Figure 3. Pin Assignments - Top View

2.2 Pin Descriptions

Pin Number	Pin Name	Description
1, 19, 20	VOUT	VOUT are the output pins that supply power to the load. The recommended operating output voltage for these pins is 0.8V to 5.1V. The maximum current that these pins can source is 4A. Renesas recommends tying all three pins to the same output PCB plane. A minimum 22µF ceramic capacitor is required from these pins to GND for stable operation. Place the output capacitor as close as possible to the OUT pins. Add an optional 100nF bypass capacitor parallel with the 22µF to reduce higher-frequency noise and supply higher frequency load currents if required. See Programming the Output Voltage for programming the output voltage and Output Capacitor (C_{OUT}) for selecting C _{OUT} .
2	SNS	SNS is the output voltage sense pin. Connect this pin to the OUT pins (1, 19, 20) if the output voltage set pins (50mV, 100mV, 200mV, 400mV, 800mV, and 1.6V pins) are used to program the output voltage. If external feedback resistors are used to program the output voltage, leave this pin floating.
3	FB	FB is the output voltage feedback pin. This pin is internally connected to the error amplifier and is compared with 0.8V of the voltage reference circuitry. The voltage divider formed around this pin with either the internal or external feedback resistors programs the LDO output voltage. See Internal Feedback Resistors and Output Voltage Set Pins for using the internal FB resistors and External Feedback Resistors for using the external FB resistors to program the output voltage.
4	PG	PG is the power good pin. This pin monitors the output voltage and signals other circuit ICs in a system connected to this pin when the output voltage is at or near its programmed value. When the output voltage exceeds -12% of its programmed value, this pin pulls LOW, indicating a fault. When the output voltage is within -12% of its programmed value, the pin is open circuit (high Z) without a pull-up resistor. Therefore, to ensure a proper logic HIGH to devices connected to this pin, Renesas recommends tying a 10kΩ (minimal) pull-up resistor. If this pin is not being used, it can be left floating.

Pin Number	Pin Name	Description
5	50mV	<p>These are the output voltage set pins. These pins can either be grounded or left floating. Connecting any pin to ground increases the output voltage by the value of the pin name. With all the pins left floating, the output voltage equals V_{REF}, which is 0.8V. With all the pins grounded, the output voltage is 3.95V. See Internal Feedback Resistors and Output Voltage Set Pins for more detail on how to use these pins to program the output voltage.</p>
6	100mV	
7	200mV	
9	400mV	
10	800mV	
11	1.6V	
8, 18	GND	GND is the ground pin. Tie this pin to the PCB ground plane and the EPAD.
12	VBIAS	VBIAS is the BIAS pin. This pin enables low-input voltage ($V_{IN} < 1.4V$) to reduce power dissipation for low-voltage applications. It also improves DC and AC performance for $V_{IN} \leq 1.4V$. A minimum 1 μ F capacitor must be connected between this pin and GND. Place this capacitor as close as possible to the BIAS pin. If not using this pin, it can be left floating or tied to GND without impacting performance.
13	CNR/SS	CNR/SS is the noise-reduction and soft-start pin. A 100nF capacitor is required between this pin and GND for LDO stability and to help reduce low-to-mid frequency noise and increase low-to-mid frequency PSRR. For optimal noise/PSRR performance, Renesas recommends using a 1 μ F capacitor on this pin. Using a larger capacitor can increase the soft-start time to reduce in-rush current. See Noise-Reduction and Soft-Start Capacitor ($C_{NR/SS}$) for more details about selecting $C_{NR/SS}$.
14	EN	EN is the enable pin. This pin can enable or disable the LDO. If the voltage on this pin is LOW, the LDO is disabled and shuts down. When the voltage is HIGH, the LDO is enabled. Important: This pin must not be left floating. Instead, tie it to the VIN pins for automatic enabling. See Enable Control for more details about the EN function.
15, 16, 17	VIN	VIN are the input voltage pins that supply power to the LDO and the LDO load. The recommended operating input voltage for these pins is 1.4V to 6.5V without BIAS and down to 1.1V with BIAS. Renesas recommends tying all three pins to the same input PCB plane. A minimum 10 μ F ceramic capacitor is required between these pins to GND to minimize the impedance of the input supply. The input capacitor also helps reduce high-frequency input noise. Place this capacitor as close as possible to the VIN pins. Add an optional 100nF bypass capacitor in parallel with the 10 μ F to reduce higher-frequency input noise and further reduce input supply impedance supply if required. See Input Capacitor (C_{IN}) for more details about selecting C_{IN} .
-	EPAD	EPAD is the exposed pad on the bottom of the package. Solder the exposed pad to the PCB ground plane and tie it directly to pins 8 and 18 to ensure the best electrical and thermal performance. See Layout Guidelines for more layout guidelines for this pin.

3. Specifications

3.1 Absolute Maximum Ratings

Caution: Do not operate at or near the maximum ratings listed for extended periods of time. Exposure to such conditions can adversely impact product reliability and result in failures not covered by warranty.

