POWER CONSIDERATIONS

This section provides information on power dissipation and junction temperature for the 840001I-25. Equations and example calculations are also provided.

1. Power Dissipation.

The total power dissipation for the 840001I-25 is the sum of the core power plus the power dissipated in the load(s). The following is the power dissipation for $V_{DD} = 3.3V + 5\% = 3.465V$, which gives worst case results.

Core and Output Power Dissipation

- Power (core, output) = $V_{DD_MAX} * (I_{DD} + I_{DDO}) = 3.465V * (83mA + 2mA) = \mathbf{294.5mW}$

LVC MOS Output Power Dissipation

- Output Impedance R_{OUT} Power Dissipation due to Loading 50Ω to $V_{DDO}/2$
Output Current $I_{OUT} = V_{DDO_MAX} / [2 * (50\Omega + R_{OUT})] = 3.465V / [2 * (50\Omega + 15\Omega)] = \mathbf{26.6mA}$
- Power Dissipation on the R_{OUT} per LVC MOS output
Power (R_{OUT}) = $R_{OUT} * (I_{OUT})^2 = 15\Omega * (26.6mA)^2 = \mathbf{10.6mW}$ per output
- Dynamic Power Dissipation at 156.25MHz
Power (156.25MHz) = $C_{PD} * Frequency * (V_{DDO})^2 = 6pF * 156.25MHz * (3.465V)^2 = \mathbf{11.26mW}$ per output

Total Power Dissipation

- Total Power**
= Power (core, output) + Power Dissipation (R_{OUT}) + Dynamic Power Dissipation (156.25MHz)
= 294.5mW + 10.6mW + 11.26mW
= **316.4mW**

2. Junction Temperature.

Junction temperature, T_j, is the temperature at the junction of the bond wire and bond pad and directly affects the reliability of the device. The maximum recommended junction temperature for HiPerClockS™ devices is 125°C.

The equation for T_j is as follows: $T_j = \theta_{JA} * Pd_total + T_A$

T_j = Junction Temperature

θ_{JA} = Junction-to-Ambient Thermal Resistance

Pd_{total} = Total Device Power Dissipation (example calculation is in section 1 above)

T_A = Ambient Temperature

In order to calculate junction temperature, the appropriate junction-to-ambient thermal resistance θ_{JA} must be used. Assuming a moderate air flow of 1 meter per second and a multi-layer board, the appropriate value is 125.5°C/W per Table 5.

Therefore, T_j for an ambient temperature of 85°C with all outputs switching is:

$$85^{\circ}\text{C} + 0.316\text{W} * 125.5^{\circ}\text{C}/\text{W} = 124.7^{\circ}\text{C}.$$

This is below the limit of 125°C.

This calculation is only an example. T_j will obviously vary depending on the number of loaded outputs, supply voltage, air flow, and the type of board (multi-layer).
