit of port n (n = 1, 2, 5 to 7, AH, AL, CD, CM, CS, CT, DH).
- <2> Select the control mode by using the port n mode control register (PMcN).

If <1> is not performed, the contents of port n may be momentarily output when the mode is changed from the port mode to the control mode.

15.7.2 Cautions on bit manipulation instruction for port n register (Pn)

When a 1-bit manipulation instruction is executed on a port that provides both input and output functions, the value of the output latch of an input port that is not subject to manipulation may be written in addition to the targeted bit.

Therefore, it is recommended to rewrite the output latch when switching any port from input mode to output mode (including switching from control mode to port mode using ST/SST instruction).

<Example> When PCS0 pin is an output port, PCS1 to PCS7 pins are input ports (all pin statuses are high level), and the value of the port latch is 00H, if the output of PCS0 pin is changed from low level to high level via a bit manipulation instruction, the value of the port latch is FFH.

Explanation: The targets of writing to and reading from the Pn register of a port whose PMnm bit is 1 are the output latch and pin status, respectively.

A bit manipulation instruction is executed in the following order in the V850E2/ME3.

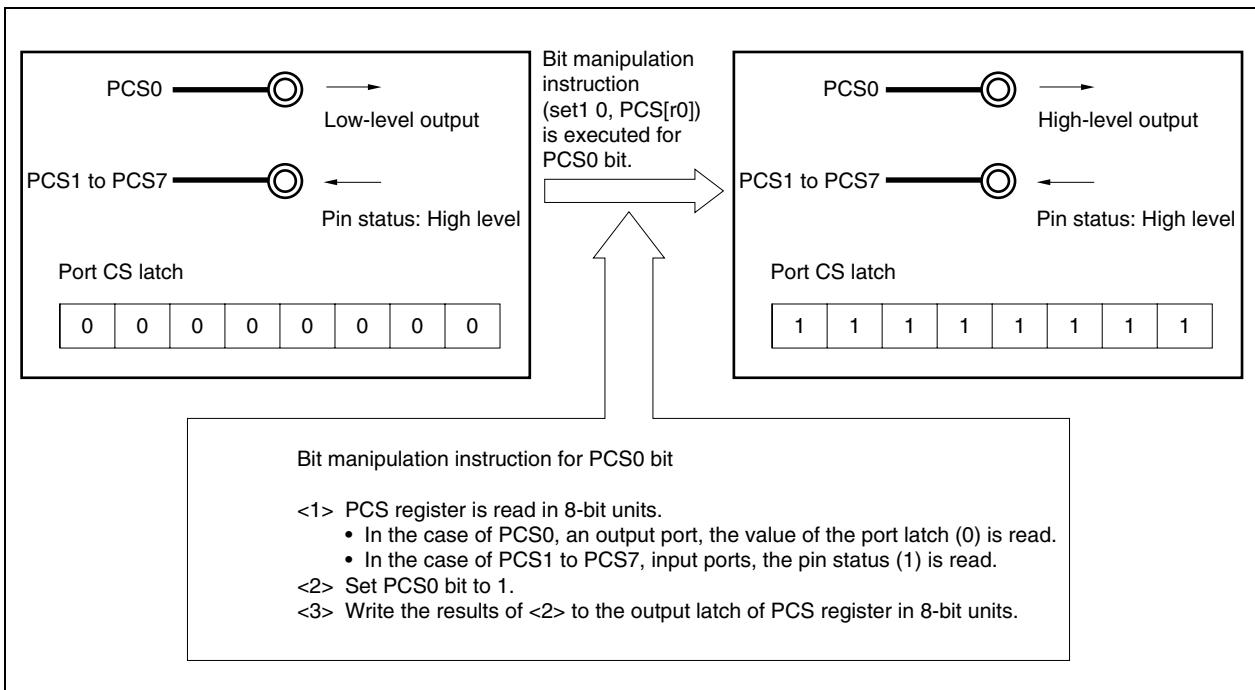

- <1> The Pn register is read in 8-bit units.
- <2> The targeted one bit is manipulated.
- <3> The Pn register is written in 8-bit units.

In step <1>, the value of the output latch (0) is read from the PCS0 pin, which is an output port, while the pin statuses are read from the PCS1 to PCS7 pins, which are input ports. If the pin statuses of PCS1 to PCS7 pins are high level at this time, the read value is FEH.

The value is changed to FFH by the manipulation in <2>.

FFH is written to the output latch by the manipulation in <3>.

Figure 15-29. Bit Manipulation Instruction (PCS0 Pin)

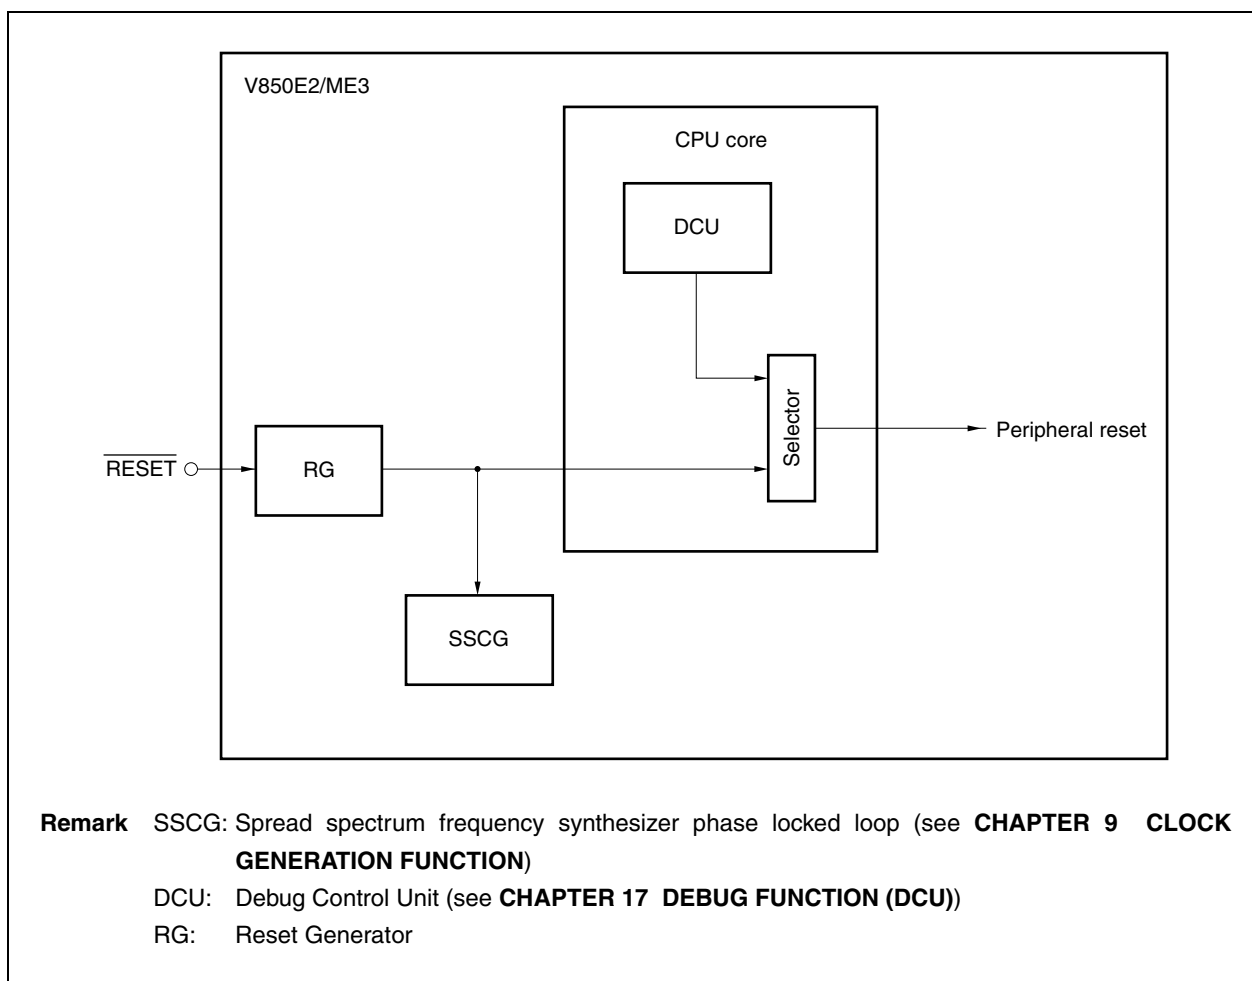

CHAPTER 16 RESET FUNCTIONS

16.1 Overview

- Reset function by $\overline{\text{RESET}}$ input
- Forced reset function by DCU (See **CHAPTER 17 DEBUG FUNCTION (DCU)**.)
- Low level is input to the $\overline{\text{RESET}}$ pin for 100 μs min. If an oscillation stabilization time of 100 μs or longer is necessary, secure the low level for as long as the necessary oscillation stabilization time.
- Reset generator (RG) eliminates noise from the $\overline{\text{RESET}}$ pin.

16.2 Configuration

During a system reset, most pins (all excluding the BUSCLK, $\overline{\text{RESET}}$, X2, EV_{DD}, EV_{SS}, IV_{DD}, IV_{SS}, PLLV_{DD}, PLLV_{SS}, OSCV_{DD}, OSCV_{SS}, UV_{DD}, AV_{DD}, AV_{REFP}, AV_{REFM}, and AV_{SS} pins) enter the high-impedance state.

Therefore, a pull-up (or pull-down) resistor must be connected to each pin of the address bus, data bus, and external bus control signals. If no resistor is connected, external memory may be destroyed when these pins enter the high-impedance state.

For the same reason, the output signals of the on-chip peripheral I/O functions and other output ports should be handled in the same manner.

16.3 Operation

When a low-level signal is input to the $\overline{\text{RESET}}$ pin, a system reset is effected and each on-chip hardware is initialized.

When the $\overline{\text{RESET}}$ pin level changes from low to high, the reset state is released and the CPU starts program execution using OSC output clock (F_x). Register contents must be initialized as required in the program.

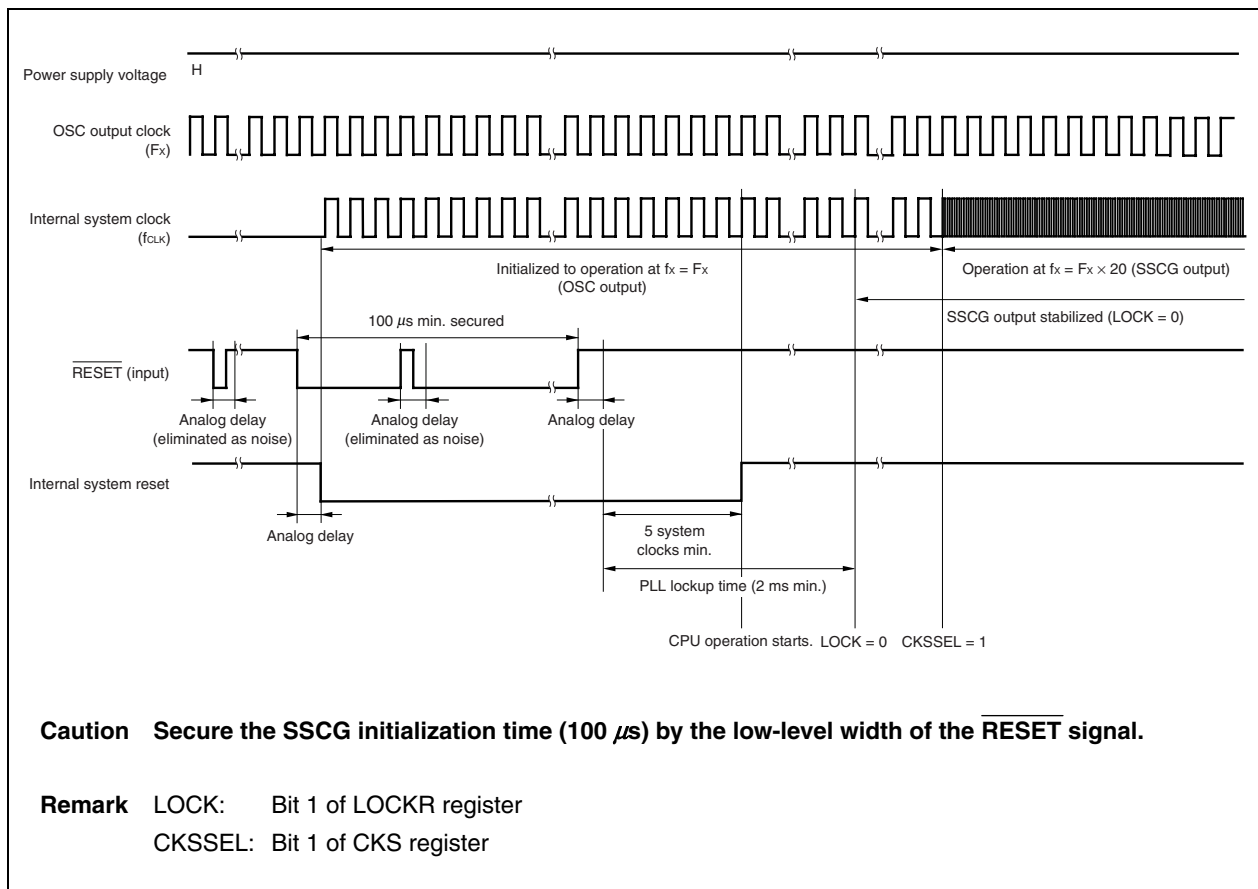

When the reset signal is cleared, the oscillation stabilization time is not inserted. When the $\overline{\text{RESET}}$ signal is to be input (reset input on power application) while the clock oscillator is stopped, therefore, a low-level width longer than the oscillation stabilization time (100 μs min.) must be secured at the $\overline{\text{RESET}}$ pin. When the $\overline{\text{RESET}}$ signal is to be input (reset input when the IDLE mode is released) while the clock oscillator is not stopped, a low level of 100 μs min. must be secured at the $\overline{\text{RESET}}$ pin.

Table 16-1. Hardware Status After Reset

Hardware	During Reset Period	After Reset Is Cleared
OSC	Oscillation/supply continues	
Clock generator	<ul style="list-style-type: none"> • Outputs OSC clock (F_x) • Output is not guaranteed before oscillation stabilization time. 	<ul style="list-style-type: none"> • Outputs OSC clock (F_x) • Operable at $f_x = F_x \times 20$ by controlling the CKS register
CPU	Stops operating	Starts operating
Internal instruction RAM, internal data RAM	Undefined	
Debug function	Stops operating	Operable
On-chip peripheral I/O registers	Initialized to specific status	
On-chip peripheral functions other than above	Stops operating	Can start operating
Pin function	See 2.2 Pin Status.	

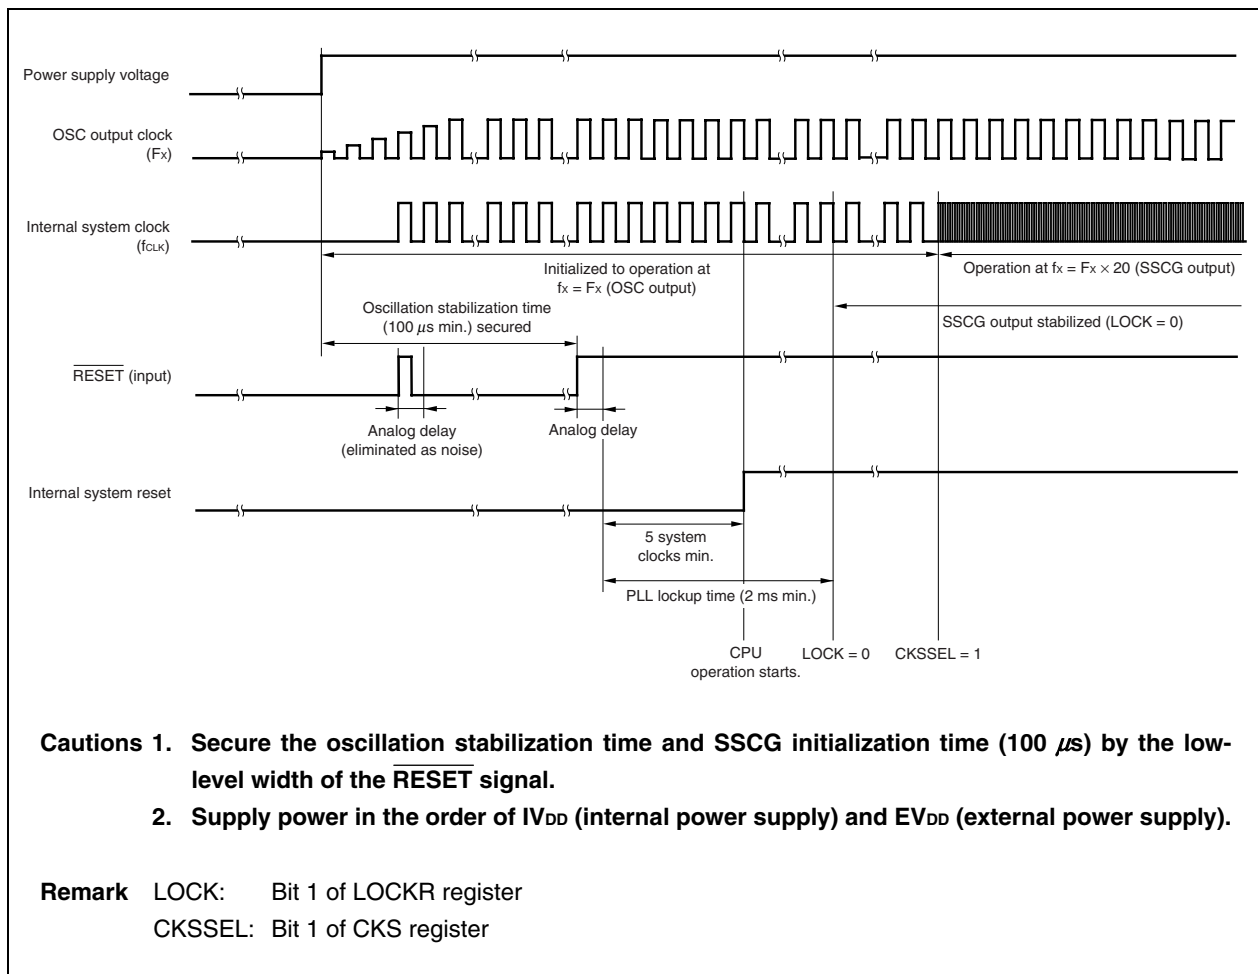

The reset operation when the $\overline{\text{RESET}}$ pin is input is illustrated below.

Figure 16-1. Reset Operation with $\overline{\text{RESET}}$ Pin Input (When IDLE Mode Is Released)

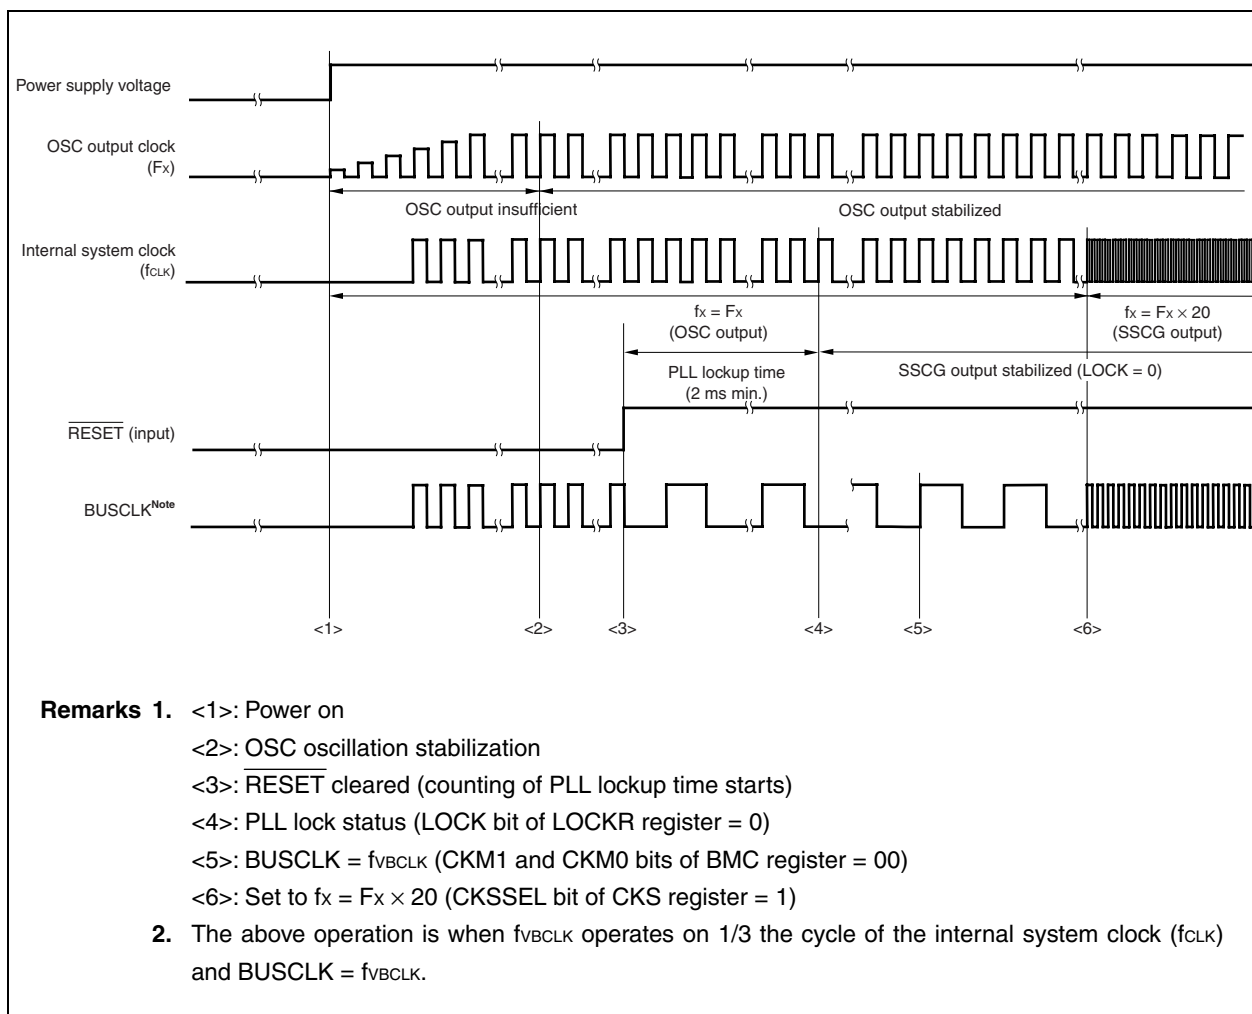

The power-on reset operation is illustrated below.

Figure 16-2. Power-on Reset Operation

The BUSCLK operation at power-on reset is illustrated below.

<R> **Figure 16-3. BUSCLK Operation at Power-on Reset (When $f_{CLK} = f_x$)**

16.4 Initialization

Initialize the contents of each register as necessary while programming.

The initial values of the CPU, internal data RAM, internal instruction RAM, and on-chip peripheral I/O after a reset are shown below.

Table 16-2. Initial Value of CPU, Internal Data RAM, Internal Instruction RAM, and On-Chip Peripheral I/O After Reset (1/6)

Internal Hardware		Register Name	Initial Value After Reset
CPU	Program registers	General-purpose register (r0)	00000000H
		General-purpose register (r1 to r31)	Undefined
		Program counter (PC)	00000000H
	System registers	Status saving registers during interrupt (EIPC, EIPSW)	Undefined
		Status saving registers during NMI (FEPC, FEPSW)	Undefined
		Interrupt source register (ECR)	00000000H
		Program status word (PSW)	00000020H
		Status saving registers during CALLT execution (CTPC, CTPSW)	Undefined
		Status saving registers during exception/debug trap (DBPC, DBPSW)	Undefined
CALLT base pointer (CTBP)		Undefined	
Internal instruction RAM, internal data RAM		–	Undefined
On-chip peripheral I/O	Bus control functions	Chip area select control register n (CSCn) (n = 0, 1)	C231H
		Bus cycle type configuration register n (BCTn) (n = 0, 1)	8888H
		Local bus sizing control register (LBS)	5555H/AAAAH ^{Note}
		Write access synchronization control register (WAS)	Undefined
		Bus mode control register (BMC)	00H
		Data wait control register n (DWCn) (n = 0, 1)	7777H
		Address setup wait control register (ASC)	FFFFH
		Bus cycle period control register (BCP)	00H
		DMA flyby transfer wait control register (FWC)	7777H
		Bus cycle control register (BCC)	FFFFH
		DMA flyby transfer idle control register (FIC)	3333H
		Instruction RAM control register (IRC)	00H
		Instruction RAM mode register (IRWE)	00H
		System wait control register (VSWC)	00CFH
	Cache function	Cache area specification register (BHC)	0000H
		Bus transaction control register (BTSC)	0005H
		Cache manipulation start address L register (CADL)	0000H
		Cache manipulation start address H register (CADH)	0000H
		Cache manipulation count specification register (CCNT)	0000H
		Cache manipulation specification register (COPR)	0000H
	Memory control functions	Page ROM configuration register (PRC)	7000H
		SDRAM configuration register n (SCRn) (n = 1, 3, 4, 6)	30C0H
		SDRAM refresh control register n (RFSn) (n = 1, 3, 4, 6)	0000H

Note For details, see 4.5.2 (1) Local bus sizing control register (LBS).

