

RH850/E1M-S2

User's Manual: Hardware

Renesas microcontroller
RH850 Family

All information contained in these materials, including products and product specifications, represents information on the product at the time of publication and is subject to change by Renesas Electronics Corp. without notice. Please review the latest information published by Renesas Electronics Corp. through various means, including the Renesas Electronics Corp. website (<http://www.renesas.com>).

Notice

1. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation or any other use of the circuits, software, and information in the design of your product or system. Renesas Electronics disclaims any and all liability for any losses and damages incurred by you or third parties arising from the use of these circuits, software, or information.
2. Renesas Electronics hereby expressly disclaims any warranties against and liability for infringement or any other disputes involving patents, copyrights, or other intellectual property rights of third parties, by or arising from the use of Renesas Electronics products or technical information described in this document, including but not limited to, the product data, drawing, chart, program, algorithm, application examples.
3. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
4. You shall not alter, modify, copy, or otherwise misappropriate any Renesas Electronics product, whether in whole or in part. Renesas Electronics disclaims any and all liability for any losses or damages incurred by you or third parties arising from such alteration, modification, copy or otherwise misappropriation of Renesas Electronics products.
5. Renesas Electronics products are classified according to the following two quality grades: "Standard" and "High Quality". The intended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below.
"Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; and industrial robots etc.
"High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control (traffic lights); large-scale communication equipment; key financial terminal systems; safety control equipment; etc.
Renesas Electronics products are neither intended nor authorized for use in products or systems that may pose a direct threat to human life or bodily injury (artificial life support devices or systems, surgical implantations etc.), or may cause serious property damages (space and undersea repeaters; nuclear power control systems; aircraft control systems; key plant systems; military equipment; etc.). Renesas Electronics disclaims any and all liability for any damages or losses incurred by you or third parties arising from the use of any Renesas Electronics product for which the product is not intended by Renesas Electronics.
6. When using the Renesas Electronics products, refer to the latest product information (data sheets, user's manuals, application notes, "General Notes for Handling and Using Semiconductor Devices" in the reliability handbook, etc.), and ensure that usage conditions are within the ranges specified by Renesas Electronics with respect to maximum ratings, operating power supply voltage range, heat radiation characteristics, installation, etc. Renesas Electronics disclaims any and all liability for any malfunctions or failure or accident arising out of the use of Renesas Electronics products beyond such specified ranges.
7. Although Renesas Electronics endeavors to improve the quality and reliability of Renesas Electronics products, semiconductor products have specific characteristics such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Further, Renesas Electronics products are not subject to radiation resistance design. Please ensure to implement safety measures to guard them against the possibility of bodily injury, injury or damage caused by fire, and social damage in the event of failure or malfunction of Renesas Electronics products, such as safety design for hardware and software including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures by your own responsibility as warranty for your products/system. Because the evaluation of microcomputer software alone is very difficult and not practical, please evaluate the safety of the final products or systems manufactured by you.
8. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. Please investigate applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive carefully and sufficiently and use Renesas Electronics products in compliance with all these applicable laws and regulations. Renesas Electronics disclaims any and all liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
9. Renesas Electronics products and technologies shall not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations. You shall not use Renesas Electronics products or technologies for (1) any purpose relating to the development, design, manufacture, use, stockpiling, etc., of weapons of mass destruction, such as nuclear weapons, chemical weapons, or biological weapons, or missiles (including unmanned aerial vehicles (UAVs)) for delivering such weapons, (2) any purpose relating to the development, design, manufacture, or use of conventional weapons, or (3) any other purpose of disturbing international peace and security, and you shall not sell, export, lease, transfer, or release Renesas Electronics products or technologies to any third party whether directly or indirectly with knowledge or reason to know that the third party or any other party will engage in the activities described above. When exporting, selling, transferring, etc., Renesas Electronics products or technologies, you shall comply with any applicable export control laws and regulations promulgated and administered by the governments of the countries asserting jurisdiction over the parties or transactions.
10. Please acknowledge and agree that you shall bear all the losses and damages which are incurred from the misuse or violation of the terms and conditions described in this document, including this notice, and hold Renesas Electronics harmless, if such misuse or violation results from your resale or making Renesas Electronics products available any third party.
11. This document shall not be reprinted, reproduced or duplicated in any form, in whole or in part, without prior written consent of Renesas Electronics.
12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products.

(Note 1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its majority-owned subsidiaries.

(Note 2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.

Notes for CMOS devices

- (1) Voltage application waveform at input pin:** Waveform distortion due to input noise or a reflected wave may cause malfunction. If the input of the CMOS device stays in the area between VIL (MAX) and VIH (MIN) due to noise, etc., the device may malfunction. Take care to prevent chattering noise from entering the device when the input level is fixed, and also in the transition period when the input level passes through the area between VIL (MAX) and VIH (MIN).
- (2) Handling of unused input pins:** Unconnected CMOS device inputs can be cause of malfunction. If an input pin is unconnected, it is possible that an internal input level may be generated due to noise, etc., causing malfunction. CMOS devices behave differently than Bipolar or NMOS devices. Input levels of CMOS devices must be fixed high or low by using pull-up or pull-down circuitry. Each unused pin should be connected to power supply or GND via a resistor if there is a possibility that it will be an output pin. All handling related to unused pins must be judged separately for each device and according to related specifications governing the device.
- (3) Precaution against ESD:** A strong electric field, when exposed to a MOS device, can cause destruction of the gate oxide and ultimately degrade the device operation. Steps must be taken to stop generation of static electricity as much as possible, and quickly dissipate it when it has occurred. Environmental control must be adequate. When it is dry, a humidifier should be used. It is recommended to avoid using insulators that easily build up static electricity. Semiconductor devices must be stored and transported in an anti-static container, static shielding bag or conductive material. All test and measurement tools including work benches and floors should be grounded. The operator should be grounded using a wrist strap. Semiconductor devices must not be touched with bare hands. Similar precautions need to be taken for PW boards with mounted semiconductor devices.
- (4) Status before initialization:** Power-on does not necessarily define the initial status of a MOS device. Immediately after the power source is turned ON, devices with reset functions have not yet been initialized. Hence, power-on does not guarantee output pin levels, I/O settings or contents of registers. A device is not initialized until the reset signal is received. A reset operation must be executed immediately after power-on for devices with reset functions.
- (5) Power ON/OFF sequence:** In the case of a device that uses different power supplies for the internal operation and external interface, as a rule, switch on the external power supply after switching on the internal power supply. When switching the power supply off, as a rule, switch off the external power supply and then the internal power supply. Use of the reverse power on/off sequences may result in the application of an overvoltage to the internal elements of the device, causing malfunction and degradation of internal elements due to the passage of an abnormal current. The correct power on/off sequence must be judged separately for each device and according to related specifications governing the device.
- (6) Input of signal during power off state:** Do not input signals or an I/O pull-up power supply while the device is not powered. The current injection that results from input of such a signal or I/O pull-up power supply may cause malfunction and the abnormal current that passes in the device at this time may cause degradation of internal elements. Input of signals during the power off state must be judged separately for each device and according to related specifications governing the device.

How to Use This Manual

1. Purpose and Target Readers

This manual is designed to provide the user with an understanding of the hardware functions and electrical characteristics of the MCU. It is intended for users designing application systems incorporating the MCU. A basic knowledge of electric circuits, logical circuits, and MCUs is necessary in order to use this manual. The manual comprises an overview of the product; descriptions of the CPU, system control functions, peripheral functions, and electrical characteristics; and usage notes.

Particular attention should be paid to the precautionary notes when using the manual. These notes occur within the body of the text, at the end of each section, and in the Usage Notes section.

The revision history summarizes the locations of revisions and additions. It does not list all revisions. Refer to the text of the manual for details.

The following documents apply to the RH850/E1M-S2 Group. Make sure to refer to the latest versions of these documents. The newest versions of the documents listed may be obtained from the Renesas Electronics Web site.

Document Type	Description	Document Title	Document No.
Data sheet	Overview of hardware and electrical characteristics		
User's manual: Hardware	Hardware specifications (pin assignments, memory maps, peripheral function specifications, electrical characteristics, timing charts) and operation description Note: Refer to the application notes for details on using peripheral functions.	RH850/E1M-S2 User's manual: Hardware	This User's Manual
User's manual: Software	Description of CPU instruction set		
Application note	Information on using peripheral functions and application examples Sample programs Information on writing programs in assembly language and C		
Renesas technical update	Product specifications, updates on documents, etc.		

2. Notation of Numbers and Symbols

The notation conventions for register names, bit names, numbers, and symbols used in this manual are described below.

(1) Register Names, Bit Names, and Pin Names

Registers, bits, and pins are referred to in the text by symbols. The symbol is accompanied by the word “register,” “bit,” or “pin” to distinguish the three categories.

Examples: the DEF bit in the ABC register
PA01 pin, VCC pin

(2) Notation of Numbers

Binary numbers are notated as nnnnB (However, the “B” may be omitted when it is clear that the number is binary), hexadecimal numbers are notated as nnnnH, and decimal numbers are notated as nnnn.

Examples Binary: 11B or 11
Hexadecimal: EFA0H
Decimal: 1234

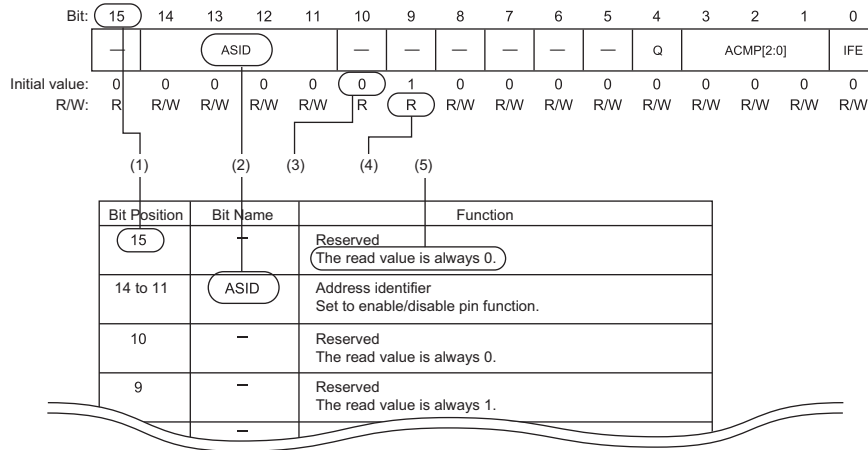

(3) Notation for Active-Low Signals

An overbar is added to the names of active-low signals.

Example \overline{ABCDEF}

3. Register Notation

Each section in this manual provides a table listing all the registers used by the corresponding module before the register descriptions in the section. The symbols and terms used in these tables are described below.

Note. • The bit names and text in the figure above are examples that are unrelated to the content of this manual.

(1) Bit Position

Indicates the bit number.

The bits are shown in the order 31 to 0 for 32-bit registers, in the order 15 to 0 for 16-bit registers, and in the order 7 to 0 for 8-bit registers.

(2) Bit Name

The short form of the name of the bit or bit field within the register.

When the individual bits of bit fields have to be clearly indicated, notation allowing this is included (e.g. ABCD[3:0]).

A reserved bit is indicated by “—”.

Instead of a bit name, a blank is used for some bits, such as those of timer counters.

(3) Value after reset

Indicates the value of each bit after a reset, i.e., the value after reset.

0: Value after reset is 0

1: Value after reset is 1

—: Value after reset is undefined

(4) R/W

Indicates whether each bit is readable or writable, or either writing to or reading from the bit is prohibited.

R/W: Bit or field is readable and writable.

R/(W): Bit or field is readable or writable.
However, writing is only performed to clear the flag.

R: Bit or field is readable.

However, “R” is indicated for all reserved bits. When writing to the bit is required, write the value stated in the bit table or the initial value.

In case of writing to writable registers that also include non-reserved bits with the R-attribute, writing to the R-attribute bits will be ignored unless otherwise specified.

W: Bit or field is writable.

However, only the value in the bit table is guaranteed when reading from the bit.

(5) Function

Describes the function enabled by setting the bit.

Table of Contents

Section 1	Overview	55
1.1	Outline	55
1.2	Features	57
1.3	Application Fields	62
1.4	Order Information	62
1.5	Pin Connection Diagram (Top View)	63
1.6	Functional Block Configuration	78
Section 2	Pins	79
2.1	Port Functions	79
2.1.1	Features	79
2.1.2	Overview	80
2.1.2.1	Terms	80
2.1.2.2	Overview of Pin Functions	80
2.1.2.3	Pin Data Input/Output	82
2.1.3	Port Type	84
2.1.4	Port Group Configuration Register	86
2.1.4.1	Outline	86
2.1.4.2	Configuration of Pin Function	88
2.1.4.3	Pin Data Input/Output	95
2.1.4.4	Configuration of Electrical Characteristics	100
2.1.4.5	Port Register Protection	103
2.1.4.6	Pin-Unit Register	105
2.1.4.7	Example of Port Configuration Flow	107
2.1.5	Functional Selection	112
2.1.5.1	Register Configuration in Use of the Alternative Function	112
2.1.5.2	Alternative Function to be used in Direct I/O Control Alternative Mode	112
2.1.5.3	Setting of the ERROROUT_C Pin	113
2.1.5.4	Register Setting in Use of an Analog Input Pin	113
2.1.5.5	Register Setting in Use of the LVDS buffer	113
2.1.5.6	Selecting of Function for JTAG Port	114
2.2	Organization of Port Groups	115
2.2.1	BGA304, BGA252 Port Function	115
2.2.1.1	List of the BGA304 and BGA252 Port Registers	115
2.2.1.2	Alternative Function List of the BGA304, BGA252 Pins	130
2.3	DNF	140
2.3.1	Example of Noise Elimination	140
2.3.2	Peripheral Function DNF	141
2.3.2.1	Overview of Peripheral Function DNF	141
2.3.2.2	Details of the Control Registers	141
2.3.2.3	DNFP01nCTLm — Digital Noise Elimination Control Register	142
2.3.2.4	Setting Procedures of Peripheral Function DNF	142
2.3.2.5	Peripheral Function Pin intended for DNF insertion	143
2.3.3	Edge Detection DNF	144
2.3.3.1	Overview of the Function	144
2.3.3.2	Details of the Control Registers	144
2.3.3.3	DNFP02nCTL — Digital Noise Elimination Control Register	145
2.3.3.4	DNFP02nEDCm — Edge Detection Control Register	146
2.3.3.5	DNFP02nEDFm — Edge Detection Flag Register	147
2.3.3.6	Setting Procedures of Edge Detection DNF	147

2.3.3.7	Pn_m Pins Intended for DNF Insertion.....	148
2.4	POD Control	150
2.4.1	Overview of the Function.....	150
2.5	Pin Description.....	153
2.5.1	Overview.....	153
2.5.2	List of Pin Functions	153
2.5.3	Pin State	168
2.5.4	Handling of Unused Pins.....	171
Section 3	CPU System	175
3.1	Overview.....	175
3.1.1	Block Configuration	175
3.2	CPU	177
3.2.1	Core Functions	177
3.2.1.1	Features	177
3.2.1.2	Register Set.....	178
3.2.2	Instruction Cache and Data Buffer	217
3.2.2.1	Features	217
3.2.2.2	Instruction Cache Function.....	218
3.2.2.3	Data Buffer Function	219
3.2.3	Inter-Processor Interrupts.....	220
3.2.3.1	Inter-Processor Interrupt Control Registers.....	220
3.2.4	Reliability Functions.....	221
3.2.4.1	PE Guard Function (PEG).....	221
3.2.4.2	PE's Internal Peripheral Device Protection Function (IPG).....	228
3.2.4.3	System Error Notification Control Function (SEG)	234
3.2.4.4	Checker Core	240
3.3	PCU	241
3.3.1	Core Functions	241
3.3.1.1	Features	241
3.3.1.2	Register Set.....	242
3.3.2	Inter-Processor Interrupts.....	270
3.3.3	Reliability Functions.....	271
3.3.3.1	System Error Notification Control Function (SEG)	271
3.4	Inter-CPU Functions	274
3.4.1	Processor Element Identifier	274
3.4.2	Inter-Processor Interrupt Function.....	274
3.4.3	Exclusive Function.....	274
3.4.3.1	Exclusive Control Register (MEV).....	275
3.4.3.2	Operation of the LDL.W and STC.W Instructions.....	276
3.5	Usage Notes	277
3.5.1	Synchronization of Store Instruction Completion and Subsequent Instruction Generation.....	277
3.5.1.1	When updated results in the control registers are reflected in the implementation of a subsequent instruction:	277
3.5.1.2	When the updated results in the control registers and memories are reflected in the instruction fetch of a subsequent instruction:	278
3.5.1.3	When switching the code flash area.....	278

3.5.1.4	When executing the SYNCM instruction to wait for the completion of update by the store instruction	278
3.5.2	Accesses to Registers by Bit-Manipulation Instructions	278
3.5.3	Ensuring Coherency after Code Flash Programming	279
3.5.4	Overwriting Context when Acknowledging Multiple Exceptions	279
3.5.5	Usage Notes on Prefetching	280
3.5.6	Setting for Blocking of Bit-Manipulation Instructions	281
Section 4	Address Space	282
4.1	Address Space	282
4.2	Address Space Viewed from Each Bus Master	283
4.2.1	Space in which instructions can be fetched	283
4.2.2	Data space accessible by CPU1	283
4.2.3	Data space accessible by PCU	283
4.2.4	Data space accessible by DMA (DMAC, DTS)	283
4.2.5	Data space accessible by H-Bus	283
4.3	Code Flash	285
4.3.1	Parallel Access to the User Area	285
4.4	Global RAM and Retention RAM	286

7.6	Setting Up DMA Transfer.....	365
7.6.1	Overview of Setting Up DMA.....	365
7.6.2	Setting Up the Overall DMA Operation.....	367
7.6.3	Setting Up the DMA Channel Setting.....	367
7.6.3.1	Setting Up the DMAC Channel Setting.....	368
7.6.3.2	Setting Up the DTS Channel Setting.....	369
7.7	DMA Trigger Source.....	370
7.7.1	List of DMA Trigger Sources.....	370
7.8	DTS Trigger Source.....	374
7.8.1	List of DTS Trigger Sources.....	374
7.9	Global Register.....	378
7.9.1	List of Global Register Addresses.....	378
7.9.2	Details of Global Registers.....	380
7.9.2.1	DMACTL — DMA Control Register.....	380
7.9.2.2	DTSCTL1 — DTS Control Register 1.....	381
7.9.2.3	DTSCTL2 — DTS Control Register 2.....	382
7.9.2.4	DTSSTS — DTS Status Register.....	383
7.9.2.5	DMACER — DMAC Error Register.....	384
7.9.2.6	DTSER1 — DTS Error Register 1.....	385
7.9.2.7	DTSER2 — DTS Error Register 2.....	386
7.9.2.8	DTSERC — DTS Error Clear Register.....	387

7.9.2.9	DM0CMV — DMAC0 Register Access Protection Violation Register	388
7.9.2.10	DM1CMV — DMAC1 Register Access Protection Violation Register	389
7.9.2.11	DTSCMV — DTS Register Access Protection Violation Register	390
7.9.2.12	CMVC — Register Access Protection Violation Clear Register	391
7.9.2.13	DTSPRn — DTS Channel Priority Setting Register (n = 0 to 7).....	392
7.9.2.14	DTRECCTL — DTSRAM ECC Control Register.....	396
7.9.2.15	DTRERINT — DTSRAM Error Notification Control Register.....	397
7.9.2.16	DTRTSCCTL — DTSRAM Test Control Register.....	398
7.9.2.17	DTRTWDAT — DTSRAM Test Write Data Register.....	399
7.9.2.18	DTRTRDAT — DTSRAM Test Read Data Register.....	400
7.9.2.19	DMnnCM — DMAC Channel Master Setting Register (nn = 00 to 07 and 10 to 17).....	401
7.9.2.20	DTSnnnCM — DTS Channel Master Setting Register (nnn = 000 to 127)	402
7.10	DMAC Channel Register	404
7.10.1	DMAC Channel Register Address	404
7.10.2	Details of DMAC Channel Registers	405
7.10.2.1	DSAn — DMAC Source Address Register.....	405
7.10.2.2	DDAn — DMAC Destination Address Register	406
7.10.2.3	DTCn — DMAC Transfer Count Register	407
7.10.2.4	DTCTn — DMAC Transfer Control Register	408
7.10.2.5	DRSAn — DMAC Reload Source Address Register.....	411
7.10.2.6	DRDAn — DMAC Reload Destination Address Register	412
7.10.2.7	DRTCn — DMAC Reload Transfer Count Register	413
7.10.2.8	DTCCn — DMAC Transfer Count Compare Register	414
7.10.2.9	DCENn — DMAC Channel Operation Enable Setting Register.....	415
7.10.2.10	DCSTn — DMAC Transfer Status Register	416
7.10.2.11	DCSTSn — DMAC Transfer Status Set Register.....	418
7.10.2.12	DCSTCn — DMAC Transfer Status Clear Register	419
7.10.2.13	DTFRn — DTFR Setting Register.....	420
7.10.2.14	DTFRRQn — DTFR Transfer Request Status Register.....	421
7.10.2.15	DTFRRQCn — DTFR Transfer Request Clear Register.....	422
7.11	DTS Channel Register.....	423
7.11.1	Transfer information of the DTS (TI).....	423
7.11.1.1	Structure of the TI.....	423
7.11.1.2	Organization of the TI in the DTSRAM.....	424
7.11.1.3	Accessing the TI.....	425
7.11.1.4	Caution about accessing the TI.....	425
7.11.2	DTS Channel Register Address	426
7.11.3	Details of DTS Channel Registers.....	427
7.11.3.1	DTSAnnn — DTS Source Address Register	427
7.11.3.2	DTDAnnn — DTS Destination Address Register	428
7.11.3.3	DTTCnnn — DTS Transfer Count Register.....	429
7.11.3.4	DTTCTnnn — DTS Transfer Control Register	430
7.11.3.5	DTRSAnnn — DTS Reload Source Address Register	433
7.11.3.6	DTRDAnnn — DTS Reload Destination Address Register	434
7.11.3.7	DTRTCnnn — DTS Reload Transfer Count Register.....	435
7.11.3.8	DTTCCnnn — DTS Transfer Count Compare Register	436
7.11.3.9	DTFSLnnn — DTSFSL Operation Setting Register	437
7.11.3.10	DTFSTnnn — DTSFSL Transfer Request Status Register.....	438
7.11.3.11	DTFSSnnn — DTSFSL Transfer Request Set Register.....	439
7.11.3.12	DTFSCnnn — DTSFSL Transfer Request Clear Register	439
Section 8	Resets.....	440
8.1	Features.....	440

8.2	Reset State	441
8.2.1	External Reset State.....	441
8.2.2	Internal Reset State.....	441
8.3	Reset Sources	442
8.4	Register Specifications	443
8.4.1	List of Registers.....	443
8.4.2	RESF — Reset Source Determination Register.....	444
8.4.3	RESFC — Reset Source Clear Register	445
8.4.4	POF — Power-On Clear Flag Register	446
8.4.5	POFC — Power-On Clear Flag Clear Register	447
8.4.6	SWRESA — Software Reset Request Register	448
8.5	Software Reset	450
8.6	RAM Retention	450
8.7	Usage Notes	450
Section 9	Power Supply Circuit.....	451
9.1	Features.....	451
9.2	Example of Connection of Power Management IC.....	452
9.3	Power-on Sequence	453
9.4	Usage Notes	453
9.5	Guide to Mounting on Boards with an EPT.....	454
9.5.1	BGA.....	454
9.5.2	Reference Information.....	455
Section 10	Power Supply Voltage Monitor.....	456
10.1	Features.....	456
10.2	Configuration	456
10.3	Register Specifications	457
10.3.1	DETFLG — CVM Detection Flag Register	458
10.3.2	DETFLGC — CVM Detection Flag Clear Register	459
10.3.3	VSCTL — CVM Control Register	460
10.3.4	HDETCTL — Upper Limit Voltage Setting Register	461
10.3.5	LDETCTL — Lower Limit Voltage Register	462
10.3.6	VSDETFCTL — Detection Signal Filter Control Register	463
10.4	Usage	464
10.5	Notes on Usage	466
Section 11	Clock Controller	467
11.1	Features.....	467
11.2	Type of Clocks	468
11.3	Input/Output Pins	470
11.3.1	How to Connect a Crystal Resonator	470
11.4	Register Specification.....	471

11.4.1	List of Registers.....	471
11.4.2	PLL0CLKS — PLL0 Status Register	472
11.4.3	PLL0CLKC1 — PLL0 Control Register 1.....	473
11.4.4	CKSC0CTL — Clock 0 Selection Control Register	475
11.4.5	CKSC0ACT — Clock 0 Selection Active Register.....	476
11.4.6	CLKD0DIV — Clock 0 Division Register	477
11.4.7	CLKD0STAT — Clock 0 Division Status Register	478
11.4.8	CKSC1CTL — Clock 1 Selection Control Register	479
11.4.9	CKSC1ACT — Clock 1 Selection Active Register.....	480
11.4.10	PROT1PHCMD — Protect 1 Command Register	481
11.4.11	PROT1PS — Protect 1 Status Register	483
11.5	Operation.....	484
11.5.1	Operation When the Divide Function Is Used	484
11.6	Notes	487
11.6.1	Board Design Notes	487
11.7	ASIC Clock	488
11.7.1	Features	488
11.7.2	488
11.7.3	Register Specifications.....	489
11.7.3.1	ACK0CKC — Clock Control Register.....	490
11.7.3.2	ACK0CKCFLG — CKC Flag Register.....	491
11.7.3.3	ACK0CKCTL — Clock Select Register	492
11.7.3.4	ACK0BRGA0CMP — BRGA0 Compare Register.....	493
11.7.3.5	ACK0CKPCMD — CKC Protect Command Register	494
11.7.3.6	ACK0CKCPS — CKC Protect Status Register	496
11.7.4	Usage.....	497
11.7.4.1	CK Pin Output Function.....	497
11.7.4.2	CK Output Baud Rate Generator Circuit (BRGA).....	497
11.7.4.3	Control Register Rewrite Protect.....	498
11.7.4.4	CK Output Switching Procedure.....	499
Section 12	Standby Controller	501
12.1	Features.....	501
12.1.1	Types of Power-Down Mode	501
12.2	Operation.....	502
12.2.1	Power Off Standby Mode	502
12.2.2	Module Standby Function.....	502
12.3	Register List.....	503
12.3.1	List of Registers.....	503
12.3.2	EPTCNT — EPT Control Register.....	504
12.3.3	PROT0PHCMD — Protection Command Register.....	505
12.3.4	PROT0PS — Protection Command Status Register.....	507
12.3.5	Module Standby Registers	508
12.3.5.1	MSRTSG — Module Standby Register – TSG2.....	508
12.3.5.2	MSRTAPA — Module Standby Register – TAPA.....	509
12.3.5.3	MSROSTM — Module Standby Register – OSTM.....	510
12.3.5.4	MSRWDTA — Module Standby Register – WDTA	510
12.3.5.5	MSRPIC — Module Standby Register – PIC	511

12.3.5.6	MSRRCAN — Module Standby Register – RS-CANFD.....	511
12.3.5.7	MSRFRAY — Module Standby Register – FlexRay.....	512
12.3.5.8	MSRRLIN — Module Standby Register – RLIN2.....	513
12.3.5.9	MSRSCI — Module Standby Register – SCI3.....	514
12.3.5.10	MSRCSIH — Module Standby Register – CSIH.....	515
12.3.5.11	MSRSAD — Module Standby Register – SAR-AD.....	516
12.3.5.12	MSRDAD — Module Standby Register – ΔΣAD.....	517
12.3.5.13	MSRATU — Module Standby Register – ATU-IV.....	518
12.3.5.14	MSRAPA — Module Standby Register – APA.....	518
12.3.5.15	MSRDFE — Module Standby Register – DFE.....	519
12.3.5.16	MSRRHSB — Module Standby Register – RHSB.....	520
12.3.5.17	MSRRSENT — Module Standby Register – RSENT.....	521
12.3.6	MSRPCMD — MSR Protection Command Register.....	522
12.3.7	MSRPS — MSR Protection Status Register.....	524

Section 13 Clocked Serial Interface H (CSIH) 525

13.1	CSIH Features.....	525
13.2	Notes on Pin Combination.....	527
13.3	Function Overview.....	528
13.4	List of the Usage Notes.....	530
13.5	Functional Description.....	532
13.5.1	Operating Modes (master/slave).....	533
13.5.2	Master/Slave Connections.....	535
13.5.3	Chip Selection (CS) Features.....	537
13.5.4	Chip Select Timing Details.....	540
13.5.5	Transmission Clock Selection.....	543
13.5.6	Data transfer modes.....	545
13.5.7	Data Length Selection.....	546
13.5.8	Serial Data Direction Selection.....	549
13.5.9	Communication in Slave Mode.....	550
13.5.10	CSIH interrupt requests.....	553
13.5.11	Handshake function.....	560
13.5.12	Error Detection.....	562
13.5.13	Loop-Back Mode.....	566
13.5.14	Enforced Chip Select Idle Setting.....	567
13.6	CSIH Control Registers.....	568
13.6.1	CSIHnCTL0 — CSIH Control Register 0.....	569
13.6.2	CSIHnCTL1 — CSIH Control Register 1.....	570
13.6.3	CSIHnCTL2 — CSIH Control Register 2.....	573
13.6.4	CSIHnSTR0 — CSIH Status Register 0.....	575
13.6.5	CSIHnSTCR0 — CSIH Status Clear Register 0.....	577
13.6.6	CSIHnCFGx — CSIH Configuration Register x.....	578
13.6.7	CSIHnTX0W — CSIH Transmit Data Register 0 for Word Access.....	583
13.6.8	CSIHnTX0H — CSIH Transmit Data Register 0 for Half Word Access.....	585
13.6.9	CSIHnRX0W — CSIH Receive Data Register 0 for Word Access.....	586
13.6.10	CSIHnRX0H — CSIH Receive Data Register 0 for Half Word Access.....	587
13.6.11	CSIHnBRSi — CSIHn Baud Rate Setting Register i.....	588

13.7	Operating Procedures.....	589
13.7.1	Procedures in Direct Access Mode	589
Section 14	Serial Communication Interface 3 (SCI3)	593
14.1	Overview.....	593
14.1.1	Features of SCI3	593
14.1.2	Outline of Functions.....	593
14.1.3	Serial Communication Modes.....	594
14.1.4	Block Diagram	594
14.2	Input/Output Pins	595
14.3	Register Descriptions.....	596
14.3.1	SCI3nRSR — Receive Shift Register.....	597
14.3.2	SCI3nRDR — Receive Data Register	597
14.3.3	SCI3nTDR — Transmit Data Register.....	597
14.3.4	SCI3nTSR — Transmit Shift Register	597
14.3.5	SCI3nSMR — Serial Mode Register	598
14.3.6	SCI3nSCR — Serial Control Register	599
14.3.7	SCI3nSSR — Serial Status Register.....	601
14.3.8	SCI3nSCMR — Serial Transfer Format Register	603
14.3.9	SCI3nSEMR — Serial Extended Mode Register.....	604
14.3.10	SCI3nBRR — Bit Rate Register	605
14.3.11	SCI3nMDDR — Modulation Duty Register.....	608
14.4	Operation in Asynchronous Mode	609
14.4.1	Transmission/Reception Format.....	610
14.4.2	Receive Data Sampling Timing and Reception Margin	611
14.4.3	Clock.....	612
14.4.4	Double-Speed Operation.....	612
14.4.5	SCI3 Initialization (Asynchronous Mode).....	613
14.4.6	Serial Data Transmission (Asynchronous Mode)	614
14.4.7	Serial Data Reception (Asynchronous Mode)	617
14.5	Multi-Processor Communication Function	621
14.5.1	Overview and Sample Connection	621
14.5.2	Multi-Processor Serial Data Transmission	622
14.5.3	Multi-Processor Serial Data Reception.....	623
14.6	Operation in Clock Synchronous Mode	627
14.6.1	Clock.....	627
14.6.2	SCI3 Initialization (Clock Synchronous Mode)	628
14.6.3	Serial Data Transmission (Clock Synchronous Mode).....	629
14.6.4	Serial Data Reception (Clock Synchronous Mode)	632
14.6.5	Simultaneous Serial Data Transmission and Reception (Clock Synchronous Mode).....	634
14.7	Bit Rate Modulation Function.....	636
14.8	Interrupt Sources	637
14.9	Usage Notes	638
14.9.1	Break Detection and Processing	638

14.9.2	Mark State and Break Output.....	638
14.9.3	Receive Error Flags and Transmit Operations in Clock Synchronous Mode.....	638
14.9.4	Relationship between Writing to SCI3nTDR and the TDRE Flag.....	638
14.9.5	Restrictions on Using an External Clock for Transmission in Clock Synchronous Mode.....	639
14.9.6	External Clock Input in Clock Synchronous Mode.....	639
Section 15 LIN Master Interface (RLIN2).....		640
15.1	Overview of RLIN2.....	640
15.1.1	Units and Channels.....	640
15.1.2	Register Base Addresses.....	640
15.1.3	Clock Supply.....	641
15.1.4	Interrupt Request.....	641
15.1.5	Reset Sources.....	641
15.1.6	External Input/Output Signals.....	641
15.2	Function.....	642
15.2.1	Functional Overview.....	642
15.2.2	Block Diagram.....	643
15.3	Registers.....	644
15.3.1	List of Registers.....	644
15.3.2	Global Registers.....	645
15.3.2.1	RLN21nGLWBR — LIN Wake-up Baud Rate Select Register.....	645
15.3.2.2	RLN21nGLBRP0 — LIN Baud Rate Prescaler 0 Register.....	646
15.3.2.3	RLN21nGLBRP1 — LIN Baud Rate Prescaler 1 Register.....	647
15.3.2.4	RLN21nGLSTC — LIN Self-Test Control Register.....	648
15.3.3	Channel Registers.....	649
15.3.3.1	RLN21nLiMD — LIN Mode Register.....	649
15.3.3.2	RLN21nLiBFC — LIN Break Field Configuration Register.....	650
15.3.3.3	RLN21nLiSC — LIN Space Configuration Register.....	651
15.3.3.4	RLN21nLiWUP — LIN Wake-up Configuration Register.....	652
15.3.3.5	RLN21nLiIE — LIN Interrupt Enable Register.....	653
15.3.3.6	RLN21nLiEDE — LIN Error Detection Enable Register.....	654
15.3.3.7	RLN21nLiCUC — LIN Control Register.....	656
15.3.3.8	RLN21nLiTRC — LIN Transmission Control Register.....	657
15.3.3.9	RLN21nLiMST — LIN Mode Status Register.....	658
15.3.3.10	RLN21nLiST — LIN Status Register.....	659
15.3.3.11	RLN21nLiEST — LIN Error Status Register.....	661
15.3.3.12	RLN21nLiDFC — LIN Data Field Configuration Register.....	663
15.3.3.13	RLN21nLiIDB — LIN ID Buffer Register.....	665
15.3.3.14	RLN21nLiCBR — LIN Checksum Buffer Register.....	666
15.3.3.15	RLN21nLiDBRb — LIN Data Buffer b Register.....	667
15.4	Interrupt Sources.....	668
15.5	Modes.....	669
15.6	LIN Reset Mode.....	671
15.7	LIN Operation Mode.....	672
15.8	LIN Wake-up Mode.....	672
15.9	Header Transmission/Response Transmission/Response Reception.....	673
15.9.1	Header Transmission.....	673
15.9.2	Response Transmission.....	674

15.9.3	Response Reception	675
15.10	Data Transmission/Reception.....	676
15.10.1	Data Transmission.....	676
15.10.2	Data Reception.....	677
15.11	Transmission/Reception Data Buffering	678
15.11.1	Transmission of LIN Frames	678
15.11.2	Reception of LIN Frames.....	679
15.12	Wake-up Transmission/Reception.....	680
15.12.1	Wake-up Transmission.....	680
15.12.2	Wake-up Reception	681
15.12.3	Wakeup Collision.....	681
15.13	Status.....	682
15.14	Error Status.....	683
15.14.1	Types of Error Status.....	683
15.14.2	Target Time Area for Error Detection	684
15.15	LIN Self-Test Mode.....	685
15.15.1	Change to LIN Self-Test Mode	686
15.15.2	Transmission in LIN Self-Test Mode	687
15.15.3	Reception in LIN Self-Test Mode.....	688
15.15.4	Terminating LIN Self-Test Mode.....	690
15.16	Baud Rate Generator.....	691
Section 16	CANFD Interface (RS-CANFD).....	693
16.1	Features of RH850/E1M-S2 RS-CANFD.....	693
16.1.1	Units and Channels	693
16.1.2	Register Base Address.....	694
16.1.3	Clock Supply.....	694
16.1.4	Interrupt Requests	694
16.1.5	Reset Sources	695
16.1.6	External Input/Output Signals.....	695
16.2	Overview.....	696
16.2.1	Functional Outline.....	696
16.2.2	Interface Modes.....	698
16.2.3	Switching the CAN FD Protocol.....	698
16.2.4	Block Diagram	699
16.3	Registers (Classical CAN Mode)	700
16.3.1	List of Registers.....	700
16.3.2	Details of Interface Mode-Related Registers.....	704
16.3.2.1	RSCANnGRMCFG — Global Interface Mode Select Register	704
16.3.3	Details of Channel-Related Registers	705
16.3.3.1	RSCANnCmCFG — Channel Configuration Register (m = 0 to 3)	705
16.3.3.2	RSCANnCmCTR — Channel Control Register (m = 0 to 3)	707
16.3.3.3	RSCANnCmSTS — Channel Status Register (m = 0 to 3)	712
16.3.3.4	RSCANnCmERFL — Channel Error Flag Register (m = 0 to 3).....	715
16.3.4	Details of Global-Related Registers	719

16.3.4.1	RSCANnGCFG — Global Configuration Register.....	719
16.3.4.2	RSCANnGCTR — Global Control Register.....	722
16.3.4.3	RSCANnGSTS — Global Status Register	724
16.3.4.4	RSCANnGERFL — Global Error Flag Register	726
16.3.4.5	RSCANnGTSC — Global Timestamp Counter Register.....	728
16.3.4.6	RSCANnGTINTSTS0 — Global TX Interrupt Status Register 0	729
16.3.4.7	RSCANnGFDCFG — Global FD Configuration Register	732
16.3.5	Details of Receive Rule-Related Registers	733
16.3.5.1	RSCANnGAFLECTR — Receive Rule Entry Control Register	733
16.3.5.2	RSCANnGAFLCFG0 — Receive Rule Configuration Register 0	734
16.3.5.3	RSCANnGAFLIDj — Receive Rule ID Register (j = 0 to 15).....	736
16.3.5.4	RSCANnGAFLMj — Receive Rule Mask Register (j = 0 to 15)	738
16.3.5.5	RSCANnGAFLP0j — Receive Rule Pointer 0 Register (j = 0 to 15)	740
16.3.5.6	RSCANnGAFLP1j — Receive Rule Pointer 1 Register (j = 0 to 15)	742
16.3.6	Details of Receive Buffer-Related Registers	743
16.3.6.1	RSCANnRMNB — Receive Buffer Number Register.....	743
16.3.6.2	RSCANnRMNDy — Receive Buffer New Data Register y (y = 0, 1).....	744
16.3.6.3	RSCANnRMIDq — Receive Buffer ID Register (q = 0 to 63).....	745
16.3.6.4	RSCANnRMPTRq — Receive Buffer Pointer Register (q = 0 to 63)	746
16.3.6.5	RSCANnRMDf0q — Receive Buffer Data Field 0 Register (q = 0 to 63).....	747
16.3.6.6	RSCANnRMDf1q — Receive Buffer Data Field 1 Register (q = 0 to 63).....	748
16.3.7	Details of Receive FIFO Buffer-Related Registers	749
16.3.7.1	RSCANnRFCCx — Receive FIFO Buffer Configuration/Control Register (x = 0 to 7).....	749
16.3.7.2	RSCANnRFSTsx — Receive FIFO Buffer Status Register (x = 0 to 7).....	751
16.3.7.3	RSCANnRFPCTRx — Receive FIFO Buffer Pointer Control Register (x = 0 to 7).....	753
16.3.7.4	RSCANnRFIDx — Receive FIFO Buffer Access ID Register (x = 0 to 7)	754
16.3.7.5	RSCANnRFPTRx — Receive FIFO Buffer Access Pointer Register (x = 0 to 7).....	755
16.3.7.6	RSCANnRFDF0x — Receive FIFO Buffer Access Data Field 0 Register (x = 0 to 7).....	756
16.3.7.7	RSCANnRFDF1x — Receive FIFO Buffer Access Data Field 1 Register (x = 0 to 7).....	757
16.3.8	Details of Transmit/Receive FIFO Buffer-Related Registers	758
16.3.8.1	RSCANnCFCCk — Transmit/Receive FIFO Buffer Configuration/ Control Register (k = 0 to 11).....	758
16.3.8.2	RSCANnCFSTSk — Transmit/Receive FIFO Buffer Status Register (k = 0 to 11).....	762
16.3.8.3	RSCANnCFPCTRk — Transmit/Receive FIFO Buffer Pointer Control Register (k = 0 to 11).....	765
16.3.8.4	RSCANnCFIDk — Transmit/Receive FIFO Buffer Access ID Register (k = 0 to 11).....	767
16.3.8.5	RSCANnCFPTRk — Transmit/Receive FIFO Buffer Access Pointer Register (k = 0 to 11).....	769
16.3.8.6	RSCANnCFDF0_k — Transmit/Receive FIFO Buffer Access Data Field 0 Register (k = 0 to 11).....	771
16.3.8.7	RSCANnCFDF0_k — Transmit/Receive FIFO Buffer Access Data Field 1 Register (k = 0 to 11).....	772
16.3.9	Details of FIFO Status-Related Registers	773
16.3.9.1	RSCANnFESTS — FIFO Empty Status Register.....	773
16.3.9.2	RSCANnFFSTS — FIFO Full Status Register	775
16.3.9.3	RSCANnFMSTS — FIFO Message Lost Status Register.....	777
16.3.9.4	RSCANnRFISTS — Receive FIFO Buffer Interrupt Flag Status Register.....	779
16.3.9.5	RSCANnCFRISTS — Transmit/Receive FIFO Buffer Receive Interrupt Flag Status Register.....	780

16.3.9.6	RSCANnCFTISTS — Transmit/Receive FIFO Buffer Transmit Interrupt Flag Status Register.....	781
16.3.10	Details of Transmit Buffer-Related Registers	782
16.3.10.1	RSCANnTMCp — Transmit Buffer Control Register (p = 0 to 63)	782
16.3.10.2	RSCANnTMSTSp — Transmit Buffer Status Register (p = 0 to 63)	784
16.3.10.3	RSCANnTMIDp — Transmit Buffer ID Register (p = 0 to 63)	786
16.3.10.4	RSCANnTMPTRp — Transmit Buffer Pointer Register (p = 0 to 63).....	788
16.3.10.5	RSCANnTMDF0_p — Transmit Buffer Data Field 0 Register (p = 0 to 63)	790
16.3.10.6	RSCANnTMDF1_p — Transmit Buffer Data Field 1 Register (p = 0 to 63)	791
16.3.10.7	RSCANnTMIECy — Transmit Buffer Interrupt Enable Configuration Register (y = 0, 1).....	792
16.3.11	Details of Transmit Buffer Status-Related Registers	794
16.3.11.1	RSCANnTMTRSTSy — Transmit Buffer Transmit Request Status Register (y = 0, 1).....	794
16.3.11.2	RSCANnTMTARSTSy — Transmit Buffer Transmit Abort Request Status Register (y = 0, 1).....	796
16.3.11.3	RSCANnTMTCASTSy — Transmit Buffer Transmit Complete Status Register (y = 0, 1).....	798
16.3.11.4	RSCANnTMTASTSy — Transmit Buffer Transmit Abort Status Register (y = 0, 1).....	800
16.3.12	Details of Transmit Queue-Related Registers	802
16.3.12.1	RSCANnTXQCCm — Transmit Queue Configuration/Control Register (m = 0 to 3).....	802
16.3.12.2	RSCANnTXQSTSm — Transmit Queue Status Register (m = 0 to 3).....	804
16.3.12.3	RSCANnTXQPCTRM — Transmit Queue Pointer Control Register (m = 0 to 3).....	806
16.3.13	Details of Transmit History-Related Registers.....	807
16.3.13.1	RSCANnTHLCCm — Transmit History List Configuration/Control Register (m = 0 to 3).....	807
16.3.13.2	RSCANnTHLSTSm — Transmit History List Status Register (m = 0 to 3)	809
16.3.13.3	RSCANnTHLPCTRM — Transmit History List Pointer Control Register (m = 0 to 3).....	811
16.3.13.4	RSCANnTHLACCm — Transmit History List Access Register (m = 0 to 3)	812
16.3.14	Details of Test-Related Registers.....	814
16.3.14.1	RSCANnGTSTCFG — Global Test Configuration Register.....	814
16.3.14.2	RSCANnGTSTCTR — Global Test Control Register.....	816
16.3.14.3	RSCANnGLOCKK — Global Lock Key Register.....	817
16.3.14.4	RSCANnRPGACCr — RAM Test Page Access Register (r = 0 to 63)	818
16.4	Registers (CAN FD Mode).....	819
16.4.1	List of Registers.....	819
16.4.2	Details of Interface Mode-Related Registers.....	823
16.4.2.1	RSCFDnCFDGRMCFG — Global Interface Mode Select Register	823
16.4.3	Details of Channel-Related Registers	824
16.4.3.1	RSCFDnCFDCmNCFG — Channel Nominal Bit Rate Configuration Register (m = 0 to 3).....	824
16.4.3.2	RSCFDnCFDCmCTR — Channel Control Register (m = 0 to 3)	826
16.4.3.3	RSCFDnCFDCmSTS — Channel Status Register (m = 0 to 3).....	831
16.4.3.4	RSCFDnCFDCmERFL — Channel Error Flag Register (m = 0 to 3).....	834
16.4.3.5	RSCFDnCFDCmDCFG — Channel Data Bit Rate Configuration register (m = 0 to 3).....	838
16.4.3.6	RSCFDnCFDCmFDCFG — Channel CAN FD Configuration Register (m = 0 to 3).....	841
16.4.3.7	RSCFDnCFDCmFDCTR — Channel CAN FD Control Register (m = 0 to 3)...	845
16.4.3.8	RSCFDnCFDCmFDSTS — Channel CAN FD Status Register (m = 0 to 3).....	846
16.4.3.9	RSCFDnCFDCmFDCRC — Channel CAN FD CRC Register (m = 0 to 3)	848

16.4.4	Details of Global-Related Registers	850
16.4.4.1	RSCFDnCFDGCFCFG — Global Configuration Register	850
16.4.4.2	RSCFDnCFDGCCTR — Global Control Register	854
16.4.4.3	RSCFDnCFDGSTS — Global Status Register	856
16.4.4.4	RSCFDnCFDGERFL — Global Error Flag Register	858
16.4.4.5	RSCFDnCFDGTSC — Global Timestamp Counter Register.....	860
16.4.4.6	RSCFDnCFDGTINTSTS0 — Global TX Interrupt Status Register 0	861
16.4.4.7	RSCFDnCFDGFDCFG — Global FD Configuration Register.....	864
16.4.5	Details of Receive Rule-related Registers.....	865
16.4.5.1	RSCFDnCFDGALECTR — Receive Rule Entry Control Register	865
16.4.5.2	RSCFDnCFDGAFLCFG0 — Receive Rule Configuration Register 0.....	866
16.4.5.3	RSCFDnCFDGAFLIDj — Receive Rule ID Register (j = 0 to 15)	868
16.4.5.4	RSCFDnCFDGAFLMj — Receive Rule Mask Register (j = 0 to 15)	870
16.4.5.5	RSCFDnCFDGAFLP0_j — Receive Rule Pointer 0 Register (j = 0 to 15).....	871
16.4.5.6	RSCFDnCFDGAFLP1_j — Receive Rule Pointer 1 Register (j = 0 to 15).....	873
16.4.6	Details of Receive Buffer-related Registers.....	874
16.4.6.1	RSCFDnCFDRMNB — Receive Buffer Number Register.....	874
16.4.6.2	RSCFDnCFDRMNDy — Receive Buffer New Data Register (y = 0, 1)	875
16.4.6.3	RSCFDnCFDRMIDq — Receive Buffer ID Register (q = 0 to 63).....	876
16.4.6.4	RSCFDnCFDRMPTRq — Receive Buffer Pointer Register (q = 0 to 63)	877
16.4.6.5	RSCFDnCFDRMFDSTSq — Receive Buffer CAN FD Status Register (q = 0 to 63).....	879
16.4.6.6	RSCFDnCFDRMDFb_q — Receive Buffer Data Field b Register (b = 0 to 4, q = 0 to 63).....	880
16.4.7	Details of Receive FIFO Buffer-related Registers	881
16.4.7.1	RSCFDnCFDRFCCx — Receive FIFO Buffer Configuration and Control Register (x = 0 to 7).....	881
16.4.7.2	RSCFDnCFDRFSTSx — Receive FIFO Buffer Status Register (x = 0 to 7).....	884
16.4.7.3	RSCFDnCFDRFPCTRx — Receive FIFO Buffer Pointer Control Register (x = 0 to 7).....	886
16.4.7.4	RSCFDnCFDRFIDx — Receive FIFO Buffer Access ID Register (x = 0 to 7).....	887
16.4.7.5	RSCFDnCFDRFPTRx — Receive FIFO Buffer Access Pointer Register (x = 0 to 7).....	888
16.4.7.6	RSCFDnCFDRFFDSTSx — Receive FIFO CAN FD Status Register (x = 0 to 7).....	890
16.4.7.7	RSCFDnCFDRFDFd_x — Receive FIFO Buffer Access Data Field d Register (d = 0 to 15, x = 0 to 7).....	891
16.4.8	Transmit/Receive FIFO Buffer Related Registers	892
16.4.8.1	RSCFDnCFDCFCCK — Transmit/receive FIFO Buffer Configuration and Control Register k (k = 0 to 11).....	892
16.4.8.2	RSCFDnCFDCFSTSk — Transmit/receive FIFO Buffer Status Register (k = 0 to 11).....	896
16.4.8.3	RSCFDnCFDCFPCTRk — Transmit/receive FIFO Buffer Pointer Control Register (k = 0 to 11).....	899
16.4.8.4	RSCFDnCFDCFIDk — Transmit/receive FIFO Buffer Access ID Register (k = 0 to 11).....	901
16.4.8.5	RSCFDnCFDCFPTRk — Transmit/receive FIFO Buffer Access Pointer Register (k = 0 to 11).....	903
16.4.8.6	RSCFDnCFDCFFDCSTSk — Transmit/Receive FIFO CAN FD Configuration/ Status Register (k = 0 to 11)	905
16.4.8.7	RSCFDnCFDCFDFd_k — Transmit/receive FIFO Buffer Access Data Field d Register (d = 0 to 15, k = 0 to 11)	907
16.4.9	Details of FIFO Status-related Registers.....	908
16.4.9.1	RSCFDnCFDFESTS — FIFO Empty Status Register	908
16.4.9.2	RSCFDnCFDFFSTS — FIFO Full Status Register.....	910
16.4.9.3	RSCFDnCFDFMSTS — FIFO Message Lost Status Register.....	912

16.4.9.4	RSCFDnCFDRFISTS — Receive FIFO Buffer Interrupt Flag Status Register	914
16.4.9.5	RSCFDnCFDCFRISTS — Transmit/receive FIFO Buffer Receive Interrupt Flag Status Register	915
16.4.9.6	RSCFDnCFDCFTISTS — Transmit/receive FIFO Buffer Transmit Interrupt Flag Status Register	916
16.4.10	Details of Transmit Buffer-related Registers	917
16.4.10.1	RSCFDnCFDTMCp — Transmit Buffer Control Register (p = 0 to 63)	917
16.4.10.2	RSCFDnCFDTMSTSp — Transmit Buffer Status Register (p = 0 to 63)	919
16.4.10.3	RSCFDnCFDTMIDp — Transmit Buffer ID Register (p = 0 to 63)	921
16.4.10.4	RSCFDnCFDTMPTRp — Transmit Buffer Pointer Register (p = 0 to 63)	923
16.4.10.5	RSCFDnCFDTMFDCTRp — Transmit Buffer CAN FD Configuration Register (p = 0 to 63)	925
16.4.10.6	RSCFDnCFDTMDFb_p — Transmit Buffer Data Field b Register (b = 0 to 4, p = 0 to 63)	927
16.4.10.7	RSCFDnCFDTMIECy — Transmit Buffer Interrupt Enable Configuration Register (y = 0, 1)	928
16.4.11	Details of Transmit Buffer Status-related Registers	930
16.4.11.1	RSCFDnCFDTMTRSTSy — Transmit Buffer Transmit Request Status Register (y = 0, 1)	930
16.4.11.2	RSCFDnCFDTMTARSTSy — Transmit Buffer Transmit Abort Request Status Register (y = 0, 1)	932
16.4.11.3	RSCFDnCFDTMTCSTSy — Transmit Buffer Transmit Complete Status Register (y = 0, 1)	934
16.4.11.4	RSCFDnCFDTMTASTSy — Transmit Buffer Transmit Abort Status Register (y = 0, 1)	936
16.4.12	Details of Transmit Queue-related Registers	938
16.4.12.1	RSCFDnCFDTXQCCm — Transmit Queue Configuration and Control Register (m = 0 to 3)	938
16.4.12.2	RSCFDnCFDTXQSTSm — Transmit Queue Status Register (m = 0 to 3)	940
16.4.12.3	RSCFDnCFDTXQPCTRm — Transmit Queue Pointer Control Register (m = 0 to 3)	942
16.4.13	Details of Transmit History-related Registers	943
16.4.13.1	RSCFDnCFDTHLCCm — Transmit History Configuration and Control Register (m = 0 to 3)	943
16.4.13.2	RSCFDnCFDTHLSTSm — Transmit History Status Register (m = 0 to 3)	945
16.4.13.3	RSCFDnCFDTHLPCTRm — Transmit History Pointer Control Register (m = 0 to 3)	947
16.4.13.4	RSCFDnCFDTHLACCm — Transmit History Access Register (m = 0 to 3)	948
16.4.14	Details of Test-related Registers	950
16.4.14.1	RSCFDnCFDGTSTCFG — Global Test Configuration Register	950
16.4.14.2	RSCFDnCFDGTSTCTR — Global Test Control Register	952
16.4.14.3	RSCFDnCFDGLOCKK — Global Lock Key Register	953
16.4.14.4	RSCFDnCFDRPGACCr — RAM Test Page Access Register (r = 0 to 63)	954
16.5	Interrupt Sources	955
16.5.1	Interrupt Sources	955
16.6	CAN Modes	959
16.6.1	Global Modes	959
16.6.1.1	Global Stop Mode	960
16.6.1.2	Global Reset Mode	960
16.6.1.3	Global Test Mode	961
16.6.1.4	Global Operating Mode	961
16.6.2	Channel Modes	962
16.6.2.1	Channel Stop Mode	963
16.6.2.2	Channel Reset Mode	963

16.6.2.3	Channel Halt Mode.....	963
16.6.2.4	Channel Communication Mode.....	964
16.6.2.5	Bus Off State.....	965
16.6.3	Initializing Registers by Transition to CAN Mode.....	966
16.7	Reception Function.....	968
16.7.1	Data Processing Using the Receive Rule Table.....	969
16.7.1.1	Acceptance Filter Processing.....	970
16.7.1.2	DLC Filter Processing.....	970
16.7.1.3	Routing Processing.....	971
16.7.1.4	Label Addition Processing.....	971
16.7.1.5	Mirror Function Processing.....	971
16.7.1.6	Timestamp.....	971
16.8	Transmission Functions.....	973
16.8.1	Transmit Priority Determination.....	974
16.8.2	Transmission Using Transmit Buffers.....	975
16.8.2.1	Transmit Abort Function.....	975
16.8.2.2	One-Shot Transmission Function (Retransmission Disabling Function).....	975
16.8.2.3	Transmit Buffer Merge Mode (Only in CAN FD Mode).....	975
16.8.3	Transmission Using FIFO Buffers.....	976
16.8.3.1	Interval Transmission Function.....	977
16.8.4	Transmission Using Transmit Queues.....	980
16.8.5	Transmit Data Padding (Only in CAN FD Mode).....	980
16.8.6	Transmit History Function.....	981
16.9	Gateway Function.....	983
16.9.1	CAN-CAN FD Gateway (Only in CAN FD Mode).....	983
16.10	Test Function.....	984
16.10.1	Standard Test Mode.....	984
16.10.2	Listen-Only Mode.....	984
16.10.3	Self-Test Mode (Loopback Mode).....	985
16.10.3.1	Self-Test Mode 0 (External Loopback Mode).....	985
16.10.3.2	Self-Test Mode 1 (Internal Loopback Mode).....	985
16.10.4	Restricted Operation Mode (Only in CAN FD Mode).....	986
16.10.5	RAM Test.....	986
16.10.6	Inter-Channel Communication Test.....	986
16.10.6.1	CRC Error Test.....	987
16.11	RS-CANFD Setting Procedure.....	988
16.11.1	Initial Settings.....	988
16.11.1.1	Clock Setting.....	990
16.11.1.2	Bit Timing Setting.....	990
16.11.1.3	Communication Speed Setting.....	992
16.11.1.4	Receive Rule Setting.....	994
16.11.1.5	Buffer Setting.....	995
16.11.1.6	Transmitter Delay Compensation (Only in CAN FD Mode).....	998
16.11.2	Reception Procedure.....	999
16.11.2.1	Receive Buffer Reading Procedure.....	999
16.11.2.2	FIFO Buffer Reading Procedure.....	1001
16.11.3	Transmission Procedure.....	1005
16.11.3.1	Procedure for Transmission from Transmit Buffers.....	1005
16.11.3.2	Procedure for Transmission from Transmit/Receive FIFO Buffers.....	1010
16.11.3.3	Procedure for Transmission from the Transmit Queue.....	1014

16.11.3.4	Transmit History Buffer Reading Procedure.....	1015
16.11.4	Test Settings.....	1016
16.11.4.1	Self-Test Mode Setting Procedure.....	1016
16.11.4.2	Procedure for Releasing the Protection.....	1017
16.11.4.3	RAM Test Setting Procedure.....	1018
16.11.4.4	Inter-Channel Communication Test Setting Procedure.....	1019
16.12	Notes on the RS-CANFD Module.....	1020
Section 17	FlexRay.....	1022
17.1	FlexRay Module.....	1022
17.1.1	Overview.....	1022
17.1.2	Terms and Abbreviations.....	1024
17.1.3	Block Diagram.....	1025
17.2	Programmer's Model.....	1029
17.2.1	Register Map.....	1029
17.2.2	FlexRay Operation Register.....	1032
17.2.2.1	FLXA0FROC — FlexRay Operation Control Register.....	1032
17.2.2.2	FLXA0FROS — FlexRay Operation Status Register.....	1035
17.2.3	Special Registers.....	1038
17.2.3.1	FLXA0FRLCK — FlexRay Lock Register.....	1038
17.2.4	Interrupt Registers.....	1039
17.2.4.1	FLXA0FREIR — FlexRay Error Interrupt Register.....	1039
17.2.4.2	FLXA0FRSIR — FlexRay Status Interrupt Register.....	1045
17.2.4.3	FLXA0FREILS — FlexRay Error Interrupt Line Select Register.....	1051
17.2.4.4	FLXA0FRSILS — FlexRay Status Interrupt Line Select Register.....	1053
17.2.4.5	FLXA0FREIES — FlexRay Error Interrupt Enable Set Register.....	1055
17.2.4.6	FLXA0FREIER — FlexRay Error Interrupt Enable Reset Register.....	1057
17.2.4.7	FLXA0FRSIES — FlexRay Status Interrupt Enable Set Register.....	1059
17.2.4.8	FLXA0FRSIER — FlexRay Status Interrupt Enable Reset Register.....	1061
17.2.4.9	FLXA0FRILE — FlexRay Interrupt Line Enable Register.....	1063
17.2.5	FlexRay Timer Registers.....	1064
17.2.5.1	FLXA0FRT0C — FlexRay Timer 0 Configuration Register.....	1064
17.2.5.2	FLXA0FRT1C — FlexRay Timer 1 Configuration Register.....	1066
17.2.5.3	FLXA0FRT2C — FlexRay Timer 2 Configuration Register.....	1068
17.2.5.4	FLXA0FRSTPW1 — FlexRay Stop Watch Register 1.....	1070
17.2.5.5	FLXA0FRSTPW2 — FlexRay Stop Watch Register 2.....	1072
17.2.6	CC Control Registers.....	1073
17.2.6.1	FLXA0FRSUCC1 — FlexRay SUC Configuration Register 1.....	1073
17.2.6.2	FLXA0FRSUCC2 — FlexRay SUC Configuration Register 2.....	1081
17.2.6.3	FLXA0FRSUCC3 — FlexRay SUC Configuration Register 3.....	1083
17.2.6.4	FLXA0FRNEMC — FlexRay NEM Configuration Register.....	1084
17.2.6.5	FLXA0FRPRTC1 — FlexRay PRT Configuration Register 1.....	1085
17.2.6.6	FLXA0FRPRTC2 — FlexRay PRT Configuration Register 2.....	1088
17.2.6.7	FLXA0FRMHDC — FlexRay MHD Configuration Register.....	1090
17.2.6.8	FLXA0FRGTUC1 — FlexRay GTU Configuration Register 1.....	1091
17.2.6.9	FLXA0FRGTUC2 — FlexRay GTU Configuration Register 2.....	1092
17.2.6.10	FLXA0FRGTUC3 — FlexRay GTU Configuration Register 3.....	1093
17.2.6.11	FLXA0FRGTUC4 — FlexRay GTU Configuration Register 4.....	1095
17.2.6.12	FLXA0FRGTUC5 — FlexRay GTU Configuration Register 5.....	1097
17.2.6.13	FLXA0FRGTUC6 — FlexRay GTU Configuration Register 6.....	1099
17.2.6.14	FLXA0FRGTUC7 — FlexRay GTU Configuration Register 7.....	1100
17.2.6.15	FLXA0FRGTUC8 — FlexRay GTU Configuration Register 8.....	1101
17.2.6.16	FLXA0FRGTUC9 — FlexRay GTU Configuration Register 9.....	1102

17.2.6.17	FLXA0FRGTUC10 — FlexRay GTU Configuration Register 10	1104
17.2.6.18	FLXA0FRGTUC11 — FlexRay GTU Configuration Register 11	1105
17.2.7	CC Status Registers	1107
17.2.7.1	FLXA0FRCCSV — FlexRay CC Status Vector Register	1107
17.2.7.2	FLXA0FRCCEV — FlexRay CC Error Vector Register	1112
17.2.7.3	FLXA0FRSCV — FlexRay Slot Counter Value Register	1114
17.2.7.4	FLXA0FRMTCCV — FlexRay Macrotick and Cycle Counter Value Register	1115
17.2.7.5	FLXA0FRRCV — FlexRay Rate Correction Value Register	1116
17.2.7.6	FLXA0FROCV — FlexRay Offset Correction Value Register	1117
17.2.7.7	FLXA0FRSFS — FlexRay Sync Frame Status Register	1118
17.2.7.8	FLXA0FRSWNIT — FlexRay Symbol Window and NIT Status Register	1121
17.2.7.9	FLXA0FRACS — FlexRay Aggregated Channel Status Register	1124
17.2.7.10	FLXA0FRESIDn — FlexRay Even Sync ID Register n (n = 1 to 15)	1128
17.2.7.11	FLXA0FROSIDn — FlexRay Odd Sync ID Register n (n = 1 to 15)	1130
17.2.7.12	FLXA0FRNMVn — FlexRay Network Management Vector Register n (n = 1 to 3)	1132
17.2.8	Message Buffer Control Registers	1133
17.2.8.1	FLXA0FRMRC — FlexRay Message RAM Configuration Register	1133
17.2.8.2	FLXA0FRFRF — FlexRay FIFO Rejection Filter Register	1137
17.2.8.3	FLXA0FRFRFM — FlexRay FIFO Rejection Filter Mask Register	1139
17.2.8.4	FLXA0FRFCL — FlexRay FIFO Critical Level Register	1140
17.2.9	Message Buffer Status Registers	1141
17.2.9.1	FLXA0FRMHDS — FlexRay Message Handler Status Register	1141
17.2.9.2	FLXA0FRLDTS — FlexRay Last Dynamic Transmit Slot Register	1144
17.2.9.3	FLXA0FRFSR — FlexRay FIFO Status Register	1145
17.2.9.4	FLXA0FRMHDF — FlexRay Message Handler Constraints Flags Register	1147
17.2.9.5	FLXA0FRTXRQi — FlexRay Transmission Request i (i = 1 to 4)	1151
17.2.9.6	FLXA0FRNDATi — FlexRay New Data Register i (i = 1 to 4)	1152
17.2.9.7	FLXA0FRMBSCi — FlexRay Message Buffer Status Changed Register i (i = 1 to 4)	1153
17.2.10	Input Buffer	1154
17.2.10.1	FLXA0FRWRDSn — FlexRay Write Data Section Register n (n = 1 to 64)	1155
17.2.10.2	FLXA0FRWRHS1 — FlexRay Write Header Section Register 1	1156
17.2.10.3	FLXA0FRWRHS2 — FlexRay Write Header Section Register 2	1159
17.2.10.4	FLXA0FRWRHS3 — FlexRay Write Header Section Register 3	1160
17.2.10.5	FLXA0FRIBCM — FlexRay Input Buffer Command Mask Register	1161
17.2.10.6	FLXA0FRIBCR — FlexRay Input Buffer Command Request Register	1163
17.2.11	Output Buffer	1165
17.2.11.1	FLXA0FRRDDSn — FlexRay Read Data Section Register n (n = 1 to 64)	1165
17.2.11.2	FLXA0FRRDHS1 — FlexRay Read Header Section Register 1	1166
17.2.11.3	FLXA0FRRDHS2 — FlexRay Read Header Section Register 2	1168
17.2.11.4	FLXA0FRRDHS3 — FlexRay Read Header Section Register 3	1170
17.2.11.5	FLXA0FRMBS — FlexRay Message Buffer Status Register	1172
17.2.11.6	FLXA0FROBCM — FlexRay Output Buffer Command Mask Register	1178
17.2.11.7	FLXA0FROBCR — FlexRay Output Buffer Command Request Register	1180
17.2.12	Data Transfer Control Register	1183
17.2.12.1	FLXA0FRITC — FlexRay Input Transfer Configuration Register	1183
17.2.12.2	FLXA0FROTC — FlexRay Output Transfer Configuration Register	1186
17.2.12.3	FLXA0FRIBA — FlexRay Input Pointer Table Base Address Register	1189
17.2.12.4	FLXA0FRFBA — FlexRay FIFO Pointer Table Base Address Register	1190
17.2.12.5	FLXA0FROBA — FlexRay Output Pointer Table Base Address Register	1191
17.2.12.6	FLXA0FRIQC — FlexRay Input Queue Control Register	1192

Section 18 Renesas High-Speed Bus (RHSB) 1305

18.1	Overview.....	1305
18.1.1	Features of RHSB	1305
18.1.2	Module Overview.....	1306
18.1.2.1	Downstream Channel Communication Functions	1306
18.1.2.2	Upstream Channel Communication Functions.....	1307
18.1.2.3	Interrupts	1307
18.1.2.4	DMA Support.....	1307
18.1.2.5	Other Features	1307
18.1.2.6	Caution	1307
18.1.3	Block Diagram	1308
18.2	Register Descriptions.....	1309
18.2.1	I/O Registers Overview.....	1309
18.2.2	Legend.....	1310
18.2.3	Description of the Registers in the Common Controller	1311
18.2.3.1	RHSBjGC — Global Configuration Register	1311
18.2.3.2	RHSBjMSR — Module Status Register.....	1313
18.2.4	Downstream (Tx) Registers.....	1315
18.2.4.1	RHSBjDCR — Downstream Configuration Register	1315
18.2.4.2	RHSBjDCR1 — Downstream Configuration Register for Period 1.....	1318
18.2.4.3	RHSBjDEC — Data Element Configuration Register.....	1319
18.2.4.4	RHSBjSDCi — Slave Device Configuration Register i (i = 0).....	1321
18.2.4.5	RHSBjDEBA _m — Data Element Bit Assignment Register m (m = 0 to 3)	1323
18.2.4.6	RHSBjEBE _i — Emergency Bit Enable Register i (i = 0, 1).....	1325
18.2.4.7	RHSBjDTC — Downstream Transmission Control Register	1326
18.2.4.8	RHSBjDCD — Downstream Command Data Register	1328
18.2.4.9	RHSBjDDR _i — Downstream Data Register i (i = 0, 1).....	1329

18.2.4.10	iRHSBjDEDi — Downstream Emergency Data Register (i = 0, 1)	1330
18.2.5	Upstream (Rx) Registers	1331
18.2.5.1	RHSBjUCR — Upstream Configuration Register	1331
18.2.5.2	RHSBjUCC — Upstream Channel Configuration Register	1333
18.2.5.3	RHSBjUCS — Upstream Channel Selection Register	1336
18.2.5.4	RHSBjUDR — Upstream Data Read Register	1338
18.2.5.5	RHSBjUDi — Upstream Data Register i (i = 0, 1)	1341
18.2.5.6	RHSBjUSS — Upstream Status Summary Register	1344
18.2.6	Interrupt Registers	1346
18.2.6.1	RHSBjIC — Interrupt Control Register	1346
18.2.6.2	RHSBjIS — Interrupt Status Register	1348
18.3	Operation States	1353
18.3.1	Operation State Description	1353
18.3.1.1	RESET State	1353
18.3.1.2	CONFIG State	1353
18.3.1.3	ACTIVE State	1353
18.3.1.4	TEST State	1354
18.3.2	Activation of the RHSB Module (Leaving RESET State)	1354
18.3.3	Deactivation of the RHSB Module (Entering RESET State)	1355
18.3.4	Changing between Operation States (ACTIVE, CONFIG, TEST)	1355
18.3.5	Leaving ACTIVE State without Interrupting Ongoing Transmission	1356
18.4	RHSB operations	1357
18.4.1	Downstream Communication	1357
18.4.1.1	Downstream Communication Phases	1358
18.4.1.2	Frame Dependent Flagging	1360
18.4.1.3	Downstream Modes	1361
18.4.1.4	Command Frame Insertion Methods in Multi-Period Repetition Mode	1368
18.4.1.5	Physical Frame Format	1370
18.4.1.6	Data Frame Assembling	1372
18.4.1.7	Command Frame Assembling	1374
18.4.1.8	Emergency Function	1375
18.4.1.9	Downstream Bit Rates	1377
18.4.1.10	Data Update and Data Frame Transmission Request	1378
18.4.1.11	Command Frame Transmission Request	1379
18.4.2	Upstream Communication	1379
18.4.2.1	Upstream Modes	1381
18.4.2.2	Individual Slave Configuration	1381
18.4.2.3	Frame Format Types	1383
18.4.2.4	Frame Storing	1384
18.4.2.5	Upstream Bit Rates	1384
18.4.2.6	Update of Decoding Status	1385
18.4.3	Timeout Detection	1386
18.4.3.1	Command Transmission with Remote Data Request	1387
18.4.3.2	Timeout Detection Details	1388
18.4.4	Test Mode Operation	1389
18.4.4.1	Test Mode Data Generation	1390
18.5	Interrupts	1391
18.5.1	Downstream Related Interrupts (Transmission)	1391
18.5.2	Upstream Related Interrupts (Reception)	1391
18.5.3	Interrupt Request Details	1392
18.6	DMA Capability	1393
18.6.1	DMA Usage for Downstream Data Transmission	1393

18.6.1.1	Configuring and Enabling Flow to Use Downstream data DMA.....	1393
18.6.1.2	Data Layout in Memory for Downstream Data DMA	1394
18.6.2	DMA Usage for Downstream Command Transmission.....	1394
18.6.2.1	Configuring and Enabling Flow to Use Downstream Command DMA	1394
18.6.2.2	Command Data Layout in Memory for Downstream Command DMA.....	1395
18.6.3	DMA Usage for Upstream Data Reception.....	1396
18.6.3.1	Configuring and Enabling Flow to Use Upstream DMA	1396
18.6.3.2	Data Layout in Memory for Upstream DMA	1396
18.7	Cross Bar (XBAR).....	1397
18.7.1	Overview.....	1397
18.7.2	Module Configuration	1397
18.7.2.1	RHSB XBAR Configuration	1397
18.7.3	Register Specifications	1398
18.7.3.1	List of Registers.....	1398
18.7.3.2	RHSBGiCRjH — Microsecond Bus Control Register H	1399
18.7.3.3	RHSBGiCRjL — Microsecond Bus Control Register L.....	1403
18.7.4	Summary of Operation	1407
Section 19 Single Edge Nibble Transmission (RSENT)		1408
19.1	Overview.....	1408
19.1.1	Number of Channels.....	1408
19.1.2	Register Base Addresses	1408
19.1.3	Clock Supply.....	1408
19.1.4	Interrupts and DTS	1409
19.1.5	Input/Output Signals	1410
19.2	Functions	1411
19.2.1	Block Diagram	1412
19.3	Registers.....	1413
19.3.1	RSENTnTSPC — RSENT Timestamp Register.....	1414
19.3.2	RSENTnTSC — RSENT Timestamp Counter.....	1416
19.3.3	RSENTnCC — RSENT Communication Configuration Register.....	1417
19.3.4	RSENTnBRP — RSENT Baud Rate Prescaler Register.....	1420
19.3.5	RSENTnIDE — RSENT Interrupt/DMA Enable Register.....	1422
19.3.6	RSENTnMDC — RSENT Mode Control Register	1425
19.3.7	RSENTnSPCT — RSENT SPC Transmission Register	1426
19.3.8	RSENTnMST — RSENT Mode Status Register	1427
19.3.9	RSENTnCS — RSENT Communication Status Register	1429
19.3.10	RSENTnCSC — RSENT Communication Status Clear Register.....	1433
19.3.11	RSENTnSRTS — RSENT Slow Channel Receive Timestamp Register.....	1435
19.3.12	RSENTnSRXD — RSENT Slow Channel Receive Data Register	1436
19.3.13	RSENTnCPL — RSENT Calibration Pulse Length Register	1438
19.3.14	RSENTnML — RSENT Message Length Register.....	1439
19.3.15	RSENTnFRTS — RSENT Fast Channel Receive Timestamp Register.....	1440
19.3.16	RSENTnFRXD — RSENT Fast Channel Receive Data Register	1441
19.4	Modes of Operation	1443
19.4.1	RESET Mode.....	1444
19.4.2	CONFIGURATION Mode	1444

19.4.3	OPERATION IDLE Mode	1444
19.4.4	OPERATION ACTIVE Mode	1444
19.4.5	Register Behavior in Operation Modes.....	1445
19.5	Clock Configuration	1446
19.5.1	Timestamp.....	1446
19.5.1.1	Timestamp Clock Configuration	1446
19.5.1.2	Timestamp Counter Operation	1446
19.5.2	Communication Clock Configuration	1448
19.5.2.1	RX BRP Setting.....	1448
19.5.2.2	RX and SPC Tick Settings	1448
19.6	RSENT Operation.....	1449
19.6.1	Changing Operation Modes.....	1449
19.6.2	Message Reception.....	1452
19.6.2.1	Calibration Pulse Reception	1452
19.6.2.2	Data Nibble Reception	1452
19.6.2.3	Fast Channel Message Reception	1453
19.6.2.4	Fast Channel Reception Flow	1457
19.6.2.5	Slow Channel Message Reception	1459
19.6.2.6	Slow Channel Reception Flow	1461
19.6.2.7	DMA Flow.....	1462
19.6.2.8	Error Flagging.....	1463
19.7	SPC Function.....	1464
19.8	Interrupts and Checks.....	1466
Section 20	Window Watchdog Timer (WDTA).....	1468
20.1	Features.....	1468
20.2	Overview.....	1469
20.2.1	Functional Overview	1469
20.2.2	Block Diagram	1469
20.3	Registers.....	1470
20.3.1	Registers Overview	1470
20.3.1.1	WDTAnWDTE — WDTA Enable Register	1471
20.3.1.2	WDTAnMD — WDTA Mode Register.....	1472
20.4	Interrupt Sources	1473
20.5	Functional Description	1474
20.5.1	WDTA after Reset Release	1474
20.5.1.1	Start modes.....	1474
20.5.1.2	Start mode selection (only for WDTA0).....	1474
20.5.1.3	WDTA settings after reset release	1474
20.5.1.4	Default start mode timing (only for WDTA0).....	1475
20.5.1.5	Software trigger start mode timing (common to WDTA0 and WDTA1).....	1476
20.5.2	WDTA Trigger.....	1477
20.5.3	Error Detection	1477
20.5.4	WDTA Error Mode	1478
20.5.5	75% Interrupt Request Signals.....	1479
20.5.6	Window Function.....	1480
Section 21	OS Timer (OSTM).....	1481

21.1	Functional Overview	1481
21.1.1	Features	1481
21.2	Registers.....	1483
21.2.1	Registers Overview	1483
21.2.2	Details of OSTM Registers	1484
21.2.2.1	OSTMnCMP — OSTM Compare Register.....	1484
21.2.2.2	OSTMnCNT — OSTM Counter Register	1485
21.2.2.3	OSTMnTO — OSTM Output Register.....	1486
21.2.2.4	OSTMnTOE — OSTM Output Enable Register	1486
21.2.2.5	OSTMnTE — OSTM Count Enable Status Register	1487
21.2.2.6	OSTMnTS — OSTM Count Start Trigger Register	1488
21.2.2.7	OSTMnTT — OSTM Count Stop Trigger Register.....	1488
21.2.2.8	OSTMnCTL — OSTM Control Register	1489
21.3	Functional Description	1490
21.3.1	Block Diagram	1490
21.3.2	Counter Clock.....	1490
21.3.3	Output Modes (only for OSTM0)	1491
21.3.4	Interrupt Request Generation	1492
21.3.5	Starting and Stopping the Timer.....	1493
21.3.6	Interval Timer Mode.....	1495
21.3.6.1	Basic Operation in Interval Timer Mode	1495
21.3.6.2	Operation when OSTMnCMP = 0000 0000H.....	1498
21.3.7	Free-Running Comparison Mode	1499
21.3.7.1	Basic Operation in Free-Running Comparison Mode.....	1499
21.3.7.2	Operation when OSTMnCMP = 0000 0000 _H	1501
Section 22	Advanced Timer Unit IV (ATU-IV).....	1502
22.1	Overview.....	1502
22.1.1	Configuration of ATU-IV	1507
22.1.2	ATU-IV Registers.....	1509
22.1.3	ATU-IV Input/Output Signals	1550
22.1.4	Clock Supply.....	1551
22.2	Common Controller.....	1552
22.2.1	Operation.....	1552
22.2.2	Common Controller Related Registers.....	1553
22.2.2.1	ATUENR — ATU-IV Master Enable Register.....	1553
22.2.2.2	CBCNT — Clock Bus Control Register	1556
22.2.2.3	NCMR — Noise Cancellation Mode Register.....	1557
22.3	Prescaler.....	1568
22.3.1	Operation.....	1568
22.3.2	Register Description of Prescalers	1569
22.3.2.1	PSCRx — Prescaler Registers x (x = 0 to 3)	1569
22.3.3	Details of Operation.....	1570
22.4	Timer A	1571
22.4.1	Operation.....	1571
22.4.2	Timer A Control Registers	1573
22.4.2.1	TCR1A — Timer Control Register 1A	1573
22.4.2.2	TCR2A — Timer Control Register 2A	1575

22.4.2.3	TCR3A — Timer Control Register 3A	1576
22.4.2.4	TCR4A — Timer Control Register 4A	1577
22.4.2.5	NCMCR1A — Noise Cancellation Mode Channel Register 1A.....	1578
22.4.2.6	NCMCR2A — Noise Cancellation Mode Channel Register 2A.....	1581
22.4.2.7	TIOR1A — Timer I/O Control Register 1A	1583
22.4.2.8	TIOR2A — Timer I/O Control Register 2A	1585
22.4.2.9	TSRA — Timer Status Register A.....	1589
22.4.2.10	TSCRA — Timer Status Clear Register A.....	1591
22.4.2.11	ICRAx — Input Capture Registers Ax (x = 0 to 6).....	1593
22.4.2.12	TCNTA — Free-Running Counter A.....	1594
22.4.2.13	TILRA — Timer Input Signal Level Register A.....	1595
22.4.2.14	TILCRA — Timer Input Signal Level Capture Register A.....	1596
22.4.2.15	NCNTAx — Noise Canceler Counters Ax (x = 0 to 6).....	1597
22.4.2.16	NCRAx — Noise Canceler Registers Ax (x = 0 to 6)	1599
22.4.3	Detailed Operation.....	1601
22.5	Timer B	1605
22.5.1	Operation.....	1605
22.5.2	Timer B Control Registers	1608
22.5.2.1	TCRB — Timer Control Register B	1608
22.5.2.2	TIORB — Timer I/O Control Register B	1610
22.5.2.3	TSRB — Timer Status Register B.....	1612
22.5.2.4	TSCR B — Timer Status Clear Register B.....	1616
22.5.2.5	TICRB — Timer Interrupt Control Register B.....	1618
22.5.2.6	TCNTB0 — Edge Interval Measuring Counter B0.....	1620
22.5.2.7	ICRB0 — Input Capture Register B0.....	1621
22.5.2.8	RECRBx — Record Registers Bx (x = 1 to 6).....	1622
22.5.2.9	RBURBx — Record Backup Registers Bx (x = 0 to 6).....	1623
22.5.2.10	ICRB3x — Input Capture Registers B3x (x = 0 to 6).....	1624
22.5.2.11	OCRB0 — Output Compare Register B0.....	1625
22.5.2.12	TCNTB1 — Event Counter B1	1626
22.5.2.13	OCRB1 — Output Compare Register B1	1627
22.5.2.14	OCRB10 — Output Compare Register B10.....	1628
22.5.2.15	OCRB11 — Output Compare Register B11.....	1629
22.5.2.16	OCRB12 — Output Compare Register B12.....	1630
22.5.2.17	ICRB1 — Input Capture Register B1.....	1631
22.5.2.18	ICRB2 — Input Capture Register B2.....	1632
22.5.2.19	LDB — Load Register B.....	1633
22.5.2.20	RLDB — Reload Register B	1634
22.5.2.21	TCNTB2 — Reload Counter B2	1635
22.5.2.22	PIMR1 — Pulse Interval Multiplier Register 1	1636
22.5.2.23	PIMR2 — Pulse Interval Multiplier Register 2	1637
22.5.2.24	TCNTB6 — Multiplied Clock Counter B6	1638
22.5.2.25	ICRB6 — Input Capture Register B6.....	1639
22.5.2.26	RARB6 — Multiplication Setting Register B6.....	1640
22.5.2.27	TCNTB6M — Frequency-Multiplied Clock Counter B6M	1641
22.5.2.28	OCRB6 — Output Compare Register B6	1642
22.5.2.29	OCRB7 — Output Compare Register B7	1643
22.5.2.30	TCNTB3 — Correcting Event Counter B3.....	1644
22.5.2.31	OCRB8 — Output Compare Register B8.....	1645
22.5.2.32	TCNTB4 — Multiplied-and-Corrected Clock Counter B4	1646
22.5.2.33	TCNTB5 — Multiplied-and-Corrected Clock Generating Counter B5	1647
22.5.2.34	TCCLFRB — Correcting Counter Clear Flag Register B	1648
22.5.2.35	TCCLFSRB — Correcting Counter Clear Flag Setting Register B.....	1649
22.5.2.36	TCCLFCRB — Correcting Counter Clear Flag Clearing Register B	1650

24.4.2.20	TSG2nSBC — TSG2n Sub-Counter Register	2079
24.4.2.21	TSG2nCMP0 — TSG2n Compare Register 0	2080
24.4.2.22	TSG2nCMP1W — TSG2n Compare Registers 1 and 2	2081
24.4.2.23	TSG2nCMP5W — TSG2n Compare Registers 5 and 6	2082
24.4.2.24	TSG2nCMP9W — TSG2n Compare Registers 9 and 10	2083
24.4.2.25	TSG2nCMP3W — TSG2n Compare Registers 3 and 4	2084
24.4.2.26	TSG2nCMP7W — TSG2n Compare Registers 7 and 8	2085
24.4.2.27	TSG2nCMP11W — TSG2n Compare Registers 11 and 12	2086
24.4.2.28	TSG2nCMP1-12 — TSG2n Compare Registers 1 to 12	2087
24.4.2.29	TSG2nDCMP0W — TSG2n Diagnostic Output Compare Registers 0 and 1	2088
24.4.2.30	TSG2nDCMP2 — TSG2n Diagnostic Output Compare Register 2	2089
24.4.2.31	TSG2nPAT0W — TSG2n Pattern Register 0	2090
24.4.2.32	TSG2nPAT1W — TSG2n Pattern Register 1	2091
24.4.2.33	TSG2nDTC0W — TSG2n Dead Time Compare Register 0	2092
24.4.2.34	TSG2nDTC1W — TSG2n Dead Time Compare Register 1	2093
24.4.2.35	TSG2nCMPU — TSG2n U Phase Compare Register	2094
24.4.2.36	TSG2nCMPV — TSG2n V Phase Compare Register	2095
24.4.2.37	TSG2nCMPW — TSG2n W Phase Compare Register	2096
24.4.2.38	TSG2nUPW — TSG2n U Phase Period Register	2097
24.4.2.39	TSG2nVPW — TSG2n V Phase Period Register	2098
24.4.2.40	TSG2nWPW — TSG2n W Phase Period Register	2099
24.4.2.41	TSG2nDTPR — TSG2n Dead Time Protection Register	2100
24.5	Basic Operation	2101
24.5.1	Basic Operation of 16-Bit Counter	2101
24.5.2	Functions of Compare Registers	2103
24.5.3	Compare Register Rewrite Operation	2105
24.5.4	List of Outputs in Each Mode	2112
24.6	Match Interrupt	2117
24.7	Flags	2120
24.7.1	Up-Count Flags (TSG2nCUF and TSG2nSUF)	2121
24.7.2	Positive/Negative Phase Simultaneous Activation Detection Flags (TSG2nTBF0 to TSG2nTBF2)	2123
24.7.3	Reload Request Flag (TSG2nRSF)	2124
24.7.4	Noise Detection Flag (TSG2nNDF)	2125
24.7.5	Pattern Order Detection Flag (TSG2nTSF)	2126
24.7.6	Pattern Error Detection Flag (TSG2nPEF)	2128
24.7.7	Pattern Inversion Detection Flag (TSG2nPRF)	2129
24.7.8	Pattern Phase Difference Detection Flag (TSG2nPPF)	2131
24.7.9	Timer Output Pattern Flag (TSG2nOPF2-TSG2nOPF0)	2132
24.7.10	Pattern Switch Detection Signal (TSG2nPTE)	2132

Section 30 Safety

30.1	Overview	2503
30.2	ECC and EDC	2504
30.2.1	Overview	2504
30.2.1.1	ECC	2504
30.2.1.2	Address Parity	2505
30.2.1.3	Data Parity	2505
30.2.2	Code Flash ECC and Address Parity	2506
30.2.2.1	Overview	2506
30.2.2.2	List of Registers	2509
30.2.2.3	Details of Registers	2510
30.2.2.4	Test Function	2518
30.2.3	Data Flash ECC	2520
30.2.3.1	Overview	2520
30.2.3.2	List of Registers	2521
30.2.3.3	Details of Registers	2522
30.2.3.4	Test Function	2527
30.2.4	Local RAM (CPU1) ECC and Address Parity	2528
30.2.4.1	Overview	2528
30.2.4.2	List of Registers	2530
30.2.4.3	Details of Registers	2531
30.2.4.4	Test Function	2541
30.2.5	Local RAM (PCU) ECC	2543
30.2.5.1	Overview	2543
30.2.5.2	List of Registers	2544
30.2.5.3	Details of Registers	2545
30.2.5.4	Test Function	2553
30.2.6	Global RAM ECC and Address Parity	2554
30.2.6.1	Overview	2554
30.2.6.2	List of Registers	2559
30.2.6.3	Details of Registers	2560
30.2.6.4	Test Function	2572
30.2.7	Instruction Cache ECC and EDC	2575
30.2.7.1	Overview	2575
30.2.7.2	List of Registers	2576
30.2.7.3	Details of Registers	2577
30.2.7.4	Test Function	2588
30.2.8	DTS RAM ECC	2589
30.2.9	ECC for Peripheral RAM (32 Bits)	2589

30.2.9.1	Overview	2589
30.2.9.2	List of Registers.....	2591
30.2.9.3	Details of Registers	2593
30.2.9.4	Notification to ECM.....	2601
30.2.9.5	Test Function.....	2601
30.2.10	ECC for Peripheral RAM (16 Bits).....	2603
30.2.10.1	Overview	2603
30.2.10.2	List of Registers.....	2605
30.2.10.3	Details of Registers	2606
30.2.10.4	Notification to ECM.....	2615
30.2.10.5	Test Function.....	2615
30.2.11	Data Parity for Data Transfer Paths	2616
30.2.11.1	List of Registers.....	2616
30.2.11.2	Details of Registers	2619
30.3	Lockstep	2623
30.3.1	List of Registers.....	2623
30.3.2	Details of Registers	2624
30.3.2.1	TESTCOMPREG0 — Comparator Test Register 0.....	2624
30.3.2.2	TESTCOMPREG1 — Comparator Test Register 1.....	2625
30.3.2.3	LS_ERR_CNT — Lockstep error control register.....	2626
30.3.2.4	LS_ERR_ST — Lockstep Error Status Register	2627
30.3.2.5	LS_ERR_ADDRESS — Lockstep Error Address Register	2628
30.3.2.6	LS_ERR_DATA — Lockstep Error Data Register.....	2629
30.4	Memory Protection.....	2630
30.4.1	Overview.....	2630
30.4.1.1	Identifiers for Slave Guard.....	2631
30.4.2	GRG (Global RAM Guard).....	2632
30.4.2.1	List of Registers.....	2632
30.4.2.2	Details of Registers	2634
30.4.3	PBG.....	2642
30.4.3.1	List of Registers.....	2644
30.4.3.2	Details of Registers	2645
30.5	Multi-Input Signature Generator (MISG).....	2649
30.5.1	Overview.....	2649
30.5.2	Block Diagram	2650
30.5.2.1	MISG	2650
30.5.2.2	Signature Generation	2651
30.5.3	Functional Specification.....	2653
30.5.3.1	Conditions for Signature Generation	2653
30.5.3.2	Automatic Signature Comparison.....	2654
30.5.3.3	Data Counter	2655
30.5.3.4	Error Notification.....	2655
30.5.4	Register Specifications	2656
30.5.4.1	Register Map	2656
30.5.4.2	MISRCDR_PE1/PCU — MISR Calculation Data Register	2658
30.5.4.3	MISR1_PE1/PCU — Multi-Input Signature Register 1.....	2659
30.5.4.4	MISR2_PE1/PCU — Multi-Input Signature Register 2.....	2660
30.5.4.5	MISRCR_PE1/PCU — MISR Control Register	2661
30.5.4.6	MISRBASEADR_PE1/PCU — MISR Monitoring Area Base Address Register	2662
30.5.4.7	MISRADRMASK_PE1/PCU — MISR Monitor Area Address Mask Register	2663
30.5.4.8	MISRDCNTCTL_PE1/PCU — MISR Data Counter Control Register	2664
30.5.4.9	MISRDCNT_PE1/PCU — MISR Data Counter Register.....	2665

30.5.4.10	MISRCMPCTL — MISR Comparator Control Register	2666
30.5.4.11	MISRCMPERSTR — MISR Compare Error Status Register	2667
30.5.4.12	MISRCMPERRSTC — MISR Compare Error Status Clear Register	2668
30.5.4.13	MISRERRCTL — MISR Error Notification Control Register.....	2669
30.5.5	Usage	2670
30.5.5.1	Usage Example 1	2670
30.5.5.2	Usage Example 2	2670
30.6	Clock Monitors	2672
30.6.1	Overview.....	2672
30.6.2	List of Registers.....	2673
30.6.2.1	Clock Monitor Channel Registers.....	2673
30.6.2.2	Shared Registers.....	2673
30.6.3	Details of Registers	2674
30.6.3.1	CLMAnCTL0 — CLMAn Control Register 0.....	2674
30.6.3.2	CLMAnCMPL — CLMAn Compare Register L.....	2674
30.6.3.3	CLMAnCMPH — CLMAn Compare Register H	2675
30.6.3.4	CLMAnPCMD — CLMAn Protection Command Register	2675
30.6.3.5	CLMAnPS — CLMAn Protection Command Status Register.....	2676
30.6.3.6	CLMATEST — CLMA Self-Test Register.....	2677
30.6.3.7	CLMATESTS — CLMA Self-Test Status Register	2678
30.6.4	Detection of Abnormal Clock Frequency	2679
30.6.5	Self-Diagnosis	2682
30.6.6	Notes on Register Setting.....	2683
30.6.6.1	Writing to Protected Registers.....	2683
30.6.6.2	Setting CLMAnCMPL/CLMAnCMPH Registers	2684
30.7	BIST.....	2685
30.8	ECM.....	2685
Section 31	Error Control Module (ECM)	2686
31.1	Overview.....	2686
31.1.1	Specification Overview	2686
31.1.2	Error Sources and Safety Processing	2687
31.1.3	Operations for ERROROUT Output	2690
31.1.3.1	Dynamic Mode Enable	2690
31.1.3.2	Dynamic Mode Disable	2690
31.1.4	Loop-Back Function.....	2690
31.1.5	Pseudo Error Generation.....	2690
31.1.6	Error Status	2691
31.1.7	Write-Protected Registers	2691
31.1.7.1	Sequence of Writing to the Write-Protected Registers.....	2691
31.1.8	Timeout Function for Interrupt Processing	2692
31.2	Block Diagram	2693
31.3	Register Specification	2694
31.3.1	List of Registers.....	2694
31.3.2	ECMmESET (m = M/C) — ECM Master/Checker Error Set Trigger Register	2696
31.3.3	ECMmECLR (m = M/C) — ECM Master/Checker Error Clear Trigger Register.....	2697
31.3.4	ECMmESSTR0 (m = M/C) — ECM Master/Checker Error Source Status Register 0....	2698
31.3.5	ECMmESSTR1 (m = M/C) — ECM Master/Checker Error Source Status Register 1....	2699
31.3.6	ECMmPCMD0 (m = M/C) — ECM Master/Checker Protection Command Register.....	2700

31.3.7	ECMEPCFG — ECM Error Pulse Configuration Register	2701
31.3.8	ECMMICFG0 — ECM Maskable Interrupt Configuration Register 0	2702
31.3.9	ECMMICFG1 — ECM Maskable Interrupt Configuration Register 1	2703
31.3.10	ECNMICFG0 — ECM FE level Interrupt Configuration Register 0	2704
31.3.11	ECNMICFG1 — ECM FE level Interrupt Configuration Register 1	2705
31.3.12	ECMIRCFG0 — ECM Internal Reset Configuration Register 0	2706
31.3.13	ECMIRCFG1 — ECM Internal Reset Configuration Register 1	2707
31.3.14	ECMEMK0 — ECM Error Mask Register 0	2708
31.3.15	ECMEMK1 — ECM Error Mask Register 1	2709
31.3.16	ECMESSTC0 — ECM Error Source Status Clear Trigger Register 0	2710
31.3.17	ECMESSTC1 — ECM Error Source Status Clear Trigger Register 1	2711
31.3.18	ECMPCMD1 — ECM Protection Command Register	2712
31.3.19	ECMPS — ECM Protection Status Register	2713
31.3.20	ECMPE0 — ECM Pseudo Error Trigger Register 0	2714
31.3.21	ECMPE1 — ECM Pseudo Error Trigger Register 1	2715
31.3.22	ECMDTMCTL — ECM Delay Timer Control Register	2716
31.3.23	ECMDTMR — ECM Delay Timer Register	2716
31.3.24	ECMDTMCMP — ECM Delay Timer Compare Register	2717
31.3.25	ECMDTMCFG0 — ECM Delay Timer Configuration Register 0	2718
31.3.26	ECMDTMCFG1 — ECM Delay Timer Configuration Register 1	2720
31.3.27	ECMDTMCFG2 — ECM Delay Timer Configuration Register 2	2721
31.3.28	ECMDTMCFG3 — ECM Delay Timer Configuration Register 3	2723
Section 32 Data CRC (DCRA)		2724
32.1	Overview	2724
32.1.1	Functional Overview	2724
32.1.2	Block Diagram	2725
32.1.3	Calculation Circuit	2726
32.2	Register Specifications	2727
32.2.1	List of Registers	2727
32.2.2	DCRA0CIN — CRC Input Register	2728
32.2.3	DCRA0COUT — CRC Data Register	2729
32.2.4	DCRA0CTL — CRC Control Register	2730
32.3	Functions	2731
Section 33 On-Chip Debugging Unit (OCD)		2732
33.1	Debug Function	2732
33.2	Calibration Function	2734
33.3	Trace Control Function	2734
33.4	Peripheral Break Control	2735
33.4.1	Overview	2735
33.5	AUD-RAM Monitor (AUDR)	2736
33.5.1	Overview	2736
33.5.2	I/O Pins	2739
33.5.3	Description of Registers	2739

33.5.3.1	AUDISR — AUDR Configuration Information Retention Register	2740
33.5.3.2	AUDMBR/AUDMBRC — AUDR Message Board Register	2741
33.5.4	RAM Monitoring	2742
33.5.4.1	Communication Protocol	2742
33.5.4.2	Operation	2742
33.5.4.3	Usage Notes on AUDR Function	2750
33.5.4.4	Enabling and Disabling the RAM Monitor Function	2750
33.6	Caution on Using On-Chip Debugger	2750
Section 34	Flash Memory	2751
34.1	Features	2751
34.2	Structure of Memory	2752
34.3	Operating Modes Associated with Flash Memory	2754
34.4	Functional Overview	2755
34.5	Serial Programming	2759
34.5.1	Environments for Programming	2759
34.6	Selection of the Communication Method	2760
34.7	Self-Programming	2761
34.7.1	Overview	2761
34.7.2	Background Operation	2761
34.8	Reading Flash Memory	2762
34.8.1	Reading Code Flash Memory	2762
34.8.2	Reading Data Flash Memory	2762
34.9	Description of Registers	2763
34.9.1	Registers Related to Data Flash Memory	2763
34.9.1.1	FRDCYCLD — Data Flash Memory Read Cycle Setting Register	2763
34.9.2	Registers Related to Write and Erase Protection of Flash Memory	2764
34.9.2.1	FHVE15 — FHVE15 Control Register	2764
34.9.2.2	FHVE3 — FHVE3 Control Register	2765
34.9.3	Registers Related to Product Information	2766
34.9.3.1	PRDNAME _n ; n = 1 to 4 — Product Name Storage Register	2767
34.10	Option Bytes	2768
34.10.1	OPBT0 — Option Byte 4 to 1 Bit Arrangement	2769
34.10.2	OPBT2 — Option Byte 12 to 9 Bits Arrangement	2771
34.10.3	OPBT3 — Option Byte 16 to 13 Bit Arrangement	2772
34.10.4	OPBT5 — Option Byte 24 to 21 Bit Arrangement	2773
34.10.5	OPBT6 — Option Byte 25 to 28 Bit Arrangement	2774
34.11	Usage Notes	2775
Section 35	Security	2777
35.1	Features	2777
35.1.1	Protection of Code Flash Memory, Data Flash Memory, and ID Codes	2777
35.1.1.1	Functions Unique to User Boot Mode	2777
35.1.1.2	Functions Unique to Serial Programming Mode	2777
35.1.1.3	Common Function of User Boot Mode and Serial Programming Mode	2778
35.1.2	Connection Restriction Function of Debug Interface	2778

35.2	Security in User Boot Mode	2779
35.2.1	SELF ID Authentication	2779
35.2.2	SELF ID Authentication and Security State	2779
35.3	Security Functions in Serial Programming Mode	2780
35.4	Restricting Connection with Debug Interfaces	2780
35.4.1	Security Levels and State of Restricting the Connection of Debug Interfaces	2781
Section 36	ICUS	2783
Section 37	Secure Watchdog Timer (SWDT)	2784
37.1	Functional Overview	2784
37.1.1	Features of SWDT	2784
37.2	Description of Registers	2786
37.2.1	SWDTnWDTE — SWDT Enable Register	2786
37.2.2	SWDTnMD — SWDT Mode Register	2787
37.2.3	SWDTnCLR — SWDT Clear Register	2788
37.2.4	SWDTnSTS0 — SWDT Status Register 0	2789
37.2.5	SWDTnSTS1 — SWDT Status Register 1	2790
37.2.6	SWDTnSTSC — SWDT Status Clear Register	2791
37.3	Operation	2792
37.3.1	Operation on Release from the Reset State	2792
37.3.2	Counter Clearing by SWDTn	2793
Section 38	On-Chip RAM	2794
38.1	List of On-Chip RAM	2794
38.2	Features	2794
38.3	RAM Data Retention	2794
38.4	Emulation RAM (ERAM)	2795
38.4.1	About the ERAM	2795
38.4.2	Code Flash Emulation using ERAM	2795
38.4.3	Memory Map of ERAM	2797
38.4.4	List of CFU Registers	2798
38.4.5	TM_CC — Cache Clear Operation Register	2799
38.4.6	TM_ME — Tuning Memory Mapping Enable Register	2800
38.4.7	TM_MS — Tuning Memory Mapping Status Register	2801
38.4.8	TM_BNK — Tuning Memory Mapping Bank Register	2802
38.4.9	TM_ERR — Tuning Memory Mapping Error Register	2803
38.4.10	TM_FST — Tuning Memory Flash Bank Register	2804
38.4.11	TM_BMC0 — Tuning Memory Bank Mapping Size Configuration Register 0	2805
38.4.12	TM_MA00 — Tuning Memory Mapping Address Register 00	2807
38.4.13	Flow of Processing for Tuning	2808
38.5	Usage Notes	2809

Section 1 Overview

The RH850/E1M-S2 is a product of the single-chip microcomputer RH850 series of Renesas Electronics.

This section describes an overview of the RH850/E1M-S2.

1.1 Outline

This product is a 32-bit single-chip microcomputer that incorporates multiple CPUs of the RH850 Series, code flash, RAM, DMA controller, CAN, high-speed communication interfaces including RHSB (microsecond bus), two types (sequential conversion type and delta-sigma type) of A/D converters, peripheral functions including digital filter processing, and an advance timer unit (ATU-IV) that is best suited for high-speed accurate power train control. This product also conforms to the Automotive Safety Integrity Level (ASIL) that is highly demanded in the recent automotive field.

(1) Installing multiple RH850 cores

This product contains a single RH850G3MH as the main CPU (each CPU is referred to as CPU1 hereafter) and a single RH850G3K as the peripheral control CPU (referred to as PCU: Peripheral Control Unit hereafter). CPU1 and the PCU support RISC-type instruction sets and have significantly improved the instruction execution speed with basic instructions (one clock cycle per instruction) and the optimized 9- and 5-stage pipeline configurations. Furthermore, this product also supports multiplication instructions using a 32-bit hardware multiplier, saturated product-sum operation instructions, and bit manipulation instructions as instructions best suited for various fields such as applications of the automobile power train control.

Two-byte basic instructions and high-level language instructions improve object code efficiency for the C compiler and reduce the program size. Furthermore, this product is suited for advanced real-time control fields thanks to high-speed interrupt response time including the processing time of the on-chip interrupt controller.

(2) On-chip code flash and data flash

This product incorporates 4-Mbyte code flash allowing high-speed accesses, which enables each CPU to access this flash memory. This memory can be reprogrammed while it is placed on an application system. This can shorten the system development period and significantly improve the serviceability after the system is delivered.

This product also has 64-Kbyte data flash that is available for storing EEPROM data.

(3) A variety of peripheral functions

This product incorporates timers (ATU-IV and APA) best suited for reducing hardware and software control loads in the automobile power train control (e.g. engine, transmission), digital filter engine (DFE), two types of A/D converters (ADCB and DS-ADC), and other devices. In addition, the RH850/E1M-S2 incorporates standard peripheral functions (UART, CAN, and RHSB) for the automotive field. It also has the global standard on-chip debug interface (NEXUS JTAG) as a debug interface. This allows construction of systems without providing these functions externally, reducing costs, quantity of components, and footprint.

(4) Conforming to functional safety

This product has been developed as a Safety Element out of Context (SEooC) according to the definition in ISO 26262. It handles memory protection, peripheral device protection, system/register protection, and clock monitoring in addition to failure detection functions, such as an ECC module, for the detection of failures of the LSI chip at an early stage. With these functions, the product is capable of fulfilling functional safety requirements (for an automotive safety integrity level or ASIL) in the automotive field.

1.2 Features

CPU1 core	RH850G3MH: 1 unit (for high-speed operation and control)
CPU1 cache memory	8 Kbytes
Minimum CPU1 instruction execution time	3.125 ns (during internal 320 MHz operation)
General CPU1 registers	Thirty-two 32-bit registers
CPU1 instruction sets	Signed multiplication (32 bits × 32 bits → 64 bits): 1 to 2 CPU clocks Saturated operation instructions (with overflow/underflow detection function) 32-bit arithmetic/logical shift instructions: 1 CPU clock Bit manipulation instructions Load/store instructions with long/short formats Signed load instructions
PCU core	RH850G3K: 1 unit (for medium-speed operation and peripheral control)
Minimum PCU instruction execution time	12.5 ns (during internal 80 MHz operation)
General PCU registers	Thirty-two 32-bit registers
PCU instruction sets	Signed multiplication (32 bits × 32 bits → 64 bits): 1 and 2 CPU clocks Saturated operation instructions (with overflow/underflow detection function) 32-bit arithmetic/logical shift instructions: 1 CPU clock Bit manipulation instructions Load/store instructions with long/short formats Signed load instructions
Memory space	4-Gbyte address space (common to program and data) (128 Mbytes accessible by the PCU)
Code flash	Two types of memory area <ul style="list-style-type: none"> • User area: 4 Mbytes (common to CPU1 and PCU) • User boot area: 32 Kbytes High-speed reading through cache enabled (only for CPU1)
Data flash	64 Kbytes (common to CPU1 and PCU)
RAM	RAM (Local RAM): 64 Kbytes (CPU1), 32 Kbytes (PCU) (Global RAM): 256 Kbytes (common to CPU1 and PCU) (32 Kbytes: Standby RAM) Emulation RAM: 8 Kbytes (readable and writable by CPU1 only)
Interrupts/exceptions	1 nonmaskable interrupt (NMI pin) 1 FE level interrupt (ECM) 491 maskable interrupts (high-speed: 23, low-speed: 468) Simultaneous distribution of interrupt sources to multiple cores (CPU1/PCU) <ul style="list-style-type: none"> • Applicable sources: non-maskable interrupt (NMI pin), FE level interrupt, 23 high-speed maskable interrupts External interrupt input function (IRQ pins) Software interrupt function (SINT) Inter-processor interrupt function (IPIR) 16-level priority specifiable for maskable interrupts For RH850 G3MH and G3K exceptions, see “ <i>RH850G3MH User's Manual: Software</i> ”, and “ <i>RH850G3K User's Manual: Software</i> ”.
DMA controller	16 channels incorporated (8 channels × 2 modules) Transfer unit: 8 bits/16 bits/32 bits/64 bits/128 bits For 64-bit × 2-burst transfer Dual-address transfer mode Address reloading function Chain transfer function Three transfer modes settable: Single transfer, block transfer 1 (specified by number of transfer times), and block transfer 2 (specified by address count) Transfer target: On-chip memory, on-chip peripheral modules (excluding DMAC and DTS) Transfer requests can be set by interrupt sources and the software.

DTS controller	<p>128 channels incorporated Transfer unit: 8 bits/16 bits/32 bits/64 bits/128 bits For 64-bit × 2-burst transfer Dual-address transfer mode Address reloading function Chain transfer function Three transfer modes settable: Single transfer, block transfer 1 (specified by number of transfer times), and block transfer 2 (specified by address count) Transfer target: On-chip memory, on-chip peripheral modules (excluding DMAC and DTS) Transfer requests can be set by interrupt sources and the software.</p>
I/O	<p>Output driving ability of specific input/output pins selectable Inversion or non-inversion of output values of specific input/output pins selectable Pull-down or pull-down off of specific input/output pins selectable</p>
Safety functions	<p>Flash memory ECC error detection function RAM ECC error detection function Peripheral module RAM ECC error detection function (DTS, APA, CAN, FlexRay, DFE) Oscillation stop detection function and oscillation function by the backup clock Error control module (ECM) Duplexing of modules (e.g. CPU1, ECM, error output pins)</p>
Error control module (ECM)	<p>Collects information of each error check system and safety function and indicates error status. When an error is detected, an error signal can be output from the error pin to the external. Interrupts and internal reset signals can be generated upon detection of an error. Provided with a function to generate a pseudo-error for debugging and self-diagnosis.</p>
Data CRC function	<p>The data CRC (cyclic redundancy check) function can verify or generate data streams protected by CRC with various lengths and different bit widths.</p>
Multi-Input signature generator (MISG)	<p>Monitors write access to specific addresses by the respective CPUs, and generates a 64-bit signature using the write data.</p>
Window watchdog timer (WDTA)	<p>Two channels incorporated Can generate a signal to the ECM when an error occurs. Can generate an interrupt at 75% of the error source (register write during counter overflow or window closing period) window.</p>
Advanced timer unit IV (ATU-IV)	<p>Timer A: 32-bit input capture × 7 channels Timer B: Angle clock generating timer × 1 channel Timer C: 32-bit input capture/output compare × 32 channels Timer D: 32-bit one-shot pulse × 40 channels 32-bit input capture × 40 channels 32-bit output compare × 40 channels Timer E: 24-bit PWM × 28 channels Timer F: 32-bit event counter × 16 channels Timer G: 32-bit interval timer × 10 channels Timer H: 32-bit interval timer × 1 channel Timer J: 32-bit input capture (with 9-stage FIFO) × 6 channels</p>
Autonomous pulse adapter (APA)	<p>1 channels incorporated</p> <ul style="list-style-type: none"> • PWM output through a total of 16 channels is possible • Changes output at an event (compare match) with no CPU load using values of peripheral modules (ATU-IV, ADCB, DS-ADC) as reference. • Can generate output patterns automatically by combining multiple events.
Motor control timer (TSG2) Timer option (TAPA)	<p>TSG2, TAPA: Two units are incorporated individually.</p> <ul style="list-style-type: none"> • Incorporates a timer unit that can control up to two 3-phase motor controls (U, V, and W). • Can forcibly set the TSG2 timer output to Hi-Z when an error is detected.
OS timer (OSTM)	<p>Three units incorporated</p> <ul style="list-style-type: none"> • A 32-bit timer assuming the use of OS • Interval timer mode or free-running timer mode settable • Synchronous start between units settable
Peripheral interconnection (PIC)	<p>One unit incorporated</p> <ul style="list-style-type: none"> • Synchronous operation using TSG2 timer and timer input/output can be connected between timers.

Serial communication interface 3 (SCI3)	<p>Four channels incorporated</p> <ul style="list-style-type: none"> • Clock synchronization or start-stop system settable • Full-duplex communication enabled • Arbitrary bit rate settable by the on-chip baud rate generator • LSB first or MSB first selectable
Serial interface H (CSIH)	<p>Four channels incorporated</p> <ul style="list-style-type: none"> • Three-wire serial synchronous data transfer • Master mode or slave mode selectable • Settable six or four chip select output signals • Arbitrary bit rate settable by the on-chip baud rate generator
CAN interface (RS-CAN-FD)	<p>Four channels incorporated</p> <ul style="list-style-type: none"> • Classical CAN mode (RS-CAN software compatibility mode) <ul style="list-style-type: none"> – Conforming to CAN ISO 11898-1:2015 – Transfer speed up to 1 Mbps – A total of 320 message buffers provided for 4 channels – Reception filtering • CAN-FD mode <ul style="list-style-type: none"> – Conforming to CAN-FD ISO 11898-1:2015 – Transfer speed up to 5 Mbps – A total of 320 message buffers provided for 4 channels – Reception filtering
FlexRay	<p>Two channels incorporated (Ach, Bch)</p> <ul style="list-style-type: none"> • Conforming to Protocol Specification 2.1 • Buffer size: A 8-Kbyte space is divided into up to 128 (for transmission, reception, and receive FIFO) • Message filtering: ID filter, channel filter, cycle counter filter • Bit rate: 10 Mbps
LIN master interface (RLIN2)	<p>One channel incorporated</p> <ul style="list-style-type: none"> • Settable to support various frame sizes • Checksum type settable • Wake-up transmission/reception enabled • Arbitrary bit rate (2400, 9600, 10417, 19200 bps) settable by the on-chip baud rate generator
Renesas high-speed bus (RHSB)	<p>Two channels incorporated</p> <p>Communication module supporting microsecond bus channels</p> <ul style="list-style-type: none"> • Down-stream communication • Up to two slaves settable individually • Functions for emergencies
RSENT	<p>Six channels incorporated</p> <ul style="list-style-type: none"> • Conforming to the SENT (single edge nibble transmission) protocol specified in the SAE J2716 standard (version JAN2010) and the SPC (short PWM code) extension to the SENT specification • Unidirectional or bidirectional transfer is possible through a single pin • Bidirectional transfer is possible through two pins • Data transfer protected by CRC is possible

AD converter (ADCB)	<p>48 channels incorporated</p> <ul style="list-style-type: none"> • 12-bit resolution, sequential conversion • Conversion speed: 1.0 μs • Independent operation of 12-bit resolution for 24 channels (ADC0) and 12-bit resolution for 24 channels (ADC1) • Track and hold circuit (ADC0: 2 channels, ADC1: 2 channels) • Scan groups for five systems settable • Two scan modes (multi-scan mode and continuous scan mode) • ADC0: Up to 40 virtual channels settable • ADC1: Up to 40 virtual channels settable • Two types of A/D conversion and addition functions incorporated • Converts the converted results to floating-point format. • Can enter data directly to the digital filter engine. • Safety functions (including self-diagnosis, data register upper limit/lower limit check, and data register parity)
Delta-sigma AD converter (DS-ADC)	<p>16 channels incorporated (8 channels \times 2 inputs)</p> <ul style="list-style-type: none"> • Advanced A/D conversion • A/D conversion system: Delta-sigma modulation system • Supports single-end input and differential input. • On-chip programmable gain amplifier (x1, x2, x4, and x8) • Can enter data directly to the digital filter engine. • Safety functions (including self-diagnosis, data register upper limit/lower limit check, and data register parity)
Power supply voltage monitor	<p>Monitors VDD voltage internally. If VDD rises above or falls below the specified voltage, an error is reported outside the LSI. Can set a time filter for error detection.</p>
Digital filter	<p>16-channel digital filtering (FIR/IIR) functions</p> <ul style="list-style-type: none"> • FIR with up to 64 taps selectable • Up to 6-order IIR selectable • Filter coefficients and data are stored in the RAM to be connected. • For filtered data: <ul style="list-style-type: none"> Accumulation processing or decimation processing enabled Peak-hold processing or comparison processing enabled • Directly inputs converted data from the on-chip A/D converter or delta-sigma AD converter to perform automatic filtering.
Secure watchdog timer (SWDT)	<p>Two channels incorporated Can generate an error signal for the ECM in response to an error. Error source (counter overflow) Confirmation of matching with a specified program counter (PC) value</p>
Intelligent cryptographic unit (ICUS)	<p>Supports the standard functions for in-vehicle security defined in the SHE (secure hardware extension) specification.</p>
On-chip debugging unit (OCD)	<p>NEXUS JTAG: One channel incorporated LDU (4-pin): One channel incorporated</p>
Boundary scan	<p>Supports boundary scan conforming to the IEEE1149.1 standard</p>

Clock controller	<p>An oscillation circuit incorporated</p> <p>20 MHz oscillation enabled without using external capacitors</p> <p>20 MHz (maximum) clock can be input from the EXTAL pin.</p> <p>Multiplication of clock enabled by the on-chip PLL</p> <p>A ring oscillator circuit incorporated</p> <p>SSCG for reducing radiation noise incorporated. However, clock without SSCG is supplied to the timer and the communication module.</p>
Operating modes	<p>Operating modes</p> <ul style="list-style-type: none">• User boot mode• Serial programming mode <p>Power-down mode</p> <ul style="list-style-type: none">• Power shutoff standby
Package	<p>304-pin plastic FBGA (0.8 mm ball pitch) (19 × 19)</p> <p>252-pin plastic FBGA (0.8 mm ball pitch) (17 × 17)</p>

1.3 Application Fields

- Automotive field (including engine control system and transmission control system)

1.4 Order Information

Product Name	Package	On-Chip ROM	Operating Temperature (T _j)	External Oscillator	Maximum Operating Frequency
R7F701215EABA	Plastic BGA-304 0.8-mm ball pitch 19 mm × 19 mm	4 MB	max. 150°C	20 MHz	240 MHz
R7F701215EABG	Plastic BGA-252 0.8-mm ball pitch 17 mm × 17 mm	4 MB	max. 150°C	20 MHz	240 MHz
R7F701216EABA	Plastic BGA-304 0.8-mm ball pitch 19 mm × 19 mm	4 MB	max. 150°C	20 MHz	320 MHz
R7F701216EABG	Plastic BGA-252 0.8-mm ball pitch 17 mm × 17 mm	4 MB	max. 150°C	20 MHz	320 MHz

We hereafter refer to FBGA as BGA respectively, unless the complete abbreviation is especially required.

1.6 Functional Block Configuration

Internal Block Diagram

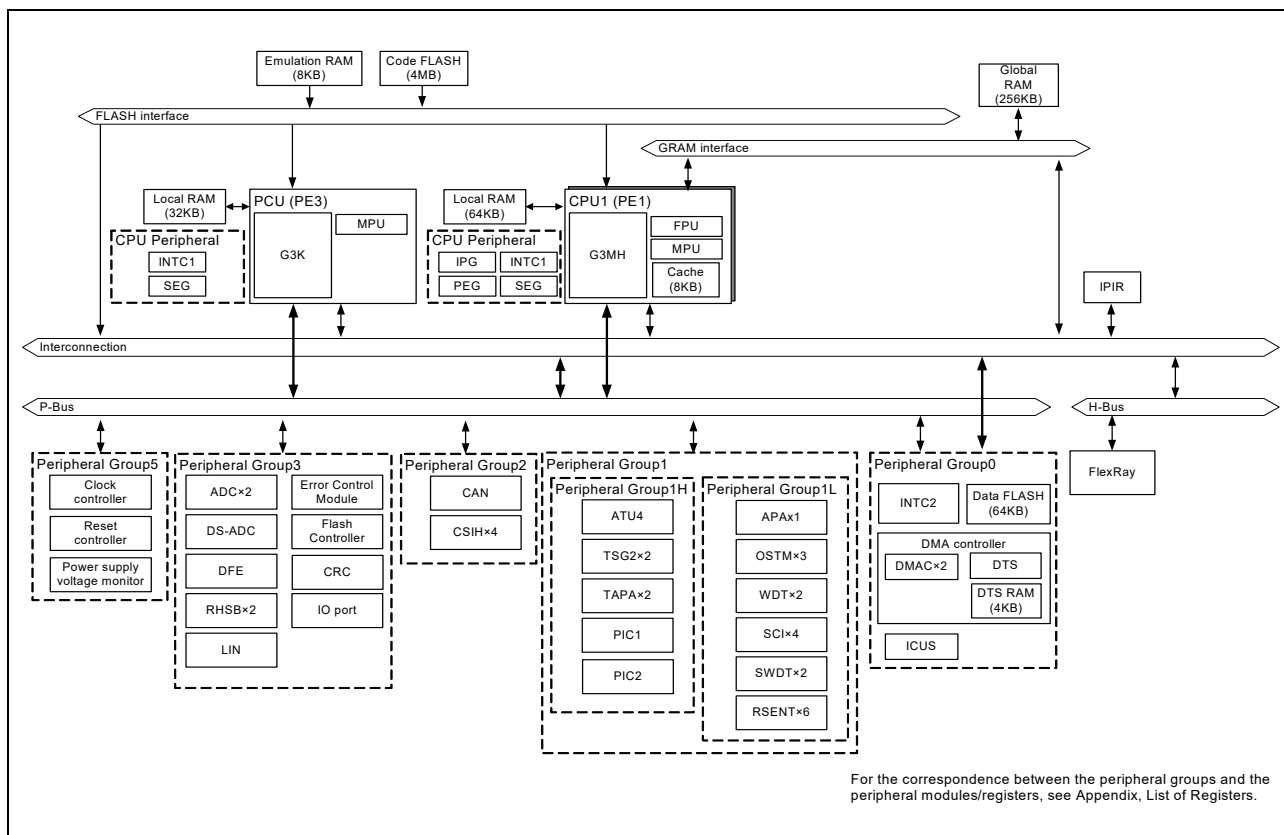

Figure 1.3 Internal Block Diagram

CPU1 and the PCU each have their own set of CPU peripherals. These CPU peripherals are assigned to the same addresses, so access by CPU1 to a register of a CPU peripheral is to the register in the CPU peripheral of CPU1; access by the PCU to a register of a CPU peripheral is to the register in the CPU peripheral of the PCU.

Section 2 Pins

2.1 Port Functions

2.1.1 Features

Port Group

This product has the following numbers of port groups:

Table 2.1 Port Groups of This Product

Product	Number of Group	Name of Group
BGA304	16	P0 to P8, P10, P11, P13 to P17
BGA252	13	P0 to P6, P11, P13 to P17

Port Group Index n

Each port group is identified by its own index “n” (n = 0 to 17) throughout this section; e.g. PMCn for the port mode control register of the Pn pin.

Register Address

All port addresses are given as an offset from the individual base addresses, <PORT_Base2> and <PORT_Base1>. **Table 2.2** shows the base addresses, <PORT_Base2> and <PORT_Base1>.

Table 2.2 Port Base Address

Base Address	Address
<PORT_Base1>	FF61 0000 _H
<PORT_Base2>	FFC1 0000 _H

2.1.2 Overview

This product has various pins for input/output (I/O) functions, known as ports. The ports are organized in port groups.

This product also has several control registers to allocate the functions other than general I/O purpose to the corresponding pins. For definitions of pin, port, and port group, see **Section 2.1.2.1, Terms**.

2.1.2.1 Terms

The terms described in this section are defined as follows.

- **Port group:**
One port has up to 16 pins, and the number of pins differs according to the port. The multiple pins of a port share the same control registers.
- **Port mode / Port:**
In port mode, a pin functions as a general-purpose I/O pin. The general-purpose I/O function is called a “port pin” and is indicated by the name Pn_m. For example, P0_7 indicates pin 7 of port 0.
- **Alternative mode:**
In alternative mode, a pin functions as an I/O pin of a peripheral function. Multiple peripheral functions may be multiplexed on a pin, and control registers select the peripheral function to be used.

2.1.2.2 Overview of Pin Functions

The pin can operate in the following three different modes:

- **Port mode (PMn.PMCn_m = 0)**
The pin operates as a general purpose I/O port in port mode. PMn.PMn_m selects input or output.
- **S/W I/O control alternative mode (PMn.PMCn_m = 1, PIPn.PIPCn_m = 0)**
The pin is operated by an alternative function in S/W I/O control alternative mode.
The selection between input and output is made by S/W via the PMn.PMn_m control bits.
- **Direct I/O control alternative mode (PMn.PMCn_m = 1, PIPn.PIPCn_m = 1)**
The pin is operated by an alternative function in direct I/O control alternative mode.
In contrast to S/W I/O control alternative mode, input/out is directly controlled by the alternative function in this mode.

Table 2.3 shows the outline of the register settings.

Table 2.3 Pin Function Configuration (Outline)

Mode	Bit			I/O
	PMn_m	PMn_m	PIPn_m	
Port mode	0	0	0/1	Output mode
		1	0/1	Input mode*1
S/W I/O control alternative mode	1	0	0	Output mode
		1	0	Input mode*2
Direct I/O control alternative mode		0/1	1	Controlled by the alternative function*2

Note 1. The input buffer should be enabled (PIBCn_m = 1).

Note 2. When used as an input pin in alternative mode, be sure to set PIBCN_m = 0.

When a pin is operated in alternative mode ($PMn.PMCn_m = 1$), one of different alternative functions (up to 7) can be selected by the $PFCn$, $PFCEn$, and $PFCAEn$ registers.

- S/W I/O control alternative mode ($PIPCn.PIPCn_m = 0$):
 - Outputs ($PMn_m = 0$): ALT-OUT1 to ALT-OUT7
 - Inputs ($PMn_m = 1$): ALT-IN1 to ALT-IN7
- Direct I/O control alternative mode ($PIPCn.PIPCn_m = 1$):
 - Input/Output of ALT-OUT1 to ALT-OUT7 and ALT-IN1 to ALT-IN7 is directly controlled by the alternative function.

Table 2.4 Outline of Alternative Mode Selection ($PMn.PMCn_m = 1$)

Function	Register				I/O
	PFCAE	PFCE	PFC	PM* ¹	
Alternative output mode 1 (ALT-OUT1)	0	0	0	0	O
Alternative input mode 1 (ALT-IN1)	0	0	0	1	I
Alternative output mode 2 (ALT-OUT2)	0	0	1	0	O
Alternative input mode 2 (ALT-IN2)	0	0	1	1	I
Alternative output mode 3 (ALT-OUT3)	0	1	0	0	O
Alternative input mode 3 (ALT-IN3)	0	1	0	1	I
Alternative output mode 4 (ALT-OUT4)	0	1	1	0	O
Alternative input mode 4 (ALT-IN4)	0	1	1	1	I
Alternative output mode 5 (ALT-OUT5)	1	0	0	0	O
Alternative input mode 5 (ALT-IN5)	1	0	0	1	I
Alternative output mode 6 (ALT-OUT6)	1	0	1	0	O
Alternative input mode 6 (ALT-IN6)	1	0	1	1	I
Alternative output mode 7 (ALT-OUT7)	1	1	0	0	O
Alternative input mode 7 (ALT-IN7)	1	1	0	1	I

Note 1. When $PIPCn.PIPCn_m = 1$, the I/O direction is directly controlled by the peripheral (alternative) function and PM is ignored.

When a pin is operated in alternative mode ($PMn.PMCn_m = 1$), one of several alternative functions can be selected by the $PFCn$, $PFCEn$, and $PFCAEn$ registers.

2.1.2.3 Pin Data Input/Output

The registers used for data input and output are described below.

The source of the data to be read via the PPRn register depends on pin mode.

Output data

In port mode (PMn.PMCn_m = 0), the value of Pn.Pn_m is output from the Pn_m pin.

Input data

A read operation of the PPRn register returns either the value of the Pn_m pin, the associated bit of the port register Pn.Pn_m, or the data output by an alternative function.

The source of the data read via PPRn depends on pin mode and setting of several control bits.

Table 2.5 summarizes the differences of PPRn read modes.

Table 2.5 PPRn_m Read Values

PMn.PMCn_m	PMn.PMn_m	PIBCn.PIBCn_m	PIPCn.PIPCn_m	Mode	PPRn_m Read Value
0	1	0	X	Port input, input buffer disabled	Pn.Pn_m bit
		1		Port input, input buffer enabled	Pn_m pin
	0	X		Port push-pull output	Pn.Pn_m bit* ¹
1	1	X	0	S/W I/O control alternative input	Pn_m pin
	0			S/W I/O control alternative output	Alternative function internal output signal* ¹
	X		1	Direct I/O control alternative mode	I/O port in alternative mode: <ul style="list-style-type: none"> • Input: Pn_m pin • Output: alternative function internal output signal*¹

Note 1. When PBDCn.PBDCn_m = 1, Pn_m pin level is read via PPRn_m bit.

The control registers in **Table 2.5** have the following effects:

- PMn.PMCn_m
This bit selects either port mode (PMn.PMCn_m = 0) or alternative function mode (PMn.PMCn_m = 1).
- PMn.PMn_m
This bit selects input (PMn.PMn_m = 1) or output (PMn.PMn_m = 0) in port mode (PMn.PMCn_m = 0) and S/W I/O control alternative mode (PMn.PMCn_m = 1, PIPCn.PIPCn_m = 0).
- PIBCn.PIBCn_m
This bit disables (PIBCn.PIBCn_m = 0) or enables (PIBCn.PIBCn_m = 1) the input buffer in input port mode (PMn.PMCn_m = 0 and PMn.PMn_m = 1). When the input buffer is disabled, PPRn_m reads the Pn.Pn_m bit, otherwise the Pn_m pin level is returned.
- PIPCn.PIPCn_m
This bit selects either the S/W or direct I/O control alternative mode.
- PBDCn.PBDCn_m
Setting this bit to 1 in output mode enables bidirectional mode for the pin. In bidirectional mode, the level on pin Pn_m can be read from PPRn.PPRn_m.

Write to the Pn Register

The data to be output via port Pn_m in port mode ($PMCN.PMCn_m = 0$) is held in the port register Pn.

The Pn data can be rewritten in the following two different ways:

- Direct write to the Pn register

New data can be directly written to the Pn register.

- Indirect operation to the Pn bit (set/reset/not)

The indirect Pn operation is possible using the following two registers:

- Port set/reset register: PSRn

When the bit $PSRn.PSRn_{(m+16)} = 1$, the value of bit $PSRn.PSRn_m$ determines the value of $Pn.Pn_m$.

Thus Pn_m can be set/reset without a direct write to Pn.

- Port NOT register: PNOTn

Setting $PNOTn.PNOTn_m = 1$ inverts the bit $Pn.Pn_m$ without a direct write to Pn.

The indirect Pn set/reset/not operation provides access to single bits (not limited to one bit) of the Pn register while leaving all other Pn bits untouched.

2.1.3 Port Type

Figure 2.1 shows the overall configuration of the pins. For the details of port blocks, see Figure 2.2.

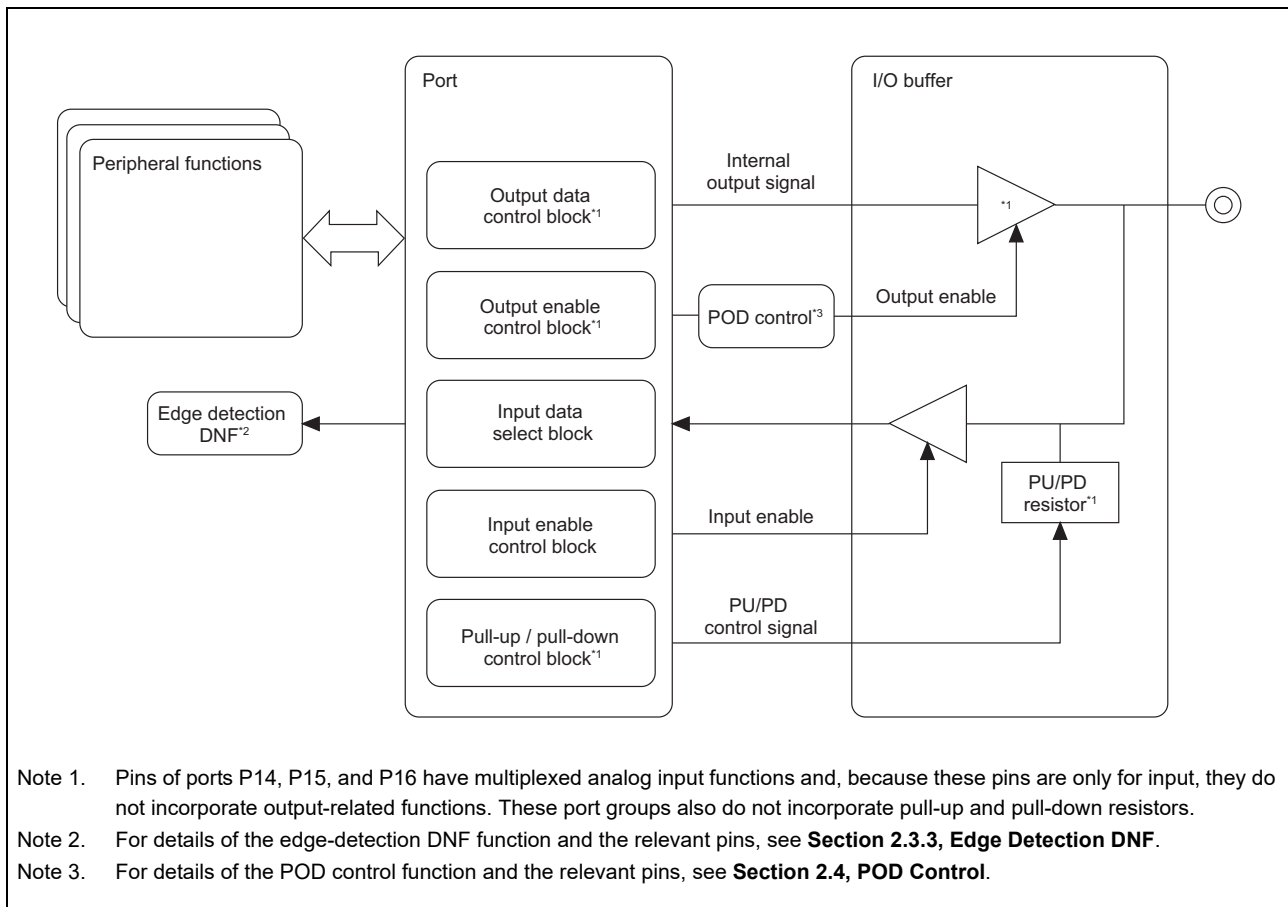

Figure 2.1 Block Diagram of Pin Configuration

Figure 2.2 shows the logical circuitry of the port control functions. The diagram is only a logical reference and does not show the real circuitry.

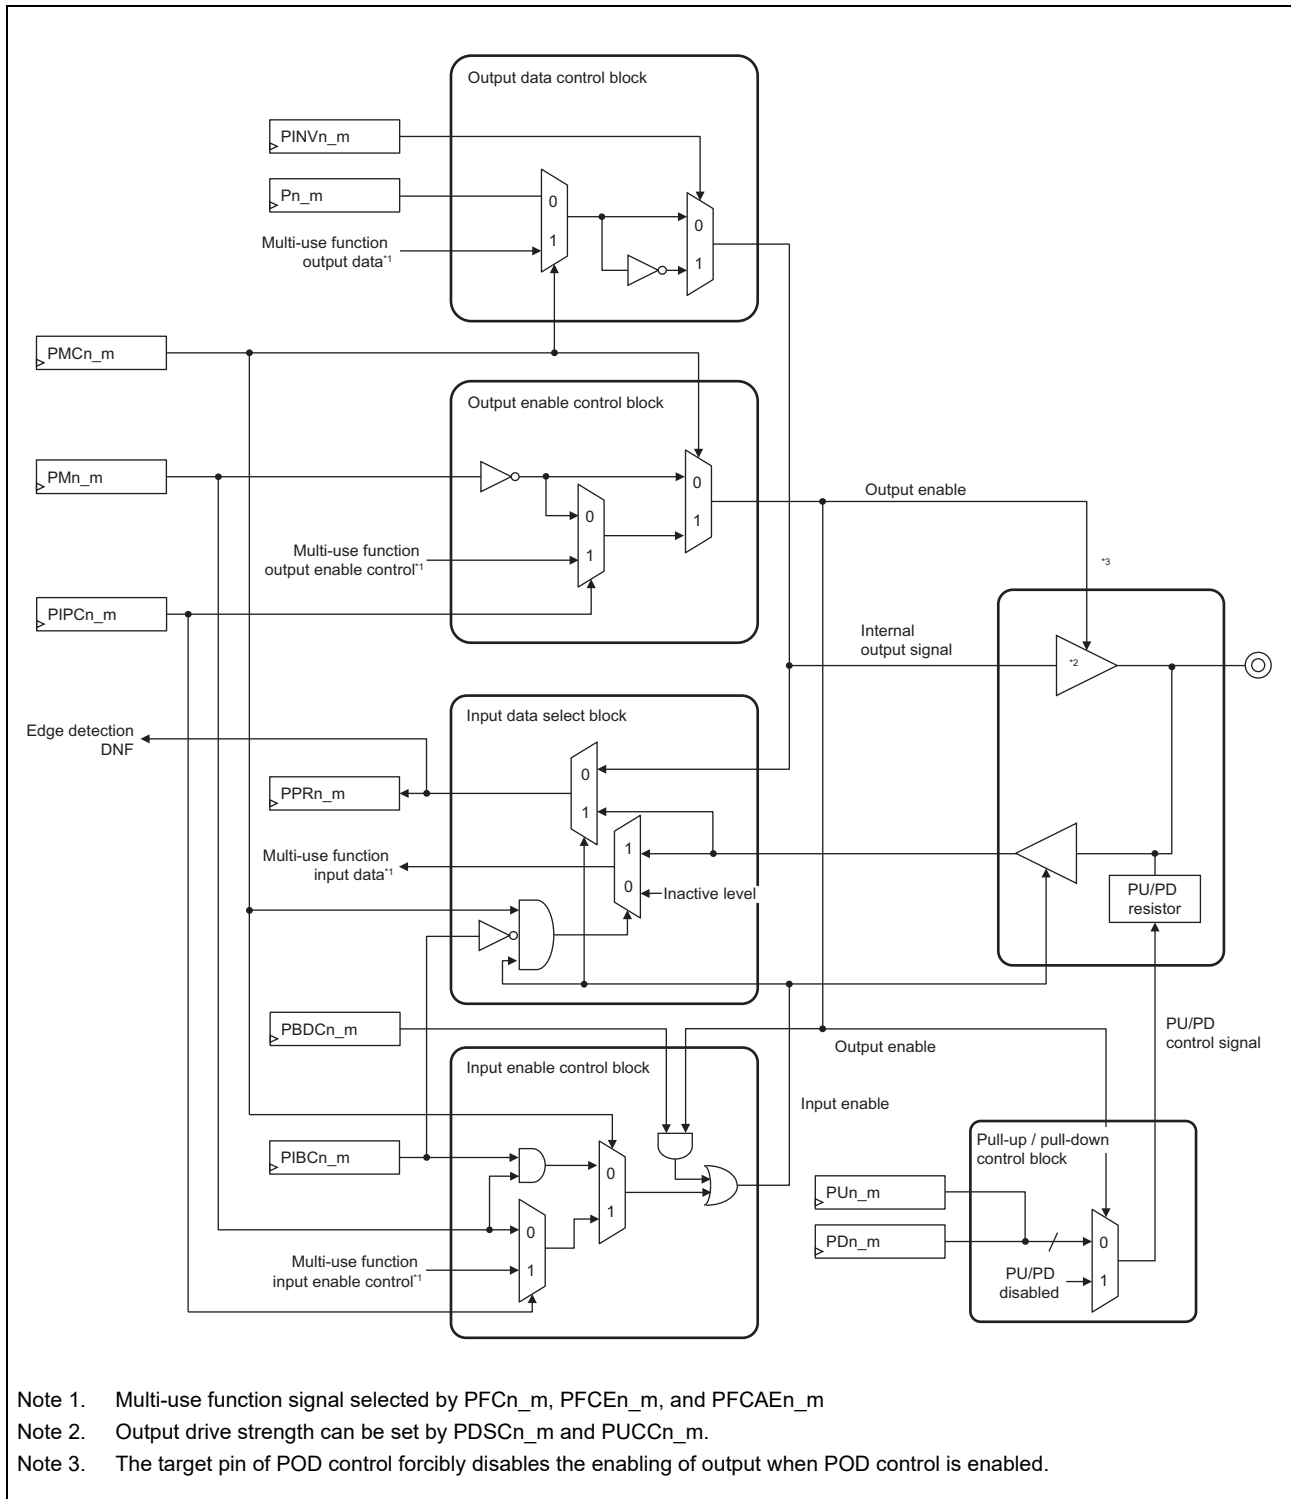

Figure 2.2 Port Control Logic Diagram

2.1.4 Port Group Configuration Register

This section starts with an overview of all configuration registers and then presents all registers in detail. The configuration registers are classified as follows:

- **2.1.4.2, Configuration of Pin Function**
- **2.1.4.3, Pin Data Input/Output**
- **2.1.4.4, Configuration of Electrical Characteristics**
- **2.1.4.5, Port Register Protection**
- **2.1.4.6, Pin-Unit Register**

2.1.4.1 Outline

The following registers are used for the configuration of the individual pins of the port groups:

Table 2.6 Registers for Port Group Configuration

Register Name	Symbol	Register Configuration Unit	Address
Port register	Pn	Port group	<PORT_Base1> + 0000 _H + n × 40 _H
Port set/reset register	PSRn	Port group	<PORT_Base1> + 0004 _H + n × 40 _H
Port NOT register	PNOTn	Port group	<PORT_Base1> + 0008 _H + n × 40 _H
Port pin read register	PPRn	Port group	<PORT_Base1> + 000C _H + n × 40 _H
Port mode register	PMn	Port group	<PORT_Base1> + 0010 _H + n × 40 _H
Port mode control register	PMcN	Port group	<PORT_Base1> + 0014 _H + n × 40 _H
Port function control register	PFCn	Port group	<PORT_Base1> + 0018 _H + n × 40 _H
Port function control expansion register	PFCEn	Port group	<PORT_Base1> + 001C _H + n × 40 _H
Port mode set/reset register	PMSRn	Port group	<PORT_Base1> + 0020 _H + n × 40 _H
Port mode control set/reset register	PMCSRn	Port group	<PORT_Base1> + 0024 _H + n × 40 _H
Port function control additional expansion register	PFCAEn	Port group	<PORT_Base1> + 0028 _H + n × 40 _H
Port output level inversion register	PINVn	Port group	<PORT_Base1> + 0030 _H + n × 40 _H
Port input buffer control register	PIBCn	Port group	<PORT_Base2> + 4000 _H + n × 40 _H
Port bidirectional control register	PBDCn	Port group	<PORT_Base2> + 4004 _H + n × 40 _H
Port IP control register	PIPCn	Port group	<PORT_Base2> + 4008 _H + n × 40 _H
Pull-up option register	PU _n	Port group	<PORT_Base2> + 400C _H + n × 40 _H
Pull-down option register	PD _n	Port group	<PORT_Base2> + 4010 _H + n × 40 _H
Port drive strength control register	PDSCn	Port group	<PORT_Base2> + 4018 _H + n × 40 _H
Port universal control register	PUCcN	Port group	<PORT_Base2> + 4028 _H + n × 40 _H
Port register protection command register	PPCMDn	Port group	<PORT_Base2> + 402C _H + n × 40 _H
Port protection status register	PPROTSn	Port group	<PORT_Base2> + 4034 _H + n × 40 _H
Port control register	PCR _{n_m}	Pin	<PORT_Base1> + 2000 _H + n × 40 _H + m × 4 _H

Note: n: Port group number
m: Bit number in a port group

Base address

The PORTn base addresses, <PORT_Base2> and <PORT_Base1> are defined in Register Addresses, **Section 2.1.1, Features**.

Register value after reset

The values after reset release depend on the port, and are not described in the following register descriptions, but are given in **Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers**.

2.1.4.2 Configuration of Pin Function

The following registers are used set the individual pins of port group n.

(1) PMCn — Port Mode Control Register

This register specifies whether the individual pins of port group n are in port mode or in alternative mode.

Access: This register is readable/writable in 16-bit units.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PMCn_15	PMCn_14	PMCn_13	PMCn_12	PMCn_11	PMCn_10	PMCn_9	PMCn_8	PMCn_7	PMCn_6	PMCn_5	PMCn_4	PMCn_3	PMCn_2	PMCn_1	PMCn_0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.7 PMCn Register Contents

Bit Position	Bit Name	Function
15 to 0	PMCn_[15:0]	Specify the operation mode of the corresponding pin: 0: Port mode 1: Alternative mode

(2) PMCSRn — Port Mode Control Set/Reset Register

This register provides an alternative method to write data to a bit in the PMCn register.

The 16 higher-order bits of PMCSRn specify whether the data in the 16 lower-order bits of PMCSRn are written to PMCn.PMCn_m.

Even when pins being used by multiple programs belong to the same port group, the PMCSRn register allows masking of the unused bits when overwriting so that independent setting of the corresponding bits by each program is possible.

Access: This register is readable/writable in 32-bit units.
Bits 31 to 16 are always read as 0000_H. Reading bits 15 to 0 returns the value of the PMCn register.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PMCSR n_31	PMCSR n_30	PMCSR n_29	PMCSR n_28	PMCSR n_27	PMCSR n_26	PMCSR n_25	PMCSR n_24	PMCSR n_23	PMCSR n_22	PMCSR n_21	PMCSR n_20	PMCSR n_19	PMCSR n_18	PMCSR n_17	PMCSR n_16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PMCSR n_15	PMCSR n_14	PMCSR n_13	PMCSR n_12	PMCSR n_11	PMCSR n_10	PMCSR n_9	PMCSR n_8	PMCSR n_7	PMCSR n_6	PMCSR n_5	PMCSR n_4	PMCSR n_3	PMCSR n_2	PMCSR n_1	PMCSR n_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.8 PMCSRn Register Contents

Bit Position	Bit Name	Function
31 to 16	PMCSRn_ [31:16]	Specify whether the value of the corresponding lower bit of PMCSRn_m is written to PMCn_m: 0: PMCn_m does not depend on PMCSRn_m. 1: The value of PMCn_m is the same as that of PMCSRn_m. Example: When PMCSRn.PMCSRn_31 = 1, the value of bit PMCSRn.PMCSRn_15 is written to bit PMCn.PMCn_15 and output.
15 to 0	PMCSRn_ [15:0]	Specify the PMCn_m value when the corresponding upper bit PMCSRn_(m+16) is 1: 0: PMCn_m = 0 1: PMCn_m = 1

(3) PIPc_n — Port IP Control Register

This register specifies whether the I/O direction of pin P_n_m is controlled by the port mode register PM_n.PM_n_m or by an alternative function.

When the P_n_m pin is operated in alternative mode (PMC_n.PMC_n_m = 1) and the alternative function directly controls the I/O direction of P_n_m, PIPc_n.PIPc_n_m must be set to 1 as well. This hands over I/O control to the alternative function and overrules the PM_n.PM_n_m setting.

Access: This register is readable/writable in 16-bit units.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIPc _n ₁₅	PIPc _n ₁₄	PIPc _n ₁₃	PIPc _n ₁₂	PIPc _n ₁₁	PIPc _n ₁₀	PIPc _n ₉	PIPc _n ₈	PIPc _n ₇	PIPc _n ₆	PIPc _n ₅	PIPc _n ₄	PIPc _n ₃	PIPc _n ₂	PIPc _n ₁	PIPc _n ₀
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.9 PIPc_n Register Contents

Bit Position	Bit Name	Function
15 to 0	PIPc _n [15:0]	Specify the I/O control mode: 0: I/O mode is selected by PM _n .PM _n _m (S/W I/O control). 1: I/O mode is selected by peripheral function (direct I/O control).

(4) PM_n — Port Mode Register

The PM_n register specifies whether the individual pins of port group n are in input mode or in output mode.

Access: This register is readable/writable in 16-bit units.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PM _n ₁₅	PM _n ₁₄	PM _n ₁₃	PM _n ₁₂	PM _n ₁₁	PM _n ₁₀	PM _n ₉	PM _n ₈	PM _n ₇	PM _n ₆	PM _n ₅	PM _n ₄	PM _n ₃	PM _n ₂	PM _n ₁	PM _n ₀
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.10 PM_n Register Contents

Bit Position	Bit Name	Function
15 to 0	PM _n [15:0]	Specify input/output mode of the corresponding pin: 0: Output mode (output enabled) 1: Input mode (output disabled)

NOTES

- To use a pin in input port mode (PMC_n.PMC_n_m = 0 and PM_n.PM_n_m = 1), the input buffer must be enabled (PIBC_n.PIBC_n_m = 1).
- PM_n_m specifies the I/O direction in port mode (PMC_n.PMC_n_m = 0) and alternative mode (PMC_n.PMC_n_m = 1) because PIPc_n.PIPc_n_m = 0 after reset.

(5) PMSRn — Port Mode Set/Reset Register

This register provides an alternative method to set a bit in the PMn register.

The 16 higher-order bits of PMSRn specify whether the data in the 16 lower-order bits of PMSRn are written to PMn.PMn_m.

Even when pins being used by multiple programs belong to the same port group, the PMSRn register allows masking of the unused bits when overwriting so that independent setting of the corresponding bits by each program is possible.

Access: This register is readable/writable in 32-bit units.
Bits 31 to 16 are always read as 0000_H. Reading bits 15 to 0 returns the value of the PMn register.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PMSRn _31	PMSRn _30	PMSRn _29	PMSRn _28	PMSRn _27	PMSRn _26	PMSRn _25	PMSRn _24	PMSRn _23	PMSRn _22	PMSRn _21	PMSRn _20	PMSRn _19	PMSRn _18	PMSRn _17	PMSRn _16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PMSRn _15	PMSRn _14	PMSRn _13	PMSRn _12	PMSRn _11	PMSRn _10	PMSRn _9	PMSRn _8	PMSRn _7	PMSRn _6	PMSRn _5	PMSRn _4	PMSRn _3	PMSRn _2	PMSRn _1	PMSRn _0

Table 2.11 PMSRn Register Contents

Bit Position	Bit Name	Function
31 to 16	PMSRn_[31:16]	Specify whether the value of the corresponding lower bit of PMSRn_m is written to PMn_m: 0: PMn_m does not depend on PMSRn_m. 1: The value of PMn_m is the same as that of PMSRn_m. Example: When PMSRn.PMSRn_31 = 1, the value of bit PMSRn.PMSRn_15 is written to bit PMn.PMn_15 and output.
15 to 0	PMSRn_[15:0]	Specify the PMn_m value when the corresponding upper bit PMSRn_(m+16) is 1: 0: PMn_m = 0 1: PMn_m = 1

(6) PIBCn — Port Input Buffer Control Register

When a pin is being used in input port mode ($PMCn.PMCn_m = 0$ and $PMn.PMn_m = 1$), this register enables or disables the input buffer. However, when the pin is used as an input pin in S/W I/O control alternative mode ($PMCn.PMCn_m = 1$ and $PIPCn.PIPCn_m = 0$) or direct I/O control alternative mode ($PMCn.PMCn_m = 1$ and $PIPCn.PIPCn_m = 1$), set $PIBCn.PIBCn_m = 0$.

And when pins are in the both-direction mode ($PBDCn.PBDCn_m = 1$), it is capable of selecting shared output level loop-back function and pin output level-read function with the setting of $PIBCn.PIBCn_m$.

Refer to **(1) PBDCn — Port Bidirectional Control Register** in **Section 2.1.4.3, Pin Data Input/Output**.

Access: This register is readable/writable in 16-bit units.

Value after reset: See **Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers**.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIBCn_15	PIBCn_14	PIBCn_13	PIBCn_12	PIBCn_11	PIBCn_10	PIBCn_9	PIBCn_8	PIBCn_7	PIBCn_6	PIBCn_5	PIBCn_4	PIBCn_3	PIBCn_2	PIBCn_1	PIBCn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.12 PIBCn Register Contents

Bit Position	Bit Name	Function
15 to 0	PIBCn_[15:0]	These bits are used to enable and disable the input buffer in input port mode. 0: Input buffer is disabled. 1: Input buffer is enabled.

NOTE

When the input buffer is disabled, a shoot-through current does not flow even if the pin level is in Hi-Z state. Thus the pin does not need to be fixed to a high or low level externally.

(7) PFCn — Port Function Control Register

This register, together with the PFCEn and PFCAEn registers, specifies an alternative function of the pins.

Some alternative functions directly controls input/output of pin Pn_m. For such an alternative functions PIPcN.PIPCn_m must be set to 1 as well.

For other alternative functions, input/output must be specified by PMn.PMn_m.

Access: This register is readable/writable in 16-bit units.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFCn_15	PFCn_14	PFCn_13	PFCn_12	PFCn_11	PFCn_10	PFCn_9	PFCn_8	PFCn_7	PFCn_6	PFCn_5	PFCn_4	PFCn_3	PFCn_2	PFCn_1	PFCn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.13 PFCn Register Contents

Bit Position	Bit Name	Function
15 to 0	PFCn_[15:0]	Specify an alternative function of a pin. See Table 2.4, Outline of Alternative Mode Selection (PMcN.PMcN_m = 1) for details.

(8) PFCEn — Port Function Control Expansion Register

This register, together with the PFCn and PFCAEn registers, specifies an alternative function of the pins.

Some alternative functions directly controls input/output of pin Pn_m. For such an alternative functions PIPCN.PIPCn_m must be set to 1 as well.

For other alternative functions, input/output must be specified by PMn.PMn_m.

Access: This register is readable/writable in 16-bit units.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFCEn_n_15	PFCEn_n_14	PFCEn_n_13	PFCEn_n_12	PFCEn_n_11	PFCEn_n_10	PFCEn_n_9	PFCEn_n_8	PFCEn_n_7	PFCEn_n_6	PFCEn_n_5	PFCEn_n_4	PFCEn_n_3	PFCEn_n_2	PFCEn_n_1	PFCEn_n_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.14 PFCEn Register Contents

Bit Position	Bit Name	Function
15 to 0	PFCEn_[15:0]	Specify an alternative function of a pin. See Table 2.4, Outline of Alternative Mode Selection (PMCN.PMCn_m = 1) for details.

(9) PFCAEn — Port Function Control Additional Expansion Register

This register, together with the PFCn and PFCEn registers, specifies an alternative function of the pins.

Some alternative functions directly controls input/output of pin Pn_m. For such an alternative functions PIPCN.PIPCn_m must be set to 1 as well.

For other alternative functions, input/output must be specified by PMn.PMn_m.

Access: This register is readable/writable in 16-bit units.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFCAEn_n_15	PFCAEn_n_14	PFCAEn_n_13	PFCAEn_n_12	PFCAEn_n_11	PFCAEn_n_10	PFCAEn_n_9	PFCAEn_n_8	PFCAEn_n_7	PFCAEn_n_6	PFCAEn_n_5	PFCAEn_n_4	PFCAEn_n_3	PFCAEn_n_2	PFCAEn_n_1	PFCAEn_n_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.15 PFCAEn Register Contents

Bit Position	Bit Name	Function
15 to 0	PFCAEn_[15:0]	Specify an alternative function of a pin. See Table 2.4, Outline of Alternative Mode Selection (PMCN.PMCn_m = 1) for details.

2.1.4.3 Pin Data Input/Output

(1) PBDCn — Port Bidirectional Control Register

This register enables the input buffer when a pin is used in output mode, and permits bidirectional mode. The Pn_m pin level is read via PPRn.PPRn_m in bidirectional mode.

- **Alternative output level loopback function**
When the Pn_m pin is used as the alternative output function, the actual pin output level based on the alternative output function can be looped back to the alternative input side by setting PBDCn.PBDCn_m = 1 and PIBCn.PIBCn_m = 0. For example, the pin output level based on the first alternative function can be looped back to the same alternative input side. Also the pin output level can be read via PPRn.PPRn_m.
- **Pin output level read function**
When the Pn_m pin is used as the general output port function or the alternative output function, the actual pin output level can be read via PPRn.PPRn_m by setting PBDCn.PBDCn_m = 1 and PIBCn.PIBCn_m = 1. Under this setting, the pin output level will never be looped back to the alternative input side even in alternative output mode.

Access: This register is readable/writable in 16-bit units.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PBDCn _15	PBDCn _14	PBDCn _13	PBDCn _12	PBDCn _11	PBDCn _10	PBDCn _9	PBDCn _8	PBDCn _7	PBDCn _6	PBDCn _5	PBDCn _4	PBDCn _3	PBDCn _2	PBDCn _1	PBDCn _0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.16 PBDCn Register Contents

Bit Position	Bit Name	Function
15 to 0	PBDCn_[15:0]	Enable/disable bidirectional mode of the corresponding pin: 0: Bidirectional mode is disabled. 1: Bidirectional mode is enabled.

