n = 0 HBG.FlexRay0
n = 1 HBG.FlexRay1

20.2.2 FlexRay Operation register

20.2.2.1 FLXAnFROC — FlexRay Operation Control Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0004_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	T2IE	T1IE	T0IE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	OEP	—	—	—	—	—	BEC	OE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R/W	R/W

Table 20.8 FLXAnFROC Register Contents

Bit Position	Bit Name	Function
31 to 19	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
18	T2IE	Timer 2 interrupt enable Bit 0: Disabled 1: Enabled
17	T1IE	Timer 1 interrupt enable Bit 0: Disabled 1: Enabled
16	T0IE	Timer 0 interrupt enable Bit 0: Disabled 1: Enabled
15 to 8	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
7	OEP	Operation Enable bit Protection Bit 0: OE is unprotected 1: OE is protected
6 to 2	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
1	BEC	Byte Endian Control Bit 0: Little endian 1: Big endian
0	OE	Operation Enable Bit 0: Operation disabled, SW reset 1: Operation Enabled

(1) FLXAnFROC.T2IE

Timer 2 interrupt enable Bit

This bit controls the timer 2 interrupt.

0: Disabled

No interrupt will be requested and the timer 2 interrupt line will be released if pending.

1: Enabled

Timer 2 interrupt will be asserted when FLXAnFROTS.T2IS is 1.

(2) FLXAnFROC.T1IE

Timer 1 interrupt enable Bit

The user should only set this bit to 1 when timer 1 interrupt is not enabled in the FlexRay Status interrupt enable register (FLXAnFRSIES.TI1E should be 0).

This bit controls the timer 1 interrupt.

0: Disabled

No interrupt will be requested and the timer 1 interrupt line will be released if pending.

1: Enabled

Timer 1 interrupt will be asserted when FLXAnFROTS.T1IS is 1.

(3) FLXAnFROC.T0IE

Timer 0 interrupt enable Bit

The user should only set this bit to 1 when timer 0 interrupt is not enabled in the FlexRay Status interrupt enable register (FLXAnFRSIES.TI0E should be 0).

This bit controls the timer 0 interrupt.

0: Disabled

No interrupt will be requested and the timer 0 interrupt line will be released if pending.

1: Enabled

Timer 0 interrupt will be asserted when FLXAnFROTS.T0IS is 1.

(4) FLXAnFROC.OEP

Operation Enable bit Protection Bit

This bit protects against unintended write access to the OE bit.

0: OE is unprotected

Write access to the OE bit is enabled

1: OE is protected

Write access to the OE bit is disabled

(5) FLXAnFROC.BEC

Byte Endian Control Bit

The user should only change this bit when FLXAnFROS.OS is 1.

This bit controls the byte order on reading and writing the FlexRay Network Management Vector register (FLXAnFRNMVn), FlexRay Write Data Section (FLXAnFRWRDSn) and FlexRay Read Data Section (FLXAnFRRDDSn). This bit also controls the byte order when reading or writing FlexRay payload data using the data transfer function.

For details about the byte alignment see **Section 20.3.17, Byte Alignment**.

0: Little endian

Byte alignment in FLXAnFRNMVn, FLXAnFRWRDSn and FLXAnFRRDDSn is in little endian style.

1: Big endian

Byte alignment in FLXAnFRNMVn, FLXAnFRWRDSn and FLXAnFRRDDSn is in big endian style.

(6) FLXAnFROC.OE

Operation Enable Bit

The user can only write to this bit when FLXAnFROC.OEP is 0.

The user should only write this bit with 0 when FLXAnFROS.OS is 1.

The user should only write this bit with 1 when FLXAnFROS.OS is 0 and the FlexRay sample clock is enabled.

This bit controls the operation state and serves the software reset of the FlexRay module. The operation status bit (FLXAnFROS.OS) indicates whether the FlexRay module is in reset state or not.

0: Operation disabled, SW reset

Forcibly moves the FlexRay module to its reset state, whatever the state of the FlexRay module is.

1: Operation Enabled

Reset state of the FlexRay module is released.

20.2.2.2 FLXAnFROS — FlexRay Operation Status Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $000C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	T2IS	T1IS	T0IS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.9 FLXAnFROS Register Contents

Bit Position	Bit Name	Function
31 to 19	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
18	T2IS	Timer 2 Interrupt Status Bit 0: Timer 2 has not matched the conditions configured in the FLXAnFRT2C register 1: Timer 2 matched the conditions configured in the FLXAnFRT2C register
17	T1IS	Timer 1 Interrupt Status Bit 0: Timer 1 has not matched the conditions configured in the FLXAnFRT1C register 1: Timer 1 matched the conditions configured in the FLXAnFRT1C register
16	T0IS	Timer 0 Interrupt Status Bit 0: Timer 0 has not matched the conditions configured in the FLXAnFRT0C register 1: Timer 0 matched the conditions configured in the FLXAnFRT0C register
15 to 1	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
0	OS	Operation Status Bit 0: Operation disabled, reset state 1: Operation enabled

(1) FLXAnFROS.T2IS

Timer 2 Interrupt Status Bit

Writing 0 has no effect on the bit value.

This bit represents that the expiration criteria configured in FLXAnFRT2C register has matched the FlexRay local time.

If enabled in FLXAnFROC.T2IE the timer 2 interrupt is generated when FLXAnFROS.T2IS is 1.

[Clearing condition]

This bit is cleared by writing 1 to FLXAnFROS.T2IS.
This bit is cleared when FLXAnFROS.OS changes from 1 to 0.

[Setting condition]

This bit is set when the expiration criteria configured in FLXAnFRT2C matches the FlexRay local time.

(2) FLXAnFROS.T1IS

Timer 1 Interrupt Status Bit

Writing 0 has no effect on the bit value.

This bit represents that the expiration criteria configured in FLXAnFRT1C register has matched the FlexRay local time.

If enabled in FLXAnFROC.T1IE the timer 1 interrupt is generated when FLXAnFROS.T1IS is 1.

[Clearing condition]

This bit is cleared by writing 1 to FLXAnFROS.T1IS.
This bit is cleared when FLXAnFROS.OS changes from 1 to 0.

[Setting condition]

This bit is set when the expiration criteria configured in FLXAnFRT1C matches the FlexRay local time.

(3) FLXAnFROS.T0IS

Timer 0 Interrupt Status Bit

Writing 0 has no effect on the bit value.

This bit represents that the expiration criteria configured in FLXAnFRT0C register has matched the FlexRay local time.

If enabled in FLXAnFROC.T0IE the timer 0 interrupt is generated when FLXAnFROS.T0IS is 1.

[Clearing condition]

This bit is cleared by writing 1 to FLXAnFROS.T0IS.
This bit is cleared when FLXAnFROS.OS changes from 1 to 0.

[Setting condition]

This bit is set when the expiration criteria configured in FLXAnFRT0C matches the FlexRay local time.

(4) FLXAnFROS.OS

Operation Status Bit

This bit represents if the FlexRay module is in the reset or the operation state.

When FLXAnFROS.OS is 0 the FlexRay module gets initialized and registers mapped to the address area <FLXn_base> + 0010_H to <FLXn_base> + $0FFF_H$ cannot be accessed; read access from these registers will return undefined data.

When FLXAnFROS.OS is 1 it is possible to access to the address area <FLXn_base> + 0010_H to <FLXn_base> + $0FFF_H$ and to perform FlexRay communication.

When FLXAnFROS.OS changes from 0 to 1 all registers in the address range <FLXn_base> + 0010_H to <FLXn_base> + $0FFF_H$ are set to the “Values after reset”.

[Clearing condition]

When FLXAnFROC.OE is set to 0. It takes up to two peripheral bus clock cycles until FLXAnFROS.OS is set to 0.

[Setting condition]

When FLXAnFROC.OE is set to 1 it takes up to four peripheral clock cycles of the clock with the lower frequency out of the FlexRay sample clock and peripheral bus clock until FLXAnFROS.OS is set to 1.

20.2.3 Special Registers

20.2.3.1 FLXAnFRLCK — FlexRay Lock Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXAn_base> + $001C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CLK[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.10 FLXAnFRLCK Register Contents

Bit	Symbol	Function
31 to 8	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
7 to 0	CLK[7:0]	Configuration Lock Key Bit

(1) FLXAnFRLCK.CLK

Configuration Lock Key Bit

The Lock Register is write-only. Reading the register will return $0000\ 0000_H$.

To leave CONFIG state by writing FLXAnFRSUCC1.CMD (command READY), the write operation has to be directly preceded by two write accesses to the Configuration Lock Key (unlock sequence). If the write sequence below is interrupted by other write accesses between the second write to the Configuration Lock Key and the write access to the FLXAnFRSUCC1 register, the CC remains in CONFIG state and the sequence has to be repeated.

First write: FLXAnFRLCK.CLK = “$1100\ 1110_B$” (0xCE)

Second write: FLXAnFRLCK.CLK = “$0011\ 0001_B$” (0x31)

Third write: FLXAnFRSUCC1.CMD

CAUTION

In case that the Host uses 8/16-bit accesses to write the listed bit fields, the programmer has to ensure that no “dummy accesses” e.g. to the remaining register bytes / words are inserted by the compiler.

20.2.4 Interrupt Registers

20.2.4.1 FLXAnFREIR — FlexRay Error Interrupt Register

The flags are set when the CC detects one of the listed error conditions. The flags remain set until the Host clears them.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0020_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	TABB	LTVB	EDB	—	—	—	—	—	TABA	LTVA	EDA

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.11 FLXAnFREIR Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
26	TABB	Transmission Across Boundary Channel B Flag 0: No transmission across slot boundary detected on channel B 1: Transmission across slot boundary detected on channel B
25	LTVB	Latest Transmit Violation Channel B Flag 0: No latest transmit violation detected on channel B 1: Latest transmit violation detected on channel B
24	EDB	Error Detected on Channel B Flag 0: No error detected on channel B 1: Error detected on channel B
23 to 19	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
18	TABA	Transmission Across Boundary Channel A Flag 0: No transmission across slot boundary detected on channel A 1: Transmission across slot boundary detected on channel A
17	LTVA	Latest Transmit Violation Channel A Flag 0: No latest transmit violation detected on channel A 1: Latest transmit violation detected on channel A
16	EDA	Error Detected on Channel A Flag 0: No error detected on channel A 1: Error detected on channel A
15 to 12	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
11	MHF	Message Handler Constraints Flag 0: No Message Handler failure detected 1: Message Handler failure detected
10	IOBA	Illegal Output buffer Access Flag 0: No illegal Host access to Output Buffer occurred 1: Illegal Host access to Output Buffer occurred

Table 20.11 FLXAnFREIR Register Contents (2/2)

Bit Position	Bit Name	Function
9	IIBA	Illegal Input Buffer Access Flag 0: No illegal Host access to Input Buffer occurred 1: Illegal Host access to Input Buffer occurred
8	EFA	Empty FIFO Access Flag 0: No Host access to empty FIFO occurred 1: Host access to empty FIFO occurred
7	RFO	Receive FIFO Overrun Flag 0: No receive FIFO overrun detected 1: A receive FIFO overrun has been detected
6	AERR	Access error flag Flag 0: Access error is not detected. 1: Access error is detected.
5	CCL	CHI Command Locked Flag 0: CHI command accepted 1: CHI command not accepted
4	CCF	Clock Correction Failure Flag 0: No clock correction error 1: Clock correction failed
3	SFO	Sync Frame Overflow Flag 0: Number of received sync frames ≤ FLXAnFRGTUC2.SNM 1: More sync frames received than configured by FLXAnFRGTUC2.SNM
2	SFBM	Sync Frames Below Minimum Flag 0: Sync node: 1 or more sync frames received, non-sync node: 2 or more sync frames received 1: Less than the required minimum of sync frames received
1	CNA	Command Not Accepted Flag 0: CHI command accepted 1: CHI command not accepted
0	PEMC	POC Error Mode Changed Flag 0: Error mode has not changed 1: Error mode has changed

(1) FLXAnFREIR.TABB

Transmission Across Boundary Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

The flag signals to the Host that a transmission across a slot boundary occurred for channel B.

(2) FLXAnFREIR.LTVB

Latest Transmit Violation Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

The flag signals a latest transmit violation on channel B to the Host.

(3) FLXAnFREIR.EDB

Error Detected on Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This bit is set whenever one of the flags FLXAnFRACS.SEDB, FLXAnFRACS.CEDB, FLXAnFRACS.CIB, FLXAnFRACS.SBVB changes from 0 to 1.

(4) FLXAnFREIR.TABA

Transmission Across Boundary Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

The flag signals to the Host that a transmission across a slot boundary occurred for channel A.

(5) FLXAnFREIR.LTVA

Latest Transmit Violation Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

The flag signals a latest transmit violation on channel A to the Host.

(6) FLXAnFREIR.EDA

Error Detected on Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This bit is set whenever one of the flags FLXAnFRACS.SEDA, FLXAnFRACS.CEDA, FLXAnFRACS.CIA, FLXAnFRACS.SBVA changes from 0 to 1.

(7) FLXAnFREIR.MHF

Message Handler Constraints Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

The flag signals a Message Handler constraints violation condition. It is set whenever one of the flags FLXAnFRMHDF.SNUA, FLXAnFRMHDF.SNUB, FLXAnFRMHDF.FNFA, FLXAnFRMHDF.FNFB, FLXAnFRMHDF.TBFA, FLXAnFRMHDF.TBFB, FLXAnFRMHDF.WAHP changes from 0 to 1.

(8) FLXAnFREIR.IOBA

Illegal Output buffer Access Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC when the Host requests the transfer of a message buffer from the Message RAM to the Output Buffer while FLXAnFROBCR.OBSYS is set to 1.

(9) FLXAnFREIR.IIBA

Illegal Input Buffer Access Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC when the Host wants to modify a message buffer via Input Buffer and one of the following conditions applies:

1. The CC is not in CONFIG or DEFAULT_CONFIG state and the Host writes to the Input Buffer Command Request register to modify the
   - Header section of message buffer 0, 1 if configured for transmission in key slot
   - Header section of static message buffers with buffer number < FLXAnFRMRC.FDB while FLXAnFRMRC.SEC = “01”
   - Header section of any static or dynamic message buffer while FLXAnFRMRC.SEC = “1x”
   - Header and / or data section of any message buffer belonging to the receive FIFO
2. The Host writes to any register of the Input Buffer while FLXAnFRIBCR.IBSYH is set to 1.

(10) FLXAnFREIR.EFA

Empty FIFO Access Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC when the Host requests the transfer of a message from the receive FIFO via Output Buffer while the receive FIFO is empty.

(11) FLXAnFREIR.RFO

Receive FIFO Overrun Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

The flag is set by the CC when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. The actual state of the FIFO is monitored in register FLXAnFRFSR.

(12) FLXAnFREIR.AERR

Access error flag Flag

Writing 0 in this bit has no effect.

This bit is cleared when writing 1 to it.

Notifies of an access error.

When the AMR, ATBF1, or ATBF2 bit in the FLXAnFRMHDS register changes from 0 to 1, this bit is set to 1.

(13) FLXAnFREIR.CCL

CHI Command Locked Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

The flag signals that the write access to the CHI command vector FLXAnFRSUCC1.CMD was not successful because the execution of the previous CHI command has not yet completed. In this case bit FLXAnFREIR.CNA is also set to 1.

(14) FLXAnFREIR.CCF

Clock Correction Failure Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set at the end of the communication cycle whenever one of the following errors occurred:

- Missing offset and / or rate correction
- Clock correction limit reached

The clock correction status is monitored in registers FLXAnFRCCEV and FLXAnFRSFS. A failure may occur during startup, therefore bit FLXAnFREIR.CCF should be set to 0 after the CC entered NORMAL_ACTIVE state.

(15) FLXAnFREIR.SFO

Sync Frame Overflow Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

It is set to 1 when either the number of sync frames received during the last communication cycle or the total number of different sync frame IDs received during the last double cycle exceeds the maximum number of sync frames as defined by FLXAnFRGTUC2.SNM.

(16) FLXAnFREIR.SFBM

Sync Frames Below Minimum Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 at the end of a cycle if the number of sync frames received during the last communication cycle was below the limit required for rate or offset correction term calculation (i.e. missing offset and / or missing rate correction). The clock correction status is monitored in FLXAnFRCCEV and FLXAnFRSFS.

This flag may be set to 1 during startup. Therefore this flag should be set to 0 by the Host after the CC entered NORMAL_ACTIVE state.

(17) FLXAnFREIR.CNA

Command Not Accepted Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

The flag signals that the write access to the CHI command vector FLXAnFRSUCC1.CMD was not successful because the requested command was not valid in the actual POC state, or because the CHI command was locked (FLXAnFREIR.CCL = 1).

(18) FLXAnFREIR.PEMC

POC Error Mode Changed Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 whenever the error mode signaled by FLXAnFRCCEV.ERRM has changed.

20.2.4.2 FLXAnFRSIR — FlexRay Status Interrupt Register

The flags are set when the CC detects one of the listed events. The flags remain set until the Host clears them.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0024_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 20.12 FLXAnFRSIR Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 26	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
25	MTSB	MTS Received on Channel B Flag (vSS!ValidMTSB) 0: No MTS symbol received on channel B 1: MTS symbol received on channel B
24	WUPB	Wakeup Pattern Channel B Flag 0: No wakeup pattern received on channel B 1: Wakeup pattern received on channel B
23 to 18	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
17	MTSA	MTS Received on Channel A Flag (vSS!ValidMTSA) 0: No MTS symbol received on channel A 1: MTS symbol received on channel A
16	WUPA	Wakeup Pattern Channel A Flag 0: No wakeup pattern received on channel A 1: Wakeup pattern received on channel A
15	SDS	Start of Dynamic Segment Flag 0: Dynamic segment not yet started 1: Dynamic segment started
14	MBSI	Message Buffer Status Interrupt Flag 0: No message buffer status change of message buffer with MBI = 1 1: Message buffer status of at least one message buffer with MBI = 1 has changed
13	SUCS	Startup Completed Successfully Flag 0: No startup completed successfully 1: Startup completed successfully
12	SWE	Stop Watch Event Flag 0: No Stop Watch Event 1: Stop Watch Event occurred
11	TOBC	Transfer Output Buffer Completed Flag 0: No transfer completed 1: Transfer between Message RAM and Output Buffer completed

Table 20.12 FLXAnFRSIR Register Contents (2/2)

Bit Position	Bit Name	Function
10	TIBC	Transfer Input Buffer Completed Flag 0: No transfer completed 1: Transfer between Input Buffer and Message RAM completed
9	TI1	Timer Interrupt 1 Flag 0: No timer interrupt 1 1: Timer interrupt 1 occurred
8	TI0	Timer Interrupt 0 Flag 0: No timer interrupt 0 1: Timer interrupt 0 occurred
7	NMVC	Network Management Vector Changed Flag 0: No change in the network management vector 1: Network management vector changed
6	RFCL	Receive FIFO Critical Level Flag 0: Receive FIFO below critical level 1: Receive FIFO critical level reached
5	RFNE	Receive FIFO Not Empty Flag 0: Receive FIFO is empty 1: Receive FIFO is not empty
4	RXI	Receive Interrupt Flag 0: No ND flag of a receive buffer with MBI = 1 has been set to 1 1: At least one ND flag of a receive buffer with MBI = 1 has been set to 1
3	TXI	Transmit Interrupt Flag 0: No frame transmitted from a transmit buffer with MBI = 1 1: At least one frame was transmitted from a transmit buffer with MBI = 1
2	CYCS	Cycle Start Interrupt Flag 0: No communication cycle started 1: Communication cycle started
1	CAS	Collision Avoidance Symbol Flag 0: No bit pattern matching the CAS symbol received 1: Bit pattern matching the CAS symbol received
0	WST	Wakeup Status Flag 0: Wakeup status unchanged 1: Wakeup status changed

(1) FLXAnFRSIR.MTSB

MTS Received on Channel B Flag (vSS!ValidMTSB)

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

Media Access Test symbol received on channel B during the preceding symbol window.

Updated by the CC for each channel at the end of the symbol window.

(2) FLXAnFRSIR.WUPB

Wakeup Pattern Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 when a wakeup pattern was received on channel B in either of the following states:

- WAKEUP
- READY
- STARTUP state

(3) FLXAnFRSIR.MTSA

MTS Received on Channel A Flag (vSS!ValidMTSA)

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

Media Access Test symbol received on channel A during the preceding symbol window.

Updated by the CC for each channel at the end of the symbol window.

(4) FLXAnFRSIR.WUPA

Wakeup Pattern Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 when a wakeup pattern was received on channel A in either of the following states:

- WAKEUP
- READY
- STARTUP state

(5) FLXAnFRSIR.SDS

Start of Dynamic Segment Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC when the dynamic segment starts.

(6) FLXAnFRSIR.MBSI

Message Buffer Status Interrupt Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC when the message buffer status FLXAnFRMBS has changed and if bit MBI of that message buffer is 1 (see **Table 20.120**).

(7) FLXAnFRSIR.SUCS

Startup Completed Successfully Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set whenever a startup completed successfully and the CC entered NORMAL_ACTIVE state.

(8) FLXAnFRSIR.SWE

Stop Watch Event Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set after a stop watch activation when the actual cycle counter and macrotick value are stored in the Stop Watch register (see FLXAnFRSTPW1 — FlexRay Stop Watch Register 1 in **Section 20.2.5.4, FLXAnFRSTPW1 — FlexRay Stop Watch Register 1**).

(9) FLXAnFRSIR.TOBC

Transfer Output Buffer Completed Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set whenever a transfer from the Message RAM to the Output Buffer has completed and FLXAnFROBCR.OBSYS has been reset by the Message Handler.

(10) FLXAnFRSIR.TIBC

Transfer Input Buffer Completed Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set whenever a transfer from Input Buffer to the Message RAM has completed and FLXAnFRIBCR.IBSYS has been reset by the Message Handler.

(11) FLXAnFRSIR.TI1

Timer 1 Interrupt Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set whenever timer 1 matches the conditions configured in register FLXAnFRT1C.

FlexRay timer 1 interrupt is generated when the T1IE bit in the FLXAnFROC register is effective.

(12) FLXAnFRSIR.TI0

Timer 0 Interrupt Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set whenever timer 0 matches the conditions configured in register FLXAnFRT0C.

FlexRay timer 0 interrupt is generated when the T0IE bit in the FLXAnFROC register is effective.

(13) FLXAnFRSIR.NMVC

Network Management Vector Changed Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This is set when a change in the Network Management Vector occurs.

(14) FLXAnFRSIR.RFCL

Receive FIFO Critical Level Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set when the receive FIFO fill level FLXAnFRFSR.RFFL is equal or greater than the critical level as configured by FLXAnFRFCL.CL.

(15) FLXAnFRSIR.RFNE

Receive FIFO Not Empty Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC when a received valid frame was stored into the empty receive FIFO. The actual state of the receive FIFO is monitored in register FLXAnFRFSR.

(16) FLXAnFRSIR.RXI

Receive Interrupt Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC whenever the set condition of a message buffers ND flag is fulfilled (see **Section 20.2.9.6, FLXAnFRNDATi — FlexRay New Data Register i (i = 1 to 4)**), and if bit MBI of that message buffer is set to 1 (see **Table 20.120**)

(17) FLXAnFRSIR.TXI

Transmit Interrupt Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC at the end of frame transmission if bit MBI in the respective message buffer is set to 1 (see **Table 20.120**).

(18) FLXAnFRSIR.CYCS

Cycle Start Interrupt Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC when a communication cycle starts.

(19) FLXAnFRSIR.CAS

Collision Avoidance Symbol Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC during STARTUP state when a CAS or a potential CAS was received.

(20) FLXAnFRSIR.WST

Wakeup Status Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set when FLXAnFRCCSV.WSV changes to a value other than UNDEFINED.

20.2.4.3 FLXAnFREILS — FlexRay Error Interrupt Line Select Register

The FlexRay Error Interrupt Line Select register assigns an interrupt generated by a specific error interrupt flag from register FLXAnFREIR to one of the two modules interrupt lines (FlexRay 0 interrupt, FlexRay 1 interrupt).

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0028_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

20.2.4.5 FLXAnFREIES — FlexRay Error Interrupt Enable Set Register

The settings in the FlexRay Error Interrupt Enable Set (FLXAnFREIES) and FlexRay Error Interrupt Enable Reset (FLXAnFREIER) register determine which status changes in the FlexRay Error Interrupt Register will result in an interrupt.

The enable bits are set by writing to FLXAnFREIES and reset by writing to FLXAnFREIER. Reading from both addresses will result in the same value.

Writing 0 has no effect on the bit value.

Writing a 1 sets the interrupt enable bit.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0030_H

Value after reset: $0000\ 0000_H$

20.2.4.6 FLXAnFREIER — FlexRay Error Interrupt Enable Reset Register

The settings in the FlexRay Error Interrupt Enable Set (FLXAnFREIES) and FlexRay Error Interrupt Enable Reset (FLXAnFREIER) register determine which status changes in the FlexRay Error Interrupt Register will result in an interrupt.

The enable bits are set by writing to FLXAnFREIES and reset by writing to FLXAnFREIER. Reading from both addresses will result in the same value.

Writing 0 has no effect on the bit value.

Writing a 1 clears the interrupt enable bit.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0034_H

Value after reset: $0000\ 0000_H$

20.2.4.7 FLXAnFRSIES — FlexRay Status Interrupt Enable Set Register

The settings in the FlexRay Status Interrupt Enable Set (FLXAnFRSIES) and FlexRay Status Interrupt Enable Reset (FLXAnFRSIER) register determine which status changes in the FlexRay Status Interrupt Register will result in an interrupt.

The enable bits are set by writing to FLXAnFRSIES and reset by writing to FLXAnFRSIER. Reading from both addresses will result in the same value.

Writing 0 has no effect on the bit value.

Writing a 1 sets the interrupt enable bit.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

20.2.4.8 FLXAnFRSIER — FlexRay Status Interrupt Enable Reset Register

The settings in the FlexRay Status Interrupt Enable Set (FLXAnFRSIES) and FlexRay Status Interrupt Enable Reset (FLXAnFRSIER) register determine which status changes in the FlexRay Status Interrupt Register will result in an interrupt.

The enable bits are set by writing to FLXAnFRSIES and reset by writing to FLXAnFRSIER. Reading from both addresses will result in the same value.

Writing 0 has no effect on the bit value.

Writing a 1 clears the interrupt enable bit.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $003C_H$

Value after reset: $0000\ 0000_H$

20.2.4.9 FLXAnFRILE — FlexRay Interrupt Line Enable Register

Each of the two module interrupt lines (FlexRay 0 interrupt, FlexRay 1 interrupt) can be enabled / disabled separately by programming bit FLXAnFRILE.EINT0 and FLXAnFRILE.EINT1.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0040_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

20.2.5 FlexRay Timer Registers

20.2.5.1 FLXAnFRT0C — FlexRay Timer 0 Configuration Register

This register is an absolute timer. It specifies the point in time when a FlexRay timer 0 interrupt occurs as the values of cycle count and macrotick (MT). When the FlexRay timer 0 passes, FLXAnFRSIR.TI0 and FLXAnFROS.T0IS are set to 1. A timer 0 interrupt then occurs while the FLXAnFROC.T0IE bit is effective.

CAUTION

The configuration of timer 0 is compared against the macrotick counter value, there is no separate counter for timer 0.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0044_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 20.20 FLXAnFRT0C Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
29 to 16	T0MO[13:0]	Timer 0 Macrotick Offset Bit Timer 0 Macrotick Offset
15	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
14 to 8	T0CC[6:0]	Timer 0 Cycle Code Bit Timer 0 Cycle Code
7 to 2	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
1	T0MS	Timer 0 Mode Select Bit 0: Single-shot mode 1: Continuous mode
0	T0RC	Timer 0 Run Control Bit 0: Timer 0 halted 1: Timer 0 running

(1) FLXAnFRT0C.T0MO

Timer 0 Macrotick Offset Bit

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXAnFRT0C.T0RC to 0.

Configures the macrotick offset from the beginning of the communication cycle where the interrupt is to occur. The FlexRay timer 0 interrupt occurs at this offset for each cycle of the cycle set.

(2) FLXAnFRT0C.T0CC

Timer 0 Cycle Code Bit

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXAnFRT0C.T0RC to 0.

The 7-bit timer 0 cycle code determines the cycle set used for generation of the FlexRay timer 0 interrupt. For details about the configuration of the cycle code see **Section 20.3.8.2, Cycle Counter Filtering**.

(3) FLXAnFRT0C.T0MS

Timer 0 Mode Select Bit

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXAnFRT0C.T0RC to 0.

Configures the timer run mode. In Single-shot mode the timer is deactivated when the timer configuration matches the configured cycle counter and macrotick value.

(4) FLXAnFRT0C.T0RC

Timer 0 Run Control Bit

Timer 0 can be activated (set FLXAnFRT0C.T0RC to 1) when the POC is either in NORMAL_ACTIVE state or in NORMAL_PASSIVE state.

Timer 0 is deactivated when leaving NORMAL_ACTIVE state or NORMAL_PASSIVE state except for transitions between the two states.

20.2.5.2 FLXAnFRT1C — FlexRay Timer 1 Configuration Register

This register is a relative timer. After the specified number of macroticks (MT) has expired, a FlexRay timer 1 interrupt is asserted. When the FlexRay timer 1 passes, FLXAnFRSIR.TI1 and FLXAnFROS.T1IS are set to 1. A timer 1 interrupt then occurs while the FLXAnFROC.T1IE bit is effective.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0048_H

Value after reset: $0002\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 20.21 FLXAnFRT1C Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
29 to 16	T1MC[13:0]	Timer 1 Macrotick Count Bit
15 to 2	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
1	T1MS	Timer 1 Mode Select Bit 0: Single-shot mode 1: Continuous mode
0	T1RC	Timer 1 Run Control Bit 0: Timer 1 halted 1: Timer 1 running

(1) FLXAnFRT1C.T1MC

Timer 1 Macrotick Count Bit

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXAnFRT1C.T1RC to 0.

Valid values are 2 to 16383 MT in continuous mode

Valid values are 1 to 16383 MT in single-shot mode

When the configured macrotick count is reached the FlexRay timer 1 interrupt is generated.

(2) FLXAnFRT1C.T1MS

Timer 1 Mode Select Bit

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXAnFRT1C.T1RC to 0.

Configures the timer run mode. In Single-shot mode the timer is deactivated when the timer configuration matches the configured cycle counter and macrotick value.

(3) FLXAnFRT1C.T1RC

Timer 1 Run Control Bit

Timer 1 can be activated (set FLXAnFRT1C.T1RC to 1) as long as the POC is either in NORMAL_ACTIVE state or in NORMAL_PASSIVE state.

Timer 1 is deactivated when leaving NORMAL_ACTIVE state or NORMAL_PASSIVE state except for transitions between the two states.

20.2.5.3 FLXAnFRT2C — FlexRay Timer 2 Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0844_H

Value after reset: $0000\ 0000_H$

Table 20.22 FLXAnFRT2C Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
29 to 16	T2MO[13:0]	Timer 2 Macrotick Offset Bit Timer 2 Macrotick Offset
15	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
14 to 8	T2CC[6:0]	Timer 2 Cycle Code Bit Timer 2 Cycle Code
7 to 2	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
1	T2MS	Timer 2 Mode Select Bit 0: Single-shot mode 1: Continuous mode
0	T2RC	Timer 2 Run Control Bit 0: Timer halted 1: Timer running

(1) FLXAnFRT2C.T2MO

Timer 2 Macrotick Offset Bit

The user can only write to these bits when FLXAnFRT2C.T2RC is 0.

Allowed range is 0 to FLXAnFRGTUC2.MPC.

These bits represent the timer macrotick value defining the timer expiration condition.

(2) FLXAnFRT2C.T2CC

Timer 2 Cycle Code Bit

The user can only write to these bits when FLXAnFRT2C.T2RC is 0.

These bits represent the cycle counter filter code defining the timer expiration condition. See **Section 20.3.8.2, Cycle Counter Filtering** for cycle filtering.

(3) FLXAnFRT2C.T2MS

Timer 2 Mode Select Bit

The user can only write to these bits when FLXAnFRT2C.T2RC is 0.

This bit represents the operation mode of the Timer 2.

0: Single-shot mode

The timer is operating in the non-repetitive (single shot) mode. Once the configured expiration criteria are matching the timer will be automatically halted.

1: Continuous mode

The timer is operating in the repetitive (continuous) mode. The timer will expire every time the configured expiration criteria are matching. The timer is not halted.

(4) FLXAnFRT2C.T2RC

Timer 2 Run Control Bit

The user can only set this bit to 1 when the POC is in NORMAL_ACTIVE or NORMAL_PASSIVE state.

This bit represents the activation state of the Timer 2.

When the expiration criteria are matching for a single shot timer, then this bit is cleared automatically and the Timer 2 is halted.

[Setting condition]

This bit is set by writing 1 to it when the POC is in NORMAL_ACTIVE or NORMAL_PASSIVE state.

[Clearing condition]

This bit is cleared when the POC state leaves the NORMAL_ACTIVE or NORMAL_PASSIVE state except for transitions between the two states.
This bit is cleared when the timer is operating in the non-repetitive (single shot) mode (FLXAnFRT2C.T2MS is 0) and the expiration criteria are matching.
This bit is cleared by writing 0 to it.

20.2.5.4 FLXAnFRSTPW1 — FlexRay Stop Watch Register 1

The stop watch is activated by the following trigger events.

- FlexRay 0 interrupt or FlexRay 1 interrupt
- Writing bit FLXAnFRSTPW1.SSWT to 1

With the macrotick counter increment following next to the stop watch activation the actual cycle counter and macrotick values are captured in register FLXAnFRSTPW1 while the slot counter values for channel A and B are captured in register FLXAnFRSTPW2.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $004C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	SMTV[13:0]													
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	SCCV[5:0]						—	EINT1	EINT0	—	SSWT	EDGE	SWMS	ESWT
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R/W	R/W	R/W	R/W

Table 20.23 FLXAnFRSTPW1 Register Contents (1/2)

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
29 to 16	SMTV[13:0]	Stop Watch Captured Macrotick Value
15, 14	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
13 to 8	SCCV[5:0]	Stop Watch Captured Cycle Counter Value
7	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
6	EINT1	Enable FlexRay Interrupt 1 Trigger Bit 0: Stop watch trigger by FlexRay 1 interrupt disabled 1: FlexRay 1 interrupt event triggers stop watch
5	EINT0	Enable FlexRay 0 Interrupt Trigger Bit 0: Stop watch trigger by FlexRay 0 interrupt disabled 1: FlexRay interrupt 0 event triggers stop watch
4	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
3	SSWT	Software Stop Watch Trigger Bit 0: Software trigger reset 1: Stop watch activated by software trigger
2	EDGE	Stop Watch Trigger Edge Select Bit 0: Falling edge 1: Rising edge
1	SWMS	Stop Watch Mode Select Bit 0: Single-shot mode 1: Continuous mode

Table 20.23 FLXAnFRSTPW1 Register Contents (2/2)

Bit Position	Bit Name	Function
0	ESWT	Enable Hardware Stop Watch Trigger Bit 0: Stop watch trigger disabled 1: Stop watch trigger enabled

(1) FLXAnFRSTPW1.SMTV

Stop Watch Captured Macrotick Value

State of the macrotick counter when the stop watch event occurred.

(2) FLXAnFRSTPW1.SCCV

Stop Watch Captured Cycle Counter Value

State of the cycle counter when the stop watch event occurred.

(3) FLXAnFRSTPW1.EINT1

Enable FlexRay 1 Interrupt Trigger Bit

Enables stop watch trigger by FlexRay 1 interrupt when FLXAnFRSTPW1.ESWT = 1.

(4) FLXAnFRSTPW1.EINT0

Enable FlexRay 0 Interrupt Trigger Bit

Enables stop watch trigger by FlexRay 0 interrupt when FLXAnFRSTPW1.ESWT = 1.

(5) FLXAnFRSTPW1.SSWT

Software Stop Watch Trigger Bit

Bits FLXAnFRSTPW1.ESWT and FLXAnFRSTPW1.SSWT cannot be set to 1 simultaneously. In this case the write access to the register is ignored, and both bits keep their previous values. Either the external stop watch trigger or the software stop watch trigger may be used.

Writing 1 in this bit activates the stop watch. This bit is reset to 0 after the cycle count and slot count, and macrotick (MT) value are stored in the FlexRay stop watch register.

(6) FLXAnFRSTPW1.EDGE

Stop Watch Trigger Edge Select Bit

(7) FLXAnFRSTPW1.SWMS

Stop Watch Mode Select Bit

(8) FLXAnFRSTPW1.ESWT

Enable Stop Watch Trigger Bit

Bits FLXAnFRSTPW1.ESWT and FLXAnFRSTPW1.SSWT cannot be set to 1 simultaneously. In this case the write access to the register is ignored, and both bits keep their previous values. Either the external stop watch trigger or the software stop watch trigger may be used.

If enabled, a FlexRay 0 interrupt event or a FlexRay 1 interrupt event activates the stop watch.

In single-shot mode, this bit is reset to 0 after the cycle count and slot count, and macrotick (MT) value are stored in the FlexRay stop watch register.

20.2.5.5 FLXAnFRSTPW2 — FlexRay Stop Watch Register 2

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0050_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	SSCVB[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	SSCVA[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.24 FLXAnFRSTPW2 Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
26 to 16	SSCVB[10:0]	Stop Watch Captured Slot Counter Value Channel B
15 to 11	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
10 to 0	SSCVA[10:0]	Stop Watch Captured Slot Counter Value Channel A

(1) FLXAnFRSTPW2.SSCVB

Stop Watch Captured Slot Counter Value Channel B

State of the slot counter for channel B when the stop watch event occurred.

(2) FLXAnFRSTPW2.SSCVA

Stop Watch Captured Slot Counter Value Channel A

State of the slot counter for channel A when the stop watch event occurred.

20.2.6 CC Control Registers

This section describes the registers provided by the CC (Communication Controller) to allow the Host to control the operation of the CC. The FlexRay protocol specification requires the Host to write application configuration data in CONFIG state only. Please consider that the configuration registers are not locked for writing in DEFAULT_CONFIG state.

The configuration data is reset when DEFAULT_CONFIG state is entered from reset. To change POC state from DEFAULT_CONFIG to CONFIG state the Host has to apply CHI command CONFIG. If the Host wants the CC to leave CONFIG state, the Host has to execute the lock release sequence as described in **Section 20.2.3.1, FLXAnFRLCK — FlexRay Lock Register**.

20.2.6.1 FLXAnFRSUCC1 — FlexRay SUC Configuration Register 1

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0080_H

Value after reset: $0C40\ 1080_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	CCHB	CCHA	MTSB	MTSA	HCSE	TSM	WUCS	PTA[4:0]				
Value after reset	0	0	0	0	1	1	0	0	0	1	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Value after reset	0	0	0	1	0	0	0	0	1	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 20.25 FLXAnFRSUCC1 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
27	CCHB	Connected to Channel B Bit Configures pChannels 0: Not connected to channel B 1: Node connected to channel B (default after reset)
26	CCHA	Connected to Channel A Bit Configures pChannels 0: Not connected to channel A 1: Node connected to channel A (default after reset)
25	MTSB	Select Channel B for MTS Transmission Bit 0: Channel B disabled for MTS transmission 1: Channel B selected for MTS transmission
24	MTSA	Select Channel A for MTS Transmission Bit 0: Channel A disabled for MTS transmission 1: Channel A selected for MTS transmission
23	HCSE	Halt due to Clock Sync Error Bit Configures pAllowHaltDueToClock 0: CC will enter / remain in NORMAL_PASSIVE 1: CC will enter HALT state
22	TSM	Transmission Slot Mode Bit Configures pSingleSlotEnabled 0: ALL Slot Mode 1: SINGLE Slot Mode (value after hard reset)

Table 20.25 FLXAnFRSUCC1 Register Contents (2/2)

Bit Position	Bit Name	Function
21	WUCS	Wakeup Channel Select Bit Configures pWakeupChannel 0: Send wakeup pattern on channel A 1: Send wakeup pattern on channel B
20 to 16	PTA[4:0]	Passive to Active Bit Configures pAllowPassiveToActive
15 to 11	CSA[4:0]	Cold Start Attempts Bit Configures gColdStartAttempts
10	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
9	TXSY	Transmit Sync Frame in Key Slot Bit Configures pKeySlotUsedForSync 0: No sync frame transmission in key slot, node is neither sync nor coldstart node 1: Key slot used to transmit sync frame, node is sync node
8	TXST	Transmit Startup Frame in Key Slot Bit Configures pKeySlotUsedForStartup 0: No startup frame transmission in key slot, node is non-coldstarter 1: Key slot used to transmit startup frame, node is leading or following coldstarter
7	PBSY	POC Busy Flag 0: POC not busy, FLXAnFRSUCC1.CMD writeable 1: POC is busy, FLXAnFRSUCC1.CMD locked
6 to 4	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
3 to 0	CMD[3:0]	CHI Command Vector Bit 0000: command_not_accepted 0001: CONFIG 0010: READY 0011: WAKEUP 0100: RUN 0101: ALL_SLOTS 0110: HALT 0111: FREEZE 1000: SEND_MTS 1001: ALLOW_COLDSTART 1010: RESET_STATUS_INDICATORS 1011: MONITOR_MODE 1100: CLEAR_RAMS others: reserved

(1) FLXAnFRSUCC1.CCHB

Connected to Channel B Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Configures whether the node is connected to channel B (pChannels).

(2) FLXAnFRSUCC1.CCHA

Connected to Channel A Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Configures whether the node is connected to channel A (pChannels).

(3) FLXAnFRSUCC1.MTSB

Select Channel B for MTS Transmission Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

FLXAnFRSUCC1.MTSB may also be changed outside DEFAULT_CONFIG or CONFIG state when the write to FLXAnFRSUCC1 register is directly preceded by the unlock sequence for the Configuration Lock Key as described in **Section 20.2.3.1, FLXAnFRLCK — FlexRay Lock Register**. This may be combined with CHI command SEND_MTS. If both bits FLXAnFRSUCC1.MTSA and FLXAnFRSUCC1.MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing FLXAnFRSUCC1.CMD = "1000_B".

The bit selects channel B for MTS symbol transmission.

(4) FLXAnFRSUCC1.MTSA

Select Channel A for MTS Transmission Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

FLXAnFRSUCC1.MTSA may also be changed outside DEFAULT_CONFIG or CONFIG state when the write to FLXAnFRSUCC1 register is directly preceded by the unlock sequence for the Configuration Lock Key as described in **Section 20.2.3.1, FLXAnFRLCK — FlexRay Lock Register**. This may be combined with CHI command SEND_MTS. If both bits FLXAnFRSUCC1.MTSA and FLXAnFRSUCC1.MTSB are set to 1 an MTS symbol will be transmitted on both channels when requested by writing FLXAnFRSUCC1.CMD = "1000_B".

The bit selects channel A for MTS symbol transmission.

(5) FLXAnFRSUCC1.HCSE

Halt due to Clock Sync Error Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Controls the transition to HALT state due to a clock synchronization error (pAllowHaltDueToClock).

(6) FLXAnFRSUCC1.TSM

Transmission Slot Mode Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Selects the value after transmission slot mode reset (pSingleSlotEnabled).

In SINGLE slot mode the CC may only transmit in the preconfigured key slot. The key slot ID is configured in the header section of message buffer 0 respectively message buffers 0 and 1 depending on bit FLXAnFRMRC.SPLM.

In case FLXAnFRSUCC1.TSM = 1, message buffer 0 respectively message buffers 0, 1 can be (re)configured in DEFAULT_CONFIG or CONFIG state only. In ALL slot mode the CC may transmit in all slots.

FLXAnFRSUCC1.TSM is a configuration bit which can only be set / reset by the Host.

The CC changes to ALL slot mode when the Host successfully applied the ALL_SLOTS command by writing FLXAnFRSUCC1.CMD = “0101” in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. The actual slot mode is monitored by FLXAnFRCCSV.SLM.

(7) FLXAnFRSUCC1.WUCS

Wakeup Channel Select Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

With this bit the Host selects the channel on which the CC sends the Wakeup pattern (pWakeupChannel).

(8) FLXAnFRSUCC1.PTA

Passive to Active Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 31 even / odd cycle pairs.

Defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the CC is allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state (pAllowPassiveToActive).

If set to “00000_B” the CC is not allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state.

(9) FLXAnFRSUCC1.CSA

Cold Start Attempts Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Must be identical in all nodes of a cluster.

Valid values are 2 to 31.

Configures the maximum number of attempts that a cold starting node is permitted to try to start up the network without receiving any valid response from another node (gColdStartAttempts).

(10) FLXAnFRSUCC1.TXSY

Transmit Sync Frame in Key Slot Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Defines whether the key slot is used to transmit sync frames (pKeySlotUsedForSync).

CAUTION

The protocol requires that both bits FLXAnFRSUCC1.TXST and FLXAnFRSUCC1.TXSY are set for coldstart nodes.

(11) FLXAnFRSUCC1.TXST

Transmit Startup Frame in Key Slot Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Defines whether the key slot is used to transmit startup frames (pKeySlotUsedForStartup).

CAUTION

The protocol requires that both bits FLXAnFRSUCC1.TXST and FLXAnFRSUCC1.TXSY are set for coldstart nodes.

(12) FLXAnFRSUCC1.PBSY

POC Busy Flag

Signals that the POC is busy and cannot accept a command from the Host. FLXAnFRSUCC1.CMD is locked against write accesses.

Set to 1 after reset during initialization of internal RAM blocks.

(13) FLXAnFRSUCC1.CMD

CHI Command Vector Bit

The Host may write any CHI command at any time, but certain commands are enabled only in certain POC states. If a command is not enabled, it will not be executed, the CHI command vector FLXAnFRSUCC1.CMD will be reset to "0000_B" = command_not_accepted, and flag FLXAnFREIR.CNA will be set to 1.

In general the Host must check FLXAnFRSUCC1.PBSY before writing a new CHI command.

In case the previous CHI command has not yet completed, FLXAnFREIR.CCL is set to 1 together with FLXAnFREIR.CNA; the CHI command needs to be repeated.

Except for HALT state, a POC state change command applied while the CC is already in the requested POC state neither causes a state change nor will FLXAnFREIR.CNA be set.

Reading FLXAnFRSUCC1.CMD shows whether the last CHI command was accepted. The actual POC state is monitored by FLXAnFRCCSV.POCS.

- command_not_accepted

  FLXAnFRSUCC1.CMD is reset to "0000_B" due to one of the following conditions:

  – Illegal command applied by the Host
  – Host applied command to leave CONFIG state without preceding config lock key
  – Host applied new command while execution of the previous Host command has not completed

– Host writes command_not_accepted

When FLXAnFRSUCC1.CMD is reset to “0000_B”, FLXAnFREIR.CNA is set to 1, and if enabled an interrupt is generated.

Commands which are not accepted are not executed.

CONFIG

Go to POC state CONFIG when called in POC states DEFAULT_CONFIG, or READY. When called in HALT state the CC transits to POC state DEFAULT_CONFIG. When called in any other state, FLXAnFRSUCC1.CMD will be reset to “0000_B” = command_not_accepted.

READY

Go to POC state READY when called in POC states CONFIG, NORMAL_ACTIVE, NORMAL_PASSIVE, STARTUP, or WAKEUP. When called in any other state, FLXAnFRSUCC1.CMD will be reset to “0000_B” = command_not_accepted.

WAKEUP

Go to POC state WAKEUP when called in POC state READY. When called in any other state, FLXAnFRSUCC1.CMD will be reset to “0000_B” = command_not_accepted.

RUN

Go to POC state STARTUP when called in POC state READY. When called in any other state, FLXAnFRSUCC1.CMD will be reset to “0000_B” = command_not_accepted.

ALL_SLOTS

Leave SINGLE slot mode and go to ALL-SLOTS mode after successful startup / integration at the next end of cycle when called in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. When called in any other state, FLXAnFRSUCC1.CMD will be reset to “0000_B” = command_not_accepted.

HALT

Set halt request FLXAnFRCCSV.HRQ to 1 and go to POC state HALT at the next end of cycle when called in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. When called in any other state, FLXAnFRSUCC1.CMD will be reset to “0000_B” = command_not_accepted.

FREEZE

Set the freeze status indicator FLXAnFRCCSV.FSI to 1 and go to POC state HALT immediately. Can be called from any state.

SEND_MTS

Send single MTS symbol during the next following symbol window on the channel configured by FLXAnFRSUCC1.MTSA, FLXAnFRSUCC1.MTSB, when called in POC state NORMAL_ACTIVE after CC entered ALL slot mode (FLXAnFRCCSV.SLM = “11”). When called in any other state, or when called while a previously requested MTS has not yet been transmitted, FLXAnFRSUCC1.CMD will be reset to “0000_B” = command_not_accepted.

ALLOW_COLDSTART

The command resets FLXAnFRCCSV.CSI to enable the node to become leading coldstarter. When called in states DEFAULT_CONFIG, CONFIG, or HALT, FLXAnFRSUCC1.CMD will be reset to "0000_B" = command_not_accepted. To become leading coldstarter it is also required that both FLXAnFRSUCC1.TXST and FLXAnFRSUCC1.TXSY are set.

RESET_STATUS_INDICATORS

Resets status flags FLXAnFRCCSV.CSNI, FLXAnFRCCSV.CSAI, and FLXAnFRCCSV.WSV to the values after reset. May be called in POC states READY and STARTUP. When called in any other state, FLXAnFRSUCC1.CMD will be reset to "0000_B" = command_not_accepted.

CLEAR_RAMS

Sets FLXAnFRMHDS.CRAM to 1 when called in DEFAULT_CONFIG or CONFIG state. When called in any other state, FLXAnFRSUCC1.CMD will be reset to "0000_B" = command_not_accepted.

FLXAnFRMHDS.CRAM is also set to 1 when the CC leaves reset. By setting FLXAnFRMHDS.CRAM all internal RAM blocks are initialized to zero. During the initialization of the RAMs, FLXAnFRSUCC1.PBSY will show POC busy. Access to the configuration and status registers is possible during execution of CHI command CLEAR_RAMS.

The initialization of the internal message RAM requires 2048 bus clock cycles. There should be no Host access to IBF or OBF during initialization of the internal RAM blocks after reset or after assertion of CHI command CLEAR_RAMS.

Before asserting CHI command CLEAR_RAMS, the Host should make sure that no transfer between Message RAM and IBF / OBF or the Temporary Buffer RAMs is ongoing and that the data transfer handler has no effect (FLXAnFRITS.ITS = 0 and FLXAnFROTS.OTS = 0). This command also resets the Message Buffer Status registers FLXAnFRMHDS, FLXAnFRLDTS, FLXAnFRFSR, FLXAnFRMHDF, FLXAnFRTXRQ1/2/3/4, FLXAnFRNDAT1/2/3/4, and FLXAnFRMBSC1/2/3/4.

CAUTIONS

1. **All accepted commands with exception of CLEAR_RAMS and SEND_MTS will cause a change of the POC state in the FlexRay domain after at most 8 cycles of the slower of the two clocks "bus clock" and "FlexRay", assumed that POC was not busy when the command was applied and that no POC state change was forced by bus activity in that time frame. Reading register FLXAnFRCCSV will show data that is additionally delayed by synchronization from the FlexRay domain to the bus clock domain. The maximum additional delay is 12 cycles of the slower of the two clocks 'bus clock' and "FlexRay".**
2. **When the user restart as leading coldstarter after it has been stopped by FREEZE or READY command, it may happen, depending on the internal state of the FlexRay module, that the FlexRay module does not transmit its startup frame in cycle 0. Only FlexRay module configurations with startup frames configured for slots 1 to 7 are affected by this behaviour.**
   - **Coldstart after hardware reset is not affected.**
   - **Even if it happened, next coldstart attempt successful. Coldstart sequence is lengthened but coldstart of FlexRay system is not prohibited by this behaviour.**
   - **If the use wants to avoid this behavior, they must use a static slot greater or equal 8 for the startup / sync message.**

The below references the CHI commands from the FlexRay Protocol Specification to the FlexRay CHI command vector FLXAnFRSUCC1.CMD.

Table 20.26 Reference to CHI Host Command Summary from FlexRay Protocol Specification

CHI command	Where processed (POC States)	CHI Command Vector CMD
ALL_SLOTS	POC: normal active, POC: normal passive	ALL_SLOTS
ALLOW_COLDSTART	All except POC: default config, POC: config, POC: halt	ALLOW_COLDSTART
CONFIG	POC: default config, POC: ready	CONFIG
CONFIG_COMPLETE	POC: config	Unlock sequence & READY
DEFAULT_CONFIG	POC: halt	CONFIG
FREEZE	All	FREEZE
HALT	POC: normal active, POC: normal passive	HALT
READY	All except POC: default config, POC: config, POC: ready, POC: halt	READY
RUN	POC: ready	RUN
WAKEUP	POC: ready	WAKEUP

20.2.6.2 FLXAnFRSUCC2 — FlexRay SUC Configuration Register 2

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0084_H

Value after reset: $0100\ 0504_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	LTN[3:0]				—	—	—	LT[20:16]				
Value after reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 20.27 FLXAnFRSUCC2 Register Contents

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
27 to 24	LTN[3:0]	Listen Timeout Noise Bit Configures (gListenNoise – 1)
23 to 21	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
20 to 0	LT[20:0]	Listen Timeout Bit Configures pdListenTimeout

(1) FLXAnFRSUCC2.LTN

Listen Timeout Noise Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

The range for gListenNoise is 2 to 16.

FLXAnFRSUCC2.LTN must be configured identical in all nodes of a cluster.

Configures the upper limit for startup and wakeup listen timeout in the presence of noise expressed as a multiple of pdListenTimeout.

CAUTION

The wakeup / startup noise timeout is calculated as follows:

pdListenTimeout × gListenNoise = FLXAnFRSUCC2.LT × (FLXAnFRSUCC2.LTN + 1)

(2) FLXAnFRSUCC2.LT

Listen Timeout Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

The range for pdListenTimeout is 1284 to 1283846 µT.

Configures wakeup / startup listen time out in µT.

20.2.6.3 FLXAnFRSUCC3 — FlexRay SUC Configuration Register 3

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0088_H

Value after reset: $0000\ 0011_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.28 FLXAnFRSUCC3 Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
7 to 4	WCF[3:0]	Maximum Without Clock Correction Fatal Bit (transition to HALT state) Configures gMaxWithoutClockCorrectionFatal
3 to 0	WCP[3:0]	Maximum Without Clock Correction Passive Bit (transition to NORMAL_PASSIVE state) Configures gMaxWithoutClockCorrectionPassive

(1) FLXAnFRSUCC3.WCF

Maximum Without Clock Correction Fatal Bit (transition to HALT state)

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 15 cycle pairs.

Must be identical in all nodes of a cluster.

Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from NORMAL_ACTIVE or NORMAL_PASSIVE to HALT state.

CAUTION

The transition to HALT state is prevented if FLXAnFRSUCC1.HCSE is not set.

(2) FLXAnFRSUCC3.WCP

Maximum Without Clock Correction Passive Bit (transition to NORMAL_PASSIVE state)

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 15 cycle pairs.

Must be identical in all nodes of a cluster.

Defines the number of consecutive even / odd cycle pairs with missing clock correction terms that will cause a transition from NORMAL_ACTIVE to NORMAL_PASSIVE state.

20.2.6.4 FLXAnFRNEMC — FlexRay NEM Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $008C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	—	NML[3:0]			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 20.29 FLXAnFRNEMC Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
3 to 0	NML[3:0]	Network Management Vector Length Bit Configures gNetworkManagementVectorLength

(1) FLXAnFRNEMC.NML

Network Management Vector Length Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 12 bytes.

The configured length must be identical in all nodes of a cluster.

These bits configure the length of the NM vector.

20.2.6.5 FLXAnFRPRTC1 — FlexRay PRT Configuration Register 1

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0090_H

Value after reset: $084C\ 0633_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RWP[5:0]						—	RXW[8:0]

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BRP[1:0]		SPP[1:0]		—	CASM[6:0]							TSST[3:0]			
Value after reset	0	0	0	0	0	1	1	0	0	0	1	1	0	0	1	1
R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.30 FLXAnFRPRTC1 Register Contents

Bit Position	Bit Name	Function
31 to 26	RWP[5:0]	Repetitions of Tx Wakeup Pattern Bit Configures pWakeupPattern
25	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
24 to 16	RXW[8:0]	Wakeup Symbol Receive Window Length Bit Configures gdWakeupSymbolRxWindow
15, 14	BRP[1:0]	Baud Rate Prescaler Bit Configures gdSampleClockPeriod and pSamplesPerMicrotick 00 = 10 Mbps 01 = 5 Mbps 10 = 2.5 Mbps 11 = 2.5 Mbps
13, 12	SPP[1:0]	Strobe Point Position Bit Configures Strobe point position 00 = Sample 5 01 = Sample 4 10 = Sample 6 11 = Sample 5
11	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
10 to 4	CASM[6:0]	Collision Avoidance Symbol Max Bit Configures gdCASRxLowMax
3 to 0	TSST[3:0]	Transmission Start Sequence Transmitter Bit Configures gdTSSTransmitter

(1) FLXAnFRPRTC1.RWP

Repetitions of Tx Wakeup Pattern Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 63.

Configures the number of repetitions (sequences) of the Tx wakeup symbol.

(2) FLXAnFRPRTC1.RXW

Wakeup Symbol Receive Window Length Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 76 to 301 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to test the duration of the received wakeup pattern.

(3) FLXAnFRPRTC1.BRP

Baud Rate Prescaler Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

The Baud Rate Prescaler configures the baud rate on the FlexRay bus. The baud rates listed below are valid with a sample clock set to 80 MHz. One bit time always consists of 8 samples independent of the configured baud rate.

00 = 10 MBit/s

gdSampleClockPeriod = 12.5 ns = 1 * “sample clock”

pSamplesPerMicrotick = 2 (1 µT = 25 ns)

01 = 5 MBit/s

gdSampleClockPeriod = 25 ns = 2 * “sample clock”

pSamplesPerMicrotick = 1 (1 µT = 25 ns)

10, 11 = 2.5 MBit/s

gdSampleClockPeriod = 50 ns = 4 * “sample clock”

pSamplesPerMicrotick = 1 (1 µT = 50 ns)

(4) FLXAnFRPRTC1.SPP

Strobe Point Position Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Defines the sample count value for strobing. The strobed bit value is set to the voted value when the sample count is incremented to the value configured by FLXAnFRPRTC1.SPP.

CAUTION

The current revision 2.1 of the FlexRay protocol requires that FLXAnFRPRTC1.SPP = “00”. The alternate strobe point positions could be used to compensate for asymmetries in the physical layer.

(5) FLXAnFRPRTC1.CASM

Collision Avoidance Symbol Max Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

CASM6 is fixed to 1.

Valid values are 67 to 99 bit times.

Configures the upper limit of the acceptance window for a collision avoidance symbol (CAS).

(6) FLXAnFRPRTC1.TSST

Transmission Start Sequence Transmitter Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 3 to 15 bit times.

Must be identical in all nodes of a cluster.

Configures the duration of the Transmission Start Sequence (TSS) in terms of bit times (1 bit time = 4 µT = 100ns @ 10Mbps).

20.2.6.6 FLXAnFRPRTC2 — FlexRay PRT Configuration Register 2

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0094_H

Value after reset: $0F2D\ 0A0E_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 20.31 FLXAnFRPRTC2 Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
29 to 24	TXL[5:0]	Wakeup Symbol Transmit Low Bit Configures gdWakeupSymbolTxLow
23 to 16	TXI[7:0]	Wakeup Symbol Transmit Idle Bit Configures gdWakeupSymbolTxIdle
15, 14	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
13 to 8	RXL[5:0]	Wakeup Symbol Receive Low Bit Configures gdWakeupSymbolRxLow
7, 6	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
5 to 0	RXI[5:0]	Wakeup Symbol Rx Idle Bit Configures gdWakeupSymbolRxIdle

(1) FLXAnFRPRTC2.TXL

Wakeup Symbol Transmit Low Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 15 to 60 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to transmit the low phase of the wakeup symbol.

(2) FLXAnFRPRTC2.TXI

Wakeup Symbol Transmit Idle Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 45 to 180 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to transmit the idle phase of the wakeup symbol.

(3) FLXAnFRPRTC2.RXL

Wakeup Symbol Receive Low Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 10 to 55 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to test the duration of the low phase of the received wakeup symbol.

(4) FLXAnFRPRTC2.RXI

Wakeup Symbol Rx Idle Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 14 to 59 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to test the duration of the idle phase of the received wakeup symbol.

20.2.6.7 FLXAnFRMHDC — FlexRay MHD Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0098_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	SLT[12:0]												
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	SFDL[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.32 FLXAnFRMHDC Register Contents

Bit Position	Bit Name	Function
31 to 29	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
28 to 16	SLT[12:0]	Start of Latest Transmit Bit Configures pLatestTx
15 to 7	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
6 to 0	SFDL[6:0]	Static Frame Data Length Bit Configures gPayloadLengthStatic

(1) FLXAnFRMHDC.SLT

Start of Latest Transmit Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7981 minislots.

Configures the maximum minislot value allowed before inhibiting frame transmission in the dynamic segment of the cycle. There is no transmission in dynamic segment if FLXAnFRMHDC.SLT is set to zero.

(2) FLXAnFRMHDC.SFDL

Static Frame Data Length Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 127.

The payload length must be identical in all nodes of a cluster.

Configures the cluster-wide payload length for all frames sent in the static segment in double bytes.

20.2.6.8 FLXAnFRGTUC1 — FlexRay GTU Configuration Register 1

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $00A0_H$

Value after reset: $0000\ 0280_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 20.33 FLXAnFRGTUC1 Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
19 to 0	UT[19:0]	Setting of Communication Cycle in Microticks Bit Configures pMicroPerCycle

(1) FLXAnFRGTUC1.UT

Setting of Communication Cycle in Microticks Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 640 to 640000 µT.

Configures the duration of the communication cycle in microticks.

20.2.6.9 FLXAnFRGTUC2 — FlexRay GTU Configuration Register 2

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $00A4_H$

Value after reset: $0002\ 000A_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	SNM[3:0]

Table 20.34 FLXAnFRGTUC2 Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
19 to 16	SNM[3:0]	Sync Node Max Bit
15, 14	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
13 to 0	MPC[13:0]	Setting of Communication Cycle in Macrotick Bit Configures gMacroPerCycle

(1) FLXAnFRGTUC2.SNM

Sync Node Max Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 15.

Must be identical in all nodes of a cluster.

Maximum number of frames within a cluster with sync frame indicator bit SYN set to 1.

(2) FLXAnFRGTUC2.MPC

Setting of Communication Cycle in Macrotick Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 10 to 16000 MT.

The cycle length must be identical in all nodes of a cluster.

Configures the duration of one communication cycle in macroticks.

20.2.6.10 FLXAnFRGTUC3 — FlexRay GTU Configuration Register 3

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $00A8_H$

Value after reset: $0202\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 20.35 FLXAnFRGTUC3 Register Contents

Bit Position	Bit Name	Function
31	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
30 to 24	MIOB[6:0]	Macrotick Initial Offset Channel B Bit Configures pMacroInitialOffset[B]
23	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
22 to 16	MIOA[6:0]	Macrotick Initial Offset Channel A Bit Configures pMacroInitialOffset[A]
15 to 8	UIOB[7:0]	Microtick Initial Offset Channel B Bit Configures pMicroInitialOffset[B]
7 to 0	UIOA[7:0]	Microtick Initial Offset Channel A Bit Configures pMicroInitialOffset[A]

(1) FLXAnFRGTUC3.MIOB

Macrotick Initial Offset Channel B Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 72 MT.

Must be identical in all nodes of a cluster.

Configures the number of macroticks between the static slot boundary and the subsequent macrotick boundary of the secondary time reference point based on the nominal macrotick duration.

(2) FLXAnFRGTUC3.MIOA

Macrotick Initial Offset Channel A Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 72 MT.

Must be identical in all nodes of a cluster.

Configures the number of macroticks between the static slot boundary and the subsequent macrotick boundary of the secondary time reference point based on the nominal macrotick duration.

(3) FLXAnFRGTUC3.UIOB

Microtick Initial Offset Channel B Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 240 µT.

Configures the number of microticks between the actual time reference point on channel B and the subsequent macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation [B] and therefore has to be set for each channel independently.

(4) FLXAnFRGTUC3.UIOA

Microtick Initial Offset Channel A Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 240 µT.

Configures the number of microticks between the actual time reference point on channel A and the subsequent macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation [A] and therefore has to be set for each channel independently.

20.2.6.11 FLXAnFRGTUC4 — FlexRay GTU Configuration Register 4

For details about configuration of FLXAnFRGTUC4.NIT and FLXAnFRGTUC4.OCS see **Section 20.3.2.5, Configuration of NIT Start and Offset Correction Start**.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $00AC_H$

Value after reset: $0008\ 0007_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	OCS[13:0]													
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.36 FLXAnFRGTUC4 Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
29 to 16	OCS[13:0]	Offset Correction Start Bit Configures (gOffsetCorrectionStart – 1)
15, 14	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
13 to 0	NIT[13:0]	Network Idle Time Start Bit Configures (gMacroPerCycle -gdNIT – 1)

(1) FLXAnFRGTUC4.OCS

Offset Correction Start Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 8 to 15998 MT.

For cluster consisting of E-Ray implementations only, it is sufficient to program FLXAnFRGTUC4.OCS = FLXAnFRGTUC4.NIT + 1.

Must be identical in all nodes of a cluster.

Determines the start of the offset correction within the NIT phase, calculated from start of cycle.

(2) FLXAnFRGTUC4.NIT

Network Idle Time Start Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 7 to 15997 MT.

Must be identical in all nodes of a cluster.

Configures the starting point of the Network Idle Time NIT at the end of the communication cycle expressed in terms of macroticks from the beginning of the cycle. The start of NIT is recognized if Macrotick = gMacroPerCycle-gdNIT -1 and the increment pulse of Macrotick is set.

20.2.6.12 FLXAnFRGTUC5 — FlexRay GTU Configuration Register 5

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $00B0_H$

Value after reset: $0E00\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.37 FLXAnFRGTUC5 Register Contents

Bit Position	Bit Name	Function
31 to 24	DEC[7:0]	Decoding Correction Bit Configures pDecodingCorrection
23 to 21	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
20 to 16	CDD[4:0]	Cluster Drift Damping Bit Configures pClusterDriftDamping
15 to 8	DCB[7:0]	Delay Compensation Channel B Bit Configures pDelayCompensation[B]
7 to 0	DCA[7:0]	Delay Compensation Channel A Bit Configures pDelayCompensation[A]

(1) FLXAnFRGTUC5.DEC

Decoding Correction Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 14 to 143 µT.

Configures the decoding correction value in microticks used to determine the primary time reference point.

(2) FLXAnFRGTUC5.CDD

Cluster Drift Damping Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 20 µT.

Configures the cluster drift damping value in microticks used in clock synchronization to minimize accumulation of rounding errors.

(3) FLXAnFRGTUC5.DCB

Delay Compensation Channel B Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 200 µT.

Used to compensate for reception delays on channel B. This covers assumed propagation delay up to cPropagationDelayMax for microticks in the range of 0.0125 to 0.05µs. In practice, the minimum of the propagation delays of all sync nodes should be applied.

(4) FLXAnFRGTUC5.DCA

Delay Compensation Channel A Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 200 µT.

Used to compensate for reception delays on channel A. This covers assumed propagation delay up to cPropagationDelayMax for microticks in the range of 0.0125 to 0.05µs. In practice, the minimum of the propagation delays of all sync nodes should be applied.

20.2.6.13 FLXAnFRGTUC6 — FlexRay GTU Configuration Register 6

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $00B4_H$

Value after reset: $0002\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	MOD[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

	—	—	—	—	—	ASR[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.38 FLXAnFRGTUC6 Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
26 to 16	MOD[10:0]	Maximum Oscillator Drift Bit Configures pdMaxDrift
15 to 11	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
10 to 0	ASR[10:0]	Accepted Startup Range Bit Configures pdAcceptedStartupRange

(1) FLXAnFRGTUC6.MOD

Maximum Oscillator Drift Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 1923 µT.

Maximum drift offset between two nodes that operate with unsynchronized clocks over one communication cycle in µT.

(2) FLXAnFRGTUC6.ASR

Accepted Startup Range Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 1875 µT.

Number of microticks constituting the expanded range of measured deviation for startup frames during integration.

20.2.6.14 FLXAnFRGTUC7 — FlexRay GTU Configuration Register 7

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $00B8_H$

Value after reset: $0002\ 0004_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	NSS[9:0]									
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

	—	—	—	—	—	—	SSL[9:0]									
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.39 FLXAnFRGTUC7 Register Contents

Bit Position	Bit Name	Function
31 to 26	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
25 to 16	NSS[9:0]	Number of Static Slots Bit Configures gNumberOfStaticSlots
15 to 10	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
9 to 0	SSL[9:0]	Static Slot Length Bit Configures gdStaticSlot

(1) FLXAnFRGTUC7.NSS

Number of Static Slots Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 1023.

The number of static slots must be identical in all nodes of a cluster.

Configures the number of static slots in a cycle.

(2) FLXAnFRGTUC7.SSL

Static Slot Length Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 4 to 659 MT.

The static slot length must be identical in all nodes of a cluster.

Configures the length of a static slot in macroticks.

20.2.6.15 FLXAnFRGTUC8 — FlexRay GTU Configuration Register 8

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $00BC_H$

Value after reset: $0000\ 0002_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	NMS[12:0]												
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	MSL[5:0]					
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
R/W	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.40 FLXAnFRGTUC8 Register Contents

Bit Position	Bit Name	Function
31 to 29	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
28 to 16	NMS[12:0]	Number of Minislots Bit Configures gNumberOfMinislots
15 to 6	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
5 to 0	MSL[5:0]	Minislot Length Bit Configures gdMinislot

(1) FLXAnFRGTUC8.NMS

Number of Minislots Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7986.

The number of minislots must be identical in all nodes of a cluster.

Configures the number of minislots within the dynamic segment of a cycle.

(2) FLXAnFRGTUC8.MSL

Minislot Length Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 63 MT.

The minislot length must be identical in all nodes of a cluster.

Configures the length of a minislot in macroticks.

20.2.6.16 FLXAnFRGTUC9 — FlexRay GTU Configuration Register 9

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $00C0_H$

Value after reset: $0000\ 0101_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DSI[1:0]	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	MAPO[4:0]					—	—	APO[5:0]					
Value after reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.41 FLXAnFRGTUC9 Register Contents

Bit Position	Bit Name	Function
31 to 18	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
17, 16	DSI[1:0]	Dynamic Slot Idle Phase Bit Configures gdDynamicSlotIdlePhase
15 to 13	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
12 to 8	MAPO[4:0]	Minislot Action Point Offset Bit Configures gdMinislotActionPointOffset
7, 6	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
5 to 0	APO[5:0]	Action Point Offset Bit Configures gdActionPointOffset

(1) FLXAnFRGTUC9.DSI

Dynamic Slot Idle Phase Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 2 Minislot.

Must be identical in all nodes of a cluster.

Configures the duration of the dynamic slot idle phase in the number of minislots. The duration has to be greater or equal than the idle detection time.

(2) FLXAnFRGTUC9.MAPO

Minislot Action Point Offset Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 31 MT.

Must be identical in all nodes of a cluster.

Configures the action point offset in macroticks within the minislots of the dynamic segment.

(3) FLXAnFRGTUC9.APO

Action Point Offset Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 63 MT.

Must be identical in all nodes of a cluster.

Configures the action point offset in macroticks within static slots and symbol window.

20.2.6.17 FLXAnFRGTUC10 — FlexRay GTU Configuration Register 10

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $00C4_H$

Value after reset: $0002\ 0005_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	MRC[10:0]

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.42 FLXAnFRGTUC10 Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
26 to 16	MRC[10:0]	Maximum Rate Correction Bit Configures pRateCorrectionOut
15, 14	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
13 to 0	MOC[13:0]	Maximum Offset Correction Bit Configures pOffsetCorrectionOut

(1) FLXAnFRGTUC10.MRC

Maximum Rate Correction Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 1923 µT.

Holds the maximum permitted rate correction value to be applied by the internal clock synchronization algorithm. The CC checks only the internal rate correction value against the maximum rate correction value (absolute value).

(2) FLXAnFRGTUC10.MOC

Maximum Offset Correction Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 5 to 15266 µT.

Holds the maximum permitted offset correction value (absolute value) to be applied by the internal clock synchronization algorithm (absolute value). The CC checks only the internal offset correction value against the maximum offset correction value.

20.2.6.18 FLXAnFRGTUC11 — FlexRay GTU Configuration Register 11

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $00C8_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 20.43 FLXAnFRGTUC11 Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
26 to 24	ERC[2:0]	External Rate Correction Bit Configures pExternRateCorrection
23 to 19	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
18 to 16	EOC[2:0]	External Offset Correction Bit Configures pExternOffsetCorrection
15 to 10	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
9, 8	ERCC[1:0]	External Rate Correction Control Bit Configures vExternRateControl 00: External rate correction is prohibited. 01: External rate correction is prohibited. 10: Subtract 11: Add
7 to 2	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
1, 0	EOCC[1:0]	External Offset Correction Control Bit Configures vExternOffsetControl 00: External offset correction is prohibited. 01: External offset correction is prohibited. 10: Subtract 11: Add

(1) FLXAnFRGTUC11.ERC

External Rate Correction Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7 µT.

Holds the external rate correction value in microticks to be applied by the internal clock synchronization algorithm. The value is subtracted / added from / to the calculated rate correction value. The value is applied during NIT.

(2) FLXAnFRGTUC11.EOC

External Offset Correction Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7 µT.

Holds the external offset correction value in microticks to be applied by the internal clock synchronization algorithm. The value is subtracted / added from / to the calculated offset correction value. The value is applied during NIT.

(3) FLXAnFRGTUC11.ERCC

External Rate Correction Control Bit

Should be modified only outside NIT (Network Idle Time).

By writing to FLXAnFRGTUC11.ERCC the external rate correction is enabled as specified below.

00 = External rate correction is prohibited.

01 = External rate correction is prohibited.

10 = Subtract

External rate correction value subtracted from calculated rate correction value

11 = Add

External rate correction value added to calculated rate correction value

(4) FLXAnFRGTUC11.EOCC

External Offset Correction Control Bit

Should be modified only outside NIT (Network Idle Time).

By writing to FLXAnFRGTUC11.EOCC the external offset correction is enabled as specified below.

00 = External offset correction is prohibited.

01 = External offset correction is prohibited.

10 = Subtract

External offset correction value subtracted from calculated offset correction value

11 = Add

External offset correction value added to calculated offset correction value

20.2.7 CC Status Registers

During 8/16-bit accesses to status variables coded with more than 8/16-bit, the variable might be updated by the CC between two accesses (non-atomic read accesses).

20.2.7.1 FLXAnFRCCSV — FlexRay CC Status Vector Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0100_H

Value after reset: $0010\ 4000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 20.44 FLXAnFRCCSV Register Contents (1/2)

Bit	Symbol	Function
31, 30	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
29 to 24	PSL[5:0]	POC Status Log Flag Status of FLXAnFRCCSV.POCS immediately before entering HALT state.
23 to 19	RCA[4:0]	Remaining Coldstart Attempts Flag Indicates vRemainingColdstartAttempts
18 to 16	WSV[2:0]	Wakeup Status Flag Indicates vPOC!WakeupStatus 000: UNDEFINED 001: RECEIVED_HEADER 010: RECEIVED_WUP 011: COLLISION_HEADER 100: COLLISION_WUP 101: COLLISION_UNKNOWN 110: TRANSMITTED 111: Reserved
15	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
14	CSI	Cold Start Inhibit Flag Indicates vColdStartInhibit 0: Cold starting of node enabled 1: Cold starting of node disabled
13	CSAI	Coldstart Abort Indicator Flag
12	CSNI	Coldstart Noise Indicator Flag Indicates vPOC!ColdstartNoise
11, 10	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.

Table 20.44 FLXAnFRCCSV Register Contents (2/2)

Bit	Symbol	Function
9, 8	SLM[1:0]	Slot Mode Flag Indicates vPOC!SlotMode 00: SINGLE 01: reserved 10: ALL_PENDING 11: ALL
7	HRQ	Halt Request Flag Indicates vPOC!CHIHaltRequest
6	FSI	Freeze Status Indicator Flag Indicates vPOC!Freeze
5 to 0	POCS[5:0]	Protocol Operation Control Status Flag

(1) FLXAnFRCCSV.PSL

POC Status Log Flag

Set the value of FLXAnFRCCSV.POCS immediately before entering HALT state.

Set to HALT when FREEZE command is applied during HALT state and FLXAnFRCCSV.FSI is not already set i.e. the HALT state was not reached by FREEZE command.

Reset to “B’000000” when leaving HALT state.

(2) FLXAnFRCCSV.RCA

Remaining Coldstart Attempts Flag

Indicates the number of remaining coldstart attempts (vRemainingColdstartAttempts).

The value after a reset of FLXAnFRCCSV.RCA during CONFIG and DEFAULT_CONFIG state is also FLXAnFRSUCC1.CSA.

The RUN command resets this counter to the maximum number of coldstart attempts as configured by FLXAnFRSUCC1.CSA.

(3) FLXAnFRCCSV.WSV

Wakeup Status Flag

Indicates the status of the current wakeup attempt (vPOC!WakeupStatus).

Reset to 0 when entering Wakeup state, by CHI command RESET_STATUS_INDICATORS, or by transition from DEFAULT_CONFIG to CONFIG state

000_B = UNDEFINED

Wakeup not yet executed by the CC.

001_B = RECEIVED_HEADER

Set when the CC finishes wakeup due to the reception of a frame header without coding violation on either channel in WAKEUP_LISTEN state.

010_B = RECEIVED_WUP

Set when the CC finishes wakeup due to the reception of a valid wakeup pattern on the configured wakeup channel in WAKEUP_LISTEN state.

011_B = COLLISION_HEADER

Set when the CC stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid header on either channel.

100_B = COLLISION_WUP

Set when the CC stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid wakeup pattern on the configured wakeup channel.

101_B = COLLISION_UNKNOWN

Set when the CC stops wakeup by leaving WAKEUP_DETECT state after expiration of the wakeup timer without receiving a valid wakeup pattern or a valid frame header.

110_B = TRANSMITTED

Set when the CC has successfully completed the transmission of the wakeup pattern.

111_B = reserved

(4) FLXAnFRCCSV.CSI

Cold Start Inhibit Flag

Indicates that the node is disabled from cold starting (vColdStartInhibit).

The flag is set to 1 whenever the POC enters READY state due to CHI command READY.

The flag has to be reset under control of the Host by CHI command ALLOW_COLDSTART (FLXAnFRSUCC1.CMD = “1001”).

(5) FLXAnFRCCSV.CSAI

Coldstart Abort Indicator Flag

Coldstart aborted.

Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state or from READY to STARTUP state.

(6) FLXAnFRCCSV.CSNI

Coldstart Noise Indicator Flag

Indicates that the cold start procedure occurred under noisy conditions (vPOC!ColdstartNoise).

Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state or from READY to STARTUP state.

(7) FLXAnFRCCSV.SLM

Slot Mode Flag

Indicates the actual slot mode of the POC (vPOC!SlotMode) in states READY, WAKEUP, STARTUP, NORMAL_ACTIVE, and NORMAL_PASSIVE.

Default value is SINGLE. Changes to ALL, depending on FLXAnFRSUCC1.TSM.

In NORMAL_ACTIVE or NORMAL_PASSIVE state the CHI command ALL_SLOTS will change the slot mode from SINGLE over ALL_PENDING to ALL.

Set FLXAnFRSUCC1.TSM to SINGLE except for NORMAL_ACTIVE or NORMAL_PASSIVE.

(8) FLXAnFRCCSV.HRQ

Halt Request Flag

Indicates that a request from the Host has been received to halt the POC at the end of the communication cycle (vPOC!CHIHaltRequest).

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

(9) FLXAnFRCCSV.FSI

Freeze Status Indicator Flag

Indicates that the POC has entered the HALT state due to CHI command FREEZE or due to an error condition requiring an immediate POC halt (vPOC!Freeze).

Reset by transition from HALT to DEFAULT_CONFIG state.

(10) FLXAnFRCCSV.POCS

Protocol Operation Control Status Flag

Indicates the actual state of operation of the CC Protocol Operation Control

$00\ 0000_B$ = DEFAULT_CONFIG state

$00\ 0001_B$ = READY state

$00\ 0010_B$ = NORMAL_ACTIVE state

$00\ 0011_B$ = NORMAL_PASSIVE state

$00\ 0100_B$ = HALT state

$00\ 0110_B$…$00\ 1110_B$ = reserved

$00\ 1111_B$ = CONFIG state

Indicates the actual state of operation of the POC in the wakeup path

$01\ 0000_B$ = WAKEUP_STANDBY state

$01\ 0001_B$ = WAKEUP_LISTEN state

$01\ 0010_B$ = WAKEUP_SEND state

$01\ 0011_B$ = WAKEUP_DETECT state

Indicates the actual state of operation of the POC in the startup path

$10\ 0000_B$ = STARTUP_PREPARE state

$10\ 0001_B$ = COLDSTART_LISTEN state

$10\ 0010_B$ = COLDSTART_COLLISION_RESOLUTION state

$10\ 0011_B$ = COLDSTART_CONSISTENCY_CHECK state

$10\ 0100_B$ = COLDSTART_GAP state

$10\ 0101_B$ = COLDSTART_JOIN State

$10\ 0110_B$ = INTEGRATION_COLDSTART_CHECK state

$10\ 0111_B$ = INTEGRATION_LISTEN state

$10\ 1000_B$ = INTEGRATION_CONSISTENCY_CHECK state

$10\ 1001_B$ = INITIALIZE_SCHEDULE state

$10\ 1010_B$ = ABORT_STARTUP state

$10\ 1011_B$ = STARTUP_SUCCESS state

others = reserved

20.2.7.2 FLXAnFRCCEV — FlexRay CC Error Vector Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0104_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	PTAC[4:0]					ERRM[1:0]		—	—	CCFC[3:0]			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.45 FLXAnFRCCEV Register Contents

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
12 to 8	PTAC[4:0]	Passive to Active Count Flag Indicates vAllowPassiveToActive
7, 6	ERRM[1:0]	Error Mode Flag Indicates vPOC!ErrorMode 00: ACTIVE 01: PASSIVE 10: COMM_HALT 11: reserved
5, 4	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
3 to 0	CCFC[3:0]	Clock Correction Failed Counter Indicates vClockCorrectionFailed

(1) FLXAnFRCCEV.PTAC

Passive to Active Count Flag

Indicates the number of consecutive even / odd cycle pairs that have passed with valid rate and offset correction terms, while the node is waiting to transit from NORMAL_PASSIVE state to NORMAL_ACTIVE state. The transition takes place when FLXAnFRCCEV.PTAC equals FLXAnFRSUCC1.PTA –1.

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

(2) FLXAnFRCCEV.ERRM

Error Mode Flag

Indicates the actual error mode of the POC (vPOC!ErrorMode).

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

(3) FLXAnFRCCEV.CCFC

Clock Correction Failed Counter

Indicates the clockcorrection failed counter of the POC (vClockCorrectionFailed).

The Clock Correction Failed Counter is incremented by one at the end of any odd communication cycle where either the missing offset correction error or missing rate correction error are active.

The Clock Correction Failed Counter is reset to 0 at the end of an odd communication cycle if neither the offset correction failed nor the rate correction failed errors are active.

The Clock Correction Failed Counter stops at 15.

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

20.2.7.3 FLXAnFRSCV — FlexRay Slot Counter Value Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0110_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	SCCB[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	SCCA[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.46 FLXAnFRSCV Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
26 to 16	SCCB[10:0]	Slot Counter Channel B Indicates vSlotCounter[B]
15 to 11	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
10 to 0	SCCA[10:0]	Slot Counter Channel A Indicates vSlotCounter[A]

(1) FLXAnFRSCV.SCCB

Slot Counter Channel B

Current slot counter value on channel B (vSlotCounter[B]). The value is incremented by the CC and reset at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXAnFRSCV.SCCA

Slot Counter Channel A

Current slot counter value on channel A (vSlotCounter[A]). The value is incremented by the CC and reset at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

20.2.7.4 FLXAnFRMTCCV — FlexRay Macrotick and Cycle Counter Value Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0114_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	CCV[5:0]

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.47 FLXAnFRMTCCV Register Contents

Bit Position	Bit Name	Function
31 to 22	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
21 to 16	CCV[5:0]	Cycle Counter Value Indicates vCycleCounter
15, 14	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
13 to 0	MTV[13:0]	Macrotick Value Indicates vMacrotick

(1) FLXAnFRMTCCV.CCV

Cycle Counter Value

Current cycle counter value (vCycleCounter). The value is incremented by the CC at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXAnFRMTCCV.MTV

Macrotick Value

Current macrotick value (vMacrotick). The value is incremented by the CC and reset at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

20.2.7.5 FLXAnFRRCV — FlexRay Rate Correction Value Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0118_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	RCV[11:0]											
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.48 FLXAnFRRCV Register Contents

Bit Position	Bit Name	Function
31 to 12	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
11 to 0	RCV[11:0]	Rate Correction Value Flag Indicates vRateCorrection

(1) FLXAnFRRCV.RCV

Rate Correction Value Flag

Indicates internal rate correction value (vRateCorrection/ two's complement) before limitation. If the FLXAnFRRCV.RCV value exceeds the limits defined by FLXAnFRGTUC10.MRC, flag FLXAnFRSFS.RCLR is set to 1.

CAUTION

The external rate correction value is added to the limited rate correction value.

20.2.7.6 FLXAnFROCV — FlexRay Offset Correction Value Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $011C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	OCV[18:16]		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OCV[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.49 FLXAnFROCV Register Contents

Bit Position	Bit Name	Function
31 to 19	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
18 to 0	OCV[18:0]	Offset Correction Value Flag Indicates vOffsetCorrection

(1) FLXAnFROCV.OCV

Offset Correction Value Flag

Indicates offset correction value (vOffsetCorrection/two's complement) before limitation. If the FLXAnFROCV.OCV value exceeds the limits defined by FLXAnFRGTUC10.MOC, flag FLXAnFRSFS.OCLR is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

CAUTION

The external offset correction value is added to the limited offset correction value.

20.2.7.7 FLXAnFRSFS — FlexRay Sync Frame Status Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0120_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	RCLR	MRCS	OCLR	MOCS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VSBO[3:0]				VSBE[3:0]				VSAO[3:0]				VSAE[3:0]			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.50 FLXAnFRSFS Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
19	RCLR	Rate Correction Limit Reached Flag 0: Rate correction below limit 1: Rate correction limit reached
18	MRCS	Missing Rate Correction Signal Flag 0: Rate correction signal valid 1: Missing rate correction signal
17	OCLR	Offset Correction Limit Reached Flag 0: Offset correction below limit 1: Offset correction limit reached
16	MOCS	Missing Offset Correction Signal Flag 0: Offset correction signal valid 1: Missing offset correction signal
15 to 12	VSBO[3:0]	Valid Sync Frames Channel B, odd communication cycle
11 to 8	VSBE[3:0]	Valid Sync Frames Channel B, even communication cycle
7 to 4	VSAO[3:0]	Valid Sync Frames Channel A, odd communication cycle
3 to 0	VSAE[3:0]	Valid Sync Frames Channel A, even communication cycle

(1) FLXAnFRSFS.RCLR

Rate Correction Limit Reached Flag

The Rate Correction Limit Reached flag signals to the Host, that the rate correction value has exceeded its limit as defined by FLXAnFRGTUC10.MRC10 to MRC0. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(2) FLXAnFRSFS.MRCS

Missing Rate Correction Signal Flag

The Missing Rate Correction flag signals to the Host, that no rate correction calculation can be performed because no pairs of even / odd sync frames were received. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(3) FLXAnFRSFS.OCLR

Offset Correction Limit Reached Flag

The Offset Correction Limit Reached flag signals to the Host, that the offset correction value has exceeded its limit as defined by FLXAnFRGTUC10.MOC. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(4) FLXAnFRSFS.MOCS

Missing Offset Correction Signal Flag

The Missing Offset Correction flag signals to the Host, that no offset correction calculation can be performed because no sync frames were received. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(5) FLXAnFRSFS.VSBO

Valid Sync Frames Channel B, odd communication cycle

These bits are only valid when FLXAnFRSUCC1.CCHB is 1.

Holds the number of valid sync frames received on channel B in the odd communication cycle. If transmission of sync frames is enabled by FLXAnFRSUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each odd communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(6) FLXAnFRSFS.VSBE

Valid Sync Frames Channel B, even communication cycle

These bits are only valid when FLXAnFRSUCC1.CCHB is 1.

Holds the number of valid sync frames received on channel B in the even communication cycle. If transmission of sync frames is enabled by FLXAnFRSUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each even communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(7) FLXAnFRSFS.VSAO

Valid Sync Frames Channel A, odd communication cycle

These bits are only valid when FLXAnFRSUCC1.CCHA is 1.

Holds the number of valid sync frames received on channel A in the odd communication cycle. If transmission of sync frames is enabled by FLXAnFRSUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each odd communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(8) FLXAnFRSFS.VSAE

Valid Sync Frames Channel A, even communication cycle

These bits are only valid when FLXAnFRSUCC1.CCHA is 1.

Holds the number of valid sync frames received on channel A in the even communication cycle. If transmission of sync frames is enabled by FLXAnFRSUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each even communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

20.2.7.8 FLXAnFRSWNIT — FlexRay Symbol Window and NIT Status Register

Symbol window related status information is updated by the CC at the end of the symbol window for each channel. NIT related status information is updated by the CC at the end of the NIT for each channel.

During startup the status data is not updated.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0124_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 20.51 FLXAnFRSWNIT Register Contents (1/2)

Bit	Symbol	Function
31 to 12	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
11	SBNB	Slot Boundary Violation during NIT Channel B Flag 0: No slot boundary violation detected 1: Slot boundary violation during NIT detected on channel B
10	SENB	Syntax Error during NIT Channel B Flag 0: No syntax error detected 1: Syntax error during NIT detected on channel B
9	SBNA	Slot Boundary Violation during NIT Channel A Flag 0: No slot boundary violation detected 1: Slot boundary violation during NIT detected on channel A
8	SENA	Syntax Error during NIT Channel A Flag 0: No syntax error detected 1: Syntax error during NIT detected on channel A
7	MTSB	MTS Received on Channel B Flag 0: No MTS symbol received on channel B 1: MTS symbol received on channel B
6	MTSA	MTS Received on Channel A Flag 0: No MTS symbol received on channel A 1: MTS symbol received on channel A
5	TCSB	Transmission Conflict in Symbol Window Channel B Flag 0: No transmission conflict detected 1: Transmission conflict in symbol window detected on channel B
4	SBSB	Slot Boundary Violation in Symbol Window Channel B Flag 0: No slot boundary violation detected 1: Slot boundary violation during symbol window detected on channel B
3	SESB	Syntax Error in Symbol Window Channel B Flag 0: No syntax error detected 1: Syntax error during symbol window detected on channel B

Table 20.51 FLXAnFRSWNIT Register Contents (2/2)

Bit	Symbol	Function
2	TCSA	Transmission Conflict in Symbol Window Channel A Flag 0: No transmission conflict detected 1: Transmission conflict in symbol window detected on channel A
1	SBSA	Slot Boundary Violation in Symbol Window Channel A Flag 0: No slot boundary violation detected 1: Slot boundary violation during symbol window detected on channel A
0	SESA	Syntax Error in Symbol Window Channel A Flag 0: No syntax error detected 1: Syntax error during symbol window detected on channel A

(1) FLXAnFRSWNIT.SBNB

Indicates a Slot Boundary Violation during NIT Channel B Flag (vSS!BViolationB).

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXAnFRSWNIT.SENB

Indicates a Syntax Error during NIT Channel B Flag (vSS!SyntaxErrorB).

Reset when leaving CONFIG state or when entering STARTUP state.

(3) FLXAnFRSWNIT.SBNA

Indicates a Slot Boundary Violation during NIT Channel A Flag (vSS!BViolationA).

Reset when leaving CONFIG state or when entering STARTUP state.

(4) FLXAnFRSWNIT.SENA

Indicates a Syntax Error during NIT Channel A Flag (vSS!SyntaxErrorA).

Reset when leaving CONFIG state or when entering STARTUP state.

(5) FLXAnFRSWNIT.MTSB

Indicates a MTS Received on Channel B Flag (vSS!ValidMTSB).

Media Access Test symbol received on channel B during the preceding symbol window. Updated by the CC for each channel at the end of the symbol window.

When this bit is set to 1, also interrupt flag FLXAnFRSIR.MTSB is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(6) FLXAnFRSWNIT.MTSA

Indicates a MTS Received on Channel A Flag (vSS!ValidMTSA).

Media Access Test symbol received on channel A during the preceding symbol window. Updated by the CC for each channel at the end of the symbol window.

When this bit is set to 1, also interrupt flag FLXAnFRSIR.MTSA is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(7) FLXAnFRSWNIT.TCSB

Indicates a Transmission Conflict in Symbol Window Channel B Flag (vSS!TxConflictB).

Reset when leaving CONFIG state or when entering STARTUP state.

(8) FLXAnFRSWNIT.SBSB

Indicates a Slot Boundary Violation in Symbol Window Channel B Flag (vSS!BViolationB).

Reset when leaving CONFIG state or when entering STARTUP state.

(9) FLXAnFRSWNIT.SESB

Indicates a Syntax Error in Symbol Window Channel B Flag (vSS!SyntaxErrorB).

Reset when leaving CONFIG state or when entering STARTUP state.

(10) FLXAnFRSWNIT.TCSA

Indicates a Transmission Conflict in Symbol Window Channel A Flag (vSS!TxConflictA).

Reset when leaving CONFIG state or when entering STARTUP state.

(11) FLXAnFRSWNIT.SBSA

Indicates a Slot Boundary Violation in Symbol Window Channel A Flag (vSS!BViolationA).

Reset when leaving CONFIG state or when entering STARTUP state.

(12) FLXAnFRSWNIT.SESA

Indicates a Syntax Error in Symbol Window Channel A Flag (vSS!SyntaxErrorA).

Reset when leaving CONFIG state or when entering STARTUP state.

20.2.7.9 FLXAnFRACS — FlexRay Aggregated Channel Status Register

The aggregated channel status provides the Host with an accrued status of channel activity for all communication slots regardless of whether they are assigned for transmission or subscribed for reception.

The aggregated channel status also includes status data from the symbol window and the network idle time.

The status data is updated (set) after each slot and aggregated until it is reset by the Host.

During startup the status data is not updated.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0128_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 20.52 FLXAnFRACS Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
12	SBVB	Slot Boundary Violation on Channel B Flag 0: No slot boundary violation observed 1: Slot boundary violation(s) observed on channel B
11	CIB	Communication Indicator Channel B Flag 0: No valid frame(s) received in slots containing any additional communication 1: Valid frame(s) received on channel B in slots containing any additional communication
10	CEDB	Content Error Detected on Channel B Flag 0: No frame with content error received 1: Frame(s) with content error received on channel B
9	SEDB	Syntax Error Detected on Channel B Flag 0: No syntax error observed 1: Syntax error(s) observed on channel B
8	VFRB	Valid Frame Received on Channel B Flag 0: No valid frame received 1: Valid frame(s) received on channel B
7 to 5	Reserved	These bits are always read as 0. The write value should be always 0.
4	SBVA	Slot Boundary Violation on Channel A Flag 0: No slot boundary violation observed 1: Slot boundary violation(s) observed on channel A
3	CIA	Communication Indicator Channel A Flag 0: No valid frame(s) received in slots containing any additional communication 1: Valid frame(s) received on channel A in slots containing any additional communication

Table 20.52 FLXAnFRACS Register Contents (2/2)

Bit Position	Bit Name	Function
2	CEDA	Content Error Detected on Channel A Flag 0: No frame with content error received 1: Frame(s) with content error received on channel A
1	SEDA	Syntax Error Detected on Channel A Flag 0: No syntax error observed 1: Syntax error(s) observed on channel A
0	VFRA	Valid Frame Received on Channel A Flag 0: No valid frame received 1: Valid frame(s) received on channel A

(1) FLXAnFRACS.SBVB

Slot Boundary Violation on Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more slot boundary violations were observed on channel B at any time during the observation period (static or dynamic slots, symbol window, and NIT).

When this flag changes from 0 to 1, interrupt flag FLXAnFREIR.EDB is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXAnFRACS.CIB

Communication Indicator Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more valid frames were received on channel B in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid frame AND had any combination of either syntax error OR content error OR slot boundary violation.

CAUTION

The set condition of the flag FLXAnFRACS.CIB is also fulfilled if there is only one single frame in the slot and the slot boundary at the end of the slot is reached during the frames channel idle recognition phase.
When this flag changes from 0 to 1, interrupt flag FLXAnFREIR.EDB is set to 1.
Reset when leaving CONFIG state or when entering STARTUP state.

(3) FLXAnFRACS.CEDB

Content Error Detected on Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more frames with a content error were received on channel B in any static or dynamic slot during the observation period.

When this flag changes from 0 to 1, interrupt flag FLXAnFREIR.EDB is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(4) FLXAnFRACS.SEDB

Syntax Error Detected on Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more syntax errors in static or dynamic slots, symbol window, and NIT were observed on channel B.

When this flag changes from 0 to 1, interrupt flag FLXAnFREIR.EDB is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(5) FLXAnFRACS.VFRB

Valid Frame Received on Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more valid frames were received on channel B in any static or dynamic slot during the observation period.

Reset when leaving CONFIG state or when entering STARTUP state.

(6) FLXAnFRACS.SBVA

Slot Boundary Violation on Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

Slot boundary violations were observed on channel A at any time during the observation period (static or dynamic slots, symbol window, and NIT).

When this flag changes from 0 to 1, interrupt flag FLXAnFREIR.EDA is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(7) FLXAnFRACS.CIA

Communication Indicator Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more valid frames were received on channel A in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid frame AND had any combination of either syntax error OR content error OR slot boundary violation.

CAUTION

The set condition of the flag FLXAnFRACS.CIA is also fulfilled if there is only one single frame in the slot and the slot boundary at the end of the slot is reached during the frames channel idle recognition phase.

When this flag changes from 0 to 1, interrupt flag FLXAnFREIR.EDA is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(8) FLXAnFRACS.CEDA

Content Error Detected on Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more frames with a content error were received on channel A in any static or dynamic slot during the observation period.

When this flag changes from 0 to 1, interrupt flag FLXAnFREIR.EDA is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(9) FLXAnFRACS.SEDA

Syntax Error Detected on Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more syntax errors in static or dynamic slots, symbol window, and NIT were observed on channel A.

When this flag changes from 0 to 1, interrupt flag FLXAnFREIR.EDA is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

(10) FLXAnFRACS.VFRA

Valid Frame Received on Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

One or more valid frames were received on channel A in any static or dynamic slot during the observation period.

Reset when leaving CONFIG state or when entering STARTUP state.

20.2.7.10 FLXAnFRESIDm — FlexRay Even Sync ID Register m (m = 1 to 15)

Registers FLXAnFRESID1 to FLXAnFRESID15 hold the frame IDs of the sync frames received in even communication cycles used for clock synchronisation up to the limit of gSyncNodeMax. The values are sorted in ascending order, with register FLXAnFRESID1 holding the lowest received sync frame ID. If the node itself transmits a sync frame in an even communication cycle, register FLXAnFRESID1 holds the respective sync frame ID as configured in message buffer 0 and flags FLXAnFRESID1.RXEA, FLXAnFRESID1.RXEB are set. The value is updated during the NIT of each even communication cycle.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0130_H to <FLXn_base> + 0168_H (<FLXn_base> + 0130_H + (n – 1) *4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RXEB	RXEA	—	—	—	—	EID[9:0]									
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.53 FLXAnFRESIDn (n = 1 to 15) Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
15	RXEB	Received / Configured Even Sync ID on Channel B Flag 0: No sync frame received on channel B / node not configured to transmit sync frames 1: Sync frame received on channel B / node configured to transmit sync frames
14	RXEA	Received / Configured Even Sync ID on Channel A Flag 0: No sync frame received on channel A / node not configured to transmit sync frames 1: Sync frame received on channel A / node configured to transmit sync frames
13 to 10	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
9 to 0	EID[9:0]	Even Sync ID (vsSyncIDListA, B even) Flag

(1) FLXAnFRESIDn.RXEB

Received / Configured Even Sync ID on Channel B Flag

Signals that a sync frame corresponding to the stored even sync ID was received on channel B or that the node is configured to be a sync node with key slot = FLXAnFRESID1.EID.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXAnFRESIDn.RXEA

Received / Configured Even Sync ID on Channel A Flag

Signals that a sync frame corresponding to the stored even sync ID was received on channel A or that the node is configured to be a sync node with key slot = FLXAnFRESID1.EID.

Reset when leaving CONFIG state or when entering STARTUP state.

(3) FLXAnFRESIDn.EID

Even Sync ID Flag (vsSyncIDListA, B even)

Sync frame ID even communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

20.2.7.11 FLXAnFROSIDm — FlexRay Odd Sync ID Register m (m = 1 to 15)

Registers FLXAnFROSID1 to FLXAnFROSID15 hold the frame IDs of the sync frames received in odd communication cycles used for clock synchronisation up to the limit of gSyncNodeMax. The values are sorted in ascending order, with register FLXAnFROSID1 holding the lowest received sync frame ID. If the node itself transmits a sync frame in an odd communication cycle, register FLXAnFROSID1 holds the respective sync frame ID as configured in message buffer 0 and flags FLXAnFROSID1.RXOA, FLXAnFROSID1.RXOB are set. The value is updated during the NIT of each odd communication cycle.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0170_H to <FLXn_base> + $01A8_H$ (<FLXn_base> + 0170_H + (n – 1)*4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	RXOB	RXOA	—	—	—	—	OID[9:0]									
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.54 FLXAnFROSIDn Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
15	RXOB	Received / Configured Odd Sync ID on Channel B Flag 0: No sync frame received on channel B / node not configured to transmit sync frames 1: Sync frame received on channel B / node configured to transmit sync frames
14	RXOA	Received / Configured Odd Sync ID on Channel A Flag 0: No sync frame received on channel A / node not configured to transmit sync frames 1: Sync frame received on channel A / node configured to transmit sync frames
13 to 10	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
9 to 0	OID[9:0]	Odd Sync ID Flag (vsSyncIDListA, B odd)

(1) FLXAnFROSIDn.RXOB

Received / Configured Odd Sync ID on Channel B Flag

Signals that a sync frame corresponding to the stored odd sync ID was received on channel B or that the node is configured to be a sync node with key slot = FLXAnFROSID1.OID.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXAnFROSIDn.RXOA

Received / Configured Odd Sync ID on Channel A Flag

Signals that a sync frame corresponding to the stored odd sync ID was received on channel A or that the node is configured to be a sync node with key slot = FLXAnFROSID1.OID.

Reset when leaving CONFIG state or when entering STARTUP state.

(3) FLXAnFROSIDn.OID

Odd Sync ID Flag (vsSyncIDListA, B odd)

Sync frame ID odd communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

20.2.7.12 FLXAnFRNMVm — FlexRay Network Management Vector Register m (m = 1 to 3)

The three network management registers hold the accrued NM vector (see **Section 20.3.7, Network Management**).

The CC updates the NM vector at the end of each communication cycle as long as the CC is either in NORMAL_ACTIVE or NORMAL_PASSIVE state.

NMVn-bytes exceeding the configured NM vector length are not valid.

For information about the byte alignment of the received NM vector in this register see **Section 20.3.17, Byte Alignment**.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $01B0_H$ to <FLXn_base> + $01B8_H$ (<FLXn_base> + $01B0_H$ + (n – 1)*4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	NM[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	NM[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.55 FLXAnFRNMVn Register Contents

Bit Position	Bit Name	Function
31 to 0	NM[31:0]	NM Vector The three network management vector registers hold the accrued NM vector (configurable 0 to 12 bytes). The NM vector to be held is generated by bit-wise logic OR for each NM vector received on each channel (valid static frames with PPI = 1) (see **Section 20.3.7, Network Management**). For information about the byte alignment of the received NM vector in this register see **Section 20.3.17, Byte Alignment**. NMVn-bytes exceeding the configured NM vector length are not valid. The Register Contents are updated at the end of each communication cycle as long as the CC is either in NORMAL_ACTIVE or NORMAL_PASSIVE state. These bits are cleared when leaving CONFIG state or when entering STARTUP state.

20.2.8 Message Buffer Control Registers

20.2.8.1 FLXAnFRMRC — FlexRay Message RAM Configuration Register

The Message RAM Configuration register defines the number of message buffers assigned to the static segment, dynamic segment, and FIFO.

The Message RAM can be divided into up three different areas; Static Buffer area, Static and Dynamic Buffer area, FIFO area. If present, the Static Buffer area is starting at Message Buffer 0.

The start of the Static and Dynamic Buffer area is configured by FLXAnFRMRC.FDB. FLXAnFRMRC.FDB defines the end of the Static Buffer area. If no Static Buffer area is present, the Static and Dynamic Buffer area starts at Message Buffer 0.

The start of the FIFO area is configured by FLXAnFRMRC.FFB. FLXAnFRMRC.FFB defines the end of the previous area, which can be either the Static Buffer area or the Static and Dynamic Buffer area. If no Static Buffer area and no Static and Dynamic Buffer area is present, the FIFO area starts at Message Buffer 0.

With FLXAnFRMRC.LCB the end of the last configured area is configured which can be the Static Buffer area, the Static and Dynamic Buffer area or the FIFO area.

Figure 20.2 shows an example configuration of the Message RAM where all there area are configured.

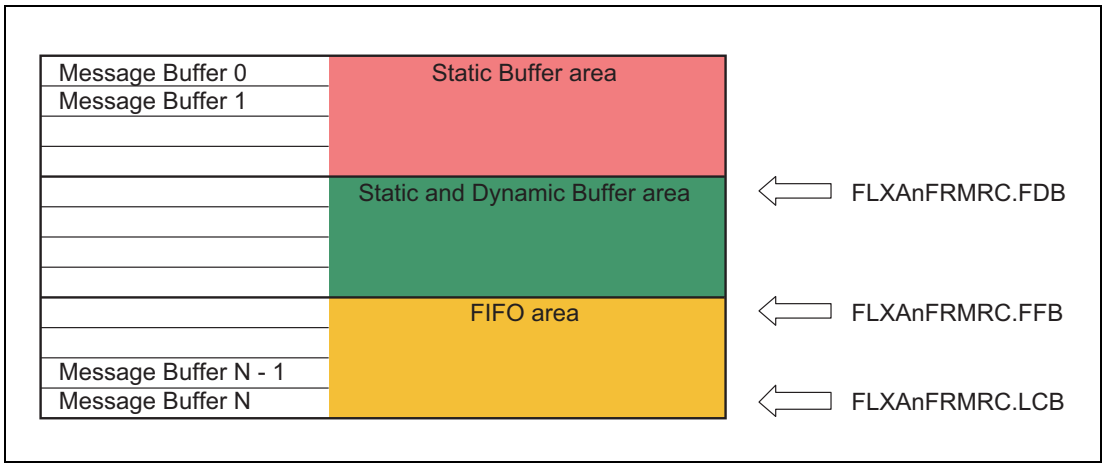

Figure 20.2 FLXAnFRNMVn Register Contents

CAUTIONS

1. **In case the node is configured as sync node (FLXAnFRSUCC1.TXSY = 1) or for single slot mode operation (FLXAnFRSUCC1.TSM = 1), message buffer 0 resp. 1 is reserved for sync frames or single slot frames and have to be configured with the node-specific key slot ID. In case the node is neither configured as sync node nor for single slot operation message buffer 0 resp. 1 is treated like all other message buffers.**
2. **The maximum number of header sections is 128. This means a maximum of 128 message buffers can be configured. The maximum length of a data section is 254 bytes. The length of the data section may be configured differently for each message buffer. For details see Section 20.3.13, Message RAM.**
3. **In case two or more message buffers are assigned to slot 1 by use of cycle filtering, all of them must be located either in the “Static Buffers” or at the**

beginning of the “Static + Dynamic Buffers” section.

4. **The FlexRay protocol specification requires that each node has to send a frame in its key slot. Therefore at least message buffer 0 is reserved for transmission in the key slot. Due to this requirement a maximum number of 127 message buffers can be assigned to the FIFO. Nevertheless, a non protocol conform configuration without a transmission slot in the static segment would still be operational.**
5. **The payload length configured and the length of the data section need to be configured identical for all message buffers belonging to the FIFO via FLXAnFRWRHS2.PL and FLXAnFRWRHS3.DP. When the CC is not in DEFAULT_CONFIG or CONFIG state reconfiguration of message buffers belonging to the FIFO is locked.**

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0300_H

Value after reset: $0180\ 0000_H$

Table 20.56 FLXAnFRMRC Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
26	SPLM	Sync Frame Payload Multiplex Bit 0: Only message buffer 0 locked against reconfiguration 1: Both message buffers 0 and 1 are locked against reconfiguration
25, 24	SEC[1:0]	Secure Buffers Bit 00: all buffers unlocked 01: static buffers locked, FIFO locked, limited transmission 10: all buffers locked 11: all buffers locked, limited transmission
23 to 16	LCB[7:0]	Last Configured Buffer Bit 0 to 127: Number of message buffers is FLXAnFRMRF.LCB + 1 128: No message buffer assigned to the FIFO
15 to 8	FFB[7:0]	First Buffer of FIFO Bit 0: All message buffers assigned to the FIFO 1 to 127: Message buffers from FLXAnFRMRC.FFB to FLXAnFRMRC.LCB assigned to the FIFO 128: No message buffer configured
7 to 0	FDB[7:0]	First Dynamic Buffer Bit 0: No group of message buffers exclusively for the static segment configured 1 to 127: Message buffers 0 to FLXAnFRMRC.FDB – 1 reserved for static segment 128: No dynamic message buffers configured

(1) FLXAnFRMRC.SPLM

Sync Frame Payload Multiplex Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

This bit is only evaluated if the node is configured as sync node (FLXAnFRSUCC1.TXSY = 1) or for single slot mode operation (FLXAnFRSUCC1.TSM = 1).

When this bit is set to 1 message buffers 0 and 1 are dedicated for sync frame transmission with different payload data on channel A and B.

When this bit is set to 0, sync frames are transmitted from message buffer 0 with the same payload data on all channels configured. Note that the channel filter configuration for message buffer 0 resp. message buffer 1 has to be chosen accordingly.

(2) FLXAnFRMRC.SEC

Secure Buffers Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Not evaluated when the CC is in DEFAULT_CONFIG or CONFIG state.

For temporary unlocking, see **Section 20.3.13.4, Host Handling of Access Errors**.

00_B = all buffers unlocked

Reconfiguration of message buffers enabled with numbers < FLXAnFRMRC.FFB enabled

Exception: In nodes configured for sync frame transmission or for single slot mode operation message buffer 0 (and if FLXAnFRMRC.SPLM = 1, also message buffer 1) is always locked

01_B = static buffers locked, FIFO locked, limited transmission

Reconfiguration of message buffers with numbers < FLXAnFRMRC.FDB and with numbers ≥ FLXAnFRMRC.FFB locked and transmission of message buffers for static segment with numbers ≥ FLXAnFRMRC.FDB disabled

10_B = all buffers locked

Reconfiguration of all message buffers locked

11_B = all buffers locked, limited transmission

Reconfiguration of all message buffers locked and transmission of message buffers for static segment with numbers ≥ FLXAnFRMRC.FDB disabled

(3) FLXAnFRMRC.LCB

Last Configured Buffer Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

When a Static and Dynamic Buffer area is configured (FLXAnFRMRC.FDB < 128), the user should configure FLXAnFRMRC.LCB ≥ FLXAnFRMRC.FDB.

When a FIFO area is configured (FLXAnFRMRC.FFB < 128), the user should configure FLXAnFRMRC.LCB ≥ FLXAnFRMRC.FFB.

(4) FLXAnFRMRC.FFB

First Buffer of FIFO Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

When a Static and Dynamic Buffer area is configured (FLXAnFRMRC.FDB < 128), the user should configure FLXAnFRMRC.FFB > FLXAnFRMRC.FDB.

(5) FLXAnFRMRC.FDB

First Dynamic Buffer Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

20.2.8.2 FLXAnFRFRF — FlexRay FIFO Rejection Filter Register

The FIFO Rejection Filter defines a user specified sequence of bits to which channel, frame ID, and cycle count of the incoming frames are compared. Together with the FIFO Rejection Filter Mask this register determines whether a message is rejected by the FIFO.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0304_H

Value after reset: $0180\ 0000_H$

Table 20.57 FLXAnFRFRF Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
24	RNF	Reject Null Frames Bit 0: Null frames are stored in the FIFO 1: Reject all null frames
23	RSS	Reject in Static Segment Bit 0: FIFO also used for static segment 1: Reject messages in static segment
22 to 16	CYF[6:0]	Cycle Counter Filter Bit Cycle Counter Filter
15 to 13	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
12 to 2	FID[10:0]	Frame ID Filter Bit 0 to 2047: Frame ID filter values
1, 0	CH[1:0]	Channel Filter Bit 00: receive on both channels 01: receive only on channel B 10: receive only on channel A 11: no reception

(1) FLXAnFRFRF.RNF

Reject Null Frames Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

If this bit is set to 1, received null frames are not stored in the FIFO.

(2) FLXAnFRFRF.RSS

Reject in Static Segment Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

If this bit is set to 1, the FIFO is used only for the dynamic segment.

(3) FLXAnFRFRF.CYF

Cycle Counter Filter Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

The 7-bit cycle counter filter determines the cycle set to which frame ID and channel rejection filter are applied. In cycles not belonging to the cycle set specified by FLXAnFRFRF.CYF, all frames are rejected. For details about the configuration of the cycle counter filter see **Section 20.3.8.2, Cycle Counter Filtering**.

(4) FLXAnFRFRF.FID

Frame ID Filter Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Determines the frame ID to be rejected by the FIFO. With the additional configuration of register FLXAnFRFRFM, the corresponding frame ID filter bits are ignored, which results in further rejected frame IDs. When FLXAnFRFRFM.MFID is zero, a frame ID filter value of zero means that no frame ID is rejected.

(5) FLXAnFRFRF.CH

Channel Filter Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

If reception on both channels is configured, also in static segment always both frames (from channel A and B) are stored in the FIFO, even if they are identical.

20.2.8.3 FLXAnFRFRFM — FlexRay FIFO Rejection Filter Mask Register

The FlexRay FIFO Rejection Filter Mask specifies which of the corresponding frame ID filter bits are relevant for rejection filtering. If a bit is set to 1, it indicates that the corresponding bit in the FLXAnFRFRF register will not be considered for rejection filtering.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0308_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 20.58 FLXAnFRFRFM Register Contents

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
12 to 2	MFID[10:0]	Mask Frame ID Filter Bit 0: Corresponding frame ID filter bit is used for rejection filtering 1: Ignore corresponding frame ID filter bit.
1, 0	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.

(1) FLXAnFRFRFM.MFID

Mask Frame ID Filter Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

20.2.8.4 FLXAnFRFCL — FlexRay FIFO Critical Level Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $030C_H$

Value after reset: $0000\ 0080_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 20.59 FLXAnFRFCL Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
7 to 0	CL[7:0]	Critical Level Bit Critical Level

(1) FLXAnFRFCL.CL

Critical Level Bit

The user can only write to these bits when FLXAnFRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

When the receive FIFO fill level FLXAnFRFSR.RFFL is equal or greater than the critical level configured by FLXAnFRFCL.CL, the receive FIFO critical level flag FLXAnFRFSR.RFCL is set to 1.

If FLXAnFRFCL.CL is programmed to values > 128, bit FLXAnFRFSR.RFCL is never set to 1.

20.2.9 Message Buffer Status Registers

20.2.9.1 FLXAnFRMHDS — FlexRay Message Handler Status Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0310_H

Value after reset: 0000 0080_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	MBU[6:0]							—	MBT[6:0]

Table 20.60 FLXAnFRMHDS Register Contents

Bit Position	Bit Name	Function
31	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
30 to 24	MBU[6:0]	Message Buffer Updated Flag Message Buffer Updated
23	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
22 to 16	MBT[6:0]	Message Buffer Transmitted Flag Message Buffer Transmitted
15	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
14 to 8	FMB[6:0]	Faulty Message Buffer Number Flag
7	CRAM	Clear all internal RAM's Flag 0: No execution of the CHI command CLEAR_RAMS 1: Execution of the CHI command CLEAR_RAMS ongoing
6	MFMB	Multiple Faulty Message Buffer Detection Flag 0 = No additional faulty message buffer. 1 = Additional faulty message buffer was detected while the FMBD flag is set to 1.
5	FMBD	Faulty Message Buffer Detection Flag 0 = No faulty message buffer. 1 = Message buffer referenced by FLXAnFRMHDS.FMB holds faulty data with a parity error.
4	ATBF2	Temporary Buffer RAM B Access Error Flag 0 = No access error 1 = Access error occurred when reading the RAM B.
3	ATBF1	Temporary Buffer RAM A Access Error Flag 0 = No access error. 1 = Access error occurred when reading the RAM A.
2	AMR	Message RAM Access Error Flag 0 = No access error 1 = Access error occurred when reading the Message RAM.
1, 0	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.

(1) FLXAnFRMHDS.MBU

Message Buffer Updated Flag

Number of message buffer that was updated last by the CC. For this message buffer the respective ND and / or MBC flag in the FLXAnFRNDAT1/2/3/4 registers and the FLXAnFRMBSC1/2/3/4 registers are also set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(2) FLXAnFRMHDS.MBT

Message Buffer Transmitted Flag

Number of last successfully transmitted message buffer.

If the message buffer is configured for single-shot mode, the respective TXR flag in the FLXAnFRTXRQ1/2/3/4 registers was reset to 0.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(3) FLXAnFRMHDS.FMB

Faulty Message Buffer Number Flag

This flag indicates that an access error occurred when reading from the message buffer referenced by FLXAnFRMHDS.FMB.

The value of this flag is only valid when FLXAnFRMHDS.AMR and flag FLXAnFRMHDS.FMBD are set to 1.

This flag is not updated while the FLXAnFRMHDS.FMBD flag is 1.

This flag is cleared by the CHI command CLEAR_RAMS.

(4) FLXAnFRMHDS.CRAM

Internal RAM Clear Flag

This flag indicates that the CHI command CLEAR_RAMS is ongoing (all bits of the message RAM, input buffer, output buffer and nonresident buffer are written to 0).

This flag is set by the CHI command CLEAR_RAMS.

(5) FLXAnFRMHDS.MFMB

Multiple Faulty Message Buffer Detection Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing 1 to it.

This bit indicates that an additional faulty message buffer was detected while the FMBD flag is set.

This bit is cleared by the CHI command CLEAR_RAMS.

(6) FLXAnFRMHDS.FMBD

Faulty Message Buffer Detection Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing 1 to it.

This bit indicates that the message buffer referenced by FLXAnFRMHDS.FMB holds faulty data due to an access error.

This bit is cleared by the CHI command CLEAR_RAMS.

(7) FLXAnFRMHD.ATBF2

Temporary Buffer RAM B Access Error Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing 1 to it.

This flag indicates that an access error occurred when reading the RAM B.

CAUTION

When this flag changes from 0 to 1, the AERR bit in the FLXAnFREIR register is set to 1. This flag can be reset by the CHI command CLEAR_RAMS.

(8) FLXAnFRMHD.ATBF1

Temporary Buffer RAM A Access Error Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing 1 to it.

This flag indicates that an access error occurred when reading the RAM A.

CAUTION

When this flag changes from 0 to 1, the AERR bit in the FLXAnFREIR register is set to 1. This flag can be reset by the CHI command CLEAR_RAMS.

(9) FLXAnFRMHDS.AMR

Message RAM Access Error Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing 1 to it.

This flag indicates that an access error occurred when reading the Message RAM.

CAUTION

When this flag changes from 0 to 1, the AERR bit in the FLXAnFREIR register is set to 1. This flag can be reset by the CHI command CLEAR_RAMS.

20.2.9.2 FLXAnFRLDTS — FlexRay Last Dynamic Transmit Slot Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0314_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	LDTB[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	LDTA[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.61 FLXAnFRLDTS Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
26 to 16	LDTB[10:0]	Last Dynamic Transmission Channel B Flag
15 to 11	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
10 to 0	LDTA[10:0]	Last Dynamic Transmission Channel A Flag

(1) FLXAnFRLDTS.LDTB

Last Dynamic Transmission Channel B Flag

Stores the value of vSlotCounter[B] at the time of the last frame transmission on channel B in the dynamic segment of this node.

It is updated at the end of the dynamic segment and is reset to zero if no frame was transmitted during the dynamic segment.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS of channel B.

(2) FLXAnFRLDTS.LDTA

Last Dynamic Transmission Channel A Flag

Stores the value of vSlotCounter[A] at the time of the last frame transmission on channel A in the dynamic segment of this node.

It is updated at the end of the dynamic segment and is reset to zero if no frame was transmitted during the dynamic segment.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS of channel A.

20.2.9.3 FLXAnFRFSR — FlexRay FIFO Status Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0318_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFFL[7:0]								—	—	—	—	—	RFO	RFCL	RFNE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.62 FLXAnFRFSR Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
15 to 8	RFFL[7:0]	Receive FIFO Fill Level Flag
7 to 3	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
2	RFO	Receive FIFO Overrun Flag 0: No receive FIFO overrun detected 1: A receive FIFO overrun has been detected
1	RFCL	Receive FIFO Critical Level Flag 0: Receive FIFO below critical level 1: Receive FIFO critical level reached
0	RFNE	Receive FIFO Not Empty Flag 0: Receive FIFO is empty 1: Receive FIFO is not empty

(1) FLXAnFRFSR.RFFL

Receive FIFO Fill Level Flag

Indicates the number of FIFO buffers filled with new data not yet read by the Host. Maximum value is 128.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(2) FLXAnFRFSR.RFO

Receive FIFO Overrun Flag

The flag is set to 1 by the CC when a receive FIFO overrun is detected.

When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. In addition, interrupt flag FLXAnFREIR.RFO is set to 1.

The flag is cleared by the next FIFO read access issued by the Host.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(3) FLXAnFRFSR.RFCL

Receive FIFO Critical Level Flag

This flag is set to 1 when the receive FIFO fill level FLXAnFRFSR.RFFL is equal or greater than the critical level as configured by FLXAnFRFCL.CL.

When FLXAnFRFSR.RFCL changes from 0 to 1 bit FLXAnFRSIR.RFCL is set to 1, and if enabled, an interrupt is generated.

The flag is cleared by the CC as soon as FLXAnFRFSR.RFFL drops below FLXAnFRFCL.CL.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(4) FLXAnFRFSR.RFNE

Receive FIFO Not Empty Flag

This flag is set to 1 by the CC when a received valid frame (data or null frame depending on rejection mask) was stored in the FIFO. In addition, interrupt flag FLXAnFRSIR.RFNE is set to 1.

The bit is reset to 0 after the Host has read all messages from the FIFO.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

20.2.9.4 FLXAnFRMHDF — FlexRay Message Handler Constraints Flags Register

Some constraints exist for the Message Handler regarding bus clock frequency, Message RAM configuration, and FlexRay bus traffic. To simplify software development, constraints violations are reported by setting flags in the FLXAnFRMHDF.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $031C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	WAHP	TNSB	TNSA	TBFB	TBFA	FNFB	FNFA	SNUB	SNUA
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.63 FLXAnFRMHDF Register Contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
8	WAHP	Write Attempt to Header Partition Flag 0: No write attempt to header partition 1: Write attempt to header partition
7	TNSB	Transmission Not Started Channel B Flag 0: No transmission not started on channel B 1: Transmission not started on channel B
6	TNSA	Transmission Not Started Channel A Flag 0: No transmission not started on channel A 1: Transmission not started on channel A
5	TBFB	Temporary buffer Access Failure B Flag 0: No TBF B access failure 1: TBF B access failure
4	TBFA	Temporary buffer Access Failure A Flag 0: No TBF A access failure 1: TBF A access failure
3	FNFB	Find Sequence Not Finished Channel B Flag 0: No find sequence not finished for channel B 1: Find sequence not finished for channel B
2	FNFA	Find Sequence Not Finished Channel A Flag 0: No find sequence not finished for channel A 1: Find sequence not finished for channel A
1	SNUB	Status Not Updated Channel B Flag 0: No overload condition occurred when updating MBS for channel B 1: MBS for channel B not updated
0	SNUA	Status Not Updated Channel A Flag 0: No overload condition occurred when updating MBS for channel A 1: MBS for channel A not updated

(1) FLXAnFRMHDF.WAHP

Write Attempt to Header Partition Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

Outside DEFAULT_CONFIG and CONFIG state this flag is set to 1 by the CC when the message handler tries to write message data into the header partition of the Message RAM due to faulty configuration of a message buffer. The write attempt is not executed, to protect the header partition from unintended write accesses.

When this flag changes from 0 to 1 in addition interrupt flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(2) FLXAnFRMHDF.TNSB

Transmission Not Started Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when the Message Handler was not ready to start a scheduled transmission on channel B at the action point of the configured slot.

When this flag changes from 0 to 1 in addition interrupt flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(3) FLXAnFRMHDF.TNSA

Transmission Not Started Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set by the CC when the Message Handler was not ready to start a scheduled transmission on channel A at the action point of the configured slot.

When this flag changes from 0 to 1 in addition interrupt flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(4) FLXAnFRMHDF.TBFB

Temporary buffer Access Failure B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when a read or write access to TBF B requested by PRT (Protocol controller) B could not complete within the available time.

When this flag changes from 0 to 1 in addition interrupt flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(5) FLXAnFRMHDF.TBFA

Temporary buffer Access Failure A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when a read or write access to TBF A requested by PRT A could not complete within the available time.

When this flag changes from 0 to 1 in addition interrupt flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(6) FLXAnFRMHDF.FNFB

Find Sequence Not Finished Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching message buffer).

When this flag changes from 0 to 1 in addition interrupt flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(7) FLXAnFRMHDF.FNFA

Find Sequence Not Finished Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when the Message Handler, due to overload condition, was not able to finish a find sequence (scan of Message RAM for matching message buffer).

When this flag changes from 0 to 1 in addition interrupt flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(8) FLXAnFRMHDF.SNUB

Status Not Updated Channel B Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when the Message Handler, due to overload condition, was not able to update a message buffer's status (FLXAnFRMBS).

When this flag changes from 0 to 1 in addition interrupt flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

(9) FLXAnFRMHDF.SNUA

Status Not Updated Channel A Flag

Writing 0 has no effect on the bit value.

This bit is cleared when writing a 1 to it.

This flag is set to 1 by the CC when the Message Handler, due to overload condition, was not able to update a message buffer's status (FLXAnFRMBS).

When this flag changes from 0 to 1 in addition interrupt flag FLXAnFREIR.MHF is set to 1.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMS.

20.2.9.5 FLXAnFRTXRQi — FlexRay Transmission Request i (i = 1 to 4)

The four registers reflect the state of the TXR flags of all configured message buffers. The flags are evaluated for transmit buffers only. If the number of configured message buffers is less than 128, the remaining TXR flags have no meaning.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0320_H to <FLXn_base> + $032C_H$ (<FLXn_base> + 0320_H + (i – 1)*4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TXRo[31:16]

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TXRo[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.64 FLXAnFRTXRQi Register Contents

Bit Position	Bit Name	Function
31:0	TXRo[31:0]	Transmission Request Flag o

(1) FLXAnFRTXRQi.TXRo (o = (i – 1)*32 to (i*32 – 1))

Transmission Request Flag o

If the flag is set to 1, the respective message buffer is ready for transmission respectively transmission of this message buffer is in progress.

In single-shot mode the flags are reset to 0 after transmission has completed.

This bit is cleared by the CHI command CLEAR_RAMS.

20.2.9.6 FLXAnFRNDATi — FlexRay New Data Register i (i = 1 to 4)

The four registers reflect the state of the ND flags of all configured message buffers. ND flags belonging to transmit buffers have no meaning. If the number of configured message buffers is less than 128, the remaining ND flags have no meaning.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0330_H to <FLXn_base> + $033C_H$ (<FLXn_base> + 0330_H + (i – 1)*4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	NDn[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	NDn[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.65 FLXAnFRNDATi Register Contents

Bit Position	Bit Name	Function
31 to 0	NDn[31:0]	New Data Flag n

(1) FLXAnFRNDATi.NDn (n = (i – 1)*32 to (i*32 – 1))

New Data Flag n

The flags are set to 1 when a valid received data frame matches the message buffer's filter configuration, independent of the payload length received or the payload length configured for that message buffer.

The flags are not set to 1 after reception of null frames except for message buffers belonging to the receive FIFO.

An ND flag is reset to 0 when the header section of the corresponding message buffer is reconfigured or when the data section has been transferred to the Output Buffer.

Reset when leaving CONFIG state or when entering STARTUP state.

This bit is cleared by the CHI command CLEAR_RAMS.

20.2.9.7 FLXAnFRMBSCi — FlexRay Message Buffer Status Changed Register i (i = 1 to 4)

The four registers reflect the state of the MBC flags of all configured message buffers. If the number of configured message buffers is less than 128, the remaining MBC flags have no meaning.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0340_H to <FLXn_base> + $034C_H$ (<FLXn_base> + 0340_H + (i – 1)*4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 20.66 FLXAnFRMBSCi (i = 1 to 4) Register Contents

Bit Position	Bit Name	Function
31 to 0	MBCm[31:0]	Message Buffer Status Changed Flag m

(1) FLXAnFRMBSCi.MBCm (m = (i – 1)*32 to (i*32 – 1))

Message Buffer Status Changed Flag m

Indicates whether the Message Handler has changed one of the status flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB in the header section (see **Section 20.2.12.5, FLXAnFRMBS — FlexRay Message Buffer Status Register** and **Section 20.3.13.1, Header Partition** of the respective message buffer.

An MBC flag is reset to 0 when the header section of the corresponding message buffer is reconfigured or when it has been transferred to the Output Buffer.

Reset when leaving CONFIG state or when entering STARTUP state.

This bit is cleared by the CHI command CLEAR_RAMS.

20.2.10 Identification Registers

20.2.10.1 FLXAnFRPV — FlexRay Product Version Register

Access: This register can be read/ in 32-bit units.

Address: <FLXn_base> + 0000_H

Value after reset: 2A10 2300_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	AID[7:0]								INV[7:0]							
Value after reset	0	0	1	0	1	0	1	0	0	0	0	1	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	JID[7:0]								—	—	—	—	—	—	—	—
Value after reset	0	0	1	0	0	0	1	1	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.67 FLXAnFRPV Register Contents

Bit Position	Bit Name	Function
31 to 24	AID[7:0]	AUTOSAR ID Fixed to $2A_H$
23 to 16	INV[7:0]	Internal version Release version of the FlexRay IP
15 to 8	JID[7:0]	JEDEC ID Fixed to 23_H
7 to 0	Reserved	When read, the value after reset always is read. When writing

(1) FLXAnFRPV.AID

AUTOSAR ID

(2) FLXAnFRPV.INV

Internal version

These bits show the release version of the FlexRay IP

The bits FLXAnFRPV.INV[7:4] show the main release number and the bits FLXAnFRPV.INV[3:0] show the sub release number.

Examples:

10h = IP release 1.0

11h = IP release 1.1

20h = IP release 2.0

(3) FLXAnFRPV.JID

JEDEC ID

20.2.11 Input Buffer

Double buffer structure consisting of Input Buffer Host and Input Buffer Shadow. While the Host can write to Input Buffer Host, the transfer to the Message RAM is done from Input Buffer Shadow. The Input Buffer holds the header and data sections to be transferred to the selected message buffer in the Message RAM. It is used to configure the message buffers in the Message RAM and to update the data sections of transmit buffers.

When updating the header section of a message buffer in the Message RAM from the Input Buffer, the Message Buffer Status as described in **Section 20.2.12.5, FLXAnFRMBS — FlexRay Message Buffer Status Register** is automatically reset to zero.

The header sections of message buffers belonging to the receive FIFO can only be (re)configured when the CC is in DEFAULT_CONFIG or CONFIG state. For those message buffers only the payload length configured and the data pointer need to be configured via FLXAnFRWRHS2.PLC and FLXAnFRWRHS3.DP. All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask.

The data transfer between Input Buffer (IBF) and Message RAM is described in detail in **Section 20.3.12.2, Host access to Message RAM**.

These registers cannot be written when the input data transfer function shown in **Section 20.3.16.1, Input Data Transfer** is used and the FLXAnFRITS.ITS bit is 1.

20.2.11.1 FLXAnFRWRDSx — FlexRay Write Data Section Register x (x = 1 to 64)

This register holds the data words to be transferred to the data section of the specified message buffer. The number of data words written to the Message RAM is defined by the payload length configured in FLXAnFRWRHS2.PLC bit.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0400_H to <FLXn_base> + $04FC_H$ (<FLXn_base> + 0400_H + (x – 1)*4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MD[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.68 FLXAnFRWRDSx Register Contents

Bit Position	Bit Name	Function
31 to 0	MD[31:0]	Message Data Bit

(1) FLXAnFRWRDSx.MD

Message Data Bit

For information about the byte alignment of the message data in this register see **Section 20.3.17, Byte Alignment**.

CAUTIONS

1. In case FLXAnFRWRHS2.PLC specifies an odd payload length, the remaining message data bytes are unused.
2. When writing to FLXAnFRWRDSn, each 32-bit word has to be filled up by one 32-bit access OR two consecutive 16-bit accesses OR four consecutive 8- bit accesses before the transfer from the Input Buffer to the Message RAM is started. If not all bytes of a 32- bit word have been written by the Host (8/16-bit access only), FLXAnFRWRDSn holds partly undefined data.
   Reset by the CHI command CLEAR_RAMS.

20.2.11.2 FLXAnFRWRHS1 — FlexRay Write Header Section Register 1

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0500_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 20.69 FLXAnFRWRHS1 Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
29	MBI	Message Buffer Interrupt Bit 0: The corresponding message buffer interrupt is disabled 1: The corresponding message buffer interrupt is enabled
28	TXM	Transmission Mode Setting Bit 0: Continuous mode 1: Single-shot mode
27	PPIT	Payload Preamble Indicator Transmit Bit 0: Payload Preamble Indicator is set to 0 1: Payload Preamble Indicator is set to 1
26	CFG	Message Buffer Direction Configuration Bit 0: The corresponding buffer is configured as Receive Buffer 1: The corresponding buffer is configured as Transmit Buffer
25, 24	CH[1:0]	Channel Filter Control Bit
23	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
22 to 16	CYC[6:0]	Cycle Code Bit
15 to 11	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
10 to 0	FID[10:0]	Frame ID Bit

(1) FLXAnFRWRHS1.MBI

Message Buffer Interrupt Enable Bit

This bit enables the message buffer interrupt.

After a dedicated receive buffer has been updated by the Message Handler, flag FLXAnFRSIR.RXI and /or FLXAnFRSIR.MBSI are set to 1. After a transmission has completed flag FLXAnFRSIR.TXI is set to 1.

(2) FLXAnFRWRHS1.TXM

Transmission Mode Setting Bit

This bit selects transmit mode of the corresponding message buffer. For transmit mode, see **Section 20.3.9.3, Transmit Buffers**.

(3) FLXAnFRWRHS1.PPIT

Payload Preamble Indicator Transmit Bit

This bit is used to control the state of the Payload Preamble Indicator in transmit frames in transmit frames of the corresponding message buffer.

If the bit is set to 1 in a static message buffer, the respective message buffer holds network management information.

If the bit is set to 1 in a dynamic message buffer the first two bytes of the payload segment may be used for message ID filtering by the receiver. Message ID filtering of received FlexRay frames is not supported by the FlexRay module, but can be done by the Host.

(4) FLXAnFRWRHS1.CFG

Message Buffer Direction Configuration Bit

This bit is used to configure the corresponding buffer as transmit buffer or as receive buffer. For message buffers belonging to the receive FIFO the bit is not evaluated.

If the user doesn't leave at least 32bit unused area at the head of Data Partition, the user should configure the Message Buffer which Data Section is located directly following the Header partition (the last configured buffer) as transmit buffer by setting this bit to “1”.

(5) FLXAnFRWRHS1.CH

Channel Filter Control Bit

The 2-bit channel filtering field associated with each buffer serves as a filter for receive buffers, and as a control field for transmit buffers.

CH[1:0]	Transmit Buffer transmit frame on	Receive Buffer store frame received from
00	No transmission	Ignore frame
01	Channel A	Channel A
10	Channel B	Channel B
11	Both channels (static segment only)	Channel A or B (store first semantically valid frame; static segment only)

CAUTION

If a message buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no frames are transmitted resp. received frames are ignored (same function as CH = “00_B”)

(6) FLXAnFRWRHS1.CYC

Cycle Code Bit

The 7-bit cycle code determines the cycle set used for cycle counter filtering.

For details about the configuration of the cycle code **Section 20.3.8.2, Cycle Counter Filtering**.

(7) FLXAnFRWRHS1.FID

Frame ID Bit

Frame ID of the selected message buffer. The frame ID defines the slot number for transmission / reception of the respective message.

Message buffers with frame ID = 0 are considered as not valid.

20.2.11.3 FLXAnFRWRHS2 — FlexRay Write Header Section Register 2

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0504_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	PLC[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	CRC[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.70 FLXAnFRWRHS2 Register Contents

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
22 to 16	PLC[6:0]	Payload Length Configured Bit
15 to 11	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
10 to 0	CRC[10:0]	Header CRC Bit (vRF!Header!HeaderCRC) Receive Buffer: Configuration not required Transmit Buffer: Header CRC is configured

(1) FLXAnFRWRHS2.PLC

Payload Length Configured Bit

Length of data section (number of 2-byte words) as configured by the Host.

During static segment the static frame payload length as configured by FLXAnFRMHDC.SFDL defines the payload length for all static frames. If the payload length configured by FLXAnFRWRHS2.PLC is shorter than this value padding bytes are inserted to ensure that frames have proper physical length. The padding pattern is "0000_H" (see **Section 20.3.9.3, Transmit Buffers**).

(2) FLXAnFRWRHS2.CRC

Header CRC Bit (vRF!Header!HeaderCRC)

Setting of the receive buffer is not required.

Transmitting of the message buffer needs the header CRC calculation and setting.

For calculation of the header CRC the payload length of the frame send on the bus has to be considered. In static segment the payload length of all frames is configured by FLXAnFRMHDC.SFDL.

20.2.11.4 FLXAnFRWRHS3 — FlexRay Write Header Section Register 3

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0508_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 20.71 FLXAnFRWRHS3 Register Contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
10 to 0	DP[10:0]	Data Pointer Bit

(1) FLXAnFRWRHS3.DP

Data Pointer Bit

Configures the pointer to the first 32-bit word of the data section of the addressed message buffer in the Message RAM.

20.2.11.5 FLXAnFRIBCM — FlexRay Input Buffer Command Mask Register

Configures how the message buffer in the Message RAM selected by register FLXAnFRIBCR is updated. When IBF Host and IBF Shadow are swapped, also mask bits FLXAnFRIBCM.LHSH, FLXAnFRIBCM.LDSH, and FLXAnFRIBCM.STXRH are swapped with bits FLXAnFRIBCM.LHSS, FLXAnFRIBCM.LDSS, and FLXAnFRIBCM.STXRS.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0510_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	STXRS	LDSS	LHSS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	—	—	STXRH	LDSH	LHSH
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 20.72 FLXAnFRIBCM Register Contents

Bit Position	Bit Name	Function
31 to 19	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
18	STXRS	Set Transmission Request Shadow Flag 0: Reset TXR flag 1: Set TXR flag, transmit buffer released for transmission (operation ongoing or finished)
17	LDSS	Load Data Section Shadow Flag 0: Data section is not updated 1: Data section selected for transfer from Input Buffer to the Message RAM (transfer ongoing or finished)
16	LHSS	Load Header Section Shadow Flag 0: Header section is not updated 1: Header section selected for transfer from Input Buffer to the Message RAM (transfer ongoing or finished)
15 to 3	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
2	STXRH	Set Transmission Request Host Bit 0: Reset TXR flag 1: Set TXR flag, transmit buffer released for transmission
1	LDSH	Load Data Section Host Bit 0: Data section is not updated 1: Data section selected for transfer from Input Buffer to the Message RAM
0	LHSH	Load Header Section Host Bit 0: Header section is not updated 1: Header section selected for transfer from Input Buffer to the Message RAM

(1) FLXAnFRIBCM.STXRS

Set Transmission Request Shadow Flag

(2) FLXAnFRIBCM.LDSS

Load Data Section Shadow Flag

(3) FLXAnFRIBCM.LHSS

Load Header Section Shadow Flag

(4) FLXAnFRIBCM.STXRH

Set Transmission Request Host Bit

If this bit is set to 1, the TXR flag for the selected message buffer is set in the FLXAnFRTXRQ1/2/3/4 registers to release the message buffer for transmission. In single-shot mode the flag is cleared by the CC after transmission has completed.

TXR is evaluated for transmit buffers only.

(5) FLXAnFRIBCM.LDSH

Set Load Data Section Host Bit

(6) FLXAnFRIBCM.LHSH

Set Load Header Section Host Bit

20.2.11.6 FLXAnFRIBCR — FlexRay Input Buffer Command Request Register

When the Host writes the number of the target message buffer in the Message RAM to FLXAnFRIBCR.IBRH, IBF Host and IBF Shadow are swapped. In addition the message buffer numbers stored under FLXAnFRIBCR.IBRH and FLXAnFRIBCR.IBRS are also swapped (see **Section 20.3.12.2 (1), Data Transfer from Input Buffer to Message RAM**).

With this write operation the FLXAnFRIBCR.IBSYS is set to 1. The Message Handler then starts to transfer the contents of IBF Shadow to the message buffer in the Message RAM selected by FLXAnFRIBCR.IBRS.

While the Message Handler transfers the data from IBF Shadow to the target message buffer in the Message RAM, the Host may write the next message into the IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, FLXAnFRIBCR.IBSYS is set back to 0 and the next transfer to the Message RAM may be started by the Host by writing the respective target message buffer number to FLXAnFRIBCR.IBRH.

If a write access to FLXAnFRIBCR.IBRH occurs while FLXAnFRIBCR.IBSYS is 1, FLXAnFRIBCR.IBSYH is set to 1. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, FLXAnFRIBCR.IBSYH is reset to 0. FLXAnFRIBCR.IBSYS remains set to 1, and the next transfer to the Message RAM is started. In addition the message buffer numbers stored under FLXAnFRIBCR.IBRH and FLXAnFRIBCR.IBRS are also swapped.

Any write access to an Input Buffer register while both FLXAnFRIBCR.IBSYS and FLXAnFRIBCR.IBSYH are set to 1 will cause the error flag FLXAnFREIR.IIBA to be set to 1.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0514_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 20.73 FLXAnFRIBCR Register Contents (1/2)

Bit Position	Bit Name	Function
31	IBSYS	Input Buffer Busy Shadow Flag 0: Transfer between IBF Shadow and Message RAM completed 1: Transfer between IBF Shadow and Message RAM in progress
30 to 23	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
22 to 16	IBRS[6:0]	Input Buffer Request Shadow Flag

Table 20.73 FLXAnFRIBCR Register Contents (2/2)

Bit Position	Bit Name	Function
15	IBSYH	Input Buffer Busy Host Flag 0: No request pending 1: Request while transfer between IBF Shadow and Message RAM in progress
14 to 7	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
6 to 0	IBRH[6:0]	Input Buffer Request Host Bit

(1) FLXAnFRIBCR.IBSYS

Input Buffer Busy Shadow Flag

Set to 1 after writing FLXAnFRIBCR.IBRH.

This bit indicates transmitting between the IBF Shadow and the Message RAM is ongoing.

When the transfer between IBF Shadow and the Message RAM has completed, FLXAnFRIBCR.IBSYS is set back to 0.

(2) FLXAnFRIBCR.IBRS

Input Buffer Request Shadow Flag

Number of the target message buffer actually updated / lately updated.

(3) FLXAnFRIBCR.IBSYH

Input Buffer Busy Host Flag

Set to 1 by writing FLXAnFRIBCR.IBRH while FLXAnFRIBCR.IBSYS is still 1.

This bit indicates transmitting between the IBF Shadow and the Message RAM is ongoing.

After the ongoing transfer between IBF Shadow and the Message RAM has completed, the FLXAnFRIBCR.IBSYH is set back to 0.

(4) FLXAnFRIBCR.IBRH

Input Buffer Request Host Bit

Selects the target message buffer in the Message RAM for data transfer from Input Buffer.

20.2.12 Output Buffer

Double buffer structure consisting of Output Buffer Host and Output Buffer Shadow. Used to read out message buffers from the Message RAM. While the Host can read from Output Buffer Host, the Message Handler transfers the selected message buffer from Message RAM to Output Buffer Shadow. The data transfer between Message RAM and Output Buffer (OBF) is described in **Section 20.3.12.2 (2), Data Transfer from Message RAM to Output Buffer**.

These registers cannot be written when the output data transfer function shown in **Section 20.3.16.2, Output Data Transfer**, in Output Data Transfer is used and the FLXAnFROTS.OTS bit is 1.

20.2.12.1 FLXAnFRRDDSx — FlexRay Read Data Section Register x (x = 1 to 64)

Holds the data words read from the data section of the addressed message buffer. This register holds the data words to be transferred to the data section of the specified message buffer. The number of data words (DWn) read from the Message RAM is defined by the payload length configured in FLXAnFRRDHS2.PLC bit.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0600_H to <FLXn_base> + $06FC_H$ (<FLXn_base> + 0600_H + (x – 1)*4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MD[31:16]

Table 20.74 FLXAnFRRDDSn Register Contents

Bit Position	Bit Name	Function
31 to 0	MD[31:0]	Message Data

(1) FLXAnFRRDDSn.MD

Message Data Flag

For information about the byte alignment of the data words in this register see **Section 20.3.17, Byte Alignment**.

CAUTION

In case FLXAnFRWRHS2.PLC specifies an odd payload length, the remaining message data bytes are unused.

Reset by the CHI command CLEAR_RAMS.

20.2.12.2 FLXAnFRRDHS1 — FlexRay Read Header Section Register 1

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0700_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	MBI	TXM	PPIT	CFG	CH[1:0]		—	CYC[6:0]

Table 20.75 FLXAnFRRDHS1 Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
29	MBI	Message Buffer Interrupt Flag
28	TXM	Transmission Mode Flag
27	PPIT	Payload Preamble Indicator Transmit Flag
26	CFG	Message Buffer Direction Configuration Flag
25, 24	CH[1:0]	Channel Filter Control Flag
23	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
22 to 16	CYC[6:0]	Cycle Code
15 to 11	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
10 to 0	FID[10:0]	Frame ID

(1) FLXAnFRRDHS1.MBI

Message Buffer Interrupt Flag

Values as configured by the Host via FLXAnFRWRHS1.MBI.

In case that the message buffer read from the Message RAM belongs to the receive FIFO this bit is set to 0.

(2) FLXAnFRRDHS1.TXM

Transmission Mode Flag

Values as configured by the Host via FLXAnFRWRHS1.TXM.

In case that the message buffer read from the Message RAM belongs to the receive FIFO this bit is set to 0.

(3) FLXAnFRRDHS1.PPIT

Payload Preamble Indicator Transmit Flag

Values as configured by the Host via FLXAnFRWRHS1.PPIT.

In case that the message buffer read from the Message RAM belongs to the receive FIFO this bit is set to 0.

(4) FLXAnFRRDHS1.CFG

Message Buffer Direction Configuration Flag

Values as configured by the Host via FLXAnFRWRHS1.CFG.

In case that the message buffer read from the Message RAM belongs to the receive FIFO this bit is set to 0.

(5) FLXAnFRRDHS1.CH

Channel Filter Control Flag

Values as configured by the Host via FLXAnFRWRHS1.CH.

In case that the message buffer read from the Message RAM belongs to the receive FIFO these bits are set to 0.

(6) FLXAnFRRDHS1.CYC

Cycle Code

Values as configured by the Host via FLXAnFRWRHS1.CYC.

In case that the message buffer read from the Message RAM belongs to the receive FIFO these bits are set to 0.

(7) FLXAnFRRDHS1.FID

Frame ID

Values as configured by the Host via FLXAnFRWRHS1.FID

In case that the message buffer read from the Message RAM belongs to the receive FIFO these bits are holding the received frame ID.

20.2.12.3 FLXAnFRRDHS2 — FlexRay Read Header Section Register 2

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0704_H

Value after reset: $0000\ 0000_H$

CAUTION

For message buffers belonging to the Static Buffer area or Static and Dynamic Buffer area FLXAnFRRDHS2 is updated from data frames only.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	PLR[6:0]							—	PLC[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	CRC[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.76 FLXAnFRRDHS2 Register Contents

Bit Position	Bit Name	Function
31	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
30 to 24	PLR[6:0]	Payload Length Received Flag (vRF!Header!Length)
23	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
22 to 16	PLC[6:0]	Payload Length Configured Flag
15 to 11	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
10 to 0	CRC[10:0]	Header CRC Flag (vRF!Header!HeaderCRC)

(1) FLXAnFRRDHS2.PLR

Payload Length Received Flag (vRF!Header!Length)

Payload length (vRF!Header!Length) value updated from received data frames (exception: if message buffer belongs to the receive FIFO FLXAnFRRDSH2.PLR is also updated from received null frames).

(2) FLXAnFRRDHS2.PLC

Payload Length Configured Flag

Length of data section (number of 2-byte words) as configured by the Host.

(3) FLXAnFRRDHS2.CRC

Header CRC Flag (vRF!Header!HeaderCRC)

Receive Buffer: Header CRC (vRF!Header!HeaderCRC) updated from received data frames

Transmit Buffer: Header CRC configured by the Host

(4) Data storage

When a message is stored into a message buffer the following behavior with respect to payload length received and payload length configured is implemented:

FLXAnFRRDHS2.PLR > FLXAnFRRDHS2.PLC:

The payload data stored in the message buffer is truncated to the payload length configured if FLXAnFRRDHS2.PLC even or else truncated to FLXAnFRRDHS2.PLC + 1.

FLXAnFRRDHS2.PLR <= FLXAnFRRDHS2.PLC:

The received payload data is stored into the message buffers data section. The remaining data bytes of the data section as configured by FLXAnFRRDHS2.PLC are filled with undefined data.

FLXAnFRRDHS2.PLR = zero:

The message buffer’s data section is filled with undefined data

FLXAnFRRDHS2.PLC = zero:

Message buffer has no data section configured. No data is stored into the message buffer's data section.

CAUTIONS

1. The Message RAM is organized in 4-byte words. When received data is stored into a message buffer’s data section, the number of 2-byte data words written into the message buffer is FLXAnFRRDHS2.PLC rounded to the next even value.
2. FLXAnFRRDHS2.PLC should be configured identical for all message buffers belonging to the receive FIFO. Header 2 is updated from data frames only.
   For message buffers belonging to the Static Buffer area or Static and Dynamic Buffer area FLXAnFRRDHS2 is updated from data frames only.

20.2.12.4 FLXAnFRRDHS3 — FlexRay Read Header Section Register 3

CAUTION

For message buffers belonging to the Static Buffer area or Static and Dynamic Buffer area FLXAnFRRDHS3 is updated from data frames only.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0708_H

Value after reset: $0000\ 0000_H$

Table 20.77 FLXAnFRRDHS3 Register Contents

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
29	RES	Reserved Bit Indicator Flag (vRF!Header!Reserved)
28	PPI	Payload Preamble Indicator (vRF!Header!PPIndicator)
27	NFI	Null Frame Indicator Flag (vRF!Header!NFIndicator) 0: Up to now no data frame has been stored into the respective message buffer 1: At least one data frame has been stored into the respective message buffer
26	SYN	Sync Frame Indicator Flag (vRF!Header!SyFIndicator) 0: The received frame is not a sync frame 1: The received frame is a sync frame
25	SFI	Startup Frame Indicator Flag (vRF!Header!SuFIndicator) 0: The received frame is not a startup frame 1: The received frame is a startup frame
24	RCI	Received on Channel Indicator Flag (vSS!Channel) 0: Frame received on channel B 1: Frame received on channel A
23, 22	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
21 to 16	RCC[5:0]	Receive Cycle Counter (vRF!Header!CycleCount)
15 to 11	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
10 to 0	DP[10:0]	Data Pointer Flag

(1) FLXAnFRRDHS3.RES

Reserved Bit Flag (vRF!Header!Reserved)

Reflects the state of the received reserved bit. The reserved bit is transmitted as 0.

(2) FLXAnFRRDHS3.PPI

Payload Preamble Indicator Flag (vRF!Header!PPIndicator)

The payload preamble indicator defines whether a network management vector or message ID is contained within the payload segment of the received frame.

0 = The payload segment of the received frame does not contain a network management vector nor a message ID

1 = Static segment: Network management vector in the first part of the payload
Dynamic segment: Message ID in the first part of the payload

(3) FLXAnFRRDHS3.NFI

Null Frame Indicator Flag (vRF!Header!NFIndicator)

Is set to 1 after storage of the first received data frame.

(4) FLXAnFRRDHS3.SYN

Sync Frame Indicator Flag (vRF!Header!SyFIndicator)

A sync frame is marked by the sync frame indicator.

(5) FLXAnFRRDHS3.SFI

Startup Frame Indicator Flag (vRF!Header!SuFIndicator)

A startup frame is marked by the startup frame indicator.

(6) FLXAnFRRDHS3.RCI

Received on Channel Indicator Flag (vSS!Channel)

Indicates the channel from which the received data frame was taken to update the respective receive buffer.

(7) FLXAnFRRDHS3.RCC

Receive Cycle Counter (vRF!Header!CycleCount)

Cycle counter value updated from received data frame.

(8) FLXAnFRRDHS3.DP

Data Pointer Flag

Pointer to the first 32-bit word of the data section of the addressed message buffer in the Message RAM.

The bit value is the same as that set in the FLXAnFRWRHS3.DP bit.

20.2.12.5 FLXAnFRMBS — FlexRay Message Buffer Status Register

The message buffer status is updated by the CC with respect to the assigned channel(s) latest at the end of the slot following the slot assigned to the message buffer.

The flags are updated only when the CC is in NORMAL_ACTIVE or NORMAL_PASSIVE state.

If only one channel (A or B) is assigned to a message buffer, the channel-specific status flags of the other channel are written to zero. If both channels are assigned to a message buffer, the channel-specific status flags of both channels are updated.

The message buffer status is updated only when the slot counter reached the configured frame ID and when the cycle counter filter matched. When the Host updates a message buffer via Input Buffer, all FLXAnFRMBS flags are reset to zero independent of which FLXAnFRIBCM bits are set or not.

For details about receive / transmit filtering see **Section 20.3.8, Filtering and Masking**, **Section 20.3.9, Transmit Process** and **Section 20.3.10, Receive Process**.

Whenever the Message Handler changes one of the flags FLXAnFRMBS.VFRA, FLXAnFRMBS.VFRB, FLXAnFRMBS.SEOA, FLXAnFRMBS.SEOB, FLXAnFRMBS.CEOA, FLXAnFRMBS.CEOB, FLXAnFRMBS.SVOA, FLXAnFRMBS.SVOB, FLXAnFRMBS.TCIA, FLXAnFRMBS.TCIB, FLXAnFRMBS.ESA, FLXAnFRMBS.ESB, FLXAnFRMBS.MLST, FLXAnFRMBS.FTA, FLXAnFRMBS.FTB the respective message buffer's MBC flag in registers FLXAnFRMBSC1/2/3/4 is set.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $070C_H$

Value after reset: 0000 0000_H

Table 20.78 FLXAnFRMBS Register Contents (1/2)

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
29	RESS	Reserved Bit Status Flag (vRF!Header!Reserved)
28	PPIS	Payload Preamble Indicator Status Flag (vRF!Header!PPIndicator) 0: PPI indicator set to 0 1: PPI indicator set to 1
27	NFIS	Null Frame Indicator Status Flag (vRF!Header!NFIndicator) 0: Received frame is a null frame 1: Received frame is not a null frame
26	SYNS	Sync Frame Indicator Status Flag (vRF!Header!SyFIndicator) 0: No sync frame received 1: The received frame is a sync frame

Table 20.78 FLXAnFRMBS Register Contents (2/2)

Bit Position	Bit Name	Function
25	SFIS	Startup Frame Indicator Status Flag (vRF!Header!SuFIndicator) 0: No startup frame received 1: The received frame is a startup frame
24	RCIS	Received on Channel Indicator Status Flag (vSS!Channel) 0: Frame received on channel B 1: Frame received on channel A
23, 22	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
21 to 16	CCS[5:0]	Cycle Count Status Flag
15	FTB	Frame Transmitted on Channel B Flag 0: No data frame transmitted on channel B 1: Data frame transmitted on channel B
14	FTA	Frame Transmitted on Channel A Flag 0: No data frame transmitted on channel A 1: Data frame transmitted on channel A
13	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
12	MLST	Message Lost Flag 0: No message lost 1: Unprocessed message was overwritten
11	ESB	Empty Slot Channel B Flag 0: Bus activity detected in the assigned slot on channel B 1: No bus activity detected in the assigned slot on channel B
10	ESA	Empty Slot Channel A Flag 0: Bus activity detected in the assigned slot on channel A 1: No bus activity detected in the assigned slot on channel A
9	TCIB	Transmission Conflict Indication Channel B Flag (vSS!TxConflictB) 0: No transmission conflict occurred on channel B 1: Transmission conflict occurred on channel B
8	TCIA	Transmission Conflict Indication Channel A Flag (vSS!TxConflictA) 0: No transmission conflict occurred on channel A 1: Transmission conflict occurred on channel A
7	SVOB	Slot Boundary Violation Observed on Channel B Flag (vSS!BViolationB) 0: No slot boundary violation observed on channel B 1: Slot boundary violation observed on channel B
6	SVOA	Slot Boundary Violation Observed on Channel A Flag (vSS!BViolationA) 0: No slot boundary violation observed on channel A 1: Slot boundary violation observed on channel A
5	CEOB	Content Error Observed on Channel B Flag (vSS!ContentErrorB) 0: No content error observed on channel B 1: Content error observed on channel B
4	CEOA	Content Error Observed on Channel A Flag (vSS!ContentErrorA) 0: No content error observed on channel A 1: Content error observed on channel A
3	SEOB	Syntax Error Observed on Channel B Flag (vSS!SyntaxErrorB) 0: No syntax error observed on channel B 1: Syntax error observed on channel B
2	SEOA	Syntax Error Observed on Channel A Flag (vSS!SyntaxErrorA) 0: No syntax error observed on channel A 1: Syntax error observed on channel A
1	VFRB	Valid Frame Received on Channel B (vSS!ValidFrameB) 0: No valid frame received on channel B 1: Valid frame received on channel B
0	VFRA	Valid Frame Received on Channel A Flag (vSS!ValidFrameA) 0: No valid frame received on channel A 1: Valid frame received on channel A

(1) FLXAnFRMBS.RESS

Reserved Bit Status Flag (vRF!Header!Reserved)

Reflects the state of the received reserved bit. The reserved bit is transmitted as 0.

For receive buffers (FLXAnFRWRHS1.CFG = 0) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(2) FLXAnFRMBS.PPIS

Payload Preamble Indicator Status Flag (vRF!Header!PPIndicator)

The payload preamble indicator defines whether a network management vector or message ID is contained within the payload segment of the received frame.

For receive buffers (FLXAnFRWRHS1.CFG = 0) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

0 = PPI indicator set to 0
The payload segment of the received frame does not contain a network management vector or a message ID

1 = PPI indicator set to 1
Static segment: Network management vector at the beginning of the payload
Dynamic segment: Message ID at the beginning of the payload

(3) FLXAnFRMBS.NFIS

Null Frame Indicator Status Flag (vRF!Header!NFIndicator)

If set to 0 the payload segment of the received frame contains no usable data.

For receive buffers (FLXAnFRWRHS1.CFG = 0) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(4) FLXAnFRMBS.SYNS

Sync Frame Indicator Status Flag (vRF!Header!SyFIndicator)

A sync frame is marked by the sync frame indicator.

For receive buffers (FLXAnFRWRHS1.CFG = 0) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(5) FLXAnFRMBS.SFIS

Startup Frame Indicator Status Flag (vRF!Header!SuFIndicator)

The startup frame indicator specifies a startup frame.

For receive buffers (FLXAnFRWRHS1.CFG = 0) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(6) FLXAnFRMBS.RCIS

Received on Channel Indicator Status Flag (vSS!Channel)

Indicates the channel on which the frame was received.

For receive buffers (FLXAnFRWRHS1.CFG = 0) this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(7) FLXAnFRMBS.CCS

Cycle Count Status Flag

Actual cycle count when status was updated.

(8) FLXAnFRMBS.FTB

Frame Transmitted on Channel B Flag

Indicates that this node has transmitted a data frame in the configured slot on channel B.

CAUTION

The FlexRay protocol specification requires that FLXAnFRMBS.FTB can only be reset by the Host. Therefore the Cycle Count Status FLXAnFRMBS.CCS for this bit is only valid for the cycle where the bit is set to 1.

(9) FLXAnFRMBS.FTA

Frame Transmitted on Channel A Flag

Indicates that this node has transmitted a data frame in the configured slot on channel A.

CAUTION

The FlexRay protocol specification requires that FLXAnFRMBS.FTA can only be reset by the Host. Therefore the Cycle Count Status FLXAnFRMBS.CCS for this bit is only valid for the cycle where this bit is set to 1.

(10) FLXAnFRMBS.MLST

Message Lost Flag

The flag is set in case the Host did not read the message before the message buffer was updated from a received data frame.

Not affected by reception of null frames except for message buffers belonging to the receive FIFO. The flag is reset to 0 by a Host write to the message buffer via IBF or when a new message is stored into the message buffer after the message buffers ND flag was reset to 0 by reading out the message buffer via OBF.

(11) FLXAnFRMBS.ESB

Empty Slot Channel B Flag

In an empty slot, there is no activity on the bus. This means that any frame transmission is not detected. This state can be checked in static and dynamic slots.

(12) FLXAnFRMBS.ESA

Empty Slot Channel A Flag

In an empty slot, there is no activity on the bus. This means that any frame transmission is not detected. This state can be checked in static and dynamic slots.

(13) FLXAnFRMBS.TCIB

Transmission Conflict Indication Channel B Flag (vSS!TxConflictB)

A transmission conflict indication is set to 1 if a transmission conflict has occurred on channel B.

(14) FLXAnFRMBS.TCIA

Transmission Conflict Indication Channel A Flag (vSS!TxConflictA)

A transmission conflict indication is set if a transmission conflict has occurred on channel A.

(15) FLXAnFRMBS.SVOB

Slot Boundary Violation Observed on Channel B Flag (vSS!BViolationB)

A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel B.

(16) FLXAnFRMBS.SVOA

Slot Boundary Violation Observed on Channel A Flag (vSS!BViolationA)

A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel A.

(17) FLXAnFRMBS.CEOB

Content Error Observed on Channel B Flag (vSS!ContentErrorB)

A content error was observed in the assigned slot on channel B.

(18) FLXAnFRMBS.CEOA

Content Error Observed on Channel A Flag (vSS!ContentErrorA)

A content error was observed in the assigned slot on channel A.

(19) FLXAnFRMBS.SEOB

Syntax Error Observed on Channel B Flag (vSS!SyntaxErrorB)

A syntax error was observed in the assigned slot on channel B.

(20) FLXAnFRMBS.SEOA

Syntax Error Observed on Channel A Flag (vSS!SyntaxErrorA)

A syntax error was observed in the assigned slot on channel A.

(21) FLXAnFRMBS.VFRB

Valid Frame Received on Channel B Flag (vSS!ValidFrameB)

A valid frame indication is set if a valid frame was received on channel B.

(22) FLXAnFRMBS.VFRA

Valid Frame Received on Channel A Flag (vSS!ValidFrameA)

A valid frame indication is set if a valid frame was received on channel A.

20.2.12.6 FLXAnFROBCM — FlexRay Output Buffer Command Mask Register

Configures how the Output Buffer is updated from the message buffer in the Message RAM selected by FLXAnFROBCR.OBRS.

Mask bits FLXAnFROBCM.RDSS and FLXAnFROBCM.RHSS are copied to the register internal storage when a Message RAM transfer is requested by FLXAnFROBCR.REQ.

When OBF Host and OBF Shadow are swapped, mask bits FLXAnFROBCM.RDSH and FLXAnFROBCM.RHSH are swapped with the register internal storage to keep them attached to the respective Output Buffer transfer.

The data transfer between Output Buffer and Message RAM is described in detail in **Section 20.3.12.2 (2), Data Transfer from Message RAM to Output Buffer**.

CAUTION

After the transfer of the header section from the Message RAM to OBF Shadow has completed, the message buffer status changed flag MBC of the selected message buffer in the FLXAnFRMBSC1/2/3/4 registers is cleared. After the transfer of the data section from the Message RAM to OBF Shadow has completed, the new data flag ND of the selected message buffer in the FLXAnFRNDAT1/2/3/4 registers is cleared.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0710_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RDSH	RHSH
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 20.79 FLXAnFROBCM Register Contents

Bit Position	Bit Name	Function
31 to 18	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
17	RDSH	Read Data Section Host Flag 0: Data section is not read 1: Data section selected for transfer from Message RAM to Output Buffer
16	RHSH	Read Header Section Host Flag 0: Header section is not read 1: Header section selected for transfer from Message RAM to Output Buffer
15 to 2	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
1	RDSS	Read Data Section Shadow Bit 0: Data section is not read 1: Data section selected for transfer from Message RAM to Output Buffer
0	RHSS	Read Header Section Shadow Bit 0: Header section is not read 1: Header section selected for transfer from Message RAM to Output Buffer

(1) FLXAnFROBCM.RDSH

Read Data Section Host Flag

(2) FLXAnFROBCM.RHSH

Read Header Section Host Flag

(3) FLXAnFROBCM.RDSS

Read Data Section Shadow Bit

(4) FLXAnFROBCM.RHSS

Read Header Section Shadow Bit

20.2.12.7 FLXAnFROBCR — FlexRay Output Buffer Command Request Register

After setting bit FLXAnFROBCR.REQ to 1 while FLXAnFROBCR.OBSYS is 0, FLXAnFROBCR.OBSYS is automatically set to 1, FLXAnFROBCR.OBRS is copied to the register internal storage, mask bits FLXAnFROBCM.RDSS and FLXAnFROBCM.RHSS are copied to register FLXAnFROBCM internal storage, and the transfer of the message buffer selected by FLXAnFROBCR.OBRS from the Message RAM to OBF Shadow is started. When the transfer between the Message RAM and OBF Shadow has completed, this is signaled by setting FLXAnFROBCM.OBSYS back to 0.

By setting bit FLXAnFROBCR.VIEW to 1 while FLXAnFROBCR.OBSYS is 0, OBF Host and OBF Shadow are swapped. Additionally mask bits FLXAnFROBCM.RDSH and FLXAnFROBCM.RHSH are swapped with the register FLXAnFROBCM internal storage to keep them attached to the respective Output Buffer transfer. FLXAnFROBCR.OBRH signals the number of the message buffer currently accessible by the Host.

If bits FLXAnFROBCR.REQ and FLXAnFROBCR.VIEW are set to 1 with the same write access while FLXAnFROBCR.OBSYS is 0, FLXAnFROBCR.OBSYS is automatically set to 1 and OBF Shadow and OBF Host are swapped. Additionally mask bits FLXAnFROBCM.RDSH and FLXAnFROBCM.RHSH are swapped with the registers internal storage to keep them attached to the respective Output Buffer transfer. Afterwards FLXAnFROBCR.OBRS is copied to the register internal storage, and the transfer of the selected message buffer from the Message RAM to OBF Shadow is started. While the transfer is ongoing the Host can read the message buffer transferred by the previous transfer from OBF Host. When the current transfer between Message RAM and OBF Shadow has completed, this is signaled by setting FLXAnFROBCR.OBSYS back to 0.

Any write access to FLXAnFROBCR[15:8] while FLXAnFROBCR.OBSYS is set to 1 will cause the error flag FLXAnFREIR.IOBA to be set to 1. In this case, this write access has no effect and the Output Buffer will not be changed.

The data transfer between Output Buffer and Message RAM is described in detail in **Section 20.3.12.2 (2), Data Transfer from Message RAM to Output Buffer**.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0714_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	OBRH[6:0]

Table 20.80 FLXAnFROBCR Register Contents

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
22 to 16	OBRH[6:0]	Output Buffer Request Host Flag
15	OBSYS	Output Buffer Busy Shadow Flag 0: No transfer in progress 1: Transfer between Message RAM and OBF Shadow in progress
14 to 10	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
9	REQ	Request Message RAM Transfer Bit 0: No request 1: Transfer to OBF Shadow requested
8	VIEW	View Shadow Buffer Bit 0: No action 1: Swap OBF Shadow and OBF Host
7	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
6 to 0	OBRS[6:0]	Output Buffer Request Shadow Bit

(1) FLXAnFROBCR.OBRH

Output Buffer Request Host Flag

Number of message buffer currently accessible by the Host via FLXAnFRRDHS[1…3], FLXAnFRMBS, and FLXAnFRRDDS[1…64].

By writing FLXAnFROBCR.VIEW to 1 OBF Shadow and OBF Host are swapped and the transferred message buffer is accessible by the Host.

(2) FLXAnFROBCR.OBSYS

Output Buffer Busy Shadow Flag

Set to 1 after setting bit FLXAnFROBCR.REQ. When the transfer between the Message RAM and OBF Shadow has completed, FLXAnFROBCR.OBSYS is set back to 0.

(3) FLXAnFROBCR.REQ

Request Message RAM Transfer Bit

Only writeable while FLXAnFROBCR.OBSYS = 0.

Requests transfer of message buffer addressed by FLXAnFROBCR.OBRS from Message RAM to OBF Shadow.

(4) FLXAnFROBCR.VIEW

View Shadow Buffer Bit

Only writeable while FLXAnFROBCR.OBSYS = 0.

Toggles between OBF Shadow and OBF Host.

(5) FLXAnFROBCR.OBRS

Output Buffer Request Shadow Bit

Only writeable while FLXAnFROBCR.OBSYS = 0.

Number of source message buffer to be transferred from the Message RAM to OBF Shadow.

If the number of the first message buffer of the receive FIFO is written to this register the Message Handler transfers the message buffer addressed by the GET Index (GIDX, see **Section 20.3.11, FIFO Function**) to OBF Shadow.

20.2.13 Data Transfer Control Register

20.2.13.1 FLXAnFRITC — FlexRay Input Transfer Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0800_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	ITM[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	IQEIE	IQFIE	—	—	—	—	—	—	IQHR	ITE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Table 20.81 FLXAnFRITC Register Contents

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
22 to 16	ITM[6:0]	Input queue Table Max Bit These bits configure the number of entries in the input pointer table the input buffer handler is capable to maintain in the input queue.
15 to 10	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
9	IQEIE	Input Queue Empty Interrupt Enable Bit 0: Disabled 1: Enabled
8	IQFIE	Input Queue Full Interrupt Enable Bit 0: Disabled 1: Enabled
7 to 2	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
1	IQHR	Input Queue Halt Request Bit 0: Input queue run request 1: Input queue halt request
0	ITE	Input Transfer Enable Bit 0: Operation Disable request 1: Operation Enable request

(1) FLXAnFRITC.ITM

Input queue Table Max Bit

The user can only write to this bit when FLXAnFRITS.ITS is 0.

These bits configure the number of entries in the input pointer table the input buffer handler is capable to maintain in the input queue.

Valid values are 00_H (1 queue entry) to $7F_H$ (128 queue entries).

Note that each entry requires two long words in the input pointer table.

(2) FLXAnFRITC.IQEIE

Input Queue Empty Interrupt Enable Bit

This bit controls the input queue empty interrupt.

0: Disabled
No interrupt will be requested and the input queue empty interrupt line will be released.

1: Enabled
Input queue empty interrupt will be asserted when FLXAnFRITS.IQEIS is 1.

(3) FLXAnFRITC.IQFIE

Input Queue Full Interrupt Enable Bit

This bit controls the input queue full interrupt.

0: Disabled
No interrupt will be requested and the input queue full interrupt line will be released.

1: Enabled
Input queue full interrupt will be asserted when FLXAnFRITS.IQFIS is 1.

(4) FLXAnFRITC.IQHR

Input Queue Halt Request Bit

The IQHR bit should not be set to 1 when FLXAnFRITS.ITS is 0.

This bit requests a halt of the input queue.

The status of the halt request is shown in the FLXAnFRITS.IQH register.

See **Section 20.3.16.1 (5), Halting the input queue** about usage of this bit.

0: Input queue run request
The input queue resumes their operation.

1: Input queue halt request
The input queue gets halted. An active input transfer will be completed but no further transfer request will start.

(5) FLXAnFRITC.ITE

Input Transfer Enable Bit

The user should only set this bit to 1 when FLXAnFRIBCR.IBSYS is 0.

The user should only set this bit to 0 when FLXAnFRITC.IQHR 0. Otherwise committed input transfers get lost.

This bit controls the operation mode of the input transfer queue.

The operation status of the input transfer queue function is shown in FLXAnFRITS.ITS.

See **Section 20.3.16.1 (1), Activation and deactivation** about usage of this bit.

0: Operation Disable request
The input transfer queue gets disabled when it becomes empty.

1: Operation Enable request
The input transfer queue gets enabled. Input data structures are transferred to the FlexRay internal message RAM.

20.2.13.2 FLXAnFROTC — FlexRay Output Transfer Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0804_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	FTM[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	FWIE	OWIE	FIE	OIE	—	—	—	—	—	—	OTCS	OTE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Table 20.82 FLXAnFROTC Register Contents

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
20 to 16	FTM[4:0]	FIFO Table Max Bit Configures the number of FIFO entries the output transfer handler is capable to maintain in the Local RAM/Global RAM.
15 to 12	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
11	FWIE	FIFO transfer Warning Interrupt Enable Bit 0: Disabled 1: Enabled
10	OWIE	Output transfer Warning Interrupt Enable Bit 0: Disabled 1: Enabled
9	FIE	FIFO transfer Interrupt Enable Bit 0: Disabled 1: Enabled
8	OIE	Output transfer Interrupt Enable Bit 0: Disabled 1: Enabled
7 to 2	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
1	OTCS	Output Transfer Condition Select Bit 0: New data only mode 1: New data and status changed mode
0	OTE	Output Transfer Enable Bit 0: Operation Disable request 1: Operation Enable request

(1) FLXAnFROTC.FTM

FIFO Table Max Bit

The user can only write to these bits when FLXAnFROTS.OTS is 0.

Configures the number of FIFO entries the output transfer handler is capable to maintain in the Local RAM/Global RAM.

Valid values are 00_H (1 FIFO entry) to $1F_H$ (32 FIFO entries).

(2) FLXAnFROTC.FWIE

FIFO transfer Warning Interrupt Enable Bit

This bit controls the FIFO transfer warning interrupt.

0: Disabled
No interrupt will be requested and the FIFO transfer warning interrupt line will be released.

1: Enabled
FIFO transfer warning interrupt will be asserted when FLXAnFROTS.FWIS is 1.

(3) FLXAnFROTC.OWIE

Output transfer Warning Interrupt Enable Bit

This bit controls the output transfer warning interrupt.

0: Disabled
No interrupt will be requested and the output transfer warning interrupt line will be released.

1: Enabled
Output transfer warning interrupt will be asserted when FLXAnFROTS.OWIS is 1.

(4) FLXAnFROTC.FIE

FIFO transfer Interrupt Enable Bit

This bit controls the FIFO transfer interrupt.

0: Disabled
No interrupt will be requested and the FIFO transfer interrupt line will be released.

1: Enabled
FIFO transfer interrupt will be asserted when FLXAnFROTS.FIS is 1.

(5) FLXAnFROTC.OIE

Output transfer Interrupt Enable Bit

This bit controls the output transfer interrupt.

0: Disabled
No interrupt will be requested and the output transfer interrupt line will be released.

1: Enabled
Output transfer interrupt will be asserted when FLXAnFROTS.OTIS is 1.

(6) FLXAnFROTC.OTCS

Output Transfer Condition Select Bit

The user can only write to this bit when FLXAnFROTS.OTS is 0.

This bit controls the output transfer condition.

0: New data only mode
The ND bits in the FLXAnFRNDATi registers are used to detect a transfer condition for dedicated receive buffer

1: New data and status changed mode
The ND bits in the FLXAnFRNDATi registers and the MBSC bits in the FLXAnFRMBSC register are used to detect a transfer condition for dedicated transmit and receive buffer

(7) FLXAnFROTC.OTE

Output Transfer Enable Bit

The user should only set this bit to 1 when FLXAnFROBCR.OBSYS is 0.

This bit controls the operation mode of the output transfer function.

The operation status of the output buffer transfer function is shown in FLXAnFROTS.OTS.

See **Section 20.3.16.2 (2), Output transfer data structure** about usage of this bit.

0: Operation Disable request
The output buffer transfer gets disabled.
An active message buffer transfer will be completed but no further transfer will start.

1: Operation Enable request
The output buffer transfer gets enabled. Message buffers are transferred from the FlexRay internal message RAM to output data structures.

The user should not change the E-Ray message RAM configuration by writing to the FLXAnFRMRC register.

20.2.13.3 FLXAnFRIBA — FlexRay Input Pointer Table Base Address Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0808_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ITA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ITA[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Table 20.83 FLXAnFRIBA Register Contents

Bit Position	Bit Name	Function
31 to 0	ITA[31:0]	Input Table Address Bit These bits configure the base address of the input pointer table.

(1) FLXAnFRIBA.ITA

Input Table Address Bit

The user can only write to this bit when FLXAnFRITS.ITS is 0.

The address should be 32 bit aligned, thus the bits FLXAnFRIBA.ITA[1:0] are always 0.

These bits configure the base address of the input pointer table.

The table is used for the input transfer queue transferring message buffers from the Local RAM/Global RAM into the FlexRay internal message RAM.

The size of the input queue is configured in FLXAnFRITC.ITM.

Note that each entry requires two long words in the input pointer table.

20.2.13.4 FLXAnFRFBA — FlexRay FIFO Pointer Table Base Address Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $080C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FTA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FTA[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Table 20.84 FLXAnFRFBA Register Contents

Bit Position	Bit Name	Function
31 to 0	FTA[31:0]	FIFO pointer Table Address Bit These bits configure the base address of the FIFO pointer table.

(1) FLXAnFRFBA.FTA

FIFO pointer Table Address Bit

The user can only write to this bit when FLXAnFROTS.OTS is 0.

The address should be 32 bit aligned, thus the bits FLXAnFRFBA.FTA[1:0] are always 0.

These bits configure the base address of the FIFO pointer table.

The table is used for message buffers transferred from the FlexRay internal FIFO to the Local RAM/ Global RAM.

The size of the FIFO is configured in FLXAnFROTC.FTM.

20.2.13.5 FLXAnFROBA — FlexRay Output Pointer Table Base Address Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0810_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OTA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

	OTA[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Table 20.85 FLXAnFROBA Register Contents

Bit Position	Bit Name	Function
31 to 0	OTA[31:0]	Output pointer Table Address Bit These bits configure the base address of the output pointer table.

(1) FLXAnFROBA.OTA

Output pointer Table Address Bit

The user can only write to this bit when FLXAnFROTS.OTS is 0.

The address should be 32 bit aligned, thus the bits FLXAnFROBA.OTA[1:0] are always 0.

These bits configure the base address of the output pointer table.

The table is used for message buffers transferred from the FlexRay internal message RAM to the Local RAM/Global RAM.

The size of the table depends on the utilization of the FlexRay internal message RAM and can have up to 128 entries.

20.2.13.6 FLXAnFRIQC — FlexRay Input Queue Control Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0814_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	IMBNR[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W

Table 20.86 FLXAnFRIQC Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
6 to 0	IMBNR[6:0]	Input Message Buffer NumbeR Bit Message buffer number added to the input queue

(1) FLXAnFRIQC.IMBNR

Input Message Buffer NumbeR Bit

The user can only write to this bit when FLXAnFRITS.IQFP is 0.

The user should not write to this register when FLXAnFRITS.ITS is 0 or when FLXAnFRITC.ITE is 0.

These bits are read as 0.

This value specifies the message buffer added to the input queue.

The number has to be identical to FLXAnFRWRHS4.IMBNR (see **Section 20.3.16.1 (3), Input pointer table**) of the input pointer table.

The address to the input data structure has to be provided in the input pointer table at the put index (FLXAnFRITS.IPIDX) before writing to this register.

Writing to this register increments the input put index (FLXAnFRITS.IPIDX).

20.2.13.7 FLXAnFRUIR — FlexRay User Input Transfer Request Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0818_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	UIDX[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.87 FLXAnFRUIR Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
7 to 0	UIDX[7:0]	User requested Input inDeX Bit Input pointer table index requested for input transfer

(1) FLXAnFRUIR.UIDX

User requested Input inDeX Bit

The user can only write to this bit when FLXAnFRITS.UIRP is 0.

The user should not write to this register when FLXAnFRITS.ITS is 0.

The user should not write to this register when FLXAnFRITS.UIRP is 1.

The user should not write to this register when FLXAnFRITS.IQH is 1.

The user should only write FLXAnFRITC.ITM + 1 to this register.

This value specifies the input pointer table index for the user requested input transfer.

The address to the input data structure has to be provided in the input pointer table at the index UIDX before writing to this register.

When writing to this register, the requested input data structure will be transferred from input data structure position to the FlexRay internal message RAM.

In opposite to queued input transfers the related DA flag in the FLXAnFRDA register is not influenced by the user input transfer.

20.2.13.8 FLXAnFRUOR — FlexRay User Output Transfer Request Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $081C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	URDS	—	—	UMBNR[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.88 FLXAnFRUOR Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
9	URDS	User request Read Data Section Bit 0: Data section is not transferred 1: Data section is transferred
8, 7	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
6 to 0	UMBNR[6:0]	User requested output Message Buffer NumbeR Bit Message buffer number requested for output transfer

(1) FLXAnFRUOR.URDS

User request Read Data Section Bit

The user can only write to this bit when FLXAnFROTS.UORP is 0.

The user should not write to this register when FLXAnFROTS.OTS is 0.

The user should not write to this register when FLXAnFROTS.UORP is 1.

0: Data section is not transferred
The data section of the message buffer selected by the bits UMBNR is not requested

1: Data section is transferred
The data section of the message buffer selected by the bits UMBNR is requested

(2) FLXAnFRUOR.UMBNR

User requested output Message Buffer NumbeR Bit

The user can only write to this bit when FLXAnFROTS.UORP is 0.

The user should not write to this register when FLXAnFROTS.OTS is 0.

The user should not write to this register when FLXAnFROTS.UORP is 1.

The user should restrict UMBNR to dedicated receive and transmit buffers when the FlexRay module is not in the CONFIG state.

When writing to this register, the header sections and optionally the data section (configurable by URDS) of the requested message buffer will be transferred from the FlexRay internal message RAM to the output data structure position defined by the output structure data pointer in the output pointer table.

20.2.14 Data Transfer Status Register

20.2.14.1 FLXAnFRITS — FlexRay Input Transfer Status Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0820_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	IGIDX[6:0]							—	IPIDX[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	IQFP	—	—	IQEIS	IQFIS	—	—	—	—	—	UIRP	IQH	ITS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Table 20.89 FLXAnFRITS Register Contents

Bit Position	Bit Name	Function
31	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
30 to 24	IGIDX[6:0]	Input queue Get InDeX Bit Represents the get index of the input pointer table
23	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
22 to 16	IPIDX[6:0]	Input queue Put InDeX Bit Represents the put index of the input pointer table
15 to 13	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
12	IQFP	Input Queue Full condition Pending Bit 0: Entries in the input queue are available 1: All entries in the input queue are occupied
11, 10	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
9	IQEIS	Input Queue Empty Interrupt Status Bit 0: No input queue empty condition detected 1: Input queue empty condition detected
8	IQFIS	Input Queue Full Interrupt Status Bit 0: No input queue full condition detected 1: Input queue full condition detected
7 to 3	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
2	UIRP	User Input transfer Request Pending Bit 0: No user input transfer request pending 1: User input transfer request pending
1	IQH	Input Queue Halted Bit 0: Input queue not halted 1: Input queue halted
0	ITS	Input Transfer Status Bit 0: Disabled 1: Enabled

(1) FLXAnFRITS.IGIDX

Input queue Get InDeX Bit

These bits are only valid when FLXAnFRITS.IQH is 1

These bits represent the input pointer index the input queue handler will transfer next.

Valid values are 00_H to FLXAnFRITC.ITM.

The get index is incremented when the input data structure has been transferred from the Local RAM/ Global RAM and the related DA flag in the FLXAnFRDA register is cleared.

The index is set to 00_H when FLXAnFRITS.ITS changes from 0 to 1.

(2) FLXAnFRITS.IPIDX

Input queue Put InDeX Bit

These bits represent the index where the next input data structure pointer in the input pointer table should be stored.

Valid values are 00_H to FLXAnFRITC.ITM.

After reaching the maximum value the put index continues from 00_H.

The index is incremented when writing to FLXAnFRIQC.IMBNR.

The index is set to 00_H when FLXAnFRITS.ITS changes from 0 to 1.

(3) FLXAnFRITS.IQFP

Input Queue Full condition Pending Bit

This bit represents that the input queue is full.

There should be no further input transfer requests, by writing to FLXAnFRIQC.IMBNR, as long as FLXAnFRITS.IQFP is 1.

[Clearing condition]

This bit is cleared when there is one free entry in the input queue.

[Setting condition]

This bit is set when all entries in the input queue are occupied.

(4) FLXAnFRITS.IQEIS

Input Queue Empty Interrupt Status Bit

Writing 0 has no effect on the bit value.

If enabled in FLXAnFRITC.IQEIE the input queue empty interrupt is generated when FLXAnFRITS.IQEIS is 1.

[Clearing condition]

This bit is cleared when writing a 1 to FLXAnFRITS.IQEIS.
This bit is cleared when FLXAnFRITS.ITS changes from 0 to 1.

[Setting condition]

This bit is set when all pending input transfers have been processed and consequently the input queue becomes empty.

(5) FLXAnFRITS.IQFIS

Input Queue Full Interrupt Status Bit

Writing 0 has no effect on the bit value.

If enabled in FLXAnFRITC.IQFIE the input queue full interrupt is generated when FLXAnFRITS.IQFIS is 1.

This flag is intended as interrupt status flag. It does not represent the current input queue status; for this status see FLXAnFRITS.IQFP.

[Clearing condition]

This bit is cleared when writing a 1 to FLXAnFRITS.IQFIS.

This bit is cleared when FLXAnFRITS.ITS changes from 0 to 1.

[Setting condition]

This bit is set when all entries in the input queue are occupied.

(6) FLXAnFRITS.UIRP

User Input transfer Request Pending Bit

This bit represents that a user input transfer is still pending.

There should be no further write access to FLXAnFRUIR.UIDX when this bit is 1.

[Clearing condition]

This bit is cleared when the user input transfer request is processed by the input transfer handler.

[Setting condition]

This bit is set when writing to FLXAnFRUIR.UIDX.

(7) FLXAnFRITS.IQH

Input Queue Halted Bit

This bit represents the status of the input queue.

There should be no further write access to FLXAnFRUIR.UIDX when this bit is 1.

[Clearing condition]

This bit is cleared when FLXAnFRITC.IQHR is set to 0.

[Setting condition]

This bit is set immediately when the FLXAnFRITC.IQHR is set to 1 and there is no ongoing input transfer.
This bit is set only after an ongoing input transfer has been completed and FLXAnFRITC.IQHR is set to 1.

(8) FLXAnFRITS.ITS

Input Transfer Status Bit

This bit represents the status of the input queue handler.

While this bit is 1, there should be no read or write access to the address area <FLXn_base> + 0400_H to <FLXn_base> + $05FF_H$ and there should be no CLEAR_RAMS command applied to FLXAnFRSUCC1.CMD register.

The input transfer queue indexes and related status flags are set to 0 when FLXAnFRITS.ITS changes from 0 to 1.

[Clearing condition]

This bit is cleared immediately when FLXAnFRITC.ITE is set to 0 and there are no pending input transfers

This bit is cleared after all pending requests have been processed and FLXAnFRITC.ITE is 0.

[Setting condition]

This bit is set when FLXAnFRITC.ITE is set to 1.

20.2.14.2 FLXAnFROTS — FlexRay Output Transfer Status Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0824_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	FFL[5:0]						—	—	—	FGIDX[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FWP	OWP	FDA	—	FWS	OWS	FIS	OTIS	—	—	—	—	—	UORP	—	OTS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Table 20.90 FLXAnFROTS Register Contents (1/2)

Bit Position	Bit Name	Function
31, 30	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
29 to 24	FFL[5:0]	FIFO Fill Level Bit Represent the number of unprocessed output FIFO structures
23 to 21	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
20 to 16	FGIDX[4:0]	FIFO Get InDeX Bit Represent the get index in the FIFO pointer table
15	FWP	FIFO transfer Warning condition Pending Bit 0: No FIFO transfer warning condition pending 1: FIFO transfer warning condition pending
14	OWP	Output transfer Warning condition Pending 0: No output transfer warning condition pending 1: Output transfer warning condition pending
13	FDA	FIFO Data Available Bit 0: No available FIFO structures 1: FIFO structures available at current FLXAnFROTS.FGIDX index
12	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
11	FWIS	FIFO transfer Warning Interrupt Status Bit 0: No FIFO transfer warning condition detected 1: FIFO transfer warning condition detected
10	OWIS	Output transfer Warning Interrupt Status Bit 0: No output transfer warning condition detected 1: Output transfer warning condition detected
9	FIS	FIFO transfer Interrupt Status Bit 0: No FIFO structure updated in Local RAM/Global RAM 1: FIFO structure updated in Local RAM/Global RAM
8	OTIS	Output transfer Interrupt Status Bit 0: No output structure updated in Local RAM/Global RAM 1: Output structure updated in Local RAM/Global RAM
7 to 3	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.

Table 20.90 FLXAnFROTS Register Contents (2/2)

Bit Position	Bit Name	Function
2	UORP	User Output transfer Request Pending Bit 0: No user output transfer request pending 1: User output transfer request pending
1	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
0	OTS	Output Transfer Status Bit 0: Disabled 1: Enabled

(1) FLXAnFROTS.FFL

FIFO Fill Level Bit

These bits represent the number of available output FIFO structures in the Local RAM/Global RAM.

Valid values are 00_H to FLXAnFROTC.FTM + 1.

The value 00_H represents that the FIFO is empty.

The value FLXAnFROTC.FTM + 1 represents that the FIFO is full and no further FIFO transfers will be done.

The FIFO fill level is incremented when a FIFO data structure has been transferred from the FlexRay internal FIFO into the Local RAM/Global RAM.

The FIFO fill level is decremented when the user releases a FIFO data structure in the Local RAM/ Global RAM by writing 1 to FLXAnFROTS.FDA.

The FIFO fill level is set to 00_H when the bit FLXAnFROTS.OTS changes from 0 to 1.

(2) FLXAnFROTS.FGIDX

FIFO Get InDeX Bit

These bits represent the index where the current output data structure pointer in the FIFO pointer table is available for reading.

Valid values are 00_H to FLXAnFROTC.FTM.

After reaching the maximum value the get index continues from 00_H.

The index is incremented when a FIFO data structure is released by writing 1 to FLXAnFROTS.FDA.

The index is set to 00_H when FLXAnFROTS.OTS changes from 0 to 1.

(3) FLXAnFROTS.FWP

FIFO transfer Warning condition Pending Bit

This bit represents the FIFO transfer warning condition.

[Clearing condition]

This bit is cleared when there are free output data structures (FLXAnFROTS.FFL <= FLXAnFROTC.FTM).

This bit is cleared when the FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

This bit is set when the output transfer handler detects a transfer condition for FIFO message buffers but there are no free output data structures (FLXAnFROTS.FFL = FLXAnFROTC.FTM + 1).

(4) FLXAnFROTS.OWP

Output transfer Warning condition Pending Bit

This bit represents the output transfer warning condition.

[Clearing condition]

This bit is cleared, when all output structure pointers that have a pending output handler transfer condition detected, are released (for dedicated transmit and receive message buffers or a user output transfer request).

[Setting condition]

This bit is set when the output transfer handler detects a transfer condition (for dedicated transmit and receive message buffers or a user output transfer request) but the related output structure pointer was not yet released by the application (data available flag is still set to 1).

This bit is set when the output transfer handler detects a transfer condition for dedicated transmit and receive message buffers but there is a pending input transfer for the same message buffer (data available flag is set to 1 due to the input transfer request).

(5) FLXAnFROTS.FDA

FIFO Data Available Bit

Writing 0 has no effect on the bit value.

When this bit is 1, the next valid output data structure is available.

The related data structure pointer is in the FIFO pointer table at FLXAnFROTS.FGIDX.

Writing 1 to FLXAnFROTS.FDA

- increments FLXAnFROTS.FGIDX and
- decrements the FIFO fill level (FLXAnFROTS.FFL)

If there are still unprocessed data structures FLXAnFROTS.FDA remains 1.

[Clearing condition]

This bit is cleared when writing 1 to FLXAnFROTS.FDA and the FIFO fill level becomes 00_H.

This bit is cleared when the FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

This bit is set when there is at least one FIFO data structure available in the Local RAM/Global RAM.

(6) FLXAnFROTS.FWIS

FIFO transfer Warning Interrupt Status Bit

Writing 0 has no effect on the bit value.

If enabled in FLXAnFROTC.FWIE the FIFO transfer warning interrupt is generated when FLXAnFROTS.FWIS is 1.

[Clearing condition]

This bit is cleared when writing a 1 to FLXAnFROTS.FWIS.

This bit is cleared when the bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

This bit is set when the output transfer handler detects a transfer condition for FIFO message buffers but there are no free output data structures (FLXAnFROTS.FFL = FLXAnFROTC.FTM + 1).

(7) FLXAnFROTS.OWIS

Output transfer Warning Interrupt Status Bit

Writing 0 has no effect on the bit value.

If enabled in FLXAnFROTC.OWIE the FIFO transfer warning interrupt is generated when FLXAnFROTS.OWIS is 1.

[Clearing condition]

This bit is cleared when writing a 1 to FLXAnFROTS.OWIS.

This bit is cleared when the bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

This bit is set when the output transfer handler detects a transfer condition (for dedicated transmit and receive message buffers or a user output transfer request) but the related output structure pointer was not yet released by the application (data available flag is still set to 1).

This bit is set when the output transfer handler detects a transfer condition for dedicated transmit and receive message buffers but there is a pending input transfer for the same message buffer (data available flag is set to 1 due to the input transfer request).

(8) FLXAnFROTS.FIS

FIFO transfer Interrupt Status Bit

Writing 0 has no effect on the bit value.

If enabled in FLXAnFROTC.FIE the FIFO transfer interrupt is generated when FLXAnFROTS.FIS is 1.

[Clearing condition]

This bit is cleared when writing a 1 to FLXAnFROTS.FIS.

This bit is cleared when the bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

This bit is set when a FIFO data structure is updated by the transfer handler or the FFL bit changes from 00_H to 01_H.

(9) FLXAnFROTS.OTIS

Output transfer Interrupt Status Bit

Writing 0 has no effect on the bit value.

If enabled in FLXAnFROTC.OIE the output transfer interrupt is generated when FLXAnFROTS.OTIS is 1.

[Clearing condition]

This bit is cleared when writing a 1 to FLXAnFROTS.OTIS.
This bit is cleared when the bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

This bit is set when an output data structure is updated by the transfer handler (from a dedicated transmit or receive message buffer or by a user output transfer request).

(10) FLXAnFROTS.UORP

User Output transfer Request Pending Bit

This bit represents that a user output transfer is still pending.

There should be no further write access to FLXAnFRUOR.UMBNR when this bit is 1.

[Clearing condition]

This bit is cleared when the user output transfer request is processed by the output transfer handler.

This bit is cleared when the bit FLXAnFROTS.OTS changes from 0 to 1.

[Setting condition]

This bit is set when writing to FLXAnFRUOR.UMBNR.

(11) FLXAnFROTS.OTS

Output Transfer Status Bit

This bit represents the status of the output transfer handler.

While this bit is 1, there should be no read or write access to the address area <FLXn_base> + 0600_H to <FLXn_base> + $07FF_H$ and there should be no CLEAR_RAMS command applied to FLXAnFRSUCC1.CMD register.

While this bit is 1, the user should not change the E-Ray message RAM configuration by writing to the FLXAnFRMRC register.

The output hander transfer indexes and related status flags are set to 0 when FLXAnFROTS.OTS changes from 0 to 1.

[Clearing condition]

This bit is cleared immediately when FLXAnFROTC.OTE is set to 0 and there are no ongoing output transfers.

This bit is cleared after an ongoing transfer has been completed and FLXAnFROTC.OTE is 0.

[Setting condition]

This bit is set when FLXAnFROTC.OTE is set to 1.

20.2.14.3 FLXAnFRAES — FlexRay Access Error Status Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0828_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	MAE	FAE	OAE	IAE	EIDX[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Table 20.91 FLXAnFRAES Register Contents

Bit Position	Bit Name	Function
31 to 12	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
11	MAE	Multiple Access Errors Bit 0: No multiple access errors occurred 1: Multiple access errors occurred
10	FAE	FIFO transfer Access Error Bit 0: No access error occurred during FIFO transfer 1: Access error occurred during FIFO transfer
9	OAE	Output transfer Access Error Bit 0: No access error occurred during output transfer 1: Access error occurred during output transfer
8	IAE	Input transfer Access Error Bit 0: No access error occurred during input transfer 1: Access error occurred during input transfer
7 to 0	EIDX[7:0]	Error InDeX Bit Data structure pointer index number

(1) FLXAnFRAES.MAE

Multiple Access Errors Bit

Writing 0 has no effect on the bit value.

This bit represents that there were multiple access errors during a data transfer.

[Clearing condition]

This bit is cleared when writing a 1 to FLXAnFRAES.MAE.

[Setting condition]

This bit is set when one of the bits FLXAnFRAES.FAE, FLXAnFRAES.OAE or FLXAnFRAES.IAE are set and

- an access to a protected address occurred during a FIFO data transfer or
- an access to a protected address occurred during an output data transfer or
- an access to a protected address occurred during an input data transfer

(2) FLXAnFRAES.FAE

FIFO transfer Access Error Bit

Writing 0 has no effect on the bit value.

This bit represents that there was an access error during a FIFO data transfer.

[Clearing condition]

This bit is cleared when writing a 1 to FLXAnFRAES.FAE.

[Setting condition]

This bit is set when a Local RAM/Global RAM access error was detected during a FIFO transfer and the bits FLXAnFRAES.OAE, FLXAnFRAES.IAE and FLXAnFRAES.MAE are 0.

(3) FLXAnFRAES.OAE

Output transfer Access Error Bit

Writing 0 has no effect on the bit value.

This bit represents that there was an access error during an output data transfer.

[Clearing condition]

This bit is cleared when writing a 1 to FLXAnFRAES.OAE.

[Setting condition]

This bit is set when a Local RAM/Global RAM access error was detected during an output transfer and the bits FLXAnFRAES.FAE, FLXAnFRAES.IAE and FLXAnFRAES.MAE are 0.

(4) FLXAnFRAES.IAE

Input transfer Access Error Bit

Writing 0 has no effect on the bit value.

This bit represents that there was an access error during an input data transfer.

[Clearing condition]

This bit is cleared when writing a 1 to FLXAnFRAES.IAE.

[Setting condition]

This bit is set when a Local RAM/Global RAM access error was detected during an output transfer and the bits FLXAnFRAES.OAE, FLXAnFRAES.FAE and FLXAnFRAES.MAE are 0.

(5) FLXAnFRAES.EIDX

Error InDeX Bit

This value is only valid when one of the bits FLXAnFRAES.FAE, FLXAnFRAES.OAE or FLXAnFRAES.IAE is 1.

When the bit FLXAnFRAES.FAE is 1, FLXAnFRAES.EIDX holds the used FIFO put index when the access error has occurred.

When the bit FLXAnFRAES.OAE is '1', FLXAnFRAES.EIDX holds the used output table entry (which is related to message buffer number) when the access error has occurred.

When the bit FLXAnFRAES.IAE is '1', FLXAnFRAES.EIDX holds the used input pointer table get index when the access error has occurred during the input transfer or user requested input transfer.

These bits are updated when one of the bits FLXAnFRAES.FAE, FLXAnFRAES.OAE or FLXAnFRAES.IAE is changing from 0 to 1.

20.2.14.4 FLXAnFRAEA — FlexRay Access Error Address Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + $082C_H$

Value after reset: $0000\ 0000_H$

Table 20.92 FLXAnFRAEA Register Contents

Bit Position	Bit Name	Function
31 to 0	AEA[31:0]	Access Error Address Bit Address in the Local RAM/Global RAM when an access error has occurred

(1) FLXAnFRAEA.AEA

Access Error Address Bit

This value is only valid when one of the bits FLXAnFRAES.FAE, FLXAnFRAES.OAE or FLXAnFRAES.IAE is 1.

These bits represent the address of the access error indicated in the FLXAnFRAES register.

These bits are updated when one of the bits FLXAnFRAES.FAE, FLXAnFRAES.OAE or FLXAnFRAES.IAE is changing from 0 to 1.

20.2.14.5 FLXAnFRDAi — FlexRay message Data Available Register i (i = 0 to 3)

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: <FLXn_base> + 0830_H to <FLXn_base> + $083C_H$ (<FLXn_base> + 0830_H + i*4)

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 20.93 FLXAnFRDAi Register Contents

Bit Position	Bit Name	Function
31 to 0	DAb[31:0]	Data Available Bit 0: No data available for destination 1: Data available for destination

(1) FLXAnFRDAi.DAb (b = i*32 to ((i+1)*32) –1)

Data Available Bit b

The user should not write a 1 to bits that are 0.

To maintain the status of input transfers, the user should not clear bits related to input transfers.

This register is used for input and output transfers.

Each flag corresponds to a FlexRay message buffer.

[Clearing condition]

Input transfer:
This bit is cleared when the input data structure has been transferred from the Local RAM/Global RAM. The data structure and the data structure pointer can be changed when the related flag is 0.

Output transfer:
This bit is cleared when writing a 1 to it.

[Setting condition]

Input transfer:
This bit is set when the corresponding message buffer number has been written to FLXAnFRIQC.IMBNR.

As long as this bit is 1, the input data structure and the data structure pointer corresponding to this input transfer request should not be changed.

Output transfer:

This bit is set when the output data structure corresponding to this message buffer has been updated. As long as this bit is 1, the data structure is stable; no further update of the data structure will be done by the output handler. While this bit is 1, the application is allowed to change the output data structure pointer in the output pointer table for this message buffer number.

20.2.15 NTU loss monitor register

20.2.15.1 NTU0RST — NTU loss monitor reset register

Access: This register can be read/written in 32-bit units.

Address: FFF9 CC00$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	NTUCRST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Table 20.94 NTU0RST Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
0	NTUCRST	NTU reset 0: No function 1: Reset the NTU operation

(1) NTU0RST.NTUCRST

NTU loss monitor reset

Setting this bit resets the NTU operation. This bit always returns 0 when it is read.

20.2.15.2 NTU0CFG — NTU configuration register

Access: This register can be read/written in 32-bit units.

Address: FFF9 CC04$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R/W	R/W

Table 20.95 NTU0CFG Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
7	CLKSEL	NTU Output Clock Select 0: NTU signal is output 1: Backup clock is output
6 to 2	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
1, 0	NTUSEL[1:0]	NTU Input Signal Select 00: FLXA0 macro tick signal is input to NTU (MT0) 01: FLXA0 cycle tick signal is input to NTU (CS0) 10: FLXA1 macro tick signal is input to NTU (MT1) 11: FLXA1 cycle tick signal is input to NTU (CS1)

(1) NTU0CFG.CLKSEL

NTU output clock select.

This bit is used to select between NTU clock signal and Backup clock signal as the output of NTU. After detection of the NTU loss signal, the application has to switch the NTU output clock using this bit.

(2) NTU0CFG.NTUSEL

NTU input clock select.

This bit is used to select between macro tick clock signal and cycle tick clock signal as the monitored input of NTU. Additionally it can be selected if FlexRay macro 0 or 1 should be used as a source.

NOTE

Not all devices are equipped with two FlexRay macros. In case only one macro is available, please do not set the NTUSEL[1:0] bits to “10” or “11”.

20.2.15.3 NTU0CLMEN — NTU enable register

Access: This register can be read/written in 32-bit units.

Address: FFF9 CC08$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	NTUCEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 20.96 NTU0CLMEN Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
0	NTUCEN	NTU Enable 0: Disable NTU operation 1: Enable NTU operation

(1) NTU0CLMEN.NTUCEN

NTU enable bit.

This bit is used to enable or disable NTU operation.

20.2.15.4 NTU0MON — NTU status register

Access: This register can be read in 32-bit units.

Address: FFF9 CC0C$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	NTUMON	NTUCMON
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 20.97 NTU0MON Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
1	NTUMON	NTU Monitor Status 0: Monitored NTU input is lost 1: Monitored NTU input is correct
0	NTUCMON	NTU Status 0: NTU does not operate 1: NTU is operating

(1) NTU0MON.NTUMON

NTU monitor status bit.

This bit shows the status of the monitored input signal.

(2) NTU0MON.NTUCMON

NTU status bit.

This bit shows the status of the NTU operation.

20.2.15.5 NTU0PRSCTL — NTU prescaler control register

Access: This register can be read/written in 8-bit units.

Address: FFF9 C008$_H$

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	NPRSCE	—	—	NPRSCCS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R	R	R/W	R/W

Table 20.98 NTU0PRSCTL Register Contents

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
4	NPRSCE	NTU Prescaler Enable 0: Disables NTU prescaler 1: Enables NTU prescaler
3, 2	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
0	NPRSCCS[1:0]	NTU Prescaler Selection 00: Prescaler counter clock is CLKP_H1 01: Prescaler counter clock is CLKP_H1/2 10: Prescaler counter clock is CLKP_H1/4 11: Prescaler counter clock is CLKP_H1/8

(1) NTU0NPRSCTL.NPRSCE

NTU prescaler enable bit.

This bit enables the NTU prescaler (NPRS). See **Figure 20.33**.

(2) NTU0NPRSCTL.NPRSCCS

NTU prescaler selection bits.

These bits set the scaling factor of the input clock (CLKP_H1).

20.2.15.6 NTU0PRSCMP — NTU prescaler compare register

Access: This register can be read/written in 8-bit units.

Address: FFF9 C00C$_H$

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	NPRSCMP[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.99 NTU0PRSCMP Register Contents

Bit Position	Bit Name	Function
7 to 0	NPRSCMP[7:0]	NTU Prescaler Compare Value Compare match value of the NTU prescaler counter

(1) NTU0PRSCMP.NPRSCMP

NTU prescaler compare match value bits.

These bits set the NTU prescaler output clock period according to the equation below:

Prescaler_output_clock_period = NPRS_counter_clock / (2 * NPRSCMP)

NPRS_counter_clock is selected using the NTU0PRSCTL register.

20.2.15.7 NTU0CCTL0 — NTU compare unit control register

Access: This register can be read/written in 8-bit units.

Address: FFF9 C800$_H$

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	NTUCCMPE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 20.100 NTU0CCTL0 Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
0	NTUCCMPE	NTU Compare Unit Enable 0: Disable NTU compare unit operation 1: Enable NTU compare unit operation

(1) NTU0CCTL0.NTUCCMPE

NTU compare unit enable bit.

This bit is used to enable or disable NTU compare unit operation.

20.2.15.8 NTU0CCMPH — NTU compare unit threshold register H

Access: This register can be read/written in 16-bit units.

Address: FFF9 C80C$_H$

Value after reset: 03FF$_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	NTUCCMPH[11:0]											
Value after reset	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.101 NTU0CCMPH Register Contents

Bit Position	Bit Name	Function
15 to 12	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
11 to 0	NTUCCMPH [11:0]	Compare Unit Upper Threshold Sets the upper threshold value of the compare unit

(1) NTU0CCMPH.NTUCCMPH[11:0]

NTU compare unit upper threshold value.

The value set in these bits is used as the upper threshold value for the compare unit. The compare unit counter is counting up using the Base clock (see **Figure 20.33**). Additionally the NTU ticks are counted. If the amount of the NTU ticks fits into the window set by the NTU0CCMPH and NTU0CCMPL registers, the NTU loss is not detected. If the amount of NTU ticks is lower than NTUCCMPL register value, or higher than NTU0CCMPH register value the NTU loss is detected and it will be signalled to the application by an interrupt. The output clock signal has to be switched to the Backup clock by the application. See **Figure 20.33**.

Setting range: 004$_H$ to FFF$_H$

The setting value must be higher than NTU0CCMPL + 003$_H$.

20.2.15.9 NTU0CCMPL — NTU compare unit threshold register L

Access: This register can be read/written in 16-bit units.

Address: FFF9 C808$_H$

Value after reset: 0001$_H$

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	NTUCCMPL[11:0]											
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.102 NTU0CCMPL Register Contents

Bit Position	Bit Name	Function
15 to 12	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
11 to 0	NTUCCMPL [11:0]	Compare Unit Upper Threshold Sets the upper threshold value of the compare unit

(1) NTU0CCMPL.NTUCCMPL[11:0]

NTU compare unit lower threshold value.

The value set in these bits is used as the upper threshold value for the compare unit. The compare unit counter is counting up using the Base clock (see **Figure 20.33**). Additionally the NTU ticks are counted. If the amount of the NTU ticks fits into the window set by the NTU0CCMPH and NTU0CCMPL registers, the NTU loss is not detected. If the amount of NTU ticks is lower than NTUCCMPL register value, or higher than NTU0CCMPH register value the NTU loss is detected and it will be signalled to the application by an interrupt. The output clock signal has to be switched to the Backup clock by the application. See **Figure 20.33**.

Setting range: 001$_H$ to FFC$_H$

The setting value must be higher than NTU0CCMPL + 0x003$_H$.

20.2.15.10NTU0CPCMD — NTU compare unit protection command register.

Access: This register can be written in 8-bit units.

Address: FFF9 C810$_H$

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	NTUCREG[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W

Table 20.103 NTU0PCMD Register Contents

Bit Position	Bit Name	Function
7 to 0	NTUCREG[7:0]	NTU Compare Unit Protection Command Protection command– A5$_H$

(1) NTU0CPCMD.NTUCREG

NTU compare unit protection command bits.

Accessing NTU protected registers is allowed when protection sequence using the NTU0CPCMD register has been done. The protection sequence flow is shown below:

- Write A5$_H$ value to the NTU0CPCMD register
- Write required value to the protected register (example: 01$_H$ to NTU0CCTL0)
- Write inverted value to the protected register (FE$_H$ to NTU0CCTL0)
- Write again required value to the protected register (01$_H$ to NTU0CCTL0)

20.2.15.11NTU0CPS — NTU compare unit protection status register

Access: This register can be read in 8-bit units.

Address: FFF9 C814$_H$

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	NTUCPRERR
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 20.104 NTU0CPS Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
0	NTUCPRERR	NTU Compare Unit Protection Status 0: Protection error did not occur 1: Protection error occurred

(1) NTU0CPS.NTUCPRERR

NTU compare unit protection status bits.

When a protected register has been accessed and the protection sequence has been broken, or not executed fully, an error is signalled by setting this bit to “1”.

20.2.15.12NTU0CPRSCTL — NTU compare unit prescaler setting register.

Access: This register can be read/written in 8-bit units.

Address: FFF9 C208$_H$

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	NCPRSCE	—	—	NCPRSCCS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R	R	R/W	R/W

Table 20.105 NTU0CPRSCTL Register Contents

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
4	NCPRSCE	NTU Compare Unit Prescaler Enable 0: Disables NTU compare unit prescaler 1: Enables NTU compare unit prescaler
3, 2	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
1, 0	NCPRSCCS [1:0]	NTU Compare Unit Prescaler Selection 00: Prescaler counter clock is output of NPRS 01: Prescaler counter clock is output of NPRS/2 10: Prescaler counter clock is output of NPRS/4 11: Prescaler counter clock is output of NPRS/8

(1) NTU0CPRSCTL.NCPRSCE

NTU compare unit prescaler enable bit.

This bit enables the NTU compare unit prescaler (NCPRS). See **Figure 20.33**

(2) NTU0CPRSCTL.NCPRSCCS

NTU compare unit prescaler selection bits.

These bits set the scaling factor of the input clock (NPRS output).

20.2.15.13NTU0CPRSCMP — NTU compare unit prescaler compare register

Access: This register can be read/written in 8-bit units.

Address: $FFF9C20C_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	NCPRSCMP[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.106 NTU0CPRSCMP Register Contents

Bit Position	Bit Name	Function
7 to 0	NCPRSCMP [7:0]	NTU Compare Unit Prescaler Compare Value Compare match value of the NTU compare unit counter

(1) NTU0CPRSCMP.NCPRSCMP

NTU compare unit prescaler compare match value bits.

These bits set the NTU compare unit prescaler output clock period according to the equation below:

Compare_Unit_Prescaler_output_clock_period = NCPRS_counter_clock / (2 * NCPRSCMP)

NCPRS_counter_clock is selected using the NTU0CPRSCTL register.

20.2.15.14NTU0BPRSCTL — NTU backup clock prescaler setting register

Access: This register can be read/written in 8-bit units.

Address: FFF9 C108$_H$

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	—	—	—	NBPRSCE	—	—	NBPRSCCS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R	R	R/W	R/W

Table 20.107 NTU0BPRSCTL Register Contents

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
4	NBPRSCE	NTU Backup Clock Prescaler Enable 0: Disables NTU backup clock prescaler 1: Enables NTU backup clock prescaler
3, 2	Reserved	When read, the value after reset always is read. When writing, always write the value after reset.
1, 0	NBPRSCCS[1:0]	NTU Backup Clock Prescaler Selection 00: Prescaler counter clock is output of NPRS 01: Prescaler counter clock is output of NPRS/2 10: Prescaler counter clock is output of NPRS/4 11: Prescaler counter clock is output of NPRS/8

(1) NTU0BPRSCTL.NBPRSCE

NTU backup clock prescaler enable bit.

This bit enables the NTU backup clock prescaler (NBPRS). See **Figure 20.33**.

(2) NTU0BPRSCTL.NBPRSCCS

NTU backup clock prescaler selection bits.

These bits set the scaling factor of the input clock (NPRS output).

20.2.15.15NTU0BPRSCMP — NTU backup clock prescaler compare register

Access: This register can be read/written in 8-bit units.

Address: FFF9 C10C$_H$

Value after reset: 00$_H$

Bit	7	6	5	4	3	2	1	0
	NBPRSCMP[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 20.108 NTU0BPRSCMP Register Contents

Bit Position	Bit Name	Function
7 to 0	NBPRSCMP [7:0]	NTU Backup Clock Prescaler Compare Value Compare match value of the NTU backup clock counter

(1) NTU0BPRSCMP.NBPRSCMP[7:0]

NTU compare unit prescaler compare match value bits.

These bits set the NTU compare unit prescaler output clock period according to the equation below:

Backup_Clock_Prescaler_output_clock_period = NBPRS_counter_clock / (2 * NBPRSCMP)

NBPRS_counter_clock is selected using the NTU0BPRSCTL register.

20.3 Operation

This chapter describes the FlexRay implementation together with the related FlexRay protocol features. More information about the FlexRay protocol itself can be found in the FlexRay protocol specification.

20.3.1 FlexRay Module Operation Control

20.3.1.1 FlexRay Module Enable

After hardware reset or after the FlexRay module has been disabled (following **Section 20.3.1.2, FlexRay Module Disable**) the FlexRay module is in the reset state (FLXAnFROS.OS is 0) and the clocks of the FlexRay core module are disabled.

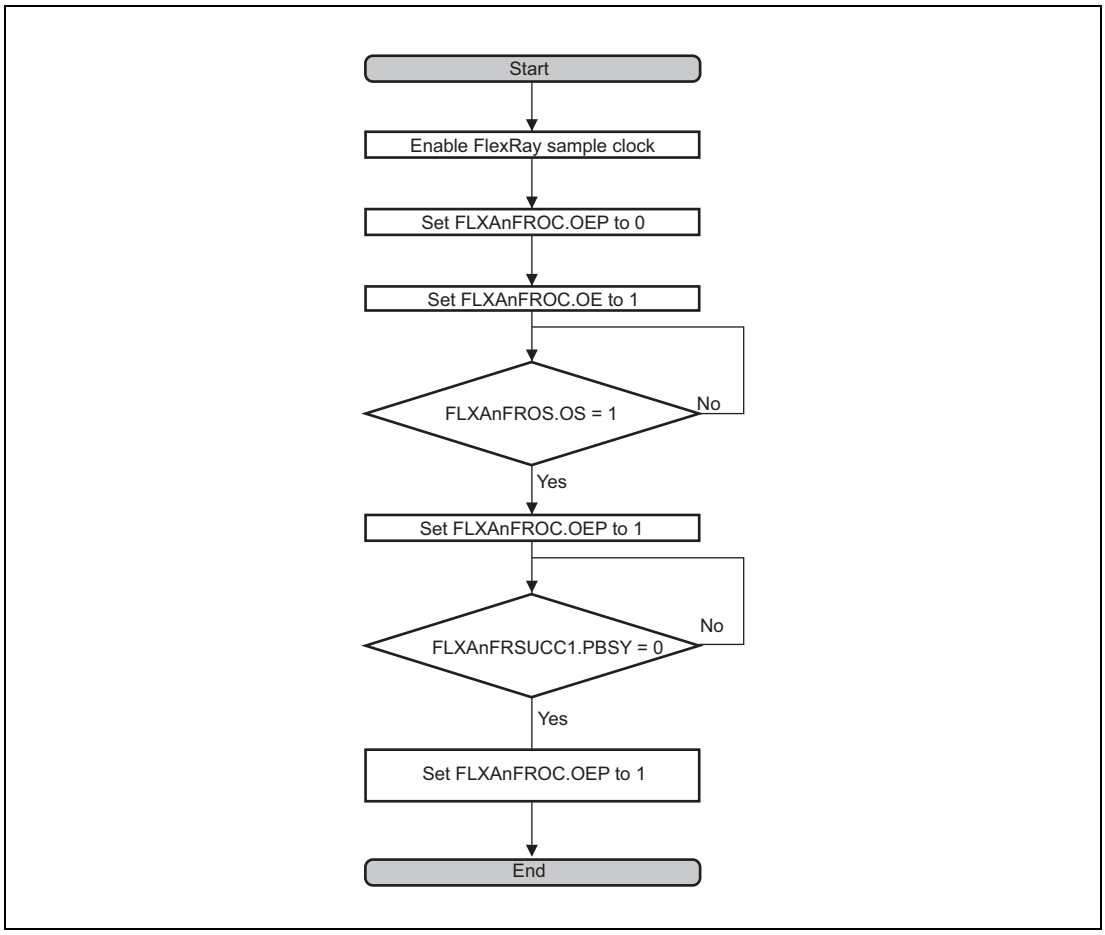

Figure 20.3 FlexRay enable flow

20.3.1.2 FlexRay Module Disable

The FlexRay module can be disabled at any time. However, it is recommended to disable the FlexRay module using the FLXAnFROC.OE register only when the FlexRay module is in HALT, CONFIG or DEFAULT_CONFIG state. Resetting the FlexRay module in any other state will terminate any ongoing FlexRay communication.

If the data transfer function is used, it is also required to disable this function before disabling the FlexRay module (see **Section 20.3.16.1 (1), Activation and deactivation** for suspending input transfer function and **Section 20.3.16.2 (2), Output transfer data structure**for suspending output transfer).

The following flow should be executed to disable the FlexRay module.

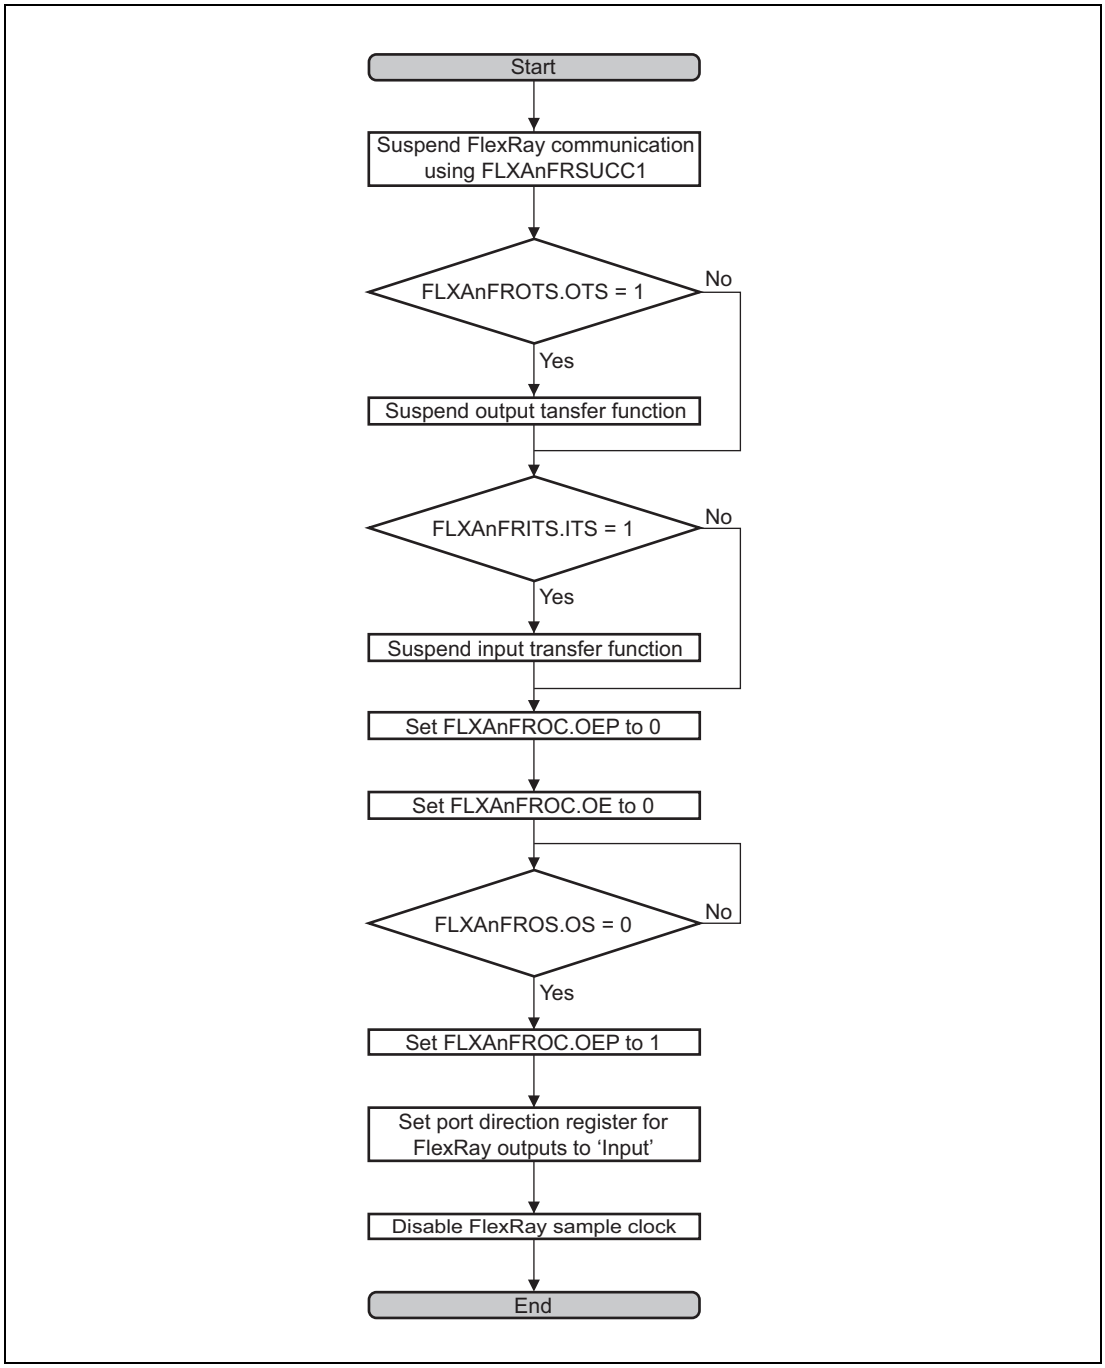

Figure 20.4 FlexRay disable flow

20.3.2 Communication Cycle

Communication on FlexRay networks is based on frames and symbols. The wakeup symbol (WUS) and the collision avoidance symbol (CAS) are transmitted outside the communication cycle to setup the time schedule. Frames and media access test symbols (MTS) are transmitted inside the communication cycle.

