General Description

The 83905 is a low skew, 1-to-6 LVCMOS / LVTTL Fanout Buffer. The low impedance LVCMOS/LVTTL outputs are designed to drive 50 Ω series or parallel terminated transmission lines. The effective fanout can be increased from 6 to 12 by utilizing the ability of the outputs to drive two series terminated lines.

The 83905 is characterized at full 3.3V, 2.5V, and 1.8V, mixed 3.3V/2.5V, 3.3V/1.8V and 2.5V/1.8V output operating supply mode. Guaranteed output and part-to-part skew characteristics along with the 1.8V output capabilities makes the 83905 ideal for high performance, single ended applications that also require a limited output voltage.

Pin Assignments

Features

- **•** Six LVCMOS / LVTTL outputs
- **•** Outputs able to drive 12 series terminated lines
- **•** Crystal Oscillator Interface
- **•** Crystal input frequency range: 10MHz to 40MHz
- **•** Output skew: 80ps (maximum)
- **•** RMS phase jitter @ 25MHz, (100Hz 1MHz): 0.26ps (typical), $V_{DD} = V_{DDO} = 2.5V$

- **•** 5V tolerant enable inputs
- **•** Synchronous output enables
- **•** Operating power supply modes: Full 3.3V, 2.5V, 1.8V Mixed 3.3V core/2.5V output operating supply Mixed 3.3V core/1.8V output operating supply Mixed 2.5V core/1.8V output operating supply
- **•** 0°C to 70°C ambient operating temperature
- **•** Lead-free (RoHS 6) packaging

Absolute Maximum Ratings

NOTE: Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These ratings are stress specifications only. Functional operation of product at these conditions or any conditions beyond those listed in the *DC Characteristics or AC Characteristics* is not implied. Exposure to absolute maximum rating conditions for extended periods may affect product reliability.

AC Electrical Characteristics

NOTE: Electrical parameters are guaranteed over the specified ambient operating temperature range, which is established when the device is mounted in a test socket with maintained transverse airflow greater than 500 lfpm. The device will meet specifications after thermal equilibrium has been reached under these conditions.

All parameters measured at $f \le f_{\text{MAX}}$ using a crystal input unless noted otherwise.

Terminated at 50 Ω to $V_{DDO}/2$.

NOTE 1: XTAL_IN can be overdriven by a single-ended LVCMOS signal. Please refer to Application Information section.

NOTE 2: Defined as skew between outputs at the same supply voltage and with equal load conditions. Measured at $V_{DDO}/2$.

NOTE 3: This parameter is defined in accordance with JEDEC Standard 65.

NOTE 4: See phase noise plot.

NOTE 5: These parameters are guaranteed by characterization. Not tested in production.

Application Information

Crystal Input Interface

Figure 2 shows an example of 83905 crystal interface with a parallel resonant crystal. The frequency accuracy can be fine tuned by adjusting the C1 and C2 values. For a parallel crystal with loading capacitance $CL = 18pF$, to start with, we suggest $C1 =$ 15pF and C2 = 15pF. These values may be slightly fine tuned further to optimize the frequency accuracy for different board

XTAL_IN XTAL_OUT C1 15_c $C₂$ 15_c X1 18pF Parallel Crystal R1 (optional) \overline{O}

layouts. Slightly increasing the C1 and C2 values will slightly reduce the frequency. Slightly decreasing the C1 and C2 values will slightly increase the frequency. For the oscillator circuit below, R1 can be used, but is not required. For new designs, it is recommended that R1 not be used.

Figure 2. Crystal Input Interface

LVCMOS to XTAL Interface

The XTAL_IN input can accept a single-ended LVCMOS signal through an AC coupling capacitor. A general interface diagram is shown in *Figure 3.* The XTAL_OUT pin can be left floating. The input edge rate can be as slow as 10ns. For LVCMOS inputs, it is recommended that the amplitude be reduced from full swing to half swing in order to prevent signal interference with the power rail and to reduce noise. This configuration requires that the output impedance of the driver (Ro) plus the series resistance (Rs) equals the transmission line impedance. In addition, matched termination at the crystal input will attenuate the signal in half. This can be done in one of two ways. First, R1 and R2 in parallel should equal the transmission line impedance. For most 50Ω applications, R1 and R2 can be 100 Ω . This can also be accomplished by removing R1 and making R2 50 Ω . By overdriving the crystal oscillator, the device will be functional, but note, the device performance is guaranteed by using a quartz crystal.

Figure 3. General Diagram for LVCMOS Driver to XTAL Input Interface

VFQFN EPAD Thermal Release Path

In order to maximize both the removal of heat from the package and the electrical performance, a land pattern must be incorporated on the Printed Circuit Board (PCB) within the footprint of the package corresponding to the exposed metal pad or exposed heat slug on the package, as shown in *Figure 4.* The solderable area on the PCB, as defined by the solder mask, should be at least the same size/shape as the exposed pad/slug area on the package to maximize the thermal/electrical performance. Sufficient clearance should be designed on the PCB between the outer edges of the land pattern and the inner edges of pad pattern for the leads to avoid any shorts.