Table 16-2. Initial Value of CPU, Internal Data RAM, Internal Instruction RAM, and On-Chip Peripheral I/O After Reset (2/6)

Internal Hardware		Register Name	Initial Value After Reset
On-chip peripheral I/O	DMA functions	DMA source address register n (DSAn) (n = 0 to 3)	Undefined
		DMA source address register nH (DSAnH) (n = 0 to 3)	Undefined
		DMA source address register nL (DSAnL) (n = 0 to 3)	Undefined
		DMA destination address register n (DDAn) (n = 0 to 3)	Undefined
		DMA destination address register nH (DDAnH) (n = 0 to 3)	Undefined
		DMA destination address register nL (DDAnL) (n = 0 to 3)	Undefined
		DMA transfer count register n (DBCn) (n = 0 to 3)	Undefined
		DMA transfer count register nH (DBCnH) (n = 0 to 3)	Undefined
		DMA transfer count register nL (DBCnL) (n = 0 to 3)	Undefined
		DMA addressing control register n (DADCn) (n = 0 to 3)	0000H
		DMA channel control register n (DCHCn) (n = 0 to 3)	00H
		DMA terminal count output control register (DTCO)	01H
		DMA trigger factor register n (DTFRn) (n = 0 to 3)	00H
		DMA interface control register n (DIFCn) (n = 0 to 3)	00H
		DMA control register (DC)	00H
		DMA restart register (DRST)	00H
		DMA single transfer mode control register (DSMC)	00H
		Interrupt/exception control functions	Interrupt control registers (P1IC0, P1IC1, P2IC1 to P2IC5, P5IC0 to P5IC2, P6IC5 to P6IC7, PDIC0 to PDIC15, PLIC0, PLIC1, OVCIC0 to OVCIC5, CCC0IC0, CCC0IC1, CCC1IC0, CCC1IC1, CCC2IC0, CCC2IC1, CCC3IC0, CCC3IC1, CCC4IC0, CCC4IC1, CCC5IC0, CCC5IC1, CMDIC0 to CMDIC3, CC10IC0, CC10IC1, CC11IC0, CC11IC1, CM10IC0, CM10IC1, CM11IC0, CM11IC1, OV1IC0, OV1IC1, UD1IC0, UD1IC1, DMAIC0 to DMAIC3, CSI3IC0, CSI3IC1, COVF3IC0, COVF3IC1, UREIC0, UREIC1, URIC0, URIC1, UTIC0, UTIC1, UIFIC0, UIFIC1, UTOIC0, UTOIC1, ADIC, US0BIC to US2BIC, USP2IC, USP4IC, RSUMIC)
	Interrupt mask register n (IMRn) (n = 0 to 5)		FFFFH

Caution “Undefined” in the above table is undefined after power-on-reset, or undefined as a result of data destruction when $\overline{\text{RESET}}\downarrow$ is input and the data write timing has been synchronized. For other $\overline{\text{RESET}}\downarrow$ signals, data is held in the same state it was in before the $\overline{\text{RESET}}$ operation.

CHAPTER 17 DEBUG FUNCTION (DCU)

The debug control unit (DCU) consists of three function units: an execution control unit (RCU) that realizes communication with JTAG and execution of debug processing, a trace control unit (TRCU) that implements trace functions, and a trigger event unit (TEU) that implements event detection functions. On-chip debugging of the V850E2/ME3 can be executed by connecting an on-chip debug emulator.

Caution The debug function is supported by the V850E2/ME3, but whether this function can be used or not depends on the debugger used.

17.1 Functional Outline

17.1.1 Debug function

(1) Debug interface

This interface establishes communication with the host machine by using the $\overline{\text{DRST}}$, DCK, DMS, DDI, and DDO signals, via an on-chip debug emulator. The communication specifications of JTAG are used for this interface. It does not support a boundary scan function.

(2) On-chip debug

On-chip debugging can be performed if wiring and connectors for debugging are provided on the target system. Connect an on-chip debug emulator to the connector for debugging.

(3) Forced reset function

The V850E2/ME3 can be forcibly reset.

(4) Forced break function

Execution of the user program can be forcibly stopped (however, the handler of the illegal instruction code exception (first address: 00000060H) cannot be used).

(5) Debug monitor function

During debugging, a memory space for debugging, different from the user memory space, is used (background monitor format). The user program can be executed starting from any address.

While execution of the user program is stopped, the user resources (such as memory and I/O) can be read/written, and the user program can be downloaded.

(6) Mask function

- (a) NMI and all maskable interrupt request signals can be masked.
- (b) When the debugger is connected, the $\overline{\text{RESET}}$ pin input on the target board is masked by default (the $\overline{\text{RESET}}$ pin input is masked when the debugger is started after power application to the V850E2/ME3). The $\overline{\text{RESET}}$ pin input can be unmasked from the debugger. If a signal is input to the $\overline{\text{RESET}}$ pin during debugging (during RUN execution), however, the following problems may occur.
 - The break function may malfunction. If this happens, restart.
 - Trace data may be illegal before and after $\overline{\text{RESET}}$ pin input. Recovery will occur after the $\overline{\text{RESET}}$ signal has been released.

17.1.2 Trace function**(1) PC trace (branch trace) function**

All branches (transition of processing) that occur during user program execution can be traced.

The trace sources can be selected from 12 types of branch sources that are classified by function, and PC trace can be started from execution of an instruction at any address, and the trace source can be changed.

Two trace start triggers are available.

(2) Data trace function

A data access issued by the CPU to any address can be traced in a range of 1 KB to 4 bytes.

Read or written data can be traced, and two data trace points are available.

However, a data access issued by the DMAC cannot be traced.

(3) Real-time trace mode

Branch and data access can be traced during real-time execution of the user program.

The trace packet of the trace source detected is stored in a trace buffer, and output from trace interface pins (TRCCLK, TRCDATA0 to TRCDATA3, and TRCEND) (some trace packets may not be traced if no more trace packets can be stored in the trace buffer).

(4) Full trace mode (non-real-time trace mode)

All branches and data accesses of the user program can be traced.

In the full trace mode, the pipeline of the CPU is temporarily held and instruction execution is stopped to secure the time of trace data output from trace interface pins, so that all trace packets can be correctly traced.

17.1.3 Event function

(1) Instruction event detection function

Event detection (10 events) via size comparison by the execution PC and range event detection (up to four pairs with each pair consisting of two events) of the execution PC can be executed.

If an instruction event source is used as a break source, two breakpoints before execution of the instruction at which an event is detected and eight breakpoints after instruction execution can be detected.

(2) Access event detection function

Events can be detected as follows.

- Comparison of access addresses (4 addresses)
- Range of access address (up to two pairs with each pair consisting of two addresses)
- Match or mismatch of access data
- Data of specific bit by masking data
- Access size

An access event source is detected after access. If an access event source is used as a break source, a break occurs after several instructions have been executed after the instruction that issued the access that caused event detection.

(3) Sequential event detection function

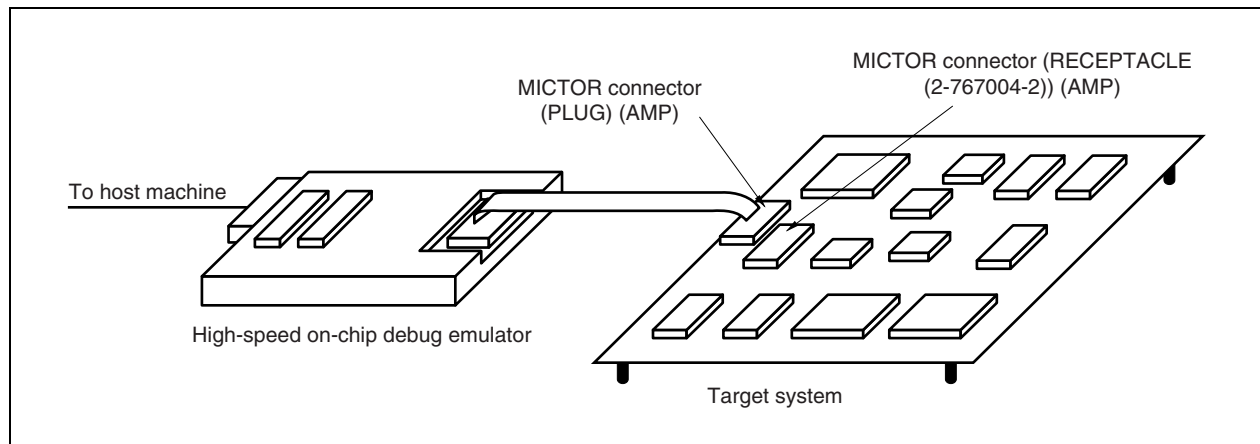

An event can be detected when up to four stages of events have successively occurred or an event that clears successive occurrence of events can be detected.

Sequential events can be counted by using a 12-bit pass counter.

17.2 Connection with On-Chip Debug Emulator

A connector for the emulator and a connection circuit must be provided on the target system.

Figure 17-1. Connecting On-Chip Debug Emulator

17.2.1 Emulator connector

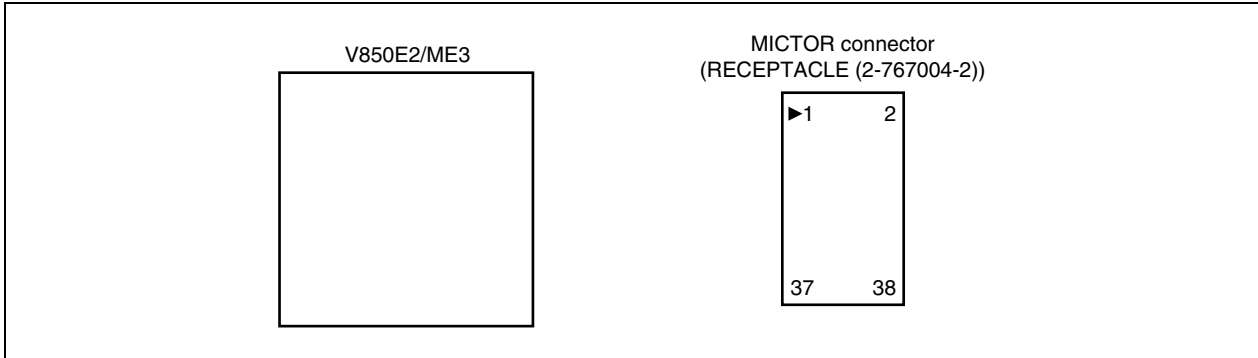

The following table shows the pin functions of the emulator connector.

Table 17-1. Emulator Connector Pin Function

Pin No.	Pin Name	I/O Direction	Pin Function
1	GND	–	–
2	GND	–	–
3	DCK	Emulator → V850E2/ME3	Clock for debug serial interface (Emulator → V850E2/ME3)
4	V _{DD}	–	+3.3 V (V850E2/ME3 → Emulator) (for monitoring power to target)
5	DMS	Emulator → V850E2/ME3	Transfer mode select for debug serial interface (Emulator → V850E2/ME3)
6	$\overline{\text{DRST}}$	Emulator → V850E2/ME3	DCU reset (Emulator → V850E2/ME3)
7	DDI	Emulator → V850E2/ME3	Data for debug serial interface (Emulator → V850E2/ME3)
8	PORT0_OUT	Emulator → V850E2/ME3	General-purpose control signal 0 (Emulator → V850E2/ME3)
9	DDO	V850E2/ME3 → Emulator	Data for debug serial interface (V850E2/ME3 → Emulator)
10	PORT1_OUT	Emulator → V850E2/ME3	General-purpose control signal 1 (Emulator → V850E2/ME3)
11	(Reserved 1)	–	(Leave this pin open)
12	PORT2_OUT	Emulator → V850E2/ME3	General-purpose control signal 2 (Emulator → V850E2/ME3)
13	(Reserved 2)	–	(Leave this pin open)
14	PORT0_IN	V850E2/ME3 → Emulator	General-purpose control signal 0 (V850E2/ME3 → Emulator)
15	(Reserved 3)	–	(Leave this pin open)
16	PORT1_IN	V850E2/ME3 → Emulator	General-purpose control signal 1 (V850E2/ME3 → Emulator)
17	TRCCLK	V850E2/ME3 → Emulator	Trace clock (V850E2/ME3 → Emulator)
18	PORT2_IN	V850E2/ME3 → Emulator	General-purpose control signal 2 (V850E2/ME3 → Emulator)
19	TRCEND	V850E2/ME3 → Emulator	Trace data end (V850E2/ME3 → Emulator)
20	TRCCE	V850E2/ME3 → Emulator	Trace packet compression enable signal (V850E2/ME3 → Emulator)
21	TRCDATA0	V850E2/ME3 → Emulator	Trace data 0 (V850E2/ME3 → Emulator)
22	TRCDATA8	V850E2/ME3 → Emulator	Trace data 8 (V850E2/ME3 → Emulator)
23	TRCDATA1	V850E2/ME3 → Emulator	Trace data 1 (V850E2/ME3 → Emulator)
24	TRCDATA9	V850E2/ME3 → Emulator	Trace data 9 (V850E2/ME3 → Emulator)
25	TRCDATA2	V850E2/ME3 → Emulator	Trace data 2 (V850E2/ME3 → Emulator)
26	TRCDATA10	V850E2/ME3 → Emulator	Trace data 10 (V850E2/ME3 → Emulator)
27	TRCDATA3	V850E2/ME3 → Emulator	Trace data 3 (V850E2/ME3 → Emulator)
28	TRCDATA11	V850E2/ME3 → Emulator	Trace data 11 (V850E2/ME3 → Emulator)
29	TRCDATA4	V850E2/ME3 → Emulator	Trace data 4 (V850E2/ME3 → Emulator)
30	TRCDATA12	V850E2/ME3 → Emulator	Trace data 12 (V850E2/ME3 → Emulator)
31	TRCDATA5	V850E2/ME3 → Emulator	Trace data 5 (V850E2/ME3 → Emulator)
32	TRCDATA13	V850E2/ME3 → Emulator	Trace data 13 (V850E2/ME3 → Emulator)
33	TRCDATA6	V850E2/ME3 → Emulator	Trace data 6 (V850E2/ME3 → Emulator)
34	TRCDATA14	V850E2/ME3 → Emulator	Trace data 14 (V850E2/ME3 → Emulator)
35	TRCDATA7	V850E2/ME3 → Emulator	Trace data 7 (V850E2/ME3 → Emulator)
36	TRCDATA15	V850E2/ME3 → Emulator	Trace data 15 (V850E2/ME3 → Emulator)
37	GND	–	–
38	GND	–	–

Remark Cautions are given on the next page.

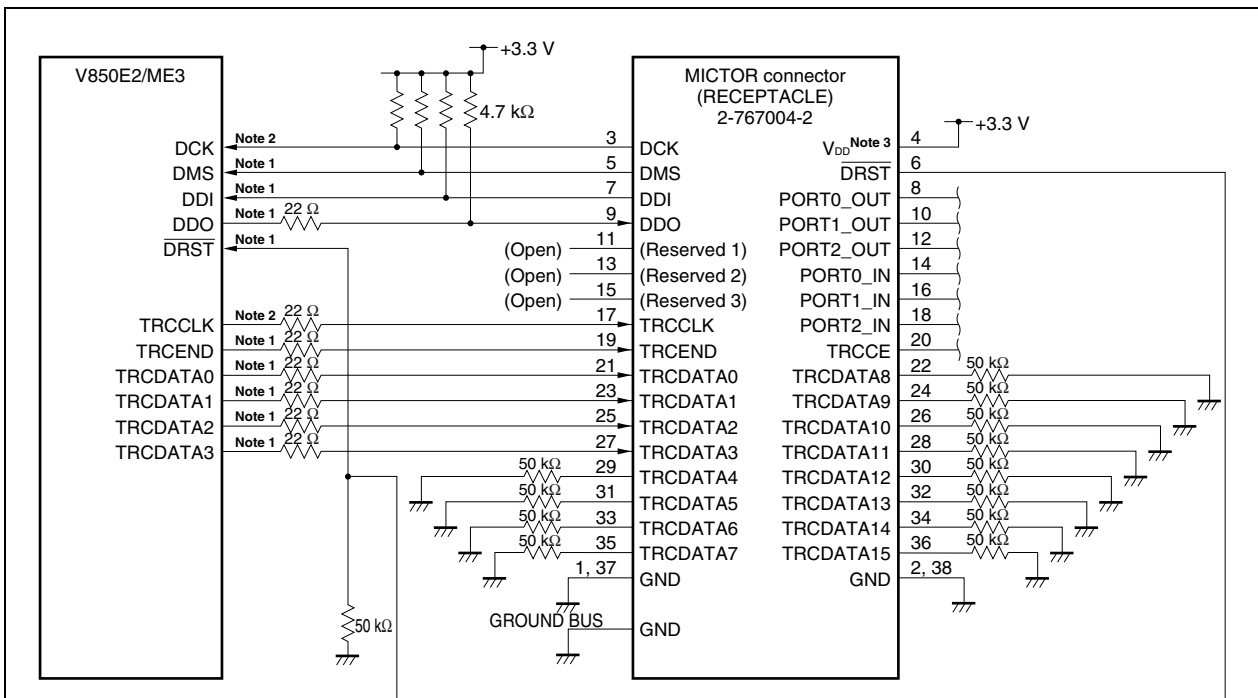

- Cautions**
1. The connection of pins not supported by the V850E2/ME3 depends on the emulator used.
 2. The pattern on the target board must satisfy the following conditions to support high-speed interfacing.
 - Lay out the pattern with the odd pins facing the device (V850E2/ME3).
 - Keep the pattern length to within 1.97 inches (50 mm).
 - Shield the clock signal with GND.

17.2.2 Recommended circuit example

The following figure shows an example of the recommended circuit of the emulator connector (on the target system side).

Figure 17-2. Example of Recommended Emulator Connection Circuit

- Notes**
1. Keep the pattern length to within 1.97 inches (50 mm).
 2. Shield the DCK and TRCCLK signals by GND.
 3. For detecting power to the target board

Caution The recommended circuit example shown above assumes that a 3.3 V interface is used.

CHAPTER 18 ELECTRICAL SPECIFICATIONS

Absolute Maximum Ratings (T_A = 25°C)

Parameter	Symbol	Conditions	Ratings	Unit
Supply voltage	I _{VDD}	I _{VDD} pin	-0.5 to +2.0	V
	I _{VSS}	I _{VSS} pin	-0.5 to +0.5	V
	E _{VDD}	E _{VDD} pin, E _{VDD} ≥ I _{VDD}	-0.5 to +4.6	V
	E _{VSS}	E _{VSS} pin	-0.5 to +0.5	V
	OSCV _{DD}	OSCV _{DD} pin	-0.5 to +4.6	V
	OSCV _{SS}	OSCV _{SS} pin	-0.5 to +0.5	V
	PLL _{VDD}	PLL _{VDD} pin	-0.5 to +2.0	V
	PLL _{VSS}	PLL _{VSS} pin	-0.5 to +0.5	V
	UV _{DD}	UV _{DD} pin	-0.5 to +4.6	V
	AV _{DD}	AV _{DD} pin, AV _{DD} < E _{VDD} ± 0.5 V	-0.5 to +4.6	V
	AV _{SS}	AV _{SS} pin	-0.5 to +0.5	V
Input voltage	V _I	Except for X1 pin, V _I < E _{VDD} + 0.3 V	-0.5 to +4.6	V
Clock input voltage	V _K	X1 pin	-0.5 to OSCV _{DD} + 0.5 ^{Note}	V
Output current, low	I _{OL}	Per pin	4.0	mA
		Total of all pins	100	mA
Output current, high	I _{OH}	Per pin	-4.0	mA
		Total of all pins	-100	mA
Output voltage	V _O	E _{VDD} = 3.3 V ± 0.3 V	-0.5 to E _{VDD} + 0.5 ^{Note}	V
Analog input voltage	V _{WASN}	ANI0 to ANI7 pins, AV _{DD} = 3.3 V ± 0.3 V	-0.3 to AV _{DD} + 0.3 ^{Note}	V
A/D converter reference input voltage	AV _{REFP}		-0.3 to AV _{DD} + 0.3 ^{Note}	V
	AV _{REFM}		-0.3 to +0.3	V
Operating ambient temperature	T _A	Output pin load capacitance ≤ 30 pF	-40 to +80	°C
Storage temperature	T _{stg}		-60 to +150	°C

Note Be sure not to exceed the absolute maximum ratings (MAX. value) of each supply voltage.

- Cautions 1.** Do not directly connect the output (or I/O) pins of IC products to each other, or to I_{VDD}, E_{VDD}, and GND. Direct connection of the output pins between an IC product and an external circuit is possible, if the output pins can be set to the high-impedance state and the output timing of the external circuit is designed to avoid output conflict.
- 2.** Product quality may suffer if the absolute maximum rating is exceeded even momentarily for any parameter. That is, the absolute maximum ratings are rated values at which the product is on the verge of suffering physical damage, and therefore the product must be used under conditions that ensure that the absolute maximum ratings are not exceeded.
- The ratings and conditions indicated for DC Characteristics and AC Characteristics represent the quality assurance range during normal operation.

Capacitance ($T_A = 25^\circ\text{C}$, $IV_{DD} = IV_{SS} = EV_{DD} = EV_{SS} = OSCV_{DD} = OSCV_{SS} = PLLV_{DD} = PLLV_{SS} = UV_{DD} = AV_{DD} = AV_{SS} = 0\text{ V}$)

Parameter	Symbol	Conditions	MIN.	TYP.	MAX.	Unit
Input capacitance	C_i	$f_c = 1\text{ MHz}$			15	pF
I/O capacitance	C_{Io}	Unmeasured pins returned to 0 V			15	pF
Output capacitance	C_o				15	pF

Operating Conditions

Part Number	Internal Operation Clock Frequency (fx)	Supply Voltage (V_{DD})
$\mu\text{PD703500GM-JEU-A}$	100 to 200 MHz	$IV_{DD} = 1.4\text{ to }1.65\text{ V}$, $PLLV_{DD} = 1.4\text{ to }1.65\text{ V}$, $EV_{DD} = 3.3\text{ V} \pm 0.3\text{ V}$, $OSCV_{DD} = 3.3\text{ V} \pm 0.3\text{ V}$, $UV_{DD} = 3.3\text{ V} \pm 0.3\text{ V}$, $AV_{DD} = 3.3\text{ V} \pm 0.3\text{ V}$
$\mu\text{PD703590GM-JEU-A}$		

<R>

Recommended Oscillator

(a) Ceramic resonator

(i) Murata Mfg. Co., Ltd. ($T_A = -20$ to $+80^\circ\text{C}$)

Type	Part Number	Oscillation Frequency f_x (MHz)	Recommended Circuit Constant		Oscillation Voltage Range		
			C1 (pF)	C2 (pF)	R_d (k Ω)	MIN. (V)	MAX. (V)
Surface mounting	CSTCR5M00G55-R0	5.000	On-chip (39)	On-chip (39)	0	3.0	3.6
	CSTCE8M00G55-R0	8.000	On-chip (33)	On-chip (33)	0	3.0	3.6
	CSTCE10M0G55-R0	10.000	On-chip (33)	On-chip (33)	0	3.0	3.6
Lead	CSTLS5M00G56-B0	5.000	On-chip (47)	On-chip (47)	0	3.0	3.6
	CSTLS8M00G56-B0	8.000	On-chip (47)	On-chip (47)	0	3.0	3.6
	CSTLS10M0G56-B0	10.000	On-chip (47)	On-chip (47)	0	3.0	3.6

Cautions 1. Connect the oscillator as close as possible to the X1 and X2 pins.

2. Do not route the wiring near broken lines.
3. Sufficiently evaluate the matching between the $\mu\text{PD703500}$, 703590 and the resonator.
4. These oscillator constants are reference values based on evaluation under a specific environment by the resonator manufacturer.

When optimization of the oscillator characteristics on the actual application is necessary, request evaluation on the mounting circuit from the resonator manufacturer.

The oscillation voltage and oscillation frequency indicate only oscillator characteristics, therefore use the $\mu\text{PD703500}$, 703590 within the DC characteristics and AC characteristics ratings for internal operation conditions.

(ii) Murata Mfg. Co., Ltd. ($T_A = -40$ to $+85^\circ\text{C}^{\text{Note}}$)

Note The operating ambient temperature of the V850E2/ME3 is $T_A = -40$ to $+80^\circ\text{C}$.

Type	Part Number	Oscillation Frequency f_x (MHz)	Recommended Circuit Constant		Oscillation Voltage Range		
			C1 (pF)	C2 (pF)	R_d (k Ω)	MIN. (V)	MAX. (V)
Surface mounting	CSTCR5M00G55Z-R0	5.000	On-chip (39)	On-chip (39)	0	3.0	3.6
	CSTCE8M00G55Z-R0	8.000	On-chip (33)	On-chip (33)	0	3.0	3.6
	CSTCE10M0G55Z-R0	10.000	On-chip (33)	On-chip (33)	0	3.0	3.6
Lead	CSTLS5M00G56Z-B0	5.000	On-chip (47)	On-chip (47)	0	3.0	3.6
	CSTLS8M00G56Z-B0	8.000	On-chip (47)	On-chip (47)	0	3.0	3.6
	CSTLS10M0G56Z-B0	10.000	On-chip (47)	On-chip (47)	0	3.0	3.6

Cautions 1. Connect the oscillator as close as possible to the X1 and X2 pins.

- 2. Do not route the wiring near broken lines.
- 3. Sufficiently evaluate the matching between the $\mu\text{PD703500}$, 703590 and the resonator.
- 4. These oscillator constants are reference values based on evaluation under a specific environment by the resonator manufacturer.

When optimization of the oscillator characteristics on the actual application is necessary, request evaluation on the mounting circuit from the resonator manufacturer.

The oscillation voltage and oscillation frequency indicate only oscillator characteristics, therefore use the $\mu\text{PD703500}$, 703590 within the DC characteristics and AC characteristics ratings for internal operation conditions.