A FlexRay communication cycle consists of the following elements:

- Static Segment
- Dynamic Segment (optional)
- Symbol Window (optional)
- Network Idle Time (NIT)

Static segment, dynamic segment, and symbol window form the Network Communication Time (NCT). For each communication channel the slot counter starts at 1 and counts up until the end of the dynamic segment is reached. Both channels share the same arbitration grid which means that they use the same synchronized macrotick.

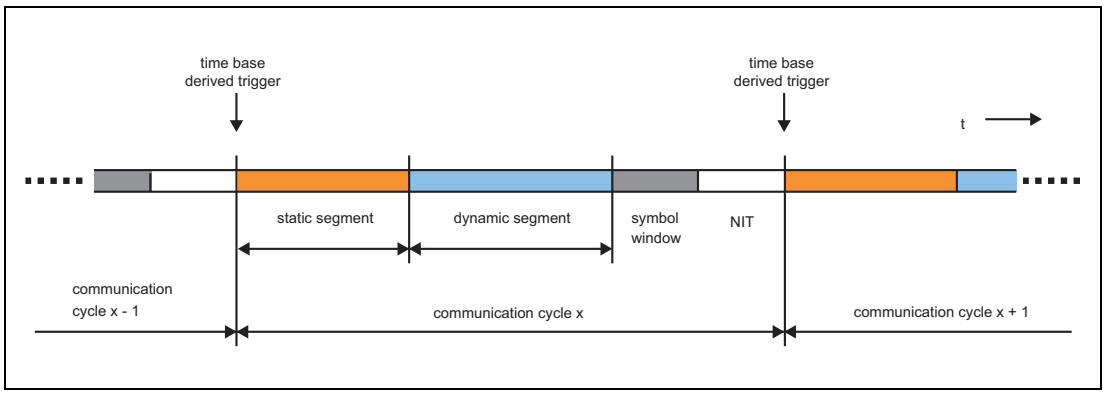

Figure 20.5 Structure of Communication Cycle

20.3.2.1 Static Segment

The Static Segment is characterized by the following features:

- Time slots of fixed length (optionally protected by bus guardian)
- Start of frame transmission at action point of the respective static slot
- Payload length same for all frames on both channels

Parameters:

Number of Static Slots (FLXAnFRGTUC7.NSS)

Static Slot Length (FLXAnFRGTUC7.SSL)

Payload Length Static (FLXAnFRMHDC.SFDL)

Action Point Offset (FLXAnFRGTUC9.APO)

20.3.2.2 Dynamic Segment

The Dynamic Segment is characterized by the following features:

- All controllers have bus access (no bus guardian protection possible)
- Variable payload length and duration of slots, different for both channels
- Start of transmission at minislot action point

Parameters:

Number of Minislots (FLXAnFRGTUC8.NMS)

Minislot Length (FLXAnFRGTUC8.MSL)

Minislot Action Point Offset (FLXAnFRGTUC9.MAPO)

Start of Latest Transmit (last minislot) (FLXAnFRMHDC.SLT)

20.3.2.3 Symbol Window

During the symbol window only one media access test symbol (MTS) may be transmitted per channel. MTS symbols are send in NORMAL_ACTIVE state to test the bus guardian.

The symbol window is characterized by the following features:

- Send single symbol
- Transmission of the MTS symbol starts at the symbol windows action point

Parameters:

Symbol Window Action Point Offset (FLXAnFRGTUC9.APO) (same as for static slots)

Network Idle Time Start (FLXAnFRGTUC4.NIT)

20.3.2.4 Network Idle Time (NIT)

During network idle time the CC has to perform the following tasks:

- Calculate clock correction terms (offset and rate)
- Distribute offset correction over multiple macroticks after offset correction start
- Perform cluster cycle related tasks

Parameters:

Network idle time start bit (FLXAnFRGTUC4.NIT)

Offset correction start bit (FLXAnFRGTUC4.OCS)

20.3.2.5 Configuration of NIT Start and Offset Correction Start

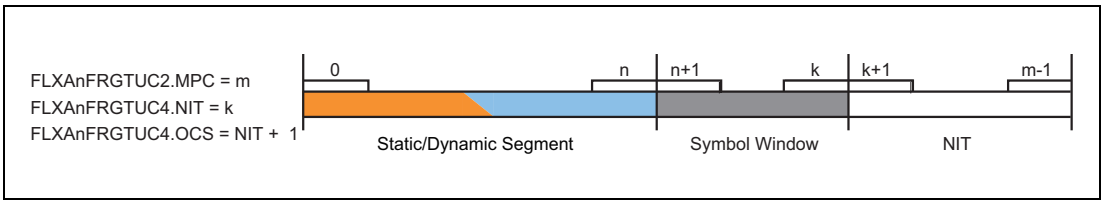

Figure 20.6 Configuration of NIT Start and Offset Correction Start

The number of macroticks per cycle gMacroPerCycle is assumed to be m. It is configured by programming FLXAnFRGTUC2.MPC = m.

The static / dynamic segment starts with macrotick 0 and ends with macrotick n:

n = static segment length + dynamic segment offset + dynamic segment length - 1MT

n = gNumberOfStaticSlots * gdStaticSlot + dynamic segment offset + gNumberOfMinislots * gdMinislot - 1 MT

The static segment length is configured by FLXAnFRGTUC7.SSL and FLXAnFRGTUC7.NSS.

The dynamic segment length is configured by FLXAnFRGTUC8.MSL and FLXAnFRGTUC8.NMS.

The dynamic segment offset is:

If gdActionPointOffset <= gdMinislotActionPointOffset:

dynamic segment offset = 0 MT

Else if gdActionPointOffset > gdMinislotActionPointOffset:

dynamic segment offset = gdActionPointOffset -gdMinislotActionPointOffset

The NIT starts with macrotick k + 1 and ends with the last macrotick of cycle m-1. It has to be configured by setting FLXAnFRGTUC4.NIT = k.

For the FlexRay module the offset correction start is required to be FLXAnFRGTUC4.OCS ≥ FLXAnFRGTUC4.NIT + 1 = k + 1.

The length of symbol window results from the number of macroticks between the end of the static / dynamic segment and the beginning of the NIT. It can be calculated by the number of macroticks (k – n).

20.3.3 Communication Modes

The FlexRay Protocol Specification defines the Time-Triggered Distributed (TT-D) mode.

20.3.3.1 Time-triggered Distributed (TT-D)

In TT-D mode the following configurations are possible:

- Pure static: Minimum 2 static slots + symbol window (optional)
- Mixed static/dynamic: Minimum 2 static slots + dynamic segment + symbol window (optional)

A minimum of two coldstart nodes needs to be configured for distributed time-triggered operation. Two fault-free coldstart nodes are necessary for the cluster startup. Each startup frame must be a sync frame, therefore all coldstart nodes are sync nodes.

20.3.4 Clock Synchronization

In TT-D mode a distributed clock synchronization is used. Each node individually synchronizes itself to the cluster by observing the timing of received sync frames from other nodes.

20.3.4.1 Global Time

Activities in a FlexRay node, including communication, are based on the concept of a global time. It is the clock synchronization mechanism that differentiates the FlexRay cluster from other node collections with independent clock mechanisms. The global time is a vector of two values; the cycle (cycle counter) and the cycle time (macrotick counter).

Cluster specific:

- Macrotick (MT) = basic unit of time measurement in a FlexRay network, a macrotick consists of an integer number of microticks (µT)
- Cycle length = duration of a communication cycle in units of macroticks (MT)

20.3.4.2 Local Time

Internally, nodes time their behavior with microtick resolution. Microticks are time units derived from the oscillator clock tick of the specific node. Therefore microticks are controller-specific units. They may have different duration in different controllers. The precision of a node's local time difference measurements is a microtick (µT).

Node specific:

- Oscillator clock → prescaler → microtick (µT)
- µT = basic unit of time measurement in a CC, clock correction is done in units of µTs
- Cycle counter + macrotick counter = nodes local view of the global time

20.3.4.3 Synchronization Process

Clock synchronization is performed by means of sync frames. Only preconfigured nodes (sync nodes) are allowed to send sync frames. In a two-channel cluster a sync node has to send its sync frame on both channels.

For synchronization in FlexRay the following constraints have to be considered:

- Max. one sync frame per node in one communication cycle
- Max. 15 sync frames per cluster in one communication cycle
- Every node has to use a preconfigured number of sync frames (FLXAnFRGTUC2.SNM) for clock synchronization
- Minimum of two sync nodes required for clock synchronization and startup

For clock synchronization the time difference between expected and observed arrival time of sync frames received during the static segment is measured. In a two channel cluster the sync node has to be configured to send sync frames on both channels. The calculation of correction terms is done during NIT (offset: every cycle, rate: every odd cycle) by using an FTM algorithm. For details see FlexRay protocol specification v2.1, chapter 8.

(1) Offset (phase) Correction

- Only deviation values measured and stored in the current cycle used
- For a two channel node the smaller value will be taken
- Calculation during NIT of every communication cycle
- Offset correction value calculated in even cycles used for error checking only
- Checked against limit values
- Correction value is a signed integer number of µTs
- Correction done in odd numbered cycles, distributed over the macroticks beginning at offset correction start up to cycle end (end of NIT) to shift nodes next start of cycle (MTs lengthened / shortened)

(2) Rate (frequency) Correction

- Pairs of deviation values measured and stored in even / odd cycle pair used
- For a two channel node the average of the differences from the two channels is used
- Calculated during NIT of odd numbered cycles
- Cluster drift damping is performed using global damping value
- Checked against limit values
- Correction value is a signed integer number of µTs
- Distributed over macroticks comprising the next even / odd cycle pair (MTs lengthened / shortened)

(3) Sync Frame Transmission

Sync frame transmission is only possible from buffer 0 and 1. Message buffer 1 may be used for sync frame transmission in case that sync frames should have different payloads on the two channels. In this case bit FLXAnFRMRC.SPLM has to be programmed to 1.

Message buffers used for sync frame transmission have to be configured with the key slot ID and can be (re) configured in DEFAULT_CONFIG or CONFIG state only. For nodes transmitting sync frames FLXAnFRSUCC1.TXSY must be set to 1.

(4) External Clock Synchronization

During normal operation, independent clusters can drift significantly. If synchronous operation across independent clusters is desired, external synchronization is necessary; even though the nodes within each cluster are synchronized. This can be accomplished with synchronous application of host-deduced rate and offset correction terms to the clusters.

- External offset / rate correction value is a signed integer
- External offset / rate correction value is added to calculated offset / rate correction value
- Aggregated offset / rate correction term (external + internal) is not checked against configured limits

20.3.5 Error Handling

The implemented error handling concept is intended to ensure that, in case of a lower layer protocol error in one single node, communication between non-affected nodes can be maintained. In some cases, higher layer program activity is required for the CC to resume normal operation. A change of the error handling state will set FLXAnFREIR.PEMC to 1 and may trigger an interrupt to the Host if enabled. The actual error mode is signaled by FLXAnFRCCEV.ERRM.

Table 20.109 Error modes of the POC (degradation model)

Error Mode	Activity
ACTIVE	Full operation, State: NORMAL_ACTIVE The CC is fully synchronized and supports the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers FLXAnFREIR and FLXAnFRSIR.
PASSIVE	Reduced operation, State: NORMAL_PASSIVE, CC self rescue allowed The CC stops transmitting frames and symbols, but received frames are still processed. Clock synchronization mechanisms are continued based on received frames. No active contribution to the cluster wide clock synchronization. The host is informed of any error condition(s) or status change by interrupt (if enabled) or by reading the error and status interrupt flags from registers FLXAnFREIR and FLXAnFRSIR.
COMM_HALT	Operation halted, State: HALT, CC self rescue not allowed The CC stops frame and symbol processing, clock synchronization processing, and the macrotick generation. The host has still access to error and status information by reading the error and status interrupt flags from registers FLXAnFREIR and FLXAnFRSIR. The bus drivers are disabled.

20.3.5.1 Clock Correction Failed Counter

When the Clock Correction Failed Counter reaches the “maximum without clock correction passive” limit defined by FLXAnFRSUCC3.WCP, the POC transits from NORMAL_ACTIVE to NORMAL_PASSIVE state. When it reaches the “maximum without clock correction fatal” limit defined by FLXAnFRSUCC3.WCF, it transits from NORMAL_ACTIVE or NORMAL_PASSIVE to HALT state.

The Clock Correction Failed Counter FLXAnFRCCEV.CCFC allows the Host to monitor the duration of the inability of a node to compute clock correction terms after the CC passed protocol startup phase. It will be incremented by one at the end of any odd communication cycle during which either the missing offset correction FLXAnFRSFS.MOCS or the missing rate correction FLXAnFRSFS.MRCS flag is set to 1.

The Clock Correction Failed Counter is reset to zero at the end of an odd communication cycle if neither the missing offset correction FLXAnFRSFS.MOCS nor the missing rate correction FLXAnFRSFS.MRCS flag is set to 1.

The Clock Correction Failed Counter stops incrementing when the “maximum without clock correction fatal” value FLXAnFRSUCC3.WCF is reached (i.e. incrementing the counter at its maximum value will not cause it to wrap around back to zero). The Clock Correction Failed Counter is initialized to zero when the CC enters READY state or when NORMAL_ACTIVE state is entered.

CAUTION

The transition to HALT state is prevented if FLXAnFRSUCC1.HCSE is not set to 1.

20.3.5.2 Passive to Active Counter

The passive to active counter controls the transition of the POC from NORMAL_PASSIVE to NORMAL_ACTIVE state. FLXAnFRSUCC1.PTA defines the number of consecutive even / odd cycle pairs that must have valid clock correction terms before the CC is allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state. If FLXAnFRSUCC1.PTA is set to zero the CC is not allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state.

20.3.5.3 HALT Command

In case the Host wants to stop FlexRay communication of the local node it can bring the CC into HALT state by asserting the HALT command. This can be done by writing FLXAnFRSUCC1.CMD = “0110”. In order to shut down communication on an entire FlexRay network, a higher layer protocol is required to assure that all nodes apply the HALT command at the same time.

The POC state from which the transition to HALT state took place can be read from FLXAnFRCCSV.PSL.

When called in NORMAL_ACTIVE or NORMAL_PASSIVE state the POC transits to HALT state at the end of the current cycle. When called in any other state FLXAnFRSUCC1.CMD will be reset to “0000” = command_not_accepted and bit FLXAnFREIR.CNA is set to 1. If enabled an interrupt to the Host is generated.

20.3.5.4 FREEZE Command

In case the Host detects a severe error condition it can bring the CC into HALT state by asserting the FREEZE command. This can be done by writing FLXAnFRSUCC1.CMD = “0111”. The FREEZE command triggers the entry of the HALT state immediately regardless of the actual POC state.

The POC state from which the transition to HALT state took place can be read from FLXAnFRCCSV.PSL.

CAUTION

When the user restart as leading coldstarter after it has been stopped by FREEZE or READY command, it may happen, depending on the internal state of the FlexRay module, that the FlexRay module does not transmit its startup frame in cycle 0. Only FlexRay module configurations with startup frames configured for slots 1 to 7 are affected by this behaviour.

Coldstart after hardware reset is not affected.

Even if it happened, next coldstart attempt successful. Coldstart sequence is lengthened but coldstart of FlexRay system is not prohibited by this behaviour.

If the use wants to avoid this behavior, they must use a static slot greater or equal 8 for the startup / sync message.

20.3.6 Communication Controller States

20.3.6.1 Communication Controller State Diagram

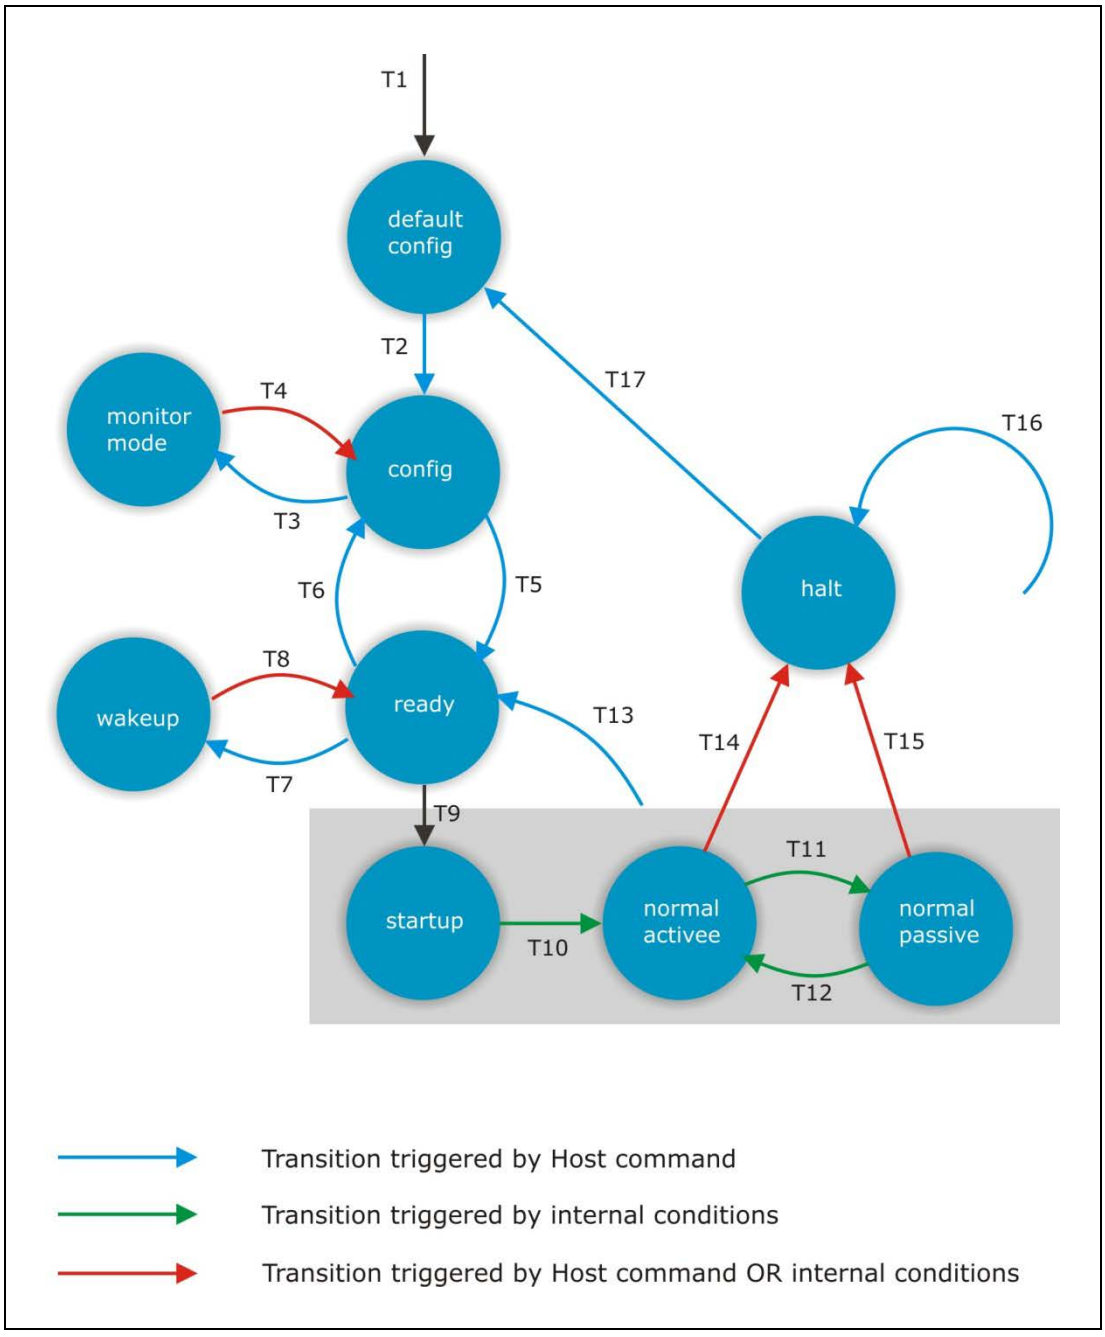

Figure 20.7 Overall State Diagram of FlexRay Communication Controller

State transitions are controlled by reset, FLXAnFR0RXDA, FLXAnFR0RXDB, by the POC state machine, and by the CHI Command Vector FLXAnFRSUCC1.CMD.

The CC transits from all states to HALT state after application of the FREEZE command (FLXAnFRSUCC1.CMD = “0111”).

Table 20.110 State Transitions of FlexRay Overall State Machine

T#	Condition	From	To
1	Reset	All States	DEFAULT_CONFIG
2	Command CONFIG, FLXAnFRSUCC1.CMD = “0001”	DEFAULT_CONFIG	CONFIG
3	Unlock sequence followed by command MONITOR_MODE, FLXAnFRSUCC1.CMD[3:0] = “1011”	CONFIG	MONITOR_MODE
4	Command CONFIG, FLXAnFRSUCC1.CMD = "0001"	MONITOR_MODE	CONFIG
5	Unlock sequence followed by command READY, FLXAnFRSUCC1.CMD = “0010”	CONFIG	READY
6	Command CONFIG, FLXAnFRSUCC1.CMD = “0001”	READY	CONFIG
7	Command WAKEUP, FLXAnFRSUCC1.CMD = “0011”	READY	WAKEUP
8	Complete, non-aborted transmission of wakeup pattern OR received WUP OR received frame header OR wakeup collision OR command READY, FLXAnFRSUCC1.CMD = “0010”	WAKEUP	READY
9	Command RUN, FLXAnFRSUCC1.CMD = “0100”	READY	STARTUP
10	Successful startup	STARTUP	NORMAL_ACTIVE
11	Clock Correction Failed counter reached Maximum Without Clock Correction Passive limit configured by FLXAnFRSUCC3.WCP	NORMAL_ACTIVE	NORMAL_PASSIVE
12	Number of valid correction terms reached the Passive to Active limit configured by FLXAnFRSUCC1.PTA	NORMAL_PASSIVE	NORMAL_ACTIVE
13	Command READY, FLXAnFRSUCC1.CMD = “0010”	STARTUP, NORMAL_ACTIVE, NORMAL_PASSIVE	READY
14	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by FLXAnFRSUCC3.WCF AND bit FLXAnFRSUCC1.HCSE set to ’1’ OR command HALT, FLXAnFRSUCC1.CMD = “0110”	NORMAL_ACTIVE	HALT
15	Clock Correction Failed counter reached Maximum Without Clock Correction Fatal limit configured by FLXAnFRSUCC3.WCF AND bit FLXAnFRSUCC1.HCSE set to ’1’ OR command HALT, FLXAnFRSUCC1.CMD = “0110”	NORMAL_PASSIVE	HALT
16	Command FREEZE, FLXAnFRSUCC1.CMD = “0111”	All States	HALT
17	Command CONFIG, FLXAnFRSUCC1.CMD = “0001”	HALT	DEFAULT_CONFIG

20.3.6.2 DEFAULT_CONFIG State

In DEFAULT_CONFIG state, the CC is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state.

The CC enters this state

- When the reset is applied (HW reset or SW reset)
- When exiting from HALT state

To leave DEFAULT_CONFIG state the Host has to write FLXAnFRSUCC1.CMD = “0001”. The CC then transits to CONFIG state.

20.3.6.3 CONFIG State

In CONFIG state, the CC is stopped. All configuration registers are accessible and the pins to the physical layer are in their inactive state. This state is used to initialize the CC configuration.

The CC enters this state

- When exiting from DEFAULT_CONFIG state
- When exiting from READY state

When the state has been entered via HALT and DEFAULT_CONFIG state, the Host can analyse status information and configuration. Before leaving CONFIG state the Host has to assure that the configuration is fault-free.

To leave CONFIG state, the Host has to perform the unlock sequence as described is **Section 20.2.3.1, FLXAnFRLCK — FlexRay Lock Register**. Directly after unlocking the CONFIG state the Host has to write FLXAnFRSUCC1.CMD to enter the next state.

CAUTION

Status bits FLXAnFRMHDS[14:0], registers FLXAnFRTXRQ1/2/3/4, and status data stored in the Message RAM are not affected by the transition of the POC from CONFIG to READY state.

When the CC is in CONFIG state it is also possible to bring the CC into a power saving mode by halting the module clocks (bus clock and sample clock). To do this the Host has to assure that all Message RAM transfers have finished before turning off the clocks.

20.3.6.4 READY State

After unlocking CONFIG state and writing FLXAnFRSUCC1.CMD = “0010” the CC enters READY state. From this state the CC can transit to WAKEUP state and perform a cluster wakeup or to STARTUP state to perform a coldstart or to integrate into a running cluster.

The CC enters this state

- When exiting from CONFIG, WAKEUP, STARTUP, NORMAL_ACTIVE, or NORMAL_PASSIVE state by writing FLXAnFRSUCC1.CMD = “0010_B” (READY command).

The CC exits from this state

- To CONFIG state by writing FLXAnFRSUCC1.CMD = “0001_B” (CONFIG command)
- To WAKEUP state by writing FLXAnFRSUCC1.CMD = “0011_B” (WAKEUP command)
- To STARTUP state by writing FLXAnFRSUCC1.CMD = “0100_B” (RUN command)

Internal counters and the CC status flags are reset when the CC enters STARTUP state.

CAUTION

Status bits FLXAnFRMHDS[14:0], registers FLXAnFRTXRQ1/2/3/4, and status data stored in the Message RAM are not affected by the transition of the POC from READY to STARTUP state.

20.3.6.5 WAKEUP State

The description below is intended to help configuring wakeup for the FlexRay IP-module. A detailed description of the wakeup procedure together with the respective SDL diagrams can be found in the FlexRay protocol specification v2.1, **Section 7.1**.

The CC enters this state

- When exiting from READY state by writing FLXAnFRSUCC1.CMD = "0011_B" (WAKEUP command).

The CC exits from this state to READY state

- After complete non-aborted transmission of wakeup pattern
- After WUP reception
- After detecting a WUP collision
- After reception of a frame header
- By writing FLXAnFRSUCC1.CMD = "0010_B" (READY command)

The cluster wakeup must precede the communication startup in order to ensure that all nodes in a cluster are awake. The minimum requirement for a cluster wakeup is that all bus drivers are supplied with power. A bus driver has the ability to wake up the other components of its node when it receives a wakeup pattern on its channel. At least one node in the cluster needs an external wakeup source.

The Host completely controls the wakeup procedure. It is informed about the state of the cluster by the bus driver and the CC and configures bus guardian (if available) and CC to perform the cluster wakeup. The CC provides to the Host the ability to transmit a special wakeup pattern on each of its available channels separately. The CC needs to recognize the wakeup pattern only during WAKEUP state.

Wakeup may be performed on only one channel at a time. The Host has to configure the wakeup channel while the CC is in CONFIG state by writing FLXAnFRSUCC1.WUCS. The CC ensures that ongoing communication on this channel is not disturbed. The CC cannot guarantee that all nodes connected to the configured channel awake upon the transmission of the wakeup pattern, since these nodes cannot give feedback until the startup phase. The wakeup procedure enables single-channel devices in a two-channel system to trigger the wakeup, by only transmitting the wakeup pattern on the single channel to which they are connected. Any coldstart node that deems a system startup necessary will then wake the remaining channel before initiating communication startup.

The wakeup procedure tolerates any number of nodes simultaneously trying to wakeup a single channel and resolves this situation such that only one node transmits the pattern. Additionally the wakeup pattern is collision resilient, so even in the presence of a fault causing two nodes to simultaneously transmit a wakeup pattern, the resulting collided signal can still wake the other nodes.

After wakeup the CC returns to READY state and signals the change of the wakeup status to the Host by setting flag FLXAnFRSIR.WST. The wakeup status vector can be read from FLXAnFRCCSV.WSV. If a valid wakeup pattern was received also either flag FLXAnFRSIR.WUPA or flag FLXAnFRSIR.WUPB is set to 1.

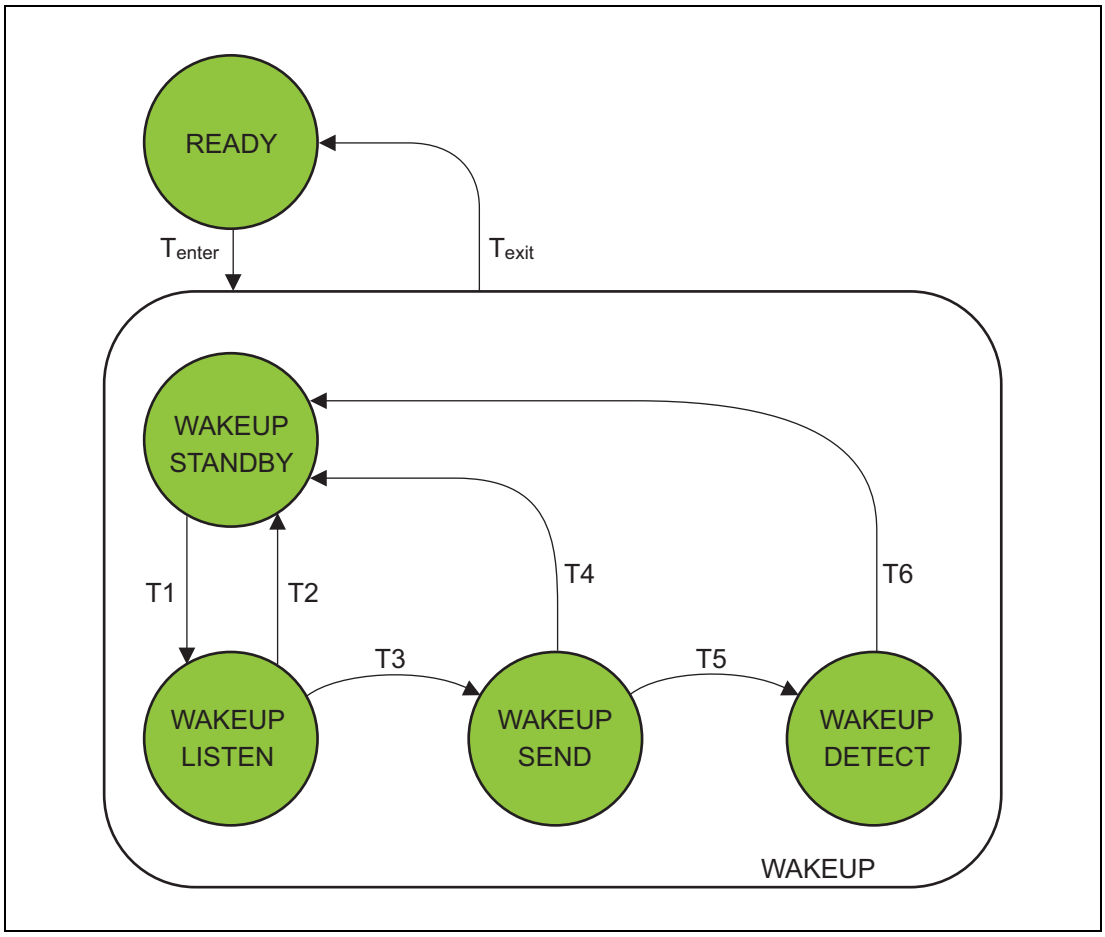

Figure 20.8 Structure of POC State WAKEUP

Table 20.111 State Transitions WAKEUP (1/2)

T#	Condition	From	To
enter	Host commands change to WAKEUP state by writing FLXAnFRSUCC1.CMD = “0011” (WAKEUP command)	READY	WAKEUP
1	CHI command WAKEUP triggers wakeup FSM to transit to WAKEUP_LISTEN state	WAKEUP_STANDBY	WAKEUP_LISTEN
2	Received WUP on wakeup channel selected by bit FLXAnFRSUCC1.WUCS or frame header on either available channel	WAKEUP_LISTEN	WAKEUP_STANDBY
3	Timer event	WAKEUP_LISTEN	WAKEUP_SEND
4	Complete, non-aborted transmission of wakeup pattern	WAKEUP_SEND	WAKEUP_STANDBY
5	Collision detected	WAKEUP_SEND	WAKEUP_DETECT
6	Wakeup timer expired or WUP detected on wakeup channel selected by bit FLXAnFRSUCC1.WUCS or frame header received on either available	WAKEUP_DETECT	WAKEUP_STANDBY

Table 20.111 State Transitions WAKEUP (2/2)

T#	Condition	From	To
exit	Wakeup completed (after T2 or T4 or T6) or Host commands change to READY state by writing FLXAnFRSUCC1.CMD = “0010” (READY command). This command also resets the wakeup FSM to WAKEUP_STANDBY state	WAKEUP	READY

The WAKEUP_LISTEN state is controlled by the wakeup timer and the wakeup noise timer. The two timers are controlled by the parameters listen timeout FLXAnFRSUCC2.LT and listen timeout noise FLXAnFRSUCC2.LTN. Listen timeout enables a fast cluster wakeup in case of a noise free environment, while listen timeout noise enables wakeup under more difficult conditions regarding noise interference.

In WAKEUP_SEND state the CC transmits the wakeup pattern on the configured channel and checks for collisions. After return from wakeup the Host has to bring the CC into STARTUP state by CHI command RUN.

In WAKEUP_DETECT state the CC attempts to identify the reason for the wakeup collision detected in WAKEUP_SEND state. The monitoring is bounded by the expiration of listen timeout as configured by FLXAnFRSUCC2.LT. Either the detection of a wakeup pattern indicating a wakeup attempt by another node or the reception of a frame header indicating ongoing communication, causes the direct transition to READY state. Otherwise WAKEUP_DETECT is left after expiration of listen timeout; in this case the reason for wakeup collision is unknown.

The Host has to be aware of possible failures of the wakeup and act accordingly. It is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal time it takes another coldstart node to become awake and to be configured.

The FlexRay Protocol Specification recommends that two different CCs shall awake the two channels.

(1) Host activities

The host must coordinate the wakeup of the two channels and must decide whether, or not, to wake a specific channel. The sending of the wakeup pattern is initiated by the Host. The wakeup pattern is detected by the remote BDs and signaled to their local Host.

Wakeup procedure controlled by Host (single-channel wakeup):

- Configure the CC in CONFIG state
  - Select wakeup channel by programming bit FLXAnFRSUCC1.WUCS
- Check local BDs whether a WUP was received
- Activate BD of selected wakeup channel
- Command CC to enter READY state
- Command CC to start wakeup on the configured channel by writing FLXAnFRSUCC1.CMD = “0011”
  - CC enters WAKEUP
  - CC returns to READY state and signals status of wakeup attempt to the Host
- Wait predefined time to allow the other nodes to wakeup and configure themselves
- Coldstart node:

  - In a dual channel cluster wait for WUP on the other channel
  - Reset coldstart inhibit flag FLXAnFRCCSV.CSI by writing FLXAnFRSUCC1.CMD = “1001” (ALLOW_COLDSTART command)
- Command CC to enter startup by writing FLXAnFRSUCC1.CMD = “0100” (RUN command)

Wakeup procedure triggered by BD:

- Wakeup recognized by BD
- BD triggers power-up of Host (if required)
- BD signals wakeup event to Host
- Host configures its local CC
- If necessary, Host commands wakeup of second channel and waits predefined time to allow the other nodes to wakeup and configure themselves
- Host commands CC to enter STARTUP state by writing FLXAnFRSUCC1.CMD = “0100” (RUN command)

(2) Wakeup pattern (WUP)

The wakeup pattern (WUP) is composed of at least two wakeup symbols (WUS). Wakeup symbol and wakeup pattern are configured by registers FLXAnFRPRTC1 and FLXAnFRPRTC2.

- Single channel wakeup, wakeup symbol may not be sent on both channels at the same time
- Wakeup symbol collision resilient for at least two sending nodes (two overlapping wakeup symbols always recognizable)
- Wakeup symbol must be configured identical in all nodes of a cluster
- Wakeup symbol transmit low time configured by FLXAnFRPRTC2.TXL
- Wakeup symbol idle time used to listen for activity on the bus, configured by FLXAnFRPRTC2.TXI
- A wakeup pattern composed of at least two Tx-wakeup symbols needed for wakeup
- Number of repetitions configurable by FLXAnFRPRTC1.RWP (2 to 63 repetitions)
- Wakeup symbol receive window length configured by FLXAnFRPRTC1.RXW
- Wakeup symbol receive low time configured by FLXAnFRPRTC2.RXL
- Wakeup symbol receive idle time configured by FLXAnFRPRTC2.RXI

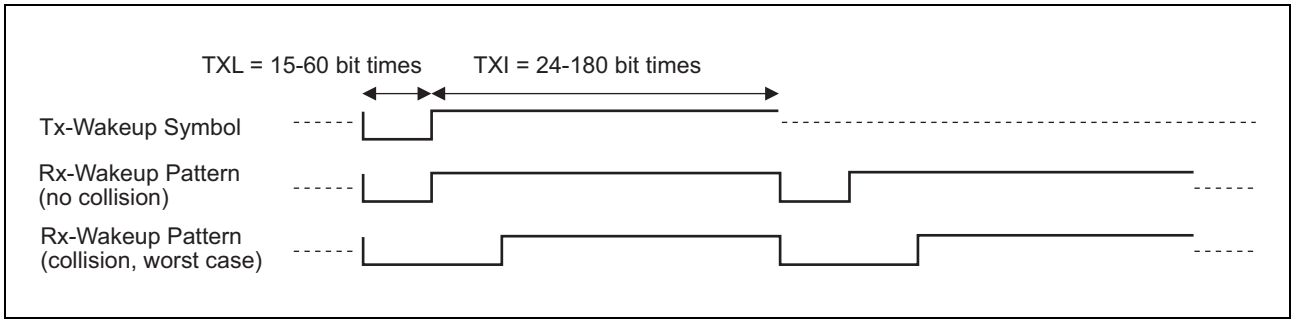

Figure 20.9 Timing of Wakeup Pattern

20.3.6.6 STARTUP State

The description below is intended to help configuring startup for the FlexRay IP-module. A detailed description of the startup procedure together with the respective SDL diagrams can be found in the FlexRay protocol specification v2.1, **Section 7.2**.

Any node entering STARTUP state that has coldstart capability should assure that both channels attached have been awakened before initiating coldstart.

It cannot be assumed that all nodes and stars need the same amount of time to become completely awake and to be configured. Since at least two nodes are necessary to start up the cluster communication, it is advisable to delay any potential startup attempt of the node having instigated the wakeup by the minimal amount of time it takes another coldstart node to become awake, to be configured and to enter startup. It may require several hundred milliseconds (depending on the hardware used) before all nodes and stars are completely awakened and configured.

Startup is performed on all channels synchronously. During startup, a node only transmits startup frames. Startup frames are both sync frames and null frames during startup.

A fault-tolerant, distributed startup strategy is specified for initial synchronization of all nodes. In general, a node may enter NORMAL_ACTIVE state via (see **Figure 20.10**):

- Coldstart path initiating the schedule synchronization (LeadingColdstart node)
- Coldstart path joining other coldstart nodes (FollowingColdstart node)
- Integration path integrating into an existing communication schedule (all other nodes)

A coldstart attempt begins with the transmission of a collision avoidance symbol (CAS). Only a coldstart node that had transmitted the CAS transmits frames in the first four cycles after the CAS, it is then joined firstly by the other coldstart nodes and afterwards by all other nodes.

A coldstart node has bits FLXAnFRSUCC1.TXST and FLXAnFRSUCC1.TXSY set to 1. Message buffer 0 holds the key slot ID which defines the slot number where the startup frame is send. In the frame header of the startup frame the startup frame indicator bit is set to 1.

In clusters consisting of three or more nodes, at least three nodes shall be configured to be coldstart nodes. In clusters consisting of two nodes, both nodes must be coldstart nodes. At least two fault-free coldstart nodes are necessary for the cluster to startup.

Each startup frame must also be a sync frame; therefore each coldstart node will also be a sync node. The number of coldstart attempts is configured by FLXAnFRSUCC1.CSA.

A non-coldstart node requires at least two startup frames from distinct nodes for integration. It may start integration before the coldstart nodes have finished their startup. It will not finish its startup until at least two coldstart nodes have finished their startup.

Both non-coldstart nodes and coldstart nodes start passive integration via the integration path as soon as they receive sync frames from which to derive the TDMA schedule information. During integration, the node has to adapt its own clock to the global clock (rate and offset) and has to make its cycle time consistent with the global schedule observable at the network. Afterwards, these settings are checked for consistency with all available network nodes. The node can only leave the integration phase and actively participate in communication when these checks are passed.

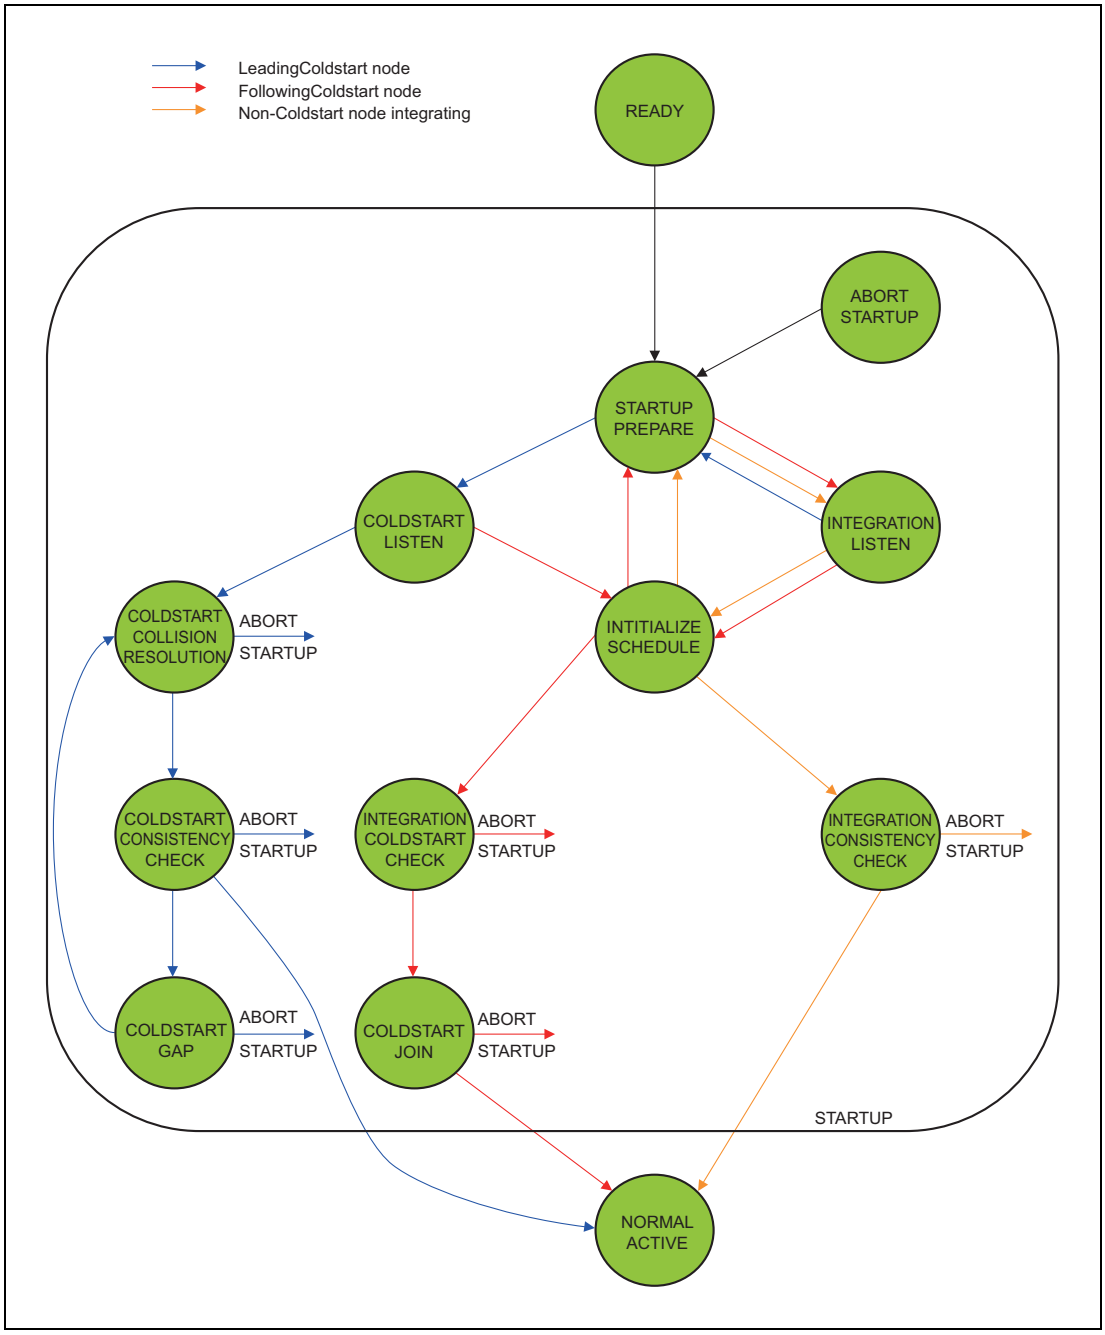

Figure 20.10 State Diagram Time-Triggered Startup

(1) Coldstart Inhibit Mode

In coldstart inhibit mode the node is prevented from initializing the TDMA communication schedule. If bit FLXAnFRCCSV.CSI is set to 1, the node is not allowed to initialize the cluster communication, i.e. entering the coldstart path is prohibited. The node is allowed to integrate to a running cluster or to transmit startup frames after another coldstart node started the initialization of the cluster communication.

The coldstart inhibit bit FLXAnFRCCSV.CSI is set to 1 whenever the POC enters READY state. The bit has to be cleared under control of the Host by CHI command ALLOW_COLDSTART (FLXAnFRSUCC1.CMD = “1001”)

(2) Startup Timeouts

The CC supplies two different µT timers supporting two timeout values, startup timeout and startup noise timeout. The two timers are started when the CC enters the COLDSTART_LISTEN state. The expiration of either of these timers causes the node to leave the initial sensing phase (COLDSTART_LISTEN state) with the intention of starting up communication.

CAUTION

The startup and startup noise timers are identical with the wakeup and wakeup noise timers and use the same configuration values FLXAnFRSUCC2.LT and FLXAnFRSUCC2.LTN.

(a) Startup Timeout

The startup timeout limits the listen time used by a node to determine if there is already communication between other nodes or at least one coldstart node actively requesting the integration of others. The startup timer is configured by programming FLXAnFRSUCC2.LT (see **Section 20.2.6.2, FLXAnFRSUCC2 — FlexRay SUC Configuration Register 2**).

The startup timeout is:

pdListenTimeout = FLXAnFRSUCC2.LT

The startup timer is restarted upon:

- Entering the COLDSTART_LISTEN state
- Both channels reaching idle state while in COLDSTART_LISTEN state

The startup timer is stopped:

- If communication channel activity is detected on one of the configured channels while the node is in the COLDSTART_LISTEN state
- When the COLDSTART_LISTEN state is left

Once the startup timeout expires, neither an overflow nor a cyclic restart of the timer is performed. The timer status is kept for further processing by the startup state machine.

(b) Startup Noise Timeout

At the same time the startup timer is started for the first time (transition from STARTUP_PREPARE state to COLDSTART_LISTEN state), the startup noise timer is started. This additional timeout is used to improve reliability of the startup procedure in the presence of noise. The startup noise timeout is configured by programming FLXAnFRSUCC2.LTN (see **Section 20.2.6.2, FLXAnFRSUCC2 — FlexRay SUC Configuration Register 2**).

The startup noise timeout is:

pdListenTimeout * gListenNoise = FLXAnFRSUCC2.LT * (FLXAnFRSUCC2.LTN + 1)

The startup noise timer is restarted upon:

- Entering the COLDSTART_LISTEN state
- Reception of correctly decoded headers or CAS symbols while the node is in COLDSTART_LISTEN state

The startup noise timer is stopped when the COLDSTART_LISTEN state is left.

Once the startup noise timeout expires, neither an overflow nor a cyclic restart of the timer is performed. The status is kept for further processing by the startup state machine. Since the startup noise timer won't be restarted when random channel activity is sensed, this timeout defines the fall-back solution that guarantees that a node will try to start up the communication cluster even in the presence of noise.

(3) Path of Leading Coldstart Node (initiating coldstart)

When a coldstart node enters COLDSTART_LISTEN, it listens to its attached channels.

If no communication is detected, the node enters the COLDSTART_COLLISION_RESOLUTION state and commences a coldstart attempt. The initial transmission of a CAS symbol is succeeded by the first regular cycle. This cycle has the number zero.

From cycle zero on, the node transmits its startup frame. Since each coldstart node may perform a coldstart attempt, it may occur that several nodes simultaneously transmit the CAS symbol and enter the coldstart path. This situation is resolved during the first four cycles after CAS transmission.

As soon as a node that initiates a coldstart attempt receives a CAS symbol or a frame header during these four cycles, it re-enters the COLDSTART_LISTEN state. Thereby, only one node remains in this path. In cycle four, other coldstart nodes begin to transmit their startup frames.

After four cycles in COLDSTART_COLLISION_RESOLUTION state, the node that initiated the coldstart enters the COLDSTART_CONSISTENCY_CHECK state. It collects all startup frames from cycle four and five and performs the clock correction. If the clock correction does not deliver any errors and it has received at least one valid startup frame pair, the node leaves COLDSTART_CONSISTENCY_CHECK and enters NORMAL_ACTIVE state.

The number of coldstart attempts that a node is allowed to perform is configured by FLXAnFRSUCC1.CSA. The number of remaining coldstarts attempts can be read from FLXAnFRCCSV.RCA. The number of remaining coldstart attempts is reduced by one for each attempted coldstart. A node may enter the COLDSTART_LISTEN state only if this value is larger than one and it may enter the COLDSTART_COLLISION_RESOLUTION state only if this value is larger than zero. If the number of coldstart attempts is one, coldstart is inhibited but integration is still possible.

(4) Path of Following Coldstart Node (responding to Leading Coldstart Node)

When a coldstart node enters the COLDSTART_LISTEN state, it tries to receive a valid pair of startup frames to derive its schedule and clock correction from the leading coldstart node.

As soon as a valid startup frame has been received the INITIALIZE_SCHEDULE state is entered. If the clock synchronization can successfully receive a matching second valid startup frame and derive a schedule from this, the INTEGRATION_COLDSTART_CHECK state is entered.

In INTEGRATION_COLDSTART_CHECK state it is assured that the clock correction can be performed correctly and that the coldstart node from which this node has initialized its schedule is still available. The node collects all sync frames and performs clock correction in the following double-cycle. If clock correction does not signal any errors and if the node continues to receive sufficient frames from the same node it has integrated on, the COLDSTART_JOIN state is entered.

In COLDSTART_JOIN state following coldstart nodes begin to transmit their own startup frames and continue to do so in subsequent cycles. Thereby, the leading coldstart node and the nodes joining it can check if their schedules agree with each other. If the clock correction signals any error, the node aborts the integration attempt. If a node in this state sees at least one valid startup frame during all even cycles in this state and at least one valid startup frame pair during all double cycles in this state, the node

leaves COLDSTART_JOIN state and enters NORMAL_ACTIVE state. Thereby it leaves STARTUP at least one cycle after the node that initiated the coldstart.

(5) Path of Non-coldstart Node

When a non-coldstart node enters the INTEGRATION_LISTEN state, it listens to its attached channels.

As soon as a valid startup frame has been received, the INITIALIZE_SCHEDULE state is entered. If the clock synchronization can successfully receive a matching second valid startup frame and derive a schedule from this, the INTEGRATION_CONSISTENCY_CHECK state is entered.

In INTEGRATION_CONSISTENCY_CHECK state the node verifies that the clock correction can be performed correctly and that enough coldstart nodes (at least 2) are sending startup frames that agree with the node's own schedule. Clock correction is activated, and if any errors are signaled, the integration attempt is aborted.

During the first even cycle in this state, either two valid startup frames or the startup frame of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

During the first double-cycle in this state, either two valid startup frame pairs or the startup frame pair of the node that this node has integrated on must be received; otherwise the node aborts the integration attempt.

If after the first double-cycle less than two valid startup frames are received within an even cycle, or less than two valid startup frame pairs are received within a double-cycle, the startup attempt is aborted.

Nodes in this state need to see two valid startup frame pairs for two consecutive double-cycles each to be allowed to leave STARTUP and enter NORMAL_OPERATION. Consequently, they leave startup at least one double-cycle after the node that initiated the coldstart and only at the end of a cycle with an odd cycle number.

20.3.6.7 NORMAL_ACTIVE State

As soon as the node that transmitted the first CAS symbol (resolving the potential access conflict and entering STARTUP via coldstart path) and one additional node have entered the NORMAL_ACTIVE state, the startup phase for the cluster has finished. In the NORMAL_ACTIVE state, all configured messages are scheduled for transmission. This includes all data frames as well as the sync frames. Rate and offset measurement is started in all even cycles (even / odd cycle pairs required).

In NORMAL_ACTIVE state the CC supports regular communication functions

- The CC performs transmissions and reception on the FlexRay bus as configured
- Clock synchronization is running
- The Host interface is operational

The CC exits from that state to

- HALT state by writing FLXAnFRSUCC1.CMD = “0110_B” (HALT command, at the end of the current cycle)
- HALT state by writing FLXAnFRSUCC1.CMD = “0111_B” (FREEZE command, immediately)
- HALT state due to change of the error state from ACTIVE to COMM_HALT
- NORMAL_PASSIVE state due to change of the error state from ACTIVE to PASSIVE
- READY state by writing FLXAnFRSUCC1.CMD = “0010_B” (READY command)

20.3.6.8 NORMAL_PASSIVE State

NORMAL_PASSIVE state is entered from NORMAL_ACTIVE state when the error state changes from ACTIVE to PASSIVE.

In NORMAL_PASSIVE state, the node is able to receive all frames (node is fully synchronized and performs clock synchronization). Contrary to the NORMAL_ACTIVE state, the node does not actively participate in communication, i.e. neither symbols nor frames are transmitted.

In NORMAL_PASSIVE state

- The CC performs reception on the FlexRay bus
- The CC does not transmit any frames or symbols on the FlexRay bus
- Clock synchronization is running
- The Host interface is operational

The CC exits from this state to

- HALT state by writing FLXAnFRSUCC1.CMD = “0110” (HALT command, at the end of the current cycle)
- HALT state by writing FLXAnFRSUCC1.CMD = “0111” (FREEZE command, immediately)
- HALT state due to change of the error state from PASSIVE to COMM_HALT
- NORMAL_ACTIVE state due to change of the error state from PASSIVE to ACTIVE. The transition takes place when FLXAnFRCCEV.PTAC equals FLXAnFRSUCC1.PTA - 1
- To READY state by writing FLXAnFRSUCC1.CMD = “0010” (READY command)

20.3.6.9 HALT State

In this state all communication (reception and transmission) is stopped.

The CC enters this state

- By writing FLXAnFRSUCC1.CMD = “0110_B” (HALT command) while the CC is in NORMAL_ACTIVE or NORMAL_PASSIVE state
- By writing FLXAnFRSUCC1.CMD = “0111_B” (FREEZE command) from all states
- When exiting from NORMAL_ACTIVE state because the clock correction failed counter reached the “maximum without clock correction fatal” limit and FLXAnFRSUCC1.HCSE is set to 1
- When exiting from NORMAL_PASSIVE state because the clock correction failed counter reached the “maximum without clock correction fatal” limit and FLXAnFRSUCC1.HCSE is set to 1

The CC exits from this state to DEFAULT_CONFIG state

- By writing FLXAnFRSUCC1.CMD = “0001_B” (CONFIG command)

When the CC enters HALT state, all configuration and status data is maintained for analysing purposes.

When the Host writes FLXAnFRSUCC1.CMD = “0110_B” (HALT command), the CC sets bit FLXAnFRCCSV.HRQ to 1 and enters HALT state at the next end of cycle.

When the Host writes FLXAnFRSUCC1.CMD = “0111_B” (FREEZE command), the CC enters HALT state immediately and sets bit FLXAnFRCCSV.FSI to 1.

The POC state from which the transition to HALT state took place can be read from FLXAnFRCCSV.PSL.

20.3.7 Network Management

The accrued Network Management (NM) vector can be read from registers FLXAnFRNMV1…3. The CC performs a bit-wise OR operation over all NM vectors out of all received valid NM frames with the Payload Preamble Indicator (PPI) bit set. Only static frames may be configured to hold NM information. The CC updates the NM vector at the end of each cycle.

The length of the NM vector can be configured from 0 to 12 bytes by FLXAnFRNEMC.NML. The NM vector length must be configured identically in all nodes of a cluster.

To configure a transmit buffer to send FlexRay frames with the PPI bit set as 1, bit PPIT in the header section of the respective transmit buffer has to be set to 1 via FLXAnFRWRHS1.PPIT. In addition the Host has to write the NM information to the data section of the respective transmit buffer.

The evaluation of the NM vector has to be done by the application running on the Host.

Section 20.3.17, Byte Alignment, for byte alignment of the received NM vector in registers FLXAnFRNMV1 to FLXAnFRNMV3.

CAUTIONS

1. **In case a message buffer is configured for transmission / reception of network management frames, the payload length configured in header 2 of that message buffer should be equal or greater than the length of the NM vector configured by FLXAnFRNEMC.NML.**
2. **When the CC transits to HALT state, the cycle count is not incremented and therefore the NM vector is not updated. In this case FLXAnFRNMV1…3 holds the value from the cycle before.**

20.3.8 Filtering and Masking

Filtering is done by comparison of the configuration of assigned message buffers against actual slot and cycle counter values and channel ID (channel A, B). A message buffer is only updated / transmitted if the required matches occur.

Filtering is done on:

- Slot Counter
- Cycle Counter
- Channel ID

The following filter combinations for acceptance / transmit filtering are allowed:

- Slot Counter + Channel ID
- Slot Counter + Cycle Counter + Channel ID

All configured filters must match in order to store a received message in a message buffer.

CAUTION

For the FIFO the acceptance filter is configured by the FIFO Rejection Filter (FLXAnFRFRF) and the FIFO Rejection Filter Mask (FLXAnFRFRFM).

A message will be transmitted in the time slot corresponding to the configured frame ID on the configured channel(s). If cycle counter filtering is enabled the configured cycle filter value must also match.

20.3.8.1 Slot Counter Filtering

Every transmit and receive buffer contains a frame ID stored in the header section. This frame ID is compared against the actual slot counter value in order to assign receive and transmit buffers to the corresponding slot.

If two or more message buffers are configured with the same frame ID and channel ID, and if they have a matching cycle counter filter value for the same slot, then the message buffer with the lowest message buffer number is used.

20.3.8.2 Cycle Counter Filtering

Cycle counter filtering is based on the notion of a cycle set. For filtering purposes, a match is detected if any one of the elements of the cycle set is matched. The cycle set is defined by the cycle code field in header section 1 of each message buffer.

If message buffer 0 resp. 1 is configured to hold the startup / sync frame or the single slot frame by bits FLXAnFRSUCC1.TXST, FLXAnFRSUCC1.TXSY, and FLXAnFRSUCC1.TSM, cycle counter filtering for message buffer 0 resp. 1 shall be disabled.

CAUTION

Sharing of a static time slot via cycle counter filtering between different nodes of a FlexRay network is not allowed.

The set of cycle numbers belonging to a cycle set is determined as described.

Table 20.112 Definition of cycle set

Cycle Code	Matching Cycle Counter Values
0b000000x	all Cycles
0b000001c	every second Cycle at (Cycle Count) mod2 = c
0b00001cc	every fourth Cycle at (Cycle Count) mod4 = cc
0b0001ccc	every eighth Cycle at (Cycle Count) mod8 = ccc
0b001cccc	every sixteenth Cycle at (Cycle Count) mod16 = cccc
0b01ccccc	every thirty-second Cycle at (Cycle Count) mod32 = ccccc
0b1cccccc	every sixty-fourth Cycle at (Cycle Count) mod64 = cccccc

The below table gives some examples for valid cycle sets to be used for cycle counter filtering.

Table 20.113 Examples for valid cycle sets

Cycle Code	Matching Cycle Counter Values
0b0000011	1-3-5-7-…. -63
0b0000100	0-4-8-12-…. -60
0b0001110	6-14-22-30-…. -62
0b0011000	8-24-40-56
0b0100011	3-35
0b1001001	9

The received message is stored only if the cycle counter value of the cycle during which the message is received matches an element of the receive buffer's cycle set. Channel ID and frame ID must also be met.

The content of a transmit buffer is transmitted on the configured channel(s) when an element of the cycle set matches the current cycle counter value. Channel ID and frame ID must also be met.

20.3.8.3 Channel ID Filtering

There is a 2-bit channel filtering field (CH) located in the header section of each message buffer in the Message RAM. It serves as a filter for receive buffers, and as a control field for transmit buffers.

Table 20.114 Channel filtering configuration

CH[1:0]	**Transmit Buffer** transmit frame	**Receive Buffer store valid receive frame**
00	no transmission	ignore frame
01	on channel A	received on channel A
10	on channel B	received on channel B
11	on both channels (static segment only)	received on channel A or B (store first semantically valid frame, static segment only)

The contents of a transmit buffer is transmitted on the channels specified in the channel filtering field when the slot counter filtering and cycle counter filtering criteria are also met. Only in static segment a transmit buffer may be set up for transmission on both channels (CH = "11_B").

Valid received frames are stored if they are received on the channels specified in the channel filtering field when the slot counter filtering and cycle counter filtering criteria are also met. Only in static segment a receive buffer may be setup for reception on both channels (CH = “11”).

CAUTION

If a message buffer is configured for the dynamic segment and both bits of the channel filtering field are set to 1, no frames are transmitted resp. received frames are ignored (same function as CH = “00”).

20.3.8.4 FIFO Filtering

For FIFO filtering registers FLXAnFRFRF and FLXAnFRFRFM are used. The FIFO filter consists of channel filter FLXAnFRFRF.CH, frame ID filter FLXAnFRFRF.FID, and cycle counter filter FLXAnFRFRF.CYF. Registers FLXAnFRFRF and FLXAnFRFRFM can be configured in DEFAULT_CONFIG or CONFIG state only. The filter configuration in the header section of message buffers belonging to the FIFO is ignored.

The 7-bit cycle counter filter determines the cycle set to which frame ID and channel rejection filter are applied. In cycles not belonging to the cycle set specified by FLXAnFRFRF.CYF, all frames are rejected.

A valid received frame is stored in the FIFO if channel ID, frame ID, and cycle counter are not rejected by the configured rejection filter and rejection filter mask, and if there is no matching dedicated receive buffer.

20.3.9 Transmit Process

20.3.9.1 Static Segment

For the static segment, if there are several messages pending for transmission, the message with the frame ID corresponding to the next sending slot is selected for transmission.

The data section of transmit buffers assigned to the static segment can be updated until the end of the preceding time slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

20.3.9.2 Dynamic Segment

In the dynamic segment, if several messages are pending, the message with the highest priority (lowest frame ID) is selected next. In the dynamic segment different slot counter sequences on channel A and channel B are possible (concurrent sending of different frame IDs on both channels).

The data section of transmit buffers assigned to the dynamic segment can be updated until the end of the preceding slot. This means that a transfer from the Input Buffer has to be started by writing to the Input Buffer Command Request register latest at this time.

The start of latest transmit configured by FLXAnFRMHDC.SLT defines the maximum minislot value allowed before inhibiting new frame transmission in the dynamic segment of the current cycle.

20.3.9.3 Transmit Buffers

FlexRay message buffers can be configured as transmit buffers by programming bit CFG in the header section of the respective message buffer to 1 via FLXAnFRWRHS1.

There exist the following possibilities to assign a transmit buffer to the CC channels:

- Static segment: channel A or channel B,
  channel A and channel B
- Dynamic segment: channel A or channel B

Message buffer 0 resp. 1 is dedicated to hold the startup frame, the sync frame, or the designated single slot frame as configured by FLXAnFRSUCC1.TXST, FLXAnFRSUCC1.TXSY, and FLXAnFRSUCC1.TSM. In this case, it can be reconfigured in DEFAULT_CONFIG or CONFIG state only. This ensures that any node transmits at most one startup / sync frame per communication cycle. Transmission of startup / sync frames from other message buffers is not possible.

All other message buffers configured for transmission in static or dynamic segment are reconfigurable during runtime depending on the configuration of FLXAnFRMRC.SEC (see **Section 20.3.12.1, Reconfiguration of Message Buffers**). Due to the organization of the data partition in the Message RAM (reference by data pointer), reconfiguration of the configured payload length and the data pointer in the header section of a message buffer may lead to erroneous configurations.

If a message buffer is reconfigured (header section updated) during runtime, it may happen that this message buffer is not send out in the respective communication cycle.

The CC does not have the capability to calculate the header CRC. The Host is supposed to provide the header CRCs for all transmit buffers. If network management is required, the Host has to set the PPIT bit in the header section of the respective message buffer to 1 and write the network management information to the data section of the message buffer (see **Section 20.3.7, Network Management**).

The payload length field configures the payload length in 2-byte words. If the configured payload length of a static transmit buffer is shorter than the payload length configured for the static segment by

FLXAnFRMHDC.SFDL, the CC generates padding bytes to ensure that frames have proper physical length. The padding pattern is "0000_H".

CAUTION

In case of an odd payload length (PLC = 1, 3, 5,...) the application has to write zero to the last 16 bit of the message buffers data section to ensure that the padding pattern is "0000_H".

Each transmit buffer provides a transmission mode flag TXM that allows the Host to configure the transmission mode for the transmit buffer. If this bit is set, the transmitter operates in the single-shot mode. If this bit is cleared, the transmitter operates in the continuous mode.

In single-shot mode the CC resets the respective TXR flag to 0 after transmission has completed. Now the Host may update the transmit buffer.

In continuous mode, the CC does not reset the respective transmission request flag TXR to 0 after successful transmission. In this case a frame is sent out each time the filter criteria match. The TXR flag can be reset to 0 by the Host by writing the respective message buffer number to the FLXAnFRIBCR register while bit FLXAnFRIBCM.STXRH is set to 0.

If two or more transmit buffers meet the filter criteria simultaneously, the transmit buffer with the lowest message buffer number will be transmitted in the respective slot.

20.3.9.4 Frame Transmission

The following steps are required to prepare a message buffer for transmission:

- Configure the transmit buffer in the Message RAM via FLXAnFRWRHS1, FLXAnFRWRHS2, and FLXAnFRWRHS3
- Write the data section of the transmit buffer via FLXAnFRWRDSn
- Transfer the configuration and message data from Input Buffer to the Message RAM by writing the number of the target message buffer to register FLXAnFRIBCR
- If configured in register FLXAnFRIBCM, the transmission request flag TXR for the respective message buffer will be set as soon as the transfer has completed, and the message buffer is ready for transmission.
- Check whether the message buffer has been transmitted by checking the respective TXR bit (TXR = 0) in the FLXAnFRTRXQ1/2/3/4 registers (single-shot mode only).

After transmission has completed, the respective TXR flag in the FLXAnFRTXRQ1/2/3/4 register is reset to 0 (single-shot mode), and, if bit MBI in the header section of the message buffer is set to 1, flag FLXAnFRSIR.TXI is set to 1. If enabled, an interrupt is generated.

20.3.9.5 Null Frame Transmission

If in static segment the Host does not set the transmission request flag to 1 before transmit time, the CC transmits a null frame with the null frame indication bit set to 0 and the payload data set to zero.

In the following cases the CC transmits a null frame:

- If the message buffer with the lowest message buffer number matching the filter criteria does not have its transmission request flag set (TXR = 0) to 1.
- No transmit buffer configured for the slot has a cycle counter filter that matches the current cycle. In this case, no message buffer status FLXAnFRMBS is updated.

Null frames are not transmitted in the dynamic segment.

20.3.10 Receive Process

20.3.10.1 Dedicated Receive Buffers

A portion of the FlexRay message buffers can be configured as dedicated receive buffers by programming bit CFG in the header section of the respective message buffer to 0 via FLXAnFRWRHS1.

The following possibilities exist to assign a receive buffer to the CC channels:

- Static segment: channel A or channel B,
  channel A and channel B (the CC stores the first semantically valid frame)
- Dynamic segment: channel A or channel B

The CC transfers the payload data of valid received messages from the shift register of the FlexRay channel protocol controller (channel A or B) to the receive buffer with the matching filter configuration. A receive buffer stores all frame elements except the frame CRC.

All message buffers configured for reception in static or dynamic segment are reconfigurable during runtime depending on the configuration of FLXAnFRMRC.SEC (see **Section 20.3.12.1, Reconfiguration of Message Buffers**). If a message buffer is reconfigured (header section updated) during runtime it may happen that in the respective communication cycle a received message is lost.

If two or more receive buffers meet the filter criteria simultaneously, the receive buffer with the lowest message buffer number is updated with the received message.

20.3.10.2 Frame Reception

The following steps are required to prepare a dedicated message buffer for reception:

- Configure the receive buffer in the Message RAM via FLXAnFRWRHS1, FLXAnFRWRHS2, and FLXAnFRWRHS3
- Transfer the configuration from Input Buffer to the Message RAM by writing the number of the target message buffer to register FLXAnFRIBCR

Once these steps are performed, the message buffer functions as an active receive buffer and participates in the internal acceptance filtering process which takes place every time the CC receives a message. The first matching receive buffer is updated from the received message.

If a valid payload segment was stored in the data section of a message buffer, the respective ND flag in the FLXAnFRNDAT1/2/3/4 registers is set to 1, and, if bit MBI in the header section of that message buffer is set to 1, flag FLXAnFRSIR.RXI is set to 1. If enabled, an interrupt is generated.

In case that bit ND was already set to 1 when the Message Handler updates the message buffer, bit FLXAnFRMBS.MLST of the respective message buffer is set to 1 and the unprocessed message data is lost.

If no frame, a null frame, or a corrupted frame was received in a slot, the data section of the message buffer configured for this slot is not updated. In this case only the respective message buffer status FLXAnFRMBS is updated.

When the Message Handler changed the message buffer status FLXAnFRMBS in the header section of a message buffer, the respective MBC flag in the FLXAnFRMBSC1/2/3/4 registers is set to 1, and if bit MBI in the header section of that message buffer is set, flag FLXAnFRSIR.MBSI is set to 1. If enabled an interrupt is generated.

If the payload length of a received frame PLR is longer than the value programmed by PLC in the header section of the respective message buffer, the data field stored in the message buffer is truncated to that length.

To read a receive buffer from the Message RAM via the Output Buffer, proceed as described in **Section 20.3.12.2 (2), Data Transfer from Message RAM to Output Buffer**.

CAUTION

The ND and MBC flags are automatically cleared by the Message Handler when the payload data and the header of a received message have been transferred to the Output Buffer, respectively.

20.3.10.3 Null Frame Reception

The payload segment of a received null frame is not copied into the matching dedicated receive buffer. If a null frame has been received, only the message buffer status FLXAnFRMBS of the matching message buffer is updated from the received null frame. All bits in header 2 and 3 of the matching message buffer remain unchanged. They are updated from received data frames only.

When the Message Handler changed the message buffer status FLXAnFRMBS in the header section of a message buffer, the respective MBC flag in the FLXAnFRMBSC1/2/3/4 register is set to 1, and if bit MBI in the header section of that message buffer is set to 1, flag FLXAnFRSIR.MBSI is set to 1. If enabled, an interrupt is generated.

20.3.11 FIFO Function

20.3.11.1 Description

A portion of the message buffers can be configured as a cyclic First-In-First-Out (FIFO) buffer. The group of message buffers belonging to the FIFO is contiguous in the register map starting with the message buffer referenced by FLXAnFRMRC.FFB and ending with the message buffer referenced by FLXAnFRMRC.LCB. Up to 127 message buffers can be assigned to the FIFO.

Every valid incoming message not matching with any dedicated receive buffer but passing the programmable FIFO filter is stored into the FIFO. In this case frame ID, payload length, receive cycle count, and the message buffer status FLXAnFRMBS of the addressed FIFO message buffer are overwritten with frame ID, payload length, receive cycle count, and the status from the received frame. Bit FLXAnFRSIR.RFNE shows that the FIFO is not empty, bit FLXAnFRSIR.RFCL is set to 1 when the receive FIFO fill level FLXAnFRFSR.RFFL is equal or greater than the critical level as configured by FLXAnFRFCL.CL, bit FLXAnFREIR.RFO shows that a FIFO overrun has been detected. If enabled, interrupts are generated.

If null frames are not rejected by the FIFO rejection filter, the null frames will be treated like data frames when they are stored into the FIFO.

There are two index registers associated with the FIFO. The PUT Index Register (PIDX) is an index to the next available location in the FIFO. When a new message has been received it is written into the message buffer addressed by the PIDX register. The PIDX register is then incremented and addresses the next available message buffer. If the PIDX register is incremented past the highest numbered message buffer of the FIFO, the PIDX register is loaded with the number of the first (lowest numbered) message buffer in the FIFO chain. The GET Index Register (GIDX) is used to address the next message buffer of the FIFO to be read. The GIDX register is incremented after transfer of the contents of a message buffer belonging to the FIFO to the Output Buffer. The PUT Index Register and the GET Index Register are not accessible by the Host.

The FIFO is completely filled when the PUT index (PIDX) reaches the value of the GET index (GIDX). When the next message is written to the FIFO before the oldest message has been read, both PUT index and GET index are incremented and the new message overwrites the oldest message in the FIFO. This will set FIFO overrun flag FLXAnFREIR.RFO to 1.

A FIFO non empty status is detected when the PUT index (PIDX) differs from the GET index (GIDX). In this case flag FLXAnFRSIR.RFNE is set to 1. This indicates that there is at least one received message in the FIFO. The FIFO empty, FIFO not empty, and the FIFO overrun states are explained in **Figure 20.11** for a three message buffer FIFO.

The programmable FlexRay FIFO Rejection Filter (FLXAnFRFRF) defines a filter pattern for messages to be rejected. The FIFO filter consists of channel filter, frame ID filter, and cycle counter filter. If bit FLXAnFRFRF.RSS is set to 1, all messages received in the static segment are rejected by the FIFO. If bit FLXAnFRFRF.RNF is set to 1, received null frames are not stored in the FIFO.

The FlexRay FIFO Rejection Filter Mask (FLXAnFRFRFM) specifies which bits of the frame ID filter in the FIFO Rejection Filter register are marked 'don't care' for rejection filtering.

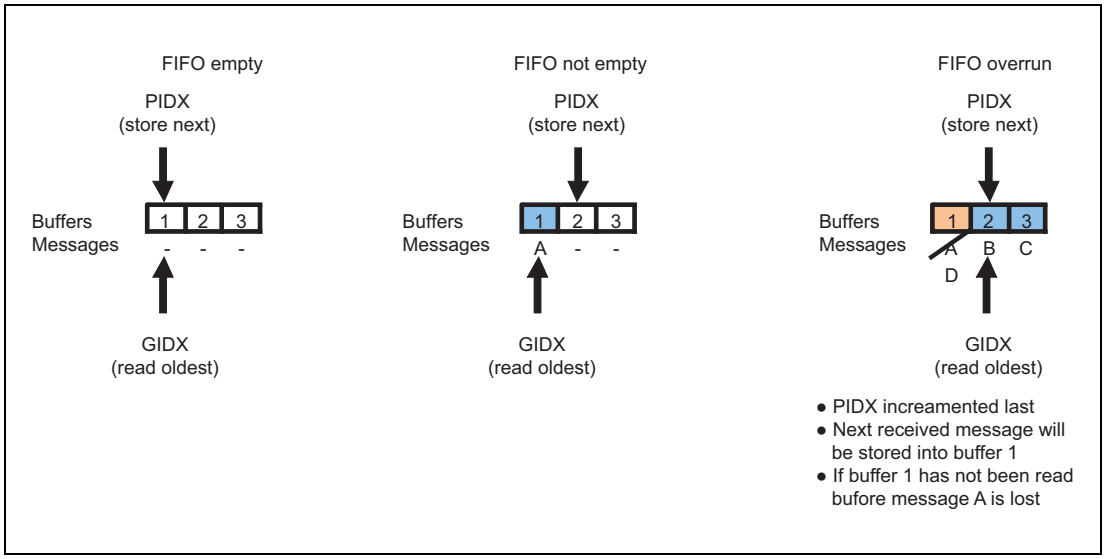

Figure 20.11 FIFO Status: Empty, Not Empty, Overrun

20.3.11.2 Configuration of the FIFO

(Re)configuration of message buffers belonging to the FIFO is only possible when the CC is in DEFAULT_CONFIG or CONFIG state. While the CC is in DEFAULT_CONFIG or CONFIG state, the FIFO function is not available.

For all message buffers belonging to the FIFO the payload length configured should be programmed to the same value via FLXAnFRWRHS2.PLC. The data pointer to the first 32-bit word of the data section of the respective message buffer in the Message RAM has to be configured via FLXAnFRWRHS3.DP.

All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask. The values configured in the header sections of the message buffers belonging to the FIFO are, with exception of DP and PLC, irrelevant.

CAUTIONS

1. **It is recommended to program the MBI bits of the message buffers belonging to the FIFO to 0 via FLXAnFRWRHS1.MBI to avoid generation of RX interrupts.**
2. **If the payload length of a received frame is longer than the value programmed by FLXAnFRWRHS2.PLC in the header section of the respective message buffer, the data field stored in a message buffer of the FIFO is truncated to that length.**

20.3.11.3 Access to the FIFO

(1) When the output buffer is used:

For FIFO access outside DEFAULT_CONFIG and CONFIG state, the Host has to trigger a transfer from the Message RAM to the Output Buffer by writing the number of the first message buffer of the FIFO (referenced by FLXAnFRMRC.FFB) to the register FLXAnFROBCR. The Message Handler then transfers the message buffer addressed by the GET Index Register (GIDX) to the Output Buffer. After this transfer the GET Index Register (GIDX) is incremented.

(2) When the data transfer function is used:

The message received in FIFO can be transferred to the Local RAM/Global RAM by using the output data transfer function. For the output data transfer function, see **Section 20.3.16.2, Output Data Transfer**, Output Data Transfer.

20.3.12 Message Handling

The Message Handler controls data transfers between the Input / Output Buffer and the Message RAM and between the Message RAM and the two Temporary buffers.

Access to the message buffers stored in the Message RAM is done under control of the Message Handler state machine. This avoids conflicts between accesses of the two FlexRay channel protocol controllers and the Host to the Message RAM.

Frame IDs of message buffers assigned to the static segment have to be in the range from 1 to FLXAnFRGTUC7.NSS. Frame IDs of message buffers assigned to the dynamic segment have to be in the range from FLXAnFRGTUC7.NSS + 1 to 2047.

Received messages with no matching dedicated receive buffer (static or dynamic segment) are stored in the receive FIFO (if configured) if they pass the FIFO rejection filter.

Access of the Host to the message buffer contents using the input or output buffer function is described in this subsection. Access to the message buffer contents using the data transfer function is mentioned in **Section 20.3.16, Usage of Data Transfer**.

20.3.12.1 Reconfiguration of Message Buffers

In case that an application needs to operate with more than 128 different messages, static and dynamic message buffers may be reconfigured during FlexRay operation. This is done by updating the header section of the respective message buffer via Input Buffer registers FLXAnFRWRHS1…3.

Reconfiguration has to be enabled via control bits FLXAnFRMRC.SEC in the Message RAM Configuration register.

If a message buffer has not been transmitted / updated from a received frame before reconfiguration starts, the respective message is lost.

The point in time when a reconfigured message buffer is ready for transmission / reception according to the reconfigured frame ID depends on the actual state of the slot counter when the update of the header section has completed. Therefore it may happen that a reconfigured message buffer is not transmitted / updated from a received frame in the cycle where it was reconfigured.

The Message RAM is scanned according to below.

Table 20.115 Scan of Message RAM

Start of Scan in Slot	Scan for Slots
1	2…15, 1 (next cycle)
8	16…23, 1 (next cycle)
16	24…31, 1 (next cycle)
24	32…39, 1 (next cycle)
…	…

A Message RAM scan is terminated with the start of NIT regardless whether it has completed or not. The scan of the Message RAM for slots 2 to 15 starts at the beginning of slot 1 of the actual cycle. The scan of the Message RAM for slot 1 is done in the cycle before by checking in parallel to each scan of the Message RAM whether there is a message buffer configured for slot 1 of the next cycle.

The number of the first dynamic message buffer is configured by FLXAnFRMRC.FDB. In case a Message RAM scan starts while the CC is in dynamic segment, the scan starts with the message buffer number configured by FLXAnFRMRC.FDB.

In case a message buffer should be reconfigured to be used in slot 1 of the next cycle, the following has to be considered:

- If the message buffer to be reconfigured for slot 1 is part of the “Static Buffers”, it will only be found if it is reconfigured before the last Message RAM scan in the static segment of the actual cycle evaluates this message buffer.
- If the message buffer to be reconfigured for slot 1 is part of the “Static + Dynamic Buffers”, it will be found if it is reconfigured before the last Message RAM scan in the actual cycle evaluates this message buffer.
- The start of NIT terminates the Message RAM scan. In case the Message RAM scan has not evaluated the reconfigured message buffer until this point in time, the message buffer will not be considered for the next cycle.

CAUTION

Reconfiguration of message buffers may lead to the loss of messages and therefore has to be used very carefully. In worst case (reconfiguration in consecutive cycles) it may happen that a message buffer is never transmitted / updated from a received frame.

20.3.12.2 Host access to Message RAM

The message transfer between Input Buffer and Message RAM as well as between Message RAM and Output Buffer is triggered by the Host by writing the number of the target / source message buffer to be accessed to FLXAnFRIBCR or FLXAnFROBCR register.

The FLXAnFRIBCM and FLXAnFROBCM registers can be used to write / read header and data section of the selected message buffer separately.

If bit FLXAnFRIBCM.STXR is set to = 1, the transmission request flag TXR of the selected message buffer is automatically set to 1 after the message buffer has been updated. If bit FLXAnFRIBCM.STXR is reset to 0, the transmission request flag TXR of the selected message buffer is reset. This can be used to stop transmission from message buffers operated in continuous mode.

Input Buffer (IBF) and Output Buffer (OBF) are build up as a double buffer structure. One half of this double buffer structure is accessible by the Host (IBF Host / OBF Host), while the other half (IBF Shadow / OBF Shadow) is accessed by the Message Handler for data transfers between IBF / OBF and Message RAM.

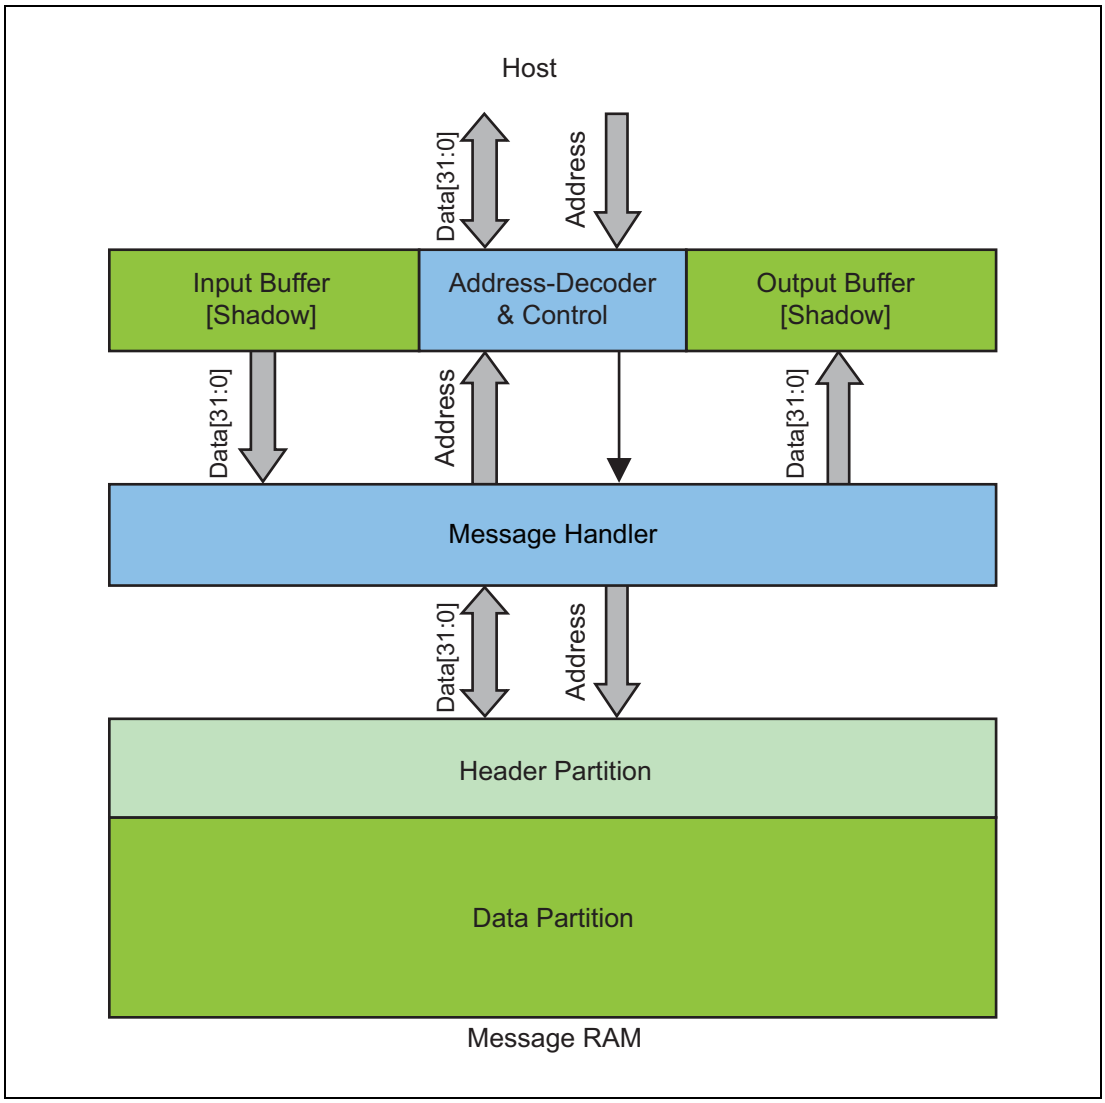

Figure 20.12 Host access to Message RAM

(1) Data Transfer from Input Buffer to Message RAM

To configure / update a message buffer in the Message RAM, the Host has to write the data to FLXAnFRWRDSn and the header to FLXAnFRWRHS1…3. The specific action is selected by configuring the FlexRay Input Buffer Command Mask FLXAnFRIBCM.

When the Host writes the number of the target message buffer in the Message RAM to FLXAnFRIBCR.IBRH, IBF Host and IBF Shadow are swapped (see **Figure 20.14**).

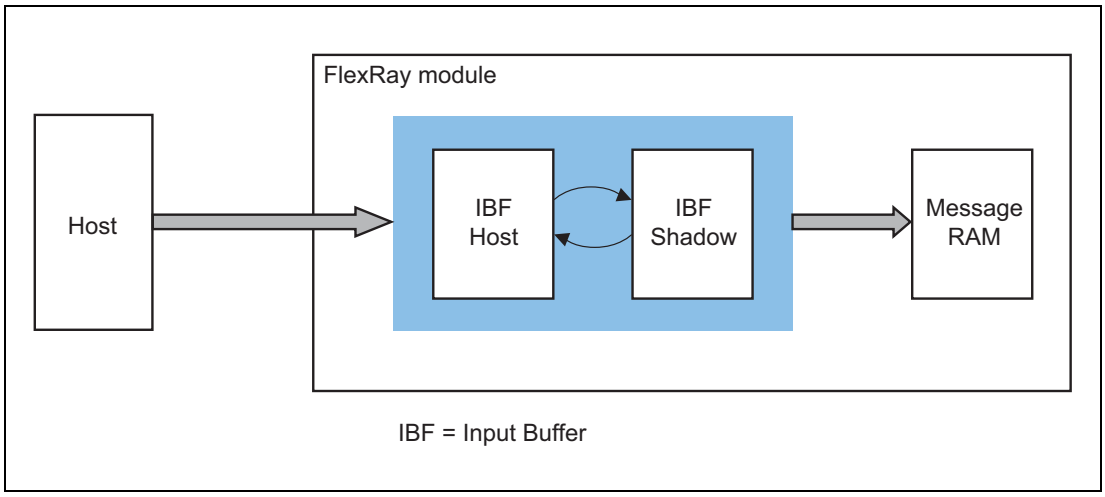

Figure 20.13 Double Buffer Structure Input Buffer

In addition the bits in the FLXAnFRIBCM and FLXAnFRIBCR registers are also swapped to keep them attached to the respective IBF section (see **Figure 20.14**).

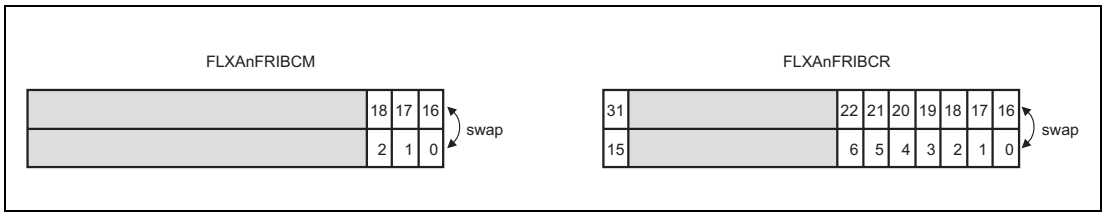

Figure 20.14 Swapping of FLXAnFRIBCM and FLXAnFRIBCR bits

With this write operation bit FLXAnFRIBCR.IBSYS is set to 1. The Message Handler then starts to transfer the contents of IBF Shadow to the message buffer in the Message RAM selected by FLXAnFRIBCR.IBRS.

While the Message Handler transfers the data from IBF Shadow to the target message buffer in the Message RAM, the Host may write the next message to IBF Host. After the transfer between IBF Shadow and the Message RAM has completed, bit FLXAnFRIBCR.IBSYS is set back to 0 and the next transfer to the Message RAM may be started by the Host by writing the respective target message buffer number to FLXAnFRIBCR.IBRH.

If a write access to FLXAnFRIBCR.IBRH occurs while FLXAnFRIBCR.IBSYS is 1, FLXAnFRIBCR.IBSYH is set to 1. After completion of the ongoing data transfer from IBF Shadow to the Message RAM, IBF Host and IBF Shadow are swapped, FLXAnFRIBCR.IBSYH is reset to 0, FLXAnFRIBCR.IBSYS remains set to 1, and the next transfer to the Message RAM is started. In addition the message buffer numbers stored under FLXAnFRIBCR.IBRH and FLXAnFRIBCR.IBRS and the command mask flags are also swapped.

Example of a 8/16/32-bit Host access sequence:

Configure / update n-th message buffer via IBF

- Wait until FLXAnFRIBCR.IBSYH is reset
- Write data section to FLXAnFRWRDSn
- Write header section to FLXAnFRWRHS1…3
- Write Command Mask: write FLXAnFRIBCM.STXRH, FLXAnFRIBCM.LDSH, FLXAnFRIBCM.LHSH
- Demand data transfer to target message buffer: write FLXAnFRIBCR.IBRH

Configure / update (n+1)th message buffer via IBF

- Wait until FLXAnFRIBCR.IBSYH is reset
- Write data section to FLXAnFRWRDSn
- Write header section to FLXAnFRWRHS1…3
- Write Command Mask: write FLXAnFRIBCM.STXRH, FLXAnFRIBCM.LDSH, FLXAnFRIBCM.LHSH
- Demand data transfer to target message buffer: write FLXAnFRIBCR.IBRH

CAUTION

Any write access to IBF while FLXAnFRIBCR.IBSYH is 1 will set error flag FLXAnFREIR.IIBA to 1. In this case the write access has no effect.

Table 20.116 Assignment of FLXAnFRIBCM Bits

Pos.	Access	Bit	Function
18	r	STXRS	Set Transmission Request Shadow ongoing or finished
17	r	LDSS	Load Data Section Shadow ongoing or finished
16	r	LHSS	Load Header Section Shadow ongoing or finished
2	r/w	STXRH	Set Transmission Request Host
1	r/w	LDSH	Load Data Section Host
0	r/w	LHSH	Load Header Section Host

Table 20.117 Assignment of FLXAnFRIBCR Bits

Pos.	Access	Bit	Function
31	r	IBSYS	IBF Busy Shadow, signals ongoing transfer from IBF Shadow to Message RAM
22…16	r	IBRS	IBF Request Shadow, number of message buffer currently / lately updated
15	r	IBSYH	IBF Busy Host, transfer request pending for message buffer referenced by IBRH
6…0	r/w	IBRH	IBF Request Host, number of message buffer to be updated next

(2) Data Transfer from Message RAM to Output Buffer

To read a message buffer from the Message RAM, the Host has to write to register FLXAnFROBCR to trigger the data transfer as configured in FLXAnFROBCM. After the transfer has completed, the Host can read the transferred data from FLXAnFRRDDSn, FLXAnFRRDHS1…3, and FLXAnFRMBS.

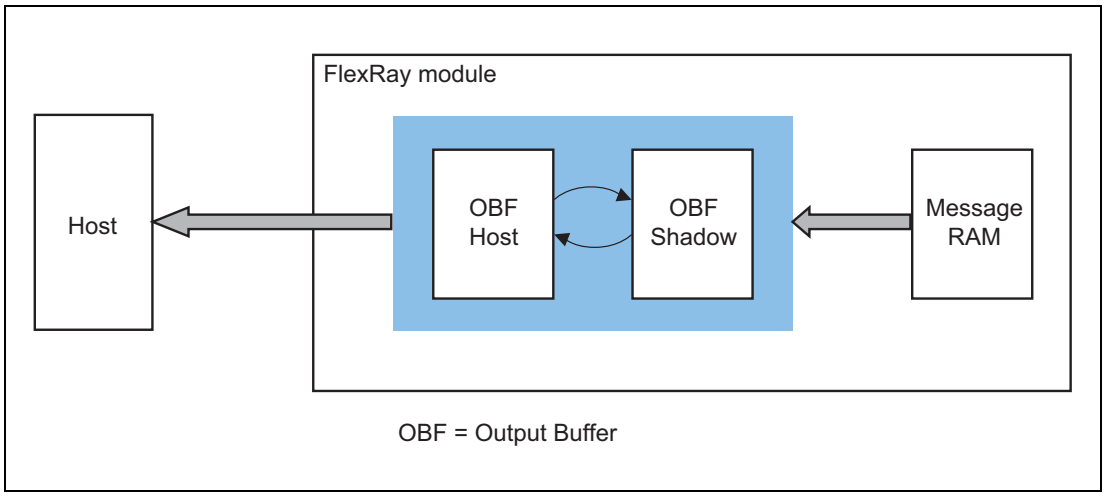

Figure 20.15 Double buffer structure Output Buffer

OBF Host and OBF Shadow as well as bits FLXAnFROBCM.RHSS, FLXAnFROBCM.RDSS, FLXAnFROBCM.RHSH, FLXAnFROBCM.RDSH and bits FLXAnFROBCR.OBRS, FLXAnFROBCR.OBRH are swapped under control of bits FLXAnFROBCR.VIEW and FLXAnFROBCR.REQ.

Writing bit FLXAnFROBCR.REQ to 1 copies bits FLXAnFROBCM.RHSS, FLXAnFROBCM.RDSS and bits FLXAnFROBCR.OBRS to an internal storage (see **Figure 20.16**).

After setting FLXAnFROBCR.REQ to 1, FLXAnFROBCR.OBSYS is set to 1, and the transfer of the message buffer selected by FLXAnFROBCR.OBRS from the Message RAM to OBF Shadow is started. After the transfer between the Message RAM and OBF Shadow has completed, the FLXAnFROBCR.OBSYS bit is set back to 0. Bits FLXAnFROBCR.REQ and FLXAnFROBCR.VIEW can only be set to 1 while FLXAnFROBCR.OBSYS is 0.

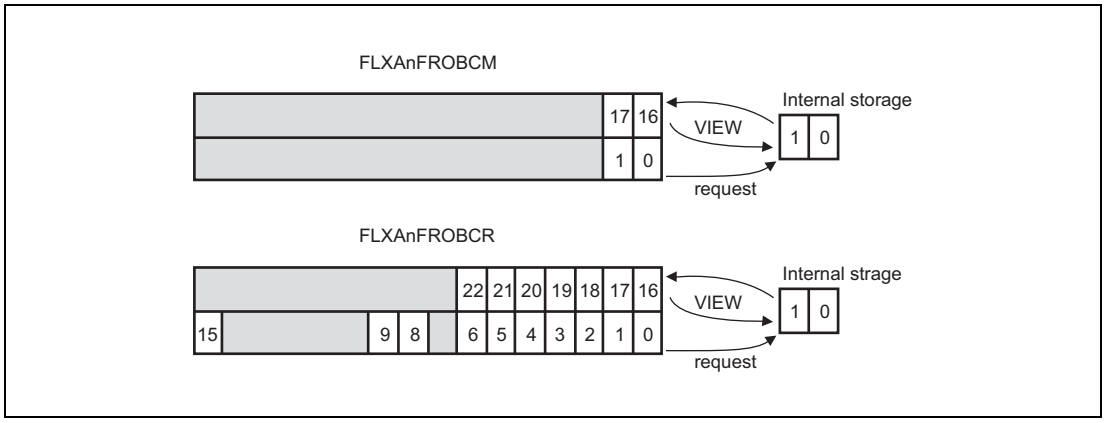

Figure 20.16 Swapping of FLXAnFROBCM and FLXAnFROBCR bits

OBF Host and OBF Shadow are swapped by setting bit FLXAnFROBCR.VIEW to 1 while bit FLXAnFROBCR.OBSYS is 0 (see **Figure 20.15**).

In addition bits FLXAnFROBCR.OBRH and bits FLXAnFROBCM.RHSH, FLXAnFROBCM.RDSH are swapped with the registers internal storage thus assuring that the message buffer number stored in FLXAnFROBCR.OBRH and the mask configuration stored in FLXAnFROBCM.RHSH, FLXAnFROBCM.RDSH matches the transferred data stored in OBF Host (see **Figure 20.16**).

Now the Host can read the transferred message buffer from OBF Host while the Message Handler may transfer the next message from the Message RAM to OBF Shadow.

If bits REQ and VIEW are set to 1 with the same write access while FLXAnFROBSYS is 0, FLXAnFROBSYS is automatically set to 1 and OBF Shadow and OBF Host are swapped. Additionally mask bits FLXAnFROBCM.RDSH and FLXAnFROBCM.RHSH are swapped with the registers internal storage to keep them attached to the respective Output Buffer transfer. Afterwards FLXAnFROBCR.OBRS is copied to the register internal storage, mask bits FLXAnFROBCM.RDSS and FLXAnFROBCM.RHSS are copied to register FLXAnFROBCM internal storage, and the transfer of the selected message buffer from the Message RAM to OBF Shadow is started. While the transfer is ongoing the Host can read the message buffer transferred by the previous transfer from OBF Host. When the current transfer between Message RAM and OBF Shadow has completed, this is signaled by setting FLXAnFROBCR.OBSYS back to 0.

Example of an 8/16/32-bit Host access to a single message buffer:

If a single message buffer has to be read out, two separate write accesses to FLXAnFROBCR.REQ and FLXAnFROBCR.VIEW are necessary:

- Wait until FLXAnFROBCR.OBSYS is reset
- Write Output Buffer Command Mask FLXAnFROBCM.RHSS, FLXAnFROBCM.RDSS
- Request transfer of message buffer to OBF Shadow by writing FLXAnFROBCR.OBRS and FLXAnFROBCR.REQ (in case of and 8-bit Host interface, FLXAnFROBCR.OBRS has to be written before FLXAnFROBCR.REQ).
- Wait until FLXAnFROBCR.OBSYS is reset
- Toggle OBF Shadow and OBF Host by writing FLXAnFROBCR.VIEW = 1
- Read out transferred message buffer by reading FLXAnFRRDDSn, FLXAnFRRDHS1…3, and FLXAnFRMBS

Example of an 8/16/32-bit Host access sequence:

Request transfer of 1st message buffer to OBF Shadow

- Wait until FLXAnFROBCR.OBSYS is reset
- Write Output Buffer Command Mask FLXAnFROBCM.RHSS, FLXAnFROBCM.RDSS for 1st message buffer
- Request transfer of 1st message buffer to OBF Shadow by writing FLXAnFROBCR.OBRS and FLXAnFROBCR.REQ (in case of an 8-bit Host interface, FLXAnFROBCR.OBRS has to be written before FLXAnFROBCR.REQ).

Toggle OBF Shadow and OBF Host to read out 1st transferred message buffer and request transfer of 2nd message buffer:

- Wait until FLXAnFROBCR.OBSYS is reset to 0

- Write Output Buffer Command Mask FLXAnFROBCM.RHSS, FLXAnFROBCM.RDSS for 2nd message buffer
- Toggle OBF Shadow and OBF Host and start transfer of 2nd message buffer to OBF Shadow simultaneously by writing FLXAnFROBCR.OBRS of 2nd message buffer, FLXAnFROBCR.REQ, and FLXAnFROBCR.VIEW (in case of and 8-bit Host interface, FLXAnFROBCR.OBRS has to be written before FLXAnFROBCR.REQ and FLXAnFROBCR.VIEW).
- Read out 1st transferred message buffer by reading FLXAnFRRDDSn, FLXAnFRRDHS1…3, and FLXAnFRMBS

…

Demand access to last requested message buffer without request of another message buffer:

- Wait until FLXAnFROBCR.OBSYS is reset to 0
- Demand access to last transferred message buffer by writing FLXAnFROBCR.VIEW
- Read out last transferred message buffer by reading FLXAnFRRDDSn, FLXAnFRRDHS1…3, and FLXAnFRMBS

Table 20.118 Assignment of FLXAnFROBCM bits

Pos.	Access	Bit	Function
17	r	RDSH	Data Section available for Host access
16	r	RHSH	Header Section available for Host access
1	r/w	RDSS	Read Data Section Shadow
0	r/w	RHSS	Read Header Section Shadow

Table 20.119 Assignment of FLXAnFROBCR bits

Pos.	Access	Bit	Function
22…16	r	OBRH	OBF Request Host, number of message buffer available for Host access
15	r	OBSYS	OBF Busy Shadow, signals ongoing transfer from Message RAM to OBF Shadow
9	r/w	REQ	Request Transfer from Message RAM to OBF Shadow
8	r/w	VIEW	View OBF Shadow, swap OBF Shadow and OBF Host
6…0	r/w	OBRS	OBF Request Shadow, number of message buffer for next request

20.3.12.3 FlexRay Protocol Controller Access to Message RAM

The two Temporary buffers (TBF A, B) are used to buffer the data for transfer between the two FlexRay Protocol Controllers and the Message RAM.

Each Temporary buffer is build up as a double buffer, able to store two complete FlexRay messages. There is always one buffer assigned to the corresponding Protocol Controller while the other one is accessible by the Message Handler.

If e.g. the Message Handler writes the next message to be sent to Temporary buffer Tx, the FlexRay Channel Protocol Controller can access Temporary buffer Rx to store the message it is actually receiving. During transmission of the message stored in Temporary buffer Tx, the Message Handler transfers the last received message stored in Temporary buffer Rx to the Message RAM (if it passes acceptance filtering) and updates the respective message buffer.

Data transfers between the Temporary buffers and the shift registers of the FlexRay Channel Protocol Controllers are done in words of 32 bit. This enables the use of a 32 bit shift register independent of the length of the FlexRay messages.

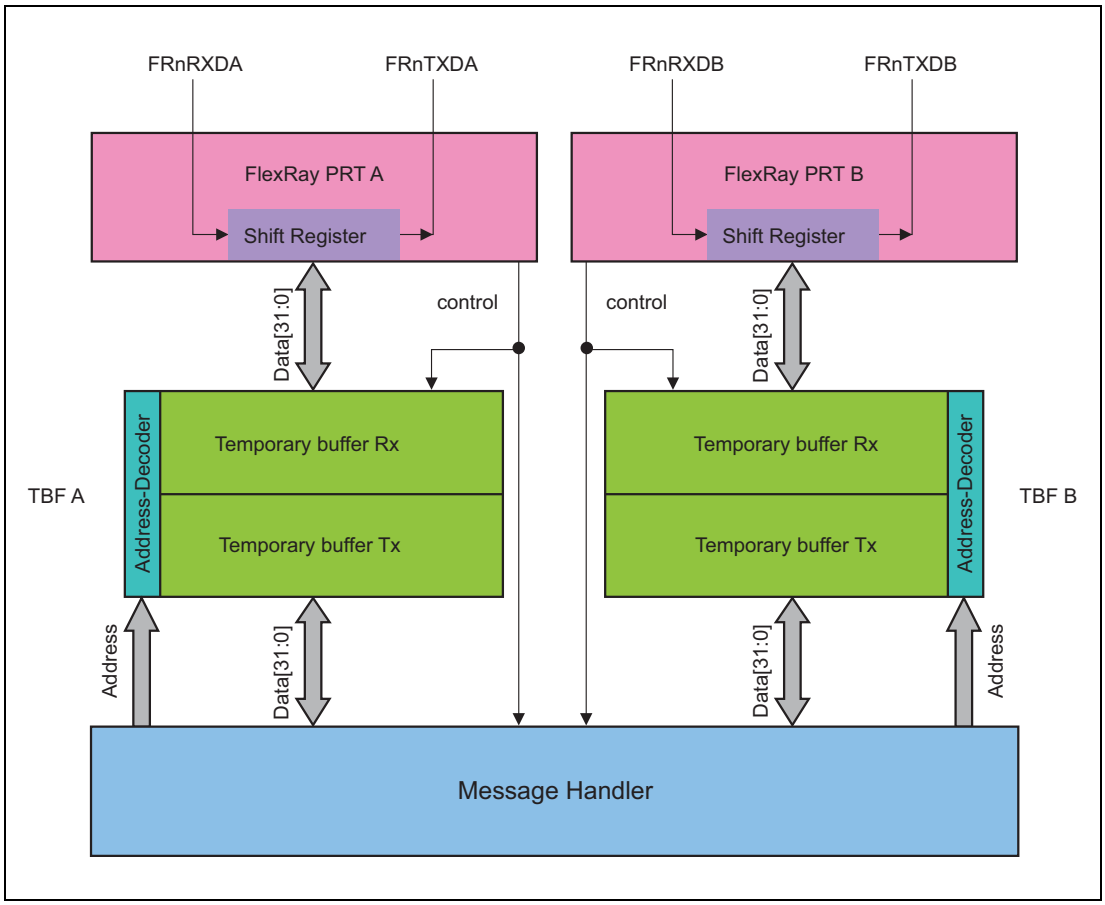

Figure 20.17 Access to Temporary Buffers

20.3.13 Message RAM

To avoid conflicts between Host access to the Message RAM and FlexRay message reception / transmission, the Host cannot directly access the message buffers in the Message RAM. These accesses are handled via the Input and Output Buffers. The Message RAM is able to store up to 128 message buffers depending on the configured payload length.

The Message RAM is able to store up to 2048 32-bit words. To achieve the required flexibility with respect to different numbers of data bytes per FlexRay frame (0…254), the Message RAM has a structure as shown in **Figure 20.18**.

The data partition is allowed to start at Message RAM word number: (FLXAnFRMRC.LCB + 1) * 4

When the Message Buffer which Data Section is located directly following the Header Partition is configured as receive buffer(FLXAnFRWRHS1.CFG set to "0") or receive FIFO, the user should leave at least 32bit unused area at the head of Data Partition. In this case the data partition is allowed to start at Message RAM word number: ((bits FLXAnFRMRC.LCB[7:0] + 1) * 4) + 1.

When the Message Buffer which Data Section is located directly following the Header Partition is configured as transmit buffer (FLXAnFRWRHS1.CFG set to "1"), the data partition is allowed to start at Message RAM word number:(bits FLXAnFRMRC.LCB[7:0] + 1) * 4.

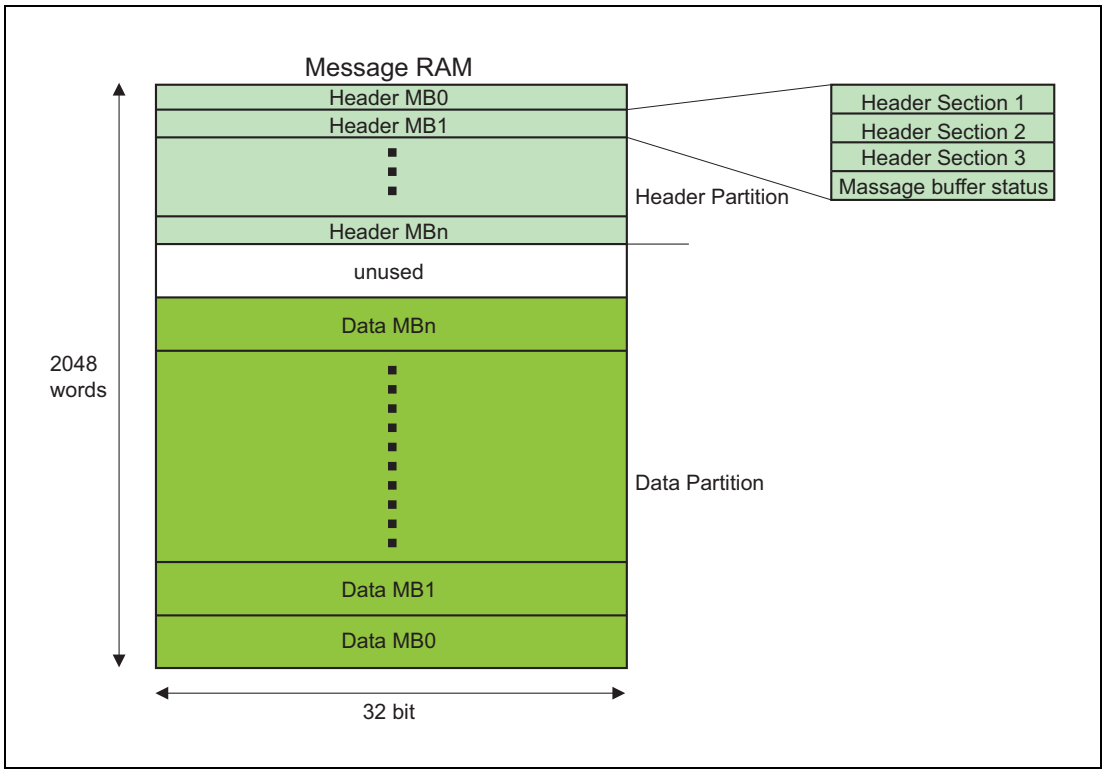

Figure 20.18 Configuration Example of Message Buffers in the Message RAM

Header Partition

Stores header sections of the configured message buffers:

- Supports a maximum of 128 message buffers
- Each message buffer has a header section of four 32 bit words
- Header 3 of each message buffer holds the 11-bit data pointer to the respective data section in the data partition

Data Partition

Flexible storage of data sections with different length. Some maximum values are:

- 30 message buffers with 254 byte data section each
- Or 56 message buffers with 128 byte data section each
- Or 128 message buffers with 48 byte data section each

CAUTION

header partition + data partition may not occupy more than 2048 32-bit words.

20.3.13.1 Header Partition

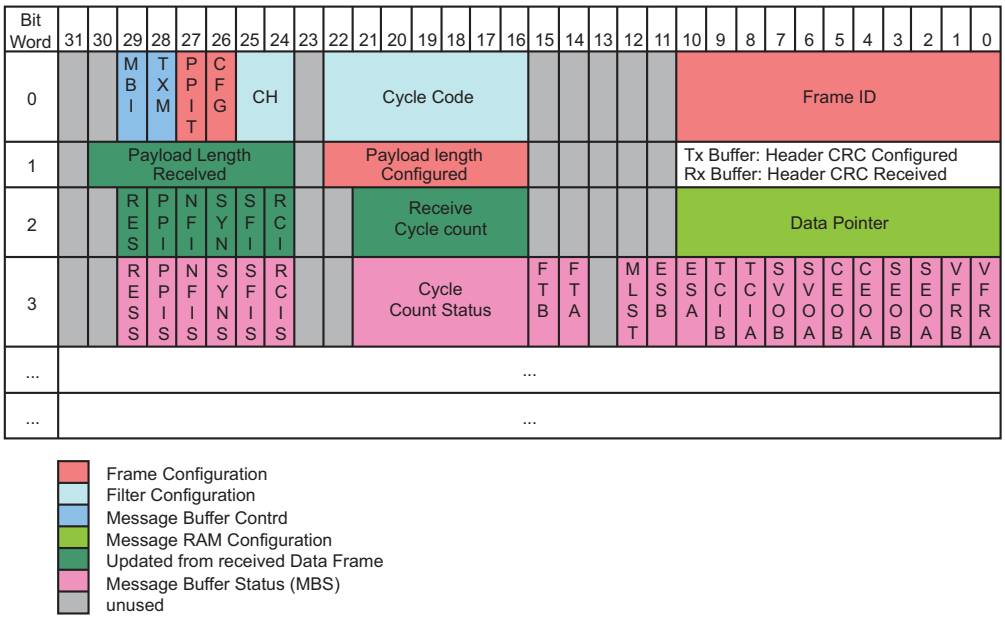
The elements used for configuration of a message buffer as well as the actual message buffer status are stored in the header partition of the Message RAM as listed in below. Configuration of the header sections of the message buffers is done via IBF (FLXAnFRWRHS1…3). Read access to the header sections is done via OBF (FLXAnFRRDHS1…3 + FLXAnFRMBS). The data pointer has to be calculated by the programmer to define the starting point of the data section for the respective message buffer in the data partition of the Message RAM. The data pointer should not be modified during runtime. For message buffers belonging to the receive FIFO (re)configuration is possible in DEFAULT_CONFIG or CONFIG state only.

The header section of each message buffer occupies four 32-bit words in the header partition of the Message RAM. The header of message buffer 0 starts with the first word in the Message RAM.

For transmit buffers the Header CRC has to be calculated by the Host.

Payload Length Received PLR, Receive Cycle Count RCC, Received on Channel Indicator RCI, Startup Frame Indicator SFI, Sync Frame Indicator SYN, Null Frame Indicator NFI, Payload Preamble Indicator PPI, and Reserved Bit RES are updated from received valid data frames only.

Table 20.120 Header Section of a Message Buffer in the Message RAM



(1) Header section 1 (word 0)

Write access via FLXAnFRWRHS1, read access via FLXAnFRRDHS1:

- Frame ID
  - Slot counter filtering configuration
- Cycle Code
  - Cycle counter filtering configuration
- CH
  - Channel filtering configuration
- CFG
  - Message buffer direction configuration: receive / transmit
- PPIT
  - Payload Preamble Indicator Transmit
- TXM
  - Transmit mode configuration: single-shot / continuous
- MBI
  - Message buffer receive / transmit interrupt enable

(2) Header section 2 (word 1)

Write access via FLXAnFRWRHS2, read access via FLXAnFRRDHS2:

- Header CRC
  - Transmit Buffer: Configured by the Host (calculated from frame header)
  - Receive Buffer: Updated from received frame
- Payload Length Configured
  - Length of data section (2-byte words) as configured by the Host
- Payload Length Received
  - Length of payload segment (2-byte words) stored from received frame

(3) Header section 3 (word 2)

Write access via FLXAnFRWRHS3, read access via FLXAnFRRDHS3:

- Data Pointer
  - Pointer to the beginning of the corresponding data section in the data partition

Read access via FLXAnFRRDHS3, valid for receive buffers only, updated from received frames:

- Receive Cycle Count
  - Cycle count from received frame
- RCI
  - Received on Channel Indicator

- SFI
  - Startup Frame Indicator
- SYN
  - Sync Frame Indicator
- NFI
  - Null Frame Indicator
- PPI
  - Payload Preamble Indicator
- RES
  - Reserved bit

(4) Message Buffer Status FLXAnFRMBS (word 3)

Read access via FLXAnFRMBS, updated by the CC at the end of the configured slot.

- VFRA
  - Valid Frame Received on channel A
- VFRB
  - Valid Frame Received on channel B
- SEOA
  - Syntax Error Observed on channel A
- SEOB

- NFIS
  - Null Frame Indicator Status
- PPIS
  - Payload Preamble Indicator Status
- RESS
  - Reserved bit Status

20.3.13.2 Data Partition

The data partition of the Message RAM stores the data sections of the message buffers configured for reception / transmission as defined in the header partition. The number of data bytes for each message buffer can vary from 0 to 254. To optimize the data transfer between the shift registers of the two FlexRay Protocol Controllers and the Message RAM as well as between the Host interface and the Message RAM, the physical width of the Message RAM is set to 4 bytes.

The data partition starts after the last word of the header partition. When configuring the message buffers in the Message RAM the programmer has to assure that the data pointers point to addresses within the data partition. **Table 20.121** below shows an example how the data sections of the configured message buffers can be stored in the data partition of the Message RAM.

The beginning and the end of a message buffer's data section is determined by the data pointer and the payload length configured in the message buffer's header section, respectively. This enables a flexible usage of the available RAM space for storage of message buffers with different data length.

If the size of the data section is an odd number of 2-byte words, the remaining 16 bits in the last 32bit word are unused (see **Table 20.121** below).

Table 20.121 Example for Structure of the Data Partition in the Message RAM

Bit Word	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

2047	unused								unused								MB0 Data5								MB0 Data4							

20.3.13.3 Message Data Integrity Check

There is a data integrity checking mechanism implemented in the FlexRay core to assure the integrity of the data stored in the related RAM. Each RAM has a checksum generator / checker attached as shown in **Figure 20.19**.

When data is written to a RAM, the local checksum generator generates the checksum. The checksum is stored together with the respective data word. The checksum is checked each time a data word is read from a RAM.

If a checksum error is detected, the respective access error flag is set. The access error flags FLXAnFRMHDS.AMR, FLXAnFRMHDS.ATBF1, FLXAnFRMHDS.ATBF2 and the faulty message buffer indicators FLXAnFRMHDS.FMBD, FLXAnFRMHDS.MFMB, FLXAnFRMHDS.FMB are located in the FlexRay Message Handler Status register. These single access error flags control the error interrupt flag FLXAnFREIR.AERR.

Figure 20.19 shows the data paths between the Input Buffer, Temporary Buffer and Message RAM.

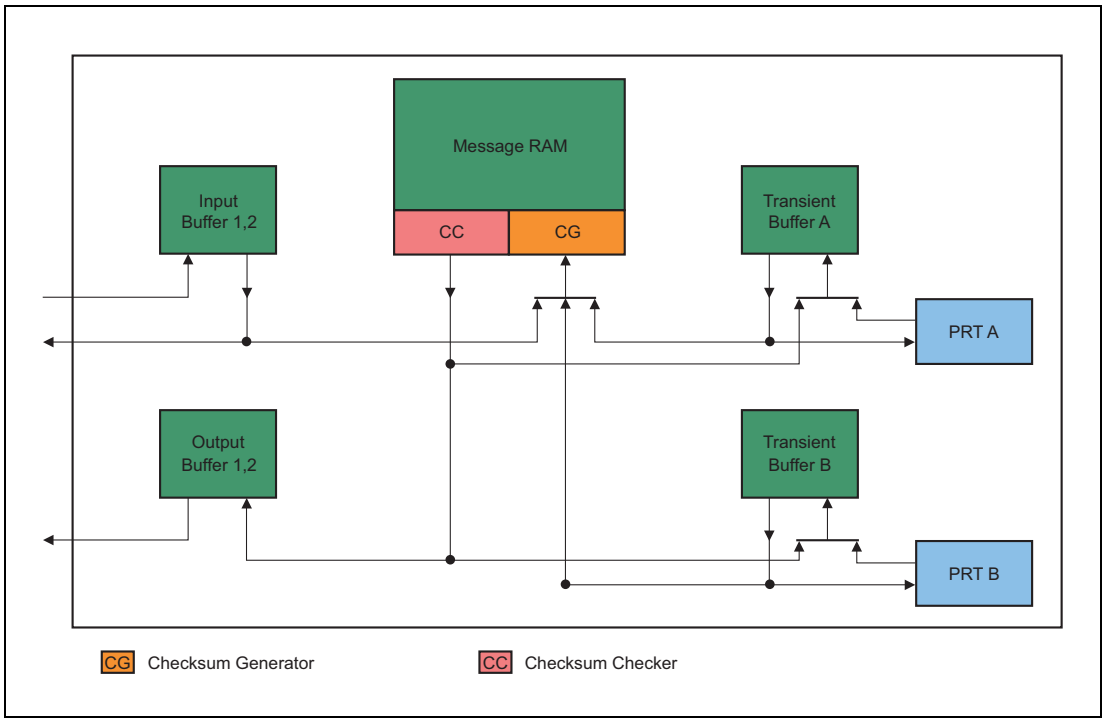

Figure 20.19 Checksum Generation and Check

When an access error has been detected the following actions will be performed:

In all cases:

- The respective access error flag in FLXAnFRMHDS register is set
- The access error flag FLXAnFREIR.AERR is set and, if enabled, a module interrupt to the Host will be generated.

Additionally in specific cases:

(1) Access error during data transfer from Input Buffer 1, 2 to Message RAM when reading header section of respective message buffer from Message RAM:

- FLXAnFRMHDS.AMR is set.
- FLXAnFRMHDS.FMBD bit is set to indicate that FLXAnFRMHDS.FMB points to a faulty message buffer.
- FLXAnFRMHDS.FMB indicates the number of the faulty message buffer.
- The data section of the respective message buffer is not updated.
- Transmit buffer: Transmission request for the respective message buffer is not set.

(2) Access error during scan of header sections in Message RAM:

- FLXAnFRMHDS.AMR is set.
- FLXAnFRMHDS.FMBD bit is set to indicate that FLXAnFRMHDS.FMB points to a faulty message buffer.
- FLXAnFRMHDS.FMB indicates the number of the faulty message buffer.
- Ignore message buffer (message buffer is skipped).

(3) Access error during data transfer from Message RAM to Temporary Buffer 1, 2:

- FLXAnFRMHDS.AMR is set.
- FLXAnFRMHDS.FMBD bit is set to indicate that FLXAnFRMHDS.FMB points to a faulty message buffer.
- FLXAnFRMHDS.FMB indicates the number of the faulty message buffer.
- Frame not transmitted, frames already in transmission are invalidated by setting the frame CRC to zero.

(4) Access error during data transfer from Temporary Buffer 1, 2 to Message RAM when reading header section of respective message buffer from Message RAM:

- FLXAnFRMHDS.AMR is set.
- FLXAnFRMHDS.FMBD bit is set to indicate that FLXAnFRMHDS.FMB points to a faulty message buffer.
- FLXAnFRMHDS.FMB indicates the number of the faulty message buffer.
- The data section of the respective message buffer is not updated.

(5) Access error during data transfer from Message RAM to Output Buffer:

- The access error flag FLXAnFRMHDS.AMR is set.

- FLXAnFRMHDS.FMBD bit is set to indicate that FLXAnFRMHDS.FMB points to a faulty message buffer.
- FLXAnFRMHDS.FMB indicates the number of the faulty message buffer.

(6) Access error during a data transfer from Temporary Buffer 1, 2 to Protocol Controller 1, 2:

- FLXAnFRMHDS.ATBF1, 2 bit is set.
- Frames already in transmission are invalidated by setting the frame CRC to zero.

(7) Access error during data transfer from Temporary Buffer 1, 2 to Message RAM when reading Temporary Buffer RAM 1, 2:

- FLXAnFRMHDS.ATBF1, 2 bit is set.
- FLXAnFRMHDS.FMBD bit is set to indicate that FLXAnFRMHDS.FMB points to a faulty message buffer.
- FLXAnFRMHDS.FMB indicates the number of the faulty message buffer.

(8) Access error during data read of Temporary Buffer RAM 1, 2:

- When an access error occurs while the Message Handler read a frame with network management information (PPI = 1) from the Temporary Buffer RAM 1, 2, the corresponding network management vector registers FLXAnFRNMV1 to 3 are not updated from this frame.

20.3.13.4 Host Handling of Access Errors

Access error caused by temporary bit flips can be fixed by:

(1) Self-healing

Access errors located in the Data Section of Message RAM, Temporary Buffer RAM A or Temporary Buffer RAM B are overwritten with the next write access to the disturbed bit(s) caused by Host access or by FlexRay communication.

(2) CLEAR_RAMS Command

The POC command CLEAR_RAMS initializes the message RAM to zero, when called in the DEFAULT_CONFIG or CONFIG state.

(3) Temporary Unlocking of Header Section

An access error in the header section of a locked message buffer can be fixed by a transfer from the Input Buffer to the locked buffer Header Section. For this transfer, the write access to the FLXAnFRIBCR (specifying the message buffer number) must be immediately preceded by the unlock sequence normally used to leave CONFIG state (see **Section 20.2.3.1, FLXAnFRLCK — FlexRay Lock Register**).

For that single transfer the respective message buffer header is unlocked, regardless whether it belongs to the FIFO or whether its locking is controlled by FLXAnFRMRC.SEC, and will be updated with new data.

20.3.14 Module Interrupt

In general, interrupts provide a close link to the protocol timing as they are triggered almost immediately when an error or status change is detected by the CC, a frame is received or transmitted, a configured timer interrupt is activated, or a stop watch event occurred. This enables the Host to react very quickly on specific error conditions, status changes, or timer events. On the other hand too many interrupts can cause the Host to miss deadlines required for the application. Therefore the CC supports enable / disable controls for each individual interrupt source separately.

An interrupt may be triggered when

- An error was detected
- A status flag is set to 1
- A timer reaches a preconfigured value
- A message transfer from Input Buffer to Message RAM or from Message RAM to Output Buffer has completed
- A message transfer from the Local RAM/Global RAM to Message RAM or from Message RAM to Local RAM/Global RAM has completed
- A stop watch event occurred

Tracking status and generating interrupts when a status change or an error occurs are two independent tasks. Regardless of whether an interrupt is enabled or not, the corresponding status is tracked and indicated by the CC. The Host has access to the actual status and error information by reading registers FLXAnFREIR, FLXAnFRSIR, FLXAnFROS, FLXAnFROTS and FLXAnFRITS.

The general purpose interrupt lines to the Host, FlexRay Interrupt 0, FlexRay Interrupt 1, are controlled by the enabled interrupts in FLXAnFREIES and FLXAnFRSIES. In addition each of the two interrupt lines can be enabled / disabled separately by programming bit FLXAnFRILE.EINT0 and FLXAnFRILE.EINT1.

The input data transfer interrupt lines to the Host, FlexRay input queue empty interrupt, FlexRay input queue full interrupt, are controlled by the enabled interrupts in FLXAnFRITS. In addition each of the input data transfer interrupts can be enabled / disabled separately by programming the related bits in FLXAnFRITC.

The output data transfer interrupt lines to the Host, FlexRay FIFO transfer warning interrupt, FlexRay output transfer warning interrupt, FlexRay FIFO transfer interrupt, FlexRay output transfer interrupt, are controlled by the enabled interrupts in FLXAnFROTS. In addition each of the output data transfer interrupts can be enabled / disabled separately by programming the related bits in FLXAnFROTC.

The three timer interrupts lines to the Host are controlled by the enabled interrupts in FLXAnFROS. In addition each of the interrupt lines can be enabled / disabled separately by programming bit FLXAnFROC.T0IE, FLXAnFROC.T1IE and FLXAnFROC.T2IE.

When a transfer between IBF / OBF and the Message RAM has completed bit FLXAnFRSIR.TIBC or FLXAnFRSIR.TOBC is set to 1.

20.3.16 Usage of Data Transfer

A mechanism is implemented to allow storage of FlexRay messages directly into the Local RAM/ Global RAM (user RAM) and have transfers between the FlexRay internal message RAM and the Local RAM/Global RAM and vice versa with minimum CPU support. The data in the Local RAM/ Global RAM should be indexed by data structure pointers located in data pointer tables stored in the Local RAM/Global RAM.

Data transfer from the Local RAM/Global RAM to the FlexRay internal message RAM (input transfer) needs to be initiated by the application. These transfers can be used to configure message buffers or to update transmit data.

A data transfer from the FlexRay internal message RAM to the Local RAM/Global RAM (output transfer) is initiated automatically by a reception into a receive message buffer or FlexRay internal FIFO or by a change in the slot status. It can be initiated also by a specific user transfer request.

The input and output data transfer can be activated independently. When the input data transfer is activated the application should not directly access message buffers using the FlexRay input buffer. When the output data transfer is activated the application should not directly access message buffers using the FlexRay output buffer.

20.3.16.1 Input Data Transfer

When the automatic input data transfer function is enabled, committed input data structures are transferred from the Local RAM/Global RAM to the FlexRay internal message RAM with minimum CPU support.

(1) Activation and deactivation

The input data transfer function should be activated before usage. The activation of the input transfer handler initializes the input queue put index (FLXAnFRITS.IPIDX) and get index (FLXAnFRITS.IGIDX) to zero. Also the interrupt status flags in the FLXAnFRITS register (IQEIS and IQFIS) are set to 0.

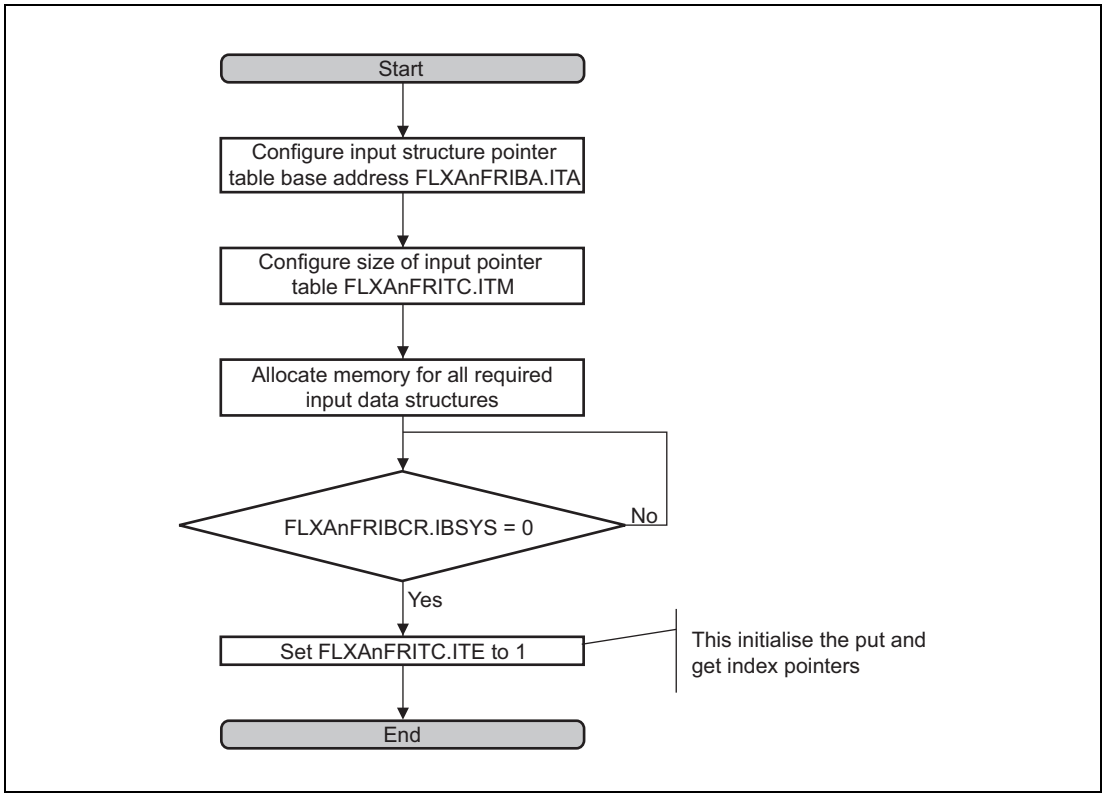

Figure 20.20 Input transfer enable flow

A deactivation request of the input transfer function can be made at any time. The input queue put index and the input queue status are maintained independently from the input transfer function state.

Before the transfer function gets disabled (status indicated by FLXAnFRITS.ITS), user requested input transfers and all committed input transfers will be completed.

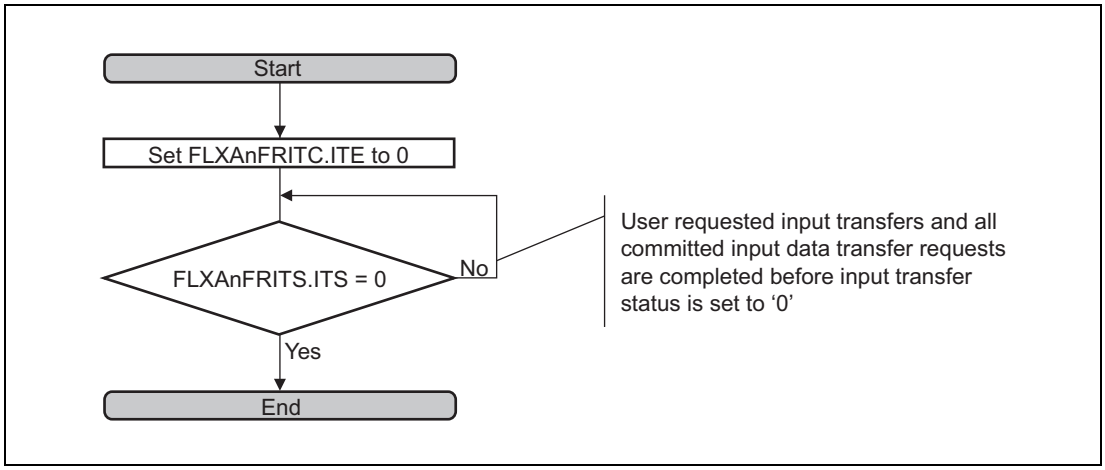

Figure 20.21 Input transfer disable flow

(2) Input data structure

The application has to reserve a location in the Local RAM/Global RAM to provide the content for message buffer configuration (input data structure).

The location of this input data structure needs to be defined by an input data structure pointer also located in the Local RAM/Global RAM.

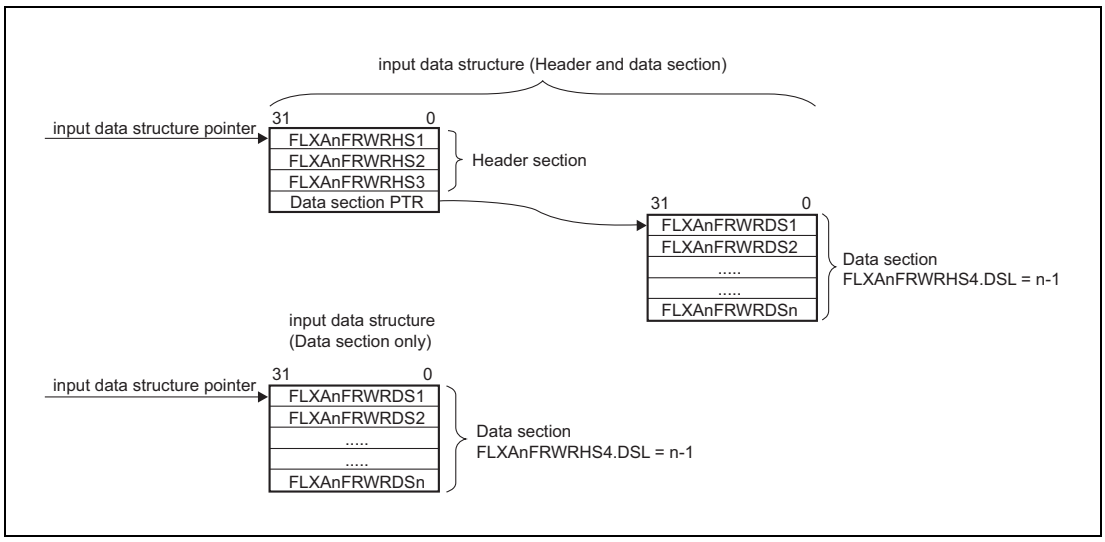

Figure 20.22 Input data structure

In general the input data structure consists of two sections, the header and the data section.

The header section consists of FLXAnFRWRHS1, FLXAnFRWRHS2, FLXAnFRWRHS3 and the data section pointer.

For bit alignment and bit function in the header section, see **Section 20.3.13.1, Header Partition**.

Depending on the settings in the control field (FLXAnFRWRHS4) located in the input pointer table, the data structure pointer is a reference to the address of FLXAnFRWRHS1 or FLXAnFRWRDS1. The data structure pointer has to be aligned to a 32 bit address.

If the bit LHS in the address related to FLXAnFRWRHS4 is set to 1 it is required to provide a valid header section. In this case FLXAnFRWRHS1 is the first element of the data structure.

If the bit LHS in the address related to FLXAnFRWRHS4 is set to 0 a header section is not required. In this case FLXAnFRWRDS1 is the first element of the data structure.

If the bit LDS in the address related to FLXAnFRWRHS4 is set to 1 it is required to provide a valid data section. The pointer to the data section is a reference to the address of the first payload long word (FLXAnFRWRDS1) and has to be aligned to a 32 bit address.

If the bit LDS in the address related to FLXAnFRWRHS4 is set to 0 a data section is not required. The data section pointer is not evaluated by the input handler.

The byte order for the FlexRay payload data in the input data structure is determined by FLXAnFROC.BEC. For information about the payload data alignment within the data section see **Section 20.3.13.2, Data Partition** and **Section 20.3.17, Byte Alignment**.

The length of the data section and the size to be allocated in the Local RAM/Global RAM depends on the configuration of the bits DSL in the address related to FLXAnFRWRHS4.

For the transfer into the FlexRay core internal message RAM the number of 16 bit words configured by FLXAnFRWRHS2.PLC is used. The application has to ensure, that a proper number of data words is provided in the Local RAM/Global RAM. In case the buffer is configured by FLXAnFRWRHS2.PLC to hold an odd payload length, the application has to write zero to the last 16 bit of the payload section to ensure that the padding data is all zero.

(3) Input pointer table

To transfer data from the input data structures located in the Local RAM/Global RAM to the FlexRay internal message RAM the related input data structure pointer and control field needs to be added to the input pointer table which is located in the Local RAM/Global RAM.

The location of the first element of this table is identified by the input pointer table base address (FLXAnFRIBA.ITA). This base address has to be aligned to a 32 bit address.

The maximum number of input requests that can be queued is defined by the Input queue Table Max register (FLXAnFRITC.ITM).

Each Input pointer table entry requires two long words. The required address range of the input pointer table for the queued transfer requests can be calculated by

$$\text{Input pointer table size (byte)} = (((\text{FLXAnFRTTC.ITM} + 1) \times D \times 2) \times 4)$$

Equation 1

The input pointer entry for the user requested input transfer should be added after the end of the input pointer table.

The pointer table index related to this entry and hence the number to be written to FLXAnFRUIR.UIDX, is FLXAnFRITC.ITM+1. The address in the input pointer table related to the user requested input transfer (user input address) can be calculated by

User input address = FLXAnFRIBA.ITA + Input pointer table size

Equation 2

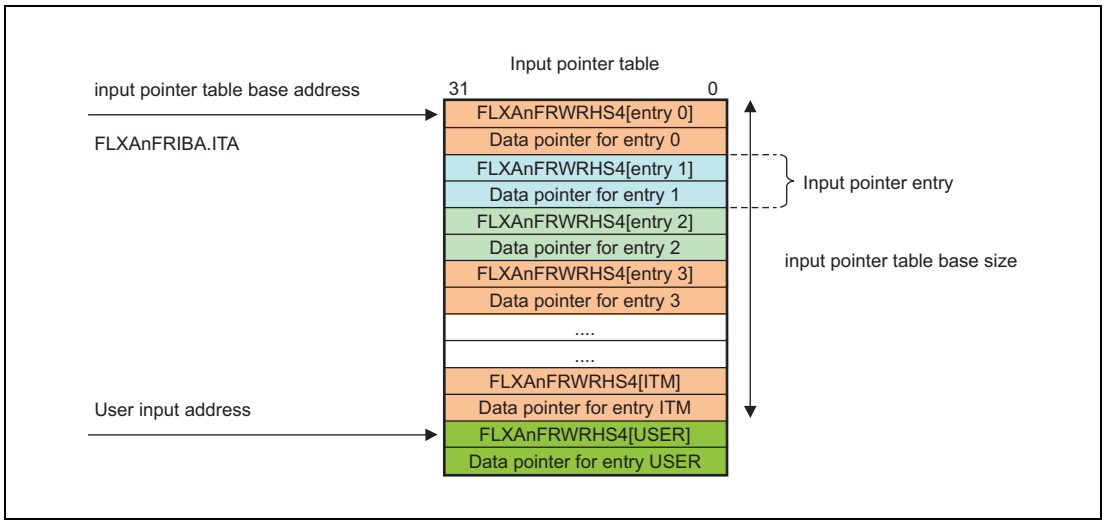

Figure 20.23 Input pointer table

The input pointer table holds the control field FLXAnFRWRHS4 and the pointers to the Local RAM/ Global RAM location where the message buffer content (header section and/or data section) is stored.

The application has to write FLXAnFRWRHS4 and the input data structure pointer at the addresses in the input pointer table related to the put index position before a transfer request is initiated.

FLXAnFRWRHS4:

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	DSL[5:0]					
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	INV	STR	LDS	LHS	—	IMBNR[6:0]						
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 20.123 FLXAnFRWRHS4 Register Contents

Bit Position	Bit Name	Function
31 to 22	Reserved	When read, an undefined value is read. When writing, always write 0.
21 to 16	DSL[5:0]	Data Section Length Bit Specifies the length of the data section in terms of 32 bit values.
15 to 12	Reserved	When read, an undefined value is read. When writing, always write 0.
11	INV	Invalidate entry Bit 0: The data structure is valid and will be transferred to the FlexRay internal message RAM. 1: The data structure is invalid. FlexRay internal message RAM is not updated using this input pointer entry.
10	STR	Set transmission request Bit 0: The bit FLXAnFRTXRQi.TXR for the message buffer selected by the bits IMBNR is set to 0. No data from this message buffer is transmitted. 1: The bit FLXAnFRTXRQi.TXR for the message buffer selected by the bits IMBNR is set to 1 to release the message buffer for transmission The application should not set the bit STR to 1 for receive buffers.
9	LDS	Load data section Bit 0: No update of data section. 1: Data section for the message buffer selected by the bits IMBNR is updated.
8	LHS	Load header section Bit 0: no update of header section. 1: Header section for the message buffer selected by the bits IMBNR is updated.
7	Reserved	When read, an undefined value is read. When writing, always write 0.
6 to 0	IMBNR[6:0]	Message buffer number to be updated Bit Selects the target message buffer number in the FlexRay internal message RAM for transfer

Note that the LHS bit should not be set for protected message buffers.

The bit LDS defines if the data section of the message buffer selected by the bits IMBNR should be updated.

If LDS is set to 1 (DSL + 1) 32 bit words of payload data are transferred from the Local RAM/Global RAM to the message buffer selected by the bits IMBNR.

If LDS is set to 0 no payload data is transferred from the Local RAM/Global RAM.

Note that the payload transferred is independent from the configured payload length (bits PLC in the address related to FLXAnFRWRHS2).

The bit INV can be used to invalidate a committed data structure. This bit should be only used to cancel the transfer of committed data structures when the input queue is halted (see **Section 20.3.16.1 (5), Halting the input queue**).

When this bit is set to 1 the message buffer number IMBNR is not updated. When the bit is set to 0 the message buffer number IMBNR is updated.

(4) Transfer function of input data structure

To use the input data structure transfer function the input transfer has to be activated (see **Section 20.3.16.1 (1), Activation and deactivation**). The activation process requires the setup of the input pointer table (see **Section 20.3.16.1 (3), Input pointer table**) in order to specify the source location (input data structures) for the data structures to be transferred. When the input transfer gets enabled the get index pointer is initialized to zero.

All FlexRay internal message buffers can be updated using the input transfer queue which is built in the input pointer table. The application has to write the pointer and control field (table entry) to the data structure to be transferred into the input pointer table. For that purpose the application has to maintain a put index for the input pointer table that indicates where the pointer has to be written to.

To commit this table entry to the input handler, the application has to write the target message buffer number to the input queue control register (FLXAnFRIQC.IMBNR). Afterwards the application has to increment the application internal put index.

By writing to the input queue control register the data available flag (FLXAnFRDAi.DA[IMBNR]) is automatically set to 1. The input transfer handler also maintains the put index pointer in the status register (FLXAnFRITS.IPIDX).

In case the input queue gets full (number of queued input transfer requests is equal to the input queue table size) FLXAnFRITS.IQFP and FLXAnFRITS.IQFIS are set to 1. The input queue full condition pending flag (FLXAnFRITS.IQFP) changes from 1 to 0 when there are entries in the input queue available, whereby the input queue full interrupt status flag (FLXAnFRITS.IQFIS) needs to be cleared by the application.

The application should not make any further write access to the bit IMBNR in the FLXAnFRIQC register as long as the bit IQFP in the FLXAnFRITS register is 1.

In case the input queue gets empty (number of queued input transfer requests changes to zero) FLXAnFRITS.IQEIS is set to 1. The input queue empty interrupt status flag (FLXAnFRITS.IQEIS) needs to be cleared by the application.

The transfer of the input data structures to the FlexRay message RAM is controlled by a get index pointer which is handled inside the FlexRay module and flagged in FLXAnFRITS.IGIDX. Note that the index is referring to the input entry and not the address offset in the input pointer table.

If the input queue is not empty, the transfer handler reads out the input pointer table entry of the transfer queue and starts the transfer of the input data structure from the address the input pointer is referring to. When all required data words are transferred to the FlexRay module, the data available flag for the transferred message buffer number is set to 0 and the get index in the transfer handler is incremented by one.

In case of an invalidated data structure (see **Section 20.3.16.1 (5), Halting the input queue**) no FlexRay internal message buffer is updated and the related data available flag is automatically set to 0. The change of the data available flag can be used to confirm the cancellation a transmit request.

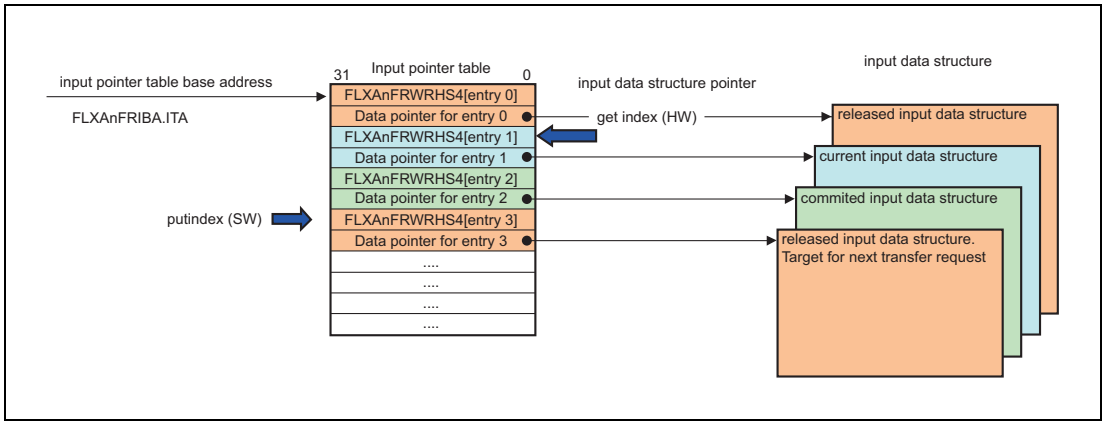

Figure 20.24 Input Pointer Table

Receive message buffers can be also configured using the input data transfer by setting up the required header sections and mark only the header section (FLXAnFRWRHS4.LDS = 0, FLXAnFRWRHS4.LHS = 1) to be updated in the FlexRay module.

(5) Halting the input queue

Committed data structures cannot be removed, but can be invalidated or updated when the input queue is halted.

To cancel data structures already committed to the input queue, the queue can be halted by writing a 1 to FLXAnFRITC.IQHR.

After the ongoing input transfer has been completed the queue is halted and FLXAnFRITS.IQH changes from 0 to 1.

To invalidate an entry of the input queue FLXAnFRWRHS4.INV has to be set to 1. All other bits in FWRHS4 should be unchanged.

Following flow shall be used to analyse whether a committed message has been already transferred to the FlexRay internal message RAM or not.

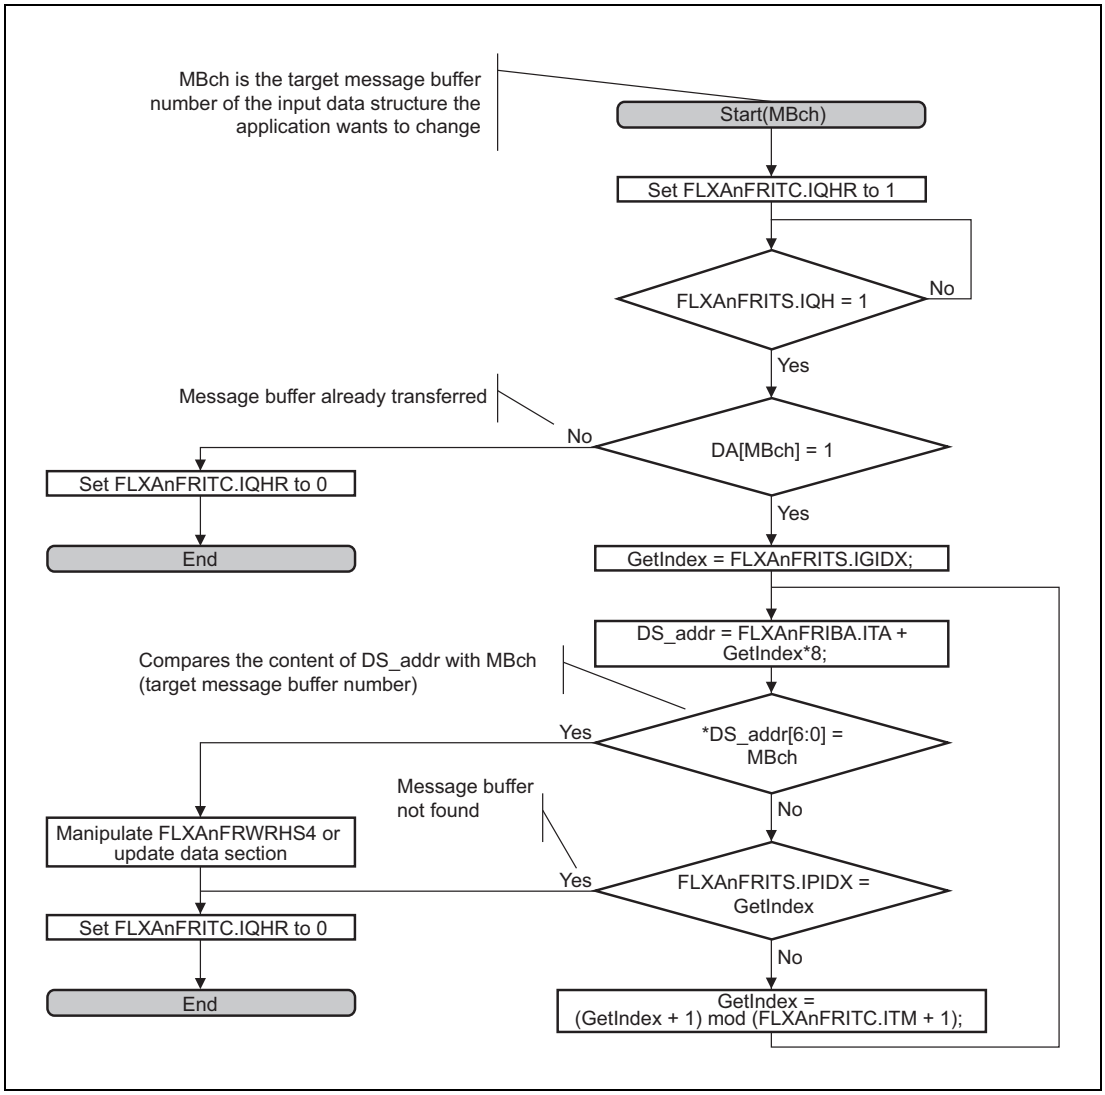

Figure 20.25 Input Table Analysis

In case the message buffer was already transferred to the FlexRay internal message RAM, the user input transfer request can be used to bypass the actual queue and update the required message buffer (see **Section 20.3.16.1 (6), Transfer function of user requested input transfers**).

(6) Transfer function of user requested input transfers

To use this function the input transfer has to be activated (see **Section 20.3.16.1 (1), Activation and deactivation**).

The application is capable, by using FLXAnFRUIR.UIDX, to request a transfer of an input data structure. The user input transfer request is serviced first.

The application has to write the pointer and control field (table entry) to the data structure to be transferred into the input pointer table. The table entry for the user input transfer request should be added after the end of the input pointer table (see **Section 20.3.16.1 (3), Input pointer table**).

To commit this table entry to the input handler, the application has to write the index (FLXAnFRITC.ITM+1) to the user input transfer request register (FLXAnFRUIR.UIDX).

By writing to the user input transfer request register, the user input transfer request pending flag (FLXAnFRITS.UIRP) is automatically set to 1.

As long this flag is 1 the application should not make any further user input transfer requests.

The user input transfer request pending flag (FLXAnFRITS.UIRP) changes from 1 to 0 when the requested input transfer is completed. As next the pending transfers are processed.

20.3.16.2 Output Data Transfer

When the output data transfer function is enabled, received messages (either in dedicated message buffers or in the FlexRay receive FIFO) are transferred to the Local RAM/Global RAM by the output data handler. The output data handler can also transfer the message buffer content to the Local RAM/ Global RAM on application request. When enabled the output handler is also capable to initiate a transfer when the message buffer status has changed.

(1) Activation and deactivation

The output data transfer function should be activated before usage. The activation of the output transfer hander will initialise the FIFO put and get index pointer and FIFO fill level (FLXAnFROTS.FGIDX and FLXAnFROTS.FFL) to zero, set the bits FLXAnFROTS.FDA, FLXAnFROTS.OWP, FLXAnFROTS.FWP and FLXAnFROTS.UORP to 0. Also the interrupt status flags FLXAnFROTS.OTIS, FLXAnFROTS.FIS, FLXAnFROTS.OWIS and FLXAnFROTS.FWIS) are set to 0.

The activation has no influence to the data available flags (FLXAnFRDAi.DA) which are related to the dedicated buffers; these flags have to be cleared by the application.

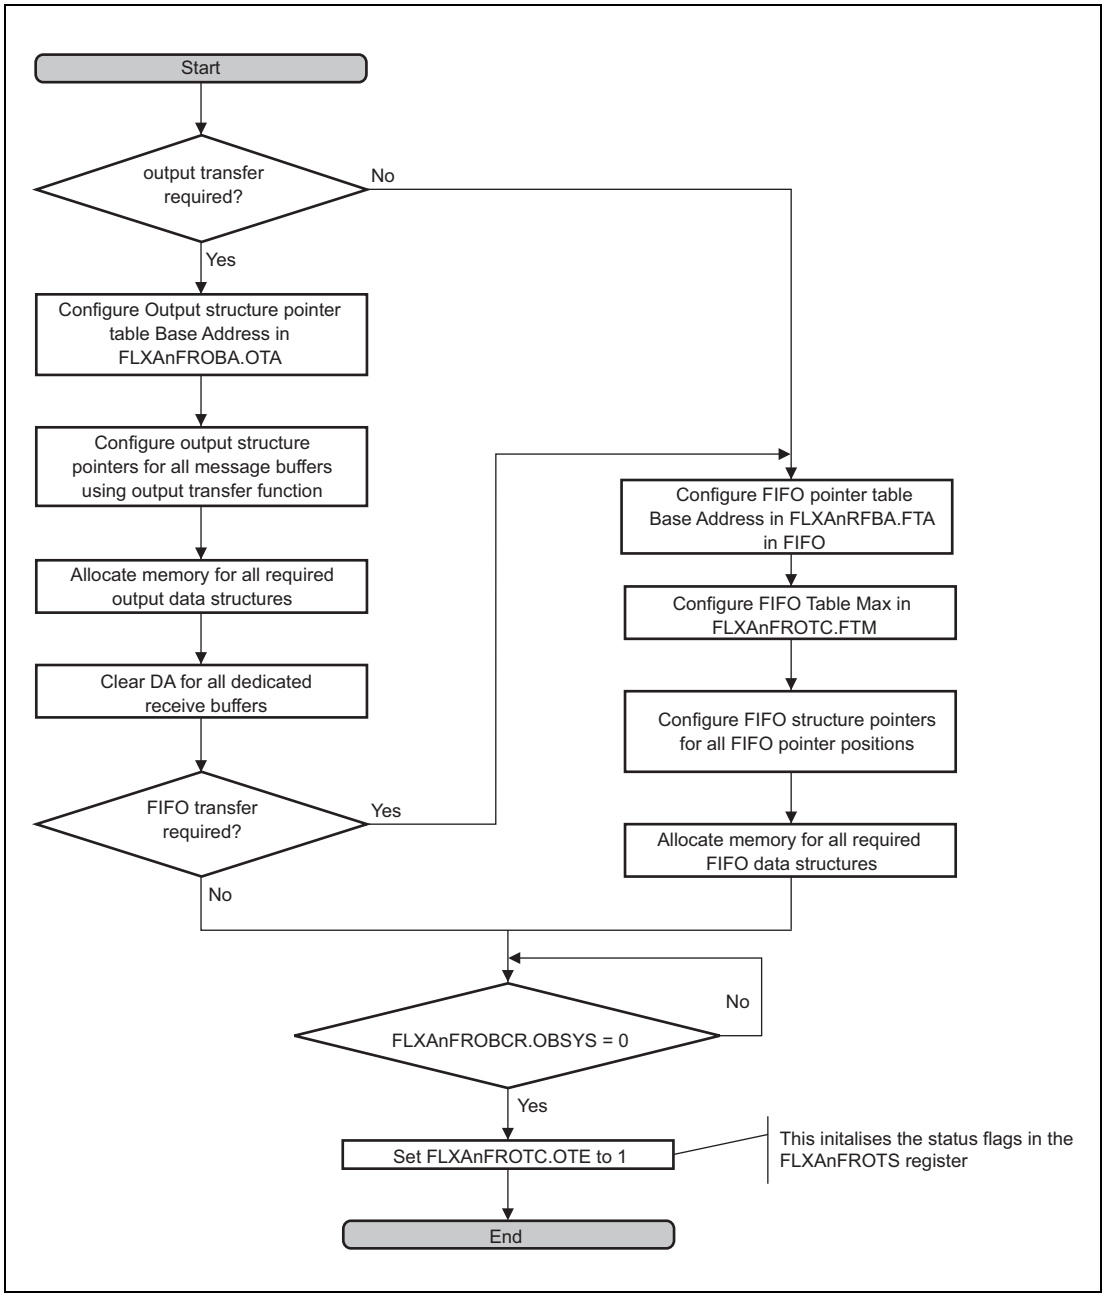

Figure 20.26 Output Transfer Enable Flow

A deactivation request of the output data transfer function can be made at any time. An ongoing transfer will be completed and the completion of this transfer will be flagged. During this time FLXAnFROTS.OTS remains 1.

When FLXAnFROTS.OTS changes from 1 to 0, the output transfer function is deactivated. The data available status flags and the FIFO get index are still maintained when the output transfer function is disabled.

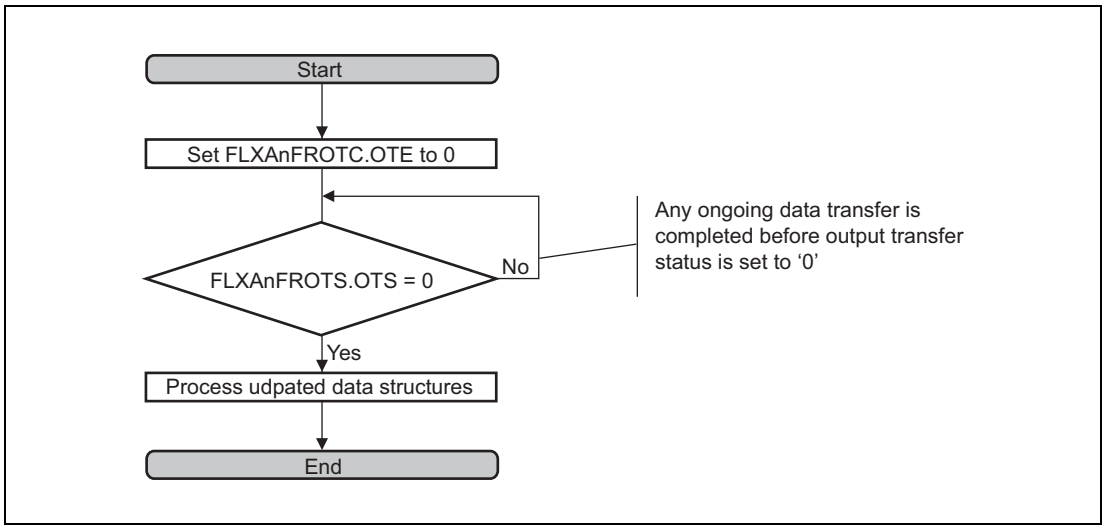

Figure 20.27 Output Transfer Disable Flow

(2) Output transfer data structure

The data in the Local RAM/Global RAM is stored in an output data structure. The location of the output data structures are determined by output data structure pointers also located in the Local RAM/ Global RAM. The output data structure and indexing is visualized in **Figure 20.28**.

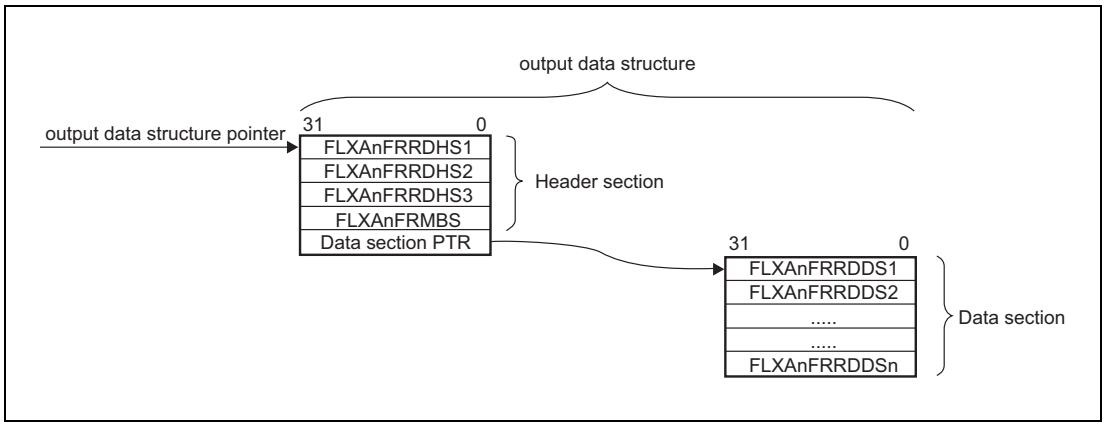

Figure 20.28 Output Data Structure

The output data structure consists of two sections, the header and data section. The header section consists of FLXAnFRRDHS1, FLXAnFRRDHS2, FLXAnFRRDHS3, FLXAnFRMBS and the data section pointer. FLXAnFRRDHS1 is the first element of the structure and has to be aligned to a 32 bit address. The data structure pointer is a reference to the address of FLXAnFRRDHS1. For information about the bit alignment and bit function within the header section see **Section 20.3.13.1, Header Partition**.

FLXAnFRRDDS1 is the first element of the data section. The data section pointer is a reference to the address of FLXAnFRRDDS1 and has to be aligned to a 32 bit address. The byte order for the FlexRay payload data in the output data structure is determined by the bit BEC in the FLXAnFROC register. For information about the payload data alignment within the data section see **Section 20.3.13.2, Data Partition**.

The length of the data section as well as the total structure size to be allocated in the Local RAM/ Global RAM depends on the configured payload length (FLXAnFRRDHS2.PLC) of the related message buffer. In case the configured payload length is an odd number of words or the received payload length (FLXAnFRRDHS2.PLR) is smaller than the configured payload length, the remaining data words in the Local RAM/Global RAM are unused and should not be used by the application.

The output data structure is identical for all three kinds of output transfers. In case only the header section is transferred the data section pointer is not evaluated by the output handler and the data section remains unchanged.

(3) Output pointer table

For the output data transfer function the application needs to setup an output pointer table in the Local RAM/Global RAM. The location of the first element of this table should be programmed into the output pointer table base address (FLXAnFROBA.OTA). This base address has to be aligned to a 32 bit address.

The size of the output pointer table is defined by the maximum of: the last configured dedicated message buffer and the highest message buffer number which will be used for the user output transfer request.

The output pointer table holds pointers (output data structure pointers) to the Local RAM/Global RAM location where a memory space is reserved for the target message buffer content (header section and data section).

There is a fixed linear relationship between the address of the entries in the output pointer table and the number of the related message buffers (see **Figure 20.29**): the output pointer table starts with the entry for message buffer number 0 at the address configured in FLXAnFROBA.OTA and continues in ascending order for each following message buffer number, by 32 bit aligned address (e.g. message buffer 1 at address OTA + 4, message buffer 2 at address OTA + 8, etc.) for all possible message buffers.

When a set ND bit is the only transfer condition (FLXAnFROTC.OTCS is set to 0) only message buffers configured as a dedicated receive buffer or that will be used for user output transfer requests need have valid pointer entries.

When a set ND bit or a set MBSC bit is the transfer condition (FLXAnFROTC.OTCS is set to 1) all dedicated receive buffer and dedicated transmit buffers need to have valid pointer entries.

(4) FIFO output pointer table

The FlexRay module internal FIFO can be extended by a queued buffer structure in the Local RAM/ Global RAM.

If the FlexRay module internal FIFO is used the application needs to setup the FIFO output pointer table. The location of the first element of this table is identified by the FIFO pointer table base address (FLXAnFRFBA.FTA). This base address has to be aligned to a 32 bit address.

The size of the FIFO pointer table and hence the maximum number of messages that can be added to the queue, is defined by FIFO Table Max (FLXAnFROTC.FTM).

The FIFO pointer table holds pointers (output data structure pointers) to the Local RAM/Global RAM location where a memory space is reserved the target message buffer content (header section and data section). For each table entry a data pointer shall be configured in this table.

(5) Transfer function of dedicated message buffers

To use this transfer function the output transfer has to be activated (see **Section 20.3.16.1 (1), Activation and deactivation**). The activation process requires to setup the output pointer table (see **Section 20.3.16.2 (3), Output pointer table**) in order to specify the destination location (output data structures) for the data to transfer. **Figure 20.29** shows how the output pointer table references the output data structures.

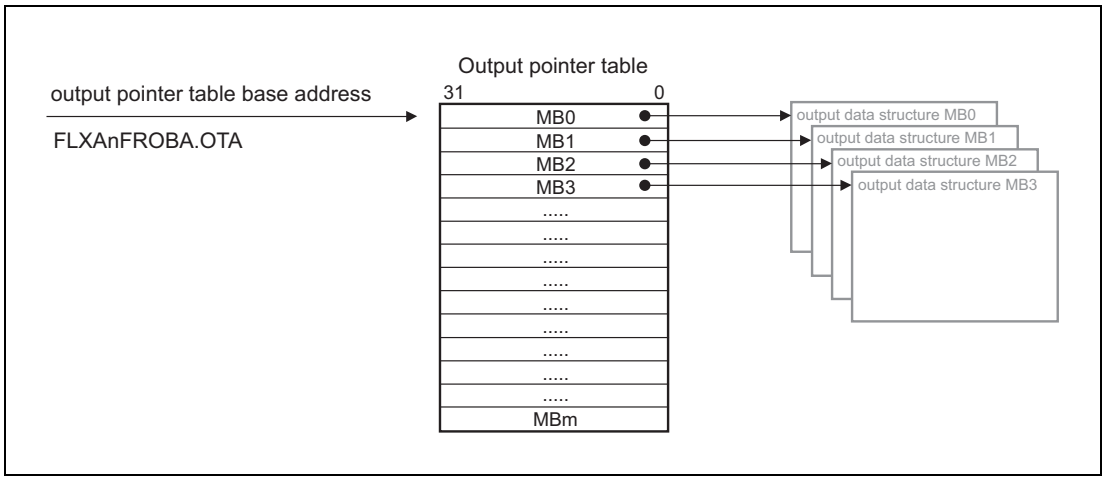

Figure 20.29 Output Data Structure and Indexing

With FLXAnFROTC.OTCS the output transfer condition can be selected between the ‘New data only mode’ and the ‘New data and status changed mode’.

In the ‘New data only mode’ an output data transfer is initiated when a valid FlexRay data frame has been stored into a dedicated receive buffer which causes the related ND flag in the FLXAnFRNDAT register to set. The ND flag in the FLXAnFRNDAT register is automatically set to 0 during the transfer procedure. The header section is also transferred and hence the MBSC flag in the FLXAnFRMBSC register is set to 0.

In the ‘New data and status changed mode’ an output data transfer is initiated as described in the ‘New data only mode’. In addition an output data transfer is initiated when only the message buffer status has been changed which causes the related MBSC flag in the FLXAnFRMBSC register to be set. In this case only the header section is transferred. The MBSC flag in the FLXAnFRMBSC register is automatically set to 0 during the transfer procedure.

After transferring the message buffer data from the FlexRay internal message RAM to the output data structure the corresponding data available flag in the FLXAnFRDAi (i = 0 to 3) registers is set to 1. The update of the output data structure is also flagged by the setting of the output transfer interrupt status flag (FLXAnFROTS.OTIS).

As long as the data available flag remains 1 the corresponding output data structure will not be updated.

In the case

- the data available flag is 1 and a valid received message was stored or
- when FLXAnFROTC.OTCS is 1 and the message buffer status was updated,

the output transfer warning interrupt flag (FLXAnFROTS.OWIS) is set to 1 notifying the application that new data is available but the output data structure transfer cannot be processed. In addition FLXAnFROTS.OWP is set to 1 that continuously flags that status of the output transfer warning condition.

If a valid receive message in the FlexRay internal message RAM is overwritten by an additional receive message, the message lost flag (FLXAnFRMBS.MLST) is set to 1. This flag can be evaluated after the message buffer has been transferred into an output data structure.

Following sections are giving a guidance how output data structures can be handled.

(a) Data section copy method

One option is to copy the information from the output data structure to a different location of the Local RAM/Global RAM and then release the output data structure by clearing the related data available flag. The application should use the copied information for further processing.

(b) Data structure pointer method

A different option is to modify the output data structure pointer in the output pointer table and to release the output data structure by clearing the related data available flag. The changed output data pointer should refer to a free data structure. The application should use the old data structure for further processing.

(c) Data section pointer method

A third option is to modify the data section pointer in the output data structure and to release the output data structure by clearing the related data available flag. The changed data section pointer should refer to a free memory area. The application should use the old data section for further processing by forwarding the data section pointer.

(6) Transfer function of FIFO message buffers

To use this buffer transfer function the output transfer has to be activated (see **Section 20.3.16.1 (1), Activation and deactivation**). The activation process requires the setup of the FIFO pointer table (see **Section 20.3.16.2 (4), FIFO output pointer table**) in order to specify a location in the Local RAM/Global RAM reserved for the storage of the required output data structures.

A FIFO data transfer is initiated when a valid FlexRay data frame has been stored in the FlexRay internal FIFO.

After transfers from the internal FIFO to the output data structure, the FIFO interrupt status flag (FLXAnFROTS.FIS) and FLXAnFROTS.FDA are set to 1. The bit FLXAnFROTS.FIS can be used as an interrupt source. The bit FLXAnFROTS.FDA indicates that the FIFO is not empty.

Up to FLXAnFROTS.FTM output structures configured in the FLXAnFROTC register can be queued.

The transfer to the extended FIFO buffer structure is controlled by index pointers. This put index is controlled by the FIFO transfer handler and is incremented after transferring a message to the output data structure.

The FIFO reception handler also maintains a get index which is flagged in FLXAnFROTS.FGIDX. The value of this get index is known by the application by either reading the status or maintaining a software variable. The get index (the value after a reset is zero) is incremented by one when the application releases the oldest entry of the FIFO queue by writing 1 to FLXAnFROTS.FDA. By comparing the put index and the get index the FIFO handler knows about the current fill level of the queued buffer structure.

The current FIFO fill level is flagged in FLXAnFROTS.FFL. When FLXAnFROTS.FDA is 1, there is at least one entry in the FIFO queue.

In case the queued buffer structure in the Local RAM/Global RAM is full (FLXAnFROTS.FFL = FLXAnFROTC.FTM+1), no further transfers are initialised, new messages remain in the FlexRay internal FIFO and the FIFO transfer warning interrupt status flag (FLXAnFROTS.FWIS) is set to 1.

In case the FlexRay internal FIFO structure becomes full, messages in the FlexRay internal FIFO structure may get overwritten. The related status flags and configuration registers of the FlexRay core module can be used to generate desired warning notifications.

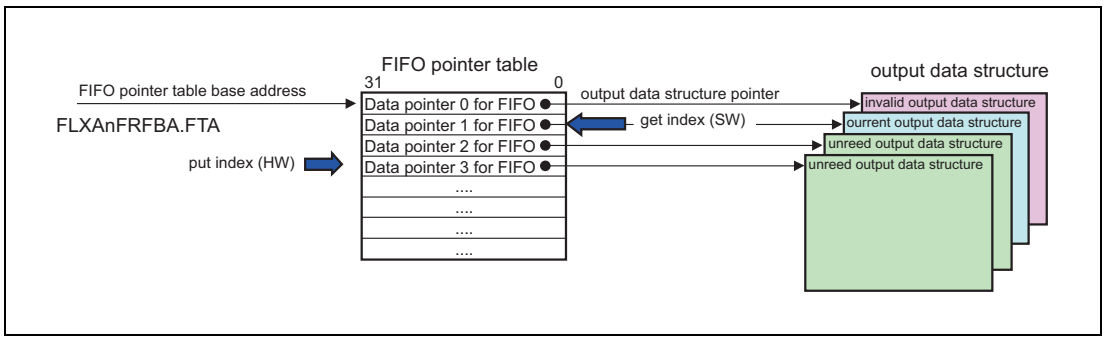

Figure 20.30 FIFO Pointer Table

(7) Transfer function of user output transfer requests

To use this transfer function the output transfer has to be activated (see **Section 20.3.16.1 (1), Activation and deactivation**). The activation process requires to setup the output pointer table (see **Section 20.3.16.2 (3), Output pointer table**) in order to specify the location in the Local RAM/ Global RAM reserved for the transfer of the data (output data structures).

The application is capable, by using FLXAnFRUOR.UMBNR, to request a transfer of dedicated message buffer to an output data structure. Except in CONFIG state, message buffers which are part of the FlexRay internal FIFO should not be requested.

The header section is always transferred to the output data structure. The transfer of the data section can be enabled by setting FLXAnFRUOR.URDS to 1. The selected message buffer content is stored in the output data structure location determined by the pointers in the output pointer table.

The data available status and transfer blocking by the DA bits in the FLXAnFRDAi register is also used for the user requested transfers. Therefore the DA bit in the FLXAnFRDAi register related to the requested buffer number (FLXAnFRUOR.UMBNR) should be released before making the transfer request.

After writing to FLXAnFRUOR.UMBNR, the bit FLXAnFROTS.UORP is set to 1 to indicate that there is a pending user transfer request. When the transfer has been processed the bit FLXAnFROTS.UORP is set to 0, the bit FLXAnFROTS.OTIS is set to 1 and the DA bit in the FLXAnFRDAi register related to the requested buffer number (FLXAnFRUOR.UMBNR) is set to 1.

User output transfer requests cannot be queued. The application should check the bit FLXAnFROTS.UORP before writing to FLXAnFRUOR.UMBNR.

User output transfer requests should not be made for message buffers which are pending in the input transfer queue.

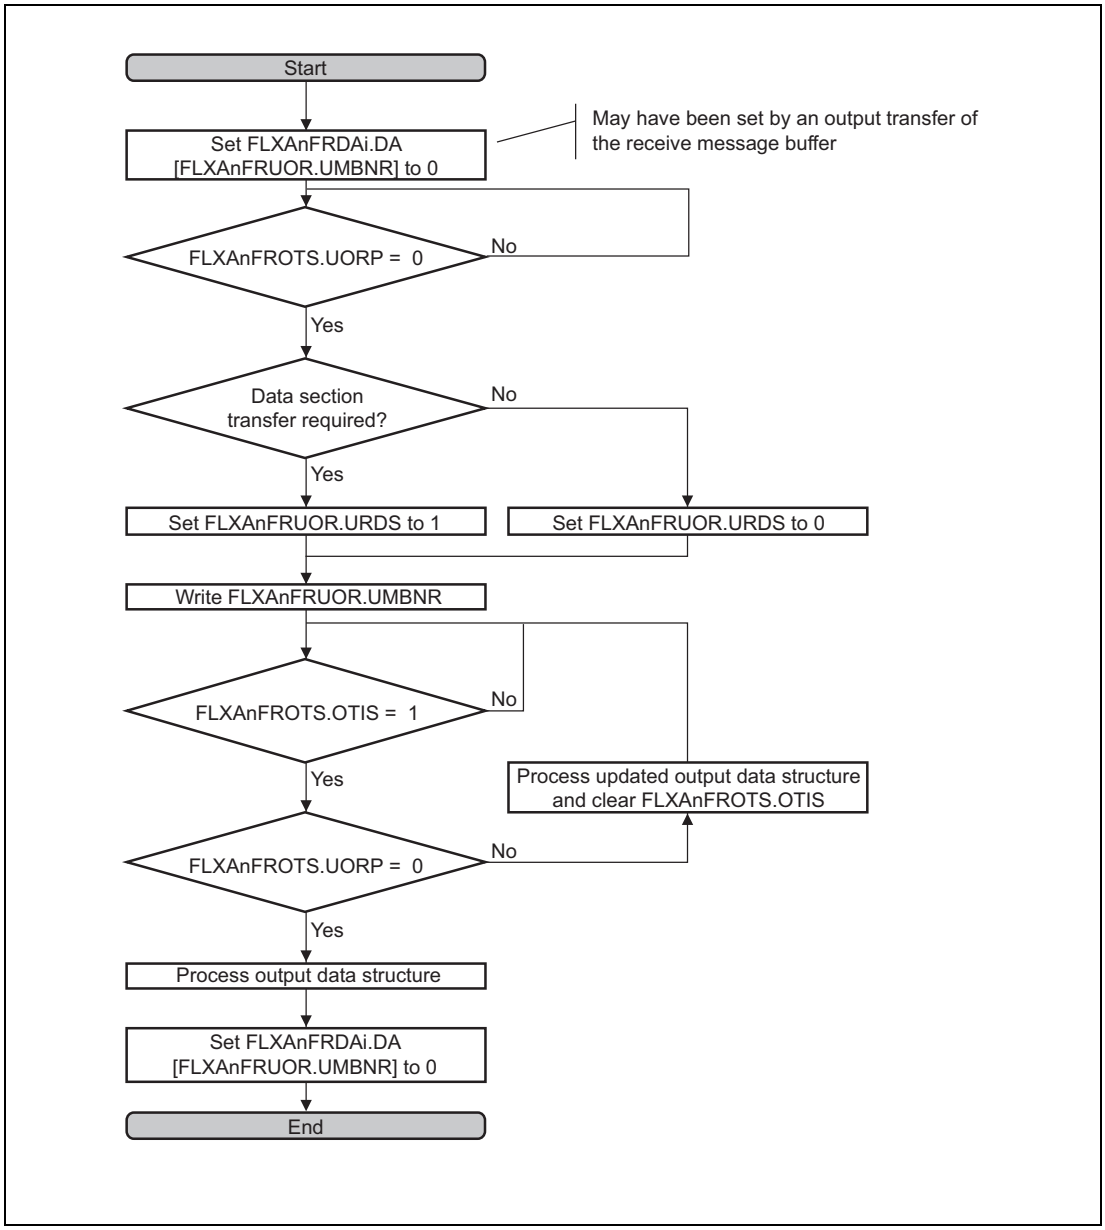

Figure 20.31 User Output Transfer Request Flow

Note that it may be possible that the data structure addressed by a user request is being updated due to a receive message buffer update (which causes the bit DA in the FLXAnFRDAi register being set). This set DA flags inhibits the user output transfer request. Therefore polling FLXAnFROTS.UORP is not a secure method to identify when the transfer of a requested message buffer has been completed. The bits FLXAnFROTS.OTIS or the DA bit in the FLXAnFRDAi register can be used instead. The exact flow depends on the software architecture.

20.3.16.3 Data Structure Transfer Scheduling

Cyclically the different types of transfer requests are checked. In order to guarantee a certain transfer time the different types of transfers have different priorities.

Use requested input transfers have highest priority followed by the transfer of data structures committed into the active input transfer queue. No new output transfer will be started as long as there is a pending input transfer request.

The three output transfer request types are checked in a specific order:

(1) All dedicated message buffers in ascending order

When FLXAnFROTC.OTCS is set to 0, set flags in the FLXAnFRNDATi register are causing a transfer of the message buffer to the output data structure if the destination area is free (DA bit in the FLXAnFRDAi register is 0).

When FLXAnFROTC.OTCS is set to 1, set flags in the FLXAnFRNDATi register or set flags in the FLXAnFRMBSCn register are causing a transfer of the message buffer to the output data structure if the destination area is free (DA bit in the FLXAnFRDAi register is 0).

(2) FlexRay internal FIFO

When the FlexRay internal FIFO is not empty and there is a free destination area, one FIFO message is transferred into the output data structure addressed by the FIFO pointer table.

(3) User output request

If there is a pending user output transfer request, one message buffer is transferred into the corresponding output data structure.

The check sequence is suspended when an input transfer occurs.

20.3.16.4 Behavior in Case of Data Transfer Access Error

The memory areas accessed by the data transfer function may be protected by a memory protection unit (MPU). When the MPU flags an access to a protected address caused by an input or output transfer, an access error event is generated and the related bit in the FLXAnFRAES register is set.

The ongoing transfer is immediately terminated but succeeding transfers are processed and may generate further access errors. Any following access errors are only flagged in FLXAnFRAES.MAE. The other status flags are not updated.

(1) Access error during input transfer

When an access error occurs during an input transfer:

- The ongoing transfer is immediately terminated. The FlexRay internal message RAM will not be updated
- The address, the FlexRay module wanted to access to, is captured in the FLXAnFRAEA register
- FLXAnFRAES.IAE is set to 1
- The input pointer table index is flagged in FLXAnFRAES.EIDX
- In case of an normal input transfer the to the transfer related DA flag in the FLXAnFRDAi register is set to 0
- In case of an user input transfer request FLXAnFRITS.UIRP is set to 0

With the given status information the application is able to identify and correct the faulty data structure.

In addition the application needs to clear the input access error flag (FLXAnFRAES.IAE).

(2) Access error during output transfer

When an access error occurs during an output transfer:

- The ongoing transfer is immediately terminated but the update of the data structure may have started.
- The address, the FlexRay module wanted to access to, is captured in the FLXAnFRAEA register
- FLXAnFRAES.OAE is set to 1
- The output pointer table index is flagged in FLXAnFRAES.EIDX
- In case of an normal output transfer the to the transfer related DA flag in the FLXAnFRDAi register remains 0 and no output transfer interrupt is generated
- In case of an user output transfer request FLXAnFROTS.UORP is set to 0

With the given status information the application is able to identify and correct the faulty data structure. The data structure in the Local RAM/Global RAM cannot be treated as valid.

In addition the application needs to clear the output access error flag (FLXAnFRAES.OAE).

The FlexRay module internal transfer of the message buffer is completed before the Local RAM/ Global RAM access error is detected. The output transfer will not be re-initiated. To avoid loss of data, the application can perform a user output transfer request of this message buffer to a correct Local RAM/Global RAM location.

(3) Access error during FIFO transfer

When an access error occurs during an FIFO transfer:

- The ongoing transfer is immediately terminated
- The address, the FlexRay module wanted to access to, is captured in the FLXAnFRAEA register
- FLXAnFRAES.FAE is set to 1
- The FIFO pointer table index is flagged in FLXAnFRAES.EIDX
- The FIFO index pointer are not changed and hence the FIFO status flags are unchanged

With the given status information the application is able to identify and correct the faulty data structure.

In addition the application needs to clear the FIFO access error flag (FLXAnFRAES.FAE).

The data in the Local RAM/Global RAM cannot be treated as valid and is not released to the application. The message cannot be recovered.

20.3.16.5 Behaviors in Case of RAM Read Errors

The FlexRay internal message RAM has an ECC checking mechanism. In case an uncorrectable RAM read error occurs, the application has to analyze the status in the FLXAnFRMHDS register and react as described in **Section 20.3.16.3, Data Structure Transfer Scheduling**. The input and output transfer handler reacts also on these errors detected in the message RAM when the error is related to an active transfer.

In addition, the Temporary Buffer RAM A and Temporary Buffer RAM B have an ECC checking mechanism as well. An uncorrectable RAM read errors does not impact the data transfer functionality but have to be handled as described in **Section 20.3.13.1 (4), Message Buffer Status FLXAnFRMBS (word 3)**.

In all cases, data causing a read error is never transferred to the Local RAM/Global RAM. If there is no recovery available in the application, the message is lost.

(1) Read error during transfer from TBF to MBF

This internal transfer is done for each valid FlexRay message received.

A read error can only occur when reading the header section in the FlexRay Message RAM (see read error flags in FLXAnFRMHDS). In this case, the message buffer needs to be re-configured.

For dedicated receive message buffers, the related ND flag in the FLXAnFRNDAT register will not get set. Consequently the affected message buffer will not be transferred to the output data structure.

For the FlexRay internal FIFO buffers, the ND flag in the FLXAnFRNDAT register is not set but the FlexRay internal FIFO put index is incremented. Due to this, a transfer procedure from the FlexRay internal FIFO buffer to the output buffer is started. However, if the read error is still present in the header section, updating of the output data structure will not start (see **Section 20.3.16.5 (2), Read error during transfer from MBF to OBF**); thus the data in the Local RAM/Global RAM remains correct.

Note that the correction or any other reconfiguration of FIFO related to message buffers while there are pending FIFO transfers may result in incorrect data in the Local RAM/Global RAM. It is strongly recommended to deactivate the output data transfer before starting the reconfiguration and flush the FlexRay internal FIFO before reactivation of the output data transfer.

(2) Read error during transfer from MBF to OBF

This internal transfer is done for every output data transfer (dedicated reception, FIFO, user requested).

A read error can occur in the header and data section (see read error flags in FLXAnFRMHDS). In both cases the message gets lost. If the error is located in the header section, the message buffer needs to be re-configured. If the error is located in the data section, the error is corrected with the next data section update.

When a read error occurs during the transfer from the message RAM to the output buffer, the output data structure will not be updated and the data available will not be set to 1. The FIFO put index and the FIFO fill level are not changed also.

In case of user output transfer request, FLXAnFROTS.UORP is set to 0 even if there was no update of the output data structure.

(3) Read error during transfer from IBF to MBF

This internal transfer is done for every input data transfer.

A read error can occur only when there is no update of the header section requested (the bit LHS in FLXAnFRWRHS4 is set to 0) due to the reading of the header section from the message RAM (see read error flags in FLXAnFRMHDS). In this case, the message buffer needs to be re-configured.

When a read error occurs during the input data transfer, the actually transferred message in the input queue gets lost.

(4) Message RAM read errors

Read errors when reading the header section are flagged in the FLXAnFRMHDS register.

Depending on the buffer type and set buffer protection, a reconfiguration of the message buffer may not be possible.

The input transfer function cannot be used to reconfigure a locked message buffer using the method described in **Section 20.3.13.4 (3), Temporary Unlocking of Header Section**.

Before reconfiguring a locked buffer, the user should disable the input transfer function and the output transfer function.

20.3.17 Byte Alignment

The alignment of the bytes received by the FlexRay protocol and the alignment of the bytes required by the application may be different. The FlexRay module provides with FLXAnFROC.BEC a byte alignment function to support different byte ordering styles.

Figure 20.32 shows the payload byte alignment in a FlexRay frame.

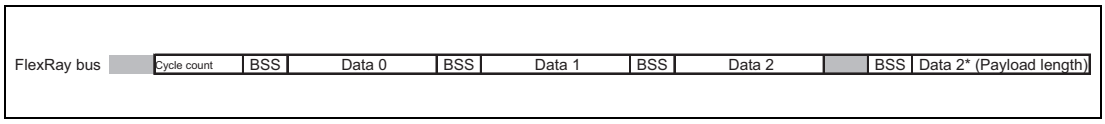

Figure 20.32 Byte Alignment on the FlexRay Bus

20.3.17.1 Little Endian Alignment

When FLXAnFROC.BEC is 0, the byte alignment is set to Little Endian.

(1) FLXAnFRNMVm (m = 1 to 3)

The byte alignment of the NMV bytes is as below.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FLXAnFRNMV1	Data 3								Data 2								Data 1								Data 0							
FLXAnFRNMV2	Data 7								Data 6								Data 5								Data 4							
FLXAnFRNMV3	Data 11								Data 10								Data 9								Data 8							

(2) FLXAnFRWRDSx (x = 1 to 64)

The byte alignment for the message payload in the FlexRay input buffer and the input data structure is as below.

FLXAnFRWRDSxMD[7:0] = $Data_{4x-4}$

FLXAnFRWRDSxMD[15:8] = $Data_{4x-3}$

FLXAnFRWRDSxMD[23:16] =$Data_{4x-2}$

FLXAnFRWRDSxMD[31:24] = $Data_{4x-1}$

Transmission order on the FlexRay bus is FLXAnFRWRDSx.MD[7:0], FLXAnFRWRDSx.MD [15:8], FLXAnFRWRDSx.MD [23:16], FLXAnFRWRDSx.MD [31:24] with the most significant bit (MSB) transmitted first.

(3) FLXAnFRRDDSx (x = 1 to 64)

The byte alignment for the message payload in the FlexRay output buffer and the output data structure is as below.

FLXAnFRRDDSxMD[7:0] = $Data_{4x-4}$

FLXAnFRRDDSxMD[15:8] = $Data_{4x-3}$

FLXAnFRRDDSxMD[23:16] =$Data_{4x-2}$

FLXAnFRRDDSxMD[31:24] = $Data_{4x-1}$

Reception order on the FlexRay bus is FLXAnFRRDDSx.MD[7:0], FLXAnFRRDDSx.MD [15:8], FLXAnFRRDDSx.MD [23:16], FLXAnFRRDDSx.MD [31:24] with the most significant bit (MSB) received first.

20.3.17.2 Big Endian Alignment

When FLXAnFROC.BEC is 1, the byte alignment is set to Big Endian.

(1) FLXAnFRNMVm (m = 1 to 3)

The byte alignment of the NMV bytes is as below.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FLXAnFRNMV1	Data 0								Data 1								Data 2								Data 3							
FLXAnFRNMV2	Data 4								Data 5								Data 6								Data 7							
FLXAnFRNMV3	Data 8								Data 9								Data 10								Data 11							

(2) FLXAnFRWRDSx (x = 1 to 64)

The byte alignment for the message payload in the FlexRay input buffer and the input data structure is as below.

FLXAnFRWRDSxMD[7:0] = $Data_{4x-1}$

FLXAnFRWRDSxMD[15:8] = $Data_{4x-2}$

FLXAnFRWRDSxMD[23:16] = $Data_{4x-3}$

FLXAnFRWRDSxMD[31:24] = $Data_{4x-4}$

Transmission order on the FlexRay bus is FLXAnFRWRDSx.MD[7:0], FLXAnFRWRDSx.MD [15:8], FLXAnFRWRDSx.MD [23:16], FLXAnFRWRDSx.MD [31:24] with the most significant bit (MSB) transmitted first.

(3) FLXAnFRRDDSx (x = 1 to 64)

The byte alignment for the message payload in the FlexRay output buffer and the output data structure is as below.

FLXAnFRRDDSxMD[7:0] = $Data_{4x-1}$

FLXAnFRRDDSxMD[15:8] = $Data_{4x-2}$

FLXAnFRRDDSxMD[23:16] = $Data_{4x-3}$

FLXAnFRRDDSxMD[31:24] = $Data_{4x-4}$

Reception order on the FlexRay bus is FLXAnFRRDDSx.MD[7:0], FLXAnFRRDDSx.MD [15:8], FLXAnFRRDDSx.MD [23:16], FLXAnFRRDDSx.MD [31:24] with the most significant bit (MSB) received first.

20.3.18 FlexRay NTU supervision

In case of normal operating condition the FlexRay is sending NTU (Network Timing Unit) HW triggers to the System timer, which enables SW to synchronize the drivers job list processing with very low effort.

For keeping SW driver synchronization (e.g. Autosar) while FlexRay communication is not working properly or is temporarily not available (e.g. loss of NTU trigger), the system timer can support SW synchronization by emulating the FlexRay NTU trigger with a configurable frequency.

To support NTU supervision the E-Ray IP is providing a dedicated output signal, which is connected to the NTU Clock Selector. This selector provides an input signal for STM0 (in case there are two STM timers, only the first one is connected to NTU Tick). The frequency of the NTU clock signal and of the Backup clock, derived from the low jitter PLL used for FlexRay communication, are continuously compared by the NTU loss monitor.

The NTU clock of the FlexRay IP is equal to a macrotick (MT) or cycle tick (CT). The backup clock can be configured to the same frequency. Additionally the eray_sclk and the PLL clock used for NTU loss monitor are the same signal. The frequency of the backup clock has to be configured during initialisation phase and cannot be changed during normal operation.

20.3.18.1 Window function

The user can configure a “NTU loss” window. If the monitored NTU tick is not detected during the open window, an error is generated:

The NTU loss monitor operation:

- NPRS, NBPRS and NCPRS divider blocks for each input clock. Dividing factor is based on the setting in the respective registers
- 12bit compare unit
- The counter inside compare unit counts number of NTU signal’s rising edges during 16 clock periods of base clock
- If the counted NTU ticks value is outside of the threshold values set in the respective registers (upper and lower) an INTC signal occurs.
- After that user can change the selected NTU source

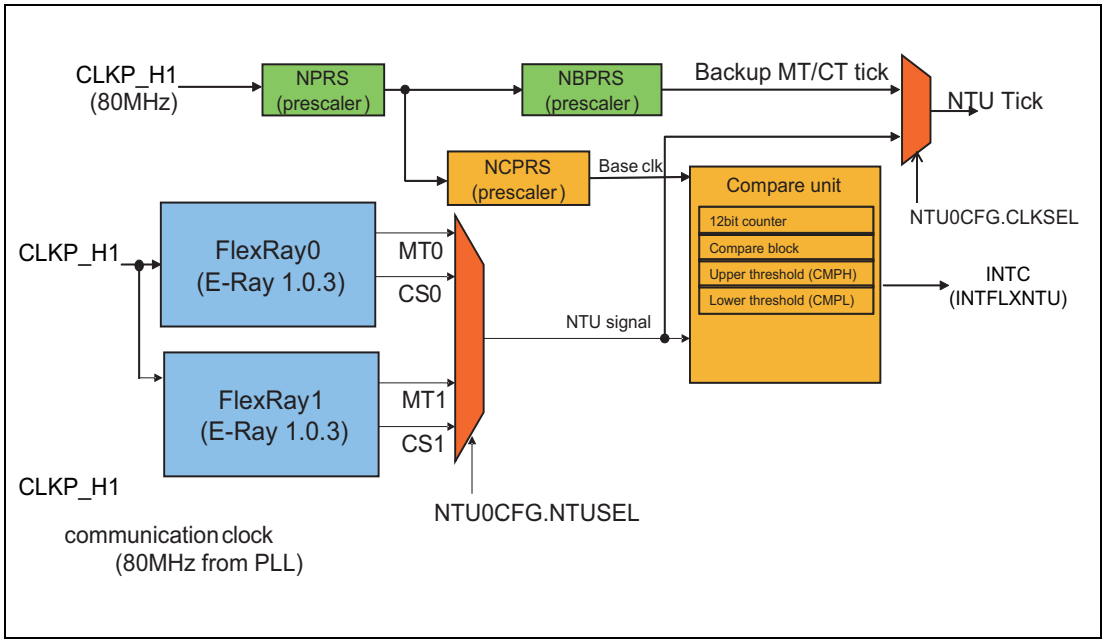

Figure 20.33 Block diagram of NTU generation for STM

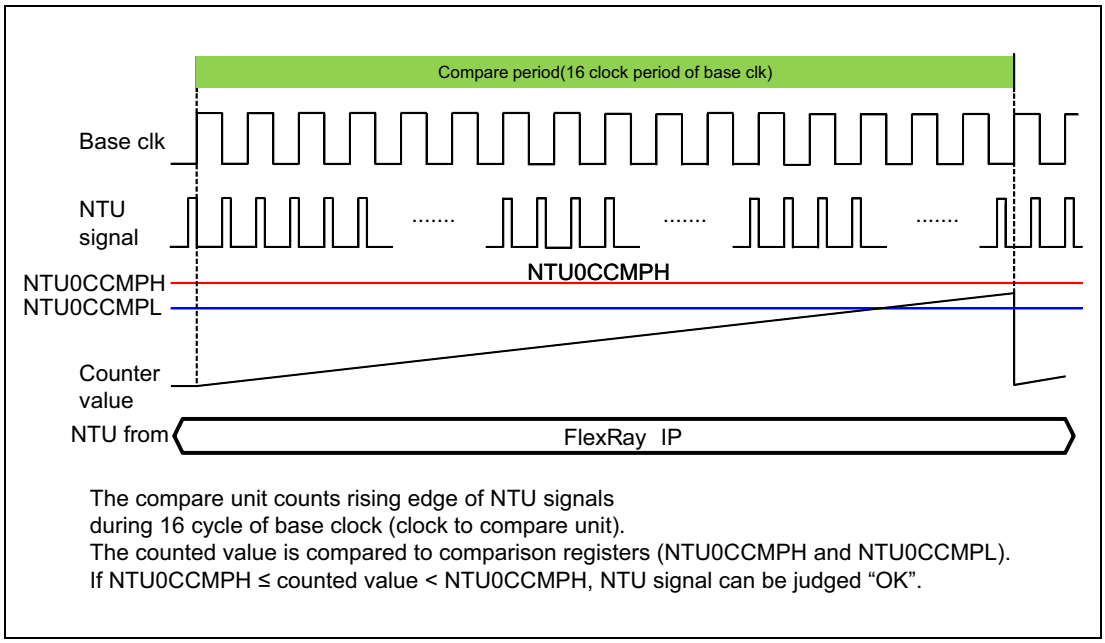

Figure 20.34 The NTU loss monitor operation in compare unit (in case of OK)

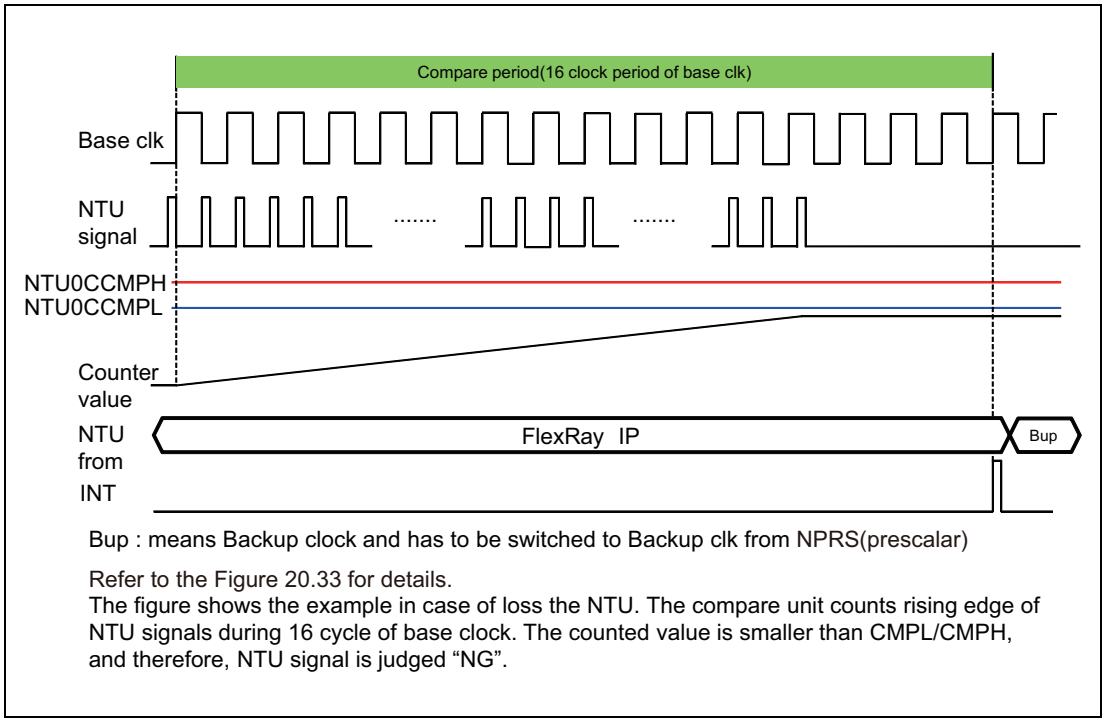

Figure 20.35 The NTU loss monitor operation in compare unit (in case of loss 1)

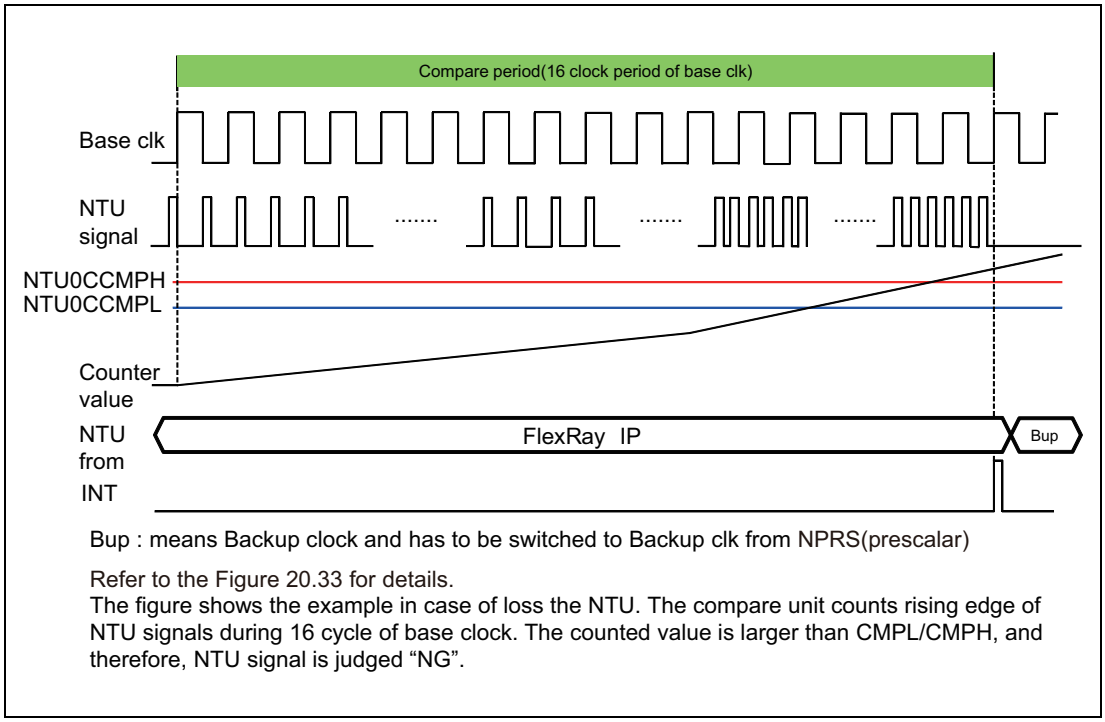

Figure 20.36 The NTU loss monitor operation in compare unit (in case of loss 2)

20.3.19 Port sharing between FlexRay IP and RLIN

FlexRay 0 channel A pins will be shared with RLIN30 module.

In detail, see **Section 2, Pin Functions**.

20.3.20 Wakeup capability

To provide a wake up capability in the FlexRay IP, detecting a falling edge of bus signal can be used as a trigger for interrupt controller. After receiving this trigger, the interrupt controller will be able to run SW to wake up the FlexRay IP.

For this functionality it is necessary to connect FLXnRXDA and FLXAnRXDB pins (n = 0, 1) with an external interrupt input (INTP), therefore port sharing between INTP and FLXnRXDA and FLXAnRXDB pins (n = 0, 1) of FlexRay IP will be implemented.

20.3.21 Limited Reset and Module stand-by

The FlexRay can be reset by limited reset from SYSCTRL. The Limited Reset is functionally equivalent to a hardware reset. Software must ensure that FlexRay is halted. (See **Section 20.3.1.2, FlexRay Module Disable)**

The FlexRay clock can be disabled by the SYSCTRL module stand-by function. Software must ensure that FlexRay is halted if module stand-by enable.

20.4 CAUTION

No.	Outline
ID1	A sequence of received WUS may generate redundant FLXAnFRSIR.WUPA/B events.
ID2	Erroneous cycle offset during startup after abort of startup or normal operation by a READY or FREEZE command
ID3	First WUS following received valid WUP may be ignored.
ID4	READY command accepted in READY state.
ID5	Slot Status vPOC!SlotMode is reset immediately when entering HALT state (CCSV.SLM[1:0] = "00").

ID1		A sequence of received WUS may generate redundant FLXAnFRSIR.WUPA/B events.
	Description	If a sequence of wakeup symbols (WUS) is received, all separated by appropriate idle phases, a valid wakeup pattern (WUP) should be detected after every second WUS. The FlexRay IP detects a valid wakeup pattern after the second WUS and then after each following WUS.
	Scope	The erratum is limited to the case where the application program frequently resets the appropriate FLXAnFRSIR.WUPA/B bits
	Effects	In the described case there are more FLXAnFRSIR.WUPA/B events seen than expected
	Workaround	Ignore redundant FLXAnFRSIR.WUPA/B events
ID2		Erroneous cycle offset during startup after abort of startup or normal operation by a READY or FREEZE command
	Description	An abort of startup or normal operation by a READY or FREEZE command near the macrotick border may lead to the effect that the state INITIALIZE_SCHEDULE is one macrotick too short during the first following integration attempt. This leads to an early cycle start in state INTEGRATION_COLDSTART_CHECK or INTEGRATION_CONSISTENCY_CHECK. As a result the integrating node calculates a cycle offset of one macrotick at the end of the first even/odd cycle pair in the states INTEGRATION_COLDSTART_CHECK or INTEGRATION_CONSISTENCY_CHECK and tries to correct this offset. If the node is able to correct the offset of one macrotick (pOffsetCorrectionOut >> gdMacrotick), the node enters NORMAL_ACTIVE with the first startup attempt. If the node is not able to correct the offset error because pOffsetCorrectionOut is too small (pOffsetCorrectionOut ≤ gdMacrotick), the node enters ABORT_STARTUP and is ready to try startup again. The next (second) startup attempt is not affected by this erratum.
	Scope	The erratum is limited to applications where READY or FREEZE command is used to leave STARTUP, NORMAL_ACTIVE, or NORMAL_PASSIVE state
	Effects	In the described case the integrating node tries to correct an erroneous cycle offset of one macrotick during startup.
	Workaround	With a configuration of pOffsetCorrectionOut >> gdMacrotick • (1+cClockDeviationMax) the node will be able to correct the offset and therefore also be able to successfully integrate.
ID3		First WUS following received valid WUP may be ignored.
	Description	When the protocol engine is in state WAKEUP_LISTEN and receives a valid wakeup pattern (WUP), it transfers into state READY and updates the wakeup status vector FLXAnFRCCSV.WSV[2:0] as well as the status interrupt flags SIR.WST and FLXAnFRSIR.WUPA/B. If the received wakeup pattern continues, the protocol engine may ignore the first wakeup symbol (WUS) following the state transition and signals the next FLXAnFRSIR.WUPA/B at the third instead of the second WUS.
	Scope	The erratum is limited to the reception of redundant wakeup patterns.
	Effects	Delayed setting of status interrupt flags FLXAnFRSIR.WUPA/B for redundant wakeup patterns
	Workaround	None needed.

ID4		READY command accepted in READY state.
	Description	The FlexRay module does not ignore a READY command while in READY state.
	Scope	The erratum is limited to the READY state.
	Effects	Flag FLXAnFRCCSV.CSI is set. Cold starting needs to be enabled by POC command ALLOW_COLDSTART (FLXAnFRSUCC1.CMD = "1001").
	Workaround	None needed.
ID5	Description	When the protocol engine is in the states NORMAL_ACTIVE or NORMAL_PASSIVE, a HALT or FREEZE command issued by the Host resets vPOC!SlotMode immediately to SINGLE slot mode (FLXAnFRCCSV.SLM[1:0] = "00"). According to the FlexRay protocol specification, the slot mode should not be reset to SINGLE slot mode before the following state transition from HALT to DEFAULT_CONFIG state.
	Scope	The erratum is limited to the HALT state
	Effects	The slot status vPOC!SlotMode is reset to SINGLE when entering HALT state.
	Workaround	None needed.

20.5 Difference among P1M-C, P1H-C and P1H-CE

Instance Name	RH850/P1x-C			
	P1M-C, P1H-C (4MB, BGA-156)	P1H-C (4MB, BGA-292)	P1H-C (8MB)	P1H-CE
FLXA0	√	√	√	√
FLXA1	—	√	√	√

Section 21 Ethernet Controller (ETNA)

This section describes the Ethernet Controller (ETNA) module.

The first subsection describes all the characteristics specific to the RH850/P1x-C such as channels, register base addresses, and input/output signal names.
The second and subsequent subsections describe characteristics of Ethernet.

21.1 Feature Overview of RH850/P1x-C Ethernet Controller

21.1.1 Number of Channels and Ports

The RH850/P1x-C includes one physical channel. This physical channel serves two MAC layer interface ports (hereafter referred to as port 0 and port 1), both of which can be made to perform transmission and reception independently.

Table 21.1 Ethernet Channels

Ethernet	P1M-C, P1H-C (4MB, BGA-156)	P1H-C (4MB, BGA-292) and P1H-CE
Number of Channels	1	1
Name	ETNA0	ETNA0
Number of Ports per Channel	1	2

Index n and m

This section identifies each Ethernet channel by “n” (n = 0) and port by m (m = 0, 1). For example, the E-DMAC Start Register is described as ETNAnEDSRm.

21.1.2 Register Addresses

Ethernet register addresses are represented by an offset from the base address <ETNAn_base>.

The following table shows the base address <ETNAn_base> of each Ethernet module.

Table 21.2 Register Base Address <ETNAn_base>

Ethernetn Channel	<ETNAn_base> Address
ETNA0	$1002\ 4000_H$

21.1.3 Clock Supply

The following clock input is supplied for the Ethernet module.

Table 21.3 Ethernet Clock Source

Clock	explanation	specification
HCLK_0	H-bus interface clock*1	CLK_HSB
HCLK_1	H-bus interface clock*1	CLK_HSB
ETH0TXCLK	MII TX CLK for ETNA0 port 0	External clock
ETH1TXCLK	MII TX CLK for ETNA0 port 1	External clock
ETH0RXCLK	MII RX CLK for ETNA0 port 0	External clock
ETH1RXCLK	MII RX CLK for ETNA0 port 1	External clock
ETH0REF50CK	RMII reference clock for ETNA0 port 0	External clock
ETH1REF50CK	RMII reference clock for ETNA0 port 1	External clock

Note 1. The input frequnecy must be in the rage of 60MHz to 80MHz

21.1.4 Interrupts and DMA/DTS

The Ethernet module can generate the following interrupt requests.

Table 21.4 Interrupt Requests

Unit Interrupt Name	Outline	Interrupt Number	DMA Trigger Number	DTS Trigger Number
ETNA0				
INTETNA0	Ethernet interrupt for Port 0 (HINT_0)	184	—	—
INTETNA1	Ethernet interrupt for Port 1 (HINT_1)	185	—	—

21.1.5 Difference table of P1M-C, P1H-C, P1H-CE product

Table 21.5 Difference of number of macro

Macro	Device				
	P1M-C	P1H-C (4MB, BGA-156)	P1H-C (4MB, BGA-292)	P1H-C (8MB)	P1H-CE
ETNA0 port 0	1	1	1	1	1
ETNA0 port 1	—	—	1	1	1

21.1.6 External Input/Output Signals

The following table shows the Ethernet input/output signals.

Table 21.6 Ethernet External Input / Output Signals

Pin Name	I/O	Function	MII	RMII
ETHmTXCLK	Input	Transmission clock	√	
ETHmRXCLK	Input	Reception clock	√	
ETHmREF50CK	Input	RMII reference clock		√
ETHmTXEN	Output	Transmission data enable	√	√
ETHmTXD3	Output	Transmission data 3	√	
ETHmTXD2	Output	Transmission data 2	√	
ETHmTXD1	Output	Transmission data 1	√	√
ETHmTXD0	Output	Transmission data 0	√	√
ETHmTXER	Output	Transmission data error	√	
ETHmRXDV	Input	Reception data valid	√	
ETHmRXD3	Input	Reception data 3	√	
ETHmRXD2	Input	Reception data 2	√	
ETHmRXD1	Input	Reception data 1	√	√
ETHmRXD0	Input	Reception data 0	√	√
ETHmRXER	Input	Reception data error	√	√
ETHmCRS	Input	MII: Carrier detection signal RMII: CRS_DV (CRS and RXDV)	√	√
ETHmCOL	Input	Collision detection signal	√	
ETHmMDC	Output	Serial management interface transfer clock	√	√
ETHmMDIO	Input/ Output	Serial management interface data input / output Input pin ETHmMDI Output pin ETHmMDO	√	√
ETHmLINKSTA	Input	Link status from PHY	√	√
ETHmWOL	Output	Wake on LAN signal (magic packet detection)	√	√

Note 1. In this device, ETHmTXER is unused and fixed to low.

Note 2. The minimum pulse width of ETHmRXER in RMII mode is depend on transfer speed mode. When operating mode is RMII mode with 10Mbps transfer speed, the minimum pulse of ETHmRXER need to be at least 1 clock of ETHmREF50CK (200ns) against RMII standard.

Note 3. ETH0LINKSTA pin is not supported by P1M-C (BGA-156) and P1H-C (4MB, BGA-156).

21.2 Overview

The Ethernet Controller (ETNA) conforms to the IEEE802.3 MAC (Media Access Control) layer standard. Connecting to an IEEE802.3 compliant physical layer device (PHY) enables the ETNA to transmit and receive Ethernet frames. The ETNA is equipped with MII (Media Independent Interface) and RMII (Reduced Media Independent Interface) and connected to the Ethernet Direct Memory Access Controller (EDMAC), which carries out high-speed data transfer (10M/100Mbps) to and from the system memory.

21.2.1 Functional Overview

Table 21.7 Outline of Ethernet function

Item	Specification
MAC (Media Access Controller)	• 100Mbps or 10Mbps data transfer • Full or half-duplex mode • PHY interface: MII, RMII
MAC port number	Implements 2 ports
DMA transfer function	• Each port implements the AHB master function and transfers the received/transmitted data from/to the RAM memory area. • Supports the 8 times of the 32-bit burst transfer. • Descriptor management system used by EDMAC (Data transfer without CPU intervention) • Single-frame/single-descriptor and single-frame/multi-descriptor operation. • Transmission/reception status indication in descriptor.
Address filter function	• Performs address filtering based on the destination address. • Up to 32 different addresses can be configured individually. • Supports the storm filter for broadcast frames. • Supports the mode enable/disable function for broadcast frames by using CAM entry table.
Others	Supports following features: • Magic packet detection and Wake-On-LAN signal output • Flow conforms to IEEE802.3 • PAUSE control frame format • CRC calculation for RX/TX frames • Configurable address filtering function (CAM function). • Integrated transmit/receive FIFO (TX = 2 KB, RX = 2 KB) • Interrupts for configurable error and status conditions • Internal loopback function (external loopback function can be realized with PHY interface) • MAC management counters

21.2.2 Block Diagram

The following **Figure 21.1** shows a block diagram of the Ethernet module.

The ETNA can transfer the transmitted or received Ethernet frame data to and from the transmit/ receive buffer in the memory at high speed using a dedicated direct memory access controller (E-DMAC).

The ETNA also has an on-chip TSU (Transfer Switching Unit) for CAM processing.

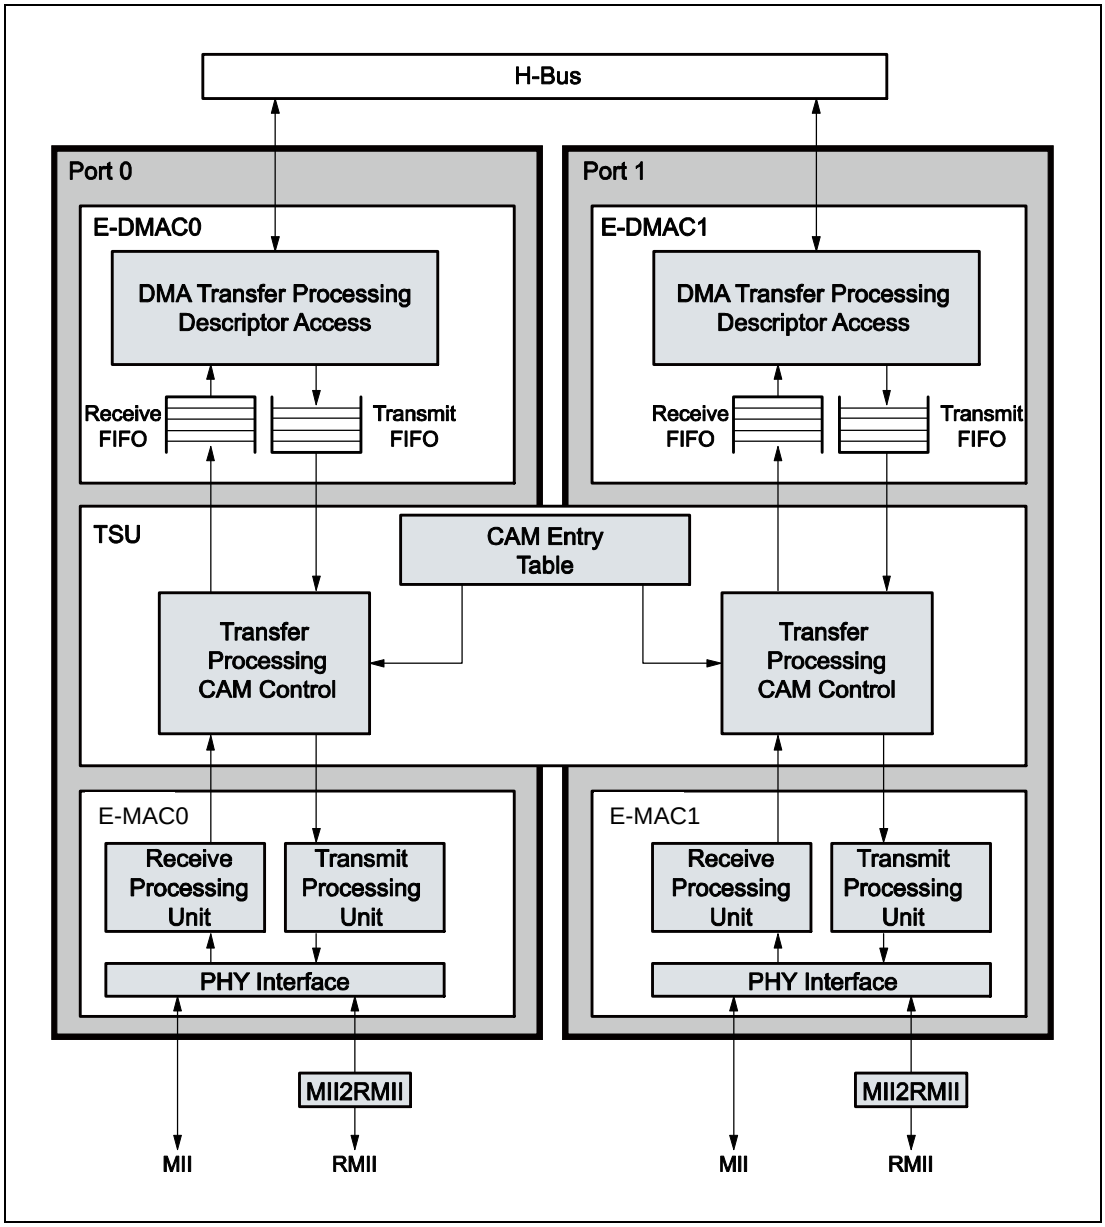

Figure 21.1 Block Diagram of Ethernet

21.3 Registers

21.3.1 Overview of Register

Ethernet is controlled and operated by the following registers.

Table 21.8 Overview of Ethernet Registers (1/8)

Description	Register Name	Access Width	Address	Access Protection	
				HBG	Other
E-DMAC Start Register 0	ETNAnEDSR0	32	<ETNAn_base> + 0000_H	HBG.Ethernet n*[1]	—
Transmit Descriptor List Start Address Register 0	ETNAnTDLAR0	32	<ETNAn_base> + 0010_H	HBG.Ethernet n*[1]	—
Transmit Descriptor Fetch Address Register 0	ETNAnTDFAR0	32	<ETNAn_base> + 0014_H	HBG.Ethernet n*[1]	—
Transmit Descriptor Finished Address Register 0	ETNAnTDFXR0	32	<ETNAn_base> + 0018_H	HBG.Ethernet n*[1]	—
Transmit Descriptor Final Flag Register 0	ETNAnTDFFR0	32	<ETNAn_base> + $001C_H$	HBG.Ethernet n*[1]	—
Receive Descriptor List Start Address Register 0	ETNAnRDLAR0	32	<ETNAn_base> + 0030_H	HBG.Ethernet n*[1]	—
Receive Descriptor Fetch Address Register 0	ETNAnRDFAR0	32	<ETNAn_base> + 0034_H	HBG.Ethernet n*[1]	—
Receive Descriptor Finished Address Register 0	ETNAnRDFXR0	32	<ETNAn_base> + 0038_H	HBG.Ethernet n*[1]	—
Receive Descriptor Final Flag Register 0	ETNAnRDFFR0	32	<ETNAn_base> + $003C_H$	HBG.Ethernet n*[1]	—

n = 0 HBG.Ethernet0
n = 1 HBG.Ethernet1

<ETNAn_base>

The base address <ETNAn_base> of Ethernet is defined by the keywords in **Table 21.2, Register Base Address <ETNAn_base>**.

Table 21.9 Register Reset Condition

Register Name	Reset Condition				
	Power On Reset	System Reset 1	System Reset 2	Application Reset 1	Limited Reset
All registers	√	√	√	√	√

21.3.2 ETNAnHDMMDRm — HDMAC Operation Mode Register m

ETNAnHDMMDRm is a 32-bit readable/writable register that specifies the operating mode of the E-DMACm.