(2) PPRn — Port Pin Read Register

This register reflects an actual Pn_m pin level, a Pn.Pn_m bit value, or an output level of the alternative function. The value to be read depends on various control settings as described in **Table 2.5, PPRn_m Read Values.**

Access: This register is only readable in 16-bit units.

Value after reset: See **Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PPRn_15	PPRn_14	PPRn_13	PPRn_12	PPRn_11	PPRn_10	PPRn_9	PPRn_8	PPRn_7	PPRn_6	PPRn_5	PPRn_4	PPRn_3	PPRn_2	PPRn_1	PPRn_0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 2.17 PPRn Register Contents

Bit Position	Bit Name	Function
15 to 0	PPRn_[15:0]	Indicate a Pn_m pin level, a Pn.Pn_m value, or alternative function output level.

(3) Pn — Port Register

This register sets and holds the Pn.Pn_m data to be output via the related Pn_m port in output port mode (PMcn.PMCn_m = 0 and PMn.PMn_m = 0).

Access: This register is readable/writable in 16-bit units.

Value after reset: See **Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Pn_15	Pn_14	Pn_13	Pn_12	Pn_11	Pn_10	Pn_9	Pn_8	Pn_7	Pn_6	Pn_5	Pn_4	Pn_3	Pn_2	Pn_1	Pn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.18 Pn Register Contents

Bit Position	Bit Name	Function
15 to 0	Pn_[15:0]	Set the output level of pin m (m = 0 to 15): 0: Low level output 1: High level output

NOTE

The bits of this register can be manipulated by various means; refer to the subsection, Write to the Pn Register in **Section 2.1.2.3, Pin Data Input/Output.**

(4) PNOTn — Port NOT Register

This register enables inverting the Pn_m bit of the port register without directly writing to Pn.

Access: This register is writable in 16-bit units. The read value is always 0000_H.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PNOTn _15	PNOTn _14	PNOTn _13	PNOTn _12	PNOTn _11	PNOTn _10	PNOTn _9	PNOTn _8	PNOTn _7	PNOTn _6	PNOTn _5	PNOTn _4	PNOTn _3	PNOTn _2	PNOTn _1	PNOTn _0
R/W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Table 2.19 PNOTn Register Contents

Bit Position	Bit Name	Function
15 to 0	PNOTn_[15:0]	Specify if Pn.Pn_m is inverted or not: 0: Pn.Pn_m is not inverted (Pn_m → Pn_m). 1: Pn.Pn_m is inverted (Pn_m → Pn_m)

(5) PSRn — Port Set/Reset Register

This register provides an alternative method to set a bit in the Pn register.

The 16 higher-order bits of PSRn specify whether the data in the 16 lower-order bits of PSRn are written to Pn.Pn_m.

Even when pins being used by multiple programs belong to the same port group, the PSRn register allows masking of the unused bits when overwriting so that independent setting of the corresponding bits by each program is possible.

Access: This register is readable/writable in 32-bit units.
Bits 31 to 16 are always read as 0000_H. Reading bits 15 to 0 returns the value of the PMCn register.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PSRn_31	PSRn_30	PSRn_29	PSRn_28	PSRn_27	PSRn_26	PSRn_25	PSRn_24	PSRn_23	PSRn_22	PSRn_21	PSRn_20	PSRn_19	PSRn_18	PSRn_17	PSRn_16
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PSRn_15	PSRn_14	PSRn_13	PSRn_12	PSRn_11	PSRn_10	PSRn_9	PSRn_8	PSRn_7	PSRn_6	PSRn_5	PSRn_4	PSRn_3	PSRn_2	PSRn_1	PSRn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.20 PSRn Register Contents

Bit Position	Bit Name	Function
31 to 16	PSRn_[31:16]	Specify whether the value of the corresponding lower bit of PSRn_m is written to Pn_m: 0: Pn_m does not depend on PSRn_m. 1: The value of Pn_m is the same as that of PSRn_m. Example: When PSRn.PSRn_31 = 1, the value of bit PSRn.PSRn_15 is written to bit Pn.Pn_15 and output.
15 to 0	PSRn_[15:0]	Specify the Pn_m value when the corresponding upper bit PSRn_(m+16) is 1: 0: Pn_m = 0 1: Pn_m = 1

(6) PINVn — Port Output Level Inversion Register

This register enables inverting the output level from a pin. It is effective when the pin is in output mode regardless of port output mode or alternative output mode.

Access: This register is readable/writable in 32-bit units.
Updating of this register needs a correct write sequence using the PPCMDn register.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

CAUTION

The upper 16 bits are also intended for the inverted value of a port register write sequence that is to be protected. See Section 2.1.4.5, Port Register Protection for details.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PINVn_15	PINVn_14	PINVn_13	PINVn_12	PINVn_11	PINVn_10	PINVn_9	PINVn_8	PINVn_7	PINVn_6	PINVn_5	PINVn_4	PINVn_3	PINVn_2	PINVn_1	PINVn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.21 PINVn Register Contents

Bit Position	Bit Name	Function
15 to 0	PINVn_[15:0]	Specify whether the output level from a pin is inverted or not. 0: Pin output level is not inverted. 1: Pin output level is inverted.

2.1.4.4 Configuration of Electrical Characteristics

(1) PUn — Pull-Up Option Register

This register specifies whether an on-chip pull-up resistor is connected to an input pin.

Access: This register is readable/writable in 16-bit units.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PUn_15	PUn_14	PUn_13	PUn_12	PUn_11	PUn_10	PUn_9	PUn_8	PUn_7	PUn_6	PUn_5	PUn_4	PUn_3	PUn_2	PUn_1	PUn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.22 PUn Register Contents

Bit Position	Bit Name	Function
15 to 0	PUn_[15:0]	Specify whether an on-chip pull-up resistor is connected to the corresponding pin: 0: No on-chip pull-up resistor is connected. 1: On-chip pull-up resistor is connected.

NOTES

- Do not set PUn.PUn_m = 1 and PDn.PDn_m = 1 to a single pin.
- The on-chip pull-up resistor has no effect when the pin is operated in output mode.

(2) PDn — Pull-Down Option Register

This register specifies whether an on-chip pull-down resistor is connected to an input pin.

Access: This register is readable/writable in 16-bit units.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PDn_15	PDn_14	PDn_13	PDn_12	PDn_11	PDn_10	PDn_9	PDn_8	PDn_7	PDn_6	PDn_5	PDn_4	PDn_3	PDn_2	PDn_1	PDn_0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 2.23 PDn Register Contents

Bit Position	Bit Name	Function
15 to 0	PDn_[15:0]	Specify whether an on-chip pull-down resistor is connected to the corresponding pin: 0: No on-chip pull-down resistor is connected. 1: On-chip pull-down resistor is connected.

NOTES

- Do not set PUn.PUn_m = 1 and PDn.PDn_m = 1 to a single pin.
- The on-chip pull-down resistor has no effect when the pin is operated in output mode.

(3) PDSCn — Port Drive Strength Control Register

This register is used to configure driving ability (driving strength) of output port pins and multiplex output pin functions in combination with the PUCcN register. Specific driving ability settings may be required, depending on the pin function to be used. For details, see **Section 40, Electrical Characteristics**.

Access: This register is readable/writable in 32-bit units.
Updating of this register needs a correct write sequence using the PPCMDn register.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

CAUTION

For protected port registers, the inverse of the value of the 16 lower-order bits is written to the 16 higher-order bits as part of the sequence for writing to a protected register. See Section 2.1.4.5, Port Register Protection for details.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 2.24 PDSCn Register Contents

Bit Position	Bit Name	Function
15 to 0	PDSCn_[15:0]	Set driving ability of output port pins and multiplex output pin functions in combination with the PUCcN register. See Table 2.25 PUCcN Register Contents for register setting and output driving ability.

(4) PUCn — Port Universal Control Register

This register is used to configure driving ability (driving strength) of output port pins and multiplex output pin functions in combination with the PDSCn register. Specific driving ability settings may be required, depending on the pin function to be used. For details, see **Section 40, Electrical Characteristics**.

Access: This register is readable/writable in 32-bit units.
Updating of this register needs a correct write sequence using the PPCMDn register.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

CAUTION

For protected port registers, the inverse of the value of the 16 lower-order bits is written to the 16 higher-order bits as part of the sequence for writing to a protected register. See Section 2.1.4.5, Port Register Protection for details.

2.1.4.5 Port Register Protection

(1) PPCMDn — Port Register Protection Command Register

This register is a command register for the port register to be protected.

Access: This register is writable in 8-bit units.
The read value of bit 7 to 0 is always 0.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—
R/W	W	W	W	W	W	W	W	W

Table 2.26 PPCMDn Register Contents

Bit Position	Bit Name	Function
7 to 0	—	The protection unlock sequence is entered by writing the fixed value (A5 _H).

(2) PPROTSn — Port Protection Status Register

This register indicates the status of a port register write sequence to be protected.

Access: This register is readable in 8-bit units.
Writing to this register is ignored.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	PPROTSn_0
R/W	R	R	R	R	R	R	R	R

Table 2.27 PPROTSn Register Contents

Bit Position	Bit Name	Function
0	PPROTSn_0	Checks a write sequence error of the port register to be protected. 0: Protection error does not occur. 1: Protection error occurs.

(3) Port Register to be Protected

- Port Drive Strength Control Register (PDSCn)
- Port Universal Control Register (PUCCn)
- Port Output Level Inversion Register (PINVn)

(4) Sequence of Writing to Port Registers for Protection

Writing to the write-protected registers is only possible with the protection unlock sequence described below.

Procedure

- 1) Write the fixed value (A5_H) to the port register protection command register PPCMDn.
- 2) Write the new setting to the write-protected register. Write the value after a reset to the reserved bits.
- 3) Write the bitwise inverse of the setting value to the same register as in step 2). Write the inverse of the value after a reset to the reserved bits.
- 4) Write the new setting to the same register as in step 2). Write the value after a reset to the reserved bits.

A value can only be written to a write-protected register by following the procedure above.

Protection is not unlocked if the procedure is not followed correctly, the setting is not written to the write-protected register, and the PPROTSn_0 bit of the port protection status register PPROTSn is set to 1. (Although this is not a requirement, you can confirm if the values set in the targeted register was correctly written by checking that the setting of the PPROTSn_0 bit is 0 after step 4.)

In case of failure to follow the sequence, repeat the procedure from the beginning.

In case of writing to another register during steps 1) to 4) of the sequence, the protection function operates as follows. Operation is also as described when any interrupt is accepted during the sequence and the interrupt handling includes access to another register.

- When the writing is to another register in the same module*¹, writing to the protected register fails and the PPROTSn_0 bit is set to 1.
- When writing is to a register in another module, writing to the protected register will successfully proceed to completion, if the remainder of the procedure is followed correctly.

Reading of another register while the sequence is in progress does not lead to failure.

Note 1. The port group configuration registers are divided into two modules. Each module includes the full set of port configuration registers, including protection-related registers.

- Port group 0
- Port groups other than port group 0

2.1.4.6 Pin-Unit Register

(1) PCRn_m — Port Control Register

Each register of a port group can be accessed via this register and a PCRn_m register can set all functions of a single pin. For example, setting bit 6 of the PCRn_m register to 1 sets bit m of the PMCn register to 1 also. Although writing to the PDSCn, PUCcN, and PINVn registers are protected, an access to them via the PCRn_m register does not require a protection unlock sequence.

CAUTIONS

- Multiple bits in the PCRn_m register can be batch-set within the ranges described in Section 2.1.4.7, Example of Port Configuration Flow (2), Individual Setting.
- When PMn_m = 1 and PMCn_m = 1, input is enabled. Configure the PUn_m/PDn_m setting in advance to prevent shoot-through current when pins are open or mid-range potential is input to them.
- If the bits are batch-set out of the range for setting of PCRn_m, the pin may output an unexpected signal level.

Access: This register is readable/writable in 32-bit units.

Value after reset: See Section 2.2.1.1, List of the BGA304 and BGA252 Port Registers.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 2.28 PCRn_m Register Contents

Bit Position	Bit Name	Function
31	—	Reserved. The read values are always 0. The write values should always be 0.
30	PINV	Same function as bit m of the PINVn register
29 to 26	—	Reserved. The read values are always 0. The write values should always be 0.
25	PUCC	Same function as bit m of the PUCcN register
24	PDSC	Same function as bit m of the PDSCn register
23 to 20	—	Reserved. The read values are always 0. The write values should always be 0.
19	PU	Same function as bit m of the PUn register
18	PD	Same function as bit m of the PDn register
17	PBDC	Same function as bit m of the PBDCn register
16	PIBC	Same function as bit m of the PIBcN register
15 to 13	—	Reserved. The read values are always 0. The write values should always be 0.
12	P	Same function as bit m of the Pn register
11 to 9	—	Reserved. The read values are always 0. The write values should always be 0.
8	PPR	Same function as bit m of the PPRn register
7	—	Reserved. The read values are always 0. The write values should always be 0.
6	PMC	Same function as bit m of the PMCn register

Table 2.28 PCRn_m Register Contents

Bit Position	Bit Name	Function
5	PIPC	Same function as bit m of the PIPCn register
4	PM	Same function as bit m of the PMn register
3	—	Reserved. The read values are always 0. The write values should always be 0.
2	PFCAE	Same function as bit m of the PFCAEn register
1	PFCE	Same function as bit m of the PFCEn register
0	PFC	Same function as bit m of the PFCn register

2.1.4.7 Example of Port Configuration Flow

The followings are examples of the port configuration flow. For port filter setting of each flow chart, see **Section 2.3.2.4, Setting Procedures of Peripheral Function DNF** or **Section 2.3.3.6, Setting Procedures of Edge Detection DNF**.

CAUTION

Even if a port is used in S/W I/O control alternative mode, it may be temporarily switched to alternative input mode in the following port configuration flows. This may occur during the period from setting of $PMCn_m = 1$ to that of $PMn_m = 0$.

(1) Batch Setting

The following shows an example to collectively set a port group.

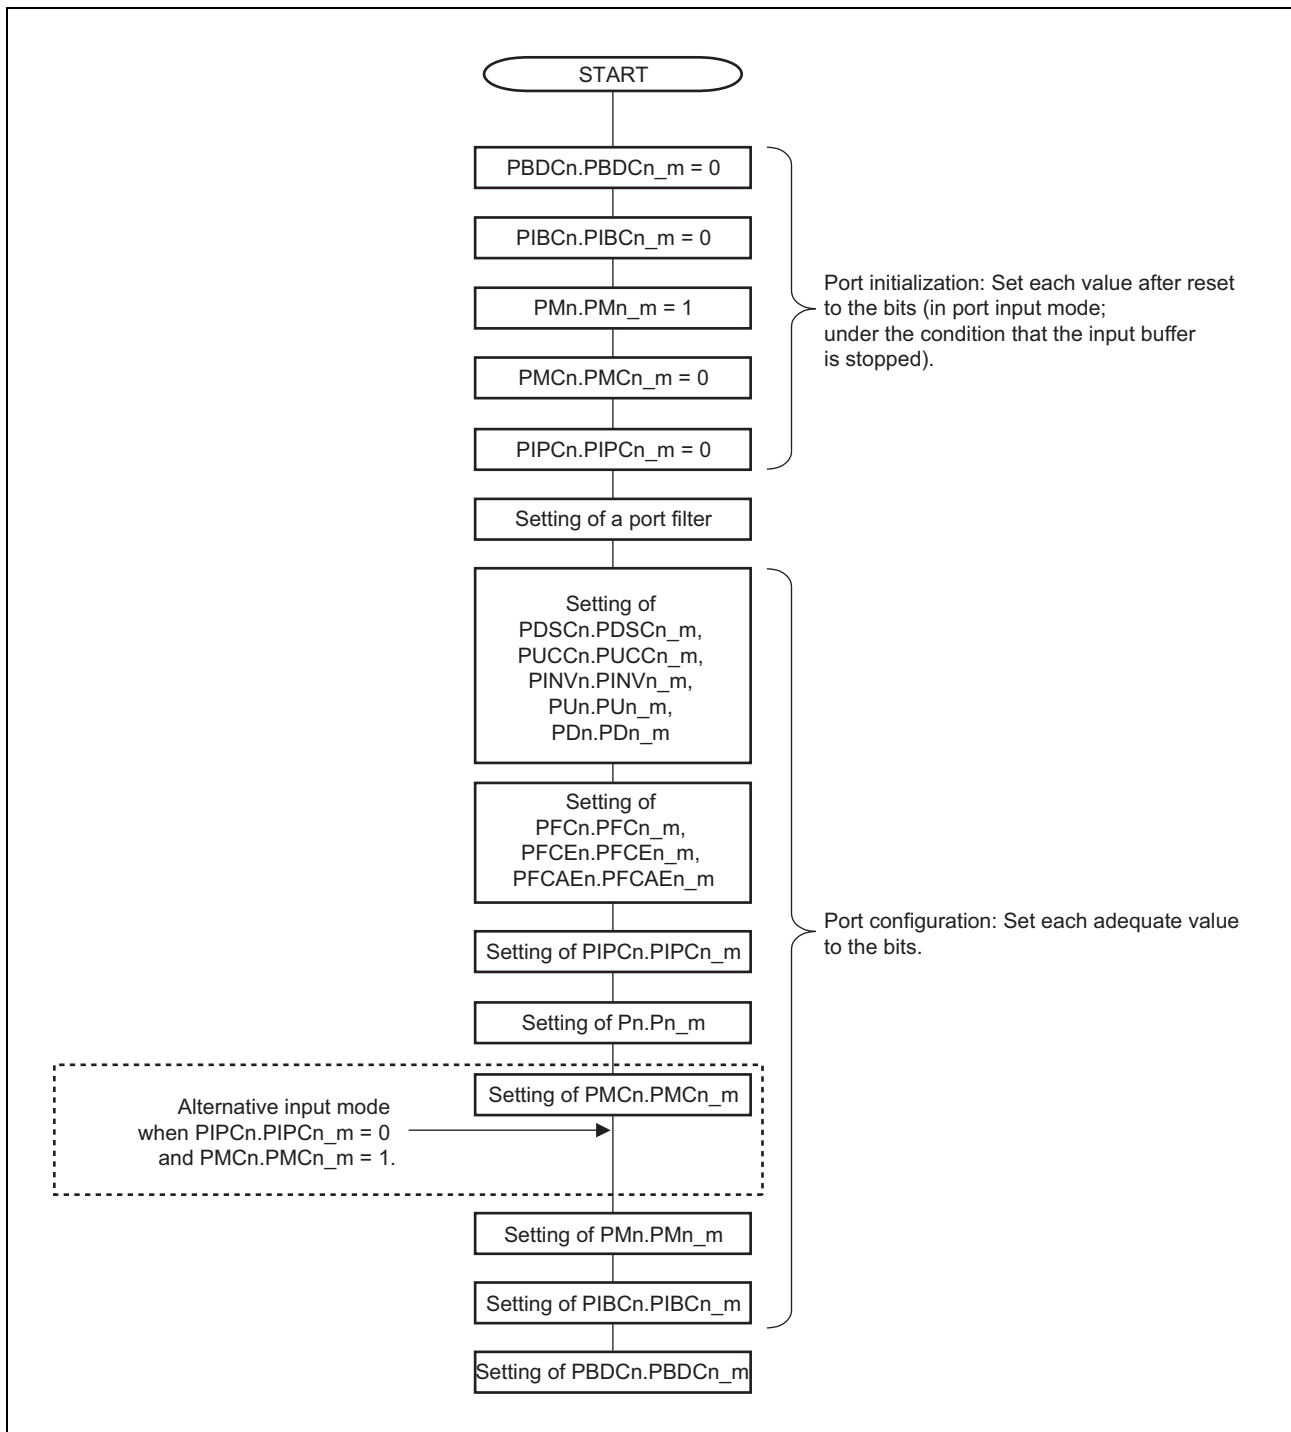

Figure 2.3 Example of Port Configuration Flow (Batch Setting)

(2) Individual Setting

The following shows an example to individually set a port group.

And it is capable of setting simultaneous bits at once within the Settable range described below by using PCRn_m register.

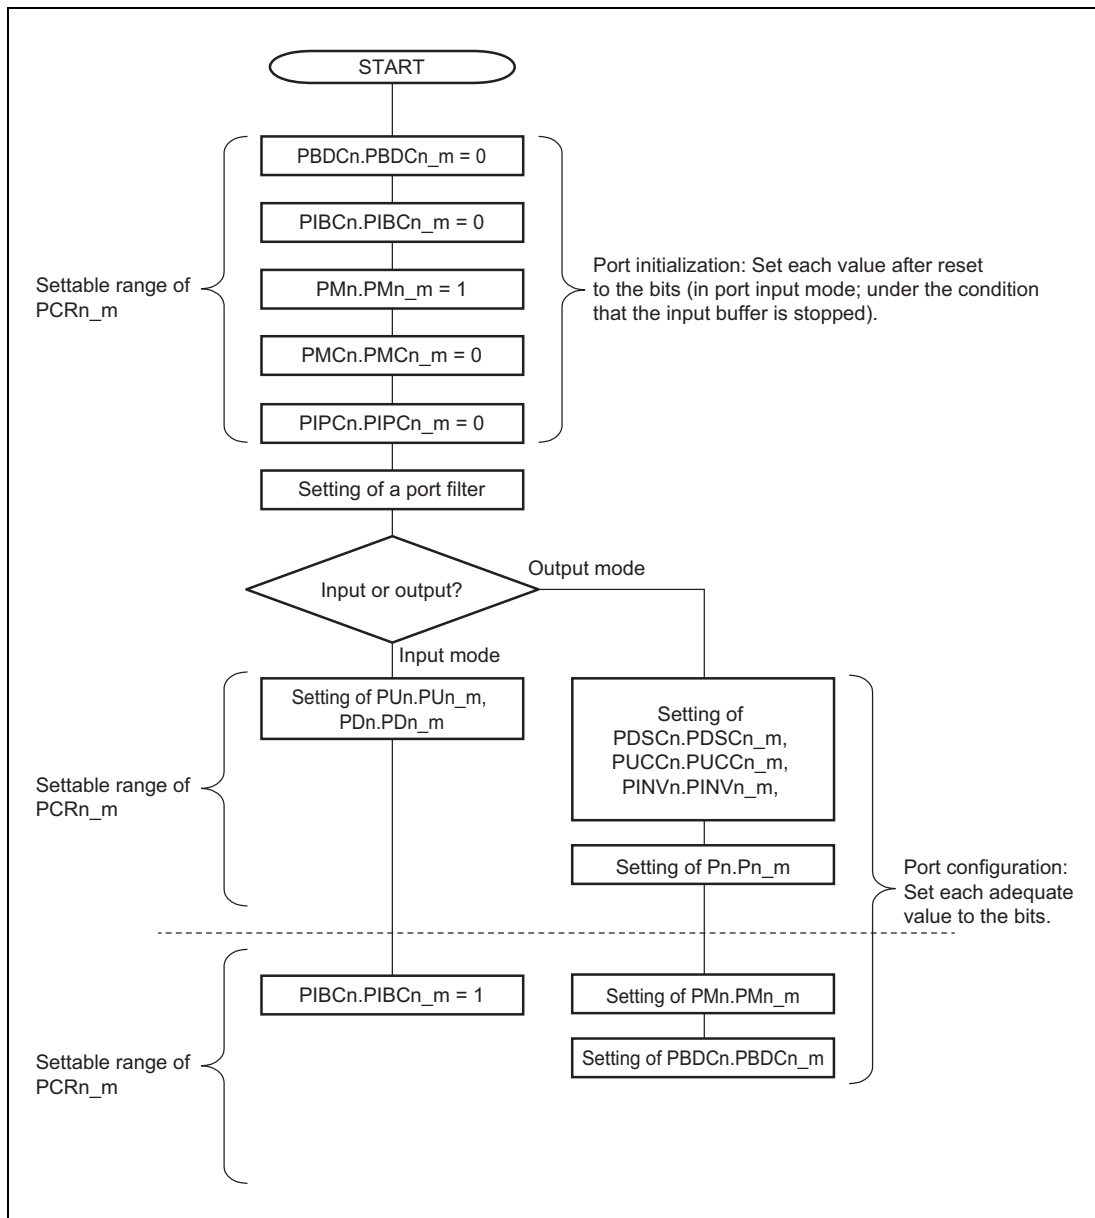

Figure 2.4 Example of Port Configuration Flow (in Port Mode)

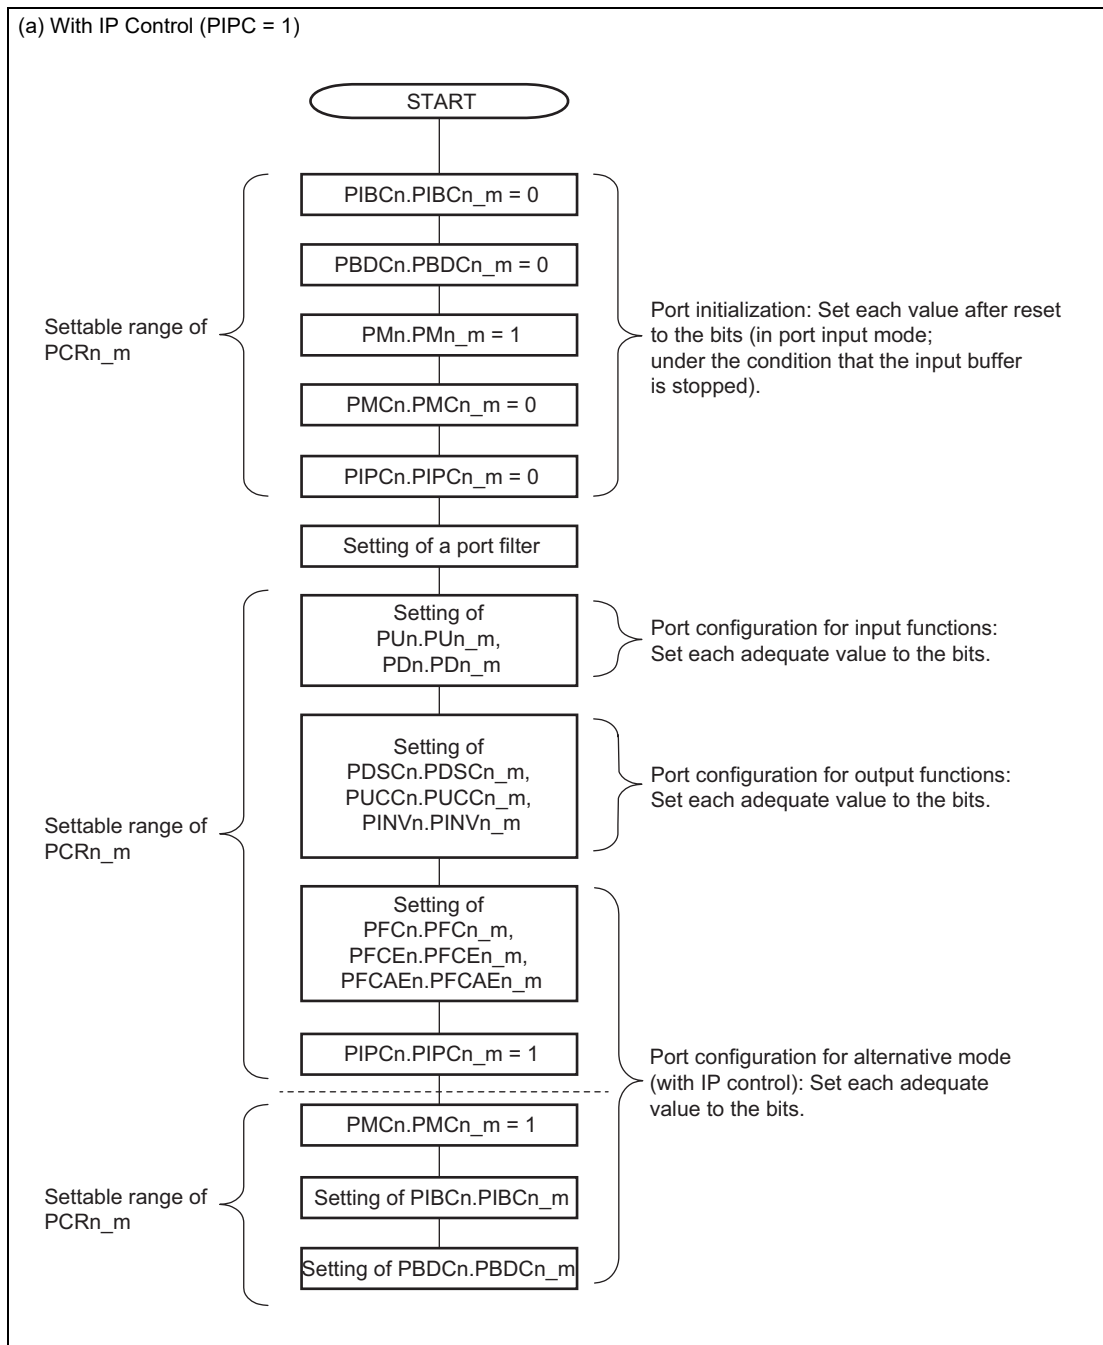

Figure 2.5 Example of Port Configuration Flow (in Alternative Mode) (1/2)

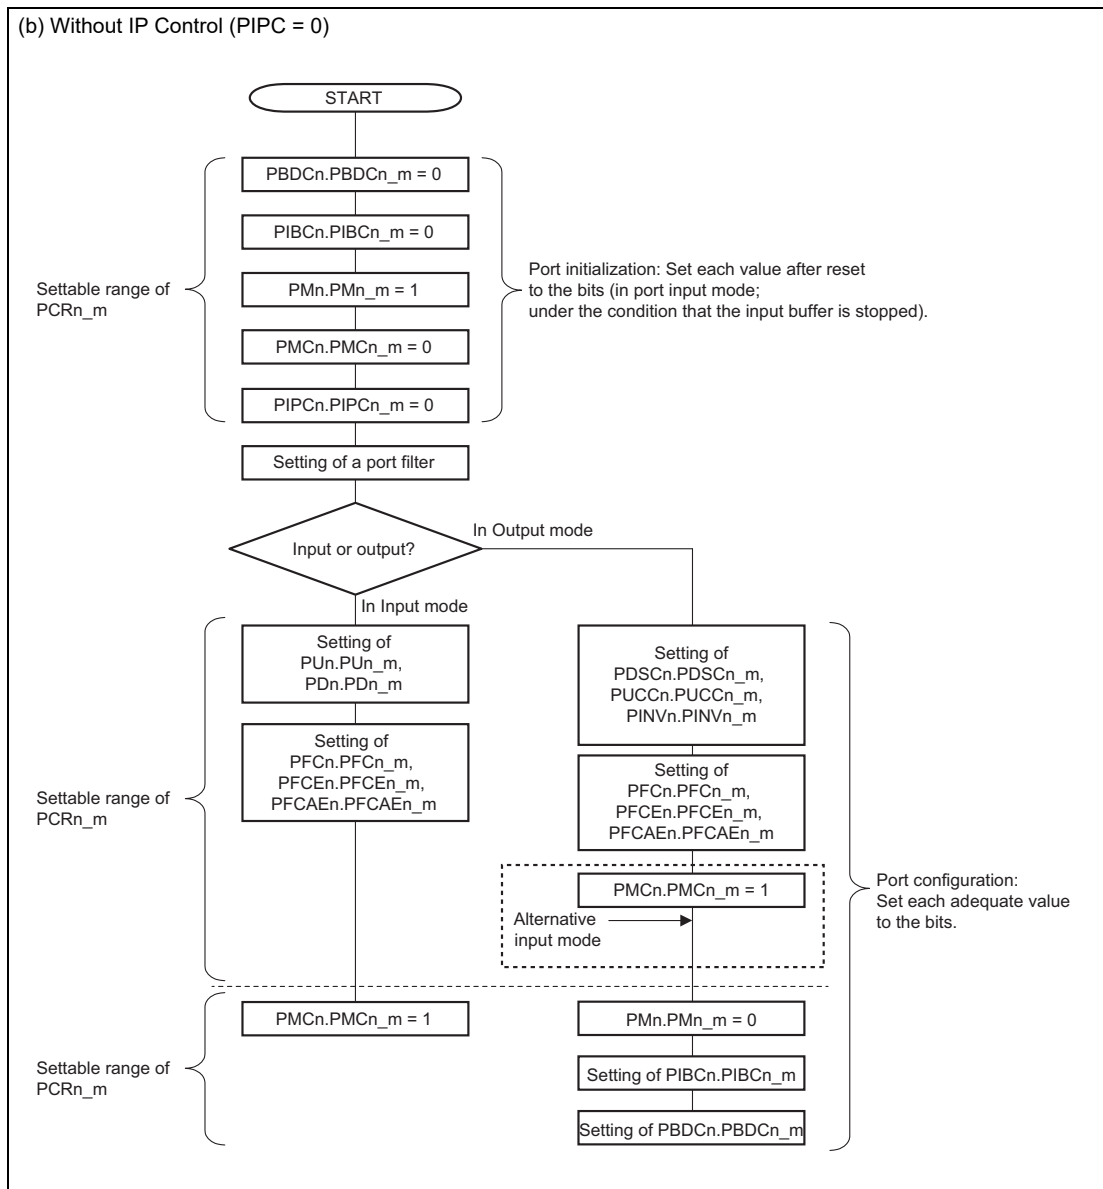

Figure 2.6 Example of Port Configuration Flow (in Alternative Mode) (2/2)

2.1.5 Functional Selection

2.1.5.1 Register Configuration in Use of the Alternative Function

When the pin alternative function is used, set $PMCn_m = 1$ and select the alternative numbers of $PFCn_m$, $PFCEn_m$, and $PFCAEn_m$. In several peripheral functions, a single alternative I/O function is allocated to multiple pins. However, such an alternative function should not be enabled in multiple pins at the same time. For example, an external interrupt input, $IRQ0$ is allocated to $P0_3$ and $P2_0$, but this alternative function can only be selected in either of them.

2.1.5.2 Alternative Function to be used in Direct I/O Control Alternative Mode

When the alternative functions described in **Table 2.29** are used, switch to direct I/O control alternative mode. When setting $PIPCn_m = 1$, the PMn_m value which has been set is ignored because the peripheral function enables or disables inputs and outputs of the buffer.

In addition, set $PIPCn_m = 0$ if you are using an alternative function not listed in **Table 2.29**.

Table 2.29 List of the Pins which Require PIPC Register Setting (1/2)

Category	Pin Name	I/O	Pin Function	Input/Output Control by Peripheral Functions
SCIn	SCInRxD	I	Receive data input	Input through the pin is enabled when the $SCI3nSCR.RE$ bit is enabling reception by $SCI3$.
	SCInTxD	O	Transmit data output	Output through the pin is enabled when the $SCI3nSCR.TE$ bit is enabling transmission by $SCI3$.
	SCInSCK	I/O	Serial clock input/output	The $SCI3nSCR.CKE[1:0]$ bits determine whether the pin is an input or output. <ul style="list-style-type: none"> Asynchronous transfer $CKE[1:0] = 00$: Both input and output through the pin are disabled. $CKE[1:0] = 01$: The pin is an output. $CKE[1:0] = 1x$: Prohibited settings Synchronous transfer $CKE[1:0] = 0x$: The pin is an output.
CSIHn	CSIHnTSSO	O	Transmit data output (data integrity verification)	<ul style="list-style-type: none"> Output control See (3) Operation of CSIHnTSSO in Section 13.5.9, Communication in Slave Mode. Input control When the $CSIHnCTL1.DCS$ bit is enabling checking the consistency of data through $CSIH$, enabling the input buffer for the pin leads to the actual output level of the pin being looped back within the device.
	CSIHnTSCK	I/O	Serial clock input/output	When then setting of $CSIHnCTL2$ is for $CSIH$ operation in slave mode, this pin is an input. When the setting is for master mode, it is an output.
	CSIHnTRY	I/O	Handshake signal input/output	When the setting of $CSIHnCTL2$ is for $CSIH$ operation in slave mode, this pin is an output. When the setting is for master mode, it is an input.
TSG2n	TSON1 to TSON6	O	Timer PWM output (Hi-Z control)	This output pin is forcibly placed in the high-impedance state under $TAPA$ control in the event of an abnormality. Output though the pin is enabled in normal operation.

Table 2.29 List of the Pins which Require PIPC Register Setting (2/2)

Category	Pin Name	I/O	Pin Function	Input/Output Control by Peripheral Functions
ATU-IV Timer C	TIOc0 to TIOc3	I/O	Input capture trigger input, output compare output	This pin is an output when ATU-IV timer C is set for compare-match operation by the TIORCx register. This pin is an input when the setting is for input- capture operation.
RSENT	RSENTnRX	I	RSENTn receive data input	Only a single-wire system of the SPC extension is the target of control when PIPCn_m = 1. Input is enabled when PIPCn_m = 1. Enabling or disabling of the SPC extension is controlled by the SPCE bit of the RSENTnCC register.
	RSENTnSPCO	O	RSENTn SPC extension output	Only a single-wire system of the SPC extension is the target of control when PIPCn_m = 1. Enabling or disabling of the SPC extension is controlled by the SPCE bit of the RSENTnCC register.

Note: n indicates the number of a given peripheral module.

2.1.5.3 Setting of the ERROROUT_C Pin

When the error-out signal output on the ERROROUT_C pin is used, enable the alternative output level loopback function for fault diagnosis.

2.1.5.4 Register Setting in Use of an Analog Input Pin

Since AN_{xxx}(ADC) DSAN_{xP} and DSAN_{xN}(DSADC) for an analog input are always connected to the A/D converter, setting of a port register to select a pin function is not required. However, when an analog input pin, which is also used for a general input port, is used, set PM_{Cn_m} = 0^{*1} and PIB_{Cn_m} = 0 (the value after reset of the port register). This prevents shoot-through current of the input buffer on the digital side during an analog voltage input. The relevant pins of this product are port groups P14, P15, and P16.

Note 1. Some pins may not be equipped with a PM_{Cn_m} bit. For which pins are and are not thus equipped, see the list of registers in **Section 2.2, Organization of Port Groups**.

2.1.5.5 Register Setting in Use of the LVDS buffer

When the LVDS buffer of RHSB is to be used, set PM_{17_m} = 0 to enable output. The output from the LVDS buffer actually being enabled takes at least 10 μs after setting PM_{17_m} = 0.

Table 2.30 Target Ports of the LVDS Buffer

Port Register	LVDS Buffer	E1M-S2
		BGA304 BGA252
PM17_0	RHSB0SOP	√
	RHSB0SON	
PM17_1	RHSB0FCLP	√
	RHSB0FCLN	
PM17_2	RHSB1SOP	√
	RHSB1SON	
PM17_3	RHSB1FCLP	√
	RHSB1FCLN	

2.1.5.6 Selecting of Function for JTAG Port

For the connection of multiple tools to the JTAG port, the interface is multiplexed on multiple sets of pins. The interface is selected by the combination of the settings of mode pins and, if the mode pins are selecting user boot mode as the operating mode, option byte OPBT2.

When any other operating mode is selected, the setting of OPBT2 has no effect and the I/F that corresponds to the operating mode is selected. For details, refer to **Section 5.2, Operating Mode**.

2.2 Organization of Port Groups

2.2.1 BGA304, BGA252 Port Function

2.2.1.1 List of the BGA304 and BGA252 Port Registers

Table 2.31 to **Table 2.46** show detailed bitmaps of control registers in each port group. In the bitmap field, “√” means an effective bit and “—” means a reserved one. Reserved areas are always read as values after reset. The write value also should be a value after reset.

The pins of port groups 7, 8, and 10 are included in the BGA304 package, but not in BGA252. For the port registers of the pins not included, the setting should not be modified (the settings should be fixed to their values after reset).

Table 2.34 List of Registers in BGA304, BGA252 Port Group 3

2.2.1.2 Alternative Function List of the BGA304, BGA252 Pins

Table 2.47 to **Table 2.62** show the list of alternative functions of each port pin. In the tables, “ — ” means a reserved bit which cannot be selected.

The pins of port groups 7, 8, and 10 is included in the BGA304 package, but not in BGA252. The setting of port registers should not be modified (the settings should be fixed to their values after reset) because the functions of the port groups, which are not included, cannot be used.

2.3 DNF

Digital Noise Filter (DNF) eliminates digital noise from external input signals. This product includes two sorts of DNF: peripheral function DNF and edge detection DNF.

2.3.1 Example of Noise Elimination

Figure 2.7 shows an example of noise elimination in peripheral function DNF and edge detection DNF. In this example, the sampling clock, the sampling count, and the current output level are set to 1/2 of the DNF input clock, two (twice), and low, respectively. “○” in the figure means that high level is detected.

In input examples 1, 2, and 3, the output level changes from low to high because the same level is detected twice in a row through sampling. In input examples 4, 5, and 6, on the other hand, the same level is not detected twice consecutively. Therefore, these inputs are regarded as noise and the input signal state is eliminated.

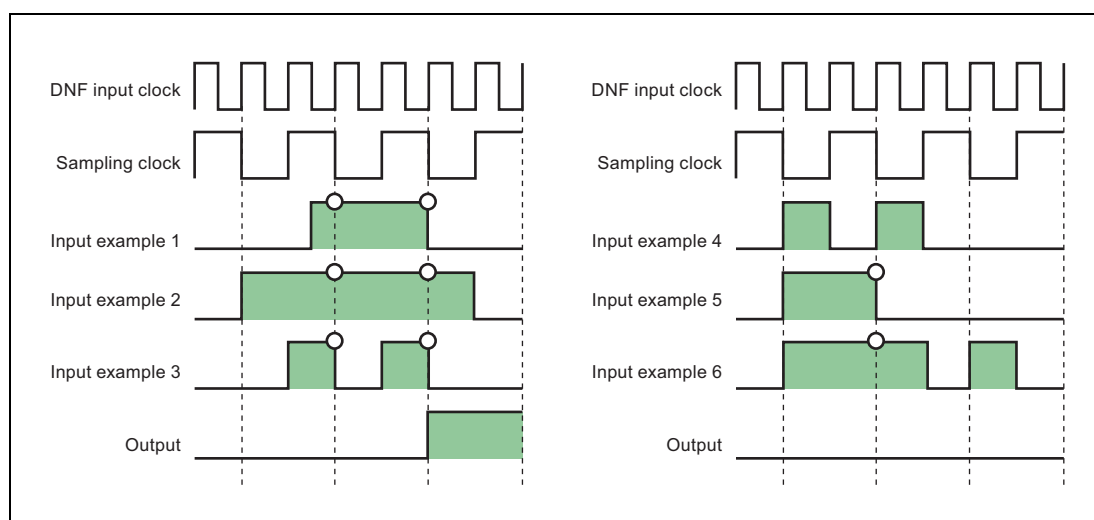

Figure 2.7 Timing Chart of Digital Noise Elimination

2.3.2 Peripheral Function DNF

2.3.2.1 Overview of Peripheral Function DNF

This DNF eliminates noise from the input function pins for the peripheral function.

Peripheral Function DNF has the following functions:

- Eliminates digital noise from input signals and outputs noiseless signals.
- Selects whether to output signals from which digital noise is eliminated or signals containing digital noise.
- Selects the digital noise elimination width from 2, 3, 4, and 5 counts of the sampling clock.
- Selects five types of sampling frequency shown below:
1/1, 1/2, 1/4, 1/8, and 1/16 of the DNF input clock.
- The conditions for noise elimination can be set by each channel via the registers.
- The DNF input clock of DNF group number 0 is a low-speed peripheral clock.
- The DNF input clock of DNF group number 1 is an unmodulated high-speed peripheral clock.
- The DNF input clock of DNF group number 8 is an unmodulated high-speed peripheral clock.

2.3.2.2 Details of the Control Registers

Table 2.63 shows base addresses of DNF. “n” indicates a number of the DNF group.

Table 2.63 Base Addresses of Peripheral Function DNF

DNFn	<DNFn_base> address
DNF0	FFC3 0000
DNF1	FFC3 0100
DNF8	FFC3 0800

2.3.2.3 DNFP01nCTLm — Digital Noise Elimination Control Register

This register sets conditions for noise elimination of channel number m in DNF group number n .

Access: This register is readable/writable in 8-bit units.

Address: <DNFn_base> + $4_H \times m$ (m : channel number)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	NFEN	SLST[1:0]		—	—	PRS[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W

Table 2.64 DNFP01nCTLm Register Contents

Bit Position	Bit Name	Function
7	NFEN	Enables/disables digital noise elimination. 0: Digital noise is not eliminated. 1: Digital noise is eliminated.
6, 5	SLST[1:0]	Specifies the sampling count for digital noise elimination. 00: Sampling count = 2 01: Sampling count = 3 10: Sampling count = 4 11: Sampling count = 5
4, 3	—	Reserved. The read values are always 0. The write values should always be 0.
2 to 0	PRS[2:0]	Specifies the sampling clock division ratio for digital noise elimination. 000: DNF input clock/1 001: DNF input clock/2 010: DNF input clock/4 011: DNF input clock/8 100: DNF input clock/16 Other than the above: Setting is prohibited.

2.3.2.4 Setting Procedures of Peripheral Function DNF

The following shows the procedures to set peripheral function DNF. If the input level to a pin varies during (4) and (5), an unexpected signal may be input to the peripheral function. Therefore, the corresponding flag at the peripheral function side or the like should be cleared in (6).

- (1) Set the PRS[2:0] and SLST[1:0] bits in the DNFP01nCTLm register.
- (2) Set the NFEN bit in the DNFP01nCTLm register. This setting can be made at the same time as (1).
- (3) Set a port register to select an alternative function.
- (4) Wait for the following time: sampling clock period \times number of samples + DNF input clock period \times 2.
- (5) Enable an operation of a peripheral function in the destination to which DNF is connected.
- (6) Clear the flag of peripheral function, and the like.

Clear the NFEN bit in the DNFP01nCTLm register, and then proceed the setting again in the order from steps (1) to (6), if the setting is to be changed while edge detection DNF is under the operation.

2.3.2.5 Peripheral Function Pin intended for DNF insertion

The signals shown in **Table 2.65** are the targets of DNF insertion.

Table 2.65 DNF Insertion Targets

DNF Group Number n	DNF Channel Number m	DNF Insertion Target Pin			E1M-S2
		Pin Name	Pin Function	Peripheral Function	BGA304 BGA252

	5	RSENT5RX	RSENT5 receive data input	RSENT5	√

2.3.3 Edge Detection DNF

2.3.3.1 Overview of the Function

This DNF detects an effective edge of a pin input signal. The signals to be used for edge detection can be selected either before or after noise elimination.

Edge detection DNF has the following functions:

- Eliminates digital noise from input signals and outputs noiseless signals.
- Selects whether to output signals from which digital noise is eliminated or signals containing digital noise.
- Selects the digital noise elimination width from 2, 3, 4, and 5 counts of the sampling clock.
- Selects five types of sampling frequency shown below:
1/1, 1/2, 1/4, 1/8, and 1/16 of the DNF input clock.
- The conditions for noise elimination can be set for all channels collectively with the register.
- The DNF input clock is a low-speed peripheral clock.

2.3.3.2 Details of the Control Registers

Table 2.66 shows base addresses of edge detection DNF. “n” indicates a number of the DNF group.

Table 2.66 Base Addresses of Edge Detection DNF

DNFn	<DNFn_base> address	E1M-S2	E1M-S2
		BGA304	BGA252
DNF2	FFC3 0200	√	√
DNF3	FFC3 0300	√	√
DNF4	FFC3 0400	√	√
DNF5	FFC3 0500	√	—
DNF6	FFC3 0600	√	√
DNF7	FFC3 0700	√	√

2.3.3.3 DNFP02nCTL — Digital Noise Elimination Control Register

This register sets noise elimination conditions which are commonly used for all channels in DNF group number n.

Access: This register is readable/writable in 8-bit units.

Address: <DNFn_base> + 00_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	SLST[1:0]		—	—	PRS[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R	R	R/W	R/W	R/W

Table 2.67 DNFP02nCTL Register Contents

Bit Position	Bit Name	Function
7	—	Reserved. The read value is always 0. The write value should always be 0.
6, 5	SLST[1:0]	Specifies the sampling count for digital noise elimination. 00: Sampling count = 2 01: Sampling count = 3 10: Sampling count = 4 11: Sampling count = 5
4, 3	—	Reserved. The read values are always 0. The write values should always be 0.
2 to 0	PRS[2:0]	Specifies the sampling clock division ratio for digital noise elimination. 000: DNF input clock / 1 001: DNF input clock / 2 010: DNF input clock / 4 011: DNF input clock / 8 100: DNF input clock / 16 Other than the above: Setting is prohibited.

2.3.3.4 DNFP02nEDCm — Edge Detection Control Register

This register controls edge detection of channel number m in DNF group number n .

Access: This register is readable/writable in 8-bit units.

Address: $\langle \text{DNFn_base} \rangle + 4_{\text{H}} + 8_{\text{H}} \times m$ (m : channel number)

Value after reset: 00_{H}

Bit	7	6	5	4	3	2	1	0
	NFEN	—	—	DMD[1:0]		—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R	R	R/W	R/W	R	R	R

Table 2.68 DNFP02nEDCm Register Contents

Bit Position	Bit Name	Function
7	NFEN	Enables/disables digital noise elimination. 0: Edge is detected for signals containing digital noise. 1: Edge is detected for signals from which digital noise is eliminated.
6, 5	—	Reserved. The read values are always 0. The write values should always be 0.
4, 3	DMD[1:0]	Enables/disables edge detection and sets edge to be detected 00: Edge detection is disabled. 01: Rising edge is detected. 10: Falling edge is detected. 11: Both edges are detected.
2 to 0	—	Reserved. The read values are always 0. The write values should always be 0.

2.3.3.5 DNFP02nEDFm — Edge Detection Flag Register

This register has an edge detection flag and a flag clear bit of channel number m in DNF group number n .

Access: This register is readable/writable in 8-bit units.

Address: $\langle \text{DNFn_base} \rangle + 8_{\text{H}} + 8_{\text{H}} \times m$ (m : channel number)

Value after reset: 00_{H}

Bit	7	6	5	4	3	2	1	0
	EDF	—	—	—	—	—	—	CLED
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	W

Table 2.69 DNFP02nEDFm Register Contents

Bit Position	Bit Name	Function
7	EDF	This bit holds a result of edge detection based on the edge detection setting for channel number m . This bit is cleared by writing 1 to the CLED bit and continues to hold 1 unless it is cleared. Its state does not change while 1 is held, even if an edge is detected. 0: Effective edge has not been detected. 1: Effective edge has been detected.
6 to 1	—	Reserved. The read values are always 0. The write values should always be 0.
0	CLED	Writing 1 to this bit clears the status flag of EDF, bit 7. In case of contention between the writing of 1 and a setting source of bit 7, EDF clearing takes priority. Even writing 0 cannot change the state. The read value is always 0.

2.3.3.6 Setting Procedures of Edge Detection DNF

The following shows the procedures to set edge detection DNF. When edge detection is performed for signals containing digital noise, the steps with (*) can be skipped. If the input level to a pin varies during (4) and (5), an unexpected signal may be input to the peripheral function. Therefore, the corresponding flag at the peripheral function side and the like should be cleared in (6).

- (1) Set the PRS[2:0] and SLST[1:0] bits in the DNFP02nCTL register. (*)
- (2) Set the NFEN bit in the DNFP02nEDCm register.
- (3) Set a port register to general input port mode.
- (4) Wait for the following time: sampling clock period \times number of samples + DNF input clock period \times 2. (*)
- (5) Enable edge detection with the DMD[1:0] bits of the DNFP02nEDCm register.
- (6) Clear the edge detection flag with the CLED bit of the DNFP02nEDFm register.

Set the DMD[1:0] bits in the DNFP02nEDCm register to 00_{B} , and then proceed the setting again in the order from steps (1) to (6), if the setting is to be changed while edge detection DNF is under the operation.

2.3.3.7 Pn_m Pins Intended for DNF Insertion

The pins shown in **Table 2.70** are the targets of DNF insertion.

2.4 POD Control

2.4.1 Overview of the Function

The output buffer of the related pins shown in **Table 2.72** can be controlled according to the $\overline{\text{POD}}$ (port output disable) pin input level. This function is always available when target pins are set to output regardless of the selected function. The output buffer is controlled by the $\overline{\text{POD}}$ pin independently of the bus cycle. POD control takes precedence over output settings of a port register and output designation of each IP, but its priority is lower than reset.

Table 2.71 State of the $\overline{\text{POD}}$ Pin

POD Pin State	Description
0	Pin output is not effective (high impedance).
1	Pin output is effective (each setting function).

2.5 Pin Description

2.5.1 Overview

This subsection describes pin functions, external pin lists, and external pin states at a reset and in other each operating status.

2.5.2 List of Pin Functions

Table 2.73 lists functions of each pin. “√” indicates with a support function and “—” without. Do not use the pins without support functions.

2.5.3 Pin State

Definition of Reset State

In description of pin state, each reset state is defined as shown in **Table 2.74**.

Table 2.74 Definition of Reset State

Reset State	Definition
External reset	Reset state from an external pin ($\overline{\text{RES}} = \text{L}$)
Internal reset	Between external reset release to internal reset release
After internal reset release	State where internal reset is released

For the pins included in each product, see **Table 1.1, Pin Numbers and Pin Names (BGA304)** and **Table 1.2, Pin Numbers and Pin Names (BGA252)** in **Section 1.5, Pin Connection Diagram (Top View)**.

Table 2.75 Pin State (1/3)

A1VSS: This pin is connected to ADSVSS. A1VREFH: This pin is connected to ADSVCC. Connections when neither the DSADC nor the ADC module is in use are listed below. A0VCC: This pin is connected to EVCC. A0VSS: This pin is connected to VSS. A0VREFH: This pin is connected to EVCC. A1VCC: This pin is connected to EVCC. A1VSS: This pin is connected to VSS. A1VREFH: This pin is connected to EVCC. 	—

Note 1. For the correspondences between the various pins and the power supply or ground, see **Section 40, Electrical Characteristics**.

Note 2. Use a resistor with a value of at least 1 kΩ for externally pulling pins up or down.

Note 3. Take care regarding the resistive division effect when using an external resistor to pull up or pull down a pin that is equipped with an internal pull-up or pull-down resistor.

Section 3 CPU System

3.1 Overview

3.1.1 Block Configuration

Figure 3.1 shows the block configuration diagram.

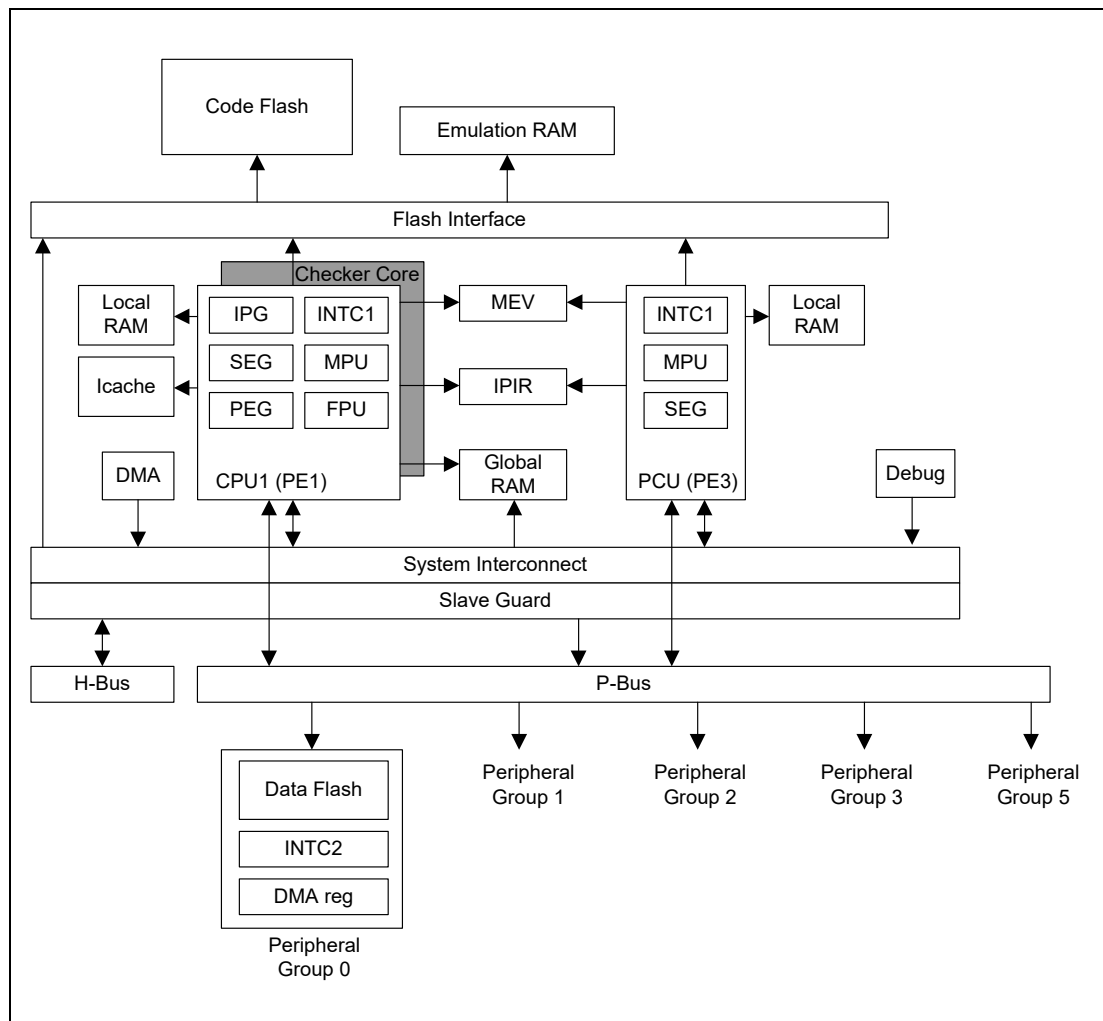

Figure 3.1 Block Configuration Diagram

CPU1 (PE1)

The RH850 G3MH core is included as a main CPU. CPU1 also includes the checker core for safety assurance.

PCU (PE3)

The RH850 G3K core is included as a PCU to control peripheral IPs (peripheral control unit).

Local RAM

Each PE has a high-speed accessible local RAM.

Global RAM

The global RAM is a mass on-chip RAM that all PEs share. Some areas of this RAM function as the retention RAM.

Code Flash

A mass code flash is included for program storage. CPU1 and PCU share the code flash and they are connected with each other via the code flash interface.

Emulation RAM

It is a RAM to emulate the code flash. The programs can be replaced by controlling from an external tool without rewriting the code flash.

Data Flash

It is a flash memory being rewritable by the CPU.

P-Bus and H-Bus

The P-Bus and H-Bus connect the peripheral IPs. The P-Bus is divided into five, Peripheral Group 0 to 3, and 5.

For the correspondence between the peripheral groups and the peripheral modules/registers, see **Appendix, List of Registers**.

INTC1, INTC2

INTC1 is an interrupt controller exclusive to each PE. INTC2 is a common interrupt controller that all PEs share, being able to set the binding destination PE of an interrupt request by the registers.

DMA

Two DMA transfer modules, DMAC and DTS, are included.

Slave Guard

The slave guard is a system to prevent unauthorized access from the specific bus master, consisting of the following guard structures:

(1) PE Guard (PEG)

The PE guard is a system to prevent unauthorized access to the resources in the PE from the external master. Access from the PE itself is only enabled but all other accesses are disabled after release from the reset state.

(2) Global RAM Guard (GRG)

The global RAM guard is a system to prevent unauthorized access to the global RAM from the external master. The global RAM is in the unprotected state (accessible from all bus masters) after release from the reset state.

(3) Peripheral Guard (PBG)

The peripheral guard is a system to prevent unauthorized access to peripheral devices from the external master. Peripheral devices are in the unprotected state (accessible from all bus masters) after release from the reset state.

3.2 CPU

3.2.1 Core Functions

3.2.1.1 Features

Table 3.1 lists features of the RH850G3MH core.

Table 3.1 Features of the RH850G3MH Core

Item	Feature
CPU	<ul style="list-style-type: none"> • Advanced 32-bit architecture for embedded control • 32-bit internal data bus • Thirty-two 32-bit general-purpose registers • RISC-type instruction sets <ul style="list-style-type: none"> – Long-/short-format load/store instructions – Three-operand instructions – Instruction sets based on C language • CPU operating modes <ul style="list-style-type: none"> – User mode, supervisor mode • Address space: 4-Gbyte linear address space for both data and instructions • Instructions: A snooze instruction (SNOOZE) is included for temporary suspension by switching the CPU clock signal (CLK_CPU) off for 32 clock cycles.
Coprocessor	<ul style="list-style-type: none"> • A floating-point operation coprocessor (FPU) mounted <ul style="list-style-type: none"> – Supports single precision (32 bits) and double precision (64 bits). – Supports data types and exceptions conforming to IEEE754. – Rounding mode: Neighborhood, 0 direction, +∞ direction, and -∞ direction – Handling denormalized numbers: Rounding down to 0 or exception notification to conform to IEEE754
Exception/ Interrupt	<ul style="list-style-type: none"> • 16 interrupt priority levels settable for each channel • Vector selection method selectable according to performance request or memory usage <ul style="list-style-type: none"> – Direct branching exception vectors – Indirect branching exception vectors referring to the address table • Supports the high-speed save/restore processing of the context by the dedicated instructions (PUSHSP and POPSP) at the generation of an interrupt
Memory Management	<ul style="list-style-type: none"> • Memory protection function (MPU): 16 areas settable
Cache	<ul style="list-style-type: none"> • Instruction cache

3.2.1.2 Register Set

This subsection explains the program registers and system registers incorporated in this CPU.

(1) Program Registers

Program registers include the general-purpose registers (r0 to r31) and program counter (PC).

The general-purpose register r0 always retains 0, but the values of the registers r1 to r31 after reset are undefined.

Table 3.2 List of Program Registers

Program Register	Name	Function	Description
General-purpose registers	r0	Zero register	Always retains "0"
	r1	Assembler reserved register	Used as working register for generating addresses
	r2	Register for address and data variables (used when the real-time OS used does not use this register)	
	r3	Stack pointer (SP)	Used for generating a stack frame when a function is called
	r4	Global pointer (GP)	Used for accessing a global variable in the data area
	r5	Text pointer (TP)	Used as a register that indicates the start of the text area (area where program code is placed)
	r6 to r29	Register for addresses and data variables	
	r30	Element pointer (EP)	Used as a base pointer for generating addresses when accessing memory
	r31	Link pointer (LP)	Used when the compiler calls a function
	Program counter	PC	Retains instruction addresses during execution of programs

Note: For further descriptions of r1, r3 to r5, and r31 used for an assembler and/or C compiler, see the the document of each software development environment.

(a) General-Purpose Registers

A total of 32 general-purpose registers (r0 to r31) are provided. All of these registers can be used for either data variables or address variables. r0 always retains 0, but the initial value of r1 to r31 is undefined.

Of the general-purpose registers, r0 to r5, r30, and r31 are assumed to be used for special purposes in software development environments, so it is necessary to note the following when using them.

1. r0, r3, and r30

These registers are implicitly used by instructions.

r0 is a register that always retains “0”. It is used for operations that use 0 and addressing with base address being 0.

r3 is implicitly used by the PREPARE, DISPOSE, PUSHSP, and POPSP instructions.

r30 is used as a base pointer when the SLD instruction or SST instruction accesses memory.

2. r1, r4, r5, and r31

These registers are implicitly used by the assembler and C compiler.

When using these registers, register contents must first be saved so they are not lost and can be restored after the registers are used.

3. r2

This register might be used by a real-time OS in some cases. If the real-time OS that is being used is not using r2, r2 can be used as a register for address variables or data variables.

(b) PC — Program Counter

The PC retains the address of the instruction being executed.

Table 3.3 PC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	PC31-1	These bits indicate the address of the instruction being executed.	R/W	*1
0	PC0	This bit is fixed to 0, and branching to an odd number address is disabled.	R/W	0

Note 1. The value after reset depends on the startup area in this product. For details, see **Section 4, Address Space**

(2) Basic System Registers

The basic system registers are used to control CPU status and to retain exception information.

System registers are read from or written to by using the LDSR or STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.4 Basic System Registers

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR0, 0	EIPC	Status save registers when acknowledging EI level exception	SV
SR1, 0	EIPSW	Status save registers when acknowledging EI level exception	SV
SR2, 0	FEPC	Status save registers when acknowledging FE level exception	SV
SR3, 0	FEPSW	Status save registers when acknowledging FE level exception	SV
SR 5, 0	PSW	Program status word	*1
SR 6, 0	FPSR	Refer to (4) FPU Function Registers	CU0 and SV
SR 7, 0	FPEPC	Refer to (4) FPU Function Registers	CU0 and SV
SR8, 0	FPST	Refer to (4) FPU Function Registers	CU0
SR9, 0	FPCC	Refer to (4) FPU Function Registers	CU0
SR10, 0	FPCFG	Refer to (4) FPU Function Registers	CU0
SR 13, 0	EIIC	EI level exception cause	SV
SR 14, 0	FEIC	FE level exception cause	SV
SR 16, 0	CTPC	CALLT execution status save register	UM
SR 17, 0	CTPSW	CALLT execution status save register	UM
SR 20, 0	CTBP	CALLT base pointer	UM
SR 28, 0	EIWR	EI level exception working register	SV
SR 29, 0	FEWR	FE level exception working register	SV
SR0, 1	MCFG0	Machine configuration	SV
SR2, 1	RBASE	Reset vector base address	SV
SR3, 1	EBASE	Exception handler vector address	SV
SR4, 1	INTBP	Base address of the interrupt handler table	SV
SR 5, 1	MCTL	CPU control	SV
SR 6, 1	PID	Processor ID	SV
SR 11, 1	SCCFG	SYSCALL operation setting	SV
SR 12, 1	SCBP	SYSCALL base pointer	SV
SR0, 2	HTCFG0	Thread configuration	SV
SR6, 2	MEA	Memory error address	SV
SR7, 2	ASID	Address space ID	SV
SR8, 2	MEI	Memory error information	SV

Note 1. The access permission differs depending on the bit. For details, see **(e) PSW — Program status word** in **(2) Basic System Registers**.

(a) EIPC — Status save register when acknowledging EI level exception

When an EI level exception is acknowledged, the address of the instruction that was being executed when the EI level exception occurred, or of the next instruction, is saved to the EIPC register (see *section 4.1.3 Types of exceptions* in *RH850G3MH User's Manual: Software*).

Because there is only one pair of EI level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

Be sure to set an even-numbered address to the EIPC register. An odd-numbered address must not be specified.

Table 3.5 EIPC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	EIPC31-1	These bits indicate the PC saved when an EI level exception is acknowledged.	R/W	Undefined
0	EIPC0	This bit indicates the PC saved when an EI level exception is acknowledged. Always set this bit to 0. Even if it is set to 1, the value transferred to the PC when the EIRET instruction is executed is 0.	R/W	Undefined

(b) EIPSW — Status save register when acknowledging EI level exception

When an EI level exception is acknowledged, the current PSW setting is saved to the EIPSW register.

Because there is only one pair of EI level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

CAUTION

Bits 11 to 9 cannot usually be changed since these bits are associated with debugging.

Table 3.6 EIPSW Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
30	UM	This bit stores the PSW.UM bit setting when an EI level exception is acknowledged.	R/W	0
29 to 19	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
18 to 16	CU2-0	These bits store the PSW.CU2 to 0 field setting when an EI level exception is acknowledged. (CU2 and CU1 are reserved for future expansion. Be sure to clear to 0.)	R/W	0
15	EBV	This bit stores the PSW.EBV bit setting when an EI level exception is acknowledged.	R/W	0
14 to 12	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
11 to 9	Debug	These bits store the PSW.Debug field when an EI level exception is acknowledged.	R/W	0
8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7	NP	This bit stores the PSW.NP bit setting when an EI level exception is acknowledged.	R/W	0
6	EP	This bit stores the PSW.EP bit setting when an EI level exception is acknowledged.	R/W	0
5	ID	This bit stores the PSW.ID bit setting when an EI level exception is acknowledged.	R/W	1
4	SAT	This bit stores the PSW.SAT bit setting when an EI level exception is acknowledged.	R/W	0
3	CY	This bit stores the PSW.CY bit setting when an EI level exception is acknowledged.	R/W	0
2	OV	This bit stores the PSW.OV bit setting when an EI level exception is acknowledged.	R/W	0
1	S	This bit stores the PSW.S bit setting when an EI level exception is acknowledged.	R/W	0
0	Z	This bit stores the PSW.Z bit setting when an EI level exception is acknowledged.	R/W	0

(c) FEPC — Status save register when acknowledging FE level exception

When an FE level exception is acknowledged, the address of the instruction that was being executed when the FE level exception occurred, or of the next instruction, is saved to the FEPC register (see *section 4.1.3 Types of exceptions* in *RH850G3MH User's Manual: Software*).

Because there is only one pair of FE level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

Be sure to set an even-numbered address to the FEPC register. An odd-numbered address must not be specified.

Table 3.7 FEPC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	FEPC31-1	These bits indicate the PC saved when an FE level exception is acknowledged.	R/W	Undefined
0	FEPC0	This bit indicates the PC saved when an FE level exception is acknowledged. Always set this bit to 0. Even if it is set to 1, the value transferred to the PC when the FERET instruction is executed is 0.	R/W	Undefined

(d) FEPSW — Status save register when acknowledging FE level exception

When an FE level exception is acknowledged, the current PSW setting is saved to the FEPSW register.

Because there is only one pair of FE level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

CAUTION

Bits 11 to 9 cannot usually be changed since these bits are associated with debugging.

Table 3.8 FEPSW Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31	—	(Reserved for future expansion. Be sure to clear to 0.)	R/W	0
30	UM	This bit stores the PSW.UM bit setting when an FE level exception is acknowledged.	R/W	0
29 to 19	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
18 to 16	CU2-0	These bits store the PSW.CU2 to 0 field setting when an FE level exception is acknowledged. (CU2 and CU1 are reserved for future expansion. Be sure to clear to 0.)	R/W	0
15	EBV	This bit stores the PSW.EBV bit setting when an FE level exception is acknowledged.	R/W	0
14 to 12	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
11 to 9	Debug	These bits store the PSW.Debug field when an EI level exception is acknowledged.	R/W	0
8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7	NP	This bit stores the PSW.NP bit setting when an FE level exception is acknowledged.	R/W	0
6	EP	This bit stores the PSW.EP bit setting when an FE level exception is acknowledged.	R/W	0
5	ID	This bit stores the PSW.ID bit setting when an FE level exception is acknowledged.	R/W	1
4	SAT	This bit stores the PSW.SAT bit setting when an FE level exception is acknowledged.	R/W	0
3	CY	This bit stores the PSW.CY bit setting when an FE level exception is acknowledged.	R/W	0
2	OV	This bit stores the PSW.OV bit setting when an FE level exception is acknowledged.	R/W	0
1	S	This bit stores the PSW.S bit setting when an FE level exception is acknowledged.	R/W	0
0	Z	This bit stores the PSW.Z bit setting when an FE level exception is acknowledged.	R/W	0

(e) PSW — Program status word

PSW (program status word) is a set of flags that indicate the program status (instruction execution result) and bits that indicate the operation status of the CPU (flags are bits in the PSW that are referenced by a condition instruction (Bcond, CMOV, etc.)).

CAUTIONS

1. When the LDSR instruction is used to change the contents of bits 7 to 0 in this register, the changed contents become valid immediately after the completion of execution of the LDSR instruction.
2. The access permission for the PSW register differs with each bit. All bits can be read, but some bits can only be written under certain conditions. See Table 3.9, Access Permission for PSW Register for the access permission for each bit.

Table 3.9 Access Permission for PSW Register

Bit	Access Permission When Reading		Access Permission When Writing
30	UM	UM	SV*1
18 to 16	CU2-0		SV*1
15	EBV		SV*1
11 to 9	Debug		Special*1
7	NP		SV*1
6	EP		SV*1
5	ID		SV*1
4	SAT		UM
3	CY		UM
2	OV		UM
1	S		UM
0	Z		UM

Note 1. The access permission for the whole PSW register is UM, so the PIE exception does not occur even if the register is written by using an LDSR instruction when PSW.UM is 1. In this case, writing is ignored.

PSW	31	30	29	19	18	16	15	14	12	11	10	9	8	7	6	5	4	3	2	1	0	Value after reset								
	0	UM	0	0	0	0	0	0	0	0	0	0	0	0	CU2-0	EBV	0	0	0	Debug	0	NP	EP	ID	SAT	CY	OV	S	Z	0000 0020 _H

Table 3.10 PSW Register Contents (1/2)

Bit Position	Bit Name	Function	R/W	Value after Reset
31	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
30	UM	This bit indicates that the CPU is in user mode (UM mode) 0: Supervisor mode 1: User mode	R/W	0
29 to 19	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
18 to 16	CU2-CU0	This bit indicates the coprocessor use permissions. When the bit corresponding to the coprocessor is 0, a coprocessor use prohibition exception is generated in response to execution of a coprocessor instruction or access to coprocessor resources (system registers). CU2 bit 18: (Reserved for future expansion. Be sure to clear to 0.) CU1 bit 17: (Reserved for future expansion. Be sure to clear to 0.) CU0 bit 16: FPU	R/W	000

Table 3.10 PSW Register Contents (2/2)

Bit Position	Bit Name	Function	R/W	Value after Reset
15	EBV	This bit indicates the reset vector and exception vector operation. See the descriptions of the RBASE register in (q) RBASE — Reset vector base address register and the EBASE register in (r) EBASE — Exception handler vector address register .	R/W	0
14 to 12	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
11 to 9	Debug	These bits are used in debugging for development tools. In normal operation, clear these bits to 0.	—	0
8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7	NP	Disables acceptance of FE level exceptions. Once an FE level exception is accepted, this bit is set to 1 and disables acceptance of EI level exceptions or FE level exceptions. For the exceptions disabled by the NP bit, see <i>table 4.1 Exception Cause List in RH850G3MH User's Manual: Software</i> . 0 : An acceptance of FE level exceptions is enabled 1 : An acceptance of FE level exceptions is disabled	R/W	0
6	EP	This bit indicates that an exception other than an interrupt is being serviced. It is set to 1 when the corresponding exception occurs. This bit does not affect acknowledging an exception request even when it is set to 1. 0: An exception other than an interrupt is not being serviced. 1: An exception other than an interrupt is being serviced.	R/W	0
5	ID	Disables acceptance of EI level exceptions. Once an IE level exception or FE level exception is accepted, this bit is set to 1 and disables acceptance of EI level exceptions. For the exceptions disabled by the ID bit, see <i>table 4.1 Exception Cause List in RH850G3MH User's Manual: Software</i> . This bit is also used to disable EI level exceptions from being acknowledged as a critical section while an ordinary program or interrupt is being serviced. It is set to 1 when the DI instruction is executed, and cleared to 0 when the EI instruction is executed. A change in the ID bit by the IE or DI instruction is effective from the next instruction. 0 : An acceptance of IE level exceptions is enabled 1 : An acceptance of IE level exceptions is disabled	R/W	1
4	SAT* ¹	This bit indicates that the operation result is saturated because the result of a saturated operation instruction operation has overflowed. This is a cumulative flag, so when the operation result of the saturated operation instruction becomes saturated, this bit is set to 1, but it is not cleared to 0 when the operation result for a subsequent instruction is not saturated. This bit is cleared to 0 by the LDSR instruction. This bit is neither set to 1 nor cleared to 0 when an arithmetic operation instruction is executed. 0: Not saturated 1: Saturated	R/W	0
3	CY	This bit indicates whether a carry or borrow has occurred in the operation result. 0: Carry and borrow have not occurred. 1: Carry or borrow has occurred.	R/W	0
2	OV* ¹	This bit indicates whether or not an overflow has occurred during an operation. 0: Overflow has not occurred. 1: Overflow has occurred.	R/W	0
1	S* ¹	This bit indicates whether or not the result of an operation is negative. 0: Result of operation is positive or 0. 1: Result of operation is negative	R/W	0
0	Z	This bit indicates whether or not the result of an operation is 0. 0: Result of operation is not 0. 1: Result of operation is 0.	R/W	0

Note 1. The operation result of the saturation processing is determined in accordance with the contents of the OV flag and S flag during a saturated operation. When only the OV flag is set to 1 during a saturated operation, the SAT flag is set to 1.

Operation result status	Flag status			Operation result after saturation processing
	SAT	OV	S	
Exceeded positive maximum value	1	1	0	7FFF FFFF _H
Exceeded negative maximum value	1	1	1	8000 0000 _H
Positive (maximum value not exceeded)	Value prior to operation is retained.	0	0	Operation result itself
Negative (maximum value not exceeded)			1	

(f) EIC — EI level exception source register

The EIC register retains the source of any EI level exception that occurs. The value retained in this register is an exception code corresponding to a specific exception source.

Table 3.11 EIC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	EIC31-0	These bits store the exception source code when an EI level exception occurs. Regarding the stored exception source code, see <i>Table 6.14, Interrupt Exception Handler and Priority</i> and <i>table 4.1 Exception Cause List</i> in <i>RH850G3MH User's Manual: Software</i> . The EIC31-16 field stores detailed exception source codes defined individually for each exception. If there is no particular definition, these bits are set to 0.	R/W	0

(g) FEIC — FE level exception source register

The FEIC register retains the source of any FE level exception that occurs. The value retained in this register is an exception code corresponding to a specific exception source.

Table 3.12 FEIC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	FEIC31-0	These bits store the exception source code when an FE level exception occurs. Regarding the stored exception source code, see <i>Table 6.14, Interrupt Exception Handler and Priority</i> and <i>table 4.1 Exception Cause List</i> in <i>RH850G3MH User's Manual: Software</i> . The FEIC31-16 field stores detailed exception source codes defined individually for each exception. If there is no particular definition, these bits are set to 0.	R/W	0

(h) CTPC — Status save register when executing CALLT register

When a CALLT instruction is executed, the address of the next instruction after the CALLT instruction is saved to CTPC. Be sure to set an even-numbered address to the CTPC register. An odd-numbered address must not be specified.

Table 3.13 CTPC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	CTPC31-1	These bits indicate the PC of the instruction after the CALLT instruction.	R/W	Undefined
0	CTPC0	This bit indicates the PC of the instruction after the CALLT instruction. Always set this bit to 0. Even if it is set to 1, the value transferred to the PC when the CTRET instruction is executed is 0.	R/W	Undefined

(i) CTPSW — Status save register when executing CALLT register

When a CALLT instruction is executed, some of the PSW (program status word) settings are saved to CTPSW.

Table 3.14 CTPSW Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
4	SAT	This bit stores the PSW.SAT bit setting when the CALLT instruction is executed.	R/W	0
3	CY	This bit stores the PSW.CY bit setting when the CALLT instruction is executed.	R/W	0
2	OV	This bit stores the PSW.OV bit setting when the CALLT instruction is executed.	R/W	0
1	S	This bit stores the PSW.S bit setting when the CALLT instruction is executed.	R/W	0
0	Z	This bit stores the PSW.Z bit setting when the CALLT instruction is executed.	R/W	0

(j) CTBP — CALLT base pointer register

The CTBP register is used to specify table addresses of the CALLT instruction and generate target addresses. Be sure to set the CTBP register to a half word address.

Table 3.15 CTBP Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	CTBP31-1	These bits indicate the base pointer address of the CALLT instruction. These bits indicate the first address in the table used by the CALLT instruction.	R/W	Undefined
0	CTBP0	These bits indicate the base pointer address of the CALLT instruction. These bits indicate the first address in the table used by the CALLT instruction. Always set this bit to 0.	R	0

(k) ASID — Address space ID register

This is the address space ID. This is used to identify the address space provided by the memory management function.

Table 3.16 ASID Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 10	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
9 to 0	ASID	This is the address space ID.	R/W	Undefined

(l) EIWR — EI level exception working register

The EIWR register is used as a working register when an EI level exception has occurred.

Table 3.17 EIWR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	EIWR31-0	These bits constitute a working register that can be used for any purpose during the processing of an EI level exception. Use this register for purposes such as storing the values of general-purpose registers.	R/W	Undefined

(m) FEWR — FE level exception working register

The FEWR register is used as a working register when an FE level exception has occurred.

Table 3.18 FEWR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	FEWR31-0	These bits constitute a working register that can be used for any purpose during the processing of an FE level exception. Use this register for purposes such as storing the values of general-purpose registers.	R/W	Undefined

(n) HTCFG0 — Thread configuration register

Table 3.19 HTCFG0 Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 19	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
18 to 16	PEID	These bits indicate the processor element number.	R	*2
15	—	(Reserved for future expansion. Be sure to set this bit to 1.)	R	1
14 to 0	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0

Note 1. The value is 0001 8000_H in CPU1 (PE1) of this product.
 Note 2. The value is 001_B in CPU1 (PE1) of this product.

(o) MEA — Memory error address register

Table 3.20 MEA Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	MEA	These bits store an address when a MAE (misaligning) or MPU violation occurs.	R/W	Undefined

(p) MEI — Memory error information register

This register is used to store information about the instruction that caused the exception when a misaligned (MAE) or memory protection (MDP) exception occurs.

Table 3.21 MEI Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 21	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
20 to 16	REG	These bits indicate the number of the source or destination register accessed by the instruction that caused the exception. For details, see Table 3.22, Instructions Causing Exceptions and Values of MEI Register .	R/W	Undefined
15 to 11	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
10, 9	DS	These bits indicate the type of data handled by the instruction that caused the exception.*1 0: Byte (8 bits) 1: Half word (16 bits) 2: Word (32 bits) 3: Double-word (64 bits) For details, see Table 3.22, Instructions Causing Exceptions and Values of MEI Register .	R/W	Undefined
8	U	These bits indicate the sign extension method of the instruction that caused the exception. 0: Signed 1: Unsigned For details, see Table 3.22, Instructions Causing Exceptions and Values of MEI Register .	R/W	Undefined
7, 6	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
5 to 1	ITYPE	These bits indicate the instruction that caused the exception. For details, see Table 3.22, Instructions Causing Exceptions and Values of MEI Register .	R/W	Undefined
0	RW	This bit indicates whether the operation of the instruction that caused the exception was read (Load-memory) or write (Store-memory) 0: Read (Load-memory) 1: Write (Store-memory) For details, see Table 3.22, Instructions Causing Exceptions and Values of MEI Register .	R/W	Undefined

Note 1. Even if the data is divided and access is made several times due to the specifications of the hardware, the original data type indicated by the instruction is stored.

Table 3.22 Instructions Causing Exceptions and Values of MEI Register (1/2)

Instruction	REG	DS	U	RW	ITYPE
SLD.B	dst	0 (Byte)	0 (Signed)	0 (Read)	00000 _B
SLD.BU	dst	0 (Byte)	1 (Unsigned)	0 (Read)	00000 _B

PREPARE	src* ⁵	2 (Word)	0 (Signed)* ⁵	1 (Write)	01100 _B
DISPOSE	dst* ⁵	2 (Word)	0 (Signed)* ⁵	0 (Read)	01100 _B
PUSHSP	src* ⁵	2 (Word)	0 (Signed)* ⁵	1 (Write)	01101 _B
POPSP	dst* ⁴ * ⁵	2 (Word)	0 (Signed)* ⁵	0 (Read)	01101 _B
SWITCH	—	1 (Half-word)	0 (Signed)	0 (Read)	10000 _B
CALLT	—	1 (Half-word)	1 (Unsigned)	0 (Read)	10001 _B
SYSCALL	—	2 (Word)	0 (Signed)* ⁵	0 (Read)	10010 _B
CACHE	—	—	—	0/1* ²	10100 _B
Interrupt (table reference)* ³	—	2 (Word)	0 (Signed)* ⁵	0 (Read)	10101 _B

Note 1. This exception occurs when the instruction executes a read access.

Note 2. It depends on actual operation.

Note 3. An exception occurs when the table reference interrupt vector is read.

Note 4. If data is to be stored in the general-purpose register r0, 0 is stored.

Note 5. The values differ from those for G3M.

Note: dst: destination register number, src: source register number

(q) RBASE — Reset vector base address register

This register indicates the reset vector address when there is a reset. If the PSW.EBV bit is 0, this vector address is also used as the exception vector address.

Table 3.23 RBASE Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 9	RBASE31-9	These bits indicate the reset vector when there is a reset. When PSW.EBV = 0, this address is also used as the exception vector. The RBASE8 to 0 bits are implicitly set to 0.	R	*1
8 to 1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	RINT	When the RINT bit is set, the offset address of the exception handler used during interrupt servicing is decremented. See (1) <i>Direct vector method</i> in section 4.4.1 <i>Resets, Exceptions, and Interrupts</i> in <i>RH850G3MH User's Manual: Software</i> for the details. This bit is valid when PSW.EBV = 0.	R	*2

Note 1. The reset vector differs depending on the startup area in this product. For details, see **Section 4, Address Space**.

Note 2. The value is 0_B in this product.

(r) EBASE — Exception handler vector address register

This register indicates the exception handler vector address. This register is valid when the PSW.EBV bit is 1.

Table 3.24 EBASE Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 9	EBASE31-9	The exception handler routine address is changed to the address resulting from adding the offset address of each exception to the base address specified for this register. The EBASE8 to 0 bits are implicitly set to 0.	R/W	Undefined
8 to 1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	RINT	When the RINT bit is set, the offset address of the exception handler used during interrupt servicing is decremented. See (1) <i>Direct vector method</i> in section 4.4.1 <i>Resets, Exceptions, and Interrupts</i> in <i>RH850G3MH User's Manual: Software</i> for the details.	R/W	Undefined

(s) INTBP — Base address of the exception handler address table register

This register indicates the base address of the address table when the address table reference method is selected as the interrupt handler address selection method.

Table 3.25 INTBP Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 9	INTBP31-9	These bits indicate the base pointer address for an interrupt prescribed in the expanded specifications. The value indicated by these bits is the first address in the table used to determine the exception handler when the interrupt prescribed by the expanded specifications (EIINT0 to EIINT511) is acknowledged. The INTBP8 to INTBP0 bits are implicitly set to 0.	R/W	Undefined
8 to 0	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0

(t) PID — Processor ID register

The PID register retains a processor identifier that is unique to the CPU. The PID register is a read-only register.

CAUTION

The PID register indicates information used to identify the incorporated CPU core and CPU core configuration. Usage such that the software behavior varies dynamically according to the PID register information is not assumed.

Table 3.26 PID Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 24	PID	Architecture identifier This identifier indicates the architecture of the processor.	R	05 _H
23 to 8		Function identifier This identifier indicates the functions of the processor. These bits indicate whether or not functions defined per bit are implemented (1: implemented, 0: not implemented). Bit 23-11 Reserved Bit 10 Double-precision floating-point operation function Bit 9 Single-precision floating-point operation function Bit 8 Memory protection function (MPU)	R	8007 _H
7 to 0		Version identifier This identifier indicates the version of the processor.	R	80 _H

Note 1. The value is 0580 0780_H in this product.

(u) SCCFG — SYSCALL operation setting register

This register is used to specify operations related to the SYSCALL instruction. Be sure to set an appropriate value to this register before using the SYSCALL instruction.

Table 3.27 SCCFG Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7 to 0	SIZE	These bits specify the maximum number of entries of a table that the SYSCALL instruction references. The maximum number of entries the SYSCALL instruction references is 1 if SIZE is 0, and 256 if SIZE is 255. By setting the maximum number of entries appropriately in accordance with the number of functions branched by the SYSCALL instruction, the memory area can be effectively used. If a vector exceeding the maximum number of entries is specified for the SYSCALL instruction, the first entry is selected. Place an error processing routine at the first entry.	R/W	Undefined

(v) SCBP — SYSCALL base pointer register

The SCBP register is used to specify a table address of the SYSCALL instruction and generate a target address. Be sure to set an appropriate value to this register before using the SYSCALL instruction.

Be sure to set a word address to the SCBP register.

Table 3.28 SCBP Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 2	SCBP31-2	These bits indicate the base pointer address of the SYSCALL instruction. These bits indicate the first address in the table used by the SYSCALL instruction.	R/W	Undefined
1, 0	SCBP1-0	These bits indicate the base pointer address of the SYSCALL instruction. These bits indicate the first address in the table used by the SYSCALL instruction. Always set this bit to 0.	R	0

(w) MCFG0 — Machine configuration register

This register indicates the CPU configuration.

Table 3.29 MCFG0 Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 24	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
23 to 16	SPID	Bit 23 to 18: These are not supported in this product (Reserved for future expansion. Be sure to clear to 0.) Bit 17, 16: These bits indicate the system protection number.	R/W	*2
15 to 3	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
2	—	(Reserved for future expansion. Be sure to set this bit to 1.)	R	1
1, 0	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0

Note 1. The value is 0001 0004_H in CPU1 (PE1) of this product.

Note 2. The value is 01_H in CPU1 (PE1) of this product.

(x) MCTL — Machine control register

This register is used to control the CPU.

Table 3.30 MCTL Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31	—	(Reserved for future expansion. Be sure to set this bit to 1.)	R	1
30 to 1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	UIC	This bit is used to control the interrupt enable/disable operation in user mode. When this bit is set to 1, executing the EI/DI instruction become possible in user mode.	R/W	0

(3) Interrupt Function Registers

The interrupt function system registers are read from or written to by using the LDSR or STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.31 Interrupt Function System Registers

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR10, 2	ISPR	Priority of interrupt being serviced	SV
SR11, 2	PMR	Interrupt priority masking	SV
SR12, 2	ICSR	Interrupt control status	SV
SR13, 2	INTCFG	Interrupt function setting	SV

(a) ISPR — Priority of interrupt being serviced register

This register holds the priority of the EIINTn interrupt being serviced. This priority value is then used to perform priority ceiling processing when multiple interrupts are generated.

Table 3.32 ISPR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 16	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
15 to 0	ISP15-0	These bits indicate the acknowledgment status of an EIINTn interrupt with a priority*1 that corresponds to the relevant bit position. 0: An interrupt request for an interrupt whose priority corresponds to the relevant bit position has not been acknowledged. 1: An interrupt request for an interrupt whose priority corresponds to the relevant position is being serviced by the CPU core.	R*3	0

The bit positions correspond to the following priority levels:

Bit	Priority
0	Priority 0 (highest)
1	Priority 1
	:
14	Priority 14
15	Priority 15

When an interrupt request (EIINTn) is acknowledged, the bit corresponding to the acknowledged interrupt request is automatically set to 1. If PSW.EP is 0 when the EIRET instruction is executed, the bit with the highest priority among the ISP15-0 bits that are set (0 is the highest priority) is cleared to 0.*2

While a bit in this register is set to 1, lower priority interrupts (EIINTn) are masked. Priority level judgment is therefore not performed when the system is determining whether to acknowledge an exception, meaning that exceptions will not be acknowledged. See section 4.1.5 *Interrupt Exception Priority and Priority Masking* in *RH850G3MH User's Manual: Software* for the details.

When performing software-based priority control using the PMR register, be sure to clear this register by using the INTCFG.ISPC bit.

- Note 1. See section 4.1.5 *Interrupt Exception Priority and Priority Masking* in *RH850G3MH User's Manual: Software* for the details.
- Note 2. Interrupt acknowledgment and auto-updating of values when the EIRET instruction is executed are disabled by setting the INTCFG.ISPC bit to 1. We recommend auto-updating, so in normal cases, clear the INTCFG.ISPC bit to 0.
- Note 3. This is R or R/W, depending on the setting of the INTCFG.ISPC bit. It is recommended to use this register as a read-only (R) register.

(b) PMR — Interrupt priority masking register

This register is used to mask the specified interrupt priority.

Table 3.33 PMR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 16	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
15 to 0	PM15-0	These bits mask an interrupt request with a priority level that corresponds to the relevant bit position. 0: Servicing of an interrupt request with a priority that corresponds to the relevant bit position is enabled. 1: Servicing of an interrupt request with a priority that corresponds to the relevant bit position is disabled.	R/W	0

The bit positions correspond to the following priority levels:

Bit	Priority
0	Priority 0 (highest)
1	Priority 1
	:
14	Priority 14
15	Priority 15 and priority 16 (lowest)

While a bit in this register is set to 1, interrupts (EIINTn) with the priority corresponding to that bit are masked. Priority level judgment is therefore not performed when the system is determining whether to acknowledge an exception, meaning that exceptions will not be acknowledged*¹.

Note 1. Specify the masks by setting the bits to 1 in order from the lowest-priority bit. For example, FF00_H can be set, but F0F0_H or 00FF_H cannot.

(c) ICSR — Interrupt control status register

This register indicates the interrupt control status in the CPU.

Table 3.34 ICSR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	PMEI	This bit indicates that an interrupt (EIINTn) with the priority level masked by the PMR register exists	R	0

(d) INTCFG — Interrupt function setting register

This register is used to specify settings related to the CPU's internal interrupt function.

Table 3.35 INTCFG Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	ISPC	<p>This bit changes how the ISPR register is written.</p> <p>0: The ISPR register is automatically updated. Updates triggered by the program (via execution of LDSR instruction) are ignored.</p> <p>1: The ISPR register is not automatically updated. Updates triggered by the program (via execution of LDSR instruction) are performed.</p> <p>If this bit is cleared to 0, the bits of the ISPR register are automatically set to 1 when an interrupt (EIINTn) is acknowledged, and cleared to 0 when the EIRET instruction is executed. In this case, the bits are not updated by an LDSR instruction executed by the program.</p> <p>If this bit is set to 1, the bits of the ISPR register are not updated by the acknowledgement of an interrupt (EIINTn) or by execution of the EIRET instruction. In this case, the bits can be updated by an LDSR instruction executed by the program.</p> <p>In normal cases, the ISPC bit should be cleared. When performing software-based priority control, however, set this bit to 1 and perform priority control by using the PMR register.</p>	R/W	0

(4) FPU Function Registers

(a) Floating-point operation registers

The FPU uses the CPU general-purpose registers (r0 to r31). There are no register files used only for floating-point operations.

- Single-precision floating-point instruction
Thirty-two 32-bit registers can be specified. These general-purpose registers correspond to r0 to r31.
- Double-precision floating-point instruction
Sixteen 64-bit registers can be specified. Paired general-purpose registers are used as register pairs ({r1, r0}, {r3, r2} ... {r31, r30}). Each register pair is specified in the instruction format with an even numbered register. Because r0 is a zero register (always holds "0"), in principle {r1, r0} should not be used by a double-precision floating-point instruction.

(b) Floating-point system registers

The FPU can use the following system registers to control floating-point operation. Reading from/writing to a floating-point system register is performed by specifying the system register number, which consists of the register number and selection identifier, with the LDSR or STSR instructions. For details of the registers, see *section 3.4.2 Floating-Point Function System Registers* in *RH850G3MH User's Manual: Software*.

Table 3.36 FPU Function System Registers

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR6, 0	FPSR	Floating-point operation setting/status	CU0 and SV
SR7, 0	FPEPC	Floating-point operation exception program counter	CU0 and SV
SR8, 0	FPST	Floating-point status	CU0
SR9, 0	FPCCR	Floating-point operation comparison result	CU0
SR10, 0	FPCFG	Floating-point function setting	CU0

(5) MPU function registers**(a) MPU function system registers**

The MPU function system registers are read from or written to by using the LDSR or STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.37 MPU Function System Registers (1/2)

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR0, 5	MPM	Memory protection operation mode setting	SV
SR1, 5	MPRC	MPU region control	SV
SR4, 5	MPBRGN	MPU base region number	SV
SR5, 5	MPTRGN	MPU end region number	SV
SR8, 5	MCA	Memory protection setting check address	SV
SR9, 5	MCS	Memory protection setting check size	SV
SR10, 5	MCC	Memory protection setting check command	SV
SR11, 5	MCR	Memory protection setting check result	SV
SR0, 6	MPLA0	Protection area minimum address	SV
SR1, 6	MPUA0	Protection area maximum address	SV
SR2, 6	MPAT0	Protection area attribute	SV
SR4, 6	MPLA1	Protection area minimum address	SV
SR5, 6	MPUA1	Protection area maximum address	SV
SR6, 6	MPAT1	Protection area attribute	SV
SR8, 6	MPLA2	Lower address of the protection area	SV
SR9, 6	MPUA2	Protection area maximum address	SV
SR10, 6	MPAT2	Protection area attribute	SV
SR12, 6	MPLA3	Protection area minimum address	SV
SR13, 6	MPUA3	Protection area maximum address	SV
SR14, 6	MPAT3	Protection area attribute	SV
SR16, 6	MPLA4	Protection area minimum address	SV
SR17, 6	MPUA4	Protection area maximum address	SV
SR18, 6	MPAT4	Protection area attribute	SV
SR20, 6	MPLA5	Protection area minimum address	SV
SR21, 6	MPUA5	Protection area maximum address	SV
SR22, 6	MPAT5	Protection area attribute	SV
SR24, 6	MPLA6	Protection area minimum address	SV
SR25, 6	MPUA6	Protection area maximum address	SV
SR26, 6	MPAT6	Protection area attribute	SV
SR28, 6	MPLA7	Protection area minimum address	SV
SR29, 6	MPUA7	Protection area maximum address	SV
SR30, 6	MPAT7	Protection area attribute	SV
SR0, 7	MPLA8	Protection area minimum address	SV
SR1, 7	MPUA8	Protection area maximum address	SV
SR2, 7	MPAT8	Protection area attribute	SV
SR4, 7	MPLA9	Protection area minimum address	SV
SR5, 7	MPUA9	Protection area maximum address	SV

Table 3.37 MPU Function System Registers (2/2)

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR6, 7	MPAT9	Protection area attribute	SV
SR8, 7	MPLA10	Protection area minimum address	SV
SR9, 7	MPUA10	Protection area maximum address	SV
SR10, 7	MPAT10	Protection area attribute	SV
SR12, 7	MPLA11	Protection area minimum address	SV
SR13, 7	MPUA11	Protection area maximum address	SV
SR14, 7	MPAT11	Protection area attribute	SV
SR16, 7	MPLA12	Protection area minimum address	SV
SR17, 7	MPUA12	Protection area maximum address	SV
SR18, 7	MPAT12	Protection area attribute	SV
SR20, 7	MPLA13	Protection area minimum address	SV
SR21, 7	MPUA13	Protection area maximum address	SV
SR22, 7	MPAT13	Protection area attribute	SV
SR24, 7	MPLA14	Protection area minimum address	SV
SR25, 7	MPUA14	Protection area maximum address	SV
SR26, 7	MPAT14	Protection area attribute	SV
SR28, 7	MPLA15	Protection area minimum address	SV
SR29, 7	MPUA15	Protection area maximum address	SV
SR30, 7	MPAT15	Protection area attribute	SV

(b) MPM — Memory protection operation mode register

The memory protection mode register is used to define the basic operating state of the memory protection function.

Table 3.38 MPM Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 11	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
10	DX	This bit is not supported in this product. (DX is reserved for future expansion. Be sure to clear to 0.)	R	0
9	DW	This bit is not supported in this product. (DW is reserved for future expansion. Be sure to clear to 0.)	R	0
8	DR	This bit is not supported in this product. (DR is reserved for future expansion. Be sure to clear to 0.)	R	0
7 to 2	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
1	SVP	In SV mode. (when PSW.UM = 0), this bit is used to specify whether to restrict access according to the SX, SW, and SR bits of the MPAT register for each protection area.*1 0: As usual, implicitly enable all access in SV mode. 1: Restrict access according to the SX, SW, and SR bits even in SV mode.*2	R/W	0
0	MPE	This bit is used to specify whether to enable or disable MPU function. 0: Disable 1: Enable	R/W	0

Note 1. If the SVP bit is set to 1, access will be restricted in accord with the setting for each protection area, even in SV mode. Therefore, specify the protection area before setting the SVP bit to prevent restriction of access by the program itself.

Note 2. If access is restricted in SV mode, execution of MDP exceptions or the MIP exception handling itself might not be possible depending on the settings. Be careful to specify settings so that access to the memory area necessary for the exception handler and exception handling is permitted.

(c) MPRC — MPU region control register

Bits used to perform special memory protection function operations are located in this register.

Table 3.39 MPRC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 16	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
15 to 0	E15-E0	These are the enable bits for each protection area. Bit En is a copy of bit MPATn.E (where n = 15 to 0). The number of the protection areas in this product is 16.	R/W	0

(d) MPBRGN — MPU base region register

This register indicates the minimum usable MPU area number.

Table 3.40 MPBRGN Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
4 to 0	MPBRGN	These bits indicate the smallest number of an MPU area. These bits are always read as 0.	R	0

(e) MPTRGN — MPU end region register

This register indicates the maximum usable MPU area number + 1.

Table 3.41 MPTRGN Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
4 to 0	MPTRGN	These bits indicate the largest number of an MPU area plus one. These bits always indicate the maximum number of MPU areas that the hardware can support. The number of the protection areas in this product is 16.	R	10 _H

(f) MCA — Memory protection setting check address register

This register is used to specify the base address of the area for which a memory protection setting check is to be performed.

Table 3.42 MCA Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	MCA31-0	These bits are used to specify the start address of the memory area subject to a memory protection setting check in bytes.	R/W	Undefined

(g) MCS — Memory protection setting check size register

This register is used to specify the size of the area for which a memory protection setting check is to be performed.

Table 3.43 MCS Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	MCS31-0	These bits specify the size of the target area to specify the size of memory area subject to a memory protection setting check in bytes. These bits specify the size in bytes of a memory area that is subject to a memory protection setting. Checking in areas below the address value in the MCS register is not possible because the specified size is handled as an unsigned integer. Do not set 0000 0000 _H in the MCS register.	R/W	Undefined

(h) MCC — Memory protection setting check command register

This register specifies the starting command for checking the memory protection setting.

Table 3.44 MCC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	MCC31- MCC0	When any value is written to the MCC register, a memory protection setting check starts. Setting the MCA and MCS registers and then writing to this register leads to storage of the result of checking in the MCR register. Since writing any value to this register starts the check, doing so does not require any extra registers when r0 is used as a source register. The result of checking is reflected in MCR according to any area setting regardless of the setting of the PSW.UM bit. The value read from the MCC register is always 0000 0000 _H .	R/W	0

(i) MCR — Memory protection setting check result register

This register is used to store the results of a memory protection setting check.

Be sure to clear bit 31 to 9 and 7 to 6.

CAUTIONS

1. If the area for which checking is specified crosses 0000 0000_H, the area is judged to have been specified incorrectly, and the MCR.OV bit is set to 1. For this reason, in access to the results of checking, check the MCR.OV bit and confirm that the result is valid (OV = 0) before using any results of checking.
2. With the default settings (for MPM.DX, MPM.DW, MPM.DR) of 1, the correct result may not be obtained. If the specified default is to be enabled, do not use the memory protection setting check function.

	Value after reset Undefined																																																

Table 3.45 MCR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 9	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
8	OV	If the specified area includes 0000 0000 _H or 7FFF FFFF _H , 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined
7, 6	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
5	SXE	If the specified area is contained within one protection area and execution is permitted for that area in supervisor mode, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined
4	SWE	If the specified area is contained within one protection area and writing to that area is permitted in supervisor mode, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined
3	SRE	If the specified area is contained within one protection area and reading from that area is permitted in supervisor mode, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined
2	UXE	If the specified area is contained within one protection area and execution is permitted for that area in user mode, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined
1	UWE	If the specified area is contained within one protection area and writing to that area is permitted in user mode, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined
0	URE	If the specified area is contained within one protection area and reading from that area is permitted in user mode, 1 is stored in this bit. In other cases, 0 is stored in this bit.	R/W	Undefined

(j) MPLAn — Protection area minimum address register

These registers indicate the minimum address of area n (where n = 0 to 15). The number of the protection areas in this product is 16.

Table 3.46 MPLAn Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 2	MPLA31-2	These bits indicate the minimum address of area n. The MPLA1-0 bits are implicitly set to 0.	R/W	Undefined
1, 0	—	Reserved for future expansion. Be sure to clear these bits to 0.	R	0

(k) MPUAn — Protection area maximum address register

These registers indicate the maximum address of area n (where n = 0 to 15). The number of the protection areas in this product is 16.

Table 3.47 MPUAn Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 2	MPUA31-2	These bits indicate the maximum address of area n. The MPUA1-0 bits are implicitly set to 1.	R/W	Undefined
1, 0	—	Reserved for future expansion. Be sure to clear these bits to 0.	R	0

(I) MPATn — Protection area attribute register

These registers indicate the attributes of area n (where n = 0 to 15). The number of the protection areas in this product is 16.

Table 3.48 MPATn Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 26	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
25 to 16	ASID	These bits indicate the ASID value to be used as the area match condition.	R/W	Undefined
15 to 8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7	E	This bit indicates whether area n is enabled or disabled. 0 : Area n is disabled. 1 : Area n is enabled.	R/W	0
6	G	0: ASID match is the condition. 1: ASID match is not the condition. When this bit is 0, the condition of the area match is MPATn.ASID = ASID.ASID. When this bit is 1, the area match of the values of MPATn.ASID and ASID.ASID is not the condition.	R/W	Undefined
5	SX	This bit indicates the execution privilege in supervisor mode.*1 0 : Execution is disabled. 1 : Execution is enabled.	R/W	Undefined
4	SW	This bit indicates the write permission in supervisor mode.*1 0 : Writing is disabled. 1 : Writing is enabled.	R/W	Undefined
3	SR	This bit indicates the read permission in supervisor mode*1 0 : Reading is disabled. 1 : Reading is enabled.	R/W	Undefined
2	UX	This bit indicates the execution privilege in user mode. 0 : Execution is disabled. 1 : Execution is enabled.	R/W	Undefined
1	UW	This bit indicates the write permission in user mode. 0 : Writing is disabled. 1 : Writing is enabled.	R/W	Undefined
0	UR	This bit indicates the read permission in user mode. 0 : Reading is disabled. 1 : Reading is enabled.	R/W	Undefined

Note 1. If access is restricted in SV mode, execution of MDP exceptions or the MIP exception handling itself might not be possible depending on the settings. Be careful to specify settings so that access to the memory area necessary for the exception handler and exception handling is permitted.

(6) Cache Operation Function registers

(a) Cache control function system registers

The cache control function system registers are read from or written to by using the LDSR or STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.49 Cache Operation Function System Registers

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR16, 4	ICTAGL	Instruction cache tag Lo access	SV
SR17, 4	ICTAGH	Instruction cache tag Hi access	SV
SR18, 4	ICDATL	Instruction cache data Lo access	SV
SR19, 4	ICDATH	Instruction cache data Hi access	SV
SR24, 4	ICCTRL	Instruction cache control	SV
SR26, 4	ICCFG	Instruction cache configuration	SV
SR28, 4	ICERR	Instruction cache error	SV

(b) ICTAGL — Instruction cache tag Lo access register

This register is used for CIST and CILD instructions for the instruction cache. This register holds values to be stored in the tag RAM of the instruction cache by the execution of CIST instructions and values read from the tag RAM of the instruction cache by the execution of CILD instructions.

Table 3.50 ICTAGL Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 11	LPN	These bits hold the values of bits 24 to 11, i.e. the physical page numbers. When writing, always write 0 to bits 31 to 25.	R/W	Undefined
10 to 6	—	Reserved for future expansion. When writing, always write 0 to these bits.	R	0
5, 4	LRU	These bits indicate the LRU information of the specified cache line. The CIST instruction cannot be used to change the LRU information to desired values.	R/W	Undefined
3	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
2	L	This bit holds the lock information.	R/W	Undefined
1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	V	This bit retains whether the specified cache line is enabled or disabled.	R/W	Undefined

(c) ICTAGH — Instruction cache tag Hi access register

This register is used for a CIST or CILD instruction for the instruction cache. This register stores the value to be stored in the instruction cache tag RAM on CIST execution and the value read from the instruction cache tag RAM on CILD execution.

Table 3.51 ICTAGH Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31	WD	When this bit is set to 1, executing a CIST instruction updates the cache data RAM.	R/W	Undefined
30	PD	When this bit is set to 1, executing a CIST instruction writes the value in the DATAECC field of this register to the ECC field of the data RAM.	R/W	Undefined
29	WT	This bit updates the cache tag RAM when this bit is set to 1 before CIST execution.	R/W	Undefined
28	PT	This bit writes the value in TAGECC field to ECC for tag RAM when this bit is set to 1 before CIST execution.	R/W	Undefined
27 to 24	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
23 to 16	DATAECC	These bits retain ECC of the data RAM.	R/W	Undefined
15 to 8	TAGECC	These bits retain ECC of the tag RAM. Be sure to clear bits 15 and 14 to 0.	R/W	Undefined
7	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
6	—	(Reserved for future expansion. Be sure to clear to 0.)	R	Undefined
5 to 2	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
1, 0	—	(Reserved for future expansion. Be sure to clear to 0.)	R	Undefined

(d) ICDATL — Instruction cache data Lo access register

This register is used for a CIST or CILD instruction for the instruction cache. This register stores the value to be stored in the instruction cache data RAM on CIST execution and the value read from the instruction cache data RAM on CILD execution.

Table 3.52 ICDATL Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	DATAL	These bits retain the value of bits 31 to 0, 95 to 64, 159 to 128, or 223 to 192 out of the instruction data of the block within the specified cache line. The offset of the index specifies the target range of bit numbers. Index offset = 0000: bits 31 to 0 Index offset = 01000: bits 95 to 64 Index offset = 10000: bits 159 to 128 Index offset = 11000: bits 223 to 192 Data alignment is shown in Figure 3.4.	R/W	Undefined

(e) ICDATH — Instruction cache data Hi access register

This register is used for a CIST or CILD instruction for the instruction cache. This register stores the value to be stored in the instruction cache data RAM on CIST execution and the value read from the instruction cache data RAM on CILD execution.

Table 3.53 ICDATH Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	DATAH	These bits retain the value of bits 63 to 32, 127 to 96, 191 to 160, or 255 to 224 out of the instruction data of the block within the specified cache line. The offset of the index specifies the target range of bit numbers. Index offset = 0000: bits 63 to 32 Index offset = 01000: bits 127 to 96 Index offset = 10000: bits 191 to 160 Index offset = 11000: bits 255 to 224 Data alignment is shown in Figure 3.4 .	R/W	Undefined

(f) ICCTRL — Instruction cache control register

This register controls the instruction cache.

Table 3.54 ICCTRL Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 17	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
16	—	(Reserved for future expansion. Be sure to clear to 1.)	R	1
15 to 9	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
8	ICHCLR	Setting this bit to 1 selects clearing of the whole instruction cache in a single operation. After this bit has been set to 1, it will be read as 1 until clearing is completed. The bit is cleared to 0 once clearing of the cache is completed.	R/W	0
7 to 3	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
2	ICHEIV	Setting this bit to 1 allows the instruction cache to be automatically disabled (ICHEN bit to be cleared to 0) when a cache error occurs.	R/W	0
1	ICHEMK	Setting this bit to 1 selects masking of cache error exception notifications for the CPU when cache errors are encountered.	R/W	1
0	ICHEN	This bit disables or enables the instruction cache. 0: Instruction cache is disabled. 1: Instruction cache is enabled. This bit is read as the previous value until the setting is actually reflected in the instruction cache.	R/W	1

(g) ICCFG — Instruction cache configuration register

This register shows the configuration of the instruction cache.

Table 3.55 ICCFG Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 15	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
14 to 8	ICHSIZE	These bits indicate the capacity (in Kbytes) of the instruction cache. The setting is 8 Kbytes in this product. 000 1000: 8 Kbytes	R	08 _H
7 to 4	ICHLINE	These bits indicate the number of lines per 1 way in the instruction cache. The setting is 64 lines in this product. 0100: 64 lines	R	2 _H
3 to 0	ICHWAY	These bits indicate the number of ways of the instruction cache. The setting is 4 ways in this product. 0100: 4 ways	R	4 _H

(h) ICERR — Instruction cache error register

This register stores cache error data of the instruction cache.

Once the ICHERR bit is set to 1, subsequent cache error data is not stored in this register until the ICHERR bit is cleared to 0. However, Error status bits (ESMH, ESPBSE, ESTE1, ESTE2, ESDC, ESDE) are accumulated.

Table 3.56 ICERR Register Contents (1/2)

Bit Position	Bit Name	Function	R/W	Value after Reset
31	CISTW	This bit is set to indicate that the destination way specified for a CISTI instruction was in error. Although the entry information is overwritten so that writing is completed, the V bit will be cleared the next time the cache line is read (i.e. reading will be judged to have missed the cache). However, setting of this bit is not accompanied by an exception for the CPU.	R/W	Undefined
30	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
29	ESMH	Error status: multi-hit	R/W	Undefined
28	ESPBSE	Error status: way error	R/W	Undefined
27	ESTE1	Error status: 1-bit error in the tag RAM	R/W	Undefined
26	ESTE2	Error status: 2-bit error in the tag RAM	R/W	Undefined
25	ESDC	Error status: 1-bit correction in the data RAM	R/W	Undefined
24	ESDE	Error status: 2-bit error in the data RAM	R/W	Undefined
23, 22	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
21	ERMMH	Error exception notification mask: multi-hit	R/W	0
20	ERMPBSE	Error exception notification mask: way error	R/W	0
19	ERMTE1	Error exception notification mask: 1-bit error in the tag RAM	R/W	0
18	ERMTE2	Error exception notification mask: 2-bit error in the tag RAM	R/W	0

Table 3.56 ICERR Register Contents (2/2)

Bit Position	Bit Name	Function	R/W	Value after Reset
17	ERMDC	Error exception notification mask: 1-bit correction in the data RAM	R/W	0
16	ERMDE	Error exception notification mask: 2-bit error in the data RAM	R/W	0
15	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
14, 13	ICHEWY	These bits retain a way number where a cache error occurs.	R/W	Undefined
12 to 5	ICHEIX	These bits retain a cache index where a cache error occurs.	R/W	Undefined
4	ICHERQ	Setting of this bit to 1 indicates that the CPU is being notified of a cache error exception. If cache error exceptions are masked, however, the CPU is not notified of an exception even when this bit is set to 1.	R/W	0
3	ICHED	This bit indicates that an error occurs in the data RAM.	R/W	0
2	ICHET	This bit indicates that an error occurs in the tag RAM.	R/W	0
1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	ICHERR	This bit is set to 1 when a cache error occurs.	R/W	0

(7) LSU Control Register

Table 3.57 LSU Control Register

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR8, 13	LSUCR	LSU Control Register	SV

(a) LSUCR — LSU Control Register

This register sets the wait for execution of instructions before and after a bit-manipulation instruction. Setting the BBOPEN bit to 1 leads to the normal detection of events in response to a load or store instruction following execution of the specified bit-manipulation instruction (CLR1, NOT1, SET1, or TST1). For precautions regarding the setting of this register, see **Section 3.5.6, Setting for Blocking of Bit-Manipulation Instructions.**

Table 3.58 LSUCR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 28	CBAKEY	These are key bits to enable reading from or writing to the BBOPEN bit of the LSUCR register. The procedure for unlocking is as follows. (1) Write 1100 to these bits. (2) Write 1101 to these bits (this is only possible when the value of these bits is 1100). The BBOPEN bit is accessible when the value of these bits is 1101. If any other value is set, the BBOPEN bit cannot be accessed. These bits are read as 0000 when the setting is not 1101.	R/W	0000
27 to 22	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
21	—	(Reserved for future expansion. Be sure to set this bit to 1. However, this bit is read as 1 only when CBAKEY = 1101. If CBAKEY is not 1101, the setting of this bit is 0.)	R	0
20	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
19	BBOPEN	This bit sets the wait between a bit-manipulation instruction and the previous and subsequent load/store instructions 0: A bit-manipulation instruction is executed without waiting for the previous load/store instruction. The subsequent load/store instruction is executed without waiting for the completion of the bit-manipulation instruction. 1: A bit-manipulation instruction is executed after waiting for the previous load/store instruction. The subsequent load/store instruction is executed after the completion of the bit-manipulation instruction. This bit is only readable or writable while CBAKEY = 1101. If CBAKEY is not 1101, this bit is read as 0.	R/W	0
18	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
17	—	(Reserved for future expansion. Be sure to set this bit to 1. However, this bit is read as 1 only when CBAKEY = 1101. If CBAKEY is not 1101, the setting of this bit is 0.)	R	0
16	—	(Reserved for future expansion. Be sure to set this bit to 1. However, this bit is read as 1 only when CBAKEY = 1101. If CBAKEY is not 1101, the setting of this bit is 0.)	R	0
15 to 0	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0

(8) Data Buffer Operation Function Registers

(a) Data buffer control function system registers

The data buffer control function system registers are read from or written to by using the LDSR or STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.59 Data Buffer Operation Function Registers

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR24,13	CDBCR	Data buffer control register	SV

(b) CDBCR — Data Buffer Control Register

This register controls the data buffer.

Table 3.60 CDBCR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 2	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
1	CDBCLR	When this bit is set to 1, the data buffer is cleared at a time. This bit is always read as 0.	W	0
0	CDBEN	This bit disables or enables the data buffer. 0: Data buffer is disabled. 1: Data buffer is enabled.	R/W	1

3.2.2 Instruction Cache and Data Buffer

3.2.2.1 Features

An 8-Kbyte and 4-way set associative instruction cache is mounted between the CPU1 and the code flash. The instruction cache and the code flash are connected to each other via a 256-bit dedicated bus to minimize penalties caused by a cache miss-hit. Also a data buffer is mounted between the CPU1 and the code flash to achieve high-speed data access. The 32-MB area from 0000 0000_H to 01FF FFFF_H in the address space is intended for the instruction cache and data buffer.

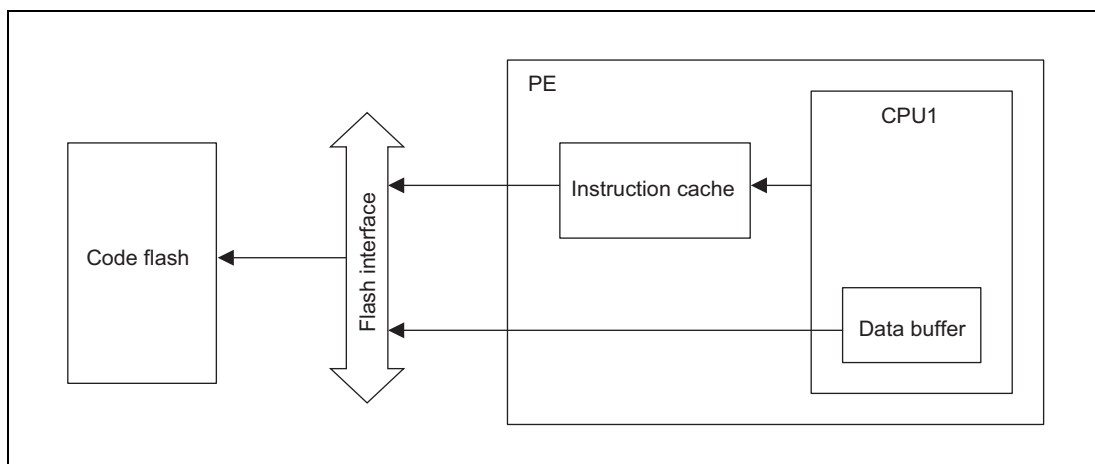

Figure 3.2 Instruction Cache and Data Buffer

3.2.2.2 Instruction Cache Function

The instruction cache is 4-way set associative and its total capacity is 8 Kbytes. The cache line size is 32 Kbytes. If a cache miss occurs, each line is refilled by a replace algorithm using LRU. The data size for fetching is 8 bytes. Eight bytes of data specified by an offset within a line are selected.

The ways are divided into two groups, way group 0 consisting of way 0 and way 1 and way group 1 consisting of way 2 and way 3. The way group can be selected and used by decoding of the address information of the access destination. CPU instruction fetches from the code flash are performed via the instruction cache.

Figure 3.3 Instruction Cache Configuration

Tag Array

- TAG Among 32 bits in the operable addresses of the data line to be cached, bits 24 to 11 are stored in this bit. The TAG bit is not initialized by reset.
- ECC The ECC of the tag array is stored in this bit. The ECC bit is not initialized by reset.

Valid/Lock

- V bit This bit indicates whether valid data is stored in the cache line. Setting of this bit to 1 makes the cache line data valid. The V bit is initialized to 0 by reset.
- L bit This bit indicates whether a cache line is locked or not. Setting of this bit to 1 locks the cache line and it cannot be replaced with new data. The L bit is valid only when the V bit is 1. The L bit is initialized by a reset.

Data Array

- DATA The 256-bit cache line data is stored per 64 bits in each bank. The storage location of each data is determined by the way and offset. Data alignment is shown in **Figure 3.4**. The DATA is not initialized by a reset.
- ECC The ECC for the data array is stored. The ECC is not initialized by a reset.

LRU

- LRU The LRU information in the same way group is stored in this data array. The LRU is initialized by a reset.

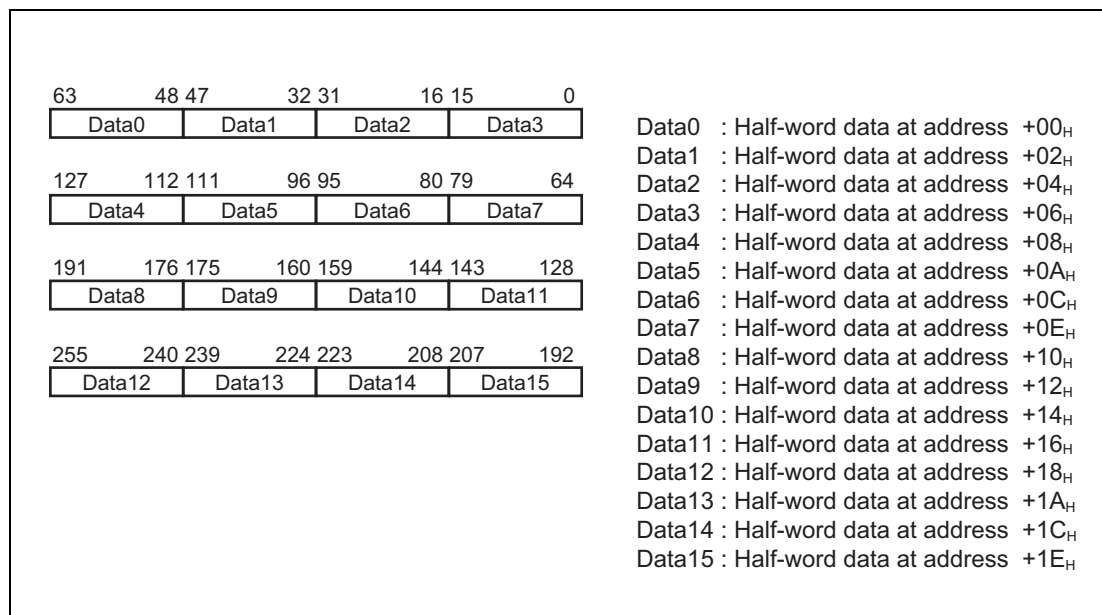

Figure 3.4 Data Alignment in the Instruction Cache

3.2.2.3 Data Buffer Function

The eight-line buffer with 128 bits per line is mounted as a data buffer. 256-bit data read from the code flash is stored in the data buffer in 128-bit units. The data is read out from the data buffer after the next access to the same address, so the code flash is not accessed again.

3.2.3 Inter-Processor Interrupts

Registers (IPIR_CHn) for interrupt communication between PEs are provided for four channels.

IPIR_CH0 to IPIR_CH3 are assigned to CH0 to CH3 of user interrupt (EIINT). An interrupt for specific PEs (including own PE) can be requested by manipulating bits corresponding to respective PEs.

3.2.3.1 Inter-Processor Interrupt Control Registers

This register is located in the CPU peripheral of each PE. IPIR_CH0 to IPIR_CH3 registers are assigned to each PE which are accessible only from their own PE.

Table 3.61 List of Registers

Register Symbol	Register Name	R/W	Value after Reset	Access Size				Address
				1	8	16	32	
IPIR_CH0	Inter-PE interrupt register 0	R/W	0000 0000 _H	√	√	√	√	FFFE EC80 _H
IPIR_CH1	Inter-PE interrupt register 1	R/W	0000 0000 _H	√	√	√	√	FFFE EC84 _H
IPIR_CH2	Inter-PE interrupt register 2	R/W	0000 0000 _H	√	√	√	√	FFFE EC88 _H
IPIR_CH3	Inter-PE interrupt register 3	R/W	0000 0000 _H	√	√	√	√	FFFE EC8C _H

(1) IPIR_CHn — Inter-PE Interrupt Register n (n = 0 to 3)

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	—	—	—	—	—	PE3	—	PE1
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W

Table 3.62 IPIR_CHn Interrupt Register Contents

Bit Position	Bit Name	Function
2	PE3	Inter-PE Interrupt Request to PE3 Writing 1 to this bit makes an interrupt request to PE3. This bit is automatically cleared to 0 when the interrupt request has been notified. 0: Inter-PE interrupt request output is not specified or an interrupt request is not being output. 1: Interrupt request output is specified or an interrupt request is being output.
0	PE1	Inter-PE Interrupt Request to PE1 Writing 1 to this bit makes an interrupt request to PE1. This bit is automatically cleared to 0 when the interrupt request has been notified. 0: Inter-PE interrupt request output is not specified or an interrupt request is not being output. 1: Interrupt request output is specified or an interrupt request is being output.

3.2.4 Reliability Functions

3.2.4.1 PE Guard Function (PEG)

(1) Overview of the PEG Function

The PEG is a constituent of the slave guard system to prevent unauthorized access to the resources in the PE from the external master. This function protects access to the local RAM in the PE. In the initial state after a reset, all access by masters other than the PE itself is disabled. Setting the registers listed in **(3) List of PEG Protection Setting Registers**, enables access by masters other than the PE itself.

1. Detecting PE guard violation
If the external master outside the PE makes an unauthorized access to the resource area in the PE for which PE guard is set, the access is detected as a PE guard violation.
2. Blocking unauthorized accesses
When a PE guard violation is detected, unauthorized accesses to the internal resources of the PE are blocked to prevent the contents of PE resources from being modified illegally.
3. Notifying occurrence of violation
When a PE guard violation is detected, it is notified to ECM. When the DMAC or DTS makes an unauthorized access, a DMA transfer error is detected.

(2) Protection Made by PEID and SPID

- Setting PEG Protection
 - Up to four areas can be set depending on the local RAM address of the own PE.
 - The area range is specified by the base address and the mask bit (4 Kbytes to 2 Mbytes).
 - “Read enable” and “write enable” can be set for each area.
 - Enabling or disabling can be selected for each area by a system protection identifier (SPID) and processor element ID number (PEID).
- Access permission by the processor element (PEID) and system protection identifier (SPID) (see **Figure 3.5**)
 1. When the local RAM area is to be accessed, go to step 2.
Otherwise, return an error response.
 2. When any of enabled area 0 to area 3 is to be accessed, go to step 3.
Otherwise, return an error response.
 3. Whether or not all the conditions below for the relevant area are met.
 - The system protection identifier (SPID) is enabled.
 - The processor element (PEID) is enabled.
 - Required operations (read/write) are enabled.
 Otherwise, return an error response.

If the operations listed in the following table are not permitted by the memory access type, an error response is returned. Bit ops (bit-manipulation instruction) and CAXI are not passed if neither reading nor writing operations are permitted.

Table 3.63 Memory Access Operation Required for Each Request Type

Request Type	Read	Write
READ	√	—
WRITE	—	√
BitOp	√	√
CAXI	√	√
LDL	√	—
STC	—	√

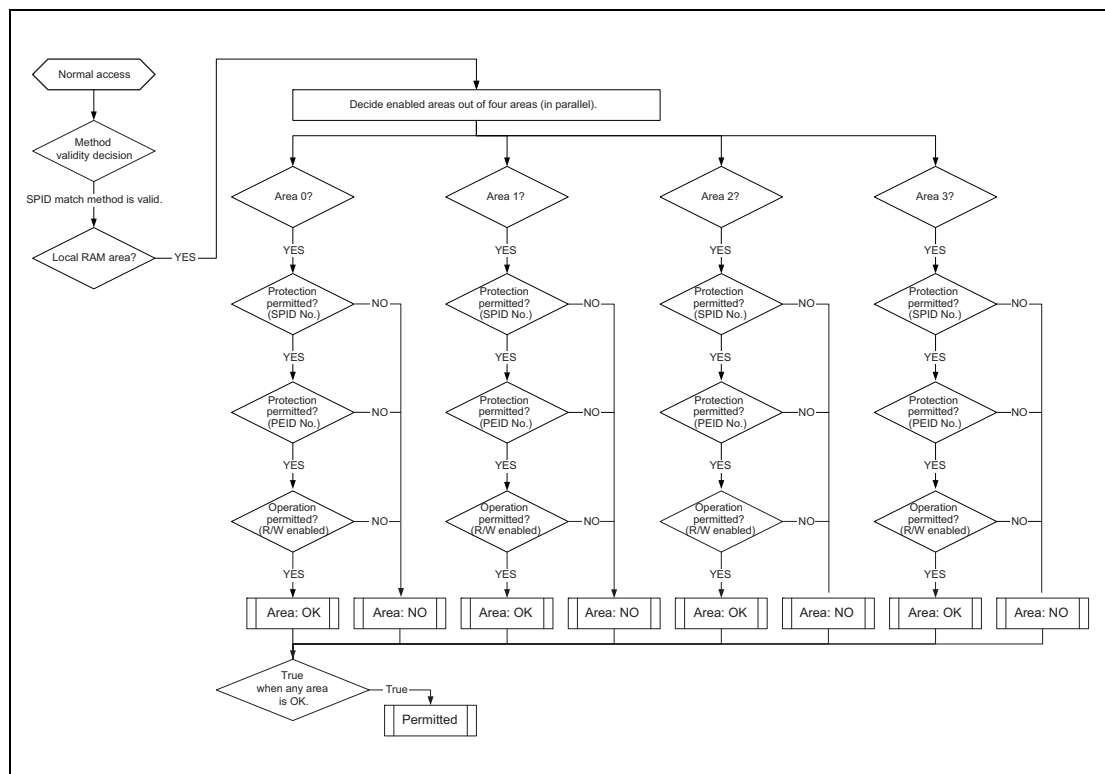

Figure 3.5 Access Permission by the Processor Element (PEID) and System Protection Identifier (SPID)

(3) List of PEG Protection Setting Registers

Make necessary settings for the following registers to protect PE resources from unauthorized accesses by the external master.

- Accesses to the peripheral device area and the local RAM area in the PE are permitted as detection targets.
- For accesses to the register set, no access restriction is provided independently for the PEG function. Set access protections such as IPG at the user side as necessary.

Table 3.64 Base Address of PEG Register: FFFE E600_H

Address Offset	Size (Byte)	Register Name	Abbreviation	Right *1	R/W	Operable Bit				Value after Reset
						1	8	16	32

+0A8 _H	4	PE guard area 2 SPID setting register	PEGG2SP	—	R/W	—	√	√	√	0000 0000 _H
+0AC _H	4	PE guard area 2 PEID setting register	PEGG2PE	—	R/W	—	√	√	√	0000 0000 _H
+0B0 _H	4	PE guard area 3 mask setting register	PEGG3MK	—	R/W	—	√	√	√	FFE0 0000 _H
+0B4 _H	4	PE guard area 3 base setting register	PEGG3BA	—	R/W	—	√	√	√	*1
+0B8 _H	4	PE guard area 3 SPID setting register	PEGG3SP	—	R/W	—	√	√	√	0000 0000 _H
+0BC _H	4	PE guard area 3 PEID setting register	PEGG3PE	—	R/W	—	√	√	√	0000 0000 _H

Note 1. The value of CPU1 (PE1) after reset is FEA0_0000_H.

(4) Register Set**(a) PEGSP — PE Guard SPID Master Decision Control Register**

This register is used to enable or disable access by an external master to the resources in the PE. The initial value of the SPEN bit is 0, which disables access to PE resources by an external master. Setting the SPEN bit to 1 enables access by an external master under the conditions set by PEGGnBA and PEGGnMK.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SPEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 3.65 PEGSP Register Contents

Bit Position	Bit Name	Function
15 to 1	—	Reserved These bits are always read as 0. The write value should always be 0.
0	SPEN	This bit enables or disables detection of accesses by the external master having SPID. 0: Detection of accesses by the external master having SPID is disabled. 1: Detection of accesses by the external master having SPID is enabled.

(b) PEGGnMK — PE Guard Area n Mask Setting Register

In combination with the PEGGnBA register, this register specifies a range or ranges within PE guard protection area n. Setting a GnMASK bit to 1 masks the corresponding address bit in the PEGGnBA register and places the corresponding area or areas inside the range of PE guard area n. The minimum size of the PE guard protection area is 4 KB. Though the PEGGnMK[31:21] bits are readable and writable, they are handled as below when determining access to the PEID and SPID, and the actual value of PEGGnMK[31:21] is ignored.

- PEGGnMK[31:21] = 1111_1111_111B

In combination with the PEGGnBA register, this register can protect the area of FEA0_0000H to FEBF_FFFFH from access by CPU1 (PE1) as an external master.

Ex.) With the settings of PEGGnBA[31:12] = FEBF6_H and PEGGnMK[31:12] = 00008_H, the PE guard protection area n is specified within the ranges from FEBF 6000_H to FEBF 6FFF_H and FEBF E000_H to FEBF EFFF_H.

Writing to the PEGGnMK register leads to the GnEN register for the PEGGnBA register of group n being automatically set to 0. This is to prevent unexpected access by an external master while the access area is being set.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	GnMASK															
Value after reset	1	1	1	1	1	1	1	1	1	1	1	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	GnMASK				—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R

Table 3.66 PEGGnMK Register Contents

Bit Position	Bit Name	Function
31 to 12	GnMASK	These bits determine whether to mask the base address PEGGnBA[31:12] that specifies the range of PE guard protection area n. 0: Target address bits are not compared when determining the PE guard area. 1: Target address bits are compared when determining the PE guard area.
11 to 0	—	Reserved These bits are always read as 0. The write value should always be 0.

(c) PEGGnBA — PE Guard Area n Base Setting Register

In combination with the PEGGnMK register, this register specifies a range or ranges within PE guard protection area n and sets the access enable conditions for the specified area. Setting the GnEN bit to 1 brings the address enable conditions specified by this register and the PEGGnMK register into effect. Though the PEGGnBA[31:21] bits are readable and writable, they are handled as below when determining access to the PEID and SPID, and the actual value of PEGGnBA[31:21] is ignored.

- Detection of access to the internal resource of CPU1 (PE1): PEGGnBA[31:21] = 1111_1110_101B

In combination with the PEGGnBA register, this register can protect the area of FEA0_0000H to FEBF_FFFFH from access by CPU1 (PE1) as an external master.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R/W	R	R/W	R/W	R/W

Note 1. The value is 1_B in CPU1 (PE1) of this product.

Table 3.67 PEGGnBA Register Contents

Bit Position	Bit Name	Function
31 to 12	GnBASE	Base address that specifies PE guard protection area n
11 to 5	—	Reserved These bits are always read as 0. The write value should always be 0.
4	GnLOCK	Prohibits writing to system registers of protection area n. This bit can be set to 1 but cannot be set to 0. 0: Writing to PEGGnMK, PEGGnBA, PEGGnSP, and PEGGnBA is permitted. 1: Writing to PEGGnMK, PEGGnBA, PEGGnSP, and PEGGnBA is not permitted.
3	—	Reserved These bits are always read as 0. The write value should always be 0.
2	GnWR	Enables write access to PE guard protection area n. 0: Write access is disabled. 1: Write access is enabled.
1	GnRD	Enables read access to PE guard protection area n. 0: Read access is disabled. 1: Read access is enabled.
0	GnEN	PE guard protection area n enable 0: Settings for access enable conditions are disabled 1: Settings for access enable conditions are enabled

CAUTION

PEGGnBA.GnEN is cleared by writing to the PEGGnMK register.

(d) PEGGnSP —PE guard area n SPID setting register

This register enables access to PE guard protection area n from the external master of SPID.

Setting the PEGGnSP[m] bit to 1 enables access by an external master having SPID = m.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	—	—	—	—	—	—	—	GnSP				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 3.68 PEGGnSP Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	GnSP	These bits enable access to PE guard protection area n from the external master of SPID. 0: Access by an external master having SPID = m is blocked. 1: Access by an external master having SPID = m is enabled.

(e) PEGGnPE —PE guard area n PEID setting register

This register enables access to PE guard protection area n from the external master of PEID.

Setting the PEGGnPE[m] bit to 1 enables access by an external master having PEID = m.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 3.69 PEGGnPE Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	GnPE	These bits enable access to PE guard protection area n from the external master of PEID. 0: Access by an external master having PEID = m is blocked. 1: Access by an external master having PEID = m is enabled.

3.2.4.2 PE's Internal Peripheral Device Protection Function (IPG)

(1) Overview of the IPG Function

The IPG is a system to prevent unauthorized accesses to peripheral devices from the CPU core equipped with the IPG. The IPG achieves the following functions. The IPG covers accesses to peripheral devices in the CPU.

(1) Detecting violation of peripheral device protection

If the CPU makes an unauthorized access to an area (peripheral device) for which peripheral device protection is set, the access is detected as “violation of peripheral device protection.”

(2) Storing unauthorized-access information

When a violation of peripheral device protection is detected, the unauthorized-access information is stored in the IPG's internal register.

(3) Blocking unauthorized accesses

When a violation of peripheral device protection is detected, unauthorized accesses to peripheral devices are blocked to prevent contents of peripheral devices from being modified illegally.

(4) Notifying violation

When a violation of peripheral device protection is detected, a system error exception (SYSERR exception) request for generating an exception is made to ask the CPU to stop the processing.

For system error exceptions (SYSERR exceptions), see **Section 3.2.4.3, System Error Notification Control Function (SEG)**.

(5) Invalidating subsequent accesses

When a violation of peripheral device protection is detected, subsequent access to all target areas by any transfer types (regardless of whether access is or is not authorized) are blocked until instructions from the CPU are received.

NOTE

Even if a request for generating an exception is immediately sent to the CPU in step (4) above, a subsequent access issued (before receiving a request from the IPG) by the CPU that does not know an occurrence of violation may illegally modify contents of peripheral devices. (Accesses after a violation has occurred result in unauthorized accesses.)

(2) IPG Function

- (1) This function invalidates accesses in response to detection of violation of peripheral device protection according to their attributes (including address, transfer type, and access right).
- (2) After an access right violation is detected until the error flag (described later) is cleared by writing by the software, subsequent accesses are invalidated. However, invalidation is applied only to accesses from the CPU and is not applied to accesses from outside the CPU core. Invalidation is performed independently of addresses.
- (3) When a request for accessing different peripheral devices simultaneously is made due to misalignment or double-word access, the access is executed when all such accesses are enabled.

(3) IPG Protection Setting Registers for Illegal Users

To protect peripheral devices from unauthorized accesses by programs in user mode, the registers below require the settings listed in the table.

- Accesses in user mode are to be detected.
- This register set is intended for IPG settings related to user mode and reading of the IPG settings within its own machine.

Table 3.70 Base Address of IPG Register: FFFE E000_H

Address Offset	Size (Byte)	Register Name	Abbreviation	Right *1	R/W	Operable Bit				Value after Reset
						1	8	16	32	
+002 _H	2	Peripheral device protection violation access information register	IPGECRUM	SV	R/W	—	—	√	—	Undefined (retained)
+008 _H	4	Peripheral device protection violation access address register	IPGADRUM	SV	R/W	—	—	—	√	Undefined (retained)
+00D _H	1	Peripheral device protection enable register	IPGENUM	SV	R/W	√	√	—	—	00 _H
+020 _H	1	Reserved		SV	R	√	√	—	—	00 _H
+021 _H	1	Reserved		SV	R	√	√	—	—	00 _H
+022 _H	1	Peripheral device protection setting register 2	IPGPMTUM2	SV	R/W	√	√	—	—	00 _H
+023 _H	1	Peripheral device protection setting register 3	IPGPMTUM3	SV	R/W	√	√	—	—	00 _H
+024 _H	1	Peripheral device protection setting register 4	IPGPMTUM4	SV	R/W	√	√	—	—	00 _H

Note 1. Registers for which "SV" is described are accessible by SV right (UM = 0).

(4) Register Set**(a) IPGECRUM — Peripheral Device Protection Violation Access Information Register**

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	DS				EX	WR	RD	VD
Value after reset	0	0	0	0	0	0	0	0	x	x	x	x	x	x	x	x
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

x: Undefined (retained)

Table 3.71 Register Contents of IPGECRUM

Bit Position	Bit Name	Function
15 to 8	—	Reserved These bits are always read as 0. The write value should always be 0.
7 to 4	DS	These bits store the data size of access that made a violation. 0100: Word (4 bytes) 0010: Half-word (2 bytes) 0001: Byte Other than above: RFU CAUTION In the G3MH core, when a violation occurred in a read access, these bits always store 0100(Word).
3	EX	This bit is set to 1 when a violation occurred in an instruction fetch read access. In other cases, this bit is cleared to 0.
2	WR	This bit is set to 1 when a violation occurred in a write access or bit operation or CAXI. In other cases, this bit is cleared to 0.
1	RD	This bit is set to 1 when a violation occurred in a read access or bit operation or CAXI. In other cases, this bit is cleared to 0.
0	VD	This bit is set to 1 when a violation of peripheral device protection is detected by a program with the relevant right. Even if another violation of peripheral device protection is detected while this bit is 1, data of this IPGECR register and the IPGADRUM register is not updated and is retained.

NOTE

When the value of the IRE bit in the IPGENUM register (described later) is 0 and a transfer type that violates peripheral device protection is detected in a mode for detection or the current operation of the program being run by the user is reading to fetch an instruction, no bit of this register is updated.

(b) IPGADRUM — Peripheral Device Protection Violation Access Address Register

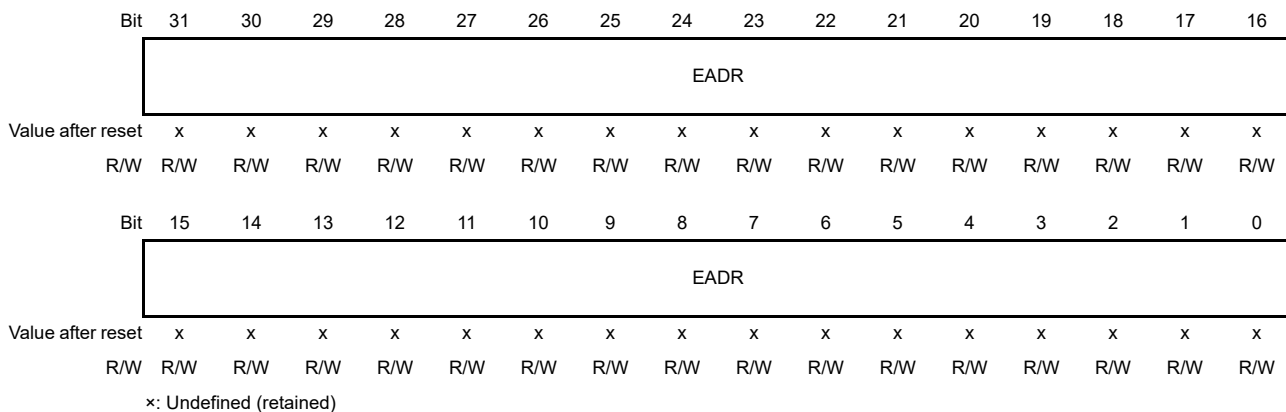

Table 3.72 Register Contents of IPGADRUM

Bit Position	Bit Name	Function
31 to 0	EADR	These bits store the address of the access in which a violation occurred.
CAUTION		
In the G3MH core, when a violation occurred in a read access, these bits always store the word-aligned address.		

NOTE

When the value of the IRE bit in the IPGENUM register (described later) is 0 and a transfer type that violates peripheral device protection is detected in a mode for detection or the current operation of the program being run by the user is reading to fetch an instruction, no bit of this register is updated.

(c) IPGENUM — Peripheral Device Protection Enable Register

Table 3.73 Register Contents of IPGENUM

Bit Position	Bit Name	Function
7 to 2	—	Reserved These bits are always read as 0. The write value should always be 0.
1	IRE	This bit sets whether to store the access information in the peripheral device protection violation access address register and the peripheral device protection violation access information register when a violation of peripheral device protection occurred in an instruction fetch access. 0: Instruction fetch access information is not stored. 1: Instruction fetch access information is stored.
CAUTION		
If you do not want to detect speculative instruction fetches (no instruction is executed in some cases), clear this bit to 0.		
0	E	This bit enables or disables the peripheral devices protection function against accesses by the relevant access right. 0: The peripheral device protection function is disabled. 1: The peripheral device protection function is enabled.

(d) IPGPMTUM2 — Peripheral Device Protection Setting Register 2

Bit	7	6	5	4	3	2	1	0
	—	—	W1	R1	—	—	W0	R0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R	R/W	R/W

Table 3.74 Register Contents of IPGPMTUM2

Bit Position	Bit Name	Function
7, 6	—	Reserved These bits are always read as 0. The write value should always be 0.
5	W1	This bit sets whether to enable write access to IPIR, MEV, and COMPTEST. 0: Write access to IPIR, MEV, and COMPTEST is treated as violation. 1: Write access to IPIR, MEV, and COMPTEST is not restricted.
4	R1	This bit sets whether to enable read access to IPIR, MEV, and COMPTEST. 0: Read access to IPIR, MEV, and COMPTEST is treated as violation. 1: Read access to IPIR, MEV, and COMPTEST is not restricted.
3, 2	—	Reserved These bits are always read as 0. The write value should always be 0.
1	W0	This bit sets whether to enable write access to INTC1. 0: Write access to INTC1 is treated as violation. 1: Write access to INTC1 is not restricted.
0	R0	This bit sets whether to enable read access to INTC1. 0: Read access to INTC1 is treated as violation. 1: Read access to INTC1 is not restricted.

(e) IPGPMTUM3 — Peripheral Device Protection Setting Register 3

Bit	7	6	5	4	3	2	1	0
	—	—	W1	R1	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R	R	R

Table 3.75 Register Contents of IPGPMTUM3

Bit Position	Bit Name	Function
7, 6	—	Reserved These bits are always read as 0. The write value should always be 0.
5	W1	This bit sets whether to enable write access to SysErrGen. 0: Write access to SysErrGen is treated as violation. 1: Write access to SysErrGen is not restricted.
4	R1	This bit sets whether to enable read access to SysErrGen. 0: Read access to SysErrGen is treated as violation. 1: Read access to SysErrGen is not restricted.
3 to 0	—	Reserved These bits are always read as 0. The write value should always be 0.

(f) IPGPMTUM4 — Peripheral Device Protection Setting Register 4

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	W0	R0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 3.76 Register Contents of IPGPMTUM4

Bit Position	Bit Name	Function
7 to 2	—	Reserved These bits are always read as 0. The write value should always be 0.
1	W0	This bit sets whether to enable write access to PEG. 0: Write access to PEG is treated as violation. 1: Write access to PEG is not restricted.
0	R0	This bit sets whether to enable read access to PEG. 0: Read access to PEG is treated as violation. 1: Read access to PEG is not restricted.

3.2.4.3 System Error Notification Control Function (SEG)

Errors due to an instruction fetch or data access can be the sources of system error exceptions. A system error exception is an FE level exception from which return or recovery is not possible.

For source codes (FEIC) of the system error exceptions and error handling, see **Table 3.79, Error Factor Codes and Handling of G3MH Core System Error Exceptions**.

SEG (SysErrGen) controls the notification and recording of the error by data access.

Errors due to instruction-fetch access are not conveyed via the SEG block, but the SEG block is notified of errors in RAM that has been cached in the instruction cache. For details, see **(2) Register Set, (a) SEGCONT — Error Notification Control Register**, and **(3) SEG Function, (c) Supplementary information on SYSERR exception**.

Multiple error occurrence inputs are categorized according to error factors, and are processed sequentially from the highest-priority error factor, generating an FE-level asynchronous exception (SYSERR).

The bit position of the SEGFLAG register becomes the priority of error factors. Error factors of lower bits take precedence over error factors of upper bits.

Error information is recorded once regardless of error frequency.

The error with the highest priority of error factor (in case errors occurred simultaneously) is valid. Recorded error information is not overwritten by subsequent errors.

(1) List of SEG Function Control Registers

Table 3.77 Base Address of SEG Register: FFFE E980_H

Address Offset	Size (Byte)	Register Name	Abbreviation	Right	R/W	Operable Bit				Value after Reset
						1	8	16	32	
+00 _H	2	Error notification control register	SEGCONT	—	R/W *1	—	—	√	—	0000 _H
+02 _H	2	Error occurrence retention register	SEGFLAG	—	R/W *1	—	—	√	—	0000 _H
+08 _H	4	Error factor retention register (address)	SEGADDR	—	R/W *1	—	—	√	√	Undefined (retained)

Note 1. Write accesses from user mode are ignored.

NOTES

- If an access is made with an address offset or operable bits other than those specified above, an error response is returned.
- Write access is only possible with the supervisor mode (UM = 0). Attempting to write, if these conditions do not hold, leads to an error response being returned.
- No restriction is provided for read accesses.
 - Read accesses to ranges permitted by other protection systems are enabled at any time.

(2) Register Set**(a) SEGCONT — Error Notification Control Register**

- This register is used to enable (= 1) or disable (= 0) notification of SYSERR request in response to error flags that store error occurrence status according to factors.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	PBPE	HBPE	GRME	LRME	CFBE	LSUE	—	ICCE	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R	R

Table 3.78 SEGCONT Register Contents (1/2)

Bit Position	Bit Name	Function
15 to 10	—	Reserved This bit is always read as 0. The write value should always be 0
9	PBPE	When the following error occurs in the read data of the P-bus <ul style="list-style-type: none"> Bus parity error
8	HBPE	When the following error occurs in the read data of the H-bus <ul style="list-style-type: none"> Bus parity error
7	GRME	When any of the following errors occurs in data access to the global RAM <ul style="list-style-type: none"> Uncorrectable ECC error (including cases where 1-bit correction is prohibited) Address parity error (including cases where the correction of mirrored bits is prohibited)
6	LRME	When any of the following errors occurs in data access to the local RAM for the given processor <ul style="list-style-type: none"> Uncorrectable ECC error (including cases where 1-bit correction is prohibited) Address parity error (including cases where the correction of mirrored bits is prohibited)
5	CFBE	When any of the following errors occurs in data access to the code flash <ul style="list-style-type: none"> Uncorrectable ECC error (including cases where 1-bit correction is prohibited) Address parity error (including cases where the correction of mirrored bits is prohibited)

Table 3.78 SEGCONT Register Contents (2/2)

Bit Position	Bit Name	Function
4	LSUE	<p>When any of the following guard errors associated with the instruction fetch and error responses are generated.</p> <ul style="list-style-type: none"> Notification of a response to an error in P-bus (excluding errors in writing to P-bus) <ul style="list-style-type: none"> An unimplemented area (FFFF 7900_H to FFFF 7EFF_H) is accessed PE's internal peripheral device protection (IPG) error Another PE's local RAM access guard (PEG) error P-bus guard error in writing access ((P-bus guarding also applies to the guarding of all registers in the INTC2 module, and to all registers for peripheral DMA and the GRAM) Notification of a response to an error in H-bus <ul style="list-style-type: none"> Error in access to the extended area (1000 0000_H to EFFF FFFF_H) Response to an error in the global RAM <ul style="list-style-type: none"> A protection violation access occurs An unimplemented area access occurs Response to an error in the local RAM <ul style="list-style-type: none"> An unimplemented area access occurs Response to an error in the code flash <ul style="list-style-type: none"> A store access occurs Response to an error in the data flash <ul style="list-style-type: none"> An uncorrectable ECC error occurs*1 Interconnect reserved area access detection notification <ul style="list-style-type: none"> An unimplemented area access occurs
3	—	<p>Reserved This bit is always read as 0. The write value should always be 0.</p>
2	ICCE	<p>Instruction cache error notification enable The error occurred in the instruction cache is handled when the instruction cache system register, ICCTRL.ICHEMK, is set to 0 (the value after reset is 1): Regarding the error occurred in the instruction cache, see Section 3.2.1.2, Register Set, (h) ICERR — Instruction cache error register.</p>
1, 0	—	<p>Reserved These bits are always read as 0. The write value should always be 0.</p>

Note 1. This is a case where an uncorrectable ECC error has occurred while ECC error notification is enabled.

Table 3.79 Error Factor Codes and Handling of G3MH Core System Error Exceptions (1/2)

Factor Codes	Error Contents
10	Reserved
11	A guard error associated with the instruction fetch and error response are generated.
12	Errors in which their notification is enabled by the SEGCONT second bit (ICCE)
13	<p>When any of the following errors associated with the instruction fetch</p> <ul style="list-style-type: none"> Bus parity error Uncorrectable ECC error (including cases where 1-bit correction is prohibited) Address parity error (including cases where the correction of mirrored bits is prohibited)
14	Errors in which their notification is enabled by the SEGCONT fourth bit (LSUE)
15	Errors in which their notification is enabled by the SEGCONT fifth bit (CFBE)
16	Errors in which their notification is enabled by the SEGCONT sixth bit (GRME)
17	Errors in which their notification is enabled by the SEGCONT seventh bit (GRME)

Table 3.79 Error Factor Codes and Handling of G3MH Core System Error Exceptions (2/2)

Factor Codes	Error Contents
18	Errors in which their notification is enabled by the SEGCONT eighth bit (HBPE)
19	Errors in which their notification is enabled by the SEGCONT ninth bit (PBPE)
1A	Reserved
1B	Reserved
1C	Reserved
1D	Reserved
1E	Reserved
1F	Reserved

(b) SEGFLAG — Error Occurrence Retention Register

- This register sets the flags of error occurrence, that store each error occurrence status by factors. Those are not automatically cleared (return to 0).
- Writing to the register enables both setting and clearing.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	PBPF	HBPF	GRMF	LRMF	CFBF	LSUF	—	ICCF	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R	R

Table 3.80 SEGFLAG Register Contents

Bit Position	Bit Name	Function
15 to 10	—	Reserved This bit is always read as 0. The write value should always be 0.
9	PBPF	Flag corresponding to bit 9 of the SEGCONT register
8	HBPF	Flag corresponding to bit 8 of the SEGCONT register
7	GRMF	Flag corresponding to bit 7 of the SEGCONT register
6	LRMF	Flag corresponding to bit 6 of the SEGCONT register
5	CFBF	Flag corresponding to bit 5 of the SEGCONT register
4	LSUF	Flag corresponding to bit 4 of the SEGCONT register
3	—	Reserved This bit is always read as 0. The write value should always be 0.
2	ICCF	Flag corresponding to bit 2 of the SEGCONT register
1, 0	—	Reserved These bits are always read as 0. The write value should always be 0.

(c) SEGADDR — Error Factor Retention Register (Address)

This register records information of an error factor that notifies a SYSERR request (only one history is recorded). It records the addresses where the error factors (PBPF, HBPF, GRMF, LRMF, CFBF, and LSUF) for 4 to 9 bits of the SEGFLAG register were found.

This cannot be modified when the error occurrence flag to enable notification is set.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Address[31:16]															
Value after reset	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
R/W	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Address[15:0]															
Value after reset	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x
R/W	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹	R/W* ¹

x: Undefined (retained)

Note 1. This cannot be modified when the error occurrence flag to enable notification is set.

Table 3.81 SEGADDR Register Contents

Bit Position	Bit Name	Function
31 to 0	Address[31:0]	These bits retain the address at which SYSERR source occurred. (If an instruction cache error (ICCE) occurred, 0 is stored. See the description of the ICERR register.)