Parameter ^[1]	Minimum	Maximum	Unit
VIN, EN, BIAS	-0.3	+7.5	V
VOUT, PG, NR/SS	-0.3	+6.5	V
50mV, 100mV, 200mV, 400mV, 800mV, 1.6V	-0.3	+6.5	V
FB	-0.3	+3.3	V
Maximum Junction Temperature	-40	+125	°C
Maximum Storage Temperature Range	-65	+150	°C
Human Body Model (Tested per JS-001-2023)	-	2	kV
Charged Device Model (Tested per JS-002-2022)	-	750	V
Latch-Up (Tested per JESD78E; Class 2, Level A)	-	100	mA

1. All voltages referenced to GND unless otherwise specified.

3.2 Recommended Operating Conditions

Parameter ^[1]	Minimum	Maximum	Unit
Supply Voltage, V _{IN}	1.1	6.5	V
Bias Voltage, V _{BIAS}	3	6.5	V
Enable Voltage, V _{EN}	0	6.5	V
Output Voltage, V _{OUT}	0.8	5.1	V
Output Current, I _{OUT}	0	4	A
Output Capacitor, C _{OUT}	22	-	μF
Input Capacitor, C _{IN}	10	-	μF
Bias Capacitor, C _{BIAS}	1	-	μF
Power-Good Pull-Up Resistance, R _{PG}	10	-	kΩ
Noise Reduction Capacitor, C _{NR/SS}	0.1	-	μF
Junction Temperature	-40	+125	°C

1. All voltages referenced to GND unless otherwise specified.

3.3 Thermal Specifications

Parameter	Package	Symbol	Conditions	Typical Value	Unit
Thermal Resistance	20-Ld 3.5mm×3.5mm QFN Package	θ _{JA} ^[1]	Junction to ambient	42	°C/W
		θ _{JC} ^[2]	Junction to case	4.5	°C/W

1. θ_{JA} is measured in free air with the component mounted on a high-effective thermal conductivity test board with direct attach features. See [TB379](#) for details.

2. For θ_{JC}, the case temperature location is the center of the exposed metal pad on the package underside.

3.4 Electrical Specifications

Operating conditions unless otherwise noted: $T_J = -40^{\circ}\text{C}$ to $+125^{\circ}\text{C}$, $V_{IN} = V_{OUT} + 400\text{mV}$ or 1.4V whichever is greater, $V_{BIAS} = \text{OPEN}$, $V_{OUT} = 0.8\text{V}$, $V_{EN} = 5\text{V}$, $I_{OUT} = 0\text{mA}$, $C_{IN} = 47\parallel 10\parallel 10\mu\text{F}$, $C_{OUT} = 47\parallel 10\parallel 10\mu\text{F}$, $C_{NR/SS} = 100\text{nF}$.

Protection						
Internal Current Limit	I_{LIM}	$V_{IN} = 1.1\text{V}$, $V_{BIAS} = 5\text{V}$, V_{OUT} forced to 90% of $V_{OUT_PROGRAMMED}$	-	7	-	A
Thermal Shutdown	T_{OTSD}	Temperature Rising	-	165	-	$^{\circ}\text{C}$
Thermal Shutdown Hysteresis	T_{OTSD_HYST}	-	-	15	-	$^{\circ}\text{C}$

- Parameters with MIN and/or MAX limits are 100% tested at $+25^{\circ}\text{C}$, unless otherwise specified. Temperature limits established by characterization and are not production tested. Compliance to limits is assured by characterization and design.
- Dropout Voltage is measured with the LDO in an open-loop configuration where FB is disconnected from VOUT. A V_{FB} lower than the reference voltage is applied to the FB pin, which causes the error amplifier to drive the main pass-transistor into saturation to try and bring the output voltage (which is sensed through FB) back up into regulation. Because VOUT is disconnected from FB, the output voltage rails up to a margin below V_{IN} and the $V_{IN} - V_{OUT}$ differential is taken to be the dropout voltage.

4. Typical Performance Curves

4.1 PSRR

Operating conditions unless otherwise noted: $T_A = 25^\circ\text{C}$, $V_{IN} = V_{OUT} + 0.4\text{V}$ or 1.4V whichever is greater, V_{BIAS} = open, $V_{OUT} = 0.8\text{V}$, V_{EN} tied directly to V_{IN} , C_{IN} = None, $C_{OUT} = 47\parallel 10\parallel 10\mu\text{F}$, $C_{NR/SS} = 1\mu\text{F}$, and PG pulled up to V_{OUT} with $10\text{k}\Omega$.

5. Applications Information

5.1 Overview

The RAA214048 is a low-noise, high PSRR, low-dropout (LDO) regulator. The LDO can source up to 4A load current with only 250mV dropout voltage. It operates from an input voltage of 1.1V to 6.5V (with a minimum 3V BIAS) for very low input voltage applications with $\pm 1\%$ accuracy over line, load, and temperature. The output voltage can be programmed from 0.8V to 3.95V using output voltage setting pins on the IC in 50mV steps or from 0.8V to 5.1V using external feedback resistors.

