Field Documentation

◆ open

`fsp_err_t(* uart_api_t::open) (uart_ctrl_t *const p_ctrl, uart_cfg_t const *const p_cfg)`

Open UART device.

Parameters

[in,out]	<code>p_ctrl</code>	Pointer to the UART control block. Must be declared by user. Value set here.
[in]	<code>uart_cfg_t</code>	Pointer to UART configuration structure. All elements of this structure must be set by user.

◆ read

`fsp_err_t(* uart_api_t::read) (uart_ctrl_t *const p_ctrl, uint8_t *const p_dest, uint32_t const bytes)`

Read from UART device. The read buffer is used until the read is complete. When a transfer is complete, the callback is called with event `UART_EVENT_RX_COMPLETE`. Bytes received outside an active transfer are received in the callback function with event `UART_EVENT_RX_CHAR`. The maximum transfer size is reported by [infoGet\(\)](#).

Parameters

[in]	p_ctrl	Pointer to the UART control block for the channel.
[in]	p_dest	Destination address to read data from.
[in]	bytes	Read data length.

◆ write

`fsp_err_t(* uart_api_t::write) (uart_ctrl_t *const p_ctrl, uint8_t const *const p_src, uint32_t const bytes)`

Write to UART device. The write buffer is used until write is complete. Do not overwrite write buffer contents until the write is finished. When the write is complete (all bytes are fully transmitted on the wire), the callback called with event `UART_EVENT_TX_COMPLETE`. The maximum transfer size is reported by [infoGet\(\)](#).

Parameters

[in]	p_ctrl	Pointer to the UART control block.
[in]	p_src	Source address to write data to.
[in]	bytes	Write data length.

```
fsp_err_t(* uart_api_t::baudSet) (uart_ctrl_t *const p_ctrl, void const *const p_baudrate_info)

Field Documentation	

◆ **open**

```

Initial configuration

Precondition

none

Parameters

[in,out]	p_ctrl	Pointer to control block. Must be declared by user. Elements set here.
[in]	p_cfg	Pointer to configuration structure. All elements of this structure must be set by user.

◆ **inputBufferSet**

```
fsp_err_t(* jpeg_api_t::inputBufferSet) (jpeg_ctrl_t *const p_ctrl, void *p_buffer, uint32_t buffer_size)
```

Assign input data buffer to JPEG codec.

Precondition

the JPEG codec module must have been opened properly.

*Note**The buffer starting address must be 8-byte aligned.***Parameters**

[in]	p_ctrl	Control block set in jpeg_api_t::open call.
[in]	p_buffer	Pointer to the input buffer space
[in]	buffer_size	Size of the input buffer

◆ outputBufferSet

```
fsp_err_t(* jpeg_api_t::outputBufferSet) (jpeg_ctrl_t *const p_ctrl, void *p_buffer, uint32_t buffer_size)
```

Assign output buffer to JPEG codec for storing output data.

Precondition

The JPEG codec module must have been opened properly.

Note

The buffer starting address must be 8-byte aligned. For the decoding process, the HLD driver automatically computes the number of lines of the image to decoded so the output data fits into the given space. If the supplied output buffer is not able to hold the entire frame, the application should call the Output Full Callback function so it can be notified when additional buffer space is needed.

Parameters

[in]	p_ctrl	Control block set in jpeg_api_t::open call.
[in]	p_buffer	Pointer to the output buffer space
[in]	buffer_size	Size of the output buffer

```

Cancel an outstanding operation.

Precondition

If the encoding or the decoding operation is finished without errors, the HLD driver automatically closes the device. In this case, application does not need to explicitly close the JPEG device.

Parameters

[in]	p_ctrl	Control block set in jpeg_api_t::open call.
------	--------	---

◆ **horizontalStrideSet**

```
fsp_err_t(* jpeg_api_t::horizontalStrideSet) (jpeg_ctrl_t *const p_ctrl, uint32_t horizontal_stride)

Parameters

[in]	p_ctrl	Control block set in jpeg_api_t::open call.
[out]	p_lines	Number of lines decoded

◆ **imageSizeGet**

```
fsp_err_t(* jpeg_api_t::imageSizeGet) (jpeg_ctrl_t *const p_ctrl, uint16_t *p_horizontal_size, uint16_t *p_vertical_size)
```

Retrieve image size during decoding operation.

Precondition

the JPEG codec module must have been opened properly.

Note

If the encoding or the decoding operation is finished without errors, the HLD driver automatically closes the device. In this case, application does not need to explicitly close the JPEG device.