DC Characteristics (T_A = -40 to +80°C, EV_{DD} = 3.3 V ±0.3 V, EV_{SS} = 0 V)

Parameter	Symbol	Conditions	MIN.	TYP.	MAX.	Unit

- (b) Other than (a)

AC test output measurement points

Load conditions

DUT (Device under test)

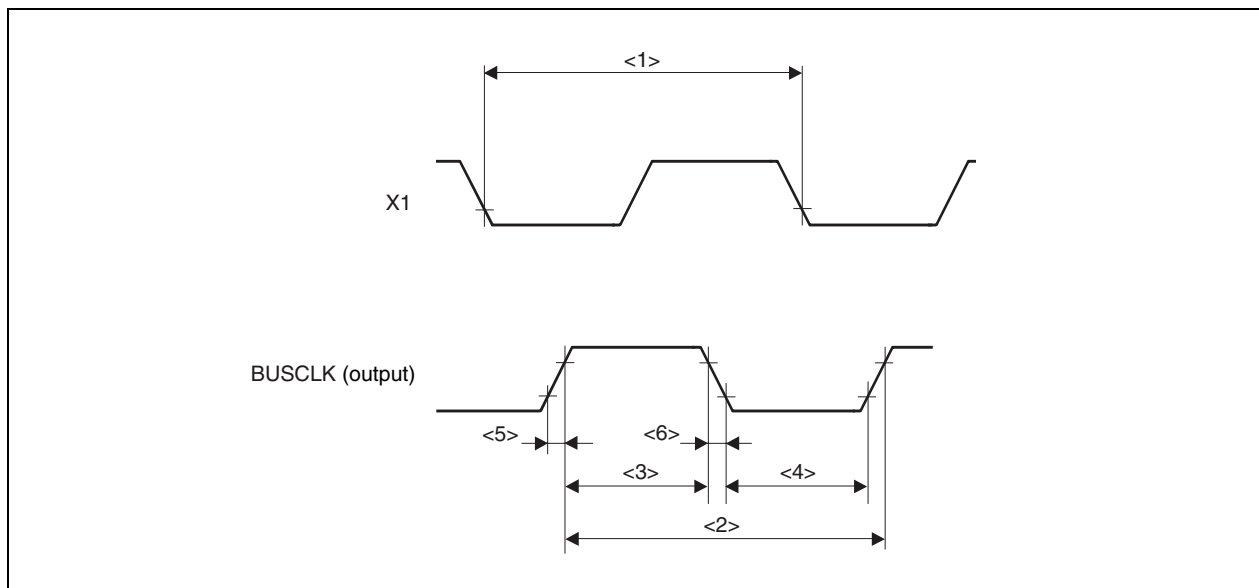

$C_L = 30$ pF

Caution If the load capacitance exceeds 30 pF due to the circuit configuration, make the load capacitance of this device 30 pF or lower by inserting a buffer, etc.

(1) Clock timing

Parameter	Symbol		Conditions	MIN.	MAX.	Unit
X1 input cycle	<1>	t_{CYX}		100	200	ns
BUSCLK output cycle	<2>	t_{CYK}	Output load capacitance ≤ 30 pF, $T_A = -40$ to 80°C	15	40	ns
BUSCLK high-level width	<3>	t_{WKH1}		$0.5T - 2$	$0.5T + 2$	ns
BUSCLK low-level width	<4>	t_{WKL1}		$0.5T - 2$	$0.5T + 2$	ns
BUSCLK rise time	<5>	t_{KR1}			3	ns
BUSCLK fall time	<6>	t_{KF1}			3	ns

Remark $T = t_{CYK}$

(2) Output waveform (other than X1, BUSCLK)

Parameter	Symbol	Conditions	MIN.	MAX.	Unit
Output rise time	<7>	toR	Other than Note	6	ns
			Note	8	ns
Output fall time	<8>	toF	Other than Note	6	ns
			Note	8	ns

Note P10/UCLK/INTP10, P12/RXD0/SI0, P20/NMI, P21/RXD1/INTP21, P22/TXD1/INTP22, P24/SI1/INTP24, P50/DMARQ0/INTP50, P51/DMAAK0/INTP51, P52/TC0/INTP52, P53/DMARQ1/TIC0/INTPC00, P54/DMAAK1/INTPC01, P55/TC1/TOC0, P65/INTPC10/TIC1/INTP65, P66/INTPC11/INTP66, P67/TOC1/INTP67, P72/DMARQ2/INTPC20/TIC2, P73/DMAAK2/INTPC21, P74/TC2/TOC2, P75/DMARQ3/INTPC30/TIC3, P76/DMAAK3/INTPC31, P77/TC3/TOC3

(3) Reset timing

Parameter	Symbol	Conditions	MIN.	MAX.	Unit
RESET pin high-level width	<9>	tWRSH	500		ns
RESET pin low-level width	<10>	tWRSL	Including oscillation stabilization time at power on. However, when the oscillation stabilization time exceeds 100 μs, secure the necessary oscillation stabilization time.	100	μs
			Excluding at power on.	100	μs

Caution Sufficiently evaluate the oscillation stabilization time.

(4) SRAM, external ROM, external I/O access timing

(a) Access timing (SRAM, external ROM, external I/O) (1/2)

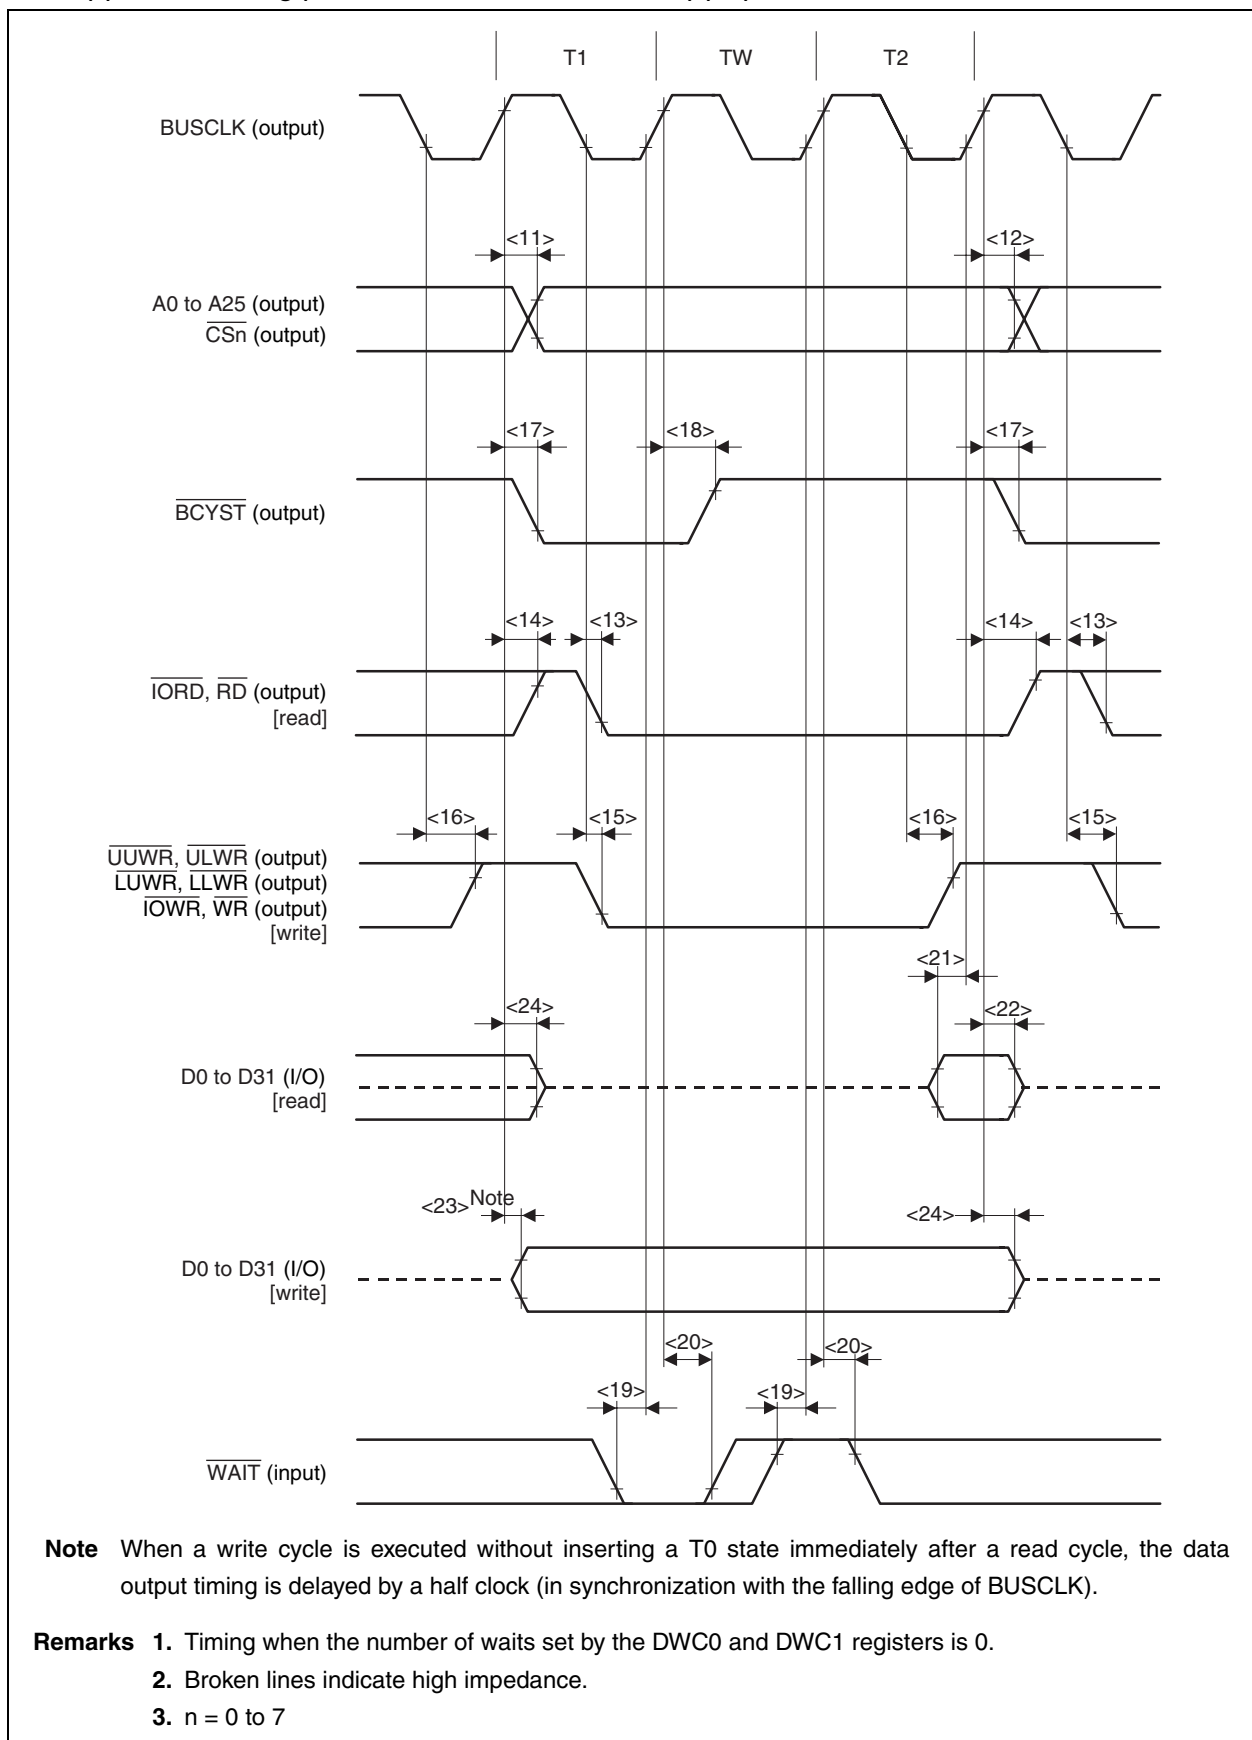

Parameter	Symbol	Conditions	MIN.	MAX.	Unit
Address, \overline{CSn} output delay time (from BUSCLK \uparrow)	<11> t_{DKA}		2	11	ns
Address, \overline{CSn} output hold time (from BUSCLK \uparrow)	<12> t_{HKA}		1	11	ns
\overline{RD} , \overline{IORD} delay time (from BUSCLK \downarrow)	<13> t_{DKRDL}		1	11	ns
\overline{RD} , \overline{IORD} delay time (from BUSCLK \uparrow)	<14> t_{DKRDH}		1	11	ns
\overline{xxWR} , \overline{IOWR} , \overline{WR} delay time (from BUSCLK \downarrow)	<15> t_{DKWRL}		1	11	ns
\overline{xxWR} , \overline{IOWR} , \overline{WR} delay time (from BUSCLK \uparrow)	<16> t_{DKWRH}		1	11	ns
\overline{BCYST} delay time (from BUSCLK \uparrow)	<17> t_{DKBSL}		2	11	ns
\overline{BCYST} delay time (from BUSCLK \uparrow)	<18> t_{DKBSH}		1	11	ns
\overline{WAIT} setup time (to BUSCLK \uparrow)	<19> t_{SWK}		6		ns
\overline{WAIT} hold time (from BUSCLK \uparrow)	<20> t_{HKW}		2		ns
Data input setup time (to BUSCLK \uparrow)	<21> t_{SKID}		6		ns
Data input hold time (from BUSCLK \uparrow)	<22> t_{HKID}		2		ns
Data output delay time (from BUSCLK \downarrow)	<23> t_{DKOD1}		2	11	ns
Data float delay time (from BUSCLK \uparrow)	<24> t_{HKOD}		2	11	ns

Remarks 1. Observe at least one of the data input hold times t_{HRDID} and t_{HKID} .

2. $n = 0$ to 7

$xx = UU, UL, LU, LL$

(a) Access timing (SRAM, external ROM, external I/O) (2/2)

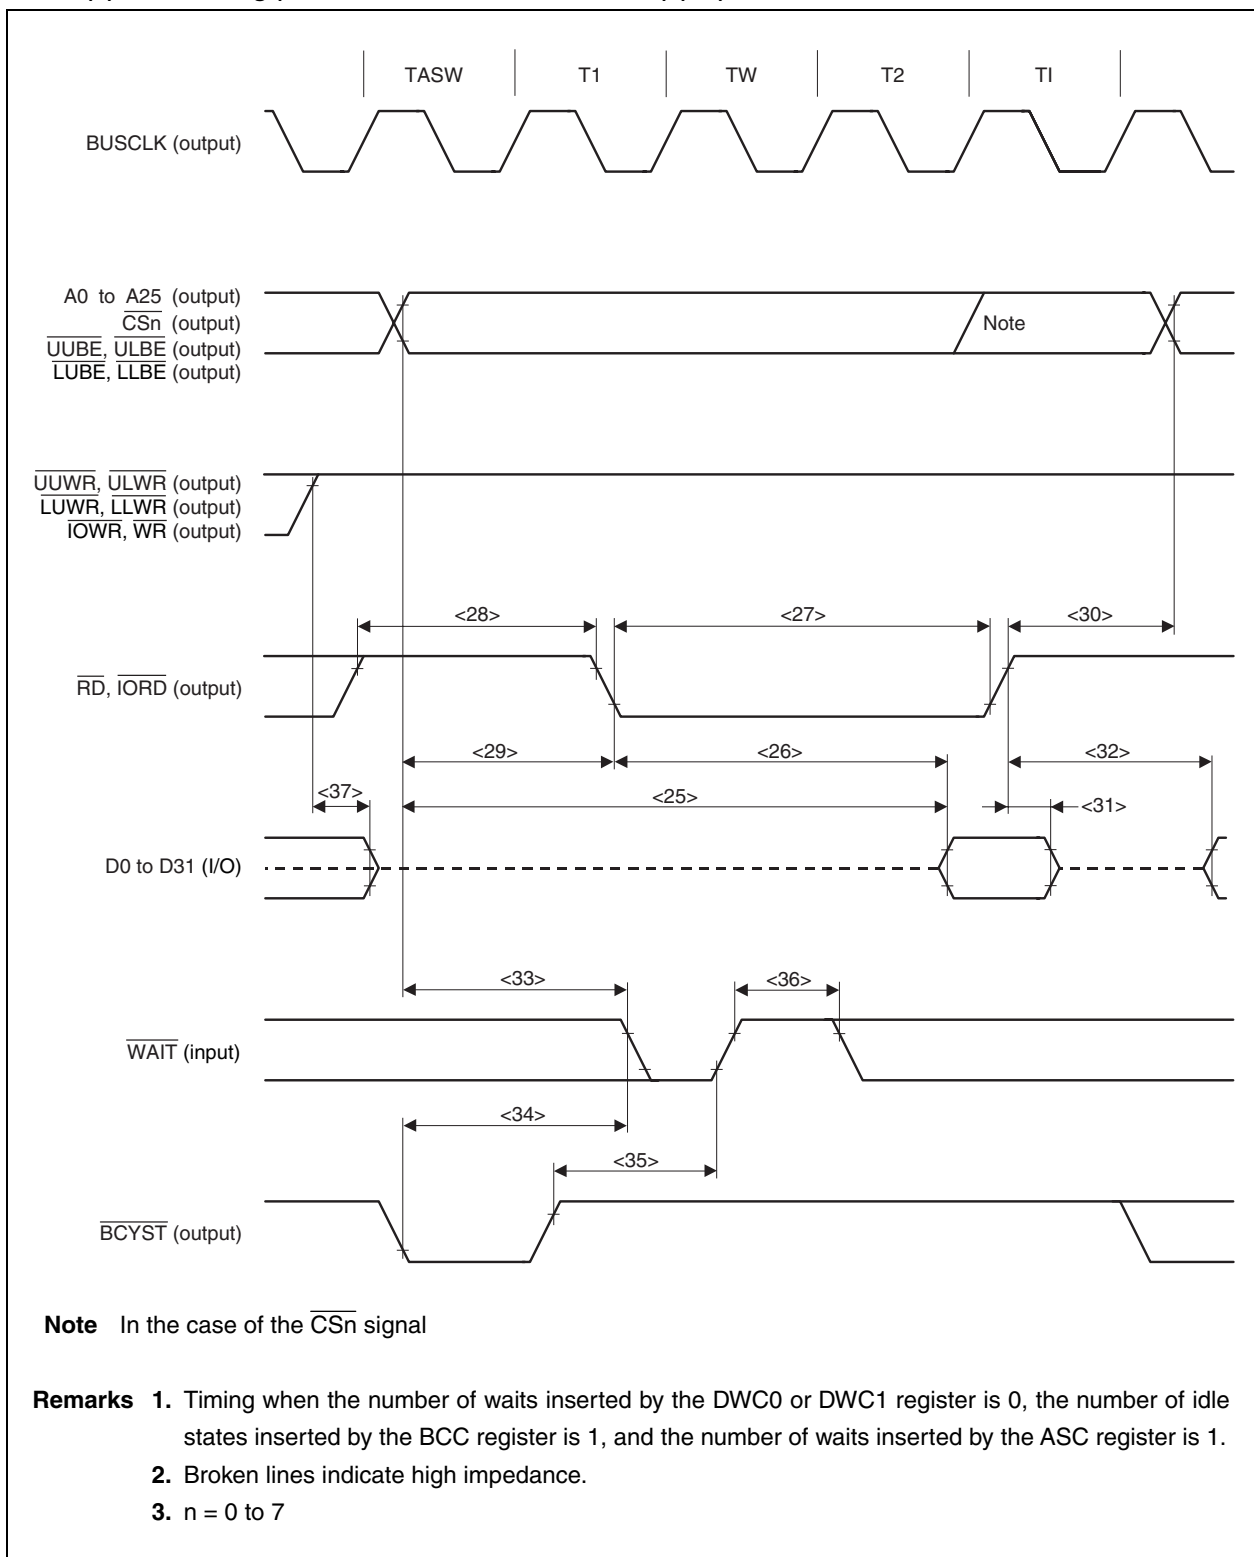

(b) Read timing (SRAM, external ROM, external I/O) (1/2)

Parameter	Symbol	Conditions	MIN.	MAX.	Unit
Data input setup time (to address)	<25>	t _{SAID}		$(2 + w + w_D + w_{AS}) T - 17$	ns
Data input setup time (to \overline{RD})	<26>	t _{SRDID}		$(1.5 + w + w_D) T - 17$	ns
\overline{RD} , \overline{IORD} low-level width	<27>	t _{WRDL}	$(1.5 + w + w_D) T - 6$		ns
\overline{RD} , \overline{IORD} high-level width	<28>	t _{WRDH}	$(0.5 + w_{AS} + i) T - 6$		ns
Delay time from address, \overline{CSn} to \overline{RD} , $\overline{IORD}\downarrow$	<29>	t _{DARD}	$(0.5 + w_{AS}) T - 7.5$		ns
Delay time from \overline{RD} , $\overline{IORD}\uparrow$ to address	<30>	t _{DRDA}	$iT - 2$		ns
Data input hold time (from \overline{RD} , $\overline{IORD}\uparrow$)	<31>	t _{HRDID}	0		ns
Delay time from \overline{RD} , $\overline{IORD}\uparrow$ to data output	<32>	t _{DRDOD}	$(0.5 + i) T - 6$		ns
\overline{WAIT} setup time (to address)	<33>	t _{SAW}	Note 1	$(1 + w_{AS}) T - 17$	ns
\overline{WAIT} setup time (to $\overline{BCYST}\downarrow$)	<34>	t _{SBSW}	Note 1	$(1 + w_{AS}) T - 17$	ns
\overline{WAIT} hold time (from $\overline{BCYST}\uparrow$)	<35>	t _{HBSW}	Note 1	$(w_{AS} + w_D) T + 2$	ns
\overline{WAIT} high-level width	<36>	t _{WWH}	Note 2	$T + 2$	ns
Data output hold time (from \overline{xxWR} , \overline{IOWR} , $\overline{WR}\uparrow$)	<37>	t _{HWROD}		$(0.5 + i) T - 5.5$	ns

- Notes 1.** At the first \overline{WAIT} sampling
2. Time necessary for releasing the wait state

- Remarks 1.** $T = t_{CYK}$
2. w : Number of waits inserted due to \overline{WAIT}
3. w_D : Number of waits inserted by DWC0 and DWC1 registers
4. Observe at least one of the data input hold times t_{HRDID} and t_{HKID}.
5. $n = 0$ to 7
 $xx = UU, UL, LU, LL$
6. i : Number of idle states
7. w_{AS} : Number of address setup waits inserted by ASC register
8. For the number of w and w_D to be inserted, refer to **4.7.3 Relationship between programmable wait and external wait.**

(b) Read timing (SRAM, external ROM, external I/O) (2/2)

(c) Write timing (SRAM, external ROM, external I/O) (1/2)

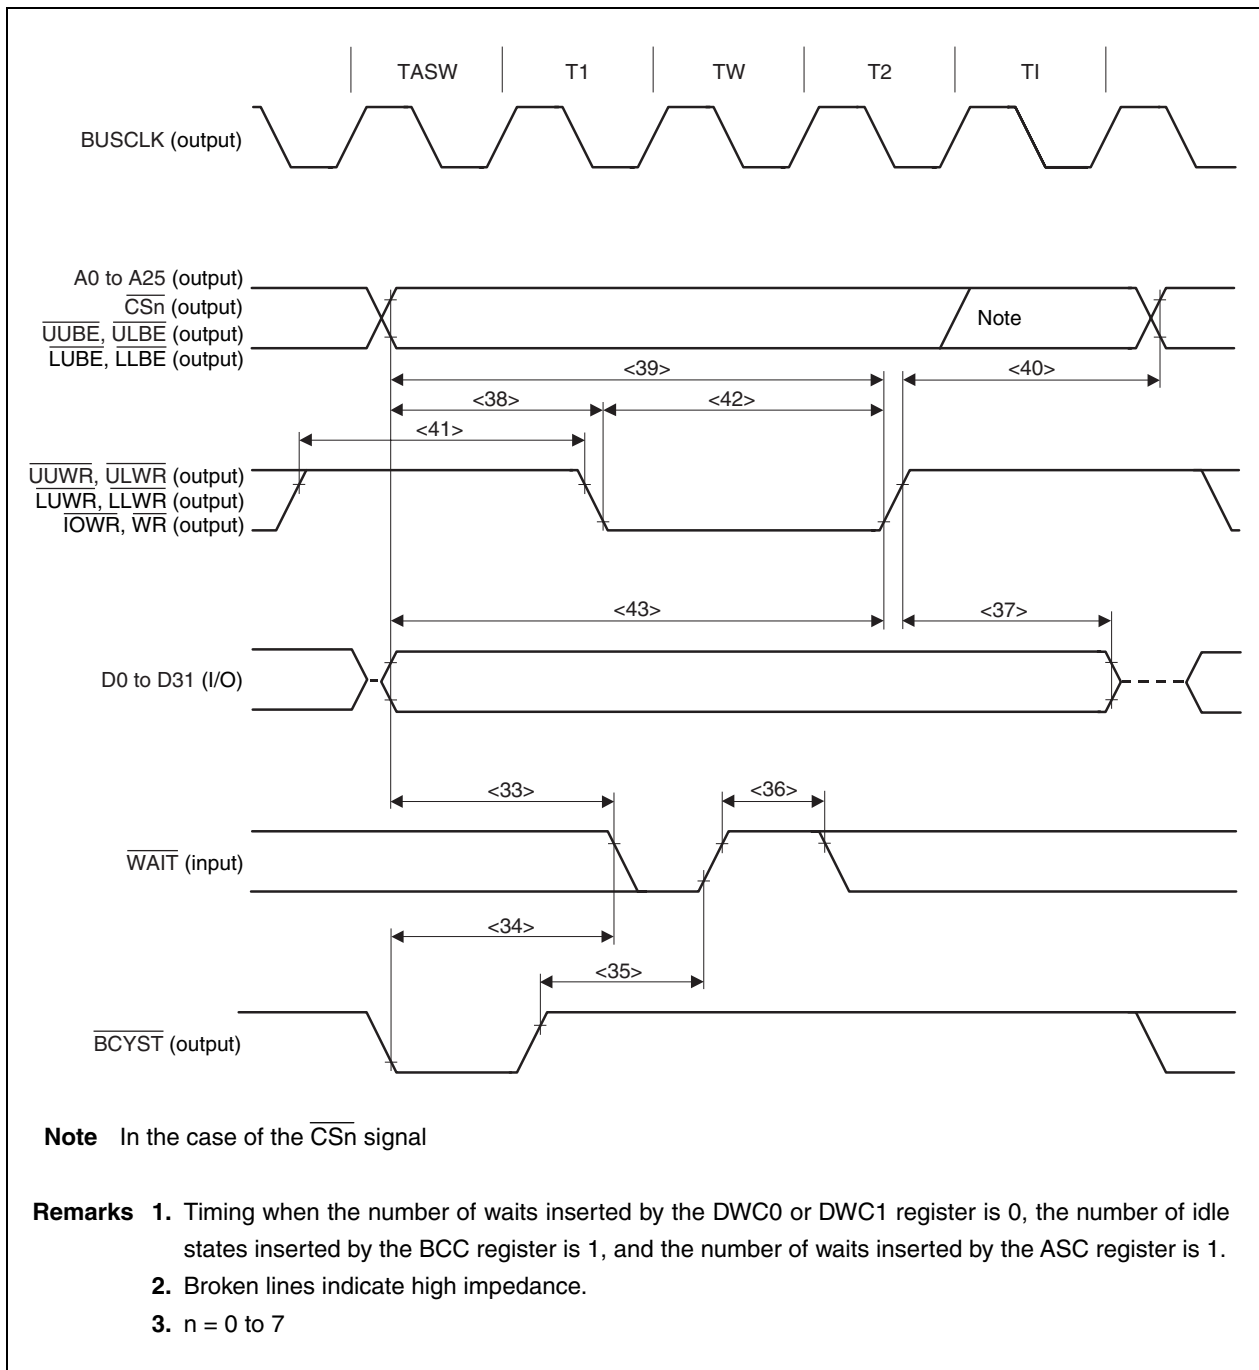

Parameter	Symbol	Conditions	MIN.	MAX.	Unit
$\overline{\text{WAIT}}$ setup time (to address)	<33> t_{SAW}	Note 1		$(1 + w_{\text{AS}}) T - 17$	ns
$\overline{\text{WAIT}}$ setup time (to $\overline{\text{BCYST}}\downarrow$)	<34> t_{SBSW}	Note 1		$(1 + w_{\text{AS}}) T - 17$	ns
$\overline{\text{WAIT}}$ hold time (from $\overline{\text{BCYST}}\uparrow$)	<35> t_{HBSW}	Note 1	$(w_{\text{AS}} + w_{\text{D}}) T + 2$		ns
$\overline{\text{WAIT}}$ high-level width	<36> t_{WWH}	Note 2	$T + 2$		ns
Delay time from address, $\overline{\text{CSn}}$ to $\overline{\text{xxWR}}$, $\overline{\text{IOWR}}$, $\overline{\text{WR}}\downarrow$	<38> t_{DAWR}		$(0.5 + w_{\text{AS}}) T - 7$		ns
Address setup time (to $\overline{\text{xxWR}}$, $\overline{\text{IOWR}}$, $\overline{\text{WR}}\uparrow$)	<39> t_{SAWR}		$(1.5 + w + w_{\text{D}} + w_{\text{AS}}) T - 10$		ns
Delay time from $\overline{\text{xxWR}}$, $\overline{\text{IOWR}}$, $\overline{\text{WR}}\uparrow$ to address	<40> t_{DWRA}		$(0.5 + i) T - 5$		ns
$\overline{\text{xxWR}}$, $\overline{\text{IOWR}}$, $\overline{\text{WR}}$ high-level width	<41> t_{WWRH}		$(1 + i + w_{\text{AS}}) T - 5$		ns
$\overline{\text{xxWR}}$, $\overline{\text{IOWR}}$, $\overline{\text{WR}}$ low-level width	<42> $t_{\text{WWR L}}$		$(1 + w + w_{\text{D}}) T - 5$		ns
Data output setup time (to $\overline{\text{xxWR}}$, $\overline{\text{IOWR}}$, $\overline{\text{WR}}\uparrow$)	<43> t_{SODWR}		$(1.5 + w_{\text{AS}} + w + w_{\text{D}}) T - 5$		ns
Data output hold time (from $\overline{\text{xxWR}}$, $\overline{\text{IOWR}}$, $\overline{\text{WR}}\uparrow$)	<37> t_{HWROD}		$(0.5 + i) T - 5.5$		ns