The RAA214048 is designed and tested with a 10 μ F ceramic input capacitor, 22 μ F ceramic output capacitor, a 1 μ F noise-reduction, a soft-start capacitor ($C_{NR/SS}$), and a 10 μ F BIAS capacitor if VBIAS is being used. The LDO is available in a 20-Ld 3.5mm \times 3.5mm QFN package.

The RAA214048 integrates the following additional features in this package:

- High output accuracy ($\pm 1\%$)
- Low output noise
- High PSRR
- No sequencing requirement between VBIAS, VIN, and VEN
- Power-good indication
- Convenient output voltage set pins to program the LDO output
- Undervoltage lockout (UVLO)
- Enable control
- Internal current limit protection
- Thermal shutdown protection
- Minimum 22 μ F ceramic output capacitor for stability
- Output capacitor automatic discharge
- BIAS pin for lower dropout voltage and lower VIN performance

5.2 Theory of Operation of NMOS LDOs

Like the majority of LDOs with an NMOS pass transistor, the RAA214048 output voltage (V_{OUT}) regulation can be modeled with a voltage reference (V_{REF}), feedback (FB) resistors, error amplifier, and NMOS pass-transistor as shown in Figure 42.

Figure 42. Simple NMOS LDO Regulator Block Diagram

The NMOS pass transistor can be modeled as a variable resistor ($r_{DS(ON)}$) that is controlled by the error amplifier to maintain a constant DC output voltage for changes in load current (I_{OUT}). Assume the input voltage (V_{IN}) remains constant and the $r_{DS(ON)}$ is adjusted for a given I_{OUT} to set V_{OUT} .

Equation 1 summarizes this relationship.

$$(EQ. 1) \quad V_{OUT} = V_{IN} - I_{OUT} \times r_{DS(ON)}$$

V_{OUT} is set using the FB resistor divider, which sets V_{OUT} to a value that corresponds to Equation 2.

$$(EQ. 2) \quad V_{OUT} = V_{REF} \times \left(1 + \frac{R_{TOP}}{R_{BOT}} \right)$$

The error amplifier compares V_{FB} with the fixed V_{REF} voltage and works to minimize the difference between V_{FB} and V_{REF} by changing the gate voltage of the NMOS pass transistor and, therefore, the $r_{DS(ON)}$.

If the I_{OUT} suddenly increases because of decreased load resistance, V_{OUT} decreases because the regulator has not responded to the change, and the $r_{DS(ON)}$ is set too high. V_{FB} correspondingly decreases and is below the V_{REF} voltage, therefore increasing the error voltage. The error amplifier senses and minimizes the error by driving the NMOS gate voltage more positively relative to the FET source to decrease the $r_{DS(ON)}$, which increases the output voltage, bringing it back into regulation.

By similar logic, a sudden decrease in I_{OUT} because of increased load resistance causes V_{OUT} to increase because the $r_{DS(ON)}$ is set too low. V_{FB} is then higher than the fixed V_{REF} voltage, increasing the error. The error amplifier senses and minimizes the error by driving the NMOS gate voltage more negatively relative to the FET source to increase the $r_{DS(ON)}$, which decreases the output voltage, bringing it back into regulation.

6. Functional Description

6.1 Low Output Noise

The LDO output noise is the internally generated noise created largely by the band-gap voltage reference and the error amplifier. The output noise is commonly represented in units of nV/\sqrt{Hz} for a specific frequency or as an integrated root-mean square (RMS) value in μV over a range of frequencies typically 10Hz to 100kHz or 100Hz to 100kHz.

The RAA214048 output noise is largely independent of the output voltage and does not require a feed-forward capacitor to achieve very low output noise. On the other hand, it depends on the output current, $C_{NR/SS}$, and C_{OUT} capacitor. The $C_{NR/SS}$ improves the low-frequency output noise of the LDO. Renesas recommends using a $1\mu F$ $C_{NR/SS}$ capacitor for the best low-output noise. See $C_{NR/SS}$ capacitor for selecting the correct noise-reduction and soft-start capacitor. C_{OUT} improves the noise at high-frequencies by reducing the high-frequency output impedance of the LDO. See the [Output Capacitor \(\$C_{OUT}\$ \)](#) section for selecting the correct output capacitor.

6.2 High Power-Supply Ripple-Rejection (PSRR)

The PSRR is how much attenuation or rejection the LDO control loop gives to externally generated input voltage noise, such as from a switching regulator. Although PSRR represents a loss in the input noise signal, it is common to see it as a positive decibel (dB) number. Mathematically, PSRR is represented as a logarithmic ratio between an input and output ripple sinusoid signal at a specific frequency as shown in Equation 3.

$$(EQ. 3) \quad PSRR(dB) = 20 \times \log \left(\frac{V_{IN(RIPPLE)}}{V_{OUT(RIPPLE)}} \right)$$

The PSRR for the RAA214048 is largely independent of the output voltage and does not require a feed-forward capacitor. On the other hand, it depends on the output current, headroom voltage ($V_{IN}-V_{OUT}$), $C_{NR/SS}$ capacitor, C_{OUT} capacitor, and PCB layout.