The setting must not be changed after transmission/reception has started.

Access: This register can be read/written in 32-bit units.

Address: ETNAnHDMMDR0: <ETNAn_base> + $0C04_H$
ETNAnHDMMDR1: <ETNAn_base> + $1C04_H$

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 21.10 ETNAnHDMMDRm register contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9	DTOm	DMA TM OUT 0: If the HREADY signal which respond to DMA request is not asserted within 15 cycles, the DMA cycle is aborted by the timeout condition. 1: The DMA timeout is not detected and the DMA cycle is not aborted **CAUTION** DMA timeout function can avoid a detection of the timeout condtion only when a transfer request to GRAM from HDMAC is operated under the condition of no aribtration with other masters. When such condition is not expected on use case, set DTOm bit into 1.
8	ITOm	I/O TM OUT 0: If the response signal which respond to I/O access request is not asserted within 15 cycles, the I/O cycle is aborted by the timeout condition. 1: The I/O timeout is not detected and the I/O cycle is not aborted.
7 to 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

21.3.3 ETNAnHDMISRm — HDMAC Interrupt Status Register m

ETNAnHDMISRm is a 32-bit readable/writable register that shows the interrupt status of the E-DMACm.

Each bit of this register is cleared by writing 1. HDISm is cleared by clearing all bits in ETNAnEESRm register.

Access: This register can be read/written in 32-bit units.

Address: ETNAnHDMISR0: <ETNAn_base> + $0C10_H$
ETNAnHDMISR1: <ETNAn_base> + $1C10_H$

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	DTOSm	—	—	—	—	MSS2m	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Table 21.11 ETNAnHDMISRm register contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is read. When writing, write the value after reset.
23	DTOSm	DMA access Time Out 1: A timeout is detected during DMA access.
22 to 19	Reserved	When read, the value after reset is read. When writing, write the value after reset.
18	MSS2m	1cycle Retry or Split Response 1: While a DMA access, the Retry or Split Response is detected only 1 cycle. The DMA behavior is the same as normal retry.
17, 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15	ITOSm	I/O access Time Out 1: A timeout is detected during I/O access to the register.
14 to 12	Reserved	When read, the value after reset is read. When writing, write the value after reset.
11	SLS3m	I/O access is Seq or Busy 1: I/O access is Seq or Busy access.
10	SLS2m	I/O access is Burst 1: I/O access is burst access.
9	SLS1m	I/O access is not 32 bit 1: I/O access is not 32 bit.
8	SLS0m	I/O access is not 4 byte boundary 1: I/O access is not 4 byte boundary.
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	HDISm	HDMAC Interrupt 1: HDMAC interrupt is detected.

21.3.4 ETNAnHDMIERm — HDMAC Interrupt Enable Register m

ETNAnHDMIERm is a 32-bit readable/writable register that enables the interrupt output of the E-DMACm.

Access: This register can be read/written in 32-bit units.

Address: ETNAnHDMIER0: <ETNAn_base> + $0C14_H$
ETNAnHDMIER1: <ETNAn_base> + $1C14_H$

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	DTOEm	—	—	—	—	MSE2m	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R/W

Table 21.12 ETNAnHDMIERm register contents

Bit Position	Bit Name	Function
31 to 24	Reserved	When read, the value after reset is read. When writing, write the value after reset.
23	DTOEm	DMA access Time Out Interrupt Enable 1: A timeout is detected during DMA access.
22 to 19	Reserved	When read, the value after reset is read. When writing, write the value after reset.
18	MSE2m	1cycle Retry or Split Response Interrupt Enable 1: While a DMA access, the Retry or Split Response is detected only 1 cycle. The DMA behavior is the same as normal retry.
17, 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15	ITOEm	I/O access Time Out Interrupt Enable 1: A timeout is detected during I/O access to HDMAC or M-Port..
14 to 12	Reserved	When read, the value after reset is read. When writing, write the value after reset.
11	SLE3m	I/O access is Seq or Busy Interrupt Enable 1: I/O access is Seq or Busy access.
10	SLE2m	I/O access is Burst Interrupt Enable 1: I/O access is burst access.
9	SLE1m	I/O access is not 32 bit Interrupt Enable 1: I/O access is not 32 bit.
8	SLE0m	I/O access is not 4 byte boundary Interrupt Enable 1: I/O access is not 4 byte boundary.
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	HDIEm	HDMAC Interrupt Enable 1: HDMAC interrupt is enabled. **Note:** This bit masks also masks any interrupt arriving from E-MAC0 (= any of events enabled in ETNAnEESIPRm like PHY link status change).

21.3.5 ETNAnARSTR — Software Reset Register

ETNAnARSTR resets only TSU block in the ETNA. By writing 1 to the ARST bit in this register, a software reset is issued to TSU block of the ETNA (for 512 cycles of the HCLK). The ARST bit is always read as 0. While a software reset is issued, register access to all blocks of the ETNA is prohibited.

Access: This register can be read/written in 32-bit units.

Address: <ETNAn_base> + 0800_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ARST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 21.13 ETNAnARSTR register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	ARST	Software Reset When 1 is written to this bit, a software reset is issued to TSU block of the ETNA (for 512 cycles of the peripheral clock). Writing 0 does not affect this bit. This bit is always read as 0. While a software reset is issued, register access to all blocks of the ETNA is prohibited. The following registers are not initialized by a software reset. ETNAnTSU_ADRH0 to ETNAnTSU_ADRH31, ETNAnTSU_ADRL0 to ETNAnTSU_ADRL31

21.3.6 ETNAnECMRm — E-MAC Mode Register m

ETNAnECMRm is a 32-bit readable/writable register that specifies the operating mode of the E-MACm. The settings in this register are normally made in the initialization process following a reset.

The operating mode setting must not be changed while the transmitting and receiving functions are enabled. To switch the operating mode, return the E-MACm and E-DMACm to their initial states by means of the SWRTm and SWRRm bits in ETNAnEDMRm before making settings again.

Access: This register can be read/written in 32-bit units.

Address: ETNAnECMR0: <ETNAn_base> + 0500_H
ETNAnECMR1: <ETNAn_base> + 1500_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	TRCCMm	—	—	RCSCm	—	DPADm	RZPFm	TZPFm/DCACm	PFRm	RXFm	TXFm
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 21.14 ETNAnECMRm register contents (1/3)

Bit Position	Bit Name	Function
31 to 27	Reserved	When read, the value after reset is read. When writing, write the value after reset.
26	TRCCMm	Counter Clear Mode Sets the method for clearing the counter register. Refer to the description of each register. 0: Cleared to 0 when the relevant register is written 1: Cleared to 0 when the relevant register is read
25, 24	Reserved	When read, the value after reset is read. When writing, write the value after reset.
23	RCSCm	Checksum Calculation Specifies whether to perform automatic calculation (hardware calculation) of the checksum of the receive frame data unit. 0: Checksum is not automatically calculated 1: Checksum is automatically calculated Note that the checksum calculation of a frame with a VLAN tag is not supported.
22	Reserved	When read, the value after reset is read. When writing, write the value after reset.
21	DPADm	Data Padding 0: Padding is inserted to data less than 60 bytes so it is transmitted as 60-byte data 1: Padding is not inserted to data less than 60 bytes and it is transmitted without changes
20	RZPFm	PAUSE Frame Reception with TIME = 0 0: Reception of a PAUSE frame whose TIME parameter value is 0 is disabled 1: Reception of a PAUSE frame whose TIME parameter value is 0 is enabled

Table 21.14 ETNAnECMRm register contents (2/3)

Bit Position	Bit Name	Function
19	TZPFm/DCACm	(DMm = 1) PAUSE Frame Usage with TIME = 0 Enable 0: Control of a PAUSE frame whose TIME parameter value is 0 is disabled. The next frame is not transmitted until the time specified by the Timer value has elapsed. If a PAUSE frame whose time specified by the Timer value is 0 is received, that PAUSE frame is discarded. 1: Control of a PAUSE frame whose TIME parameter value is 0 is enabled. When the data size in the receive FIFO becomes smaller than the ETNAnFCFTRm setting before the time specified by the Timer value elapses, an automatic PAUSE frame with a Timer value of 0 is transmitted. On receiving a PAUSE frame with a Timer value of 0, the transmission wait state is canceled. (DMm = 0) Disable CRS Assert Check 1: CRS (TINT3) is not checked in half-duplex transmit mode 0: CRS (TINT3) is checked in half-duplex transfer mode
18	PFRm	PAUSE Frame Receive Mode 0: PAUSE frame is not transferred to E-DMAC 1: PAUSE frame is transferred to E-DMAC
17	RXFm	Operating Mode for Receiving Port Flow Control 0: PAUSE frame detection is disabled 1: Flow control for the receiving port is enabled
16	TXFm	Operating Mode for Transmitting Port Flow Control 0: Flow control for the transmitting port is disabled (Automatic PAUSE frame is not transmitted) 1: Flow control for the transmitting port is enabled (Automatic PAUSE frame is transmitted as required)
15, 14	Reserved	When read, the value after reset is read. When writing, write the value after reset.
13	MCTm	Multicast Address Frame Receive Mode 0: Frames other than the multicast address set by the CAM entry table 0 to 31 (H/L) registers are received. However, if the on-chip CAM entry table reference is disabled, all multicast address frames are received. 1: Only the multicast address set by the CAM entry table 0 to 31 (H/L) registers is received.
12 to 10	Reserved	When read, the value after reset is read. When writing, write the value after reset.
9	MPDEm	Magic Packet Detection Enable Enables or disables Magic Packet detection by hardware to allow activation from the Ethernet. 0: Magic Packet detection is not enabled 1: Magic Packet detection is enabled
8, 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6	REm	Reception Enable If a switch is made from receiving function enabled (RE = 1) to disabled (RE = 0) while a frame is being received, the receiving function will be enabled until reception of the corresponding frame is completed. 0: Receiving function is disabled 1: Receiving function is enabled
5	TEm	Transmission Enable If a switch is made from transmitting function enabled (TE0 = 1) to disabled (TE0 = 0) while a frame is being transmitted, the transmitting function will be enabled until transmission of the corresponding frame is completed. 0: Transmitting function is disabled 1: Transmitting function is enabled
4	Reserved	When read, the value after reset is read. When writing, write the value after reset.

Table 21.14 ETNAnECMRm register contents (3/3)

Bit Position	Bit Name	Function
3	ILBm	Internal Loop Back Mode Specifies loopback mode in the ETNA. 0: Normal data transmission/reception is performed 1: Data loopback is performed inside the E-MAC0 in the ETNA when DM0 = 1
2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	DMm	Duplex Mode Specifies the ETNA transfer method. 0: Half-duplex transfer is specified 1: Full-duplex transfer is specified
0	PRMm	Promiscuous Mode Setting this bit enables all Ethernet frames to be received. All Ethernet frames means all receivable frames, irrespective of differences or enabled/disabled status (destination address, broadcast address, multicast bit, etc.). 0: ETNA performs normal operation 1: ETNA performs promiscuous mode operation

Note: All bits, except for TEm and REm, should be changed while the transmitting function is disabled (TEm = 0) and the receiving function is disabled (REm = 0).

21.3.7 ETNAnECSRm — MAC Status Register m

ETNAnECSRm is a 32-bit readable/writable register that indicates the status in the E-MACm. This status can be notified to the CPU by interrupts. When 1 is written to any bits of this register, the corresponding flags can be cleared. Writing 0 does not affect the flag. For bits that generate interrupts, the interrupt can be enabled or disabled by the corresponding bit in ETNAnECSIPRm.

The interrupts generated due to this status register are indicated in each ECIm bit in ETNAnEESRm of the E-DMACm for port m.

Access: This register can be read/written in 32-bit units.

Address: ETNAnECSR0: <ETNAn_base> + 0510_H
ETNAnECSR1: <ETNAn_base> + 1510_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	PFROIm	—	LINKIm	MPDm	ICDm
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R/W	R/W

Table 21.15 ETNAnECSRm register contents

Bit Position	Bit Name	Function
31 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	PFROIm	PAUSE Frame Retransmit Retry Over Indicates whether the retransmit count for retransmitting a PAUSE frame when flow control is enabled has exceeded the retransmit upper-limit set in the automatic PAUSE frame retransmit count register (ETNAnTPAUSERm). 0: PAUSE frame retransmit count has not exceeded the upper limit 1: PAUSE frame retransmit count has exceeded the upper limit For clearing this bit to 0, please refer the following procedures. (1) Read TPFRCRm for clearing TPFRCR0. (2) Write 1 to this bit.
3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2	LINKIm	ETHmLINKSTA Signal Change 0: ETHmLINKSTA is not changed 1: ETHmLINKSTA is changed
1	MPDm	Magic Packet Detection Indicates that a Magic Packet has been detected on the line. 0: Magic Packet has not been detected 1: Magic Packet has been detected
0	ICDm	Illegal Carrier Detection Indicates that the PHY-LSI has detected an illegal carrier on the line. If a change in the signal input from the PHY-LSI occurs in a period shorter than the software recognition period, the correct information may not be obtained. Refer to the timing specification for the PHY-LSI used. 0: PHY-LSI has not detected an illegal carrier on the line 1: PHY-LSI has detected an illegal carrier on the line

Note: ETH0LINKSTA pin is not supported by P1M-C (BGA-156) and P1H-C (4MB, BGA-156).

21.3.8 ETNAnECSIPRm — E-MAC Interrupt Permission Register m

ETNAnECSIPRm is a 32-bit readable/writable register that enables or disables the interrupt sources indicated by ETNAnECSRm. Each bit can disable or enable interrupts corresponding to the bits in ETNAnECSRm in combination with ECImIP bit in ETNAnEESIPRm and HDIEm bit in ETNAnHDMIERm.

Access: This register can be read/written in 32-bit units.

Address: ETNAnECSIPR0: <ETNAn_base> + 0518_H
ETNAnECSIPR1: <ETNAn_base> + 1518_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 21.16 ETNAnECSIPRm register contents

Bit Position	Bit Name	Function
31 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	PFROIPm	PAUSE Frame Retransmit Interrupt Enable 0: Interrupt notification by the PFROI bit is disabled 1: Interrupt notification by the PFROI bit is enabled
3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2	LINKIPm	ETHmLINKSTA Signal Change 0: Interrupt notification by the ETHmLINKSTA change is disabled 1: Interrupt notification by the ETHmLINKSTA change is enabled
1	MPDIPm	Magic Packet Detect Interrupt Enable 0: Interrupt notification by the MPD bit is disabled 1: Interrupt notification by the MPD bit is enabled
0	ICDIPm	Illegal Carrier Detect Interrupt Enable 0: Interrupt notification by the ICD bit is disabled 1: Interrupt notification by the ICD bit is enabled

21.3.9 ETNAnPIRm — PHY Interface Register m

ETNAnPIRm is a 32-bit readable/writable register that provides a means of accessing the PHY-LSI internal registers via the MDIO.

Access: This register can be read/written in 32-bit units.

Address: ETNAnPIR0: <ETNAn_base> + 0520_H
ETNAnPIR1: <ETNAn_base> + 1520_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R/W	R/W	R/W

Table 21.17 ETNAnPIRm register contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3	MDIm	Management Data-In Indicates the level of the ET_MDIO pin.
2	MDOm	Management Data-Out Outputs the value set in this bit from the ET_MDIO pin when the MMD bit is 1.
1	MMDm	Management Mode Direction Specifies the data read/write direction. 0: Read direction is specified 1: Write direction is specified
0	MDCm	Management Data Clock Outputs the value set in this bit from the ET_MDC pin, and supplies the MII with the management data clock.

21.3.10 ETNAnPLSRm — PHY link status Register m

ETNAnPLSRm is a 32-bit register that monitors the ETHmLINKSTA signal status.

Access: This register can be read in 32-bit units.

Address: ETNAnPLSR0: <ETNAn_base> + 0528_H
ETNAnPLSR1: <ETNAn_base> + 1528_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LINKm
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 21.18 ETNAnPLSRm register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is read.
0	LINKm	ETHmLINKSTA Status For P1M-C (BGA-156) and P1H-C (4MB, BGA-156): 0: Channel m ETHmLINKSTA signal is “0” For other products: 0: Channel m ETHmLINKSTA signal is “0” 1: Channel m ETHmLINKSTA signal is “1”

Note: ETH0LINKSTA pin is not supported by P1M-C (BGA-156) and P1H-C (4MB, BGA-156).

21.3.11 ETNAnPIPRm — PHY interrupt polarity register m

ETNAnPIPRm is a 32-bit readable/writable register that specifies the polarity of the PHY interrupt.

Access: This register can be read/written in 32-bit units.

Address: ETNAnPIPR0: <ETNAn_base> + $052C_H$
ETNAnPIPR1: <ETNAn_base> + $152C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.19 ETNAnPIPRm register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	PHYILm	Port m PHY interrupt Polarity 0: Active level is Low-level 1: Active level is High-level

21.3.12 ETNAnMAHRm — MAC Address High Register m

ETNAnMAHRm is a 32-bit readable/writable register that specifies the upper 32 bits of the 48-bit MAC address. The settings in this register are normally made in the initialization process after a reset. The MAC address setting must not be changed while the transmitting and receiving functions are enabled. Return the E-MACm and E-DMACm to their initial states by means of the SWRTm and SWRRm bits in ETNAnEDMRm before making settings again.

Access: This register can be read/written in 32-bit units.

Address: ETNAnMAHR0: <ETNAn_base> + $05C0_H$
ETNAnMAHR1: <ETNAn_base> + $15C0_H$

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MAm[47:32]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.20 ETNAnMAHRm register contents

Bit Position	Bit Name	Function
31 to 0	MAm[47:16]	MAC Address Bits 47 to 16 These bits are used to set the upper 32 bits of the MAC address. If the MAC address is 01-23-45-67-89-AB (hexadecimal), set 01234567_H in this register.

21.3.13 ETNAnMALRm — MAC Address Low Register m

ETNAnMALRm is a 32-bit readable/writable register that specifies the lower 16 bits of the 48-bit MAC address. The settings in this register are normally made in the initialization process after a reset. The MAC address setting must not be changed while the transmitting and receiving functions are enabled. Return the E-MACm and E-DMACm to their initial states by means of the SWRTm and SWRRm bits in ETNAnEDMRm before making settings again.

Access: This register can be read/written in 32-bit units.

Address: ETNAnMALR0: <ETNAn_base> + $05C8_H$
ETNAnMALR1: <ETNAn_base> + $15C8_H$

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 21.21 ETNAnMALRm register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15 to 0	MAm[15:0]	MAC Address Bits 15 to 0 These bits are used to set the lower 16 bits of the MAC address. If the MAC address is 01-23-45-67-89-AB (hexadecimal), set $0000\ 89AB_H$ in this register.

21.3.14 ETNAnRFLRm — Receive Frame Length Register m

ETNAnRFLRm is a 32-bit readable/writable register that specifies the maximum frame length (in bytes) that can be received. The settings in this register must not be changed while the receiving function is enabled.

Access: This register can be read/written in 32-bit units.

Address: ETNAnRFLR0: <ETNAn_base> + 0508_H
ETNAnRFLR1: <ETNAn_base> + 1508_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RFLm[17:16]

Table 21.22 ETNAnRFLRm register contents

Bit Position	Bit Name	Function
31 to 18	Reserved	When read, the value after reset is read. When writing, write the value after reset.
17 to 0	RFLm[17:0]	Receive Frame Length The frame data described here refers to all fields from the destination address up to the CRC data. Frame contents from the destination address up to the data are actually transferred to memory. CRC data is not included in the transfer. When data that exceeds the specified value is received, the part of data that exceeds the specified value is discarded. 00000_H to $005EE_H$: 1,518 bytes $005EF_H$: 1,519 bytes $005F0_H$: 1,520 bytes : : $007FF_H$: 2,047 bytes 00800_H: 2,048 bytes : : 01000_H: 4,096 bytes : : 10000_H: 65,536 bytes : : 20000 to $3FFFF_H$: 131,072 bytes

21.3.15 ETNAnTROCRm — Transmit Retry Over Counter Register m

ETNAnTROCRm is a 16-bit counter that indicates the number of frames that were unable to be transmitted in 16 transmission attempts including the retransfer. When 16 transmission attempts have failed, this register is incremented by 1. When the value in this register reaches 0000 $FFFF_H$, count-up is halted. This register is cleared to 0 when it is read with the TRCCMm bit in ETNAnECMRm set to 1. When the TRCCMm bit in ETNAnECMRm is 0, this register is cleared to 0 by writing any value to TROCm.

Access: This register can be read/written in 32-bit units.

Address: ETNAnTROCR0: <ETNAn_base> + 0700_H
ETNAnTROCR1: <ETNAn_base> + 1700_H

Value after reset: 0000 0000_H This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TROCm[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 21.23 ETNAnTROCRm register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15 to 0	TROCm[15:0]	Transmit Retry Over Count These bits indicate the number of frames that were unable to be transmitted in 16 transmission attempts including the retransfer.

21.3.16 ETNAnCDCRm — Delayed Collision Detect Counter Register m

ETNAnCDCRm is a 16-bit counter that indicates the number of all delayed collisions that occurred on the line after the start of data transmission. When the value in this register reaches 0000 $FFFF_H$, count-up is halted. This register is cleared to 0 when it is read with the TRCCMm bit in ETNAnECMRm set to 1. When the TRCCMm bit in ETNAnECMRm is 0, this register is cleared to 0 by writing any value to COSDCm.

Access: This register can be read/written in 32-bit units.

Address: ETNAnCDCR0: <ETNAn_base> + 0708_H
ETNAnCDCR1: <ETNAn_base> + 1708_H

Value after reset: 0000 0000_H This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 21.24 ETNAnCDCRm register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15 to 0	COSDCm[15:0]	Delayed Collision Detect Count These bits indicate the number of all delayed collisions after the start of data transmission.

21.3.17 ETNAnLCCRm — Lost Carrier Counter Register m

ETNAnLCCRm is a 16-bit counter that indicates the number of times the carrier was lost during data transmission. When the value in this register reaches 0000 $FFFF_H$, count-up is halted. This register is cleared to 0 when it is read with the TRCCMm bit in ETNAnECMRm set to 1. When the TRCCMm bit in ETNAnECMRm is 0, this register is cleared to 0 by writing any value to LCCm.

Access: This register can be read/written in 32-bit units.

Address: ETNAnLCCR0: <ETNAn_base> + 0710_H
ETNAnLCCR1: <ETNAn_base> + 1710_H

Value after reset: 0000 0000_H This register is initialized by system reset.

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15 to 0	LCCm[15:0]	Lost Carrier Count These bits indicate the number of times the carrier was lost during data transmission.

21.3.18 ETNAnCEFCRm — CRC Error Frame Receive Counter Register m

ETNAnCEFCRm is a 16-bit counter that indicates the number of times a frame with a CRC error was received. When the value in this register reaches 0000 $FFFF_H$, count-up is halted. This register is cleared to 0 when it is read with the TRCCMm bit in ETNAnECMRm set to 1. When the TRCCMm bit in ETNAnECMRm is 0, this register is cleared to 0 by writing any value to CEFCm.

Access: This register can be read/written in 32-bit units.

Address: ETNAnCEFCR0: <ETNAn_base> + 0740_H
ETNAnCEFCR1: <ETNAn_base> + 1740_H

Value after reset: 0000 0000_H This register is initialized by system reset.

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15 to 0	CEFCm[15:0]	CRC Error Frame Count These bits indicate the number of CRC error frames received.

21.3.19 ETNAnFRECRm — Frame Receive Error Counter Register m

ETNAnFRECRm is a 16-bit counter that indicates the number of frames for which a receive error was generated by the signal ETNAmRXER input from the PHY-LSI. ETNAnFRECRm is incremented each time the signal ETNAmRXER becomes active. When the value in this register reaches 0000 $FFFF_H$, count-up is halted. This register is cleared to 0 when it is read with the TRCCMm bit in ETNAnECMRm set to 1. When the TRCCMm bit in ETNAnECMRm is 0, this register is cleared to 0 by writing any value to FRECm.

Access: This register can be read/written in 32-bit units.

Address: ETNAnFRECR0: <ETNAn_base> + 0748_H
ETNAnFRECR1: <ETNAn_base> + 1748_H

Value after reset: 0000 0000_H This register is initialized by system reset.

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15 to 0	FRECm[15:0]	Frame Receive Error Count These bits indicate the number of errors during frame reception.

21.3.20 ETNAnTSFRCRm — Too-Short Frame Receive Counter Register m

ETNAnTSFRCRm is a 16-bit counter that indicates the number of frames received with a length fewer than 64 bytes. When the value in this register reaches 0000 $FFFF_H$, count-up is halted. This register is cleared to 0 when it is read with the TRCCMm bit in ETNAnECMRm set to 1. When the TRCCMm bit in ETNAnECMRm is 0, this register is cleared to 0 by writing any value to TSFCm.

Access: This register can be read/written in 32-bit units.

Address: ETNAnTSFRCR0: <ETNAn_base> + 0750_H
ETNAnTSFRCR1: <ETNAn_base> + 1750_H

Value after reset: 0000 0000_H This register is initialized by system reset.

Table 21.28 ETNAnTSFRCRm register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15 to 0	TSFCm[15:0]	Too-Short Frame Receive Count These bits indicate the number of frames received with a length of less than 64 bytes.

21.3.21 ETNAnTLFRCRm — Too-Long Frame Receive Counter Register m

ETNAnTLFRCRm is a 16-bit counter that indicates the number of frames received with a length exceeding the value specified by the receive frame length register (ETNAnRFLRm). When the value in this register reaches 0000 $FFFF_H$, count-up is halted. This register is not incremented when a frame containing residual bits is received. In this case, the reception of the frame is indicated in the residual-bit frame receive counter register (ETNAnRFCRm). This register is cleared to 0 when it is read with the TRCCMm bit in ETNAnECMRm set to 1. When the TRCCMm bit in ETNAnECMRm is 0, this register is cleared to 0 by writing any value to TLFCm.

Access: This register can be read/written in 32-bit units.

Address: ETNAnTLFRCR0: <ETNAn_base> + 0758_H
ETNAnTLFRCR1: <ETNAn_base> + 1758_H

Value after reset: 0000 0000_H This register is initialized by system reset.

Table 21.29 ETNAnTLFRCRm register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15 to 0	TLFCm[15:0]	Too-Long Frame Receive Count These bits indicate the number of frames received with a length exceeding the value in ETNAnRFLRm.

21.3.22 ETNAnRFCRm — Residual-Bit Frame Receive Counter Register m

ETNAnRFCRm is a 16-bit counter that indicates the number of frames received containing residual bits (less than an 8-bit unit). When the value in this register reaches 0000 $FFFF_H$, count-up is halted. This register is cleared to 0 when it is read with the TRCCMm bit in ETNAnECMRm set to 1. When the TRCCMm bit in ETNAnECMRm is 0, this register is cleared to 0 by writing any value to RFCm.

Access: This register can be read/written in 32-bit units.

Address: ETNAnRFCR0: <ETNAn_base> + 0760_H
ETNAnRFCR1: <ETNAn_base> + 1760_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15 to 0	RFCm[15:0]	Residual-Bit Frame Receive Count These bits indicate the number of frames received containing residual bits.

21.3.23 ETNAnMAFCRm — Multicast Address Frame Receive Counter Register m

ETNAnMAFCRm is a 16-bit counter that indicates the number of frames received with a specified multicast address. When the value in this register reaches 0000 $FFFF_H$, count-up is halted. This register is cleared to 0 when it is read with the TRCCMm bit in ETNAnECMRm set to 1. When the TRCCMm bit in ETNAnECMRm is 0, this register is cleared to 0 by writing any value to MAFCm.

Access: This register can be read/written in 32-bit units.

Address: ETNAnMAFCR0: <ETNAn_base> + 0778_H
ETNAnMAFCR1: <ETNAn_base> + 1778_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Table 21.31 ETNAnMAFCRm register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15 to 0	MAFCm[15:0]	Multicast Address Frame Count These bits indicate the number of multicast frames received.

21.3.24 ETNAnAPRm — Automatic PAUSE Frame Register m

ETNAnAPRm is used to set the TIME parameter value of an automatic PAUSE frame. When an automatic PAUSE frame is transmitted, the value set in this register is used as the TIME parameter of the PAUSE frame.

Access: This register can be read/written in 32-bit units.

Address: ETNAnAPR0: <ETNAn_base> + 0554_H
ETNAnAPR1: <ETNAn_base> + 1554_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 21.32 ETNAnAPRm register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15 to 0	APm[15:0]	Automatic PAUSE These bits set the TIME parameter value of an automatic PAUSE frame. One bit is equivalent to 512 bit-time. When flow control is enabled in transmission (PAUSE frame transmission) (TXFm bit in ETNAnECMRm = 1), set a value other than 0000_H in these bits. 0000_H: — 0001_H: 512 × 1 bit-time 0002_H: 512 × 2 bit-time : : $FFFF_H$: 512 × 65,535 bit-time Note: The bit-time becomes as follows according to the transfer speed. 100 Mbps: 1 bit-time = 10 ns 10 Mbps: 1 bit-time = 100 ns

21.3.25 ETNAnMPRm — Manual PAUSE Frame Register m

ETNAnMPRm is used to set the TIME parameter value of a manual PAUSE frame. When writing the Timer value to this register, manual PAUSE frame transmission is started. When a manual PAUSE frame is transmitted, the value set in this register is used as the TIME parameter of the PAUSE frame.

Access: This register can be read/written in 32-bit units.

Address: ETNAnMPR0: <ETNAn_base> + 0558_H
ETNAnMPR1: <ETNAn_base> + 1558_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15 to 0	MPm[15:0]	Manual PAUSE These bits set the TIME parameter value of a manual PAUSE frame. One bit is equivalent to 512 bit-time. 0000_H: — 0001_H: 512 × 1 bit-time 0002_H: 512 × 2 bit-time : : $FFFF_H$: 512 × 65,535 bit-time Note: The bit-time becomes as follows according to the transfer speed. 100 Mbps: 1 bit-time = 10 ns 10 Mbps: 1 bit-time = 100 ns

21.3.26 ETNAnTPAUSERm — Automatic PAUSE Frame Retransmit Count Register m

ETNAnTPAUSERm is used to set the upper limit for the number of times to retransmit an automatic PAUSE frame. The settings in this register must not be changed while the transmitting function is enabled.

Access: This register can be read/written in 32-bit units.

Address: ETNAnTPAUSER0: <ETNAn_base> + 0564_H
ETNAnTPAUSER1: <ETNAn_base> + 1564_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

21.3.27 ETNAnTPFRCRm — Automatic PAUSE Frame Retransmit Counter Register m

ETNAnTPFRCRm is a 16-bit counter that indicates the number of times to retransmit an automatic PAUSE frame. This register is cleared to 0 when it is read or the E-HDMAC entered busy condition.

Access: This register can be read/written in 32-bit units.

Address: ETNAnTPFRCR0: <ETNAn_base> + 0568_H
ETNAnTPFRCR1: <ETNAn_base> + 1568_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read.
15 to 0	PFRTCm[15:0]	Pause Frame Retry Counter The number of times to retransmit an automatic PAUSE frame between the start of a busy condition and its end.

21.3.28 ETNAnPFTCRm — PAUSE Frame Transmit Counter Register m

ETNAnPFTCRm is a 16-bit counter that indicates the number of times a PAUSE frame is transmitted. This register is cleared to 0 when it is read.

Access: This register can be read/written in 32-bit units.

Address: ETNAnPFTCR0: <ETNAn_base> + $055C_H$
ETNAnPFTCR1: <ETNAn_base> + $155C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

15 to 0	PFRXCm[15:0]	PAUSE Frame Receive Count These bits indicate the number of PAUSE frames received when flow control is enabled in reception (RXFm bit in ETNAnECMRm = 1).

21.3.30 ETNAnEMRm — ETNA Mode Register m

ETNAnEMRm is used to set the operating mode of the ETNA.

Access: This register can be read/written in 32-bit units.

Address: ETNAnEMR0: <ETNAn_base> + $05B0_H$
ETNAnEMR1: <ETNAn_base> + $15B0_H$

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

2	SPEEDm	Transfer Speed SPEEDm 1: 100Mbps 0: 10Mbps
1, 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

21.3.31 ETNAnBCFRRm — Broadcast Frame Receive Count Set Register m

ETNAnBCFRRm is a register that sets the number of times broadcast frames are received consecutively.

Access: This register can be read/written in 32-bit units.

Address: ETNAnBCFRR0: <ETNAn_base> + $056C_H$
ETNAnBCFRR1: <ETNAn_base> + $156C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 21.39 ETNAnBCFRRm register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15 to 0	BCFm[15:0]	Consecutive Broadcast Frame Reception Count Setting ETNA can receive frames with the broadcast address consecutively until the number of receptions reaches the value set in these bits. If the number of consecutive broadcast frame reception exceeds BCFm configuration, the subsequent broadcast frames are discarded. 0000_H: No limitation on the number of receptions 0001_H: Receive one frame : : $FFFF_H$: Receive 65535 frames

21.3.32 ETNAnCRBCFRRm — Count Reset of BCFRR m

ETNAnCRBCFRRm counts the number of times that consecutive broadcast frame reception exceeds the times defined by ETNAnBCFRRm.

Access: This register can be read/written in 32-bit units.

Address: ETNAnCRBCFRR0: <ETNAn_base> + 0570_H
ETNAnCRBCFRR1: <ETNAn_base> + 1570_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 21.40 ETNAnCRBCFRRm register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15 to 0	CNTm[15:0]	Reset number counter of ETNAnBCFRRm CNTm is incremented only when the number of times that consecutive broadcast frame reception exceeds ETNAnBCFRRm configuration. If CNTm become $FFFF_H$, count-up is halted. In case the final reception frame is the broadcast frame, CNTm is not incremented until non broadcast frame is received.

21.3.33 ETNAnTSU_CTRST — TSU Counter Reset Register

ETNAnTSU_CTRST clears the transmit and receive frame counters to 0.

Access: This register can be read/written in 32-bit units.

Address: ETNAnTSU_CTRST: <ETNAn_base> + 0804_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is read. When writing, write the value after reset.
8	CTRST	TSU Counter Reset When 1 is written to this bit, the values of registers ETNAnTXNLCR0/ ETNAnTXNLCR1, ETNAnTXALCR0/ETNAnTXALCR1, ETNAnRXNLCR0/ ETNAnRXNLCR1, ETNAnRXALCR0/ETNAnRXALCR1 are cleared to 0. Writing 0 does not affect this bit. This bit is always read as 0.
7 to 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

21.3.34 ETNAnTSU_FWSLm — Receive Function Set Register

ETNAnTSU_FWSLm sets the processing method of each frame in port m reception.
This register setting must not be changed while the transmitting and receiving functions are enabled. Return the E-MACm and E-DMACm to their initial states by means of the SWRTm and SWRRm bits in ETNAnEDMRm before making settings again.

Access: This register can be read/written in 32-bit units.

Address: ETNAnTSU_FWSL0: <ETNAn_base> + 0830_H
ETNAnTSU_FWSL1: <ETNAn_base> + 0834_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit Position	Bit Name	Function
31 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	RMSAm	Receive Mode using Source Address 0: SA (source address) has no effect for the frame reception. 1: SA (source address) has effect for the frame reception as follows. Frames that are discarded by VLAN-filtering are not received. SA (source address) is existed in the entry table / DA(destination address) is existed in the entry → Received SA (source address) is existed in the entry table / DA(destination address) is not existed in the entry → Discarded SA (source address) is not existed in the entry table → Received
3 to 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

21.3.35 ETNAnTSU_FWSLC — TSU Function Set Register (Common)

When the CAM is used, the referred area in the CAM entry table (partially or wholly) can be specified by the ETNAnTSU_POST1 to ETNAnTSU_POST4 registers. ETNAnTSU_FWSLC enables settings by the ETNAnTSU_POST1 to ETNAnTSU_POST4 registers. This register setting must not be changed while the transmitting and receiving functions are enabled. Return the E-MACm and E-DMACm to their initial states by means of the SWRTm and SWRRm bits in ETNAnEDMRm before making settings again.

Access: This register can be read/written in 32-bit units.

Address: ETNAnTSU_FWSLC: <ETNAn_base> + 0838_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Table 21.43 ETNAnTSU_FWSLC register contents

Bit Position	Bit Name	Function
31 to 14	Reserved	When read, the value after reset is read. When writing, write the value after reset.
13	POSTENU	Enables the settings of the POST field of CAM entry tables 0 to 15 (settings by the ETNAnTSU_POST1 and ETNAnTSU_POST2 registers). 0: Disables the settings of the POST field. (The CAM entry table is referred to only in port 0 reception.) 1: Enables the settings of the POST field. (The CAM entry table reference conditions follow the POST field settings.)
12	POSTENL	Enables the settings of the POST field of CAM entry tables 16 to 31 (settings by the ETNAnTSU_POST3 and ETNAnTSU_POST4 registers). 0: Disables the settings of the POST field. (The CAM entry table is referred to only in port 1 reception.) 1: Enables the settings of the POST field. (The CAM entry table reference conditions follow the POST field settings.)
11 to 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

21.3.36 ETNAnTSU_FWSR — TSU Status Register

ETNAnTSU_FWSR is a 32-bit readable/writable register that indicates the status during TSU operations.

Access: This register can be read/written in 32-bit units.

Address: ETNAnTSU_FWSR: <ETNAn_base> + 0850_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.44 ETNAnTSU_FWSR register contents

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is read. When writing, write the value after reset.
20	RINT50	E-MAC0 Residual-Bit Frame Receive Set to 1 when a frame containing residual bits (less than an 8-bit unit) is received in the E-MAC0.
19	RINT40	E-MAC0 Too-Long Frame Receive Set to 1 when a frame exceeding the value set by ETNAnRFLR0 is received in the E-MAC0.
18	RINT30	E-MAC0 Too-Short Frame Receive Set to 1 when a frame with a length of less than 64 bytes is received in the E-MAC0.
17	RINT20	E-MAC0 Frame Receive Error Set to 1 when a receive error is detected on the signal RX_ER from the PHY-LSI (ETNAmRXER) in the E-MAC0.
16	RINT10	E-MAC0 CRC Error Frame Receive Set to 1 when a receive frame results in a CRC error in the E-MAC0.
15 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	RINT51	E-MAC1 Residual-Bit Frame Receive Set to 1 when a frame containing residual bits (less than an 8-bit unit) is received in the E-MAC1.
3	RINT41	E-MAC1 Too-Long Frame Receive Set to 1 when a frame exceeding the value set by ETNAnRFLR1 is received in the E-MAC1.
2	RINT31	E-MAC1 Too-Short Frame Receive Set to 1 when a frame with a length of less than 64 bytes is received in the E-MAC1.
1	RINT21	E-MAC1 Frame Receive Error Set to 1 when a receive error is detected on the signal RX_ER from the PHY-LSI (ETNAmRXER) in the E-MAC1.
0	RINT11	E-MAC1 CRC Error Frame Receive Set to 1 when a receive frame results in a CRC error in the E-MAC1.

21.3.37 ETNAnTSU_FWINMK — TSU Status Interrupt Mask Register

ETNAnTSU_FWINMK is a 32-bit readable/writable register that sets the interrupt mask for status bits in ETNAnTSU_FWSR.

Access: This register can be read/written in 32-bit units.

Address: ETNAnTSU_FWINMK: <ETNAn_base> + 0854_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

21.3.38 ETNAnTSU_VTAGm — VLANtag Set Register

ETNAnTSU_VTAGm enables or disables the frame receive/discard evaluation function based on the VLAN number in port m receive operations, and also sets the VLAN number. This register setting must not be changed while the transmitting and receiving functions are enabled. Return the E-MACm and E-DMACm to their initial states by means of the SWRTm and SWRRm bits in ETNAnEDMRm before making settings again.

Access: This register can be read/written in 32-bit units.

Address: ETNAnTSU_VTAG0: <ETNAn_base> + 0858_H
ETNAnTSU_VTAG1: <ETNAn_base> + $085C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit Position	Bit Name	Function
31	VTAGm	Port m VLAN tag Evaluation Function 0: Disables receive/discard evaluation for frames based on the VLAN number 1: Enables receive/discard evaluation for frames based on the VLAN number
30 to 12	Reserved	When read, the value after reset is read. When writing, write the value after reset.
11 to 0	VIDm	V-LAN ID Setting (VID) These bits set the VLAN number received by port m receive frames.

21.3.39 ETNAnTSU_ADSBSY — CAM Entry Table Busy Register

When CAM entry table registers (ETNAnTSU_ADRH0 to ETNAnTSU_ADRH31 and ETNAnTSU_ADRL0 to ETNAnTSU_ADRL31) are set by register writing, the ADSBSY bit in this register is set to 1 (when the process of reflecting the contents of the CAM entry table registers in the CAM controller is completed inside the TSU, the ADSBSY bit is automatically restored to 0).

Access to ETNAnTSU_ADRH0 to ETNAnTSU_ADRH31 and ETNAnTSU_ADRL0 to ETNAnTSU_ADRL31 is prohibited, while the ADSBSY bit in this register is set to 1. This register is a read-only status register, which must not be written to.

Access: This register can be read in 32-bit units.

Address: ETNAnTSU_ADSBSY: <ETNAn_base> + 0860_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 21.47 ETNAnTSU_ADSBSY register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is read.
0	ADSBSY	CAM Entry Table Setting Busy When ETNAnTSU_ADRH0 to ETNAnTSU_ADRH31 and ETNAnTSU_ADRL0 to ETNAnTSU_ADRL31 are set by register writing during the E-MAC0/1 are receiving any frame, this bit is set to 1. When the process of reflecting the contents of the CAM entry table registers in the CAM controller is completed inside the TSU, this bit is automatically restored to 0. Access to ETNAnTSU_ADRH0 to ETNAnTSU_ADRH31 and ETNAnTSU_ADRL0 to ETNAnTSU_ADRL31 is prohibited, while this bit is set to 1. Writing to this register is also prohibited.

21.3.40 ETNAnTSU_TEN — CAM Entry Table Enable Register

ETNAnTSU_TEN enables or disables the settings of ETNAnTSU_ADRH0 to ETNAnTSU_ADRH31 and ETNAnTSU_ADRL0 to ETNAnTSU_ADRL31.

Access: This register can be read/written in 32-bit units.

Address: ETNAnTSU_TEN: <ETNAn_base> + 0864_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

21.3.41 ETNAnTSU_POST1 — CAM Entry Table POST1 Register

When using the CAM, the conditions for referring to each CAM entry table can be specified by using the ETNAnTSU_POST1 to ETNAnTSU_POST4 registers. ETNAnTSU_POST1 specifies the conditions for referring to ETNAnTSU_ADRH0 to ETNAnTSU_ADRH7 and ETNAnTSU_ADRL0 to ETNAnTSU_ADRL7. The settings of this register are valid when the POSTENU bit in ETNAnTSU_FWSLC is set to 1.

This register setting must not be changed while the transmitting and receiving functions are enabled. Return the E-MACm and E-DMACm to their initial states by means of the SWRTm and SWRRm bits in ETNAnEDMRm before making settings again.

Access: This register can be read/written in 32-bit units.

Address: ETNAnTSU_POST1: <ETNAn_base> + 0870_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Table 21.49 ETNAnTSU_POST1 register contents (1/2)

Bit Position	Bit Name	Function
31 to 28	POST0[3:0]	These bits set the conditions for referring to CAM entry table 0. By setting multiple bits to 1, multiple conditions can be selected. POST0[3]: CAM entry table 0 is referred to in port 0 reception. POST0[1]: CAM entry table 0 is referred to in port 1 reception.
27 to 24	POST1[3:0]	These bits set the conditions for referring to CAM entry table 1. By setting multiple bits to 1, multiple conditions can be selected. POST1[3]: CAM entry table 1 is referred to in port 0 reception. POST1[1]: CAM entry table 1 is referred to in port 1 reception.
23 to 20	POST2[3:0]	These bits set the conditions for referring to CAM entry table 2. By setting multiple bits to 1, multiple conditions can be selected. POST2[3]: CAM entry table 2 is referred to in port 0 reception. POST2[1]: CAM entry table 2 is referred to in port 1 reception.
19 to 16	POST3[3:0]	These bits set the conditions for referring to CAM entry table 3. By setting multiple bits to 1, multiple conditions can be selected. POST3[3]: CAM entry table 3 is referred to in port 0 reception. POST3[1]: CAM entry table 3 is referred to in port 1 reception.
15 to 12	POST4[3:0]	These bits set the conditions for referring to CAM entry table 4. By setting multiple bits to 1, multiple conditions can be selected. POST4[3]: CAM entry table 4 is referred to in port 0 reception. POST4[1]: CAM entry table 4 is referred to in port 1 reception.
11 to 8	POST5[3:0]	These bits set the conditions for referring to CAM entry table 5. By setting multiple bits to 1, multiple conditions can be selected. POST5[3]: CAM entry table 5 is referred to in port 0 reception. POST5[1]: CAM entry table 5 is referred to in port 1 reception.

Table 21.49 ETNAnTSU_POST1 register contents (2/2)

Bit Position	Bit Name	Function
7 to 4	POST6[3:0]	These bits set the conditions for referring to CAM entry table 6. By setting multiple bits to 1, multiple conditions can be selected. POST6[3]: CAM entry table 6 is referred to in port 0 reception. POST6[1]: CAM entry table 6 is referred to in port 1 reception.
3 to 0	POST7[3:0]	These bits set the conditions for referring to CAM entry table 7. By setting multiple bits to 1, multiple conditions can be selected. POST7[3]: CAM entry table 7 is referred to in port 0 reception. POST7[1]: CAM entry table 7 is referred to in port 1 reception.

21.3.42 ETNAnTSU_POST2 — CAM Entry Table POST2 Register

When using the CAM, the conditions for referring to each CAM entry table can be specified by using the ETNAnTSU_POST1 to ETNAnTSU_POST4 registers. ETNAnTSU_POST2 specifies the conditions for referring to ETNAnTSU_ADRH8 to ETNAnTSU_ADRH15 and ETNAnTSU_ADRL8 to ETNAnTSU_ADRL15. The settings of this register are valid when the POSTENU bit in ETNAnTSU_FWSLC is set to 1.

This register setting must not be changed while the transmitting and receiving functions are enabled. Return the E-MACm and E-DMACm to their initial states by means of the SWRTm and SWRRm bits in ETNAnEDMRm before making settings again.

Access: This register can be read/written in 32-bit units.

Address: ETNAnTSU_POST2: <ETNAn_base> + 0874_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Table 21.50 ETNAnTSU_POST2 register contents (1/2)

Bit Position	Bit Name	Function
31 to 28	POST8[3:0]	These bits set the conditions for referring to CAM entry table 8. By setting multiple bits to 1, multiple conditions can be selected. POST8[3]: CAM entry table 8 is referred to in port 0 reception. POST8[1]: CAM entry table 8 is referred to in port 1 reception.
27 to 24	POST9[3:0]	These bits set the conditions for referring to CAM entry table 9. By setting multiple bits to 1, multiple conditions can be selected. POST9[3]: CAM entry table 9 is referred to in port 0 reception. POST9[1]: CAM entry table 9 is referred to in port 1 reception.
23 to 20	POST10[3:0]	These bits set the conditions for referring to CAM entry table 10. By setting multiple bits to 1, multiple conditions can be selected. POST10[3]: CAM entry table 10 is referred to in port 0 reception. POST10[1]: CAM entry table 10 is referred to in port 1 reception.
19 to 16	POST11[3:0]	These bits set the conditions for referring to CAM entry table 11. By setting multiple bits to 1, multiple conditions can be selected. POST11[3]: CAM entry table 11 is referred to in port 0 reception. POST11[1]: CAM entry table 11 is referred to in port 1 reception.
15 to 12	POST12[3:0]	These bits set the conditions for referring to CAM entry table 12. By setting multiple bits to 1, multiple conditions can be selected. POST12[3]: CAM entry table 12 is referred to in port 0 reception. POST12[1]: CAM entry table 12 is referred to in port 1 reception.
11 to 8	POST13[3:0]	These bits set the conditions for referring to CAM entry table 13. By setting multiple bits to 1, multiple conditions can be selected. POST13[3]: CAM entry table 13 is referred to in port 0 reception. POST13[1]: CAM entry table 13 is referred to in port 1 reception.

Table 21.50 ETNAnTSU_POST2 register contents (2/2)

Bit Position	Bit Name	Function
7 to 4	POST14[3:0]	These bits set the conditions for referring to CAM entry table 14. By setting multiple bits to 1, multiple conditions can be selected. POST14[3]: CAM entry table 14 is referred to in port 0 reception. POST14[1]: CAM entry table 14 is referred to in port 1 reception.
3 to 0	POST15[3:0]	These bits set the conditions for referring to CAM entry table 15. By setting multiple bits to 1, multiple conditions can be selected. POST15[3]: CAM entry table 15 is referred to in port 0 reception. POST15[1]: CAM entry table 15 is referred to in port 1 reception.

21.3.43 ETNAnTSU_POST3 — CAM Entry Table POST3 Register

When using the CAM, the conditions for referring to each CAM entry table can be specified by using the ETNAnTSU_POST1 to ETNAnTSU_POST4 registers. ETNAnTSU_POST3 specifies the conditions for referring to ETNAnTSU_ADRH16 to ETNAnTSU_ADRH23 and ETNAnTSU_ADRL16 to ETNAnTSU_ADRL23. The settings of this register are valid when the POSTENL bit in ETNAnTSU_FWSLC is set to 1.

This register setting must not be changed while the transmitting and receiving functions are enabled. Return the E-MACm and E-DMACm to their initial states by means of the SWRTm and SWRRm bits in ETNAnEDMRm before making settings again.

Access: This register can be read/written in 32-bit units.

Address: ETNAnTSU_POST3: <ETNAn_base> + 0878_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Table 21.51 ETNAnTSU_POST3 register contents (1/2)

Bit Position	Bit Name	Function
31 to 28	POST16[3:0]	These bits set the conditions for referring to CAM entry table 16. By setting multiple bits to 1, multiple conditions can be selected. POST16[3]: CAM entry table 16 is referred to in port 0 reception. POST16[1]: CAM entry table 16 is referred to in port 1 reception.
27 to 24	POST17[3:0]	These bits set the conditions for referring to CAM entry table 17. By setting multiple bits to 1, multiple conditions can be selected. POST17[3]: CAM entry table 17 is referred to in port 0 reception. POST17[1]: CAM entry table 17 is referred to in port 1 reception.
23 to 20	POST18[3:0]	These bits set the conditions for referring to CAM entry table 18. By setting multiple bits to 1, multiple conditions can be selected. POST18[3]: CAM entry table 18 is referred to in port 0 reception. POST18[1]: CAM entry table 18 is referred to in port 1 reception.
19 to 16	POST19[3:0]	These bits set the conditions for referring to CAM entry table 19. By setting multiple bits to 1, multiple conditions can be selected. POST19[3]: CAM entry table 19 is referred to in port 0 reception. POST19[1]: CAM entry table 19 is referred to in port 1 reception.
15 to 12	POST20[3:0]	These bits set the conditions for referring to CAM entry table 20. By setting multiple bits to 1, multiple conditions can be selected. POST20[3]: CAM entry table 20 is referred to in port 0 reception. POST20[1]: CAM entry table 20 is referred to in port 1 reception.
11 to 8	POST21[3:0]	These bits set the conditions for referring to CAM entry table 21. By setting multiple bits to 1, multiple conditions can be selected. POST21[3]: CAM entry table 21 is referred to in port 0 reception. POST21[1]: CAM entry table 21 is referred to in port 1 reception.

Table 21.51 ETNAnTSU_POST3 register contents (2/2)

Bit Position	Bit Name	Function
7 to 4	POST22[3:0]	These bits set the conditions for referring to CAM entry table 22. By setting multiple bits to 1, multiple conditions can be selected. POST22[3]: CAM entry table 22 is referred to in port 0 reception. POST22[1]: CAM entry table 22 is referred to in port 1 reception.
3 to 0	POST23[3:0]	These bits set the conditions for referring to CAM entry table 23. By setting multiple bits to 1, multiple conditions can be selected. POST23[3]: CAM entry table 23 is referred to in port 0 reception. POST23[1]: CAM entry table 23 is referred to in port 1 reception.

21.3.44 ETNAnTSU_POST4 — CAM Entry Table POST4 Register

When using the CAM, the conditions for referring to each CAM entry table can be specified by using the ETNAnTSU_POST1 to ETNAnTSU_POST4 registers. ETNAnTSU_POST4 specifies the conditions for referring to ETNAnTSU_ADRH24 to ETNAnTSU_ADRH31 and ETNAnTSU_ADRL24 to ETNAnTSU_ADRL31. The settings of this register are valid when the POSTENL bit in ETNAnTSU_FWSLC is set to 1.

This register setting must not be changed while the transmitting and receiving functions are enabled. Return the E-MACm and E-DMACm to their initial states by means of the SWRTm and SWRRm bits in ETNAnEDMRm before making settings again.

Access: This register can be read/written in 32-bit units.

Address: ETNAnTSU_POST4: <ETNAn_base> + $087C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Table 21.52 ETNAnTSU_POST4 register contents (1/2)

Bit Position	Bit Name	Function
31 to 28	POST24[3:0]	These bits set the conditions for referring to CAM entry table 24. By setting multiple bits to 1, multiple conditions can be selected. POST24[3]: CAM entry table 24 is referred to in port 0 reception. POST24[1]: CAM entry table 24 is referred to in port 1 reception.
27 to 24	POST25[3:0]	These bits set the conditions for referring to CAM entry table 25. By setting multiple bits to 1, multiple conditions can be selected. POST25[3]: CAM entry table 25 is referred to in port 0 reception. POST25[1]: CAM entry table 25 is referred to in port 1 reception.
23 to 20	POST26[3:0]	These bits set the conditions for referring to CAM entry table 26. By setting multiple bits to 1, multiple conditions can be selected. POST26[3]: CAM entry table 26 is referred to in port 0 reception. POST26[1]: CAM entry table 26 is referred to in port 1 reception.
19 to 16	POST27[3:0]	These bits set the conditions for referring to CAM entry table 27. By setting multiple bits to 1, multiple conditions can be selected. POST27[3]: CAM entry table 27 is referred to in port 0 reception. POST27[1]: CAM entry table 27 is referred to in port 1 reception.
15 to 12	POST28[3:0]	These bits set the conditions for referring to CAM entry table 28. By setting multiple bits to 1, multiple conditions can be selected. POST28[3]: CAM entry table 28 is referred to in port 0 reception. POST28[1]: CAM entry table 28 is referred to in port 1 reception.
11 to 8	POST29[3:0]	These bits set the conditions for referring to CAM entry table 29. By setting multiple bits to 1, multiple conditions can be selected. POST29[3]: CAM entry table 29 is referred to in port 0 reception. POST29[1]: CAM entry table 29 is referred to in port 1 reception.

Table 21.52 ETNAnTSU_POST4 register contents (2/2)

Bit Position	Bit Name	Function
7 to 4	POST30[3:0]	These bits set the conditions for referring to CAM entry table 30. By setting multiple bits to 1, multiple conditions can be selected. POST30[3]: CAM entry table 30 is referred to in port 0 reception. POST30[1]: CAM entry table 30 is referred to in port 1 reception.
3 to 0	POST31[3:0]	These bits set the conditions for referring to CAM entry table 31. By setting multiple bits to 1, multiple conditions can be selected. POST31[3]: CAM entry table 31 is referred to in port 0 reception. POST31[1]: CAM entry table 31 is referred to in port 1 reception.

21.3.45 ETNAnTSU_ADRH0 to ETNAnTSU_ADRH31 — CAM Entry Table 0H to 31H Registers

ETNAnTSU_ADRH0 to ETNAnTSU_ADRH31 are entry tables referred to by the CAM in reception. Each of these registers sets the upper 32 bits of the 48-bit MAC address. Maximum 32 entries of MAC addresses can be registered. The CAM entry rable setting must not be changed while the transmitting and receiving functions are enabled. ETNAnTSU_ADRHm is written at the same time with ETNAnTSU_ADRLm writing which is given after ETNAnTSU_ADRHm writing.

Access: This register can be read/written in 32-bit units.

Address:

Table 21.53 ETNAnTSU_ADRHm register contents

Bit Position	Bit Name	Function
31 to 0	ADRH i [31:0] (i: 0 to 31)	MAC Address Bits These bits set the upper 32 bits of the MAC address. When the MAC address is 01-23-45-67-89-AB (displayed in hexadecimal), set 01234567_H in this register.

Note: Set the CAM entry tables following the procedure below.
1. Check that the ADSBSY bit in ETNAnTSU_ADSBSY is cleared to 0.
2. Set the upper 32 bits of the MAC addresses by ETNAnTSU_ADRH0 to ETNAnTSU_ADRH31.
3. Set the lower 16 bits of the MAC addresses by ETNAnTSU_ADRL0 to ETNAnTSU_ADRL31.

21.3.46 ETNAnTSU_ADRL0 to ETNAnTSU_ADRL31 — CAM Entry Table 0L to 31L Registers

ETNAnTSU_ADRL0 to ETNAnTSU_ADRL31 are entry tables referred to by the CAM in reception. Each of these registers sets the lower 16 bits of the 48-bit MAC address. Maximum 32 entries of MAC addresses can be registered. The CAM entry table setting must not be changed while the transmitting and receiving functions are enabled.

Access: This register can be read/written in 32-bit units.

Address:

ETNAnTSU_ADRL0: <ETNAn_base> + 0904_H	ETNAnTSU_ADRL1: <ETNAn_base> + $090C_H$

0	ENRm	E-DMAC Receiving Unit Start 0: Stops the E-DMACm receiving unit 1: Starts the E-DMACm receiving unit

21.3.52 ETNAnEDMRm — E-DMAC Mode Register m

ETNAnEDMRm is a 32-bit readable/writable register that specifies E-DMACm resetting and the transmit/receive descriptor length. This register is to be set before the transmitting or receiving function is enabled (before the TRm[1:0] bit in ETNAnEDTRRm or the RRm bit in ETNAnEDRRRm is set to 1). However, the SWRRm and SWRTm bits can be written to even after the transmitting or receiving function is enabled. If a software reset is executed with this register during data transmission, abnormal data may be transmitted on the line. Execute a software reset with this register before specifying the transmit/receive descriptor length or modifying the settings of ETNAnTDLARm, ETNAnRDLARm, and so forth, the setting of ETNAnECMRm (E-MACm mode register), and the settings of registers related to the E-DMACm and E-MACm operation.

To execute a software reset with this register, 1 must be written to both the SWRTm and SWRRm bits simultaneously. Writing 1 to the SWRTm and SWRRm bits initializes the E-MACm registers and E-DMACm registers, except for ETNAnTDLARm, ETNAnRDLARm, and ETNAnRMFCRm of the E-DMACm. The TSU registers (registers whose names are prefixed with ETNAnTSU_) are not initialized. Writing 1 to the SWRTm and SWRRm bits in ETNAnEDMRm initializes the registers related to the E-DMACm and E-MACm, whereas, writing 1 to the SWRTm and SWRRm bits in ETNAnEDMRm initializes the registers related to the E-DMACm and E-MACm. Note that during the period a software reset is issued (for 1200 cycles of the HCLK), accesses to all Ethernet-related registers are prohibited.

Access: This register can be read/written in 32-bit units.

Address: ETNAnEDMR0: <ETNAn_base> + 0400_H
ETNAnEDMR1: <ETNAn_base> + 1400_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6	DEm	Transmit/Receive Frame Endian Sets the endian mode for DMA transfer of frame data between the transmit/receive FIFO and transmit/receive buffer. 0: Big endian (longword access) 1: Little endian (longword access)
5, 4	DLm[1:0]	Transmit/Receive Descriptor Length These bits specify the descriptor length. (See Descriptors and Descriptor List.) 00: 16 bytes 01: 32 bytes 10: 64 bytes 11: Setting prohibited

Table 21.60 ETNAnEDMRm register contents (2/2)

Bit Position	Bit Name	Function
3, 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	SWRTm	Software Reset of Transmit FIFO Controller [Writing] 0: Disabled 1: Software reset started [Reading] 0: Software reset not executed (or completed) 1: Software reset being executed Software reset takes the time about 512 to 1200 HCLK cycles. When Software reset was finished, this bit is cleared automatically. Note: When ENTm of the ETNAnEDSRm register is 0, Software Reset does not work however this bit was set. “Read and Write operation of registers mapped among 0000 0400_H to 0000 $07FF_H$ are canceled during this bit is set.
0	SWRRm	Software Reset of Receive FIFO Controller [Writing] 0: Disabled 1: Software reset started [Reading] 0: Software reset not executed (or completed) 1: Software reset being executed Software reset takes the time about 512 to 1200 HCLK cycles. When Software reset was finished, this bit is cleared automatically. Note: When ENRm of the ETNAnEDSRm register is 0, Software Reset does not work however this bit was set. “Read and Write operation of registers mapped among 0000 0400_H to 0000 $07FF_H$ are canceled during this bit is set.

21.3.53 ETNAnEDTRRm — E-DMACm Transmit Request Register m

ETNAnEDTRRm is a 32-bit readable/writable register that issues transmit directives to the E-DMACm. After writing 11 to bits TRm[1:0] in this register, the E-DMACm reads the transmit descriptor at the address specified by ETNAnTDLARm. If the TACT bit of this transmit descriptor is set to 1 (valid), transmit DMA transfer by the E-DMACm starts. When DMA transfer based on the first transmit descriptor is completed, the E-DMACm reads the next transmit descriptor. If the TACT bit of that transmit descriptor is set to 1 (valid), the E-DMACm continues transmit DMA operation. If the TACT bit of a transmit descriptor is cleared to 0 (invalid), the E-DMACm clears bits TRm[1:0] and stops transmit DMA operation.

Access: This register can be read/written in 32-bit units.

Address: ETNAnEDTRR0: <ETNAn_base> + 0408_H
ETNAnEDTRR1: <ETNAn_base> + 1408_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TRm[1:0]	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 21.61 ETNAnEDTRRm register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TRm[1:0]	Transmit Request 00, 01, 10: Transmission-halted state If 00, 01, or 10 is written to these bits, the E-DMACm stops DMA transfer of the currently processed transmit descriptor, reads the next transmit descriptor, and then clears these bits. (Write-back is completed for the valid transmit descriptors that have been detected up till then.) The E-DMACm clears these bits when transmit descriptor empty occurs, or transmission of a transmit descriptor has completed. (Write-back is completed for the valid transmit descriptors that have been detected up till then.) 11: Transmit DMA operation by E-DMACm After writing 11 to these bits, the E-DMACm starts reading a transmit descriptor.

21.3.54 ETNAnEDRRRm — E-DMACm Receive Request Register m

ETNAnEDRRRm is a 32-bit readable/writable register that issues receive directives to the E-DMACm. After writing 1 to the RRm bit in this register, the E-DMACm reads the receive descriptor at the address specified by ETNAnRDLARm. If the RACT bit of this receive descriptor is set to 1 (valid), and the receive FIFO holds a receive frame, the E-DMACm starts receive DMA transfer. When DMA transfer based on the first receive descriptor is completed, the E-DMACm reads the next receive descriptor. If the RACT bit of that receive descriptor is set to 1 (valid), the E-DMACm continues receive DMA operation. However, if the receive FIFO holds no receive data, the E-DMACm places receive DMA operation in the standby state. If the RACT bit of the receive descriptor is cleared to 0 (invalid), the E-DMACm clears the RRm bit and stops receive DMAC operation.

Access: This register can be read/written in 32-bit units.

Address: ETNAnEDRRR0: <ETNAn_base> + 0410_H
ETNAnEDRRR1: <ETNAn_base> + 1410_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Table 21.62 ETNAnEDTRRm register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	RRm	Receive Request 0: Receiving function is disabled[*1] If 0 is written to this bit, the E-DMACm stops receive operation after DMA transfer of one frame has completed and then clears this bit. The E-DMACm clears this bit when receive descriptor empty occurs. 1: Receive descriptor is read, and the E-DMACm is ready to receive

Note 1. If the receiving function is disabled during frame reception, write-back is not performed successfully to the receive descriptor. Following pointers to read a receive descriptor become abnormal and the E-DMACm cannot operate successfully. In this case, to make E-DMACm reception enabled again, execute a software reset by the SWRTm and SWRRm bits in ETNAnEDMRm. To disable the E-DMACm receiving function without executing a software reset, specify the REm bit in ETNAnECMRm. Next, after the E-DMACm has completed the reception and write-back to the receive descriptor has been confirmed, disable the receiving function using this register.

21.3.55 ETNAnTDLARm — Transmit Descriptor List Start Address Register m

ETNAnTDLARm is a 32-bit readable/writable register that specifies the start address of the transmit descriptor list. Descriptors have a boundary configuration in accordance with the descriptor length indicated by the DLm[1:0] bits in ETNAnEDMRm. This register must not be modified during transmission. Modifications to this register should only be made in the transmission-halted state specified by bits TRm[1:0] (= 00) in the E-DMACm transmit request register (ETNAnEDTRRm).

Access: This register can be read/written in 32-bit units.

Address: ETNAnTDLAR0: <ETNAn_base> + 0010_H
ETNAnTDLAR1: <ETNAn_base> + 1010_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

21.3.56 ETNAnRDLARm — Receive Descriptor List Start Address Register m

ETNAnRDLARm is a 32-bit readable/writable register that specifies the start address of the receive descriptor list. Descriptors have a boundary configuration in accordance with the descriptor length indicated by the DLm[1:0] bits in ETNAnEDMRm. This register must not be modified during reception. Modifications to this register should only be made while reception is disabled by the RRm bit (= 0) in the E-DMACm receive request register (ETNAnEDRRRm).

Access: This register can be read/written in 32-bit units.

Address: ETNAnRDLAR0: <ETNAn_base> + 0030_H
ETNAnRDLAR1: <ETNAn_base> + 1030_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

21.3.57 ETNAnEESRm — E-MAC/E-DMAC Status Register m

ETNAnEESRm is a 32-bit readable/writable register that shows communications status information on the E-DMACm in combination with the E-MACm. The information in this register is reported in the form of interrupt sources. Individual bits are cleared by writing 1 (however, bit 22 (ECIm) is a read-only bit that is not cleared by writing 1) and are not affected by writing 0. Each interrupt source can also be masked by means of the corresponding bit in the E-MACm/E-DMAC status interrupt permission register (ETNAnEESIPRm).

The interrupts generated by this status register are HINT_0 for port 0 and HINT_1 for port 1. For interrupt priorities, see **Section 6, Interrupt Controller (INTC).**

Access: This register can be read/written in 32-bit units.

Address: ETNAnEESR0: <ETNAn_base> + 0428_H
ETNAnEESR1: <ETNAn_base> + 1428_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Table 21.65 ETNAnEESRm register contents (1/3)

Bit Position	Bit Name	Function
31, 30	TWBm[1:0]	Write-Back Complete Indicates that write-back from the E-DMACm to the corresponding descriptor after frame transmission has completed. This operation is enabled only when the TWBI bit in the transmit descriptor that includes the end of the transmit frame is set to 1. 00: Write-back has not completed, or no transmission directive 11: Write-back has completed Others: Setting disabled
29	TCm[1]	Frame Transmission Complete Indicates, in combination with the TCm[0] bit, that all the data specified by the transmit descriptor has been transmitted from the E-MACm. This bit is set to 1 on assuming the completion of transmission. This is when transmission of one frame is completed and the transmit descriptor valid bit (TACT) of the next transmit descriptor not being set in single-frame/single-descriptor operation or when the last data of a frame has been transmitted and the transmit descriptor valid bit (TACT) of the next descriptor not being set in multi-buffer frame processing based on single-frame/multi-descriptor operation. After frame transmission has completed, the E-DMACm writes the transmission status back to the relevant descriptor. TCm[1:0] 00: Transmission has not completed, or no transmission directive 11: Transmission has completed Others: Setting disabled
28	Reserved	When read, the value after reset is read. When writing, write the value after reset.
27	ROCm	Receive Overflow Frame Write-Back Complete 0: Write-back has not completed for the frame causing receive overflow 1: Write-back has completed for the frame causing receive overflow

Table 21.65 ETNAnEESRm register contents (2/3)

Bit Position	Bit Name	Function
26	Reserved	When read, the value after reset is read. When writing, write the value after reset.
25	RABTm	Receive Abort Detect Indicates that the E-MACm aborts receiving a frame because of failures during frame reception. 0: Frame reception has not been aborted or no reception directive 1: Frame reception has been aborted
24	RFCOFm	Receive Frame Counter Overflow Indicates that the frame counter in the receive FIFO has overflowed. 0: Receive frame counter has not overflowed 1: Receive frame counter has overflowed
23	Reserved	When read, the value after reset is read. When writing, write the value after reset.
22	ECIm	E-MACm Status Register Source This bit is a read-only bit. When the source of an ETNAnECSRm interrupt is cleared, this bit is also cleared. 0: E-MACm status interrupt source has not been detected 1: E-MACm status interrupt source has been detected
21	TCm[0]	Frame Transmission Complete Indicates, in combination with the TCm[1] bit, that all the data specified by the transmit descriptor has been transmitted from the E-MACm. For details, see the description of the TCm[1] bit.
20	TDEm	Transmit Descriptor Empty Indicates that the transmit descriptor valid bit (TACT) of a transmit descriptor read by the E-DMACm is not set if the previous descriptor does not represent the end of a frame in multi-buffer frame processing based on single-frame/multi-descriptor operation. As a result, an incomplete frame may be sent. 0: Transmit descriptor active bit TACT = 1 detected 1: Transmit descriptor active bit TACT = 0 detected When transmit descriptor empty (TDE = 1) occurs, execute a software reset and initiate transmission. In this case, transmission starts from the address that is stored in the transmit descriptor list start address register (ETNAnTDLARm).
19	Reserved	When read, the value after reset is read. When writing, write the value after reset.
18	FRm	Frame Reception Indicates that a frame has been received and the receive descriptor has been updated. This bit is set to 1 each time a frame is received. 0: Frame has not been received 1: Frame has been received
17	RDEm	Receive Descriptor Empty Indicates that the RACT bit of a receive descriptor read by the E-DMACm for receive DMA operation is cleared to 0 (invalid). When receive descriptor empty (RDE = 1) occurs, reception can be resumed by setting the RACT bit (cleared to 0) of the receive descriptor to 1 and then writing 1 to the RRm bit in ETNAnEDRRRm. 0: Receive descriptor active bit RACT = 1 detected 1: Receive descriptor active bit RACT = 0 detected
16	RFOFm	Receive FIFO Overflow Indicates that the receive FIFO has overflowed during frame reception. 0: Overflow has not occurred 1: Overflow has occurred
15 to 11	Reserved	When read, the value after reset is read. When writing, write the value after reset.
10	DLCm	Detect Loss of Carrier Indicates that loss of the carrier has been detected during frame transmission. 0: Loss of carrier has not been detected 1: Loss of carrier has been detected

Table 21.65 ETNAnEESRm register contents (3/3)

Bit Position	Bit Name	Function
9	CDm	Delayed Collision Detect Indicates that a delayed collision has been detected during frame transmission. 0: Delayed collision has not been detected 1: Delayed collision has been detected
8	TROm	Transmit Retry Over Indicates that a retry-over condition has occurred during frame transmission. Total 16 transmission retries including 15 retries based on the back-off algorithm have failed after the E-MACm transmission starts. 0: Transmit retry-over condition not detected 1: Transmit retry-over condition detected
7	RMAFm	Receive Multicast Address Frame 0: Multicast address frame has not been received 1: Multicast address frame has been received
6, 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	RRFm	Receive Residual-Bit Frame 0: Residual-bit frame has not been received 1: Residual-bit frame has been received
3	RTLFm	Receive Too-Long Frame Indicates that a frame whose byte size exceeds the upper limit for the receive frame length set by ETNAnRFLRm has been received. 0: Too-long frame has not been received 1: Too-long frame has been received
2	RTSFm	Receive Too-Short Frame Indicates that a frame of fewer than 64 bytes has been received. 0: Too-short frame has not been received 1: Too-short frame has been received
1	PREm	PHY-LSI Receive Error(ETNAmRXER) 0: PHY-LSI receive error or carrier extension error has not been detected 1: PHY-LSI receive error or carrier extension error has been detected
0	CERFm	CRC Error on Received Frame 0: CRC error has not been detected 1: CRC error has been detected

21.3.58 ETNAnEESIPRm — E-MAC/E-DMAC Status Interrupt Permission Register m

ETNAnEESIPRm is a 32-bit readable/writable register that enables interrupts corresponding to individual bits in the E-MACm/E-DMACm status register (ETNAnEESRm) in combination with HDIEm bit in ETNAnHDMIERm. An interrupt is enabled by writing 1 to the corresponding bit.

Access: This register can be read/written in 32-bit units.

Address: ETNAnEESIPR0: <ETNAn_base> + 0430_H
ETNAnEESIPR1: <ETNAn_base> + 1430_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

0	CERFmIP	CRC Error on Received Frame Interrupt Enable 0: CRC error interrupt is disabled 1: CRC error interrupt is enabled

21.3.59 ETNAnTRSCERm — Transmit/Receive Status Copy Enable Register m

ETNAnTRSCERm specifies whether the information for the transmit and receive state reported by bits 25, and 7 and 4 to 0 in the E-MACm/E-DMACm status register (ETNAnEESRm) is to be reflected in the RFE bit of the corresponding descriptor. The bits in this register correspond to bits 25, 7 and bit 4 to 0 in ETNAnEESRm. When a bit is cleared to 0, and the receive status (bits 25, 7 and 5 to 0 in ETNAnEESRm) is reflected in the RFE bit of the receive descriptor. In this case, the state of a status bit set to 1 is reflected as the RFE bit set to 1. When a bit is set to 1, the occurrence of the corresponding source is not reflected in the descriptor. After this Ethernet module is reset, all bits are cleared to 0.

Access: This register can be read/written in 32-bit units.

Address: ETNAnTRSCER0: <ETNAn_base> + 0438_H
ETNAnTRSCER1: <ETNAn_base> + 1438_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

21.3.60 ETNAnRMFCRm — Receive Missed-Frame Counter Register m

ETNAnRMFCRm is a 16-bit counter that indicates the number of frames that could not be saved in the receive buffer and so were discarded during reception. When the receive FIFO overflows, the receive frames in the FIFO are discarded. The number of frames discarded at this time is counted. When the value in this register reaches $FFFF_H$, count-up is halted. Clear the counter by writing 0000_H in this register.

Access: This register can be read/written in 32-bit units.

Address: ETNAnRMFCR0: <ETNAn_base> + 0440_H
ETNAnRMFCR1: <ETNAn_base> + 1440_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15 to 0	MFCm[15:0]	Missed-Frame Counter These bits indicate the number of frames that are discarded and not transferred to the receive buffer during reception.

21.3.61 ETNAnFDRm — FIFO Depth Register m

ETNAnFDRm is a 32-bit readable/writable register that specifies the sizes of the transmit and receive FIFOs.

Access: This register can be read/written in 32-bit units.

Address: ETNAnFDR0: <ETNAn_base> + 0450_H
ETNAnFDR1: <ETNAn_base> + 1450_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 21.69 ETNAnFDRm register contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is read. When writing, write the value after reset.
12 to 8	TFDm[4:0]	Transmit FIFO Size Specifies 256 bytes to 2 Kbytes in 256-byte units as the size of the transmit FIFO whose maximum size is 8 Kbytes. The setting must not be changed after transmission/reception has started. 00_H: 256 bytes 01_H: 512 bytes : : 07_H: 2048 bytes Settings from 08_H to FF_H are prohibited.
7 to 0	RFDm[7:0]	Receive FIFO Size Specifies 256 bytes to 12 Kbytes in 256-byte units as the size of the receive FIFO whose maximum size is 64 Kbytes. The setting must not be changed after transmission/reception has started. 00_H: 256 bytes 01_H: 512 bytes 02_H: 768 bytes 03_H:1024 bytes 04_H: 1280 bytes : : 07_H: 2048 bytes Settings from 08_H to FF_H are prohibited.

NOTE

The transmit frame which has the size beyond TFDm configuration can not be transmitted. TFDm must be specified for the size larger than or equal to maximum frame size to transmit.

21.3.62 ETNAnRMCRm — Receiving Method Control Register m

ETNAnRMCRm is a 32-bit readable/writable register that specifies the control method for the REm bit in ETNAnECMRm while a frame is received. This register must be set during the receiving-halted state.

Access: This register can be read/written in 32-bit units.

Address: ETNAnRMCR0: <ETNAn_base> + 0458_H
ETNAnRMCR1: <ETNAn_base> + 1458_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 21.70 ETNAnRMCRm register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	RNCm	Receive Enable Control Sets whether to continue frame reception. 0: Upon completion of reception of one frame, the E-DMACm writes the receive status to the descriptor and clears the RRm bit in ETNAnEDRRRm to 0. 1: Upon completion of reception of one frame, the E-DMACm writes (writes back) the receive status to the descriptor. In addition, the E-DMACm reads the next descriptor and prepares for reception of the next frame.

21.3.63 ETNAnRDFARm — Receive Descriptor Fetch Address Register m

ETNAnRDFARm stores the descriptor start address that is required when the E-DMACm fetches descriptor information from the receive descriptor. Which receive descriptor information is used for processing by the E-DMACm can be recognized by monitoring addresses displayed in this register. The address from which the E-DMACm is actually fetching a descriptor may be different from the value read from this register. In the initial setting, set the address of the receive descriptor at which receive processing is to be started.

Access: This register can be read/written in 32-bit units.

Address: ETNAnRDFAR0: <ETNAn_base> + 0034_H
ETNAnRDFAR1: <ETNAn_base> + 1034_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit Position	Bit Name	Function
31 to 0	RDFAm[31:0]	Receive Descriptor Fetch Address Writing to these bits during the reception is prohibited.

21.3.64 ETNAnRDFXRm — Receive Descriptor Finished Address Register m

ETNAnRDFXRm stores the start address of the receive descriptor for which the E-DMACm has just completed the write-back processing. Up to which receive descriptor has been processed by the E-DMACm can be recognized by monitoring addresses displayed in this register. In the initial setting, set the address of the descriptor immediately before the descriptor that is pointed to by the address in ETNAnRDFARm.

Access: This register can be read/written in 32-bit units.

Address: ETNAnRDFXR0: <ETNAn_base> + 0038_H
ETNAnRDFXR1: <ETNAn_base> + 1038_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

Bit Position	Bit Name	Function
31 to 0	RDFXm[31:0]	Receive Descriptor Finished Address Writing to these bits during the reception is prohibited.

21.3.65 ETNAnRDFFRm — Receive Descriptor Final Flag Register m

ETNAnRDFFRm indicates whether the receive descriptor for which the E-DMACm has just completed the write-back processing and whose start address is stored in ETNAnRDFXRm is at the end of the receive descriptor queue (descriptor list).

Access: This register can be read/written in 32-bit units.

Address: ETNAnRDFFR0: <ETNAn_base> + $003C_H$
ETNAnRDFFR1: <ETNAn_base> + $103C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

31 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	RDLFm	Receive Descriptor Queue Last Flag Indicates whether the receive descriptor for which the E-DMACm has just completed the write-back processing and whose start address is stored in ETNAnRDFXRm is at the end of the receive descriptor queue (descriptor list). 0: Not the last descriptor in the receive descriptor queue 1: Last descriptor in the receive descriptor queue

21.3.66 ETNAnTDFARm — Transmit Descriptor Fetch Address Register m

ETNAnTDFARm stores the descriptor start address that is required when the E-DMACm fetches descriptor information from the transmit descriptor. Which transmit descriptor information is used for processing by the E-DMACm can be recognized by monitoring addresses displayed in this register. The address from which the E-DMACm is actually fetching a descriptor may be different from the value read from this register. In the initial setting, set the address of the transmit descriptor at which transmit processing is to be started.

Access: This register can be read/written in 32-bit units.

Address: ETNAnTDFAR0: <ETNAn_base> + 0014_H
ETNAnTDFAR1: <ETNAn_base> + 1014_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

31 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	TDLFm	Transmit Descriptor Queue Last Flag Indicates whether the transmit descriptor for which the E-DMACm has just completed the write-back processing and whose start address is stored in ETNAnTDFXRm is at the end of the transmit descriptor queue (descriptor list). 0: Not the last descriptor in the transmit descriptor queue 1: Last descriptor in the transmit descriptor queue

21.3.69 ETNAnFCFTRm — Overflow Alert FIFO Threshold Register m

ETNAnFCFTRm is a 32-bit readable/writable register that sets the flow control of the E-MACm. The threshold can be set by the size of the receive FIFO data (bits RFDm[7:0]) and the number of receive frames (bits RFFm[4:0]).

If the same receive FIFO size as set by the FIFO depth register (ETNAnFDRm) is set when flow control is turned on according to the RFDm setting condition, flow control is turned on with (FIFO data size – 64) bytes. For instance, when the RFDm bits in ETNAnFDRm = 7 and the RFSm bits in this register = 7, flow control is turned on when (2,048 to 64) bytes of data is stored in the receive FIFO. The value set in the RFSm bits in this register should be equal to or less than that set in the RFDm bits in ETNAnFDRm.

Flow control is turned on when either of the setting conditions of bits RFFm[4:0] and bits RFSm[7:0] is satisfied. Flow control is turned off when neither of the conditions is satisfied (release).

Access: This register can be read/written in 32-bit units.

Address: ETNAnFCFTR0: <ETNAn_base> + 0468_H
ETNAnFCFTR1: <ETNAn_base> + 1468_H

Value after reset: 0017 $00FF_H$ This register is initialized by system reset.

8 to 0	RDAMm	Receive FIFO used size

21.3.72 ETNAnRPADIRm — Receive Data Padding Insert Register m

ETNAnRPADIRm is a 32-bit readable/writable register that inserts padding in receive data. When changing the settings of this register, execute a software reset by means of the SWRTm and SWRRm bits in the E-DMACm mode register (ETNAnEDMRm) before making settings again.

Access: This register can be read/written in 32-bit units.

Address: ETNAnRPADIR0: <ETNAn_base> + 0460_H
ETNAnRPADIR1: <ETNAn_base> + 1460_H

Value after reset: $0000\ 0000_H$ This register is initialized by system reset.

20 to 16	PADSm[4:0]	Padding Size 00_H: No padding insertion 01_H: 1-byte insertion : : $1F_H$: 31-byte insertion
15 to 0	PADRm[15:0]	Padding Slot 0000_H: Inserts specified size of padding at the first byte 0001_H: Inserts specified size of padding at the second byte : : $FFFF_H$: Inserts specified size of padding at the 64K byte

NOTE

When PADRm[15:0] is not 0000_H, the sum of PADRm[1:0] and PADSm[1:0] must be 100_B or 000_B

21.4 Operation

21.4.1 Limited Reset and Module Stop

As for this module, Limited Reset and Module Stop are possible.
After enforcement of Termination Procedure, please carry out Limited Reset and Module Stop.
There is no enforcement condition of Limited Reset and Module Stop if you carry out Termination Procedure.
See **Section 21.4.38** for Termination Procedure.

21.4.2 Basic Frame

The basic frame format defined in IEEE 802.3 consists of the preamble (PA), start frame delimiter (SFD), destination address (DA), source address (SA), type/length field (TYPE/LEN), data field (DATA) and frame check sequence field FCS).

The defined packet size is from 64 bytes (minimum) to 1518 bytes (maximum) excluding the PA and the SFD.

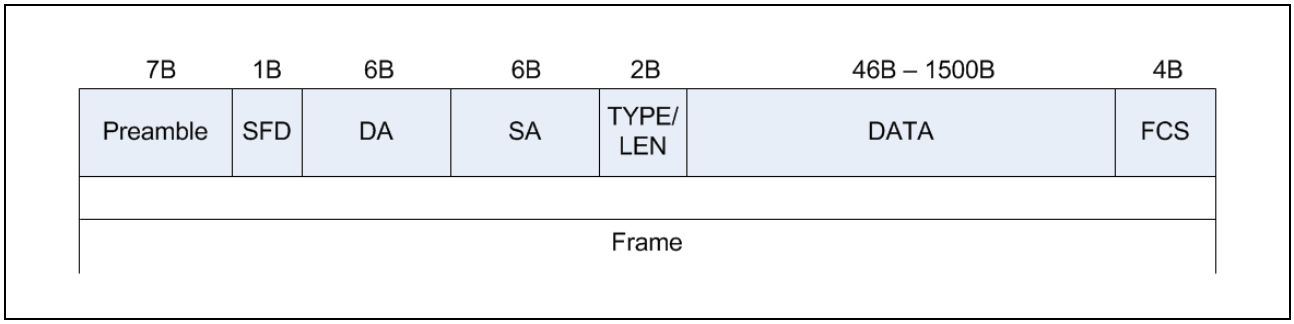

Figure 21.2 Basic frame structure

(1) Preamble and SFD

The preamble and SFD fields consist of a repetition of "10_B" for 62 bits followed by "11_B" at the end. They represent the start of an Ethernet frame.

(2) Destination address (DA)

The destination address field indicates the destination MAC address that may be a unicast address, a multicast address or a broadcast address.

(3) Source address (SA)

The source address field contains the source MAC address.

(4) Frame type and length (TYPE/LEN)

An Ethernet frame uses this field to specify the protocol type. An IEEE802.3 frame uses this field to indicate the length of the data field.

(5) Payload data (DATA)

The payload data field contains the data up to 1500 bytes. The Ethernet controller uses the data in this field for CRC (Cyclic Redundancy Check) calculation for the FCS.

(6) Frame check sequence (FCS)

The frame check sequence field is used to write a 32-bit CRC to check the payload data.

21.4.3 PAUSE Control Frame

A pause control frame contains 64-byte in a special format . The DA field is fixed to “01-80-C2-00-00-01H”. The Type/Length field contains “8808_H” which indicates a control frame. The OP code contains “0001_H” which indicates pause control. The parameter field is specified with the time parameter. The unused area following the parameter field is filled with PAD data consisting of zeros.

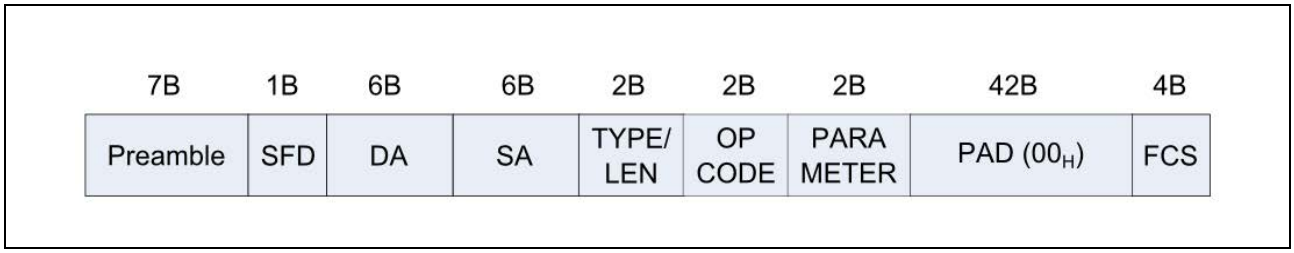

Figure 21.3 Pause control frame structure

21.4.4 Magic Packet™

The magic packet™ is a broadcast frame that contains anywhere in the payload 6 times “0xFF” followed by the MAC address of target device repeated 16 times.

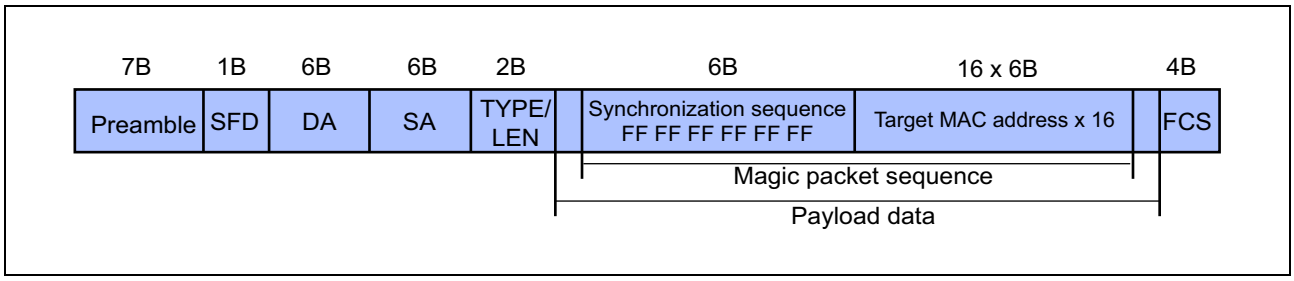

Figure 21.4 Magic packet structure

21.4.5 Transmission

The transmission function of the ETNA creates a frame as defined in IEEE802.3 from the data stored in the transmission FIFO through EDMAC transfer and outputs the frame to a PHY device. Upon collision detection, the frame is retransmitted using the back-off algorithm.

21.4.6 Transmission Clock

The transmission of ETNA is synchronized with the external transmission clock (ETHmTXCLK).

21.4.7 Collision Detection and Retransmission

In half-duplex mode, if a collision within the collision window (512 bits data) is detected before the maximum allowable number of collisions (default = 15) is not exceeded, the ETNA gets the transmission to wait using the random back-off algorithm and retransmits the data.

21.4.8 CRC Function

The CRC function generates a CRC code and appends it to the FCS field when ETNA is sending a frame.

21.4.9 Transmission Frame Data Padding Function

The specified minimal frame length is 64 bytes. If the data field in a frame is shorter than 46 bytes, padding data (0x00) is added to the data to meet the minimal frame size.

21.4.10 Full-/half-duplex Communication

The ETNA supports both full- and half-duplex communication modes. In full-duplex mode, the carrier (CRS) and collisions (COL) are not detected.

21.4.11 Inter-packet Gap (IPG)

The inter-packet gap (prescribed in IEEE802.3 standard) between transmit frames can be changed. When changing the IPG setting, adequately check that the respective devices can operate smoothly.

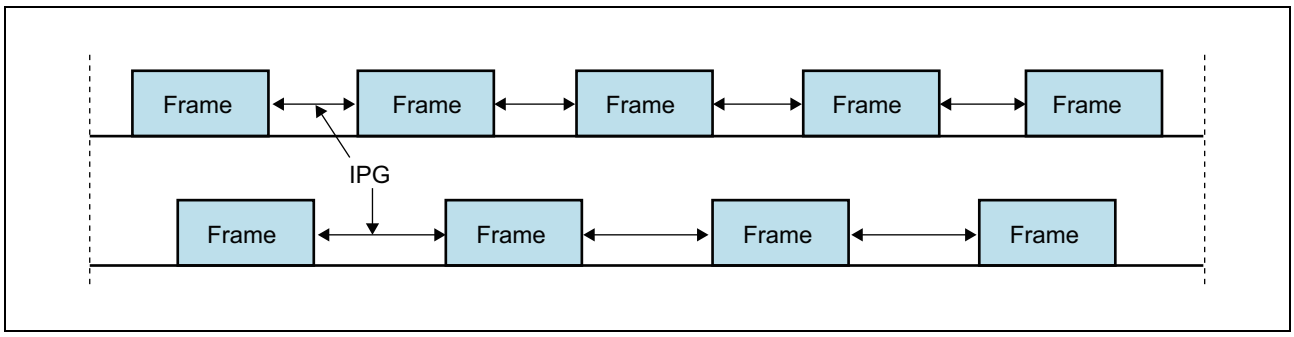

Figure 21.5 Changing IPG and transmission efficiency

21.4.12 Reception

The ETNA creates a reception frame by performing SFD detection, destination address check, frame length check, CRC check, etc. on the received data via MII.

21.4.13 Reception Clock

The ETNA receives data in synchronization with the reception clock (ETHmRXCLK).

21.4.14 Detection of Preamble and SFD

After detection of a preamble and SFD the ETNA starts with the frame reception.

21.4.15 CRC Function

The ETNA calculates a 4-byte CRC and compares it with the FCS field of the received frame. The check result is indicated as a status flag in the descriptor after the frame data has been written to the memory. The reception controller reports an error status if a CRC error occurs.

21.4.16 Promiscuous Mode

The promiscuous mode can be en/disabled in the ETNA. In promiscuous mode all incoming frames from MII are received. In non-promiscuous mode only the frames that address to the device MAC address, multicast and broadcast frames can be received.

21.4.17 Magic Packet Detection

The Magic Packet detection function provides a Wake-On-LAN feature that activates peripheral device connected to a LAN from a host device or other sources. With a Magic Packet reception is performed regardless of the destination address in the frame header. Only in case the 16 times duplicated destination address contained in the Magic Packet Sequence matches the MAC address specified in the device, the CPU will be informed by the Magic Packet detection interrupt and the Wake-On-LAN (ETHmWOL) signal notifies that a Magic Packet has been detected.

21.4.18 Flow Control

The flow control function in the ETNA is in compliance with IEEE802.3. The flow control can be applied to both receive and transmit operation.

21.4.19 PAUSE Frame Transmission

In full-duplex mode two types of PAUSE frame transmission are available for the flow control:

1. Automatic PAUSE frame transmission
   For receiving frames, PAUSE frames are automatically transmitted when the volume of data written to the reception FIFO reaches the threshold value. The TIME parameter included in the PAUSE frame is set by APR register. The automatic PAUSE frame transmission is repeated until the number of data in the receive FIFO becomes less than the value set in FCFTR register.
2. Manual PAUSE frame transmission
   PAUSE frame can also be transmitted by software instructions. When writing the timer value to MPR register, PAUSE frame transmission is started. With this method, PAUSE frame is transmitted only once.

21.4.20 PAUSE Frame Reception

If the PAUSE frame reception function is enabled, after a PAUSE frame is received, the next frame is not transmitted until the time indicated by the timer value of the PAUSE frame elapses. However, the on-going transmission of a frame continues when a PAUSE frame has been received.

21.4.21 Loopback Function

When the IBL bit in ECMR register is set to 1 and the full-duplex mode is enabled, the MII transmission data stream is looped back as MII reception data stream inside the E-MAC.

21.4.22 MAC Management Counters

Following MAC layer management counters are supported in ETNA:

- Transmit retry over counter: number of frames that were unable to be transmitted in 16 attempts
- PAUSE frame transmit counter: number of transmitted PAUSE frames
- Delayed collision detect counter: number of all delayed collisions after start of data transmission
- Lost carrier counter: number of times the carrier was lost during data transmission
- Frame transmit OK counter: number of frames successfully transmitted
- Frame transmit counter: number of frames successfully and erroneously transmitted
- Checksum error frame receive counter: number of received frames with a checksum error
- Frame receive error counter: number of receive error caused by RX_ER signal during reception
- Too short frame receive counter: number of received frames with a length of less than 64 bytes
- Too long frame receive counter: number of received frames with a length exceeding the value in RFLR register
- Residual bit frame receive counter: number of received frames containing residual bits
- Carrier extension lost counter: number of received frames with carrier extension lost
- Carrier extension error counter: number of received frames with an illegal carrier extension
- Multicast frame received counter: number of received multicast frames
- PAUSE frame receive counter: number of received PAUSE frames
- Frame receive OK counter: number of frames successfully received
- Frame receive counter: number of frames successfully and erroneously received

21.4.23 ETNA Operation

The ETNA consists of the following three function units:

- DMA transfer controller (E-DMAC):
  DMA transfer between the transmit/receive buffer in the memory and the transmit/receive FIFO
- MAC controller (E-MAC):
  Transmission/reception processing between the transmit/receive FIFO and the MII
- Transfer Switching Unit (TSU):
  CAM processing

Using its direct memory access (DMA) function, the E-DMAC performs DMA transfer of frame data between a user-specified Ethernet frame transmission/reception data storage destination (accessible memory space: transmit buffer/receive buffer) and the transmit/receive FIFO in the E-DMAC. The user cannot read and write data from and to the transmit/receive FIFO using the register.
To enable the E-DMAC to perform DMA transfer, information (data) including a transmit/receive data storage address and so forth, referred to as a descriptor, is required. The E-DMAC reads transmit data from the transmit buffer or writes receive data to the receive buffer according to the descriptor information. By arranging multiple descriptors as a descriptor row (list) (to be placed in a readable/writable memory space), multiple Ethernet frames can be transmitted or received continuously.
The E-DMAC consists of two systems: one for port 0 and the other for port 1, and both operate independently for transmission and reception.

The E-MAC constructs an Ethernet frame using the data written to the transmit FIFO and transmits the frame to the MII. It also performs a CRC check of an Ethernet frame received from the MII and deconstructs the frame to write to the receive FIFO.
The E-MAC consists of two controllers: E-MAC0 for port 0 and E-MAC1 for port 1, which correspond to E-DMAC0 and E-DMAC1, respectively.

The TSU, which is placed between the E-DMAC and E-MAC, references the CAM entry table to select one of the following tasks according to the Ethernet frame destination address (DA) input to the E-MAC.

- Receives data and writes to the receive FIFO.
- Discards data.

Note: **Figure 21.6, ETNA Data Path and Various Settings** shows the frame data path and an overview of each setting.

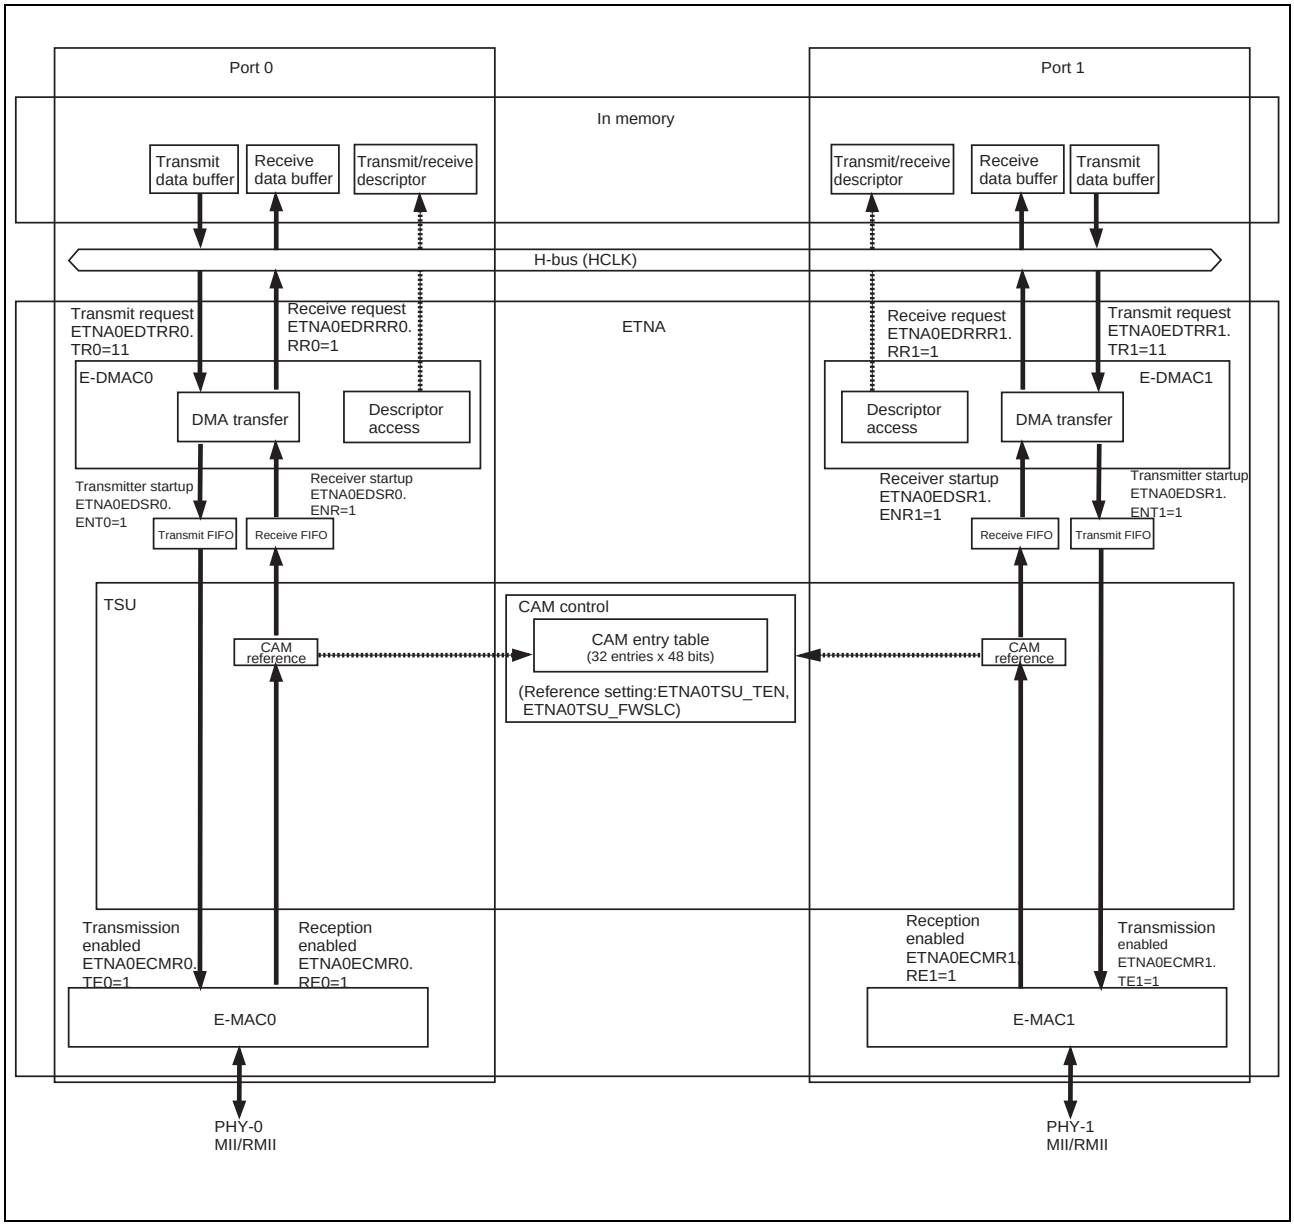

Figure 21.6 ETNA Data Path and Various Settings

21.4.24 Descriptors and Descriptor List

The E-DMAC performs DMA transfer according to the information (data), referred to as a descriptor, written in memory space. There are two types of descriptors: transmit descriptors and receive descriptors. Before a DMA transfer, DMA transfer information including a transmit/receive frame data storage address must be set by software.

The E-DMAC automatically starts reading a transmit/receive descriptor when the TRm[1:0] bits in ETNAnEDTRRm are set to 11 or the RRm bit in ETNAnEDRRRm is set to 1, and performs DMA transfer of frame data between the transmit/receive buffer and transmit/receive FIFO according to the information stored in the descriptor. After completion of Ethernet frame transmission/reception, the E-DMAC disables the descriptor valid/invalid bit and reflects the result of transmission/reception in the status bits.

Descriptors are placed in a readable/writable memory space. The address of the start descriptor (descriptor to be read first by the E-DMAC) is set in ETNAnTDLARm/ETNAnRDLARm. When multiple descriptors are prepared as a descriptor row (descriptor list), the descriptors are placed in continuous addresses (memory) according to the descriptor length set in the DLm0 and DLm1 bits in ETNAnEDMRm.

The E-DMAC consists of two systems: one for port 0 and the other for port 1. The DMAC for transmission and the DMAC for reception operate independently, and the DMAC for port 0 and the DMAC for port 1 operate independently. Place descriptors for transmission and reception and descriptors for port 0 and port 1 in those address spaces that do not overlap. If addresses are overlapped, E-DMAC does not successfully operate.

21.4.25 Transmit Descriptor

Figure 21.7 shows the configuration of a transmit descriptor and the relationship with a transmit buffer.

The data of a transmit descriptor consists of TD0, TD1, TD2, and padding data in groups of 32 bits from top to end. The length of padding data is determined according to the descriptor length specified by the DLm0 and DLm1 bits in ETNAnEDMRm.

TD0 indicates whether the transmit descriptor is valid or invalid, and information about the descriptor configuration and status. TD1 indicates the length of data in a transmit buffer to be transferred (TDL) as specified by the descriptor. TD2 indicates the start address of a transmit buffer that holds data to be transferred (TBA).

Depending on the descriptor specification, one transmit descriptor can specify all transmit data of one frame (single-frame/single-buffer) or multiple descriptors can specify the transmit data of one frame (single-frame/multi-buffer). As an example of single-frame/multi-buffer operation, the data portion that is used in a fixed manner in each Ethernet frame transmission can be referenced by multiple descriptors. For example, multiple descriptors can share the destination address and transmit source address in an Ethernet frame, and the remaining data can be stored in each separate buffer.

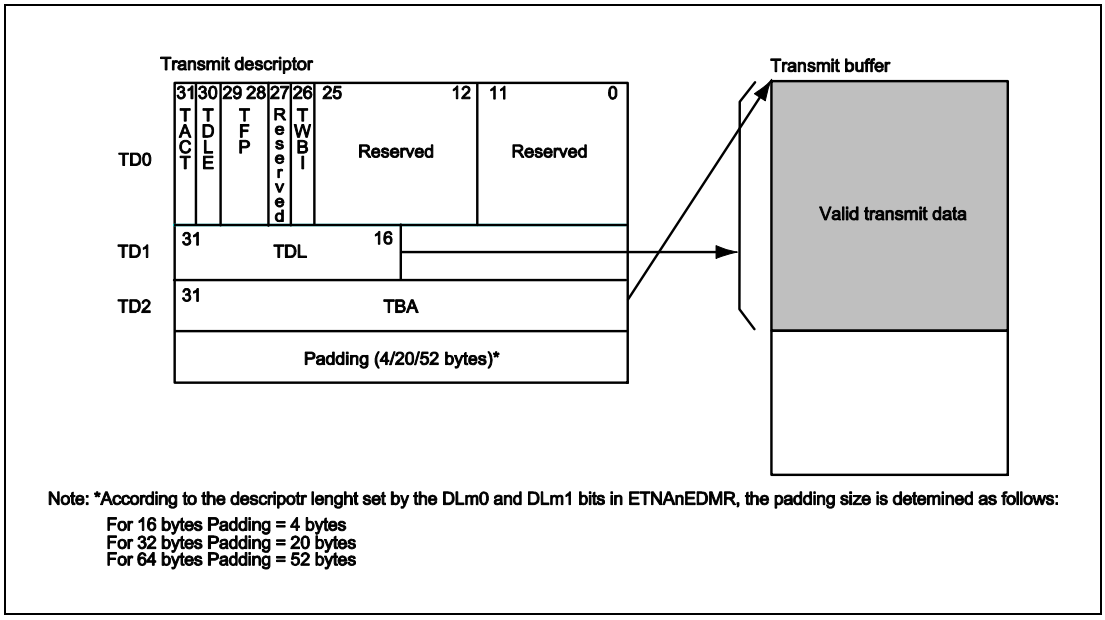

Figure 21.7 Relationship between Transmit Descriptor and Transmit Buffer

Note: Transmit descriptor ring has to be prepared at least five buffers. If transmit descriptor ring is set to less than five buffers, the descriptor ring may be looped two times by one transmit request. Because fetching all descriptors in the ring finishes before the write back process of the first buffers transmission completion.

(1) Transmit Descriptor 0 (TD0)

Before the TRm[1:0] bits in ETNAnEDTRRm are set to 11, the user sets whether the bits of the descriptor are valid or invalid bit and sets other descriptor configuration. After Ethernet frame transmission, the E-DMAC disables the valid/invalid bits of the descriptor and writes status information. This operation is referred to as write-back.

When using TD0, the user should write desired values to bits 31 to 28 and 26 according to the descriptor configuration. Bits 27 and 25 to 0 should be cleared to 0.

Table 21.81 TD0 description (1/2)

Bit	Bit name	Value after reset	R/W	Description
31	TACT	0	R/W	Transmit Descriptor Valid/Invalid Indicates whether the corresponding descriptor is valid or invalid. To make this bit valid, store transmit data in a transmit buffer (user-specified transmit data storage destination) beforehand, then write 1 to this bit. The E-DMAC clears this bit to 0 after data transfer. 0: Indicates that this transmit descriptor is invalid Indicates the initial setting state, the state after 0 is written, or (in case the user writes 1 to this bit) that this bit is cleared to 0 because the E-DMAC data transfer processing is completed. If this state is recognized when the E-DMAC reads a descriptor, the E-DMAC clears the TRm[1:0] bits in ETNAnEDTRRm to 0, and halts transfer operation related to transmission by the E-DMAC. 1: Indicates that this transmit descriptor is valid After the user writes 1 to this bit, this bit indicates that data is not transferred yet or data is being transferred. When there is a descriptor row (descriptor list) consisting of multiple continuous descriptors, the E-DMAC can continue operation when this bit of the next descriptor is valid.
30	TDLE	0	R/W	Transmit Descriptor List End Indicates whether the corresponding descriptor is the last descriptor of the descriptor row (descriptor list). 0: Not last descriptor After transfer of the corresponding descriptor, the E-DMAC reads the next one in the list of continuous descriptors. 1: Last descriptor After transfer of the corresponding descriptor, the E-DMAC reads the descriptor placed at the address indicated by ETNAnTDLARm.

Table 21.81 TD0 description (2/2)

Bit	Bit name	Value after reset	R/W	Description
29, 28	TFP[1:0]	00	R/W	Transmit Frame Position These bits indicate whether information of this descriptor represents information about the start, middle, or end of the transmit frame. 00: The information of the descriptor represents information about the middle of the frame. 01: The information of the descriptor represents information about the end of the frame. 10: The information of the descriptor represents information about the start of the frame. 11: The information of the descriptor represents all information about the frame (single-frame/single-descriptor (single-buffer)). Reference When one frame is divided for use, the method of specifying this bit for a descriptor row according to the number of divisions is described below. • For single-frame/single-descriptor operation First descriptor: TFP[1:0] = 11 • For single-frame/two-descriptor operation First descriptor: TFP[1:0] = 10 Second descriptor: TFP[1:0] = 01 • For single-frame/three-descriptor operation First descriptor: TFP[1:0] = 10 Second descriptor: TFP[1:0] = 00 Third descriptor: TFP[1:0] = 01 When the number of divisions is large, a descriptor row is configured by adding intermediate descriptors with TFP[1:0] = 00.
27	—	All 0	—	Reserved This bit is always read as 0. The write value should always be 0.
26	TWBI	0	R/W	Write-Back Completion Interrupt Notification 0: Does not notify of a write-back completion interrupt 1: After a write-back operation to this descriptor is complete, this bit sets the TWBm and TWBm bits in ETNAnEESRm to 11 and notifies the CPU of a write-back completion interrupt. This bit is valid only for the descriptor including the end of transmit frame (TFP = 01 or 11). This bit is cleared to 0 by the E-DMAC write-back operation.
25 to 0	—	All 0	—	Reserved These bits are always read as 0. The write value should always be 0.

(2) Transmit Descriptor 1 (TD1)

TD1 indicates the data length of the transmit buffer used by the corresponding descriptor.

The user should set TD1 before the start of a read by the E-DMAC.

Table 21.82 TD1 description

Bit	Bit name	Value after reset	R/W	Description
31 to 16	TDL	All 0	R/W	Transmit Buffer Data Length (in bytes) These bits indicate the data length of the corresponding transmit buffer in bytes. The maximum length is 64 Kbytes to 32 bytes ($FFE0_H$).
15 to 0	—	All 0	—	Reserved These bits are always read as 0. The write value should always be 0.

(3) Transmit Descriptor 2 (TD2)

TD2 indicates the start address of the corresponding 32-bit width transmit buffer. An address value should be specified in a longword boundary.

Table 21.83 TD2 description

Bit	Bit name	Value after reset	R/W	Description
31 to 0	TBA	All 0	R/W	Transmit Buffer Start Address These bits set the start address of the corresponding transmit buffer in a 4-byte boundary.

If descriptors are set below, the E-DMAC does not return to normal operation until a system reset is performed.

- TFP (transmit frame position) is not logically correct
  Example: The TFP bits are set to 11 in a descriptor (descriptor A) and the TFP bits are set to 01 in the next descriptor (descriptor B). This specification means that there is no descriptor indicating the start of the transmit frame specified by descriptor B.
- TBL (transmit buffer length) is set to 0

When one transmit frame is divided into three parts or more with transmit descriptors, the E-DMAC performs the following write-back operation:

- A write-back operation is performed for a transmit descriptor including information for the start of the transmit frame (TFP = 10 or 11) and for a transmit descriptor including information for the end of the frame (TFP = 01 or 11).
- A write-back operation is not performed for a transmit descriptor for the middle of the frame (TFP = 00).

Before changing a transmit descriptor with the software, make sure that a write-back operation has been performed (TACT = 0) for the transmit descriptor including information for the end of the frame (TFP = 01 or 11) to avoid overwriting (re-setting) an unprocessed transmit descriptor.

21.4.26 Receive Descriptor

Figure 21.8 shows the relationship between a receive descriptor and receive buffer.

The data of a receive descriptor consists of RD0, RD1, RD2, and padding data in groups of 32 bits from top to end. The length of padding data is determined according to the descriptor length specified by the DLm0 and DLm1 bits in ETNAnEDMRm.

RD0 indicates whether the receive descriptor is valid or invalid, and information about descriptor configuration and status. RD1 indicates the length of data that can be received in the receive buffer specified by the descriptor (RBL) and the length of the received frame data (RDL). RD2 indicates the start address of the receive buffer for storing receive data (RBA).

Depending on the descriptor specification, one receive descriptor can specify the storing of all receive data of one frame in a receive buffer (single-frame/single-buffer) or multiple descriptors can specify the storing of the receive data of one frame in receive buffers (single-frame/multi-buffer). As an example of single-frame/multi-buffer operation, suppose that a row of multiple descriptors (descriptor list) is prepared, RBL of each descriptor is 480 bytes, and a 1514-byte Ethernet frame is received. In such a case, the received Ethernet frame is transferred sequentially to buffers, 480 bytes for each buffer, starting with the first descriptor. Only the last 74 bytes are transferred to the fourth buffer. When a frame longer than RBL of a descriptor is received, the E-DMAC transfers the remaining data to the receive buffer by using the subsequent descriptors. As an example of efficient single-frame/multi-buffer operation, information items on different processing layers in an Ethernet frame can be separated from each other by using different buffers. For example, the destination address, transmit source address, type field data in an Ethernet frame, and 18 bytes padding can be stored in buffer 1 (set RBL to 32 bytes) and the remaining data can be stored in buffer 2 (set RBL to 1504 bytes). All receive frames, of course, can be stored in a single buffer if multiple descriptors are prepared and RBL of each descriptor is set to more than 1514 bytes (maximum Ethernet frame length).

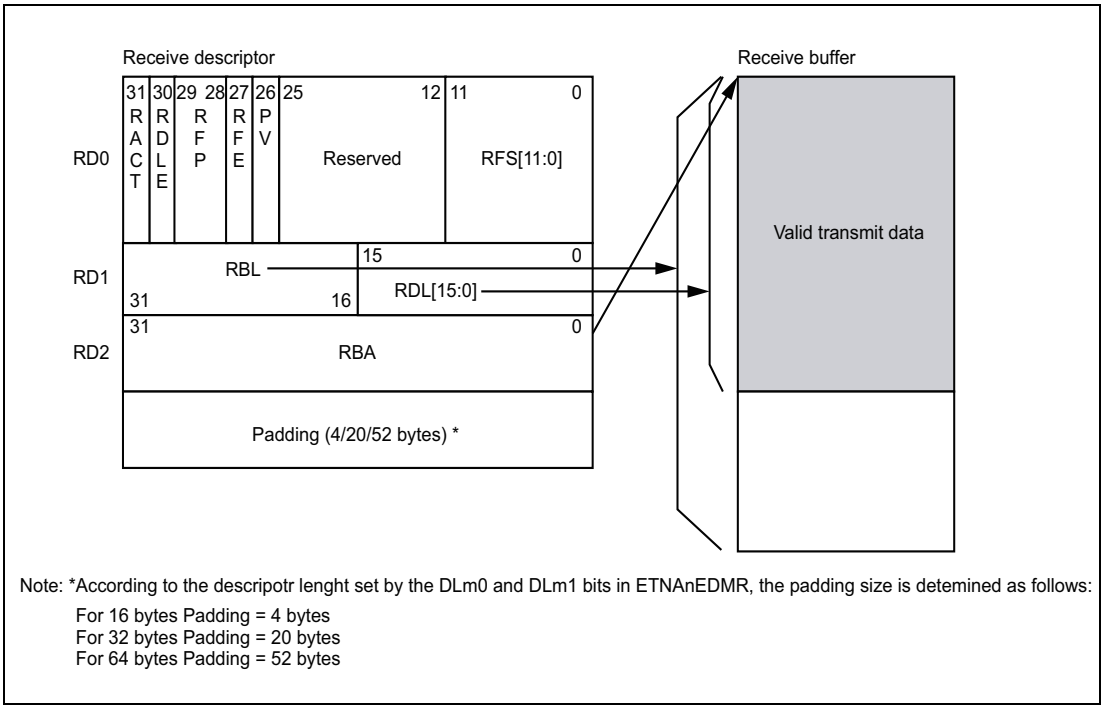

Figure 21.8 Relationship between Receive Descriptor and Receive Buffer

(1) Receive Descriptor 0 (RD0)

The user sets whether the bits of the descriptor are valid or invalid and whether the descriptor represents the end of the descriptor list in RD0 before the RRm bit in ETNAnEDRRRm is set to 1 and the start of a read by the E-DMAC. After receive DMA transfer of an Ethernet frame by the E-DMAC, the E-DMAC disables the valid/invalid bits of the descriptor and writes status information. This operation is referred to as write-back.

When using RD0, the user should write desired values to bits 31 and 30 according to the descriptor configuration. Bits 29 to 0 should be cleared to 0.

Table 21.84 RD0 description (1/3)

Bit	Bit name	Value after reset	R/W	Description
31	RACT	0	R/W	Receive Descriptor Valid/Invalid Indicates whether this descriptor is valid or invalid. To make this bit valid, prepare a receive buffer (user-specified receive data storage destination) beforehand, then write 1 to this bit. The E-DMAC clears this bit to 0 after data transfer or when a receive error has occured. 0: Indicates that this receive descriptor is invalid Indicates the initial setting state, the state after 0 is written to, or (in case the user writes 1 to this bit) that this bit is cleared to 0 because the E-DMAC data transfer processing is completed If this state is recognized when the E-DMAC reads a descriptor, the E-DMAC clears the RRm bit in ETNAnEDRRRm to 0, and halts transfer operation related to reception by the E-DMAC 1: Indicates that this receive descriptor is valid Indicates that data is not transferred yet after the user writes 1 to this bit, or that data is being transferred When there is a descriptor row (descriptor list) consisting of multiple continuous descriptors, the E-DMAC can continue operation when this bit of the next descriptor is valid
30	RDLE	0	R/W	Receive Descriptor List End Indicates whether this descriptor is the last descriptor of the descriptor row (descriptor list). 0: Not last descriptor After transfer of this descriptor, the E-DMAC reads the next one in the list of continuous descriptors 1: Last descriptor After transfer of this descriptor, the E-DMAC reads the descriptor placed at the address indicated by ETNAnRDLARm

Table 21.84 RD0 description (2/3)

Bit	Bit name	Value after reset	R/W	Description
29, 28	RFP[1:0]	00	R/W	Receive Frame Position 1, 0 The E-DMAC indicates by write-back operation whether information of the corresponding descriptor represents information about the start, middle, or end of the receive frame. 00: The information of the descriptor represents information about the middle of the frame 01: The information of the descriptor represents information about the end of the frame 10: The information of the descriptor represents information about the start of the frame 11: The information of the descriptor represents all information about the frame (single-frame/single-descriptor (single-buffer)) Reference The relationship between a frame after reception of one frame and a descriptor is described below. • For single-frame/single-descriptor operation First descriptor: RFP[1:0] = 11 • For single-frame/two-descriptor operation First descriptor: RFP[1:0] = 10 Second descriptor: RFP[1:0] = 01 • For single-frame/three-descriptor operation First descriptor: RFP[1:0] = 10 Second descriptor: RFP[1:0] = 00 Third descriptor: RFP[1:0] = 01 When the number of divisions is large, a descriptor row is configured by adding intermediate descriptors with RFP[1:0] = 00.
27	RFE	0	R/W	Receive Frame Error Occurrence Indicates that an error occurred in the receive frame. 0: RFS11 to RFS0 are all 0 1: One of RFS11 to RFS0 is 1 Each of RFS8 to RFS0 can be masked by using ETNAnTRSCERm. RFS11 to RFS9 cannot be masked. This bit is set by the E-DMAC write-back operation.
26	PV	0	R/W	Padding Insertion Indicates whether the padding specified by ETNAnRPADIRm was inserted in the receive frame processed with this descriptor or not. 0: No padding inserted 1: Padding inserted This bit can be changed by the E-DMAC write-back processing.
25 to 12	—	All 0	—	Reserved These bits are always read as 0. The write value should always be 0.

Table 21.84 RD0 description (3/3)

Bit	Bit name	Value after reset	R/W	Description
11 to 0	RFS[11:0]	All 0	R/W	Receive Frame Status Indicate the status of the corresponding frame. A bit below, when set to 1, indicates the occurrence of the corresponding event. If an event indicated by any of RFS9 to RFS0 occurs, the frame is not received completely. RFS[11:10]: Reserved RFS[9]: Receive FIFO overflow (corresponding to the RFOF bit in ETNAnEESRm) RFS[8]: Detection of reception abort (Corresponding to the RABT bit in ETNAnEESRm) RFS[7]: Multicast address frame received (corresponding to the RMAF bit in ETNAnEESRm) RFS[6]: Reserved RFS[5]: Reserved RFS[4]: Residual-bit frame receive error (corresponding to the RRF bit in ETNAnEESRm) RFS[3]: Long frame receive error (corresponding to the RTLF bit in ETNAnEESRm) RFS[2]: Short frame receive error (corresponding to the RTSF bit in ETNAnEESRm) RFS[1]: PHY-LSI receive error (corresponding to the PRE bit in ETNAnEESRm) RFS[0]: CRC error on receive frame (corresponding to the CERF bit in ETNAnEESRm)

(2) Receive Descriptor 1 (RD1)

In RD1, the user specifies the data length of a receive buffer usable by the corresponding descriptor. After reception of a frame, RD1 indicates the length of a frame received by the E-DMAC.

The user should set RD1 before the start of a read by the E-DMAC.

Table 21.85 RD1 description

Bit	Bit name	Value after reset	R/W	Description
31 to 16	RBL	All 0	R/W	Receive Buffer Data Length (in bytes, to be specified with a 32-byte boundary) These bits set the length of data that can be received by the corresponding receive buffer with an integral multiple of 32 bytes. The maximum receive buffer data length is 64 Kbytes – 32 bytes ($FFE0_H$).
15 to 0	RDL	All 0	R	Receive Data Length These bits indicate the data length of a receive frame stored in the receive buffer. Receive data transferred to the receive buffer does not include CRC data (4 bytes) placed at the end of a frame. As a receive frame length, the number of bytes (valid data bytes) not including CRC data are reported. In single-frame/multi-buffer (descriptor) operation, only the receive data length of the last descriptor is valid. The receive data length of an intermediate descriptor has no meaning. The padding size set by ETNAnRPADIRm is not included.

(3) Receive Descriptor 2 (RD2)

RD2 indicates the start address of the corresponding receive buffer. Set the start address of a receive buffer with a 32-byte boundary.

Table 21.86 RD1 description

Bit	Bit name	Value after reset	R/W	Description
31 to 0	RBA	All 0	R/W	Receive Buffer Start Address These bits set the start address of the corresponding receive buffer with a 32-byte boundary.

The E-DMAC performs DMA transfer for a receive frame from the address specified by RBA (receive buffer address) to the receive buffer in 32-byte units. RBL (receive buffer length) must be set to be an integral multiple of 32 bytes.

If data to be transferred is less than 32 bytes, invalid data will be written to memory.

[Example]

When the receive frame length is 170 bytes and the required receive buffer capacity is 192 bytes (32 bytes × 6), the sixth DMA-transfer causes invalid data to be written to the receive buffer (In the 32-byte DMA data, the former 10 bytes are valid and the latter 22 bytes are invalid).

Padding of the value 0 can be inserted into only one position in the receive frame by setting ETNAnRPADIRm. The padding size can be selected from 1 byte to 31 bytes in byte units. When padding is inserted into a receive frame, a receive buffer area equal to the total of “receive frame length and padding size”is required. ETNAnRPADIRm setting is valid for all receive frames.

RFE (receive frame error occurrence), PV (padding insertion), RFS (receive frame status) and RFL (receive frame length) are only set in the receive descriptor including information for the end of the frame (RFP = 01 or 11) by a write-back operation.

Before re-setting a receive descriptor with the software, completion of a write-back operation for the receive descriptor (RACT = 0) must be confirmed to avoid rewriting to (and re-setting) an unprocessed receive descriptor.

21.4.27 Descriptor and Transmit/Receive Buffer

(1) Transmission

Each transmit descriptor specifies one transmit buffer. The E-DMAC transfers a transmit frame stored in a transmit buffer specified by a transmit descriptor to the transmit FIFO. Multiple transmit frames stored in transmit buffers specified by multiple descriptors can be connected into one transmit frame and transferred to the transmit FIFO.

Figure 21.9 shows the relationship between the transmit descriptors and transmit buffers.

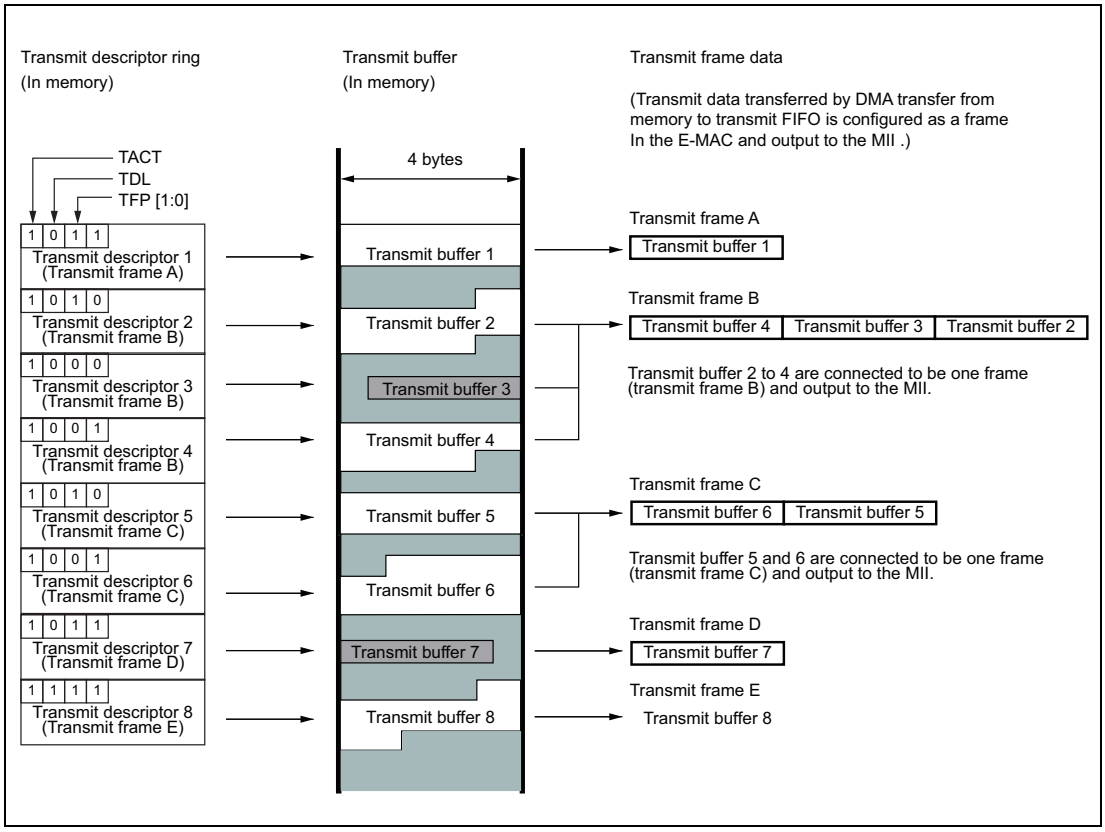

Figure 21.9 Relationship between Transmit Descriptor and Transmit Buffer

Note: Transmit descriptor ring has to be prepared at least five buffers. If transmit descriptor ring is set to less than five buffers, the descriptor ring may be looped two times by one transmit request. Because fetching all descriptors in the ring finishes before the write back process of the first buffers transmission completion

(2) Reception

Each receive descriptor specifies one receive buffer. The E-DMAC receives a receive frame from the receive FIFO and stores it in a receive buffer specified by a receive descriptor. If the receive frame size exceeds the receive buffer size, the remaining data of the receive frame can be stored in a different receive buffer specified by a different receive descriptor. Thus, one receive frame can be stored in multiple receive buffers.

Figure 21.10, Relationship between Receive Descriptor and Receive Buffer shows the relationship between the receive descriptors and receive buffers.

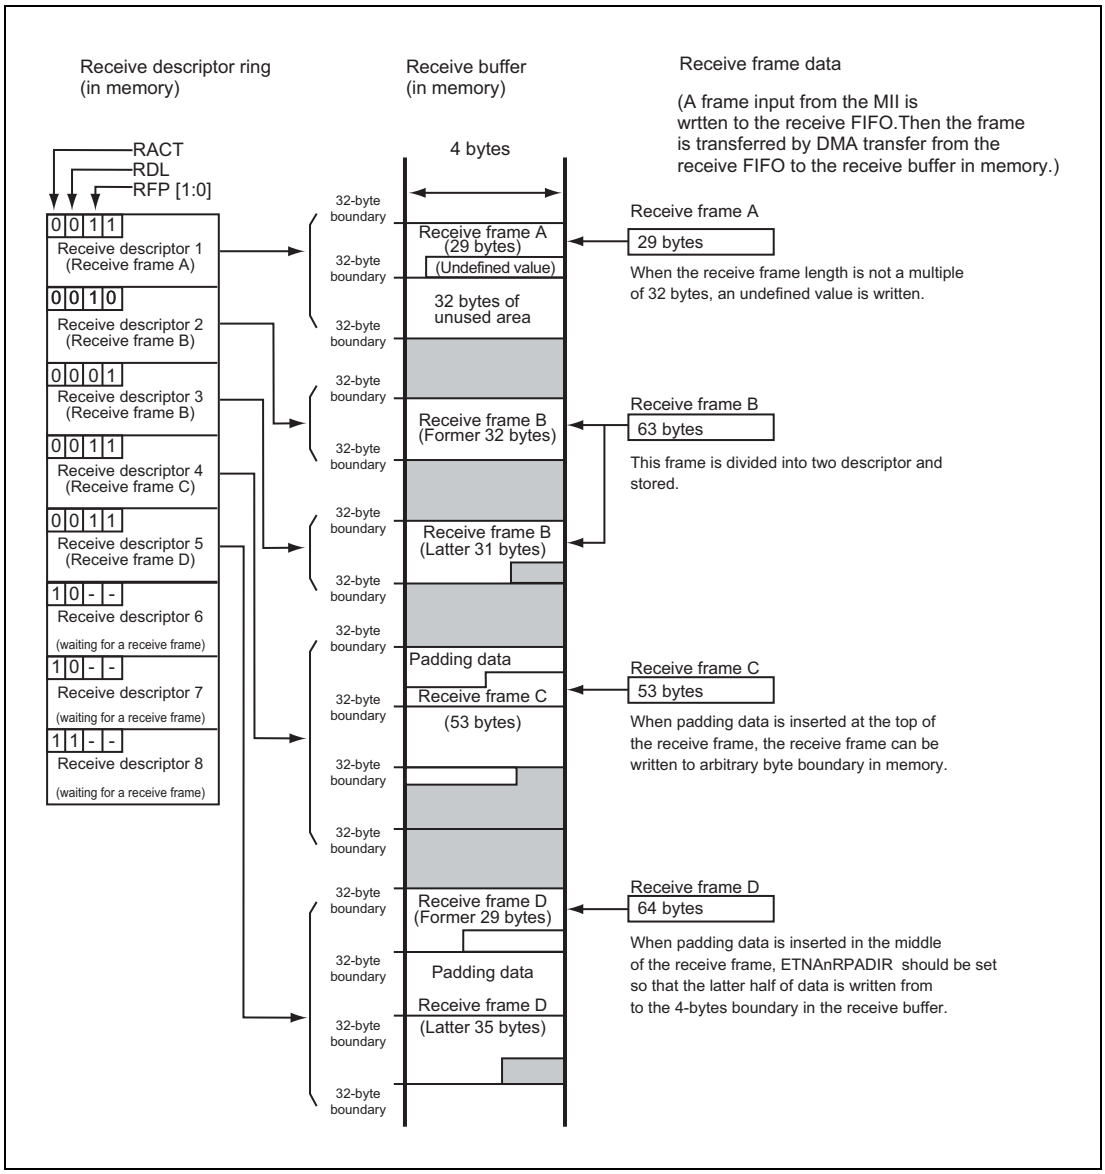

Figure 21.10 Relationship between Receive Descriptor and Receive Buffer

21.4.28 Descriptor Pointer

The E-DMACm controls the transmit and receive descriptor addresses in memory and the processing priority by using the following registers.

(1) Registers related to a transmit descriptor

- ETNAnTDLARm: Address of the start descriptor in a list of transmit descriptors.
- ETNAnTDFARm: Address of the transmit descriptor to be processed
- ETNAnTDFXRm: Address of the transmit descriptor that finished processing (set by a write-back operation) last
- ETNAnTDFFRm: Indicates whether the transmit descriptor for which the E-DMACm has just completed the write-back processing and whose start address is stored in ETNAnTDFXRm is at the end of the transmit descriptor queue (descriptor list).

(2) Registers related to receive descriptor:

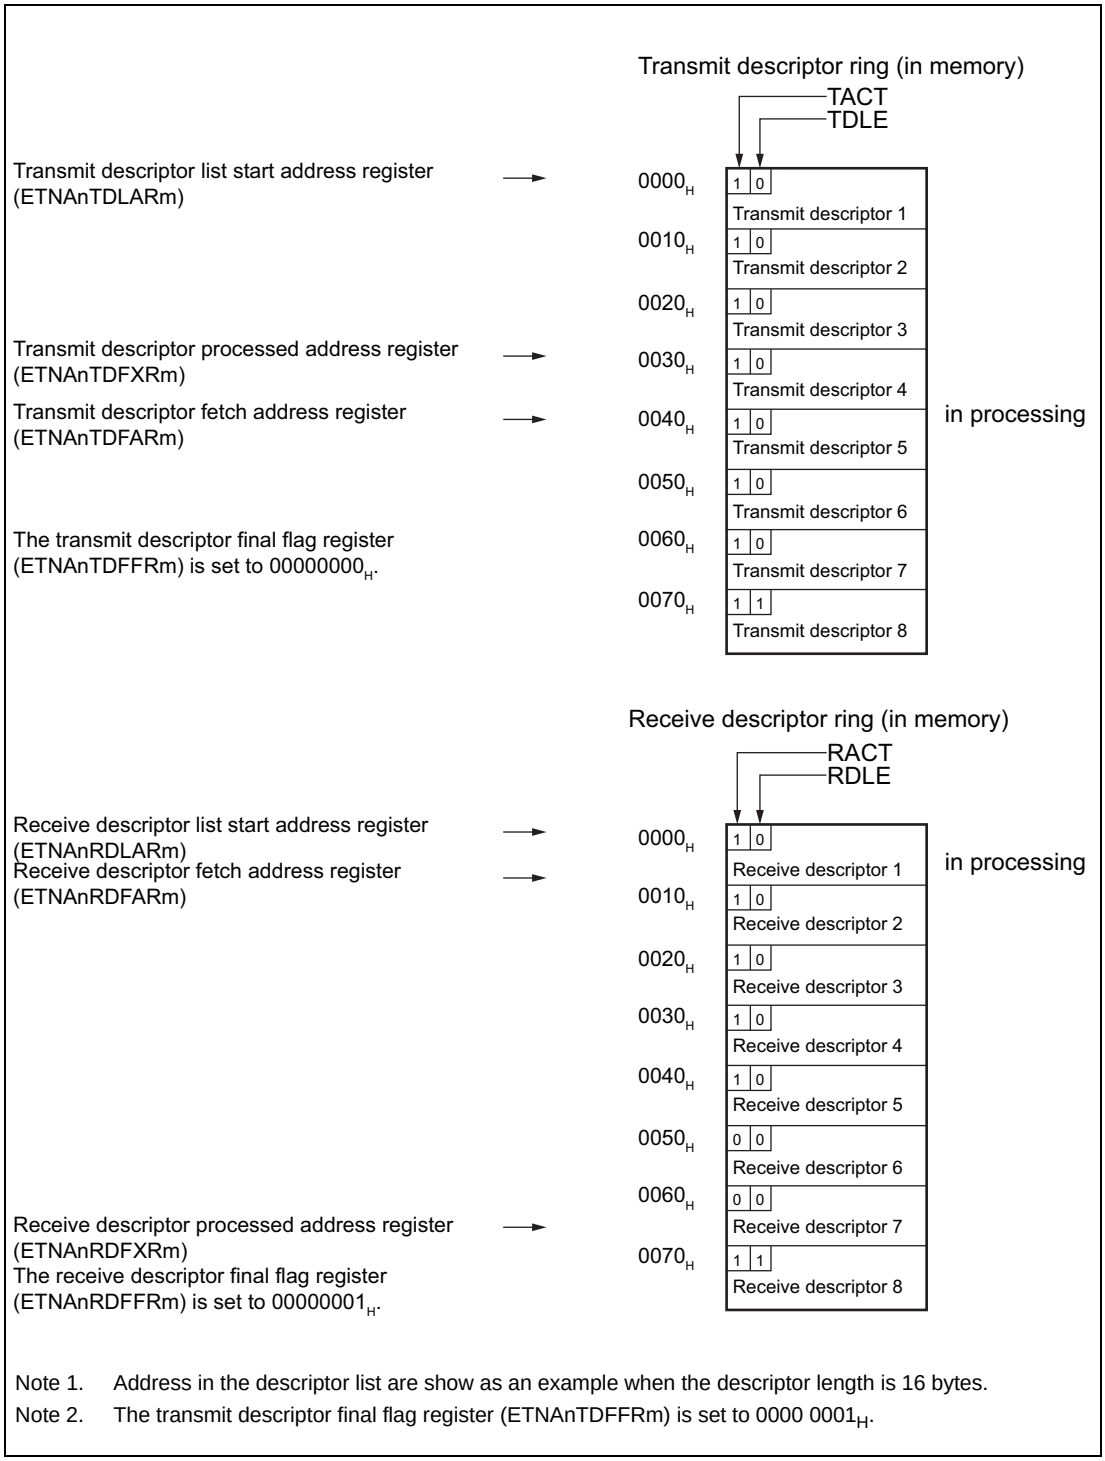
- ETNAnRDLARm: Address of the start descriptor in a list of receive descriptors.
- ETNAnRDFARm: Address of the receive descriptor to be processed
- ETNAnRDFXRm: Address of the receive descriptor that finished processing (set by a write-back operation) last
- ETNAnRDFFRm: Indicates whether the receive descriptor for which the E-DMACm has just completed the write-back processing and whose start address is stored in ETNAnRDFXRm is at the end of the receive descriptor queue (descriptor list).

Transmit descriptors and receive descriptors have a ring structure. When the TDLE (RDLE) value of the processed transmit (receive) descriptor is 0, the next descriptor will be processed. The next descriptor is the transmit (receive) descriptor at the address obtained by adding the processed transmit (receive) descriptor address to the descriptor length specified by the DLm[1:0] bit in ETNAnEDMRm. When the TDLE (RDLE) value of the processed transmit (receive) descriptor is 1, the transmit descriptor indicated by ETNAnTDLARm (ETNAnRDLARm) will be processed next. **Figure 21.11** shows the relationship between the transmit/receive descriptor ring and read pointer.

The transmit descriptor list must be large enough to point to five or more transmit frames. If four or less transmit frames are pointed to in a list, E-DMACm operation is not guaranteed. Accordingly, do not set that all the transmit descriptors in a ring are used by four or less descriptors. The receive descriptor list does not have this restriction. For example, one receive frame can use all receive descriptors in a list.

In the initial setting, the start address of a descriptor list must be set to ETNAnTDLARm (ETNAnRDLARm) and ETNAnTDFARm (ETNAnRDFARm), and the end descriptor address of the descriptor list to ETNAnTDFXRm (ETNAnRDFXRm) by the software.

The E-DMAC updates ETNAnTDFARm (ETNAnRDFARm), ETNAnTDFXRm (ETNAnRDFXRm) and the DLm[1:0] bit in ETNAnTDFFRm (DLm[1:0] bit in ETNAnRDFFRm) each time a descriptor is processed.



Note 1. Address in the descriptor list are show as an example when the descriptor length is 16 bytes.

Note 2. The transmit descriptor final flag register (ETNAnTDFFRm) is set to 0000 0001H.

Figure 21.11 Relationship between Transmit/Receive Descriptor and Descriptor Pointing Registers

21.4.29 Transmission Procedure and Processing Flow

When 11 is written to the TRm[1:0] bits in ETNAnEDTRRm with the TEm bit in ETNAnECMRm set to 1 and there is empty space of 32 bytes or more in the transmit FIFO, the E-DMAC reads the descriptor following the previously used descriptor from the transmit descriptor list (or the descriptor indicated by ETNAnTDLARm at the initial startup).

If the TACT bit of the read descriptor is set to 1 (valid), the E-DMAC sequentially reads transmit frame data from the transmit buffer start address specified by TD2 and transfers the data to the transmit FIFO. The E-DMAC configures a transmit frame and starts transmission to the MII. After DMA transfer of data equivalent to the buffer length specified in the descriptor, the following processing is carried out according to the TFP value.

- TFP = 10 (start of a frame)
  Descriptor write-back (writing 0 to the TACT bit) is performed after completion of DMA transfer.
- TFP = 01 or 11 (end of a frame)
  Descriptor write-back (writing 0 to the TACT bit and writing status) is performed after completion of frame transmission.
- TFP = 00 (frame continued)
  Descriptor write-back is not performed. The TACT bit retains the value 1.

As long as the TACT bit of a read descriptor is set to 1 (valid), the reading of E-DMAC descriptors and the transmission of frames continue.

When a descriptor with the TACT bit cleared to 0 (invalid) is read, the E-DMAC performs the following processing and completes transmit processing.

- Clears the TRm[1:0] bits in ETNAnEDTRRm to 00.
- Writes the TCm bits in ETNAnEESRm to 11 and generates an interrupt.

The E-DMAC can store up to four frames of data in the transmit FIFO.

When one of the following conditions is met, the MAC transmit processing unit reads the data from the transmit FIFO to configure a frame and sends it to the MII.

- One or more frame of data is stored in the transmit FIFO.
- Transmit FIFO full.

Figure 21.12 shows an example of transmission flow.

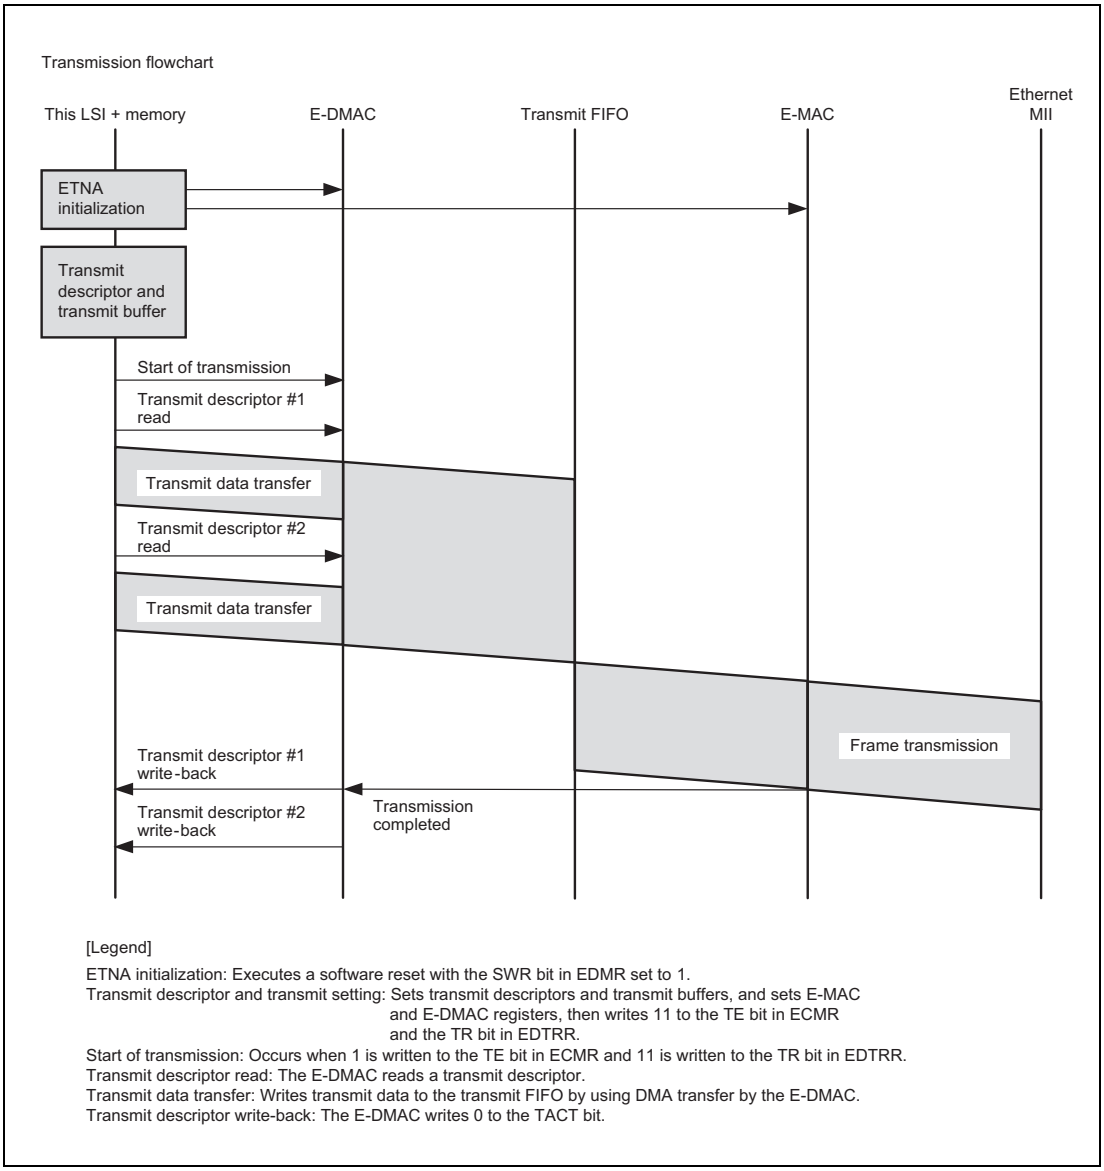


Figure 21.12 Sample Transmission Flowchart (Single-Frame/Two-Description in store and forward mode)

Figure 21.13 shows the status change of the MAC transmitter. This operation is common among port 0 and port 1.

1. When the TEn bit in ETNAnECMRm is set, the transmitter enters the transmit idle state.
2. When a transmit request is issued by the transmit E-DMAC, the E-MAC sends the preamble to MII after a transmission delay caused by the carrier detection and frame interval time. If full-duplex transfer is selected, which does not require carrier detection, the preamble is sent as soon as a transmit request is issued by the E-DMAC.
3. The transmitter sends the SFD, data, and CRC sequentially. At the end of transmission, the transmit E-DMAC generates a transmission complete interrupt (TC). If a collision or the carrier-not-detected state occurs during data transmission, these are reported as interrupt sources.
4. After waiting for the frame interval time, the transmitter enters the idle state, and if there is more transmit data, continues transmitting.

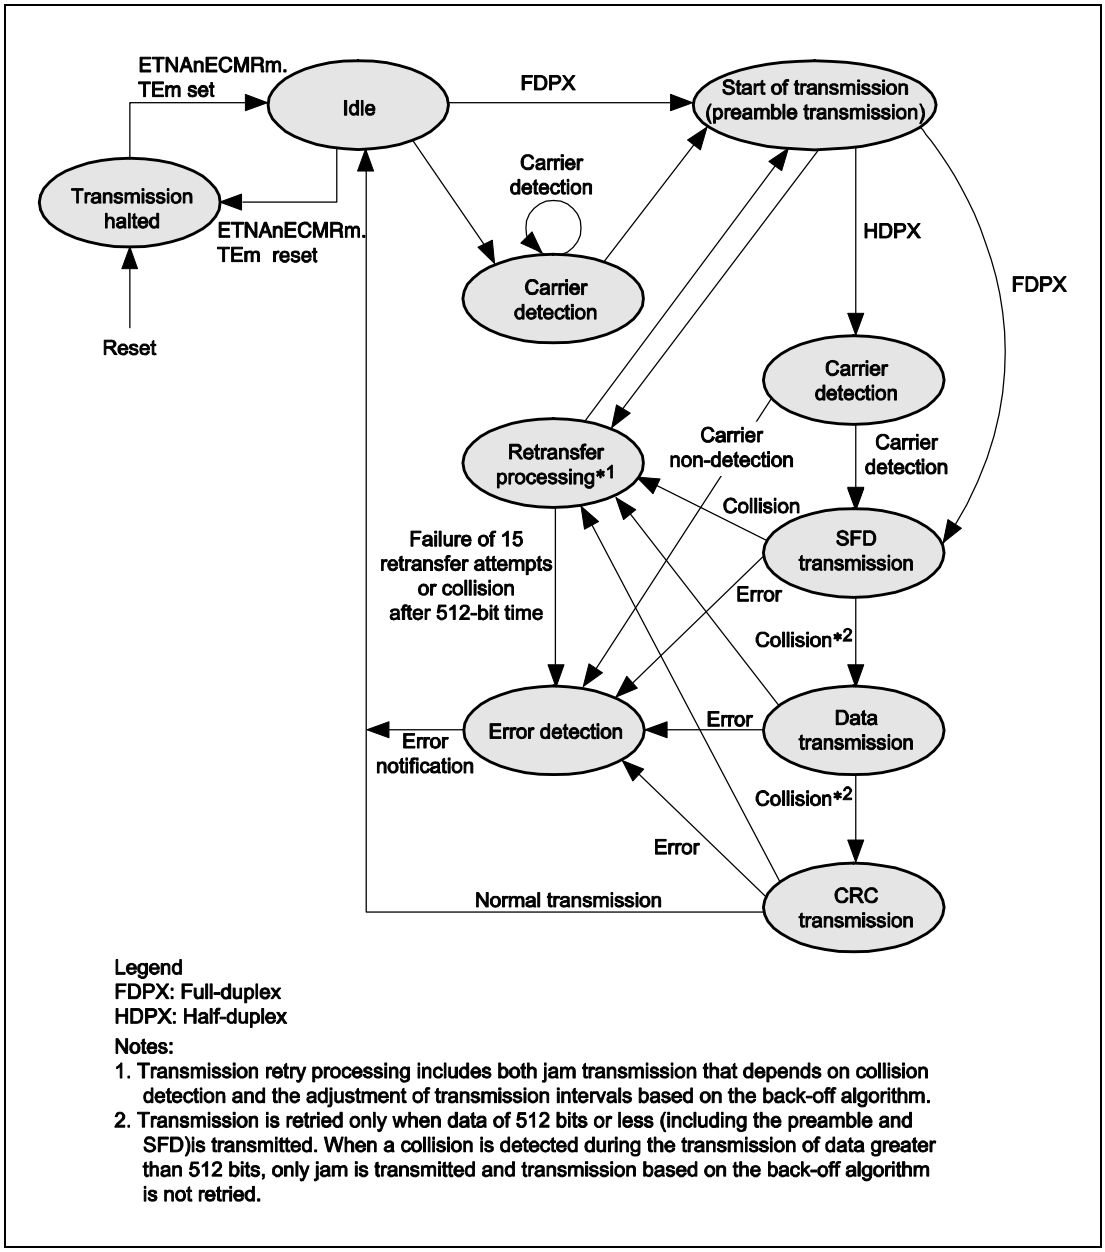

Figure 21.13 MAC Transmitter State Transitions

21.4.30 Transmission Error Processing

(1) Transmit Descriptor Empty

When the TFP bits of the descriptor previously processed are set to 00 or 10 and the TACT bit of the read transmit descriptor is set to 0 (invalid), a transmit descriptor empty state is determined and 1 is written to the TDE bit in ETNAnEESRm, and then an interrupt is issued.

When a transmit descriptor state is empty, start transmission processing after a software reset.

21.4.31 Reception Procedure and Processing Flow

The MAC receiver separates the frame from the MII into preamble, SFD, data and CRC, and transfers the fields from DA (destination address) to the data to the receive FIFO. Up to 24 frames can be written in the receive FIFO. **Figure 21.14** shows the status change of the MAC receiver. This operation is common among port 0 and port 1.

1. When the REm bit in ETNAnECMRm is set to 1, the receiver enters the receive idle state.
2. When an SFD (start frame delimiter) is detected after a receive packet preamble, the receiver starts receive processing. A frame with an invalid pattern is discarded.
3. In normal mode, the receiver starts data reception if the destination address of the frame specifies the one that the product has or broadcast or multicast. In promiscuous mode, data reception starts regardless of the frame type.
4. Following data reception from the MII, the receiver carries out a CRC check. The result is indicated as a status bit in the descriptor after the frame data has been written to the receive FIFO. Reports an error status in the case of an abnormality.

After one frame has been received, if the REm bit in ETNAnECMRm is set to 1, the receiver prepares to receive the next frame.

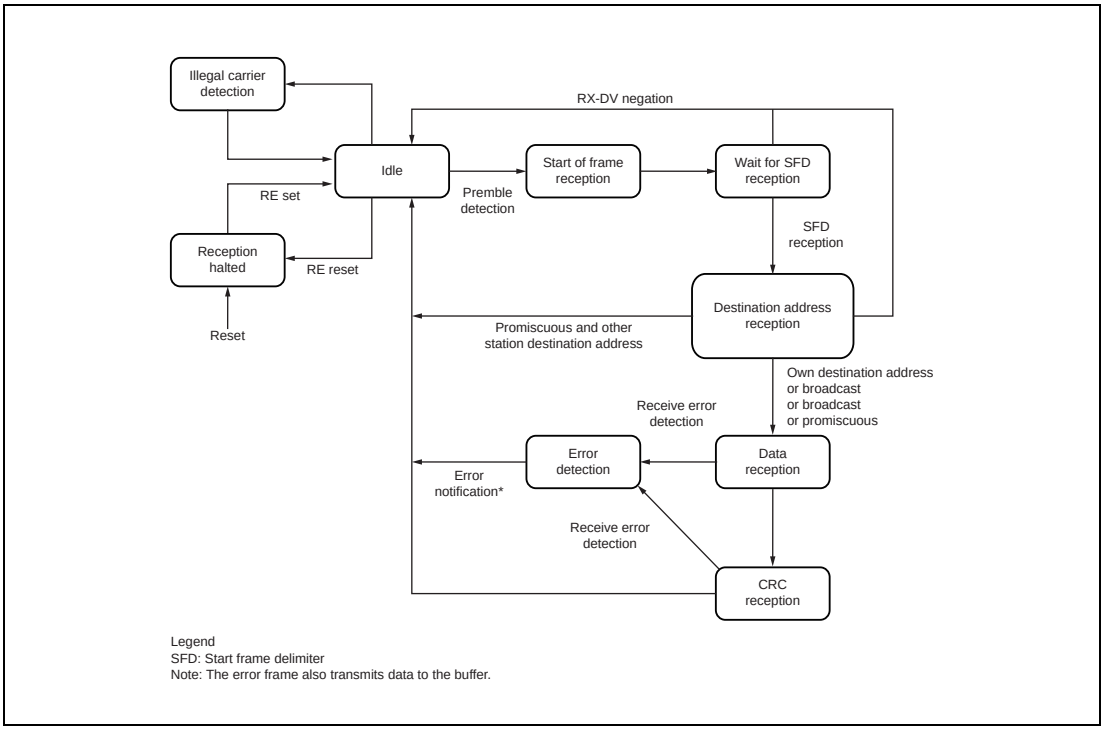

Figure 21.14 MAC Receiver State Transitions

CAM evaluation can be referenced during frame processing in reception (for details on the CAM function, see **Section 21.4.33, CAM Function**).

When 1 is written to the RRm bit in ETNAnEDRRRm while the REm bit in ETNAnECMRm is set to 1, the E-DMAC reads the descriptor following the previously used descriptor from the receive descriptor list (or the descriptor indicated by ETNAnRDLARm at the initial startup) then enters the receive wait state. If 32 bytes or more of data or the last byte of the receive frame is stored in the receive FIFO, the E-DMAC transfers receive FIFO data to the receive buffer specified by RD2 according to the receive descriptor with the RACT bit set to 1 (valid).

If the data length of a received frame is longer than the buffer length specified by RD1, the E-DMAC performs a write-back operation to the descriptor (set RFP to 10 or 00) when the buffer is full, then reads the next descriptor. The E-DMAC then continues to transfer data to the receive buffer specified by the new RD2.

When the following conditions are satisfied, a write-back operation is performed for the descriptor (RFP = 11 or 01), 11 is written to the FR bits in ETNAnEESRm, and an interrupt is issued.

- The receive buffer has been full during DMA transfer.
- DMA transfer to the receive buffer of the last byte of the receive frame has been completed.

After the reception processing of the frame, the next descriptor reading standby state begins. At this time, if 32 bytes or more of data or the last byte of the receive frame is stored in the receive FIFO, the next receive descriptor process is performed continuously.

When the RACT bit of the read receive descriptor is 0 (invalid), the receive descriptor empty state is determined and the RDE bit in ETNAnEESRm is written to 1, and then an interrupt is issued.

To receive frames continuously, set the RNC bit in ETNAnRMCRm to 1. The value after reset is 0.

Figure 21.15 shows an example of reception flow.

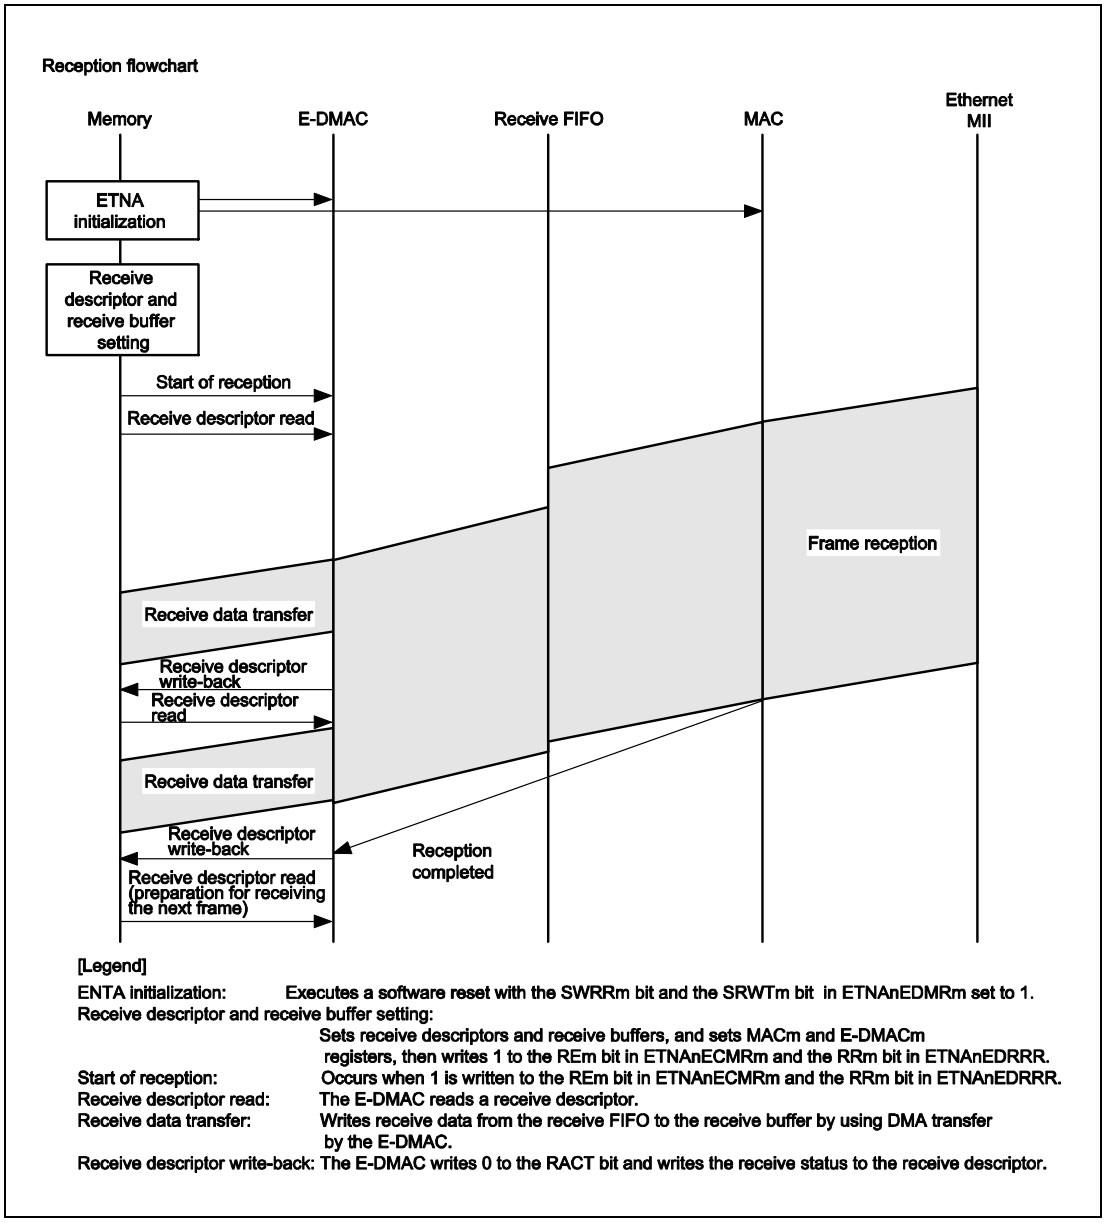

Figure 21.15 Sample Reception Flowchart (Single-Frame/Two-Descriptor)

21.4.32 Reception Error Processing

(1) Reception Error

When a reception error occurs, the FR and RABT bits in ETNAnEESRm are set to 1 and an interrupt is issued after a write-back operation for the receive descriptor related to the reception error frame.

If a reception error occurs when the length of the frame received from the MII is less than 32 bytes, DMA transfer to the receive buffer for the frame is not performed. At this time, the receive frame is discarded in the E-DMAC (flush function). However, if padding is inserted in the receive frame by ETNAnRPADIRm, the flush function is performed when the frame length including the padding bytes is less than 32 bytes.

(2) Receive FIFO Overflow

In any of the following cases, the E-MAC cannot receive frames from the MII because it has no space to store receive frames, and all the receive frames that have been transferred to the E-MAC will be discarded in the E-MAC (receive FIFO overflow).

- Receive FIFO is full of data waiting for DMA transfer (the receive FIFO has no space).
- The number of receive frames waiting for DMA transfer is 24 in total (the receive frame information managing area has no empty space; up to 24 frames can be managed).

If an overflow occurs due to the former case, the RFE bit in ETNAnEESRm is set to 1 and an interrupt is generated. If an overflow occurs due to the latter case, the RFCOF bit in ETNAnEESRm is set to 1 and an interrupt is generated. Each time a receive frame is discarded due to an overflow, ETNAnRMFCRm is incremented. However, ETNAnRMFCRm is not incremented for a receive frame that is cut off due to insufficient receive FIFO space. If a receive frame is cut off due to insufficient receive FIFO space (the frame is partially stored in the receive FIFO), the E-DMAC performs the following operation:

- Performs DMA transfers for the cut-off frame stored in the receive FIFO to the receive buffer.
- After the DMA transfer, performs a write-back operation on the receive descriptor.
- After the write-back operation, sets the ROC bit in ETNAnEESRm to 1 and generates an interrupt.

When the receive FIFO is full of data waiting for DMA transfer, frame reception from the MII can be resumed if DMA transfer is performed from the receive FIFO to the receive buffer and 32 bytes or more of empty space is generated in the receive FIFO. When the number of receive frames waiting for DMA transfer is 24 in total, frame reception from the MII can be resumed if one or more frame has been DMA transferred from the receive FIFO to the receive buffer. For restarting frame reception from the MII, when the E-DMAC resumes frame reception from the MII, it only accepts from the start of the frame.

(3) Flow Control

When the amount of receive data or the number of receive frames in the receive FIFO leads to one of the following conditions, the E-DMAC notifies the E-MAC to control E-MAC writing to the receive FIFO.

- When the space used in the receive FIFO exceeds the data amount specified by ETNAnFCFTRm
- When the number of receive frames in the receive FIFO exceeds the value specified by ETNAnFCFTRm

The threshold of the receive data amount can be set in a range from 256 to 65536 bytes in 256-byte units.

The threshold of receive frames can be set in a range from 1 to 24 frames (by the frame) in frame units.

(4) Receive Descriptor Empty

When the RACT bit of the read descriptor is 0 (invalid), the receive descriptor empty state is determined and DMA transfer is stopped. Then the following operation is performed.

- Writes the RRm bit in ETNAnEDRRRm to 0
- Sets the RDE bit in ETNAnEESRm to 1 and generates an interrupt to the CPU.

To resume the DMA transfer to the receive buffer, the interrupt source needs to be cleared by software, the receive descriptor needs to be re-set and the RRm bit in ETNAnEDRRRm should be set to 1.

Even if receive descriptor is empty, frame reception from the MII to the receive FIFO is continued if there is empty space left in the receive FIFO and receive frame information management area. Therefore, even if a receive descriptor empty state is determined, the DMA transfer can be performed without discarding the frames received from the MII if DMA transfer to the receive buffer can be resumed before an overflow occurs.

21.4.33 CAM Function

Frames input to the E-MAC are grouped into the following four types; unicast for the product, broadcast, multicast, and unicast to other destinations. The MAC addresses of unicast for the product and broadcast are fixed, and determined only by register settings. Consequently, only multicast and unicast to other destinations determine whether to receive or not and whether to transfer or not by using the CAM (unicast frames whose destination MAC addresses match the product are called unicast frames to the product, and those that do not are called unicast frames to other destinations).

Furthermore, the evaluation of receive of unicast to other destinations and multicast frames by using CAM are performed by referencing the registered MAC addresses of the CAM entry table in the TSU. By using this function, receive FIFO overflow can be prevented caused by accumulation of frame data not required for reception, and CPU processing for determining receive can be reduced.

Each entry in the CAM table can be assigned to port 0, port 1 or both of them by using POST registers (ETNAnTSU_POST1 to 4). When the corresponding bit is set to 1, the CAM evaluation results are used for determining receive. In other words, when the corresponding bit of the POST table is cleared to 0, receive evaluation will be the same as when CAM is not used shown in **Table 21.87 Receive Frame Processing**

The on-chip CAM has entry tables which can register the MAC address of 32 entries, the details of which can be set by ETNAnTSU_ADRH0 to ENATnTSU_ADRH31 and ETNAnTSU_ADRL0 to ETNAnTSU_ADRL31. The setting to enable/disable referencing of the on-chip CAM entry table is performed by the CAM entry table enable setting register which sets whether to perform CAM evaluation or not, and the CAM entry table POST setting register for setting whether to use the CAM determination results for determining receive. When on-chip CAM entry table referencing during receive is enabled, the destination address in the frame and MAC address registered in the CAM entry table are compared, and it is determined whether to transfer the frames input to the E-MAC to E-DMAC (have E-DMAC receive the frames) or discard the frames. **Table 21.87 Receive Frame Processing** shows the processing method of frames (receive or discard) in reception from E-MAC0 to E-DMAC0 or that from E-MAC1 to E-DMAC1,

Table 21.87 Receive Frame Processing

CAM Entry Table Referencing Results	Types of Frame	PRMm = 0 (Normal mode)		PRMm = 1 (Promiscuous Mode)	
		MCTm = 0	MCTm = 1	MCTm = 0	MCTm = 1
CAM hit	unicast for the product	Discarded		Discarded	
	Broadcast	Discarded		Discarded	
	Multicast	Discarded	Received	Discarded	Received
	unicast to other product	Received		Discarded	
CAM mishit	unicast for the product	Received		Received	
	Broadcast	Received		Received	
	Multicast	Received	Discarded	Received	Discarded
	unicast to other product	Discarded		Received	
CAM disable	unicast for the product	Same as CAM mishit			
	Broadcast				
	Multicast				
	unicast to other product				

[Legend]
PRMm (Bit 0 in ETNAnECMRm): Promiscuous Mode
(0: Normal mode, 1: Promiscuous Mode)
MCTm (Bit 13 in ETNAnECMRm):Multicast receive mode
(0: Receive when CAM mishit, 1: Receive when CAM hit)

21.4.34 Transmit/Receive Processing of Multi-Buffer Frame (Single-Frame/Multi-Descriptor)

(1) Multi-Buffer Frame Transmit Processing in store and forward mode

During multi-buffer frame transmission, the processing shown in **Figure 21.16** is carried out by the E-DMAC.

In the figure the transmit descriptor is shown as active (TACT bit = 1), in case either buffer data has already been transmitted successfully or not. After all descriptors of multi-buffer frame are processed, frame transmission is started. If transmission complete interrupts are enabled in ENTAnEESIPRm, an interrupt is generated immediately after the final descriptor write-back at the end of frame transmission.

E-DMAC does descriptor write-back only to the first and last descriptors

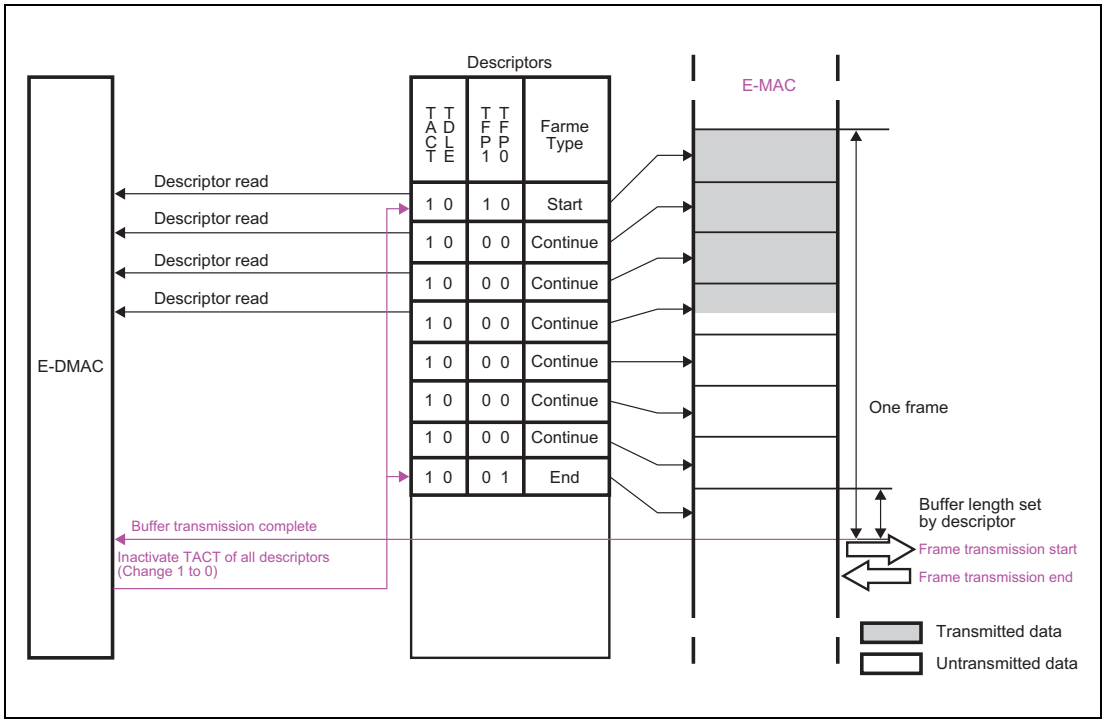

Figure 21.16 E-DMAC Operation of multi-buffer frame transmission in store and forward mode

(2) Receive Processing in the Case of Multi-Buffer Frame

If an error occurs during reception in the case of a multi-buffer frame where a receive frame is divided for storage in multiple buffers, the E-DMAC performs the processing shown in **Figure 21.17, E-DMAC Operation after Receive Error**.

In the figure, the invalid receive descriptors (with the RACT bit cleared to 0) represent the successful reception of data to be stored in buffers, and the valid receive descriptors (with the RACT bit set to 1) represent unreceived buffers. If a frame receive error occurs with a descriptor shown in the figure, the status is written back to the corresponding descriptor.

If error interrupts are enabled in ETNAnEESIPRm, an interrupt is generated immediately after the write-back. If there is a new frame receive request, reception is continued from the buffer after that in which the error occurred.

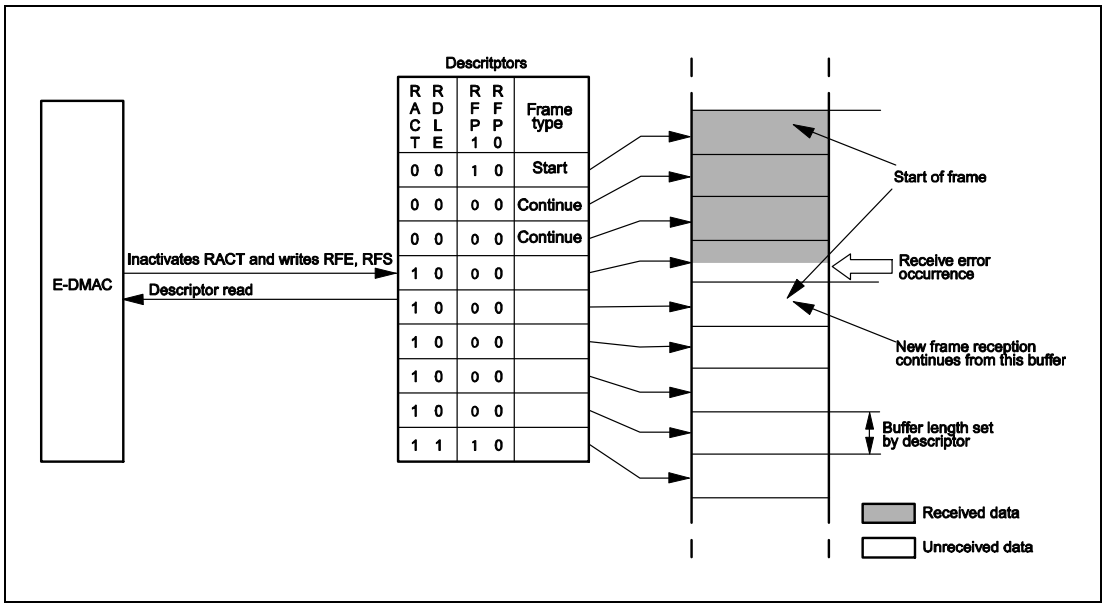

Figure 21.17 E-DMAC Operation after Receive Error

21.4.35 Padding Insertion in Receive Data

In the E-DMAC, 1 to 31 bytes of padding can be inserted in any byte position of receive data to improve software handling capability. By using this function, for instance, inserting 2-byte padding after the MAC header (14 bytes) of Ethernet frame enables data following the MAC header to set in 4-byte boundary.

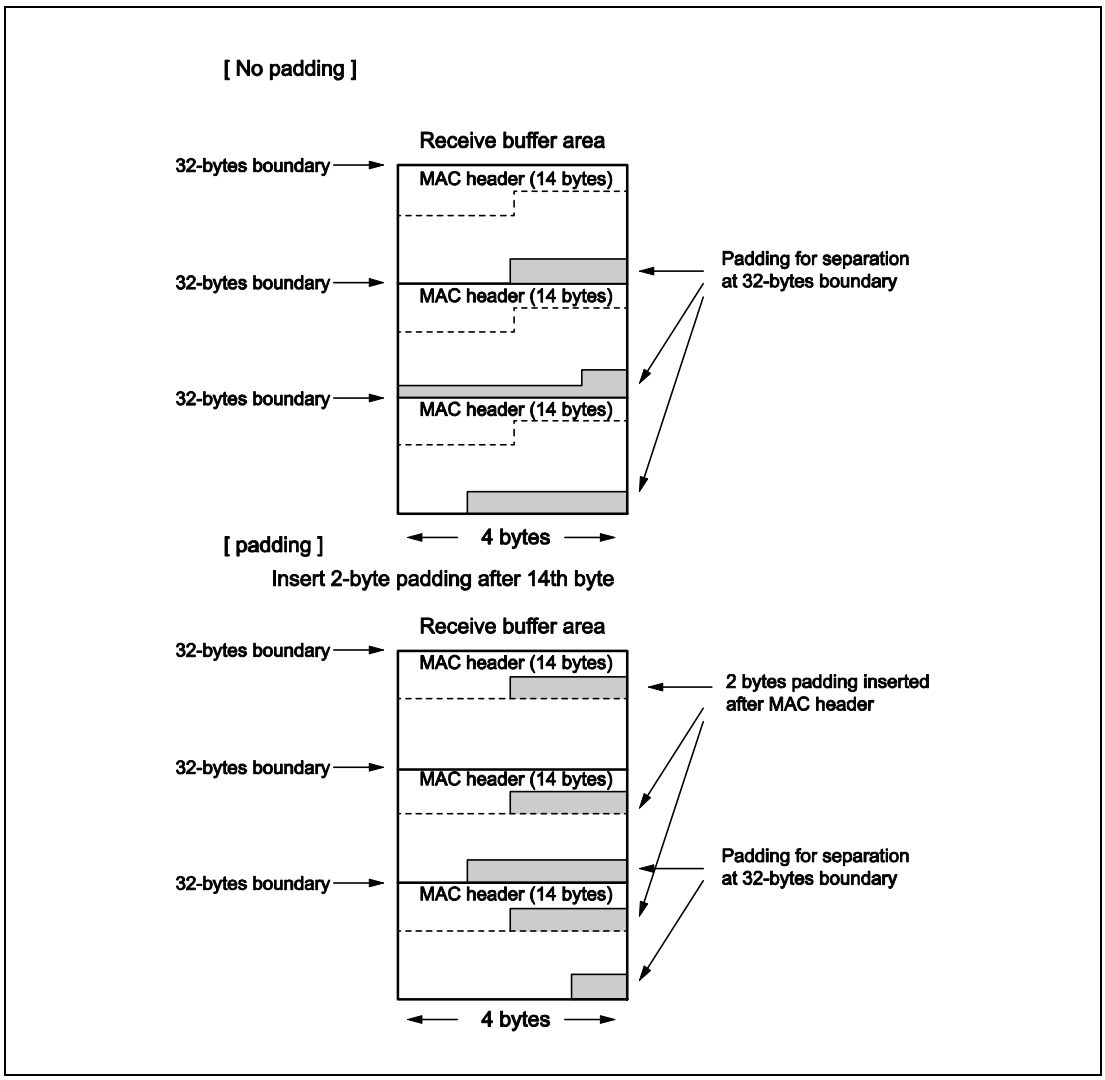

Figure 21.18 Padding Insertion in Receive Data

21.4.36 Interrupt Sources

The ETNA issues three types of interrupts: receive/transmit interrupts for port 0 (INTETNA0), receive/transmit interrupts for port 1 (INTETNA1) and detected status with transfer for TSU. **Table 21.88, List of ETNA Interrupts and detected statuses** shows these three interrupts, the interrupt sources, interrupt status registers/bits set at interrupt occurrence, and interrupt generation timing.

INTETNA0 or INTETNA1 interrupts are generated in correspondence with the port 0 or port 1 transmit/receive operation. When an interrupt source is generated, it is set in ETNAnEESR0 or ETNAnEESR1 and an interrupt is issued. For some interrupt sources, the ETNAnEESR0/ETNAnEESR1 setting and an interrupt are performed after a write-back operation to a descriptor is completed, not immediately after the interrupt source is detected. Interrupt sources other than the MAC status register source (ECIm bit) are cleared by writing a 1 to the corresponding source bit. The MAC status register source (ECIm bit) is cleared by writing a 1 to the corresponding source bit in ETNAnECSRm. Interrupt source bits retain the values until they are cleared. INTETNAn port 0 or port 1 interrupt source is allowed to issue interrupts by setting the corresponding bit in ETNAnEESIPR0 or ETNAnEESIPR1. Each MAC state register source (ECI bit) is allowed to issue an interrupt by setting the corresponding bit in ETNAnECSIPRm. In the value after reset, interrupts are disabled. Interrupt events generated inside E-MAC (e.g. link layer status) will be routed through E-DMAC, so that masking E-DMAC interrupt by HDIEm bit of ETNAnHDMIERm also masks any E-MAC interrupt event enabled in ETNAnECSIPRm.

Table 21.88, List of ETNA Interrupts and detected statuses shows these three interrupts, interrupt sources, interrupt status registers and bits set at interrupt occurrence and interrupt generation timing.

Table 21.88 List of ETNA Interrupts and detected statuses (1/3)

Interrupt/ Status	Interrupt Source/Status	Register and Bit	Generation Timing
Transmit/ receive interrupt for port 0 (INTETNA0)	Write-back completed	ETNAnEESR0.TWB0	After write-back
	Receive overflow frame write-back completed	ETNAnEESR0.ROC0	After write-back
	Reception abort detection	ETNAnEESR0.RABT0	After write-back
	Receive frame counter overflow	ETNAnEESR0.RFCOF0	When the interrupt source is detected
	MAC status register source	ETNAnEESR0.ECI0	When the interrupt source is detected
	Frame transmission completed	ETNAnEESR0.TC0	After write-back
	Transmit descriptor empty	ETNAnEESR0.TDE0	When the interrupt source is detected
	Frame reception	ETNAnEESR0.FR0	After write-back
	Receive descriptor empty	ETNAnEESR0.RDE0	When the interrupt source is detected
	Receive FIFO overflow	ETNAnEESR0.RFOF0	When the interrupt source is detected
	Detect Loss of Carrier	ETNAnEESR0.DLC0	When the interrupt source is detected
	Delayed Collision Detect	ETNAnEESR0.CD0	When the interrupt source is detected
	Transmit Retry Over	ETNAnEESR0.TRO0	When the interrupt source is detected

Table 21.88 List of ETNA Interrupts and detected statuses (2/3)

Interrupt/ Status	Interrupt Source/Status	Register and Bit	Generation Timing
Transmit/ receive interrupt for port 0 (INTETNA0)	Receive Multicast Address Frame	ETNAnEESR0.RMAF0	After write-back
	Receive Residual-Bit Frame	ETNAnEESR0.RRF0	After write-back
	Receive Too-Long Frame	ETNAnEESR0.RTLF0	After write-back
	Receive Too-Short Frame	ETNAnEESR0.RTSF0	After write-back
	PHY-LSI Receive Error	ETNAnEESR0.PRE0	After write-back
	CRC Error on Received Frame	ETNAnEESR0.CERF0	After write-back
Transmit/ receive interrupt for port 1 (INTETNA1)	Write-Back Completed	ETNAnEESR1.TWB1	After write-back
	Receive Overflow Frame Write-Back Completed	ETNAnEESR1.ROC1	After write-back
	Receive Abort Detect	ETNAnEESR1.RABT1	After write-back
	Receive Frame Counter Overflow	ETNAnEESR1.RFCOF1	When the interrupt source is detected
	MAC1 Status Register Source	ETNAnEESR1.ECI1	When the interrupt source is detected
	Frame Transmission Completed	ETNAnEESR1.TC1	After write-back
	Transmit Descriptor Empty	ETNAnEESR1.TDE1	When the interrupt source is detected
	Frame Reception	ETNAnEESR1.FR1	After write-back
	Receive Descriptor Empty	ETNAnEESR1.RDE1	When the interrupt source is detected
	Receive FIFO Overflow	ETNAnEESR1.RFOF1	When the interrupt source is detected
	Detect Loss of Carrier	ETNAnEESR1.DLC1	When the interrupt source is detected
	Delayed Collision Detect	ETNAnEESR1.CD1	When the interrupt source is detected
	Transmit Retry Over	ETNAnEESR1.TRO1	When the interrupt source is detected
	Receive Multicast Address Frame	ETNAnEESR1.RMAF1	After write-back
	Receive Residual-Bit Frame	ETNAnEESR1.RRF1	After write-back
	Receive Too-Long Frame	ETNAnEESR1.RTLF1	After write-back
	Receive Too-Short Frame	ETNAnEESR1.RTSF1	After write-back
	PHY-LSI Receive Error	ETNAnEESR1.PRE1	After write-back
	CRC Error on Received Frame	ETNAnEESR1.CERF1	After write-back

Table 21.88 List of ETNA Interrupts and detected statuses (3/3)

Interrupt/ Status	Interrupt Source/Status	Register and Bit	Generation Timing
Detected status with transfer for TSU	MAC0 Residual-Bit Frame Receive	ETNAnTSU_FWSR.RINT50	When the interrupt source is detected
	MAC0 Too-Long Frame Receive	ETNAnTSU_FWSR.RINT40	When the interrupt source is detected
	MAC0 Too-Short Frame Receive	ETNAnTSU_FWSR.RINT30	When the interrupt source is detected
	MAC0 Frame Receive Error	ETNAnTSU_FWSR.RINT20	When the interrupt source is detected
	MAC0 CRC Error Frame Receive	ETNAnTSU_FWSR.RINT10	When the interrupt source is detected
	MAC1 Residual-Bit Frame Receive	ETNAnTSU_FWSR.RINT51	When the interrupt source is detected
	MAC1 Too-Long Frame Receive	ETNAnTSU_FWSR.RINT41	When the interrupt source is detected
	MAC1 Too-Short Frame Receive	ETNAnTSU_FWSR.RINT31	When the interrupt source is detected
	MAC1 Frame Receive Error	ETNAnTSU_FWSR.RINT21	When the interrupt source is detected
	MAC1 CRC Error Frame Receive	ETNAnTSU_FWSR.RINT11	When the interrupt source is detected

21.4.37 Activation Procedure

This Ethernet module should be activated by the following procedure:

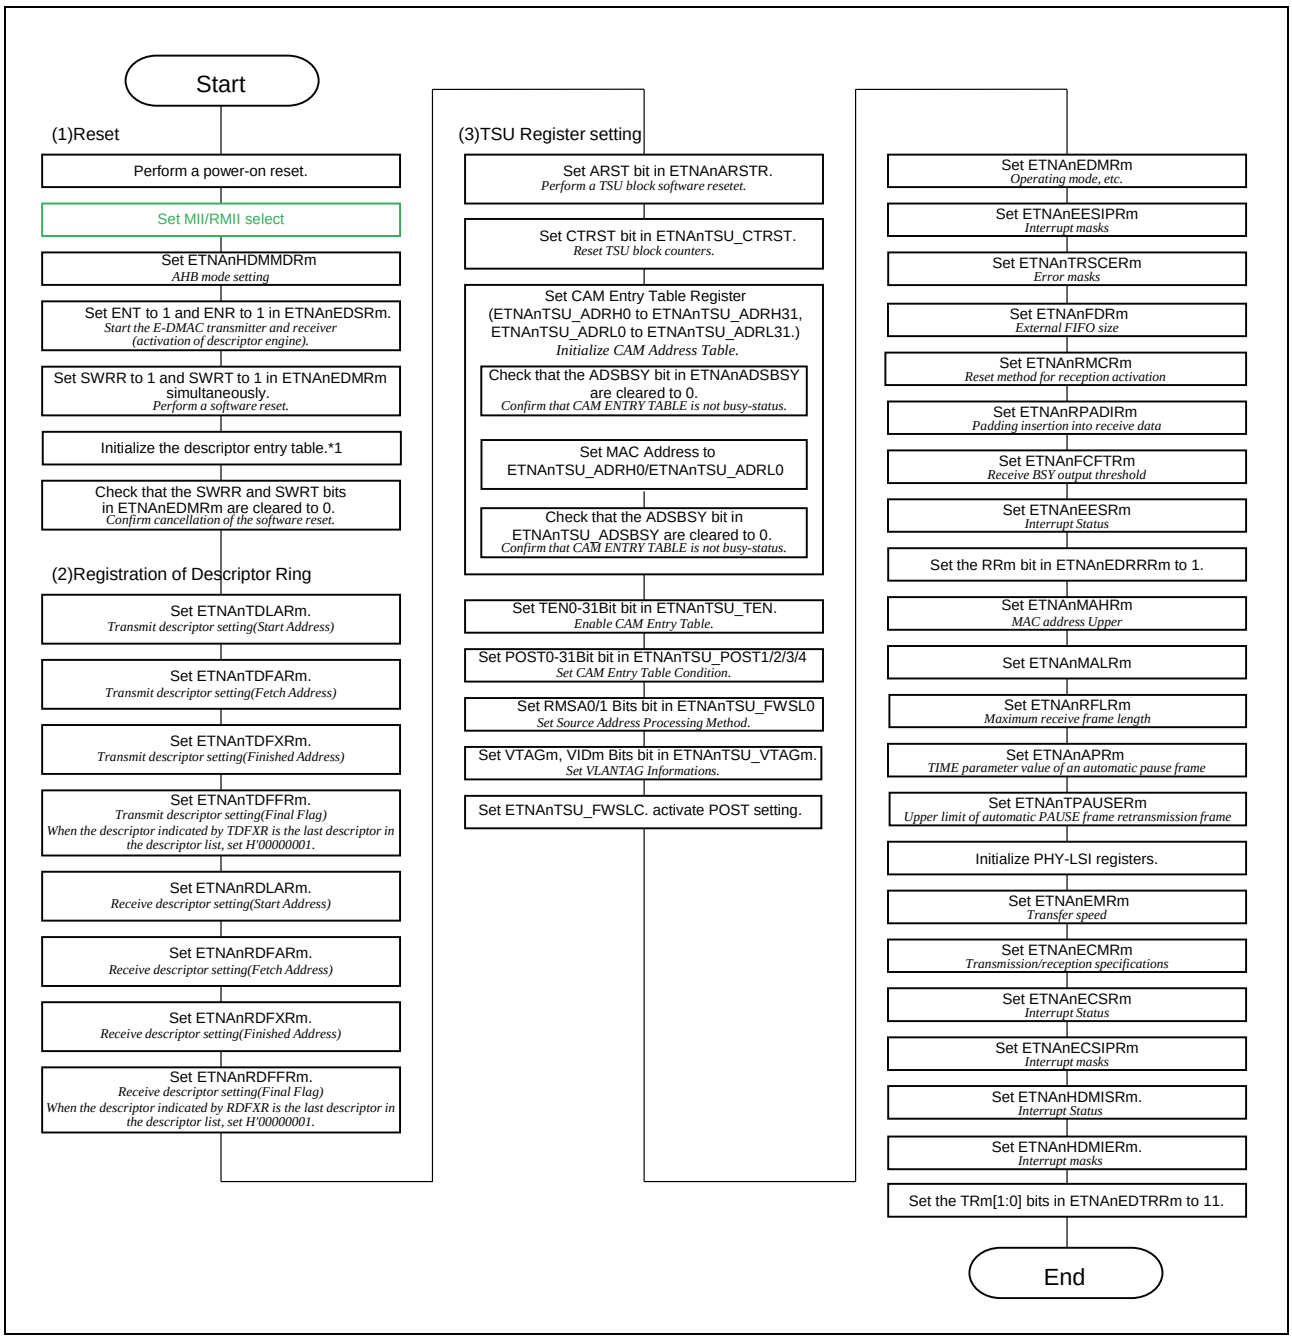

Figure 21.19 Transmit/Receive Start Procedure

Note 1. If the termination procedure which written in the next page is not conformed, the descriptor ring may be stopped halfway by unexpected write back which is caused by the transmission or the reception before the termination procedure.

21.4.38 Termination Procedure

The figure below shows the transmit/receive stop procedure.

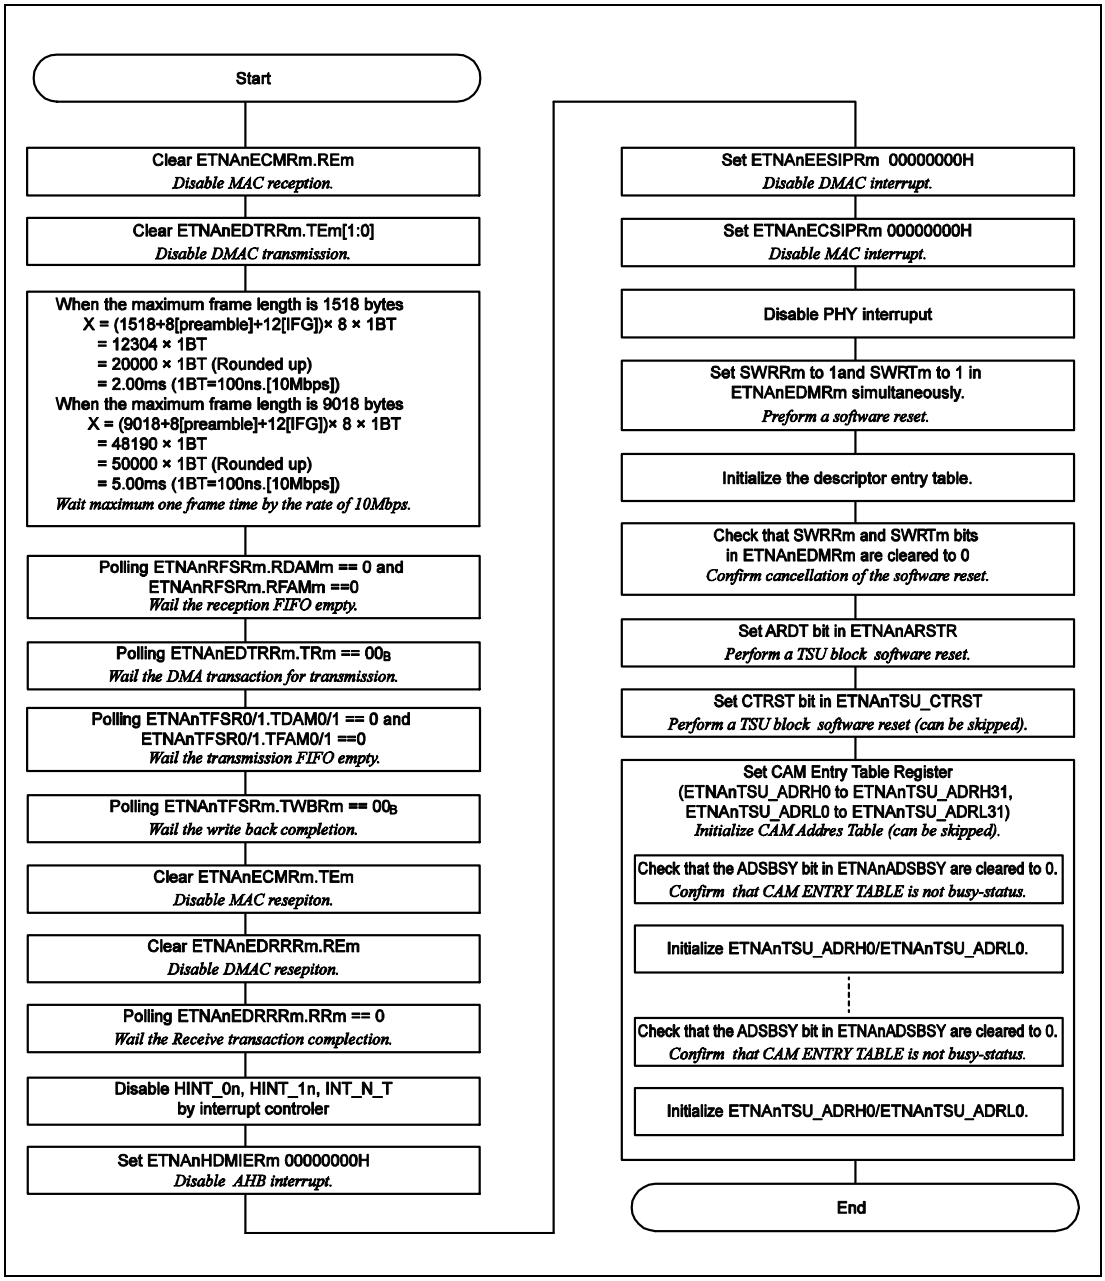

Figure 21.20 Transmit Stop Procedure

Even when a software reset for DMA transfer controller (E-DMAC) is issued, stop the transmission/ reception according to the procedure described above.

21.4.39 Flow Control

This Ethernet module supports flow control functions conforming to IEEE802.3x for full-duplex operation. The flow control can be applied to both receive and transmit operations. When transmitting PAUSE frames, flow control can be performed by the following two procedures.

21.4.40 Automatic PAUSE Frame Transmission

For receive frames, PAUSE frames are automatically transmitted when the number of data written to the receive FIFO reaches the value set in ETNAnFCFTRm. The TIME parameter included in the PAUSE frame is set by ETNAnAPRm. The automatic PAUSE frame transmission is repeated until the number of data in the receive FIFO becomes less than the value set in ETNAnFCFTRm as the receive data is read from the FIFO. Using ETNAnTPAUSERm, the upper limit of retransmission counts of the PAUSE frames can also be set in the range from 1 to 65535. In this case, PAUSE frame transmission is repeated until the number of receive FIFO data becomes less than the ETNAnFCFTRm value, or the number of transmits reaches the value set by ETNAnTPAUSERm. The transmission counter is cleared to 0 when the next PAUSE frame is transmitted after the number of data in the receive FIFO becomes less than the ETNAnFCFTRm value.

The automatic PAUSE frame transmission is enabled when the TXFm bit in ETNAnECMRm is 1.

21.4.41 Manual PAUSE Frame Transmission

PAUSE frames are transmitted by directives from the software. When writing the Timer value to ETNAnMPRm, manual PAUSE frame transmission is started. With this method, PAUSE frame transmission is carried out only once.

21.4.42 PAUSE Frame Reception

The next frame is not transmitted until the time indicated by the Timer value elapses after receiving a PAUSE frame. However, the transmission of the current frame is continued. A received PAUSE frame is valid only when the RXFm bit in ETNAnECMRm is set to 1. The number of times of PAUSE frame receptions is counted.

21.4.43 0-Time PAUSE Frame Control

Flow control is performed using a PAUSE frame with the TIME parameter value set to 0. The PAUSE frame with the TIME parameter set to 0 can be enabled or disabled by the ZPFm bit in ETNAnECMRm.

- When PAUSE frame control with the TIME parameter value set to 0 is enabled
  A PAUSE frame with the TIME parameter value set to 0 is transmitted when the number of data in the receive FIFO is less than the ETNAnFCFTRm value before the time indicated by the TIME parameter value has not elapsed. When a PAUSE frame with the time indicated by the TIME parameter value set to 0 is received, the transmit standby state is canceled.
- When PAUSE frame control with the TIME parameter value set to 0 is disabled
  A PAUSE frame with the TIME parameter value set to 0 is not transmitted. When a PAUSE frame with the TIME parameter value set to 0 is received, the PAUSE frame is discarded.

21.4.44 Back-Pressure Flow Control

Back-pressure mode is supported in half-duplex mode. In this mode, when the receive FIFO is full and can not be stored new frames, the following reception frame is forced to retry by the collision which is caused by dummy transmission of the Back Pressure.

21.4.45 Magic Packet Detection

This Ethernet module supports the Magic Packet format like shown below:

DESTINATION (6byte)	SOURCE (6byte)	MISC (2byte~)	FF FF FF FF FF FF	MAC_ADDR×16 (ETNAnMAHRm/LRm)	MISC (0byte~)	CRC (4byte)

This Ethernet module has a Magic Packet detection function. This function provides a Wake-On-LAN (WOL) facility that starts each peripheral device connected to a LAN from the host device or other source. This enables to construct a system in which a peripheral device receives a Magic Packet sent from the host device or other source, and starts itself. When the Magic Packet is detected, data is stored in the FIFO by the broadcast packet that has received data previously and the E-MAC is notified of the receiving status. To return to normal operation, the E-MAC, TSU and E-DMAC must be initialized by using ARSTm bit in ETNAnARSTR.

With a Magic Packet reception is performed regardless of the destination address in the frame header. Only in case the 16 times duplicated destination address contained in the Magic Packet Sequence matches the MAC address specified in the device, the CPU will be informed by the Magic Packet detection interrupt and the Wake-On-LAN (ETHmWOL) signal notifies that a Magic Packet has been detected. Further information on Magic Packets can be found in the technical documentation published by AMD Corporation.

The procedure for using the WOL function with this LSI is as follows.

1. Disable interrupt source output by means of the various interrupt enable/mask registers.
2. Set the MPDEm bit in ETNAnECMRm.
3. Set the MPDIP bit in ETNAnECSIPRm to the enable setting.
4. If necessary, set the chip operating mode to sleep mode or set peripheral modules to module standby mode.

When a Magic Packet is detected, an interrupt is sent to the system.

21.5 Connection to PHY-LSI

21.5.1 Accessing MII Registers

MII registers in the PHY-LSI are accessed via ETNAnPIRm. ETNAnPIRm is used as a serial interface conforming to the MII frame format specified in IEEE802.3u.

21.5.2 MII Management Frame Format

Figure 21.21 shows the format of an MII management frame. To access an MII register, a management frame is implemented by the program in accordance with the procedures shown in MII Register Access Procedure.

Access Type	MII Management Frame							
Item	PRE	ST	OP	PHYAD	REGAD	TA	DATA	IDLE
Bits	32	2	2	5	5	2	16	–
Read	1..1	01	10	00001	RRRRR	Z0	D...D	–
Write	1..1	01	01	00001	RRRRR	10	D...D	X

[Legend]
PRE: 32 consecutive 1
ST: Write of 01 indicating start of frame
OP: Write of code indicating access type
PHYAD: Write of 00001 when the PHY-LSI address is 1 (sequential write starting with the MSB)
The PHYAD bits vary with the PHY-LSI address.
REGAD: Write of 00001 when the register address is 1 (Sequential write starting with the MSB)
The REGAD bits vary with the PHY-LSI register address.
TA: Time for switching data transmission source on the MII interface
(a) Write: 10 written
(b) Read: Bus release [notation: Z0] performed
DATA: 16-bit data. Sequential write or read starting with the MSB
(a) Write: 16-bit data write
(b) Read: 16-bit data read
IDLE: Wait time until next MII management format input
(a) Write: Independent bus release [notation: X] performed
(b) Read: Bus already released at TA (control unnecessary)

Figure 21.21 MII Management Frame Format

21.5.3 MII Register Access Procedure

The program accesses MII registers via ETNAnPIRm. Access is implemented by a combination of 1-bit-unit data write, 1-bit-unit data read, bus release, and independent bus release. **Figure 21.22** shows the MII register access timing. The timing will differ depending on the PHY-LSI type.

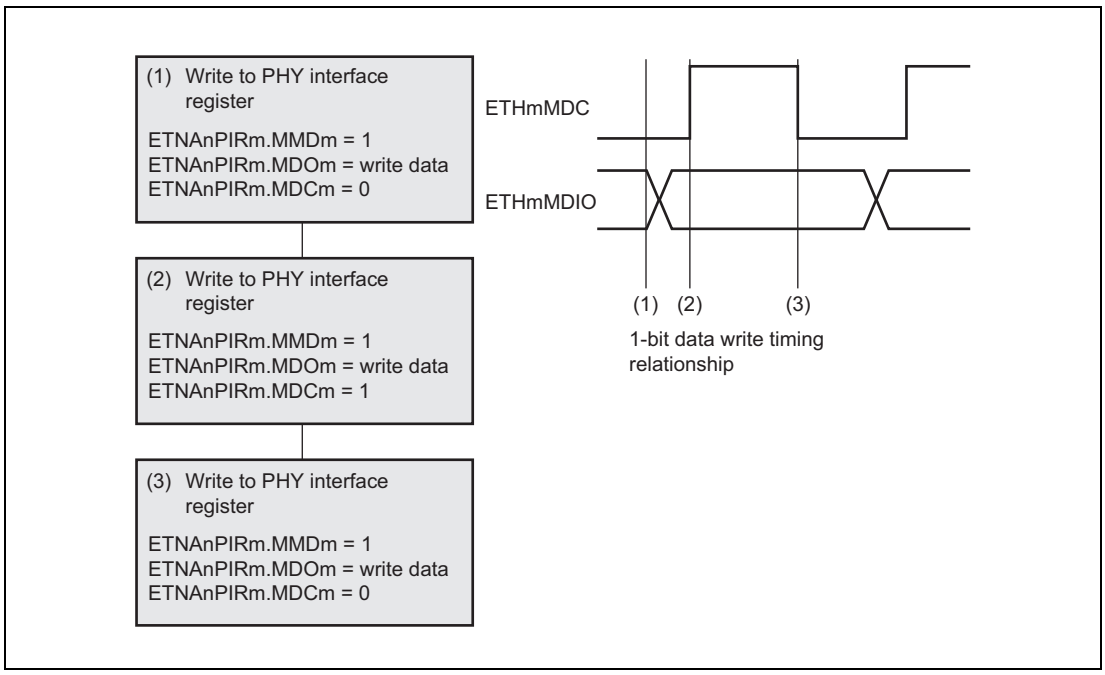

Figure 21.22 1-Bit Data Write Flowchart

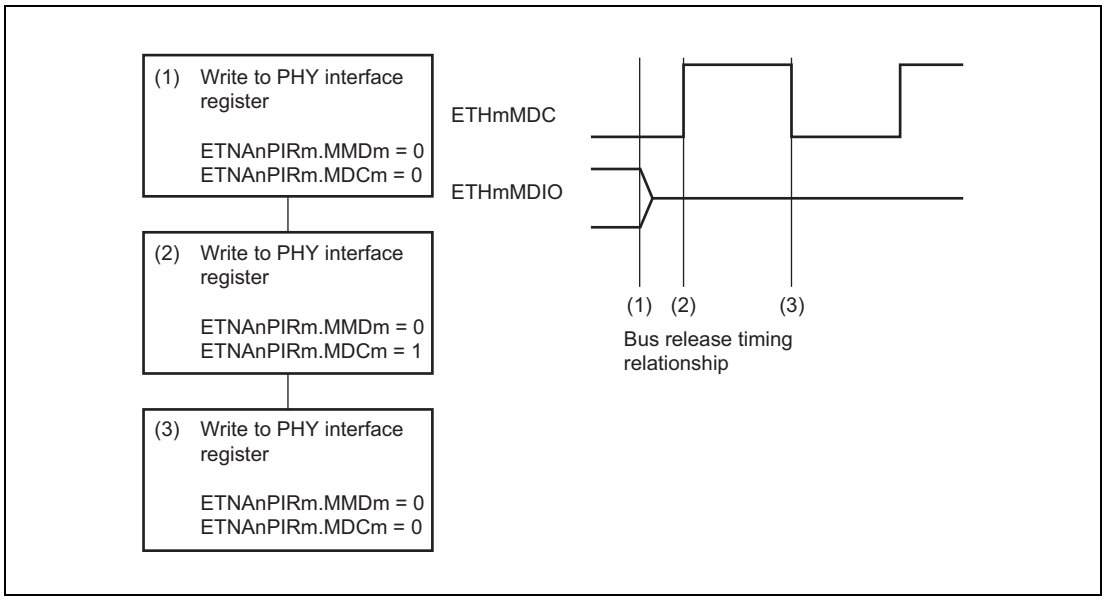

Figure 21.23 Bus Release Flowchart (TA in Read in Figure 21.21)

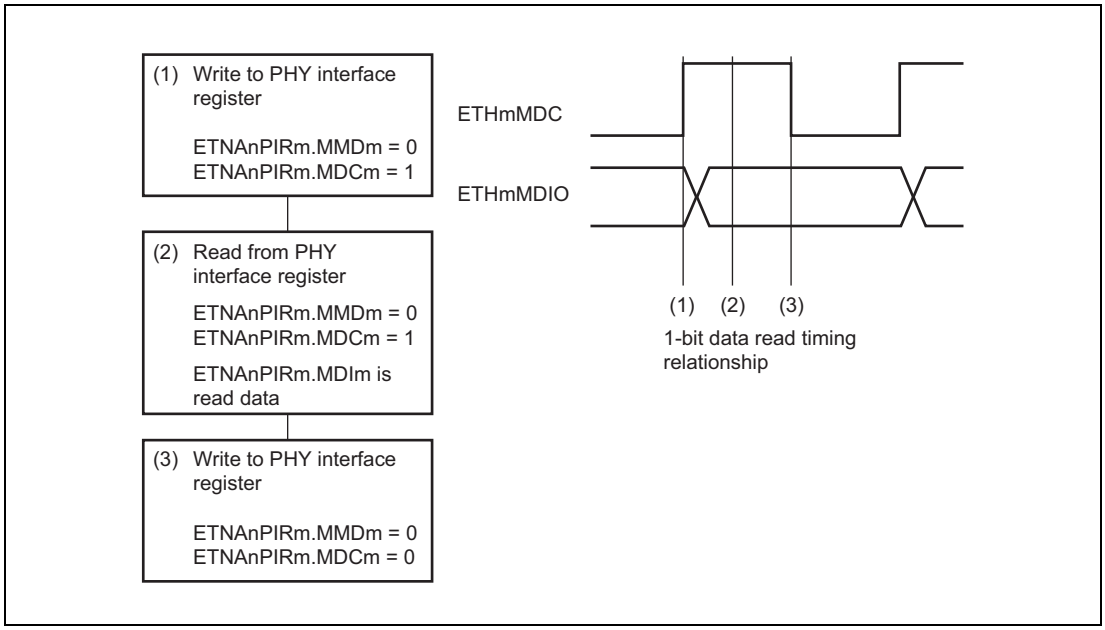

Figure 21.24 1-Bit Data Read Flowchart

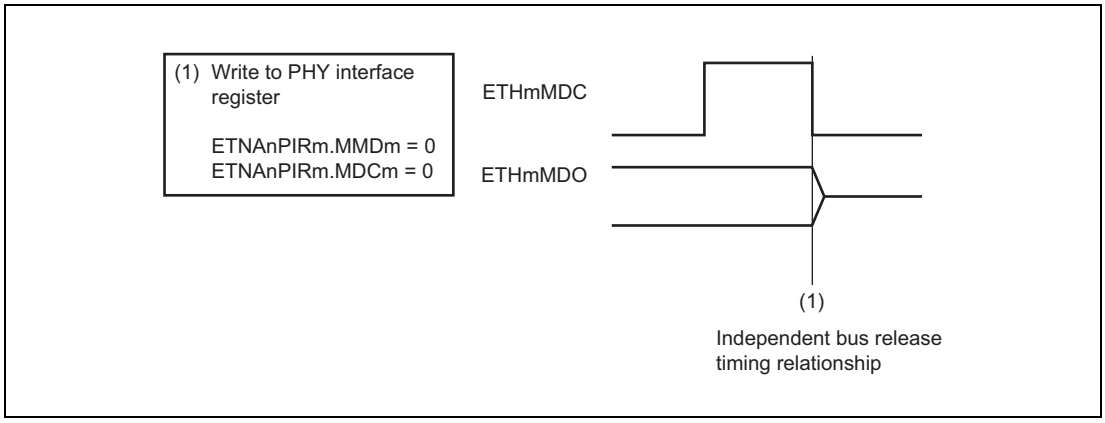

Figure 21.25 Independent Bus Release Flowchart (IDLE in Write in Figure 21.21)

21.6 Usage Notes

21.6.1 Checksum Calculation of Ethernet Frames

This LSI is capable of calculating the checksum data of the received frames. Only the data fields of the Ethernet frames are subject to calculation. Specifically, a data field follows the length/type field and is followed by the CRC field. Calculation involves 16-bit addition only; it does not involve bit reversal.

NOTE

Also for the frames with VLANTag inserted, the 15th byte from the top and the following bytes before the CRC field are subject to calculation.

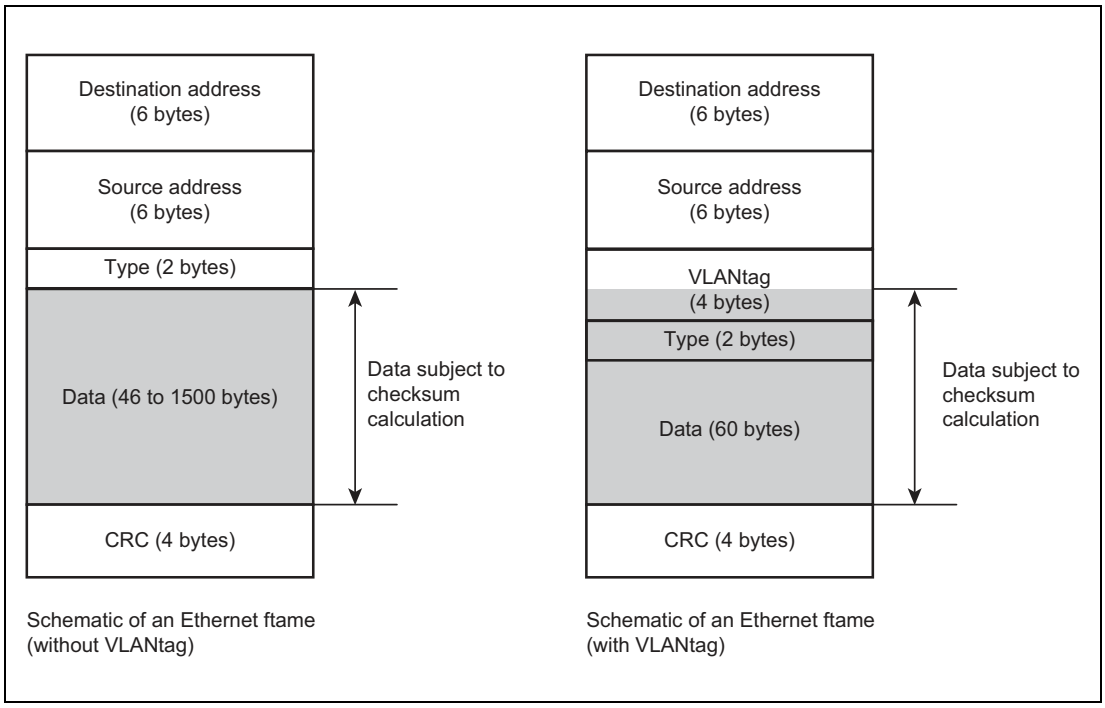

Figure 21.26 Data Subject to Checksum Calculation

21.7 Configuration of MII/RMII Mode

The bridge function of MII-to-RMII and RMII-to-MII is realized by converting the receive signal from RMII to MII and the transmit signal from MII to RMII by the MII2RMII block. The operation is performed in multiple different communication modes depending on the setting of the mode signal. **Table 21.89** lists the mode setting in each communication mode.

Table 21.89 Operation State in Each Communication Mode

Communication mode	I/F specifications	MII	RMII	RMII	RMII	RMII
	Communication rate	10 M/100 M	10 Mbps	10 Mbps	100 Mbps	100 Mbps
	Communication system	Full/half duplex	Half duplex	Full duiplex	Half duplex	Full duiplex
Register setting	ETNAnEDSRm.GPOm bit	0	1			
	ETNAnEMRm.SPEEDm1 bit	—	0		1	
	ETNAnECMRm.DMm bit	—	0	1	0	1

Section 22 Single Edge Nibble Transmission (SENT)

This section describes the Renesas single edge nibble transmission (RSENT) module.

The first subsection describes all the characteristics specific to the RH850/P1x-C such as channels, register base addresses, and input/output signal names.
The second and subsequent subsections describe characteristics common to of SENT.

22.1 RH850/P1x-C SENT Overview

22.1.1 Number of Channels

The RH850/P1x-C includes up to ten SENT channels.

Table 22.1 SENT Channels

	SENT
Number of Channels	n
Name	RSENTn

Index n

This section identifies each RSENT channel by “n” (n = 0 to 9). For example, the RSENT timestamp register is described as RSENTnTSPC.

Table 22.2 The number of channels in each product

Channel index	P1M-C (QFP, BGA-292)	P1M-C (BGA-156)	P1H-C (4MB, BGA-292)	P1H-C (4MB, BGA-156)	P1H-C (8MB)	P1H-CE
Channel number(n)	6 (0 to 5)	4 (0 to 3)	8 (0 to 7)	4 (0 to 3)	8 (0 to 7)	10 (0 to 9)

22.1.2 Register Addresses

RSENT register addresses are represented by an offset from the base address <RSENTn_base>.

The following table shows the base address <RSENTn_base> of each RSENT module.

Table 22.3 Register Base Address <RSENTn_base>

RSENTn Channel	<RSENTn_base> Address	P1M-C (QFP, BGA-292)	P1M-C (BGA-156)	P1H-C (4MB, BGA-292)	P1H-C (4MB, BGA-156)	P1H-C (8MB)	P1H-CE
RSENT0	FFCD C000$_H$	√	√	√	√	√	√
RSENT1	FFCD C100$_H$	√	√	√	√	√	√
RSENT2	FFCD C200$_H$	√	√	√	√	√	√
RSENT3	FFCD C300$_H$	√	√	√	√	√	√
RSENT4	FFCD C400$_H$	√	—	√	—	√	√
RSENT5	FFCD C500$_H$	√	—	√	—	√	√
RSENT6	FFCD C600$_H$	—	—	√	—	√	√
RSENT7	FFCD C700$_H$	—	—	√	—	√	√
RSENT8	FFCD C800$_H$	—	—	—	—	—	√
RSENT9	FFCD C900$_H$	—	—	—	—	—	√

22.1.3 Clock Supply

The following clock input is supplied for the RSENT module.

Table 22.4 Clock Supply

Unit Name	Clock for the Unit	Supply Clock Name
RSENTn	P-Bus interface clock (PCLK)	CLK_LSB
	RSENT communication clock(CLKC)	CLKP_H1

Note: CLK_LSB frequency can be in the range of 16MHz to 40MHz.
CLKP_H1 frequency can be either 16MHz or in the range of 32MHz to 80MHz.

For detail of clock supply, see **Section 12, Clock Controller**.

22.1.4 Interrupts and DMA requests

The RSENT module can generate the following interrupt requests.

Table 22.5 Interrupt Requests (1/2)

Unit Interrupt Name	Outline	Interrupt Number	DMA Trigger Number	DTS Trigger Number
RSENT0				
INTSENT0SI	RSENT status interrupt	208	—	—
INTSENT0RI	RSENT receive interrupt	209	98	108
RSENT1				
INTSENT1SI	RSENT status interrupt	210	—	—
INTSENT1RI	RSENT receive interrupt	211	99	109
RSENT2				
INTSENT2SI	RSENT status interrupt	212	—	—
INTSENT2RI	RSENT receive interrupt	213	100	110
RSENT3				
INTSENT3SI	RSENT status interrupt	214	—	—
INTSENT3RI	RSENT receive interrupt	215	101	111
RSENT4				
INTSENT4SI	RSENT status interrupt	216	—	—
INTSENT4RI	RSENT receive interrupt	217	102	112
RSENT5				
INTSENT5SI	RSENT status interrupt	218	—	—
INTSENT5RI	RSENT receive interrupt	219	103	113
RSENT6

INTSENT6RI	RSENT receive interrupt	221	104	114
RSENT7				
INTSENT7SI	RSENT status interrupt	222	—	—
INTSENT7RI	RSENT receive interrupt	223	105	115
RSENT8				
INTSENT8SI	RSENT status interrupt	224	—	—
INTSENT8RI	RSENT receive interrupt	225	106	116

Table 22.5 Interrupt Requests (2/2)

Unit Interrupt Name	Outline	Interrupt Number	DMA Trigger Number	DTS Trigger Number
RSENT9				
INTSENT9SI	RSENT status interrupt	226	—	—
INTSENT9RI	RSENT receive interrupt	227	107	117

22.1.5 RSENT Hardware Reset

The RSENT module and its registers are initialized by the following reset signal.

Table 22.6 Register Reset Condition

		Reset Condition				
Unit Name	Register Name	Power On Reset	System Reset 1	System Reset 2	Application Reset 1	Limited Reset
RSENTn	All registers	√	√	√	√	√

Note: See **Section 8, Reset Controller**.
And RSENTn have RESET mode, see **Section 22.4.1.1, RESET Mode**.

22.1.6 External Input/Output Signals

The following table shows the RSENT input/output signals.

Table 22.7 RSENTn Input/Output Signals

RSENTn Signal	Function	Connected to
RSENT0		
sent_rx	RSENT data input	Port SENT0RX
sent_spc	RSENT SPC extension output	Port SENT0SPCO
RSENT1		
sent_rx	RSENT data input	Port SENT1RX
sent_spc	RSENT SPC extension output	Port SENT1SPCO
RSENT2		
sent_rx	RSENT data input	Port SENT2RX
sent_spc	RSENT SPC extension output	Port SENT2SPCO
RSENT3		
sent_rx	RSENT data input	Port SENT3RX
sent_spc	RSENT SPC extension output	Port SENT3SPCO
RSENT4		
sent_rx	RSENT data input	Port SENT4RX
sent_spc	RSENT SPC extension output	Port SENT4SPCO
RSENT5		
sent_rx	RSENT data input	Port SENT5RX
sent_spc	RSENT SPC extension output	Port SENT5SPCO
RSENT6		
sent_rx	RSENT data input	Port SENT6RX
sent_spc	RSENT SPC extension output	Port SENT6SPCO
RSENT7		
sent_rx	RSENT data input	Port SENT7RX
sent_spc	RSENT SPC extension output	Port SENT7SPCO
RSENT8		
sent_rx	RSENT data input	Port SENT8RX
sent_spc	RSENT SPC extension output	Port SENT8SPCO
RSENT9		
sent_rx	RSENT data input	Port SENT9RX
sent_spc	RSENT SPC extension output	Port SENT9SPCO

22.2 Overview

Overview of Functions

The RSENT interface supports the following standard specification (SAE J2716 version JAN2010) functions:

- Triple speed expansion Tick Time: Clock cycle (1 µs to 90 µs)
- Variable data transmission rate
  - 24.7 kbps to 64.9 kbps: 3 µs clock rate 6 nibble data
  - 74.1 kbps to 194.8 kbps: 1 µs clock rate 6 nibble data
- Unidirectional communication: Between the sensor and MCU
- Bidirectional communication: Between the sensor and MCU (supported in SPC mode)
- Single edge data transmission: Coded by the temporal distance of two serially-detected falling edges on a data line
- Transmission frame with up to 6 data nibbles and additional status and communication nibble
- Data transmission protected with CRC is available.
  - CRC data can be read with the RSENTnSRXD.SCRC and RSENTnFRXD.FCRC bits.
- Calibration phase in each data frame (RSENTnCPL.CPLV bits)
- Multiple sensors can be connected to one RSENT channel by means of the SPC function.
- Interrupt functions: Receive interrupt and status interrupt.
- DMA function: Receive interrupt is used for DMA trigger
  (DMA line is same as receive interrupt line.)
- The timestamp function: Master or slave can be selected for the RSENT module. (RSENTnTSPC.TMS bit)

Each RSENT macro consists of one RSENT channel.

Each time stamp counter of the macros can run independently, or in order to synchronise the timestamp across multiple channels, one instance can be set as master and reset the configured consecutive time stamp counters. Depending on the total number of instances, more than one master-slave(s) pairs can be configured.

Each RSENT macro supports below requirements in addition to SAE J2716 specification of JAN2010:

R1: 32-Bit-Register for serial sensor data (24Bit + CRC6 + READ-Bit)

R2: Includes comparator for sensor data evaluation

R3: CRC check of received sensor data implemented but CRC code transparent

R4: 32-Bit counter for time stamp (resolution: 1µs)

R5: clock ticks down to 1µs

R6: SPC (Short PWM Code) extension

- Enables bidirectional communication channel
- Master can pull down the signal to initiate SENT message

- The RSENT circuit consists of the following functions:
  - Data receive part
  - Clock recovery
  - Register group

22.2.1 Block Diagram

The following figure shows a block diagram of the RSENT module.