(3) SEG Function**(a) SEG function: Notifying a SYSERR request due to an error flag**

- Setting an error flag takes precedence over clearing the same flag.
 - Simultaneous clearing operation is ignored.
- Priority of error factors
 - The bit position of the notification-enabled SEGFLAG register becomes the priority of error factors. Error factors of lower bits take precedence over error factors of upper bits. Notification is made from the highest-priority error factor.
 - The bit position of error factors is notified as a “SYSERR factor code.”
- Conditions for starting SYSERR request notification
 - Even if a notification-disabled flag is set to 1, notification is not made.
 - Notification is made immediately after a notification-enabled flag is set to 1.
 - After clearing, notification is made depending on the flag state (re-arbitration).
- Finishing notification at a SYSERR request response
 - Even after notification is finished, the flag is not cleared automatically.
 - Notification is not made until re-arbitration is performed by setting or clearing the flag.
 - If an error flag that is prioritized higher than the error factor is set prior to a request response, the notification information may be replaced with an upper SYSERR factor code.

(b) SEG function: Recording error factor information

- When notification-enabled error occurrence is input, the error address is retained in the above register.
 - No information is retained by setting or clearing an error flag described in **(a) SEG function: Notifying a SYSERR request due to an error flag** above.
 - When multiple error occurrence inputs are present simultaneously, information other than the prioritized error factor is not retained.
- While the notification-enabled error flag described in **(a) SEG function: Notifying a SYSERR request due to an error flag** above is set to 1, overwrite to the above register is inhibited
 - If error occurrence input continues, information of subsequent error factors is not retained.
 - To reset the inhibition of overwrite to the register, clear either SEGCONT or SEGFLAG register (or both of them).

(c) Supplementary information on SYSERR exception

- The PSW.EBV bit retains its value and the base address for the exception handler is not changed even when a SYSERR exception is generated.
- Detection of errors in the instruction cache
Even when an error is detected in the instruction cache, a rerun-typed SYSERR exception caused by instruction fetch does not occur. Execution of the instruction by the CPU still proceeds; the entry which led to the error is automatically invalidated and fetching is repeated, this time from the code flash memory. The SEG block will be informed that a cache error has occurred if the setting of the ICHEMK bit of the ICCTRL cache-control system register is 0. See **(h) ICERR — Instruction cache error register** in **Section 3.2.1.2, Register Set** for the details on instruction cache error.

3.2.4.4 Checker Core

The CPU1 has the checker core for safety assurance, resulting in a highly reliable system. Monitoring the outputs from the CPU1 and the checker core with the comparator all the time enables immediate detection of the CPU1 abnormal operations. Duplication by the checker core covers the CPU core, FPU, MPU, PEG, IPG, SEG, and INTC1. The CPU1 can also conduct a fault diagnosis test of its own comparator through a pseudo-error generated by the COMPTEST module. For details of the COMPTEST module, see **Section 30, Safety**.

CAUTION

Reading of any register with an undefined value after a reset in a PE or writing to memory or a register outside the PE may cause a lock step comparison error. The values of some program registers and system registers are undefined after a reset, so pay attention to this when saving register values on the stack in RAM.

3.3 PCU

3.3.1 Core Functions

3.3.1.1 Features

Table 3.82 lists features of the RH850G3K core.

Table 3.82 Features of the RH850G3K Core

Item	Feature
CPU	<ul style="list-style-type: none"> • Advanced 32-bit architecture for embedded control • 32-bit internal data bus • Thirty-two 32-bit general-purpose registers • RISC-type instruction sets <ul style="list-style-type: none"> – Long-/short-format load/store instructions – Three-operand instructions – Instruction sets based on C language • CPU operating modes <ul style="list-style-type: none"> – User mode and supervisor mode • Address space: 128-Mbyte linear address space for both data and instructions • Instructions: A snooze instruction (SNOOZE) is included for temporary suspension by switching the high-speed peripheral clock signal (CLK_HSB) off for 32 clock cycles.
Coprocessor	<ul style="list-style-type: none"> • Coprocessor is not incorporated
Exception/ Interrupt	<ul style="list-style-type: none"> • 8 interrupt priority levels settable for each channel • Vector selection method selectable according to performance request or memory usage <ul style="list-style-type: none"> – Direct branching exception vectors – Indirect branching exception vectors referring to the address table • Supports the high-speed save/restore processing of the context by the dedicated instructions (PUSHSP and POPSP) at the generation of an interrupt
Memory Management	<ul style="list-style-type: none"> • Memory protection function (MPU): Eight areas settable
Cache	<ul style="list-style-type: none"> • Cache is not incorporated

CAUTION

The PCU should be handled properly when it is not used.

For instance, use the HALT instruction to stop the PCU.

3.3.1.2 Register Set

(1) Program Registers

Program registers include the general-purpose registers (r0 to r31) and the program counter (PC).

The general-purpose register r0 always retains 0, but the values of the registers r1 to r31 after reset are undefined.

Table 3.83 Program Registers

Program Register	Name	Function	Description
General-purpose registers	r0	Zero register	Always retains "0"
	r1	Assembler reserved register	Used as a working register for generating addresses
	r2	Register for address and data variables (used when the real-time OS used does not use this register)	
	r3	Stack pointer (SP)	Used for generating a stack frame when a function is called
	r4	Global pointer (GP)	Used for accessing a global variable in the data area
	r5	Text pointer (TP)	Used as a register that indicates the start of the text area (area where program code is placed)
	r6 to r29	Register for addresses and data variables	
	r30	Element pointer (EP)	Used as a base pointer for generating addresses when accessing memory
	r31	Link pointer (LP)	Used when the compiler calls a function
Program counter	PC	Retains instruction addresses during execution of programs	

NOTE

For further descriptions of r1, r3 to r5, and r31 used for an assembler and/or C compiler, see the specification of each software development environment.

(a) General-Purpose Registers

A total of 32 general-purpose registers (r0 to r31) are provided. All of these registers can be used for either data variables or address variables. Of the general-purpose registers, r0 to r5, r30, and r31 are assumed to be used for special purposes in software development environments, so it is necessary to note the following when using them.

1. r0, r3, and r30

These registers are implicitly used by instructions.

r0 is a register that always retains “0”. It is used for operations that use 0, addressing with base address being 0, etc.

r3 is implicitly used by the PREPARE, DISPOSE, PUSHSP, and POPSP instructions.

r30 is used as a base pointer when the SLD instruction or SST instruction accesses memory.

2. r1, r4, r5, and r31

These registers are implicitly used by the assembler and C compiler.

When using these registers, register contents must first be saved so they are not lost and can be restored after the registers are used.

3. r2

This register might be used by a real-time OS in some cases. If the real-time OS that is being used is not using r2, r2 can be used as a register for address variables or data variables.

(b) PC — Program Counter

The PC retains the address of the instruction being executed.

Table 3.84 PC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	PC31-1	These bits indicate the address of the instruction being executed.	R/W	*1
0	PC0	This bit is fixed to 0, and branching to an odd number address is disabled.	R/W	0

Note 1. In this product, the value after reset differs depending on the startup area. For details, see **Section 4, Address Space**.

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27.

(2) Basic System Registers

The basic system registers are used to control CPU status and to retain exception information.

System registers are read from or written to by using the LDSR or STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.85 Basic System Registers

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR0, 0	EIPC* ¹	Status save registers when acknowledging EI level exception	SV
SR1, 0	EIPSW	Status save registers when acknowledging EI level exception	SV
SR2, 0	FEPC* ¹	Status save registers when acknowledging FE level exception	SV
SR3, 0	FEPSW	Status save registers when acknowledging FE level exception	SV
SR 5, 0	PSW	Program status word	*2
SR 13, 0	EIIC	EI level exception cause	SV
SR 14, 0	FEIC	FE level exception cause	SV
SR 16, 0	CTPC* ¹	CALLT execution status save register	UM
SR 17, 0	CTPSW	CALLT execution status save register	UM
SR 20, 0	CTBP* ¹	CALLT base pointer	UM
SR 28, 0	EIWR	EI level exception working register	SV
SR 29, 0	FEWR	FE level exception working register	SV
SR0, 1	MCFG0	Machine configuration	SV
SR2, 1	RBASE	Reset vector base address	SV
SR3, 1	EBASE* ¹	Exception handler vector address	SV
SR4, 1	INTBP* ¹	Base address of the interrupt handler table	SV
SR 5, 1	MCTL	CPU control	SV
SR 6, 1	PID	Processor ID	SV
SR 11, 1	SCCFG	SYSCALL operation setting	SV
SR 12, 1	SCBP* ¹	SYSCALL base pointer	SV
SR0, 2	HTCFG0	Process number	SV
SR6, 2	MEA* ¹	Memory error address	SV
SR7, 2	ASID	Address space ID	SV
SR8, 2	MEI	Memory error information	SV

Note 1. For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27.

Note 2. The access permission differs depending on the bit. For details, see **Table 3.90, Access Permission for PSW Register**.

(a) EIPC — Status save register when acknowledging EI level exception register

When an EI level exception is acknowledged, the address of the instruction that was being executed when the EI level exception occurred, or of the next instruction, is saved to the EIPC register (see *section 4.1.3 Types of Exceptions* in *RH850G3K User's Manual: Software*).

Because there is only one pair of EI level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

Be sure to set an even-numbered address to the EIPC register. An odd-numbered address must not be specified.

Table 3.86 EIPC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	EIPC31-1	These bits indicate the PC saved when an EI level exception is acknowledged.	R/W	Undefined
0	EIPC0	This bit indicates the PC saved when an EI level exception is acknowledged. Always set this bit to 0. Even if it is set to 1, the value transferred to the PC when the EIRET instruction is executed is 0.	R/W	Undefined

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27 of EIPC.

(b) EIPSW — Status save register when acknowledging EI level exception register

When an EI level exception is acknowledged, the current PSW setting is saved to the EIPSW register.

Because there is only one pair of EI level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

CAUTION

Bits 11 to 9 cannot usually be changed since these bits are associated with debugging.

Table 3.87 EIPSW Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
30	UM	This bit stores the PSW.UM bit setting when an EI level exception is acknowledged.	R/W	0
29 to 19	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
18 to 16	CU2-0	These bits store the PSW.CU2 to 0 field setting when an EI level exception is acknowledged. (Reserved for future expansion. Be sure to clear to 0.)	R/W	0
15	EBV	This bit stores the PSW.EBV bit setting when an EI level exception is acknowledged.	R/W	0
14 to 12	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
11 to 9	Debug	These bits store the PSW.Debug field when an EI level exception is acknowledged.	R/W	0
8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7	NP	This bit stores the PSW.NP bit setting when an EI level exception is acknowledged.	R/W	0
6	EP	This bit stores the PSW.EP bit setting when an EI level exception is acknowledged.	R/W	0
5	ID	This bit stores the PSW.ID bit setting when an EI level exception is acknowledged.	R/W	1
4	SAT	This bit stores the PSW.SAT bit setting when an EI level exception is acknowledged.	R/W	0
3	CY	This bit stores the PSW.CY bit setting when an EI level exception is acknowledged.	R/W	0
2	OV	This bit stores the PSW.OV bit setting when an EI level exception is acknowledged.	R/W	0
1	S	This bit stores the PSW.S bit setting when an EI level exception is acknowledged.	R/W	0
0	Z	This bit stores the PSW.Z bit setting when an EI level exception is acknowledged.	R/W	0

(c) FEPC — Status save register when acknowledging FE level exception register

When an FE level exception is acknowledged, the address of the instruction that was being executed when the FE level exception occurred, or of the next instruction, is saved to the FEPC register (see *section 4.1.3 Types of Exceptions* in *RH850G3K User's Manual: Software*) in the Software Manual.

Because there is only one pair of FE level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

Be sure to set an even-numbered address to the FEPC register. An odd-numbered address must not be specified.

Table 3.88 FEPC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	FEPC31-1	These bits indicate the PC saved when an FE level exception is acknowledged.	R/W	Undefined
0	FEPC0	This bit indicates the PC saved when an FE level exception is acknowledged. Always set this bit to 0. Even if it is set to 1, the value transferred to the PC when the FERET instruction is executed is 0.	R/W	Undefined

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27 of FEPC.

(d) FEPSW — Status save register when acknowledging FE level exception register

When an FE level exception is acknowledged, the current PSW setting is saved to the FEPSW register.

Because there is only one pair of FE level exception status save registers, when processing multiple exceptions, the contents of these registers must be saved by a program.

CAUTION

Bits 11 to 9 cannot usually be changed since these bits are associated with debugging.

Table 3.89 FEPSW Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
30	UM	This bit stores the PSW.UM bit setting when an FE level exception is acknowledged.	R/W	0
29 to 19	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
18 to 16	CU2-0	These bits store the PSW.CU2 to 0 field setting when an FE level exception is acknowledged. (Reserved for future expansion. Be sure to clear to 0.)	R R/W	0
15	EBV	This bit stores the PSW.EBV bit setting when an FE level exception is acknowledged.	R/W	0
14 to 12	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
11 to 9	Debug	These bits store the PSW.Debug field when an FE level exception is acknowledged.	R/W	0
8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7	NP	This bit stores the PSW.NP bit setting when an FE level exception is acknowledged.	R/W	0
6	EP	This bit stores the PSW.EP bit setting when an FE level exception is acknowledged.	R/W	0
5	ID	This bit stores the PSW.ID bit setting when an FE level exception is acknowledged.	R/W	1
4	SAT	This bit stores the PSW.SAT bit setting when an FE level exception is acknowledged.	R/W	0
3	CY	This bit stores the PSW.CY bit setting when an FE level exception is acknowledged.	R/W	0
2	OV	This bit stores the PSW.OV bit setting when an FE level exception is acknowledged.	R/W	0
1	S	This bit stores the PSW.S bit setting when an FE level exception is acknowledged.	R/W	0
0	Z	This bit stores the PSW.Z bit setting when an FE level exception is acknowledged.	R/W	0

(e) PSW — Program status word register

PSW (program status word) is a set of flags that indicate the program status (instruction execution result) and bits that indicate the operation status of the CPU (flags are bits in the PSW that are referenced by a condition instruction (Bcond, CMOV, etc.)).

When the LDSR instruction is used to change the contents of each bit in this register, the changed contents become valid from the instruction following the LDSR instruction.

The access permission for the PSW register differs depending on the bit. All bits can be read, but some bits can only be written under certain conditions. See **Table 3.90, Access Permission for PSW Register** for the access permission for each bit.

Table 3.90 Access Permission for PSW Register

Bit	Access Permission When Reading	Access Permission When Writing
30	UM	SV*1
18 to 16	CU2-0	SV*1
15	EBV	SV*1
11 to 9	Debug	Special*1
7	NP	SV*1
6	EP	SV*1
5	ID	SV*1
4	SAT	UM
3	CY	UM
2	OV	UM
1	S	UM
0	Z	UM

Note 1. The access permission for the whole PSW register is UM, so the PIE exception does not occur even if the register is written by using an LDSR instruction when PSW.UM is 1. In this case, writing is ignored.

**Table 3.91 PSW Register Contents (1/2)**

Bit Position	Bit Name	Function	R/W	Value after Reset
31	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
30	UM	This bit indicates that the CPU is in user mode (UM mode) 0: Supervisor mode 1: User mode	R/W	0
29 to 19	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
18 to 16	CU2-0	(Reserved for future expansion. Be sure to clear to 0.)	R	000
15	EBV	This bit indicates the reset vector and exception vector operation. See the descriptions of the RBASE register in (q) RBASE — Reset vector base address register and the EBASE register in (r) EBASE — Exception handler vector address register .	R/W	0
14 to 12	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
11 to 9	Debug	These bits are used in the debugging functions of development tools. In normal operation, clear these bits to 0.	—	0
8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0

Table 3.91 PSW Register Contents (2/2)

Bit Position	Bit Name	Function	R/W	Value after Reset
7	NP	Disables acceptance of FE level exceptions. Once an FE level exception is accepted, this bit is set to 1 and disables acceptance of EI level exceptions or FE level exceptions. For the exceptions disabled by the NP bit, see <i>table 4.1 Exception Cause List</i> in <i>RH850G3K User's Manual: Software</i> . 0 : An acceptance of FE level exceptions is enabled 1 : An acceptance of FE level exceptions is disabled	R/W	0
6	EP	Disables acceptance of EI level exceptions. Once an IE level exception or FE level exception is accepted, this bit is set to 1 and disables acceptance of EI level exceptions. For the exceptions disabled by the ID bit, see <i>table 4.1 Exception Cause List</i> in <i>RH850G3K User's Manual: Software</i> . This bit does not affect acknowledging an exception request even when it is set to 1. A change in the ID bit by the IE or DI instruction is enabled from the next instruction. 0 : An interrupt is not being serviced. 1 : An exception other than an interrupt is being serviced.	R/W	0
5	ID	Disables acceptance of EI level exceptions. Once an IE level exception or FE level exception is accepted, this bit is set to 1 and disables acceptance of EI level exceptions. For the exceptions disabled by the ID bit, see <i>table 4.1 Exception Cause List</i> in <i>RH850G3K User's Manual: Software</i> . This bit is also used to disable EI level exceptions from being acknowledged as a critical section while an ordinary program or interrupt is being serviced. It is set to 1 when the DI instruction is executed, and cleared to 0 when the EI instruction is executed. A change in the ID bit by the IE or DI instruction is enabled from the next instruction. 0 : An acceptance of IE level exceptions is enabled 1 : An acceptance of IE level exceptions is disabled	R/W	1
4	SAT* ¹	This bit indicates that the operation result is saturated because the result of a saturated operation instruction operation has overflowed. This is a cumulative flag, so when the operation result of the saturated operation instruction becomes saturated, this bit is set to 1, but it is not cleared to 0 when the operation result for a subsequent instruction is not saturated. This bit is cleared to 0 by the LDSR instruction. This bit is neither set to 1 nor cleared to 0 when an arithmetic operation instruction is executed. 0 : Not saturated 1 : Saturated	R/W	0
3	CY	This bit indicates whether a carry or borrow has occurred in the operation result. 0 : Carry and borrow have not occurred. 1 : Carry or borrow has occurred.	R/W	0
2	OV* ¹	This bit indicates whether or not an overflow has occurred during an operation. 0 : Overflow has not occurred. 1 : Overflow has occurred.	R/W	0
1	S* ¹	This bit indicates whether or not the result of an operation is negative. 0 : Result of operation is positive or 0. 1 : Result of operation is negative	R/W	0
0	Z	This bit indicates whether or not the result of an operation is 0. 0 : Result of operation is not 0. 1 : Result of operation is 0.	R/W	0

Note 1. The operation result of the saturation processing is determined in accordance with the contents of the OV flag and S flag during a saturated operation. When only the OV flag is set to 1 during a saturated operation, the SAT flag is set to 1.

Operation result status	Flag status			Operation result after saturation processing
	SAT	OV	S	
Exceeded positive maximum value	1	1	0	7FFF FFFF _H
Exceeded negative maximum value	1	1	1	8000 0000 _H

Operation result status	Flag status			Operation result after saturation processing
	SAT	OV	S	
Positive (maximum value not exceeded)	Value prior to operation is retained.	0	0	Operation result itself
Negative (maximum value not exceeded)			1	

(f) EIIC — EI level exception cause register

The EIIC register retains the cause of any EI level exception that occurs. The value retained in this register is an exception code corresponding to a specific exception cause.

Table 3.92 EIIC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	EIIC31-0	These bits store the exception cause code when an EI level exception occurs. Regarding the stored exception source code, see <i>Table 6.14, Interrupt Exception Handler and Priority</i> and <i>table 4.1 Exception Cause List</i> in <i>RH850G3K User's Manual: Software</i> . The EIIC31-16 field stores detailed exception cause codes defined individually for each exception. If there is no particular definition, these bits are set to 0.	R/W	0

(g) FEIC — FE level exception cause register

The FEIC register retains the cause of any FE level exception that occurs. The value retained in this register is an exception code corresponding to a specific exception cause.

Table 3.93 FEIC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	FEIC31-0	These bits store the exception cause code when an FE level exception occurs. Regarding the stored exception source code, see <i>Table 6.14, Interrupt Exception Handler and Priority</i> and <i>table 4.1 Exception Cause List</i> in <i>RH850G3K User's Manual: Software</i> . The FEIC31-16 field stores detailed exception cause codes defined individually for each exception. If there is no particular definition, these bits are set to 0.	R/W	0

(h) CTPC — Status save register when executing CALLT register

When a CALLT instruction is executed, the address of the next instruction after the CALLT instruction is saved to CTPC. Be sure to set an even-numbered address to the CTPC register. An odd-numbered address must not be specified.

Table 3.94 CTPC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	CTPC31-1	These bits indicate the PC of the instruction after the CALLT instruction.	R/W	Undefined
0	CTPC0	This bit indicates the PC of the instruction after the CALLT instruction. Always set this bit to 0. Even if it is set to 1, the value transferred to the PC when the CTRET instruction is executed is 0.	R/W	Undefined

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27 of CTPC.

(i) CTPSW — Status save register when executing CALLT register

When a CALLT instruction is executed, some of the PSW (program status word) settings are saved to CTPSW.

Table 3.95 CTPSW Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 5	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
4	SAT	This bit stores the PSW.SAT bit setting when the CALLT instruction is executed.	R/W	0
3	CY	This bit stores the PSW.CY bit setting when the CALLT instruction is executed.	R/W	0
2	OV	This bit stores the PSW.OV bit setting when the CALLT instruction is executed.	R/W	0
1	S	This bit stores the PSW.S bit setting when the CALLT instruction is executed.	R/W	0
0	Z	This bit stores the PSW.Z bit setting when the CALLT instruction is executed.	R/W	0

(j) CTBP — CALLT base pointer register

The CTBP register is used to specify table addresses of the CALLT instruction and generate target addresses. Be sure to set the CTBP register to a half word address.

Table 3.96 CTBP Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	CTBP31-1	These bits indicate the base pointer address of the CALLT instruction. These bits indicate the first address in the table used by the CALLT instruction.	R/W	Undefined
0	CTBP0	These bits indicate the base pointer address of the CALLT instruction. These bits indicate the first address in the table used by the CALLT instruction. Always set this bit to 0.	R	0

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27 of CTBP.

(k) ASID — Address space ID register

This is the address space ID. This is used to identify the address space provided by the memory management function.

Table 3.97 ACID Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 10	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
9 to 0	ASID	This is the address space ID.	R/W	Undefined

(l) EIWR — EI level exception working register

The EIWR register is used as a working register when an EI level exception has occurred.

Table 3.98 EIWR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	EIWR31-0	These bits constitute a working register that can be used for any purpose during the processing of an EI level exception. Use this register for purposes such as storing the values of general-purpose registers.	R/W	Undefined

(m) FEWR — FE level exception working register

The FEWR register is used as a working register when an FE level exception has occurred.

Table 3.99 FEWR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	FEWR31-0	These bits constitute a working register that can be used for any purpose during the processing of an FE level exception. Use this register for purposes such as storing the values of general-purpose registers.	R/W	Undefined

(n) HTCFG0 — Thread configuration register

Table 3.100 HTCFG0 Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 19	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
18 to 16	PEID	These bits indicate the processor element number.	R	*2
15	—	(Reserved for future expansion. Be sure to set this bit to 1.)	R	1
14 to 0	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0

Note 1. The value is 0003 8000_H in PCU (PE3) of this product.
 Note 2. The value is 011_B in PCU (PE3) of this product.

(o) MEA — Memory error address register

Table 3.101 MEA Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	MEA	These bits store the address when an MAE (misaligned) or MPU exception occurs.	R/W	Undefined

(p) MEI — Memory error information register

This register is used to store information about the instruction that caused the exception when a misaligned (MAE) or memory protection (MDP) exception occurs. This information is used during emulation.

Table 3.102 MEI Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 21	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
20 to 16	REG4-0	These bits indicate the number of the source or destination register accessed by the instruction that caused the exception. For details, see Table 3.103, Instructions Causing Exceptions and Values of MEI Register .	R/W	Undefined
15 to 11	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
10, 9	DS	These bits indicate the type of data handled by the instruction that caused the exception.*1 0: Byte (8 bits) 1: Half word (16 bits) 2: Word (32 bits) 3: Double-word (64 bits) For details, see Table 3.103, Instructions Causing Exceptions and Values of MEI Register .	R/W	Undefined
8	U	These bits indicate the sign extension method of the instruction that caused the exception. 0: Signed 1: Unsigned For details, see Table 3.103, Instructions Causing Exceptions and Values of MEI Register .	R/W	Undefined
7, 6	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
5 to 1	ITYPE4-0	These bits indicate the instruction that caused the exception. For details, see Table 3.103, Instructions Causing Exceptions and Values of MEI Register .	R/W	Undefined
0	RW	This bit indicates whether the operation of the instruction that caused the exception was read (Load-memory) or write (Store-memory) 0: Read (Load-memory) 1: Write (Store-memory) For details, see Table 3.103, Instructions Causing Exceptions and Values of MEI Register .	R/W	Undefined

Note 1. Even if the data is divided and access is made several times due to the specifications of the hardware, the original data type indicated by the instruction is stored.

Table 3.103 Instructions Causing Exceptions and Values of MEI Register (1/2)

Instruction	REG	DS	U	RW	ITYPE
SLD.B	dst	0 (Byte)	0 (Signed)	0 (Read)	00000 _B
SLD.BU	dst	0 (Byte)	1 (Unsigned)	0 (Read)	00000 _B

SYSCALL	—	2 (Word)	1 (Unsigned)	0 (Read)	10010 _B
Interrupt (table reference)* ²	—	2 (Word)	1 (Unsigned)	0 (Read)	10101 _B

Note 1. This exception occurs when the instruction executes a read access.

Note 2. An exception occurs when the table reference interrupt vector is read.

NOTE

dst: destination register number, src: source register number

(q) RBASE — Reset vector base address register

This register indicates the reset vector address when there is a reset. If the PSW.EBV bit is 0, this vector address is also used as the exception vector address.

Table 3.104 RBASE Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 9	RBASE31-9	These bits indicate the reset vector when there is a reset. When PSW.EBV = 0, this address is also used as the exception vector. The EBASE8 to 0 bits are implicitly set to 0.	R	*1
8 to 1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	RINT	When the RINT bit is set, the offset address of the exception handler used during interrupt servicing is decremented. This bit is valid when PSW.EBV = 0.	R	0

Note 1. The reset vector differs depending on the startup area. For details, see **Section 4, Address Space**.

(r) EBASE — Exception handler vector address register

This register indicates the exception handler vector address. This register is valid when the PSW.EBV bit is 1.

Table 3.105 EBASE Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 9	EBASE31-9	The exception handler routine address is changed to the address resulting from adding the offset address of each exception to the base address specified for this register. The EBASE8 to 0 bits are implicitly set to 0.	R/W	Undefined
8 to 1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	RINT	When the RINT bit is set, the offset address of the exception handler used during interrupt servicing is decremented.	R/W	Undefined

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27 of EBASE.

(s) INTBP — Base address of the interrupt handler table register

This register indicates the base address of the address table when the table reference method is selected as the interrupt handler address selection method.

Table 3.106 INTBP Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 9	INTBP31-9	These bits indicate the base pointer address for an interrupt prescribed in the expanded specifications. The value indicated by these bits is the first address in the table used to determine the exception handler when the interrupt prescribed by the expanded specifications (EIINT0 to EIINT511) is acknowledged. The EBASE8 to 0 bits are implicitly set to 0.	R/W	Undefined
8 to 0	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27 of INTBP.

(t) PID — Processor ID register

The PID register retains a processor identifier that is unique to the CPU. The PID register is a read-only register.

CAUTION

The PID register indicates information used to identify the incorporated CPU core and CPU core configuration. Usage such that the software behavior varies dynamically according to the PID register information is not assumed.

Table 3.107 PID Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 24	PID	Architecture identifier This identifier indicates the architecture of the processor.	R	F5 _H
23 to 8		Function identifier This identifier indicates the functions of the processor. These bits indicate whether or not functions defined per bit are implemented (1: implemented, 0: not implemented). Bit 23 to 9: Reserved Bit 8: Memory protection unit (MPU) function	R	0001 _H
7 to 0		Version identifier This identifier indicates the version of the processor.	R	36 _H

Note 1. The value is F500 0136_H in this product.

(u) SCCFG — SYSCALL operation setting register

This register is used to specify operations related to the SYSCALL instruction. Be sure to set an appropriate value to this register before using the SYSCALL instruction.

Table 3.108 SCCFG Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7 to 0	SIZE	These bits specify the maximum number of entries of a table that the SYSCALL instruction references. The maximum number of entries the SYSCALL instruction references is 1 if SIZE is 0, and 256 if SIZE is 255. By setting the maximum number of entries appropriately in accordance with the number of functions branched by the SYSCALL instruction, the memory area can be effectively used. If a vector exceeding the maximum number of entries is specified for the SYSCALL instruction, the first entry is selected. Place an error processing routine at the first entry.	R/W	Undefined

(v) SCBP — SYSCALL base pointer register

The SCBP register is used to specify a table address of the SYSCALL instruction and generate a target address. Be sure to set an appropriate value to this register before using the SYSCALL instruction.

Be sure to set a word address to the SCBP register.

Table 3.109 SCBP Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 2	SCBP31-2	These bits indicate the base pointer address of the SYSCALL instruction. These bits indicate the first address in the table used by the SYSCALL instruction.	R/W	Undefined
1, 0	SCBP1-0	These bits indicate the base pointer address of the SYSCALL instruction. These bits indicate the first address in the table used by the SYSCALL instruction. Always set this bit to 0.	R	0

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27 of SCBP.

(w) MCFG0 — Machine configuration register

This register indicates the CPU configuration.

Table 3.110 MCFG0 Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 24	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
23 to 16	SPID	Bit 23 to 18: These are not supported in this product. (Reserved for the future expansion. Be sure to clear to 0) Bit 17, 16: These bits indicate the system protection number.	R/W	*2
15 to 3	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
2	—	(Reserved for future expansion. Be sure to set this bit to 1.)	R	1
1, 0	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0

Note 1. The value is 0003 0004_H in PCU (PE3) of this product.

Note 2. The value is 03_H in PCU (PE3) of this product.

(x) MCTL — Machine control register

This register is used to control the CPU.

Table 3.111 MCTL Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31	—	(Reserved for future expansion. Be sure to set this bit to 1.)	R	1
30 to 2	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
1	MA	This bit specifies the operation when a misaligned access occurs. 0: An exception is generated in response to a misaligned access.*1 1: A misalignment exception is not generated and access still proceeds.*1	R/W	0
0	UIC	This bit is used to control the interrupt enable/disable operation in user mode. When this bit is set to 1, executing the EI/DI instruction in user mode becomes possible.	R/W	0

Note 1. This bit does not control the generation of misalignment exceptions in response to access by double-word instructions.

(3) Interrupt function registers

Table 3.112 Interrupt Function System Registers

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR10, 2	ISPR	Priority of interrupt being serviced	SV
SR11, 2	PMR	Interrupt priority masking	SV
SR12, 2	ICSR	Interrupt control status	SV
SR13, 2	INTCFG	Interrupt function setting	SV

(a) ISPR — Priority of interrupt being serviced register

This register holds the priority of the EIINTn interrupt being serviced. This priority value is then used to perform priority ceiling processing when multiple interrupts are generated.

Table 3.113 ISPR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7 to 0	ISP7-0	These bits indicate the acknowledgment status of an EIINTn interrupt with a priority*1 that corresponds to the relevant bit position. 0: An interrupt request for an interrupt whose priority corresponds to the relevant bit position has not been acknowledged. 1: An interrupt request for an interrupt whose priority corresponds to the relevant position is being serviced by the CPU core.	R*3	0

The bit positions correspond to the following priority levels:

Bit	Priority
0	Priority 0 (highest)
1	Priority 1
	:
6	Priority 6
7	Priority 7

When an interrupt request (EIINTn) is acknowledged, the bit corresponding to the acknowledged interrupt request is automatically set to 1. If PSW.EP is 0 when the EIRET instruction is executed, the bit with the highest priority among the ISP7 to 0 bits that are set (0 is the highest priority) is cleared to 0*2.

While a bit in this register is set to 1, lower priority interrupts (EIINTn) are masked. Priority level judgment is therefore not performed when the system is determining whether to acknowledge an exception, meaning that exceptions will not be acknowledged. See section 4.1.5 *Interrupt Exception Priority and Priority Masking* in *RH850G3K User's Manual: Software*.

When performing software-based priority control using the PMR register, be sure to clear this register by using the INTCFG.ISPC bit.

- Note 1. See section 4.1.5 *Interrupt Exception Priority and Priority Masking* in *RH850G3K User's Manual: Software* for the details.
- Note 2. Interrupt acknowledgment and auto-updating of values when the EIRET instruction is executed are disabled by setting the INTCFG.ISPC bit to 1. We recommend auto-updating, so in normal cases, clear the INTCFG.ISPC bit to 0.
- Note 3. This is R or R/W, depending on the setting of the INTCFG.ISPC bit. It is recommended to use this register as a read-only (R) register.

(b) PMR — Interrupt priority masking register

This register is used to mask the specified interrupt priority.

Table 3.114 PMR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7 to 0	PM7-0	These bits mask an interrupt request with a priority level that corresponds to the relevant bit position. 0: Servicing of an interrupt request with a priority that corresponds to the relevant bit position is enabled. 1: Servicing of an interrupt request with a priority that corresponds to the relevant bit position is disabled.	R/W	0

The bit positions correspond to the following priority levels:

Bit	Priority
0	Priority 0 (highest)
1	Priority 1
	:
6	Priority 6
7	Priority 7 (lowest)

While a bit in this register is set to 1, interrupts (EIINTn) with the priority corresponding to that bit are masked. Priority level judgment is therefore not performed when the system is determining whether to acknowledge an exception, meaning that exceptions will not be acknowledged*¹.

Note 1. Specify the masks by setting the bits to 1 in order from the lowest-priority bit. For example, F0_H can be set, but CC_H or 0F_H cannot.

(c) ICSR — Interrupt control status register

This register indicates the interrupt control status in the CPU.

Table 3.115 ICSR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	PMEI	This bit indicates that an interrupt (EIINTn) with the priority level masked by the PMR register exists	R	0

(d) INTCFG — Interrupt function setting register

This register is used to specify settings related to the CPU's internal interrupt function.

Table 3.116 INTCFG Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 1	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
0	ISPC	<p>This bit changes how the ISPR register is written.</p> <p>0: The ISPR register is automatically updated. Updates triggered by the program (via execution of LDSR instruction) are ignored.</p> <p>1: The ISPR register is not automatically updated. Updates triggered by the program (via execution of LDSR instruction) are performed.</p> <p>If this bit is cleared to 0, the bits of the ISPR register are automatically set to 1 when an interrupt (EIINTn) is acknowledged, and cleared to 0 when the EIRET instruction is executed. In this case, the bits are not updated by an LDSR instruction executed by the program. If this bit is set to 1, the bits of the ISPR register are not updated by the acknowledgement of an interrupt (EIINTn) or by execution of the EIRET instruction. In this case, the bits can be updated by an LDSR instruction executed by the program.</p> <p>In normal cases, the ISPC bit should be cleared. When performing software-based priority control, however, set this bit to 1 and perform priority control by using the PMR register.</p>	R/W	0

(4) FPU Function Registers

This product does not include an FPU.

(5) MPU Function Registers**(a) MPU function system registers**

The MPU function system registers are read from or written to by using the LDSR or STSR instructions and specifying the system register number, which is made up of a register number and selection ID.

Table 3.117 MPU Function System Registers (1/2)

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR0, 5	MPM	Memory protection operation mode setting	SV
SR1, 5	MPRC	MPU region control	SV
SR4, 5	MPBRGN	MPU base region number	SV
SR5, 5	MPTRGN	MPU end region number	SV
SR11, 5	MCR	Memory protection setting check result	SV
SR0, 6	MPLA0	Protection area minimum address	SV
SR1, 6	MPUA0	Protection area maximum address	SV
SR2, 6	MPAT0	Protection area attribute	SV
SR4, 6	MPLA1	Protection area minimum address	SV
SR5, 6	MPUA1	Protection area maximum address	SV
SR6, 6	MPAT1	Protection area attribute	SV
SR8, 6	MPLA2	Lower address of the protection area	SV
SR9, 6	MPUA2	Protection area maximum address	SV
SR10, 6	MPAT2	Protection area attribute	SV
SR12, 6	MPLA3	Protection area minimum address	SV
SR13, 6	MPUA3	Protection area maximum address	SV
SR14, 6	MPAT3	Protection area attribute	SV
SR16, 6	MPLA4	Protection area minimum address	SV
SR17, 6	MPUA4	Protection area maximum address	SV
SR18, 6	MPAT4	Protection area attribute	SV
SR20, 6	MPLA5	Protection area minimum address	SV
SR21, 6	MPUA5	Protection area maximum address	SV
SR22, 6	MPAT5	Protection area attribute	SV
SR24, 6	MPLA6	Protection area minimum address	SV
SR25, 6	MPUA6	Protection area maximum address	SV
SR26, 6	MPAT6	Protection area attribute	SV
SR28, 6	MPLA7	Protection area minimum address	SV
SR29, 6	MPUA7	Protection area maximum address	SV
SR30, 6	MPAT7	Protection area attribute	SV
SR0, 7	MPLA8	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR1, 7	MPUA8	Not implemented. A value of 0 is returned when read and writing is ignored.	SV

Table 3.117 MPU Function System Registers (2/2)

Register No. (reg.ID, sel.ID)	Symbol	Function	Access Permission
SR2, 7	MPAT8	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR4, 7	MPLA9	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR5, 7	MPUA9	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR6, 7	MPAT9	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR8, 7	MPLA10	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR9, 7	MPUA10	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR10, 7	MPAT10	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR12, 7	MPLA11	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR13, 7	MPUA11	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR14, 7	MPAT11	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR16, 7	MPLA12	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR17, 7	MPUA12	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR18, 7	MPAT12	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR20, 7	MPLA13	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR21, 7	MPUA13	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR22, 7	MPAT13	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR24, 7	MPLA14	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR25, 7	MPUA14	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR26, 7	MPAT14	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR28, 7	MPLA15	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR29, 7	MPUA15	Not implemented. A value of 0 is returned when read and writing is ignored.	SV
SR30, 7	MPAT15	Not implemented. A value of 0 is returned when read and writing is ignored.	SV

(b) MPM — Memory protection operation mode register

The memory protection mode register is used to define the basic operating state of the memory protection function.

Table 3.118 MPM Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 11	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
10	DX	This bit specifies the default operation when an instruction is executed at an address that does not exist in a protection area. 0: Disable executing an instruction at an address that does not exist in a protection area. 1: Enable executing an instruction at an address that does not exist in a protection area.	R/W	0
9	DW	This bit specifies the default operation when writing to an address that does not exist in a protection area. 0: Disable writing to an address that does not exist in a protection area. 1: Enable writing to an address that does not exist in a protection area.	R/W	0
8	DR	This bit specifies the default operation when reading from an address that does not exist in a protection area. 0: Disable reading from an address that does not exist in a protection area. 1: Enable reading from an address that does not exist in a protection area.	R/W	0
7 to 2	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
1	SVP ^{*3, *4}	In SV mode (when PSW.UM = 0), this bit is used to specify whether to restrict access according to the SX, SW, and SR bits of the MPAT register for each protection area. ^{*1} 0: As usual, implicitly enable all access in SV mode. 1: Restrict access according to the SX, SW, and SR bits even in SV mode. ^{*2}	R/W ^{*4}	0
0	MPE	This bit is used to specify whether to enable or disable MPU function. 0: Disable 1: Enable	R/W	0

Note 1. When the SVP bit is set to 1, access will become restricted after a certain number of clock cycles, even in SV mode. Therefore, specify the protection area before setting the SVP bit to prevent restriction of access by the program itself.

Note 2. If access is restricted in SV mode, execution of MDP exceptions or the MIP exception handling itself might not be possible depending on the settings. Be careful to specify settings so that access to the memory area necessary for the exception handler and exception handling is permitted.

Note 3. Access by the CPU in supervisor mode is not restricted during the processing of SYSCALL instructions while SVP = 1 and in table references in response to EIINT interrupts involving table reference.

Note 4. When the SVP bit is set to 1 to use the debugger, enable execution of instruction by SV mode in the FE60 0000_H to FE7F FFFF_H area. When a debugger manufactured by a third party executes instructions by downloading code to the global RAM area or local RAM area of PE1, enable instructions for SV mode in said areas.

(c) MPRC — MPU region control register

Bits used to perform special memory protection function operations are located in this register.

Table 3.119 MPRC Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 16	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
15 to 8	E15-E8	These bits are not supported in this product. (Reserved for future expansion. Be sure to clear to 0.)	R	0
7 to 0	E7-E0	These are the enable bits for each protection area. Bit En is a copy of bit MPATn.E (where n = 3 to 0). The number of the protection areas in this product is 8.	R/W	0

(d) MPBRGN — MPU base region register

This register indicates the minimum usable MPU area number.

Table 3.120 MPBRGN Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 4	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
3 to 0	MPBRGN	These bits indicate the smallest number of an MPU area.	R	0000

(e) MPTRGN — MPU end region register

This register indicates the maximum usable MPU area number.

Table 3.121 MPTRGN Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 4	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
3 to 0	MPTRGN	These bits indicate the largest number of an MPU area.	R	0111

(f) MCR — Memory protection setting check result

This product does not incorporate the memory protection setting function.

This register is reserved for the future expansion.

Table 3.122 MCR Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 0	—	(Reserved for future expansion)	R	0000 003F _H

(g) MPLAn — Protection area minimum address register

These registers indicate the minimum address of area n (n = 0 to 7).

Table 3.123 MPLAn Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 2	MPLA31-2	These bits indicate the minimum address of area n. The MPLA1-0 bits are implicitly set to 0.	R/W	Undefined
1, 0	—	Reserved for future expansion. Be sure to clear these bits to 0.	R	0

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27 of MPLAn.

(h) MPUAn — Protection area maximum address register

These registers indicate the maximum address of area n (n = 0 to 7).

Table 3.124 MPUAn Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 2	MPUA31-2	These bits indicate the maximum address of area n. The MPUA1-0 bits are implicitly set to 1.	R/W	Undefined
1, 0	—	Reserved for future expansion. Be sure to clear these bits to 0.	R	0

CAUTION

For a CPU whose instruction addressing range is 128 MB, a value resulting from a sign-extension of bit 26 is automatically set to bits 31 to 27 of MPUAn.

(i) MPATn — Protection area attribute register

These registers indicate the attributes of area n (where n = 0 to 7).

Table 3.125 MPATn Register Contents

Bit Position	Bit Name	Function	R/W	Value after Reset
31 to 26	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
25 to 16	ASID	These bits indicate the ASID value to be used as the area match condition.	R/W	0
15 to 8	—	(Reserved for future expansion. Be sure to clear to 0.)	R	0
7	E	This bit indicates whether area n is enabled or disabled. 0: Area n is disabled. 1: Area n is enabled.	R/W	0
6	G	0: ASID match is the condition. 1: ASID match is not the condition. When this bit is 0, the condition of the area match is MPATn.ASID = ASID.ASID. When this bit is 1, the area match of the values of MPATn.ASID and ASID.ASID is the condition.	R/W	Undefined
5	SX	This bit indicates the execution privilege for supervisor mode.*1 0: The execution is disabled. 1: The execution is enabled.	R/W	Undefined
4	SW	This bit indicates the write permission for supervisor mode.*1 0: Writing is disabled. 1: Writing is enabled.	R/W	Undefined
3	SR	This bit indicates the read permission for supervisor mode*1 0: Reading is disabled. 1: Reading is enabled.	R/W	Undefined
2	UX	This bit indicates the execution privilege for user mode. 0: The execution is disabled. 1: The execution is enabled.	R/W	Undefined
1	UW	This bit indicates the write permission for user mode. 0: Writing is disabled. 1: Writing is enabled.	R/W	Undefined
0	UR	This bit indicates the read permission for user mode. 0: Reading is disabled. 1: Reading is enabled.	R/W	Undefined

Note 1. If access is restricted in SV mode, execution of MDP exceptions or the MIP exception handling itself might not be possible depending on the settings. Be careful to specify settings so that access to the memory area necessary for the exception handler and exception handling is permitted.

(6) Cache operation function registers

The RH850/E1M-S2 does not have cache processing function registers.

(7) Data buffer operation function registers

The RH850/E1M-S2 does not have data buffer operation function registers.

3.3.2 Inter-Processor Interrupts

The PCU includes an inter-processor interrupt control register (IPIR_CH0-3). It is a CPU peripheral and its functions and addresses are the same as those of the CPU1. IPIR_CH0 to IPIR_CH3 registers are assigned to each PE which are accessible only from their own PE. For details, see **Section 3.4.2, Inter-Processor Interrupt Function.**

3.3.3 Reliability Functions

3.3.3.1 System Error Notification Control Function (SEG)

Errors due to an instruction fetch or data access can be the sources of system error exceptions. A SYSERR exception is an FE level exception from which return or recovery is not possible.

For source codes (FEIC) of the SYSTEM exceptions and error handling, see **Table 3.127, Error Factor Codes and Handling of G3K Core SYSERR Exceptions**. When a system error exception is accepted, the PSW.EBV bit is cleared to 0 and the exception handler always refers to RBASE.

SEG (SysErrGen) controls interrupt notification and recording after a system error occurred by a data access.

(1) Register Set

(a) SEG_CONT — System Error Control Register

This register enables and disables the error notification of each SYSERR source. When the bit is set to 1, SYSERR notification of error occurrence is enabled. When it is cleared to 0, SYSERR notification is disabled although the error flag in response to the error factor occurrence is set.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—									RMWE	—	RAME	—	EXTE	FCHE	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R	R/W	R/W	R

Table 3.126 SEG_CONT Register Contents

Bit Position	Bit Name	Function
15 to 7	—	Reserved These bits are always read as 0. The write value should always be 0.
6	RMWE	Local RAM Read/Modify/Write Error Notification Enable: This bit enables SYSERR notification of an ECC error that occurs when a read access is made to the local RAM during read/modify/write operation after a byte or half word write is made to the local RAM.
5	—	Reserved This bit is always read as 0. The write value should always be 0.
4	RAME	Local RAM ECC Error Notification Enable: This bit enables the SYSERR notification of an ECC error occurred when the CPU accesses the data in the local RAM area.
3	—	Reserved This bit is always read as 0. The write value should always be 0.
2	EXTE	P-Bus/H-Bus/Global RAM Area Error Notification Enable: This bit enables SYSERR notification of an error occurring when the P-Bus/H-Bus/Global RAM area is accessed. Such errors include: <ul style="list-style-type: none"> • P-Bus: Data Parity Error, Guard Error • H-Bus: Error response in the slave modules • Global RAM: Data ECC Error, Address Parity Error, Guard Error
1	FCHE	Code Flash Error Notification Enable: This bit enables the SYSERR notification of an error occurred when the CPU accesses the data in the code flash. Such errors include: <ul style="list-style-type: none"> • Data ECC Error • Address Parity Error
0	—	Reserved This bit is always read as 0. The write value should always be 0.

Table 3.127 Error Factor Codes and Handling of G3K Core SYSERR Exceptions

Factor Code	Error Contents
10	Reserved
11	Instruction fetch errors
12	Reserved
13	Reserved
14	Errors in which their notification is enabled by the SEG_CONT register. Errors that have occurred can be identified by reading the SEG_FLAG register
15	Reserved
16	Reserved
17	Reserved
18	Reserved
19	Reserved
1A	Reserved
1B	Reserved
1C	Reserved
1D	Reserved
1E	Reserved
1F	Reserved

(b) SEG_FLAG — System Error Flag Register

This register indicates the flags to store the status under which each SYSERR factor occurs. When a SYSERR factor occurs, the corresponding error factor flag is set to 1. The SYSERR can also be generated by direct writing to the register and setting the flag to 1. Each flag can be cleared by writing 0 after reading the state of 1.

Even if 0 is written in a subsequent write operation to a flag already set to 0 during reading, the flag is set in response to an error occurring between the read and the write.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	RMWF	—	RAMF	—	EXTF	FCHF	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R	R/W	R/W	R

Table 3.128 SEG_FLAG Register Contents

Bit Position	Bit Name	Function
15 to 7	—	Reserved These bits are always read as 0. The write value should always be 0.
6	RMWF	Flag corresponding to bit 6 of the SEG_CONT register
5	—	Reserved This bit is always read as 0. The write value should always be 0.
4	RAMF	Flag corresponding to bit 4 of the SEG_CONT register
3	—	Reserved This bit is always read as 0. The write value should always be 0.
2	EXTF	Flag corresponding to bit 2 of the SEG_CONT register
1	FCHF	Flag corresponding to bit 1 of the SEG_CONT register
0	—	Reserved This bit is always read as 0. The write value should always be 0.

3.4 Inter-CPU Functions

3.4.1 Processor Element Identifier

The PEID, each processor element ID number, can be read from the PEID field in the HTCFCG0 register. Which CPU core performs a specific program can be understood by referring to the PEID. The following shows the PEID of this product.

CPU core	PEID
CPU1 (PE1)	001 _B
PCU (PE3)	011 _B

3.4.2 Inter-Processor Interrupt Function

Both CPU1 and the PCU individually have IPIR registers as their own peripheral functions. Setting of the IPIR register enables an EI-level interrupt request from a PE to another PE. For details, see **Section 3.2.3, Inter-Processor Interrupts**.

3.4.3 Exclusive Function

The local RAM, global RAM, and exclusive control register (MEV) are available as a resource for exclusive control. As atomic operation instruction, the instructions of LDL/STC, CAXI, SET1, CLR1, and NOT1 can be performed for the local RAM and global RAM, and the instructions of CAXI, SET1, CLR1, and NOT1 can be performed for the exclusive control register (MEV). These registers are also accessible by the LD and ST instructions but not regarded as atomic operation.

CAUTION

Access to the local RAM of the PCU or an MEV register by using the CAXI, SET1, CLR1, or NOT1 instructions are atomic operations, but access to the local RAM of CPU1 or global RAM by the same instructions is not. Use the MEV for exclusive control of PCU and CPU1.

3.4.3.1 Exclusive Control Register (MEV)

This register supports exclusive control for variables shared between PEs (common resources).

(MEV = Mutual Exclusion Variable Register)

- 32 32-bit MEV registers are included.
- 1-, 8-, 16-, and 32-bit accesses are available for each MEV.
- Accesses from CPU1 (PE1) and the PCU (PE3) can be made.
- Atomic operation instructions of CAXI, SET1, CLR1, and NOT1 can be performed.

CPU1 and the PCU each have an independent access path for the MEV registers. Therefore, when CPU1 and the PCU each access different MEV registers, they do not need to wait for access. When they access the same MEV register, however, waiting for access is required.

Table 3.129 Base Address of SEG Register: FFFE EC00_H

Register Symbol	Register Name	R/W	Value after Reset	Operable Bit				Access Size
				1	8	16	32	
G0MEV0	Exclusive Control Register 0	R/W	0000 0000 _H	√	√	√	√	+00 _H

G0MEV31	Exclusive Control Register 31	R/W	0000 0000 _H	√	√	√	√	+7C _H

3.4.3.2 Operation of the LDL.W and STC.W Instructions

The LDL.W and STC.W instructions can be used to obtain atomic read-modify-write operations for accurate processing in the updating of memory by multicore systems. The LDL.W and STC.W instructions operate as follows. The LDL.W and STC.W instructions are only in the instruction set for the CPU (G3M) and not in that for the PCU (G3K). For the operation of the LDL.W and STC.W instructions, refer to the *RH850G3M User's Manual: Software*.

- Link generation: The CPU is capable of generating links to both the local RAM and global RAM. Executing the LDL.W instruction on the target RAM for the operation leads to link address being registered, the link flag being set, and a link being generated in response to reading by the instruction. Two link flag systems are provided, one each for the following two areas of RAM.

- (1) The local RAM for the given processor: 1
- (2) The global RAM: 1

Since these link flags are generated independently of each other, a link that was previously generated (e.g. by the CPU to the local RAM) is not lost when the CPU executes the LDL.W instruction for the other RAM (e.g. the global RAM).

- Success in storing: After a link has been generated, storing will only proceed in response to executing an STC.W instruction corresponding to the generated link.
- Failure in storing: If a link is lost, storing does not proceed even when an STC.W instruction for the corresponding address is processed. Storing also does not proceed when an STC.W instruction that does not correspond to the link is processed.
- Condition for successful storing: If the following condition is met, the STC.W instruction is judged to be for the address corresponding to the link.
 - The address for the LDL.W instruction which generated the link matches that for the STC.W instruction.
- Loss of the link: If any of the following occurs, the link flag is cleared and the link is lost.
 - Any of the following processing by the CPU for which the link was generated:
 - An STC.W instruction being executed. The corresponding link (for (1) or (2) above) will be lost irrespective of the success or failure of storing.
 - Occurrence of an exception or the CPU executing an instruction to return from an exception processing routine (FERET or EIRET). The link for the linked RAM area and the link flag are cleared.
 - A successive LDL.W instruction being executed for a location corresponding to the link flag for the linked RAM. The link generated in response to the preceding LDL.W instruction will be lost. Do not execute such processing.
 - Storing operations other than execution of a STC.W instruction for the address* indicated by the link. Do not execute such processing.
 - Access as described below by another bus master:
 - Any storing operation, including execution of an STC.W instruction for the address* indicated by the link. The corresponding link will be lost.

Note. Refers to the addresses of locations that match the 27 higher-order address bits of the address for which the link was created.

Success of the STC.W instruction means that the LDL.W and STC.W instructions have realized an atomic Read-Modify-Write operation.

3.5 Usage Notes

3.5.1 Synchronization of Store Instruction Completion and Subsequent Instruction Generation

When a control register is updated by a store instruction, there is a time lag from execution of the store instruction by the CPU to actual updating of the control register. Therefore, appropriate processing for synchronization is required to ensure that control registers reflect updated values before execution of subsequent instructions. The processing for synchronization is shown below.

For details of the procedure regarding updating of the system registers by the LDSR instruction and synchronization with subsequent instructions, refer to *APPENDIX A, HAZARD RESOLUTION PROCEDURE FOR SYSTEM REGISTERS* in the *RH850G3MH User's Manual: Software* or the *RH850G3K User's Manual: Software*.

3.5.1.1 When updated results in the control registers are reflected in the implementation of a subsequent instruction:

Example 1: An interrupt may be enabled by implementation of an EI instruction after an interrupt request is cleared by access from the control register in the INTC2 and the peripheral circuits. Proceed as follows in this case.

- (1) Store instruction to update a control register (ST.W, etc.)
- (2) Dummy reading of the above-mentioned control register (LD.W, etc.)*¹
- (3) SYNCP
- (4) Subsequent instruction (EI, etc.)

Example 2: Implement the same processing even when the access required after waiting to secure the updating of a given control register (register A) is to another control register (register B). This includes the following cases: the interlinked operation of different peripheral modules and when releasing the interrupt mask in INTC after making peripheral module settings.

However, this processing is unnecessary if control registers A and B are in the same peripheral group.

For the correspondence between the peripheral groups and the peripheral modules/registers, see **Appendix, List of Registers**.

- (1) Issue the instruction for storage to update control register A (ST.W, etc.)
- (2) Dummy-read the above control register (LD.W, etc.)*¹
- (3) Issue SYNCP.
- (4) Issue the instruction to access control register B (ST.W, LD.W, etc.)

The same processing is also required when access to control registers and memory within the scope of protection starts after waiting for the completion of settings for safety functions such as memory protection, ECC checking, and so on.

Note 1. Dummy reading of any register of the same peripheral group can be used instead.

3.5.1.2 When the updated results in the control registers and memories are reflected in the instruction fetch of a subsequent instruction:

- (a) If you wish to write an instruction to the RAM and then branch to the RAM to execute the written instruction, handle this as follows.
- (1) Store instruction to update a memory (ST.W, etc.)
 - (2) Dummy reading of the above-mentioned memory (LD.W, etc.)
 - (3) SYNCP
 - (4) SYNCI
 - (5) Subsequent instruction (branch instruction, etc.)
- (b) When branching to a target memory after waiting for the completion of updating the control registers for memory protection and ECC, handle this as follows.
- (1) Store instruction to update a control register (ST.W, etc.)
 - (2) Dummy reading of the control register (LD.W, etc.)
 - (3) SYNCP
 - (4) SYNCI
 - (5) Subsequent instruction (branch instruction, etc.)

3.5.1.3 When switching the code flash area

In this case, refer to (7) *Updating the FCUFAREA Register*, in section 9, *Usage Notes*, in the *RH850/E1x-FCC2 Flash Memory User's Manual: Hardware Interface*.

3.5.1.4 When executing the SYNCM instruction to wait for the completion of update by the store instruction

When executing the SYNCM instruction to wait for the completion of updating the destination for access by the preceding store instruction, the CPU that executes the store instruction and the destination for access must be as follows.

CPU that Executes the Store Instruction	Destination for Access by the Store Instruction
CPU1	Local RAM (self), Local RAM (PE1), Global RAM

3.5.2 Accesses to Registers by Bit-Manipulation Instructions

Processing of a bit-manipulation instruction takes the form of atomic reading, modification, and writing of an eight-bit unit. Thus, access by a bit-manipulation instruction is only possible for registers for which reading and writing in 8-bit units is possible. However, take care in the cases of registers that contain multiple flag bits, since the read-modify-write cycle may also clear flags other than that which was the target for clearing.

Write access to the FlexRay registers by using bit-manipulation instructions is not atomic. Access by other masters may interrupt the read-modify-write processing of these instructions.

3.5.3 Ensuring Coherency after Code Flash Programming

The CPU has an efficient instruction cache and data buffer for the code flash area.

Therefore, after using self-programming to program the code flash memory, clear the instruction cache and data buffer to ensure coherency. The instruction cache and data buffer can be cleared by using the ICCTRL register and the CDBCR register, respectively. The instruction cache and data buffer can also be cleared at the same time by using the TM_CC register. For details of the TM_CC register, see **Section 38.4.5, TM_CC — Cache Clear Operation Register**.

When the PCU is in use, use the TM_CC register in the same way to clear the cache and buffer after programming the code flash memory. After that, apply an external reset.

3.5.4 Overwriting Context when Acknowledging Multiple Exceptions

Exceptions may be acknowledged regardless of the states of the ID or NP bits of the PSW register. This depends on the type of exception. When multiple exceptions occur, the contents of the system registers which hold the context information are overwritten. Regarding the conditions for acknowledging exceptions from each source and the possibility of return and recovery, see the list of exception sources in *RH850G3MH User's Manual: Software* and *RH850G3K User's Manual: Software*.

3.5.5 Usage Notes on Prefetching

CPU executes speculative instruction fetching from locations later than the current value of the program counter to maintain the throughput of instruction fetches. Reading from memory due to such prefetching may proceed even from locations to which instruction codes have not been assigned (note 1 in **Figure 3.6**). Please note the following. The CPU does not execute values read in such cases.

These notes apply to instruction fetching from memory in general.

- Occurrence of ECC errors due to values in memory being undefined

This prefetching may lead to an ECC error in case of reading from the code flash memory after it has been erased or from the Local RAM or Global before initialization. When instruction codes are assigned to memory, initialize said area with values as desired (note 1 in **Figure 3.6**).

- Detection of illegal access by the GRG or IPG

The GRG or IPG may detect such prefetching as illegal access. To prevent prefetching being detected as an illegal access, do not allow any region of overlap area with said areas (note 1 in **Figure 3.6**) and areas to which access is prohibited by the GRG or IPG. Reading from an area protected by the MPU does not cause a memory protection exception.

- Access to Access Prohibited Area

Assign instruction codes to memory without allowing any overlap between said area (note 1 in **Figure 3.6**) and an access-prohibited area.

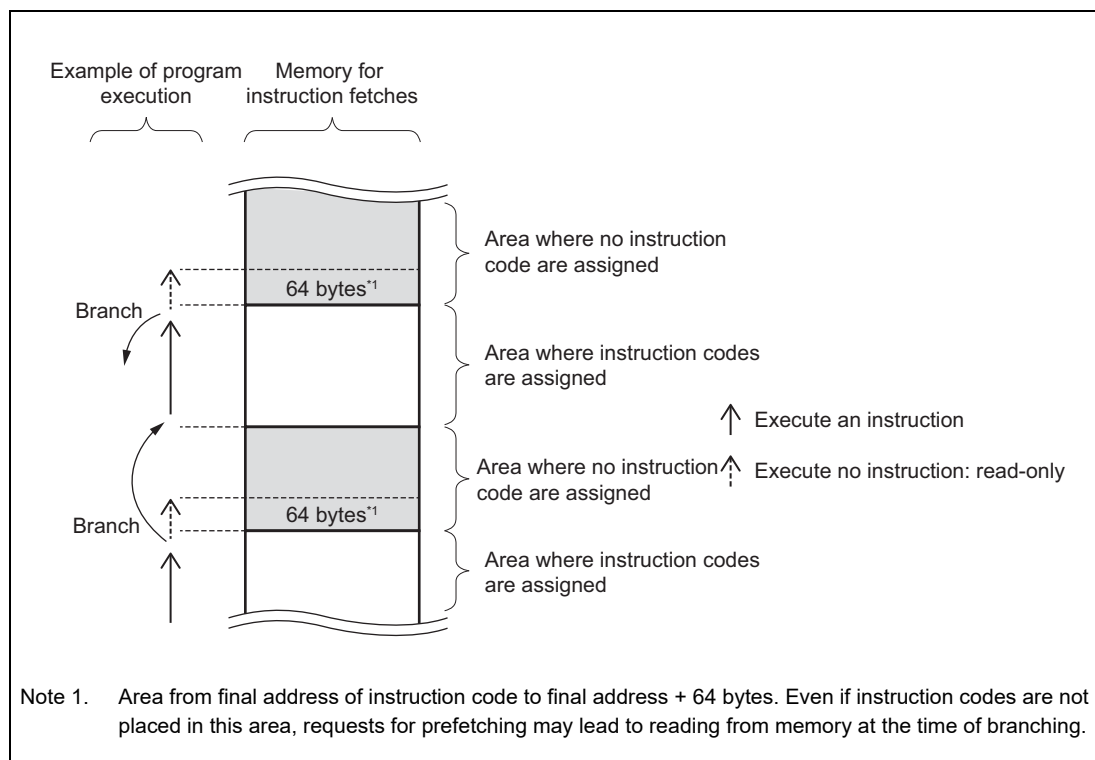

Figure 3.6 Area that Requires Attention Regarding Prefetching

3.5.6 Setting for Blocking of Bit-Manipulation Instructions

A bit-manipulation instruction (SET1, NOT1, CLR1, or TST1) is executed after waiting for the completion of execution of the previous load/store instruction by setting the BBOPEN bit of the system register (LSUCR[19]) to 1. The subsequent load/store instruction is executed after waiting for the completion of execution of the bit-manipulation instruction. Access to the BBOPEN bit requires manipulating the CBAKEY bits (LSUCR[31:28]) to unlock the key. When setting the BBOPEN bit, take care not to set other reserved bits to a value other than the specified one. In addition, we recommend relocking the CBAKEY bits after setting the BBOPEN bit. The following are example sequences of instructions for setting the BBOPEN bit.

A sequence of instructions for unlocking CBAKEY to set BBOPEN to 1 and locking CBAKEY

* The instructions must be executed while interrupts are disabled.

```
mov 0xc02b0000, r1
mov 0xd02b0000, r2 -- set BBOPEN
ldsr r1, sr8, 13 -- LSUCR
ldsr r2, sr8, 13
ldsr r2, sr8, 13
ldsr r1, sr8, 13
ldsr r0, sr8, 13 -- close CBAKEY
```

A sequence of instructions for unlocking CBAKEY to clear BBOPEN to 0 and locking CBAKEY

* The instructions must be executed while interrupts are disabled.

```
mov 0xc0230000, r1
mov 0xd0230000, r2 -- clear BBOPEN
ldsr r1, sr8, 13 -- LSUCR
ldsr r2, sr8, 13
ldsr r2, sr8, 13
ldsr r1, sr8, 13
ldsr r0, sr8, 13 -- close CBAKEY
```

Setting the BBOPEN bit (LSUCR[19]) to 1 may lead to deterioration of performance in a program that uses bit-manipulation instructions. Care must be taken when setting the BBOPEN bit to 1.

Section 4 Address Space

Table 4.1 shows the address space of the RH850/E1M-S2.

When making an access to the on-chip I/O register space, access the addresses shown in **Appendix, List of Registers**. Do not access an address that is not specified in **Table 4.1** and an area where any access is prohibited. If an unspecified address or reserved area is accessed, operation is not guaranteed.

4.1 Address Space

Table 4.1 Address Space

Address	Address Space Type	Size
0000 0000 _H to 003F FFFF _H (0001 7000 _H to 0001 7FFF _H)	Code flash (user area read) (FCU firmware storage area (Map is switched by FCUFAREA register))* ³	4 MB (4 KB)
0040 0000 _H to 00FF FFFF _H	Access prohibited	
0100 0000 _H to 0100 7FFF _H	Code flash (user boot area read)	32 KB
0100 8000 _H to 0FFF FFFF _H	Access prohibited	
0103 7000 _H to 0103 7FFF _H	FCU firmware storage area 2* ³	4KB
0103 8000 _H to 0FFF FFFF _H	Access prohibited	
1000 0000 _H to 1FFF FFFF _H	On-chip I/O register	256 MB
2000 0000 _H to FEBE FFFF _H	Access prohibited	
FEBF 0000 _H to FEBF FFFF _H	Local RAM (CPU1)	64 KB
FEC0 0000 _H to FEDE FFFF _H	Access prohibited	
FEDF 0000 _H to FEDF FFFF _H	Local RAM (self) * ¹	64 KB
FEE0 0000 _H to FEED FFFF _H	Access prohibited	
FEEE 0000 _H to FEF1 FFFF _H	Global RAM area	256 KB
FEF2 0000 _H to FEFF FFFF _H	Access prohibited	
FF00 0000 _H to FFFD FFFF _H (FF20 0000 _H to FF20 FFFF _H) (FFA1 2000 _H to FFA1 2FFF _H)	On-chip I/O register (Data flash (read/write)) (FCU RAM)	16 MB to 128 KB (64 KB) (4 KB)
FFFE 0000 _H to FFFE DFFF _H	Access prohibited	
FFFE E000 _H to FFFE FFFF _H	On-chip I/O register (self* ²)	8 KB
FFFF 0000 _H to FFFF 4FFF _H	Access prohibited	
FFFF 5000 _H to FFFF FFFF _H	On-chip I/O register	44 KB

Note 1. When accessing a local RAM from CPU1 or other unit, accessing the local RAM (CPU1) allows access to the local RAM in CPU1 and accessing the local RAM (self) allows access to the local RAM in each PE (CPU1/PCU). The local RAM (self) areas have the following differences because the local RAM (self) capacity differs between CPU1 and the PCU.

- CPU1 local RAM (self): FEDF 0000_H to FEDF FFFF_H (64 KB)
- PCU local RAM (self): FEDF 8000_H to FEDF FFFF_H (32 KB)

Also note that some tools do not support access to the local RAM of CPU1 via the local RAM (self) area. For details, see the manual for the tool you are using. If this is the case, access to the local RAM area of CPU1 is via the local RAM (CPU1) area and access to the local RAM of the PCU is via the local RAM (self) area.

Note 2. The on-chip I/O register (self) has CPU peripheral function. CPU peripheral function is typically unique to each PE and no access is allowed to the CPU peripheral of other PE. However, the exclusive control register (MEV) is an exception and shares the function between PEs.

Note 3. For details, see the *RH850/E1x-FCC2 Flash Memory User's Manual: Hardware Interface*.

4.2 Address Space Viewed from Each Bus Master

Figure 4.1 shows address spaces viewed from each bus master.

4.2.1 Space in which instructions can be fetched

1. Instructions of CPU1 and the PCU can be fetched from the code flash, local RAM and global RAM.
2. The reset vector (RBASE initial value) of CPU1 and the PCU:
 - When starting up from the user boot area, its head address is 0100 0000_H.
 - When starting up from the user area, its head address is 0000 0000_H.

4.2.2 Data space accessible by CPU1

All spaces are accessible.

4.2.3 Data space accessible by PCU

All spaces are accessible. However, an access from CPU1 to the on-chip I/O register, 1000 0000_H to 1FFF FFFF_H is not available. Use FC00 0000_H to FE5F FFFF_H for such access.

4.2.4 Data space accessible by DMA (DMAC, DTS)

See Figure 4.1 for the accessible spaces from the DMA.

4.2.5 Data space accessible by H-Bus

See Figure 4.1 for the accessible spaces from the H-Bus.

	Access from CPU1	Access from PCU	Access from DMA	Access from H-Bus
FFFF FFFF _H	On-chip I/O register	On-chip I/O register	On-chip I/O register	On-chip I/O register
FFFF 5000 _H FFFF 4FFF _H	Access prohibited	Access prohibited	Access prohibited	Access prohibited
FFFF 0000 _H FFFE FFFF _H	On-chip I/O register (self)	On-chip I/O register (self)		
FFFE E000 _H FFFE DFFF _H	Access prohibited	Access prohibited	Access prohibited	Access prohibited
FFFE 0000 _H FFFD FFFF _H	On-chip I/O register	On-chip I/O register	On-chip I/O register	On-chip I/O register
FF00 0000 _H FEFF FFFF _H	Access prohibited	Access prohibited	Access prohibited	Access prohibited
FEF2 0000 _H FEF1 FFFF _H	Global RAM	Global RAM	Global RAM	Global RAM
EEEE 0000 _H FEED FFFF _H	Access prohibited	Access prohibited	Access prohibited	Access prohibited
FE00 0000 _H FEDF FFFF _H	Local RAM (self)	Local RAM (self)	Access prohibited	Access prohibited
FEDF 8000 _H FEDF 7FFF _H	Access prohibited	Access prohibited		
FEDF 0000 _H FEDE FFFF _H	Access prohibited	Access prohibited	Access prohibited	Access prohibited
FEC0 0000 _H FEBF FFFF _H	Local RAM (CPU1)	Local RAM (CPU1)	Local RAM (CPU1)	Local RAM (CPU1)
FEBF 0000 _H FEBE FFFF _H	Access prohibited	Access prohibited	Access prohibited	Access prohibited
FE60 0000 _H FE5F FFFF _H	Access prohibited	Use FC00 0000 _H to FEF9 FFFF _H for an access from the PCU to the on-chip I/O register area, 1000 0000 _H to 1FFF FFFF _H .	Access prohibited	Access prohibited
FC00 0000 _H FBFF FFFF _H		Not accessible		
2000 0000 _H 1FFF FFFF _H	On-chip I/O register	Not accessible	On-chip I/O register	On-chip I/O register
1000 0000 _H 0FFF FFFF _H	Access prohibited	Access prohibited	Access prohibited	Access prohibited
0400 0000 _H 03FF FFFF _H	Access prohibited	Access prohibited	Access prohibited	Access prohibited
0103 8000 _H 0103 7FFF _H	FCU firmware	FCU firmware		
0103 7000 _H 0103 6FFF _H	Access prohibited	Access prohibited	Access prohibited	Access prohibited
0100 8000 _H 0100 7FFF _H	Code flash (user boot area)	Code flash (user boot area)		
0100 0000 _H 00FF FFFF _H	Access prohibited	Access prohibited	Code flash (user area)	Code flash (user area)
0040 0000 _H 003F FFFF _H	Code flash (user area)	Code flash (user area)		
0000 0000 _H	Code flash (user area)	Code flash (user area)	Code flash (user area)	Code flash (user area)

Note: The following color coding is used in the map above.

Fetch and data access available.
Data access available.
Access prohibited
Not accessible

Figure 4.1 Address Space Viewed from Each Bus Master

4.3 Code Flash

4.3.1 Parallel Access to the User Area

The user area of the code flash memory is in a two-mat configuration. User settings for memory areas can divide memory in the two mats composing the user area into two banks, A and B. In this case, one bus master may access bank A and another access bank B without a wait for arbitration of contention for the access path.

When multiple bus masters access the same bank, bank A or bank B, access is arbitrated in round-robin fashion.

The capacities of bank A and bank B can be changed to suit different applications, and the user sets up the division by using an option byte. The following restriction applies to the setting.

1. User mat 0 is fixed as being in bank A and this cannot be changed.

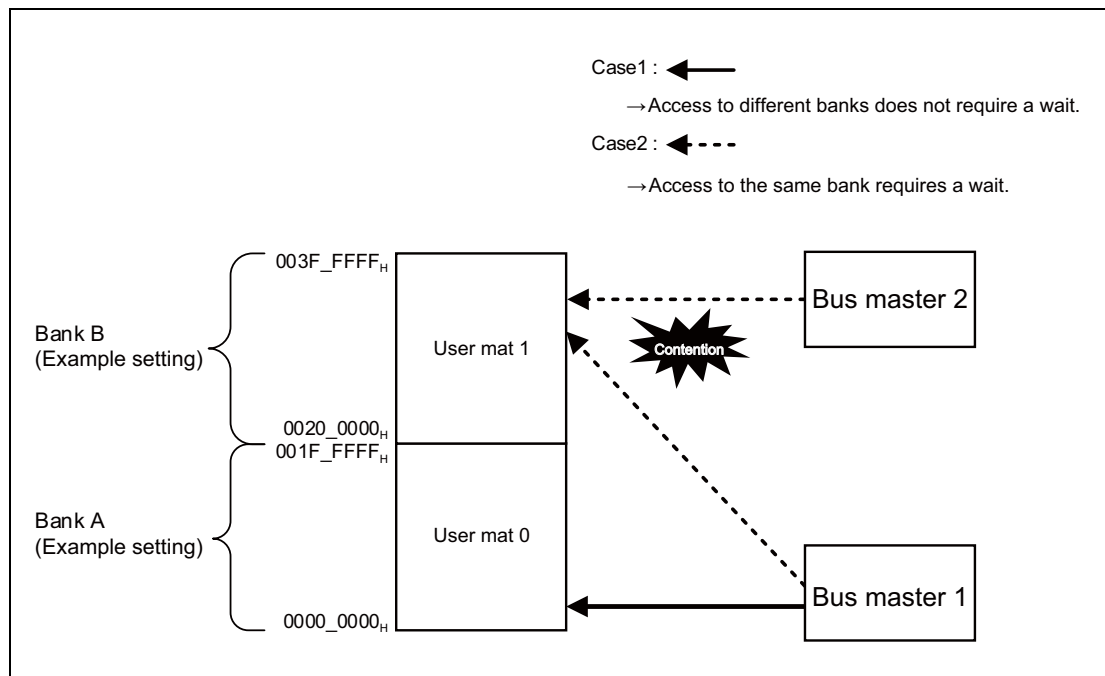

Figure 4.2 Operation in Access to Banks A and B (Example Settings)

For details of the setting procedure, see **Section 34, Flash Memory**.

4.4 Global RAM and Retention RAM

The global RAM is divided into two, bank A and bank B. Different banks can be accessed concurrently. The upper 32 Kbytes of bank A is the retention RAM that retains data even during power-off standby state.

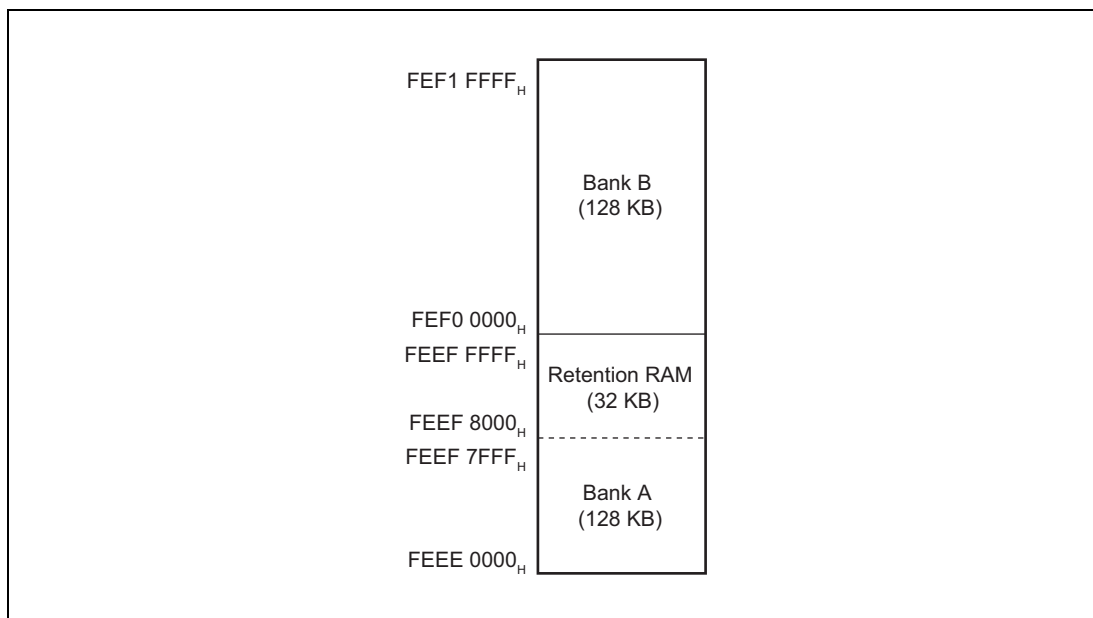

Figure 4.3 Global RAM

Section 5 Operating Mode

5.1 Features

This LSI has three mode pins to determine the operating mode (MD0, MD1, and FLMODE).

5.2 Operating Mode

This LSI has multiple operating modes, which can be selected with the three pins (MD1, MD0, and FLMODE) and the setting of STMSEL1/STMSEL0 in option byte 0. For the procedures to set STMSEL1/STMSEL0, see **Section 34, Flash Memory**. **Table 5.1** shows the list of the operating modes.

Table 5.1 Selection of Operating Mode

Value Set in the Pin			Value Set in Option Byte 0		Operating Mode	Startup Area	Types of Debug Interface*1	Remarks
MD1	MD0	FLMODE	STM SEL1	STM SEL0				
0	0	0	0	0	User boot mode	User area	The debug interface can be selected by using the option bytes OPBT2. See Section 34.10.2, OPBT2 — Option Byte 12 to 9 Bits Arrangement for the details.	On-chip debug is available.
0	0	0	0	1	User boot mode	User boot area		
0	0	0	1	x	Serial programming mode	Boot area	Writer I/F (2 wire UART)	Serial programming is available
0	0	1	x	x	Boundary scan mode	—	JTAG	Boundary scan is available.
0	1	0	x	x	Serial programming mode	Boot area	Writer I/F (2 wire UART)	Serial programming is available
0	1	1	x	x	Serial programming mode	Boot area	Writer I/F (CSI (Clocked Serial Interface))	Serial programming is available

Note: X = don't care.

Note 1. For the correspondence between the pin function and pin state in each debug interface, see **Section 2.5.3, Pin State**.

5.2.1 User Boot Mode

After release from the reset state, instruction fetch is carried out from the user boot area or the user area.

5.2.2 Serial Programming Mode

After release from the reset state, the LSI boots up from the on-chip boot program and starts connection in the specified transmission method. For details, see **Section 34, Flash Memory**.

5.2.3 Boundary Scan Mode

This is a mode to use the boundary scan function in accordance with the standard of IEEE1149.1. For details, see **Section 39, Boundary Scan**.

Section 6 Interrupt

The interrupt controller (INTC) determines priority of interrupt sources and controls interrupt requests to the CPU. The INTC has a register to set priority of each interrupt. Interrupt requests are processed according to the priority set in this register by the user.

6.1 Overview

- Simultaneous distribution of interrupt sources to multiple cores
 - A single interrupt source can be distributed to multiple CPU cores.
(Distribution target cores: CPU1/PCU)
 - Target interrupt sources: Nonmaskable interrupt 1 source, FE level interrupt 1 source, EI level interrupts 23 sources
- Interrupt sources
 - Nonmaskable interrupt:
External pin NMI interrupt (FENMI) 1 source
 - FE level interrupt:
ECM interrupt (FEINT) One source
 - EI level interrupt (maskable) (EIINT)
 - high-speed interrupts (EIINT0 to 31) 23 sources
 - Inter-processor interrupts
 - ECM interrupts
 - External pin IRQ interrupts
 - Software interrupts
 - Constant-cycle timer (OSTM)
 - DMA error interrupts
 - ICU-S interrupts
 - Low-speed interrupts (EIINT32 to 511) 468 sources
 - Timer
 - Communication
 - A/D converter
 - DMAC/DTS, etc.
- Priority levels for Interrupt
Priority levels of IRQ (external interrupts) and maskable interrupts can be set in the interrupt control registers according to interrupt requests, up to 16 levels for CPU1 and 8 levels for PCU.
- Detecting methods of external interrupt (NMI/IRQ)
A method of detecting NMI sources can be selected from two types: rising edge and falling edge. A method of detecting IRQ sources can be selected from four types: high level, low level, rising edge, and falling edge.
- Direct branching method or table referencing method is selectable by setting two types of interrupt handler address setting registers.
- Inter-processor interrupts
High-speed inter-processor interrupts are enabled.
- Software interrupts (SINT)
Interrupts of desired priority can be generated from the program by setting software interrupt registers.

- Sharing interrupt sources
The number of exception handler addresses can be decreased by merging multiple interrupt sources.

Interrupts are controlled by the following interrupt controllers:

- INTC1
CPU1 and PCU have their own interrupt controllers.
Each PE accesses to the INTC1 register that corresponds to respective PEs.
INTC1 controls High-speed interrupt and has the following functions:
 - Priority setting
 - Interrupt mask setting
- INTC2
INTC2 is a common interrupt controller that CPU1 and PCU share.
INTC2 controls low-speed interrupts and has the following functions.
 - Priority setting
 - Interrupt mask setting
 - Binding setting

6.2 Register Specifications

The INTC has registers listed in tables below. These registers are mainly used to set interrupt priority and to control detection of external interrupt input signals.

6.2.1 Register Configuration

Table 6.1 Interrupt Control

Address	Register Symbol	Register Name	R/W	Access width	Value after Reset
FFFE EA00 _H -FFFE EA3E _H (EIC0 to 31) FFFF B040 _H -FFFF B3FE _H (EIC32 to 511)	EICn* ¹	EI level interrupt control register	R/W	8, 16	008F _H * ⁵ 808F _H * ⁶
FFFE EAF0 _H (IMR0) FFFF B404 _H -FFFF B43C _H (IMR1 to IMR15)	IMRn* ²	EI level interrupt mask register	R/W	8, 16, 32	FFFF FFFF _H
FFFE EB00 _H -FFFE EB7C _H (EIBD0 to 31) FFFF B880 _H -FFFF BFFC _H (EIBD32 to 511)	EIBDn* ³	EI level interrupt bind register	R/W	32	* ⁴

Note 1. n = 0 to 511

Note 2. n = 0 to 15

Note 3. n = 0 to 511

Note 4. n = 0 to 31: the same value as that of the PEID bit
n = 32 to 511: 0000 0001_H

Note 5. When an edge is detected (The PCU register of EICn (n = 0 to 31) is located at 0087_H.)

Note 6. When a level signal is detected (The PCU register of EICn (n = 0 to 31) is located at 8087_H.)

Among the registers shown in **Table 6.1**, the EIC0 to 31, IMR0, and EIBD0 to 31 are located in INTC1 of the CPU peripheral field included in each CPU. Each register of these only can be accessed from CPU1 or PCU which includes it. Writing is only possible in supervisor mode (PSW.UM = 0).

Of the registers listed in **Table 6.1**, EIC32 to EIC511, IMR1 to IMR15, and EIBD32 to EIBD511 are located in INTC2, the controller for interrupts from peripheral group 0. Writing to these registers is only possible for a PE bound to EIBDn (n = 32 to 511) or in supervisor mode. When writing to IMR1 to IMR15, only the bits corresponding to the conditions described above are overwritten; other bits are not updated.

In the register areas listed in **Table 6.1**, the values of those listed as reserved for the given channel numbers in **Table 6.14, Interrupt Exception Handler and Priority**, must retain their initial values.

Table 6.2 External Interrupts, Software Interrupts, and NMI

Address	Register Symbol	Register Name	R/W	Access width	Value after Reset
FFC0 0000 _H	NMICTL	NMI interrupt control register	R/W	8	00 _H
FFC0 0010 _H	EXINTCTL	External interrupt control register	R/W	8, 16	0000 _H
FFC0 0014 _H	EXINTSTR	External interrupt status register	R	8	00 _H
FFC0 0018 _H	EXINTSTC	External interrupt status clear register	W	8	00 _H
FFC0 0020 _H	SINTR0	Software interrupt register 0	R/W	8	00 _H
FFC0 0024 _H	SINTR1	Software interrupt register 1	R/W	8	00 _H
FFC0 0028 _H	SINTR2	Software interrupt register 2	R/W	8	00 _H
FFC0 002C _H	SINTR3	Software interrupt register 3	R/W	8	00 _H

Table 6.3 Interrupt Merge Function

Address	Register Symbol	Register Name	R/W	Access width	Value after Reset

Table 6.4 ATU-IV Interrupt Control

Address	Register Symbol	Register Name	R/W	Access width	Value after Reset
FFF9 8040 _H	TIMER	Timer interrupt mask enable register	R/W	8	00 _H

6.2.2 EIC0 to EIC511 — EI Level Interrupt Control Registers 0 to 511

These registers are used to set interrupt control conditions for each EI level interrupt source, and one register is provided for each source of this type. For each source, see **Table 6.14, Interrupt Exception Handler and Priority**.

CAUTION

If 0 is written to the EIRFn bit immediately after a peripheral module generates the corresponding interrupt request upon detection of an edge (before an interrupt is accepted by the CPU), the request may be lost.

Writing 1 to the EIRFn bit immediately after an interrupt is accepted by the CPU may lead to re-issuing of the request.

This includes the use of bit-manipulation instructions (set1, clr1, and not1) for writing to any of these registers. For bit-manipulation instructions, see also Section 3.5.2, **Accesses to Registers by Bit-Manipulation Instructions**.

Executing a bit-manipulation instruction to the lower bytes including the EIMKn bit has no effect on the EIRFn bit.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EICTn	—	—	EIRFn	—	—	—	—	EIMKn	EITBn	—	—	EIPn			
Value after reset	*1	0	0	0	0	0	0	0	1	0	0	0	1	1	1	1
R/W	R	R	R	R/W	R	R	R	R	R/W	R/W	R	R	R/W	R/W	R/W	R/W

Note 1. 0: Edge detection, 1: Level detection

Table 6.5 EIC Register Contents (1/2)

Bit Position	Bit Name	Function
15	EICTn	Interrupt Channel Type The following values are read according to the interrupt input interface. This is a read-only bit. 0: Edge detection 1: Level detection The write value should be the value after reset.
14, 13	—	Reserved These bits are always read as 0. The write value should always be 0.
12	EIRFn	Interrupt Request Flag Operation varies with the interrupt input interface. 0: No interrupt request (Initial value) 1: Interrupt request present <ul style="list-style-type: none"> Edge detection This flag is automatically cleared to 0 when an interrupt request of the self-channel is accepted by the CPU core. When the EIRFn bit is set to 1, an EI level maskable interrupt n (EIINTn) is generated in the same way as acceptance of an interrupt request. Level detection This bit cannot be set or cleared by the software. This is a read-only bit.
11 to 8	—	Reserved These bits are always read as 0. The write value should always be 0.

Table 6.5 EIC Register Contents (2/2)

Bit Position	Bit Name	Function
7	EIMKn	<p>Interrupt Mask</p> <p>While this bit is set to 1, interrupt requests set in the interrupt request flag (EIRFn) are masked to inhibit interrupt requests from the channel to the CPU core. Notification of presence of unprocessed interrupts is not made and the PMEI bit in ICSR is not set from channels for which this bit is set to 1. Even when interrupt processing is disabled by the setting of this bit, an input of interrupt signal is not masked and the interrupt request flag is set. Setting this bit is also reflected in the setting of corresponding bit of the interrupt mask register (IMR).</p> <p>0: Interrupt processing is enabled. 1: Interrupt processing is disabled. (Initial value)</p>
6	EITBn	<p>Interrupt Vector Method Select</p> <p>0: Direct branching method based on priority 1: Table referencing method</p>
5, 4	—	<p>Reserved</p> <p>These bits are always read as 0. The write value should always be 0.</p>
3 to 0	EIPn ^{*1}	<p>These bits specify 16 interrupt priority levels (0: highest priority, 15: lowest priority).</p> <p>If two or more EI level interrupt requests are generated simultaneously, a source with higher priority specified by these bits is selected and is sent to the CPU core. If the priority specified by these bits is equal, a source of smaller channel number is selected as fixed priority.</p>

Note: n = 0 to 511

The values of those listed as reserved for the given channel numbers in **Table 6.14, Interrupt Exception Handler and Priority**, must retain their values after a reset.

- Note 1. In the case of the EIC0 to EIC31 registers of the PCU, bits EIPn 2 to EIPn 0 are used to specify eight interrupt priority levels. (Set EIPn 3 to 0).
- When interrupts corresponding to EIC32 to EIC511 are bound to the PCU, however, the interrupt priority is judged from the three bits of EIPn 3 to EIPn 1, which the PCU handles as if they were bits EIPn 2 to EIPn 0. (When an interrupt is bound to the PCU, the setting of EIPn 0 in the corresponding EICn is ignored.).

6.2.3 IMR0 to IMR15 — EI Level Interrupt Mask Registers 0 to 15

These registers are aggregation of the EIMK bit in the EIC register. Setting of the corresponding EIMK bit is reflected in each bit in the IMRn register. Furthermore, setting of the IMRn register is reflected in the corresponding EIMK bit.

IMR0

6.2.4 EIBD0 to EIBD511 — EI Level Interrupt Bind Registers 0 to 511

These registers are provided for each EI level interrupt source to make correspondence between each source and PE. For each source, see **Table 6.14, Interrupt Exception Handler and Priority**.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Note 1. EIBD32 to EIBD511: 001

Table 6.6 EIBD0 to EIBD511 Registers Contents

Bit Position	Bit Name	Function
31 to 18	—	Reserved The write value should always be 0.
17, 16	GPID	These bits are provided only in EIBD32 to EIBD511. Set either of the following values for these bits according to the PEID setting. 00: When CPU1 is selected by PEID as a bind destination 01: When PCU is selected by PEID as a bind destination These bits are reserved for EIBD0 to EIBD31. The write value should always be 0. These bits are always read as 0.
15 to 3	—	Reserved The write value should always be 0.
2 to 0	PEID	These bits specify an interrupt bind (request) destination. However, these bits are fixed in EIBD0 to EIBD31 and cannot be modified. 001: Interrupts are bound to CPU1. 011: Interrupts are bound to the PCU. To execute interrupt of the corresponding source, be sure to set either value above.

Note: The values of those listed as reserved for the given channel numbers in **Table 6.14, Interrupt Exception Handler and Priority**, must retain their values after a reset.

NOTE

Changing the corresponding EIBDn register during the processing of an EIINT request is prohibited.

6.2.5 NMICTL — NMI Interrupt Control Register

NMICTL is an 8-bit register to set the detection mode of falling edge, or rising edge for the NMI interrupt input.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	NMIS	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 6.7 NMICTL Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved
1, 0	NMIS	NMI Interrupt Detecting Method Select These bits select an NMI interrupt signal detecting method from low level, high level, falling edge, and rising edge. 0 0: An interrupt request is detected by the NMI input falling edge. 0 1: An interrupt request is detected by the NMI input rising edge. 1 0: Setting prohibited 1 1: Setting prohibited

6.2.6 EXINTCTL — External Interrupt Control Register

EXINTCTL is a 16-bit register to specify a low level, high level, falling edge, or rising edge detection mode individually for external interrupt input pins IRQ7 to IRQ0.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	IRQ7S		IRQ6S		IRQ5S		IRQ4S		IRQ3S		IRQ2S		IRQ1S		IRQ0S	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 6.8 EXINTCTL Register Contents

Bit Position	Bit Name	Function
15, 14	IRQ7S	External Interrupt Detecting Method Select
13, 12	IRQ6S	These bits select an IRQ7 to IRQ0 interrupt signal detecting method from low level, high level, falling edge, and rising edge.
11, 10	IRQ5S	0 0: An interrupt request is detected by the IRQn input low level.*1
9, 8	IRQ4S	0 1: An interrupt request is detected by the IRQn input high level.*1
7, 6	IRQ3S	1 0: An interrupt request is detected by the IRQn input falling edge.
5, 4	IRQ2S	1 1: An interrupt request is detected by the IRQn input rising edge.
3, 2	IRQ1S	
1, 0	IRQ0S	

Note 1. When level detection is selected, the active level should be retained until an interrupt request is accepted.

6.2.7 EXINTSTR — External Interrupt Status Register

EXINTSTR is an 8-bit register that indicates interrupt requests of external interrupt input pins IRQ7 to IRQ0. When edge detection is specified for IRQ7 to IRQ0 interrupts, interrupt requests retained in the EXINTSTC register can be cleared.

Bit	7	6	5	4	3	2	1	0
	IRQ7F	IRQ6F	IRQ5F	IRQ4F	IRQ3F	IRQ2F	IRQ1F	IRQ0F
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 6.9 EXINTSTR Register Contents

Bit Position	Bit Name	Function
7	IRQ7F	External Interrupt Request
6	IRQ6F	These bits indicate IRQ7 to IRQ0 interrupt request status.
5	IRQ5F	<ul style="list-style-type: none"> When level detection is selected
4	IRQ4F	0: No IRQn interrupt request is present. 1: IRQn interrupt requests are present. [Clearing condition]
3	IRQ3F	[Clearing condition] The IRQn input is not the level corresponding to IRQn1S and IRQn0S in EXINTCTL.
2	IRQ2F	[Setting condition] The IRQn input is the level corresponding to IRQn1S and IRQn0S in EXINTCTL.
1	IRQ1F	<ul style="list-style-type: none"> When edge detection is selected
0	IRQ0F	0: No IRQn interrupt request has been detected. 1: IRQn interrupt requests have been detected. [Clearing condition] Writing 1 to the IRQnC bit in EXINTSTC [Setting condition] An edge corresponding to IRQn1S and IRQn0S in EXINTCTL is generated.

Note 1. n = 0 to 7

6.2.8 EXINTSTC — External Interrupt Status Clear Register

EXINTSTC is an 8-bit register to clear IRQnF in EXINTSTR in case edge detection is selected as an IRQn detecting method. Writing 1 to IRQnC clears the corresponding IRQnF bit in EXINTSTR.

Bit	7	6	5	4	3	2	1	0
	IRQ7C	IRQ6C	IRQ5C	IRQ4C	IRQ3C	IRQ2C	IRQ1C	IRQ0C
Value after reset	0	0	0	0	0	0	0	0
R/W	W	W	W	W	W	W	W	W

Table 6.10 EXINTSTC Register Contents

Bit Position	Bit Name	Function
7	IRQ7C	External Interrupt Request Clear
6	IRQ6C	These bits clear the interrupt request status in case edge detection method is selected for detecting IRQ7 to IRQ0 interrupts.
5	IRQ5C	
4	IRQ4C	• When level detection is selected These bits have no function.
3	IRQ3C	• When edge detection is selected Writing 1 clears the corresponding IRQnF bit in the EXINTSTR register.
2	IRQ2C	
1	IRQ1C	
0	IRQ0C	

Note 1. n = 0 to 7

6.2.9 SINTR0 to SINTR3 — Software Interrupt Registers

SINTR0 to SINTR3 are 8-bit registers to control software interrupts 0 to 3 (SINT0 to SINT3).

Writing 01_H to these registers increments the value of a counter; writing 00_H decrements it. When the value of the counter for any of these registers is one or more, the corresponding interrupt from among software interrupts 0 to 3 (SINT0 to SINT3) is generated. When reading the value from any of these registers, it is the current value of the counter.

Bit	7	6	5	4	3	2	1	0
	SINTCn[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 6.11 SINTR0 to SINTR3 Register Contents

Bit Position	Bit Name	Function
7 to 0	SINTCn[7:0]	Software Interrupt Request This bit generates a software interrupt. [Reading operation] The number of SINTn interrupt request counts is read out. [Writing operation] Writing 01_H : increments the counter.*1 Writing 00_H : decrements the counter.*2

Note 1. When 01_H is written to the register while the value of the counter is FF_H , the counter is not incremented and its value remains FF_H .

Note 2. When 00_H is written to the register while the value of the counter is 00_H , the counter is not decremented and its value remains 00_H .

6.2.10 PINT0 to PINT7, PINTCLR0 to PINTCLR7 — Peripheral Interrupt Status Registers and Peripheral Interrupt Status Clear Registers

The DTS transfer completion interrupt and transfer count match interrupt are merged in 32-channel units. PINT0 to PINT7 contain the interrupt status flags to indicate the originating channels for these interrupts. When multiple interrupt sources are generated within the same register among PINT0 to PINT7, only bit 1 on the lower-order side of the bits is set.

Writing the read value of the peripheral interrupt status register (PINT0 to PINT7) to the interrupt clear register (PINTCLR0 to PINTCLR7) of the same channel in the interrupt handler leads to clearing of interrupts.

31 to 0	INTDTS[63:32]	DTS transfer completion interrupt status on ch63 to ch32

PINT2

Bit Position	Bit Name	Function
31 to 0	INTDTS[95:64]	DTS transfer completion interrupt status on ch95 to ch64

PINT3

Bit Position	Bit Name	Function
31 to 0	INTDTS[127:96]	DTS transfer completion interrupt status on ch127 to ch96

PINT4

Bit Position	Bit Name	Function
31 to 0	INTCTDTS[31:0]	DTS transfer count match interrupt status on ch31 to ch0

PINT5

Bit Position	Bit Name	Function
31 to 0	INTCTDTS [63:32]	DTS transfer count match interrupt status on ch63 to ch32

PINT6

Bit Position	Bit Name	Function
31 to 0	INTCTDTS [95:64]	DTS transfer count match interrupt status on ch95 to ch64

PINT7

Bit Position	Bit Name	Function
31 to 0	INTCTDTS [127:96]	DTS transfer count match interrupt status on ch127 to ch96

PINTCLR0

Bit Position	Bit Name	Function
31 to 0	INTCLR[31:0]	These bits clear the DTS transfer completion interrupt status on ch31 to ch0. These bits write the read value of the PINT0 in the interrupt handler.

PINTCLR1

Bit Position	Bit Name	Function
31 to 0	INTCLR[63:32]	These bits clear the DTS transfer completion interrupt status on ch63 to ch32. These bits write the read value of the PINT1 in the interrupt handler.

PINTCLR2

Bit Position	Bit Name	Function
31 to 0	INTCLR[95:64]	These bits clear the DTS transfer completion interrupt status on ch95 to ch64. These bits write the read value of the PINT2 in the interrupt handler.

PINTCLR3

Bit Position	Bit Name	Function
31 to 0	INTCLR[127:96]	These bits clear the DTS transfer completion interrupt status on ch127 to ch96. These bits write the read value of the PINT3 in the interrupt handler.

PINTCLR4

Bit Position	Bit Name	Function
31 to 0	INTCTCLR[31:0]	These bits clear the DTS transfer count match interrupt status on ch31 to ch0. These bits write the read value of the PINT4 in the interrupt handler.

PINTCLR5

Bit Position	Bit Name	Function
31 to 0	INTCTCLR [63:32]	These bits clear the DTS transfer count match interrupt status on ch63 to ch32. These bits write the read value of the PINT5 in the interrupt handler.

PINTCLR6

Bit Position	Bit Name	Function
31 to 0	INTCTCLR [95:64]	These bits clear the DTS transfer count match interrupt status on ch95 to ch64. These bits write the read value of the PINT6 in the interrupt handler.

PINTCLR7

Bit Position	Bit Name	Function
31 to 0	INTCTCLR [127:96]	These bits clear the DTS transfer count match interrupt status on ch127 to ch96. These bits write the read value of the PINT7 in the interrupt handler.

6.2.11 TIMER — Timer Interrupt Mask Enable Register

TIMER is an 8-bit readable/writable register to enable or disable interrupt requests of subblocks 4 to 6 of the ATU-IV timer D. **Table 6.13, TIMER Register Target Interrupts** lists applicable interrupts.

Since these interrupts are merged with the TSG2 interrupts and input to the INTC, set the corresponding IMEn bits to 1 when using the TSG2. When subblock 4 of the timer D is used only as a DMA trigger source, set the IME2 bit to 1. When subblock 6 of the timer D is used only as an A/D converter or a trigger output to the DFE, set the IME0 bit to 1. Do not modify these bits while subblock 4, 5, or 6 of the ATU-IV timer D is operating.

TIMER can be read and written on a byte basis.

TIMER is initialized to 00_H by a reset.

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	IME2	IME1	IME0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 6.12 TIMER Register Contents

Bit Position	Bit Name	Function
7 to 3	—	Nothing is allocated to these bits. These bits should always be 0.
2	IME2	This bit enables or disables interrupt requests of subblock 4 of ATU-IV timer D. 0: Interrupt requests are enabled. 1: Interrupt requests are disabled.
1	IME1	This bit enables or disables interrupt requests of subblock 5 of ATU-IV timer D. 0: Interrupt requests are enabled. 1: Interrupt requests are disabled.
0	IME0	This bit enables or disables interrupt requests of subblock 6 of ATU-IV timer D. 0: Interrupt requests are enabled. 1: Interrupt requests are disabled.

The following lists the target interrupts.

Table 6.13 TIMER Register Target Interrupts

TIMER Register Target Bit	ATU-IV Timer D Subblock	Interrupt Channel	Interrupt Name
IME2	4	180	DCNTD40 down-counter underflow interrupt
		181	DCNTD41 down-counter underflow interrupt
		182	DCNTD42 down-counter underflow interrupt
		183	DCNTD43 down-counter underflow interrupt
IME1	5	184	OCR1D50 compare match interrupt
		185	OCR2D50 compare match interrupt
		186	OCR1D51 compare match interrupt
		187	OCR2D51 compare match interrupt
		188	OCR1D52 compare match interrupt
		189	OCR2D52 compare match interrupt
		190	OCR1D53 compare match interrupt
		191	OCR2D53 compare match interrupt
		192	TCNT1D5 overflow interrupt
		193	TCNT2D5 overflow interrupt
		194	DCNTD50 down-counter underflow interrupt
		195	DCNTD51 down-counter underflow interrupt
		196	DCNTD52 down-counter underflow interrupt
		197	DCNTD53 down-counter underflow interrupt
IME0	6	198	OCR1D60 compare match interrupt
		199	OCR2D60 compare match interrupt
		200	OCR1D61 compare match interrupt
		201	OCR2D61 compare match interrupt
		202	OCR1D62 compare match interrupt
		203	OCR2D62 compare match interrupt
		204	OCR1D63 compare match interrupt
		205	OCR2D63 compare match interrupt
		206	TCNT1D6 overflow interrupt
		207	TCNT2D6 overflow interrupt

6.3 Interrupt Sources

Interrupt sources are grouped into five: external interrupt (NMI/IRQ), ECM interrupt, inter-processor interrupt, software interrupt, and peripheral module interrupt.

6.3.1 NMI Interrupts

NMI interrupts are external interrupts input from the NMI pin. Falling edge or rising edge is selectable by the setting of the NMI Interrupt Detecting Method Select bits (NMIS) in the NMI interrupt control register (NMICTL).

NMI interrupts are accepted at the high priority even when other FE level interrupt has been generated. NMI interrupts cannot be masked regardless of the state of PSW.NP in the CPU system register. NMI interrupts are non-maskable interrupts from which return or recovery is not possible.

6.3.2 IRQ Interrupts

IRQ interrupts are input from IRQ7 to IRQ0 pins. For IRQ interrupts, low level, high level, falling edge, or rising edge is selectable for each pin by the setting of the External Interrupt Detecting Method Select bits (IRQ7S to IRQ0S) in the external interrupt control register (EXINTCTL). Furthermore, interrupt priority levels can be set for each source in interrupt control registers, 16 levels for CPU1 and 8 levels for PCU.

When low level is selected as an IRQ interrupt detecting method, an interrupt request signal is sent to the INTC while IRQ7 to IRQ0 pins are low level. When IRQ7 to IRQ0 pins become high level, no interrupt request signal is sent to the INTC. The active level should be retained until an interrupt request is accepted. Interrupt requests can be checked by reading IRQ Interrupt Request bits (IRQ7F to IRQ0F) in the external interrupt status register (EXINTSTR).

When edge detection is selected as an IRQ interrupt detecting method, an interrupt request is detected by a change in IRQ7 to IRQ0 pins, and an interrupt request signal is sent to the INTC. Reading bits EXINTSTR.IRQ7F to EXINTSTR.IRQ0F checks whether the corresponding IRQ interrupt request is detected. In addition, the IRQ interrupt request can be cleared by writing 1 to the bit corresponding to EXINTSTC when an edge is detected.

When returning from the IRQ interrupt exception handler, clear the external interrupt status register (EXINTSTR) to prevent re-acceptance by mistake, and then issue an instruction to return from interrupt.

6.3.3 ECM Interrupts

The Error Control Module (ECM) generates ECM interrupt requests by merging error interrupts from multiple sources. For details, see **Section 31, Error Control Module (ECM)**.

6.3.4 Inter-Processor Interrupts

Four registers (IPIR_CHn) for conveying interrupts between PEs are provided.

IPIR_CH0 to IPIR_CH3 are assigned to CH0 to CH3 of user interrupt (EIINT). An interrupt for specific PEs (including own PE) can be requested by manipulating bits corresponding to respective PEs. Interrupt priority levels can be set for each source in interrupt control registers, 16 levels for CPU1 and 8 levels for PCU.

6.3.5 Software Interrupts

The software interrupts (SINT) are generated by the setting of the SINTR0 to SINTR3 registers. Multiple interrupt requests can be queued.

Interrupt priority levels can be set for each source in interrupt control registers, 16 levels for CPU1 and 8 levels for PCU.

6.3.6 On-Chip Peripheral Module Interrupts

On-chip peripheral module interrupts occur in on-chip peripheral modules listed below.

- Code flash/Data flash
- Serial communication interface 3 (SCI3)
- OS timer (OSTM)
- Window watchdog timer (WDTA)
- Advanced timer unit IV (ATU-IV)
- Motor control timer (TSG2)
- Autonomous pulse control adapter (APA)
- AD converter (ADCB)
- AD addition function (ASF)
- Delta-sigma AD converter (DS-ADC)
- Serial communication interface H (CSIH)
- CAN interface (RS-CANFD)
- FlexRay
- LIN master interface (RLIN2)
- Renesas high-speed bus (RHSB)
- Direct memory access controller (DMAC, DTS)
- Digital filter engine (DFE)
- Intelligent cryptographic unit (ICU-S)
- Renesas single edge nibble transmission (RSENT)

Since different interrupt vectors are assigned to each source, the interrupt exception handler need not decide sources. Interrupt priority levels can be set for each source in interrupt control registers, 16 levels for CPU1 and 8 levels for PCU.

6.4 Interrupt Exception Handler and Priority Operations

Table 6.14 lists interrupt sources, source codes, exception handler offset addresses, and interrupt priority.

There are two specifications for exception handler addresses: (1) standard specifications where exception handler addresses are determined by the PSW.EBV bit in the CPU core, RBASE register, and EBASE register and (2) extended specifications where exception handler addresses for interrupts are specified individually for each channel.

In the standard specifications, an offset address is added to the base address (RBASE register /EBASE register) in the CPU core to generate an exception handler address. The following two methods are provided for giving an interrupt offset address. For channels other than the interrupt channel, the specified offset address is given.

- An offset address is determined within a range of +100_H to +1F0_H according to the priority level (0 to 15) specified for each channel, regardless of interrupt channels (Note 1, 2, 3 in **Table 6.14**).
- Every offset address is + 100_H regardless of the priority level. This is a function to reduce the memory occupation size of the exception handler (Note 1, 2, 3 in **Table 6.14**).

In the extended specifications, a table for reading exception handler addresses for each interrupt channel is provided. The handler address is extracted by referencing the table. The table reference position is obtained by the following calculation formula (Note 1, 2, 3 in **Table 6.14**). The INTBP register exists in the CPU core.

Exception handler address read position = INTBP + channel number × 4-byte

For RH850G3MH and G3K exceptions, refer to “RH850G3MH User’s Manual: Software and RH850G3K User’s Manual: Software”.

For system error exceptions, see **Section 3, CPU System**.

Priority can be set for each channel. If specified priority levels are equal, an interrupt source of smaller channel number is selected as fixed priority.

Table 6.14 Interrupt Exception Handler and Priority (1/14)

Functional Module	Interrupt Source Name	Level Interrupt Note	Number of Interrupt Channel (EIINT)	Source Code	Offset Address		Table Reference Note1, 2, 3	Interrupt Priority (Value after Reset)	Default Priority
					RINT = 0 Note1, 2, 3	RINT = 1 Note1, 2, 3

Table 6.14 Interrupt Exception Handler and Priority (14/14)

Functional Module	Interrupt Source Name	Level Interrupt Note	Number of Interrupt Channel (EIINT)	Source Code	Offset Address			Interrupt Priority (Value after Reset)	Default Priority
					Direct Branch		Table Reference Note1, 2, 3		
					RINT = 0 Note1, 2, 3	RINT = 1 Note1, 2, 3			
RSENT	RSENT4 status interrupt (INT_SENT_ST4)	√	505	11F9	The offset address is determined within a range of +100 _H to +1F0 _H according to the priority, regardless of interrupt channels.	The offset address is always +100 _H regardless of priority.	+7E4 _H	0 to 15(15)	High ↑
	RSENT5 status interrupt (INT_SENT_ST5)	√	506	11FA			+7E8 _H	0 to 15(15)	
	Reserved		507	11FB					
	Reserved		508	11FC					
	Reserved		509	11FD					
	Reserved		510	11FE					
	Reserved		511	11FF					

Note: To clear an interrupt request of level interrupt, the status register in each module should be cleared during interrupt processing by software. To clear the status register, see **Section 3.5.1, Synchronization of Store Instruction Completion and Subsequent Instruction Generation**. The EICTn bit in EICn is set to 1. The EIRFn bit in EICn cannot be cleared by software.

Notes 1, 2, and 3: See **Section 6.4, Interrupt Exception Handler and Priority Operations**.

Note 1. See **RH850/E1x-FCC2 Flash Memory User's Manual Hardware Interface**.

6.5 Operation

6.5.1 External Interrupts (NMI/IRQ)

NMI and IRQ interrupts are input from external devices. Four detection methods for these interrupts are selectable (2 types for NMI and 4 types for IRQ). For the interrupt detection flow, see **Section 6.5.6, Interrupt Processing Flow**.

6.5.2 Inter-Processor Interrupt

For the operation of software interrupts, see **Section 3.2.3.1, Inter-Processor Interrupt Control Registers** and **Section 6.5.6, Interrupt Processing Flow**.

6.5.3 Software Interrupt

For the operation of software interrupts, see **Section 6.2.9, SINTR0 to SINTR3 — Software Interrupt Registers** and **Section 6.5.6, Interrupt Processing Flow**.

6.5.4 DTS Interrupt Merge Function

Up to 128 transfer end interrupts and up to 128 transfer count match interrupts are aggregated into one interrupt in units of 32 interrupts.

When multiple interrupt source conditions are satisfied, only the single bit on the lower-order side of the corresponding bits in the status registers (PINT0 to PINT7) is set to judge which interrupt is accepted. For the flow of interrupts in the merging of DTS interrupts, see **Section 6.5.6, Interrupt Processing Flow**.

Table 6.15 DTS Interrupt-Related Registers

Interrupt Source	CH	Status Register	Clear Register
DTS transfer end interrupt	0 to 31	PINT0	PINTCLR0
	32 to 63	PINT1	PINTCLR1
	64 to 95	PINT2	PINTCLR2
	96 to 127	PINT3	PINTCLR3
DTS transfer count match interrupt	0 to 31	PINT4	PINTCLR4
	32 to 63	PINT5	PINTCLR5
	64 to 95	PINT6	PINTCLR6
	96 to 127	PINT7	PINTCLR7

6.5.5 ATU-IV/TSG2 Merge Function

ATU-IV timer interrupts and TSG2 interrupts are shared, and functional restrictions shown in **Table 6.16** are provided for these interrupts.

Table 6.17 shows combinations of share.

Table 6.16 Functional Restrictions for Interrupts when Using ATU-IV Timer D and TSG2

ATU-IV timerD (4, 5, 6)				TSG2* ¹		Functional Restriction
(1)	(2)	(3)	(4)	(5)	(6)	
ch4	ch5	ch6	For the peripheral trigger	TSG2_0	TSG2_1	
√	√	√	√	x	x	TSG2 is not available when ATU-IV is used.
x	x	x	x	√	√	ATU-IV timer D is not available when TSG2 is used.
x	x	x	√	√	√	ATU-IV (timer D4 to 6) is not available when TSG2 is used, but the peripheral trigger function of ATU-IV is available.
x	x	√	√	√	x	Combination of channels for ATU-IV and TSG2 is possible except for some channels.
√	x	x	√	x	√	

Note 1. Cycle interrupt, peak interrupt, and trough interrupt of TSG2 are not merged and can be independently used.

Table 6.17 Sharing of ATU-IV and TSG2

ATU-IV	TSG2* ¹	Sharing
(1) and (2)* ²	(5)	OR
(2)* ³ and (3)	(6)	OR

Note 1. Cycle interrupt, peak interrupt, and trough interrupt of TSG2 are not merged and can be independently used.

Note 2. Compare match interrupt (eight) and Overflow interrupt (two) of Timer D ch5

Note 3. Down-counter underflow interrupt of Timer D ch5 (four)

6.5.6 Interrupt Processing Flow

6.5.6.1 NMI Processing Flow

Figure 6.1 shows an example of NMI processing flow.

- Select an NMI detecting method (falling edge or rising edge) by setting the NMICTL register.
- After an NMI has been detected, an interrupt request is sent to the INTC.
- NMI interrupts are accepted at the high priority even when other FE level interrupt has been generated. NMI interrupts cannot be masked regardless of the state of PSW.NP in the CPU system register. NMI interrupts are non-maskable interrupts from which return or recovery is not possible.

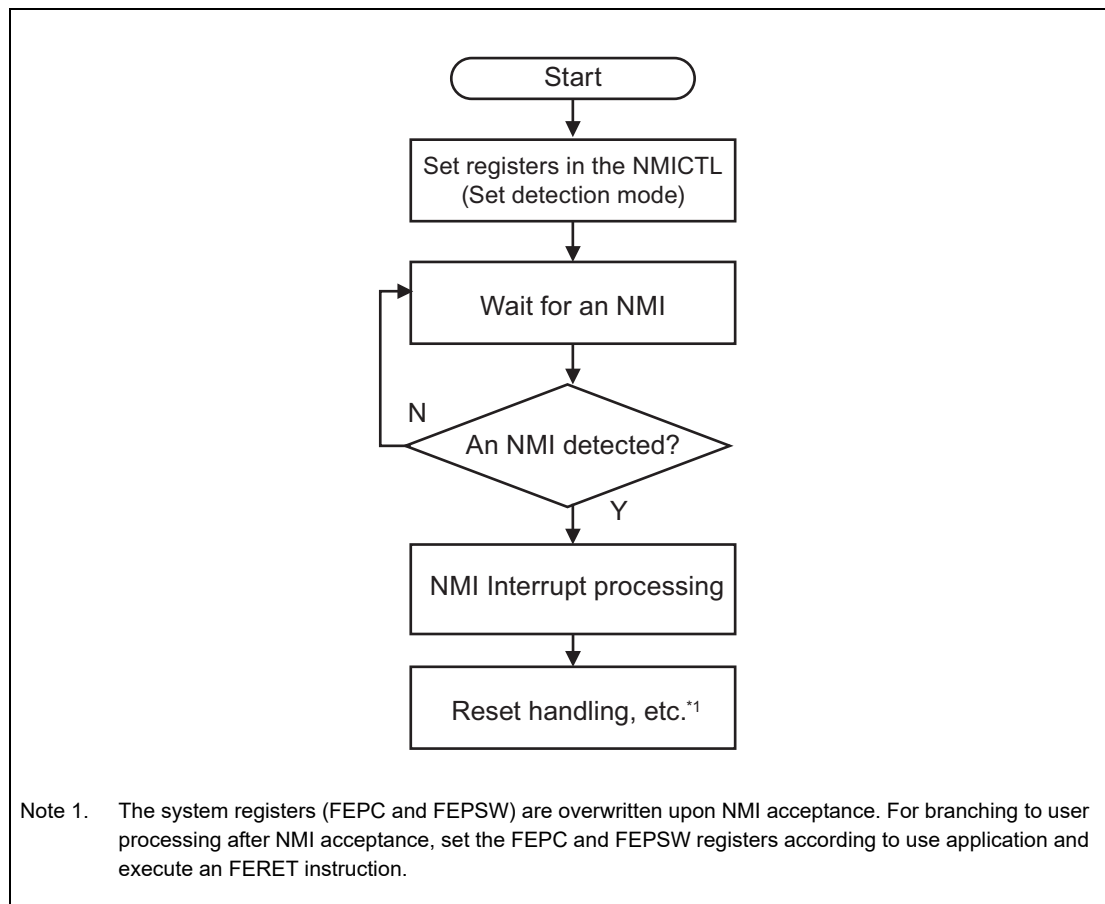

Figure 6.1 Example of NMI Processing Flow

6.5.6.2 External Interrupt Processing Flow

Figure 6.2 shows an example of IRQ (external interrupt) processing flow.

- Select an IRQ detecting method (edge detection or level detection) by setting the EXINTCTL register.
- After detection of an IRQ, an interrupt request is issued to the INTC.
- After recovery on completion of interrupt processing within the INTC in the case of level detection, confirm that the IRQn pin is negated before issuing the instruction to return from the interrupt.
- After recovery on completion of interrupt processing within the INTC in the case of edge detection, clear the interrupt request bit in the EXINTSTR register, and then issue the instruction to return from the interrupt.

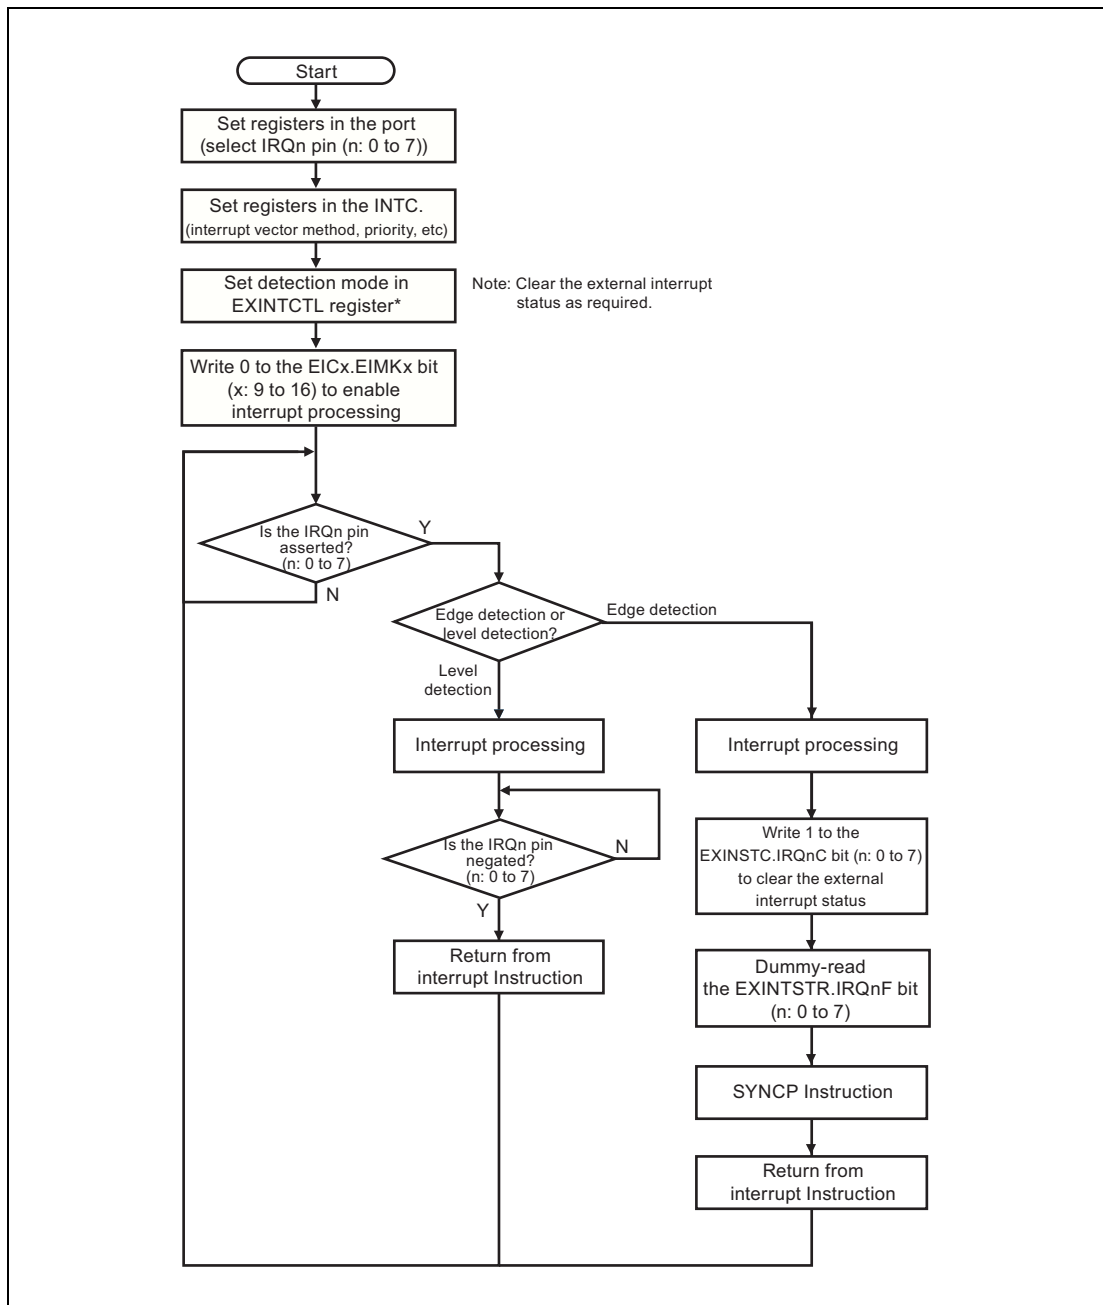

Figure 6.2 Example of External Interrupt Processing Flow

6.5.6.3 Inter-Processor Interrupt Flow

Figure 6.3 shows a flow example of inter-processor interrupt processing.

- Inter-processor interrupting generates an interrupt request by writing 1 to applicable bits of PE to which interrupts of the inter-PE interrupt registers (IPIR0 to IPIR3) are requested.
- The settings of interrupt request of the inter-PE interrupt registers (IPIR0 to IPIR3) are automatically cleared to 0 after notification of an interrupt request is complete.

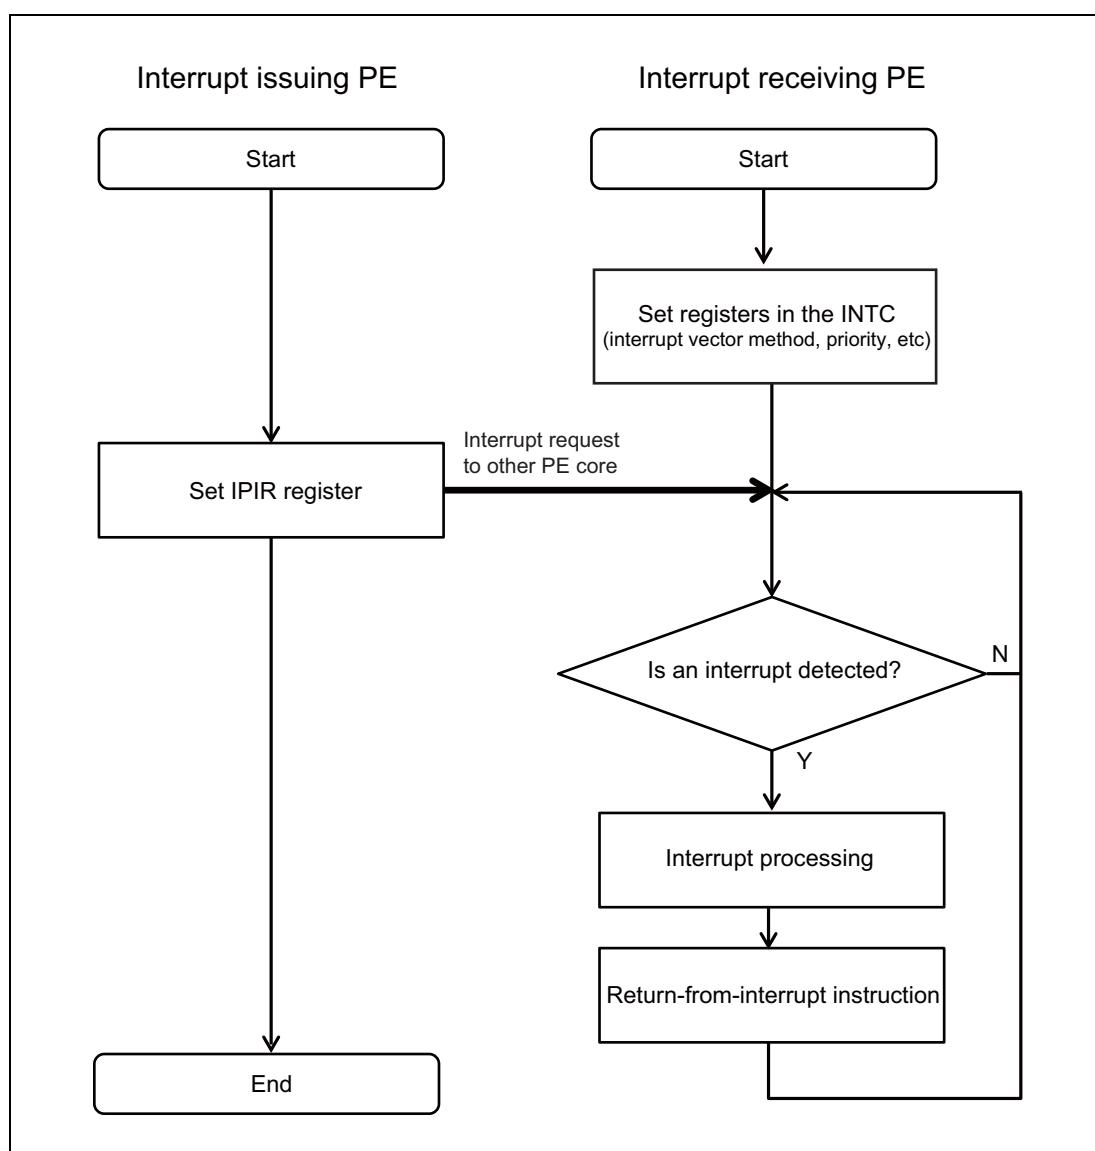

Figure 6.3 Example of Inter-Processor Interrupt Processing Flow

6.5.6.4 Software Interrupt Processing Flow

Figure 6.4 shows the flow example of software interrupt processing.

- Software interrupt requests are controlled by writing 00_H or 01_H to the counter registers (SINTR0 to SINTR3).
- Writing 00_H leads to the counter's value being decremented by 1.
- Writing 01_H leads to the counter's value being incremented by 1.
- If the incremented counter value is 1 or above, an interrupt request for the INTC is generated.
- Decrement the counter by 1 during interrupt processing in the INTC, and if SINTR_n is 00_H after issuing the instruction to return from the interrupt, wait for the writing of 01_H to SINTR_n.

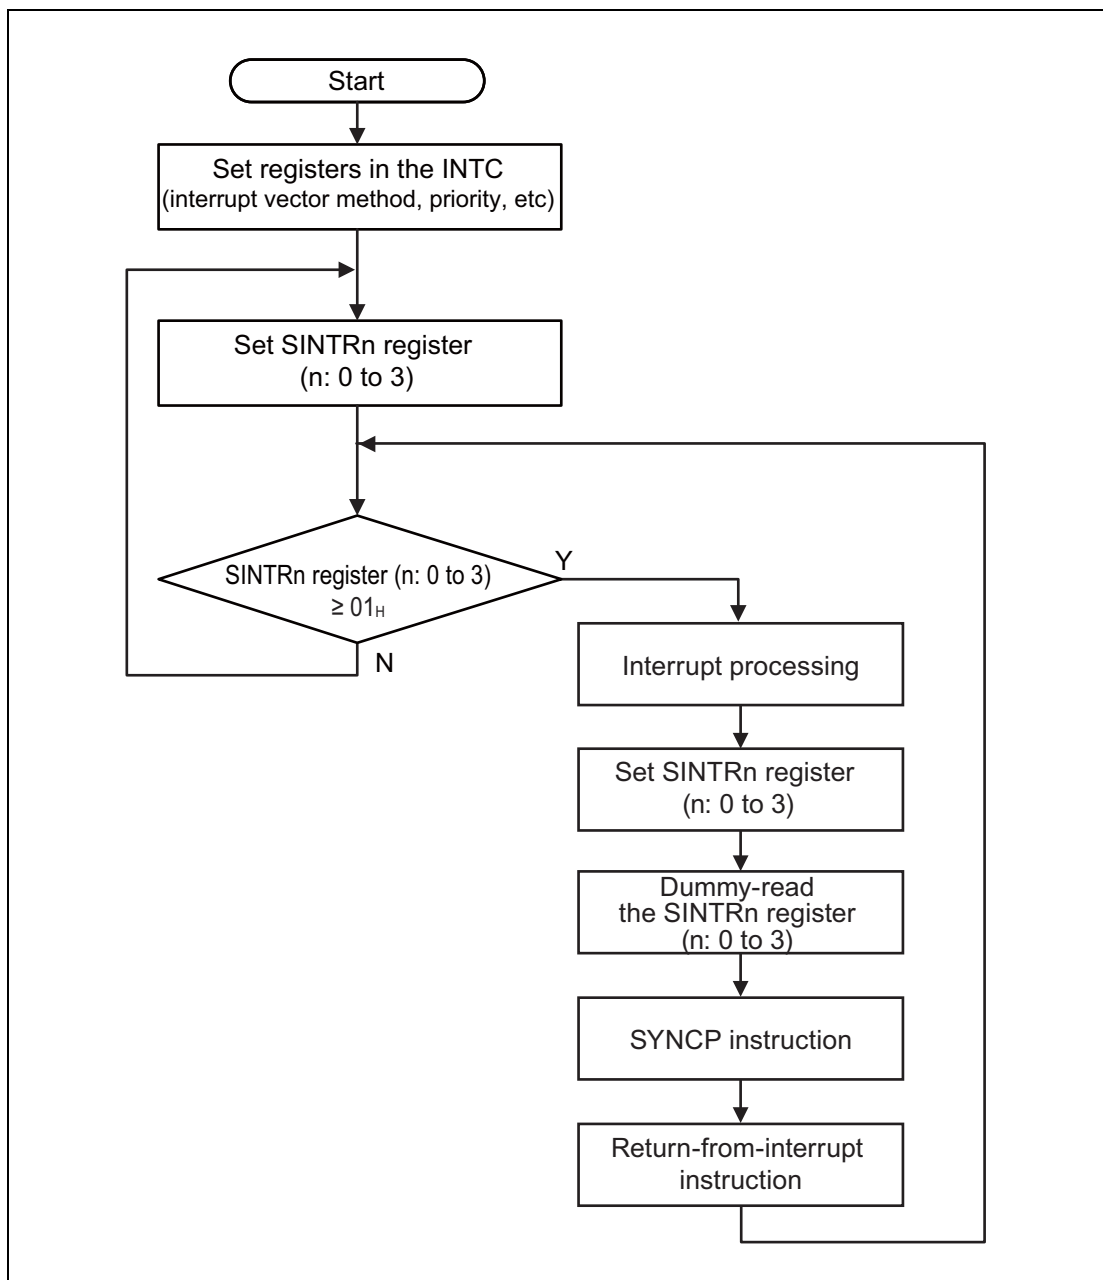

Figure 6.4 Example of Software Interrupt Processing Flow

6.5.6.5 DTS Interrupt Processing Flow

Figure 6.5 shows an example of DTS interrupt processing flow.

- When only one interrupt request is generated out of bundled 32 interrupt sources
 - The bit corresponding to the interrupt request in the PINTn register is set to 1 and an interrupt request is output.
 - On completion of other interrupt processing, write 1 to the interrupt clear register (PINTCLRn) to clear the interrupt request before issuing the return from interrupt instruction, then wait for the next one.
- When multiple interrupt sources are generated out of bundled 32 interrupt sources
 - The bit on the lower-order side is extracted out of bits with interrupt request and only the extracted bit in the PINTn register is set to 1, and an interrupt request is output.
 - On completion of other interrupt processing, write 1 to the target bit in the interrupt clear register (PINTCLRn) to clear the interrupt request, then issue the return from interrupt instruction.
 - After clearing the interrupt request bits for which interrupt processing has proceeded, in the same way as the previous time, the bit on the lower-order side of the PINTn register that corresponds to an interrupt request is extracted and an interrupt request is issued.
 - These steps are repeated until all interrupt sources bundled into 32 bits are cleared.

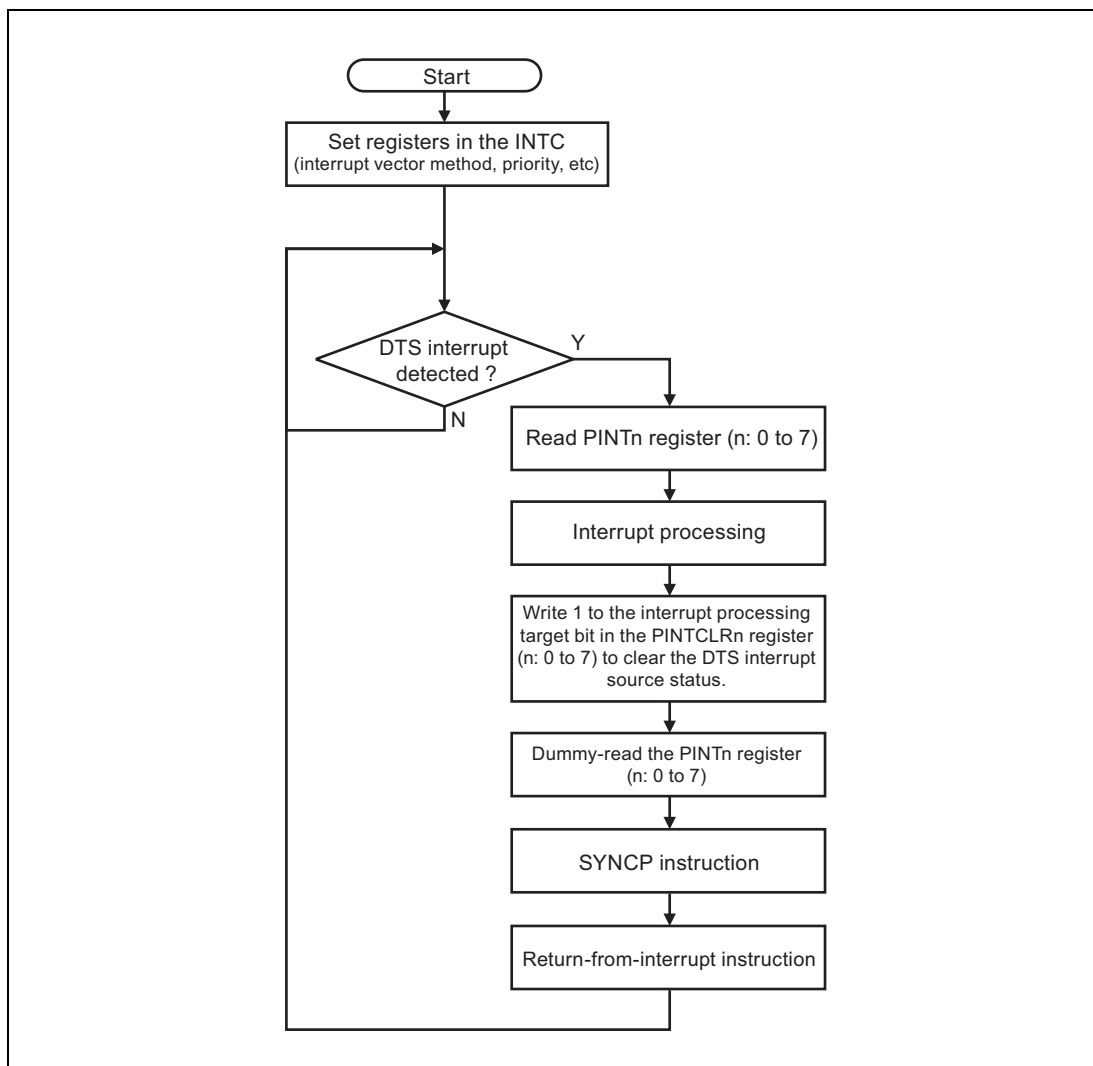

Figure 6.5 Example of DTS Interrupt Processing Flow

6.6 Interrupt Response Times

Table 6.18 Interrupt Response Times

Target	Interrupt Request Source			Number of Cycles for Processing			Total (in the case of edge detection by fixed vector method a))
	INTC Connection	Operating Clock	Synchronization	INTC2	INTC1	In CPU1/PCU	
CPU1	Directly input to INTC1	High speed/Low speed peripheral clock	0	—	$2 \times I\phi$ $<1 \times I\phi>$	Refer to the descriptions under CPU1 below	$7 \times I\phi$
		Unmodulated high speed peripheral clock	—				—
		Unmodulated low speed peripheral clock	$5 \times P\phi$ $<2 \times P\phi>$				$5 \times P\phi + 7 \times I\phi$
	Input via INTC2	High speed/Low speed peripheral clock	0	$3 \times P\phi + 1 \times I\phi$ $<2 \times P\phi + 1 \times I\phi>$	—	Refer to the descriptions under CPU1 below	$3 \times P\phi + 6 \times I\phi$
		Unmodulated high speed peripheral clock	$4 \times P\phi$ $<2 \times P\phi>$				$7 \times P\phi + 6 \times I\phi$
		Unmodulated low speed peripheral clock	$5 \times P\phi$ $<2 \times P\phi>$				$8 \times P\phi + 6 \times I\phi$
PCU	Directly input to INTC1	High speed/Low speed peripheral clock	0	—	$2 \times P\phi$ $<1 \times P\phi>$	Refer to the descriptions under PCU below	$7 \times P\phi$
		Unmodulated high speed peripheral clock	—				—
		Unmodulated low speed peripheral clock	$5 \times P\phi$ $<2 \times P\phi>$				$12 \times P\phi$
	Input via INTC2	High speed/Low speed peripheral clock	0	$4 \times P\phi$ $<3 \times P\phi>$	—	Refer to the descriptions under PCU below	$9 \times P\phi$
		Unmodulated high speed peripheral clock	$4 \times P\phi$ $<2 \times P\phi>$				$13 \times P\phi$
		Unmodulated low speed peripheral clock	$5 \times P\phi$ $<2 \times P\phi>$				$14 \times P\phi$

Note: The numbers in < > indicate the numbers of cycles in the case of level detection.
 $I\phi = \text{CLK_CPU}$
 $P\phi = 4I\phi$ at 320 MHz,
 $= 3I\phi$ at 240 MHz

Vector method	Cache HIT/MISS	In CPU1 (320 MHz)	In CPU1 (240 MHz)	Vector method	In PCU
Fixed vector method	a) ISR entry is hit	$5 \times I\phi$	$5 \times I\phi$	a) Fixed vector method	$5 \times P\phi$
	b) ISR entry is missed	$9 \times I\phi$	$9 \times I\phi$		
Vector table reference method	c) Vector code Flash assigned, ISR entry is hit	$13 \times I\phi$	$13 \times I\phi$	b) Vector table reference method Code flash assigned	$12 \times P\phi$
	d) Vector code Flash assigned, ISR entry is missed	$18 \times I\phi$	$18 \times I\phi$		

Note: $I\phi = \text{CLK_CPU}$
 $P\phi = 4I\phi$ at 320 MHz,
 $= 3I\phi$ at 240 MHz

6.7 Using Interrupt Request Signals to Initiate Data Transfer

An interrupt request signal activates the DMAC/DTS to perform data transfer.

For details, see **Section 7, DMA**.

Section 7 DMA

7.1 Overview

7.1.1 Overview

Direct memory access (DMA) is used to access data without going through the CPU.

DMA consists of two types of DMA transfer modules: DMAC and DTS. A DMAC includes registers for storing transfer information, and a DTS stores transfer information in the dedicated RAM (DTSRAM). DMA has two 8-channel DMAC modules and one 128-channel DTS module.

In this manual, DTFR denotes the function to select among hardware DMA transfer sources for a DMAC and retain the DMA transfer request, and DTSFSL denotes the function to retain a DMA transfer request for each DTS channel. The DTFR can handle 128 types of hardware DMA transfer sources, and the DTSFSL can handle 128 types of them.

The address space that can be used for DMA transfer is a 4 GB address space represented by a 32-bit address. For information about which resource is assigned to a particular area in the 4 GB address space and which area is accessible from DMA, see **Section 4, Address Space**.

7.1.2 Term Definition

Table 7.1 shows the terms used in this section.

Table 7.1 List of Term Definitions

Term	Meaning
DMA transfer	A general term for data transfer carried out by DMA.
DMA cycle	A series of actions that consist of reading an amount of data specified by the transfer size (8/16/32/64/128 bits) from the address specified by the source address and writing it to the address specified by the destination address. The first half of the DMA cycle (reading part) is called a read cycle, and the second half (writing part) is called a write cycle.
Hardware DMA transfer source	A trigger for a DMA transfer request given by an internal peripheral device.
Hardware DMA transfer request	A DMA transfer request generated by a hardware DMA transfer source.
Software DMA transfer request	A DMA transfer request generated by software writing to a register.
DMA transfer request	A trigger to start DMA transfer with a DMAC and DTS.
Transfer information (TI)	The information required for DMA transfer, including the source address, destination address, transfer data size, and transfer count. The transfer information for a DTS is specifically termed as TI.
DTSRAM	RAM used by a DTS to store the transfer information.
Single transfer	DMA transfer consisting of one DMA cycle started by one DMA transfer request.
Block transfer 1	DMA transfer consisting of a number of DMA cycles specified by the transfer count in the transfer information, started by one DMA transfer request.
Block transfer 2	DMA transfer consisting of a number of DMA cycles specified by the address reload count in the transfer information, started by one DMA transfer request.
Block transfer	A general term for both block transfer 1 and block transfer 2.
Last transfer	The DMA cycle carried out when the transfer count in the transfer information is 1.
Address reload transfer	The DMA cycle carried out when the address reload count in the transfer information is 1 if the reload function 2 is used.
Suspension	An action of pausing DMA transfer during block transfer. You can resume DMA transfer after suspension.
Resume	An action of resuming suspended DMA transfer.
Aborting transfer	An action of aborting DMA transfer in the middle. You cannot resume DMA transfer after that.

7.2 DMA Function

7.2.1 Basic Operation of DMA Transfer

7.2.1.1 Transfer Mode

DMA has three transfer modes.

Single Transfer

One DMA cycle is executed when a DMA transfer request is accepted.

Block Transfer 1

A number of DMA cycles specified in the transfer count register are executed when a DMA transfer request is accepted.

Block Transfer 2

A number of DMA cycles specified by the address reload count are executed when a DMA transfer request is accepted. If the address reload count is larger than the value in the transfer count register, a number of DMA cycles specified in the transfer count register are executed.

7.2.1.2 Executing a DMA Cycle

In a DMA cycle, dual-address transfer (two-cycle transfer) proceeds.

DMA always executes a write cycle after a read cycle is complete. For example, if the transfer data size is 128 bits, a write cycle is executed after a read cycle for the 128-bit data is finished. A write cycle never starts in the middle of a read cycle.

7.2.1.3 Updating Transfer Information

When a DMA cycle is executed, DMA updates transfer information as follows.

Source Address and Destination Address

Transfer information will be updated as described in **Table 7.2** according to the settings for the source address and destination address and the settings in the transfer control register such as the count directions of source address and destination address and transfer data size.

Table 7.2 Updating the Source Address and the Destination Address (1/2)

Direction of Count	Transfer Data Size	Address after Update
Increment	8 bit	(address before update) + 0000 0001 _H
	16 bit	(address before update) + 0000 0002 _H
	32 bit	(address before update) + 0000 0004 _H
	64 bit	(address before update) + 0000 0008 _H
	128 bit	(address before update) + 0000 0010 _H

Table 7.2 Updating the Source Address and the Destination Address (2/2)

Direction of Count	Transfer Data Size	Address after Update
Decrement	8 bit	(address before update) – 0000 0001 _H
	16 bit	(address before update) – 0000 0002 _H
	32 bit	(address before update) – 0000 0004 _H
	64 bit	(address before update) – 0000 0008 _H
	128 bit	(address before update) – 0000 0010 _H
Fixed	—	Same as the address before update.

When you use the reload function, a special update rule is applied other than the one described in **Table 7.2** for the last transfer and the address reload transfer. For details, see **Section 7.2.3, Reload Function**.

Transfer Count/Address Reload Count

The transfer count is decremented by one for every DMA cycle.

The address reload count is decremented by one for every DMA cycle when the reload function 2 or block transfer 2 is used. When the reload function 2 or block transfer 2 is not used, it is not updated.

When you use the reload function, a special update rule is applied for the last transfer and the address reload transfer. For details, see **Section 7.2.3, Reload Function**.

Other transfer information

Other transfer information is not updated during execution of a DMA cycle.

7.2.1.4 Last Transfer and Address Reload Transfer

The last transfer means a DMA cycle executed when the value in the transfer count register, which shows the remaining number of transfers, is one. The last transfer differs in operation compared to other DMA cycles as follows.

- The transfer completion flag (DCSTn.TC) is set when the last transfer is complete. (Only applicable for a DMAC)
- The channel operation enable (DCENn.DTE) bit is cleared when the last transfer is complete. (Only applicable for a DMAC. When the continuous transfer is disabled.)
- When the transfer completion interrupt output enable is set, a transfer completion interrupt is output when the last transfer is complete.
- When the reload function 1 is enabled, the reload function 1 is executed at the timing of the last transfer. For details, see **Section 7.2.3, Reload Function**.

The address reload transfer means a DMA cycle executed when the reload function 2 is enabled and the address reload count is one. The reload function 2 is executed during the address reload transfer. For details, see **Section 7.2.3, Reload Function**.

7.2.1.5 Transfer Completion Interrupt and Transfer Count Match Interrupt Outputs

DMA can output a transfer completion interrupt and a transfer count match interrupt.

Transfer Completion Interrupt Output

When the transfer completion interrupt output enable (DTCTn.TCE) is set in the transfer control register, a DMAC requests a transfer completion interrupt when the last transfer is complete.

When the transfer completion interrupt output enable (DTTCTn.TCE) is set in the transfer control register, a DTS requests a DTS transfer completion interrupt when the last transfer is complete.

Transfer Count Match Interrupt Output

When the transfer count match interrupt enable (DTCTn.CCE) is set in the transfer control register, a DMAC requests a DMAC transfer count match interrupt when the DMA cycle in which the transfer count compare register and the transfer count have the same value is complete.

When the transfer count match interrupt enable (DTTCTn.CCE) is set in the transfer control register, a DTS requests a DTS transfer count match interrupt at the completion of the DMA cycle in which the transfer count compare register and the transfer count have the same value.

Figure 7.1 shows the operation of the transfer completion interrupt and the transfer count match interrupt.

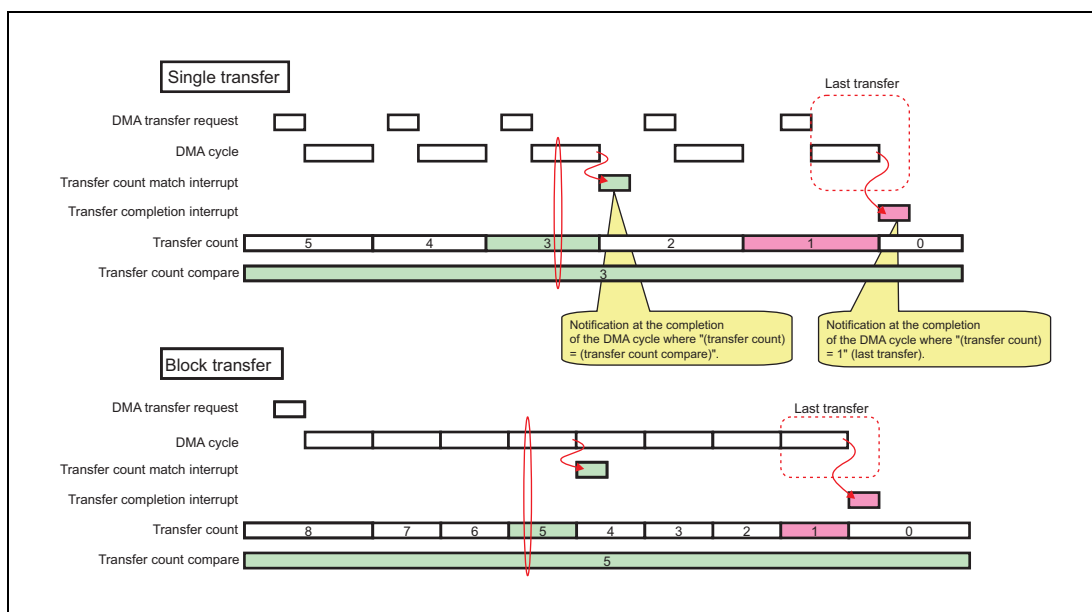

Figure 7.1 Transfer Completion Interrupt and Transfer Count Match Interrupt

7.2.1.6 Continuous Transfer

If the continuous transfer is not used, a DMAC sets the transfer completion flag (DCSTn.TC) and clears the channel operation enable (DCENn.DTE) bit when the last transfer is complete. In this case, a DMA transfer request is not accepted when the request is generated after the completion of the last transfer.

If the continuous transfer is used, the channel operation enable (DCENn.DTE) bit is not cleared when the last transfer is complete, and a DMA transfer request can be accepted even when the transfer completion flag is set. If DMA is used for a case where a specified number of DMA transfers are executed repetitively, software overhead associated with clearing the transfer completion flag and setting the channel operation enable bit after the completion of the last transfer can be reduced by using the continuous transfer.

The continuous transfer is enabled by setting the continuous transfer enable (DTCTn.MLE) in the DMAC transfer control register.

The continuous transfer is designed to work with the reload function 1. The continuous transfer function itself does not update the source address register, destination address register, and transfer count register. If, after the last transfer is complete, you want to restore the source address register, destination address register, and transfer count register to the state before the DMA transfer starts, use the reload function 1 and set the values of the source address register, destination address register, and the transfer count register before the DMA transfer starts to the reload source address register, reload destination address register, and reload transfer count register respectively.

A DTS does not have a setting corresponding to the continuous transfer enable (DTCTn.MLE) for a DMAC. This is because a DTS does not have bits like the transfer completion flag (DCSTn.TC) and the channel operation enable (DCENn.DTE) a DMAC has.

A DTS does not start DMA transfer when a DMA transfer request is generated while the transfer count is 0. (This corresponds to the case for a DMAC where the continuous transfer is not used.)

If the reload function 1 is used for a DTS and the value other than 0 is reloaded to the transfer count when the last transfer is complete, DMA transfer can start when the next DMA transfer request is accepted. (This corresponds to the case for a DMAC where the continuous transfer is used.)

Figure 7.2 shows an operation of continuous transfer by a DMAC.

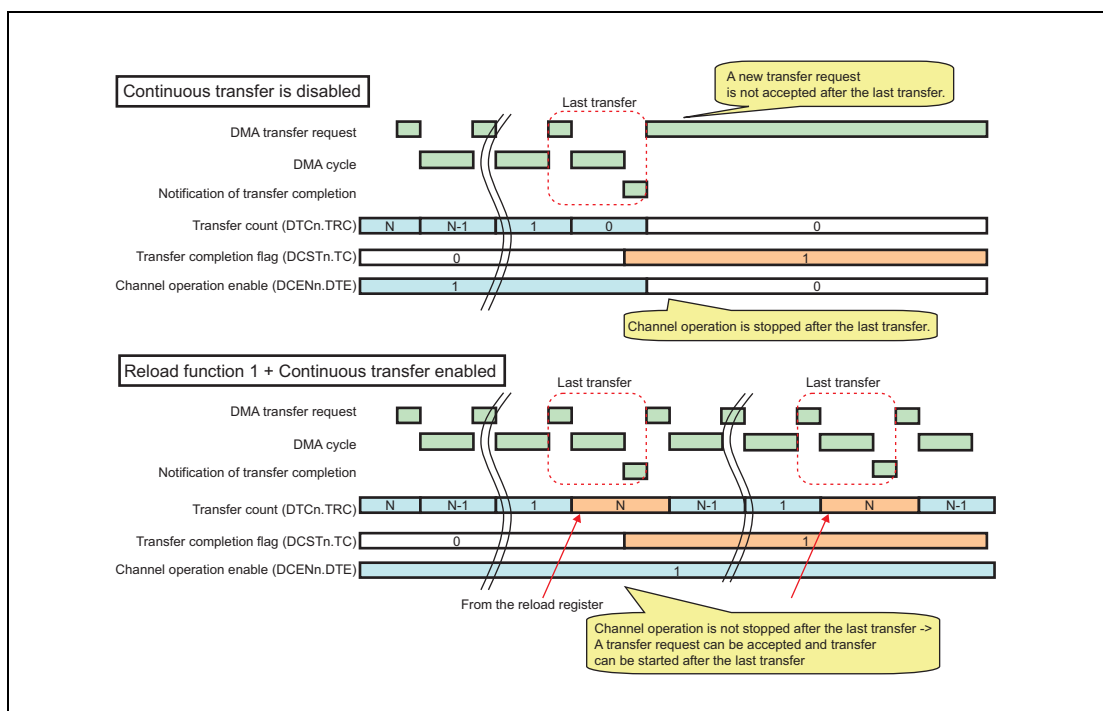

Figure 7.2 Operation of Continuous Transfer by a DMAC

7.2.2 Channel Priority Order

This subsection explains arbitration between multiple DMA channels.

7.2.2.1 DMAC Channel Arbitration

A DMAC selects one channel out of eight channels with arbitration. Arbitration is done according to the fixed priority order. The priority order is “channel 0 > channel 1 > channel 2 > channel 3 > channel 4 > channel 5 > channel 6 > channel 7” for DMAC0, and “channel 8 > channel 9 > channel 10 > channel 11 > channel 12 > channel 13 > channel 14 > channel 15” for DMAC1.

Arbitration is done for every DMA cycle. No arbitration occurs between the read and write of a DMA cycle.

If, at the timing when one DMA cycle in the middle of a block transfer of a channel is complete, there is a DMA transfer request from a channel with a higher priority than the channel, a DMA cycle of the channel with the higher priority will be executed next as the result of arbitration.

If a DMAC executes the block transfer 1 or block transfer 2, DMAC channel arbitration is done for every DMA cycle, and possibly a DMA cycle of another DMAC channel with a higher priority can cut in.

Figure 7.3 DMAC Channel Arbitration

Cycle numbers shown in **Figure 7.3** are for explanation purpose only. They do not indicate an actual number of cycles necessary for executing DMA transfer.

In **Figure 7.3**, DMA transfer requests for channels 0 and 2 are generated at Cycle 1. As a result of arbitration, a DMA cycle for channel 0 starts because its priority is higher. At Cycle 4, a DMA cycle for channel 2 starts. At Cycle 5, a DMA transfer request for channel 1 is generated. The DMA cycle for channel 2 is still ongoing and no arbitration is done at this point. At Cycle 7, a DMA cycle for channel 1 starts. Channel 1 uses block transfer. Another DMA cycle continues at Cycle 10 because there are no DMA transfer requests from other channels. At Cycle 11, a DMA transfer request for channel 0 is generated. The DMA cycle for channel 1 is still ongoing and no arbitration is done at this point. At Cycle 12, the DMA cycle for channel 1 is complete. At Cycle 13, a DMA cycle for channel 0 starts as a result of arbitration between DMA channels 0 and 1.