The JPEG codec module must have been opened properly. The JPEG Codec can only perform one operation at a time and requires different configuration for encode and decode. This function facilitates easy switching between the two modes in case both are needed in an application.

Parameters

[in]	p_ctrl	Control block set in jpeg_api_t::open call.
[in]	mode	Mode to switch to

Field Documentation		

◆ **open**

```
fsp_err_t(* slcdc_api_t::open) (slcdc_ctrl_t *const p_ctrl, slcdc_cfg_t const *const p_cfg)
```

Open SLCDC.

Parameters

[in,out]	p_ctrl	Pointer to display interface control block. Must be declared by user.
[in]	p_cfg	Pointer to display configuration structure. All elements of this structure must be set by the user.

◆ **write**

```
fsp_err_t(* slcdc_api_t::write) (slcdc_ctrl_t *const p_ctrl, uint8_t const start_segment, uint8_t const *p_data, uint8_t const segment_count)
```

Write data to the SLCDC segment data array. Specifies the initial display data. Except when using 8-time slice mode, store values in the lower 4 bits when writing to the A-pattern area and in the upper 4 bits when writing to the B-pattern area.

Parameters

[in]	p_ctrl	Pointer to display interface control block.
[in]	start_segment	Specify the start segment number to be written.
[in]	p_data	Pointer to the display data to be written to the specified segments.
[in]	segment_count	Number of segments to be written.

◆ **modify**

```
fsp_err_t(* slcdc_api_t::modify) (slcdc_ctrl_t *const p_ctrl, uint8_t const segment, uint8_t const data_mask, uint8_t const data)
```

Rewrite data in the SLCDC segment data array. Rewrites the LCD display data in 1-bit units. If a bit is not specified for rewriting, the value stored in the bit is held as it is.

Parameters

[in]	p_ctrl	Pointer to display interface control block.
[in]	segment	The segment to be written.
[in]	data_mask	Mask the data being displayed. Set 0 to the bit to be rewritten and set 1 to the other bits. Multiple bits can be rewritten.
[in]	data	Specify display data to rewrite to the specified segment.

◆ **start**

```
fsp_err_t(* slcdc_api_t::start) (slcdc_ctrl_t *const p_ctrl)
```

Enable display signal output. Displays the segment data on the LCD.

Parameters

------	--------	---

◆ **setContrast**

```
fsp_err_t(* slcdc_api_t::setContrast) (slcdc_ctrl_t *const p_ctrl, slcdc_contrast_t const contrast)
```

Set the display contrast. This function can be used only when the internal voltage boosting method is used for drive voltage generation.

Parameters

[in]	p_ctrl	Pointer to display interface control block.
------	--------	---

◆ **setDisplayArea**

```
fsp_err_t(* slcdc_api_t::setDisplayArea) (slcdc_ctrl_t *const p_ctrl, slcdc_display_area_t const display_area)

7.3.8.2 Key Matrix Interface

[Interfaces](#) » [Input](#)

Detailed Description

Interface for key matrix functions.

Summary

The KEYMATRIX interface provides standard Key Matrix functionality including event generation on a rising or falling edge for one or more channels at the same time. The generated event indicates all channels that are active in that instant via a bit mask. This allows the interface to be used with a matrix configuration or a one-to-one hardware implementation that is triggered on either a rising or a falling edge.

◆ `st_ble_evt_data_t`

```
struct st_ble_evt_data_t
```

`st_ble_evt_data_t` is the type of the data notified in a GAP Event.

Data Fields

<code>uint16_t</code>	<code>param_len</code>	The size of GAP Event parameters.

Function Documentation

◆ R_BLE_GAP_Init()

```
ble_status_t R_BLE_GAP_Init ( ble_gap_app_cb_t gap_cb)
```

Initialize the Host Stack.

Host stack is initialized with this function. Before using All the R_BLE APIs, it's necessary to call this function. A callback function is registered with this function. In order to receive the GAP event, it's necessary to register a callback function. The result of this API call is notified in BLE_GAP_EVENT_STACK_ON event.

Parameters

[in]	gap_cb	A callback function registered with this function.
------	--------	--

Return values

BLE_SUCCESS(0x0000)	Success
BLE_ERR_INVALID_PTR(0x0001)	gap_cb is specified as NULL.
BLE_ERR_INVALID_STATE(0x0008)	The reason for this error is as follows: <ul style="list-style-type: none"> • Host Stack was already initialized. • The task for host stack is not running.
BLE_ERR_MEM_ALLOC_FAILED(0x000C)	Insufficient memory is needed to generate this function.

◆ **R_BLE_GAP_Terminate()**

