

Four Output Differential Buffer for PCI-Express

Recommended Application:

DB400 Intel Yellow Cover part with PCI-Express support.

Output Features:

- 4 - 0.7V current-mode differential output pairs
- Supports zero delay buffer mode and fanout mode
- Bandwidth programming available

Key Specifications:

- Outputs cycle-cycle jitter: < 50ps
- Outputs skew: < 50ps
- +/- 300ppm frequency accuracy on output clocks

Features/Benefits:

- Supports tight ppm accuracy clocks for Serial-ATA
- Spread spectrum modulation tolerant, 0 to -0.5% down spread and +/- 0.25% center spread
- Supports undriven differential output pair in PD# and SRC_STOP# for power management.

Pin Configuration

BYPASS#/PLL	12		17	HIGH_BW#
SCLK	13		16	SRC_STOP#
SDATA	14		15	PD#

28-pin SSOP & TSSOP

Not recommended for new designs

Pin Description

PIN #	PIN NAME	PIN TYPE	DESCRIPTION
1	VDD	PWR	Power supply, nominal 3.3V
2	SRC_IN	IN	0.7 V Differential SRC TRUE input
3	SRC_IN#	IN	0.7 V Differential SRC COMPLEMENTARY input
4	GND	PWR	Ground pin.
5	VDD	PWR	Power supply, nominal 3.3V
6	DIF_1	OUT	0.7V differential true clock outputs
7	DIF_1#	OUT	0.7V differential complement clock outputs
8	OE_1	IN	Active high input for enabling outputs. 0 = tri-state outputs, 1= enable outputs
9	DIF_2	OUT	0.7V differential true clock outputs
10	DIF_2#	OUT	0.7V differential complement clock outputs
11	VDD	PWR	Power supply, nominal 3.3V
12	BYPASS#/PLL	IN	Input to select Bypass(fan-out) or PLL (ZDB) mode 0 = Bypass mode, 1= PLL mode
13	SCLK	IN	Clock pin of SMBus circuitry, 5V tolerant.
14	SDATA	I/O	Data pin for SMBus circuitry, 5V tolerant.
15	PD#	IN	Asynchronous active low input pin used to power down the device. The internal clocks are disabled and the VCO and the crystal are stopped.
16	SRC_STOP#	IN	Active low input to stop diff outputs.
17	HIGH_BW#	IN	3.3V input for selecting PLL Band Width 0 = High, 1= Low
18	VDD	PWR	Power supply, nominal 3.3V
19	DIF_5#	OUT	0.7V differential complement clock outputs
20	DIF_5	OUT	0.7V differential true clock outputs
21	OE_6	IN	Active high input for enabling outputs. 0 = tri-state outputs, 1= enable outputs
22	DIF_6#	OUT	0.7V differential complement clock outputs
23	DIF_6	OUT	0.7V differential true clock outputs
24	VDD	PWR	Power supply, nominal 3.3V
25	GND	PWR	Ground pin.
26	IREF	OUT	This pin establishes the reference current for the differential current-mode output pairs. This pin requires a fixed precision resistor tied to ground in order to establish the appropriate current. 475 ohms is the standard value.
27	GNDA	PWR	Ground pin for the PLL core.
28	VDDA	PWR	3.3V power for the PLL core.

General Description

ICS9DB104 follows the Intel DB400 Differential Buffer Specification. This buffer provides four SRC clocks for PCI-Express, next generation I/O devices. ICS9DB104 is driven by a differential input pair from a CK409/CK410 main clock generator, such as the ICS952601 or ICS954101. ICS9DB104 can run at speeds up to 200MHz. It provides outputs meeting tight cycle-to-cycle jitter (50ps) and output-to-output skew (50ps) requirements.

¹Guaranteed by design and characterization, not 100% tested in production.

²All Long Term Accuracy and Clock Period specifications are guaranteed with the assumption that the input clock complies with CK409/CK410 accuracy requirements

³ $I_{REF} = V_{DD}/(3 \times R_R)$. For $R_R = 475\Omega$ (1%), $I_{REF} = 2.32\text{mA}$. $I_{OH} = 6 \times I_{REF}$ and $V_{OH} = 0.7\text{V}$ @ $Z_O = 50\Omega$.