It should be noted that, even though a block transfer of channel 1 has been already started, a DMA cycle of not channel 1 but channel 0 is executed at Cycle 13 because the priority of the latter is higher.

At Cycle 15, the DMA cycle for channel 0 is complete. At Cycle 16, a DMA cycle for channel 1 starts again. At Cycle 18, the last DMA cycle of the block transfer of channel 1 is complete.

7.2.2.2 DTS Channel Arbitration

If there are DMA transfer requests from multiple DTS channels, the DTSFSL arbitrates those DTS channels. For each DTS channel, a priority can be selected from four levels using DTS channel priority setting registers.

If there are DMA transfer request from multiple DTS channels, the arbitration is done as follows.

1. A channel with a higher priority level in the setting of DTS channel priority setting registers has a priority.
2. If two channels have the same priority level in the setting of DTS channel priority setting registers, a channel with a lower channel number has a priority.

The DTSFSL sends the DTS a DMA transfer request for the channel selected by arbitration. The DTS executes DMA transfer when it accepts the DMA transfer request.

Unlike DMA transfer with a DMAC, DMA transfer with a DTS does not allow arbitration between DTS channels in the middle of a block transfer. That means, even if a DMA transfer request with a higher priority comes during a block transfer for a channel with a lower priority, the DMA transfer with a higher priority does not start until the current block transfer for the channel with a lower priority is complete*1.

Note 1. The timing of completion of the block transfer is when the last transfer for the block transfer 1 or the last transfer or address reload transfer for the block transfer 2 occurs.

When a DTS executes the block transfer 1 or block transfer 2, a DMA cycle of a DTS channel with a higher priority does not take over the ongoing block transfer until the last transfer.

Figure 7.4 DTS Channel Arbitration

Cycle numbers shown in **Figure 7.4** are for explanation purpose only. They do not indicate an actual number of cycles necessary for executing DMA transfer.

In **Figure 7.4**, DMA transfer requests for channels 0, 1, and 2 are generated at Cycle 1. The channel priority for channels 0 and 2 is 0 and is higher than the channel priority for channel 1, which is 3. In addition, if two channels have the same priority, the channel with the smaller channel number has a higher priority. Consequently, the priority order for arbitration is “channel 0 > channel 2 > channel 1”, and a DMA cycle for channel 0 starts because its priority is the highest. At Cycle 4, as a result of arbitration between channels 1 and 2, a DMA cycle for channel 2 starts. At Cycle 7, a DMA cycle for channel 1 starts. Channel 1 uses block transfer. Another DMA cycle continues at Cycle 10 because there are no DMA transfer requests from other channels. At Cycle 11, a DMA transfer request for channel 0 is generated. The DMA cycle for channel 1 is still ongoing and no arbitration is done until the block transfer of channel 1 is complete.

At Cycle 15, the block transfer of channel 1 is complete. At Cycle 16, a DMA cycle for channel 0 starts.

7.2.2.3 Interface Arbitration

DMAC0, DMAC1, and DTS work independently and execute DMA transfer.

When DMAC0, DMAC1, and DTS requests are in contention, the interface arbitrates this in round-robin fashion.

7.2.3 Reload Function

7.2.3.1 Overview of the Reload Function

The reload function updates a portion of transfer information, more specifically, the source address, destination address, transfer count, and address reload count, to the predefined values during DMA transfer.

The reload function has two types of functions: reload function 1 and reload function 2.

7.2.3.2 Operation of Reload Function 1

When the reload function 1 is enabled, actions described in **Table 7.3** are executed at the timing of the last transfer according to the reload function 1 setting.

Table 7.3 Operation of Reload Function 1

Reload Function 1 Setting (DTCTn.RLD1M[1:0])	Register	Action at the Last Transfer
00 (Reload function 1 disabled.)	Source address	Not reloaded.
	Destination address	Not reloaded.
	Transfer count	Not reloaded.
	Address reload count	Not reloaded.
01 (Reload function 1 enabled. Reloading source address and transfer count.)	Source address	The reload source address is copied to this.
	Destination address	Not reloaded.
	Transfer count	The reload transfer count is copied to this.
	Address reload count	<ul style="list-style-type: none"> If the reload function 2 is disable: Not reloaded. If the reload function 2 is enabled: The reload address reload count is copied to this.
10 (Reload function 1 enabled. Reloading destination address and transfer count.)	Source address	Not reloaded.
	Destination address	The reload destination address is copied to this.
	Transfer count	The reload transfer count is copied to this.
	Address reload count	<ul style="list-style-type: none"> If the reload function 2 is disable: Not reloaded. If the reload function 2 is enabled: The reload address reload count is copied to this.
11 (Reload function 1 enabled. Reloading source address, destination address, and transfer count.)	Source address	The reload source address is copied to this.
	Destination address	The reload destination address is copied to this.
	Transfer count	The reload transfer count is copied to this.
	Address reload count	<ul style="list-style-type: none"> If the reload function 2 is disable: Not reloaded If the reload function 2 is enabled: The reload address reload count is copied to this.

Figure 7.5 shows an operation of the reload function 1.

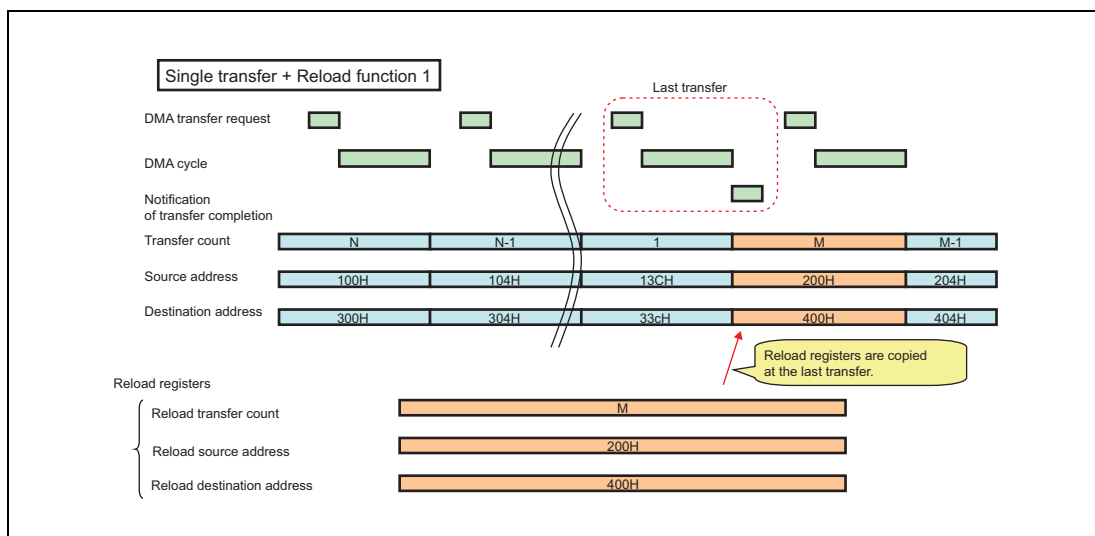

Figure 7.5 Operation of Reload Function 1

7.2.3.3 Reload Function 2

When the reload function 2 is enabled, actions described in Table 7.4 are executed at the timing of the address reload transfer according to the reload function 2 setting.

Table 7.4 Operation of Reload Function 2

Reload Function 2 Setting (DTCTn.RLD2M[1:0])	Register	Action at the Address Reload Transfer
00 (Reload function 2 disabled.)	Source address	Not reloaded.
	Destination address	Not reloaded.
	Address reload count	Not reloaded.
01 (Reload function 2 enabled. Reloading source address.)	Source address	The reload source address is copied to this.
	Destination address	Not reloaded.
	Address reload count	The reload address reload count is copied to this.
10 (Reload function 2 enabled. Reloading destination address.)	Source address	Not reloaded.
	Destination address	The reload destination address is copied to this.
	Address reload count	The reload address reload count is copied to this.
11 (Reload function 2 enabled. Reloading source address and destination address.)	Source address	The reload source address is copied to this.
	Destination address	The reload destination address is copied to this.
	Address reload count	The reload address reload count is copied to this.

Figure 7.6 shows an operation of the reload function 2.

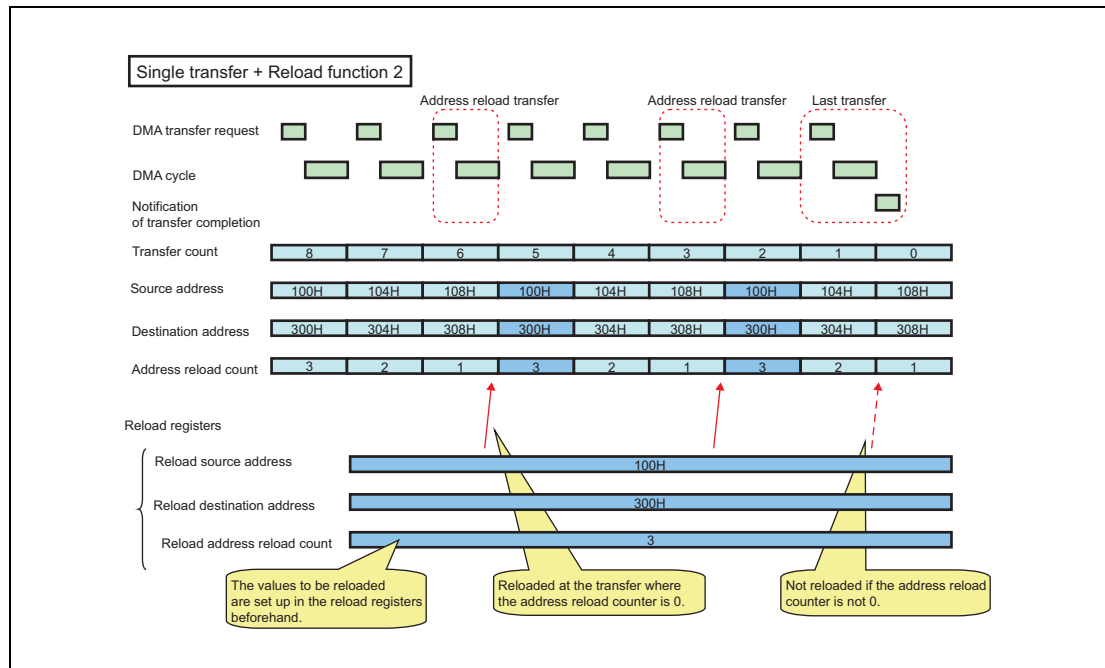

Figure 7.6 Operation of Reload Function 2

Figure 7.7 shows an operation when both the reload function 1 and the reload function 2 are used simultaneously.

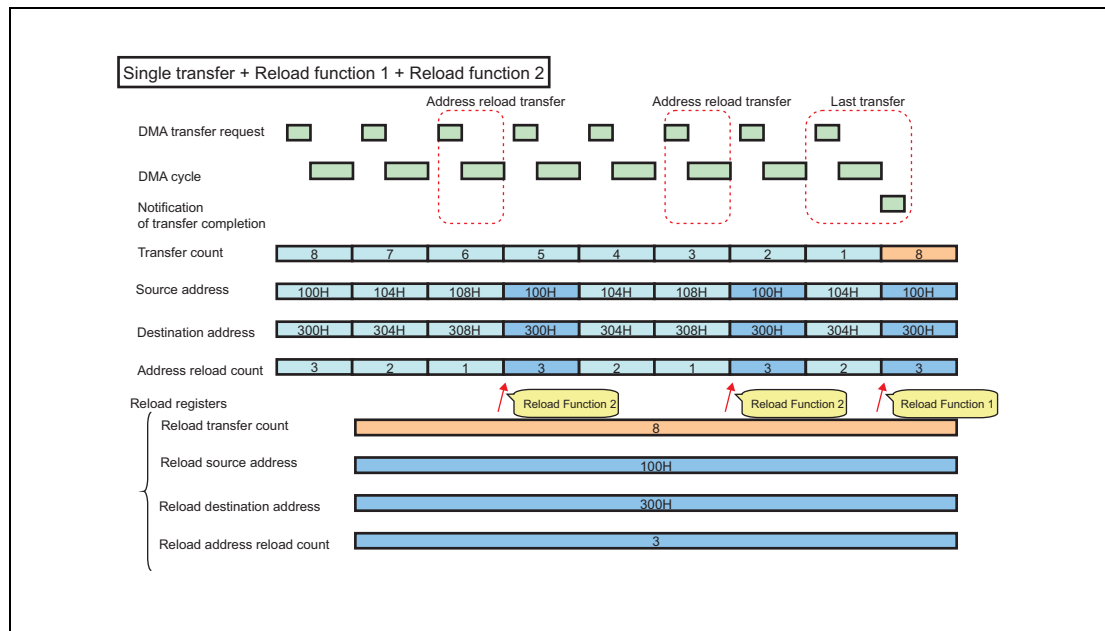

Figure 7.7 Operation when combining the reload function 1 and the reload function 2

7.2.3.4 Timing of Setting DMAC Reload Registers

You can set up the reload source address register, reload destination address register, and reload transfer count register any time (even during DMA transfer). As an exception, if you update the reload source address register, reload destination address register, and reload transfer count register during DMA transfer, there may be a conflict between reloading at the last transfer or address reload transfer and updating the reload register. In order to avoid this conflict, setting up reload registers must be completed before the last transfer or address reload transfer starts.

If you need to update the reload source address register, reload destination address register, and reload transfer count register during DMA transfer, one way to know the right timing of update is to use a DMA transfer count match interrupt. In this case, you must set up the DMA transfer count compare register (DTCCn) so that you can have enough margin for the time necessary to update the reload registers.

7.2.3.5 Timing of Setting DTS Reload Registers

It should be noted that the right timing of setting up the reload source address information, reload destination address information, and reload transfer count information differs depending on the transfer mode.

In the single transfer mode, the TI fetched at the beginning of the last transfer or address reload transfer is used for reload at the completion of the DMA cycle. Therefore, if you use the reload function for single transfer, the reload source address information, reload destination address information, and reload transfer count information in the TI must be set up before the beginning of the last transfer or address reload transfer.

During block transfer, TI is fetched only at the beginning of DMA transfer. The TI fetched at the beginning of the DMA transfer is used for reload at the last transfer or address reload transfer. Therefore, if you use the reload function for block transfer, the reload source address information, reload destination address information, and reload transfer count information in the TI must be set up before the beginning of the DMA transfer. If you update the reload source address information, reload destination address information, and reload transfer count information in the TI in the middle of a block transfer, those new settings will not be used for reload at the completion of the block transfer.

7.2.4 Chain Function

7.2.4.1 Overview

DMA offers a function called chain function. If you use the chain function, the completion of the DMA cycle or last transfer for one channel can trigger a DMA transfer request for another channel. A DMA transfer request for another channel initiated by the chain function is called a chain request.

You can select the condition for generating a chain request from the following two options.

- Always chain: A chain request is generated at the completion of every DMA cycle.
- Chain at the last transfer: A chain request is generated at the completion of the last transfer.

Figure 7.8 shows an operation of the case “always chain”.

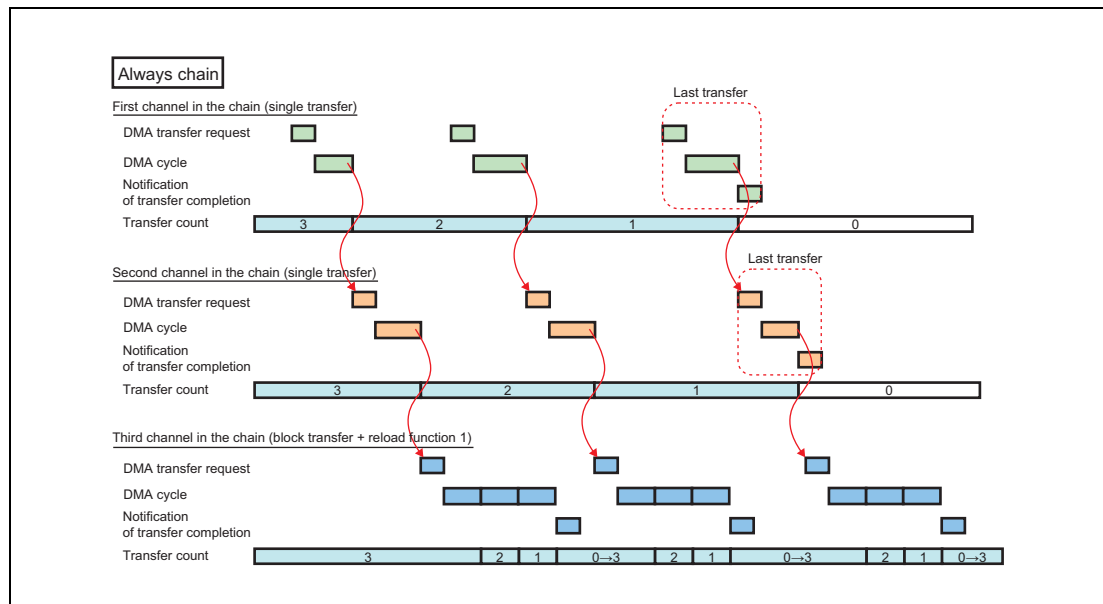

Figure 7.8 Operation of the Case “Always Chain”

Figure 7.9 shows an operation of the case “chain at the last transfer”.

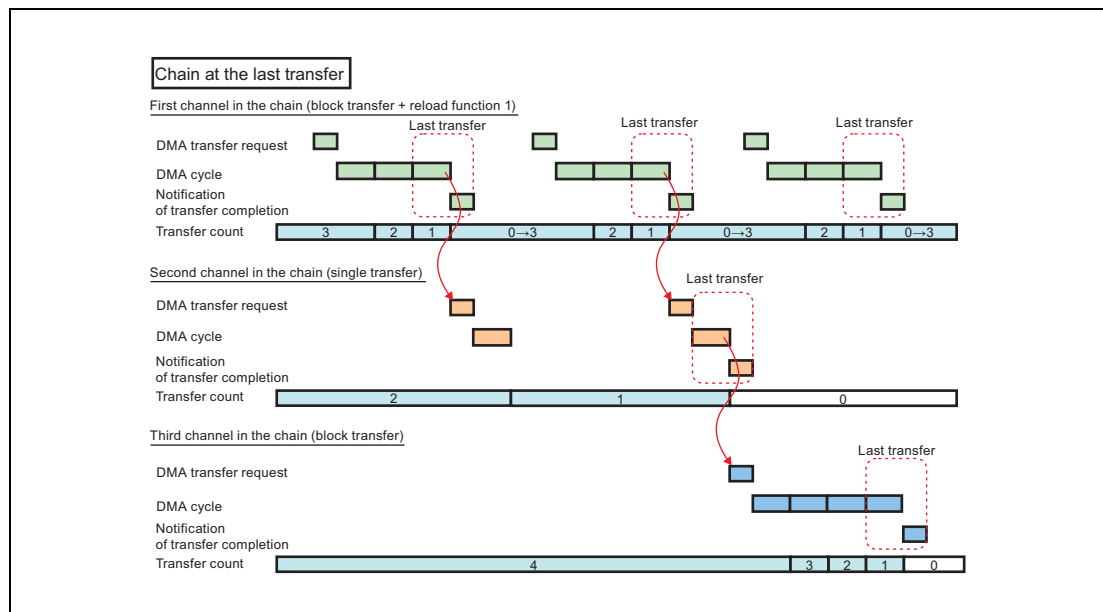

Figure 7.9 Operation of the Case “Chain at the Last Transfer”.

7.2.4.2 Setting Up the Chain Function

For a DMAC, you need to write to the chain enable (DTCTn.CHNE) and the next channel in the chain selection (DTCTn.CHNSEL) in the DMAC transfer control register in order to set up the type of chain function and the next channel number in the chain.

For a DTS, you need to write to the chain enable (DTTCTnnn.CHNE) and the next channel in the chain selection (DTTCTnnn.CHNSEL) in the DTS transfer control register in order to set up the type of chain function and the next channel number in the chain.

7.2.4.3 Caution for Using the Chain Function

The chain function sets the software DMA transfer request flag of the next channel in the chain as a part of its function. Therefore, you need to set up the channel settings of the next channel in the chain in the same way as when the software DMA transfer request is used. If you specify a channel using the hardware DMA transfer request for the next channel in the chain, the chain function does not work.

A channel and its next channel in the chain must belong to the same module (DMAC0, DMAC1, and DTS). You cannot specify a channel in another module for its next channel in the chain.

7.2.5 DMAC Operation

7.2.5.1 Types of DMA Transfer Requests and Assigning DMA Transfer Requests

A DMAC starts DMA transfer by accepting a hardware DMA transfer request or software DMA transfer request. The DMA transfer request selection assignment (DRS) bit in the DMAC transfer control register (DTCTn) determines whether a hardware DMA transfer request or a software DMA transfer request is used.

In the case of a hardware DMA transfer request for a DMAC, one out of 128 hardware DMA transfer sources is selected and assigned for each channel of the DMAC in the DTFR. This assignment is configured in the DTFR setting registers.

7.2.5.2 Generating and Accepting a Software DMA Transfer Request

By setting the software DMA transfer request flag (SR) in the DMAC transfer status register (DCSTn) using the DMAC transfer status set register (DCSTS_n), a software DMA transfer request can be generated.

The software DMA transfer request flag is automatically cleared when the DMAC processes the DMA transfer request. The timing when the software DMA transfer request flag is automatically cleared differs depending on the transfer mode of the DMA transfer to be executed.

- In the single transfer mode, the software DMA transfer request flag is cleared whenever the software DMA transfer request is accepted.
- In the block transfer 1 mode, the software DMA transfer request flag is cleared when the last transfer starts.
- In the block transfer 2 mode, the software DMA transfer request flag is cleared when the last transfer or address reload transfer starts.

The software DMA transfer request flag can also be cleared by software using the DMAC transfer status clear register (DTSTC_n). When you abort a DMA transfer of a DMAC channel, you must clear the software DMA transfer request flag.

7.2.6 DTS Operation

7.2.6.1 Types of DMA Transfer Requests and Assigning DMA Transfer Requests

A DTS starts DMA transfer by accepting a hardware DMA transfer request or software DMA transfer request. A transfer request for a DTS is retained in the transfer request pending bit of the DTSFSL for each channel.

As for the DTSFSL, both a hardware DMA transfer request and a software DMA transfer request are retained in the same transfer request pending bit. When executing DMA transfer, a DTS does not care whether a DMA transfer request is a hardware DMA transfer request or software DMA transfer request.

In the case of a hardware DMA transfer request for a DTS, each of 128 hardware DMA transfer sources is assigned to one of 128 channels in the DTSFSL in the fixed manner. You cannot change this assignment by, for example, register settings.

7.2.6.2 Generating and Accepting a DMA Transfer Request

When the DTSFSL detects a hardware DMA transfer source input, the DTSFSL sets the transfer request pending bit and retains the hardware DMA transfer source as a DMA transfer request. If the transfer request pending bit is set and the transfer request enable bit (DTFSLn.nn.REQEN) in the DTSFSL operation setting register is set, the DTSFSL notifies the DTS of the DMA transfer request.

Software can also generate a DMA transfer request by setting the transfer request pending bit (DTFSTn.nn.DRQ) using the DTSFSL transfer request set register (DTFSSn.nn).

The DTSFSL can retain only one DMA transfer request per channel. If, while the transfer request pending bit for a channel is set, a new hardware DMA transfer source input for the same channel comes, the new hardware DMA transfer source input is ignored.

When the DTS accepts a DMA transfer request, it notifies of the acceptance of the DMA transfer request.

The transfer request pending bit is automatically cleared when the DTS accepts the DMA transfer request. The DTSFSL clears the transfer request pending bit automatically when the DTS accepts the DMA transfer request regardless of the type of the DMA transfer to be executed by the DTS.

The transfer request pending bit can also be cleared using the DTSFSL transfer request clear register (DTFSCn.nn). If the transfer request pending bit of a channel is cleared before the DTS accepts the DMA transfer request, DMA transfer of the channel is not executed.

7.2.6.3 Executing DMA Transfer

When the DTS accepts a DMA transfer request for a channel, the DTS executes DMA transfer of the channel. If there are DMA transfer requests from multiple channels, the DTSFSL arbitrates the DTS channels and picks up one channel for a DMA transfer request.

While the DTS is executing DMA transfer, the DTS transfer status (DTSSTS.DTSACT) bit in the DTS status register is set. In addition, the channel number of the currently ongoing DMA transfer is set in the DTS transfer channel (DTSSTS.DTSACH).

When the DMA transfer is complete or aborted because of DMA transfer error or writing to registers and no channel is currently executing DMA transfer, the DTS transfer status (DTSSTS.DTSACT) bit is cleared.

7.2.6.4 DTSRAM Access

A DTS accesses the DTSRAM when DMA transfer starts and finishes.

A DTS's action of reading transfer information from the DTSRAM when DMA transfer starts is called TI fetch.

A DTS's action of updating the transfer information on the DTSRAM when DMA transfer finishes is called TI write back.

A single transfer performs a TI fetch at the beginning of a DMA cycle and a TI write back at the end of a DMA cycle.

A block transfer performs a TI fetch at the beginning of the first DMA cycle and a TI write back at the end of the DMA cycle that satisfies the block transfer completion condition (the last transfer or address reload transfer).

Therefore, in the case of single transfer, the transfer information on the DTSRAM is updated for each DMA cycle. In the case of block transfer, the transfer information on the DTSRAM is updated after the completion of the block transfer. If software reads the transfer information on the DTSRAM during execution of a block transfer, the transfer information at the beginning of the block transfer is read.

7.3 Suspending, Resuming, and Aborting DMA Transfer and Clearing the DMA Transfer Request

7.3.1 Suspending and Resuming DMA Transfer by Software Control

The DMA control register (DMACTL) is used to suspend DMA transfer for all channels.

When the DMA suspension bit in the DMA control register (DMACTL.DMASPD) is set, DMA puts all channels into the suspended state. If all channels are in the suspended state and the DMA suspension bit is cleared, DMA restores all channels from the suspended state to the normal state and resumes the DMA transfer of the suspended channel.

When all channels are put into the suspended state, DMA transfer is suspended for all channels without changing the value of the DCENn.DTE bit of each DMAC channel and the DTSCTL1.DTSUST bit of the DTS.

CAUTION

To suspend or resume currently ongoing DMA transfer by the DTS, the DMA transfer request enable bit (DTFSLnnn.REQEN) must be switched to disable and enable arbitration for the given channel. For details, refer to the notes in Section 7.3.3, Suspending, Resuming, and Aborting Transfer by the DTS.

7.3.2 Suspending, Resuming, and Aborting Transfer by a DMAC Channel

You can suspend DMA transfer by a DMAC channel by clearing the channel operation enable bit in the DMAC channel operation enable setting register (DCENn.DTE) or setting the DMA suspension bit in the DMA control register (DMACTL.DMASPD). If a DMA cycle is ongoing, DMA transfer is suspended after the currently ongoing DMA cycle is finished. If you set the DCENn.DTE bit again or clear the DMACTL.DMASPD bit while DMA transfer is suspended, the suspended DMA transfer by the DMAC channel is resumed.

If you want to abort currently ongoing DMA transfer by a DMAC channel, clear the channel operation enable bit in the DMAC channel operation enable setting register (DCENn.DTE), and then clear the hardware DMA transfer request in the DTFR in the case of a hardware DMA transfer request, and clear the software DMA transfer request flag (DCSTn.SR) by using the DMAC transfer request flag clear bit in the DMAC transfer status clear register (DCSTCn.SRC) in the case of a software DMA transfer request.

While the continuous transfer enable bit (DTCTn.MLE) is set, the channel operation enable bit (DCENn.DTE) remains set. Even if the channel operation enable bit (DCENn.DTE) is cleared by software during the DMA cycle of the last transfer, the function of the continuous transfer enable bit (DTCTn.MLE) is given priority and the channel operation enable bit (DCENn.DTE) is set again after the completion of the last transfer.

If you want to suspend the DMAC channel while continuous transfer is in use, clear the continuous transfer enable bit (DTCTn.MLE) of the DMAC transfer control register, and then clear the channel operation enable bit (DCENn.DTE) of the DMAC channel operation enable setting register to suspend the DMA transfer. When and only when this operation is performed, writing to the DMAC transfer control register (DTCTn) is allowed while channel operation is enabled (DCENn.DTE = 1).

Figure 7.10 shows an example of suspending, resuming, and aborting transfer by a DMAC channel.

In **Figure 7.10**, both channels 0 and 1 are executing block transfer. At time tick 1, DMA transfer of channel 1 starts. At time tick 2, a DMA transfer request for channel 0 is accepted. As a result of DMAC channel arbitration, DMA transfer of channel 0 starts because channel 0 has a higher priority than channel 1. At time tick 3, the last transfer of channel 0 is complete, and the remaining DMA transfer in the block transfer of channel 1 starts. At time tick 4, the last transfer of channel 1 is complete. After time tick 5, DMA transfer of channel 0 and DMA transfer of channel 1 are executed similarly. At time tick 7, the DMA transfer of channel 0 is suspended and, as a result of DMAC channel arbitration, the DMA transfer of channel 1 starts. At time tick 8, the last transfer of channel 1 is complete, and then, at time tick 9, the DMA transfer of channel 0 resumes. At time tick 10, the last transfer of channel 0 is suspended again, and then, at time tick 11, the DMA transfer of channel 0 is aborted. At time tick 12, the suspended state for channel 0 is cleared, but DMA transfer is not executed because the DMA transfer is aborted at time tick 11.

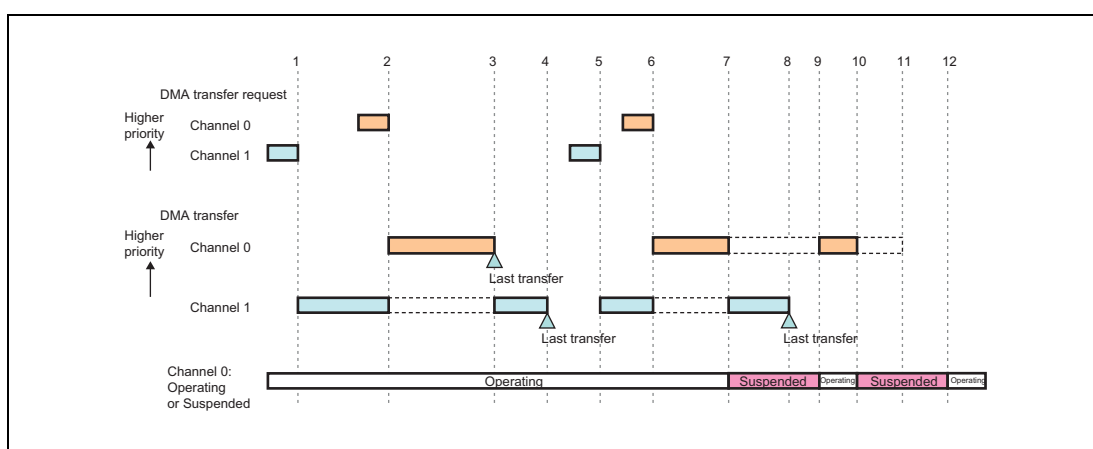

Figure 7.10 Example of Suspending, Resuming, and Aborting Transfer by a DMAC Channel

7.3.3 Suspending, Resuming, and Aborting Transfer by the DTS

You can suspend currently ongoing DMA transfer by the DTS by setting the DTS suspend bit in the DTS control register 1 (DTSCCTL1.DTSUST) or the DMA suspend bit in the DMA control register (DMACTL.DMASPD).^{*1} If a DMA cycle is ongoing, DMA transfer is suspended at the time when the DMA cycle is finished. If the ongoing DMA cycle is a single transfer or a transfer that completes a block transfer (the last transfer or address reload transfer), DMA transfer is suspended after a TI write back after the completion of the DMA cycle.

If the ongoing DMA cycle is a type other than the above, the DMA transfer is suspended after the completion of the DMA cycle without a TI write back. To resume DMA transfer while it is suspended, clear the DTS suspend bit in the DTS control register 1 or the DMA suspend bit in the DMA control register.^{*1}

Note 1. Before suspending or resuming currently ongoing DMA transfer by the DTS, the DMA transfer request enable bit (DTFSLnnn.REQEN) must be switched to disable and enable arbitration for the given channel. To suspend or resume DMA transfer, follow the procedure below.

(a) Procedure for suspending the DTS

1. Clear the DMA transfer request enable bit (DTFSLnnn.REQEN) for all DTS channels for which the DMA transfer request enable bit (DTFSLnnn.REQEN) has been set.
2. Set the DTSCCTL1.DTSUST or DMACTL.DMASPD bit.

(b) Procedure for resuming the DTS

1. Set the DMA transfer request enable bit (DTFSL_{nnn}.REQEN) for DTS channels, which was cleared in step 1 of (a).
2. Clear the DTSCTL1.DTSUST or DMACTL.DMASPD bit that was set in step 2 of (a).

If you want to abort currently ongoing DMA transfer by the DTS, suspend the DTS by using the DTS suspend bit in the DTS control register 1 (DTSCTL1.DTSUST), and then set the DTS transfer abort request bit in the DTS control register 2 (DTSCTL2.DTSTIT) to abort currently suspended DMA transfer. If transfer is aborted, no TI write back is executed. In addition, aborting DMA transfer does not change the value of the DTS suspend bit (DTSCTL1.DTSUST). If you want the DTS to accept another DMA transfer request after the abort, set the DMA transfer request enable bit (DTFSL_{nnn}.REQEN) for DTS channels, and then clear the DTS suspend bit.

Figure 7.11 shows an example of suspending, resuming, and aborting transfer by the DTS.

In Figure 7.11, channels 0, 1, and 2 are executing block transfer. At time tick 1, a DMA transfer request for channel 1 is accepted and DMA transfer starts. At time tick 2, DMA transfer requests for channels 0 and 2 are generated. At time tick 3, the last transfer of channel 1 is complete, and as a result of DTS channel arbitration, a DMA transfer request for channel 0 is accepted, and DMA transfer of channel 0 starts because channel 0 has a higher priority than channel 2. At time tick 4, the last transfer of channel 0 is complete, and DMA transfer of channel 2 starts. At time tick 5, the DTS is put into the suspended state, and the DMA transfer of channel 2 is suspended. At time tick 6, DMA transfer requests for channels 0 and 1 are generated. At time tick 7, the suspended state for the DTS is cleared, and the DMA transfer of channel 2, which has been suspended in the middle of a block transfer, is resumed. If DMA transfer is suspended in the middle of a block transfer, no DTS channel arbitration is done when it is resumed. At time tick 8, the last transfer of channel 2 is complete, and as a result of DTS channel arbitration, a DMA transfer request for channel 0 is accepted and the DMA transfer starts because channel 0 has a higher priority than channel 2. At time tick 9, the DTS is put into the suspended state, and at time tick 10, the suspended DMA transfer of channel is aborted. When the suspended state of the DTS 0 is cleared at time tick 11, DMA transfer of channel 1 starts because there is no currently ongoing DMA transfer and channel 1 is the only channel with a DMA transfer request.

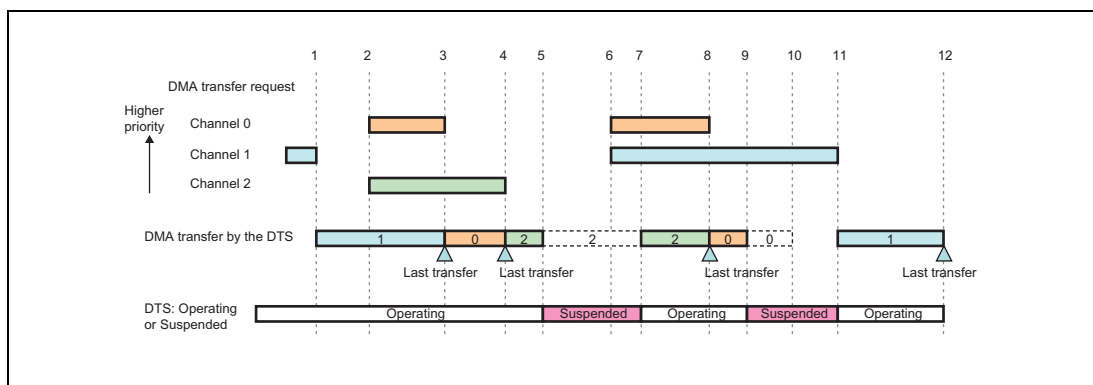

Figure 7.11 Example of Suspending, Resuming, and Aborting Transfer by the DTS

7.3.4 Masking and Clearing a Hardware DMA Transfer Request by the DTFR

If a DMAC uses a hardware DMA transfer request, you can temporarily disable (mask) the hardware DMA transfer request output from the DTFR to the DMAC by clearing the hardware DMA transfer source selection enable bit (DTFRn.REQEN) in the DTFR setting register.

Also, if a hardware DMA transfer source is used, you can clear a hardware DMA transfer request retained in the DTFR by using the hardware DMA transfer request clear (DTFRn.DRQC) bit in the DTFR transfer request clear register.

Even if you suspend or abort DMA transfer of a DMAC channel, the hardware DMA transfer request selection/hold circuit of the DTFR is still running, and consequently, the DTFR may retain a hardware DMA transfer request that came to the DTFR during the suspension or transfer abort period of the DMAC channel. When you resume or start DMA transfer of a DMAC channel, clear the hardware DMA transfer request retained in the DTFR as required.

When a DMAC is used with hardware transfer request and block transfer 1 or 2, if the hardware transfer source selection enable bit is disabled (DTFRn.REQEN = 0), the ongoing block transfer is aborted.

7.3.5 Masking and Clearing a Hardware DMA Transfer Request by the DTSFSL

As for a DTS, you can temporarily disable (mask) a DMA transfer request from a channel to the DTS by clearing the transfer request enable bit (DTSFSLnnn.REQEN) in the DTSFSL operation setting register. (The masking is actually done by excluding the channel from the candidates in DTS channel arbitration in the DTSFSL.)

Also, you can clear a DMA transfer request retained in the DTSFSL by using the transfer request clear (DTSFSLnnn.DRQC) bit in the DTSFSL transfer request clear register.

Regardless of the state of the DTS and the transfer request enable bit (DTSFSLnnn.REQEN) of the DTSFSL, the DTSFSL always monitors the hardware transfer source input, and a DMA transfer request for a channel is set when a hardware transfer source for the channel is input to the DTSFSL. When you resume or start DTS transfer, clear the hardware DMA transfer request retained in the DTSFSL as required.

7.3.6 List of Functions for Suspending, Resuming, and Aborting Transfer

Table 7.5 List of Functions for Suspending, Resuming, and Aborting Transfer

Function	How to execute the function	Operation	Possibility of aborting DMA transfer	Master that can execute the function (See Section 7.5, Reliability Function.)
DMA suspension and resume by software control	Setting and clearing the DMACTL.DMASPD.*2	All channels are in the suspended state.	Not possible*1	Special master
Suspension and resume of a DMAC channel	Clearing and setting the DCENn.DTE in each channel register.*3	DMA transfer of a channel is suspended.	Possible (by clearing the DMA transfer request flag during suspension)	Special master, and general master assigned to the channel.
Suspension and resume of a DTS	Setting and clearing the DTSCCTL1.DTSUST.*2	DMA transfer of a DTS is suspended.	Possible (by setting the DTSCCTL2.DTSTIT during suspension)	Special master

Note 1. In order to abort DMA transfer, you need to either abort transfer for the DMAC channel or abort transfer for the DTS.

Note 2. To suspend or resume currently ongoing DMA transfer by the DTS, the DMA transfer request enable bit (DTFSLnnn.REQEN) must be switched to disable and enable arbitration for the given channel. For details, refer to the notes in **Section 7.3.3, Suspending, Resuming, and Aborting Transfer by the DTS.**

Note 3. While continuous transfer is in use, set and clear the continuous transfer enable bit (DTCTn.MLE) first.

7.4 Error Control

7.4.1 Type of Error

DMA can generate the following two types of errors.

- DMA Transfer Error

This error is generated when error is detected in the read cycle or write cycle in a DMA cycle.

This error can be generated in all DMAC and DTS channels during execution of DMA transfer.

- DTSRAM Error

This error is generated when ECC error is detected in the DTSRAM read access by a DTS.

This error can be generated in the TI fetch during execution of DMA transfer for a DTS or while software is accessing the DTS channel registers.

7.4.2 DMA Transfer Error

A DMA transfer error leads to the generation of a DMA transfer error interrupt (DMAERR).

A DMA transfer error is detected independently for the DMAC channels and the DTS, but the DMA transfer error interrupt (DMAERR) is common to the DMAC and the DTS.

7.4.2.1 Operation of a DMAC When DMA Transfer Error Occurs

When DMA transfer error occurs in a DMAC, the transfer error flag (DCSTn.ER) in the DMAC transfer status register of the channel with the DMA transfer error. The DMAC error register (DMACER) shows the transfer error flags of all 16 DMAC channels.

While the transfer error flag of a channel is set, a new DMA cycle is not executed if the transfer error case DMA transfer disable setting (DTCTn.ESE) bit is set. On the other hand, a DMA cycle is executed regardless of the value of the transfer error flag if the transfer error case DMA transfer disable setting (DTCTn.ESE) bit is cleared.

If you want to abort the DMA transfer of a channel with DMA transfer error, follow the procedure to abort DMA transfer of the DMAC channel.

If DMA transfer error occurs during the read cycle of a DMA cycle, the write cycle is not executed. If DMA transfer error occurs during the write cycle of a DMA cycle, the validity of the write is not guaranteed.

Regardless of whether DMA transfer error occurs in the read cycle or write cycle of a DMA cycle, the source address, destination address, transfer count, and address reload count registers are updated.

7.4.2.2 Operation of a DTS When DMA Transfer Error Occurs

When DMA transfer error occurs in a DTS, the DTS error flag (DTSER1.DTSER) in the DTS error register is set, and the DTS channel number with the DMA transfer error is stored in the DTS error channel (DTSER1.DTSERCH) in the same register.

If DMA transfer error occurs in a single transfer, a TI write back is executed to finish the DMA cycle.

If DMA transfer error occurs in the middle of a block transfer and the transfer error case DMA transfer abort setting (DTTCTnnn.ESE) is set, the remaining DMA cycles in the block transfer are not executed, but a TI write back is executed to finish the DMA cycle. At the same time, the DTS transfer status (DTSSTS.DTSACT) bit in the DTS status register is cleared. If DMA transfer error occurs in the middle of a block transfer and the transfer error case DMA transfer abort setting (DTTCTnnn.ESE) is cleared, the block transfer continues regardless of the DMA transfer error.

If DMA transfer error occurs during the read cycle of a DMA cycle, the write cycle is not executed. If DMA transfer error occurs during the write cycle of a DMA cycle, the validity of the write is not guaranteed.

Regardless of whether DMA transfer error occurs in the read cycle or write cycle of a DMA cycle, the source address, destination address, transfer count, and address reload count registers are updated, and the TI is updated by a TI write back.

If the DTS error flag in the DTS error register is set, a TI fetch is executed when the DTS accepts a DMA transfer request for the channel with the same channel number as the one stored in the DTS error channel. If, as a result of the TI fetch, the transfer error case DMA transfer abort setting (DTTCTnnn.ESE) is found to be set, a DMA cycle and a TI write back are not executed. If the transfer error case DMA transfer abort setting (DTTCTnnn.ESE) is cleared, DMA transfer is executed.

If the DTS error flag in the DTS error register is set, DMA transfer is executed when the DTS accepts a DMA transfer request for a channel with a channel number other than the one stored in the DTS error channel.

7.4.3 DTSRAM Error

There are two types of DTSRAM errors detected in the DTSRAM read access: 1-bit ECC error and 2-bit ECC error.

If a 1-bit ECC error is detected during a TI fetch, error corrected data is used, and DMA transfer continues. If a 1-bit ECC error is detected during DTS channel register access from software, error corrected data is returned as read data. In either case, the DTSRAM 1-bit error flag (DTSER2.RAMSED) in the DTS error register 2 is set, and the address of the error location in the DTSRAM is stored to the DTSRAM 1-bit error address (DTSER2.RAMSEDAD).

In addition, the error is notified to the ECM.

If a 2-bit ECC error is detected during a TI fetch, handling of the DMA transfer request is terminated without executing a DMA cycle and TI write back. If a 2-bit ECC error is detected during DTS channel register access from software, peripheral bus error is notified. In either case, the DTSRAM 2 bit error flag (DTSER2.RAMDED) in the DTS error register 2 is set, and the address of the error location in the DTSRAM is stored to the DTSRAM 2 bit error address (DTSER2.RAMDEDAD). In addition, the error is notified to the ECM.

7.5 Reliability Function

7.5.1 Overview

In this product, DMA is a resource used by multiple masters (CPU1 or PCU). In order for DMA to support multi-core configuration, the following reliability functions are offered.

- Register access protection function
- Master information inherit function

7.5.2 Register Access Protection Function

This product is designed to assign each DMA channel to CPU1 or PCU.

The register access protection function allows access to the transfer information of each DMA channel from the master (CPU1 or PCU) assigned to the channel but prohibits access from other masters.

The register access protection function enables you, for example, to prevent the settings of the channel from being read or updated by masters other than the one assigned to the channel.

7.5.2.1 Identifying the Accessing Master

DMA identifies a master based on the ID of the accessing CPU (PEID), and whether the CPU is in supervisor mode (PSW.UM = 0) or user mode (PSW.UM = 1).

7.5.2.2 Master Access

Master access includes the following two types.

- Special master access (CPU1 supervisor mode (UM = 0))
- General master access (accesses other than special master access)

In special master access, access to all registers is allowed.

In general master access, read access is allowed to all registers, but write access is allowed to channel registers of the channels assigned by the channel assignment (see Section **Section 7.5.2.3, Channel Assignment**).

7.5.2.3 Channel Assignment

To each channel, DMA can assign a master (CPU1 or PCU) so that the master is allowed to use the channel. Channel assignment is configured in the channel master setting register (DMnnCM in the case of a DMAC and DTSnnnCM in the case of a DTS) in supervisor mode (UM = 0) by CPU1.

In general master access, the master assigned to a channel by channel assignment is allowed to have write access to the channel registers of the channel. If the channel registers of a channel is write-accessed by a master other than the master assigned to the channel, the access is called illegal access. For information about illegal access, see **Section 7.5.2.4, Illegal Access**.

7.5.2.4 Illegal Access

DMA handles the following access as illegal access.

- (a) Write access to global registers by a general master
- (b) Write access to channel registers of a channel by a general master other than the master assigned to the channel by channel assignment

DMA does not handle any read access by masters as illegal access.

DMA's actions against illegal access are as follows.

For both cases (a) and (b),

- Write access is ignored.

Only for the case (b),

- The information about the illegal access is stored in a register access protection violation register.
- The DMAC0, DMAC1, and DTS have their own register access protection violation registers (DM0CMV, DM1CMV, and DTSCMV respectively).
- The ECM is notified of DMAVIOL (illegal DMA access).

Only the special master can have write access to the register access protection violation registers. The special master can check whether illegal access has occurred by checking the register access protection violation registers periodically.

In addition, it is recommended that, when a master tries to use DMA and configures transfer information in the channel registers, the master should check whether the configuration has been successfully completed without illegal access by, for example, reading back the settings.

7.5.3 Master Information Inherit Function

In this product, DMA access inherits master information that is equivalent to the master information of the CPU1 or PCU assigned to the DMA channel.

The master information that is output from DMA is as in **Table 7.6**.

Table 7.6 Master Information That Is Output from DMA

Meaning	Value that is output from DMA
UM	Same as the UM bit value in the channel master setting register
SPID	Same as the SPID bit value in the channel master setting register
PEID	7
DMA access	1

7.5.4 Other Reliability Functions

7.5.4.1 Restriction on the Next Channel in the Chain

The reliability function limits the channels you can select as the next channel in the chain.

When you use the chain function, the channel master settings of a channel and its next channel in the chain must be the same.

The chain function is designed so that a channel and its next channel in the chain are managed by the same master.

When DMA detects that different masters are assigned to a channel and its next channel in the chain, it is deemed illegal and the chain function is suppressed. More specifically, when DMA tries to execute the chain function, DMA compares the chain master settings of the channel and its next channel in the chain, and if the settings are the same for PEID and UM, the chain function is allowed and a chain request is sent to the next channel. If the settings are not the same for PEID and UM, a chain request is not sent.

7.6 Setting Up DMA Transfer

7.6.1 Overview of Setting Up DMA

Table 7.7 Channel Assignment (1/2)

No.	Master that configures the setting	Description	Register		Necessity of the setting	
1	Special master (supervisor mode (UM = 0) of CPU1)	Overall DMA operation setting	DTSPR0 to DTSPR7	DTS channel priority setting register	Mandatory (if a DTS is used)	
2			DM00CM to DM17CM	DMAC channel master setting register	Mandatory (if a DMAC is used)	
3			DTS0CM to DTS127CM	DTS channel master setting register	Mandatory (if a DTS is used)	
4			Status clear	DTSERC	DTS error clear register	Recommended
5				CMVC	Channel protection violation clear register	Recommended
6	Master assigned to the DMAC channel	Channel setting	DSAn	DMAC source address register	Mandatory	
7			DDAn	DMAC destination address register	Mandatory	
8			DTCn	DMAC transfer count register	Mandatory	
9			DTCTn	DMAC transfer control register	Mandatory	
10			DRSAn	DMAC reload source address register	Mandatory if the reload function is used	
11			DRDAn	DMAC reload destination address register	Mandatory if the reload function is used	
12			DRTCn	DMAC reload transfer count register	Mandatory if the reload function is used	
13			DTCCn	DMAC transfer count compare register	Mandatory if the transfer count match interrupt is used	
14			DTFRn	DTFR setting register	Mandatory	
15			Status clear	DCSTCn	DMAC transfer status clear register	Mandatory
16				DTFRRQCn	DTFR transfer request clear register	Recommended
17				Channel operation enable	DCENn	DMAC channel operation enable setting register

Table 7.7 Channel Assignment (2/2)

No.	Master that configures the setting	Description	Register		Necessity of the setting	
18	Master assigned to the DTS channel	Channel setting	DTSA _{nnn}	DTS source address register	Mandatory	
19			DTDA _{nnn}	DTS destination address register	Mandatory	
20			DTTC _{nnn}	DTS transfer count register	Mandatory	
21			DTTCT _{nnn}	DTS transfer control register	Mandatory	
22			DTRSA _{nnn}	DTS reload source address register	Mandatory if the reload function is used	
23			DTRDA _{nnn}	DTS reload destination address register	Mandatory if the reload function is used	
24			DTRTC _{nnn}	DTS reload transfer count register	Mandatory if the reload function is used	
25			DTTC _{nnn}	DTS transfer count compare register	Mandatory if the transfer count match interrupt is used	
26			Status clear	DTFSC _{nnn}	DTSFSL transfer request clear register	Recommended
27			Transfer request enable	DTFSL _{nnn}	DTSFSL operation setting register	Mandatory

7.6.2 Setting Up the Overall DMA Operation

You need to set up the overall DMA operation before you start using DMA.

To configure the overall DMA operation, the special master (supervisor mode (UM = 0) of CPU1) needs to set up global registers. Global registers can be set up only by special master access. For details, see **Section 7.5, Reliability Function**.

The following registers must be set up to configure the overall DMA operation.

- DTS channel priority setting registers (DTSPRn, n = 0 to 7)
Those registers configure the priority level of each DTS channel used for DTS channel arbitration.
- DMAC channel master setting registers (DMnnCM)
- DTS channel master setting registers (DTSnnnCM)
Those registers configure channel assignment. (For details, see **Section 7.5, Reliability Function**.)
If the DMAC channel master setting registers and the DTS channel master setting registers are not properly set, DMA channel setting and DMA transfer cannot be executed properly.

Also, if errors are detected in the following registers while the overall DMA operation is set up, clearing the errors is recommended.

- DTS error register 1 (DTSER1)
- DTS error register 2 (DTSER2)
- DMAC0 register access protection violation register (DM0CMV)
- DMAC1 register access protection violation register (DM1CMV)
- DTS register access protection violation register (DTSCMV)

7.6.3 Setting Up the DMA Channel Setting

The DMA channel setting defines the transfer information and transfer source for each DMAC and DTS channel.

To configure the DMA channel setting, the master assigned to each channel by the channel assignment needs to set up channel registers.

7.6.3.1 Setting Up the DMAC Channel Setting

Follow the procedure below to set up the DMAC channel setting and use the DMAC.

(1) Disabling the DMAC Channel Operation

If the channel operation enable (DTE) in the DMAC channel operation enable setting register (DCENn) is set, clear the DTE bit to disable the channel operation.

(2) Setting Up the Transfer Information

When you set up the transfer information of the DMAC, the following registers need to be set up.

- DMAC source address register (DSAn)
- DMAC destination address register (DDAn)
- DMAC transfer count register (DTCn)
- DMAC transfer control register (DTCTn)
- DMAC reload source address register (DRSAn)
- DMAC reload destination address register (DRDAn)
- DMAC reload transfer count register (DRTCn)
- DMAC transfer count compare register (DTCCn)

(3) Setting Up the DMA Transfer Request

While setting the transfer information, you need to set up the DMA transfer request selection assignment (DTCTn.DRS) bit in the DMAC transfer control register (DTCTn) to define whether the hardware or software DMA transfer request is used.

You cannot use both the hardware and software DMA transfer requests for the same channel at the same time.

If you use the hardware DMA transfer request, you need to select one source used as the hardware DMA transfer request out of 128 hardware DMA transfer sources using the hardware DMA transfer source selection (DTFRn.REQSEL) in the DTFR setting register. Also, you need to enable the hardware DMA transfer source selection (DTFRn.REQEN) in the same register.

The DTFR may retain a hardware DMA transfer request that came before the hardware DMA transfer source is selected. Clear the hardware DMA transfer request (DTFRRQn.DRQ) retained in the DTFR using the DTFR transfer request clear register (DTFRRQCn) if necessary.

If you use the software DMA transfer request, disable the hardware DMA transfer source selection (DTFRn.REQEN) in the DTFR setting register.

(4) Clearing the Transfer Status

The DMAC transfer status register (DCSTn) may retain the result of the previous DMA transfer. You need to clear the flags in the DMAC transfer status register using the DMAC transfer status clear register (DCSTCn).

(5) Enabling the DMAC Channel Operation

Set the channel operation enable (DCENn.DTE) bit in the DMAC channel operation enable setting register to enable the channel operation.

After the channel operation enable bit is set, the DMAC can accept a DMA transfer request and start DMA transfer.

7.6.3.2 Setting Up the DTS Channel Setting

Follow the procedure below to set up the DTS channel setting and use the DTS.

(1) Disabling the Transfer Request by the DTSFSL

Clear the transfer request enable (DTFSL_{nnn}.REQEN) bit in the DTSFSL operation setting register of the DTS channel you want to set up the channel setting for. This procedure is not mandatory but recommended in order to prevent a DMA transfer request from being sent mistakenly to the DTS channel currently being configured.

It is also recommended to check the DTS status register (DTSSTS) and confirm that DMA transfer is not ongoing for the DTS channel currently being configured.

(2) Setting Up the Transfer Information

When you set up the transfer information of the DTS, the following registers need to be set up to configure the transfer information.

- DTS source address register (DTSAnnn)
- DTS destination address register (DTDA_{nnn})
- DTS transfer count register (DTTC_{nnn})
- DTS transfer control register (DTTCT_{nnn})
- DTS reload source address register (DTRSA_{nnn})
- DTS reload destination address register (DTRDA_{nnn})
- DTS reload transfer count register (DTRTC_{nnn})
- DTS transfer count compare register (DTTCC_{nnn})

(3) Setting Up the DMA Transfer Request

Unlike a DMAC, a DTS does not care whether a DMA transfer request is a hardware DMA transfer request or software DMA transfer request. A DTS has a transfer request pending bit for each channel in the DTSFSL, and both a hardware and software DMA transfer requests are retained in the same transfer request pending bit (DTFST_{nnn}.DRQ). Therefore, a DTS has no setting for selecting whether the hardware or software transfer request is used.

The DTSFSL may retain a DMA transfer request that came before the transfer information is set up. Clear the DMA transfer request (DTFST_{nnn}.DRQ) retained in the DTSFSL if necessary, using the DTSFSL transfer request clear register (DTFSC_{nnn}).

(4) Enabling the Transfer Request by the DTSFSL

Set the transfer request enable (DTFSL_{nnn}.REQEN) bit in the DTSFSL operation setting register to enable the DMA transfer request for the DTS channel.

After the transfer request enable bit for the DTSFSL is set, the DTS can accept a DMA transfer request and start DMA transfer.

7.7 DMA Trigger Source

7.7.1 List of DMA Trigger Sources

The DMA trigger source assignment for DMA channel n is set in the DTFR setting register (DTFRn).

Table 7.8 List of DMA Trigger Sources (3/4)

	Shared with DTSTRG	Function/Module	DMA Trigger Source
DMACTRG[79]	—	APA0	APA0 PWM output ch.0 status modify interrupt
DMACTRG[80]	—		APA0 PWM output ch.1 status modify interrupt
DMACTRG[81]	—		APA0 PWM output ch.2 status modify interrupt
DMACTRG[82]	—		APA0 PWM output ch.3 status modify interrupt
DMACTRG[83]	—		APA0 PWM output ch.4 status modify interrupt
DMACTRG[84]	—		APA0 PWM output ch.5 status modify interrupt
DMACTRG[85]	—		APA0 PWM output ch.6 status modify interrupt
DMACTRG[86]	—		APA0 PWM output ch.7 status modify interrupt
DMACTRG[87]	—		APA0 PWM output ch.8 status modify interrupt
DMACTRG[88]	—		APA0 PWM output ch.9 status modify interrupt
DMACTRG[89]	—		APA0 PWM output ch.10 status modify interrupt
DMACTRG[90]	—		APA0 PWM output ch.11 status modify interrupt
DMACTRG[91]	—		APA0 PWM output ch.12 status modify interrupt
DMACTRG[92]	—		APA0 PWM output ch.13 status modify interrupt
DMACTRG[93]	—		APA0 PWM output ch.14 status modify interrupt
DMACTRG[94]	—		APA0 PWM output ch.15 status modify interrupt
DMACTRG[95]	—	DS-ADC	DSADI0 DSADC0 A/D conversion completion interrupt (DMA request)
DMACTRG[96]	—		DSADI1 DSADC1 A/D conversion completion interrupt (DMA request)
DMACTRG[97]	—		DSADI2 DSADC2 A/D conversion completion interrupt (DMA request)
DMACTRG[98]	—		DSADI3 DSADC3 A/D conversion completion interrupt (DMA request)
DMACTRG[99]	—		DSADI4 DSADC4 A/D conversion completion interrupt (DMA request)
DMACTRG[100]	—		DSADI5 DSADC5 A/D conversion completion interrupt (DMA request)
DMACTRG[101]	—		DSADI6 DSADC6 A/D conversion completion interrupt (DMA request)
DMACTRG[102]	—		DSADI7 DSADC7 A/D conversion completion interrupt (DMA request)
DMACTRG[103]	DTSTRG[90]	RHSB_0	Downstream data DMA request
DMACTRG[104]	DTSTRG[91]		Upstream DMA request
DMACTRG[105]	DTSTRG[93]	RHSB_1	Downstream data DMA request
DMACTRG[106]	DTSTRG[94]		Upstream DMA request
DMACTRG[107]	—	SCI_0	RXI (receive data full)
DMACTRG[108]	—		TXI (transmit data empty)
DMACTRG[109]	—	SCI_1	RXI (receive data full)
DMACTRG[110]	—		TXI (transmit data empty)
DMACTRG[111]	—	SCI_2	RXI (receive data full)
DMACTRG[112]	—		TXI (transmit data empty)
DMACTRG[113]	—	SCI_3	RXI (receive data full)
DMACTRG[114]	—		TXI (transmit data empty)
DMACTRG[115]	—	ICU-S	DMA write request
DMACTRG[116]	—		DMA read request
DMACTRG[117]	—	External interrupt	IRQ0 interrupt*2
DMACTRG[118]	—		IRQ1 interrupt*2
DMACTRG[119]	—		IRQ2 interrupt*2
DMACTRG[120]	—		IRQ3 interrupt*2
DMACTRG[121]	—	Reserved	—

Table 7.8 List of DMA Trigger Sources (4/4)

	Shared with DTSTRG	Function/Module	DMA Trigger Source
DMACTRG[122]	—	Reserved	—
DMACTRG[123]	—	Reserved	—
DMACTRG[124]	—	Reserved	—
DMACTRG[125]	—	Data flash	Signal for DMA program command*3
DMACTRG[126]	—	Reserved	—
DMACTRG[127]	—	Reserved	—

Note 1. The name of DMA trigger source may be different from that of output signal in each module.

Note 2. When the IRQ interrupt is used as the DMA source, set the external interrupt detection method select bit in the external interrupt control register (EXINTCTL) to high level (01_H).

Note 3. See *RH850/E1x-FCC2 Flash Memory User's Manual Hardware Interface*.

7.8 DTS Trigger Source

7.8.1 List of DTS Trigger Sources

Table 7.9 shows the DTS trigger source assignment for DTS channel n.

Table 7.9 List of DTS Trigger Sources (1/4)

	Shared with DMACTRG	Function/Module	DMA Trigger Source
DTSTRG[0]	—	OSTM	OSTM0 interrupt (OSTM0TINT)
DTSTRG[1]	—		OSTM1 interrupt (OSTM1TINT)
DTSTRG[2]	—		OSTM2 interrupt (OSTM2TINT)
DTSTRG[3]	—	Reserved	—

0084 _H	DTRERINT	DTSRAM Error notification control register	√	*2
0094 _H	DTRTSCTL	DTSRAM test control register	√	*2
0098 _H	DTRTWDAT	DTSRAM test write data register	√	*2
009C _H	DTRTRDAT	DTSRAM test read data register	√	*2
0100 _H	DM00CM	DMAC channel 0 channel master setting register	√	*2
0104 _H	DM01CM	DMAC0 channel 1 channel master setting register	√	*2
0108 _H	DM02CM	DMAC0 channel 2 channel master setting register	√	*2
010C _H	DM03CM	DMAC0 channel 3 channel master setting register	√	*2
0110 _H	DM04CM	DMAC0 channel 4 channel master setting register	√	*2
0114 _H	DM05CM	DMAC0 channel 5 channel master setting register	√	*2
0118 _H	DM06CM	DMAC0 channel 6 channel master setting register	√	*2
011C _H	DM07CM	DMAC0 channel 7 channel master setting register	√	*2
0120 _H	DM10CM	DMAC1 channel 0 channel master setting register	√	*2
0124 _H	DM11CM	DMAC1 channel 1 channel master setting register	√	*2
0128 _H	DM12CM	DMAC1 channel 2 channel master setting register	√	*2
012C _H	DM13CM	DMAC1 channel 3 channel master setting register	√	*2
0130 _H	DM14CM	DMAC1 channel 4 channel master setting register	√	*2

Table 7.10 List of Global Register Addresses (2/2)

Offset Address	Register Symbol	Meaning	Accessed Permission	
			Special Master	General Master
0134 _H	DM15CM	DMAC1 channel 5 channel master setting register	√	*2
0138 _H	DM16CM	DMAC1 channel 6 channel master setting register	√	*2
013C _H	DM17CM	DMAC1 channel 7 channel master setting register	√	*2
0200 _H + 4 × [DTS channel number] ^{*1} (0200 _H - 03FC _H)	DTS _{nnn} CM ^{*1}	DTS channel nnn channel master setting register	√	*2

Note 1. [DTS channel number] and “nnn” in the register symbols and meanings are numbers in the range from 000 to 127.

Note 2. Only read access is allowed.

7.9.2 Details of Global Registers

7.9.2.1 DMACTL — DMA Control Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8000_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DMA SPD
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 7.11 DMACTL Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should be 0.
0	DMA SPD	<p>DMA suspension</p> <p>This bit shows whether DMA transfer for all channels is suspended. If a user writes 1 to this bit, DMA transfer for all channels can be suspended. If a user writes 0 to this bit, suspension of DMA transfer for all channels can be cleared. The suspension controlled by this bit is independent from the suspension controlled by the transfer enable bit (DTE) of each DMAC channel and the suspension setting bit (DTSUST) for a DTS. That means, if this bit is 1, all DMA transfers are suspended regardless of the values of the DTE bit of each channel and the DTSUST bit of the DTS.</p> <p>Writing to this bit does not affect the DTE bit of each channel and the DTSUST bit of the DTS.</p> <p>0: DMA suspension cleared 1: DMA suspension request/DMA suspension ongoing</p>

Note: To suspend or resume currently ongoing DMA transfer by the DTS, the DMA transfer request enable bit (DTFSLnnn.REQEN) must be switched to disable and enable arbitration for the given channel. For details, refer to the notes in **Section 7.3.3, Suspending, Resuming, and Aborting Transfer by the DTS.**

7.9.2.2 DTSTCTL1 — DTS Control Register 1

Access: This register can be read/written in 32-bit units.

Address: FFFF 8010_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DTS UST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 7.12 DTSTCTL1 Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should be 0.
0	DTSUST	DTS suspension This bit shows whether DMA transfer of a DTS is suspended. If a user writes 1 to this bit, DMA transfer of a DTS can be suspended. 0: DTS suspension cleared 1: DTS suspension request/DTS suspension ongoing

Note: To suspend or resume currently ongoing DMA transfer by the DTS, the DMA transfer request enable bit (DTFSL_{nnn}.REQEN) must be switched to disable and enable arbitration for the given channel. For details, refer to the notes in **Section 7.3.3, Suspending, Resuming, and Aborting Transfer by the DTS.**

7.9.2.3 DTSTCTL2 — DTS Control Register 2

Access: This register can be read/written in 32-bit units.

Address: FFFF 8014_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DTSTIT
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 7.13 DTSTCTL2 Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should be 0.
0	DTSTIT	DTS transfer abort request While the DTS is suspended, a user can write 1 to this bit to abort the suspended DMA transfer. When the suspended DMA transfer of a DTS is aborted, the DTSSTS.DTSACT bit is cleared to 0. This bit is always read as 0.

7.9.2.4 DTSSTS — DTS Status Register

Access: This register can be read in 32-bit units.

Address: FFFF 8018_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	DTS CYC	DTSACH[6:0]							DTS ACT
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.14 DTSSTS Register Contents

Bit Position	Bit Name	Function
31 to 9	—	Reserved
8	DTSCYC	DMA cycle execution state This bit shows whether a DMA cycle is ongoing in the DTS. 0: DMA cycle is not ongoing. 1: DMA cycle is ongoing.
7 to 1	DTSACH[6:0]	DTS transfer channel If there is a channel in the DTS executing DMA transfer, the channel number is shown. If there is no channel in the DTS executing DMA transfer, the channel number of the last DMA transfer is shown.
0	DTSACT	DTS transfer status This bit shows whether there is a channel in the DTS executing DMA transfer. 0: There is a channel in the DTS executing DMA transfer. 1: There is no channel in the DTS executing DMA transfer. If the DTS is put into the suspended state while there is a channel executing DMA transfer, this bit remains 1. If a DTS transfer abort request is made using the DTSCTL2.DTSTIT bit, the suspended DTS transfer is aborted, and this bit is cleared to 0. When DMA transfer error occurs and the DMA transfer is aborted, this bit is cleared.

7.9.2.5 DMACER — DMAC Error Register

Access: This register can be read in 32-bit units.

Address: FFFF 8020_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	DM1ER[7:0]							DM0ER[7:0]								
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.15 DMACER Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved
15 to 8	DM1ER[7:0]	DMAC1 DMA transfer error status These bits show the DMA transfer error status of channels 0 through 7 of the DMAC1. Each bit is mapped from the DCSTn.ER bit of each channel of the DMAC1 and is read-only. 0: DMA transfer error is not generated 1: DMA transfer error is generated
7 to 0	DM0ER[7:0]	DMAC0 DMA transfer error status These bits show the DMA transfer error status of channels 0 through 7 of the DMAC0. Each bit is mapped from the DCSTn.ER bit of each channel of the DMAC0 and is read-only. 0: DMA transfer error is not generated 1: DMA transfer error is generated

7.9.2.6 DTSER1 — DTS Error Register 1

Access: This register can be read in 32-bit units.

Address: FFFF 8024_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	DTSERCH[6:0]						—	—	—	—	—	—	—	DTSERWR	DTSER
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.16 DTSER1 Register Contents

Bit Position	Bit Name	Function
31 to 15	—	Reserved
14 to 8	DTSERCH[6:0]	DTS error channel These bits show the DTS channel number of the first DMA transfer error after the DTSER bit is cleared to 0. These bits are read-only and cannot be cleared.
7 to 2	—	Reserved
1	DTSERWR	DTS DMA transfer error occurring cycle This bit is updated at the same time as setting of the DTS DMA transfer error flag (DTSER), indicating which cycle of read or write the DMA transfer error occurs in. This bit is not updated when a new DMA transfer error occurs after the DTSER bit has been set. If the DTSER bit is cleared, this bit is also cleared to 0. 0: DMA transfer error occurs in read cycle. 1: DMA transfer error occurs in write cycle.
0	DTSER	DTS DMA transfer error flag This bit shows whether DMA transfer error is generated in the DTS. 0: DMA transfer error is not generated 1: DMA transfer error is generated If DMA transfer error is generated in the DTS while this bit is 0, this bit is set, and DTSERCH6-0 retains the DTS channel number of the DMA transfer error. If DMA transfer error is generated in the DTS while this bit is 1, this bit remains 1, and DTSERCH6 to 0 does not change. This bit can be cleared by using the DTSERC register.

7.9.2.7 DTSER2 — DTS Error Register 2

Access: This register can be read in 32-bit units.

Address: FFFF 8028_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RAM DED	RAMDE DOV	—	—	RAMDEDAD[11:0]											
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.17 DTSER2 Register Contents (1/2)

Bit Position	Bit Name	Function
31	RAMDED	DTSRAM 2-bit error flag This bit shows whether the 2-bit error is generated in the read access to the DTSRAM. 0: 2-bit error is not generated in the DTSRAM 1: 2-bit error is generated in the DTSRAM If 2-bit error is generated in the DTSRAM with the read access while this bit is 0, this bit is set, and RAMDEDAD11-0 retains the DTSRAM address of the error. If 2-bit error is generated in the DTSRAM with the read access while this bit is 1, this bit remains 1, and RAMDEDAD11-0 do not change. This bit can be cleared by using the DTSERC register.
30	RAMDEDOV	DTSRAM 2-bit error overflow flag This bit is set when the RAMDED bit is 1 and the 2-bit error occurs in DTSRAM read access whose address is different from that specified by the RAMDEDAD11 to 0 bits. This bit can be cleared by operation of the DTSERC register.
29, 28	—	Reserved
27 to 16	RAMDEDAD [11:0]	DTSRAM 2-bit error address These bits show the DTSRAM address of the first DTSRAM 2-bit error with the read access after the RAMDED bit is cleared to 0. These bits are read-only and cannot be cleared.
15	RAMSED	DTSRAM 1-bit error flag This bit shows whether the 1-bit error is generated in the read access to the DTSRAM. 0: 1-bit error is not generated in the DTSRAM 1: 1-bit error is generated in the DTSRAM If 1-bit error is generated in the DTSRAM with the read access while this bit is 0, this bit is set, and RAMSEDAD11 to 0 retains the DTSRAM address of the error. If 1-bit error is generated in the DTSRAM with the read access while this bit is 1, this bit remains 1, and RAMSEDAD11-0 do not change. This bit can be cleared by using the DTSERC register.
14	RAMSEDOV	DTSRAM 1-bit error overflow flag This bit is set when the RAMSED bit is 1 and the 1-bit error occurs in DTSRAM read access whose address is different from that specified by the RAMSEDAD11 to 0 bits. This bit can be cleared by operation of the DTSERC register.
13, 12	—	Reserved

Table 7.17 DTSER2 Register Contents (2/2)

Bit Position	Bit Name	Function
11 to 0	RAMSEDAD [11:0]	DTSRAM 1-bit error address These bits show the DTSRAM address of the first DTSRAM 1-bit error with the read access after the RAMSED bit is cleared to 0. These bits are read-only and cannot be cleared.

7.9.2.8 DTSERC — DTS Error Clear Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 802C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RAMDEDC	RAMDEDOVC	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	RAMSEDC	RAMSEDOVC	—	—	—	—	—	—	—	—	—	—	—	—	—	DTSERC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 7.18 DTSERC Register Contents

Bit Position	Bit Name	Function
31	RAMDEDC	DTSRAM 2-bit error flag clear If a user writes 1 to this bit, the DTSRAM 2-bit error flag (DTSER2.RAMDED) is cleared. 0 is always read from this bit.
30	RAMDEDOVC	DTSRAM 2-bit error overflow flag clear When the user writes 1 to this bit, the DTSRAM 2-bit error overflow flag (DTSER2.RAMDEDOV) is cleared. The read value of this bit is always 0.
29 to 16	—	Reserved These bits are always read as 0. The write value should be 0.
15	RAMSEDC	DTSRAM 1-bit error flag clear If a user writes 1 to this bit, the DTSRAM 1-bit error flag (DTSER2.RAMSED) is cleared. 0 is always read from this bit.
14	RAMSEDOVC	DTSRAM 1-bit error overflow flag clear When the user writes 1 to this bit, the DTSRAM 1-bit error overflow flag (DTSER2.RAMSEDOV) is cleared. The read value of this bit is always 0.
13 to 1	—	Reserved These bits are always read as 0. The write value should be 0.
0	DTSERC	DTS error flag clear If a user writes 1 to this bit, the DTS DMA error flag (DTSER1.DTSER) is cleared. 0 is always read from this bit.

7.9.2.9 DM0CMV — DMAC0 Register Access Protection Violation Register

Access: This register can be read in 32-bit units.

Address: FFFF 8030_H

Value after reset: 0000 0000_H

7.9.2.14 DTRECCTL — DTSRAM ECC Control Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8080_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PROT[1:0]		—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SEC DIS	ECC DIS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 7.31 DTRECCTL Register Contents

Bit Position	Bit Name	Function
31, 30	PROT[1:0]	These bits enable or disable writing to the ECCDIS and SECDIS bits. The written data is not retained. The read value is always 0. These bits should be written when (PROT1, PROT0) = (0, 1)
29 to 2	—	Reserved These bits are always read as 0. The write value should be 0.
1	SECDIS	DTSRAM SEC error correction disable This bit enables or disables SEC error correction when the ECCDIS bit is 0. 1-bit ECC error detection operation is always executed when ECCDIS bit is 0 regardless of the state of this bit. Set (PROT1, PROT0) = (0, 1) at the same time as writing to this bit. 0: Error correction is enabled when the SEC error is detected. 1: Error correction is disabled when the SEC error is detected.
0	ECCDIS	DTSRAM ECC disable This bit enables or disables DTSRAM ECC error detection and correction. Set (PROT1, PROT0) = (0, 1) at the same time as writing to this bit. 0: Error detection and correction are enabled. 1: Error detection and correction are disabled. The encoding function is effective when error detection and correction are disabled

7.9.2.15 DTRERINT — DTSRAM Error Notification Control Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8084_H

Value after reset: 0000 0002_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DEDIE	SEDIE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 7.32 DTRERINT Register Contents

Bit Position	Bit Name	Function
31 to 2	—	Reserved These bits are always read as 0. The write value should be 0.
1	DEDIE	DTSRAM 2-bit error notification enable This bit enables or disables notification of 2-bit error detection to the ECM when the ECCDIS bit in DTRECCTL is 0. 0: Notification of 2-bit error to ECM is disabled. 1: Notification of 2-bit error to ECM is enabled.
0	SEDIE	DTSRAM 1-bit error notification enable This bit enables or disables notification of 1-bit error detection to the ECM when the ECCDIS bit in DTRECCTL is 0. 0: Notification of 1-bit error to ECM is disabled. 1: Notification of 1-bit error to ECM is enabled.

7.9.2.16 DTRTCTL — DTSRAM Test Control Register

This register is used for ECC test (self-diagnosis). It enables setting of ECC test mode and selection of ECC data to be written to the DTSRAM.

Access: This register can be read/written in 32-bit units.

Address: FFFF 8094_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PROT[1:0]		—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ECC TST	DAT SEL
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Table 7.33 DTRTCTL Register Contents

Bit Position	Bit Name	Function
31, 30	PROT[1:0]	These bits enable or disable writing to the ECCTST and DATSEL bits. The written data is not retained. The read value is always 0. These bits should be written when (PROT1, PROT0) = (0, 1)
29 to 2	—	Reserved These bits are always read as 0. The write value should be 0.
1	ECCTST	DTSRAM ECC Test Mode This bit enables or disables DTSRAM ECC test mode. Set (PROT1, PROT0) = (0, 1) at the same time as writing to this bit. 0: ECC test mode is enabled. 1: ECC test mode is disabled.
0	DATSEL	ECC Test Data Selection This bit is valid when ECCTST is 1 and selects ECC data to be written to the DTSRAM. Set (PROT1, PROT0) = (0, 1) at the same time as writing to this bit. 0: ECC encoded from the written data is used. 1: The value specified by the DTSRAM test data writing register (DTRTWDAT) is used.

7.9.2.17 DTRTWDAT — DTSRAM Test Write Data Register

This register is used for ECC test (self-diagnosis). It specifies ECC data to be written to the DTSRAM after ECC test mode is enabled (ECCTST = 1).

Access: This register can be read/written in 32-bit units.

Address: FFFF 8098_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.34 DTRTWDAT Register Contents

Bit Position	Bit Name	Function
31 to 7	—	Reserved These bits are always read as 0. The write value should be 0.
6 to 0	TWDAT[6:0]	ECC Test Write Data These bits specify ECC data to be written to the DTSRAM when DTRTSCTL.ECCTST = 1 and DTRTSCTL.DATSEL = 1. Writing to these bits is enabled when DTRTSCTL.ECCTST = 1 When DTRTSCTL.ECCTST = 0, these bits cannot be written and its read value is 0.

7.9.2.18 DTRTRDAT — DTSRAM Test Read Data Register

This register is used for ECC test (self-diagnosis). It reads out ECC data of the DTSRAM after ECC test mode is enabled (ECCTST = 1).

Access: This register can be read in 32-bit units.

Address: FFFF 809C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 7.35 DTRTRDAT Register Contents

Bit Position	Bit Name	Function
31 to 7	—	Reserved
6 to 0	TRDAT[6:0]	ECC Test Read Data These bits retain the last ECC data read out from the DTSRAM when DTRTSCTL.ECCTST = 1. Writing to these bits is enabled when DTRTSCTL.ECCTST = 1. When DTRTSCTL.ECCTST = 0, the read value of these bits is 0.

7.9.2.19 DMnnCM — DMAC Channel Master Setting Register (nn = 00 to 07 and 10 to 17)

Access: This register can be read/written in 32-bit units.

Address: FFFF 8100_H + 4_H × Ch. No. n (n = 0 to 7)
 FFFF 8120_H + 4_H × Ch. No. n - 10 (n = 10 to 17)

Value after reset: 0000 0010_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R

Table 7.36 DMnnCM Register Contents

Bit Position	Bit Name	Function ion
31 to 7	—	Reserved These bits are always read as 0. The write value should be 0.
6 to 4	PEID[2:0]	Channel master PEID setting Specify the PEID information of the master assigned to the channel.
3, 2	SPID[1:0]	Channel master SPID setting Specify the SPID information used by the master assigned to the channel.
1	UM	Channel master UM setting Specifies the UM information of the master assigned to the channel.
0	—	Reserved This bit is always read as 0. The write value should be 0.

CAUTION

DM00CM to DM07CM configure the channel master information of the DMAC0 channel 0 to 7 respectively.

DM10CM to DM17CM configure the channel master information of the DMAC1 channel 0 to 7 respectively.

For information about the functions this register offers, see **Section 7.5, Reliability Function**.

7.9.2.20 DTSnnnCM — DTS Channel Master Setting Register (nnn = 000 to 127)

Access: This register can be read/written in 32-bit units.

Address: FFFF 8200_H + 4_H × Ch. No. n (n = 0 to 127)

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	PEID[2:0]			SPID[1:0]		UM	—
Value after reset	Undefined															
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CMC[15:0]															
Value after reset	Undefined															
	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 7.37 DTS Channel Master Setting Register Contents

Bit Position	Bit Name	Function
31 to 23	—	Reserved When read, the value returned is undefined. The write value should be 0.
22 to 20	PEID[2:0]	Channel master PEID setting Specify the PEID information of the master assigned to the channel.
19, 18	SPID[1:0]	Channel master SPID setting Specify the SPID information used by the master assigned to the channel.
17	UM	Channel master UM setting Specifies the UM information of the master assigned to the channel.
16	—	Reserved When read, the value returned is undefined. The write value should be 0.
15 to 0	CMC[15:0]	Transfer count compare In terms of contents, this field is the same as bits [15:0] of Section 7.11.3.8, DTTCCnnn — DTS Transfer Count Compare Register.

CAUTION

DTS000CM to DTS127CM configure the channel master information of the DTS channel 0 to 127 respectively.

For information about the functions this register offers, see **Section 7.5, Reliability Function.**

CAUTION

The 16 low-order bits of this register are shared with the DTS transfer count compare register, one of the DTS channel registers.

If you write to this register, the DTS transfer count compare register is updated as well.

Recommended setup procedure of the DTS channel master setting register

When the special master configures the overall DMA operation, the channel master setting must be configured in bits 22 to 17 in this register, and 0 must be specified in bits 15 to 0 and the reserved bits 31 to 23, and 16.

When the master assigned to the channel updates the value of the transfer count compare, use the DTS transfer count compare register instead.

Bits 31 to 23 of this register are reserved, but you can read and write those bits. Our recommendation is as follows. When you write to those bits, write 0. When you read from those bits, discard the read value by software.

7.10 DMAC Channel Register

7.10.1 DMAC Channel Register Address

Address = Base address “FFFF 8000_H” + Offset address

Table 7.38 DMAC Channel Register Address

Offset Address	Register Symbol	Meaning	Accessed Permission	
			Special Master	General Master
0400 _H + 40 _H × [channel number]	DSAn	DMAC source address	√	√
0404 _H + 40 _H × [channel number]	DDAn	DMAC destination address	√	√
0408 _H + 40 _H × [channel number]	DTCn	DMAC transfer count	√	√
040C _H + 40 _H × [channel number]	DTCTn	DMAC transfer control	√	√
0410 _H + 40 _H × [channel number]	DRSAn	DMAC reload source address	√	√
0414 _H + 40 _H × [channel number]	DRDAn	DMAC reload destination address	√	√
0418 _H + 40 _H × [channel number]	DRTCn	DMAC reload transfer count	√	√
041C _H + 40 _H × [channel number]	DTCCn	DMAC transfer count compare	√	√
0420 _H + 40 _H × [channel number]	DCENn	DMAC channel operation enable setting	√	√
0424 _H + 40 _H × [channel number]	DCSTn	DMAC transfer status	√	√
0428 _H + 40 _H × [channel number]	DCSTSn	DMAC transfer status set	√	√
042C _H + 40 _H × [channel number]	DCSTCn	DMAC transfer status clear	√	√
0430 _H + 40 _H × [channel number]	DTFRn	DTFR setting	√	√
0434 _H + 40 _H × [channel number]	DTFRRQn	DTFR transfer request status	√	√
0438 _H + 40 _H × [channel number]	DTFRRQCn	DTFR transfer request clear	√	√

Note 1. The [channel number] in the offset addresses and “n” in the register symbols are numbers in the range from 0 to 15, and the correspondence between the channel number n and the channel is as follows.

Channel number n	Channel
0	DMAC0 channel 0
1	DMAC0 channel 1
2	DMAC0 channel 2
3	DMAC0 channel 3
4	DMAC0 channel 4
5	DMAC0 channel 5
6	DMAC0 channel 6
7	DMAC0 channel 7
8	DMAC1 channel 0
9	DMAC1 channel 1
10	DMAC1 channel 2
11	DMAC1 channel 3
12	DMAC1 channel 4
13	DMAC1 channel 5
14	DMAC1 channel 6
15	DMAC1 channel 7

7.10.2 Details of DMAC Channel Registers

The “n” in the register symbols indicates the DMA channel number (n = 0 to 15).

7.10.2.1 DSA_n — DMAC Source Address Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8400_H + 40_H × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SA[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 7.39 DSA_n Register Contents

Bit Position	Bit Name	Function
31 to 0	SA[31:0]	Source address Specifies the DMA transfer source address. Those bits are updated whenever a DMA cycle is executed. If you read from those bits, the transfer source address for the next DMA cycle is read.

CAUTIONS

1. It is forbidden to write to those bits when the channel operation is enabled (DTE bit = 1). If you do, the correct operation is not guaranteed.
2. The address must be set up while the DTE bit is 0.
3. DMA transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size is as follows. (* denotes an arbitrary one bit.)

The correct operation is not guaranteed if you select other setting.

Data Size	SA3	SA2	SA1	SA0
8 bits	*	*	*	*
16 bits	*	*	*	0
32 bits	*	*	0	0
64 bits	*	0	0	0
128 bits	0	0	0	0

7.10.2.2 DDAn — DMAC Destination Address Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8404_H + 40_H × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 7.40 DDAn Register Contents

Bit Position	Bit Name	Function
31 to 0	DA[31:0]	Destination address Specifies the DMA transfer destination address. Those bits are updated whenever a DMA cycle is executed. If you read from those bits, the transfer destination address for the next DMA cycle is read.

CAUTIONS

1. It is forbidden to write to those bits when the channel operation is enabled (DTE bit = 1). If you do, the correct operation is not guaranteed.
2. The address must be set up while the DTE bit is 0.
3. If transfer error is generated in the read cycle of DMA transfer, the write cycle is not executed, but the destination address is updated.
4. DMA transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size is as follows. (× denotes an arbitrary one bit.)

The correct operation is not guaranteed if you select other setting.

Data Size	DA3	DA2	DA1	DA0
8 bits	×	×	×	×
16 bits	×	×	×	0
32 bits	×	×	0	0
64 bits	×	0	0	0
128 bits	0	0	0	0

7.10.2.3 DTCn — DMAC Transfer Count Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8408_H + 40_H × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ARC[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 7.41 DTCn Register Contents

Bit Position	Bit Name	Function										
31 to 16	ARC[15:0]	<p>Address reload count</p> <p>Specifies the number of transfers until the address reload when the reload function 2 is used, and also specifies the number of transfers when the block transfer 2 is used. If you read from those bits during DMA transfer, the address reload count for the next DMA cycle is read.</p> <p>When the reload function 2 or block transfer 2 is used, ARC[15:0] bits are decremented by one for every DMA cycle. When the reload function 2 or block transfer 2 is not used, ARC[15:0] bits are not updated.</p> <p>If the value is 0000_H, it means that the number of transfers until the address reload when the reload function 2 is used and the number of transfers when the block transfer 2 is used are 65536.</p>										
15 to 0	TRC[15:0]	<p>Transfer count</p> <p>Configures the number of transfers. TRC[15:0] bits are decremented by one whenever a DMA cycle is executed. If you read from those bits, the remaining number of transfers for the next DMA cycle is read. If the reload function is not used, after the last transfer is complete, the value at the completion (0000_H) is retained.</p> <table border="1" style="width: 100%; margin-top: 10px;"> <thead> <tr> <th>TRC[15:0]</th> <th>Operation</th> </tr> </thead> <tbody> <tr> <td>0000_H</td> <td>The number of transfers is 65536, or the transfer is complete.</td> </tr> <tr> <td>0001_H</td> <td>The number of transfers or remaining transfers is 1.</td> </tr> <tr> <td>:</td> <td>:</td> </tr> <tr> <td>FFFF_H</td> <td>The number of transfers or remaining transfers is 65535.</td> </tr> </tbody> </table>	TRC[15:0]	Operation	0000 _H	The number of transfers is 65536, or the transfer is complete.	0001 _H	The number of transfers or remaining transfers is 1.	:	:	FFFF _H	The number of transfers or remaining transfers is 65535.
TRC[15:0]	Operation											
0000 _H	The number of transfers is 65536, or the transfer is complete.											
0001 _H	The number of transfers or remaining transfers is 1.											
:	:											
FFFF _H	The number of transfers or remaining transfers is 65535.											

CAUTIONS

1. It is forbidden to write to those bits when the channel operation is enabled (DTE bit = 1). If you do, the correct operation is not guaranteed.
2. If transfer error is generated in the read cycle of DMA transfer, the write cycle is not executed, but the transfer count and the address reload count are updated.

7.10.2.4 DTCTn — DMAC Transfer Control Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 840C_H+ 40_H × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 7.42 DTCTn Register Contents (1/3)

Bit Position	Bit Name	Function
31 to 28	—	Reserved These bits are always read as 0. The write value should be 0.
27	ESE	Transfer error case DMA transfer disable setting Configures whether a DMA cycle is executed when the DCSTn.ER bit is set due to DMA transfer error. If this bit is cleared to 0, even when the DCSTn.ER bit is set due to DMA transfer error, the following DMA cycles can be executed. If this bit is set to 1, the following DMA cycles are not executed when the DCSTn.ER bit is set due to DMA transfer error. 0: DMA cycles are executed while the DCSTn.ER bit is set. 1: DMA cycles are not executed while the DCSTn.ER bit is set.
26	DRS	DMA transfer request selection assignment Selects the type of DMA transfer requests to be accepted. 0: Software DMA transfer request 1: Hardware DMA transfer request
25 to 21	—	Reserved These bits are always read as 0. The write value should be 0.
20 to 18	CHNSEL[2:0]	Next channel in the chain Specify the next channel in the chain. The next channel must be another channel in the same DMAC. You cannot specify a channel in the different DMAC or in the DTS. You cannot specify the same channel for the next channel. (If you do, the correct operation is not guaranteed.)
17, 16	CHNE[1:0]	Chain enable Select the chain function. 00: Disabled 01: Chain at the last transfer A chain request is generated at the completion of the DMA cycle in which the remaining transfer count is one. 10: (Setting prohibited. No guarantee of operation) 11: Always chain A chain request is generated at the completion of every DMA cycle.
15	CCE	Transfer count match interrupt enable If this bit is set, a transfer count match interrupt is generated at the completion of the DMA cycle in which the transfer count compare register and the remaining transfer count have the same value.
14	TCE	Transfer completion interrupt enable If this bit is set, a transfer completion interrupt is generated at the completion of the last transfer.

Table 7.42 DTCTn Register Contents (2/3)

Bit Position	Bit Name	Function															
13	MLE	<p>Continuous transfer enable</p> <p>If this bit is set, the DTE bit is not cleared at the completion of DMA transfer. In addition, even if the TC bit is not cleared, DMA transfer starts when there is a DMA transfer request.</p> <p>0: The DTE bit is cleared at the completion of DMA transfer. In addition, the next DMA transfer can start only after the TC bit is cleared.</p> <p>1: The DTE bit is not cleared at the completion of DMA transfer. In addition, even if the TC bit is not cleared, DMA transfer starts when there is a DMA transfer request.</p>															
12, 11	RLD2M[1:0]	<p>Reload function 2 setting</p> <p>Configure the reload function 2.</p> <p>00: Reload function 2 is disabled.</p> <p>01: Reload function 2 is enabled.</p> <p>The source address and address reload count are reloaded at the completion of the DMA cycle in which the address reload count is 1.</p> <p>10: Reload function 2 is enabled.</p> <p>The destination address and address reload count are reloaded at the completion of the DMA cycle in which the address reload count is 1.</p> <p>11: Reload function 2 is enabled.</p> <p>The source address, destination address, and address reload count are reloaded at the completion of the DMA cycle in which the address reload count is 1.</p>

0	1	Decrement															
1	0	Fixed															
0	1	Setting prohibited (No guarantee of operation)															

Table 7.42 DTCTn Register Contents (3/3)

Bit Position	Bit Name	Function																												
4 to 2	DS[2:0]	Transfer data size Specify the transfer data size.																												
		<table border="1"> <thead> <tr> <th>DS2</th> <th>DS1</th> <th>DS0</th> <th>Transfer Data Size</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>0</td> <td>8 bits</td> </tr> <tr> <td>0</td> <td>0</td> <td>1</td> <td>16 bits</td> </tr> <tr> <td>0</td> <td>1</td> <td>0</td> <td>32 bits</td> </tr> <tr> <td>0</td> <td>1</td> <td>1</td> <td>64 bits</td> </tr> <tr> <td>1</td> <td>0</td> <td>0</td> <td>128 bits</td> </tr> <tr> <td colspan="3">Other than the above</td> <td>Setting prohibited (No guarantee of operation)</td> </tr> </tbody> </table>	DS2	DS1	DS0	Transfer Data Size	0	0	0	8 bits	0	0	1	16 bits	0	1	0	32 bits	0	1	1	64 bits	1	0	0	128 bits	Other than the above			Setting prohibited (No guarantee of operation)
DS2	DS1	DS0	Transfer Data Size																											
0	0	0	8 bits																											
0	0	1	16 bits																											
0	1	0	32 bits																											
0	1	1	64 bits																											
1	0	0	128 bits																											
Other than the above			Setting prohibited (No guarantee of operation)																											
1, 0	TRM[1:0]	Transfer mode Specify the DMA transfer mode. 00: Single transfer 01: Block transfer 1 (The number of transfers is specified by the transfer count.) 10: Block transfer 2 (The number of transfers is specified by the address reload count.) 11: Setting prohibited (No guarantee of operation)																												

CAUTIONS

1. While channel operation is enabled (DTE bit = 1), changing the value of the MLE bit from “1” to “0” is only possible (correct operation is not guaranteed when the value of any bit other than the MLE bit is changed).
2. If forbidden settings are used for some of the bits, the correct operation is not guaranteed.

7.10.2.5 DRSA_n — DMAC Reload Source Address Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8410_H + 40_H × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000_H

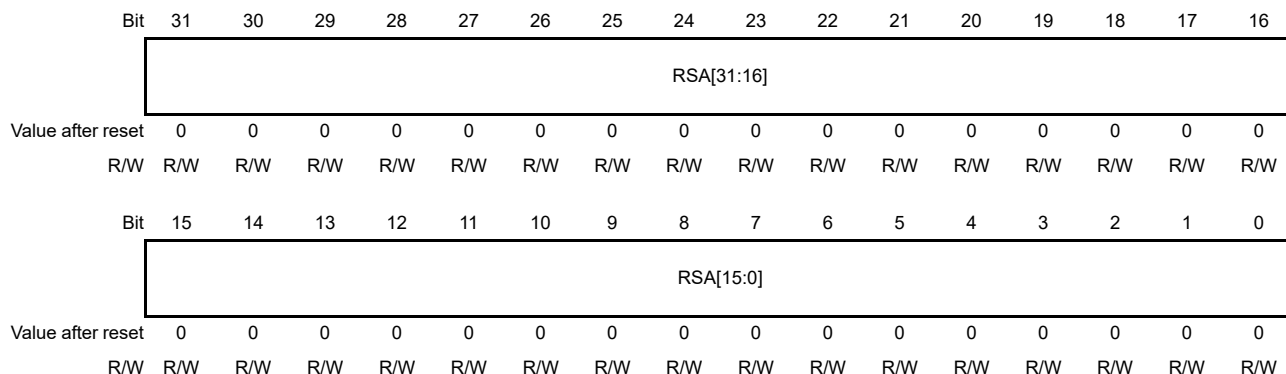

Table 7.43 DRSA_n Register Contents

Bit Position	Bit Name	Function
31 to 0	RSA[31:0]	Reload source address Specifies the source address to be reloaded to the DMA source address register when the reload function 1 or reload function 2 is used.

CAUTION

DMA transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size is as follows. (× denotes an arbitrary one bit.) The correct operation is not guaranteed if you select other setting.

Data Size	RSA3	RSA2	RSA1	RSA0
8 bits	×	×	×	×
16 bits	×	×	×	0
32 bits	×	×	0	0
64 bits	×	0	0	0
128 bits	0	0	0	0

7.10.2.6 DRDAn — DMAC Reload Destination Address Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8414_H + 40_H × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 7.46 DTCCn Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. The write value should be 0.
15 to 0	CMC[15:0]	Transfer count compare Configure the transfer count to be compared to the transfer count register. At the completion of the DMA cycle in which the remaining transfer count is the same as the value in this register, the transfer count match flag (DCSTn.CC) in the DMAC transfer status register is set. Furthermore, if the transfer count match interrupt enable (DTCTn.CCE) bit is 1, a transfer count match interrupt is generated. If 0000 _H is set, comparison with the transfer count is disabled. In this case, the transfer count match flag in the DMAC transfer status register is never set, and a transfer count match interrupt is never generated.

CAUTION

It is forbidden to write to those bits when the channel operation is enabled (DTE bit = 1). If you do, the correct operation is not guaranteed.

7.10.2.9 DCENn — DMAC Channel Operation Enable Setting Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8420_H + 40_H × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 7.47 DCENn Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should be 0.
0	DTE	Channel operation enable Specifies whether to enable or disable the transfer operation of the channel. If the DTE bit is 1, DMA transfer starts when there is a DMA transfer request. If the MLE bit is 0, the DTE bit is cleared automatically at the completion of the DMA transfer. In addition, if 0 is written to the DTE bit during DMA transfer, the DMA transfer is suspended. If 1 is written to the DTE bit during suspension, the suspension is cleared and the DMA transfer resumes. 0: Channel operation is disabled/Channel suspended 1: Channel operation is enabled/Channel suspension cleared

7.10.2.10 DCSTn — DMAC Transfer Status Register

Access: This register can be read in 32-bit units.

Address: FFFF 8424_H + 40_H × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 7.48 DCSTn Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 12	—	Reserved
11	ERWR	DMA Transfer Error occurring cycle This bit is updated at the same time as setting of the DMA transfer error flag (ER), indicating which cycle of read or write the DMA transfer error occurs in. This bit is not updated when a new DMA transfer error occurs after the ER bit has been set. If the ER bit is cleared, this bit is also cleared to 0. 0: DMA transfer error occurs in read cycle. 1: DMA transfer error occurs in write cycle.
10, 9	—	Reserved
8	CY	DMA cycle execution state This bit shows whether a DMA cycle is ongoing in this channel. 0: DMA cycle is not ongoing. 1: DMA cycle is ongoing.
7	ER	Transfer error flag This bit is set when DMA transfer error is generated. If this bit is 1 and the DTCTn.ESE bit is set, a DMA cycle is not executed when a DMA transfer request is generated. 0: No DMA transfer error is generated 1: DMA transfer error is generated
6	—	Reserved
5	CC	Transfer count match flag This bit is set at the completion of the DMA cycle in which the remaining transfer count is the same as the value set in the transfer compare register. 0: No compare match has occurred with the transfer count compare register. 1: Compare match has occurred with the transfer count compare register.
4	TC	Transfer completion flag This bit is set at the completion of the last transfer and shows whether the DMA transfer is complete. If the MLE bit is 0 and this bit is 1, a DMA cycle is not executed when a DMA transfer request is generated. 0: DMA transfer incomplete 1: DMA transfer complete
3, 2	—	Reserved

Table 7.48 DCSTn Register Contents (2/2)

Bit Position	Bit Name	Function
1	DR	<p>Hardware DMA transfer request status</p> <p>This bit shows whether there is a hardware DMA transfer request (DMARQ) from the DTFR.</p> <p>This bit changes regardless of the value of the DTE bit when a hardware DMA transfer request from the DTFR is generated. If the software DMA transfer request is selected by the transfer request selection bit (DRS) in the DMAC transfer control register, this bit is not set even when a hardware DMA transfer request is input from the DTFR.</p> <p>0: There is no hardware DMA transfer request 1: There is a hardware DMA transfer request</p>
0	SR	<p>Software DMA transfer request flag</p> <p>This bit shows whether there is a software DMA transfer request (DMARQ). This bit is automatically cleared at the completion of the last transfer. A user can set this bit by writing 1 to the SRS bit in the DMAC transfer status set register. In addition, a user can clear this bit by writing 1 to the SRC bit in the DMAC transfer status clear register, but if this is done, the ongoing DMA transfer is aborted and cannot be resumed.</p> <p>0: There is no software DMA transfer request 1: There is a software DMA transfer request</p>

7.10.2.11 DCSTSn — DMAC Transfer Status Set Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 8428_H + 40_H × Ch. No. n (n = 0 to 15)

Value after reset: 0000 0000_H

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DRQC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 7.53 DTFRRQCn Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should be 0.
0	DRQC	Hardware DMA transfer request clear If the hardware DMA transfer request is an edge detection type* ¹ , a user can clear the DTFRRQn.DRQ bit by writing 1 to this bit. If the hardware DMA transfer request is a level input type* ¹ , the DTFRRQn.DRQ bit cannot be cleared by writing to this bit. 0 is always read from this bit.

Note 1. Whether the hardware DMA transfer request is an edge detection type or level input type depends on the hardware DMA transfer source selected by DTFRn.REQSEL. The hardware DMA transfer request is only an edge detection type.

7.11 DTS Channel Register

7.11.1 Transfer information of the DTS (TI)

7.11.1.1 Structure of the TI

The transfer information of the DTS is called TI. One set of TI consists of 32 bits. 8 sets of TI are assigned for each channel. The 8 sets of TI is called TI-A, TI-B, TI-C, TI-D, TI-E, TI-F, TI-G, and TI-H.

Figure 7.12 shows the structure of the TI.

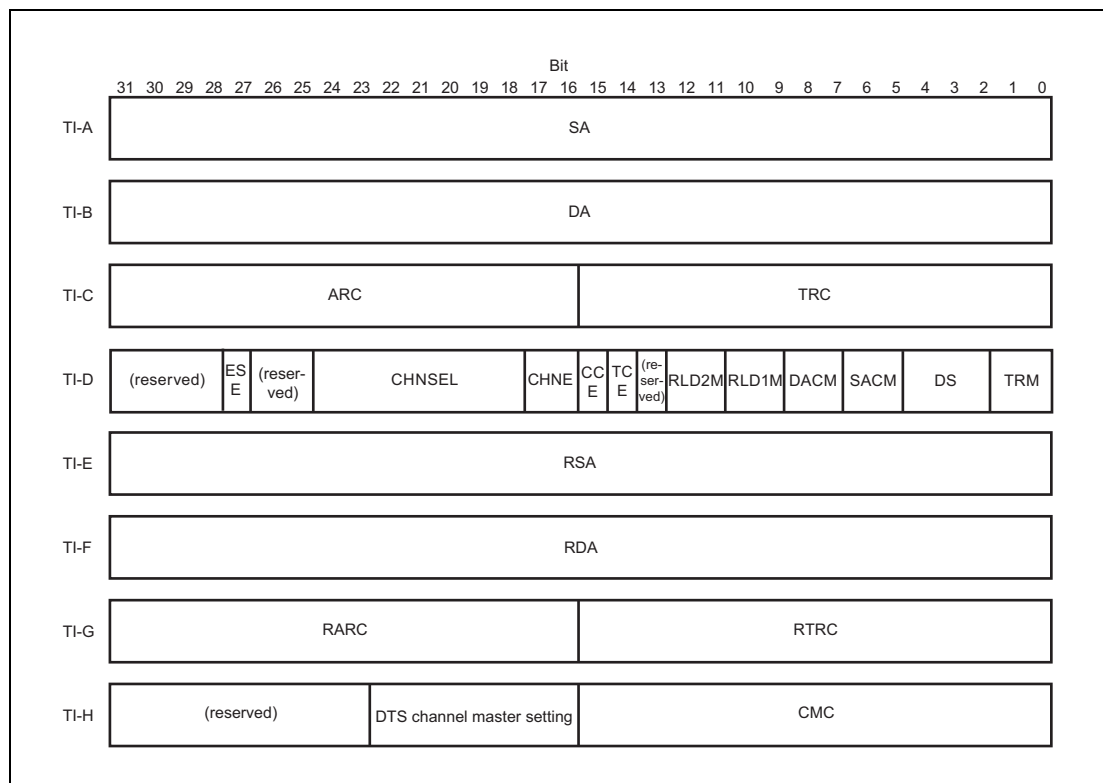

Figure 7.12 Structure of the TI

7.11.1.2 Organization of the TI in the DTSRAM

A user indirectly accesses the DTSRAM by way of the DTS channel registers for each channel and the DTS channel master setting registers.

Therefore, usually, a user does not have to think about the address organization of the TI in the DTSRAM. As an exception, when ECC error occurs while the DTSRAM is read, the address of the ECC error in the DTSRAM is stored to the DTSRAM error register 2 (DTSER2), one of the global registers. In order to know which channel and TI have generated the error, you need to understand the address organization of the TI in the DTSRAM.

Figure 7.13 shows the address organization of the TI in the DTSRAM.

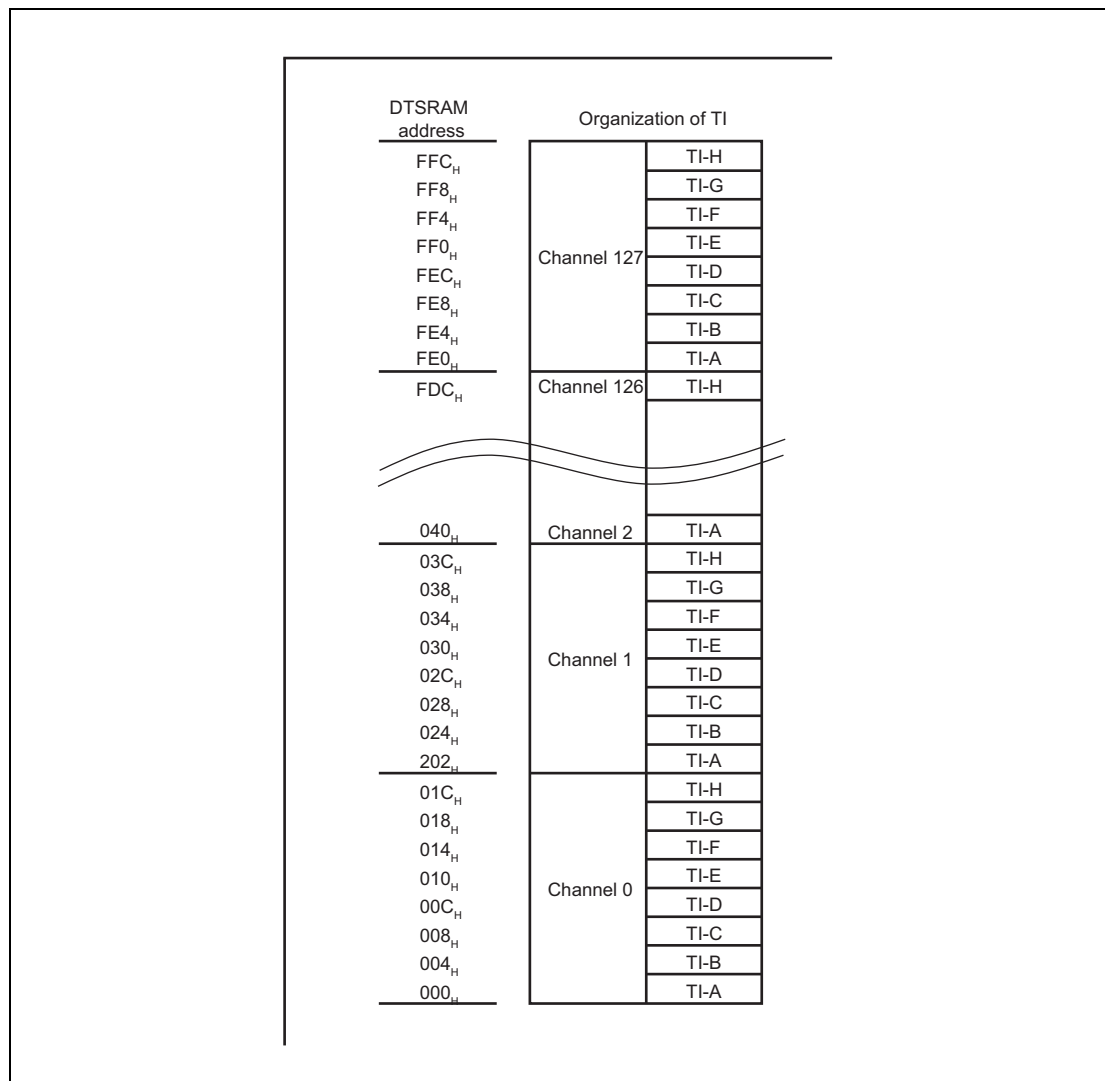

Figure 7.13 Organization of the TI in the DTSRAM

7.11.1.3 Accessing the TI

TI-A can be accessed by way of the DTS source address register (DTSAnnn) for each channel.

TI-B can be accessed by way of the DTS destination address register (DTDAnnn) for each channel.

TI-C can be accessed by way of the DTS transfer count register (DTTCnnn) for each channel.

TI-D can be accessed by way of the DTS transfer control register (DTTCTnnn) for each channel.

TI-E can be accessed by way of the DTS reload source address register (DTRSAnnn) for each channel.

TI-F can be accessed by way of the DTS reload destination address register (DTRDAnnn) for each channel.

TI-G can be accessed by way of the DTS reload transfer count register (DTRTCnnn) for each channel.

TI-H can be accessed by way of the channel master setting register (DTSnnnCM), which is a global register, and the transfer count compare register (DTTCCnnn) for each channel.

7.11.1.4 Caution about accessing the TI

The data of the DTS channel master setting register and the data of the DTS transfer count compare register are stored to the same TI-H.

Access to the DTS channel master setting register (DTSnnnCM) is actually 32-bit access to the whole TI-H. Therefore, when you write to the DTS channel master setting register, the lower 16-bit data, which is the data for the DTS transfer count compare (CMC), is updated at the same time. When you read from the DTS channel master setting register, the value of the DTS transfer count compare (CMC) is read as the lower 16-bit data.

When you read from the DTS transfer count compare register (DTTCCnnn), 32-bit data is read from the TI-H, but only the lower 16-bit data is actually seen in the result of the register read. When you write to the DTS transfer count compare register (DTTCCnnn), lower 16-bit read/modify/write access to the 32-bit TI-H is used. Data in the TI immediately after the reset is undefined. It should be noted that, if you try to write to the DTS transfer count compare register (DTTCCnnn) before setting up the DTS channel master setting register, ECC error may be detected during the read of the read/modify/write access.

Bits 31 to 23 of the TI-H are not used, but you can read and write those bits by accessing the DTS channel master setting register. Our recommendation is as follows. When you write to those bits, write 0. When you read from those bits, discard the read value by software.

After the reset, the values in the DTSRAM, which stores the TI, are undefined. After the reset, if you read TI before you write to the TI, ECC error is generated. Therefore, the first access to the following registers after the reset must be write access. The first access after the reset should never be read access.

- DTS source address register (DTSAnnn)
- DTS destination address register (DTDAnnn)
- DTS transfer count register (DTTCnnn)
- DTS transfer control register (DTTCTnnn)
- DTS reload source address register (DTRSAnnn)
- DTS reload destination address register (DTRDAnnn)
- DTS reload transfer count register (DTRTCnnn)
- Channel master setting registers (DTSnnnCM)

In addition, after the reset, the first access to the DTS transfer count compare register (DTTCnnn) must be always after write access to the channel master setting register (DTSnnnCM).

You can access the TI from a CPU while the DTS is executing DMA transfer. But if you do so, the following should be noted.

- While a channel is executing DMA transfer, the TI of the channel should not be updated by TI access from a CPU. If this situation happens, the result of the DMA transfer and the contents of the TI may mismatch.
- If TI access is requested from a CPU while a TI fetch or TI write back is executed, the TI access is executed after the completion of the TI fetch or TI write back. If a TI fetch or TI write back is requested while a TI access request from a CPU is processed, the TI fetch or TI write back is executed after the processing of the TI access is complete.

7.11.2 DTS Channel Register Address

Address = Base address “FFFF 9000_H” + Offset address

Table 7.54 DTS Channel Register Address

Offset Address	Register Symbol	Meaning	Accessed Permission	
			Special Master	General Master
0000 _H + 40 _H × [channel number]	DTSA _{nnn}	DTS source address	√	√
0004 _H + 40 _H × [channel number]	DTDA _{nnn}	DTS destination address	√	√
0008 _H + 40 _H × [channel number]	DTTC _{nnn}	DTS transfer count	√	√
000C _H + 40 _H × [channel number]	DTTC _{Tnnn}	DTS transfer control	√	√
0010 _H + 40 _H × [channel number]	DTRSA _{nnn}	DTS reload source address	√	√
0014 _H + 40 _H × [channel number]	DTRDA _{nnn}	DTS reload destination address	√	√
0018 _H + 40 _H × [channel number]	DTRTC _{nnn}	DTS reload transfer count	√	√
001C _H + 40 _H × [channel number]	DTTC _{Cnnn}	DTS transfer count compare	√	√
0020 _H + 40 _H × [channel number]	DTFSL _{nnn}	DTSFSL operation setting	√	√
0024 _H + 40 _H × [channel number]	DTFST _{nnn}	DTSFSL transfer request status	√	√
0028 _H + 40 _H × [channel number]	DTFSS _{nnn}	DTSFSL transfer request set	√	√
002C _H + 40 _H × [channel number]	DTFSC _{nnn}	DTSFSL transfer request clear	√	√

Note: The [channel number] in the offset addresses is a number in the range from 0 to 127.
The “nnn” in the register symbols is a 3-digit number in the range from 000 to 127.

7.11.3 Details of DTS Channel Registers

The “nnn” in the register symbols indicates the DTS channel number (nnn = 000 to 127).

7.11.3.1 DTSAnnn — DTS Source Address Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 9000_H + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: Undefined

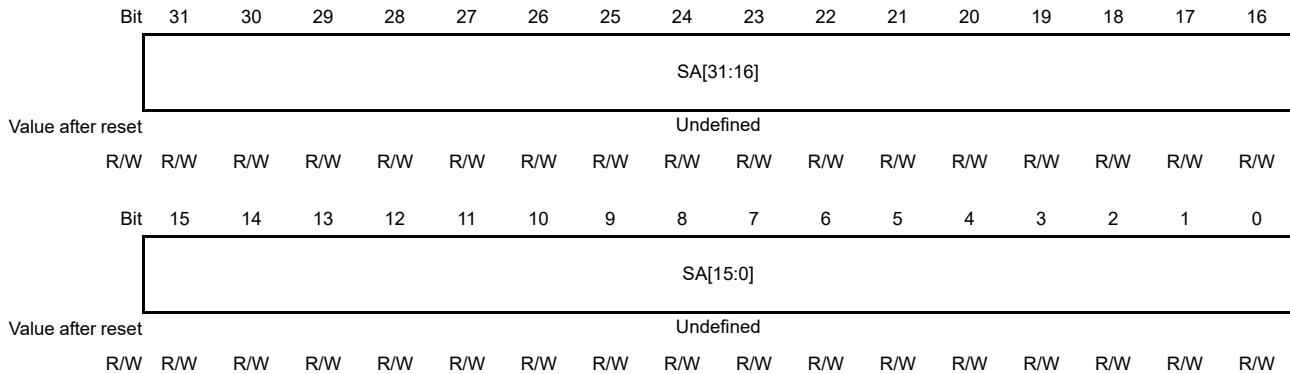

Table 7.55 DTSAnnn Register Contents

Bit Position	Bit Name	Function
31 to 0	SA[31:0]	Source address Specifies the DMA transfer source address. SA[31:0] are updated at the timing of the TI write back and retains the DMA transfer source address for the next DMA transfer.

CAUTION

DMA transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size is as follows. (* denotes an arbitrary one bit.) The correct operation is not guaranteed if you select other setting.

Data Size	SA3	SA2	SA1	SA0
8 bits	*	*	*	*
16 bits	*	*	*	0
32 bits	*	*	0	0
64 bits	*	0	0	0
128 bits	0	0	0	0

7.11.3.2 DTDAnn — DTS Destination Address Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 9004_H + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: Undefined

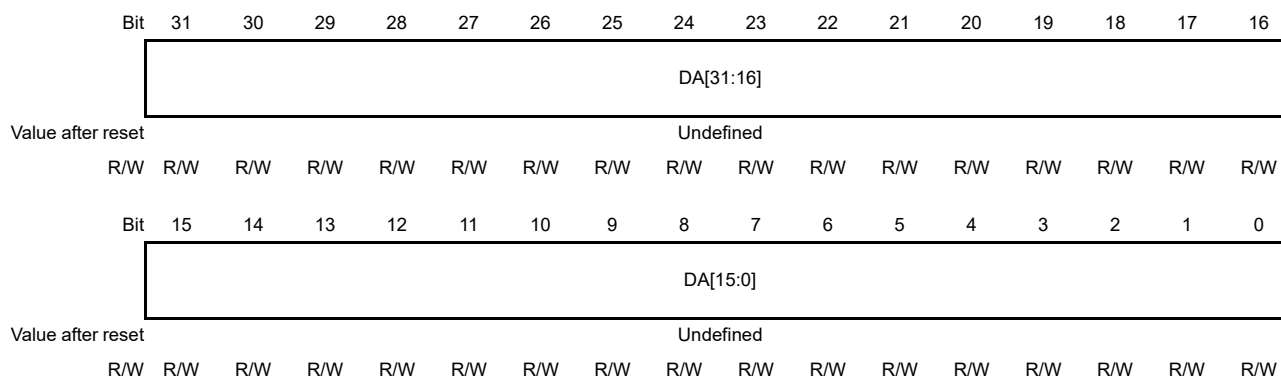

Table 7.56 DTDAnn Register Contents

Bit Position	Bit Name	Function
31 to 0	DA[31:0]	Destination address Specify the DMA transfer destination address. DA[31:0] are updated at the timing of the TI write back and retains the DMA transfer destination address for the next DMA transfer.

CAUTIONS

1. If DMA transfer error is generated in the read cycle of DMA transfer, the write cycle is not executed, but the destination address is updated.
2. DMA transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size is as follows. (* denotes an arbitrary one bit.) The correct operation is not guaranteed if you select other setting.

Data Size	DA3	DA2	DA1	DA0
8 bits	*	*	*	*
16 bits	*	*	*	0
32 bits	*	*	0	0
64 bits	*	0	0	0
128 bits	0	0	0	0

7.11.3.3 DTTcnnn — DTS Transfer Count Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 9008_H + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: Undefined

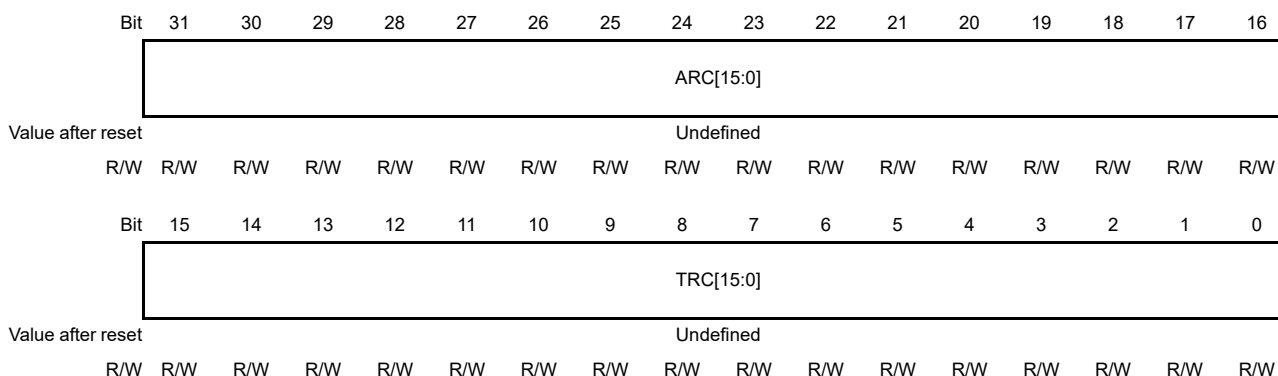

Table 7.57 DTTcnnn Register Contents

Bit Position	Bit Name	Function										
31 to 16	ARC[15:0]	<p>Address reload count</p> <p>Specify the number of transfers until the address reload when the reload function 2 is used, and also specifies the number of transfers when the block transfer 2 is used. When the reload function 2 or block transfer 2 is used, ARC[15:0] are decremented by one for every DMA cycle and updated at the timing of the T1 write back. When the reload function 2 or block transfer 2 is not used, ARC[15:0] are not updated.</p> <p>If 0000_H is set, address reload is disabled.</p> <p>If the value at the start of a DMA cycle is 0000_H, subtraction from the address reload count does not proceed even after the DMA cycle.</p>										
15 to 0	TRC[15:0]	<p>Transfer count</p> <p>Configure the number of transfers. TRC[15:0] are decremented by one whenever a DMA cycle is executed. It is updated at the timing of the T1 write back. If the reload function is not used, after the last transfer is complete, the value at the completion (0000_H) is retained.</p> <p>If 0000_H is set, DMA transfer is not executed even when a DMA transfer request is accepted.</p> <table border="1" style="width: 100%; border-collapse: collapse; margin-top: 10px;"> <thead> <tr style="background-color: #cccccc;"> <th style="text-align: left;">TRC[15:0]</th> <th style="text-align: left;">Operation</th> </tr> </thead> <tbody> <tr> <td>0000_H</td> <td>Transfer is disabled or complete.</td> </tr> <tr> <td>0001_H</td> <td>The number of transfers or remaining transfers is 1.</td> </tr> <tr> <td style="text-align: center;">:</td> <td style="text-align: center;">:</td> </tr> <tr> <td>FFFF_H</td> <td>The number of transfers or remaining transfers is 65535.</td> </tr> </tbody> </table>	TRC[15:0]	Operation	0000 _H	Transfer is disabled or complete.	0001 _H	The number of transfers or remaining transfers is 1.	:	:	FFFF _H	The number of transfers or remaining transfers is 65535.
TRC[15:0]	Operation											
0000 _H	Transfer is disabled or complete.											
0001 _H	The number of transfers or remaining transfers is 1.											
:	:											
FFFF _H	The number of transfers or remaining transfers is 65535.											

CAUTIONS

1. If transfer error is generated in the read cycle of DMA transfer, the write cycle is not executed, but the transfer count and the address reload count are updated.
2. Unlike a DMAC, “0000_H” in the transfer count of the DTS does not mean “65536 transfers” but means that transfer is disabled or complete.

7.11.3.4 DTTCTnnn — DTS Transfer Control Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 900C_H + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 7.58 DTTCTnnn Register Contents (1/3)

Bit Position	Bit Name	Function
31 to 28	—	Reserved When read, the value returned is undefined. The write value should be 0.
27	ESE	Transfer error case DMA transfer abort setting Specifies whether to abort DMA transfer when DMA transfer error is generated. If this bit is cleared to 0, DMA transfer continues when DMA transfer error is generated. If this bit is set to 1, DMA transfer is aborted when DMA transfer error is generated. 0: DMA transfer continues when DMA transfer error is generated. 1: DMA transfer is aborted when DMA transfer error is generated.
26, 25	—	Reserved When read, the value returned is undefined. The write value should be 0.
24 to 18	CHNSEL[6:0]	Next channel in the chain Specifies the next channel in the chain. The next channel must be another channel in the DTS. You cannot specify a channel in a DMAC. You cannot specify the same channel for the next channel. (If you do, the correct operation is not guaranteed.)
17, 16	CHNE[1:0]	Chain enable Selects the chain function. 00: Disabled 01: Chain at the last transfer A chain request is generated at the completion of the DMA cycle in which the remaining transfer count is one. 10: (Setting prohibited. No guarantee of operation) 11: Always chain A chain request is generated at the completion of every DMA cycle.
15	CCE	Transfer count match interrupt enable If this bit is set, a transfer count match interrupt is generated at the completion of the DMA cycle in which the transfer count compare register and the remaining transfer count have the same value.
14	TCE	Transfer completion interrupt enable If this bit is set, a transfer completion interrupt is generated at the completion of the last transfer.
13	—	Reserved When read, the value returned is undefined. The write value should be 0.

Table 7.58 DTTCTnnn Register Contents (3/3)

Bit Position	Bit Name	Function
1, 0	TRM[1:0]	Transfer mode Specifies the DMA transfer mode. 00: Single transfer 01: Block transfer 1 (The number of transfers is specified by the transfer count.) 10: Block transfer 2 (The number of transfers is specified by the address reload count.) 11: Setting prohibited (No guarantee of operation)

CAUTIONS

1. If forbidden settings are used for some of the bits, the correct operation is not guaranteed.
2. Bits 31 to 28, 26, 25, and 13 are unused, but you can read and write those bits. Our recommendation is as follows. When you write to those bits, write 0. When you read from those bits, discard the read value.

7.11.3.5 DTRSAnn — DTS Reload Source Address Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 9010_H + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: Undefined

Table 7.59 DTRSAnn Register Contents

Bit Position	Bit Name	Function
31 to 0	RSA[31:0]	Reload source address Specify the source address to be reloaded when the reload function 1 or reload function 2 is used.

CAUTION

DMA transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size is as follows. (× denotes an arbitrary one bit.) The correct operation is not guaranteed if you select other setting.

Data Size	RSA3	RSA2	RSA1	RSA0
8 bits	×	×	×	×
16 bits	×	×	×	0
32 bits	×	×	0	0
64 bits	×	0	0	0
128 bits	0	0	0	0

7.11.3.6 DTRDAnnn — DTS Reload Destination Address Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 9014_H + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: Undefined

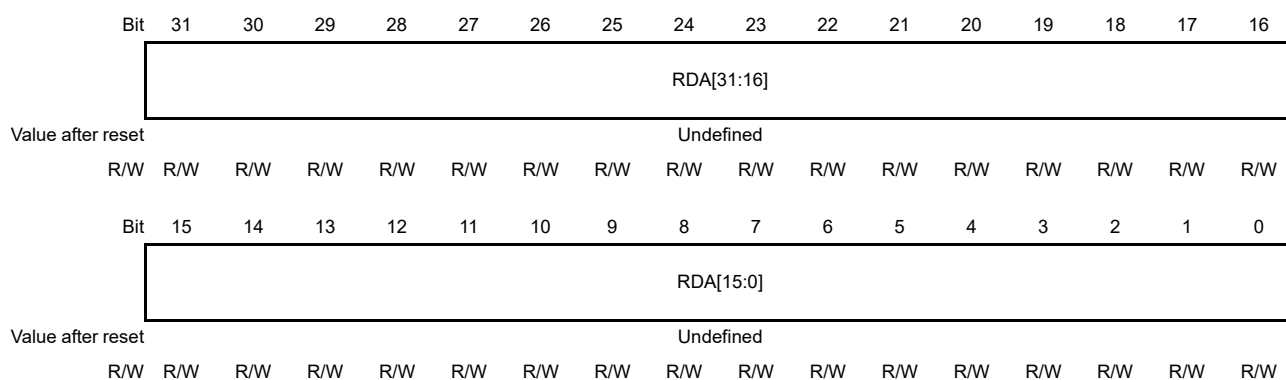

Table 7.60 DTRDAnnn Register Contents

Bit Position	Bit Name	Function
31 to 0	RDA[31:0]	Reload destination address Specifies the destination address to be reloaded when the reload function 1 or reload function 2 is used.

CAUTION

DMA transfer for misaligned data is not supported. The possible lowest four bits of the address for each transfer data size is as follows. (× denotes an arbitrary one bit.) The correct operation is not guaranteed if you select other setting.

Data Size	RDA3	RDA2	RDA1	RDA0
8 bits	×	×	×	×
16 bits	×	×	×	0
32 bits	×	×	0	0
64 bits	×	0	0	0
128 bits	0	0	0	0

7.11.3.7 DTRTC_{nnn} — DTS Reload Transfer Count Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 9018_H + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: Undefined

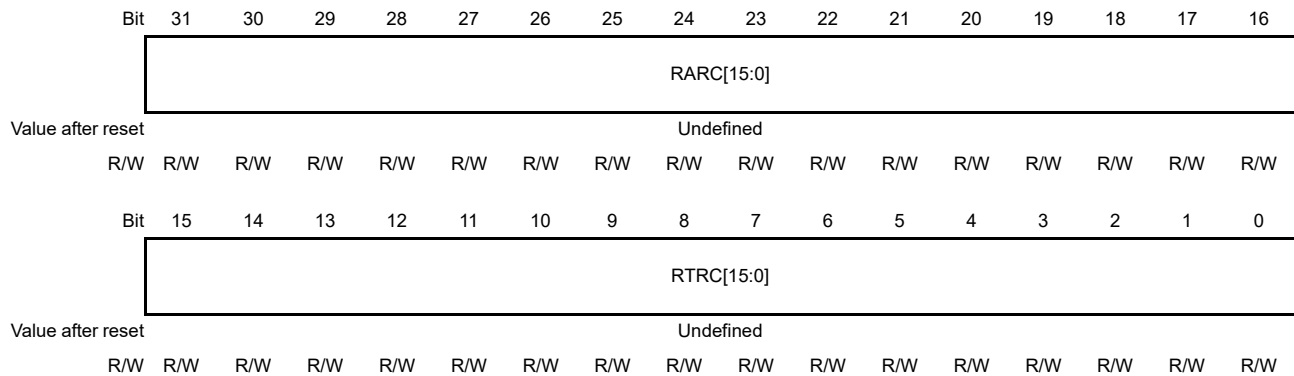

Table 7.61 DTRTC_{nnn} Register Contents

Bit Position	Bit Name	Function
31 to 16	RARC[15:0]	Reload address reload count Specifies the value to be reloaded to the address reload count when the reload function 2 is used.
15 to 0	RTRC[15:0]	Reload transfer count Specifies the value to be reloaded to the transfer count when the reload function 1 is used.
RTRC[15:0]		Operation
		0000 _H No DMA transfer
		0001 _H 1 transfer
		:
		FFFF _H 65535 transfers

7.11.3.8 DTTCCnnn — DTS Transfer Count Compare Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 901C_H + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 7.62 DTTCCnnn Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. The write value should be 0.
15 to 0	CMC[15:0]	Transfer count compare Configures the transfer count to be compared to the transfer count register. If the transfer count match interrupt enable (DTTCTnnn.CCE) bit in the DTS transfer control register is 1, a transfer count match interrupt is generated at the completion of the DMA cycle in which the remaining transfer count is the same as the value in this register. If 0000 _H is set, comparison with the transfer count is disabled. In this case, a transfer count match interrupt is not generated.

CAUTION

This register must be accessed after the DTS channel master setting register is set up. If you access this register without setting up the DTS channel master setting register after the reset, ECC error may be generated during access to this register.

7.11.3.9 DTFSL_{nnn} — DTSFSL Operation Setting Register

Access: This register can be read/written in 32-bit units.

Address: FFFF 9020_H + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	REQEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 7.63 DTFSL_{nnn} Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should be 0.
0	REQEN	DMA transfer request enable This bit selects whether a DMA transfer request from this channel retained in the DTSFSL is used as a candidate in DTS channel arbitration. 0: A DMA transfer request from this channel is not used as a candidate in DTS channel arbitration. 1: A DMA transfer request from this channel is used as a candidate in DTS channel arbitration. If this bit is 0, even if the DTSFSL retains a DMA transfer request, this channel is not a candidate in DTS channel arbitration inside the DTSFSL, and consequently a DMA transfer request from this channel is not generated.

7.11.3.10 DTFSTnnn — DTSFSL Transfer Request Status Register

Access: This register can be read in 32-bit units.

Address: FFFF 9024_H + 40_H × Ch. No. n (n = 0 to 127)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DRQC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 7.66 DTFSCnnn Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0. The write value should be 0.
0	DRQC	DMA transfer request clear A user can clear the DTFSTnnn.DRQ bit by writing 1 to this bit. 0 is always read from this bit.

Section 8 Resets

8.1 Features

- The $\overline{\text{RES}}$ pin incorporates a noise canceller.
- The source of a reset can be determined by referring the reset source determination register.
- The CPU can assert reset by setting a register.

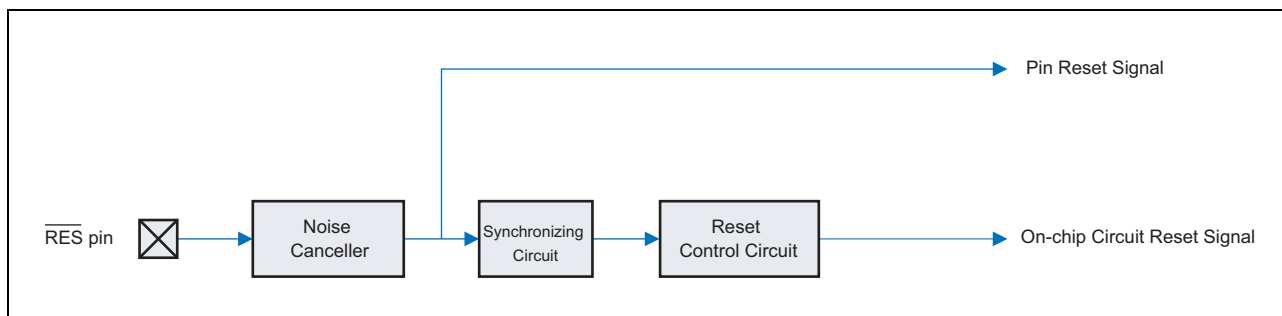

Figure 8.1 Reset Circuit

8.2 Reset State

8.2.1 External Reset State

When a low-level pulse longer than the noise cancel width (t_{RESNCW}) is input to the \overline{RES} pin, external reset is received and this product transits to the external reset state. When external reset is received, individual pins transit to the external reset state. Refer to **Table 2.75 Pin State**, in **Section 2, Pins**, for the state of individual pins during external reset.

The low-level pulse width of the input signal must be longer than t_{RESW6} because the \overline{RES} pin incorporates a noise cancelling circuit. This product transits to the internal reset state by driving the \overline{RES} pin to the high-level after the required low-level period.

CAUTION

Refer to Section 40, Electrical Characteristics, for t_{RESNCW} and t_{RESW6} .

8.2.2 Internal Reset State

When a high-level signal longer than the noise cancel width (t_{RESNCW}) is input to the \overline{RES} pin in the external reset state, this product transits to the internal reset state. Refer to **Table 2.75, Pin State**, in **Section 2, Pins**, for the state of individual pins.

The internal reset state is released in 200 μ s (max.) after external reset release, and the CPU starts the reset exception process.

CAUTION

Refer to Section 40, Electrical Characteristics, for t_{RESNCW} .

8.3 Reset Sources

The following are the reset sources of this product.

Some registers are only initialized by the external reset state. That is, they are only initialized by input of the low level on the $\overline{\text{RES}}$ pin.

However, most registers are initialized by both external and internal reset states. This means that they are initialized by resets from any source.

Regarding sources for the initialization of registers, see the descriptions of the registers in the relevant sections. Where there is no explicit description of the sources for resetting and initializing a register, the register is initialized by both external and internal reset states. That is, such registers are initialized by resets from any source. However, the value after reset of some registers are undefined. Take care since the values of such registers following a reset are not fixed.

Source	Description
When the $\overline{\text{RES}}$ pin is driven to the low level	Transits to the external reset state.
When the ECM issues a reset request	Transits to the internal reset state.
When the debugger issues a reset (forced reset)	Transits to the external reset state.
When the CPU sets the software reset request register	Transits to the internal reset state

8.4 Register Specifications

8.4.1 List of Registers

Table 8.1 List of Registers

Reset Source Determination

Address	Register Name	Description	Access Width	Value after Reset	Access Protection
FFF8 2800 _H	RESF	Reset source determination register	32	0000 0000 _H	
FFF8 2808 _H	RESFC	Reset source clear register	32	0000 0000 _H	

Power-On Detection

Address	Register Name	Description	Access Width	Value after Reset	Access Protection
FFF8 AC10 _H	POF	Power-on clear flag register	32	0000 000X _H	
FFF8 AC14 _H	POFC	Power-on clear flag clear register	32	0000 0000 _H	

Software Reset Control

Address	Register Name	Description	Access Width	Value after Reset	Access Protection
FFF8 AC18 _H	SWRESA	Software Reset Request Register	32	0000 0000 _H	PROT1PHCMD

8.4.2 RESF — Reset Source Determination Register

This register determines the reset source.

The flags of this register can be cleared by the RESFC register and can be initialized by an external reset.

The register is initialized only by an external reset. It cannot be initialized by an internal reset.

Access: This register can be read in 32-bit units.

Address: FFF8 2800_H

Value after reset: 0000 0000_H

0	RESF0	Software reset Indicates that a reset event occurred. 0: Event not occurred 1: Event occurred

8.4.3 RESFC — Reset Source Clear Register

This register clears the reset source indicated by the RESF register.

This register is always read as 00_H and can be initialized by an external reset.

The register is initialized only by an external reset. It cannot be initialized by an internal reset.

Access: This register can be read/written in 32-bit units.

Address: FFF8 2808_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

1	RESFC1	ECM reset Clears the status bit. 0: Do not clear 1: Clear
0	RESFC0	Software reset Clears the status bit. 0: Do not clear 1: Clear

8.4.4 POF — Power-On Clear Flag Register

This register determines whether SYSVCC detects the transition of the power from off to on. The POF flag becomes 1 (cold start) when SYSVCC detects the transition of the power from off to on.

Note that this register does not change even when “0” or “1” is written.

This register becomes 0 when 0 or 1 is written to the POFC bit of the POFC register.

The POF flag does not change even when other reset sources occur while the POF flag has been set to 0 (warm start can be determined).

Access: This register can be read/written in 32-bit units.

Address: FFF8 AC10_H

Value after reset: 0000 000X_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	POF	Cold start event detection Indicates that a cold start event occurred. 0: Not occurred 1: Occurred

8.4.5 POFC — Power-On Clear Flag Clear Register

This register clears the POF register. This register can be reset by either an internal or external reset.

Access: This register can be read/written in 32-bit units.

Address: FFF8 AC14_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are read as 0. The write value should always be 0.
0	POFC	The POF bit in the POF register is cleared to 0 when 0 or 1 is written to the POFC bit in the POFC register.

8.4.6 SWRESA — Software Reset Request Register

This register generates an internal reset when accessed. A software reset is issued when 1 is written to SWRESA. This register can be protected by the PROT1PHCMD register. This register can be reset by either an internal or external reset.

Access: This register can be read/written in 32-bit units.

Address: FFF8 AC18_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 8.6 SWRESA Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are read as 0. The write value should always be 0.
0	SWRESA	0: — (default) 1: Internal reset enabled (internal reset triggered)

Example) Sequence of writing to register SWRESA

Writing to register SWRESA is only possible with the protection unlock sequence described in Section 11, Clock Controller.

Procedure

1. Write the fixed value (0000 00A5_H) to register PROT1PHCMD.
2. Write the setting value (0000 0001_H) to register SWRESA.
3. Write the inverse (FFFF FFFE_H) to register SWRESA.
4. Write the new setting value (0000 0001_H) to register SWRESA.

The setting value (0000 0001_H) can only be written to register SWRESA by following the procedure above.

Protection is not unlocked if the procedure is not followed correctly, the setting value (0000 0001_H) is not written to register SWRESA, and the PROT1PS.PROTERR bit is set to 1.

In case of failure to follow the sequence, repeat the procedure from the beginning.

In case of writing to another register during steps 1 to 4 of the sequence, the protection function operates as follows. Operation is also as described when any interrupt is accepted during the sequence and the interrupt handling includes access to another register.

- When the writing is to another register in the same module*¹, writing to the protected register fails and the PROT1PS.PROTERR bit is set to 1.

- When writing is to a register in another module, writing to the protected register will successfully proceed to completion, if the remainder of the procedure is followed correctly.

Reading of another register while the sequence is in progress does not lead to failure.

Note 1. For the target register, refer to Section 11.4.10, PROT1PHCMD — Protect 1 Command Register.

8.5 Software Reset

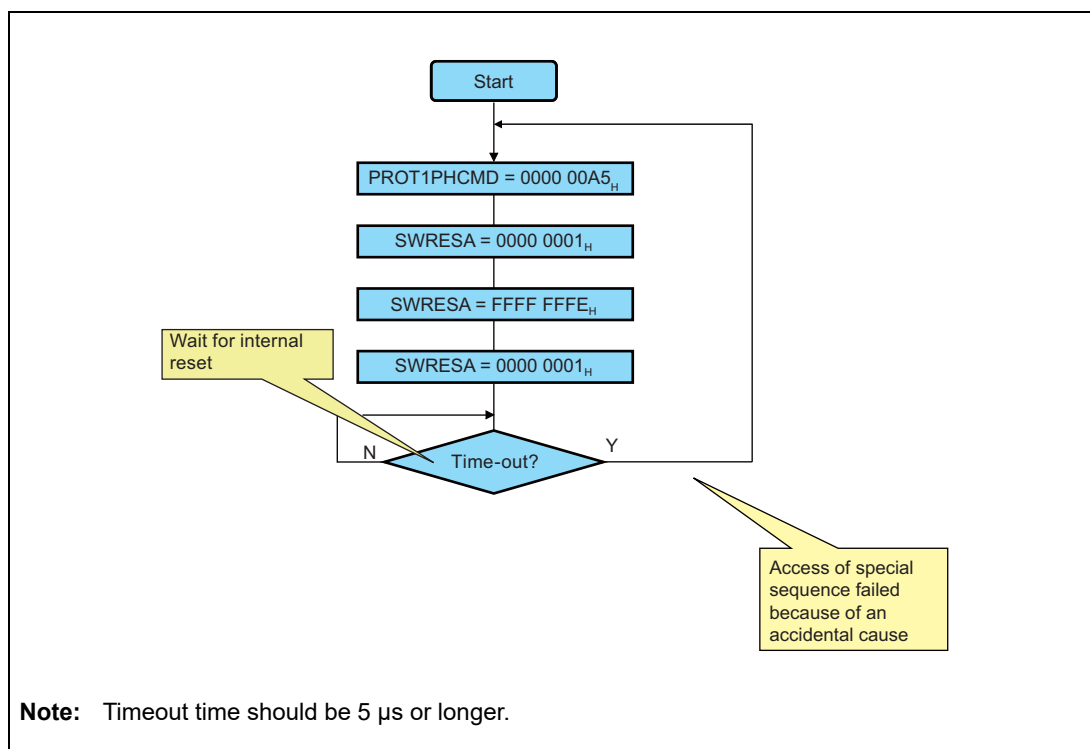

Figure 8.2 Flow of Software Reset

8.6 RAM Retention

The values of RAM in retention area are not destroyed by reset.

8.7 Usage Notes

The debug function includes a reset masking function. To prevent unexpected operations of this function, fix the $\overline{\text{TRST}}$ pin to the low level when the debug function is not used.

Section 9 Power Supply Circuit

9.1 Features

- External Pass Transistor (EPT) method

With EPT	Without EPT
Operable with 2-output power management IC (5 V, 3.3 V)	Operable with 3-output power management IC (5 V, 3.3 V, 1.25 V)

- System power supply pins (SYSVCC)
In the standby state, SYSVCC supplies power to the system logic and retention RAM.

Power Supply Name for Power Supply Pin	Pin Name	Power Supply Voltage in Operation	Uses of Power Supply
SYSVCC	—	3.0 V to 3.6 V	Power for system logic and retained RAM
VCC	—	3.0 V to 3.6 V	Power for oscillator, EPT, and flash programming
PLLVCC	—	3.0 V to 3.6 V	PLL
VDD	—	1.15 V to 1.35 V	Core power (direct power supply) and stabilizing capacity for core power
EVCC	—	4.5 V to 5.5 V	Port (5 V)
LVDVCC	—	3.0 V to 3.6 V	MSC (VccLVDS)
TTLVCC	—	3.0 V to 3.6 V/4.5 V to 5.5 V	MSC (VccTTL), Port (5V, 3.3V)
A0VCC/A1VCC	—	4.5 V to 5.5 V	Power for SAR AD
—	A0VREFH/ A1VREFH	4.5 V to 5.5 V	Reference voltage for SAR AD
ADSVCC	—	4.5 V to 5.5 V	Power for $\Delta\Sigma$ AD
—	ADSVREFH	4.5 V to 5.5 V	Reference voltage for power for $\Delta\Sigma$ AD
—	EPTVOUT	—	EPT control for VDD Note: The voltage is not externally applied.
—	RAMVCL	—	Stabilizing capacity for retained RAM
—	ADSVCL	—	Stabilizing capacity for power for $\Delta\Sigma$ AD

9.2 Example of Connection of Power Management IC

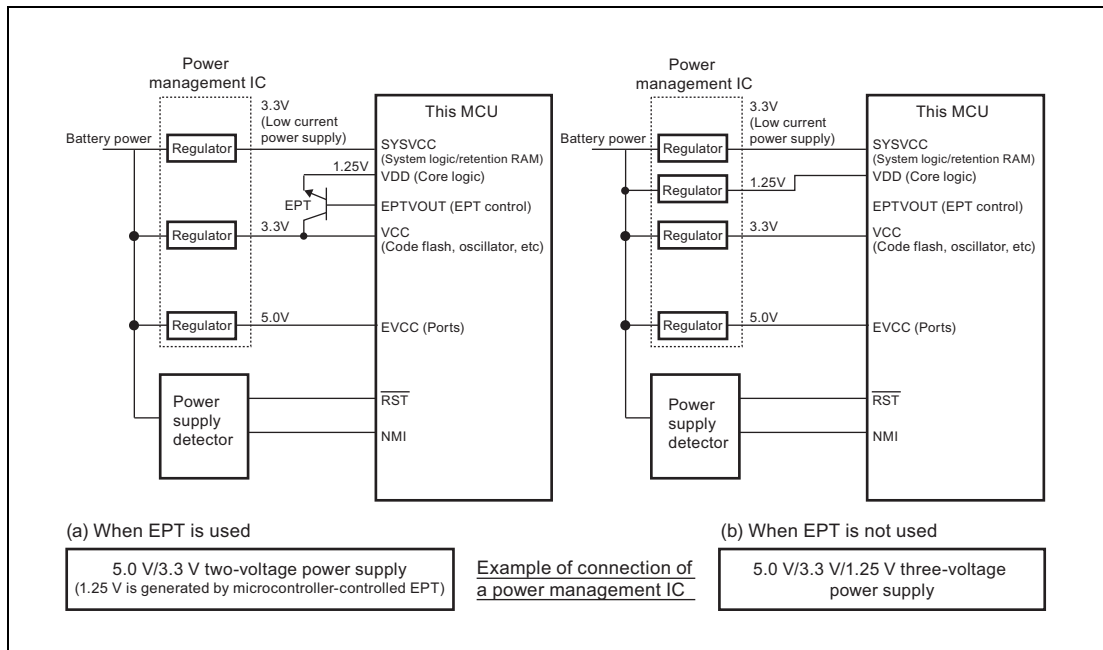

Figure 9.1 Power: Examples of Connection of a Power Management IC

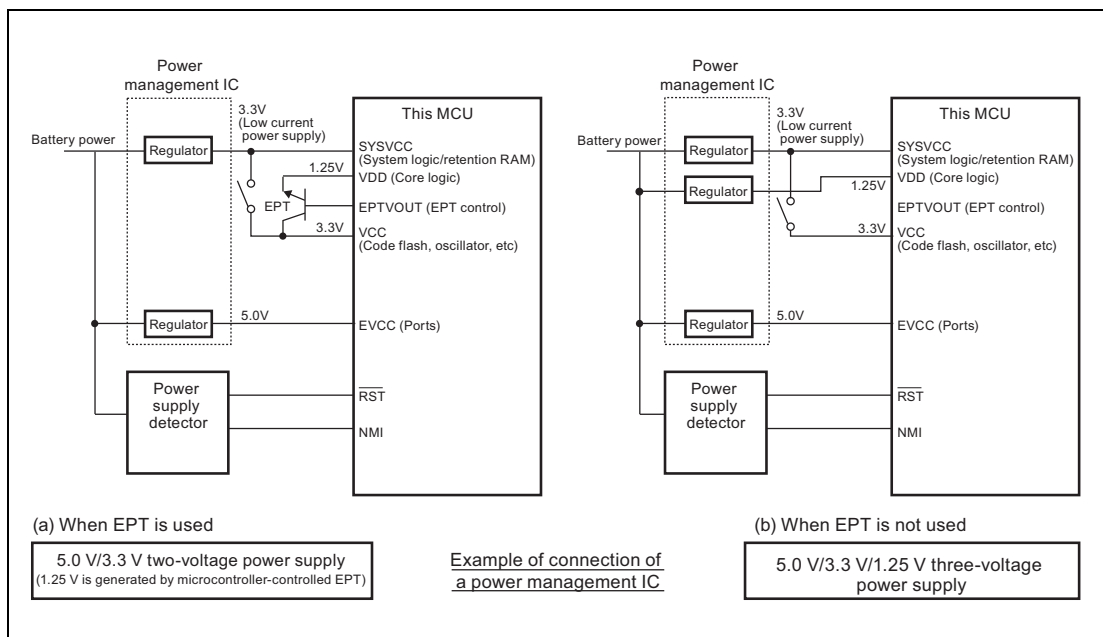

Figure 9.2 Power: Examples of Connection of a Power Management IC, Switched Off

9.3 Power-on Sequence

For details, see **Section 40, Electrical Characteristics**.

9.4 Usage Notes

Handling of power supply pins are described in this section. For handling of unused pins, see **Section 2.5.4, Handling of Unused Pins**.

Power Supply Name for Power Supply Pin	Pin Name	Required Setting	Recommended Handling
SYSVCC		Decoupling capacity: 0.1 μ F \pm 30%	
VCC		Stabilizing capacity for power: 10 μ F \pm 30% or higher	Decoupling capacitor for each pin
PLLVCC			Shared with VCC Decoupling capacitor for each pin
VDD			Same as Guide to Mounting on Boards with an EPT in the following section
EVCC			Connect an external capacitor to suit the conditions of usage.
LVDVCC			Connect an external capacitor to suit the conditions of usage.
TTLVCC			Connect an external capacitor to suit the conditions of usage.
A0VCC/ A1VCC			See the application note separately issued.
	A0VREFH /A1VREFH		See the application note separately issued.
ADSVCC			See the application note separately issued.
	ADSVREFH		See the application note separately issued.
	EPTVOUT	See Section 2.5.4, Handling of Unused Pins when EPT is not used. See Section 9.5, Guide to Mounting on Boards with an EPT when EPT is used.	
	RAMVCL	Stabilizing capacity for power: 0.22 μ F \pm 30%	
	ADSVCL		See the application note separately issued.

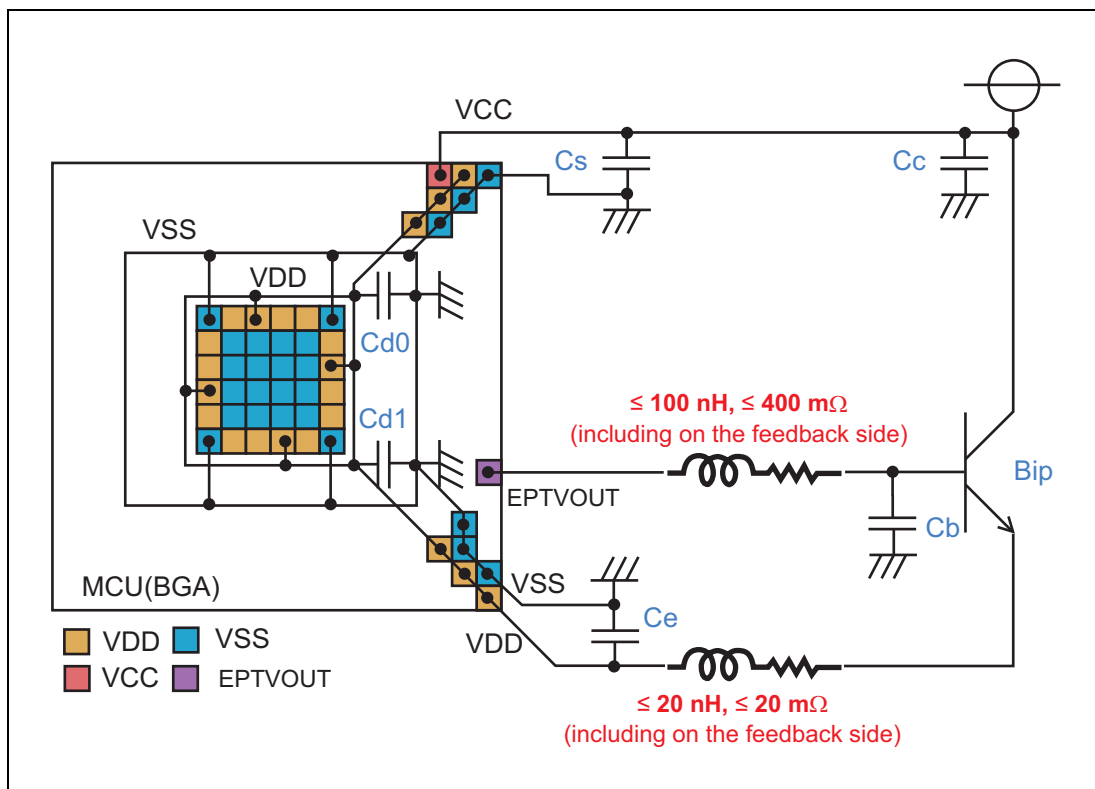

9.5 Guide to Mounting on Boards with an EPT

Comply with the guidelines below in mounting to obtain a VDD within the specified range if you are using a 2SD1899 npn bipolar transistor from Renesas as an EPT to handle the VDD power supply.

However, the guidelines specifically apply when the EPT is that stated above. Using a different transistor will require separate detailed consideration.

9.5.1 BGA

Placement of bypass capacitors: $2 \times 2.2 \mu\text{F}$ (1608) if directly below the package and chip; $4.7 \mu\text{F}$ (2012) if drawn out externally to the package

Symbol	Spec	Notes
Bip	—	NPN Bip., DC Gain 100 to 400 2SD1899 Renesas
Cc	$\geq 5 \mu\text{F}$	—
Cb	$1 \mu\text{F} \pm 30\%$	Capacitance tolerance: $\pm 10\%$, Temperature characteristics: X7R, X8R, ESR: $< 50 \text{ m}\Omega$

Symbol	Spec	Notes
Ce	4.7 μ F \pm 30%	Capacitance tolerance: \pm 10%, Temperature characteristics: X7R, X8R, ESR: < 50 m Ω Dimensions: 2012 * Arranged close to the package
Cdn (n: 0,1)	2.2 μ F \pm 30% x2	Capacitance tolerance: \pm 10%, Temperature characteristics: X7R, X8R, ESR: < 50 m Ω Dimensions: 1608 * Two arranged directly below the package/chip
Cs	\geq 0.6 μ F	ESR: < 50 m Ω * Connected just proximal to the place between the VCC and VSS pins. If there is more than one VCC pin, the value in the left is the total capacity of these pins.

CAUTIONS

1. Values for the parasitic L and R components produced by connection of VSS are based on the assumption that VSS is supplied through a plane of the board (with copper thickness of 35 μ m and pitch of at least 1 mm for both VSS and VDD).
2. We recommend also forming the pattern for VDD as a plane. If this is impossible, make the wiring patterns as broad as is possible.

9.5.2 Reference Information

Rough values of the parasitic L and R components for printed circuit boards are listed below.

Width of wiring runs (mm)	Inductance (nH/m)	Resistance (m Ω /m)
0.7	621	1210
1	555	913
2	432	571
4	263	257
6	200	183

CAUTION

The values are based on the assumption that VSS is supplied through a plane of the board (with copper thickness of 35 μ m and pitch of at least 1 mm for both VSS and VDD).

Section 10 Power Supply Voltage Monitor

10.1 Features

- The power supply voltage monitor is used for monitoring the VDD electric potential supplied to the core logic.
- The power supply voltage monitor has H- and L-side voltage detectors, which detect if the VDD is more or less than the specified voltage.
- Writing to the registers which select run or stop of the power supply voltage monitor function should be made in a specific sequence so that they cannot be incorrectly rewritten because of program malfunction and the like.
- If the power supply voltage monitor detects an error, it gives the error notice to external devices outside of LSI.