The higher the output current, the lower the PSRR is across all frequencies compared to a lower output current. The PSRR at low- and mid-frequencies can be improved by increasing the headroom voltage, but this comes at the cost of increased power dissipation. If the headroom is lowered, it decreases the power dissipation and lowers the PSRR at low- to mid-frequencies.

6.3 VBIAS, VIN, and VEN Sequencing

The RAA214048 the VBIAS, VIN, and VEN pins do not need to be powered on in any specific order. Table 1 gives the status of the LDO and various circuits depending on the status of VBIAS, VIN, and VEN.

Table 1. VBIAS, VIN, and VEN Functionality

VIN Status	VBIAS Status	VEN Status	LDO Status	Active Discharge	VPG Status
$V_{IN} \geq V_{UVLO(RISING)}$	$V_{BIAS} \geq V_{UVLO(BIAS)(RISING)}$	$V_{EN} = HIGH$	ON	OFF	$V_{PG} = HIGH$ or High-Z when $V_{OUT} \geq 0.88 \times V_{OUT_SET}$
	$V_{BIAS} < V_{UVLO(BIAS)(RISING)}$	$V_{EN} = LOW$	OFF	ON ^[1]	$V_{PG} = LOW$
$V_{IN} \leq V_{UVLO(FALLING)}$	Status does not matter	Status does not matter			

1. The output discharge circuitry remains enabled if V_{IN} does not drop below 0.9V (typical) or V_{BIAS} does not drop below 2.75V (typical).

6.4 UVLO

The RAA214048 integrates an internal UVLO circuit to keep the output voltage safely DISABLED if the input voltage or bias voltage is below the UVLO threshold. When the input voltage is above the UVLO threshold, the part is ENABLED, and the output voltage ramps up into regulation. The UVLO hysteresis prevents input voltage noise from causing the output to oscillate.

When the input voltage is below the UVLO, an internal 300Ω discharge resistor connects the LDO output to ground to quickly discharge the output capacitor. The resistor is connected to the output capacitor when the input voltage exceeds 0.9V but less than the UVLO threshold of 1V (typical). Figure 43 illustrates the UVLO operation.

Figure 43. UVLO Operation

- a – The input voltage has not reached the UVLO Rising threshold (1V), so the LDO remains disabled. The 300Ω internal discharge resistor is connected to the output voltage if the input voltage is above the UVLO rising threshold between 0.9V and 1V.
- b – The LDO is enabled, and the output rises to its regulated programmed value when the UVLO RISING threshold is reached by the input voltage (1V). At the same time, the 300Ω discharge resistor is disconnected from VOUT.
- c – A brownout occurs, but the LDO remains enabled, and the 300Ω discharge resistor remains disconnected because the input voltage has not reached the UVLO FALLING threshold (0.9V). The output voltage can still fall out of regulation.
- d – Output is regulated to its programmed output voltage value.
- e – The input voltage is turned OFF but has not yet crossed the UVLO FALLING threshold (0.9V), so the LDO is still enabled, and the 300Ω discharge resistor remains disconnected. The output voltage can fall out of regulation.
- f – The input voltage turns OFF, and the output voltage falls because of the load and 300Ω discharge resistor, which remains connected to VOUT if the input voltage is between 0.9V and 1V. The LDO is disabled.
- g – The LDO remains disabled because the input voltage has not reached the UVLO RISING threshold (1V). The 300Ω internal discharge resistor remains connected to the output voltage if the input voltage is between 0.9V and 1V.
- h – Output is regulated to its programmed output voltage value.

6.5 Power-Good (PG) Indication

The Power-good (PG) pin is an open-drain NMOS-FET. The PG pin circuitry monitors the FB pin voltage to indicate whether the output voltage is 12% below its programmed value (Undervoltage (UV) threshold). When the output voltage is 12% below its programmed value, the PG circuitry drives the NMOS FET ON and indicates LOW on the PG pin. If the output voltage exceeds 88% of its programmed value, the PG circuitry drives the NMOS-FET OFF, and the PG pin becomes HIGH. When the output voltage is below the PG UV thresholds, the fast-start-up circuitry is activated to bring the output voltage above the 88% nominal value.

Renesas recommends using a 10kΩ or greater pull-up resistor to tie the PG pin to VIN, VOUT, or an external supply to ensure a proper HIGH voltage to any downstream logic device such as an MCU or FPGA. If the PG pin is not used, it can be left floating. The 10kΩ lower limit results from the maximum pull-down strength of the NMOS-FET. Working outside of this range may result in invalid digital logic level readings.