While the land pattern on the PCB provides a means of heat transfer and electrical grounding from the package to the board through a solder joint, thermal vias are necessary to effectively conduct from the surface of the PCB to the ground plane(s). The land pattern must be connected to ground through these vias. The vias act as "heat pipes". The number of vias (i.e. "heat pipes") are

application specific and dependent upon the package power dissipation as well as electrical conductivity requirements. Thus, thermal and electrical analysis and/or testing are recommended to determine the minimum number needed. Maximum thermal and electrical performance is achieved when an array of vias is incorporated in the land pattern. It is recommended to use as many vias connected to ground as possible. It is also recommended that the via diameter should be 12 to 13mils (0.30 to 0.33mm) with 1oz copper via barrel plating. This is desirable to avoid any solder wicking inside the via during the soldering process which may result in voids in solder between the exposed pad/slug and the thermal land. Precautions should be taken to eliminate any solder voids between the exposed heat slug and the land pattern. Note: These recommendations are to be used as a guideline only. For further information, please refer to the Application Note on the Surface Mount Assembly of Amkor's Thermally/Electrically Enhance Leadframe Base Package, Amkor Technology.

Recommendations for Unused Input and Output Pins

Inputs:

LVCMOS Control Pins

All control pins have internal pull-ups or pull-downs; additional resistance is not required but can be added for additional protection. A 1 $k\Omega$ resistor can be used.

Outputs:

LVCMOS Outputs

All unused LVCMOS output can be left floating. There should be no trace attached.

Layout Guideline

Figure 5 shows an example of 83905 application schematic. The schematic example focuses on functional connections and is not configuration specific. In this example, the device is operated at V_{DD} = 3.3V and V_{DDO} = 1.8V. The crystal inputs are loaded with an 18pf load resonant quartz crystal. The tuning capacitors (C1, C2) are fairly accurate, but minor adjustments might be required. Refer to the pin description and functional tables in the datasheet to ensure the logic control inputs are properly set. For the LVCMOS output drivers, two termination examples are shown in the schematic. For additional termination examples are shown in the LVCMOS Termination Application Note.

As with any high speed analog circuitry, the power supply pins are vulnerable to random noise. To achieve optimum jitter performance, power supply isolation is required. The 83905 provides separate V_{DD} and V_{DDO} power supplies to isolate any high switching noise from coupling into the internal oscillator. In order to achieve the best possible filtering, it is highly

recommended that the 0.1uF capacitors on the device side of the ferrite beads be placed on the device side of the PCB as close to the power pins as possible. This is represented by the placement of these capacitors in the schematic. If space is limited, the ferrite beads, 10uF and 0.1uF capacitor connected to the board supplies can be placed on the opposite side of the PCB. If space permits, place all filter components on the device side of the board.

Power supply filter recommendations are a general guideline to be used for reducing external noise from coupling into the devices. The filter performance is designed for a wide range of noise frequencies. This low-pass filter starts to attenuate noise at approximately 0kHz. If a specific frequency noise component is known, such as switching power supplies frequencies, it is recommended that component values be adjusted and if required, additional filtering be added. Additionally, good general design practices for power plane voltage stability suggests adding bulk capacitance in the local area of all devices.

Figure 5. Schematic of Recommended Layout

Power Considerations

This section provides information on power dissipation and junction temperature for the 83905. Equations and example calculations are also provided.

1. Power Dissipation.

The total power dissipation for the 83905 is the sum of the core power plus the analog power plus the power dissipated due to the load. The following is the power dissipation for $V_{DD} = 3.3V + 5% = 3.465V$, which gives worst case results.

- Power (core)_{MAX} = V_{DD} _{MAX} $*$ (I_{DD} + I_{DDO}) = 3.465V $*$ (10mA + 5mA) = **51.9mW**
- Output Impedance R_{OUT} Power Dissipation due to Loading 50 Ω to $V_{\text{DD}}/2$ Output Current $I_{\text{OUT}} = V_{\text{DD_MAX}} / [2 \times (50\Omega + R_{\text{OUT}})] = 3.465 \text{V} / [2 \times (50\Omega + 7\Omega)] = 30.4 \text{mA}$
- Power Dissipation on the R_{OUT} per LVCMOS output Power (R_{OUT}) = R_{OUT} * (I_{OUT})² = 7 Ω * (30.4mA)² = **6.5mW per output**
- Total Power Dissipation on the R_{OUT} **Total Power** $(R_{OUT}) = 6.5$ **mW** $*$ 6 = 39mW

Dynamic Power Dissipation at 25MHz

Power (25MHz) = C_{PD} * Frequency * (V_{DD})² = 19pF * 25MHz * (3.465V)² = **5.70mW per output Total Power** (25MHz) = 5.70mW * 6 = **34.2mW**

Total Power Dissipation

```
• Total Power
```
- = Power (core) $_{MAX}$ + Total Power (R_{OUT}) + Total Power (25MHz) = 51.98mW + 39mW + 34.2mW
- **= 125.1mW**

2. Junction Temperature.

Junction temperature, Tj, is the temperature at the junction of the bond wire and bond pad and directly affects the reliability of the device. The maximum recommended junction temperature is 125°C.

The equation for Tj is as follows: Tj = θ_{JA} * Pd_total + T_A

 Tj = Junction Temperature

 θ_{IA} = Junction-to-Ambient Thermal Resistance

Pd_total = Total Device Power Dissipation (example calculation is in section 1 above)

 T_A = Ambient Temperature

In order to calculate junction temperature, the appropriate junction-to-ambient thermal resistance θ_{JA} must be used. Assuming no air flow and a multi-layer board, the appropriate value is 100.3°C/W per Table 7 below.

Therefore, Tj for an ambient temperature of 70°C with all outputs switching is:

 70° C + 0.125W *100.3°C/W = 82.5°C. This is below the limit of 125°C.

This calculation is only an example. Tj will obviously vary depending on the number of loaded outputs, supply voltage, air flow and the type of board (multi-layer).