- Notes 1.** At the first $\overline{\text{WAIT}}$ sampling
2. Time necessary for releasing the wait state

Remarks 1. $T = t_{\text{CYK}}$

- 2.** w : Number of waits inserted due to $\overline{\text{WAIT}}$
- 3.** w_{D} : Number of waits inserted by DWC0 and DWC1 registers
- 4.** $n = 0$ to 7
 $xx = \text{UU, UL, LU, LL}$
- 5.** i : Number of idle states
- 6.** w_{AS} : Number of address setup waits inserted by ASC register
- 7.** For the number of w and w_{D} to be inserted, refer to **4.7.3 Relationship between programmable wait and external wait.**

(c) Write timing (SRAM, external ROM, external I/O) (2/2)

(d) DMA flyby transfer timing (transfer from SRAM to external I/O) (1/2)

Parameter	Symbol	Conditions	MIN.	MAX.	Unit
$\overline{\text{WAIT}}$ setup time (to $\text{BUSCLK}\uparrow$)	<19> t_{SWK}		6		ns
$\overline{\text{WAIT}}$ hold time (from $\text{BUSCLK}\uparrow$)	<20> t_{HKW}		2		ns
$\overline{\text{RD}}$ low-level width	<27> t_{WRDL}		$(1.5 + w + w_{\text{FW}}) T - 6$		ns
$\overline{\text{RD}}$ high-level width	<28> t_{WRDH}		$(0.5 + w_{\text{AS}} + i) T - 6$		ns
Delay time from address, $\overline{\text{CS}}_n$ to $\overline{\text{RD}}\downarrow$	<29> t_{DARD}		$(0.5 + w_{\text{AS}}) T - 7.5$		ns
Delay time from $\overline{\text{RD}}\uparrow$ to address	<30> t_{DRDA}		$iT - 2$		ns
Delay time from $\overline{\text{RD}}\uparrow$ to data output	<32> t_{DRDOD}		$(0.5 + i) T - 6$		ns
$\overline{\text{WAIT}}$ setup time (to address)	<33> t_{SAW}	Note		$(1 + w_{\text{AS}} + w_{\text{FW}}) T - 17$	ns
$\overline{\text{WAIT}}$ setup time (to $\overline{\text{BCYST}}\downarrow$)	<34> t_{BSW}	Note		$(1 + w_{\text{AS}} + w_{\text{FW}}) T - 17$	ns
$\overline{\text{WAIT}}$ hold time (from $\overline{\text{BCYST}}\uparrow$)	<35> t_{BSW}	Note	$(w_{\text{AS}} + w_{\text{FW}}) T + 2$		ns
$\overline{\text{WAIT}}$ high-level width	<36> t_{WWH}		$T + 2$		ns
Delay time from address to $\overline{\text{IOWR}}\downarrow$	<38> t_{DAWR}		$(0.5 + w_{\text{AS}}) T - 7$		ns
Address setup time (to $\overline{\text{IOWR}}\uparrow$)	<39> t_{SAWR}		$(1.5 + w + w_{\text{FW}} + w_{\text{AS}}) T - 10$		ns
Delay time from $\overline{\text{IOWR}}\uparrow$ to address	<40> t_{DWRA}		$(0.5 + i) T - 5$		ns
$\overline{\text{IOWR}}$ high-level width	<41> t_{WWRH}		$(0.5 + i + w_{\text{AS}}) T - 5$		ns

Delay time from $\overline{\text{IOWR}}\uparrow$ to $\overline{\text{RD}}\uparrow$	<44> t_{DIWRRD}		$0.5T - 4$		ns
Delay time from $\overline{\text{DMAAK}}_m\downarrow$ to $\overline{\text{IOWR}}\downarrow$	<45> t_{DDAWR}		$(0.5 + w_{\text{AS}}) T - 7.5$		ns
Delay time from $\overline{\text{IOWR}}\uparrow$ to $\overline{\text{DMAAK}}_m\uparrow$	<46> t_{DWRDA}		$(1.5 + i) T - 10$		ns

Note At the second and subsequent $\overline{\text{WAIT}}$ sampling

Remarks 1. $T = t_{\text{CYK}}$

2. w : Number of waits inserted due to $\overline{\text{WAIT}}$

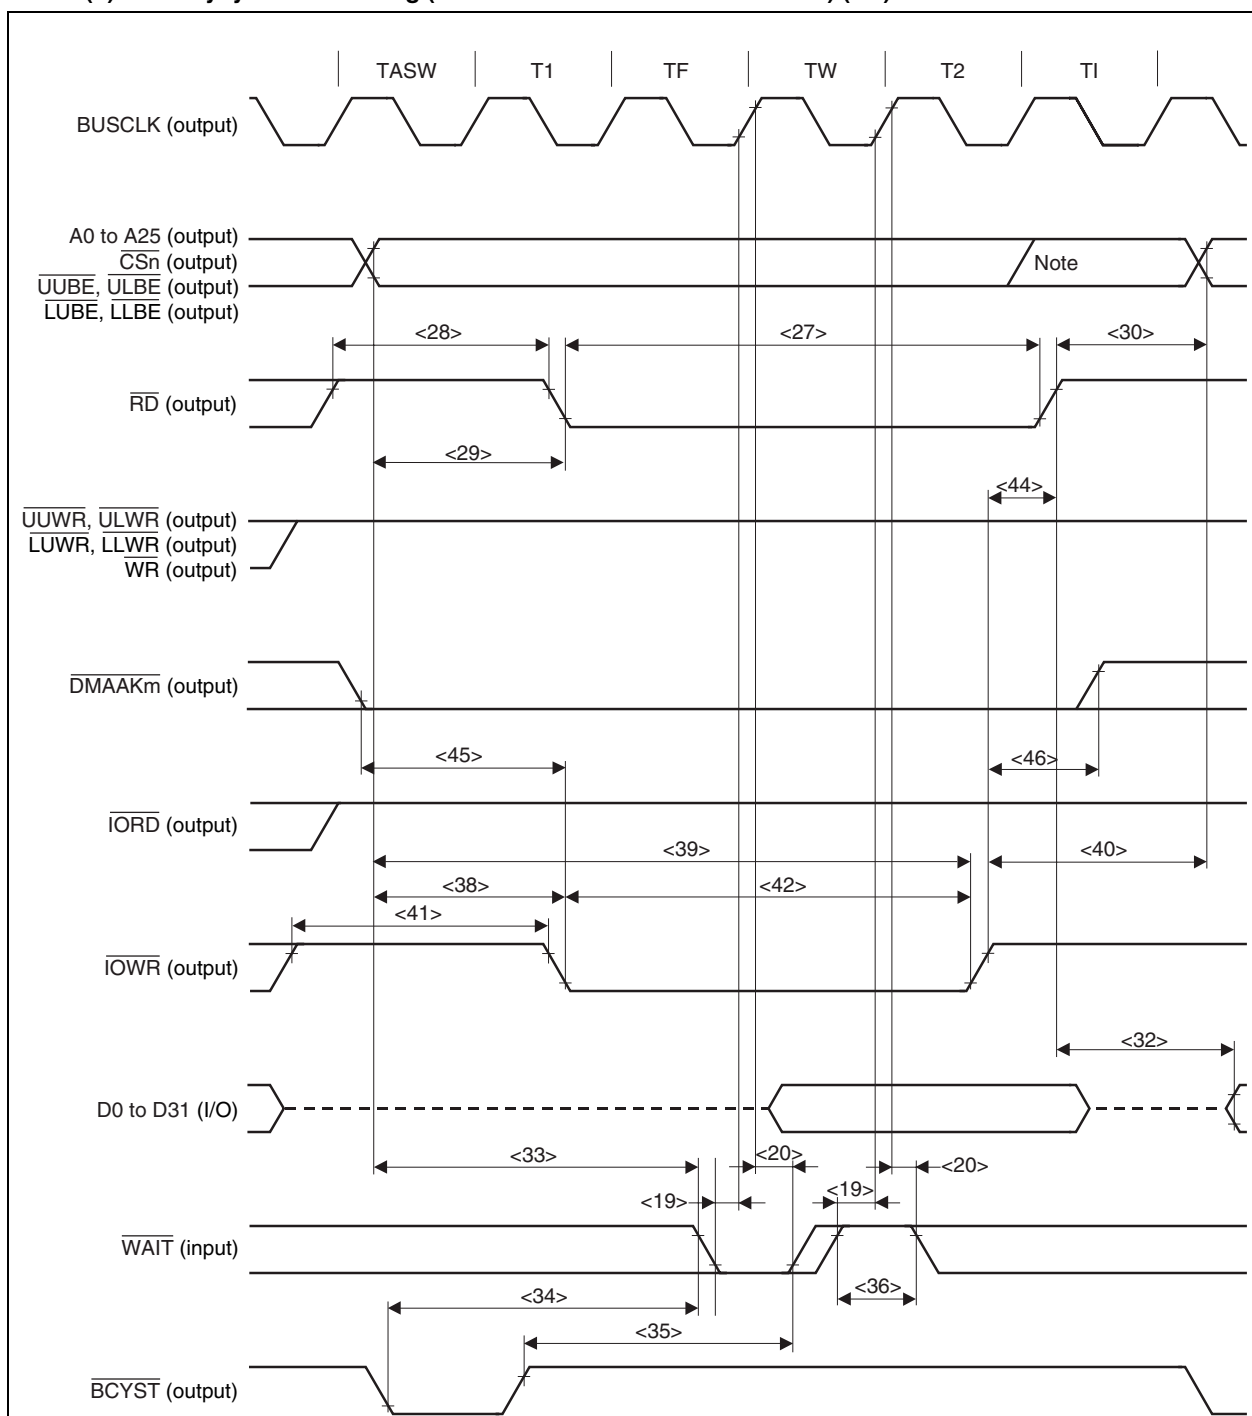

3. w_{FW} : Number of waits inserted by FWC register

4. $n = 0$ to 7, $m = 0$ to 3

5. i : Number of idle states

6. w_{AS} : Number of address setup waits inserted by ASC register

(d) DMA flyby transfer timing (transfer from SRAM to external I/O) (2/2)

Note In the case of the \overline{CSn} signal

- Remarks**
1. Timing when the number of waits inserted by the FWC register is 1, the number of idle states inserted by the FIC register is 1, and the number of waits inserted by the ASC register is 1.
 2. Broken lines indicate high impedance.
 3. $n = 0$ to 7, $m = 0$ to 3

(e) DMA flyby transfer timing (transfer from external I/O to SRAM) (1/2)

Parameter	Symbol	Conditions	MIN.	MAX.	Unit
$\overline{\text{WAIT}}$ setup time (to $\text{BUSCLK}\uparrow$)	<19>	t _{SWK}	6		ns
$\overline{\text{WAIT}}$ hold time (from $\text{BUSCLK}\uparrow$)	<20>	t _{HKW}	2		ns

$\overline{\text{WAIT}}$ setup time (to $\overline{\text{BCYST}}\downarrow$)	<34>	t _{SBSW}	Note	$(1 + w_{AS} + w_{FW}) T - 17$	ns
$\overline{\text{WAIT}}$ hold time (from $\overline{\text{BCYST}}\uparrow$)	<35>	t _{HBSW}	Note	$(w_{AS} + w_{FW}) T + 2$	ns
$\overline{\text{WAIT}}$ high-level width	<36>	t _{WWH}	$T + 2$		ns
Delay time from address to $\overline{\text{xxWR}}$, $\overline{\text{WR}}\downarrow$	<38>	t _{DAWR}	$(0.5 + w_{AS}) T - 7$		ns
Address setup time (to $\overline{\text{xxWR}}$, $\overline{\text{WR}}\uparrow$)	<39>	t _{SAWR}	$(1.5 + w + w_{FW} + w_{AS}) T - 10$		ns
Delay time from $\overline{\text{xxWR}}$, $\overline{\text{WR}}\uparrow$ to address	<40>	t _{DWRA}	$(0.5 + i) T - 5$		ns
$\overline{\text{xxWR}}$, $\overline{\text{WR}}$ high-level width	<41>	t _{WWRH}	$(1 + i + w_{AS}) T - 5$		ns
$\overline{\text{xxWR}}$, $\overline{\text{WR}}$ low-level width	<42>	t _{WWRL}	$(1 + w + w_{FW}) T - 5$		ns
Delay time from $\overline{\text{xxWR}}$, $\overline{\text{WR}}\uparrow$ to $\overline{\text{IORD}}\uparrow$	<47>	t _{DWRIRD}	$0.5T - 4$		ns
Delay time from $\overline{\text{DMAAK}}_m\downarrow$ to $\overline{\text{IORD}}\downarrow$	<48>	t _{DDARD}	$(0.5 + w_{AS}) T - 7.5$		ns
Delay time from $\overline{\text{IORD}}\uparrow$ to $\overline{\text{DMAAK}}_m\uparrow$	<49>	t _{DRDDA}	$(0.5 + i) T - 7.5$		ns

Note At the second and subsequent $\overline{\text{WAIT}}$ sampling

Remarks 1. $T = t_{CYK}$

2. w : Number of waits inserted due to $\overline{\text{WAIT}}$

3. w_{FW} : Number of waits inserted by FWC register

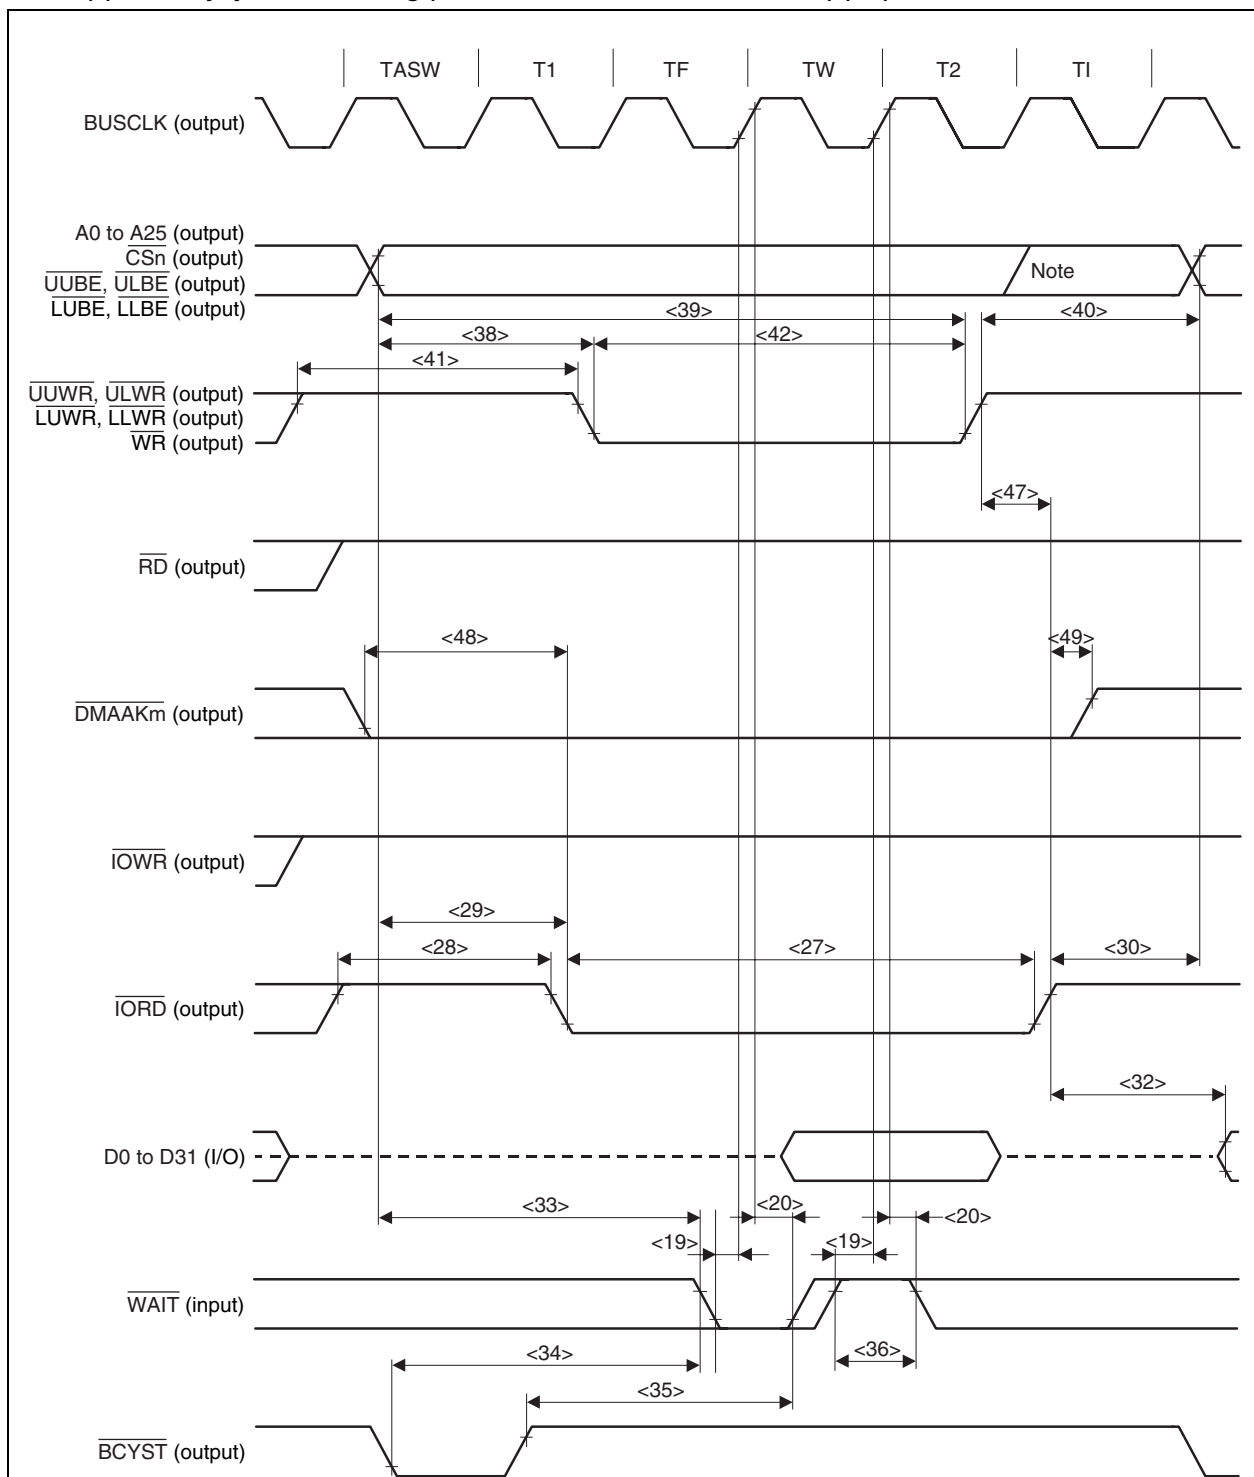

4. $n = 0$ to 7, $m = 0$ to 3

$xx = \text{UU, UL, LU, LL}$

5. i : Number of idle states inserted when a write cycle is inserted after a read cycle

6. w_{AS} : Number of address setup waits inserted by ASC register

(e) DMA flyby transfer timing (transfer from external I/O to SRAM) (2/2)

Note In the case of the \overline{CSn} signal

- Remarks**
1. Timing when the number of waits inserted by the FWC register is 1, the number of idle states inserted by the FIC register is 1, and the number of waits inserted by the ASC register is 1.
 2. Broken lines indicate high impedance.
 3. $n = 0$ to 7, $m = 0$ to 3

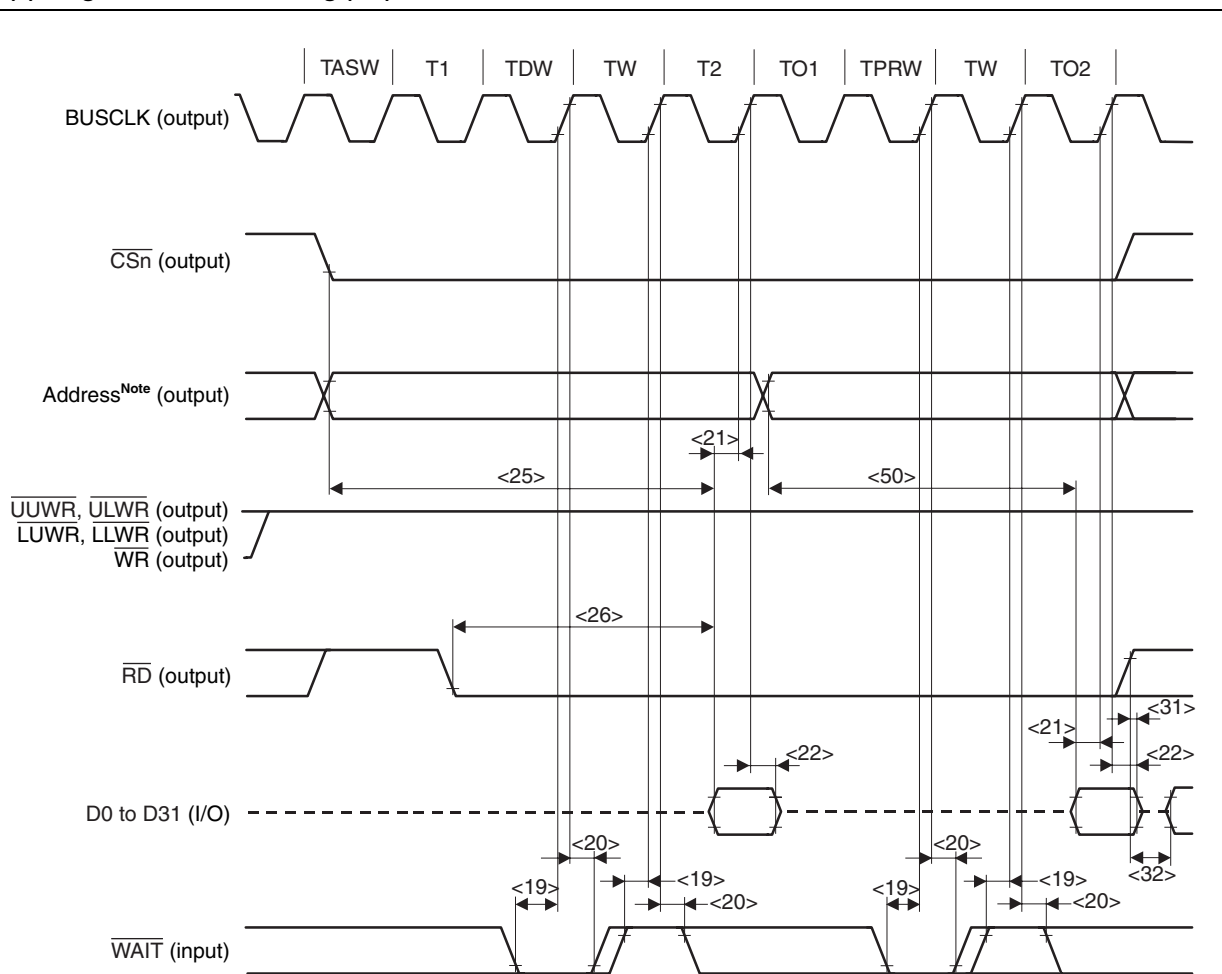

(5) Page ROM access timing (1/2)

Parameter	Symbol	Conditions	MIN.	MAX.	Unit
$\overline{\text{WAIT}}$ setup time (to $\text{BUSCLK}\uparrow$)	<19> t_{SWK}		6		ns
$\overline{\text{WAIT}}$ hold time (from $\text{BUSCLK}\uparrow$)	<20> t_{HKW}		2		ns
Data input setup time (to $\text{BUSCLK}\uparrow$)	<21> t_{SKID}		6		ns
Data input hold time (from $\text{BUSCLK}\uparrow$)	<22> t_{HKID}		2		ns
Off-page data input setup time (to address)	<25> t_{SAID}			$(2 + w + w_D + w_{AS}) T - 17$	ns
Off-page data input setup time (to $\overline{\text{RD}}$)	<26> t_{SRDID}			$(1.5 + w + w_D) T - 17$	ns
Data input hold time (from $\overline{\text{RD}}\uparrow$)	<31> t_{HRDID}		2		ns
Delay time from $\overline{\text{RD}}\uparrow$ to data output	<32> t_{DRDOD}		$(0.5 + i) T - 6$		ns
On-page data input setup time (to address)	<50> t_{SOAID}			$(2 + w + w_{PR}) T - 17$	ns

Remarks 1. $T = t_{\text{CYK}}$

2. w : Number of waits inserted due to $\overline{\text{WAIT}}$
3. w_D : Number of waits inserted by DWC0 and DWC1 registers
4. w_{PR} : Number of waits inserted by PRC register
5. i : Number of idle states inserted when a write cycle is inserted after a read cycle
6. w_{AS} : Number of address setup waits inserted by ASC register
7. Observe at least one of the data input hold times t_{HRDID} and t_{HKID} .
8. For the number of w and w_D to be inserted, refer to **4.7.3 Relationship between programmable wait and external wait**.