6.6 Enable Control

The RAA214048 uses the EN pin voltage (V_{EN}) to enable or disable the LDO. On power-up, if the enable voltage remains lower than the V_{EN} Rising threshold ($V_{EN} \leq 1V$), the LDO remains DISABLED. If V_{EN} exceeds the V_{EN} Rising threshold ($V_{EN} \geq 1V$ typical), the LDO is ENABLED. When V_{EN} falls below the V_{EN} falling threshold ($V_{EN} \leq 0.9V$), the LDO is DISABLED. The V_{EN} hysteresis (100mV) prevents the enable voltage noise from causing the output to oscillate. When the LDO is disabled, the shutdown current is typically 9μA.

When the LDO is disabled, and the input voltage is greater than or equal to 0.9V, the same 300Ω discharge resistor controlled by the UVLO circuitry is connected between the LDO output and GND to discharge the output capacitor quickly.

Connect the EN pin directly to the input voltage for automatic start-up or to a logic controller such as an FPGA MCU. Some logic pins use an open-collector or open-drain transistor to pull LOW and float when HIGH. Make sure to connect a 10kΩ pull-up resistor to ensure proper logic HIGH. To ensure proper Enable control operation, ensure the V_{EN} signal source can swing above and below the threshold values.

6.7 Internal Current Limit (ILIM)

The internal current limit (ILIM) circuitry limits the maximum output current the RAA214048 can source to the load during start-up because of in-rush current or during faults such as output short-circuits. ILIM is set above the maximum recommended output current of the RAA214048 (4A).

During in-rush current or fault events, the LDO becomes a constant current source, and as a result, any decrease in load resistance causes a decrease in the output voltage. The LDO returns to regulation when the short or overcurrent condition is removed. Because of the high power dissipation caused by overcurrent faults, the LDO may begin to cycle ON and OFF because of the thermal shutdown circuitry. The thermal shutdown circuitry turns the LDO OFF when the die junction temperature exceeds thermal fault conditions (+165°C) and turns the LDO ON after cooling to +150°C when the LDO output is OFF.

6.8 Thermal Protection

The RAA214048 is protected against thermal overloads caused by excessive power dissipation, such as during overcurrent conditions or high ambient temperatures.

When the die junction temperature exceeds +165°C, the thermal shutdown circuit disables the LDO, shutting off the output and allowing the LDO to cool. A 15°C hysteresis is included to prevent the LDO from uncontrollably heating and cooling.

Prolonged exposure to a junction temperature exceeding +125°C reduces the long-term stability and life of the LDO. Therefore, the design must consider the ambient temperature that the LDO works in, the junction-to-ambient thermal resistance (θ_{JA}), and any fault conditions that can cause the junction to exceed the recommended operating range. In some applications, a heat sink may need to be implemented. See Power Dissipation and Thermals to approximate the maximum junction temperature for an application.

6.9 Output Capacitor Automatic Discharge

The RAA214048 features a 300Ω discharge resistor that rapidly discharges the output capacitor when the LDO is disabled. The UVLO and ENABLE circuitry control the 300Ω discharge resistor.

The 300Ω discharge resistor is connected to the LDO output when the LDO is disabled using the ENABLE or UVLO circuitry and when the input voltage or VBIAS voltage is greater than or equal to 1V. If the input voltage collapses faster than the discharge circuitry can discharge the output capacitor, the output voltage may be greater than the input voltage. In this case, C_{OUT} discharges through the NMOS transistor body diode.

6.10 BIAS

Using a BIAS voltage $\geq 3.3V$ for V_{IN} s less than 3.3V improves the dropout voltage and PSRR.

6.11 Output Accuracy

The RAA214048 features an output voltage accuracy of 1% maximum, including the errors introduced by the internal reference, load regulation, line regulation, and operating temperature as specified by the Electrical Characteristics tables. The output voltage accuracy specifies minimum and maximum output voltage error with respect to the nominal output voltage stated as a percent.

7. Application Requirements

7.1 Input Voltage

The RAA214048 operates with an input voltage of 1.4V to 6.5V on the VIN pin (without BIAS) and from 1.1V to 6.5V on the VIN pin (with a minimum of 3V BIAS). If $V_{IN} \geq V_{BIAS}$, it is pointless to use the BIAS pin.

The input supply must be able to supply the required current the LDO needs to supply to the load. For proper regulation, ensure the input voltage is higher than the sum of the output voltage and the maximum dropout voltage expected for a given application as expressed in [Equation 4](#).

$$(EQ. 4) \quad V_{IN} > V_{OUT} + V_{DROPOUT(max)}$$

7.2 Programming the Output Voltage

The output voltage can be programmed using convenient output voltage set pins on the IC or traditional external feedback resistors.

7.2.1 Internal Feedback Resistors and Output Voltage Set Pins

The RAA214048 has convenient IC pins that connect an array of internal FB resistors to program the output voltage easily. In this configuration, the output voltage can be programmed from 0.8V to 3.95V in steps of 50mV.