```
ble_status_t R_BLE_GAP_Terminate ( void )
```

Terminate the Host Stack.

Host stack is terminated with this function. In order to reset all the Bluetooth functions, it's necessary to call this function. The result of this API call is notified in BLE_GAP_EVENT_STACK_OFF event.

Return values

BLE_SUCCESS(0x0000)	Success
BLE_ERR_INVALID_STATE(0x0008)	Host stack hasn't been initialized.

◆ **R_BLE_GAP_UpdConn()**

```
ble_status_t R_BLE_GAP_UpdConn ( uint16_t conn_hdl, uint8_t mode, uint16_t accept,
st_ble_gap_conn_param_t * p_conn_updt_param )
```

Update the connection parameters.

This function updates the connection parameters or replies a request for updating connection parameters notified by BLE_GAP_EVENT_CONN_PARAM_UPD_REQ event. When the connection parameters has been updated, BLE_GAP_EVENT_CONN_PARAM_UPD_COMP event is notified to the application layer.

Parameters

[in]	conn_hdl	Connection handle identifying the link to be updated.						
[in]	mode	<table border="1"> <thead> <tr> <th>macro</th> <th>description</th> </tr> </thead> <tbody> <tr> <td>BLE_GAP_CONN_UPD_MODE_REQ (0x01)</td> <td>Request for updating the connection parameters.</td> </tr> <tr> <td>BLE_GAP_CONN_UPD_MODE_RSP (0x02)</td> <td>Reply a connection parameter update request.</td> </tr> </tbody> </table>	macro	description	BLE_GAP_CONN_UPD_MODE_REQ (0x01)	Request for updating the connection parameters.	BLE_GAP_CONN_UPD_MODE_RSP (0x02)	Reply a connection parameter update request.
macro	description							
BLE_GAP_CONN_UPD_MODE_REQ (0x01)	Request for updating the connection parameters.							
BLE_GAP_CONN_UPD_MODE_RSP (0x02)	Reply a connection parameter update request.							
[in]	accept	When mode is BLE_GAP_CONN_UPD_MODE_RSP, accept or reject the connection parameters update request. If mode is BLE_GAP_CONN_U						

PD_MODE_REQ, accept is ignored.

macro	description
BLE_GAP_CO NN_UPD_AC CEPT (0x0000)	Accept the update request.
BLE_GAP_CO NN_UPD_REJ ECT (0x0001)	Reject the update request.

◆ **R_BLE_GAP_SetDataLen()**

```
ble_status_t R_BLE_GAP_SetDataLen ( uint16_t conn_hdl, uint16_t tx_octets, uint16_t tx_time )
```

Update the packet size and the packet transmit time.

This function requests for changing the maximum transmission packet size and the maximum packet transmission time. When Controller has received the request from host stack, BLE_GAP_EVENT_SET_DATA_LEN_COMP event is notified to the application layer. When the transmission packet size or the transmission time has been changed, BLE_GAP_EVENT_DATA_LEN_CHG event is notified to the application layer.

Parameters

[in]	conn_hdl	Connection handle identifying the link whose the transmission packet size or the transmission time to be changed.
[in]	tx_octets	Maximum transmission packet size. Valid range is 0x001B - 0x00FB.

◆ **R_BLE_GAP_SetPhy()**

```
ble_status_t R_BLE_GAP_SetPhy ( uint16_t conn_hdl, st_ble_gap_set_phy_param_t * p_phy_param )
```

Set the phy for connection.

This function sets the PHY preferences for the connection. The result of this API call is notified in BLE_GAP_EVENT_PHY_SET_COMP event. When the PHY has been updated, BLE_GAP_EVENT_PHY_UPD event is notified to the application layer.

After PHY update, the PHY accept configuration of local device is the same as the values in BLE_GAP_EVENT_PHY_UPD event.

For example, after calling [R_BLE_GAP_SetPhy\(\)](#), if tx_phy, rx_phy by BLE_GAP_EVENT_PHY_UPD event are updated to 2M PHY, the PHY accept configuration is 2M PHY only.

Therefore after receiving BLE_GAP_EVENT_PHY_UPD event, if local device wants to accept the other PHY configuration, it needs to call [R_BLE_GAP_SetPhy\(\)](#) with the desired PHY accept configuration.

Because the maximum transmission packet size or the maximum transmission time might be updated by PHY update, if the same packet size or transmission time as the previous one is desired, change the maximum transmission packet size or the maximum transmission time by [R_BLE_GAP_SetDataLen\(\)](#).

BLE_ISO_CIS_REJECT(0x01)	Reject the CIS request.
macro	description

```

Create the ISO data path between the Host and the Controller for a CIS.