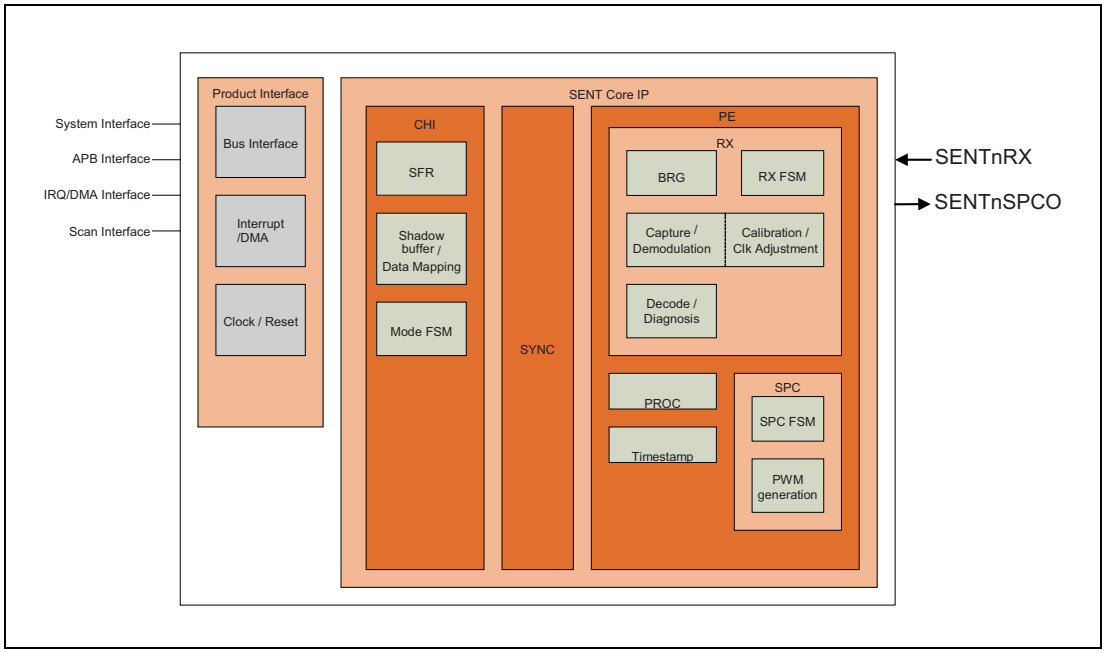

Figure 22.1 Block Diagram of RSENT

22.3 Registers

RSENTn is controlled and operated by the following registers.

Table 22.8 Overview of RSENTn Registers

Register Name	Abbreviation	Address	Access Protection	
			PBG	Other
RSENT timestamp register	RSENTnTSPC	<RSENTn_base> + 0000_H	PBG4#1.PG4-SENT	—
RSENT timestamp counter	RSENTnTSC	<RSENTn_base> + 0004_H	PBG4#1.PG4-SENT	—
RSENT communication configuration register	RSENTnCC	<RSENTn_base> + 0010_H	PBG4#1.PG4-SENT	—
RSENT baud rate prescaler register	RSENTnBRP	<RSENTn_base> + 0014_H	PBG4#1.PG4-SENT	—
RSENT interrupt/DMA enable register	RSENTnIDE	<RSENTn_base> + 0018_H	PBG4#1.PG4-SENT	—
RSENT mode control register	RSENTnMDC	<RSENTn_base> + $001C_H$	PBG4#1.PG4-SENT	—
RSENT SPC transmission register	RSENTnSPCT	<RSENTn_base> + 0020_H	PBG4#1.PG4-SENT	—
RSENT mode status register	RSENTnMST	<RSENTn_base> + 0024_H	PBG4#1.PG4-SENT	—
RSENT communication status register	RSENTnCS	<RSENTn_base> + 0028_H	PBG4#1.PG4-SENT	—
RSENT communication status clear register	RSENTnCSC	<RSENTn_base> + $002C_H$	PBG4#1.PG4-SENT	—
RSENT slow channel receive timestamp register	RSENTnSRTS	<RSENTn_base> + 0030_H	PBG4#1.PG4-SENT	—
RSENT slow channel receive data register	RSENTnSRXD	<RSENTn_base> + 0034_H	PBG4#1.PG4-SENT	—
RSENT calibration pulse length register	RSENTnCPL	<RSENTn_base> + 0038_H	PBG4#1.PG4-SENT	—
RSENT message length register	RSENTnML	<RSENTn_base> + $003C_H$	PBG4#1.PG4-SENT	—
RSENT fast channel receive timestamp register	RSENTnFRTS	<RSENTn_base> + 0040_H	PBG4#1.PG4-SENT	—
RSENT fast channel receive data register	RSENTnFRXD	<RSENTn_base> + 0044_H	PBG4#1.PG4-SENT	—
RSENT0 timestamp mode selection register	RSENT0TSSEL	$FFCDCF00_H$	PBG4#1.PG4-SENT	—
RSENT1 timestamp mode selection register	RSENT1TSSEL	$FFCDCF04_H$	PBG4#1.PG4-SENT	—
RSENT2 timestamp mode selection register	RSENT2TSSEL	$FFCDCF08_H$	PBG4#1.PG4-SENT	—
RSENT3 timestamp mode selection register	RSENT3TSSEL	$FFCDCF0C_H$	PBG4#1.PG4-SENT	—
RSENT4 timestamp mode selection register	RSENT4TSSEL	$FFCDCF10_H$	PBG4#1.PG4-SENT	—
RSENT5 timestamp mode selection register	RSENT5TSSEL	$FFCDCF14_H$	PBG4#1.PG4-SENT	—
RSENT6 timestamp mode selection register	RSENT6TSSEL	$FFCDCF18_H$	PBG4#1.PG4-SENT	—
RSENT7 timestamp mode selection register	RSENT7TSSEL	$FFCDCF1C_H$	PBG4#1.PG4-SENT	—
RSENT8 timestamp mode selection register	RSENT8TSSEL	$FFCDCF20_H$	PBG4#1.PG4-SENT	—
RSENT9 timestamp mode selection register	RSENT9TSSEL	$FFCDCF24_H$	PBG4#1.PG4-SENT	—

<RSENTn_base>

The base address <RSENTn_base> of RSENTn is defined by the keywords in **Table 22.3, Register Base Address <RSENTn_base>**.

22.3.1 RSENTnTSPC — RSENT Timestamp Register

Access: This register can be read/written in 32-bit units.

Address: <RSENTn_base> + 0000_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TMS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	TTM[6:0]							—	TTPV[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 22.9 RSENTnTSPC register contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is read. When writing, write the value after reset.
16	TMS	Timestamp Mode Selection 0: Master mode 1: Slave mode
15	Reserved	When read, the value after reset is read. When writing, write the value after reset.
14 to 8	TTM[6:0]	Timestamp Tick Multiplier 0000000_B: 1 0000001_B: 2 0000010_B: 3 : 1111111_B: 128
7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 0	TTPV[6:0]	Timestamp Tick Prescaler Value 0000000_B: 1 0000001_B: 2 0000010_B: 3 : 1111111_B: 128

RSENTnTSPC.TMS (Timestamp Mode Selection)

This bit defines the timestamp counter synchronization mode.

For information about the timestamp clock settings, see **Section 22.4.2.1, Timestamp**.

When this bit is set to 0, the timestamp counter operates in master mode.

When writing $0000\ 0000_H$ to RSENTnTSC, the timestamp counter is cleared. In addition all RSENT timestamp counters operating as slave of RSENT are also cleared. For master-slave interconnection, see **Section 22.4.2.1(2), Timestamp Counter Operation**.

When this bit is set to 1, the timestamp counter operates in slave mode.

The timestamp counter is only cleared when writing $0000\ 0000_H$ to the timestamp counter of RSENT module that operates in master mode.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001).

The RSENT module operating in slave mode should have the same timestamp counter prescaler settings as the RSENT module that operates in master mode.

The CPU should not set this bit to 1 for RSENT module that operates in master mode.

RSENTnTSPC.TTM (Timestamp Tick Multiplier)

These bits define the multiplication value of the 1-µs time tick used for the timestamp counter.

For timestamp clock configuration, see **Section 22.4.2.1, Timestamp**.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001).

RSENTnTSPC.TTPV (Timestamp Tick Prescaler Value)

These bits define the prescaler value to generate a 1-µs clock tick.

For timestamp clock configuration, see **Section 22.4.2.1, Timestamp**.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001).

The CPU should configure this value in such a way that, based on the supplied communication clock, a 1-µs clock tick is generated.

22.3.2 RSENTnTSC — RSENT Timestamp Counter

Access: This register can be read/written in 32-bit units.

Address: <RSENTn_base> + 0004_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TS[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TS[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 22.10 RSENTnTSC register contents

Bit Position	Bit Name	Function
31 to 0	TS[31:0]	Timestamp counter value

RSENTnTSC.TS (Timestamp)

These bits indicate the current timestamp counter value.

The CPU can write to these bits values other than $0000\ 0000_H$ only if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001).Even if any value is written in these bits, these bits are initialized.

When the timestamp counter is configured to operate in slave mode (RSENTnTSPC.TMS = 1), writing to this register has no effect when the RSENT module is in either of the OPERATION IDLE or OPERATION ACTIVE modes (the RSENTnMST.OMS bits are either 011 or 101).

The timestamp counter is incremented on every timestamp counter tick (as configured in the RSENTnTSPC.TTPV and RSENTnTSPC.TTM bits) when the RSENT module is in either of the OPERATION IDLE or OPERATION ACTIVE modes (the RSENTnMST.OMS bits are either 011 or 101).

When the timestamp counter is configured to operate in master mode (RSENTnTSPC.TMS = 0), the CPU writes $0000\ 0000_H$ to these bits and RSENTnTSC.TS is set to $0000\ 0000_H$.

When the timestamp counter is configured to operate in slave mode (RSENTnTSPC.TMS = 1), the CPU writes $0000\ 0000_H$ to the RSENTnTSC.TS bits of RSENT module that operates in master mode and the RSENTnTSC.TS bits are set to $0000\ 0000_H$.

22.3.3 RSENTnCC — RSENT Communication Configuration Register

Access: This register can be read/written in 32-bit units.

Address: <RSENTn_base> + 0010_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	SOPC	FCM	SCCD	FCCD	DFC	SMF[1:0]		PPTC	PPC	NDN[2:0]			SPCE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 22.11 RSENTnCC register contents (1/2)

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset is read. When writing, write the value after reset.
12	SOPC	SPC Output Polarity Control 0: SPC pulse active high 1: SPC pulse active low
11	FCM	Frame Check Method 0: Check against next calibration pulse 1: Check against previous calibration pulse
10	SCCD	Slow Channel CRC Check 0: Slow channel CRC check enabled 1: Slow channel CRC check disabled
9	FCCD	Fast Channel CRC Check 0: Fast channel CRC check enabled 1: Fast channel CRC check disabled
8	DCF	Data nibble CRC Format 0: SAE J2716 2010 format 1: pre SAE J2716 2010 format
7, 6	SMF	Serial Message Format 00: No serial message extraction 01: Short serial message format 10: Enhanced serial message format 11: Setting prohibited
5	PPTC	Pause Pulse Type Configuration 0: Pause pulse for variable message length 1: Pause pulse for fixed message length
4	PPC	Pause Pulse Configuration 0: Pause pulse absent 1: Pause pulse present
3 to 1	NDN[2:0]	Number of Data Nibbles 000: 1 data nibble 001: 2 data nibbles 010: 3 data nibbles 011: 4 data nibbles 100: 5 data nibbles 101: 6 data nibbles Other than above: Setting prohibited

Table 22.11 RSENTnCC register contents (2/2)

Bit Position	Bit Name	Function
0	SPEC	SPC Mode Enable 0: SPC mode disabled 1: SPC mode enabled

RSENTnCC.SOPC (SPC Output Polarity Control)

When this bit is set to 0, the SPC pulse is sent as an active high signal. The default output value is low level.

When this bit is set to 1, the SPC pulse is sent as an active low signal. The default output value is high level.

For SPC operation, see also **Section 22.4.4, SPC Function**.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001).

NOTE

Any change to this bit from the default value becomes effective on the output value when entering the OPERATION_ACTIVE mode (MST.OMS is 3'b101). When entering RESET mode (MST.OMS is 3'b000), the output level is set to the default value (low level).

RSENTnCC.FCM (Frame Check Method)

When this bit is set to 0, the current calibration pulse is compared to the next received calibration pulse.

The buffer update mechanism is operating according to the preferred option as described in SAE J2716 2010.

When this bit is set to 1, the current calibration pulse is compared to the previously received calibration pulse.

The buffer update mechanism is operating according to the second option as described in SAE J2716 2010 which should be only used if extra latency to process the second calibration pulse cannot be tolerated.

For buffer update timings, see also **Section 22.4.3.2(3), Fast Channel Message Reception**.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001).

RSENTnCC.SCCD (Slow Channel CRC Check Disable)

When this bit is set to 1, the CRC check for the slow channel is disabled. In this case, messages are stored in the slow channel message buffer with the received CRC.

When this bit is set to 1, the RSENTnCS.SCS bit is not set.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001).

RSENTnCC.FCCD (Fast Channel CRC Check Disable)

When this bit is set to 1, the CRC check for the fast channel is disabled. In this case, messages are stored in the fast channel message buffer with the received CRC.

When this bit is set to 1, the RSENTnCS.FCS bit is not set.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001).

RSENTnCC.DCF (Data nibble CRC Format)

This bit selects between the SAE J2716 2010 data nibble CRC format and the legacy format.

When this bit is set to 0 the recommended CRC implementation according to SAE J2716 2010 section 5.4.2.2 is selected.

When this bit is set to 1 the legacy CRC implementation according to SAE J2716 2008 is selected.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (RSENTnMST.OMS = 001_B)

RSENTnCC.SMF (Serial Message Format)

These bits define the serial message format expected to be received for automatic extraction.

When these bits are set to 00, no serial message is extracted and the status and communication nibble are provided in the RSENTnSRXD register.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001).

The CPU shall set these bits to 00 when RSENTnCC.SPCE is set to 1 and more than one sensor is connected to the RSENT module.

RSENTnCC.PPTC (Pause Pulse Type Configuration)

This bit defines the pause pulse type.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

The CPU should not set this bit to 1 when the RSENTnCC.PPC bit is set to 0.

RSENTnCC.PPC (Pause Pulse Configuration)

This bit defines the presence or absence of the pause pulse.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnCC.NDN (Number of Data Nibbles)

These bits define the number of data nibbles included in an SENT message.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnCC.SPCE (SPC Mode Enable)

This bit enables the SPC mode.

For details about SPC mode operation, see also **Section 22.4.4, SPC Function**.

The CPU can only write to this bit if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

22.3.4 RSENTnBRP — RSENT Baud Rate Prescaler Register

Access: This register can be read/written in 32-bit units.

Address: <RSENTn_base> + 0014_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	TTF[3:0]				—	TTI[6:0]

R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 22.12 BRP register contents

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the value after reset is read. When writing, write the value after reset.
27 to 24	TTF[3:0]	Time Tick Fraction 0000: 0.0 µs 0001: 0.1 µs 0010: 0.2 µs : 1000: 0.8 µs 1001: 0.9 µs Other than above: Setting prohibited
23	Reserved	When read, the value after reset is read. When writing, write the value after reset.
22 to 16	TTI[6:0]	Time Tick Integer 0000000: 1 µs 0000001: 2 µs 0000010: 3 µs : 1011000: 89 µs 1011001: 90 µs Other than above: Setting prohibited
15	Reserved	When read, the value after reset is read. When writing, write the value after reset.
14 to 8	SCDV[6:0]	Sample Clock Division Value 0000100: 5 Other than above: Setting prohibited
7 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	SCMV[3:0]	Sample Clock Multiplication Value 0000: 1 Other than above: Setting prohibited

RSENTnBRP.TTF (Time Tick Fraction)

These bits define the fractional part of the tick length in 0.1-µs granularity.

For tick length configuration, see **Section 22.4.2.2(2) RX and SPC Tick Settings**.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnBRP.TTI (Time Tick Integer)

These bits define the integer part of the tick length.

For tick length configuration, see **Section 22.4.2.2(2) RX and SPC Tick Settings**.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnBRP.SCDV (Sample Clock Division Value)

These bits define the division value for the sample clock generation logic.

For RSENTnBRP settings, see **Section 22.4.2.2(1) RX BRP Setting**.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

RSENTnBRP.SCMV (Sample Clock Multiplication Value)

These bits define the multiplication value for the sample clock generation logic.

For RSENTnBRP settings, see **Section 22.4.2.2(1) RX BRP Setting**.

The CPU can only write to these bits if the RSENT module is in the CONFIGURATION mode (the RSENTnMST.OMS bits are 001_B).

22.3.5 RSENTnIDE — RSENT Interrupt/DMA Enable Register

Access: This register can be read/written in 32-bit units.

Address: <RSENTn_base> + 0018_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	SEIE	SMIE	SCIE	NRIE	CVIE	CLIE	FNIE	FEIE	FMIE	FCIE	FRIE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 22.13 RSENTnIDE register contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is read. When writing, write the value after reset.
10	SEIE	Slow Channel Encoding Error Interrupt Control 0: Interrupt disabled 1: Interrupt enabled
9	SMIE	Slow Channel Message Lost Interrupt Control 0: Interrupt disabled 1: Interrupt enabled
8	SCIE	Slow Channel CRC Error Interrupt Control 0: Interrupt disabled 1: Interrupt enabled
7	NRIE	No Response Error Interrupt Control 0: Interrupt disabled 1: Interrupt enabled
6	CVIE	Calibration Pulse Length Variation Error Interrupt Control 0: Interrupt disabled 1: Interrupt enabled
5	CLIE	Calibration Pulse Length Error Interrupt Control 0: Interrupt disabled 1: Interrupt enabled
4	FNIE	Fast Channel Nibble Count Error Interrupt Control 0: Interrupt disabled 1: Interrupt enabled
3	FEIE	Fast Channel Nibble Encoding Error Interrupt Control 0: Interrupt disabled 1: Interrupt enabled
2	FMIE	Fast Channel Message Lost Interrupt Control 0: Interrupt disabled 1: Interrupt enabled
1	FCIE	Fast Channel CRC Error Interrupt Control 0: Interrupt disabled 1: Interrupt enabled
0	FRIE	Fast Channel Receive Interrupt Control 0: Interrupt disabled 1: Interrupt enabled

RSENTnIDE.SEIE (Slow Channel Encoding Error Interrupt Control)

This bit enables the generation of the slow channel encoding error interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.SMIE (Slow Channel Message Lost Interrupt Control)

This bit enables the generation of the slow channel message lost interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.SCIE (Slow Channel CRC Error Interrupt Control)

This bit enables the generation of the slow channel CRC error interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.NRIE (No Response Error Interrupt Control)

This bit enables the generation of the no response error interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

The CPU should not set this bit when the SPC mode is disabled (RSENTnCC.SPCE set to 0).

RSENTnIDE.CVIE (Calibration Pulse Length Variation Error Interrupt Control)

This bit enables the generation of the calibration pulse length variation error interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.CLIE (Calibration Pulse Length Error Interrupt Control)

This bit enables the generation of the calibration pulse length error interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the SENTnMST.OMS bits are 000_B).

RSENTnIDE.FNIE (Fast Channel Nibble Count Error Interrupt Control)

This bit enables the generation of the fast channel nibble count error interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.FEIE (Fast Channel Nibble Encoding Error Interrupt Control)

This bit enables the generation of the fast channel nibble encoding error interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the SENTnMST.OMS bits are 000_B).

RSENTnIDE.FMIE (Fast Channel Message Lost Interrupt Control)

This bit enables the generation of the fast channel message lost interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the SENTnMST.OMS bits are 000_B).

RSENTnIDE.FCIE (Fast Channel CRC Error Interrupt Control)

This bit enables the generation of the fast channel CRC error interrupt.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

RSENTnIDE.FRIE (Fast Channel Receive Interrupt Control)

This bit enables the generation of the fast channel receive interrupt.

The fast channel receive interrupt can be also used to notify a DMA request.

The CPU cannot write to this bit if the RSENT module is in the RESET mode (the RSENTnMST.OMS bits are 000_B).

22.3.6 RSENTnMDC — RSENT Mode Control Register

Access: This register can be read/written in 32-bit units.

Address: <RSENTn_base> + $001C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	OMC[2:0]		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 22.14 RSENTnMDC register contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2 to 0	OMC[2:0]	Operation Mode Control 000: RESET 001: CONFIGURATION 011: OPERATION IDLE 101: OPERATION ACTIVE Other than above: Setting prohibited

RSENTnMDC.OMC (Operation Mode Control)

These bits are used to control the operation mode of the RSENT module.

- 000: RESET

  In RESET mode, the mode can only be changed to CONFIGURATION mode.

- 001: CONFIGURATION

  In CONFIGURATION mode, the mode can only be changed to RESET mode or OPERATION ACTIVE mode.

- 011: OPERATION IDLE

  In OPERATION IDLE mode, the mode can be changed to OPERATION ACTIVE mode, CONFIGURATION mode, or RESET mode.

- 101: OPERATION ACTIVE

  In OPERATION ACTIVE mode, the mode can be changed to OPERATION IDLE mode, CONFIGURATION mode, or RESET mode. However, it is recommended to process to the OPERATION IDLE mode first.

  For the recommended methods to change between operation modes, see **Section 22.4.3.1, Changing Operation Modes**.

- Other than above: Setting prohibited

The CPU should not write any other value than listed above into this register.
The CPU should follow the mode change flows as shown in section **Section 22.4.3.1, Changing Operation Modes**.

NOTE

When the CPU is requesting a not supported mode change, writing to this register has no effect.

22.3.7 RSENTnSPCT — RSENT SPC Transmission Register

Access: This register can be read/written in 32-bit units.

Address: <RSENTn_base> + 0020_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	TLL[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 22.15 RSENTnSPCT register contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 0	TLL[6:0]	Length of the Trigger Low Phase in Ticks 0000000: 1 tick 0000001: 2 ticks 0000010: 3 ticks : 1111110: 127 ticks 1111111: 128 ticks

RSENTnSPCT.TLL (Trigger Low Length)

These bits define the length of the SPC trigger pulse.

When the CPU writes to these bits, an SPC trigger pulse with the configured length is sent starting from the next SPC trigger tick. In case RSENTnCS.NRS is set by the RSENT module following a write to these bits, noSPC trigger pulse is sent..

For details about SPC communication, see **Section 22.4.4, SPC Function**.

The CPU can only write to these bits if the RSENT module is in the OPERATION ACTIVE mode (the RSENTnMST.OMS bits are 101_B) and SPC communication is enabled (RSENTnCC.SPCE is 1_B).

It is important to note that two consecutive write access might not cause a no response error as the previous request might not have started yet.

After writing to this register, the CPU should wait for at least one SPC trigger tick before writing again to this register.

22.3.8 RSENTnMST — RSENT Mode Status Register

Access: This register is read-only in 32-bit units.

Address: <RSENTn_base> + 0024_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	OMS[2:0]		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 22.16 RSENTnMST register contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is read.
2 to 0	OMS[2:0]	Operation Mode Status 000: RESET 001: CONFIGURATION 011: OPERATION IDLE 101: OPERATION ACTIVE Other than above: Reserved

RSENTnMST.OMS (Operation Mode Status)

These bits indicate the current operation mode.

These bits are read only.

These bits are updated after a mode change request is made in the RSENTnMDC.OMC register.

- 000: RESET mode

  When in RESET mode, all registers are set to their reset values and write access to all registers except the RSENTnMDC register is disabled.
  When in RESET mode, RSENT communication is disabled.

- 001: CONFIGURATION mode

  When in CONFIGURATION mode, write access to the timestamp registers (RSENTnTSPC and RSENTnTSC register), configuration registers (RSENTnCC and RSENTnBRP register), RSENTnIDE register, and mode control register (RSENTnMDC.OMC) is enabled.
  When in CONFIGURATION mode, RSENT communication is disabled.
  When entering CONFIGURATION mode, all status registers and receive buffer registers are set to their reset values.

- 011: OPERATION IDLE mode

  In OPERATION IDLE mode, no reception or SPC trigger transmission is possible.
  When entering OPERATION IDLE mode, frames in the receive buffer can be analyzed as in OPERATION ACTIVE mode, but no new frames are received.

- 101: OPERATION ACTIVE mode

  In OPERATION ACTIVE mode, reception and SPC trigger transmission are possible.

- Other than above: Reserved

22.3.9 RSENTnCS — RSENT Communication Status Register

Access: This register is read-only in 32-bit units.

Address: <RSENTn_base> + 0028_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	SES	SMS	SCS	NRS	CVS	CLS	FNS	FES	FMS	FCS	FRS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 22.17 RSENTnCS register contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is read.
10	SES	Slow channel Encoding Error Interrupt Status 0: Not detected 1: Detected
9	SMS	Slow Channel Message Lost Interrupt Status 0: Not detected 1: Detected
8	SCS	Slow Channel CRC Error Interrupt Status 0: Not detected 1: Detected
7	NRS	No Response Error Interrupt Status 0: Not detected 1: Detected
6	CVS	Calibration Pulse Length Variation Error Interrupt Status 0: Not detected 1: Detected
5	CLS	Calibration Pulse Length Error Interrupt Status 0: Not detected 1: Detected
4	FNS	Fast Channel Nibble Count Error Interrupt Status 0: Not detected 1: Detected
3	FES	Fast Channel Nibble Encoding Error Interrupt Status 0: Not detected 1: Detected
2	FMS	Fast Channel Message Lost Interrupt Status 0: Not detected 1: Detected
1	FCS	Fast Channel CRC Error Interrupt Status 0: Not detected 1: Detected
0	FRS	Fast Channel Receive Interrupt Status 0: Not detected 1: Detected

RSENTnCS.SES (Slow Channel Encoding Error Status)

This bit represents the slow channel encoding error status.

This bit is read only.

In the short serial message format (RSENTnCC.SMF = 01), this bit is set when the sequence on serial start bit (bit #3) is different from “1000000000000000” (a single 1 and 15 0s).

In the enhanced serial message format (RSENTnCC.SMF = 10), this bit is set when following the reception of a start sequence (“01111110”) on the serial data bit 3, bit 13 or bit 18 are not received as ‘0’.

This bit is cleared when writing 1 to RSENTnCSC.SEC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.SMS (Slow Channel Message Lost Status)

This bit represents the slow channel message lost status.

This bit is read only.

This bit is set when there is an attempt to update the slow channel message buffer, but the previous message has not been read yet.

This bit is cleared when writing 1 to RSENTnCSC.SMC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.SCS (Slow Channel CRC Error Status)

This bit represents the slow channel CRC error status.

This bit is read only.

This bit is set when a CRC error is detected on the slow channel and the slow channel CRC detection is enabled (RSENTnCC.SCCD is set to 0).

This bit is cleared when writing 1 to RSENTnCSC.SCC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.NRS (No Response Error Status)

This bit represents the no response error status.

This bit is read only.

This bit is set when

- the CPU writes to the RSENTnSPCT.TLL bits and
- SPC mode enabled (RSENTnCC.SPCE set to 1) and
- no complete response was received from the sensor for the previous SPC trigger.

This bit is cleared when writing 1 to RSENTnCSC.NRC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.CVS (Calibration Pulse Length Variation Error Status)

This bit represents the calibration pulse length variation error status.

This bit is read only.

When RSENTnCC.PPTC is 0, then this bit is set when two successive calibration pulses differ by more than 1.5625%.

When RSENTnCC.PPTC is 1, this bit is never set. In this mode (pause pulse with fixed message length), the CPU needs to check the variation of the ratio of calibration pulse to message length by reading the RSENTnCPL and RSENTnML registers.

This bit is cleared when writing 1 to RSENTnCSC.CVC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.CLS (Calibration Pulse Length Error Status)

This bit represents the calibration pulse length error status.

This bit is read only.

This bit is set when the measured calibration pulse length is less than 42 clock ticks or more than 70 clock ticks (deviation of 25% from nominal length).

This bit is cleared when writing 1 to RSENTnCSC.CLC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.FNS (Fast Channel Nibble Count Error Status)

This bit represents the fast channel nibble count error status.

This bit is read only.

This bit is set when there is an unexpected number of falling edges after the detection of a calibration pulse or between two calibration pulses.

This bit is cleared when writing 1 to RSENTnCSC.FNC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.FES (Fast Channel Nibble Encoding Error Status)

This bit represents the fast channel nibble encoding error status.

This bit is read only.

This bit is set when on the fast channel a measured nibble period is less than 12 clock ticks or more than 27 clock ticks.

This bit is cleared when writing 1 to RSENTnCSC.FEC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.FMS (Fast Channel Message Lost Status)

This bit represents the fast channel message lost status.

This bit is read only.

This bit is set when the fast channel message buffer is updated, but the previous messages in the foreground and background buffer have not been read yet.

This bit is cleared when writing 1 to RSENTnCSC.FMC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.FCS (Fast Channel CRC Error Status)

This bit represents the fast channel CRC error status.

This bit is read only.

This bit is set when a CRC error is detected on the fast channel and the fast channel CRC detection is enabled (RSENTnCC.FCCD is set to 0).

This bit is cleared when writing 1 to RSENTnCSC.FCC.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

RSENTnCS.FRS (Fast Channel Receive Status)

This bit represents the fast channel receive status.

This bit is read only.

This bit is set when the fast channel receive message buffer was updated.

This bit is cleared when the CPU reads the RSENTnFRXD.FND bit.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

If the set condition occurs simultaneously with the clear condition, the bit is set.

22.3.10 RSENTnCSC — RSENT Communication Status Clear Register

Access: This register can be written in 32-bit units.

Address: <RSENTn_base> + $002C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	SEC	SMC	SCC	NRC	CVC	CLC	FNC	FEC	FMC	FCC	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 22.18 RSENTnCSC register contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is read. When writing, write the value after reset.
10	SEC	Slow Channel Encoding Error Clear 0: — 1: Clear
9	SMC	Slow Channel Message Lost Clear 0:— 1: Clear
8	SCC	Slow Channel CRC Error Clear 0: — 1: Clear
7	NRC	No Response Error Clear 0: — 1: Clear
6	CVC	Calibration Pulse Length Variation Error Clear 0: — 1: Clear
5	CLC	Calibration Pulse Length Error Clear 0: — 1: Clear
4	FNC	Fast Channel Nibble Count Error Clear 0: — 1: Clear
3	FEC	Fast Channel Nibble Encoding Error Clear 0: — 1: Clear
2	FMC	Fast Channel Message Lost Clear 0: — 1: Clear
1	FCC	Fast Channel CRC Error Clear 0: — 1: Clear
0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

RSENTnCSC.SEC (Slow channel Encoding error Clear)

Writing 1 sets RSENTnCS.SES to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.SMC (Slow Channel Message Lost Clear)

Writing 1 sets RSENTnCS.SMS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.SCC (Slow Channel CRC Error Clear)

Writing 1 sets RSENTnCS.SCS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.NRC (No Response Error Clear)

Writing 1 sets RSENTnCS.NRS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.CVC (Calibration Pulse Length Variation Error Clear)

Writing 1 sets RSENTnCS.CVS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.CLC (Calibration Pulse Length Error Clear)

Writing 1 sets RSENTnCS.CLS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.FNC (Fast Channel Nibble Count Error Clear)

Writing 1 sets RSENTnCS.FNS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.FEC (Fast Channel Nibble Encoding Error Clear)

Writing 1 sets RSENTnCS.FES to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.FMC (Fast Channel Message Lost Clear)

Writing 1 sets RSENTnCS.FMS to 0.

Writing 0 has no effect.

This bit is always read as 0.

RSENTnCSC.FCC (Fast Channel CRC Error Clear)

Writing 1 sets RSENTnCS.FCS to 0.

Writing 0 has no effect.

This bit is always read as 0.

22.3.11 RSENTnSRTS — RSENT Slow Channel Receive Timestamp Register

Access: This register is read-only in 32-bit units.

Address: <RSENTn_base> + 0030_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	STS[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	STS[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 22.19 RSENTnSRTS register contents

Bit Position	Bit Name	Function
31 to 0	STS	Slow Channel Receive Timestamp

RSENTnSRTS.STS (Slow Channel Timestamp)

These bits are read only.

These bits are updated when the slow channel receive buffer is updated with the timestamp counter value of the last frame provided to the slow channel message.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

22.3.12 RSENTnSRXD — RSENT Slow Channel Receive Data Register

Access: This register is read-only in 32-bit units.

Address: <RSENTn_base> + 0034_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SND	—	SCRC[5:0]						—	—	—	SMGC	IDD[19:16]			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IDD[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 22.20 RSENTnSRXD register contents

Bit Position	Bit Name	Function
31	SND	Slow Channel New Data 0: Slow channel frame data is not updated since last read. 1: Slow channel frame data is updated since last read.
30	Reserved	When read, the value after reset is read.
29 to 24	SCRC[5:0]	Slow Channel CRC Data
23 to 21	Reserved	When read, the value after reset is read.
20	SMGC	Slow Channel Message Configuration 0: — 1: The slow channel receive message buffer is updated.
19 to 0	IDD[19:0]	Slow Channel Data / ID Information

RSENTnSRXD.SND (Slow Channel New Data)

This bit indicates that the slow channel message buffer is holding data that has not been read.

This bit is read only.

This bit is set when the slow channel receive message buffer is updated.

This bit is cleared automatically whenever it is read.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

RSENTnSRXD.SCRC (Slow Channel CRC)

These bits are representing the slow channel CRC data.

These bits are read only.

These bits are updated when the slow channel receive message buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

RSENTnSRXD.SMGC (Slow Channel Message Configuration)

This bit represents the slow channel message configuration bit.

This bit is read only.

This bit is updated when the slow channel receive message buffer is updated.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

RSENTnSRXD.IDD (ID/ Data)

These bits are representing the slow channel data and ID information.

The alignment within this register depends on the message format. For details, see **Section 22.4.3.2(5), Slow Channel Message Reception**.

These bits are read only.

These bits are updated when the slow channel receive message buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

22.3.13 RSENTnCPL — RSENT Calibration Pulse Length Register

Access: This register is read-only in 32-bit units.

Address: <RSENTn_base> + 0038_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CPLV16
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CPLV[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 22.21 RSENTnCPL register contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is read.
16 to 0	CPLV[16:0]	Calibration Pulse Length Value of Received Message

RSENTnCPL.CPLV (Calibration Pulse Length Value)

These bits are used by the CPU to calculate the ratio of two consecutive calibration pulses or the calibration pulse to message length in pause pulse with fixed message length mode for message diagnostics.

These bits are read only.

These bits are updated with the measured calibration pulse length in sample clock ticks when the fast channel receive message buffer is updated.

In modes other than pause pulse with fixed message length (CC.PPTC = 1'b1) or SPC mode (CC.SPCE = 1'b1), these bits are invalid and should not be used.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

22.3.14 RSENTnML — RSENT Message Length Register

Access: This register is read-only in 32-bit units.

Address: <RSENTn_base> + $003C_H$

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	MLV[20:16]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MLV[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 22.22 RSENTnML register contents

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is read.
20 to 0	MLV[20:0]	Message Length Value of Received Message

RSENTnML.MLV (Message Length Value)

These bits are used by the CPU to calculate the ratio of the calibration pulse to message length in pause pulse with fixed message length mode for message diagnostics.

These bits are read only.

These bits are updated with the measured message length in sample clock ticks when the fast channel receive message buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

In modes other than pause pulse with fixed message length, these bits are invalid and should not be used.

22.3.15 RSENTnFRTS — RSENT Fast Channel Receive Timestamp Register

Access: This register is read-only in 32-bit units.

Address: <RSENTn_base> + 0040_H

Value after reset: 0000 0000_H This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FTS[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FTS[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 22.23 RSENTnFRTS register contents

Bit Position	Bit Name	Function
31 to 0	FTS[31:0]	Fast Channel Receive Timestamp

RSENTnFRTS.FTS (Fast Channel Timestamp)

These bits are read only.

These bits are updated when the fast channel receive message buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

22.3.16 RSENTnFRXD — RSENT Fast Channel Receive Data Register

Access: This register is read-only in 32-bit units.

Address: <RSENTn_base> + 0044_H

Value after reset: $0000\ 0000_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SNDM	FND	FCCN[1:0]		FCRC[3:0]				ND[23:16]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ND[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 22.24 RSENTnFRXD register contents

Bit Position	Bit Name	Function
31	SNDM	Slow Channel New Data Mirror 0: Slow channel frame data is not updated since last read. 1: Slow channel frame data is updated since last read.
30	FND	Fast Channel New Data 0: Fast channel frame data is not updated since last read. 1: Fast channel frame data is updated since last read.
29, 28	FCCN[1:0]	Fast Channel Communication Nibble
27 to 24	FCRC[3:0]	Fast Channel CRC Data
23 to 0	ND[23:0]	Fast Channel Nibble Data

RSENTnFRXD.SNDM (Slow Channel New Data Mirror)

This bit indicates that the slow channel message buffer is holding data that has not been read.

This bit is read only.

This bit is set when the slow channel receive message buffer is updated.

This bit is cleared automatically whenever the slow channel new data bit (RSENTnSRXD.SND) is read.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

RSENTnFRXD.FND (Fast Channel New Data)

This bit indicates that the fast channel message buffer is holding data that has not been read.

This bit is read only.

This bit is set when the fast channel receive message buffer is updated.

This bit is cleared automatically whenever it is read.

This bit is cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

RSENTnFRXD.FCCN (Fast Channel Communication Nibble)

These bits are representing the fast channel communication nibble bits [1:0].

These bits are read only.

These bits are updated when the fast channel receive message buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

RSENTnFRXD.FCRC (Fast Channel CRC)

These bits are representing the fast channel CRC data.

These bits are read only.

These bits are updated when the fast channel receive message buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

RSENTnFRXD.ND (Nibble Data)

These bits are representing the fast channel nibble data.

The alignment of the nibble data depends on nibble count. For details, see **Section 22.4.3.2(3), Fast Channel Message Reception**.

These bits are read only.

These bits are updated when the fast channel receive message buffer is updated.

These bits are cleared when the RSENTnMST.OMS bits are changed to 001 (CONFIGURATION).

22.3.17 RSENT0TSSEL — RSENT0 Timestamp Mode Selection Register

This register controls the master channel of the RSENT module.

Writing to this register is only allowed when the RSENT module is in the CONFIGURATION mode (RSENTMST.OMS[2:0] = 001), or in the RESET mode (RSENTMST.OMS[2:0] = 000).

Access: This register can be read/written in 32-bit units.

Address: FFCD CF00$_H$

Value after reset: 0000 0000$_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	MSSEL 03	MSSEL 02	MSSEL 01	MSSEL 00
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 22.25 RSENT0TSSEL register contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	MSSEL0[3:0]	Master Selection for RSENT0 0000: No master or RSENT0 is master. 0001: No master or RSENT0 is master. 0010: RSENT1 is the master of RSENT0. 0011: RSENT2 is the master of RSENT0. 0100: RSENT3 is the master of RSENT0. 0101: RSENT4 is the master of RSENT0. 0110: RSENT5 is the master of RSENT0. 0111: RSENT6 is the master of RSENT0. 1000: RSENT7 is the master of RSENT0. 1001: RSENT8 is the master of RSENT0. 1010: RSENT9 is the master of RSENT0. Other than above: Setting prohibited

22.3.18 RSENT1TSSEL — RSENT1 Timestamp Mode Selection Register

This register controls the master channel of the RSENT module.

Writing to this register is only allowed when the RSENT module is in the CONFIGURATION mode (RSENTMST.OMS[2:0] = 001), or in the RESET mode (RSENTMST.OMS[2:0] = 000).

Access: This register can be read/written in 32-bit units.

Address: FFCD CF04$_H$

Value after reset: 0000 0000$_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 22.26 RSENT1TSSEL register contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	MSSEL1[3:0]	Master Selection for RSENT1 0000: No master or RSENT1 is master. 0001: RSENT0 is the master of RSENT1. 0010: No master or RSENT1 is master. 0011: RSENT2 is the master of RSENT1. 0100: RSENT3 is the master of RSENT1. 0101: RSENT4 is the master of RSENT1. 0110: RSENT5 is the master of RSENT1. 0111: RSENT6 is the master of RSENT1. 1000: RSENT7 is the master of RSENT1. 1001: RSENT8 is the master of RSENT1. 1010: RSENT9 is the master of RSENT1. Other than above: Setting prohibited

22.3.19 RSENT2TSSEL — RSENT2 Timestamp Mode Selection Register

This register controls the master channel of the RSENT module.

Writing to this register is only allowed when the RSENT module is in the CONFIGURATION mode (RSENTMST.OMS[2:0] = 001), or in the RESET mode (RSENTMST.OMS[2:0] = 000).

Access: This register can be read/written in 32-bit units.

Address: FFCD CF08$_H$

Value after reset: 0000 0000$_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 22.27 RSENT2TSSEL register contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	MSSEL2[3:0]	Master Selection for RSENT2 0000: No master or RSENT2 is master. 0001: RSENT0 is the master of RSENT2. 0010: RSENT1 is the master of RSENT2. 0011: No master or RSENT2 is master. 0100: RSENT3 is the master of RSENT2. 0101: RSENT4 is the master of RSENT2. 0110: RSENT5 is the master of RSENT2. 0111: RSENT6 is the master of RSENT2. 1000: RSENT7 is the master of RSENT2. 1001: RSENT8 is the master of RSENT2. 1010: RSENT9 is the master of RSENT2 Other than above: Setting prohibited

22.3.20 RSENT3TSSEL — RSENT3 Timestamp Mode Selection Register

This register controls the master channel of the RSENT module.

Writing to this register is only allowed when the RSENT module is in the CONFIGURATION mode (RSENTMST.OMS[2:0] = 001), or in the RESET mode (RSENTMST.OMS[2:0] = 000).

Access: This register can be read/written in 32-bit units.

Address: FFCD CF0C$_H$

Value after reset: 0000 0000$_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	MSSEL3[3:0]	Master Selection for RSENT3 0000: No master or RSENT3 is master. 0001: RSENT0 is the master of RSENT3. 0010: RSENT1 is the master of RSENT3. 0011: RSENT2 is the master of RSENT3. 0100: No master or RSENT3 is master. 0101: RSENT4 is the master of RSENT3. 0110: RSENT5 is the master of RSENT3. 0111: RSENT6 is the master of RSENT3. 1000: RSENT7 is the master of RSENT3. 1001: RSENT8 is the master of RSENT3. 1010: RSENT9 is the master of RSENT3. Other than above: Setting prohibited

22.3.21 RSENT4TSSEL — RSENT4 Timestamp Mode Selection Register

This register controls the master channel of the RSENT module.

Writing to this register is only allowed when the RSENT module is in the CONFIGURATION mode (RSENTMST.OMS[2:0] = 001), or in the RESET mode (RSENTMST.OMS[2:0] = 000).

Access: This register can be read/written in 32-bit units.

Address: FFCD CF10$_H$

Value after reset: 0000 0000$_H$ This register is initialized by various types of reset.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

22.4 Operation

22.4.1 Modes of Operation

The RSENT module can be in one of the following modes:

- RESET mode
- CONFIGURATION mode
- OPERATION IDLE mode
- OPERATION ACTIVE mode

Figure 22.2 shows the possible transitions between the channel modes:

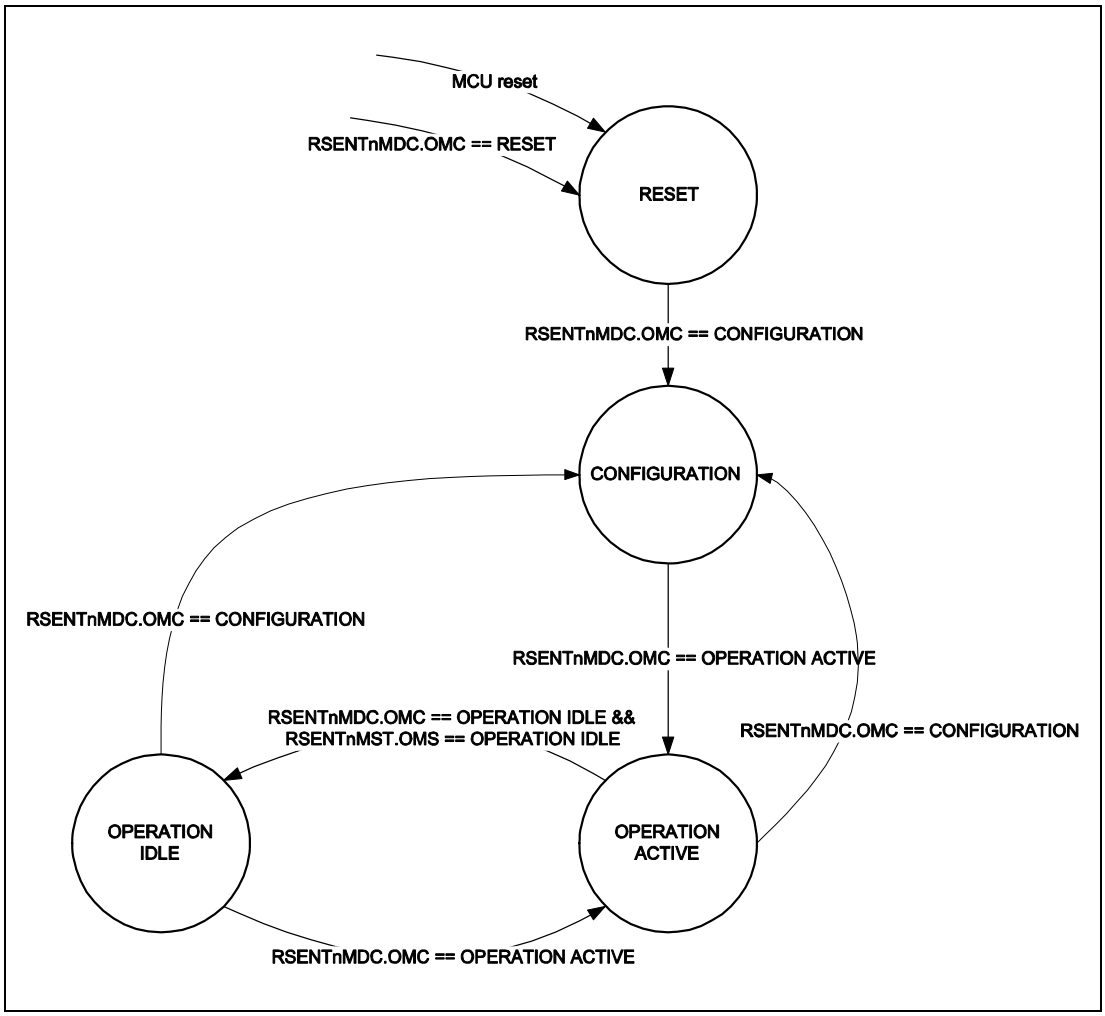

Figure 22.2 Transition between Operation Modes

The current operation mode status can be seen in the RSENTnMST.OMS bits.

22.4.1.1 RESET Mode

This mode is the initial mode that the RSENT module automatically enters after the hardware reset (MCU reset) is cleared. Its purpose is to provide a clean reset of the registers in the RSENT module.

The RESET mode is also entered after the RSENTnMDC.OMC bits have been set to 000_B. In this state, all, configuration, control (except RSENTnMDC.OMC bits), and status registers are set to their reset value. Any on-going transmission or reception process is stopped immediately and the interface pins of the RSENT module are set to their default values.

Read access to all registers is possible in this state. Write access is limited to the RSENTnMDC register.

22.4.1.2 CONFIGURATION Mode

The CONFIGURATION mode is entered after the RSENTnMDC.OMC bits have been set to 001_B.

Any on-going transmission or reception process is stopped immediately and the interface pins of the RSENT module are set to their default values.

In this state, all status registers (RSENTnCS) and the receive buffer registers (RSENTnSRTS, RSENTnSRXD, RSENTnCPL, RSENTnML, RSENTnFRTS, and RSENTnFRXD) are set to their default value.

Read access to all registers is possible in this state.

Write access is limited to both timestamp registers (TSCP and RSENTnTSC) and configuration registers (RSENTnCC, RSENTnBRP, RSENTnIDE, and RSENTnMDC).

22.4.1.3 OPERATION IDLE Mode

This mode is entered after the RSENTnMDC.OMC bits have been set to 011_B.

In OPERATION IDLE mode, no reception and transmission are done.

When entering OPERATION IDLE mode, frames in the receive buffer can be analyzed as in OPERATION ACTIVE mode, but no new frames are received.

Read access to all registers is possible in this state.

Write access is granted only to RSENTnTSC, RSENTnIDE, RSENTnMDC, and RSENTnCSC.

22.4.1.4 OPERATION ACTIVE Mode

This mode is entered after the RSENTnMDC.OMC bits have been set to 101_B.

In OPERATION ACTIVE mode, transmission and reception can take place.

Read access to all registers is possible in this state.

Write access is granted only to RSENTnTSC, RSENTnIDE, RSENTnMDC, RSENTnSPCT, and RSENTnCSC.

22.4.1.5 Register Behavior in Operation Modes

Table 22.35 shows the register behavior when the RSENT module transitions to the indicated operation modes. The table also gives an overview about the access restriction in each operation mode.

Table 22.35 Register Behavior in Operation Modes

		MCU Reset	RESET		CONFIGURATION		OPERATION IDLE		OPERATION ACTIVE	
Register Name	**Symbol**	**Change**	**Change**	**R/W**	**Change**	**R/W**	**Change**	**R/W**	**Change**	**R/W**

Fast channel receive data register	RSENTnFRXD	$0000\ 0000_H$	$0000\ 0000_H$	R	$0000\ 0000_H$	R	Unchanged	R	Unchanged	R

Note 1. Means write restriction exists.

22.4.2 Clock Configuration

22.4.2.1 Timestamp

(1) Timestamp Clock Configuration

RSENT incorporates the timestamp counter.

The minimum required resolution of the timestamp is 1 µs. Depending on the applied communication frequency, the user should configure the RSENTnTSPC.TTPV bits to achieve the 1-µs resolution. The input frequency is divided by the configured timestamp prescaler value RSENTnTSPC.TTPV.

Depending on the configured tick lengths, the resolution can be decreased by configuring the RSENTnTSPC.TTM bits. The already divided input frequency is divided further by the value of the TSPC.TTM bits.

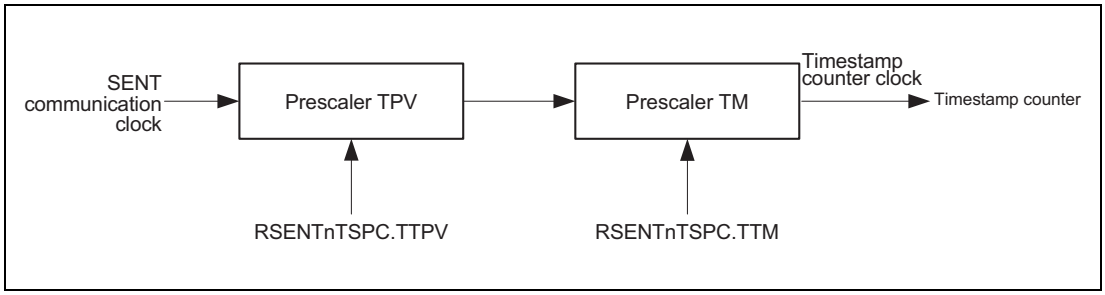

Figure 22.3 Timestamp Counter Clock Generation

(2) Timestamp Counter Operation

The timestamp counter value can be initialized to any value by writing to the RSENTnTSC.TS bits only when the RSENT module is in CONFIGURATION mode.

When timestamp counters are configured to operate in master mode (RSENTnTSPC.TMS = 0), the CPU can reset the timestamp counter by writing 0000 0000_H to the RSENTnTSC.TS bits when the RSENT module is in OPERATION_IDLE or OPERATION_ACTIVE mode.

When timestamp counters are configured to operate in slave mode (RSENTnTSPC.TMS = 1), the timestamp counter is cleared when the CPU writes 0000 0000_H to the RSENTnTSC.TS bits of master RSENT module when the RSENT module is in OPERATION_IDLE or OPERATION_ACTIVE mode. The RSENT module operating in slave mode should have the same timestamp counter prescaler settings as master RSENT module. When timestamp counter synchronization occurs, the internal timestamp counter prescalers are also synchronized.

The current timestamp counter value can be read from the RSENTnTSC.TS bits.

When the RSENT module is in OPERATION ACTIVE mode, each received message is stored with its related timestamp. Timestamp values are taken for fast channel and slow channel data.

The timestamp value is captured when the calibration pulse is detected.

The timestamp value for the fast channel is stored in the RSENTnFRTS.STS bits when the fast channel receive message buffer is updated.

The timestamp value for the slow channel is stored in the RSENTnSRTS.STS bits. The timestamp value for the slow channel is identical to the timestamp value of the last fast channel message contributing to the slow channel message.

In case timestamp counter synchronization is required, the following flow should be used.

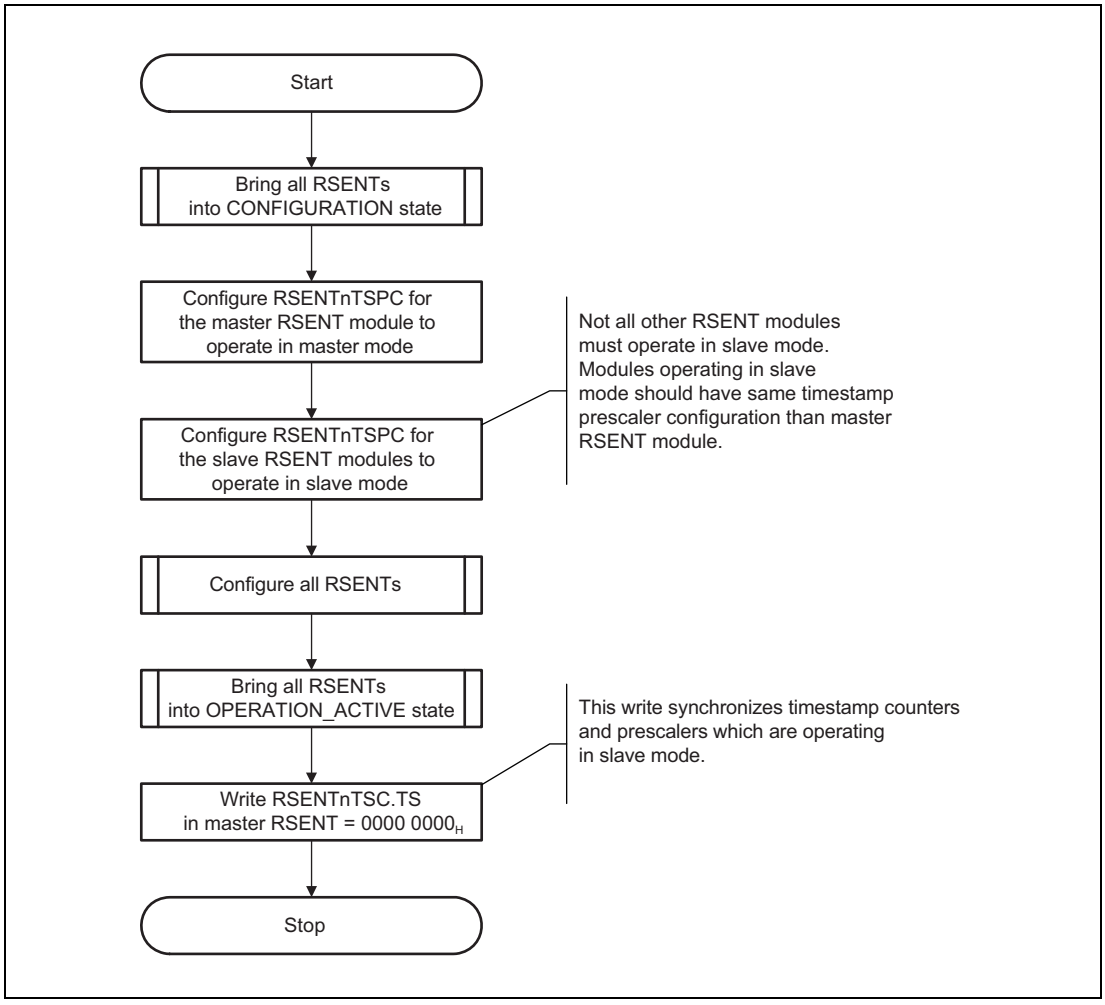

Figure 22.4 Timestamp Counter Synchronization

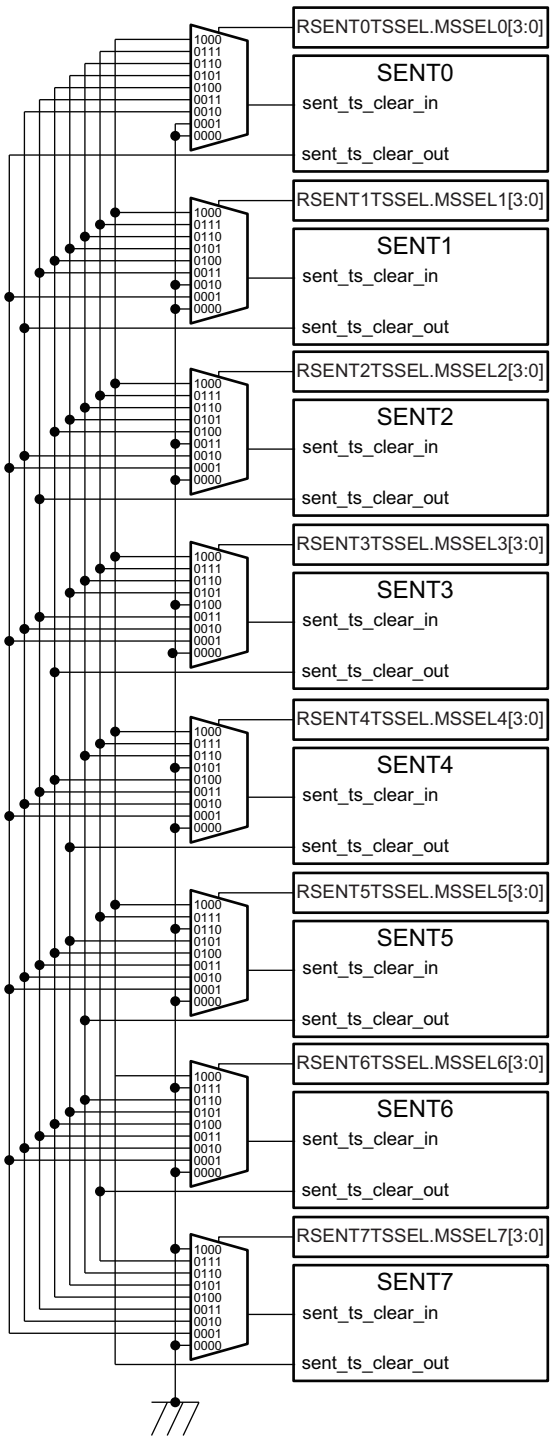
Further synchronization can be done as long as master RSENT module is in either OPERATION_ACTIVE or OPERATION_IDLE state.

In order to realize the specified timestamp counter synchronization the RSENT modules are interconnected as shown **Figure 22.5**.



Note: Only P1H-CE has SENT8 and SENT9.

Figure 22.5 Timestamp Signal Connection among Channels

22.4.2.2 Communication Clock Configuration

(1) RX BRP Setting

Depending on the applied “RSENT communication clock” frequency the RSENTnBRP.SCDV and RSENTnBRP.SCMV registers must be configured to achieve the required sample frequency (f_{SAMPLE}) of 16MHz.

The values should be selected according to the following formula, in such a way that the lowest terms (e.g. 2/3 instead of 4/6) is generated.

Divide the communication clock (RSENT communication clock) and select the values of RSENTnBRP.SCMV and RSENTnBRP.SCDV to achieve f_{SAMPLE} of 16MHz.

fSAMPLE = 16MHz = $f_{COMUNICATION}$ × (RSENTnBRP.SCMV/RSENTnBRP.SCDV)

The communication clock is selected frequency within the range of 32MHz to 80MHz or equal to 16MHz

$$f_{SAMPLE} = 16MHz = f_{COMUNICATION} \times \frac{RSENTnBRP.SCMV}{RSENTnBRP.SCDV}$$

(2) RX and SPC Tick Settings

The used tick length in RX and SPC function can be configured with the RSENTnBRP.TTI and RSENTnBRP.TTF bits. Tick lengths from 1.0 µs to 90.0 µs with a resolution of 0.1 µs can be configured.

The RSENTnBRP.TTI holds the integer part of the tick length and the RSENTnBRP.TTF bits hold the fractional part of the tick length. The tick length is then calculated by:

$$T_{TICK} = T_{RSENTnBRP.TTI} + T_{RSENTnBRP.TTF}$$

NOTE

Set Tick lengths more than 10us when clkc frequency set less than 32MHz.

22.4.3 RSENT Operation

22.4.3.1 Changing Operation Modes

Once initialization has been completed in CONFIGURATION mode, operation can be enabled by entering OPERATION ACTIVE mode. This is done by setting the RSENTnMDC.OMC bits to OPERATION ACTIVE and waiting for the RSENTnMST.OMS to transition to OPERATION ACTIVE.

Once in OPERATION ACTIVE mode the RSENT module begins to receive messages or SPC communication can be started depending on the configuration.

Figure 22.6 shows the communication enabled flow assuming that the RSENT module is in RESET mode:

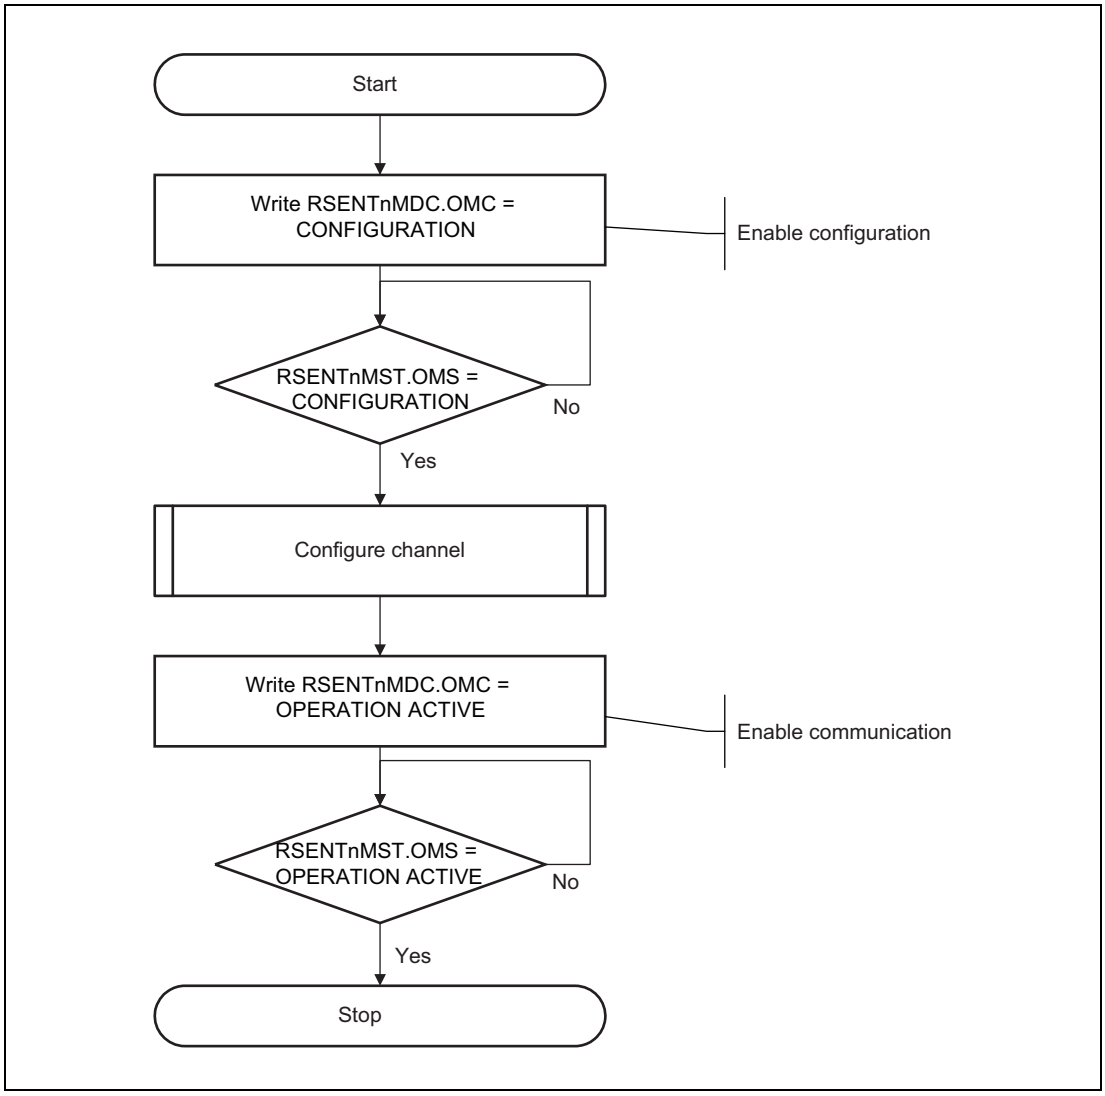


Figure 22.6 Communication Enable Flow

To leave OPERATION ACTIVE mode, communication should be disabled first by transitioning to OPERATION IDLE mode. This is done by setting the RSENTnMDC.OMC bits to OPERATION IDLE and waiting for the RSENTnMST.OMS bits to transition to OPERATION IDLE.

The transition between OPERATION ACTIVE and OPERATION IDLE depends on the setting of the RSENTnCC.SPCE bit.

(1) RSENTnCC.SPCE = 0

In case a reception is currently ongoing, the mode change from OPERATION ACTIVE to OPERATION IDLE takes place when the receive buffer was updated (see **Section 22.4.3.2(3), Fast Channel Message Reception**).

In case no reception is ongoing, the mode change from OPERATION ACTIVE to OPERATION IDLE takes place immediately.

(2) RSENTnCC.SPCE = 1

In case a reception is ongoing, the mode change from OPERATION ACTIVE to OPERATION IDLE takes place when the falling edge of the end pulse is received.

In case a no response error is flagged, the mode change from OPERATION ACTIVE to OPERATION IDLE takes place at the same time as the error flagging.

The mode change from OPERATION ACTIVE to OPERATION IDLE takes place when the sequence of making a SPC trigger and receiving the response has been completed. This means when a response was already received, the transition takes place immediately. When the response is still pending, the mode change from OPERATION ACTIVE to OPERATION IDLE takes place when the falling edge of the end pulse is received.

CONFIGURATION mode can be entered at any time by writing CONFIGURATION to the RSENTnMDC.OMC bits and waiting for the RSENTnMST.OMS to transition to CONFIGURATION.

Once CONFIGURATION mode is entered, the remaining status and message information stored in the RSENT module is lost since status and message information is cleared in CONFIGURATION mode.

Figure 22.7 shows the communication disable flow assuming that the RSENT module is in OPERATION ACTIVE mode.

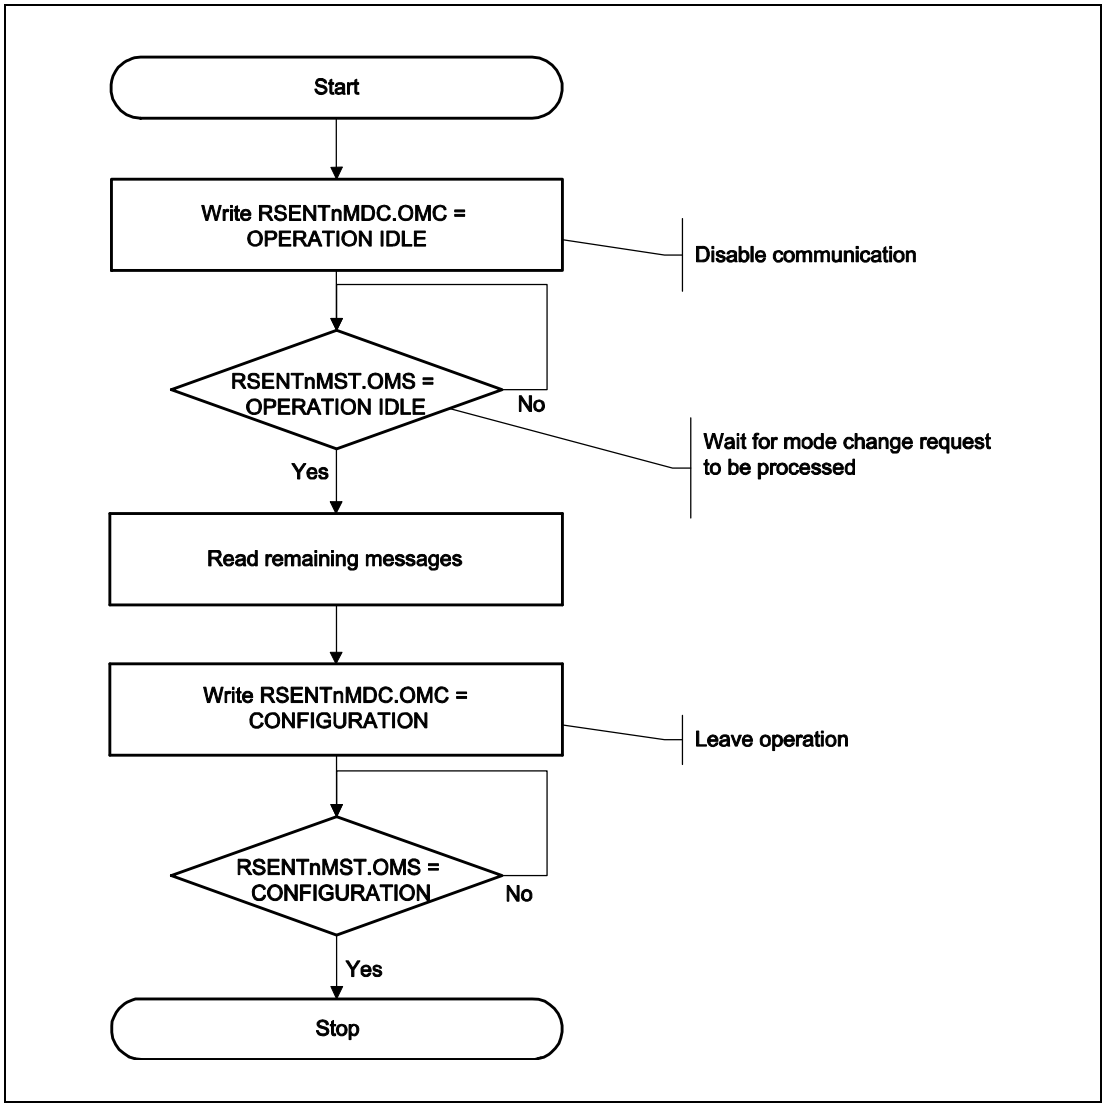

Figure 22.7 Communication Disable Flow

Table 22.36 Transition time from each mode

Transition	Condition	Transition Time
RESET to CONFIGURATION		5 PCLK + 3 CLKC
CONFIGURATION to OPERATION ACTIVE		5 PCLK + 6 CLKC
OPERATION ACTIVE to OPERATION IDLE		Falling edge of next frame sync nibble + 5 sample clocks + 4 CLKC + 4 PCLK
	In case frame reception has not started	5 PCLK + 1 sample clock + 7 CLKC
OPERATION IDLE to CONFIGURATION		4 PCLK + 4 CLKC
OPERATION ACTIVE to CONFIGURATION		5 PCLK + 7 CLKC + 1 sample clock
OPERATION IDLE to OPERATION ACTIVE		5 PCLK + 6 CLKC

22.4.3.2 Message Reception

RSENT message reception is composed of the calibration pulse reception followed by the data nibble pulse reception.

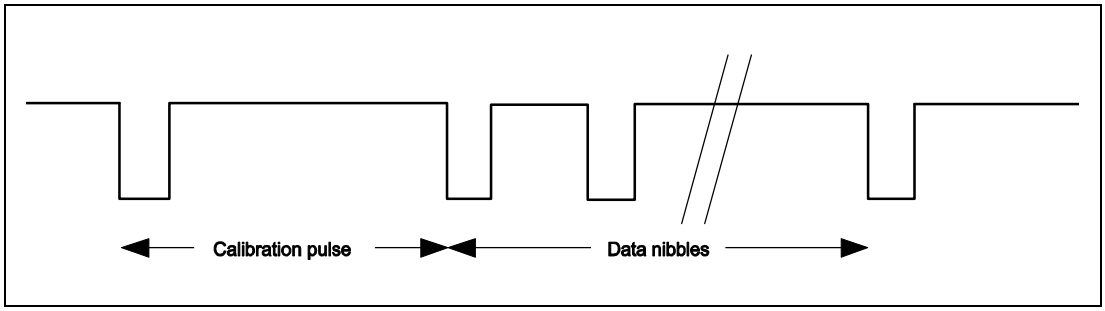

Figure 22.8 RSENT Received Message Structure

(1) Calibration Pulse Reception

Within the calibration pulse reception phase the internally generated clock tick is adjusted to the transmit clock speed.

In addition, the calibration pulse is used to end the previous message and perform message diagnostics. The RSENT module supports automatic calibration pulse length diagnostics in variable message length modes (RSENTnCC.PPTC = 0). In case the calibration pulse ratio check fails, the calibration pulse length variation error flag (RSENTnCS.CVS) is set to 1.

(2) Data Nibble Reception

The receive function of the RSENT module is a capture and compare function. The RSENT module receives sensor information encoded by the temporal distance of two consecutive falling edges on the data line. The temporal distance (in # of clock ticks) is captured and compared against a set of values to determine the actual nibble value. The data encoding is illustrated in **Table 22.37** below.

Table 22.37 Data Nibble Encoding

Nibble Period (# Clock Ticks)	Nibble Value (Binary)
12	0000_B
13	0001_B
14	0010_B
15	0011_B
16	0100_B
17	0101_B
18	0110_B
19	0111_B
20	1000_B
21	1001_B
22	1010_B
23	1011_B
24	1100_B
25	1101_B
26	1110_B
27	1111_B

The received data nibbles are composed into an RSENT message which is then stored in the fast channel receive message buffer.

Any other received nibble period during the reception of data nibbles will cause a fast channel nibble encoding error.

(3) Fast Channel Message Reception

Messages received on the fast message channel are stored in a receive buffer.

A fast channel receive buffer is composed of the calibration pulse length register (RSENTnCPL), the message length register (RSENTnML), the fast channel receive timestamp register (RSENTnFRTS), and the fast channel receive data register (RSENTnFRXD).

All registers are placed on successive addresses that allows transferring the register content into memory using DMA.

The RSENT module is equipped with a double receive buffer structure that allows the storage of two complete RSENT messages including the related timestamp and message length information. Message decoding and assembling are done in a separate register stage.

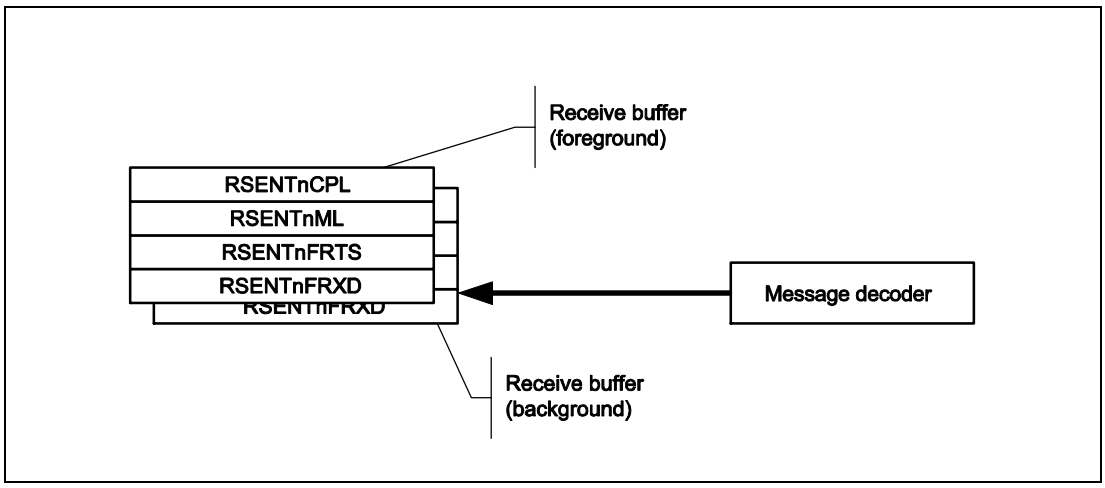

Figure 22.9 Fast Channel Receive Message Buffer

The first received message is placed into the message buffer that can be accessed by the CPU. This buffer (except the RSENTnFRXD.SNDM bit) is not updated any more until the RSENTnFRXD.FND bit was read.

When a new message is placed into a receive buffer, the RSENTnFRXD.FND bit is set. At the same time, the RSENTnCS.FRS bit is set and, if enabled, a receive interrupt request is generated.

When the foreground receive buffer is holding an unprocessed message (the RSENTnFRXD.FND bit is 1), any further incoming message is placed in the background buffer. The background buffer is updated with any further incoming messages. In case an unprocessed background message buffer message is overwritten, the RSENTnCS.FMS bit is set to 1.

When the CPU reads the RSENTnFRXD.FND bit and there is valid data in the background buffer, the data previously located in the background buffer becomes available in the receive buffer and is accessible by the CPU. If enabled, a new interrupt request for fast channel data is generated and RSENTnCS.FRS is set.

When the RSENTnFRXD.FND/ RSENTnCS.FRS bit is not set, the data in the receive buffer is not defined and the CPU should not access the receive buffer.

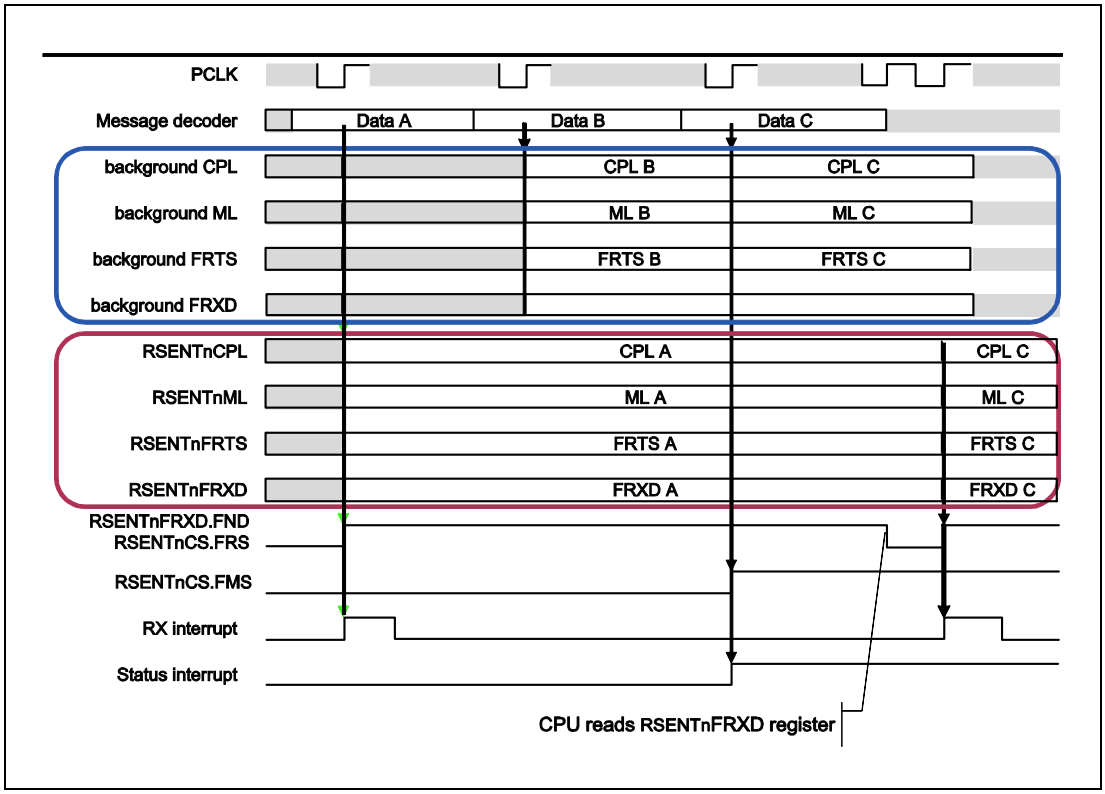

Figure 22.10 Fast Channel Receive Buffer Update Timing

The update timing of the receive buffer depends on the applied configuration as depicted in **Figure 22.11** to **Figure 22.14**.

The data alignment in the RSENTnFRXD register depends on the nibble data count (RSENTnCC.NDN).

Table 22.38 Data Nibble Alignment in RSENTnFRXD Register

RSENTnCC.NDN	23:20	19:16	15:12	11:8	7:4	3:0
000_B	Undefined	Undefined	Undefined	Undefined	Undefined	Nibble 1
001_B	Undefined	Undefined	Undefined	Undefined	Nibble 1	Nibble 2
010_B	Undefined	Undefined	Undefined	Nibble 1	Nibble 2	Nibble 3
011_B	Undefined	Undefined	Nibble 1	Nibble 2	Nibble 3	Nibble 4
100_B	Undefined	Nibble 1	Nibble 2	Nibble 3	Nibble 4	Nibble 5
101_B	Nibble 1	Nibble 2	Nibble 3	Nibble 4	Nibble 5	Nibble 6

1. SAE operation with variable message length and preferred check method (RSENTnCC.SPCE = 0, RSENTnCC.PPTC = 0, RSENTnCC.FCM = 0)

In this operation mode, the RSENT module automatically performs the check for successive calibration pulse variation according to the preferred option in the J2716 2010 specification. In this mode, message diagnostics is done after the calibration pulse was received following a message.

If this check is passed, the receive message buffer is updated.

If this check is not passed, the receive message buffer is not updated and RSENTnCS.CVS is set to 1.

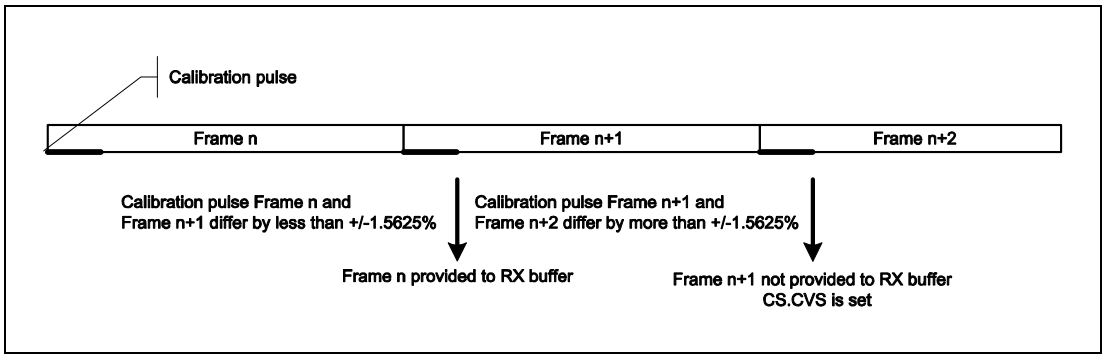

Figure 22.11 Buffer Update in Variable Message Length Mode and Preferred Check Method

2. SAE operation with variable message length and optional check method (RSENTnCC.SPCE = 0, RSENTnCC.PPTC = 0, RSENTnCC.FCM = 1)

In this operation mode, the RSENT module automatically performs the check for successive calibration pulse variation according to the optional frame check method as described in the J2716 2010 specification. In this mode, the calibration pulse of the current frame is compared to the calibration pulse of the last valid preceding frame.

If this check is passed, the receive message buffer is updated.

If this check is not passed, the receive message buffer is not updated and RSENTnCS.CVS is set to 1.

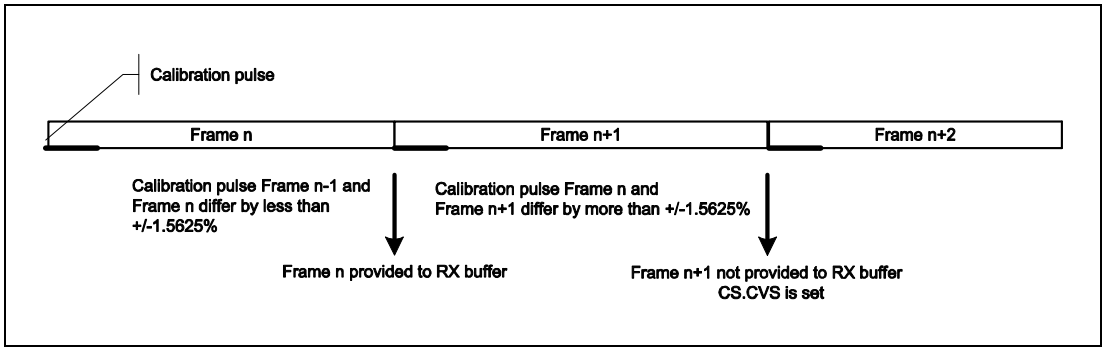

Figure 22.12 Buffer Update in Variable Message Length Mode and Optional Check Method

3. SAE operation with fixed message length (RSENTnCC.SPCE = 0, RSENTnCC.PPTC = 1)

In this mode, the RSENT module does not perform the check for calibration pulse and message length ratio according to the preferred option in the J2716 2010 specification. In this mode, the RSENT module provides the calibration pulse length in the RSENTnCPL register and the message length information in the RSENTnML register. The numbers provided are based on samples.

The message buffer is updated at the beginning of the following calibration pulse irrespective of the values in the RSENTnCPL and RSENTnML registers. The CPU needs to calculate the ratio and either accept or discard the message.

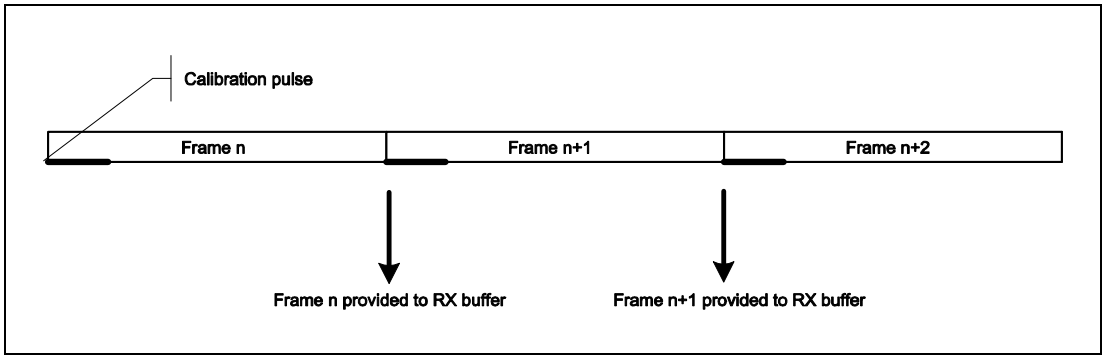

Figure 22.13 Buffer Update in Fixed Message Length Mode

The RSENTnCS.CVS (calibration pulse width variation error status) bit is never set in this mode.

4. SPC operation (RSENTnCC.SPCE = 1)

In this operation mode, sensor data transmission is done following a SPC master trigger pulse. Within SAE RSENT communication, the calibration pulse or pause pulse is terminating the previous message. In SPC communication, the sensor is only sending data following a SPC trigger request. An end pulse sent by the sensor is terminating the message. The message buffer is updated at the beginning of the end pulse.

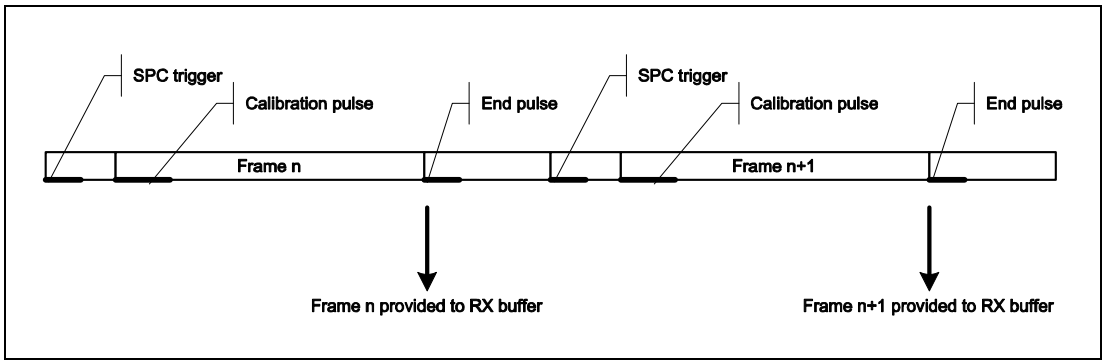

Figure 22.14 Buffer Update in SPC Mode

The RSENTnCS.CVS (calibration pulse width variation error status) bit is never set in this mode.

The RSENT module provides the calibration pulse length in the RSENTnCPL register and the message length information in the RSENTnML register. The numbers provided are based on samples. The CPU needs to calculate the ratio of calibration pulses and/or message length and either accept or discard the message.

In case of variable message length mode, the RSENT module cannot perform this check because the receive timing of the next calibration pulse depends on the next SPC trigger timing.

(4) Fast Channel Reception Flow

In **Figure 22.15**, the recommended reception flow for the fast channel receive buffer is shown.

When using a polling or event driven method, the CPU should only read the setting of the RSENTnCS.FRS bit to check the availability of new fast channel data.

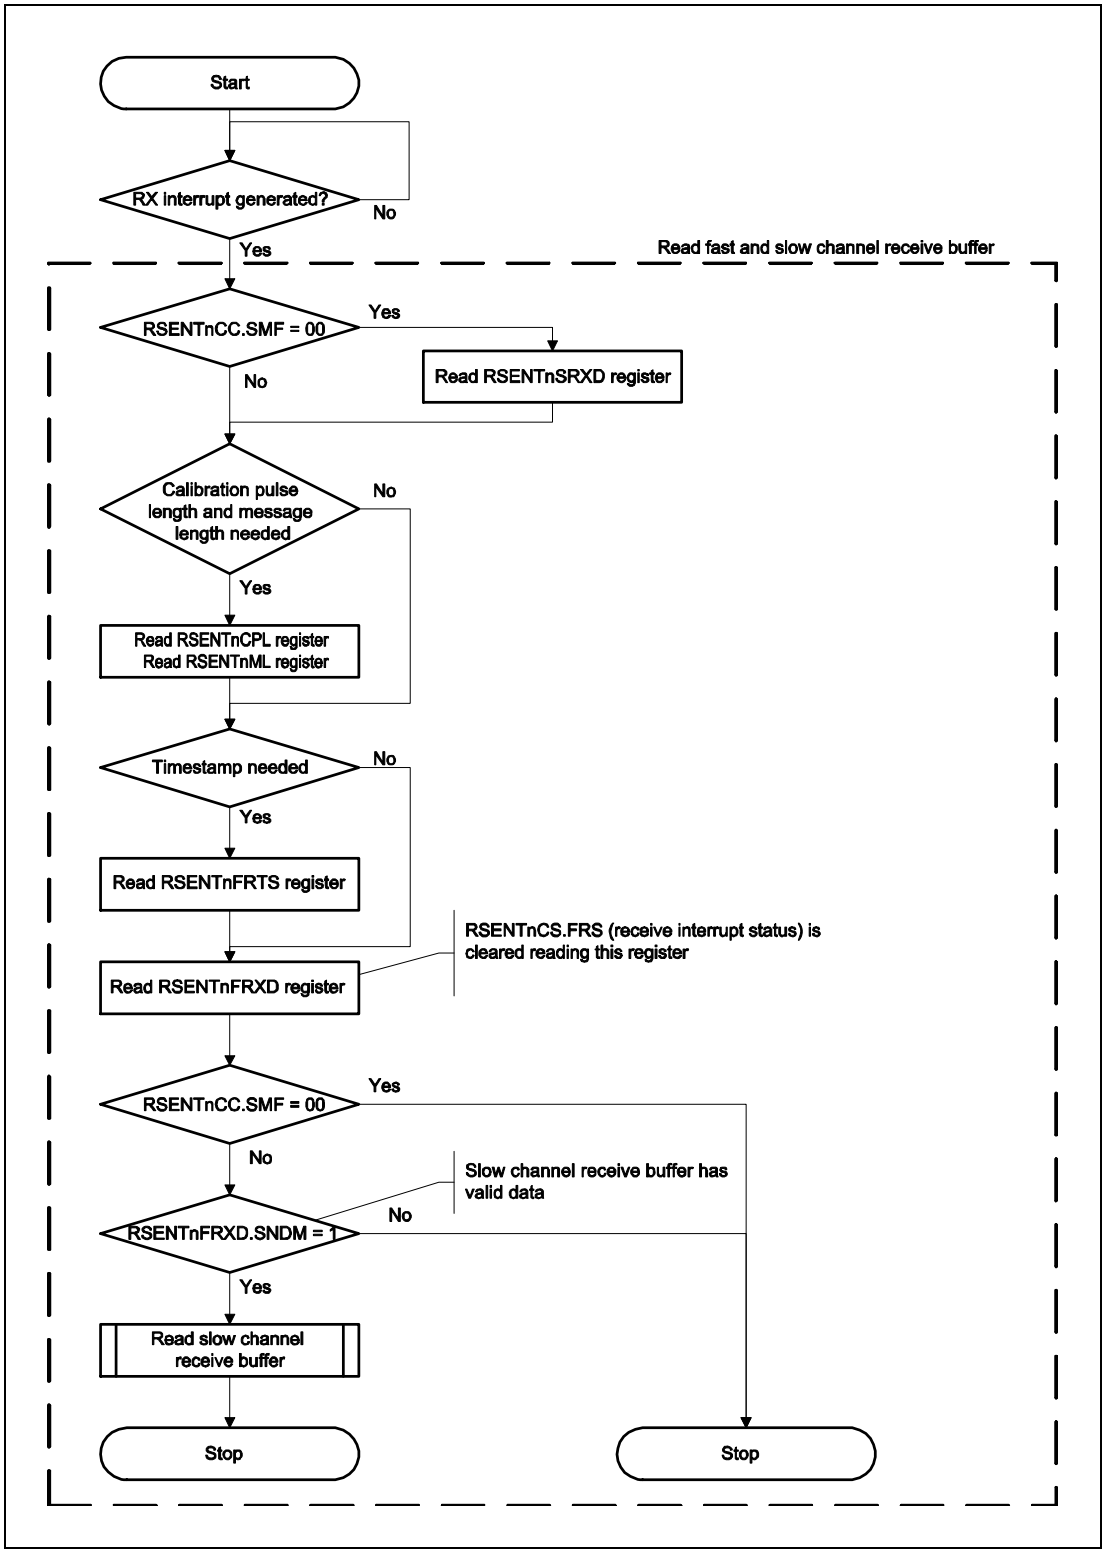

Figure 22.15 Fast Channel Reception Flow

In any case, the CPU should keep the order in reading the receive buffer registers as shown in the flow. The RSENTnFRXD register should be the last register to be accessed.

The handling of the slow channel receive buffer is described in **(6) Slow Channel Reception Flow**.

In case of SAE communication with pause pulse and fixed message length, the flow must be extended by checking of the ratio of the calibration pulse to message length. This variation check must be performed by the CPU. In case the variation check fails, the CPU must discard the received message.

(5) Slow Channel Message Reception

The RSENT module supports extraction of the slow message out of the fast channel messages by using the bits 3 and 2 out of the status and communication nibble. In order to enable the slow channel extraction, the CPU should set the RSENTnCC.SMF bits to the expected serial message format.

When no serial message extraction is selected (RSENTnCC.SMF = 00), the RSENTnSRXD register becomes part of the fast channel receive buffer structure (including background buffer) and RSENTnSRTS register should be ignored. The status and communication nibble is placed in the RSENTnSRXD.IDD bits. Furthermore no slow channel new data and slow channel message lost flags are generated.

In order to receive the slow channel serial message, all fast channel serial messages contributing to a slow channel serial message must be received successfully and the received slow channel serial message must comply with the selected serial message format.

A message lost on the fast channel does not impact the reception on the slow channel.

A slow channel receive buffer is composed of the slow channel receive timestamp register (RSENTnSRTS) and the slow channel receive data register (RSENTnSRXD).

In opposite to the fast channel receive buffer, the slow channel receive buffer does not support a double receive buffer structure; only a single receive buffer structure is available.

Message decoding and assembling is done in a separate register stage.

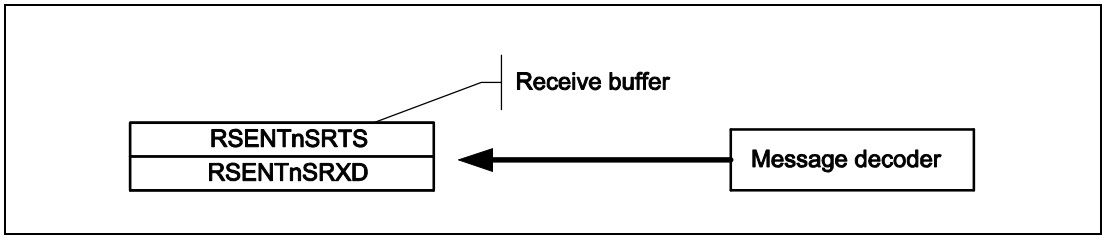

Figure 22.16 Slow Channel Receive Message Buffer

The slow channel receive buffer is updated at the same time as the fast channel receive buffer that holds the last status and communication nibble required for the slow channel message. The RSENTnSRXD.SND bit is set to 1 at the same time.

Further updates to the buffer are not carried out until after the RSENTnSRXD.SND bit has been read.

When the receive buffer is holding an unprocessed message (RSENTnSRXD.SND is 1), any further incoming message is lost (the slow channel receive buffer is not updated) and RSENTnCS.SMS is set to 1.

When the CPU reads the RSENTnSRXD register, RSENTnSRXD.SND is automatically cleared.

The RSENTnSRTS register is updated with the current timestamp counter register value of the last frame contributing to the slow channel message.

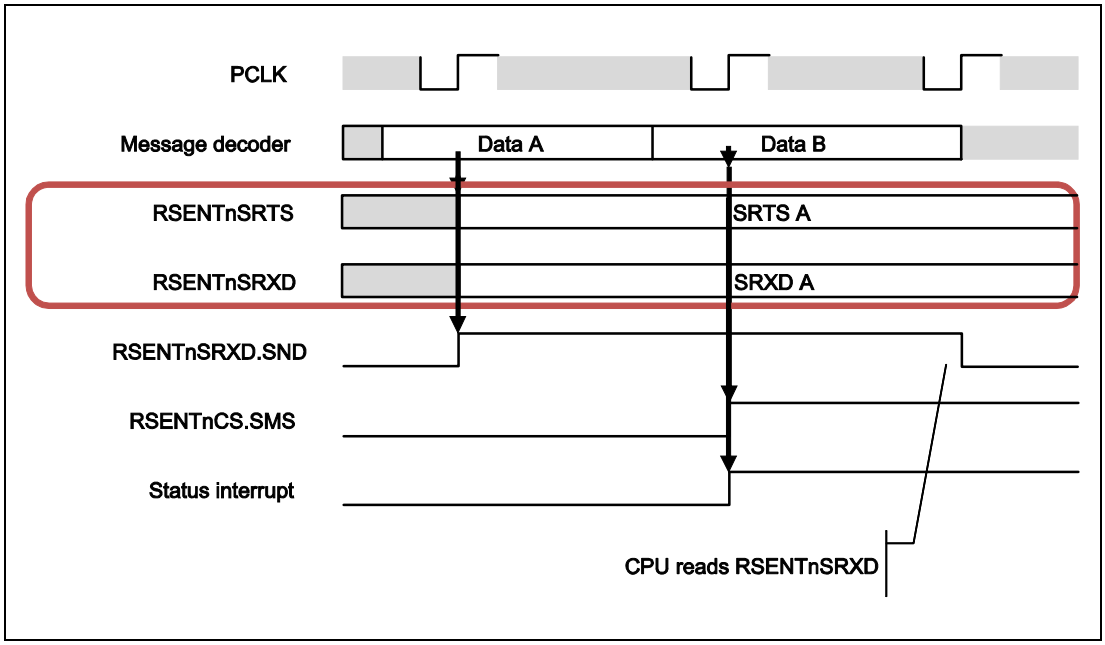

Figure 22.17 Slow Channel Receive Buffer Update Timing

The data alignment in the RSENTnSRXD register depends on the slow channel message format (RSENTnCC.SMF) and the received configuration bit.

Table 22.39 Data Alignment in RSENTnSRXD Register

RSENTnCC.SMF	RSENTnSRXD.SMGC	RSENTnSRXD.IDD[19:16]	RSENTnSRXD.IDD[15:12]	RSENTnSRXD.IDD[11:8]	RSENTnSRXD.IDD[7:4]	RSENTnSRXD.IDD[3:0]
00_B	Undefined	Undefined	Undefined	Undefined	Undefined	Status and communication nibble
01_B	Undefined	Undefined	Undefined	Message ID[3:0]	DATA[7:4]	DATA[3:0]
10_B	0	Message ID[7:4]	Message ID[3:0]	DATA[11:8]	DATA[7:4]	DATA[3:0]
10_B	1	Message ID[3:0]	DATA[15:12]	DATA[11:8]	DATA[7:4]	DATA[3:0]

(6) Slow Channel Reception Flow

In **Figure 22.18**, the recommended reception flow for the slow channel receive buffer is shown. When the slow channel receive data is required, this process should be executed as part of the fast channel reception flow.

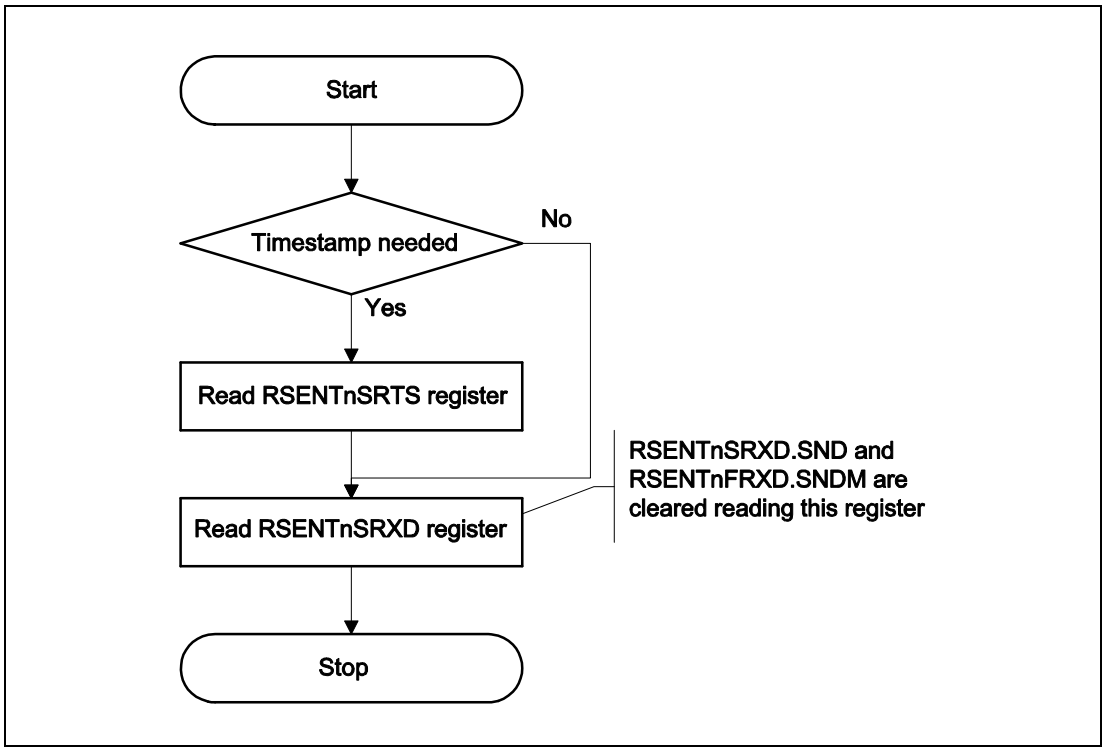

Figure 22.18 Slow Channel Reception Flow

In any case, the CPU should keep the order in reading the slow channel receive buffer registers as shown in the flow. The RSENTnSRXD.SND bit should be accessed as last.

(7) DMA Flow

In case of DMA usage, the start address for the DMA usage and the number of transfers define which part of the receive buffer will be transferred. The RSENTnFRXD register should be the last register to be accessed using a 32 bit access method.

In case of SAE communication with pause pulse and fixed message length, the flow must be extended by checking of the ratio of the calibration pulse to message length. This variation check must be performed by the CPU. In case the variation check fails, the CPU must discard the received message.

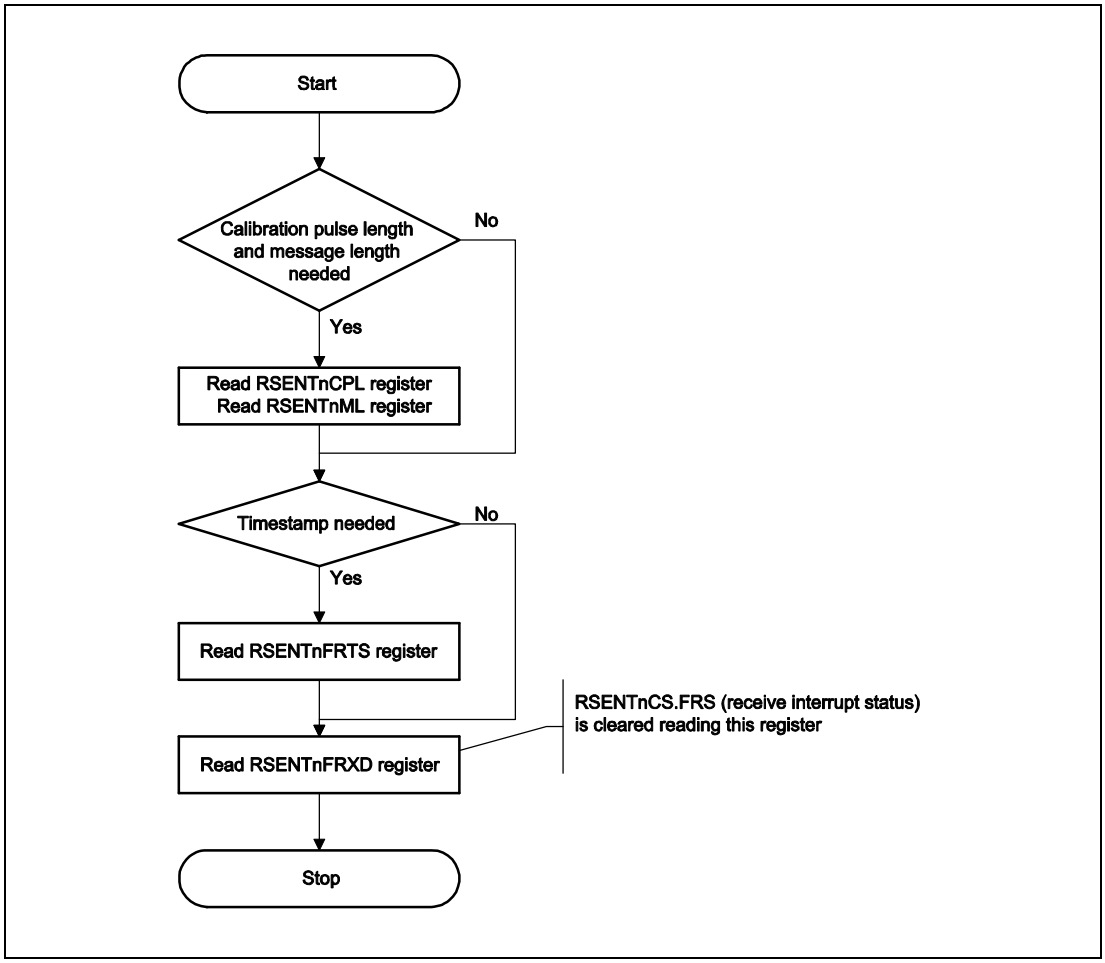

Figure 22.19 DMA Reception Flow

In the software processing, when the transferred data set, the CPU should check the status of the transferred RSENTnFRXD.SNDM bit. If this bit is set to 1, then the user needs to read the slow channel receive buffer if needed.

(8) Error Flagging

Message lost errors (shown in RSENTnCS.SMS, RSENTnCS.FMS) are flagged when a new message was decoded and all message diagnostics passed.

The SPC communication error (shown in RSENTnCS.NRS) is flagged when the CPU writes to RSENTnSPCT.TLL before/during response reception.

The update timings for fast channel reception errors (RSENTnCS.CVS, RSENTnCS.CLS, RSENTnCS.FNS, RSENTnCS.FES and RSENTnCS.FCS) and slow channel reception errors (RSENTnCS.SCS and RSENTnCS.SES) depends on the configuration of RSENTnCC.SPCE, RSENTnCC.FCM, RSENTnCC.PPC and RSENTnCC.PPTC. The update timings for each configuration are shown in **Table 22.40** and **Table 22.41**.

In case a nibble encoding error or calibration pulse length error is detected, message reception is terminated immediately. No further error flagging for this message is done. Message decoding starts again after a calibration pulse without calibration length error (RSENTnCS.CLS) is detected.

Table 22.40 Error flag set timing when CC.SPCE = 0

RSENTnCC.SPCE	**0**	**0**	**0**	**0**	**0**	**0**	**0**	**0**

RSENTnCS.CVS	—	X	—	—	—	X	—	—

EC: End of calibration pulse
IM: Immediately when detected
—: Not set
X: Invalid configuration

NOTE

In case the sensor stops communication, no buffer update or status update for last message takes place. The SW should take care of this by timeout checks.

When a transition to OPERATION IDLE is configured in RSENTnMDC.OMC and an error is detected in the message in which the mode transition was requested, the error is not flagged and the message is aborted.

In case of a fast channel encoding error or a calibration pulse length error the OPERATION IDLE mode is entered immediately.

In case of a fast channel nibble count error, fast channel CRC error, or fast channel calibration pulse variation error the OPERATION IDLE state is entered at the end of the next STATUS/COM nibble.

RERSENTnCS.FNS is only set after a valid calibration pulse was detected and all following nibbles have a valid length (≥12 ticks and ≤27 ticks) or no nibble was received between two valid calibration pulses.

RSENTnCS.FES is only set if the nibble with an encoding error occurred in the communication and status nibble, CRC nibble or in one of the expected data nibbles.

If SPC is enabled (RSENTnCC.SPCE = 1), RSENTnCS.CLS is set if a calibration pulse was expected but the pulse length does not meet the calibration pulse range. If SPC is disabled (RSENTnCC.SPCE = 0), RSENTnCS.CLS is set only after a valid calibration pulse has been received and a calibration pulse was expected but the pulse length does not meet the calibration pulse range.

During re-synchronisation additional error flags might be set which is not affecting the reception of the following frame

22.4.4 SPC Function

The RSENT module supports an extension of the J2716 specification known as SPC. The user can enable or disable the SPC extension by setting the RSENTnCC.SPCE bit.

In SPC mode the RX line will be driven low to initiate RSENT message transmission. In the RH850/P1x-C this can be realized by controlling an external transistor by the RSENTnSPCO pin.

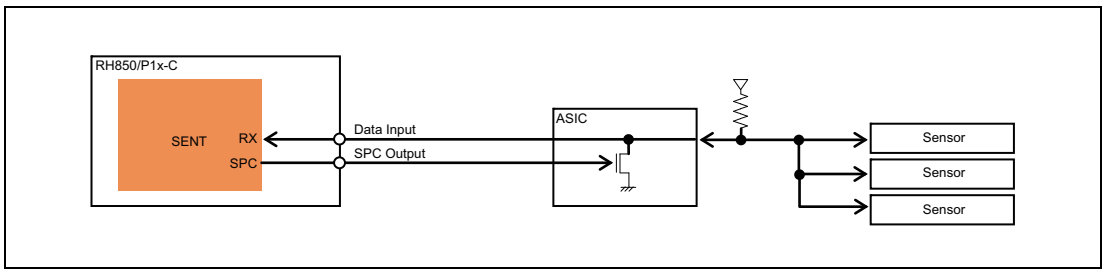

Figure 22.20 Sample Circuit of External Transistor

The user can configure the polarity of the Port RSENTnSPCO.

The text below describes the behavior of the RSENTnSPCO port with the default settings of RSENTnCC.SOPC. When the default value of RSENTnCC.SOPC is changed, the polarity is inverted.

RX line will be held low for a configured length of tick time specified in the RSENTnSPCT.TLL bits.The Tick time is configured with the RSENTnBRP.TTI bits and the RSENTnBRP.TTF bits which are equal to the transmission tick time. For details, see **Section 22.4.2.2(2), RX and SPC Tick Settings**.

In a single sensor system, this function can be used to trigger data transmission from the sensor. Further data can be sent to the sensor by varying the trigger pulse length. In a multi sensor system, this function can be used to address a dedicated sensor and request a data transmission.

Once RSENT SPC initialization is complete, transmission can be triggered by writing the trigger pulse width to the RSENTnSPCT.TLL register. When a transmission is triggered, the trigger pulse with the configured length is sent. Then a frame reception is expected. After frame reception was done, a new trigger pulse can be sent.

Writing to RSENTnSPCT.TLL requests a SPC trigger transmission. After writing to RSENTnSPCT.TLL, the CPU should read RSENTnCS.NRS to check whether the previous request was completed or not.

In case RSENTnCS.NRS is set, no SPC trigger is sent and any potentially ongoing reception at this time is aborted. The CPU should clear RSENTnCS.NRS by writing 1 to RSENTnCSC.NRC. The CPU can write again to RSENTnSPCT.TLL to request a SPC trigger transmission.

In case RSENTnCS.NRS is not set, the CPU should set a reception timeout counter in software. If a reception occurs before the timeout counter elapses, the user should process the received slow and fast channel data as shown in the fast channel reception flow (**Figure 22.15**) and slow channel reception flow (**Figure 22.18**).

When the timeout counter elapses without any successful reception, the addressed sensor seems not to send any valid response. The CPU should analyze the RSENTnCS register to analyze the reason for no successful reception. A new request can be made considering that when RSENTnCS.NRS gets set no SPC trigger is sent.

According to the SPC protocol, a frame is received when the falling edge of the end pulse has been detected. It is the user responsibility to not make a SPC trigger request during the end pulse as this might not be recognized by the sensor.

Purpose of the timeout function is to define a timeout window for response reception in software.

Figure 22.21 shows a transmission flow with a timeout function implemented in software. The timeout function is optional and can be omitted if not needed.

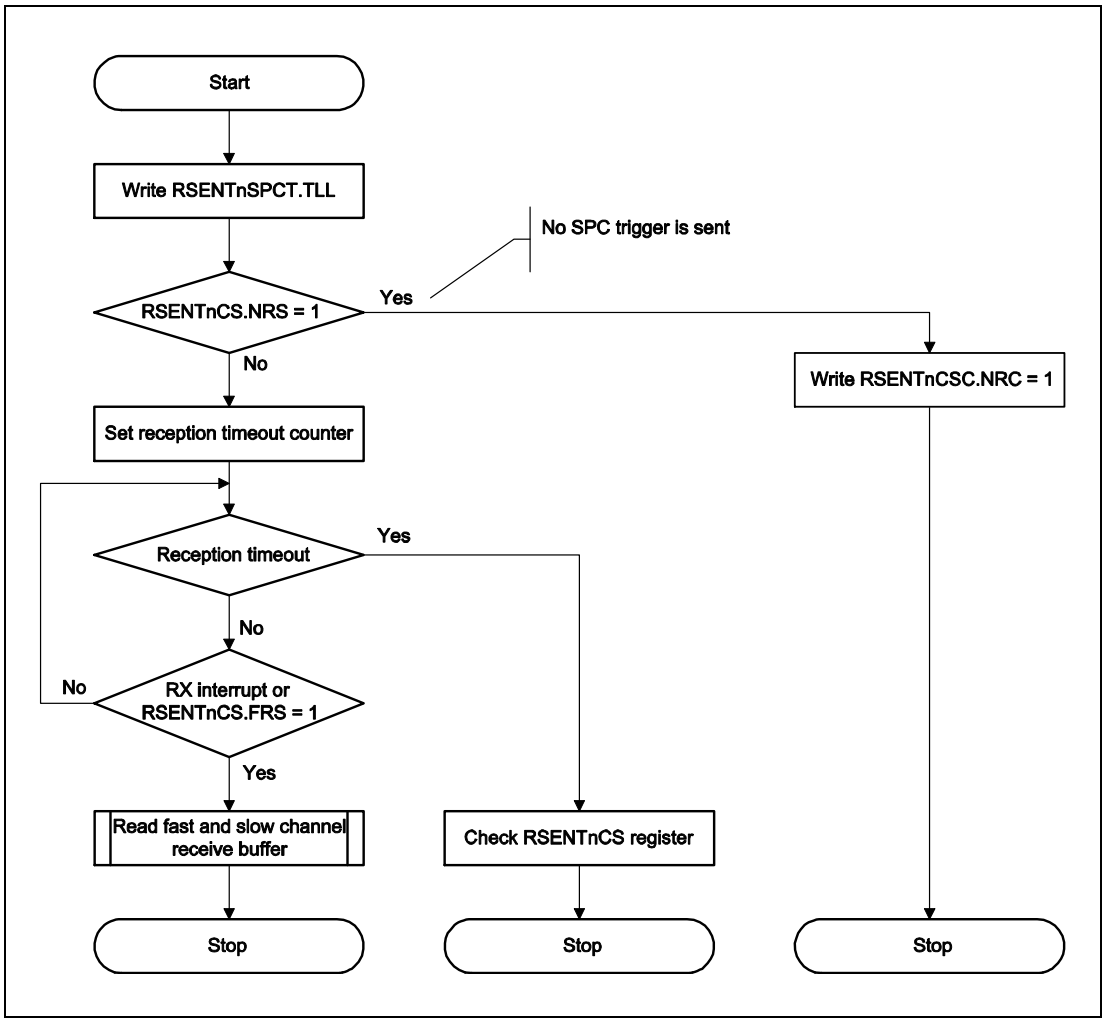

Figure 22.21 Transmission Flow

22.4.5 Interrupts and Checks

The RSENT module provides two interrupt lines.

The successful fast channel receive interrupt notifies the CPU that the fast channel receive buffer was updated and is holding a set of valid received data. Also, the reception status bit is set (RSENTnCS.FRS).

The status interrupt notifies the CPU that at least one of the error flags or message lost flags in the RSENTnCS register is set.

Whether a status flag in the RSENTnCS register is contributing to the generation of an interrupt event or not can be set individually.

The execution of the CRC checks can be disabled for the slow channel and fast channel individually. In case a check is disabled, the CRC of the received message is not checked and the related error flag is never set.

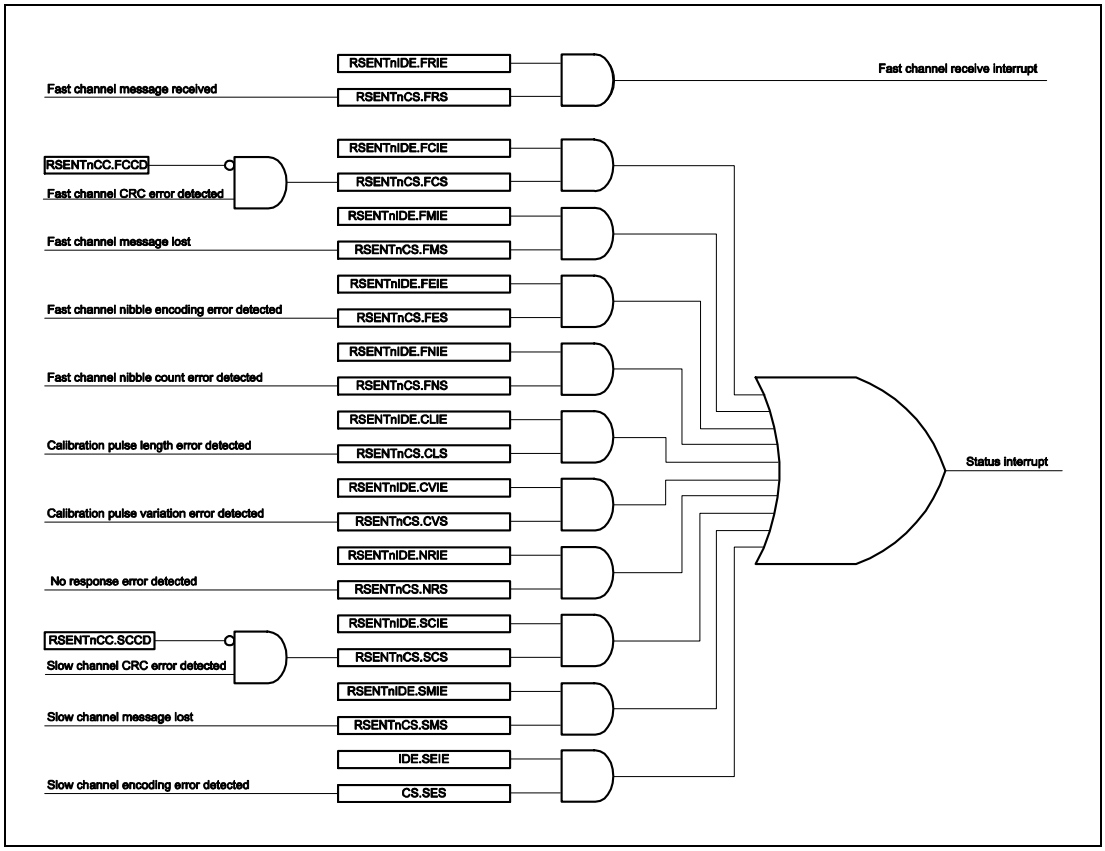

Figure 22.22 Interrupt Structure

Table 22.42 gives an overview about the relationship between set status flags and the buffer update.

Table 22.42 Status Flag Influence to Receive Buffer Behavior

RSENTnCS	Fast Channel Receive Buffer	Slow Channel Receive Buffer
FRS	Updated	Updated if last slow channel nibble received and RSENTnCS.SES = 0 and RSENTnCS.SCS = 0
FCS	Not updated	Not impacted. Fast channel CRC does not cover the communication and status nibble
FMS	Background buffer overwritten	Not impacted
FES	Not updated	Receive process aborted. Search for new start condition
FNS	Not updated	Receive process aborted. Search for new start condition
CLS	Not updated	Receive process aborted. Search for new start condition
CVS	Not updated	Receive process aborted. Search for new start condition
NRS	Not updated	Receive process aborted. Search for new start condition
SCS	Not impacted	Not updated
SMS	Not impacted	Message lost
SES	Not impacted	Receive process aborted. Search for new start condition

22.4.6 Limited Reset and Module stand-by

The RSENTn can be reset by limited reset from SYSCTRL. The Limited Reset is functionally equivalent to a hardware reset. Software must ensure that RSENTn is halted (RESET Mode or CONFIGURATION Mode). (See **Section 22.4.1, Modes of Operation**)

The RSENT clock can be disabled by the SYSCTRL module stand-by function. Software must ensure that RSENT is RESET mode or CONFIGURATION mode if module stand-by enable.

22.5 Difference among P1M-C, P1H-C and P1H-CE

Table 22.43 Different specification of RSENT

Device	P1M-C (QFP, BGA-292)	P1M-C (BGA-156)	P1H-C (4MB, BGA-292)	P1H-C (4MB, BGA-156)	P1H-C (8MB)	P1H-CE
RSENT channel	6	4	8	4	8	10

Section 23 Window Watchdog Timer A (WDTA)

23.1 Features

The purpose of the Window Watchdog Timer A (WDTA) is to detect deadlock of CPU operation. WDTA is implemented as 1 or 2 macros in each device. One monitors so that PE1 won't be going out of control. Also, other monitors PE2. This timer generates an error signal if the counter is not cleared by CPU within a certain counter value. If the timer is cleared, MCU can keep normal operation. Additionally to detect failure mode, when the CPU feeds data for clearing the watchdog timer counter in incorrect timing due to unexpected CPU operation, extra feature are necessary such as a window trigger, VAC(Varying Activation Code) etc.

23.1.1 Number of Units and Channels

Table 23.1 Number of WDTA channel

	Device			
Macro	P1M-C	P1H-C (4MB)	P1H-C (8MB)	P1H-CE
WDTA0	1	1	1	1
WDTA1	0	1	1	1

23.1.2 Register Base Address

WDTAn base addresses are listed in the following table. WDTAn register addresses are given as offsets from the base addresses in general.

Table 23.2 Register Base Address

Base Address Name	Base Address
<WDTA0_base>	FFED 0000_H
<WDTA1_base>	FFED 1000_H

23.1.3 Clock Supply

Table 23.3 Clock Supply

Unit Name	Specification	Description
WDTA0/ WDTA1	High speed system clock : CLK_HSB	APB Bus clock
WDTA0/ WDTA1	WDTA counter clock : WDTACLKI	WDT count clock*1 1/1 or 1/32 of CLK_IOSC*2

Note 1. Selectable by using the corresponding option byte

Note 2. See **Section 12, Clock Controller**

23.1.4 Interrupt Request

WDTAn interrupt requests are listed in the following table.

Table 23.4 Interrupt Requests

Unit Name	Interrupt Name	Interrupt Number	DMA Number	Description
WDTA0	INTWDTA0	8	—	WDTA0 75% interrupt for PE1
WDTA0				
WDTA1	INTWDTA1	8	—	WDTA1 75% interrupt for PE2
WDTA1				

Table 23.5 Internal Error Signal

Unit Name	Interrupt for Unit	Description	Connected to
WDTA0	WDTA0TERR*[1]	WDTA0 error signal	ECM
WDTA1	WDTA1TERR*[1]	WDTA1 error signal	ECM

Note 1. For details about error input to ECM, refer to **Section 29, Error Control Module (ECM)**

23.1.5 External Input / Output Pins

WDTAn has no external pins

23.2 Overview

23.2.1 Functional Overview

The Window Watchdog Timer A generates the ECM error signal if the 16-bit counter overflows or if any other error condition is fulfilled. The counter is cleared and restarted every time a WDTA trigger occurs while the window is open.
At 75% of the maximum counter value, the WDTA can generate an interrupt request INTWDTA0 and INTWDTA1. After reset release, the start-up options specify the start mode and the WDTA settings. The settings can be modified by writing the Watchdog Timer mode register WDTAnMD.

The Window Watchdog Timer A has the following functions:

- Operation mode after reset selectable by using start-up options
- Fixed activation code and variable activation code (VAC) selectable
- Two start modes available:
  - Default start mode (automatic start)
  - Software trigger start mode
- Generation of an error signal to ECM on error detection
- Interrupt request generation at 75% of the counter overflow value
- Window function

23.2.2 Block Diagram

Figure 23.1 shows the main components of the Window Watchdog Timer A

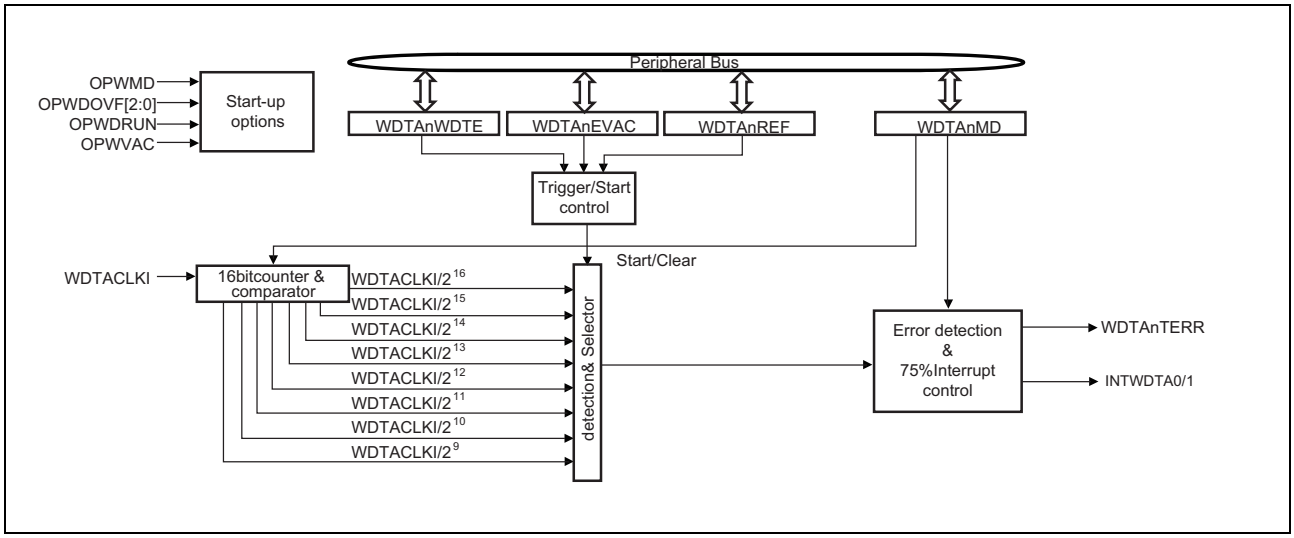

Figure 23.1 Block diagram of the Window Watchdog Timer A

23.3 Registers

23.3.1 List of Registers

WDTAn registers are listed in the following table.

Table 23.6 Register list

Address	Register name	Description	Access Size[bit]	Value after reset	Access Protection	
					PBG	Other
*	*	WDTA0	8	*	PBG2.PG2-WDT0	—
*	*	WDTA1	8	*	PBG2.PG2-WDT1	—

*: Regarding address, register name, and value after reset of WDTAn, see the following table

Table 23.7 Register Reset Condition

Register Name	Reset condition				
	Power On Reset	System Reset1	System Reset2	Application Reset1	Limited Reset
All registers	√	√	√	√	—

Table 23.8 List of WDTn Registers

Module	Register	Symbol	Address
WDTAn	WDTA enable register	WDTAnWDTE	<WDTAn_base> + 0000_H
WDTAn	WDTA VAC enable register	WDTAnEVAC	<WDTAn_base> + 0004_H
WDTAn	WDTA reference value register	WDTAnREF	<WDTAn_base> + 0008_H
WDTAn	WDTA mode register	WDTAnMD	<WDTAn_base> + $000C_H$

23.3.2 WDTAnWDTE — WDTA enable register

This register is the WDTA start control and trigger register if the VAC function is not used (start-up option OPWDVAC = 0).

NOTE

See the **Table 23.17, WDTA start-up options**.

WDTA trigger

Writing AC_H to this register restarts the counter.The behavior of this register depends on activation of the VAC function, see **Table 23.11, WDTAnWDTE behavior**.

Access: This register can be read/written in 8-bit units.

Address: <WDTAn_base> + 0000_H

Value after reset: The value after reset depends on the start-up options OPWDEN, OPWDRUN and OPWDVAC. See **Table 23.10, WDTAnRUN value after reset**.
This register is initialized by a reset of any type.

Bit	7	6	5	4	3	2	1	0
	WDTAnRUN	—	—	—	—	—	—	—
Value after reset	—	0	1	0	1	1	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 23.9 WDTAnWDTE register contents

Bit Position	Bit Name	Function
7	WDTAnRUN	Enables/disables the WDTAn: 0: WDTAn disabled 1: WDTAn enabled Since the WDTA can not be stopped once it was started, this bit can only be cleared by a reset.
6 to 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

This bit is only valid if VAC is disabled (OPWDVAC = 0). In this case, the initial value of bit WDTAnRUN depends on other start-up options as listed below.

Table 23.10 WDTAnRUN value after reset

Start-up options		
OPWDVAC	**OPWDRUN**	**Value after reset of WDTAnRUN**
0	1	1
Other than above		0

The behavior of WDTAnWDTE during read/write accesses depends on activation of the VAC mode, as shown in **Table 23.11** below.

Table 23.11 WDTAnWDTE behavior

	WDTAnWDTE		
OPWDVAC	**Read**	**Write**	**Remark**
0	AC_H	WDTA trigger AC_H*1	VAC disabled, WDTAnWDTE enabled
1	$2C_H$	ignored	VAC enabled, WDTAnWDTE disabled

Note 1. Any other write value will lead to an error detection.

23.3.3 WDTAnMD — WDTA mode register

This register specifies the overflow interval time, the 75% interrupt enable/disable, and the window-open period.

It can be updated only once after reset release and before the first trigger. The updated value is effective after the next WDTA trigger.

Updating this register after the WDTA has been started leads to error detection, but the read value of this register can be written without generating an error.

Access: This register can be read/written in 8-bit units.

Address: <WDTAn_base> + $000C_H$

Value after reset: The value after reset depends on the start-up options OPWDOVF[2:0].
This register is initialized by a reset of any type.

Bit	7	6	5	4	3	2	1	0
	—	WDTAnOVF[2:0]			WDTAnWIE	—	WDTAnWS[1:0]	
Value after reset	0	—	—	—	0	1	1	1
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 23.12 WDTAnMD register contents

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 4	WDTAnOVF[2:0]	Selects the overflow interval time (µs)

WDTAn OVF2	WDTAn OVF1	WDTAn OVF0	Overflow interval time
0	0	0	2^9 / WDTACLKI
0	0	1	2^{10} / WDTACLKI
0	1	0	2^{11} / WDTACLKI
0	1	1	2^{12} / WDTACLKI
1	0	0	2^{13} / WDTACLKI
1	0	1	2^{14} / WDTACLKI
1	1	0	2^{15} / WDTACLKI
1	1	1	2^{16} / WDTACLKI

The reset values of WDTAnOVF[2:0] depend on start-up option OPWDOVF[2:0].

3	WDTAnWIE	Enables/disables the 75% interrupt request INTWDTA0/1: 0: INTWDTA0/1 disabled(value after reset) 1: INTWDTA0/1 enabled
2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	WDTAnWS[1:0]	Selects the window-open period:

WDTAn WS1	WDTAn WS0	Window-open period
0	0	25%
0	1	50%
1	0	75%
1	1	100% (Default)

23.3.4 WDTAnEVAC — WDTA enable VAC register

This register is the start control and trigger register if the VAC function is used (start-up option OPWDVAC = 1).

WDTA trigger

Writing the correct activation code to this register restarts the counter.

The behavior of this register depends on activation of the VAC function. See **Table 23.15, WDTAnEVAC behavior**.

Access: This register can be read/written in 8-bit units.

Address: <WDTAn_base> + 0004_H

Value after reset: The value after reset depends on the start-up options OPWDEN,OPWRUN and OPWDVAC. See **Table 23.14, WDTAnEVAC value after reset**
This register is initialized by a reset of any type.

Bit	7	6	5	4	3	2	1	0
	WDTAnEVAC7	—	—	—	—	—	—	—
Value after reset	—	0	1	0	1	1	0	0
R/W	R/W	R	R	R	R	R	R	R

Table 23.13 WDTAnEVAC register contents

Bit Position	Bit Name	Function
7	WDTAnEVAC7	Enables/disables the WDTAn: 0: WDTAn disabled 1: WDTAn enabled Since the WDTA cannot be stopped once it was started, this bit can only be cleared by a reset. Thus even if bit 7 of the activation code is 0, the WDTA will not stop.
6 to 0	Reserved	When read, the value after reset is read. When writing, write the value after reset.

This bit is only valid if VAC is enabled (OPWDVAC = 1). In this case, the value after reset of the WDTAnEVAC7 bit depends on other start-up options as listed below.

Table 23.14 WDTAnEVAC value after reset

Start-up options		
OPWDRUN	**Start mode**	**Value after reset of WDTAnEVAC7**
0	Software trigger	0
1	Default	1
Ignored	Software trigger	0
Ignored	Default	1

The behavior of WDTAnEVAC during read/write accesses depends on activation of the VAC mode, as shown in **Table 23.15** below.

Table 23.15 WDTAnEVAC behavior

	WDTAnEVAC		
OPWDVAC	**Read**	**Write**	**Remark**
0	$2C_H$	Ignored	VAC disabled
1	Last written VAC	ExpectWDTE*[1]	VAC enabled

Note 1. Any other write value will lead to an error detection.

23.3.5 WDTAnREF — WDTA reference value register

This register contains the reference value for calculating the activation code of the VAC function. It is automatically updated after every trigger operation.

If VAC is disabled (OPWDVAC = 0), reading this register returns 00_H.

Access: This register can be read/written in 8-bit units.

Address: <WDTAn_base> + 0008_H

Value after reset: 00_H
This register is initialized by a reset of any type.

Bit	7	6	5	4	3	2	1	0
	WDTAnREF[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 23.16 WDTAnREF register contents

Bit Position	Bit Name	Function
7 to 0	WDTAnREF[7:0]	Reference value for activation code calculation.

23.4 Operation

23.4.1 WDTA Start-up Options

The start-up options determine the start-up configuration of the WDTA after reset release. They are described in **Table 23.17, WDTA start-up options**.

Table 23.17 WDTA start-up options

Start-up option	Function	Description	Connected to
OPWD0MD	WDTA slow/fast mode	Switches between slow and fast mode: 0: WDTA slow mode (WDTACLKI = 1/32 of CLK_IOSC) 1: WDTA fast mode (WDTACLKI = 1/1 of CLK_IOSC)	• WDTA0: Flash option*1 • WDTA1: Flash option*1
OPWDOVF[2:0]	Count clock setting	Specifies the reset value of the count clock control bits WDTAnMD.WDTAnOVF[2:0].	• WDTA0/WDTA1: Flash option*1
OPWDRUN	Start mode setting	Specifies the start mode: 0: Software trigger start mode 1: Default start mode	• WDTA0: Flash option*1 • WDTA1: Flash option*1
OPWDVAC	Variable Activation Code (VAC) selection	Specifies the trigger register for the generation of counter re-start triggers to keep the counter from overflowing. 0: WDTAnWDTE (fixed) 1: WDTAnEVAC (variable) When WDTAnWDTE is selected, the value to be written to the register (activation code) is fixed (AC_H). When WDTAnEVAC is selected, the activation code to be written to the register is variable.	• WDTA0: Flash option*1 • WDTA1: Flash option*1

Note 1. Refer **Section 32.12**

NOTE

The Window Watchdog Timer A generates an error signal for ECM if an error occurred. If the ECM is configured to generate a reset as a result on this error signal, it is indicated in a reset status register:

23.4.2 WDTA after reset release

23.4.2.1 Start modes

The WDTA provides two modes for the counter start after reset release:

- Software trigger start mode
  The counter value remains 0000_H after reset release.
  The counter is started with the first WDTA trigger.
- Default start mode
  The counter starts automatically after reset release.

23.4.2.2 Start mode selection

The start mode can be selected by the start-up options.

The start mode selection is listed in Table Start mode selection.

Table 23.18 Start mode selection

Start-up options		
OPWDRUN	**Reset type**	**Start mode**
0	Ignored	Software trigger
1		Default

23.4.2.3 WDTA settings after reset release

The WDTA settings are as follows between reset release and the first trigger:

Table 23.19 WDTA settings after reset release

Function	Setting	Remark
Start mode	Specified by start-up options	
Count clock		
75% interrupt mode	Disabled	
Window-open period	100%	If default start mode is specified, the first trigger is valid any time before the counter overflows.

Change WDTA settings

After the first trigger, the WDTA continues according to the settings of the Watchdog Timer mode register WDTAnMD.

To change the WDTA settings, WDTAnMD must be written before the first trigger. Changing the value of WDTAnMD after the first trigger leads to an error.

If WDTAnMD is not changed before the first trigger, the WDTA mode is specified by the value after reset of WDTAnMD.

The new or value after reset of WDTAnMD applies after the first trigger.

23.4.2.4 Default start mode timing

The default start mode timing and the changes to the WDTA settings are illustrated in **Figure 23.2**.

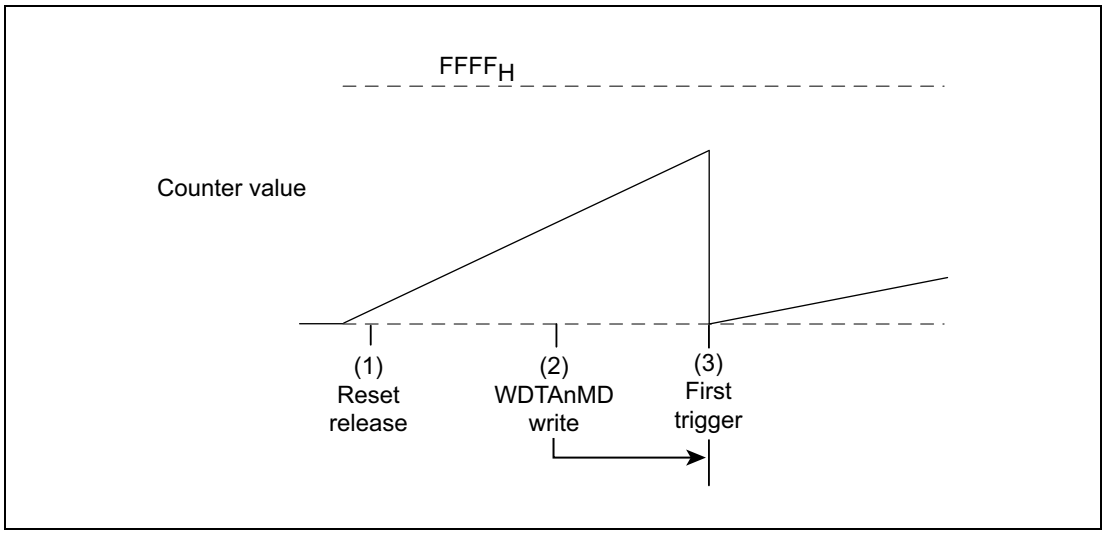

Figure 23.2 Timing diagram of WDTA start in default start mode

The timing diagram above shows the following:

(1) After reset release, the counter starts immediately.
The count clock is specified by the start-up options, for example:
– Count clock after reset release = WDTACLKI / 2^{13}
(OPWDOVF[2:0] = 100_B)

(2) WDTAnMD is written with WDTAnMD.WDTAnOVF[2:0] = 111_B before the first trigger.
However, the settings are not applied immediately.

(3) The first trigger must occur before the counter overflows.
After the first trigger, the settings specified in WDTAnMD are applied, for example a new count clock:
– Count clock after first trigger = WDTACLKI / 2^{16} (WDTAnMD.WDTAnOVF[2:0] = 111_B

23.4.2.5 Software trigger start mode timing

The software trigger start mode timing and the changes to the WDTA settings are illustrated in **Figure 23.3**.

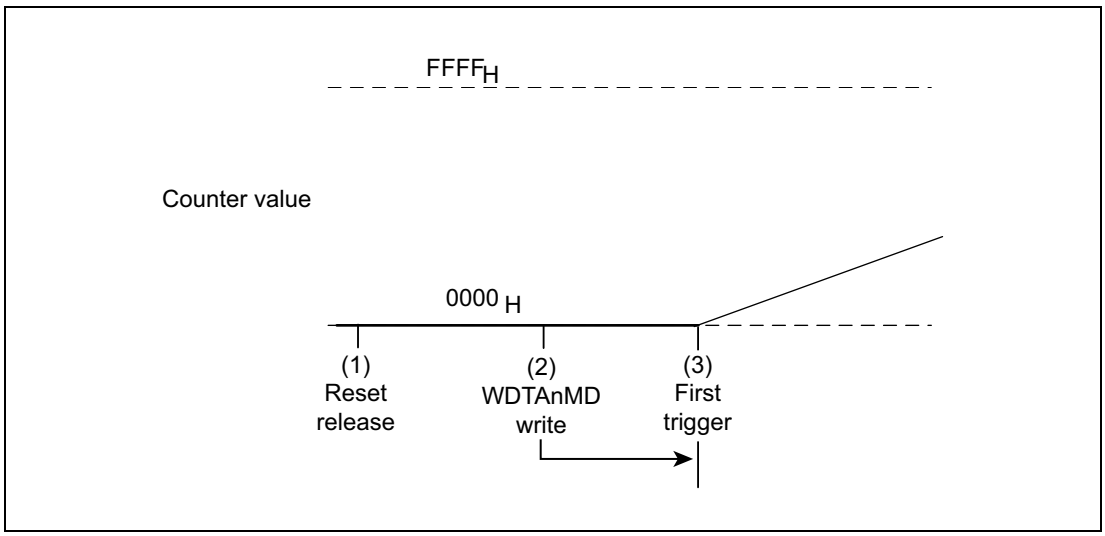

Figure 23.3 Timing diagram of WDTA start in software trigger start mode

The timing diagram above shows the following:

(1) After reset release, the counter remains 0000_H until the first trigger.
The count clock is specified by the start-up options, but it does not have any effect.

(2) WDTAnMD is written before the first trigger. However, the settings are not applied immediately.

(3) The counter starts at the first trigger.
The count clock and other settings specified in WDTAnMD are applied.

23.4.3 WDTA trigger

The WDTA trigger has the following functions:

- Counter start trigger in software trigger start mode
- Counter restart trigger to avoid counter overflow

The trigger register to be used differs depending on whether the activation code is fixed or variable. The type of activation code and the associated trigger register are specified by using the start-up option OPWDVAC.

Table 23.20 Trigger register and activation code

Type of activation code	Trigger register	Activation code
Fixed	WDTAnWDTE	AC_H
Variable	WDTAnEVAC	For details, refer to Calculation variable activation codes

23.4.3.1 Calculating variable activation codes

The variable activation code (ExpectWDTE) is calculated using a reference value in register WDTAnREF. The reference value in WDTAnREF is updated each time the trigger register WDTAnEVAC is written.

- Use the expression below to calculate the variable activation code (ExpectWDTE):
  ExpectWDTE = AC_H – WDTAnREF (old)
- Use the expression below to calculate how the WDTAnREF value is updated:
  WDTAnREF (new) = rotate left 1 bit (ExpectWDTE)

The table below lists the variable activation codes according to the number of triggers.

Table 23.21 Expected variable activation code development

No[*1]	WDTAnREF (old)		ExpectWDTE (AC_H — WDTAnREF)		WDTAnREF (new)	
0	0000 0000	00_H	1010 1100	AC_H	0101 1001	59_H
1	0101 1001	59_H	0101 0011	53_H	1010 0110	$A6_H$
2	1010 0110	$A6_H$	0000 0110	06_H	0000 1100	$0C_H$
…	…	…	…	…	…	…

Note 1. Number of triggers after reset

NOTE

Bit 7 of the WDTAnEVAC register (WDTAnEVAC7) cannot be cleared to 0 after the WDTA has been started. Thus even if bit 7 of the activation code is 0, the WDTA will not stop.

23.4.4 Error detection

The conditions for error detection are:

- Overflow interval time is exceeded (counter overflow)
- Wrong activation code is written to the trigger register
- Writing to the trigger register while the window is closed.
- Illegal update of Watchdog Timer mode register WDTAnMD:
  - Writing a new value to WDTAnMD after the first trigger leads to an error detection.
  - Writing the same value to WDTAnMD after the first trigger does not lead to an error detection.
- When an error is detected, an error signal for ECM (WDTAnTERR) is generated.

Figure 23.4 shows the error signal to ECM generation when the counter overflows and default start mode is selected.

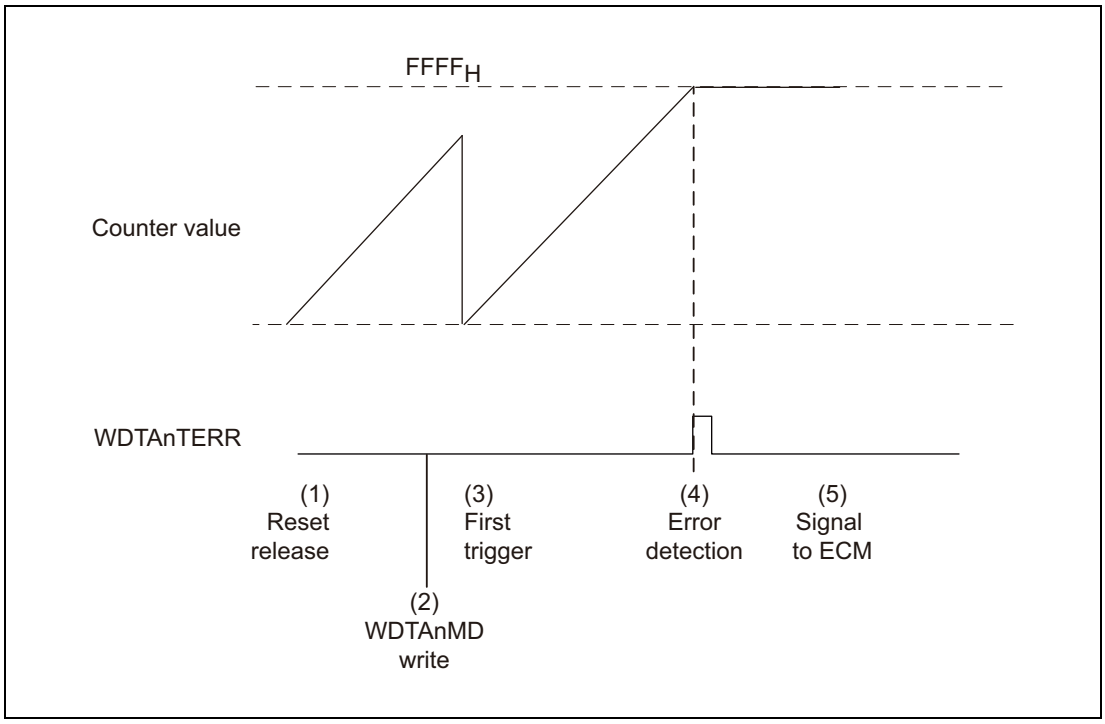

Figure 23.4 Timing diagram of WDTA error signal to ECM module

The timing diagram above shows the following:

(1) After reset release, the counter starts (default start mode is selected).

(2) WDTAnMD is written before the first trigger. However, the settings are not applied immediately.

(3) The counter is cleared at the first trigger and the new WDTA settings are applied.

(4) When the counter overflows, an error is detected. The WDTAnTERR is generated. The counter value remains until a reaction from ECM occurs.

23.4.5 75% interrupt request signals

When the counter reaches 75% of the maximum counter value, the interrupt request INTWDTAn is generated.

By use of WDTAnMD.WDTAnWIE this function can be enabled or disabled afterwards.

Figure 23.5 shows the 75% interrupt request generation under following conditions:

- Default start mode selected
- Count clock changes after first trigger

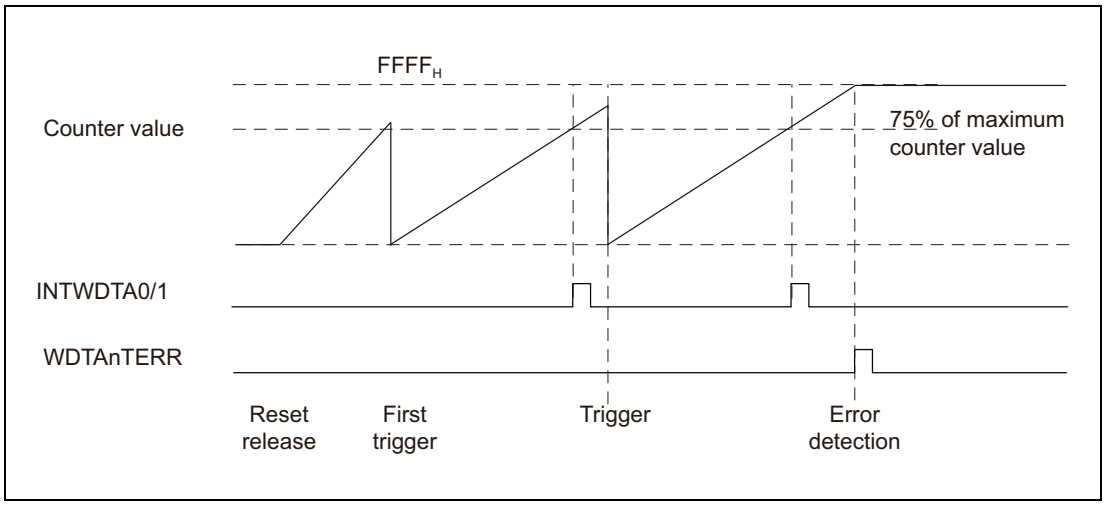

Figure 23.5 Timing diagram of WDTA 75% interrupt request signals

23.4.6 Window function

When the window-open period is set to less than 100%, an error is detected if the trigger occurs while the window is closed.

The definition of the window-open period differs before and after the first trigger:

- After reset release, the window-open period is 100%.
- After the first trigger, the window-open period is specified by bits WDTAnMD.WDTAnWS[1:0].

Figure 23.6 shows WDTA operation with a window-open period of 25% and with default start mode selected.

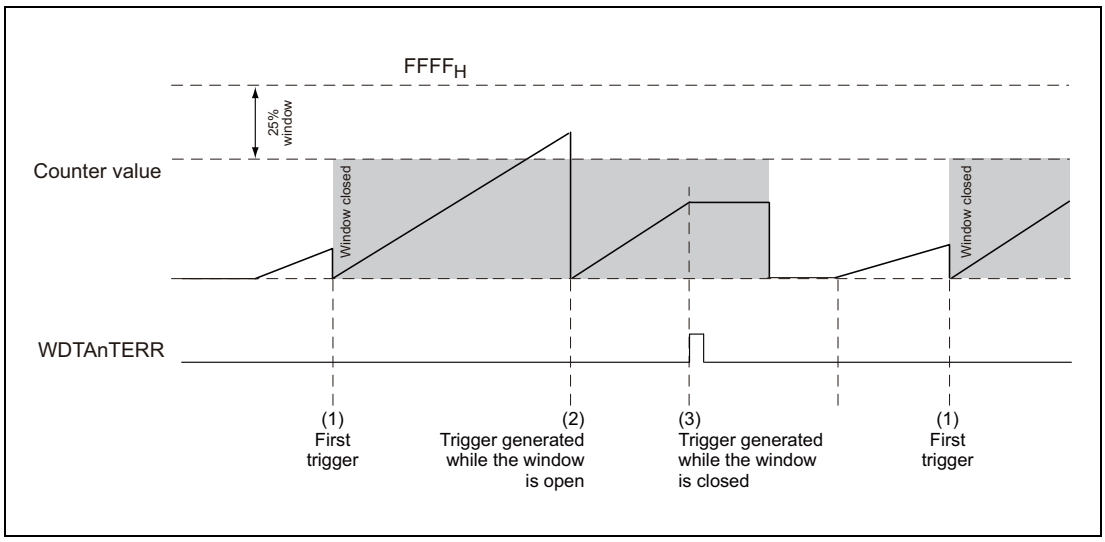

Figure 23.6 Timing diagram of WDTA window function

The timing diagram above shows the following:

(1) The window-open period is fixed to 100% for the first trigger.

(2) A trigger generated while the window is open does not lead to an error.

(3) A trigger generated while the window is closed generates an error signal to ECM module.

23.5 Cautions

1. Register access to WDTA0 is allowed from PE1 only. Do not access to WDTA0 from other masters.
   Register access to WDTA1 is allowed from PE2 only. Do not access to WDTA1 from other masters.
   Initial setting of each PBUS guard allows access from PE1/ PE2 to each WDTs. At first after start up, change the setting of PBUS guard for WDT0 to allow access from PE1 only. Also, change the setting of PBUS guard for WDT1 to allow access from PE2 only.
2. When WDT is default (automatic) start mode, WDT counter setting as default start mode begins to count up at the same time with a PE start up even if other PE doesn't start fetch. Please be careful in order to clear a counter of each WDT before reaching default threshold. When WDT counter can't be cleared before reaching the threshold, please use WDT by a Software start mode.

23.6 Difference among P1M-C, P1H-C and P1H-CE

There are differences in channels, interrupts, and external pins. For details, see **Table 23.1**, and **Table 23.4**.

Section 24 System Timer (STM)

24.1 Features

The system timer (STM) is intended for typical operating system tasks like scheduling and synchronization of SW processes and supervision of timing budgets in single and multi-core environments. It will also be used for generation of wait loops or synchronization of SW processes with HW events. A set of 4 hardware counter channels allows running typical OS services like task scheduling and time budget monitoring on individual time bases. This reduces efforts to emulate additional timer channels in SW normally derived from only one common hardware timer. Multiple compare registers per counter channel can be used to start cyclic tasks with a defined temporal offset. A dedicated wide 64-bit counter channel enables the generation of a unique timestamp covering long period operation periods without overflow (e.g. complete automotive driving cycle) and thus eliminates any additional overflow SW handling.

24.1.1 Number of Units and Channels

Table 24.1 Number of STM channel

Macro	Device				Description
	P1M-C	P1H-C (4MB)	P1H-C (8MB)	P1H-CE	
STM0	1	1	1	1	STM0 connect to NTU clock from FlexRay. Interrupt 8 of STM0 is non-maskable interrupt for PE1.
STM1	0	1	1	1	STM1 don't connect to NTU clock from FlexRay. Interrupt 8 of STM1 is non-maskable interrupt for PE2.

24.1.2 Register Base Address

STMn base addresses are listed in the following table. STMn register addresses are given as offsets from the base addresses in general.

Table 24.2 Register Base Address

Base Address Name	Base Address
<STM0_base>	FFDD 8000H
<STM1_base>	FFDD 9000H

24.1.3 Clock Supply

Table 24.3 Clock Supply

Unit Name	Specification	Description
STM0	High speed system clock: CLK_HSB	Peripheral clock (PCLK) and Counter clock source
	FlexRay NTU clock	Counter clock source
STM1	High speed system clock: CLK_HSB	Peripheral clock (PCLK) and Counter clock source

24.1.4 Interrupt Request

STMn interrupt requests are listed in the following table.

Table 24.4 STMn interrupt requests

Unit Name	Interrupt Name	Interrupt Number	DMA Number	Description
STM0	INTSTM00	41	—	—
STM0	INTSTM01	42	—	—
STM0	INTSTM02	12	—	—
STM0	INTSTM03	13	—	—
STM0	INTSTM04	14	—	—
STM0	INTSTM05	15	—	—
STM0	INTSTM06	135	—	—
STM0	INTSTM07	136	—	—
STM0	FEINT for PE1	FEINT	—	Non-maskable interrupt for PE1
STM1	INTSTM10	43	—	—
STM1	INTSTM11	44	—	—
STM1	INTSTM12	45	—	—
STM1	INTSTM13	46	—	—
STM1	INTSTM14	137	—	—
STM1	INTSTM15	138	—	—
STM1	INTSTM16	139	—	—
STM1	INTSTM17	140	—	—
STM1	FEINT for PE2	FEINT	—	Non-maskable interrupt for PE2

24.1.5 External Input / Output Pins

STMn has no external pins

24.2 Overview

24.2.1 Functional overview

- 1x64-bit / 3x32-bit counter channel
- Atomic read/write access to all registers
- 4 compare channels per counter channel (bit width corresponding to counter channel)
- Free-run compare mode, counting up
- Clock sources: Peripheral Clock PCLK, FlexRay NTU clock
- 9 interrupts (8x maskable, 1x non maskable high priority)
- Configurable assignment of interrupts to compare and overflow events
- Common register to start / stop multiple counter channels synchronously by one single register access
- Common status register, reflecting all channels' compare match and overflow flags by one single register access
- Anytime write access to compare registers, anytime read access to counter registers
- Application reset 1 (SW reset) for individual channels can be masked. When masked, counter keeps running on reset occurrence and counter register will not be initialized.

24.2.2 Counter channels and compare registers

The System Timer is composed of one 64-bit channel and three 32-bit counter channels. Each counter is equipped with 4 compare registers with corresponding bit width.

The counter registers can be read at any time, both while counter is running or stopped. The compare registers can be written at any time.

The CPU architecture supports 64-bit write access on the 32-bit peripheral bus. However in case of individual 32-bit write accesses to 64-bit counter or compare registers of channel 0, the updated register value will be processed after write to the upper 32-bit register. The appropriate write sequence must therefore be specified by software (i.e., that the register must be accessed from the lower 32 bits, and then the upper 32 bits.)

In case of reading the 64-bit counter value while the counter is running, the current 64-bit counter value will be captured first and read access will be performed on the captured value then. This is to avoid that the upper or lower 32-bit value changes between the two consecutive 32-bit read accesses.

24.2.3 Block Diagram

The following block diagram shows the main components of the System Timer.

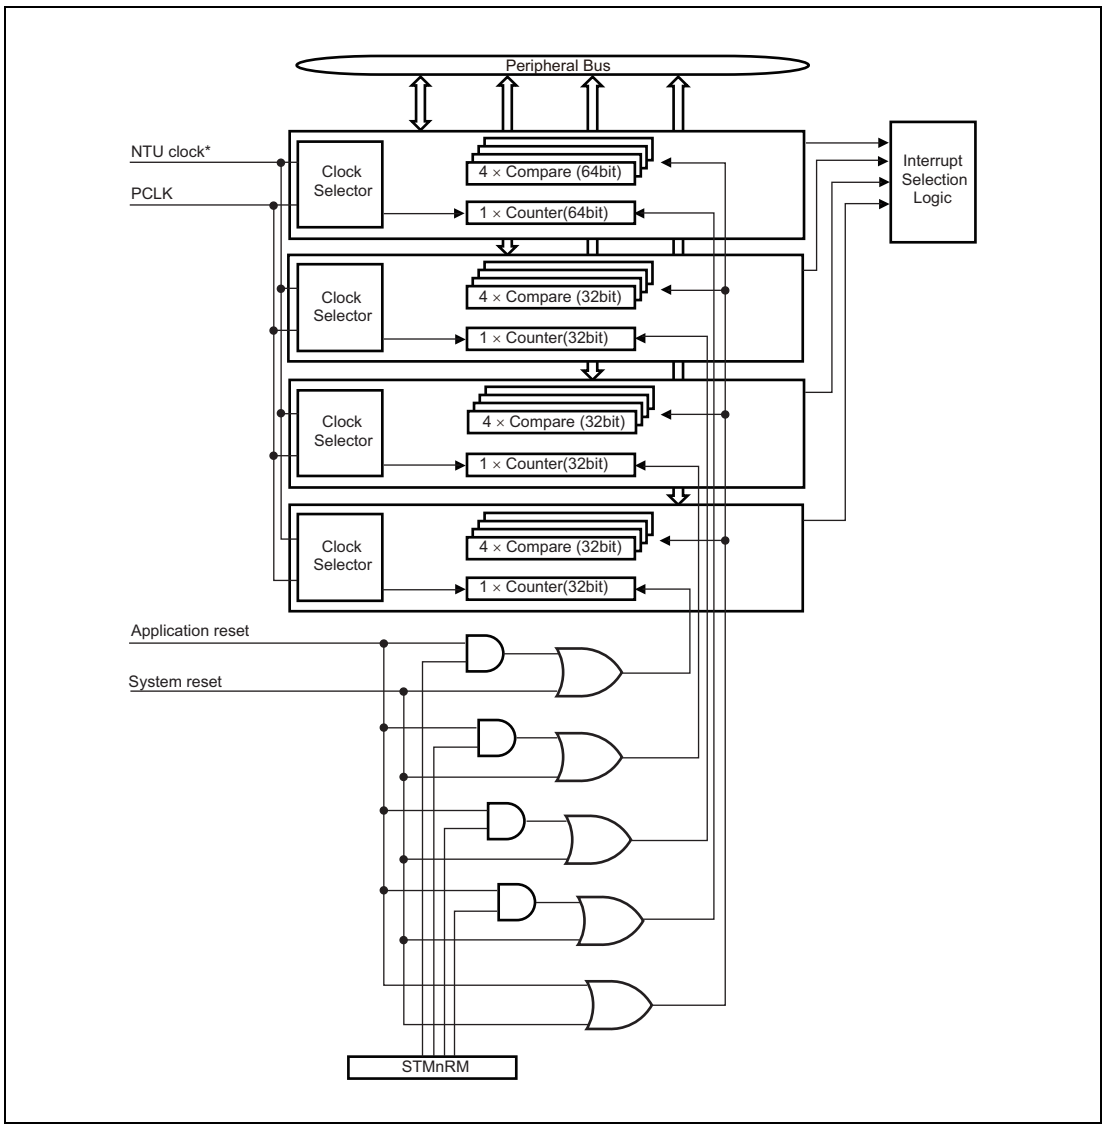

Figure 24.1 STMn block diagram

NOTE

STM1 does not support NTU clock function

24.3 Registers

This section contains a description of all registers of the System Timer.

24.3.1 List of Registers

The System Timer is controlled and operated by the following registers:

Table 24.5 Register list

Address	Register name	Description	Access Size[bit]	Value after reset	Access Protection	
					PBG	Other
*[1]	*[1]	STM0	32	*[1]	PBG2.PG2-SSTM0	—
*[1]	*[1]	STM1	32	*[1]	PBG2.PG2-SSTM1	—

Note 1. Regarding address, register name, and value after reset of STMn, see the following table

Table 24.6 Register Reset Condition

Register Name	Reset condition				
	Power On Reset	System Reset1	System Reset2	Application Reset1	Limited Reset
STMnRM	√	√	√	—	—
Other registers	√	√	√	√	—

Note: “Other Registers” will only be reset if the corresponding channel is not masked in STMnRM register.

Table 24.7 List of System Timer registers (1/2)

Channel	Register Name	Symbol	Address
CNT 0,1,2,3 Common Register	Timer Counter Source Clock Selection Register	STMnCKSEL*[1]	<STMn_base> + 0000_H
	Timer Counter Start Register	STMnTS	<STMn_base> + 0010_H
	Timer Counter Stop Register	STMnTT	<STMn_base> + 0014_H
	Timer Counter Status Register	STMnCSTR	<STMn_base> + 0018_H

CNT 3	Timer Counter Register	STMnCNT3	<STMn_base> + $00B0_H$
	Timer Compare match Register A	STMnCMP3A	<STMn_base> + $00C0_H$
	Timer Compare match Register B	STMnCMP3B	<STMn_base> + $00C4_H$
	Timer Compare match Register C	STMnCMP3C	<STMn_base> + $00C8_H$
	Timer Compare match Register D	STMnCMP3D	<STMn_base> + $00CC_H$

Note 1. STM1 does not have STM1CKSEL register.

24.3.2 STMnCKSEL — STMn timer counter source clock selection register

Access: STMnCKSEL register can be read/written in 32-/8-bit units.

Address: <STMn_base> + 0000_H

Value after reset: 0000 0000_H This register is initialized by a reset of any type.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	—	—	—	—	CKSEL3	CKSEL2	CKSEL1	CKSEL0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 24.8 STMnCKSEL register contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	CKSELm	This bit selects the input clock for counter channel m (m = 0 to 3). 0: PCLK (Peripheral clock) This clock is dependent from the configured CPU and peripheral bus clock. 1: FlexRay NTU clock This clock is derived from the FlexRay IP's network time unit. It can be used to synchronize SW processes (e.g. AUTOSAR job list) with the Flexray network. See the FlexRay chapter for a detailed description of the NTU clock generation.

24.3.3 STMnTS — STMn timer counter start register

Access: STMnTS register can be written in 32-/8-bit units.

Address: <STMn_base>+ 0010_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	W	W	W	W

Table 24.9 STMnTS register contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When writing, write the value after reset.
3 to 0	TSm	This bit starts the counter channel m. 0: No function 1: Starts the counter and sets STMnCSTR.CSTm = 1. Setting this bit is ignored as long as STMnCSTR.CSTm = 1.

NOTES

1. A reset from any source will initialize the bits unless the masking function has been selected in the STMn SW reset mask register (STMnRM) for channel m. If masking function is selected, the function related to register bits TSm is not affected by SW reset (application reset 1).
2. STMnTS is read always as $0000\ 0000_H$.

24.3.4 STMnTT — STMn timer counter stop register

Access: STMnTT register can be written in 32-/8-bit units.

Address: <STMn_base> + 0014_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	—	—	—	—	TT3	TT2	TT1	TT0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	W	W	W	W

Table 24.10 STMnTT register contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When writing, write the value after reset.
3 to 0	TTm	This bit stops the counter channel m. 0: No function 1: Stops the counter and clears STMnCSTR.CSTm bit. Setting this bit is ignored as long as STMnCSTR.CSTm = 0.

NOTES

1. A reset from any source will initialize the bits unless the masking function has been selected in the STMn SW reset mask register (STMnRM) for channel m. If masking function is selected, the function related to register bits TTm is not affected by SW reset (application reset 1)
2. STMnTT is read always as $0000\ 0000_H$.

24.3.5 STMnCSTR — STMn timer counter status register

Access: STMnCSTR register can be read in 32-/8-bit units.

Address: <STMn_base> + 0018_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 24.11 STMnCSTR register contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is read.
3 to 0	CSTm	This bit indicates whether the counter is enabled or disabled. 0: Counter disabled 1: Counter enabled This bit is set to 1 in response to STMnTS.TS being set to 1. Setting STMnTT.TTn to 1 re-sets this bit to 0.

NOTE

A reset from any source will initialize the bits unless the masking function has been selected in the STMn SW reset mask register (STMnRM) for channel m. If masking function is selected, the function related to register bits CSTm is not affected by SW reset (application reset 1).

24.3.6 STMnSTR — STMn timer status register

Access: STMnSTR register can be read in 32-/8-bit units.

Address: <STMn_base> + 0020_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	OVF3	OVF2	OVF1	OVF0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 24.12 STMnSTR register contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is read.
19 to 16	OVFm	Overflow flag of timer channel m (m = 0 to 3) 0: No overflow has occurred 1: Overflow has occurred Once set to 1 by overflow event, this bit remains 1 until cleared by SW write to overflow reset bit in STMn status clear register (STMnSTC.OVRm).
15 to 0	CMml	This bit indicates whether a compare match has occurred on compare register l (l = A, B, C, D) of timer channel m (m = 0 to 3) 0: No compare match has occurred 1: Compare match has occurred Once set to 1 by compare match, this bit remains 1 until cleared by SW write to the compare match reset bit in STMn status clear register (STMnSTC.CMRml).

NOTE

A reset from any source will initialize the bits unless the masking function has been selected in the STMn SW reset mask register (STMnRM) for channel m. If masking function is selected, the function related to register bits CSTm is not affected by SW reset (application reset 1).

24.3.7 STMnSTC — STMn timer status clear register

Access: STMnSTC register can be written in 32-/8-bit units.

Address: <STMn_base> + 0024_H

Value after reset: $0000\ 0000_H$ This register is initialized by a reset of any type.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	OVR3	OVR2	OVR1	OVR0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	W	W	W	W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMR3D	CMR3C	CMR3B	CMR3A	CMR2D	CMR2C	CMR2B	CMR2A	CMR1D	CMR1C	CMR1B	CMR1A	CMR0D	CMR0C	CMR0B	CMR0A
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Table 24.13 STMnSTC register contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When writing, write the value after reset.
19 to 16	OVRm	Reset overflow flag of timer channel m (m = 0 to 3) 0: no function 1: Reset overflow flag (STMnSTR.OVF = 0)
15 to 0	CMRml	Reset compare match flag of compare register l (l = A, B, C, D) of timer channel m (m = 0 to 3) 0: no function 1: Reset compare match event flag (STMnSTR.CMml = 0)

NOTE

STMnSTC is read always as $0000\ 0000_H$.

In case an overflow or compare match interrupt occurs while the OVRm / CMRml flag is cleared by SW, the interrupt will have higher priority and set the flag.

24.3.8 STMnIS — STMn timer interrupt selection register

Access: STMnIS register can be read/written in 32-/8-bit units.

Address: <STMn_base> + 0030_H

Value after reset: $0000\ 0000_H$ This register is initialized by a reset of any type.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

11	Setting prohibited	Setting prohibited	Setting prohibited	Setting prohibited	Setting prohibited	Setting prohibited	Setting prohibited	Setting prohibited

NOTE

It is prohibited to map the same system timer event to multiple STMINT interrupts.

Interrupt INTn8 is not listed in this register overview as its assignment is not configurable.

Please refer also to **Section 24.4.1, Interrupt assignment**.

24.3.9 STMnRM — STMn timer SW reset mask register

Access: STMnRM register can be read/written in 32-/8-bit units.

Address: <STMn_base> + 0034_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	RM3	RM2	RM1	RM0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 24.16 STMnRM register contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	RMm	This bit masks the SW reset (application reset 1) for counter channel (m = 0 to 3). When SW reset is masked for channel m it behaves as follows: • The counter continues counting up operation. SW reset occurrence has no impact on the counter operation and the counter value. • The count enable status will not be changed by SW reset; no stop trigger will be generated by occurrence of SW reset. All other STM registers will be reset independent whether masking was selected or not. The input clock will be set to the default value PCLK. 0: Reset mask disabled for channel m (Channel m responds to SW reset (application reset 1)) 1: Reset mask enabled for channel m (Channel m does not responds to SW reset (application reset 1))

NOTE

A reset from any source will initialize the bits unless the masking function has been selected in the STMn reset mask register (STMnRM) for channel m. If masking function is selected, the related register bits RMm will not be changed by SW reset (application reset 1).

24.3.10 STMnCNT0L — STMn timer counter register low (lower 32-bit)

Access: This register can be read/written in 32-/8-bit units.

Address: <STMn_base> + 0040_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CNT0L[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.17 STMnCNT0L register contents

Bit Position	Bit Name	Function
31 to 0	CNT0L[31:0]	Lower 32-bit of 64-bit counter value (channel 0)

NOTES

1. A reset from any source will initialize the bits unless the masking function has been selected in the STMn SW reset mask register (STMnRM) for this channel. If masking function is selected, the register contents will not be changed by SW reset (application reset 1)
2. This register is part of a 64-bit register. The architecture supports 64-bit write access to the upper and lower register. However in case of individual 32-bit write accesses the total 64-bit register value will become effective after the higher 32-bit value has been written to. The appropriate write sequence must therefore be specified by software (i.e., that the register must be accessed from the lower 32 bits, and then the upper 32 bits.)
   Independent from access width, the user should use appropriate PBus-Guard setting to control the access to a 64-bit register. This is to avoid that during an access from one bus master (e.g. PE) another bus master (e.g. DMA) will access to the same register resulting in an invalid update of the register value.
3. Read access to counter registers is supported both while counter is running and stopped.
   In case of reading the 64-bit counter value while the counter is running, the current 64-bit counter value will be captured on read access to the lower 32-bit value. The captured upper 32-bit value can be read afterwards. This is to avoid that the upper or lower 32-bit value changes between the two consecutive 32-bit read accesses.
4. Write access is permitted only, while counter is stopped.

24.3.11 STMnCNT0H — STMn timer counter register high (upper 32-bit)

Access: This register can be read/written in 32-/8-bit units.

Address: <STMn_base> + 0044_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CNT0H[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CNT0H[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 24.18 STMnCNT0H register contents

Bit Position	Bit Name	Function
31 to 0	CNT0H[31:0]	Upper 32-bit of 64-bit counter value (channel 0)

NOTES

1. A reset from any source will initialize the bits unless the masking function has been selected in the STMn SW reset mask register (STMnRM) for this channel. If masking function is selected, the register contents will not be changed by SW reset (application reset 1)
2. This register is part of a 64-bit register. The architecture supports 64-bit write access to the upper and lower register. However in case of individual 32-bit write accesses the total 64-bit register value will become effective after the higher 32-bit value has been written to. The appropriate write sequence must therefore be specified by software (i.e., that the register must be accessed from the lower 32 bits, and then the upper 32 bits.)
   Independent from access width, the user should use appropriate PBus-Guard setting to control the access to a 64-bit register. This is to avoid that during an access from one bus master (e.g. PE) another bus master (e.g. DMA) will access to the same register resulting in an invalid update of the register value.
3. Read access to counter registers is supported both while counter is running and stopped.
   In case of reading the 64-bit counter value while the counter is running, the current 64-bit counter value will be captured on read access to the lower 32-bit value. The captured upper 32-bit value can be read afterwards. This is to avoid that the upper or lower 32-bit value changes between the two consecutive 32-bit read accesses.
4. Write access is permitted only, while counter is stopped.

24.3.12 STMnCMP0IL — STMn timer compare match register low (lower 32-bit)

Access: This register can be read/written in 32-/8-bit units.

Address: STMnCMP0AL:<STMn_base> + 0050_H
STMnCMP0BL:<STMn_base> + 0058_H
STMnCMP0CL:<STMn_base> + 0060_H
STMnCMP0DL:<STMn_base> + 0068_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 24.19 STMnCMP0IL register contents

Bit Position	Bit Name	Function
31 to 0	CMP0IL[31:0]	Lower 32-bit of 64-bit compare value (channel 0, I = A, B, C, D)

NOTE

This register is part of a 64-bit register. The architecture supports 64-bit write access to the upper and lower register. However in case of individual 32-bit write accesses the total 64-bit register value will become effective after the higher 32-bit value has been written to. The appropriate write sequence must therefore be specified by software (i.e., that the register must be accessed from the lower 32 bits, and then the upper 32 bits.)
Independent from access width, the user should use appropriate PBus-Guard setting to control the access to a 64-bit register. This is to avoid that during an access from one bus master (e.g. PE) another bus master (e.g. DMA) will access to the same register resulting in an invalid update of the register value.

24.3.13 STMnCMP0IH — STMn timer compare match register high (upper 32-bit)

Access: This register can be read/written in 32-/8-bit units.

Address: STMnCMP0AH:<STMn_base> + 0054_H
STMnCMP0BH:<STMn_base> + $005C_H$
STMnCMP0CH:<STMn_base> + 0064_H

Table 24.20 STMnCMP0IH register contents

Bit Position	Bit Name	Function
31 to 0	CMP0IH[31:0]	Upper 32-bit of 64-bit compare value (channel 0, I = A, B, C, D)

NOTE

This register is part of a 64-bit register. The architecture supports 64-bit write access to the upper and lower register. However in case of individual 32-bit write accesses the total 64-bit register value will become effective after the higher 32-bit value has been written to. The appropriate write sequence must therefore be specified by software (i.e., that the register must be accessed from the lower 32 bits, and then the upper 32 bits.)
Independent from access width, the user should use appropriate PBus-Guard setting to control the access to a 64-bit register. This is to avoid that during an access from one bus master (e.g. PE) another bus master (e.g. DMA) will access to the same register resulting in an invalid update of the register value.

24.3.14 STMnCNTm — STMn timer counter register

Access: This register can be read/written in 32-/8-bit units.

Address: STMnCNT1:<STMn_base> + 0070_H
STMnCNT2:<STMn_base> + 0090_H
STMnCNT3:<STMn_base> + $00B0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 24.21 STMnCNTm register contents

Bit Position	Bit Name	Function
31 to 0	CNTm[31:0]	32-bit counter value of channel m (m = 1 to 3)

NOTES

1. A reset from any source will initialize the bits unless the masking function has been selected in the STMn SW reset mask register (STMnRM) for this channel. If masking function is selected, the register contents will not be changed by SW reset (application reset 1).
2. Read access to counter registers is supported both while counter is running and stopped.
3. Write access is permitted only, while counter is stopped.

24.3.15 STMnCMPml — STMn timer compare match register

Access: This register can be read/written in 32-/8-bit units.

Address: STMnCMP1A: <STMn_base> + 0080_H, STMnCMP1B: <STMn_base> + 0084_H,
STMnCMP1C: <STMn_base> + 0088_H, STMnCMP1D: <STMn_base> + $008C_H$,
STMnCMP2A: <STMn_base> + $00A0_H$, STMnCMP2B: <STMn_base> + $00A4_H$,
STMnCMP2C: <STMn_base> + $00A8_H$, STMnCMP2D: <STMn_base> + $00AC_H$,
STMnCMP3A: <STMn_base> + $00C0_H$, STMnCMP3B: <STMn_base> + $00C4_H$,
STMnCMP3C: <STMn_base> + $00C8_H$, STMnCMP3D: <STMn_base> + $00CC_H$,

Value after reset: $0000\ 0000_H$ This register is initialized by a reset of any type.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 24.22 STMnCMPml register contents

Bit Position	Bit Name	Function
31 to 0	CMPml[31:0]	32-bit of compare value of channel m (m = 1 to 3), compare register l (l = A, B, C, D)

24.4 Operation

24.4.1 Interrupt assignment

The System Timer (STM) provides 9 individual interrupt signals, one out of these (INT8) as non-maskable with high priority (Note: non-maskable high-priority interrupt cannot be linked to channel 0 and OVF event). The assignment of interrupts to the compare registers and counter channel's overflag signal can be configured in the Interrupt Selection

Logic as described in **Figure 24.1, STMn block diagram**, **Table 24.23, Configurable Interrupt vector assignment**.The overflow signals of channel 0-3 will be ORed and mapped to one common, selectable interrupt vector. The ORed compare signals of channel 1 are fix assigned to one common non-maskable interrupt (INTn8). Additioonally they can be assigned to further non-maskable interrupts

For details on interrupt controller, see "Interrupt Functions".

Table 24.23 Configurable Interrupt vector assignment

		Selectable Interrupt Vector		Fix Interrupt vector
STM channel	**Interrupt source**	**Alt0**	**Alt1**	**FEINT**
0 (64-bit)	Compare match A	INTn0	—	—
	Compare match B	INTn1	—	—
	Compare match C	INTn2	—	—
	Compare match D	INTn3	—	—
1 (32-bit)	Compare match A	INTn4	—	INTn8
	Compare match B	INTn5	—	
	Compare match C	INTn6	—	
	Compare match D	INTn7	—	
2 (32-bit)	Compare match A	INTn0	INTn4	—
	Compare match B	INTn1	INTn5	—
	Compare match C	—	—	—
	Compare match D	—	—	—
3 (32-bit)	Compare match A	INTn2	INTn6	—
	Compare match B	INTn3	INTn7	—
	Compare match C	—	—	—
	Compare match D	—	—	—
0	ORed OVF flags channel 0 to 3 [OVF0 v OVF1 v OVF2 v OVF3]	INTn3	INTn7	
1				
2				
3				

Note 1. FE-level maskable interrupt (FEINT)

Note 2. INTn8 occurence can be masked as described in **Section 6.8.7, FEINT Source selection**

24.4.2 Cautions

24.4.2.1 Interrupt cautions

(1) Interrupt after reset

After the reset of the STM (PRESET or SW reset which not be masked), both counters and compare match registers are initialized to 0. So when you enable the counter in STM directly after the reset, the compare match interrupt request will be sent out and the flag of compare match will also be set.You must ignore the compare match requests and clear the compare match flags first. The above case could be avoided by setting the compare match registers with any value but 0 before you enable the counters after the reset of STM.

(2) Interrupt request when corresponding flag has been set

STM0STR is the status register in STM, the interrupt request according to the compare match event or overflow event within STM will be not send out if the corresponding flag in STM0STR has been already set. But if the interrupt request conflicts with the clear of the corresponding flag, the interrupt request will be send out.

24.4.2.2 Overlap of one-pulse interrupt

Generally the output interrupt requests of STM are one-pulse signals but in the case below the OVFI and INT8_STM will not be one-pulse signals. So you should take care of those cases in STM.

case1: OVFI overlapped for several cycles

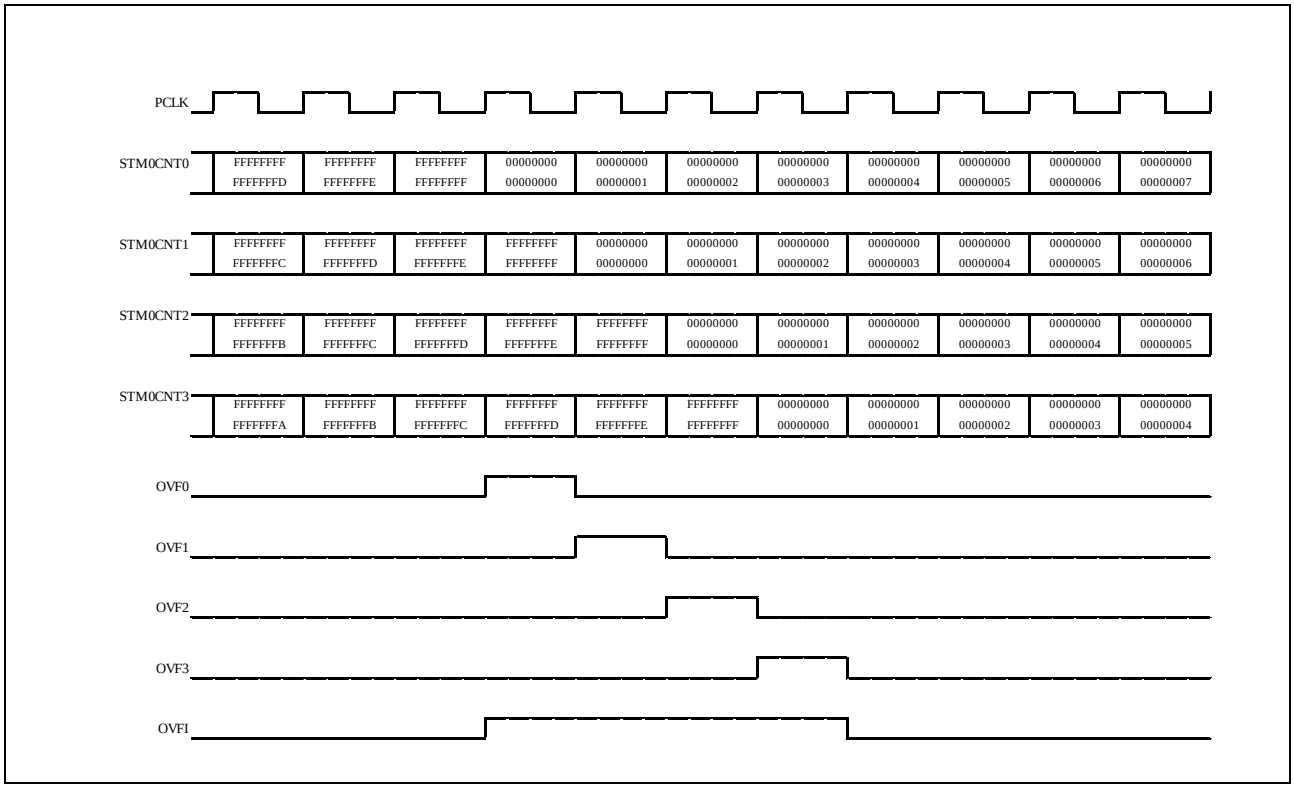

Figure 24.2 OVFI overlapped for several cycles

Case2: INT8_STM overlapped for several cycles

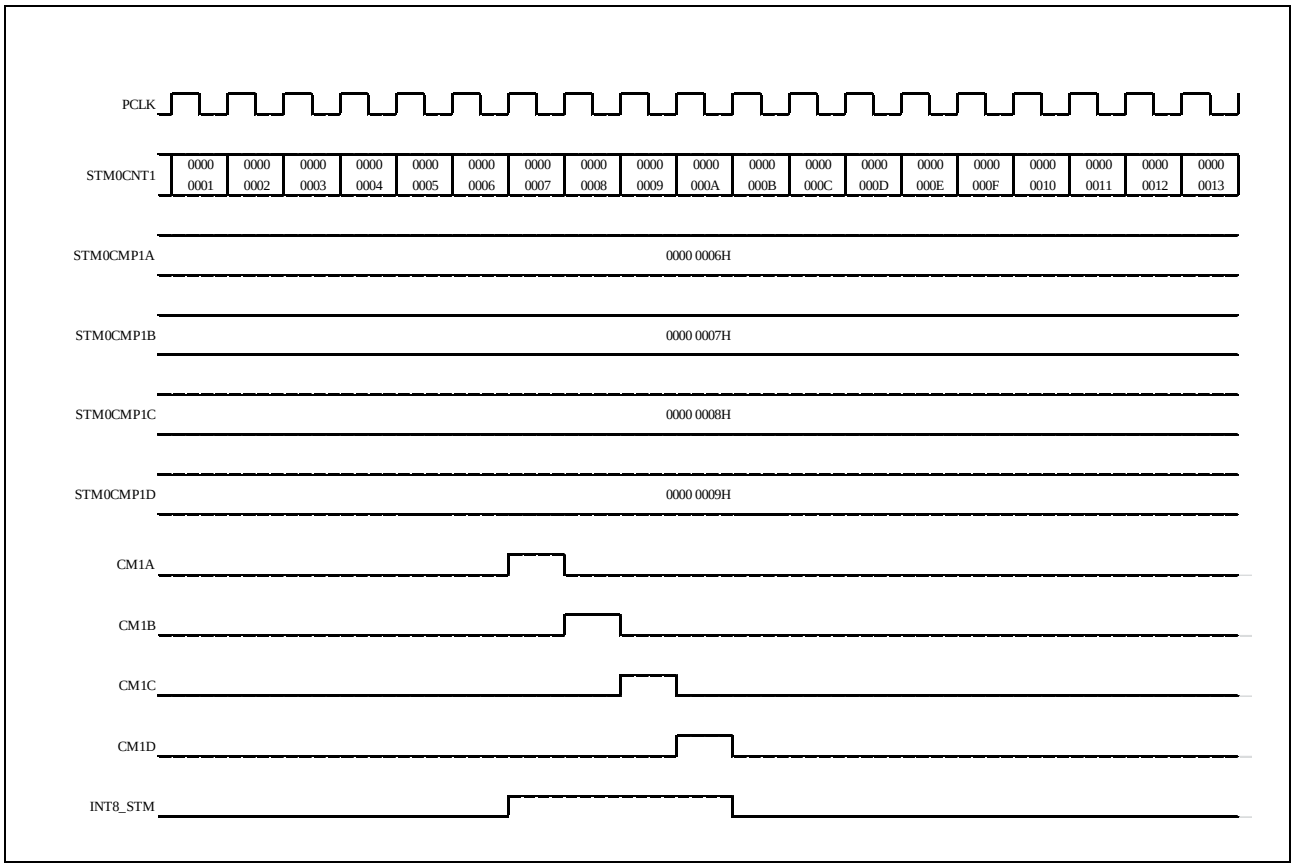

Figure 24.3 INT8_STM overlapped for several cycles

24.4.3 Attention in using

24.4.3.1 Confliction of compare match with writing of compare register

When compare match is conflicting with the writing of compare register, the compare match flag will be set with the consideration of not losing the compare event, and the compare match register will be written in too.

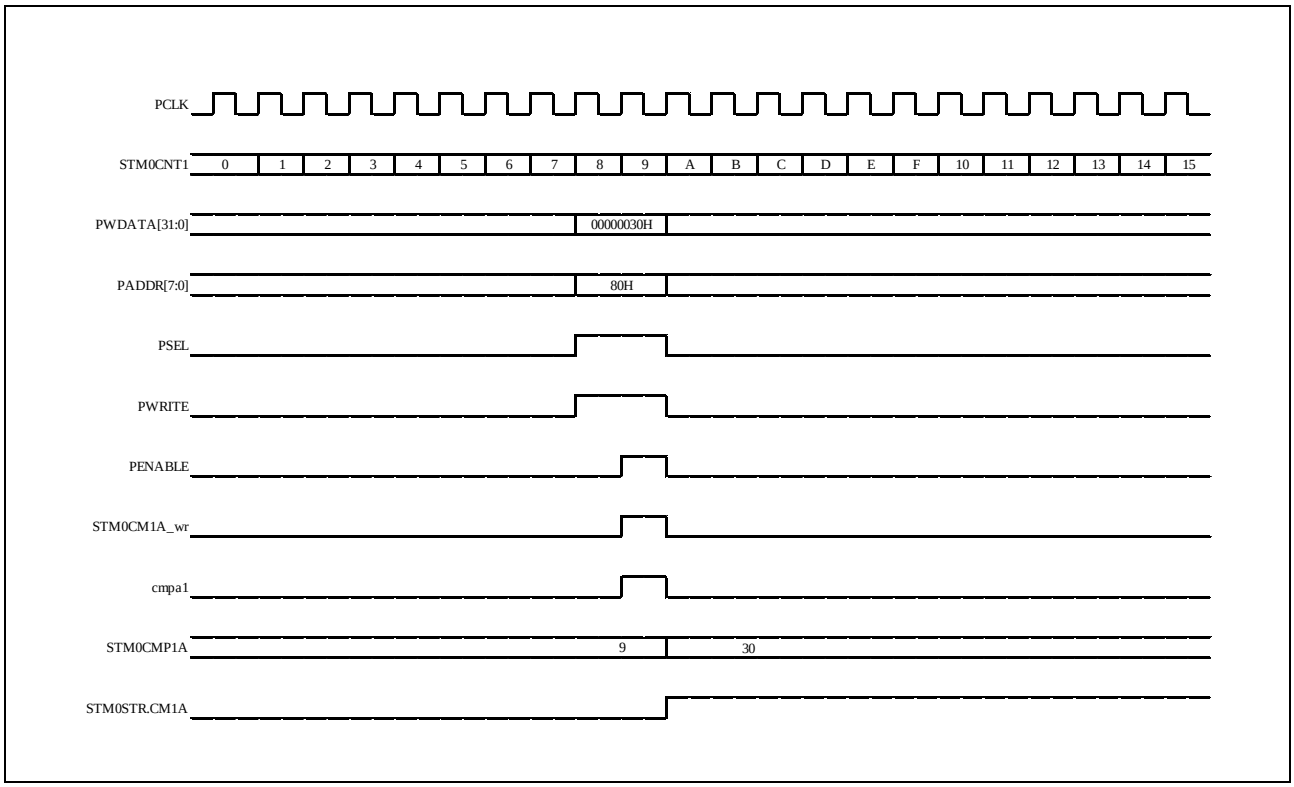

Figure 24.4 Compare match event conflicting with write access (counting with PCLK)

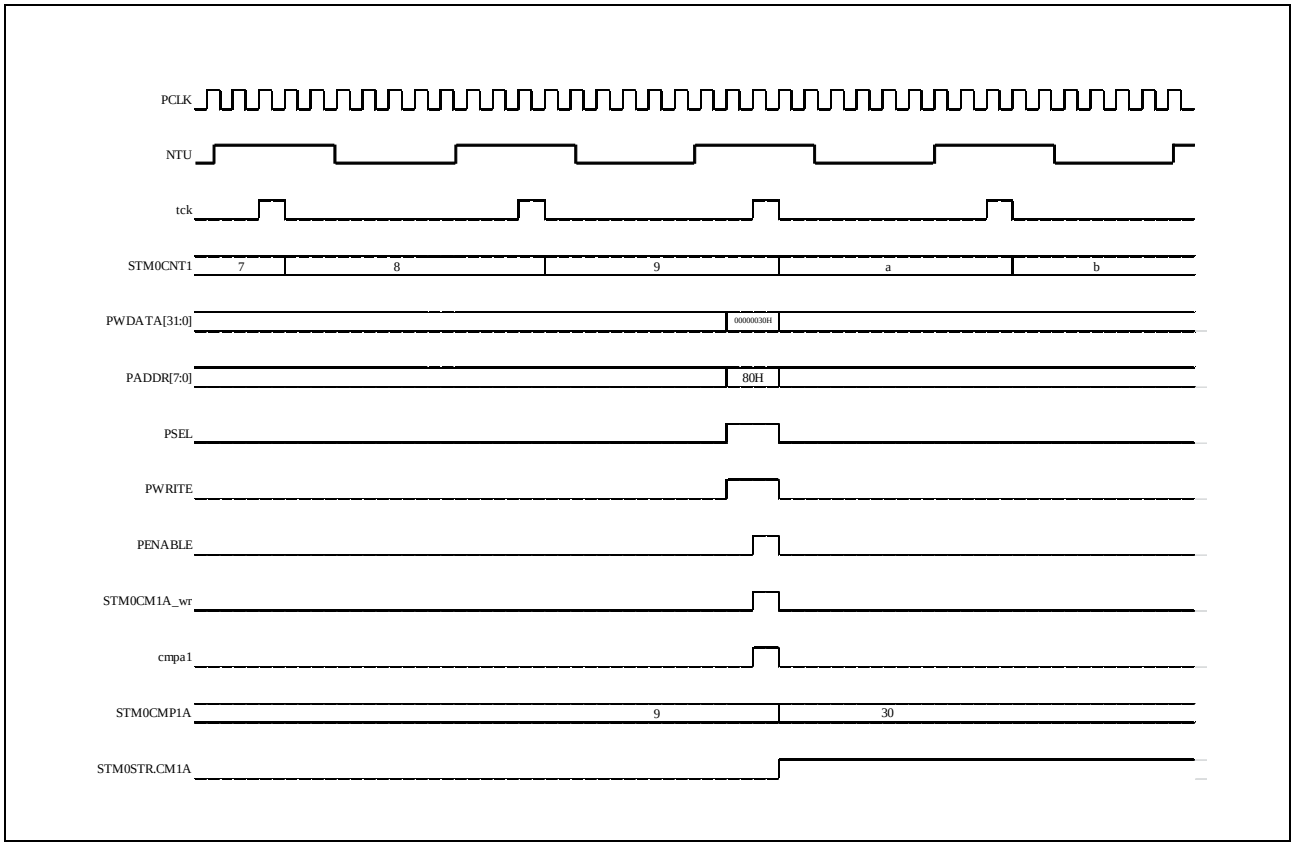

Figure 24.5 Compare match event conflicting with write

24.4.3.2 Confliction of compare match flag(overflow flag) set with its clear

When the compare match (overflow) flag's set conflict with its clear, compare match (overflow) flag will be set but the clear will be ignored whether the flag is 1 or 0 at that moment.You can get details from the below figure.

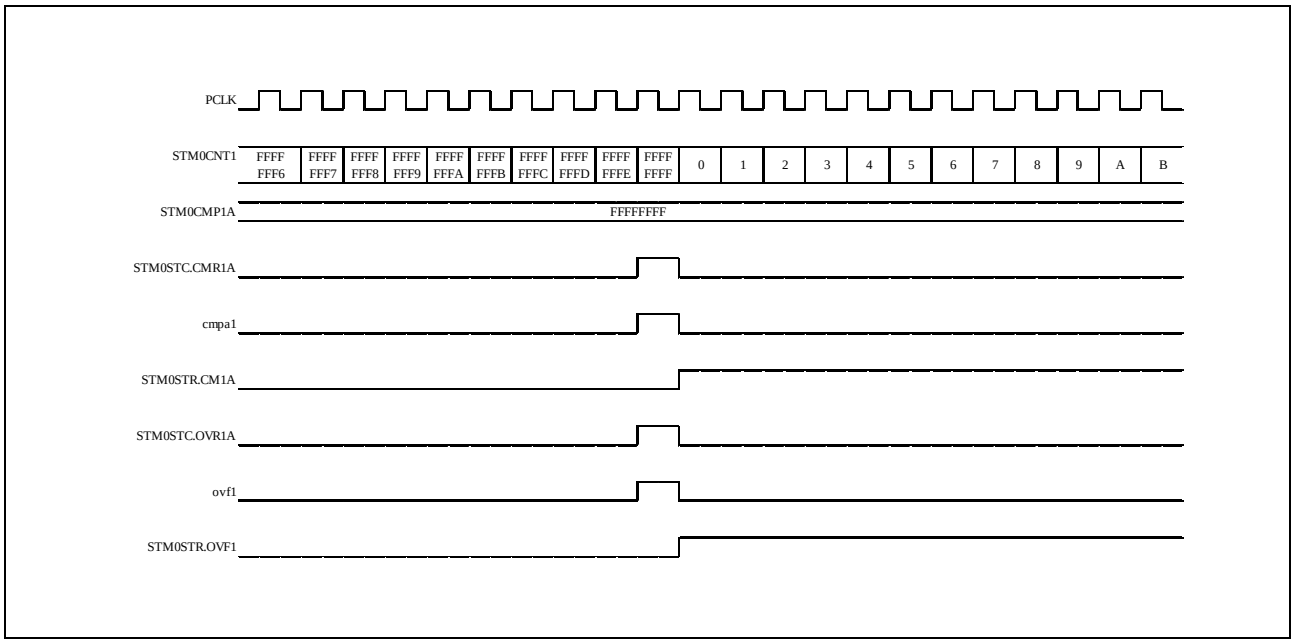

Figure 24.6 Compare match event conflicting with its clear

24.4.3.3 Confliction of flag (compare match/overflow) set with counter stop

When the set signal of the flag conflict with the counter stop ,the flag will not be set until the coming of next count source clock after restart of the count. To compare match flag, if you update the compare match register or counter register with other values within the stop of the counter register, the flag will not be set even though the coming of next count source clock after restart of the count.To the overflow flag, if you update the counter register with other values within its stop, the flag will not be set even though the coming of next count source clock after restart of the count. In the figure below, the compare match flat will be set when the counter restarted if you had not updated the compare match register but if you had updated the compare match register during counter stop the compare match flat will not be set when the counter restarted.

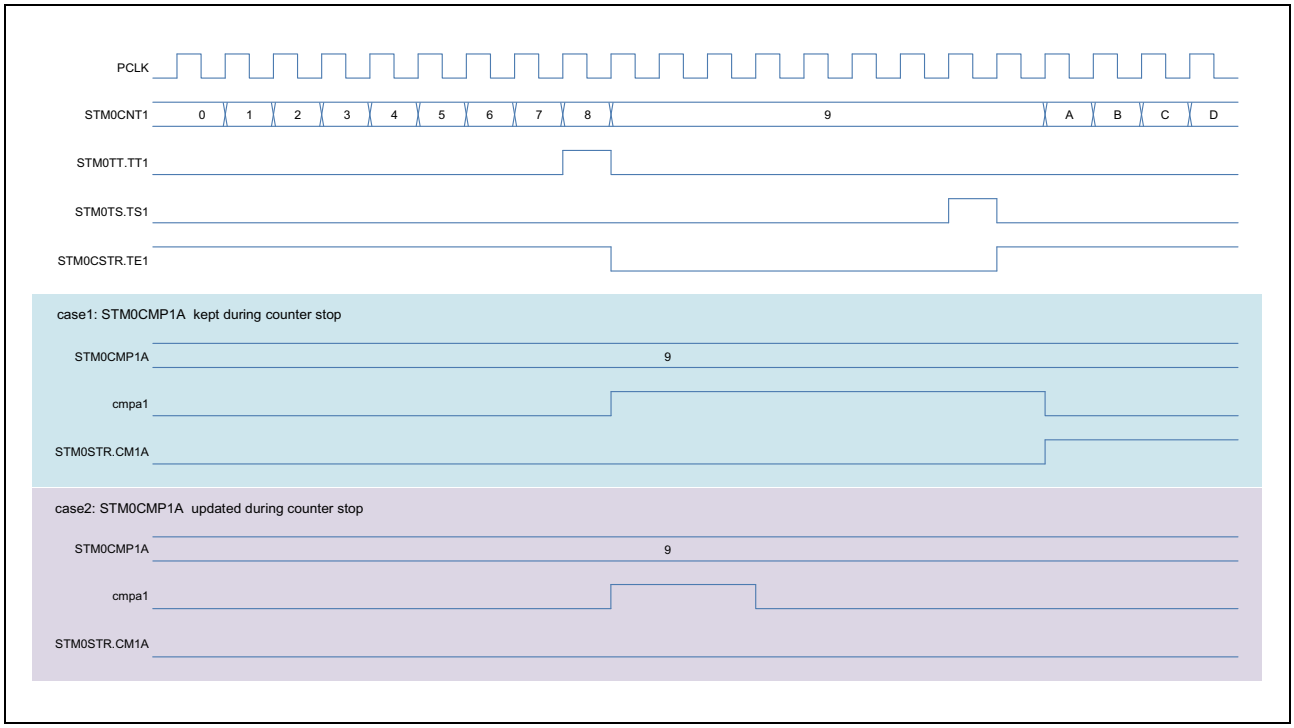

Figure 24.7 Compare match event conflicting with counter stop

24.4.3.4 Confliction of flag set with emulation mode start

When the set signal of the flag conflict with emulation mode, the flag will not be set.And when restore from the emulation mode it would be check once again whether the flag should be set or not.

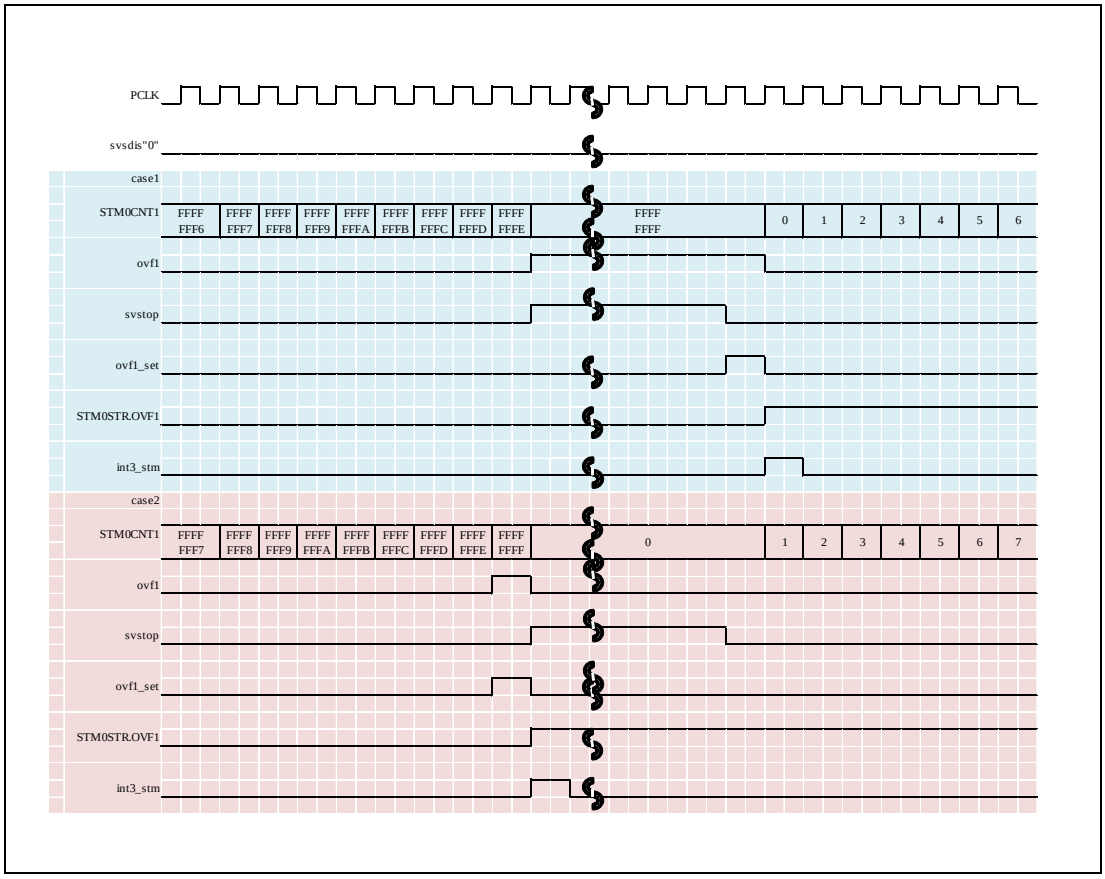

Figure 24.8 Overflow event conflicting with emulation mode

24.4.3.5 Confliction of interrupt requirement with flag clear

When the flag has been set in STM0STR, the interrupt requirement according to the corresponding flag set event will not be sent out,but only in the case that the corresponding flag clear happens at the same time .And in this case not only the interrupt requirement will be sent out but also the flag will not be cleared.

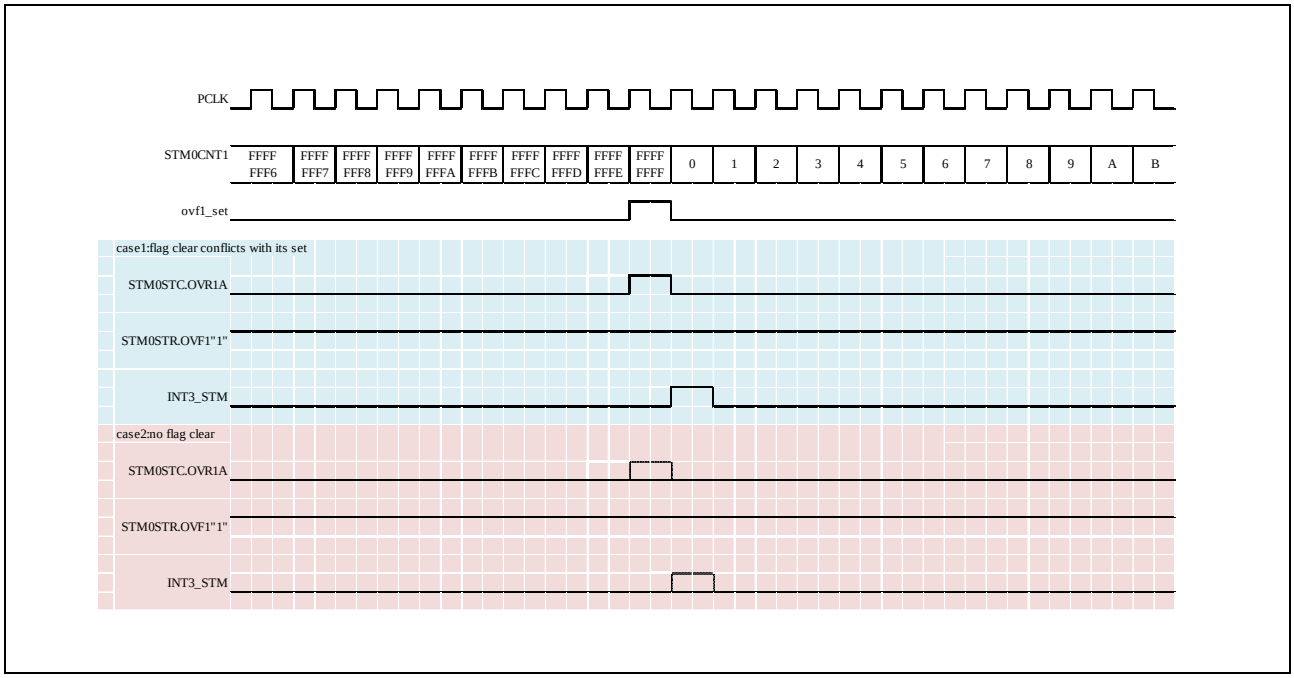

Figure 24.9 Interrupt requirement conflicting with flag clear

24.4.4 Access to register

Including the registers of STM0STR, STM0STC, all the counter registers and compare match registers should be access by 32-bit only.

The bit width of compare match register and the counter register in CNT0 is 64-bit. To those register, 64-bit access is supported and the 64-bit access will be divided into twice accesses of the 32-bit peripheral bus which used in STM. In case of individual 32-bit write or read accesses to 64-bit counter or compare registers of CNT0, the upper 32-bit register will be processed after the lower 32-bit register. Writing access to a 64-bit register, the register value will be updated when the upper 32-bit register is processed while reading access to a 64-bit register, the value of the register at that moment will be read out.

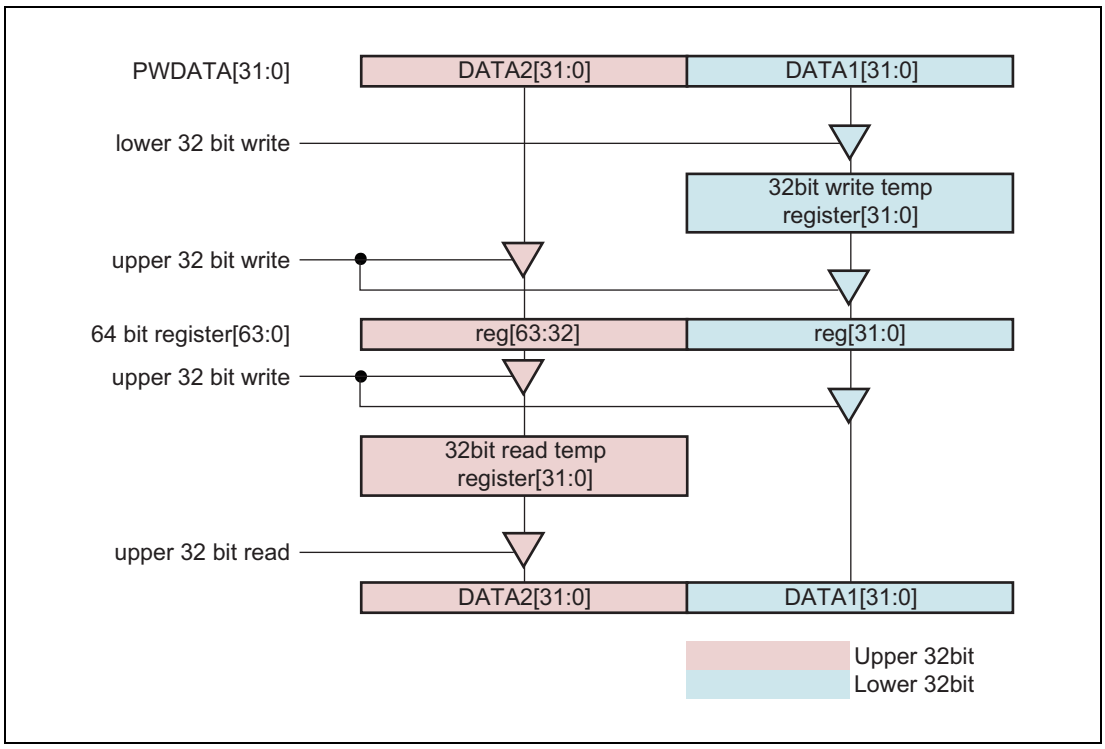

Figure 24.10 Access to register

24.4.5 Resets

There are Application reset and System reset in STM. To System reset, all of the STM registers will be initialized, to the Application reset, you can mask it or not. All of the registers behave as shown in the below table upon the Application reset or System reset.

Table 24.24 Reset

Registers or bits in STM		Application reset		System reset
		Masked (RMm = 1)	UnMask (RMm = 0)	
Counters	Counters in CNTm	KEPT	INIT	INIT
	Counters in other channels	INIT	INIT	INIT
Compare match register	Compare match register	INIT	INIT	INIT
STMnTS	TSm	KEPT	INIT	INIT
	Other TS bits in STMnTS[3:0]	INIT	INIT	INIT
STMnTT	TTm	KEPT	INIT	INIT
	Other TT bits in STMnTT[3:0]	INIT	INIT	INIT
STMnCSTR	Tem	KEPT	INIT	INIT
	other TE bits in STMnCSTR[3:0]	INIT	INIT	INIT
STMnSTR	OVFm	KEPT	INIT	INIT
	Other OVF or CM bits in STMnSTR[19:0]	INIT	INIT	INIT
STMnSTC	STMnSTC[19:0]	INIT	INIT	INIT
STMnRM	RMm	KEPT	KEPT	INIT
	Other RM bits in STMnRM[3:0]	INIT	INIT	INIT
STMnCKSEL	STMnCKSEL[3:0]	INIT	INIT	INIT
STMnIS	STMnIS[15:0]	INIT	INIT	INIT

Note 1. m: m = 0 to 3
Note 2. INIT: initialized
Note 3. KEPT: values are kept

24.5 Difference among P1M-C, P1H-C and P1H-CE

There are differences in channels, interrupts, and external pins. For details, see **Table 24.1**, and **Table 24.5**.

Section 25 Generic Timer Module (GTM)

Generic timer module (GTM) is a modular timer unit used to support chassis control applications. It is designed to unload the CPU from a high interrupt load. Most of the task of GTM can run independently from the CPU.

25.1 Feature

25.1.1 IP version

The table below shows IP version in each device.

Table 25.1 IP version

IP	P1M-C (Config 2)	P1H-C, P1H-CE (Config 3)
GTM-IP	GTM-IP 207	GTM-IP 208

25.1.2 Number of Sub-Units and Channels

The table below shows the availability of the GTM.

Table 25.2 Sub-Units and Channels

	P1M-C			P1H-C, P1H-CE		
Submodule	Number of Instances	Instance name	Channels	Number of Instances	Instance name	Channels
ARU	1	—	—	1	—	—
CMU	1	—	8 (n = 0 to 7)	1	—	8 (n = 0 to 7)
TBU	1	—	2 (n = 0, 1)	1	—	2 (n = 0, 1)
TIM	2	TIM0, TIM1	8 (TIM0: n = 0 to 7) 8 (TIM1: n = 0 to 7)	2	TIM0, TIM1	8 (TIM0: n = 0 to 7) 8 (TIM1: n = 0 to 7)
ATOM	2	ATOM0, ATOM1	8 (ATOM0: n = 0 to 7) 4 (ATOM1: n = 0 to 3)	3	ATOM0, ATOM1*2, ATOM2*3	8 (ATOM0: n = 0 to 7) 8 (ATOM1: n = 0 to 7) 5 (ATOM2: n = 0 to 4)
DTM	2	DTM24, DTM26	4 (DTM24: n = 0 to 3) 4 (DTM26: n = 0 to 3)	3	DTM24, DTM26, DTM28	4 (DTM24: n = 0 to 3) 4 (DTM26: n = 0 to 3) 4 (DTM28: n = 0 to 3)
MCS*1	1	MCS0	9 (MCS0: n = 0 to 8)	2	MCS0, MCS1	9 (MCS0: n = 0 to 8) 6 (MCS1: n = 0 to 5)
MCFG	—	—	—	1	—	—
ICM	1	—	—	1	—	—
CMP	1	—	—	1	—	—
MON	1	—	—	1	—	—

Note 1. Each instance has a memory of 2x256 32-bit words.

Note 2. P1H-C (4MB, BGA-156) does not support ATOM1 (Ch. 4 to 7) output terminal, but internal functions are available.

Note 3. P1H-C (4MB, BGA-156) does not support ATOM2 all channels output terminal, but internal functions are available.

25.1.3 Register/RAM Base Address

GTM base addresses are listed in the following table. GTM register and RAM addresses are given as offsets from the base addresses in general.

Table 25.3 Register and RAM Base Addresses

Base Address Name	Base Address
<GTM0_base>	FFE0 0000_H

25.1.4 Clock Supply

Clock supply by and to GTM is listed in the following table.

Table 25.4 Clock Supply

Unit Name	Clock for the Unit	Supply Clock Name
GTM	AEI-bus clock (AEI_CLK)	CLK_HSB
	GTM global clock ((AEI_)SYS_CLK)	CLK_HSB

25.1.5 Interrupt and DMA/DTS Requests

GTM interrupt requests are listed in the following table.

Table 25.5 Interrupt Requests (1/2)

Interrupt Name	Description	Interrupt Number	DMA Trigger Number	DTS Trigger Number	Supporting Device	
					P1M-C	P1H-C, P1H-CE
INTGTM0ERR	GTM Error Interrupt	47	—	—	√	√

ESO0Z	I	Hi-Z control for timer output via PIC	√	√
ESO1Z			√	√
ESO2Z			—	√

Note 1. Output buffer of these signals could be controlled to Hi-Z by PIC.

25.2 Overview

25.2.1 Functional Overview

GTM is a modular timer unit and consists at least of the following submodules.

- Advanced Routing Unit (ARU)
- Clock Management Unit (CMU)
- Time Base Unit (TBU)
- Timer Input Module (TIM)
- ARU-connected Timer Output Module (ATOM)
- Multi-Channel Sequencer (MCS)
- Interrupt Concentrator Module (ICM)
- Output Compare Unit (CMP)
- Monitoring Unit (MON)
- Dead Time Module (DTM)
- Memory Configuration Module (MCFG; Available only in P1H-C, and P1H-CE)

25.2.2 Block Diagram

The following figure shows the block diagram.

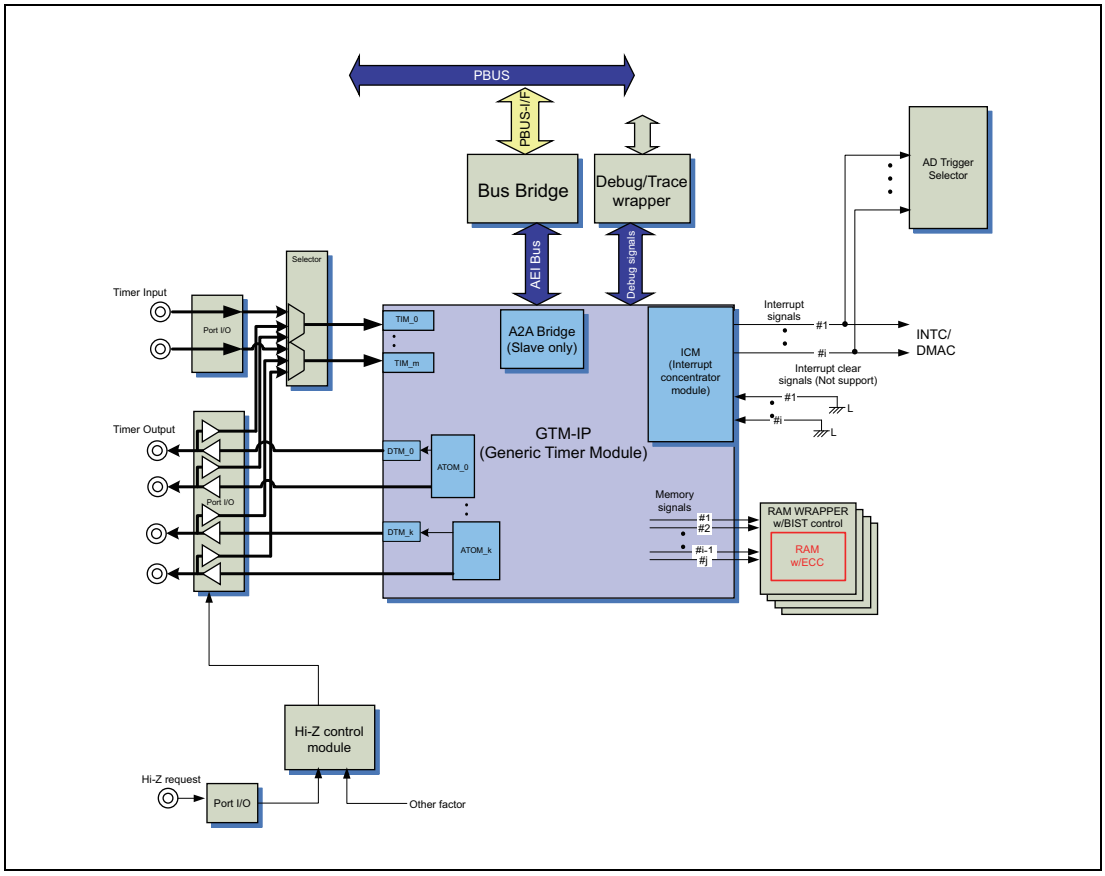

Figure 25.1 GTM integration diagram

25.3 Registers

25.3.1 List of Registers

GTM registers are listed in the following table.