Important: To use the internal FB resistors and convenient IC voltage set pins to program the output voltage, the SNS pin must be shorted to the VOUT(s) pins.

The Voltage Set pins are labeled 50mV (Pin 5), 100mV (pin 6), 200mV (Pin 7), 400mV (Pin 9), 800mV (Pin 10) and 1.6V (Pin 11). These pins are either grounded or left floating using the PCB layout. Grounding these pins adds the voltages assigned to each grounded pin to the 0.8V reference voltage as shown in [Equation 5](#).

$$(EQ. 5) \quad V_{OUT} = 0.8V + \Sigma(\text{Grounded Output Voltage Set Pins})$$

For example, to program the output voltage to 3.3V, ground the 1.6V, 800mV, and 100mV pins. The sum of these three pins (2.5V) added to the 0.8V reference equals the required 3.3V output. [Figure 44](#) through [Figure 53](#) illustrate how to connect the LDO output voltage set pins to get various common output voltage rails.

7.2.2 External Feedback Resistors

The RAA214048 output voltage can be programmed down to 0.8V and up to 5.1V using external FB resistors (R_{TOP} and R_{BOT}) as shown in Figure 54.

Important: The SNS pin must be left floating to use the external FB resistors to program the output voltage.

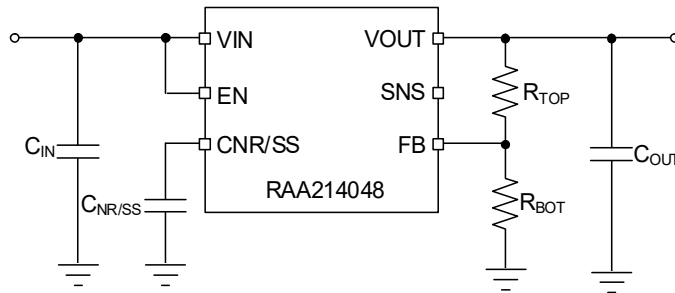

Figure 54. Simplified External FB Resistor Schematic

Use Equation 6 to calculate V_{OUT} .

$$(EQ. 6) \quad V_{OUT} = 0.8V \times \left(1 + \frac{R_{TOP}}{R_{BOT}} \right)$$

Calculate the R_{BOT} resistor for any target output voltage by rearranging Equation 6 to get Equation 7.

$$(EQ. 7) \quad R_{BOT} = R_{TOP} \times \left(\frac{0.8V}{V_{OUT} - 0.8V} \right)$$

Similarly, use Equation 8 to calculate the R_{TOP} resistor.

$$(EQ. 8) \quad R_{TOP} = R_{BOT} \times \left(\frac{V_{OUT}}{0.8V} - 1 \right)$$

Table 3 lists recommended FB resistor values to obtain some standard output voltages for the RAA214048. The FB resistors are commercially available in 1% tolerances. This list is non-exhaustive.

Table 3. Recommended FB Resistor Values for Common Output Voltages ($V_{REF} = 0.8V$)

7.3 Bias Voltage

A 3V to 6.5V voltage must be applied to VBIAS to lower the minimum input voltage from 1.4V to 1.1V. For lower dropout voltages when $V_{IN} > 1.4V$, apply a 3V to 6.5V voltage to VBIAS.

7.4 External Bypass Capacitor Selection

The RAA214048 requires using C_{IN} , C_{OUT} , and $C_{NR/SS}$ bypass capacitors to operate properly. The C_{BIAS} bypass capacitor is only required if using BIAS. Otherwise, it can be left out with no impact on LDO performance.

Multi-layer ceramic capacitors (MLCC) are a great choice for bypass capacitors because of their small size, low ESR, low ESL, and wider operating temperature than tantalums and aluminum capacitors. When choosing a ceramic capacitor for an application, it is important to consider the voltage rating, voltage coefficient, and temperature coefficient.

During PCB layout, place C_{IN} , C_{OUT} , $C_{NR/SS}$, and C_{BIAS} as close as practical to their respective pins to minimize trace inductance. Renesas recommends verifying the expected capacitance and capacitor performance in the circuit before production.

7.4.1 Input Capacitor (C_{IN})

The minimum input capacitor required on the VIN pin for proper operation and stability is 10 μ F. A 10 μ F input capacitor also helps reduce the damaging effects of large input impedances because of long input traces or high source impedances. Additional bypass capacitors with different self-resonant frequencies can be paralleled with 10 μ F to keep the input impedance low across a wider frequency range if required.

Input capacitors greater than 10 μ F can also help minimize input voltage drops during significant changes in load current and during start-up and do not affect stability.

Important: Ensure that the combination of trace and wire inductance and the input capacitor chosen does not cause unwanted ringing because of the resonance formed by the LC tank circuit. Keep input traces and wires short to minimize resonance.

7.4.2 Output Capacitor (C_{OUT})

The RAA214048 is stable with a 22µF minimum ceramic output capacitor on the V_{OUT} pin.