This function behaviors depending on the platform. For SoC without Bluetooth Audio support, only the following value are valid in param path:

field	value
path_id	BLE_ISO_DATA_PATH_HCI
coding_format	0xFF (Vendor specific coding format)

Parameters

This function copies SDU payload into host's buffer and push the buffer into host's TX queue. Once the payload is accepted by controller scheduler, [BLE_ISO_EVENT_ISO_TX_COMP](#) event is sent back to application. Due to limitation of host buffer capacity, the maximum size of SDU payload is 251 bytes ([BLE_ISO_DATA_MAX_PDU](#)).

```

Send SDU payload to a ISO channel of conn_hdl without copying data.

This function behaviors similar to R_BLE_ISO_SendData, but without copying SDU payload to the buffer in host. For this reason application should hold the buffer until a [BLE_ISO_EVENT_ISO_TX_COMP](#) event with the same conn_hdl and seq_number of p_sdu_info is received. The maximum size of SDU payload defined by [BLE_ISO_DATA_MAX_SDU](#).

◆ R_BLE_GATTC_Init()

```
ble_status_t R_BLE_GATTC_Init ( uint8_t cb_num)
```

This function initializes the GATT Client and registers the number of the callbacks for GATT Client event.

Specify the `cb_num` parameter to a value between 1 and `BLE_GATTC_MAX_CB`.

[R_BLE_GATTC_RegisterCb\(\)](#) registers the callback.

The result of this API call is returned by a return value.

Parameters

[in]	<code>cb_num</code>	The number of callbacks to be registered.
------	---------------------	---

Return values

<code>BLE_SUCCESS(0x0000)</code>	Success
<code>BLE_ERR_INVALID_ARG(0x0003)</code>	The <code>cb_num</code> parameter is out of range.

◆ **R_BLE_GATTC_RegisterCb()**

```
ble_status_t R_BLE_GATTC_RegisterCb ( ble_gattc_app_cb_t cb, uint8_t priority )
```

This function registers a callback function for GATT Client event.

The number of the callback that may be registered by this function is the value specified by [R_BLE_GATTC_Init\(\)](#).

The result of this API call is returned by a return value.

Parameters

[in]	cb	Callback function for GATT Client event.
[in]	priority	The priority of the callback function. Valid range is $1 \leq \text{priority} \leq \text{BLE_GATTC_MAX_CB}$. A lower priority number means a higher priority level.

```
ble_status_t R_BLE_GATTC_WriteLongChar ( uint16_t conn_hdl, st_ble_gatt_hdl_value_pair_t *
p_write_data, uint16_t offset )
```

This function writes a Long Characteristic in a GATT Server.

The result of a write that has been done every segmentation is notified to the application layer in BLE_GATTC_EVENT_CHAR_PART_WRITE_RSP event.

The maximum writable size to a Long Characteristic with this function is 512 bytes.

When all of the contents has been written to the Long Characteristic,

BLE_GATTC_EVENT_LONG_CHAR_WRITE_COMP event is notified to the application layer.

Parameters

[in]	conn_hdl	Connection handle identifying the GATT Server to be written.
[in]	p_write_data	Value to be written to the Long Characteristic.
[in]	offset	Offset that indicates the location to be written. Normally, set 0 to this parameter. If this parameter sets to a value other than 0, adjust the offset parameter and the length of the value to be written not to exceed the length of the Long Characteristic.

Return values

BLE_SUCCESS(0x0000)	Success
BLE_ERR_INVALID_PTR(0x0001)	The p_write_data parameter or the p_value field in the value field in the p_write_data parameter is specified as NULL.

◆ R_BLE_GATTC_ReliableWrites()