Table 25.7 List of Registers (1/37)

Module name	Address	Symbol	Register Name	Access Width	Support		Access Protection	
					207	208	PBG	Other
GTM0	<GTM0_base> + 00000_H	GTM0GTMREV	GTM-IP Version control register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00004_H	GTM0GTMRST	GTM-IP Global reset register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00008_H	GTM0GTMCTRL	GTM-IP Global control register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + $0000C_H$	GTM0GTMAEIADDRXPT	GTM-IP AEI Timeout exception address register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00010_H	GTM0GTMIRQNOTIFY	GTM-IP Interrupt notification register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00014_H	GTM0GTMIRQEN	GTM-IP Interrupt enable register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00018_H	GTM0GTMIRQFORCINT	GTM-IP Software interrupt generation register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + $0001C_H$	GTM0GTMIRQMODE	GTM-IP top level interrupts mode selection.	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00020_H	GTM0GTMEIRQEN	GTM-IP Error interrupt enable register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00024_H	GTM0GTMHWCONF	GTM-IP Hardware Configuration	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00030_H	GTM0GTMBRIDGEMODE	The operation mode for the AEI bridge	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00034_H	GTM0GTMBRIDGEPTR1	AEI bridge status pointer 1	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00038_H	GTM0GTMBRIDGEPTR2	AEI bridge status pointer 2	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00040_H	GTM0GTMTIM0AUXINSRC	GTM-IP TIM0 module AUX_IN source selection register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00044_H	GTM0GTMTIM1AUXINSRC	GTM-IP TIM1 module AUX_IN source selection register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + $0005C_H$	GTM0GTMEXTCAPEN0	GTM-IP trigger event forwarding in from TIM0 and TIM1 to MCS 0.	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00060_H	GTM0GTMEXTCAPEN1	GTM-IP trigger event forwarding in from TIM1 to MCS1.	32	—	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00098_H	GTM0GTMATOM0OUT	GTM-IP ATOM output level	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + $0009C_H$	GTM0GTMATOM2OUT	GTM-IP ATOM output level	32	—	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00100_H	GTM0TBUCHEN	TBU global channel enable	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00104_H	GTM0TBU0CTRL	TBU channel 0 control	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00108_H	GTM0TBU0BASE	TBU channel 0 base	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + $0010C_H$	GTM0TBU1CTRL	TBU channel 1 control	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00110_H	GTM0TBU1BASE	TBU channel 1 base	32	√	√	PBG2. PG2-GTM0	—

Table 25.7 List of Registers (2/37)

Module name	Address	Symbol	Register Name	Access Width	Support		Access Protection	
					207	208	PBG	Other
GTM0	<GTM0_base> + 00180_H	GTM0MONSTATUS	Monitor Status register	32	√	√	PBG2. PG2-GTM0	—
GTM	<GTM0_base> + 00184_H	GTM0MONACTIVITY0	Monitor activity register 0	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + $0018C_H$	GTM0MONACTIVITYMCS0	Monitor activity register for MCS0	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00190_H	GTM0MONACTIVITYMCS1	Monitor activity register for MCS1	32	—	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00200_H	GTM0CMPEN	Comparator enable register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00204_H	GTM0CMPIRQNOTIFY	Event notification register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00208_H	GTM0CMPIRQEN	Interrupt enable register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + $0020C_H$	GTM0CMPIRQFORCINT	Interrupt force register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00210_H	GTM0CMPIRQMODE	IRQ mode configuration register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00214_H	GTM0CMPEIRQEN	Error interrupt enable register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00280_H	GTM0ARUACCESS	ARU access register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00284_H	GTM0ARUDATAH	ARU access register upper data word	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00288_H	GTM0ARUDATAL	ARU access register lower data word	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + $0028C_H$	GTM0ARUDBGACCESS0	Debug access channel 0	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00290_H	GTM0ARUDBGDATA0H	Debug access 0 transfer register upper data word	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00294_H	GTM0ARUDBGDATA0L	Debug access 0 transfer register lower data word	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00298_H	GTM0ARUDBGACCESS1	Debug access channel 1	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + $0029C_H$	GTM0ARUDBGDATA1H	Debug access 1 transfer register upper data word	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + $002A0_H$	GTM0ARUDBGDATA1L	Debug access 1 transfer register lower data word	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + $002A4_H$	GTM0ARUIRQNOTIFY	ARU Interrupt notification register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + $002A8_H$	GTM0ARUIRQEN	ARU Interrupt enable register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + $002AC_H$	GTM0ARUIRQFORCINT	Register for forcing the *ARU_NEW_DATA*_IRQ interrupt	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + $002B0_H$	GTM0ARUIRQMODE	IRQ mode configuration register	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + $002B4_H$	GTM0ARUCADDREND	ARU caddr counter end value	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00300_H	GTM0CMUCLKEN	Clock enable	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00304_H	GTM0CMUGCLKNUM	Global clock control numerator	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00308_H	GTM0CMUGCLKDEN	Global clock control denominator	32	√	√	PBG2. PG2-GTM0	—

Table 25.7 List of Registers (3/37)

Module name	Address	Symbol	Register Name	Access Width	Support		Access Protection	
					207	208	PBG	Other
GTM0	<GTM0_base> + 0030C$_H$	GTM0CMUCLK0CTRL	Control for clock source 0	32	√	√	PBG2. PG2-GTM0	—
GTM0	<GTM0_base> + 00310$_H$	GTM0CMUCLK1CTRL	Control for clock source 1	32	√	√	PBG2. PG2-GTM0	—

25.4 Operation

25.4.1 Peripheral Bus Access

Due to its complexity, the GTM is attached to a bus system as a slave unit so as to provide register and MCS RAM access through the AEI interface to the CPU software and DMA functions. Please note that an access to the GTM registers and RAM modules has to be always 32-bit wide.

GTM contains MCS RAM structures. These RAM structures are not shared with other functionality and can be accessed via the bus system in a certain address range. For details of the memory map, see **Section 25.18.5, Memory Address Ranges** or **Section 25.19.5, Memory Address Ranges**.

GTM is accessible by all cores with the same access speed except the ICUMC core. See "**Section 3, CPU System**" for more details on CPU to peripheral access speed.

25.4.2 Reset

GTM is resettable by a dedicated bit, which allows the software to set GTM in reset state without using external reset. See "**Section 8, Reset Controller**".

25.4.3 Interrupt Factors

GTM generates up to 180 interrupt factors, which are visible outside of the GTM and are connected to the Interrupt Controller. These are ICM output interrupts as described in **Section 25.15.3, ICM Interrupt Signals**. The exact number of interrupts and their source depends on the GTM configuration. For details of each device, see **Section 25.1.5**.

25.4.4 Connection to ADCF

GTM can trigger the AD conversion start. The signals, which should trigger the conversion, are connected to the ADCF module inside this device. As trigger sources following signals are used:

- TIM_IRQ, after ICM
- ATOM_OUT
- MCS_IRQ, after ICM

Signals specified above are multiplexed together and routed to the ADCF. Multiplication scheme is described in "**Section 26, Peripheral Interconnect (PIC)**". The GTM can trigger the AD groups 0 to 4. In "**Section 26, Peripheral Interconnect (PIC)**" more details regarding the ADCF trigger selection can also be found.

25.4.5 Connection from ADCF

Every group of the ADCF generates one conversion end interrupt. This signal can be used to trigger the TIM channel of the GTM to save the timestamp information. After that, the TIM can start the DMA to transfer ADCF group's channels conversion results and the timestamp information to the memory. The ADCF group conversion end signals are connected in one-to-one manner to the TIM. The input signal to the TIM has to be defined during configuration of the TIM, for example: TIM0 channel 0 - external input signal or ADCF converter group 0 signal. The scheme of the ADCF to TIM connections is shown below:

- ADCF0 group 0 end of conversion interrupt -> TIM0 input 0 or TIM1 input 0 exclusively
- ADCF0 group 1 end of conversion interrupt -> TIM0 input 1 or TIM1 input 1 exclusively
- ADCF0 group 2 end of conversion interrupt -> TIM0 input 2 or TIM1 input 2 exclusively
- ADCF0 group 3 end of conversion interrupt -> TIM0 input 3 or TIM1 input 3 exclusively
- ADCF0 group 4 end of conversion interrupt -> TIM0 input 4 or TIM1 input 4 exclusively
- ADCF1 group 0 end of conversion interrupt -> TIM1 input 0
- ADCF1 group 1 end of conversion interrupt -> TIM1 input 1
- ADCF1 group 2 end of conversion interrupt -> TIM1 input 2
- ADCF1 group 3 end of conversion interrupt -> TIM1 input 3
- ADCF1 group 4 end of conversion interrupt -> TIM1 input 4

Please refer also to the "**Section 26, Peripheral Interconnect (PIC)**" for more information.

25.4.6 Sub-Module

Every ATOM submodule is connected to a 4-channel DTM (Dead Time Module) inside of the GTM. For the first 4 channels of the ATOM submodule, the connection to the DTM is selectable by a runtime configuration of the GTM registers. See **Section 25.12, Dead Time Module (DTM)** for DTM submodule description.

25.4.7 Safety Mechanism

The RAMs are protected by an ECC function. The ECC function is accessible and testable. For more details regarding ECC function, see "**Section 33, RAM Modules**". An ECC error will also be signaled to the respective MCS submodule.

An output signal from ATOM submodule can be read back using TIM submodule using the same pin. This function is a part of the safety mechanism. Please therefore see "**Section 28, Functional Safety**" for more details. Refer also to "**Section 26, Peripheral Interconnect (PIC)**" for more details.

The DTM submodule output signals are set into Hi-Z state automatically in reaction to an external input signal on the ESO (Emergency Shut-off) pin or on the error signal from ECM. Please refer also to "**Section 26, Peripheral Interconnect (PIC)**" and "**Section 29, Error Control Module (ECM)**" for more details.

25.4.8 Procedure of Module Standby and Limited Reset

This module supports module standby and limited reset functions. Before these functions are enabled, all of the followings must be ensured:

- Disable output pins of ATOM
  - Write the following register
    - GTM0ATOMiAGCOUTENSTAT = 5555_H
  - Read the following register and wait the value matching
    - GTM0ATOMiAGCOUTENSTAT == 0_H
- Stop operation of TBU
  - Write the following register
    - GTM0TBUCHEN = 5_H
  - Read the following register and wait the value matching
    - GTM0TBUCHEN == 0_H
- Disable all interrupts of sub-modules
  - Write the following registers
    - GTM0GTMIRQEN = 0_H
    - GTM0GTMEIRQEN = 0_H
    - GTM0ARUIRQEN = 0_H
    - GTM0TIMixIRQEN = 0_H
    - GTM0TIMixEIRQEN = 0_H
    - GTM0ATOMixIRQEN = 0_H
    - GTM0MCSixIRQEN= 0_H
    - GTM0MCSixEIRQEN = 0_H
    - GTM0CMPIRQEN = 0_H
    - GTM0CMPEIRQEN = 0_H
- Stop operation of MCS
  - Write the following registers
    - GTM0MCSixCTRL = 0_H
    - GTM0MCSiCAT = $1FF_H$
    - GTM0MCS0CWT = $1FF_H$
  - Read the following register and wait the value matching
    - GTM0MCSixCTRL[0] == 0_H
- No peripheral access to GTM

25.5 Introduction

25.5.1 Overview

This document is the specification for the Generic Timer Module (GTM). It contains a module framework with submodules of different functionality. These submodules can be combined in a configurable manner to form a complex timer module that serves different application domains and different classes within one application domain. Because of this scalability and configurability the timer is called generic.

The scalability and configurability is reached with an architecture philosophy where dedicated hardware submodules are located around a central routing unit (called Advanced Routing Unit (ARU)). The ARU can connect the submodules in a flexible manner. The connectivity is software programmable and can be configured during runtime.

Nevertheless, the GTM-IP is designed to unload the CPU or a peripheral core from a high interrupt load. Most of the tasks inside the GTM-IP can run -once setup by an external CPU- independent and in parallel to the software. There may be special situations, where the CPU has to take action but the goal of the GTM design was to reduce these situations to a minimum.

The hardware submodules have dedicated functionalities, e.g. there are timer input modules where incoming signals can be captured and characterized together with a notion of time. By combination of several submodules through the ARU complex functions can be established. E.g. the signals characterized at an input module can be routed to a signal processing unit where an intermediate value about the incoming signal frequency can be calculated.

The modules that help to implement such complex functions are called *infrastructural components* further on. These components are present in all GTM variants. However, the number of these components may vary from device to device.

Other submodules have a more general architecture and can fulfil typical timer functions, e.g. there are MCS and IO modules. A third group of submodules is responsible for supporting the implementation of safety functions to fulfil a defined safety level. The module ICM is responsible for interrupt services and defines the fourth group.

Each GTM-IP is build up therefore with submodules coming from those four groups. The application class is defined by the amount of components of those submodules integrated into the implemented GTM-IP.

25.5.2 Document Structure

The structure of this document is motivated out of the aforementioned submodule classes. **Section 25.6, GTM Architecture** describes the dedicated GTM-IP implementation this specification is written for. It gives an overview about the implemented submodules.

The following **Section 25.6** up to **Section 25.9** deals with the so called infrastructural components for routing, clock management and common time base functions. **Section 25.10**, **Section 25.11** and **Section 25.12** describe the signal input and output modules while the following **Section 25.13** explains the signal processing and generation submodule. **Section 25.14** describes the memory configuration submodule. The next sections provide a detailed description of application specific and safety related modules like the CMP and MON submodules. **Section 25.16** describes a module that bundles several interrupts coming from the other submodules and connect them to the outside world.

These submodule groups are shown in the following table:

Chapter	Submodule	Group
25.7	Advanced Routing Unit (ARU)	Infrastructural components
25.8	Clock Management Unit (CMU)	Infrastructural components
25.9	Time Base Unit (TBU)	Infrastructural components
25.10	Timer Input Module (TIM)	IO Modules
25.11	ARU-connected Timer Output Module (ATOM)	IO Modules
25.12	Dead Time Module (DTM)	IO Modules
25.13	Multi Channel Sequencer (MCS)	Signal generation and processing
25.14	Memory Configuration (MCFG)	Memory Configuration
25.15	Interrupt Concentrator Module (ICM)	Interrupt services
25.16	Output Compare Unit (CMP)	Safety features
25.17	Monitoring Unit (MON)	Safety features

25.6 GTM Architecture

25.6.1 Overview

As already mentioned in **Section 25.5, Introduction** the GTM-IP forms a generic timer platform that serves different application domains and different classes within these application domains. Depending on these multiple requirements of application domains multiple device configurations with different count of submodules (i.e. ATOM, MCS, TIM, TOM) and different count of channel per submodule (if applicable) are possible. In this section as an example of possible device configurations the GTM-IP_208 realization is outlined. The architecture of the GTM-IP_208 is depicted in **Figure 25.2**. The device dependent configuration (i.e. the count of submodules) is listed in **Section 25.19, GTM Device 208**.

25.6.1.1 GTM Architecture Block Diagram

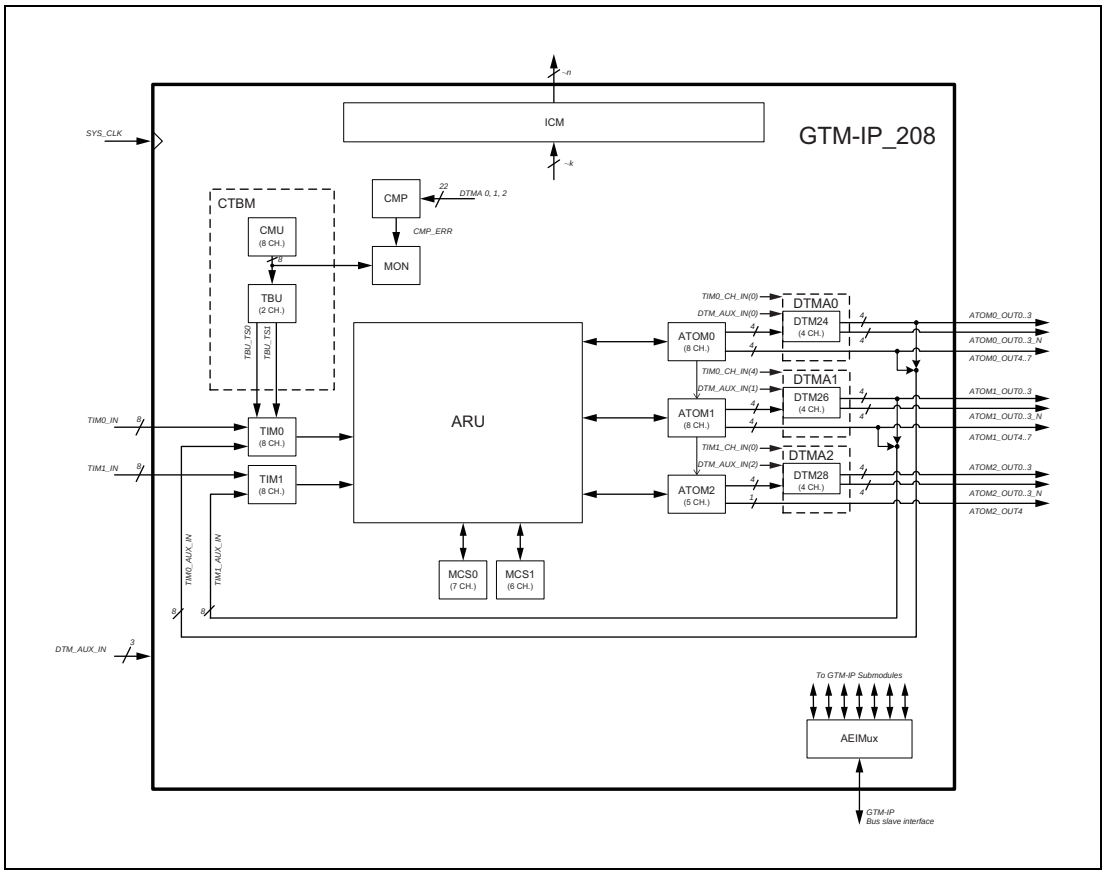

Figure 25.2 GTM Architecture Block Diagram

The central component of the GTM-IP is the Advanced Routing Unit (ARU) where most of the submodules are located around and connected to. This ARU forms together with the Clock Management Unit (CMU) and the Time Base Unit (TBU) the infrastructural part of the GTM. The ARU is able to route data from a connected source submodule to a connected destination submodule. The routing is done in a deterministic manner with a round-robin scheduling scheme of connected channels which receive data from ARU and with a worst case round-trip time.

The routed data word size of the ARU is 53 bit. The data word can logically be split into three parts. These parts are shown in **Figure 25.3, ARU Data Word** . Bits 0 to 23 and bits 24 to 47 typically hold data for the operation registers of the GTM-IP. This can be for example the duty cycle and period duration of a measured PWM input signal or the output characteristic of an output PWM to be generated. Another possible content of Data0 and Data1 can be two 24 bit values of the GTM-IP time bases TBU_TS0 and TBU_TS1. Bits 48 to 52 can contain control bits to send control information from one submodule to another. These ARU Control Bits (ACB) can have a different meaning for different submodules.

It is also possible to route data from a source to a destination and the destination can act later on as source for another destination. These routes through the GTM-IP are further on called data streams. For a detailed description of the ARU submodule see **Section 25.7, Advanced Routing Unit (ARU)** .

25.6.1.2 ARU Data Word Description

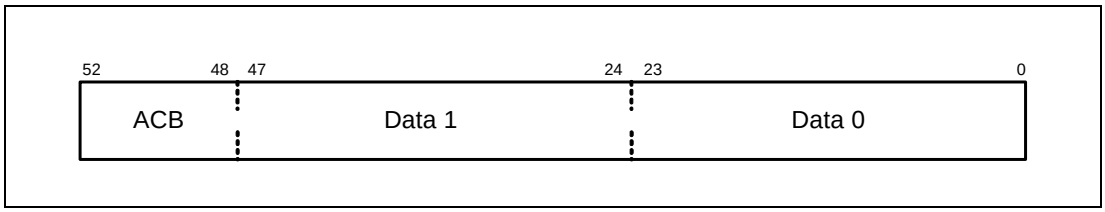

Figure 25.3 ARU Data Word

Signals are transferred into the GTM-IP at the Timer Input Modules (TIM). These modules are able to filter the input signals and annotate additional information. Each channel is for example able to measure pulse high or low times and the period of a PWM signal in parallel and route the values to ARU for further processing. The internal operation registers of the TIM submodule are 24 bits wide.

The Clock Management Unit (CMU) serves up to 8 different clocks for the GTM. It acts as a clock divider for the system clock. The counters implemented inside other submodules are typically driven from this submodule. Please note, that the CMU clocks are implemented as enable signals for the counters while the whole system runs with the GTM global clock SYS_CLK. This global clock typically corresponds to the microcontroller bus clock the GTM-IP is connected to and should not exceed 100MHz because of the power dissipation of the used transistors where the GTM is implemented with.

The TBU provides up to twice independent common time bases for the GTM-IP. In general, the number of time bases depends on the implemented device.

Signal outputs are generated with the ARU-connected TOMs (ATOM) and the corresponding Dead Time Modules (DTM).

The ATOMs offer the additional functionality to generate complex output signals without CPU interaction by serving these complex waveform characteristics by other submodules that are connected to the ARU like the Multi Channel Sequencer (MCS). The operation and shadow registers of the ATOM channels are 24 bit wide to have a higher resolution and to have the opportunity to compare against time base values coming from the TBU.

It is possible to trigger ATOM channels for a successor ATOM submodule through a trigger line between ATOM(x)_CH(7) and ATOM(x+1)_CH(0). But to avoid long trigger paths the GTM-IP integrator can configure after which ATOM submodule instance a register is placed into the trigger signal chain. Each register results in one SYS_CLK cycle delay of the trigger signal. See device specification of silicon vendor for unregistered trigger chain length.

Together with the MCS the ATOM is able to generate an arbitrary predefined output sequence at the GTM-IP output pins. The output sequence is defined by instructions located in RAM connected to the MCS submodule. The instructions define the points were an output signal should change or to react on other signal inputs. The output points can be one or two time stamps (or even angle stamp in case of an engine management system) provided by the TBU. Since the MCS is able to read data from the ARU it is also able to operate on incoming data routed from the TIM. Additionally, the MCS can process data that is located in its connected RAMs. The MCS RAM is located logically inside the MCS while the silicon vendor has to implement its own RAM technology there.

The two modules Compare Module (CMP) and Monitor Module (MON) implement safety related features. The CMP compares two output channels of an ATOM and sends the result to the MON submodule were the error is signalled to the CPU. The MON module is also able to monitor the ARU and CMU activities.

In the described implementation the submodules of the GTM-IP have a huge amount of different interrupt sources. These interrupt sources are grouped and concentrated by the Interrupt Concentrator Module (ICM) to form a much easier manageable bunch of interrupts that are visible outside of the GTM-IP.

On the GTM-IP top level there are some configurable signal connections from the signal output of the DTM modules to the input signals of the TIM modules.

The trigger out of TIM (i.e. the signals TIM[i]_EXT_CAPTURE(7:0) of each TIM instance i) are routed to ATOM instance [i] and TOM instance [i] with i=0..NTIM-1 (NTIM defines the number of available TIM instances, see **Table 25.2, Sub-Units and Channels**).

This TIM trigger can be used to trigger inside the ATOM or TOM instance either a channel or the global control register of AGC or TGC0/TGC1 unit.

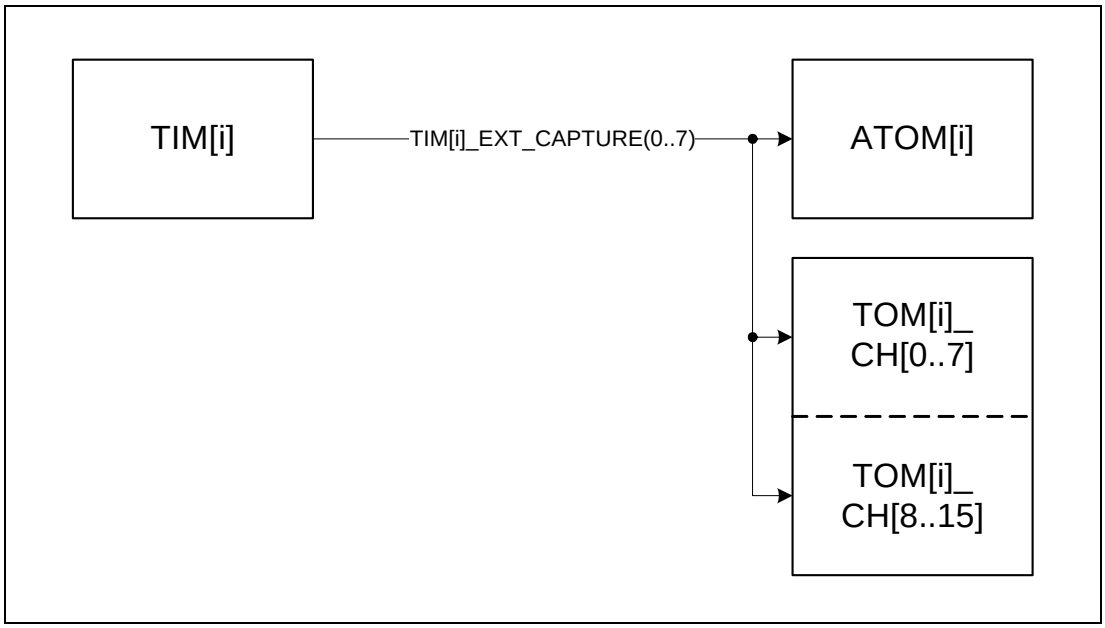

Figure 25.4 The trigger out of TIM(1)

The trigger out of TIM (i.e. the signals TIM[i]_EXT_CAPTURE(7:0) of each TIM instance i) are additionally routed to the MCS instance [i]. This trigger forwarding can be enabled by register GTM0GTMEXTCAPENi.

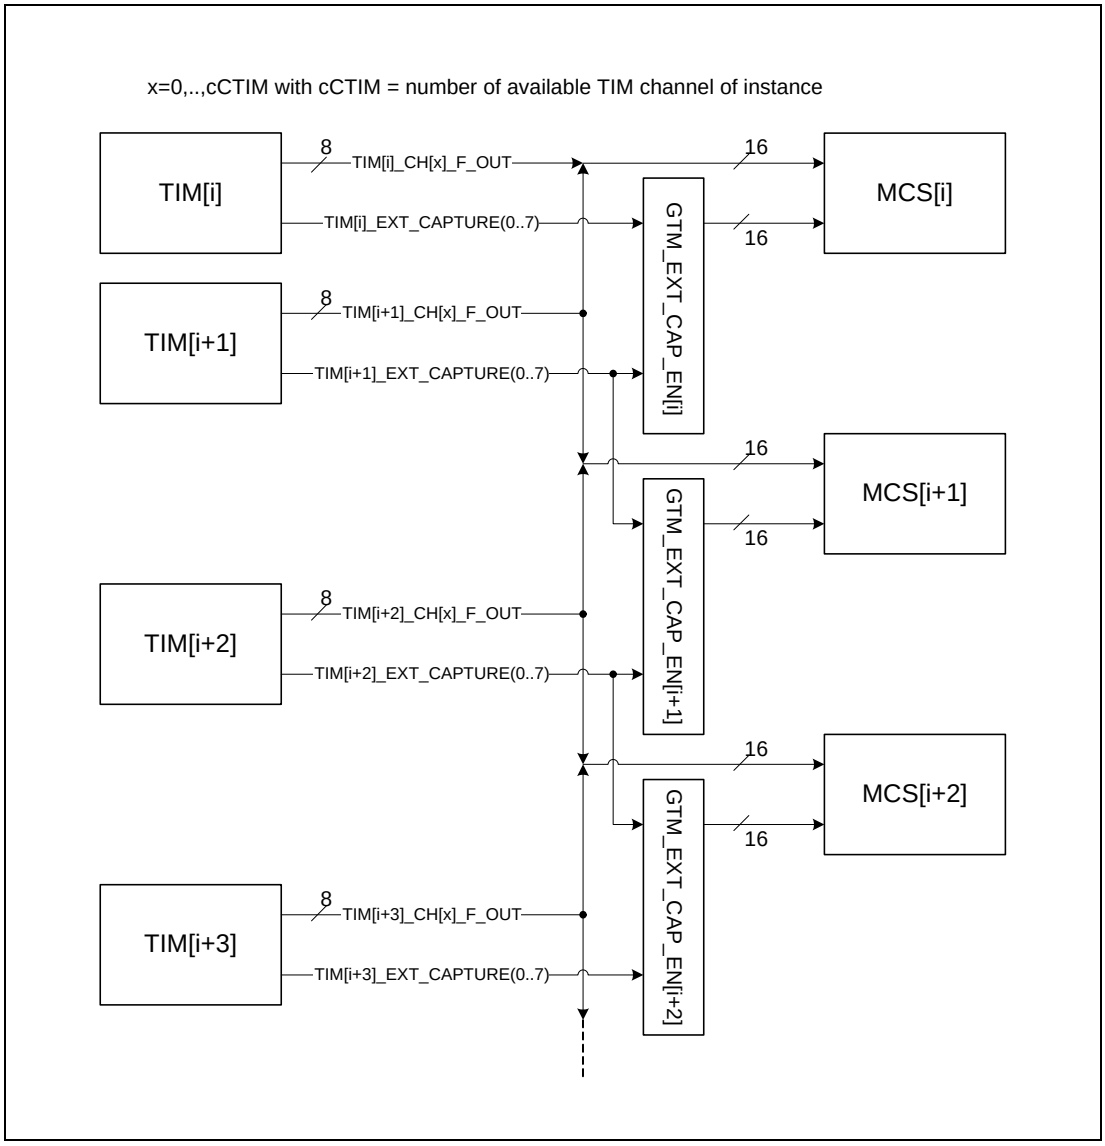

Figure 25.5 The trigger out of TIM(2)

25.6.2 GTM-IP Interfaces

In general the GTM-IP can be divided into four interface groups. Two interface groups represent the ports of the GTM-IP where incoming signals are assembled and outgoing signals are created. These interfaces are therefore connected to the GTM-IP input submodule TIM and to the GTM-IP output submodules DTM.

Another interface is the bus interface where the GTM-IP can be connected to the SoC system bus. This generic bus interface is described in more detail in **Section 25.6.2.1, GTM-IP Generic Bus Interface (AEI)** . The last interface is the interrupt controller interface. The GTM-IP provides several interrupt lines coming from the various submodules. These interrupt lines are concentrated inside the ICM and have to be adapted to the dedicated microcontroller environment where each interrupt handling can look different. The interrupt concept is described in more detail in **Section 25.6.5, GTM-IP Interrupt Concept** .

25.6.2.1 GTM-IP Generic Bus Interface (AEI)

The GTM-IP is equipped with a generic bus interface that can be widely adapted to different SoC bus systems. This generic bus interface is called AE-Interface (AEI). The adaptation of the AEI to SoC buses is typically done with a bridge module translating the AEI signals to the SoC bus signals of the silicon vendor. The AEI bus signals are depicted in the following table:

Table 25.9 AEI bus signals

Signal name	I/O	Description	Bit width
AEI_SEL	I	GTM-IP select line	1
AEI_ADDR	I	GTM-IP address	32
AEI_PIPE	I	AEI Address phase signal	1
AEI_W1R0	I	Read/Write access	1
AEI_WDATA	I	Write data bus	32
AEI_RDATA	O	Read data bus	32
AEI_READY	O	Data ready signal	1
AEI_STATUS	O	AEI Access status	2

The AEI Status Signal may drive one of the following values:

Table 25.10 AEI Status signal

AEI_STATUS	Description
00	No Error
01	Illegal Byte Addressing
10	Illegal Address Access
11	Unsupported Address

The signal value “00” is driven if no error occurred during AEI access.

The signal value “01” is driven if the bus address is not an integer multiple of 4 (byte addressing).

The signal value “11” is driven if the address is not handled in the GTM.

The signal value “10” is driven if an illegal write access to one of the following register is performed:

(a) register is protected (e.g. protected by bit RF_PROT).

(b) writing a writable bit field of a register which is not implemented in the device with a value different from the reset value.

In case of an illegal write access signalled by status “10” the register will not be modified.

Reading registers will never return status “10”.

Write access to following addresses returns status "10" under special conditions:

25.6.2.2 GTM-IP Multi-master and multi-tasking support

To support multi-master and multi-task access to the registers of the GTM-IP a dedicated write-access scheme is used for critical control bits inside the IP that need such a mechanism. This can be for example a shared register where more than one channel can be controlled globally by one register write access. Such register bits are implemented inside the GTM-IP with a double bit mechanism, where the writing of ‘00’ and ‘11’ has no effect on the register bit and where ‘01’ sets the bit and ‘10’ resets the bit. If the CPU wants to read the status of the bit it always gets a ‘00’ if the bit is reset and it gets a ‘11’ if the bit is set.

25.6.3 ARU Routing Concept

One central concept of the GTM-IP is the routing mechanism of the ARU submodule for data streams. Each data word transferred between the ARU and its connected submodule is 53 bit wide. It is important to understand this concept in order to use the resources of the GTM-IP effectively. Each module that is connected to the ARU may provide an arbitrary number of ARU write channels and an arbitrary number of ARU read channels. In the following, the ARU write channels are named data sources and the ARU read channels are named data destinations.

The concept of the ARU intends to provide a flexible and resource efficient way for connecting any data source to an arbitrary data destination. In order to save resource costs, the ARU does not implement a switch matrix, but it implements a data router with serialized connectivity providing the same interconnection flexibility. **Figure 25.6** shows the ARU data routing principle. Data sources are marked with a green rectangle and the data destinations are marked with yellow rectangles. The dashed lines in the ARU depict the configurable connections between data sources and data destinations. A connection between a data source and a data destination is also called a data stream.

25.6.3.1 Principle of data routing using ARU

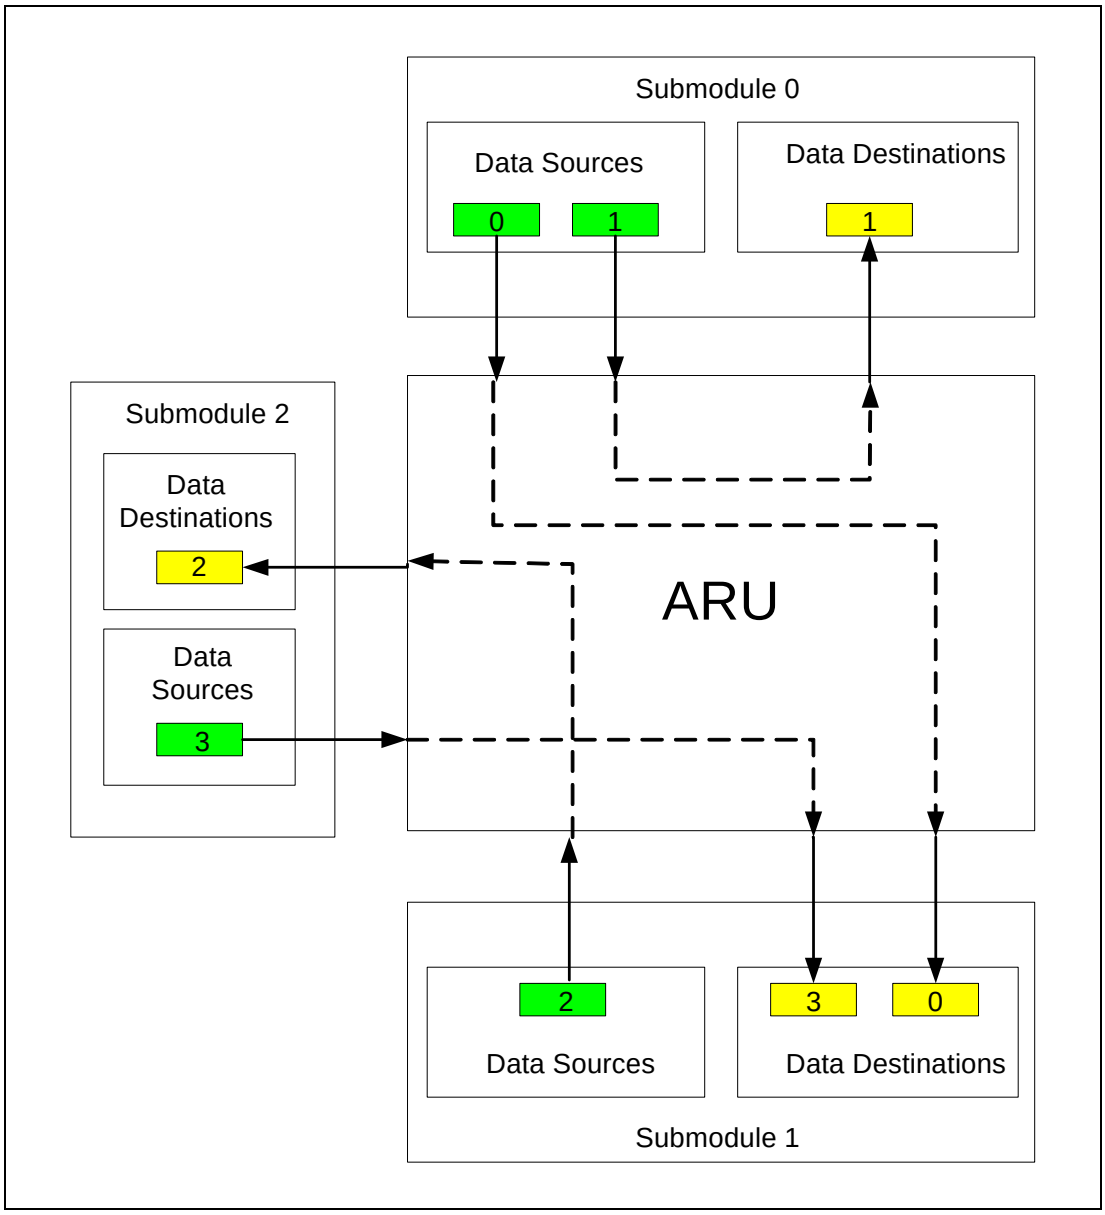

Figure 25.6 Principle of data routing using ARU

The configuration of the data streams is realized according to the following manner: Each data source has its fixed and unique source address: The fixed address of each data source is pointed out by the numbers in the green boxes of **Figure 25.6**. The address definitions of all available data sources in the GTM-IP can be obtained from **Table 25.204, ARU Write Address Overview**, **Table 25.211, ARU Write Address Overview**. The connection from a specific data source to a specific data destination is defined by configuring the corresponding address of a data source in the desired data destination. The configured address of each data destination is pointed out by the numbers in the yellow boxes of **Figure 25.6**.

Normally, the destination is idle and waits for data from the source. If the source offers new data, the destination does a destructive read, processes the data and goes idle again. The same data is never read twice.

The functionality of the ARU is as follows: The ARU sequentially polls the data destinations of the connected modules in a round-robin order. If a data destination requests new data from its configured data source and the data source has data available, the ARU delivers the data to the destination and it informs both, the data source and destination that the data is transferred. The data source marks the delivered ARU data as invalid which means that the destination consumed the data.

It should be noted that each data source should only be connected to a single data destination. This is because the destinations consume the data. If two destinations would reference the same source one destination would consume the data before the other destination could consume it. Since the data transfers are blocking, the second destination would block until it receives new data from the source. On the other hand, the transfer from a data source to the ARU is also blocking, which means that the source channel can only provide new data to the ARU when an old data word is consumed by a destination. In order to speed up the process of data transfers, the ARU handles two different data destinations in parallel.

Following table gives an overview about the number of channels for the GTM-IP_208 variant used as a reference within this chapter.

Table 25.11 The number of channels for the GTM-IP_208 variant

Submodule	Number of data sources	Number of data destinations
ARU	1	0
CMU	0	0
TBU	0	0
TIM 0-1	16	0
ATOM 0-2	21	21
DTM	0	0
MCS 0-1	39	13
ICM	0	0
CMP	0	0
MON	0	0
Total	77	34

25.6.3.2 ARU Round Trip Time

The ARU uses a round-robin arbitration scheme with a fixed round trip time for all connected data destinations. This means that the time between two adjacent read requests resulting from a data destination channel always takes the round trip time, independently if the read request succeeds or fails.

25.6.3.3 ARU Blocking Mechanism

Another important concept of the ARU is its blocking mechanism that is implemented for transferring data from a data source to a data destination. This mechanism is used by ARU connected submodules to synchronize the submodules to the routed data streams. **Figure 25.7** explains the blocking mechanism.

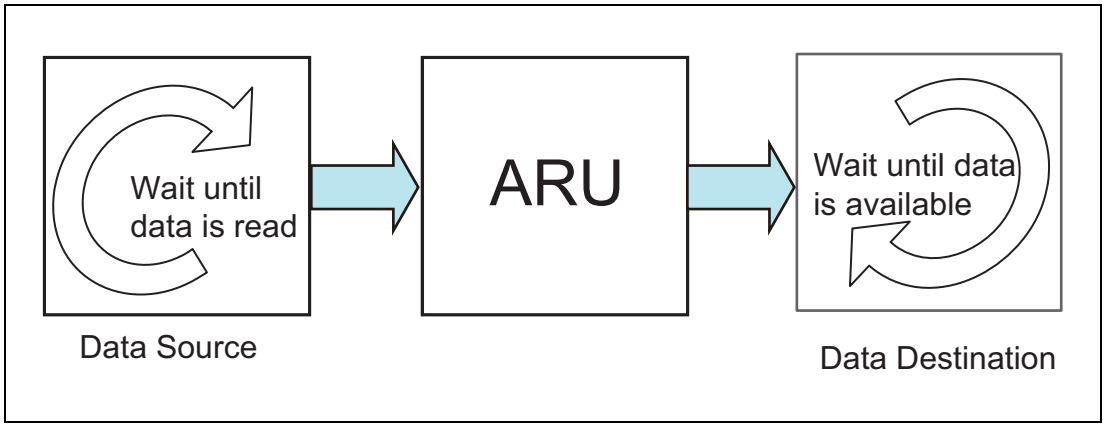

Figure 25.7 Graphical representation of ARU blocking mechanism

If a data destination requests data from a data source over the ARU but the data source does not have any data yet, it has to wait until the data source provides new data. In this case the submodule that owns the data destination may perform other tasks. When a data source produces new data faster than a data destination can consume the data the source raises an error interrupt and signals that the data could not be delivered in time. The new data is marked as valid for further transfers and the old data is overwritten.

In any case the round trip time for the ARU has a fixed reset value for a specific device configuration. The end value of the roundtrip counter can be changed with a configuration register GTM0ARUCADDREND inside the ARU. For more details see the ARU specific chapter.

Please refer also to **Section 25.18, GTM Device 207** and **Section 25.19, GTM Device 208**.

It is possible to reset the ARU roundtrip counter ARU_CADDR manually synchronous to CMU clock enable from configuration register inside CMU module. See CMU specific chapter for more details.

25.6.4 GTM-IP Clock and Time Base Management (CTBM)

Inside the GTM-IP several subunits are involved in the clock and time base management of the whole GTM. **Figure 25.8** shows the connections and sub blocks involved in these tasks. The sub blocks involved are called Clock and Time Base Management (CTBM) modules further on.

25.6.4.1 GTM-IP Clock and time base management architecture

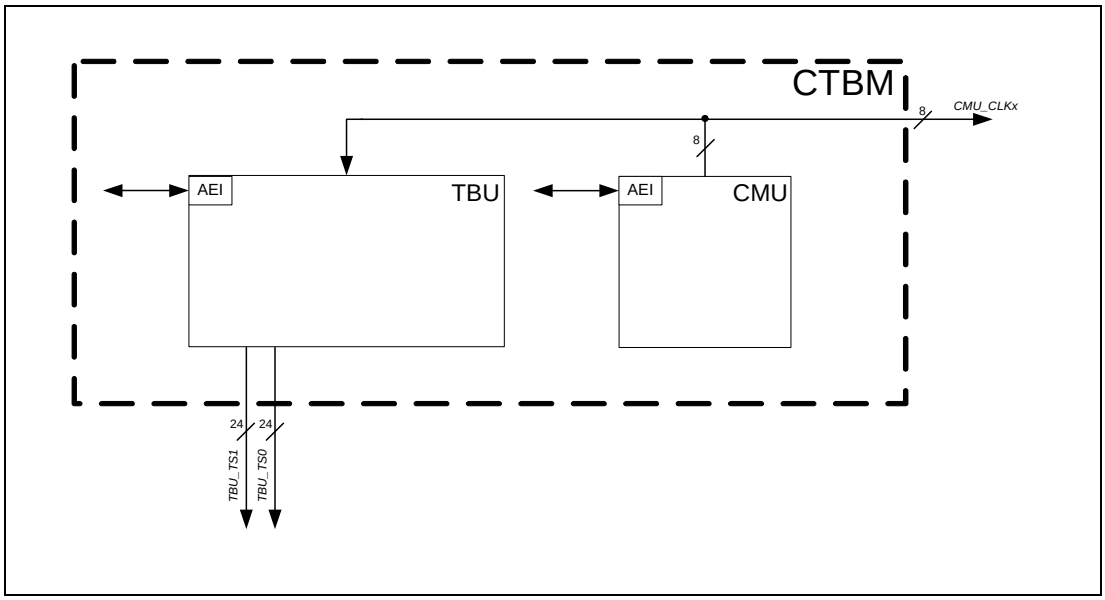

Figure 25.8 GTM-IP Clock and time base management architecture

One important module of the CTBM is the Clock Management Unit (CMU) which generates 8 clocks for the submodules of the GTM. For a detailed description of the CMU functionality and clocks see **Section 25.8, Clock Management Unit (CMU)** .

Inside the Time Base Unit (TBU) one of these eight clocks is used per channel to generate a common time base for the GTM. The TBU functionality is described in **Section 25.9, Time Base Unit (TBU)**.

In this device the TBU submodule generates the two time base signals TBU_TS0 and TBU_TS1 which are widely used inside the GTM as common time bases for signal characterization and generation.

25.6.5 GTM-IP Interrupt Concept

The submodules of the GTM-IP can generate thousands of interrupts on behalf of internal events. This high amount of interrupts is combined inside the Interrupt Concentrator Module (ICM) into interrupt groups. In this interrupt groups the GTM-IP submodule interrupt signals are bundled to a smaller set of interrupts. Out of these interrupt sets a smaller amount of interrupt signals is created and signalled outside of the GTM-IP as a signal GTM_<MOD>_IRQ, whereas <MOD> identifies the name of the corresponding GTM-IP submodule.

Moreover, each output signal GTM_<MOD>_IRQ has a corresponding input signal GTM_<MOD>_IRQ_CLR that can be used for clearing the interrupts. This input signals can be used by the surrounding microcontroller system as:

- acknowledge signal from a DMA controller
- validation signal from ADC
- clear signal from an GTM-external interrupt controller to do an atomic clear while entering an ISR routine

The controlling of the individual interrupts is done inside the submodules. If a submodule consists of several submodule channels that are most likely to work independent from each other (like TIM, MCS and ATOM), each submodule channel has its own interrupt control and status register set, named as interrupt set in the following. Other submodules (ARU, CMP and global GTM functionality) have a common interrupt set for the whole submodule.

The interrupt set consists of four registers: The IRQ_EN register, the IRQ_NOTIFY register, the IRQ_FORCINT register, and the IRQ_MODE register. While the registers IRQ_EN, IRQ_NOTIFY, and IRQ_FORCINT signalize the status and allow controlling of each individual interrupt source within an interrupt set, the register IRQ_MODE configures the interrupt mode that is applied to all interrupts that belong to the same interrupt set.

In order to support a wide variety of microcontroller architectures and interrupt systems with different interrupt signal output characteristics and internal interrupt handling the following four modes can be configured:

- Level mode
- Pulse mode
- Pulse-Notify mode
- Single-Pulse mode

These interrupt modes are described in more details in the following subsections.

The register IRQ_EN allows the enabling and disabling of an individual interrupt within an interrupt set. Independent of the configured mode, only enabled interrupts can signalize an interrupts on its signal GTM_<MOD>_IRQ.

The register IRQ_NOTIFY collects the occurrence of interrupt events. The behavior for setting a bit in this register depends on the configured mode and thus it is described later on in the mode descriptions.

Independent of the configured mode any write access with value ‘1’ to a bit in the register IRQ_NOTIFY always clears the corresponding IRQ_NOTIFY bit.

Moreover, the enabling of a disabled interrupt sources with a write access to the register IRQ_EN also clears the corresponding bit in the IRQ_NOTIFY register but only if the error interrupt source EIRQ_EN is disabled. However, if the enabling of a disabled interrupt is simultaneous to an incoming interrupt event, the interrupt event is dominant and the register IRQ_NOTIFY is not cleared.

Additionally, each write access to the register IRQ_MODE, clears all bits in the IRQ_NOTIFY register. It should be notified that the clearing of IRQ_NOTIFY is applied independently of the written data (e.g. no mode change).

Thus, a secure way for reconfiguring the interrupt mode of an interrupt set, is to disable all interrupts of the interrupt set with the register IRQ_EN, define the new interrupt mode by writing register IRQ_MODE, followed by enabling the desired interrupts with the register IRQ_EN.

Thus, a secure way for reconfiguring the interrupt mode of an error interrupt set, is to disable all error interrupts of the error interrupt set with the register EIRQ_EN, define the new interrupt mode by writing register IRQ_MODE, followed by enabling the desired error interrupts with the register EIRQ_EN.

The register IRQ_FORCINT is used by software for triggering individual interrupts with a write access with value ‘1’. Since a write access to IRQ_FORCINT only generates a single pulse, IRQ_FORCINT is not implemented as a true register and thus any read access to IRQ_FORCINT always results with a value of ‘0’.

It should be noted, that the mechanism for triggering interrupts with IRQ_FORCINT is globally disabled after reset. It has to be explicitly enabled by clearing the bit RF_PROT in the register GTM0GTMCTRL (see **Section 25.6.9.3, GTM0GTMCTRL**)

For the modules AEI-bridge, TIM, MCS and CMP each interrupt may configured to raise instead of the normal interrupt an error interrupt if enabled by the corresponding error interrupt enable bit in register EIRQ_EN.

Note, it is possible for one source to enable the normal interrupt and the error interrupt in parallel. Because of both interrupt clear signals could reset the notify bit this could cause problems in a system and therefore it is inadvisable.

Similar to enabling an interrupt, the enabling of a disabled error interrupt source with a write access to the register EIRQ_EN also clears the corresponding bit in the IRQ_NOTIFY register only if the interrupt source IRQ_EN is disabled. However, if the enabling of a disabled error interrupt is simultaneous to an incoming interrupt event, the interrupt event is dominant and the register IRQ_NOTIFY is not cleared.

All enabled error interrupts are or-combined inside the ICM and assigned to the dedicated GTM port gtm_err_irq. A corresponding input gtm_err_irq_clr allows the reset of this error interrupt from outside the GTM (hardware clear).

To be able to detect the module source of the error interrupt the ICM provides the register GTM0ICMIRQGMEI.

The error interrupt causing channel can be determined for the modules TIM by evaluating the ICM register GTM0ICMIRQGCEI1.

The error interrupt causing channel can be determined for MCS by evaluating the ICM register GTM0ICMIRQGCEI3.

25.6.5.1 Level interrupt mode

The default interrupt mode is the Level Interrupt Mode. In this mode each occurred interrupt event is collected in the register IRQ_NOTIFY, independent of the corresponding enable bit of register IRQ_EN and EIRQ_EN.

An interrupt event, which is defined as a pulse on the signal Int_out of **Figure 25.9** , may be triggered by the interrupt source of the submodule or by software performing a write access to the corresponding register IRQ_FORCINT, with a disabled bit RF_PROT in register GTM0GTMCTRL.

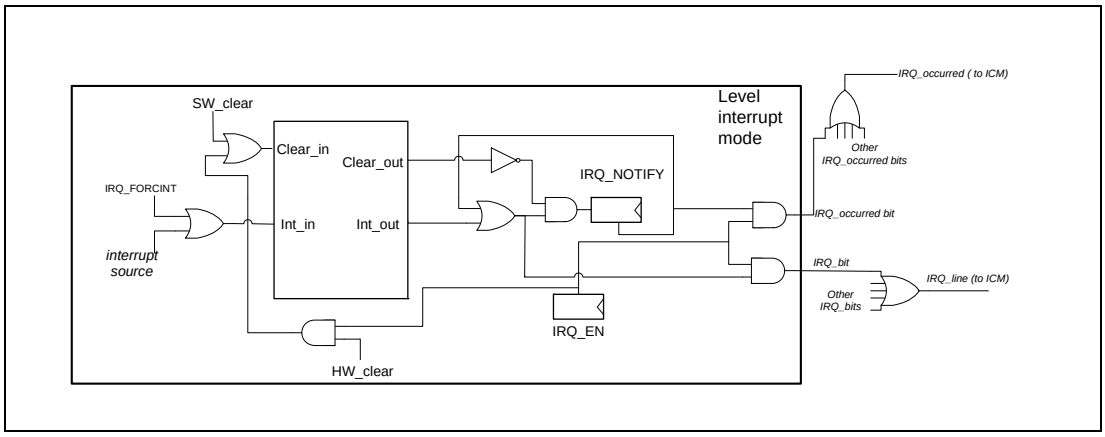

Figure 25.9 Level interrupt mode scheme

A collected interrupt bit in register IRQ_NOTIFY may be cleared by a clear event, which is defined as a pulse on signal Clear_out of **Figure 25.9**. A clear event can be performed with a write access with value '1' to the corresponding bit in the register IRQ_NOTIFY leading to a pulse on signals SW_clear. A clear event may also result from an externally connected signal GTM_<MOD>_IRQ_CLR, which is routed to the signal HW_clear of **Figure 25.9**. However, the hardware clear mechanism is only possible, if the corresponding interrupt is enabled by register IRQ_EN.

As the **Table 25.12** shows, interrupt events are dominant in the case of a simultaneous interrupt event and clear event.

Table 25.12 Priority of Interrupt Events and Clear Events

Int_in	Clear_in	Int_out	Clear_out
0	0	0	0
0	1	0	1
1	0	1	0
1	1	1	0

As it can be seen from the **Figure 25.9** an occurred interrupt event is signalled as a constant signal level with value 1 to the signal IRQ_bit, if the corresponding interrupt is enabled in register IRQ_EN.

With exception of the submodules ARU and DPLL, the signal IRQ_bit is OR-combined with the neighboring IRQ_bit signals of the same interrupt set and they are routed as a signal IRQ_line to the interrupt concentrator module (ICM). The interrupt signals IRQ_bit of the submodules DPLL and ARU are routed directly as a signal IRQ_line to the submodule ICM. In some cases (submodules TOM and ATOM) the ICM may further OR-combine several IRQ_line signals to an outgoing interrupt signal GTM_<MOD>_IRQ. In the other cases the IRQ_line signals are directly connected to the outgoing signals GTM_<MOD>_IRQ, within the submodule ICM.

The signal IRQ_occurred is connected in a similar way as the signal IRQ_line, however this signal is used for monitoring the interrupt state of the register IRQ_NOTIFY in the registers of the ICM.

The additional error interrupt enable mechanism for level interrupt is shown below.

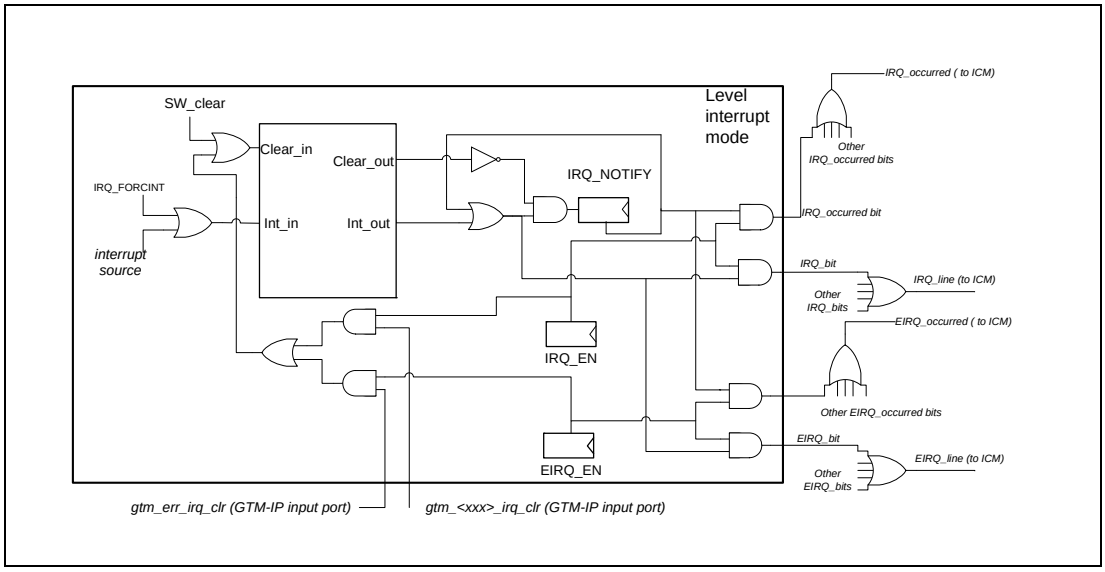

Figure 25.10 Level interrupt scheme for modules AEI-bridge, TIM, MCS, CMP

A collected interrupt bit in register IRQ_NOTIFY may be cleared by a clear event, which is defined as a pulse on signal Clear_out of **Figure 25.10**. A clear event can be performed with a write access with value '1' to the corresponding bit in the register IRQ_NOTIFY leading to a pulse on signals SW_clear. A clear event may also result from externally connected signal gtm_<MOD>_irq_clr or gtm_err_irq_clr, which is routed as a HW_clear to Clear_in of **Figure 25.10**. However, the hardware clear mechanism is only possible, if the corresponding interrupt or error interrupt is enabled by register IRQ_EN or EIRQ_EN.

As it can be seen from the **Figure 25.10** an occurred interrupt event is signalled as a constant signal level with value 1 to the signal IRQ_bit, if the corresponding interrupt is enabled in register IRQ_EN.

25.6.5.2 Pulse interrupt mode

The Pulse interrupt mode behavior can be observed from **Figure 25.11**.

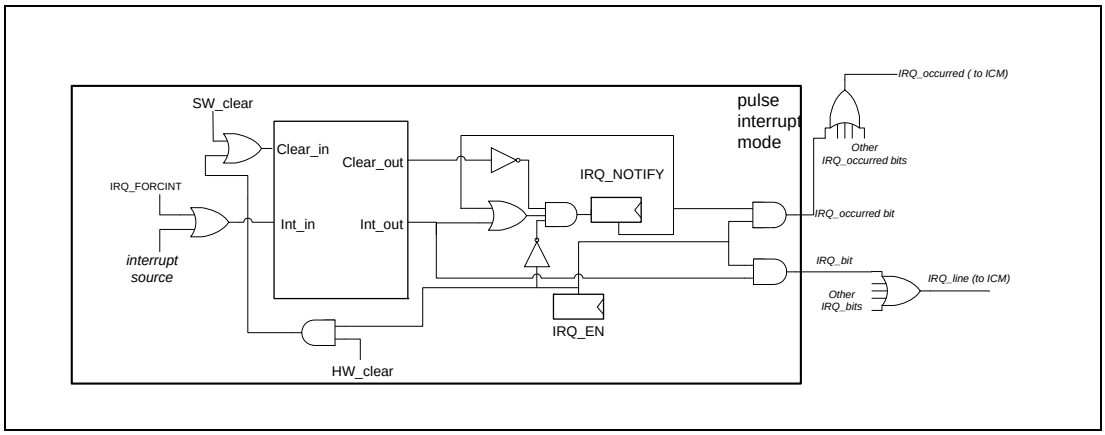

Figure 25.11 Pulse interrupt mode scheme

In Pulse Interrupt Mode each Interrupt Event will generate a pulse on the IRQ_bit signal if IRQ_EN is enabled.

As it can be seen from the figure, the interrupt bit in IRQ_NOTIFY register is always cleared if IRQ_EN is enabled.

However, if an interrupt is disabled in the register IRQ_EN, an occurred interrupt event is captured in the register IRQ_NOTIFY, in order to allow polling for disabled interrupts by software.

Disabled interrupts may be cleared by an interrupt clear event.

In Pulse interrupt mode, the signal IRQ_occurred is always 0.

The additional error interrupt enable mechanism for pulse interrupt is shown below.

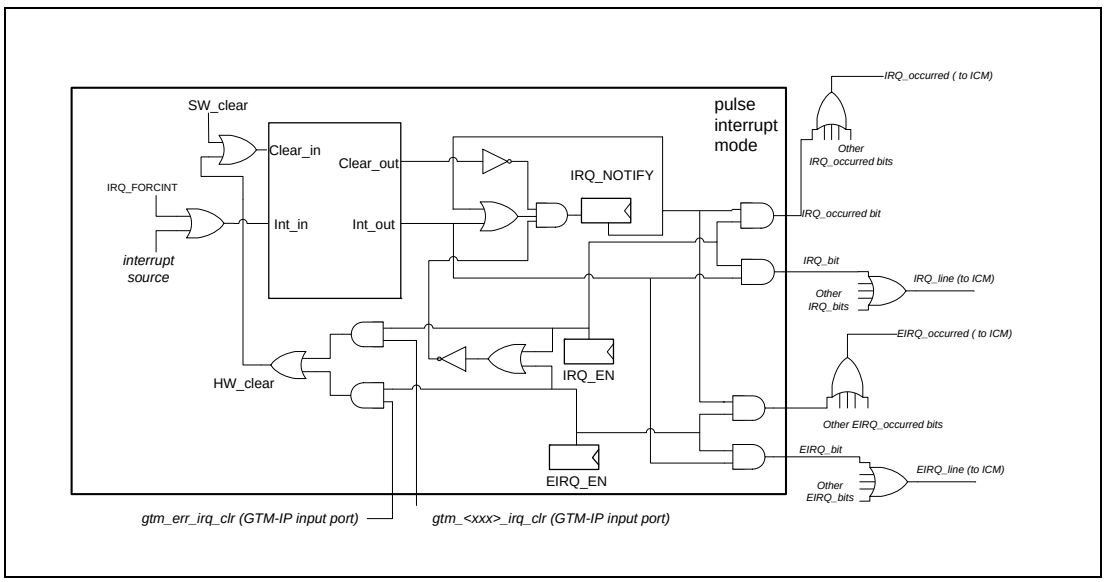

Figure 25.12 Pulse interrupt scheme for modules AEI-bridge, TIM, MCS, CMP

In Pulse Interrupt Mode each Interrupt Event will generate a pulse on the EIRQ_bit signal if EIRQ_EN is enabled.

As it can be seen from the figure, the interrupt bit in IRQ_NOTIFY register is always cleared if EIRQ_EN or IRQ_EN are enabled.

However, if an error interrupt is disabled in the register EIRQ_EN, an occurred error interrupt event is captured in the register IRQ_NOTIFY, in order to allow polling for disabled error interrupts by software.

Disabled error interrupts may be cleared by an error interrupt clear event.

In Pulse interrupt mode, the signal EIRQ_occurred is always 0.

25.6.5.3 Pulse-notify interrupt mode

In Pulse-notify Interrupt mode, all interrupt events are captured in the register IRQ_NOTIFY. If an interrupt is enabled by the register IRQ_EN, each interrupt event will also generate a pulse on the IRQ_bit signal. The signal IRQ_occurred will be high if interrupt is enabled in register IRQ_EN and the corresponding bit of register IRQ_NOTIFY is set. The Pulse-notify interrupt mode is shown in **Figure 25.13**.

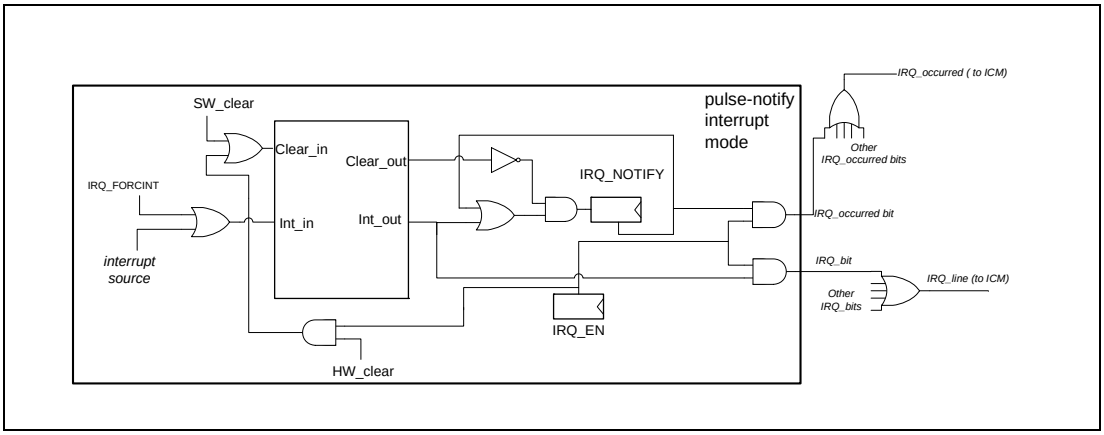

Figure 25.13 Pulse-notify interrupt mode scheme

The additional error interrupt enable mechanism for pulse-notify interrupt is shown below

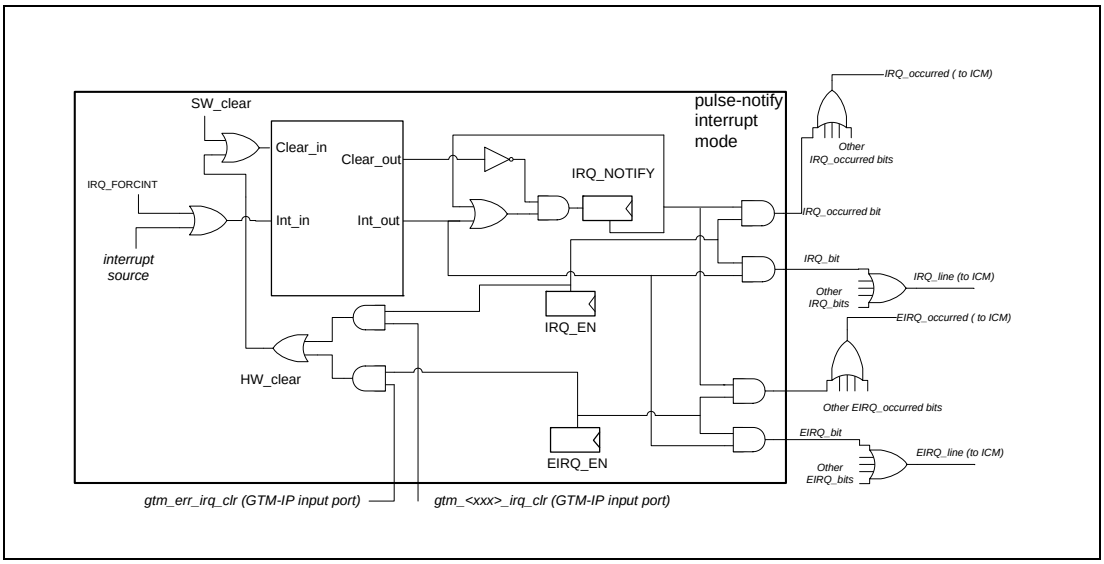

Figure 25.14 Pulse-notify interrupt scheme for modules AEI-bridge, TIM, MCS, CMP

In Pulse-notify Interrupt mode, all error interrupt events are captured in the register IRQ_NOTIFY. If an error interrupt is enabled by the register EIRQ_EN, each error interrupt event will also generate a pulse on the EIRQ_bit signal. The signal EIRQ_occurred will be high if error interrupt is enabled in register EIRQ_EN and the corresponding bit of register IRQ_NOTIFY is set. The Pulse-notify interrupt mode for error interrupts is shown in **Figure 25.14**.

25.6.5.4 Single-pulse interrupt mode

In Single-pulse Interrupt Mode, an interrupt event is always captured in the register IRQ_NOTIFY, independent of the state of IRQ_EN. However, only the first interrupt event of an enabled interrupt within a common interrupt set is forwarded to signal IRQ_line. Additional interrupt events of the same interrupt set cannot generate pulses on the signal IRQ_line, until the corresponding bits in register IRQ_NOTIFY of enabled interrupts are cleared by a clear event. The IRQ_occurred signal line will be high, if the IRQ_EN and the IRQ_NOTIFY register bits are set. The Single-pulse interrupt mode is shown in **Figure 25.15**.

The only exceptions are the modules ARU and DPLL. In these modules the IRQ_occurred bit of each interrupt is directly connected (without OR-conjunction of neighboring IRQ_occurred bits) to the inverter for suppressing further interrupt pulses.

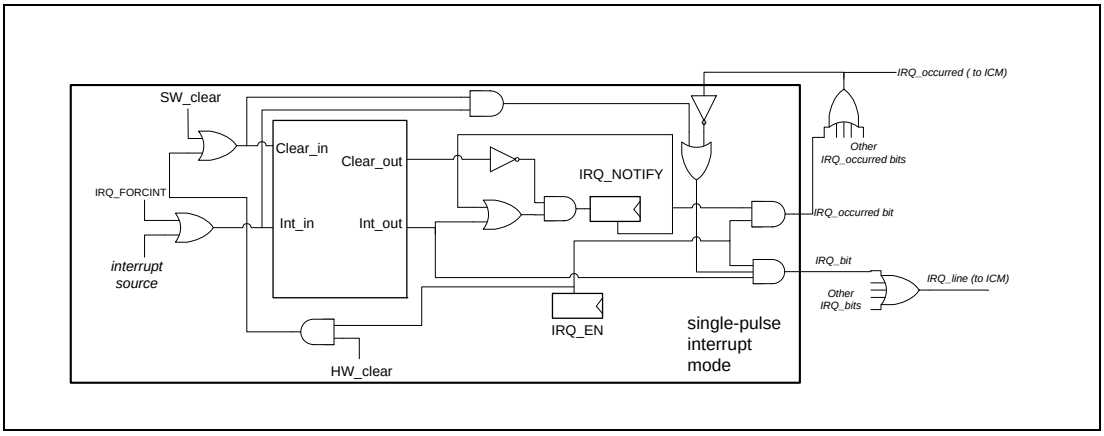

Figure 25.15 Single-pulse interrupt mode scheme

To avoid unexpected IRQ behavior in the single pulse mode, all desired interrupt sources should be enabled by a single write access to IRQ_EN and the notification bits should be cleared by a single write access to the register IRQ_NOTIFY.

The additional error interrupt enable mechanism for single-pulse interrupt is shown below

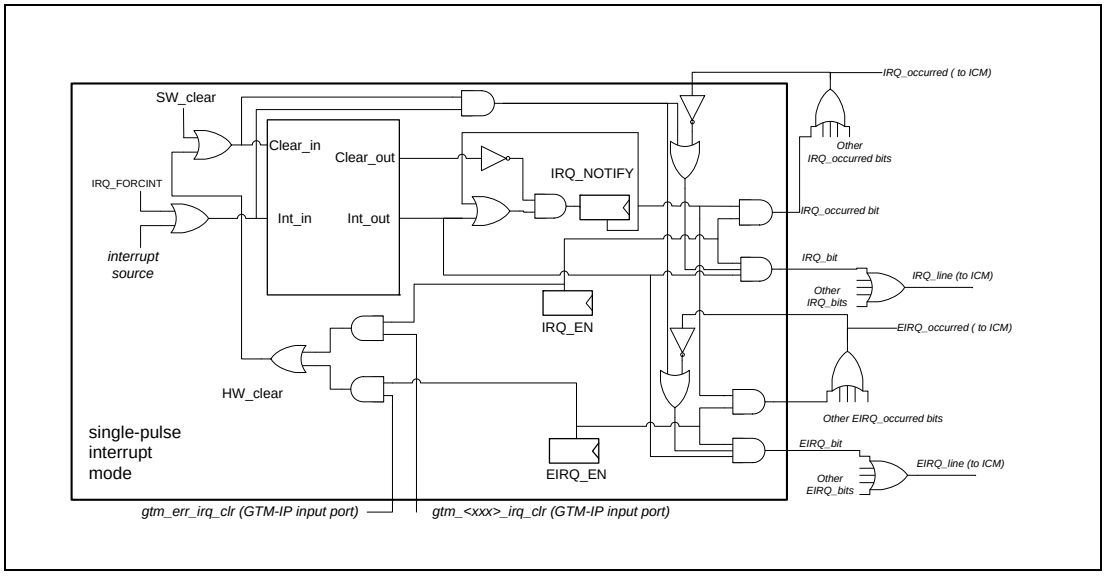

Figure 25.16 Single-pulse interrupt scheme for modules AEI-bridge, TIM, MCS, CMP

In Single-pulse Interrupt Mode, an error interrupt event is always captured in the register IRQ_NOTIFY, independent of the state of EIRQ_EN. However, only the first error interrupt event of an enabled error interrupt within a common error interrupt set is forwarded to signal EIRQ_line. Additional error interrupt events of the same error interrupt set cannot generate pulses on the signal EIRQ_line, until the corresponding bits in register IRQ_NOTIFY of enabled error interrupts are cleared by a clear event. The EIRQ_occurred signal line will be high, if the EIRQ_EN and the IRQ_NOTIFY register bits are set. The Single-pulse interrupt mode for error interrupts is shown in **Figure 25.16**.

To avoid unexpected EIRQ behavior in the single pulse mode, all desired error interrupt sources should be enabled by a single write access to EIRQ_EN and the notification bits should be cleared by a single write access to the register IRQ_NOTIFY.

An exception is the module ARU.

In this module the EIRQ_occurred bit of each error interrupt is directly connected (without OR-conjunction of neighboring EIRQ_occurred bits) to the inverter for suppressing further error interrupt pulses.

25.6.5.5 GTM-IP Interrupt concentration method

Because of the grouping of interrupts inside the ICM, it can be necessary for the software to access the ICM submodule first to determine the interrupt set that is responsible for an interrupt. A second access to the responsible register IRQ_NOTIFY is then necessary to identify the interrupt source, serve it and to reset the interrupt flag in register IRQ_NOTIFY afterwards. The interrupt flags are never reset by an access to the ICM. For a detailed description of the ICM submodule see **Section 25.15, Interrupt Concentrator Module (ICM)** .

25.6.6 GTM-IP Software Debugger Support

For software debugger support the GTM-IP comes with several features. E.g. status register bits must not be altered by a read access from a software debugger. To avoid this behavior to reset a status register bit by software, the CPU has to write a '1' explicitly to the register bit to reset its content.

The **Table 25.13** describes the behavior of some GTM-IP registers with special functionality on behalf of read accesses from the AEI bus interface.

25.6.6.1 Register behavior in case of Software Debugger accesses

Table 25.13 Register behavior in case of Software Debugger accesses

Module	Register	Description
TIM	GTM0TIMixGPR0/1	The overflow bit is not altered in case of a Debugger read access to this registers.
ATOM	GTM0ATOMixSR0/1	In SOMC mode a read access to this register by the Debugger does not release the channel for a new compare/match event.

Further on, some important states inside the GTM-IP submodule have to be signalled to the outside world, when reached and should for example trigger the software debugger to stop program execution. For this internal state signalling see the GTM-IP module integration guide.

The GTM provides an external signal gtm_halt, which disables clock signal SYS_CLK for debugging purposes. If SYS_CLK is disabled, a connected debugger can read any GTM related register and the GTM internal RAMs using AEI. Moreover, the debugger can also perform write accesses to the internal RAMs and to all GTM related registers in order to enable advanced debugging features (e.g. modifications of register contents in single step mode).

25.6.7 GTM-IP Programming conventions

To serve different application domains the GTM-IP is a highly configurable module with many configuration modes. In principle the submodules of the GTM-IP are intended to be configured at system start-up to fulfil certain functionality for the application domain the microcontroller runs in.

For example, a TIM input channel can be used to monitor an application specific external signal, and this signal has to be filtered. Therefore, the configuration of the TIM channel filter mode will be specific to the external signal characteristic. While it can be necessary to adapt the filter thresholds during runtime an adaptation of the filter mode during runtime is not reasonable. Thus, the change of the filter mode during runtime can lead to an unexpected behavior.

In general, the programmer has to be careful when reprogramming configuration registers of the GTM-IP submodules during runtime. It is recommended to disable the channels before reconfiguration takes place to avoid unexpected behavior of the GTM-IP.

25.6.8 GTM-IP TOP-Level Configuration Registers Overview

GTM-IP TOP-level contains following configuration registers:

Table 25.14 Register list

Symbol	Register Name	Details in Section
GTM0GTMREV	GTM-IP Version control register	**25.6.9.1**
GTM0GTMRST	GTM-IP Global reset register	**25.6.9.2**
GTM0GTMCTRL	GTM-IP Global control register	**25.6.9.3**
GTM0GTMAEIADDRXPT	GTM-IP AEI Timeout exception address register	**25.6.9.4**
GTM0GTMIRQNOTIFY	GTM-IP Interrupt notification register	**25.6.9.5**
GTM0GTMIRQEN	GTM-IP Interrupt enable register	**25.6.9.6**
GTM0GTMEIRQEN	GTM-IP Error interrupt enable register	**25.6.9.12**
GTM0GTMIRQFORCINT	GTM-IP Software interrupt generation register	**25.6.9.7**
GTM0GTMIRQMODE	GTM-IP top level interrupts mode selection. Please note that this mode selection is only valid for the three interrupts described in **Section 25.6.9.5, GTM0GTMIRQNOTIFY**	**25.6.9.8**
GTM0GTMTIMiAUXINSRC (i = 0, 1)	GTM-IP TIM[i] module AUX_IN source selection register	**25.6.9.13**
GTM0GTMHWCONF	GTM-IP Hardware Configuration	**25.6.9.14**
GTM0GTMATOMiOUT (i = 0, 2)	GTM-IP ATOM output level	**25.6.9.15**
GTM0GTMEXTCAPENi (i = 0, 1)	GTM-IP trigger event forwarding in from TIM[i] and TIM[i+1] to MCS instance [i].	**25.6.9.16**

25.6.9 GTM-IP TOP-Level Configuration Registers Description

25.6.9.1 GTM0GTMREV

Access: This register can be read in 32-bit units.

Address: <GTM_base> + 00000_H

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DEV_CODE2				DEV_CODE1				DEV_CODE0				MAJOR			
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MINOR				NO				STEP							
Value after reset	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 25.15 GTM0GTMREV Register Contents

Bit Position	Bit Name	Function
31 to 28	DEV_CODE2	Device encoding digit 2.
27 to 24	DEV_CODE1	Device encoding digit 1.
23 to 20	DEV_CODE0	Device encoding digit 0.
19 to 16	MAJOR	Major version number Define major version number of GTM-IP specification.
15 to 12	MINOR	Minor version number Define minor version number of GTM-IP specification.
11 to 8	NO	Delivery number Define delivery number of GTM-IP specification.
7 to 0	STEP	Release step GTM Release step.

NOTES

1. The numbers are encoded in BCD. Values “A” – “F” are characters.
2. See **Section 25.18.3.1, GTM0GTMREV** and **Section 25.19.3.1, GTM0GTMREV** for reset value.

25.6.9.2 GTM0GTMRST

Access: This register can be read/written in 32-bit units.

Address: <GTM_base> + 00004_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 25.17 GTM0GTMCTRL Register Contents

Bit Position	Bit Name	Function
31 to 9	Reserved	These bits are always read as 0. When written, write the initial value.
8 to 4	TO_VAL	AEI timeout value. These bits define the number of cycles after which a timeout event occurs. When TO_VAL equals zero (0) the AEI timeout functionality is disabled.
3, 2	Reserved	These bits are always read as 0. When written, write the initial value.
1	TO_MODE	AEI timeout mode. 0: Observe: If timeout_counter=0 the address and rw signal in addition with timeout flag will be stored to the GTM0GTMAEIADDRXPT register. Following timeout_counter=0 accesses will not overwrite the first entry in the aei_addr_timeout register. Clearing the timeout flag/aei_status error_code will reenable the storing of a next faulty access. 1: Abort: In addition to observe mode the pending access will be aborted by signalling an illegal module access on aei_status and sending ready. In case of a read deliver as data 0 by serving of next AEI accesses.
0	RF_PROT	RST and FORCINT protection. 0: SW RST (global), SW interrupt FORCINT, and SW RAM reset functionality is enabled 1: SW RST (global), SW interrupt FORCINT, and SW RAM reset functionality is disabled

25.6.9.4 GTM0GTMAEIADDRXPT

Access: This register can be read in 32-bit units.

Address: <GTM_base> + $0000C_H$

Value after reset: $0000\ 0000_H$

Table 25.18 GTM0GTMAEIADDRXPT Register Contents

Bit Position	Bit Name	Function
31 to 9	Reserved	These bits are always read as 0
20	TO_W1R0	AEI timeout Read/Write flag. This bit defines the AEI Read/Write flag for which the AEI timeout event occurred.
19 to 0	TO_ADDR	AEI timeout address. This bit field defines the AEI address for which the AEI timeout event occurred.

25.6.9.5 GTM0GTMIRQNOTIFY

Access: This register can be read/written in 32-bit units.

Address: <GTM_base> + 00010_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 25.23 GTM0GTMBRIDGEMODE Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 24	BUFF_DPT	Buffer depth of AEI bridge. Signals the buffer depth of the GTM AEI bridge implementation. **NOTE** Reset value depends on the hardware configuration chosen by silicon vendor. For detail, see **Section 25.18.4.1, GTM0GTMBRIDGEMODE**, or **Section 25.19.4.1, GTM0GTMBRIDGEMODE**.
23 to 17	Reserved	These bits are always read as 0. When written, write the initial value.
16	BRG_RST	Bridge software reset. 0: No bridge reset request. 1: Bridge reset request. **NOTE** This bit is cleared automatically after write.
15 to 13	Reserved	These bits are always read as 0. When written, write the initial value.
12	SYNC_INPUT_REG	Additional pipelined stage in synchronous bridge mode 0: No additional pipelined stage implemented. 1: Additional pipelined stage implemented. All accesses in synchronous mode will be increased by one clock cycle. **NOTE** Reset value depends on the hardware configuration chosen by silicon vendor. For detail, see **Section 25.18.4.1, GTM0GTMBRIDGEMODE**, or **Section 25.19.4.1, GTM0GTMBRIDGEMODE**.
11, 10	Reserved	These bits are always read as 0. When written, write the initial value.
9	BUFF_OVL	Buffer overflow register. 0: No buffer overflow occurred. 1: Buffer overflow occurred. A buffer overflow can occur while multiple aborts are issued by the external bus or a pipelined instruction is started while FBC = 0 (see GTM0GTMBRIDGEPTR1 register).
8	MODE_UP_PGR	Mode update in progress. 0: No update in progress. 1: Update in progress.

Table 25.23 GTM0GTMBRIDGEMODE Register Contents (2/2)

Bit Position	Bit Name	Function
7 to 2	Reserved	These bits are always read as 0. When written, write the initial value.
1	MSK_WR_RSP	Mask write response. 0: Do not mask the write response 1: Mask write response
0	BRG_MODE	Defines the operation mode for the AEI bridge. 0: AEI bridge operates in sync_bridge mode 1: AEI bridge operates in async_bridge mode **NOTE** Reset value depends on the hardware configuration chosen by silicon vendor. For detail, see **Section 25.18.4.1, GTM0GTMBRIDGEMODE**, or **Section 25.19.4.1, GTM0GTMBRIDGEMODE**.

25.6.9.10 GTM0GTMBRIDGEPTR1

Access: This register can be read in 32-bit units.

Address: <GTM_base> + 00034_H

Value after reset: $0xx0\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RSP_TRAN_RDY						FBC						ABT_TRAN_PGR			
Value after reset	0	0	0	0	0	0	–	–	–	–	–	–	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ABT_TRAN_PGR	TRAN_IN_PGR					FIRST_RSP_PTR					NEW_TRAN_PTR				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 25.24 GTM0GTMBRIDGEPTR1 Register Contents

Bit Position	Bit Name	Function
31 to 26	RSP_TRAN_RDY	Response transactions ready. Amount of ready response transactions.
25 to 20	FBC	Free buffer count. Number of free buffer entries. **NOTE** Initial value depends on the hardware configuration chosen by silicon vendor. (see BUFF_DPT in GTM0GTMBRIDGEMODE register).
19 to 15	ABT_TRAN_PGR	Aborted transaction in progress pointer.
14 to 10	TRAN_IN_PGR	Transaction in progress pointer (acquire)
9 to 5	FIRST_RSP_PTR	First response pointer. Signals the actual value of first response pointer.
4 to 0	NEW_TRAN_PTR	New transaction pointer. Signals the actual value of the new transaction pointer.

NOTES

1. This register operates on the AEI_CLK domain.
2. This register holds diagnosis information about the AEI bus bridge. Each access to the GTM_IP will update the defined pointer bit fields. Depending on the mode of GTM_MODE_BRIDGE (BRG_MODE, MSK_WR_RESP), the AEI protocol and operating frequency which is use, the 4 pointer bitfields will change at different clock cycles relative to the start of the transaction. This leads to the fact that reading the register can show values not equal to the defined Initial Value, even directly after a write to GTM0GTMBRIDGEMODE with BRG_RST = 1 was done.

25.6.9.11 GTM0GTMBRIDGEPTR2

Access: This register can be read in 32-bit units.

Address: <GTM_base> + 00038_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.28 GTM0GTMHWCONF Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 20	Reserved	These bits are always read as 0.
19	IRQ_MODE_SINGLE_PULSE	IRQ_MODE_SINGLE_PULSE 0: single pulse mode not available 1: single pulse mode available
18	IRQ_MODE_PULSE_NOTIFY	IRQ_MODE_PULSE_NOTIFY 0: pulse notify mode not available 1: pulse notify mode available
17	IRQ_MODE_PULSE	IRQ_MODE_PULSE 0: pulse mode not available 1: pulse mode available
16	IRQ_MODE_LEVEL	IRQ_MODE_LEVEL 0: level mode not available 1: level mode available
15	Reserved	These bits are always read as 0.
14	ARU_CONNECT_CONFIG	Defines number of parallel ARU ports 0: 2 ARU ports available (two independent counter) 1: 1 ARU port available
13	ERM	ERM: enable RAM1 MSB for available MCS modules 0: MSB of RAM1 address not used 1: MSB of RAM1 address used
12	RAM_INIT_RST	RAM_INIT_RST: RAM initialization from reset 0: RAM is not initialized after reset 1: RAM is initialized after reset
11 to 8	Reserved	These bits are always read as 0.
7 to 5	ATOM_TRIG_CHAIN	ATOM trigger chain length without synchronization register It defines after which ATOM instance count a synchronization register is introduced into trigger chain (after ATOM_TRIG_<i> output if instance i and ATOM_TRIG_<i+1> input of instance i+1). Valid values are 1 to 7. 1 means that after each instance a synchronization register is placed.

Table 25.28 GTM0GTMHWCONF Register Contents (2/2)

Bit Position	Bit Name	Function
4	ATOM_OUT_RST	ATOM_OUT reset level 0: ATOM_OUT reset level is '0' 1: ATOM_OUT reset level is '1' **NOTE** This reset level defines the reset value of bit SL for all ATOM channel
3	Reserved	These bits are always read as 0.
2	SYNC_INPUT_REG	Additional pipelined stage in synchronous bridge mode 0: No additional pipelined stage implemented. 1: Additional pipelined stage implemented. All accesses in synchronous mode will be increased by one clock cycle.
1	BRIDGE_MODE_RST	Bridge mode after reset 0: Bridge starts in synchronous mode after reset 1: Bridge starts in asynchronous mode after reset
0	GRSTEN	Global Reset Enable 0: Global GTM reset register disabled 1: Global GTM reset register enabled

25.6.9.15 GTM0GTMATOMiOUT (i = 0, 2)

Access: This register can be read in 32-bit units.

Address: GTM0GTMATOM0OUT: <GTM_base> + 00098_H
GTM0GTMATOM2OUT: <GTM_base> + $0009C_H$

Value after reset: Undefined

25.7 Advanced Routing Unit (ARU)

25.7.1 Overview

The Advanced Routing Unit (ARU) is a flexible infrastructure component for transferring 53 bit wide data (five control bits and two 24 bit values) between several submodules of the GTM core in a configurable manner.

Since the concept of the ARU has already been described in **Section 25.6.3, ARU Routing Concept**, this section only describes additional ARU features that can be used by the software for configuring and debugging ARU related data streams.

Also the definition of ‘streams’ and ‘channels’ in the ARU context is done in **Section 25.6.3, ARU Routing Concept**.

25.7.2 Special Data Sources

Besides the addresses of the submodule related data sources as described in **Table 25.204, ARU Write Address Overview**, **Table 25.211, ARU Write Address Overview**, the ARU provides two special data sources that can be used for the configuration of data streams. These data sources are defined as follows:

Address $1FF_H$: Data source that provides always a 53 bit data word with zeros. A read access to this memory location will never block a requesting data destination.

Address $1FE_H$: Data source that never provides a data word. A read access to this memory location will always block a requesting data destination. This is the reset value of the read registers inside the data destinations.

Address 000_H: This address is reserved and can be used to bring data through the ARU registers GTM0ARUDATAH and GTM0ARUDATAL into the system by writing the write address 000_H into the GTM0ARUACCESS register. This means that software test data can be brought into the GTM-IP by the CPU.

25.7.3 ARU Access via AEI

Besides the data transfer between the connected submodules, there are two possibilities to access ARU data via the AEI.

25.7.3.1 Default ARU Access

The default ARU access incorporates the registers GTM0ARUACCESS, which is used for initiation of a read or write request and the registers GTM0ARUDATAH and GTM0ARUDATAL that provide the ARU data word to be transferred.

The status of a read or write transfer can be determined by polling specific bits in register GTM0ARUACCESS. Furthermore the acc_ack bit in the interrupt notify register is set after the read or write access is performed to avoid data loss e.g. on access cancelation.

A pending read or write request may also be cancelled by clearing the associated bit.

In the case of a read request, the AEI access behaves as a read request initiated by a data destination of a module. The read request is served by the ARU immediately when no other destination has a pending read request. This means, that an AEI read access does not take part in the scheduling of the destination channels and that the time between two consecutive read accesses is not limited by the round trip time.

On the other hand, the AEI access has the lowest priority behind the ARU scheduler that serves the destination channels. Thus, in worst case, the read request is served after one round trip of the ARU, when all destination channels would request data at the same point in time.

In the case of the write request, the ARU provides the write data at the address defined by the ADDR bit field inside the GTM0ARUACCESS register.

To avoid data loss, the reserved ARU address 0_H has to be used to bring data into the system. Otherwise, in case the address specified inside the ADDR bit field is defined for another submodule that acts as a source at the ARU data loss may occur and no deterministic behavior is guaranteed.

This is because the regular source submodule is not aware that its address is used by the ARU itself to provide data to a destination.

It is guaranteed that the ARU write data is send to the destination in case of both modules want to provide data at the same time.

Configuring both read and write request bits results in a read request, if the write request bit inside the register isn't already set. The read request bit will be set but not the write request bit. The following table describes the important cases of the bit 12 (RREQ) and bit 13 (WREQ) of the GTM0ARUACCESS register:

Table 25.31 ARU Access

AEI write access : aei_wdata (13:12)	Actual value of GTM0ARUACCESS (13:12)	Next value of GTM0ARUACCESS (13:12)	Comment
0 0	0 1	0 0	Cancel read request
0 0	1 0	0 0	Cancel write request
0 1	1 0	1 0	Unchanged register
1 0	0 1	0 1	Unchanged register
1 1	0 0	0 1	Both read and write request results in a read request
1 1	1 0	1 0	As before but WREQ bit is already set → unchanged register

25.7.3.2 Debug Access

The debug access mode enables to inspect routed data of configured data streams during runtime.

The ARU provides two independent debug channels, whereas each is configured by a dedicated ARU read address in register GTM0ARUDBGACCESS0 and GTM0ARUDBGACCESS1 respectively.

The registers GTM0ARUDBGDATA0H and GTM0ARUDBGDATA0L (GTM0ARUDBGDATA1H and GTM0ARUDBGDATA1L) provide read access to the latest data word that the corresponding data source sent through the ARU.

Any time when data is transferred through the ARU from a data source to the destination requesting the data the interrupt signal ARU_NEW_DATA0_IRQ (ARU_NEW_DATA1_IRQ) is raised.

For advanced debugging purposes, the interrupt signal can also be triggered by software using the register GTM0ARUIRQFORCINT.

Please note, that the debug mechanism should not be used by the application, when a HW-Debugger is used to trace the ARU communication. In that case, the debug registers are used by the HW-Debugger to specify the ARU streams that should be traced.

25.7.4 ARU Interrupt Signals

The following table describes ARU interrupt signals:

Table 25.32 ARU Interrupt Signals

Signal	Description
ARU_NEW_DATA0_IRQ	Indicates that data is transferred through the ARU using debug channel GTM0ARUDBGACCESS0.
ARU_NEW_DATA1_IRQ	Indicates that data is transferred through the ARU using debug channel GTM0ARUDBGACCESS1.
ACC_ACK_IRQ	ARU access acknowledge IRQ.

25.7.5 ARU Configuration Registers Overview

The following table shows a conclusion of configuration registers address offsets and initial values.

Table 25.33 Register List

Symbol	Register Name	Details in Section
GTM0ARUACCESS	ARU access register	**25.7.6.1**
GTM0ARUDATAH	ARU access register upper data word	**25.7.6.2**
GTM0ARUDATAL	ARU access register lower data word	**25.7.6.3**
GTM0ARUDBGACCESS0	Debug access channel 0	**25.7.6.4**
GTM0ARUDBGDATA0H	Debug access 0 transfer register upper data word	**25.7.6.5**
GTM0ARUDBGDATA0L	Debug access 0 transfer register lower data word	**25.7.6.6**
GTM0ARUDBGACCESS1	Debug access channel 0	**25.7.6.7**
GTM0ARUDBGDATA1H	Debug access 1 transfer register upper data word	**25.7.6.8**
GTM0ARUDBGDATA1L	Debug access 1 transfer register lower data word	**25.7.6.9**
GTM0ARUIRQNOTIFY	ARU Interrupt notification register	**25.7.6.10**
GTM0ARUIRQEN	ARU Interrupt enable register	**25.7.6.11**
GTM0ARUIRQFORCINT	Register for forcing the ARU_NEW_DATA_IRQ interrupt	**25.7.6.12**
GTM0ARUIRQMODE	IRQ mode configuration register	**25.7.6.13**
GTM0ARUCADDREND	ARU caddr counter end value	**25.7.6.14**

25.7.6 ARU Configuration Registers Description

25.7.6.1 GTM0ARUACCESS

Access: This register can be read/written in 32-bit units.

Address: <GTM_base> + 00280_H

Value after reset: $0000\ 01FE_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	WREQ	RREQ	—	—	—	ADDR								
Value after reset	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	0
R/W	R	R	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 25.34 GTM0ARUACCESS Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 14	Reserved	These bits are always read as 0. When written, write the initial value.
13	WREQ	Initiate write request 0: No write request is pending 1: Mark data in registers GTM0ARUDATAH and GTM0ARUDATAL as valid **NOTES** 1. This bit is cleared automatically after transaction. Moreover, it can be cleared by software to cancel a write request. 2. WREQ bit are only writable if RREQ bit is zero, so to switch from WREQ to RREQ a cancel request has to be performed before. 3. Configuring both RREQ and WREQ bits results in a read request, so WREQ bit will not be set 4. The data is provided at address ADDR. This address has to be programmed as the source address in the destination submodule channel. In worst case, the data is provided after one full ARU round trip.
12	RREQ	Initiate read request 0: No read request is pending 1: Set read request to source channel addressed by ADDR **NOTES** 1. This bit is cleared automatically after transaction. Moreover, it can be cleared by software to cancel a read request. 2. RREQ bit are only writable if WREQ bit is zero, so to switch from RREQ to WREQ a cancel request has to be performed before. 3. Configuring both RREQ and WREQ bits results in a read request, so RREQ bit will be set if the WREQ bit of the register isn't already set. 4. The ARU read request on address ADDR is served immediately when no other destination has actually a read request when the RREQ bit is set by CPU. In a worst case scenario, the read request is served after one round trip of the ARU, but this is only the case when every destination channel issues a read request at consecutive points in time.
11 to 9	Reserved	These bits are always read as 0. When written, write the initial value.

Table 25.34 GTM0ARUACCESS Register Contents (2/2)

Bit Position	Bit Name	Function
8 to 0	ADDR	ARU address Define the ARU address used for transferring data **NOTES** 1. For an ARU write request, the preferred address 0_H have to be used. 2. A write request to the address $1FF_H$ (always full address) or $1FE_H$ (always empty address) are ignored and doesn't have any effect. 3. ARU address bits ADDR are only writable if RREQ and WREQ bits are zero

Note: The register GTM0ARUACCESS can be used either for reading or for writing at the same point in time.

25.7.6.2 GTM0ARUDATAH

Access: This register can be read/written in 32-bit units.

Address: <GTM_base> + 00284_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	DATA

Table 25.36 GTM0ARUDATAL Register Contents

Bit Position	Bit Name	Function
31 to 29	Reserved	These bits are always read as 0.
28 to 0	DATA	Lower ARU data word **NOTES** 1. Transfer lower ARU data word addressed by ADDR. The data bits 0 to 23 of an ARU word are mapped to the data bits 0 to 23 of this register and the data bits 48 to 52 of an ARU word are mapped to the data bits 24 to 28 of this register when data is read by the CPU. 2. For writing data into the ARU by the CPU the bits 24 to 28 are not transferred to bit 48 to 52 of the ARU word. Only bits 0 to 23 are written to bits 0 to 23 of the ARU word.

25.7.6.4 GTM0ARUDBGACCESS0

Access: This register can be read/written in 32-bit units.

Address: <GTM_base> + $0028C_H$

Value after reset: $0000\ 01FE_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.47 GTM0ARUCADDREND Register Contents

Bit Position	Bit Name	Function
31 to 7	Reserved	These bits are always read as 0. When written, write the initial value.
6 to 0	CADDR_END	Set end value of ARU caddr counter **NOTES** 1. The ARU roundtrip counter aru_caddr runs from zero to caddr_end value. 2. Shorten the ARU roundtrip cycle by setting a smaller number than the defined reset value will cause that not all ARU-connected modules will be served. 3. Making the roundtrip cycle longer than the reset value would cause longer ARU roundtrip time and as a result some ARU-connected modules will not be served as fast as possible for this device. 4. The reset value is device-specific. For more information see **Section 25.18.3.2, GTM0ARUCADDREND** and **Section 25.19.3.2, GTM0ARUCADDREND**. 5. This bit is write protected by bit RF_PROT of register GTM0GTMCTRL.

25.8 Clock Management Unit (CMU)

25.8.1 Overview

The Clock Management Unit (CMU) is responsible for clock generation of the counters and of the GTM-IP. The CMU generate different clock sources for the whole GTM-IP. **Figure 25.17** shows a block diagram of the CMU.

The Configurable Clock Generation (CFGU) subunit provides eight dedicated clock sources for the following GTM submodules: TIM, ATOM, TBU, and MON. Each instance of such a submodule can choose an arbitrary clock source, in order to specify wide-ranging time bases.

The clock source signals CMU_CLK[x] (x = 0 to 7) are implemented in form of enable signals for the corresponding registers, which means that the actual clock signal of all registers always use the SYS_CLK signal.

The four configurable clock signals CMU_CLK0, CMU_CLK1, CMU_CLK6 and CMU_CLK7 are connected to the TIM filter counters.

25.8.1.1 CMU Block Diagram

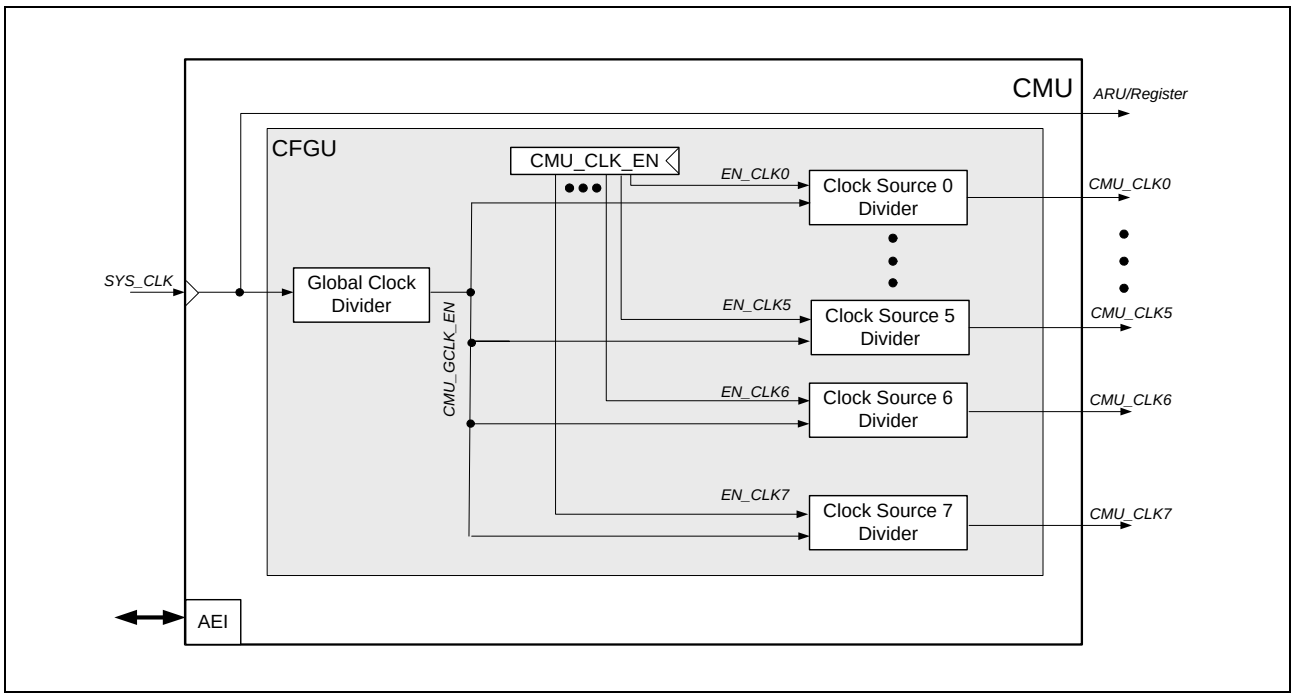

Figure 25.17 CMU Block Diagram

25.8.2 Global Clock Divider

The sub block Global Clock Divider can be used to divide the GTM-IP global input clock signal SYS_CLK into a common subdivided clock signal.

The divided clock signal of the sub block Global Clock Divider is implemented as an enable signal that enables dedicated clocks from the SYS_CLK signal to generate the user specified divided clock frequency.

The resulting fractional divider (Z/N) specified through equation:

$T_{CMU\_GCLK\_EN} = (Z/N)*T_{SYS\_CLK}$

is implemented according the following algorithm

(Z: CMU_GCLK_NUM(23:0) ; N: GCLK_DEN(23:0) ; Z, N >0):

(1) Set remainder (R), operand1 (OP1) and operand2 (OP2) register during init-phase (with implicit conversion to signed):
R = Z, OP1 = N, OP2 = N-Z;

(2) After leaving init-phase (at least one CMU_CLK[x] has been enabled) the sign of remainder R for each SYS_CLK cycle will be checked:

(3) If R>0 keep updating remainder and keep CMU_GCLK_EN = ‘0’:
R = R-OP1;

(4) If R<0 update remainder and set CMU_GCLK_EN = ‘1’:
R = R-OP2;

After at most (Z/N+1) subtractions (3) there will be a negative R and an active phase of the generated clock enable (for one cycle) will be triggered (4). The remainder R is a measure for the distance to a real Z/N clock and will be regarded for the next generated clock enable cycle phase. The new R value will be R = R + (Z-N). In the worst case the remainder R will sum up to an additional cycle in the generated clock enable period after Z-cycles. In the other cases equally distributed additional cycles will be inserted for the generated clock enable. If Z is an integer multiple of N no additional cycles will be included for the generated clock enable at all.

Note that for a better resource sharing all arithmetic has been reduced to subtractions and the initialization of the remainder R uses the complement of (Z-N).

25.8.3 Configurable Clock Generation Subunit (CFGU)

The CMU subunit CFGU provides up to eight configurable clock divider blocks that divide the common CMU_GCLK_EN signal into dedicated enable signals for the GTM-IP sub blocks.

The configuration of the eight different clock signals CMU_CLK[x] (x: 0 to 7) always depends on the configuration of the global clock enable signal CMU_GCLK_EN. Additionally, each clock source has its own configuration data, provided by the control register GTM0CMUCLKxCTRL (x: 0 to 7).

According to the configuration of the Global Clock Divider, the configuration of the Clock Source x Divider is done by setting an appropriate value in the bit field CLK_CNT[x] of the register GTM0CMUCLKxCTRL.

The frequency fx =1/Tx of the corresponding clock enable signal CMU_CLK[x] can be determined by the unsigned representation of CLK_CNT[x] of the register GTM0CMUCLKxCTRL in the following way:

$T_{CMU\_CLK[x]} = (CLK\_CNT[x] + 1) * T_{CMU\_GCLK\_EN}$

The corresponding wave form is shown in **Figure 25.18**.

To avoid unexpected behavior of the hardware, the configuration of a register GTM0CMUCLKxCTRL can only be changed, when the corresponding clock signal CMU_CLK[x] is disabled.

Further, any changes to the registers GTM0CMUGCLKNUM and GTM0CMUGCLKDEN can only be performed, when all clock enable signals CMU_CLK[x] are disabled.

The clock source signals CMU_CLK[x] (x: 0 to 7) are implemented in form of enable signals for the corresponding registers, which means that the actual clock signal of all registers always use the SYS_CLK signal.

The hardware guarantees that all clock signals CMU_CLK[x], which were enabled simultaneous, are synchronized to each other. Simultaneous enabling does mean that the bits EN_CLK[x] in the register GTM0CMUCLKEN are set by the same write access.

25.8.4 Wave Form of Generated Clock Signal CMU_CLK[x]

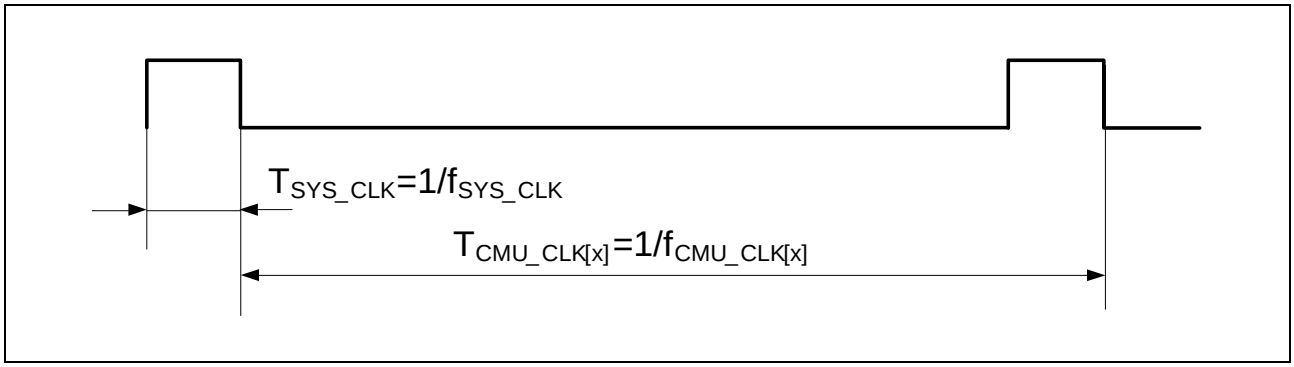

Figure 25.18 Wave Form of Generated Clock Signal CMU_CLK[x]

25.8.5 CMU Configuration Registers Overview

Following configuration registers are considered in CMU submodule:

Table 25.48 Register List

Symbol	Register Name	Details in Section
GTM0CMUCLKEN	Clock enable	**25.8.6.1**
GTM0CMUGCLKNUM	Global clock control numerator	**25.8.6.2**
GTM0CMUGCLKDEN	Global clock control denominator	**25.8.6.3**
GTM0CMUCLK0CTRL	Control for clock source 0	**25.8.6.4**
GTM0CMUCLK1CTRL	Control for clock source 1	**25.8.6.4**
GTM0CMUCLK2CTRL	Control for clock source 2	**25.8.6.4**
GTM0CMUCLK3CTRL	Control for clock source 3	**25.8.6.4**
GTM0CMUCLK4CTRL	Control for clock source 4	**25.8.6.4**
GTM0CMUCLK5CTRL	Control for clock source 5	**25.8.6.4**
GTM0CMUCLK6CTRL	Control for clock source 6	**25.8.6.4**
GTM0CMUCLK7CTRL	Control for clock source 7	**25.8.6.4**
GTM0CMUGLBCTRL	Synchronizing ARU and clock source	**25.8.6.5**

25.8.6 CMU Configuration Register Description

25.8.6.1 GTM0CMUCLKEN

Access: This register can be read/written in 32-bit units.

Address: <GTM_base> + 00300_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	EN_FXCLK		EN_ECLK2		EN_ECLK1		EN_ECLK0	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 25.49 GTM0CMUCLKEN Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	These bits are always read as 0. When written, write the initial value.
23, 22	EN_FXCLK	Enable all CMU_FXCLK, see bits 1, 0 **NOTE** EN_ECLK0-2 and EN_FXCLK not implemented for this device. Writing values unequal 0 will result in AEI_STATUS signal "10"
21, 20	EN_ECLK2	Enable ECLK 2 generation subunit, see bits 1, 0
19, 18	EN_ECLK1	Enable ECLK 1 generation subunit, see bits 1, 0
17, 16	EN_ECLK0	Enable ECLK 0 generation subunit, see bits 1, 0
15, 14	EN_CLK7	Enable clock source 7, see bits 1, 0
13, 12	EN_CLK6	Enable clock source 6, see bits 1, 0
11, 10	EN_CLK5	Enable clock source 5, see bits 1, 0
9, 8	EN_CLK4	Enable clock source 4, see bits 1, 0
7, 6	EN_CLK3	Enable clock source 3, see bits 1, 0
5, 4	EN_CLK2	Enable clock source 2, see bits 1, 0
3, 2	EN_CLK1	Enable clock source 1, see bits 1, 0
1, 0	EN_CLK0	Enable clock source 0 00: Clock source is disabled (ignore write access) 01: Disable clock signal and reset internal states 10: Enable clock signal 11: Clock signal enabled (ignore write access) **NOTES** 1. Any read access to an EN_CLK[x] bit field will always result in a value 00 or 11 indicating current state. A modification of the state is only performed with the values 01 and 10. Writing the values 00 and 11 is always ignored. 2. Any disabling to EN_CLK[x] will be reset internal counters for configurable clocks.

25.8.6.2 GTM0CMUGCLKNUM

Access: This register can be read/written in 32-bit units.

Address: <GTM_base> + 00304_H

Value after reset: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	CMU_GCLK_NUM							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMU_GCLK_NUM															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 25.50 GTM0CMUGCLKNUM Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	These bits are always read as 0. When written, write the initial value.
23 to 0	CMU_GCLK_NUM	Numerator for global clock divider. Defines numerator of the fractional divider. **NOTES** 1. Value can only be modified when all clock enables EN_CLK[x] are disabled. 2. The CMU hardware alters the content of GTM0CMUGCLKNUM and GTM0CMUGCLKDEN automatically to 1_H, if GTM0CMUGCLKNUM is specified less than GTM0CMUGCLKDEN or one of the values is specified with a value zero. Thus, a secure way for altering the values is writing twice to the register GTM0CMUGCLKNUM followed by a single write to register GTM0CMUGCLKDEN.

25.8.6.3 GTM0CMUGCLKDEN

Access: This register can be read/written in 32-bit units.

Address: <GTM_base> + 00308_H

Value after reset: $0000\ 0001_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	GCLK_DEN							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GCLK_DEN															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 25.51 GTM0CMUGCLKDEN Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	These bits are always read as 0. When written, write the initial value.
23 to 0	GCLK_DEN	Denominator for global clock divider. Defines denominator of the fractional divider **NOTES** 1. Value can only be modified when all clock enables EN_CLK[x] are disabled. 2. The CMU hardware alters the content of GTM0CMUGCLKNUM and GTM0CMUGCLKDEN automatically to 0x1, if GTM0CMUGCLKNUM is specified less than GTM0CMUGCLKDEN or one of the values is specified with a value zero. Thus, a secure way for altering the values is writing twice to the register GTM0CMUGCLKNUM followed by a single write to register GTM0CMUGCLKDEN.

25.8.6.4 GTM0CMUCLKxCTRL (x = 0 to 7)

Access: This register can be read/written in 32-bit units.

Address: GTM0CMUCLK0CTRL: <GTM_base> + $0030C_H$
GTM0CMUCLK1CTRL: <GTM_base> + 00310_H
GTM0CMUCLK2CTRL: <GTM_base> + 00314_H
GTM0CMUCLK3CTRL: <GTM_base> + 00318_H
GTM0CMUCLK4CTRL: <GTM_base> + $0031C_H$
GTM0CMUCLK5CTRL: <GTM_base> + 00320_H
GTM0CMUCLK6CTRL: <GTM_base> + 00324_H
GTM0CMUCLK7CTRL: <GTM_base> + 00328_H

Value after reset: $0000\ 0000_H$

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 25.53 GTM0CMUGLBCTRL Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	These bits are always read as 0. When written, write the initial value.
0	ARU_ADDR_RSTGLB	Reset ARU address counter **NOTES** 1. Writing value “1” to this bit field results in a request to reset of the ARU address counter. The next following write access to register GTM0CMUCLKEN applies the ARU reset and resets this bit. This feature can be used to synchronize the ARU round trip time to the CMU clocks. 2. This bit is write protected. Before writing to this bit set bit RF_PROT of register GTM0GTMCTRL to '0'.

25.9 Time Base Unit (TBU)

25.9.1 Overview

The Time Base Unit TBU provides common time bases for the GTM-IP. The TBU submodule is organized in channels, where the number of channels is device dependent. There are at most two channels implemented inside the TBU. The TBU channel 0 time base register GTM0TBU0BASE is 27 bits and it is configurable whether the lower 24 bit or the upper 24 bit are provided to the GTM as signal TBU_TS0. The TBU channels 1 has a time base register GTM0TBU1BASE of 24 bit length. The time base register value TBU_TS1 are provided to subsequent submodules of the GTM.

The TBU_UP1 signals are set to high for a single SYS_CLK period, whenever the corresponding signal TBU_TS1 is getting updated. The signal TBU_UP0_L is set to high for a single SYS_CLK period if the signal TBU_TS0 and TBU_TS1 is getting updated and TBU_UP0_H is set to high for a single SYS_CLK period, whenever if the upper 24 bit of TBU_TS0 are updated.

The time base channels can run independently of each other and can be enabled and disabled synchronously by control bits in a global TBU channel enable register GTM0TBUCHEN. **Section 25.9.1.1, TBU Block Diagram** shows a block diagram of the Time Base Unit.

25.9.1.1 TBU Block Diagram

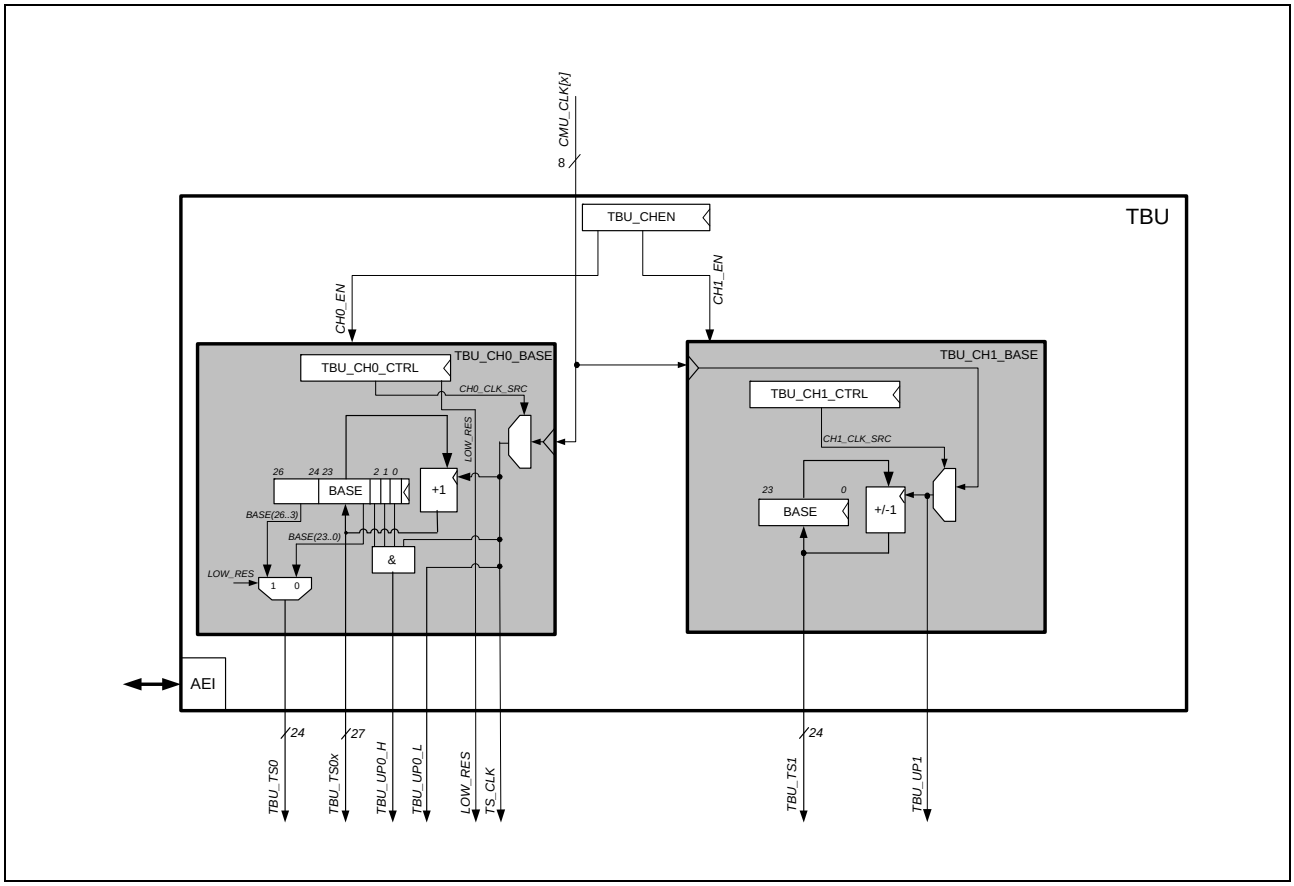

Figure 25.19 BU Block Diagram

The configuration of the independent time base channels TBU_BASE_[z] (z = 0, 1) is done via the AEI interface. Each TBU channel may select one of the eight CMU_CLK[x] (x = 0 to 7) signals coming from the CMU submodule.

25.9.2 TBU Time Base Channels

The time base values are generated within the TBU time base channels in two independent operation modes.

25.9.2.1 TBU Channel Modes

TBU channel 0 provides a 27 bit counter in a free running counter mode. Dependent on the bit field LOW_RES of register GTM0TBU0CTRL, the lower 24 bits (bit 0 to 23) or the upper 24 bits (bits 3 to 26) are provided to the GTM submodules.

TBU channel 1 is running as a free running counter.

The time base register GTM0TBU1BASE can be initialized with a start value just before enabling the corresponding TBU channel.

Moreover, the time base register GTM0TBU1BASE can always be read in order to determine the actual value of the counter.

The time base register GTM0TBU1BASE is updated on every specified incoming clock event by the selected signal CMU_CLK[x] (dependent on GTM0TBUzCTRL register). In general the time base register GTM0TBU1BASE is incremented on every CMU_CLK[x] clock tick.

25.9.3 TBU Configuration Registers Overview

Following table shows a conclusion of configuration registers address offsets and initial values.

Table 25.54 Register List

Symbol	Register Name	Details in Section
GTM0TBUCHEN	TBU global channel enable	**25.9.4.1**
GTM0TBU0CTRL	TBU channel 0 control	**25.9.4.2**
GTM0TBU0BASE	TBU channel 0 base	**25.9.4.3**
GTM0TBU1CTRL	TBU channel 1 control	**25.9.4.4**
GTM0TBU1BASE	TBU channel 1 base	**25.9.4.5**

25.9.4 TBU Registers description

25.9.4.1 GTM0TBUCHEN

Access: This register can be read/written in 32-bit units.

Address: <GTM_base> + 00100_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 25.59 GTM0TBU1BASE Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	These bits are always read as 0. When written, write the initial value.
23 to 0	BASE	Time base value for channel 1 **NOTES** 1. The value of BASE can only be written if the corresponding TBU channel y is disabled. 2. If the corresponding channel y is enabled, a read access to this register provides the current value of the underlying counter.

25.10 Timer Input Module (TIM)

25.10.1 Overview

The Timer Input Module (TIM) is responsible for filtering and capturing input signals of the GTM. Several characteristics of the input signals can be measured inside the TIM channels. For advanced data processing the detected input characteristics of the TIM module can be routed through the ARU to subsequent processing units of the GTM.

Input characteristics mean either time stamp values of detected input rising or falling edges together with the new signal level or the number of edges received since channel enable together with the actual time stamp or PWM signal durations for a whole PWM period.

The architecture of TIM is shown in **Figure 25.20**.

25.10.1.1 TIM Block Diagram

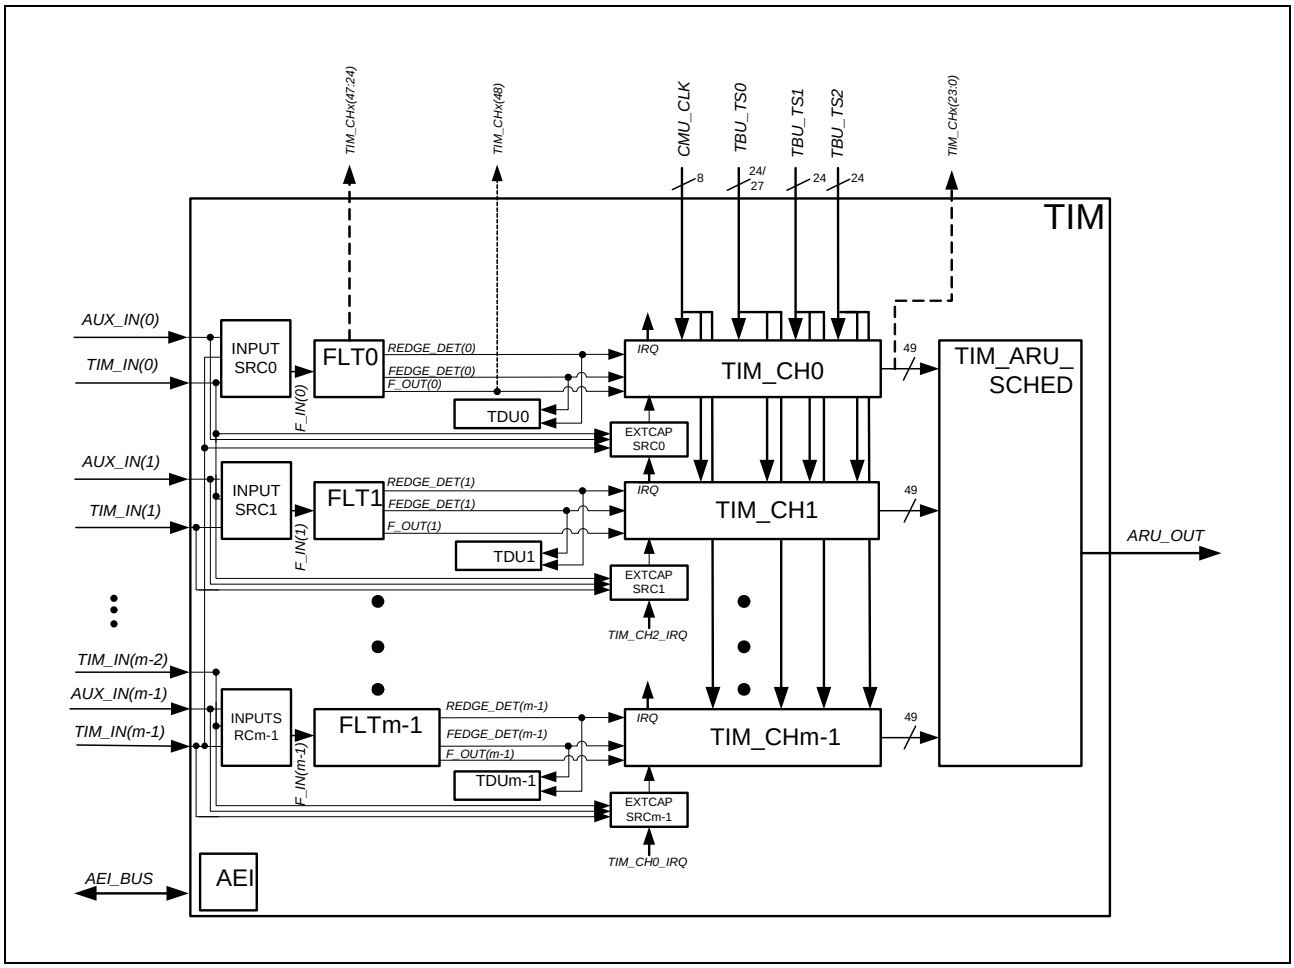

Figure 25.20 TIM Block Diagram

The number of channels m inside a TIM submodule depends on the device.

Each of the *m* dedicated input signals are filtered inside the FLTx subunit of the TIM Module. It should be noted that the incoming input signals are synchronized to the clock SYS_CLK, resulting in a delay of two SYS_CLK periods for the incoming signals.

The submodule TIM provides different filter mechanisms described in more detail in **Section 25.10.2, TIM Filter Functionality (FLT)** . After filtering, the signal is routed to the corresponding TIM channel.

The measurement values can be read by the CPU directly via the AEI-Bus or they can be routed through the ARU to other submodules of the GTM.

For timeout detection of an incoming signal (no subsequent edge detected during a specified duration) each individual channel has a Timeout Detection Unit (TDU).

The two (three) time bases coming from the TBU are connected to the TIM channels to annotate time stamps to incoming signals. For TIM0 the extended 27 bit width time base TBU_TS0 is connected to the TIM channels, and the user has to select if the lower 24 bits (TBU_TS0[23:0]) or the higher 24 bits (TBU_TS0[26:3]) are stored inside the GPR0 and GPR1 registers.

25.10.1.2 Input source selection INPUTSRCx

It can be configured which source shall be used for processing in the FLT,TDU,TIM_CH units. It can be selected by the bit fields CICTRL and MODE_x, VAL_x in the register GTM0TIM0INSRC which source is in use.

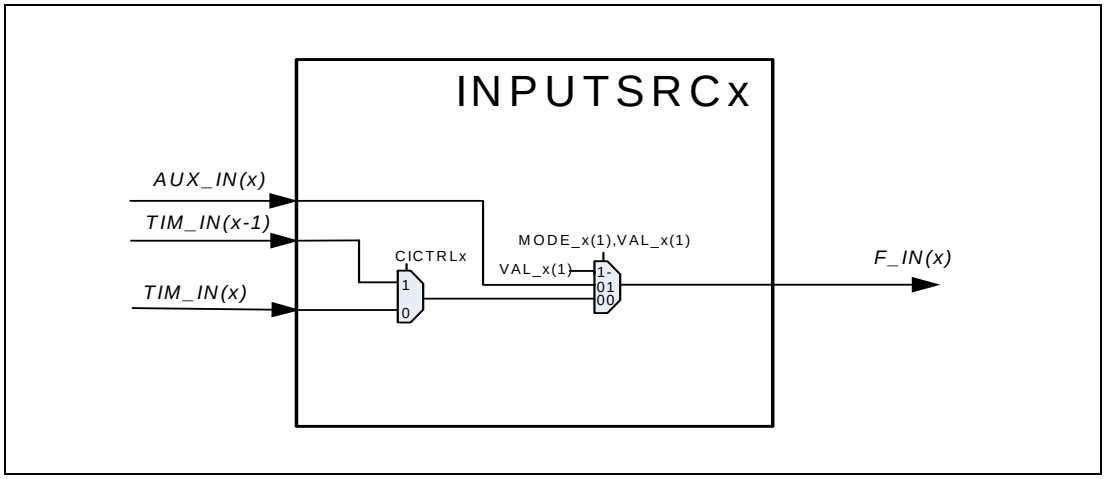

Figure 25.21 INPUTSRC Block Diagram

In a certain MODE_x, VAL_x combination the input signal F_IN(x) can be driven by VAL_x(1) with 0 or 1 directly.

Due to the fact that all 8 channels are bundled in the register GTM0TIM0INSRC a synchronous control of all 8 input channels is possible.

Two adjacent channels can be combined by setting the CICTRL bit field in the corresponding GTM0TIMixCTRLregister. This allows for a combination of complex measurements on one input signal with two TIM channels.

The additional input signal AUX_IN[x] can be selected as an input signal. See **Section 25.6.1.1, GTM Architecture Block Diagram** .

25.10.1.3 Input observation

It is possible to observe for all channels of one instance by reading TIM_INP_VAL the actual signal values of the following processing stages:

- TIM_IN(7:0) signals after TIM input synchronization
- TIM F_IN(7:0) signals after TIM INPUTSRC selection (input to TIM_FLT)
- TIM F_OUT(7:0) signals after TIM filter functionality (output of TIM_FLT)

25.10.1.4 External capture source selection EXTCAPSRCx

Each channel can operate on an external capture signal EXT_CAPTURE. The source to use for this signal can be configured by the bit field EXT_CAP_SRCx in the register GTM0TIM00ECTRL .

The EXT_CAPTURE signal will be distributed to other GTM modules (e.g. TOM/ATOM) .

NOTE

The EXT_CAPTURE signal generation is independent of the signal EXT_CAP_EN.

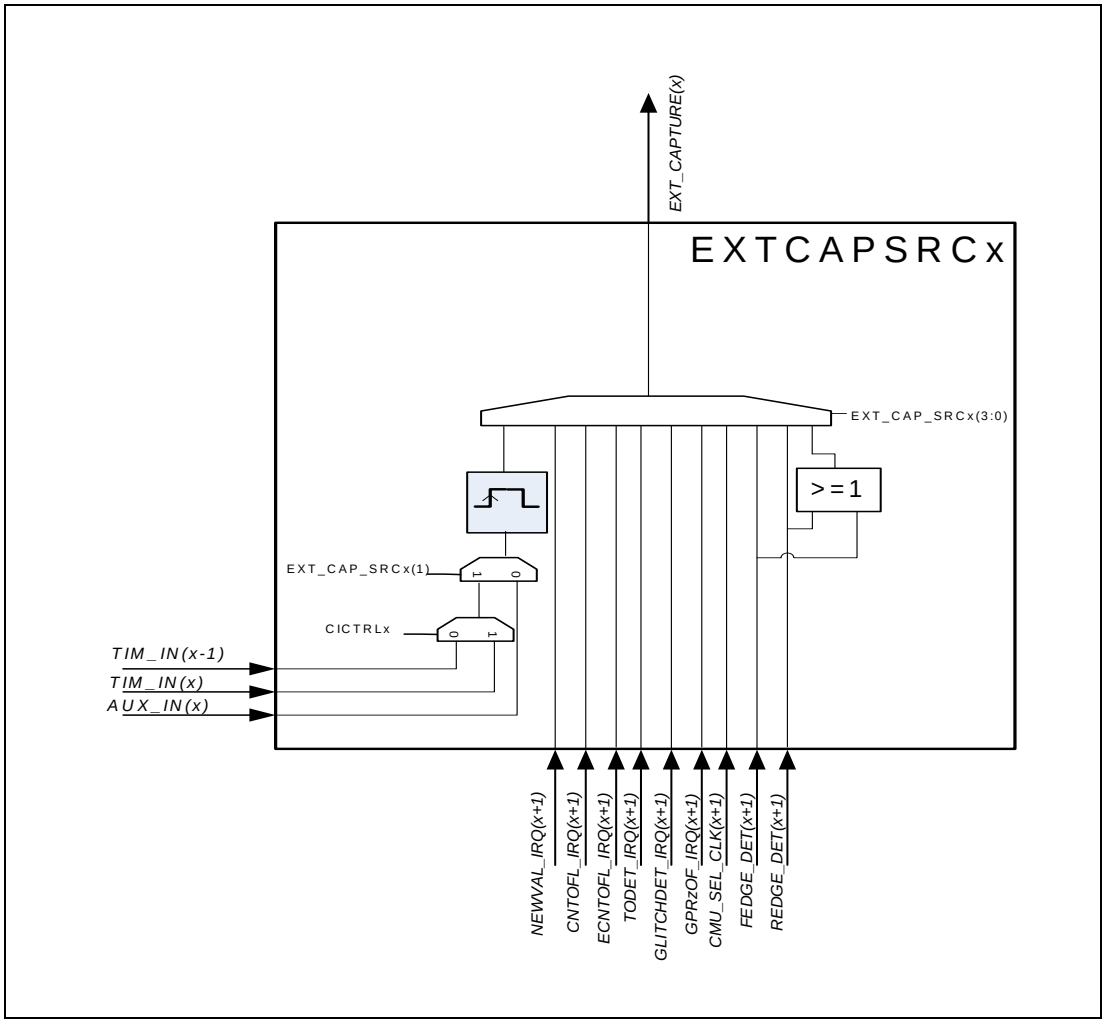

Figure 25.22 XTCAPSRC Block Diagram

The external capture functionality can be enabled for the TIM channel x with the bit EXT_CAP_EN in the register GTM0TIMixCTRL, it will trigger on each rising edge. A pulse generation for each rising edge of the selected input signal TIM_IN[x] and AUX_IN[x] is applied.

The six TIM channel interrupt sources can be triggered by the operation in the certain TIM channel modes. Alternatively they can be issued by a soft trigger using the corresponding bits in the register GTM0TIMixIRQFORCINT.

25.10.2 TIM Filter Functionality (FLT)

25.10.2.1 Overview

The TIM submodule provides a configurable filter mechanism for each input signal. These filter mechanism is provided inside the FLT subunit.

FLT architecture is shown in **Figure 25.23**.

The filter includes a clock synchronization unit (CSU), an edge detection unit (EDU), and a filter counter associated to the filter unit (FLTU).

The CSU is synchronizing the incoming signal F_IN to the selected filter clock frequency, which is controlled with the bit field FLT_CNT_FRQ of register GTM0TIMixCTRL.

The synchronized input signal F_IN_SYNC is used for further processing within the filter.

It should be noted that glitches with a duration less than the selected CMU clock period are lost.

The filter modes can be applied individually to the falling and rising edges of an input signal. The following filter modes are available:

- Immediate edge propagation mode,
- Individual de-glitch time mode (up/down counter)
- Individual de-glitch time mode (hold counter).

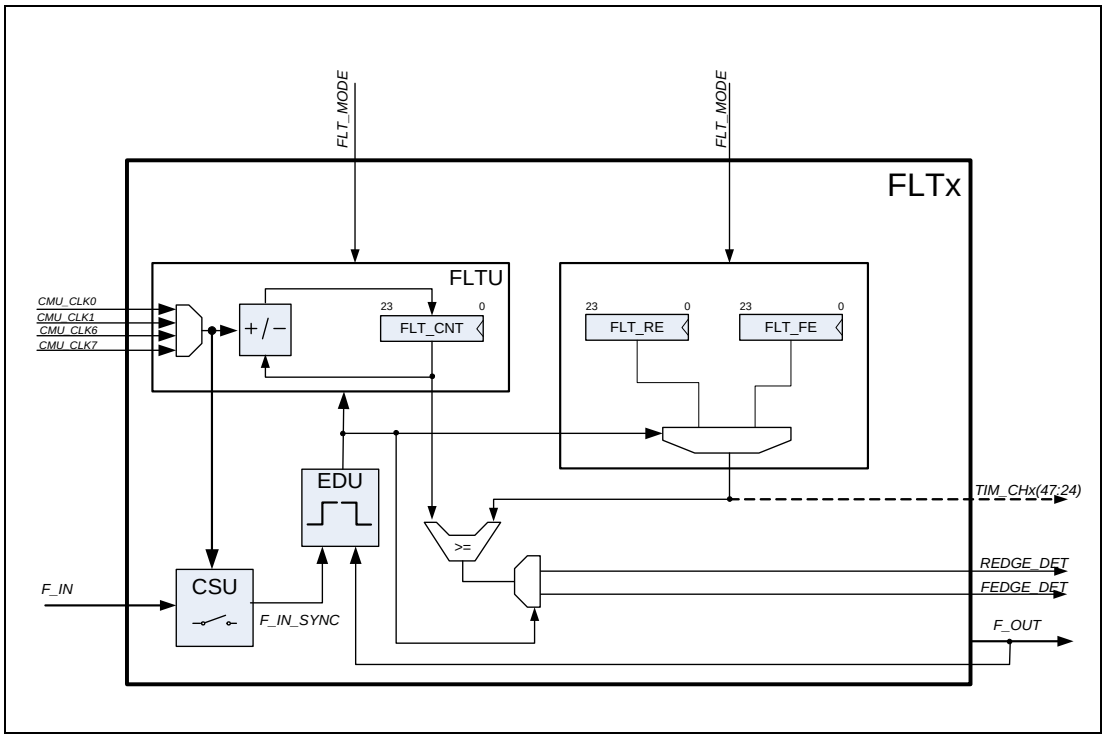

Figure 25.23 FLT Architecture

The filter parameters (deglitch and acceptance time) for the rising and falling edge can be configured inside the two filter parameter registers FLT_RE (rising edge) and FLT_FE (falling edge). The exact meaning of the parameter depends on the filter mode.

However the delay time T of both filter parameters FLT_xE can always be determined by:

$T = (FLT\_xE + 1) * T_{FLT\_CLK}$,

whereas T_{FLT_CLK} is the clock period of the selected CMU clock signal in bit field FLT_CNT_FRQ of register GTM0TIMixCTRL.

When a glitch is detected on an input signal a status flag GLITCHDET is set inside the GTM0TIMixIRQNOTIFY register.

Table 25.60 gives an overview about the meanings for the registers FLT_RE and FLT_FE. In the individual deglitch time modes, the actual filter threshold for a detected regular edge is provided on the TIM[i]_CH[x] (47:24) output line. In the case of immediate edge propagation mode, a value of zero is provided on the TIM[i]_CH[x] (47:24) output line.

Table 25.60 Filter Parameter summary for the different Filter Modes

Filter mode	Meaning of FLT_RE	Meaning of FLT_FE
Immediate edge propagation	Acceptance time for rising edge	Acceptance time for falling edge
Individual de-glitch time (up/ down counter)	De-glitch time for rising edge	De-glitch time for falling edge
Individual de-glitch time (hold counter)	De-glitch time for rising edge	De-glitch time for falling edge

A counter FLT_CNT is used to measure the glitch and acceptance times.

The frequency of the FLT_CNT counter is configurable in bit field FLT_CNT_FRQ of register GTM0TIMixCTRL.

The counter FLT_CNT can either be clock with the CMU_CLK0, CMU_CLK1, CMU_CLK6 or the CMU_CLK7 signal. These signals are coming from the CMU submodule.

The FLT_CNT, FLT_FE and FLT_RE registers are 24-bit width. For example, when the resolution of the CMU_CLK0 signal is 50ns this allows maximal de-glitch and acceptance times of about 838ms for the filter.

25.10.2.2 TIM Filter Modes

(1) Immediate Edge Propagation Mode

In immediate edge propagation mode after detection of an edge the new signal level on F_IN_SYNC is propagated to F_OUT with a delay of one TFLT_CLK period and the new signal level remains unchanged until the configured acceptance time expires.

For each edge type the acceptance time can be specified separately in the FLT_RE and FLT_FE registers.

Each signal change on the input F_IN_SYNC during the duration of the acceptance time has no effect on the output signal level F_OUT of the filter but it sets the glitch GLITCHDET bit in the GTM0TIMixIRQNOTIFY register.

After it expires an acceptance time the input signal F_IN_SYNC is observed and on signal level change the filter raises a new detected edge and the new signal level is propagated to F_OUT.

Independent of a signal level change the value of F_OUT is always set to F_IN_SYNC, when the acceptance time expires (see also **Figure 25.25**).

Figure 25.24 shows an example for the immediate edge propagation mode, in the case of rising edge detection. Both, the signal before filtering (F_IN) and after filtering (F_OUT) are shown. The acceptance time at1 is specified in the register FLT_RE.

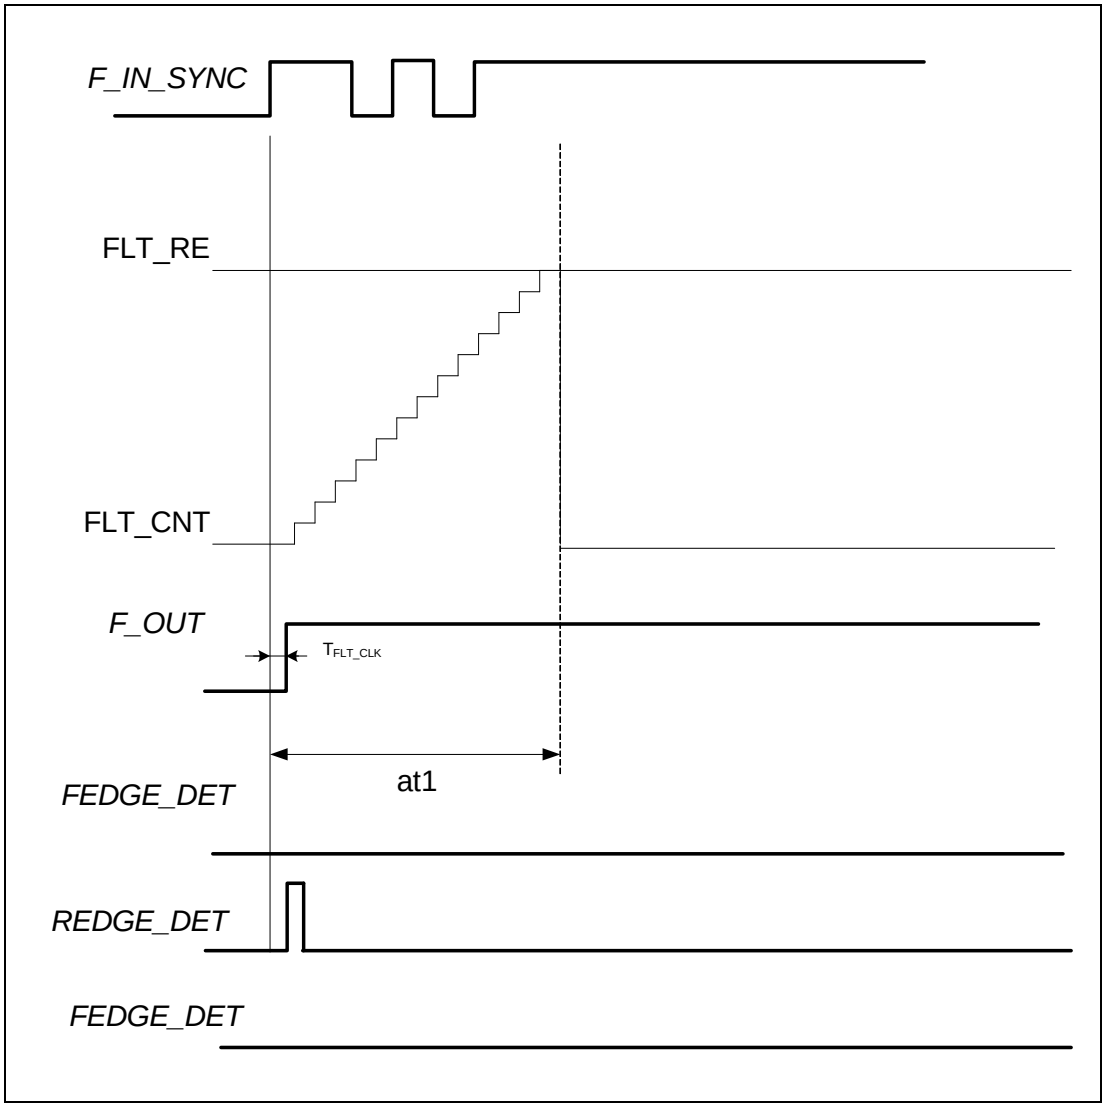

Figure 25.24 Immediate Edge Propagation Mode in the case of a rising edge

In immediate edge propagation mode the glitch measurement mechanism is not applied to the edge detection. Detected edges on F_IN_SYNC are transferred directly to F_OUT.

The counter FLT_CNT is incremented until acceptance time threshold is reached.

Figure 25.25 shows a more complex example of the TIM filter, in which both, rising and falling edges are configured in immediate edge propagation mode.

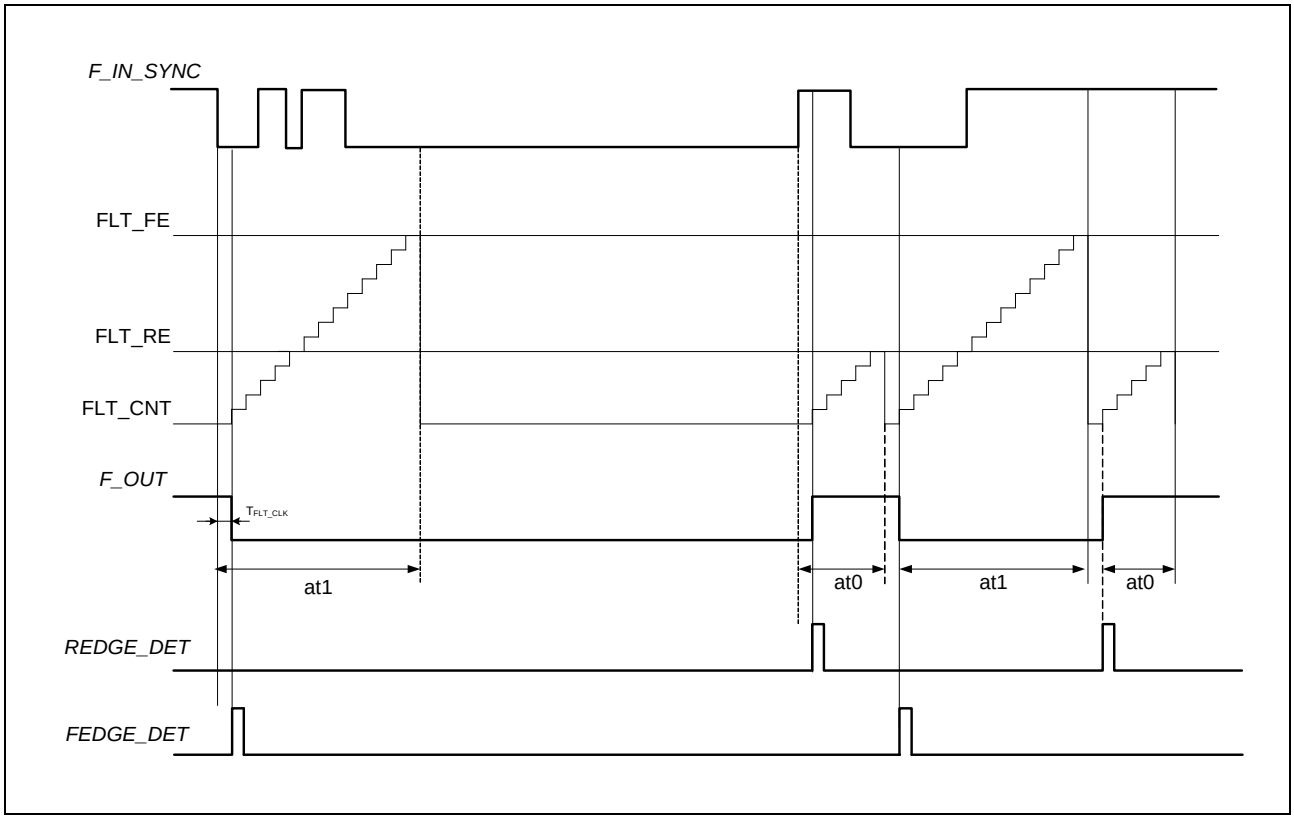

Figure 25.25 Immediate Edge Propagation Mode in the case of a rising and falling edge

If the FLT_CNT has reached the acceptance time for a specific signal edge and the signal F_IN_SYNC has already changed to the opposite level of F_OUT, the opposite signal level is set to F_OUT and the acceptance time measurement is started immediately. **Figure 25.25** shows this scenario at the detection of the first rising edge and the second falling edge.

(2) Individual De-Glitch Time Mode (up/down counter)

In individual de-glitch time mode (up/down counter) each edge of an input signal can be filtered with an individual de-glitch threshold filter value mentioned in the registers FLT_RE and FLT_FE, respectively.

The filter counter register FLT_CNT is incremented when the signal level on F_IN_SYNC is unequal to the signal level on F_OUT and decremented if F_IN_SYNC equals F_OUT.

After FLT_CNT has reached a value of zero during decrementation the counter is stopped immediately.

If a glitch is detected a glitch detection bit GLITCHDET is set in the GTM0TIMixIRQNOTIFY register.

The detected edge signal together with the new signal level is propagated to F_OUT after the individual de-glitch threshold is reached. **Figure 25.26** shows the behavior of the filter in individual de-glitch time (up/down counter) mode in the case of the rising edge detection.

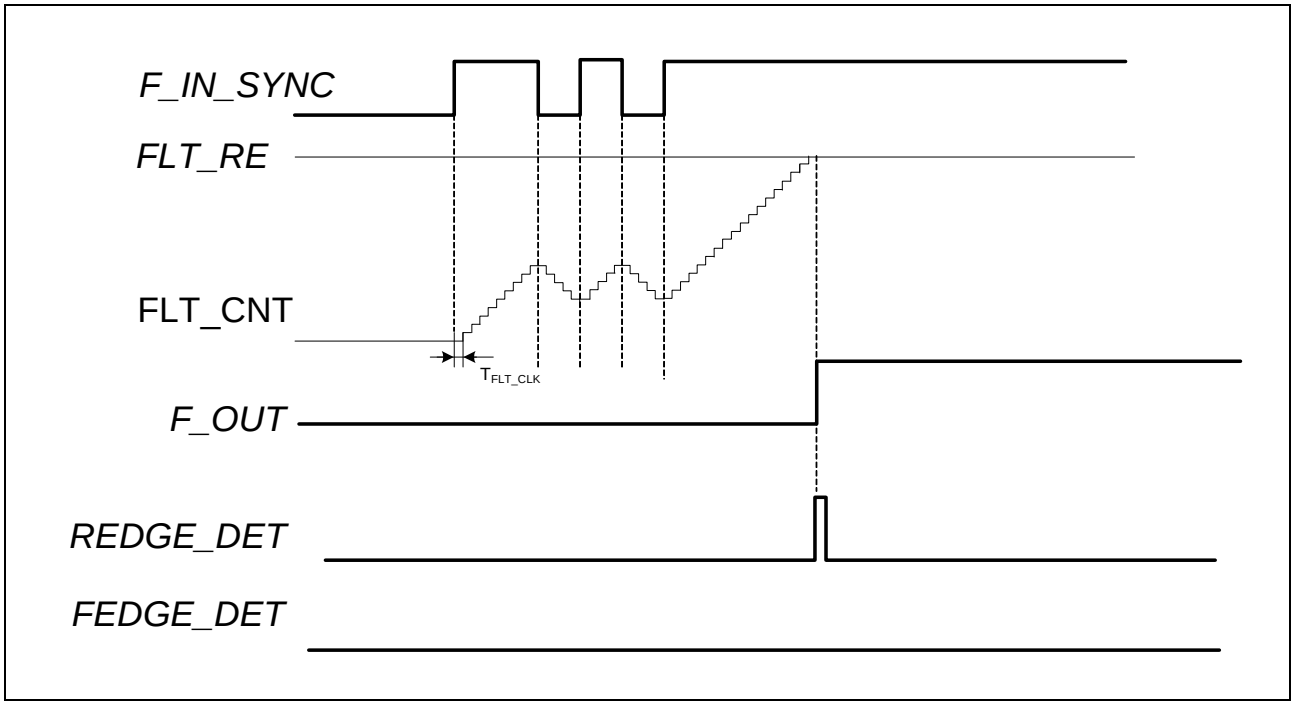

Figure 25.26 Individual De-Glitch Time Mode (up/down counter) in the case of a rising edge

(3) Individual De-Glitch Time Mode (hold counter)

In individual de-glitch time mode (hold counter) each edge of an input signal can be filtered with an individual de-glitch threshold filter value mentioned in the registers FLT_RE and FLT_FE, respectively.

The filter counter register FLT_CNT is incremented when the signal level on F_IN_SYNC is unequal to the signal level on F_OUT and the counter value of FLT_CNT is hold if F_IN equals F_OUT.

If a glitch is detected the glitch detection bit GLITCHDET is set in the GTM0TIMixIRQNOTIFY register.

The detected edge signal together with the new signal level is propagated to F_OUT after the individual de-glitch threshold is reached. **Figure 25.27** shows the behavior of the filter in individual de-glitch time (hold counter) mode in the case of the rising edge detection.

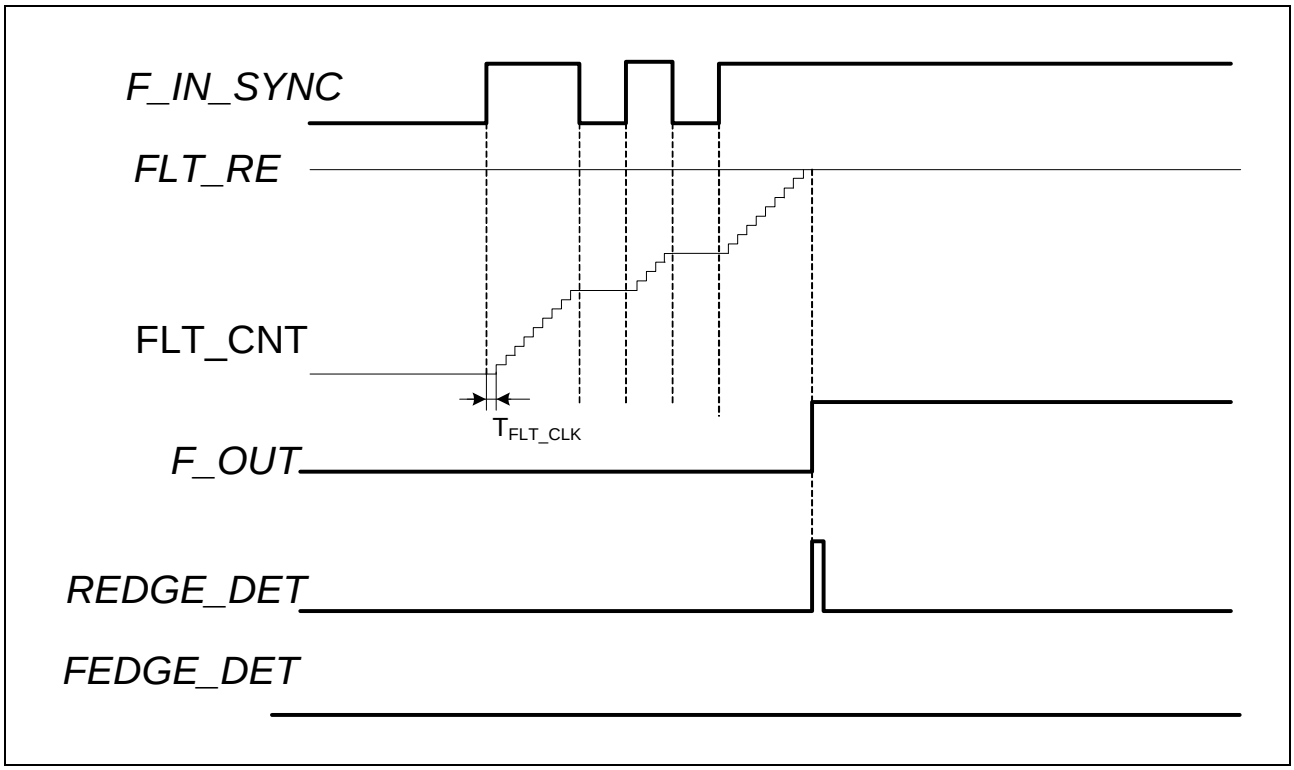

Figure 25.27 Individual De-Glitch Time Mode (hold counter) in the case of a rising edge

(4) Immediate Edge Propagation and Individual De-Glitch Mode

As already mentioned, the three different filter modes can be applied individually to each edge of the measured signal.

However, if one edge is configured with immediate edge propagation and the other edge with an individual deglitch mode (whether up/down counter or hold counter) a special consideration has to be applied.

Assume that the rising edge is configured for immediate edge propagation and the falling edge with individual deglitch mode (up/down counter) as shown in **Figure 25.28**.

If the falling edge of the incoming signal already occurs during the measuring of the acceptance time of the rising edge, the measurement of the deglitch time on the falling edge is started delayed, but immediately after the acceptance time measurement phase of the rising edge has finished.

Consequently, the deglitch counter can not measure the time TERROR, as shown in **Figure 25.28**.

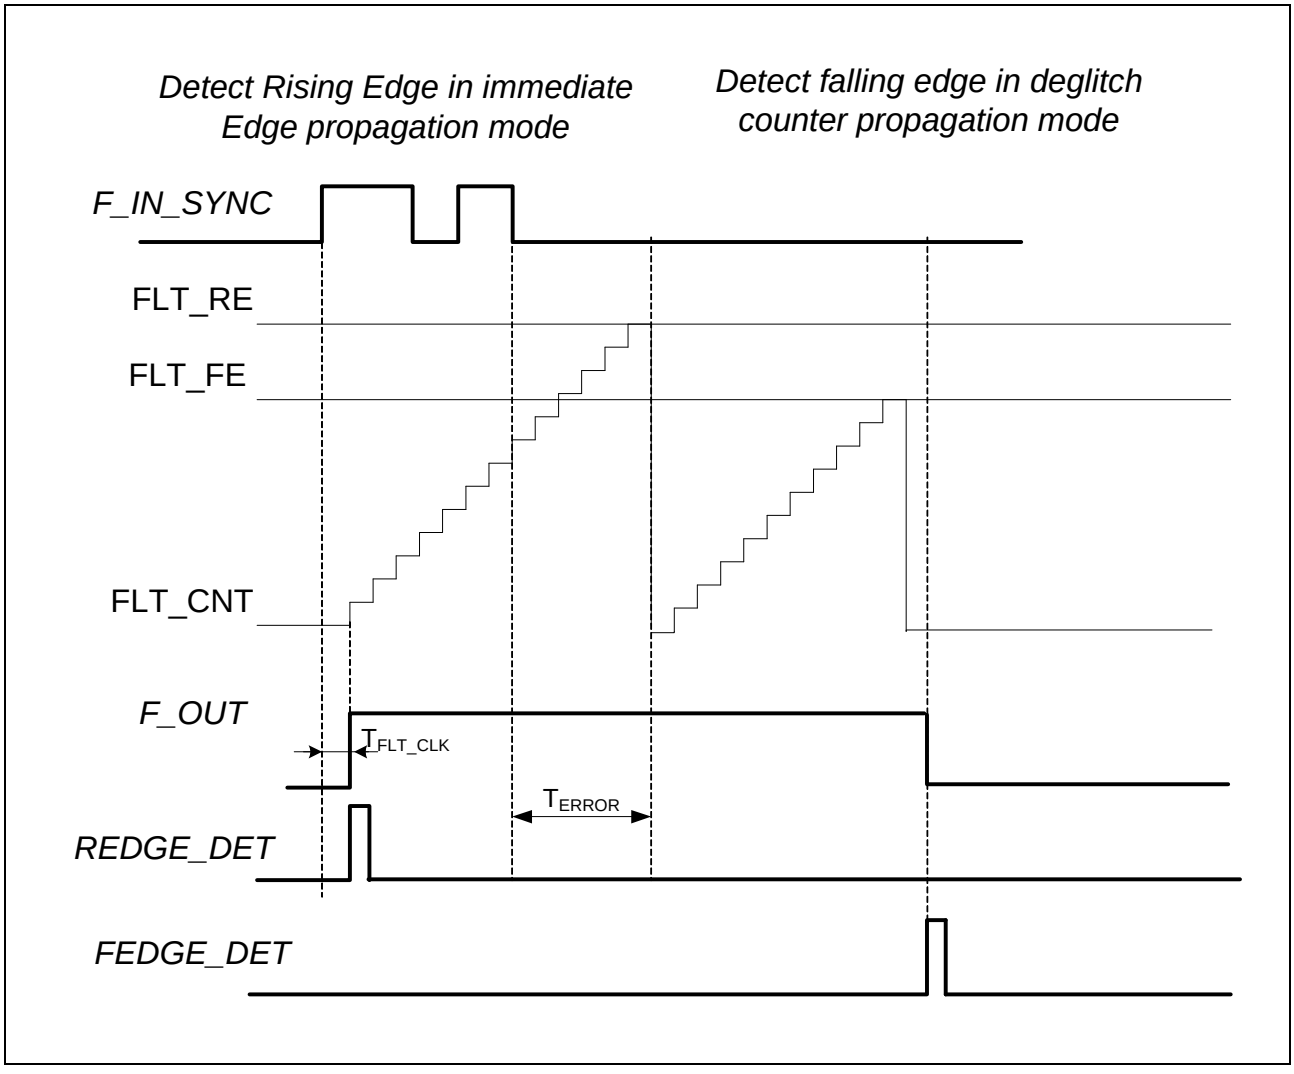

Figure 25.28 Mixed mode measurement

25.10.2.3 TIM Filter reconfiguration

If FLT_EN=1 a change of FLT_RE or FLT_FE will take place immediately.

If FLT_EN=1 a change of FLT_MODE_RE or FLT_MODE_FE will be used with the next occurring corresponding edge. If the mode is changed while the filter unit is processing a certain mode, it will end this edge filtering in the mode as started.

If FLT_EN=1 a change of FLT_CTR_RE or FLT_CTR_FE will take place immediately.

25.10.3 Timeout Detection Unit (TDU)

The Timeout Detection Unit (TDU) is responsible for timeout detection of the TIM input signals.

Each channel of the TIM submodule has its own Timeout Detection Unit (TDU) where a timeout event can be set up on the filtered input signal of the corresponding channel.

The TDU architecture is shown in **Section 25.10.3.1, Architecture of the TDU Subunit**.

25.10.3.1 Architecture of the TDU Subunit

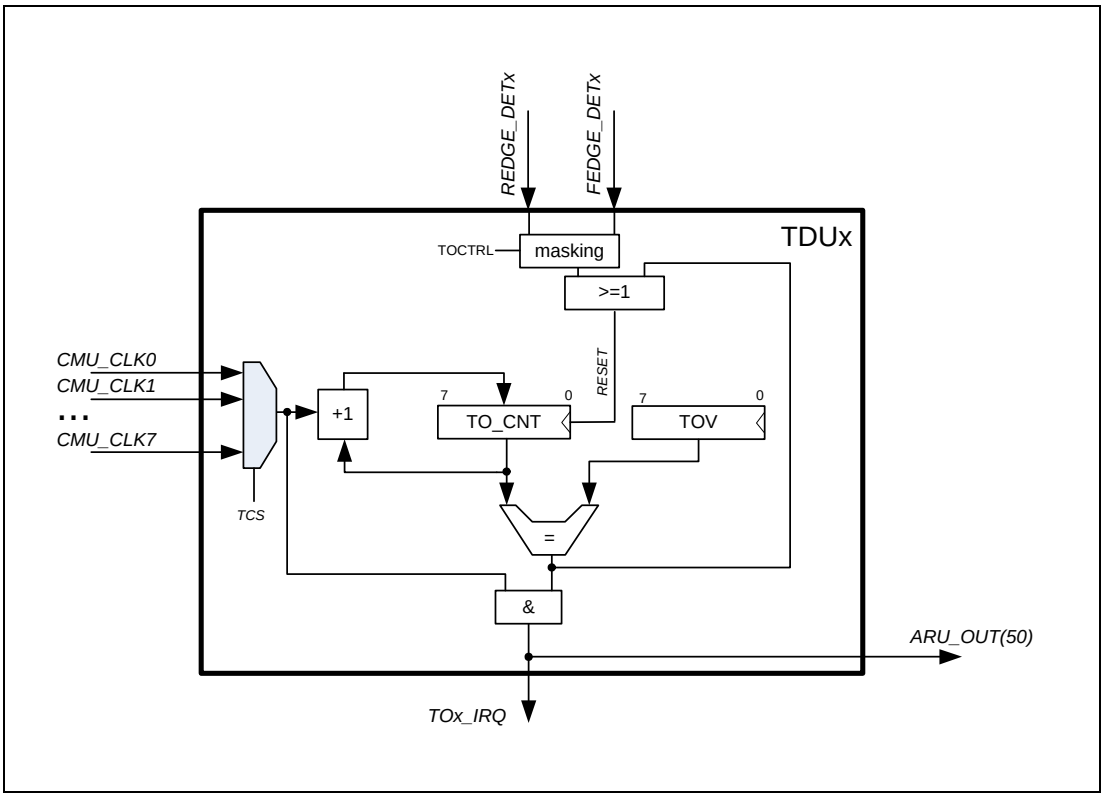

Figure 25.29 Architecture of the TDU Subunit

It is possible to detect timeouts with the resolution of the specified CMU_CLKx input signal selected with the bit field TCS of the register GTM0TIMixTDUV. The individual timeout values have to be specified in number of ticks of the selected input clock signal and have to be specified in the field TOV of timeout value register GTM0TIMixTDUV of the TIM channel x.

The exact time out value TTDU can be calculated with:

T_{TDU}=(TOV+1)*T_{CMU_CLKx},

whereas TCMU_CLKx is the clock period of the selected CMU clock signal.

Timeout detection can be enabled or disabled individually inside the GTM0TIMixCTRLregister by setting/resetting the TOCTRL bit.

Timeout detection can be enabled to be sensitive to falling, rising or both edges of the input signal by writing the corresponding values to the bit field TOCTRL.

The counter TO_CNT is reset by each detected valid input edge coming either from the filtered input signal or when the timeout value TOV is reached by the counter TO_CNT.

After such a reset or by enabling the channel inside the GTM0TIMixCTRLregister the counter TO_CNT starts counting again from value 0 with the specified clock input signal.

Otherwise, timeout measurements starts immediately after the TOCTRL bit inside the GTM0TIMixCTRLregister is written (enabled).

The TDU generates an interrupt signal TIM_TODETx_IRQ whenever a timeout is detected for an individual input signal, and the TODET bit is set inside the GTM0TIMixIRQNOTIFY register.

In addition, when the ARU access is enabled with the ARU_EN bit inside the GTM0TIMixCTRLregister, the actual values stored inside the registers GTM0TIMixGPR0 and GTM0TIMixGPR1 are sent together with the last stored signal level to the ARU if a timeout event occurs.

To signal that a timeout occurred, the ARU_OUT(50) bit (ACB(2)) is set. The bit ACB(0) will be updated with the timeout event to the signal level on which the timeout was detected.

Thus, a destination could determine if a timeout occurred at the TIM input by evaluating ACB bit 2.

Since the TIM channel still monitors its input pin although the timeout happened, a valid edge could occur at the input pin while the timeout information is still valid at the ARU. In that case, the new edge associated data is stored inside the registers GTM0TIMixGPR0 and GTM0TIMixGPR1, the GPR overflow detected bit is set together in the ACB field (ACB(1)) with the timeout bit (ACB(2)) and the values are marked as valid to the ARU.

The ACB bit 2 is cleared, when a successful ARU write access by the TIM channel took place.

The ACB bit 1 is cleared, when a successful ARU write access by the TIM channel took place.

When a valid edge initiates an ARU write access which has not ended while a new timeout occurs the GPR overflow detected bit (ACB(1)) is set. The bit ACB(0) will be updated to the level on which the timeout occurred.

When a timeout occurred and initiates an ARU write access which has not ended while a new timeout occurs the GPR overflow detected bit (ACB(1)) is not set.

The following table clarifies the meaning of the ACB Bits for valid data provided by a TIM channel:

Table 25.61 The ACB Bits for valid data provided by a TIM channel

ACB4/3	ACB2	ACB1	ACB0	Description
dc	0	0	SL	Valid edge detected
dc	0	1	SL	Input edge overwritten by subsequent edge
dc	1	0	SL	Timeout detected without valid edge
dc	1	1	SL	Timeout detected with subsequent valid edge detected

25.10.4 TIM Channel Architecture

25.10.4.1 Overview

Each TIM channel consist of an input edge counter ECNT, a Signal Measurement Unit (SMU) with a counter CNT, a counter shadow register CNTS for SMU counter and two general purpose registers GPR0 and GPR1 for value storage.

The value TOV of the timeout register GTM0TIMixTDUV is provided to TDU subunit of each individual channel for timeout measurement. The architecture of the TIM channel is depicted in **Figure 25.30**.

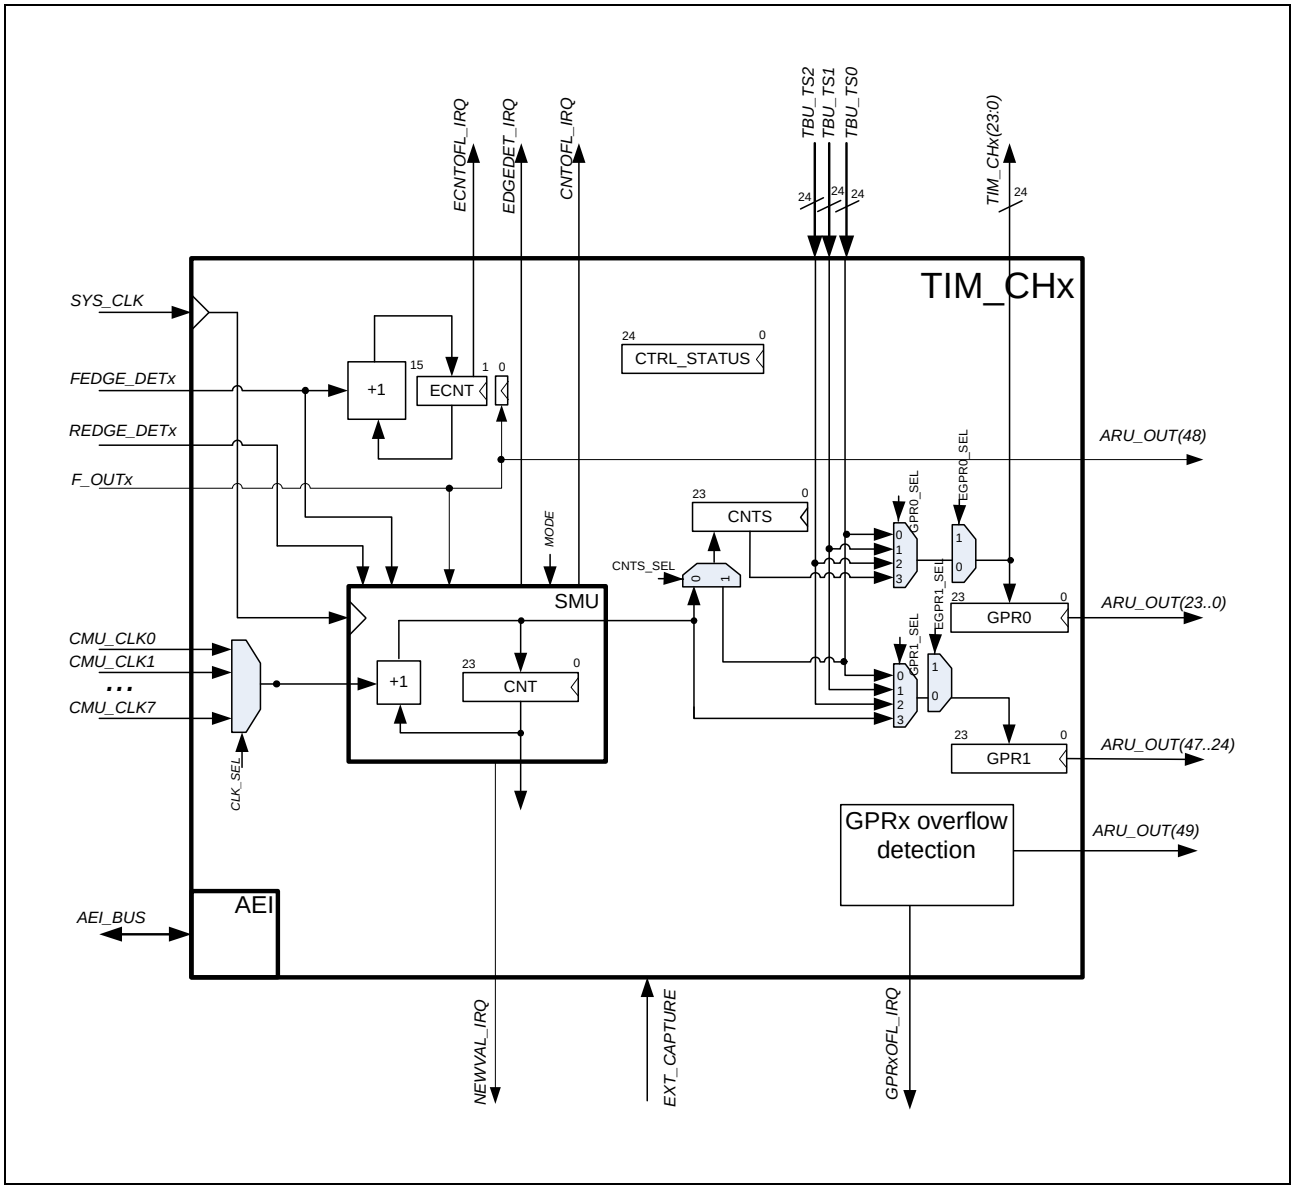

Figure 25.30 TIM Channel Architecture

Each TIM channel receives both input trigger signals REDGE_DETx and FEDGE_DETx, generated by the corresponding filter module in order to signalize a detected echo of the input signal F_INx. The signal F_OUTx shows the filtered signal of the channel's input signal F_INx.

The edge counter ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level

is part of the counter and can be obtained by bit 0 of ECNT. (However, the actual counter implementation counts only falling edges on ECNT[n:1] bits. It generates ECNT by composing the ECNT[n:1] bits with F_OUTx as bit 0).

Thus, the whole ECNT counter value is always odd, when a positive edge was received and always even, when a negative edge was received.

The current ECNT[7:0] register content is made visible on the bits 31 down to 24 of the registers GPR0, GPR1, and CNTS. This allows the software to detect inconsistent read accesses to registers GPR0, GPR1, and CNTS. However, the update strategy of these registers depends on the selected TIM modes, and thus the consistency check has to be adapted carefully.

It can be chosen with the bit field FR_ECNT_OFL when an ECNT overflow is signalled on ECNTOFL. An ECNT overflow can be signalled on 8 bit or full range resolution.

While reading the register GTM0TIMixECNT the bit ECNT[0] shows the input signal value F_OUTx independent of the state (enabled / disabled) of the channel. If a channel gets disabled (OSM mode or resetting TIM_EN) the content of GTM0TIMixECNT will be frozen until a read of the register takes place. This read will reset the ECNT counter. Continuing reads will show the input signal value in bit ECNT[0] again.

When new data is written into GPR0 and GPR1 the NEWVAL bit is set in GTM0TIMixIRQNOTIFY register and depending on corresponding enable bit value the NEWVALx_IRQ interrupt is raised.

Each TIM input channel has an ARU connection for providing data via the ARU to the other GTM submodules. The data provided to the ARU depends on the TIM channel mode and its corresponding adjustments (e.g. multiplexer configuration).

The bit ARU_EN of register GTM0TIMixCTRLdecides, whether the measurement results of registers GPR0 and GPR1 are consumed by another submodule via ARU (ARU_EN = 1) or the CPU via AEI (ARU_EN = 0).

To guarantee a consistent delivery of data from the GPR0 and GPR1 registers to the ARU or the CPU each TIM channel has to ensure that the data is consumed before it is overwritten with new values.

If new data was produced by the TIM channel (bit NEWVAL is set inside GTM0TIMixIRQNOTIFY register) while the old data is not consumed by the ARU (ARU_EN = 1) or CPU (ARU_EN = 0), the TIM channel sets the GPROFL bit inside the status register GTM0TIMixIRQNOTIFY and it overwrites the data inside the registers GPR0 and GPR1. In addition when ARU_EN = 1 the bit ACB(1) is set to 1 to indicate the overflow in the ARU data.

If the CPU is selected as consumer for the registers GPR0 and GPR1 (ARU_EN = 0), the acknowledge for reading out data is performed by a read access to the register GPR0. Thus, register GPR1 should be read always before GPR0.

If the ARU is selected as consumer for the registers GPR0 and GPR1 (ARU_EN = 1), the acknowledge for reading out data is performed by the ARU itself. However, the registers GPR0 and GPR1 could be read by CPU without giving an acknowledge.

25.10.4.2 TIM Channel Modes

The TIM provides six different measurement modes that can be configured with the bit field TIM_MODE of register GTM0TIMixCTRL. The measurement modes are described in the following subsections. Besides these different basic measurement modes, there exist distinct configuration bits in the register GTM0TIMixCTRLfor a more detailed controlling of each mode. The meanings of these bits are as follows:

- DSL: control the signal level for the measurement modes (e.g. if a measurement is started with rising edge or falling edge, or if high level pulses or low level pulses are measured.
- EGPR0_SEL, GPR0_SEL and EGPR1_SEL, GPR1_SEL: control the actual content of the registers GPR0 and GPR1 after a measurement has finished.
- CNTS_SEL: control the content of the registers CNTS. The actual time for updating the CNTS register is mode dependent.
- OSM: activate measurement in one-shot mode or continuous mode. In one-shot mode only one measurement cycle is performed and after that the channel is disabled.
- NEWVAL: The NEWVAL IRQ interrupt is triggered at the end of a measurement cycle, signalling that the registers GPR0 and GPR1 are updated.
- ARU_EN: enables sending of the registers GPR0 and GPR1 together with the actual signal level (in bit 48) and the overflow signal GPROFL (in bit 49), and the timeout status information (bit 50) to the ARU.
- EXT_CAP_EN: forces an update of the registers GPR0 and GPR1 and CNTS (TIM channel mode dependant) only on each rising edge of the EXT_CAPTURE signal and triggers a NEWVAL IRQ interrupt. If this mode is disabled the NEWVAL IRQ interrupt is triggered at the end of each measurement cycle.

For each channel the source of the EXT_CAPTURE signal can be configured with the bit fields EXT_CAP_SRC in the register GTM0TIM00ECTRL.

(1) TIM PWM Measurement Mode (TPWM)

In TIM PWM Measurement Mode the TIM channel measures duty cycle and period of an incoming PWM signal. The DSL bit defines the polarity of the PWM signal to be measured.

When measurement of pulse high time and period is requested (PWM with a high level duty cycle, DSL=1), the channel starts measuring after the first rising edge is detected by the filter.

Measurement is done with the CNT register counting with the configured clock coming from CMU_CLKx until a falling edge is detected.

Then the counter value is stored inside the shadow register CNTS (if CNTS_SEL = 0) and the counter CNT counts continuously until the next rising edge is reached.

On this following rising edge the content of the CNTS register is transferred to GPR0 and the content of CNT register is transferred to GPR1, assuming settings for the selectors GPR0_SEL= 11 and GPR1_SEL= 11. By this, GPR0 contains the duty cycle length and GPR1 contains the period. It should be noted, that the bits 1 to 7 of the ECNT may be used to check data consistency of the registers GPR0 and GPR1.

In addition the CNT register is cleared NEWVAL status bit inside of GTM0TIMixIRQNOTIFY status register and depending on corresponding interrupt enable condition TIM_NEWVALx_IRQ interrupt is raised.

The CNTS register update is not performed until the measurement is started (first edge defined by DSL is detected). Afterwards each edge leaving the level defined by DSL is performing a CNTS register update.

If a PWM with a low level duty cycle should be measured (DSL = 0), the channel waits for a falling edge until measurement is started. On this edge the low level duty cycle time is stored first in CNTS and then finally in GPR0 and the period is stored in GPR1.

When a PWM period was successfully measured, the data in the registers GPR0 and GPR1 is marked as valid for reading by the ARU when the ARU_EN bit is set inside GTM0TIMixCTRLregister, the NEWVAL bit is set inside the GTM0TIMixIRQNOTIFY register, and a new measurement is started.

If the preceding PWM values were not consumed by a reader attached to the ARU (ARU_EN bit enabled) or by the CPU the TIM channel set GPROFL status bit in GTM0TIMixIRQNOTIFY and depending on corresponding interrupt enable bit value raises a GPROFL_IRQ and overwrites the old values in GPR0 and GPR1. A new measurement is started afterwards.

If the register CNT produces an overflow during the measurement, the bit CNTOFL is set inside the register GTM0TIMixIRQNOTIFY and interrupt TIM_CNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register GTM0TIMixIRQNOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

(a) External capture TIM PWM Measurement Mode (TPWM)

If external capture is enabled, the pwm measurement is done continuously. The actual measurement values are captured to GPRx if an external capture event occurs.

Operation is done depending on cmu clock, ISL, DSL bit and the input signal value defined in next table:

Table 25.62 External capture TIM PWM Measurement Mode (TPWM)

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
0	1	0	—	0	CNT++
1	1	0	—	0	no
Rising edge	—	0	0	0	capture CNT value in CNTS
Falling edge	—	0	0	0	CNT = 0
Rising edge	—	0	1	0	no
Falling edge	—	0	1	0	capture CNT value in CNTS; CNT = 0
1	1	0	—	1	CNT++
0	1	0	—	1	no
Falling edge	—	0	0	1	capture CNT value in CNTS
Rising edge	—	0	0	1	CNT = 0
Falling edge	—	0	1	1	no
Rising edge	—	0	1	1	capture CNT value in CNTS; CNT = 0
—	—	Rising edge	—	—	do GPRx capture ; issue NEWVAL_IRQ
—	0	0	—	—	no

The CNTS register update is not performed until the measurement is started (first edge defined by DSL is detected). Afterwards the update of the CNTS register is defined by ISL,DSL combinations in the table above.

(2) TIM Pulse Integration Mode (TPIM)

In TIM Pulse Integration Mode each TIM channel is able to measure a sum of pulse high or low times on an input signal, depending on the selected signal level bit DSL of register GTM0TIMixCTRLregister.

The pulse times are measured by incrementing the TIM channel counter CNT whenever the pulse has the specified signal level DSL. The counter is stopped whenever the input signal has the opposite signal level.

The counter CNT counts with the CMU_CLKx clock specified by the CLK_SEL bit field of the GTM0TIMixCTRLregister.

The CNT register is reset at the time the channel is activated (enabling via AEI write access) and it accumulates pulses while the channel is staying enabled.

Whenever the counter is stopped, the registers CNTS, GPR0 and GPR1 are updated according to settings of its corresponding input multiplexers, using the bits EGPR0_SEL, EGPR1_SEL, GPR0_SEL, GPR1_SEL, and CNTS_SEL. It should be noted, that the bits 1 to 7 of the ECNT may be used to check data consistency of the registers GPR0 and GPR1.

When the ARU_EN bit is set inside the GTM0TIMixCTRLregister the measurement results of the registers GPR0 and GPR1 can be send to subsequent submodules attached to the ARU.

(a) External capture TIM Pulse Integration Mode (TPIM)

If external capture is enabled, the pulse integration is done until next external capture event occurs.

Operation is done depending on cmu clock, DSL bit and the input signal value defined in next table:

Table 25.63 External capture TIM Pulse Integration Mode (TPIM)

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description
0	1	0	—	0	CNT++
1	1	0	—	0	no
1	1	0	—	1	CNT++
0	1	0	—	1	no
—	—	Rising edge	—	—	do capture ; issue NEWVAL_IRQ; CNT = 0
—	0	0	—	—	no

(3) TIM Input Event Mode (TIEM)

In TIM Input Event Mode the TIM channel is able to count edges.

It is configurable if rising, falling or both edges should be counted. This can be done with the bit fields DSL and ISL in GTM0TIMixCTRLregister.

In addition, a TIM[i]_NEWVAL[x]_IRQ interrupt is raised when the configured edge was received and this interrupt was enabled.

The counter register CNT is used to count the number of edges, and the bit fields EGPR0_SEL, EGPR1_SEL,GPR0_SEL, GPR1_SEL, and CNTS_SEL can be used to configure the desired update values for the registers GPR0, GPR1 and CNTS. These register are updated whenever the edge counter CNT is incremented due to the arrival of a desired edge.

If the preceding data was not consumed by a reader attached to the ARU or by the CPU the TIM channel sets GPROFL status bit and raises a GPROFL[x]_IRQ if it was enabled in GTM0TIMixIRQEN register and overwrites the old values in GPR0 and GPR1 with the new ones.

If the register CNT produces an overflow during the measurement, the bit CNTOFL is set inside the register GTM0TIMixIRQNOTIFY and interrupt TIM_CNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register GTM0TIMixIRQNOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

The TIM Input Event Mode does not depend on the bit field CLK_SEL of register GTM0TIMixCTRL.

(a) External capture TIM Input Event Mode (TIEM)

If external capture is enabled, capturing is done depending on the DSL, ISL bit and the input signal value defined in next table:

Table 25.64 External capture TIM Input Event Mode (TIEM)

Input signal F_OUTx	External capture	ISL	DSL	Action description
—	Rising edge	1	—	do capture; issue NEWVAL_IRQ; CNT++
—	0	1	—	no
1	Rising edge	0	1	do capture; issue NEWVAL_IRQ; CNT++
0	—	0	1	no
0	Rising edge	0	0	do capture; issue NEWVAL_IRQ; CNT++
1	—	0	0	no

(4) TIM Input Prescaler Mode (TIPM)

In the TIM Input Prescaler Mode the number of edges which should be detected before a TIM[i]_NEWVAL[x]_IRQ is raised is programmable. In this mode it must be specified in the CNTS register after how many edges the interrupt has to be raised.

A value of 0 in CNTS means that after one edge an interrupt is raised and a value of 1 means that after two edges an interrupt is raised, and so on.

The edges to be counted can be selected by the bit fields DSL and ISL of register GTM0TIMixCTRL.

With each triggered interrupt, the registers GPR0 and GPR1 are updated according to bits EGPR0_SEL, EGPR1_SEL,GPR0_SEL and GPR1_SEL.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register GTM0TIMixIRQNOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

The TIM Input Prescaler Mode does not depend on the bit field CLK_SEL of register GTM0TIMixCTRL.

(a) External capture TIM Input Prescaler Mode (TIPM)

If external capture is enabled, the external capture events are counted instead of the input signal edges.

Operation is done depending on the external capture signal, DSL, ISL bit and the input signal value defined in next table:

Table 25.65 External capture TIM Input Prescaler Mode (TIPM)

Input signal F_OUTx	External capture	ISL	DSL	Action description

—	Rising edge	1	—	if CNT == CNTS then
				do capture ;issue NEWVAL_IRQ; CNT = 0
				else
				CNT++
				endif

—	0	1	—	no

1	Rising edge	0	1	if CNT == CNTS then
				do capture ;issue NEWVAL_IRQ; CNT = 0
				else
				CNT++
				endif

0	—	0	1	no

0	Rising edge	0	0	if CNT == CNTS then
				do capture ;issue NEWVAL_IRQ; CNT = 0
				else
				CNT++
				endif

1	—	0	0	no

(5) TIM Bit Compression Mode (TBCM)

The TIM Bit Compression Mode can be used to combine all filtered input signals of a TIM submodule to a parallel m bit data word, which can be routed to the ARU, where m is the number of channels available in the TIM submodule.

Figure 25.31 gives an overview of the TIM bit compression mode.

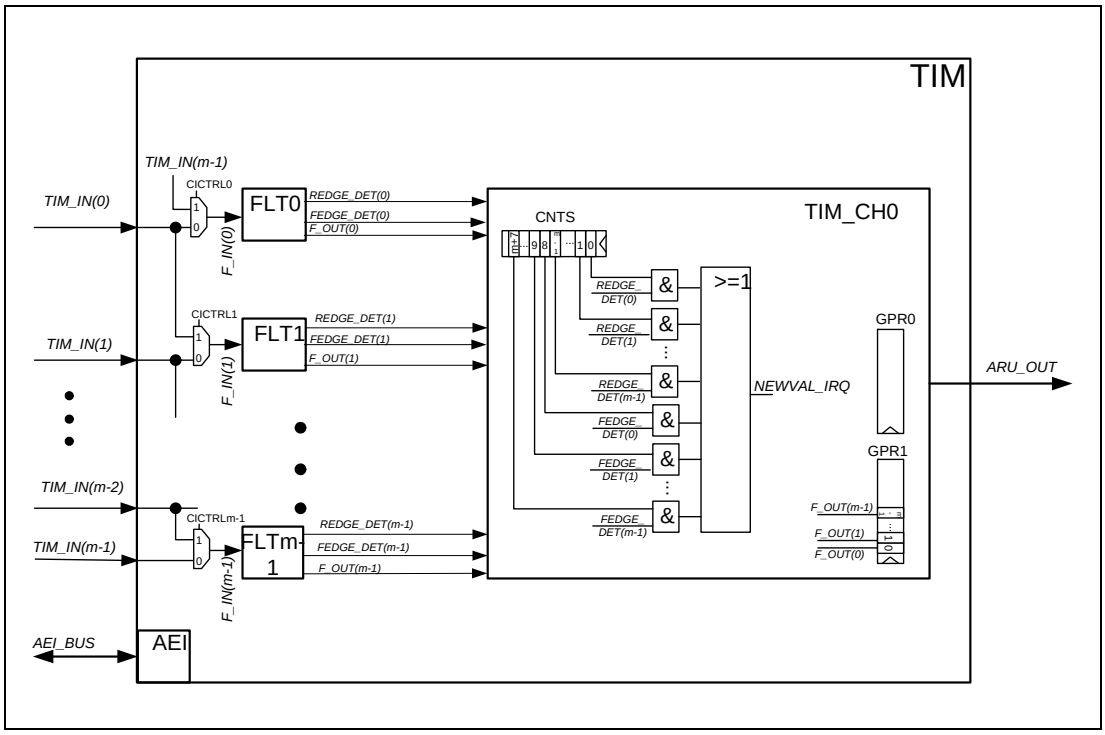

Figure 25.31 TIM Bit Compression Mode

The register CNTS of a channel is used to configure the event that releases the NEWVAL_IRQ and samples the input signals F_IN(0) to F_IN(m–1) in ascending order as a parallel data word in GPR1.

The bits 0 to m–1 of the CNTS register are used to select the REDGE_DET signals of the TIM filters 0 to m–1 as a sampling event, and the bits 8 to (7+m) are used to select the FEDGE_DET signals of the TIM filters 0 to m–1, respectively. If multiple events are selected, the events are OR-combined (see also **Figure 25.31**).

EGPR0_SEL,GPR0_SEL selects the timestamp value, which is routed through the ARU. GPR1_SEL is not applicable in TBCM mode.

If the bit ARU_EN of register GTM0TIMixCTRLis set, the sampled data of register GPR1 is routed together with a time stamp of register GPR0 to the ARU, whenever the NEWVAL_IRQ is released.

In TIM Bit compression mode, the register ECNT increments with each NEWVAL_IRQ, which means that the value of ECNT may depend on all m input signals. Consequently, the LSB of ECNT does not reflect the actual level of the input signal TIM_IN(x).

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register GTM0TIMixIRQNOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

The TIM Bit Compression Mode does not depend on the bit field CLK_SEL of register GTM0TIMixCTRL.

(a) External capture Bit Compression Mode (TBCM)

If external capture is enabled, capturing is done depending on the DSL, ISL bit and the input signal value defined in next table:

Table 25.66 External capture Bit Compression Mode (TBCM)

Input signal F_OUTx	External capture	ISL	DSL	Action description
—	Rising edge	1	—	do capture ;issue NEWVAL_IRQ; CNT++
—	0	1	—	no
1	Rising edge	0	1	do capture ;issue NEWVAL_IRQ; CNT++
0	—	0	1	no
0	Rising edge	0	0	do capture ;issue NEWVAL_IRQ; CNT++
1	—	0	0	no

(6) TIM Gated Periodic Sampling Mode (TGPS)

In the TIM Gated Periodic Sampling Mode the number of CMU clock cycles which should elapse before capturing and raising TIM[i]_NEWVAL[x]_IRQ is programmable. In this mode it must be specified in the CNTS register after how many CMU clock cycles the interrupt has to be raised.

A value of 0 in GTM0TIMixCNTS means that after one CLK_SEL edge a trigger/interrupt is raised, and a value of 1 means that after two edges a trigger/interrupt is raised, and so on.

In the GTM0TIMixCNT register the elapsed cycles were incremented and compared against GTM0TIMixCNTS. If GTM0TIMixCNT is greater or equal to GTM0TIMixCNTS a trigger will be raised. This allows by writing a value to GTM0TIMixCNTS that the actual period time can be changed on the fly.

Operation is done depending on cmu clock, DSL, ISL bit and the input signal value defined in next table:

Table 25.67 TIM Gated Periodic Sampling Mode (TGPS)

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description

—	1	0	1	—	if CNT == CNTS then
					do capture ;issue NEWVAL_IRQ; CNT = 0
					else
					CNT++
					endif

0	0	0	0	1	no

1	1	0	0	1	if CNT == CNTS then
					do capture ;issue NEWVAL_IRQ; CNT = 0
					else
					CNT++
					endif

0	0	—	0	1	no

0	1	0	0	0	if CNT == CNTS then
					do capture ;issue NEWVAL_IRQ; CNT = 0
					else
					CNT++
					endif

1	0	0	0	0	no
—	0	0	—	—	no

In this mode the GTM0TIMixGPR1 operates as a shadow register for GTM0TIMixCNTS. This would allow that the period for the next sampling period could be specified. The update of GTM0TIMixCNTS will only take place once on a trigger if the GTM0TIMixGPR1 was written by the CPU. This means that the captured value from the previous trigger can be read by the CPU from GTM0TIMixGPR1 and afterwards the new sampling period for the next sampling period (the one after the actual sampling period) could be written.

With each triggered interrupt, the registers GPR0 and GPR1 are updated according to bits GPR0_SEL, GPR1_SEL, EGPR0_SEL and EGPR1_SEL.

When selecting ECNT as a source for the capture registers, GPRx will show the edge count and the input signal value at point of capture. Selecting GPR0_SEL = '11' and EGPR0_SEL = '0' for TIM channel 0 all 8 TIM input signals will be captured to GPR0[7:0].

In the TGPS Mode the bit field CLK_SEL of register GTM0TIMixCTRLwill define the selected CMU clock which will be used.

The behavior of the ECNT counter is configurable by ECNT_RESET. If set to 1 on each interrupt (period expired) the ECNT will be reset. Otherwise it operates in wrap around mode.

If the register ECNT produces an overflow during the measurement, the bit ECNTOFL is set inside the register GTM0TIMixIRQNOTIFY and interrupt TIM_ECNTOFL[x]_IRQ is raised depending on corresponding interrupt enable condition.

(a) External capture TIM Gated Periodic Sampling Mode (TGPS)

If external capture is enabled, the external capture events will capture the GPRx, reset the counter CNT and issue a NEWVAL_IRQ.

Operation is done depending on the cmu clock, external capture signal, DSL, ISL bit and the input signal value defined in next table:

Table 25.68 External capture TIM Gated Periodic Sampling Mode (TGPS)

Input signal F_OUTx	selected CMU Clock	External capture	ISL	DSL	Action description

—	1	0	1	—	if CNT == CNTS then
					do capture; issue NEWVAL_IRQ; CNT = 0
					else
					CNT++
					endif

0	0	0	0	1	no

1	1	0	0	1	if CNT == CNTS then
					do capture; issue NEWVAL_IRQ; CNT = 0
					else
					CNT++
					endif

0	0	—	0	1	no

0	1	0	0	0	if CNT == CNTS then
					do capture; issue NEWVAL_IRQ; CNT = 0
					else
					CNT++
					endif

1	0	0	0	0	no
—	0	0	—	—	no
—	—	rising edge	—	—	do capture; issue NEWVAL_IRQ; CNT = 0

25.10.5 TIM Interrupt Signals

TIM provides 6 interrupt lines per channel. These interrupts are shown below:

Table 25.69 TIM Interrupt Signals

Signal	Description
TIM[i]_NEWVAL[x]_IRQ	New measurement value detected by SMU of channel x (x: 0 to 7)
TIM[i]_ECNTOFL[x]_IRQ	ECNT counter overflow of channel x (x: 0 to 7)
TIM[i]_CNTOFL[x]_IRQ	SMU CNT counter overflow of channel x (x: 0 to 7)
TIM[i]_GPROFL[x]_IRQ	GPR0 and GPR1 data overflow, old data was not read out before new data has arrived at input pin of channel x (x: 0 to 7)
TIM[i]_TODET[x]_IRQ	Time out reached for input signal of channel x (x: 0 to 7)
TIM[i]_GLITCHDET_IRQ	A glitch was detected by the TIM filter of channel x (x: 0 to 7)

25.10.6 TIM Configuration Registers Overview

TIM contains following configuration registers:

Table 25.70 Register list

Symbol	Register Name	Detail in Section
GTM0TIMixCTRL	channel x control	**25.10.7.1**, **25.10.7.2**
GTM0TIM00ECTRL	channel x (x: 0 to 7) extended control	**25.10.7.19**
GTM0TIMixFLTRE	channel x (x: 0 to 7) filter parameter 0	**25.10.7.3**
GTM0TIMixFLTFE	channel x (x: 0 to 7) filter parameter 1	**25.10.7.4**
GTM0TIMixTDUV	channel x (x: 0 to 7) TDU control.	**25.10.7.16**
GTM0TIMixTDUC	channel x (x: 0 to 7) TDU counter.	**25.10.7.17**
GTM0TIMixGPR0	channel x (x: 0 to 7) general purpose 0	**25.10.7.5**
GTM0TIMixGPR1	channel x (x: 0 to 7) general purpose 1	**25.10.7.6**
GTM0TIMixCNT	channel x (x: 0 to 7) SMU counter	**25.10.7.7**
GTM0TIMixECNT	channel x (x: 0 to 7) SMU edge counter	**25.10.7.18**
GTM0TIMixCNTS	channel x (x: 0 to 7) SMU shadow counter	**25.10.7.8**
GTM0TIMixIRQNOTIFY	channel x (x: 0 to 7) interrupt notification	**25.10.7.9**
GTM0TIMixIRQEN	channel x (x: 0 to 7) interrupt enable	**25.10.7.10**
GTM0TIMixEIRQEN	channel x (x: 0 to 7) error interrupt enable	**25.10.7.15**
GTM0TIMixIRQFORCINT	channel x (x: 0 to 7) software interrupt force	**25.10.7.11**
GTM0TIMixIRQMODE	IRQ mode configuration register (x: 0 to 7)	**25.10.7.12**
GTM0TIMiRST	TIM global software reset	**25.10.7.13**
GTM0TIMiINSRC	TIM AUX IN source selection	**25.10.7.14**
GTM0TIMiINPVAL	TIM input value observation	**25.10.7.20**

25.10.7 TIM Configuration Registers Description

25.10.7.1 GTM0TIM1xCTRL (x = 0 to 7)

Access: This register can be read/written in 32-bit units.

Address: GTM0TIM10ECTRL: <GTM_base> + 01824_H

Table 25.71 GTM0TIM1xCTRL Register Contents (1/4)

Bit Position	Bit Name	Function
31, 30	TOCTRL	Timeout control 00: Timeout feature disabled 11: Timeout feature enabled for both edges 01: Timeout feature enabled for rising edge only 10: Timeout feature enabled for falling edge only
29	EGPR1_SEL	Extension of GPR1_SEL bit field. Details described in GPR1_SEL bit field.
28	EGPR0_SEL	Extension of GPR0_SEL bit field. Details described in GPR0_SEL bit field.
27	FR_ECNT_OFL	Extended Edge counter overflow behavior 0: Overflow will be signalled on ECNT bit width = 8 1: Overflow will be signalled on EECNT bit width (full range)
26 to 24	CLK_SEL	CMU clock source select for channel. 000: CMU_CLK0 selected 001: CMU_CLK1 selected 010: CMU_CLK2 selected 011: CMU_CLK3 selected 100: CMU_CLK4 selected 101: CMU_CLK5 selected 110: CMU_CLK6 selected 111: CMU_CLK7 selected
23	FLT_CTR_FE	Filter counter mode for falling edge. 0: Up/Down Counter 1: Hold Counter **NOTE** This bit is only applicable in Individual Deglitch Time Mode.

Table 25.71 GTM0TIM1xCTRL Register Contents (2/4)

Bit Position	Bit Name	Function
22	FLT_MODE_FE	Filter mode for falling edge. 0: Immediate edge propagation mode 1: Individual de-glitch mode
21	FLT_CTR_RE	Filter counter mode for rising edge. 0: Up/Down Counter 1: Hold Counter **NOTE** This bit is only applicable in Individual Deglitch Time Mode.
20	FLT_MODE_RE	Filter mode for rising edge. 0: Immediate edge propagation mode 1: Individual de-glitch mode
19	EXT_CAP_EN	Enables external capture mode. The selected TIM mode is only sensitive to external capture pulses the input event changes are ignored. 0: External capture disabled 1: External capture enabled
18, 17	FLT_CNT_FRQ	Filter counter frequency select 00: FLT_CNT counts with CMU_CLK0 01: FLT_CNT counts with CMU_CLK1 10: FLT_CNT counts with CMU_CLK6 11: FLT_CNT counts with CMU_CLK7
16	FLT_EN	Filter enable for channel x (x = 0 to 7) 0: Filter disabled and internal states are reset 1: Filter enabled **NOTE** If the filter is disabled all filter related units (including CSU) are bypassed, which means that the signal F_IN is directly routed to signal F_OUT.
15	ECNT_RESET	Enables resetting the ECNT counter in periodic sampling mode 0: ECNT counter operating in wrap around mode 1: ECNT counter is reset with periodic sampling
14	ISL	Ignore signal level 0: Use DSL bit for selecting active signal level 1: Ignore DSL and treat both edges as active edge **NOTE** This bit is only applicable in Input Event mode (TIEM).
13	DSL	Signal level control 0: Measurement starts with falling edge (low level measurement) 1: Measurement starts with rising edge (high level measurement)
12	CNTS_SEL	Selection for CNTS register 0: Use CNT register as input 1: Use TBU_TS0 as input **NOTE** The functionality of the CNTS_SEL is disabled in the modes TIPM and TBCM.

Table 25.71 GTM0TIM1xCTRL Register Contents (3/4)

Bit Position	Bit Name	Function
11, 10	GPR1_SEL	Selection for GPR1 register If EGPR1_SEL =0: 00: Use TBU_TS0 as input 01: Use TBU_TS1 as input 10: Use TBU_TS2 as input 11: Use CNT as input If EGPR1_SEL =1: 00: Use ECNT as input 01: Use TIM_INP_VAL as input 10: Reserved 11: Reserved **NOTES** 1. In TBCM mode: EGPR1_SEL = 1, GPR1_SEL=01 selects TIM_INP_VAL as input, in all other cases TIM Filter F_OUT is used. 2. If a reserved value is written to the EGPR1_SEL, GPR1_SEL bit fields, the hardware will use TBU_TS0 input.
9, 8	GPR0_SEL	Selection for GPR0 register If EGPR0_SEL =0: 00: Use TBU_TS0 as input 01: Use TBU_TS1 as input 10: Use TBU_TS2 as input 11: Use CNTS as input;if TGPS mode in channel = 0 is selected use TIM Filter F_OUT as input If EGPR0_SEL =1: 00: Use ECNT as input 01: Use TIM_INP_VAL as input 10: Reserved 11: Reserved **NOTE** If a reserved value is written to the EGPR0_SEL, GPR0_SEL bit fields, the hardware will use TBU_TS0 input.
7	Reserved	These bits are always read as 0. When written, write the initial value.
6	CICTRL	Channel Input Control. 0: Use signal TIM_IN(x) as input for channel x 1: Use signal TIM_IN(x-1) as input for channel x (or TIM_IN(m-1) if x is 0)
5	ARU_EN	GPR0 and GPR1 register values routed to ARU 0: Registers content not routed 1: Registers content routed
4	OSM	One-shot mode 0: Continuous operation mode 1: One-shot mode **NOTE** After finishing the action in one-shot mode the TIM_EN bit is cleared automatically.

Table 25.71 GTM0TIM1xCTRL Register Contents (4/4)

Bit Position	Bit Name	Function
3 to 1	TIM_MODE	TIM channel x (x = 0 to 7) mode 000: PWM Measurement Mode (TPWM) 001: Pulse Integration Mode (TPIM) 010: Input Event Mode (TIEM) 011: Input Prescaler Mode (TIPM) 100: Bit Compression Mode (TBCM) 101: Gated Periodic Sampling Mode (TGPS) **NOTES** 1. If an undefined value is written to the TIM_MODE register, the hardware switches automatically to TIM_MODE = 000 (TPWM mode). 2. The TIM_MODE register should not be changed while the TIM channel is enabled. 3. If the TIM channel is enabled and operating in TPWM or TPIM mode after the first valid edge defined by DSL has occurred, a reconfiguration of DSL,ISL,TIM_MODE will not change the channel behavior. Reading these bit fields after reconfiguration will show the newly configured settings but the initial channel behavior will not change. Only a disabling of the TIM channel by setting TIM_EN = 0 and reenabling with TIM_EN = 1 will change the channel operation mode.
0	TIM_EN	TIM channel x (x = 0 to 7) enable 0: Channel disabled 1: Channel enabled **NOTES** 1. Enabling of the channel resets the registers ECNT, GTM0TIMixCNT, GTM0TIMixGPR0, and GTM0TIMixGPR1 to their reset values. 2. After finishing the action in one-shot mode the TIM_EN bit is cleared automatically. Otherwise, the bit must be cleared manually.

25.10.7.2 GTM0TIM0xCTRL (x = 0 to 7)

Access: This register can be read/written in 32-bit units.

Address: GTM0TIM00ECTRL: <GTM_base> + 01024_H

12	CNTS_SEL	Selection for CNTS register 0: Use CNT register as input 1: Use TBU_TS0 as input **NOTE** The functionality of the CNTS_SEL is disabled in the modes TIPM and TBCM.

Table 25.72 GTM0TIM0xCTRL Register Contents (3/4)

Bit Position	Bit Name	Function
11, 10	GPR1_SEL	Selection for GPR1 register If EGPR1_SEL = 0: 00: Use TBU_TS0 as input 01: Use TBU_TS1 as input 10: Use TBU_TS2 as input 11: Use CNT as input If EGPR1_SEL =1: 00: Use ECNT as input 01: Use TIM_INP_VAL as input 10: Reserved 11: Reserved **NOTES** 1. In TBCM mode: EGPR1_SEL=1, GPR1_SEL=01 selects TIM_INP_VAL as input, in all other cases TIM Filter F_OUT is used. 2. If a reserved value is written to the EGPR1_SEL, GPR1_SEL bit fields , the hardware will use TBU_TS0 input.
9, 8	GPR0_SEL	Selection for GPR0 register If EGPR0_SEL = 0: 00: Use TBU_TS0 as input 01: Use TBU_TS1 as input 10: Use TBU_TS2 as input 11: Use CNTS as input;if TGPS mode in channel = 0 is selected use TIM Filter F_OUT as input If EGPR0_SEL =1: 00: Use ECNT as input 01: Use TIM_INP_VAL as input 10: Reserved 11: Reserved **NOTE** If a reserved value is written to the EGPR0_SEL, GPR0_SEL bit fields, the hardware will use TBU_TS0 input.
7	TBU0_SEL	TBU_TS0 bits input select for TIM0_CH[x]_GPRz (z: 0, 1) 0: Use TBU_TS0(23 to 0) to store in TIM0_CH[x]_GPR0/TIM0_CH[x]_GPR1 1: Use TBU_TS0(26 to 3) to store in TIM0_CH[x]_GPR0/TIM0_CH[x]_GPR1
6	CICTRL	Channel Input Control. 0: Use signal TIM_IN(x) as input for channel x 1: Use signal TIM_IN(x-1) as input for channel x (or TIM_IN(m-1) if x is 0)
5	ARU_EN	GPR0 and GPR1 register values routed to ARU 0: Registers content not routed 1: Registers content routed
4	OSM	One-shot mode 0: Continuous operation mode 1: One-shot mode **NOTE** After finishing the action in one-shot mode the TIM_EN bit is cleared automatically.

Table 25.72 GTM0TIM0xCTRL Register Contents (4/4)

Bit Position	Bit Name	Function
3 to 1	TIM_MODE	TIM channel x (x = 0 to 7) mode 000: PWM Measurement Mode (TPWM) 001: Pulse Integration Mode (TPIM) 010: Input Event Mode (TIEM) 011: Input Prescaler Mode (TIPM) 100: Bit Compression Mode (TBCM) 101: Gated Periodic Sampling Mode (TGPS) **NOTES** 1. If an undefined value is written to the TIM_MODE register, the hardware switches automatically to TIM_MODE = 000 (TPWM mode). 2. The TIM_MODE register should not be changed while the TIM channel is enabled. 3. If the TIM channel is enabled and operating in TPWM or TPIM mode after the first valid edge defined by DSL has occurred, a reconfiguration of DSL,ISL,TIM_MODE will not change the channel behavior. Reading these bit fields after reconfiguration will show the newly configured settings but the initial channel behavior will not change. Only a disabling of the TIM channel by setting TIM_EN = 0 and reenabling with TIM_EN = 1 will change the channel operation mode.
0	TIM_EN	TIM channel x (x = 0 to 7) enable 0: Channel disabled 1: Channel enabled **NOTES** 1. Enabling of the channel resets the registers ECNT, GTM0TIMixCNT, GTM0TIMixGPR0, and GTM0TIMixGPR1 to their reset values. 2. After finishing the action in one-shot mode the TIM_EN bit is cleared automatically. Otherwise, the bit must be cleared manually.

25.10.7.3 GTM0TIMixFLTRE (i = 0,1, x = 0 to 7)

Access: This register can be read/written in 32-bit units.

Address:

	GPR0															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 25.75 GTM0TIMixGPR0 Register Contents

Bit Position	Bit Name	Function
31 to 24	ECNT	Edge counter. **NOTE** The ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of ECNT.
23 to 0	GPR0	Input signal characteristic parameter 0.

NOTES

1. The ECNT register is reset to its initial value when the channel is enabled. Please note, that bit 0 depends on the input level coming from the filter unit and defines the reset value immediately.
2. The content of this register has different meaning for the TIM channels modes. The content directly depends on the bit fields EGPR0_SEL, GPR0_SEL of register GTM0TIMixCTRL.

25.10.7.6 GTM0TIMixGPR1 (i = 0,1, x = 0 to 7)

Access: This register can be read/written in 32-bit units.

Table 25.76 GTM0TIMixGPR1 Register Contents

Bit Position	Bit Name	Function
31 to 24	ECNT	Edge counter. **NOTE** The ECNT counts every incoming filtered edge (rising and falling). The counter value is uneven in case of detected rising, and even in case of detected falling edge. Thus, the input signal level is part of the counter and can be obtained by bit 0 of ECNT.
23 to 0	GPR1	Input signal characteristic parameter 1. **NOTE** In TBCM mode if EGPR1_SEL=1, GPR1_SEL=01 then TIM_INP_VAL is used as input in all other cases TIM Filter F_OUT is used as input and Bits GPR1(23:8) = 0

NOTES

1. The ECNT register is reset to its initial value when the channel is enabled. Please note, that bit 0 depends on the input level coming from the filter unit and defines the reset value immediately.
2. The content of this register has different meaning for the TIM channels modes. The content directly depends on the bit fields EGPR1_SEL, GPR1_SEL of register GTM0TIMixCTRL.
3. The content of this register can only be written in TIM channel mode TGPS.

25.10.7.7 GTM0TIMixCNT (i = 0,1, x = 0 to 7)

Access: This register can be read in 32-bit units.

Address:

GTM0TIM00CNT: <GTM_base> + 01008_H,	GTM0TIM10CNT: <GTM_base> + 01808_H
GTM0TIM01CNT: <GTM_base> + 01088_H,	GTM0TIM11CNT: <GTM_base> + 01888_H
GTM0TIM02CNT: <GTM_base> + 01108_H,	GTM0TIM12CNT: <GTM_base> + 01908_H

Table 25.79 GTM0TIMixIRQNOTIFY Register Contents

Bit Position	Bit Name	Function
31 to 6	Reserved	These bits are always read as 0. When written, write the initial value.
5	GLITCHDET	Glitch detected on channel x, (x = 0 to 7). 0: No glitch detected for last edge 1: Glitch detected for last edge **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
4	TODET	Timeout reached for input signal of channel x, (x = 0 to 7). See bit 0.
3	GPROFL	GPR0 and GPR1 data overflow, old data not read out before new data has arrived at input pin, (x = 0 to 7). See bit 0.
2	CNTOFL	SMU CNT counter overflow of channel x, (x = 0 to 7). See bit 0.
1	ECNTOFL	ECNT counter overflow of channel x, (x = 0 to 7). See bit 0.
0	NEWVAL	New measurement value detected by in channel x (x =0 to 7) 0: No event was occurred 1: NEWVAL was occurred on the TIM channel **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

25.10.7.10GTM0TIMixIRQEN (i = 0,1, x = 0 to 7)

Access: This register can be read/written in 32-bit units.

Address:

Table 25.84 GTM0TIMiINSRC Register Contents (1/2)

Bit Position	Bit Name	Function
31, 30	MODE_7	Input source to Channel 7, see bits 3, 2.
29, 28	VAL_7	Value to be fed to Channel 7, see bits 1, 0.
27, 26	MODE_6	Input source to Channel 6, see bits 3, 2.
25, 24	VAL_6	Value to be fed to Channel 6, see bits 1, 0.
23, 22	MODE_5	Input source to Channel 5, see bits 3, 2.
21, 20	VAL_5	Value to be fed to Channel 5, see bits 1, 0.
19, 18	MODE_4	Input source to Channel 4, see bits 3, 2.
17, 16	VAL_4	Value to be fed to Channel 4, see bits 1, 0.
15, 14	MODE_3	Input source to Channel 3, see bits 3, 2.
13, 12	VAL_3	Value to be fed to Channel 3, see bits 1, 0.
11, 10	MODE_2	Input source to Channel 2, see bits 3, 2.
9, 8	VAL_2	Value to be fed to Channel 2, see bits 1, 0.
7, 6	MODE_1	Input source to Channel 1, see bits 3, 2.
5, 4	VAL_1	Value to be fed to Channel 1, see bits 1, 0.
3, 2	MODE_0	Input source to Channel 0 multicore encoding in use (MODE_x(1) defines the state of the signal) 00: State is 0 (ignore write access) 01: Change state to 0 10: Change state to 1 11: State is 1 (ignore write access) Function table: MODE_x(1) = 0 , VAL_x(1) = 0: The input signal defined by bit field CICTRL of the TIM channel is used as input source. MODE_x(1) = 0 , VAL_x(1) = 1: The signal TIM_AUX_IN of the TIM channel is used as input source. MODE_x(1) = 1 : The state VAL_x(1) defines the input level for the TIM channel. **NOTE** Any read access to a MODE_x bit field will always result in a value 00 or 11 indicating current state. A modification of the state is only performed with the values 01 and 10. Writing the values 00 and 11 is always ignored.

Table 25.84 GTM0TIMiINSRC Register Contents (2/2)

Bit Position	Bit Name	Function
1, 0	VAL_0	Value to be fed to Channel 0 multicore encoding in use (VAL_x(1) defines the state of the signal) 00: State is 0 (ignore write access) 01: Change state to 0 10: Change state to 1 11: State is 1 (ignore write access) Function depends on the combination of VAL_x(1) and MODE_x(1) see MODE_0 description. **NOTE** Any read access to a VAL_x bit field will always result in a value 00 or 11 indicating current state. A modification of the state is only performed with the values 01 and 10. Writing the values 00 and 11 is always ignored.

25.11 ARU-connected Timer Output Module (ATOM)

25.11.1 Overview

The ARU-connected Timer Output Module (ATOM) is able to generate complex output signals without CPU interaction due to its connectivity to the ARU. Typically, output signal characteristics are provided over the ARU connection through submodules connected to ARU like e.g. the MCS, DPLL or PSM. Each ATOM submodule contains eight output channels which can operate independently from each other in several configurable operation modes. A block diagram of the ATOM submodule is depicted in **Figure 25.32**.

The following design variables are used inside this chapter. See **Section 25.18, GTM Device 207** and **Section 25.19, GTM Device 208** for correct value.

NOTE

cCATO	: ATOM channel count; number of channels per instance – 1

25.11.1.1 ATOM block diagram

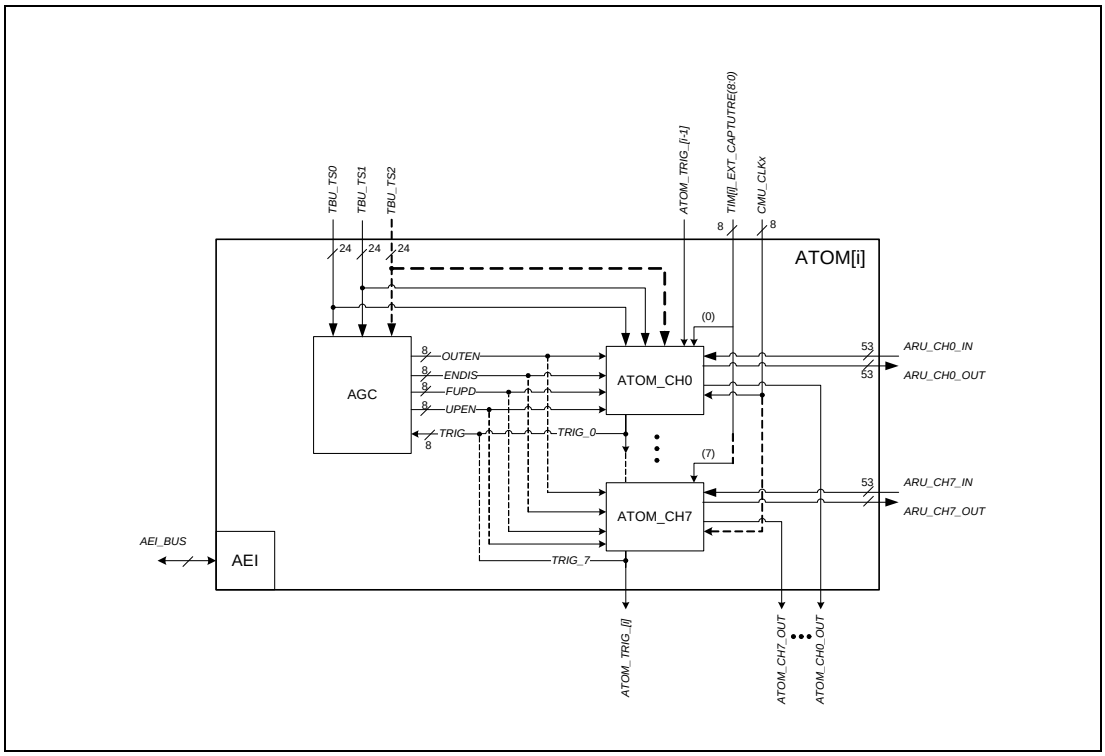

Figure 25.32 ATOM block diagram

The architecture of the ATOM submodule is similar to the TOM submodule, but there are some differences. First, the ATOM integrates only eight output channels. Hence, there exists one ATOM Global Control subunit (AGC) for the ATOM channels. The ATOM is connected to the ARU and can set up individual read requests from the ARU and write requests to the ARU. Furthermore, the ATOM channels are able to generate signals on behalf of time stamps and the ATOM channels are able to generate a serial output signal on behalf of an internal shift register.

Each ATOM channel provides five modes of operation:

- ATOM Signal Output Mode Immediate (SOMI)
- ATOM Signal Output Mode Compare (SOMC)
- ATOM Signal Output Mode PWM (SOMP)
- ATOM Signal Output Mode Serial (SOMS)
- ATOM Signal Output Mode Buffered Compare (SOMB)

These modes are described in more detail in **Section 25.11.3, ATOM Channel modes** .

The ATOM channels' operation registers (e.g. counter, compare registers) are 24 bit wide. Moreover, the input clocks for the ATOM channels come from the configurable CMU_CLKx signals of the CMU submodule. This gives the freedom to select a programmable input clock for the ATOM channel counters. The ATOM channel is able to generate a serial bit stream, which is shifted out at the ATOM[i]_CH[x]_OUT output. When configured in this serial shift mode (SOMS) the selected CMU clock defines the shift frequency.

Each ATOM channel provides a so called operation and shadow register set. With this architecture it is possible to work with the operation register set, while the shadow register set can be reloaded with new parameters over CPU and/or ARU.

When update via ARU is selected, it is possible to configure if both shadow registers are updated via ARU or only one of the shadow registers is updated for SOMP mode.

On the other hand, the shadow registers can be used to provide data to the ARU when one or both of the compare units inside an ATOM channel match. This feature is only applicable in SOMC mode.

In TOM channels it is possible to reload the content of the operation registers with the content of the corresponding shadow registers and change the clock input signal for the counter register simultaneously. This simultaneous change of the input clock frequency together with reloading the operation registers is also implemented in the ATOM channels.

In addition to the feature that the CPU can select another CMU_CLKx during operation (i.e. updating the shadow register bit field CLK_SRC_SR of the GTM0ATOMixCTRL register), the selection can also be changed via the ARU. Then, for the clock source update, the ACBI register bits of the GTM0ATOMixSTAT register are used as a shadow register for the new clock source.

In general, the behavior of the compare units CCU0 and CCU1 and the output signal behavior is controlled with the ACB bit field inside the GTM0ATOMixCTRL register when the ARU connection is disabled and the behavior is controlled via ARU through the ACBI bit field of the GTM0ATOMixSTAT register, when the ARU is enabled.

Since the ATOM is connected to the ARU, the shadow registers of an ATOM channel can be reloaded via the ARU connection or via CPU over its AEI interface. When loaded via the ARU interface, the shadow registers act as a buffer between the ARU and the channel operation registers. Thus, a new parameter set for a PWM can be reloaded via ARU into the shadow registers, while the operation registers work on the actual parameter set.

The trigger signal ATOM_TRIG_[i–1] of ATOM instance i comes from the preceding instance i–1, the trigger ATOM_TRIG_[i] is routed to succeeding instance i+1.

Note, ATOM0 is connected to its own output ATOM_TRIG_0, i.e. the last channel of ATOM instance 0 can trigger the first channel of ATOM instance 0 (this path is registered, which means delayed by one SYS_CLK period).

25.11.1.2 ATOM Global control (AGC)

Synchronous start and stop of more than one output channel is possible with the AGC subunit. This subunit has the same functionality as the TGC subunit of the TOM submodule. For a description of the AGC subunit functionality, please refer therefore to chapter **(2) AGC Subunit**.

(1) Overview

There exist one global channel control unit (AGC) to drive a number of individual ATOM channels synchronously by external or internal events.

An AGC can drive up to eight ATOM channels.

The ATOM submodule supports four different kinds of signalling mechanisms:

- Global enable/disable mechanism for each ATOM channel with control register GTM0ATOMiAGCENDISCTRL and status register GTM0ATOMiAGCENDISSTAT
- Global output enable mechanism for each ATOM channel with control register GTM0ATOMiAGCOUTENCTRL and status register GTM0ATOMiAGCOUTENSTAT
- Global force update mechanism for each ATOM channel with control register GTM0ATOMiAGCFUPDCTRL
- Update enable of the register CM0, CM1 and CLK_SRC for each ATOM channel with the control bit field UPEN_CTRL[z] of GTM0ATOMiAGCGLBCTRL

(2) AGC Subunit

Each of the first three individual mechanisms (enable/disable of the channel, output enable and force update) can be driven by three different trigger sources.

The three trigger sources are :

- the host CPU (bit HOST_TRIG of register GTM0ATOMiAGCGLBCTRL)
- the TBU time stamp (signal TBU_TS0..2 if available)
- the internal trigger signal TRIG (bunch of trigger signals TRIG_[x]) which can be either the trigger TRIG_CCU0 of channel x, the trigger of preceeding channel x-1 (i.e signal TRIG_[x–1]) or the external trigger TIM_EXT_CAPTURE(x) of assigned TIM channel x.