A larger value output capacitor generally improves the transient response because of significant changes in load current. Still, it can also increase the load transient response time because of the decreased loop bandwidth.

The high-frequency PSRR can be improved to target specific frequencies, such as from a switching regulator, if the output capacitor PSRR peak is chosen to equal the switching frequency of the upstream supply noise.

Additional output capacitors can be paralleled with the 22µF to improve PSRR and output noise performance across a wider frequency range.

7.4.3 Noise-Reduction and Soft-Start Capacitor (C_{NR/SS})

The minimum noise-reduction and soft-start bypass capacitor (C_{NR/SS}) required for LDO stability on the NR/SS pin is 100nF. This capacitor also helps reduce the low-to-mid frequency output noise and increase the low-to-mid frequency PSRR. Renesas recommends using a 1µF C_{NR/SS} for the best noise and PSRR performance. During the layout of this capacitor, minimize leakage currents around the NR/SS pin, as large leakage currents can cause DC offsets and add additional noise to the LDO output.

Note: A C_{NR/SS} less than 1µF does not give the best possible noise and PSRR performance.

The soft start-up time of the RAA214048 can be estimated with the value of the capacitor C_{NR/SS} along with the output voltage (V_{OUT}) using Equation 9, where T_{SS} is in µs, V_{OUT} is in V, and C_{NR/SS} is in µF.

$$(EQ. 9) \quad T_{SS} = 140 \times V_{OUT} \times C_{NR/SS} + 34 + 3 \times \frac{V_{OUT} - 1.1}{C_{NR/SS}}$$

The charging current of the soft start is related to the output voltage V_{OUT}. The soft start-up time of the RAA214048 is defined as the time it takes for the output voltage to rise from 10% to 90% of its final value as soon as the V_{EN} crosses its threshold.

Table 4 shows the measured start-up time. A difference between the estimated and measured start-up time may exist, which is mainly caused by the current charging C_{NR/SS} changes when the V_{OUT} changes.

Table 4. Measured Start-Up Time Based on V_{OUT} and C_{NR/SS}

C _{NR/SS} Option	Measured Start-Up Time (µs)			
	0.8V	1.1V	3.3V	5.1V
0.1µF	31	43	156	298
1µF	218	300	573	654

Some ceramic capacitors experience a piezoelectric response that causes the capacitor to generate noise when exposed to mechanical stress or thermal transients. In the LDO, this appears as increased low-frequency noise on the output. The cause of this is the dielectric material used in the capacitor. Most high-dielectric type capacitors like X5R and X7R have a significant piezoelectric response. Low-dielectric ceramic capacitors such as NP0 or C0G do not have piezoelectric properties and are recommended to solve piezoelectric problems. The drawback of NP0 or C0G capacitors is that they are expensive and large if commercially available.

7.4.4 Bias Capacitor (C_{BIAS})

The minimum BIAS bypass capacitor required when using BIAS for low input voltage applications (<1.4V) is 10 μ F.

7.5 Power Dissipation and Thermals

In applications with high ambient temperatures, large headroom voltages, and large load currents, the heat dissipated inside the package can become large enough to cause the junction temperature to exceed the maximum recommended operating temperature of +125°C. The die junction temperature of the RAA214048 must not exceed +125°C to ensure reliable operation. Therefore, getting a rough estimate of the expected LDO thermal performance in a system PCB is critical. To do this properly, a designer must determine the maximum expected power dissipation, the operating ambient temperature, and the PCB+package thermal resistance.

7.5.1 Power Dissipation

Use [Equation 10](#) to calculate the power dissipation (P_D).

$$(EQ. 10) \quad P_D = (V_{IN} - V_{OUT}) \times I_{OUT} + V_{IN} \times I_Q$$

Because the power dissipation contribution from the quiescent (or ground) current (I_Q) is typically very small compared to the current the LDO needs to supply to the load, [Equation 10](#) can be simplified to [Equation 11](#).

$$(EQ. 11) \quad P_D = (V_{IN} - V_{OUT}) \times I_{OUT}$$

Therefore, the headroom voltage ($V_{IN} - V_{OUT}$) and the output current determine the power dissipated inside the die.

7.5.2 The Junction Temperature (T_J) and Thermal Resistance (θ_{JA})

The Junction temperature is the sum of the environmental temperature, and the junction temperature rises because of power dissipation. The junction temperature is typically calculated with [Equation 12](#) if the ambient temperature, power dissipation, and junction-to-ambient thermal resistance of the PCB+LDO (θ_{JA}).

$$(EQ. 12) \quad T_J = T_A + \theta_{JA} \times P_D$$

The θ_{JA} is the resistance to heat flow between the junction and the outside environment and largely depends on the device package and the PCB design. The θ_{JA} includes the junction-to-EPAD thermal resistance and junction-to-package top thermal resistance. Both are determined by the package features, dimensions, areas, thicknesses, and materials and are therefore fixed. The remaining θ_{JA} largely depends on the total PCB copper area, copper weight, location of thermal planes, PCB layout, and location of the LDO on the PCB, amongst other things. Therefore, to compare the θ_{JA} of different products, it is important to ensure the products were tested on similar PCBs, which is why the JEDEC standard exists.