```
ble_status_t R_BLE_GATTC_ReliableWrites ( uint16_t conn_hdl,
st_ble_gattc_reliable_writes_char_pair_t* p_char_pair, uint8_t pair_num, uint8_t auto_flag )
```

This function performs the Reliable Writes procedure described in GATT Specification.

When the data written to the Characteristic has been transmitted, BLE_GATTC_EVENT_CHAR_PART_WRITE_RSP event is notified to the application layer. If the data included in the event is different from the data that GATT Client has sent, host stack automatically cancels the Reliable Writes.

After all of the contents has been sent to the GATT Server, if the auto_flag parameter has been set to BLE_GATTC_EXEC_AUTO, the GATT Server automatically writes the data to the Characteristic. If the auto_flag parameter has been set to BLE_GATTC_EXEC_NOT_AUTO, BLE_GATTC_EVENT_RELIABLE_WRITES_TX_COMP event notifies the application layer in GATT Client that all of the contents has been sent to the GATT Server. Then GATT Client requests for writing the data to the Characteristic to the GATT Server with R_BLE_GATTC_ExecWrite(). When the write has been done, BLE_GATTC_EVENT_RELIABLE_WRITES_COMP event is notified to the application layer.

Parameters

[in]	conn_hdl	Connection handle identifying the GATT Server to be written.						
[in]	p_char_pair	Pair of Characteristic Value and Characteristic Value Handle identifying the Characteristic to be written by Reliable Writes.						
[in]	pair_num	The number of the pairs specified by the p_char_pair parameter. Valid range is 0 < pair_num ≤ BLE_GATTC_RELIABLE_WRITES_MAX_CHAR_PAIR.						
[in]	auto_flag	The flag that indicates whether auto execution or not. <table border="1" data-bbox="1072 1570 1469 1874"> <thead> <tr> <th>macro</th> <th>description</th> </tr> </thead> <tbody> <tr> <td>BLE_GATTC_EXEC_AUTO(0x01)</td> <td>Auto execution.</td> </tr> <tr> <td>BLE_GATTC_EXEC_NOT_AUTO(0x02)</td> <td>Not auto execution.</td> </tr> </tbody> </table>	macro	description	BLE_GATTC_EXEC_AUTO(0x01)	Auto execution.	BLE_GATTC_EXEC_NOT_AUTO(0x02)	Not auto execution.
macro	description							
BLE_GATTC_EXEC_AUTO(0x01)	Auto execution.							
BLE_GATTC_EXEC_NOT_AUTO(0x02)	Not auto execution.							

Return values

BLE_SUCCESS(0x0000)	Success
BLE_ERR_INVALID_PTR(0x0001)	The reason for this error is as follows:

	<ul style="list-style-type: none"> • The p_char_pair parameter is specified as NULL. • The p_value field in the value field in the write_data field in the p_char_pair parameter is specified as NULL.
BLE_ERR_INVALID_ARG(0x0003)	<p>The reason for this error is as follows:</p> <ul style="list-style-type: none"> • The pair_num parameter or the auto_flag parameter is out of range. • The value_len field in the value field in the write_data field in the p_char_pair parameter is 0.
BLE_ERR_INVALID_OPERATION(0x0009)	While processing other request, this function was called.
BLE_ERR_MEM_ALLOC_FAILED(0x000C)	Insufficient memory is needed to generate this function or to store the temporary write data.
BLE_ERR_INVALID_HDL(0x000E)	The GATT Server specified by conn_hdl was not found.

◆ **R_BLE_GATTC_ExecWrite()**

```
ble_status_t R_BLE_GATTC_ExecWrite ( uint16_t conn_hdl, uint8_t exe_flag )
```

If the auto execute of Reliable Writes is not specified by [R_BLE_GATTC_ReliableWrites\(\)](#), this function is used to execute a write to Characteristic.

When all of the contents has been sent to the GATT Server, BLE_GATTC_EVENT_RELIABLE_WRITES_TX_COMP event notifies the application layer. After this event has been received, execute the write by this function. The result of the write is notified by BLE_GATTC_EVENT_RELIABLE_WRITES_COMP event.

Parameters

[in]	conn_hdl	Connection handle identifying the target GATT Server.						
[in]	exe_flag	The flag that indicates whether execution or cancellation. <table border="1" data-bbox="1075 898 1469 1285"> <thead> <tr> <th>macro</th> <th>description</th> </tr> </thead> <tbody> <tr> <td>BLE_GATTC_EXECUTE_WRITE_CANCEL_FLAG(0x00)</td> <td>Execute the write.</td> </tr> <tr> <td>BLE_GATTC_EXECUTE_WRITE_FLAG(0x01)</td> <td>Cancel the write.</td> </tr> </tbody> </table>	macro	description	BLE_GATTC_EXECUTE_WRITE_CANCEL_FLAG(0x00)	Execute the write.	BLE_GATTC_EXECUTE_WRITE_FLAG(0x01)	Cancel the write.
macro	description							
BLE_GATTC_EXECUTE_WRITE_CANCEL_FLAG(0x00)	Execute the write.

Return values

BLE_SUCCESS(0x0000)	Success
BLE_ERR_INVALID_ARG(0x0003)	The exe_flag parameter is out of range.
BLE_ERR_INVALID_OPERATION(0x0009)	The reason for this error is as follows: <ul style="list-style-type: none"> GATT Client has not requested for Reliable Writes by R_BLE_GATTC_ReliableWrites(). Although auto execution has been specified by R_BLE_GATTC_ReliableWrites(), this function was called.
BLE_ERR_MEM_ALLOC_FAILED(0x000C)	Insufficient memory is needed to generate this function.
BLE_ERR_INVALID_HDL(0x000E)	The GATT Server specified by conn_hdl was not found.

Function Documentation

◆ **R_BLE_L2CAP_RegisterCfPsm()**