(5) Page ROM access timing (2/2)

Note On-page addresses and off-page addresses are shown below.

PRC register				On-page address	Off-page address
MA6	MA5	MA4	MA3		
0	0	0	0	A0 to A2	A3 to A25
0	0	0	1	A0 to A3	A4 to A25
0	0	1	1	A0 to A4	A5 to A25
0	1	1	1	A0 to A5	A6 to A25
1	1	1	1	A0 to A6	A7 to A25

Remarks 1. Timing in the following case.

Number of waits inserted by DWC0 or DWC1 register (TDW): 1

Number of waits inserted by PRC register (TPRW): 1

Number of waits inserted by ASC register (TASW): 1

2. Broken lines indicate high impedance.

3. n = 0 to 7

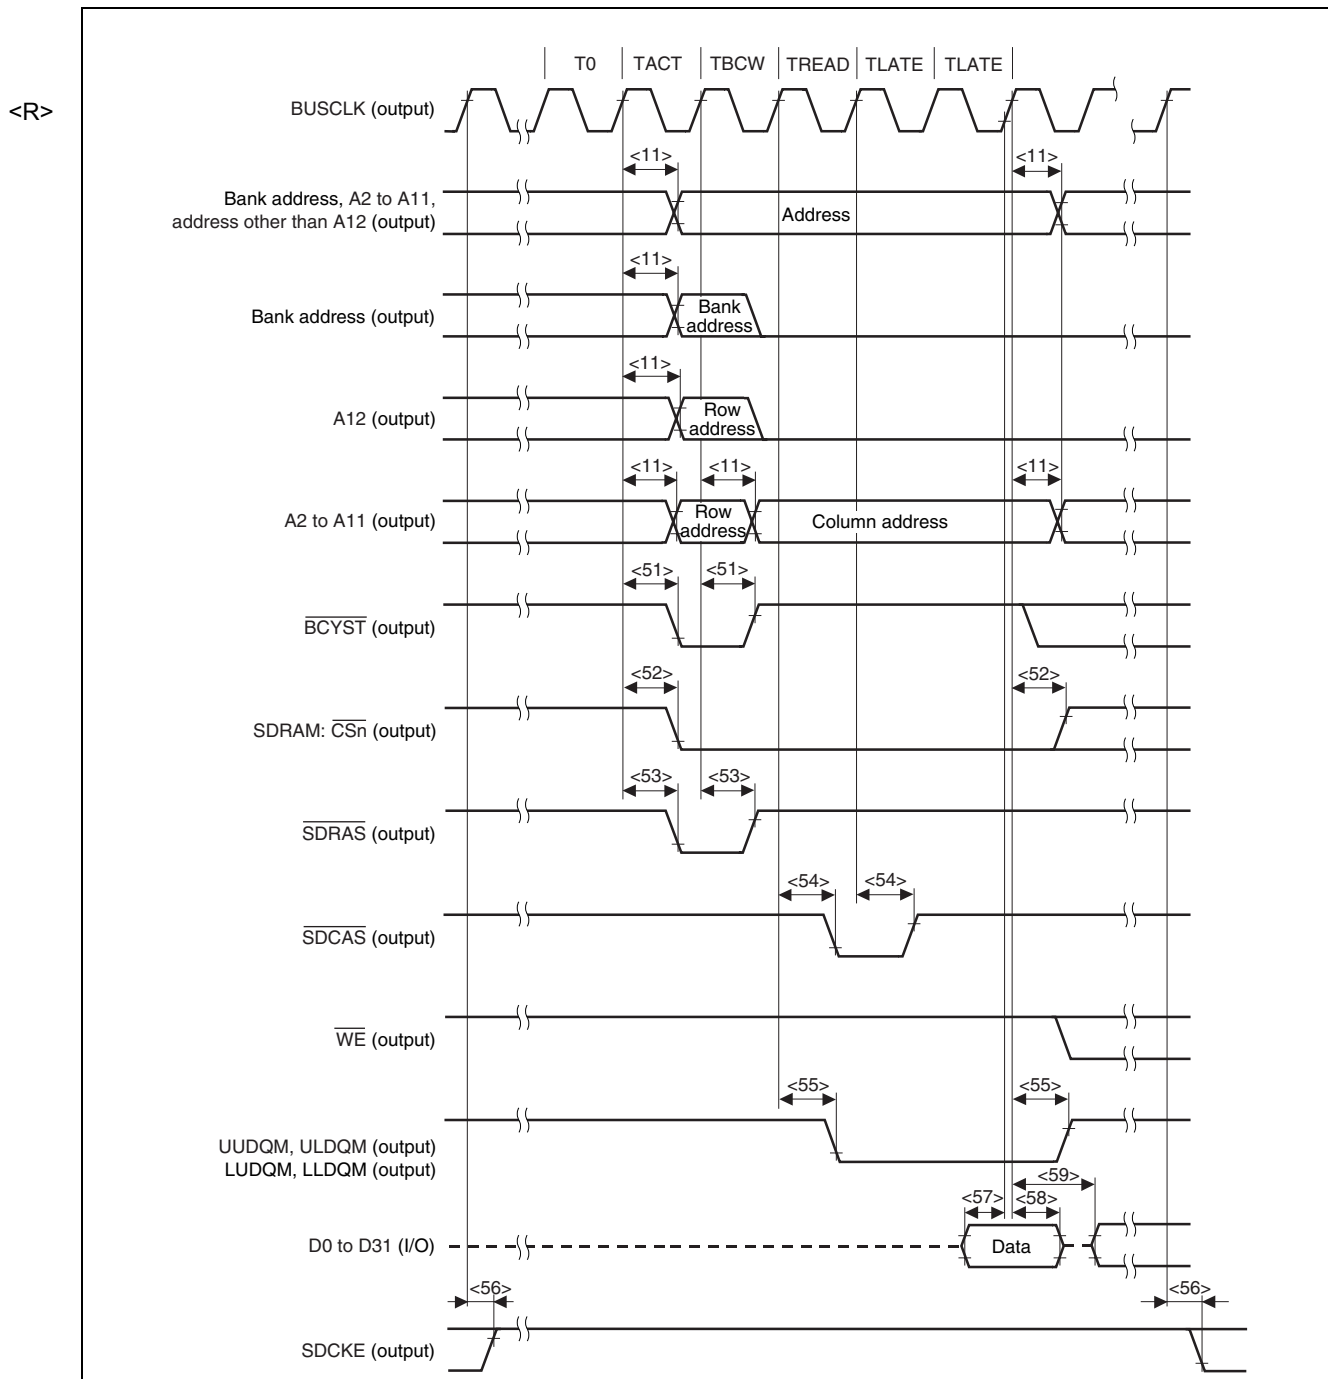

(6) SDRAM access timing**(a) Read timing (SDRAM access) (1/2)**

Parameter	Symbol	Conditions	MIN.	MAX.	Unit
Address delay time (from BUSCLK \uparrow)	<11> t _{DKA}		2	11	ns
$\overline{\text{BCYST}}$ delay time (from BUSCLK \uparrow)	<51> t _{DKBC}		1	11	ns
$\overline{\text{CSn}}$ delay time (from BUSCLK \uparrow)	<52> t _{DKCS}		1	11	ns
$\overline{\text{SDRAS}}$ delay time (from BUSCLK \uparrow)	<53> t _{DKRAS}		1	11	ns
$\overline{\text{SDCAS}}$ delay time (from BUSCLK \uparrow)	<54> t _{DKCAS}		1	11	ns
xxDQM delay time (from BUSCLK \uparrow)	<55> t _{DKDQM}		2	11	ns
SDCKE delay time (from BUSCLK \uparrow)	<56> t _{DKCKE}		1	11	ns
Data input setup time (SDRAM read, from BUSCLK \uparrow)	<57> t _{SDRMK}		6		ns
Data input hold time (SDRAM read, from BUSCLK \uparrow)	<58> t _{HKDRM}		2		ns
Delay time from BUSCLK \uparrow to data output	<59> t _{DSDOD}		(0.5 + i) T		ns

Caution If an SRAM (external I/O) cycle that uses the $\overline{\text{xxWR}}$ signal is generated immediately after a read cycle to SDRAM, an SRAM (external I/O) writing error may occur. In this case, set the BCC register to insert an idle state in the SDRAM space or execute a countermeasure using external circuits. However, no writing error occurs in a synchronization design in which the $\overline{\text{xxWR}}$ signal is sampled using BUSCLK.

- Remarks**
1. T = t_{cyk}
 2. i: Number of idle states
 3. n = 1, 3, 4, 6
xx = UU, UL, LU, LL

(a) Read timing (SDRAM access) (2/2)

- Remarks**
1. Number of waits inserted by BCW1n and BCW0n bits of the SCRn register (TBCW): 2
 2. Broken lines indicate high impedance.
 3. n = 1, 3, 4, 6

(b) Write timing (SDRAM access) (1/2)

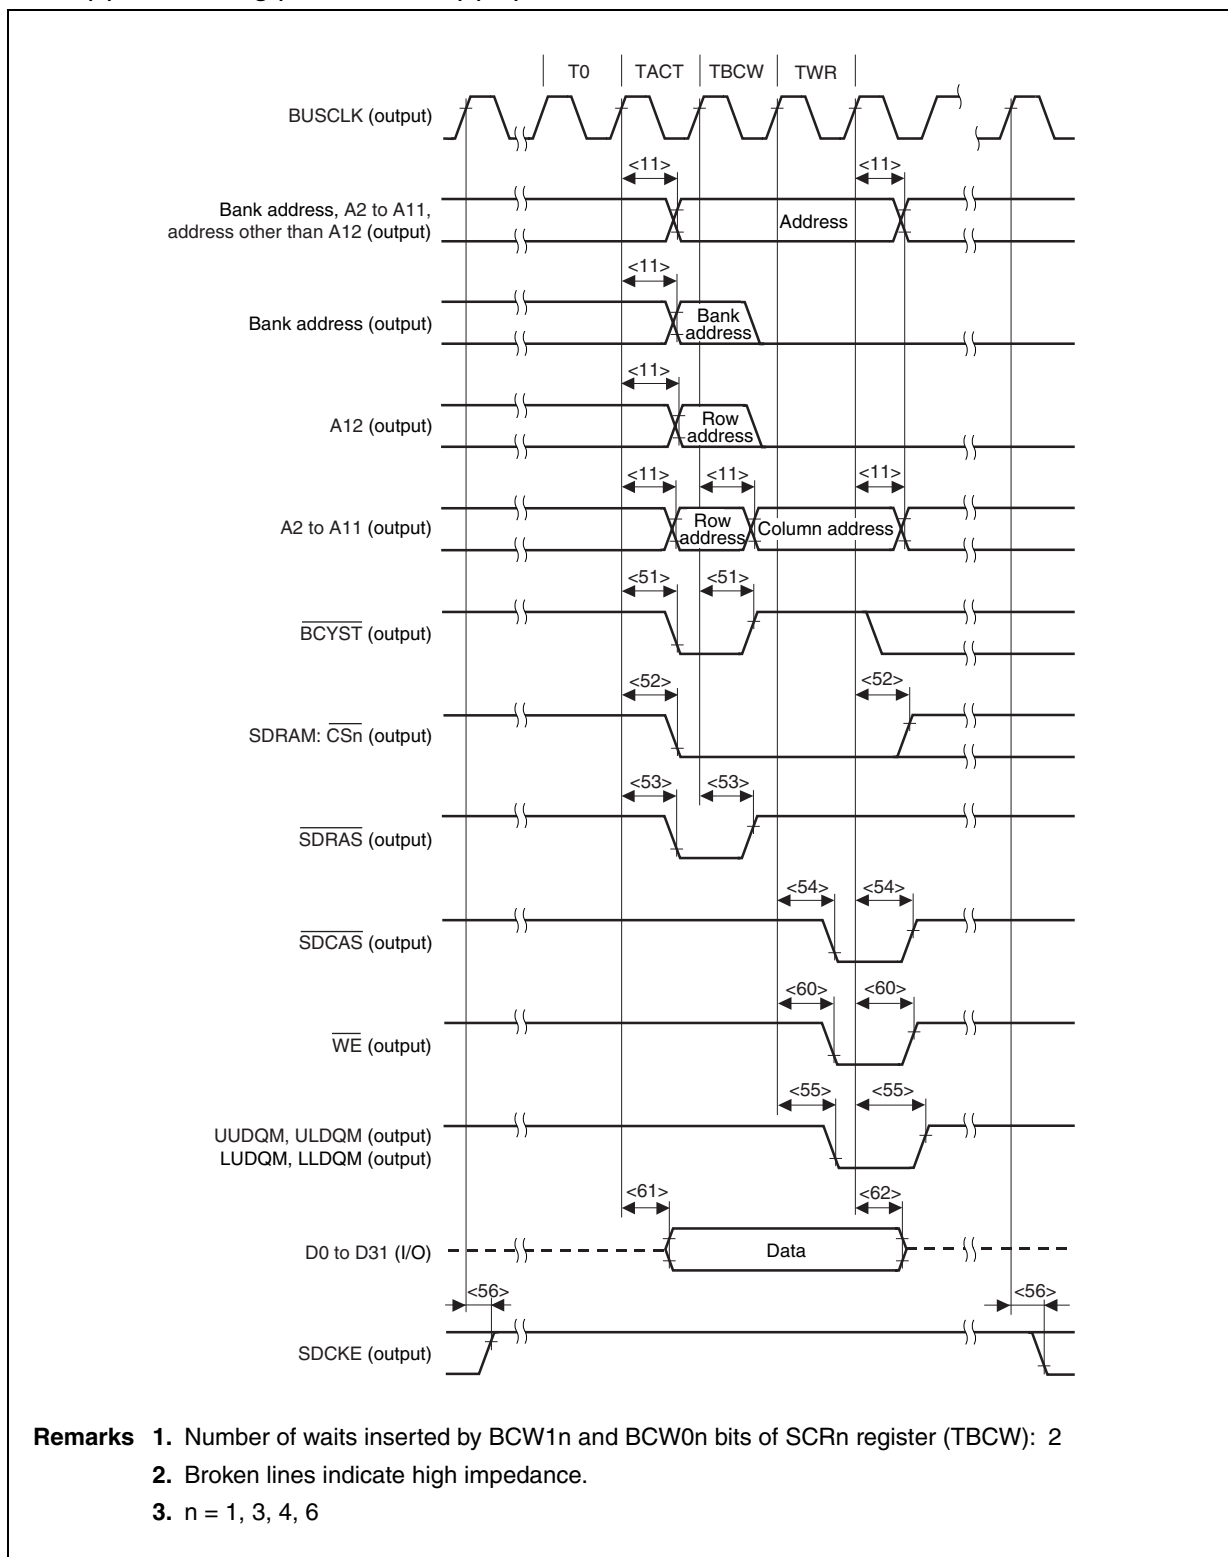

Parameter	Symbol	Conditions	MIN.	MAX.	Unit
Address delay time (from BUSCLK↑)	<11> t _{DKA}		2	11	ns
\overline{BCYST} delay time (from BUSCLK↑)	<51> t _{DKBC}		1	11	ns
\overline{CSn} delay time (from BUSCLK↑)	<52> t _{DKCS}		1	11	ns
\overline{SDRAS} delay time (from BUSCLK↑)	<53> t _{DKRAS}		1	11	ns
\overline{SDCAS} delay time (from BUSCLK↑)	<54> t _{DKCAS}		1	11	ns
xxDQM delay time (from BUSCLK↑)	<55> t _{DKDQM}		2	11	ns
SDCKE delay time (from BUSCLK↑)	<56> t _{DKCKE}		1	11	ns
\overline{WE} delay time (from BUSCLK↑)	<60> t _{DKWE}		2	11	ns
Data output delay time (from BUSCLK↑)	<61> t _{DKDT}		2	11	ns
Data float delay time (from BUSCLK↑)	<62> t _{HZKDT}		2	11	ns

Caution If an SRAM (external I/O) cycle that uses the \overline{xxWR} signal is generated immediately after a read cycle to SDRAM, an SRAM (external I/O) writing error may occur. In this case, execute a countermeasure using external circuits.

However, no writing error occurs in a synchronization design in which the \overline{xxWR} signal is sampled using BUSCLK.

Remark n = 1, 3, 4, 6
xx = UU, UL, LU, LL

(b) Write timing (SDRAM access) (2/2)

(c) DMA flyby transfer timing (transfer from external I/O to SDRAM) (1/2)

Parameter	Symbol	Conditions	MIN.	MAX.	Unit
Address delay time (from BUSCLK↑)	<11> t_{DKA}		2	11	ns
\overline{IORD} ↓ delay time (from BUSCLK↓)	<13> t_{DKRDL}		1	11	ns
\overline{IORD} ↑ delay time (from BUSCLK↑)	<14> t_{DKRDH}		1	11	ns
\overline{BCYST} delay time (from BUSCLK↑)	<51> t_{DKBC}		1	11	ns
\overline{CSn} delay time (from BUSCLK↑)	<52> t_{DKCS}		1	11	ns
\overline{SDRAS} delay time (from BUSCLK↑)	<53> t_{DKRAS}		1	11	ns
\overline{SDCAS} delay time (from BUSCLK↑)	<54> t_{DKCAS}		1	11	ns
xxDQM delay time (from BUSCLK↑)	<55> t_{DKDQM}		2	11	ns
\overline{SDCKE} delay time (from BUSCLK↑)	<56> t_{DKCKE}		1	11	ns
\overline{WE} delay time (from BUSCLK↑)	<60> t_{DKWE}		2	11	ns
\overline{DMAAKx} output delay time (from BUSCLK↑)	<65> t_{DKDA}		0	13	ns
\overline{DMAAKx} output hold time (from BUSCLK↑)	<66> t_{HKDA}		0	13	ns
\overline{IORD} low-level width	<102> t_{WRDL}		$(1.5 + w_{FW}) T - 6$		ns
\overline{IORD} high-level width	<103> t_{WRDH}		$(0.5 + w_{AS} + i) T - 6$		ns
Delay time from \overline{IORD} ↑ to data output	<104> t_{DRDOD}		$(0.5 + i) T - 6$		ns

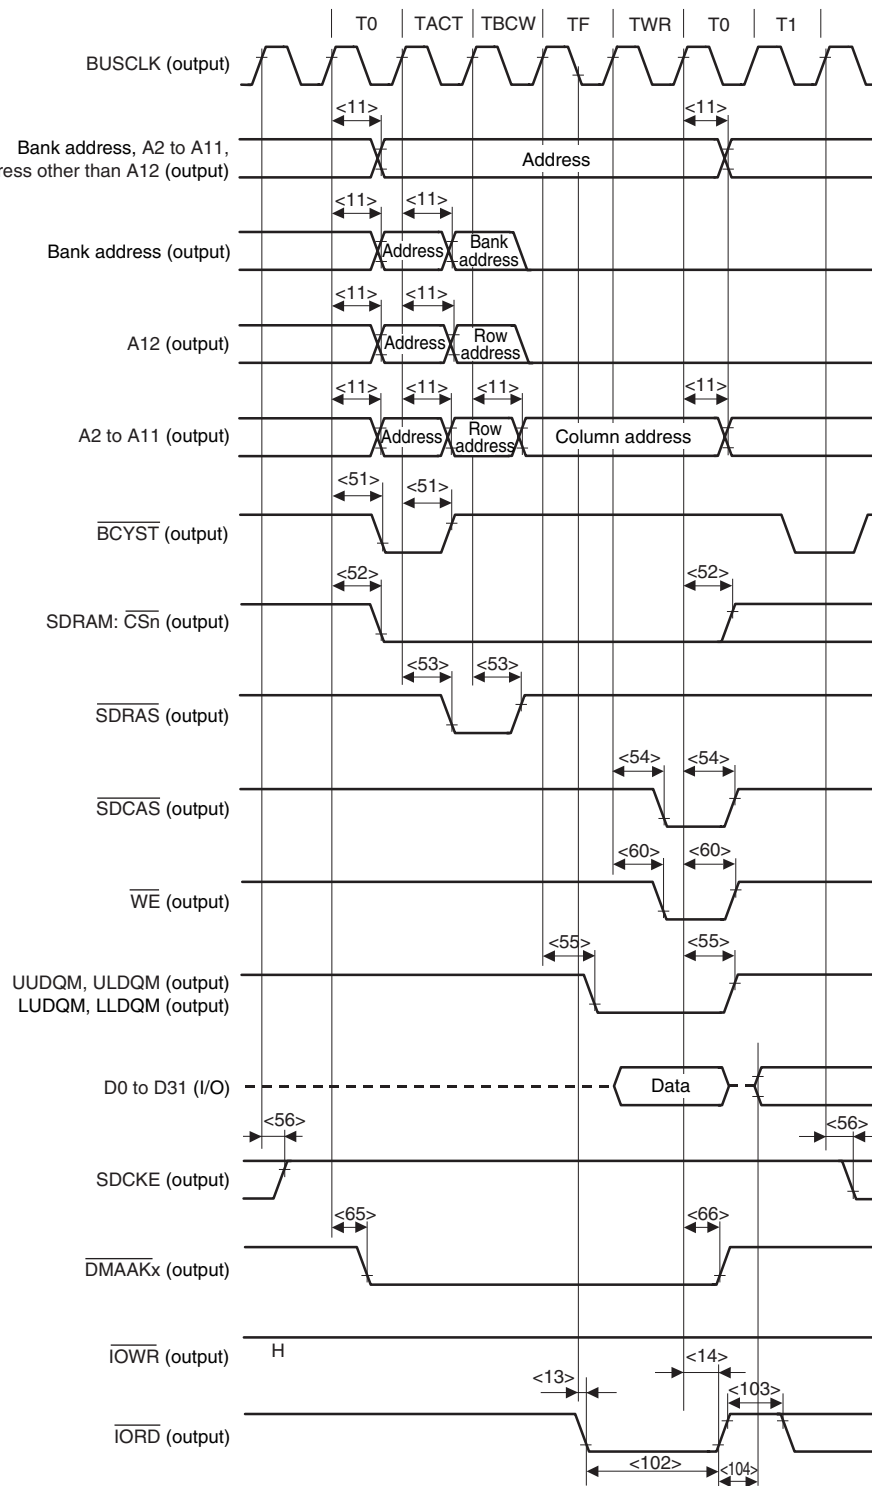

<R>

Remarks 1. $T = t_{CYK}$ **2.** i : Number of idle states**3.** w_{AS} : Number of address setup waits inserted by ASC register**4.** w_{FW} : Number of data waits inserted by FWC register**5.** $n = 1, 3, 4, 6$

xx = UU, UL, LU, LL

x = 0 to 3

(c) DMA flyby transfer timing (transfer from external I/O to SDRAM) (2/2)

- Remarks**
1. Broken lines indicate high impedance.
 2. n = 1, 3, 4, 6
x = 0 to 3

(7) DMAC timing

(a) Level mode (1/3)

f_{BUSCLK} = 66 MHz (f_{CLK} = 200 MHz, f_{VBCLK} = 66 MHz)

Parameter	Symbol	Conditions	MIN.	MAX.	Unit
$\overline{\text{DMARQn}}$ setup time (to BUSCLK \uparrow)	<63> t _{SDRK}	2-cycle transfer	8		ns
$\overline{\text{DMARQn}}$ hold time (from $\overline{\text{DMAAKn}}$ ↓)	<64> t _{HKDR}	2-cycle transfer	0	4T – 20	ns
				8T – 20	ns
$\overline{\text{DMAAKn}}$ output delay time (from BUSCLK \uparrow)	<65> t _{DKDA}	2-cycle transfer	0	13	ns
$\overline{\text{DMAAKn}}$ output hold time (from BUSCLK \uparrow)	<66> t _{HKDA}	2-cycle transfer	0	13	ns
$\overline{\text{DMAAKn}}$ low level width	<67> t _{WDAL}	2-cycle transfer	Note 1		ns
$\overline{\text{TCn}}$ output delay time (from BUSCLK \uparrow)	<68> t _{DKTC}	2-cycle transfer	2	13	ns
$\overline{\text{TCn}}$ output hold time (from BUSCLK \uparrow)	<69> t _{HKTC}	2-cycle transfer	2	13	ns

Notes 1. “Time shown in Table 7-4” + “Extension width by active width extension function of the $\overline{\text{DMAAKn}}$ signal” – 8^{Note 2}

2. The second DMA transfer request disable timing in single transfer.

Remarks 1. n = 0 to 3

2. T = t_{CYK}

(a) Level mode (2/3)

f_{BUSCLK} = 50 MHz (f_{CLK} = 200 MHz, f_{VBCLK} = 100 MHz)

Parameter	Symbol	Conditions	MIN.	MAX.	Unit
$\overline{\text{DMARQn}}$ setup time (to $\text{BUSCLK}\uparrow$)	<63> t _{SDRK}	2-cycle transfer	8		ns
$\overline{\text{DMARQn}}$ hold time (from $\overline{\text{DMAAKn}}\downarrow$)	<64> t _{HKDR}	2-cycle transfer	0	2T – 20	ns
				5T – 20	ns

$\overline{\text{DMAAKn}}$ output delay time (from BUSCLK \uparrow)	<65> t _{DKDA}	2-cycle transfer	0	T _{CPU} + 13	ns
$\overline{\text{DMAAKn}}$ output hold time (from BUSCLK \uparrow)	<66> t _{HKDA}	2-cycle transfer	0	T _{CPU} + 13	ns
$\overline{\text{DMAAKn}}$ low level width	<67> t _{WDAL}	2-cycle transfer	Note 2		ns
$\overline{\text{TCn}}$ output delay time (from BUSCLK \uparrow)	<68> t _{DKTC}	2-cycle transfer	2	13	ns
$\overline{\text{TCn}}$ output hold time (from BUSCLK \uparrow)	<69> t _{HKTC}	2-cycle transfer	2	13	ns

Notes 1. Time to $\overline{\text{DMAAKn}}$ high level from BUSCLK \uparrow after $\overline{\text{DMAAKn}}$ rises**2.** "Time shown in Table 7-4" + "Extension width by active width extension function of the $\overline{\text{DMAAKn}}$ signal" - 8^{Note 2}**3.** The second DMA transfer request disable timing in single transfer.**Remarks 1.** n = 0 to 3**2.** $\overline{\text{DMARQn}}$ signal mask width by W_{DRMK} = DIFCn register**3.** T = t_{CYK}**4.** T_{CPU} = 1/f_{VBCLK}

(b) Mask mode (3/3)

Remarks 1. The minimum $\overline{\text{DMAAKn}}$ inactive time is as follows.