10.2 Configuration

Figure 10.1 shows the block diagram of the power supply voltage monitor.

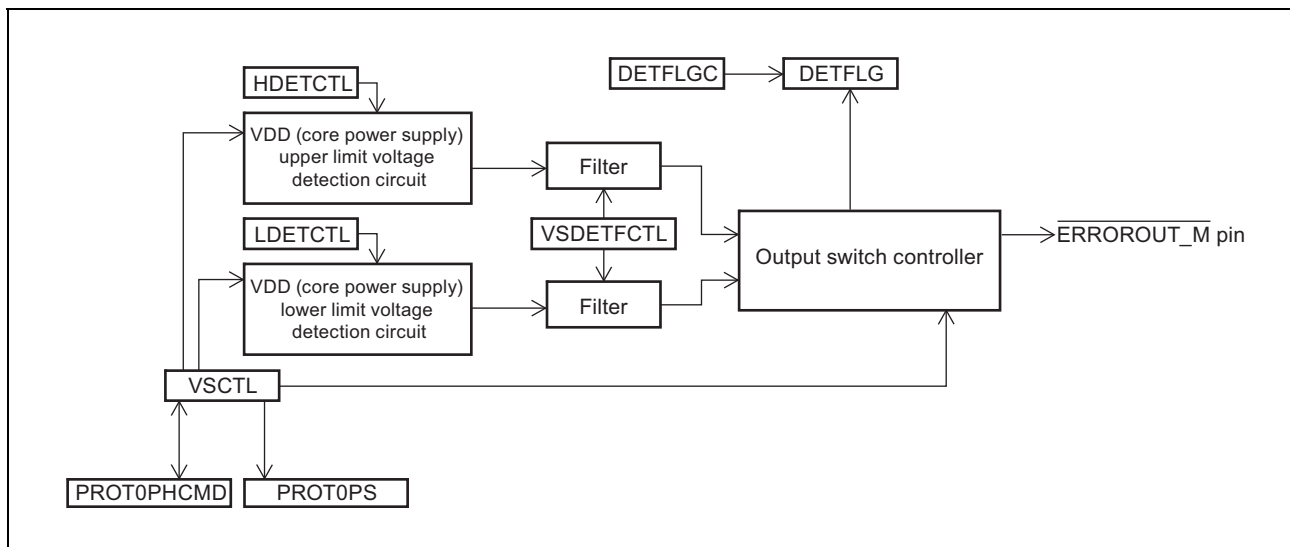

Figure 10.1 Block Diagram of the Power Supply Voltage Monitor

Note 1. See Section 10.3, Register Specifications for the registers shown in the diagram above.

10.3 Register Specifications

Table 10.1 shows the specifications of registers.

Table 10.1 Register Specifications

Register Name	Abbreviation	R/W	Value After Reset	Address	Access Size	Access Protection
CVM detection flag register	DETF LG	R	0000 0000 _H	FFF8 2820 _H	32

Detection signal filter control register	VSDETFCTL	R/W	0000 0000 _H	FFF8 2C1C _H	32	

10.3.1 DETFLG — CVM Detection Flag Register

This register indicates the detection state of upper/lower limit voltage. This register can only be reset by an external reset signal. This register also can be reset by the DETFLGC register.

Access: This register can be read in 32-bit units.

Address: FFF8 2820_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0	HDETF LGC	Upper Limit Voltage Detection Flag Clear 0: Upper limit voltage detection flag is not cleared. 1: Upper limit voltage detection flag is cleared.

10.3.3 VSCTL — CVM Control Register

This register enables or disables the CVM. This register is protected by the PROT0PHCMD register.

See the description of the PROT0PHCMD register for the details.

This register can only be reset by an external reset signal.

Access: This register can be read/written in 32-bit units.

Address: FFF8 2C10_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 10.4 VSCTL Register Contents

Bit Position	Bit Name	Function
31 to 3	—	Reserved These bits are read as 0. The write value should always be 0.
2	EOUTEN	0: Error output is masked. 1: Error output is not masked.
1	VSHEN	0: Upper limit voltage detection is disabled. 1: Upper limit voltage detection is enabled.
0	VSLEN	0: Lower limit voltage detection is disabled. 1: Lower limit voltage detection is enabled.

It takes 200 μ s to start CVM operation after the VSHEN or VSLEN bit is enabled.

10.3.4 HDETCTL — Upper Limit Voltage Setting Register

This register controls the detection level of upper limit voltage. This register can only be reset by an external reset signal.

Access: This register can be read/written in 32-bit units.

Address: FFF8 2C14_H

Value after reset: 0000 0003_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

VDDREFH1	VDDREFH0	Upper limit voltage detection level
0	0	1.50 V

Setting other than the above is prohibited.

10.3.5 LDETCTL — Lower Limit Voltage Register

This register controls the detection level of lower limit voltage. This register can only be reset by an external reset signal.

Access: This register can be read/written in 32-bit units.

Address: FFF8 2C18_H

Value after reset: 0000 0003_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 10.7 VSDEFCTL Register Contents

Bit Position	Bit Name	Function															
31 to 2	—	Reserved These bits are read as 0. The write value should always be 0.															
1, 0	DETF[1:0]	Digital Noise Filter Width Setting															
<table border="1"> <thead> <tr> <th>DETF1</th> <th>DETF0</th> <th>Digital noise filter width</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Bypass the filter.</td> </tr> <tr> <td>0</td> <td>1</td> <td>Filtering cycle: 16 clk</td> </tr> <tr> <td>1</td> <td>0</td> <td>Filtering cycle: 32 clk</td> </tr> <tr> <td>1</td> <td>1</td> <td>Filtering cycle: 64 clk</td> </tr> </tbody> </table>			DETF1	DETF0	Digital noise filter width	0	0	Bypass the filter.	0	1	Filtering cycle: 16 clk	1	0	Filtering cycle: 32 clk	1	1	Filtering cycle: 64 clk
DETF1	DETF0	Digital noise filter width															
0	0	Bypass the filter.															
0	1	Filtering cycle: 16 clk															
1	0	Filtering cycle: 32 clk															
1	1	Filtering cycle: 64 clk															
The sampling clock of the digital noise filter is ROSC (240 KHz).																	

10.4 Usage

The operation flow from CVM detection condition setting to actual detection is as follows:

1. Set the voltage conditions for H- and L-side voltage detection in the upper and lower voltage limit setting registers (HDETCTL and LDETCTL), respectively. Also set the voltage detection noise filter width in the detection signal filter control register, and complete to set all CVM-related registers. The CVM's H- and L-side enable bits (VSHEN and VSLEN) of the CVM control register (VSCTL) and the error notice to external devices outside of LSI (EOUTEN) are then specified to start operation.
2. When VDD exceeds the specified upper limit voltage, an error signal is output to external devices outside of LSI according to the settings of the EOUTEN bit in the VSCTL register and the upper limit voltage detection flag (the HDETFLG bit in the DETFLG register) is set. When VDD falls below the specified lower limit voltage, an error signal is output to external devices outside of LSI according to the settings of the EOUTEN bit in the VSCTL register and the lower limit voltage detection flag (the LDETFLG bit in the DETFLG register) is set.
3. Check the upper and lower limit voltage detection flags after H- and L-side voltage detection to verify the details of the corresponding detection.

The $\overline{\text{ERROROUT_M}}$ pin (master) of the error control module (ECM) is also used in common for the CVM error output pin.

When output from the $\overline{\text{ERROROUT_M}}$ pin is used in CVM, make related settings under the following procedures.

Figure 10.2 Flowchart

10.5 Notes on Usage

- The power supply voltage monitor operates only after release from the external reset state. The power supply voltage monitor operation is stopped during the external reset state, and various registers are initialized.
- The setting registers and flag registers are only initialized by an external reset. They cannot be initialized by an internal reset requested by the CPU or ECM.

Section 11 Clock Controller

11.1 Features

- An oscillation circuit is included (Main OSC).
- Oscillation at 20 MHz is possible without using external capacitors (only with limited resonators).
- A 20-MHz clock can be input from the EXTAL pin.
A 20-MHz external clock can be directly input from the EXTAL pin, separately from the main OSC.

CAUTION

XTAL should be an open circuit when an external clock signal is being directly input.

- On-chip PLLs are included and can be used to divide clock frequencies.
- PLL0 is capable of operating as a spread spectrum clock generator (SSCG) for reducing radiated noise.
The clock signal produced by PLL1 is not frequency modulated (i.e. is a clean clock signal) and so is suitable for use with timers and communications modules.
- The ring oscillator circuits (ROSC) is included.
- Interrupts can be generated when the Main OSC goes outside the frequency range specified by the clock monitor. For how to use the clock monitor, see **Section 30, Safety**.
- The clock frequencies can be increased stepwise by software for suppressing inrush currents after release from the reset state.
Set the division ratios (1/4, 1/2, and 1/1) for the CPU clock and the peripheral clocks, and follow the clock gear up sequence.*1
- A frequency divided clock set by a 1-MHz clock and a baud rate generator (BRG) can be output from the CK pin.

Note 1. In this product, set the division ratio of the divider 0A/1A to 1/1 (No division) after executing the clock gear up sequence.

11.2 Type of Clocks

Table 11.1 shows the list of clocks, **Table 11.2** shows the operation clocks of each functional module, and **Figure 11.1** shows the block diagram of clocks.

Table 11.1 List of Clocks

When operating at 20 MHz input frequency (Main OSC)

Clock Name	Symbol	Clock Frequency* ³			Remarks
		Division Ratio of Divider 0A/ Divider 1A			
		1/1	1/2	1/4	
CPU clock	CLK_CPU	320 MHz* ¹ 240 MHz* ²	160 MHz* ¹ 120 MHz* ²	80 MHz* ¹ 60 MHz* ²	PLL0 (SSCG can be selected)
High speed peripheral clock	CLK_HSB	80 MHz	40 MHz	20 MHz	
Low speed peripheral clock (peripheral clock)	CLK_LSB	40 MHz	20 MHz	10 MHz	
Unmodulated high speed peripheral clock	CLKC_HSB	80 MHz	40 MHz	20 MHz	PLL1 (SSCG cannot be selected)
Unmodulated low speed peripheral clock	CLKC_LSB	40 MHz	20 MHz	10 MHz	
Low speed ROSC clock	CLK_ROSCL		240 KHz		
ASIC clock (1 MHz clock)	CLKA_ASIC		1MHz		1/20 x Main OSC
WDTA counter clock	WDTACLKI		250 KHz		1/80 x Main OSC

Note 1. For the products with 320 MHz (max.) CPUs

Note 2. For the products with 240 MHz (max.) CPUs

Note 3. In this product, set the division ratio of the divider 0A/1A to 1/1 (No division) after executing the clock gear up sequence.

Table 11.2 Clocks and Functional Modules

Clock Name	Functional Module Name
CPU clock	CPU
High speed peripheral clock	PCU, INTC, DMAC, DTS, CSIH, DFE, FlexRay, ICUS
Low speed peripheral clock (peripheral clock)	ECM, CRC, PORT
Unmodulated high speed peripheral clock	RHSB, ΔΣAD, TSG2, TAPA, PIC
Unmodulated low speed peripheral clock	CAN, LIN, ATU-IV, APA, WDTA* ¹ , OSTM, SCI, AD, RSENT, SWDTA* ¹
Low speed ROSC clock	CLM
WDTA counter clock	WDTA* ¹ , SWDTA* ¹

Note 1. The PCLK of the WDTA or SWDTA (the clock on the P-Bus) is the unmodulated low-speed peripheral clock and the operating clock of the WDTA or SWDTA is the WDTA counter clock.

The PCLK mentioned in the section of each function module means the clock frequency listed in the 1/1 division ratio in **Table 11.1**, which corresponds to the clock name listed in **Table 11.2**.

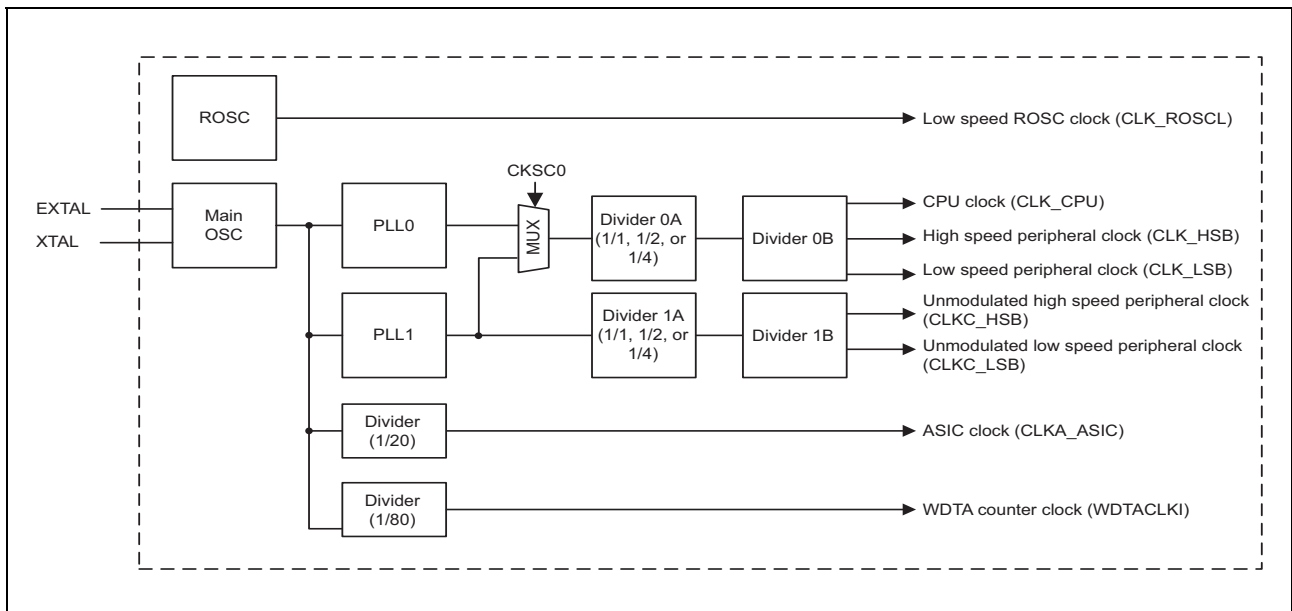

Figure 11.1 Block Diagram of Clock Controller

11.3 Input/Output Pins

Table 11.3 shows the pins related to the clock controller.

Table 11.3 Pins Related to the Clock Controller

Name	Pin Name	Input/Output	Function
External clock	EXTAL	Input	Input of a crystal resonator or external clock
Crystal	XTAL	Output	Connected to a crystal resonator
Clock output	CK	Output	1-MHz clock/BRG output
PLL power	PLLVCC	Input	Power supply for the PLL multiply circuit
PLL ground	PLLVSS	Input	Power supply for the PLL multiply circuit

11.3.1 How to Connect a Crystal Resonator

Figure 11.2 shows how to connect a crystal resonator. When the resonator recommended by the Company is used (the detail information is separately provided), any external component such as a load capacitor and a dumping resistor is not necessarily required for oscillation in general. However, proper operation should be verified under actual conditions prior to use.

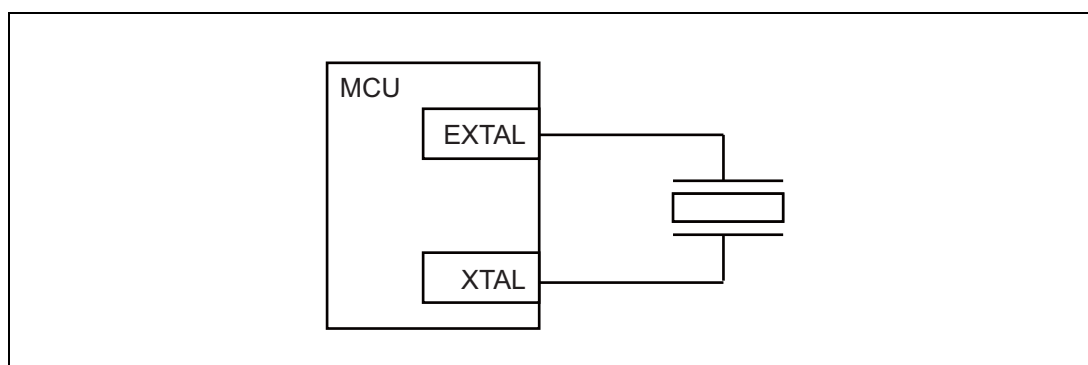

Figure 11.2 Connection Example of Crystal Resonator 1

11.4 Register Specification

11.4.1 List of Registers

Table 11.4 shows the list of registers.

Table 11.4 Registers Related to the Clock Controller

Register Name (abbreviation)	R/W	Value after Reset	Address	Access Size	Access Protection
PLL0 status register (PLL0CLKS)	R	0000 0001 _H	FFF8 8004 _H	32	
PLL0 control register 1 (PLL0CLKC1)	R/W	0000 0000 _H	FFF8 8200 _H	32	PROT1PHCMD
Clock 0 selection control register (CKSC0CTL)	R/W	0000 0020 _H	FFF8 9000 _H	32	PROT1PHCMD
Clock 0 selection active register (CKSC0ACT)	R	0000 0020 _H	FFF8 9008 _H	32	
Clock 0 division register (CLKD0DIV)	R/W	0000 0004 _H	FFF8 8800 _H	32	PROT1PHCMD
Clock 0 division status register (CLKD0STAT)	R	0000 0001 _H	FFF8 8804 _H	32	
Clock 1 selection control register (CKSC1CTL)	R/W	0000 0021 _H	FFF8 9040 _H	32	PROT1PHCMD
Clock 1 selection active register (CKSC1ACT)	R	0000 0021 _H	FFF8 9048 _H	32	
Protect 1 command register (PROT1PHCMD)	R/W	0000 0000 _H	FFF8 B000 _H	32	
Protect 1 status register (PROT1PS)	R	0000 0000 _H	FFF8 B004 _H	32	

11.4.2 PLL0CLKS — PLL0 Status Register

This register indicates the state of the PLL0 clock effective, active, or stable.

This register is initialized by either an internal or external reset.

Access: This register can be read in 32-bit units.

Address: FFF8 8004_H

Value after reset: 0000 0001_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	—	—	—	—	—	CLK ACT	CLK STAB	CLKEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0 ^{*1}	0 ^{*1}	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note 1. Depends of the read timing after the CPU starts operation.

Table 11.5 PLL0CLKS Register Contents

Bit Position	Bit Name	Function
31 to 3	—	Reserved These bits are always read as 0.
2	CLKACT	PLL0 Clock Source State 0: PLL0 clock source is inactive. 1: PLL0 clock source is active.
1	CLKSTAB	PLL0 Clock Stable State 0: PLL0 is unstable. 1: PLL0 is stable.
0	CLKEN	PLL0 Clock Operating State 0: PLL0 is stopped. 1: PLL0 is operating.

11.4.3 PLL0CLKC1 — PLL0 Control Register 1

This register controls the operation of the spread spectrum clock generator (SSCG) for PLL0.

This register can be set when PLL0 is running.

This register is protected by the PROT1PHCMD register.

This register is initialized by either an internal or external reset.

Access: This register can be read/written in 32-bit units.

Address: FFF8 8200_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 11.6 PLL0CLKC1 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 10	—	Reserved These bits are always read as 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
9	SSMODE1	SSCG Control 0: Modulation disabled 1: Modulation enabled
8	—	Reserved This bit is always read as 0. When writing to this bit, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
7 to 3	SELMFREQ [4:0]	SSCG Cycle Setting The modulation cycle of SSCG can be selected by setting these bits. Selectable settings are as follows: 1 0 0 0 _B : 80.65 kHz 1 0 0 1 _B : 75.76 kHz 1 0 1 0 _B : 69.44 kHz 1 0 1 1 _B : 65.79 kHz 1 0 1 0 _B : 62.50 kHz 1 0 1 1 _B : 59.52 kHz 1 0 1 1 _B : 58.14 kHz 1 0 1 1 _B : 50.00 kHz 1 1 0 0 _B : 41.67 kHz 1 1 0 0 _B : 39.68 kHz 1 1 0 1 _B : 37.31 kHz 1 1 0 1 _B : 33.33 kHz 1 1 1 0 _B : 30.12 kHz 1 1 1 0 _B : 25.00 kHz 1 1 1 0 _B : 20.00 kHz Do not set any other value while SSMODE1 is set to 1.

Table 11.6 PLL0CLKC1 Register Contents (2/2)

Bit Position	Bit Name	Function
2 to 0	SELMPERCENT [2:0]	SSCG Modulation Range Setting The modulation range of SSCG can be selected by setting these bits. Selectable settings are as follows: 1 0 0 _B : -5.0% Do not set any other value while SSMODE1 is set to 1.

When changing the modulation depth of PLL0, turn off the SSCG and then wait for at least 1.6 ms.

11.4.4 CKSC0CTL — Clock 0 Selection Control Register

This register is used for selection of a clock source for the frequency divider 0A.

This register is protected by the PROT1PHCMD register.

This register is initialized by either an internal or external reset.

Access: This register can be read/written in 32-bit units.

Address: FFF8 9000_H

Value after reset: 0000 0020_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 11.7 CKSC0CTL Register Contents

Bit Position	Bit Name	Function
31 to 6	—	Reserved These bits are always read as 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
5 to 0	CKSC[5:0]	These bits select a clock source for the frequency divider 0A. 100000 _B : Selects the PLL1 clock. 100011 _B : Selects the PLL0 clock. Setting other than the above is prohibited.

11.4.5 CKSC0ACT — Clock 0 Selection Active Register

This register indicates the state of a clock source for the frequency divider 0A.

This register is initialized by either an internal or external reset.

Access: This register can be read in 32-bit units.

Address: FFF8 9008_H

Value after reset: 0000 0020_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 11.8 CKSC0ACT Register Contents

Bit Position	Bit Name	Function
31 to 6	—	Reserved These bits are always read as 0.
5 to 0	CLKACT[5:0]	These bits indicate that switching of a clock source for divider 0A is completed when their values are the same as those specified in the CKSC[5:0] bits in the CKSC0CTL register.

11.4.6 CLKD0DIV — Clock 0 Division Register

This register specifies a frequency division ratio of divider 0A.

This register is protected by the PROT1PHCMD register.

This register is initialized by either an internal or external reset.

Access: This register can be read/written in 32-bit units.

Address: FFF8 8800_H

Value after reset: 0000 0004_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 11.9 CLKD0DIV Register Contents

Bit Position	Bit Name	Function
31 to 3	—	Reserved These bits are always read as 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
2 to 0	CLKD0DIV[2:0]	These bits select a frequency division ratio of divider 0A. 001 _B : No division 010 _B : Divided by 2 100 _B : Divided by 4 Setting other than the above is prohibited.

11.4.7 CLKD0STAT — Clock 0 Division Status Register

This register indicates a clock state of the frequency divider 0A.

This register is initialized by either an internal or external reset.

Access: This register can be read in 32-bit units.

Address: FFF8 8804_H

Value after reset: 0000 0001_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 11.10 CLKD0STAT Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0.
0	CLKD0SYNC	Divider Synchronization Status 0: Divider 0A is switching to the division ratio specified in CLKD0DIV. 1: Divider 0A is running at the division ratio specified in CLKD0DIV.

11.4.8 CKSC1CTL — Clock 1 Selection Control Register

This register is used for selection of an output clock for the frequency divider 1A.

This register is protected by the PROT1PHCMD register.

This register is initialized by either an internal or external reset.

Access: This register can be read/written in 32-bit units.

Address: FFF8 9040_H

Value after reset: 0000 0021_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 11.11 CKSC1CTL Register Contents

Bit Position	Bit Name	Function
31 to 6	—	Reserved These bits are always read as 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
5 to 0	CKSC[5:0]	These bits select an output clock for the frequency divider 1A. 100001 _B : Selects 1/4 clock of PLL1. 100010 _B : Selects 1/2 clock of PLL1. 100100 _B : Selects 1/1 clock of PLL1. Setting other than the above is prohibited.

11.4.9 CKSC1ACT — Clock 1 Selection Active Register

This register indicates a clock state of the frequency divider 1A.

This register is initialized by either an internal or external reset.

Access: This register can be read in 32-bit units.

Address: FFF8 9048_H

Value after reset: 0000 0021_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 6	—	Reserved These bits are always read as 0.
5 to 0	CLKACT[5:0]	These bits indicate that switching of an output clock for the frequency divider 1A is completed when their values are the same as those specified in the CKSC[5:0] bits in the CKSC1CTL register. 100001 _B : 1/4 of PLL1 100010 _B : 1/2 of PLL1 100100 _B : 1/1 of PLL1

11.4.10 PROT1PHCMD — Protect 1 Command Register

PROT1PHCMD is a protection command register to start the protection unlocking sequence necessary for access to write-protected registers.

This register is initialized by either an internal or external reset.

Access: This register can be read/written in 32-bit units.

Address: FFF8 B000_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 11.13 PROT1PHCMD Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are always read as 0.
7 to 0	PCMD[7:0]	Write protection command register

This register is used in protecting against inadvertent access to write-protected registers, i.e. registers to which writing raises the possibility of serious effects on application systems, such as programs crashing and the like.

Writing to the write-protected registers is only possible with the protection unlock sequence described below.

1. Write the fixed value (0000 00A5_H) to register PROT1PHCMD.
2. Write the new setting to the write-protected register. Write the value after a reset to the reserved bits.
3. Write the bitwise inverse of the setting value to the same register as in step 2. Write the inverse of the value after a reset to the reserved bits.
4. Write the new setting to the same register as in step 2. Write the value after a reset to the reserved bits.

A value can only be written to a write-protected register by following the procedure above.

Protection is not unlocked if the procedure is not followed correctly, the setting is not written to the write-protected register, and the PROT1PS.PROTERR bit is set to 1. (Although this is not a requirement, you can confirm if the values set in the targeted register was correctly written by checking that the setting of the PROT1PS.PROTERR bit is 0 after step 4.)

In case of failure to follow the sequence, repeat the procedure from the beginning.

In case of writing to another register during steps 1 to 4 of the sequence, the protection function operates as follows. Operation is also as described when any interrupt is accepted during the sequence and the interrupt handling includes access to another register.

- When the writing is to another register in the same module*¹, writing to the protected register fails and the PROT1PS.PROTERR bit is set to 1.
- When writing is to a register in another module, writing to the protected register will successfully proceed to completion, if the remainder of the procedure is followed correctly.

Reading of another register while the sequence is in progress does not lead to failure.

Note 1. The applicable registers for PROT1PHCMD are those allocated to the address range from FFF88004_H to FFF8B004_H.

For the register names, symbols, and module names, see **Appendix, List of Registers**.

11.4.11 PROT1PS — Protect 1 Status Register

PROT1PS is a status register of the protection unlocking sequence. This register indicates whether an error occurs or not in access to write-protected registers.

This register is initialized by either an internal or external reset.

Access: This register can be read/written in 32-bit units.

Address: FFF8 B004_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PROT ERR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 11.14 PROT1PS Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are always read as 0.
0	PROTERR	Protection Error Flag 0: Protection error does not occur. 1: Protection error occurs.

Operating conditions of the PROTERR bit

[Setting Condition]

Access to a write-protected register without executing the step of the protection unlocking sequence that involves the PROT1PHCMD register

[Clearing Condition]

Writing of 0000 00A5_H to the PROT1PHCMD register (step 1 in the protection unlocking sequence)

11.5 Operation

11.5.1 Operation When the Divide Function Is Used

Follow the procedure given below to reduce current fluctuations produced by switching the clock signals during startup.

1. When a user program is running after release from the reset state, PLL0 or PLL1 will be oscillating and PLL1 will be in use as the internal operating clock. Also, the division ratio of divider 0A is set to 1/4.
Read the PLL0CLKS register and verify that its value is 07_H, indicating that PLL0 operation is stable.
2. Write 23_H to the CKSC[5:0] bits in CKSC0CTL to select PLL0 as the clock source.
3. When switching the clock source, wait at least 105, or 140 cycles of the CPU clock in the respective cases of products with CPUs having maximum operating frequencies of 240 MHz, or 320 MHz. After that, read CKSC0ACT and verify that the value of the CKSC0ACT.CLKACT[5:0] bits is 23_H.
4. Write 010_B to the CLKD0DIV[2:0] bits in CLKD0DIV to select 1/2 as the division ratio for the divider.
5. For switching of the division ratio, wait at least 105, or 140 cycles of the CPU clock in the respective cases of products with CPUs having maximum operating frequencies of 240 MHz, or 320 MHz. Then read CLKD0STAT and verify that the value of the CLKD0SYNC is 1.
6. Write 001_B to the CLKD0DIV[2:0] bits in CLKD0DIV to select 1/1 as the division ratio for the divider.
7. For switching of the division ratio, wait at least 105, or 140 cycles of the CPU clock in the respective cases of products with CPUs having maximum operating frequencies of 240 MHz, or 320 MHz. Then read CLKD0STAT and verify that the value of the CLKD0SYNC is 1.

For switching division ratio of the divider 1A on the PLL1, follow the procedures of 4 to 7 above.

Figure 11.3 shows an example of the procedure for switching the clocks (and shifting the clock gear up for both clocks). **Table 11.15** lists the clock frequencies in each step of the process.

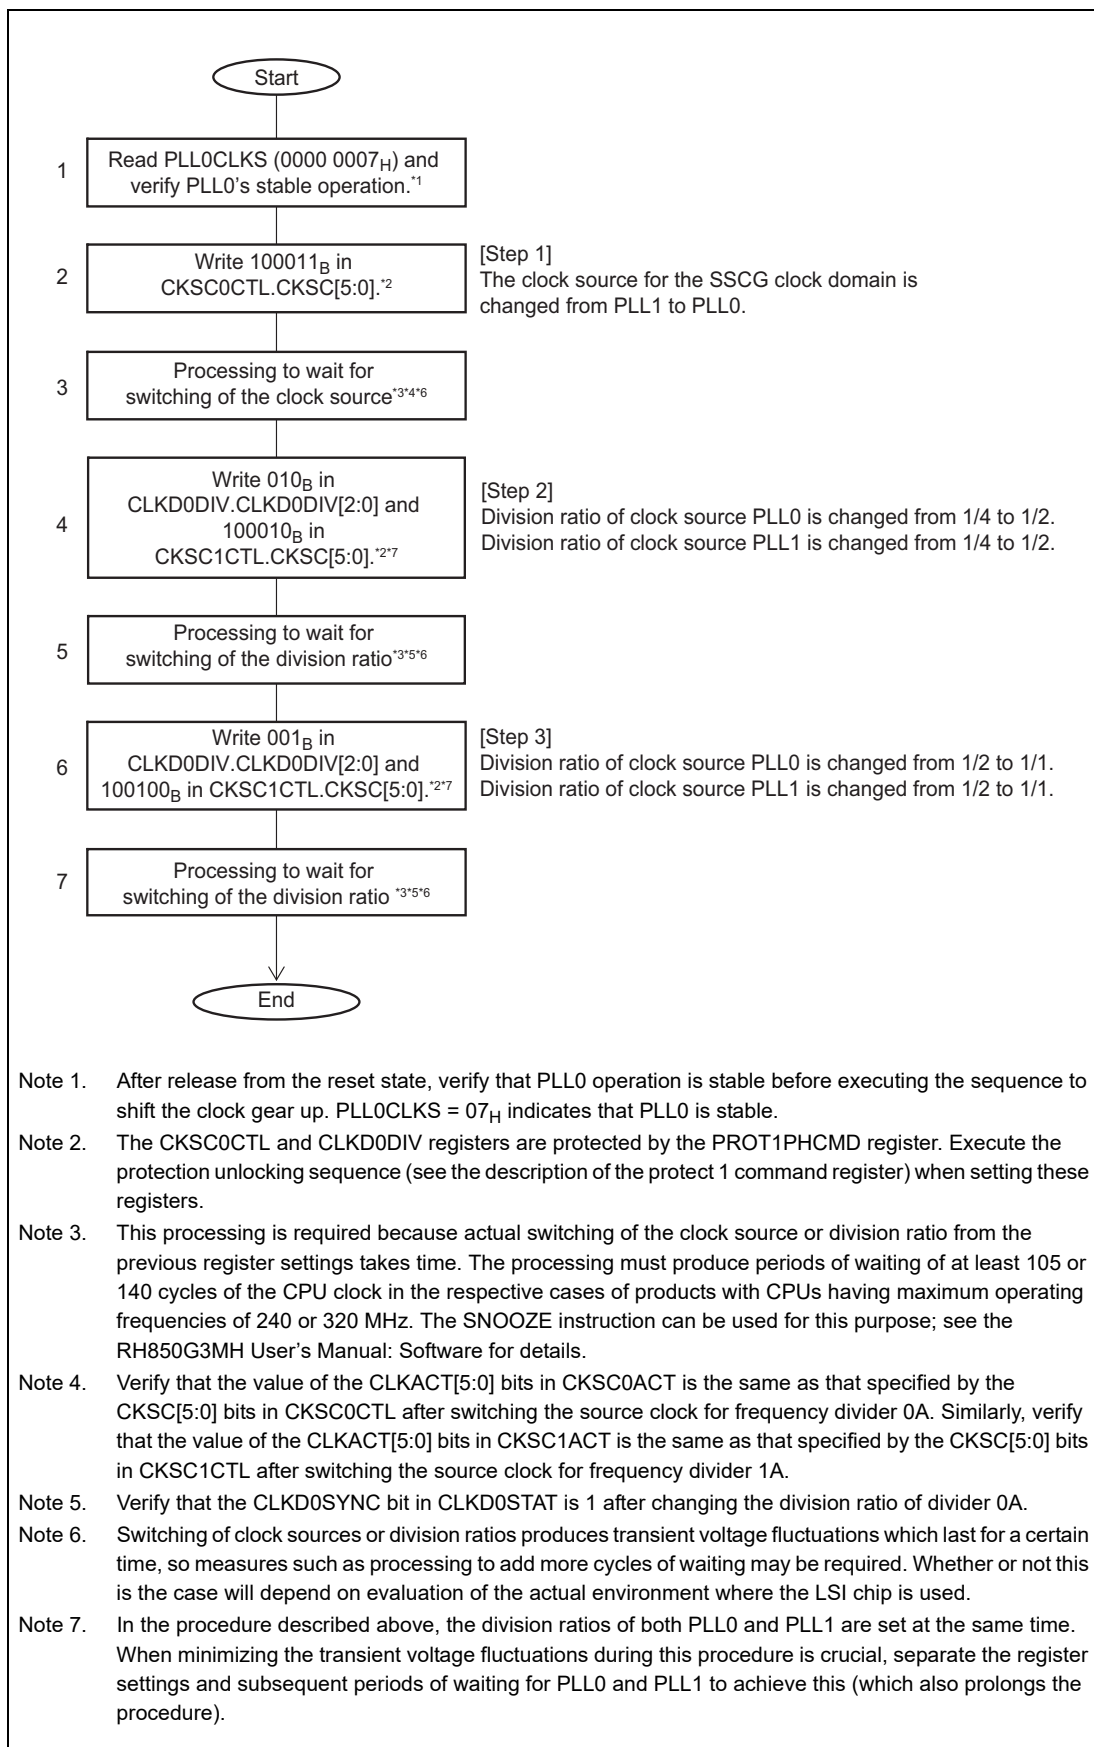

Figure 11.3 Example of Sequence for Shifting the Clock Gear Up

Table 11.15 Frequencies in the Process of Shifting the Clock Gear Up

	CLK_CPU		CLK_HSB	CLK_LSB	CLKC_HSB	CLKC_LSB
	Products with 320-MHz (max.) CPUs	Products with 240-MHz (max.) CPUs				
Before Step 1	80	60	20	10	20	10
Between Step 1 and Step 2	80	60	20	10	20	10
Between Step 2 and Step 3	160	120	40	20	40	20
After Step 3	320	240	80	40	80	40

11.6 Notes

Avoid using commands that employ the computing unit, such as FPU operations, while the division ratio is being changed. Increased current fluctuation may make the operation unstable.

11.6.1 Board Design Notes

As shown in **Figure 11.4**, do not cross any other signal lines over the signal lines to the EXTAL and XTAL pins. Induction may inhibit proper oscillation.

Figure 11.4 Board Design Notes

11.7 ASIC Clock

11.7.1 Features

- ASIC Clock provides a function to select a clock output from the CK pin.
- The frequency-divided clock*² set by the 1-MHz clock*¹ or the baud rate generator (BRG) can be selected through the register settings.
- After release from power-off standby, the 1-MHz clock is output from the CK pin.
- When stop or run of a clock is selected, rewriting to a register should be done in a specific sequence so that the register is not incorrectly rewritten due to program malfunction.

Note 1. 1-MHz clock: 1/20 clock of the 20-MHz main OSC

Note 2. BGR (Baud Rate Generator): 1/N clock of the unmodulated low speed peripheral Configuration

11.7.2

Figure 11.5 shows the diagram of ASIC clock output configuration.

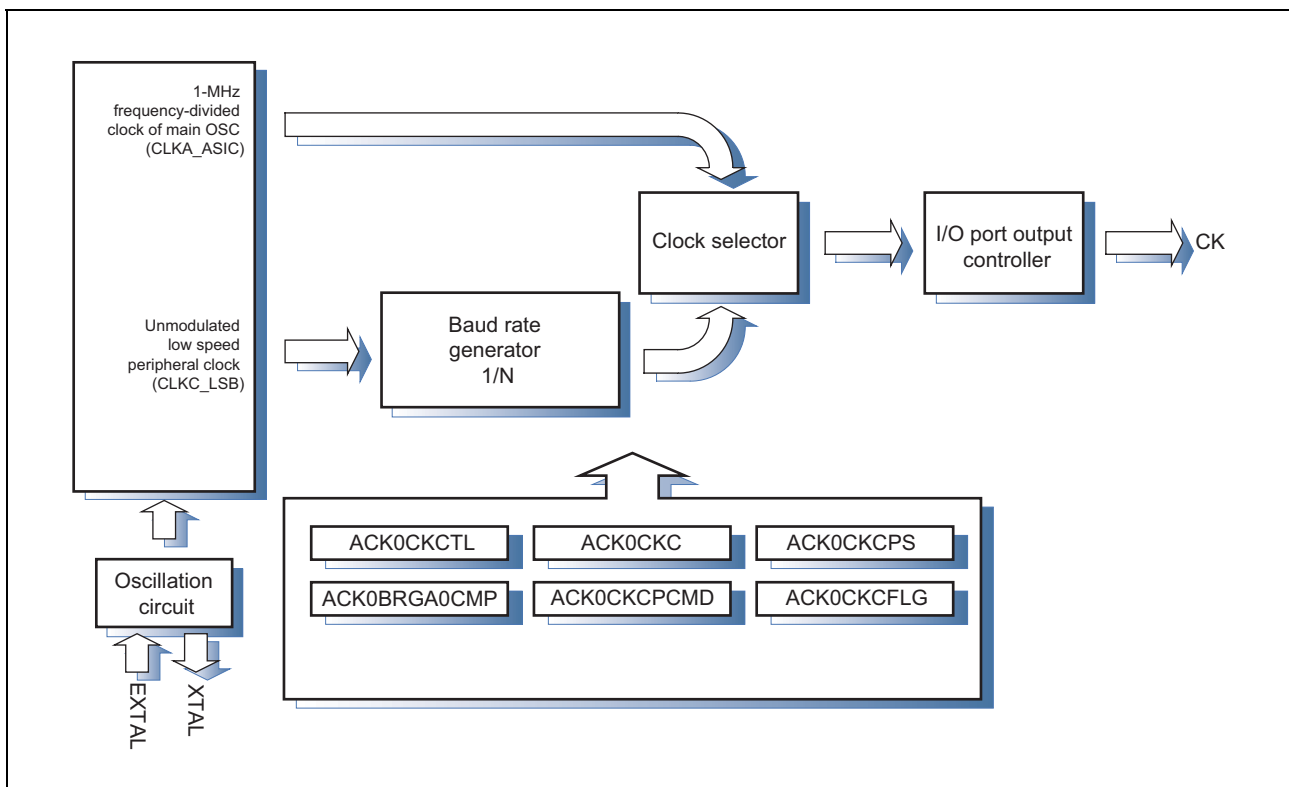

Figure 11.5 Block Diagram of ASIC Clock

11.7.3 Register Specifications

The following shows the specifications of registers.

Table 11.16 Pin Specifications

Register Name	Abbreviation	R/W	Value after Reset	Address	Access Size	Access Protection
Clock control register	ACK0CKC	R/W	01 _H	FFC0 4000 _H	8	ACK0CKCPCMD
CKC flag register	ACK0CKCFLG	R	01 _H	FFC0 4004 _H	8	
Clock select register	ACK0CKCTL	R/W	00 _H	FFC0 4008 _H	8	
BRGA0 compare register	ACK0BRGA0CMP	R/W	00 _H	FFC0 400C _H	8	
CKC protect command register	ACK0CKCPCMD	W	—	FFC0 4100 _H	8	
CKC protect status register	ACK0CKCPS	R	00 _H	FFC0 4104 _H	8	

11.7.3.1 ACK0CKC — Clock Control Register

This is an 8-bit register to control the system clock frequency. Therefore, this register can be only written in combination of specific instruction sequences so that it is not incorrectly rewritten due to program malfunction.

Protection of this register can be canceled by writing to the command register (ACK0CKPCMD).

When a specific register is read out, however, a specific instruction sequence is not required.

Access: This register can be read/written in 8-bit units.

Address: FFC0 4000_H

Value after reset: 01_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	DCLK0
Value after reset	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R/W

Table 11.17 ACK0CKC Register Contents

Bit Position	Bit Name	Description
7 to 1	—	Reserved These bits are always read as 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	DCLK0	Clock Output Control 0: Clock output inhibit mode Output of a clock from the CK pin is prohibited (fixed to low level). Further reduction of power consumption and suppression of radiation noise from the CK pin can be achieved because CK operation is completely stopped. 1: Clock output The clock selected by the ACK0CKCTL is output from the CK pin.

Note 1. Up to three cycles of the clock signal output from the the CK pin (the clock signal selected by ACK0CKCTL) are required to stop clock output to the CK pin after writing 0 to the DCLK0 bit. The clock output stop state can be checked by reading the DCLKF0 bit in the ACK0CKFLG register.

11.7.3.2 ACK0CKFLG — CKC Flag Register

The ACK0CKFLG register indicates the status of clock output control.

Access: This register can be read in 8-bit units.

Address: FFC0 4004_H

Value after reset: 01_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	DCLKF0
Value after reset	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R

Table 11.18 ACK0CKFLG Register Contents

Bit Position	Bit Name	Description
7 to 1	—	Reserved These bits are always read as 0.
0	DCLKF0	This bit indicates the status of clock output control. 0: Output from the CK pin is stopped. 1: The clock selected by the ACK0CKCTL is output from the CK pin.

11.7.3.3 ACK0CKCTL — Clock Select Register

The ACK0CKCTL is an 8-bit register to select a clock output from the CK pin.

This register can be written in 8-bit units when the DCLKF0 bit in the CKC flag register is 0.

The ACK0CKCTL register is always readable also.

For the DCLKF0 bit, see **Section 11.7.3.2, ACK0CKCFLG — CKC Flag Register**.

Access: This register can be read/written in 8-bit units.

Address: FFC0 4008_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	CKSL[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 11.19 ACK0CKCTL Register Contents

Bit Position	Bit Name	Description
7 to 2	—	Reserved These bits are always read as 0. When writing, always write 0.
1, 0	CKSL[1:0]	These bits select a clock output from the CK pin. 00: 1-MHz clock (1/20 clock of the 20-MHz main OSC) 01: BRG (Baud Rate Generator) Setting other than the above is prohibited.

CAUTION

Writing to the ACK0CKCTL register (selection of a clock output to the CK pin) can only be performed when the clock output to the CK pin is stopped (the DCLKF0 bit in the ACK0CKCFLG register is 0).

11.7.3.4 ACK0BRGA0CMP — BRGA0 Compare Register

The ACK0BRGA0CMP is a register to store a value to be compared with the baud rate counter.

Access: This register can be read/written in 8-bit units.

Address: FFC0 400C_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	BRGA0CMP[4:0]				
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Table 11.20 ACK0BRGA0CMP Register Contents

Bit Position	Bit Name	Description
7 to 5	—	Reserved These bits are always read as 0. When writing, always write 0.
4 to 0	BRGA0CMP [4:0]	These bits set a compare value. For the settings, see Table 11.22, Unmodulated Low Speed Peripheral Clock Frequency (value set in the ACK0BRGA0CMP register and frequency to be output).

CAUTION

Writing to the ACK0BRGA0CMP register (selection of a value to be compared with the baud rate counter) can only be performed when the clock output to the CK pin is stopped (the DCLKF0 bit in the CKCFLG register is 0).

11.7.3.5 ACK0CKPCMD — CKC Protect Command Register

The ACK0CKPCMD register is used to protect against any writing operation to a register that might have a material effect on the application systems. This ensures the systems are not incorrectly stopped due to program malfunction.

The value of the ACK0CKC register can only be rewritten by a sequence specified in advance, and an unauthorized write operation is eliminated.

Access: This register can be written in 8-bit units. The read value is always undefined.

Address: FFC0 4100_H

Value after reset: Undefined

Bit	7	6	5	4	3	2	1	0
Value after reset	—	—	—	—	—	—	—	—
R/W	W	W	W	W	W	W	W	W

Writing to the ACK0CKC register is only possible with the protection unlock sequence described below.

Procedure

1. Write the fixed value (A5_H) to register ACK0CKPCMD.
2. Write the new setting to register ACK0CKC. Write the value after a reset to the reserved bits.
3. Write the bitwise inverse of the setting value to register ACK0CKC. Write the inverse of the value after a reset to the reserved bits.
4. Write the new setting to register ACK0CKC. Write the value after a reset to the reserved bits.

A value can only be written to register ACK0CKC by following the procedure above.

Protection is not unlocked if the procedure is not followed correctly, the setting is not written to the ACK0CKC register, and the ACK0CKCPS.CKCPREERR bit is set to 1. (Although this is not a requirement, you can confirm if the values set in the targeted register was correctly written by checking that the setting of the ACK0CKCPS.CKCPREERR bit is 0 after step 4.)

In case of failure to follow the sequence, repeat the procedure from the beginning.

In case of writing to another register during steps 1 to 4 of the sequence, the protection function operates as follows. Operation is also as described when any interrupt is accepted during the sequence and the interrupt handling includes access to another register.

- When the writing is to another register in the same module*¹, writing to the protected register fails and the ACK0CKCPS.CKCPREERR bit is set to 1.
- When writing is to a register in another module, writing to the protected register will successfully proceed to completion, if the remainder of the procedure is followed correctly.

Reading of another register while the sequence is in progress does not lead to failure.

Note 1. "Another register in the same module" indicates a register under the same module name as that containing the write-protected register. For the module names of the registers, see **Appendix, List of Registers**.

11.7.3.6 ACK0CKCPS — CKC Protect Status Register

The ACK0CKCPS is a register to which the CKCPRERR flag indicating a protection error occurrence is allocated.

If the ACK0CKC register is not written to in the correct sequence, including the command register settings, the write operation is not performed on the target register. A protection error then occurs and the status flag (CKCPRERR) is set to 1.

The ACK0CKCPS register is cleared at each start of the specific sequence.

Access: This register can be read in 8-bit units.

Address: FFC0 4104_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CKCPR ERR
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 11.21 ACK0CKCPS Register Contents

Bit Position	Bit Name	Description
7 to 1	—	Reserved These bits are always read as 0.
0	CKCPRERR	Protection Error Detection 0: Protection error has not occurred. 1: Protection error has occurred.

11.7.4 Usage

11.7.4.1 CK Pin Output Function

A clock source output from the CK pin can be selected and provided in this function.

1-MHz clock is output from the CK pin during the reset period immediately after release from power-off standby. A clock source output from the CK pin can be selected among the 1-MHz clock and the frequency-divided clocks set by the BRG (Baud Rate Generator) through switching of the ACK0CKCTL register.

Selectable clock source

- 1-MHz clock (1/20 clock of the 20-MHz main OSC) (Initial value)
- BRG (Baud Rate Generator)

11.7.4.2 CK Output Baud Rate Generator Circuit (BRGA)

In the baud rate generator circuit, the unmodulated low speed peripheral clock (CLKC_LSB) is divided and output from the CK pin.

The BRGA0 inverts the CK output in response to compare match between the specified value of the BRGA0CMP[4:0] bit in the ACK0BRGA0CMP register and the value of the baud rate counter.

The CK output is fixed to low when the DCLK0-bit in the ACK0CKC register is set to 0.

Table 11.22 lists the frequencies of unmodulated low speed peripheral clocks that can be set.

Table 11.22 Unmodulated Low Speed Peripheral Clock Frequency (value set in the ACK0BRGA0CMP register and frequency to be output)

BRGA0CMP4	BRGA0CMP3	BRGA0CMP2	BRGA0CMP1	BRGA0CMP0	Output Frequency [MHz]
0	0	0	0	0	1.25
1	0	1	0	0	2.00
1	0	1	0	1	1.90
1	0	1	1	0	1.82
1	0	1	1	1	1.74
1	1	0	0	0	1.67
1	1	0	0	1	1.60
1	1	0	1	0	1.54
1	1	0	1	1	1.48
1	1	1	0	0	1.43
1	1	1	0	1	1.38
1	1	1	1	0	1.33
1	1	1	1	1	1.29

Note 1. Setting other than the above is prohibited.

11.7.4.3 Control Register Rewrite Protect

As shown in **Figure 11.6**, the ACK0CKC register to control the output clock from the CK pin can only be rewritten in a specific sequence due to this protect function. Switching of a clock source is prohibited while a clock is running. The ACK0CKCTL register can only be rewritten when the DCLKF0 bit in the CKC flag register is set to 0.

In addition, rewriting of the compare values is prohibited while the baud rate counter is running. The ACK0BRGA0CMP register can only be rewritten when the DCLKF0 bit in the CKC flag register is set to 0.

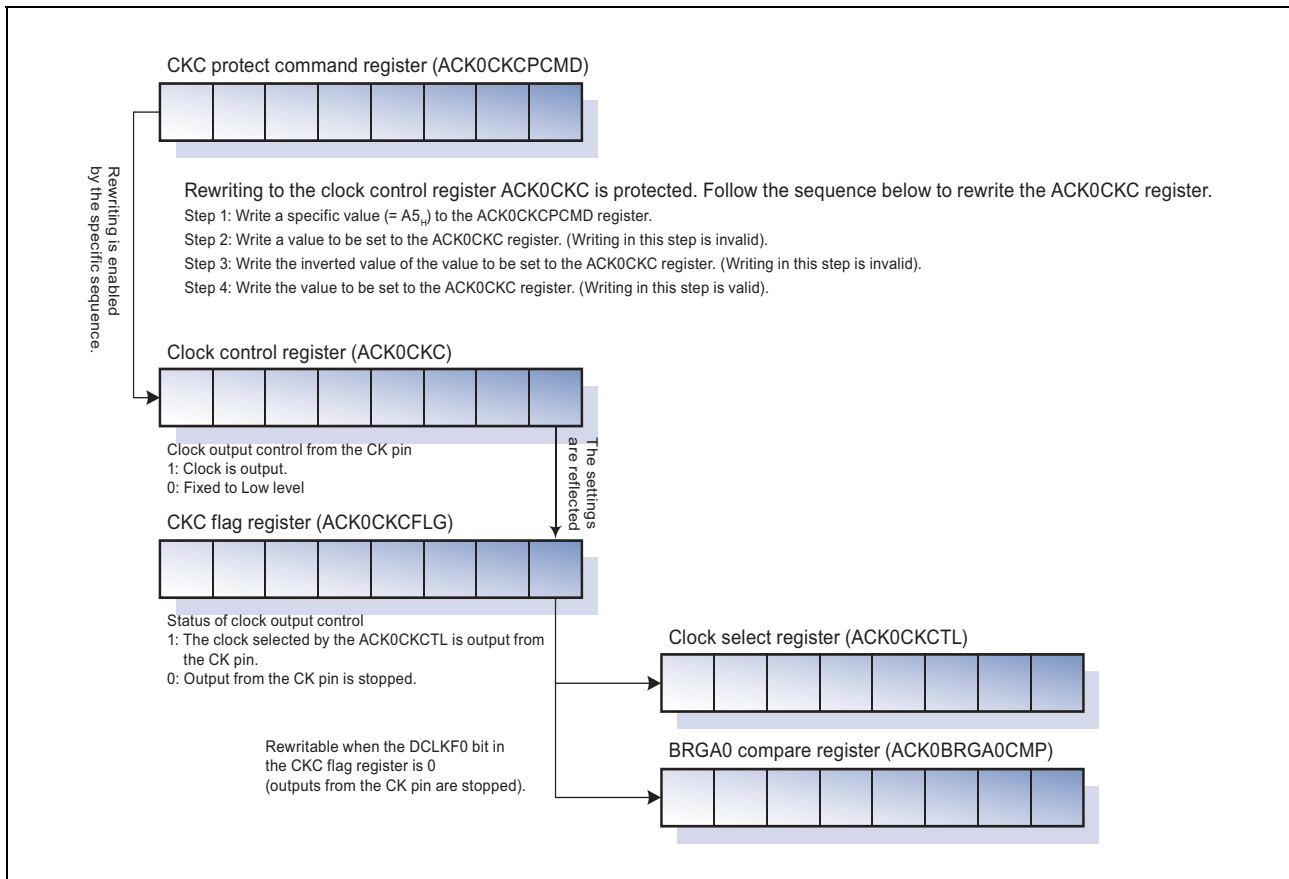

Figure 11.6 Rewriting Protect

11.7.4.4 CK Output Switching Procedure

Follow the procedure below to switch the output clock from the CK pin.

(1) Stop an output from the CK pin.

Rewrite the DCLK0 bit in the clock control register (ACK0CKC) to stop an output from the CK pin.

- Write A5_H to the ACK0CKCPCMD register.
- Write 00_H to the ACK0CKC register.
- Write FF_H to the ACK0CKC register.
- Write 00_H to the ACK0CKC register.

Read the DCLKF0 bit in the CKC flag register (ACK0CKCFLG) to verify that the output from the CK pin has been stopped.

(2) Select a clock source

Rewrite the CKSL[1:0] bits in the clock selection register (ACK0CKCTL) to select a clock source.

Also rewrite the BRGA0CMP[4:0] bits in the BRGA0 compare register (ACK0BRGA0CMP) to select a clock cycle for the baud rate generator.

(3) Restart an output from the CK pin

Rewrite the DCLK0 bit in the clock control register (ACK0CKC) to restart an output from the CK pin.

- Write A5_H to the ACK0CKCPCMD register.
- Write 01_H to the ACK0CKC register.
- Write FE_H to the ACK0CKC register.
- Write 01_H to the ACK0CKC register.

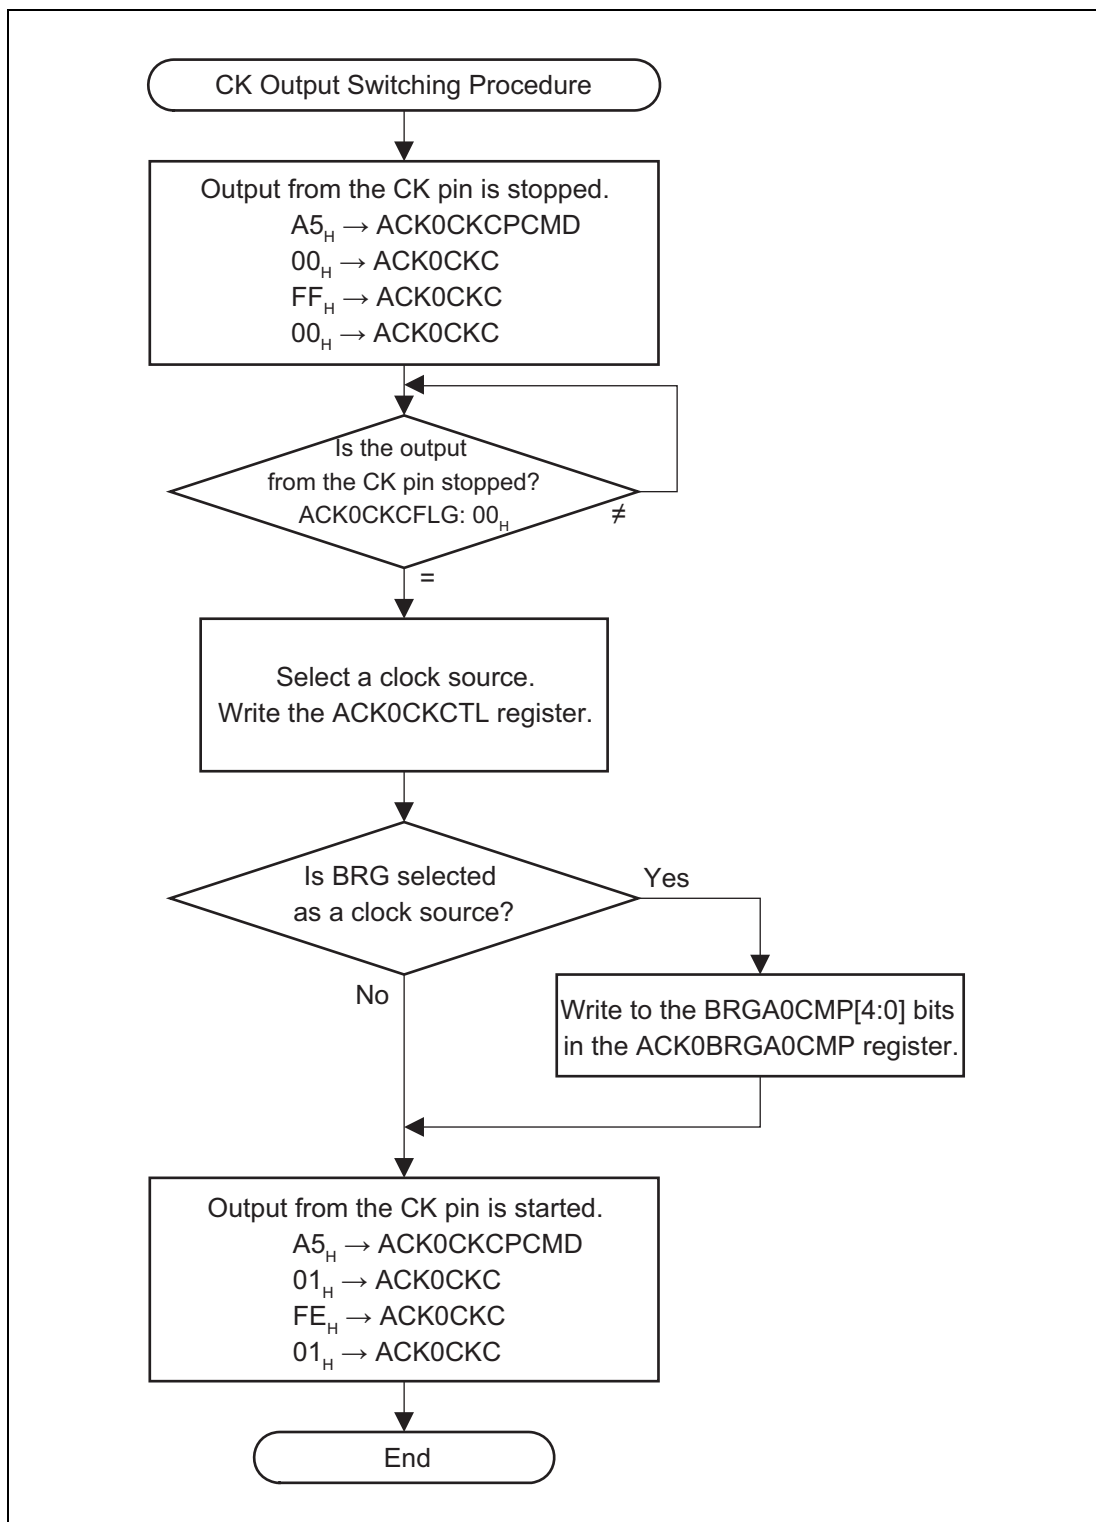

Figure 11.7 CK Output Switching Procedure

Section 12 Standby Controller

This product supports various power-down modes: two modes of power off standby mode and HALT mode, and module standby function that can stop peripheral modules. The power consumption of the LSI can be reduced by selecting a suitable mode for the application.

12.1 Features

12.1.1 Types of Power-Down Mode

Power-down modes are comprised of the modes and function as follows:

- Power off standby mode

Only RAM retention is possible in this mode. Low leakage is realized by turning off the power outside of the LSI. The oscillation also stops.

The transition occurs by asserting the $\overline{\text{RES}}$ pin and turning off the power (EVCC).

The CPU in this state transits to the external reset state by a rising edge of the turned off power and securing the oscillation stabilization time.

- HALT mode

When the HALT instruction is executed, the CPU transits to HALT mode and stops instruction execution.

Each CPU can be controlled individually.

The CPU returns from this state by the occurrence of a reset input, interrupt, or exception.

- Module standby

This function stops the clock for peripheral macros to reduce the power consumption in accordance with register settings.

Since peripheral modules are in operation after release from the reset state, it is recommended that the modules not to be used be set to the module stop state before clock gear-up.

Modules which have been set in the module stop state should not be activated again (after setting a corresponding bit in the module standby register to 1, do not clear it to 0). In such a case (when the bit is cleared to 0), proper operation cannot be guaranteed.

12.2 Operation

12.2.1 Power Off Standby Mode

The CPU transits to power-off standby mode when EVCC power is set to 0V after asserting the $\overline{\text{RES}}$ pin. In power-off standby mode, leakage current can be reduced because the oscillator is stopped and the core power is turned off. For products with the EPT, the EPT controls VDD turn-off.

In power-off standby mode, the data in the RAM can be retained as long as SYSVCC is kept within the specified voltage range.

For the target RAMs, see **Section 38, On-Chip RAM**.

For recovery from power-off standby mode, restore EVCC and VCC to the specified voltage to allow the CPU to return to the external reset state. Then negate the $\overline{\text{RES}}$ pin after securing the oscillation stabilization time to allow the CPU to return to the normal state.

Refer to **Section 40, Electrical Characteristics**, for the power-off sequences.

12.2.2 Module Standby Function

(1) Transition to module standby

Setting a corresponding bit in the module standby register to 1 can stop clock supply to the corresponding internal peripheral module. We recommend setting module standby before clock gear-up (while the module is disabled) to reduce the power consumption.

The module standby registers are protected from unauthorized writing due to incorrect programming operation and the like.

For details, see **Section 12.3.6, MSRPCMD — MSR Protection Command Register**.

(2) Release from module standby

For release from module standby, place the LSI in the internal or external reset state.

Proper operation cannot be guaranteed when the module standby state which has been already set is released by writing 0 to the module standby register.

12.3 Register List

12.3.1 List of Registers

All registers can be accessed by CPU.

Table 12.1 Register Configuration

Address	Register name	Description	Access Width	Value after Reset	Access protection
FFF8 2C0C	EPTCNT	EPT control register	32	0000 0000 _H	PROT0PHCMD

12.3.2 EPTCNT — EPT Control Register

This register enables or disables the EPT.

This register is protected by the PROT0PHCMD register.

This register can only be reset by an external reset signal.

Access: This register can be read/written in 32-bit units.

Address: FFF8 2C0C

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Table 12.2 EPTCNT Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved These bits are read as 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	EPTCNT	0: EPT is enabled. 1: EPT is disabled.

When the EPT is not used, the EPT control can be powered down by setting 1 in the register above, resulting in power consumption reduction.

12.3.3 PROT0PHCMD — Protection Command Register

This register is used as a special sequence register.

This register can be reset by either an internal or external reset.

Access: This register can be read/written in 32-bit units.

Address: FFF8 3000

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	PCMD[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 12.3 PROT0PHCMD Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved The read value is always 0. When writing, write 0.
7 to 0	PCMD[7:0]	Writing protection command register

Writing to the write-protected registers is only possible with the protection unlock sequence described below.

1. Write the fixed value (0000 00A5_H) to register PROT0PHCMD.
2. Write the new setting to the write-protected register. Write the value after a reset to the reserved bits.
3. Write the bitwise inverse of the setting value to the same register as in step 2. Write the inverse of the value after a reset to the reserved bits.
4. Write the new setting to the same register as in step 2. Write the value after a reset to the reserved bits.

A value can only be written to a write-protected register by following the procedure above.

Protection is not unlocked if the procedure is not followed correctly, the setting is not written to the write-protected register, and the PROT0PS.PROTERR bit is set to 1.

(Although this is not a requirement, you can confirm if the values set in the targeted register was correctly written by checking that the setting of the PROT0PS.PROTERR bit is 0 after step 4.)

In case of failure to follow the sequence, repeat the procedure from the beginning.

In case of writing to another register during steps 1 to 4 of the sequence, the protection function operates as follows. Operation is also as described when any interrupt is accepted during the sequence and the interrupt handling includes access to another register.

- When the writing is to another register in the same module*¹, writing to the protected register fails and the PROT0PS.PROTERR bit is set to 1.
- When writing is to a register in another module, writing to the protected register will successfully proceed to completion, if the remainder of the procedure is followed correctly.

Reading of another register while the sequence is in progress does not lead to failure.

Note 1. The applicable registers for PROT0PHCMD are those allocated to the address range from FFF82410_H to FFF83004_H.
For the register names, symbols, and module names, see **Appendix, List of Registers**.

12.3.4 PROT0PS — Protection Command Status Register

This register is used as a status register of special sequence registers. This register can be reset by either an internal or an external reset signal.

Access: This register can be read in 32-bit units.

Address: FFF8 3004

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PROT ERR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 12.4 PROT0PS Register Contents

Bit Position	Bit Name	Function
31 to 1	—	Reserved The read value is always 0.
0	PROTERR	Protection error flag 0: An protection error has not occurred. 1: An protection error has occurred.

12.3.5 Module Standby Registers

The module standby registers can be read/written in 8-bit units and control each module operation in power-down mode.

12.3.5.1 MSRTSG — Module Standby Register – TSG2

Access: This register can be read/written in 8-bit units.

Address: FFC0 5000

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	MS_TSG21	MS_TSG20
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 12.5 MSRTSG Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
1	MS_TSG21	Setting this bit to 1 stops clock supply to TSG21. 0: TSG21 is operating. 1: Clock supply to TSG21 is stopped.
0	MS_TSG20	Setting this bit to 1 stops clock supply to TSG20. 0: TSG20 is operating. 1: Clock supply to TSG20 is stopped.

12.3.5.2 MSRTAPA — Module Standby Register – TAPA

Access: This register can be read/written in 8-bit units.

Address: FFC0 5004

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	MS_TAPA3	MS_TAPA2	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R	R

Table 12.6 MSRTAPA Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
3	MS_TAPA3	Setting this bit to 1 stops clock supply to TAPA3. 0: TAPA3 is operating. 1: Clock supply to TAPA3 is stopped.
2	MS_TAPA2	Setting this bit to 1 stops clock supply to TAPA2. 0: TAPA2 is operating. 1: Clock supply to TAPA2 is stopped.
1, 0	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.

12.3.5.3 MSROSTM — Module Standby Register – OSTM

Access: This register can be read/written in 8-bit units.

Address: FFC0 5008

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	MS_OSTM2	MS_OSTM1	MS_OSTM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 12.7 MSROSTM Register Contents

Bit Position	Bit Name	Function
7 to 3	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
2	MS_OSTM2	Setting this bit to 1 stops clock supply to OSTM2. 0: OSTM2 is operating. 1: Clock supply to OSTM2 is stopped.
1	MS_OSTM1	Setting this bit to 1 stops clock supply to OSTM1. 0: OSTM1 is operating. 1: Clock supply to OSTM1 is stopped.
0	MS_OSTM0	Setting this bit to 1 stops clock supply to OSTM0. 0: OSTM0 is operating. 1: Clock supply to OSTM0 is stopped.

12.3.5.4 MSRWDTA — Module Standby Register – WDTA

Access: This register can be read/written in 8-bit units.

Address: FFC0 500C

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	MS_WDTA1	MS_WDTA0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 12.8 MSRWDTA Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
1	MS_WDTA1	Setting this bit to 1 stops clock supply to WDTA1. 0: WDTA1 is operating. 1: Clock supply to WDTA1 is stopped.
0	MS_WDTA0	Setting this bit to 1 stops clock supply to WDTA0. 0: WDTA0 is operating. 1: Clock supply to WDTA0 is stopped.

12.3.5.5 MSRPIC — Module Standby Register – PIC

Access: This register can be read/written in 8-bit units.

Address: FFC0 5010

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	MS_PIC2	MS_PIC1
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 12.9 MSRPIC Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
1	MS_PIC2	Setting this bit to 1 stops clock supply to PIC2. 0: PIC2 is operating. 1: Clock supply to PIC2 is stopped.
0	MS_PIC1	Setting this bit to 1 stops clock supply to PIC1. 0: PIC1 is operating. 1: Clock supply to PIC1 is stopped.

12.3.5.6 MSRRCAN — Module Standby Register – RS-CANFD

Access: This register can be read/written in 8-bit units.

Address: FFC0 5014

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	MS_RCAN
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 12.10 MSRRCAN Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	MS_RCAN	Setting this bit to 1 stops clock supply to RS-CANFD. 0: RS-CANFD is operating. 1: Clock supply to RS-CANFD is stopped.

12.3.5.7 MSRFRAY — Module Standby Register – FlexRay

Access: This register can be read/written in 8-bit units.

Address: FFC0 5018

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	MS_FRAY	—	—	—	MS_DSAD2_7
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R/W	R	R	R	R/W

Table 12.11 MSRFRAY Register Contents

Bit Position	Bit Name	Function
7 to 5	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
4	MS_FRAY	Setting this bit to 1 stops clock supply to FlexRay. 0: FlexRay is operating. 1: Clock supply to FlexRay is stopped.
3 to 1	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	MS_DSAD2_7	Setting this bit to 1 stops clock supply to channels 2 to 7 of ΔΣAD. 0: ΔΣAD is operating. 1: Clock supply to channels 2 to 7 is stopped.

12.3.5.8 MSRRLIN — Module Standby Register – RLIN2

Access: This register can be read/written in 8-bit units.

Address: FFC0 501C

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	MS_RLIN0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 12.12 MSRRLIN Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	MS_RLIN0	Setting this bit to 1 stops clock supply to RLIN0. 0: RLIN0 is operating. 1: Clock supply to RLIN0 is stopped.

12.3.5.9 MSRSCI — Module Standby Register – SCI3

Access: This register can be read/written in 8-bit units.

Address: FFC0 5020

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	MS_SCI3	MS_SCI2	MS_SCI1	MS_SCI0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 12.13 MSRSCI Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
3	MS_SCI3	Setting this bit to 1 stops clock supply to SCI3. 0: SCI3 is operating. 1: Clock supply to SCI3 is stopped.
2	MS_SCI2	Setting this bit to 1 stops clock supply to SCI2. 0: SCI2 is operating. 1: Clock supply to SCI2 is stopped.
1	MS_SCI1	Setting this bit to 1 stops clock supply to SCI1. 0: SCI1 is operating. 1: Clock supply to SCI1 is stopped.
0	MS_SCI0	Setting this bit to 1 stops clock supply to SCI0. 0: SCI0 is operating. 1: Clock supply to SCI0 is stopped.

12.3.5.10 MSRCSIH — Module Standby Register – CSIH

Access: This register can be read/written in 8-bit units.

Address: FFC0 5024

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	MS_CSIH3	MS_CSIH2	MS_CSIH1	MS_CSIH0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 12.14 MSRCSIH Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
3	MS_CSIH3	Setting this bit to 1 stops clock supply to CSIH3. 0: CSIH3 is operating. 1: Clock supply to CSIH3 is stopped.
2	MS_CSIH2	Setting this bit to 1 stops clock supply to CSIH2. 0: CSIH2 is operating. 1: Clock supply to CSIH2 is stopped.
1	MS_CSIH1	Setting this bit to 1 stops clock supply to CSIH1. 0: CSIH1 is operating. 1: Clock supply to CSIH1 is stopped.
0	MS_CSIH0	Setting this bit to 1 stops clock supply to CSIH0. 0: CSIH0 is operating. 1: Clock supply to CSIH0 is stopped.

12.3.5.11 MSRSAD — Module Standby Register – SAR-AD

Access: This register can be read/written in 8-bit units.

Address: FFC0 5028

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	MS_SARAD1	MS_SARAD0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 12.15 MSRSAD Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
1	MS_SARAD1	Setting this bit to 1 stops clock supply to SAR-AD1. 0: SAR-AD1 is operating. 1: Clock supply to SAR-AD1 is stopped.
0	MS_SARAD0	Setting this bit to 1 stops clock supply to SAR-AD0. 0: SAR-AD0 is operating. 1: Clock supply to SAR-AD0 is stopped.

12.3.5.12 MSRDAD — Module Standby Register – $\Delta\Sigma$ AD

Access: This register can be read/written in 8-bit units.

Address: FFC0 502C

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	MS_DSAD67	MS_DSAD45	MS_DSAD23	MS_DSAD
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 12.16 MSRDAD Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
3	MS_DSAD67	Setting this bit to 1 stops clock supply to channels 6 and 7 of $\Delta\Sigma$ AD. 0: Channels 6 and 7 of $\Delta\Sigma$ AD are operating. 1: Clock supply to channels 6 and 7 of $\Delta\Sigma$ AD is stopped.
2	MS_DSAD45	Setting this bit to 1 stops clock supply to channels 4 and 5 of $\Delta\Sigma$ AD. 0: Channels 4 and 5 of $\Delta\Sigma$ AD are operating. 1: Clock supply to channels 4 and 5 of $\Delta\Sigma$ AD is stopped.
1	MS_DSAD23	Setting this bit to 1 stops clock supply to channels 2 and 3 of $\Delta\Sigma$ AD. 0: Channels 2 and 3 of $\Delta\Sigma$ AD are operating. 1: Clock supply to channels 2 and 3 of $\Delta\Sigma$ AD is stopped.
0	MS_DSAD	Setting this bit to 1 stops clock supply to channels 0 to 7 of $\Delta\Sigma$ AD. 0: Channels 0 to 7 of $\Delta\Sigma$ AD are operating. 1: Clock supply to channels 0 to 7 of $\Delta\Sigma$ AD is stopped.

12.3.5.13 MSRATU — Module Standby Register – ATU-IV

Access: This register can be read/written in 8-bit units.

Address: FFC0 5030

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	MS_ATU
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 12.17 MSRATU Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	MS_ATU	Setting this bit to 1 stops clock supply to ATU. 0: ATU is operating. 1: Clock supply to ATU is stopped.

12.3.5.14 MSRAPA — Module Standby Register – APA

Access: This register can be read/written in 8-bit units.

Address: FFC0 5034

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	MS_APA0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 12.18 MSRAPA Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	MS_APA0	Setting this bit to 1 stops clock supply to APA0. 0: APA0 is operating. 1: Clock supply to APA0 is stopped.

12.3.5.15 MSRDFE — Module Standby Register – DFE

Access: This register can be read/written in 8-bit units.

Address: FFC0 5038

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	MS_DFE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 12.19 MSRDFE Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
0	MS_DFE	Setting this bit to 1 stops clock supply to DFE. 0: DFE is operating. 1: Clock supply to DFE is stopped.

12.3.5.16 MSRRHSB — Module Standby Register – RHSB

Access: This register can be read/written in 8-bit units.

Address: FFC0 503C

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	MS_RHSB1	MS_RHSB0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 12.20 MSRRHSB Register Contents

Bit Position	Bit Name	Function
7 to 2	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
1	MS_RHSB1	Setting this bit to 1 stops clock supply to RHSB1. 0: RHSB1 is operating. 1: Clock supply to RHSB1 is stopped.
0	MS_RHSB0	Setting this bit to 1 stops clock supply to RHSB0. 0: RHSB0 is operating. 1: Clock supply to RHSB0 is stopped.

12.3.5.17 MSRRSENT — Module Standby Register – RSENT

Access: This register can be read/written in 8-bit units.

Address: FFC0 5044

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	MS_RSENT5	MS_RSENT4	MS_RSENT3	MS_RSENT2	MS_RSENT1	MS_RSENT0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 12.21 MSRRSENT Register Contents

Bit Position	Bit Name	Function
7, 6	—	Reserved The read value is always 0. When writing to these bits, follow the procedure of the protection unlock sequence to write the value after a reset or the bitwise inverse of the value after a reset.
5	MS_RSENT5	Setting this bit to 1 stops clock supply to RSENT5. 0: RSENT5 is operating. 1: Clock supply to RSENT5 is stopped.
4	MS_RSENT4	Setting this bit to 1 stops clock supply to RSENT4. 0: RSENT4 is operating. 1: Clock supply to RSENT4 is stopped.
3	MS_RSENT3	Setting this bit to 1 stops clock supply to RSENT3. 0: RSENT3 is operating. 1: Clock supply to RSENT3 is stopped.
2	MS_RSENT2	Setting this bit to 1 stops clock supply to RSENT2. 0: RSENT2 is operating. 1: Clock supply to RSENT2 is stopped.
1	MS_RSENT1	Setting this bit to 1 stops clock supply to RSENT1. 0: RSENT1 is operating. 1: Clock supply to RSENT1 is stopped.
0	MS_RSENT0	Setting this bit to 1 stops clock supply to RSENT0. 0: RSENT0 is operating. 1: Clock supply to RSENT0 is stopped.

12.3.6 MSRPCMD — MSR Protection Command Register

The MSRPCMD register is used for protection against writing operation to the registers which may have a material effect on the system so that the application system is not incorrectly stopped due to program malfunction and the like.

The values of the module standby registers can be rewritten by a sequence specified in advance and unauthorized writing operation to them is eliminated.

Access: This register can be written in 8-bit units. The read value is undefined.

Address: FFC0 5070

Value after reset: Undefined

Bit	7	6	5	4	3	2	1	0
Value after reset	—	—	—	—	—	—	—	—
R/W	W	W	W	W	W	W	W	W

Writing to the write-protected registers is only possible with the protection unlock sequence described below.

1. Write the fixed value (A5_H) to register MSRPCMD.
2. Write the new setting to the write-protected register. Write the value after a reset to the reserved bits.
3. Write the bitwise inverse of the setting value to the same register as in step 2. Write the inverse of the value after a reset to the reserved bits.
4. Write the new setting to the same register as in step 2. Write the value after a reset to the reserved bits.

A value can only be written to a write-protected register by following the procedure above.

Protection is not unlocked if the procedure is not followed correctly, the setting is not written to the write-protected register, and the MSRPS.MSRPRERR bit is set to 1.

(Although this is not a requirement, you can confirm if the values set in the targeted register was correctly written by checking that the setting of the MSRPS.MSRPRERR bit is 0 after step 4.)

In case of failure to follow the sequence, repeat the procedure from the beginning.

In case of writing to another register during steps 1 to 4 of the sequence, the protection function operates as follows. Operation is also as described when any interrupt is accepted during the sequence and the interrupt handling includes access to another register.

- When the writing is to another register in the same module*¹, writing to the protected register fails and the MSRPS.MSRPRERR bit is set to 1.
- When writing is to a register in another module, writing to the protected register will successfully proceed to completion, if the remainder of the procedure is followed correctly.

Reading of another register while the sequence is in progress does not lead to failure.

Note 1. “Another register in the same module” indicates a register under the same module name as that containing the write-protected register. For the module names of the registers, see **Appendix, List of Registers**.

12.3.7 MSRPS — MSR Protection Status Register

The MSRPS register is the one to which the MSRPRERR flag indicating a protection error occurrence is allocated.

When an operation to write to the module standby register is not performed in a correct sequence including command register settings, such writing to the target register does not proceed. A protection error occurs and the status flag (MSRPRERR) is set to 1.

Access: This register can be read in 8-bit units.

Address: FFC0 5074

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	MSRPRERR
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 12.22 MSRPS Register Contents

Bit Position	Bit Name	Function
7 to 1	—	Reserved The read value is always 0.
0	MSRPRERR	Protection error detection 0: Protection error does not occur. 1: Protection error occurs.

Section 13 Clocked Serial Interface H (CSIH)

This section contains a generic description of the Clocked Serial Interface H (CSIH).

13.1 CSIH Features

Channels

This microcontroller has the following number of channels of the Clocked Serial Interface H.

Table 13.1 Channels of CSIH

Clocked Serial Interface H	
Number of channels	4
Name	CSIH0, CSIH1, CSIH2, CSIH3

Index n

Throughout this section, the individual channels of a Clocked Serial Interface H is identified by the index “n” (n = 0 to 3), for example, CSIHnCTL0 for the CSIHn control register 0.

Index x

The Clocked Serial Interface H has up to 6 chip select signals. Throughout this section, the individual chip select signals are identified by the index “x”; thus a certain chip select signal is denoted as CSIHnTCSSx. The number of chip select signals for each channel of CSIH is given in the following table.

Table 13.2 Number of CSIH Chip Select Signals

CSIHn Channel	Chip Select Index
CSIH0	CSIH0TCSSx (x = 0 to 5)
CSIH1	CSIH1TCSSx (x = 0 to 3)
CSIH2	CSIH2TCSSx (x = 0 to 3)
CSIH3	CSIH3TCSSx (x = 0 to 3)

Register addresses

All CSIHn register addresses are given as address offsets to the individual base address <CSIHn_base>.

The base address <CSIHn_base> of each CSIHn is listed in the following table.

Table 13.3 Register Base Addresses <CSIHn_base>

CSIHn Channel	<CSIHn_base> Address
CSIH0	FFD8 0000 _H
CSIH1	FFD8 2000 _H
CSIH2	FFD8 4000 _H
CSIH3	FFD8 6000 _H

Data consistency check

The following table lists the port pins on which CSIHnTSO pin functions are multiplexed and the availability of data consistency checking. See **Section 13.5.12, Error Detection** for details about data consistency checking.

Table 13.4 CSIHn Data Consistency Checking and Port Pins

CSIHn I/O Port Signal	Function	Alternative Function	Data Consistency Check
CSIH0			
CSIH0TSO	P0_1	ALT_OUT5	Available
CSIH1			
CSIH1TSO	P13_1	ALT_OUT6	Available
CSIH1TSO	P0_7	ALT_OUT6	Available
CSIH2			
CSIH2TSO	P4_8	ALT_OUT6	Available
CSIH2TSO	P0_12	ALT_OUT7	Available
CSIH3			
CSIH3TSO	P4_1	ALT_OUT7	Available
CSIH3TSO	P7_1	ALT_OUT6	Available

13.2 Notes on Pin Combination

CSIH uses multiple pins for one channel and the pins should be used in groups as given in the following table.

Group		CSIHn TCK	CSIHn TSI	CSIHn TSO	CSIHn TCSS0	CSIHn TCSS1	CSIHn TCSS2	CSIHn TCSS3	CSIHn TSSI	CSIHn TRY
CSIH1	A	P0_8	P0_6	P0_7	P0_9	P0_10	P0_11	P0_12	P0_13	P0_14
	B	P13_2	P13_0	P13_1	P13_3	P13_4	—	—	—	—
CSIH2	C	P4_9	P4_7	P4_8	P4_10	P4_11	P4_12	P4_13	P4_3	P4_4
	D	P0_13	P0_11	P0_12	P0_14	P1_0	P1_1	P1_2	P1_3	P1_4
CSIH3	E	P4_2	P4_0	P4_1	P4_3	P4_4	P4_5	P4_6	P4_7	P4_8
	F	P7_2	P7_0	P7_1	P7_3	P7_4	P7_5	P7_6	P7_7	P7_8

13.3 Function Overview

Overview of Functions

- Three-wire serial synchronous data transfer
- Master mode and slave mode selectable
- Multiple slaves configuration plus RCB (Recessive Configuration for Broadcasting) thanks to up to six configurable chip select output signals
- Built-in slave select function (slave select input signal ($\overline{\text{CSIHnTSSI}}$))
- Built-in baud rate generator
- Baud rate adjustable; in slave mode determined by input clock
- Maximum transmission speed:
 - in master mode: PCLK/8: 10 Mbps
 - in slave mode: PCLK/20: 4 Mbps
- Phase of clock and data selectable
- Data transfer with MSB or LSB first selectable
- Transfer data length selectable from 2 to 16 bits in 1-bit units
- EDL (Extended Data Length) function for transferring data with more than 16 bits
- Three selectable transfer modes:
 - transmit-only mode
 - receive-only mode
 - transmit/receive mode
- Built-in handshake function
- Error detection (data consistency check, parity, and overrun)
- Support of job concept
- JOB enable control bit for AUTOSAR is provided
- LBM (Loop Back Mode) function for self-test
- Enforced chip select idle setting

The block diagram shows the main components of the CSH.

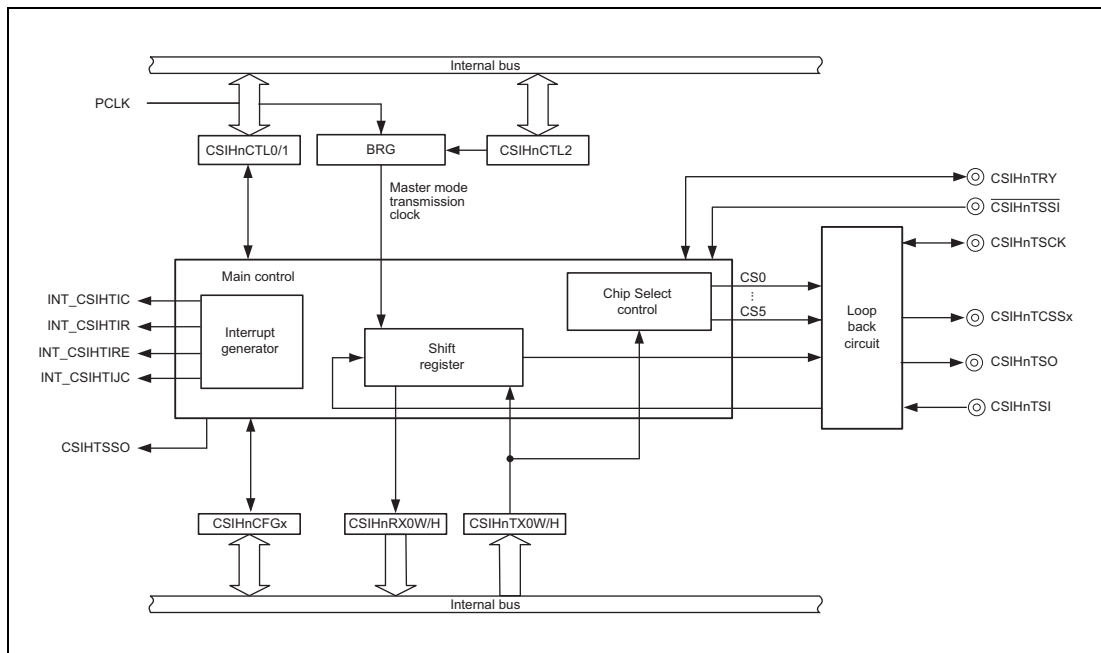

Figure 13.1 CSIH Block Diagram

In master mode, the transmission clock CSIHnTSCK is generated by the built-in baud rate generator (BRG). In slave mode, the transmission clock is provided from an external source.

The loop back circuit disconnects the CSIH completely from the ports and supports internal self-test.

CAUTION

This section describes the following modes:

- The “operating mode” separates between master and slave mode. In this context, only a master can control and communicate with several slaves (for details see Section 13.5.1, Operating Modes (master/slave)).
- The “job mode” is related to the AUTOSAR job concept (for details see Section 13.5.3, Chip Selection (CS) Features, (3) Job concept).
- The “data transfer mode” specifies the kind of the communication – transmit-only, receive only, or transmit/receive (for details see Section 13.5.6, Data transfer modes).

13.4 List of the Usage Notes

Table 13.5 Important Points for Register and Bit Operation (1/2)

Register name	Bit name	Contents
CSIHnCTL0	CSIHnPWR	If this bit is cleared during communication, ongoing communication is aborted.
CSIHnCTL0	CSIHnTXE CSIHnRXE	Do not modify any of these bits while CSIHnCTL0.CSIHnPWR = 0. (These bits and the CSIHnCTL0.CSIHnPWR bit can be modified at the same time.) Do not modify these bits while CSIHnSTR0.CSIHnTSF = 1 because ongoing communication is aborted and operation of this setting is not assured.
CSIHnCTL0	CSIHnJOBE	Do not modify this bit while CSIHnCTL0.CSIHnPWR = 0. This bit is only valid when CSIHnCTL1.CSIHnEDLE = 1. Setting this bit is prohibited in slave mode.
CSIHnCTL0	CSIHnMBS	Do not modify this bit while CSIHnCTL0.CSIHnPWR = 0. (This bit and the CSIHnCTL0.CSIHnPWR bit can be modified at the same time.) Modification of this bit is only allowed while CSIHnSTR0.CSIHnTSF = 0.
CSIHnCTL1	CSIHnCKR	Modification of the value of this bit is only permitted while CSIHnCTL0.CSIHnPWR = 0. If CS is not used, use this bit instead of CSIHnCFG0-5.CSIHnCKPx. CSIHnCFG0-5.CSIHnCKP must be set to 0. This bit must be used in slave mode.
CSIHnCTL1	CSIHnSLIT CSIHnCSL7-0 CSIHnDCS CSIHnCSRI CSIHnEDLE CSIHnHSE	Modification of the value of these bits is only permitted while CSIHnCTL0.CSIHnPWR = 0.
CSIHnCTL1	CSIHnJE CSIHnLBM	Modification of the value of these bits is only permitted while CSIHnCTL0.CSIHnPWR = 0. Setting these bits prohibited in slave mode.
CSIHnCTL1	CSIHnSSE	Modification of the value of this bit is only permitted while CSIHnCTL0.CSIHnPWR = 0. Setting this bit to 1 is prohibited in master mode.
CSIHnCTL1	CSIHnSIT	Modification of the value of this bit is only permitted while CSIHnCTL0.CSIHnPWR = 0. This bit is only valid in master mode. In slave mode, no delay is generated.
CSIHnCTL2	CSIHnPRS2-0	Modification of the value of these bits is only permitted while CSIHnCTL0.CSIHnPWR = 0. Max baud rate configuration is as follows. <ul style="list-style-type: none"> • Master mode: PCLK/8 • Slave mode: PCLK/20
CSIHnSTR0	CSIHnTSF	Writing is prohibited. Only reading is effective.
CSIHnSTR0	CSIHnDCE CSIHnPE CSIHnOVE	These bits are Initialized when CSIHnCTL0.CSIHnPWR = 0 → 1 or CSIHnCTL0.CSIHnPWR = 1 → 0.
CSIHnCFGx	CSIHnBRSSx1-0 CSIHnRCBx CSIHnIDLx CSIHnIDx2-0 CSIHnHDx3-0 CSIHnINx3-0 CSIHnSPx3-0	Modification of the value of these bits is only permitted while CSIHnCTL0.CSIHnPWR = 0. Set these bits to 0 in slave mode.
CSIHnCFGx	CSIHnPSx1-0 CSIHnDLSx3-0 CSIHnDIRx CSIHnDAPx	Modification of the value of these bits is only permitted while CSIHnCTL0.CSIHnPWR = 0. In slave mode, the setting of the CSIHnCFG0 is used. Therefore, all these bits of CSIHnCFG 1 to 5 must be set to 0.

Table 13.5 Important Points for Register and Bit Operation (2/2)

Register name	Bit name	Contents
CSIHnCFGx	CSIHnCKPx	Modification of the value of this bit is only permitted while CSIHnCTL0.CSIHnPWR = 0. Since the CSIHnCTL1.CSIHnCKR bit is used in slave mode, set this bit to 0. If CS is not used, use CSIHnCTL1.CSIHnCKR instead of this bit and this bit must be set to 0.
CSIHnTX0W	CSIHnEOJ	This bit is only available while CSIHnCTL1.CSIHnEDLE = 1. When CSIHnCTL1.CSIHnJE = 0, the value is ignored even if the read value is 1. In slave mode, this bit must be set to "0".
CSIHnTX0W	CSIHnEDL	This bit is only available while CSIHnCTL1.CSIHnEDLE = 1. When CSIHnCTL1.CSIHnEDLE = 0, the value is ignored even if the read value is 1.
CSIHnTX0W	CSIHnCS7-0	Setting these bits to FF _H is prohibited in master mode. These bits must be set to FE _H in slave mode.
CSIHnTX0W CSIHnTX0H		Write access to these bits is prohibited when CSIHnCTL0.CSIH0TXE = CSIHnCTL0.CSIH0RXE = 0.
CSIHnRX0W CSIHnRX0H		These bits are initialized when CSIHnCTL0.CSIHnPWR = 0 → 1 or CSIHnCTL0.CSIHnPWR = 1 → 0.
CSIHnBRSi		Modification of the value of these bits is only permitted while CSIHnCTL0.CSIHnPWR = 0. The maximum baud rates are determined in combination with the setting of the CSIHnCTL2.PRS2-0 bits and are as follows. <ul style="list-style-type: none"> • Master mode: PCLK/8 • Slave mode: PCLK/20

13.5 Functional Description

The Clocked Serial Interface uses three signals for communication:

- Transmission clock CSIHnTSCK (output in master mode, input in slave mode)
- Data output signal CSIHnTSO
- Data input signal CSIHnTSI

Additional signals are available for external control and monitoring.

- $\overline{\text{CSIHnTSSI}}$: Slave select input signal
- CSIHnTRY: Handshake signal
- CSIHnTCSSx: Chip select signals

Data transmission is bit-wise and serial, and synchronous to the transmission clock.

The following table shows the most important registers for setting up the CSIH.

Table 13.6 Main Registers of CSIH

Register	Function
CSIHnCTL0	Enables/disables transmission clock, and permits/ prohibits data transmission and data reception. Defines end-of-job behavior and enables/disables buffering (bypass of the buffer).
CSIHnCTL1	Controls options like interrupt timing, extended data length, job feature, data consistency check, loop-back mode, handshake, etc.
CSIHnCTL2	Selects master/slave mode, and the baud rate of the internal generator (BRG) in master mode
CSIHnBRSi	Registers to configure the baud rate for each chip select signal
CSIHnCFGx	Registers to configure the communication protocol for each chip select signal

13.5.1 Operating Modes (master/slave)

For a particular CSIH module, the master or slave mode determines the source of the serial clock.

(1) Master mode

In master mode, the serial transmission clock is generated by the internal baud rate generator (BRG) and provided to the slave(s) by signal CSIHnTSCK.

Master mode is enabled by setting CSIHnCTL2.CSIHnPRS[2:0] to any value other than but 111_B. In master mode, the BRG frequency can be set by combining the CSIHnCTL2.CSIHnPRS[2:0] bits and the CSIHnBRSi.CSIHnBRSi[11:0] bits.

Chip select signals

In master mode, one or several chip select signals can be used. If several slaves are connected to the master, the chip select signals can be used to address one or several of the slaves. Only a selected slave is then enabled for communication.

The communication protocol and additional parameters are stored separately for each chip select signal. This makes it possible to adapt the data transfer individually to the requirements of each slave. For details, see **Section 13.5.3, Chip Selection (CS) Features**.

Clock default setting

The default level of CSIHnTSCK depends on the clock inverse bit CSIHnCTL1.CSIHnCKR of CSIHnTSCK: It is high level when CSIHnCTL1.CSIHnCKR = 0, and is low level when CSIHnCTL1.CSIHnCKR = 1.

The example below shows the communication in master mode for a data length of 8 bits, CSIHnCTL1.CSIHnCKR = 0, CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0, and MSB first:

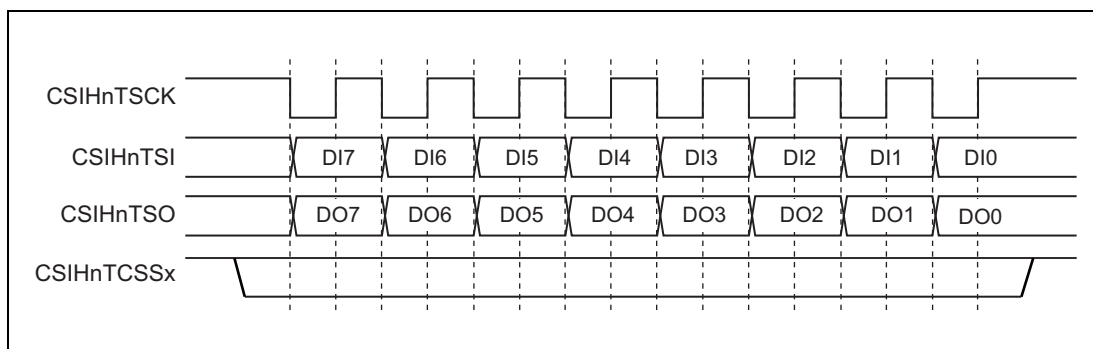

Figure 13.2 Transmission/Reception in Master Mode

(2) Slave mode

In slave mode, another device is the communication master and provides the transmission clock. Send/receive operation normally starts as soon as a clock signal is detected.

Slave mode is selected by setting the CSIHnCTL2.CSIHnPRS[2:0] bits to 111_B.

In slave mode, the transmission protocol setting of the CSIHnCFG0 register is enabled (setting of the CSIHnCFG1 to CSIHnCFGx registers is disabled).

- CSIHnPS0[1:0]: parity usage
- CSIHnDLS0[3:0]: data length selection
- CSIHnDIR0: data direction
- CSIHnCKP0, CSIHnDAP0: clock and data phase

CAUTION

When using slave mode, the baud rate generator (BRG) should be disabled by setting the CSIHnBRSi[11:0] bits in CSIHnBRSi to 000_H.

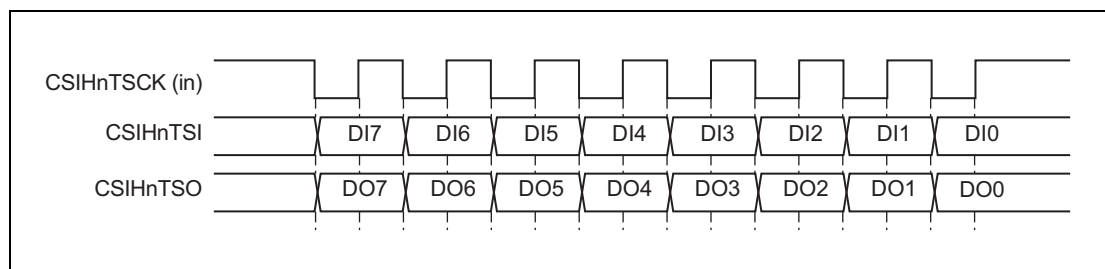

Figure 13.3 Transmission/Reception in Slave Mode

13.5.2 Master/Slave Connections

(1) One master and one slave

The following figure illustrates the connections between one master and one slave.

Figure 13.4 Direct Master/Slave Connection

(2) One master and multiple slaves

The following figure illustrates the connections between one master and multiple slaves. In this example, the master provides one chip select (CS) signal to each of the slaves. This signal is connected to the slave select input $\overline{\text{CSIHnTSSI}}$ of the slave.

The $\overline{\text{CSIHnTSSI}}$ signal can be enabled/disabled by the CSIHnCTL1.CSIHnSSE bit.

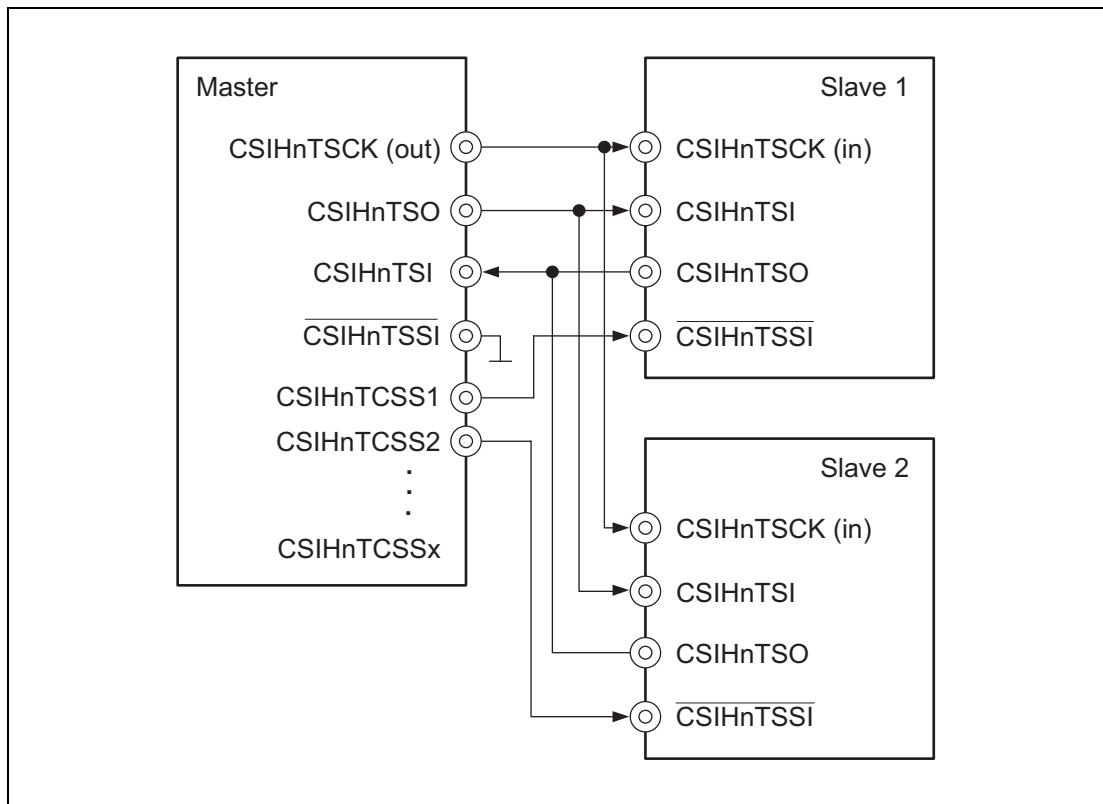

Figure 13.5 Master to Multiple Slaves Connection

By default, the chip select level is active low. That means, a slave is selected (enabled) as a CSIH slave when its $\overline{\text{CSIHnTSSI}}$ signal has low level. However, to adapt the CS to other devices, the output level of each chip select signal can also be programmed to be active high.

If a slave is not selected, it will neither receive nor transmit data. In addition, while transmit-only mode or transmit/receive mode is set ($\text{CSIHnCTL0.CSIHnTXE} = 1$), its output CSIHnTSO of a slave that is not selected is set to input mode in order to avoid interference with the output of another slave that was selected.

13.5.3 Chip Selection (CS) Features

The chip select signal, CSIHnTCSSx can be used by the master to select one or several slaves for communication.

(1) Configuration registers

The parameters for each chip select signal CSIHnTCSSx are defined in the corresponding configuration register CSIHnCFGx. The parameters include the communication protocol and additional CS parameters.

The communication protocol specifies:

- Data length: The number of bits to be sent or received.
- Transfer direction: MSB or LSB first.
- Parity usage: Odd, even, 0 parity or none.
- Clock phase and data phase.

Additional parameters for each chip select signal that is only available in master mode are:

- Prescaler selection of the baud rate generator separately for each chip select signal
- Chip select priority: Separates between “dominant” and “recessive” chip select signals. The priority applies if two or more chip selects signals with different configurations are simultaneously activated for message broadcasting. In this case, the configuration that is set as dominant is used.

The principle is also called “Recessive Configuration for Broadcasting” (RCB).

CAUTION

It is forbidden to specify several chip select signals as dominant with different configurations unless all dominant chip selects have the same configuration.

- Chip select timing:
 - Setup time T_{setup} : The time from setting the CS signal active to starting data output.
 - Inter-data time T_{inter} : The time between data and the next data while the same CS signal is active.
 - Hold time T_{hold} : Hold time of CS active level before changing the CS.
 - Idle time T_{idle} : Inactive time after terminating a CS signal or after every data transfer to the same CSx.

The CS timings of the setup time, the inter-data time, the hold time, and the idle time are illustrated in the figure below. When the CSIHnCFGx.CSIHnIDLx bit is set to 1, idle time is inserted every transfer regardless of the CS signal.

Figure 13.6 provides an example when the default CSIHnTCSS1 and CSIHnTCSS2 signals are active low (CSIHnCTL1.CSIHnCSL1 bit = 0, CSIHnCTL1.CSIHnCSL2 bit = 0). The active level can be specified individually for each CS.

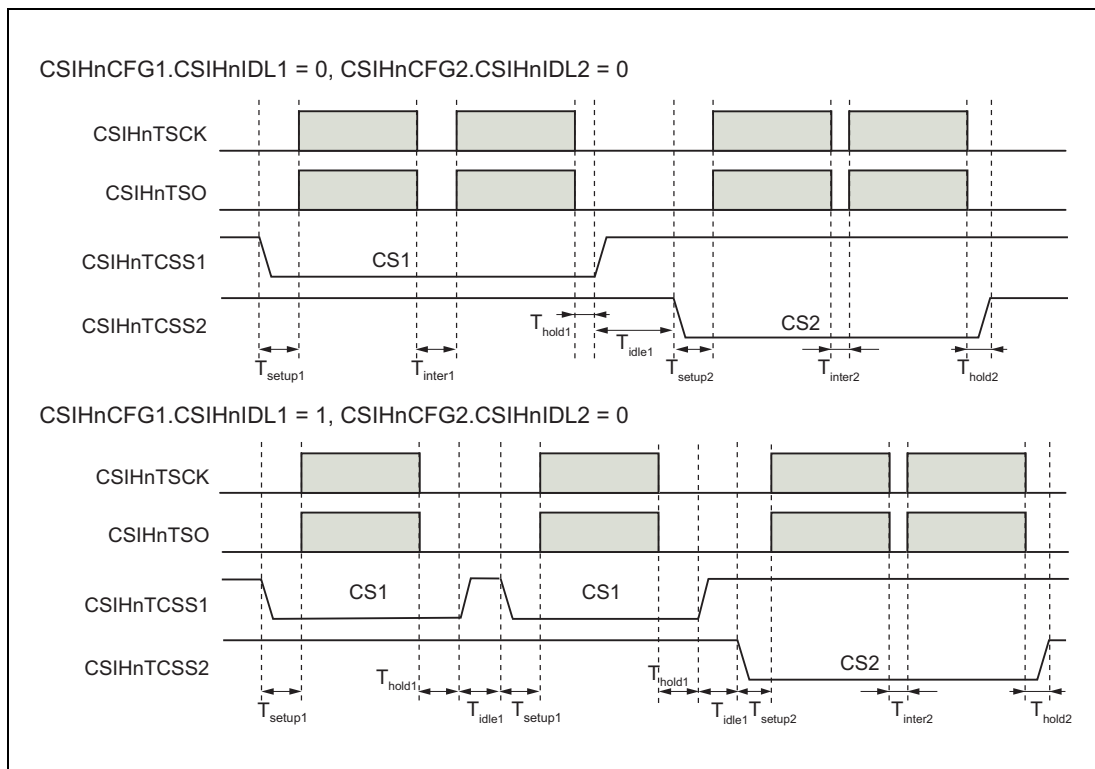

Figure 13.6 Chip Select Timings

Note that each CS signal can have a different value for setup, inter-data time, hold time, and idle time.

A particular chip select signal is activated by setting the appropriate bit in the transmission register CSIHnTX0W.CSIHnCS[7:0].

CSIHnRX0W.CSIHnCS[7:0] in the reception register indicates the chip select signal associated with the received data.

(2) CS example

The following figure shows an example of two consecutive data transmissions.

The first communication uses CS0 to communicate with one single slave. The second enables CS0 and CS1 to broadcast a message to two slaves. The priority of CS0 is set to “recessive: low priority”, the priority of CS1 to “dominant: high priority”.

Therefore, the second communication is conducted by using the CS1 setting in the dominant.

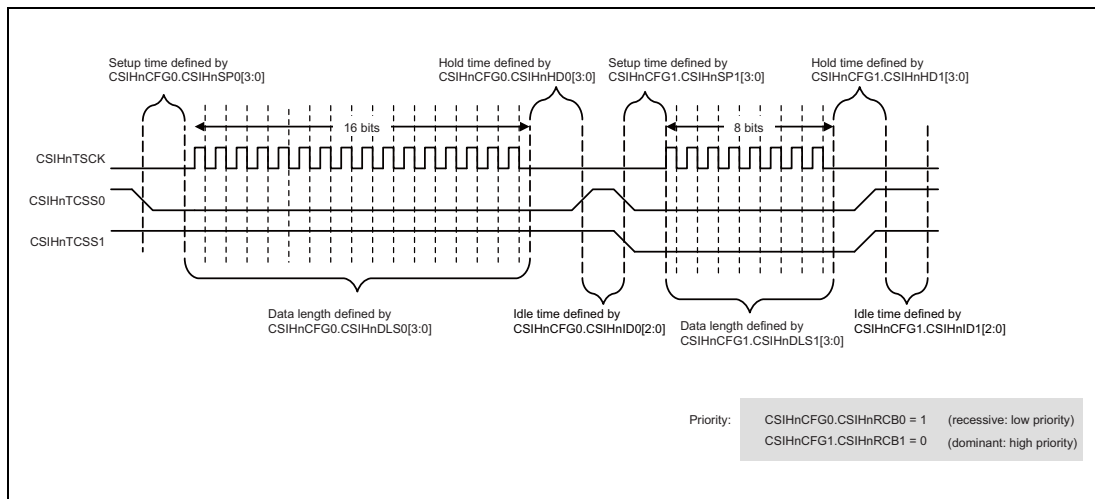

Figure 13.7 Chip Select and RCB Example

(3) Job concept

In terms of CSIH, a job consists of a number of data that are transferred.

Job mode enable

The job mode can only be enabled in master mode. The job mode is enabled and disabled by CSIHnCTL1.CSIHnJE, while the CSIH is disabled by CSIHnCTL0.CSIHnPWR = 0.

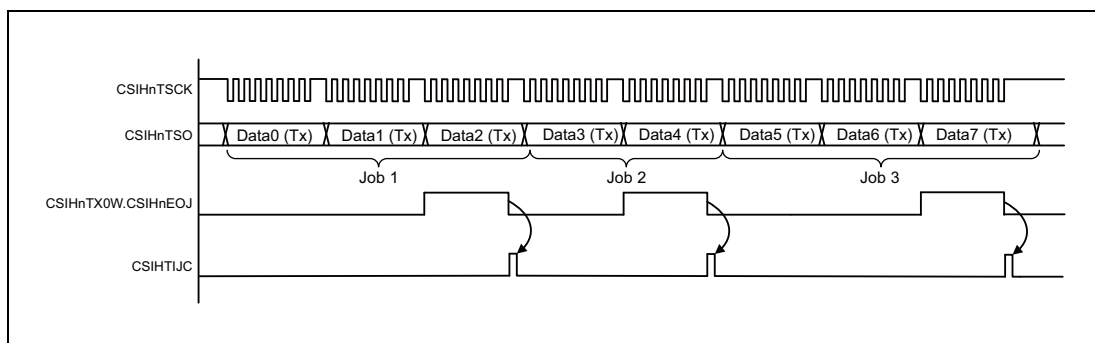

Figure 13.8 Job Examples

A job ends by transmitting data with the end-of-job bit set, i.e. data with CSIHnTX0W.CSIHnEOJ = 1.

A communication stop can be specified to occur after a job has finished. This is done by setting CSIHnCTL0.CSIHnJOB. When CSIHnJOB is set, the communication continues until data is sent, for which the CSIHnEOJ bit was set. After this data is sent, the communication is stopped and the job completion interrupt INT_CSIHTIJC is generated.

13.5.4 Chip Select Timing Details

(1) Changing the clock phase

The serial clock level specified by $CSIHnCFGx.CSIHnCKPx$ may be changed when communication is disabled. The minimum value for idle time is 0.5 of a cycle of the transmission clock ($CSIHnTSCK$) when the clock phases are the same, and one cycle when the phases are different.

If the idle time is set to 0.5 transmission clock periods (in $CSIHnCFGx.CSIHnIDx[2:0]$) and two consecutive data are sent with different $CSIHnCFGx.CSIHnCKPx$ configuration, the idle time is automatically extended to one period of $CSIHnTSCK$.

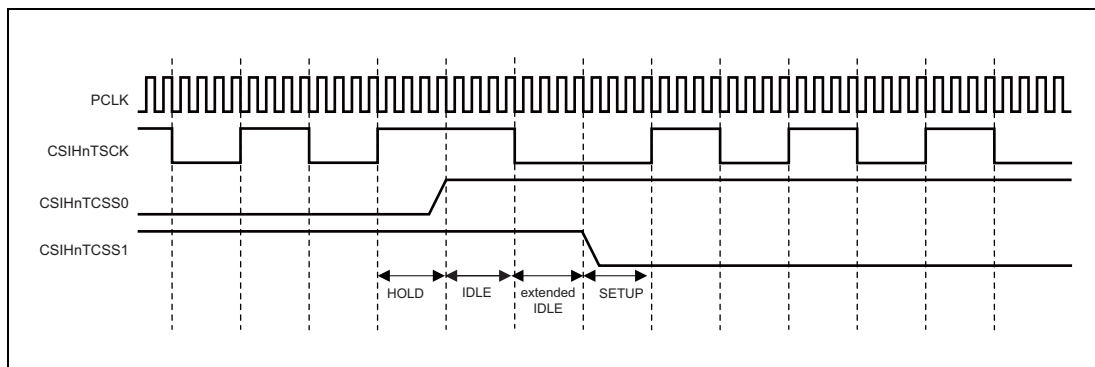

Figure 13.9 Clock Phase Timing
 $PCLK/8, Thold0 = Tsetup1 = 0 (0.5CSIHnTSCK), Tidle0 = 0 (0.5CSIHnTSCK), CSIHnCFG0.CSIHnCKP0 = 0 (CSIHnTCSS0) \rightarrow CSIHnCFG1.CSIHnCKP1 = 1 (CSIHnTCSS1)$

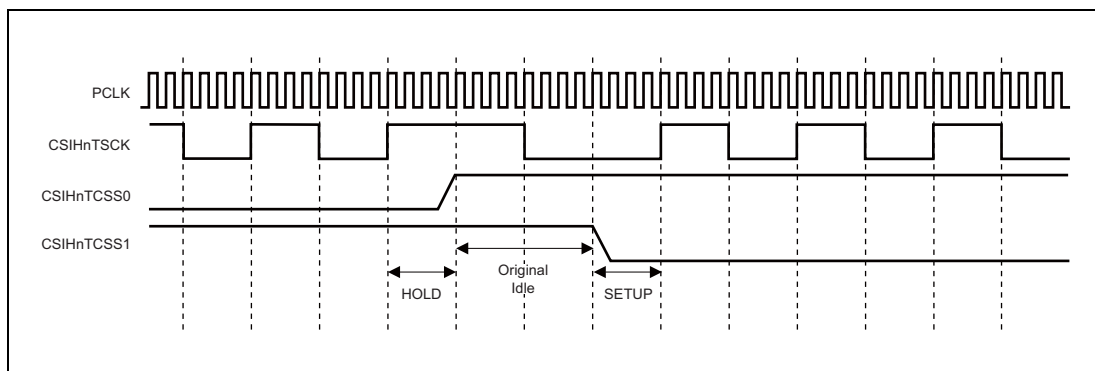

Figure 13.10 Clock Phase Timing
 $PCLK/8, Thold0 = Tsetup1 = 0 (0.5CSIHnTSCK), Tidle0 = 1 (1CSIHnTSCK), CSIHnCFG0.CSIHnCKP0 = 0 (CSIHnTCSS0) \rightarrow CSIHnCFG1.CSIHnCKP1 = 1 (CSIHnTCSS1)$

Figure 13.11 Clock Phase Timing
PCLK/8, Thold0 = Tsetup1 = 0 (0.5CSIHnTSCk), Tidle0 = 0
(0.5CSIHnTSCk), CSIHnCFG0.CSIHnCKP0 = 0 (CSIHnTCSS0)→
CSIHnCFG2.CSIHnCKP2 = 0 (CSIHnTCSS2)

(2) Changing the data phase

The CSIHnCFGx.CSIHnDAPx bit is used to define the phase of the data bit that is based on the clock.

The relationship between the CSIHnCFGx.CSIHnDAPx bit and hold/setup period is as followed.

The hold period is the time from the last edge of the serial clock (CSIHnTSCk) to the point where CSIHnTCSSx becomes inactive level.

The setup period is the time from the point where the CSIHnTCSSx becomes active level and to the point where transmit data (CSIHnTSO) is output.

Therefore, there is a 0.5 CSIHnTSCk gap until the edge of the serial clock (CSIHnTSCk) is output due to the setting of CSIHnCFGx.CSIHnDAPx.

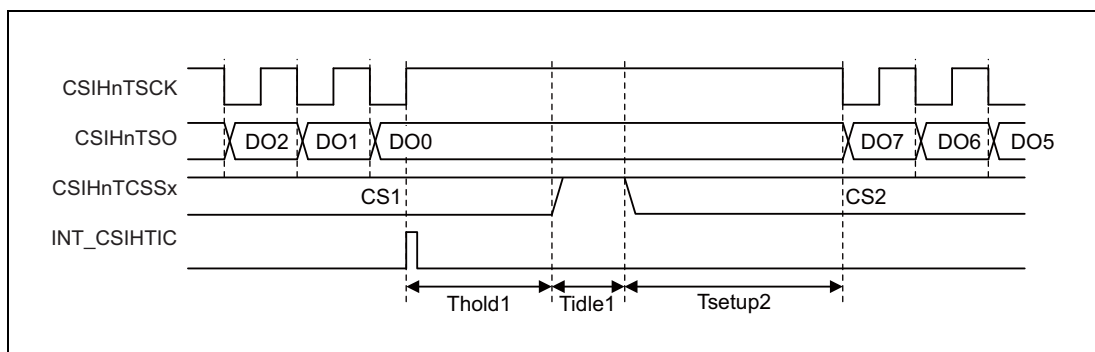

Figure 13.12 Data Phase Timing with CSIHnCFG1.CSIHnCKP1 = 0, CSIHnCFG1.CSIHnDAP1 = 0 and CSIHnCFG2.CSIHnCKP2 = 0, CSIHnCFG2.CSIHnDAP2 = 0

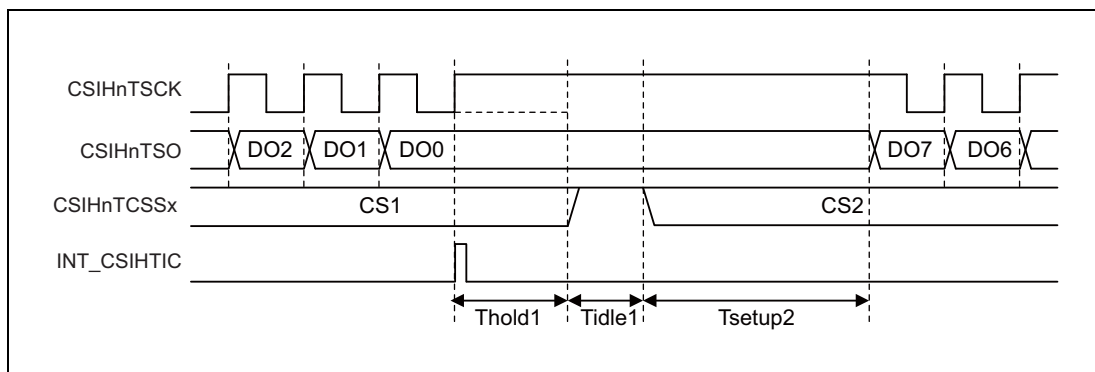

Figure 13.13 Data Phase Timing with CSIHnCFG1.CSIHnCKP1 = 1, CSIHnCFG1.CSIHnDAP1 = 0 and CSIHnCFG2.CSIHnCKP2 = 0, CSIHnCFG2.CSIHnDAP2 = 1

13.5.5 Transmission Clock Selection

In master mode, the transmission baud rate is selectable using the following bits:

- CSIHnCTL2.CSIHnPRS[2:0]
- CSIHnBRSi.CSIHnBRS[11:0]
- CSIHnCFGx.CSIHnBRSSx[1:0]

While the settings in the CSIHnCTL2.CSIHnPRS[2:0] and CSIHnBRSi.CSIHnBRS[11:0] determine the baud rate of the transmission clock CSIHnTSCK, SIHnCFGx.CSIHnBRSSx[1:0] allows to select a baud rate setting for each chip select signal from the four settings of CSIHnBRS3 to CSIHnBRS0.

The following figure shows a block diagram of the baud rate generator.

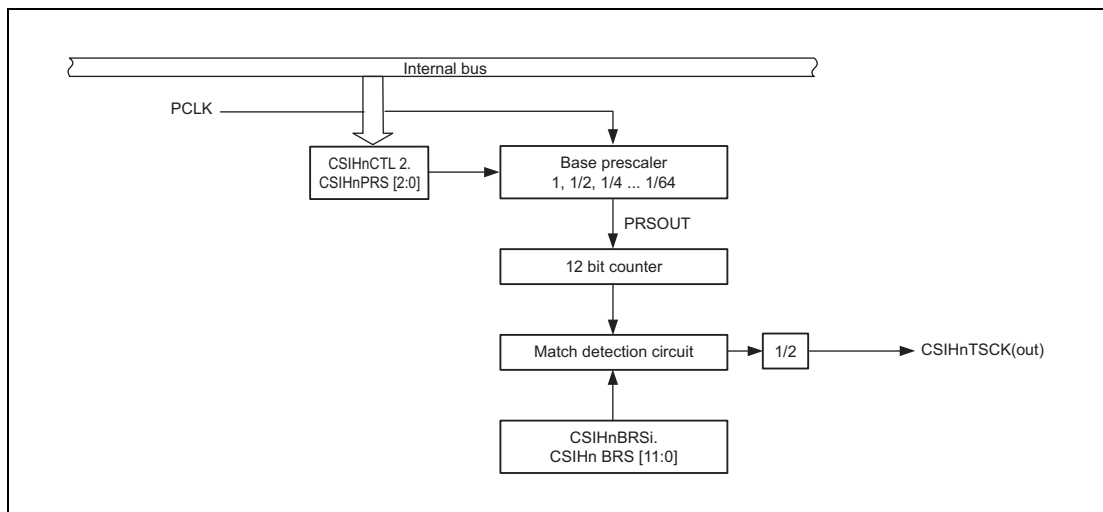

Figure 13.14 Baud Rate Generator Block Diagram

Setting CSIH0BRS[3:0].CSIHnBRS[11:0] to 000_H disables the baud rate generator, and thus all CSIHnTSCK are stopped.

Baud rate calculation

The baud rate is calculated as:

$$\text{CSIHnTSCk} = \text{PCLK} / (2^m \times k \times 2)$$

Where

$$m = \text{CSIHnCTL2.CSIHnPRS}[2:0] = 0 \text{ to } 6$$

$$k = \text{CSIH0BRSSx} (x = 0 \text{ to } 3).\text{CSIHBRS0} \text{ 11 - 0} = 1 \text{ to } 4095$$

(when CSIH0BRSS1 - 0 = 0)

$$\text{CSIH0BRSSx} (x = 0 \text{ to } 3).\text{CSIHBRS1} \text{ 11 - 0} = 1 \text{ to } 4095$$

(when CSIH0BRSS1 - 0 = 1)

$$\text{CSIH0BRSSx} (x = 0 \text{ to } 3).\text{CSIHBRS2} \text{ 11 - 0} = 1 \text{ to } 4095$$

(when CSIH0BRSS1 - 0 = 2)

$$\text{CSIH0BRSSx} (x = 0 \text{ to } 3).\text{CSIHBRS3} \text{ 11 - 0} = 1 \text{ to } 4095$$

(when CSIH0BRSS1 - 0 = 3)

Baud rate limits

When setting the baud rate, please note:

- Maximum acceptable baud rate in master mode is PCLK/8.
- Maximum acceptable baud rate in slave mode is PCLK/20 (must be ensured by the external master).
- Minimum baud rate in both modes is PCLK/524160.

Example

If PCLK = 80 MHz, the maximum baud rate is as follows:

- 10 Mbps (PCLK/8) in master mode
- 4 Mbps (PCLK/20) in slave mode

The minimum baud rate is 152.625 bps (PCLK/524160).

13.5.6 Data transfer modes

(1) Transmit-only mode

Setting CSIHnCTL0.CSIHnTXE = 1 and CSIHnCTL0.CSIHnRXE = 0 puts the CSIH in transmit-only mode.

- Transmission starts when transmit data is written to the CSIHnTX0W or CSIHnTX0H register.

(2) Receive-only mode

Setting CSIHnCTL0.CSIHnTXE = 0 and CSIHnCTL0.CSIHnRXE = 1 puts the CSIH in receive-only mode.

- Reception starts when dummy data is written in the CSIHnTX0W or CSIHnTX0H register.

In slave mode, reception starts as soon as the CSIHnTSCK transmission clock from the master is received. It is not necessary to write data to the CSIHnTX0W or CSIHnTX0H register of the slave.

(3) Transmit/receive mode

Setting CSIHnCTL0.CSIHnTXE = 1 and CSIHnCTL0.CSIHnRXE = 1 puts the CSIH in transmit/receive mode.

- Communication starts when transmit data is written to the CSIHnTX0W or CSIHnTX0H register.

(4) Summary

The following table summarizes this section. It shows how data transfer is started in operating and transfer modes.

Table 13.7 Start of Data Transfer

Operating mode	Transfer mode	
	Transmit-only Transmit/receive	Receive-only
Direct access	Master	Writing to the CSIHnTX0W register or the CSIHnTX0H register
	Slave	Incoming clock from the master

13.5.7 Data Length Selection

(1) Data length between 2 and 16 bits

The length of a data packet is selectable for each chip select signal from 2 to 16 bits using $CSIHnCFGx.CSIHnDLSx[3:0]$. The examples below show the communication with MSB first ($CSIHnCFGx.CSIHnDIRx = 0$).

Data length = 16 bits ($CSIHnCFGx.CSIHnDLSx[3:0] = 0000_B$)

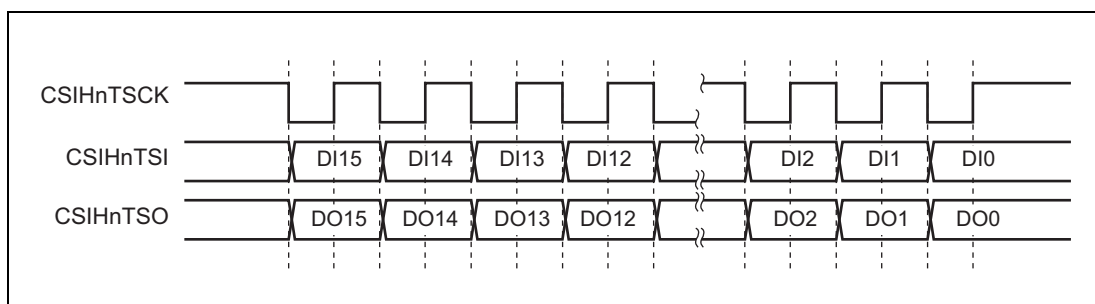

Figure 13.15 16 Bit Data Length, MSB First

Data length = 14 bits ($CSIHnCFGx.CSIHnDLSx[3:0] = 1110_B$):

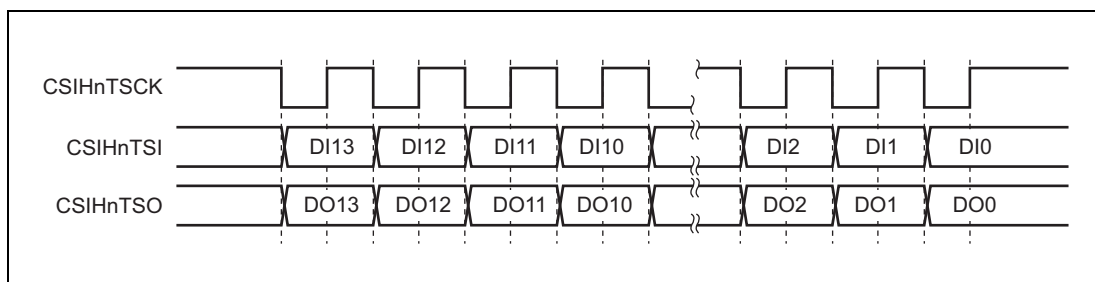

Figure 13.16 14 Bit Data Length, MSB First

(2) Data length greater than 16 bits

If the data to be sent/received exceeds 16 bits, the extended data length (EDL) feature can be used.

The EDL function is enabled by setting the `CSIHnCTL1.CSIHnEDLE` bit to 1.

The EDL function works as follows:

- The data has to be broken into 16-bit blocks plus remainder. For example, data of 42 bits would be broken into two 16-bit blocks plus 10 bits.
- The bit length of the remainder is set in `CSIHnCFGx.CSIHnDLSx[3:0]` as data length.
- For transmitting the 16-bit blocks, `CSIHnTX0W.CSIHnEDL` must be set to 1. In this case, the data written to `CSIHnTX0W` is sent as a 16-bit data length regardless of the `CSIHnCFGx.CSIHnDLSx[3:0]` bit setting.
- The transfer is complete after a block with the specified data length (the remainder of data specified with `CSIHnTX0W.CSIHnEDL = 0`) has been sent.

Example

Example for sending 40-bit data (123456789A_H) to CS0:

40 bits are split into two 16-bit blocks plus 8 bits.

- Initialize `CSIHnCFG0.CSIHnDLS0[3:0] = 8`.
- To send 123456789A_H with MSB first, write the following sequence to `CSIHnTX0W`:
 - 20FE 1234_H (`CSIHnTX0W.CSIHnEDL = 1`)
 - 20FE 5678_H (`CSIHnTX0W.CSIHnEDL = 1`)
 - 00FE 009A_H (`CSIHnTX0W.CSIHnEDL = 0`)

The following figure illustrates the timing.

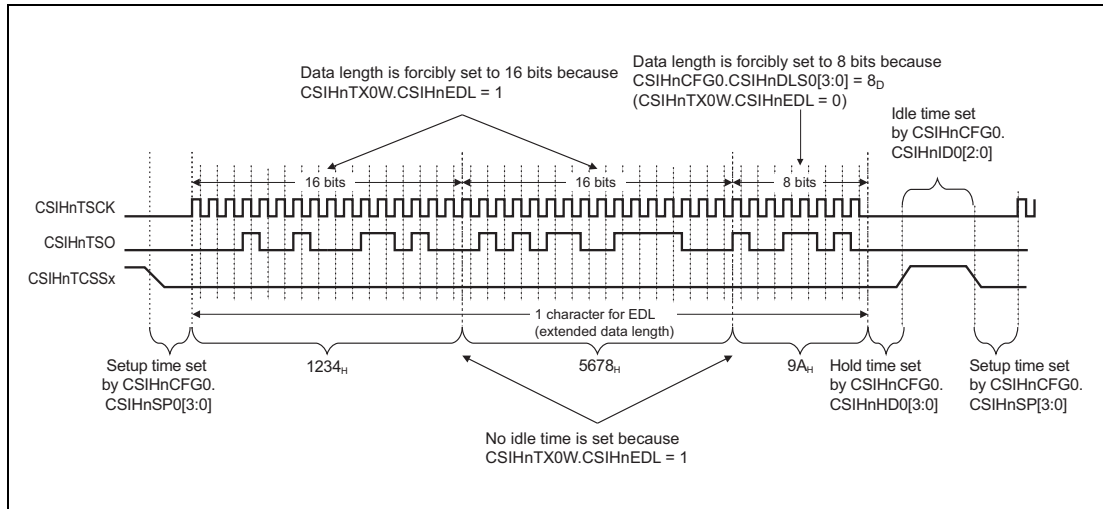

Figure 13.17 EDL Timing Diagram

NOTES

1. If parity is enabled, the parity bit is added after the last bit.
2. When extended data length (EDL) mode is used for transmission, use the same chip select signal.
3. To consider the data direction, pay attention to the following example:

Data to be sent: 123456_H

MSB first:

Set CSIHnCFGx.CSIHnDIRx = 0

Write CSIHnTX0W = 2000 1234_H (EDL bit = 1)

Write CSIHnTX0W = 0000 0056_H (EDL bit = 0)

LSB first:

Set CSIHnCFGx.CSIHnDIRx = 1

Write CSIHnTX0W = 2000 3456_H (EDL bit = 1)

Write CSIHnTX0W = 0000 0012_H (EDL bit = 0)

4. When EDL is enabled in job mode (CSIHnCTL1.CSIHnJE = 1 and CSIHnCTL1.CSIHnEDLE = 1), operation is not guaranteed if CSIHnTX0W.CSIHnEOJ is set to 1 while CSIHnTX0W.CSIHnEDL remains 1.

5. EDL mode cannot be used in receive-only mode in slave mode. (CSIHnCTL2.CSIHnPRS[2:0] = 111_B, CSIHnCTL0.CSIHnTXE = 0, CSIHnCTL0.CSIHnRXE = 1)

13.5.8 Serial Data Direction Selection

The serial data direction is selectable for each chip select signal using the CSIHnDIRx bit in the CSIHnCFGx register.

The examples below show communication for a data length of 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B).

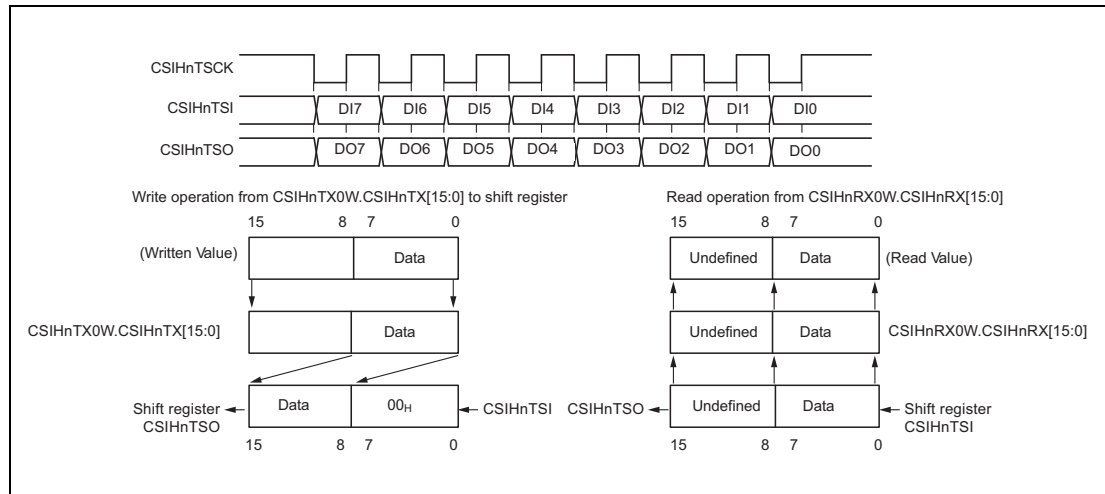

Figure 13.18 Serial Data Direction Select Function - MSB First (CSIHnDIRx = 0)

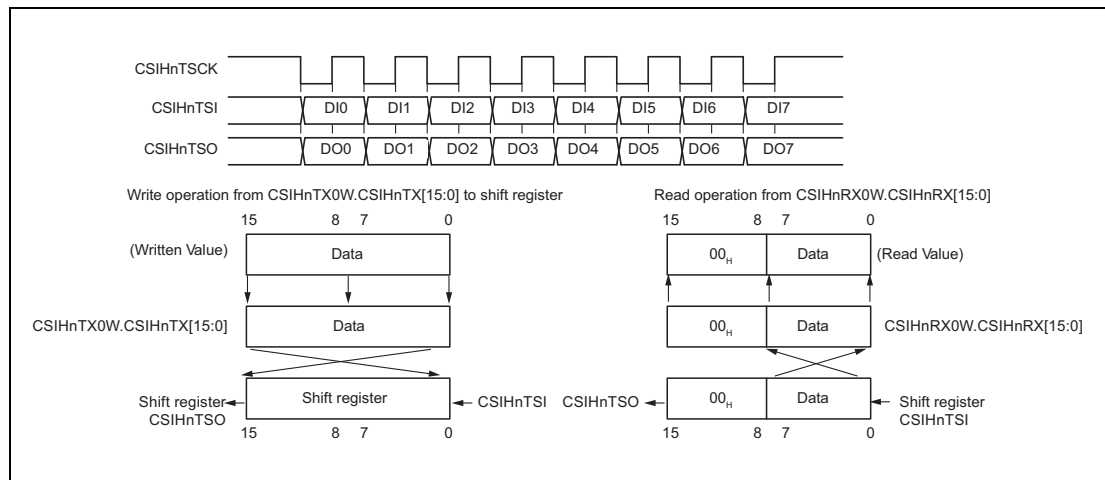

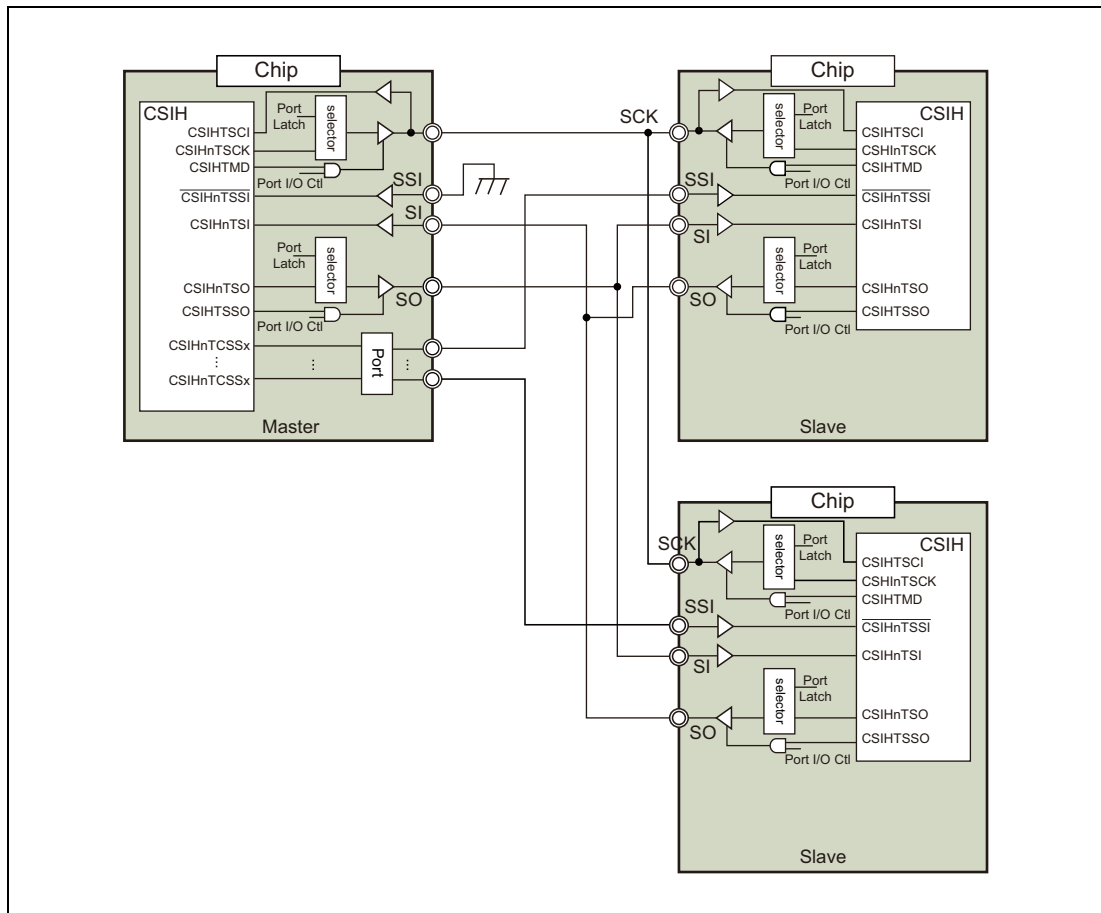

Figure 13.19 Serial Data Direction Select Function - LSB First (CSIHnDIRx = 1)

13.5.9 Communication in Slave Mode

(1) System outline

By the slave select function, the CSIH can realize one master and multiple slaves communication. The master chip outputs slave select signal (CSIHnTCSSx) to one of the slave chip. Each slave chip judges itself whether own CSIH is selected target slave or not. If selected, slave chip should control I/O function of SO pin to be an output pin. Then the slave chip can send transmission data to the master chip. If it is not selected as slave chip, SO pin should be an input function to avoid conflict of SO output from other selected slave chip. And also, not selected slave chip doesn't receive any data even if serial clock comes from master chip. By connecting master chip SI pin and multiple SO pins of all slave chips on a board, one master and multiple slaves communication can be realized. Putting level hold circuit to this serial data line is recommended.

(2) Communication timing

The following figure illustrates the communication signals and timings in slave mode.

In slave mode, the data transfer configuration is determined by the CSIHnCFG0 register.

Figure 13.20 Transmit/Receive Communication Timing in Slave Mode

- (1) CSIH is put into slave mode by setting $\text{CSIHnCTL2.CSIHnPRS}[2:0] = 111_B$. $\text{CSIHnCFG0.CSIHnCKP0}$ and $\text{CSIHnCFG0.CSIHnDAP0}$ are 0.
- (2) The data length is 8 bits ($\text{CSIHnCFG0.CSIHnDLS0}[3:0] = 1000_B$). The data direction is MSB first ($\text{CSIHnCFG0.CSIHnDIR0} = 0$).
- (3) Transmit/receive mode is set ($\text{CSIHnCTL0.CSIHnCSIHnPWR} = 1$, $\text{CSIHnCTL0.CSIHnTXE} = 1$, $\text{CSIHnCTL0.CSIHnRXE} = 1$). Communication start is permitted.
- (4) The transfer status flag $\text{CSIHnSTR0.CSIHnTSF}$ is automatically set when transfer data is written to the CSIHnTX0W or CSIHnTX0H transmission register.
- (5) As long as signal $\overline{\text{CSIHnTSSI}}$ is high, transmission/reception is not started, even if an external transmission clock CSIHnTSCK is applied. Input at CSIHnTSI is ignored.
- (6) When $\overline{\text{CSIHnTSSI}}$ falls to low level, indicating that CSIHnTSO is enabled, transmission is enabled.
- (7) On detection of the external clock signal CSIHnTSCK , the slave transmits data to CSIHnTSO and simultaneously captures data from CSIHnTSI .
- (8) Interrupt INT_CSIHTIR indicates when the reception is complete. The CSIHnRX0W/H register can be read.

(3) Operation of CSIHTSSO

CSIHnPWR	CSIHnTXE	CSIHnRXE	CSIHnSSE	CSIHTSSO
0	—	—	—	H
1	—	—	0	H
	0		1	H
	1		1	Inverse of CSIHnTSSI level

The CSIHTSSO signal is a signal to control the I/O function of the CSIHnTSSO pin in case of using the slave select function.

The CSIHnTSSO pin is enabled when the CSIHTSSO signal is “High” (the CSIHnTSSO pin is being driven).

The CSIHnTSSO pin is disabled when the CSIHTSSO signal is “Low” (the CSIHnTSSO pin is not being driven).

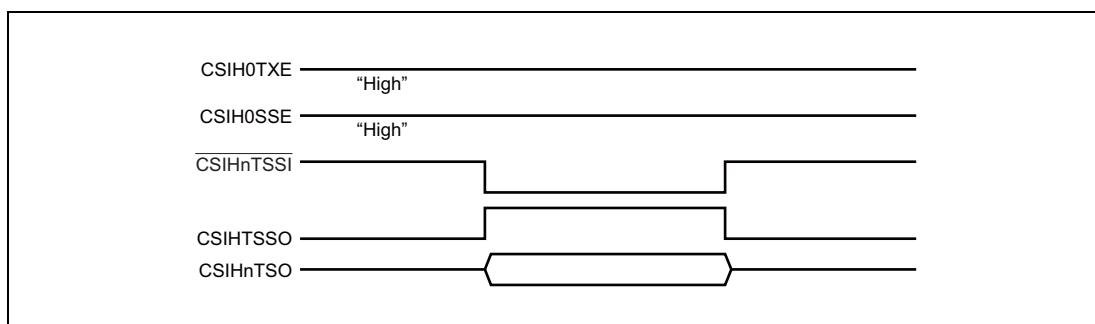

Figure 13.21 Operation of CSIHTSSO

CAUTION

If CSIHnTSSI pin is changed during communication (CSIH0STR0.CSIH0TSF = 1), current communication is not assured.

13.5.10 CSIH interrupt requests

CSIH can generate the following interrupt requests:

- INT_CSIHTIC (communication status interrupt)
- INT_CSIHTIR (reception status interrupt)
- INT_CSIHTIRE (communication error interrupt)
- INT_CSIHTIJC (job completion interrupt)

(1) Overview

The error interrupt INT_CSIHTIRE is generated when an error is detected. The generation of the other interrupts depends on the job mode, and – in case of the job completion interrupt INT_CSIHTIJC – also the operating mode.

The job completion interrupt INT_CSIHTIJC is only generated when job mode is enabled (CSIHnCTL1.CSIHnJE = 1). It is not available in slave mode.

The following table gives an overview.

Table 13.8 Interrupt Generation

Mode	Interrupt	Cause of interrupt	
		Job mode disabled CSIHnCTL1.CSIHnJE = 0	Job mode enabled CSIHnCTL1.CSIHnJE = 1
Direct access	INT_CSIHTIC (communication status interrupt)	Single data transfer	Single data transfer (except for job abortion*2)
	INT_CSIHTIR (reception status interrupt)	Data received and CSIHnCTL0.CSIHnRXE = 1	Data received <i>and</i> CSIHnCTL0.CSIHnRXE = 1
	INT_CSIHTIRE (communication error interrupt)	Error detected	Error detected
	INT_CSIHTIJC*1 (job completion interrupt)	Not applicable	Job abortion*2

Note 1. INT_CSIHTIJC is not available in slave mode.

Note 2. Job abortion condition: CSIHnTX0W.CSIHnEOJ = 1 and CSIHnCTL0.CSIHnJOBE = 1

(2) Interrupt delay

In master mode, all interrupts generated by the master can be delayed by one half period of the transmission clock, CSIHnTSCK. This is not possible in slave mode.

The delay is specified by setting CSIHnCTL1.CSIHnSIT = 1.

The following example illustrates the interrupt delay function, assuming a setting of CSIHnCTL1.CSIHnSIT = 1 (interrupt delay enabled), CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0 (normal clock and data phase), and CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B (data length 8 bits).

Figure 13.22 Interrupt Delay Function (CSIHnCTL1.CSIHnSIT = 1)

Setting CSIHnCTL1.CSIHnSIT = 1 adds half period delay to the transmission clock. This delays also the end of the present chip select signal (CSIHnTCSSx).

(3) INT_CSIHTIC (communication status interrupt)

Depending on the job mode, this interrupt is generated according to the conditions shown in the following table.

Table 13.9 INT_CSIHTIC Interrupt Generation

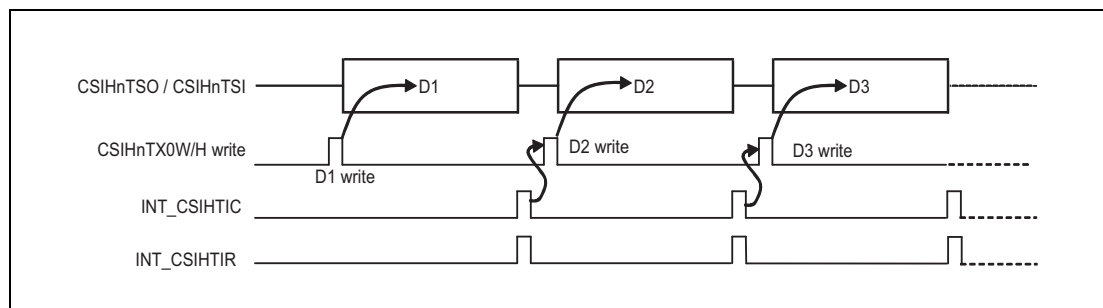

Memory mode	Cause of interrupt	
	Job mode disabled CSIHnCTL1.CSIHnJE = 0	Job mode enabled CSIHnCTL1.CSIHnJE = 1
Direct access	Generated after every data transfer.	Generated after every data transfer, except when the communication was aborted.

INT_CSIHTIC in direct access mode

The examples below show the INT_CSIHTIC behavior in direct access mode.

The examples assume:

- Master mode
- Direct access mode
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Normal clock and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- Data length 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Normal INT_CSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

**Figure 13.23 Generation of INT_CSIHTIC after Transfer (CSIHnCTL1.CSIHnSLIT = 0)**

If job mode is enabled (CSIHnCTL1.CSIHnJE = 1) and a job ends because data is sent with CSIHnTX0W.CSIHnEOJ = 1 and communication stop is requested (CSIHnCTL0.CSIHnJOBE = 1), then INT_CSIHTIC is replaced by the job completion interrupt INT_CSIHTIC.

INT_CSIHTIC can also be set up to occur as soon as the CSIHnTX0W/H register is free for the next data. This is specified by setting CSIHnCTL1.CSIHnSLIT = 1.

The effect is illustrated in the figure below.

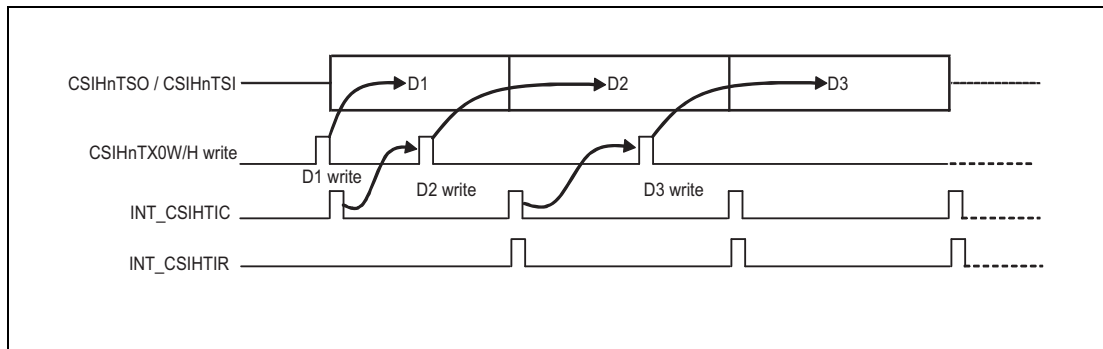

Figure 13.24 Immediate Generation of INT_CSIHTIC (CSIHnCTL1.CSIHnSLIT = 1)

Thus, the new data can be written in advance.

CAUTION

This mode allows faster data transfer but is only available in direct access mode.

INT_CSIHTIC in job mode

The example below shows the INT_CSIHTIC behavior in job mode.

The example assumes:

- Master mode
- Job mode enabled (CSIHnCTL1.CSIHnJE = 1)
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Normal clock and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- Data length 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)
- Normal INT_CSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)

Figure 13.25 Generation of INT_CSIHTIC in Job Mode

The rules for generating INT_CSIHTIC in job mode are shown in the following table.

Table 13.10 Generation of INT_CSIHTIC in Job Mode

CSIHnTX0W. CSIHnEOJ	INT_CSIHTIC
0	Not generated
0	Generated
1	Not generated
1	CSIHnCTL0.CSIHnJOBE = 0: Generated
	CSIHnCTL0.CSIHnJOBE = 1: Not generated, replaced by interrupt INT_CSIHTIJC

(4) INT_CSIHTIR (reception status interrupt)

This interrupt is generated according to the conditions below.

Table 13.11 INT_CSIHTIR Interrupt Generation

Mode	Cause of interrupt	
	Job mode disabled CSIHnCTL1.CSIHnJE = 0	Job mode enabled CSIHnCTL1.CSIHnJE = 1
Direct access	Generated after every data transfer.	

INT_CSIHTIR in direct access mode

The example below shows the INT_CSIHTIR behavior in direct access mode.

The example below assumes:

- Master mode
- Direct access mode
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Normal clock and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSHnCFGx.CSIHnDAPx = 0)
- Data length 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B)

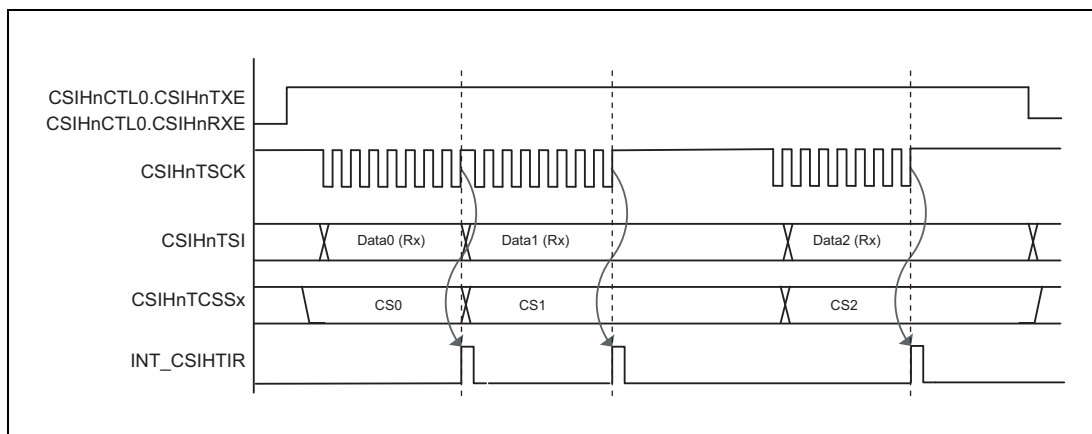

Figure 13.26 Generation of INT_CSIHTIR in Direct Access Memory Mode

(5) INT_CSIHTIRE (communication error interrupt)

This interrupt is generated whenever an error is detected.

For details about generation interruption timing, see **Section 13.5.12, Error Detection**.

Table 13.12 Data Error Types

Error type	Communication status after error interrupt	Comment
Parity error	Interrupt is generated and communication continues	—
Data consistency error	Interrupt is generated and communication continues	—
Overrun error	Interrupt is generated and communication continues	This error interrupt is only generated when CSIHnCTL1.CSIHnHSE = 0 (without handshake) in slave mode.

The type of error that caused the generation of INT_CSIHTIRE is flagged in register CSIHnSTR0.

Additionally a parity error flag and a data consistency error flag are attached to the received data in CSIHnRX0W.

For details about the various error types, see **Section 13.5.12, Error Detection**.

(6) INT_CSIHTIJC (job completion interrupt)

This interrupt supports the handling of jobs. See **Section 13.5.3 (3), Job concept**. This interrupt is only available in master mode.

Job mode is enabled by setting CSIHnCTL1.CSIHnJE = 1. When CSIHnCTL1.CSIHnJE = 0, INT_CSIHTIJC is not generated.

This interrupt is generated according to the condition shown in the following table.

Table 13.13 INT_CSIHTIJC Interrupt Generation

Mode	Interrupt Sources	
	Job mode disabled CSIHnCTL1.CSIHnJE = 0	Job mode enabled CSIHnCTL1.CSIHnJE = 1
Direct access	Not applicable	Indicates that the communication has stopped at the end of a job after a job abortion* ¹ was triggered

Note 1. Job abortion condition: CSIHnTX0W.CSIHnEOJ = 1 and CSIHnCTL0.CSIHnJOBE = 1

13.5.11 Handshake function

CSIH features a handshake function to synchronize the master and the slave devices. This function can be enabled/disabled by the CSIHnCTL1.CSIHnHSE bit. For handshake, the CSIHnTRY signal is used. The busy timing depends on the setting of the data phase selection bit CSIHnCFGx.CSIHnDAPx.