General SMBus serial interface information for the ICS9DB104

How to Write:

- Controller (host) sends a start bit.
- Controller (host) sends the write address $DC_{(h)}$
- ICS clock will **acknowledge**
- Controller (host) sends the beginning byte location = N
- ICS clock will **acknowledge**
- Controller (host) sends the data byte count = X
- ICS clock will **acknowledge**
- Controller (host) starts sending **Byte N through Byte N + X - 1**
- ICS clock will **acknowledge** each byte **one at a time**
- Controller (host) sends a Stop bit

Controller (Host)		ICS (Slave/Receiver)
T	starT bit	
Slave Address $DC_{(h)}$		
WR	WRite	
		ACK
Beginning Byte = N		
		ACK
Data Byte Count = X		
		ACK
Beginning Byte N	X Byte	
○		ACK
○		○
○		○
Byte N + X - 1		○
		ACK
P	stoP bit	

How to Read:

- Controller (host) will send start bit.
- Controller (host) sends the write address $DC_{(h)}$
- ICS clock will **acknowledge**
- Controller (host) sends the beginning byte location = N
- ICS clock will **acknowledge**
- Controller (host) will send a separate start bit.
- Controller (host) sends the read address $DD_{(h)}$
- ICS clock will **acknowledge**
- ICS clock will send the data byte count = X
- ICS clock sends **Byte N + X - 1**
- ICS clock sends **Byte 0 through byte X (if $X_{(h)}$ was written to byte 8).**
- Controller (host) will need to acknowledge each byte
- Controller (host) will send a not acknowledge bit
- Controller (host) will send a stop bit

Controller (Host)		ICS (Slave/Receiver)
T	starT bit	
Slave Address $DC_{(h)}$		
WR	WRite	
		ACK
Beginning Byte = N		
		ACK
RT	Repeat starT	
Slave Address $DD_{(h)}$		
RD	ReaD	
		ACK
		Data Byte Count = X
ACK		
ACK		Beginning Byte N
○		○
○		○
○		○
		Byte N + X - 1
N	Not acknowledge	
P	stoP bit

Bit 0		-	BC0		RW	-	-	1

PD#

The PD# pin cleanly shuts off all clocks and places the device into a power saving mode. PD# must be asserted before shutting off the input clock or power to insure an orderly shutdown. PD is asynchronous active-low input for both powering down the device and powering up the device. When PD# is asserted, all clocks will be driven high, or tri-stated (depending on the PD# drive mode and Output control bits) before the PLL is shut down.

PD# Assertion

When PD# is sampled low by two consecutive rising edges of DIF#, all DIF outputs must be held High, or tri-stated (depending on the PD# drive mode and Output control bits) on the next High-Low transition of the DIF# outputs. When the PD# drive mode bit is set to '0', all clock outputs will be held with DIF driven High with $2 \times I_{REF}$ and DIF# tri-stated. If the PD# drive mode bit is set to '1', both DIF and DIF# are tri-stated.

PD# De-assertion

Power-up latency is less than 1 ms. This is the time from de-assertion of the PD# pin, or VDD reaching 3.3V, or the time from valid SRC_IN clocks until the time that stable clocks are output from the device (PLL Locked). If the PD# drive mode bit is set to '1', all the DIF outputs must driven to a voltage of >200 mV within 300 ms of PD# de-assertion.

SRC_STOP#

The SRC_STOP# signal is an active-low asynchronous input that cleanly stops and starts the DIF outputs. A valid clock must be present on SRC_IN for this input to work properly. The SRC_STOP# signal is de-bounced and must remain stable for two consecutive rising edges of DIF# to be recognized as a valid assertion or de-assertion.

SRC_STOP# - Assertion (transition from '1' to '0')

Asserting SRC_STOP# causes all DIF outputs to stop after their next transition (if the control register settings allow the output to stop). When the SRC_STOP# drive bit is '0', the final state of all stopped DIF outputs is DIF = High and DIF# = Low. There is no change in output drive current. DIF is driven with $6 \times I_{REF}$. DIF# is not driven, but pulled low by the termination. When the SRC_STOP# drive bit is '1', the final state of all DIF output pins is Low. Both DIF and DIF# are not driven.

SRC_STOP# - De-assertion (transition from '0' to '1')

All stopped differential outputs resume normal operation in a glitch-free manner. The de-assertion latency to active outputs is 2-6 DIF clock periods, with all DIF outputs resuming simultaneously. If the SRC_STOP# drive control bit is '1' (tri-state), all stopped DIF outputs must be driven High (>200 mV) within 10 ns of de-assertion.

SRC_STOP_1 (SRC_Stop = Driven, PD = Driven)

SRC_STOP_2 (SRC_Stop = Tri-state, PD = Driven)

SRC_STOP_3 (SRC_Stop = Driven, PD = Tristate)

SRC_STOP_4 (SRC_Stop = Tristate, PD = Tristate)