• fBUSCLK = 66 MHz (fCLK = 200 MHz, fVBCLK = 66 MHz)

Transfer mode	Transfer source	Transfer destination	Inactive time
Single transfer, single-step transfer	External memory/ external I/O	External memory/ external I/O on-chip peripheral I/O/ internal data RAM	7T
	On-chip peripheral I/O/ internal data RAM	External memory/ external I/O	15T
Block transfer	—	—	7T

• fBUSCLK = 50 MHz (fCLK = 200 MHz, fVBCLK = 100 MHz)

Transfer mode	Transfer source	Transfer destination	Inactive time
Single transfer, single-step transfer	External memory/ external I/O	External memory/ external I/O on-chip peripheral I/O/ internal data RAM	3.5T
	On-chip peripheral I/O/ internal data RAM	External memory/ external I/O	7.5T
Block transfer	—	—	3.5T

2. n = 0 to 3

(c) Edge mode (1/3)

f_{BUSCLK} = 66 MHz (f_{CLK} = 200 MHz, f_{VCLK} = 66 MHz)

Parameter	Symbol	Conditions	MIN.	MAX.	Unit
$\overline{\text{DMARQn}}$ hold time 3	<110> t _{HKDR3}	2-cycle transfer/ flyby transfer	2T		ns
$\overline{\text{DMARQn}}$ high level time 1 (from $\overline{\text{DMARQn}}\uparrow$)	<72> t _{WDRH1}	2-cycle transfer/ flyby transfer	2T		ns
$\overline{\text{DMARQn}}$ high level time 2 (from $\overline{\text{DMAAKn}}\uparrow$)	<73> t _{WDRH2}	2-cycle transfer/ flyby transfer	0		ns
$\overline{\text{DMAAKn}}$ output delay time (from BUSCLK \uparrow)	<65> t _{DKDA}	2-cycle transfer/ flyby transfer	0	13	ns
$\overline{\text{DMAAKn}}$ output hold time (from BUSCLK \uparrow)	<66> t _{HKDA}	2-cycle transfer/ flyby transfer	0	13	ns
$\overline{\text{DMAAKn}}$ low level width	<67> t _{WDAL}	2-cycle transfer	Note 1		ns
		flyby transfer	2T + W _{AS} + W _{FW} + W _{IC} - 8		ns
$\overline{\text{TCn}}$ output delay time (from BUSCLK \uparrow)	<68> t _{DKTC}	2-cycle transfer/ flyby transfer	2	13	ns
$\overline{\text{TCn}}$ output hold time (from BUSCLK \uparrow)	<69> t _{HKTC}	2-cycle transfer/ flyby transfer	2	13	ns

Notes 1. "Time shown in Table 7-4" + "Extension width by active width extension function of the $\overline{\text{DMAAKn}}$ signal" - 8^{Note 2}

2. The second DMA transfer request disable timing in single transfer.

Remarks 1. n = 0 to 3

2. T = t_{CYK}

3. W_{AS} = Number of address setup waits inserted by ASC register

W_{FW} = Number of data waits inserted by FWC register

W_{IC} = Number of idle states inserted by FIC register

(c) Edge mode (2/3)

f_{BUSCLK}= 50 MHz (f_{CLK} = 200 MHz, f_{VBCLK} = 100 MHz)

Parameter	Symbol	Conditions	MIN.	MAX.	Unit
$\overline{\text{DMARQn}}$ hold time 3	<110> t _{HKDR3}	2-cycle transfer/ flyby transfer	2T		ns
$\overline{\text{DMARQn}}$ high level time 1 (from $\overline{\text{DMARQn}}\uparrow$)	<72> t _{WDRH1}	2-cycle transfer/ flyby transfer	2T		ns
$\overline{\text{DMARQn}}$ high level time 2 (from $\overline{\text{DMAAKn}}\uparrow$)	<73> t _{WDRH2}	2-cycle transfer/ flyby transfer	0		ns
$\overline{\text{DMAAKn}}$ output delay time (from $\overline{\text{BUSCLK}}\uparrow$)	<65> t _{DKDA}	2-cycle transfer	0	T _{CPU} + 13	ns
		flyby transfer	0	13	ns
$\overline{\text{DMAAKn}}$ output hold time (from $\overline{\text{BUSCLK}}\uparrow$)	<66> t _{HKDA}	2-cycle transfer	0	T _{CPU} + 13	ns
		flyby transfer	0	13	ns
$\overline{\text{DMAAKn}}$ low level width	<67> t _{WDAL}	2-cycle transfer	Note 1		ns
		flyby transfer	2T + W _{AS} + W _{FW} + W _{IC} - 8		ns
$\overline{\text{TCn}}$ output delay time (from $\overline{\text{BUSCLK}}\uparrow$)	<68> t _{DKTC}	2-cycle transfer/ flyby transfer	2	13	ns
$\overline{\text{TCn}}$ output hold time (from $\overline{\text{BUSCLK}}\uparrow$)	<69> t _{HKTC}	2-cycle transfer/ flyby transfer	2	13	ns

Notes 1. "Time shown in Table 7-4" + "Extension width by active width extension function of the $\overline{\text{DMAAKn}}$ signal" - 8^{Note 2}

2. The second DMA transfer request disable timing in single transfer.

Remarks 1. n = 0 to 3

2. T = t_{CYK}

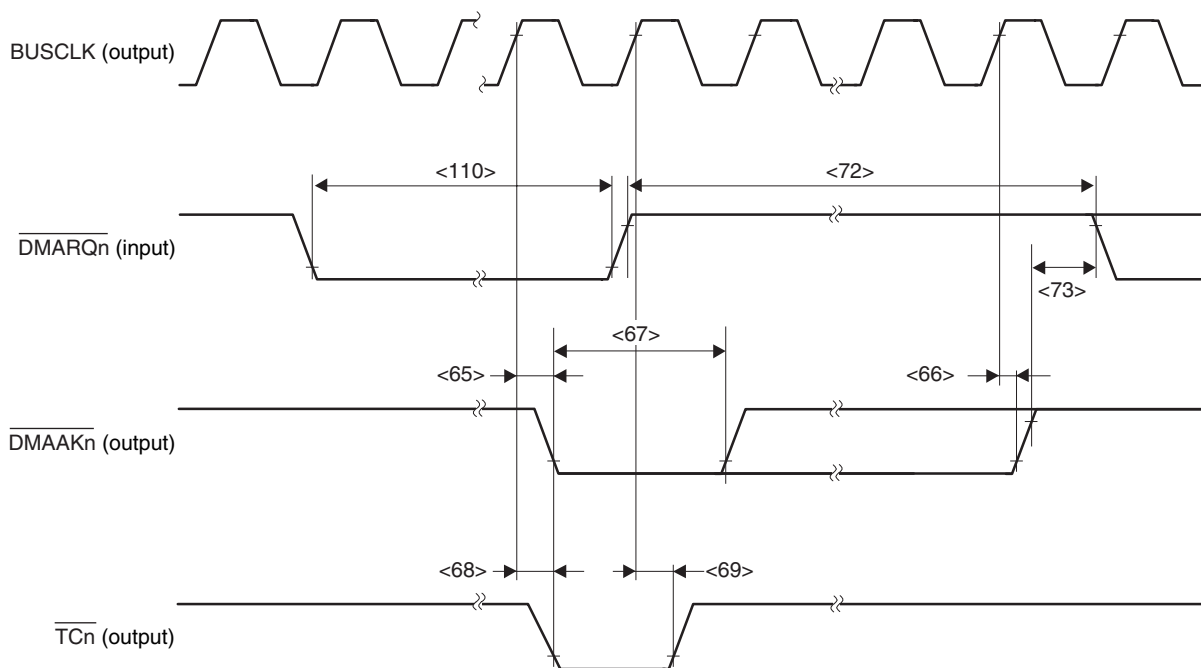

3. T_{CPU} = 1/f_{VBCLK}

4. W_{AS} = Number of address setup waits inserted by ASC register

W_{FW} = Number of data waits inserted by FWC register

W_{IC} = Number of idle states inserted by FIC register

(c) Edge mode (3/3)

Remarks 1. The minimum $\overline{\text{DMAAKn}}$ inactive time is as follows.

• fBUSCLK = 66 MHz (fCLK = 200 MHz, fVBCLK = 66 MHz)

Transfer mode	Transfer source	Transfer destination	Inactive time
Single transfer, single-step transfer	External memory/ external I/O	External memory/ external I/O on-chip peripheral I/O/ internal data RAM	7T
	On-chip peripheral I/O/ internal data RAM	External memory/ external I/O	15T
Block transfer	–	–	7T

• fBUSCLK = 50 MHz (fCLK = 200 MHz, fVBCLK = 100 MHz)

Transfer mode	Transfer source	Transfer destination	Inactive time
Single transfer, single-step transfer	External memory/ external I/O	External memory/ external I/O on-chip peripheral I/O/ internal data RAM	3.5T
	On-chip peripheral I/O/ internal data RAM	External memory/ external I/O	7.5T
Block transfer	–	–	3.5T

2. n = 0 to 3

(8) Bus hold timing (1/2)

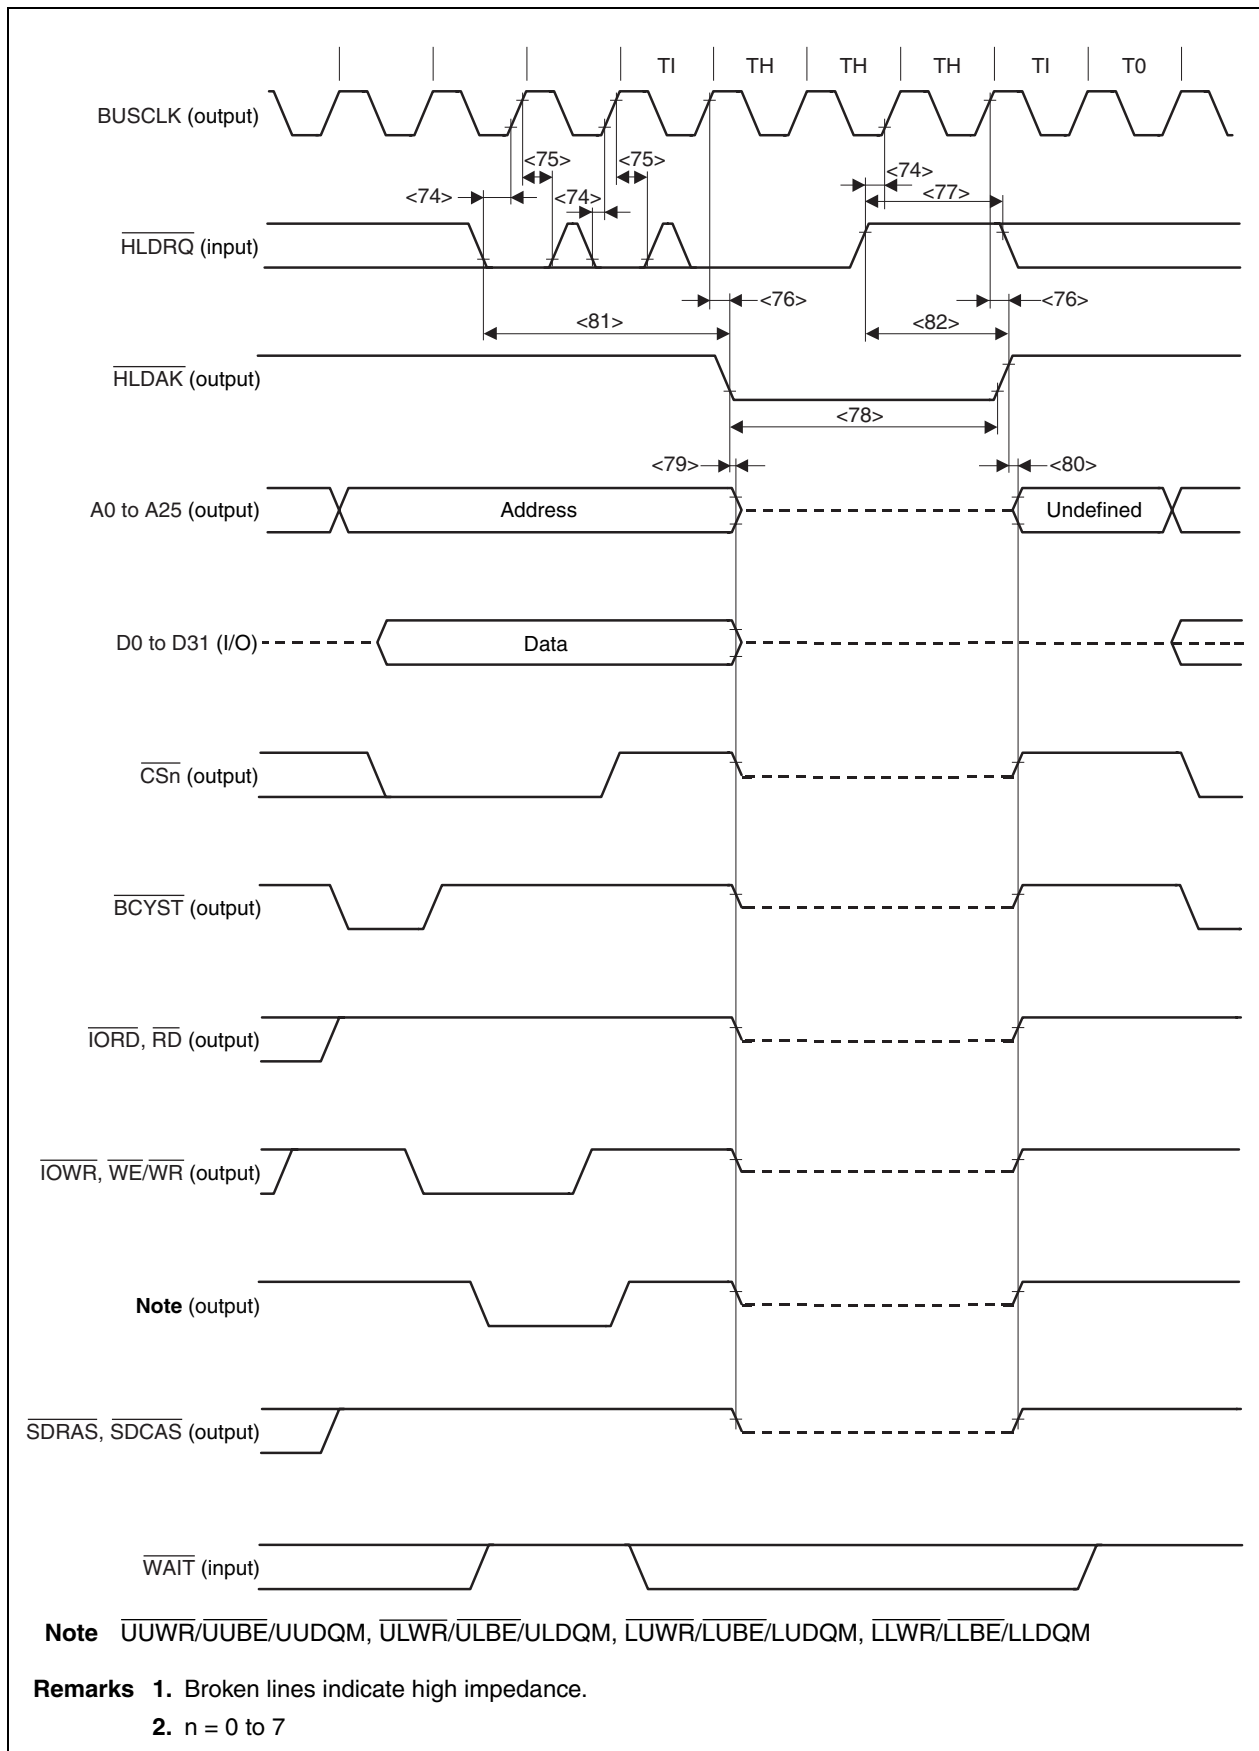

Parameter	Symbol	Conditions	MIN.	MAX.	Unit
$\overline{\text{HLDRQ}}$ setup time (to $\text{BUSCLK}\uparrow$)	<74> t_{SHRK}		10		ns
$\overline{\text{HLDRQ}}$ hold time (from $\text{BUSCLK}\uparrow$)	<75> t_{HKHR}		2		ns
Delay time from $\text{BUSCLK}\uparrow$ to $\overline{\text{HLDAK}}$	<76> t_{DKHA}		1	11	ns
$\overline{\text{HLDRQ}}$ high-level width	<77> t_{WHQH}		$T + 12$		ns
$\overline{\text{HLDAK}}$ low-level width	<78> t_{WHAL}		$T - 11$		ns
Delay time from $\overline{\text{HLDAK}}\downarrow$ to bus float	<79> t_{DKCF}		0	11	ns
Delay time from $\overline{\text{HLDAK}}\uparrow$ to bus output	<80> t_{DHAC}		0	11	ns
Delay time from $\overline{\text{HLDRQ}}\downarrow$ to $\overline{\text{HLDAK}}\downarrow$	<81> t_{DHQA1}	Note 1	4T		ns
		Note 2	3T		ns
Delay time from $\overline{\text{HLDRQ}}\uparrow$ to $\overline{\text{HLDAK}}\uparrow$	<82> t_{DHQA2}		T	$2T + 12$	ns

Notes 1. BUSCLK divided by 2

2. BUSCLK divided by 4

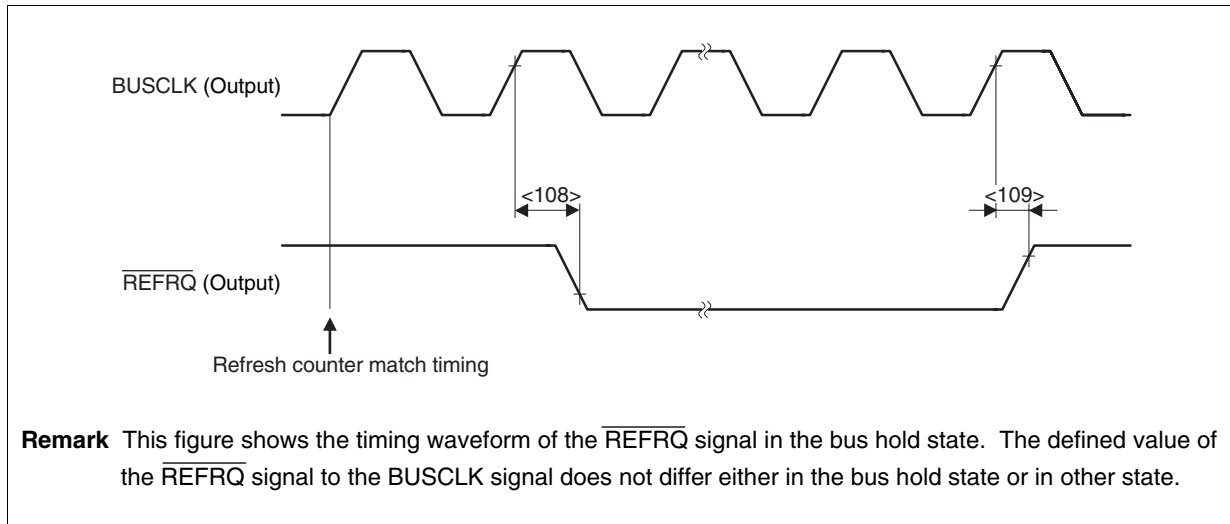

Remark $T = t_{\text{CYK}}$

(8) Bus hold timing (2/2)

(9) Refresh timing

Parameter	Symbol	Conditions	MIN.	MAX.	Unit
$\overline{\text{REFRQ}}\downarrow$ delay time (from $\text{BUSCLK}\uparrow$)	<108> t_{DRFQL}		1	11	ns
$\overline{\text{REFRQ}}\uparrow$ delay time (from $\text{BUSCLK}\uparrow$)	<109> t_{DRQH}		1	11	ns

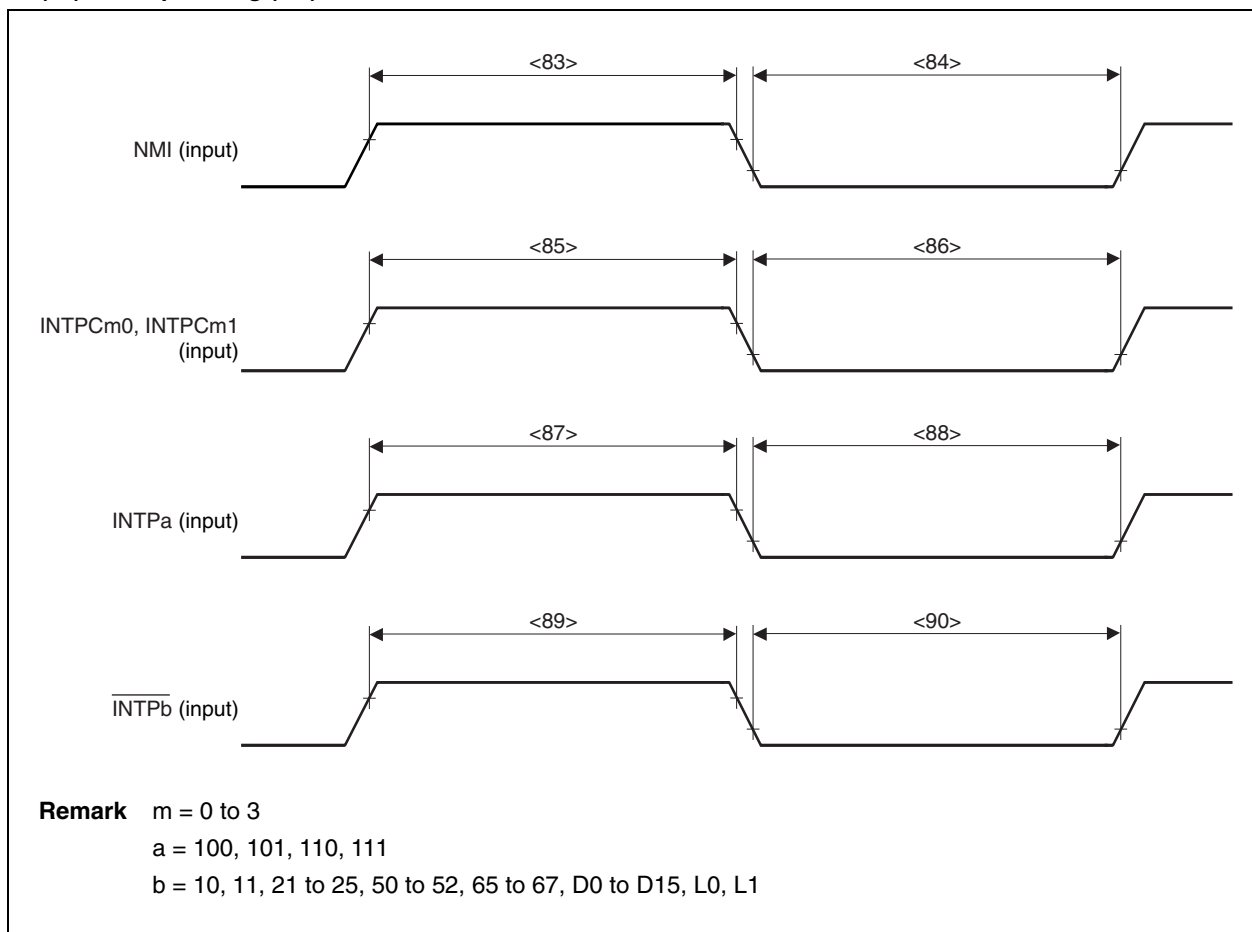

(10) Interrupt timing (1/2)

Parameter	Symbol	Conditions		MIN.	MAX.	Unit
NMI high-level width	<83>	t _{WNH}		500		ns
NMI low-level width	<84>	t _{WNL}		500		ns
INTPCm0, INTPCm1 pin (m = 0 to 3) high-level width	<85>	t _{WITCH}	When noise elimination has been set	(Number of set elimination clocks + 1)/(fx/4) + 10		ns
			When clock-through has been set	1/(fx/4) × 2 + 10		ns
INTPCm0, INTPCm1 pin (m = 0 to 3) low-level width	<86>	t _{WITCL}	When noise elimination has been set	(Number of set elimination clocks + 1)/(fx/4) + 10		ns
			When clock-through has been set	1/(fx/4) × 2 + 10		ns
INTPa pin high-level width	<87>	t _{WIT1H}	When noise elimination has been set	Noise elimination clock = fx/4 selected	(Number of set elimination clocks + 1)/(fx/4) + 10	ns
				Noise elimination clock = fx/32 selected	(Number of set elimination clocks + 1)/(fx/32) + 10	ns
			When clock-through has been set ^{Note}	Noise elimination clock = fx/4 selected	1/(fx/4) × 2 + 10	ns
INTPa pin low-level width	<88>	t _{WIT1L}	When noise elimination has been set	Noise elimination clock = fx/4 selected	(Number of set elimination clocks + 1)/(fx/4) + 10	ns
				Noise elimination clock = fx/32 selected	(Number of set elimination clocks + 1)/(fx/32) + 10	ns
			When clock-through has been set ^{Note}	Noise elimination clock = fx/4 selected	1/(fx/4) × 2 + 10	ns
INTPb high-level width	<89>	t _{WITPH}	Both edge and level detection	500 + 1/(fx/4) + 10		ns
INTPb low-level width	<90>	t _{WITPL}	Both edge and level detection	500 + 1/(fx/4) + 10		ns

Note When clock-through has been set, do not select a noise elimination clock of fx/32.