7.5.3 Approximating the θ_{JA} using Thermal Shutdown

The thermal shutdown circuitry inside the LDO can determine the θ_{JA} of a PCB design and how the θ_{JA} of the lab evaluation PCBs were determined. The test requires the PCB to be exposed to temperatures near +165°C and, therefore, is not a valid test method for everyone.

The following is needed to run the test:

- A way to power the LDO could be the system PCB itself or a power supply that powers the LDO only.
- A light load that dissipates ~500mW across the LDO pass transistor. Use an electronic load or a resistor load.
- A way to heat the entire PCB in a controlled way until the LDO thermal shutdown circuitry is triggered, such as a lab oven.
- A way to monitor and/or trigger on the LDO VOUT to capture when the thermal shutdown circuitry has triggered, as an oscilloscope trigger, multimeter.
- A way to measure the temperature of the PCB (such as a thermocouple).

Complete the following steps if using an oscilloscope:

1. Power up the LDO in the oven at room temperature.
2. Set the oscilloscope to measure VOUT. Verify that the voltage makes sense before starting the test.
3. Set the oscilloscope to trigger at about ½ of the programmed output voltage. Set the oscilloscope to trigger on the FALLING edge of the trigger voltage.
4. Take the oven temperature to +125°C and let the PCB soak at that for 3-5 minutes.
5. Increment the oven by +1°C and soak for 15-30 seconds.
6. Stop when the voltmeter reads roughly 0V and record the ambient temperature (T_{AMBIENT}) from the temperature sensor.
7. Calculate the θ_{JA} using Equation 13, where T_{AMBIENT} is the oven temperature that caused the LDO to thermally shut down, recorded in step 6. T_{SHUTDOWN} is the thermal shutdown RISING threshold, which can be found in the electrical specifications table (+165°C), and P_{D} is the ~500mW power dissipated by the LDO.

$$\text{(EQ. 13)} \quad \theta_{\text{JA}} = \frac{T_{\text{SHUTDOWN}} - T_{\text{AMBIENT}}}{P_{\text{D}}}$$

Complete the following steps if using a multimeter:

1. Power up the LDO in the oven at room temperature.
2. Set the multimeter to measure VOUT. Verify that the voltage makes sense before starting the test.
3. Take the oven temperature to +125°C and let the PCB soak at that for 3-5 minutes.
4. Increment the oven by +1°C and soak for 15-30 seconds.
5. Stop when the oscilloscope triggers and record the ambient temperature (T_{AMBIENT}) from the temperature sensor.
6. Calculate the θ_{JA} using Equation 13 where T_{AMBIENT} is the oven temperature which caused the LDO to thermally shutdown recorded in step 5, and T_{SHUTDOWN} is the thermal shutdown RISING threshold which can be found in the electrical specifications table (+165°C), and P_{D} is the ~500mW power dissipated by the LDO.

7.5.4 Psi (Ψ) Thermal Estimation

When the board temperature (T_{B}) is known use the Ψ metrics to estimate the junction temperature rise. These metrics are supposed to be independent of copper area. The typical Ψ_{JB} for the 20-Ld 3.5mm×3.5mm QFN package is 16 °C/W.

$$\text{(EQ. 14)} \quad T_{\text{J}} = T_{\text{B}} + (P_{\text{D}} \times \Psi_{\text{JB}})$$

8. Layout Guidelines

The following are recommendations for the RAA214048 to achieve optimal electrical and thermal performance:

- Place all the required components for the LDO on the same layer as the IC.
- Place a minimum 10 μ F ceramic input bypass capacitor as close as practical between the VIN pins and GND.
- Place a minimum 22 μ F ceramic output bypass capacitor as close as practical between the VOUT pins and GND.
- Place a minimum 1 μ F ceramic bypass capacitor as close as practical between the BIAS pin and GND.
- Place the CNR/SS bypass capacitor as close as practical between the NR/SS pin and GND.
- The feedback trace should be short, direct, and away from other noisy traces.
- Place the feedback resistors as close as possible to the IC.
- The package thermal EPAD is the largest heat conduction path for the LDO package. It should be soldered to a copper pad on the PCB underneath the IC.
- The PCB thermal copper pad should have as many plated vias as possible to increase the heat flow from the package thermal EPAD to the inner/bottom GND PCB areas.
- Keep the PCB thermal copper pad vias small but not so small that their inside diameter prevents the solder from wicking through during reflow.
- It is important to have a complete connection of the plated through-hole to each plane.
- If possible, add thermal vias around the PCB package to help improve heat spread from areas around the IC to other layers of the board.
- The top copper GND layer that the EPAD is connected to is the least thermally resistant path for heat flow. Therefore, minimize the components and traces that cut this layer.