(1) Slave mode

When CSIHnCTL1.CSIHnHSE = 1 and the slave is busy, the CSIHnTRY signal outputs low level (0). This can happen in the following case:

Case 1: When transmission is not ready (no next transmission data)

Case 2: When reception register is full:

Because the slave is in receive-only or transmit/receive mode but previously received data is still in the CSIHnRX0W/H register, new data cannot be copied from the shift register to CSIHnRX0W/H (CSIHnRX0W/H full condition).

The data length of 8 bits is assumed in the following example.

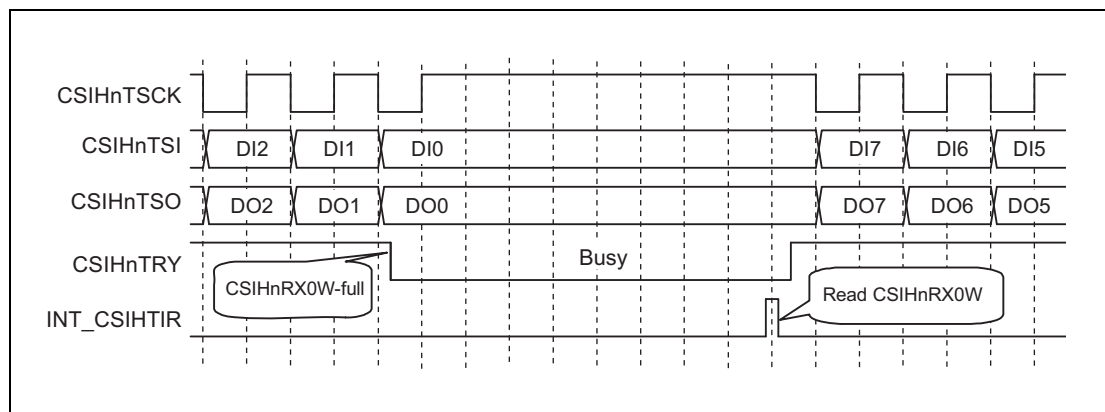

Figure 13.27 Busy Signal from the Slave (Direct Access Mode; CSIHnCFGx.CSIHnDAPx = 0)

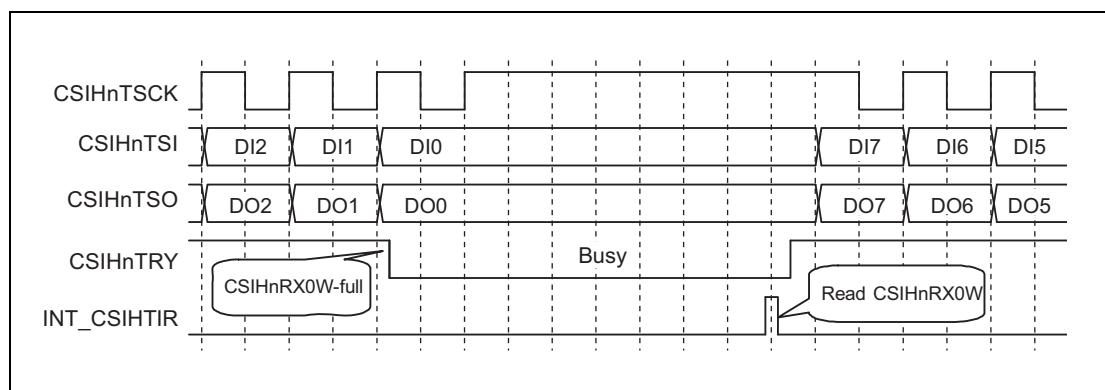

Figure 13.28 Busy Signal from the Slave (CSIHnCFGx.CSIHnDAPx = 1)

(2) Master mode

When the master detects CSIHnTRY being 0 while CSIHnCTL1.CSIHnHSE is 1, the subsequent transfer is put on hold and the master enters the waiting state. It suspends the CSIHnTSCK clock.

The CSIHnTRY level is checked at each half clock cycle of CSIHnTSCK.

The chip select signal is output during the waiting state.

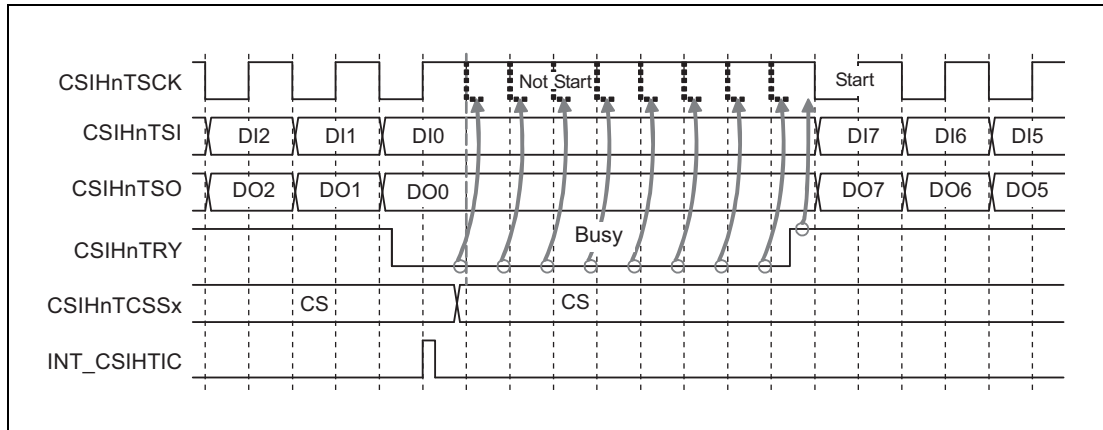

Figure 13.29 Master’s Reaction on CSIHnTRY (CSIHnCFGx.CSIHnDAPx = 0)

CSIHnTRYI must be pulled down by the slave before the next transfer starts. When the slave changes the CSIHnTRYI signal to low level during data transfer, the serial clock from the master stops at the completion of data transfer.

The master resumes the communication as soon as CSIHnTRY becomes high level (the slave is “ready”).

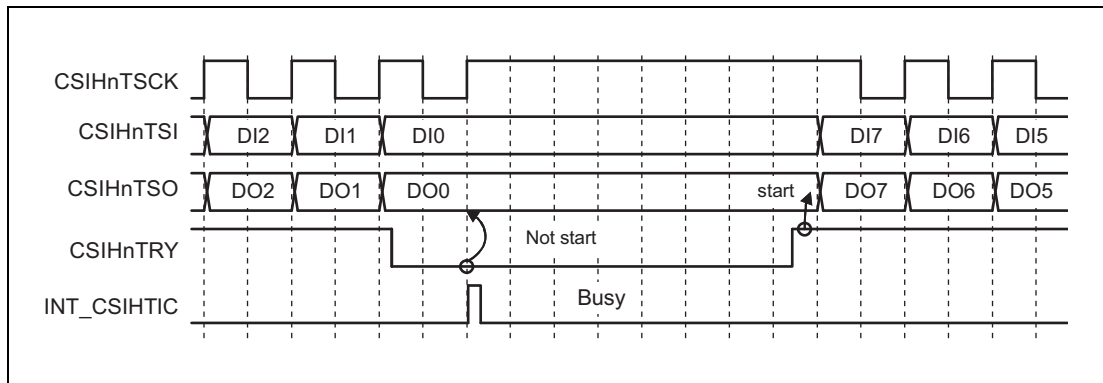

Figure 13.30 Master’s Reaction on CSIHnTRY (CSIHnCFGx.CSIHnDAPx = 1)

CAUTIONS

1. If multiple slaves are connected, the master must only detect the CSIHnTRY signal of the slave it has selected for communication.
2. Even when the slave changes the CSIHnTRY signal to low level during a transmission, the transmitting operation is continued until its successful completion.

13.5.12 Error Detection

CSIH can detect three error types:

- Data consistency error (transmission data)
- Parity error (received data)
- Overrun error (received data)

Check for parity and data consistency can be enabled/disabled individually.

If one of these errors is detected, the interrupt request, INT_CSIHTIRE is generated and the corresponding flags are set.

(1) Data consistency check

The purpose of the data consistency check is to ensure that the data physically sent as output signal is identical to the original data that was copied to the shift register.

The data consistency check can be enabled/disabled by the CSIHnCTL1.CSIHnDCS bit. It is not active if data transmission is disabled (CSIHnCTL0.CSIHnTXE = 0).

When the data consistency check is active, the data transferred from CSIHnTX0W or CSIHnTX0H to the shift register is copied to a separate register. In addition, the physical levels at CSIHnTSO are read back via the CSIHTDCS signal into an own shift register.

After completion of the transmission, the sent data is compared with the original transmission data.

Mismatch is considered as a data consistency error:

- Interrupt INT_CSIHTIRE is generated.
- The CSIHnSTR0.CSIHnDCE bit is set.

Additionally, CSIHnRX0W.CSIHnTDCE bit of data that contains the error is set.

The data consistency check function is illustrated in the following block diagram.

Figure 13.31 Data Consistency Check Functional Block Diagram

(2) Parity check

CSIH can append a parity bit to the last data bit (even if extended data length is used).

The use and type of parity is specified in `CSIHnCFGx.CSIHnPSx[1:0]`.

Parity check is enabled if `CSIHnCFGx.CSIHnPSx[1] = 1`.

The parity bit is checked after a reception is complete. In case of parity error:

- Interrupt `INT_CSIHTIRE` is generated.
- The `CSIHnSTR0.CSIHnPE` bit is set.

Additionally, `CSIHnRX0W.CSIHnRPE` of data that contains the error is set.

The figure below shows an example.

- Data length is 8 bits.
- The data to be transmitted is `05H` and `35H`.
- Data direction is LSB first.
- Parity type is odd.

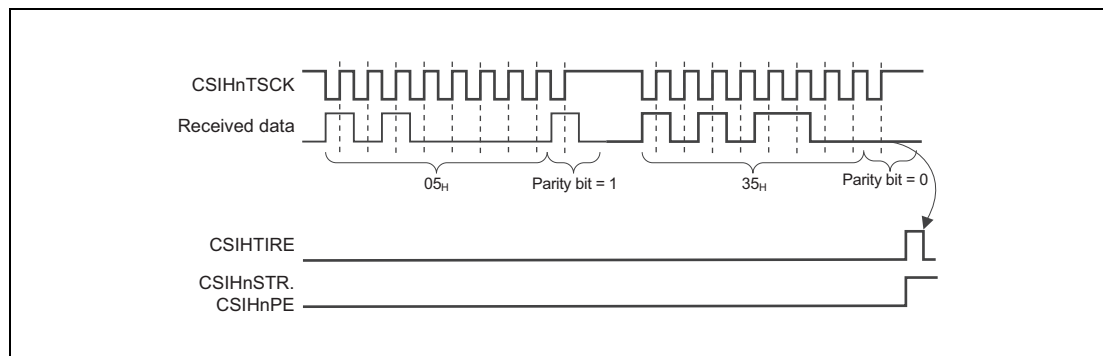

Figure 13.32 Parity Check Example

The parity bit of the first data is 1. There is no parity error, because the total number of ones (including the parity bit) is odd.

The parity bit of the second data is 0. This is detected as a parity error, because the total number of ones (including the parity bit) is even.

If the EDL (extended data length) function is used, the parity bit is added after the last bit of the data.

(3) Overrun error

An overrun error can happen in direct access mode. The overrun error is not generated if data reception is disabled ($\text{CSIHnCTL0.CSIHnRXE} = 0$).

Direct access

In direct access mode, this error occurs when newly received data cannot be transferred from the shift register to the reception register CSIHnRX0W/H . This happens when CSIHnRX0W/H was not read and therefore contains previous reception data.

The following figure illustrates the function.

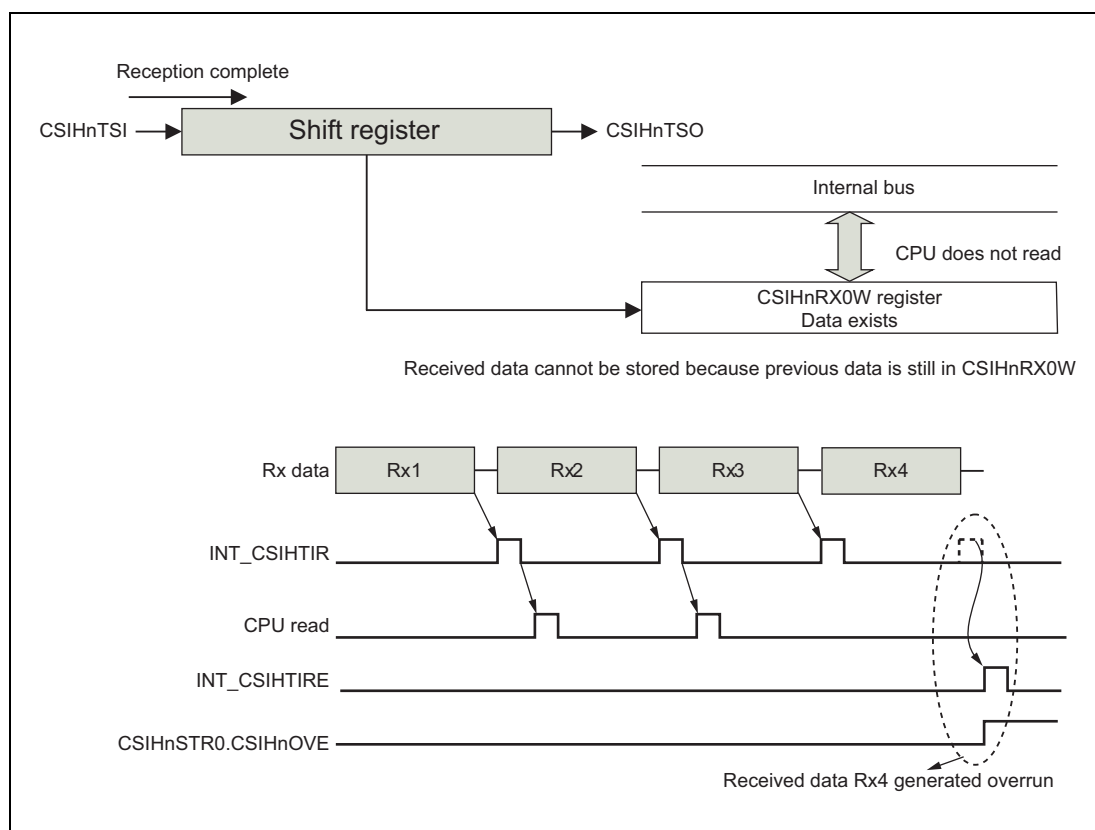

Figure 13.33 Overrun Error Detection in Direct Access

An overrun error causes the following incidents.

- INT_CSIHTIRE interrupt is generated instead of INT_CSIHTIR interrupt
- $\text{CSIHnSTR0.CSIHnOVE}$ bit is set
- CSIHnRX0W is rewritten by the received data

NOTE

In slave mode, overrun errors can be avoided by using handshake function. When handshaking is used in slave mode, the receiver (slave) signals the transmitter (master) that the receiver is busy. The transmitter waits until the receiver reads its own register and is ready again.

For details, see **Section 13.5.11, Handshake function**.

13.5.13 Loop-Back Mode

Loop-back mode is a special mode for self-test. This feature is only available in master mode.

When this mode is active (CSIHnCTL1.CSIHnLBM = 1), CSIHnTCSSx is fixed inactive level (the active level is defined by the value of CSIHnCTL1.CSIH0CSLx), and the transmit and receive signals are internally connected, as shown in the figures below. The signals CSIHnTSCK, CSIHnTSO, CSIHnTSI and CSIHnTCSSx are disconnected from the ports. In addition, the CSIHnTSO output level is fixed to low, and CSIHnTSCK is set to the reset level (high) regardless of the value of CSIHnCFGx.CSIHnCKPx register. The rest of CSIH works as in normal operation.

In order to test CSIH, put it in loop-back mode and carry out normal transfer operations. Then check that the received data is the same as the transmitted data.

A loopback test does not affect the destination to which the device is connected.

Table 13.14 Pin Output Level in Loopback Mode

Pin Name	Output Level
CSIHnTSCK(out)	High level
CSIHnTCSSx	Inactive level
CSIHnTSO	Low level (does not depend on the previous values)
Interrupt	Normal function
CSIHnTRY	Normal function (low level)

Figure 13.34 Normal Operation

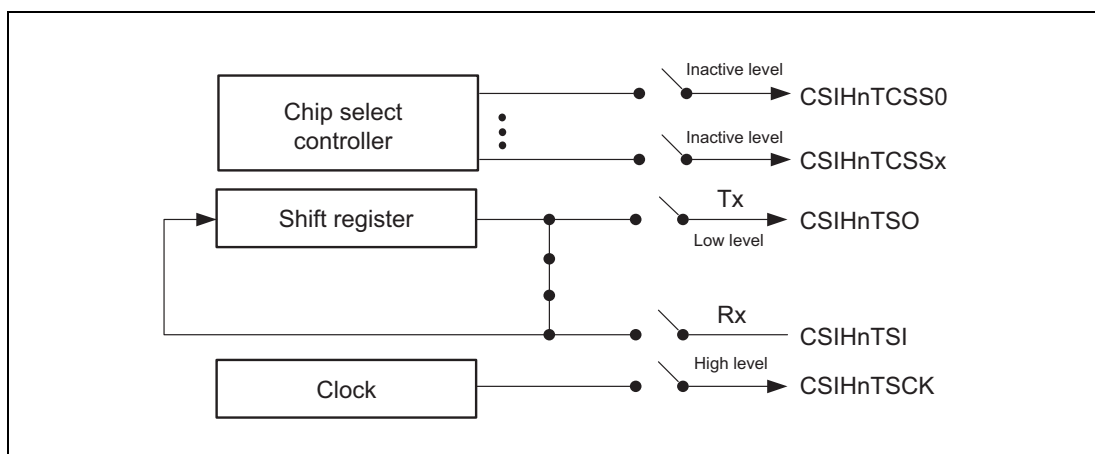

Figure 13.35 Operation in Loop-Back Mode

13.5.14 Enforced Chip Select Idle Setting

The CSIH is able to insert an idle state between the two consecutive transfer data by the setting of CSIHnCFGx.CSIHnIDLx (x: Chip select signal x). Detail is as follows.

1. When CSIHnCFGx.CSIHnIDLx = 0
 - If the setting of CSIHnTCSSx for a next transfer data is the same as that for the previous one, an idle state is not inserted and an inter-data time is inserted.
 - If the setting of CSIHnTCSSx for a next transfer data is different from the previous one, an idle state is inserted.
2. When CSIHnCFGx.CSIHnIDLx = 1
 - An idle state is always inserted even if the setting of CSIHnTCSSx for a next transfer data is the same as that for the previous one.

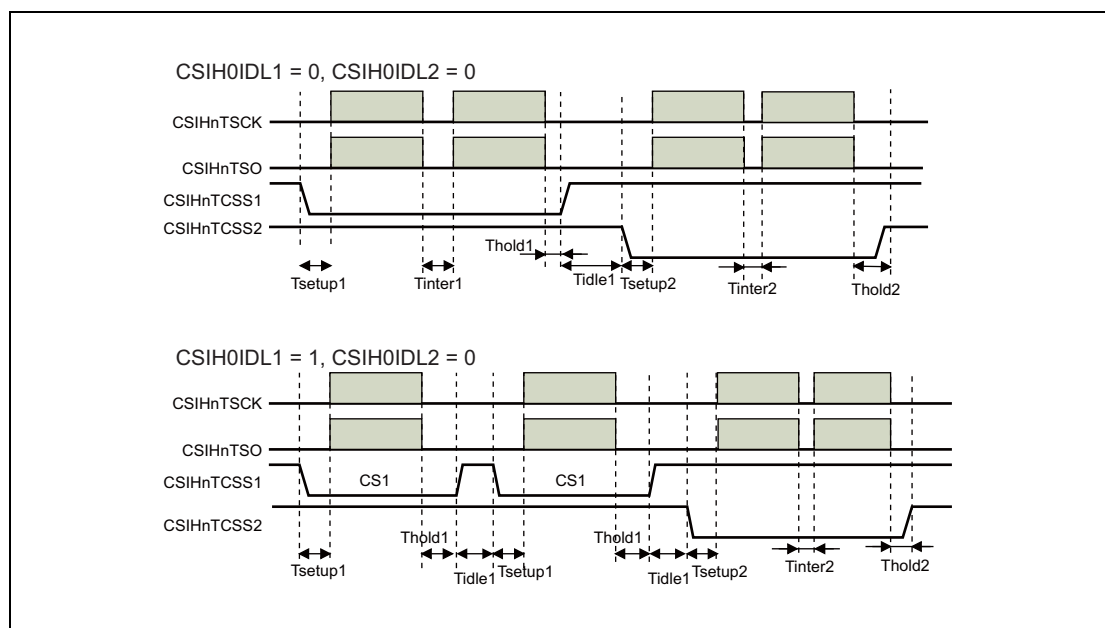

Figure 13.36 Enforced Chip Select Idle Example

13.6 CSIH Control Registers

CSIHn is controlled and operated by means of the registers in the following table.

Table 13.15 CSIH Register Overview

Register name	Shortcut	Address
CSIH control register 0	CSIHnCTL0	<CSIHn_base> + 0000 _H
CSIH control register 1	CSIHnCTL1	<CSIHn_base> + 0010 _H
CSIH control register 2	CSIHnCTL2	<CSIHn_base> + 0014 _H
CSIH status register 0	CSIHnSTR0	<CSIHn_base> + 0004 _H
CSIH status clear register 0	CSIHnSTCR0	<CSIHn_base> + 0008 _H
CSIH configuration register 0	CSIHnCFG0	<CSIHn_base> + 1044 _H
CSIH configuration register 1	CSIHnCFG1	<CSIHn_base> + 1048 _H
CSIH configuration register 2	CSIHnCFG2	<CSIHn_base> + 104C _H
CSIH configuration register 3	CSIHnCFG3	<CSIHn_base> + 1050 _H
CSIH configuration register 4	CSIHnCFG4	<CSIHn_base> + 1054 _H
CSIH configuration register 5	CSIHnCFG5	<CSIHn_base> + 1058 _H
CSIH transmit data register 0 for word access	CSIHnTX0W	<CSIHn_base> + 1008 _H
CSIH transmit data register 0 for half word access	CSIHnTX0H	<CSIHn_base> + 100C _H
CSIH receive data register 0 for word access	CSIHnRX0W	<CSIHn_base> + 1010 _H
CSIH receive data register 0 for half word access	CSIHnRX0H	<CSIHn_base> + 1014 _H
CSIHn baud rate setting register 0	CSIHnBRS0	<CSIHn_base> + 1068 _H
CSIHn baud rate setting register 1	CSIHnBRS1	<CSIHn_base> + 106C _H
CSIHn baud rate setting register 2	CSIHnBRS2	<CSIHn_base> + 1070 _H
CSIHn baud rate setting register 3	CSIHnBRS3	<CSIHn_base> + 1074 _H

<CSIHn_base>

The base addresses <CSIHn_base> of the CSIHn are defined in the first part of this section under the key word “Register addresses”.

13.6.1 CSIHnCTL0 — CSIH Control Register 0

This register controls the operation clock and enables/disables transmission/reception and the memory part for transmission and/or reception. It forces the stop of communication at the end of the current job.

Access: This register can be read/written in 8-bit or 1-bit units.

Address: <CSIHn_base> + 0000_H

Value after reset: 00_H This register is initialized by reset operation.

Bit	7	6	5	4	3	2	1	0
	CSIHnPWR	CSIHnTXE	CSIHnRXE	—	—	—	CSIHnJOBE	CSIHnMBS
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R	R	R	R/W	R/W

Table 13.16 CSIHnCTL0 Register Contents

Bit Position	Bit Name	Function
7	CSIHnPWR	Controls the operation clock. 0: Stops operation clock. 1: Provides operation clock. Clearing CSIHnPWR to 0 resets the internal circuits, stops operation, and sets CSIH to standby state. No clock is provided to internal circuits. If CSIHnPWR is cleared during communication, ongoing communication is immediately aborted. In this case, communication setting must be started over.
6	CSIHnTXE	Permits or prohibits transmission. 0: Prohibits transmission. 1: Permits transmission.
5	CSIHnRXE	Permits or prohibits reception. 0: Prohibits reception. 1: Permits reception.
4 to 2	—	Reserved When writing, write the value after reset.
1	CSIHnJOBE	Stops communication at the end of the current job (Communication ends if data is written to the transmission buffer when CSIHnTX0W.CSIHnEOJ = 1 (job completion)): 0: Communication stop is not requested. 1: Stops communication. This bit can be used to abort an ongoing job. This bit is cleared to 0 automatically. If this bit is set to 1, the read value is always 0.
0	CSIHnMBS	Enables direct access mode. 0: CSIH transmit/receive operation is prohibited. 1: Direct access mode Write 1 in the CSIHnMBS bit for transmission/reception via the CSIH.

NOTES

- Do not modify any of CSIHnTXE, CSIHnRXE, CSIHnJOBE, and CSIHnMBS bits while CSIHnPWR = 0.
Do not modify the CSIHnMBS bit when CSIHnPWR = 1.
The CSIHnTXE, CSIHnRXE, and CSIHnMBS bits can be modified when the CSIHnPWR bit is changed from 0 to 1.
To change the CSIHnMBS bit, do so at the same time as when the CSIHnPWR bit is changed from 0 to 1.
- Do not modify CSIHnTXE, CSIHnRXE, or CSIHnMBS while data transmission is pending or going on, i.e. if CSIHnSTR0.CSIHnTSF = 1.

13.6.2 CSIHnCTL1 — CSIH Control Register 1

This register specifies the interrupt timing and the interrupt delay mode. It enables/disables extended data length control, data consistency check, loop-back mode, handshake functionality, and job mode. It selects the active output level of each chip select signal and the behavior of the chip select signals after the transfer of the final data.

Access: This register can be read/written in 32-bit units.

Address: <CSIHn_base> + 0010_H

Value after reset: 0000 0000_H This register is initialized by reset operation.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CAUTION

Changing the contents of this register is only permitted when CSIHnCTL0.CSIHnPWR = 0.

Table 13.17 CSIHnCTL1 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 18	—	Reserved The write value should be the initial value.
17	CSIHnCKR	CSIHnTSCK Clock Inverting Function 0: Default of CSIHnTSCK is high level. 1: Default of CSIHnTSCK is low level. For details, see Section 13.6.6, CSIHnCFGx — CSIH Configuration Register x .
<p>CAUTION</p> <p>Clear the CSIHnCKPx bit in CSIHnCFGx to 0 when this bit is used without the chip select function.</p>		
16	CSIHnSLIT	Selects the timing of interrupt INT_CSIHTIC. 0: Normal interrupt timing (interrupt is generated after the transfer) 1: As soon as the contents of the CSIHnTX0W/H register are transferred to the shift register, an interrupt is generated. For details, see Section 13.5.10, CSIH interrupt requests, (3) INT_CSIHTIC (communication status interrupt) .
15 to 8	CSIHnCSL[7:0]	Selects the active output level of chip select signal x (CSIHnTCSSx). (n = 0 to 7) 0: Chip select is active low. 1: Chip select is active high. For details, see Section 13.5.3, Chip Selection (CS) Features .

Table 13.17 CSIHnCTL1 Register Contents (2/2)

Bit Position	Bit Name	Function
7	CSIHnEDLE	Enables/disables extended data length (EDL) mode. 0: Disables extended data length mode. 1: Enables extended data length mode. For details, see Section 13.5.7, Data Length Selection, (2) Data length greater than 16 bits.
6	CSIHnJE	Enables/disables job mode. 0: Disables job mode. 1: Enables job mode. For details, see Section 13.5.3, Chip Selection (CS) Features, (3) Job concept. The CSIHnCTL0.CSIHnJOBE and CSIH0TX0W.CSIH0EOJ bits are enabled only when CSIHnJE = 1. Setting this bit in slave mode is prohibited. NOTE: When CSIHnJE = 0, interrupt INTC_CSIHnTIC is generated after one unit of data transmission is completed. When CSIHnJE = 1, interrupt INTC_CSIHnTIC is also generated after one unit of data transmission is completed. In the case of CSIHnTX0W.CSIHnEOJ = 1 and CSIHnCTL0.CSIHnJOBE = 1, however, interrupt INTC_CSIHnTIJC is generated instead of INTC_CSIHnTIC.
5	CSIHnDCS	Enables/disables data consistency check. 0: Disables data consistency check. 1: Enables data consistency check. For details, see Section 13.5.12, Error Detection, (1) Data consistency check.
4	CSIHnCSRI	Defines chip select signal behavior after last data transfer. 0: Chip select signal holds the active level. 1: Chip select signal returns to the inactive level. The last data is determined at the interrupt timing when CSIHnCTL1.CSIHnSLIT is 1.
3	CSIHnLBM	Controls loop-back mode (LBM). 0: Deactivates loop-back mode. 1: Activates loop-back mode. For details, see Section 13.5.13, Loop-Back Mode.
2	CSIHnSIT	Selects interrupt delay mode. 0: No delay is generated. 1: Half clock delay is generated for all interrupts. This bit is only valid in master mode. In slave mode, no delay is generated. For details, see Section 13.5.10, CSIH interrupt requests, (2) Interrupt delay.
1	CSIHnHSE	Enables/disables handshake function. 0: Disables the handshake function. 1: Enables the handshake function. For details refer to Section 13.5.11, Handshake function.
0	CSIHnSSE	Enables/disables the slave select function. 0: Input signal CSIHnTSSI is disabled. 1: Input signal CSIHnTSSI is recognized. If the slave select function is not used, this bit must be set to 0 (see also Section 13.5.2, Master/Slave Connections.)

Details about CSIHnCTL1.CSIHnSSE are shown in the following tables.

Table 13.18 Operation of the Slave Select Function During Reception

CSIHnCTL0. CSIHnRXE	CSIHnCTL1. CSIHnSSE	$\overline{\text{CSIHnTSSI}}$	Receive operation
0	—	—	Reception is prohibited
1	0	—	Possible
1	1	0	Possible
1	1	1	Disabled

CSIHnCTL0. CSIHnTXE	CSIHnCTL1. CSIHnSSE	$\overline{\text{CSIHnTSSI}}$	Transmit operation
0	—	—	Transmission is prohibited
1	0	—	Possible
1	1	0	Possible
1	1	1	Disabled

13.6.3 CSIHnCTL2 — CSIH Control Register 2

This register selects operating mode and the basic clock value, and specifies the baud rate.

For details see **Section 13.5.5, Transmission Clock Selection**.

Access: This register can be read/written in 16-bit units.

Address: <CSIHn_base> + 0014_H

Value after reset: E000_H This register is initialized by reset operation.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CSIHnPRS[2:0]			—	—	—	—	—	—	—	—	—	—	—	—	—

	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R

CAUTION

Changing the contents of this register is only permitted when CSIHnCTL0.CSIHnPWR = 0.

Table 13.20 CSIHnCTL2 Register Contents

Bit Position	Bit Name	Function																																				
15 to 13	CSIHnPRS[2:0]	Selects the basic clock (PRSOUT).																																				
		<table border="1"> <thead> <tr> <th>CSIHnPRS2</th> <th>CSIHnPRS1</th> <th>CSIHnPRS0</th> <th>Prescaler Section Bits</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>0</td> <td>PCLK (Master mode)</td> </tr> <tr> <td>0</td> <td>0</td> <td>1</td> <td>PCLK/2 (Master mode)</td> </tr> <tr> <td>0</td> <td>1</td> <td>0</td> <td>PCLK/4 (Master mode)</td> </tr> <tr> <td>0</td> <td>1</td> <td>1</td> <td>PCLK/8 (Master mode)</td> </tr> <tr> <td>1</td> <td>0</td> <td>0</td> <td>PCLK/16 (Master mode)</td> </tr> <tr> <td>1</td> <td>0</td> <td>1</td> <td>PCLK/32 (Master mode)</td> </tr> <tr> <td>1</td> <td>1</td> <td>0</td> <td>PCLK/64 (Master mode)</td> </tr> <tr> <td>1</td> <td>1</td> <td>1</td> <td>External clock input from CSIHnTSCK (Slave mode)</td> </tr> </tbody> </table>	CSIHnPRS2	CSIHnPRS1	CSIHnPRS0	Prescaler Section Bits	0	0	0	PCLK (Master mode)	0	0	1	PCLK/2 (Master mode)	0	1	0	PCLK/4 (Master mode)	0	1	1	PCLK/8 (Master mode)	1	0	0	PCLK/16 (Master mode)	1	0	1	PCLK/32 (Master mode)	1	1	0	PCLK/64 (Master mode)	1	1	1	External clock input from CSIHnTSCK (Slave mode)
CSIHnPRS2	CSIHnPRS1	CSIHnPRS0	Prescaler Section Bits																																			
0	0	0	PCLK (Master mode)																																			
0	0	1	PCLK/2 (Master mode)																																			
0	1	0	PCLK/4 (Master mode)																																			
0	1	1	PCLK/8 (Master mode)																																			
1	0	0	PCLK/16 (Master mode)																																			
1	0	1	PCLK/32 (Master mode)																																			
1	1	0	PCLK/64 (Master mode)																																			
1	1	1	External clock input from CSIHnTSCK (Slave mode)																																			
12 to 0	—	Reserved When writing, write the value after reset.																																				

CAUTION

Max baud rate configuration is as follows.

- Master mode is PCLK/8.
- Slave mode is PCLK/20.

In master mode, the following bits are used to set the transmission baud rate:

CSIHnCTL2.CSIHnPRS2 to 0, CSIHnCFGx.CSIHnBRSSx1 to 0, CSIHnBRSi.CSIHnBRSi11 to 0

In addition, any of the four different baud rate settings that are specified by the CSIHnBRSi (i = 0 to 3).CSIHnBRSi11 to 0 (i = 0 to 3) bit is selected according to the chip select signal. To select the baud rate setting for each chip select signal, use the CSIHnCFGx.CSIHnBRSSx1 to 0 bit.

The following table shows the relationship between CSIHnCFGx.CSIHnBRSSx1 to 0 and CSIHnBRSi (i = 0 to 3).CSIHnBRSi11 to 0 (i = 0 to 3).

CSIHnCFGx CSIHnBRSSx1 to 0	Baud Rate Setting Bits to be Selected
00	CSIHnBRS0.CSIH0BRS0 11 to 0
01	CSIHnBRS1.CSIH0BRS1 11 to 0
10	CSIHnBRS2.CSIH0BRS2 11 to 0
11	CSIHnBRS3.CSIH0BRS3 11 to 0

When the value of CSIHnPRS[2:0] is m, the following table shows the relationship between the baud rate setting (CSIHnBRSi[11:0]) and the baud rate selected by the CSIHnBRSSx[1:0] bits.

CSIHnBRSSx11 to 0 (k)	Baud Rate Selection Bits
0	BRG stopped
1	$PLCK / (2^m \times 1 \times 2)$
2	$PLCK / (2^m \times 2 \times 2)$
3	$PLCK / (2^m \times 3 \times 2)$
4	$PLCK / (2^m \times 4 \times 2)$
:	:
k	$PLCK / (2^m \times k \times 2)$
:	:
4095	$PLCK / (2^m \times 4095 \times 2)$

13.6.4 CSIHnSTR0 — CSIH Status Register 0

This register indicates the status of CSIH.

Access: This register can be read in 32-bit units.

Address: <CSIHn_base> + 0004_H

Value after reset: 0000 0010_H This register is initialized by reset operation.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function																		
31 to 8	—	Reserved																		
7	CSIHnTSF	Transfer status flag 0: Idle state 1: Communication is in progress or being prepared. The timing to set or clear this bit is as follows. <table border="1" style="margin-left: 20px;"> <thead> <tr> <th>Master mode</th> <th>Set by</th> <th>Cleared by</th> </tr> </thead> <tbody> <tr> <td>Transmit-only mode</td> <td rowspan="3">Data is written to a transmit register</td> <td rowspan="3">Within a half clock of the last serial clock edge</td> </tr> <tr> <td>Transmit/receive mode</td> </tr> <tr> <td>Receive-only mode</td> </tr> </tbody> </table> <table border="1" style="margin-left: 20px;"> <thead> <tr> <th>Slave mode</th> <th>Set by</th> <th>Cleared by</th> </tr> </thead> <tbody> <tr> <td>Transmit-only mode</td> <td rowspan="2">Writing to a transmit register</td> <td rowspan="2">Within a half clock of the last serial clock edge</td> </tr> <tr> <td>Transmit/receive mode</td> </tr> <tr> <td>Receive-only mode</td> <td>Input timing of CSIHnTSCK</td> <td></td> </tr> </tbody> </table>	Master mode	Set by	Cleared by	Transmit-only mode	Data is written to a transmit register	Within a half clock of the last serial clock edge	Transmit/receive mode	Receive-only mode	Slave mode	Set by	Cleared by	Transmit-only mode	Writing to a transmit register	Within a half clock of the last serial clock edge	Transmit/receive mode	Receive-only mode	Input timing of CSIHnTSCK	
Master mode	Set by	Cleared by																		
Transmit-only mode	Data is written to a transmit register	Within a half clock of the last serial clock edge																		
Transmit/receive mode																				
Receive-only mode																				
Slave mode	Set by	Cleared by																		
Transmit-only mode	Writing to a transmit register	Within a half clock of the last serial clock edge																		
Transmit/receive mode																				
Receive-only mode	Input timing of CSIHnTSCK																			
6 to 4	—	Reserved																		
3	CSIHnDCE	Data consistency check error flag 0: No data consistency error is detected. 1: Data consistency error is detected. This bit is cleared by writing 1 to CSIHnSTCR0.CSIHnDCEC. When this bit is set to 1 and cleared to 0 simultaneously, setting to 1 is prioritized. This bit is initialized when CSIHnCTL0.CSIHnPWR changes from 0 to 1 or from 1 to 0.																		
2	—	Reserved																		
1	CSIHnPE	Parity error flag 0: No parity error is detected. 1: Parity error is detected. For details, see (2) Parity check in Section 13.5.12, Error Detection . This bit is cleared by the CSIHnPEC bit in CSIHnSTCR0. When this bit is set to 1 and cleared to 0 simultaneously, clearing to 0 is prioritized.																		

Table 13.21 CSIHnSTR0 Register Contents (2/2)

Bit Position	Bit Name	Function
0	CSIHnOVE	Overrun error flag 0: No overrun error is detected. 1: Overrun error is detected. This bit is cleared by writing 1 to CSIHnSTCR0.CSIHnOVEC. When this bit is set to 1 and cleared to 0 simultaneously, setting to 1 is prioritized. This bit is Initialized when CSIHnCTL0.CSIHnPWR changes from 0 to 1 or from 1 to 0.

13.6.5 CSIHnSTCR0 — CSIH Status Clear Register 0

This register clears the status flags of the CSIHnSTR0 status register.

Access: This register can be read/written in 16-bit units.
When read, the value 0000_H is always returned.

Address: <CSIHn_base> + 0008_H

Value after reset: 0000_H This register is initialized by reset operation.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	CSIHn DCEC	—	CSIHn PEC	CSIHn OVEC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R/W

Table 13.22 CSIHnSTCR0 Register Contents

Bit Position	Bit Name	Function
15 to 4	—	Reserved When writing, write the value after reset.
3	CSIHnDCEC	Controls the data consistency error flag clear command. 0: No operation. The read value is always 0. 1: Clears the data consistency error flag (CSIHnSTR0.CSIHnDCE).
2	—	Reserved When writing, write the value after reset.
1	CSIHnPEC	Controls the parity error flag clear command. 0: No operation. The read value is always 0. 1: Clears the parity error flag (CSIHnSTR0.CSIHnPE).
0	CSIHnOVEC	Controls the overrun error flag clear command. 0: No operation. The read value is always 0. 1: Clears the overrun error flag (CSIHnSTR0.CSIHnOVE).

13.6.6 CSIHnCFGx — CSIH Configuration Register x

These registers specify for each chip select signal CSIHnTCSSx prescaler, parity, data length, recessive configuration for broadcasting, serial data direction, clock and data phase, idle enforcement configuration, idle time, hold time, inter-data time and setup time.

Slave mode

In slave mode, the transmission protocol setting of the CSIHnCFG0 register is effective.

- CSIHnPS0[1:0]: parity usage
- CSIHnDLS0[3:0]: data length selection
- CSIHnDIR0: data direction
- CSIHnCKP0, CSIHnDAP0: clock and data phase

The settings of the registers other than CSIHnCFG0 are ignored in slave mode.

Access: This register can be read/written in 32-bit units.

Address: CSIHnCFG0: <CSIHn_base> + 1044_H
 CSIHnCFG1: <CSIHn_base> + 1048_H
 CSIHnCFG2: <CSIHn_base> + 104C_H
 CSIHnCFG3: <CSIHn_base> + 1050_H
 CSIHnCFG4: <CSIHn_base> + 1054_H
 CSIHnCFG5: <CSIHn_base> + 1058_H

Value after reset: 0000 0000_H This register is initialized by reset operation.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

13.6.7 CSIHnTX0W — CSIH Transmit Data Register 0 for Word Access

This register stores transmission data. In addition, it specifies the communication interrupt request, the end-of-job, the extended data length, and the chip select activation.

Access: This register can be read/written in 32-bit units.

Address: <CSIHn_base> + 1008_H

Value after reset: Undefined

CAUTIONS

When CSIH0CTL0.CSIH0TXE = CSIH0CTL0.CSIH0RXE = 0 in direct access mode, write access to this register is prohibited.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 13.24 CSIHnTX0W Register Contents (1/2)

Bit position	Bit name	Function
31	—	Reserved When writing, write the value after reset.
30	CSIHnEOJ	Specifies the end of a job. 0: Indicates that the job does not end. The job continues. 1: Indicates end-of-job data. CAUTION This bit is only valid when job mode is enabled (CSIHnCTL1.CSIHnJE = 1). This bit must be set to 0 in slave mode.
29	CSIHnEDL	Specifies whether the associated data requires the extended data length (EDL) option. 0: Normal operation 1: Enables the extended data length. The associated data is transmitted as a 16-bit packet. No inter-data time or idle time will be inserted after the data is transmitted. If CSIHnCTL1.CSIHnEDLE = 1 and CSIHnTX0W.CSIHnEDL = 1, the subsequent data must have the same CS selection. If CS is modified for the subsequent data, the correct operation is not assured. CAUTION This bit is only available if CSIHnCTL1.CSIHnEDLE = 1.
28 to 24	—	Reserved When writing, write the value after reset.

Table 13.24 CSIHnTX0W Register Contents (2/2)

Bit position	Bit name	Function
23 to 16	CSIHnCSx	<p>Activates one or several chip select signals.</p> <p>0: Activates chip select x for the associated transmission. 1: Deactivates chip select x for the associated transmission. Setting CSIHnTX0W.CSIHnCS[7:0] = FF_H is prohibited.</p> <p>CAUTION</p> <p>If several chip select signals are enabled for broadcasting, the configuration of one with CSIHnCFGx.CSIHnRCBx = 0 (dominant) is used. In this case, all dominant chip select signals must be set to precisely the same value. In slave mode, set the CSIHnCSx bit to FE_H.</p>
15 to 0	CSIHnTX[15:0]	Stores the transmission data.

13.6.8 CSIHnTX0H — CSIH Transmit Data Register 0 for Half Word Access

This register stores the transmission data. This register is the same as bits 15 to 0 of register CSIHnTX0W.

Access: This register can be read/written in 16-bit units.

Address: <CSIHn_base> + 100C_H

Value after reset: Undefined

CAUTIONS

When CSIH0CTL0.CSIH0TXE = CSIH0CTL0.CSIH0RXE = 0 in direct access mode, write access to this register is prohibited.

Table 13.25 CSIHnTX0H Register Contents

Bit position	Bit name	Function
15 to 0	CSIHnTX[15:0]	Stores the transmission data.

13.6.9 CSIHnRX0W — CSIH Receive Data Register 0 for Word Access

This register stores the received data.

Access: This register can be read in 32-bit units.

Address: <CSIHn_base> + 1010_H

Value after reset: Undefined

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CAUTION

This register can be read in direct access mode and transmit-only buffer mode while CSIHnCTL0.CSIHnPWR = 1.

This register is initialized when CSIHnCTL0.CSIHnPWR changes from 0 to 1 or from 1 to 0.

Table 13.26 CSIHnRX0W Register Contents

Bit position	Bit name	Function
31 to 26	—	Reserved
25	CSIHnRPE	Indicates whether a reception data parity error was detected. 0: No parity error was detected on the associated reception data. 1: A parity error was detected on the associated reception data.
24	CSIHnTDCE	Indicates whether a transmission data consistency error was detected. 0: No consistency error was detected on the associated transmission data. 1: A consistency error was detected on the associated transmission data.
23 to 16	CSIHnCSx	Indicates which chip select signal was activated. 0: Chip select x was activated for the associated reception. 1: Chip select x was deactivated for the associated reception.
15 to 0	CSIHnRX[15:0]	Stores the received data.

13.6.10 CSIHnRX0H — CSIH Receive Data Register 0 for Half Word Access

This register stores the received data. This register is the same as bits 15 to 0 of register CSIHnRX0W.

Access: This register can only be read in 16-bit units.

Address: <CSIHn_base> + 1014_H

Value after reset Undefined

CAUTIONS

This register can be read in direct access mode and transmit-only buffer mode while CSIHnCTL0.CSIHnPWR = 1.

This register is initialized when CSIHnCTL0.CSIHnPWR changes from 0 to 1 or from 1 to 0.

Table 13.27 CSIHnRX0H Register Contents

Bit position	Bit name	Function
15 to 0	CSIHnRX[15:0]	Stores the received data.

13.6.11 CSIHnBRSi — CSIHn Baud Rate Setting Register i

This register sets the baud rate for each chip select signal.

CSIHnCFGx.CSIHnBRSSx1-0 bits, one of the four types of baud rate settings can be selected for each chip select signal.

Access: This register can be read/written in 16-bit units.

Address: CSIHnBRS0: <CSIHn_base> + 1068_H
 CSIHnBRS1: <CSIHn_base> + 106C_H
 CSIHnBRS2: <CSIHn_base> + 1070_H
 CSIHnBRS3: <CSIHn_base> + 1074_H

Value after reset: 0000_H. This register is initialized by reset operation.

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	CSIHnBRSi[11:0]

Table 13.28 CSIHnBRSi Register Contents

Bit Position	Bit Name	Function
15 to 12	—	Reserved The write value should be the initial value.
11 to 0	CSIHnBRSi [11:0]	0: BRG stopped 1: PCLK / (2 ^m × 1 × 2) 2: PCLK / (2 ^m × 2 × 2) 3: PCLK / (2 ^m × 3 × 2) 4: PCLK / (2 ^m × 4 × 2) : k: PCLK / (2 ^m × k × 2) : 4095: PCLK / (2 ^m × 4095 × 2) m is the value of CSIHnCTL2.CSIHnPRS[2:0].

13.7 Operating Procedures

13.7.1 Procedures in Direct Access Mode

Two examples for a master are provided, one with job mode disabled, and the other one with job mode enabled.

(1) Transmission/reception in master mode when job mode is disabled

The procedures below are based on the assumption that:

- The transmission data length is 8 bits ($\text{CSIHnCFGx.CSIHnDLSx}[3:0] = 1000_{\text{B}}$).
- Transmission direction is MSB first ($\text{CSIHnCFGx.CSIHnDIRx} = 0$).
- Normal clock and data phase ($\text{CSIHnCFGx.CSIHnCKPx} = 0$, $\text{CSIHnCFGx.CSIHnDAPx} = 0$).
- No interrupt delay ($\text{CSIHnCTL1.CSIHnSIT} = 0$).
- Job mode is disabled ($\text{CSIHnCTL1.CSIHnJE} = 0$).
- Normal INT_CSIHTIC interrupt timing ($\text{CSIHnCTL1.CSIHnSLIT} = 0$).
- Direct access mode ($\text{CSIHnCTL0.CSIHnMBS} = 1$).

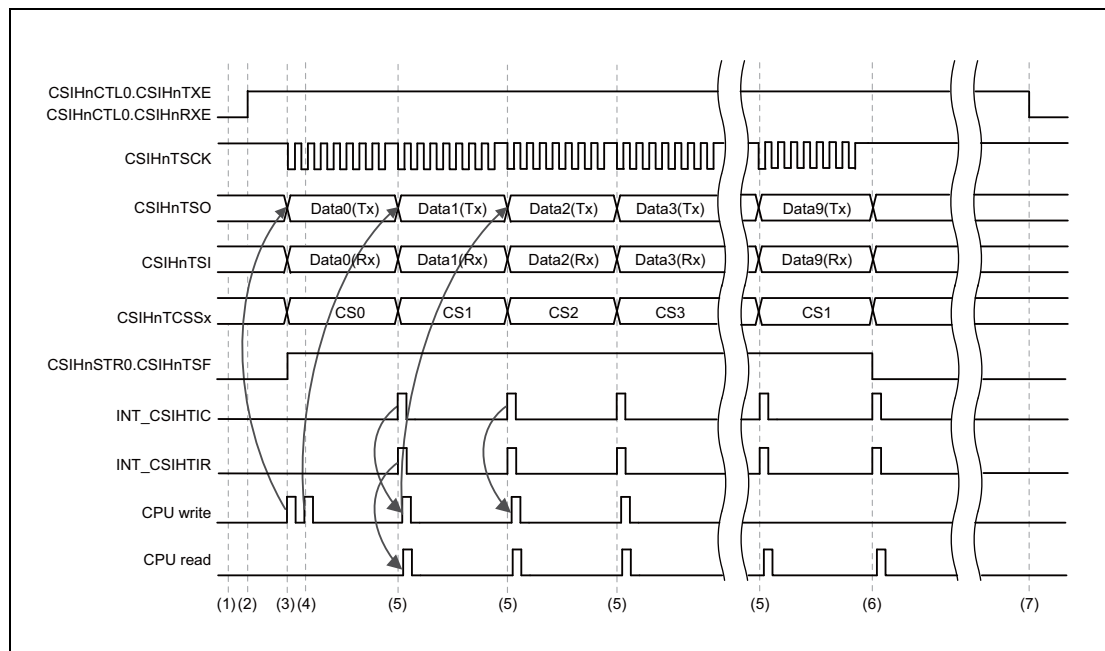

Figure 13.37 Master in Direct Access Mode, CSIHnCTL1.CSIHnJE = 0

Procedure:

- (1) Configure the communication protocol in the CSIHnCFGx register. This example uses chip select signals CS0 to CS3.
Specify the transfer mode and job mode by setting the corresponding bits in registers CSIHnCTL1 and CSIHnCTL2.
- (2) In the CSIHnCTL0 register, set CSIHnPWR = 1 (enables the clock), CSIHnTXE = 1 (permits transmission), CSIHnRXE = 1 (permits reception), and CSIHnMBS = 1 (direct access mode).
- (3) Write the first data to be sent to the transmission register, CSIHnTX0W. Within the same write operation, activate CS0. Transmission starts automatically when the first data becomes available.
- (4) Write the second data to CSIHnTX0W. If required, you can change the CS to address a different device. Writing the second data immediately after the first one avoids unnecessary delays between the data.
- (5) After every transmission/reception of a data, the interrupts INT_CSIHTIC and INT_CSIHTIR are generated:
 - INT_CSIHTIC indicates that the next data can be written to CSIHnTX0W.
 - INT_CSIHTIR indicates that the reception register, CSIHnRX0W must be read.
- (6) No more write action is required after completion of data 8. Data 9 (the last packet) has been written in advance.
However, reception register CSIHnRX0W must be read after completion of writing data 8 and 9.
- (7) Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to prohibit the transmit/receive operation. When no communication is conducted, set CSIHnCTL0.CSIHnPWR to 0 to minimize power consumption of the CSIHn.

(2) Transmission/reception in master mode when job mode is enabled

The procedure below is based on the assumption that:

- The transmission data length is 8 bits (CSIHnCFGx.CSIHnDLSx[3:0] = 1000_B).
- Transmission direction is MSB first (CSIHnCFGx.CSIHnDIRx = 0).
- Normal clock and data phase (CSIHnCFGx.CSIHnCKPx = 0, CSIHnCFGx.CSIHnDAPx = 0)
- No interrupt delay (CSIHnCTL1.CSIHnSIT = 0)
- Job mode is enabled (CSIHnCTL1.CSIHnJE = 1).
- Normal INT_CSIHTIC interrupt timing (CSIHnCTL1.CSIHnSLIT = 0)
- Direct access mode (CSIHnCTL0.CSIHnMBS = 1)
- Two jobs, each of them sends three data.

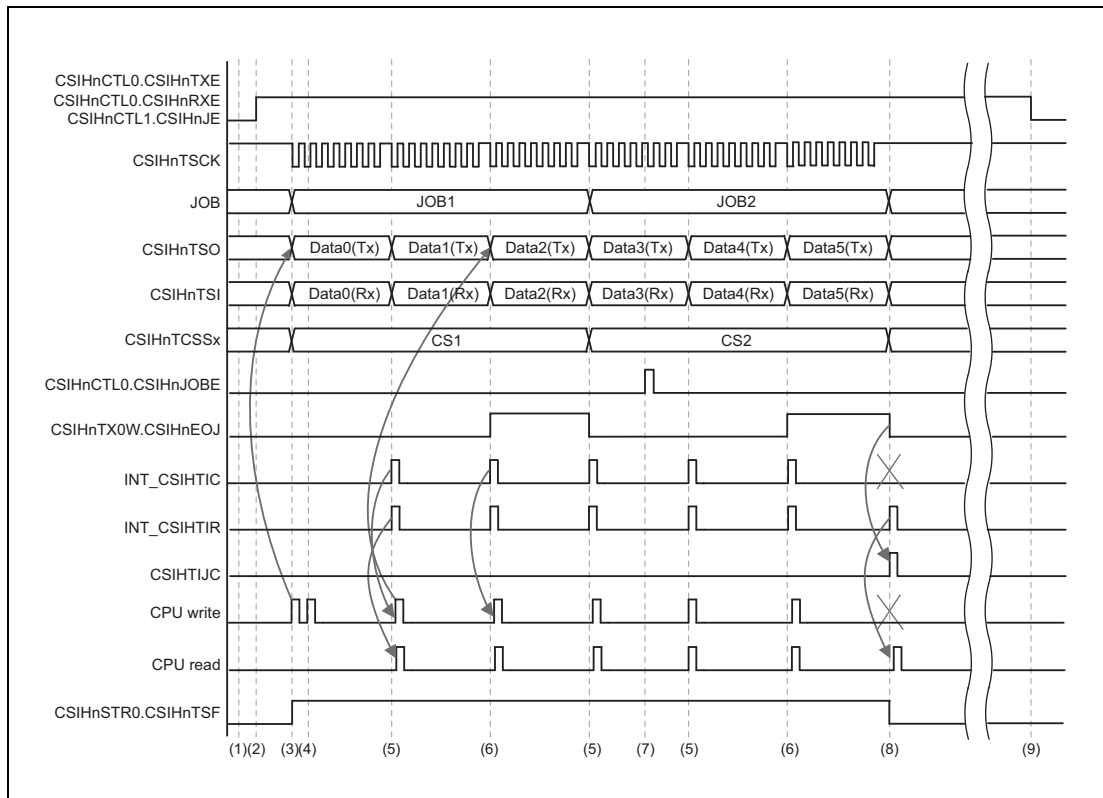

Figure 13.38 Master in Direct Access Mode, CSIHnCTL1.CSIHnJE = 1

Procedure:

- (1) Configure the communication protocol in the CSIHnCFGx register. This example uses chip select signals CS1 and CS2.
Specify the transfer mode and job mode by setting the corresponding bits in registers CSIHnCTL1 and CSIHnCTL2.
- (2) In the CSIHnCTL0 register, set CSIHnPWR = 1 (enables the clock), CSIHnTXE = 1 (permits transmission), CSIHnRXE = 1 (permits the reception), and CSIHnMBS = 1 (selects direct access mode).
- (3) Write the first data to be sent to the transmission register CSIHnTX0W. Transmission starts automatically when the first data becomes available.
The CSIHnSTR0.CSIHnTSF flag indicates that communication is in progress.
- (4) Write the second data to CSIHnTX0W. Writing the second data immediately after the first one avoids unnecessary delays between the data.
- (5) After every data transmission/reception, the interrupt requests, INT_CSIHTIC and INT_CSIHTIR are generated.
 - INT_CSIHTIC indicates that the next data can be written to CSIHnTX0W.
 - INT_CSIHTIR indicates that the reception register, CSIHnRX0W must be read.
- (6) Setting CSIHnTX0W.CSIHnEOJ = 1 indicates that the last data of the current job is sent. After that, the next job may begin.
- (7) By setting CSIHnCTL0.CSIHnJOBE = 1, communication is forced to stop at the end of the current job (JOB2).
- (8) After the forced stop of communication, the interrupt request, INT_CSIHTIC is replaced by INT_CSIHTIJC. INT_CSIHTIR is generated as usual.
The interrupt request, INT_CSIHTIJC indicates a forced stop of communication at the end of the current job.
The interrupt request, INT_CSIHTIC is not generated. Additionally, the transmission data available in the CSIHnTX0W register is not sent.
- (9) Finally, clear CSIHnCTL0.CSIHnTXE and CSIHnCTL0.CSIHnRXE to prohibit the transmit/receive operation. When no communication is conducted, set CSIHnCTL0.CSIHnPWR to 0 to minimize power consumption of the CSIHn.
To start another transmission without stopping communication, perform steps 3 and later.

Section 14 Serial Communication Interface 3 (SCI3)

14.1 Overview

The serial communication interface 3 (SCI3: Serial Communication Interface 3) can handle two methods of serial communications: asynchronous and clock synchronous serial communications. Asynchronous serial data communications can be carried out with standard asynchronous communication LSIs such as Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communication Interface Adapter (ACIA). Asynchronous mode is equipped with a serial communications function between multiple processors (multi-processor communications function).

14.1.1 Features of SCI3

Number of channels

This product contains the serial communication interface for the number of channels shown below.

SCI3	
Number of channels	4
Name	SCI3n (n = 0 to 3)

Meaning of “n”

In this section, each channel of the serial communication interface 3 is identified by “n” (n = 0 to 3). For example, a serial mode register is written as SCI3nSMR.

14.1.2 Outline of Functions

- The serial data communication mode can be configured for asynchronous communications or clock synchronous communications.
- Full-duplex communications are available. The independent transmitter unit and receiver unit allow simultaneous transmission and reception. Both the transmitter and the receiver have a double-buffered structure, enabling continuous data transmission and reception.
- An arbitrary bit rate is selectable with the on-chip baud rate generator. An external clock is also selectable as a transmission/reception clock source.
- LSB-first or MSB-first transfer is selectable (except for asynchronous 7-bit data.)
- Interrupt sources: 4 types consisting of transmit-end, transmit-data-empty, receive-data-full, and receive-error. Transmit-data-empty and receive-data-full interrupt sources can activate the DMAC.
- Module standby can be set for each channel (for details of module standby, see **Section 12, Standby Controller**).
- The bit rate modulation function can reduce errors averagely (even in a high bit rate) by correcting the output of the on-chip baud rate generator (except for the maximum speed in clock synchronous mode).
- The pin level of serial input data can be checked.
- On-chip 6-bit divider (PSC)

14.1.3 Serial Communication Modes

Asynchronous mode

- Data length: 7 bits or 8 bits selectable
- Stop bit length: 1 bit or 2 bits selectable
- Parity: Even parity, odd parity, or none selectable
- Receive error detection: Parity error, overrun error, and framing error
- Break detection: A break can be detected by reading a register in the case of a framing error.

Clock synchronous mode

- Data length: 8 bits
- Receive error detection: Overrun error

14.1.4 Block Diagram

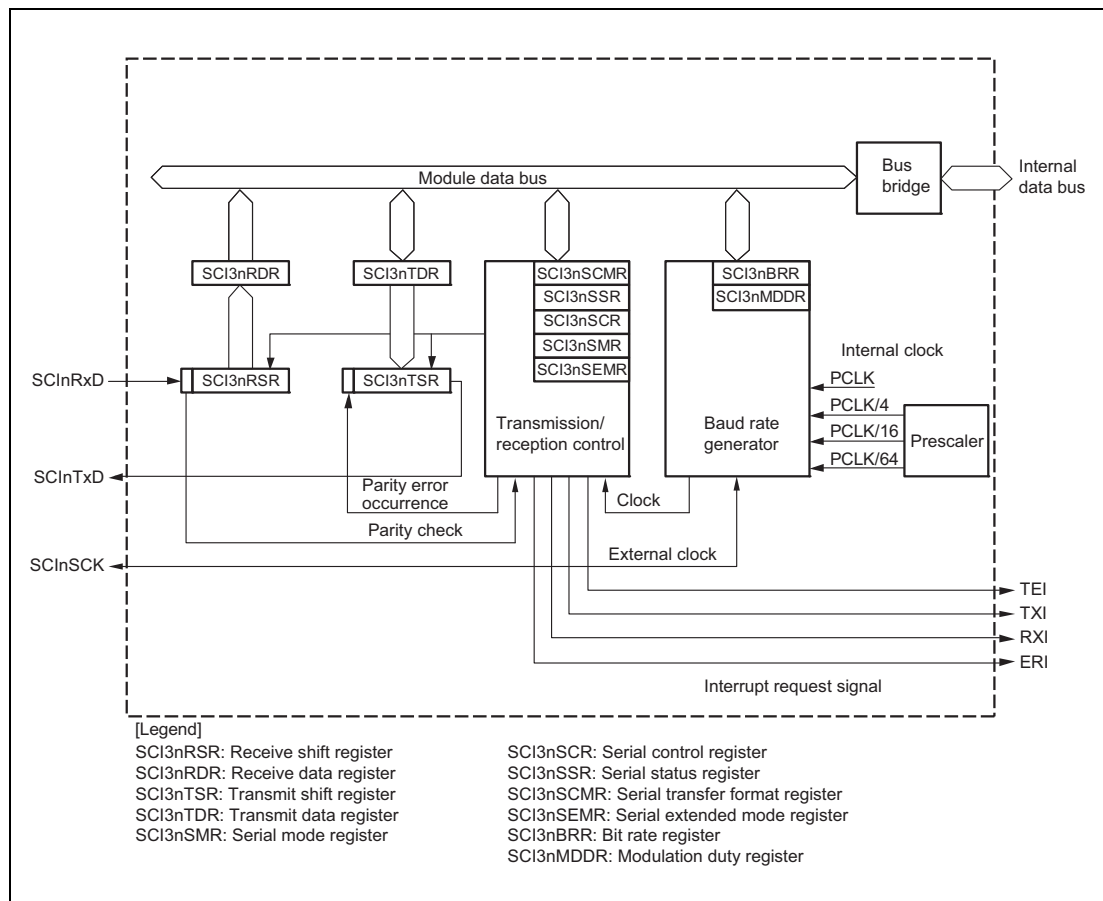

Figure 14.1 SCI3 Block Diagram

14.2 Input/Output Pins

The SCI3 has the input/output pins listed in **Table 14.1**.

Table 14.1 Pin Configuration

Name	Symbol	I/O	Function
Clock input/output pin	SCInSCK	Input	Serial clock input
		Output	Serial clock output
Receive data input pin	SCInRxD	Input	Receive data input
Transmit data output pin	SCInTxD	Output	Transmit data output

14.3 Register Descriptions

SCI3n register addresses are given as offsets from the base address <SCI3n_base>.

The base addresses <SCI3n_base> of each SCI3 are listed in **Table 14.2**.

Table 14.2 Register Base Address <SCI3n_base>

SCI3n Channel	SCI3n_base Address
SCI30	FFD9 0000 _H
SCI31	FFD9 1000 _H
SCI32	FFD9 2000 _H
SCI33	FFD9 3000 _H

The SCI3 has the registers listed in **Table 14.2**. Some registers have limitations in read/write by the CPU.

Table 14.3 Register Configuration

Register Name	Symbol	Value after Reset	Address	Access Size
Receive shift register	SCI3nRSR	—	—	—
Serial mode register	SCI3nSMR	00 _H	<SCI3n_base>+ 0000 _H	8
Bit rate register / Modulation duty register	SCI3nBRR/ SCI3nMDDR	FF _H	<SCI3n_base>+ 0004 _H	8
Serial control register	SCI3nSCR	00 _H	<SCI3n_base>+ 0008 _H	8
Transmit data register	SCI3nTDR	FF _H	<SCI3n_base>+ 000C _H	8
Transmit shift register	SCI3nTSR	—	—	—
Serial status register	SCI3nSSR	84 _H	<SCI3n_base>+ 0010 _H	8
Receive data register	SCI3nRDR	00 _H	<SCI3n_base>+ 0014 _H	8
Serial transfer format register	SCI3nSCMR	F2 _H	<SCI3n_base>+ 0018 _H	8
Serial extended mode register	SCI3nSEMR	04 _H	<SCI3n_base>+ 001C _H	8

CAUTIONS

SCI3nBRR and SCI3nMDDR are allocated to the same address (relative address 4). The SCI3nMDDRS bit in SCI3nSEMR is used to switch these registers.

Relative addresses $4n + 1$, $4n + 2$, and $4n + 3$ ($n = 0$ to 7) are reserved areas. These areas are always read as 0. Writing is invalid.

14.3.1 SCI3nRSR — Receive Shift Register

SCI3nRSR is a shift register which is used to receive serial data input from the SCI3nRxD pin and convert it to parallel data. When one frame of data has been received, it is automatically transferred to SCI3nRDR. SCI3nRSR cannot be directly accessed by the CPU.

14.3.2 SCI3nRDR — Receive Data Register

SCI3nRDR is an 8-bit register to store receive data. The value of SCI3nRDR after a reset is 00_H. When one frame of data has been received, it is transferred from SCI3nRSR to this register allowing SCI3nRSR to receive the next data. SCI3nRSR and SCI3nRDR function as a double-buffer in this way, allowing continuous receive operations. Be sure to check that the RDRF flag in SCI3nSSR is set to 1 before reading SCI3nRDR. SCI3nRDR cannot be written from the CPU.

When the data length is 7 bits, received data is stored in bits 0 to 6. Bit 7 is fixed to 0.

At this time, the fixed value of bit 7 is not affected by the SINV bit in the SCI3nSCMR register.

14.3.3 SCI3nTDR — Transmit Data Register

SCI3nTDR is an 8-bit register to store transmit data. The value of SCI3nTDR after a reset is FF_H. When SCI3nTSR empty is detected, the transmit data written to SCI3nTDR is transferred to SCI3nTSR and transmission starts. The double-buffered structure of SCI3nTDR and SCI3nTSR allows continuous serial transmission. If the next transmit data has been written to SCI3nTDR when one frame of data is sent, the transmit data is transferred to SCI3nTSR to continue transmission. SCI3nTDR can always be read and written by the CPU. Be sure to check that the TDRE flag in SCI3nSSR is set to 1 before writing transmit data to SCI3nTDR.

14.3.4 SCI3nTSR — Transmit Shift Register

SCI3nTSR is a shift register to transmit serial data. To perform serial data transmission, transmit data written to SCI3nTDR is automatically transferred to SCI3nTSR, and is then sent to the SCI3nTxD pin. SCI3nTSR cannot be directly accessed by the CPU.

14.3.5 SCI3nSMR — Serial Mode Register

SCI3nSMR is a register used to select the transfer format and the clock source for the on-chip baud rate generator.

Access: This register can be read/written in 8-bit units.

Address: <SCI3n_base> + 0000_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	CM	CHR	PE	PM	STOP	MP	CKS[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1

Note 1. Writable only when TE = RE = 0.

Table 14.4 SCI3nSMR Register Contents

Bit Position	Bit Name	Function
7	CM	Communications Mode 0: Asynchronous mode 1: Clock synchronous mode
6	CHR	Character Length (Valid only in asynchronous mode) 0: Selects 8 bits as the data length. 1: Selects 7 bits as the data length. LSB-first is fixed and the MSB (bit 7) in SCI3nTDR is not transmitted in transmission. In clock synchronous mode, the data length is fixed to 8 bits.
5	PE	Parity Enable (Valid only in asynchronous mode) When this bit is set to 1, a parity bit is added to transmit data and the parity bit is checked in reception. Regardless of the setting of this bit, no parity bit is added or checked in the multi-processor format.
4	PM	Parity Mode (Valid only when PE = 1 in asynchronous mode) 0: Selects even parity. 1: Selects odd parity. When even parity is set, parity bit is added so that the total number of 1 bits in the transmit/receive character plus the parity bit is even. Similarly, when odd parity is set, parity bit is added so that the total number of 1 bits in the transmit/receive character plus the parity bit is odd.
3	STOP	Stop Bit Length (Valid only in asynchronous mode) 0: 1 stop bit for transmission 1: 2 stop bits for transmission In reception, only the first stop bit is checked regardless of the setting of this bit. If the second stop bit is 0, it is treated as the start bit of the next transmission frame.
2	MP	Multi-Processor Mode (Valid only in asynchronous mode) When this bit is set to 1, the multi-processor communication function is enabled. In multi-processor mode, settings of the PE and PM bits are invalid.
1, 0	CKS[1:0]	Clock Select 1, 0 These bits select the clock source for the on-chip baud rate generator. 00: PCLK clock (m = 0) 01: PCLK/4 clock (m = 1) 10: PCLK/16 clock (m = 2) 11: PCLK/64 clock (m = 3) For the relation between the setting of these bits and the baud rate, see Section 14.3.10, SCI3nBRR — Bit Rate Register . The character m is the decimal notation of the value of m in Section 14.3.10, SCI3nBRR — Bit Rate Register .

14.3.6 SCI3nSCR — Serial Control Register

SCI3nSCR is a register used for the transmission/reception control, interrupt control, and transmission/reception clock source selection listed below. For interrupt requests, see **Section 14.8, Interrupt Sources**.

Access: This register can be read/written in 8-bit units.

Address: <SCI3n_base> + 0008_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	TIE	RIE	TE	RE	MPIE	TEIE	CKE[1:0]	
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W*1	R/W*1	R/W	R/W	R/W*2	R/W*2

Note 1. While the CM bit in SCI3nSMR is 1, a value of 1 can be written only when TE = 0 and RE = 0. After the TE or RE bit is set to 1, only 0 can be written to TE and RE. While the CM bit in SCI3nSMR is 0, writing is enabled at any timing.

Note 2. Writable only when TE = 0 and RE = 0. Also, writable at the same time when TE = 0 and RE = 0 are written.

Table 14.5 SCI3nSCR Register Contents (1/2)

Bit Position	Bit Name	Function
7	TIE	Transmit Interrupt Enable When this bit is set to 1, TXI interrupt request is enabled. TXI interrupt request can be cancelled by reading 1 from the TDRE flag and then clearing the flag to 0, or clearing the TIE bit.
6	RIE	Receive Interrupt Enable When this bit is set to 1, RXI and ERI interrupt requests are enabled. RXI and ERI interrupt requests can be cancelled by reading 1 from the RDRF, FER, PER, or ORER flag and then clearing the flag to 0, or clearing the RIE bit.
5	TE	Transmit Enable When this bit is set to 1, transmission is enabled. In this state, serial transmission is started by writing transmit data to SCI3nTDR and clearing the TDRE flag in SCI3nSSR to 0. Be sure to set SCI3nSMR before setting the TE bit to 1 to determine the transmission format. When this bit is set to 0 to disable transmission, the TDRE flag in SCI3nSSR is fixed to 1.
4	RE	Receive Enable When this bit is set to 1, reception is enabled. In this state, serial reception is started by detecting a start bit in asynchronous mode or the input of synchronous clock in clock synchronous mode. Be sure to set SCI3nSMR before setting the RE bit to 1 to determine the reception format. Even if reception is disabled by clearing this bit, the RDRF, FER, PER, and ORER flags are not affected and the previous value is retained.
3	MPIE	Multiprocessor Interrupt Enable (Valid only when MP in SCI3nSMR = 1 in asynchronous mode) When this bit is set to 1 and the data with the multi-processor bit set to 0 is received, the data is not read and setting the RDRF, FER, and ORER flags in SCI3nSSR to 1 is disabled. When the data with the multi-processor bit set to 1 is received, this bit is automatically cleared to 0, and normal reception is resumed. For details, see Section 14.5, Multi-Processor Communication Function . When the receive data includes MPB = 0 in SCI3nSSR, the receive data is not transferred from SCI3nRSR to SCI3nRDR, a receive error is not detected, and setting the RDRF, FER, and ORER flags in SCI3nSSR to 1 is disabled. When the receive data includes MPB = 1 in SCI3nSSR, the MPB bit in SCI3nSSR is set to 1, the MPIE bit is automatically cleared to 0, the RXI and ERI interrupt requests are enabled (if the RIE bit in SCI3nSCR is set to 1), and setting the FER and ORER flags to 1 is enabled.

Table 14.5 SCI3nSCR Register Contents (2/2)

Bit Position	Bit Name	Function
2	TEIE	Transmit End Interrupt Enable When this bit is set to 1, TEI interrupt request is enabled. TEI interrupt request can be cancelled by reading 1 from the TDRE flag and then clearing the flag to 0 to clear the TEND flag to 0, or clearing the TEIE bit.
1, 0	CKE[1:0]	Clock Enable 1, 0 These bits select the clock source and the SCInSCK pin function. For asynchronous mode 00: On-chip baud rate generator (The SCInSCK pin functions as an input/output port.) 01: On-chip baud rate generator (The clock with the same frequency as the bit rate is output from the SCInSCK pin.) 1X: Setting prohibited For clock synchronous mode 0X: Internal clock (The SCInSCK pin functions as a clock output pin.) 1X: External clock (The SCInSCK pin functions as a clock input pin.)

Note 1. X: Don't care

NOTE

When writing to any bit other than the MPIE bit of this register, use a store instruction such that the value of the MPIE bit becomes 0.

Note that when using a bit-manipulation instruction for writing to this register, the read-modify-write operation may inadvertently set the MPIE bit to 1.

14.3.7 SCI3nSSR — Serial Status Register

SCI3nSSR consists of SCI3 status flags and transfer multi-processor bits.

The TDRE, RDRF, ORER, PER, and FER flags can be cleared only.

Access: This register can be read/written in 8-bit units.

Address: <SCI3n_base> + 0010_H

Value after reset: 84_H

Bit	7	6	5	4	3	2	1	0
	TDRE	RDRF	ORER	FER	PER	TEND	MPB	MPBT
Value after reset	1	0	0	0	0	1	0	0
R/W	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R	R	R/W

Note 1. Only 0 can be written to clear the flag.

Table 14.6 SCI3nSSR Register Contents (1/2)

Bit Position	Bit Name	Function
7	TDRE	Transmit Data Register Empty Indicates whether or not transmit data exists in SCI3nTDR. [Setting conditions] <ul style="list-style-type: none"> When the TE bit in SCI3nSCR is 0 When the data in SCI3nTDR has been transferred to SCI3nTSR so that new data can be written to SCI3nTDR [Clearing condition] <ul style="list-style-type: none"> Writing 0 to TDRE after reading TDRE = 1 When transmit data is written to TDR while TE = 1
6	RDRF	Receive Data Register Full Indicates whether or not receive data exists in SCI3nRDR [Setting condition] <ul style="list-style-type: none"> When reception finishes successfully and the receive data is transferred from SCI3nRSR to SCI3nRDR [Clearing conditions] <ul style="list-style-type: none"> Writing 0 to RDRF after reading RDRF = 1 When data is read from SCI3nRDR Even when the RE bit in SCI3nSCR is cleared, the RDRF flag is not affected and the previous value is retained. Note that completing the reception of the next data with the RDRF flag set to 1 will cause an overrun error, resulting in the loss of the receive data.
5	ORER	Overrun Error Indicates that an overrun error has occurred during reception and the reception abended. [Setting condition] <ul style="list-style-type: none"> When the next data is received while RDRF = 1 In SCI3nRDR, receive data prior to an overrun error is retained, but data received after the overrun error occurrence is lost. When the ORER flag is set to 1, subsequent serial reception cannot be continued. In clock synchronous mode, serial transmission also cannot be continued. [Clearing condition] <ul style="list-style-type: none"> Writing 0 to ORER after reading ORER = 1 Even when the RE bit in SCI3nSCR is cleared, the ORER flag is not affected and the previous value is retained.

Table 14.6 SCI3nSSR Register Contents (2/2)

Bit Position	Bit Name	Function
4	FER	<p>Framing Error</p> <p>Indicates that a framing error has occurred during reception in asynchronous mode and the reception abended.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> When the stop bit is 0 In 2-stop-bit mode, only whether the first stop bit is 1 is checked but the second stop bit is not checked. Although the receive data when a framing error has occurred is transferred to SCI3nRDR, the RDRF flag is not set. In addition, while the FER flag is set to 1, the subsequent receive data is not transferred to SCI3nRDR. <p>[Clearing condition]</p> <ul style="list-style-type: none"> Writing 0 to FER after reading FER = 1 Even when the RE bit in SCI3nSCR is cleared to 0, the FER flag is not affected and the previous value is retained.
3	PER	<p>Parity Error</p> <p>Indicates that a parity error has occurred during reception in asynchronous mode and the reception abended.</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> Although the receive data when a parity error has occurred is transferred to SCI3nRDR, the RDRF flag is not set. In addition, while the PER flag is set to 1, the subsequent receive data is not transferred to SCI3nRDR. <p>[Clearing condition]</p> <ul style="list-style-type: none"> Writing 0 to PER after reading PER = 1 Even when the RE bit in SCI3nSCR is cleared to 0, the PER flag is not affected and the previous value is retained.
2	TEND	<p>Transmit End</p> <p>[Setting conditions]</p> <ul style="list-style-type: none"> When the TE bit in SCI3nSCR is 0 When the TDRE flag is 1 while the last bit of a transmit character is being transmitted <p>[Clearing condition]</p> <ul style="list-style-type: none"> Writing 0 to the TDRE flag after reading TDRE = 1 When transmit data is written to SCI3nTDR while TE = 1
1	MPB	<p>Multi-Processor Bit</p> <p>Holds the value of the multi-processor bit in the received frame.</p>
0	MPBT	<p>Multi-Processor Bit Transfer</p> <p>Sets the value of the multi-processor bit to be added to the transmit frame.</p>

14.3.8 SCI3nSCMR — Serial Transfer Format Register

SCI3nSCMR is a register to select transfer format for both asynchronous mode and clock synchronous mode.

Access: This register can be read/written in 8-bit units.

Address: <SCI3n_base> + 0018_H

Value after reset: F2_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	SDIR	SINV	—	—
Value after reset	1	1	1	1	0	0	1	0
R/W	R	R	R	R	R/W* ¹	R/W* ¹	R	R

Note 1. Writable only when TE = 0 and RE = 0.

Table 14.7 SCI3nSCMR Register Contents

Bit Position	Bit Name	Function
7 to 4	—	Reserved These bits are always read as 1. When writing, write the value after reset.
3	SDIR	Serial Data Transfer Direction (Valid in asynchronous mode and clock synchronous mode) This bit is used to select the direction of serial/parallel conversion. 0: Transfer with LSB-first 1: Transfer with MSB-first This bit is valid only when the transfer format is 8-bit data. For 7-bit data, LSB-first transfer is used.
2	SINV	Serial Data Invert (Valid in asynchronous mode and clock synchronous mode) This bit is used to invert the transfer data logic level. The SINV bit does not affect the logic level of the parity bit. To invert the parity bit, invert the PM bit in SCI3nSMR. 0: SCI3nTDR data is transmitted as it is, and receive data is stored in SCI3nRDR as it is. 1: SCI3nTDR data is inverted and transmitted, and receive data is inverted and stored in SCI3nRDR.
1	—	Reserved These bits are always read as 1. When writing, write the value after reset.
0	—	Reserved These bits are always read as 0. When writing, write the value after reset.

14.3.9 SCI3nSEMR — Serial Extended Mode Register

SCI3nSEMR is a register to select a 1-bit period.

Access: This register can be read/written in 8-bit units.

Address: <SCI3n_base> + 001C_H

Value after reset: 04_H

Bit	7	6	5	4	3	2	1	0
	BRME	MDDRS	—	—	ABCS	RXDMON	—	—
Value after reset	0	0	0	0	0	1	0	0
R/W	R/W* ¹	R/W* ¹	R	R	R/W* ¹	R	R	R

Note 1. Writable only when TE = 0 and RE = 0.

Table 14.8 SCI3nSEMR Register Contents

Bit Position	Bit Name	Function
7	BRME	Bit Rate Modulation Enable When this bit is set to 1, the bit rate modulation function is enabled.
6	MDDRS	Modulation Duty Register Select This bit is used to select an accessible register. 0: SCI3nBRR is accessible. 1: SCI3nMDDR is accessible.
5, 4	—	Reserved These bits are always read as 0. When writing, write the value after reset.
3	ABCS	Asynchronous Reference Clock Select (Valid only in asynchronous mode) This bit is used to select the reference clock for 1-bit period. 0: Operates on the reference clock with a frequency of 16 times the transfer rate. 1: Operates on the reference clock with a frequency of 8 times the transfer rate (double-speed operation).
2	RXDMON	Serial Input Data Monitor This bit indicates the SCInRxD pin state. 0: SCInRxD pin state is the low level. 1: SCInRxD pin state is the high level.
1, 0	—	Reserved These bits are always read as 0. When writing, write the value after reset.

14.3.10 SCI3nBRR — Bit Rate Register

SCI3nBRR is an 8-bit register to adjust the bit rate. Since each SCI3 channel has an independent baud rate generator, different bit rates can be set for each channel. **Table 14.9** shows the relationship between the setting (N) in SCI3nBRR and the bit rate (B) in normal asynchronous mode and clock synchronous mode. The value of SCI3nBRR after a reset. SCI3nBRR is allocated at the same address as SCI3nMDDR and is selected when MDDRS in SCI3nSEMR is 0. This register is writable only when TE = 0 and RE = 0.

Table 14.9 Relationship between Setting N in SCI3nBRR and Bit Rate B

Mode	ABCS Setting	Bit Rate	Mean Error
Asynchronous	0	$B = \frac{\phi \times 10^6}{64 \times 2^{2m-1} \times (N+1)}$	$\text{Error (\%)} = \left\{ \frac{\phi \times 10^6}{B \times 64 \times 2^{2m-1} \times (N+1)} - 1 \right\} \times 100$
	1	$B = \frac{\phi \times 10^6}{32 \times 2^{2m-1} \times (N+1)}$	$\text{Error (\%)} = \left\{ \frac{\phi \times 10^6}{B \times 32 \times 2^{2m-1} \times (N+1)} - 1 \right\} \times 100$
Clock synchronous	—	$B = \frac{\phi \times 10^6}{8 \times 2^{2m-1} \times (N+1)}$	

Note: B: Bit rate (bit/s)
 N: SCI3nBRR setting for baud rate generator ($0 \leq N \leq 255$)
 ϕ : Operating frequency PCLK (MHz)
 m: Determined by the SCI3nSMR setting shown in the following table.

SMR Setting		
CKS1	CKS0	m
0	0	0
0	1	1
1	0	2
1	1	3

Table 14.10 lists sample N settings of the SCI3nBRR register in asynchronous mode. **Table 14.11** lists the maximum settable bit rates.

Table 14.10 Examples of BRR Settings for Bit Rates (Asynchronous Mode)

Bit Rate (bit/s)	Operating Frequency $\phi = 40$ (MHz)							
	SCI3nSEMR.ABCS = 0				SCI3nSEMR.ABCS = 1			
	m	N	Actual Bit Rate (bit/s)	Error (%)	m	N	Actual Bit Rate (bit/s)	Error (%)
110	3	177	109.73	-0.25	—	—	—	—
150	3	129	150.24	0.16	3	255	152.59	1.73
300	3	64	300.48	0.16	3	129	300.48	0.16
600	2	129	600.96	0.16	3	64	600.96	0.16
1200	2	64	1201.92	0.16	2	129	1201.92	0.16

14.3.11 SCI3nMDDR — Modulation Duty Register

SCI3nMDDR is a register to correct the bit rate adjusted by SCI3nBRR. The value of SCI3nMDDR after a reset is FF_H. When the BRME bit in SCI3nSEMR is set to 1, the bit rate generated by the on-chip baud rate generator is corrected to SCI3nMDDR/256 on average. **Table 14.14** shows the relationship between the SCI3nMDDR setting and the bit rate B. SCI3nMDDR is allocated at the same address as SCI3nBRR and is selected when MDDRS in SCI3nSEMR is 1. This register is writable only when TE = 0 and RE = 0. Bit 7 is fixed to 1.

Table 14.14 Relationship between SCI3nMDDR Setting and Bit Rate B when Bit Rate Modulation Function Is Used

Mode	ABCS Setting	Bit Rate	Mean Error
Asynchronous	0	$B = \frac{\phi \times 10^6}{64 \times 2^{2m-1} \times (256/\text{MDDR}) \times (N+1)}$	$\text{Error (\%)} = \left\{ \frac{\phi \times 10^6}{B \times 64 \times 2^{2m-1} \times (256/\text{MDDR}) \times (N+1)} - 1 \right\} \times 100$
	1	$B = \frac{\phi \times 10^6}{32 \times 2^{2m-1} \times (256/\text{MDDR}) \times (N+1)}$	$\text{Error (\%)} = \left\{ \frac{\phi \times 10^6}{B \times 32 \times 2^{2m-1} \times (256/\text{MDDR}) \times (N+1)} - 1 \right\} \times 100$
Clock synchronous	—	$B = \frac{\phi \times 10^6}{8 \times 2^{2m-1} \times (256/\text{MDDR}) \times (N+1)}$	

Note: B: Bit rate (bit/s)
 N: SCI3nBRR setting of baud rate generator ($0 \leq N \leq 255$)
 ϕ : Operating frequency PCLK (MHz)
 m: See **Table 14.9, Relationship between Setting N in SCI3nBRR and Bit Rate B.**
 MDDR: SCI3nMDDR setting ($128 \leq \text{MDDR} \leq 255$)

14.4 Operation in Asynchronous Mode

Figure 14.2 shows the general format for asynchronous serial communications. One frame consists of a start bit (low level), transmit/receive data, a parity bit, and stop bits (high level). In asynchronous serial communications, the communication line is usually held in the mark state (high level). The SCI3 monitors the communication line, and when the SCI3 detects the space state (low level), it recognizes a start bit and starts serial communications. Inside the SCI3, the transmitter and the receiver are independent, enabling full-duplex communications. Both the transmitter and the receiver have a double-buffered structure so that data can be read or written during transmission or reception, enabling continuous data transmission and reception.

Figure 14.2 Data Format in Asynchronous Serial Communications (Example with 8-Bit Data, Parity, Two Stop Bits)

14.4.1 Transmission/Reception Format

Table 14.15 lists settable transmission/reception formats in asynchronous mode. Any of 12 transmission/reception formats can be selected according to the SCI3nSMR setting. For details of the multi-processor bit, see **Section 14.5, Multi-Processor Communication Function**.

Table 14.15 Serial Transmission/Reception Formats (Asynchronous Mode)

SMR Setting				Serial Transmission/Reception Format and Frame Length												
CHR	PE	MP	STOP	1	2	3	4	5	6	7	8	9	10	11	12	
0	0	0	0	S	8-bit data								STOP			
0	0	0	1	S	8-bit data								STOP	STOP		
0	1	0	0	S	8-bit data								P	STOP		
0	1	0	1	S	8-bit data								P	STOP	STOP	
1	0	0	0	S	7-bit data							STOP				
1	0	0	1	S	7-bit data							STOP	STOP			
1	1	0	0	S	7-bit data							P	STOP			
1	1	0	1	S	7-bit data							P	STOP	STOP		
0	—	1	0	S	8-bit data								MPB	STOP		
0	—	1	1	S	8-bit data								MPB	STOP	STOP	
1	—	1	0	S	7-bit data							MPB	STOP			
1	—	1	1	S	7-bit data							MPB	STOP	STOP		

Note: S: Start bit
 STOP: Stop bit
 P: Parity bit
 MPB: Multi-processor bit

14.4.2 Receive Data Sampling Timing and Reception Margin

In asynchronous mode, the SCI3 operates on a reference clock with a frequency of 16 times (8 times for the double-speed mode) the bit rate. In reception, the SCI3 samples the falling edge of the beginning of the start bit (low level) using the reference clock and performs internal synchronization. As shown in **Figure 14.3**, data is latched at the middle of each bit by sampling receive data at the rising edge of the eighth pulse (fourth pulse for the double-speed mode) of the reference clock.

Thus the reception margin in asynchronous mode is determined by formula (1) below.

$$M = \left| \left(0.5 - \frac{1}{2N} \right) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100 [\%] \quad \dots \text{formula (1)}$$

M: Reception margin

N: Ratio of bit rate to clock ($N = 16$ when $ABCS$ in $SCI3nSEMR = 0$, $N = 8$ when $ABCS = 1$)

D: Duty cycle of clock ($D = 0.5$ to 1.0)

L: Frame length ($L = 9$ to 12)

F: Absolute value of clock frequency deviation

Assuming that F (absolute value of clock frequency deviation) = 0, D (duty cycle of clock) = 0.5, and $N = 16$ in formula (1), the reception margin is obtained by the formula below.

$$M = \{0.5 - 1/(2 \times 16)\} \times 100 [\%] = 46.875\%$$

However, this is only the calculated value, and a margin of 20% to 30% should be allowed in system design.

When the bit rate modulation function is used, the reference clock frequency is corrected on average.

Figure 14.3 Receive Data Sampling Timing in Asynchronous Mode

14.4.3 Clock

An internal clock generated by the on-chip baud-rate generator can be set as the SCI3's transmission/reception clock according to the settings of the CM bit in SCI3nSMR and the CKE1 and CKE0 bits in SCI3nSCR. When the SCI3 is operated on an internal clock, the clock can be output from the SCInSCK pin.

For details of clock synchronous mode, see **Section 14.6, Operation in Clock Synchronous Mode**.

In asynchronous mode, the frequency of the clock output is equal to the bit rate and the phase is such that the rising edge of the clock comes at the center of the transmit data, as shown in **Figure 14.4**.

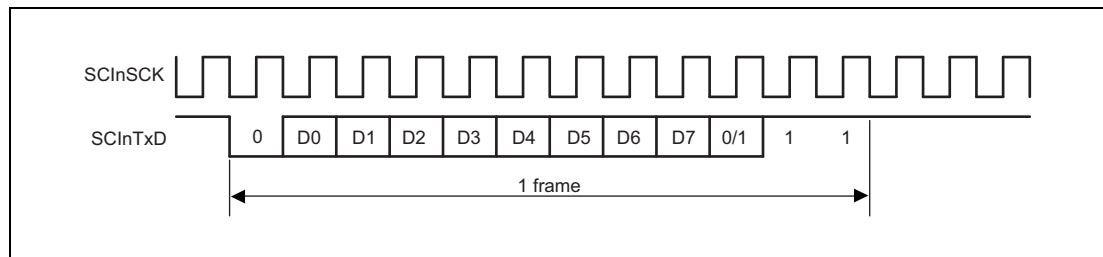

Figure 14.4 Phase Relationship between Output Clock and Transmit Data (Asynchronous Mode)

14.4.4 Double-Speed Operation

In addition to the operation described in **Section 14.4.3, Clock**, double-speed operation is enabled by the setting of the ABCS bit in SCI3nSEMR.

In double-speed operation, the same operation on a clock with a frequency of 16 times the bit rate in normal operation can be conducted on a clock with a frequency of 8 times the bit rate, meaning that the SCI3 operates on a double transfer rate using the same reference clock.

Double-speed operation can be configured with an internal clock generated by the on-chip baud-rate generator.

14.4.5 SCI3 Initialization (Asynchronous Mode)

Before transmitting and receiving data, clear the TE and RE bits in SCI3nSCR and then initialize the SCI3 according to the sample flowchart in **Figure 14.5**. Before changing the operating mode or transfer format, be sure to clear the TE and RE bits to 0. Note that clearing the TE bit to 0 sets the TDRE flag to 1, but clearing the RE bit to 0 initializes neither the RDRF, PER, FER, and ORER flags nor SCI3nRDR.

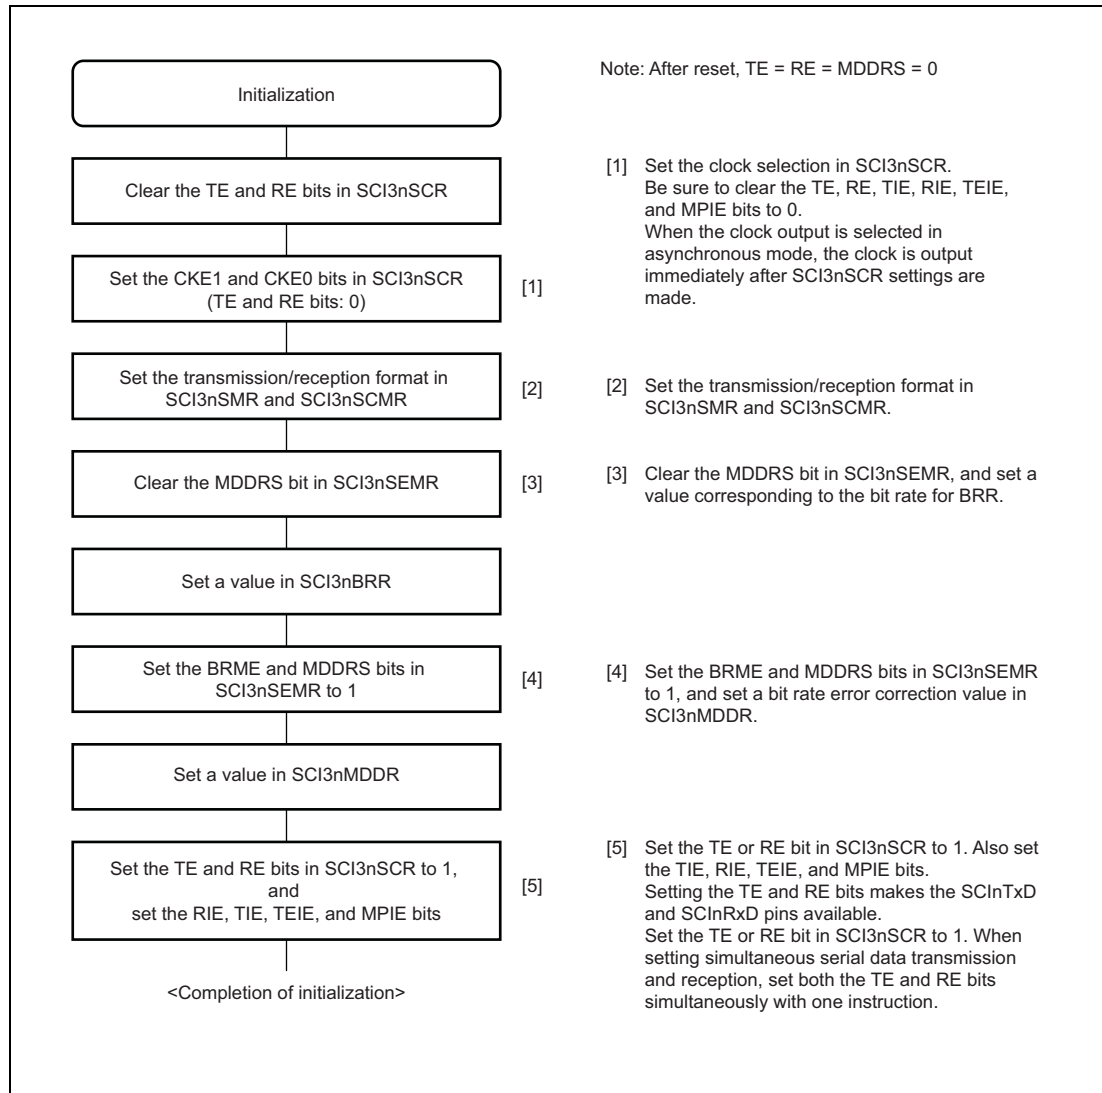

Figure 14.5 Sample Flowchart for SCI3 Initialization

14.4.6 Serial Data Transmission (Asynchronous Mode)

Figure 14.6 shows an example of operation for data transmission in asynchronous mode. In data transmission, the SCI3 operates as described below.

1. When transmit data is written to SCI3nTDR, the TDRE flag is automatically cleared to 0. The SCI3 monitors the TDRE flag in SCI3nSSR. When the flag is cleared, the SCI3 recognizes that data has been written to SCI3nTDR and transfers data from SCI3nTDR to SCI3nTSR. When writing transmit data to SCI3nTDR at a trigger of TXI interrupt request, set the TIE bit to 1 and then set the TE bit to 1 or set both TIE and TE bits simultaneously with one instruction to generate a TXI interrupt request for starting data transfer.
2. Transmission starts after data is transferred from SCI3nTDR to SCI3nTSR and the TDRE flag is set to 1. If the TIE bit in SCI3nSCR is set to 1 at this time, a TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to SCI3nTDR in this TXI interrupt processing routine before transmission of the previously transferred data is completed. When using a TEI interrupt request, write the last transmit data to SCI3nTDR and then clear the TIE bit to 0 and set the TEIE bit to 1.
3. Data is sent from the SCInTxD pin in the following order: start bit, transmit data, parity bit or multi-processor bit (may be omitted depending on the format), and stop bit.
4. The TDRE flag is checked when the stop bit is output.
5. When the TDRE flag is 0, the next transmit data is transferred from SCI3nTDR to SCI3nTSR. After the stop bit has been sent, transmission of the next frame starts.
6. When the TDRE flag is 1, the TEND flag in SCI3nSSR is set to 1, the stop bit is sent, and then 1 is output to enter the mark state. If the TEIE bit in SCI3nSCR is set to 1 at this time, a TEI interrupt request is generated.

Figure 14.7 shows a sample flowchart for data transmission. **Figure 14.8** shows a sample flowchart for stopping the SCI3 after data transmission.

Supplementary note on operation when data transmission in asynchronous mode is enabled

When the TE bit is set to 1, the high level (preamble) is output for a frame. When transmit data is written to SCI3nTDR while the preamble is output, the data is transferred from SCI3nTDR to SCI3nTSR following the completion of the preamble output.

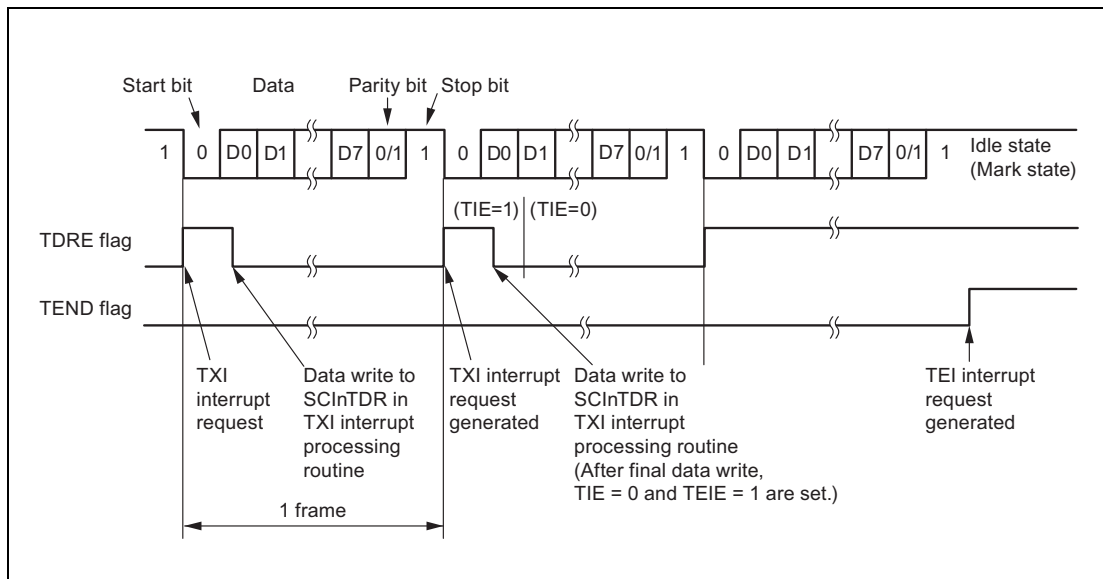

Figure 14.6 Example of Operation for Transmission in Asynchronous Mode (Example with 8-Bit Data, Parity, One Stop Bit)

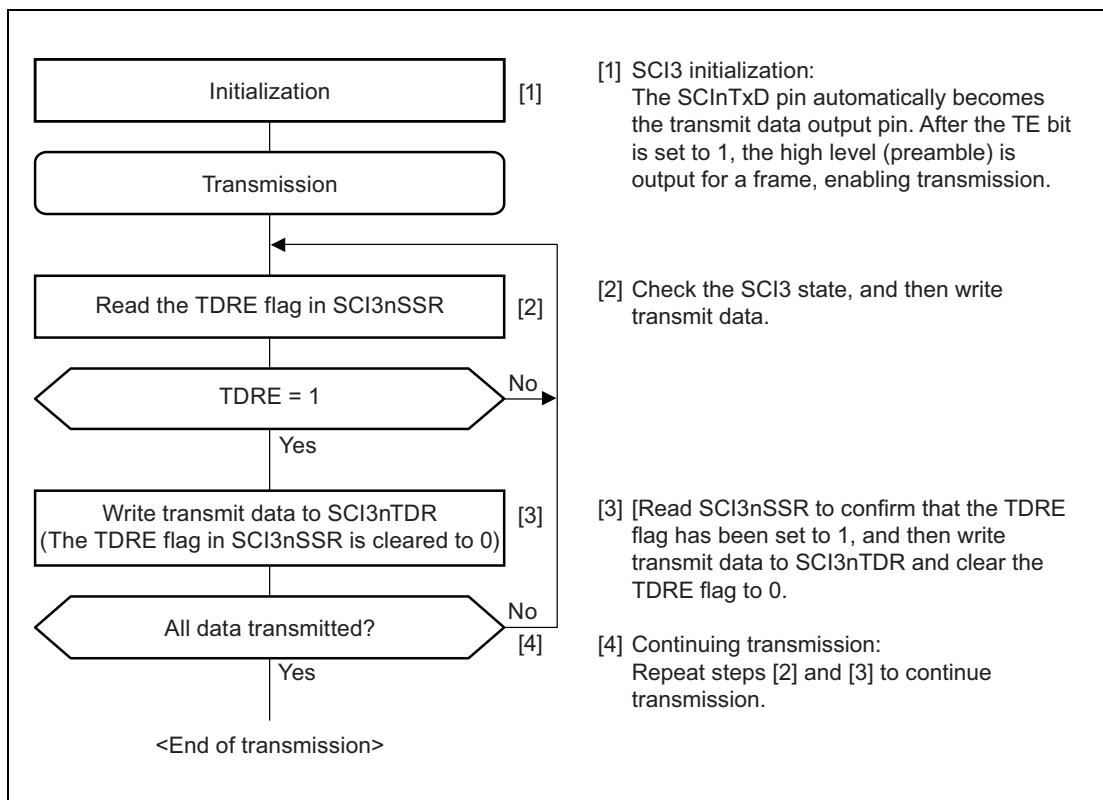

Figure 14.7 Example of Serial Transmission Flowchart

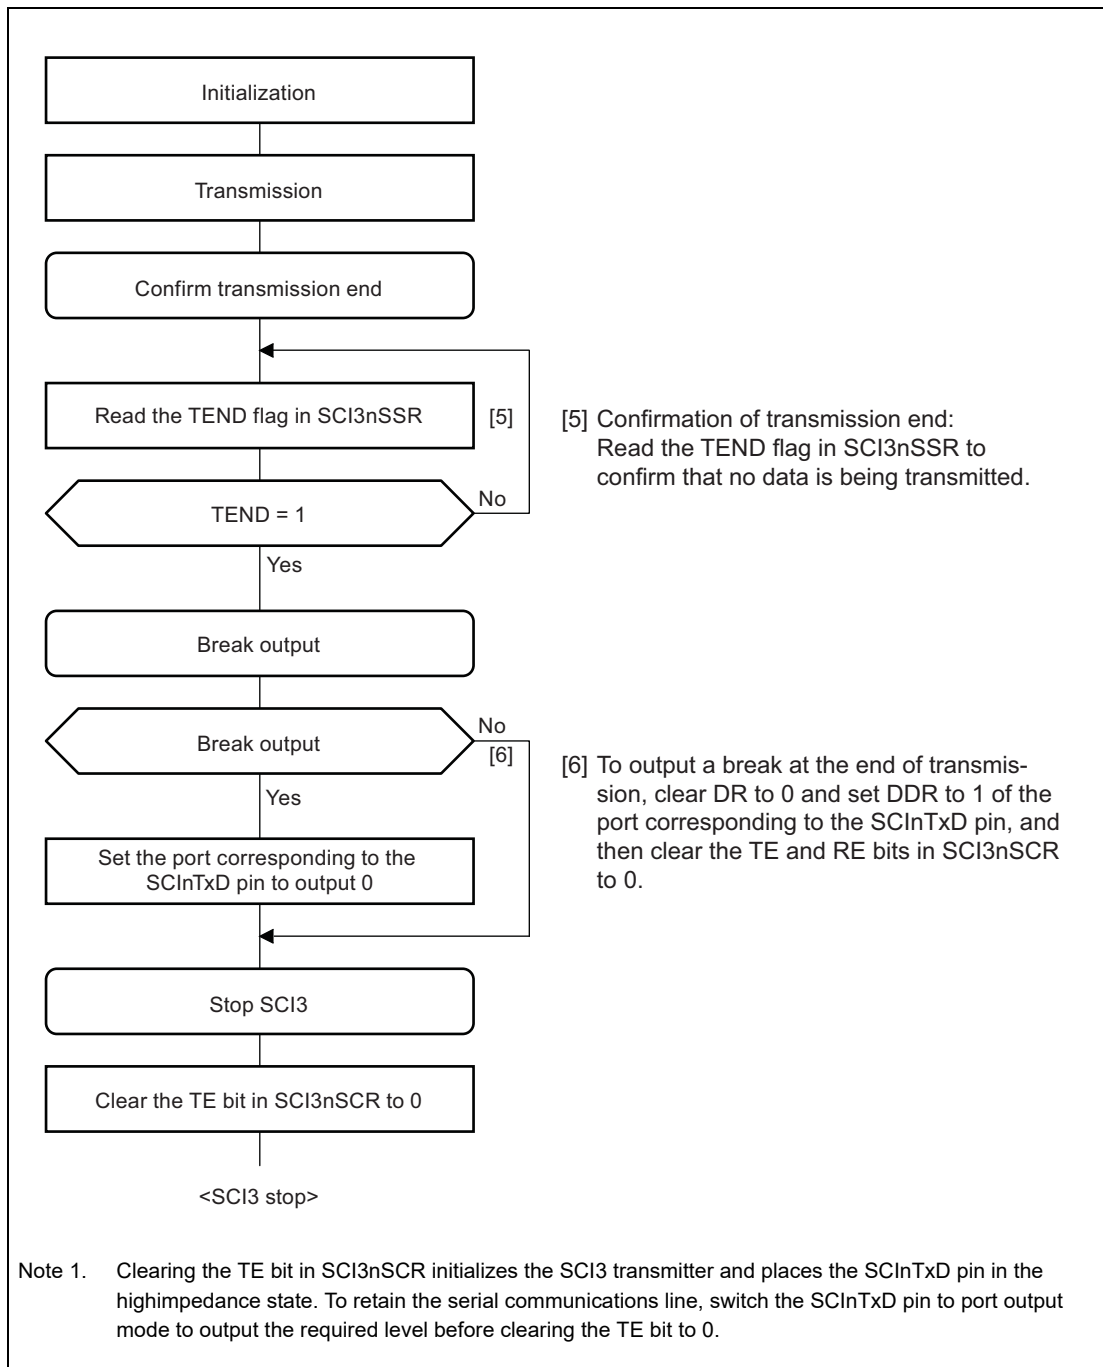

Figure 14.8 Example Flowchart for Stopping the SCI3 after Serial Transmission

14.4.7 Serial Data Reception (Asynchronous Mode)

Figure 14.9 shows an example of the operation for data reception in asynchronous mode. In data reception, the SCI3 operates as described below.

1. When the SCI3 monitors the communications line and detects a start bit, it performs internal synchronization, stores receive data in SCI3nRSR, and checks the parity bit and the stop bit.
2. When an overrun error occurs (the next data has been received with the RDRF flag in SCI3nSSR set to 1), the ORER flag in SCI3nSSR is set to 1. If the RIE bit in SCI3nSCR is set to 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to SCI3nRDR. The RDRF flag retains the state of being set to 1.
3. When a parity error is detected, the PER flag in SCI3nSSR is set to 1 and receive data is transferred to SCI3nRDR. If the RIE bit in SCI3nSCR is set to 1 at this time, an ERI interrupt request is generated.
4. When a framing error (when the stop bit is 0) is detected, the FER flag in SCI3nSSR is set to 1 and receive data is transferred to SCI3nRDR. If the RIE bit in SCI3nSCR is set to 1 at this time, an ERI interrupt request is generated.
5. When reception finishes successfully, the RDRF flag in SCI3nSSR is set to 1 and receive data is transferred to SCI3nRDR. If the RIE bit in SCI3nSCR is set to 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to SCI3nRDR in this RXI interrupt processing routine before reception of the next receive data is completed. Reading SCI3nRDR automatically clears the RDRF flag to 0.

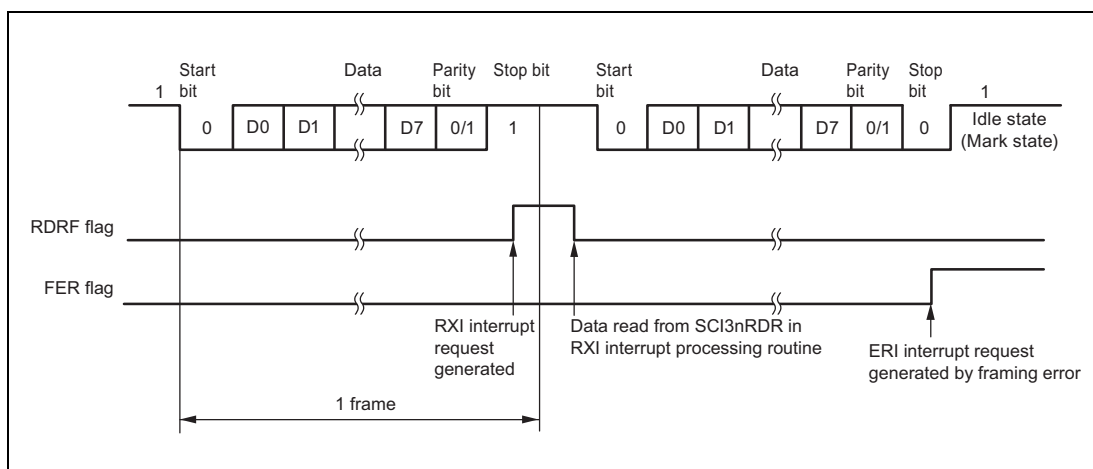

Figure 14.9 Example of Operation for Reception in Asynchronous Mode (Example with 8-Bit Data, Parity, One Stop Bit)

Table 14.16 lists the states of the SCI3nSSR status flags and receive data handling when a receive error is detected. When a receive error is detected, the RDRF flag retains the status before receiving the data. Subsequent data reception is disabled while a receive error flag is set to 1. Accordingly, clear the ORER, FER, PER, and RDRF flags before continuing data reception. **Figure 14.10** or **Figure 14.11** shows sample flowchart for data reception.

Table 14.16 SCI3nSSR Status Flags and Receive Data Handling

SCI3nSSR Status Flags				Receive Data	Receive Status
RDRF ^{*1}	ORER	FER	PER		
1	0	0	0	Transferred to SCI3nRDR	Successful reception
0	0	1	0	Transferred to SCI3nRDR	Framing error
0	0	0	1	Transferred to SCI3nRDR	Parity error
0	0	1	1	Transferred to SCI3nRDR	Framing error + parity error
1*	1	0	0	Lost	Overrun error
1*	1	1	0	Lost	Overrun error + framing error
1*	1	0	1	Lost	Overrun error + parity error
1*	1	1	1	Lost	Overrun error + framing error + parity error

Note 1. In the case of an overrun error, the RDRF flag retains the state before the data reception.

Note: A sign "+" indicates that two or more receive states occur simultaneously in a single reception operation.

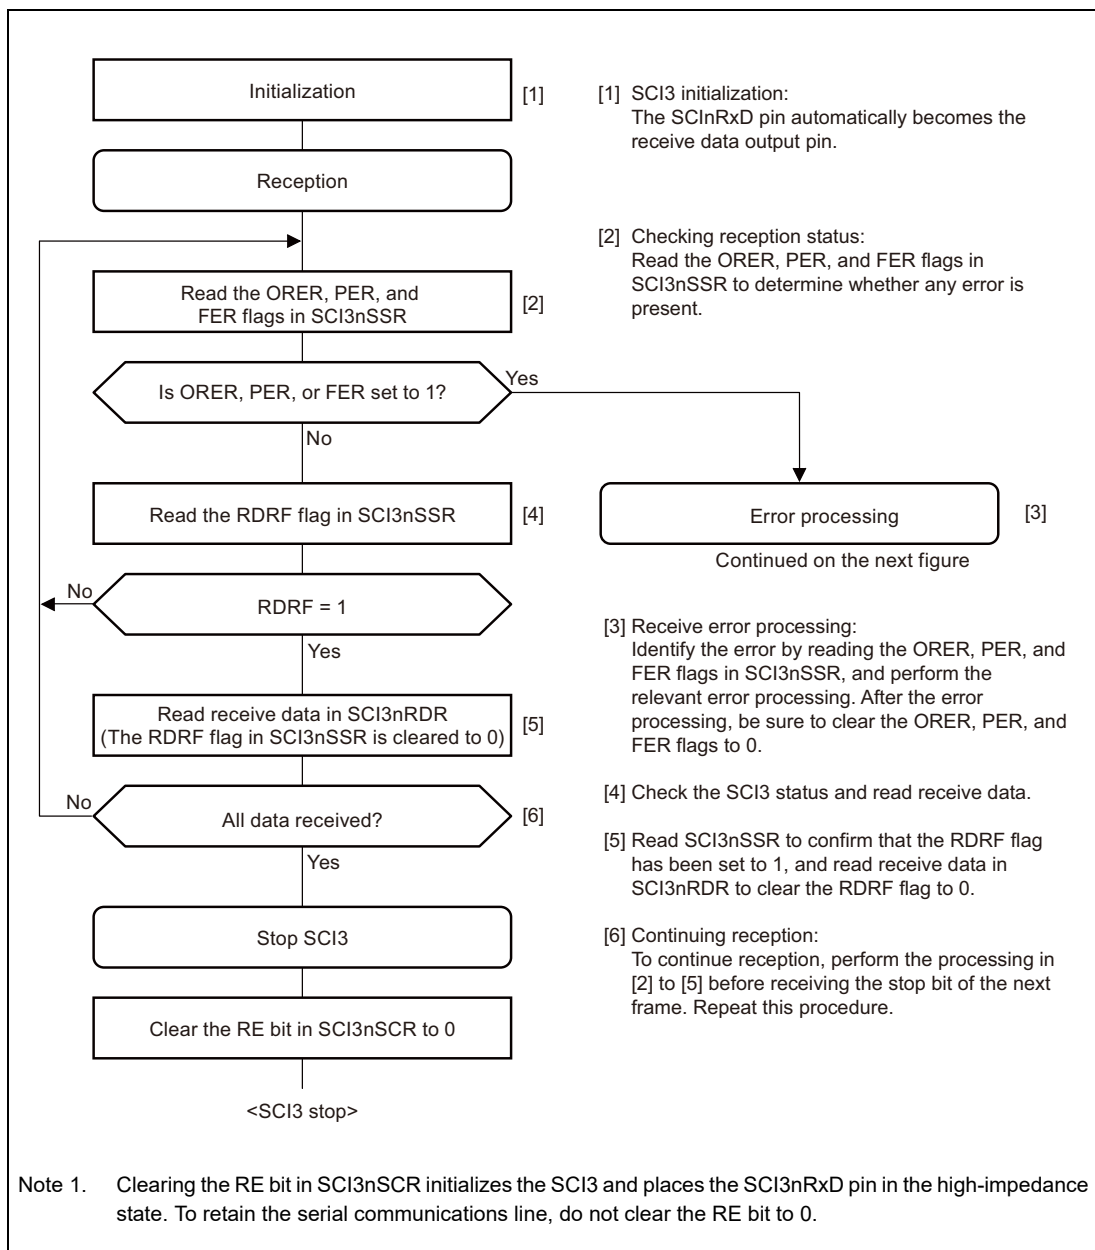

Figure 14.10 Example of Serial Reception Flowchart (1)

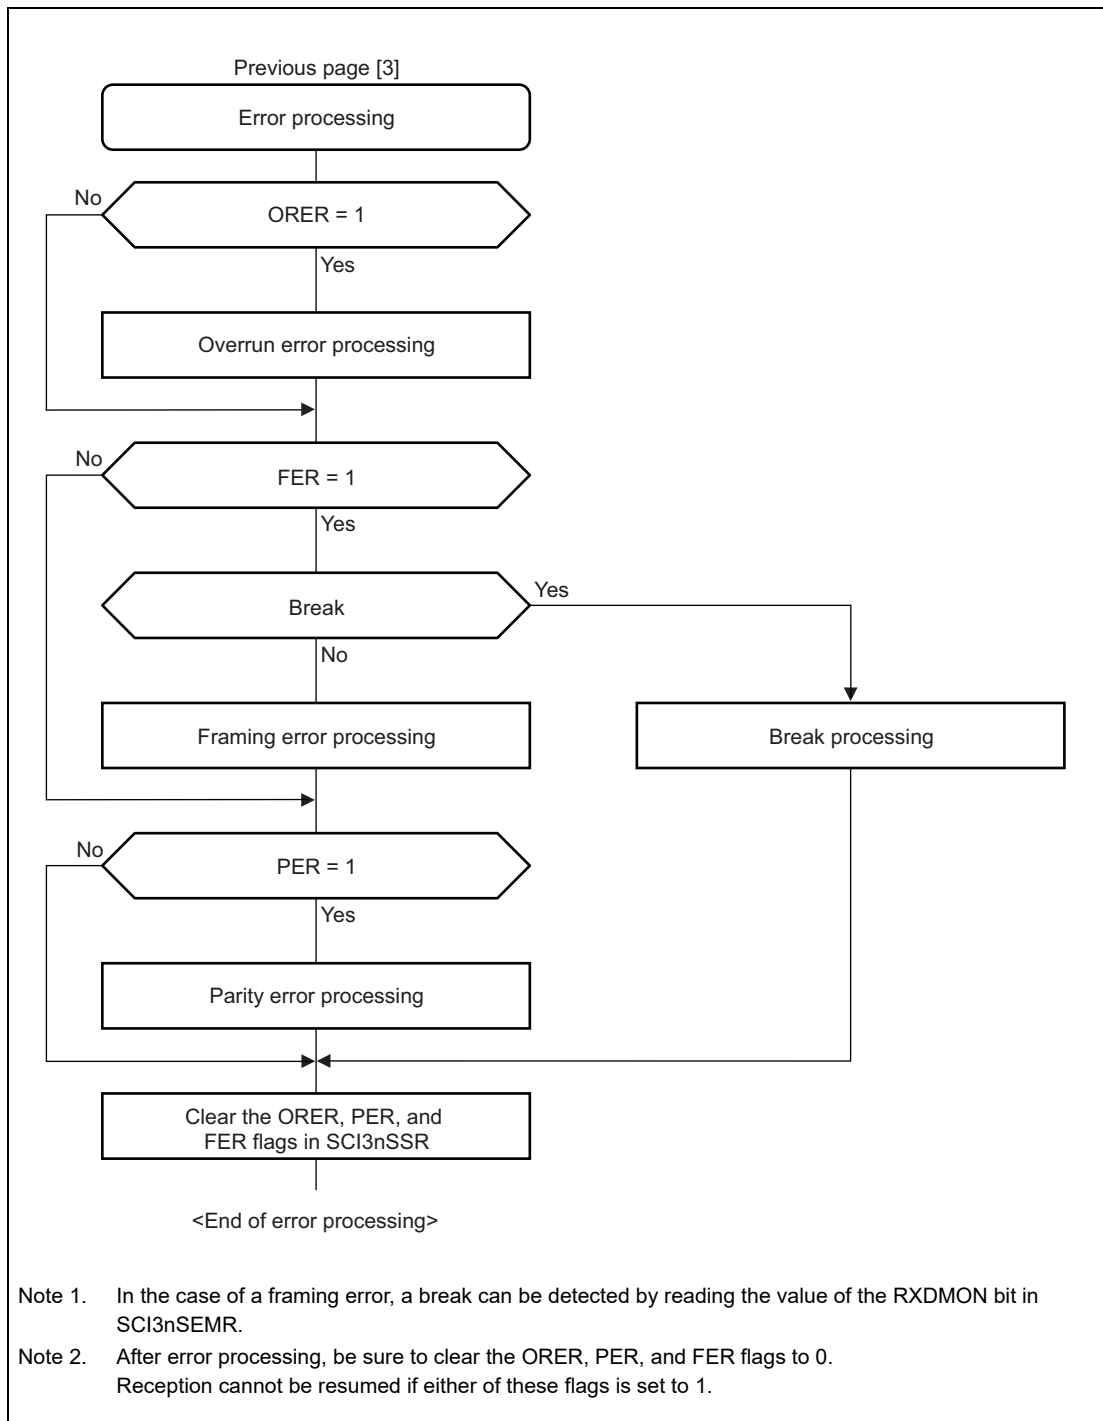

Figure 14.11 Example of Serial Reception Flowchart (2)

14.5 Multi-Processor Communication Function

14.5.1 Overview and Sample Connection

Using the multi-processor communication function allows data transmission and reception by sharing a communication line between multiple processors by using asynchronous serial communication in which the multi-processor bit is added. In multi-processor communication, a unique ID code is allocated to each receiving station. Serial communication cycles consist of an ID transmission cycle to specify the receiving station and a data transmission cycle to transmit data to the specified receiving station. The multi-processor bit is used to distinguish the ID transmission cycle from the data transmission cycle. When the multi-processor bit is set to 1, it indicates the ID transmission cycle. When the multi-processor bit is set to 0, it indicates the data transmission cycle. **Figure 14.12** shows an example of communication between processors by using the multi-processor format. First, a transmitting station sends communication data in which the multi-processor bit (= 1) is added to the ID code of the receiving station. Next, the transmitting station sends communication data in which the multi-processor bit (= 0) is added to the transmit data. Upon receiving the communication data in which the multi-processor bit is set to 1, the receiving station compares the received ID with the ID of the receiving station itself. When these IDs match, the receiving station receives communication data that is subsequently transmitted. If these IDs do not match, the receiving station skips communication data until it receives communication data in which the multi-processor bit is set to 1.

To support this function, the SCI3 provides the MPIE bit in SCI3nSCR. When the MPIE bit is set to 1, transfer of receive data from SCI3nRSR to SCI3nRDR, detection of a receive error, and setting the RDRF, FER, and ORER flags in SCI3nSSR are disabled until data in which the multi-processor bit is set to 1 is received. Upon receiving a character in which the multi-processor bit is set to 1, the MPB bit in SCI3nSSR is set to 1 and the MPIE bit is automatically cleared to 0, thus returning to a normal reception operation. When the RIE bit in SCI3nSCR is set to 1 at this time, an RXI interrupt request is generated. While the MPIE bit is cleared to 0, reception operation is conducted regardless of the multi-processor bit value. The multi-processor bit is stored in the MPB bit in SCI3nSSR.

When the multi-processor format is specified, specification of the parity bit is disabled. Apart from this, there is no difference from the operation in the normal asynchronous mode. A clock that is used for multi-processor communications is also the same as the clock used in the normal asynchronous mode.

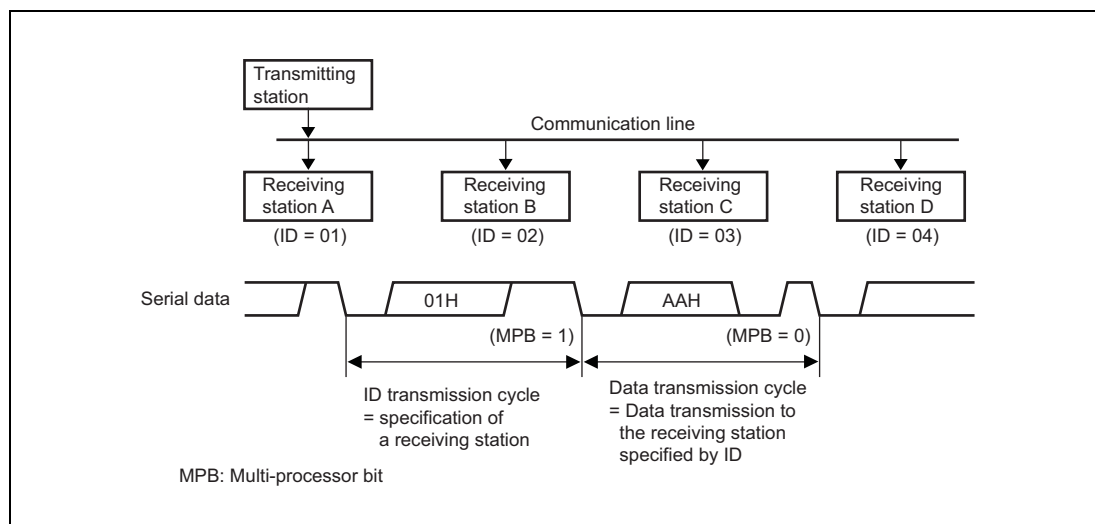

Figure 14.12 Example of Communication Using the Multi-Processor Format (Example of Transmission of Data AA_H to Receiving Station A)

14.5.2 Multi-Processor Serial Data Transmission

Figure 14.13 shows a sample flowchart of multi-processor data processing. In the ID transmission cycle, send the ID with the MPBT bit in SCI3nSSR set to 1. In the data transmission cycle, send data with the MPBT bit in SCI3nSSR cleared to 0. Other operations are the same as operations in asynchronous mode.

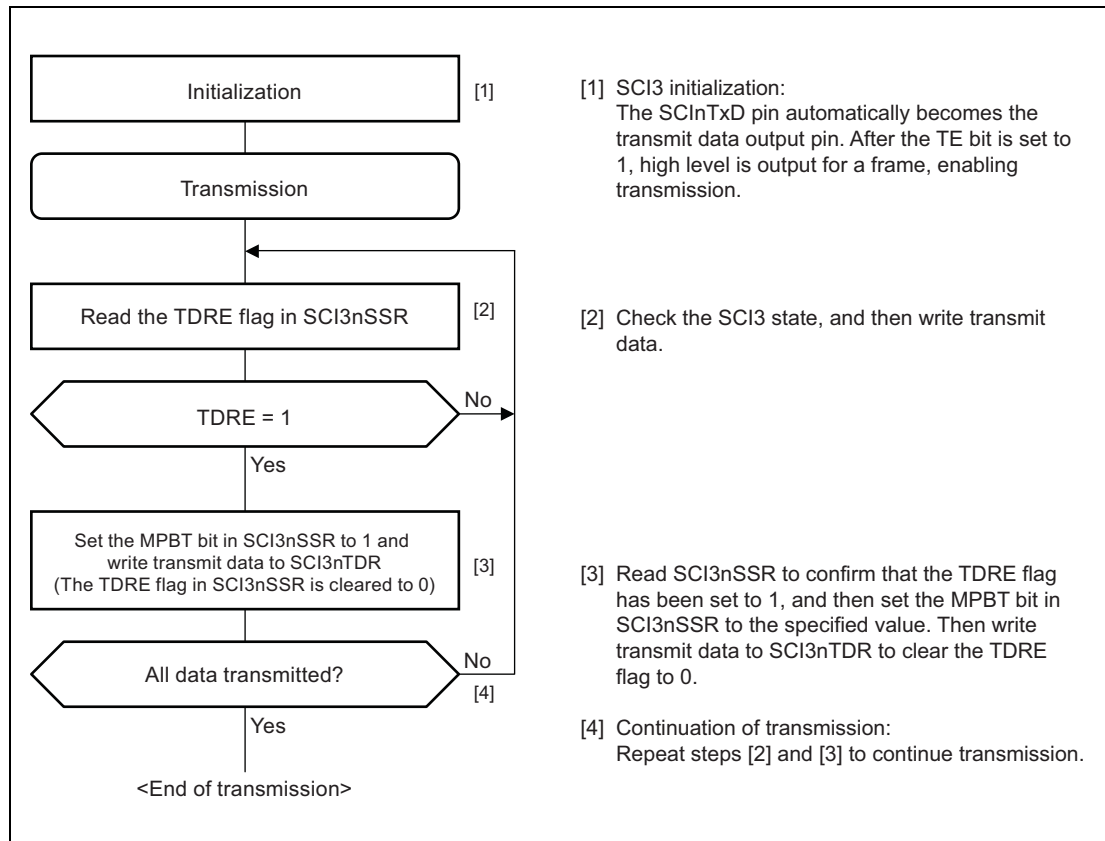

Figure 14.13 Example of Multi-Processor Serial Transmission Flowchart

14.5.3 Multi-Processor Serial Data Reception

Figure 14.15 to Figure 14.17 shows sample flowcharts of multi-processor data reception. When the MPIE bit in SCI3nSCR is set to 1, reading the communication data is skipped until communication data in which the multi-processor bit is set to 1 is received. When communication data in which the multi-processor bit is set to 1 is received, the receive data is transferred to SCI3nRDR. At this time, an RXI interrupt request is generated. Other operations are the same as operations in asynchronous mode. Figure 14.14 shows an example of operation for reception.

CAUTION

Do not write data to SCI3nSCR when communication data in which the multi-processor bit is set to 1 is received. The MPIE bit may not become the desired state.

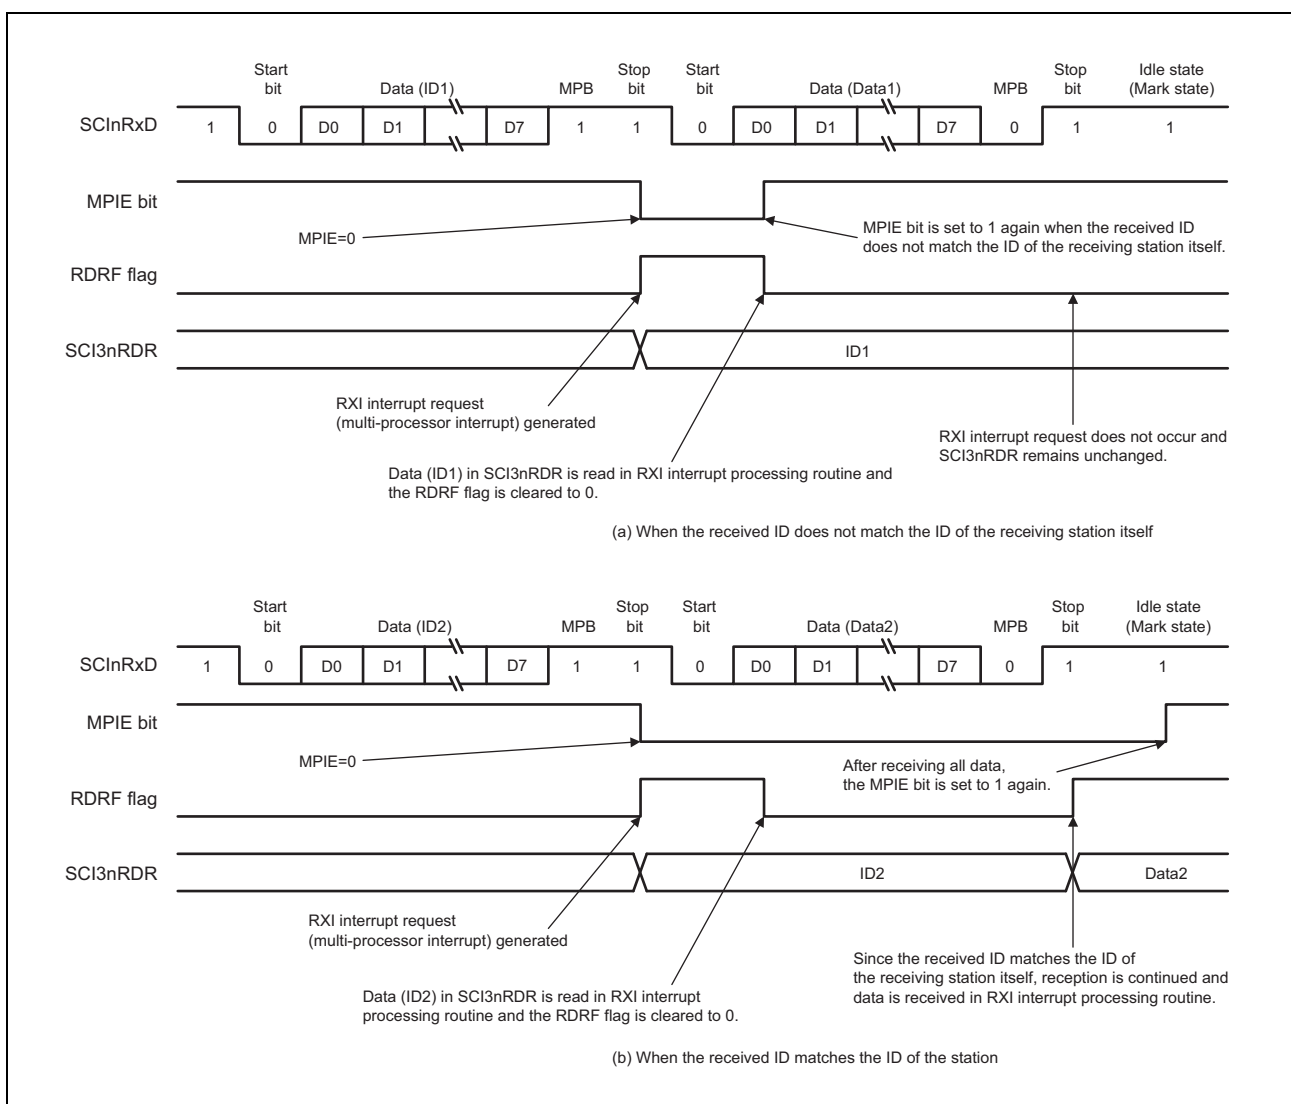

Figure 14.14 Example of SCI3 Reception (8-Bit Data, Multi-Processor Bit, One Stop Bit)

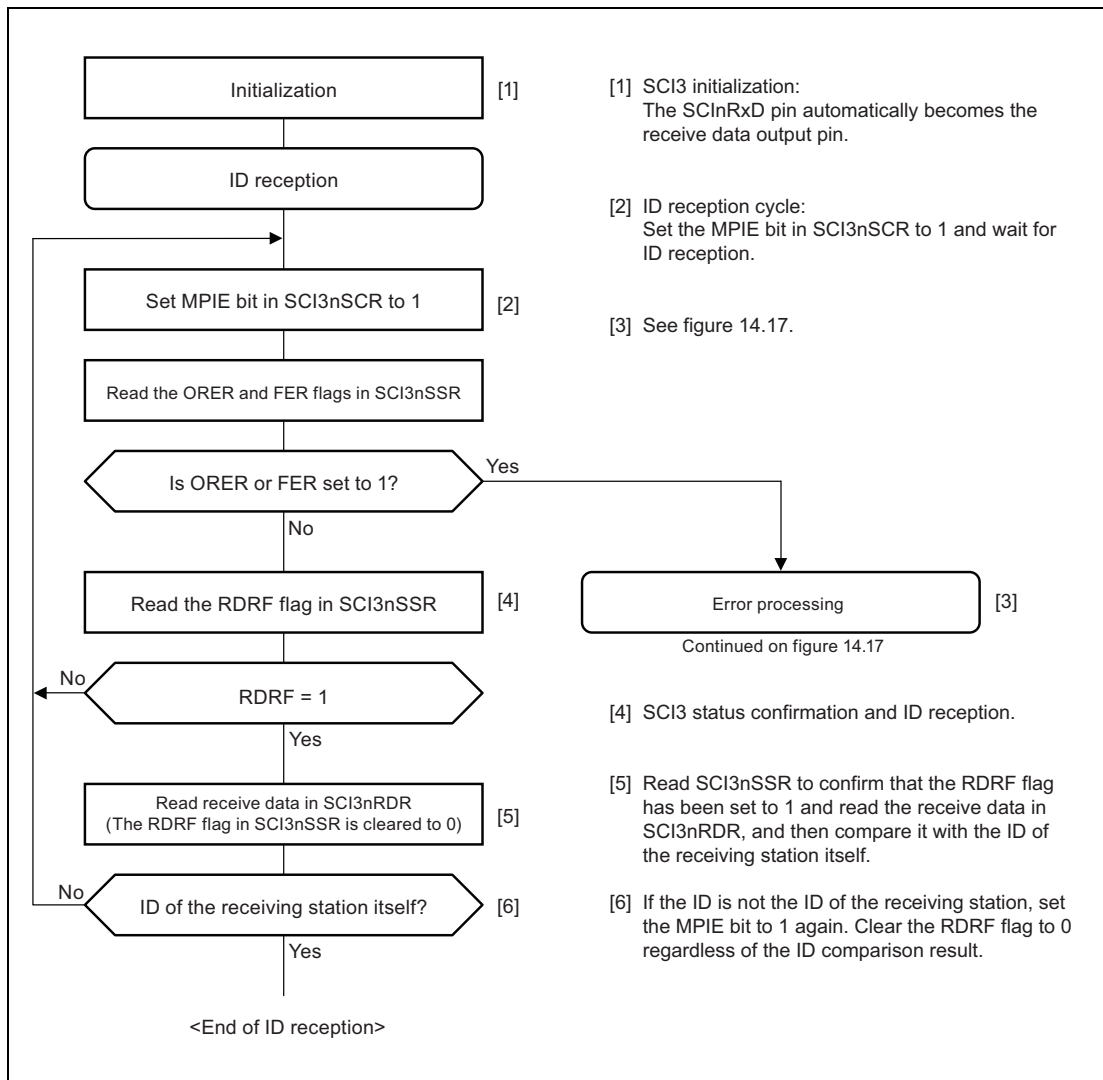

Figure 14.15 Example of Multi-Processor Serial Reception Flowchart (1)

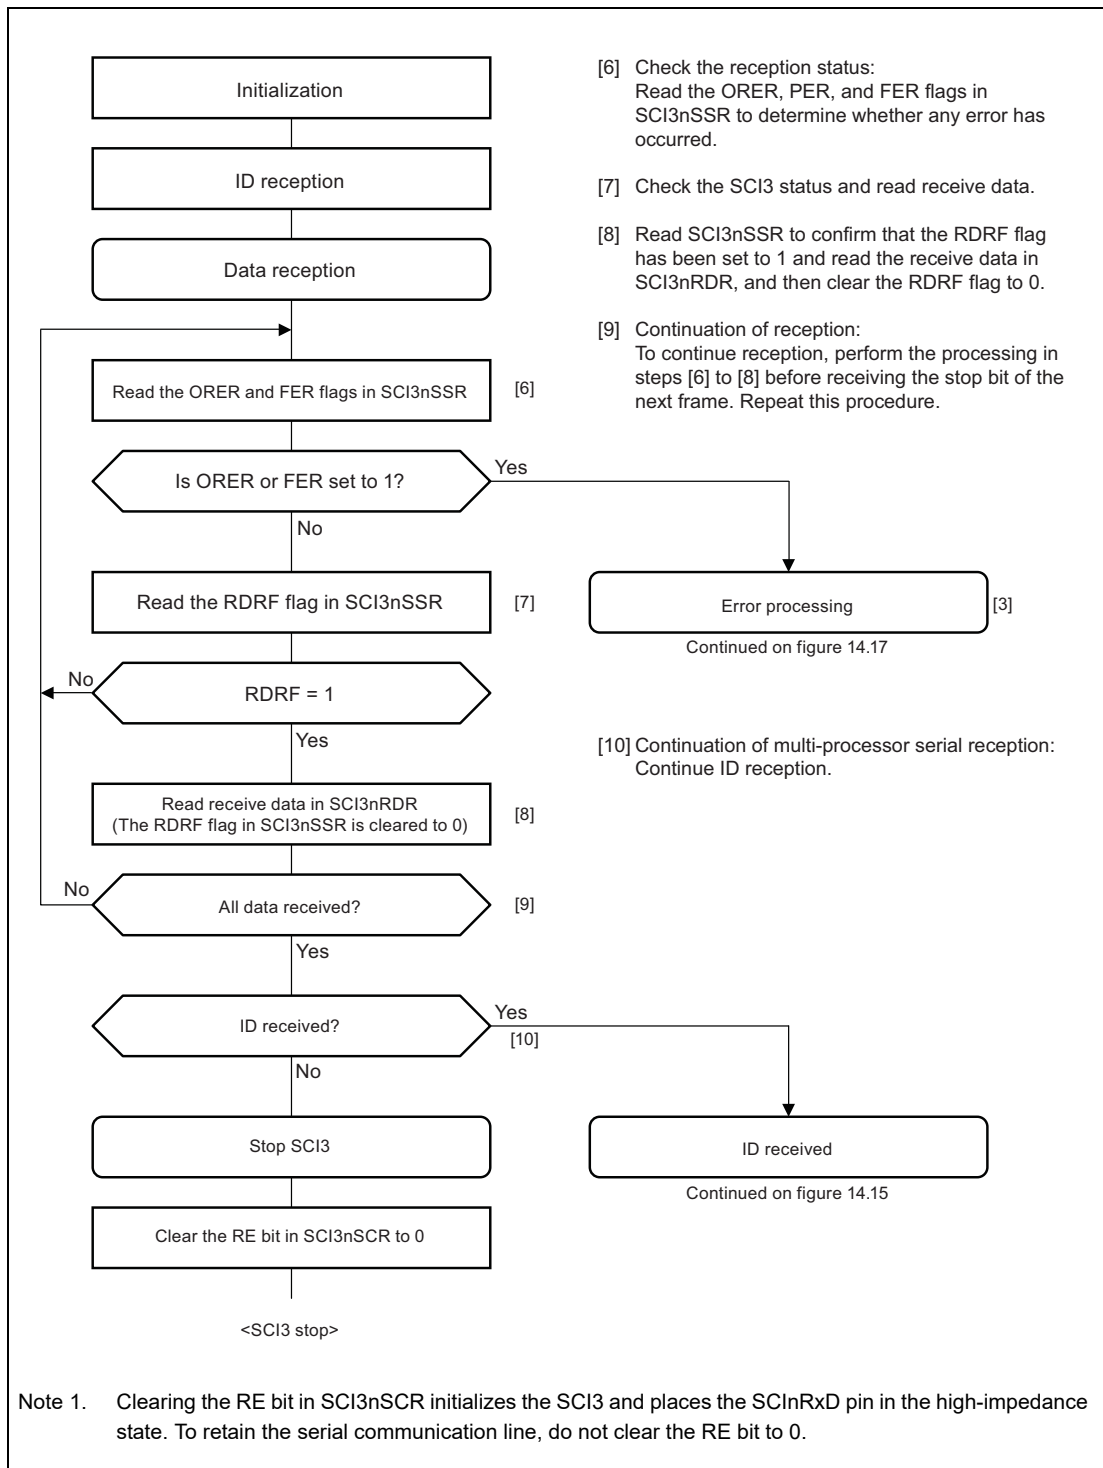

Figure 14.16 Example of Multi-Processor Serial Reception Flowchart (2)

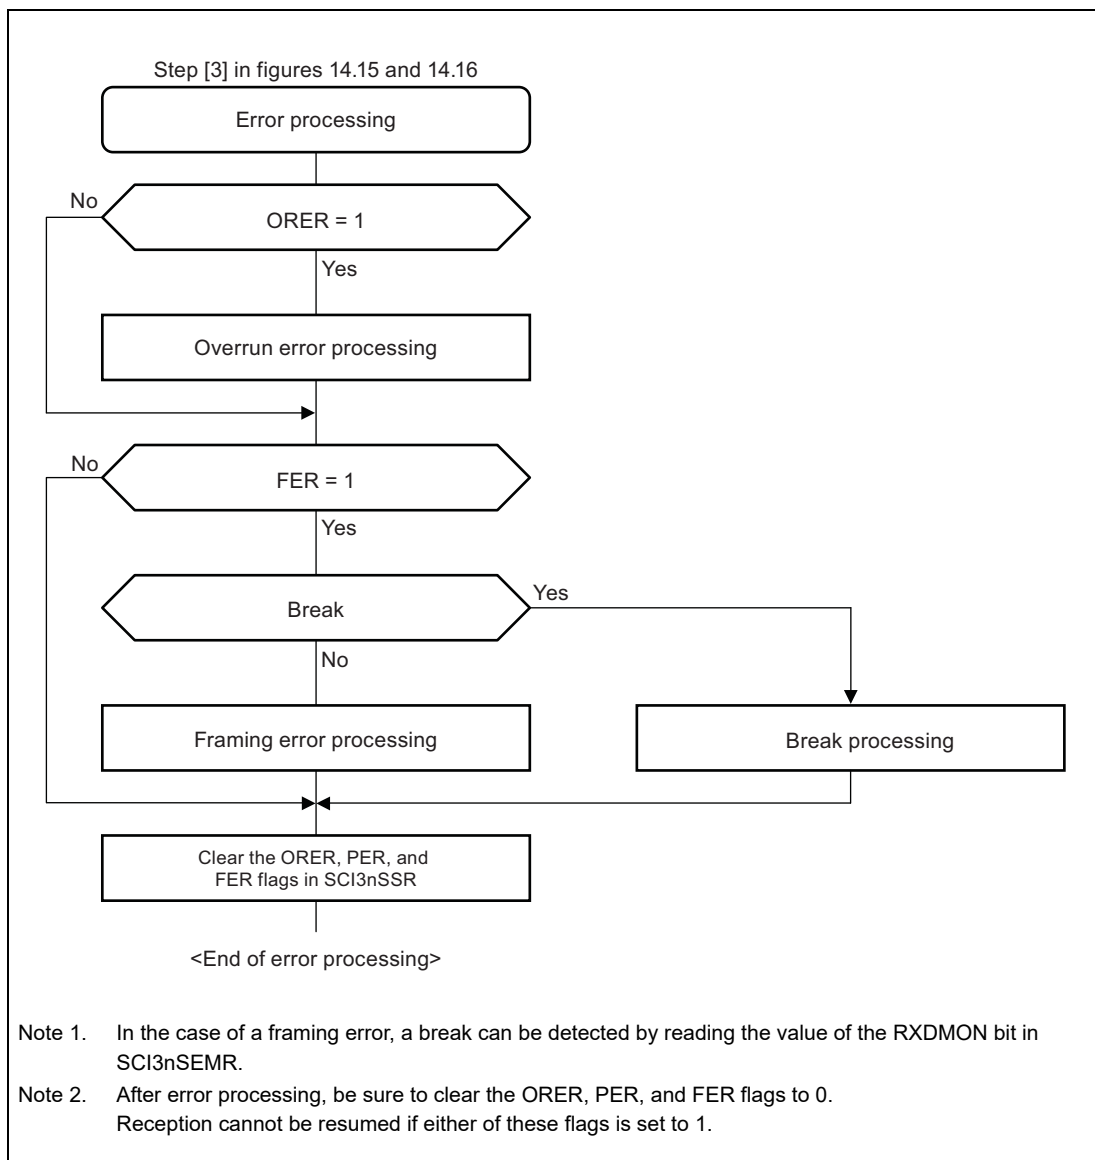

Figure 14.17 Example of Multi-Processor Serial Reception Flowchart (3)

14.6 Operation in Clock Synchronous Mode

Figure 14.18 shows the data format for clock synchronous serial data communication. In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. One character in transfer data consists of 8-bit data. In data transmission with the synchronization clock output, the SCI3 outputs data from one falling edge to the next falling edge of the synchronization clock. In data transmission with the synchronization clock input, the SCI3 outputs the first data (bit 0) after starting transfer immediately after clearing the TDRE bit in SCI3nSSR to 0, and then outputs the next bit data after 2 to 3 ϕ clock cycles from the falling edge of the synchronization clock. In data reception, the SCI3 receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the communication line holds the last-bit output state. In clock synchronous mode, neither parity bit nor multi-processor bit can be added. The transmitter and the receiver are independent in the SCI3, enabling full-duplex communication by using a common clock. Both the transmitter and the receiver have a double-buffered structure so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.

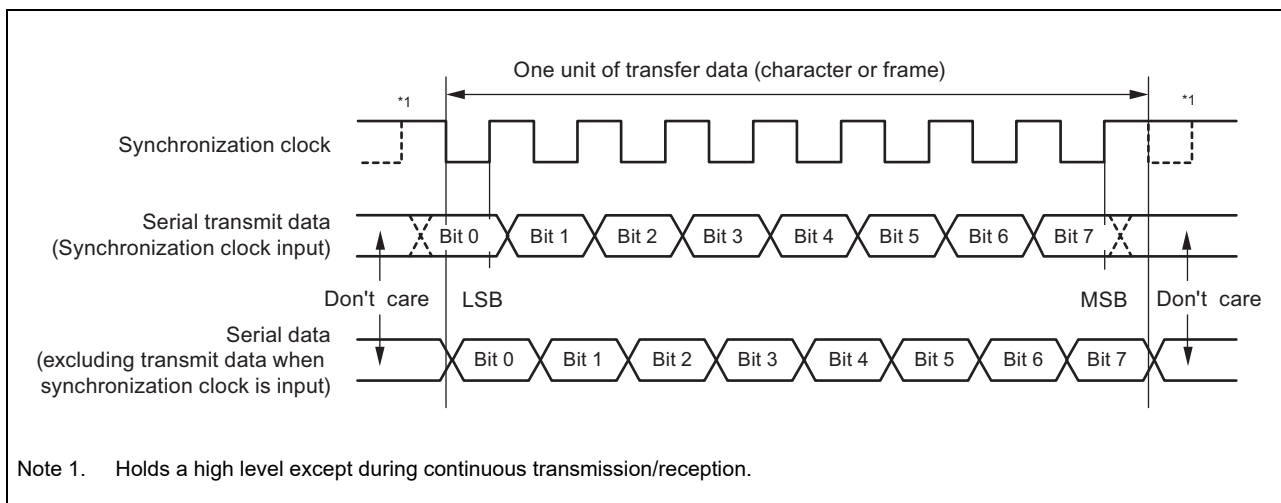

Figure 14.18 Data Format in Clock Synchronous Mode (LSB-First)

14.6.1 Clock

An internal clock generated by the on-chip baud rate generator or an external synchronous clock that is input from the SCInSCK pin can be selected by the setting of the CKE1 and CKE0 bits in SCI3nSCR. When operating the SCI3 on the internal clock, a synchronous clock is output from the SCInSCK pin. Eight pulses of the synchronous clock are output during transfer of one character, and the clock is held high while no data is transferred.

14.6.2 SCI3 Initialization (Clock Synchronous Mode)

Before transmitting and receiving data, clear the TE and RE bits in SCI3nSCR to 0 and then initialize the SCI3 according to the sample flowchart in **Figure 14.19**. To switch the operation between transmission, reception, and transmission/reception, clear the TE and RE bits to 0 and then set these bits to the desired value. Before changing the transfer format, be sure to clear the TE and RE bits to 0. Note that clearing the TE bit to 0 sets the TDRE flag to 1, but clearing the RE bit to 0 initializes neither the RDRF, PER, FER, and ORER flags nor SCI3nRDR.

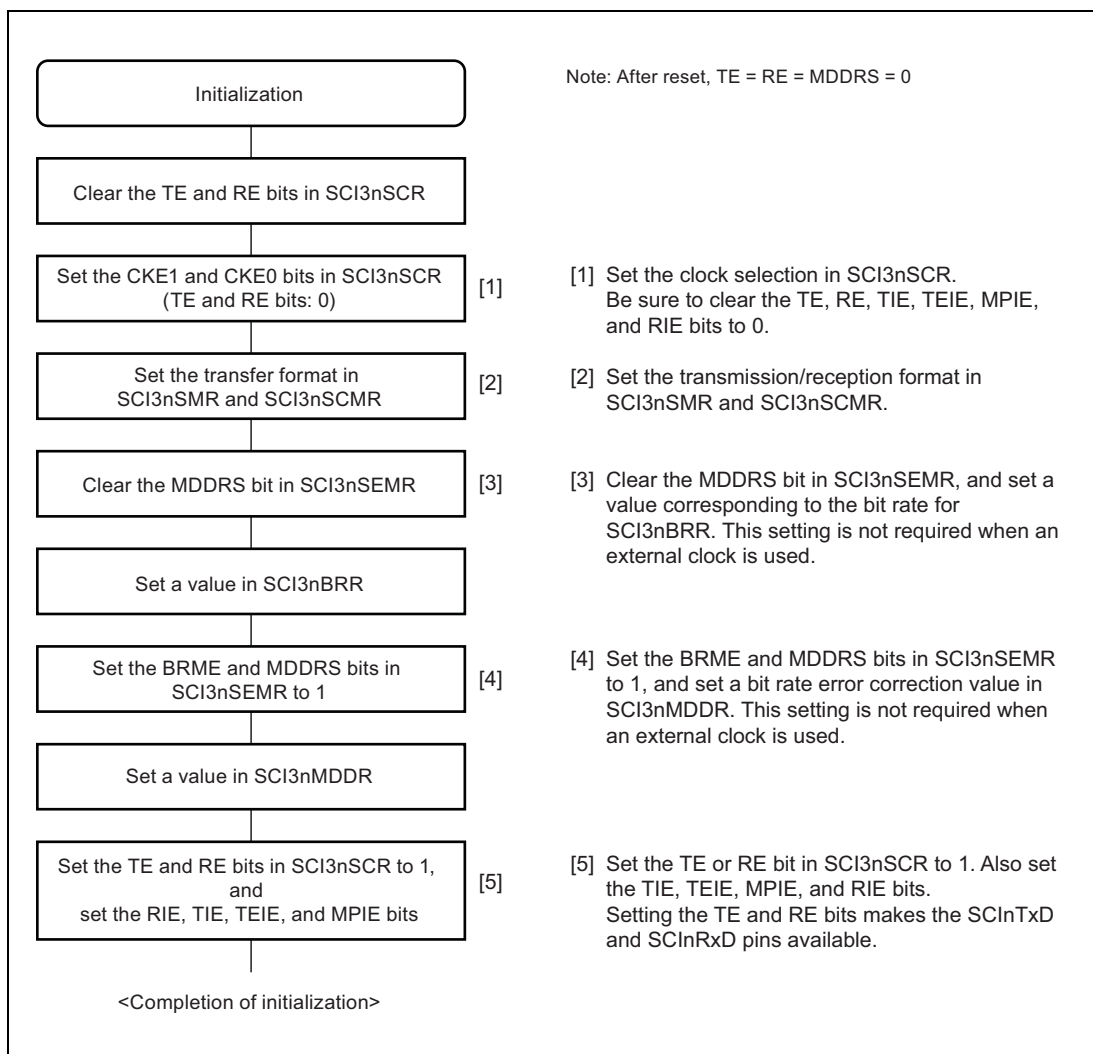

Figure 14.19 Example of SCI3 Initialization Flowchart

14.6.3 Serial Data Transmission (Clock Synchronous Mode)

Figure 14.20 shows an example of the operation for serial transmission in clock synchronous mode. In serial data transmission, the SCI3 operates as described below.