The first way is to trigger the control mechanism by a direct register write access via host CPU (bit HOST_TRIG of register AOM[i]_AGC_GLB_CTRL).

The second way is provided by a compare match trigger on behalf of a specified time base coming from the module TBU (selected by bits TBU_SEL) and the time stamp compare value defined in the bit field ACT_TB of register GTM0ATOMiAGCACTTB.

Note, a signed compare of ACT_TB and selected TBU_TS[x] is performed.

The third possibility is the input TRIG (bunch of trigger signals TRIG_[x]) coming from the ATOM channels 0 to 7.

The corresponding trigger signal TRIG_[x] coming from channel [x] can be masked by the register GTM0ATOMiAGCINTTRIG.

To enable or disable each individual ATOM channel, the registers GTM0ATOMiAGCENDISCTRL and/or GTM0ATOMiAGCENDISSTAT have to be used.

The register GTM0ATOMiAGCENDISSTAT controls directly the signal ENDIS. A write access to this register is possible.

The register GTM0ATOMiAGCENDISCTRL is a shadow register that overwrites the value of register AOM[i]_AGC_ENDIS_STAT if one of the three trigger conditions matches.

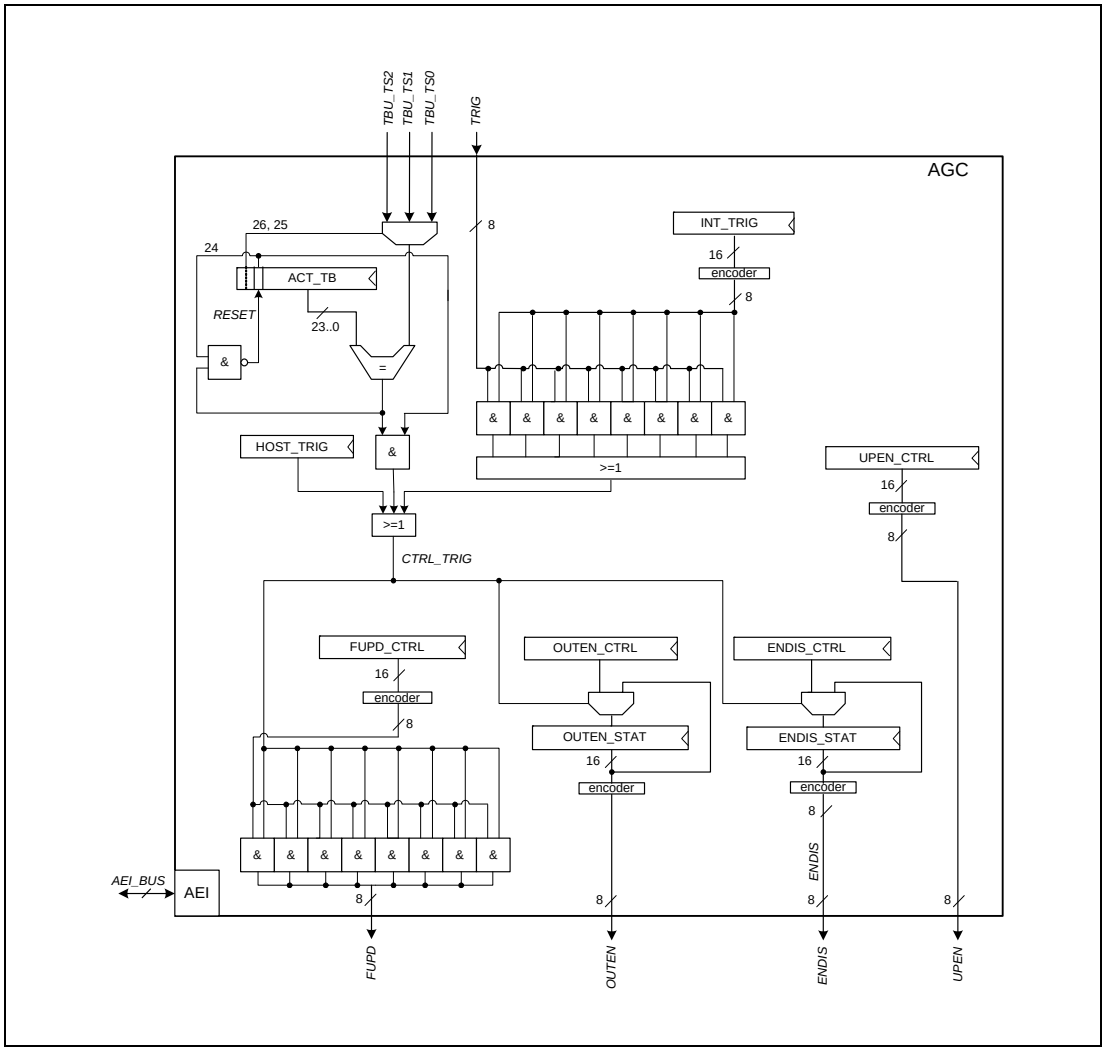

Figure 25.33 ATOM Global channel control mechanism

The output of the individual ATOM channels can be controlled using the register GTM0ATOMiAGCOUTENCTRL and GTM0ATOMiAGCOUTENSTAT.

The register GTM0ATOMiAGCOUTENSTAT controls directly the signal OUTEN. A write access to this register is possible.

The register GTM0ATOMiAGCOUTENCTRL is a shadow register that overwrites the value of register GTM0ATOMiAGCOUTENSTAT if one of the three trigger conditions matches.

If a ATOM channel is disabled by the register GTM0ATOMiAGCOUTENSTAT, the actual value of the channel output at ATOM_CH[x]_OUT is defined by the signal level bit (SL) defined in the channel control register GTM0ATOMixCTRL.

If the output is enabled, the output at ATOM_CH[x]_OUT depends on value of Flip-Flop SOUR.

The register GTM0ATOMiAGCFUPDCTRL defines which of the ATOM channels receive a FORCE_UPDATE event if the trigger signal CTRL_TRIG is raised.

The register bits UPEN_CTRL[x] defines for which ATOM channel the update of the working register CM0, CM1 and CLK_SRC by the corresponding shadow register SR0, SR1 and CLK_SRC_SR is

enabled. If update is enabled, the register CM0, CM1 and CLK_SRC will be updated on reset of counter register CN0 (see **Figure 25.34**).

(3) ATOM Channel mode overview

Each ATOM channel offers the following different operation modes:

In ATOM Signal Output Mode Immediate (SOMI), the ATOM channels generate an output signal immediately after receiving an ARU word according to the two signal level output bits of the ARU word received through the ACBI bit field. Due to the fact, that the ARU destination channels are served in a round robin order, the output signal can jitter in this mode with a jitter of the ARU round trip time.

In ATOM Signal Output Mode Compare (SOMC), the ATOM channel generates an output signal on behalf of time stamps that are located in the ATOM operation registers. These time stamps are compared with the time stamps, the TBU generates. The ATOM is able to receive new time stamps either by CPU or via the ARU. The new time stamps are directly loaded into the channels operation register. The shadow registers are used as capture registers for two time base values, when a compare match of the channels operation registers occurs.

In ATOM Signal Output Mode PWM (SOMP), the ATOM channel is able to generate simple and complex PWM output signals like the TOM submodule by comparing its operation registers with a submodule internal counter. In difference to the TOM, the ATOM shadow registers can be reloaded by the CPU and by the ARU in the background, while the channel operates on the operation registers.

In ATOM Signal Output Mode Serial (SOMS), the ATOM channel generates a serial output bit stream on behalf of a shift register. The number of bits shifted and the shift direction is configurable. The shift frequency is determined by one of the CMU_CLKx clock signals. See **Section 25.11.3.4, ATOM Signal Output Mode Serial (SOMS)** for further details.

In ATOM Signal Output Buffered Compare (SOMB), the ATOM channel generates an output signal on behalf of time stamps that located in the ATOM operation registers. These time stamps are compared with the time stamps, the TBU generates. The ATOM is able to receive new compare values either by CPU or via the ARU. The new compare values received via ARU are stored first in the shadow register and only if previous compare match is occurred, the operation register are updated with the content of the shadow register.

25.11.2 ATOM Channel architecture

Each ATOM channel is able to generate output signals according to four operation modes. The architecture of the ATOM channels is similar to the architecture of the TOM channels. The general architecture of an ATOM channel is depicted in **Figure 25.34**.

25.11.2.1 ATOM channel architecture

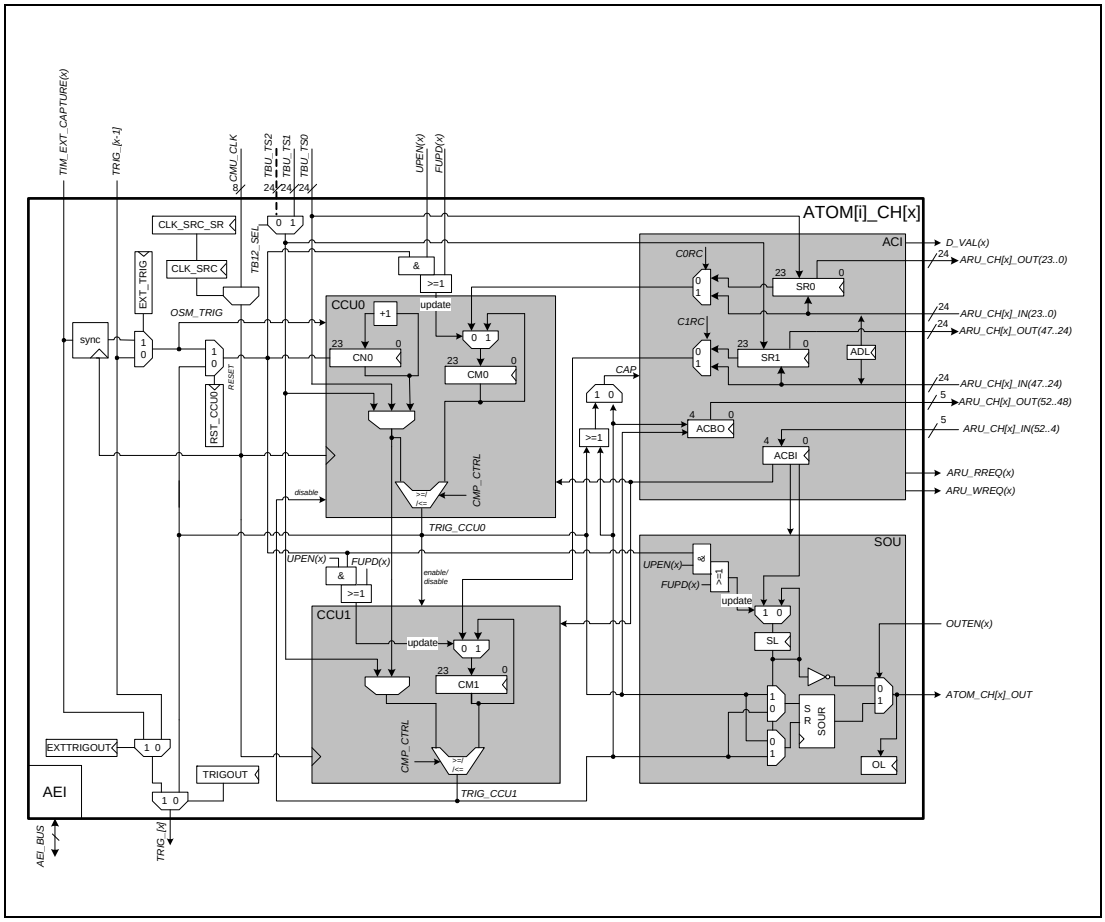

Figure 25.34 ATOM channel architecture

In all ATOM channels the operation registers CN0, CM0 and CM1 and the shadow registers SR0 and SR1 are the 24 bit width. The comparators inside CCU0 and CCU1 provide a selectable signed greater/equal or less/equal comparison to compare against the GTM time bases TBU_TS0, TBU_TS1 and, if available, TBU_TS2 . See **Section 25.9, Time Base Unit (TBU)** for further details. For an overview of the implemented TBU submodule version see **Section 25.6.1.1, GTM Architecture Block Diagram** . The CCU0 and CCU1 units have different tasks for the different ATOM channel modes.

The signed compare is used to detect time base overflows and to guarantee, that a compare match event can be set up for the future even when the time base will first overflow and then reach the compare value. Please note, that for a correct behavior of this signed compare, the new compare value must not be specified larger/smaller than half of the range of the total time base value ($7FFFFF_H$).

In SOMC/SOMB mode, the two compare units CCUx can be used in combination to each other. When used in combination, the trigger lines TRIG_CCU0 and TRIG_CCU1 can be used to enable/disable the other compare unit on a match event. See **Section 25.11.3.2, ATOM Signal Output Mode**

Compare (SOMC) and **Section 25.11.3.5, ATOM Signal Output Mode Buffered Compare(SOMB)** for further details.

The Signal Output Unit (SOU) generates the output signal for each ATOM channel. This output signal level depends on the ATOM channel mode and on the SL bit of the GTM0ATOMixCTRL register in combination with the two control bits. These two control bits ACB(1) and ACB(0) can either be received via CPU in the ACB register field of the GTM0ATOMixCTRL register or via ARU in the ACBI bit field of the GTM0ATOMixSTAT register.

The SL bit in the GTM0ATOMixCTRL register defines in all modes the operational behavior of the ATOM channel.

When the channel and its output is disabled, the output signal level of the channel is the inverse of the SL bit.

In SOMI, SOMC and SOMB mode the output signal level depends on the SL, ACB0 and ACB1 bits. In SOMP mode the output signal level depends on the two trigger signals TRIG_CCU0 and TRIG_CCU1 since theses two triggers define the PWM timing characteristics and the SL bit defines the level of the duty cycle. In SOMS mode the output signal level is defined by the bit pattern that has to be shifted out by the ATOM channel. The bit pattern is located inside the CM1 register.

The ARU Communication Interface (ACI) subunit is responsible for requesting data routed through ARU to the ATOM channel in SOMI, SOMP, SOMB and SOMS modes, and additionally for providing data to the ARU in SOMC mode.

In SOMC mode the ACI shadow registers have a different behavior and are used as output buffer registers for data send to ARU.

25.11.2.2 ARU Communication Interface

The ATOM channels have an ARU Communication Interface (ACI) subunit. This subunit is responsible for data exchange from and to the ARU. This is done with the two implemented registers SR0, SR1, and the ACBI and ACBO bit fields that are part of the GTM0ATOMixSTAT register. The ACI architecture is shown in **Figure 25.35**.

If the ARU_EN bit is set inside the GTM0ATOMixCTRL register, the ATOM channel is enabled by setting the enable bits inside the GTM0ATOMiAGCENDISSTAT register and the CPU hasn't written data not equal to zero into the CM0, CM1, SR0, SR1 register, the ATOM channel will first request data from the ARU before the signal generation starts in SOMP, SOMS, SOMC and SOMB mode.

Note: if in SOMP mode there is data inside the CM0 or SR0 register not equal to '0' the channel counter CN0 will start counting immediately, regardless whether the channel has received ARU data yet.

Note: if in SOMS mode there is data inside the CM0 or SR0 register not equal to '0' the channel will start shifting immediately, regardless whether the channel has received ARU data yet.

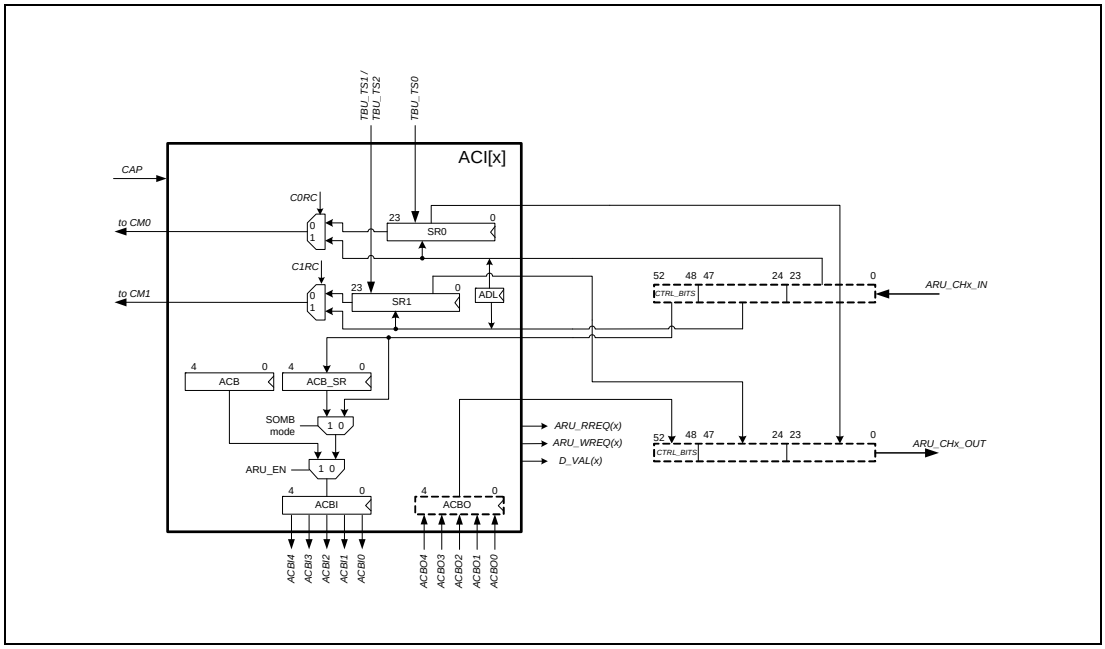

Figure 25.35 ACI architecture overview

Incoming ARU data (53 bit width signal ARU_CHx_IN) is split into three parts by the ACI and communicated to the ATOM channel registers. In SOMI, SOMP, SOMS and SOMB modes incoming ARU data ARU_CHx_IN is split in a way that the lower 24 bits of the ARU data (23 down to 0) are stored in the SR0 register, the upper bits (47 down to 24) are stored in the SR1 register. The bits 52 down to 48 (CTRL_BITS) are stored in SOMI, SOMP and SOMS mode in the ACBI bit field of the register GTM0ATOMixSTAT, in SOMB mode in the internal ACB_SR register.

The ATOM channel has to ensure, that in a case when the channel operation registers CM0 and CM1 are updated with the SR0 and SR1 register content and an ARU transfer to these shadow registers happens in parallel that either the old data in both shadow registers is transferred into the operation registers or both new values from the ARU are transferred.

In SOMC mode incoming ARU data ARU_CHx_IN is written directly to the ATOM channel operation register in the way that the lower 24 bits (23 down to 0) are written to CM0, and the bits 47 down to 24 are written to register CM1. The bits 52 down to 48 are stored in the ACBI bit field of the GTM0ATOMixSTAT register and control the behavior of the compare units and the output signal of the ATOM channel.

In SOMC mode the SR0 and SR1 registers serve as capture registers for the time stamps coming from TBU whenever a compare match event is signalled by the CCU0 and/or CCU1 subunits via the CAP signal line. These two time stamps are then provided together with actual ATOM channel status information located in the ACBO bit field to the ARU at the dedicated ARU write address of the ATOM channel when the ARU is enabled.

The encoding of the ARU control bits in the different ATOM operation modes is described in more detail in the following chapters.

25.11.3 ATOM Channel modes

As described above, each ATOM channel can operate independently from each other in one of five dedicated output modes:

- ATOM Signal Output Mode Immediate (SOMI)
- ATOM Signal Output Mode Compare (SOMC)
- ATOM Signal Output Mode PWM (SOMP)
- ATOM Signal Output Mode Serial (SOMS)
- ATOM Signal Output Mode Buffered Compare (SOMB)

The Signal Output Mode PWM (SOMP) is principally the same like the output mode for the TOM submodule except the bit reverse mode which is not included in the ATOM. In addition, it is possible to reload the shadow registers over the ARU without the need of a CPU interaction. The three other modes provide additional functionality for signal output control. All operation modes are described in more detail in the following sections.

Note that in any output mode, if a channel is enabled, one-shot mode is disabled (OSM = 0; only used in modes SOMP and SOMS) and CM0 >= CN0, the counter CN0 is incrementing until it reaches CM0.

To avoid unintended counting of CN0 after enabling a channel, it is recommended to reset a channel (or at least CN0 and CM0) before any change on the mode bits MODE, ARU_EN and OSM.

25.11.3.1 ATOM Signal Output Mode Immediate (SOMI)

In ATOM Signal Output Mode Immediate (SOMI), the ATOM channel generates output signals on the ATOM[i]_CH[x]_OUT output port immediate after update of the bit ACBI(0) of register GTM0ATOMixSTAT or ACB(0) bit of register GTM0ATOMixCTRL.

If ARU access is enabled by setting bit ARU_EN in register GTM0ATOMixCTRL, the update of the output ATOM[i]_CH[x]_OUT depends on the bit ACBI(0) of register GTM0ATOMixSTAT received at the ACI subunit and the bit SL bit of register GTM0ATOMixCTRL. The remaining 48 ARU bits (47 down to 0) have no meaning in this mode.

If ARU access is disabled, the update of the output ATOM[i]_CH[x]_OUT depends on the bit ACB(0) and the bit SL of register GTM0ATOMixCTRL.

The initial ATOM channel port pin ATOM[i]_CH[x]_OUT signal level has to be specified by the SL bit field of the GTM0ATOMixCTRL register when OUTEN_CTRL register bit field OUTEN_CTRLx is disabled (see **Section 25.11.6.5, GTM0ATOMiAGCOUTENCTRL (i = 0 to 2)**) for details.

In SOMI mode the output behavior depends on the SL bit of register GTM0ATOMixCTRL and the bit ACBI(0) of the GTM0ATOMixSTAT register or the bit ACB0 of register GTM0ATOMixCTRL:

Table 25.91 ATOM Signal Output Mode Immediate (SOMI)

SL	ACBI(0)/ACB(0)	Output Behavior
0	0	Set output to inverse of SL (1)
0	1	Set output to SL (0)
1	0	Set output to inverse of SL (0)
1	1	Set output to SL (1)

The signal level bit ACBI(0) is transferred to the SOU subunit of the ATOM and made visible at the output port according to the table above immediately after the data was received by the ACI. This can introduce a jitter on the output signal since the ARU channels are served in a time multiplexed fashion.

(1) GTM0ATOMixCTRL in SOMI mode (i = 0, x = 0 to 7, i = 1, x = 0 to 7, i = 2, x = 0 to 4)

Access: This register can be read/written in 32-bit units.

25.11.3.2 ATOM Signal Output Mode Compare (SOMC)

(1) Overview

In ATOM Signal Output Mode Compare (SOMC) the output action is performed in dependence of the comparison between input values located in CM0 and/or CM1 registers and the two (three) time base values TBU_TS0 or TBU_TS1 (or TBU_TS2) provided by the TBU. For a description of the time base generation see the TBU specification in **Section 25.9, Time Base Unit (TBU)**. It is configurable, which of the two (three) time bases is to be compared with one or both values in CM0 and CM1.

The behavior of the two compare units CCU0 and CCU1 is controlled either with the bits 4 down to 2 of ACB bit field inside the GTM0ATOMixCTRL register, when the ARU connection is disabled or with the ACBI bit field of the GTM0ATOMixSTAT register, when the ARU is enabled. In that case the ACB bit field is updated via the ARU control bits 52 down to 48.

The CCUx trigger signals TRIG_CCU0 and TRIG_CCU1 always create edges, dependent on the predefined signal level in SL bit in combination with two control bits that can be specified by either ARU or CPU within the aforementioned GTM0ATOMixCTRL or GTM0ATOMixSTAT registers.

In SOMC mode the channel is always disabled after the specified compare match event occurred. The shadow registers are used to store two time stamp values at the match time. The channel can be enabled again by first reading the shadow registers, either by CPU or ARU and by providing new data for CMx registers through CPU or ARU. For a detailed description see **(2), SOMC Mode under CPU control** and **(3), SOMC Mode under ARU control**.

If three time bases exist for the GTM-IP there must be a preselection between TBU_TS1 and TBU_TS2 for the ATOM channel. This can be done with TB12_SEL bit in the GTM0ATOMixCTRL register.

The comparison in CCU0/1 with time base TBU_TS1 or TBU_TS2 can be done on a greater/equal or less/equal compare according to the CMP_CTRL bit. This control bit has no effect to a compare unit CCU0 or CCU1 that compares against TBU_TS0. In this case always a greater/equal compare is done. The bit CMP_CTRL is part of the GTM0ATOMixCTRL register.

When configured in SOMC mode, the channel port pin has to be initialized to an initial signal level. This initial level after enabling the ATOM channel is determined by the SL bit in the GTM0ATOMixCTRL register. If the output is disabled, the signal level is set to the inverse level of the SL bit.

If the channel is disabled, the register SOUR is set to the SL bit in the GTM0ATOMixCTRL register.

On a compare match event the shadow register SR0 and SR1 are used to capture the TBU time stamp values. SR0 always holds TBU_TS0 and SR1 either holds TBU_TS1 or TBU_TS2 dependent on the TB12_SEL bit in the GTM0ATOMixCTRL register.

Please note, that when the channel is disabled and the compare registers are written, the compare registers CMx are loaded with the written value and the channel starts with the comparison on behalf of this values, when the channel is enabled.

(2) SOMC Mode under CPU control

As already mentioned above the ATOM channel can be controlled either by CPU or by ARU. When the channel should be controlled by CPU, the ARU_EN bit inside the GTM0ATOMixCTRL register has to be reset.

The output of the ATOM channel is set on a compare match event depending on the ACB10 bit field in combination with the SL bit both located in the GTM0ATOMixCTRL register. The output behavior according to the ACB10 bit field in the control register is shown in the following table:

Table 25.93 The output behavior according to the ACB10 bit field in the control register

SL	ACB10(5)	ACB10(4)	Output behavior
0	0	0	No signal level change at output (exception in **Table 25.96, ATOM CCUx Serve first definition ACB42 = '001'**)
0	0	1	Set output signal level to 1
0	1	0	Set output signal level to 0
0	1	1	Toggle output signal level (exception in **Table 25.96, ATOM CCUx Serve first definition ACB42 = '001'**)
1	0	0	No signal level change at output(exception in **Table 25.96, ATOM CCUx Serve first definition ACB42 = '001'**)
1	0	1	Set output signal level to 0
1	1	0	Set output signal level to 1
1	1	1	Toggle output signal level (exception in **Table 25.96, ATOM CCUx Serve first definition ACB42 = '001'**)

The capture/compare strategy of the two CCUx units can be controlled with the ACB42 bit field inside the GTM0ATOMixCTRL register. The meaning of these bits is shown in the following table:

Table 25.94 The meaning of ACB42 bits (1/2)

ACB42(8)	ACB42(7)	ACB42(6)	CCUx control
0	0	0	Serve First: Compare in CCU0 using *TBU_TS0* and in parallel in CCU1 using *TBU_TS1* or *TBU_TS2*. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACB10(5) and ACB10(4). Details see **Table 25.96**
0	0	1	Serve First: Compare in CCU0 using *TBU_TS0* and in parallel in CCU1 using *TBU_TS1* or *TBU_TS2*. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACB10(5) and ACB10(4). Details see **Table 25.96**
0	1	0	Compare in CCU0 only, use time base *TBU_TS0*. Output signal level is defined by combination of SL, ACB10(5) and ACB10(4) bits.
0	1	1	Compare in CCU1 only, use time base *TBU_TS1* or *TBU_TS2*. Output signal level is defined by combination of SL, ACB10(5) and ACB10(4) bits.
1	0	0	Serve Last: Compare in CCU0 and then in CCU1 using *TBU_TS0*. Output signal level when CCU0 matches is defined by combination of SL, ACB10(5) and ACB10(4). On the CCU1 match the output level is toggled.

Table 25.94 The meaning of ACB42 bits (2/2)

ACB42(8)	ACB42(7)	ACB42(6)	CCUx control
1	0	1	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU0 matches is defined by combination of SL, ACB10(5) and ACB10(4). On the CCU1 match the output level is toggled.
1	1	0	Serve Last: Compare in CCU0 using TBU_TS0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU1 matches is defined by combination of SL, ACB10(5) and ACB10(4).
1	1	1	Not used when ARU disabled.

The behavior of the ACBI/ACB42 bit combinations ‘000’ and ‘001’ is described in more detail in **Table 25.95, ATOM CCUx Serve first definition ACB42 = ‘000’** and **Table 25.96, ATOM CCUx Serve first definition ACB42 = ‘001’**.

						1	1	toggle

If the ATOM channel is enabled, the CM0 and/or CM1 registers and the ACB42 bit field of the GTM0ATOMixCTRL register can be updated by the CPU as long as the first match event occurs in case of a serve last compare strategy or as long as the overall match event in case of the other compare strategies.

After a compare match event that causes an update of the shadow registers SR0/SR1 and before reading the SR0 and/or SR1 register via ARU, the update of the registers CM0 and/or CM1 is possible but has no effect.

To set up a new compare action, first the SR0 and/or SR1 register containing captured values have to be read and then new compare values have to be written into the register CM0 and/or CM1.

Which CMx register has to be updated depends on the compare strategy defined in the ACB42 bit field of the channel control register. Since the channel immediately starts with the comparison after the CMx register was/were written, the compare strategy has to be updated before the CMx registers are written.

For the serve last compare strategies, if the register CM0 and CM1 are updated, it can happen that one or both compare values are already located in the past. In any way the ATOM channel will first wait until both compare values are written before it starts the time base comparisons to avoid a deadlock.

The CPU can check at any time if at least one of the ATOM channels' capture compare register contains valid data and waits for a compare event to happen. This is signalled by the DV bit inside the GTM0ATOMixSTAT register.

Note, for serve last compare strategies, if DV bit is currently not set, writing to CM0 or CM1 sets immediately the DV bit although the compare is only started if both values are written.

In SOMC mode and CCUx control mode 'serve last' exist an exception for update of register CM0/CM1. If in this mode the CCU0 compare match event occurred, the update of register CM0/CM1 via CPU is blocked until the CCU1 compare match event.

In the serve last mode (ACB42 = “100” or ACB42 = “101”) it is possible to generate very small spikes on the output pin by loading CM0 and CM1 with two time stamp values for TBU_TS0, TBU_TS1 or TBU_TS2 close together. The output pin will then be set or reset dependent on the SL bit and the specified ACB10(5) and ACB10(4) bits in the ACB10 bit field of the GTM0ATOMixCTRL register on the first match event and the output will toggle on the second compare event in the CCU1 compare unit.

It is important to note, that the bigger (smaller) time stamp has to be loaded into the CM1 register, since the CCU0 will enable the CCU1 once it has reached its comparison time stamp. The order of the comparison time stamps depends on the defined greater/equal or less/equal comparison of the CCUx units.

In addition to storing the captured time stamps in the shadow registers, the ATOM channel provides the result of the compare match event in the ACBO(4) and ACBO(3) bits of the GTM0ATOMixSTAT register. The meaning of the bits is shown in the following table:

Table 25.97 ACDO bits

ACBO(4)	ACBO(3)	Indication
0	1	CCU0 compare match occurred
1	0	CCU1 compare match occurred

Please note, that in case of the ‘serve last’ compare strategy, when the SLA-bit in the GTM0ATOMixCTRL register is not set, the ACBO(4) bit is always set and the ACBO(3) bit is always reset after the compare match event occurred.

The ACBO bit field is reset, when the DV bit is set.

Depending on the capture compare unit where the time base matched the interrupt CCU0TCx_IRQ or CCU1TCx_IRQ is raised.

The behavior of an ATOM channel in SOMC mode under CPU control is visualized in **Figure 25.36** .

NOTE

In case of 'serve first' compare strategy, if both events CCU0 and CCU1 occur at the same point in time, both interrupts will be raised.

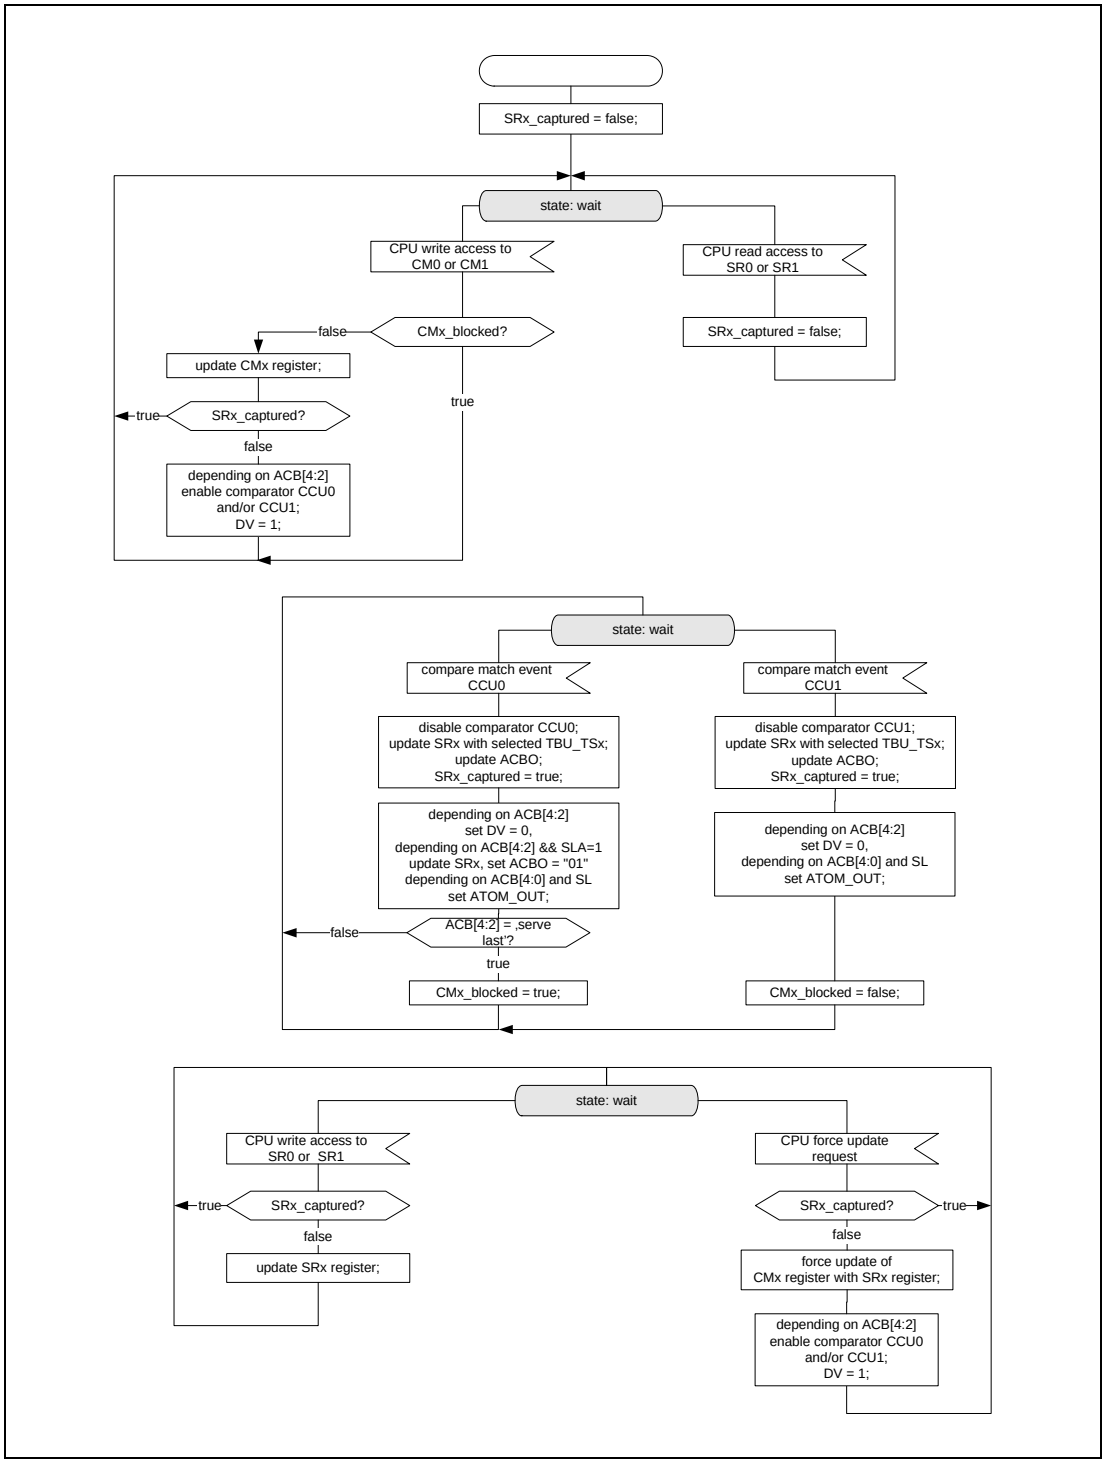

Figure 25.36 SOMC state diagram for channel under CPU control

(3) SOMC Mode under ARU control

When the channel should be controlled by ARU, the ARU_EN bit inside the GTM0ATOMixCTRL register has to be set.

In case, the ATOM channel is under ARU control the content for the compare registers CM0 and CM1 as well as the update of the compare strategy can be loaded via the 53 bit ARU word.

The ARU word 23 to 0 is loaded into the CM0 register while the ARU word 47 to 24 is loaded into the CM1 register. The five ARU control bits 52 to 48 are loaded into the ACBI bit field of the GTM0ATOMixSTAT register and control the channel compare strategy as well as the output behavior in case of compare match events.

For the five ARU control bits 52 to 48 the bits 49 and 48 are loaded into the ACBI bits 1 and 0. The output behavior also depends on the setting of the SL bit inside of the GTM0ATOMixCTRL register and is shown in the following table:

Table 25.98 The output behavior depends on the setting of the SL bit

SL	ACBI(1)	ACBI(0)	Output behavior
0	0	0	No signal level change at output (exception in **Table 25.95** and **Table 25.96**)
0	0	1	Set output signal level to 1
0	1	0	Set output signal level to 0
0	1	1	Toggle output signal level (exception in **Table 25.95** and **Table 25.96**)
1	0	0	No signal level change at output (exception in **Table 25.95** and **Table 25.96**)
1	0	1	Set output signal level to 0
1	1	0	Set output signal level to 1
1	1	1	Toggle output signal level(exception in **Table 25.95** and **Table 25.96**)

For the five ARU control bits 52 to 48 the bits 52 to 50 are loaded into the ACBI bits 4 to 2. With these three bits the capture/compare units CCUx can be controlled as shown in the following table:

Table 25.99 CCUxcontrol (1/2)

ACBI(4)	ACBI(3)	ACBI(2)	CCUx control
0	0	0	Serve First: Compare in CCU0 using TBU_TS0 and in parallel in CCU1 using TBU_TS1 or TBU_TS2. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACBI(1) and ACBI(0). Details see **Table 25.96**
0	0	1	Serve First: Compare in CCU0 using TBU_TS0 and in parallel in CCU1 using TBU_TS1 or TBU_TS2. Disable other CCUx on compare match. Output signal level on the compare match of the matching CCUx unit is defined by combination of SL, ACBI(1) and ACBI(0). Details see **Table 25.95**
0	1	0	Compare in CCU0 only, use time base TBU_TS0. Output signal level is defined by combination of SL, ACBI(1) and ACBI(0) bits.
0	1	1	Compare in CCU1 only, use time base TBU_TS1 or TBU_TS2. Output signal level is defined by combination of SL, ACBI(1) and ACBI(0) bits.
1	0	0	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS0. Output signal level when CCU0 matches is defined by combination of SL, ACBI(1) and ACBI(0). On the CCU1 match the output level is toggled.

Table 25.99 CCUxcontrol (2/2)

ACBI(4)	ACBI(3)	ACBI(2)	CCUx control
1	0	1	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU0 matches is defined by combination of SL, ACBI(1) and ACBI(0). On the CCU1 match the output level is toggled.
1	1	0	Serve Last: Compare in CCU0 using TBU_TS0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU1 matches is defined by combination of SL, ACBI(1) and ACBI(0).
1	1	1	Change ARU read address to ATOM_RDADDR1 DV flag is not set. Neither ACBI(1) nor ACBI(0) is evaluated.

It is important to note that the bit combination “111” for the ACBI(4), ACBI(3) and ACBI(2) bits forces the channel to request new compare values from another destination read address defined in the ATOM_RDADDR1 bit field of the GTM0ATOMixRDADDR register. After data was successfully received and the compare event occurred the ATOM channel switches back to ATOM_RDADDR0 to receive the next data from there.

After the specified compare match event, the captured time stamps are stored in SR0 and SR1 and the compare result is stored in the ACBO bit field of the GTM0ATOMixSTAT register. The meaning of the ACBO(4) and ACBO(3) bits of the GTM0ATOMixSTAT is shown in the following table:

Table 25.100 ACBO bits

ACBO(4)	ACBO(3)	Return value to ARU
0	1	CCU0 compare match occurred
1	0	CCU1 compare match occurred

Please note, that in case of the ‘serve last’ compare strategy, when the SLA-bit in the GTM0ATOMixCTRL register is not set, the ACBO(4) bit is always set and the ACBO(3) bit is always reset after the compare match event occurred.

The ACBO bit field is reset, when the DV bit is set.

Depending on the capture compare unit where the time base matched the interrupt CCU0TCx_IRQ or CCU1TCx_IRQ is raised.

When CCU0 and CCU1 is used for comparison it is possible to generate very small spikes on the output pin by loading CM0 and CM1 with two time stamp values for TBU_TS0, TBU_TS1 or TBU_TS2 close together. The output pin will then be set or reset dependent on the SL bit and the specified ACBI(0) and ACBI(1) bits in the ACBI bit field of the GTM0ATOMixSTAT register on the first match event and the output will toggle on the second match event.

It is important to note, that the bigger (smaller) time stamp has to be loaded into the CM1 register, since the CCU0 will enable the CCU1 once it has reached its comparison time stamp. The order of the comparison time stamps depends on the defined greater/equal or less/equal comparison of the CCUx units.

For compare strategy ‘serve last’ the CCU0 and CCU1 compare match may occur sequentially. During different phases of compare match the CPU access rights to register CM0 and CM1 as well as to WR_REQ bit is different. These access rights by CPU to register CM0 and CM1 and the WR_REQ are depicted in the following figure.

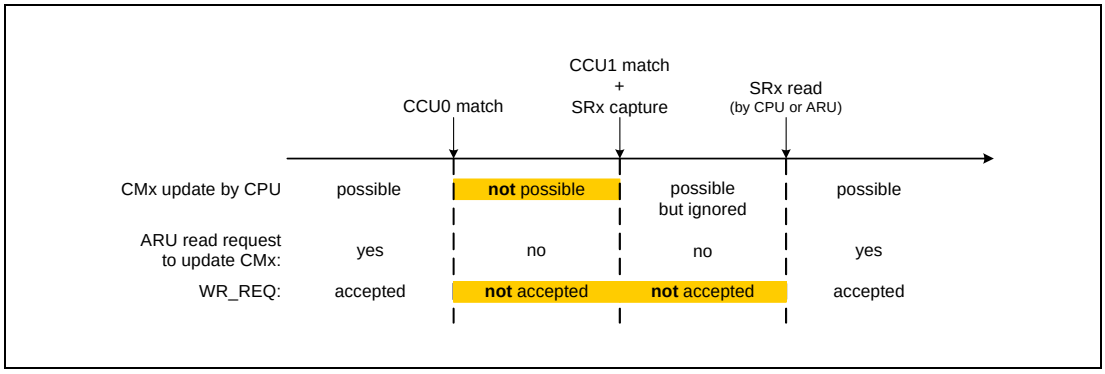

Figure 25.37 CPU access rights in case of compare strategy 'serve last

(a) ARU Non-Blocking mode

When the compare registers are updated via ARU the update behavior of the channel is configurable with the ABM bit inside the GTM0ATOMixCTRL register. When the ABM bit is reset, the ATOM channel is in ARU non-blocking mode.

In this ARU non-blocking mode, data received via ARU is continuously transferred to the registers CM0 and CM1 and the bit field ACBI of register GTM0ATOMixSTAT as long as no specified compare match event occurs.

After a compare match event that causes an update of the shadow register SR0/SR1 and before reading the SR0/SR1 register via CPU or ARU, the update of the registers CM0/ CM1 via CPU or ARU is possible but has no effect.

To set up a new compare action, first the SR0/SR1 registers containing captured values have to be read and then new compare values have to be written into the register CM0/CM1. This can be done either by ARU or by CPU.

When the CPU does the register accesses, only one of the shadow registers has to be read. Dependent on the compare strategy, the CPU has to write one or both of the compare registers.

In SOMC mode and CCUx control mode ‘serve last’ exist an exception for update of register CM0/ CM1. If in this mode the CCU0 compare match event occurred, the update of register CM0/CM1 via CPU or ARU is blocked until the CCU1 compare match event occurs.

The CPU can check at any time if the ATOM channel has received valid data from the ARU and waits for a compare event to happen. This is signalled by the DV bit inside the GTM0ATOMixSTAT register.

The behavior of an ATOM channel in SOMC mode, when ARU is enabled and ARU blocking mode is disabled is shown in **Figure 25.38**.

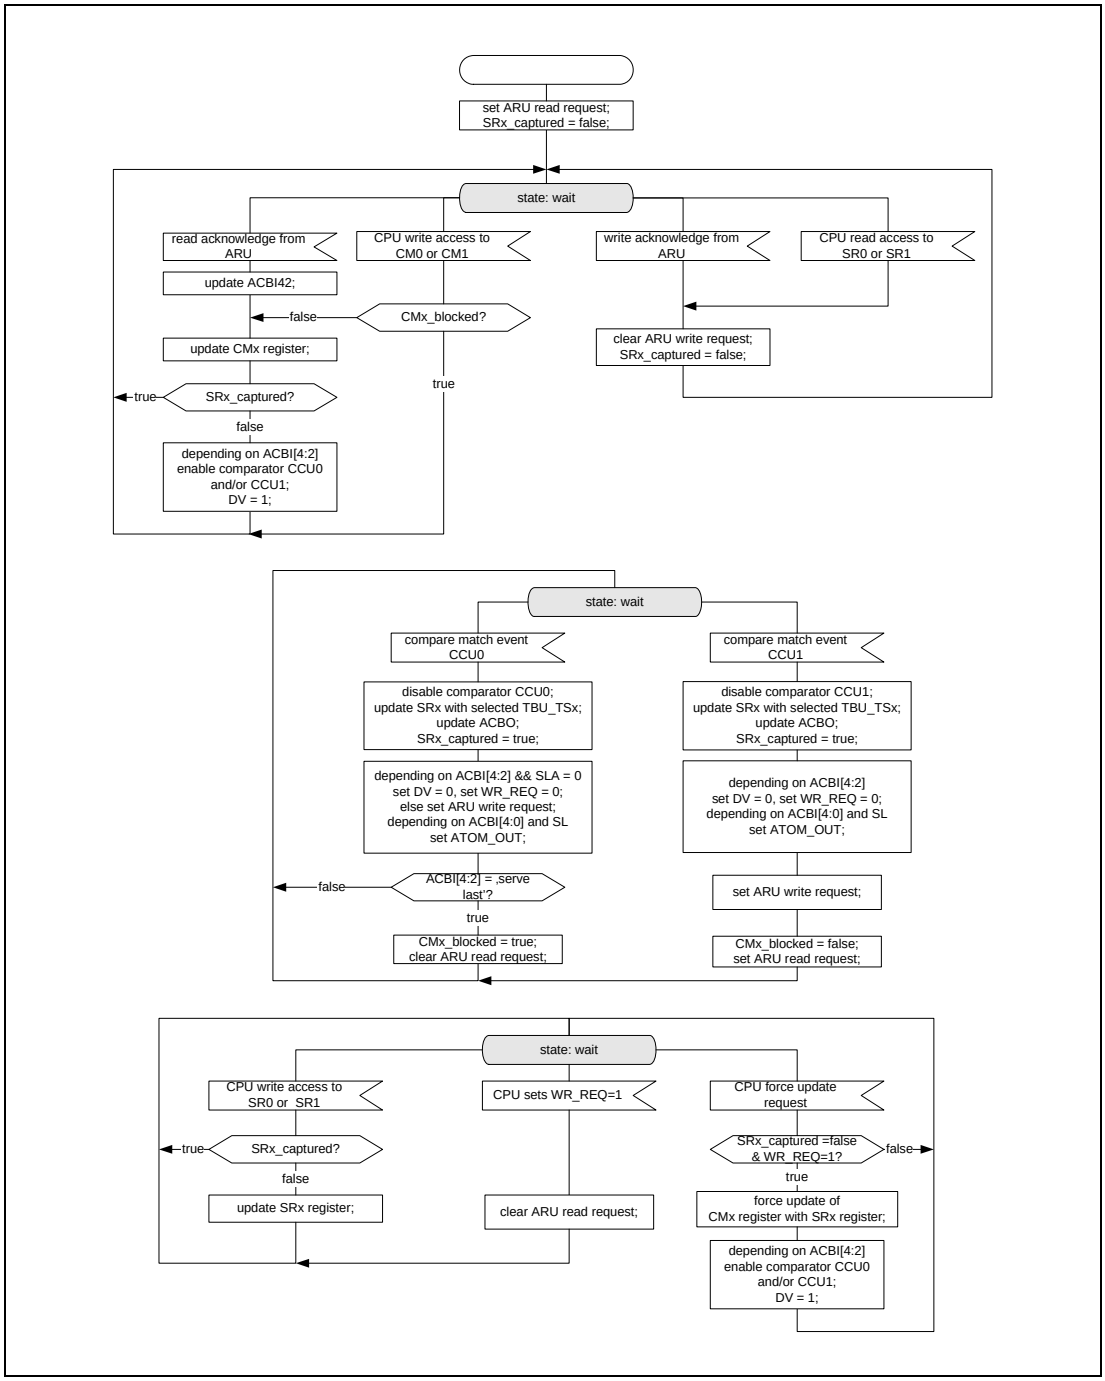

Figure 25.38 SOMC State diagram for SOMC mode, ARU enabled, ABM disabled

(b) ARU Blocking mode

When the compare registers are updated by ARU, the ATOM channel can be configured to receive ARU data in a blocking manner. This can be configured by setting the ABM bit in the GTM0ATOMixCTRL register.

If the ABM and ARU_EN bits are set, the (one) two compare values for CM0 and/or CM1 can be provided by ARU or CPU. If the compare registers CM0 and/or CM1 are/is updated, the ATOM channel waits for the compare match event to happen. No further data is requested from the ARU.

When the specified compare match event happens, the shadow registers SR0 and SR1 are updated together with the ACBO bits in the GTM0ATOMixSTAT register. The data in the shadow registers is marked as valid for the ARU and the DV bit is reset inside the GTM0ATOMixCTRL register.

If the register SR0 and SR1 holding the captured TBU time stamp values are read by either the ARU or the CPU, the next write access to or update of the register CM0 or CM1 via ARU or the CPU enables the new compare match check again.

At least one of the registers SR0 or SR1 has to be read, before new data is requested from ARU.

The CPU can check at any time if the ATOM channel has received valid data from the ARU and waits for a compare event to happen. This is signalled by a set DV bit inside the GTM0ATOMixSTAT register.

The behavior of an ATOM channel in SOMC mode, when ARU is enabled and ARU blocking mode is enabled is shown in **Figure 25.39**.

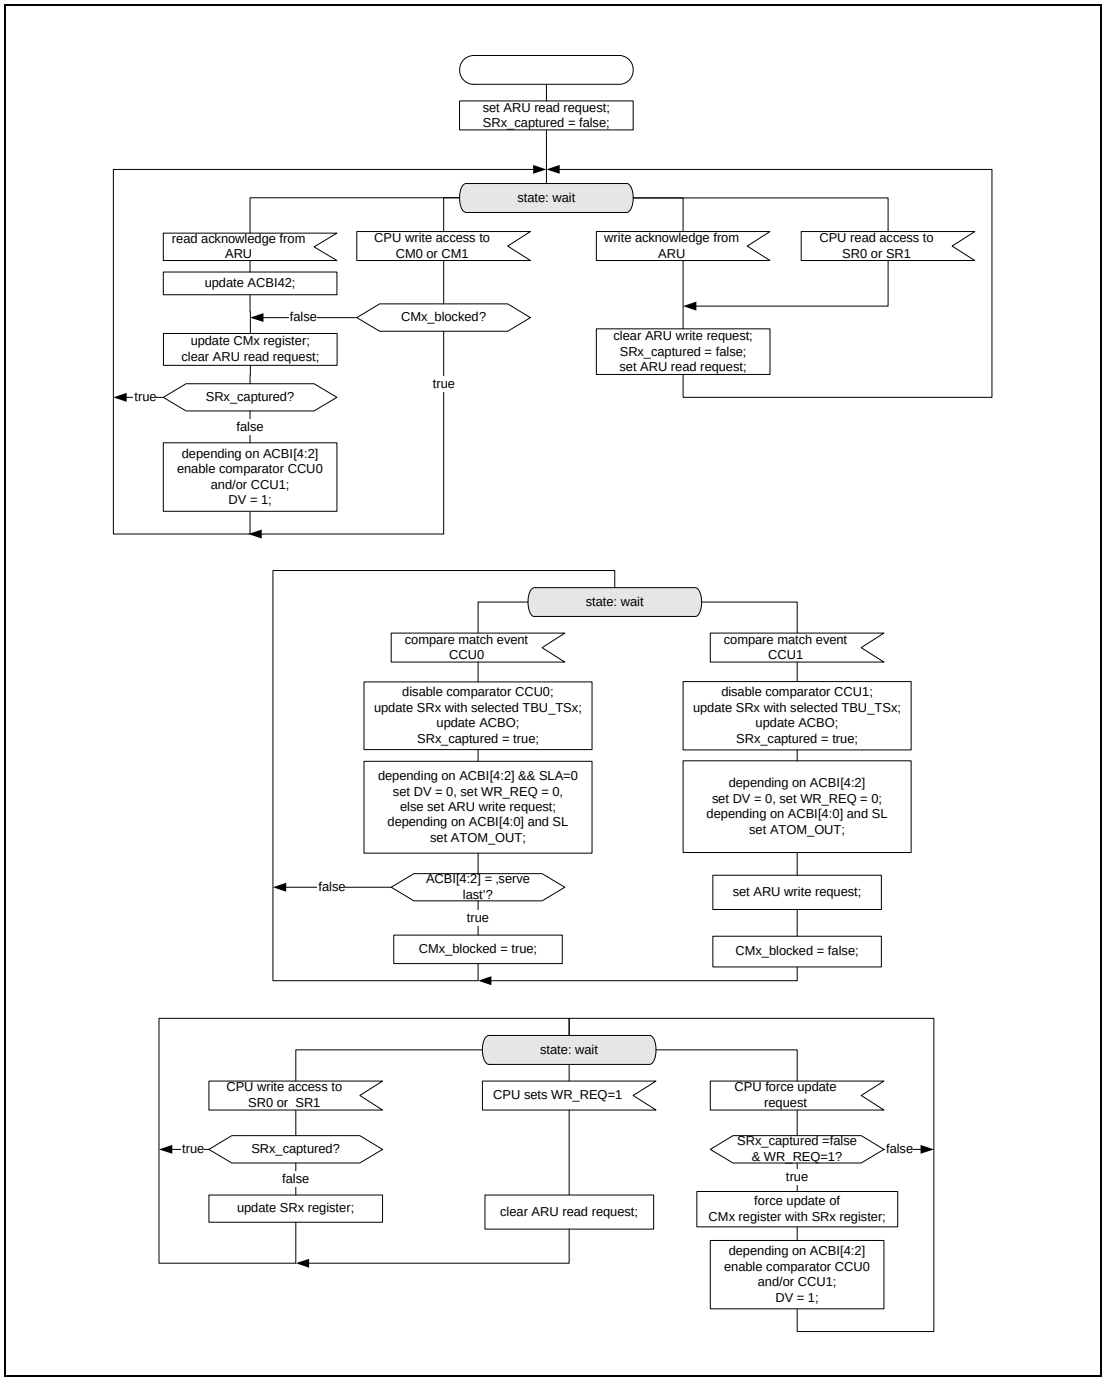

Figure 25.39 SOMC State diagram for SOMC mode, ARU enabled and ABM enabled

(c) ATOM SOMC Late update mechanism

Although, the ATOM channel may be controlled by data received via the ARU, the CPU is able to request at any time a late update of the compare register. This can be initiated by setting the WR_REQ bit inside the GTM0ATOMixCTRL register. By doing this, the ATOM will request no further data from ARU (if ARU access was enabled). The channel will in any case continue to compare against the values stored inside the compare registers (if bit DV was set). The CPU can now update the new compare values until the compare event happens by writing to the shadow registers, and force the ATOM channel to update the compare registers by writing to the force update register bits in the AGC register.

If the WR_REQ bit is set and a compare match event happens, any further access to the shadow registers SR0, SR1 is blocked and the force update of this channel is blocked. In addition, the WRF bit is set in the GTM0ATOMixSTAT register. Thus, the CPU can determine that the late update failed by reading the WRF bit.

If a compare match event already happened, the WR_REQ bit could not be set until the channel is unlocked for a new compare match event by reading the shadow registers. In addition, the WRF bit is set if the CPU tries to write the WR_REQ bit in that case.

If between a correct WR_REQ bit set, a correct shadow register write, and before the force update is requested by the AGC a match event occurs on the old compare values, the WRF bit will be set.

The WRF bit will be set in any case if the CPU tries to write to a blocked shadow register.

The WR_REQ bit and the DV bit will be reset on a compare match event.

A blocked force update mechanism will be enabled again after a read access to the register SR0 or SR1 by either the ARU or the CPU.

The ATOM SOMC late update mechanism from CPU is shown in **Figure 25.40**.

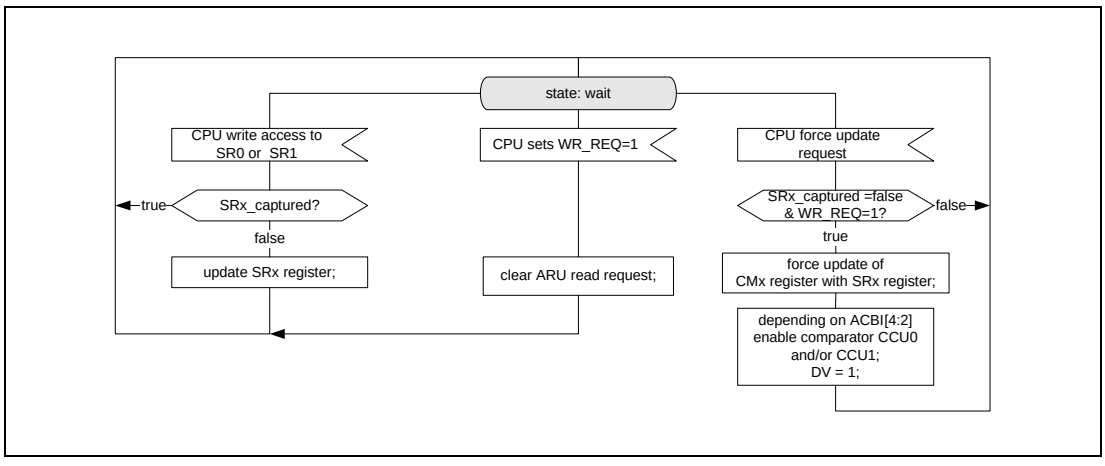

Figure 25.40 SOMC State diagram for late update requests by CPU

(4) Register GTM0ATOMixCTRL in SOMC mode (i = 0, x = 0 to 7, i = 1, x = 0 to 7, i = 2, x = 0 to 4)

Access: This register can be read/written in 32-bit units.

Address:
GTM0ATM00CTRL: <GTM_base> + $0D004_H$,
GTM0ATM01CTRL: <GTM_base> + $0D084_H$,

Table 25.101 GTM0ATOMixCTRL in SOMC mode Register Contents (1/4)

Bit Position	Bit Name	Function
31 to 28	Reserved	These bits are always read as 0. When written, write the initial value.
27	ABM	ARU blocking mode 0: ARU blocking mode disabled: ATOM reads continuously from ARU and updates CM0, CM1 independent of pending compare match event 1: ARU blocking mode enabled: after updating CM0,CM1 via ARU, no new data is read from ARU until compare match event occurred and SR0 and/or SR1 are read.
26	Not used	Not used in this mode.

Table 25.101 GTM0ATOMixCTRL in SOMC mode Register Contents (2/4)

Bit Position	Bit Name	Function
25	SLA	Serve last ARU communication strategy. 0: Capture SRx time stamps after CCU0 match event not provided to ARU 1: Capture SRx time stamps after CCU0 match event provided to ARU **NOTES** 1. Please note, that setting of this bit has only effect, when ACBI(4:2) is configured for serve last compare strategy (“100”, “101”, or “110”). 2. When this bit is not set, the captured time stamps in the shadow registers SRx are only provided after the CCU1 match occurred. The ACBO(4:3) bits always return “10” in that case. 3. By setting this bit, the ATOM channel also provides the captured time stamps after the CCU0 match event to the ARU. The ACBO(4:3) bits are set to “01” in that case. After the CCU1 match event, the time stamps are captured again in the SRx registers and provided to the ARU. The ACBO(4:3) bits are set to “10”. When the data in the shadow registers after the CCU0 match was not consumed by an ARU destination and the CCU1 match occurs, the data in the shadow registers is overwritten by the new captured time stamps. The ATOM channel does not request new data from the ARU when the CCU0 match values are read from an ARU destination.
24	TRIGOUT	Trigger output selection (output signal TRIG_CHx) of module ATOM_CHx. 0: TRIG_[x] is TRIG_[x-1] or TIM_EXT_CAPTURE(x) 1: TRIG_[x] is TRIG_CCU0
23	EXTTRIGOUT	Select TIM_EXT_CAPTURE(x) as potential output signal TRIG_[x] 0: Signal TRIG_[x-1] is selected as output on TRIG_[x] (if TRIGOUT = 1) 1: Signal TIM_EXT_CAPTURE(x) is selected as output on TRIG_[x] (if TRIGOUT = 1)
22, 21	Not used	Not used in this mode.
20	Not used	Not used in this mode.
19 to 17	Reserved	These bits are always read as 0. When written, write the initial value.
16	WR_REQ	CPU write request bit 0: No late update requested by CPU 1: Late update requested by CPU **NOTES** 1. The CPU can disable subsequent ARU read requests by the channel and can update the shadow registers with new compare values, while the compare units operate on old compare values received by former ARU accesses, if occurred. 2. On a compare match event, the WR_REQ bit will be reset by hardware. 3. At the point of the force update only the shadow registers SR0 and SR1 are transferred into the CM0, CM1 registers. The output action is still defined by the ACBI bit field described by the ARU together with the old compare values for CM0/CM1.
15	Reserved	This bit is always read as 0. When written, write the initial value.
14 to 12	Not used	Not used in this mode.

Table 25.101 GTM0ATOMixCTRL in SOMC mode Register Contents (3/4)

Bit Position	Bit Name	Function
11	SL	Initial signal level after channel is enabled. 0: Low signal level 1: High signal level **NOTES** 1. Reset value depends on the hardware configuration chosen by silicon vendor. 2. If the output is disabled, the output ATOM_OUT[x] is set to inverse value of SL. 3. If the channel and output are disabled, in MODE=01 (SOMC mode) the output register of SOU unit is set to value of SL. If the output is enabled afterwards, the output ATOM_OUT[x] is equal to the value of SL.
10	Reserved	These bits are always read as 0. When written, write the initial value.
9	CMP_CTRL	CCUx compare strategy select. 0: Greater/equal compare against TBU time base values (TBU_TS1/2 ≥ CM0/1) 1: Less/equal compare against TBU time base values (TBU_TS1/2 ≤ CM0/1) **NOTE** The compare unit CCU0 or CCU1 that compares against TBU_TS0 (depending on CCUx control mode defined by ACBI(4:2) or ACB42) always performs a greater/equal comparison, independent on CMP_CTRL bit.
8 to 6	ACB42	ATOM control bits ACB(4), ACB(3), ACB(2) 000: Compare in CCU0 and CCU1 in parallel, disable the CCUx on a compare match on either of compare units. Use TBU_TS0 in CCU0 and TBU_TS1 or TBU_TS2 in CCU1. 001: Compare in CCU0 and CCU1 in parallel, disable the CCUx on a compare match on either compare units. Use TBU_TS0 in CCU0 and TBU_TS1 or TBU_TS2 in CCU1. 010: Compare in CCU0 only against TBU_TS0. 011: Compare in CCU1 only against TBU_TS1 or TBU_TS2. 100: Compare first in CCU0 and then in CCU1. Use TBU_TS0. 101: Compare first in CCU0 and then in CCU1. Use TBU_TS1 or TBU_TS2. 110: Compare first in CCU0 and then in CCU1. Use TBU_TS0 in CCU0 and TBU_TS1 or TBU_TS2 in CCU1. 111: Reserved. **NOTE** These bits are only applicable if ARU_EN = '0'.
5, 4	ACB10	Signal level control bits. 00: No signal level change at output (exception in **Table 25.95** and **Table 25.96** mode ACB42 = 001). 01: Set output signal level to 1 when SL bit = 0 else output signal level to 0. 10: Set output signal level to 0 when SL bit = 0 else output signal level to 1. 11: Toggle output signal level (exception in **Table 25.95** and **Table 25.96** mode ACB42 = 001). **NOTE** These bits are only applicable if ARU_EN = '0'.
3	ARU_EN	ARU Input stream enable. 0: ARU Input stream disabled 1: ARU Input stream enabled

Table 25.101 GTM0ATOMixCTRL in SOMC mode Register Contents (4/4)

Bit Position	Bit Name	Function
2	TB12_SEL	Select time base value TBU_TS1 or TBU_TS2. 0: TBU_TS1 selected for comparison 1: TBU_TS2 selected for comparison **NOTE** This bit is only applicable if three time bases are present in the GTM-IP. Otherwise, this bit is reserved.
1, 0	MODE	ATOM channel mode select. 01: ATOM Signal Output Mode Compare (SOMC)

25.11.3.3 ATOM Signal Output Mode PWM (SOMP)

In ATOM Signal Output Mode PWM (SOMP) the ATOM submodule channel is able to generate complex PWM signals with different duty cycles and periods. Duty cycles and periods can be changed synchronously and asynchronously. Synchronous change of the duty cycle and/or period means that the duty cycle or period duration changes after the end of the preceding period. An asynchronous change of period and/or duty cycle means that the duration changes during the actual running PWM period.

The signal level of the pulse generated inside the period can be configured inside the channel control register (SL bit of GTM0ATOMixCTRL register). The initial signal output level for the channel is the reverse pulse level defined by the SL bit. **Figure 25.41** clarifies this behavior.

In SOMP mode, depending on configuration bits RST_CCU0 of register GTM0ATOMixCTRL the counter register CN0 can be reset either when the counter value is equal to the compare value CM0 or when signalled by the ATOM[i] trigger signal TRIG_[x-1] of the preceding channel [x-1] (which can also be the last channel of preceding instance TOM[i-1]) or the trigger signal TIM_EXT_CAPTURE(x) of the assigned TIM channel [x].

In this case, if UPEN_CTRL[x]=1, also the working register CM0, CM1 and CLK_SRC are updated.

Note: As an exception, the input TRIG_[0] of instance ATOM0 is triggered by its own last channel cCATO via signal TRIG_[cCATO]. See **Section 25.18, GTM Device 207** and **Section 25.19, GTM Device 208** for value cCATO of ATOM0.

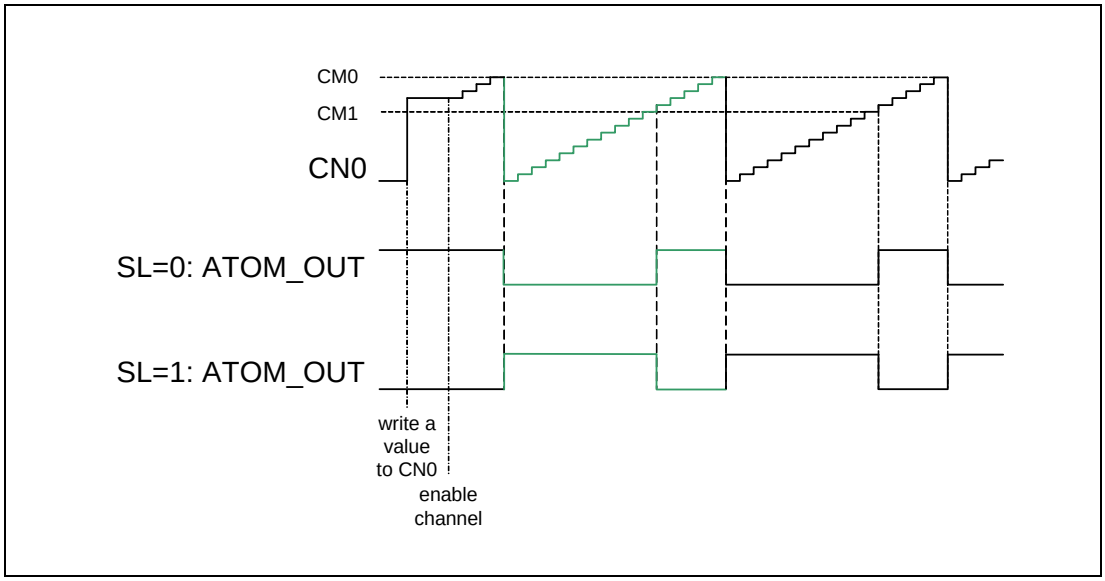

Figure 25.41 PWM Output behavior with respect to the SL bit in the GTM0ATOMixCTRL register

On an asynchronous update, it is guaranteed, that no spike occurs at the output port of the channel due to a too late update of the operation registers. The behavior of the output signal due to the different possibilities of an asynchronous update during a PWM period is shown in **Figure 25.42** .

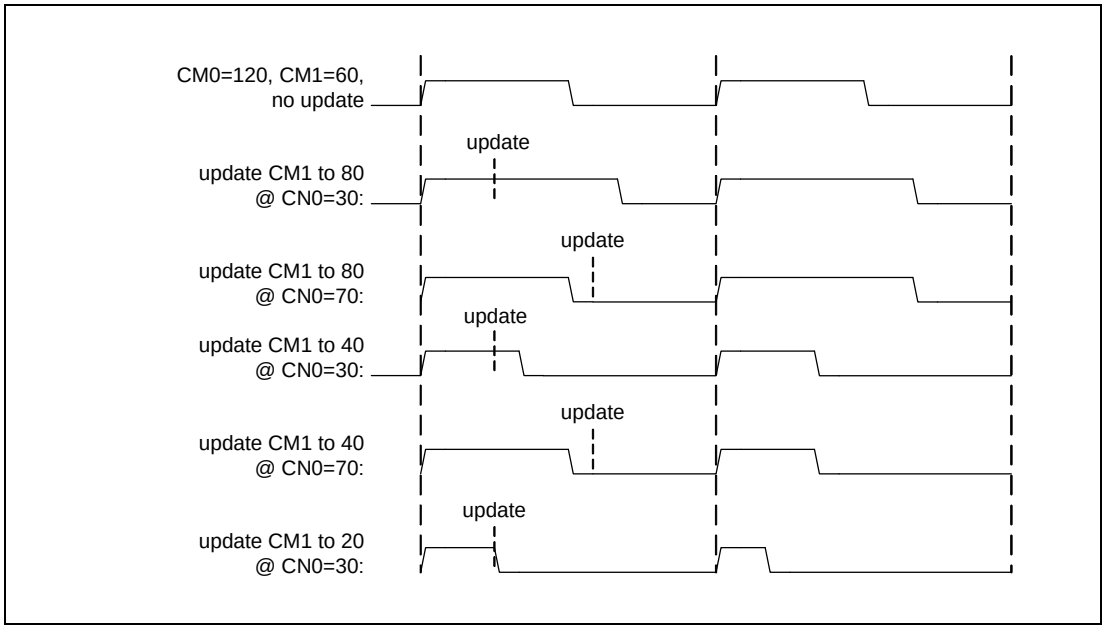

Figure 25.42 PWM Output behavior in case of an asynchronous update of the duty cycle

The duration of the pulse high or low time and period is measured with the counter in subunit CCU0. The trigger of the counter is one of the eight CMU clock signals configurable in the channel control register GTM0ATOMixCTRL. The register CM0 holds the duration of the period and the register CM1 holds the duration of the duty cycle in clock ticks of the selected CMU clock.

If counter register CN0 of channel x is reset by its own CCU0 unit (i.e. the compare match of CN0 ≥ CM0 configured by RST_CCU0 = 0), following statements are valid:

- CN0 counts from 0 to CM0-1 and is then reset to 0
- When CN0 is reset from CM0 to 0, an edge to SL is generated.
- When CN0 is incrementing and reaches CN0 > CM1, an edge to !SL is generated.
- if CM0 = 0 or CM0=1, the counter CN0 is constant 0.
- if CM1 = 0, the output is !SL = 0% duty cycle
- if CM1 >= CM0 and CM0>1, the output is SL = 100% duty cycle

If the counter register CN0 of channel x is reset by the trigger signal coming from another channel or the assigned TIM module (configured by RST_CCU0 = 1), following statements are valid:

- CN0 counts from 0 to MAX-1 and is then reset to 0 by trigger signal
- CM0 defines the edge to SL value, CM1 defines the edge to !SL value.
- if CM0 = CM1, the output switches to SL if CN0 = CM0 = CM1 (CM0 has higher priority)
- if CM0 = 0 and CM1= = MAX, the output is SL = 100% duty cycle
- if CM0 > MAX, the output is !SL = 0 % duty cycle, independent of CM1.

In case the counter value CN0 reaches the compare value in register CM0 or the channel receives an external update trigger via the FUPD(x) signal, a synchronous update is performed. A synchronous update means that the registers CM0 and CM1 are updated with the content of the shadow registers SR0 and SR1 and the CLK_SRC register is updated with the value of the CLK_SRC_SR register.

The clock source for the counter can be changed synchronously at the end of a period. If ARU access is disabled, this is done by using the bit field CLK_SRC_SR of register GTM0ATOMixCTRL as shadow registers for the next CMU clock source.

If ARU access is enabled, the bits ACBI(4), ACBI(3) and ACBI(2) received via ARU and stored in register ATOM_[i]_CH[x]_STAT are used as shadow register for the update of the CMU clock source register CLK_SRC.

For the synchronous update mechanism the generation of a complex PWM output waveform is possible without CPU interaction by reloading the shadow registers SR0, SR1 and the ACBI bit field over the ACI subunit from the ARU, while the ATOM channel operates on the CM0 and CM1 registers.

This internal update mechanism is established, when the old PWM period ends. The shadow registers are loaded into the operation registers, the counter register is reset, the new clock source according to the CLK_SRC_SR or ACBI(4), ACBI(3) and ACBI(2) bits is selected and the new PWM generation starts.

In parallel, the ATOM channel issues a read request to the ARU to reload the shadow registers with new values while the ATOM channel operates on the operation registers. To guarantee the reloading, the PWM period must not be smaller than the worst case ARU round trip time and source for the PWM characteristic must provide the new data within this time. Otherwise, the old PWM values are used from the shadow registers.

When updated over the ARU the user has to ensure that the new period duration is located in the lower (bits 23 to 0) and the duty cycle duration is located in the upper (bits 47 to 24) ARU data word and the new clock source is specified in the ARU control bits 52 to 50.

This pipelined data stream character is shown in **Figure 25.43** .

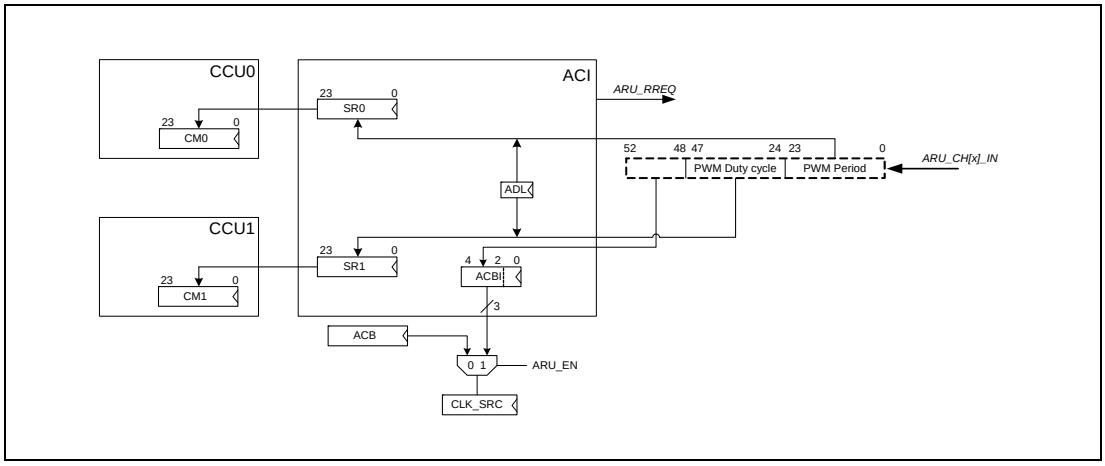

Figure 25.43 ARU Data input stream pipeline structure for SOMP mode

When an ARU transfer is in progress which means the ARU_RREQ is served by the ARU, the ACI locks the update mechanism of CM0, CM1 and CLK_SRC until the read request has finished. The CCU0 and CCU1 operate on the old values when the update mechanism is locked.

The shadow registers SR0 and SR1 can also be updated over the AEI bus interface. When updated via the AEI bus the CM0 and CM1 update mechanism has to be locked via the AGC_GLB_CTRL register with the UPENx signal in the AGC subunit. To select the new clock source in this case, the CPU has to write to the CLK_SRC_SR bit field of the GTM0ATOMixCTRL register.

For an asynchronous update of the duty cycle and/or period the new values must be written directly into the compare registers CM0 and/or CM1 while the counter CN0 continues counting. This update can be done only via the AEI bus interface immediately by the CPU or by the FUPD(x) trigger signal triggered from the AGC global trigger logic. Values received through the ARU interface are never loaded asynchronously into the operation registers CM0 and CM1. Therefore, the ATOM channel can generate a PWM signal on the output port pin ATOM[i]_CH[x]_OUT on behalf of the content of the CM0 and CM1 registers, while it receives new PWM values via the ARU interface ACI in its shadow registers.

On a compare match of CN0 and CM0 or CM1 the output signal level of ATOM[i]_CH[x]_OUT is toggled according to the signal level output bit SL in the GTM0ATOMixCTRL register.

Thus, the duty cycle output level can be changed during runtime by writing the new duty cycle level into the SL bit of the channel configuration register. The new signal level becomes active for the next trigger CCU_TRIGx (since bit SL is written).

Since the ATOM[i]_CH[x]_OUT signal level is defined as the reverse duty cycle output level when the ATOM channel is enabled, a PWM period can be shifted earlier by writing an initial offset value to CN0 register. By doing this, the ATOM channel first counts until CN0 reaches CM0 and then it toggles the output signal at ATOM[i]_CH[x]_OUT.

(1) SOMP One-shot mode

The ATOM channel can operate in One-shot mode when the OSM bit is set in the channel control register. One-shot mode means that a single pulse with the pulse level defined in bit SL is generated on the output line.

First the channel has to be enabled by setting the corresponding ENDIS_STAT value.

In One-shot mode the counter CN0 will not be incremented once the channel is enabled.

A write access to the register CN0 triggers the start of pulse generation (i.e. the increment of the counter register CN0).

If the counter CN0 is reset from CM0 back to zero, the first edge at ATOM[i]_CH[x]_OUT is generated.

To avoid an update of CMx register with content of SRx register at this point in time, the automatic update should be disabled by setting UPEN_CTRL[x] = 00 (in register GTM0ATOMixCTRL)

The second edge is generated if CN0 is greater or equal than CM1 (i.e. CN0 was incremented until it has reached CM1 or CN0 is greater than CM1 after an update of CM1).

If the counter CN0 has reached the value of CM0 a second time, the counter stops.

The new value of CN0 determines the start delay of the first edge. The delay time of the first edge is given by (CM0-CN0) multiplied with period defined by current value of CLK_SRC.

Figure 25.44 clarifies the pulse generation in SOMP One-shot mode.

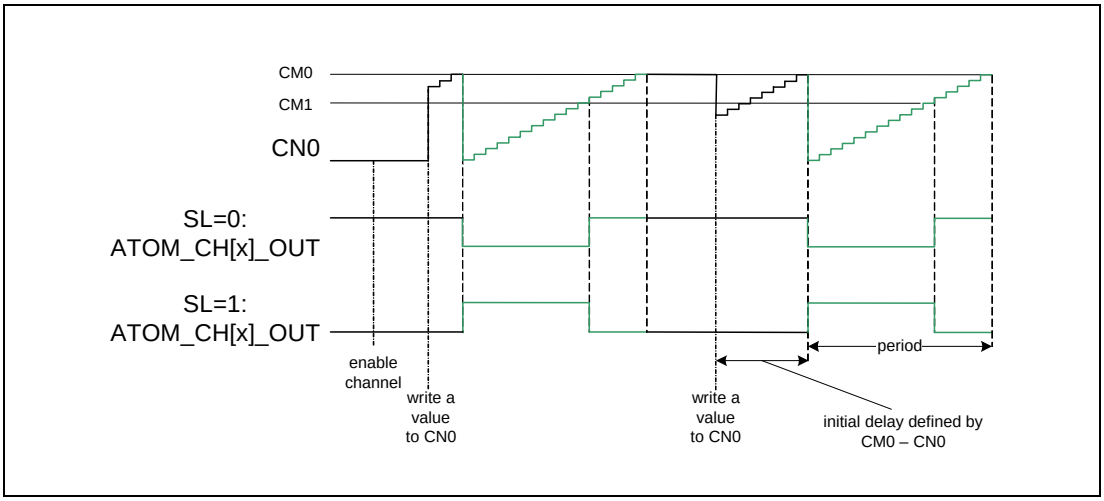

Figure 25.44 PWM Output with respect to configuration bit SL in One-shot mode: trigger by writing to CN0

Further output of single pulses can be started by a write access to register CN0.

If CN0 is already incrementing (i.e. started by writing to CN0 a value CN0start < CM0), the affect of a second write access to CN0 depends on the phase of CN0:

phase 1: update of CN0 before CN0 reaches first time CM0

phase 2: update of CN0 after CN0 has reached first time CM0 but is less than CM1

phase 3: update of CN0 after CN0 has reached first time CM0 and CN0 is greater than or equal CM1

In phase 1: writing to counter CN0 a value CN0new < CM0 leads to a shift of first edge (generated if CN0 reaches CM0 first time) by the time CM0-CN0new.

In phase 2: writing to incrementing counter CN0 a value CN0new < CM1 while CN0old is below CM1 leads to a lengthening of the pulse. The counter CN0 stops if it reaches CM0.

In phase 3: Writing to incrementing counter CN0 a value CN0new while CN0old is already greater than or equal CM1 leads to an immediate restart of a single pulse generation inclusive the initial delay defined by CM0 - CN0new.

If a channel is configured to one-shot mode and configuration bit OSM_TRIG is set to 1, the trigger signal OSM_TRIG (i.e. TRIG_[x-1] or TIM_EXT_CAPTURE(x)) triggers start of one pulse generation.

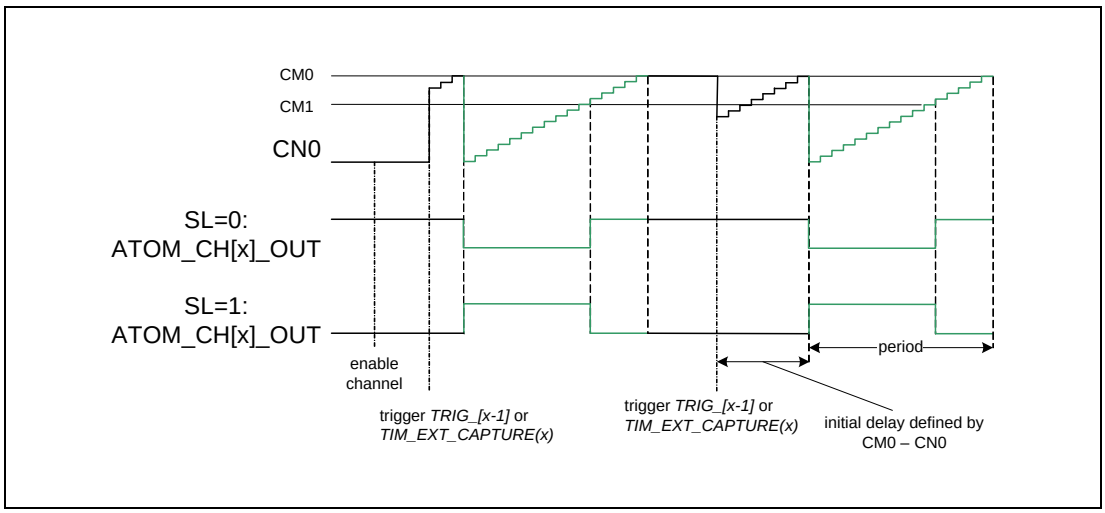

Figure 25.45 PWM Output with respect to configuration bit SL in one-shot mode: trigger by TRIG_[x-1] orTIM_EXT_CAPTURE(x)

(2) PCM mode (pulse count modulation)

At the output ATOM[i]_CH[x]_OUT a pulse count modulated signal can be generated instead of the simple PWM output signal in SOMP mode.

The PCM mode is enabled by setting bit BITREV to 1 (bit 6 in GTM0ATOMixCTRL register).

Please note that it is device specific, in which channel the PCM mode is available. See **Section 25.18, GTM Device 207**and **Section 25.19, GTM Device 208**.

With the configuration bit BITREV = 1 a bit-reversing of the counter output CN0 is configured. In this case the bits LSB and MSB are swapped, the bits LSB+1 and MSB-1 are swapped, the bits LSB+2 and MSB–2 are swapped and so on.

The effect of bit-reversing of the CN0 register value is shown in the following **Figure 25.46**.

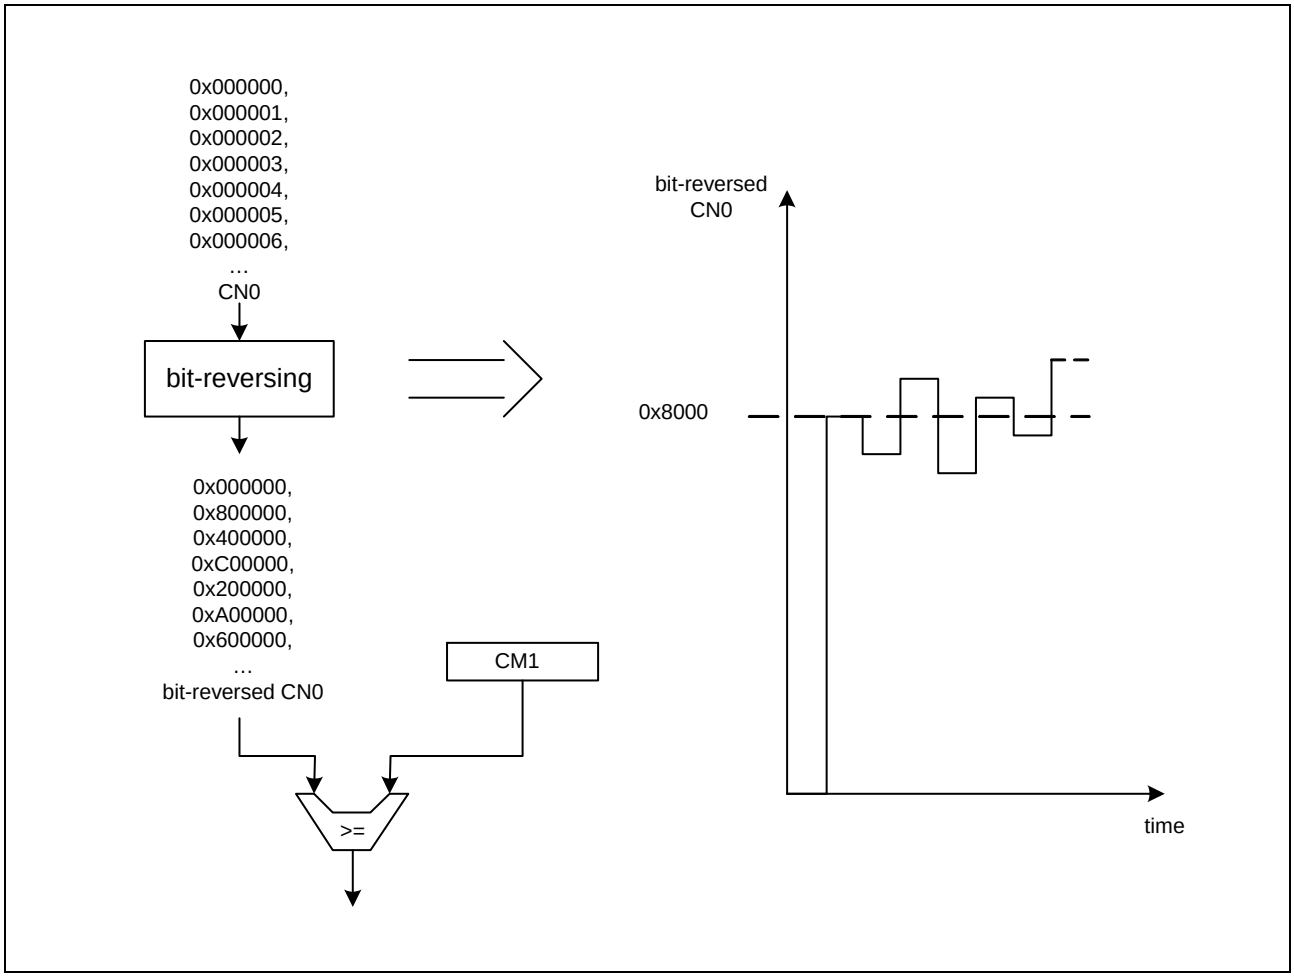

Figure 25.46 Bit reversing of counter CN0 output

In the PCM mode the counter register CN0 is incremented by every clock tick depending on configured CMU clock (CMU_CLK).

The output of counter register CN0 is first bit-reversed and then compared with the configured register value CM1.

If the bit-reversed value of register CN0 is greater or equal than CM1, the SR-FlipFlop of submodule SOU is set (i.e. set to inverse value of SL) otherwise the SR-FlipFlop is reset (i.e. to the value of SL). This generates at the output ATOM[i]_CH[x]_OUT a pulse count modulated signal.

In PCM mode the CM0 register - in which the period is defined - normally has to be set to its maximum value $FFFFFF_H$.

To reduce time period of updating duty cycle value in CM1 register, it is additionally possible to setup period value in CM0 register to smaller values than maximum value as described before.

Possible values for CM0 register are each 2 exponentiated with even numbered values e.g. 800000_H, 400000_H, 200000_H ... .

In this case the duty cycle has to be configured in the following manner.

Depending on how much the period in CM0 register is decreased - means shifted right starting from 1000000_H – the duty cycle in CM1 register has to be shifted left (= rotated: shift MSB back into LSB) with same value, e.g. :

period CM0 = 001000_H → shifted 8 bits right from 1000000_H

→ so duty cycle has to be shifted left 8 bit :

e.g.50 % duty cycle = 0008000_H → shift 8 bits left → CM1 = 800000_H

More examples :

period CM0	→	duty cycle	→	shift	→	CM1
$FFFFFF_H$	→	800000_H	→	no shift	→	800000_H
800000_H	→	400000_H	→	shift 1 bit left	→	800000_H
400000_H	→	100000_H	→	shift 2 bits left	→	400000_H
200000_H	→	$0FFFFF_H$	→	shift 3 bits left	→	$7FFFF8_H$
100000_H	→	033333_H	→	shift 4 bits left	→	333330_H
080000_H	→	005555_H	→	shift 5 bits left	→	$0AAAA0_H$
...						
000020_H	→	000008_H	→	shift 19 bits left	→	400000_H
000010_H	→	000005_H	→	shift 20 bits left	→	500000_H
...						

NOTE

In this mode the interrupt CCU1TC (see register GTM0ATOMixIRQNOTIFY) is set every time if bitreverse value of CN0 is greater or equal than CM1 which may be multiple times during one period. Therefore, from application point of view it is not useful to enable this interrupt.

(3) GTM0ATOMixCTRL in SOMP mode (i = 0, x = 0 to 7, i = 1, x = 0 to 7, i = 2, x = 0 to 4)

Access: This register can be read/written in 32-bit units.

Address:
GTM0ATM00CTRL: <GTM_base> + $0D004_H$,

Table 25.102 GTM0ATOMixCTRL in SOMP mode Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 28	Reserved	These bits are always read as 0. When written, write the initial value.
27	Not used	Not used in this mode.
26	OSM	One-shot mode 0: Continuous PWM generation after channel enable 1: A single pulse is generated
25	Reserved	These bits are always read as 0. When written, write the initial value.
24	TRIGOUT	Trigger output selection (output signal TRIG_CHx) of module ATOM_CHx. 0: TRIG_[x] is TRIG_[x-1] or TIM_EXT_CAPTURE(x). 1: TRIG_[x] is TRIG_CCU0
23 to 21	Not used	Not used in this mode.
20	RST_CCU0	Reset source of CCU0 0: Reset counter register CN0 to 0 on matching comparison with CM0 1: Reset counter register CN0 to 0 on trigger TRIG_[x-1] or TIM_EXT_CAPTURE(x) . **NOTE** If RST_CCU0 = 1 and UPEN_CTRLx = 1 are set, TRIG_[x-1] or TIM_EXT_CAPTURE(x) triggers also the update of work register (CM0, CM1 and CLK_SRC).
19 to 17	Reserved	These bits are always read as 0. When written, write the initial value.
16	Not used	Not used in this mode.
15	Reserved	This bit is always read as 0. When written, write the initial value.

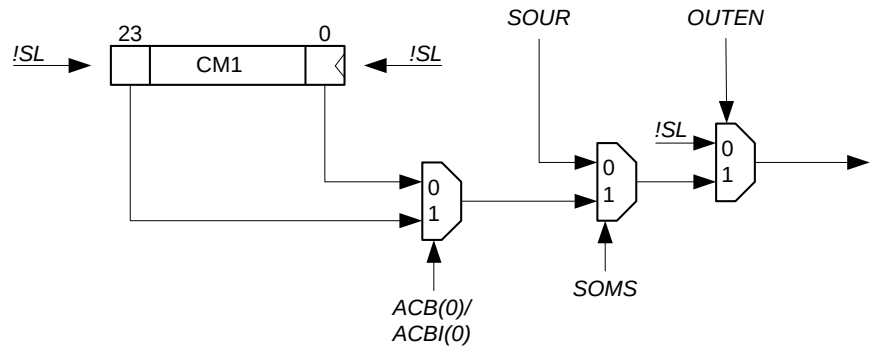
Table 25.102 GTM0ATOMixCTRL in SOMP mode Register Contents (2/2)

Bit Position	Bit Name	Function
14 to 12	CLK_SRC_SR	Shadow register for CMU clock source register CLK_SRC 000: CMU_CLK0 selected 001: CMU_CLK1 selected 010: CMU_CLK2 selected 011: CMU_CLK3 selected 100: CMU_CLK4 selected 101: CMU_CLK5 selected 110: CMU_CLK6 selected 111: CMU_CLK7 selected **NOTES** 1. This register is a shadow register for the CMU_CLKx select. Thus, if the CMU_CLK source for PWM generation should be changed during operation, the old CMU_CLK has to operate until the update of the ATOM channels internal CLK_SRC register by the CLK_SRC_SR content is done either by an end of a period or a FORCE_UPDATE. 2. After (channel) reset the selected CLK_SRC value is the SYS_CLK (input of Global Clock Divider). To use one of the CMU_CLKx, it is required to perform a forced update of CLK_SRC with the value of CLK_SRC_SR value before/with enabling the channel. 3. These bits are only applicable if ARU_EN = '0'.
11	SL	Signal level for pulse of PWM. 0: Low signal level 1: High signal level **NOTE** Reset value depends on the hardware configuration chosen by silicon vendor. If the output is disabled, the output ATOM_OUT[x] is set to inverse value of SL.
10, 9	Reserved	These bits are always read as 0. When written, write the initial value.
8, 7	Not used	Not used in this mode.
6	BITREV	Bit-reversing of output of counter register CN0. This bit enables the PCM mode. **NOTE** It is device specific, in which channel the PCM mode is available. See device specific **Section 25.18, GTM Device 207** and **Section 25.19, GTM Device 208** for this information.
5, 4	ADL	ARU data select for SOMP. 00: Load both ARU words into shadow registers 01: Load ARU low word (Bits 23 to 0) into shadow register SR0 10: Load ARU high word (Bits 47 to 24) into shadow register SR1 11: Reserved **NOTE** This bit field is only used in SOMP mode to select the ARU data source.
3	ARU_EN	ARU Input stream enable. 0: ARU Input stream disabled 1: ARU Input stream enabled
2	Not used	Not used in this mode.
1, 0	MODE	ATOM channel mode select. 10: ATOM Signal Output Mode PWM (SOMP)

25.11.3.4 ATOM Signal Output Mode Serial (SOMS)

In ATOM Signal Output Mode Serial (SOMS) the ATOM channel acts as a serial output shift register where the content of the CM1 register in the CCU1 unit is shifted out whenever the unit is triggered by the selected CMU_CLK input clock signal. The shift direction is configurable with the ACB(0) bit inside the GTM0ATOMixCTRL register when ARU is disabled and the ACBI(0) bit inside the GTM0ATOMixSTAT register when ARU is enabled.

The data inside the CM1 register has to be aligned according to the selected shift direction in the ACB(0)/ACBI(0) bit. This means that when a right shift is selected, that the data word has to be aligned to bit 0 of the CM1 register and when a left shift is selected, that the data has to be aligned to bit 23 of the CM1 register.



Note: The !SL means inverse value of SL.

Figure 25.47 SOMS Mode output generation

Figure 25.47 shows the output generation in case of SOMS mode is selected.

In SOMS mode CCU0 runs in counter/compare mode and counts the number of bits shifted out so far. The total number of bits that should be shifted is defined as CM0. The total number of bits that are visible at ATOM_OUT is CM0+1.

When the output is disabled the ATOM_OUT is set to the inverse SL bit definition.

When the content of the CM1 register is shifted out, the inverse signal level is shifted into the CM1 register.

When the output is enabled while UPEN_CTRL[x] is disabled, the ATOM_OUT signal level is defined by CM1 bit 0 or 23, dependent on the shift direction defined by ACB(0) or ACBI(0) register setting. **Figure 25.48** should clarify the ATOM channel start-up behavior in this case for right shift. For left shift the CM1 bit 0 in **Figure 25.48** has to be replaced by CM1 bit 23.

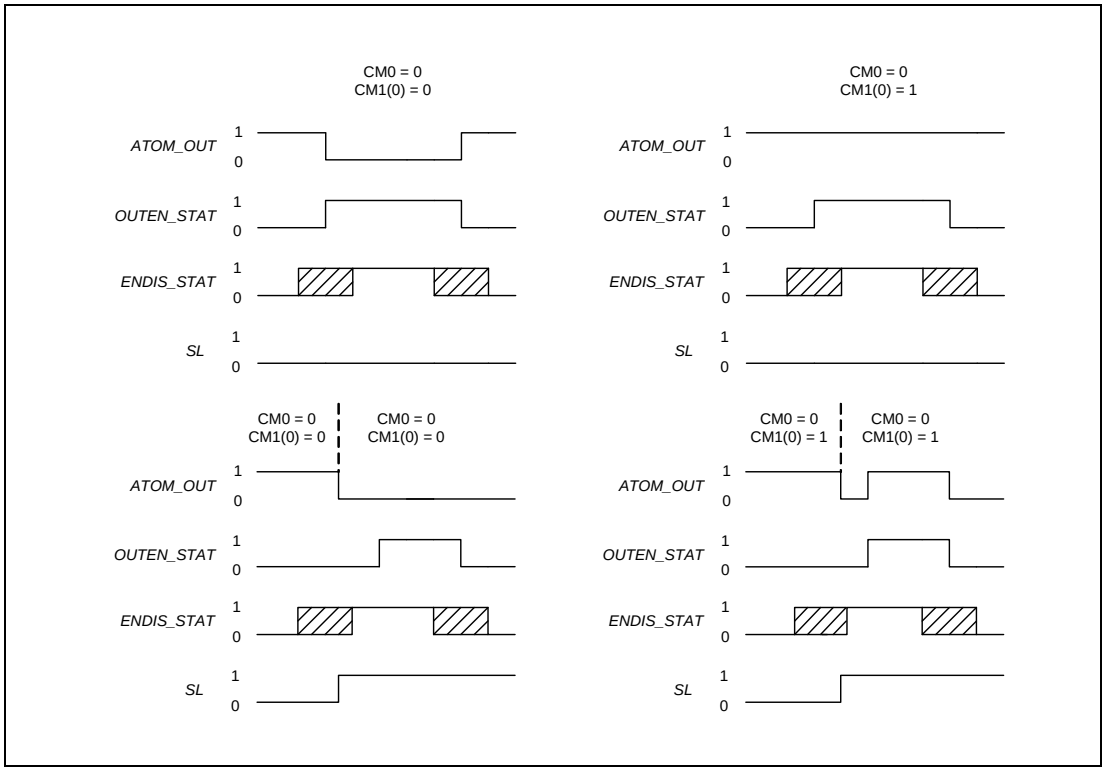


Figure 25.48 SOMS Output signal level at start-up, UPEN_CTRL[x] disabled

If UPEN_CTRL[x] is set and the channel is enabled, the output level is defined by bit 0 or 23 of CM1 register dependent on the shift direction. **Figure 25.49** shows the output behavior in that case.

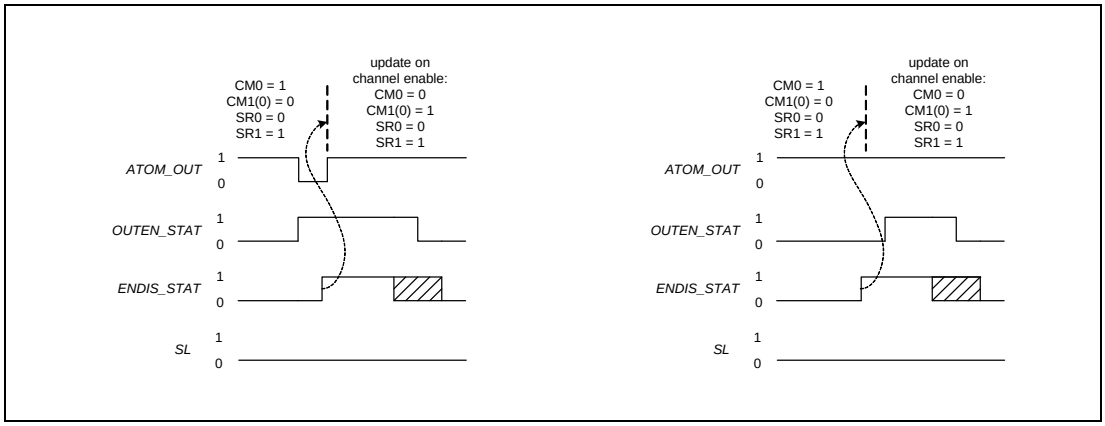

Figure 25.49 SOMS Output signal level at start-up, UPEN_CTRL[x] enabled

When the serial data to be shifted is provided via ARU the number of bits that should be shifted has to be defined in the lower 24 bits of the ARU word (23 to 0) and the data that is to be shifted has to be defined in the ARU bits 47 to 24 aligned according to the shift direction. This shift direction has to be defined in the ARU word bit 48 (SL0 bit).

If bit UPEN_CTRL[x] of a channel x is set, after update of CM0/CM1 register with the content of the SR0/SR1 register, a new ARU read request is set up.

If bit UPEN_CTRL[x] of a channel x is not set, no (further) ARU read request is set up (because the SR0/SR1 register are never used for update) and the ATOM may stop shifting after CN0 has reached CM0. Note, that in this case also no automatic restart of shifting is possible.

If a channel is enabled with the settings SOMS mode and ARU_EN = 1, the first received values from ARU are stored in register SR0 and SR1. If CN0 and CM0 are 0 (i.e. CN0 is not counting) and the update of channel x is enabled (UPEN_CTRL[x] = 1), an immediate update of the register CM0 and CM1 is also done. This update of CM0 and CM1 triggers the start of shifting.

It is recommended to configure the ATOM channel in One-shot mode when the ARU_EN bit is not set, since the ATOM channel would reload new values from the shadow registers when CN0 reaches CM0.

(1) SOMS mode with ARU_EN = 1 and OSM = 0, UPEN_CTRL[x] = 1:

In case of bit ARU_EN is set and bit OSM is not set, the channel is running in the SOMS continuous mode. Then, if the content of the CM0 register equals the counter CN0, the CM0 and CM1 registers are reloaded with the SR0 and SR1 content and new values are requested from the ARU. If the update of the shadow registers does not happen before CN0 reaches CM0 the old values of SR0 and SR1 are used to reload the operation registers.

In contrast to controlling the channel via AEI, the shift direction defined by ARU word bit 48 has only effect after the update of CMx operation registers from the SRx registers.

(2) SOMS mode with ARU_EN = 1 and OSM = 1, UPEN_CTRL[x] = 1:

In case of bit ARU_EN is set and bit OSM is set, the channel is running in the SOMS one-shot mode. Then, if the content of the CM0 register equals the counter CN0 and if new values are available in SR0 and SR1 (bit DV set), the CM0 and CM1 registers are reloaded with the SR0 and SR1 content and new values are requested from the ARU. If no new values are available in SR0 and SR1, the register CM0 and CM1 will not be updated, the counter CN0 stops and the ATOM channel continues to request new data from ARU. A later reception of new ARU data in SR0 and SR1 will immediately force the update of the register CM0 and CM1 and restart the counter CN0.

(3) SOMS mode with ARU_EN = 0 and OSM = 0, UPEN_CTRL[x] = 1:

In case of bit ARU_EN is not set and bit OSM is not set, the ATOM channel updates its CM0/CM1 register with the content of the SR0/SR1 register and restarts shifting immediately. The first bit of new CM1 register value will be applied at the output without any gap to the last bit of the previous CM1 register value.

(4) SOMS mode with ARU_EN = 0 and OSM = 1, UPEN_CTRL[x] = 1:

In case of bit ARU_EN is not set and bit OSM is set, the ATOM channel stops shifting when CN0 reaches CM0 and no update of CM0 and CM1 is performed.

Then, the shifting of the channel can be restarted again by writing a zero (0) to the CN0 register again. Please note, that the CN0 register should be written with a zero since the CN0 register counts the number of bits shifted out by the ATOM channel.

The writing of a zero to CN0 causes also an immediate update of CM0/CM1 register with the content of SR0/SR1 register.

(5) Interrupts in SOMS mode

In ATOM Signal Output Mode Serial only the interrupt CCU0TC (GTM0ATOMixIRQNOTIFY) in case of CN0 ≥ CM0 is generated. The interrupt CCU1TC has no meaning and is not generated.

(6) GTM0ATOMixCTRL in SOMS mode (i = 0, x = 0 to 7, i = 1, x = 0 to 7, i = 2, x = 0 to 4)

Access: This register can be read/written in 32-bit units.

14 to 12	CLK_SRC_SR	Shift frequency select for channel 000: CMU_CLK0 selected 001: CMU_CLK1 selected 010: CMU_CLK2 selected 011: CMU_CLK3 selected 100: CMU_CLK4 selected 101: CMU_CLK5 selected 110: CMU_CLK6 selected 111: CMU_CLK7 selected **NOTE** This register is a shadow register for the CMU_CLKx select. Thus, if the channel should operate on another CMU_CLK then CMU_CKL0 at the beginning, the different CMU_CLK has to be specified inside this register and the CMU_CLK has to be configured with a FORCE_UPDATE in that case before the channel operation would start.
11	SL	Defines signal level when channel and output is disable 0: High signal level 1: Low signal level **NOTES** 1. Reset value depends on the hardware configuration chosen by silicon vendor. 2. If the output is disabled, the output ATOM_OUT[x] is set to inverse value of SL. 3. If the output is enabled, the output ATOM_OUT[x] is set to bit 0 or 23 of CM1 register. 4. The inverse value of SL is shifted into the CM1 register. 5. An enable or disable of the channel x has no effect on ATOM_OUT[x].
10, 9	Reserved	These bits are always read as 0. When written, write the initial value.
8 to 5	Not used	Not used in this mode.
4	ACB0	Shift direction for CM1 register 0: Right shift of data is started from bit 0 of CM1 1: Left shift of data is started from bit 23 of CM1 **NOTES** 1. The data that has to be shifted out has to be aligned inside the CM1 register according to the defined shift direction. 2. This bit is only applicable if ARU_EN = ‘0’. 3. If the direction (ACB0) is changed the output ATOM_OUT[x] switches immediately to the other 'first' bit of CM1 (bit 0 if ACB0 = 0, bit 23 if ACB0 = 1).
3	ARU_EN	ARU Input stream enable. 0: ARU Input stream disabled 1: ARU Input stream enabled
2	Not used	Not used in this mode.
1, 0	MODE	ATOM channel mode select. 11: ATOM Signal Output Mode Serial (SOMS)

25.11.3.5 ATOM Signal Output Mode Buffered Compare(SOMB)

(1) Overview

In ATOM Signal Output Mode buffered Compare (SOMB) the output action is performed according to the comparison result of the input values located in CM0 and/or CM1 registers and the two (three) time base values TBU_TS0 or TBU_TS1 (or TBU_TS2) provided by the TBU. For a description of the time base generation see the TBU specification in **Section 25.9, Time Base Unit (TBU)**. It is configurable, which of the two (three) time bases is to be compared with one or both values in CM0 and CM1.

The compare strategy of the two compare units CCU0 and CCU1 is controlled by the value of bit field ACBI of register GTM0ATOMixSTAT. This bit field is only readable by CPU. If ARU is disabled, the bit field ACBI can only be updated with the value of bit field ACB of register GTM0ATOMixCTRL. If ARU is enabled, the ACBI bit field can be updated with the value of shadow register ACB_SR which contains a value received via ARU or the value of bit field ACB of register GTM0ATOMixCTRL.

The table below lists all valid control configurations for bit field ACBI of register GTM0ATOMixSTAT.

Table 25.104 ATOM SOMB compare strategies

ACBI(4)	ACBI(3)	ACBI(2)	CCUx control
0	0	0	Reserved. Has no effect.
0	0	1	Reserved. Has no effect.
0	1	0	Compare in CCU0 only, use time base TBU_TS0. Output signal level is defined by combination of SL, ACB10/ACBI(1..0) bits.
0	1	1	Compare in CCU1 only, use time base TBU_TS1 or TBU_TS2. Output signal level is defined by combination of SL, ACBI[1:0] bits.
1	0	0	Serve Last: Compare in CCU0 and then in CCU1 using *TBU_TS0*. Output signal level when CCU0 matches is defined by combination of SL, ACBI[1:0] . On the CCU1 match the output level is toggled.
1	0	1	Serve Last: Compare in CCU0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU0 matches is defined by combination of SL, ACBI[1:0] . On the CCU1 match the output level is toggled.
1	1	0	Serve Last: Compare in CCU0 using TBU_TS0 and then in CCU1 using TBU_TS1 or TBU_TS2. Output signal level when CCU1 matches is defined by combination of SL, ACBI[1:0]
1	1	1	Cancels pending comparison.

The CCUx trigger signals TRIG_CCU0 and TRIG_CCU1 creates edges depending on the combination of the predefined signal level in SL bit and the two control bits ACBI[1:0].

In SOMB mode, if ARU access is enabled, the new compare values received via ARU are always stored in the shadow register SR0 and SR1 and the ACB bits are stores in an internal register ACB_SR.

If the scheduled compare matches in CCU0 and/or CCU1 are occurred and the SRx register contain new valid values, the register CM0 and CM1 are updated automatically with the content of the corresponding SRx register, the ACBI bit field is updated with the content of internal ACB_SR register and the DV bit of register GTM0ATOMixSTAT is set. If the SRx register and the CMx register contain no valid value, the compare units are waiting in an idle state.

On a compare match of one of the compare units CCUx units the output ATOM_OUT is set according to combination of ACBI bit 1 down to 0 (in register GTM0ATOMixSTAT) and the SL bit of register GTM0ATOMixCTRL.

Table 25.105 ATOM SOMB output control by ACBI[1:0] and SL

SL	ACBI(1)	ACBI(0)	Output Behavior
0	0	0	No signal level change at output.
0	0	1	Set output signal level to 1.
0	1	0	Set output signal level to 0.
0	1	1	Toggle output signal level.
1	0	0	No signal level change at output.
1	0	1	Set output signal level to 0.
1	1	0	Set output signal level to 1.
1	1	1	Toggle output signal level.

In opposite to SOMC mode no time stamp value of TBU is captured in SRx register.

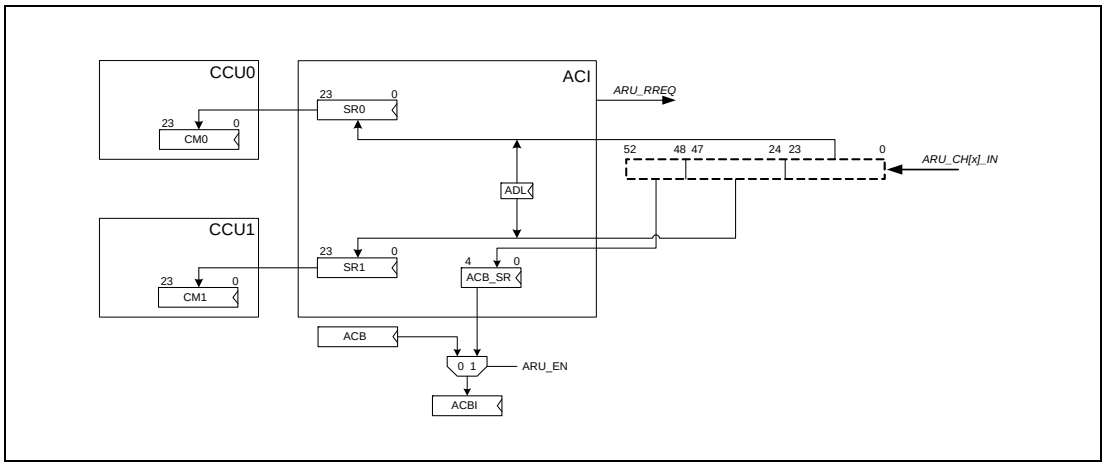

Figure 25.50 ARU interface behavior in SOMB mode

The flag DV of register GTM0ATOMixSTAT indicates that at least one of the CMx register contains valid data and a compare event may be pending (if channel is enabled).

The DV flag is reset if none of the CMx register contains valid data.

(2) SOMB under CPU control

If bit ARU_EN of register GTM0ATOMixCTRL is not set, the ATOM channel can only be controlled via CPU.

Writing to one of the CMx register sets automatically the DV bit to validate the new compare value. A comparison depending on value ACBI of register GTM0ATOMixSTAT is started immediately.

Because only the ACB bit of register GTM0ATOMixCTRL can be written and this bit field serves as a shadow register for the work register ACBI (bit field of register GTM0ATOMixSTAT), it is recommended to first update the ACB bit field before updating CMx/SRx register.

The compare strategy is controlled by the value stored in bit field ACBI of register GTM0ATOMixSTAT. If ARU is disabled, this bit field can only be updated with the value of bit field ACB of register GTM0ATOMixCTRL.

The update of bit field ACBI can be triggered by a forced update or the normal update mechanism controlled by bit UPEN_CTRL[x] in register GTM0ATOMiAGCGLBCTRL.

Writing to one of the SRx register and triggering a forced update, updates the CMx register with the value of SRx register and the ACBI bit field with the content of ACB bit field of register GTM0ATOMiAGCGLBCTRL. A new comparison is started.

Writing to one of the SRx register while update of CMx register is disabled (UPEN_CTRL[x] = 0 in GTM0ATOMiAGCGLBCTRL) and enabling update afterwards, triggers the update of CMx register and the ACBI bit field and starts comparison if previous comparison is finished (DV bit was reset).

If ARU access is disabled (ARU_EN = 0), a force update updates the CMx register with the content of SRx register and the ACBI bit field with the content of ACB bit field of register GTM0ATOMixCTRL.

(3) SOMB under ARU control

If both compare units CCU0/CCU1 are finished with previous job (depending on compare strategy) and the SRx register contain no new value, they are waiting until new data was received via ARU and stored in SRx register. Then, an immediately update takes place.

If both compare units are finished with previous job (depending on compare strategy) and there are new data available in SRx register, the update the CMx register with the value of the SRx register and the ACBI bit field with the value of internal ACB_SR register takes place and a new compare job is started immediately.

After an update of the CMx register, a new ARU read request is set.

New compare values received via the ARU are stored in shadow register SRx. The ACB bits received via ARU are stored in the internal register ACB_SR.

If ARU access is enabled (ARU_EN = 1), a force update updates the CMx register with the content of SRx register and the ACBI bit field with the content of internal ACB_SR register.

For compare strategy ‘serve last’ the CCU0 and CCU1 compare match may occur sequentially. During different phases of compare match the CPU access rights to register CM0 and CM1 as well as to WR_REQ bit is different. These access rights by CPU to register CM0 and CM1 and the WR_REQ are depicted in the following figure.

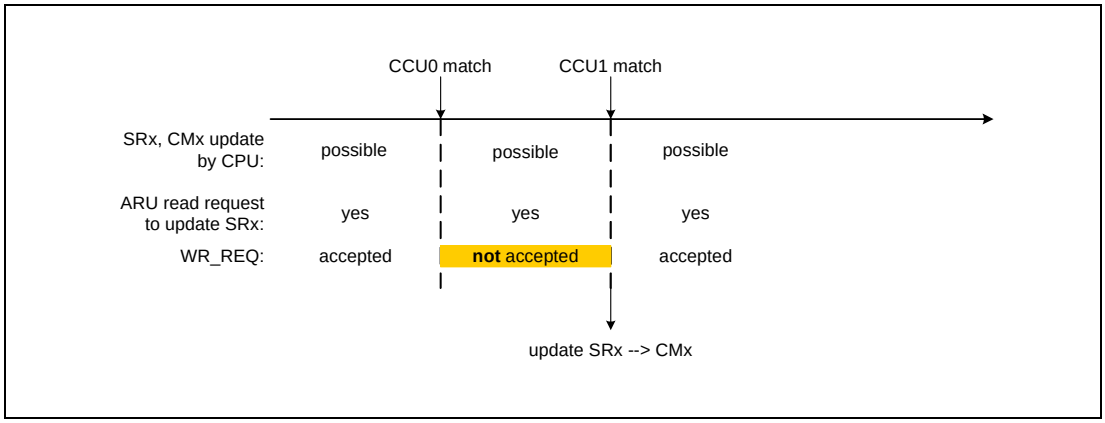

Figure 25.51 CPU access rights in case of compare strategy ‘serve last’

(a) ARU Non-blocking mode

If bit ABM in register GTM0ATOMixCTRL is not set, the ARU blocking mode is disabled. In this case the ATOM channel is continuously reading via ARU and storing new values in the SRx register and the ACB shadow register ACB_SR.

If ARU_EN is not set, the bit ABM has no meaning.

(b) ARU Blocking mode

If bit ABM in register GTM0ATOMixCTRL is set, the ARU blocking mode is enabled. In this case the ATOM channel stops requesting new SRx values via ARU after reception of a new SRx value and restarts requesting a new value via ARU after compare match on both compare units (depending on compare strategy) followed by the immediate update of the CMx register with content of SRx register and an update of ACBI with the content of ACB_SR.

If ARU_EN is not set, the bit ABM has no meaning.

(c) Late Update by CPU

Although, the ATOM channel may be controlled by data received via the ARU, the CPU is able to request at any time a late update of the compare register. This can be initiated by setting the WR_REQ bit inside the GTM0ATOMixCTRL register.

If none of the two compare match event happened, the ATOM channel accepts the setting of WR_REQ bit. In this case, the ATOM will request no further data from ARU (if ARU access was enabled) and will disable the update of CMx register with the content of SRx register on a compare match event.

If at least one of the requested compare match events happened (depending on strategy) the WR_REQ bit is not set and the WRF flag in register GTM0ATOMixSTAT is set to indicate that the late update was not successful.

The channel will in any case continue to compare against the values stored inside the compare registers (if bit DV was set). The CPU can now update the compare values by writing to the shadow registers and force the ATOM channel to update the compare registers by writing to the force update register bits in the AGC register.

With a force update the WR_REQ bit is reset automatically and the ARU read request is set up again (if ARU access was enabled).

(4) GTM0ATOMixCTRL in SOMB mode (i = 0, x = 0 to 7, i = 1, x = 0 to 7, i = 2, x = 0 to 4)

Access: This register can be read/written in 32-bit units.

Address:

Table 25.106 GTM0ATOMixCTRL in SOMB mode Register Contents (1/3)

Bit Position	Bit Name	Function
31	Reserved	This bit is always read as 0. When written, write the initial value.
30	SOMB mode	SOMB mode 0: ATOM channel mode defined by bit filed MODE. 1: ATOM SOMB mode enabled
29, 28	Reserved	These bits are always read as 0. When written, write the initial value.
27	ABM	ARU blocking mode 0: ARU blocking mode disabled: ATOM reads continuously from ARU and updates CM0, CM1 independent of pending compare match event. 1: ARU blocking mode enabled: after updating CM0,CM1 via ARU, no new data is read from ARU until compare match event occurred and SR0 and/or SR1 are read.
26, 25	Not used	Not used in this mode.
24	TRIGOUT	Trigger output selection (output signal TRIG_CHx) of module ATOM_CHx. 0: TRIG_[x] is TRIG_[x-1] or TIM_EXT_CAPTURE(x). 1: TRIG_[x] is TRIG_CCU0
23	EXTTRIGOUT	Select TIM_EXT_CAPTURE(x) as potential output signal TRIG_[x] 0: Signal TRIG_[x-1] is selected as output on TRIG_[x] (if TRIGOUT = 1). 1: Signal TIM_EXT_CAPTURE(x) is selected as output on TRIG_[x] (if TRIGOUT = 1).
22, 21	Not used	Not used in this mode.
20	Not used	Not used in this mode.
19 to 17	Reserved	These bits are always read as 0. When written, write the initial value.
16	WR_REQ	CPU Write request bit for late compare register update.

Table 25.106 GTM0ATOMixCTRL in SOMB mode Register Contents (2/3)

Bit Position	Bit Name	Function
15	Reserved	This bit is always read as 0. When written, write the initial value.
14 to 12	Not used	Not used in this mode.
11	SL	Initial signal level after channel enable. 0: Low signal level 1: High signal level **NOTES** 1. Reset value depends on the hardware configuration chosen by silicon vendor. 2. If the output is disabled, the output ATOM_OUT[x] is set to inverse value of SL. 3. If the channel and output are disabled, in MODE = 01 (SOMC mode) the output register of SOU unit is set to value of SL. If the output is enabled afterwards, the output ATOM_OUT[x] is equal to the value of SL.
10	Reserved	This bit is always read as 0. When written, write the initial value.
9	CMP_CTRL	CCUx compare strategy select. 0: Greater/equal compare against TBU time base values (TBU_TS1/2 ≥ CM0/1) 1: Less/equal compare against TBU time base values (TBU_TS1/2 ≤ CM0/1) **NOTE** The compare unit CCU0 or CCU1 that compares against TBU_TS0 (depending on CCUx control mode defined by ACB_CM(4:2)) always performs a greater/equal comparison, independent on CMP_CTRL bit.
8 to 6	ACB[4:2]	ATOM SOMB compare strategy For details see **Table 25.105** 000: Reserved. Has no effect. 001: Reserved. Has no effect. 010: Compare in CCU0 only against TBU_TS0. 011: Compare in CCU1 only against TBU_TS1 or TBU_TS2. 100: Compare first in CCU0 and then in CCU1. Use TBU_TS0. 101: Compare first in CCU0 and then in CCU1. Use TBU_TS1 or TBU_TS2. 110: Compare first in CCU0 and then in CCU1. Use TBU_TS0 in CCU0 and TBU_TS1 or TBU_TS2 in CCU1. 111: Cancel pending comparisons. **NOTE** These bits are only applicable if ARU_EN = '0'.
5, 4	ACB[1:0]	Signal level control bits. For details see **Table 25.105** 00: No signal level change at output. 01: Set output signal level to 1 when SL bit = 0 else output signal level to 0. 10: Set output signal level to 0 when SL bit = 0 else output signal level to 1. 11: Toggle output signal level. **NOTE** These bits are only applicable if ARU_EN = ‘0’.
3	ARU_EN	ARU Input stream enable. 0: ARU Input stream disabled 1: ARU Input stream enabled

Table 25.106 GTM0ATOMixCTRL in SOMB mode Register Contents (3/3)

Bit Position	Bit Name	Function
2	TB12_SEL	Select time base value TBU_TS1 or TBU_TS2. 0: TBU_TS1 selected for comparison 1: TBU_TS2 selected for comparison **NOTE** This bit is only applicable if three time bases are present in the GTM-IP. Otherwise, this bit is reserved.
1, 0	MODE	ATOM channel mode select. Not used in ATOM SOMB mode.

25.11.4 ATOM Interrupt signals

The following table describes ATOM interrupt signals:

Table 25.107 ATOM interrupt signals

Signal	Description
CCU0TCx_IRQ	CCU0 Trigger condition interrupt for channel x
CCU1TCx_IRQ	CCU1 Trigger condition interrupt for channel x

25.11.5 ATOM Register overview

The following table shows a conclusion of ATOM register address offset and initial values.

Table 25.108 Register list

Symbol	Register Name	Details in Section

15, 14	ENDIS_CTRL7	ATOM channel 7 enable/disable update value. See bits 1, 2
13, 12	ENDIS_CTRL6	ATOM channel 6 enable/disable update value. See bits 1, 2
11, 10	ENDIS_CTRL5	ATOM channel 5 enable/disable update value. See bits 1, 2
9, 8	ENDIS_CTRL4	ATOM channel 4 enable/disable update value. See bits 1, 2
7, 6	ENDIS_CTRL3	ATOM channel 3 enable/disable update value. See bits 1, 2
5, 4	ENDIS_CTRL2	ATOM channel 2 enable/disable update value. See bits 1, 2
3, 2	ENDIS_CTRL1	ATOM channel 1 enable/disable update value. See bits 1, 2
1, 0	ENDIS_CTRL0	ATOM channel 0 enable/disable update value. If an ATOM channel is disabled, the counter CN0 is stopped and the Flip-Flop SOUR is set to the inverse value of control bit SL. On an enable event, the counter CN0 starts counting from its current value. Write of following double bit values is possible: 00: Don't care, bits 1, 0 of register ENDIS_STAT will not be changed on an update trigger 01: Disable channel on an update trigger 10: Enable channel on an update trigger 11: Don't change bits 1, 0 of this register **NOTE** If the channel is disabled (ENDIS[0] = 0) or the output is disabled (OUTEN[0] = 0), the ATOM channel 0 output ATOM_OUT[0] is the inverted value of bit SL.

25.11.6.3 GTM0ATOMiAGCENDISSTAT (i = 0 to 2)

Access: This register can be read/written in 32-bit units.

Address: GTM0ATOM0AGCENDISSTAT: <GTM_base> + $0D048_H$
GTM0ATOM1AGCENDISSTAT: <GTM_base> + $0D848_H$
GTM0ATOM2AGCENDISSTAT: <GTM_base> + $0E048_H$

Value after reset: $0000\ 0000_H$

Table 25.112 GTM0ATOMiAGCACTTB Register Contents

Bit Position	Bit Name	Function
31 to 27	Reserved	These bits are always read as 0. When written, write the initial value.
26, 25	TBU_SEL	Selection of time base used for comparison 00: TBU_TS0 selected 01: TBU_TS1 selected 10: TBU_TS2 selected 11: Same as 00 **NOTE** The bit combination “10” is only applicable if the TBU of the device contains three time base channels. Otherwise, this bit combination is also reserved. See GTM Architecture block diagram on page 3 to determine the number of channels for TBU of this device.
24	TB_TRIG	Set trigger request 0: No trigger request 1: Set trigger request **NOTE** This flag is reset automatically if the selected time base unit (TBU_TS0 or TBU_TS1 or TBU_TS2 if present) has reached the value ACT_TB and the update of the register were triggered.
23 to 0	ACT_TB	specifies the signed compare value with selected signal TBU_TS[x], x = 0 to 2. If selected TBU_TS[x] value is in the interval [ACT_TB-007FFFFFh, ACT_TB] the event is in the past and the trigger is generated immediately. Otherwise the event is in the future and the trigger is generated if selected TBU_TS[x] is equal to ACT_TB.

25.11.6.5 GTM0ATOMiAGCOUTENCTRL (i = 0 to 2)

Access: This register can be read/written in 32-bit units.

Address: GTM0ATOM0AGCOUTENCTRL: <GTM_base> + $0D050_H$
GTM0ATOM1AGCOUTENCTRL: <GTM_base> + $0D850_H$

Table 25.117 GTM0ATOMixCTRL Register Contents (1/4)

Bit Position	Bit Name	Function
31	Reserved	These bits are always read as 0. When written, write the initial value.
30	SOMB	SOMB mode 0: ATOM channel mode defined by bit field MODE 1: ATOM SOMB mode enabled
29, 28	Reserved	These bits are always read as 0. When written, write the initial value.
27	ABM	ARU blocking mode 0: ARU blocking mode disabled: ATOM reads continuously from ARU and updates CM0, CM1 independent of pending compare match event 1: ARU blocking mode enabled: after updating CM0,CM1 via ARU, no new data is read from ARU until compare match event is occurred. **NOTE** This bit is only applicable in SOMC mode.
26	OSM	One-shot mode 0: Continuous PWM generation after channel enable 1: A single pulse is generated **NOTE** This bit is only applicable in SOMP and SOMS modes.

Table 25.117 GTM0ATOMixCTRL Register Contents (2/4)

Bit Position	Bit Name	Function
25	SLA	Serve last ARU communication strategy 0: Capture SRx time stamps after CCU0 match event not provided to ARU 1: Capture SRx time stamps after CCU0 match event provided to ARU **NOTES** 1. This bit is only applicable in SOMC mode. 2. Please note, that setting of this bit has only effect, when ACBI(4:2) is configured for serve last compare strategy (“100”, “101”, or “110”). 3. When this bit is not set, the captured time stamps in the shadow registers SRx are only provided after the CCU1 match occurred. The ACBO(4:3) bits always return "10" in that case. 4. By setting this bit, the ATOM channel also provides the captured time stamps after the CCU0 match event to the ARU. The ACBO(4:3) bits are set to “01” in that case. After the CCU1 match event, the time stamps are captured again in the SRx registers and provided to the ARU. The ACBO(4:3) bits are set to “10”. When the data in the shadow registers after the CCU0 match was not consumed by an ARU destination and the CCU1 match occurs, the data in the shadow registers is overwritten by the new captured time stamps. The ATOM channel does not request new data from the ARU when the CCU0 match values are read from an ARU destination.
24	TRIGOUT	Trigger output selection (output signal TRIG_CHx) of module ATOM_CHx. 0: TRIG_[x] is TRIG_[x-1] orTIM_EXT_CAPTURE(x). 1: TRIG_[x] is TRIG_CCU0
23	EXTTRIGOUT	Select TIM_EXT_CAPTURE(x) as potential output signal TRIG_[x] 0: Signal TRIG_[x-1] is selected as output on TRIG_[x] (if TRIGOUT = 1) 1: Signal TIM_EXT_CAPTURE(x) is selected as output on TRIG_[x] (if TRIGOUT = 1)
22	EXT_TRIG	Select TIM_EXT_CAPTURE(x) as trigger signal 0: Signal TIM_[x-1] is selected as trigger to reset CN0 or to start single pulse generation. 1: Signal TIM_EXT_CAPTURE(x) is selected
21	OSM_TRIG	Enable trigger of one-shot pulse by trigger signal *OSM_TRIG* 0: Signal OSM_TRIG can not trigger start of single pulse generation 1: Signal OSM_TRIG can trigger start of single pulse generation (only if bit OSM = 1) **NOTE** This bit should only be set if bit OSM=1 and bit RST_CCU0 = 0.
20	RST_CCU0	Reset source of CCU0 0: Reset counter register CN0 to 0 on matching comparison with CM0 1: Reset counter register CN0 to 0 on trigger TRIG_[x-1] orTIM_EXT_CAPTURE(x). **NOTES** 1. If RST_CCU0=1 and UPEN_CTRLx=1 are set, TRIG_[x-1] or TIM_EXT_CAPTURE(x) triggers also the update of work register (CM0, CM1 and CLK_SRC). 2. This bit is only applicable in SOMP mode. 3. This bit should only be set if bit OSM=0 (i.e. in continuous mode)
19 to 17	Reserved	These bits are always read as 0. When written, write the initial value.
16	WR_REQ	CPU Write request bit for late compare register update. **NOTE** This bit is only applicable in SOMC and SOMB mode.
15	Reserved	These bits are always read as 0. When written, write the initial value.

Table 25.117 GTM0ATOMixCTRL Register Contents (3/4)

Bit Position	Bit Name	Function
14 to 12	CLK_SRC_SR	Actual CMU clock source (SOMS)/ shadow register for CMU clock source (SOMP). 000: CMU_CLK0 selected 001: CMU_CLK1 selected 010: CMU_CLK2 selected 011: CMU_CLK3 selected 100: CMU_CLK4 selected 101: CMU_CLK5 selected 110: CMU_CLK6 selected 111: CMU_CLK7 selected **NOTES** 1. After (channel) reset the selected CLK_SRC value is the SYS_CLK (input of Global Clock Divider). To use in SOMP mode one of the CMU_CLKx, it is required to perform a forced update of CLK_SRC with the value of CLK_SRC_SR value before/with enabling the channel. 2. This register is a shadow register for the CMU_CLKx select. Thus, if the CMU_CLK source for PWM generation should be changed during operation, the old CMU_CLK has to operate until the update of the ATOM channels internal CLK_SRC register by the CLK_SRC_SR content is done either by an end of a period or a FORCE_UPDATE.
11	SL	Initial signal level. 0: Low signal level 1: High signal level **NOTES** 1. Reset value depends on the hardware configuration chosen by silicon vendor. 2. If the output is disabled, the output ATOM_OUT[x] is set to inverse SL independent of the ATOM channel mode. 3. In SOMP, SOMI, SOMS mode, if the channel is disabled, the internal register SOUR inside ATOM sub unit SOU is set to inverse value of SL. By enabling the channel the register SOUR is not changed. Thus, if the output is enabled afterwards, the output ATOM_OUT[x] is the inverse value of SL. 4. In SOMC mode, if the channel is disabled, the internal register SOUR inside ATOM sub unit SOU is set to value of SL. By enabling the channel the register SOUR is not changed. Thus, if the output is enabled and the channel is disabled, the output ATOM_OUT[x] is the value of SL. 5. In SOMS mode, this bit is only applicable when the channel and its output are disabled.
10	Reserved	This bit is always read as 0. When written, write the initial value.
9	CMP_CTRL	CCUx compare strategy select. 0: Greater/equal compare against TBU time base values (TBU_TSx ≥ CMx) 1: Less/equal compare against TBU time base values (TBU_TSx ≤ CMx) **NOTE** This bit is only applicable in SOMC mode.
8 to 4	ACB	ATOM Mode control bits. **NOTES** 1. These bits have different meaning in the different ATOM channel modes. See the mode description **Section 25.11.3, ATOM Channel modes** .
3	ARU_EN	ARU Input stream enable. 0: ARU Input stream disabled 1: ARU Input stream enabled

Table 25.117 GTM0ATOMixCTRL Register Contents (4/4)

Bit Position	Bit Name	Function
2	TB12_SEL	Select time base value TBU_TS1 or TBU_TS2. 0: TBU_TS1 selected for comparison 1: TBU_TS2 selected for comparison **NOTE** This bit is only applicable in SOMC mode.
1, 0	MODE	ATOM channel mode select. 00: ATOM Signal Output Mode Immediate (SOMI) 01: ATOM Signal Output Mode Compare (SOMC) 10: ATOM Signal Output Mode PWM (SOMP) 11: ATOM Signal Output Mode Serial (SOMS)

(2) GTM0ATOMixSTAT (i = 0, x = 0 to 7, i = 1, x = 0 to 7, i = 2, x = 0 to 4)

Access: This register can be read/written in 32-bit units.

Address:
GTM0ATOM00STAT: <GTM_base> + $0D01C_H$, GTM0ATOM10STAT: <GTM_base> + $0D81C_H$
GTM0ATOM01STAT: <GTM_base> + $0D09C_H$, GTM0ATOM11STAT: <GTM_base> + $0D89C_H$

Table 25.118 GTM0ATOMixSTAT Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 29	Reserved	These bits are always read as 0. When written, write the initial value.
28 to 24	ACBO	ATOM Internal status bits. ACBO[3] = 1: CCU0 Compare match occurred ACBO[4] = 1: CCU1 Compare match occurred **NOTES** 1. These bits are only set in SOMC mode. 2. ACBO is reset to 0b00000 on an update of register CM0 or CM1 (via ARU or CPU) 3. In SOMC mode these bits are sent as ARU control bits 52 to 48.
23	Reserved	These bits are always read as 0. When written, write the initial value.
22	WRF	Write request of CPU failed for late update. 0: Late update was successful, CCUx units wait for comparison. 1: Late update failed. The bit WRF can be reset by writing a 1 to it. **NOTE** This bit is only applicable in SOMC and SOMB mode.

Table 25.118 GTM0ATOMixSTAT Register Contents (2/2)

Bit Position	Bit Name	Function
21	DV	Valid ARU Data stored in compare registers. 0: No valid data stored in register CM0 and/or CM1, no comparison is activated. 1: Valid data stored in CM0 and/or CM1, comparison activated. **NOTE** This bit is only applicable in SOMC and SOMB mode. The CPU can determine the status of the ARU transfers with this bit. After the compare event occurred, the bit is reset by hardware.
20 to 16	ACBI	ATOM Mode control bits. **NOTES** 1. For ATOM SOMI, SOMC, SOMP and SOMS mode this register serves as a mirror for the five ARU control bits received through the ARU interface. The bits are valid, when the DV bit is set. 2. For SOMB mode this bit field serves as the work register of the compare strategy. It can be updated with the value of bit field ACB of register GTM0ATOMixCTRL or the value of internal shadow register ACB_SR.
15 to 1	Reserved	These bits are always read as 0. When written, write the initial value.
0	OL	Actual output signal level of ATOM_CHx_OUT. 0: Actual output signal level is low 1: Actual output signal level is high **NOTE** Reset value is the inverted value of bit SL which depends on the hardware configuration chosen by silicon vendor.

25.11.6.9 GTM0ATOMixRDADDR (i = 0, x = 0 to 7, i = 1, x = 0 to 7, i = 2, x = 0 to 4)

Access: This register can be read/written in 32-bit units.

Address: GTM0ATOM00RDADDR: <GTM_base> + $0D000_H$, GTM0ATOM10RDADDR: <GTM_base> + $0D800_H$

Table 25.119 GTM0ATOMixRDADDR Register Contents

Bit Position	Bit Name	Function
31 to 25	Reserved	These bits are always read as 0. When written, write the initial value.
24 to 16	RDADDR1	ARU Read address 1. **NOTES** 1. The ATOM channel switches to this read address, when requested in the ARU control bits 52 to 48 with the pattern “111--”. The channel switches back to the RDADDR0 after one ARU data package was received on RDADDR1. 2. This read address is only applicable in SOMC mode. 3. This bit field is only writeable if channel is disabled.
15 to 9	Reserved	These bits are always read as 0. When written, write the initial value.
8 to 0	RDADDR0	ARU Read address 0. **NOTES** 1. This read address is used by the ATOM channel to receive data from ARU immediately after the channel and ARU access is enabled (see **Section (1), GTM0ATOMixCTRL (i = 0, x = 0 to 7, i = 1, x = 0 to 7, i = 2, x = 0 to 4)** for details). 2. This bit field is only writeable if channel is disabled.

25.11.6.10 GTM0ATOMixCN0 (i = 0, x = 0 to 7, i = 1, x = 0 to 7, i = 2, x = 0 to 4)

25.12 Dead Time Module (DTM)

25.12.1 Overview

The following figure gives an overview of the structure of the Dead Time Module (DTM).

25.12.1.1 DTM overview

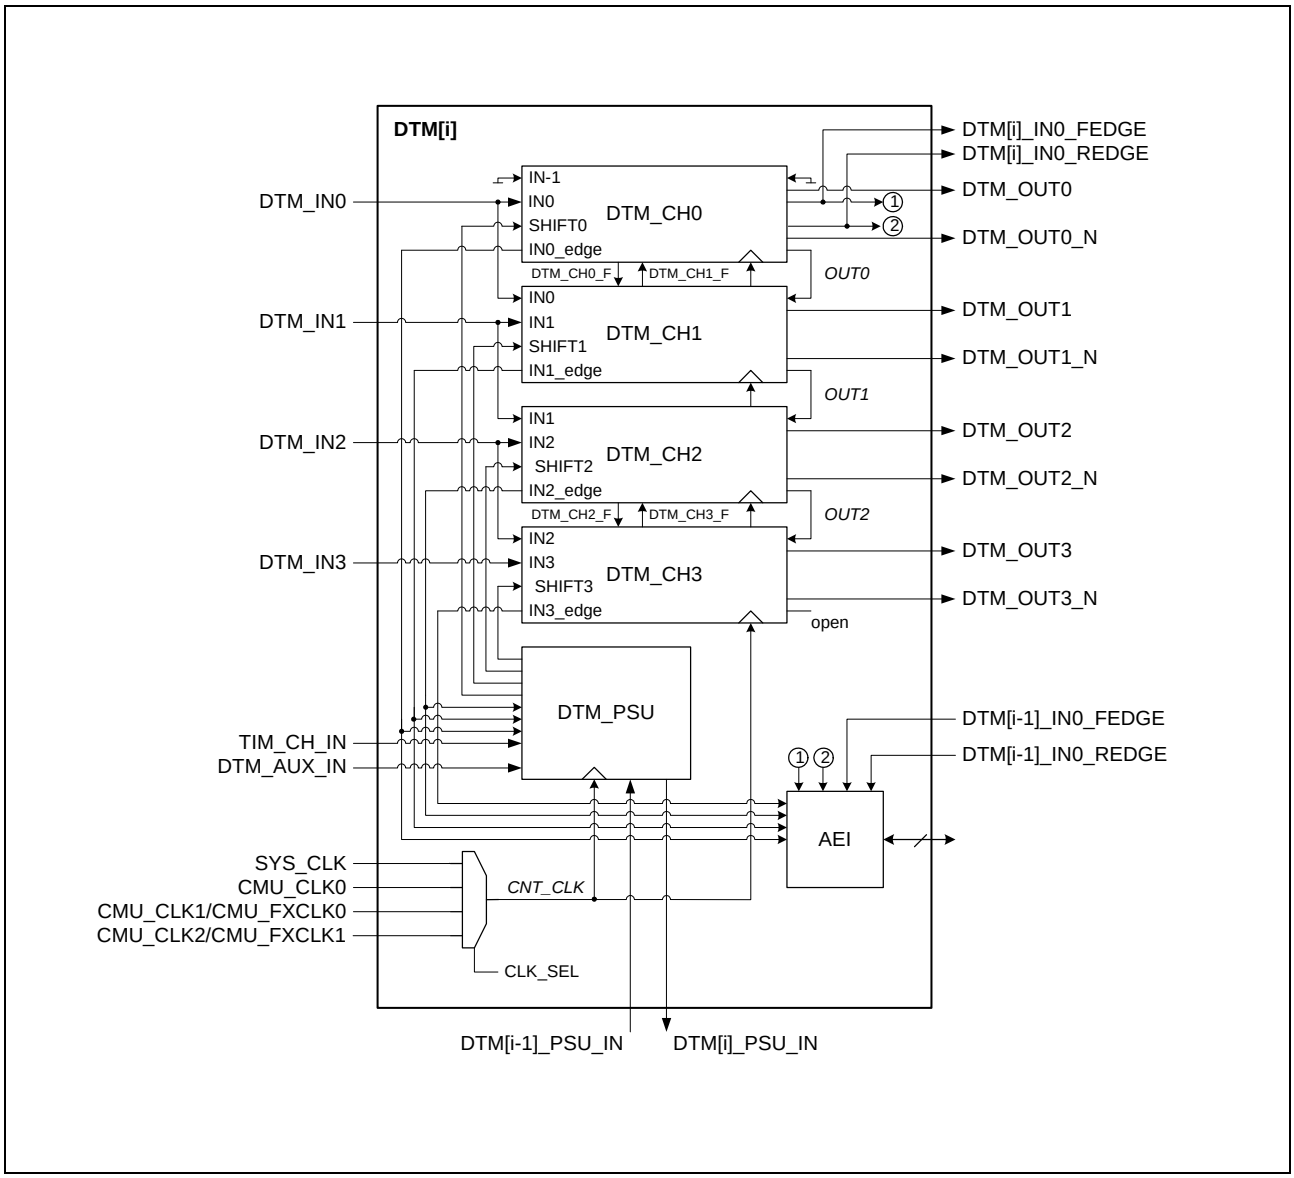

Figure 25.52 DTM block diagram

The main function of the DTM is to derive for each input DTM_IN0 to DTM_IN3 the individual inverse signal (DTM[i]_OUT[x]_N) and to apply an edge specific delay between the edge of the original signal and the edge of the derived inverted signal (i.e., the dead time). This function is mainly used for controlling of half bridges.

A second function provided by DTM is to set the outputs of one channel to the value of the preceding channel if requested by a trigger on input TIM_CH_IN or DTM_AUX_IN. This feature allows a phase shift on one PWM signal to the phase of the preceding PWM signal up to the next edge on this channel.

The third function provided by DTM is to (N)AND/(N)OR/X(N)OR combine the input DTM_IN[x] signal of one DTM channel with the signal on input TIM_CH_IN or DTM_AUX_IN (selected inside DTM_PSU and assigned to one of the signals SHIFT[x]) or with the output 1 (signal OUT[x]) of preceding channel.

As a result OUT2 may be the combined signal of DTM_IN0 and TIM_CH_IN or DTM_AUX_IN and the signal DTM_IN1. For OUT3 this chain can be combined again with signal DTM_IN3.

The outputs of each channel may be swapped individually to provide the function of combining signals on each output of a channel.

In general, the DTM instances are placed behind the TOM and the ATOM instances, i.e., the outputs TOM_OUT[x] and ATOM_OUT[x] are each routed to a DTM instance.

Additionally, some TIM instances are also connected to the DTM instances.

These connections between DTM and the modules TIM, TOM and ATOM are depicted in **25.12.1.2**.

Note, for unavailable DTM[i] instances the signal DTM[i-1]_PSU_IN is passed through to DTM[i]_PSU_IN, DTM[i-1]_IN0_FEDGE and DTM[i-1]_IN0_REDGE are passed through to DTM[i]_IN0_FEDGE and DTM[i]_IN0_REDGE.

Note, depending on device configuration, not every DTM instance is available. E.g. a device may only have one DTM connected to the first four channels of ATOM. In this case, the other four channels (4 to 7) are connected directly to GTM outputs.

For detailed information, which DTM instance is available, see corresponding device specific **Table 25.2, Sub-Units and Channels** of this specification [1].

25.12.1.2 Connections of TIM, TOM and ATOM to DTM

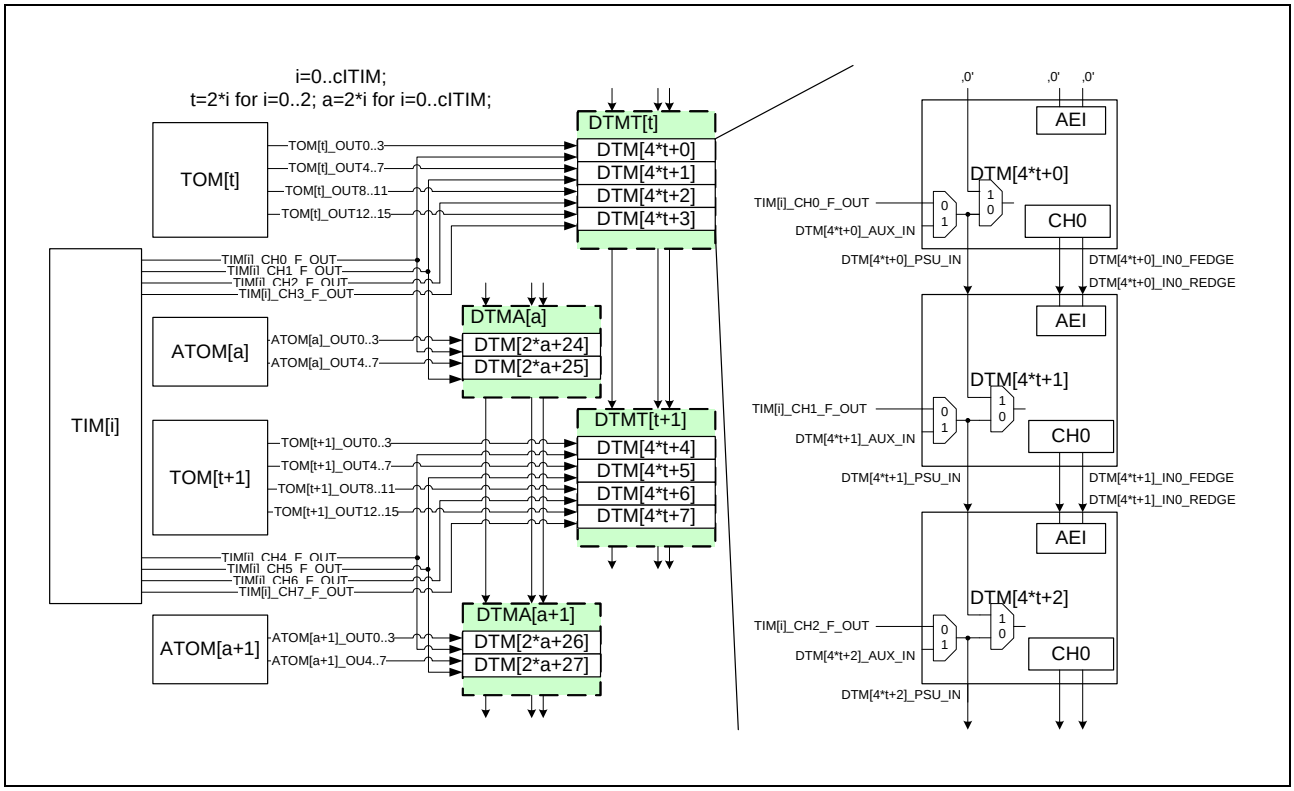

Figure 25.53 Connections of TIM, TOM and ATOM to DTM

For each TIM instance index i it can be calculates which instance of DTM and thus also which DTM channel is connected to which TIM channel, TOM channel or ATOM channel.

Four DTM instances behind a TOM instance x are grouped together in a hierarchy called DTMT[x].

Two DTM instances behind an ATOM instance x are grouped together in a hierarchy called DTMA[x].

A DTM instance is only available if there exist at least one TOM or ATOM instance and one TIM instance that can be connected to it.

25.12.2 DTM Channel

The following figure depicts the functions of a DTM channel.

25.12.2.1 DTM channel 0 overview

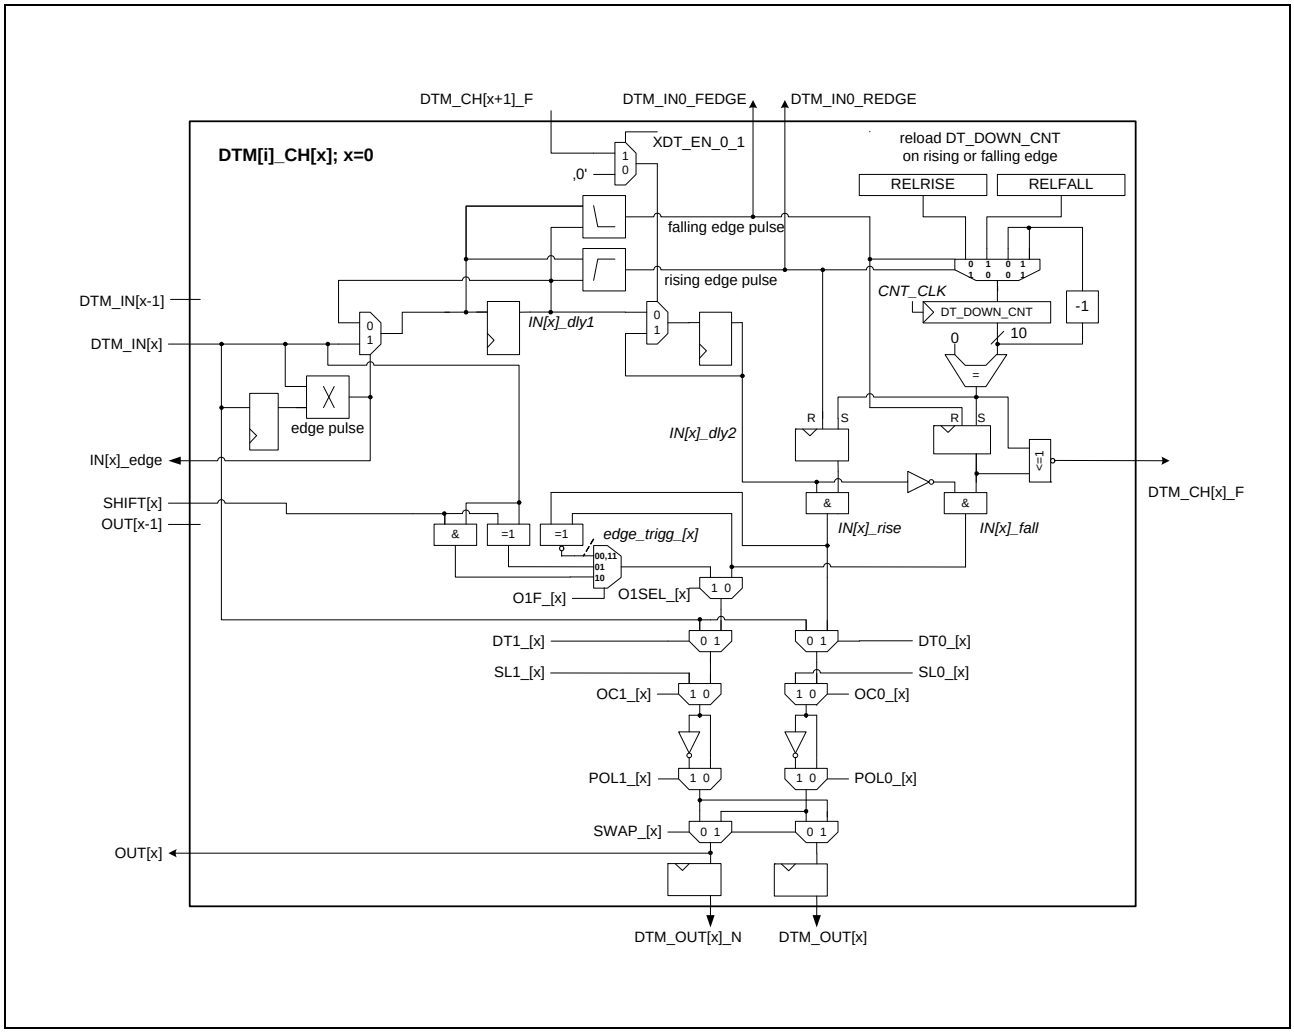

Figure 25.54 DTM channel 0 block diagram

25.12.2.2 DTM channel 1 to 3 overview

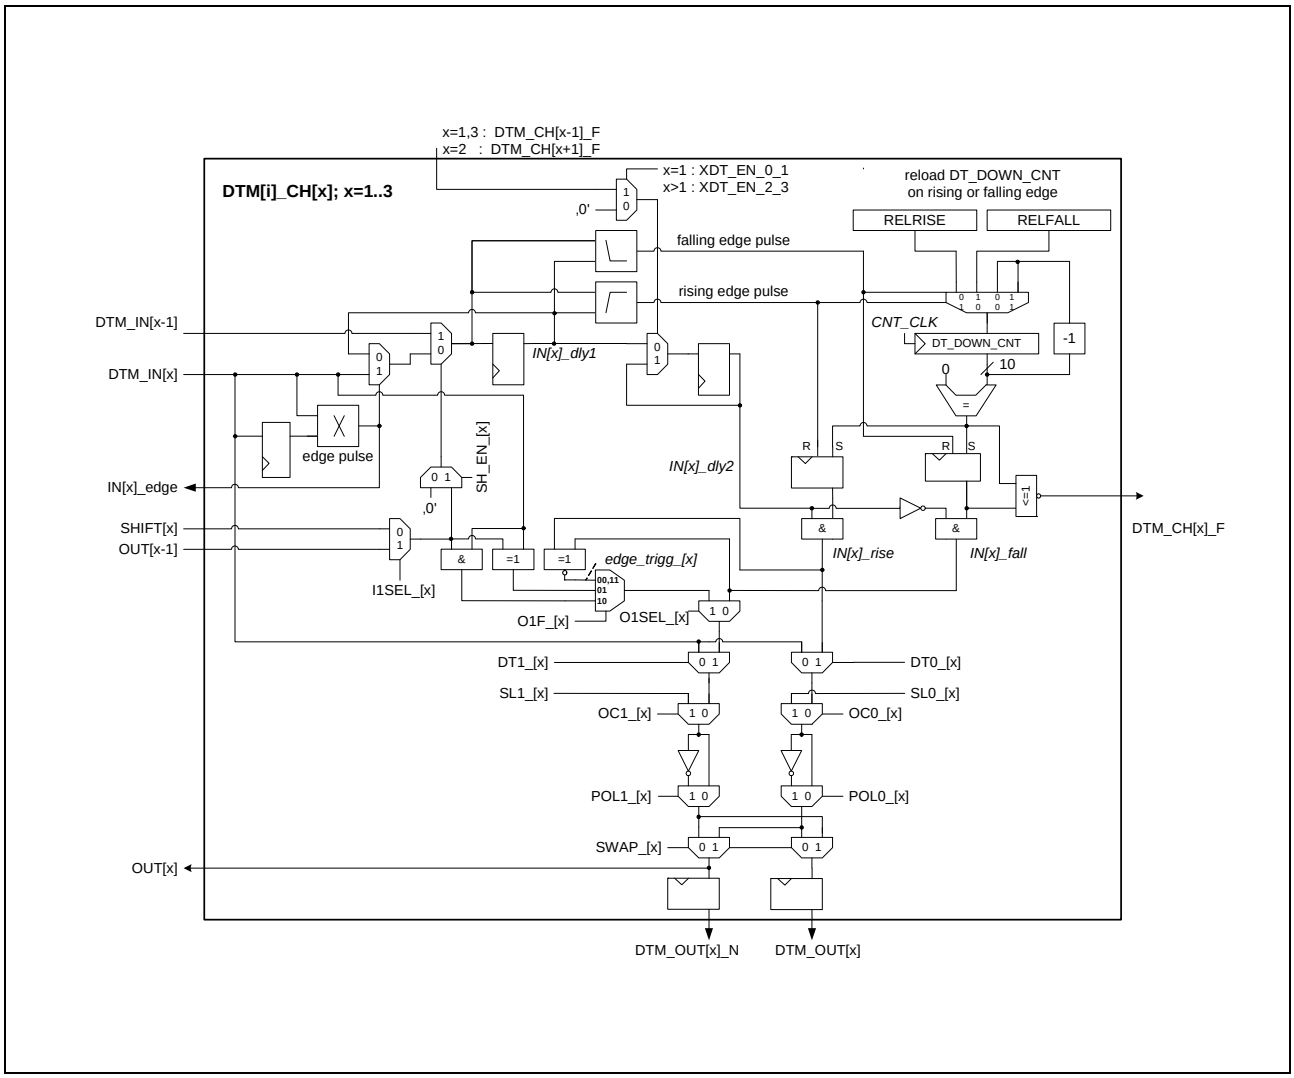

Figure 25.55 DTM channel 1 to 3 block diagram

The main feature of each channel is to derive the inverse signal out of the input signal DTM_IN[x], apply an edge dependent delay on the two resulting signal paths and provide these signals at the outputs DTM[i]_OUT[x] and DTM[i]_OUT[x]_N.

There are two possibilities to apply dead time on GTM output signals.

One is to use one DTM channel per TOM/ATOM channel and generate inside the DTM the second inverse signal. This is called the standard dead time generation.

The second way is to generate two signals out of two TOM/ATOM channel and to apply inside the DTM only the dead time by using two cross linked DTM channel. This is called the cross dead time generation.

25.12.2.3 Standard dead time generation

Standard dead time generation means that per DTM channel out of one input signal the inverse output signal is generated additionally and on both output signals the dead time between their edges is applied.

The dead time can be configured for each edge individually. The bit field RELRISE in register GTM0DTMixDTV contains the reload value for the counter and defines the delay for rising edges in multiples of selected clock ticks.

The bit field RELFALL in register GTM0DTMixDTV contains the reload value for the counter and defines the delay for falling edges in multiples of selected clock ticks.

The counter is reloaded with the value of RELRISE on a rising edge and reloaded with the value of RELFALL on a falling edge on input DTM_IN[x] (or DTM_IN[x-1] in case of shift enable SH_EN_[x]).

On a reload of the counter the FlipFlop following the counter output comparator is reset and stays reset until the counter has reached 0.

After reload, the counter DT_DOWN_CNT counts down until it reaches 0 and stops at 0.

The signal flow for function of standard dead time signal generation is depicted in following figure

25.12.2.4 Wave signals for function of dead time generation

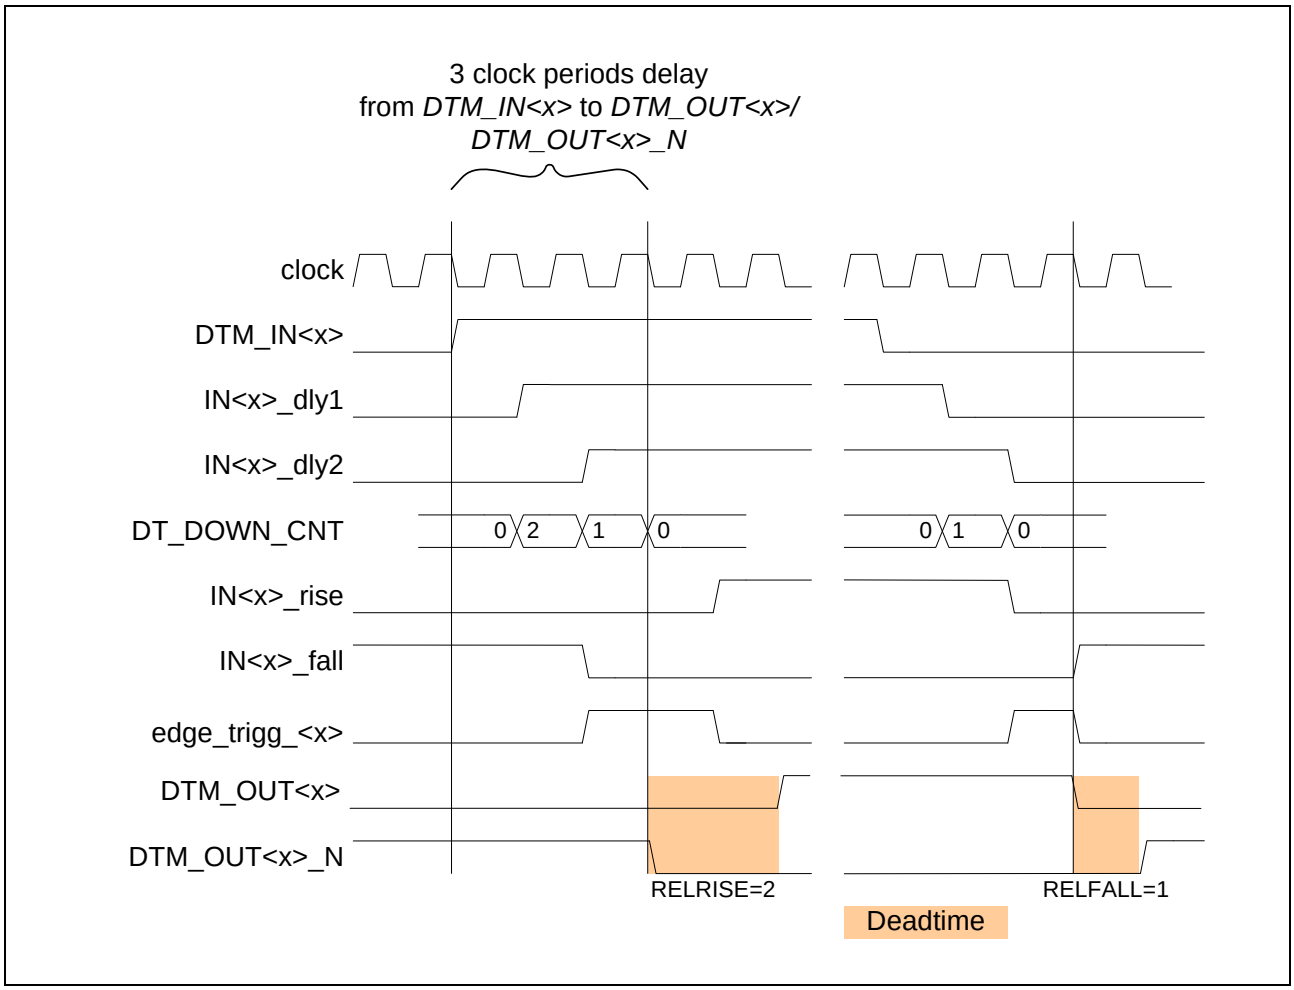

Figure 25.56 Wave signals for function of dead time generation

NOTES

1. The delay from the input signal DTM_IN[x] to the output signals DTM[i]_OUT[x] and DTM[i]_OUT[x]_N is three system clock periods by disabled feed through (see DT0/1_[x] in GTM0DTMiCHCTRL2).
2. The delay from the input signal DTM_IN[x] to the output signals DTM[i]_OUT[x] and DTM[i]_OUT[x]_N is one system clock periods by enabled feed through (see DT0/1_[x] in GTM0DTMiCHCTRL2).
3. The reset level of the output signals DTM[i]_OUT[x] connected from ATOM module depends on the hardware configuration value atom_out_reset_level_c chosen by silicon vendor.
4. The reset level of the output signals DTM[i]_OUT[x]_N connected from ATOM module depends on the inverted hardware configuration value atom_out_reset_level_c chosen by silicon vendor.

25.12.2.5 Cross channel dead time

A second way to apply a dead time value on two output signals is the cross channel dead time.

In opposite to the dead time described in **25.12.2.3** the cross channel dead time mode does not generate out of one signal the corresponding inverse signal but tries to apply the dead time on the input signals of two neighbored DTM channel.

To do this, two neighbored DTM input signals (on DTM channel 0 and 1 or on DTM channel 2 and 3) are cross linked together in the way that a falling edge on one channel leads to a hold phase of current signal value on the cross linked channel.

This behavior is reached by the following:

A falling edge on e.g. channel 0 reloads the DT_DOWN_CNT with the value of RELFALL. While this counter is counting down, the output signal of the cross linked channel 1 keeps its value. If the counter DT_DOWN_CNT has reached 0 again, the channel 1 output is released and can follow the value on its input.

The timing of the cross channel dead time is depicted in the following figure:

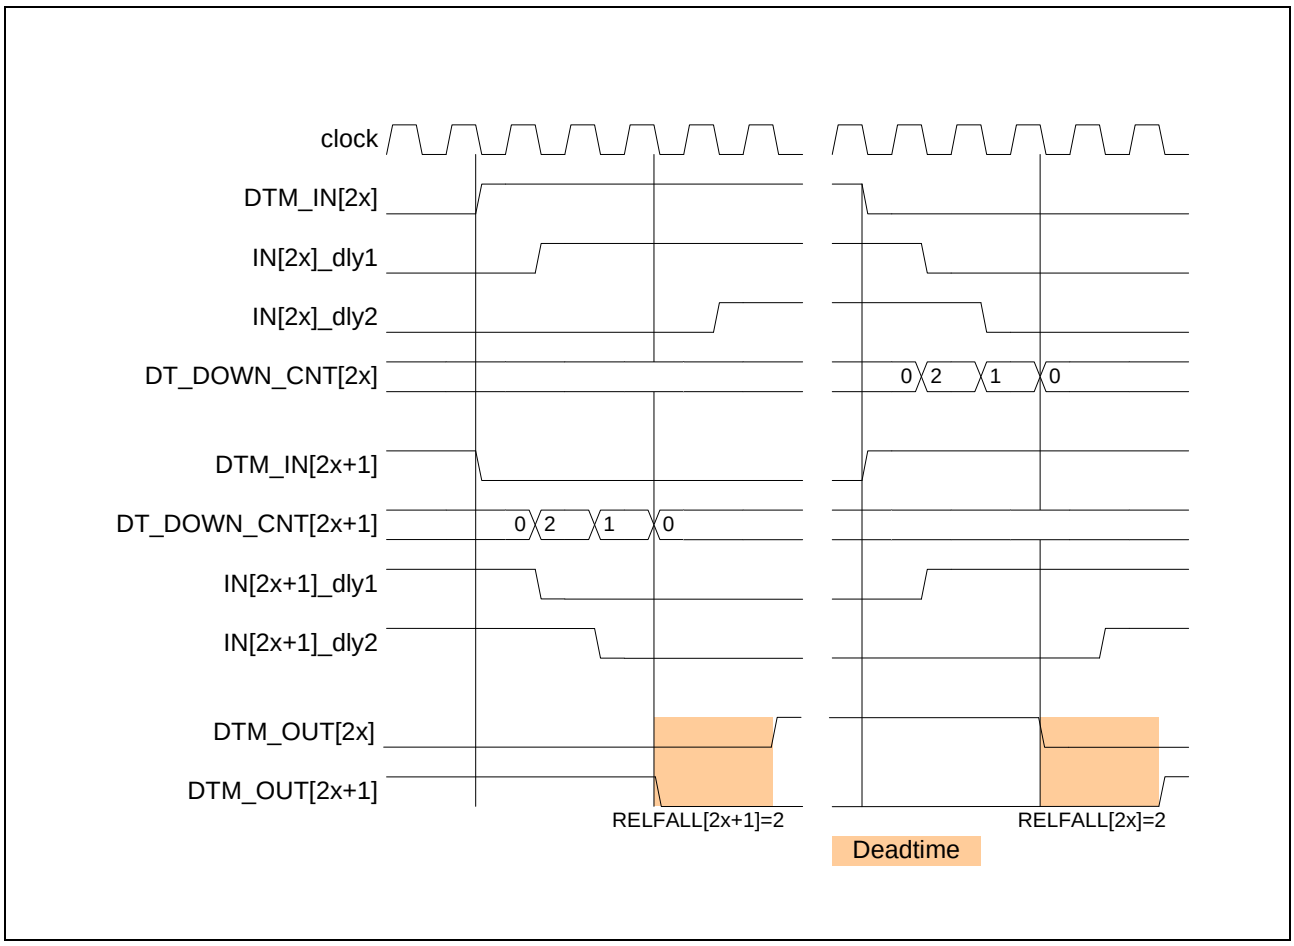

Figure 25.57 Cross channel dead time timing diagram

25.12.3 Phase Shift Control Unit

The phase shift unit (DTM_PSU) is depicted in the following figure. It supports the second major function of the DTM module to allow phase shifting of PWM signal on one of the channels.

25.12.3.1 Phase Shift Unit overview

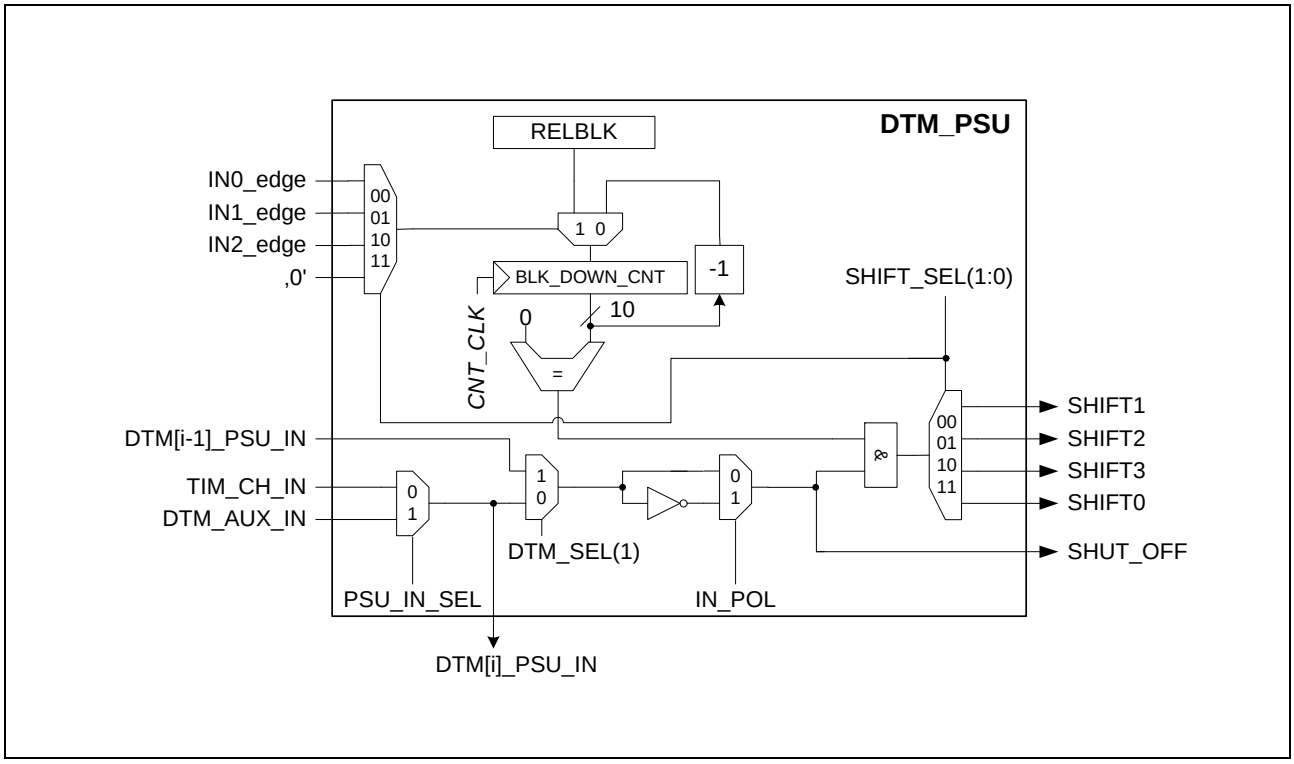

Figure 25.58 Phase Shift Unit overview

This submodule provides an additional counter BLK_DOWN_CNT and reload register RELBLK (bit field of register GTM0DTMiPSCTRL). The counter is reloaded on an edge detected on one of the selected signals IN0_edge to IN2_edge (selected by bit field SHIFT_SEL in register GTM0DTMiPSCTRL). Then, the counter counts down until it reaches 0. While the counter is counting down, it blocks the trigger (i.e. the selected one of the signals SHIFT[x]) of one of the channels by one of the input signals TIM_CH_IN or DTM_AUX_IN.

If the counter BLK_DOWN_CNT is not counting, a pulse on the input TIM_CH_IN or DTM_AUX_IN is forwarded to one of the selected DTM_PSU outputs SHIFT[x]. This signal triggers in the selected channel (if SH_EN_x=1) the update of the first Flip-Flop on channel x (i.e. representing IN[x]_DLY) to the input value DTM_IN[x-1] of the preceding channel. If this update leads to an edge, the succeeding part of DTM channel derives the inverse signal and applies the corresponding dead time (i.e. the edge delay) to the output signals of the channel.

NOTE

For channel x=0 input signals DTM_IN[x-1] and OUT[x-1] are unused and I1SEL_[x] and SH_EN_[x] are defined as 0.

The following figure shows an example of phase shifting on channel 1.

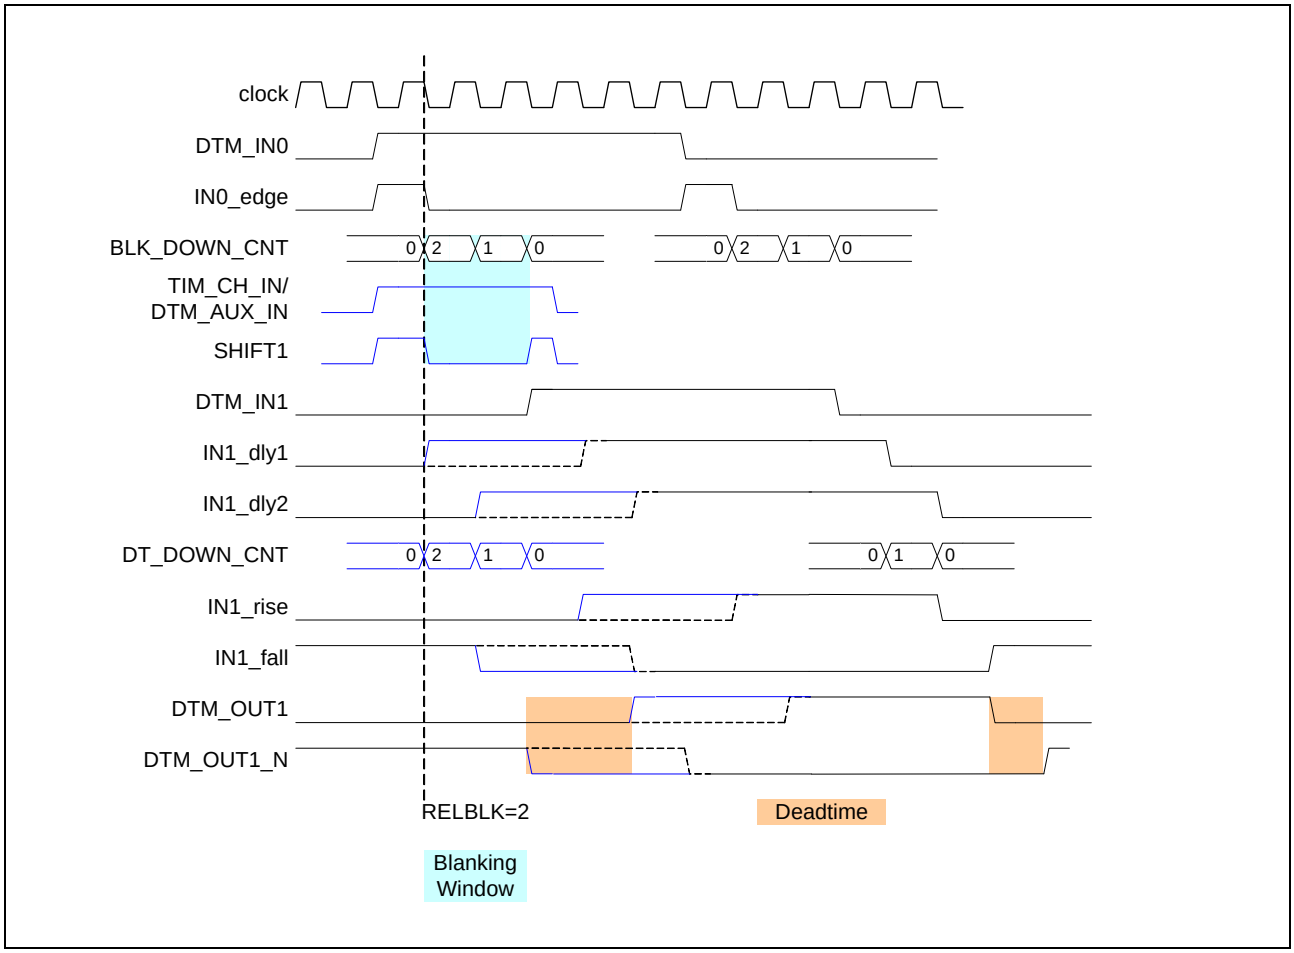

Figure 25.59 Example wave of phase shift on channel 1

25.12.4 Multiple output signal combination

Each channel provides additionally the possibility to combine the channel inputs DTM_IN[x] and SHIFT[x] or OUT[x-1] (selected by I1SEL_[x]) by an AND or an XOR gate (selected by O1F_[x]).

It is recommended to use the combination of signals only if bit field RELBLK of register GTM0DTMiPSCTRL is 0. Otherwise, the signals TIM_CH_IN/DTM_AUX_IN may be disturbed by the blanking window counter.

Together with the inverter inside submodule DTM_PSU (selected by IN_POL), the inverter on each output of a channel (selected by POL0_[x]/POL1_[x]) and the possibility to change polarity of DTM_IN[x] inside connected TOM/ATOM channel, a (N)AND, (N)OR or X(N)OR combination of the signals is possible.

25.12.4.1 Combination of input signal TIM_CH_IN/AUX_IN with TOM/ATOM signal

If the input selection I1SEL_[x] of a channel x is set to 0, the output selection O1SEL_[x] is set to 1 and SWAP_[x] is set to 0, depending on PSU_IN_SEL either TIM_CH_IN or DTM_AUX_IN can be combined with signal DTM_IN[x].

The function of combination on DTM output DTM[i]_OUT[x]_N (and also OUT[x]) is defined by O1F_[x] in the following way:

Table 25.129 The function of combination on DTM output DTM[i]_OUT[x]_N

	O1F_x	POL1_x	IN_POL	(A)TOM output inverted
XOR	01	0	0	no
AND	10	0	0	no
XNOR	01	1	0	no
NAND	10	1	0	no
XNOR	01	1	1	yes
OR	10	1	1	yes
XOR	01	0	1	yes
NOR	10	0	1	yes

Note: The inversion of the (A)TOM output can be reached by switching the **SL** bit (for TOM and ATOM SOMP/SOMC mode).

25.12.4.2 Combination of multiple TOM/ATOM output signals

If the input selection I1SEL_[x] of a channel x (with x = 1 to 3) is set to 1, the output selection O1SEL_[x] is set to 1 and SWAP_[x] is set to 0, the output of the preceding DTM channel OUT[x-1] can be combined with signal DTM_IN[x].

The function of combination on DTM output DTM[i]_OUT[x]_N (and also OUT[x]) is defined by O1F_[x] in the following way:

Table 25.130 The function of combination on DTM output DTM[i]_OUT[x]_N

	O1F_x	POL1_x	POL1_x-1	(A)TOM output inverted
XOR	01	0	0	no
AND	10	0	0	no
XNOR	01	1	0	no
NAND	10	1	0	no
XNOR	01	1	1	yes
OR	10	1	1	yes
XOR	01	0	1	yes
NOR	10	0	1	yes

By setting I1SEL_[x] to 1 on all four channel, a combination of all four signals DTM_IN0 to DTM_IN3 can be achieved (combinatorial chain).

To allow also combination of signals generated for output DTM[i]_OUT[x], the outputs 0 and 1 can be swapped by setting bit SWAP_ [x] for channel x.

25.12.4.3 Pulse generation on edge

Another feature of the DTM is to generate on the second output DTM[i]_OUT[x]_N a pulse on every edge of corresponding input signal DTM[i]_IN[x].

This can be reached by configuring O1SEL_[x] to ‘1’, i.e. selecting signal edge_trigg_[x] as the output signal (O1F_[x] has to be '00'). The signal edge_trigg_[x] is depicted in **Figure 25.56, Wave signals for function of dead time generation**.

The pulse length can be adjusted individually for each edge type by the configuration value REL_RISE and REL_FALL of register DTM[i]_CH[x]_DV.

The parameter REL_RISE defines the pulse length in case of a rising edge on input DTM[i]_IN[x], the parameter REL_FALL define the pulse length in case of a falling edge on input DTM[i]_IN[x].

25.12.5 Synchronous update of channel control register 2

It is possible to use the shadow register GTM0DTMiCHCTRL2SR and a selected edge of one of the channel 0 to 3 to update the work register GTM0DTMiCHCTRL2.

The update mechanism and it's configuration is depicted in the following figure.

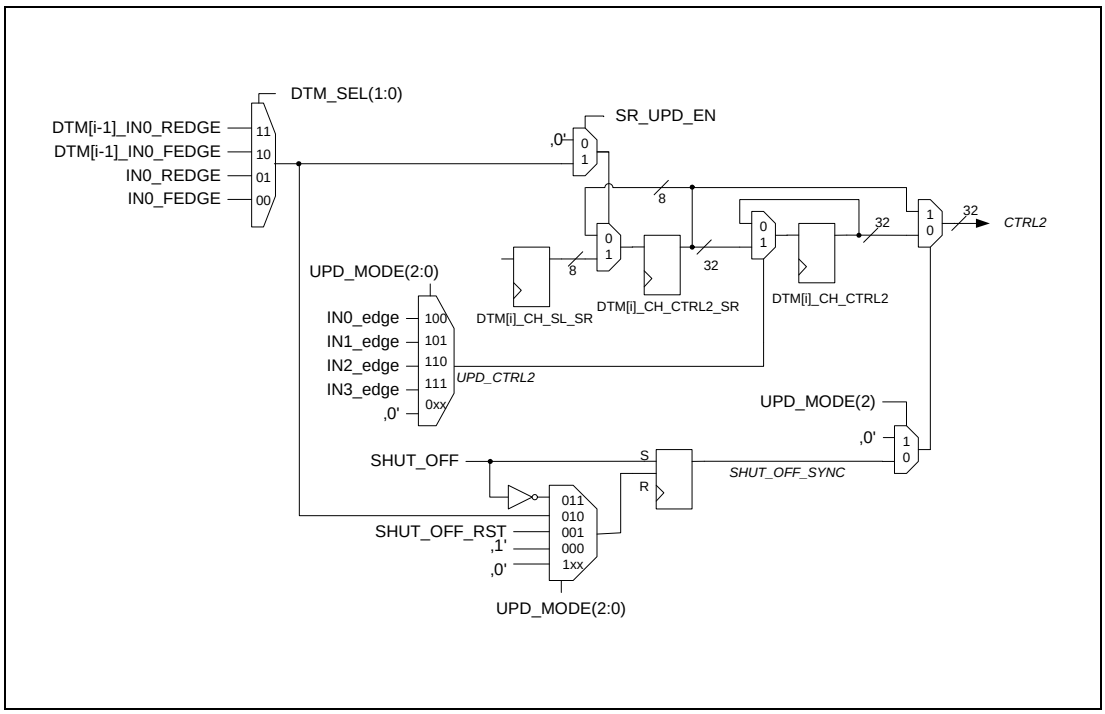

Figure 25.60 Synchronous update mechanism of register GTM0DTMiCHCTRL2

If enabled by the bit field UPD_MODE of register GTM0DTMiCTRL (i.e. UPD_MODE = 1xx), the register GTM0DTMiCHCTRL2SR serves as a shadow register of register GTM0DTMiCHCTRL2. The update is then triggered by an edge on one of the selected inputs DTM_IN0 to DTM_IN3.

The synchronous update allows the user to change output polarity, the selection of constant signal level, the constant signal level itself and the switch to/from feed through path on all four channels in parallel synchronized to one of the input edges on DTM_IN0 to DTM_IN3.

25.12.6 DTM output shut off

A fast shut off for the eight outputs of DTM instance i can be triggered by one of the two assigned inputs TIM[n]_CH_IN or DTM[i]_AUX_IN or the two inputs TIM[m]_CH_IN or DTM[i-1]_AUX_IN of the previous DTM instance i-1. (DTM_AUX_IN inputs are clamped to low (no function) for the P1x-C devices). The selection of the trigger signal source is done by the bits PSU_IN_SEL and DTM_SEL(1) (see **Figure 25.58**). The selected trigger signal is named SHUT_OFF.

Enabling of the shut off feature is done by setting UPD_MODE(2:0) to one of the values “001”, “010” or “011”.

The shut off behavior of the DTM outputs is defined by the value of register GTM0DTMiCHCTRL2SR.

If the shut off feature is enabled by UPD_MODE, as long as the signal SHUT_OFF_SYNC is ‘0’, the register GTM0DTMiCHCTRL2 defines the output signal behavior.

If the signal SHUT_OFF_SYNC is ‘1’, the register GTM0DTMiCHCTRL2SR defines the output signal behavior.

The signal SHUT_OFF_SYNC is set to ‘1’ if signal SHUT_OFF switches to ‘1’ and is reset depending on value of UPD_MODE(2:0). The reset is higher prioritized than set

There are three different ways to reset the signal SHUT_OFF_SYNC to ‘0’:

- The CPU writes a ‘1’ to bit SHUT_OFF_RST of register DTM_CH_CTRL1
- Synchronous to an edge on DTM channel 0 input of this DTM instance i or on an edge on DTM channel 0 input of preceding DTM instance i-1.
- Asynchronous if signal SHUT_OFF switches back to '0'

Figure 25.60 depicts the shut off feature and the different shut off release possibilities.

Note: The reset of SHUT_OFF_SYNC has higher priority then the set of this signal.

For the eight SL bits (SLx_y_SR) of the shadow register GTM0DTMiCHCTRL2SR exist a second shadow register DTM[i]_CH_SR.

If enabled by configuration bit SR_UPD_EN of register GTM0DTMiCTRL, the update of SL bits of register GTM0DTMiCHCTRL2SR can be triggered by one of the signals selected by bit field DTM_SEL of register GTM0DTMiCTRL. This trigger signal is either the rising or the falling edge detected on DTM[i]_IN0 of instance i or the rising or the falling edge on DTM[i-1]_IN0 of preceding instance i-1.

As depicted in **Figure 25.54** the DTM input signal TIM_CH_IN/DTM_AUX_IN can be forwarded to the succeeding instance. Thus, it can be used to trigger shut off in two consecutive DTM instances.

25.12.7 Configuration Register Overview

The following table gives an overview of the DTM configuration register.

Table 25.131 Register list

Symbol	Register Name	Details in Section
GTM0DTMiCTRL	Global Configuration and Control Register	**25.12.8.1**
GTM0DTMiCHCTRL1	Channel Control Register 1	**25.12.8.2**
GTM0DTMiCHCTRL2	Channel Control Register 2	**25.12.8.3**
GTM0DTMiCHCTRL2SR	Channel Control Register 2 Shadow	**25.12.8.4**
GTM0DTMiPSCTRL	Phase Shift Unit Configuration and Control Register	**25.12.8.5**
GTM0DTMixDTV	Dead Time Reload Values; x = 0 to 3	**25.12.8.6**
DTM[i]_CH_SR	Channel Shadow Register	**25.12.8.7**

25.12.8 Configuration Register Description

25.12.8.1 GTM0DTMiCTRL (i = 24, 26, 28)

Access: This register can be read/written in 32-bit units.

Address: GTM0DTM24CTRL: <GTM_base> + 13600_H
GTM0DTM26CTRL: <GTM_base> + 13680_H
GTM0DTM28CTRL: <GTM_base> + 13700_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

25.13 Multi Channel Sequencer (MCS)

25.13.1 Overview

The Multi Channel Sequencer (MCS) sub module is a generic data processing module that is connected to the ARU. One of its major applications is to calculate complex output sequences that may depend on the time base values of the TBU and are processed in combination with the ATOM sub module. Other applications can use the MCS sub module to perform extended data processing of input data resulting from the TIM sub module. Moreover, some applications may process data provided by the CPU within the MCS sub module, and the calculated results are sent to the outputs using the ATOM sub modules.

The following parameters are design variables for the MCS hardware structure that can vary in its range for different module instances:

W - Word width of the data path

T - Number of available MCS channels

RDW - RAM data width of connected RAM

RAW - RAM address width used by the MCS for addressing memory

NPS - Number of pipeline stages

USR - Use second RAM (0 - one RAM available, 1 – two RAMs available)

All MCS instances in the GTM use the values W = 24, RDW = 32, and NPS = 5. The values for T and RAW are device specific and vary between the following values:

T = 3, 6, or 9

RAW = 9

USR = 0 or 1.

25.13.2 Architecture

25.13.2.1 MCS Architecture

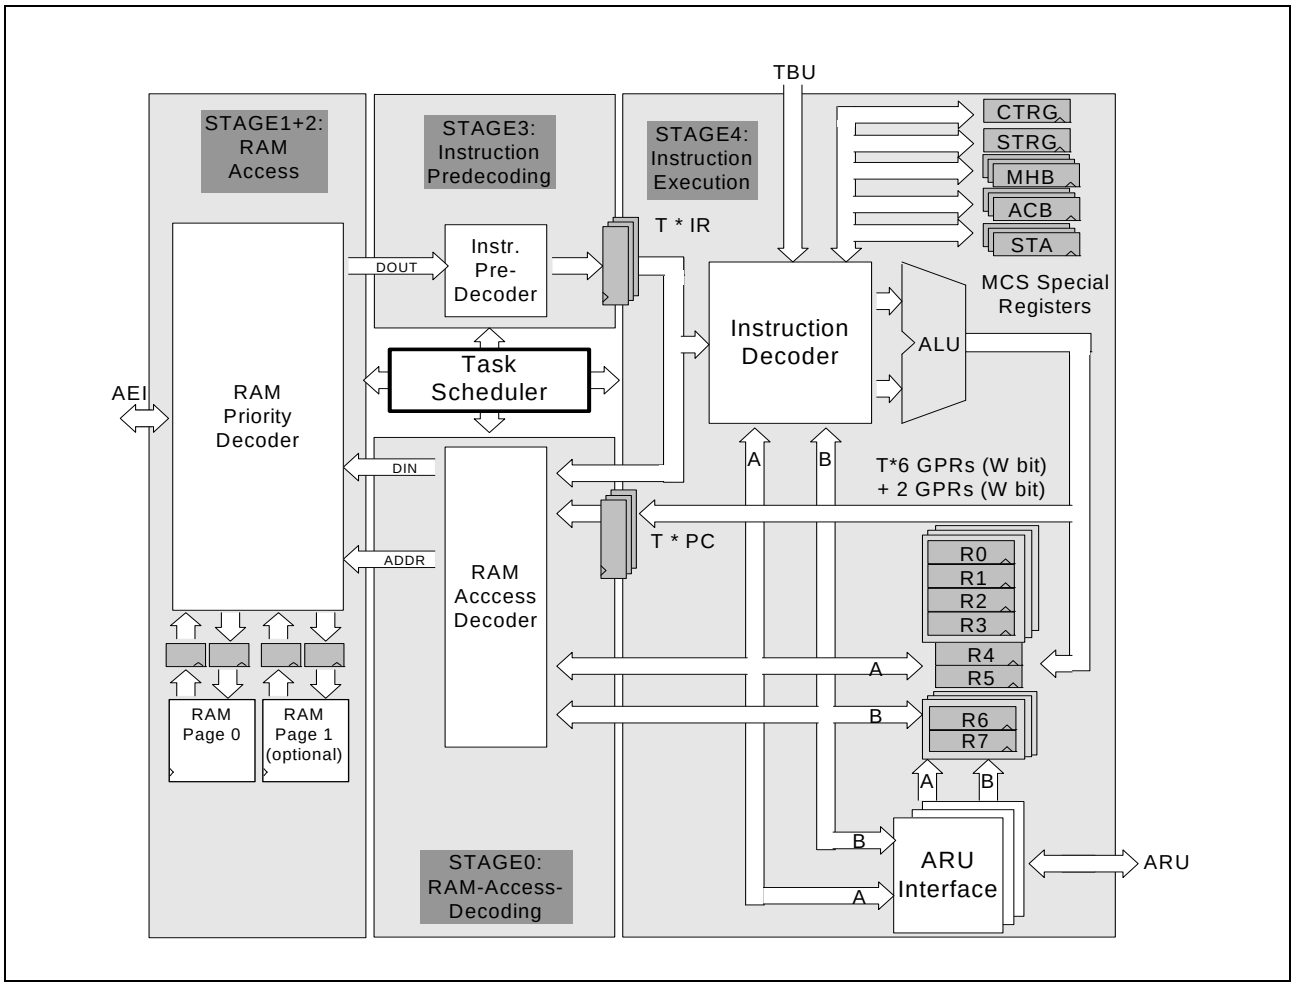

Figure 25.61 MCS Architecture block diagram

Figure 25.61 gives an overview of the MCS architecture.

The MCS module mainly embeds a single data path with five pipeline stages, consisting of a W-bit wide Arithmetic Logic Unit (ALU), several decoders, and a connection to one or two RAM modules (depending on parameter USR) located outside of the MCS sub module.

The data path of the MCS is shared by T so called MCS-channels, whereas each MCS-channel executes a dedicated micro-program that is stored inside the RAM connected to the MCS module.

The connected RAM may contain arbitrary sized code and data sections that are accessible by all MCS-channels and the CPU via AEI bus interface. More details about the RAM can be found in **Section 25.13.4, Memory Organization**

An MCS-channel can also be considered as an individual task of a processor that is scheduled to the commonly used data path at a specific point in time. The execution of the different MCS-channels on the different pipeline stages is controlled by a central hardware related task scheduler, which enables fast task switches within a single clock cycle. Details about the task scheduler and the available scheduling algorithms can be found in **Section 25.13.3, Scheduling**.

Typically, if data has to be exchanged between different MCS-channels and/or the CPU, the connected RAM, which is accessible by all MCS-channels and the CPU, can be used.

Besides the commonly used data path, each MCS-channel has a dedicated ARU interface for communication with other ARU connected modules, an Instruction Register (IR), a Program Counter Register (PC), a Status Register (STA), an ARU Control Bit Register (ACB), a Memory High Byte Register (MHB) and a Register Bank with eight W bit general purpose registers (R0, R1, ...R7). With exception to the registers R4 and R5, all of these registers are only visible within its dedicated MCS-channel and thus the MCS-channels cannot exchange data using registers. The registers R4 and R5 are common to all MCS-channels and thus they can also be used for sharing data between MCS-channels. Moreover, the general purpose registers (R0, R1, ... R7) are also writable by the CPU, an thus an MCS channel may also consume data from the CPU using its general purpose registers.

The MCS also provides a common 16 bit wide trigger register that can be accessed by all MCS channels in order to trigger other MCS-channels located in the same module. Writing to STRG sets bits and writing to CTRG clears bits in the common trigger register. To enable triggering of MCS-channels by CPU, the CPU can set bits in the common trigger register by writing to GTM0MCSiSTRG and clear bits by writing to GTM0MCSiCTRG.

Considering the architecture in the figure above, the main actions of the different pipeline stages are as follows:

Pipeline stage 0 performs a setup of address, input data, and control signals for the next RAM access of a specific MCS-channel.

The actual RAM access of a specific MCS-channel is executed in pipeline stage 1 and 2, assuming an external connection of a synchronous RAM with a latency of one clock cycle.

Pipeline stage 3 performs pre-decoding and dispatching of instructions and data resulting from the RAM.

Finally, in pipeline stage 4 the current instruction is executed.

Since the internal registers of the MCS can be updated by different sources (MCS write access, CPU write access, ARU read access) a write conflict occurs if more than one source wants to write to the same register. In this case the result of the register is unpredictable. However, the software should setup its application in a way that such conflicts do not occur.

One exception is the common trigger register, which may be written by multiple sources (different MCS channels and CPU) in order to enable triggering of different MCS channels. Typically, the software should setup its application in a manner that different sources should not write the same bits in the trigger register.

25.13.3 Scheduling

The MCS provides a hardware related task scheduler, which globally controls the execution of the tasks in the different pipeline stages. The task scheduler implements four different scheduling modes, that can be selected by the SCD_MODE bit field in the GTM0MCSiCTRLSTAT register. Depending on the selected scheduling mode, the task scheduler is selecting a dedicated MCS channel that will be executed in pipeline stage 0 in the next clock cycle. Additionally, MCS channels that are already present in the pipeline are shifted to its successor pipeline stage, with each clock cycle. This means, that the execution time of an MCS-channel in a specific pipeline stage is always one clock cycle.

The MCS task scheduler may also schedule an empty cycle to pipeline stage 0, in order to grant a time slice to the CPU for accessing the connected RAM.

It should be noted, if the task scheduler assigns an MCS-task to pipeline stage 0, but this task does not access the RAM, the CPU can access the corresponding RAM, even if the scheduler did not reserve an empty clock cycle.

In the following, the available scheduling modes are described.

25.13.3.1 Round Robin Scheduling

The Round Robin Scheduling Mode implements the simplest scheduling algorithm. This algorithm schedules a predefined set of MCS channels in the range [0; SCD_CH] in ascending order. After the last channel SCD_CH has been assigned to the pipeline, an empty cycle is scheduled in order to enable RAM access for the CPU. The parameter SCD_CH can be controlled by the register GTM0MCSiCTRLSTAT. If the value of SCD_CH is greater than T-1, the scheduler assumes a value of T-1 for bit field SCD_CH.

Figure 25.62 shows a timing example of the Round Robin Scheduling with T = 8 MCS-channels (marked as C_0 to C_7) that are scheduled together with a CPU access to a pipeline with and NPS = 5 stages. It is assumed that bit field SCD_CH is set to 8.

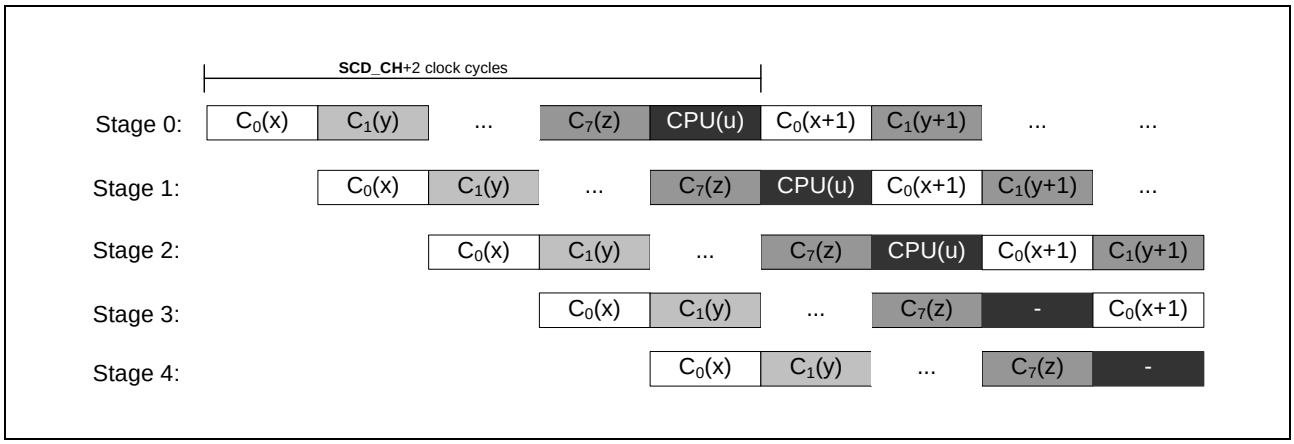

Figure 25.62 Timing of Round Robin Scheduling

The identifier Ci(x) denotes that MCS-channel i is currently executing the instruction or data located in the memory at position x in the corresponding pipeline stage. The figure shows, which MCS-channel is activated in specific pipeline stage at a specific point in time.

Moreover, the figure shows, that the Round Robin scheduling is always repeated after SCD_CH+2 clock cycles, which means that the time duration of an instruction cycle is SCD_CH+2 clock cycles. However, if the value SCD_CH + 2 is less than NPS, the duration of an instruction cycle is limited by

the depth of the pipeline to NPS clock cycles. Thus the effective execution time of a single cycle instruction is always MIN(SCD_CH+2, NPS) clock cycles, ignoring the latency of the pipeline.

The Round Robin scheduling algorithm has the characteristic that it fairly distributes all time slices to all MCS-channels and the CPU. This means, that the program execution time of a specific task is independent from the activity of any neighboring task or the CPU RAM access, and thus a correct estimation of the actual program execution time is very easy. However, the round-robin scheduling may waste clock cycles by scheduling MCS-channels that are not ready to execute an instruction (e.g. MCS-channel is disabled by CPU). The following scheduling modes overcome this issue.

25.13.3.2 Accelerated Scheduling

In order to improve the computational performance, the accelerated scheduling mode provides two key features. Firstly, the scheduler only selects MCS-channels that are not suspended and thus can actually execute an instruction. Secondly, the scheduler applies instruction prefetching to minimize empty cycles in the pipeline. An MCS-channel is marked as suspended due to one of the reasons:

- An MCS-channel is executing a read or write request to an ARU connected sub module (instruction ARD, AWR, ARDI, AWRI, NARD, NARDI).
- An MCS-channel waits on a register match event (e.g. instruction WURM), in order to wait on a desired register value (e.g. trigger event from another MCS channel).
- An MCS-channel is disabled.

In the case of instruction prefetching, the scheduler will assign an MCS-channel C_p to pipeline stage 0, which is already present in another pipeline stage. This means, that the execution of the last instruction of C_p located in the memory MEM(PC/4) is not yet finished completely, whereas PC is the current value of the program counter of MCS-channel C_p. Thus, the newly scheduled MCS-channel C_p will prefetch a successor instruction MEM(PC/4+PFO) under the assumption that there will be no branch and no memory access in the program between the instructions MEM(PC/4) and MEM(PC/4+PFO). The prefetch offset value PFO is determined by counting the number of already scheduled MCS channels C_p in the pipeline. However, if the assumption fails, the pipeline will be flushed by replacing all MCS-channel C_p of the pipeline with an empty cycle, as soon as the instruction decoder detects a branch or a memory access. In general, each MCS-channel can accept instruction prefetching. However, there are some cases in which an upcoming flushing of the pipeline can be easily detected by the MCS hardware due to evaluation of internal states. Therefore, it is defined that an MCS-channel accepts instruction prefetching only under the following conditions:

- An MCS-channel is currently not in the second cycle of a two-cycle control flow instruction (instruction CALL, RET).
- An MCS-channel is currently not in the second cycle of a three-cycle memory access instruction (instruction MWRL, MWRIL).

The accelerated scheduling mode guarantees, that the time duration of an instruction cycle varies between 1 and T+1 cycles. Hence, a single cycle instructions has an effective execution time between 1 to T+1 clock cycles, depending on the number of suspended MCS-channels and the actual instruction sequence. The worst case execution time occurs if all channels are active and the CPU also accesses the RAM. The best case occurs e.g. if only one MCS-channel is enabled and the executed program sequence has only linear code without branches and memory access.

The algorithm of the accelerated scheduling mode first, evaluates the state of all available MCS-channels as well as a CPU request to the RAMs and then it decides if a specific MCS-channel or an empty cycle is assigned to pipeline stage 0 in the next clock cycle. It should be noted that the accelerated scheduling mode treats RAM access requests from the CPU in a similar manner as MCS-

channels, which means that empty cycles for RAM requests are only inserted into the pipeline if there is an active RAM request from the CPU or no other task can be scheduled.

In order to fairly trade all available MCS-channels as well as CPU RAM requests and to guarantee a worst case execution time of T+1 clock cycles, an additional task prioritization scheme is applied used that dynamically prioritizes all MCS-channels and a CPU memory access depending on the history of the scheduler's decisions. The algorithm of the accelerated scheduler mode is executed every clock cycle and it works in the following manner:

1. Try to find an MCS-channel C_r with highest priority that is not suspended and not already scheduled to the pipeline stages 0 to NPS-2. If C_r is found assign C_r to pipeline stage 0 and finish scheduling for current clock cycle.
2. Otherwise, try to find an MCS-channel C_p with highest priority that is not suspended and accepts instruction prefetching. If C_p is found assign C_p to pipeline stage 0 and finish scheduling for current clock cycle.
3. Otherwise, try to find an MCS-channel C_s with highest priority that is suspended and accepts instruction prefetching. If C_s is found assign C_s to pipeline stage 0 and finish scheduling for current clock cycle.
4. Otherwise, assign an empty cycle to pipeline stage 0 and finish scheduling for current clock cycle.

The underlying task prioritization scheme tracks the history of the scheduled MCS-channels in a list consisting of T+1 items. The list is initialized with all MCS-channels followed by a reserved time slot for the CPU RAM access. The position of an MCS-channel within this list implicitly defines the priority, while the back of this list holds the MCS-channel with highest priority. Whenever the scheduling algorithm described above has found an MCS-channel C_r or C_p it to be scheduled in the next clock cycle, it removes this item from the list and put it to the front of the list. In order to fairly prioritize all MCS-channels, the algorithm also removes the item at the back of the list to the second position in the list, after the inserted scheduled front item. Since the list always contains all possible MCS-channels and with each clock cycles each non-scheduled item is moved at least one position towards the end of list, it is obvious that each MCS-channel will have the highest priority not later than T+1 clock cycles.

Figure 25.63 shows a timing example of the accelerated scheduling with NPS=5 pipeline stages.

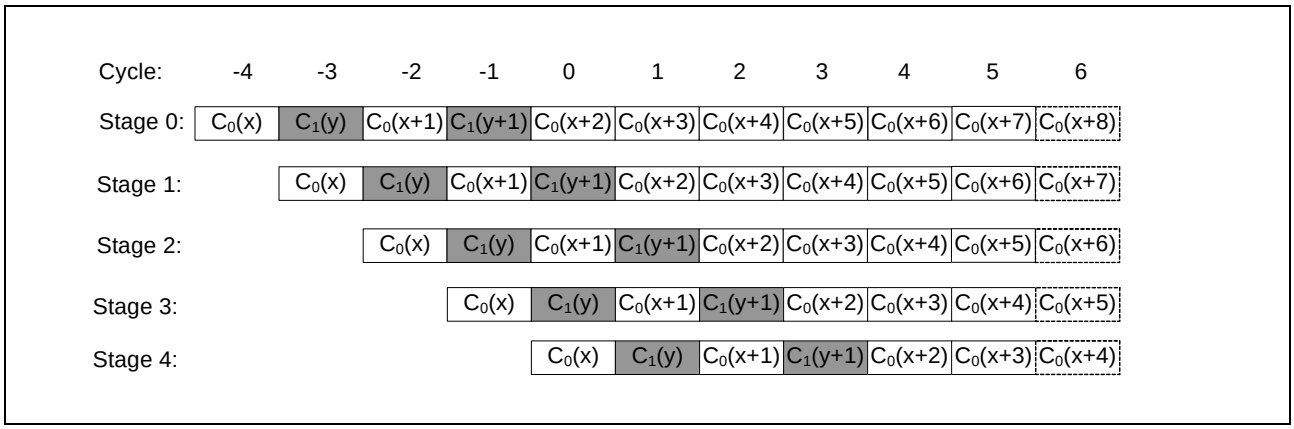

Figure 25.63 Timing of Accelerated Scheduling

The example assumes that initially MCS-channels 0 and 1 are enabled and the program for each MCS-channel is located in the RAM as follows:

MCS-Channel 0

Memory Location	Instruction
x+0	ADDL R0, 7
x+1	XOR R0, R1
x+2	SHR R0, 7
x+3	JBC STA, Z, 4*(x+9)
x+4	MOVL R2, 5

MCS-Channel 1

Memory Location	Instruction
y+0	MOVL STA, 0

Figure 25.64 The example assumes that initially MCS-channels 0 and 1

Since both channels are ready to run, the scheduler fairly selects the channels in an alternating order, as it can be obtained in stage 0 at the clock cycles before cycle 1. Since MCS-channel 1 is disabling itself at cycle 1 with the instruction of memory location y, the scheduler will only select MCS-channel 0 in the following by applying instruction prefetching. But it should be noted, the scheduler applies instruction prefetching during the whole sequence, due to the fact that the number of enabled channels is always less than the available number of pipeline stages NPS. The actual state of pipeline in cycle 6 depends on conditional branch instruction of memory location x + 3. If the branch is not taken, the linear code execution of MCS-channel 0 is continued as shown in the Figure. However, if the branch to memory location x+9 is taken, in cycle 6 the scheduler will fetch the instruction C_0(x+9) in stage 0 and flush the stages 1 to NPS-1. Note, the flushing of the pipeline only concerns the prefetched instructions of the MCS-channel that is currently executed in the last stage. If pipeline stage 1 of cycle 5 would belong to another channel than 0, only the stages greater than 2 would be flushed.

25.13.3.3 Single Prioritization Scheduling

The Single Prioritization Scheduling mode is an extended variant of the Accelerated Scheduling mode, which additionally applies a task prioritization of a single MCS-channel. In this mode, the bit field SCD_CH of register GTM0MCSiCTRLSTAT is used to identify a dedicated MCS-channel that is always preferred during scheduling. This means, that the scheduler will assign preferred MCS-channel SCD_CH to pipeline stage 0, as long as this channel is not suspended. If the preferred MCS-channel is entering its suspended state, the scheduling algorithm switches to the accelerated scheduling as previously described in **Section 25.13.3.2, Accelerated Scheduling**. Whenever the MCS-channel SCD_CH is resuming from its suspended state, the scheduler switches back and assign the channel SCD_CH to pipeline stage 0 until the next suspension event occurs. If the bifield SCD_CH contains the value T or higher, the task scheduler will always prioritize CPU access to the RAM. This means, whenever the task scheduler detects that the CPU wants to access an MCS-RAM, the scheduler will assign an empty cycle into pipeline stage 0. If the CPU does not access the RAM any more, it switches back to the accelerated mode, as described previously in **Section 25.13.3.2, Accelerated Scheduling**.

In consequence, the Single Prioritization Scheduling mode cannot guarantee a maximum time duration of an instruction cycle for the overall execution of all MCS-channels, since it strongly depends on the activity of the prioritized MCS-channel SCD_CH. However, the Single Prioritization Scheduling mode provides the fastest possible execution for MCS-channel SCD_CH. Moreover, during the time spawn, in which the prioritized MCS-channel SCD_CH is suspended, this mode guarantees a duration of 1 to T+1 clock cycles of an instruction cycle for all non-prioritized channels.

25.13.3.4 Multiple Prioritization Scheduling

The Multiple Prioritization Scheduling mode is an extended variant of the Accelerated Scheduling mode, which additionally applies a task prioritization for multiple MCS-channels. In this mode, the bit field SCD_CH of register GTM0MCSiCTRLSTAT is used to identify a set of dedicated MCS-channels, which are always preferred during scheduling. The identifiers of the prioritized MCS-channels are in the range [0; SCD_CH] and the non-prioritized channels are in the range [SCD_CH+1; T-1]. The individual priority for the set of prioritized MCS-channels is applied in descending order, which means that MCS-channel 0 has the highest priority, followed MCS-channel 1, which has the second highest priority, and so on. The non-prioritized MCS-channels do not have any priority. A value of T-1 or higher for the bifield SCD_CH means that all T MCS-channels are prioritized MCS-channels.

With each clock cycle, the Multiple Prioritization Scheduling mode will assign the non-suspended MCS-channel with the highest priority from the set of prioritized MCS-channels to pipeline stage 0, as long as there are non-suspended prioritized MCS-channels available. If all prioritized MCS-channels are suspended, the scheduling algorithm switches to the accelerated scheduling as previously described in **Section 25.13.3.2, Accelerated Scheduling** and it schedules the non-prioritized channels. Whenever a prioritized MCS-channel is resuming from its suspended state, the scheduler switches back and applies the described prioritization scheme until the next suspension event of occurs.

In consequence, the Multiple Prioritization Scheduling mode cannot guarantee a maximum time duration of an instruction cycle for the overall execution of all MCS-channels, since it strongly depends on the activity of the prioritized MCS-channels. However, the Multiple Prioritization Scheduling mode provides the fastest possible execution for prioritized MCS-channels. Moreover, during the time spawn, in which all prioritized MCS-channels are suspended, this mode guarantees a duration of 1 to T+1 clock cycles of an instruction cycle for all non-prioritized channels.

25.13.4 Memory Organization

The MCS module supports a memory layout of up to $2^{RAW+USR}$ memory locations each RDW bit wide leading to a maximum byte wise address range from 0 to $2^{RAW+USR+2}$–1.

If two RAM modules are used (USR = 1) the entire address space of the MCS is divided into two seamless memory pages. Further, if the GTM provides a memory configuration sub module (MCFG), memory page 0 begins from (byte wise) address 0 and ranges to address MP0-4 and memory page 1 ranges from MP0 to MP1-4, while MP0 and MP1 are configuration parameters provided by MCFG. If USR is 1 but there is no MCFG module available, the actual parameters MP0 and MP1 can be found in [1]. The actual for addresses for accessing the memories via AEI can also be found in [1].

The RAM priority decoder of the MCS will always handle a RAM access from an MCS channel with a higher priority compared to a RAM access from AEI.

However, if a set of active MCS channels are only accessing one common RAM page, the MCS will grant any AEI accesses to the other RAM page in parallel to the MCS related RAM accesses, which means that AEI may get the full bandwidth to a dedicated RAM.

Basically, the actual access time to the RAMs via AEI depends on the actual scheduling mode and the activity of tasks. In the modes Round Robin Scheduling and Accelerated Scheduling the scheduler guarantees a maximum write access time of T + 3 clock cycles and a maximum read access time of T+ 6 clock cycles (assuming that the AEI bridge is configured with standard protocol in synchronous mode). In the scheduling modes Single Prioritization Scheduling and Multiple Prioritization Scheduling, the scheduler cannot guarantee a maximum access time for AEI RAM access.

Depending on the silicon vendor configuration, the connected RAM pages are initialized with zeros in the case of an MCS module reset.

If an ECC Error occurs while an MCS-channel reads data from a memory module, the corresponding MCS-channel is disabled and the ERR bit in register STA is raised.

25.13.5 Instruction Set

This section describes the entire instruction set of the MCS sub module. First, a brief overview over all available instructions is given and a detailed description of each instruction can be found in **Section 25.13.5.2, Data Transfer Instructions** to **Section 25.13.5.7, Other Instructions**.

In general, each instruction is RDW bit wide but the duration of each instruction varies between several instruction cycles. As already described in **Section 25.13.3, Scheduling** , the number of required clock cycles for an instruction cycle can be fixed or variable, depending on the selected scheduling mode. In the case of the Round Robin Scheduling, the duration is fixed with T+1 clock cycles, in the case of the Accelerated Scheduling the duration is variable in the range between 1 and T+1 clock cycles, and in all other Scheduling modes the duration is also variable and may even be more than T+1 clock cycles, depending on the application.

Before the available instructions are described, some commonly used terms, abbreviations and expressions are introduced:

OREG: The operation register set OREG = {R0, R1, R2, ..., R7, STA, ACB, CTRG, STRG, TBU_TS0, TBU_TS1, MHB} includes all MCS accessible internal registers, as well as the global time bases TBU_TS0, and TBU_TS1 that are provided by the sub module TBU.

AREG: The ARU register set AREG = {R0, R1, R2, ..., R7, ZERO} includes the all registers that can be written by incoming ARU transfers (ARD, ARDI, NARD, and NARDI instructions). These registers include all eight general purpose registers. The dummy register ZERO may be used to discard an incoming 24 bit ARU word.

NOTE

In the following, the register sets OREG and AREG are referred by the instructions. Typically, an operation announces W data bits. Whenever, a register of OREG implements less than W bits, it is assumed that these register bits only define the lower significant bits of an operation. The missing most significant bits are always read and written as zeros.

WLIT: The set WLIT = {0,1, ..., 2^{W}-1} is a W bit wide literal value used for encoding immediate operands.

ALIT: The set ALIT = {0,1, ..., $2^{RAW+USR}$-1} is a RAW + USR bit wide literal value used for encoding memory addresses.

AOLIT: The set AOLIT = {-$2^{RAW+USR-1}$, ..., -1,0,1, ..., $2^{RAW+USR-1}$-1} is a RAW + USR bit wide literal value used for encoding relative memory address offsets.

ARDLIT: The set ARDLIT = {0,1, ..., 2^{9}-1} is a 9 bit literal used for ARU read addresses.

AWRLIT: The set AWRLIT = {0,1, ..., 23} is used as ARU write indexes, selecting one of the 24 ARU write address.

SFTLIT: The set SFTLIT = {0,1, ..., W} is used as literal value for shift instructions.

BITLIT: The set BITLIT = {0,1, ..., 15} is a 4 bit literal used for bit indexing.

MSKLIT: The set MSKLIT = {0,1, ..., 2^{15}-1} is a 16 bit literal used for bit-masking.

BIT SELECTION: The expression VAR[i] represents the i-th bit of a variable VAR.

BIT RANGE SELECTION: The expression VAR[m:n] represents the bit slice of variable VAR that is ranging from bit n to bit m.

MEMORY ADRESSING: The expression MEM(X) represents the RDW bit wide value at location x ($x \in$ ALIT) of the memory. The expression MEM(x)[m:n] represents the bit slice ranging from bit n to m of the RDW bit wide word at memory location x.

ARU ADRESSING: In the case of ARU reading, the expression ARU(x) represents the 2*W+5 bit wide ARU word of ARU channel at read address x ($x \in$ ARDLIT). In the case of ARU writing, the expression ARU(x) represents a 2*W+5 bit wide ARU word that is written to an ARU channel indexed by the index x ($x \in$ AWRLIT). The index x selects a single ARU write channel from the pool of the MCS sub module's allocated ARU write channels. An MCS sub module has 24 dedicated ARU write channels, indexed by values 0 to 23. The expression ARU(x)[m:n] represents the bit slice ranging from bit n to m of the 2*W+5 bit wide ARU word.

Table 25.139 summarizes the entire instruction set of the MCS and **Table 25.140** shows the encoding of the individual instructions.

Table 25.139 Instruction Set Summary (1/3)

Class	Mnemonic	Operation	Instruction cycles	Synopsis
Data transfer	MOVL A, C	A ← C	1	Move Literal, A in OREG, C in WLIT

The individual instructions are decoded by evaluating the bits ‘0’ and ‘1’ at its expected positions, as mentioned in the table above. If the instruction decoder detects an invalid combination of these bits, the corresponding MCS-channel is disabled and the ERR bit in the register STA is set. Bit positions marked as ‘–’ are not relevant for the instruction. The bit position ‘a’, ‘b’, and ‘c’ are reserved for binary encoding of the instruction arguments A, B, and C.

25.13.5.2 Data Transfer Instructions

(1) MOVL Instruction

Syntax: MOVL A, C

Operation: A ← C

Status: Z

Duration: 1 instruction cycle

Description: Transfer literal value C (C ∈ WLIT) to register A (A∈ OREG).
The zero bit Z of status register STA is set, if the transferred value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(2) MOV Instruction

Syntax: MOV A, B

Operation: A ← B

Status: Z

Duration: 1 instruction cycle

Description: Transfer register B (B ∈ OREG) to register A (A ∈ OREG).
The zero bit Z of status register STA is set, if the transferred value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(3) MRD Instruction

Syntax: MRD A, C

Operation: A ← MEM(C)[W-1:0];
MHB ← MEM(C)[RDW-1:W]

Status: Z

Duration: 2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Description: Transfer the lower W bits of memory content at location C (C ∈ ALIT) to register A (A ∈ OREG).
The upper RDW-W bits of the memory content at location C are transferred to the MHB register.
The zero bit Z of status register STA is set, if the lower W bits of the transferred value are zero, otherwise the zero bit is cleared.
If the MHB register is selected as destination register A (A ∈ OREG), the bits 0 to RDW-W-1 of the referred memory location are transferred to MHB.
The program counter PC is incremented by the value 4.

(4) MWR Instruction

Syntax: MWR A, C

Operation: MEM(C)[W-1:0] ← A;
MEM(C)[RDW-1:W] ← MHB

Status: —

Duration: 2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Description: Transfer W bit value of register A (A ∈ OREG) together with the MHB register to the memory at location C (C ∈ ALIT).
The W bit value of register A is stored in the lower significant bits (bit 0 to W-1) of the memory location.
The MHB register is stored in bits W to RDW-W-1 of the referred memory location.
The program counter PC is incremented by the value 4.