```
ble_status_t R_BLE_L2CAP_RegisterCfPsm ( ble_l2cap_cf_app_cb_t cb, uint16_t psm, uint16_t lwm )
```

This function registers PSM that uses L2CAP CBFC Channel and a callback for L2CAP event.

Only one callback is available per PSM. Configure in each PSM the Low Water Mark of the LE-Frames that the local device can receive.

When the number of the credit reaches the Low Water Mark, BLE_L2CAP_EVENT_CF_LOW_RX_CRD_IND event is notified to the application layer.

The number of PSM is defined as BLE_L2CAP_MAX_CBFC_PSM.

The result of this API call is returned by a return value.

Parameters

[in]	cb	Callback function for L2CAP event.									
[in]	psm	Identifier indicating the protocol/profile that uses L2CAP CBFC Channel. <table border="1"> <thead> <tr> <th>type</th> <th>range</th> <th>description</th> </tr> </thead> <tbody> <tr> <td>Fixed, SIG assigned</td> <td>0x0001 - 0x007F</td> <td>PSM defined by SIG. For more information on PSM, refer Bluetooth SIG Assigned Number (https://www.bluetooth.com/specifications/assigned-numbers).</td> </tr> <tr> <td>Dynamically allocated</td> <td>0x0080 - 0x00FF</td> <td>Statically allocated PSM by custom protocol or dynamically</td> </tr> </tbody> </table>	type	range	description	Fixed, SIG assigned	0x0001 - 0x007F	PSM defined by SIG. Call this function before the notification(BLE_VS_EVENT_TX_FLOW_STATE_CHG event) has been started by [R_BLE_VS_StartTxFlowEvtNtf\(\)](#).

The result is returned from this API.

Vendor Specific API supports the flow control function(TxFlow) for the transmission on L2CAP fixed channel in Basic Mode such as GATT.

Host stack has 10 transmission packet buffers for the transmission.

When the number of the available transmission packet buffers has been less than Low Water Mark, the state of TxFlow transmits into the TxFlow OFF state from the TxFlow ON state that is the initial state and host stack notifies the application layer of timing to stop packet transmission.

When host stack has sent the transmission packets to Controller and the number of the available transmission packet buffers has been more than High Water Mark, the state of TxFlow transmits into the TxFlow ON state from the TxFlow OFF state and host stack notifies the application layer of

timing to restart packet transmission.

It is possible to perform flow control on a fixed channel by using the event notification.

Parameters

[in]	tx_queue_lwm	Low Water Mark. Set 0-9 less than tx_queue_hwm to the parameter. When the number of the available transmission packet buffers has been less than the value specified by the tx_queue_lwm parameter, host stack notifies the application layer of the timing to stop packet transmission.
[in]	tx_queue_hwm	High Water Mark. Set 1-10 more than tx_queue_lwm to the parameter. When the number of the available transmission packet buffers has been more than the value specified by the tx_queue_hwm parameter, host stack notifies the application layer of the timing to restart packet transmission.

Return values

BLE_SUCCESS(0x0000)	Success
BLE_ERR_INVALID_ARG(0x0003)	The tx_queue_lwm parameter or the tx_queue_hwm parameter is out of range.

Modules[Low Power Modes Interface](#)

Interface for accessing low power modes.

7.3.12.1 Low Power Modes Interface[Interfaces](#) » [Power](#)**Detailed Description**

Interface for accessing low power modes.

Summary

This section defines the API for the LPM (Low Power Mode) Driver. The LPM Driver provides functions for controlling power consumption by configuring and transitioning to a low power mode. The LPM driver supports configuration of MCU low power modes using the LPM hardware peripheral. The LPM driver supports low power modes deep standby, standby, sleep, and snooze.

Note

Not all low power modes are available on all MCUs.

ELC Interface

Interface for the Event Link Controller.

I/O Port Interface

Interface for accessing I/O ports and configuring I/O functionality.

7.3.16.1 CGC Interface

[Interfaces](#) » [System](#)

Detailed Description

Interface for clock generation.

Summary