1. When transmit data is written to SCI3nTDR, the TDRE flag is automatically cleared to 0. The SCI3 monitors the TDRE flag in SCI3nSSR. When the flag is cleared, the SCI3 recognizes that data has been written to SCI3nTDR and transfers data from SCI3nTDR to SCI3nTSR, starting output of the first bit when the synchronization clock is input. To write transmit data to SCI3nTDR at a trigger of TXI interrupt request, set the TIE bit to 1 and then set the TE bit to 1 or set both TIE and TE bits simultaneously with one instruction to generate a TXI interrupt request for starting data transfer.
2. Transmission starts after data is transferred from SCI3nTDR to SCI3nTSR, and the TDRE flag is set to 1. When the TIE bit in SCI3nSCR is set to 1 at this time, a TXI interrupt request is generated. Continuous transmission is enabled by writing the next transmit data to SCI3nTDR in this TXI interrupt processing routine before the previously transferred data has been transmitted. When a TEI interrupt request is used, the TIE bit is cleared to 0 after the last transmit data has been written to SCI3nTDR, and the TEIE bit is set to 1.
3. 8-bit data is output from the SCInTxD pin in synchronization with the output clock (when clock output mode has been specified) or in synchronization with the input clock (when external clock has been specified).
4. The SCI3 checks for the TDRE flag at the time of the last bit output.
5. When the TDRE flag is 0, the next transmit data is transferred from SCI3nTDR to SCI3nTSR, and serial transmission of the next frame starts.
6. When the TDRE flag is 1, the TEND flag in SCI3nSSR is set to 1 and the SCInSCK pin retains the output state of the last bit. If the TEIE bit in SCI3nSCR is set to 1 at this time, a TEI interrupt request is generated. The SCInSCK pin is held high.

Figure 14.21 shows a sample flowchart of serial data transmission. Also, **Figure 14.22** shows a sample flowchart for stopping the SCI3 after data transmission. Transmission will not start even if the TDRE flag is cleared while a receive error flag (ORER) is set to 1. Be sure to clear the receive error flags to 0 before starting transmission. Note that clearing the RE bit to 0 does not clear the receive error flags.

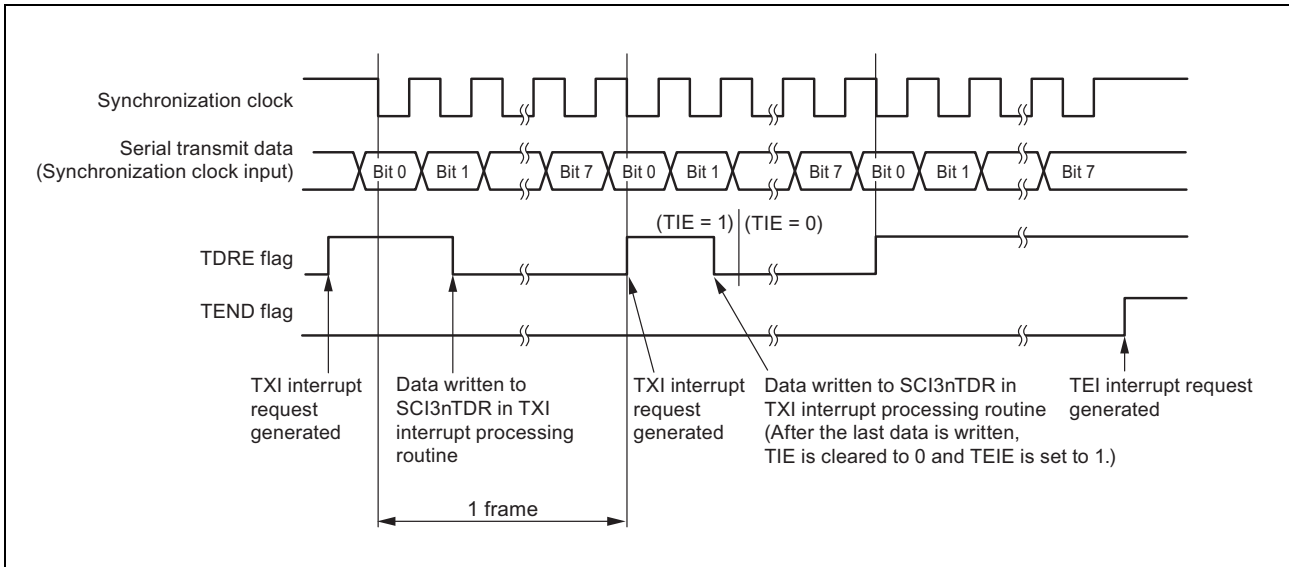

Figure 14.20 Example of Operation for Transmission in Clock Synchronous Mode

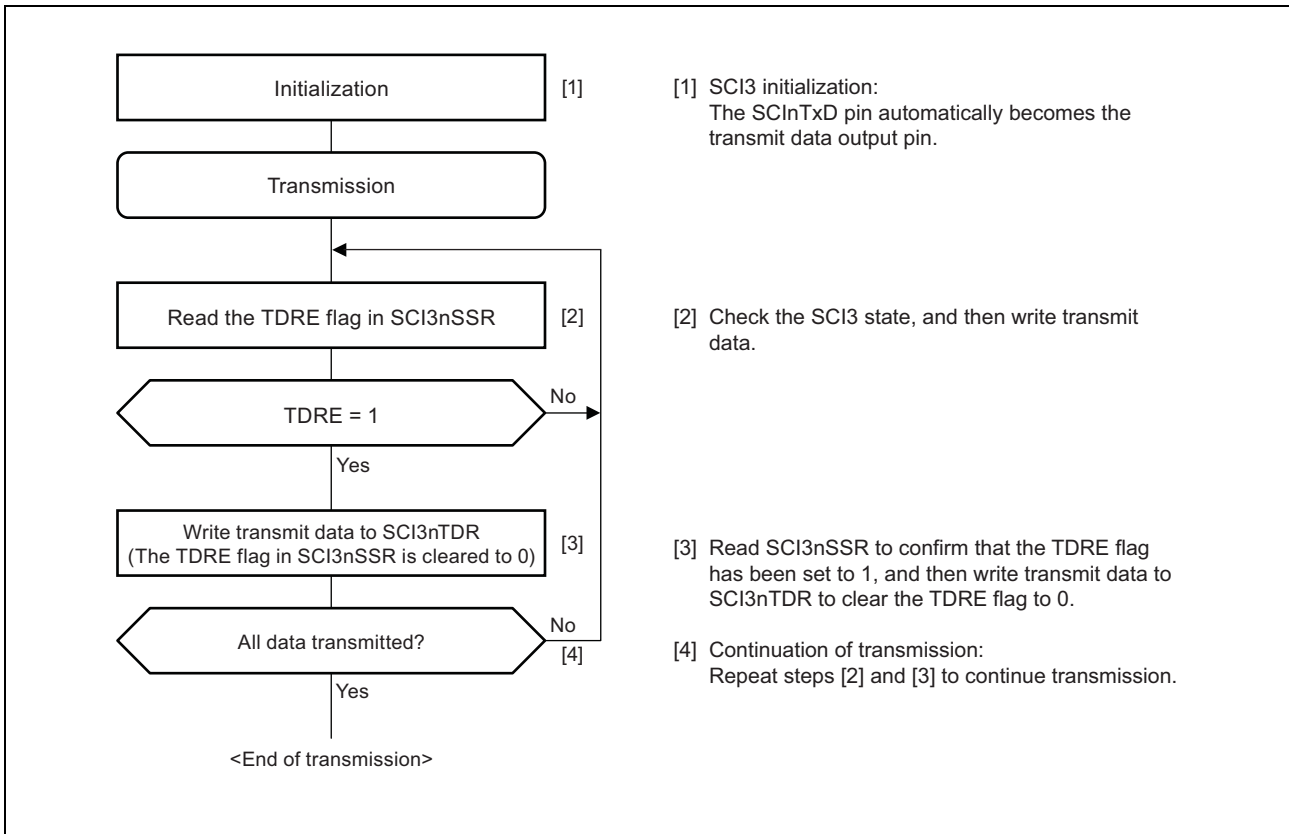

Figure 14.21 Example of Serial Transmission Flowchart

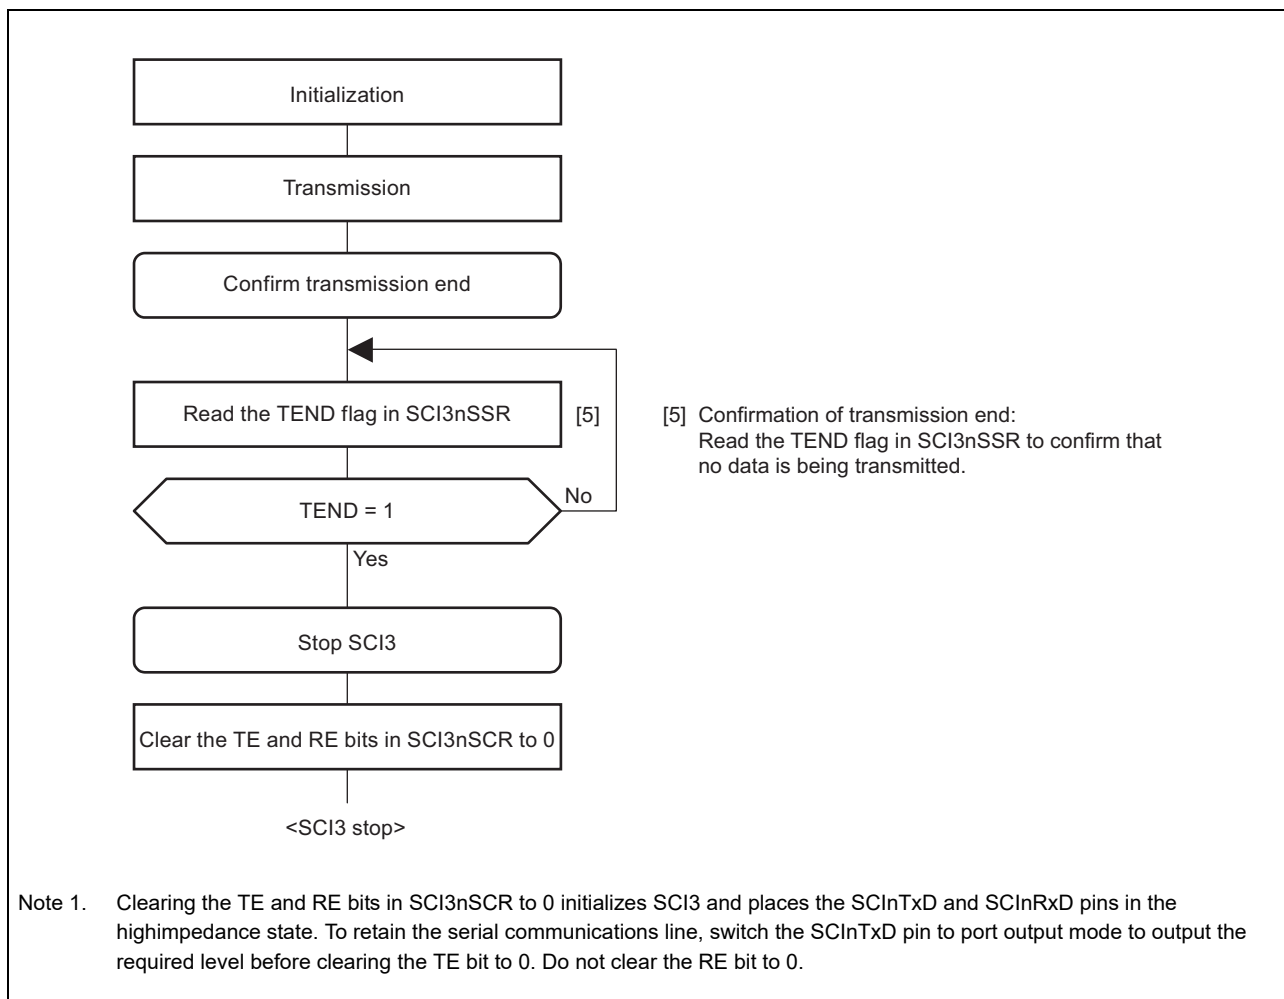

Figure 14.22 Example Flowchart for Stopping the SCI3 after Serial Transmission

14.6.4 Serial Data Reception (Clock Synchronous Mode)

Figure 14.23 shows an example of SCI3 operation for serial reception in clock synchronous mode. In serial data reception, the SCI3 operates as described below.

1. The SCI3 performs internal initialization and starts receiving data in synchronization with a synchronization clock input or output, and stores receive data in SCI3nRSR.
2. When an overrun error occurs (the reception of the next data is completed with the RDRF flag in SCI3nSSR set to 1), the ORER flag in SCI3nSSR is set to 1. If the RIE bit in SCI3nSCR is set to 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to SCI3nRDR. The RDRF flag retains the state of being set to 1.
3. When data has been successfully received, the RDRF flag in SCI3nSSR is set to 1 and the receive data is transferred to SCI3nRDR. When the RIE bit in SCI3nSCR is set to 1 at this time, an RXI interrupt request is generated. Continuous reception is enabled by reading the receive data transferred to SCI3nRDR in this RXI interrupt processing routine before reception of the next data is completed. Reading SCI3nRDR automatically clears the RDRF flag to 0.

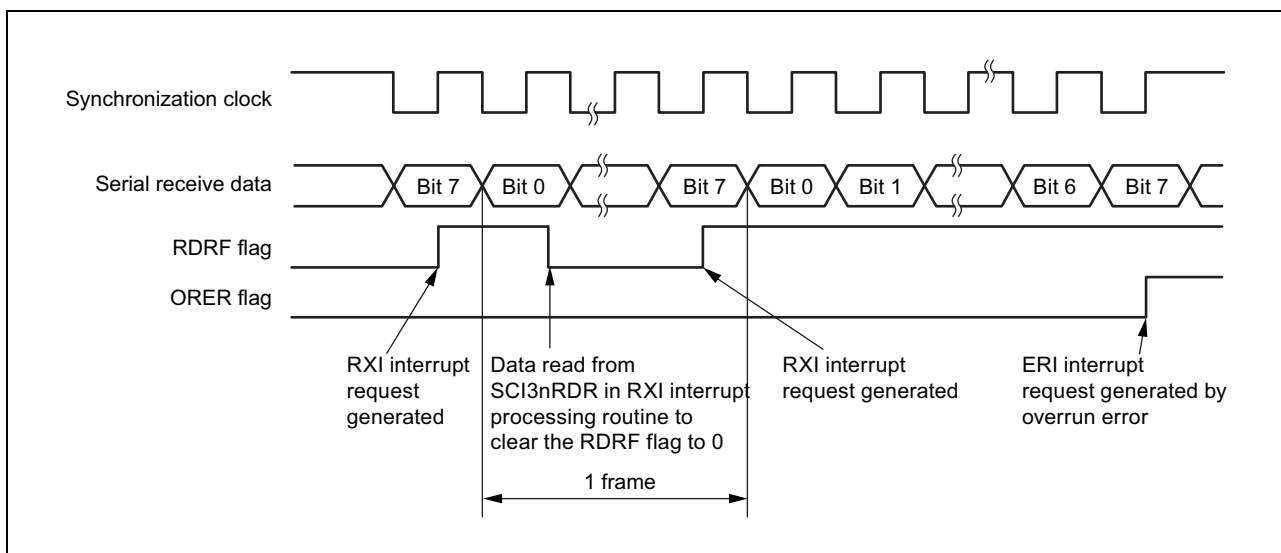

Figure 14.23 Example of SCI3 Operation for Reception

Subsequent transmission and reception are disabled with a receive error flag set to 1. Therefore, be sure to clear the ORER, FER, PER, and RDRF flags before continuing reception. **Figure 14.24** shows an example of flowchart for data reception.

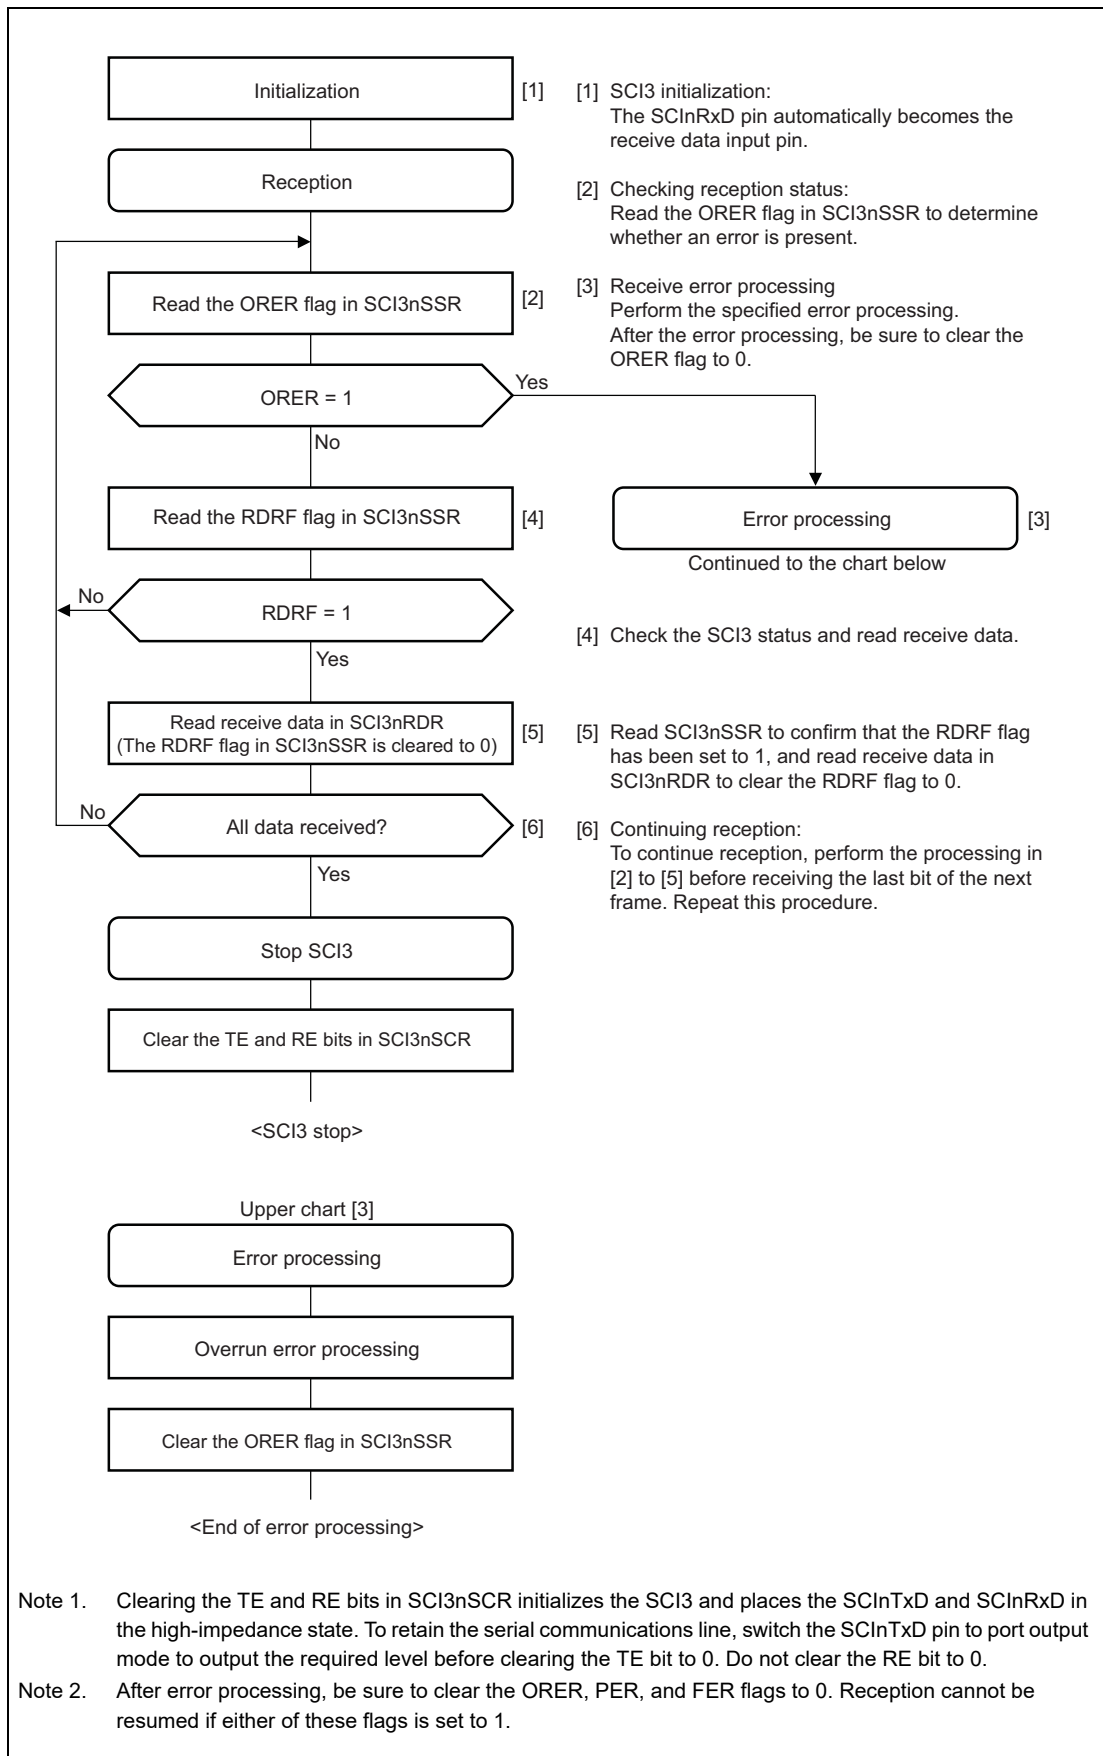

Figure 14.24 Example of Serial Reception Flowchart

14.6.5 Simultaneous Serial Data Transmission and Reception (Clock Synchronous Mode)

Figure 14.25 shows a sample flowchart for simultaneous data transmit and receive operations. After the SCI3 is initialized, perform the following procedure for simultaneous data transmit and receive operations.

1. To change transmit mode to simultaneous transmit and receive mode, check that the SCI3 has finished transmission and the TDRE and TEND flags are set to 1. Then clear the TE bit to 0 and then set the TE and RE bits to 1 with a single instruction.
2. To change receive mode to simultaneous transmit and receive mode, check that the SCI3 has finished reception and clear the RE bit to 0. Then check that the RDRF and error flags (ORER, FER, and PER) are cleared to 0 and then set the TE and RE bits to 1 with a single instruction.

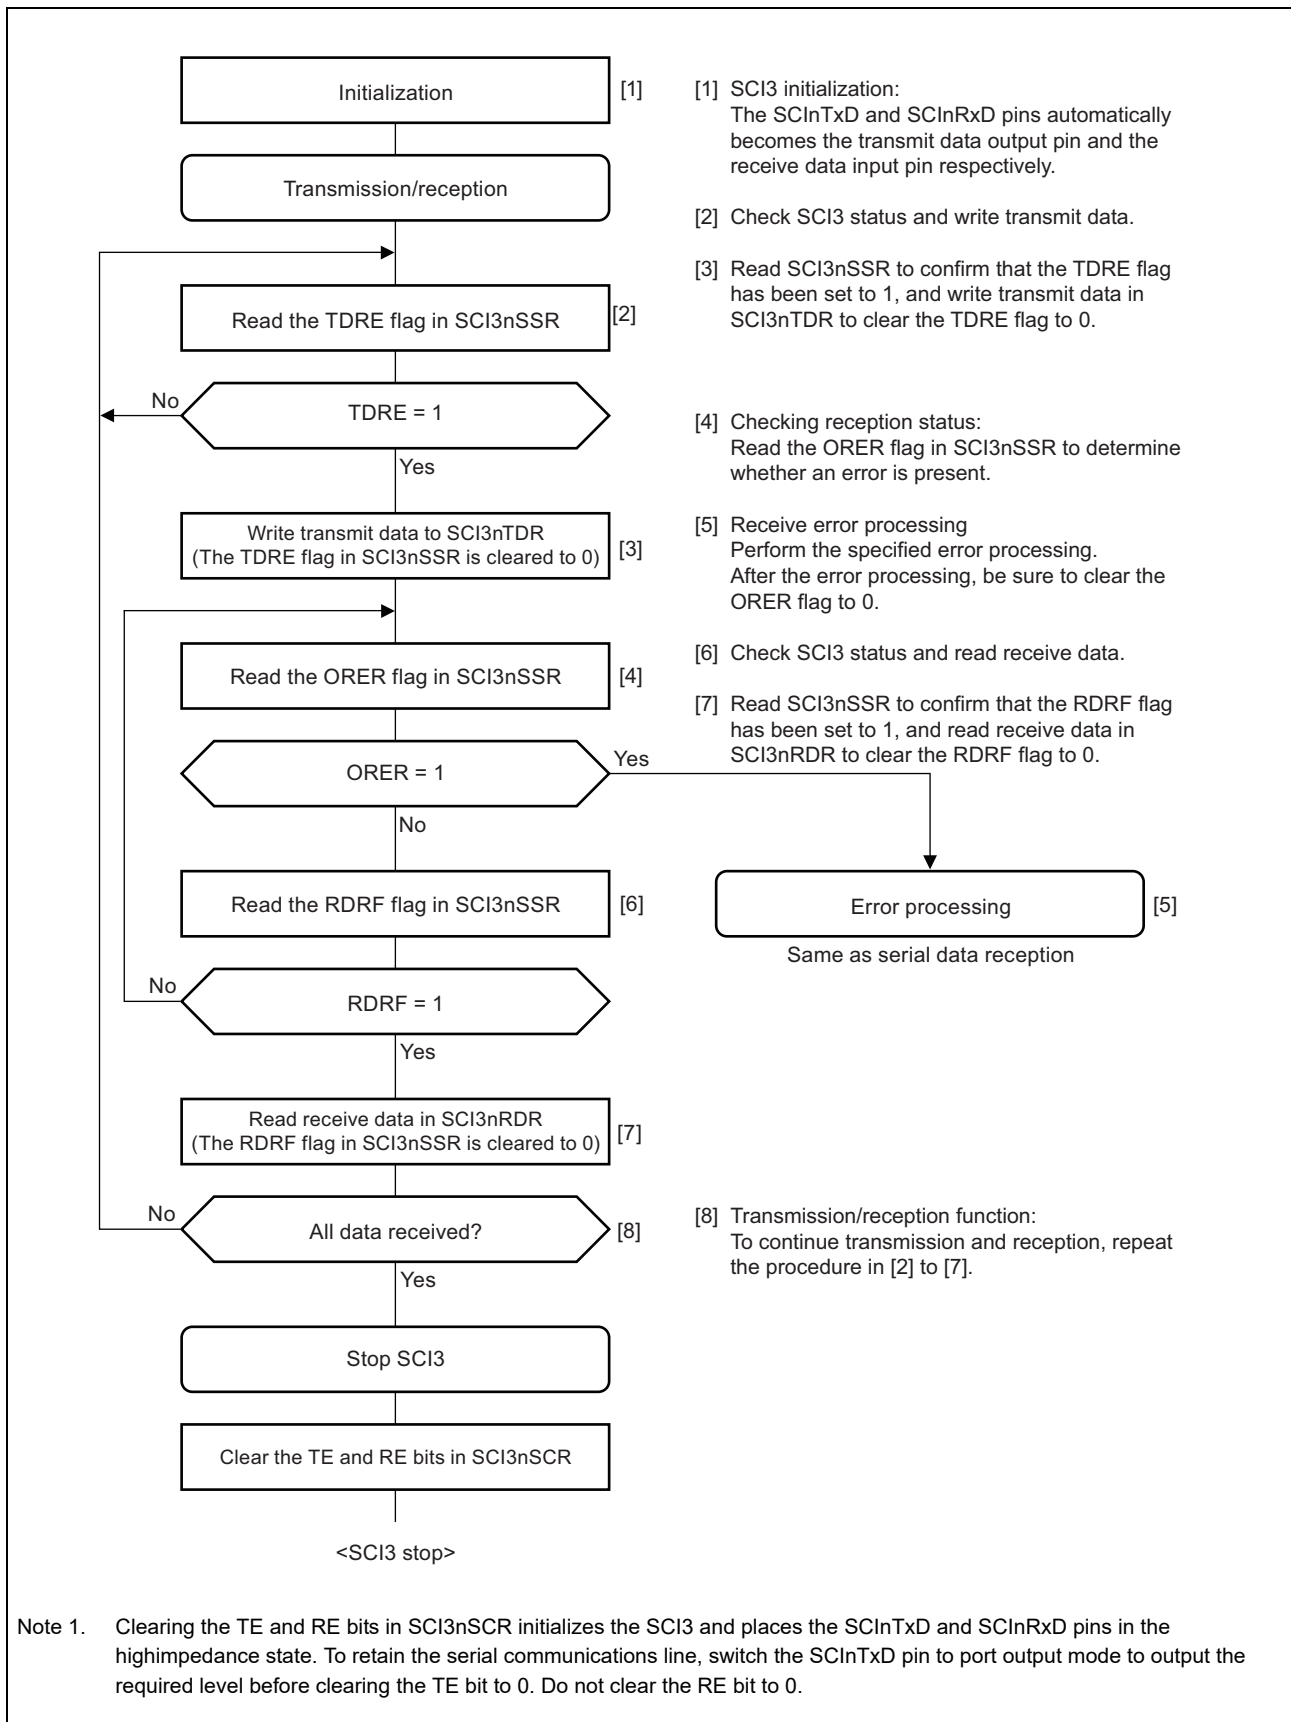

Figure 14.25 Example of Simultaneous Serial Transmission and Reception Flowchart

14.7 Bit Rate Modulation Function

The bit rate modulation function corrects a bit rate by averagely enabling the internal clocks specified by the CKS1 and CKS0 bits in SCI3nSMR for the number specified by SCI3nMDDR out of 256 clocks.

Figure 14.26 shows an example of asynchronous mode in which ϕ clock is selected with the CKS1 and CKS0 bits, SCI3nBRR is set to 0, and SCI3nMDDR is set to 160. In this example, the reference clock cycle is corrected to 256/160 on average and the bit rate is corrected to 160/256. Note that the pulse widths of the internal reference clock expand or contract for the amount of the selected internal clocks because there is a deviation in the enabling of the internal clocks.

Do not use this function with the maximum speed settings (CKS1 and CKS0 bits = 0 in SCI3nSMR, CKE1 bit = 0 in SCI3nSCR, and SCI3nBRR = 0) for clock synchronous mode.

Figure 14.26 Example of Internal Reference Clock when the Bit Rate Modulation Function is Used

14.8 Interrupt Sources

Table 14.17 lists interrupt sources. Each interrupt source outputs an individual interrupt request signal. These interrupt sources can be enabled independently with the enable bit in SCI3nSCR.

A TXI interrupt request is generated when the TDRE flag in SCI3nSSR is set to 1. A TEI interrupt request is generated when the TEND flag in SCI3nSSR is set to 1. A TXI interrupt request can activate the DMAC to handle data transfer. The TDRE flag is automatically cleared to 0 when data is transferred using the DMAC.

CAUTION

The TDRE and TEND flags cannot be cleared to 0 while the TE bit in SCI3nSCR is 0. Since the TEND flag is the level interrupt request flag for a TEI interrupt, do not set the TEIE bit in SCI3nSCR to 1 while the TE bit is 0.

An RXI interrupt request is generated when the RDRF flag in SCI3nSSR is set to 1. An ERI interrupt is generated when either of the ORER, PER, and FER flags in SCI3nSSR is set to 1. An RXI interrupt request can activate the DMAC to handle data transfer. The RDRF flag is automatically cleared to 0 when data is transferred using the DMAC.

A TEI interrupt request is generated when the TEND flag is set to 1 with the TEIE bit set to 1.

CAUTION

If a TEI interrupt request and a TXI interrupt request are generated at the same time, the TXI interrupt request is accepted first. Note that clearing the TDRE flag to 0 at this time in the TXI interrupt processing routine also clears the TEND flag to 0 automatically, disabling the branch to the TEI interrupt processing routine.

Table 14.17 SCI3 Interrupt Sources

Name	Interrupt Source	Interrupt Flag	DMAC Activation
ERI	Receive error	ORER, FER, PER	Not possible
RXI	Receive data full	RDRF	Possible
TXI	Transmit data empty	TDRE	Possible
TEI	Transmit end	TEND	Not possible

14.9 Usage Notes

14.9.1 Break Detection and Processing

A break can be detected by reading the RXDMON bit in SCI3nSEMR when detecting a framing error. Since all inputs from the SCInRxD pin are 0 in the break state, the FER flag is set to 1 and the PER flag may also be set to 1. The SCI3 also continues data reception after it receives a break. For this reason, note that the FER flag is set to 1 again even after the FER flag is cleared to 0.

14.9.2 Mark State and Break Output

While the TE bit is 0 (transmission/reception disabled), the SCInTxD pin can output any level by switching the SCInTxD pin to a general output port. This allows the SCInTxD pin to be the mark state or break output during data transmission.

14.9.3 Receive Error Flags and Transmit Operations in Clock Synchronous Mode

During the clock synchronous simultaneous data transmit/receive operation, transmission cannot be started when a receive error flag (ORER) is set to 1, even if the TDRE flag is cleared to 0. Be sure to clear the receive error flags to 0 before starting transmission. Note that the receive error flags cannot be cleared to 0 even by clearing the RE bit to 0.

14.9.4 Relationship between Writing to SCI3nTDR and the TDRE Flag

The TDRE flag in SCI3nSSR is a status flag indicating that transmit data in SCI3nTDR has been transferred to SCI3nTSR. The TDRE flag is set to 1 when the SCI3 transfers data from SCI3nTDR to SCI3nTSR.

Data can be written to SCI3nTDR regardless of the status of the TDRE flag. However, writing new data to SCI3nTDR while the TDRE flag is 0 will make the data stored in SCI3nTDR lost because it has not been transferred to SCI3nTSR. Therefore, make sure to check that the TDRE flag is set to 1 before writing transmit data to SCI3nTDR.

14.9.5 Restrictions on Using an External Clock for Transmission in Clock Synchronous Mode

When using an external synchronization clock, clear the TDRE flag to 0 and then input a transmission clock (Figure 14.27). Also in continuous transmission mode, clear the TDRE flag to 0 and then input a transmission clock for the next frame.

Figure 14.27 Restrictions on Using an External Clock for Transmission in Clock Synchronous Mode

14.9.6 External Clock Input in Clock Synchronous Mode

For the external SCInSCK clock input in clock synchronous mode, see Section 40.3.7, SCI/FLSCI Timing.

Section 15 LIN Master Interface (RLIN2)

This section contains a generic description of the LIN master interface (RLIN2).

15.1 Overview of RLIN2

15.1.1 Units and Channels

This microcontroller has the following number of RLIN2 units and channels.

Table 15.1 Units

RLIN2	
Units	1
Name	RLIN210

Table 15.2 Unit Configurations and Channels

Unit Name RLIN21n	Channels per Unit	Unit Channel Number	Channel Name RLIN2m
RLIN210	1	0	RLIN20

Table 15.3 Index

Index	Meaning
n	Throughout this section, the individual RLIN2 units are identified by the index "n" (n = 0).
m	Throughout this section, the individual channels are identified by the index "m" (m = 0).
i	Throughout this section, the individual channels of units that configure RLIN2 are identified by the index "i" (i = 0).
b	Throughout this section, the individual data buffers implemented in RLIN2 are identified by the index "b" (b = 1 to 8).

For example, RLIN21nGLWBR are the LIN wake-up baud rate select registers, which are the global registers of RLIN21nmLiMD are the LIN mode registers, which are the channel registers.

15.1.2 Register Base Addresses

RLIN2 base addresses are listed in the following table.

RLIN2 register addresses are given as offsets from the base addresses in general.

Table 15.4 Register Base Addresses

Base Address Name	Base Address
<RLIN210_base>	FFCE 0000 _H

15.1.3 Clock Supply

RLIN2 clock is listed in following table.

Table 15.5 Clock Supply

Unit Name	Clock for the Unit	Supply Clock Name
RLIN21n	pclk (P-Bus Clock)	CLK_LSB (low-speed peripheral clock)
	clkc (LIN communication clock source)	CLKC_LSB (unmodulated low-speed peripheral clock)

15.1.4 Interrupt Request

RLIN2 interrupt requests are listed in the following table.

Table 15.6 Interrupt Requests

Unit Interrupt Name	Outline	Interrupt Number
INTRLIN0	Transmit complete interrupt/ receive complete interrupt/ error detection interrupt (RLIN210 interrupt)	429

15.1.5 Reset Sources

RLIN2 reset sources are listed in the following table. RLIN2 is initialized by these reset sources.

Table 15.7 Reset Sources

Unit Name	Reset Source
RLIN21n	Any reset source

15.1.6 External Input/Output Signals

External input/output signals of RLIN2 are listed below.

Table 15.8 I/O Signals of RLIN2n

Unit Signal Name	Outline	Alternative Port Pin Signal
RLIN210		
RLIN20RX	RLIN210 receive data input	LRX0
RLIN20TX	RLIN210 transmit data output	LTX0

15.2 Function

15.2.1 Functional Overview

The LIN master interface is a hardware LIN communication controller that complies to LIN Specification Package Revision 1.3, 2.0, 2.1, 2.2, and SAEJ2602 (SEP 2005), and automatically performs frame communication and error determination.

Table 15.9 gives the LIN master interface specifications and **Figure 15.1** shows a block diagram of the LIN master interface.

Table 15.9 LIN Master Interface Specifications

Item	Specifications	
Channel count	1 channel	
LIN communication function	Protocol	LIN Specification Package Revision 1.3, 2.0, 2.1, 2.2, and SAEJ2602 (SEP 2005)
	Variable frame structure	<ul style="list-style-type: none"> • Break transmission width: 13 to 28 Tbits • Break delimiter transmission width: 1 to 4 Tbits • Inter-byte space (header): 0 to 7 Tbits (space between Sync field and ID field)*¹ • Response space: 0 to 7 Tbits*¹ • Inter-byte space: 0 to 3 Tbits (space between data bytes in response area) • Transmission wake-up: 1 to 16 Tbits
	Checksum	<ul style="list-style-type: none"> • Automatic operation for both transmission and reception • Classic or enhanced selectable (for each frame)
	Response field data byte count	Variable from 0 to 8 bytes
Frame communication modes	<ul style="list-style-type: none"> • Mode in which header transmission and response transmission/reception is started with a single transmission start request • Mode in which header transmission and response transmission are started with separate transmission start requests (frame separate mode) 	
Wake-up transmission and reception	LIN wake-up mode provided <ul style="list-style-type: none"> • Wake-up transmission (1 to 16 Tbits) • Wake-up reception Low-level width of input signals measured 	
Status	<ul style="list-style-type: none"> • Successful frame/wake-up transmission • Successful header transmission • Successful frame/wake-up reception*² • Successful data 1 reception • Error detection • Operation mode (LIN reset mode, LIN wake-up mode, LIN operation mode, LIN self-test mode) 	
Error status	<ul style="list-style-type: none"> • Bit error • Checksum error • Frame timeout error • Physical bus error • Framing error 	
Baud rate selection	Baud rate conforming to the LIN specifications generated using baud rate generator	
Test mode	Self-test mode for user evaluation	
Interrupt function	<ul style="list-style-type: none"> • Successful frame/wake-up transmission • Successful frame/wake-up reception*² • Error detection These three logical OR of these three operations events is are the interrupt sources (INTRLINm) for each channel.	

Note 1. Since the same register is used for setting, the inter-byte space (header) = response space.

Note 2. For wake-up reception, the low level width of the input signal is indicated.

15.2.2 Block Diagram

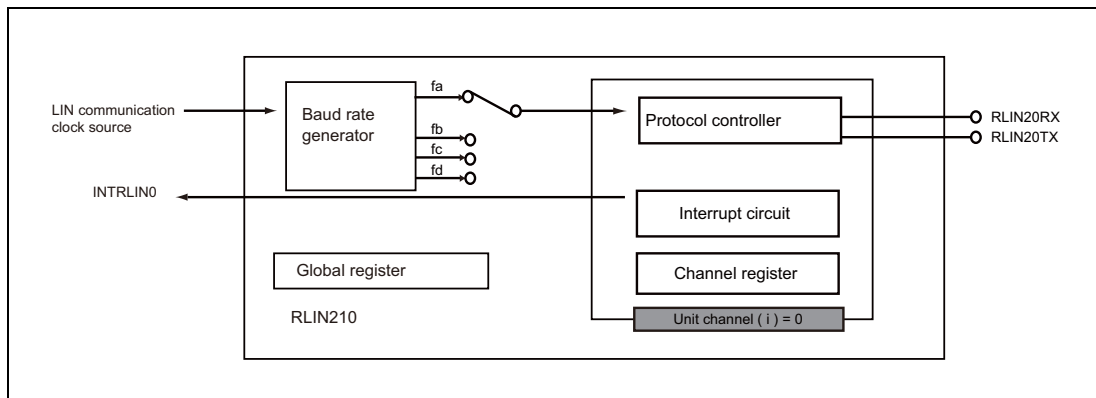

Figure 15.1 LIN Master Interface Block Diagram

15.3 Registers

The registers of the LIN master interface are configured with global registers and channel registers. As the global registers are allocated for each unit, they can be set respectively in units. As the channel registers are allocated for each channel, they can be controlled respectively in channels.

15.3.1 List of Registers

RLIN2 registers are listed in the following table.

For information on <RLIN21n_base>, see **Section 15.1.2, Register Base Addresses**.

Table 15.10 LIN Master Interface Registers Overview

Module name	Register name	Shortcut	Address
Global registers			
RLN21nG	LIN wake-up baud rate select register	RLN21nGLWBR	<RLIN21n_base> + 01 _H
RLN21nG	LIN baud rate prescaler 0 register	RLN21nGLBRP0	<RLIN21n_base> + 02 _H
RLN21nG	LIN baud rate prescaler 1 register	RLN21nGLBRP1	<RLIN21n_base> + 03 _H
RLN21nG	LIN self test control register	RLN21nGLSTC	<RLIN21n_base> + 04 _H
Channel registers			
RLN21nm	LIN mode register	RLN21nmLiMD	<RLIN21n_base> + 08 _H
RLN21nm	LIN break field configuration register	RLN21nmLiBFC	<RLIN21n_base> + 09 _H
RLN21nm	LIN space configuration register	RLN21nmLiSC	<RLIN21n_base> + 0A _H
RLN21nm	LIN wake-up configuration register	RLN21nmLiWUP	<RLIN21n_base> + 0B _H
RLN21nm	LIN interrupt enable register	RLN21nmLiIE	<RLIN21n_base> + 0C _H
RLN21nm	LIN error detection enable register	RLN21nmLiEDE	<RLIN21n_base> + 0D _H
RLN21nm	LIN control register	RLN21nmLiCUC	<RLIN21n_base> + 0E _H
RLN21nm	LIN transmission control register	RLN21nmLiTRC	<RLIN21n_base> + 10 _H
RLN21nm	LIN mode status register	RLN21nmLiMST	<RLIN21n_base> + 11 _H
RLN21nm	LIN status register	RLN21nmLiST	<RLIN21n_base> + 12 _H
RLN21nm	LIN error status register	RLN21nmLiEST	<RLIN21n_base> + 13 _H
RLN21nm	LIN data field configuration register	RLN21nmLiDFC	<RLIN21n_base> + 14 _H
RLN21nm	LIN ID buffer register	RLN21nmLiIDB	<RLIN21n_base> + 15 _H
RLN21nm	LIN check sum buffer register	RLN21nmLiCBR	<RLIN21n_base> + 16 _H
RLN21nm	LIN data buffer 1 register	RLN21nmLiDBR1	<RLIN21n_base> + 18 _H
RLN21nm	LIN data buffer 2 register	RLN21nmLiDBR2	<RLIN21n_base> + 19 _H
RLN21nm	LIN data buffer 3 register	RLN21nmLiDBR3	<RLIN21n_base> + 1A _H
RLN21nm	LIN data buffer 4 register	RLN21nmLiDBR4	<RLIN21n_base> + 1B _H
RLN21nm	LIN data buffer 5 register	RLN21nmLiDBR5	<RLIN21n_base> + 1C _H
RLN21nm	LIN data buffer 6 register	RLN21nmLiDBR6	<RLIN21n_base> + 1D _H
RLN21nm	LIN data buffer 7 register	RLN21nmLiDBR7	<RLIN21n_base> + 1E _H
RLN21nm	LIN data buffer 8 register	RLN21nmLiDBR8	<RLIN21n_base> + 1F _H

15.3.2 Global Registers

15.3.2.1 RLN21nGLWBR — LIN Wake-up Baud Rate Select Register

Access: This register can be read/written in 8-bit units.

Address: <RLIN21n_base> + 01_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	LWBR0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R/W

Table 15.11 RLN21nGLWBR Register Contents

Bit Position	Bit Name	Function
7 to 1	Reserved	The write value should be the value after reset.
0	LWBR0	Wake-up Baud Rate Select 0: In LIN wake-up mode, the clock specified by the LCKS bit setting in the RLN21nmLiMD register is used. (when LIN1.3 is used) 1: In LIN wake-up mode, the clock fa is used regardless of the setting of the LCKS bit of the RLN21nmLiMD register. (When LIN2.x is used)

Set the RLN21nGLWBR register when all channels in the same unit are in LIN reset mode (while the OMM0 bit in the RLN21nmLiMST register is 0).

LWBR0 Bit (Wake-up Baud Rate Select)

When LIN Specification Package Revision 1.3 is used, set the LWBR0 bit in the RLN21nGLWBR register to 0. This allows the 2.5-Tbit or longer low-level width of the input signal to be measured. When LIN Specification Package Revision 2.x is used, set the LWBR0 bit to 1.

With this setting, fa is selected as the LIN system clock (fLIN) during LIN wake-up mode regardless of the setting of the LCKS bit in the RLN21nmLiMD register (the LCKS bit is not changed) and the 2.5-Tbit or longer low-level width of the input signal to be measured.

Setting the baud rate to 19200 bps while fa is selected allows the 130μs or longer low-level width of the input signal to be detected during LIN wake-up mode regardless of the setting of the LCKS bit in the RLN21nmLiMD register.

15.3.2.2 RLN21nGLBRP0 — LIN Baud Rate Prescaler 0 Register

Access: This register can be read/written in 8-bit units

Address: <RLIN21n_base> + 02_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LBRP0[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 15.12 RLN21nGLBRP0 Register Contents

Bit Position	Bit Name	Function
7 to 0	LBRP0[7:0]	Assuming that the value set in this register is N (0 to 255), the baud rate prescaler 0 divides the frequency of the LIN communication clock source by N + 1. Setting Range: 00 _H to FF _H

Set the RLN21nGLBRP0 register when all channels in the same unit are in LIN reset mode (while the OMM0 bit in the RLN21nmLiMST register is 0).

The value set in this register is used to control the frequency of baud rate clock source fa, fb, and fc.

Assuming that the value set in this register is N, the baud rate prescaler 0 divides the frequency of the LIN communication clock source by N+1.

15.3.2.3 RLN21nGLBRP1 — LIN Baud Rate Prescaler 1 Register

Access: This register can be read/written in 8-bit units.

Address: <RLIN21n_base> + 03_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LBRP1[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 15.13 RLN21nGLBRP1 Register Contents

Bit Position	Bit Name	Function
7 to 0	LBRP1[7:0]	Assuming that the value set in this register is M (0 to 255), the baud rate prescaler 1 divides the frequency of the LIN communication clock source by M+1. Setting Range: 00 _H to FF _H

Set the RLN21nGLBRP1 register when all channels in the same unit are in LIN reset mode (while the OMM0 bit in the RLN21nmLiMST register is 0).

The value set in this register is used to control the frequency of baud rate clock source f_d .

Assuming that the value set in this register is M, the baud rate prescaler 1 divides the frequency of the LIN communication clock source by M+1.

15.3.2.4 RLN21nGLSTC — LIN Self-Test Control Register

This register is used to unlock protection of LIN self-test mode.

Set the RLN21nGLSTC register when all channels in the same unit are while the OMM0 bit in the RLN21nmLiMST register is 0 (in LIN reset mode).

For making transition to LIN self-test mode, refer to **Section 15.15, LIN Self-Test Mode**.

Access: This register can be read/written in 8-bit units.

Address: <RLN21n_base> + 04_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	LSTM[7:0]							
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1

Note 1. Writing is ignored in modes other than LIN reset mode.

Table 15.14 RLN21nGLSTC Register Contents

Bit Position	Bit Name	Function
7 to 0	LSTM	LIN Self-Test Mode 0: The module is not in LIN self-test mode.*1 1: The module is in LIN self-test mode.*2 Writing A7 _H , 58 _H , and 01 _H successively to the RLN21nGLSTC register places the module into LIN self-test mode. Setting other than the above is prohibited. If any other value is set, the read value is undefined.

Note 1. For leaving LIN self-test mode, see **Section 15.15.4, Terminating LIN Self-Test Mode**. When LIN self-test mode is terminated, 00_H is read.

Note 2. See **Section 15.15.1, Change to LIN Self-Test Mode** for how to change to LIN self-test mode. When transition to LIN self-test mode is completed, 01_H is read.

15.3.3 Channel Registers

15.3.3.1 RLN21nmLiMD — LIN Mode Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiMD: <RLN21n_base> + 08_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	LCKS[1:0]		—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R	R

Table 15.15 RLN21nmLiMD Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	The write value should be the value after reset.
3, 2	LCKS[1:0]	LIN System Clock Select b3 b2 0 0: fa (Clock generated by baud rate prescaler 0) 0 1: fb (1/2 clock generated by baud rate prescaler 0) 1 0: fc (1/8 clock generated by baud rate prescaler 0) 1 1: fd (1/2 clock generated by baud rate prescaler 1)
1, 0	Reserved	These bits are always read as 0. The write value should always be 0.

Set the RLN21nmLiMD register while the OMM0 bit in the RLN21nmLiMST register is 0 (in LIN reset mode).

LCKS[1:0] Bits (LIN System Clock Select)

The LCKS bits select the clock to be input to the protocol controller.

With 00_B set, the protocol controller is provided with fa (clock generated by baud rate prescaler 0).

With 01_B set, the protocol controller is provided with fb (1/2 clock generated by baud rate prescaler 0).

With 10_B set, the protocol controller is provided with fc (1/8 clock generated by baud rate prescaler 0).

With 11_B set, the protocol controller is provided with fd (1/2 clock generated by baud rate prescaler 1).

When the LWBR0 bit in the RLN21nGLWBR is 1 (when LIN 2.x is used) and the RLN21nmLiMST register is 01_H (LIN wake-up mode), regardless of the setting of the LWBR0 bit, fa is input to the protocol controller (LCKS bit is not changed).

15.3.3.2 RLN21nmLiBFC — LIN Break Field Configuration Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiBFC: <RLIN21n_base> + 09_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	BDT[1:0]		BLT[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Table 15.16 RLN21nmLiBFC Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	The write value should be the value after reset.
5, 4	BDT[1:0]	Transmission Break Delimiter (High Level) Width Setting b5 b4 0 0: 1 Tbit 0 1: 2 Tbits 1 0: 3 Tbits 1 1: 4 Tbits
3 to 0	BLT[3:0]	Transmission Break (Low Level) Width Setting b3 b0 0 0 0 0: 13 Tbits 0 0 0 1: 14 Tbits 0 0 1 0: 15 Tbits : 1 1 1 0: 27 Tbits 1 1 1 1: 28 Tbits

Set the RLN21nmLiBFC register while the OMM0 bit in the RLN21nmLiMST register is 0 (in LIN reset mode).

Some combinations of the set values result in the length of a frame exceeding the timeout time. Set the appropriate values in this register.

BDT[1:0] Bits (Transmission Break Delimiter (High Level) Width Setting)

This bit is used to set the break high level width of transmission frame header.

1 Tbit to 4 Tbits can be set.

BLT[3:0] Bits (Transmission Break (Low Level) Width Setting)

This BLT bits set the break low level width of transmission frame header.

13 Tbits to 28 Tbits can be set.

15.3.3.3 RLN21nmLiSC — LIN Space Configuration Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiSC: <RLIN21n_base> + 0A_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	IBS[1:0]		—	IBHS[2:0]		
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R/W	R	R/W	R/W	R/W

Table 15.17 RLN21nmLiSC Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	The write value should be the value after reset.
5, 4	IBS[1:0]	Inter-Byte Space Select b5 b4 0 0: 0 Tbit 0 1: 1 Tbit 1 0: 2 Tbits 1 1: 3 Tbits
3	Reserved	The write value should be the value after reset.
2 to 0	IBHS[2:0]	Inter-Byte Space (Header)/Response Space Select b2 b0 0 0 0: 0 Tbit 0 0 1: 1 Tbit 0 1 0: 2 Tbits 0 1 1: 3 Tbits 1 0 0: 4 Tbits 1 0 1: 5 Tbits 1 1 0: 6 Tbits 1 1 1: 7 Tbits

Set the RLIN21nmLiSC register while the OMM0 bit in the RLN21nmLiMST register is 0 (in LIN reset mode).

Some combinations of the set values result in the length of a frame or a response exceeding the timeout time. Set the appropriate values in this register.

IBS[1:0] Bits (Inter-Byte Space Select)

The IBS bits set the width of the inter-byte space of the transmission frame response field.

0 Tbit to 3 Tbits can be set.

These bits are enabled only during response transmission; these are disabled during response reception.

IBHS[2:0] Bits (Inter-Byte Space (Header)/Response Space Select)

The IBHS bits set the width of the inter-byte space (header) of the transmission frame header field and the response space.

0 Tbit to 7 Tbits can be set.

The response space setting is enabled only during response transmission; setting is disabled during response reception.

The inter-byte space (header) is equal to the response space.

15.3.3.4 RLN21nmLiWUP — LIN Wake-up Configuration Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiWUP: <RLIN21n_base> + 0B_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	WUTL[3:0]				—	—	—	—
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R	R	R	R

Table 15.18 RLN21nmLiWUP Register Contents

Bit Position	Bit Name	Function
7 to 4	WUTL[3:0]	Wake-up Transmission Low level Width Select b7 b4 0 0 0 0: 1 Tbit 0 0 0 1: 2 Tbits 0 0 1 0: 3 Tbits 0 0 1 1: 4 Tbits : 1 1 0 0: 13 Tbits 1 1 0 1: 14 Tbits 1 1 1 0: 15 Tbits 1 1 1 1: 16 Tbits
3 to 0	Reserved	The write value should be the value after reset.

Set the RLN21nmLiWUP register while the OMM0 bit in the RLN21nmLiMST register is 0 (in LIN reset mode).

WUTL[3:0] Bits (Wake-up Transmission Low level Width Select)

The WUTL bits set the low level width of the wake-up signal transmission. 1 Tbit to 16 Tbits can be set.

When the LWBR0 bit in the RLN21nGLWBR is 1 (when LIN 2.x is used), regardless of the setting of the the LCKS bit in the RLN21nmLiMD register, fa is selected as the LIN system clock (fLIN) (LCKS bit is not changed).

15.3.3.5 RLN21nmLiE — LIN Interrupt Enable Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiE: <RLIN21n_base> + 0C_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	ERRIE	FRCIE	FTCIE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W

Table 15.19 RLN21nmLiE Register Contents

Bit Position	Bit Name	Function
7 to 3	Reserved	The write value should be the value after reset.
2	ERRIE	Error Detection Interrupt Request Enable 0: Disables error detection interrupt request. 1: Enables error detection interrupt request.
1	FRCIE	Successful Frame/Wake-up Reception Interrupt Request Enable 0: Disables successful frame/wake-up reception interrupt request. 1: Enables successful frame/wake-up reception interrupt request.
0	FTCIE	Successful Frame/Wake-up Transmission Interrupt Request Enable 0: Disables successful frame/wake-up transmission interrupt request. 1: Enables successful frame/wake-up transmission interrupt request.

Set the RLN21nmLiE register while the OMM0 bit in the RLN21nmLiMST register is 0 (in LIN reset mode).

ERRIE Bit (Error Detection Interrupt Request Enable)

The ERRIE bit enables or disables interrupt request generation upon detection of an error.

With 0 set, the interrupt request is not generated when the ERR flag in the RLN21nmLiST register is set to 1.

With 1 set, the interrupt request is generated when the ERR flag in the RLN21nmLiST register is set to 1.

Error sources can be the bit error, physical bus error, frame timeout error, framing error, and checksum error.

Detection of the bit error, physical bus error, frame/response timeout error, and framing error can be enabled or disabled using the RLN21nmLiEDE register.

FRCIE Bit (Successful Frame/Wake-up Reception Interrupt Request Enable)

The FRCIE bit enables or disables interrupt request generation upon successful reception of a frame or a wake-up signal (counting of low level width of the input signal).

With 0 set, the interrupt request is not generated when the FRC flag in the RLN21nmLiST register is set to 1.

With 1 set, the interrupt request is generated when the FRC flag in the RLN21nmLiST register is set to 1.

FTCIE Bit (Successful Frame/Wake-up Transmission Interrupt Request Enable)

The FTCIE bit enables or disables interrupt request generation upon successful transmission of a frame or a wake-up signal.

With 0 set, the interrupt request is not generated when the FTC flag in the RLN21nmLiST register is set to 1.

With 1 set, the interrupt request is generated when the FTC flag in the RLN21nmLiST register is set to 1.

15.3.3.6 RLN21nmLiEDE — LIN Error Detection Enable Register

Access: This register can be read/written in 8-bit units

Address: RLN21nmLiEDE: <RLIN21n_base> + 0D_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	FERE	FTERE	PBERE	BERE
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W

Table 15.20 RLN21nmLiEDE Register Contents

Bit Position	Bit Name	Function
7 to 4	Reserved	The write value should be the value after reset.
3	FERE	Framing Error Detection Enable 0: Disables framing error detection. 1: Enables framing error detection.
2	FTERE	Frame Timeout Error Detection Enable 0: Disables frame timeout error detection. 1: Enables frame timeout error detection.
1	PBERE	Physical Bus Error Detection Enable 0: Disables physical bus error detection. 1: Enables physical bus error detection.
0	BERE	Bit Error Detection Enable 0: Disables bit error detection. 1: Enables bit error detection.

Set the RLN21nmLiEDE register while the OMM0 bit in the RLN21nmLiMST register is 0_B (in LIN reset mode).

FERE Bit (Framing Error Detection Enable)

The FERE bit enables or disables detection of the framing error.

With 0 set, the framing error is not detected.

With 1 set, the framing error is detected.

When this bit is set to 1, the detection result is indicated in the FER flag in the RLN21nmLiEST register.

For details of the framing error, refer to **Section 15.14, Error Status**.

FTERE Bit (Frame Timeout Error Detection Enable)

The FTERE bit enables or disables detection of the frame timeout error.

With 0 set, the frame timeout error is not detected.

With 1 set, the frame timeout error is detected.

When this bit is set to 1, the detection result is indicated in the FTER flag in the RLN21nmLiEST register.

Do not use the timeout error if response data of 9 bytes or more is to be transmitted or received.

For details of the frame timeout error, refer to **Section 15.14, Error Status**.

PBERE Bit (Physical Bus Error Detection Enable)

The PBERE bit enables or disables detection of the physical bus error.

With 0 set, the physical bus error is not detected.

With 1 set, the physical bus error is detected.

When this bit is set to 1, the detection result is indicated in the PBER flag in the RLN21nmLiEST register.

For details of the physical bus error, refer to **Section 15.14, Error Status**.

BERE Bit (Bit Error Detection Enable)

The BERE bit enables or disables detection of the bit error.

With 0 set, the bit error is not detected.

With 1 set, the bit error is detected.

When this bit is set to 1, the detection result is indicated in the BER flag in the RLN21nmLiEST register.

For details of the bit error, refer to **Section 15.14, Error Status**.

15.3.3.7 RLN21nmLiCUC — LIN Control Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiCUC: <RLIN21n_base> + 0E_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OM1	OM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 15.21 RLN21nmLiCUC Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	The write value should be the value after reset.
1	OM1	LIN Mode Select 0: LIN wake-up mode 1: LIN operation mode
0	OM0	LIN Reset 0: LIN reset mode 1: Release from LIN reset mode

Set the RLN21nmLiCUC register to 01_H to cause a transition to LIN wake-up mode after release from LIN reset mode, and set the register to 03_H to cause a transition to LIN operation mode.

In LIN self-test mode, set the RLN21nmLiCUC register to 03_H after a transition to LIN self-test mode is completed.

After a value is written to this register, confirm that the value written is actually indicated in the RLN21nmLiMST register before writing another value.

OM1 Bit (LIN Mode Select)

The OM1 bit selects the specific LIN operation mode (either LIN wake-up mode or LIN operation mode) after release from LIN reset mode.

Setting this bit to 0 causes a transition to LIN wake-up mode.

Setting this bit to 1 causes a transition to LIN operation mode.

This bit is valid only when the OMM0 bit in the RLN21nmLiMST register is 1.

Writing a value to this bit is disabled while the FTS bit in the RLN21nmLiTRC register is 1.

OM0 Bit (LIN Reset)

The OM0 bit selects either a transition to LIN reset mode or release from LIN reset mode.

Setting this bit to 0 causes a transition to LIN reset mode.

Setting this bit to 1 leads to release from LIN reset mode.

15.3.3.8 RLN21nmLiTRC — LIN Transmission Control Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiTRC: <RLIN21n_base> + 10_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	RTS	FTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W

Table 15.22 RLN21nmLiTRC Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	The write value should be the value after reset.
1	RTS	Response Transmission Start 0: Response transmission is stopped in frame separate mode. 1: Response transmission is started in frame separate mode.
0	FTS	Frame Transmission/Wake-up Transmission /Reception Start 0: Frame Transmission/wake-up transmission /reception is stopped. 1: Frame Transmission/wake-up transmission reception is started.

RTS Bit (Response Transmission Start)

Set the RTS bit to 1 in frame separate mode after header transmission is started (FTS bit is 1) and response transmission data is ready. Once set, this bit is automatically cleared to 0 upon completion of frame communication or transition to LIN reset mode.

Only 1 can be written to this bit; 0 cannot be written.

To write 1 to this bit, write 02_H to the RLN21nmLiTRC register using the store instruction.

Writing a value to this bit is disabled when the OMM0 bit is 0 (in LIN reset mode).

Do not write 1 to this bit when the OMM0 bit is 0 (in LIN wakeup mode).

Writing a value to this bit is disabled when the FTS bit is 0 (frame transmission or wake-up transmission/reception is halted).

FTS Bit (Frame Transmission/Wake-up Transmission/Reception Start)

Set the FTS bit to 1 to start frame/wake-up transmission.

Also set this bit to 1 to allow wake-up reception (counting of the low level width of the input signal).

Only 1 can be written to this bit; 0 cannot be written.

Writing a value to this bit is disabled when the OMM0 bit is 0 (in LIN reset mode). This bit is set to 0 upon completion of frame or wake-up communication and transition to LIN reset mode.

15.3.3.9 RLN21nmLiMST — LIN Mode Status Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiMST: <RLIN21n_base> + 11_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	OMM1	OMM0
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R

Table 15.23 RLN21nmLiMST Register Contents

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is read.
1	OMM1	LIN Mode Status Monitor 0: The LIN master interface is in LIN wake-up mode. 1: The LIN master interface is in LIN operation mode.
0	OMM0	LIN Reset Status Monitor 0: The LIN master interface is in LIN reset mode. 1: The LIN master interface is not in LIN reset mode.

OMM1 Bit (LIN Mode Status Monitor)

The OMM1 bit indicate the current operating mode. The OMM0 bit value is invalid while this bit is 0_B (in LIN reset mode).

OMM0 Bit (LIN Reset Status Monitor)

The OMM0 bit indicates the current operating mode.

15.3.3.10 RLN21nmLiST — LIN Status Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiST: <RLIN21n_base> + 12_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	HTRC	D1RC	—	—	ERR	—	FRC	FTC
Value after reset	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R	R	R	R	R/W	R/W

Table 15.24 RLN21nmLiST Register Contents

Bit Position	Bit Name	Function
7	HTRC	Successful Header Transmission Flag 0: Header transmission has not been completed. 1: Header transmission has been completed.
6	D1RC	Successful Data 1 Reception Flag 0: Data 1 Reception has not been completed. 1: Data 1 Reception has been completed.
5, 4	Reserved	The write value should be the value after reset.
3	ERR	Error Detection Flag 0: No error has been detected. 1: Error has been detected.
2	Reserved	The write value should be the value after reset.
1	FRC	Successful Frame/Wake-up Reception Flag 0: Frame or wake-up reception has not been completed. 1: Frame or wake-up reception has been completed.
0	FTC	Successful Frame/Wake-up Transmission Flag 0: Frame or wake-up transmission has not been completed. 1: Frame or wake-up transmission has been completed.

The RLN21nmLiST register is automatically cleared to 00_H upon transition to LIN reset mode and start of the next communication (the FTS bit in the RLN21nmLiTRC register is 1).

In LIN reset mode, writing to the register is disabled.

In LIN reset mode, the register retains 00_H.

Writing to this register is prohibited while the FTS bit in the RLN21nmLiTRC register is 1 (frame transmit or wake-up transmission/reception is started)

To clear the specific bits in the register, write 0 to the bits to be cleared and write 1 to the other bits using the store instruction.

HTRC Flag (Successful Header Transmission Flag)

Only 0 can be written to the HTRC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The HTRC flag is set to 1 upon completion of header transmission, but an interrupt request is not generated. To clear the bit to 0 before the next communication (the FTS bit in the RLN21nmLiTRC register is 1), write 0 to the bit in LIN operation mode.

D1RC Flag (Successful Data 1 Reception Flag)

Only 0 can be written to the D1RC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The D1RC flag is set to 1 upon completion of data 1 reception. Here, an interrupt request is not generated. To clear the bit to 0 before the next communication, write 0 to the bit in LIN operation mode.

ERR Flag (Error Detection Flag)

The ERR flag is set to 1 upon detection of an error (at least one of the RLN21nmLiEST flags is 1). Here, an interrupt request is generated if the ERRIE bit in the RLN21nmLiIE register is 1 (interrupt request is enabled). To clear the bit to 0 before the next communication (the FTS bit in the RLN21nmLiTRC register is 1), write 0 to the CSER, FER, FTER, PBER, and BER flags in the RLN21nmLiEST register in LIN operation mode or LIN wake-up mode. This clears the ERR flag to 0.

FRC Flag (Successful Frame/Wake-up Reception Flag)

Only 0 can be written to the FRC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The FRC flag is set to 1 upon completion of frame or wake-up reception. Here, an interrupt request is generated if the FRCIE bit in the RLN21nmLiIE register is 1 (interrupt request is enabled). To clear the bit to 0 before the next communication (the FTS bit in the RLN21nmLiTRC register is 1), write 0 to the bit in LIN operation mode or LIN wake-up mode.

FTC Flag (Successful Frame/Wake-up Transmission Flag)

Only 0 can be written to the FTC flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The FTC flag is set to 1 upon completion of frame or wake-up transmission. Here, an interrupt request is generated if the FTCIE bit in the RLN21nmLiIE register is 1 (interrupt request is enabled). To clear the bit to 0 before the next communication (the FTS bit in the RLN21nmLiTRC register is 1), write 0 to the bit in LIN operation mode or LIN wake-up mode.

15.3.3.11 RLN21nmLiEST — LIN Error Status Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiEST: <RLIN21n_base> + 13_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	CSER	—	FER	FTER	PBER	BER
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R/W	R	R/W	R/W	R/W	R/W

Table 15.25 RLN21nmLiEST Register Contents

Bit Position	Bit Name	Function
7, 6	Reserved	The write value should be the value after reset.
5	CSER	Checksum Error Flag 0: Checksum error has not been detected. 1: Checksum error has been detected.
4	Reserved	The write value should be the value after reset.
3	FER	Framing Error Flag 0: Framing error has not been detected. 1: Framing error has been detected.
2	FTER	Frame Timeout Error Flag 0: Frame timeout error has not been detected. 1: Frame timeout error has been detected.
1	PBER	Physical Bus Error Flag 0: Physical bus error has not been detected. 1: Physical bus error has been detected.
0	BER	Bit Error Flag 0: Bit error has not been detected. 1: Bit error has been detected.

The RLN21nmLiEST register is automatically cleared to 00_H upon transition to LIN reset mode and start of the next communication (the FTS bit in the RLN21nmLiTRC register is 1).

In LIN reset mode, writing to the register is disabled and the register retains 00_H.

When the FTS bit in the RLN21nmLiTRC register is 1 (frame transmission or wake-up transmission/reception is started), do not write a value to this register.

To clear the specific bits in the register, write 0 to the bits to be cleared and write 1 to the other bits using the store instruction.

CSER Flag (Checksum Error Flag)

Only 0 can be written to the CSER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The CSER flag is set to 1 upon checksum error detection. To clear the bit to 0 before the next communication (the FTS bit in the RLN21nmLiTRC register is 1), write 0 to the bit in LIN operation mode.

FER Flag (Framing Error Flag)

When the FERE bit in the RLN21nmLiEST register is 1 (flaming error detection is enabled) and a flaming error is detected, 1 is written. To clear the bit to 0 before the next communication (the FTS bit in the RLN21nmLiTRC register is 1), write 0 to the bit in LIN operation mode.

FTER Flag (Frame Fimeout Error Flag)

Only 0 can be written to the FTER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The FTER flag is set to 1 when the FTERE bit in the RLN21nmLiEDE register is 1 (frame timeout error detection enable) and the frame timeout error is detected. To clear the bit to 0 before the next communication (the FTS bit in the RLN21nmLiTRC register is 1), write 0 to the bit in LIN operation mode.

PBER Flag (Physical Bus Error Flag)

Only 0 can be written to the PBER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The PBER flag is set to 1 when the PBERE bit in the RLN21nmLiEDE register is 1 (physical bus error detection enable) and the physical error is detected. To clear the bit to 0 before the next communication (the FTS bit in the RLN21nmLiTRC register is 1), write 0 to the bit in LIN operation mode or LIN wake-up mode.

BER Flag (Bit Error Flag)

Only 0 can be written to the BER flag; when 1 is written, the bit retains the value that has been retained before 1 is written.

The BER flag is set to 1 when the BERE bit in the RLN21nmLiEDE register is 1 (bit error detection enable) and the bit error is detected. To clear the bit to 0 before the next communication (the FTS bit in the RLN21nmLiTRC register is 1), write 0 to the bit in LIN operation mode or LIN wake-up mode.

15.3.3.12 RLN21nmLiDFC — LIN Data Field Configuration Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiDFC: <RLIN21n_base> + 14_H

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	FSM	CSM	RFT	RFDL[3:0]			
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 15.26 RLN21nmLiDFC Register Contents

Bit Position	Bit Name	Function
7	Reserved	The write value should be the value after reset.
6	FSM	Frame Separate Mode Select 0: Frame separate mode is not set. 1: Frame separate mode is set.
5	CSM	Checksum Select 0: Classic checksum mode 1: Enhanced checksum mode
4	RFT	Response Field Communication Direction Select 0: Reception 1: Transmission
3 to 0	RFDL[3:0]	Response Field Length Select b3 b0 0 0 0 0: 0 bytes (+ checksum) 0 0 0 1: 1 byte (+ checksum) 0 0 1 0: 2 bytes (+ checksum) : 0 1 1 1: 7 bytes (+ checksum) 1 0 0 0: 8 bytes (+ checksum) Settings other than the above are prohibited.

Set the RLN21nmLiDFC register when the FTS bit in the RLN21nmLiTRC register is 0 (frame transmission or wake-up transmission/reception is halted).

FSM Bit (Frame Separate Mode Select)

The FSM bit sets the response transmission mode.

With 0 set, frame separate mode is not selected. In this case, after header transmission is started (the FTS bit in the RLN21nmLiTRC register is 1), response is transmitted/received without the RTS bit in the RLN21nmLiTRC register being set.

With 1 set, frame separate mode is selected. When the RTS bit in the RLN21nmLiTRC register is set to 1 during header transmission, response is transmitted after header transmission is completed.

Header transmission is successfully completed (the HTRC bit in the RLN21nmLiST register is 1).

Response transmission is requested (the RTS bit in the RLN21nmLiTRC register is 1).

For response reception (the RFT bit is 0), set the FSM bit to 0.

When causing a transition to LIN self-test mode, set this bit to 0 before transition.

For details of frame separate mode, refer to **Section 15.11.1, Transmission of LIN Frames**.

CSM Bit (Checksum Select)

The CSM bit sets the checksum mode.

With 0 set, classic checksum mode is selected.

With 1 set, enhanced checksum mode is selected.

When the frame timeout error is used (the FTERE bit in the RLN21nmLiEDE register is 1), the specific timeout time depends on the setting of this bit. For details of the bit error, refer to **Section 15.14, Error Status**.

RFT Bit (Response Field Communication Direction Select)

The RFT bits set the direction of the response field communication and wake-up signal.

With 0 set, reception is performed in the response field. In LIN wake-up mode, wake-up reception is performed (low level width of the input signal is counted).

With 1 set, transmission is performed in the response field. In LIN wake-up mode, wake-up transmission is performed.

RFDL[3:0] Bits (Response Field Length Select)

The RFDL bits set the length of the response field data.

The data length can be 0 to 8 bytes excluding the checksum size.

15.3.3.13 RLN21nmLiIDB — LIN ID Buffer Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiIDB: <RLIN21n_base> + 15_H

Value after reset: Undefined

Table 15.27 RLN21nmLiIDB Register Contents

Bit Position	Bit Name	Function
7	IDP1	Parity Setting (P1) Sets the parity bits (P1) to be transmitted in the ID field.
6	IDP0	Parity Setting (P0) Sets the parity bits (P0) to be transmitted in the ID field.
5 to 0	ID[5:0]	ID Setting Sets the 6-bit ID value to be transmitted in the ID field.

Set the RLN21nmLiIDB register when the FTS bit in the RLN21nmLiTRC register is 0 (frame transmission or wake-up transmission/reception is halted).

In LIN self-test mode, this register operates as follows:

Write the value to be transmitted to the register before communication. After frame transmission is completed (after loopback), the inverse of the value transmitted can be read from the register.

For details of LIN self-test mode, see **Section 15.15, LIN Self-Test Mode**.

IDP Bits (Parity Setting)

The IDP bits set the parity bits (P0 and P1) to be transmitted in the ID field of the LIN frame. IDP0 is P0 and IDP1 is P1. Since parity is not automatically calculated, set the calculation result. Note that if the erroneous result is set, it is transmitted as is.

ID Bits (ID Setting)

The ID bit sets the 6-bit ID value to be transmitted in the ID field of the LIN frame.

15.3.3.14 RLN21nmLiCBR — LIN Checksum Buffer Register

Access: This register can be read/written in 8-bit units.
However, this register can be read/written in 8-bit units in LIN self-test mode.

Address: RLN21nmLiCBR: <RLIN21n_base> + 16_H

Value after reset: Undefined

Table 15.28 RLN21nmLiCBR Register Contents

Bit Position	Bit Name	Function
7 to 0	CKSM[7:0]	Holds the checksum value transmitted or received.

In LIN operation mode, this register operates as follows:

- When the RFT bit in the RLN21nmLiDFC register is 1 (transmission):
The value transmitted can be read from the register. Read the value after transmission is completed.
Writing to this register is invalid.
- When the RFT bit in the RLN21nmLiDFC register is 0 (reception):
The value received can be read from the register. Read the value after reception is completed.
Writing to this register is invalid.

In LIN self-test mode, this register operates as follows:

- When the RFT bit in the RLN21nmLiDFC register is 1 (transmission):
The inverse of the value received can be read from the register after frame transmission/reception completion (after loop-back).
Writing to this register is invalid.
- When the RFT bit in the RLN21nmLiDFC register is 0 (reception):
The value to be received should be written to the register before communication.
The inverse of the value received can be read from the register after frame transmission/reception is completed (after loop-back).

See **Section 15.15, LIN Self-Test Mode** for the details on LIN self-test mode.

Set the RLN21nmLiCBR register when the FTS bit in the RLN21nmLiTRC register is 0 (frame transmission or wake-up transmission/reception is halted).

15.3.3.15 RLN21nmLiDBRb — LIN Data Buffer b Register

Access: This register can be read/written in 8-bit units.

Address: RLN21nmLiDBR1: <RLIN21n_base> + 18_H, RLN21nmLiDBR2: <RLIN21n_base> + 19_H,
RLN21nmLiDBR3: <RLIN21n_base> + 1A_H, RLN21nmLiDBR4: <RLIN21n_base> + 1B_H,
RLN21nmLiDBR5: <RLIN21n_base> + 1C_H, RLN21nmLiDBR6: <RLIN21n_base> + 1D_H,
RLN21nmLiDBR7: <RLIN21n_base> + 1E_H, RLN21nmLiDBR8: <RLIN21n_base> + 1F_H

Value after reset: Undefined

Table 15.29 RLN21nmLiDBRm (m = 1 to 8) Register Contents

Bit Position	Bit Name	Function
7 to 0	LDB[7:0]	Sets the data to be transmitted or allows the received data to be read. Setting Range: 00 _H to FF _H

- For response transmission:

The RLN21nmLiDBRm registers set the data to be transmitted in the response field.
Use these registers with the following settings.

- RFT in RLN21nmLiDFC register is 1 (transmission)
- FSM in RLN21nmLiDFC register is 0 (not frame separate mode)
- FTS bit in RLN21nmLiTRC register is 0 (frame transmission or wake-up transmission/
reception is halted)

or

- RFT in RLN21nmLiDFC register is 1 (transmission)
- FSM in RLN21nmLiDFC register is 1 (frame separate mode)
- RTS in RLN21nmLiTRC register is 0 (response transmission is halted)

- For response reception:

The RLN21nmLiDBRm registers hold the data received in the response field.
The received data is overwritten. If an error is detected, the data up to the byte in which the error
was detected are stored in the register.

Do not read these registers when the FTS bit is 1 (frame transmission or wake-up transmission/
reception is started)

In LIN self-test mode, these registers operate as follows:

The value to be transmitted should be written to the registers before communication.

The inverse of the value received can be read from the register after frame transmission/reception
completion (after loop back).

See **Section 15.15, LIN Self-Test Mode** for the details on the LIN self-test mode.

15.4 Interrupt Sources

The LIN interrupts are interrupt requests generated by the LIN master interface.

There are three interrupt factors for each channel; frame/wake-up transmit completion, frame/wake-up receive completion, and error detection.

The interrupt request from three interrupt states, frame/wake-up transmit completion, frame/wake-up receive completion, and error detection, is ORed to be one interrupt request “LIN interrupt”.

The respective interrupt request is output when the corresponding flag in the RLN21nmLiST register is set to 1 while the corresponding bit in the RLN21nmLiIE register is 1 (interrupt enabled). However, if an interrupt is requested when the corresponding flag in the RLN21nmLiST register has been set to 1, it is ignored. Therefore, clear the corresponding flag to 0 to enable the interrupt.

Figure 15.2 shows a block diagram of the LIN interrupt.

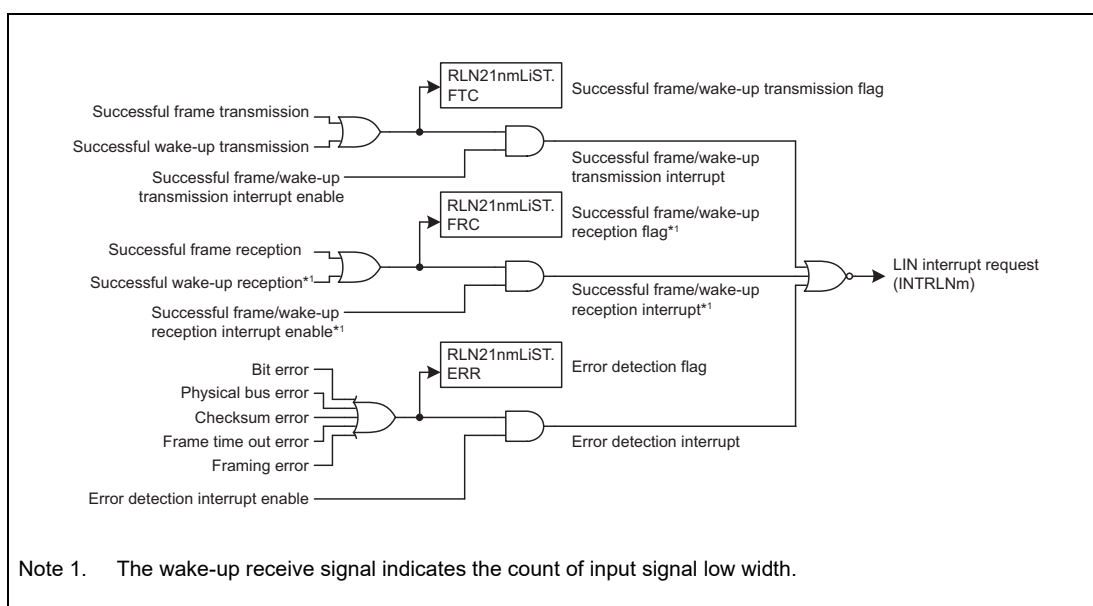

Figure 15.2 LIN Interrupt Block Diagram

15.5 Modes

The LIN Master Interface provides the following four modes, depending upon the specific function to be performed:

- LIN reset mode
- LIN operation mode
- LIN wake-up mode
- LIN self-test mode

The transition of the operating modes except LIN self-test mode is controlled independently for respective channels.

Figure 15.3 shows mode transitions. **Table 15.30** describes mode transition conditions. **Table 15.31** lists operations available in each mode.

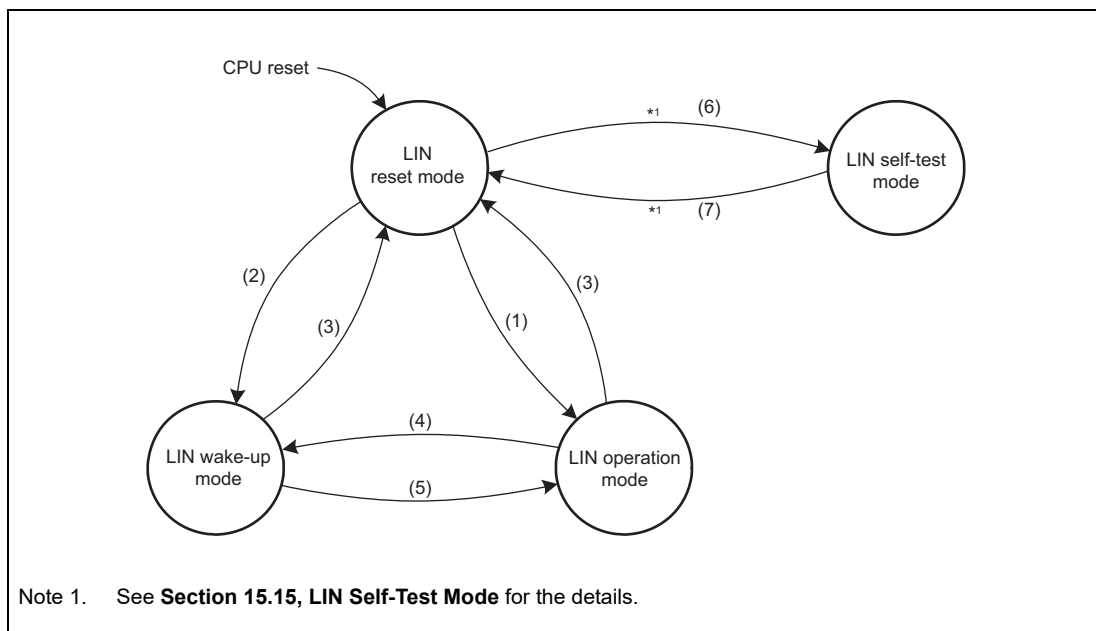

Figure 15.3 Mode Transitions

Table 15.30 Transition Condition of Each Mode

Mode transition		Transition condition
1	LIN reset mode → LIN operation mode	RLN21nmLiCUC.OM1, OM0 = 11 _B
2	LIN reset mode → LIN wake-up mode	RLN21nmLiCUC.OM1, OM0 = 01 _B
3	LIN wake-up mode → LIN reset mode LIN operation mode	RLN21nmLiCUC.OM0 = 0 _B
4	LIN operation mode → LIN wake-up mode	RLN21nmLiCUC.OM1, OM0 = 01 _B
5	LIN wake-up mode → LIN operation mode	RLN21nmLiCUC.OM1, OM0 = 11 _B
6	LIN reset mode → LIN self-test mode	See Section 15.15, LIN Self-Test Mode.
7	LIN self-test mode → LIN reset mode	See Section 15.15, LIN Self-Test Mode.

Table 15.31 Operations Available in Each Mode

LIN operation mode	LIN wake-up mode	LIN self-test mode
Header transmission	Wake-up transmission	Self test
Response transmission	Wake-up reception	
Response reception	Error detection	
Error detection		

Whether a transition has been made to LIN reset mode, the LIN mode, or the UART mode can be verified by reading the OMM1 and OMM0 bits in the RLN21nmLiMST register.

For a description of the LIN self-test mode, see **Section 15.15, LIN Self-Test Mode.**

15.6 LIN Reset Mode

Setting the OM0 bit in the RLN21nmLiCUC register to 0_B (LIN reset mode) causes a transition to LIN reset mode. The change to LIN reset mode can be verified by determining that the OMM0 bit in the RLN21nmLiMST register has been set to 0_B (LIN reset mode). In this mode, the LIN communication stops.

From LIN reset mode, transitions to LIN operation mode, LIN wake-up mode, and LIN self-test mode can be made.

When the mode changes to LIN reset mode, the following registers are initialized to their reset values, and as long as LIN reset mode is in effect, they retain their value after resets.

- RLN21nmLiTRC register
- RLN21nmLiST register
- RLN21nmLiEST register

The following registers retain their previous values even when a transition to LIN reset mode is made:

- RLN21nGLWBR register
- RLN21nGLBRP0 register
- RLN21nGLBRP1 register
- RLN21nmLiMD register
- RLN21nmLiBFC register
- RLN21nmLiSC register
- RLN21nmLiWUP register
- RLN21nmLiIE register
- RLN21nmLiEDE register
- RLN21nmLiDFC register
- RLN21nmLiIDB register
- RLN21nmLiCBR register
- RLN21nmLiDBRb register

15.7 LIN Operation Mode

In LIN operation mode, frame processing (header transmission, header reception, response transmission, response reception, and error detection) can be performed.

During a transition from LIN reset mode to LIN mode, setting the OM1 and OM0 bits in the RLN21nmLiCUC register to 11_B changes the mode to LIN operation mode, changing the OMM1 and OMM0 bits in the RLN21nmLiMST register to 11_B. Communication settings should be performed after the RLN21nmLiMST register has become 11_B.

15.8 LIN Wake-up Mode

In LIN wake-up mode, wake-up signal processing (wake-up transmission, wake-up reception, and error detection) can be performed.

During a transition from LIN reset mode to LIN mode, setting the OM1 and OM0 bits in the RLN21nmLiCUC register to 01_B changes the mode to LIN wake-up mode, changing the OMM1 and OMM0 bits in the RLN21nmLiMST register to 01_B. Communication settings should be performed after the RLN21nmLiMST register has become 01_B.

15.9 Header Transmission/Response Transmission/Response Reception

15.9.1 Header Transmission

Figure 15.4 shows the operation of the LIN master interface (LIN master mode) in header transmission. **Table 15.32** provides processing in header transmission.

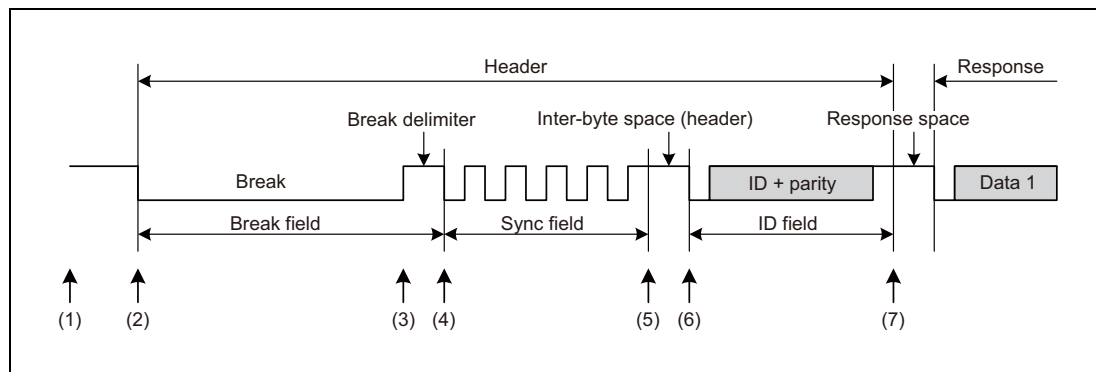

Figure 15.4 Operation in Header Transmission

Table 15.32 Processing in Header Transmission

Software processing	LIN Master Interface processing
(1) <ul style="list-style-type: none"> • Sets a baud rate • Enables interrupt • Enables error detection • Sets frame configuration parameters • Changes LIN operation mode • Sets information on the frame to be transmitted (ID, parity, data length, response direction, Checksum method, and transmission data) 	Waits for the setting of the FTS bit in the RLIN21nmLiTRC register to 1 by software (idle).
(2) Sets the FTS bit in the RLIN21nmLiTRC register to 1 (frame transmission or wake-up transmission/reception started)	Transmits a break.
(3) Waits for an interrupt request	Transmits a break delimiter.
(4)	Transmits a sync field (55 _H).
(5)	Transmits an inter-byte space (header).
(6)	Transmits an ID field.
(7)	Sets a successful header transmission flag.

NOTE

For information about error detection, refer to **Section 15.14, Error Status**.

15.9.2 Response Transmission

Figure 15.5 shows the operation of the LIN Master Interface (LIN master mode) in response transmission. Table 15.33 provides processing in response transmission.

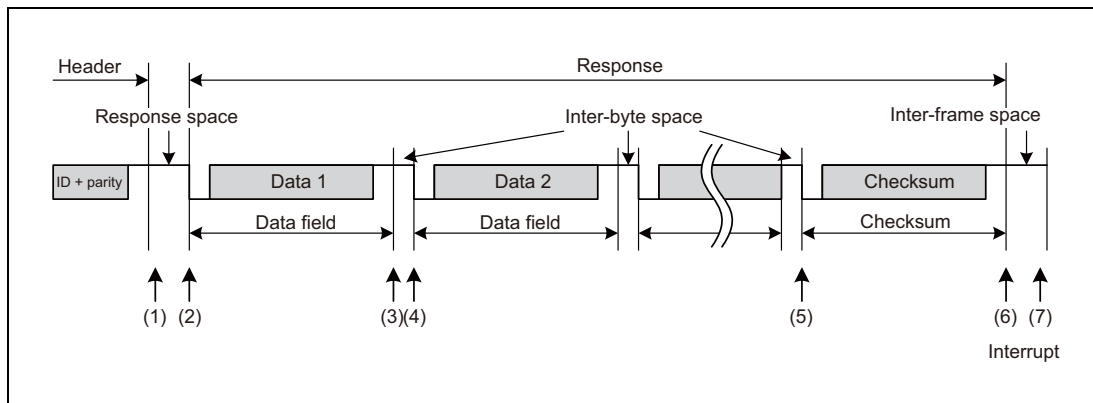

Figure 15.5 Operation in Response Transmission

Table 15.33 Processing in Response Transmission

Software processing	LIN Master Interface processing

(5)	<ul style="list-style-type: none"> Receives the checksum when the start bit is detected. Determines the checksum. Sets the successful frame/wake-up reception flag. Sets the FTS bit in the RLN21nmLiTRC register to 0 (frame transmission or wake-up transmission/reception stopped).
(6) <ul style="list-style-type: none"> Processing after communication Reads the received data. Checks the RLN21nmLiST register, and clears flags. 	Idle

NOTE

For information about error detection, refer to **Section 15.14, Error Status**.

15.10 Data Transmission/Reception

15.10.1 Data Transmission

One bit of data is transmitted per 1 Tbit.

The data that is transmitted returns to the reception data input pin via the LIN transceiver. The received data and the transmitted data are compared bit by bit, and the results are stored in the BER flag in the RLN21nmLiEST register (see **Section 15.14, Error Status**).

In LIN Master interface, the sampling point for received data, 1 Tbit is generated to be $16f_{LIN}$, and thus is at the 13th clock cycle (81.25% position).

Figure 15.7 shows an example of data transmission timing.

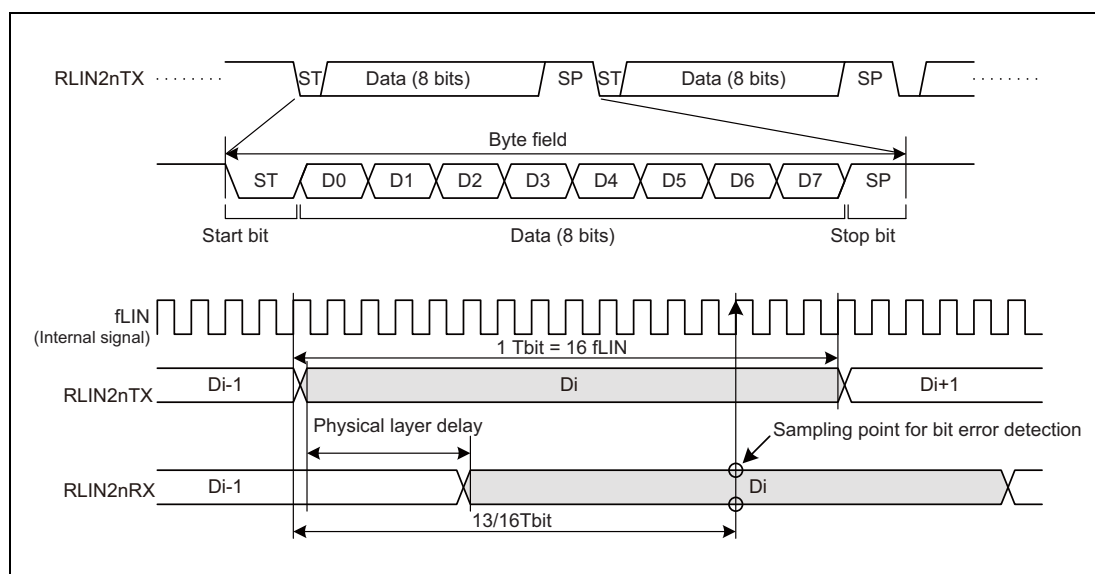

Figure 15.7 Example of Data Transmission Timing

15.10.2 Data Reception

Data reception is performed by using the synchronized RLIN2nRX signal (an internal signal) that is the input from the LRX0 pin synchronized with the LIN system clock (fLIN).

The byte field is synchronized at the falling edge of the start bit for the synchronized RLIN2nRX signal. After the falling edge is detected, sampling is performed again 0.5 Tbit later, and the falling edge is recognized as a start bit if the synchronized RLIN2nRX signal is low level. The falling edge is not recognized as a start bit if the RLIN2nRX signal after the clearing of the resetting is low-level-fixed or if a high level is detected on re-sampling.

After the start bit is detected, the system samples 1 bit per Tbit.

Figure 15.8 shows an example of data reception timing.

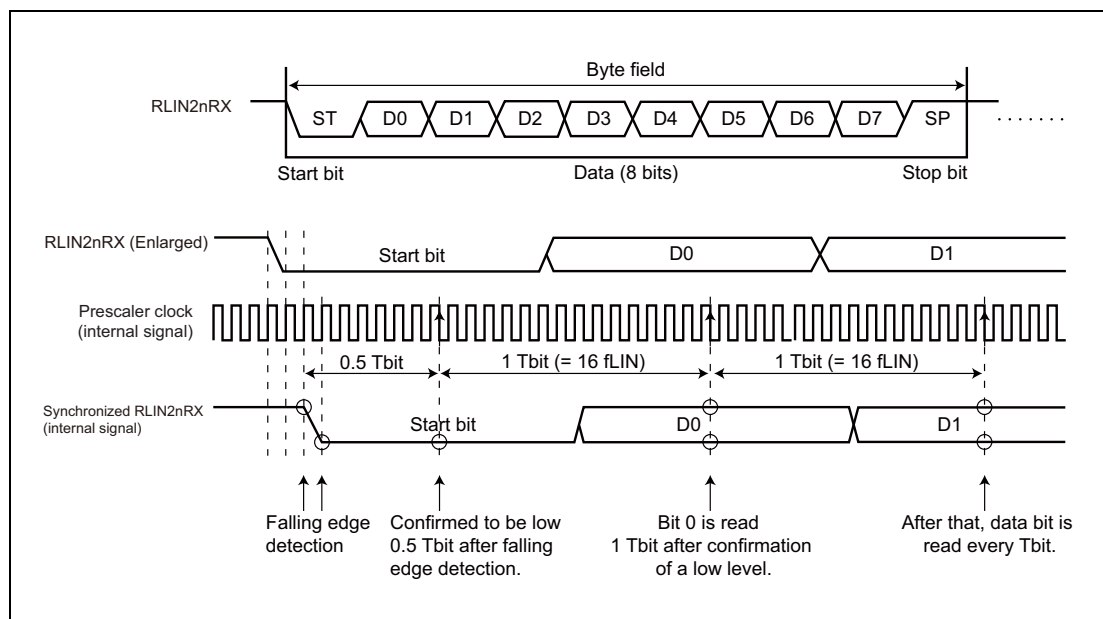

Figure 15.8 Example of Data Reception Timing

15.11 Transmission/Reception Data Buffering

This section explains the buffer processing that takes place when the LIN Master Interface sends or receives data continuously.

15.11.1 Transmission of LIN Frames

For an 8-byte transmission, the contents stored in registers RLN21nmLiDBR1 to RLN21nmLiDBR8 are sequentially transmitted to data areas 1 to 8 of the LIN frame. In the case of a 4-bytes transmission, the contents stored in registers RLN21nmLiDBR1 to RLN21nmLiDBR4 are transmitted to data areas 1 to 4 of the LIN frame, but the contents of registers RLN21nmLiDBR5 to RLN21nmLiDBR8 are not transmitted. The transmitted checksum data is stored in the RLN21nmLiCBR register.

Figure 15.9 depicts the LIN transmission processing and the required buffer.

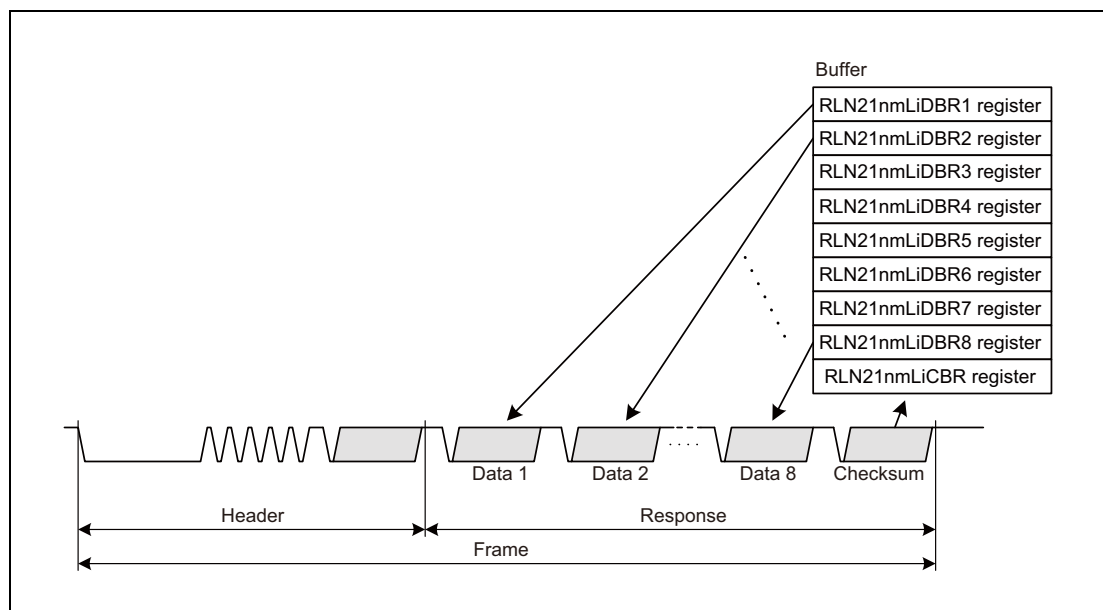

Figure 15.9 LIN Transmission Processing and Required Buffer

(1) Frame Separate Mode

Setting the FSM bit in the RLN21nmLiDFC register to 1 turns on the frame separate mode.

In frame separate mode, a header and a response are transmitted when prompted by separate transmission start requests.

When the transmission of a header is finished, the HTRC flag in the RLN21nmLiST register turns 1 (successful header transmission).

15.11.2 Reception of LIN Frames

For an 8-byte reception, the contents of data areas 1 to 8 of the LIN frame is stored in registers RLN21nmLiDBR1 to RLN21nmLiDBR8, respectively, upon receipt of a stop bit. In the case of a 4-byte reception, the contents of data areas 1 to 4 of the LIN frame are stored in registers RLN21nmLiDBR1 to RLN21nmLiDBR4, respectively; however, no data is stored in registers RLN21nmLiDBR5 to RLN21nmLiDBR8. Also, the received checksum data is stored in the RLN21nmLiCBR register.

Figure 15.10 depicts the LIN reception processing and the required buffer.

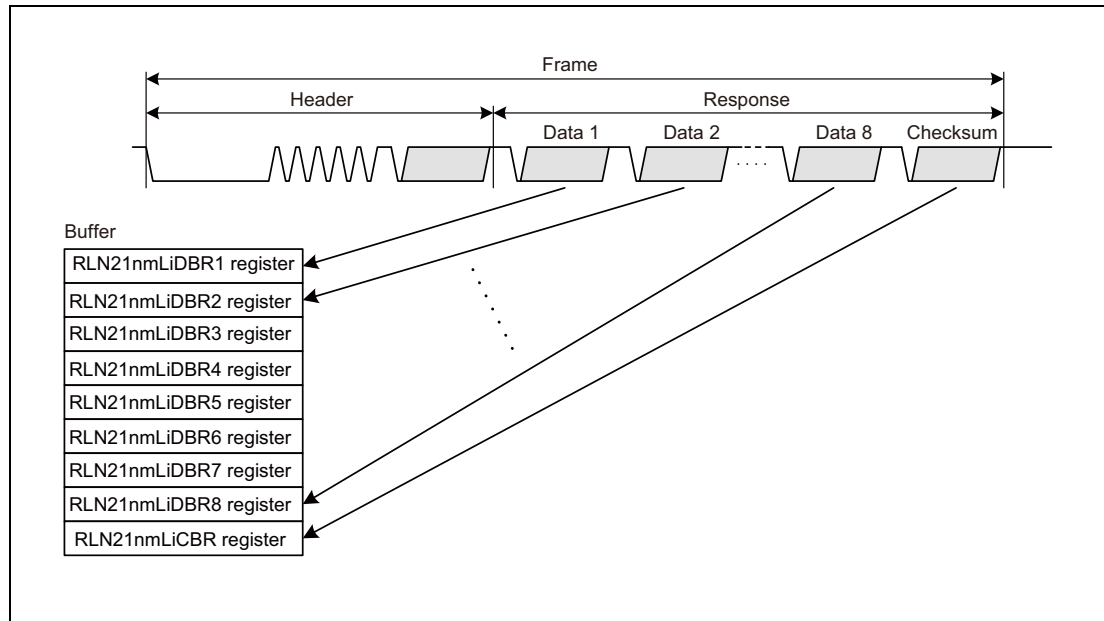

Figure 15.10 LIN Reception Processing and Required Buffer

(1) Reception of Data 1

When the reception of the first byte of data is finished, the DIRC flag in the RLN21nmLiST register turns 1 (successful data 1 reception).

15.12 Wake-up Transmission/Reception

The wake-up transmission/reception can be used in LIN wake-up mode.

15.12.1 Wake-up Transmission

In LIN wake-up mode, setting the RFT bit in the RLN21nmLiDFC register to 1 (transmission) and the FTS bit in the RLN21nmLiTRC register to 1 (frame transmission or wake-up transmission/reception started) causes a wake-up signal to be output from the output pin. The low level width of the wake-up signal should be set using the WUTL[3:0] bits in the RLN21nmLiWUP register.

However, when the setting of the LWBR0 bit in the RLN21nGLWBR register is 1 (if LIN2.x is in use), the width at low level of the LIN system clock (fLIN) becomes that of fa regardless of the setting of LCKS bits in the RLN21nmLiMD register. Setting the bit rate when 19200 bps is selected as fa and setting the WUTL[3:0] bits in the RLN21nmLiWUP register to 0100_B (5 Tbits) enables output of a signal with width at low level of 260 μs in LIN wakeup mode regardless of the setting of LCKS bits in the RLN21nmLiMD register.

If a wake-up low is output without any error, the FTC flag in the RLN21nmLiST register turns 1 (successful frame or wake-up transmission); when the FTCIE bit in the RLN21nmLiIE register is 1 (successful frame/wakeup transmission interrupt enabled), an interrupt request is generated.

If an error is detected, wake-up transmission is suspended and the error flag of the detected error (PBER flag or BER flag in the RLN21nmLiEST register) is set to 1 (detection of a physical bus error or bit error).

Figure 15.11 shows the wake-up transmission timing.

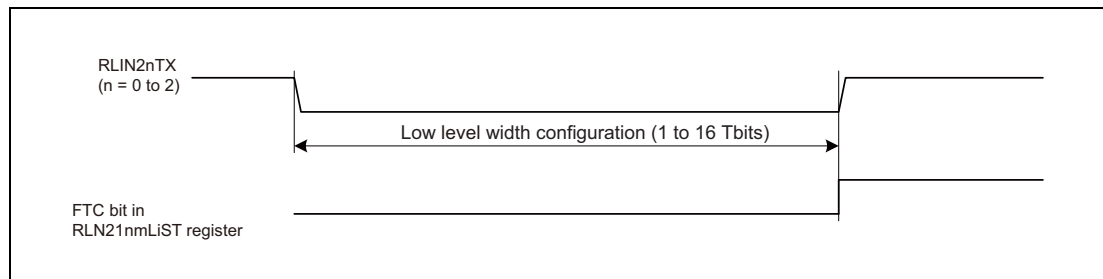

Figure 15.11 Wake-up Transmission Timing

15.12.2 Wake-up Reception

The detection of a wake-up signal involves the use of an input signal low level width count function. The input signal low level width count function measures the low level width of the input signal to the LRX0 pin, using the same sampling point as data reception. This allows the 2.5-Tbit or longer low-level width of the input signal of fLIN to be measured.

When LIN Specification Package Revision 1.3 is used, set the LWBR0 bit in the RLN21nmGLWBR register to 0. When LIN Specification Package Revision 2.x is used, set the RLN21nmGLWBR register to 1.

When LWBR0 bit is set to 1, regardless of the setting of the LCKS bit in the RLN21nmLiMD register, fa is selected as the LIN system clock (fLIN) (the LCKS bit is not changed).

Setting the baud rate to 19200 bps while fa is selected allows the 130 μ s or longer low-level width of the input signal to be detected during LIN wake-up mode regardless of the setting of the RLN21nmLiMD register.

When using this function, in LIN wake-up mode set the RFT bit in the RLN21nmLiDFC register to 0 (reception), and the FTS bit in the RLN21nmLiTRC register to 1 (frame transmission or wake-up transmission/reception a started).

When the low level width to be measured is reached, the FRC flag in the RLN21nmLiST register turns 1 (successful frame/wake-up reception). If the FRCIE bit in the RLN21nmLiIE register is 1 (successful frame or wake-up reception interrupt enabled), an interrupt request is generated.

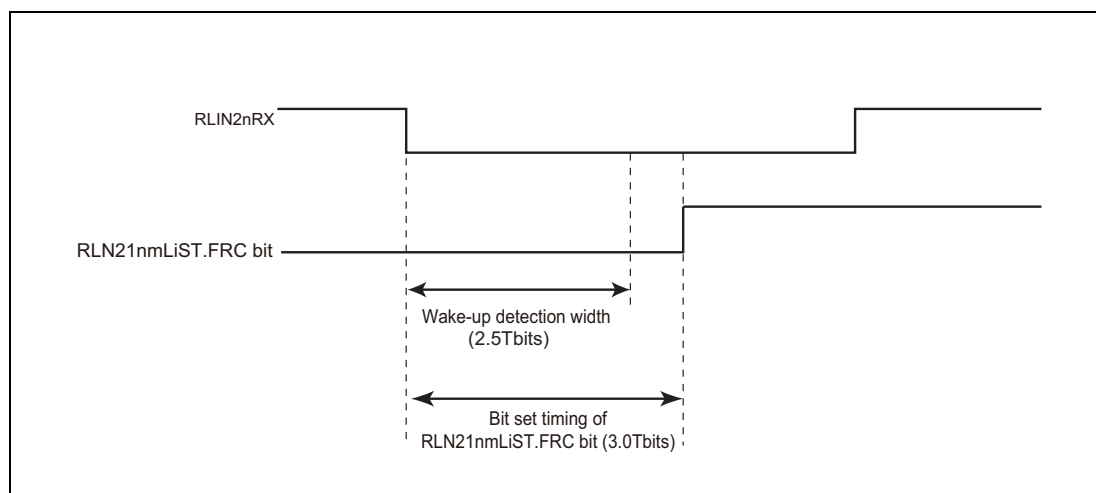

Figure 15.12 Input Signal Low Level Count Function

15.12.3 Wakeup Collision

If the master node and the slave node transmit wakeup signals simultaneously, a collision will occur on the LIN bus, though a collision of wakeup signals is not detected in the LIN master interface.

15.13 Status

During LIN mode operation, the LIN Master Interface can detect seven types of statuses.

The three statuses, successful frame/wake-up transmission, successful frame/wake-up reception, error detection, scan generate interrupt requests.

Table 15.35 shows the types of statuses available.

Table 15.35 Types of Statuses

Status	Status Set Condition	Status Clear Condition	Operation Mode Capable of Status Detection	Corresponding Bit	Interrupt
Reset	After the OM0 bit in the RLN21nmLiCUC register is set to not-LIN-reset-mode, if actually the LIN Master Interface is cleared from LIN reset mode.	After the OM0 bit in the RLN21nmLiCUC register is set to LIN reset mode, if actually the LIN Master Interface enters LIN reset mode.	All modes	OMM0 bit in RLN21nmLiMS T register	—
Operation mode	After the OM1 bit in the RLN21nmLiCUC register is set to LIN operation mode, if actually the LIN Master Interface enters LIN operation mode.	After the OM1 bit in the RLN21nmLiCUC register is set to LIN wake-up mode, if actually the LIN Master Interface enters LIN wake-up mode.	<ul style="list-style-type: none"> LIN operation mode LIN wake-up mode 	OMM1 bit in RLN21nmLiMS T register	—
Frame/wake-up transmission end	When a frame (header transmission + response transmission), a wake-up signal, or a data group is transmitted successfully.	<ul style="list-style-type: none"> When another communication is started When cleared by software After transition to LIN reset mode 	<ul style="list-style-type: none"> LIN operation mode LIN wake-up mode 	FTC flag in RLN21nmLiST register	√
Frame/wake-up reception end	When a frame (header transmission + response reception), a wake-up signal, or a data group is received successfully.	<ul style="list-style-type: none"> When another communication is started When cleared by software After transition to LIN reset mode 	<ul style="list-style-type: none"> LIN operation mode LIN wake-up mode 	FRC flag in RLN21nmLiST register	√
Error detection	If any of the PRER flag, CSER flag, FER flag, FTER flag, PBER flag, and BER flags in the RLN21nmLiEST register turns 1 (error detected).	<ul style="list-style-type: none"> When another communication is started When cleared by software ^{*1} After transition to LIN reset mode 	<ul style="list-style-type: none"> LIN operation mode LIN wake-up mode 	ERR flag in RLN21nmLiST register	√
Data 1 reception end	The RFT bit in the RLN21nmLiDFC register is 0 (reception) and the first byte of the response field is received. ^{*2}	<ul style="list-style-type: none"> When another communication is started When cleared by software After transition to LIN reset mode 	LIN operation mode	D1RC flag in RLN21nmLiST register	—
Header transmission end	When a header field is transmitted successfully.	<ul style="list-style-type: none"> When another communication is started When cleared by software After transition to LIN reset mode 	LIN operation mode	HTRC flag in RLN21nmLiST register	—

Note 1. In LIN operation mode, the ERR flag in the RLN21nmLiST register is cleared to 0 by writing 0 to the CSER flag, FER flag, FER flag, FTER flag, PBER flag or BER flags in the RLN21nmLiEST register.

Note 2. Not detected when the RFDL [3:0] bits in the RLN21nmLiDFC register are 0000_B (0-byte + checksum).

15.14 Error Status

15.14.1 Types of Error Status

The LIN Master Interface can detect five types of error status in LIN master mode. The condition of these error statuses can be checked by means of the corresponding bits in the RLN21nmLiEST register.

All error statuses represent interrupt events.

Table 15.36 shows the types of error status.

Table 15.36 Types of Error Status

Status	Error Detection Condition	Operation Mode Capable of Error Detection	Communication	Enable/Disable Detection	Corresponding Bit
Bit error	The transmitted data and the data on the LIN bus monitored by the receive pin do not match*1	<ul style="list-style-type: none"> LIN operation mode LIN wake-up mode 	Suspended	√	BER flag in RLN21nmLiEST register
Physical bus error	<ul style="list-style-type: none"> LIN bus is detected to be high level when sending a break LIN bus is detected to be low level when sending a break delimiter LIN bus is detected to be high level when sending a wake-up 	<ul style="list-style-type: none"> LIN operation mode LIN wake-up mode 	Suspended	√	PBER flag in RLN21nmLiEST register
Timeout error	A frame or response transmission/reception does not terminate within a given time*2	LIN operation mode	Suspended	√	FTER flag in RLN21nmLiEST register
Framing error	In response field reception, a stop bit of each data byte is low level	LIN operation mode	Suspended	√	FER flag in RLN21nmLiEST register
Checksum error	In response field reception, the result of checksum test gives an error	LIN operation mode	—	—	CSER flag in RLN21nmLiEST register

Note 1. If a bit error is detected, processing is stopped after a stop bit is sent. If a bit error is detected in a non-data area, such as an inter-byte space, the transmission is suspended immediately after the bit which had the error is sent. If a bit error is detected during the transmission of a wake-up, the transmission of the wake-up is suspended after the bit which had the error is sent.

Note 2. The timeout time depends on the response field data length (the RFDL 3:0] bits in the RLN21nmLiDFC register) and the checksum selection (the CSM bit in the RLN21nmLiDFC register), and this can be calculated according to the following formula:

On classic selection (when the CSM bit in RLN21nmLiDFC is 0): Timeout time = 49 + (number of data bytes + 1) × 14 [Tbit]

On enhanced selection (when the CSM bit in RLN21nmLiDFC is 1): Timeout time = 48 + (number of data bytes + 1) × 14 [Tbit]

The aforementioned timeout time is a time greater than the TFRAME_MAX of LIN Specification Package Revision 1.3 on classic selection, or the TFRAME_MAX of LIN Specification Package Revision 2.x on enhanced selection.

The error status is cleared when the next communication is started, by software, or at a transition to LIN reset mode.

15.14.2 Target Time Area for Error Detection

Figure 15.13 shows the time domain in which the LIN master interface performs monitoring for error detection.

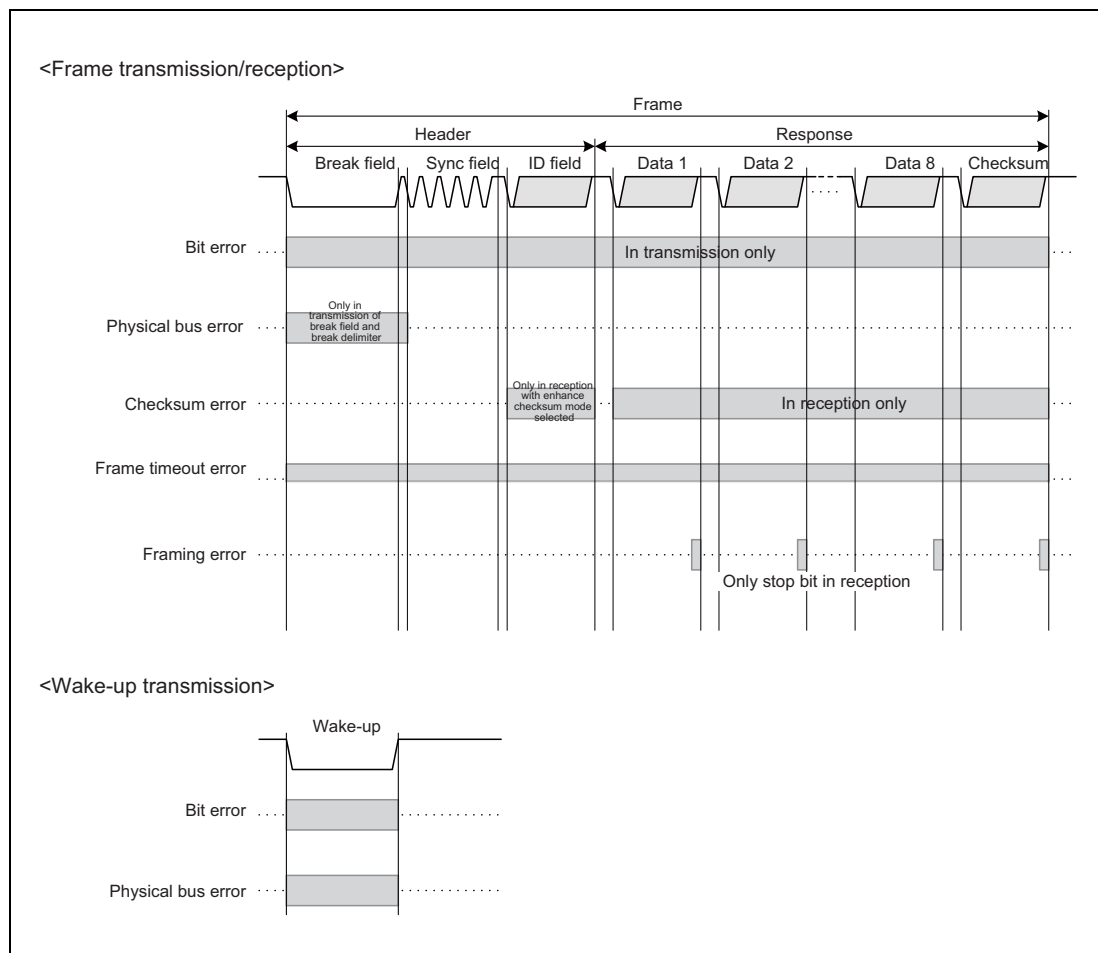

Figure 15.13 Target Time Area for Error Detection

15.15 LIN Self-Test Mode

The LIN Master Interface provides LIN self-test mode. When LIN self-test mode is turned on, RLIN2nTX and RLIN2nRX are disconnected from the external pin, and the internal RLIN2nTX and RLIN2nRX are connected. Thus, the frame transmitted from RLIN2nTX is returned to the internal RLIN2nRX (loop back).

The functions of the LIN self-test mode operate in the following conditions:

- LIN self-test mode (transmission): header transmission and response transmission
- LIN self-test mode (reception): header reception and response reception

In LIN self-test mode, the operation is at the fastest baud rate, regardless of the setting of the baud rate generator. Regardless of the setting of the baud rate related registers, the baud rate operates at the LIN communication clock source/16 [bps].

In LIN self-test mode, the following functions are not supported:

- LIN Wake-up function
- Frame separate mode

Do not use above functions.

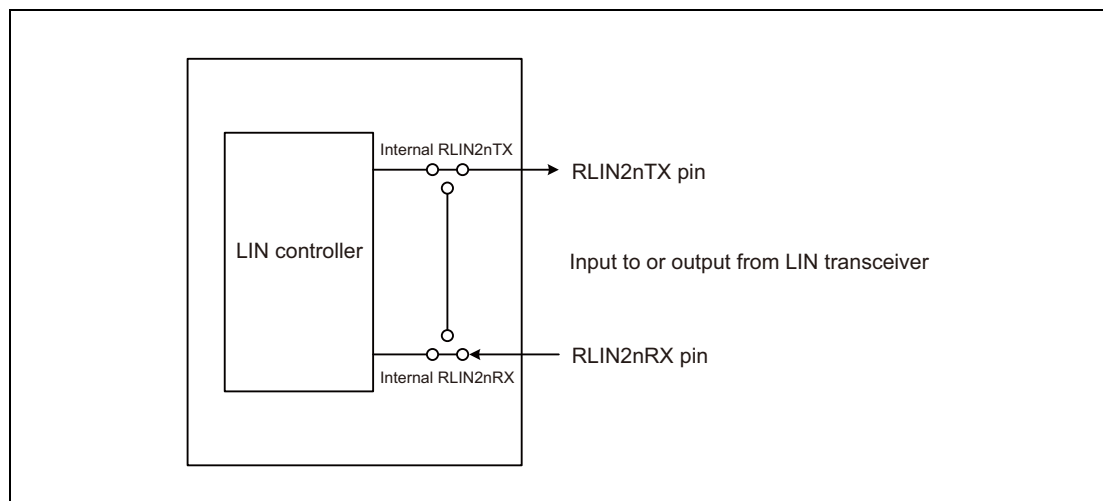

Figure 15.14 Connection in LIN Reset Mode, LIN Wake-Up Mode, and LIN Operation Mode

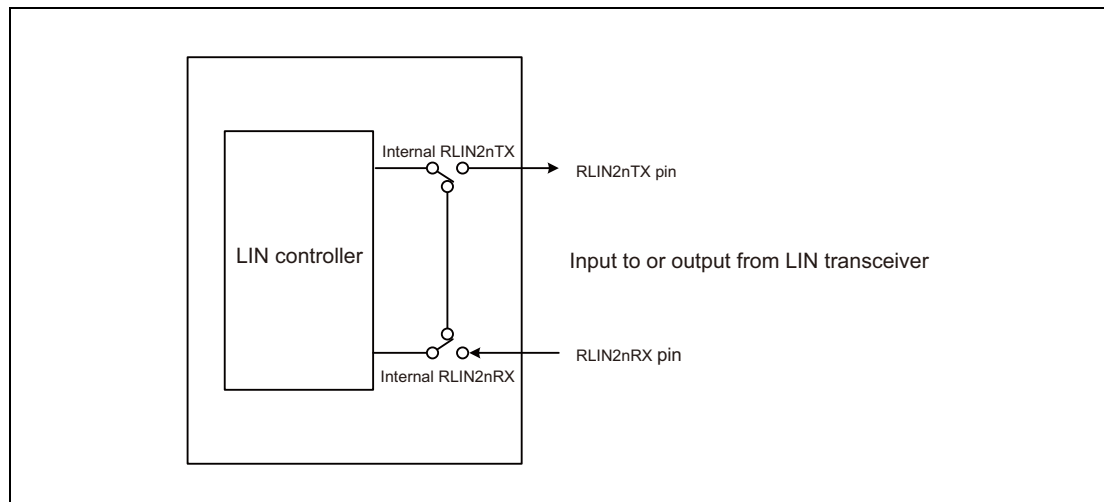

Figure 15.15 Connection in LIN Self-Test Mode

15.15.1 Change to LIN Self-Test Mode

Writing to the RLN21nGLSTC register enables LIN self-test mode.

The RLN21nGLSTC register becoming 01_H indicates that the mode is transit to LIN self-test mode.

When changing to LIN self-test mode, be sure to execute a specific sequence. In that sequence, information must be written three times consecutively to the LIN self-test control register, as follows:

- Change to LIN reset mode regarding all channels in the unit.
Set the OM0 bit in the RLN21nmLiCUC register to 0 (LIN reset mode).
Read the OMM0 bit in the RLN21nmLiMST register; verify that it is 0 (LIN reset mode).
- 1st write: RLN21nGLSTC register = $1010\ 0111_B$ ($A7_H$)
- 2nd write: RLN21nGLSTC register = $0101\ 1000_B$ (58_H)
- 3rd write: RLN21nGLSTC register = $0000\ 0001_B$ (01_H)
- Verify the transition to LIN self-test mode
Read the RLN21nGLSTC register; verify that it is 01_H (LIN self-test mode).

If the key of the first write ($A7_H$) is written twice by mistake, the transition to LIN self-test mode is suspended. The above sequence should be retried from the step of first write. In addition, if a write to another LIN-related register in the same unit is performed during transition to LIN self-test mode (three consecutive write operations to the RLN21nGLSTC register), the transition is also suspended.

15.15.2 Transmission in LIN Self-Test Mode

To execute a self-test on transmission, perform the procedure below:

- Set the baud rate related registers
 RLN21nGLBRP0 register = xxxx xxxx_B *1
 RLN21nGLBRP1 register = xxxx xxxx_B *1
 RLN21nmLiMD register = 0000 xx00_B *1
- Set interrupt enable register and error enable related registers
 RLN21nmLiIE register = 0000 0xxx_B *2
 RLN21nmLiEDE register = 0000 xxxx_B
- Set the break field and space related registers.
 RLN21nmLiBFC register = 00xx xxxx_B
 RLN21nmLiSC register = 00xx 0xxx_B
- Release from the LIN reset mode
 Write 11_B to the OM1 and OM0 bits in the RLN21nmLiCUC register, and check that the OMM1 and OMM0 bits in the RLN21nmLiMST register are 11_B.
- Set the transmit frame related registers.
 RLN21nmLiDFC register = 00x1 xxxx_B
 RLN21nmLiIDB register = xxxx xxxx_B
 RLN21nmLiDBR1 to RLN21nmLiDBR8 registers = xxxx xxxx_B
- Header transmission → response transmission started
 Set the FTS bit in the RLN21nmLiTRC register to 1 (frame transmission or wake-up transmission/reception started).
 The LIN self-test mode (transmission) is executed. In this mode, interrupt are generated, and status and error status are also updated. The checksum is automatically calculated by the LIN master interface.
 To suspend the LIN self-test mode (transmission) while it is running, set the OM0 bit in the RLN21nmLiCUC register to 0 (LIN reset mode), which causes a transition to the LIN reset mode.
- When the transmission is completed, the inverse of the looped-back frame data is stored in the RLN21nmLiIDB, RLN21nmLiDBRb, and RLN21nmLiCBR registers (the data is inverted before being stored because the transmitted value should be compared with the looped-back value). Then, the FTS bit in the RLN21nmLiTRC register is cleared.
- If the transmission fails to complete due to an error, the applicable error flag is set and the FTS bit in the RLN21nmLiTRC register is cleared.

NOTE

x: Don't care

Note 1. The following register settings are not reflected to the operation of the LIN self-test mode. The LCKS bit in the RLN21nGLBRP0 register, RLN21nGLBRP1 register, and RLN21nmLiMD register. Therefore, those settings are not necessary.

Note 2. If necessary, set the related registers described in **Section 6, Interrupt**.

15.15.3 Reception in LIN Self-Test Mode

To execute a self-test on LIN master transmission, perform the procedure below:

- Set the baud rate, noise filter, and interrupt output related registers.
 - RLN21nGLBRP0 register = xxxx xxxx_B *1
 - RLN21nGLBRP1 register = xxxx xxxx_B *1
 - RLN21nmLiMD register = 0000 xx00_B *1
- Set the interrupt enable and error enable related registers.
 - RLN21nmLiIE register = 0000 0xxx_B *2
 - RLN21nmLiEDE register = 0000 xxxx_B
- Set the break field and space related registers.
 - RLN21nmLiBFC register = 00xx xxxx_B
 - RLN21nmLiSC register = 00xx 0xxx_B *1
- Release from the LIN reset mode

Write 11_B to the OM1 and OM0 bits in the RLN21nmLiCUC register, and check that the OMM1 and OMM0 bits in the RLN21nmLiMST register are 11_B.
- Set the receive frame related registers.
 - RLN21nmLiDFC register = 00x0 xxxx_B
 - RLN21nmLiIDB register = xxxx xxxx_B
 - RLN21nmLiDBR1 to RLN21nmLiDBR8 registers = xxxx xxxx_B
 - RLN21nmLiCBR register = xxxx xxxx_B

Since the checksum value to be transmitted is not automatically calculated, set the calculation value to the RLN21nmLiCBR register. If an incorrect checksum is set at this time, the checksum error can be tested.
- Header transmission → response reception started

Set the FTS bit in the RLN21nmLiTRC register to 1 (frame transmission or wake-up transmission/reception started).

The LIN self-test mode (reception) is executed. In this mode, interrupt are generated, and status and error status are also updated.

To suspend the LIN self-test mode (reception) while it is running, set the OM0 bit in the RLN21nmLiCUC register to 0 (LIN reset mode), which causes a transition to the LIN reset mode.
- When the reception is completed, the inverse of the looped-back frame data is stored in the RLN21nmLiIDB, RLN21nmLiDBRb, and RLN21nmLiCBR registers (the data is inverted before being stored because the set value should be compared with the looped-back value). Then, the FTS bit in the RLN21nmLiTRC register is cleared.
- If the reception fails to complete due to an error, the applicable error flag is set and the FTS bit in the RLN21nmLiTRC register is cleared.

NOTE

x: Don't care

Note 1. The following register settings are not reflected to the operation of the LIN self-test mode. The LCKS bit in the RLN21nGLBRP0 register, the RLN21nGLBRP1 register, and the RLN21nmLiMD register, and the IBS bit and IBHS bit (response space only) in the RLN21nmLiSC register. Therefore, those settings are not necessary.

Note 2. If necessary, set the related registers described in **Section 6, Interrupt**.

15.15.4 Terminating LIN Self-Test Mode

To terminate LIN self-test mode, perform the procedure below:

- All the channels in the unit make a transition to LIN reset mode
Write 0 to the OM0 bit in the RLN21nmLiCUC register to make a transition to LIN reset mode. However, if the OMM1 and OMM0 bits in the RLN21nmLiMST register are not “11_B” in any channels of the unit after the transition to LIN self-test mode, write “11_B” to the OM1 and OM0 bits in the RLN21nmLiCUC register in any one channel. Check that the OMM1 and OMM0 bits in the RLN21nmLiMST register are set to “11_B”, and then make a transition to LIN reset mode.
- Verify release from LIN self-test mode.
Read the RLN21nGLSTC register; confirm that it is 00_H (not in LIN self-test mode)
- Verify the transition to LIN reset mode.
Read the OMM0 bit in the RLN21nmLiMST register; verify that it is 0 (LIN reset mode).

15.16 Baud Rate Generator

The LIN system clock (fLIN) is the clock that is made by dividing the LIN communication clock source by the baud rate generator, and the bit rate is made by dividing that clock by 16. The inverse of this bit rate is the bit time (Tbit).

Figure 15.16 shows a block diagram of baud rate generation.

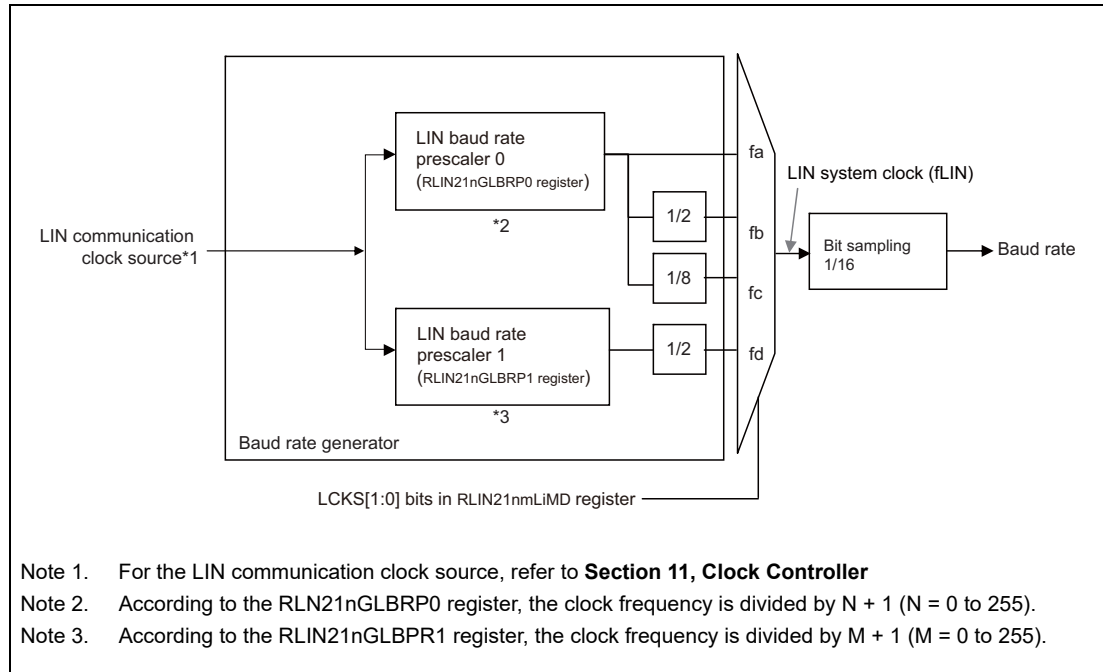

Figure 15.16 Block Diagram of Baud Rate Generation in LIN Master Mode

Set the LIN communication clock source to the range from 40 MHz.

By setting the RLIN21nGLBRP0 register so that fa is 307200 Hz (= 19200 × 16), the resulting bit rates are fa = 19200 × 16, fb = 9600 × 16 and fc = 2400 × 16. These bit rates are frequency-divided by 16 in the bit timing generator, enabling bit rates of 19200 bps, 9600 bps and 2400 bps to be generated. Also, by setting the RLIN21nGLBRP1 register so that fd is 166672 Hz (= 10417 × 16), the resulting bit rate is fd = 10417 × 16. This bit rate is frequency-divided by 16 in the bit timing generator, enabling 10417 bps to be generated.

The formula for baud rate is as shown below.

Baud rate:

= {Frequency of LIN communication clock source} / ((RLIN21nGLBRP0) + 1) / 16 [bps] (When fa is selected)

= {Frequency of LIN communication clock source} / ((RLIN21nGLBRP0) + 1) / 2 / 16 [bps] (When fb is selected)

= {Frequency of LIN communication clock source} / ((RLIN21nGLBRP0) + 1) / 8 / 16 [bps] (When fc is selected)

= {Frequency of LIN communication clock source} / ((RLIN21nGLBRP1) + 1) / 2 / 16 [bps] (When fd is selected)

Table 15.37 shows examples of baud rate (19200, 10417, 9600, and 2400 bps) generation and also the corresponding errors.

Table 15.37 Examples of Baud Rate (19200, 10417, 9600, and 2400 bps) Generation

LIN Communication Clock Source	Baud Rate Generator 0 (N+1) Frequency-Divided	Baud Rate Generator 1 (M+1) Frequency-Divided	System Clock	Baud Rate	Error
40MHz	130	—	fa	19230.77	+0.16%
	—	120	fd	10416.67	-0.003%
	130	—	fb	9615.38	+0.16%
	130	—	fc	2403.85	+0.16%

Section 16 CANFD Interface (RS-CANFD)

This section contains a generic description of the CANFD Interface (RS-CANFD).

The first part of this section describes all RH850/E1M-S2 specific properties, such as the number of units, register base addresses, etc.

The remainder of the section describes the functions and registers of RS-CANFD.

16.1 Features of RH850/E1M-S2 RS-CANFD

16.1.1 Units and Channels

This microcontroller has the following number of RS-CANFD units.

Table 16.1 Number of Units

Package	BGA304	BGA252
Number of Units		1
Name	RSCFDn (n = 0)	

The individual products have the CANFD interface channel listed below.

Table 16.2 Unit Configurations and Channels

Unit Name	Channel Name	BGA304	BGA252
RSCFD0	CAN0	√	√
	CAN1	√	√
	CAN2	√	√
	CAN3	√	√

The RS-CANFD has two interface modes (classical CAN mode and CAN FD mode) and uses different registers for each mode. There are two types of register names RSCANnXXX and RSCFDnCFDXXX (XXX: arbitrary) depending on interface modes. When explaining specifications common to two registers, register names are described as RSCFDn(CFD)XXX.

Table 16.3 Index (1/2)

Index	Meaning
n	Throughout this section, the individual RS-CANFD units are generically indicated by the index "n" (n = 0); for example, RSCFDn(CFD)GCTR is the global control register of the RSCFDn unit.
m	Throughout this section, the individual channels of RS-CANFD units are generically indicated by the index "m" (m = 0 to 3); for example, RSCFDn(CFD)CmSTS is the channel m status register.
j	The individual registers associated with receive rule table are generically indicated by the index "j" (j = 0 to 15); for example, RSCFDn(CFD)GAFLIDj is the receive rule ID register.
k	The individual transmit/receive FIFO buffers are generically indicated by the index "k" (k = 0 to [channel m × 3 + 2]); for example, RSCFDn(CFD)CFCK is the transmit/receive FIFO buffer configuration/control register.
x	The individual receive FIFO buffers are generically identified by the index "x" (x = 0 to 7); for example, RSCFDn(CFD)RFSTsX is the receive FIFO buffer status register.

Table 16.3 Index (2/2)

Index	Meaning
d	Data field registers of transmit/receive FIFO buffers and receive FIFO buffers are identified by "d" (classical CAN mode: d = 0 or 1, CAN FD mode: d = 0 to 15). For example, the transmit/receive FIFO buffer data field register is described as RSCFDn(CFD)CFDFd_k.
q	The individual receive buffers are generically indicated by the index "q" (q = 0 to [channel m × 16 + 15]); for example, RSCFDn(CFD)RMIDq is the receive buffer ID register.
p	The individual transmit buffers are generically indicated by the index "p" (p = 0 to [channel m × 16 + 15]); for example, RSCFDn(CFD)TMCp is the transmit buffer control register.
b	Data field registers of receive buffers and transmit buffers are identified by "b" (classical CAN mode: b = 0 or 1, CAN FD mode: b = 0 to 4). For example, the receive buffer data field register is described as RSCFDn(CFD)RMDFb_q.
r	The individual RAM tests for CAN are generically indicated by the index "r" (r = 0 to 63); for example, RSCFDn(CFD)RPGACCr is the RAM test page access register.
y	The registers not covered above are indicated by the letter "y" (y = 0 or 1); for example, RSCFDn(CFD)RMNDy is a receive buffer new data register.

Note: If the value of an index exceeds the range described in this section due to your target product, write the value after reset when writing to bits outside the index range.

16.1.2 Register Base Address

The base addresses of registers in RSCFDn are described in the list below.

All Access to RSCFDn register addresses are given as address offsets to the base address.

Table 16.4 Register Base Address

Base Address Name	Base Address
<RSCFD0_base>	FFD0 0000 _H

16.1.3 Clock Supply

The clocks listed below are supplied to the RSCFDn.

Table 16.5 Clock Supply

Unit Name	Clock for the Unit	Supply Clock Name
RSCFDn	clk_xincan ^{*1}	Main OSC
	clkc ^{*1}	CLKC_LSB (Unmodulated low-speed peripheral clock)
	pclk ^{*1}	CLK_HSB (high-speed peripheral clock)

Note 1. pclk must satisfy the following conditions so that no event of the CAN engine clock is overlooked.

- pclk ≥ 2×clkc
- pclk ≥ 2×clk_xincan

16.1.4 Interrupt Requests

RSCFDn interrupt requests are listed in the following table.

Table 16.6 Interrupt Requests

Unit Interrupt Signal		Outline	Interrupt Number
RSCFD0			
INTRCANGERR		CAN global error interrupt	413
INTRCANGRECC		CAN receive FIFO interrupt	412
CAN0	INTRCAN0ERR	CAN0 error interrupt	415
	INTRCAN0REC	CAN0 transmit/receive FIFO receive completion interrupt	414
	INTRCAN0TRX	CAN0 transmit interrupt	416
CAN1	INTRCAN1ERR	CAN1 error interrupt	418
	INTRCAN1REC	CAN1 transmit/receive FIFO receive completion interrupt	417
	INTRCAN1TRX	CAN1 transmit interrupt	419
CAN2	INTRCAN2ERR	CAN2 error interrupt	421
	INTRCAN2REC	CAN2 transmit/receive FIFO receive completion interrupt	420
	INTRCAN2TRX	CAN2 transmit interrupt	422
CAN3	INTRCAN3ERR	CAN3 error interrupt	424
	INTRCAN3REC	CAN3 transmit/receive FIFO receive completion interrupt	423
	INTRCAN3TRX	CAN3 transmit interrupt	425

16.1.5 Reset Sources

RSCFDn reset sources are listed in the following table. RSCFDn is initialized by these reset sources.

Table 16.7 Reset Sources

Unit name	Reset Sources
RSCFDn	All reset sources

16.1.6 External Input/Output Signals

External input/output signals of RSCFDn are listed below.

Table 16.8 External Input/Output Signals

Unit Signal Name	Outline	Alternative Port Pin Signal
RSCFD0		
CANmRX	CANm receive data input	CRXm
CANmTX	CANm transmit data output	CTXm

16.2 Overview

16.2.1 Functional Outline

Table 16.9 shows the RS-CANFD module specifications. **Figure 16.1** shows the RS-CANFD module block diagram.

Table 16.9 RS-CANFD Module Specifications (1/3)

Item	Specification
Number of channels	4
Protocol	ISO11898-1 compliant Using CAN FD frames is selectable by switching interface modes.
Communication speed	<p>Classical CAN mode:</p> <ul style="list-style-type: none"> Up to 1 Mbps $\text{Communication speed (CANm bit time clock)} = \frac{1}{\text{CANm bit time}}$ $\text{CANm bit time} = \text{CANmTq} \times \text{Tq count per bit}$ $\text{CANmTq} = \frac{(\text{BRP}[9:0] \text{ bits in the RSCANnCmCFG register} + 1)}{f_{\text{CAN}}}$ <p>f_{CAN}: Frequency of CAN clock (selected by the DCS bit in the RSCANnGCFCG register)</p> <p>CAN FD mode:</p> <ul style="list-style-type: none"> Nominal bit rate: up to 1 Mbps; data bit rate: up to 5 Mbps $\text{Transmission rate (CANm nominal bit time clock)} = \frac{1}{\text{CANm nominal bit time}}$ $\text{Transmission rate (CANm data bit time clock)} = \frac{1}{\text{CANm data bit time}}$ $\text{CANm nominal bit time} = \text{CANmTq}(N) \times \text{Tq count per nominal bit}$ $\text{CANm data bit time} = \text{CANmTq}(D) \times \text{Tq count per data bit}$ $\text{CANmTq}(N) = \frac{(\text{NBRP}[9:0] \text{ bits in the RSCFDnCFDCmNCFG register} + 1)}{f_{\text{CAN}}}$ $\text{CANmTq}(D) = \frac{\text{CANmTq}(D) (\text{DBRP}[7:0] \text{ bits in the RSCFDnCFDCmDCFCG register} + 1)}{f_{\text{CAN}}}$ <p>f_{CAN}: Frequency of CAN clock (selected by the DCS bit in the RSCFDnCFDGCFCG register)</p> <p>$m = 0$ to 3 Tq: Time quantum</p>
Buffer	<p>320 buffers in total</p> <ul style="list-style-type: none"> Individual buffers: 64 buffers (16 buffers ×4 channels) Transmit buffer: 16 buffers per channel Transmit queue: Single queue per channel (shared with the transmit buffer; up to 16 buffers allocatable) Shared buffers: 256 buffers for all channels Receive buffer: 0 to 64 buffers for all channels Receive FIFO buffer: 8 FIFO buffers for all channels (up to 128 buffers allocatable to each) Transmit/receive FIFO buffer: 3 FIFO buffers per channel (up to 128 buffers allocatable to each) ECC included

Table 16.9 RS-CANFD Module Specifications (2/3)

Item	Specification
Reception function	<ul style="list-style-type: none"> Receives data frames and remote frames. Selects ID format (standard ID, extended ID, or both IDs) to be received. Sets interrupt enable/disable for each FIFO. Mirror function (CAN mode receives its own transmitted message.) Timestamp function (to record message reception time as a 16-bit timer value)
Reception filter function	<ul style="list-style-type: none"> Selects receive messages according to 256 receive rules. Sets the number of receive rules (0 to 128) for each channel. Acceptance filter processing: Sets ID and mask for each receive rule. DLC filter processing: Sets DLC check value for each acceptance rule.
Receive message transfer function	<ul style="list-style-type: none"> Routing function to transfer receive messages to arbitrary destinations (can be transferred to up to 8 buffers) Transfer destination: Receive buffer, receive FIFO buffer, and/or transmit/receive FIFO buffer Label addition function Stores label information together with the message in a receive buffer and FIFO buffer.
Transmission function	<ul style="list-style-type: none"> Transmits data frames and remote frames. Selects ID format (standard ID, extended ID, or both IDs) to be transmitted. Sets interrupt enable/disable for each transmit buffer and transmit/receive FIFO buffer. Selects ID priority transmission or transmit buffer number priority transmission. Transmit request can be aborted (possible to confirm with a flag) One-shot transmission function
Interval transmission function	Transmit messages at intervals (transmit mode or gateway mode of transmit/receive FIFO buffers)
Transmit queue function	Transmits all stored messages according to the ID priority.
Transmit history function	Stores the history information of transmitted messages. Adds timestamp (recording message transmission time as a 16-bit timer value) to the history information.
Gateway function	A received message is automatically routed to a different channel.
Bus off recovery mode selection	Selects the method for returning from bus off state. <ul style="list-style-type: none"> ISO11898-1 compliant Automatic entry to channel halt mode at bus-off entry Automatic entry to channel halt mode at bus-off end Entry to channel halt mode by program request Transition to the error-active state by program request (forcible return from bus-off)
Error status monitoring	<ul style="list-style-type: none"> Monitors CAN protocol errors (stuff error, form error, ACK error, CRC error, bit error, ACK delimiter error, and bus dominant lock). Detects error status transitions (error warning, error passive, bus off entry, and bus off recovery) Reads the error counter. Monitors DLC errors.
Interrupt source	14 sources <ul style="list-style-type: none"> Global Interrupts (2 sources) Receive FIFO interrupt Global error interrupt Channel interrupts (3 sources/channel) CANm transmit interrupt (m = 0 to 3) <ul style="list-style-type: none"> CANm transmit complete interrupt CANm transmit abort interrupt CANm transmit/receive FIFO transmit complete interrupt (in transmit mode, gateway mode) CANm transmit history interrupt CANm transmit queue interrupt CANm transmit/receive FIFO receive complete interrupt (in receive mode, gateway mode) CANm error interrupt

Table 16.9 RS-CANFD Module Specifications (3/3)

Item	Specification
CAN stop mode	Reduces power consumption by stopping clock supply to the RS-CANFD module.
CAN clock source	Clkc or clk_xincan selectable
Test function	Test function for user evaluation <ul style="list-style-type: none"> • Listen-only mode • Self-test mode 0 (external loopback) • Self-test mode 1 (internal loopback) • Restricted operation mode • RAM test (read/write test) • Inter-channel communication test (CRC error test enabled)

16.2.2 Interface Modes

The RS-CANFD has two interface modes.

- Classical CAN mode: Handles only classical CAN frames.
- CAN FD mode: Handles classical CAN frames and CAN FD frames.

These two modes use different register maps with the same base address. Register maps change by switching interface modes.

Interface modes are switched by the RCMC bit in the RSCFDn(CFD)GRMCFG register.

16.2.3 Switching the CAN FD Protocol

For compliance with the ISO 11898-1:2015 standard, the CAN FD module of the E1M-S2 has a new CRC field that includes a stuffing counter. This can be selected by setting bit number 10 in option bytes 4 to 1 (OPBT0) to 0.

In the default state, the setting of bit number 10 in option bytes 4 to 1 (OPBT0) is 1, which selects a CRC field (ISO/CD 11898-1(August 12, 2014 version)). This is compatible with the CAN FD protocol of the E1x-FCC2.

16.2.4 Block Diagram

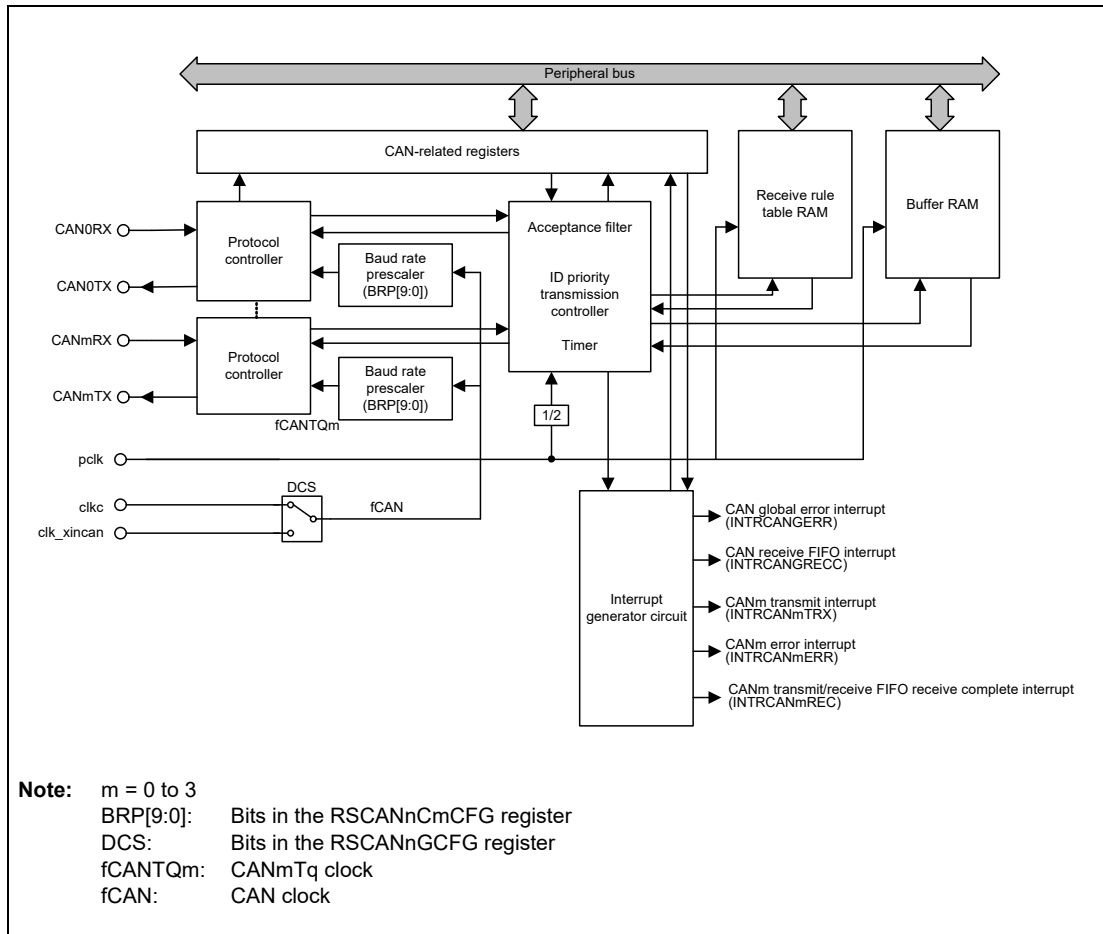

Figure 16.1 RS-CANFD Module Block Diagram

In CAN FD mode, different clock signals are input to the baud rate prescaler and the protocol controller respectively. See **Section 16.11.1.3, Communication Speed Setting**.

16.3 Registers (Classical CAN Mode)

16.3.1 List of Registers

The following tables list RS-CANFD registers to be used in classical CAN mode.

For details about <RSCFDn_base>, see **Section 16.1.2, Register Base Address**.

For details about registers initialized in Global reset mode or Channel reset mode, see following.

- **Table 16.174, Registers Initialized in Global Reset Mode or Channel Reset Mode**
- **Table 16.175, Registers Initialized Only in Global Reset Mode**

Table 16.10 Registers (1/2)

Module Name	Register Name	Symbol	Address
Interface mode-related registers			
RSCFDn	Global interface mode select register	RSCANnGRMCFG	<RSCFDn_base> + 04FC _H
Channel-related registers			
RSCFDn	Channel m configuration register	RSCANnCmCFG	<RSCFDn_base> + 0000 _H + (10 _H × m)
RSCFDn	Channel m control register	RSCANnCmCTR	<RSCFDn_base> + 0004 _H + (10 _H × m)
RSCFDn	Channel m status register	RSCANnCmSTS	<RSCFDn_base> + 0008 _H + (10 _H × m)
RSCFDn	Channel m error flag register	RSCANnCmERFL	<RSCFDn_base> + 000C _H + (10 _H × m)
Global-related registers			
RSCFDn	Global configuration register	RSCANnGCFG	<RSCFDn_base> + 0084 _H
RSCFDn	Global control register	RSCANnGCTR	<RSCFDn_base> + 0088 _H
RSCFDn	Global status register	RSCANnGSTS	<RSCFDn_base> + 008C _H
RSCFDn	Global error flag register	RSCANnGERFL	<RSCFDn_base> + 0090 _H
RSCFDn	Global timestamp counter register	RSCANnGTSC	<RSCFDn_base> + 0094 _H
RSCFDn	Global TX interrupt status register 0	RSCANnGTINTSTS0	<RSCFDn_base> + 0460 _H
RSCFDn	Global FD configuration register	RSCANnGFDCFG	<RSCFDn_base> + 0474 _H
Receive rule-related registers			
RSCFDn	Receive rule entry control register	RSCANnGAFLECTR	<RSCFDn_base> + 0098 _H
RSCFDn	Receive rule configuration register 0	RSCANnGAFLCFG0	<RSCFDn_base> + 009C _H
RSCFDn	Receive rule ID register j	RSCANnGAFLIDj	<RSCFDn_base> + 0500 _H + (10 _H × j)
RSCFDn	Receive rule mask register j	RSCANnGAFLMj	<RSCFDn_base> + 0504 _H + (10 _H × j)
RSCFDn	Receive rule pointer 0 register j	RSCANnGAFLP0_j	<RSCFDn_base> + 0508 _H + (10 _H × j)
RSCFDn	Receive rule pointer 1 register j	RSCANnGAFLP1_j	<RSCFDn_base> + 050C _H + (10 _H × j)
Receive buffer-related registers			
RSCFDn	Receive buffer number register	RSCANnRMNB	<RSCFDn_base> + 00A4 _H
RSCFDn	Receive buffer new data register y	RSCANnRMNDy	<RSCFDn_base> + 00A8 _H + (04 _H × y)
RSCFDn	Receive buffer ID register q	RSCANnRMIDq	<RSCFDn_base> + 0600 _H + (10 _H × q)
RSCFDn	Receive buffer pointer register q	RSCANnRMPTRq	<RSCFDn_base> + 0604 _H + (10 _H × q)
RSCFDn	Receive buffer data field 0 register q	RSCANnRMDf0_q	<RSCFDn_base> + 0608 _H + (10 _H × q)

16.3.2 Details of Interface Mode-Related Registers

16.3.2.1 RSCANnGRMCFG — Global Interface Mode Select Register

Access: RSCANnGRMCFG can be read/written in 32-bit units.
RSCANnGRMCFG_L and RSCANnGRMCFG_H can be read/written in 16-bit units.
RSCANnGRMCFG_LL, RSCANnGRMCFG_LH, RSCANnGRMCFG_HL, and RSCANnGRMCFG_HH can be read/written in 8-bit units.

Address: RSCANnGRMCFG: <RSCFDn_base> + 04FC_H

RSCANnGRMCFG_L: <RSCFDn_base> + 04FC_H,
RSCANnGRMCFG_H: <RSCFDn_base> + 04FE_H

RSCANnGRMCFG_LL: <RSCFDn_base> + 04FC_H,
RSCANnGRMCFG_LH: <RSCFDn_base> + 04FD_H,
RSCANnGRMCFG_HL: <RSCFDn_base> + 04FE_H,
RSCANnGRMCFG_HH: <RSCFDn_base> + 04FF_H,

Value after reset: 0000 0000_H

Table 16.15 RSCANnGRMCFG Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
0	RCMC	Interface Mode Select 0: Classical CAN mode 1: CAN FD mode

Note 1. The RSCANnGRMCFG and RSCFDnCFDGRMCFG registers are identical. Set either of these registers.

Modify the RSCANnGRMCFG register only in global reset mode. Before setting other RS-CANFD registers, set this register.