- Remarks 1.** The noise elimination clock and clock-through are set values of the NCWC0 to NCWC3, NCW10, and NCW11 registers.
- 2.** fx: Main clock
- 3.** a = 100, 101, 110, 111
b = 10, 11, 21 to 25, 50 to 52, 65 to 67, D0 to D15, L0, L1

(10) Interrupt timing (2/2)

(11) Timer C timing

Parameter	Symbol	Conditions	MIN.	MAX.	Unit	
TICn high-level width	<91>	t _{WTCH}	When noise elimination has been set	(Number of set elimination clocks + 1) / (f _x /4) + 10		ns
			When clock-through has been set	1 / (f _x /4) × 2 + 10		ns
TICn low-level width	<92>	t _{WTCL}	When noise elimination has been set	(Number of set elimination clocks + 1) / (f _x /4) + 10		ns
			When clock-through has been set	1 / (f _x /4) × 2 + 10		ns

- Remarks** 1. n = 0 to 3
 2. The noise elimination clock and clock-through are set values of the NCWC0 to NCWC3 registers.

(12) Timer ENC1 timing

Parameter	Symbol	Conditions	MIN.	MAX.	Unit	
TCLR1n, TCUD1n, TIUD1n pin high-level width	<93>	When noise elimination has been set	Noise elimination clock = $fx/4$ selected	(Number of set elimination clocks +1)/($fx/4$) +10		ns
			Noise elimination clock = $fx/32$ selected	(Number of set elimination clocks +1)/($fx/32$) +10		ns
		When clock-through has been set ^{Note}	Noise elimination clock = $fx/4$ selected	$1/(fx/4) \times 2 + 10$		ns
TCLR1n, TCUD1n, TIUD1n pin low-level width	<94>	When noise elimination has been set	Noise elimination clock = $fx/4$ selected	(Number of set elimination clocks +1)/($fx/4$) +10		ns
			Noise elimination clock = $fx/32$ selected	(Number of set elimination clocks +1)/($fx/32$) +10		ns
		When clock-through has been set ^{Note}	Noise elimination clock = $fx/4$ selected	$1/(fx/4) \times 2 + 10$		ns

Note When clock-through has been set, do not select a noise elimination clock of $fx/32$.

Remarks 1. $n = 0, 1$

2. The noise elimination clock and clock-through are the set values of the NCW10 and NCW11 registers.

(13) CSI30, CSI31 timing (1/3)

(a) Master mode

Parameter	Symbol	Condition	MIN.	MAX.	Unit
\overline{SCKn} cycle	<95> t_{CYSK1}	output	160		ns
\overline{SCKn} high-level width	<96> t_{WSK1H}	output	$0.5 t_{CYSK1} - 12$		ns
\overline{SCKn} low-level width	<97> t_{WSK1L}	output	$0.5 t_{CYSK1} - 12$		ns
SIn setup time (to $\overline{SCKn}\uparrow$)	<98> t_{SSISK}		12		ns
SIn setup time (to $\overline{SCKn}\downarrow$)			12		ns
SIn hold time (from $\overline{SCKn}\uparrow$)	<99> t_{HSKSI}		7		ns
SIn hold time (from $\overline{SCKn}\downarrow$)			7		ns
SOn output delay time (from $\overline{SCKn}\downarrow$)	<100> t_{DSKSO}			7	ns
SOn output delay time (from $\overline{SCKn}\uparrow$)				7	ns
SOn output hold time (from $\overline{SCKn}\uparrow$)	<101> t_{HSKSO}		$0.5 t_{CYSK1} - 5$		ns
SOn output hold time (from $\overline{SCKn}\downarrow$)			$0.5 t_{CYSK1} - 5$		ns

Remark n = 0, 1

(b) Slave mode

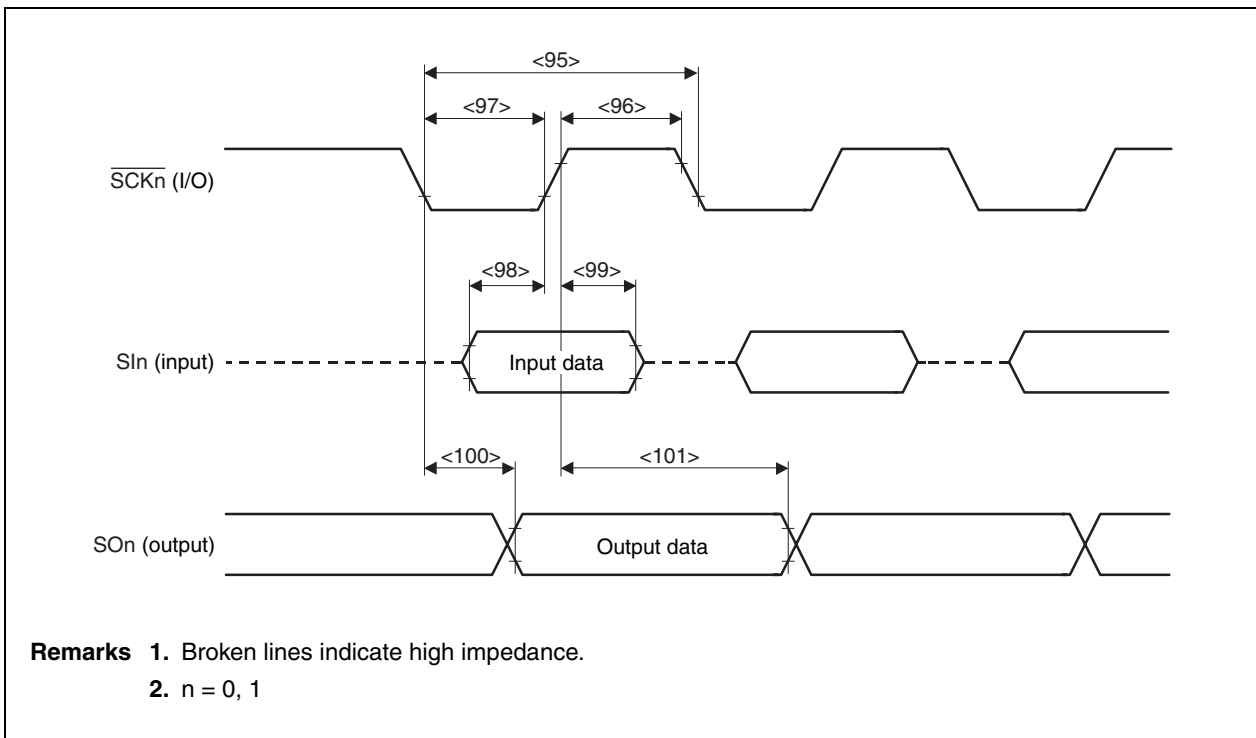

Parameter	Symbol	Condition	MIN.	MAX.	Unit
\overline{SCKn} cycle	<95> t_{CYSK1}	Input	160		ns
\overline{SCKn} high-level width	<96> t_{WSK1H}	Input	$0.5 t_{CYSK1} - 12$		ns
\overline{SCKn} low-level width	<97> t_{WSK1L}	Input	$0.5 t_{CYSK1} - 12$		ns
SIn setup time (to $\overline{SCKn}\uparrow$)	<98> t_{SSISK}		30		ns
SIn setup time (to $\overline{SCKn}\downarrow$)			30		ns
SIn hold time (from $\overline{SCKn}\uparrow$)	<99> t_{HSKSI}		$1.5T + 15$		ns
SIn hold time (from $\overline{SCKn}\downarrow$)			$1.5T + 15$		ns
SOn output delay time (from $\overline{SCKn}\downarrow$)	<100> t_{DSKSO}			12	ns
SOn output delay time (from $\overline{SCKn}\uparrow$)					12
SOn output hold time (from $\overline{SCKn}\uparrow$)	<101> t_{HSKSO}		t_{WSK1H}		ns
SOn output hold time (from $\overline{SCKn}\downarrow$)			t_{WSK1H}		ns

Remarks 1. n = 0, 1

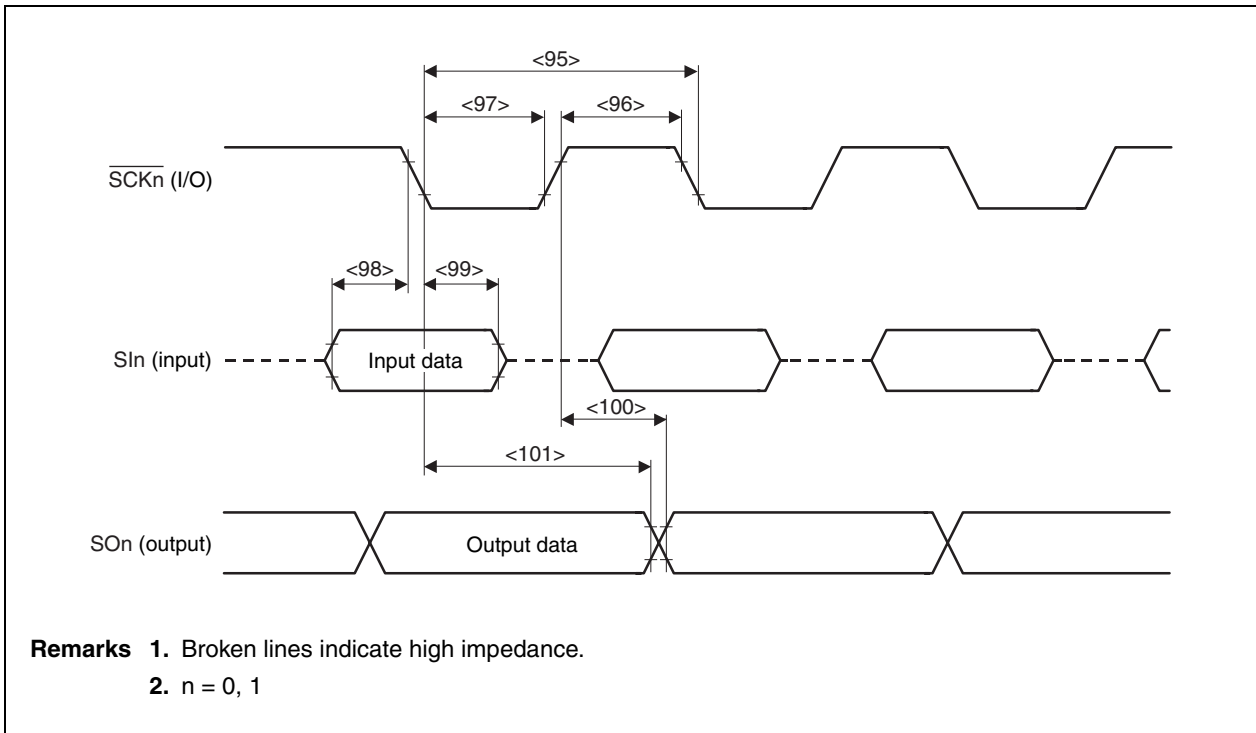

2. $T = f_x/4$

(13) CSI30, CSI31 timing (2/3)

(c) Timing when CKPn and DAPn bits of CSIC3n register = 00

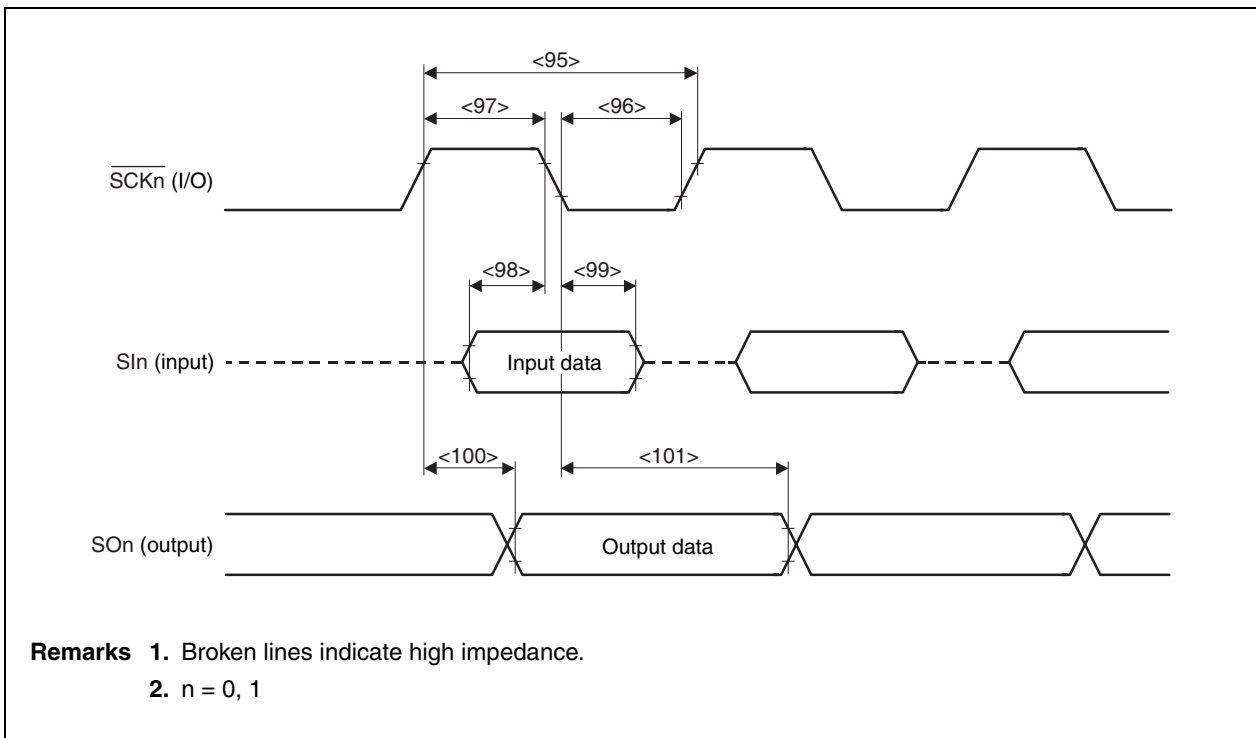

(d) Timing when CKPn and DAPn bits of CSIC3n register = 01

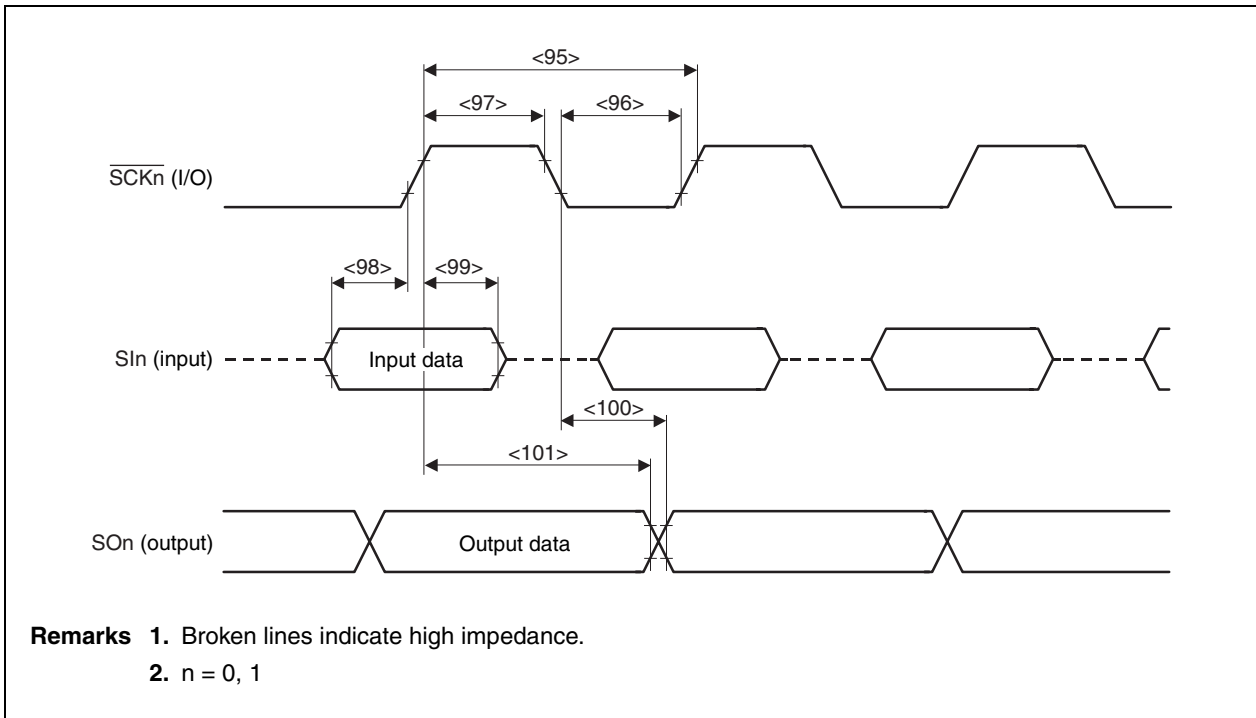

(13) CSI30, CSI31 timing (3/3)

(e) Timing when CKPn and DAPn bits of CSIC3n register = 10

(f) Timing when CKPn and DAPn bits of CSIC3n register = 11

A/D Converter Characteristics (EV_{DD} = AV_{DD} = AV_{REFP} = 3.0 to 3.6 V, EV_{SS} = AV_{SS} = AV_{REFM} = 0 V)

<R>

Parameter	Symbol	Conditions	MIN.	TYP.	MAX.	Unit
Resolution	–		10			bit
Overall error ^{Note 1}	–				±0.49	%FSR
Quantization error	–				±1/2	LSB
Conversion time	–	t _{CONV}	2.00		10	μs
Sampling time	–	t _{SAMP}	3 × conversion clock ^{Note 2} /16			Clock
Zero-scale error ^{Note 1}	–	–			±0.49	%FSR
Full-scale error ^{Note 1}	–	–			±0.49	%FSR
Integral linearity error ^{Note 3}	–	–			±4	LSB
Differential linearity error ^{Note 3}	–	–			±4	LSB
Analog input voltage	–	V _{WASN}	AV _{REFM}		AV _{REFP}	V
AV _{DD} power supply current	–	I _{DD}			10	mA
ADTRG high-level width	<105>	t _{WAH}	500			ns
ADTRG low-level width	<106>	t _{WAL}	500			ns

- Notes 1.** Excluding quantization error (±0.05%FSR).
- 2.** The conversion clock indicates the number of clocks set by the ADM1 register.
- 3.** Excluding quantization error (±0.5LSB).

Remark LSB: Least Significant Bit
 FSR: Full Scale Range
 %FSR indicates the ratio to the full-scale value.

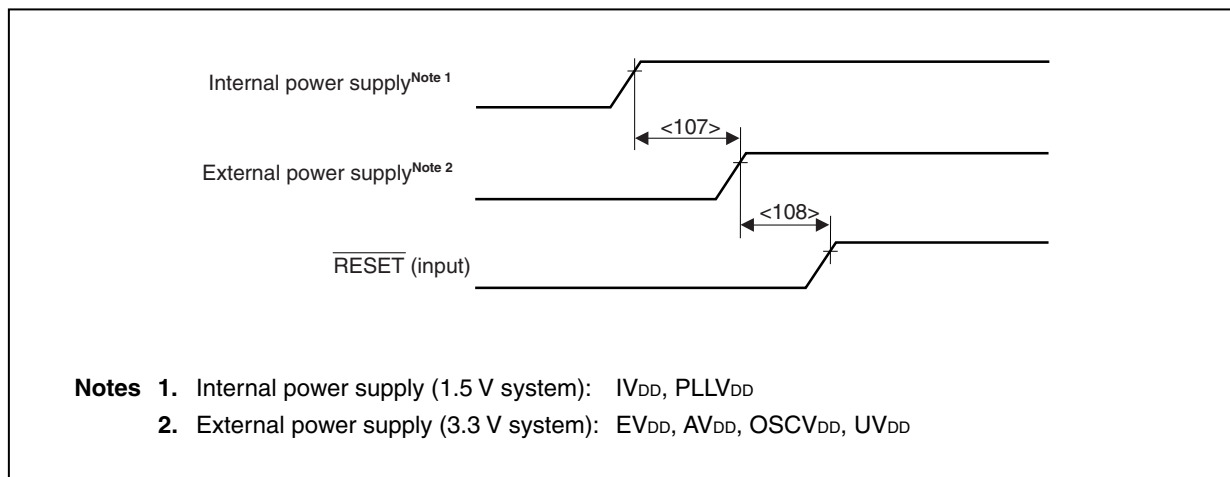

Supply Voltage Application/Cutoff Timing

($T_A = -40$ to $+80^\circ\text{C}$, $I_{VDD} = PLLV_{DD} = 1.4$ to 1.65 V, $EV_{DD} = AV_{DD} = OSCV_{DD} = UV_{DD} = 3.3$ V ± 0.3 V, $IV_{SS} = EV_{SS} = AV_{SS} = PLLV_{SS} = OSCV_{SS} = 0$ V, output pin load capacitance: $C_L = 30$ pF)

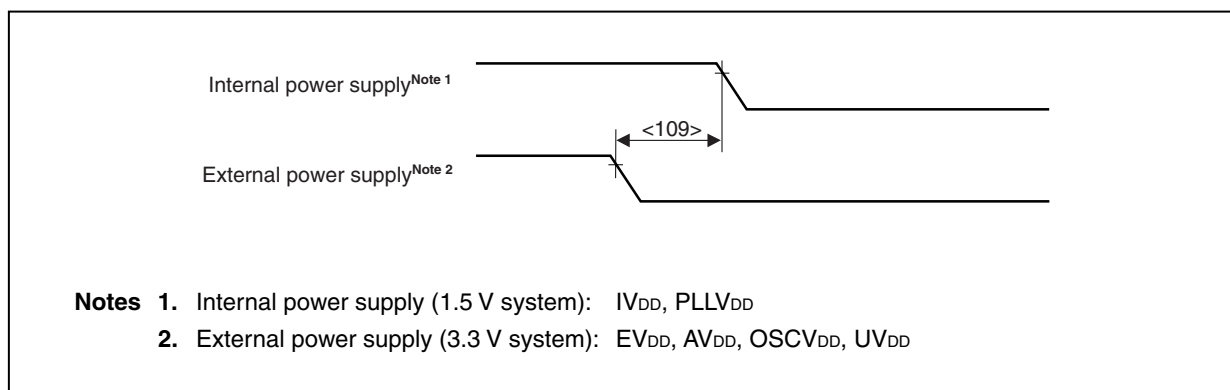

Parameter	Symbol	Conditions	MIN.	MAX.	Unit
Delay time from internal power supply rise to external power supply rise	<107> t_{DVIE}		0	10	s
Delay time from external power supply rise to $\overline{\text{RESET}}\uparrow$	<108> t_{DVER}		$T_{osc} + 1$		ms
Delay time from external power supply fall to internal power supply fall	<109> t_{DVEI}		0	10	s

Remark T_{osc} : Oscillation stabilization time of main clock oscillator (varies depending on the resonator or oscillator used)

(a) Supply Voltage Application Timing

(b) Supply Voltage Application Timing

CHAPTER 20 RECOMMENDED SOLDERING CONDITIONS

The V850E2/ME3 should be soldered and mounted under the following recommended conditions.
For technical information, see the following website.

Semiconductor Device Mount Manual (<http://www.renesas.com/prod/package/index.html>)

Table 20-1. Surface Mounting Type Soldering Conditions

μPD703500GM-JEU-A: 176-pin plastic QFP (fine pitch) (24 × 24)

<R> **μPD703590GM-JEU-A: 176-pin plastic QFP (fine pitch) (24 × 24)**

Soldering Method	Soldering Conditions	Recommended Condition Symbol
Infrared reflow	Package peak temperature: 260°C, Time: 60 seconds max. (at 220°C or higher), Count: Three times or less, Exposure limit: 7 days ^{Note} (after that, prebake at 125°C for 20 to 72 hours)	IR60-207-3
Wave soldering	For details, consult a Renesas Electronics sales representative.	–
Partial heating	Pin temperature: 350°C max., Time: 3 seconds max. (per pin row)	–

Note After opening the dry pack, store it at 25°C or less and 65% RH or less for the allowable storage period.

Caution Do not use different soldering methods together (except for partial heating).

Remarks 1. Products with -A at the end of the part number are lead-free products.

2. For soldering methods and conditions other than those recommended above, consult a Renesas Electronics sales representative.