The CGC interface provides the ability to configure and use all of the CGC module's capabilities. Among the capabilities is the selection of several clock sources to use as the system clock source. Additionally, the system clocks can be divided down to provide a wide range of frequencies for various system and peripheral needs.

Clock stability can be checked and clocks may also be stopped to save power when not needed. The API has a function to return the frequency of the system and system peripheral clocks at run time. There is also a feature to detect when the main oscillator has stopped, with the option of calling a user provided callback function.

The general timer interface provides standard timer functionality including periodic mode, one-shot mode, PWM output, and free-running timer mode. After each timer cycle (overflow or underflow), an interrupt can be triggered.

If an instance supports output compare mode, it is provided in the extension configuration `timer_on_<instance>_cfg_t` defined in `r_<instance>.h`.

◆ [transfer_info_t](#)

struct transfer_info_t		
This structure specifies the properties of the transfer.		
Warning		
When using DTC, this structure corresponds to the descriptor block registers required by the DTC. The following components may be modified by the driver: p_src , p_dest , num_blocks , and length .		
When using DTC, do NOT reuse this structure to configure multiple transfers. Each transfer must have a unique transfer_info_t .		
When using DTC, this structure must not be allocated in a temporary location. Any instance		

of this structure must remain in scope until the transfer it is used for is closed.

Note

When using DTC, consider placing instances of this structure in a protected section of memory.

void const *volatile	p_src	Source pointer.
void *volatile	p_dest	Destination pointer.
volatile uint16_t	num_blocks	Number of blocks to transfer when using TRANSFER_MODE_BLOCK (both DTC and DMAC) or TRANSFER_MODE_REPEAT (DMAC only) or TRANSFER_MODE_REPEAT_BLOCK (DMAC only), unused in other modes.

Enumeration Type Documentation

◆ **transfer_mode_t**

enum <code>transfer_mode_t</code>	
Transfer mode describes what will happen when a transfer request occurs.	
Enumerator	
<code>TRANSFER_MODE_NORMAL</code>	In normal mode, each transfer request causes a transfer of <code>transfer_size_t</code> from the source pointer to the destination pointer. The transfer length is decremented and the source and address pointers are updated according to <code>transfer_addr_mode_t</code> . After the transfer length reaches 0, transfer requests will not cause any further transfers.
<code>TRANSFER_MODE_REPEAT</code>	Repeat mode is like normal mode, except that when the transfer length reaches 0, the pointer to the repeat area and the transfer length will be reset to their initial values. If DMAC is used, the transfer repeats only <code>transfer_info_t::num_blocks</code> times. After the transfer repeats <code>transfer_info_t::num_blocks</code> times, transfer requests will not cause any further transfers. If DTC is used, the transfer repeats continuously (no limit to the number of repeat transfers).
<code>TRANSFER_MODE_BLOCK</code>	In block mode, each transfer request causes <code>transfer_info_t::length</code> transfers of <code>transfer_size_t</code> . After each individual transfer, the source and destination pointers are updated according to <code>transfer_addr_mode_t</code> . After the block transfer is complete, <code>transfer_info_t::num_blocks</code> is decremented. After the <code>transfer_info_t::num_blocks</code> reaches 0, transfer requests will not cause any further transfers.
<code>TRANSFER_MODE_REPEAT_BLOCK</code>	In addition to block mode features, repeat-block mode supports a ring buffer of blocks and offsets within a block (to split blocks into arrays of their first data, second data, etc.)

◆ **transfer_size_t**

enum transfer_size_t	
Transfer size specifies the size of each individual transfer. Total transfer length = <code>transfer_size_t * transfer_length_t</code>	
Enumerator	