(5) MWRL Instruction

Syntax: MWRL A, C

Operation: MEM(C)[W-1:0] ← A

Status: —

Duration: 3 instruction cycles but not faster than 1+2*NPS clock cycles due to pipeline flushing.

Description: Transfer W bit value of register A (A ∈ OREG) to memory at location C (C ∈ ALIT).
The W bit value of register A is stored in the lower significant bits (bit 0 to W-1) of the memory location and the bits W to RDW-W are left unchanged.
The program counter PC is incremented by the value 4.
It should be noted that this operation is not an atomic instruction.

(6) MRDI Instruction

Syntax: MRDI A, B [, C]

Operation: A ← MEM(B[RAW+USR+1:2] + C)[W-1:0]
MHB ← MEM(B[RAW+USR+1:2] + C)[RDW-1:W]

Status: Z

Duration: 2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Description: Transfer the bits 0 to W–1 of a memory location to register A (A ∈ OREG) using indirect addressing.
The upper RDW-W bits of this memory location are transferred to MHB register.
The memory location where to read from depends on register B (B ∈ OREG) and literal C (C ∈ AOLIT) and it is defined as B[RAW+USR+1:2] + C.
If the optional operand C is not available in the assembler syntax, the MCS assembler generates code with a default value of 0 for operand C.
The zero bit Z of status register STA is set, if the transferred bits 0 to W-1 are zero, otherwise the zero bit is cleared.
If the MHB register is selected as destination register A (A ∈ OREG), the bits 0 to RDW–W–1 of the referred memory location are transferred to MHB.
The program counter PC is incremented by the value 4.

(7) MWRI Instruction

Syntax: MWRI A, B [, C]

Operation: MEM(B[RAW+USR+1:2] + C)[W-1:0] ← A;
MEM(B[RAW+USR+1:2] + C)[RDW-1:W] ← MHB

Status: —

Duration: 2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Description: Transfer value of register A (A ∈ OREG) to the least significant bits 0 to W–1 of a memory location using indirect addressing.
The MHB register is moved to the bits W to RDW-1 at the same memory location.
The memory location where to write to depends on register B (B ∈ OREG) and literal C (C ∈ AOLIT) and it is defined as B[RAW+USR+1:2] + C.
If the optional operand C is not available in the assembler syntax, the MCS assembler generates code with a default value of 0 for operand C.
The program counter PC is incremented by the value 4.

(8) MWRIL Instruction

Syntax: MWRIL A, B

Operation: MEM(B[RAW+USR+1:0])[W-1:0] ← A;

Status: —

Duration: 3 instruction cycles but not faster than 1+2*NPS clock cycles due to pipeline flushing.

Description: Transfer W bit value of A (A ∈ OREG) to memory using indirect addressing.
The memory location where to write to is defined by the bits 2 to RAW+1 of register B (B ∈ OREG).
The W bit value is stored in the lower significant bits (bit 0 to W-1) of the memory location and the bits W to RDW–1 are left unchanged.
The program counter PC is incremented by the value 4.
It should be noted that this operation is not an atomic instruction.

(9) POP Instruction

Syntax: POP A

Operation: A ← MEM(R7[RAW+USR+1:2])[W-1:0];
R7 ← R7 – 4;
MHB ← MEM(R7[RAW+USR+1:2])[RDW–1:W];
SP_CNT ← SP_CNT – 1

Status: Z, EN

Duration: 2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Description: Transfer the lower significant bits (bit 0 to W–1) from the top of stack to register A (A ∈ OREG), followed by decrementing the stack pointer register R7 with the value 4.
The upper bits W to RDW-1 from the top of the stack are transferred to register MHB.
If the MHB register is selected as destination register A (A ∈ OREG), the bits 0 to RDW–W–1 from the top of the stack are transferred to MHB.
The memory location for the top of the stack is identified by the bits 2 to RAW+1 of the stack pointer register R7.
The zero bit Z of status register STA is set, if the lower W bit of the transferred value is zero, otherwise the zero bit is cleared.

The program counter PC is incremented by the value 4.
The SP_CNT bit field inside the GTM0MCSixCTRL register is decremented.
If an underflow on the SP_CNT bit field occurs, the STK_ERR[i]_IRQ is raised.
If an underflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCS[i]_CTRL is set, the current MCS-channel is disabled by clearing the EN bit of STA.

(10) PUSH Instruction

Syntax: PUSH A

Operation: R7 ← R7 + 4;
MEM(R7[RAW+USR+1:2])[W-1:0] ← A;
MEM(R7[RAW+USR+1:2])[RDW-1:W] ← MHB
SP_CNT ← SP_CNT + 1;

Status: EN

Duration: 2 instruction cycles but not faster than 1+NPS clock cycles due to pipeline flushing.

Description: Increment the stack pointer register R7 with the value 4, followed by transferring a W bit value of operand A (A ∈ OREG) together with a MHB register to the new top of the stack. The W bit value of A is stored in the bits 0 to W-1 of the memory location.
The content of the MHB register is stored in the bit W to RDW-1 of the memory location.
The memory location for the top of the stack is referred by the bits 2 to RAW+1 of the stack pointer register.
The program counter PC is incremented by the value 4.
The SP_CNT bit field inside the GTM0MCSixCTRL register is incremented.
If an overflow on the SP_CNT bit field occurs, the STK_ERR[i]_IRQ is raised.
If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCS[i]_CTRL is set, the current MCS-channel is disabled by clearing the EN bit of STA.
If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCS[i]_CTRL is set, the memory write operation for the A and MHB is discard.

25.13.5.3 ARU Instructions

(1) ARD Instruction

Syntax: ARD A, B, C

Operation: A ← ARU(C)[W-1:0];
B ← ARU(C)[2*W-1:W];
ACB ← ARU(C)[4+2*W:2*W]

Status: CAT

Duration: suspends current MCS-channel

Description: Perform a blocking read access to the ARU and transfer both W bit values received at the ARU port to the registers A and B (A ∈ AREG, B ∈ AREG), whereas A holds the lower W bit ARU word and B holds the upper W bit ARU word.
If A and B see the same register, only the upper W bit ARU word is stored and the lower W bit ARU word is discard.
If any transferred W bit value from the ARU should not stored in a register, the dummy register ZERO ∈ AREG can be selected in A or B to discard the corresponding ARU

data. Actually, all address values of A and B that exceed the range 0 to 7 discard the corresponding ARU data.
The received ARU control bits are stored in the register ACB.
The literal C (C ∈ ARDLIT) define the ARU address where to read from.
At the beginning of the instruction execution the CAT bit in the register STA is always cleared. After the execution of the instruction the CAT bit is updated in order to show if the instruction finished successfully (CAT = 0) or it was cancelled by the CPU (CAT = 1).
The program counter PC is incremented by the value 4.

(2) ARDI Instruction

Syntax: ARDI A, B

Operation:
A ← ARU(R6[8:0])[W-1:0];
B ← ARU(R6[8:0])[2*W-1:W];
ACB ← ARU(R6[8:0])[4+2*W:2*W]

Status: CAT

Duration: suspends current MCS-channel

Description: Perform a blocking read access to the ARU and transfer both W bit values received at the ARU port to the registers A and B (A ∈ AREG, B ∈ AREG), whereas A holds the lower W bit ARU word and B holds the upper W bit ARU word.
If A and B see the same register, only the upper W bit ARU word is stored and the lower W bit ARU word is discard.
If any transferred W bit value from the ARU should not stored in a register, the dummy register ZERO ∈ AREG can be selected in A or B to discard the corresponding ARU data. Actually, all address values of A and B that exceed the range 0 to 7 discard the corresponding ARU data.
The received ARU control bits are stored in the register ACB.
The read address is obtained from the bits 0 to 8 of the channels register R6.
At the beginning of the instruction execution the CAT bit in the register STA is always cleared. After the execution of the instruction the CAT bit is updated in order to show if the instruction finished successfully (CAT = 0) or it was cancelled by the CPU (CAT = 1).
The program counter PC is incremented by the value 4.

(3) AWR Instruction

Syntax: AWR A, B, C

Operation:
ARU(C)[W-1:0] ← A;
ARU(C)[2*W-1:W] ← B;
ARU(C)[4+2*W:2*W] ← ACB;

Status: CAT

Duration: suspends current MCS-channel

Description: Perform a blocking write access to the ARU and transfer two W bit values to the ARU port using the registers A and B (A ∈ OREG, B ∈ OREG), whereas A holds the lower W bit ARU word and B holds the upper W bit ARU word.
The ARU control bits to be sent are taken from the register ACB.
The literal C (C ∈ AWRLIT) define an index into the pool of ARU write address that is used for writing data.

Each MCS sub module has a pool of several write addresses that can be shared between all MCS-channels arbitrarily.
At the beginning of the instruction execution the CAT bit in the register STA is always cleared. After the execution of the instruction the CAT bit is updated in order to show if the instruction finished successfully (CAT = 0) or it was cancelled by the CPU (CAT = 1).
The program counter PC is incremented by the value 4.

(4) AWRI Instruction

Syntax: AWRI A, B

Operation: ARU(R6[4:0])[W-1:0] ← A;
ARU(R6[4:0])[2*W-1:W] ← B;
ARU(R6[4:0])[4+2*W:2*W] ← ACB;

Status: CAT

Duration: suspends current MCS-channel

Description: Perform a blocking write access to the ARU and transfer two W bit values to the ARU port using the registers A and B (A ∈ OREG, B ∈ OREG), whereas A holds the lower W bit ARU word and B holds the upper W bit ARU word.
The ARU control bits to be sent are taken from the register ACB.
The bits 0 to 4 of the register R6 define an index into the pool of ARU write address that is used for writing data.
Each MCS sub module has a pool of several write addresses that can be shared between all MCS-channels arbitrarily.
At the beginning of the instruction execution the CAT bit in the register STA is always cleared. After the execution of the instruction the CAT bit is updated in order to show if the instruction finished successfully (CAT = 0) or it was cancelled by the CPU (CAT = 1).
The program counter PC is incremented by the value 4.

(5) NARD Instruction

Syntax: NARD A, B, C

Operation: A ← ARU(C)[W-1:0];
B ← ARU(C)[2*W:W];
ACB ← ARU(C)[4+2*W:2*W]

Status: SAT

Duration: suspends current MCS-channel for a maximum of one ARU round trip cycle

Description: Perform a non-blocking read access to the ARU trying to transfer both W bit values received at the ARU port to the registers A and B (A ∈ AREG, B ∈ AREG), whereas A holds the lower W bit ARU word, B holds the upper W bit ARU word, and the ACB register holds the received ARU control bits.
The literal C (C ∈ ARDLIT) define the ARU address where to read from.
If the transfer finished successfully, the bit SAT of the register STA is set and the transferred values are stored in the registers A, B, and ACB.
If the transfer failed due to missing data at requested source, the bit SAT of the register STA is cleared and registers A, B, and ACB are not changed.
If A and B see the same register, only the upper W bit ARU word is stored and the lower W bit ARU word is discard.

If any transferred W bit value from the ARU should not stored in a register, the dummy register ZERO ∈ AREG can be selected in A or B to discard the corresponding ARU data. Actually, all address values of A and B that exceed the range 0 to 7 discard the corresponding ARU data.
The program counter PC is incremented by the value 4.

(6) NARDI Instruction

Syntax: NARDI A, B

Operation: A ← ARU(R6[8:0])[W-1:0];
B ← ARU(R6[8:0])[2*W-1:W];
ACB ← ARU(R6[8:0])[4+2*W:2*W]

Status: SAT

Duration: suspends current MCS-channel for a maximum of one ARU round trip cycle

Description: Perform a non-blocking read access to the ARU trying to transfer both W bit values received at the ARU port to the registers A and B (A ∈ AREG, B ∈ AREG), whereas A holds the lower W bit ARU word, B holds the upper W bit ARU word, and the ACB register holds the received ARU control bits.
The read address is obtained from the bits 0 to 8 of the channels register R6.
If the transfer finished successfully, the bit SAT of the register STA is set and the transferred values are stored in the registers A, B, and ACB.
If the transfer failed due to missing data at requested source, the bit SAT of the register STA is cleared and registers A, B, and ACB are not changed.
If A and B see the same register, only the upper W bit ARU word is stored and the lower 24 bit ARU word is discard.
If any transferred W bit value from the ARU should not stored in a register, the dummy register ZERO ∈ AREG can be selected in A or B to discard the corresponding ARU data. Actually, all address values of A and B that exceed the range 0 to 7 discard the corresponding ARU data.
The program counter PC is incremented by the value 4.

25.13.5.4 Arithmetic Logic Instructions

(1) ADDL Instruction

Syntax: ADDL A, C

Operation: A ← A + C

Status: Z, CY, N, V

Duration: 1 instruction cycle

Description: Perform addition operation of a register A (A ∈ OREG) with a W bit literal value C (C ∈ WLIT) and store the result in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The carry bit CY of status register STA is set, if an unsigned overflow/underflow occurred during addition, otherwise the bit is cleared. An unsigned overflow has occurred when the result of the operation cannot be represented in the interval [0; 2^{W-1}-1], assuming that both operands A and C are unsigned values within the interval [0; 2^{W-1}-1].
The overflow bit V of status register STA is set, if a signed overflow/underflow

occurred during addition, otherwise the bit is cleared. A signed overflow/underflow has occurred when the result of the operation cannot be represented in the interval [-2^{W-1}; $2^{W-1}-1$], assuming that both operands A and C are signed values within the interval [-2^{W-1}; $2^{W-1}-1$].
The negative bit N of status register STA equals the most significant bit of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.
The program counter PC is incremented by the value 4.

(2) ADD Instruction

Syntax: ADD A, B

Operation: A ← A + B

Status: Z, CY, N, V

Duration: 1 instruction cycle

Description: Perform addition operation of a register A (A ∈ OREG) with an operand B (B ∈ OREG) and store the result in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The carry bit CY of status register STA is set, if an unsigned overflow occurred during addition, otherwise the bit is cleared. An unsigned overflow has occurred when the result of the operation cannot be represented in the interval [0; $2^{W-1}-1$], assuming that both operands A and B are unsigned values within the interval [0; $2^{W-1}-1$].
The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during addition, otherwise the bit is cleared. A signed overflow/underflow has occurred when the result of the operation cannot be represented in the interval [-2^{W-1}; $2^{W-1}-1$], assuming that both operands A and B are signed values within the interval [-2^{W-1}; $2^{W-1}-1$].
The negative bit N of status register STA equals the most significant bit of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.
The program counter PC is incremented by the value 4.

(3) SUBL Instruction

Syntax: SUBL A, C

Operation: A ← A - C

Status: Z, CY, N, V

Duration: 1 instruction cycle

Description: Perform subtraction operation of a register A (A ∈ OREG) with a W bit literal value C (C ∈ WLIT) and store the result in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The carry bit CY of status register STA is set, if an unsigned underflow occurred during subtraction, otherwise the bit is cleared. An unsigned underflow has occurred when the result of the operation cannot be represented in the interval [0; $2^{W-1}-1$], assuming that both operands A and C are unsigned values within the interval [0; $2^{W-1}-1$].
The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during subtraction, otherwise the bit is cleared. A signed overflow/underflow

has occurred when the result of the operation cannot be represented in the interval [-2^{W-1}; 2^{W-1}-1], assuming that both operands A and C are signed values within the interval [-2^{W-1}; 2^{W-1}-1].
The negative bit N of status register STA equals the most significant bit of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.
The program counter PC is incremented by the value 4.

(4) SUB Instruction

Syntax: SUB A, B

Operation: A ← A – B

Status: Z, CY, N, V

Duration: 1 instruction cycle

Description: Perform subtraction operation of a register A (A ∈ OREG) with an operand B (B ∈ OREG) and store the result in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The carry bit CY of status register STA is set, if an unsigned underflow occurred during subtraction, otherwise the bit is cleared. An unsigned underflow has occurred when the result of the operation cannot be represented in the interval [0; 2^{W-1}-1], assuming that both operands A and B are unsigned values within the interval [0; 2^{W-1}-1].
The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during subtraction, otherwise the bit is cleared. A signed overflow/underflow has occurred when the result of the operation cannot be represented in the interval [-2^{W-1}; 2^{W-1}-1], assuming that both operands A and B are signed values within the interval [-2^{W-1}; 2^{W-1}-1].
The negative bit N of status register STA equals the most significant bit of the operation result, in order to determine if a calculated signed result is negative (N=1) or positive (N=0), assuming that no overflow/underflow occurred.
The program counter PC is incremented by the value 4.

(5) NEG Instruction

Syntax: NEG A, B

Operation: A ← –B

Status: Z, N, V

Duration: 1 instruction cycle

Description: Perform negation operation (2's Complement) with an operand B (B ∈ OREG) and store the result in a register A (A ∈ OREG).
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during subtraction, otherwise the bit is cleared. A signed overflow/underflow has occurred when the result of the operation cannot be represented in the interval [-2^{W-1}; 2^{W-1}-1], assuming that both operands A and B are signed values within the interval [-2^{W-1}; 2^{W-1}-1].
The negative bit N of status register STA equals the most significant bit of the operation result, in order to determine if a calculated signed result is negative (N = 1) or positive

(N = 0), assuming that no overflow/underflow occurred.
The program counter PC is incremented by the value 4.

(6) ANDL Instruction

Syntax: ANDL A, C

Operation: A ← A AND C

Status: Z

Duration: 1 instruction cycle

Description: Perform bitwise AND conjunction of a register A (A ∈ OREG) with a W bit literal value C (C ∈ WLIT) and store the result in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(7) AND Instruction

Syntax: AND A, B

Operation: A ← A AND B

Status: Z

Duration: 1 instruction cycle

Description: Perform bitwise AND conjunction of a register A (A ∈ OREG) with an operand B (B ∈ OREG) and store the result in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(8) ORL Instruction

Syntax: ORL A, C

Operation: A ← A OR C

Status: Z

Duration: 1 instruction cycle

Description: Perform bitwise OR conjunction of a register A (A ∈ OREG) with a W bit literal value C (C ∈ WLIT) and store the result in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(9) OR Instruction

Syntax: OR A, B

Operation: A ← A OR B

Status: Z

Duration: 1 instruction cycle

Description: Perform bitwise OR conjunction of a register A (A ∈ OREG) with an operand B (B ∈ OREG) and store the result in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the

zero bit is cleared.
The program counter PC is incremented by the value 4.

(10) XORL Instruction

Syntax: XORL A, C

Operation: A ← A XOR C

Status: Z

Duration: 1 instruction cycle

Description: Perform bitwise XOR conjunction of a register A (A ∈ OREG) with a W bit literal value C (C ∈ WLIT) and store the result in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(11) XOR Instruction

Syntax: XOR A, B

Operation: A ← A XOR B

Status: Z

Duration: 1 instruction cycle

Description: Perform bitwise XOR conjunction of a register A (A ∈ OREG) with an operand B (B ∈ OREG) and store the result in register A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(12) SHR Instruction

Syntax: SHR A, C

Operation: A ← A >> C

Status: Z, CY

Duration: 1 instruction cycle

Description: Perform right shift operation C (C ∈ SFTLIT) times of register A (A ∈ OREG). The most significant bits that are shifted into A are cleared.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The carry bit CY of status register STA is updated to the last LSB that is shifted out of the register.
The program counter PC is incremented by the value 4.

(13) SHL Instruction

Syntax: SHL A, C

Operation: A ← A << C

Status: Z, CY

Duration: 1 instruction cycle

Description: Perform left shift operation C (C ∈ SFTLIT) times of register A (A ∈ OREG). The lower significant bits that are shifted into A are cleared.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The carry bit CY of status register STA is updated to the previous MSB that is shifted out of the register. It should be noticed, if the register A contains less than W bits, CY is always 0.
The program counter PC is incremented by the value 4.

(14) ASRU Instruction

Syntax: ASRU A, B

Operation: A ← A >> B

Status: Z

Duration: 1 instruction cycle

Description: Perform arithmetic unsigned right shift operation, which means that the unsigned operand of register A (A ∈ OREG) is right shifted B times (B ∈ OREG). Operand B is also an unsigned type. The most significant bits that are shifted into A are cleared.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(15) ASRS Instruction

Syntax: ASRS A, B

Operation: A ← A >> B

Status: Z

Duration: 1 instruction cycle

Description: Perform arithmetic signed right shift operation, which means that the signed operand of register A (A ∈ OREG) is right shifted B times (B ∈ OREG). Operand B is an unsigned type. The operation also performs a sign extension, which means that value of the most significant bits that are shifted into A are determined by the most significant bit of the original operand A.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(16) ASL Instruction

Syntax: ASL A, B

Operation: A ← A << B

Status: Z, CY, V

Duration: 1 instruction cycle

Description: Perform arithmetic left shift operation for signed and unsigned numbers, which means that the operand of register A (A ∈ OREG) is left shifted B times (B ∈ OREG). Operand B is always an unsigned type.
The carry bit CY of status register STA is set, if an unsigned overflow occurred during shifting, otherwise the bit is cleared. An unsigned overflow has occurred if the

calculated result $A*2^B$ cannot be represented in the interval [0; 2^W-1], assuming that both operands A and B are unsigned values within the interval [0; 2^W-1].
The overflow bit V of status register STA is set, if a signed overflow/underflow occurred during shifting, otherwise the bit is cleared. A signed overflow/underflow has occurred when the calculated result $A*2^B$ cannot be represented in the interval [-2^{W-1}; 2^{W-1}-1], assuming that signed operand A is within the interval [-2^{W-1}; 2^{W-1}-1] and the unsigned operand B is within the interval [0; 2^{W-1}-1].
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(17) MINU Instruction

Syntax: MINU A, B

Operation: A ← MIN(A, B)

Status: Z

Duration: 1 instruction cycle

Description: Determine the minimum of an unsigned operand A (A ∈ OREG) and an unsigned operand B (B ∈ OREG). If A is less than or equal to B, A is left unchanged. Otherwise, if A is greater than B, the operand B is moved to A.
The zero bit Z of status register STA is set, if the calculated result of A is zero, otherwise the zero bit is cleared.

(18) MINS Instruction

Syntax: MINS A, B

Operation: A ← MIN(A, B)

Status: Z

Duration: 1 instruction cycle

Description: Determine the minimum of a signed operand A (A ∈ OREG) and a signed operand B (B ∈ OREG). If A is less than or equal to B, A is left unchanged. Otherwise, if A is greater than B, the operand B is moved to A.
The zero bit Z of status register STA is set, if the calculated result of A is zero, otherwise the zero bit is cleared.

(19) MAXU Instruction

Syntax: MAXU A, B

Operation: A ← MAX(A, B)

Status: Z

Duration: 1 instruction cycle

Description: Determine the maximum of an unsigned operand A (A ∈ OREG) and an unsigned operand B (B ∈ OREG). If A is greater than or equal to B, A is left unchanged. Otherwise, if A is less than B, the operand B is moved to A.
The zero bit Z of status register STA is set, if the calculated result of A is zero, otherwise the zero bit is cleared.

(20) MAXS Instruction

Syntax: MAXS A, B

Operation: A ← MAX(A, B)

Status: Z

Duration: 1 instruction cycle

Description: Determine the maximum of a signed operand A (A ∈ OREG) and a signed operand B (B ∈ OREG). If A is greater than or equal to B, A is left unchanged. Otherwise, if A is less than B, the operand B is moved to A.
The zero bit Z of status register STA is set, if the calculated result of A is zero, otherwise the zero bit is cleared.

25.13.5.5 Test Instructions

(1) ATUL Instruction

Syntax: ATUL A, C

Operation: A – C

Status: Z, CY

Duration: 1 instruction cycle

Description: Arithmetic Test with an unsigned operand A (A ∈ OREG) and an unsigned W bit literal value C (C ∈ WLIT).
The carry bit CY of status register STA is set if unsigned operand A is less than unsigned literal C.
Otherwise, the carry bit CY of status register STA is cleared if unsigned operand A is greater than or equal to unsigned literal C.
The zero bit Z of status register STA is set, if A equals to C.
Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to C.
The program counter PC is incremented by the value 4.

(2) ATU Instruction

Syntax: ATU A, B

Operation: A – B

Status: Z, CY

Duration: 1 instruction cycle

Description: Arithmetic Test with an unsigned operand A (A ∈ OREG) and an unsigned operand B (B ∈ OREG).
The carry bit CY of status register STA is set if unsigned operand A is less than unsigned operand B.
Otherwise, the carry bit CY of status register STA is cleared if unsigned operand A is greater than or equal to unsigned operand B.
The zero bit Z of status register STA is set, if A equals to B.
Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to B. The program counter PC is incremented by the value 4.

(3) ATSL Instruction

Syntax: ATSL A, C

Operation: A - C

Status: Z, CY

Duration: 1 instruction cycle

Description: Arithmetic Test with a signed operand A (A ∈ OREG) and a signed W bit literal value C (C ∈WLIT).
The carry bit CY of status register STA is set if signed operand A is less than signed literal C.
Otherwise, the carry bit CY of status register STA is cleared if signed operand A is greater than or equal to signed literal C.
The zero bit Z of status register STA is set, if A equals to C.
Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to C. The program counter PC is incremented by the value 4.

(4) ATS Instruction

Syntax: ATS A, B

Operation: A – B

Status: Z, CY

Duration: 1 instruction cycle

Description: Arithmetic Test with a signed operand A (A ∈ OREG) and a signed operand B (B ∈ OREG).
The carry bit CY of status register STA is set if signed operand A is less than signed operand B.
Otherwise, the carry bit CY of status register STA is cleared if signed operand A is greater than or equal to signed operand B.
The zero bit Z of status register STA is set, if A equals to B.
Otherwise, the zero bit Z of status register STA is cleared, if A is unequal to B. The program counter PC is incremented by the value 4.

(5) BTL Instruction

Syntax: BTL A, C

Operation: A AND C

Status: Z

Duration: 1 instruction cycle

Description: Bit test of an operand A (A ∈ OREG) with a W bit literal bit mask C (C ∈ WLIT).
The bit test is performed by applying a bitwise logical AND operation with operand A and the bit mask C without storing the result.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

(6) BT Instruction

Syntax: BT A, B

Operation: A AND B

Status: Z

Duration: 1 instruction cycle

Description: Bit test of an operand A (A ∈ OREG) with an operand B (B ∈ OREG), whereas usually one of the operands is a register holding a bit mask.
The bit test is performed by applying a bitwise logical AND operation with register A and register B without storing the result.
The zero bit Z of status register STA is set, if the calculated value is zero, otherwise the zero bit is cleared.
The program counter PC is incremented by the value 4.

25.13.5.6 Control Flow Instructions

(1) JMP Instruction

Syntax: JMP C

Operation: PC ← C << 2

Status: —

Duration: 1 instruction cycle but not faster than NPS clock cycles due to pipeline flushing.

Description: Execute unconditional jump to the memory location C (C ∈ ALIT).
The program counter PC is loaded with literal C.

(2) JBS Instruction

Syntax: JBS A, B, C

Operation: PC ← C << 2 if A[B] is set

Status: —

Duration: 1 instruction cycle but if the jump is executed, it is not faster than NPS clock cycles due to pipeline flushing.

Description: Execute conditional jump to the memory location C (C ∈ ALIT).
The program counter PC is loaded with literal C, if the bit at position B (B ∈ BITLIT) of operand A (A ∈ OREG) is set.
Otherwise, if the bit is cleared, the program counter PC is incremented by the value 4.

(3) JBC Instruction

Syntax: JBC A, B, C

Operation: PC ← C << 2 if A[B] is cleared

Status: —

Duration: 1 instruction cycle but if the jump is executed, it is not faster than NPS clock cycles due to pipeline flushing.

Description: Execute conditional jump to the memory location C (C ∈ ALIT).
The program counter PC is loaded with literal C, if the bit at position B (B ∈ BITIT) of operand A (A ∈ OREG) is cleared.
Otherwise, if the bit is set, the program counter PC is incremented by the value 4.

(4) CALL Instruction

Syntax: CALL C

Operation:
R7 ← R7 + 4;
MEM(R7[RAW+USR+1:2])[RAW+USR+1:2] ← PC + 4;
PC ← C << 2;
SP_CNT ← SP_CNT + 1

Status: EN

Duration: 2 instruction cycles but not faster than 2*NPS clock cycles due to pipeline flushing.

Description: Call subprogram at memory location C (C ∈ ALIT).
The stack pointer register R7 is incremented by the value 4.
The memory location for the top of the stack is identified by the bits 2 to RAW+1 of the stack pointer register.
After the stack pointer is incremented, the incremented value of the PC is transferred to the top of the stack.
The program counter PC is loaded with literal C.
The SP_CNT bit field inside the GTM0MCSixCTRL register is incremented. If an overflow on the SP_CNT bit field occurs, the STK_ERR[i]_IRQ is raised.
If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register GTM0MCSiCTRLSTAT is set, the channel current MCS-channel is disabled by clearing the EN bit of STA.
If an overflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register GTM0MCSiCTRLSTAT is set, the memory write operation of the incremented PC is discarding.

(5) RET Instruction

Syntax: RET

Operation:
PC ← MEM(R7[RAW+USR+1:2])[RAW+USR+1:0];
R7 ← R7 - 4;
SP_CNT ← SP_CNT – 1

Status: EN

Duration: 2 instruction cycles but not faster than 2*NPS clock cycles due to pipeline flushing.

Description: Return from subprogram.
The program counter PC is loaded with current value on the top of the stack.
Finally, the stack pointer register R7 is decremented by the value 4.
The memory location for the top of the stack is identified by the bits 2 to RAW+1 of the stack pointer register.
The SP_CNT bit field inside the GTM0MCSixCTRL register is decremented.
If an underflow on the SP_CNT bit field occurs, the STK_ERR[i]_IRQ is raised.
If an underflow on the SP_CNT bit field occurs and the bit HLT_SP_OFL of register MCS[i]_CTRL is set, the channel current MCS-channel is disabled by clearing the EN bit of STA.

25.13.5.7 Other Instructions

(1) WURM Instruction

Syntax: WURM A, B, C

Operation: Wait until register match.

Status: CWT

Duration: Suspends current MCS-channel. Fastest latency for resuming up from a suspended WURM instruction is 2+NPS clock cycles.

Description: Suspend current MCS-channel until the following register match condition occurs:

A = (B AND MASK),
whereas A ∈ OREG, B ∈ OREG, AND is a bitwise AND operation with bitmask MASK. The bits 16 to 23 of MASK are set to true and the bits 0 to 15 are copied from the instructions literal C ∈ MSKLIT. If the match condition evaluates to true, the suspended MCS channel is resumed and the program counter PC is incremented by the value 4 meaning that the MCS channel continues its program. However, if the match condition is true at the beginning of the instruction execution, the instruction does not suspend the channel and the program counter PC is incremented by the value 4.
At the beginning of the instruction execution the CWT bit in the register STA is always cleared. After the execution of the instruction the CWT bit is updated in order to show if the instruction finished successfully (CWT = 0) or it was cancelled by the CPU (CWT = 1). If the CWT bit is set simultaneously with the occurrence of the register match condition, the register match condition has the higher priority resulting in a cleared CWT bit.
This instruction can be used to wait for one or more trigger events generated by other MCS-channels or the CPU. In this case register B is the trigger register STRG, A is a general purpose register holding the bits with the trigger condition to wait for and C is the bitmask that enables trigger bits of interest. The trigger bits can be set by other MCS channels with a write access (e.g. using a MOVL instruction) to the STRG register or the CPU with a write access to the GTM0MCSiSTRG register. The trigger bits are not cleared automatically by hardware after resuming an MCS-channel, but they have to be cleared explicitly with a write access to the register CTRG by the MCS-channel or with a write access to the register GTM0MCSiCTRG by the CPU. Please note that more than one channel can wait for the same trigger bit to continue.
The instruction can also be used to wait on a specific time/angle event provided by the TBU. In this case register B is the interesting TBU register TBU_TS0 or TBU_TS1, register A is a general purpose register holding the value to wait for and bitmask C should be set to 0xFFFF.

(2) WURMX Instruction

Syntax: WURMX A, B

(3) NOP Instruction

Syntax: NOP

Operation: —

Status: —

Duration: 1 instruction cycle

Description: No operation is performed.
The program counter PC is incremented by the value 4.

25.13.6 MCS Internal Register Overview

25.13.6.1 MCS Internal Registers Overview

Table 25.141 Register list

Symbol	Register Name	Details in Section
R[x]	General Purpose Register x (x = 0 to 7),	**25.13.7.1**
STA	Status Register	**25.13.7.2**
ACB	ARU Control Bit Register	**25.13.7.3**
CTRG	Clear Trigger Bits Register	**25.13.7.4**
STRG	Set Trigger Bits Register	**25.13.7.5**
TBU_TS0	TBU Timestamp TS0 Register	**25.13.7.6**
TBU_TS1	TBU Timestamp TS1 Register	**25.13.7.7**
MHB	Memory High Byte Register	**25.13.7.8**

25.13.7 MCS Internal Register Description

This section describes the MCS internal registers that can be directly addressed with the MCS instruction set. Many of the registers can also be addressed by the CPU but with another Register Label (for details see **Section 25.13.9, MCS Configuration Register Description**). Some of the internal registers are also shared between neighboring MCS channels.

25.13.7.1 Register R[y] (y = 0 to 7)

Access: This register can be read/written in 24-bit units.

Address: —

Value after reset: $00\ 0000_H$

Bit	23	22	21	20	19	18	17	16

Table 25.142 R[y] Register Contents

Bit Position	Bit Name	Function
23 to 0	DATA	Data field of general purpose register.

NOTES

1. Register R4 is a commonly used register, which can be accessed by all MCS-channels and the CPU. This register can be used for fast data transfer between the MCS-channels.
2. Register R5 is a commonly used register, which can be accessed by all MCS-channels and the CPU. This register can be used for fast data transfer between the MCS-channels.
3. Register R6 used also as index/address register for indirect ARU addressing instructions.
4. Register R7 is also used as stack pointer register, if stack operations are used in the MCS micro program.

25.13.7.2 Register STA

Access: This register can be read in 24-bit units.

Address: —

Value after reset: $00\ 0000_H$

Bit	23	22	21	20	19	18	17	16
	—	—	—	—	—	SP_CNT		
Value after reset	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R

Table 25.143 STA Register Contents (1/3)

Bit Position	Bit Name	Function
23 to 19	Reserved	These bits are always read as 0.
18 to 16	SP_CNT	Stack pointer counter value. **NOTE** Actual stack depth of channel. The bit field is incremented on behalf of a CALL or PUSH instruction and decremented on behalf of a RET or POP instruction. The MCS channel STK_ERR_IRQ is raised, when an overflow or underflow is detected on this bit field.
15 to 11	Reserved	These bits are always read as 0.
10	SAT	Successful ARU transfer bit. 0: Non-blocking ARU transfer failed due to missing data. 1: Non-blocking ARU transfer finished successfully.
9	CWT	Cancel WURM instruction bit. 0: Last WURM instruction was not cancelled. 1: CPU cancelled last WURM instruction of channel. **NOTE** This bit is updated after each WURM instruction and it should be evaluated immediately after the WURM instruction. Otherwise, the CPU could set the bit leading to a bad status information in the MCS program.
8	CAT	Cancel ARU transfer bit. 0: Last ARU transfer was not cancelled. 1: CPU cancelled last ARU transfer. **NOTE** This bit is updated after each ARU transfer and it should be evaluated immediately after the ARU instruction. Otherwise, the CPU could set the bit leading to a bad status information in the MCS program.

Table 25.143 STA Register Contents (2/3)

Bit Position	Bit Name	Function
7	N	Negative bit. The negative bit is updated by arithmetic instructions in order to indicate a negative result.
6	V	Overflow bit. The overflow bit is updated by arithmetic instructions in order to indicate a signed under/overflow.
5	Z	Zero bit. The zero bit is updated by several arithmetic, logic and data transfer instructions to indicate a result of zero.
4	CY	Carry bit. The carry bit is updated by several arithmetic and logic instructions. In arithmetic operations, the carry bit indicates an unsigned under/overflow.
3	MCA	MON Activity signalling for MCS channel. 0: No activity signalled to sub module MON. 1: Activity signalled to sub module MON. **NOTE** When this bit is set the corresponding channel in the MON sub module register GTMMONACTIVITY0 is set (see **Section 25.17.8.2, GTMMONACTIVITY0**. This bit is automatically cleared after writing it by the MCS channel program.
2	ERR	Set Error Signal. 0: No Error occurred. 1: Error occurred. **NOTES** 1. The ERR bit of an MCS-channel reflects an Error status that may be caused by one of the following conditions: – MCS-channel sets the ERR bit by software (e.g. with instruction ORL STA, 0x4) – ECC RAM Error occurred while accessing the connected RAM (also disables the MCS-channel by clearing bit EN and the first error occurred updates bit field ERR_SRC_ID of register GTM0MCSiCTRLSTAT) – Decoding an instruction with an invalid opcode (also disables the MCS-channel by clearing bit EN and the first error occurred updates bit field ERR_SRC_ID of register GTM0MCSiCTRLSTAT) – A memory address range overflow occurred (also disables the MCS-channel by clearing bit EN and the first error occurred updates bit field ERR_SRC_ID of register GTM0MCSiCTRLSTAT) 2. If the ERR bit is set due to a memory address range overflow any read or write access to the RAM is blocked. 3. If the GTM includes a MON sub module, the ERR signal is always captured by this module. 4. An MCS-channel can set the error bit by writing value 1 to bit ERR. Writing a value 0 to this bit does not cancel the error signal, and thus has no effect. In Addition, writing a value 1 to ERR always triggers the ERR interrupt, independently from the current state of the error signal. 5. The ERR bit can only be cleared by CPU, by writing a 1 to the GTM0MCSiERR register (see **Section 25.13.9.17, GTM0MCSiERR (i = 0, 1)**). 6. An MCS-channel can read the ERR bit in order to determine the current state of the error signal. The MCS-channel reads a value 1 if an ERR occurred previously, but not cleared by CPU. If an MCS-channel reads a value 0 no error was set or it has been cleared by CPU.

Table 25.143 STA Register Contents (3/3)

Bit Position	Bit Name	Function
1	IRQ	Trigger IRQ. 0: No triggered IRQ signal. 1: Trigger IRQ signal. **NOTES** 1. An MCS-channel triggers an IRQ by writing value 1 to bit IRQ. Writing a value 0 to this bit does not cancel the IRQ, and thus has no effect. 2. This bit mirrors bit 0 of the register GTM0MCSixIRQNOTIFY. 3. The IRQ bit can only be cleared by CPU, by writing a 1 to the corresponding GTM0MCSixIRQNOTIFY register (see **Section 25.13.9.6, GTM0MCSixIRQNOTIFY (i = 0, x = 0 to 8, i = 1, x = 0 to 5)**). 4. An MCS-channel can read the IRQ bit in order to determine the current state of the IRQ handling. The MCS-channel reads a value 1 if an IRQ was released but not cleared by CPU. If an MCS-channel reads a value 0 no IRQ was released or it has been cleared by CPU.
0	EN	Enable current MCS-channel. 0: Disable current MCS-channel. 1: Enable current MCS-channel.

NOTE

Writing to bits of the register STA with instructions that do implicitly a read-modify-write operation (e.g. “ANDL STA, $FFFFFE_H$” or “OR STA, R0”) is dangerous, since writing back the possibly modified content of the read access (which reflects status information) may cause undesirable results. A secure way for writing to bits of the register STA is to use instructions that do not read the content of STA (e.g. “MOVL STA, 0x0 or MOV STA, R1”).

25.13.7.3 Register ACB

Access: This register can be read in 24-bit units.

Address: —

Value after reset: $0000\ 0000_H$

Bit	23	22	21	20	19	18	17	16

NOTES

1. The result of a read access to this register differs in dependency of the bit field EN_TIM_FOUT of register GTM0MCSiCTRLSTAT.
2. The trigger bits TRGx (x = 0 to 15) are accessible by all MCS channels as well as the CPU. Setting a trigger bit can be performed with the STRG register, in the case of an MCS-channel or the GTM0MCSiSTRG register in the case of the CPU. Clearing a trigger bit can be performed with the CTRG register, in the case of an MCS-channel or the GTM0MCSiCTRG register in the case of the CPU. Trigger bits can be used for signalizing specific events to MCS-channels or the CPU. An MCS-channel suspended with a WURM instruction can be resumed by setting the appropriate trigger bit.
3. Besides setting the trigger bits with register STRG/GTM0MCSiSTRG, the k-th trigger bit TRGk can also be set by the external capture event that is enabled by the k-th bit of register GTM0GTMEXTCAPENi. If bit k bit is disabled, the k-th trigger bit TRGk can only be set by MCS or CPU.

25.13.7.5 Register STRG

Access: This register can be read in 24-bit units.

Table 25.148 TBU_TS1 Register Contents

Bit Position	Bit Name	Function
23 to 0	TS	Current TBU time stamp 1.

NOTE

Any write access to a time base register discards the written data. A write access to a time base register may be used to destroy an unused 24-bit data word of an ARU read transfer.

25.13.7.8 Register MHB

Access: This register can be read/written in 24-bit units.

Address: —

Value after reset: $00\ 0000_H$

Bit	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—

Table 25.149 MHB Register Contents

Bit Position	Bit Name	Function
23 to 8	Reserved	These bits are always read as 0. When written, write the initial value.
7 to 0	DATA	High Byte of a memory transfer.

25.13.8 MCS Configuration Registers Overview

The MCS Configuration registers of the MCS module are accessible by the AEI bus interface. Some of these registers simply mirror MCS Internal registers to the AEI. Details can be found in the table below and in the individual register descriptions.

Table 25.150 Register list

Symbol	Register Name	Details in Section
GTM0MCSixCTRL	MCS Channel control register (x = 0 to 8) Most bits mirror the internal task specific register STA.	**25.13.9.1**
GTM0MCSixACB	MCS Channel ACB register (x = 0 to 8) The Register mirrors the internal task specific register ACB.	**25.13.9.4**
GTM0MCSixMHB	Memory High Byte register (x = 0 to 8) The Register mirrors the internal task specific register MHB.	**25.13.9.5**
GTM0MCSixPC	MCS Channel Program counter register (x = 0 to 8)	**25.13.9.2**
GTM0MCSixRy	MCS Channel GPRx registers (x = 0 to 8; y = 0 to 7). These registers mirror the internal task specific registers R[y].	**25.13.9.3**
GTM0MCSixIRQNOTIFY	MCS Channel x interrupt notification register (x = 0 to 8)	**25.13.9.6**
GTM0MCSixIRQEN	MCS Channel x interrupt enable register (x = 0 to 8)	**25.13.9.7**
GTM0MCSixIRQFORCINT	MCS Channel x software interrupt generation register (x = 0 to 8)	**25.13.9.8**
GTM0MCSixIRQMODE	IRQ mode configuration register (x = 0 to 8)	**25.13.9.9**
GTM0MCSixEIRQEN	MCS Channel x error interrupt enable register (x = 0 to T–1)	**25.13.9.10**
GTM0MCSiCTRLSTAT	MCS Control and Status register	**25.13.9.11**
GTM0MCSiCTRG	MCS Clear trigger control register.	**25.13.9.12**
GTM0MCSiSTRG	MCS Set trigger control register	**25.13.9.13**
GTM0MCSiRESET	MCS Channel reset register	**25.13.9.14**
GTM0MCSiERR	MCS Error register	**25.13.9.15**
GTM0MCSiCAT	Cancel ARU transfer register.	**25.13.9.16**
GTM0MCS0CWT	Cancel WURM instruction.	**25.13.9.17**

25.13.9 MCS Configuration Register Description

25.13.9.1 GTM0MCSixCTRL (i = 0, x = 0 to 8, i = 1, x = 0 to 5)

Access: This register can be read/written in 32-bit units.

Address:
GTM0MCS00CTRL: <GTM_base> + 30020_H.
GTM0MCS01CTRL: <GTM_base> + $300A0_H$.
GTM0MCS02CTRL: <GTM_base> + 30120_H.
GTM0MCS03CTRL: <GTM_base> + $301A0_H$.
GTM0MCS04CTRL: <GTM_base> + 30220_H.
GTM0MCS05CTRL: <GTM_base> + $302A0_H$.
GTM0MCS06CTRL: <GTM_base> + 30320_H.
GTM0MCS07CTRL: <GTM_base> + $303A0_H$.
GTM0MCS08CTRL: <GTM_base> + 30420_H.
GTM0MCS10CTRL: <GTM_base> + 31020_H
GTM0MCS11CTRL: <GTM_base> + $310A0_H$
GTM0MCS12CTRL: <GTM_base> + 31120_H
GTM0MCS13CTRL: <GTM_base> + $311A0_H$
GTM0MCS14CTRL: <GTM_base> + 31220_H
GTM0MCS15CTRL: <GTM_base> + $312A0_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.151 GTM0MCSixCTRL Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 19	Reserved	These bits are always read as 0. When written, write the initial value.
18 to 16	SP_CNT	Stack pointer counter value. Actual stack depth of channel. The bit field is incremented on behalf of a CALL or PUSH instruction and decremented on behalf of a RET or POP instruction. The MCS channel STK_ERR_IRQ is raised, when an overflow or underflow is detected on this bit field.
15 to 11	Reserved	These bits are always read as 0. When written, write the initial value.
10	SAT	Successful ARU transfer bit. 0: Non-blocking ARU transfer failed due to missing data. 1: Non-blocking ARU transfer finished successfully. **NOTE** This bit is read only and it mirrors the internal state of the ARU transfer status flag SAT.
9	CWT	Cancel WURM instruction state. **NOTE** This bit is read only and it mirrors the internal cancel WURM instruction status flag CWT.
8	CAT	Cancel ARU transfer state. **NOTE** This bit is read only and it mirrors the internal state of the ARU transfer status flag SAT.

Table 25.151 GTM0MCSixCTRL Register Contents (2/2)

Bit Position	Bit Name	Function
7	N	Negative bit state. **NOTE** This bit is read only and it mirrors the internal cancel ARU transfer status flag CAT.
6	V	Overflow bit state. **NOTE** This bit is read only and it mirrors the internal carry flag V.
5	Z	Zero bit state. **NOTE** This bit is read only and it mirrors the internal zero flag Z.
4	CY	Carry bit state. **NOTE** This bit is read only and it mirrors the internal carry flag CY.
3	Reserved	These bits are always read as 0. When written, write the initial value.
2	ERR	Error state. 0: No error signal pending in MCS-channel x. 1: Error signal is pending in MCS-channel x. **NOTE** This bit is read only and it mirrors the internal error state.
1	IRQ	Interrupt state. 0: No interrupt pending in MCS-channel x. 1: Interrupt is pending in MCS-channel x. **NOTE** This bit is read only and it mirrors the internal IRQ state.
0	EN	Enable MCS-channel 0: Disable current MCS-channel. 1: Enable current MCS-channel. **NOTES** 1. Enabling or disabling of an MCS-channel is synchronized to the ending of an instruction and thus it may take several clock cycles, e.g. active memory transfers or pending WURM transfers have to be finished before disabling the MCS-channel. The internal state of a channel can be obtained by reading the bit EN. 2. To disable an MCS channel reliably the EN bit should be cleared followed by setting the CAT and CWT bit in order to cancel any pending WURM or ARU instructions. 3. The EN bit is write protected during RAM reset phase.

25.13.9.2 GTM0MCSixPC (i = 0, x = 0 to 8, i = 1, x = 0 to 5)

Access: This register can be read/written in 32-bit units.

Address:
GTM0MCS00PC: <GTM_base> + 30040_H.
GTM0MCS01PC: <GTM_base> + $300C0_H$.
GTM0MCS02PC: <GTM_base> + 30140_H.
GTM0MCS03PC: <GTM_base> + $301C0_H$.
GTM0MCS04PC: <GTM_base> + 30240_H.
GTM0MCS05PC: <GTM_base> + $302C0_H$.
GTM0MCS06PC: <GTM_base> + 30340_H.
GTM0MCS07PC: <GTM_base> + $303C0_H$.
GTM0MCS08PC: <GTM_base> + 30440_H.
GTM0MCS10PC: <GTM_base> + 31040_H
GTM0MCS11PC: <GTM_base> + $310C0_H$
GTM0MCS12PC: <GTM_base> + 31140_H
GTM0MCS13PC: <GTM_base> + $311C0_H$
GTM0MCS14PC: <GTM_base> + 31240_H
GTM0MCS15PC: <GTM_base> + $312C0_H$

Value after reset: 0000 0000+4*x_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 25.152 GTM0MCSixPC (x = 0 to 8) Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	These bits are always read as 0. When written, write the initial value.
15 to 0	PC	Current Program Counter. **NOTES** 1. The program counter is only writable if the corresponding MCS-channel is disabled. The bits 0 and 1 are always written as zeros. 2. The actual width of the program counter depends on the MCS configuration. The actual width is RAW+USR+2 bits meaning that only the bits 0 to RAW+USR+1 are available and the other bits (RAW+USR+2 to 31) are reserved.

25.13.9.3 GTM0MCSixRy (x = 0 to 8, y = 0 to 7)

Access: This register can be read/written in 32-bit units.

Address: See **Table 25.154**

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 25.153 GTM0MCSixRy (x = 0 to 8, y = 0 to 7) Register Contents

Bit Position	Bit Name	Function
31 to 24	Reserved	These bits are always read as 0. When written, write the initial value.
23 to 0	DATA	Data of general purpose register R[y].

NOTES

1. This register is the same as described in **Section 25.13.7.1, Register R[y] (y = 0 to 7)**.
2. For the register GTM0MCSixR6 **Section 25.13.7.1, Register R[y] (y = 0 to 7)** an additional write protection during an active ARDI or NARDI instruction is applied.

Table 25.157 GTM0MCSixIRQNOTIFY (x = 0 to 8) Register Contents

Bit Position	Bit Name	Function
31 to 3	Reserved	These bits are always read as 0. When written, write the initial value.
2	ERR_IRQ	MCS channel x ERR interrupt. 0: No IRQ released 1: MCS-channel ERR IRQ released. **NOTES** 1. If the ERR bit of register STA is triggered the ERR_IRQ will also be set. 2. This bit will be cleared on a CPU write access with a value ‘1’. A read access leaves the bit unchanged.
1	STK_ERR_IRQ	Stack counter overflow/underflow of channel x. 0: No IRQ released 1: A stack counter overflow or underflow occurred **NOTE** This bit will be cleared on a CPU write access with a value ‘1’. A read access leaves the bit unchanged.
0	MCS_IRQ	Interrupt request by MCS-channel x. 0: No IRQ released 1: IRQ released by MCS-channel **NOTES** 1. This bit will be cleared on a CPU write access with a value ‘1’. A read access leaves the bit unchanged. 2. By writing a '1' to this register, the IRQ flag in the MCS channel status register STA is cleared.

25.13.9.7 GTM0MCSixIRQEN (i = 0, x = 0 to 8, i = 1, x = 0 to 5)

Access: This register can be read/written in 32-bit units.

Address:
GTM0MCS00IRQEN: <GTM_base> + 30048_H.
GTM0MCS01IRQEN: <GTM_base> + $300C8_H$.

Bit Position	Bit Name	Function
31 to 25	Reserved	These bits are always read as 0. When written, write the initial value.
24	EN_TIM_FOUT	Enable routing of TIM[i]_CH[x]_F_OUT signal. 0: Read access to register CTRG/GTM0MCSiCTRG provides state of the internal trigger registers. 1: Read access to register CTRG/GTM0MCSiCTRG provides state of the external signal TIM[i]_CH[x]_F_OUT.
23, 22	Reserved	These bits are always read as 0. When written, write the initial value.
21, 20	ERR_SRC_ID	Error source identifier. 00: No HW generated Error occurred. 01: Detected ECC error. 10: Detected memory overflow. 11: Detected invalid opcode. **NOTE** This register is updated once, if an ECC error, a memory overflow, or an invalid opcode was detected by the MCS. The register is set to its initial value 00 after each write access to an existing ERR bit in the register GTM0MCSiERR. If multiple errors occur, ERR_SRC_ID is holding the first type of error which has occurred.
19, 18	Reserved	These bits are always read as 0. When written, write the initial value.
17	HLT_SP_OFL	Halt on stack pointer overflow. 0: No halt on MCS-channel stack pointer counter over/underflow. 1: MCS-channel is disabled if a stack pointer counter over/underflow occurs.

Table 25.162 GTM0MCSiCTRLSTAT Register Contents (2/2)

Bit Position	Bit Name	Function
16	RAM_RST	RAM reset bit 0: READ: no RAM reset is active / WRITE: do nothing. 1: READ: MCS currently resets RAM content / WRITE: trigger RAM reset. **NOTES** 1. The RAM reset initializes the memory content with zeros. RAM access and enabling of MCS channels is disabled during active RAM reset. 2. This bit is only writable if the bit RF_PROT in register GTM0GTMCTRL is cleared and all MCS-channels are disabled. 3. The actual reset values of this bit depends on the silicon vendor configuration. The reset value is 1, if the RAM reset is performed together with the sub module reset, otherwise the reset value is 0. If the reset value is 1, the reset value is changed to 0 by hardware, when the RAM reset finished.
15 to 12	Reserved	These bits are always read as 0. When written, write the initial value.
11 to 8	SCD_CH	Channel selection for scheduling algorithm. MCS-channel identifier used by several scheduling modes. **NOTE** The actual width of the bit field SCD_CH is calculated as $\lceil \log2(T+1) \rceil$. Unused most significant bits are reserved and read as zero.
7 to 2	Reserved	These bits are always read as 0. When written, write the initial value.
1, 0	SCD_MODE	Select MCS scheduling mode 00: Accelerated Scheduling. 01: Round Robin Scheduling. 10: Single Priority Scheduling. 11: Multiple Priority Scheduling.

25.13.9.12GTM0MCSiCTRG (i =0 ,1)

Access: This register can be read/written in 32-bit units.

NOTES

1. The result of a read access to this register differs in dependency of the bit field EN_TIM_FOUT of register GTM0MCSiCTRLSTAT.
2. The trigger bits TRGx (x = 0 to 15) are accessible by all MCS channels as well as the CPU. Setting a trigger bit can be performed with the STRG register, in the case of an MCS-channel or the GTM0MCSiSTRG register in the case of the CPU. Clearing a trigger bit can be performed with the CTRG register, in the case of an MCS-channel or the GTM0MCSiCTRG register in the case of the CPU. Trigger bits can be used for signalizing specific events to MCS-channels or the CPU. An MCS-channel suspended with a WURM instruction can be resumed by setting the appropriate trigger bit.
3. Besides setting the trigger bits with register STRG/GTM0MCSiSTRG, the k-th trigger bit TRGk can also be set by the external capture event that is enabled by the k-th bit of register GTM0GTMEXTCAPENi. If bit k bit is disabled, the k-th trigger bit TRGk can only be set by MCS or CPU.
4. In the scheduling modes Accelerated Scheduling and Round Robin Scheduling, a write access to GTM0MCSiCTRG may take up to T + 1 clock cycles, since the write access is scheduled to the next CPU time slot determined by the MCS scheduler. In the modes Single Prioritization Scheduling and Multiple Prioritization Scheduling, no upper limit access time for a write access to GTM0MCSiCTRG can be guaranteed. The High Prioritized tasks have to be disabled in order to guarantee fast write access to GTM0MCSiCTRG.

25.13.9.13GTM0MCSiSTRG (i = 0, 1)

Access: This register can be read/written in 32-bit units.

Address: GTM0MCS0STRG: <GTM_base> + $3002C_H$

0	TRG0	Trigger bit 0 0: READ: trigger bit is cleared / WRITE: do nothing 1: READ: trigger bit is set / WRITE: set trigger bit

NOTES

1. The trigger bits TRGx (x = 0 to 15) are accessible by all MCS channels as well as the CPU. Setting a trigger bit can be performed with the STRG register, in the case of an MCS-channel or the GTM0MCSiSTRG register in the case of the CPU. Clearing a trigger bit can be performed with the CTRG register, in the case of an MCS-channel or the GTM0MCSiCTRG register in the case of the CPU. Trigger bits can be used for signalizing specific events to MCS-channels or the CPU. An MCS-channel suspended with a WURM instruction can be resumed by setting the appropriate trigger bit.
2. Besides setting the trigger bits with register STRG/GTM0MCSiSTRG, the k-th trigger bit TRGk can also be set by the external capture event that is enabled by the k-th bit of register GTM0GTMEXTCAPENi. If bit k bit is disabled, the k-th trigger bit TRGk can only be set by MCS or CPU.
3. In the scheduling modes Accelerated Scheduling and Round Robin Scheduling, a write access to GTM0MCSiSTRG may take up to T + 1 clock cycles, since the write access is scheduled to the next CPU time slot determined by the MCS scheduler. In the modes Single Prioritization Scheduling and Multiple Prioritization Scheduling, no upper limit access time for a write access to GTM0MCSiSTRG can be guaranteed. The High Prioritized tasks have to be disabled in order to guarantee fast write access to GTM0MCSiSTRG.

25.13.9.14GTM0MCSiRESET (i = 0, 1)

Access: This register can be read/written in 32-bit units.

Address: GTM0MCS0RESET: <GTM_base> + 30068_H
GTM0MCS1RESET: <GTM_base> + 31068_H

Value after reset: $0000\ 0000_H$

Table 25.165 GTM0MCSiRESET Register Contents

Bit Position	Bit Name	Function
31 to 9	Reserved	These bits are always read as 0. When written, write the initial value.
8	RST8	Software reset of channel 8 0: No action 1: Reset channel
7	RST7	Software reset of channel 7 0: No action 1: Reset channel
6	RST6	Software reset of channel 6 0: No action 1: Reset channel
5	RST5	Software reset of channel 5 0: No action 1: Reset channel
4	RST4	Software reset of channel 4 0: No action 1: Reset channel
3	RST3	Software reset of channel 3 0: No action 1: Reset channel
2	RST2	Software reset of channel 2 0: No action 1: Reset channel
1	RST1	Software reset of channel 1 0: No action 1: Reset channel
0	RST0	Software reset of channel 0 0: No action 1: Reset channel

NOTES

1. Only the first T bits of this register (bit 0 to 8) are functionally implemented. The other bits (bit 9 to 31) are reserved bits.
2. The RSTx (x = 0 to 8) bits is cleared automatically after write access of CPU. All channel related registers of channel x are set to their reset values and channel operation is stopped immediately.
3. Channel related registers of channel x are all registers GTM0MCSix*, all MCS internal registers accessible by the corresponding channel, with exception of the common trigger register (accessed by GTM0MCSiCTRG/GTM0MCSiSTRG) and the commonly used general purpose registers GTM0MCSixR4 and GTM0MCSixR5.

25.13.9.15GTM0MCSiCAT (i = 0, 1)

Access: This register can be read/written in 32-bit units.

Address: GTM0MCS0CAT: <GTM_base> + $3006C_H$
GTM0MCS1CAT: <GTM_base> + $3106C_H$

Value after reset: $0000\ 0000_H$

Table 25.166 GTM0MCSiCAT Register Contents

Bit Position	Bit Name	Function
31 to 9	Reserved	These bits are always read as 0. When written, write the initial value.
8	CAT8	Cancel ARU transfer for channel 8. 0: Do nothing. 1: Cancel any pending ARU read or write transfer.
7	CAT7	Cancel ARU transfer for channel 7. 0: Do nothing. 1: Cancel any pending ARU read or write transfer.
6	CAT6	Cancel ARU transfer for channel 6. 0: Do nothing. 1: Cancel any pending ARU read or write transfer.
5	CAT5	Cancel ARU transfer for channel 5. 0: Do nothing. 1: Cancel any pending ARU read or write transfer.
4	CAT4	Cancel ARU transfer for channel 4. 0: Do nothing. 1: Cancel any pending ARU read or write transfer.
3	CAT3	Cancel ARU transfer for channel 3. 0: Do nothing. 1: Cancel any pending ARU read or write transfer.
2	CAT2	Cancel ARU transfer for channel 2. 0: Do nothing. 1: Cancel any pending ARU read or write transfer.
1	CAT1	Cancel ARU transfer for channel 1. 0: Do nothing. 1: Cancel any pending ARU read or write transfer.
0	CAT0	Cancel ARU transfer for channel 0. 0: Do nothing. 1: Cancel any pending ARU read or write transfer.

NOTES

1. Only the first T bits of this register (bit 0 to 8) are functionally implemented. The other bits (bit 9 to 31) are reserved bits.
2. The CATx (x = 0 to 8) bit inside the STA register of the corresponding MCS-channel is set and any pending ARU read or write request is cancelled. The MCS-channel resumes with the instruction after the ARU transfer instruction.
3. The CATx (x = 0 to 8) bit is cleared by the corresponding MCS channel, when the channel reaches an ARU read or write instruction.

25.13.9.16GTM0MCS0CWT (i = 0, 1)

Access: This register can be read/written in 32-bit units.

Address: GTM0MCS0CWT: <GTM_base> + 30070_H
GTM0MCS1CWT: <GTM_base> + 31070_H

5	ERR5	Error State of MCS-channel 5. 0: No error signal. 1: Error signal is pending.
4	ERR4	Error State of MCS-channel 4. 0: No error signal. 1: Error signal is pending.
3	ERR3	Error State of MCS-channel3 . 0: No error signal. 1: Error signal is pending.
2	ERR2	Error State of MCS-channel 2. 0: No error signal. 1: Error signal is pending.
1	ERR1	Error State of MCS-channel 1. 0: No error signal. 1: Error signal is pending.
0	ERR0	Error State of MCS-channel 0. 0: No error signal. 1: Error signal is pending.

NOTES

1. Only the first T bits of this register (bit 0 to 8) are functionally implemented. The other bits (bit 9 to 31) are reserved bits.
2. The CPU can read the ERRx (x = 0 to 8) bits in order to determine the current error state of the corresponding MCS-channel x.
3. The error state is also evaluated by the sub module MON, if this module is available.
4. Writing a value 1 to this bit resets the corresponding error state and resets the channel internal ERR bit in the STA and channel CTRL registers. Moreover, each write access to this bit also sets the ERR_SRC_ID bit field of register GTM0MCSiCTRLSTAT to its reset value.

25.14 Memory Configuration (MCFG)

25.14.1 Overview

The Memory Configuration submodule (MCFG) is an infrastructure module that organizes physical memory blocks and maps them to the RAM ports 0 and 1 of available Multi Channel Sequencer (MCS) modules.

The following parameters are design variables for the MCFG hardware structure that can vary in its range for different devices:

- MAW - Memory address width of a large physical memory block.
- ERM - Enable RAM1 MSB (0 - RAM1 MSB disabled,
  1 - RAM1 MSB enabled,

The actual values for these parameters can be obtained from the device specific **Section 25.18, GTM Device 207** and **Section 25.19, GTM Device 208**.

It should be noted that the actual value of the parameter ERM can be obtained by the bit ERM of the register GTM0GTMHWCONF.

Depending on the value of parameter ERM, the MCFG module assumes externally connected physical RAM modules with different sizes. If ERM = 0, MCFG assumes that each MCS instance provides a large physical memory block with 2^{MAW} memory locations each 32 bit wide which leads to a RAM module with 2^{MAW+2} (byte wise) memory addresses. Further each MCS instance provides a small physical memory block with 2^{MAW-1} memory locations each 32 bit wide leading to a RAM module with 2^{MAW+1} (byte wise) memory addresses. If ERM = 1, MCFG assumes that each MCS instance provides two large physical memory block each with 2^{MAW} memory locations each 32-bit leading to a RAM module with 2^{MAW+2} (byte wise) memory addresses.

In order to support different memory sizes for different MCS instances, the MCFG module provides three layout configurations for reorganization of memory pages mapped to the RAM ports of neighboring MCS modules. **Table 25.169, Memory Layout Configurations (ERM = 0)** shows all layout configurations for the case that ERM = 0 and **Table 25.171, Memory Layout Configurations (ERM = 1)** shows the layout configurations for the case that ERM = 1. Each box in these pictures represents a physical memory block.

The layout configuration DEFAULT is always assigning a memory block of size $2^{MAW} \times 32$ bits to MCS RAM port 0. Depending on ERM, RAM port 1 of each MCS is whether assigned to a memory block of size $2^{MAW-1} \times 32$ bits (ERM = 0) or a memory block of size $2^{MAW} \times 32$ bits (ERM = 1).

The layout configuration SWAP is swapping the memory block assigned to RAM port 1 of the current MCS instance with the memory block assigned to RAM port 0 of the successive MCS instance. If ERM = 0, this means that the memory of the current MCS instance is increased by $2^{MAW-1} \times 32$ bits but the memory of the successor is decreased by $2^{MAW-1} \times 32$ bits compared to the DEFAULT configuration. If ERM = 1, the SWAP configuration has no effect on the memory sizes of the individual MCS instances.

The layout configuration BORROW is borrowing the memory block assigned to RAM port 0 of the successive MCS instance for the current instance. This means, the memory of the current MCS module is increased by $2^{MAW} \times 32$ bits but the memory of the successor is decreased by $2^{MAW} \times 32$ bits compared to the DEFAULT configuration.

Considering the order the mentioned MCS modules, it should be noted that the successor of the last MCS instance is the first MCS instance MCS0.

The actual sizes of the memory pages mapped to the MCS RAM ports 0 and 1 depends on the layout configuration for of current instance MCS[i] and the layout configuration of the preceding memory instance MCS[i-1]. The sizes of these memory pages can be obtained by the layout parameters MP0 and MP1, as described in the specification of the MCS.

Table 25.170, Memory Layout Parameters (ERM = 0) and **Table 25.172, Memory Layout Parameters (ERM = 1)** summarize the layout parameters MP0 and MP1 of MCS instance MCS[i] for the case that ERM = 0 and ERM = 1. Note that the predecessor of instance MCS0 is last available MCS instance.

The addressing of memory port 0 ranges from 0 to MP0–4 and the addressing of memory page 1 ranges from MP0 to MP1–4.

This document assumes that the GTM implementation embeds 7 MCS instances. However, the actual number of implemented MCS instances can be obtained from [1].

25.14.1.1 Memory Layout Configurations (ERM = 0)

Table 25.169 Memory Layout Configurations (ERM = 0)

	DEFAULT	SWAP	BORROW
Configuration for instance MCS[i]	2^{MAW} × 32 bit 2^{MAW-1} × 32 bit	2^{MAW} × 32 bit 2^{MAW} × 32 bit	2^{MAW} × 32 bit 2^{MAW} × 32 bit 2^{MAW-1} × 32 bit
Configuration for instance MCS[i+1]	2^{MAW} × 32 bit 2^{MAW-1} × 32 bit	2^{MAW-1} × 32 bit 2^{MAW-1} × 32 bit	2^{MAW-1} × 32 bit

25.14.1.2 Memory Layout Parameters (ERM = 0)

Table 25.170 Memory Layout Parameters (ERM = 0)

			Memory Layout Option of preceding MCS instance MCS[i-1]		
			DEFAULT	**SWAP**	**BORROW**
Memory Layout Option of current MCS instance MCS[i]	DEFAULT	MP0	2^{MAW+2}	2^{MAW+1}	0
		MP1	$2^{MAW+2}+2^{MAW+1}$	2^{MAW+2}	2^{MAW+1}
	SWAP	MP0	2^{MAW+2}	2^{MAW+1}	0
		MP1	2^{MAW+3}	$2^{MAW+2}+2^{MAW+1}$	2^{MAW+2}
	BORROW	MP0	2^{MAW+2}	2^{MAW+1}	0
		MP1	$2^{MAW+3}+2^{MAW+1}$	2^{MAW+3}	$2^{MAW+2}+2^{MAW+1}$

25.14.1.3 Memory Layout Configurations (ERM = 1)

Table 25.171 Memory Layout Configurations (ERM = 1)

7, 6	MEM3	Configure Memory pages for MCS-instance MCS3. 00: DEFAULT configuration 01: SWAP configuration 10: BORROW configuration 11: Reserved
5, 4	MEM2	Configure Memory pages for MCS-instance MCS2. 00: DEFAULT configuration 01: SWAP configuration 10: BORROW configuration 11: Reserved
3, 2	MEM1	Configure Memory pages for MCS-instance MCS1. 00: DEFAULT configuration 01: SWAP configuration 10: BORROW configuration 11: Reserved
1, 0	MEM0	Configure Memory pages for MCS-instance MCS0. 00: DEFAULT configuration 01: SWAP configuration 10: BORROW configuration 11: Reserved

NOTE

It should be noted that the actual GTM-IP implementation may embed less than 7 MCS instances (see **Table 25.2 Sub-Units and Channels**). In this case this register only implements the register bits for available MCS instances.

25.15 Interrupt Concentrator Module (ICM)

25.15.1 Overview

The Interrupt Concentrator Module (ICM) is used to bundle the GTM-IP interrupt lines of the individual submodules in a reasonable manner into interrupt groups. By this bundling a smaller amount of interrupt lines is visible at the outside of the GTM-IP.

The individual interrupts of the GTM-IP submodules and channels have to be enabled or disabled inside the submodules and channels.

The feed through architecture of bundled interrupt lines is used for the submodules AEI, ARU, CMP, TIM, ATOM and MCS.

To determine the detailed interrupt source the microcontroller has to read the submodule/channel interrupt notification register NOTIFY and serve the channel individual interrupt.

Please note, that the interrupts are only visible inside the ICM and in consequence outside of the GTM-IP, when the interrupt is enabled inside the submodules themselves.

25.15.2 Bundling

The GTM-IP submodule individual interrupt sources are connected to the ICM. There, the individual interrupt lines are either feed through and signalled to the outside world or bundled a second time into groups and are then signalled to the outside world.

The ICM interrupt bundling is described in the following sections.

25.15.2.1 GTM Infrastructure Interrupt Bundling

The first interrupt group contains interrupts of the infrastructure and safety components of the GTM. This interrupt group includes therefore interrupt lines coming from the AEI, ARU and CMP submodules. In this interrupt group each individual channel of the submodules has its own interrupt line to the outside world.

Thus, the active interrupt line can be used by the CPU to determine the GTM-IP submodule channel that raised the interrupt. The interrupts are also represented in the GTM0ICMIRQG0 register. This register is typically not read by the CPU, but it is readable.

25.15.2.2 TIM Interrupt Bundling

Inside this group submodules which handle GTM-IP input signals are treated. This is the case for the TIM[i] submodules. Each TIM submodule channel is able to generate six (6) individual interrupts if enabled inside the TIM channel. This six interrupts are bundled into one interrupt per TIM channel connected to the ICM.

The ICM does no further bundling. Thus, for the GTM-IP 32 interrupt lines TIM[i]_IRQ[y] are provided for the external microcontroller. The channel responsible for the interrupt can be determined by the raised interrupt line.

In addition, the GTM0ICMIRQG2 register is mirror for the TIM submodule channel interrupts and typically not read out by the CPU, but it is readable.

25.15.2.3 MCS Interrupt Bundling

For complex signal output generation, the MCS submodules are used inside the GTM-IP. Each of these MCS submodules could have 32 channels with one interrupt line. This interrupt line is connected to the ICM submodule and is feed through directly to the outside world.

In addition the interrupt line status for the first 8 channels of each MCS are shown in the GTM0ICMIRQG4 and GTM0ICMIRQG5 register.The interrupt line status for all 32 channels of each MCS are shown in the GTM0ICMIRQGMCSiCI register. Typically, the interrupt source is determined by the corresponding interrupt line and the GTM0ICMIRQ4 and GTM0ICMIRQGMCSiCI register are typically not read out by the CPU, but they are readable.

25.15.2.4 ATOM Interrupt Bundling

The interrupts coming from the ATOM[i] submodules are registered in the GTM0ICMIRQG9. Up to four ATOM's are bundled in one ICM register. To identify the ATOM submodule channel where the interrupt occurred, the CPU has to read out the GTM0ICMIRQG9 register first before it goes to the ATOM submodule channel itself.

The GTM0ICMIRQG9 register bits are cleared automatically, when their corresponding interrupt in the submodule channels is cleared.

25.15.2.5 Module Error Interrupt Bundling

The Module Error Interrupt group handles the error interrupts coming from the TIM, CMP submodule of the GTM-IP. The Module Error interrupts are additionally identified in the GTM0ICMIRQGMEIerror interrupt group register. This register is typically not read out by the CPU, but it is readable.

The GTM0ICMIRQGMEI register bits are cleared automatically, when their corresponding error interrupt in the submodule is cleared.

25.15.2.6 TIM Channel Error Interrupt Bundling

The TIM Channel Error Interrupt group handles the error interrupts coming from the TIM channel of the GTM-IP. The TIM Channel Error interrupts are additionally identified for the submodules TIM0 and TIM1 in the GTM0ICMIRQGCEI1 error interrupt group register. This register is typically not read out by the CPU, but it is readable.

The GTM0ICMIRQGCEI1 register bits are cleared automatically, when their corresponding error interrupt in the submodule channel is cleared.

25.15.2.7 MCS Channel Error Interrupt Bundling

The MCS Channel Error Interrupt group handles the error interrupts coming from the MCS channel of the GTM-IP. All 32 MCS Channel Error interrupts are additionally identified for each submodules MCS[i] in the GTM0ICMIRQGMCSiCEI error interrupt group register. The first 8 MCS Channel Error interrupts are additionally identified for the submodules MCS0, MCS1, MCS2 and MCS3 in the GTM0ICMIRQGCEI3 error interrupt group register. These register are typically not read out by the CPU, but they are readable.

The GTM0ICMIRQGMCSiCEI, GTM0ICMIRQGCEI3 register bits are cleared automatically, when their corresponding error interrupt in the submodule channel is cleared.

25.15.3 ICM Interrupt Signals

Following table shows the GTM-IP interrupt lines that are visible at the outside of the IP.

Table 25.175 ICM Interrupt Signals

Signal	Description
GTM_AEI_IRQ	AEI Shared interrupt
GTM_ARU_IRQ[2:0]	[0]: ARU_NEW_DATA0 Interrupt [1]: ARU_NEW_DATA1 Interrupt [2]: ARU_ACC_ACK Interrupt
GTM_CMP_IRQ	CMP Shared interrupt
GTM_TIM[i]_IRQ[x]	TIM Shared interrupts (i: 0 to number of TIM's-1) (x = 0 to 7)
GTM_MCS[i]_IRQ[x]	MCS Interrupt for channel x (x = 0 to 31) (i: 0 to number of MCS's-1)
GTM_ATOM[i]_IRQ[x]	ATOM Shared interrupts (i: 0 to number of ATOM's-1) (x = 0 to 7)
GTM_ERR_IRQ	GTM Error Interrupt

25.15.4 ICM Configuration Registers Overview

ICM contains following configuration registers:

Table 25.176 Register list

Symbol	Register Name	Details in Section
GTM0ICMIRQG0	ICM Interrupt group register covering infrastructural and safety components (ARU, AEI, CMP)	**25.15.5.1**
GTM0ICMIRQG2	ICM Interrupt group register covering TIM0, TIM1	**25.15.5.2**
GTM0ICMIRQG4	ICM Interrupt group register covering MCS0 to MCS1 submodules	**25.15.5.3**
GTM0ICMIRQG9	ICM Interrupt group register covering GTM-IP output submodules ATOM0, ATOM1, ATOM2	**25.15.5.4**
GTM0ICMIRQGMEI	ICM Interrupt group register for module error interrupt information	**25.15.5.5**
GTM0ICMIRQGCEI1	ICM Interrupt group register 1 for channel error interrupt information	**25.15.5.6**
GTM0ICMIRQGCEI3	ICM Interrupt group register 3 for channel error interrupt information	**25.15.5.7**
GTM0ICMIRQGMCS0CI	ICM Interrupt group MCS 0 for Channel Interrupt information	**25.15.5.8**
GTM0ICMIRQGMCS0CEI	ICM Interrupt group MCS 0 for Channel Error Interrupt information	**25.15.5.9**
GTM0ICMIRQGMCS1CI	ICM Interrupt group MCS 1 for Channel Interrupt information	**25.15.5.10**
GTM0ICMIRQGMCS1CEI	ICM Interrupt group MCS 1 for Channel Error Interrupt information	**25.15.5.11**

25.15.5 ICM Configuration Registers Description

25.15.5.1 GTM0ICMIRQG0 (GTM Infrastructure Interrupt Group)

Access: This register can be read in 32-bit units.

Address: <GTM_base> + 00600_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

25.16 Output Compare Unit (CMP)

25.16.1 Overview

The Output Compare Unit (CMP) is designed for the use in safety relevant applications. The main idea is to have the possibility to duplicate outputs in order to be compared in this unit. Because of the simple EXOR function used it is necessary to ensure the total cycle accurate output behavior of the output modules to be compared. This is given when two DTM units produce output signals at the same time stamp. It is not necessary to compare each output channel with each other.

The CMP enables the comparison of 20 channels of the DTM units respectively and is restricted to neighbor channels. Thus, channel 0 is compared with channel 1, channel 2 with 3 and so on until the comparison of channel 18 with channel 19.

25.16.1.1 Architecture of the Compare Unit

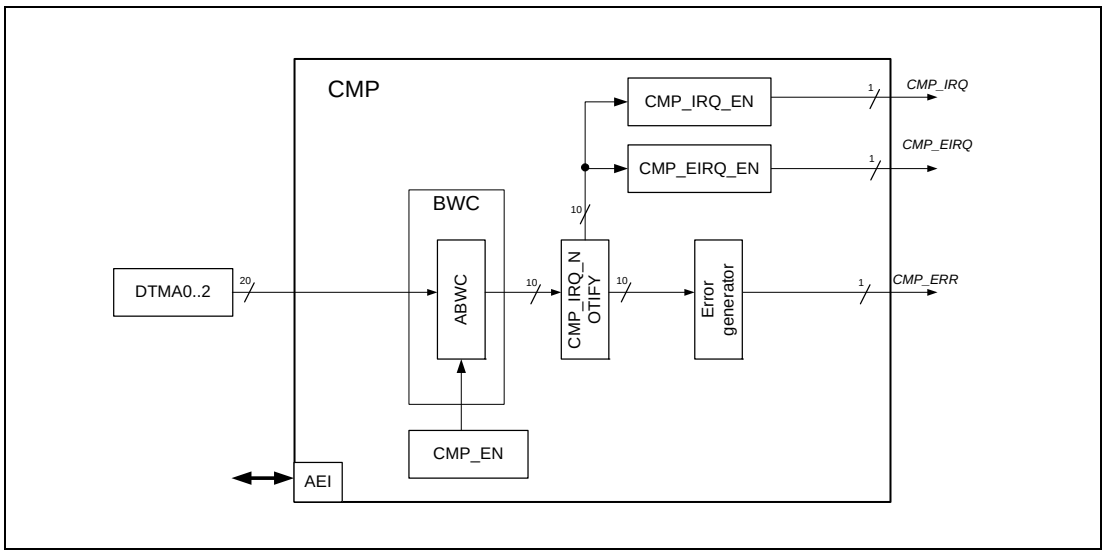

Figure 25.65 Architecture of the Compare Unit

25.16.2 Bitwise Compare Unit (BWC)

The Bitwise Compare Unit compares in pairs the combinations shown in following table

Table 25.188 Bitwise Compare Unit (BWC)

ABWC Comparator Number	DTMA Bit Number one	DTMA Bit Number Two	Output Number
0	0	1	0
1	2	3	1
2	4	5	2
3	6	7	3
4	8	9	4
5	10	11	5
6	12	13	6
7	14	15	7
8	16	17	8
9	18	19	9

25.16.3 Configuration of the Compare Unit

Because of the restrictions described in the section above the Compare Unit consists of 10 antivalence (EXOR) elements, a select register GTM0CMPEN which selects the corresponding comparisons and a status register GTM0CMPIRQNOTIFY which shows and stores each mismatching result, when selected.

For each DTMA with an odd-channel DTM the MSB is not used for comparison to make sure of correct EXOR functionality.

For each with GTM0CMPIRQEN enabled mismatching error an interrupt signal on CMP_IRQ is generated.

For each with GTM0CMPIRQEN enabled mismatching error an interrupt signal on CMP_EIRQ is generated.

25.16.4 Error Generator

The error generator generates an error signal to be transmitted directly to the MON unit and independently from the CMP_IRQ and CMP_EIRQ. The error is set when in the GTM0CMPIRQNOTIFY register at least one bit is set. The GTM0CMPIRQNOTIFY bits are not mask able for this purpose.

The CMP_ERR output reflects its status in the status register of the Monitor Unit, which is to be polled by the CPU.

25.16.5 CMP Interrupt Signal

The CMP submodule has two interrupt signals, one normal interrupt and one error interrupt. The source of both interrupt can be determined by reading the GTM0CMPIRQNOTIFY register under consideration of GTM0CMPIRQEN register and GTM0CMPIRQEN register. Each source can be forced separately for debug purposes using the interrupt force GTM0CMPIRQFORCINT register. GTM0CMPIRQMODE configures interrupt output characteristic. All interrupt modes are described in detail in **Section 25.6.5, GTM-IP Interrupt Concept** .

Table 25.189 CMP Interrupt Signal

Signal	Description
CMP_EIRQ	Mismatching interrupt of outputs to be compared, when enabled
CMP_IRQ	Mismatching interrupt of outputs to be compared, when enabled

25.16.6 CMP Configuration Registers Overview

CMP contains following configuration registers:

Table 25.190 Register list

Symbol	Register Name	Details in Section
GTM0CMPEN	Comparator enable register	**25.16.7.1**
GTM0CMPIRQNOTIFY	Event notification register	**25.16.7.2**
GTM0CMPIRQEN	Interrupt enable register	**25.16.7.3**
GTM0CMPIRQFORCINT	Interrupt force register	**25.16.7.4**
GTM0CMPIRQMODE	IRQ mode configuration register	**25.16.7.5**
GTM0CMPEIRQEN	Error interrupt enable register	**25.16.7.6**

25.16.7 CMP Configuration Registers Description

25.16.7.1 GTM0CMPEN

Access: This register can be read/written in 32-bit units.

Address: <GTM_base> + 00200_H

25.17 Monitor Unit (MON)

25.17.1 Overview

The Monitor Unit (MON) is designed for the use in safety relevant applications. The main idea is to have a possibility to supervise common used circuitry and resources. In this way the activity of the clocks is supervised. In addition the characteristics of output signals can be checked in a MCS channel by a re-read-in via TIM and routing to the MCS. When the comparison fails an error signal is ge1nerated in MCS and sent to the monitor unit. One error signal per MCS summarizes the errors of all channels. By generating of an activity signal per channel for each such performed comparison, the activity of TIM, ARU and the used clocks is checked implicitly.

In addition the ARU cycle time could be also compared in a MCS channel to given values.

25.17.1.1 MON Block Diagram

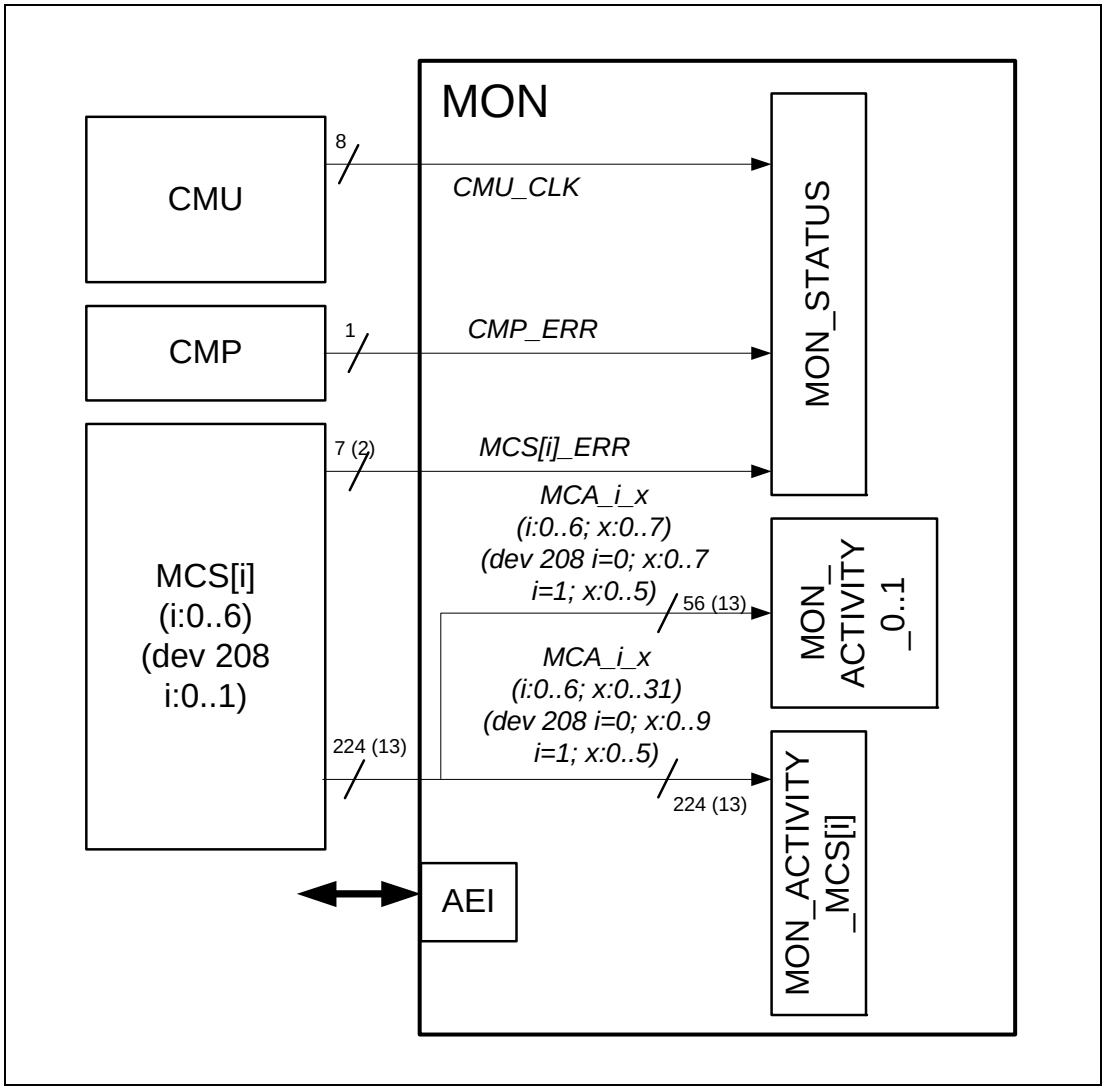

Figure 25.66 MON Block Diagram

25.17.1.2 Realization without Activity Checker of the clock signals

An activity checker of the clock signals used is not needed because these signals are only enables to be used in combination with the system clock. Therefore the clock enables are to be checked to have a high value.

25.17.2 Clock Monitoring

The monitor unit has a connection to each of the 8 clocks CMU_CLK[x] (x = 0 to 7), provided by the CMU. Some of these clocks can be used for special tasks (see **Section 25.8, Clock Management Unit (CMU)**).

The supervising of the clocks is done by scanning for activity of each clock.

A high value is defined as the state to be monitored.

When a high value of the clock enable is detected, the corresponding bit in the status register GTM0MONSTATUS is set.

The status register bits are reset by writing a one.

When the register is polled by the CPU and the time between two read accesses is higher than the period of the slowest clock, all bits of the corresponding clocks must have been set.

When polling in shorter time distances, not for all clocks an activity can be shown, although they are still working.

Because of the realization without a select register for the clock signals only the bits of the status register are to be considered for which the clock signal is enabled in the CMU.

25.17.3 CMP error Monitoring

The signal CMP_ERR is to be received directly from module CMP and is set if an error occurred.

25.17.4 Checking the Characteristics of Signals by MCS

By use of the MCS some given properties of signals can be checked. Such signals can be generated output signals of ATOM channels, which are re-read in into a TIM and the time stamp information is routed via ARU to the MCS module.

The corresponding MCS signal performs the check according to given properties. In this way signal high or low time as well as signal periods can be checked, also taking into account tolerances. When the check fails a MCS internal error signal is generated and ORed with the error signals of the other channels of the MCS module to an summarized error signal GTM0MCSiERR (i = 0 to 1).

For each MCS a summarized error signal is transmitted to MON and monitored in the GTM0MONSTATUS register.

In order to check the execution of the comparison for each MCS channel an activity signal is generated. In the MCA_x (x = 0 to 31) vector 32 bits for each MCS[i](i = 0 to 6) instance are combined. The activity signals are stored in the GTM0MONACTIVITYMCSi register. In addition the first 8 bits of MCS0 to 3 are stored in GTMMONACTIVITY0. The bits are set by a one signal and reset by writing a one to it (preferably after polling the status of the register).

For the first 8 MCS channels the activity information is stored twice (GTMMONACTIVITY0, GTM0MONACTIVITYMCSi). The same actitity bit is reset by writing one register only.

Because the activity signal shows the execution of a comparison, the involved units for providing the signals and execution of comparison (like TIM, ARU and MCS itself) are checked implicitly to work accordingly. Also the involved clocks and time bases are checked in this way.

25.17.5 Checking ARU Cycle Time

The cycle time of the ARU can be checked, when this is essential for safety purposes. This check can be performed by an MCS channel. It should be noted that the MCS program for measuring the ARU round trip time must add a tolerance value.

The resulting error is reported to the MON unit using the summarized error signal GTM0MCSiERR for each MCS module in addition to an interrupt, generated in MCS. The same signals and status bits are used as in the case of checking the signal characteristics.

The corresponding MCS is programmed to get a fixed data value at address 0x1FF. The data value is always zero and is not blocked. When getting the access the time stamp value TBU_TS0 is stored in a register. The next time getting the access the new TBU_TS0 value is stored and the difference between both values is compared with a given value. When the comparison fails, an error flag is set in the MCS internal status register, an interrupt is generated and the error signal GTM0MCSiERR is provided.

When the check is performed, an activity signal MCA_x (x = 0 to 31) is provided for each channel x for each MCS[i](i = 0 to 6) instance together with a summarized interrupt GTM0MCSiERR for each MCS.

The activity signal sets a bit in the GTMMONACTIVITY0 register.

The bits in the GTMMONACTIVITY0 registers are reset by writing a one.

When the check fails, an interrupt is generated and the error signal GTM0MCSiERR is provided for the MON unit.

Figure 25.66 shows the block diagram of the Monitor Unit.

25.17.6 MON Interrupt Signals

The MON submodule has no interrupt signals.

25.17.7 MON Registers Overview

Following configuration registers are considered in MON sub module

Table 25.197 Register list

Symbol	Register Name	Details in Section
GTM0MONSTATUS	Monitor Status register	**25.17.8.1**
GTMMONACTIVITY0	Monitor activity register 0	**25.17.8.2**
GTM0MONACTIVITYMCSi	Monitor activity register for MCS [z] (z = 0 to 6)	**25.17.8.3**

25.17.8 MON Configuration Registers Description

25.17.8.1 GTM0MONSTATUS

Access: This register can be read/written in 32-bit units.

Address: <GTM_base> + 00180_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	MCS6_ERR	MCS5_ERR	MCS4_ERR	MCS3_ERR	MCS2_ERR	MCS1_ERR	MCS0_ERR	—	—	—	CMP_ERR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 25.198 GTM0MONSTATUS Register Contents (1/3)

Bit Position	Bit Name	Function
31 to 27	Reserved	These bits are always read as 0. When written, write the initial value.
26	MCS6_ERR	Error detected at MCS6 **NOTE** This bit will be readable only.
25	MCS5_ERR	Error detected at MCS5 **NOTE** This bit will be readable only.
24	MCS4_ERR	Error detected at MCS4 **NOTE** This bit will be readable only.
23	MCS3_ERR	Error detected at MCS3 **NOTE** This bit will be readable only.
22	MCS2_ERR	Error detected at MCS2 **NOTE** This bit will be readable only.
21	MCS1_ERR	Error detected at MCS1 **NOTE** This bit will be readable only.

Table 25.198 GTM0MONSTATUS Register Contents (2/3)

Bit Position	Bit Name	Function
20	MCS0_ERR	Error detected at MCS0 **NOTE** This bit will be readable only.
19 to 17	Reserved	These bits are always read as 0. When written, write the initial value.
16	CMP_ERR	Error detected at CMP **NOTE** This bit will be readable only.
15 to 8	Reserved	These bits are always read as 0. When written, write the initial value.
7	ACT_CMU7	CMU_CLK7 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
6	ACT_CMU6	CMU_CLK6 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
5	ACT_CMU5	CMU_CLK5 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
4	ACT_CMU4	CMU_CLK4 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
3	ACT_CMU3	CMU_CLK3 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
2	ACT_CMU2	CMU_CLK2 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
1	ACT_CMU1	CMU_CLK1 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Table 25.198 GTM0MONSTATUS Register Contents (3/3)

Bit Position	Bit Name	Function
0	ACT_CMU0	CMU_CLK0 activity **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

NOTES

1. Bits16 and 20 to 26 are set, when the corresponding unit reports an error.
2. Bits 0 to 7 are set, when a high low slope is detected at the considered clock.
3. The MCS can be programmed to generate an error, when the comparison of signal values (duty time, cycle time) fails or also when the cycle time of the ARU (checking of the TBU_TS0 between two periodic accesses) is out of the expected range.

25.17.8.2 GTMMONACTIVITY0

Access: This register can be read/written in 32-bit units.

17	MCA_2_1	Activity of check performed in module MCS 2 at channel 1. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
16	MCA_2_0	Activity of check performed in module MCS 2 at channel 0. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Table 25.199 GTMMONACTIVITY0 Register Contents (3/4)

Bit Position	Bit Name	Function
15	MCA_1_7	Activity of check performed in module MCS 1 at channel 7. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
14	MCA_1_6	Activity of check performed in module MCS 1 at channel 6. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
13	MCA_1_5	Activity of check performed in module MCS 1 at channel 5. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
12	MCA_1_4	Activity of check performed in module MCS 1 at channel 4. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
11	MCA_1_3	Activity of check performed in module MCS 1 at channel 3. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
10	MCA_1_2	Activity of check performed in module MCS 1 at channel 2. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
9	MCA_1_1	Activity of check performed in module MCS 1 at channel 1. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
8	MCA_1_0	Activity of check performed in module MCS 1 at channel 0. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
7	MCA_0_7	Activity of check performed in module MCS 0 at channel 7. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
6	MCA_0_6	Activity of check performed in module MCS 0 at channel 6. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Table 25.199 GTMMONACTIVITY0 Register Contents (4/4)

Bit Position	Bit Name	Function
5	MCA_0_5	Activity of check performed in module MCS 0 at channel 5. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
4	MCA_0_4	Activity of check performed in module MCS 0 at channel 4. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
3	MCA_0_3	Activity of check performed in module MCS 0 at channel 3. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
2	MCA_0_2	Activity of check performed in module MCS 0 at channel 2. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
1	MCA_0_1	Activity of check performed in module MCS 0 at channel 1. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
0	MCA_0_0	Activity of check performed in module MCS 0 at channel 0. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

NOTE

When not all MCS modules are implemented or the channels are not used for check purposes with supervising, the corresponding activity bits remain zero.

25.17.8.3 GTM0MONACTIVITYMCSi (i = 0, 1)

Access: This register can be read/written in 32-bit units.

Address: GTM0MONACTIVITYMCS0: <GTM_base> + $0018C_H$
GTM0MONACTIVITYMCS1: <GTM_base> + 00190_H

Value after reset: $0000\ 0000_H$

Bit Position	Bit Name	Function
31	MCA_31	Activity of check performed in module MCS[i] at channel 31. **NOTE** This bit will be cleared on a CPU write access of value ‘1’. A read access leaves the bit unchanged.
30	MCA_30	Activity of check performed in module MCS[i] at channel 30. **NOTE** This bit will be cleared on a CPU write access of value ‘1’. A read access leaves the bit unchanged.
29	MCA_29	Activity of check performed in module MCS[i] at channel 29. **NOTE** This bit will be cleared on a CPU write access of value ‘1’. A read access leaves the bit unchanged.
28	MCA_28	Activity of check performed in module MCS[i] at channel 28. **NOTE** This bit will be cleared on a CPU write access of value ‘1’. A read access leaves the bit unchanged.
27	MCA_27	Activity of check performed in module MCS[i] at channel 27. **NOTE** This bit will be cleared on a CPU write access of value ‘1’. A read access leaves the bit unchanged.
26	MCA_26	Activity of check performed in module MCS[i] at channel 26. **NOTE** This bit will be cleared on a CPU write access of value ‘1’. A read access leaves the bit unchanged.

Table 25.200 GTM0MONACTIVITYMCSi Register Contents (2/4)

Bit Position	Bit Name	Function
25	MCA_25	Activity of check performed in module MCS[i] at channel 25. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
24	MCA_24	Activity of check performed in module MCS[i] at channel 24. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
23	MCA_23	Activity of check performed in module MCS[i] at channel 23. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
22	MCA_22	Activity of check performed in module MCS[i] at channel 22. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
21	MCA_21	Activity of check performed in module MCS[i] at channel 21. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
20	MCA_20	Activity of check performed in module MCS[i] at channel 20. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
19	MCA_19	Activity of check performed in module MCS[i] at channel 19. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
18	MCA_18	Activity of check performed in module MCS[i] at channel 18. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
17	MCA_17	Activity of check performed in module MCS[i] at channel 17. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
16	MCA_16	Activity of check performed in module MCS[i] at channel 16. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Table 25.200 GTM0MONACTIVITYMCSi Register Contents (3/4)

Bit Position	Bit Name	Function
15	MCA_15	Activity of check performed in module MCS[i] at channel 15. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
14	MCA_14	Activity of check performed in module MCS[i] at channel 14. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
13	MCA_13	Activity of check performed in module MCS[i] at channel 13. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
12	MCA_12	Activity of check performed in module MCS[i] at channel 12. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
11	MCA_11	Activity of check performed in module MCS[i] at channel 11. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
10	MCA_10	Activity of check performed in module MCS[i] at channel 10. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
9	MCA_9	Activity of check performed in module MCS[i] at channel 9. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
8	MCA_8	Activity of check performed in module MCS[i] at channel 8. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
7	MCA_7	Activity of check performed in module MCS[i] at channel 7. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
6	MCA_6	Activity of check performed in module MCS[i] at channel 6. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

Table 25.200 GTM0MONACTIVITYMCSi Register Contents (4/4)

Bit Position	Bit Name	Function
5	MCA_5	Activity of check performed in module MCS[i] at channel 5. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
4	MCA_4	Activity of check performed in module MCS[i] at channel 4. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
3	MCA_3	Activity of check performed in module MCS[i] at channel 3. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
2	MCA_2	Activity of check performed in module MCS[i] at channel 2. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
1	MCA_1	Activity of check performed in module MCS[i] at channel 1. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.
0	MCA_0	Activity of check performed in module MCS[i] at channel 0. **NOTE** This bit will be cleared on a CPU write access of value '1'. A read access leaves the bit unchanged.

NOTES

1. Unused MCA bits are reserved.
2. Read as zero should be written as zero.

For detail, see **Section 25.13.9.11, GTM0MCSiCTRLSTAT (i = 0, 1)**.

25.18.5 Memory Address Ranges

The following table lists the address ranges of all memory mapped RAM regions implemented in the GTM-IP. The submodule address offsets are already applied in this table. Since the GTM-IP supports a configurable RAM size for several RAM ports, the table list minimum and maximum value for the upper memory addresses, whereas the maximum addresses can be found in brackets.

Table 25.203 Memory Address Ranges

Submodule	Memory Address Ranges
MCS0_MEMORY	$0003\ 8000_H$ to $0003\ 87FC_H$

25.18.6 ARU

25.18.6.1 ARU Write Address Overview

Table 25.204 ARU Write Address Overview

Name	Address
ARU_ACCESS	000_H
TIM [0 .. 1]	
TIM0_WRADDR[0..7]	001_H to 008_H
TIM1_WRADDR[0..7]	009_H to 010_H
unused	011_H to 038_H
misc	
unused	039_H to 076_H
MCS [0]	
MCS0_WRADDR[0..23]	077_H to $08E_H$
unused	$08F_H$ to $11E_H$
ATOM [0 .. 1]	
ATOM0_WRADDR[0..7]	$11F_H$ to 126_H
ATOM1_WRADDR[0..3]	127_H to $12A_H$
unused	$12B_H$ to $17E_H$
misc	
unused	$17F_H$ to $1FD_H$
ARU_EMPTY_ADDR	$1FE_H$
ARU_FULL_ADDR	$1FF_H$

25.18.6.2 ARU Round Trip Time

The round trip time of Device 207 is 22 * SYS_CLK for a one-ARU-slave configuration. A two-ARU-slave configuration is not implemented.

25.18.6.3 ARU port addressing

Each ARU connected data sink has its own specific address. The ARU caddr counter which represents the ARU roundtrip cycle is addressing each data sink. The following table describes the addressing order of the ARU-connected modules/data sinks.

Table 25.205 ARU port addressing

Name	caddr
reserved	0
ATOM-0	
channel-0	1
channel-1	2
channel-2	3
channel-3	4
channel-4	5
channel-5	6
channel-6	7

25.18.7 ATOM

Bit-reversed mode (PCM) in ATOM SOMP is available in the following channels:

Table 25.206 Bit-reversed mode (PCM) in ATOM SOMP

Module	Ch-0	Ch-1	Ch-2	Ch-3	Ch-4	Ch-5	Ch-6	Ch-7
ATOM-0	no	no	no	yes	no	no	no	yes
ATOM-1	no	no	no	yes	—	—	—	—

25.18.8 GTM Application constraints

If setting up an application on GTM-IP one has to take following constraints into account. Otherwise, the GTM-IP may not be able to fulfil the specified behavior.

Table 25.207 GTM Application constraints

#	Module	Description	Required value	Effect, when not considered
1	MCS	Worst Case Execution Time of an N-cycle instruction.	≤ 9*N system clock periods	MCS program execution may be too long for the application's requirements.
2	ATOM	If channel is triggered by preceding channel via TRIG_<x-1> signal, the selected CMU_CLK of both channels has to be the same	Identical CMU_CLK	The trigger of preceding channel my be lost
3	TIM	If a TIM channel x uses ARU transfer with enabled TDU, the minimal time T_{IN} between two subsequent measurement cycles has to be greater than the maximum time T_{SAMPLE} between two subsequent ARU read request events on TIM channel x.	$T_{IN} > T_{SAMPLE}$ (MCS: T_{SAMPLE} = max. time between two (N)ARD(I) instructions for TIM channel x)	The ARU destination of TIM channel x is cannot distinguish between a measurement cycle overflow and a timeout with subsequent valid measurement cycle.
4	ARU	The ARU round trip time is device specific.

25.19.5 Memory Address Ranges

The following table lists the address ranges of all MCS memory mapped RAM regions implemented in the GTM-IP. The submodule address offsets are already applied in this table. Since the GTM-IP supports a configurable RAM size for several RAM ports, the table list minimum and maximum value for the upper memory addresses, whereas the maximum addresses can be found in brackets.

Table 25.210 Memory Address Ranges

Submodule	Memory Address Ranges
MCS0_MEMORY	$0003\ 8000_H$ to $0003\ 87FC_H$ ($0003\ 8BFC_H$)
MCS1_MEMORY	$0004\ 0000_H$ to $0004\ 07FC_H$ ($0004\ 0BFC_H$)

25.19.6 ARU

25.19.6.1 ARU Write Address Overview

Table 25.211 ARU Write Address Overview

Name	Address
ARU_ACCESS	000_H
TIM [0 .. 1]	
TIM0_WRADDR[0..7]	001_H to 008_H
TIM1_WRADDR[0..7]	009_H to 010_H
unused	011_H to 038_H
misc	
unused	039_H to 076_H
MCS [0 .. 1]	
MCS0_WRADDR[0..23]	077_H to $08E_H$
MCS1_WRADDR[0..23]	$08F_H$ to $0A6_H$
unused	$0A7_H$ to $11E_H$
ATOM [0 .. 2]	
ATOM0_WRADDR[0..7]	$11F_H$ to 126_H
ATOM1_WRADDR[0..7]	127_H to $12E_H$
ATOM2_WRADDR[0..4]	$12F_H$ to 133_H
unused	$0x134_H$ to $17E_H$
misc	
unused	$0x17F_H$ to $1FD_H$
ARU_EMPTY_ADDR	$0x1FE_H$
ARU_FULL_ADDR	$0x1FF_H$

25.19.6.2 ARU Round Trip Time

The round trip time of Device 208 is 37 * SYS_CLK for a one-ARU-slave configuration and 20 * SYS_CLK for a two-ARU-slave configuration.

25.19.6.3 ARU port partitioning

Depending on the ARU connectivity configuration in the gtm_config_pack.vhd (aru_connect_config_c) the submodules ATOM0..2 and MCS0..1 are connected to different ARU ports as described in the table below.

The real configuration can be determined by evaluating bit ARU_CONNECT_CONFIG of register GTM_HW_CONF.

Table 25.212 ARU port partitioning

	aru_connect_config_c = 0		aru_connect_config_c = 1	
	port 1	port 2	port 1	(port 2)
ATOM-0	x		x	
ATOM-1		x	x	
ATOM-2		x	x	
MCS-0	x		x	
MCS-1		x	x	

25.19.6.4 ARU port addressing

Each ARU connected data sink has its own specific address. The ARU caddr counter which represents the ARU roundtrip cycle is addressing each data sink. The following table describes the addressing order of the ARU-connected modules/data sinks.

Table 25.213 ARU port addressing (1/2)

25.19.7 ATOM

Bit-reversed mode (PCM) in ATOM SOMP is available in the following channels:

Table 25.214 Bit-reversed mode (PCM) in ATOM SOMP

Module	Ch-0	Ch-1	Ch-2	Ch-3	Ch-4	Ch-5	Ch-6	Ch-7
ATOM-0	no	no	no	yes	no	no	no	yes
ATOM-1	no	no	no	yes	no	no	no	yes
ATOM-2	no	no	no	yes	no	—	—	—

25.19.8 GTM Application constraints

If setting up an application on GTM-IP one has to take following constraints into account. Otherwise, the GTM-IP may not be able to fulfil the specified behavior.

Table 25.215 GTM Application constraints

#	Module	Description	Required value	Effect, when not considered
1	MCS	Worst Case Execution Time of an N-cycle instruction.	<= 9*N system clock periods	MCS program execution may be too long for the application's requirements.
2	ATOM	If channel is triggered by preceding channel via TRIG_<x-1> signal, the selected CMU_CLK of both channels has to be the same	Identical CMU_CLK	The trigger of preceding channel my be lost
3	TIM	If a TIM channel x uses ARU transfer with enabled TDU, the minimal time T_{IN} between two subsequent measurement cycles has to be greater than the maximum time T_{SAMPLE} between two subsequent ARU read request events on TIM channel x.	$T_{IN} > T_{SAMPLE}$ (MCS: T_{SAMPLE} = max. time between two (N)ARD(I) instructions for TIM channel x)	The ARU destination of TIM channel x is cannot distinguish between a measurement cycle overflow and a timeout with subsequent valid measurement cycle.
4	ARU	The ARU round trip time is device specific.		

25.20 CAUTION

No.	Outline
ID1	GTM - GTM_HALT has static 5 clocks latency (Direction of use)
ID2	GTM - TOM/ATOM SOMP mode: initial delay of one shot pulse triggered by preceding channel (Direction of use)
ID3	GTM - MCS: Evaluation of CAT bit after blocking ARU instruction (Direction of use)
ID4	GTM - TIM: Incorrect signal level bit ECNT[0] in mode TIEM, TPWM, TIPM, TPIM, TGPS (Direction of use)
ID5	GTM - DTM: cross channel dead time does not prevent two cross linked outputs to be high (Direction of use)
ID6	GTM - (A)TOM: no CCU1 interrupt in case of CM1 = 0 or 1 and RST_CCU0 = 1 (Direction of use)
ID7	GTM - TIM: incorrect signal level on TIM_MODE change if TIM channel is disabled (Direction of use)
ID8	GTM - TIM: unexpected CNTS register update in TPWM OSM mode (Direction of use)
ID9	GTM - TOM/ATOM: no update of CM0/CM1/CLK_SRC via trigger signal from preceding instance if selected CMU_CLKx is not SYS_CLK (Direction of use)
ID10	GTM - ATOM: data loss in SOMS one-shot mode if ARU is enabled and the period of the selected CMU_CLKx is greater than ARU-cycle-time/2. (Direction of use)
ID11	GTM - DTM: shut-off priority causes spikes at DTM output (Direction of use)
ID12	GTM - ATOM SOMB mode: if ARU_EN = 1, a force update does not update ACBI flags but uses value from ATOM_CH_CTRL register (Technical limitation)
ID13	GTM - TOM/ATOM: async update in SOMP mode with CM1 = 0 and selected CMU clock unequal sys_clk not functional (Direction of use)
ID14	GTM - (A)TOM: output signal is postponed one period for the values CM0 = 1 and CM1 > CM0 if CN0 is reset by the trigger of a preceding channel (RST_CCU0 = 1) (Direction of use)
ID15	GTM - TOM/ATOM: wrong output behavior in SOMP oneshot mode when oneshot pulse is triggered by TIM_EXT_CAPTURE(x)
ID16	GTM - TOM/ATOM: wrong output behavior in SOMP oneshot mode when oneshot pulse is triggered by TRIG_[x-1]
ID17	GTM - ATOM: Unexpected restart of a SOMS oneshot cycle while GTM0ATOMixCM0 is zero
ID18	GTM - TIM: ARU bit ACB(0) (signal level) incorrect in case a second ARU request occurs while the actual request is just acknowledged
ID19	GTM - GTM Bus Bridge: Incorrect AEI access execution in case the previous AEI access was aborted with the access timeout abort function.
ID20	GTM - TOM/ATOM: Generation of TRIG_CCU0/TRIG_CCU1 trigger signals skipped in initial phase of A/TOM SOMP one-shot mode.
ID21	GTM - TOM/ATOM: False generation of TRIG_CCU1 trigger signal in SOMP one-shot mode with OSM_TRIG = 1 when CM1 is set to value 1.
ID22	ATOM SOMS mode: Shift cycle is not executed correctly in case the reload condition is deactivated with GTM0ATOMiAGCGLBCTRL.UPEN_CTRL[x] = 0b00
ID23	ATOM SOMP mode: Reset of GTM0ATOMixCN0 with TIM_EXT_CAPTURE are not correctly synchronized to selected CMU_CLK/CMU_FXCLK.
ID24	SPEC-ATOM: Specification of the smallest possible PWM Period in SOMP mode wrong, when ARU_EN = 1

No.	Outline
ID25	IRQ: Missing pulse in single-pulse interrupt mode on simultaneous interrupt and clear event
ID26	(A)TOM: potentially wrong output signal in case of RST_CCU0 = 1 and CM0 = 1 on triggered channel in SOMP mode.
ID27	ATOM-RTL: Missing edge on output signal ATOM_OUT when CN0 is reset with force update event.
ID28	SPEC-ATOM: Wrong register bit field descriptions for GTM0ATOMixCTRL.
ID29	SPEC-ATOM: Control bits of the TRIG_[x] multiplexer are switched.
ID30	TIM: Potentially wrong capture values
ID31	TIM: Missing glitch detection interrupt event
ID32	TIM: Unexpected increment of filter counter
ID33	TIM: Glitch detection interrupt event of filter is not a single cycle pulse
ID34	ATOM: Missing CCU0TCx_IRQ interrupt signal
ID35	SPEC-TIM: Wrong description for TBCM mode
ID36	SPEC-TIM: Wrong description in TBCM mode regarding GTM0TIM1xCTRL.GPR1_SEL(GTM0TIM0xCTRL.GPR1_SEL) bit field.

ID1		GTM - GTM_HALT has static 5 clocks latency
	Description	When GTM_HALT related event is detected by GTM TEU module, the GTM system stops after 5 clocks.
	Workaround	None
ID2		GTM - TOM/ATOM SOMP mode: initial delay of one shot pulse triggered by preceding channel
	Description	In case of following configuration of TOM/AOM SOMP mode, the first pulse on trigger from preceding channel is not generated: The triggered channel is configured to • RST_CCU0 = 0, • OSM = 1, • OSM_TRIG = 1, • CN0 = MAX-1, And the preceding channel which triggers the single pulse generation is configured to • TRIGOUT = 1 • CM0 = MAX -> the triggering channel counts from 0 to MAX-1 until it triggers (Description is based of Errata description GTM-IP-176)
	Workaround	Preset CN0 of triggered channel to CN0 < MAX-1
ID3		GTM - MCS: Evaluation of CAT bit after blocking ARU instruction
	Description	The specification for the instructions ARD, AWR, ARDI, and AWRI claims that the CAT bit can be evaluated by the MCS program in order to check if the last ARU transfer was successful (CAT=0) or cancelled by Software (CAT=1). However, since the CAT bit can be set directly by Software to cancel an ARU transfer at any time the bit does not reflect the status information reliably. Bad case: If the CPU software is setting CAT between the time of ARU data arrival and evaluation of CAT bit. (Description is based of Errata description GTM-IP-178)
	Workaround	If the mechanism for cancelling blocking ARU transfers by CPU is used and data consistency by ARU transfers is important, a possible workaround may check the consistency by inspection of the transferred data (e.g. checking for linear increment of ECNT for data transfers from TIM to MCS).
ID4		GTM - TIM: Incorrect signal level bit ECNT[0] in mode TIEM, TPWM, TIPM, TPIM, TGPS
	Description	In case of re-enabling a previously disabled TIM channel the bit ECNT[0] might not reflect the actual signal level of the corresponding input TIM[i]_CH[x]_FOUT until the next input edge occurs. This situation can only occur if between disabling and re-enabling the ECNT register is not read. (Description is based of Errata description GTM-IP-181)
	Workaround	1. After disabling the TIM channel, ensure that the ECNT register is read at least once and afterwards the TIM channel can be re-enabled 2. Before re-enabling a TIM channel, issue a TIM channel reset to reconfigure the TIM channel control registers.

ID5		GTM - DTM: cross channel dead time does not prevent two cross linked outputs to be high
	Description	In case of full/half bridge controlling where the low side switch signal is not the inverse signal of the high side switch signal, one can use the DTM cross channel dead time mode to introduce dead time. Then two neighbored TOM/ATOMchannel generate two PWM signals at the DTM inputs DTM_IN[2x] and DTM_IN[2x+1] and the DTM should introduce the dead time wherever necessary and avoid enabling of both output signals at the same point in time. The final output signals are available at DTM_OUT[2x] and DTM_OUT[2x+1]. If both DTM inputs have their edges at the same point in time (typically, one has arising edge while the other one has a falling edge) the correct dead time is applied. If it happens that both DTM input signals are high over a common time period, the DTM erroneously does not prevent from setting both outputs DTM_OUT[2x] and DTM_OUT[2x+1]. In typical applications this causes a damage of the switches. (Description is based of Errata description GTM-IP-201)
	Workaround	In case of DTM cross channel mode enabled, avoid by TOM/ATOM signal generation that both cross linked DTM inputs DTM_IN[2x] and DTM_IN[2x+1] are high (i.e. '1') at the same point in time.
ID6		GTM - (A)TOM: no CCU1 interrupt in case of CM1 = 0 or 1 and RST_CCU0 = 1
	Description	In case of channel x has configuration of RST_CCU0=1 (i.e. CN0 is reset by trigger input) and CN0 counts from 0 to MAX: • if CM1 = 0, CM0>0 -> no CCU1 interrupt is generated • if CM1 = 1, CM0=MAX+1 -> only one time a CCU1 interrupt is generated (Description is based of Errata description GTM-IP-202)
	Workaround	Use for triggering channel y (i.e. the channel that triggers on channel x the reset of counter CN0) the configuration of CM0 = MAX, CM1 = 1. In case of duty cycle configuration of CM1=0 and CM0>0 on channel x use instead of CCU1 interrupt on channel x the CCU0 interrupt of triggering channel y. In case of duty cycle configuration of CM1 = 1 and CM0 = MAX + 1 on channel x use instead of CCU1 interrupt on channel x the CCU1 interrupt of triggering channel y.
ID7		GTM - TIM: incorrect signal level on TIM_MODE change if TIM channel is disabled
	Description	If TIM_EN = 0 and TIM_MODE = "100" (TBCM) and corresponding channel input signal is high any write of TIM_MODE! = "100" while TIM_EN = 0 will not update the signal level bit ECNT[0]. Expected operation is that ECNT[0] will be set to the actual channel input value on TIM_MODE change. (Description is based of Errata description GTM-IP-204)
	Workaround	Never set unnecessary TIM_MODE = "100" followed by TIM_MODE! = "100" while TIM_EN = 0.
ID8		GTM - TIM: unexpected CNTS register update in TPWM OSM mode
	Description	If OSM = 1 and TIM_MODE = "000" (TPWM) an active edge defined by DSL will stop the measurement. In case of an inactive edge following after 1 GTM system clock cycle the active edge the CNTS register will be reset unexpected. (Description is based of Errata description GTM-IP-205)
	Workaround	1. Use CMU clock in TIM channel with frequency lesser than system clock 2. Enable filter and configure filter parameter in a way that two consecutive edges will never occur with distance of GTM system clock.
ID9		GTM - TOM/ATOM: no update of CM0/CM1/CLK_SRC via trigger signal from preceding instance if selected CMU_CLKx is not SYS_CLK
	Description	No update of CM0, CM1 and CLK_SRC is done although the update is enabled by register TOM[i]_TGC[y]_GLB_CTRL / ATOM[i]_AGC_GLB_CTRL if selected CMU_CLKx is not SYS_CLK. (Description is based of Errata description GTM-IP-209)
	Workaround	One of the following workaround should be applied: 1. The channel of instance i+1 that should be triggered has to use a clock of period identical to SYS_CLK period 2. Set up on instance i+1 a redundant channel to trigger other channel of instance i+1 like it was set up on instance i to trigger other channel. Then, start both instances synchronously by using the TBU time base comparator of AGC/TGCx unit (i.e. the ATOM[i]_AGC_ATC_TB / TOM[i]_TGC[y]_ACT_TB register)

ID10		GTM - ATOM: data loss in SOMS one-shot mode if ARU is enabled and the period of the selected CMU_CLKx is greater than ARU-cycle-time/2.
	Description	ATOM in SOMS one-shot mode starts to requests new data from ARU with ARU_EN = 1. If new data is delivered by ARU and stored into SR0/1 register, the data will be transferred to CM0/1 register and the ATOM starts to shift with next selected CMU_CLKx. In parallel ATOM requests immediately new data from ARU. If ARU will deliver next data before the first bit of the first data is shifted out which means before the next CMU_CLKx takes place, the data will be stored into SR0/1 register but it will not be marked as valid (bit DV not set) and therefore it will be ignored. (Description is based of Errata description GTM-IP-210)
	Workaround	It has to be ensured, that the time between delivering of two new data from ARU is greater than CMU_CLKx periods. This can be reached by delivering the data by MCS instead of by FIFO. The issue can only occur if the ARU roundtrip time is greater than 2 CMU_CLKx periods.
ID11		GTM - DTM: shut-off priority causes spikes at DTM output
	Description	If DTM shut-off feature is configured with GTM0DTMiCTRL.UPD_MODE = 0b010 and GTM0DTMiCTRL.DTM_SEL = 0b00 .. 0b11 an edge at input DTM[i-1]_IN0_REDGE, DTM[i-1]_IN0_FEDGE, IN0_REDGE or IN0_FEDGE while shutoff is active (i.e. signal shut_off is high) cause a small pulse at DTM output DTM_OUT[x]_N. Which edge type on input DTM[i-1]_IN0_REDGE, DTM[i-1]_IN0_FEDGE, IN0_REDGE or IN0_FEDGE triggers a pulse at the output depends on DTM_SEL. If DTM shut-off feature is configured with UPD_MODE = 0b001 an edge at TIM_CH_IN0, TIM_CH_IN1 or DTM_AUX_IN or DTM[i-1]_PSU_IN while shut-off is active (i.e. signal shut_off is high) cause a small pulse at DTM output DTM_OUT[x]_N. The root cause of the problem is the specified behavior for DTM: "Note: The reset of SHUT_OFF_SYNC has higher priority than the set of this signal."
	Workaround	Do not use GTM0DTMiCTRL.UPD_MODE = 0b010 or 0b001 for reset of shut-off.
ID12		GTM - ATOM SOMB mode: if ARU_EN=1, a force update does not update ACBI flags but uses value from ATOM_CH_CTRL register
	Description	In case of ATOM SOMB mode and ARU_EN=1, if the channel has received new values via ARU and the new values were stored in register SR0, SR1 and ACB_SR register, a force update does not update the ACBI register with the content of register ACB_SR. Instead, the value of register ATOM_CH_CTRL is updated to ACBI register.
	Workaround	Do not used a forced update if data for ATOM is provided via ARU (ARU_EN = 1).
ID13		GTM - TOM/ATOM: async. update in SOMP mode with CM1 = 0 and selected CMU clock unequal sys_clk not functional
	Description	An asynchronous update of the duty cycle by writing value 0 to CM1 register while a CMU clock unequal sys_clk is selected is not working. It is expected that the output signal level is set immediately to inactive level but it will remain at actual level.
	Workaround	Writing value 1 instead of 0 to CM1 register.
ID14		GTM - (A)TOM: output signal is postponed one period for the values CM0 = 1 and CM1 > CM0 if CN0 is reset by the trigger of a preceding channel (RST_CCU0 = 1)
	Description	If counter CN0 is reset by the trigger of a preceding channel (bit RST_CCU0 of register TOM[i]_CH[x]_CLRL/ATOM[i]_CH[x]_CTRL is set), then the value of CM0 defines the signal edge to SL (signal level), whereas CM1 defines the edge to !SL (inverted signal level). If – in this case – the value 1 is configured for the output edge to SL (CM0 = 1) and CM1 is configured to greater than CM0 (CM1 > CM0), the expected output edge will be postponed by one period.
	Workaround	Instead of configuring CM0 = 1, it is also possible to configure CM1 = 1 and to invert SL to get the expected edge at counter value 1 (CN0 = 1).

ID15		GTM - TOM/ATOM: wrong output behavior in SOMP oneshot mode when one shot pulse is triggered by TIM_EXT_CAPTURE(x)
	Description	If TOM/ATOM is configured in SOMP oneshot mode (OSM = 1) and the oneshot trigger is configured to TIM_EXT_CAPTURE(x) (OSM_TRIG = 1, EXT_TRIG = 1) the output behavior is not as expected depending on the selected CMU clock. 1. If the selected CMU clock is configured to SYS_CLK (ATOM: GTM0CMUCLKxCTRL, TOM: CMU_FXCLK0 used) no initial oneshot period (CN0 is set to zero and then counts until CN0 ≥ CM0) is executed and the output is set to SL immediately and not as expected after the first initial period. 2. If the selected CMU clock is configured to GTM0CMUCLKxCTRL > 0 (ATOM)/ CMU_FXCLK1 (TOM) then an initial period is executed but the output is set immediately to SL and not as expected when the second oneshot period starts.
	Workaround	For GTM generation v2 no workaround available because up/down counter mode is not available. If it is possible configure the selected CMU clock to SYS_CLK period. Then the generated oneshot pulse length is correct but without executing of the initial period.
ID16		GTM - TOM/ATOM: wrong output behavior in SOMP oneshot mode when oneshot pulse is triggered by TRIG_[x-1]
	Description	If TOM/ATOM is configured in SOMP oneshot mode (OSM = 1) and the oneshot trigger is configured to trigger signal from trigger chain TRIG_[x-1] (OSM_TRIG = 1, EXT_TRIG = 0) the output signal is set immediately to SL and not as expected after a delay of the first initial oneshot period (CN0 counts from 0 until it reaches the value of CM0). The first initial oneshot period isn't executed.
	Workaround	For GTM generation v2 no workaround available because up/down counter mode is not available. If it is possible work without the initial period for GTM generation v2 because the generated pulse length is correct.
ID17		GTM - ATOM: Unexpected restart of a SOMS oneshot cycle while GTM0ATOMixCM0 is zero
	Description	If ATOM is set to SOMS oneshot mode (bit field MODE of GTM0ATOMixCTRL is set to 0b11 and bit field OSM in register GTM0ATOMixCTRL is set) a oneshot cycle is started immediately by writing a value unequal to zero to GTM0ATOMixSR0 register while the value of GTM0ATOMixCM0 register is zero.
	Workaround	Avoid value 0 in GTM0ATOMixCM0 register if SOMS oneshot mode is enabled (bit field OSM in register GTM0ATOMixCTRL).
ID18		GTM - TIM: ARU bit ACB(0) (signal level) incorrect in case a second ARU request occurs while the actual request is just acknowledged
	Description	An issued ARU request will be served at least after the ARU round trip time. If one aei_sys_clk clock before the ARU request is acknowledged a new capture event occurs (overflow condition due to e.g. input change) the bit ACB(0) will not show the new value. The overflow bit ACB(1) and the ARU data words selected by (E)GPR[0, 1]_SEL) will show the correct behavior only the ACB(0) will show the previous state.
	Workaround	Workaround 1: Ensure that events which trigger a ARU request occur with a greater timely distance than the ARU round trip time. Workaround 2: Use the signal level information embedded in the ARU data words (selectable by ECNT/TIM_INP_VAL). This data will show the correct signal level.
ID19		GTM - GTM Bus Bridge: Incorrect AEI access execution in case the previous AEI access was aborted with the access timeout abort function.
	Description	In case the GTM internal AEI access timeout abort function is in use (GTM0GTMCTRL.TO_VAL ! = 0 and GTM0GTMCTRL.TO_MODE = 1), a following AEI access can be corrupted: a) A write access might not be executed (register/ memory not written to the specified value) b) A read access can return random data (read value does not reflect the content of the addressed register / memory). Hint: As a timeout based abort of a GTM register access is assumed to be an error scenario, the internal state of the GTM might be exposed. To ensure the proper behavior after such an severe incident, the GTM IP should be re-initialized as part of a recovery action on system level.
	Workaround	Do not use the AEI access abort mode, use the observe mode instead (Set GTM0GTMCTRL.TO_MODE = 0). Enable additionally the timeout observe IRQ by setting GTM0GTMIRQEN.AEI_TO_XPT_IRQ_EN = 1 to invoke higher level recovery mechanisms for GTM re-initialization. (e.g. abort the pending access to the GTM and reinitialize the GTM_IP from hardware reset).

ID20		GTM - TOM/ATOM: Generation of TRIG_CCU0/TRIG_CCU1 trigger signals skipped in initial phase of TOM/ATOM SOMP one-shot mode.
	Description	Configuration in use: GTM0ATOMixCTRL.OSM=1 GTM0ATOMixCTRL.OSM_TRIG=0 GTM0ATOMixCTRL.MODE=10 Expected behavior: The generation of one-shot pulses in TOM/ATOM can be initiated by a write to CN0. In this case the pulse generation comprises of an initial phase where the signal level at TOM/ATOM output is inactive followed by a pulse. The duration of the initial phase can be controlled by the written value of CN0, where the duration is defined by CM0-CN0. After the counter CN0 reaches the value of CM0-1, the pulse starts with its active edge, CN0 is reset, and starts counting again. When CN0 reaches CM1-1, the inactive edge of the pulse occurs. Due to the fact, that the capture compare units CCU0 and CCU1 compare also in the initial phase of the pulse generation, the trigger conditions for these comparators apply also in this initial phase. Thus, the TRIG_CCU0 and TRIG_CCU1 signals also occur in the initial phase of the one-shot pulse. When these trigger signals are enabled in the GTM0ATOMixIRQEN, an interrupt signal is generated by TOM/ATOM on the CCU0TC and CCU1TC trigger conditions and the corresponding GTM0ATOMixIRQNOTIFY bits are set. Observed behavior: For certain start values of CN0 and dependent on the history of pulse generation, the trigger signals TRIG_CCU0 and TRIG_CCU1 are skipped. As a consequence, this can led to missing interrupts CCU0TC and CCU1TC on behalf of their missing trigger signals TRIG_CCU0 and TRIG_CCU1. For the first pulse generation after enabling the channel, all trigger signals TRIG_CCU0 and TRIG_CCU1 appear as expected and described in the section expected behavior. If the channel stays enabled and a new value CN0 is written to trigger a subsequent one-shot pulse, the TRIG_CCU0/TRIG_CCU1 triggers in the initial phases of subsequent one-shot pulses are skipped under the following conditions: – For TRIG_CCU0 trigger: if the one-shot pulse is started by writing a value to CN0 greater or equal to CM0-1. – For TRIG_CCU1 trigger: if the one-shot pulse is started by writing a value to CN0 greater or equal to CM1-1.
	Workaround	1. Workaround: Disabling, resetting (channel reset), re-enabling and initializing of the channel between each one-shot pulse will ensure the correct behavior of CCU0TC and CCU1TC interrupt source. 2. Workaround: Starting a new one-shot pulse by writing twice the counter CN0 whereas the first value, which is written to CN0 should be zero followed by the value which defines the length of the initial phase. Be aware that in this case, the total length of the initial phase until the pulse is started, is influenced by the time between the two write accesses to CN0.

ID21		GTM - TOM/ATOM: False generation of TRIG_CCU1 trigger signal in SOMP one-shot mode with OSM_TRIG = 1 when CM1 is set to value 1.
	Description	Configuration in use: GTM0ATOMixCTRL.OSM = 1 GTM0ATOMixCTRL.OSM_TRIG = 0 GTM0ATOMixCTRL.MODE = 10 Expected behavior: The generation of one-shot pulses in TOM/ATOM can be initiated by the trigger event TRIG_[x-1] from trigger chain or by TIM_EXT_CAPTURE(x) trigger event from TIM, whereas the counter CN0 is reset to zero and starts counting. In this case the pulse generation comprises of an initial phase where the signal level at TOM/ATOM output is inactive followed by a pulse. The duration of the initial phase is always as long until the counter CN0 reaches CM0-1. After the counter CN0 reaches the value of CM0-1, the pulse starts with its active edge, CN0 is reset, and starts counting again. When CN0 reaches CM1-1, the inactive edge of the pulse occurs. Due to the fact, that the capture compare units CCU0 and CCU1 compare also in the initial phase of the pulse generation, the trigger conditions for these comparators apply also in this initial phase. Thus, the TRIG_CCU0 and TRIG_CCU1 signals also occur in the initial phase of the one-shot pulse. When these trigger signals are enabled in the GTM0ATOMixIRQEN, an interrupt signal is generated by TOM/ATOM on the CCU0TC and CCU1TC trigger conditions and the corresponding GTM0ATOMixIRQNOTIFY bits are set. Observed behavior: If the compare register CM1 is set to 1 and a new one-shot pulse is triggered, two effects can be observed. – The first observed behavior is that the capture compare unit doesn't generate the TRIG_CCU1 trigger signal in the initial phase of the one-shot cycle. – The second observed behavior is that at the end of the operation phase of the one-shot cycle, where CN0 reaches CM0-1 a second time, the capture compare unit generates a TRIG_CCU1 trigger signal which is not expected at this point in time.
	Workaround	Instead of using value 1 for CM1 it could be possible to generate the same pulse length by using a higher CMU_FXCLK/CMU_CLK frequency. Then, to get the same pulse length, the value of CM1 has to be multiplied by the difference of the two CMU_FXCLK/CMU_CLK frequencies. Be aware that this workaround is only possible, if you are not already using the CMU_FXCLK0 because there is no higher CMU_FXCLK frequency to select. Example for TOM: Instead of using CMU_FXCLK1, which has the divider value 2**4, use CMU_FXCLK0, which has the divider value 2**0. In this case, CM1 has to be configured with value 2**4 minus 2**0 which is equal to 2**4=16. Hint: To get the same length of period, which defines the length of the initial phase, the value for the period in CM0 has to be multiplied by the same value. A second limitation is that the maximum length of the period, which is configured in CM0, is limited. Using a higher CMU_FXCLK/CMU_CLK frequency reduces the maximum possible period.

ID22		ATOM SOMS mode: Shift cycle is not executed correctly in case the reload condition is deactivated with GTM0ATOMiAGCGLBCTRL.UPEN_CTRL[x] = 0b00
	Description	ATOM is configured to SOMS continuous mode by setting the following configuration bitfields: GTM0ATOMixCTRL.MODE = 11 GTM0ATOMixCTRL.OSM = 0 GTM0ATOMixCTRL.ARU_EN = 0 GTM0ATOMiAGCGLBCTRL.UPEN_CTRL[x] = 0b00 Expected behavior: After the counter CN0 reaches CM0, no reload cycle is executed due to the configuration of UPEN_CTRL[x] = 0b00. Instead of a reload cycle a shift cycle has to be executed to ensure an continuous shifting. Observed behavior: Neither a reload cycle nor a shift cycle is executed when the counter CN0 reaches CM0. The shifting stops and the shift register CM1 as well as the output ATOM[i]_CH[x]_OUT stays unexpectedly stable for two shift clock cycles whereas the counter CN0 continuously counting further on.
	Workaround	Increase the number of bits that have to be shifted out inside CM0 register to the maximum value of 23 to ensure a continuous shifting of all bits of the shift register CM1.
ID23		ATOM SOMP mode: Reset of GTM0ATOMixCN0 with TIM_EXT_CAPTURE are not correctly synchronized to selected CMU_CLK/CMU_FXCLK.
	Description	To reset the counter GTM0ATOMixCN0 (SOMP mode in ATOM), the input signal TIM_EXT_CAPTURE can be used by configuration of GTM0ATOMixCTRL.EXT_TRIG = 1 GTM0ATOMixCTRL.RST_CCU0 = 1 The reset of the counter GTM0ATOMixCN0 should happen synchronously to the internal selected CMU clock CMU_CLK/CMU_FXCLK. Therefore a synchronization stage is implemented to synchronize the input signal TIM_EXT_CAPTURE to the internal selected CMU clock CMU_CLK/CMU_FXCLK. It can be observed, that the rest of the counter is done immediately with the occurrence of the input signal TIM_EXT_CAPTURE and not as expected synchronously to the selected CMU clock enable CMU_CLK/CMU_FXCLK. As a consequence of this, the output signal for the compare values 0 and 1 of GTM0ATOMixCM1.CM1 and GTM0ATOMixCM0.CM0 will not be set correctly.
	Workaround	1. Select a CMU clock enable signal CMU_CLK/CMU_FCLK by appropriate setting of GTM0ATOMixCTRL.CLK_SRC_SR which is setup inside the CMU module in that way, that each system clock is enabled. In the words this means that the selected clock enable signal CMU_CLK/CMU_FXCLK should be always active high. 2. Avoid the compare values 0 and 1 for the operation register bitfields GTM0ATOMixCM1.CM1 and GTM0ATOMixCM0.CM0

ID24		SPEC-ATOM: Specification of the smallest possible PWM Period in SOMP mode wrong, when ARU_EN = 1
	Description	Configuration in use: GTM0ATOMixCTRL.MODE = 0b10 (SOMP), GTM0ATOMixCTRL.ARU_EN = 1, ATOM[i]_AGC_GLB_CTRL.UPEN_CTRLx = 1 Functionality: When GTM0ATOMixCTRL.ARU_EN = 1 and ATOM[i]_AGC_GLB_CTRL.UPEN_CTRLx = 1 the PWM period and duty cycle (PWM characteristic) can be reloaded via ARU in SOMP mode. The ATOM generates a PWM on the operation registers GTM0ATOMixCM0.CM0 and GTM0ATOMixCM1.CM1 while the new values received via ARU are stored in the shadow registers GTM0ATOMixSR0.SR0 and GTM0ATOMixSR1.SR1. Reloading of the GTM0ATOMixCM0.CM0 and GTM0ATOMixCM1.CM1 registers with the values from GTM0ATOMixSR0.SR0 and GTM0ATOMixSR1.SR1 takes place, when the old PWM period expires (GTM0ATOMixCN0.CN0 reaches GTM0ATOMixCM0.CM0 in up counter mode or GTM0ATOMixCN0.CN0 reaches 0 in up/down counter mode). Therefore, it is important, that the new PWM characteristic is available in the shadow registers GTM0ATOMixSR0.SR0 and GTM0ATOMixSR1.SR1 before GTM0ATOMixCN0.CN0 reaches GTM0ATOMixCM0.CM0 (up counter mode) or 0 (up/down counter mode). Problem description: The GTM-IP specification defines as minimal possible PWM period, where the PWM characteristic can be reloaded in a predictable manner so that new data is always available in time at the ATOM channel, to be the ARU round trip time of the specific microcontroller device. This is not correct, because the data needs two additional ARU clock cycles to flow through the ARU from a source to the ATOM channel plus one clock cycle for loading the value from the shadow registers GTM0ATOMixSR0.SR0 and GTM0ATOMixSR1.SR1 to the registers GTM0ATOMixCM0.CM0 and GTM0ATOMixCM1.CM1. When the PWM period is smaller than the ARU round trip time plus three ARU clock cycles, the PWM output is not correct.
	Workaround	The PWM period has to be larger than ARU round trip time + 3 ARU clock cycles. This can be reached by either choosing a smaller device, or by using ARU dynamic routing, or by reducing the value of ARU_CADDR_END to a value, which fits the PWM period. So, PWM period greater than ARU_CADDR_END + 1 + 3 ARU clock cycles.
ID25		IRQ: Missing pulse in single-pulse interrupt mode on simultaneous interrupt and clear event
	Description	In single-pulse interrupt mode ([MODULE]_IRQ_MODE = 0b11) only the first interrupt event of the interrupt bits of the interrupt notify register inside this module generates a pulse on the output signal IRQ_line, if the associated interrupt is enabled ([MODULE]_IRQ_EN=1). All further interrupt events have no effect on the output signal IRQ_line until all enabled interrupts are cleared, except when an interrupt and a clear event (HW_clear or a SW_clear) occur at the same time.
	Workaround	On a SW clear prevent HW clear events and read the interrupt notify register to check on new interrupts without a received interrupt pulse on IRQ_line. In this case repeat the SW clear step to enable interrupt generation again. When disabling the HW clear is not an option refrain from using the single-pulse interrupt mode.

ID26		(A)TOM: potentially wrong output signal in case of RST_CCU0 = 1 and CM0 = 1 on triggered channel in SOMP mode.
	Description	When the reset of GTM0ATOMixCN0 of a TOM or ATOM channel is triggered by a preceding channel or assigned TIM module (RST_CCU0 = 1) and the ATOM channel is configured in SOMP mode, the CM0 value defines the edge to SL and CM1 defines the edge to !SL. Expected behavior: When SR0 is configured to '1', and CM0 is updated with SR0 = 1 on trigger signal coming from previous channel, an edge to SL is expected, when CN0 = CM0 = 1. Observed behavior: When CM0 is updated synchronously from SR0 for the next period, and CM0 > 1 at the actual period, no edge to SL is generated when CM0 = CN0 = 1 for the first period after CM0 = 1 becomes active (was updated to CM0 = 1 from SR0).
	Workaround	In addition to configuring SR0 = 1 and letting the (A)TOM channel update CM0 with ‘1’ at the start of the next period, a hot reconfiguration of CM0 = 1 can be done. However, the hot reconfiguration needs to be done after the edge to SL was performed in the actual period. Otherwise the CM0 value would be overwritten by ‘1’ and the edge to SL would be generated immediately after hot reconfiguration and not at the intended old CM0 value. The workaround is applicable where the system can update the CM0 value in time; otherwise the setting of CM0 = 1 should not be used.
ID27		ATOM-RTL: Missing edge on output signal ATOM_OUT when CN0 is reset with force update event.
	Description	The channel is configured in continuous up-counter mode. Then a new period is started with a force update event and reset of CN0 is activated. Configuration for ATOM: GTM0ATOMixCTRL.MODE = 0b10 (SOMP mode) GTM0ATOMiAGCFUPDCTRL.FUPD_CTRL[k] = 1 GTM0ATOMiAGCFUPDCTRL.RSTCN0_CH[k] = 1 Expected behavior: After the counter GTM0ATOMixCN0.CN0 has been reset and therefore a new period has to be started and the output signal ATOM_OUT has to be set immediately to SL value (GTM0ATOMixCTRL(SOMP).SL) and after the counter reaches GTM0ATOMixCM1. An edge on ATOM_OUT to inverted SL value (GTM0ATOMixCTRL(SOMP).SL) is expected. Observed behavior: An edge on the output signal ATOM_OUT to SL value (GTM0ATOMixCTRL(SOMP).SL) at the beginning of the new period does not happen. Instead, the output signal ATOM_OUT holds its last value. A second observation is in case of the SL value (GTM0ATOMixCTRL(SOMP).SL) changes synchronously together with the force update event, an edge on ATOM_OUT to the inverted SL value (GTM0ATOMixCTRL(SOMP).SL) when GTM0ATOMixCN0.CN0 reaches GTM0ATOMixCM1 does not happen.
	Workaround	No workaround available.
ID28		SPEC-ATOM: Wrong register bit field descriptions for GTM0ATOMixCTRL.
	Description	The specification of the ATOM Channel control register for SOMP mode (GTM0ATOMixCTRL) is wrong in two points: First, in the register overview figure the register bit fields for bits 21, 22, and 23 are marked as "not used". However, these register bits are implemented as described in the bit field description. Second, in the register bit fields description subsection, a duplicate entry exists where the register bits 23:21 are marked as "not used".
	Workaround	Use the bit field descriptions for bits 23:21 as described GTM0ATOMixCTRL in **Section 25.11.6.8, GTM0ATOMiAGCINTTRIG (i = 0 to 2)**.

ID29		SPEC-ATOM: Control bits of the TRIG_[x] multiplexer are switched.
	Description	There is an error in the **Figure 25.34** for the ATOM Channel architecture. The control bits of the TRIG_[x] multiplexer are switched. The correct behavior is: When the multiplexer is configured with a '0', one of the signals TIM_EXT_CAPTURE(x) or TRIG[x-1] is used for TRIG[x]. When the multiplexer is configured with '1', the TRIG_CCU0 signal is used. Only the figure is wrong. The register bit description in the ATOM Channels control register is correct.
	Workaround	Use the register bit description in the ATOM Channels control register instead of the figure.
ID30		TIM: Potentially wrong capture values
	Description	Effects: GTM0TIMixCNT register is not reset and wrong values could be captured into GTM0TIMixGPR0 and GTM0TIMixGPR1 registers. Configuration: The TIM channel is configured in TIEM, TIPM or TGPS mode by setting of GTM0TIMixCTRL.TIM_MODE = 0b010, 0b011, 0b101. The TIM channel is disabled (GTM0TIMixCTRL.TIM_EN = 0) and later enabled again (GTM0TIMixCTRL.TIM_EN = 1). Expected behavior: The registers GTM0TIMixCNT, GTM0TIMixECNT.ECNT[15:1], GTM0TIMixGPR0 and GTM0TIMixGPR1 are set to their reset values. In case of an input signal edge or an input capture event or an active selected CMU clock (TGPS mode) at the same time as the channel is enabled, this event has to be taken into account and the GTM0TIMixCNT register must be updated/incremented based on its reset value. Due to this a capture event can happen depending on the configured TIM mode and the register values. Observed behavior: If no input signal event or input capture event or active selected CMU clock (TGPS mode) occurs, the registers GTM0TIMixCNT, GTM0TIMixECNT.ECNT[15:1], GTM0TIMixGPR0 and GTM0TIMixGPR1 are set to their reset values as expected. If an input signal event or an input capture event or an active selected CMU clock (TGPS mode) occurs at same time as the channel gets enabled, the GTM0TIMixCNT register continues to count (or update) based on the previous (old) value. As a result, a capture could be performed too early and/or with the wrong values. The GTM0TIMixECNT.ECNT[15:1] register is set to its reset value as expected. **Note:** The TIM channel modes TPWM, TPIM and TBCM (GTM0TIMixCTRL.TIM_MODE = 0b000, 0b001, 0b100) are not affected.
	Workaround	Workaround 1: Reset the TIM channel by setting of GTM0TIMiRST.RST_CHx = 1 before enabling the TIM channel. Workaround 2: The following sequence has to be executed on the disabled channel but before the actual enabling of the channel, to ensure that the GTM0TIMixCNT register is set to its reset value when the channel is enabled: 1. Configure GTM0TIMixCNTS = 0 2. Enable the TIM channel with the following configuration inside the GTM0TIMixCTRL register: – TIM_EN = 1 – TIM_MODE = 0b101 (TGPS) – ISL = 1 – OSM = 1 – ARU_EN = 0 – select a fast CMU_CLK_RES, e.g. CLK_SEL = 0b000 3. Wait until an edge on the selected CMU_CLK_RES occurs. This can be observed on the NEWVAL IRQ notify register. This event sets the GTM0TIMixCNT register to its reset value. 4. Disable TIM channel (GTM0TIMixCTRL.TIM_EN = 0) 5. Configure the former TIM channel configuration in GTM0TIMixCTRL register and enable the TIM channel again.

ID31		TIM: Missing glitch detection interrupt event
	Description	Effects: The GTM0TIMixIRQNOTIFY.GLITCHDET bit is not set. Thus, no interrupt is triggered. Furthermore, the external capture source EXT_CAPTURE(x) is not triggered, if its source is set to TIM_GLITCHDET_IRQ. Configuration: TIM filter is configured in immediate edge propagation mode by setting GTM0TIMixCTRL.FLT_MODE_RE = 0 or GTM0TIMixCTRL.FLT_MODE_FE = 0. The filter is enabled by setting GTM0TIMixCTRL.FLT_EN = 1. Expected behavior: As long as the filter threshold is not reached and the input signal level unexpectedly changes, it is an input glitch occurs, the internal glitch detection interrupt event signal (TIM_GLITCHDET_IRQ) should have a HIGH pulse of one cluster clock cycle. Observed behavior: When the input signal glitch occurs at the same time the filter counter reaches its threshold, the internal glitch detection interrupt event signal (TIM_GLITCHDET_IRQ) does not occur.
	Workaround	The filter counter threshold can be set to the next higher value. Thus, a former not detected glitch would be detected. In that case, the output signal would be changed (one clock cycle longer), when the input signal is a single cycle pulse.
ID32		TIM: Unexpected increment of filter counter
	Description	Effects: If an input edge occurs during the acceptance time, the following output signal change will happen one selected CMU clock cycle earlier than expected. Configuration: TIM filter is configured in immediate edge propagation mode by setting GTM0TIMixCTRL.FLT_MODE_RE = 0 or GTM0TIMixCTRL.FLT_MODE_FE = 0. The filter is enabled by setting GTM0TIMixCTRL.FLT_EN = 1. The filter counter threshold is set to 0 by setting either GTM0TIMixFLTRE.FTL_RE = 0 or GTM0TIMixFLTFE.FTL_FE = 0. Expected behavior: When the input signal level changes, the filter counter should stay at 0. Observed behavior: When the input signal level changes, the filter counter counts to 1 and is not reset.
	Workaround	If acceptable, use a threshold greater than 0. Otherwise there is no workaround available.
ID33		TIM: Glitch detection interrupt event of filter is not a single cycle pulse
	Description	Effects: Effect 1: The longer lasting HIGH signal of the glitch detection interrupt event signal (TIM_GLITCHDET_IRQ) may lead to an unexpected behaviour within the GTM only if TIM_GLITCHDET_IRQ is used for the external capture signal EXT_CAPTURE(x). Effect 2: If the related interrupt notify register (The GTM0TIMixIRQNOTIFY) is cleared by software while the TIM_GLITCHDET_IRQ signal is still HIGH, the interrupt will unexpectedly retrigger. Configuration: The TIM filter must be enabled by setting GTM0TIMixCTRL.FLT_EN = 1. Expected behavior: As long as the filter threshold is not reached and the input signal level changes unexpectedly, the glitch detection interrupt event signal. Observed behavior: When the input signal level changes unexpectedly for longer than one clock cycle, the glitch detection interrupt event signal (TIM_GLITCHDET_IRQ) is HIGH for as long as the unexpected signal change is present.
	Workaround	No workaround in hardware. For the unexpected retrigger of the interrupt directly after an interrupt clear step, the interrupt routine has to consider that the interrupt might be invalid.

ID34		ATOM: Missing CCU0TCx_IRQ interrupt signal
	Description	Effects: Interrupt signal CCU0TCx_IRQ is not triggered. Configuration: The channel is configured in SOMP (ATOM) and will be triggered by a preceding channel with configuration of GTM0ATOMixCTRL.RST_CCU0 = 1. Expected behavior: When the counter GTM0ATOMixCN0.CN0 reaches the value of GTM0ATOMixCM0.CM0, the interrupt signal CCU0TCx_IRQ must be triggered. Observed behavior: In the first period after GTM0ATOMixCM0.CM0 is changed to the value 0 or 1, no CCU0TCx_IRQ interrupt signal is triggered. **Note:** When the second period starts after GTM0ATOMixCM0.CM0 is changed to the value 0 or 1 and stays at that value, then the CCU0TCx_IRQ interrupt signal generation works correctly.
	Workaround	No workaround available. It needs to checked if the application can accept the interrupt occurring with the second period.
ID35		SPEC-TIM: Wrong description for TBCM mode
	Description	Effects: The input signal level defined by GTM0TIM1xCTRL.DSL(GTM0TIM0xCTRL.DSL) with GTM0TIM1xCTRL.ISL(GTM0TIM0xCTRL.ISL)=0 is not taken into account. In TIM Bit Compression Mode with External Capture (GTM0TIM1xCTRL.EXT_CAP_EN = 1(GTM0TIM0xCTRL.EXT_CAP_EN = 1)) the capture is done only with the external capture signal without dependency to the input signal level. Therefore the bit field GTM0TIM1xCTRL.ISL(GTM0TIM0xCTRL.ISL) must be set to 1. The value 0 for GTM0TIM1xCTRL.ISL(GTM0TIM0xCTRL.ISL) is prohibited. The bit field GTM0TIM1xCTRL.DSL(GTM0TIM0xCTRL.DSL) is not relevant. The following specification sections in the TBCM chapter have to be adapted as follows: In the prose text: "If external capture is enabled, capturing is done for GTM0TIM1xCTRL.ISL = 1(GTM0TIM0xCTRL=1) as defined in the next table. The value 0 for GTM0TIM1xCTRL.ISL(GTM0TIM0xCTRL.ISL) is prohibited." In the Table: – In the action description of row 1 the part "GTM0TIMixCNT++" has to be removed. – All rows starting with row 3 have to be replaced with only one row where the content for the column of GTM0TIM1xCTRL.ISL(GTM0TIM0xCTRL.ISL) has to be filled with "0 - prohibited". All other columns in row 3 have to be marked with "-" (Don't Care). **Note:** When the second period starts after GTM0ATOMixCM0.CM0 is changed to the value 0 or 1 and stays at that value, then the CCU0TCx_IRQ interrupt signal generation works correctly.
	Workaround	Do not configure GTM0TIM1xCTRL.ISL(GTM0TIM0xCTRL.ISL) to 0 (which is actually prohibited).
ID36		SPEC-TIM: Wrong description in TBCM mode regarding GTM0TIM1xCTRL.GPR1_SEL(GTM0TIM0xCTRL.GPR1_SEL) bit field.
	Description	Effects: The captured value depends on the bit field GTM0TIM1xCTRL.GPR1_SEL (GTM0TIM0xCTRL.GPR1_SEL) in contrast to the notion in the specification. In TIM Bit Compression Mode it is described that the bit field GTM0TIM1xCTRL.GPR1_SEL(GTM0TIM0xCTRL.GPR1_SEL) is not applicable. That is not the case and therefore the sentence mentioning that the bit field GTM0TIM1xCTRL.GPR1_SEL(GTM0TIM0xCTRL.GPR1_SEL) " is not applicable in TBCM mode" in the section "TIM Bit Compression Mode" has to be ignored.
	Workaround	The value of the bit field GTM0TIM1xCTRL.GPR1_SEL (GTM0TIM0xCTRL.GPR1_SEL) must be taken into account.

25.21 Difference among P1M-C, P1H-C and P1H-CE

There are differences in channels, interrupts, and external pins. For details, See **Table 25.2**, **Table 25.5**, and **Table 25.6**.

Section 26 Peripheral Interconnect (PIC)

26.1 Feature

This section contains a generic description of the Peripheral Interconnection (PIC). The first part of this section describes all RH850/P1x-C specific properties, such as the number of units, register base addresses, etc. The remainder of the section describes the functions and registers of the PIC (PIC2C).

26.1.1 Number of Units and Channels

This device has the following number of units of the PIC.

Table 26.1 Units and Channels

Product	P1M-C, P1H-C, P1H-CE
Number of Units	1
Name	PIC2C

26.1.2 Register Base Address

PIC base addresses are listed in the following table. PIC register addresses are given as offsets from the base addresses in general.

Table 26.2 Register Base Address

Base Address Name	Base Address
<PIC2C_base>	FFD6 8000_H

26.1.3 Clock Supply

Supply clocks by and to PIC are listed in the following table.

Table 26.3 Clock Supply

Explanation	Specification
All of module operations	High speed system clock: CLK_HSB

26.1.4 Interrupt and DMA/DTS Requests

This module has no interrupt and DMA/DTS requests.

26.1.5 External Input and Output Pins

The table below shows the pin function information.

Table 26.4 Pin Function Information

Pin Name	I/O	Description	Supporting Device	
			P1M-C, P1H-C (4MB, BGA-156)	P1H-C (4MB, BGA-292), P1H-C (8MB), P1H-CE
ESO0Z	I	Hi-Z control for GTM output	√	√
ESO1Z			√	√
ESO2Z			—	√

26.2 Overview

26.2.1 Functional Overview

PIC connects some peripherals with each other in order to achieve enhanced functionality of a stand-alone function.

PIC has following features:

- ADCF trigger select function
- Signal routing function for GTM:
  - ADCF conversion interrupt routed to GTM input
  - Baud rate measurement for an UART (RLIN3)
  - Hi-Z control function over external pin for GTM output
  - GTM output monitor for PWM diagnostic

26.2.2 Block Diagram

The following figure shows the block diagram.

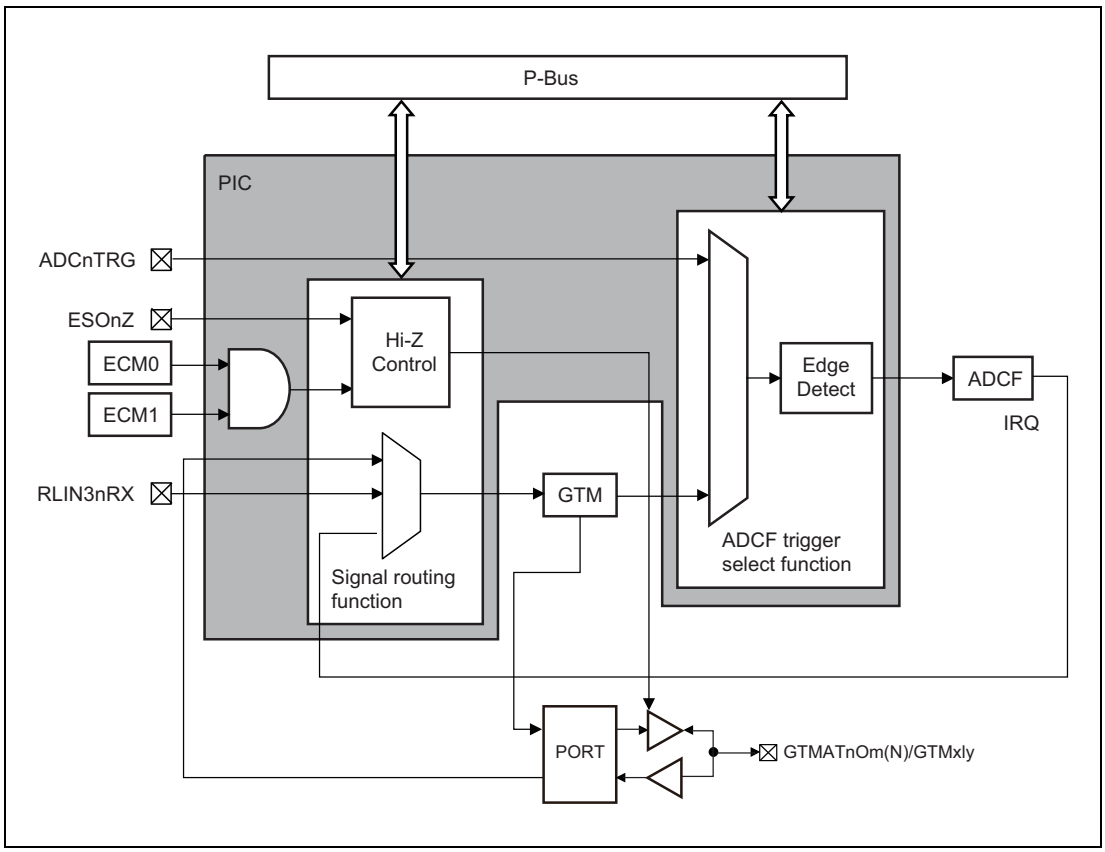

Figure 26.1 Block diagram of PIC

26.3 Registers

26.3.1 List of Registers

Table 26.5 List of Registers

Address Offset*1	Register Name	Description	Access Width	Value after reset	Access Protection	
					PBG	Other
00_H	PIC2CTRGPREMUX0	A/D converter trigger select 0	32	0000 0000_H	PBG3#0.PG3-one	—
04_H	PIC2CTRGPREMUX1	A/D converter trigger select 1	32	0000 0000_H	PBG3#0.PG3-one	—
10_H	PIC2CTRGMUX0	A/D converter trigger select control 0	32	0000 0000_H	PBG3#0.PG3-one	—
14_H	PIC2CTRGMUX1	A/D converter trigger select control 1	32	0000 0000_H	PBG3#0.PG3-one	—
18_H	PIC2CEDGSEL0	A/D converter trigger edge control 0	32	0000 0000_H	PBG3#0.PG3-one	—
$1C_H$	PIC2CEDGSEL1	A/D converter trigger edge control 1	32	0000 0000_H	PBG3#0.PG3-one	—
20_H	PIC2CENP2TIM0	Path to TIM0 enable control register	32	0000 0000_H	PBG3#0.PG3-one	—
24_H	PIC2CENP2TIM1	Path to TIM1 enable control register	32	0000 0000_H	PBG3#0.PG3-one	—
28_H	PIC2CENHIZDTM	Hi-Z function for GTM output enable control register	32	0000 0000_H	PBG3#0.PG3-one	—

Note 1. The base address is described in **Table 26.2**.

NOTE

An unintended pulse may be generated and propagated into connected modules when switching any PIC register settings. So each PIC register setting should be changed only during the relevant function of connected module disabled.

Table 26.6 Register Reset Condition

Register Name	Reset Condition				
	Power On Reset	System Reset 1	System Reset 2	Application Reset 1	Limited Reset
All registers	√	√	√	√	—

26.3.2 PIC2CTRGPREMUXn — A/D converter trigger select n (n = 0/1)

The PIC2CTRGPREMUX0 and PIC2CTRGPREMUX1 registers select GTM triggers respectively for ADCF0 and ADCF1.

Access: This register can be read/written in 32-bit units

Address: PIC2CTRGPREMUX0 <PIC2C_base> + 00_H
PIC2CTRGPREMUX1 <PIC2C_base> + 04_H

Value after reset: 0000 0000_H

$3F_H$	MCS1_IRQ_5	—	√

Note: If the selection code of PREMUX indicates unused signal such as PREMUXnx=100100 for device P1M-C, the result of PREMUX selection is 0.

26.3.3 PIC2CTRGMUXn — A/D converter trigger select control n (n = 0/1)

The PIC2CTRGMUX0 and PIC2CTRGMUX1 registers select the trigger of ADCF external pin or GTM trigger respectively for ADCF0 and ADCF1.

Access: This register can be read/written in 32-bit units

Address: PIC2CTRGMUX0 <PIC2C_base> + 10_H
PIC2CTRGMUX1 <PIC2C_base> + 14_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 26.13 PIC2CENHIZDTM register contents

Bit Position	Bit Name	Function
31 to 6	Reserved	When read, the value after reset is read. Writing is ignored.
5	HIZ2ECM	Enables/disables Hi-Z control by ECM for GTM ATOM2 outputs 0: Disabled 1: Enabled
4	HIZ1ECM	Enables/disables Hi-Z control by ECM for GTM ATOM1 outputs 0: Disabled 1: Enabled
3	HIZ0ECM	Enables/disables Hi-Z control by ECM for GTM ATOM0 outputs 0: Disabled 1: Enabled
2	HIZ2ESO	Enables/disables Hi-Z control by ESO2Z for GTM ATOM2 outputs 0: Disabled 1: Enabled
1	HIZ1ESO	Enables/disables Hi-Z control by ESO1Z for GTM ATOM1 outputs 0: Disabled 1: Enabled
0	HIZ0ESO	Enables/disables Hi-Z control by ESO0Z for GTM ATOM0 outputs 0: Disabled 1: Enabled

26.4 Operation

26.4.1 ADCF trigger select function

Each ADCF is equipped with five scan groups. For every scan group there is a hardware trigger signal.

To increase the amount of possible trigger sources the PIC implements a multiplexer structure which allows the selection of different trigger signals. This function is built with basically two multiplexers per scan group. The first multiplexer makes a pre-selection of the GTM output signals so that only the selected signal is routed over the chip to the input of the second multiplexer.

The second multiplexer is connected to the trigger input of the ADCF. The input signals for the second multiplexer come from the GTM and one comes from a port (ADCnTRG).

The configurable edge detectors are implemented in the output of multiplexers. The edge detectors can be configured to detect rising, falling or both edges of an incoming signal.

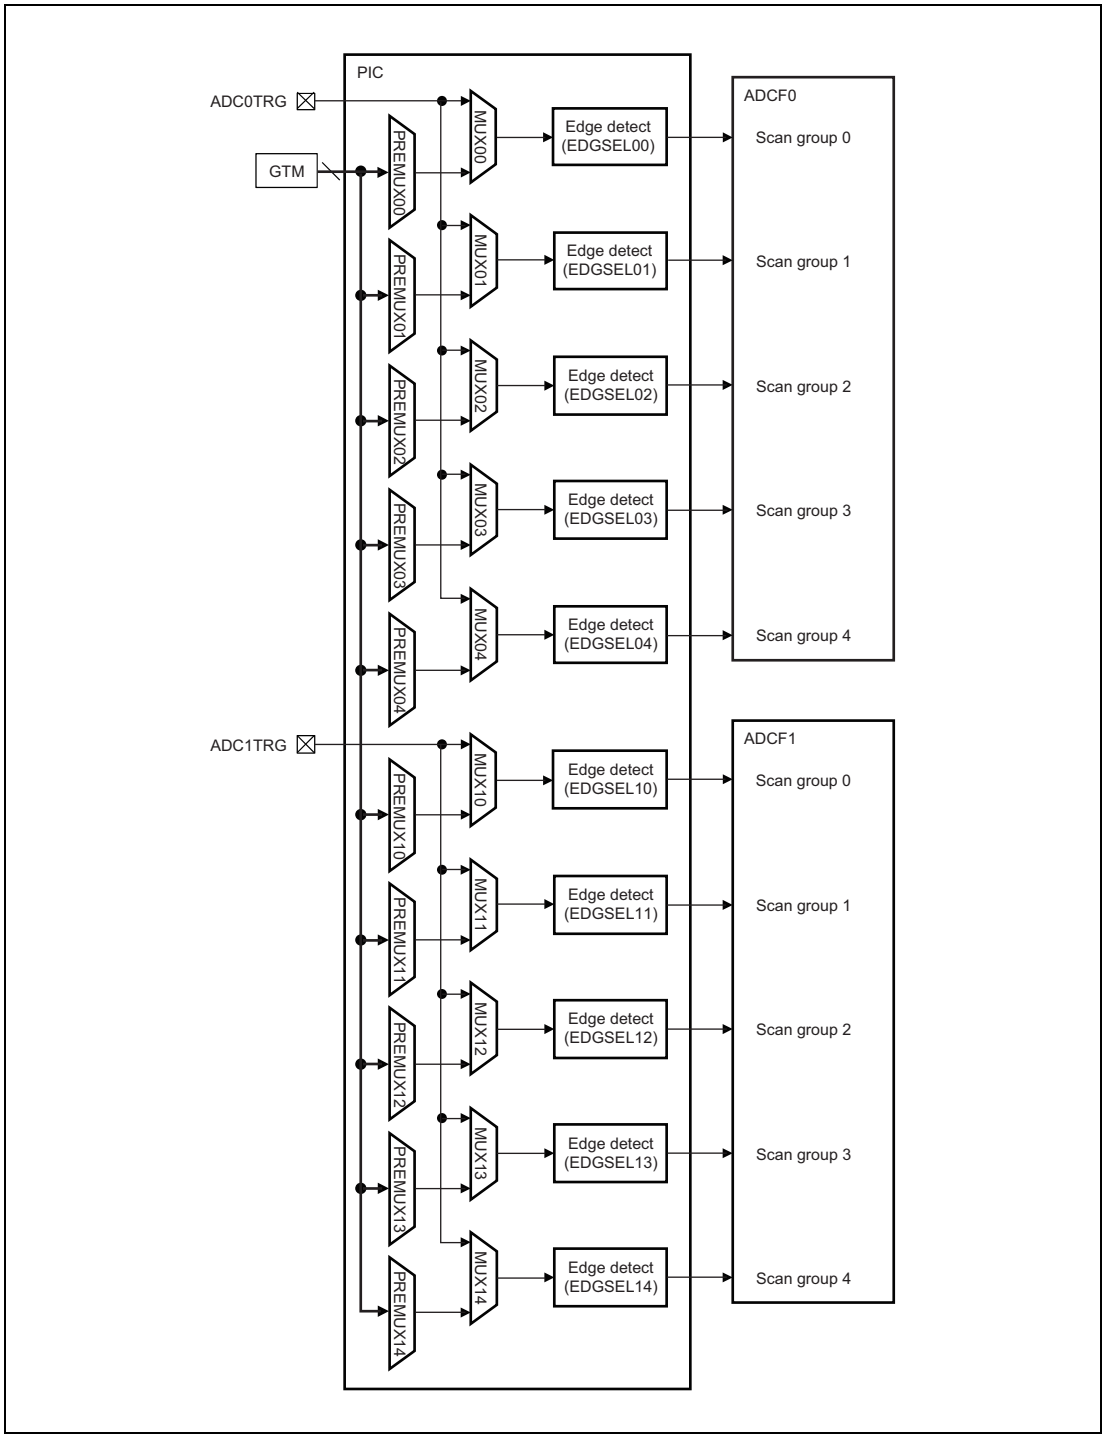

Figure 26.2 Connection from GTM trigger sources to ADCF trigger inputs

26.4.2 ADCF conversion interrupt routed to GTM input

Each ADCF channel group has an interrupt signalizing that the ADCF conversion has ended. This interrupt can be multiplexed to the GTM inputs.

Table 26.14 Possible connection of ADCF interrupts to GTM inputs

Interrupt source	GTM input
ADCF0 IRQ conversion group 0	TIM0_0, TIM1_0
ADCF0 IRQ conversion group 1	TIM0_1, TIM1_1
ADCF0 IRQ conversion group 2	TIM0_2, TIM1_2
ADCF0 IRQ conversion group 3	TIM0_3, TIM1_3
ADCF0 IRQ conversion group 4	TIM0_4, TIM1_4
ADCF1 IRQ conversion group 0	TIM1_0
ADCF1 IRQ conversion group 1	TIM1_1
ADCF1 IRQ conversion group 2	TIM1_2
ADCF1 IRQ conversion group 3	TIM1_3
ADCF1 IRQ conversion group 4	TIM1_4

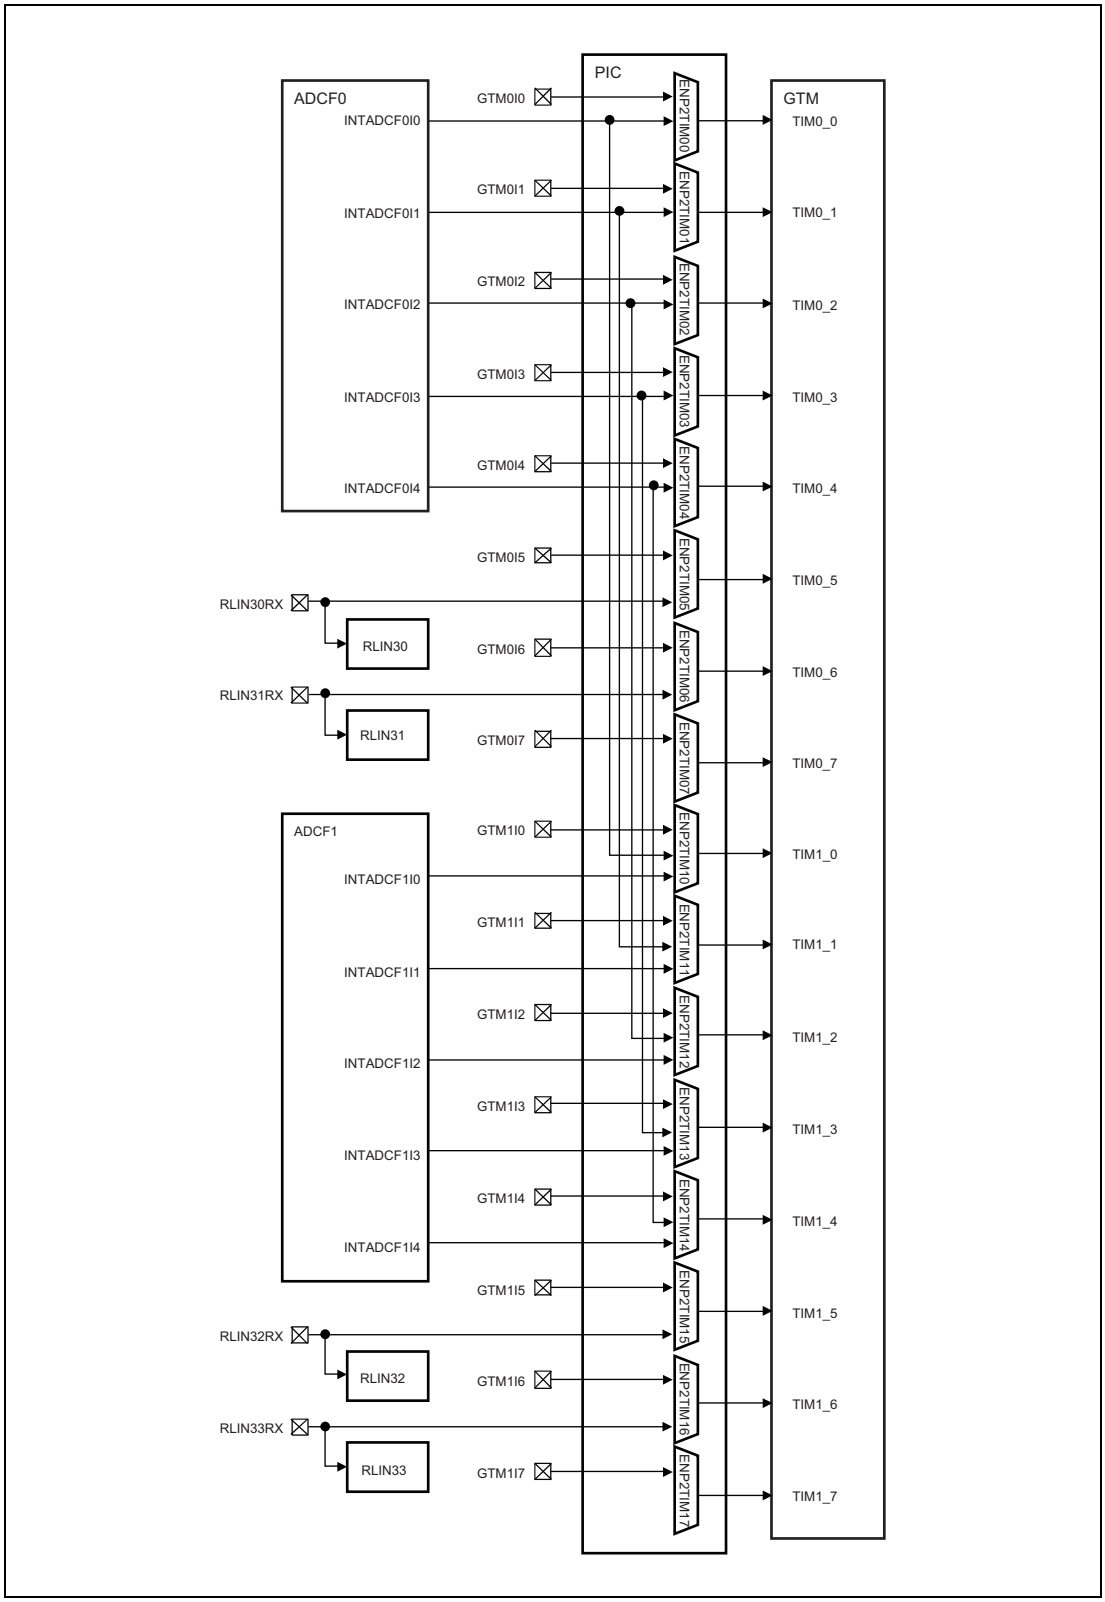

Figure 26.3 Connections for GTM inputs from external pin, ADCF, and RLIN3

26.4.3 Baud rate measurement for an UART (RLIN3)

To measure the baud rate of the received data a connection from the RLIN3 soft macro data input (RX) to GTM input is made. The connection can be selected by a control register.

Table 26.15 Connections between RLIN3 and GTM

Signal source	GTM input	Supporting device	
		P1M-C, P1H-C (4MB, BGA-156)	P1H-C (4MB, BGA-292), P1H-C (8MB), P1H-CE
RLIN30RX	TIM0_5	√	√
RLIN31RX	TIM0_6	√	√
RLIN32RX	TIM1_5	—	√
RLIN33RX	TIM1_6	—	√

26.4.4 Hi-Z control function over external pin for GTM output

The I/O driven by GTM output can be set to Hi-Z over an external pin but also by the ECM module within 50ns. The path to Hi-Z control of the I/O buffers can be enabled by a register in the PIC module. The signals from the ECM and from the ESO pin can be masked independently from each other.

For this device, GTM has three output groups and each group has an independent Hi-Z control signal. The controlled output signals are GTMATnOm and GTMATnOmN with n = 0 to 2 and m = 0 to 3.

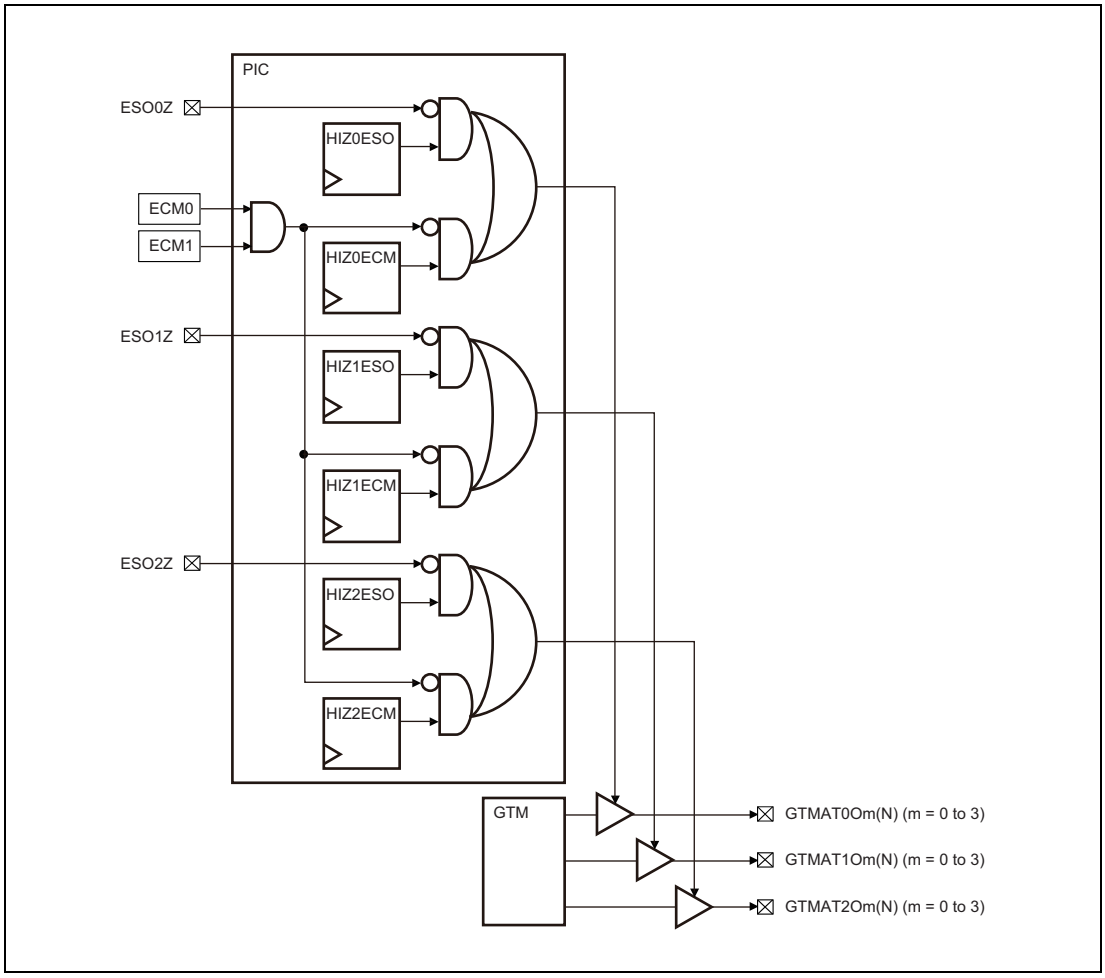

Figure 26.4 Hi-Z control of GTM output

NOTE

In P1M-C, the input from ECM1 is clamped to non-active state, that is high, because of ECM1 not existing.

26.4.5 GTM output monitor for PWM diagnostic

This function helps to verify the output of the GTM by loop-back. The monitoring point is in the IO-buffer itself were the input path must be enabled over the port function. The signal is routed back to GTM input over the PIC. In the PIC this path can be enabled over a register. The block diagram is shown in **Figure 26.5**.

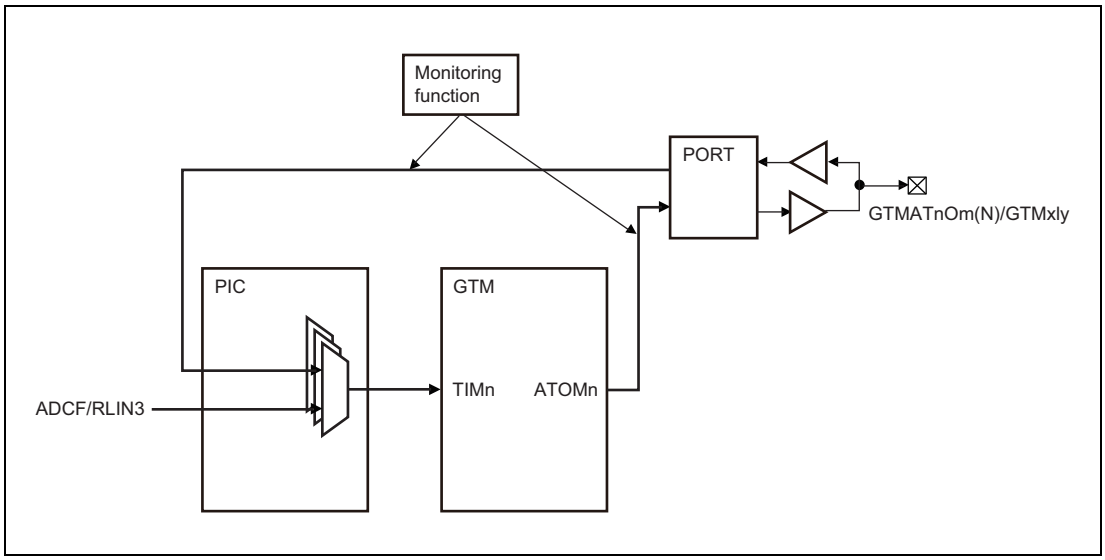

Figure 26.5 Block diagram for GTM output monitoring function

The assignment of the GTM outputs and the corresponding GTM inputs is bound to the pin multiplexing since the monitoring point is the pin itself. For details of the assignment, see "**Section 2, Pin Functions**".

NOTE

For this function the respective port has to be set into bi-directional mode and TIMn inputs have to be configured accordingly.

26.5 Difference among P1M-C, P1H-C and P1H-CE

Table 26.16 shows each device different specification.

Table 26.16 Each device different specification

Specification	P1M-C	P1H-C, P1H-CE
Number of GTM trigger sources	ATOM0: 12 ATOM1: 8 ATOM2: — TIM0: 8 TIM1: 8 MCS0: 9 MCS1: — (Total: 45)	ATOM0: 12 ATOM1: 12 ATOM2: 9 TIM0: 8 TIM1: 8 MCS0: 9 MCS1: 6 (Total: 64)
Number of RLIN3 trigger sources	RLIN3: 2	RLIN3: 4*1
Number of groups for Hi-Z control	ESOnZ: 2 (n = 0 to 1)	ESOnZ: 3*1 (n = 0 to 2)

Note 1. P1H-C (4MB, BGA-156) does not support RLIN32-33 and ESO2Z.

Section 27 A/D Converter (ADCF)

This section contains a generic description of the A/D converter (ADCF).

The first part of the section describes all RH850/P1x-C specific properties such as the number of units, register base address, etc.

The remainder of the section describes the function of ADCF and registers.

27.1 Features of RH850/P1x-C ADCF

27.1.1 Number of Units

This LSI has the following number of units of ADCF.

Table 27.1 Units

Products	P1M-C, P1H-C, P1H-CE
Number of units	2
Name	ADCFn (n = 0, 1)

Table 27.2 Index

Index	Meaning
n	Throughout this section, the individual ADCF units are identified by the index “n” (n = 0, 1), for example, ADCFnVCRj for the virtual channel register n.
m	Throughout this section, the number of each ADCF channel is indicated by the index “m”. This index is difference among products. (See **Table 27.44**)
j	Throughout this section, the number of data registers and virtual channels are identified by the index “j”, for example, ADCFnDRj for the data register j . This index is difference among products. (See **Table 27.44**)
x	Throughout this section, the scan group is indicated by the letter “x” (x = 0 to 4).
y	Throughout this section, the number of A/D timers are indicated by the letter “y” (y = 3, 4).

27.1.2 Register Base Address

ADCF base addresses are listed in the following table.

ADCF register addresses are given as offsets from the individual base address.

Table 27.3 Register Base Address

Base Address Name	Base Address
<ADCF0_base>	FFF9 1000_H
<ADCF1_base>	FFF9 2000_H

27.1.3 Clock Supply

Clock supply to ADCF is listed in the following table.

Table 27.4 Clock Supply

Unit Name	Supply Clock Name
ADCFn	Low-speed system clock (CLK_LSB)

Note: Only when CLK_LSB = 8 MHz – 40 MHz, the electrical characteristics can be guranteed.

27.1.4 Interrupts and DMA

ADCF interrupt requests are listed in the following table.

Table 27.5 Interrupt Requests

Interrupt name	Outline	Interrupt Number	DMA Trigger Number	DTS Trigger Number (Primary)
ADCF0				
INTADCF0I0	ADCF0 scan group 0 end interrupt	81	66	26
INTADCF0I1	ADCF0 scan group 1 end interrupt	82	67	27
INTADCF0I2	ADCF0 scan group 2 end interrupt	83	68	28
INTADCF0I3	ADCF0 scan group 3 end interrupt	84	69	29
INTADCF0I4	ADCF0 scan group 4 end interrupt	85	70	30
INTADCF0ERR	ADCF0 AD error interrupt	80	—	—
ADMPXI0	ADCF0 MPX DMA trigger request	—	71	—
ADCF1				
INTADCF1I0	ADCF1 scan group 0 end interrupt	167	72	31
INTADCF1I1	ADCF1 scan group 1 end interrupt	168	73	32
INTADCF1I2	ADCF1 scan group 2 end interrupt	169	74	33
INTADCF1I3	ADCF1 scan group 3 end interrupt	170	75	34
INTADCF1I4	ADCF1 scan group 4 end interrupt	171	76	35
INTADCF1ERR	ADCF1 AD error interrupt	166	—	—
ADMPXI1	ADCF1 MPX DMA trigger request	—	77	—

Note: ADC parity error interrupt is connected to ECM (error control module).

The Error interrupt is logical sum of the following interrupt.

- Upper/Lower Limit compare error
- Overwrite error
- ID error

27.1.5 Hardware Reset

ADCF reset sources are listed in the following table. ADCF is initialized by these reset condition.

Table 27.6 Reset Condition

Reset Name	Reset condition				
	Power On Reset	System Reset 1	System Reset 2	Application Reset 1	Limited Reset
All Registers	√	√	√	√	√

27.1.6 External Input/Output Signals

External input/output signals of ADCF are listed in the following table.

Table 27.7 External Input/Output Signals

Pin Name Definition in this section	Pin Name Definition in RH850/P1x-C	Outline
A0Vcc	A0VCC	Power supply pin for the input analog part
A0Vss	A0VSS	Ground pin for the input analog part
A1Vcc	A1VCC	Power supply pin for the input analog part
A1Vss	A1VSS	Ground pin for the input analog part
A0VREFH	A0VREFH	Reference voltage pin for the input analog part
A1VREFH	A1VREFH	Reference voltage pin for the input analog part
A0VREFL	—	Reference voltage pin for the input analog part (Merged A0VSS)
A1VREFL	—	Reference voltage pin for the input analog part (Merged A1VSS)
AN0Im	ADC0Im	ADCF0 12-bit resolution analog input pin, physical channel m.
AN1Im	ADC1Im	ADCF1 12-bit resolution analog input pin, physical channel m.
ADTRG0	ADC0TRG	External input trigger pin
ADTRG1	ADC1TRG	External input trigger pin
ADEND0	ADC0CNV	A/D conversion timing monitor pin
ADEND1	ADC1CNV	A/D conversion timing monitor pin

Please substitute “Pin Name Definition in RH850/P1x-C” for “Pin Name Definition in this section” when using RH850/P1x-C.

The input channel for the external analog multiplexer (MPX) is fixed to one dedicated physical input channel and is different for the implemented ADCFn modules.

- The physical input channel for MPX for ADCF0 is AN0I06
- The physical input channel for MPX for ADCF1 is AN1I00

27.1.7 Analog Channels

A/D conversion is available for ADCF0 and ADCF1. For corresponding channel number for each product, see **Section 27.7, Difference among P1M-C, P1H-C and P1H-CE**.

27.1.8 Virtual Channel

Each ADCF has virtual channels shown **Table 27.44**. Analog channels for which A/D conversion is to be made and other accompanying information are set for each virtual channel. By sequentially performing the processing for the virtual channels indicated by the start virtual channel pointer and the end virtual channel pointer in each scan group, scans (which can perform A/D conversion for any analog channels in any order) can be executed.

27.2 Overview

27.2.1 Functional Overview

ADCF has the following features.

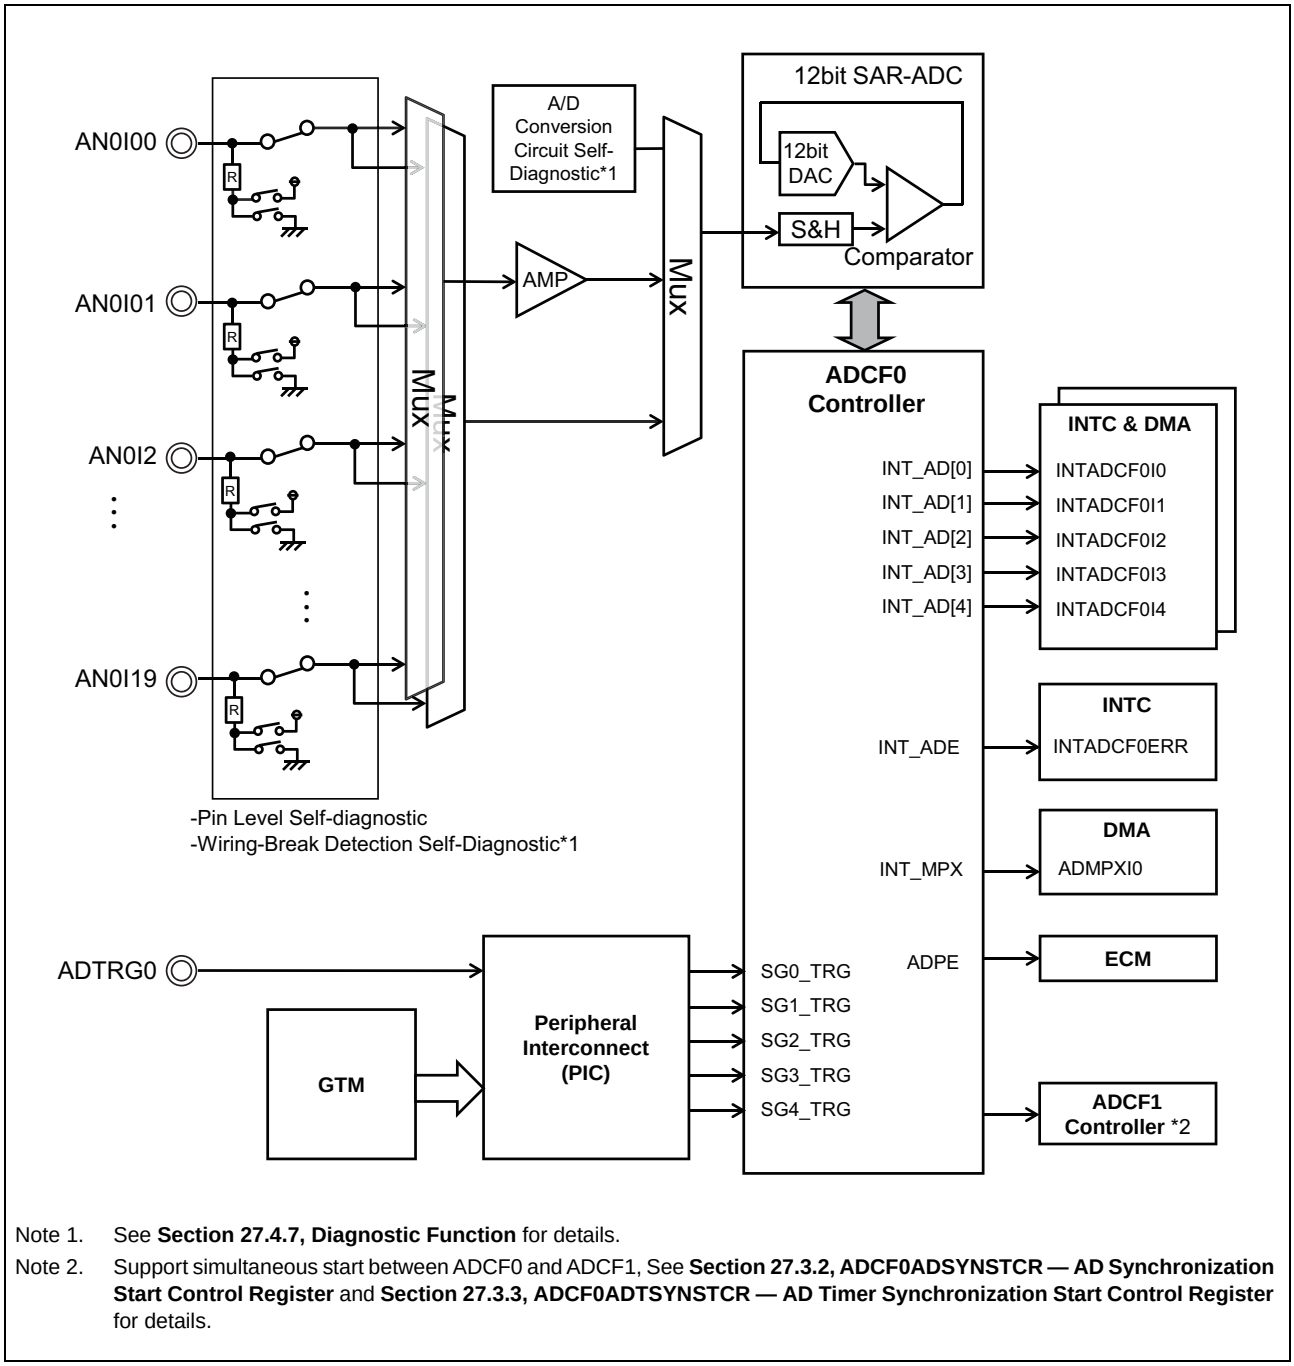
- Advanced A/D converter
  Resolution: 12 bits
  A/D conversion method: Successive approximation method
  Conversion speed: 1.0μs
- Supporting five scan groups
  Each ADCF has five scan groups. Scan settings can be made independently for each scan group.
- Two scan modes
  Each ADCF has two scan modes.
  Multicycle scan mode: Specified number of scans are executed.
  Continuous scan mode: Scans are repeatedly executed without limit.
- Interval function
  The ADCF can start scan groups in any cycle by using the A/D timer equipped in the scan groups 3 and 4. This enables scans with intervals inserted.
- A/D-converted value adding function
  The ADCF performs A/D conversion sequentially twice or four times for a channel, and stores the addition result in the data register. The addition count can be set for each virtual channel.
  The effect of the moving average filter can be gained by using this result. However, this function does not always ensure that A/D conversion accuracy is improved.
- Extended physical channels
  Each ADCF can extend physical channels by using an external analog multiplexer. (Available channel are AN0I06 and AN1I00.)
- Virtual channel concept
  Number of virtual channels larger than number of physical channels.
  Each virtual channels can freely be assigned to each physical conversion channels.
- Data registers
  Data registers corresponding to virtual channels are provided.
- Start trigger for each scan group
  Hardware triggers and software triggers can start processing of each scan group. Only scan groups 3 and 4 can start processing by an A/D timer trigger.
- Asynchronous/synchronous suspend and resume function
  A processing for a scan group can interrupt an ongoing processing for another scan group. The priority is as follows:
  Low High
  SG0 < SG1 < SG2 < SG3 < SG4 (SG: Scan group)
  If a request for a higher-priority SG is present while a lower-priority SG is being processed, the lower-priority SG is suspended after the ongoing virtual channel processing is stopped (synchronous suspend) or after the ongoing virtual channel processing is immediately stopped (asynchronous suspend), and then the processing for the higher-priority SG is performed. After the processing for the higher-priority SG is completed, the suspended virtual channel processing of the lower-priority SG resumes

Also, you can set as follows: when a higher-priority SG interrupts an SG0 processing, asynchronous suspend occurs, but when a higher-priority SG interrupts a lower-priority SG other than SG0, synchronous suspend occurs.

- Supporting scan end interrupt and DMA transfer
  Each scan group can generate an interrupt request to the INTC and activate the DMAC each time a processing for the virtual channel indicated by the end virtual channel pointer ends or a virtual channel ends.
- An analog conversion voltage settable
  The A0VREFH pin and the A1VREFH pin can be used to set the voltage range for analog conversion.
- Abundant safety functions
  The ADCF is equipped with abundant safety functions, including A/D conversion circuit diagnostic function, pin-level diagnostic function, wiring-break detection, normality check for analog selection, upper-limit/lower-limit check for data registers, parity check for data registers, overwrite check for data registers, and read and clear function for data registers.

27.2.2 Block Diagram

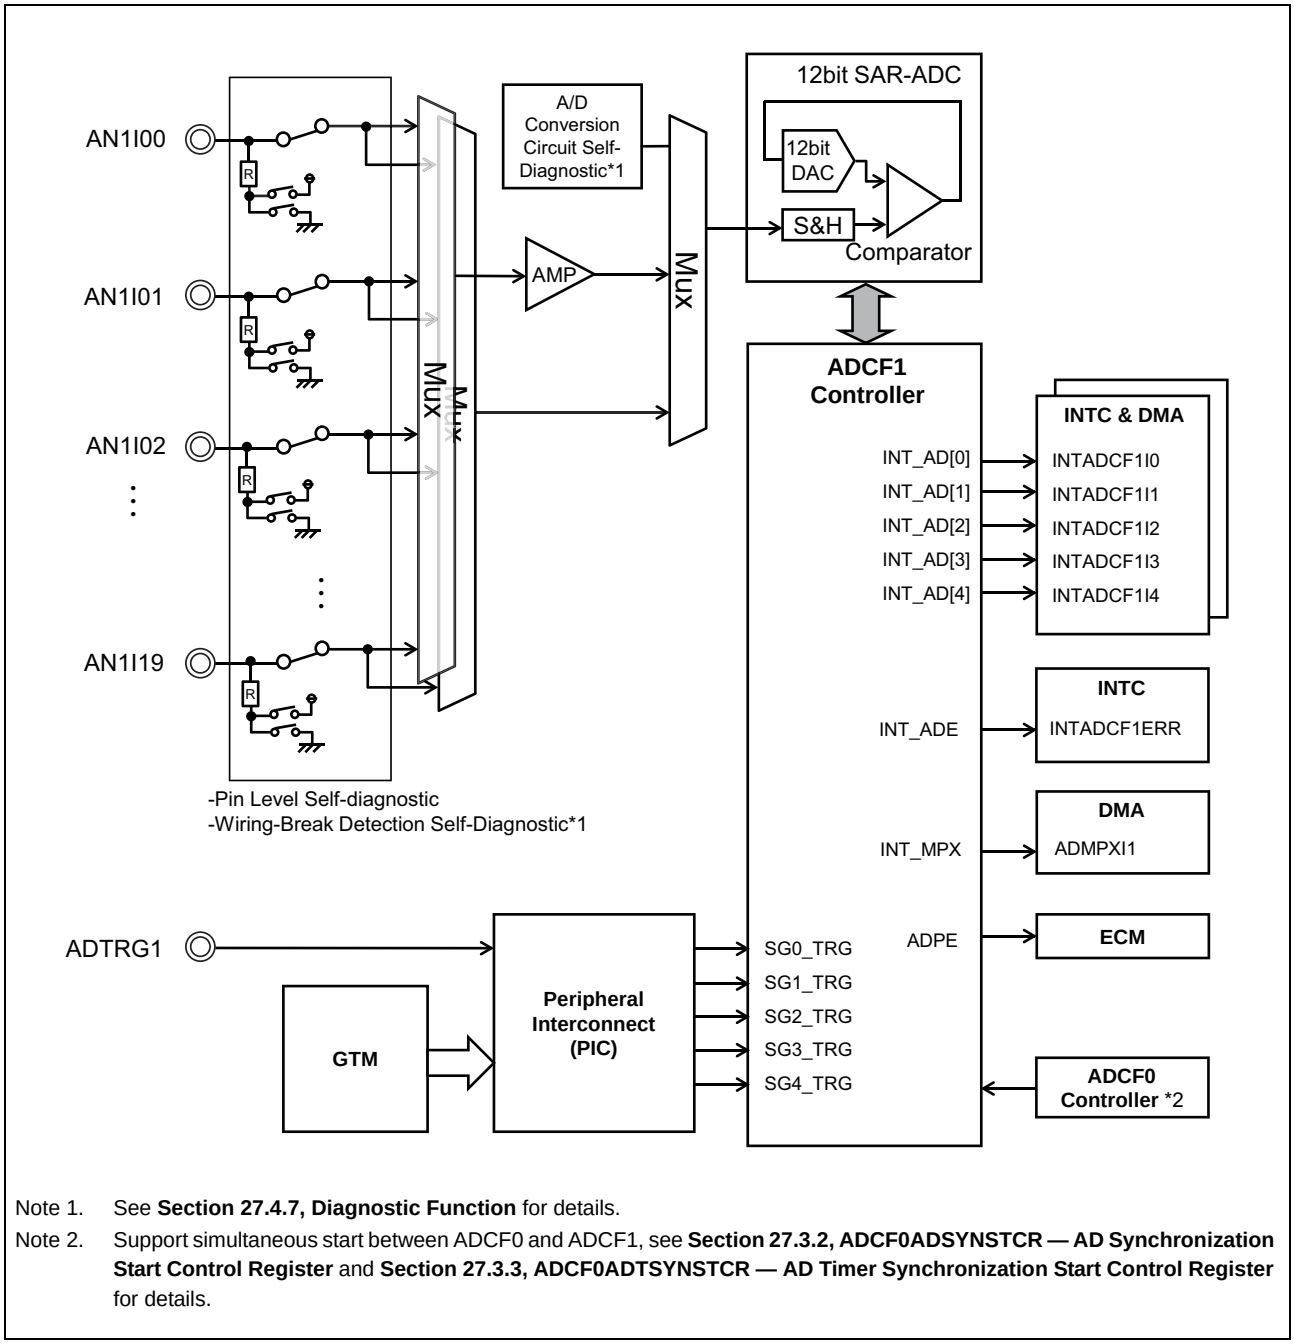
Figure 27.1 and **Figure 27.2** shows the block diagrams of ADCF.



Note 1. See **Section 27.4.7, Diagnostic Function** for details.

Note 2. Support simultaneous start between ADCF0 and ADCF1, See **Section 27.3.2, ADCF0ADSYNSTCR — AD Synchronization Start Control Register** and **Section 27.3.3, ADCF0ADTSYNSTCR — AD Timer Synchronization Start Control Register** for details.

Figure 27.1 Block Diagram (CH0)



Note 1. See **Section 27.4.7, Diagnostic Function** for details.

Note 2. Support simultaneous start between ADCF0 and ADCF1, see **Section 27.3.2, ADCF0ADSYNSTCR — AD Synchronization Start Control Register** and **Section 27.3.3, ADCF0ADTSYNSTCR — AD Timer Synchronization Start Control Register** for details.

Figure 27.2 Block Diagram (CH1)

27.2.3 Physical Channels, Virtual Channels and Scan Groups

Each physical channel m refers to an external A/D Converter input ANnIm.
A virtual channel is the A/D Converter channel from the application software's perspective.
The number j of virtual channels is larger than the number of physical channels m.
Each virtual channel j can be assigned to each physical channel via the GCTRL[4:0] bits of its virtual channel register ADCFnVCRj.

An arbitrary number of consecutive virtual channels can be combined as one of the five scan groups SGx, with x = 0 to 4.

The set of virtual channels of a scan group is defined by the

- scan group x start virtual channel pointer ADCFnSGVCSPx.VCSP[5:0]
- scan group x end virtual channel pointer ADCFnSGVCEPx.VCEP[5:0]

The conversion results of the virtual channels are stored in the ADCFnDRj registers.
Each 32-bit ADCFnDRj register stores the result of two consecutive virtual channels j and (j+1).
The conversion results is also stored in the data supplementary information register ADCFnDIRj (j = 0 to 35). This register contains some additional information about the conversion.

The figure below shows an example with the following configuration:

- Scan group x virtual channels: j = 4 to 9
- Virtual to physical channel assignment:

Register setting	Virtual channel j	Physical channel m
ADCFnVCR4.GCTRL[4:0] = 1	4	ANnI01
ADCFnVCR5.GCTRL[4:0] = 3	5	ANnI03
ADCFnVCR6.GCTRL[4:0] = 3	6	ANnI03
ADCFnVCR7.GCTRL[4:0] = 9	7	ANnI09
ADCFnVCR8.GCTRL[4:0] = 8	8	ANnI08
ADCFnVCR9.GCTRL[4:0] = 6	9	ANnI06

After a conversion start trigger for scan group x the first virtual channel ADCFnVCR4, i.e. the assigned physical channel ANnI01, is converted and the result is stored in ADCFnDR4.DR4[15:0].
The next conversion result goes to ADCFnDR4.DR5[15:0].
An internal scan pointer is increment and moves to the next virtual channel.

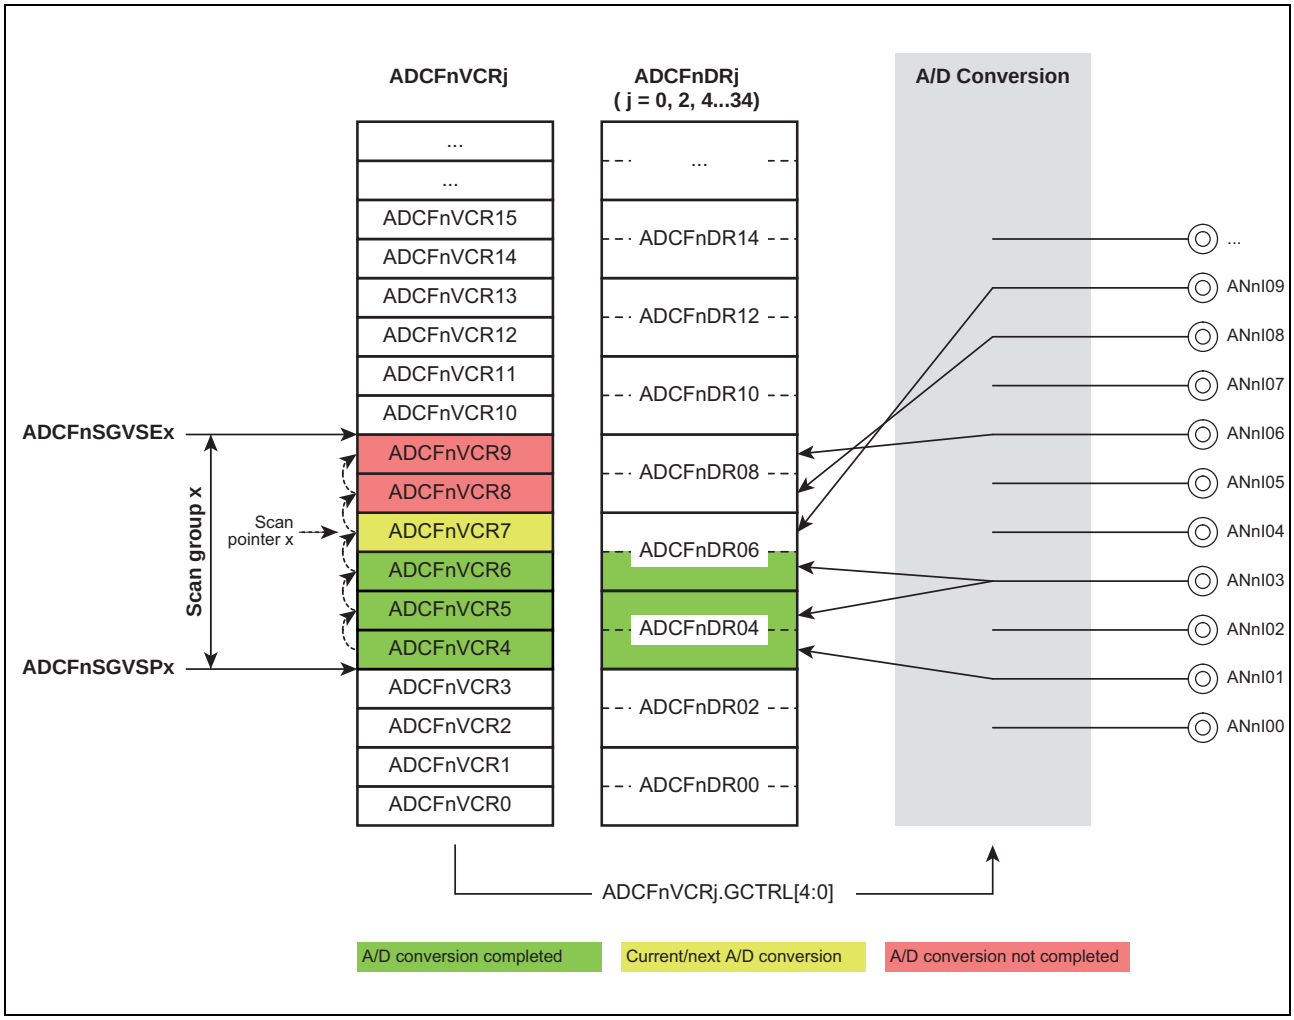


Figure 27.3 Virtual and Physical Channels

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3 Registers

27.3.1 List of Registers

ADCF registers are listed in the following table.

Table 27.8 List of Registers (1/2)

Register Name	Symbol	Address	Access Protection	
			PBG	Others
ADC common registers				
AD synchronization start control register	ADCF0ADSYNSTCR	<ADCF0_base> + 300_H	PBG4#0 .PG4-ADC0	—
AD timer synchronization start control register	ADCF0ADTSYNSTCR	<ADCF0_base> + 304_H	PBG4#0 .PG4-ADC0	—
ADC specific registers (virtual channel)				
Virtual channel register j (j = 0 to 35)	ADCFnVCRj	<ADCFn_base> + j × 4_H	*1	—
Data register j (j = 0, 2, 4....34)	ADCFnDRj	<ADCFn_base> + 100_H + j × 2_H	*1	—
Data supplementary information register j (j = 0 to 35)	ADCFnDIRj	<ADCFn_base> + 200_H + j × 4_H	*1	—
ADC specific registers (control)				
AD halt register	ADCFnADHALTR	<ADCFn_base> + 380_H	*1	—
AD control register 1	ADCFnADCR1	<ADCFn_base> + 384_H	*1	—
MPX current control register	ADCFnMPXCURCR	<ADCFn_base> + 388_H	*1	—
MPX current register	ADCFnMPXCURR	<ADCFn_base> + $38C_H$	*1	—
MPX optional wait register	ADCFnMPXOWR	<ADCFn_base> + 390_H	*1	—
AD control register 2	ADCFnADCR2	<ADCFn_base> + 398_H	*1	—
A/D Conversion Monitor Virtual Channel Pointer	ADCFnADENDP0	<ADCFn_base> + $3A0_H$	*1	—
ADC specific registers (safety-related)				
Safety control register	ADCFnSFTCR	<ADCFn_base> + $3C0_H$	*1	—
Pin level diagnostic control register	ADCFnTDCR	<ADCFn_base> + $3C4_H$	*1	—
Upper-limit/lower-limit table register 0	ADCFnULLMTBR0	<ADCFn_base> + $3CC_H$	*1	—
Upper-limit/lower-limit table register 1	ADCFnULLMTBR1	<ADCFn_base> + $3D0_H$	*1	—
Upper-limit/lower-limit table register 2	ADCFnULLMTBR2	<ADCFn_base> + $3D4_H$	*1	—
Error clear register	ADCFnECR	<ADCFn_base> + $3D8_H$	*1	—
Upper-limit/lower-limit error register	ADCFnULER	<ADCFn_base> + $3DC_H$	*1	—
Overwrite error register	ADCFnOWER	<ADCFn_base> + $3E0_H$	*1	—
Parity error register	ADCFnPER	<ADCFn_base> + $3E4_H$	*1	—
ID error register	ADCFnIDER	<ADCFn_base> + $3E8_H$	*1	—
Scan group specific registers				
Scan group x start control register	ADCFnSGSTCRx	<ADCFn_base> + x × 80_H+480_H	*1	—
AD timer y start control register	ADCFnADTSTCRy	<ADCFn_base> + y × 80_H+488_H	*1	—
AD timer y end control register	ADCFnADTENDCRy	<ADCFn_base> + y × 80_H+$48C_H$	*1	—
Scan group x control register	ADCFnSGCRx	<ADCFn_base> + x × 80_H+490_H	*1	—
Scan group x start virtual channel pointer	ADCFnSGVCSPx	<ADCFn_base> + x × 80_H+494_H	*1	—
Scan group x end virtual channel pointer	ADCFnSGVCEPx	<ADCFn_base> + x × 80_H+498_H	*1	—
Scan group x multicycle register	ADCFnSGMCYCRx	<ADCFn_base> + x × 80_H+$49C_H$	*1	—
Scan group x status register	ADCFnSGSRx	<ADCFn_base> + x × 80_H+$4A4_H$	*1	—

Table 27.8 List of Registers (2/2)

Register Name	Symbol	Address	Access Protection	
			PBG	Others
AD timer initial phase register y	ADCFnADTIPRy	<ADCFn_base> + y × 80_H+$4A8_H$	*1	—
AD timer period register y	ADCFnADTPRRy	<ADCFn_base> + y × 80_H+$4AC_H$	*1	—
Scan group x upper-limit/lower-limit table select register	ADCFnULLMSRx	<ADCFn_base> + x × 80_H + $4B0_H$	*1	—

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

Note 1. In the case of
n = 0 PBG4#0.PG4-ADC0
n = 1 PBG4#0.PG4-ADC1

27.3.2 ADCF0ADSYNSTCR — AD Synchronization Start Control Register

ADCF0ADSYNSTCR is an 8-bit write-only register that controls simultaneous start of A/D conversion for each scan group of ADCF0 and ADCF1. The register bits are always read as 0.

Access: This register can be written in 8-bit units.

Address: <ADCF0_base> + 300_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ADSTART
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 27.9 ADCF0ADSYNSTCR register contents

Bit Position	Bit Name	Function
7 to1	Reserved	When writing, write the value after reset.
0	ADSTART	Starts A/D conversion for scan groups of ADCF0 and ADCF1. Start condition of SGx of ADCFn: For SGx of ADCFn, 1 is written to ADSTART when SGACT is 0 and ADSTARTE is 1. A/D conversion is started simultaneously for the scan groups (of ADCF0 and ADCF1) for which ADSTARTE has been set to 1.

27.3.3 ADCF0ADTSYNSTCR — AD Timer Synchronization Start Control Register

ADCF0ADTSYNSTCR is an 8-bit write-only register that controls simultaneous start of count operation for each A/D timer of ADCF0 and ADCF1. The register bits are always read as 0.

Access: This register can be written in 8-bit units.

Address: <ADCF0_base> + 304_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ADTSTART
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 27.10 ADCF0ADTSYNSTCR register contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	ADTSTART	Starts count operation of the A/D timer of ADCF0 and ADCF1. Start condition of SGx of ADCFn: For A/D timer x of ADCFn, 1 is written to ADTSTART when ADTACT is 0 and ADTSTARTE is 1. Count operation is started simultaneously for the A/D timers (of ADCF0 and ADCF1) for which ADTST has been set to 1. **Note:** x = 3, 4

27.3.4 ADCFnVCRj — Virtual Channel Register j

ADCFnVCRj is a 32-bit readable/writable register used for each virtual channel.

Access: This register can be read/written in 32-bit units.

Address: <ADCFn_base> + j x 4_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PUE	PDE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CNVCLS[2:0]			—	—	—	—	—	ADIE	—	—	GCTRL[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Table 27.11 ADCFnVCRj register contents (1/2)

Bit Position	Bit Name	Function
31 to 18	Reserved	When read, the value after reset is read. When writing, write the value after reset.
17, 16	PUE, PDE	Pull-Up/Down resistor 00: Pull-Up and Pull-Down resistor disabled 01: Pull-Down resistor enabled. The resistor is enabled during the sample time. 10: Pull-Up resistor enabled. The resistor is enabled during the sample time. 11: Setting prohibited. **NOTE** Set PUE=0 and PDE=0 when pin level diagnostic function enable. For more details, see **Section 27.4.7.3, Wiring-Break Detection Diagnostic Function**
15 to13	CNVCLS[2:0]	Conversion type 0_H: Normal A/D conversion 3_H: Diagnosis 4_H: Normal A/D conversion of addition mode 5_H: Normal A/D conversion with the MPX 6_H: Normal A/D conversion with the MPX of addition mode Other than above: Setting prohibited
12 to 8	Reserved	When read, the value after reset is read. When writing, write the value after reset.
7	ADIE	Virtual channel end interrupt enable 0: ADInx is not output at virtual channel end of virtual channel j in SGx 1: ADInx is output at virtual channel end of virtual channel j in SGx ADIE in ADCFnSGCRx is independent of ADIE in ADCFnVCRj. For details, see **Section 27.4.15, Scan End Interrupt Request**.
6, 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.

Table 27.11 ADCFnVCRj register contents (2/2)

Bit Position	Bit Name	Function
4 to 0	GCTRL[4:0]	General control Write 0 to the bits which are not used among GCTRL[4:0].

CNVCLS[2:0]	GCTRL[4:0]
0_H: Normal A/D conversion	GCTRL[4:0] : Physical Channel
3_H: Diagnosis	GCTRL[4:0] : Voltage level in diagnosis 00_H: AnVREFH × 0 04_H: AnVREFH × 1/4 08_H: AnVREFH × 1/2 $0C_H$: AnVREFH × 3/4 10_H: AnVREFH × 1 Other than above: Setting prohibited
4_H: Normal A/D conversion of addition mode	GCTRL[4:0] : Physical channel *The count specified by ADDNT is applied to the number of additions
5_H: Normal A/D conversion with the MPX	GCTRL[4:0] : MPX channel is set. MPX value to be transferred to the external analog multiplexer is specified. An interrupt request (INTADCFnMPX) or a DMA request is output by GCTRL[4:0] transfer to ADCFnMPXCURR at the start of virtual channel. The MPX value can be transferred to the external analog multiplexer by transferring ADCFnMPXCURR to PyDR or PyMDR of I/O port after an interrupt or start of DMAC. See **Section 27.4.3**, for more detail.
6_H : Normal A/D conversion with the MPX of addition mode	GCTRL[4:0] : MPX channel is set MPX value to be transferred to the external analog multiplexer is specified. An interrupt request (INTADCFnMPX) or a DMA request is output by GCTRL[4:0] transfer to ADCFnMPXCURR at the start of virtual channel. The MPX value can be transferred to the external analog multiplexer by transferring ADCFnMPXCURR to PyDR or PyMDR of I/O port after an interrupt or start of DMAC. See **Section 27.4.3, Example of Operation of External Analog Multiplexer** for details. The number of addition times specified by ADDNT is applied.
Other than above : Setting prohibited	—

CAUTION

To prevent malfunction, perform ADCFnVCRj settings after the following settings and confirmation.

1. Confirm for all scan groups that ADSTARTE = 0_H
2. Confirm for all scan groups that TRGMD = 0_H
3. Confirm for all scan groups that SGACT = 0_H

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.5 ADCFnDRj — Data Register j

This register is a 32-bit read-only register, which stores the A/D conversion results corresponding to ADCFnVCRj and ADCFnVCR (j + 1). As the A/D conversion results, the conversion result for ADCFnVCR (j + 1) is stored in the upper 16 bits, and the conversion result for ADCFnVCRj is stored in the lower 16 bits.
ADCFnDRj format depends on the DFMT setting of ADCFnVCRj and the ADDNT setting (when CNVCLS[2:0] = 4_H, 6_H). ADCFnDRj is cleared to 0000_H when ADCFnDRj or ADCFnDIRj is read while RDCLRE is set to 1.

Access: This register can be read only in 32-bit units.

Address: <ADCFn_base> + 100_H + j × 2_H

Value after reset: 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DR(j+1)[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DRj[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.12 ADCFnDRj register contents

Bit Position	Bit Name	Function
31 to 16	DR(j+1)[15:0]	These bits are used to store the A/D conversion result data. (The A/D conversion result for the channel set in ADCFnVCR (j + 1) are transferred.)
15 to 0	DRj[15:0]	These bits are used to store the A/D conversion result data. (The A/D conversion result for the channel set in ADCFnVCRj are transferred.)

NOTE

j = 0, 2, …, 34

For signed fixed-point format (DFMT = 0)

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Convert once	S													0	0	0
Convert twice	S														0	0
Convert 4 timers	S															0

Position of decimal point

For signed integer format (DFMT = 1)

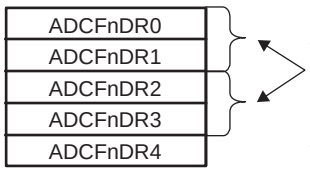
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Convert once	S	S	S	S												
Convert twice	S	S	S													
Convert 4 timers	S	S														

Position of decimal point

S	: Sign bit (always 0)
0	: Zero extension

The format setting in ADDNT is valid when CNVCLS[2:0] = 4_H, 6_H.

If CNVCLS[2:0] is not 4_H, 6_H, the format is “convert once.”



Read access is made in 32-bit unit also when ADCFnDRj or ADCFnDRj+1 is read as 16-bit data.
Therefore, its 16 higher-order bits or 16 lower-order bits are also accessed, resulting in the same state as read access (DIRj.WFLG is cleared and ADCFnDRj and ADCFnDIRj when RDCLRE = 1 are cleared).

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.6 ADCFnDIRj — Data Supplementary Information Register j

ADCFnDIRj is a 32-bit read-only register that stores supplementary information of ADCFnDRj and A/D converted value. ADCFnDIRj is provided for each virtual channel. ADCFnDIRj is cleared to 0000 0000_H when ADCFnDRj or ADCFnDIRj is read while RDCLRE is set to 1. WFLG is cleared when ADCFnDRj or ADCFnDIRj is read regardless of the RDCLRE setting. This register must always be read as 32-bit data. ADCFnDRj is read from the16 lower-order bits.

Access: This register can be read in 32-bit units.

Address: <ADCFn_base> + $200_H + j \times 4_H$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	WFLG	PRTY	—	—	—	ID[4:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DRj															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.13 ADCFnDIRj register contents

Bit Position	Bit Name	Function
31 to 26	Reserved	When read, the value after reset is read.
25	WFLG	Write Flag 1: Setting condition An A/D converted value is stored in ADCFnDRj 0: Clearing conditions ADCFnDRj or ADCFnDIRj is read.
24	PRTY	Parity Parity bit (even parity) for DRj and ID[4:0].
23 to 21	Reserved	When read, the value after reset is read.
20 to 16	ID[4:0]	Contains the physical channel information of the converted channel..
15 to 0	DRj	same as ADCFnDRj

CNVCLS[2:0]	GCTRL[4:0]
0_H: Normal A/D conversion	ID[4:0] : Physical Channel
3_H: Self-diagnosis	ID[4:0] : Voltage level in self-diagnosis 00_H: AnVREFH × 0 04_H: AnVREFH × 1/4 08_H: AnVREFH × 1/2 $0C_H$: AnVREFH × 3/4 10_H: AnVREFH × 1 Other than above : Setting prohibited
4_H: Normal A/D conversion of addition mode	ID[4:0] : Physical channel
5_H: Normal A/D conversion with the MPX	ID[4:0] : Physical channel
6_H : Normal A/D conversion with the MPX of addition mode	ID[4:0] : Physical channel
Other than above : Setting prohibited	—

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.7 ADCFnADHALTR — AD Halt Register

ADCFnADHALTR is an 8-bit write-only register that halts the ADC. The register bits are always read as 0.

Access: This register can be written in 8-bit units.

Address: <ADCFn_base> + 380_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	HALT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 27.14 ADCFnADHALTR register contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	HALT	Halt All scan groups and AD timers are halted and initialized, and the ADC becomes the idle state. Writing 0: Not halted. Writing 1: Halted.

27.3.8 ADCFnADCR1 — AD Control Register 1

ADCFnADCR1 is an 8-bit readable/writable register for ADC common control.

Access: This register can be read/written in 8-bit units.

Address: <ADCFn_base> + 384_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	SUSMTD[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 27.15 ADCFnADCR1 register contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	SUSMTD [1:0]	Suspend Method These bits select the suspend method when a higher-priority scan group interrupts a lower-priority scan group. Synchronous suspend: If a request from a higher-priority SG is present while a lower-priority SG is being processed, processing for the lower-priority SG is suspended after the ongoing virtual channel processing is completed, and then processing for the higher-priority SG is executed. After processing for the higher-priority SG is completed, the suspended virtual channel processing for the lower-priority SG is resumed. Asynchronous suspend: If a request from a higher-priority SG is present while a lower-priority SG is being processed, the ongoing virtual channel processing is immediately suspended, and then processing for the higher-priority SG is executed. After processing for the higher-priority SG is completed, the suspended virtual channel processing for the lower-priority SG is resumed. 0_H: Synchronous suspend 1_H: Asynchronous suspend when a higher-priority SG interrupts SG0 Synchronous suspend when a higher-priority SG interrupts a lower-priority SG (except for SG0) 2_H: Asynchronous suspend 3_H: Setting prohibited For the detail, see **Figure 27.8, Example of Synchronous Suspend and Resume Operation** and **Figure 27.9, Example of Asynchronous Suspend and Resume Operation**.

CAUTION

To prevent malfunction, perform ADCFnADCR1 settings after the following settings and confirmation.