APPENDIX B INSTRUCTION SET LIST

B.1 Conventions

(1) Register symbols used to describe operands

Register Symbol	Explanation
reg1	General-purpose registers: Used as source registers.
reg2	General-purpose registers: Used mainly as destination registers. Also used as source register in some instructions.
reg3	General-purpose registers: Used mainly to store the remainders of division results and the higher order 32 bits of multiplication results.
bit#3	3-bit data for specifying the bit number
immX	X bit immediate data
dispX	X bit displacement data
regID	System register number
vector	5-bit data that specifies the trap vector (00H to 1FH)
cccc	4-bit data that shows the conditions code
sp	Stack pointer (SP)
ep	Element pointer (r30)
listX	X item register list

(2) Register symbols used to describe opcodes

Register Symbol	Explanation
R	1-bit data of a code that specifies reg1 or regID
r	1-bit data of the code that specifies reg2
w	1-bit data of the code that specifies reg3
D	1-bit displacement data (indicates the higher bits of displacement data)
d	1-bit displacement data
l	1-bit immediate data (indicates the higher bits of immediate data)
i	1-bit immediate data
cccc	4-bit data that shows the condition codes (refer to B.1 (6) Condition codes.)
CCCC	4-bit data that shows the condition codes of Bcond instruction
bbb	3-bit data for specifying the bit number
L	1-bit data that specifies a general-purpose register in the register list
S	1-bit data that specifies the EIPC/FEPC or EIPSW/FEPSW register in the register list
P	1-bit data that specifies the PSW register in the register list

(3) Register symbols used in operations

Register Symbol	Explanation
←	Input for
GR []	General-purpose register
SR []	System register
zero-extend (n)	Expand n with zeros until word length.
sign-extend (n)	Expand n with signs until word length.
load-memory (a, b)	Read size b data from address a.
store-memory (a, b, c)	Write data b into address a in size c.
load-memory-bit (a, b)	Read bit b of address a.
store-memory-bit (a, b, c)	Write c to bit b of address a.
saturated (n)	Execute saturated processing of n (n is a 2's complement). If, as a result of calculations, n ≥ 7FFFFFFFH, let it be 7FFFFFFFH. n ≤ 80000000H, let it be 80000000H.
result	Reflects the results in a flag.
Byte	Byte (8 bits)
Halfword	Half word (16 bits)
Word	Word (32 bits)
+	Addition
−	Subtraction
	Bit concatenation
×	Multiplication
÷	Division
%	Remainder from division results
AND	Logical product
OR	Logical sum
XOR	Exclusive OR
NOT	Logical negation
logically shift left by	Logical shift left
logically shift right by	Logical shift right
arithmetically shift right by	Arithmetic shift right

(4) Register symbols used in execution clock

Register Symbol	Explanation
i	If executing another instruction immediately after executing the first instruction (issue).
r	If repeating execution of the same instruction immediately after executing the first instruction (repeat).
l	If using the results of instruction execution in the instruction immediately after the execution (latency).

(5) Register symbols used in flag operations

Identifier	Explanation
(Blank)	No change
0	Clear to 0
X	Set or cleared in accordance with the results.
R	Previously saved values are restored.

(6) Condition codes

Condition Name (cond)	Condition Code (cccc)	Condition Formula	Explanation
V	0 0 0 0	$OV = 1$	Overflow
NV	1 0 0 0	$OV = 0$	No overflow
C/L	0 0 0 1	$CY = 1$	Carry Lower (Less than)
NC/NL	1 0 0 1	$CY = 0$	No carry Not lower (Greater than or equal)
Z	0 0 1 0	$Z = 1$	Zero Equal
NZ	1 0 1 0	$Z = 0$	Not zero Not equal
NH	0 0 1 1	$(CY \text{ or } Z) = 1$	Not higher (Less than or equal)
H	1 0 1 1	$(CY \text{ or } Z) = 0$	Higher (Greater than)
S/N	0 1 0 0	$S = 1$	Negative
NS/P	1 1 0 0	$S = 0$	Positive
T	0 1 0 1	–	Always (Unconditional)
SA	1 1 0 1	$SAT = 1$	Saturated
LT	0 1 1 0	$(S \text{ xor } OV) = 1$	Less than signed
GE	1 1 1 0	$(S \text{ xor } OV) = 0$	Greater than or equal signed
LE	0 1 1 1	$((S \text{ xor } OV) \text{ or } Z) = 1$	Less than or equal signed
GT	1 1 1 1	$((S \text{ xor } OV) \text{ or } Z) = 0$	Greater than signed

APPENDIX C REVISION HISTORY

C.1 Major Revisions in This Edition

Page	Description
Throughout	Addition of product name μ PD703590GM-JEU-A
p.140	Addition of Caution to 4.9 Internal Instruction RAM Control Function
p.149	Modification of 4.11.6 (1) SDRAM (when read, latency = 2, no idle state insertion)
p.453	Modification of Figure 10-18. TMENC1n Block Diagram (During Timer Output Operation)
p.454	Modification of Figure 10-19. Timer Output Example (When ALVT1n0 Bit = 0 Is Set)
p.595	Modification of description of SETRQ bit in 12.4.1 (11) UF0 INT status 0 register (UF0IS0)
p.780	Modification of 15.2. (2) Function when each port's pins are reset and registers that set the port/control mode
p.771	Modification of Figure 14-3. Block Diagram of Type D-1
p.871	Modification of Figure 16-3. BUSCLK Operation at Power-on Reset (When fCLK = fX)
p.905	Modification of (a) Read timing (SDRAM access) in AC Characteristics of CHAPTER 18 ELECTRICAL SPECIFICATIONS
p.908	Modification of (c) DMA flyby transfer timing (transfer from external I/O to SDRAM) in AC Characteristics of CHAPTER 18 ELECTRICAL SPECIFICATIONS
p.928	Modification of A/D Converter Characteristics (EVDD = AVDD = AVREFP = 3.0 to 3.6 V, EVSS = AVSS = AVREFM = 0 V) of CHAPTER 18 ELECTRICAL SPECIFICATIONS

C.2 Revision History up to Previous Edition

(1/7)

Edition	Description	Applied to:
2nd edition	<ul style="list-style-type: none"> • Deletion of product name μPD703500GM-JEU • Addition of lead-free product μPD703500GM-JEU-A • Modification of package name LQFP → QFP • Addition of registers DSA0 to DSA3, DDA0 to DDA3, DBC0 to DBC3 registers • Modification of register name DMAIF0 to DMAIF3 registers → DIFC0 to DIFC3 registers • Modification of operating ambient temperature T_A = -40 to +85°C → T_A = -40 to +80°C 	Throughout
	Modification of description in 1.4 Ordering Information	CHAPTER 1
	Modification of description in 1.6.1 Internal block diagram	INTRODUCTION
	Modification of description in 2.2 Pin Status	CHAPTER 2 PIN FUNCTIONS
	Modification of description in 3.2.1 (2) Program counter (PC)	CHAPTER 3
	Addition of Note 2 to Table 3-2 System Register Numbers	CPU FUNCTION
	Addition of description to 3.2.2 (6) Exception/debug trap status saving registers (DBPC and DBPSW)	
	Modification of description in 3.4.3 (4) External memory area	
	Addition and modification of description in 3.4.5 Peripheral I/O registers	
	Modification of description in 3.4.7 System wait control register (VSWC)	
	Modification of description in 3.4.8 <2> (i) VSWC register	
	Addition of 3.5 (1) Allocation to address 0000000H	
	Addition of Caution to 4.4 (1) Bus cycle type configuration registers 0, 1 (BCT0, BCT1)	CHAPTER 4
	Modification of description in 4.5.1 Number of access clocks	BUS CONTROL
	Modification of description in 4.5.3 (2) (a) <2> Access to address (4n + 1)	FUNCTION
	Modification of description in 4.5.3 (3) (a) <2> Access to address (4n + 1)	
	Modification of description in 4.5.3 (3) (a) <4> Access to address (4n + 3)	
	Modification and addition of caution description in 4.5.4 (1) Write buffer function	
	Addition of Caution to 4.5.4 (2) Write access synchronization control register (WAS)	
	Modification and addition of caution description in 4.6 (1) Bus mode control register (BMC)	
	Addition of Caution 4 description to 4.7.1 (2) Address setup wait control register (ASC)	
	Deletion of caution description in 4.7.1 (4) DMA flyby transfer wait control register (FWC)	
	Modification of description in Table 4-1 Bus Cycles in Which Wait Function Is Valid	
	Modification of Figure 4-3 Example of Transfer from External ROM to Internal Instruction RAM	
	Addition of 4.15 Cautions	

(2/7)

Edition	Description	Applied to:	
2nd edition	Modification of description in 5.3 (1) Bus transaction control register (BTSC)	CHAPTER 5 CACHE FUNCTION	
	Deletion of caution description in 5.3 (2) Cache area specification register (BHC)		
	Modification of description in 5.3 (3) Cache manipulation specification register (COPR)		
	Addition of 5.9 (5) Cautions on setting BHC register		
	Addition of 6.3.3 (1) Address output and SDRAM connection and (2) Bank address output	CHAPTER 6 MEMORY ACCESS CONTROL FUNCTION	
	Addition of Caution 4 to 6.3.4 SDRAM configuration registers 1, 3, 4, 6 (SCR1, SCR3, SCR4, SCR6)		
	Modification of Figure 6-9 SDRAM Single Read Cycle (b) During off-page access (latency = 2, idle state 2 insertion)		
	Deletion of description in 6.3.5 (2) SDRAM single write cycle		
	Addition of Caution 2 to 6.3.6 (1) SDRAM refresh control registers 1, 3, 4, 6 (RFS1, RFS3, RFS4, RFS6)		
	Modification of description in 6.3.8 SDRAM initialization sequence		
	Addition of 6.4 Cautions		
	Modification of description in 7.1 Features		CHAPTER 7 DMA FUNCTIONS (DMA CONTROLLER)
	Modification of description in 7.3.2 DMA source address registers 0 to 3 (DSA0 to DSA3)		
	Modification of description in 7.3.3 DMA destination address registers 0 to 3 (DDA0 to DDA3)		
	Modification of description in 7.3.4 DMA transfer count registers 0 to 3 (DBC0 to DBC3)		
	Modification of description in 7.3.8 DMA terminal count output control register (DTC)		
	Modification of caution description in 7.3.9 DMA trigger factor registers 0 to 3 (DTFR0 to DTFR3)		
	Modification of description in 7.3.10 DMA interface control registers 0 to 3 (DIFC0 to DIFC3)		
	Modification of remark description in Table 7-3 Correlation Between External Access (Execution to External I/O/External Memory) and Active Width of DMAAkn Signal		
	Modification of note description in Figure 7-14 Circuit Example When Flyby Transfer Is Performed Between External I/O and SRAM		
	Modification and addition of note description in Table 7-5 Relationship Between Transfer Type and Transfer Target		
	Modification of description in 7.9 (4) Request by USB (enabled only in single transfer mode)		
	Addition of caution description to 7.14 Maximum Response Time for DMA Transfer Request		
	Addition of description in 7.15 Cautions		
	Addition of Caution to 8.1 Features	CHAPTER 8 INTERRUPT/EX CEPTION PROCESSING FUNCTION	
	Modification of remark description in Table 8-1 Interrupt/Exception Source List		
	Modification of caution description in Figure 8-9 RETI Instruction Processing		
	Addition of Caution to 8.5.1 (2) Restore		
	Addition of Caution to 8.5.2 (2) Restore		
	Addition of 8.8 Cautions		
	Modification of figure in 9.2 Configuration	CHAPTER 9 CLOCK GENERATION FUNCTION	
	Modification of description in 9.3.1 (2) Setting data to clock control register (CKC)		
	Modification of description in 9.3.2 Clock source select register (CKS)		
	Modification of description in 9.3.4 SSCG control register (SSCGC)		
Modification of description in 9.5 (1) Minimum value of operating frequency (f_{MIN})			

(3/7)

Edition	Description	Applied to:		
2nd edition	Modification of description in 9.6.2 (2) Power-save control register (PSC)	CHAPTER 9 CLOCK GENERATION FUNCTION		
	Deletion of Note in 9.6.3 (2) Release of HALT mode			
	Addition of Caution 2 to 9.6.4 (1) Setting and operation status			
	Addition of Cautions to 9.6.4 (2) Release of IDLE mode			
	Addition of 9.7 Cautions			
2nd edition	Addition of description to 10.1.8 Cautions	CHAPTER 10 TIMER/COUNT ER FUNCTION		
	Addition of 10.3.8 Cautions			
2nd edition	Modification of caution description in 11.2.3 (5) UARTBn receive data register AP (UBnRXAP), UARTBn receive data register (UBnRX) (n = 0, 1)	CHAPTER 11 SERIAL INTERFACE FUNCTION		
	Modification of caution description in 11.2.3 (8) UARTBn FIFO control register 2 (UBnFIC2) (n = 0, 1)			
	Addition of description to 11.2.9 Cautions			
	Addition of description to 11.3.7 Cautions			
	2nd edition		Addition of description to 12.3.1 (2) (i) SET_INTERFACE() request	CHAPTER 12 USB FUNCTION CONTROLLER (USBF)
Addition of remark to 12.4.1 (26) UF0 INT & DMARQ register (UF0IDR)				
Modification of description in 12.4.1 (32) UF0 GPR register (UF0GPR)				
Addition of Caution to 12.4.2 (9) UF0 bulk in 1 register (UF0BI1)				
Addition of Caution to 12.4.2 (10) UF0 bulk in 2 register (UF0BI2)				
Addition of Caution 2 to 12.4.4 (1) USB function 0 DMA channel select register (UF0CS)				
Addition of Figure 12-10 Flowchart of Program When Host Is Disconnected and Then Reconnected				
Addition of Figure 12-11 Flowchart of Program When Power Is Supplied				
Addition of description to Figure 12-22 CPUDEC Request for Control Transfer				
Addition of description to Figure 12-23 Processing for Bulk Transfer (IN) (Endpoint1)				
Modification of description in Figure 12-29 Example of Processing After Power Application/Power Failure				
2nd edition		Modification of description in Figure 13-1 Block Diagram of A/D Converter	CHAPTER 13 A/D CONVERTER	
		Modification of description in Table 13-1 Setting of A/D Conversion Operation Time		
		Addition of description to 13.8 Cautions		
2nd edition		Modification of description in 15.2 (2) Function when each port's pins are reset and registers that set the port/control mode	CHAPTER 15 PORT FUNCTIONS	
	Addition of description to 15.3.2 Port 2			
	Addition of description to 15.3.9 (2) (c) Port CS function control register (PFCCS)			
	Addition of 15.7 Cautions			
2nd edition	Modification of description in Table 16-2 Initial Value of CPU, Internal Data RAM, Internal Instruction RAM, and On-Chip Peripheral I/O After Reset	CHAPTER 16 RESET FUNCTIONS		
	Deletion of description in 17.1.1 Debug function	CHAPTER 17 DEBUG FUNCTION (DCU)		

(4/7)

Edition	Description	Applied to:
2nd edition	Modification of description of Absolute Maximum Ratings in CHAPTER 18 ELECTRICAL SPECIFICATIONS (TARGET)	CHAPTER 18 ELECTRICAL SPECIFICATIONS
	Addition of Recommended Oscillator to CHAPTER 18 ELECTRICAL SPECIFICATIONS (TARGET)	
	Modification of description in AC Characteristics (1) Clock timing in CHAPTER 18 ELECTRICAL SPECIFICATIONS (TARGET)	
	Modification of description in AC Characteristics (4) (a) Access timing (SRAM, external ROM, external I/O) in CHAPTER 18 ELECTRICAL SPECIFICATIONS (TARGET)	
	Modification of description in AC Characteristics (4) (d) DMA flyby transfer timing (transfer from SRAM to external I/O) in CHAPTER 18 ELECTRICAL SPECIFICATIONS (TARGET)	
	Modification of description in AC Characteristics (6) (a) Read timing (SDRAM access) in CHAPTER 18 ELECTRICAL SPECIFICATIONS (TARGET)	
	Modification of description in AC Characteristics (6) (b) Write timing (SDRAM access) in CHAPTER 18 ELECTRICAL SPECIFICATIONS (TARGET)	
	Modification of description in AC Characteristics (6) (c) DMA flyby transfer timing (transfer from external I/O to SDRAM) in CHAPTER 18 ELECTRICAL SPECIFICATIONS (TARGET)	
	Modification of description in AC Characteristics (8) Bus hold timing in CHAPTER 18 ELECTRICAL SPECIFICATIONS (TARGET)	
	Modification of description in AC Characteristics (12) CSI30, CSI31 timing in CHAPTER 18 ELECTRICAL SPECIFICATIONS (TARGET)	
	Addition of description to A/D Converter Characteristics in CHAPTER 18 ELECTRICAL SPECIFICATIONS (TARGET)	
	Addition of Supply Voltage Application/Cutoff Timing in CHAPTER 18 ELECTRICAL SPECIFICATIONS (TARGET)	
	3rd edition	
Addition of APPENDIX C REVISION HISTORY		APPENDIX C REVISION HISTORY
• Deletion of “preliminary” indication		Throughout
Modification of description in 3.4.5 On-chip peripheral I/O registers		CHAPTER 3 CPU FUNCTION
3rd edition	Addition of description to 4.9 (1) Instruction RAM control register (IRC)	CHAPTER 4 BUS CONTROL FUNCTION
	Addition of Caution to Table 6-1 Example of Interval Factor Settings	CHAPTER 6 MEMORY ACCESS CONTROL FUNCTION
	Modification of description in 6.3.7 (2) Release by INTP_n input (n = 10, 11, 21 to 25, 50 to 52, 65 to 67, D0 to D15, L0, L1)	CHAPTER 6 MEMORY ACCESS CONTROL FUNCTION

(5/7)

Edition	Description	Applied to:
3rd edition	Modification of description in 7.3.2 DMA source address registers 0 to 3 (DSA0 to DSA3)	CHAPTER 7 DMA FUNCTIONS (DMA CONTROLLER)
	Modification of description in 7.3.3 DMA destination address registers 0 to 3 (DDA0 to DDA3)	
	Modification of description in 7.3.4 DMA transfer count registers 0 to 3 (DBC0 to DBC3)	
	Modification of description in 7.3.5 DMA addressing control registers 0 to 3 (DADC0 to DADC3)	
	Modification of description in 7.3.6 DMA channel control registers 0 to 3 (DCHC0 to DCHC3)	
	Modification of description in 7.3.9 DMA trigger factor registers 0 to 3 (DTFR0 to DTFR3)	
	Modification of description in 7.3.9 (1) DMA request detection function	
	Modification of description in 7.4.1 Single transfer mode	
	Modification of Figure 7-9 Timing of 2-Cycle DMA Transfer (SDRAM → SRAM): Single Transfer Mode (SRAM Data 1 Wait, SDRAM Latency = 2, BMC Register = 00H, Level Detection Mode)	
	Modification of description in 7.5.1 (1) Timing of $\overline{\text{DMARQn}}$ and $\overline{\text{DMAAKn}}$ signals for 2-cycle transfer	
	Modification of description in Table 7-2 Data Transfer Circuit for 2-Cycle Transfer	
	Modification of description in 7.5.1 (2) $\overline{\text{DMAAKn}}$ signal active width extension function	
	Modification of description in Table 7-4 Minimum Value of Active Width of $\overline{\text{DMAAKn}}$ Signal During 2-Cycle Transfer	
	Modification of description in 7.12 Forcible Termination	
	Modification of description in Figure 7-25 Example of Forcible Termination of DMA Transfer	
	Modification of description in Table 7-8 Number of Minimum Execution Clocks in DMA Cycle	
	Modification of description in 7.14 Maximum Response Time for DMA Transfer Request	
	Modification of description in 7.15 (5) $\overline{\text{DMAAKn}}$ signal output, (9) Cautions on setting DCHCn register	
	Addition of description to 9.2 Configuration	CHAPTER 9 CLOCK GENERATION FUNCTION
	Modification of description in 9.3.4 SSCG control register (SSCGC)	CHAPTER 10 TIMER/COUNTER FUNCTION
	Deletion of caution description in 10.3.5 (6) Status registers 10, 11 (STATUS10, STATUS11)	CHAPTER 10 TIMER/COUNTER FUNCTION
	Addition of Caution 2 to 11.3.3 (1) Clocked serial interface mode registers 30, 31 (CSIM30, CSIM31)	CHAPTER 11 SERIAL INTERFACE FUNCTION
	Modification of description in 11.3.3 (7) Transfer data number specification registers 30, 31 (SFN30, SFN31)	CHAPTER 11 SERIAL INTERFACE FUNCTION
	Modification of Caution description in 12.1 Overview	CHAPTER 12 USB FUNCTION CONTROLLER (USBF)
	Addition of Caution to 12.4.1 (11) UF0 INT status 0 register (UF0IS0)	CHAPTER 12 USB FUNCTION CONTROLLER (USBF)
	Addition of Caution to 12.4.1 (12) UF0 INT status 1 register (UF0IS1)	CHAPTER 12 USB FUNCTION CONTROLLER (USBF)
	Modification of description in Figure 12-1 Operation of UF0E0R Register	CHAPTER 12 USB FUNCTION CONTROLLER (USBF)
	Modification of description in Figure 12-2 Operation of UF0E0ST Register	CHAPTER 12 USB FUNCTION CONTROLLER (USBF)
	Modification of description in Figure 12-3 Operation of UF0E0W Register	CHAPTER 12 USB FUNCTION CONTROLLER (USBF)

(6/7)

Edition	Description	Applied to:
3rd edition	Modification of description in Figure 12-4 Operation of UF0BO1 Register	CHAPTER 12 USB FUNCTION CONTROLLER (USBF)
	Modification of description in Figure 12-5 Operation of UF0BO2 Register	
	Modification of description in 12.4.2 (9) UF0 bulk in 1 register (UF0BI1)	
	Modification of description in 12.4.2 (10) UF0 bulk in 2 register (UF0BI2)	
	Modification of caution description in 12.4.3 (9) UF0 address register (UF0ADRS)	
	Modification of description in 12.4.3 (10) UF0 configuration register (UF0CNF)	
	Modification of Caution description in 12.4.3 (11) UF0 interface 0 register (UF0IF0)	
	Modification of Caution description in 12.4.3 (12) UF0 interface 1 to 4 registers (UF0IF1 to UF0IF4)	
	Modification of description in 12.4.4 (1) USB function 0 DMA channel select register (UF0CS)	
	Modification of description in Figure 12-25 Normal Processing for Bulk Transfer (OUT) (Endpoint2)	
	Modification of Figure 12-30 DMA Processing by Bulk Transfer (OUT)	
3rd edition	Modification of Caution description in 15.3.1 (2) (b) Port 1 mode control register (PMC1)	CHAPTER 15 PORT FUNCTIONS
	Modification of Caution description in 15.3.1 (2) (c) Port 1 function control register (PFC1)	
	Modification of specs in DC Characteristics in CHAPTER 18 ELECTRICAL SPECIFICATIONS	CHAPTER 18 ELECTRICAL SPECIFICATIONS
	Deletion of conditions in AC Characteristics (1) Clock timing in CHAPTER 18 ELECTRICAL SPECIFICATIONS	
	Modification of specs in AC Characteristics (4) (a) Access timing (SRAM, external ROM, external I/O) in CHAPTER 18 ELECTRICAL SPECIFICATIONS	
	Modification of specs in AC Characteristics (6) (a) Read timing (SDRAM access) in CHAPTER 18 ELECTRICAL SPECIFICATIONS	
	Modification of specs in AC Characteristics (6) (b) Write timing (SDRAM access) in CHAPTER 18 ELECTRICAL SPECIFICATIONS	
	Modification of specs in AC Characteristics (6) (c) DMA flyby transfer timing (transfer from external I/O to SDRAM) in CHAPTER 18 ELECTRICAL SPECIFICATIONS	
	Modification of description in AC Characteristics (7) DMAC timing in CHAPTER 18 ELECTRICAL SPECIFICATIONS	
	Modification of specs in AC Characteristics (8) Bus hold timing in CHAPTER 18 ELECTRICAL SPECIFICATIONS	
	Modification of specs in Supply Voltage Application/Cutoff Timing in CHAPTER 18 ELECTRICAL SPECIFICATIONS	
Addition of C.2 Revision History up to Previous Edition	APPENDIX C REVISION HISTORY	
4th edition	Addition of Note to Figure 3-4. Memory Map	CHAPTER 3 CPU FUNCTION
4th edition	Modification of Caution description in 3.4.3 (1) (a)	
4th edition	Modification of initial value in 3.4.5 On-chip peripheral I/O registers	CHAPTER 4 BUS CONTROL FUNCTION
4th edition	Addition of Caution to 4.3.1 (1) Chip area select control registers 0, 1 (CSC0, CSC1)	

(7/7)

Edition	Description	Applied to:
4th edition	Modification of description in 6.2.4 Page ROM configuration register (PRC)	CHAPTER 6 MEMORY ACCESS CONTROL FUNCTION
	Deletion of description in 7.3.7 DMA restart register (DRST)	CHAPTER 7 DMA FUNCTIONS (DMA CONTROLLER)
	Modification of Remark in 7.3.9 DMA trigger factor registers 0 to 3 (DTFR0 to DTFR3)	
	Modification of description in 7.3.9 (1) DMA request detection function	
	Modification of description in 7.3.10 DMA interface control registers 0 to 3 (DIFC0 to DIFC3)	
	Addition of Caution to 8.3.4 Interrupt control register (xxICn)	CHAPTER 8 INTERRUPT/EXCEPTION PROCESSING FUNCTION
	Modification of description in 8.3.8 (7) Valid edge select registers C0 to C3 (SESC0 to SESC3)	
	Modification of description in 9.5.2 (6) Serial communication (transmission or reception) transfer rate of UARTB	CHAPTER 9 CLOCK GENERATION FUNCTION
	Modification of description in 10.1.5 (3) Valid edge select registers C0 to C3 (SESC0 to SESC3)	CHAPTER 10 TIMER/COUNTER FUNCTION
	Modification of description in 10.1.8 (13) Setting trigger mode	
	Addition of Caution to and modification of description in 11.2.3 (10) UARTBn FIFO status register 1 (UBnFIS1) (n = 0, 1)	CHAPTER 11 SERIAL INTERFACE FUNCTION
	Modification of description in 11.3.1 Features	
	Addition of 13.8 (15) Re-conversion start trigger input during stabilization time, (16) Variation of A/D conversion results, (17) A/D conversion result hysteresis characteristics	CHAPTER 13 A/D CONVERTER
	Modification of description in Table 16-2. Initial Value of CPU, Internal Data RAM, Internal Instruction RAM, and On-Chip Peripheral I/O After Reset	CHAPTER 16 RESET FUNCTIONS
Modification of description of AC Characteristics (8) Bus hold timing in CHAPTER 18 ELECTRICAL SPECIFICATIONS	CHAPTER 18 ELECTRICAL SPECIFICATIONS	
Addition of AC Characteristics (9) Refresh timing in CHAPTER 18 ELECTRICAL SPECIFICATIONS