TRANSFER_SIZE_1_BYTE	Each transfer transfers a 8-bit value.
TRANSFER_SIZE_2_BYTE	Each transfer transfers a 16-bit value.
TRANSFER_SIZE_4_BYTE	Each transfer transfers a 32-bit value.
TRANSFER_SIZE_8_BYTE	Each transfer transfers a 64-bit value.

◆ **transfer_addr_mode_t**

enum transfer_addr_mode_t	
Address mode specifies whether to modify (increment or decrement) pointer after each transfer.	
Enumerator	
TRANSFER_ADDR_MODE_FIXED	Address pointer remains fixed after each transfer.
TRANSFER_ADDR_MODE_OFFSET	Offset is added to the address pointer after each transfer.
TRANSFER_ADDR_MODE_INCREMENTED	Address pointer is incremented by associated transfer_size_t after each transfer.
TRANSFER_ADDR_MODE_DECREMENTED	Address pointer is decremented by associated transfer_size_t after each transfer.

◆ **transfer_repeat_area_t**

enum transfer_repeat_area_t	
Repeat area options (source or destination). In TRANSFER_MODE_REPEAT , the selected pointer returns to its original value after transfer_info_t::length transfers. In TRANSFER_MODE_BLOCK and TRANSFER_MODE_REPEAT_BLOCK , the selected pointer returns to its original value after each transfer.	
Enumerator	
TRANSFER_REPEAT_AREA_DESTINATION	Destination area repeated in TRANSFER_MODE_REPEAT or TRANSFER_MODE_BLOCK or TRANSFER_MODE_REPEAT_BLOCK .
TRANSFER_REPEAT_AREA_SOURCE	Source area repeated in TRANSFER_MODE_REPEAT or TRANSFER_MODE_BLOCK or TRANSFER_MODE_REPEAT_BLOCK .

◆ **transfer_chain_mode_t**

enum transfer_chain_mode_t	
Chain transfer mode options.	
<i>Note</i> <i>Only applies for DTC.</i>	
Enumerator	
TRANSFER_CHAIN_MODE_DISABLED	Chain mode not used.
TRANSFER_CHAIN_MODE_EACH	Switch to next transfer after a single transfer from this transfer_info_t .
TRANSFER_CHAIN_MODE_END	Complete the entire transfer defined in this transfer_info_t before chaining to next transfer.

◆ **transfer_irq_t**

enum transfer_irq_t	
Interrupt options.	
Enumerator	
TRANSFER_IRQ_END	<p>Interrupt occurs only after last transfer. If this transfer is chained to a subsequent transfer, the interrupt will occur only after subsequent chained transfer(s) are complete.</p> <p>Warning DTC triggers the interrupt of the activation source. Choosing TRANSFER_IRQ_END with DTC will prevent activation source interrupts until the transfer is complete.</p>
TRANSFER_IRQ_EACH	<p>Interrupt occurs after each transfer.</p> <p><i>Note</i> <i>Not available in all HAL drivers. See HAL driver for details.</i></p>

◆ **transfer_start_mode_t**

enum transfer_start_mode_t	
Select whether to start single or repeated transfer with software start.	
Enumerator	
TRANSFER_START_MODE_SINGLE	Software start triggers single transfer.
TRANSFER_START_MODE_REPEAT	Software start transfer continues until transfer is complete.

Function Documentation◆ **ptxPLAT_DisableInterrupts()**

```
void ptxPLAT_DisableInterrupts ( struct ptxPlat * plat)
```

Disable Interrupts.

This is used to disable IRQs from the underlying HW-platform.

Parameters

[in]	plat	Pointer to an initialized component structure.
------	------	--

◆ **ptxPLAT_EnableInterrupts()**

```
void ptxPLAT_EnableInterrupts ( struct ptxPlat * plat)
```

Enable Interrupts.

This is used to (re-)enable IRQs from the underlying HW-platform.

Parameters

[in]	plat	Pointer to an initialized component structure.
------	------	--

◆ ptxPLAT_CheckRxActive()

```
uint8_t ptxPLAT_CheckRxActive ( struct ptxPlat * plat)
```

Check if PLAT interface reception is taking place at the moment.

Note

The function is called in message reception loop after WFI -after CPU exits Sleep mode. This is relevant for UART interface since reception is interrupt driven (every byte received in ISR) and race condition might occur while checking if message has been received. If there is Rx activity on UART, WFI does not get called anymore in that loop. For other interfaces this function call always returns 0 and CPU enters sleep mode in every iteration.

Parameters

[in]	plat	Pointer to an initialized component structure.
------	------	--

Returns

Rx status: 0 - no rx activity, 1 - rx activity ongoing.