(1) ADSTARTE of all scan groups is 0,

(2)TRGMD[0] of scan groups 0,1, 2 is 0_H and TRGMD[1:0] of scan groups 3, 4 is 0_H.

(3) SGACT of all scan groups is 0 (before scan groups are started)

27.3.9 ADCFnMPXCURCR — MPX Current Control Register

ADCFnMPXCURCR is a register that controls the ADCFnMPXCURR format.

Access: This register can be read/written in 8-bit units.

Address: <ADCFn_base> + 388_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	MSKCFMT0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 27.16 ADCFnMPXCURCR register contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	MSKCFMT0	MSKC format specification Specifies the MSKC[3:0] format of ADCFnMPXCURR MSKCFMT0 0: MSKC[3:0] = 0000 1: MSKC[3:0] = 1111

CAUTION

To prevent malfunction, perform ADCFnMPXCURCR settings after the following settings and confirmation.

(1) ADSTARTE of all scan groups is 0

(2)TRGMD[0] of scan groups 0,1, 2 is 0_H and TRGMD[1:0] of scan groups 3, 4 is 0_H

(3) SGACT of all scan groups is 0 (before scan groups are started)

27.3.10 ADCFnMPXCURR — MPX Current Register

ADCFnMPXCURR is a 32-bit read-only register that stores the MPX value for an external analog multiplexer.

Access: This register can be read in 32-bit units.

Address: <ADCFn_base> + $38C_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	MSKC[3:0]			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	MPXCUR[3:0]			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 27.17 ADCFnMPXCURR register contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is read.
19 to 16	MSKC[3:0]	Mask Control The format depends on the MSKCFMT0 setting of ADCFnMPXCURCR. For details, see **Section 27.3.9, ADCFnMPXCURCR — MPX Current Control Register**.
15 to 4	Reserved	When read, the value after reset is read.
3 to 0	MPXCUR[3:0]	Current MPX value When a virtual channel for which CNVCLS[2:0] in ADCFnVCRj is set to 5_H or 6H is started, GCTRL[3:0] in ADCFnVCRj is transferred to MPXCUR[3:0]. At this time, a DMA transfer request is generated. enabling the MPX value to be sent to an external analog multiplexer. When PSRn is used, transfer the MPX value as a 32-bit value. This enables rewriting only the necessary ports by using the format control in MSKC[3:0]. For details, see **Section 27.4.3, Example of Operation of External Analog Multiplexer**.

27.3.11 ADCFnMPXOWR — MPX Optional Wait Register

ADCFnMPXOWR is a register that specifies the wait time to be inserted for an external analog multiplexer.

Access: This register can be read/written in 8-bit units.

Address: <ADCFn_base> + 390_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	MPXOW[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 27.18 ADCFnMPXOWR register contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3 to 0	MPXOW	MPX Optional Wait These bits specify the wait time to be inserted before A/D conversion is started after a virtual channel for which CNVCLS[2:0] in ADCFnVCRj is 5_H or 6_H is started. 0_H: 0 µs 1_H: 1 µs 2_H: 2 µs 3_H: 3 µs 4_H: 4 µs 5_H: 5 µs 6_H: 6 µs 7_H: 7 µs 8_H: 8 µs 9_H: 9 µs A_H: 10 µs B_H to F_H: Setting prohibited For details, see **Section 27.4.3, Example of Operation of External Analog Multiplexer**.

CAUTION

To prevent malfunction, perform ADCFnMPXOWR settings after the following settings and confirmation.

(1) ADSTARTE of all scan groups is 0

(2) TRGMD[0] of scan groups 0,1, 2 is 0_H and TRGMD[1:0] of scan groups 3, 4 is 0_H.

(3) SGACT of all scan groups is 0 (before scan groups are started).

27.3.12 ADCFnADCR2 — AD Control Register 2

ADCFnADCR2 is an 8-bit readable/writable register for ADCF common control.

Access: This register can be read/written in 8-bit units.

Address: <ADCFn_base> + 398_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	DFMT	—	—	—	ADDNT
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R	R	R	R/W

Table 27.19 ADCFnADCR2 register contents

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	DFMT	Data Format 0: Signed fixed-point format 1: Signed integer format This bit specifies the format of data to be transferred to ADCFnDRj. For details of data format, see **Section 27.3.5, ADCFnDRj — Data Register j**.
3 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	ADDNT	Addition Count Select 0: Add twice 1: Add 4 times This register is valid only when CNVCLS[2:0] is 4_H, 6_H.

CAUTION

To prevent malfunction, perform ADCFnADCR2 settings after the following settings and confirmation.

(1) ADSTARTE of all scan groups is 0

(2) TRGMD[0] of scan groups 0,1, 2 is 0_H and TRGMD[1:0] of scan groups 3, 4 is 0_H.

(3) SGACT of all scan groups is 0 (before scan groups are started)

27.3.13 ADCFnADENDP0 — A/D Conversion Monitor Virtual Channel Pointer

ADCFnADENDP0 is an 8-bit readable/writable register that selects a virtual channel that outputs the A/D conversion timing to ADENDn.

Access: This register can be read/written in 8-bit units.

Address: ADCFnADENDP0: <ADCFn_base> + $3A0_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	ENDP[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 27.20 ADCFnADENDP0 register contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is read. Writing is ignored.
5 to 0	ENDP[5:0]	A/D Conversion Monitor Virtual Channel Pointer When the virtual channel selected by ADCFnADENDP0 is started, a high level is output to from the ADENDn pin. When the virtual channel selected by ADCFnADENDP0 ends, a low level is output.

CAUTION

To prevent malfunction, perform ADCFnADENDP0 settings after the following settings and confirmation.

(1) ADSTARTE of all scan groups is 0,

(2) TRGMD[0] of scan groups 0,1, 2 is 0_H and TRGMD[1:0] of scan groups 3, 4 is 0_H.

(3) SGACT of all scan groups is 0 (before scan groups are started)

27.3.14 ADCFnSFTCR — Safety Control Register

ADCFnSFTCR is an 8-bit readable/writable register for safety control.

Access: This register can be read/written in 8-bit units.

Address: <ADCFn_base> + $3C0_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	RDCLRE	ULEIE	OWEIE	PEIE	IDEIE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 27.21 ADCFnSFTCR register contents

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	RDCLRE	Read and Clear Enable 0: ADCFnDRj and ADCFnDIRj are not cleared by reading ADCFnDRj or ADCFnDIRj. 1: ADCFnDRj and ADCFnDIRj are cleared by reading ADCFnDRj or ADCFnDIRj. **CAUTION** ADCFnDIRj.WFLG is cleared by reading ADCFnDRj or ADCFnDIRj regardless of the RDCLRE setting.
3	ULEIE	Upper-Limit/Lower-Limit Error Interrupt Enable 0: Disabled 1: Enabled
2	OWEIE	Overwrite Error Interrupt Enable 0: Disabled 1: Enabled
1	PEIE	Parity Error Interrupt Enable 0: Disabled 1: Enabled
0	IDEIE	ID Error Interrupt Enable 0: Disabled 1: Enabled

CAUTION

To prevent malfunction, perform settings of ADCFnSFTCR after the following settings and confirmation.
(1) ADSTARTE of all scan groups is 0,
(2) TRGMD[0] of scan groups 0,1, 2 is 0_H and TRGMD[1:0] of scan groups 3, 4 is 0_H.
(3) SGACT of all scan groups is 0 (before scan groups are started)

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.15 ADCFnTDCR —Pin Level Diagnostic Control Register

ADCFnTDCR is an 8-bit readable/writable register that controls the pin level diagnosis.

Access: This register can be read/written in 8-bit units.

Address: <ADCFn_base> + $3C4_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	TDE	—	—	—	—	—	TDLV[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R	R	R	R/W	R/W

Table 27.22 ADCFnTDCR register contents

Bit Position	Bit Name	Function
7	TDE	Pin Level diagnosis Enable 0: Pin level diagnosis is disabled. 1: Pin level diagnosis is enabled. When TDE is set to 1, all analog pins are disconnected from the input buffer. When TDE is set to 0, all analog pins are connected to the input buffer. When TDE is set to 1, the voltage is fixed to the level specified by TDLV[1:0]. Performing A/D conversion in this state and checking the A/D converted value allows diagnosis of the path from an analog pin to the ADCF. **CAUTIONS** 1. When TDE = 1, be sure to sent both the PUE and PDE bits of ADCFnVCRj to 0 2. Set ADCFnTDCR.TDE to 0 before setting the PUE bits of ADCFnVCRj to 1. Similarly, when setting ADCFnTDCR.TDE to 1, set the PUE and PDE bites of ADCFnVCRj for A/D conversion to 0 while ADCFnTDCR.TDE = 1 (the recommended setting is 0 for the PUE and PDE bits of all ADCFnVCRj registers).
6 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TDLV[1:0]	Pin Level diagnosis Level 0_H: Even numbers of physical channel groups are discharged to AnVSS, and odd numbers of physical channel groups are charged to AnVCC. 1_H: Even numbers of physical channel groups are charged to AnVCC, and odd numbers of physical channel groups are discharged to AnVSS. 2_H: Even numbers of physical channel groups are discharged to AnVSS, and odd numbers of physical channel groups are charged to 1/2*AnVCC. 3_H: Even numbers of physical channel groups are charged to 1/2*AnVCC, and odd numbers of physical channel groups are discharged to AnVSS.

CAUTION

To prevent malfunction, perform settings of ADCFnTDCR after the following settings and confirmation.

(1) ADSTARTE of all scan groups is 0

(2) TRGMD[0] of scan groups 0,1, 2 is 0_H and TRGMD[1:0] of scan groups 3, 4 is 0_H.

(3) SGACT of all scan groups is 0 (before scan groups are started)

27.3.16 ADCFnULLMTBR0 to 2 — Upper-Limit/Lower-Limit Table Registers 0 to 2

ADCFnULLMTBR0-2 are 32-bit readable/writable registers that set the upper-limit and lower-limit values of an A/D converted value. Specify any of ADCFnULLMTBR0 to 2 by ULS[1:0] in ADCFnULLMSRx.

Access: This register can be read/written in 32-bit units.

Address: ADCFnULLMTBR0: <ADCFn_base> + $3CC_H$
ADCFnULLMTBR1: <ADCFn_base> + $3D0_H$
ADCFnULLMTBR2: <ADCFn_base> + $3D4_H$

Value after reset: $7FFE\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ULMTB[15:0]															
Value after reset	0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LLMTB[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 27.23 ADCFnULLMTBR register contents

Bit Position	Bit Name	Function
31 to 16	ULMTB[15:0]	Upper Limit Table These bits specify the upper-limit value of an A/D converted value. ULE (upper limit/lower limit error) is set when the following condition is met. ULMTB[15:0] < A/D converted value The ULMTB[15:0] format is the signed fixed-point format regardless of the format of ADCFnDRj. If the signed integer format is selected for the ADCFnDRj format, the ADCFnDRj format is replaced with the signed fixed-point format, and then the values are compared. Note that ULMTB[15] and ULMTB[0] are always fixed to 0.
15 to 0	LLMTB[15:0]	Lower Limit Table These bits specify the lower-limit value of an A/D converted value. ULE (upper limit/lower limit error) is set when the following condition is met. LLMTB[15:0] > A/D converted value The LLMTB[15:0] format is the signed fixed-point format regardless of the format of ADCFnDRj. If the signed integer format is selected for the ADCFnDRj format, the ADCFnDRj format is replaced with the signed fixed-point format, and then the values are compared. Note that LLMTB[15] and LLMTB[0] are always fixed to 0.

CAUTION

To prevent malfunction, perform settings of ADCFnULLMTBR0 to 2 after the following settings and confirmation.

(1) ADSTARTE of all scan groups is 0,

(2) TRGMD[0] of scan groups 0,1, 2 is 0_H and TRGMD[1:0] of scan groups 3, 4 is 0_H.

(3) SGACT of all scan groups is 0 (before scan groups are started)

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.17 ADCFnECR — Error Clear Register

ADCFnECR is an 8-bit write-only register that controls error clear. The register bits are always read as 0.

Access: This register can be read in 8-bit units.

Address: <ADCFn_base> + $3D8_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	ULEC	OWEC	PEC	IDEC
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	W	W	W	W

Table 27.24 ADCFnECR register contents

Bit Position	Bit Name	Function
7 to 4	Reserved	When writing, write the value after reset.
3	ULEC	Upper Limit/Lower Limit Error Clear Writing 0: Not cleared Writing 1: Cleared
2	OWEC	Overwrite Error Clear Writing 0: Not cleared Writing 1: Cleared
1	PEC	Parity Error Clear Writing 0: Not cleared Writing 1: Cleared
0	IDEC	ID Error Clear Writing 0: Not cleared Writing 1: Cleared

27.3.18 ADCFnULER — Upper-Limit/Lower-Limit Error Register

ADCFnULER is an 8-bit read-only register that indicates upper limit/lower limit errors.

Access: This register can be read in 8-bit units.

Address: <ADCFn_base> + $3DC_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	ULE	—	ULECAP[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 27.25 ADCFnULER register contents

Bit Position	Bit Name	Function
7	ULE	Upper Limit/Lower Limit Error 0: No error 1: An error is present. Setting condition The A/D converted value exceeds the range of the specified upper limit/lower limit table Clearing condition A value of 1 is written to ULEC.
6	Reserved	When read, the value after reset is read.
5 to 0	ULECAP[5:0]	Upper Limit/Lower Limit Error Capture The virtual channel at the time when an upper limit/lower limit error occurred is captured. Capturing condition ULE = 0 and the A/D converted value exceeds the range of the specified upper limit/lower limit table. Clearing condition A value of 1 is written to ULEC

CAUTION

ADCFnULER is updated when the AD converted value is written to ADCFnDRj.

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.19 ADCFnOWER — Overwrite Error Register

ADCFnOWER is an 8-bit read-only register that indicates an overwrite error.

Access: This register can be read in 8-bit units.

Address: <ADCFn_base> + $3E0_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	OWE	—	OWECAP[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 27.26 ADCFnOWER register contents

Bit Position	Bit Name	Function
7	OWE	Overwrite Error 0: No error 1: An error is present. Setting condition The A/D converted value is written to ADCFnDRj when WFLG = 1 Clearing condition A value of 1 is written to OWEC
6	Reserved	When read, the value after reset is read.
5 to 0	OWECAP[5:0]	Overwrite Error Capture The virtual channel at the time when an overwrite error occurred is captured. Capturing condition The A/D converted value is written to ADCFnDRj when OWE = 0 and WFLG = 1. Clearing condition A value of 1 is written to OWEC

CAUTION

ADCFnOWER is updated when the AD converted value is written to ADCFnDRj.

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.20 ADCFnPER — Parity Error Register

ADCFnPER is an 8-bit read-only register that indicates a parity error.

Access: This register can be read in 8-bit units.

Address: <ADCFn_base> + $3E4_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	PE	—	PECAP[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 27.27 ADCFnPER register contents

Bit Position	Bit Name	Function
7	PE	Parity Error 0: No error 1: An error is present. Setting condition A parity error is detected. Clearing condition A value of 1 is written to PEC.
6	Reserved	When read, the value after reset is read.
5 to 0	PECAP[5:0]	Parity Error Capture The virtual channel at the time when a parity error occurred is captured. Capturing condition A parity error is detected when PE = 0. Clearing condition A value of 1 is written to PEC.

CAUTION

ADCFnPER is updated when ADCFnDRj or ADCFnDIRj is read.

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.21 ADCFnIDER — ID Error Register

ADCFnIDER is an 8-bit read-only register that indicates an ID error.

Access: This register can be read in 8-bit units.

Address: <ADCFn_base> + $3E8_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	IDE	—	IDECAP[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 27.28 ADCFnIDER register contents

Bit Position	Bit Name	Function
7	IDE	ID Error 0: No error 1: An error is present. Setting condition The physical channel specified in ADCFnVCRj does not match the physical channel actually converted. Clearing condition A value of 1 is written to IDEC.
6	Reserved	When read, the value after reset is read.
5 to 0	IDECAP[5:0]	ID Error Capture The virtual channel at the time when an ID error occurred is captured. Capturing condition The physical channel specified in ADCFnVCRj does not match the physical channel actually converted when IDE = 0. Clearing condition A value of 1 is written to IDEC.

CAUTION

ADCFnIDER is updated when the AD converted value is written to ADCFnDRj.

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.22 ADCFnSGSTCRx — Scan Group x Start Control Register

ADCFnSGSTCRx is an 8-bit write-only register that controls the start of scan group x. The register bits are always read as 0.

Access: This register can be written in 8-bit units.

Address: ADCFnSGSTCR0: <ADCFn_base> + 480_H
ADCFnSGSTCR1: <ADCFn_base> + 500_H
ADCFnSGSTCR2: <ADCFn_base> + 580_H
ADCFnSGSTCR3: <ADCFn_base> + 600_H
ADCFnSGSTCR4: <ADCFn_base> + 680_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	SGST
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 27.29 ADCFnSGSTCRx register contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	SGST	Scan Group Start Condition for starting scan group x: A value of 1 is written to SGST when SGACT = 0

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.23 ADCFnADTSTCRy — AD Timer y Start Control Register

ADCFnADTSTCRy is an 8-bit write-only register that controls the start of AD timer y. The register bits are always read as 0.

Access: This register can be written in 8-bit units.

Address: ADCFnADTSTCR3: <ADCFn_base> + 608_H
ADCFnADTSTCR4: <ADCFn_base> + 688_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ADTST
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 27.30 ADCFnADTSTCRy register contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	ADTST	A/D Timer Start Condition for starting A/D timer y: A value of 1 is written to ADTST when ADTACT = 0

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.24 ADCFnADTENDCRy — AD Timer y End Control Register

ADCFnADTENDCRy is an 8-bit write-only register that controls the end of the AD timer y. The register bits are always read as 0.

Access: This register can be written in 8-bit units.

Address: ADCFnADTENDCR3: <ADCFn_base> + $60C_H$
ADCFnADTENDCR4: <ADCFn_base> + $68C_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	ADTEND
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 27.31 ADCFnADTENDCRy register contents

Bit Position	Bit Name	Function
7 to 1	Reserved	When writing, write the value after reset.
0	ADTEND	A/D Timer End Condition for finishing A/D timer y: A value of 1 is written to ADTEND when ADTACT = 1

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.25 ADCFnSGCRx — Scan Group x Control Register

ADCFnSGCRx is an 8-bit readable/writable register that controls scan group x.

Access: This register can be read/written in 8-bit units.

Address: ADCFnSGCR0: <ADCFn_base> + 490_H
ADCFnSGCR1: <ADCFn_base> + 510_H
ADCFnSGCR2: <ADCFn_base> + 590_H
ADCFnSGCR3: <ADCFn_base> + 610_H
ADCFnSGCR4: <ADCFn_base> + 690_H

Value after reset: 00_H

- When x = 0 to 2

Bit	7	6	5	4	3	2	1	0

R/W	R	R/W	R/W	R/W	R	R	R/W	R/W

Table 27.33 ADCFnSGCRx register contents (x = 3, 4)

Bit Position	Bit Name	Function
7	ADTSTARTE	AD Timer Synchronization Start Enable 0: ADSTART is disabled. 1: ADSTART is enabled.
6	ADSTARTE	Scan Group Synchronization Start Enable 0: ADSTART is disabled. 1: ADSTART is enabled.
5	SCANMD	Scan Mode 0: Multicycle scan mode 1: Continuous scan mode In multicycle scan mode, scans are repeated as many times as specified in ADCFnSGMCYCRx. In continuous scan mode, scans are repeated with no limit of times.
4	ADIE	Scan End Interrupt Enable 0: ADInx is not output at the end of scan for SGx. 1: ADInx is output at the end of scan for SGx. ADIE of ADCFnSGCRx is independent of ADIE of ADCFnVCRj. For details, see **Section 27.4.15, Scan End Interrupt Request**.
3, 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	TRGMD[1:0]	Trigger Mode 0_H: Trigger input to SGx is disabled. Trigger input to the AD timer x is disabled. 1_H: The SGx_TRG hardware trigger is selected for the trigger input to SGx. Trigger input to the AD timer x is disabled. 2_H: The AD timer trigger x is selected for the trigger input to SGx. Trigger input to AD timer x is disabled. 3_H: The AD timer trigger x is selected for the trigger input to SGx. The SGx_TRG hardware trigger is selected for the trigger input to AD timer x.

CAUTIONS

1. To prevent malfunctions, make settings for SCANMD and ADIE of ADCDnSGCRx after making or confirming the following settings.
   (1) ADSTARTE of scan group x is 0 and TRGMD of scan group x is 0_H.
   (2) SGACT of scan group x is 0 (before the scan group is started).
2. If a trigger of lower-priority scan group is input to a scan group for which continuous scan mode is set (SCANMD = 1_H), the trigger is not accepted. Therefore, it is assumed that continuous scan mode is set to scan group 0.

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.26 ADCFnSGVCSPx — Scan Group x Start Virtual Channel Pointer

ADCFnSGVCSPx is an 8-bit readable/writable register that specifies the start pointer of a virtual channel.

Access: This register can be read/written in 8-bit units.

Address: ADCFnSGVCSP0: <ADCFn_base> + 494_H
ADCFnSGVCSP1: <ADCFn_base> + 514_H
ADCFnSGVCSP2: <ADCFn_base> + 594_H
ADCFnSGVCSP3: <ADCFn_base> + 614_H
ADCFnSGVCSP4: <ADCFn_base> + 694_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	VCSP[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 27.34 ADCFnSGVCSPx register contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is read. When writing, write the value after reset.
5 to 0	VCSP[5:0]	Start Virtual Channel Pointer These bits select the virtual channel from which the scan is to be started. When SGx is started, processing for the virtual channels from ADCFnSGVCSPx to ADCFnSGVCEPx is executed.

CAUTIONS

1. ADCFnSGVCSPx must be equal to or smaller than ADCFnSGVCEPx.
2. To prevent malfunction, perform settings of ADCFnSGVCSPx after the following settings and confirmation.
   (1) ADSTARTE of all scan groups is 0
   (2) TRGMD[0] of scan groups 0,1, 2 is 0_H and TRGMD[1:0] of scan groups 3, 4 is 0_H.
   (3) SGACT of all scan groups is 0 (before scan groups are started)
3. Do not set a value greater than the number of virtual channels provided.

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.27 ADCFnSGVCEPx — Scan Group x End Virtual Channel Pointer

ADCFnSGVCEPx is an 8-bit readable/writable register that specifies the end pointer of a virtual channel.

Access: This register can be read/written in 8-bit units.

Address: ADCFnSGVCEP0: <ADCFn_base> + 498_H
ADCFnSGVCEP1: <ADCFn_base> + 518_H
ADCFnSGVCEP2: <ADCFn_base> + 598_H
ADCFnSGVCEP3: <ADCFn_base> + 618_H
ADCFnSGVCEP4: <ADCFn_base> + 698_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	VCEP[5:0]					
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 27.35 ADCFnSGVCEPx register contents

Bit Position	Bit Name	Function
7, 6	Reserved	When read, the value after reset is read. When writing, write the value after reset.
5 to 0	VCEP[5:0]	End Virtual Channel Pointer These bits select the virtual channel from which the scan is to be ended. When SGx is started, processing for the virtual channels from ADCFnSGVCSPx to ADCFnSGVCEPx is executed.

CAUTIONS

1. ADCFnSGVCSPx must be equal to or smaller than ADCFnSGVCEPx.
2. To prevent malfunction, perform settings of ADCFnSGVCEPx after the following settings and confirmation.
   (1) ADSTARTE of all scan groups is 0
   (2) TRGMD[0] of scan groups 0,1, 2 is 0_H and TRGMD[1:0] of scan groups 3, 4 is 0_H.
   (3) SGACT of all scan groups is 0 (before scan groups are started)
3. Do not set a value greater than the number of virtual channels provided.

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.28 ADCFnSGMCYCRx — Scan Group x Multicycle Register

ADCFnSGMCYCRx is an 8-bit readable/writable register that specifies the number of scan times in multicycle scan mode.

Access: This register can be read/written in 8-bit units.

Address: ADCFnSGMCYCR0: <ADCFn_base> + $49C_H$
ADCFnSGMCYCR1: <ADCFn_base> + $51C_H$
ADCFnSGMCYCR2: <ADCFn_base> + $59C_H$
ADCFnSGMCYCR3: <ADCFn_base> + $61C_H$
ADCFnSGMCYCR4: <ADCFn_base> + $69C_H$

Value after reset: 00_H

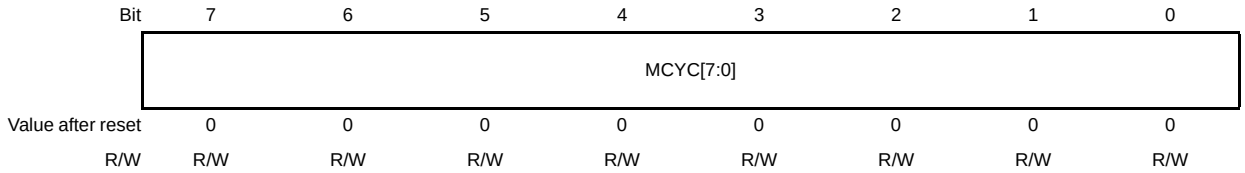

Table 27.36 ADCFnSGMCYCRx register contents

Bit Position	Bit Name	Function
7 to 0	MCYC[7:0]	Multicycle These bits specify the number of scan times in multicycle scan mode Number of scan times = MCYC[7:0] + 1 When SGx is started, scans are repeated for virtual channels from ADCFnSGVCSPx to ADCFnSGVCEPx as many times as specified in ADCFnSGMCYCRx.

CAUTION

To prevent malfunction, perform settings of ADCFnSGMCYCRx after the following settings and confirmation.

(1) ADSTARTE of all scan groups is 0

(2) TRGMD[0] of scan groups 0,1, 2 is 0_H and TRGMD[1:0] of scan groups 3, 4 is 0_H.

(3) SGACT of all scan groups is 0 (before scan groups are started)

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.29 ADCFnSGSRx — Scan Group x Status Register

ADCFnSGSRx is an 8-bit read-only register that indicates the status of scan group x.

Access: This register can be read in 8-bit units.

Address: ADCFnSGSR0: <ADCFn_base> + $4A4_H$
ADCFnSGSR1: <ADCFn_base> + 524_H
ADCFnSGSR2: <ADCFn_base> + $5A4_H$
ADCFnSGSR3: <ADCFn_base> + 624_H
ADCFnSGSR4: <ADCFn_base> + $6A4_H$

Value after reset: 00_H

- x = 0 to 2

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	SGACT	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 27.37 ADCFnSGSRx register contents (x = 0 to 2)

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read.
1	SGACT	Scan Group Status 0: There is no conversion in SGx pending. 1: There is a conversion in SGx pending. If this bit is 1, the status of SGx is either of the following: • trigger request is held pending • the conversion is ongoing • the conversion is held pending due to occurrence a higher priority conversion
0	Reserved	When read, the value after reset is read.

- x = 3, 4

Bit	7	6	5	4	3	2	1	0

Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 27.38 ADCFnSGSRx register contents (x = 3, 4)

Bit Position	Bit Name	Function
7 to 3	Reserved	When read, the value after reset is read.
2	ADTACT	A/D Timer Status 0: A/D timer x is in idle state. 1: A/D timer x is running
1	SGACT	Scan Group Status 0: There is no conversion in SGx pending. 1: There is a conversion in SGx pending. If this bit is 1, the status of SGx is either of the following: • trigger request is held pending • the conversion is ongoing • the conversion is held pending due to occurrence a higher priority conversion
0	Reserved	When read, the value after reset is read.

CAUTION

The SGSRx status flags will be set with a certain delay after the set event has occurred.

For the delay time refer to Section 27.4.9, Analog Input Sampling and Scan Group Processing Time.

Consider this behavior when reading the status of this bit.

Alternatively use the corresponding interrupt / interrupt status flag to monitor the conversion status.

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.30 ADCFnADTIPRy — AD Timer Initial Phase Register y

ADCFnADTIPRy is a 32-bit readable/writable register that sets the initial phase of A/D timer y.

Access: This register can be read/written in 32-bit units.

Address: ADCFnADTIPR3: <ADCFn_base> + 628_H
ADCFnADTIPR4: <ADCFn_base> + $6A8_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	ADTIP[20:16]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 27.39 ADCFnADTIPRy register contents

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is read. When writing, write the value after reset.
20 to 0	ADTIP[20:0]	A/D Timer Initial Phase These bits set the initial phase of A/D timer y. (1) After A/D timer y is started, ADCFnADTIPRy is loaded to A/D timer y and the timer counts down. (2) After A/D timer y becomes 0, A/D timer trigger y is output for one cycle, ADCFnADTPRRy is loaded to A/D timer y, and the timer counts down again. After that, (2) is repeated. For details, see **Section 27.4.6, Example of A/D Timer Operation**.

CAUTION

To prevent malfunction, perform ADCFnADTIPRy settings when ADTACT of scan group y is 0 (before A/D timer is started), ADTSTARTE of scan group y is 0, and TRGMD[1:0] of scan group y is not 3_H.

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.31 ADCFnADTPRRy — AD Timer Period Register y

ADCFnADTPRRy is a 32-bit readable/writable register that sets the cycle of A/D timer y.

Access: This register can be read/written in 32-bit units.

Address: ADCFnADTPRR3: <ADCFn_base> + $62C_H$
ADCFnADTPRR4: <ADCFn_base> + $6AC_H$

Value after reset: $001F\ FFFF_H$

Table 27.40 ADCFnADTPRRy register contents

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is read. When writing, write the value after reset.
20 to 0	ADTPR[20:0]	A/D Timer Cycle These bits set the cycle of A/D timer y. (1) After A/D timer y is started, ADCFnADTIPRy is loaded to A/D timer y and the timer counts down. (2) After A/D timer y becomes 0, A/D timer trigger y is output for one cycle, ADCFnADTPRRy is loaded to A/D timer y, and the timer counts down again. After that, (2) is repeated. For details, see **Section 27.4.6, Example of A/D Timer Operation**.

CAUTION

To prevent malfunction, perform ADTPPRy settings when ADTACT of scan group y is 0 (before A/D timer is started), ADTSTARTE of scan group y is 0, and TRGMD[1:0] of scan group y is not 3_H.

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.3.32 ADCFnULLMSRx — Scan Group x Upper-Limit/Lower-Limit Table Select Register

ADCFnULLMSRx is an 8-bit readable/writable register that controls scan group x.

Access: This register can be read/written in 8-bit units.

Address: ADCFnULLMSR0: <ADCFn_base> + $4B0_H$
ADCFnULLMSR1: <ADCFn_base> + 530_H
ADCFnULLMSR2: <ADCFn_base> + $5B0_H$
ADCFnULLMSR3: <ADCFn_base> + 630_H
ADCFnULLMSR4: <ADCFn_base> + $6B0_H$

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	ULS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 27.41 ADCFnULLMSRx register contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1, 0	ULS	Upper Limit/Lower Limit Table Select 0_H: Neither upper limit nor lower limit is checked. 1_H: Upper limit and lower limit are checked in ADCFnULLMTBR0. 2_H: Upper limit and lower limit are checked in ADCFnULLMTBR1. 3_H: Upper limit and lower limit are checked in ADCFnULLMTBR2. Upper limit and lower limit are checked by using the upper limit/lower limit table selected by ULS[1:0] when storing the A/D converted value in ADCFnDRj.

CAUTION

To prevent malfunction, perform settings of ADCFnULLMSRx after the following settings and confirmation.

(1) ADSTARTE of all scan groups is 0

(2)TRGMD[0] of scan groups 0, 1, 2 is 0_H and TRGMD[1:0] of scan groups 3, 4 is 0_H.

(3) SGACT of all scan groups is 0 (before scan groups are started)

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.4 Function

27.4.1 Examples of Normal AD Conversion Operation

27.4.1.1 Multicycle Scan Mode

The following figure shows an example of operation when converting four virtual channels by 2-cycle scan for scan group 0 in multicycle scan mode by using normal A/D conversion mode (CNVCLS[2:0] = 0_H).

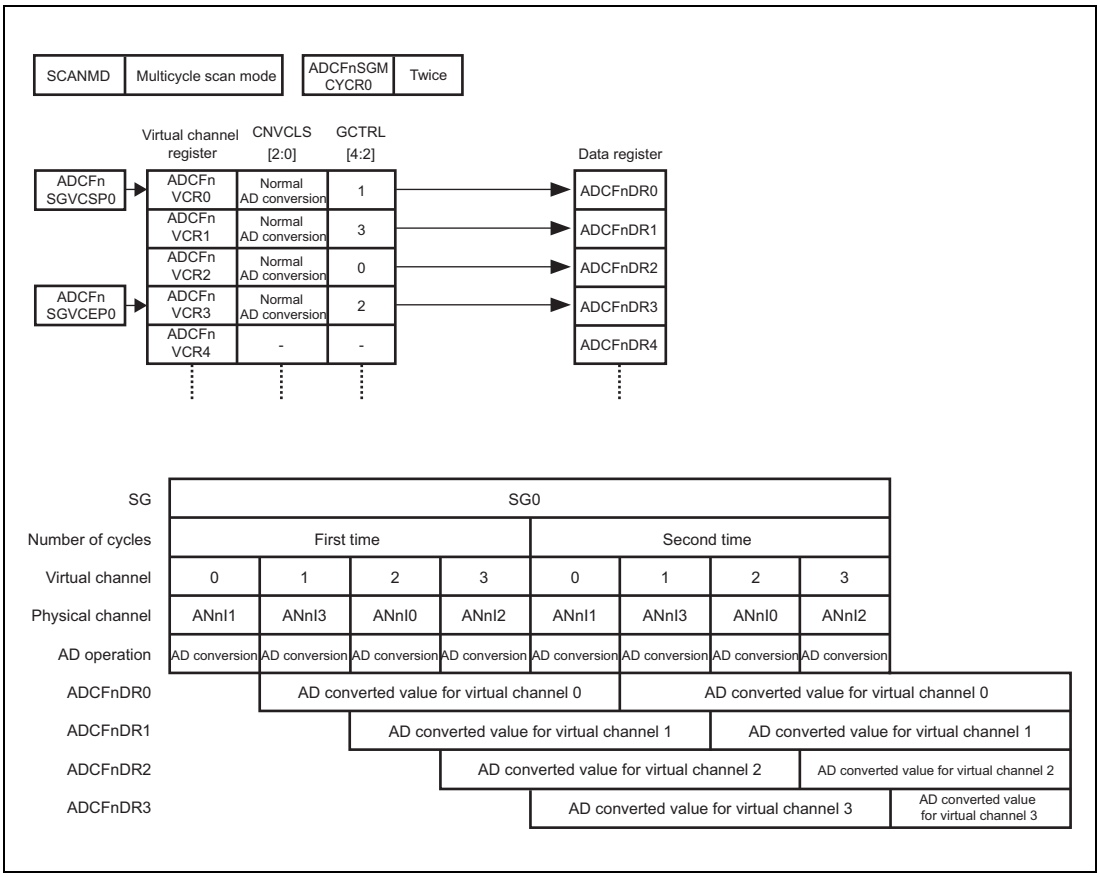

Figure 27.4 Example of Operation in Multicycle Scan Mode

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.4.1.2 Continuous Scan Mode

Figure 27.5 shows an example of operation when converting four virtual channels for scan group 0 in continuous scan mode by using normal A/D conversion mode (CNVCLS[2:0] = 0_H).

In this mode, if a trigger of a lower-priority scan group is input to a scan group for which continuous scan mode is set (SCANMD = 1_H), the trigger is not accepted. Therefore, it is assumed that continuous scan mode is set for scan group 0.

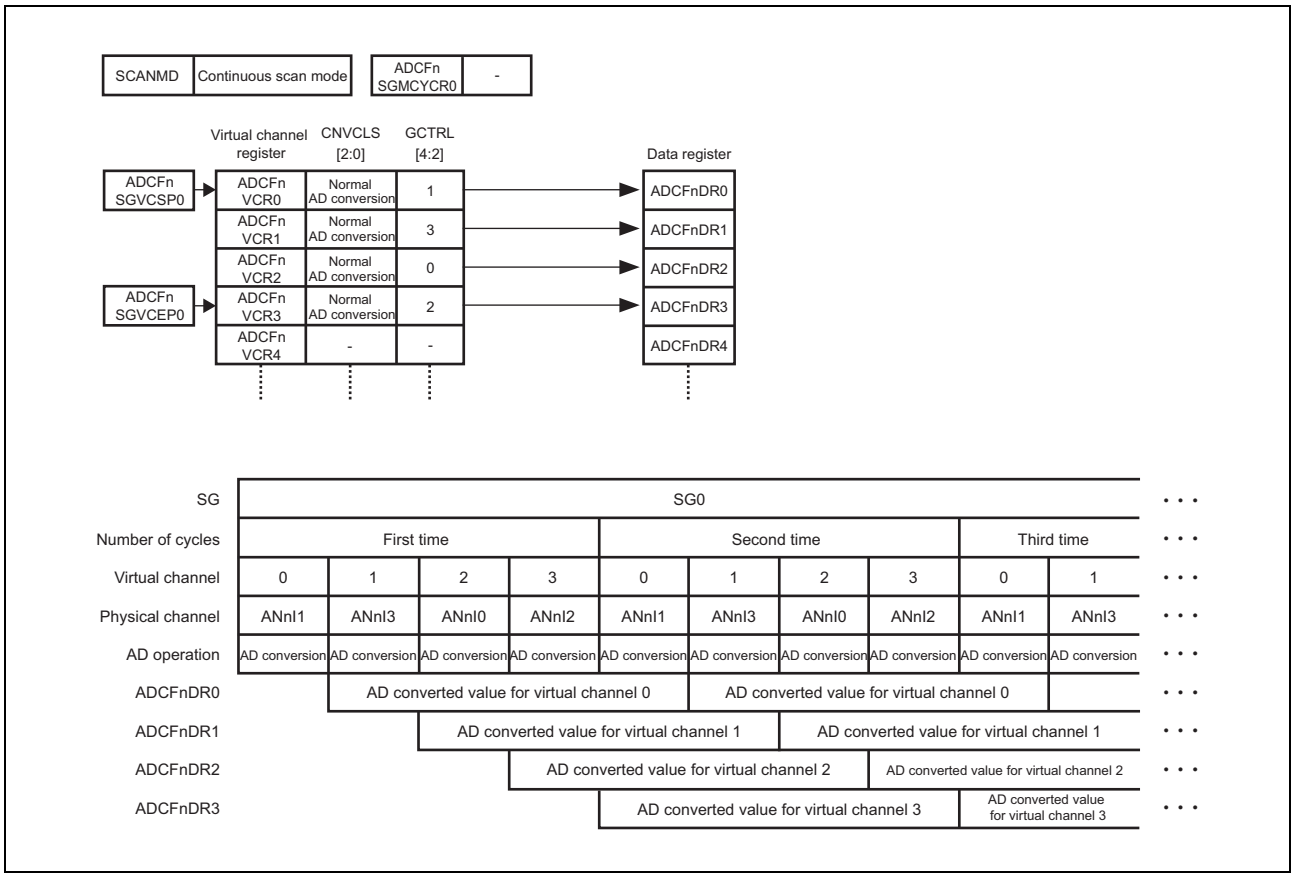

Figure 27.5 Example of Operation in Continuous Scan Mode

27.4.2 Example of Normal A/D Conversion Operation in Addition Mode

Figure 27.6 shows an example of operation when converting four virtual channels for scan group 0 by using normal A/D conversion (CLVCLS[2:0] = 4_H) in addition mode.

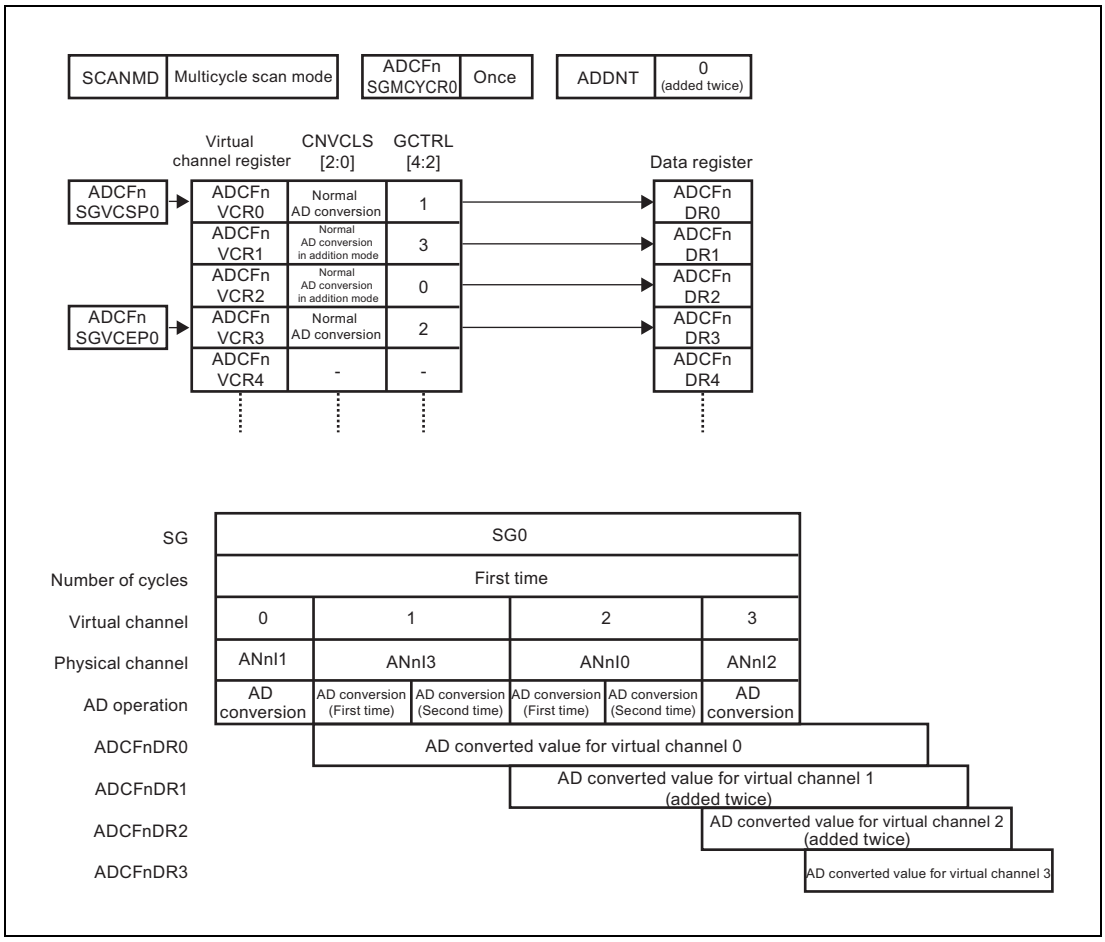

Figure 27.6 Example of Normal A/D Conversion Operation in Addition Mode

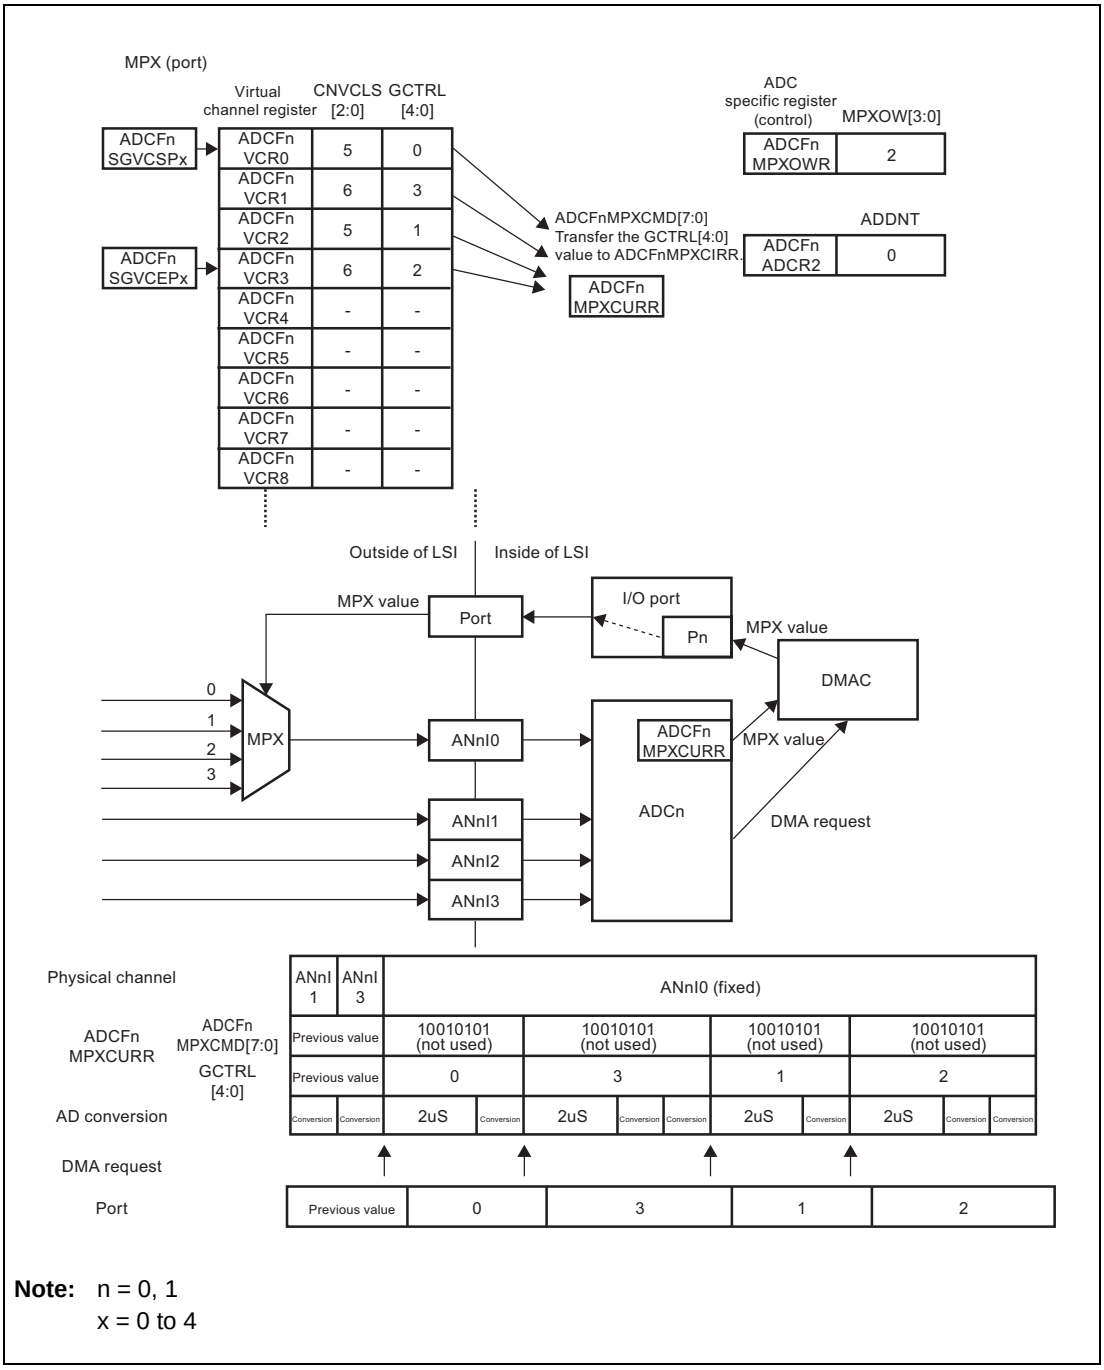
27.4.3 Example of Operation of External Analog Multiplexer

The following shows examples of operation of an external analog multiplexer using normal A/D conversion with the MPX mode (CNVCLS[2:0] = 5_H) or normal A/D conversion with the MPX mode of addition mode (CNVCLS[2:0] = 6_H).

27.4.3.1 Example of Using an External Analog Multiplexer (Port Output)

Figure 27.7 shows an example of port output using an external analog multiplexer.



Note: n = 0, 1
x = 0 to 4

Figure 27.7 Example of Using an External Analog Multiplexer (Port Output)

The input channel for the external analog multiplexer (MPX) is fixed to one dedicated physical input channel and is different for the implemented ADCFn modules:

- The physical input channel for MPX for ADCF0 is AN0I06
- The physical input channel for MPX for ADCF1 is AN1I00

27.4.3.2 Usage Notes for an External Analog Multiplexer

When you use an external MPX, conform to the following notes so as not to cause system crash.

Except for the exceptions below, set the MPX wait as follows:

- An MPX value is transferred at a port: Insert a wait of 1usec or more.

Exception 1) When an external MPX is used for one scan group

If an external MPX is used for SG0 when SUSMTD[1:0] = 1_H, or if an external MPX is used for any of SG from SG0 to SG3 when SUSMTD[1:0] = 2_H, set the MPX wait as follows:

- An MPX value is transferred at a port: Insert a wait of 1usec or more.

Exception 2) When an external MPX is used for multiple scan groups

If an external MPX is used when SUSMTD[1:0] = 1_H or 2_H, conform to the following notes:

- For the start virtual channel of each scan group, the external MPX should be disabled. (However, for the start virtual channel of the scan group whose priority is the lowest among the scan groups for which the external MPX is used, the MPXE bit can be set to 1, which does not cause problems.)

Furthermore, set the MPX wait as follows.

- An MPX value is transferred at a port: Insert a wait of 1usec or more.

27.4.4 Example of Synchronous Suspend and Resume Operation

Figure 27.8 shows an example of synchronous suspend and resume operation when a higher-priority SG interrupts a lower-priority SG.

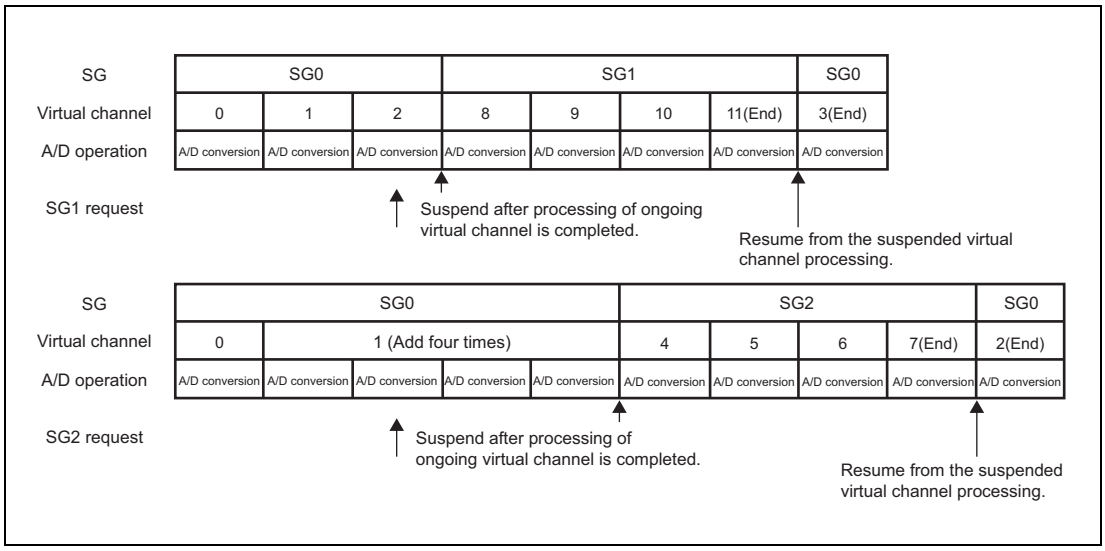


Figure 27.8 Example of Synchronous Suspend and Resume Operation

CAUTION

Priority of scan groups:

Low High

SG0 < SG1 < SG2 < SG3 < SG4

27.4.5 Example of Asynchronous Suspend and Resume Operation

Figure 27.9 shows an example of asynchronous suspend and resume operation when a higher-priority SG interrupts a lower-priority SG.

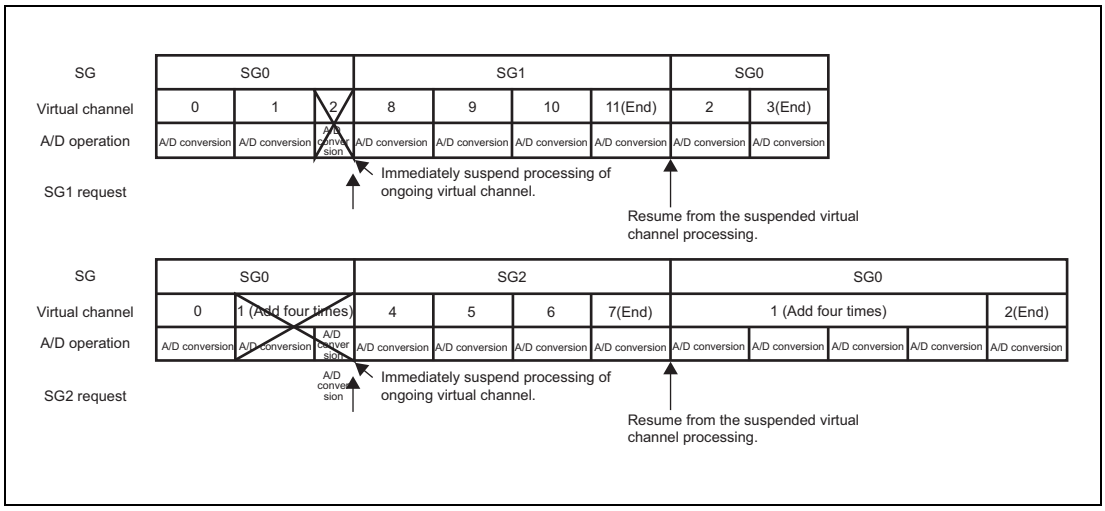

Figure 27.9 Example of Asynchronous Suspend and Resume Operation

CAUTION

Priority of scan groups:

Low High

SG0 < SG1 < SG2 < SG3 < SG4

27.4.6 Example of A/D Timer Operation

Figure 27.10 shows an example of A/D timer operation.

The A/D timer counts are based on the internal ADC clock ADCFCLK.

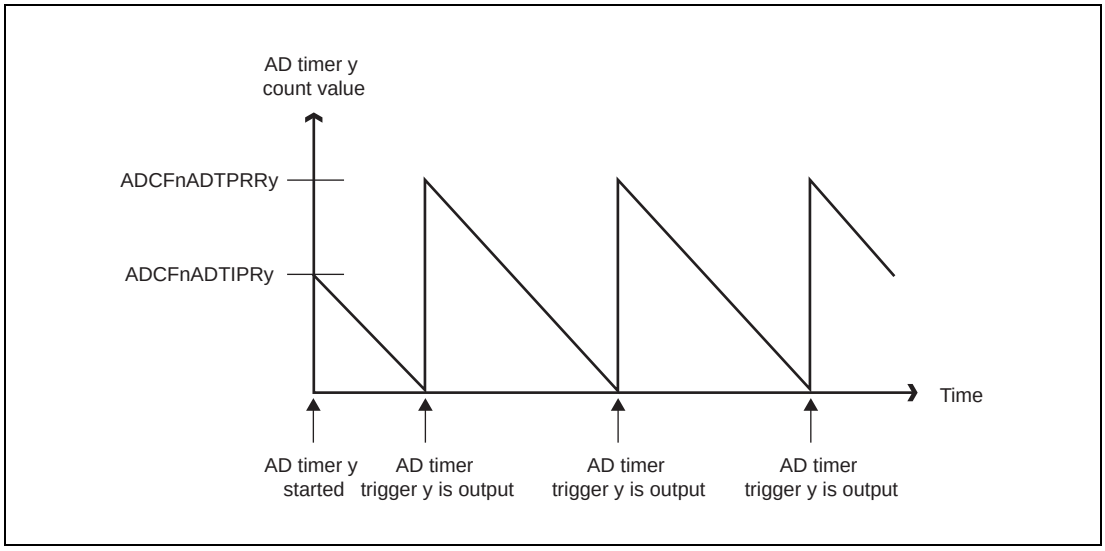

Figure 27.10 Example of A/D Timer Operation

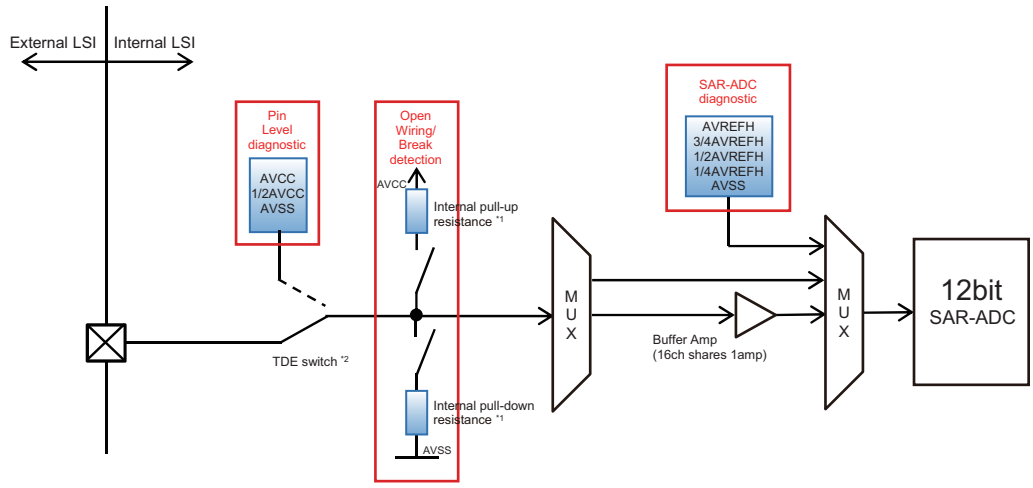
NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.4.7 Diagnostic Function

The ADCF is equipped with the following diagnostic functions.

- PIN level diagnostic function
- SAR-ADC diagnostic function
- Open wiring and break detection



Note 1. For Internal pull-up/down resistance data, see **Section 35.4.3, Analog Input Pins (ADCnIm) Characteristics**.

Note 2. For TDE switch resistance data, see **Section 35.7.3, A/D Converter Characteristics**.

Figure 27.11 diagnosis circuits

27.4.7.1 Pin Level Diagnostic Function

The pin level diagnostic function performs A/D conversion that is set to a different voltage for even-number physical channel groups and odd-number physical channel groups to check an abnormal path from the ANI.

The different voltage setting is made in ADCFnTDCR and can be detected by combination of AnVSS, AnVCC, and 1/2 × AnVCC.

Features and settings of the pin level diagnostic function of the ADCF are described below.

[Features]

1. Users can select desired physical channels to be tested.
2. AnVSS, AnVCC, or 1/2AnVCC is selectable as a diagnosis level.
3. Performing A/D conversion for SG0 to SG4 makes the pin level diagnostic function available.

[Settings]

1. Make settings according to the initial settings (**Figure 27.19, Initial Settings**).
2. Set CNVCLS[2:0] = 0_H and optional channels for GCTRL[4:0] in the virtual channel setting register ADCFnVCRj.

3. Set TDE = 1_H and optional pin level diagnosis level for TDLV[1:0] in the pin level diagnostic function setting register.
4. Make other settings required for A/D conversion according to the initial settings (**Figure 27.19, Initial Settings**).
5. Assert triggers of SG0 to SG4 and perform A/D conversion.

27.4.7.2 A/D Conversion Circuit Diagnostic Function

The A/D conversion circuit diagnostic function is used to verify that A/D conversion operates correctly.

The voltage value setting is made in GCTRL[4:0] when CNVCLS[2:0] = 3_H, and can be converted for AnVREFH × 1, AnVREFH × 3/4, AnVREFH × 1/2, AnVREFH × 1/4, and AnVSS.

Features and settings of the A/D conversion circuit diagnostic function of the ADCF are described below.

[Features]

1. AnVREFH × 1, AnVREFH × 3/4, AnVREFH × 1/2, AnVREFH × 1/4, or AnVSS is selectable as a diagnosis voltage level.
2. Performing A/D conversion for SG0 to SG4 makes the A/D conversion circuit diagnostic function available.

[Settings]

1. Make settings according to the initial settings (**Figure 27.19, Initial Settings**)
2. Set CNVCLS[2:0] = 3_H and optional diagnosis voltage level for GCTRL[4:0] in the virtual channel setting register ADCFnVCRj (j = 0 to 35).
3. Make other settings required for A/D conversion according to the initial settings (**Figure 27.19, Initial Settings**).
4. Assert triggers of SG0 to SG4 and perform A/D conversion.

CAUTION

When an injection current is applied on a pin that A/D conversion is operated just before using A/D conversion circuit diagnostic function, the accuracy of A/D conversion in the diagnostic function may be affected. So A/D conversion must be operated for a pin without injection current before using A/D conversion circuit diagnostic function.

NOTE

When the input voltage exceeds the supply voltage or fall below the ground voltage, injection current occurs.

(1) When both A/D conversion and A/D conversion circuit diagnostic is operated in the same SG, a pin of no injection current must be selected before A/D conversion circuit diagnostic.

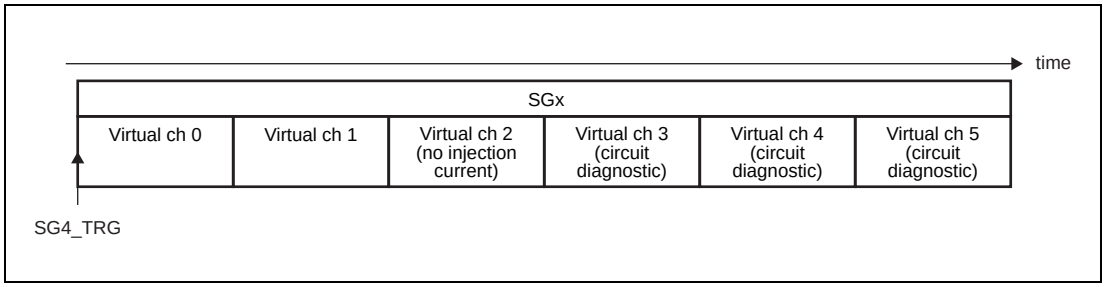


Figure 27.12 Example of SG with both A/D conversion and A/D conversion circuit diagnostic function in the same SG

(2) When a SG has higher priority than SG of A/D conversion circuit diagnostic, A/C conversion circuit diagnostic may be suspended and resumed by the operation of SG with higher priority. In this case, execute A/D conversion for a pin*1 without injection current at the last of SG with higher priority.

Note 1. Possible to use an unused pin instead of a pin of no injection current

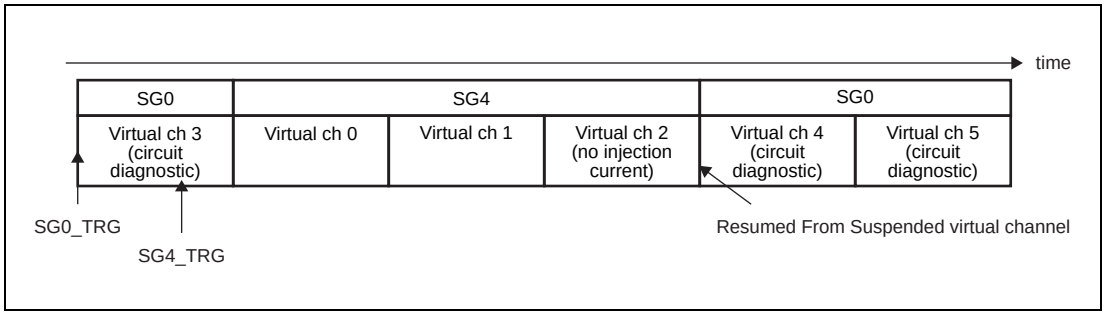

Figure 27.13 Example of SG with higher priority than SG of A/D conversion circuit diagnostic

27.4.7.3 Wiring-Break Detection Diagnostic Function

The wiring-break detection diagnostic function detects wiring-break of the ANI. The pull-down and pull-up methods are used to detect a wiring break. If a wiring break is present when using the pull-down method, the A/D conversion result is lowered to and kept at approximately 0 V, which is the prescribed minimum level, which indicates that a wiring break has occurred. If a wiring break is present when using the pull-up method, the A/D conversion result is raised to and kept at approximately AnVCC, which is the prescribed maximum level, which indicates that a wiring break has occurred. The pull-up and pull-down is active during the sampling time tSPL. And During the conversion time tSAR the resistors are disconnected.

[Feature]

1. Users can select desired physical channels for which wiring-break is to be detected.

[Settings]

1. Make settings according to the initial settings (**Figure 27.19, Initial Settings**).
2. Set CNVCLS[2:0] = 0_H PDE to 1_H, PUE to 0_H, and optional channels for GCTRL[4:0] in the virtual channel setting register ADCFnVCRj (j = 0 to 35)

3. Set CNVCLS[2:0] to 0_H, PDE to 0_H, PUE to 1_H, and specify the physical channels set in step 2 for GCTRL[4:0] in virtual channel setting registers ADCFnVCR(j+1) (j = 0 to 35).
4. Set CNVCLS[2:0] to 0_H, PDE to 0_H, PUE to 0_H, and specify the physical channels set in step 2 for GCTRL[4:0] in virtual channel setting registers ADCFnVCR (j + 2) (j = 0 to 35).
5. Assert the corresponding triggers of SG0 to SG4, and then perform regular A/D conversion based on the settings specified in the ADCFnVCRj to ADCFnVCR (j + 2) registers.
6. The CPU compares the result of A/D conversion performed based on ADCFnVCRj (pull-down method) and the result of A/D conversion performed based on ADCFnVCR (j + 1) (pull-up method), compares the result of A/D conversion performed based on ADCFnVCR (j + 1) (pull-up method) and the result of A/D conversion performed based on ADCFnVCR (j + 2) (regular A/D conversion result), and then determines whether or not a wiring break has occurred.

NOTE

This function charge/discharge external capacitor. The next conversion need to consider signal settling time.

To prevent misdetection of wire-break of the ANI, the analog input need to be kept constant voltage level during wiring-break detection diagnosis.

27.4.8 ADC conversion time

Below table shows the ADC conversion time under different internal clock frequency. For more details see clock chapter.

Table 27.42 ADC conversion time

ADCFCLK	Total conversion time
40 MHz (when CPU clock is 240MHz/160MHz)	1.00 µs
30 MHz (when CPU clock is 120MHz)	1.33 µs

27.4.9 Analog Input Sampling and Scan Group Processing Time

ADCF has embedded-sample & hold circuit. After SGST bit of ADCFnSGCRx is set to 1 and scan group start delay time (t_D) has passed, the ADC executes sampling and then starts sequential compare transition processing.

Scan group processing time (t_{SG}) includes scan group start delay time (t_D), sampling time (t_{SPL}), sequential compare conversion processing time (t_{SAR}), and scan group end delay time (t_{ED}). **Table 27.43, Scan Group Processing Time** shows scan group processing time.

In multicycle scan mode, the scan group processing time (t_{SG}) can be calculated in the formula below when i = the number of virtual channels and j = the number of multicycles.

$t_{SG} = t_D + (t_{SPL} + t_{SAR}) \times i \times j + t_{ED}$

1st cycle scan in continuous scan mode: $t_D + (t_{SPL} + t_{SAR}) \times i$

2nd and onward scan in continuous scan mode: $(t_{SPL} + t_{SAR}) \times i$

Table 27.43 Scan Group Processing Time

Item	Symbol	Period	Unit
Scan group start delay time	t_D	(2 to 4) × Pϕ + 5 × Iϕ	Pϕ (CLK_LSB) Iϕ (ADCFCLK)
Sampling time	t_{SPL}	18 × Iϕ	Iϕ (ADCFCLK)
Sequential compare conversion processing time	t_{SAR}	22 × Iϕ	Iϕ (ADCFCLK)
Scan group end delay time	t_{ED}	(2 to 4) × Iϕ + 3 × Pϕ	Pϕ (CLK_LSB) Iϕ (ADCFCLK)
Scan group processing time	t_{SG}	47 × Iϕ + 5 × Pϕ to 49 × Iϕ + 7 × Pϕ	Pϕ (CLK_LSB) Iϕ (ADCFCLK)

27.4.10 Hardware Trigger Functions

For each scan group x a trigger input SGx_TRG is provide, that starts the conversion of the respective scan group's channels.

The scan group conversion trigger signals SGx_TRG can be generated by several sources:

- Scan groups SG0 to SG4
  External trigger signals ADTRGn.
  For details about the connected trigger signals see **Section 26, Peripheral Interconnect (PIC)**.
- Scan groups SG3 to SG4
  SG3, SG4 can be started by A/D timer
  AD time can be started by the trigger signals from PIC

The external trigger signals ADCFnTRGx are passed through digital noise filters to eliminate noise and signal glitches.

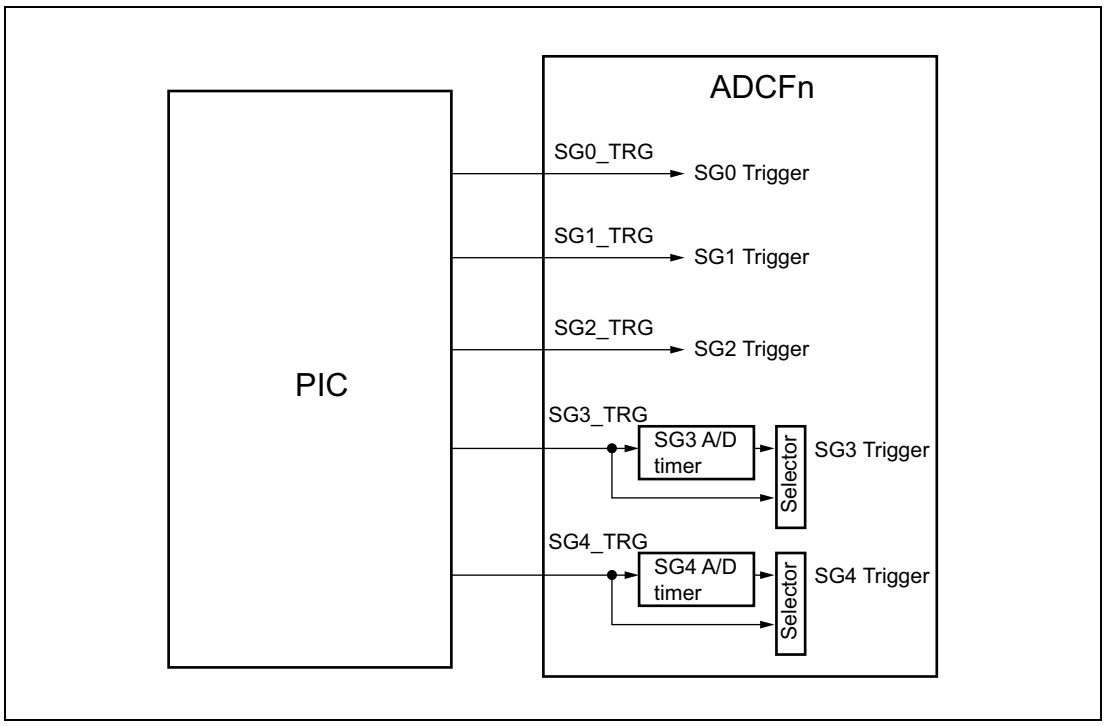

Figure 27.14 Outline of A/D Converter Hardware Trigger Selection

27.4.11 Starting a Scan Group by Using a Hardware Trigger

Scan group x can be started by using an input from hardware trigger SGx_TRG. To start scan group x by an input from hardware trigger SGx_TRG, set TRGMD in ADCFnSGCRx to 1_H. When the selected hardware trigger SGx_TRG is input in this state, SGACT is set to 1. The timing since SGACT is set to 1 until scan group x is started is the same as the timing when SGST is set to 1 by a software trigger.

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

When an SGx start trigger is generated during scanning (ADCFnSGSRx.SGACT = 1) for same SGx, the SGx start trigger is ignored.

27.4.12 Starting a Scan Group by Using an A/D Timer Trigger

Scan group 3 or 4 can be started by using a trigger from A/D timer 3 or 4. To start scan group 3 or 4 by using a trigger from A/D timer 3 or 4, set TRGMD in ADCFnSGCR3 or ADCFnSGCR4 to 2_H. Furthermore, set ADTST of scan group 3 or 4 to 1 to start A/D timer 3 or 4.

When a timer trigger is input in this state, SGACT is set to 1. The timing since SGACT is set to 1 until scan group 3 or 4 is started is the same as the timing when SGST is set to 1 by a software trigger.

27.4.13 Starting A/D Timer by Using a Hardware Trigger

A/D timer 3 or 4 can be started by using a hardware trigger SG3_TRG or SG4_TRG input. To start A/D timer 3 or 4 by using a hardware trigger SG3_TRG or SG4_TRG input, set TRGMD in ADCFnSGCR3 or ADCFnSGCR4 to 3_H. When the selected external trigger is input in this state, A/D timer 3 or 4 starts. Furthermore, a trigger from A/D timer 3 or 4 starts scan group 3 or 4.

27.4.14 Monitoring Function by Using the A/D Conversion Monitor Pin

ADENDn can be used to monitor the processing timing of the virtual channel specified by ADCFnADENDP0.

Figure 27.15 shows the A/D conversion monitor timing.

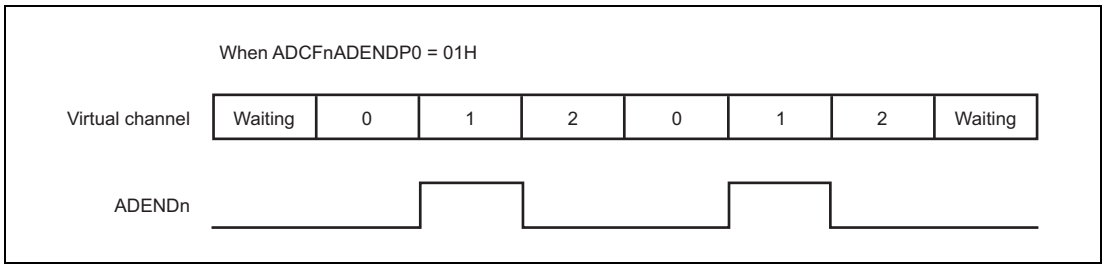

Figure 27.15 A/D Conversion Monitor Timing

CAUTION

If the high-level voltage is output from ADENDn in a lower-priority scan group and a higher-priority scan group suspends (asynchronous suspend) the processing of the lower-priority scan group, the low-level voltage is output from ADENDn. Since the suspended virtual channel processing for the lower-priority scan group resumes after that, the high-level voltage is output again from ADENDn.

27.4.15 Scan End Interrupt Request

Scan group x can issue a scan end interrupt request (ADInx) to the INTC. When ADIE in ADCFnSGCRx is set to 1, ADInx can be output after the SGx scan ends. When ADIE in ADCFnSGCRx is set to 0, the ADInx output at the end of the SGx scan can be disabled. When ADIE in ADCFnVCRj is set to 1, ADInx can be output when A/D conversion for virtual channel j in SGx ends. When ADIE in ADCFnVCRj is set to 0, the ADInx output at the end of the A/D conversion for virtual channel j in SGx can be disabled. The setting of ADIE in ADCFnSGCRx is independent of the setting of ADIE in ADCFnVCRj.

Example 1) A scan is executed for virtual channel 0 or 1 in SG0 when ADIE in ADCFnSGCR0 is 0, ADIE in ADCFnVCR0 is 1, and ADIE in ADCFnVCR1 is 0.
ADIn0 is output when A/D conversion ends for virtual channel 0.

Example 2) A scan is executed for virtual channel 0 or 1 in SG0 when ADIE in ADCFnSGCR0 is 0, ADIE in ADCFnVCR0 is 1, and ADIE in ADCFnVCR1 is 1.
ADIn0 is output when A/D conversion ends for virtual channel 0 and virtual channel 1.

Example 3) A scan is executed for virtual channel 0 or 1 in SG0 when ADIE in ADCFnSGCR0 is 1, ADIE in ADCFnVCR0 is 0, and ADIE in ADCFnVCR1 is 0.
ADIn0 is output when a scan ends (at the end of A/D conversion for virtual channel 1).
ADIn0 is output at each two cycles (or more) in multicycle scan mode, or each time a scan ends (at the end of A/D conversion for virtual channel 1) in continuous scan mode.

Furthermore, the DMAC can be activated when ADInx occurs.

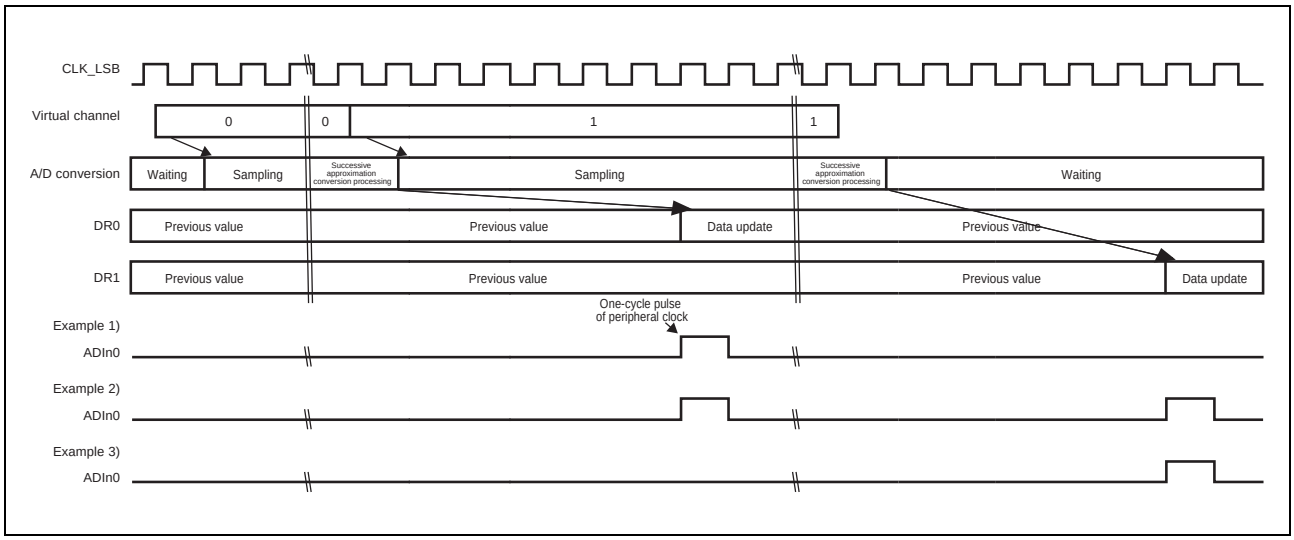

Figure 27.16 Scan Conversion End Interrupt Occurrence Timing

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.4.16 MPX Interrupt Request

The ADC can issue an MPX request (ADMPXIn) to the DMAC. ADMPXIn is generated when a virtual channel for which CNVCLS[2:0] in ADCFnVCRj is set to 5_H or 6_H is started.

The DMAC can be activated when ADMPXIn occurs.

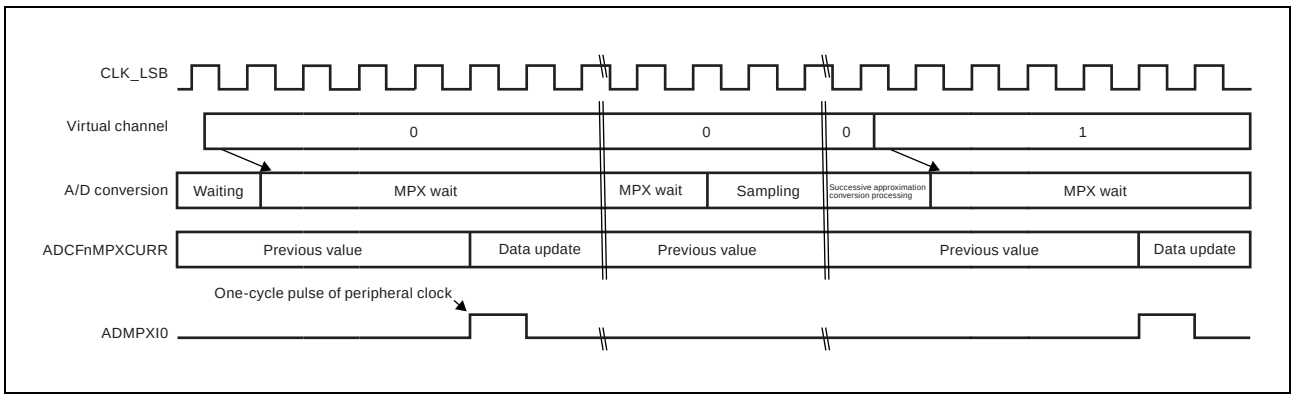

Figure 27.17 Example of an MPX Interrupt Occurrence

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.4.17 A/D Error Interrupt Request and A/D Parity Error Notification

The ADCF can issue an A/D error interrupt request (ADEm) to the INTC and an A/D parity error notification (ADPEm) to the error control module (ECM). For an error source for which ULEIE, OWEIE, and IDEIE in ADCFnSFTCR is set to 1, the OR condition of the error source is issued as ADEm. For an error source for which ULEIE, OWEIE, and IDEIE in ADCFnSFTCR is set to 0, ADEm can be disabled. ADPEm is enabled when PEIE in ADCFnSFTCR is set to 1. ADPEm is disabled when PEIE in ADCFnSFTCR is set to 0.

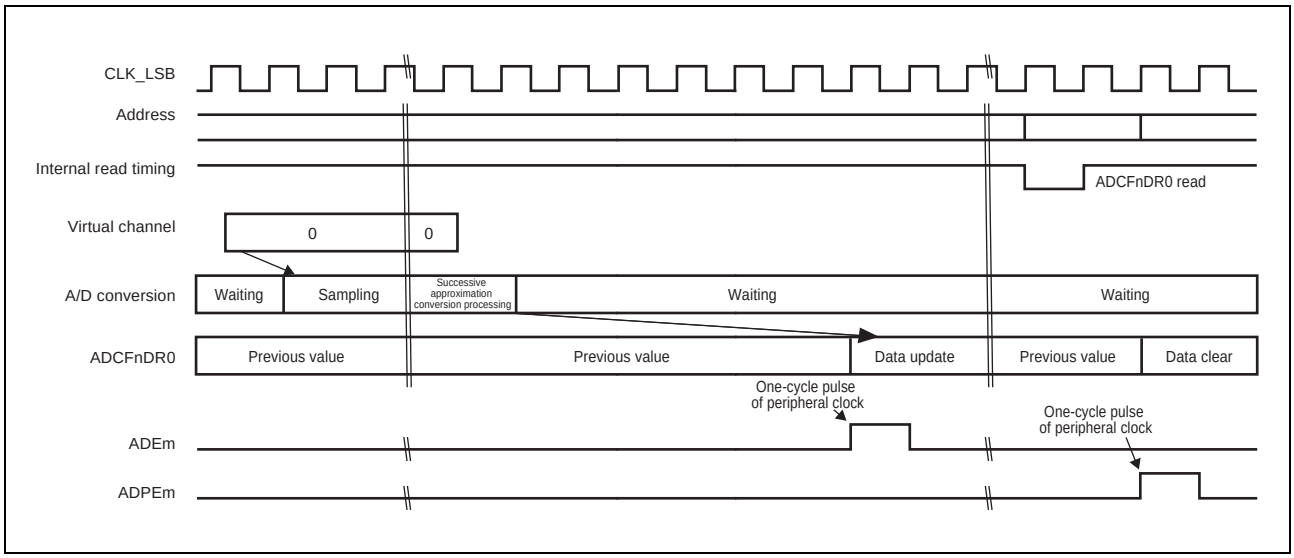

Figure 27.18 Example of an Occurrence of A/D Error Interrupt and A/D Parity Error Notification

NOTE

For the number of units and indices, see **Section 27.1.1, Number of Units**.

27.5 Operation

27.5.1 Initial Settings

AD conversion of the ADCF starts by setting the registers shown in **Figure 27.19**. For trigger input, see **Section 27.5.2, Trigger Input Flow**.

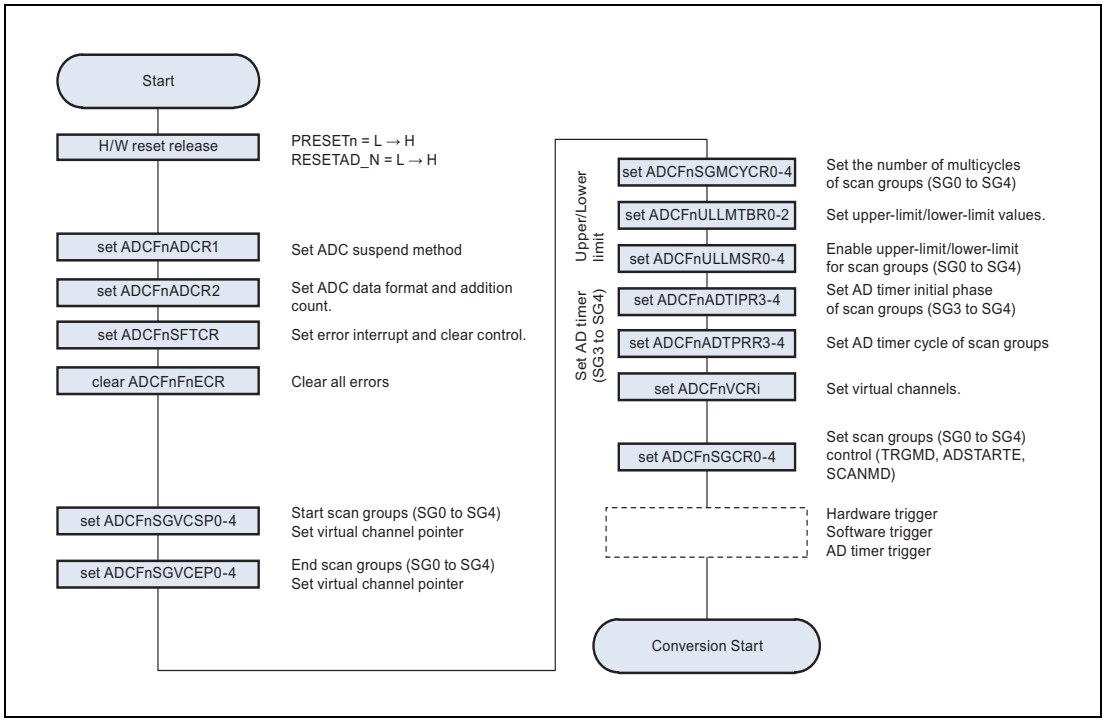

Figure 27.19 Initial Settings

27.5.2 Trigger Input Flow

A/D conversion start triggers of the ADCF include hardware triggers, software triggers, and A/D timer triggers. Scan group x (x = 0 to 4) supports the software trigger specified by ADSTART and SGST (SG0 to SG4), the hardware trigger of SGx_TRG (x = 0 to 4), and the A/D timer trigger (SG3 and SG4).

A/D conversion starts according to the trigger input flows shown in **Figure 27.20, Trigger Input Flow (SG0 to SG2)** and **Figure 27.21, Trigger Input Flow (SG3 to SG4)**, For the initial settings flow shown in these figures, see **Section 27.5.1, Initial Settings**.

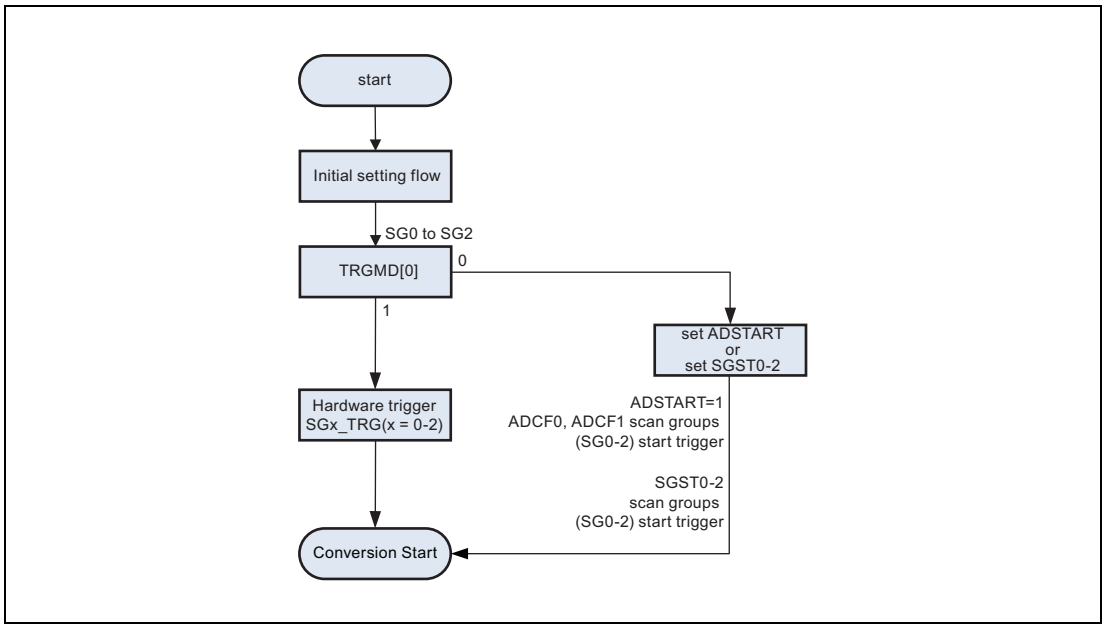

Figure 27.20 Trigger Input Flow (SG0 to SG2)

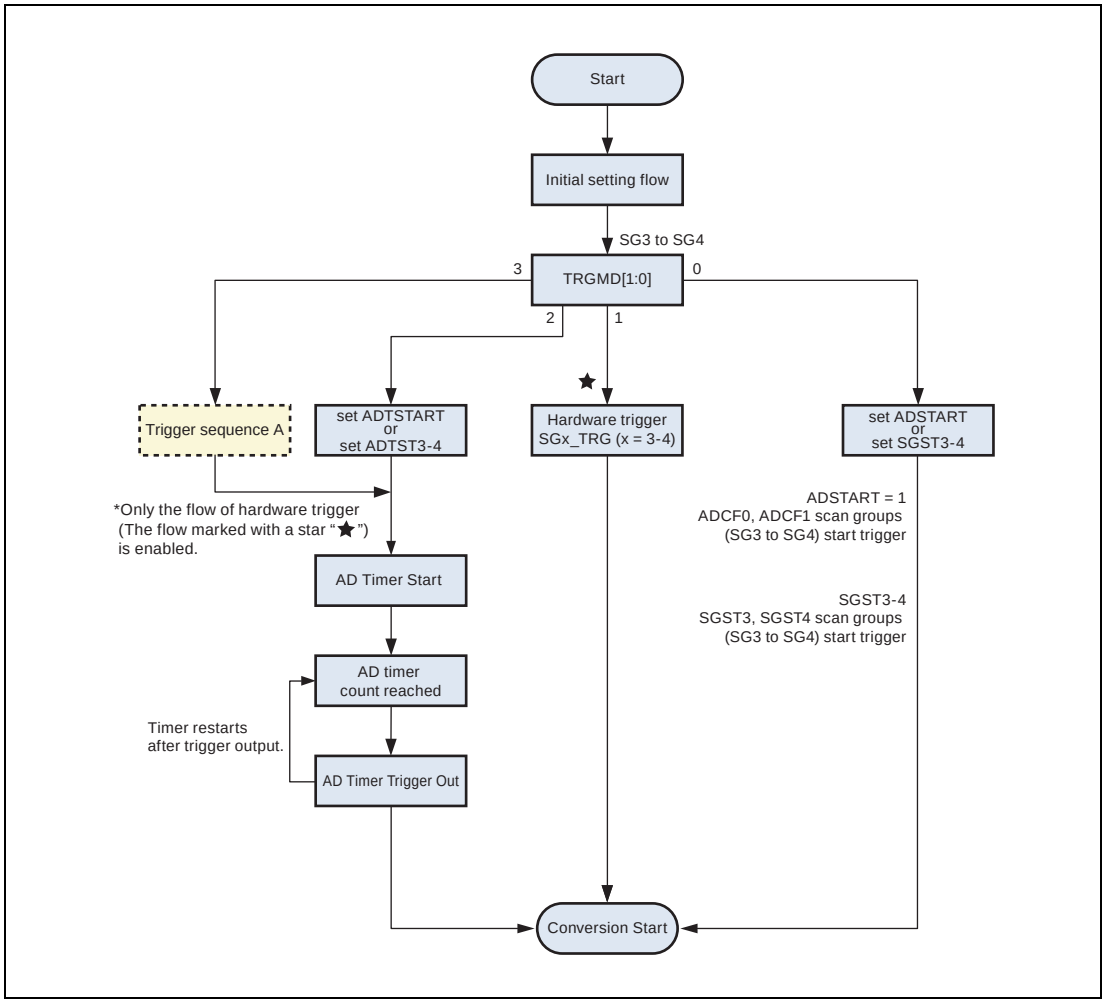

Figure 27.21 Trigger Input Flow (SG3 to SG4)

27.5.3 Terminating Procedure

The ADCF is forcibly terminated according to the processing flow shown in **Figure 27.22**.

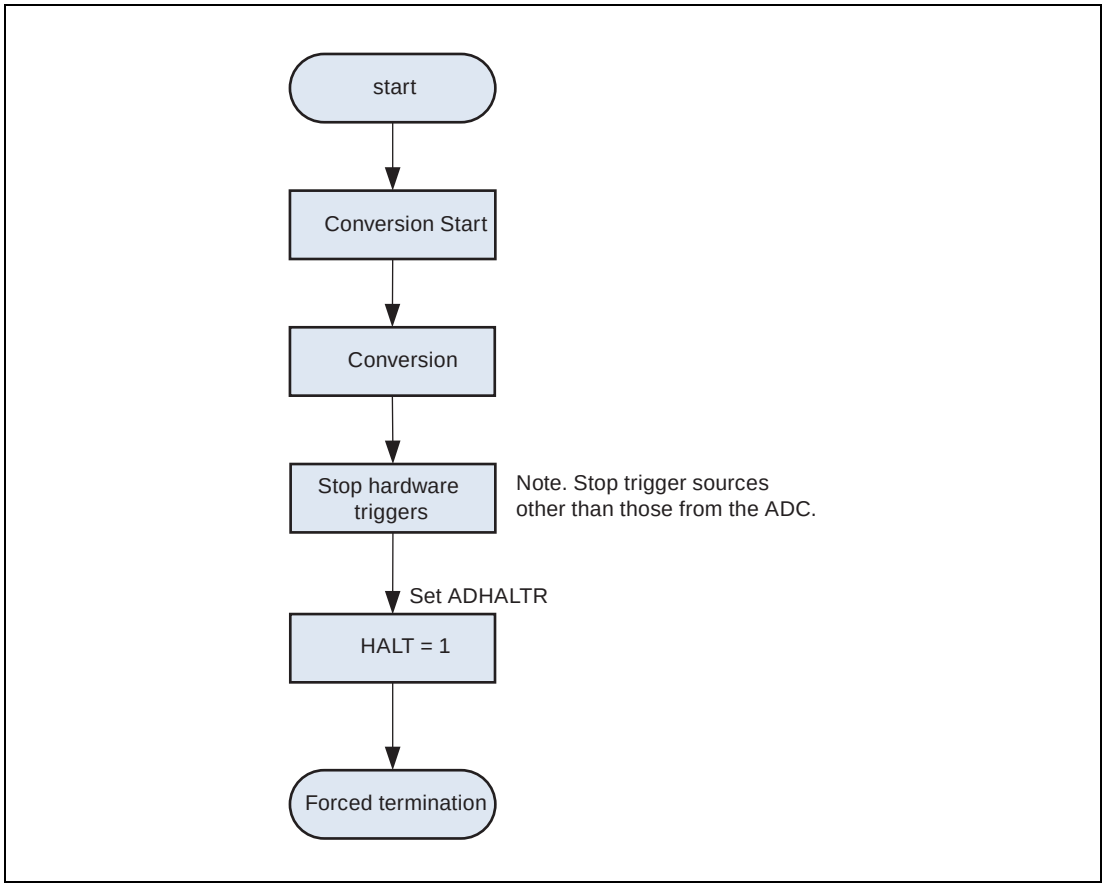

Figure 27.22 Terminating Procedure

27.5.4 Limited Reset and Module stand-by

The ADCF can be reset by limited reset from SYSCTRL. The Limited Reset is functionally equivalent to a hardware reset. Software must ensure that ADCF is halted. See **Section 27.5.3, Terminating Procedure**.

The ADCF clock can be disabled by the SYSCTRL module stand-by function. Software must ensure that ADCF is halted if module stand-by enable.

27.6 Definition of A/D Conversion Accuracy

A/D conversion accuracy is defined below.

- Resolution
  Number of digital output codes of the A/D converter
- Quantization error
  An error essentially contained in A/D converters, which is given as 1/2LSB (**Figure 27.23**).
- Offset error
  Deviation of the analog input voltage value from the ideal A/D conversion characteristics when the digital output changes from the minimum voltage value 000_H to 001_H. However, the quantization error is not included (**Figure 27.23**).
- Full-scale error
  Deviation of the analog input voltage value from the ideal A/D conversion characteristics when the digital output changes from FFE_H to FFF_H. However, the quantization error is not included (**Figure 27.23**)
- DNL (Differential nonlinear error)
  Deviation between the ideal digital output code width (Vq) and the actual digital output code width (Va), which is given as (Va – Vq)/Vq. However, the offset error, the full-scale error, and the quantization error are not included (**Figure 27.23**).
- INL (Integral nonlinear error)
  Deviation of the actual value from the ideal A/D conversion characteristics, from the zero voltage to the full-scale voltage, which is given as an integral of DNL from 000_H to a digital output code. However, the offset error, the full-scale error, and the quantization error are not included (**Figure 27.23**).
- Total overall error (TOE)
  Deviation between the digital value and the analog input value. The offset error, the full-scale error, the quantization error, DNL, and INL are included (**Figure 27.23**).

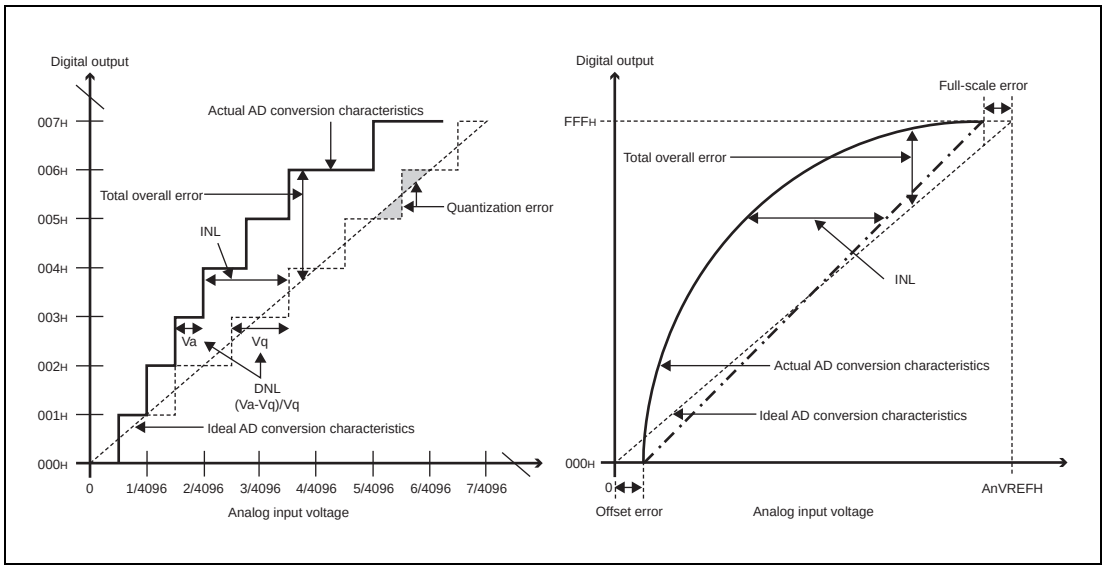

Figure 27.23 Definition of A/D Conversion Accuracy

27.7 Difference among P1M-C, P1H-C and P1H-CE

ADCFn module instance n = 0, 1 (refer to the table below for the different products)

- Physical channel index m
- Virtual channel index j

Table 27.44 Different specifications of ADCF

Section 28 Functional Safety

28.1 Overview

This chip is used for the automotive applications within a functional safety related context. Therefore the development according the relevant functional safety standard ISO26262 is considered. As this chip is intended for a broad range of chassis and non-chassis application with different environmental conditions and target functionality, the development is conducted based on a SEooC (Safety Element out of Context). Safety analysis based on ISO26262 such as FMEA, FTA and common cause failure analysis and safety implementations are conducted, and reports of each analysis and implemented measures will be provided to customer accordingly as ISO 26262 work products.

The 40-nm multi-core safety platform follows a structured approach as shown in basic safety architecture.

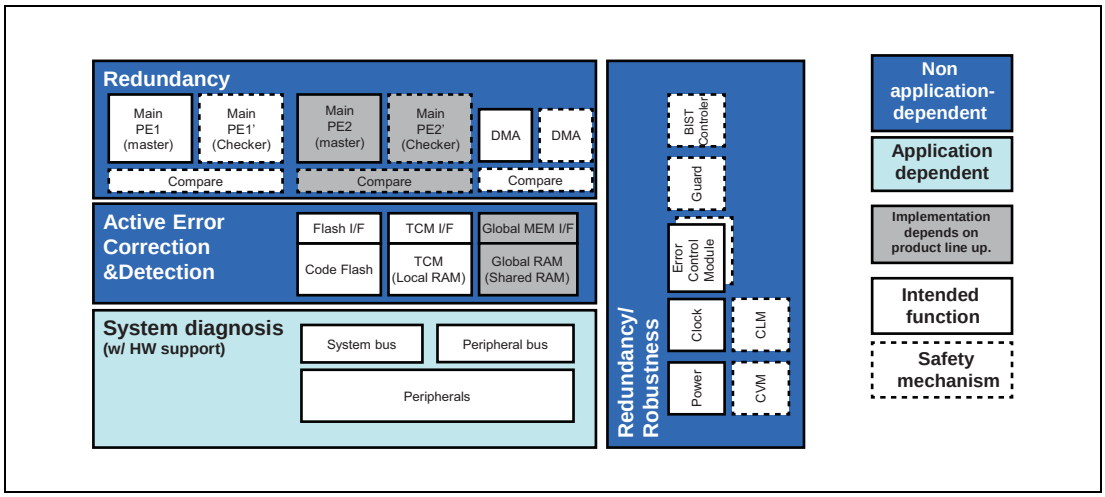

Figure 28.1 Basic safety architecture.

The platform can be categorized into application independent parts or dependent parts.

- Application independent parts includes the MCU parts
  - related to data processing i.e. CPU, DMA
  - related to data storage i.e. volatile and non-volatile memories
  - related to the MCU infrastructure common to all i.e. clock, reset and power supply
- Application dependent parts includes the MCU parts
  - related to interfaces to external. These are mainly the MCU peripherals, related busses and GPIO

P1M-C and P1H-C are developed according to safety plan which is compiled by product safety manager.

Based on MCU Technical Safety Concept and HW Safety Requirements point of view, Major safety mechanisms are listed as follows.

- Error Correction Code (ECC) and Error Detection Code (EDC)
- Lockstep Function of Redundant Data Processing Units (CPU, DMA) with compare units
- Memory Protection Unit (MPU) and Slave Guards for Processor Element (PEG), Internal Peripheral Modules (IPG), Global RAM (GRG) and Peripheral Bus (PBG)

- Field BIST at start-up test
- Error Control Module (ECM), for signaling error pin at failure detection by safety mechanisms
- Core Voltage Monitor (CVM)
- Clock Monitor (CLMA)
- Watch Dog Timer (WDTA)
- Data CRC (DCRB)
- Triple Modular Redundant (TMR) registers, for application independent parts to ensure robustness against transient faults caused by Single Event Effects (SEE)
- Safety Oriented Chip Layout

Safety work products can be referred to see how much these safety measures prevent risk from potential hardware faults. For details please contact your Safety Manager.

28.2 ECC and EDC

28.2.1 Overview

28.2.1.1 ECC

This product incorporates ECC for the following memories. The ECC enables detection and correction of errors of the data retained in the memories. The ECC also enables detection and correction of errors produced between the ECC encoder and memories; and memories and ECC decoder.

Table 28.1 ECC Overview.

Applicable Memory	Applicable Data Width [bits]	Operation upon Error Detection				
		Detection/ Correction	Notice to ECM	Error Status	Address Capture	Failure Insertion
Code flash	128	SEC-DED	Possible	Possible	Possible	Possible
Data flash Local RAM (CPU1, CPU2) Global RAM	32	SEC-DED	Possible	Possible	Possible	Possible
Instruction cache (data)	64	SED-DED	Possible	Possible	Possible	Possible
Instruction cache (tag)	32	SED-DED	Possible	Possible	Possible	Possible
RAM for DTS	32	SEC-DED	Possible	Possible	Possible	Possible
Peripheral RAM (32 bits)	32	SEC-DED	Possible	Possible*1	Possible*1	Possible*1
Data transfer path	32	SEC-DED	Possible	Possible	Possible	Possible

Note 1. Except for Ethernet.

ECC code

ECC code with a Hamming distance of minimum 4 is used. Combination of data and ECC code space excludes all 0s or all 1s for RAM and code flash.

Detection/Correction

SEC-DED: 1-bit errors can be detected and corrected, and 2-bit errors can only be detected.

SED-DED: 1-bit errors and 2-bit errors can only be detected.

Notice to ECM

An error detected can be notified to the ECM (Error Control Module).

Error Status

The status of an error detected is retained.

Address Capture

The address of an error detected is retained.

Failure Insertion

An ECC error can be intentionally caused to enable self-diagnosis of the ECC decoder operation.

28.2.1.2 Address Parity

This product incorporates address EDC (parity) for the following memories. The address EDC allows detection of errors during address decoding. The EDC also allows detection of errors produced at addresses between the parity encoder and memories.

Table 28.2 Address Parity Overview.

Applicable Memory	Parity Bit	Notice to ECM	Error Status	Address Capture	Failure Insertion
Code flash	1 bit	Possible	Possible	Possible	Possible

28.2.2 Code Flash ECC and Address Parity

28.2.2.1 Overview

The code flash ECC for accesses from PE1, PE2 and over System Interconnect (VCI2CFB) is summarized in the table below.

Table 28.3 Code Flash ECC

Item	Description
ECC error detection and correction	ECC error detection and correction can be either enabled or disabled. When enabled, either of the following settings can be selected. • ECC error detection and correction are carried out (2-bit error detection and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). When disabled, neither error detection nor correction is carried out. In the initial state, this function is enabled, and 1-bit error detection, correction and notification and 2-bit error detection and notification are carried out.
Address parity	Address parity check can be either enabled or disabled. Address parity is checked during address decoding. In the initial state, this function is enabled.
Error notification	Upon occurrence of an ECC error or parity error, it is notified to the Error Control Module. ECC Error: • Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. • Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. In the initial state, error notification is enabled upon detection of an ECC 2-bit error, and error notification is enabled upon detection of an ECC 1-bit error. Parity Error: • Error notification can be either enabled or disabled upon detection of an address parity error. In the initial state, error notification is enabled upon detection of an address parity error. Overflow Error: • Error notification can be either enable or disable upon detection of an address buffer overflow error for ECC 1-bit error In the initial state, error notification is enabled upon detection of an address buffer overflow error. The error notification signal is issued to the ECM, where an ECC 2-bit error and an address parity error are handled as one source, and an ECC 1-bit error and overflow error are handled as one source, respectively. An ECC 1-bit error signal is always issued to the ECM, even when the ECC-1bit error address is already sotred in the error address buffer.
Error status	A status register is provided, which indicates the statuses of ECC 2-bit error detection, ECC 1-bit error detection, and address parity error detection. A four-stage buffer is provided for 1-bit errors. An one-stage buffer is provided for 2-bit error and the buffer is shared for parity error. The status register indicates the state of each stage. The error status can be cleared using the clear register.
Address capture	The address is captured when an ECC 2-bit error, an ECC 1-bit error, or an address parity error is detected. The error status serves as the enable bit of the capture address.

28.2.2.2 List of Registers

Table 28.4 List of Registers

Address	Symbol	Register Name	R/W	Value after reset	Access Size	PBG	Other Protection
FFC6 2000_H	UCFERRINT	FLI (Code-Flash) Data and Address Error Information Control Register	R/W	0000 0047_H	32/16/8	APBGRD_ PFSS1.SP4	—

Note 1. P1H-CE and P1H-C devices only. P1M-C device doesn't have these registers.

28.2.2.3 Details of Registers

(1) UCFERRINT — FLI (Code-Flash) Data and Address Error Information Control Register

UCFERRINT register controls whether error information is reported to ECM, when data ECC 2-bit error, data ECC 1-bit error, ECC 1-bit error overflow, and address parity error are detected by Code Flash access from PE1, PE2 or accesses over the System Interconnect to Code Flash.

Access: UCFERRINT can be read/written in 32/16/8-bit units.

Address: FFC6 2000_H

Value after reset: 0000 0047_H

Table 28.5 UCFERRINT register contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6	SEOVFIE	ECC 1bit error overflow report enable bit Overflow report control bit when 1bit error overflow flag (SERROVF) in UCFOVFSTR register is set. 0: ECC 1-bit error overflow report disabled 1: ECC 1-bit error overflow report enabled
5 to 3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2	APEIE	Address parity error report enable bit Control error report of address parity error detection when address parity check is enabled. 0: Address parity error report disabled 1: Address parity error report enabled
1	DEDIE	ECC 2-bit error report enable bit Control error report of 2-bit error detection when ECC error detection/correction is enabled 0: ECC 2-bit error report disabled 1: ECC 2-bit error report enabled
0	SEDIE	ECC 1-bit error report enable bit Control error report of 1-bit error detection when ECC error detection/correction is enabled 0: ECC 1-bit error report disabled 1: ECC 1-bit error report enabled

(2) UCFSERSTCLR — FLI (Code-Flash) ECC SED Status Clear Register

UCFSERSTCLR register is used to clear SEDF[0:3] in UCFSERSTR, SERROVF in UCFOVFSTR, and error address in UCFnSEDADR (n = 1 to 4). This is write only register and read value is always “0”. UCFSERSTCLR register has a lower priority than a set factor. Priority is given to a set factor when UCFSERSTCLR and a set factor compete. A set factor means a trigger of setting SEDF[0:3] in UCFSERSTR, setting SERROVF in UCFOVFSTR, or capturing an error address in UCF[1:4]SEDADR.

Access: UCFSERSTCLR can be written only in 32/16/8-bit units.

Address: FFC6 2004_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

3 to 0	SSTCLR[3:0]	1-bit error flag clear n th 1: All 1-bit error flag clear UCFSERSTR.SEDFn, UCFOVFSTR.SERROVF, UCFnSEDADR.SEADR

(3) UCFDERSTCLR — FLI (Code-Flash) ECC DED/Address Parity Error Status Clear Register

UCFDERSTCLR register is used to clear DEDF and APEF in UCFDERSTR and error address in UCFDEDADR. This is write only register and read value is always “0”. UCFDERSTCLR register has a lower priority than a set factor. Priority is given to a set factor when UCFDERSTCLR and a set factor compete. A set factor means a trigger of setting APEF/DEDF in UCFDERSTR.

Access: UCFDERSTCLR can be written only in 32/16/8-bit units.

Address: FFC6 2008$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31 to 1	Reserved	When writing, write the value after reset.
0	DSTCLR	1: All 2-bit error flag clear UCFDERSTR.APEF, UCFDERSTR.DEDF, UCFDEDADR.DEADR

(4) UCFOVFSTR — FLI (Code-Flash) Error Count Overflow Status Register

UCFOVFSTR register monitor if error overflow occurs. Overflow occurs when a SED with the error address never captured is detected in the case that ECC 1-bit error status register is full. If the ECC 1-bit error status register is full and the error address is the same as the one of the error addresses already captured, this flag is not set. SERROVF flag is cleared by system reset, or cleared when at least one of SSTCLR[0:3] in UCFSERSTCLR register is asserted.

Access: UCFOVFSTR can be read in 32/16/8-bit units.

Address: FFC6 200C$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 28.8 UCFOVFSTR register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is read.
0	SERROVF	1-bit error overflow flag This error flag is set if the followings occur. • A SED occurrence when all bits (SEDF[0:3]) of ECC 1-bit error status register (UCFSERSTR) are set. • If the ECC 1-bit error status register is full and the error address is the same as one of the error addresses already captured, this flag is not set.

Note: As the overflow flag, only SED flags are prepared. Because DED is prepared for only one error address buffer, an overflow flag for DED is not necessary.

(5) UCFSERSTR — FLI (Code-Flash) ECC SED Status Register

UCFSERSTR is the error monitor register for 1-bit ECC error. Each error flag is “0”and when a new error occurs, an error status flag is set. An error flag is set at the lowest number empty bit of UCFSERSTR (e.g. If SEDF[0][1][3] have been set to “1” and all other bits have been empty, a next flag is set to SEDF[2].). If multiple SED causes are detected simultaneously and there are empty bits sufficiently, detected SEDs are all set (e.g. if a SED and another SED which occurs at a different address are detected simultaneously, both SEDFs are set.). However, if SEDs occur at a same address simultaneously, only one of errors is set according to the fixed priority. The priority order is the PE1, PE2, and VCI2CFB, the higher priority it has. (e.g. if a SED which is input from the PE1 path and an SED which is input from the PE2 path are detected simultaneously and those occur at the same address, only SEDF from the PE1 path is set and SEDF from the PE2 path is not set.) And also, an error address which has already captured in UCFnSEDADR (n = 1 to 4) must not be captured again. UCFSERSTR register is cleared by system reset or SSTCLR[0:3] in UCFSERSTCLR register.

Access: UCFSERSTR can be read in 32/16/8-bit units.

Address: FFC6 2020_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.9 UCFSERSTR register contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is read.
3 to 0	SEDF[3:0]	ECC 1-bit error monitor flag n th Condition for “0”: system reset or write “1” to SSTCLRn in UCFSERSTCLR Condition for “1”: ECC 1-bit error is detected.

(6) UCFDERSTR — FLI (Code-Flash) ECC DED/Address Parity Error Status Register

UCFDERSTR is the error monitor register for 2-bit ECC error and address parity error. All error flags are “0” and when a new error occurs, an error status flag is set. If multiple error causes which are input from each different slave port are detected simultaneously, only one of detected errors is set according to the fixed priority. The reason is that there is only one 2-bit error Address Register. The priority order is the PE1, PE2, and VCI2CFB. (e.g. if a DED which is input from the PE1 path and an APE which is input from the PE2 path are detected simultaneously, only DEDF from the PE1 path is set and APEF from the PE2 path is not set.) If multiple error causes occur from same slave port simultaneously, detected errors are all set. (e.g. if DED and APE are simultaneously input from the PE1 path, both DEDF and APEF are set.) UCFDERSTR register is cleared by system reset or DSTCLR in UCFDERSTCLR register.

Access: UCFDERSTR can be read in 32/16/8-bit units.

Address: FFC6 2030_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 28.10 UCFDERSTR register contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is read.
2	APEF	Address parity error monitor flag Condition to “0”: system reset or write “1” to DSTCLR in UCFDERSTCLR Condition to “1”: APEF/DEDF is all “0” and address parity error is detected.
1	Reserved	When read, the value after reset is read.
0	DEDF	ECC 2-bit error monitor flag Condition to “0”: system reset or write “1” to DSTCLR in UCFDERCTCLR Condition to “1”: DEDF is “0” and ECC 2-bit error is detected.

(7) UCFnSEDADR — FLI (Code-Flash) n ECC SED Address Register (n = 1 to 4)

UCFnSEDADR (n = 1 to 4) register is used to hold the address when an error is detected. Error address capture trigger is same as corresponding SEDF(n-1) set in UCFSERSTR. UCFnSEDADR (n = 1 to 4) is cleared by system reset or SSTCLR(n-1) in UCFSERSTCLR register.

Access: UCF*n*SEDADR can be read in 32-bit units.

Address: UCF1SEDADR: FFC6 2040$_H$
UCF2SEDADR: FFC6 2044$_H$
UCF3SEDADR: FFC6 2048$_H$
UCF4SEDADR: FFC6 204C$_H$

- Error address SED : (FLI (Code-Flash)_Base_Address[31:25] , SEDARn[24:4])

(8) UCFDEDADR — FLI (Code-Flash) ECC DED/Address Parity Error Address Register

UCFDEDADR register is used to hold the address when an error is detected. Error address capture trigger is same as corresponding APEF/DEDF set in UCFDERSTR. If this register has captured an error address, the register doesn't capture any more address before it is cleared. UCFDEDADR is cleared by system reset or DSTCLR in UCFDERSTCLR register.

Access: UCFDEDADR can be read in 32-bit units.

Address: FFC6 $20C0_H$

Value after reset: $0000\ 0000_H$

1	APTESTA	Address Parity Check TEST Bit (Bank-A) 0: Address Parity Not Inverted (Normal Mode) 1: Address Parity Inverted (Test Mode)
0	APARIDIS	Address Parity disable bit Setting Address Parity Check to enable/disable. 0: Address Parity Check is enable 1: Address Parity Check is disable

(10) CFECCCTL_VCI2CFBA/PE1/PE2 — FLI (Code-Flash) ECC Control Register

CFECCCTL_VCI2CFBA/PE1/PE2 register control the ECC error detection/correction and 1-bit error correction. Writing ECC control registers must be executed with PROT[1:0] = 01_B.

For the related access part, please consider this register:

CFECCCTL_VCI2CFBA: accesses over System Interconnect to Code Flash.

CFECCCTL_PE1 FLI: access from PE1

CFECCCTL_PE2 FLI: access from PE2.

Access: CFECCCTL_VCI2CFBA/PE1/PE2 can be read/written in 32/16-bit units.

Address:
CFECCCTL_VCI2CFBA: FFC6 2200_H

0	ECCDIS	ECC disable bit Setting ECC error detection/correction to enable/disable. 0: ECC error detection/correction is enable 1: ECC error detection/correction is disable

(11) CFSTSTCTL_VCI2CFBA/PE1/PE2 — FLI (Code-Flash) Sub-Test Control Register

The CFSTSTCTL registers are used for the ECC test (self-diagnosis). These registers are dedicated for code flash. After ECC test mode is enabled by setting ECCTST = 1, the ECC bits and address parity bit can be read directly.

For the related access part, please consider this register:

CFSTSTCTL_VCI2CFBA: accesses over system interconnect to Code Flash.

CFSTSTCTL_PE1 FLI: access from PE1.

CFSTSTCTL_PE2 FLI: access from PE2.

Access: CFSTSTCTL_VCI2CFBA/PE1/PE2 can be read/written in 32/16-bit units.

Address: CFSTSTCTL_VCI2CFBA: FFC6 22F0$_H$
CFSTSTCTL_PE1: FFC6 24F0$_H$
CFSTSTCTL_PE2: FFC6 26F0$_H$

31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15, 14	PROT[1:0]	Protection Bit 01: write is enable Other: write is disable These bits are always read as 0.
13 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	ECCTST	ECC test bit for Code Flash By setting ECC test mode bit to “1” (ECCTST = 1), CPU can read ECC bit and address parity bit directly. Then read data have parity bit on bit 9 and ECC bits on bit 0 to 8.

The CPU has a small data buffer. If an old value remains in this buffer, the correct value cannot be read even when the ECCTST bit is switched. When switching the ECCTST bit, be sure to clear the data buffer. For how to clear the data buffer, see **3.2.1.2 (7) Data Buffer Operation Function Registers**. This note is valid only for the CFSTSTCTL_PE1/PE2 register.

28.2.2.4 Test Function

Through appropriate register setting, the code flash data, ECC bits, and address parity bit can be read out.

(1) Reading code flash data

(a) Set the ECCDIS bit in the code flash ECC control register to 1 to disable ECC error detection and correction.

(b) When ECCDIS = 1, neither error detection nor correction proceeds when the code flash is read; the data output from the code flash is read unchanged.

How to exit this test mode:

(a) Set the ECCDIS bit in the code flash ECC control register to 0 to enable ECC error detection and correction.

(2) Reading the ECC and address parity bits

(a) Set the ECCDIS bit in the code flash ECC control register to 1 to disable ECC error detection and correction.

(b) Set the ECCTST bit in the code flash sub-test control register to 1 to set test mode.

(c) When the code flash is read, the ECC and address parity bits are read instead of the code flash data.

How to exit this test mode:

(a) Set the ECCDIS bit in the code flash ECC control register to 0 to enable ECC error detection and correction.

(b) Set the ECCTST bit in the code flash sub-test control register to 0 to set normal mode.

(3) Self-diagnosis of ECC check function

Self-diagnosis of the ECC decoder for the access ports is possible by reading data from ECC test area. For the detail of ECC test area, refer **Section 32, Flash Memory**.

(4) Self-diagnosis of address parity check function

(a) Set the APTESTA (or APTESTB) bit in the code flash address parity control register to 1 to invert parity bit.

(b) When code flash data on any address in bank A (or bank B) is read, a fault can be injected to the address parity checker and self-diagnosis of the address parity check function is enabled

How to exit this test mode:

(a) Set the APTETA (or APTESTB) bit in the code flash address parity control register to 0 to set normal mode.

NOTE

P1H-C (4MB), P1H-C (8MB): The test code can be fetched from e.g. Local RAM.
P1M-C: The test code has to be fetched from e.g. Local RAM.
Otherwise, a pre-fetching during the test will cause the occurrence of SYSERR exception due to the inverted address parity bit.

28.2.3 Data Flash ECC

28.2.3.1 Overview

The data flash ECC is summarized in the table below.

Table 28.16 Data Flash ECC

Item	Description
ECC error detection and correction	ECC error detection and correction can be either enabled or disabled. When enabled, either of the following settings can be selected. • ECC error detection and correction are carried out (2-bit error detection and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). When disabled, neither error detection nor correction is carried out. In the initial state, this function is enabled, and 1-bit error detection and correction and 2-bit error detection and notification are carried out.
Error notification	Upon occurrence of an ECC error, it is notified to the Error Control Module. ECC Error: • Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. • Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. In the initial state, error notification is enabled upon detection of an ECC 2-bit error, and error notification is disabled upon detection of an ECC 1-bit error. Overflow Error: • Error notification can be either enable or disable upon detection of an address buffer overflow error. In the initial state, error notification is enabled upon detection of an address buffer overflow error. The error notification signal is output, where an ECC 2-bit error, an ECC 1-bit error and an overflow error is handled as one source, respectively.
Error status	A status register is provided, which indicates the statuses of ECC 2-bit error detection and ECC 1-bit error detection. If an error occurs while no error status is set, the corresponding status is set. The error status can be cleared using the clear register.
Address capture	If an ECC error occurs while no error status is set, the address at which the associated error has occurred is captured. The address is captured when an ECC 2-bit error or an ECC 1-bit error is detected. The error status serves as the enable bit of the capture address. When error status is set and already latched ECC 1bit error or 2bit error occurs, error overflow is notified.

28.2.3.2 List of Registers

Table 28.17 List of Registers

Address	Symbol	Register Name	R/W	Value after reset	Access Size	PBG	Other Protection
FFC5 B000$_H$	DFECCCTL0	Data Flash ECC control register	R/W	0000 0000$_H$	32/16	—	—
FFC5 B004$_H$	DFERSTR0	Data Flash error status register	R	0000 0000$_H$	32	—	—
FFC5 B008$_H$	DFERSTC0	Data Flash error status clear register	W	0000 0000$_H$	32/16/8	—	—
FFC5 B00C$_H$	DFOVFSTR0	Data Flash error overflow status register	R	0000 0000$_H$	32	—	—
FFC5 B010$_H$	DFOVFSTC0	Data Flash error overflow status clear register	W	0000 0000$_H$	32/16/8	—	—
FFC5 B014$_H$	DFERRINT0	Data Flash error notification control register	R/W	0000 0006$_H$	32/16/8	—	—
FFC5 B018$_H$	DFEADR0	Data Flash 1st error address register	R	0000 0000$_H$	32	—	—
FFC5 B01C$_H$	DFTSTCTL0	Data flash test control register	R/W	0000 0000$_H$	32/16	—	—
FFC5 C000$_H$	DFECCCTL1	Data Flash ECC control register	R/W	0000 0000$_H$	32/16	—	—

FFC5 C014$_H$	DFERRINT1	Data Flash error notification control register	R/W	0000 0006$_H$	32/16/8	—	—
FFC5 C018$_H$	DFEADR1	Data Flash 1st error address register	R	0000 0000$_H$	32	—	—
FFC5 C01C$_H$	DFTSTCTL1	Data flash test control register	R/W	0000 0000$_H$	32/16	—	—

28.2.3.3 Details of Registers

(1) DFECCCTLn — Data flash ECC control register for n (bank number)

DFECCCTLn enables or disables ECC error detection and 1-bit error correction for read access to each data flash bank.

Set the PROT1 and PROT0 bits to 01_B when writing to DFECCCTLn.

Access: DFECCCTLn can be read/written in 32/16-bit units.

Address: DFECCCTL0: FFC5 $B000_H$
DFECCCTL1: FFC5 $C000_H$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PROT1	PROT0	—	—	—	—	—	—	—	—	—	—	—	—	SECDIS	ECCDIS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 28.18 DFECCCTLn register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15	PROT1	Enables or disables modification of the ECCDIS and SECDIS bits. The value written is not retained. These bits are always read as 0. Set (PROT1, PROT0) = (0, 1) when writing to DFECCCTLn.
14	PROT0	
13 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	SECDIS	1-Bit Error Correction Disable Enables or disables 1-bit error correction when ECC error detection and correction are enabled. Write a value to this bit simultaneously with setting (PROT1, PROT0) = (0, 1). 0: Enables correction of the 1-bit error detected. 1: Disables correction of the 1-bit error detected.
0	ECCDIS	ECC Disable Enables or disables ECC error detection and correction. Write a value to this bit simultaneously with setting (PROT1, PROT0) = (0, 1). In the initial state, ECC error detection and correction are enabled. 0: Enables ECC error detection and correction. 1: Disables ECC error detection and correction.

(2) DFERSTRn — Data flash error status register (n = 0, 1)

DFERSTRn monitors occurrence of errors.

The SEDF bit is set if an ECC 1-bit error is detected while ECC error detection and correction are enabled, and the DEDF bit is set if an ECC 2-bit error is detected.

Access: DFERSTRn can be read only in 32-bit units.

Address: DFERSTR0: FFC5 $B004_H$
DFERSTR1: FFC5 $C004_H$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DEDF	SEDF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.19 DFERSTRn register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is read.
1	DEDF	ECC 2-Bit Error Monitor Flag 0: An ECC 2-bit error is not generated. 1: An ECC 2-bit error is generated. Clearing condition: ERRCLR bit is set in Data Flash error status clear register. Setting condition: ECC 2-bit error is generated.
0	SEDF	ECC 1-bit error Monitor Flag 0: An ECC 1-bit error is not generated. 1: An ECC 1-bit error is generated. Clearing condition: ERRCLR bit is set in Data Flash error status clear register. Setting condition: ECC 1-bit error is generated with both SEDF and DEDF being 0.

(3) DFERSTCn — Data flash error status clear register (n = 0, 1)

DFERSTCn clears the error flags in the Data Flash error status register.

Access: DFERSTCn can be written only in 32/16/8-bit units.

Address: DFERSTC0: FFC5 $B008_H$
DFERSTC1: FFC5 $C008_H$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ERRCLR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Table 28.20 DFERSTCn register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When writing, write the value after reset.
0	ERRCLR	SEDF/DEDF Flag Clear 0: No effect (Setting the ERRCLR bit to 0 does not affect the DEDF and SEDF flags in DFERSTRn.) 1: The SEDF/DEDF flag in DFERSTRn is cleared.

(4) DFOVFSTRn — Data flash error overflow status register (n = 0, 1)

DFOVFSTRn monitors occurrence of Data Flash error overflow.

Access: DFOVFSTRn can be read only in 32-bit units.

Address: DFOVFSTR0: FFC5 B00C$_H$
DFOVFSTR1: FFC5 C00C$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ERR OVF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.21 DFOVFSTRn register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is read.
0	ERROVF	Error Overflow Flag ERROVF is set if the following occur • An ECC 1-bit error is occurred when DFERSTRn .SEDF = 1 and access address is different from DFEADRn. • An ECC 1-bit error is occurred when DFERSTRn .DEDF = 1 • An ECC 2-bit error is occurred when DFERSTRn .SEDF = 1 • An ECC 2-bit error is occurred when DFERSTRn .DEDF = 1 and access address is different from DFEADRn. 0: Not occurred 1: Occurred Clearing condition: Set the ERROVFCLR bit in DFOVFSTC to 1.

(5) DFOVFSTCn — Data flash error overflow status clear register (n = 0, 1)

DFOVFSTCn clears the Data Flash error overflow flag.

Access: DFOVFSTCn can be written only in 32/16/8-bit units.

Address: DFOVFSTC0: $FFC5B010_H$
DFOVFSTC1: $FFC5C010_H$

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ERR OVF CLR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Table 28.22 DFOVFSTCn register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When writing, write the value after reset.
0	ERROVFCLR	Error Overflow Flag Clear 0: No effect (Setting the ERROVFCLR bit to 0 does not affect the flag in DFOVFSTR.) 1: The ERROVF flag in the DFOVFSTR register is cleared.

(6) DFERRINTn — Data flash error notification control register (n = 0, 1)

DFERRINTn enables or disables generation of the error notification signal upon detection of an address buffer overflow error, an ECC 2-bit error and an ECC 1-bit error.

Access: DFERRINTn can be read/written in 32/16/8-bit units.

Address: DFERRINT0: $FFC5B014_H$
DFERRINT1: $FFC5\ C014_H$

Value after reset: $0000\ 0006_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	EOVFIE	DEDIE	SEDIE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 28.23 DFERRINTn register contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is read. When writing, write the value after reset.
2	EOVFIE	ECC Error Address Overflow Notification Control Enables or disables generation of the error notification signal upon detection of an address buffer overflow error. 0: Error address overflow report disabled 1: Error address overflow report enabled
1	DEDIE	ECC 2-bit error Notification Control Enables or disables generation of the error notification signal upon detection of a 2-bit error when ECC error detection and correction are enabled. 0: Disables notification of the ECC 2-bit error. 1: Enables notification of the ECC 2-bit error.
0	SEDIE	ECC 1-bit error Notification Control Enables or disables generation of the error notification signal upon detection of a 1-bit error when ECC error detection and correction are enabled. 0: Disables notification of the ECC 1-bit error. 1: Enables notification of the ECC 1-bit error.

(7) DFEADRn — Data flash 1st error address register (n = 0, 1)

DFEADRn holds the address if the following occur.

- An ECC 1bit error or 2 bit error occurred when DFERSTRn.SEDF = 0 and DFERSTRn.DEDF = 0
- An ECC 2bit error occurred when DFERSTRn.SEDF = 1 and DFERSTRn.DEDF = 0

Access: These registers can be read only in 32-bit units.

Address: DFEADR0: FFC5 $B018_H$
DFEADR1: FFC5 $C018_H$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	DFEAREA[1:0]		DFEADR[18:16]		
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DFEADR[15:2]														—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.24 DFEADRn register contents

Bit Position	Bit Name	Function
31 to 21	Reserved	When read, the value after reset is read.
20, 19	DFEAREA[1:0]	ECC Error Area DFEAREA is a read-only field to monitor the area at which an ECC error has occurred. This register holds an area information. $0x_B$: User area. (base address BankA: FF20 0000_H, BankB: FF30 0000_H) 10_B: Configuration seting area. (Only Serial programming mode) (base address BankA: FF28 0000_H, BankB: nothing) 11_B: OTP seting area. (Only Serial programming mode) (base address BankA: FF2C 0000_H, BankB: FF3C 0000_H) (OTP setting area is not required for Bank B in P1M-C) Configuration and OTP setting areas are accessed under a specific condition relating to the setting of OTP or option byte. For the detail, see user's manual of flash library or flash memory hardware interface.
18 to 2	DFEADR[18:2]	ECC Error Address DFEADR is a read-only field to monitor the address at which an ECC error has occurred. This register holds an internal address. Convert it to the actual address by adding the data flash base address described in DFEAREA.
1, 0	Reserved	When read, the value after reset is read.

(8) DFTSTCTLn — Data flash test control register (n = 0, 1)

DFTSTCTLn is used for ECC testing.

The data of the ECC bit can be read after setting the ECC test mode (ECCTST = 1).

Set PROT[1:0] = 01 when writing to the DFTSTCTL register.

Access: DFTSTCTLn can be read/written in 32/16-bit units.

Address: DFTSTCTL0: FFC5 B01C$_H$
DFTSTCTL1: FFC5 C01C$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PROT1	PROT0	—	—	—	—	—	—	—	—	—	—	—	—	—	ECC TST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 28.25 DFTSTCTLn register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15	PROT1	Enables or disables modification of the ECCTST bit. The value written is not retained. These bits are always read as 0. Set (PROT1, PROT0) = (0, 1) when writing to DFECCCTL.
14	PROT0	
13 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	ECCTST	ECC Test By setting ECC test mode bit to “1” (ECCTST = 1), CPU can read ECC bit. Write a value to this bit simultaneously with setting (PROT1, PROT0) = (0, 1).

28.2.3.4 Test Function

Data in the ROM and the ECC bits can be read through the setting of the data flash test control register (DFTSTCTL).

(1) Reading the ROM data

(a) Set the ECCDIS bit in the data flash ECC control register to 1 to disable ECC error detection and correction.

(b) When ECCDIS = 1, neither error detection nor correction proceeds when the data flash is read; the data output from the data flash is read unchanged.

How to exit this test mode:

(a) Set the ECCDIS bit in the data flash ECC control register to 0 to enable ECC error detection and correction.

(2) Reading the ECC bits

(a) Set the ECCDIS bit in the data flash ECC control register to 1 to disable ECC error detection and correction.

(b) Set the ECCTST bit in the data flash control register to 1 to set test mode.

(c) When the data flash is read, the 7 lower-order bits of read data are read as ECC data.

How to exit this test mode:

(a) Set the ECCDIS bit in the data flash ECC control register to 0 to enable ECC error detection and correction.

(b) Set the ECCTST bit in the data flash test control register to 0 to set normal mode.

(3) Self-diagnosis of ECC check function

Self-diagnosis of the ECC decoder is possible by writing incorrect data to the data flash memory beforehand (fault injection) and then reading this data. A 1- or 2-bit ECC error fault can be injected by generating correct ECC bits once and inverting only the appropriate bits.

For details on programming of the data flash, see "*RH850/P1x-C Flash Memory User's Manual: Hardware Interface*".

28.2.4 Local RAM (CPU1/CPU2) ECC

28.2.4.1 Overview

Local RAM ECC of CPU1/CPU2 is summarized in the table below.

Table 28.26 Local RAM ECC

Item	Description
ECC error detection and correction	ECC error detection and correction can be either enabled or disabled. When enabled, either of the following settings can be selected. • ECC error detection and correction are carried out (2-bit error detection and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). When disabled, neither error detection nor correction is carried out. In the initial state, the ECC function is enabled; 1-bit error detection, correction, and notification, and 2-bit error detection and notification are carried out.
Error notification	Upon occurrence of an ECC error, it is notified to the Error Control Module. **ECC Error:** • Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. • Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. In the initial state, notification of the 2-bit error is enabled and notification of the 1-bit error is enabled. **Overflow Error:** • Error notification can be either enable or disable upon detection of an address buffer overflow error for ECC 1-bit error In the initial state, error notification is enabled upon detection of an address buffer overflow error. The error notification signal is output, where an ECC 2-bit error, an ECC 1-bit error and an overflow error is handled as individual source. An ECC 1-bit error signal is only issued to the ECM, if the ECC 1-bit error address is not yet stored in the error address buffer.
Error status	A status register is provided, which indicates the statuses of ECC 2-bit error detection, ECC 1-bit error detection. If an error occurs while no error status is set, the corresponding status is set. The error status can be cleared using the clear register.
Address capture	Multi-stage address buffers are provided for an ECC 1bit error as similar to a code flash ECC. 1-bit error: Eight stages (in 32-bit units) 2-bit error: One stage (in 32-bit units) The address is captured when an ECC 2-bit error or an ECC 1-bit error is detected. The error status serves as the enable bit of the capture address.

28.2.4.2 List of Registers

Table 28.27 List of Registers (1/4)

Address	Symbol	Register Name	R/W	Value after reset	Access Size	PBG	Other Protection

Note 1. P1H-CE and P1H-C devices only. P1M-C device doesn't have these registers.

28.2.4.3 Details of Registers

(1) LRECCCTL_PE1/PE2 — Local-RAM ECC Control Register

LRECCCTL_PE1/PE2 register control the ECC error detection/correction and 1-bit error correction. Writing ECC control registers must be executed with PROT[1:0] = 01_B.

Access: LRECCCTL_PE1/PE2 can be read/written in 32/16-bit units.

Address: LRECCCTL_PE1: FFC6 5400_H
LRECCCTL_PE2: FFC6 5800_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PROT[1:0]		—	—	—	—	—	—	—	—	—	—	—	—	SECDIS	ECCDIS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 28.28 LRECCCTL_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15, 14	PROT[1:0]	Protection Bit 01: write is enable Other: write is disable These bits are always read as 0.
13 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	SECDIS	ECC 1-bit error correction enable bit When using ECC error detection/correction (ECCDIS = 0), setting 1-bit error correction to enable/disable. 0: Correction is carried out when 1-bit is detected 1: Correction is not carried out when 1-bit is detected
0	ECCDIS	ECC disable bit Setting ECC error detection/correction to enable/disable. 0: ECC error detection/correction is enable 1: ECC error detection/correction is disable

(2) LRERRINT_PE1/PE2 — Local-RAM Error Information Control Register

LRERRINT_PE1/PE2 register controls whether error information is reported to ECM, when data ECC 2-bit error, ECC 1 bit error overflow and data ECC 1-bit error are detected.

Access: LRERRINT_PE1/PE2 can be read/written in 32/16/8-bit units.

Address: LRERRINT_PE1: FFC6 5404_H
LRERRINT_PE2: FFC6 5804_H

Value after reset: 0000 0043_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	EOVFIE	—	—	—	—	DEDIE	SEDIE
Value after reset	0	0	0	0	0	0	0	0	0	1	0	0	0	0	1	1
R/W	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R/W	R/W

Table 28.29 LRERRINT_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6	EOVFIE	ECC 1bit error overflow report enable bit Overflow report control bit when 1bit error overflow flag (SERROVFn) in LROVFSTR register is set. 0: ECC 1bit error overflow report disabled 1: ECC 1bit error overflow report enabled
5 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	DEDIE	ECC 2-bit error report enable bit Control error report of 2-bit error detection when ECC error detection/correction is enabled 0: ECC 2-bit error report disabled 1: ECC 2-bit error report enabled
0	SEDIE	ECC 1-bit error report enable bit Control error report of 1-bit error detection when ECC error detection/correction is enabled 0: ECC 1-bit error report disabled 1: ECC 1-bit error report enabled

(3) LRSERSTCLR_PE1/PE2 — Local-RAM ECC SED Status Clear Register

LRSERSTCLR_PE1/PE2 register is used to clear SEDFmn (m = 1 to 8, n = 0 to 3) in LRSERSTR_PE1/PE2 and SERROVFn (n = 0 to 3) in LROVFSTR_PE1/PE2, and error address in LRmSEDADRn_PE1/PE2. This is write only register and read value is always “0”.

Access: LRSERSTCLR_PE1/PE2 can be written in 32/16/8-bit units.

Address: LRSERSTCLR_PE1: FFC6 5408$_H$
LRSERSTCLR_PE2: FFC6 5808$_H$

Value after reset: 0000 0000$_H$

Table 28.30 LRSERSTCLR_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 0	SSTCLRmn (m = 1 to 8) (n = 0 to 3)	1-bit error flag clear (bank n) 1: All 1-bit error flag clear LRSERSTR_PE1/PE2.SEDFmn, LROVFSTR_PE1/PE2.SERROVFn, LRmSEDADRn_PE1/PE2.SEADR

(4) LRDERSTCLR_PE1/PE2 — Local-RAM ECC DED Status Clear Register

LRDERSTCLR_PE1/PE2 register is used to clear DEDFn (n = 0 to 3) in LRDERSTR_PE1/PE2 and DERROVFn (n=0 to 3) in LROVFSTR_PE1/PE2 and error address in LRDEDADRn_PE1/PE2 (n = 0 to 3). This is write only register and read value is always “0”.

Access: LRDERSTCLR_PE1/PE2 can be written in 32/16/8-bit units.

Address: LRDERSTCLR_PE1: FFC6 540C$_H$
LRDERSTCLR_PE2: FFC6 580C$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31 to 4	Reserved	When writing, write the value after reset.
3 to 0	DSTCLR[3:0]	2-bit error flag clear (bank n) 1: All 2-bit error flag clear LRDERSTR_PE1/PE2.DEDFn, LROVFSTR_PE1/PE2.DERROVFn LRDEDADRn_PE1/PE2.DEADR

(5) LROVFSTR_PE1/PE2 — Local-RAM Error Count Overflow Status Register

LROVFSTR_PE1/PE2 register monitor if error overflow occurs. Overflow occurs when different overflow*1 is detected in the case that error status is full. If the error status is full and the same error (same error cause and same error address) has occurred, then this flag is not set. SERROVF*n* (*n* = 0 to 3) , DERROVFn (n=0 to 3) flag is cleared by system reset or SSTCLR*mn* (*m* = 1 to 8, *n* = 0 to 3) ,DSTCLRn (n=0-3) in LRSERSTCLR_PE1/PE2 , LRDERSTCLR_PE1/PE2 register.

Note 1. Different means that the error satisfying one of the following conditions.

- Detected address is different
- Detected error status flag is different.

Access: LROVFSTR_PE1/PE2 can be read in 32/16/8-bit units.

Address: LROVFSTR_PE1: FFC6 5410$_H$
LROVFSTR_PE2: FFC6 5810$_H$

Value after reset: 0000 0000$_H$

Table 28.32 LROVFSTR_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is read.
7 to 4	DERROVF[3:0]	2-bit error overflow flag (bankn) This error flag is set if the followings occur. • DEDFn in LRDERSTR_PE1/PE2 is set. • Error with neither the same error cause nor the same address occur.
3 to 0	SERROVF[3:0]	1-bit error overflow flag (bankn) This error flag is set if the followings occur. • SEDFn in LRSERSTR_PE1/PE2 is set. • Error with neither the same error cause nor the same address occur.

(6) LRSERSTR_PE1/PE2 — Local-RAM ECC SED Status Register

LRSERSTR_PE1/PE2 is the error monitor register. If the error flag is “0” for each bank and a new error occurs, the error status flag is set. LRSERSTR_PE1/PE2 register is cleared by system reset or SSTCLR*mn* (*m* = 1 to 8, *n* = 0 to 3) in LRSERSTCLR_PE1/PE2 register.

Access: LRSERSTR_PE1/PE2 can be read in 32/16/8-bit units.

Address: LRSERSTR_PE1: FFC6 5440$_H$
LRSERSTR_PE2: FFC6 5840$_H$

Table 28.33 LRSERSTR_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 0	SEDF*mn* (*m* = 1 to 8) (*n* = 0 to 3)	ECC 1-bit error monitor flag (bank n) Condition to “0”: system reset or write “1” to SSTCLR*mn* in LRSERSTCLR_PE1/PE2 Condition to “1”: SEDF*mn* is “0” and ECC 1-bit error is detected.

(7) LRDERSTR_PE1/PE2 — Local-RAM ECC DED Status Register

LRDERSTR_PE1/PE2 is the error monitor register. If an error flag is “0” for a specific bank and a new ECC 2-bit error occurs by reading from this bank, then the error status flag is set. LRDERSTR_PE1/PE2 register is cleared by system reset or DSTCLRn (n = 0 to 3) in LRDERSTCLR_PE1/PE2 register.

Access: LRDERSTR_PE1/PE2 can be read in 32/16/8-bit units.

Address: LRDERSTR_PE1: FFC6 5450$_H$
LRDERSTR_PE2: FFC6 5850$_H$

Value after reset: 0000 0000$_H$

Table 28.34 LRDERSTR_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 26	Reserved	When read, the value after reset is read.
25	DEDF3	ECC 2-bit error monitor flag (bank 3) Condition to “0”: system reset or write “1” to DSTCLR3 in LRDERSTCLR_PE1/PE2 Condition to “1”: DEDF3 is “0” and ECC 2-bit error is detected.
24 to 18	Reserved	When read, the value after reset is read.
17	DEDF2	ECC 2-bit error monitor flag (bank 2) Condition to “0”: system reset or write “1” to DSTCLR2 in LRDERSTCLR_PE1/PE2 Condition to “1”: DEDF2 is “0” and ECC 2-bit error is detected.
16 to 10	Reserved	When read, the value after reset is read.
9	DEDF1	ECC 2-bit error monitor flag (bank 1) Condition to “0”: system reset or write “1” to DSTCLR1 in LRDERSTCLR_PE1/PE2 Condition to “1”: DEDF1 is “0” and ECC 2-bit error is detected.
8 to 2	Reserved	When read, the value after reset is read.
1	DEDF0	ECC 2-bit error monitor flag (bank 0) Condition to “0”: system reset or write “1” to DSTCLR0 in LRDERSTCLR_PE1/PE2 Condition to “1”: DEDF0 is “0” and ECC 2-bit error is detected.
0	—	Reserved. These bits are always read as 0. The write value should also be 0.

(8) LR*m*SEDADR*n*_PE1/PE2 — Local-RAM 1st to 8th SED Address Register *n* (*m* = 1 to 8, *n* = 0 to 3)

LR*m*SEDADR*n*_PE1/PE2 (*m* = 1 to 8, *n* = 0 to 3) register is used to hold the address when an error is detected. Error address capture trigger is same as corresponding SEDF*mn* (*m* = 1 to 8, *n* = 0 to 3) set in LRSERSTR_PE1/PE2. LR*m*SEDADR*n*_PE1/PE2 (*m* = 1 to 8, *n* = 0 to 3) is cleared by system reset or SSTCLR*mn* (*m* = 1 to 8, *n* = 0 to 3) in LRSERSTCLR_PE1/PE2 register.

Access: LR*m*SEDADR*n*_PE1/PE2 can be read in 32-bit units.

31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15, 14	PROT[1:0]	Protection Bit 01: write is enable Other: write is disable These bits are always read as 0.
13 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	ECCTST	ECC Test Mode Bit 0: Normal Mode 1: ECC Test Mode
0	DATSEL	Data Select Bits Need ECCTST = 1 0: RAM Data Select 1: ECC bit Select

Table 28.38 Local RAM Test Mode

ECCTST	DATSEL	Write Data
0	0	Data and ECC bits is updated (normal mode)
0	1	Data and ECC bits is updated (normal mode)
1	0	Data only is updated. ECC bits is not updated
1	1	Lower 7 bits of data are written as ECC bits. Data is not updated.

(11) LRTDATBFn_PE1/PE2 — Local-RAM Test Data Read Buffer*n* (n = 0, 1)

Access: LRTDATBF0_PE1/PE2 can be read in 32-bit units.

Address: LRTDATBF0_PE1: FFC6 5608$_H$ LRTDATBF1_PE1: FFC6 560C$_H$
LRTDATBF0_PE2: FFC6 5A08$_H$ LRTDATBF1_PE2: FFC6 5A0C$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—		—	LRDATABF[22:16]

Table 28.39 LRTDATBF0_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset is read.
22 to 16	LRDATABF [22:16]	ECC Data at Word (2n + 1) are stored into this register in the read operation from LRAM when ECCTST = 1.
15 to 7	Reserved	When read, the value after reset is read.
6 to 0	LRDATABF[6:0]	ECC Data at Word (2n) are stored into this register in the read operation from LRAM when ECCTST = 1.

28.2.4.4 Test Function

Through appropriate register setting, desired values can be written as RAM data and to the ECC bits. Also, data in the RAM and the ECC bits can all be read.

(1) Writing RAM data

(a) Set the ECCTST bit in the local RAM test control register to 1 to set test mode.

(b) Set the corresponding DATSEL bit in the local RAM test control register to 0 to select RAM data for access when writing.

(c) When data is written to the local RAM, only the RAM data can be modified without updating the ECC bits.

How to exit this test mode:

(a) Set the ECCTST bit in the local RAM test control register to 0 to disable test mode (normal mode).

(2) Reading RAM data

(a) Set the ECCDIS bit in the local RAM ECC control register to 1 to disable ECC error detection and correction.

(b) Read the local RAM. Since neither error detection nor correction proceeds when the local RAM is read, the RAM data is read unchanged.

How to exit this test mode:

(a) Set the ECCDIS bit in the local RAM ECC control register to 0 to enable ECC error detection and correction.

(3) Writing to the ECC bits

(a) Set the ECCTST bit in the local RAM test control register to 1 to set test mode.

(b) Set the corresponding DATSEL bit in the local RAM test control register to 1 to select the ECC bits for access when writing.

(c) When data is written to the local RAM, only the ECC bits can be modified without updating the RAM data. At that time, bit[7:0] are respectively written to the ECC bits.

How to exit this test mode:

(a) Set the ECCTST bit in the local RAM test control register to 0 to disable test mode (normal mode).

(4) Reading the ECC bits

(a) Set the ECCTST bit in the local RAM test control register to 1 to set test mode.

(b) When the local RAM is read, the ECC bits are stored in the bank corresponding to local RAM test data read buffer 0 or local RAM test data read buffer 1.

How to exit this test mode:

(a) Set the ECCTST bit in the local RAM test control register to 0 to disable test mode (normal mode).

(5) Self-diagnosis of the ECC check function

Desired values can be written to the RAM data and/or ECC bits by following the procedure described in (1) or (3) above. Therefore, a fault can be injected by, for example, inverting appropriate bits of the RAM data and/or ECC bits. After that, self-diagnosis of the ECC decoder is possible by reading the local RAM in normal mode and checking the result of error correction or detection.

28.2.5 Global RAM ECC

28.2.5.1 Overview

The global RAM ECC is summarized in the table below.

The below described ECC protection consider all possible global RAM accesses from PE1, PE2, H-Bus, System Interconnect and read access for read-modify-write processing unit of 8-bit and 16-bit data.

Further the related Suffix will be used:

“_GRAMC”: PE1, PE2, read-accesses for read-modify-write processing when 8-bit or 16-bit data

“_VCI2GRAM”: system interconnect

“_AXI2GRAM” : H-Bus

Table 28.40 Global RAM ECC

Item	Description
ECC error detection and correction	ECC error detection and correction can be either enabled or disabled. When enabled, either of the following settings can be selected. • ECC error detection and correction are carried out (2-bit error detection and 1-bit error detection and correction are carried out). • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). When disabled, neither error detection nor correction is carried out. In the initial state, the ECC function is enabled, and 1-bit error detection and correction and 2-bit error detection and notification are carried out.
Address ECC	Address ECC check can be either enabled or disabled. Address ECC detects address error on bus between before Global RAM and master. In the initial state, 1-bit error detection, 2-bit error detection and notification are carried out. **NOTE** Even though ECC circuit with 1-bit error correction capability is implemented, still a 1-bit error indicates a sever fault and shall be properly treated in accordance with the safety requirements (see **Section 28.2.9.1**)
Error notification	Upon occurrence of an ECC error or Address ECC error, it is notified to the Error Control Module. **ECC Error:** • Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. • Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. In the initial state, error notification is enabled upon detection of an ECC 2-bit error, and error notification is enabled upon detection of an ECC 1-bit error. **Address ECC Error:** • Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. • Error notification can be either enabled or disabled upon detection of an ECC 1bit error. In the initial state, error notification is enabled upon detection of an ECC 2-bit and ECC 1-bit error. **Overflow Error:** • Error notification can be either enable or disable upon detection of an address buffer overflow error for Data ECC 1-bit error. In the initial state, error notification is enabled upon detection of an address buffer overflow error. ECC 2-bit error, address ECC 2-bit error, ECC 1-bit error, overflow error and address ECC 1-bit error are handled as each individual source. An ECC 1-bit error signal is only issued to the ECM, if the ECC 1-bit error address is not yet stored in the error address buffer.
Error status	A status register is provided, which indicates the statuses of ECC 2-bit error detection, ECC 1-bit error detection, and Address ECC error detection. If an error occurs while no error status is set, the corresponding status is set. The error status can be cleared using the clear register.
Address capture	Multi-stage address buffers are provided for a 1-bit data error, and check is performed in each stage. The address is latched when the state of each stage is clear. • 1-bit data error: 32 stages • 2-bit data and address ECC, shared: One stage The address is captured when an ECC 2-bit error, an ECC 1-bit error, or an Address ECC error is detected. The error status serves as the enable bit of the capture address.

28.2.5.2 List of Registers

Table 28.41 List of Registers (1/3)

Address	Symbol	Register Name	R/W	Value after reset	Access Size	PBG	Other Protection

FFC64200$_H$	GRECCCTL_VCI2GRAM	Global-RAM ECC Control Register	R/W	0000 0000$_H$	32/16	APBGRD_ PFSS1.SP4	—

Table 28.41 List of Registers (3/3)

Address	Symbol	Register Name	R/W	Value after reset	Access Size	PBG	Other Protection
$FFC64400_H$	GRECCCTL_PE1*1	Global-RAM ECC Control Register	R/W	0000 0000_H	32/16	APBGRD_ PFSS1.SP1	—
$FFC64600_H$	GRECCCTL_PE2*1,*2	Global-RAM ECC Control Register	R/W	0000 0000_H	32/16	APBGRD_ PFSS1.SP2	—
$FFC64E00_H$	GRECCCTL_AXI2GRAM	Global-RAM ECC Control Register	R/W	0000 0000_H	32/16	APBGRD_ PFSS1.SP4	—

Note 1. This register doesn't have any functions.

Note 2. P1H-CE, P1H-C devices only. P1M-C device doesn't have these registers.

Note: The registers with symbols "_GRAMC", "_VCI2GRAM", and "_AXI2GRAM" as suffixes are provided to the particular ECC controllers: the registers with "_GRAMC" are provided to the ECC controller for access from the CPU1 and CPU2 to GRAM, and for read-accesses for read-modify-write processing when 8-bit or 16-bit data is written to GRAM, the registers with "_VCI2GRAM" are provided to the ECC controller for access from the system interconnect to GRAM, and the registers with "_AXI2GRAM" are provided to the ECC controller for access from H-bus.

28.2.5.3 Details of Registers

(1) UGRERRINT — Global-RAM Error Information Control Register

UGRERRINT register controls whether error information is reported to ECM, when address/data ECC 2-bit error, address/data ECC 1-bit error, and ECC 1-bit error overflow are detected.

Access: UGRERRINT can be read/written in 32/16/8-bit units.

Address: FFC6 4000$_H$

Value after reset: 0000 0073$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	SEOVFIE	ADEDIE	ASEDIE	—	—	DEDIE	SEDIE
Value after reset	0	0	0	0	0	0	0	0	0	1	1	1	0	0	1	1
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R	R/W	R/W

Table 28.42 UGRERRINT register contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6	SEOVFIE	ECC 1-bit error overflow report enable bit Overflow report control bit when 1-bit error overflow flag (SERROVF) in UGROVFSTR register is set. 0: ECC 1-bit error overflow report disabled 1: ECC 1-bit error overflow report enabled
5	ADEDIE	Address ECC 2-bit error on bus report enable bit Control error report of 2-bit error detection when address ECC error detection/correction is enabled. 0: Address ECC 2-bit error report disabled 1: Address ECC 2-bit error report enabled
4	ASEDIE	Address ECC 1-bit error on bus report enable bit Control error report of 1-bit error detection when address ECC error detection/correction is enabled. 0: Address ECC 1-bit error report disabled 1: Address ECC 1-bit error report enabled
3, 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	DEDIE	ECC 2-bit error report enable bit Control error report of 2-bit error detection when ECC error detection/correction is enabled 0: ECC 2-bit error report disabled 1: ECC 2-bit error report enabled
0	SEDIE	ECC 1-bit error report enable bit Control error report of 1-bit error detection when ECC error detection/correction is enabled 0: ECC 1-bit error report disabled 1: ECC 1-bit error report enabled

(2) UGRSERSTCLR — Global-RAM ECC SED Status Clear Register

UGRSERSTCLR register is used to clear SEDF[0:31] in UGRSERSTR, SERROVF in UGROVFSTR, and error address in UGR[1:32]SEDADR. This is write only register and read value is always “0”. UGRSERSTCLR register has a lower priority than a set factor. Priority is given to a set factor when UGRSERSTCLR and a set factor compete. A set factor means a trigger of setting SEDF[0:31] in UGRSERSTR, setting SERROVF in UGROVFSTR, or capturing an error address in UGR[1:32]SEDADR.

Access: UGRSERSTCLR can be written in 32/16/8-bit units.

Address: FFC6 4004_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SSTCLR[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SSTCLR[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Table 28.43 UGRSERSTCLR register contents

Bit Position	Bit Name	Function
31 to 0	SSTCLR[31:0]	Data ECC 1-bit error flag clear n th 1: Following flag and address clear UGRSERSTR.SEDFn, UGROVFSTR.SERROVF, UGRnSEDADR.SEADR

(3) UGRDERSTCLR — Global-RAM ECC DED Status Clear Register

UGRDERSTCLR register is used to clear ADEDF/ASEDF and DEDF in UGRDERSTR and error address in UGR00DEDADR. This is write only register and read value is always “0”.
UGRDERSTCLR register has a lower priority than a set factor. Priority is given to a set factor when UGRDERSTCLR and a set factor compete. A set factor means a trigger of setting ADEDF/ASEDF and DEDF in UGRDERSTR.

Access: UGRDERSTCLR can be written in 32/16/8-bit units.

Address: FFC6 4008$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DSTCLR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Table 28.44 UGRDERSTCLR register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When writing, write the value after reset.
0	DSTCLR	Data ECC 2-bit error flag and address ECC error flag clear 1: Following flag and address clear UGRDERSTR.ADEDF, UGRDERSTR.ASEDF, UGRDERSTR.DEDF, UGR00DEDADR.DEADR

(4) UGROVFSTR — Global-RAM Error Count Overflow Status Register

UGROVFSTR register monitor if error overflow occurs. Overflow occurs when a SED with the error address never captured is detected in the case that ECC 1-bit error status register is full. If the ECC 1-bit error status register is full and the error address is the same as one of the error addresses already captured, this flag is not set. SERROVF flag is cleared by system reset, or cleared when at least one of SSTCLR[0:31] in UGRSERSTCLR register is asserted.

Access: UGROVFSTR can be read in 32/16/8-bit units.

Address: FFC6 400C$_H$

Value after reset: 0000 0000$_H$

Table 28.45 UGROVFSTR register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is read.
0	SERROVF	1-bit error overflow flag This error flag is set if the followings occur. • A SED occurrence when all bits(SEDF [0:31]) of ECC 1-bit error status register (UGRSERSTR) are set. • If the ECC 1-bit error status register is full and the error address is the same as one of the error addresses already captured, this flag is not set.

Note: As the overflow flag, only SED flags are prepared. Because DED is prepared for only one error address buffer, an overflow flag for DED is not necessary.

(5) UGRSERSTR — Global-RAM ECC SED Status Register

UGRSERSTR is the error monitor register. Each error flag is “0”and when a new error occurs, an error status flag is set. An error flag is set at the lowest number empty bit of UGRSERSTR (e.g. If SEDF[0][1][3] have been set to “1” and all other bits have been empty, a next flag is set to SEDF[2].). If multiple SED causes are detected simultaneously and there are empty bits sufficiently, detected SEDs are all set (e.g. if a SED and another SED which occurs at a different address are detected simultaneously, both SEDFs are set.). However, if SEDs occur at a same address simultaneously, only one of errors is set according to the fixed priority. The priority order is PE1, PE2, system interconnect and H-bus. (e.g. if a SED which is input from PE1 path and an SED which is input from PE2 path are detected simultaneously and those occur at the same address, only SEDF from the PE1 path is set and SEDF from the PE2 path is not set.) And also, an error address which has already captured in UGR[1:32]SEDADR must not be captured again. UGRSERSTR register is cleared by system reset or SSTCLR[0:31] in UGRSERSTCLR register.

Access: UGRSERSTR can be read in 32/16/8-bit units.

Address: FFC6 4020$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 28.46 UGRSERSTR register contents

Bit Position	Bit Name	Function
31 to 0	SEDF[31:0]	ECC 1-bit error monitor flag SEDF[m] in mth buffer Condition to “0”: system reset or write “1” to SSTCLRn in UGRSERSTCLR Condition to “1”: ECC 1-bit error is detected.

(6) UGRDERSTR — Global-RAM ECC DED Status Register

UGRDERSTR is the error monitor register. All error flags are “0” and when a new error occurs, an error status flag is set. If multiple error causes which are input from each different slave port are detected simultaneously, only one of detected errors is set according to the fixed priority. The reason is that there is only one 2-bit error Address Register. The priority order is PE1, PE2, system interconnect and H-bus. (e.g. if a DED which is input from PE1 path and an ASED which is input from PE2 path are detected simultaneously, only DEDF from the PE1 path is set and ASEDF from the PE2 path is not set.) If multiple error causes occur from same slave port simultaneously, detected errors are all set. (e.g. if DED and ASED are simultaneously input from PE1 path, both DEDF and ASEDF are set.) UGRDERSTR register is cleared by system reset or DSTCLR in UGRDERSTCLR register.

Access: UGRDERSTR can be read in 32/16/8-bit units.

Address: FFC6 4030$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	—	—	—	—	—	—	ADEDF	ASEDF	—	—	—	DEDF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.47 UGRDERSTR register contents

Bit Position	Bit Name	Function
31 to 6	Reserved	When read, the value after reset is read.
5	ADEDF	Address ECC 2-bit error monitor flag Condition to “0”: system reset or write “1” to DSTCLR in UGRDERSTCLR Condition to “1”: ADEDF is “0” and address ECC 2-bit error is detected.
4	ASEDF	Address ECC 1-bit error monitor flag Condition to “0”: system reset or write “1” to DSTCLR in UGRDERSTCLR Condition to “1”: ASEDF is “0” and address ECC 1-bit error is detected.
3 to 1	Reserved	When read, the value after reset is read.
0	DEDF	ECC 2-bit error monitor flag Condition to “0”: system reset or write “1” to DSTCLR in UGRDERCTCLR Condition to “1”: DEDF is “0” and ECC 2-bit error is detected.

Note: As the ASEDF flag, this register has been named for capturing ECC 2-bit error (DED) error status, but the register captures Address ECC 1-bit error (ASED) too. Because ASED is also an emergency error and S/W should check the status immediately, ASED is treated like a DED error.

(7) UGR*n*SEDADR — Global-RAM *n* ECC SED Address Register (*n* = 1 to 32)

UGR*n*SEDADR register is used to hold the address when a 1-bit error is detected. Error address capture trigger is same as corresponding SEDF(*n*-1) set in UGRSERSTR. UGR*n*SEDADR is cleared by system reset or SSTCLR(*n*-1) in UGRSERSTCLR register.

Access: UGR*n*SEDADR can be read in 32-bit units.

Address:

- Error address SED : (GRAM_Base_Address[31:21] , SEDARn[20:0])

P1H-CE (P1M-C mode), P1H-CE (P1H-C (4MB) mode), P1H-CE (P1H-C (8MB) mode):

- GRAM_Base_Address = 0xFEE5_8000
- Error address SED : (GRAM_Base_Address[31:21] , SEDARn[20:0])

(8) UGR00DEDADR — Global-RAM ECC DED Address Register

UGR00DEDADR register is used to hold the address when an error is detected. Error address capture trigger is same as corresponding ADEDF/ASEDF/DEDF set in UGRDERSTR. If this register has captured an error address, the register doesn't capture any more address. UGR00DEDADR is cleared by system reset or DSTCLR in UGRDERSTCLR register.

Access: UGR00DEDADR can be read in 32-bit units.

Address: FFC6 40C0$_H$

Value after reset: 0000 0000$_H$

NOTE

P1M-C:

- GRAM_Base_Address = 0xFEED_8000
- Error address DED : (GRAM_Base_Address[31:21] , DEADR[20:0])

P1H-C (4MB), P1H-C (8MB):

- GRAM_Base_Address = 0xFEE8_8000
- Error address DED : (GRAM_Base_Address[31:21] , DEADR[20:0])

P1H-CE (P1M-C mode), P1H-CE (P1H-C (4MB) mode), P1H-CE (P1H-C (8MB) mode):

- GRAM_Base_Address = 0xFEE5_8000
- Error address DED : (GRAM_Base_Address[31:21] , DEADR[20:0])

(9) GRECCCTL_GRAMC — Global-RAM ECC Control Register

GRECCCTL_GRAMC register controls the ECC error detection/correction and 1-bit error correction on address and data ECC. Writing ECC control register must be executed with PROT[1:0] = 01_B.

Access: GRECCCTL_GRAMC can be read/written in 32/16-bit units.

Address: FFC6 4100_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 28.50 GRECCCTL_GRAMC register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15, 14	PROT[1:0]	Protection Bit 01: write is enable Other: write is disable These bits are always read as 0.
13 to 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	ASECDIS	Address ECC 1-bit error correction enable bit When using ECC error detection/correction (AECCDIS = 0), setting 1-bit error correction to enable/disable. 0: Correction is carried out when 1-bit error is detected 1: Correction is not carried out when 1-bit error is detected
3	AECCDIS	Address ECC disable bit Setting ECC error detection/correction to enable/disable. 0: ECC error detection/correction is enable 1: ECC error detection/correction is disable
2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	SECDIS	Data ECC 1-bit error correction enable bit When using ECC error detection/correction (ECCDIS = 0), setting 1-bit error correction to enable/disable. 0: Correction is carried out when 1-bit error is detected 1: Correction is not carried out when 1-bit error is detected
0	ECCDIS	Data ECC disable bit Setting ECC error detection/correction to enable/disable. 0: ECC error detection/correction is enable 1: ECC error detection/correction is disable

(10) GRTSTCTL — Global-RAM Test Control Register

GRTSTCTL register control the ECC error injection. Writing this registers must be executed with PROT[1:0] = 01_B.

Access: GRTSTCTL can be read/written in 32/16-bit units.

Address: FFC6 4104_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 28.51 GRTSTCTL register contents (1/2)

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15, 14	PROT[1:0]	Protection Bit 01: write is enable Other: write is disable These bits are always read as 0.
13 to 4	Reserved	When read, the value after reset is read. When writing, write the value after reset.
3	ECCTST	ECC Test Mode Bit 0: Normal Mode 1: ECC Test Mode
2	DECINEN	GRAMC ECC Decoder Error Injection Enable Bit Need ECCTST = 1. 0: Not Select Data of ECC Decoder Input Buffer 1: Select Data of ECC Decoder Input Buffer

Table 28.51 GRTSTCTL register contents (2/2)

Bit Position	Bit Name	Function
1, 0	DATSEL[1:0]	Read Buffer Storage Data Select 0 and 1 This bit is valid when ECCTST = 1. This bit selects the value to be stored in the read buffer GRTDATBFn, the value to be written to each field, and the value to be input to the ECC decoder for use in updating of data at the time of RMW access. Write a value to this bit simultaneously with setting (PROT1, PROT0) = (0, 1). 00: – GRTDATBFn: When reading involves an RMW cycle, the ECC bits are stored. – Global RAM: When writing involves an RMW cycle, the data area that is updated depends on the unit of access and the location accessed. The ECC bits are not updated. 01: – GRTDATBFn: When reading involves an RMW cycle, the ECC bits are stored. – Global RAM: When writing involves an RMW cycle, only the ECC bits are updated. The data area is not updated. 10: – GRTDATBFn: When access is RMW, this register holds the result of ECC decoding for the data read out in the read portion of the RMW cycle. Its value is not updated in the case of access that is not RMW. – Global RAM: Operates in the same way as in normal operating mode (i.e. when ECCTST = 0). 11: – GRTDATBFn: When access is RMW, this register holds the result of ECC decoding for use in the updating of data at the time of RMW access. Its value is not updated in the case of access that is not RMW. – Global RAM: Operates in the same way as in normal operating mode (i.e. when ECCTST = 0). – When and only when these settings are the case, the value of the GRDECINBF0 or 1 register is input to the ECC decoder for use in updating of data at the time of RMW access instead of the write data being sent to the CPU etc. In any case, the result of reading by the CPU, DMAC, etc. is the same value as would normally be read out.

(11) GRTDATBF[0/1][L/H] — Global-RAM Test Data Read Buffer (Lower/Upper 32 bit of Bank0/1)

Access: GRTDATBF can be read in 32/16/8-bit units.

Address: GRTDATBF0L: FFC6 4108$_H$
GRTDATBF0H: FFC6 410C$_H$
GRTDATBF1L: FFC6 4110$_H$
GRTDATBF1H: FFC6 4114$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GRTDATBF[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GRTDATBF[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.52 GRTDATBF register contents

Bit Position	Bit Name	Function
31 to 0	GRTDATBF [31:0]	These bits are valid when while ECCTST = 1 (selecting test mode) in the global RAM test control register. • When (DATSEL1, DATSEL0) = (0, 0) or (0, 1) When reading from the RAM, the ECC bits are respectively stored in GRTDATBF[6:0]. 0 is stored in GRTDATBF[31:7]. • When (DATSEL1, DATSEL0) = (1, 0) When access is RMW, the output data from the ECC decoder for reading (after updating) are stored in GRTDATBF[31:0]. • When (DATSEL1, DATSEL0) = (1, 1) When access is RMW, the output data from the ECC decoder for use in updating of data (after updating) are stored in GRTDATBF[31:0].

NOTE

The GRAM consists of two banks, where bank 0 is synonymous to bank A and bank 1 is synonymous to bank B for this register.

The GRAM interface has 64 bit width, but the ECC is always made on both 32 bit words. Therefore the ECC/data of the 64 bit aligned lower 32 bits can be found in the GRTDATBFnL register, while the ECC/data of the 64 bit aligned upper 32 bits is found in the GRTDATBFnH register.

Please note that the location of the ECC/data of a 32 bit variable (with 32 bit alignment) depends on the address bit A2 (whereby A1 and A0 are 0). When A2 is 0, the ECC/data can be found in GRTDATBFnL register, and when A2 is 1 the ECC/data can be found in GRTDATBFnH register.

(12) GRDECINBF0 — GRAMC ECC Decoder Input Data Buffer 0

Access: GRDECINBF0 can be read/written in 32/16/8-bit units.

Address: FFC6 4118$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 28.54 GRDECINBF1 register contents

Bit Position	Bit Name	Function
31 to 7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 0	GRDECINBF1 [6:0]	These bits are valid when ECCTST = 1 (selecting test mode) in the global RAM test control register. When DECINEN = 1, the value of this register is input to the ECC decoder as data for use in updating in response to the execution of an RMW instruction. The value is treated as if it were 7 bits of data from the ECC. This register is common to banks A and B and provides the values for both the 32 higher-order bits and the 32 lower-order bits.

(14) GRECCCTL_VCI2GRAM/PE1/PE2/AXI2GRAM — Global-RAM ECC Control Register

GRECCCTL_VCI2GRAM/PE1/PE2/AXI2GRAM register control the ECC error detection/correction and 1-bit error correction. Writing ECC control registers must be executed with PROT[1:0] = 01_B.

For the related access part, please consider this register:

GRECCCTL_VCI2GRAM: access over system interconnect

GRECCCTL_PE1: *1

GRECCCTL_PE2: *1

GRECCCTL_AXI2GRAM: access over H-BUS.

Note 1. GRECCCTL_PE1/PE2 registers can be written and read. However even if these registers are set, the setting doesn't affect the operation.
Use GRECCCTL_GRAMC to disable/enable GRAM ECC decoders of PE1 and PE2.

Access: GRECCCTL_VCI2GRAM/PE1/PE2/AXI2GRAM can be read/written in 32/16-bit units.

Address:

GRECCCTL_VCI2GRAM:	FFC6 4200_H
GRECCCTL_PE1:	FFC6 4400_H
GRECCCTL_PE2:	FFC6 4600_H
GRECCCTL_AXI2GRAM:	FFC6 $4E00_H$

Value after reset: 0000 0000_H

Table 28.55 GRECCCTL_VCI2GRAM/PE1/PE2/AXI2GRAM register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15, 14	PROT[1:0]	Protection Bit 01: write is enable Other: write is disable These bits are always read as 0.
13 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	SECDIS	Data ECC 1-bit error correction enable bit When using ECC error detection/correction (ECCDIS = 0), setting 1-bit error correction to enable/disable. 0: Correction is carried out when 1-bit is detected 1: Correction is not carried out when 1-bit is detected
0	ECCDIS	Data ECC disable bit Setting ECC error detection/correction to enable/disable. 0: ECC error detection/correction is enable 1: ECC error detection/correction is disable

28.2.5.4 Test Function

Through appropriate register setting, desired values can be written as RAM data and to the ECC bits. Also, data in the RAM and the ECC bits and the ECC decoder output data for RMW can all be read.

It is possible to input the desired data in the ECC decoder for RMW.

(1) Writing RAM data

(a) Set the ECCTST bit in the global RAM test control register to 1 to set test mode.

(b) Set the corresponding DATSEL1 to 0 and DATSEL0 to 0 in the global RAM test control register to select RAM data for access when writing.

(c) When data is written to the global RAM, only the RAM data can be modified without updating the ECC bits.

How to exit this test mode:

(a) Set the ECCTST bit in the global RAM test control register to 0 to disable test mode (normal mode).

(2) Reading RAM data

(a) Set the ECCDIS bit in the global RAM ECC control register to 1 to disable ECC error detection and correction.

(b) Read the global RAM. Since neither error detection nor correction proceeds when the global RAM is read, the RAM data is read unchanged.

How to exit this test mode:

(a) Set the ECCDIS bit in the global RAM ECC control register to 0 to enable ECC error detection and correction.

(3) Writing to the ECC bits

(a) Set the ECCTST bit in the global RAM test control register to 1 to set test mode.

(b) Set the corresponding DATSEL1 bit to 0 and DATSEL0 bit to 1 in the global RAM test control register to select the ECC bits for access when writing.

(c) When data is written to the global RAM, only the ECC bits can be modified without updating the RAM data. At that time, bit[7:0] are respectively written to the ECC bits.

How to exit this test mode:

(a) Set the ECCTST bit in the global RAM test control register to 0 to disable test mode (normal mode).

(4) Reading the ECC bits

(a) Set the ECCTST bit in the global RAM test control register to 1 to set test mode.

(b) Setting the DATSEL1 and DATSEL0 bits in the global RAM test control register to 0 and 1, respectively, to select the ECC for access when reading.

(c) When data in the global RAM is read, the ECC bits are stored in the corresponding register from among global RAM test data read buffers 0 to 3.

How to exit this test mode:

(a) Set the ECCTST bit in the global RAM test control register to 0 to disable test mode (normal mode).

(5) Self-diagnosis of the ECC check function for the access ports

Desired values can be written to the RAM data and/or ECC bits by following the procedure described in (1) or (3) above. Therefore, a fault can be injected by, for example, inverting appropriate bits of the RAM data and/or ECC bits. After that, self-diagnosis of the ECC decoder is possible by reading the global RAM in normal mode and checking the result of error correction or detection.

(6) Self-diagnosis of the ECC decoder for the data read out in an RMW operation

(a) Suitable erroneous values are injected as RAM data or to the ECC bits by following procedure (1) or (3) above.

(b) Setting the DATSEL1 and DATSEL0 bits in the test control registers for the global RAM to 1 and 0, respectively, makes the output data from the ECC decoder for the data read out in an RMW operation the target for reading.

(c) After RMW processing for the global RAM proceeds, the data read out in an RMW operation for global RAM are stored in the corresponding register from among global RAM test data read buffers 0 to 3. Checking the result allows self-diagnosis of the ECC decoder for the data read out in an RMW operation.

(7) Self-diagnosis of the ECC decoder for the data being updated at the time of RMW access

(a) Setting the DATSEL1 and DATSEL0 bits in the global RAM test control register to 1 makes the output data from the ECC decoder for the data being updated at the time of RMW access the target for reading.

(b) Through the above setting, the input data from the ECC decoder for the data being updated at the time of RMW access is switched to ECC decoder input buffer 0 or 1 (GRDECINBF0 or 1) from write data sent from the access ports. As a result, suitable erroneous values can be injected by setting an appropriate value in ECC decoder input buffer 0 or 1.

28.2.6 Instruction Cache ECC and EDC

28.2.6.1 Overview

The instruction cache ECC is summarized in the table below.

Table 28.56 Instruction Cache ECC

Item	Description
ECC error detection	ECC error detection can be either enabled or disabled. When enabled, the following settings can be selected. • ECC error detection is carried out (2-bit error detection and 1-bit error detection are carried out). When disabled, error detection is not carried out. In the initial state, the ECC function is enabled, and 1-bit error detection, and notification, and 2-bit error detection and notification are carried out.
Error notification	Upon occurrence of an ECC error, it is notified to the Error Control Module. **ECC Error:** • Error notification can be either enabled or disabled upon detection of an ECC 2-bit error. • Error notification can be either enabled or disabled upon detection of an ECC 1-bit error. In the initial state, notification of the ECC 2-bit error is enabled, and notification of the ECC 1-bit error is enabled. An ECC 1-bit error signal is only issued to the ECM, if the ECC 1-bit error address is not yet stored in the error address buffer.
Error status	A status register is provided, which indicates the status of ECC 2-bit error detection and ECC 1-bit error detection. If an error occurs while no error status is set, the corresponding status is set. The error status can be cleared using the clear register.
Address capture	If an ECC error occurs while no error status is set, the address at which the associated error has occurred is captured. The address is captured when an ECC 2-bit error or an ECC 1-bit error is detected. The error status serves as the enable bit of the capture address.

28.2.6.3 Details of Registers

(1) IDECCCTL_PE1/PE2 — Instruction Cache Data RAM Data ECC Control Register

IDECCCTL_PE1/PE2 registers control the ECC error detection. Writing ECC control registers can only be executed with PROT[1:0] = 01_B.

Access: IDECCCTL_PE1/PE2 can be read/written in 32/16-bit units.

Address: IDECCCTL_PE1: FFC6 0400_H
IDECCCTL_PE2: FFC6 0600_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 28.58 IDECCCTL_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15, 14	PROT[1:0]	Protection Bit 01: write is enable Other: write is disable These bits are always read as 0.
13 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	ECCDIS	ECC disable bit Setting ECC error detection to enable/disable. 0: ECC error detection is enable 1: ECC error detection is disable

(2) IDERRINT_PE1/PE2 — Instruction Cache Data RAM Error Information Control Register

IDERRINT_PE1/PE2 registers controls whether error information is reported to ECM, when data ECC 2-bit error and data ECC 1-bit error are detected.

Access: IDERRINT_PE1/PE2 can be read/written in 32/16/8-bit units.

Address: IDERRINT_PE1: FFC6 0404_H
IDERRINT_PE2: FFC6 0604_H

Value after reset: $0000\ 0003_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 28.59 IDERRINT_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	DEDIE	ECC 2-bit error notification enable bit Control error notification of 2-bit error detection when ECC error detection is enabled 0: ECC 2-bit error notification disabled 1: ECC 2-bit error notification enabled
0	SEDIE	ECC 1-bit error notification enable bit Control error notification of 1-bit error detection when ECC error detection is enabled 0: ECC 1-bit error notification disabled 1: ECC 1-bit error notification enabled

(3) IDSERSTCLR_PE1/PE2 — Instruction Cache Data RAM Data ECC SED Status Clear Register

IDSERSTCLR_PE1/PE2 registers are used to clear SEDF0/1 in IDSERSTR_PE1/PE2 and SERROVF0/1 in IDOVFSTR_PE1/PE2, and error address in IDSEDADR0/1_PE1/PE2. These are write only registers and read value is always “0”.

Access: IDSERSTCLR_PE1/PE2 can be written in 32/16/8-bit units.

Address: IDSERSTCLR_PE1: FFC6 0408_H
IDSERSTCLR_PE2: FFC6 0608_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SSTCLR1	SSTCLR0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W	W

Table 28.60 IDSERSTCLR_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When writing, write the value after reset.
1	SSTCLR1	1-bit error flag clear (bank 1) 1: All 1-bit error flag clear IDSERSTR_PE1/PE2.SEDF1, IDOVFSTR_PE1/PE2.SERROVF1, IDSEDADR1_PE1/PE2.SEADR
0	SSTCLR0	1-bit error flag clear (bank 0) 1: All 1-bit error flag clear IDSERSTR_PE1/PE2.SEDF0, IDOVFSTR_PE1/PE2.SERROVF0, IDSEDADR0_PE1/PE2.SEADR

(4) IDDERSTCLR_PE1/PE2 — Instruction Cache Data RAM Data ECC DED Status Clear Register

IDDERSTCLR_PE1/PE2 register is used to clear DEDF0/1 in IDDERSTR_PE1/PE2 and DERROVF0/1 in IDOVFSTR_PE1/PE2, and error address in IDDEDADR0/1_PE1/PE2. This is write only register and read value is always “0”.

Access: IDDERSTCLR_PE1/PE2 can be written in 32/16/8-bit units.

Address: IDDERSTCLR_PE1: FFC6 040C$_H$
IDDERSTCLR_PE2: FFC6 060C$_H$

Value after reset: 0000 0000$_H$

Bit Position	Bit Name	Function
31 to 2	Reserved	When writing, write the value after reset.
1	DSTCLR1	2-bit error flag clear (bank 1) 1: All 2-bit error flag clear IDDERSTR_PE1/PE2.DEDF1, IDOVFSTR_PE1/PE2.DERROVF1 IDDEDADR1_PE1/PE2.DEADR
0	DSTCLR0	2-bit error flag clear (bank 0) 1: All 2-bit error flag clear IDDERSTR_PE1/PE2.DEDF0, IDOVFSTR_PE1/PE2.DERROVF0, IDDEDADR0_PE1/PE2.DEADR

(5) IDOVFSTR_PE1/PE2 — Instruction Cache Data RAM Error Count Overflow Status Register

IDOVFSTR_PE1/PE2 registers monitor if error overflow occurs. Overflow occurs when different overflow*1 is detected in the case that error status is full. If the error status is full and the same error (same error cause and same error address) has occurred, then this flag is not set. SERROVF0/1, DERROVF0/1 flag is cleared by system reset or SSTCLR0/1, DSTCLR0/1 in IDSERSTCLR_PE1/PE2, IDDERSTCLR_PE1/PE2 register.

Note 1. Different means that the error satisfying one of the following conditions.

- Detected address is different.
- Detected error status flag is different.

Access: IDOVFSTR_PE1/PE2 can be read in 32/16/8-bit units.

Address: IDOVFSTR_PE1: FFC6 0410$_H$
IDOVFSTR_PE2: FFC6 0610$_H$

Value after reset: 0000 0000$_H$

Table 28.62 IDOVFSTR_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 6	Reserved	When read, the value after reset is read.
5	DERROVF1	2-bit error overflow flag (bank1) This error flag is set if the followings occur. • DEDF1 in IDDERSTR_PE1/PE2 is set. • Error with neither the same error cause nor the same address occur.
4	DERROVF0	2-bit error overflow flag (bank0) This error flag is set if the followings occur. • DEDF0 in IDDERSTR_PE1/PE2 is set. • Error with neither the same error cause nor the same address occur.
3 to 2	Reserved	When read, the value after reset is read.
1	SERROVF1	1-bit error overflow flag (bank1) This error flag is set if the followings occur. • SEDF1 in IDSERSTR_PE1/PE2 is set. • Error with neither the same error cause nor the same address occur.
0	SERROVF0	1-bit error overflow flag (bank0) This error flag is set if the followings occur. • SEDF0 in IDSERSTR_PE1/PE2 is set. • Error with neither the same error cause nor the same address occur.

(6) IDSERSTR_PE1/PE2 — Instruction Cache Data RAM Data ECC SED Status Register

IDSERSTR_PE1/PE2 is the error monitor register. All error flag is “0” for each bank and a new error occurs, the error status flag is set. IDSERSTR_PE1/PE2 register is cleared by system reset or SSTCLR1/0 in IDSERSTCLR_PE1/PE2 register.

Access: IDSERSTR_PE1/PE2 can be read in 32/16/8-bit units.

Address: IDSERSTR_PE1: FFC6 0420_H
IDSERSTR_PE2: FFC6 0620_H

Value after reset: $0000\ 0000_H$

Table 28.63 IDSERSTR_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is read.
8	SEDF1	ECC 1-bit error monitor flag (bank 1) Condition for “0”: system reset or write “1” to SSTCLR1 in IDSERSTCLR_PE1/PE2 Condition for “1”: SEDF1 is “0” and ECC 1-bit error is detected.
7 to 1		When read, the value after reset is read.
0	SEDF0	ECC 1-bit error monitor flag (bank 0) Condition for “0”: system reset or write “1” to SSTCLR0 in IDSERSTCLR_PE1/PE2 Condition for “1”: SEDF0 is “0” and ECC 1-bit error is detected.

(7) IDDERSTR_PE1/PE2 — Instruction Cache Data RAM Data ECC DED Status Register

IDDERSTR_PE1/PE2 is the error monitor register. If an error flag is “0” for a specific bank and a new ECC 2-bit error occurs by reading from this bank, then the error status flag is set. IDDERSTR_PE1/PE2 register is cleared by system reset or DSTCLR1/0 in IDDERSTCLR_PE1/PE2 register.

Access: IDDERSTR_PE1/PE2 can be read in 32/16/8-bit units.

Address: IDDERSTR_PE1: FFC6 0450_H
IDDERSTR_PE2: FFC6 0650_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 28.64 IDDERSTR_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is read.
9	DEDF1	ECC 2-bit error monitor flag (bank 1) Condition to “0”: system reset or write “1” to DSTCLR1 in IDDERSTCLR_PE1/PE2 Condition to “1”: DEDF1 is “0” and ECC 2-bit error is detected.
8 to 2	Reserved	When read, the value after reset is read.
1	DEDF0	ECC 2-bit error monitor flag (bank 0) Condition to “0”: system reset or write “1” to DSTCLR0 in IDDERSTCLR_PE1/PE2 Condition to “1”: DEDF0 is “0” and ECC 2-bit error is detected.
0	Reserved	When read, the value after reset is read.

(8) IDSEDADR0/1_PE1/PE2 — Instruction Cache Data RAM (Bank0/1) Data ECC SED Address Register

IDSEDADR0/1_PE1/PE2 registers are used to hold the address when an SED error is detected. Error address capture trigger is same as corresponding SEDF0/1 set in IDSERSTR_PE1/PE2. IDSEDADR0/1_PE1/PE2 are cleared by system reset or SSTCLR1/0 in IDSERSTCLR_PE1/PE2 register.

Access: IDSEDADR0/1_PE1/PE2 can be read in 32-bit units.

Address: IDSEDADR0_PE1: FFC6 0460_H
IDSEDADR1_PE1: FFC6 0464_H
IDSEDADR0_PE2: FFC6 0660_H
IDSEDADR1_PE2: FFC6 0664_H

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 28.65 IDSEDADR0/1_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is read.
8 to 0	SEADR[8:0]	1-bit error detection address bank n (n = 0 or 1)

(9) IDDEDADR0/1_PE1/PE2 — Instruction Cache Data RAM (Bank0/1) Data ECC DED Address Register

IDDEDADR0/1_PE1/PE2 register is used to hold the address when a DED error is detected. Error address capture trigger is same as corresponding DEDF0/1 set in IDDERSTR_PE1/PE2. IDDEDADR0/1_PE1/PE2 is cleared by system reset or DSTCLR0/1 in IDDERSTCLR_PE1/PE2 register.

Access: IDDEDADR0/1_PE1/PE2 can be read in 32-bit units.

Address: IDDEDADR0_PE1: FFC6 04E0$_H$
IDDEDADR1_PE1: FFC6 04E4$_H$
IDDEDADR0_PE2: FFC6 06E0$_H$
IDDEDADR1_PE2: FFC6 06E4$_H$

Value after reset: 0000 0000$_H$

Table 28.66 IDDEDADR0/1_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is read.
8 to 0	DEADR[8:0]	2-bit error detection address bank n (n = 0 or 1)

(10) ITECCCTL_PE1/PE2 — Instruction Cache Tag RAM ECC Control Register

ITECCCTL_PE1/PE2 register control the ECC error detection. Writing ECC control registers can only be executed with PROT[1:0] = 01_B.

Access: ITECCCTL_PE1/PE2 can be read/written in 32/16-bit units.

Address: ITECCCTL_PE1: FFC6 1400_H
ITECCCTL_PE2: FFC6 1600_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 28.67 ITECCCTL_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15, 14	PROT	Protection Bit 01: write is enable Other: write is disable These bits are always read as 0.
13 to 1	Reserved	When read, the value after reset is read. When writing, write the value after reset.
0	ECCDIS	ECC disable bit Setting ECC error detection to enable/disable. 0: ECC error detection is enable 1: ECC error detection is disable

(11) ITERRINT_PE1/PE2 — Instruction Cache Tag RAM Error Information Control Register

ITERRINT_PE1/PE2 register controls whether error information is reported to ECM, when data ECC 2-bit error and data ECC 1-bit error are detected.

Access: ITERRINT_PE1/PE2 can be read/written in 32/16/8-bit units.

Address: ITERRINT_PE1: FFC6 1404$_H$
ITERRINT_PE2: FFC6 1604$_H$

Value after reset: 0000 0003$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 28.68 ITERRINT_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is read. When writing, write the value after reset.
1	DEDIE	ECC 2-bit error report enable bit Control error report of 2-bit error detection when ECC error detection is enabled 0: ECC 2-bit error report disabled 1: ECC 2-bit error report enabled
0	SEDIE	ECC 1-bit error report enable bit Control error report of 1-bit error detection when ECC error detection is enabled 0: ECC 1-bit error report disabled 1: ECC 1-bit error report enabled

(12) ITSERSTCLR_PE1/PE2 — Instruction Cache Tag RAM ECC SED Status Clear Register

ITSERSTCLR_PE1/PE2 registers are used to clear SEDF in ITSERSTR_PE1/PE2 and SERROVF in ITOVFSTR_PE1/PE2, and error address in ITSEDADR_PE1/PE2. These are write only registers and read value is always “0”.

Access: ITSERSTCLR_PE1/PE2 can be written in 32/16/8-bit units.

Address: ITSERSTCLR_PE1: FFC6 1408_H
ITSERSTCLR_PE2: FFC6 1608_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Table 28.69 ITSERSTCLR_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When writing, write the value after reset.
0	SSTCLR	1-bit error flag clear 1: All 1-bit error flag clear ITSERSTR_PE1/PE2.SEDF, ITOVFSTR_PE1/PE2.SERROVF, ITSEDADR_PE1/PE2.SEADR

(13) ITDERSTCLR_PE1/PE2 — Instruction Cache Tag RAM ECC DED Status Clear Register

ITDERSTCLR_PE1/PE2 register is used to clear DEDF in ITDERSTR_PE1/PE2, and DERROVF in ITOVFSTR_PE1/PE2, error address in ITDEDADR_PE1/PE2. This is write only register and read value is always “0”.

Access: ITDERSTCLR_PE1/PE2 can be written in 32/16/8-bit units.

Address: ITDERSTCLR_PE1: FFC6 140C$_H$
ITDERSTCLR_PE2: FFC6 160C$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 28.70 ITDERSTCLR_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When writing, write the value after reset.
0	DSTCLR	2-bit error flag clear (bank 0) 1: All 2-bit error flag clear ITDERSTR_PE1/PE2.DEDF, ITOVFSTR_PE1/PE2.DERROVF, ITDEDADR_PE1/PE2.DEADR

(14) ITOVFSTR_PE1/PE2 — Instruction Cache Tag RAM Error Count Overflow Status Register

ITOVFSTR_PE1/PE2 register monitor if error overflow occurs. Overflow occurs when different overflow*1 is detected in the case that error status is full. If the error status is full and the same error (same error cause and same error address) has occurred, then this flag is not set. SERROVF , DERROVF flag is cleared by system reset or SSTCLR , DSTCLR in ITSERSTCLR_PE1/PE2, ITDERSTCLR_PE1/PE2 register.

Note 1. Different means that the error satisfying one of the following conditions.

- Detected address is different
- Detected error status flag is different.

Access: ITOVFSTR_PE1/PE2 can be read in 32/16/8-bit units.

Address: ITOVFSTR_PE1: FFC6 1410$_H$
ITOVFSTR_PE2: FFC6 1610$_H$

Value after reset: 0000 0000$_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 28.71 ITOVFSTR_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 5	Reserved	When read, the value after reset is read.
4	DERROVF	2-bit error overflow flag This error flag is set if the followings occur. • DEDF in ITDERSTR_PE1/PE2 is set. • Error with neither the same error cause nor the same address occur.
3 to 1	Reserved	When read, the value after reset is read.
0	SERROVF	1-bit error overflow flag This error flag is set if the followings occur. • SEDF in ITSERSTR_PE1/PE2 is set. • Error with neither the same error cause nor the same address occur.

(15) ITSERSTR_PE1/PE2 — Instruction Cache Tag RAM ECC SED Status Register

ITSERSTR_PE1/PE2 is the error monitor register for SED. Error flag is “0” and a new error occurs, error status flag is set. ITSERSTR_PE1/PE2 register is cleared by system reset or SSTCLR in ITSERSTCLR_PE1/PE2 register.

Access: ITSERSTR_PE1/PE2 can be read only in 32-bit units.

Address: ITSERSTR_PE1: FFC6 1420_H
ITSERSTR_PE2: FFC6 1620_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 28.72 ITSERSTR_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is read.
0	SEDF	ECC 1-bit error monitor flag Condition to “0”: system reset or write “1” to SSTCLR in ITSERSTCLR_PE1/PE2 Condition to “1”: SEDF is “0” and ECC 1-bit error is detected.

(16) ITDERSTR_PE1/PE2 — Instruction Cache Tag RAM ECC DED Status Register

ITDERSTR_PE1/PE2 is the DED error monitor register. Error flag is “0” and a new error occurs, error status flag is set. ITDERSTR_PE1/PE2 register is cleared by system reset or DSTCLR in ITDERSTCLR_PE1/PE2 register.

Access: ITDERSTR_PE1/PE2 can be read in 32/16/8-bit units.

Address: ITDERSTR_PE1: FFC6 1450_H
ITDERSTR_PE2: FFC6 1650_H

Value after reset: 0000 0000_H

Table 28.73 ITDERSTR_PE1/PE2 register contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is read.
1	DEDF	ECC 2-bit error monitor flag Condition to “0”: system reset or write “1” to DSTCLR in ITDERSTCLR_PE1/PE2 Condition to “1”: DEDF is “0” and ecc 2-bit error is detected.
0	Reserved	When read, the value after reset is read.

(17) ITSEDADR_PE1/PE2 — Instruction Cache Tag RAM SED Address Register

ITSEDADR_PE1/PE2 register is used to hold the address when an SED error is detected. Error address capture trigger is same as corresponding SEDF set in ITSERSTR_PE1/PE2. ITSEDADR_PE1/PE2 is cleared by system reset or SSTCLR in ITSERSTCLR_PE1/PE2 register.

Access: ITSEDADR_PE1/PE2 can be read in 32-bit units.

Address: ITSEDADR_PE1: FFC6 1460_H
ITSEDADR_PE2: FFC6 1660_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

28.2.6.4 Test Function

A cache instruction is used to write the desired values as RAM data and to the ECC bits, and read data in the RAM and the ECC bits directly.

Since instructions as described above go through the same encoding or decoding path as a normal cache fill or instruction fetch, only such instructions can be used in inserting and confirming errors.

For details, see RH850/P1x-C Series User's Manual: Software.

28.2.7 DTS RAM ECC

See **Section 7, DMA**.

28.2.8 ECC for Peripheral RAM (32 Bits)

28.2.8.1 Overview

This is an ECC module for the RAM of the following peripheral modules.

FlexRay, CSIHn (n = 0 to 3), Ethernet, MCAN, GTM

(1) CSIHn (n = 0 to 3), MCAN, GTM

Error Detection and Correction

Seven-bit ECC data is appended to the 32-bit RAM data.

This ECC circuit provides ECC 2-bit error detection and ECC 1-bit error detection and correction.

Enabling or Disabling ECC Error Detection and Correction

- ECC error detection can be either enabled or disabled.
- 1-bit ECC error correction can be either enabled or disabled.
- If all the bits of RAM output data are stuck to 0 or 1, it is detected as an ECC 2-bit error.

ECM error notifications

- An error notification is issued upon detection of an ECC 2-bit error (issuance can be either enabled or disabled).
- An error notification is issued upon detection of an ECC 1-bit error (issuance can be either enabled or disabled).

Once an error notification is issued, another error notification is not issued until the corresponding error status is cleared even if another ECC error is detected.

Error Status

- Detection of ECC 2- and 1-bit errors can be monitored.
- Special registers are provided to clear error status.

Address Capture

- Only one address at which an ECC error has occurred can be captured.
- A signal is generated upon detection of ECC 2-bit or 1-bit error, and the signal is used as a trigger to capture the error-causing address (when the first (1-bit or 2-bit) error is detected after the flag is cleared).

Testing Function (Error Injection)

- By setting the test mode, register values can be used as the data to be output to the RAM. When a peripheral module writes to the RAM, the ECEDB[31:0] register value can be written to the RAM data section, and the ECERDB[6:0] register value can be written to the ECC bit section.

- By setting the test mode, the ECC bit section can be latched when RAM data is read, and the value can be confirmed.
- By setting the test mode, the ECC bit (encoding circuit) and syndrome code (decoding circuit), which are generated from the input data, can be confirmed.

(2) Ethernet

Error Detection and Correction

Seven-bit ECC data is appended to the 32-bit RAM data.

This ECC circuit provides ECC 2-bit error detection and ECC 1-bit error detection and correction.

Enabling or Disabling ECC Error Detection and Correction

To enable or disable an ECC error detection is not selectable; this function is always enabled.

To enable or disable an ECC 1-bit error correction is not selectable; this function is always enabled.

ECM error notifications

- An error notification is generated upon detection of an ECC 2-bit error (generation can’t be disabled).
- An error notification is generated upon detection of an ECC 1-bit error (generation can’t be disabled).

Error Status

None

Address Capture

None

Testing Function (Error Injection)

None

(3) FlexRay

Error Detection and Correction

Seven-bit ECC data is appended to the 32-bit RAM data.
This ECC circuit provides ECC 2-bit error detection and ECC 1-bit error detection and correction.

Enabling or Disabling ECC Error Detection and Correction

- ECC error detection can be either enabled or disabled.
- 1-bit ECC error correction can be either enabled or disabled.
- If all the bits of RAM output data are stuck to 0 or 1, it is detected as an ECC 2-bit error.

ECM error notifications

- An error notification is issued upon detection of an ECC 2-bit error (issuance can be either enabled or disabled).
- An error notification is issued upon detection of an ECC 1-bit error (issuance can be either enabled or disabled).
  Once an error notification is issued, another error notification is not issued until the corresponding error status is cleared even if another ECC error is detected.

Error Status

- Detection of ECC 2- and 1-bit errors can be monitored.
- Special registers are provided to clear error status.

Address Capture

- Only one address at which an ECC error has occurred can be captured.
- A signal is generated upon detection of ECC 2-bit or 1-bit error, and the signal is used as a trigger to capture the error-causing address (when the first (1-bit or 2-bit) error is detected after the flag is cleared).

Testing Function (Error Injection)

None

28.2.8.2 List of Registers

(1) List of ECC Modules

The RAMs of the multiple peripheral functions are provided with the ECC modules. The following table shows the peripheral functions provided with the ECC modules, the corresponding ECC module names, and base addresses of the ECC modules.

Table 28.76 ECC Module List

Peripheral Functions		Symbol	ECC Module Names and Register Base Addresses		PBG	Other Protection
			Module Name	Base Address <base_addr>		
FlexRay	Message RAM (MRAM)	ECCFLX0	ECCFLX0	FFC7 2000$_H$	PBG3#0.PG3-Startup	—
	Temporary buffer (TBF A)	ECCFLX0T0	ECCFLX0T0	FFC7 2100$_H$	PBG3#0.PG3-Startup	—
	Temporary buffer (TBF B)	ECCFLX0T1	ECCFLX0T1	FFC7 2200$_H$	PBG3#0.PG3-Startup	—
	Message RAM (MRAM)	ECCFLX1	ECCFLX1	FFC7 2400$_H$	PBG3#0.PG3-Startup	—
	Temporary buffer (TBF A)	ECCFLX1T0	ECCFLX1T0	FFC7 2500$_H$	PBG3#0.PG3-Startup	—
	Temporary buffer (TBF B)	ECCFLX1T1	ECCFLX1T1	FFC7 2600$_H$	PBG3#0.PG3-Startup	—

	CSIH1	ECCCSIH1	ECCCSIH1	FFC7 8000$_H$	PBG1#0.PG1-Startup	—
	CSIH2	ECCCSIH2	ECCCSIH2	FFC7 0100$_H$	PBG3#0.PG3-Startup	—
	CSIH3	ECCCSIH3	ECCCSIH3	FFC7 8100$_H$	PBG1#0.PG1-Startup	—
MCAN	ECCTTCAN0	ECCTTCAN0	ECCTTCAN0	FFC7 1000$_H$	PBG3#0.PG3-Startup	—
	ECCMCAN0	ECCMCAN0	ECCMCAN0	FFC7 9000$_H$	PBG1#0.PG1-Startup	—
	ECCMCAN1	ECCMCAN1	ECCMCAN1	FFC7 1100$_H$	PBG3#0.PG3-Startup	—
	ECCMCAN2	ECCMCAN2	ECCMCAN2	FFC7 9100$_H$	PBG1#0.PG1-Startup	—
GTM	ECCGTM0	ECCGTM0	ECCGTM0	FFE8 0000$_H$	PBG2.PG2-Startup	—
	ECCGTM1	ECCGTM1	ECCGTM1	FFE8 0100$_H$	PBG2.PG2-Startup	—
	ECCGTM2	ECCGTM2	ECCGTM2	FFE8 0200$_H$	PBG2.PG2-Startup	—
	ECCGTM3	ECCGTM3	ECCGTM3	FFE8 0300$_H$	PBG2.PG2-Startup	—

(2) List of Registers

Each ECC module has the registers shown in the following table.

Table 28.77 List of Registers

Register Name	Additional Abbreviation*2	R/W	Value after reset	Address	Access Size
ECC control register*1	CTL	R/W	$001X_H$	<base_addr> + 00_H	32
ECC test mode control register*3	TMC	R/W	0000_H	<base_addr> + 04_H	32
ECC bit data control test register*3	TRC	R/W	$0000\ 0000_H$	<base_addr> + 08_H	32
ECC encoder and decoder data test register*3	TED	R/W	$0000\ 0000_H$	<base_addr> + $0C_H$	32
ECC error address register	EAD0	R	$0000\ 0000_H$	<base_addr> + 10_H	32

Note 1. The reset value of the LSB in the ECC control register is undefined.

Note 2. “Additional Abbreviation” is added to the symbol in the list of ECC modules that correspond to peripheral functions. For example, ECCCSIH2TMC represents the ECC test mode control register of CSIH2.

Note 3. Except for FlexRay

(3) Register Map

Table 28.78 Register Map

Abbreviation	31 24	23 16	15 8	7 0	Address
CTL	— (00_H)	CTL[23:16]	CTL[15:8]	CTL[7:0]	$nn00_H$
TMC	— (00_H)	— (00_H)	TMC[15:8]	TMC[7:0]	$nn04_H$
TRC	SYND[7:0]	HORD[7:0]	ECRD[7:0]	ERDB[7:0]	$nn08_H$
TED	ECEDB[31:24]	ECEDB[23:16]	ECEDB[15:8]	ECEDB[7:0]	$nn0C_H$
EAD0	ECEAD[31:24]	ECEAD[23:16]	ECEAD[15:8]	ECEAD[7:0]	$nn10_H$

28.2.8.3 Details of Registers

(1) CTL — ECC control register

The CTL register controls the mode of the ECC for target peripheral modules.

Bits 7, 5, 4 and 3 should be set (written) while the target peripheral module operation is stopped.

In addition, when writing to bit 7, EMCA1 and EMCA0 need to be 01_B.

Access: This register can be read/written in 32-bit units.

Address: See **Table 28.76, ECC Module List** and **Table 28.78, Register Map**.

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ECDEDF0	ECSEDF0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EMCA1	EMCA0	—	—	ECOVF	ECER2C	ECER1C	—	ECTHM	—	EC1ECP	EC2EDIC	EC1EDIC	ECER2F	ECER1F	ECEMF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	Un-defined
R/W	R/W*1	R/W*1	R	R	R	R/W*1	R/W*1	R	R/W	R	R/W	R/W	R/W	R	R	R

Note 1. This bit is always read as 0.

Table 28.79 CTL register contents (1/3)

Bit Position	Bit Name	Function
31 to 18	Reserved	When read, the value after reset is read. When writing, write the value after reset.
17	ECDEDF0	
16	ECSEDF0	

ECDEDF0	ECSEDF0	Operation explanation
0	0	There is no error address in EAD0 after reset or clearing ECER2F and ECER1F bits. Clearing at (1) reset (2) writing ECER2C = 1 or ECER1C = 1 (3) selecting through mode enable (ECTHM = 1)
1	0	Address captured in EAD0 shows that ECC 2-bit error has occurred and the related address is captured.
0	1	Address captured in EAD0 shows that ECC 1-bit error has occurred and the related address is captured.
1	1	Setting prohibited

Bit Position	Bit Name	Function
15	EMCA1	Access control bits 1 and 0 to ECC mode selection bit These bits specify whether updating the ECTHM bit (bit 7) is disabled or enabled. The value written to these bits is not retained. When these bits are read, the read value is always 0. When these bits are 01_B, writing to bit 7 is enabled.
14	EMCA0	
13, 12	Reserved	When read, the value after reset is read. When writing, write the value after reset.

Table 28.79 CTL register contents (2/3)

Bit Position	Bit Name	Function
11	ECOVFF	By detecting an error while the error status is set and the new error has another address than the already latched (not cleared or reset is not issued), this bit is set and error notification is generated. **ECOVFF** / **Operation explanation** 0: Overflow is not occurred after reset or clearing ECER2F and ECER1F. Clearing at (1) reset (2) writing ECER2C = 1 or ECER1C = 1 (3) selecting through mode enable (ECTHM = 1) 1: Error address register overflowed.
10	ECER2C	ECC 2-bit error detection flag clear bit This bit is used to clear bit 2, the status flag (ECER2F). This bit is always read as 0. Write 1 to this bit while the ECER2F bit is set to clear the ECER2F bit. When a conflict between this bit writing and ECER2F bit setting occurs, writing to this bit has a priority.
9	ECER1C	ECC 1-bit error detection correction accumulation flag clear bit This bit is used to clear bit 1, the status flag (ECER1F). This bit is always read as 0. Write 1 to this bit while the ECER1F bit is set to clear the ECER1F bit. When a conflict between this bit writing and ECER1F bit setting occurs, writing to this bit has a priority.
8	Reserved	When read, the value after reset is read. When writing, write the value after reset.
7	ECTHM	ECC function through mode selection bit Set this bit to select whether to pass through the function of the ECC decoder. When writing to this bit, (0, 1) should be written to (EMCA1, EMCA0) at the same time. Set this bit to 1 to disable the ECC function. 0: Passing through mode is disabled (normal operation mode). 1: Passing through mode is enabled. The encoder is not affected. The decoder stops error detection and bit correction.
6	Reserved	When read, the value after reset is read. When writing, write the value after reset.
5	EC1ECP	ECC 1-bit error correction enable bit This bit specifies whether to enable or disable 1-bit error correction when the ECC error detection/correction is enabled. 0: When 1-bit error is detected, the error will be corrected. 1: When 1-bit error is detected, the error will not be corrected.
4	EC2EDIC	ECC 2-bit error detection error notification control bit This bit controls whether to generate an error notification when 2-bit error is detected. 0: When 2-bit error is detected, an error notification will not be generated. 1: When 2-bit error is detected, an error notification will be generated.
3	EC1EDIC	ECC 1-bit error detection error notifications control bit This bit controls whether to generate an error notification when 1-bit error is detected. 0: When 1-bit error is detected, an error notification will not be generated. 1: When 1-bit error is detected, an error notification will be generated.
2	ECER2F	ECC 2-bit error detection flag bit This flag indicates whether 2-bit error is detected during read access to the RAM when error determination is enabled. When 2-bit error notification is enabled and this flag is set, a 2-bit error notification signal is output. Write 1 to the ECER2C bit (bit 10) to clear the flag. If 2-bit error is detected again while this bit is set, an error notification request will not be generated. 0: 2-bit error has not occurred since this bit was cleared. 1: 2-bit error has occurred.

Table 28.79 CTL register contents (3/3)

Bit Position	Bit Name	Function
1	ECER1F	1-bit error detection/correction flag bit This flag indicates whether 1-bit error is detected during read access to the RAM when error determination is enabled. Write 1 to the ECER1C bit (bit 9) to clear the flag. 0: 1-bit error has not occurred since this bit was cleared. 1: 1-bit error has occurred.
0	ECEMF	ECC error message flag This flag indicates whether an error exists in the current read data bus. This bit is updated whenever the RAM outputs data. Because the value after reset of the RAM data is undefined, If the RAM is read before initialization, this bit may be set. 0: The current RAM output data does not have bit errors. 1: The current RAM output data have bit errors.

CAUTION

Bits 2 and 1 should be cleared when the ECC error message flag (ECEMF) is not set.

We recommend initializing the RAM before clearing bits 2 and 1.

(2) TMC — ECC test mode control register

The TMC register is used to switch to the test mode, and this register is for test mode.

When writing to bit 7, ETMA1 and ETMA0 need to be 10_B.

Access: This register can be read/written in 32-bit units.

Address: See **Table 28.76, ECC Module List** and **Table 28.78, Register Map**.

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ETMA1	ETMA0	—	—	—	—	—	—	ECTMCE	—	—	ECTRRS	ECREOS	ECENS	ECDCS	ECREIS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W*1	R/W*1	R	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Note 1. This bit is always read as 0.

Table 28.80 TMC register contents (1/2)

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is read. When writing, write the value after reset.
15	ETMA1	Access control bits 1 and 0 to ECC test mode bit These two bits specify whether updating the ECTMCE bit (bit 7) is disabled or enabled. The value written to these bits is not retained. When these bits are read, the read value is always 0. When these bits are 10_B, writing to bit 7 is enabled.
14	ETMA0	
13 to 8	Reserved	When read, the value after reset is read. When writing, write the value after reset.
7	ECTMCE	ECC test mode enable bit This bit specifies whether to enable access to the test registers and test control bits. When writing to this bit, (1, 0) should be written to (ETMA1, ETMA0) at the same time. 0: Access to the test mode registers and bits is disabled. 1: Access to the test mode registers and bits is enabled.
6, 5	Reserved	When read, the value after reset is read. When writing, write the value after reset.
4	ECTRRS	ECC RAM read test mode selection bit This bit is used to generate a RAM read cycle. Writing to this bit is enabled only when ECTMCE = 1 (can be set simultaneously). This bit is cleared when ECTMCE = 0 (cleared synchronously). 0: A RAM read cycle is not generated even when TED is read. 1: A RAM read cycle is generated when TED is read. In addition, the TED read value depends on the ECDCS bit (bit 1). The ERDB read value depends on the ECREIS bit (bit 0).
3	ECREOS	ECC bit output data selection bit This bit specifies which is output to the ECC bit output, the ECC encoder output data or the value of the ERDB register. Writing to this bit is enabled only when ECTMCE = 1 (can be set simultaneously). This bit is cleared when ECTMCE = 0 (cleared synchronously). 0: Encoding result is output to the ECC bit output. 1: TRC.ERDB[6:0] is output to the ECC bit output.

Table 28.80 TMC register contents (2/2)

Bit Position	Bit Name	Function
2	ECENS	ECC encoder input selection bit This bit specifies which is input to the encoder, the data from the peripheral macro or the value of the TED.ECEDB[31:0]. Writing to this bit is enabled only when ECTMCE = 1 (can be set simultaneously). This bit is cleared when ECTMCE = 0 (cleared synchronously). 0: Write data from the peripheral macro to the RAM is input to the ECC encoder as input data. 1: TED.ECEDB[31:0] is input to the ECC encoder as input data.
1	ECDCS	ECC decoder input selection bit This bit specifies which is input to the decoder as the lower 32-bit data of the decoder input, the lower 32-bit data from RAM or the value of TED.ECEDB[31:0]. Writing to this bit is enabled only when ECTMCE = 1 (can be set simultaneously). This bit is cleared when ECTMCE = 0 (cleared synchronously). 0: The lower 32-bit data from the RAM is input to the data area (lower 32-bit data) to the decoder circuit. 1: TED.ECEDB[31:0] is input to the data area to the decoder circuit.
0	ECREIS	ECC bit input data selection bit This bit specifies which is input as the upper 7-bit data of the decoder input, the upper 7-bit data (redundant bit area) from the RAM or the value of the TRC.ECERDB[6:0]. Writing to this bit is enabled only when ECTMCE = 1 (can be set simultaneously). This bit is cleared when ECTMCE = 0 (cleared synchronously). 0: Upper 7 bits of RAM output data are input to the ECC redundant bit area to the decoder circuit. 1: TRC.ECERDB[6:0] is input to the ECC redundant bit area to the decoder circuit.

(3) TED — ECC encoder and decoder data test register

TED is a test register for 32-bit data for ECC encoding/decoding.

In test mode, the value of this register can be used as input data for the encoder or decoder circuit.

Access: When TMC.ECTMCE = 1, this register can be read/written in 32-bit units.
When TMC.ECTMCE = 0, the value of this register is always 0000_H.

Address: See **Table 28.76, ECC Module List** and **Table 28.78, Register Map**.

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ECEDB[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ECEDB[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28.81 TED register contents

Bit position	Bit Name	Function
31 to 0	ECEDB[31:0]	When TMC.ECENS = 1, the value of this register is used as the input data to the encoder circuit and sent to the RAM. When TMC.ECDCS = 1, the value of this register is used as the bit 31 to 0 of the input data to the decoder circuit. In addition, when TMC.ECTRRS = 1, the read value from this register switches from the value of this register to the RAM output data.

(4) TRC — ECC redundant bit data control test register

This register is a 32-bit test register for the ECC redundant bit area and consists of four 8-bit registers, SYND, HORD, ECRD, and ERDB.

Access: When TMC.ECTMCE = 1, this register can be read/written in 32-bit units.
When TMC.ECTMCE = 0, the value of this register is always 0000_H.

Address: See **Table 28.76, ECC Module List** and **Table 28.78, Register Map**.

Value after reset: $0000\ 0000_H$

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SYND (See **(5)**)								HORD (See **(6)**)							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ECRD (See **(7)**)								ERDB (See **(8)**)							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

(5) SYND — ECC decoder syndrome data register

SYND is a read-only register to confirm the syndrome code generated by the decoding circuit in test mode (ECTMCE = 1).

Write access to SYND is ignored.

Access: When TMC.ECTMCE = 1, this register can be read only in 8-bit units.
When TMC.ECTMCE = 0, the value of this register is always 00_H.

Address: See **Table 28.76, ECC Module List** and **Table 28.78, Register Map**.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	SYND6	SYND5	SYND4	SYND3	SYND2	SYND1	SYND0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 28.82 SYND register contents

Bit position	Bit Name	Function
7	Reserved	When read, the value after reset is read.
6 to 0	SYND[6:0]	When reading this register bits, the syndrome code (synd[6:0]) generated in the decoder circuit based on the input data can be read. The value of this register changes as the input data changes. Note that this register is enabled only when ECTMCE = 1, and the value is always 00_H when ECTMCE = 0.

(6) HORD — ECC 7-Bit redundant data holding test register

HORD holds the 7-bit ECC redundant area (upper 7-bit RAM data), which cannot be confirmed by the peripheral module, when the peripheral module accesses the RAM for reading in test mode (ECTMCE = 1).

Access: When TMC.ECTMCE = 1, this register can be read only in 8-bit units.
When TMC.ECTMCE = 0, the value of this register is always 00_H.

Address: See **Table 28.76, ECC Module List** and **Table 28.78, Register Map**.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	HORD6	HORD5	HORD4	HORD3	HORD2	HORD1	HORD0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 28.83 HORD register contents

Bit position	Bit Name	Function
7	Reserved	When read, the value after reset is read.
6 to 0	HORD[6:0]	When the peripheral module reads the RAM in test mode (ECTMCE = 1), this register fetches the upper 7 bits of the RAM output data. In addition, if TMC.ECTRRS = 1, the value of the RAM output data is fetched to this register when the ECEDB[15:0] register is read. Note that this register is enabled only when ECTMCE = 1.

(7) ECRD — ECC encoder test register

ECRD is a read-only register to read the 7-bit redundant section generated by the encoding circuit in test mode (ECTMCE = 1).

Access: When TMC.ECTMCE = 1, this register can be read only in 8-bit units.
When TMC.ECTMCE = 0, the value of this register is always 00_H.

Address: See **Table 28.76, ECC Module List** and **Table 28.78, Register Map**.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	ECRD6	ECRD5	ECRD4	ECRD3	ECRD2	ECRD1	ECRD0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 28.84 ECRD register contents

Bit position	Bit Name	Function
7	Reserved	When read, the value after reset is read.
6 to 0	ECRD[6:0]	ECRD is used to hold the ECC bits generated from the input data of the peripheral module. These bits can be checked to confirm correct encoding. The read value is the encoding result (ecc[6:0]), and not the ECC redundant bit output value. Note that this register is enabled only when ECTMCE = 1.

(8) ERDB — ECC bit input and output substitution buffer register

ERDB is a buffer register for the data that substitutes for the input and output data for the 7-bit ECC redundant data area in test mode (ECTMCE = 1).

ERDB can be read and written to in ECC test mode (ECTMCE = 1).

Access: When TMC.ECTMCE = 1, this register can be read/written in 8-bit units.
When TMC.ECTMCE = 0, the value of this register is always 00_H.

Address: See **Table 28.76, ECC Module List** and **Table 28.78, Register Map**.

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	ERDB6	ERDB5	ERDB4	ERDB3	ERDB2	ERDB1	ERDB0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 28.85 ERDB register contents

Bit position	Bit Name	Function
7	Reserved	When read, the value after reset is read. When writing, write the value after reset.
6 to 0	ERDB[6:0]	When ECREOS = 1, the value of this resister is output to the ECC redundant bit output pins and sent to the RAM instead of the 7-bit long redundant bits generated by the encoder circuit. When ECREIS = 1, the value of this register is used by the decoder circuit instead of the upper 7 bits of the data input to the decoder circuit. In addition, when ECTRRS = 1, the read value from this register switches from the written value to this register to the RAM output data.

(9) EAD0 — ECC error address register

EAD0 is a read-only register to hold the address at which an ECC error has occurred.

Access: This register can be read in 32-bit units.

Address: See **Table 28.76, ECC Module List** and **Table 28.78, Register Map**.

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ECEAD[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ECEAD[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 28.86 EAD0 register contents

Bit position	Bit Name	Function
31 to 0	ECEAD[31:0]	EAD0 is a read-only register to hold the address at which an ECC error has occurred. If an ECC error is detected while ECC error detection is enabled, the RAM address is latched using the detection signal as a trigger, and the address is stored in EAD0 as the address at which the ECC error has occurred. The address is stored upon detection of the first ECC error while no error status is set. However, if a 1-bit error is followed by a 2-bit error, the address of the latter is stored. Only one address can be held in EAD0.

28.2.8.4 Test Function

(1) Writing RAM data

Write data to the peripheral RAM. However, ECC corresponding to the write data is simultaneously written to the ECC bits. To write an arbitrary value to the ECC bits, use ECC test mode shown in (3).

(2) Reading RAM data

(a) Set the ECTHM bit in the ECC control register to 1 to disable ECC error detection/correction.

(b) Read the peripheral RAM data. The RAM data is directly read because error detection or correction is not performed during reading.

Exiting this test mode

(a) Set the ECTHM bit in the ECC control register to 0 to enable ECC error detection/correction.

(3) Writing ECC bits

(a) Set the ECTMCE bit in the ECC test mode control register to 1 to specify ECC test mode.

(b) Write a value to be written to the ECC bits to TRC.ERDB[6:0].

(c) Set the ECREOS bit in the ECC test mode control register to 1 to select TRC.ERDB[6:0] to be written to the ECC bits.

(d) When data is written to the peripheral RAM, the TRC.ERDB[6:0] value is written to the ECC bits.

Exiting this test mode

(a) Set the ECTMCE bit in the ECC test mode control register to 0 to specify normal mode.

(4) Reading ECC bits

(a) Set the ECTMCE bit in the ECC test mode control register to 1 to specify ECC test mode.

(b) When the peripheral RAM data is read, the value of the ECC bits is stored in TRC.HORD[6:0].

Exiting this test mode

(a) Set the ECTMCE bit in the ECC test mode control register to 0 to specify normal mode.

28.2.9 Safety Mechanism on Data Transfer Path

28.2.9.1 ECC protection on Bus

Below the target paths of ECC protection on bus are indicated. It is possible to detect an error of address and data line from an access master to an access slave. If ECC error is detected, error is signaled to ECM.

Table 28.87 ECC protection on Bus

Access Source (Master)	Access Destination (Slave)
CPU1, CPU2, DMAC, DTS	GTM, ADCF, RAM of CPU1/2, Global RAM, all PBUS group except for path to AURORA

Data protection targets have controller of ECC decoder and user can configure detection, signaling and so on. Error information is stored in status registers when error occurs.

In the case of an address error detection, even if detected error is 1 bit error, MCU suggests to have serious unrecoverable problem.

28.2.9.2 Safety Feature for GRAM Access

The GRAM IF (also known as GRAM Controller (GRAMC)), comprises the Write-Through-Buffer (WT-Buffer) for performance enhancements, the Read-Modify-Write (RmW) to allow various access bit-width (64 / 32 / 16 / 8 bit) and the arbiter for arbitration of several masters. See CPU section, GRAM Accesses for more explanation about user function.

Here, the safety mechanisms of the GRAMC are described:

1. WT-Buffer: The data in WT-Buffer is protected by data ECC, and other logics like Control, Address and Vld are redundant.
2. Address path: The address path of the data is protected by address ECC. The address ECC is generated inside the PE and evaluated at output of GRAMC.
3. RmW: For 8-bit and 16-bit write accesses, the data ECC has to be recomputed, hence the read modify write circuits are implemented redundant. The RmW circuits in before the arbiter do not comprise a state machine, therefore the RmW state checker is just implemented for the RmW circuit after the arbiter.
4. ReqBuff: The request buffers are protected by address ECC and data ECC.
5. Arbiter: The arbiter is implemented redundant.
6. RespBuff: The response buffers are protected by data ECC and the packet ID. If the ID of request packet doesn’t match with one of response packet, GRAM master cannot proceed to the next process. As a result, other safety mechanism such as watch dog timer for PE or E2E communication for HBUS peripherals will detect failure by expiration.

28.2.9.3 Fault Detection Mechanism of Arbitration

Bus arbiters in PFSS have arbiter check function which detects unintended arbiter status. Detected arbitration error is notified to ECM. Target arbiters are as follow:

Table 28.88 Arbiter check

Target arbiter	Function
GRAMC	Global RAM arbiter is redundant.
FABTSS	Code Flash arbiter is redundant.
System interconnect	Arbitration check function

28.2.9.4 List of Registers

Table 28.89 List of Registers (1/8)

Address	Symbol	Register Name	R/W	Value after reset	Access Size	PBG	Other Protection