RCMC Bit

Setting this bit to 0 makes classical CAN mode available. To switch CAN FD mode to classical CAN mode, set the value after reset to all registers and bits allocated to the register map of CAN FD mode and then modify the RSCANnGRMCFG register.

16.3.3 Details of Channel-Related Registers

16.3.3.1 RSCANnCmCFG — Channel Configuration Register (m = 0 to 3)

Access: RSCANnCmCFG can be read/written in 32-bit units.
RSCANnCmCFGL and RSCANnCmCFGH can be read/written in 16-bit units.
RSCANnCmCFGLL, RSCANnCmCFGLH, RSCANnCmCFGHL, and RSCANnCmCFGHH can be read/written in 8-bit units.

Address: RSCANnCmCFG: <RSCFDn_base> + 0000_H + (10_H × m)

RSCANnCmCFGL: <RSCFDn_base> + 0000_H + (10_H × m),
RSCANnCmCFGH: <RSCFDn_base> + 0002_H + (10_H × m)

19 to 16	TSEG1 [3:0]	Time Segment 1 Control b19 b18 b17 b16 0 0 0 0: Setting is prohibited for channels for CAN communications. 0 0 0 1: Setting is prohibited for channels for CAN communications. 0 0 1 0: Setting is prohibited for channels for CAN communications. 0 0 1 1: 4Tq 0 1 0 0: 5Tq 0 1 0 1: 6Tq 0 1 1 0: 7Tq 0 1 1 1: 8Tq 1 0 0 0: 9Tq 1 0 0 1: 10Tq 1 0 1 0: 11Tq 1 0 1 1: 12Tq 1 1 0 0: 13Tq 1 1 0 1: 14Tq 1 1 1 0: 15 Tq 1 1 1 1: 16 Tq
15 to 10	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
9 to 0	BRP [9:0]	Prescaler Division Ratio Set When these bits are set to P (0 to 1023), the baud rate prescaler divides fCAN by P + 1.

Modify the RSCFD0CMCFG register in channel reset mode or channel halt mode. Set this register in channel reset mode before shifting to channel communication mode or channel halt mode. For a description of the bit timing parameters and settings, see **Section 16.11.1, Initial Settings**.

SJW[1:0] Bits

These bits are used to specify a Tq value for the resynchronization jump width. Allowed values are 1 Tq to 4 Tq, inclusive.

Set a value less than or equal to the value of the TSEG2 bits.

TSEG2[2:0] Bits

These bits are used to specify a Tq value for the length of phase segment 2 (PHASE_SEG2).

Allowed values are 2 Tq to 8 Tq, inclusive.

Set a value smaller than the value of the TSEG1 bits.

TSEG1[3:0] Bits

These bits are used to specify a Tq value for the total length of the propagation segment (PROP_SEG) and phase segment 1 (PHASE_SEG1).

Allowed values are 4 Tq to 16 Tq, inclusive.

BRP[9:0] Bits

The CANmTq clock (fCANTQm) is calculated by dividing the CAN clock (fCAN) by the baud rate prescaler ((BRP[9:0]) + 1). One clock cycle of the CANmTq clock is 1 time quantum (Tq).

16.3.3.2 RSCANn CmCTR — Channel Control Register (m = 0 to 3)

Access: RSCANn CmCTR can be read/written in 32-bit units.
RSCANn CmCTRL and RSCANn CmCTRH can be read/written in 16-bit units.
RSCANn CmCTRLL, RSCANn CmCTRLH, RSCANn CmCTRHL, and RSCANn CmCTRHH can be read/written in 8-bit units.

Address: RSCANn CmCTR: <RSCFDn_base> + 0004_H + (10_H × m)

RSCANn CmCTRL: <RSCFDn_base> + 0004_H + (10_H × m),
RSCANn CmCTRH: <RSCFDn_base> + 0006_H + (10_H × m)

RSCANn CmCTRLL: <RSCFDn_base> + 0004_H + (10_H × m),
RSCANn CmCTRLH: <RSCFDn_base> + 0005_H + (10_H × m),
RSCANn CmCTRHL: <RSCFDn_base> + 0006_H + (10_H × m),
RSCANn CmCTRHH: <RSCFDn_base> + 0007_H + (10_H × m)

Value after reset: 0000 0005_H

1,0	CHMDC[1:0]	Mode Select b1 b0 0 0: Channel communication mode 0 1: Channel reset mode 1 0: Channel halt mode 1 1: Setting prohibited

CRCT Bit

This bit is used to test the CRC generation circuit in the RS-CANFD module. Setting this bit to 1 inverts the first bit of the ID field when a message is received. With this inversion of bit, the CRC calculation result does not match the normal CRC value of the received frame, which can detect a CRC error (the CERR bit in the RSCANnCMERFL register is 1).

When using this function, note the following.

- This function is available while the CTME bit in the RSCANnCMCTR register is 1 (communication test mode enabled).
- This function cannot communicate with other CAN nodes. Use this function for inter-channel communication test (the CmICBCE bit in the RSCANnGTSTCFG register is 1).

- Bit inversion in the ID field may cause bit stuffing rule violation. In that case, no CRC error is detected but a stuff error is detected.

Modify this bit only in channel halt mode. This bit is always 0 in channel reset mode.

CTMS[1:0] Bits

These bits are used to select a communication test mode. Modify these bits in channel halt mode. These bits are set to 0 in channel reset mode.

CTME Bit

Setting this bit to 1 enables communication test mode. Modify this bit in channel halt mode. This bit is set to 0 in channel reset mode.

ERRD Bit

This bit is used to control display mode of bits 14 to 8 in the RSCANnCMERFL register.

When this bit is cleared (0), if an error is detected with all bits 14 to 8 of RSCANnCMERFL set to 0, only the flag corresponding to the first error is set to 1.

When this bit is set to 1, if two or more errors occur, the flags for both or all detected errors are set to 1.

When this bit is set to 1, all the flags of errors that have occurred are set to 1 regardless of the error occurrence order.

Modify this bit in channel reset mode or channel halt mode.

BOM[1:0] Bits

These bits are used to select a bus off recovery mode of the RS-CANFD module.

When the BOM[1:0] bits are set to 00_B, return from the bus off state is compliant with the CAN specifications. That is, the RS-CANFD module reenters the CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. A bus off recovery interrupt request is generated at the time of return from the bus off state. If the CHMDC[1:0] bits are set to 10_B (channel halt mode) before recessive bits are detected 128 times, the RS-CANFD module does not transition to channel halt mode until recessive bits are detected 128 times.

When the RS-CANFD module reaches the bus off state when the BOM[1:0] bits are set to 01_B, the CHMDC[1:0] bits in the RSCANnCMCTR register (m = 0 to 3) are set to 10_B and the RS-CANFD module transitions to channel halt mode. No bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits in the RSCANnCMSTS register are cleared to 00_H.

When the RS-CANFD module reaches the bus off state when the BOM[1:0] bits are set to 10_B, the CHMDC[1:0] bits are set to 10_B and the RS-CANFD module transitions to channel halt mode after return from the bus off state (11 consecutive recessive bits are detected 128 times). A bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to 00_H.

When the BOM[1:0] bits are set to 11_B and the CHMDC[1:0] bits are set to 10_B while the RS-CANFD module is in the bus off state, the RS-CANFD module transitions to channel halt mode. No bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to 00_H. However, if 11 consecutive recessive bits are detected 128 times and the RS-CANFD module has recovered to the error active state from the bus off state before the CHMDC[1:0] bits are set to 10_B, a bus off recovery interrupt request is generated.

When the RS-CANFD module transitions to channel halt mode (at bus off entry when the BOM[1:0] bits are 01_B or at bus off end when the BOM[1:0] bits are 10_B), if the CHMDC[1:0] bits are written by a program at the same time, writing by a program takes precedence. Modify BOM[1:0] bits in channel reset mode.

TAIE Bit

When transmit abort of the transmit buffer is completed with the TAIE bit set to 1, an interrupt request is generated. Modify this bit in channel reset mode.

ALIE Bit

When the ALF flag in the RSCANnCMERFL register is set to 1 with the ALIE bit set to 1, an error interrupt request is generated. Modify this bit in channel reset mode.

BLIE Bit

When the BLF flag in the RSCANnCMERFL register is set to 1 with the BLIE bit set to 1, an error interrupt request is generated. Modify this bit in channel reset mode.

OLIE Bit

When the OVLV flag in the RSCANnCMERFL register is set to 1 with the OLIE bit set to 1, an error interrupt request is generated. Modify this bit in channel reset mode.

BORIE Bit

When the BORF flag in the RSCANnCMERFL register is set to 1 with the BORIE bit set to 1, an error interrupt request is generated. Modify this bit in channel reset mode.

BOEIE Bit

When the BOEF flag in the RSCANnCMERFL register is set to 1 with the BOEIE bit set to 1, an error interrupt request is generated. Modify this bit in channel reset mode.

EPIE Bit

When the EPF flag in the RSCANnCMERFL register is set to 1 with the EPIE bit set to 1, an error interrupt request is generated. Modify this bit in channel reset mode.

EWIE Bit

When the EWF flag in the RSCANnCMERFL register is set to 1 with the EWIE bit set to 1, an error interrupt request is generated. Modify this bit in channel reset mode.

BEIE Bit

When the BEF flag in the RSCANnCMERFL register is set to 1 with the BEIE bit set to 1, an error interrupt request is generated. Modify this bit in channel reset mode.

RTBO Bit

Setting this bit to 1 (forcible return from the bus off state) in the bus off state returns the state forcibly from the bus off state to the error active state. This bit is automatically cleared to 0. Setting this bit to 1 clears the TEC[7:0] and REC[7:0] bits in the RSCANnCMSTS register to 00_H and also clears the BOSTS flag in the RSCANnCMSTS register to 0 (not in bus off state). The other registers remain

unchanged. No bus off recovery interrupt request due to return from the bus off state is generated. Use this bit only when the BOM[1:0] bits in the RSCANnCMCTR register are 00_B (ISO11898-1 compliant).

A delay of up to 1 CAN bit time occurs after the RTBO bit is set to 1 until the RS-CANFD module transitions to the error active state. Set this bit to 1 in channel communication mode.

CSLPR Bit

Setting this bit to 1 places the channel in channel stop mode.

Clearing this bit to 0 makes the channel leave from channel stop mode.

Do not rewrite this bit in channel communication mode or in channel halt mode.

CHMDC[1:0] Bits

These bits are used to select a channel mode (channel communication mode, channel reset mode, or channel halt mode). For details, see **Section 16.6.2, Channel Modes**. Setting the CSLPR bit to 1 in channel reset mode allows transition to channel stop mode. Do not set these bits to 11_B. When the RS-CANFD module has transitioned to channel halt mode by the setting of the BOM[1:0] bits, the CHMDC[1:0] bits automatically becomes 10_B.

16.3.3.3 RSCANn CmSTS — Channel Status Register (m = 0 to 3)

Access: RSCANn CmSTS can be read/written in 32-bit units.
RSCANn CmSTSL and RSCANn CmSTSH can be read/written in 16-bit units.
RSCANn CmSTSLL, RSCANn CmSTSLH, RSCANn CmSTSHL, and RSCANn CmSTSHH can be read/written in 8-bit units.

Address: RSCANn CmSTS: <RSCFDn_base> + 0008_H + (10_H × m)

RSCANn CmSTSL: <RSCFDn_base> + 0008_H + (10_H × m),

31 to 24	TEC [7:0]	The transmit error counter (TEC) can be read.
23 to 16	REC [7:0]	The receive error counter (REC) can be read.
15 to 8	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
7	COMSTS	Communication Status Flag 0: Communication is not ready. 1: Communication is ready.
6	RECSTS	Receive Status Flag 0: Bus idle, in transmission, or bus off state 1: In reception
5	TRMSTS	Transmit Status Flag 0: Bus idle or in reception 1: In transmission or bus off state
4	BOSTS	Bus Off Status Flag 0: Not in bus off state 1: In bus off state
3	EPSTS	Error Passive Status Flag 0: Not in error passive state 1: In error passive state
2	CSLPSTS	Channel Stop Status Flag 0: Not in channel stop mode 1: In channel stop mode
1	CHLTSTS	Channel Halt Status Flag 0: Not in channel halt mode 1: In channel halt mode

Table 16.18 RSCANn CmSTS Register Contents (2/2)

Bit Position	Bit Name	Function
0	CRSTSTS	Channel Reset Status Flag 0: Not in channel reset mode 1: In channel reset mode

TEC[7:0] Bits

These bits indicate the transmit error counter value. For transmit error counter increment/decrement conditions, see the *CAN specification (ISO11898-1)*.

These bits are cleared to 0 in channel reset mode.

REC[7:0] Bits

These bits indicate the receive error counter value. For receive error counter increment/decrement conditions, see the *CAN specification (ISO11898-1)*.

These bits are cleared to 0 in channel reset mode.

COMSTS Flag

This flag indicates that communication is ready.

This flag becomes 1 when the RS-CANFD module has detected 11 consecutive recessive bits after it has transitioned from channel reset mode or channel halt mode to channel communication mode. This flag is cleared to 0 in channel reset mode or channel halt mode.

RECSTS Flag

This flag is set to 1 when reception has started, and is cleared to 0 when the bus has become idle or transmission has started.

TRMSTS Flag

This flag is set to 1 when transmission has started, and is cleared to 0 when the bus has become idle or reception has started. This flag remains 1 in the bus off state.

BOSTS Flag

This flag is set to 1 when the TEC[7:0] value exceeds 255 and the RS-CANFD module has entered the bus off state (TEC[7:0] value > 255), and is cleared to 0 when the RS-CANFD module has exited the bus off state.

EPSTS Flag

This flag is set to 1 when the TEC[7:0] or REC[7:0] value exceeds 127 and the RS-CANFD module has entered the error passive state ($128 \leq \text{TEC}[7:0] \text{ value} \leq 255$ or $128 \leq \text{REC}[7:0] \text{ value}$), and is cleared to 0 when the RS-CANFD module has exited the error passive state or has entered channel reset mode.

CSLPSTS Flag

This flag is set to 1 when the RS-CANFD module has transitioned to channel stop mode, and is cleared to 0 when the RS-CANFD module has returned from channel stop mode.

CHLTSTS Flag

This flag is set to 1 when the RS-CANFD module has transitioned to channel halt mode, and is cleared to 0 when the RS-CANFD module has exited channel halt mode.

CRSTSTS Flag

This flag is set to 1 when the RS-CANFD module has transitioned to channel reset mode, and is cleared to 0 when the RS-CANFD module has transitioned to channel communication mode or channel halt mode. This flag remains 1 if the RS-CANFD module transitions from channel reset mode to channel stop mode.

16.3.3.4 RSCANnCmERFL — Channel Error Flag Register (m = 0 to 3)

Access: RSCANnCmERFL can be read/written in 32-bit units.
 RSCANnCmERFLL and RSCANnCmERFLH can be read/written in 16-bit units.
 RSCANnCmERFLLL, RSCANnCmERFLLH, RSCANnCmERFLHL, and RSCANnCmERFLHH can be read/written in 8-bit units.

Address: RSCANnCmERFL: <RSCFDn_base> + 000C_H + (10_H × m)

RSCANnCmERFLL: <RSCFDn_base> + 000C_H + (10_H × m),
 RSCANnCmERFLH: <RSCFDn_base> + 000E_H + (10_H × m)

RSCANnCmERFLLL: <RSCFDn_base> + 000C_H + (10_H × m),
 RSCANnCmERFLLH: <RSCFDn_base> + 000D_H + (10_H × m),
 RSCANnCmERFLHL: <RSCFDn_base> + 000E_H + (10_H × m),
 RSCANnCmERFLHH: <RSCFDn_base> + 000F_H + (10_H × m)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CRCREG[14:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1

Note 1. The only effective value for writing to this flag bit is 0, which clears the status. Any other writing to the bit results in retention of the status and does not change the value.

Table 16.19 RSCANnCmERFL Register Contents (1/2)

Bit Position	Bit Name	Function
31	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
30 to 16	CRCREG[14:0]	CRC Calculation Data A CRC value calculated based on the transmitted message or received message is indicated.
15	Reserved	This bit is always read as 0. When writing, write 0.
14	ADERR	ACK Delimiter Error Flag 0: No ACK delimiter error is detected. 1: ACK delimiter error is detected.
13	B0ERR	Dominant Bit Error Flag 0: No dominant bit error is detected. 1: Dominant bit error is detected.
12	B1ERR	Recessive Bit Error Flag 0: No recessive bit error is detected. 1: Recessive bit error is detected.
11	CERR	CRC Error Flag 0: No CRC error is detected. 1: CRC error is detected.
10	AERR	ACK Error Flag 0: No ACK error is detected. 1: ACK error is detected.
9	FERR	Form Error Flag 0: No form error is detected. 1: Form error is detected.

Table 16.19 RSCANnCMERFL Register Contents (2/2)

Bit Position	Bit Name	Function
8	SERR	Stuff Error Flag 0: No stuff error is detected. 1: Stuff error is detected.
7	ALF	Arbitration Lost Flag 0: No arbitration lost is detected. 1: Arbitration lost is detected.
6	BLF	Bus Lock Flag 0: No channel bus lock is detected. 1: Channel bus lock is detected.
5	OVLf	Overload Flag 0: No overload is detected. 1: Overload is detected.
4	BORF	Bus Off Recovery Flag 0: No bus off recovery is detected. 1: Bus off recovery is detected.
3	BOEF	Bus Off Entry Flag 0: No bus off entry is detected. 1: Bus off entry is detected.
2	EPF	Error Passive Flag 0: No error passive is detected. 1: Error passive is detected.
1	EWf	Error Warning Flag 0: No error warning is detected. 1: Error warning is detected.
0	BEF	Bus Error Flag 0: No channel bus error is detected. 1: Channel bus error is detected.

See the *CAN specification (ISO11898-1)* if you want to check error occurrence conditions. To clear each flag of this register, write 0 by the program. These flags cannot be set to 1 by the program. If any of these flags becomes 1 at the timing when the program writes 0 to the flag, the flag is set to 1. Each flag is cleared to 0 in channel reset mode.

As for bits 14 to 8 in the RSCANnCMERFL register, if an error is detected with all flags of bits 14 to 8 set to 0 when the ERRD bit in the RSCANnCMCTR register is set to 0 (only the first error information is displayed), the corresponding flag is set to 1.

CRCREG[14:0] Flags

When the CTME bit in the RSCANnCMCTR register is set to 1 (communication test mode is enabled), the CRC value calculated based on the transmitted or received message can be read. When the CTME bit is set to 0 (communication test mode is disabled), these bits are always read as 0.

These flags are cleared to 0 in channel reset mode.

ADERR Flag

This flag is set to 1 when a form error has been detected in the ACK delimiter during transmission.

B0ERR Flag

This flag is set to 1 when a recessive bit has been detected even though a dominant bit was transmitted.

B1ERR Flag

This flag is set to 1 when a dominant bit has been detected even though a recessive bit was transmitted.

CERR Flag

This flag is set to 1 when a CRC error has been detected.

AERR Flag

This flag is set to 1 when an ACK error has been detected.

FERR Flag

This flag is set to 1 when a form error has been detected.

SERR Flag

This flag is set to 1 when a stuff error has been detected.

ALF Flag

This flag is set to 1 when an arbitration lost has been detected.

BLF Flag

This flag is set to 1 when 32 consecutive dominant bits have been detected on the CAN bus in channel communication mode. After that, the detection processing restarts at either timing below.

- A recessive bit is detected after the BLF bit has been modified from 1 to 0.
- The RS-CANFD module transitions to channel reset mode or channel halt mode and returns to channel communication mode after the BLF bit has been modified from 1 to 0.

OVLV Flag

This flag is set to 1 when the overload frame transmit condition has been detected when performing reception or transmission.

BORF Flag

This flag is set to 1 when 11 consecutive recessive bits have been detected 128 times and the RS-CANFD module returns from the bus off state. However, this flag is not set to 1 if the RS-CANFD module returns from the bus off state in either of the following cases before 11 consecutive recessive bits are detected 128 times.

- The CHMDC[1:0] bits in the RSCANnCMCTR register are set to 01_B (channel reset mode).
- The RTBO bit in the RSCANnCMCTR register is set to 1 (forcible return from the bus off state).
- The BOM[1:0] bits in the RSCANnCMCTR register are set to 01_B (transition to channel halt mode at bus off entry).
- The CHMDC[1:0] bits in the RSCANnCMCTR register are set to 10_B (channel halt mode) before 11 consecutive recessive bits are detected 128 times with the BOM[1:0] bits set to 11_B (transition to channel halt mode upon a request from the program during bus off).

BOEF Flag

This flag is set to 1 when the state becomes bus off state (TEC[7:0] value > 255). This flag is also set to 1 when the state becomes bus off state with the BOM[1:0] bits in the RSCANnCMCTR register (m = 0 to 3) set to 01_B (transition to channel halt mode at bus off entry).

EPF Flag

This flag becomes 1 when the RS-CANFD module becomes error passive state (REC[7:0] or TEC[7:0] value > 127). This flag becomes 1 only when the REC[7:0] or TEC[7:0] value exceeds 127 for the first time. Therefore, if the program writes 0 to this flag with the REC[7:0] or TEC[7:0] value remaining over 127, this bit is not set to 1 until both REC [7:0] and TEC[7:0] values become 127 or less and then either the REC[7:0] or TEC[7:0] value exceeds 127 again.

EWF Flag

This flag is set to 1 only when the REC[7:0] or TEC[7:0] value exceeds 95 for the first time. Therefore, if the program writes 0 to this flag with the REC[7:0] or TEC[7:0] value remaining over 95, this bit is not set to 1 until both REC [7:0] and TEC[7:0] values become 95 or less and then either the REC[7:0] or TEC[7:0] value exceeds 95 again.

BEF Flag

This flag is set to 1 when any one of the ADERR, B0ERR, B1ERR, CERR, AERR, FERR, and SERR flags in the RSCANnCMERFL register is set to 1.

NOTE

When writing 0 to flags of this register, write 0 to corresponding flags and 1 to other flags by using a store instruction.

16.3.4 Details of Global-Related Registers

16.3.4.1 RSCANnGCFG — Global Configuration Register

Access: RSCANnGCFG can be read/written in 32-bit units.
RSCANnGCFG_L and RSCANnGCFG_H can be read/written in 16-bit units.
RSCANnGCFG_LL, RSCANnGCFG_LH, RSCANnGCFG_HL, and RSCANnGCFG_HH can be read/written in 8-bit units.

Address: RSCANnGCFG: <RSCFDn_base> + 0084_H

RSCANnGCFG_L: <RSCFDn_base> + 0084_H, RSCANnGCFG_H: <RSCFDn_base> + 0086_H

RSCANnGCFG_LL: <RSCFDn_base> + 0084_H, RSCANnGCFG_LH: <RSCFDn_base> + 0085_H,
RSCANnGCFG_HL: <RSCFDn_base> + 0086_H, RSCANnGCFG_HH: <RSCFDn_base> + 0087_H

Value after reset: 0000 0000_H

Table 16.20 RSCANnGCFG Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 16	ITRCP[15:0]	Interval Timer Prescaler Set When these bits are set to q, the peripheral function clock A is divided by q. When using interval timer, setting 0000 _H is prohibited.
15 to 13	TSBTCS[1:0]	Timestamp Clock Source Select b15 b14 b13 0 0 0 : Channel 0 bit time clock 0 0 1 : Channel 1 bit time clock 0 1 0 : Channel 2 bit time clock 0 1 1 : Channel 3 bit time clock 1 0 0 : Setting prohibited 1 0 1 : Setting prohibited 1 1 0 : Setting prohibited 1 1 1 : Setting prohibited
12	TSSS	Timestamp Source Select 0: pclk/n2*1 1: Bit time clock is used as the source clock of the timestamp counter.

Table 16.20 RSCANnGCFG Register Contents (2/2)

Bit Position	Bit Name	Function
11 to 8	TSP[3:0]	Timestamp Clock Source Division b11 b10 b9 b8 0 0 0 0 : Not divided 0 0 0 1 : Divided by 2 0 0 1 0 : Divided by 4 0 0 1 1 : Divided by 8 0 1 0 0 : Divided by 16 0 1 0 1 : Divided by 32 0 1 1 0 : Divided by 64 0 1 1 1 : Divided by 128 1 0 0 0 : Divided by 256 1 0 0 1 : Divided by 512 1 0 1 0 : Divided by 1024 1 0 1 1 : Divided by 2048 1 1 0 0 : Divided by 4096 1 1 0 1 : Divided by 8192 1 1 1 0 : Divided by 16384 1 1 1 1 : Divided by 32768
7	TMTSCE	Transmission Timestamp Enable 0: Transmission timestamp is disabled. 1: Transmission timestamp is enabled.
6	EEFE	ECC Error Flag Enable 0: The ECC error flag is disabled. 1: The ECC error flag is enabled.
5	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
4	DCS	CAN Clock Source Select 0: clk 1: clk_xincan
3	MME	Mirror Function Enable 0: Mirror function is disabled. 1: Mirror function is enabled.
2	DRE	DLC Replacement Enable 0: DLC replacement is disabled. 1: DLC replacement is enabled.
1	DCE	DLC Check Enable 0: DLC check is disabled. 1: DLC check is enabled.
0	TPRI	Transmit Priority Select 0: ID priority 1: Transmit buffer number priority

Note 1. Set TSBTCS[2:0] to 000_B before select pclk/2 as the timestamp count source.

Modify the RSCANnGCFG register in global reset mode.

ITRCP[15:0] Bits

These bits are used to set a clock source division value of the interval timer for FIFO buffers. For details, see **Section 16.8.3.1, Interval Transmission Function**.

TSBTCS[2:0] Bits

When the TSSS bit is 1, these bits are used to select the channel of the bit time clock that will be the clock source of the timestamp counter.

TSSS Bit

This bit is used to select a clock source of the timestamp counter.

TSP[3:0] Bits

These bits specify the prescaler used to divide the clock source (selected by the TSBTCS[2:0] and TSSS bits) to generate the timestamp counter clock signal.

TMTSCE Bit

Setting this bit to 1 makes it possible to store the timestamp of a transmitted message in the transmit history buffer. The timestamp is stored in TMTS[15:0] bits in the RSCANnTHLACCm register.

EEFE Bit

Setting this bit to 1 sets the EEFm bit in the RSCANnGERFL register to 1 when a 2-bit ECC error is detected during the transmission priority determination. At this time, the message in which a 2-bit ECC error was detected is not transmitted.

DCS Bit

When this bit is set to 0, clk_c is used as the clock source of the CAN clock (fCAN).

When this bit is set to 1, the main clock is used as the clock source of the CAN clock.

MME Bit

Setting this bit to 1 makes the mirror function available.

DRE Bit

When the DRE bit is set to 1, the DLC value of the receive rule is stored in the buffer instead of the DLC value of the received message after the DLC value has passed through the DLC filter. In this case, a value of 00_H is stored in the data byte that exceeds the DLC value of the receive rule.

When the DCE bit is set to 1 (DLC check is enabled), the DLC replacement function is available.

DCE Bit

Setting this bit to 1 makes the DLC check function available. Set the GAFLDLC[3:0] bits in the RSCANnGAFLP0j register to 0000_B before clearing the DCE bit in the RSCANnGCFG register to 0.

TPRI Bit

This bit is used to set the transmit priority.

When this bit is set to 0, ID priority is selected and the transmit priority complies with the CAN bus arbitration rule (ISO11898-1 specifications). When this bit is set to 1, transmit buffer number priority is selected and the lowest-numbered transmit buffer among those specified for transmission takes precedence.

While the transmit queue is in use, clear this bit to 0.

16.3.4.2 RSCANnGCTR — Global Control Register

Access: RSCANnGCTR can be read/written in 32-bit units.
RSCANnGCTRL and RSCANnGCTRH can be read/written in 16-bit units.
RSCANnGCTRL, RSCANnGCTRLH, RSCANnGCTRLH, and RSCANnGCTRHH can be read/written in 8-bit units.

Address: RSCANnGCTR: <RSCFDn_base> + 0088_H

RSCANnGCTRL: <RSCFDn_base> + 0088_H, RSCANnGCTRH: <RSCFDn_base> + 008A_H

RSCANnGCTRL: <RSCFDn_base> + 0088_H, RSCANnGCTRLH: <RSCFDn_base> + 0089_H,
RSCANnGCTRLH: <RSCFDn_base> + 008A_H, RSCANnGCTRHH: <RSCFDn_base> + 008B_H

Value after reset: 0000 0005_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.21 RSCANnGCTR Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
16	TSRST	Timestamp Counter Reset Setting the TSRST bit to 1 resets the timestamp counter. This bit is always read as 0.
15 to 11	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
10	THLEIE	Transmit History Buffer Overflow Interrupt Enable 0: Transmit history buffer overflow interrupt is disabled. 1: Transmit history buffer overflow interrupt is enabled.
9	MEIE	FIFO Message Lost Interrupt 0: FIFO message lost interrupt is disabled. 1: FIFO message lost interrupt is enabled.
8	DEIE	DLC Error Interrupt Enable 0: DLC error interrupt is disabled. 1: DLC error interrupt is enabled.
7 to 3	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
2	GSLPR	Global Stop Mode 0: Other than global stop mode 1: Global stop mode
1, 0	GMDC[1:0]	Global Mode Select b1 b0 0 0: Global operating mode 0 1: Global reset mode 1 0: Global test mode 1 1: Setting prohibited

TSRST Bit

This bit is used to reset the timestamp counter. When this bit is set to 1, the RSCANnGTSC register is cleared to 0000_H.

THLEIE Bit

When the THLEIE bit is set to 1 and the THLES flag in the RSCANnGERFL register is set to 1, an interrupt request is generated. Modify this bit in global reset mode.

MEIE Bit

When the MEIE bit is set to 1 and the MES flag in the RSCANnGERFL register is set to 1, an interrupt request is generated. Modify this bit in global reset mode.

DEIE Bit

When the DEIE bit is set to 1 and the DEF flag in the RSCANnGERFL register is set to 1, an interrupt request is generated. Modify this bit in global reset mode.

GSLPR Bit

Setting this bit to 1 places the RS-CANFD module in global stop mode.

Clearing this bit to 0 makes the RS-CANFD module leave from global stop mode.

Do not modify this bit from 0 to 1 in global operation mode or global test mode.

GMDC[1:0] Bits

These bits are used to select a mode of the entire RS-CANFD module (global operating mode, global reset mode, or global test mode). For details, see **Section 16.6.1, Global Modes**. Setting the GSLPR bit to 1 in global reset mode makes the RS-CANFD module transition to global stop mode.

16.3.4.3 RSCANnGSTS — Global Status Register

Access: RSCANnGSTS can be read/written in 32-bit units.
RSCANnGSTSL and RSCANnGSTSH can be read/written in 16-bit units.
RSCANnGSTSLL, RSCANnGSTSLH, RSCANnGSTSHL, and RSCANnGSTSHH can be read/written in 8-bit units.

Address: RSCANnGSTS: <RSCFDn_base> + 008C_H

RSCANnGSTSL: <RSCFDn_base> + 008C_H, RSCANnGSTSH: <RSCFDn_base> + 008E_H

RSCANnGSTSLL: <RSCFDn_base> + 008C_H, RSCANnGSTSLH: <RSCFDn_base> + 008D_H,
RSCANnGSTSHL: <RSCFDn_base> + 008E_H, RSCANnGSTSHH: <RSCFDn_base> + 008F_H

Value after reset: 0000 000D_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 16.22 RSCANnGSTS Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
3	GRAMINIT	CAN RAM Initialization Status Flag 0: CAN RAM initialization is completed. 1: CAN RAM initialization is ongoing.
2	GSLPSTS	Global Stop Status Flag 0: Not in global stop mode 1: In global stop mode
1	GHLTSTS	Global Test Status Flag 0: Not in global test mode 1: In global test mode
0	GRSTSTS	Global Reset Status Flag 0: Not in global reset mode 1: In global reset mode

GRAMINIT Flag

This flag indicates the initialization status of the CAN RAM.

This flag is set to 1 after the MCU has been reset, and is cleared to 0 when CAN RAM initialization is completed.

GSLPSTS Flag

This flag is set to 1 when the RS-CANFD module has transitioned to global stop mode, and is cleared to 0 when the RS-CANFD module has returned from global stop mode.

GHLTSTS Flag

This flag is set to 1 when the RS-CANFD module has transitioned to global test mode, and is cleared to 0 when the RS-CANFD module has exited global test mode.

GRSTSTS Flag

This flag is set to 1 when the RS-CANFD module has transitioned to global reset mode, and is cleared to 0 when the RS-CANFD module has exited global reset mode. This flag remains 1 if the RS-CANFD module has transitioned from global reset mode to global stop mode.

16.3.4.4 RSCANnGERFL — Global Error Flag Register

Access: RSCANnGERFL can be read/written in 32-bit units.
 RSCANnGERFLL and RSCANnGERFLH can be read/written in 16-bit units.
 RSCANnGERFLLL, RSCANnGERFLLH, RSCANnGERFLHL, and RSCANnGERFLHH can be read/written in 8-bit units.

Address: RSCANnGERFL: <RSCFDn_base> + 0090_H
 RSCANnGERFLL: <RSCFDn_base> + 0090_H, RSCANnGERFLH: <RSCFDn_base> + 0092_H
 RSCANnGERFLLL: <RSCFDn_base> + 0090_H, RSCANnGERFLLH: <RSCFDn_base> + 0091_H,
 RSCANnGERFLHL: <RSCFDn_base> + 0092_H, RSCANnGERFLHH: <RSCFDn_base> + 0093_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	EEF3	EEF2	EEF1	EEF0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R/W*1	R/W*1	R/W*1
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	THLES	MES	DEF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1

Note 1. The only effective value for writing to this flag bit is 0, which clears the status. Any other writing to the bit results in retention of the status and does not change the value.

Table 16.23 RSCANnGERFL Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
19	EEF3	ECC Error Flag for Channel 3 0: No 2-bit ECC error when deciding transmission priority 1: A 2-bit ECC error when deciding transmission priority
18	EEF2	ECC Error Flag for Channel 2 0: No 2-bit ECC error when deciding transmission priority 1: A 2-bit ECC error when deciding transmission priority
17	EEF1	ECC Error Flag for Channel 1 0: No 2-bit ECC error when deciding transmission priority 1: A 2-bit ECC error when deciding transmission priority
16	EEF0	ECC Error Flag for Channel 0 0: No 2-bit ECC error when deciding transmission priority 1: A 2-bit ECC error when deciding transmission priority
15, 14	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
13 to 8	Reserved	When read, the undefined value is returned. When writing to these bits, write the value after reset.
7, 6	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
5	Reserved	When read, the undefined value is returned. When writing to this bit, write the value after reset.
4, 3	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
2	THLES	Transmit History Buffer Overflow Status Flag 0: No transmit history buffer overflow is present. 1: A transmit history buffer overflow is present.

Table 16.23 RSCANnGERFL Register Contents (2/2)

Bit Position	Bit Name	Function
1	MES	FIFO Message Lost Status Flag 0: No FIFO message lost error is present. 1: A FIFO message lost error is present.
0	DEF	DLC Error Flag 0: No DLC error is present. 1: A DLC error is present.

All flags in the RSCANnGERFL register are cleared to 0 in global reset mode.

EEFm Flag

While the EEFE bit in the RSCANnGCFG register is 1, when a 2-bit ECC error is detected during the transmission priority determination of channel m ($m = 0$ to 3), the EEFm flag is set to 1, disabling message transmission. This flag can be cleared to 0 by writing 0 by the program.

THLES Flag

The THLES flag is set to 1 when any one of the THLELT flags in the RSCANnTHLSTSm register ($m = 0$ to 3) is set to 1.

This flag is cleared to 0 when the THLELT flags of all channels are set to 0.

MES Flag

The MES flag is set to 1 when any one of the RFMLT flags in the RSCANnRFSTSc register ($x = 0$ to 7) or the CFMLT flags in the RSCANnCFSTSk register ($k = 0$ to 11) is set to 1.

This flag is cleared to 0 when all the RFMLT flags and CFMLT flags are set to 0.

DEF Flag

The DEF flag is set to 1 when an error has been detected during the DLC check. This flag can be cleared to 0 by writing 0 by the program.

NOTE

To clear the flag of the register to 0, the program must write 0 to the given flag. When writing 0, use a store instruction to write 0 to the given flag and 1 to the other flags.

16.3.4.5 RSCANnGTSC — Global Timestamp Counter Register

Access: RSCANnGTSC can be read/written in 32-bit units.
RSCANnGTSC and RSCANnGTSCCH can be read/written in 16-bit units.

Address: RSCANnGTSC: <RSCFDn_base> + 0094_H

RSCANnGTSC: <RSCFDn_base> + 0094_H, RSCANnGTSCCH: <RSCFDn_base> + 0096_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TS[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 16.24 RSCANnGTSC Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned.
15 to 8	TS[15:0]	Timestamp value The timestamp counter value can be read. Counter value: 0000 _H to FFFF _H

TS[15:0] Bits

When the TS[15:0] bits are read, the read value shows the timestamp counter (16-bit free-running counter) value at that time. The TS[15:0] value at the time when the SOF of the received message is detected is stored in the receive buffer or the FIFO buffer. The timestamp counter is initialized in global reset mode.

Start timing and stop timing of the timestamp counter depend on the count source.

- When the TSSS bit value in the RSCANnGCFG register is 0 (pclk):
The timestamp counter starts counting when the RS-CANFD module has transitioned to global operating mode. This counter stops counting when the RS-CANFD module has transitioned to global stop mode or global test mode.
- When the TSSS bit value in the RSCANnGCFG register is 1 (CANm bit time clock):
The timestamp counter starts counting when the corresponding channel has transitioned to channel communication mode. This counter stops counting when the corresponding channel has transitioned to channel reset mode or channel halt mode.

16.3.4.6 RSCANnGTINTSTS0 — Global TX Interrupt Status Register 0

Access: RSCANnGTINTSTS0 can be read/written in 32-bit units.
RSCANnGTINTSTS0L and RSCANnGTINTSTS0H can be read/written in 16-bit units.
RSCANnGTINTSTS0LL, RSCANnGTINTSTS0LH, RSCANnGTINTSTS0HL, and RSCANnGTINTSTS0HH can be read/written in 8-bit units.

Address: RSCANnGTINTSTS0: <RSCFDn_base> + 0460_H

RSCANnGTINTSTS0L: <RSCFDn_base> + 0460_H, RSCANnGTINTSTS0H: <RSCFDn_base> + 0462_H

RSCANnGTINTSTS0LL: <RSCFDn_base> + 0460_H, RSCANnGTINTSTS0LH: <RSCFDn_base> + 0461_H,
RSCANnGTINTSTS0HL: <RSCFDn_base> + 0462_H, RSCANnGTINTSTS0HH: <RSCFDn_base> + 0463_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R*1	R*1	R*1	R*1	R*1	R	R	R	R*1	R*1	R*1	R*1	R*1

Note 1. The bit is automatically cleared in global reset or channel reset mode.

Table 16.25 RSCANnGTINTSTS0 Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 29	Reserved	When read, the value after reset is returned.
28	THIF3	TX History List Interrupt Channel 3 0: Channel 3 TX history list interrupt flag is not set. 1: Channel 3 TX history list interrupt flag is set.
27	CFTIF3	COM FIFO TX Mode Interrupt Flag Channel 3 0: Channel 3 COM FIFO TX mode interrupt flag is not set. 1: Channel 3 COM FIFO TX mode interrupt flag is set.
26	TQIF3	TX Queue Interrupt Flag Channel 3 0: Channel 3 TX queue interrupt flag is not set. 1: Channel 3 TX queue interrupt flag is set.
25	TAIF3	TX Abort Interrupt Flag Channel 3 0: Channel 3 TX abort interrupt flag is not set. 1: Channel 3 TX abort interrupt flag is set.
24	TSIF3	Transmit Buffer Interrupt Status Flag Channel 3 0: Channel 3 Transmit successful completion interrupt flag is not set. 1: Channel 3 Transmit successful completion interrupt flag is set.
23 to 21	Reserved	When read, the value after reset is returned.
20	THIF2	TX History List Interrupt Channel 2 0: Channel 2 TX history list interrupt flag is not set. 1: Channel 2 TX history list interrupt flag is set.
19	CFTIF2	COM FIFO TX Mode Interrupt Flag Channel 2 0: Channel 2 COM FIFO TX mode interrupt flag is not set. 1: Channel 2 COM FIFO TX mode interrupt flag is set.
18	TQIF2	TX Queue Interrupt Flag Channel 2 0: Channel 2 TX queue interrupt flag is not set. 1: Channel 2 TX queue interrupt flag is set.

Table 16.25 RSCANnGTINTSTS0 Register Contents (2/2)

Bit Position	Bit Name	Function
17	TAIF2	TX Abort Interrupt Flag Channel 2 0: Channel 2 TX abort interrupt flag is not set. 1: Channel 2 TX abort interrupt flag is set.
16	TSIF2	TX Success Interrupt Flag Channel 2 0: Channel 2 TX successful completion interrupt flag is not set. 1: Channel 2 TX successful completion interrupt flag is set.
15 to 13	Reserved	When read, the value after reset is returned.
12	THIF1	TX History List Interrupt Channel 1 0: Channel 1 TX history list interrupt flag is not set. 1: Channel 1 TX history list interrupt flag is set.
11	CFTIF1	COM FIFO TX Mode Interrupt Flag Channel 1 0: Channel 1 COM FIFO TX mode interrupt flag is not set. 1: Channel 1 COM FIFO TX mode interrupt flag is set.
10	TQIF1	TX Queue Interrupt Flag Channel 1 0: Channel 1 TX queue interrupt flag is not set. 1: Channel 1 TX queue interrupt flag is set.
9	TAIF1	Transmit Buffer Abort Interrupt Status Flag Channel 1 0: Channel 1 Transmit buffer abort interrupt flag is not set. 1: Channel 1 Transmit buffer abort interrupt flag is set.
8	TSIF1	TX Success Interrupt Flag Channel 1 0: Channel 1 TX successful completion interrupt flag is not set. 1: Channel 1 TX successful completion interrupt flag is set.
7 to 5	Reserved	When read, the value after reset is returned.
4	THIF0	TX History List Interrupt Channel 0 0: Channel 0 TX history list interrupt flag is not set. 1: Channel 0 TX history list interrupt flag is set.
3	CFTIF0	COM FIFO TX Mode Interrupt Flag Channel 0 0: Channel 0 COM FIFO TX mode interrupt flag is not set. 1: Channel 0 COM FIFO TX mode interrupt flag is set.
2	TQIF0	TX Queue Interrupt Flag Channel 0 0: Channel 0 TX queue interrupt flag is not set. 1: Channel 0 TX queue interrupt flag is set.
1	TAIF0	Transmit Buffer Abort Interrupt Flag Channel 0 0: Channel 0 Transmit buffer abort interrupt flag is not set. 1: Channel 0 Transmit buffer abort interrupt flag is set.
0	TSIF0	TX Success Interrupt Flag Channel 0 0: Channel 0 TX successful completion interrupt flag is not set. 1: Channel 0 TX successful completion interrupt flag is set.

TSIFm Bit

When the RSCANnTMIECy.TMIE bit is set to 1 (transmit buffer interrupt is enabled) and corresponding RSCANnTMSTSp.TMTRF[1:0] flags are set to 10_B (transmission has been completed, without transmit abort request) or 11_B (transmission has been completed, with transmit abort request), the TSIFm bit becomes 1.

The TSIFm flag becomes 0 by setting 00_B to all the TMTRF[1:0] flags which satisfy the condition to lead TSIFm = 1. The TSIFm flag also becomes 0 by setting the TMIE bit to 0.

TAIFm Bit

When RSCANnCmCTR.TAIE bit is set to 1 (transmit abort interrupt is enabled) and the RSCANnTMSTSp.TMTRF[1:0] flags are 01_B (transmit abort has been completed), the TAIFm bit becomes 1.

The TAI_{Fm} flag becomes 0 by setting 00_B to all the TMTRF[1:0] flags of which transmit abort has been completed.

TQIF_m Bit

When the RSCAN_nTXQCC_m.TXQIE bit is set to 1 (transmit queue interrupt is enabled) and the RSCAN_nTXQST_m.TXQIF bit is set to 1 (a transmit queue interrupt request is present), the TQIF_m bit becomes 1.

When the RSCAN_nTXQST_m.TXQIF bit (transmit queue interrupt request) is set to 0, the TQIF_m bit becomes 0. The TQIF_m flag also becomes 0 by setting the TXQIE bit to 0.

CFTIF_m Bit

When the RSCAN_nCFCC_k.CFTXIE bit is set to 1 (transmit/receive FIFO transmit interrupt is enabled) and the RSCAN_nCFST_{Sk}.CFTXIF bit is set to 1 (a transmit/receive FIFO transmit interrupt request is present), the CFTIF_m bit becomes 1.

The CFTIF_m bit becomes 0 by setting all the RSCAN_nCFST_{Sk}.CFTXIF bits to 0. The CFTIF_m flag also becomes 0 by setting the CFTXIE bit to 0.

THIF_m Bit

When the RSCAN_nTHLCC_m.THLIE bit is set to 1 (transmit history interrupt is enabled) and the RSCAN_nTHLST_m.THLIF bit is set to 1 (a transmit history interrupt request is present), the THIF_m bit becomes 1.

The THIF_m bit becomes 0 by setting the RSCAN_nTHLST_m.THLIF bit to 0. The THIF_m flag also becomes 0 by setting the THLIE bit to 0.

16.3.4.7 RSCANnGFDCFG — Global FD Configuration Register

Access: RSCANnGFDCFG can be read/written in 32-bit units.
RSCANnGFDCFG L and RSCANnGFDCFG H can be read/written in 16-bit units.
RSCANnGFDCFG LL, RSCANnGFDCFG LH, RSCANnGFDCFG HL, and RSCANnGFDCFG HH can be read/written in 8-bit units.

Address: RSCANnGFDCFG: <RSCFDn_base> + 0474_H
RSCANnGFDCFG L: <RSCFDn_base> + 0474_H, RSCANnGFDCFG H: <RSCFDn_base> + 0476_H
RSCANnGFDCFG LL: <RSCFDn_base> + 0474_H, RSCANnGFDCFG LH: <RSCFDn_base> + 0475_H,
RSCANnGFDCFG HL: <RSCFDn_base> + 0476_H, RSCANnGFDCFG HH: <RSCFDn_base> + 0477_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.26 RSCANnGFDCFG Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
9, 8	TSCCFG[1:0]	Timestamp Capture Setting b9 b8 0 0: Captured at a sample point in the SOF bit. 0 1: Captured when a valid frame has been transmitted/received. 1 0: Setting prohibited 1 1: Setting prohibited
7 to 1	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
0	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.

TSCCFG Bits

These bits select a point where a timestamp value is captured. Modify this bit only in global reset mode.

16.3.5 Details of Receive Rule-Related Registers

16.3.5.1 RSCANnGAFLECTR — Receive Rule Entry Control Register

Access: RSCANnGAFLECTR can be read/written in 32-bit units.
RSCANnGAFLECTRL and RSCANnGAFLECTRH can be read/written in 16-bit units.
RSCANnGAFLECTRLL, RSCANnGAFLECTRLH, RSCANnGAFLECTRHL, and RSCANnGAFLECTRHH can be read/written in 8-bit units.

Address: RSCANnGAFLECTR: <RSCFDn_base> + 0098_H

RSCANnGAFLECTRL: <RSCFDn_base> + 0098_H, RSCANnGAFLECTRH: <RSCFDn_base> + 009A_H

RSCANnGAFLECTRLL: <RSCFDn_base> + 0098_H, RSCANnGAFLECTRLH: <RSCFDn_base> + 0099_H,
RSCANnGAFLECTRHL: <RSCFDn_base> + 009A_H, RSCANnGAFLECTRHH: <RSCFDn_base> + 009B_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 16.27 RSCANnGAFLECTR Register Contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
8	AFLDAE	Receive Rule Table Write Enable 0: Receive rule table write is disabled. 1: Receive rule table write is enabled.
7 to 5	Reserved	These bits are always read as 0. The write value should always be 0.
4 to 0	AFLPN [4:0]	Receive Rule Table Page Number Configuration A page number can be selected from a range of page 0 (0000 _B) to page 15 (01111 _B).

AFLDAE Bit

Setting this bit to 0 disables data writing to the receive rule table. After data writing to the receive rule table is completed, set this bit to 0 to disable writing to the receive rule table. The receive rule table can be read regardless of the value of this bit.

Set the AFLDAE bit to 1 in global reset mode.

AFLPN[4:0] Bits

These bits are used to set the page number of the receive rule table. Sixteen receive rules can be set per page.

Set these bits to a value within a range of 00000_B to 01111_B.

16.3.5.2 RSCANnGAFLCFG0 — Receive Rule Configuration Register 0

Access: RSCANnGAFLCFG0 can be read/written in 32-bit units.
 RSCANnGAFLCFG0L and RSCANnGAFLCFG0H can be read/written in 16-bit units.
 RSCANnGAFLCFG0LL, RSCANnGAFLCFG0LH, RSCANnGAFLCFG0HL, and RSCANnGAFLCFG0HH can be read/written in 8-bit units.

Address: RSCANnGAFLCFG0: <RSCFDn_base> + 009C_H
 RSCANnGAFLCFG0L: <RSCFDn_base> + 009C_H, RSCANnGAFLCFG0H: <RSCFDn_base> + 009E_H
 RSCANnGAFLCFG0LL: <RSCFDn_base> + 009C_H, RSCANnGAFLCFG0LH: <RSCFDn_base> + 009D_H,
 RSCANnGAFLCFG0HL: <RSCFDn_base> + 009E_H, RSCANnGAFLCFG0HH: <RSCFDn_base> + 009F_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RNC0[7:0]								RNC1[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 16.28 RSCANnGAFLCFG0 Register Contents

Bit Position	Bit Name	Function
31 to 24	RNC0[7:0]	Number of Channel 0 Rules The number of rules for channel 0
23 to 16	RNC1[7:0]	Number of Channel 1 Rules The number of rules for channel 1
15 to 8	RNC2[7:0]	Number of Channel 2 Rules The number of rules for channel 2
7 to 0	RNC3[7:0]	Number of Channel 3 Rules The number of rules for channel 3

Modify the RSCANnGAFLCFG0 register in global reset mode.

Up to “64 × (number of channels)” rules can be registered to the receive rule tables in the entire module. The number of receive rules per channel should meet the following conditions.

- The maximum number of rules per channel is 128.
- The total of the number of rules allocated to each channel is not larger than the number of rules permitted to the entire module.

RNC0[7:0] Bits

These bits are used to set the number of rules to be registered in the channel 0 receive rule table.

Set these bits to a value within a range of 00_H to 80_H.

RNC1[7:0] Bits

These bits are used to set the number of rules to be registered in the channel 1 receive rule table.

Set these bits to a value within a range of 00_H to 80_H.

RNC2[7:0] Bits

These bits are used to set the number of rules to be registered in the channel 2 receive rule table.

Set these bits to a value within a range of 00_H to 80_H.

RNC3[7:0] Bits

These bits are used to set the number of rules to be registered in the channel 3 receive rule table.

Set these bits to a value within a range of 00_H to 80_H.

16.3.5.3 RSCANnGAFLIDj — Receive Rule ID Register (j = 0 to 15)

Access: RSCANnGAFLIDj can be read/written in 32-bit units.
 RSCANnGAFLIDjL and RSCANnGAFLIDjH can be read/written in 16-bit units.
 RSCANnGAFLIDjLL, RSCANnGAFLIDjLH, RSCANnGAFLIDjHL, and RSCANnGAFLIDjHH can be read/written in 8-bit units.

Address: RSCANnGAFLIDj: <RSCFDn_base> + 0500_H + (10_H × j)
 RSCANnGAFLIDjL: <RSCFDn_base> + 0500_H + (10_H × j),
 RSCANnGAFLIDjH: <RSCFDn_base> + 0502_H + (10_H × j)
 RSCANnGAFLIDjLL: <RSCFDn_base> + 0500_H + (10_H × j),
 RSCANnGAFLIDjLH: <RSCFDn_base> + 0501_H + (10_H × j),
 RSCANnGAFLIDjHL: <RSCFDn_base> + 0502_H + (10_H × j),
 RSCANnGAFLIDjHH: <RSCFDn_base> + 0503_H + (10_H × j)

Value after reset: 0000 0000_H

Table 16.29 RSCANnGAFLIDj Register Contents

Bit Position	Bit Name	Function
31	GAFLIDE	ID Select 0: Standard ID 1: Extended ID
30	GAFLRTR	RTR Select 0: Data frame 1: Remote frame
29	GAFLLB	Receive Rule Target Message Select 0: When a message transmitted from another CAN node is received 1: When a message transmitted from own node is received
28 to 0	GAFLID[28:0]	ID Set Set the ID of the receive rule. For the standard ID, set the ID in bits b10 to b0 and set bits b28 to b11 to 0.

Modify the RSCANnGAFLIDj register in global reset mode when the AFLDAE bit in the RSCANnGAFLECTR register is set to 1 (receive rule table write is enabled).

GAFLIDE Bit

This bit is used to select the ID format (standard ID or extended ID) of the receive rule. This bit is compared with the IDE bit in the received message during the acceptance filter processing.

GAFLRTR Bit

This bit is used to select the frame format (data frame or remote frame) of the receive rule. This bit is compared with the RTR bit in the received message during the acceptance filter processing.

GAFLLB Bit

Setting this bit to 0 causes data processing to be performed using the receive rule when a message transmitted from another CAN node is received.

Setting this bit is to 1 when the mirror function is used causes data processing to be performed using the receive rule when a message transmitted from the own CAN node is received.

GAFLID[28:0] Bits

These bits are used to set the ID field of the receive rule. The ID set by these bits is compared with the ID in the received message during the acceptance filter processing.

16.3.5.4 RSCANnGAFLMj — Receive Rule Mask Register (j = 0 to 15)

Access: RSCANnGAFLMj can be read/written in 32-bit units.
RSCANnGAFLMjL and RSCANnGAFLMjH can be read/written in 16-bit units.
RSCANnGAFLMjLL, RSCANnGAFLMjLH, RSCANnGAFLMjHL, and RSCANnGAFLMjHH can be read/written in 8-bit units.

Address: RSCANnGAFLMj: <RSCFDn_base> + 0504_H + (10_H × j)

RSCANnGAFLMjL: <RSCFDn_base> + 0504_H + (10_H × j),
RSCANnGAFLMjH: <RSCFDn_base> + 0506_H + (10_H × j)

RSCANnGAFLMjLL: <RSCFDn_base> + 0504_H + (10_H × j),
RSCANnGAFLMjLH: <RSCFDn_base> + 0505_H + (10_H × j),
RSCANnGAFLMjHL: <RSCFDn_base> + 0506_H + (10_H × j),
RSCANnGAFLMjHH: <RSCFDn_base> + 0507_H + (10_H × j)

Value after reset: 0000 0000_H

Table 16.30 RSCANnGAFLMj Register Contents

Bit Position	Bit Name	Function
31	GAFLIDEM	IDE Mask 0: The IDE bit is not compared. 1: The IDE bit is compared.
30	GAFLRTRM	RTR Mask 0: The RTR bit is not compared. 1: The RTR bit is compared.
29	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
28 to 0	GAFLIDM [28:0]	ID Mask 0: The corresponding ID bit is not compared. 1: The corresponding ID bit is compared.

Modify the RSCANnGAFLMj register in global reset mode when the AFLDAE bit in the RSCANnGAFLECTR register is set to 1 (receive rule table write is enabled).

GAFLIDEM Bit

When this bit is set to 1, filter processing is performed only for messages of the ID format specified by the GAFLIDE bit of the RSCANnGAFLIDj register.

When this bit is set to 0, it is regarded that all received messages have matched the specified ID. To set the GAFLIDEM bit to 0, set the GAFLIDM[28:0] bits to all 0 at the same time.

GAFLRTRM Bit

This bit is used to mask the RTR bit of the receive rule.

GAFLIDM[28:0] Bits

These bits are used to mask the corresponding ID bits of the receive rule.

16.3.5.5 RSCANnGAFLP0j — Receive Rule Pointer 0 Register (j = 0 to 15)

Access: RSCANnGAFLP0_j can be read/written in 32-bit units.
RSCANnGAFLP0_jL and RSCANnGAFLP0_jH can be read/written in 16-bit units.
RSCANnGAFLP0_jLL, RSCANnGAFLP0_jLH, RSCANnGAFLP0_jHL, and RSCANnGAFLP0_jHH can be read/written in 8-bit units.

Address: RSCANnGAFLP0_j: <RSCFDn_base> + 0508_H + (10_H × j)

RSCANnGAFLP0_jL: <RSCFDn_base> + 0508_H + (10_H × j),
RSCANnGAFLP0_jH: <RSCFDn_base> + 050A_H + (10_H × j)

RSCANnGAFLP0_jLL: <RSCFDn_base> + 0508_H + (10_H × j),
RSCANnGAFLP0_jLH: <RSCFDn_base> + 0509_H + (10_H × j),
RSCANnGAFLP0_jHL: <RSCFDn_base> + 050A_H + (10_H × j),
RSCANnGAFLP0_jHH: <RSCFDn_base> + 050B_H + (10_H × j)

Value after reset: 0000 0000_H

Table 16.31 RSCANnGAFLP0j Register Contents

Bit Position	Bit Name	Function
31 to 28	GAFLDLC [3:0]	Receive Rule DLC Set b31 b30 b29 b28 0 0 0 0 : DLC check is disabled. 0 0 0 1 : 1 data byte 0 0 1 0 : 2 data bytes 0 0 1 1 : 3 data bytes 0 1 0 0 : 4 data bytes 0 1 0 1 : 5 data bytes 0 1 1 0 : 6 data bytes 0 1 1 1 : 7 data bytes 1 X X X : 8 data bytes
27 to 16	GAFLPTR [11:0]	Receive Rule Label Set Set the 12-bit label information.
15	GAFLRMV	Receive Buffer Enable 0: No receive buffer is used. 1: A receive buffer is used.
14 to 8	GAFLRMDP [6:0]	Receive Buffer Number Select Set the receive buffer number to store received messages.
7 to 0	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.

Modify the RSCANnGAFLP0j register in global reset mode when the AFLDAE bit in the RSCANnGAFLECTR register is set to 1 (receive rule table write is enabled).

GAFLDLC[3:0] Bits

These bits are used to set the minimum data length necessary for receiving messages. If the data length of a message that is being filtered is equal to or larger than the value set by the GAFLDLC[3:0] bits, the message passes the DLC check. Setting these bits to 0000_B disables the DLC check function, allowing messages with any data length to pass the DLC check.

GAFLPTR[11:0] Bits

These bits are used to set a 12-bit label to be attached to messages that have passed through the filter. A label is attached when a message is stored in the receive buffer or the FIFO buffer.

GAFLRMV Bit

When this bit is set to 1, received messages that have passed through the filter are stored in the receive buffer selected by the GAFLRMDP[6:0] bits.

GAFLRMDP[6:0] Bits

These bits are used to select the number of a receive buffer that stores received messages having passed through the filter when the GAFLRMV bit is set to 1. Set these bits to a value smaller than the value set by the NRXMB[7:0] bits in the RSCANnRMNB register.

16.3.5.6 RSCANnGAFLP1j — Receive Rule Pointer 1 Register (j = 0 to 15)

Access: RSCANnGAFLP1_j can be read/written in 32-bit units.
 RSCANnGAFLP1_jL and RSCANnGAFLP1_jH can be read/written in 16-bit units.
 RSCANnGAFLP1_jLL, RSCANnGAFLP1_jLH, RSCANnGAFLP1_jHL, and RSCANnGAFLP1_jHH can be read/written in 8-bit units.

Address: RSCANnGAFLP1_j: <RSCFDn_base> + 050C_H + (10_H × j)

RSCANnGAFLP1_jL: <RSCFDn_base> + 050C_H + (10_H × j),
 RSCANnGAFLP1_jH: <RSCFDn_base> + 050E_H + (10_H × j)

RSCANnGAFLP1_jLL: <RSCFDn_base> + 050C_H + (10_H × j),
 RSCANnGAFLP1_jLH: <RSCFDn_base> + 050D_H + (10_H × j),
 RSCANnGAFLP1_jHL: <RSCFDn_base> + 050E_H + (10_H × j),
 RSCANnGAFLP1_jHH: <RSCFDn_base> + 050F_H + (10_H × j)

Value after reset: 0000 0000_H

Table 16.32 RSCANnGAFLP1j Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
19 to 8	GAFLFDP[19:8]	Transmit/Receive FIFO Buffer k Select (Bit position –8 = target transmit/receive FIFO buffer number k) 0: Transmit/receive FIFO buffer is not selected. 1: Transmit/receive FIFO buffer is selected.
7 to 0	GAFLFDP[7:0]	Receive FIFO Buffer x Select (Bit position = target receive FIFO buffer number x) 0: Receive FIFO buffer is not selected. 1: Receive FIFO buffer is selected.

Modify the RSCANnGAFLP1j register in global reset mode when the AFLDAE bit in the RSCANnGAFLECTR register is set to 1 (receive rule table write is enabled).

GAFLFDP [19:0] Bits

These bits are used to specify FIFO buffers that store received messages having passed through the filter. Up to eight FIFO buffers are selectable. However, when the GAFLRMV bit in the RSCANnGAFLP0j register is set to 1 (a receive buffer is used), up to seven FIFO buffers are selectable. Selectable buffers are receive FIFO buffers and the transmit/receive FIFO buffers for which the CFM[1:0] bits in the RSCANnCFCCk register are set to 00_B (receive mode) or 10_B (gateway mode).

16.3.6 Details of Receive Buffer-Related Registers

16.3.6.1 RSCANnRMNB — Receive Buffer Number Register

Access: RSCANnRMNB can be read/written in 32-bit units.
RSCANnRMNBL and RSCANnRMNBH can be read/written in 16-bit units.
RSCANnRMNBLL, RSCANnRMNBLH, RSCANnRMNBHL, and RSCANnRMNBHH can be read/written in 8-bit units.

Address: RSCANnRMNB: <RSCFDn_base> + 00A4_H
RSCANnRMNBL: <RSCFDn_base> + 00A4_H, RSCANnRMNBH: <RSCFDn_base> + 00A6_H
RSCANnRMNBLL: <RSCFDn_base> + 00A4_H, RSCANnRMNBLH: <RSCFDn_base> + 00A5_H,
RSCANnRMNBHL: <RSCFDn_base> + 00A6_H, RSCANnRMNBHH: <RSCFDn_base> + 00A7_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 16.33 RSCANnRMNB Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
7 to 0	NRXMB [7:0]	Receive Buffer Number Configuration Set the number of receive buffers. Set a value of 0 to 64.

Modify the RSCANnRMNB register in global reset mode.

NRXMB[7:0] Bits

These bits are used to set the total number of receive buffers of the entire RS-CANFD module. The maximum value is “16 × (number of channels)”.

Setting these bits to all 0 makes receive buffers unavailable.

16.3.6.2 RSCANnRMNDy — Receive Buffer New Data Register y (y = 0, 1)

Access: RSCANnRMNDy can be read/written in 32-bit units.
 RSCANnRMNDyL and RSCANnRMNDyH can be read/written in 16-bit units.
 RSCANnRMNDyLL, RSCANnRMNDyLH, RSCANnRMNDyHL, and RSCANnRMNDyHH can be read/written in 8-bit units.

Address: RSCANnRMNDy: <RSCFDn_base> + 00A8_H + (04_H × y)
 RSCANnRMNDyL: <RSCFDn_base> + 00A8_H + (04_H × y),
 RSCANnRMNDyH: <RSCFDn_base> + 00AA_H + (04_H × y)
 RSCANnRMNDyLL: <RSCFDn_base> + 00A8_H + (04_H × y),
 RSCANnRMNDyLH: <RSCFDn_base> + 00A9_H + (04_H × y),
 RSCANnRMNDyHL: <RSCFDn_base> + 00AA_H + (04_H × y),

Table 16.34 RSCANnRMNDy Register Contents

Bit Position	Bit Name	Function
31 to 16	RMNSq	Receive Buffer Receive Complete Flag q (q = y × 32 + 31 to y × 32 + 16) 0: Receive buffer q contains no new message. 1: Receive buffer q contains a new message.
15 to 0	RMNSq	Receive Buffer Receive Complete Flag q (q = y × 32 + 15 to y × 32 + 0) 0: Receive buffer q contains no new message. 1: Receive buffer q contains a new message.

Write 0 to the RSCANnRMNDy register in global operating mode or global test mode.

RMNSq Flags (q = 0 to 63)

Each flag is set to 1 when a process starts to store a message in the corresponding receive buffer.

To clear these flags to 0, write 0 by the program. Use a store instruction to write “0” to the flag and “1” to other flags. These bits cannot be set

to 0 while a message is being stored. Time for storing a message is 10 pclk clock cycles.

These flags are cleared to 0 in global reset mode.

16.3.6.3 RSCANnRMIDq — Receive Buffer ID Register (q = 0 to 63)

Access: RSCANnRMIDq can be read/written in 32-bit units.
 RSCANnRMIDqL and RSCANnRMIDqH can be read/written in 16-bit units.
 RSCANnRMIDqLL, RSCANnRMIDqLH, RSCANnRMIDqHL, and RSCANnRMIDqHH can be read/written in 8-bit units.

Address: RSCANnRMIDq: <RSCFDn_base> + 0600_H + (10_H × q)

RSCANnRMIDqL: <RSCFDn_base> + 0600_H + (10_H × q),

Table 16.35 RSCANnRMIDq Register Contents

Bit Position	Bit Name	Function
31	RMIDE	Receive Buffer IDE 0: Standard ID 1: Extended ID
30	RMRTR	Receive Buffer RTR 0: Data frame 1: Remote frame
29	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
28 to 0	RMID [28:0]	Receive Buffer ID Data The standard ID or extended ID of received message can be read. Read bits b10 to b0 for standard ID. Bits b28 to b11 are read as 0.

RMIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the message stored in the receive buffer.

RMRTR Bit

This bit indicates the frame format (data frame or remote frame) of the message stored in the receive buffer.

RMID[28:0] Bits

These bits indicate the ID of the message stored in the receive buffer.

16.3.6.4 RSCANnRMPTRq — Receive Buffer Pointer Register (q = 0 to 63)

Access: RSCANnRMPTRq can be read/written in 32-bit units.
RSCANnRMPTRqL and RSCANnRMPTRqH can be read/written in 16-bit units.
RSCANnRMPTRqLL, RSCANnRMPTRqLH, RSCANnRMPTRqHL, and RSCANnRMPTRqHH can be read/written in 8-bit units.

Address: RSCANnRMPTRq: <RSCFDn_base> + 0604_H + (10_H × q)

RSCANnRMPTRqL: <RSCFDn_base> + 0604_H + (10_H × q),
RSCANnRMPTRqH: <RSCFDn_base> + 0606_H + (10_H × q)

Bit Position	Bit Name	Function
31 to 28	RMDLC [3:0]	Receive Buffer DLC Data b31 b30 b29 b28 0 0 0 0: No data bytes 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 X X X: 8 data bytes
27 to 16	RMPTR [11:0]	Receive Buffer Label Data Label information of the received message can be read.
15 to 0	RMTS [15:0]	Receive Buffer Timestamp Data Timestamp value of the received message can be read.

RMDLC[3:0] Bits

These bits indicate the data length of the message stored in the receive buffer.

RMPTR[11:0] Bits

These bits indicate the label information of the message stored in the receive buffer.

RMTS[15:0] Bits

These bits indicate the timestamp value of the message stored in the receive buffer.

16.3.6.5 RSCANnRMDF0q — Receive Buffer Data Field 0 Register (q = 0 to 63)

Access: RSCANnRMDF0_q can be read/written in 32-bit units.
RSCANnRMDF0_qL and RSCANnRMDF0_qH can be read/written in 16-bit units.
RSCANnRMDF0_qLL, RSCANnRMDF0_qLH, RSCANnRMDF0_qHL, and RSCANnRMDF0_qHH can be read/written in 8-bit units.

Address: RSCANnRMDF0_q: <RSCFDn_base> + 0608_H + (10_H × q)

RSCANnRMDF0_qL: <RSCFDn_base> + 0608_H + (10_H × q),
RSCANnRMDF0_qH: <RSCFDn_base> + 060A_H + (10_H × q)

RSCANnRMDF0_qLL: <RSCFDn_base> + 0608_H + (10_H × q),
RSCANnRMDF0_qLH: <RSCFDn_base> + 0609_H + (10_H × q),

Table 16.37 RSCANnRMDF0q Register Contents

Bit Position	Bit Name	Function
31 to 24	RMDB3 [7:0]	Receive Buffer Data Byte 3 Data in the message stored in the receive buffer can be read.
23 to 16	RMDB2 [7:0]	Receive Buffer Data Byte 2 Data in the message stored in the receive buffer can be read.
15 to 8	RMDB1 [7:0]	Receive Buffer Data Byte 1 Data in the message stored in the receive buffer can be read.
7 to 0	RMDB0 [7:0]	Receive Buffer Data Byte 0 Data in the message stored in the receive buffer can be read.

When the RMDLC[3:0] value in the RSCANnRMPTRq register is smaller than 1000_B, data bytes for which no data is set are read as 00_H.

16.3.6.6 RSCANnRMDF1q — Receive Buffer Data Field 1 Register (q = 0 to 63)

Access: RSCANnRMDF1_q can be read/written in 32-bit units.
RSCANnRMDF1_qL and RSCANnRMDF1_qH can be read/written in 16-bit units.
RSCANnRMDF1_qLL, RSCANnRMDF1_qLH, RSCANnRMDF1_qHL, and RSCANnRMDF1_qHH can be read/written in 8-bit units.

Address: RSCANnRMDF1_q: <RSCFDn_base> + 060C_H + (10_H × q)

RSCANnRMDF1_qL: <RSCFDn_base> + 060C_H + (10_H × q),
RSCANnRMDF1_qH: <RSCFDn_base> + 060E_H + (10_H × q)

RSCANnRMDF1_qLL: <RSCFDn_base> + 060C_H + (10_H × q),

Table 16.38 RSCANnRMDF1q Register Contents

Bit Position	Bit Name	Function
31 to 24	RMDB7 [7:0]	Receive Buffer Data Byte 7 Data in the message stored in the receive buffer can be read.
23 to 16	RMDB6 [7:0]	Receive Buffer Data Byte 6 Data in the message stored in the receive buffer can be read.
15 to 8	RMDB5 [7:0]	Receive Buffer Data Byte 5 Data in the message stored in the receive buffer can be read.
7 to 0	RMDB4 [7:0]	Receive Buffer Data Byte 4 Data in the message stored in the receive buffer can be read.

When the RMDLC[3:0] value in the RSCANnRMPTRq register is smaller than 1000_B, data bytes for which no data is set are read as 00_H.

16.3.7 Details of Receive FIFO Buffer-Related Registers

16.3.7.1 RSCANnRFCCx — Receive FIFO Buffer Configuration/Control Register (x = 0 to 7)

Access: RSCANnRFCCx can be read/written in 32-bit units.
RSCANnRFCCxL and RSCANnRFCCxH can be read/written in 16-bit units.
RSCANnRFCCxLL, RSCANnRFCCxLH, RSCANnRFCCxHL, and RSCANnRFCCxHH can be read/written in 8-bit units.

Address: RSCANnRFCCx: <RSCFDn_base> + 00B8_H + (04_H × x)

RSCANnRFCCxL: <RSCFDn_base> + 00B8_H + (04_H × x),
RSCANnRFCCxH: <RSCFDn_base> + 00BA_H + (04_H × x)

RSCANnRFCCxLL: <RSCFDn_base> + 00B8_H + (04_H × x),
RSCANnRFCCxLH: <RSCFDn_base> + 00B9_H + (04_H × x),
RSCANnRFCCxHL: <RSCFDn_base> + 00BA_H + (04_H × x),
RSCANnRFCCxHH: <RSCFDn_base> + 00BB_H + (04_H × x)

Value after reset: 0000 0000_H

Table 16.39 RSCANnRFCCx Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
15 to 13	RFIGCV [2:0]	Receive FIFO Interrupt Request Timing Select b15 b14 b13 0 0 0: When FIFO is 1/8 full. 0 0 1: When FIFO is 2/8 full. 0 1 0: When FIFO is 3/8 full. 0 1 1: When FIFO is 4/8 full. 1 0 0: When FIFO is 5/8 full. 1 0 1: When FIFO is 6/8 full. 1 1 0: When FIFO is 7/8 full. 1 1 1: When FIFO is full.
12	RFIM	Receive FIFO Interrupt Source Select 0: An interrupt occurs when the condition set by the RFIGCV[2:0] bits is met. 1: An interrupt occurs each time a message has been received.
11	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
10 to 8	RFDC [2:0]	Receive FIFO Buffer Depth Configuration b10 b9 b8 0 0 0: 0 messages 0 0 1: 4 messages 0 1 0: 8 messages 0 1 1: 16 messages 1 0 0: 32 messages 1 0 1: 48 messages 1 1 0: 64 messages 1 1 1: 128 messages

Table 16.39 RSCANnRFCCx Register Contents (2/2)

Bit Position	Bit Name	Function
7 to 2	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
1	RFIE	Receive FIFO Interrupt Enable 0: Receive FIFO interrupt is disabled. 1: Receive FIFO interrupt is enabled.
0	RFE	Receive FIFO Buffer Enable 0: No receive FIFO buffer is used. 1: Receive FIFO buffers are used.

RFIGCV[2:0] Bits

These bits are used to specify the number of received messages for generating a receive FIFO interrupt request when the RFIM bit is set to 0 with a fraction for the total number of buffers (the setting of RFDC[2:0]).

When the RFDC[2:0] bits are set to 001_B (4 messages), set the RFIGCV[2:0] bits to 001_B, 011_B, 101_B, or 111_B. Modify these bits in global reset mode.

RFIM Bit

This bit is used to select a FIFO interrupt source. Modify this bit in global reset mode.

RFDC[2:0] Bits

These bits are used to select the number of messages that can be stored in a single receive FIFO buffer. If these bits are set to 000_B, do not use any receive FIFO buffer. Modify these bits in global reset mode.

RFIE Bit

Setting the RFIE bit to 1 enables receive FIFO interrupts. Modify this bit with the RFE bit set to 0 (no receive FIFO buffer is used).

RFE Bit

Setting the RFE bit to 1 makes receive FIFO buffers available. Clearing this bit to 0 sets the RFEMP flag in the RSCANnRFSTSx register to 1 (the receive FIFO buffer contains no unread message (buffer empty)). Modify this bit in global operating mode or global test mode.

After all other bits in the RSCANnRFCCx register have been set, set this bit to 1 by using another instruction.

This bit is set to 0 in global reset mode.

16.3.7.2 RSCANnRFSTs_x — Receive FIFO Buffer Status Register (x = 0 to 7)

Access: RSCANnRFSTs_x can be read/written in 32-bit units.
RSCANnRFSTs_xL and RSCANnRFSTs_xH can be read/written in 16-bit units.
RSCANnRFSTs_xLL, RSCANnRFSTs_xLH, RSCANnRFSTs_xHL, and RSCANnRFSTs_xHH can be read/written in 8-bit units.

Address: RSCANnRFSTs_x: <RSCFDn_base> + 00D8_H + (04_H × x)

RSCANnRFSTs_xL: <RSCFDn_base> + 00D8_H + (04_H × x),
RSCANnRFSTs_xH: <RSCFDn_base> + 00DA_H + (04_H × x)

RSCANnRFSTs_xLL: <RSCFDn_base> + 00D8_H + (04_H × x),
RSCANnRFSTs_xLH: <RSCFDn_base> + 00D9_H + (04_H × x),
RSCANnRFSTs_xHL: <RSCFDn_base> + 00DA_H + (04_H × x),
RSCANnRFSTs_xHH: <RSCFDn_base> + 00DB_H + (04_H × x)

Value after reset: 0000 0001_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFMC[7:0]							—	—	—	—	RFIF	RFMLT	RFLL	RFEMP	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R/W*1	R	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the status. Any other writing to the bit results in retention of the status and does not change the value.

Table 16.40 RSCANnRFSTs_x Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
15 to 8	RFMC[7:0]	Receive FIFO Unread Message Counter The number of unread messages stored in the receive FIFO buffer is displayed.
7 to 4	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
3	RFIF	Receive FIFO Interrupt Request Flag 0: No receive FIFO interrupt request is present. 1: A receive FIFO interrupt request is present.
2	RFMLT	Receive FIFO Message Lost Flag 0: No receive FIFO message is lost. 1: A receive FIFO message is lost.
1	RFLL	Receive FIFO Buffer Full Status Flag 0: The receive FIFO buffer is not full. 1: The receive FIFO buffer is full.
0	RFEMP	Receive FIFO Buffer Empty Status Flag 0: The receive FIFO buffer contains unread messages. 1: The receive FIFO buffer contains no unread message (buffer empty).

RFMC[7:0] Flags

These flags indicate the number of unread messages in the receive FIFO buffer. These flags become 00_H when the RFE bit in the RSCANnRFCC_x register is set to 0.

RFIF Flag

This flag is set to 1 when the conditions for receive FIFO interrupt request generation set by the RFIGCV[2:0] bits and the RFIM bit in the RSCANnRFCCx register are satisfied. This flag is cleared to 0 in global reset mode or by writing 0 to this flag. Modify this bit in global operating mode or global test mode.

RFMLT Flag

This flag is set to 1 if it is attempted to store a new message when the receive FIFO buffer is full. In this case, the new message is discarded.

This flag is cleared to 0 in global reset mode or by writing 0 to this flag.

Modify this bit in global operating mode or global test mode.

To clear the flag of the register to 0, the program must write 0 to the given flag. When writing 0, use a store instruction to write 0 to the given flag and 1 to the other flags.

RFFLL Flag

This flag is set to 1 when the number of messages stored in the receive FIFO buffer matches the FIFO buffer depth set by the RFDC[2:0] bits in the RSCANnRFCCx register.

If the number of messages stored in the receive FIFO buffer becomes smaller than the FIFO buffer depth set by the RFDC[2:0] bits, this flag is cleared to 0. This flag is also cleared to 0 when the RFE bit in the RSCANnRFCCx register is set to 0 (no receive FIFO buffer is used) or in global reset mode.

RFEMP Flag

This flag is set to 1 when all messages in the receive FIFO buffer have been read. This flag is also set to 1 when the RFE bit in the RSCANnRFCCx register is 0 or in global reset mode.

This flag is cleared to 0 when even a single received message has been stored in the receive FIFO buffer.

NOTE

To clear the RFMLT or RFIF flag to 0, use a store instruction to write "0" to the given flag and "1" to the other flags. Note that when using a bit-manipulation instruction for writing to this register, the read-modify-write operation may inadvertently clear the flags.

16.3.7.3 RSCANnRFPCTR_x — Receive FIFO Buffer Pointer Control Register (x = 0 to 7)

Access: RSCANnRFPCTR_x can be read/written in 32-bit units.
RSCANnRFPCTR_{xL} and RSCANnRFPCTR_{xH} can be read/written in 16-bit units.
RSCANnRFPCTR_{xLL}, RSCANnRFPCTR_{xLH}, RSCANnRFPCTR_{xHL}, and RSCANnRFPCTR_{xHH} can be read/written in 8-bit units.

Address: RSCANnRFPCTR_x: <RSCFDn_base> + 00F8_H + (04_H × x)

RSCANnRFPCTR_{xL}: <RSCFDn_base> + 00F8_H + (04_H × x),
RSCANnRFPCTR_{xH}: <RSCFDn_base> + 00FA_H + (04_H × x)

RSCANnRFPCTR_{xLL}: <RSCFDn_base> + 00F8_H + (04_H × x),
RSCANnRFPCTR_{xLH}: <RSCFDn_base> + 00F9_H + (04_H × x),
RSCANnRFPCTR_{xHL}: <RSCFDn_base> + 00FA_H + (04_H × x),
RSCANnRFPCTR_{xHH}: <RSCFDn_base> + 00FB_H + (04_H × x)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 16.41 RSCANnRFPCTR_x Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When writing to these bits, write the value after reset.
7 to 0	RFPC [7:0]	Receive FIFO Pointer Control When FF _H is written to these bits, the read pointer moves to the next unread message in the receive FIFO buffer.

RFPC[7:0] Bits

When FF_H is written to the RFPC[7:0] bits, the read pointer moves to the next unread message in the receive FIFO buffer. At this time, the RFMC[7:0] (receive FIFO unread message counter) value in the RSCANnRFSTS_x register is decremented by 1. Read the RSCANnRFID_x, RSCANnRFPTR_x, RSCANnRFDF0_x, and RSCANnRFDF1_x registers to read messages in the receive FIFO buffer, and then write FF_H to the RFPC[7:0] bits.

Write FF_H to these bits when the RFE bit in the RSCANnRFCC_x register is set to 1 (receive FIFO buffers are used) and the RFEMP flag in the RSCANnRFSTS_x register is 0 (the receive FIFO buffer contains unread messages).

16.3.7.4 RSCANnRFIDx — Receive FIFO Buffer Access ID Register (x = 0 to 7)

Access: RSCANnRFIDx can be read/written in 32-bit units.
 RSCANnRFIDxL and RSCANnRFIDxH can be read/written in 16-bit units.
 RSCANnRFIDxLL, RSCANnRFIDxLH, RSCANnRFIDxHL, and RSCANnRFIDxHH can be read/written in 8-bit units.

Address: RSCANnRFIDx: <RSCFDn_base> + 0E00_H + (10_H × x)

RSCANnRFIDxL: <RSCFDn_base> + 0E00_H + (10_H × x),
 RSCANnRFIDxH: <RSCFDn_base> + 0E02_H + (10_H × x)

RSCANnRFIDxLL: <RSCFDn_base> + 0E00_H + (10_H × x),
 RSCANnRFIDxLH: <RSCFDn_base> + 0E01_H + (10_H × x),
 RSCANnRFIDxHL: <RSCFDn_base> + 0E02_H + (10_H × x),
 RSCANnRFIDxHH: <RSCFDn_base> + 0E03_H + (10_H × x)

Value after reset: 0000 0000_H

Table 16.42 RSCANnRFIDx Register Contents

Bit Position	Bit Name	Function
31	RFIDE	Receive FIFO Buffer IDE 0: Standard ID 1: Extended ID
30	RFRTR	Receive FIFO Buffer RTR 0: Data frame 1: Remote frame
29	Reserved	When read, the value after reset is returned.
28 to 0	RFID [28:0]	Receive FIFO Buffer ID Data The standard ID or extended ID of received message can be read. Read bits b10 to b0 for standard ID. Bits b28 to b11 are read as 0.

RFIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the message stored in the receive FIFO buffer.

RFRTR Bit

This bit indicates the frame format (data frame or remote frame) of the message stored in the receive FIFO buffer.

RFID[28:0] Bits

These bits indicate the ID of the message stored in the receive FIFO buffer.

16.3.7.5 RSCANnRFPTRx — Receive FIFO Buffer Access Pointer Register (x = 0 to 7)

Access: RSCANnRFPTRx can be read/written in 32-bit units.
RSCANnRFPTRxL and RSCANnRFPTRxH can be read/written in 16-bit units.
RSCANnRFPTRxLL, RSCANnRFPTRxLH, RSCANnRFPTRxHL, and RSCANnRFPTRxHH can be read/written in 8-bit units.

Address: RSCANnRFPTRx: <RSCFDn_base> + 0E04_H + (10_H × x)

RSCANnRFPTRxL: <RSCFDn_base> + 0E04_H + (10_H × x),

RFDLC[3:0] Bits

These bits indicate the data length of the message stored in the receive FIFO buffer.

RFPTR[11:0] Bits

These bits indicate the label information of the message stored in the receive FIFO buffer.

RFTS[15:0] Bits

These bits indicate the timestamp value of the message stored in the receive FIFO buffer.

16.3.7.6 RSCANnRFDF0x — Receive FIFO Buffer Access Data Field 0 Register (x = 0 to 7)

Access: RSCANnRFDF0_x can be read/written in 32-bit units.
RSCANnRFDF0_xL and RSCANnRFDF0_xH can be read/written in 16-bit units.
RSCANnRFDF0_xLL, RSCANnRFDF0_xLH, RSCANnRFDF0_xHL, and RSCANnRFDF0_xHH can be read/written in 8-bit units.

Address: RSCANnRFDF0_x: <RSCFDn_base> + 0E08_H + (10_H × x)

RSCANnRFDF0_xL: <RSCFDn_base> + 0E08_H + (10_H × x),

Table 16.45 RSCANnRFDF1x Register Contents

Bit Position	Bit Name	Function
31 to 24	RFDB7 [7:0]	Receive FIFO Buffer Data Byte 7
23 to 16	RFDB6 [7:0]	Receive FIFO Buffer Data Byte 6
15 to 8	RFDB5 [7:0]	Receive FIFO Buffer Data Byte 5
7 to 0	RFDB4 [7:0]	Data in the message stored in the receive FIFO buffer can be read.

When the RFDLC[3:0] value in the RSCANnRFPTRx register is smaller than 1000_B, data bytes for which no data is set are read as 00_H.

16.3.8 Details of Transmit/Receive FIFO Buffer-Related Registers

16.3.8.1 RSCANnCFCCk — Transmit/Receive FIFO Buffer Configuration/Control Register (k = 0 to 11)

Access: RSCANnCFCCk can be read/written in 32-bit units.
RSCANnCFCCkL and RSCANnCFCCkH can be read/written in 16-bit units.
RSCANnCFCCkLL, RSCANnCFCCkLH, RSCANnCFCCkHL, and RSCANnCFCCkHH can be read/written in 8-bit units.

Address: RSCANnCFCCk: <RSCFDn_base> + 0118_H + (04_H × k)

RSCANnCFCCkL: <RSCFDn_base> + 0118_H + (04_H × k),
RSCANnCFCCkH: <RSCFDn_base> + 011A_H + (04_H × k)

RSCANnCFCCkLL: <RSCFDn_base> + 0118_H + (04_H × k),
RSCANnCFCCkLH: <RSCFDn_base> + 0119_H + (04_H × k),
RSCANnCFCCkHL: <RSCFDn_base> + 011A_H + (04_H × k),
RSCANnCFCCkHH: <RSCFDn_base> + 011B_H + (04_H × k)

7 to 3	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
2	CFTXIE	Transmit/Receive FIFO Transmit Interrupt Enable 0: Transmit/receive FIFO transmit interrupt is disabled. 1: Transmit/receive FIFO transmit interrupt is enabled.
1	CFRXIE	Transmit/Receive FIFO Receive Interrupt Enable 0: Transmit/receive FIFO receive interrupt is disabled. 1: Transmit/receive FIFO receive interrupt is enabled.
0	CFE	Transmit/Receive FIFO Buffer Enable 0: No transmit/receive FIFO buffer is used. 1: Transmit/receive FIFO buffers are used.

CFITT[7:0] Bits

These bits are used to set a message transmission interval for continuous message transmission from a transmit/receive FIFO buffer whose CFM[1:0] bits are set to 01_B (transmit mode) or 10_B (gateway mode).

Clear the CFE bit to 0 (no transmit/receive FIFO buffer is used) before modifying the CFITT[7:0] bits.

CFTML[3:0] Bits

These bits are used to set the number of the transmission buffer to be linked to the transmission and reception FIFO buffers when the CFM[1:0] bits are set to 01B (transmission mode) or 10B (gateway mode). Three transmission and reception FIFO buffers are available per channel and channel number m to which FIFO buffer k is allocated is the integer part of the quotient $k/3$. The number p of the transmission buffer to be linked to FIFO buffer k will be $(16 \times m) + \text{CFTML}[3:0]$ (See **Table 16.13**).

For the relationship between transmission and reception FIFO buffer k and transmission buffer p , see **Table 16.11** and **Table 16.12**.

Setting the CFDC[2:0] bits to 001_B or greater enables the setting of the CFTML[3:0] bits.

Do not make a link to the transmission queue of the same channel or any transmission buffer allocated to the transmission queue. Modify these bits in global reset mode.

CFITR Bit

This bit is enabled when the CFITSS bit is 0.

When this bit is 0, the interval timer clock source is selected as the $\text{pclk}/2$ divided by the value of the ITRCP [15:0] bits of the RSCANnGCFG register.

When this bit is 1, the interval timer clock source is selected as the $\text{pclk}/2$ divided by (ITRCP [15:0] bits $\times 10$) of the RSCANnGCFG register.

Modify this bit while the CFE bit is set to 0 (no transmit/receive FIFO buffer is used).

CFITSS Bit

When this bit is 0, the clock selected by the CFITR bit is the count source of the interval timer.

When this bit is 1, the bit time clock of the channel that is linked to FIFO is the count source of the interval timer.

Modify this bit while the CFE bit is set to 0 (no transmit/receive FIFO buffer is used).

CFM[1:0] Bits

These bits are used to select a transmit/receive FIFO mode. Modify these bits in global reset mode.

CFIGCV[2:0] Bits

These bits are used to specify the number of received messages for generating a transmit/receive FIFO receive interrupt request when the CFM[1:0] bits are set to 00B (receive mode) or 10B (gateway mode) and the CFIM bit is set to 0 with a fraction for the total number of buffers (the setting of CFDC[2:0]).

When the CFDC[2:0] bits are set to 001_B (4 messages), set the CFIGCV[2:0] bits to 001_B, 011_B, 101_B, or 111_B.

Modify this bit in global reset mode.

CFIM Bits

This bit is used to select a transmit/receive FIFO interrupt source. Modify this bit in global reset mode.

CFDC[2:0] Bit

These bits are used to set the number of messages that can be stored in a single transmit/receive FIFO buffer. If no transmit/receive FIFO buffer is used, set these bits to 000_B. Modify these bits in global reset mode.

CCTXIE Bit

When this bit is set to 1 and the CCTXIF flag in the CFSTSk register becomes 1, a transmit/receive FIFO transmit interrupt request is generated.

Modify this bit with the CFE bit set to 0 (no transmit/receive FIFO buffer is used).

CFRXIE Bit

When this bit is set to 1 and the CCTXIF flag in the RSCANnCFSTSk register becomes 1, a transmit/receive FIFO receive interrupt request is generated.

Modify this bit with the CFE bit set to 0.

CFE Bit

Setting this bit to 1 makes transmit/receive FIFO buffers available.

When this bit is set to 0 in transmit mode or gateway mode, if a message in the transmit/receive FIFO buffer is being transmitted or to be transmitted next, the transmit/receive FIFO buffer becomes empty after completion of transmission, CAN bus error detection, or arbitration lost. In other cases or in receive mode, the transmit/receive FIFO buffer becomes empty immediately.

This bit is cleared to 0 when the following conditions are met.

- Receive mode: Global reset mode
- Transmit mode or gateway mode: Channel reset mode

Modify this bit in the following mode.

- Receive mode: Global operating mode or global test mode
- Transmit mode or gateway mode: Channel communication mode or channel halt mode

After all other bits in the RSCANnCFCCk register have been set, set this bit to 1 by using another instruction.

16.3.8.2 RSCANnCFSTSk — Transmit/Receive FIFO Buffer Status Register (k = 0 to 11)

Access: RSCANnCFSTSk can be read/written in 32-bit units.
RSCANnCFSTSkL and RSCANnCFSTSkH can be read/written in 16-bit units.
RSCANnCFSTSkLL, RSCANnCFSTSkLH, RSCANnCFSTSkHL, and RSCANnCFSTSkHH can be read/written in 8-bit units.

Address: RSCANnCFSTSk: <RSCFDn_base> + 0178_H + (04_H × k)

RSCANnCFSTSkL: <RSCFDn_base> + 0178_H + (04_H × k),
RSCANnCFSTSkH: <RSCFDn_base> + 017A_H + (04_H × k)

RSCANnCFSTSkLL: <RSCFDn_base> + 0178_H + (04_H × k),
RSCANnCFSTSkLH: <RSCFDn_base> + 0179_H + (04_H × k),
RSCANnCFSTSkHL: <RSCFDn_base> + 017A_H + (04_H × k),
RSCANnCFSTSkHH: <RSCFDn_base> + 017B_H + (04_H × k)

Value after reset: 0000 0001_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	CFMC[7:0]							—	—	—	CFTXIF	CFRXIF	CFMLT	CFLL	CFEMP	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R/W*1	R/W*1	R	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the status. Any other writing to the bit results in retention of the status and does not change the value.

Table 16.47 RSCANnCFSTSk Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
15 to 8	CFMC [7:0]	Transmit/Receive FIFO Message Counter The number of messages stored in the transmit/receive FIFO buffer is indicated.
7 to 5	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
4	CFTXIF	Transmit/Receive FIFO Transmit Interrupt Request Flag 0: No transmit/receive FIFO transmit interrupt request is present. 1: A transmit/receive FIFO transmit interrupt request is present.
3	CFRXIF	Transmit/Receive FIFO Receive Interrupt Request Flag 0: No transmit/receive FIFO receive interrupt request is present. 1: A transmit/receive FIFO receive interrupt request is present.
2	CFMLT	Transmit/Receive FIFO Message Lost Flag 0: No transmit/receive FIFO message is lost. 1: A transmit/receive FIFO message is lost.
1	CFLL	Transmit/Receive FIFO Buffer Full Status Flag 0: The transmit/receive FIFO buffer is not full. 1: The transmit/receive FIFO buffer is full.
0	CFEMP	Transmit/Receive FIFO Buffer Empty Status Flag 0: The transmit/receive FIFO buffer contains messages. 1: The transmit/receive FIFO buffer contains no message (buffer empty).

CFMC[7:0] Bits

The CFMC[7:0] bits indicate the following values that depend on the setting of the CFM[1:0] bits in the RSCANnCFCCk register.

- When CFM[1:0] value is 01_B (transmit mode): Number of untransmitted messages in the buffer
- When CFM[1:0] value is 00_B (receive mode): Number of unread received messages in the buffer
- When CFM[1:0] value is 10_B (gateway mode): Number of untransmitted received messages in the buffer

These bits are cleared to 0 when any of the following conditions is met.

- When CFM[1:0] value is 00_B: global reset mode
- When CFM[1:0] value is 01_B or 10_B: channel reset mode
- When the CFE bit value in RSCFDnCFDCFCCk is 0

CFTXIF Flag

The CFTXIF flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] value is 01_B or 10_B and the source selected by the CFIM bit in the RSCANnCFCCk register occurred.

The CFTXIF flag is set to 0 when any of the following conditions is met.

- When 0 is written in the CFTXIF flag.
- When the CFM[1:0] value is 00_B: global reset mode
- When the CFM[1:0] is 01_B or 10_B: channel reset mode

This flag is set to 0 in global operation mode or global reset mode.

To clear the flag of the register to 0, the program must write 0 to the given flag. When writing 0, use a store instruction to write 0 to the given flag and 1 to the other flags.

CFRXIF Flag

The CFRXIF flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] value is 00_B or 10_B and the source selected by the CFIM bit in the RSCANnCFCCk register occurred.

The CFRXIF flag is set to 0 when any of the following conditions is met.

- When 0 is written in the CFRXIF flag.
- When the CFM[1:0] value is 00_B: global reset mode
- When the CFM[1:0] is 01_B or 10_B: channel reset mode

This flag is set to 0 in global operation mode or global reset mode.

To clear the flag of the register to 0, the program must write 0 to the given flag. When writing 0, use a store instruction to write 0 to the given flag and 1 to the other flags.

CFMLT Flag

The CFMLT flag is set to 1 when any of the following conditions is met.

- When transmit or receive FIFO buffer is full, and a new message is stored in this register.

In this case, a new message is terminated.

The CFMLT flag is set to 0 when any of the following conditions is met.

- When 0 is written in the CFMLT flag.
- When the CFM[1:0] value is 00_B: global reset mode
- When the CFM[1:0] is 01_B or 10_B: channel reset mode

This flag is set to 0 in global operation mode or global reset mode.

To clear the flag of the register to 0, the program must write 0 to the given flag. When writing 0, use a store instruction to write 0 to the given flag and 1 to the other flags.

CFLL Flag

The CFLL flag is set to 1 when any of the following conditions is met.

- When the number of messages stored in the transmit and receive FIFO buffer is equal to the FIFO buffer stages set by the CFDF[2:0] bits

The CFLL flag is set to 0 when any of the following conditions is met.

- When the number of messages stored in the transmit and receive FIFO buffer is smaller than the FIFO buffer stages set by the CFDF[2:0] bits.
- When the CFE bit is 0 (no transmit/receive FIFO buffer is used): Not during transmit abort
- When the CFM[1:0] value is 00_B: global reset mode
- When the CFM[1:0] is 01_B or 10_B: channel reset mode

CFEMP Flag

The CFEMP flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] value is 00_B: All messages have been read or global reset mode.
- When the CFM[1:0] value is 01_B or 10_B: All messages have been transmitted or channel reset mode.
- When the CFE bit is 0 (no transmit/receive FIFO buffer is used): Not during transmit abort

The CFEMP flag is cleared to 0 when any of the following conditions is met.

- When the CFM[1:0] value is 00_B or 10_B: Any one of received messages has been stored in the transmit/receive FIFO buffer.
- When the CFM[1:0] value is 01_B: A value FF_H has been written to the RSCANnCFPCTRk register after data was written to the RSCANnCFIDk, RSCANnCFPTRk, RSCANnCFDF0k, and RSCANnCFDF1k registers.

NOTE

To clear the CFTXIF, CFRXIF, and CFMLT flags to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using a store instruction, set 1 to other flags.

16.3.8.3 RSCANnCFPCTRk — Transmit/Receive FIFO Buffer Pointer Control Register (k = 0 to 11)

Access: RSCANnCFPCTRk can be read/written in 32-bit units.
RSCANnCFPCTRkL and RSCANnCFPCTRkH can be read/written in 16-bit units.
RSCANnCFPCTRkLL, RSCANnCFPCTRkLH, RSCANnCFPCTRkHL, and RSCANnCFPCTRkHH can be read/written in 8-bit units.

Address: RSCANnCFPCTRk: <RSCFDn_base> + 01D8_H + (04_H × k)

RSCANnCFPCTRkL: <RSCFDn_base> + 01D8_H + (04_H × k),
RSCANnCFPCTRkH: <RSCFDn_base> + 01DA_H + (04_H × k)

Table 16.48 RSCANnCFPCTRk Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When writing to these bits, write the value after reset.
7 to 0	CFPC [7:0]	Transmit/Receive FIFO Pointer Control <ul style="list-style-type: none"> Receive mode: Writing FF_H to these bits moves the read pointer to the next unread message in the transmit/receive FIFO buffer. Transmit mode: Writing FF_H to these bits moves the write pointer to the next stage of the transmit/receive FIFO buffer. Gateway mode: Setting prohibited

CFPC[7:0] Bits

- Receive mode (CFM[1:0] value in the RSCANnCFCK register is 00_B):
Writing FF_H to the CFPC[7:0] bits moves the read pointer to the next unread message in the transmit/receive FIFO buffer. At this time, the CFMC[7:0] value (transmit/receive FIFO message counter) in the RSCANnCFSTSk register is decremented by 1. Read the RSCANnCFIDk, RSCANnCFPTRk, RSCANnCFDF0_k, and RSCANnCFDF1_k registers to read messages in the transmit/receive FIFO buffer, and then write FF_H to the CFPC[7:0] bits.
When writing FF_H to these bits, make sure that the CFE bit in the RSCANnCFCK register is set to 1 (transmit/receive FIFO buffers are used) and the CFEMP flag in the RSCANnCFSTSk register is 0 (the transmit/receive FIFO buffer contains messages).

- Transmit mode (CFM[1:0] value in the RSCANnCFCCk register is 01_B):
Writing FF_H to the CFPC[7:0] bits stores the data written to the RSCANnCFIDk, RSCANnCFPTRk, RSCANnCFDF0_k, and RSCANnCFDF1_k registers in the transmit/receive FIFO buffer and moves the write pointer to the next stage of the transmit/receive FIFO buffer. At this time, the CFMC[7:0] value is incremented by 1. Write transmit messages to the RSCANnCFIDk, RSCANnCFPTRk, RSCANnCFDF0_k, and RSCANnCFDF1_k registers and then write FF_H to the CFPC[7:0] bits.
When writing FF_H to these bits, make sure that the CFE bit in the RSCANnCFCCk register is set to 1 and the CFFLL flag in the RSCANnCFSTSk register is 0 (the transmit/receive FIFO buffer is not full).
- Gateway mode (CFM[1:0] value in the RSCANnCFCCk register is 10_B):
Setting prohibited

16.3.8.4 RSCANnCFIDk — Transmit/Receive FIFO Buffer Access ID Register (k = 0 to 11)

Access: RSCANnCFIDk can be read/written in 32-bit units.
RSCANnCFIDkL and RSCANnCFIDkH can be read/written in 16-bit units.
RSCANnCFIDkLL, RSCANnCFIDkLH, RSCANnCFIDkHL, and RSCANnCFIDkHH can be read/written in 8-bit units.

Address: RSCANnCFIDk: <RSCFDn_base> + 0E80_H + (10_H × k)

RSCANnCFIDkL: <RSCFDn_base> + 0E80_H + (10_H × k),
RSCANnCFIDkH: <RSCFDn_base> + 0E82_H + (10_H × k)

RSCANnCFIDkLL: <RSCFDn_base> + 0E80_H + (10_H × k),
RSCANnCFIDkLH: <RSCFDn_base> + 0E81_H + (10_H × k),
RSCANnCFIDkHL: <RSCFDn_base> + 0E82_H + (10_H × k),

Table 16.49 RSCANnCFIDk Register Contents

Bit Position	Bit Name	Function
31	CFIDE	Transmit/Receive FIFO Buffer IDE bit 0: Standard ID 1: Extended ID
30	CFRTR	Transmit/Receive FIFO Buffer RTR bit 0: Data frame 1: Remote frame
29	THLEN	Transmit History Data Store Enable bit This bit is valid only when the CFM[1:0] value is 01 _B (transmit mode). 0: Transmit history data is not stored in the buffer. 1: Transmit history data is stored in the buffer.
28 to 0	CFID [28:0]	Transmit/Receive FIFO Buffer ID Data <ul style="list-style-type: none"> When CFM[1:0] value is 01_B (transmit mode): Set standard ID or extended ID. For standard ID, write an ID to bits b10 to b0 and write 0 to bits b28 to b11. When CFM[1:0] value is 00_B (receive mode): Standard ID or extended ID in the received message can be read. For standard ID, read bits b10 to b0. Bits b28 to b11 are read as 0.

This register is writable only when the CFM[1:0] value of the RSCANnCFCCk register is 01_B (transmit mode). This register is readable only when the CFM[1:0] value is 00_B (receive mode). This register should not be read or written when the CFM[1:0] value is 10_B (gateway mode).

CFIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, set the ID format of the message to be transmitted from the transmit/receive FIFO buffer.

CFRTR Bit

This bit indicates the data format (data frame or remote frame) of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, set the data format of the message to be transmitted from the transmit/receive FIFO buffer.

THLEN Bit

When this bit is set to 1, the transmit history data (label information, buffer number, and buffer type) of transmitted messages is stored in the transmit history buffer after transmission is completed.

This bit is enabled when the CFM[1:0] value is 01_B (transmit mode).

CFID[28:0] Bits

These bits indicate the ID of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B.

When the CFM[1:0] value is 01_B, set the ID of the message to be transmitted from the transmit/receive FIFO buffer.

16.3.8.5 RSCANnCFPTRk — Transmit/Receive FIFO Buffer Access Pointer Register (k = 0 to 11)

Access: RSCANnCFPTRk can be read/written in 32-bit units.
RSCANnCFPTRkL and RSCANnCFPTRkH can be read/written in 16-bit units.
RSCANnCFPTRkLL, RSCANnCFPTRkLH, RSCANnCFPTRkHL, and RSCANnCFPTRkHH can be read/written in 8-bit units.

Address: RSCANnCFPTRk: <RSCFDn_base> + 0E84_H + (10_H × k)

RSCANnCFPTRkL: <RSCFDn_base> + 0E84_H + (10_H × k),
RSCANnCFPTRkH: <RSCFDn_base> + 0E86_H + (10_H × k)

RSCANnCFPTRkLL: <RSCFDn_base> + 0E84_H + (10_H × k),
RSCANnCFPTRkLH: <RSCFDn_base> + 0E85_H + (10_H × k),
RSCANnCFPTRkHL: <RSCFDn_base> + 0E86_H + (10_H × k),
RSCANnCFPTRkHH: <RSCFDn_base> + 0E87_H + (10_H × k)

Table 16.50 RSCANnCFPTRk Register Contents

Bit Position	Bit Name	Function
31 to 28	CFDLC [3:0]	Transmit/Receive FIFO Buffer DLC Data b31 b30 b29 b28 0 0 0 0 : 0 data bytes 0 0 0 1 : 1 data byte 0 0 1 0 : 2 data bytes 0 0 1 1 : 3 data bytes 0 1 0 0 : 4 data bytes 0 1 0 1 : 5 data bytes 0 1 1 0 : 6 data bytes 0 1 1 1 : 7 data bytes 1 X X X : 8 data bytes
27 to 16	CFPTR [11:0]	Transmit/Receive FIFO Buffer Label Data <ul style="list-style-type: none"> When CFM[1:0] value is 01_B (transmit mode): Set the label information to be stored in the transmit history buffer. Only CFPTR[7:0] bits are valid. When CFM[1:0] value is 00_B (receive mode): The label information of the received message can be read.
15 to 0	CFTS [15:0]	Transmit/Receive FIFO Buffer Timestamp Data These bits are valid only when the CFM[1:0] value is 00 _B (receive mode). The timestamp value of the received message can be read.

This register is writable only when the CFM[1:0] value of the RSCANnCFCCk register is 01_B (transmit mode). This register is readable only when the CFM[1:0] value is 00_B (receive mode). This register should not be read or written when the CFM[1:0] value is 10_B (gateway mode).

CFDLC[3:0] Bits

These bits indicate the data length of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, set the data length of the message to be transmitted from the transmit/receive FIFO buffer. If 9-byte or more data length is set, 8-byte data is transmitted.

CFPTR[11:0] Bits

These bits indicate the label information attached to the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, the CFPTR[7:0] value is stored in the transmit history buffer when message transmission has been completed.

CFTS[15:0] Bits

These bits indicate the timestamp value of the message stored in the transmit/receive FIFO buffer.

These bits are valid when the CFM[1:0] value is 00_B.

16.3.8.6 RSCANnCFDF0_k — Transmit/Receive FIFO Buffer Access Data Field 0 Register (k = 0 to 11)

Access: RSCANnCFDF0_k can be read/written in 32-bit units.
RSCANnCFDF0_kL and RSCANnCFDF0_kH can be read/written in 16-bit units.
RSCANnCFDF0_kLL, RSCANnCFDF0_kLH, RSCANnCFDF0_kHL, and RSCANnCFDF0_kHH can be read/written in 8-bit units.

Address: RSCANnCFDF0_k: <RSCFDn_base> + 0E88_H + (10_H × k)

RSCANnCFDF0_kL: <RSCFDn_base> + 0E88_H + (10_H × k),

This register should not be read or written when the CFM[1:0] value is 10_B (gateway mode)

16.3.9 Details of FIFO Status-Related Registers

16.3.9.1 RSCANnFESTS — FIFO Empty Status Register

Access: RSCANnFESTS can be read/written in 32-bit units.
RSCANnFESTSL and RSCANnFESTSH can be read/written in 16-bit units.
RSCANnFESTSLL, RSCANnFESTSLH, RSCANnFESTSHL, and RSCANnFESTSHH can be read/written in 8-bit units.

Address: RSCANnFESTS: <RSCFDn_base> + 0238_H

RSCANnFESTSL: <RSCFDn_base> + 0238_H, RSCANnFESTSH: <RSCFDn_base> + 023A_H

RSCANnFESTSLL: <RSCFDn_base> + 0238_H, RSCANnFESTSLH: <RSCFDn_base> + 0239_H,
RSCANnFESTSHL: <RSCFDn_base> + 023A_H, RSCANnFESTSHH: <RSCFDn_base> + 023B_H

Value after reset: 007F FFFF_H

Table 16.53 RSCANnFESTS Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned.
19	CF11EMP	Transmit/Receive FIFO Buffer Empty Status Flag
18	CF10EMP	0: Transmit/receive FIFO buffer k contains a message. 1: Transmit/receive FIFO buffer k contains no message.
17	CF9EMP	(k = 0 to 11)
16	CF8EMP	
15	CF7EMP	
14	CF6EMP	
13	CF5EMP	
12	CF4EMP	
11	CF3EMP	
10	CF2EMP	
9	CF1EMP	
8	CF0EMP	
7	RF7EMP	Receive FIFO Buffer Empty Status Flag
6	RF6EMP	0: Receive FIFO buffer x contains an unread message. 1: Receive FIFO buffer x contains no unread message.
5	RF5EMP	(x = 0 to 7)
4	RF4EMP	
3	RF3EMP	
2	RF2EMP	
1	RF1EMP	
0	RF0EMP	

The RSCANnFESTS register is set to 003F FFFF_H in global reset mode.

CFkEMP Flag (k = 0 to 11)

The CFkEMP flag is set to 1 when the CFEMP flag in the RSCANnCFSTSk register is set to 1 (the transmit/receive FIFO buffer contains no message). When the CFEMP flag is cleared to 0 (the transmit/receive FIFO buffer contains messages), the CFkEMP flag is cleared to 0.

RFxEMP Flag (x = 0 to 7)

The RFxEMP flag is set to 1 when the RFEMP flag in the RSCANnRFSTSt register is set to 1 (the receive FIFO buffer contains no unread message). When the RFEMP flag is cleared to 0 (the receive FIFO buffer contains unread messages), the RFxEMP flag is cleared to 0.

16.3.9.2 RSCANnFFSTS — FIFO Full Status Register

Access: RSCANnFFSTS can be read/written in 32-bit units.
RSCANnFFSTS_L and RSCANnFFSTS_H can be read/written in 16-bit units.
RSCANnFFSTS_L_L, RSCANnFFSTS_L_H, RSCANnFFSTS_H_L, and RSCANnFFSTS_H_H can be read/written in 8-bit units.

Address: RSCANnFFSTS: <RSCFDn_base> + 023C_H

RSCANnFFSTS_L: <RSCFDn_base> + 023C_H, RSCANnFFSTS_H: <RSCFDn_base> + 023E_H

RSCANnFFSTS_L_L: <RSCFDn_base> + 023C_H, RSCANnFFSTS_L_H: <RSCFDn_base> + 023D_H,
RSCANnFFSTS_H_L: <RSCFDn_base> + 023E_H, RSCANnFFSTS_H_H: <RSCFDn_base> + 023F_H

Table 16.54 RSCANnFFSTS Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned.
19	CF11FLL	Transmit/Receive FIFO Buffer Full Status Flag
18	CF10FLL	0: Transmit/receive FIFO buffer k is not full. 1: Transmit/receive FIFO buffer k is full.
17	CF9FLL	(k = 0 to 11)
16	CF8FLL	
15	CF7FLL	
14	CF6FLL	
13	CF5FLL	
12	CF4FLL	
11	CF3FLL	
10	CF2FLL	
9	CF1FLL	
8	CF0FLL	
7	RF7FLL	Receive FIFO Buffer Full Status Flag
6	RF6FLL	0: Receive FIFO buffer x is not full. 1: Receive FIFO buffer x is full.
5	RF5FLL	(x = 0 to 7)
4	RF4FLL	
3	RF3FLL	
2	RF2FLL	
1	RF1FLL	
0	RF0FLL	

The RSCANnFFSTS register is cleared to 0000 0000_H in global reset mode.

CFkFLL Flag (k = 0 to 11)

The CFkFLL flag is set to 1 when the CFFLL flag in the RSCANnCFSTSk register is set to 1 (the transmit/receive FIFO buffer is full). When the CFFLL flag is cleared to 0, the CFkFLL flag is cleared to 0 (the transmit/receive FIFO buffer is not full).

RFxFLL Flag (x = 0 to 7)

The RFxFLL flag is set to 1 when the RFFLL flag in the RSCANnRFSTSc register is set to 1 (the receive FIFO buffer is full). When the RFFLL flag is cleared to 0 (the receive FIFO buffer is not full), the RFxFLL flag is cleared to 0.

16.3.9.3 RSCANnFMSTS — FIFO Message Lost Status Register

Access: RSCANnFMSTS can be read/written in 32-bit units.
RSCANnFMSTSL and RSCANnFMSTSH can be read/written in 16-bit units.
RSCANnFMSTSLL, RSCANnFMSTSLH, RSCANnFMSTSHL, and RSCANnFMSTSHH can be read/written in 8-bit units.

Address: RSCANnFMSTS: <RSCFDn_base> + 0240_H

RSCANnFMSTSL: <RSCFDn_base> + 0240_H, RSCANnFMSTSH: <RSCFDn_base> + 0242_H

RSCANnFMSTSLL: <RSCFDn_base> + 0240_H, RSCANnFMSTSLH: <RSCFDn_base> + 0241_H,
RSCANnFMSTSHL: <RSCFDn_base> + 0242_H, RSCANnFMSTSHH: <RSCFDn_base> + 0243_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	CF11 MLT	CF10 MLT	CF9 MLT	CF8 MLT

11	CF3MLT	
10	CF2MLT	
9	CF1MLT	
8	CF0MLT	
7	RF7MLT	Receive FIFO Buffer Message Lost Status Flag 0: No receive FIFO buffer x message is lost. 1: A receive FIFO buffer x message is lost. (x = 0 to 7)
6	RF6MLT	
5	RF5MLT	
4	RF4MLT	
3	RF3MLT	
2	RF2MLT	
1	RF1MLT	
0	RF0MLT	

The RSCANnFMSTS register is cleared to 0000 0000_H in global reset mode.

CFkMLT Flag (k = 0 to 11)

The CFkMLT flag is set to 1 when the CFMLT flag in the RSCANnCFSTS_k register is set to 1 (a transmit/receive FIFO message is lost). When the CFMLT flag is cleared to 0, the CFkMLT flag is cleared to 0.

RFxMLT Flag (x = 0 to 7)

The RFxMLT flag is set to 1 when the RFMLT flag in the RSCANnRFSTS_x register is set to 1 (a receive FIFO message is lost). When the RFMLT flag is cleared to 0, the RFxMLT flag is cleared to 0.

16.3.9.4 RSCANnRFISTS — Receive FIFO Buffer Interrupt Flag Status Register

Access: RSCANnRFISTS can be read/written in 32-bit units.
RSCANnRFISTS_{SL} and RSCANnRFISTS_{SH} can be read/written in 16-bit units.
RSCANnRFISTS_{SLL}, RSCANnRFISTS_{SLH}, RSCANnRFISTS_{SHL}, and RSCANnRFISTS_{SHH} can be read/written in 8-bit units.

Address: RSCANnRFISTS: <RSCFDn_base> + 0244_H

RSCANnRFISTS_{SL}: <RSCFDn_base> + 0244_H, RSCANnRFISTS_{SH}: <RSCFDn_base> + 0246_H

RSCANnRFISTS_{SLL}: <RSCFDn_base> + 0244_H, RSCANnRFISTS_{SLH}: <RSCFDn_base> + 0245_H,
RSCANnRFISTS_{SHL}: <RSCFDn_base> + 0246_H, RSCANnRFISTS_{SHH}: <RSCFDn_base> + 0247_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 16.56 RSCANnRFISTS Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned.
7	RF7IF	Receive FIFO Buffer Interrupt Request Status Flag
6	RF6IF	0: No receive FIFO buffer x interrupt request is present. 1: A receive FIFO buffer x interrupt request is present.
5	RF5IF	(x = 0 to 7)
4	RF4IF	
3	RF3IF	
2	RF2IF	
1	RF1F	
0	RF0F	

The RSCANnRFISTS register is cleared to 0000 0000_H in global reset mode.

RFxIF Flag (x = 0 to 7)

The RFxIF flag is set to 1 when the RFIF flag in the RSCANnRFISTS_x register is set to 1 (a receive FIFO interrupt request is present). When the RFIF flag is cleared to 0, the RFxIF flag is cleared to 0.

16.3.9.5 RSCANnCFRISTS — Transmit/Receive FIFO Buffer Receive Interrupt Flag Status Register

Access: RSCANnCFRISTS can be read/written in 32-bit units.
RSCANnCFRISTSL and RSCANnCFRISTSH can be read/written in 16-bit units.
RSCANnCFRISTSLL, RSCANnCFRISTSLH, RSCANnCFRISTSHL, and RSCANnCFRISTSHH can be read/written in 8-bit units.

Address: RSCANnCFRISTS: <RSCFDn_base> + 0248_H

RSCANnCFRISTSL: <RSCFDn_base> + 0248_H, RSCANnCFRISTSH: <RSCFDn_base> + 024A_H

RSCANnCFRISTSLL: <RSCFDn_base> + 0248_H, RSCANnCFRISTSLH: <RSCFDn_base> + 0249_H,
RSCANnCFRISTSHL: <RSCFDn_base> + 024A_H, RSCANnCFRISTSHH: <RSCFDn_base> + 024B_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 16.57 RSCANnCFRISTS Register Contents

Bit Position	Bit Name	Function
31 to 12	Reserved	When read, the value after reset is returned.
11	CF11RXIF	Transmit/Receive FIFO Buffer Receive Interrupt Request Status Flag 0: No transmit/receive FIFO buffer k receive interrupt request is present. 1: A transmit/receive FIFO buffer k receive interrupt request is present. (k = 0 to 11)
10	CF10RXIF	
9	CF9RXIF	
8	CF8RXIF	
7	CF7RXIF	
6	CF6RXIF	
5	CF5RXIF	
4	CF4RXIF	
3	CF3RXIF	
2	CF2RXIF	
1	CF1RXIF	
0	CF0RXIF	

The RSCANnCFRISTS register is cleared to 0000 0000_H in global reset mode.

CFxRXIF Flag (x = 0 to 11)

The CFxRXIF flag is set to 1 when the CFRXIF flag in the RSCANnCFSTSk register is set to 1 (a transmit/receive FIFO receive interrupt request is present). When the CFRXIF flag is cleared to 0, the CFxRXIF flag is cleared to 0.

16.3.9.6 RSCANnCFTISTS — Transmit/Receive FIFO Buffer Transmit Interrupt Flag Status Register

Access: RSCANnCFTISTS can be read/written in 32-bit units.
RSCANnCFTISTSL and RSCANnCFTISTSH can be read/written in 16-bit units.
RSCANnCFTISTSL, RSCANnCFTISTSLH, RSCANnCFTISTSHL, and RSCANnCFTISTSHH can be read/written in 8-bit units.

Address: RSCANnCFTISTS: <RSCFDn_base> + 024C_H

RSCANnCFTISTSL: <RSCFDn_base> + 024C_H, RSCANnCFTISTSH: <RSCFDn_base> + 024E_H

RSCANnCFTISTSL: <RSCFDn_base> + 024C_H, RSCANnCFTISTSLH: <RSCFDn_base> + 024D_H,
RSCANnCFTISTSHL: <RSCFDn_base> + 024E_H, RSCANnCFTISTSHH: <RSCFDn_base> + 024F_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	CF11 TXIF	CF10 TXIF	CF9 TXIF	CF8 TXIF	CF7 TXIF	CF6 TXIF	CF5 TXIF	CF4 TXIF	CF3 TXIF	CF2 TXIF	CF1 TXIF	CF0 TXIF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 16.58 RSCANnCFTISTS Register Contents

Bit Position	Bit Name	Function
31 to 12	Reserved	When read, the value after reset is returned.
11	CF11TXIF	Transmit/Receive FIFO Buffer Transmit Interrupt Request Status Flag 0: No transmit/receive FIFO buffer k transmit interrupt request is present. 1: A transmit/receive FIFO buffer k transmit interrupt request is present. (k = 0 to 11)
10	CF10TXIF	
9	CF9TXIF	
8	CF8TXIF	
7	CF7TXIF	
6	CF6TXIF	
5	CF5TXIF	
4	CF4TXIF	
3	CF3TXIF	
2	CF2TXIF	
1	CF1TXIF	
0	CF0TXIF	

The RSCANnCFTISTS register is cleared to 0000 0000_H in global reset mode.

CFkTXIF Flag (k = 0 to 11)

The CFkTXIF flag is set to 1 when the CFTXIF flag in the RSCANnCFSTSk register is set to 1 (a transmit/receive FIFO transmit interrupt request is present). When the CFTXIF flag is cleared to 0, the CFkTXIF flag is cleared to 0.

16.3.10 Details of Transmit Buffer-Related Registers

16.3.10.1 RSCANnTMCp — Transmit Buffer Control Register (p = 0 to 63)

Access: RSCANnTMCp can be read/written in 8-bit units.

Address: RSCANnTMCp: <RSCFDn_base> + 0250_H + (01_H × p)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	TMOM	TMTAR	TMTR
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W*1	R/W*1

Note 1. The only effective value for writing to this bit is 1, which sets the bit. Any other writing to the bit results in retention of the status and does not change the value.

Table 16.59 RSCANnTMCp Register Contents

Bit Position	Bit Name	Function
7 to 3	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
2	TMOM	One-Shot Transmission Enable 0: One-shot transmission is disabled. 1: One-shot transmission is enabled.
1	TMTAR	Transmit Abort Request 0: Transmit abort is not requested. 1: Transmit abort is requested.
0	TMTR	Transmit Request 0: Transmission is not requested. 1: Transmission is requested.

When the RSCANnTMCp register meets any of the following conditions, set it to 00_H.

- The RSCANnTMCp register (p = m × 16 + of the CFTML[3:0] value) corresponds to the transmit buffer number selected by the CFTML[3:0] bits in the RSCANnCFCCk register.
- The RSCANnTMCp register (p = (m × 16 + 15) to (m × 16 + 15 the TXQDC[3:0] value)) corresponds to the transmit buffer allocated to the transmit queue by the TXQDC[3:0] bits in the RSCANnTXQCCm register (m = 0 to 3).

Bits in the RSCANnTMCp register are cleared to all 0 in channel reset mode. Modify the RSCANnTMCp register in channel communication mode or channel halt mode.

TMOM Bit

Setting this bit to 1 enables one-shot transmission. If transmission fails, retransmission defined in the CAN protocol is not performed.

Modify the TMOM bit when the TMTRM flag in the RSCANnTMSTSp register is set to 0. To set the TMOM bit to 1, also set the TMTR bit together.

TMTAR Bit

Setting this bit to 1 generates a transmit abort request for the message stored in the transmit buffer. However, a message that is being transmitted or to be transmitted next cannot be aborted.

When the TMTR bit is set to 1, the TMTAR bit can be set to 1.

The TMTAR bit is cleared to 0 when any of the following conditions is set. It is not cleared to 0 by writing 0 by the program.

- Transmission has been completed.
- Transmit abort has been completed.
- An error or arbitration lost has been detected.

If this bit becomes 0 at the timing when the program writes 1 to this bit, this bit becomes 0.

TMTR Bit

Setting this bit to 1 transmits the message stored in the transmit buffer.

The TMTR bit is cleared to 0 when any of the following conditions is met. It is not cleared to 0 by writing 0 by the program.

- Transmission has been completed.
- Transmit abort has been completed by setting the TMTAR bit to 1.
- An error or arbitration lost has been detected with the TMOM bit set to 1.

Set the TMTR bit to 1 when the TMTRF[1:0] flag in the RSCANnTMSTSp register is 00_B.

16.3.10.2 RSCANnTMSTSp — Transmit Buffer Status Register (p = 0 to 63)

Access: RSCANnTMSTSp can be read/written in 8-bit units.

Address: RSCANnTMSTSp: <RSCFDn_base> + 02D0_H + (01_H × p)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	TMTARM	TMTRM	TMTRF[1:0]		TMTSTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R

Table 16.60 RSCANnTMSTSp Register Contents

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
4	TMTARM	Transmit Buffer Transmit Abort Request Status Flag 0: No transmit abort request is present. 1: A transmit abort request is present.
3	TMTRM	Transmit Buffer Transmit Request Status Flag 0: No transmit request is present. 1: A transmit request is present.
2,1	TMTRF[1:0]	Transmit Buffer Transmit Result Flag b2 b1 0 0: Transmission is in progress or no transmit request is present. 0 1: Transmit abort has been completed. 1 0: Transmission has been completed (without transmit abort request). 1 1: Transmission has been completed (with transmit abort request).
0	TMTSTS	Transmit Buffer Transmit Status Flag 0: Transmission is not in progress. 1: Transmission is in progress.

The RSCANnTMSTSp register is cleared to all 0 in channel reset mode.

TMTARM Flag

The TMTARM flag is set to 1 when the TMTAR bit in the RSCANnTMCp register is set to 1, and is cleared to 0 when the TMTAR bit is set to 0.

TMTRM Flag

The TMTRM flag is set to 1 when the TMTR bit in the RSCANnTMCp register is set to 1, and is cleared to 0 when the TMTR bit is set to 0.

TMTRF[1:0] Flag

This flag indicates the result of transmission from the transmit buffer.

00_B: Transmission is in progress or no transmit request is present.

01_B: Transmission from the transmit buffer was aborted.

10_B: Transmission has been completed with the TMTAR bit in the RSCANnTMCp register set to 0 (transmit abort is not requested).

11_B: Transmission has been completed with the TMTAR bit in the RSCANnTMCp register set to 1 (transmit abort is requested).

Write 00_B to the TMTRF[1:0] flag in channel communication mode or channel halt mode. Do not write any value other than 00_B to this flag.

TMTSTS Flag

This flag is set to 1 when transmission from the transmit buffer starts, and is cleared to 0 when transmission from the transmit buffer has been completed or stopped due to a bus error or arbitration lost.

16.3.10.3 RSCANnTMIDp — Transmit Buffer ID Register (p = 0 to 63)

Access: RSCANnTMIDp can be read/written in 32-bit units.
 RSCANnTMIDpL and RSCANnTMIDpH can be read/written in 16-bit units.
 RSCANnTMIDpLL, RSCANnTMIDpLH, RSCANnTMIDpHL, and RSCANnTMIDpHH can be read/written in 8-bit units.

Address: RSCANnTMIDp: <RSCFDn_base> + 1000_H + (10_H × p)

RSCANnTMIDpL: <RSCFDn_base> + 1000_H + (10_H × p),
 RSCANnTMIDpH: <RSCFDn_base> + 1002_H + (10_H × p)

RSCANnTMIDpLL: <RSCFDn_base> + 1000_H + (10_H × p),
 RSCANnTMIDpLH: <RSCFDn_base> + 1001_H + (10_H × p),
 RSCANnTMIDpHL: <RSCFDn_base> + 1002_H + (10_H × p),
 RSCANnTMIDpHH: <RSCFDn_base> + 1003_H + (10_H × p)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TMIDE TMRTR THLEN			TMID[28:16]

Table 16.61 RSCANnTMIDp Register Contents

Bit Position	Bit Name	Function
31	TMIDE	Transmit Buffer IDE 0: Standard ID 1: Extended ID
30	TMRTR	Transmit Buffer RTR 0: Data frame 1: Remote frame
29	THLEN	Transmit History Data Store Enable 0: Transmit history data is not stored in the buffer. 1: Transmit history data is stored in the buffer.
28 to 0	TMID [28:0]	Transmit Buffer ID Data Set standard ID or extended ID. For standard ID, write an ID to bits b10 to b0 and write 0 to bits b28 to b11.

Modify this register when the TMTRM bit in the corresponding RSCANnTMSTSp register is set to 0 (no transmit request is present). If this register is linked to any transmit/receive FIFO buffer, do not write data to this register. Write data only to the transmit buffer p (p = m × 16 + 15) when this register is allocated to the transmit queue.

TMIDE Bit

This bit is used to set the ID format of the message to be transmitted from the transmit buffer.

TMRTR Bit

This bit is used to set the data format of the message to be transmitted from the transmit buffer.

THLEN Bit

Setting this bit to 1 stores a transmitted message in the transmit history buffer after transmission is completed.

TMID[28:0] Bits

These bits are used to set the ID of the message to be transmitted from the transmit buffer.

16.3.10.4 RSCANnTMPTRp — Transmit Buffer Pointer Register (p = 0 to 63)

Access: RSCANnTMPTRp can be read/written in 32-bit units.
RSCANnTMPTRpL and RSCANnTMPTRpH can be read/written in 16-bit units.
RSCANnTMPTRpLL, RSCANnTMPTRpLH, RSCANnTMPTRpHL, and RSCANnTMPTRpHH can be read/written in 8-bit units.

Address: RSCANnTMPTRp: $\langle \text{RSCFDn_base} \rangle + 1004_{\text{H}} + (10_{\text{H}} \times p)$

RSCANnTMPTRpL: $\langle \text{RSCFDn_base} \rangle + 1004_{\text{H}} + (10_{\text{H}} \times p)$,
RSCANnTMPTRpH: $\langle \text{RSCFDn_base} \rangle + 1006_{\text{H}} + (10_{\text{H}} \times p)$

RSCANnTMPTRpLL: $\langle \text{RSCFDn_base} \rangle + 1004_{\text{H}} + (10_{\text{H}} \times p)$,
RSCANnTMPTRpLH: $\langle \text{RSCFDn_base} \rangle + 1005_{\text{H}} + (10_{\text{H}} \times p)$,
RSCANnTMPTRpHL: $\langle \text{RSCFDn_base} \rangle + 1006_{\text{H}} + (10_{\text{H}} \times p)$,
RSCANnTMPTRpHH: $\langle \text{RSCFDn_base} \rangle + 1007_{\text{H}} + (10_{\text{H}} \times p)$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.62 RSCANnTMPTRp Register Contents

Bit Position	Bit Name	Function
31 to 28	TMDLC [3:0]	Transmit Buffer DLC Data b31 b30 b29 b28 0 0 0 0: 0 data bytes 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 x x x: 8 data bytes
27 to 24	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
23 to 16	TMPTR [7:0]	Transmit Buffer Label Data Set the label information to be stored in the transmit history buffer.
15 to 0	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.

Modify this register when the TMTRM bit in the corresponding RSCANnTMSTSp register is set to 0 (no transmit request is present). If this register is linked to any transmit/receive FIFO buffer, do not write data to this register. Write data only to the transmit buffer p ($p = m \times 16 + 15$) when this register is allocated to the transmit queue.

TMDLC[3:0] Bits

These bits are used to set the data length of the message to be transmitted from the transmit buffer when the TMRTR bit in the RSCANnTMIDp register is set to 0 (data frame). If the setting for the data length is 1001B or above, 8-byte data is transmitted.

When the TMRTR bit is set to 1 (remote frame), set the data length of a requested message.

TMPTR[7:0] Bits

When message transmission has been completed, the TMPTR[7:0] value is stored in the transmit history buffer.

16.3.10.5 RSCANnTMDF0_p — Transmit Buffer Data Field 0 Register (p = 0 to 63)

Access: RSCANnTMDF0_p can be read/written in 32-bit units.
RSCANnTMDF0_pL and RSCANnTMDF0_pH can be read/written in 16-bit units.
RSCANnTMDF0_pLL, RSCANnTMDF0_pLH, RSCANnTMDF0_pHL, and RSCANnTMDF0_pHH can be read/written in 8-bit units.

Address: RSCANnTMDF0_p: <RSCFDn_base> + 1008_H + (10_H × p)

RSCANnTMDF0_pL: <RSCFDn_base> + 1008_H + (10_H × p),
RSCANnTMDF0_pH: <RSCFDn_base> + 100A_H + (10_H × p)

RSCANnTMDF0_pLL: <RSCFDn_base> + 1008_H + (10_H × p),
RSCANnTMDF0_pLH: <RSCFDn_base> + 1009_H + (10_H × p),
RSCANnTMDF0_pHL: <RSCFDn_base> + 100A_H + (10_H × p),
RSCANnTMDF0_pHH: <RSCFDn_base> + 100B_H + (10_H × p)

Table 16.63 RSCANnTMDF0_p Register Contents

Bit Position	Bit Name	Function
31 to 24	TMDB3 [7:0]	Transmit Buffer Data Byte 3
23 to 16	TMDB2 [7:0]	Transmit Buffer Data Byte 2
15 to 8	TMDB1 [7:0]	Transmit Buffer Data Byte 1
7 to 0	TMDB0 [7:0]	Transmit Buffer Data Byte 0
		Set transmit buffer data.

Modify this register when the TMTRM bit in the corresponding RSCANnTMSTSp register is set to 0 (no transmit request is present). If this register is linked to any transmit/receive FIFO buffer, do not write data to this register. Write data only to the transmit buffer p (p = m × 16 + 15) when this register is allocated to the transmit queue.

16.3.10.6 RSCANnTMDF1_p — Transmit Buffer Data Field 1 Register (p = 0 to 63)

Access: RSCANnTMDF1_p can be read/written in 32-bit units.
RSCANnTMDF1_pL and RSCANnTMDF1_pH can be read/written in 16-bit units.
RSCANnTMDF1_pLL, RSCANnTMDF1_pLH, RSCANnTMDF1_pHL, and RSCANnTMDF1_pHH can be read/written in 8-bit units.

Address: RSCANnTMDF1_p: <RSCFDn_base> + 100CH + (10H × p)

RSCANnTMDF1_pL: <RSCFDn_base> + 100CH + (10H × p),
RSCANnTMDF1_pH: <RSCFDn_base> + 100EH + (10H × p)

Table 16.65 RSCANnTMIECy Register Contents

Bit Position	Bit Name	Function
31 to 16	TMIEp	Transmit Buffer Interrupt Enable bits p (p = y × 32 + 31 to y × 32 + 16) 0: Transmit buffer interrupt is disabled. 1: Transmit buffer interrupt is enabled.
15 to 0	TMIEp	Transmit Buffer Interrupt Enable bits p (p = y × 32 + 15 to y × 32 + 0) 0: Transmit buffer interrupt is disabled. 1: Transmit buffer interrupt is enabled.

TMIEp Bits (p = 0 to 63)

When any of these bits is set to 1 and the corresponding transmission has been completed, a transmit buffer interrupt request is generated.

Modify these bits when the TMTRM flag in the corresponding RSCANnTMSTSp register is 0 (no transmit request is present).

Write 0 to the bits corresponding to the transmit buffers linked to transmit/receive FIFO buffers or the transmit buffers allocated to the transmit queue.

Table 16.66 shows the bit allocation.

Table 16.71 RSCANnTMCSTSy Register Contents

Bit Position	Bit Name	Function
31 to 16	TMCSTSp	Transmit Buffer Transmit Complete Status Flag p (p = y × 32 + 31 to y × 32 + 16) 0: Transmission has not been completed. 1: Transmission has been completed.
15 to 0	TMCSTSp	Transmit Buffer Transmit Complete Status Flag p (p = y × 32 + 15 to y × 32 + 0) 0: Transmission has not been completed. 1: Transmission has been completed.

TMCSTSp Flags (p = 0 to 63)

When the TMTRF[1:0] flag in the RSCANnTMSTSp register is set to 10_B (transmission has been completed (without transmit abort request)) or 11_B (transmission has been completed (with transmit abort request)), the corresponding TMCSTSp flag is set to 1.

These flags are cleared to 0 when the TMTRF[1:0] flag is set to 00_B or in channel reset mode.

Table 16.72 shows the bit allocation.

16.3.12 Details of Transmit Queue-Related Registers

16.3.12.1 RSCANnTXQCCm — Transmit Queue Configuration/Control Register (m = 0 to 3)

Access: RSCANnTXQCCm can be read/written in 32-bit units.
RSCANnTXQCCmL and RSCANnTXQCCmH can be read/written in 16-bit units.
RSCANnTXQCCmLL, RSCANnTXQCCmLH, RSCANnTXQCCmHL, and RSCANnTXQCCmHH can be read/written in 8-bit units.

Address: RSCANnTXQCCm: <RSCFDn_base> + 03A0_H + (04_H × m)

RSCANnTXQCCmL: <RSCFDn_base> + 03A0_H + (04_H × m),
RSCANnTXQCCmH: <RSCFDn_base> + 03A2_H + (04_H × m)

RSCANnTXQCCmLL: <RSCFDn_base> + 03A0_H + (04_H × m),
RSCANnTXQCCmLH: <RSCFDn_base> + 03A1_H + (04_H × m),
RSCANnTXQCCmHL: <RSCFDn_base> + 03A2_H + (04_H × m),
RSCANnTXQCCmHH: <RSCFDn_base> + 03A3_H + (04_H × m)

Value after reset: 0000 0000_H

Table 16.75 RSCANnTXQCCm Register Contents

Bit Position	Bit Name	Function
31 to 14	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
13	TXQIM	Transmit Queue Interrupt Source Select bit 0: When the buffer becomes empty upon completion of message transmission, a transmit queue interrupt source occurs. 1: A transmit queue interrupt source occurs each time a message has been transmitted.
12	TXQIE	Transmit Queue Interrupt Enable 0: Transmit queue interrupt is disabled. 1: Transmit queue interrupt is enabled.
11 to 8	TXQDC [3:0]	Transmit Queue Depth Configuration Setting these bits to g (g = 2 to 15) makes the “g + 1” transmit queue available. Setting these bits to 0 disables the transmit queue. Setting these bits to 1 is prohibited.
7 to 1	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
0	TXQE	Transmit Queue Enable 0: The transmit queue is not used. 1: The transmit queue is used.

TXQIM Bit

This bit is used to select a transmit queue interrupt source. Modify this bit in channel reset mode.

TXQIE Bit

When the TXQIE bit is set to 1 and the source selected by the TXQIM bit occurs, an interrupt request is generated.

Set the TXQE bit to 0 when modifying the TXQIE bit.

TXQDC[3:0] Bits

These bits are used to set the number of transmit buffers to be allocated to the transmit queue. Transmit buffers are allocated to the transmit queues in the descending order of buffer numbers from $(m \times 16 + 15)$ to $(m \times 16 + 0)$ (See **Table 16.14**). For an example of buffer allocation, see **Figure 16.9**. Modify these bits only in channel reset mode.

TXQE Bit

Setting this bit to 1 makes the transmit queue available. Modify this bit in channel communication mode or channel halt mode. This bit is cleared to 0 in channel reset mode.

Set the TXQDC[3:0] bits to 0010_B or more before setting the TXQE bit to 1.

16.3.12.2 RSCANnTXQSTSm — Transmit Queue Status Register (m = 0 to 3)

Access: RSCANnTXQSTSm can be read/written in 32-bit units.
RSCANnTXQSTSmL and RSCANnTXQSTSmH can be read/written in 16-bit units.
RSCANnTXQSTSmLL, RSCANnTXQSTSmLH, RSCANnTXQSTSmHL, and RSCANnTXQSTSmHH can be read/written in 8-bit units.

Address: RSCANnTXQSTSm: <RSCFDn_base> + 03C0_H + (04_H × m)

RSCANnTXQSTSmL: <RSCFDn_base> + 03C0_H + (04_H × m),
RSCANnTXQSTSmH: <RSCFDn_base> + 03C2_H + (04_H × m)

RSCANnTXQSTSmLL: <RSCFDn_base> + 03C0_H + (04_H × m),
RSCANnTXQSTSmLH: <RSCFDn_base> + 03C1_H + (04_H × m),
RSCANnTXQSTSmHL: <RSCFDn_base> + 03C2_H + (04_H × m),
RSCANnTXQSTSmHH: <RSCFDn_base> + 03C3_H + (04_H × m)

Value after reset: 0000 0001_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	TXQIF	TXQFL L	TXQ EMP
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the status. Any other writing to the bit results in retention of the status and does not change the value.

Table 16.76 RSCANnTXQSTSm Register Contents

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
12 to 8	Reserved	When read, the undefined value is returned. When writing to these bits, write the value after reset.
7 to 3	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
2	TXQIF	Transmit Queue Interrupt Request Flag 0: No transmit queue interrupt request is present. 1: A transmit queue interrupt request is present.
1	TXQFL	Transmit Queue Full Status Flag 0: The transmit queue is not full. 1: The transmit queue is full.
0	TXQEMP	Transmit Queue Empty Status Flag 0: The transmit queue contains messages. 1: The transmit queue contains no message (transmit queue empty).

TXQIF Flag

The TXQIF flag is set to 1 when the source set by the TXQIM bit in the RSCANnTXQCCm register has occurred.

The TXQIF flag is cleared to 0 in channel reset mode or by writing 0 to this flag. This flag is not cleared to 0 by setting the TXQE bit in the RSCANnTXQCCm register to 0 (the transmit queue is not used).

TXQFLL Flag

The TXQFLL flag is set to 1 when the number of messages set for the transmit queue matches the transmit queue depth set by the TXQDC[3:0] bits in the RSCANnTXQCCm register.

This flag is cleared to 0 in any of the following cases.

- The number of messages set for the transmit queue is smaller than the transmit queue depth set by the TXQDC[3:0] bits.
- In channel reset mode

TXQEMP Flag

The TXQEMP flag is cleared to 0 when even a single message is set for the transmit queue.

This flag is set to 1 in any of the following cases.

- The TXQE bit is set to 0 (the transmit queue is not used).
- The transmit queue becomes empty.
- In channel reset mode

16.3.12.3 RSCANnTXQPCTRm — Transmit Queue Pointer Control Register (m = 0 to 3)

Access: RSCANnTXQPCTRm can be read/written in 32-bit units.
RSCANnTXQPCTRmL and RSCANnTXQPCTRmH can be read/written in 16-bit units.
RSCANnTXQPCTRmLL, RSCANnTXQPCTRmLH, RSCANnTXQPCTRmHL, and RSCANnTXQPCTRmHH can be read/written in 8-bit units.

Address: RSCANnTXQPCTRm: <RSCFDn_base> + 03E0_H + (04_H × m)

RSCANnTXQPCTRmL: <RSCFDn_base> + 03E0_H + (04_H × m),
RSCANnTXQPCTRmH: <RSCFDn_base> + 03E2_H + (04_H × m)

RSCANnTXQPCTRmLL: <RSCFDn_base> + 03E0_H + (04_H × m),
RSCANnTXQPCTRmLH: <RSCFDn_base> + 03E1_H + (04_H × m),
RSCANnTXQPCTRmHL: <RSCFDn_base> + 03E2_H + (04_H × m),
RSCANnTXQPCTRmHH: <RSCFDn_base> + 03E3_H + (04_H × m)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	—	—	—	—	TXQPC[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Table 16.77 RSCANnTXQPCTRm Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
7 to 0	TXQPC [7:0]	Transmit Queue Pointer Control Writing FF _H to these bits moves the write pointer of the transmit queue to the next queue.

TXQPC[7:0] Bits

Writing FF_H to the TXQPC[7:0] bits moves the write pointer to the next transmit queue and generates a transmit request of the message. Write transmit messages to the RSCANnTMIDp, RSCANnTMPTRp, RSCANnTMDF0_p, RSCANnTMDF1_p registers (p = 15, 31, 47, 63) before writing FF_H to the TXQPC[7:0] bits.

When writing FF_H to these bits, make sure that the TXQE bit in the RSCANnTXQCCm register is set to 1 (the transmit queue is used) and the TXQFLL flag in the RSCANnTXQSTSm register is 0 (the transmit queue is not full).

16.3.13 Details of Transmit History-Related Registers

16.3.13.1 RSCANnTHLCCm — Transmit History List Configuration/Control Register (m = 0 to 3)

Access: RSCANnTHLCCm can be read/written in 32-bit units.
 RSCANnTHLCCmL and RSCANnTHLCCmH can be read/written in 16-bit units.
 RSCANnTHLCCmLL, RSCANnTHLCCmLH, RSCANnTHLCCmHL, and RSCANnTHLCCmHH can be read/written in 8-bit units.

Address: RSCANnTHLCCm: <RSCFDn_base> + 0400_H + (04_H × m)

RSCANnTHLCCmL: <RSCFDn_base> + 0400_H + (04_H × m),
 RSCANnTHLCCmH: <RSCFDn_base> + 0402_H + (04_H × m)

RSCANnTHLCCmLL: <RSCFDn_base> + 0400_H + (04_H × m),
 RSCANnTHLCCmLH: <RSCFDn_base> + 0401_H + (04_H × m),

Table 16.78 RSCANnTHLCCm Register Contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
10	THLDTE	Transmit History Target Buffer Select 0: Entry from transmit/receive FIFO buffers and transmit queue 1: Entry from transmit buffers, transmit/receive FIFO buffers, and transmit queue
9	THLIM	Transmit History Interrupt Source Select 0: When 12 sets of data have been stored in the transmit history buffer 1: When a single set of transmit history data has been stored
8	THLIE	Transmit History Interrupt Enable 0: Transmit history interrupt is disabled. 1: Transmit history interrupt is enabled.
7 to 1	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
0	THLE	Transmit History Buffer Enable 0: Transmit history buffer is not used. 1: Transmit history buffer is used.

THLDTE Bit

When this bit is set to 0, the transmit history data of messages transmitted from transmit/receive FIFO buffers and the transmit queue is stored in the transmit history buffer. When this bit is set to 1, the transmit history data of messages transmitted from transmit buffers, transmit/receive FIFO buffers, and the transmit queue is stored in the transmit history buffer.

Modify this bit only in channel reset mode.

THLIM Bit

This bit is used to select a transmit history interrupt source.

Modify this bit only in channel reset mode.

THLIE Bit

When the THLIE bit is set to 1 and the source selected by the THLIM bit has occurred, a transmit history interrupt request is generated. Modify the THLIE bit with the THLE bit set to 0.

THLE Bit

Setting this bit to 1 makes the transmit history buffer available. When data transmission from the buffer selected by the THLDTE bit has been completed, the transmit history data of the transmitted messages is stored in the transmit history buffer.

Modify this bit in channel communication mode or channel halt mode.

This bit is cleared to 0 in channel reset mode.

16.3.13.2 RSCANnTHLSTSm — Transmit History List Status Register (m = 0 to 3)

Access: RSCANnTHLSTSm can be read/written in 32-bit units.
RSCANnTHLSTSmL and RSCANnTHLSTSmH can be read/written in 16-bit units.
RSCANnTHLSTSmLL, RSCANnTHLSTSmLH, RSCANnTHLSTSmHL, and RSCANnTHLSTSmHH can be read/written in 8-bit units.

Address: RSCANnTHLSTSm: <RSCFDn_base> + 0420_H + (04_H × m)

RSCANnTHLSTSmL: <RSCFDn_base> + 0420_H + (04_H × m),
RSCANnTHLSTSmH: <RSCFDn_base> + 0422_H + (04_H × m)

RSCANnTHLSTSmLL: <RSCFDn_base> + 0420_H + (04_H × m),
RSCANnTHLSTSmLH: <RSCFDn_base> + 0421_H + (04_H × m),
RSCANnTHLSTSmHL: <RSCFDn_base> + 0422_H + (04_H × m),
RSCANnTHLSTSmHH: <RSCFDn_base> + 0423_H + (04_H × m)

Value after reset: 0000 0001_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	THLMC[4:0]				—	—	—	—	THLIF	THLELT	THLFLL	THLEMP	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R/W*1	R	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the status. Any other writing to the bit results in retention of the status and does not change the value.

Table 16.79 RSCANnTHLSTSm Register Contents

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
12 to 8	THLMC [4:0]	Transmit History Buffer Unread Data Counter These bits indicate the number of unread data sets stored in the transmit history buffer.
7 to 4	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
3	THLIF	Transmit History Interrupt Request Flag 0: No transmit history interrupt request is present. 1: A transmit history interrupt request is present.
2	THLELT	Transmit History Buffer Overflow Flag 0: Transmit history buffer overflow has not occurred. 1: Transmit history buffer overflow has occurred.
1	THLFLL	Transmit History Buffer Full Status Flag 0: Transmit history buffer is not full. 1: Transmit history buffer is full.
0	THLEMP	Transmit History Buffer Empty Status Flag 0: Transmit history buffer contains unread data. 1: Transmit history buffer contains no unread data (buffer empty).

THLMC[4:0] Bits

These bits indicate the number of unread data sets stored in the transmit history buffer. These bits are cleared to 0 in channel reset mode.

THLIF Flag

The THLIF flag is set to 1 when the interrupt source set by the THLIM bit in the RSCANnTHLCCm register has occurred.

This flag is cleared to 0 in channel reset mode or by writing 0 to this flag by the program.

To clear the flag of the register to 0, the program must write 0 to the given flag. When writing 0, use a store instruction to write 0 to the given flag and 1 to the other flags.

THLELT Flag

The THLELT flag is set to 1 when it is attempted to store new transmit history data while the transmit history buffer is full. In this case, the new data is discarded. This flag becomes 0 in channel reset mode or by writing 0 to this flag.

To clear the flag of the register to 0, the program must write 0 to the given flag. When writing 0, use a store instruction to write 0 to the given flag and 1 to the other flags.

THLFLL Flag

The THLFLL flag is set to 1 when 16 data sets have been stored in the transmit history buffer, and is cleared to 0 when the number of data sets stored in the transmit history buffer has decreased to less than 16. This bit is also cleared to 0 in channel reset mode or when the THLE bit in the RSCANnTHLCCm register is set to 0 (transmit history buffer is not used).

THLEMP Flag

The THLEMP flag is cleared to 0 when even a single set of transmit history data has been stored in the transmit history buffer.

This flag is set to 1 when all the data in the transmit history buffer has been read. This flag is also set to 1 in channel reset mode or when the THLE bit in the RSCANnTHLCCm register is set to 0 (transmit history buffer is not used).

NOTE

To clear the THLIF and THLELT flags to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using a store instruction, set 1 to other flags.

16.3.13.3 RSCANnTHLPCTRm — Transmit History List Pointer Control Register (m = 0 to 3)

Access: RSCANnTHLPCTRm can be read/written in 32-bit units.
 RSCANnTHLPCTRmL and RSCANnTHLPCTRmH can be read/written in 16-bit units.
 RSCANnTHLPCTRmLL, RSCANnTHLPCTRmLH, RSCANnTHLPCTRmHL, and RSCANnTHLPCTRmHH can be read/written in 8-bit units.

Address: RSCANnTHLPCTRm: <RSCFDn_base> + 0440_H + (04_H × m)

RSCANnTHLPCTRmL: <RSCFDn_base> + 0440_H + (04_H × m),
 RSCANnTHLPCTRmH: <RSCFDn_base> + 0442_H + (04_H × m)

RSCANnTHLPCTRmLL: <RSCFDn_base> + 0440_H + (04_H × m),
 RSCANnTHLPCTRmLH: <RSCFDn_base> + 0441_H + (04_H × m),
 RSCANnTHLPCTRmHL: <RSCFDn_base> + 0442_H + (04_H × m),
 RSCANnTHLPCTRmHH: <RSCFDn_base> + 0443_H + (04_H × m)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Table 16.80 RSCANnTHLPCTRm Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When writing to these bits, write the value after reset.
7 to 0	THLPC [7:0]	Transmit History List Pointer Control Writing FF _H to these bits moves the read pointer to the next unread data in the transmit history buffer.

THLPC[7:0] Bits

When the THLPC[7:0] bits are set to FF_H, the read pointer moves to the next data in the transmit history buffer. At this time, the THLMC[4:0] (transmit history buffer unread data counter) value in the RSCANnTHLSTSm register is decremented by 1. After reading the RSCANnTHLACCm register, write FF_H to the THLPC[7:0] bits.

When writing FF_H to these bits, make sure that the THLE bit in the RSCANnTHLCCm register is set to 1 (transmit history buffer is used) and the THLEMP flag in the RSCANnTHLSTSm register is 0.

16.3.13.4 RSCANnTHLACCm — Transmit History List Access Register (m = 0 to 3)

Access: RSCANnTHLACCm can be read/written in 32-bit units.
RSCANnTHLACCmL and RSCANnTHLACCmH can be read/written in 16-bit units.
RSCANnTHLACCmLL, RSCANnTHLACCmLH, RSCANnTHLACCmHL, and RSCANnTHLACCmHH can be read/written in 8-bit units.

Address: RSCANnTHLACCm: <RSCFDn_base> + 1800_H + (04_H × m)

RSCANnTHLACCmL: <RSCFDn_base> + 1800_H + (04_H × m),
RSCANnTHLACCmH: <RSCFDn_base> + 1802_H + (04_H × m)

RSCANnTHLACCmLL: <RSCFDn_base> + 1800_H + (04_H × m),
RSCANnTHLACCmLH: <RSCFDn_base> + 1801_H + (04_H × m),
RSCANnTHLACCmHL: <RSCFDn_base> + 1802_H + (04_H × m),
RSCANnTHLACCmHH: <RSCFDn_base> + 1803_H + (04_H × m)

Value after reset: 0000 0000_H

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 16.81 RSCANnTHLACCm Register Contents

Bit Position	Bit Name	Function
31 to 16	TMTS[15:0]	Timestamp Data The timestamp data of stored data can be read.
15 to 8	TID[7:0]	Label Data The label information of stored data can be read.
7	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
6 to 3	BN[3:0]	Buffer Number Data The buffer number of transmit source (transmit buffer, transmit/receive FIFO or transmit queue) can be read.
2 to 0	BT[2:0]	Buffer Type Data b2 b1 b0 0 0 1: Transmit buffer 0 1 0: Transmit/receive FIFO buffer 1 0 0: Transmit queue

TMTS[15:0] Bits

When the TMTSCE bit in the RSCANnGCFG register is 1, timestamp values in transmit history data stored in the transmit history buffer are displayed. When the TMTSCE bit is 0, the TMTS[15:0] bits are always read as 0.

TID[7:0] Bits

These bits indicate the label information of transmit history data stored in the transmit history buffer.

BN[3:0] Bits

These bits indicate the transmit source buffer number of transmit history data stored in the transmit history buffer.

BT[2:0] Bits

These bits indicate the transmit source buffer type of transmit history data stored in the transmit history buffer.

16.3.14 Details of Test-Related Registers

16.3.14.1 RSCANnGTSTCFG — Global Test Configuration Register

Access: RSCANnGTSTCFG can be read/written in 32-bit units.
RSCANnGTSTCFG_L and RSCANnGTSTCFG_H can be read/written in 16-bit units.
RSCANnGTSTCFG_LL, RSCANnGTSTCFG_LH, RSCANnGTSTCFG_HL, and RSCANnGTSTCFG_HH can be read/written in 8-bit units.

Address: RSCANnGTSTCFG: <RSCFDn_base> + 0468_H

RSCANnGTSTCFG_L: <RSCFDn_base> + 0468_H, RSCANnGTSTCFG_H: <RSCFDn_base> + 046A_H

RSCANnGTSTCFG_LL: <RSCFDn_base> + 0468_H, RSCANnGTSTCFG_LH: <RSCFDn_base> + 0469_H,

RSCANnGTSTCFG_HL: <RSCFDn_base> + 046A_H, RSCANnGTSTCFG_HH: <RSCFDn_base> + 046B_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.82 RSCANnGTSTCFG Register Contents

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
22 to 16	RTMPS [6:0]	RAM Test Page Configuration Set a value within a range of page 0 (00 _H) to page 49 (31 _H).
15 to 4	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
3	C3ICBCE	CAN3 Inter-Channel Communication Test Enable 0: CAN3 inter-channel communication test is disabled. 1: CAN3 inter-channel communication test is enabled.
2	C2ICBCE	CAN2 Inter-Channel Communication Test Enable 0: CAN2 inter-channel communication test is disabled. 1: CAN2 inter-channel communication test is enabled.
1	C1ICBCE	CAN1 Inter-Channel Communication Test Enable 0: CAN1 inter-channel communication test is disabled. 1: CAN1 inter-channel communication test is enabled.
0	C0ICBCE	CAN0 Inter-Channel Communication Test Enable 0: CAN0 inter-channel communication test is disabled. 1: CAN0 inter-channel communication test is enabled.

Modify the RSCANnGTSTCFG register in global test mode.

RTMPS[6:0] Bits

These bits are used to set the RAM test target page number for RAM test. Set a value from 00_H to 31_H.

C3ICBCE Bit

This bit is cleared to 0 in global reset mode.

C2ICBCE Bit

This bit is cleared to 0 in global reset mode.

C1ICBCE Bit

This bit is cleared to 0 in global reset mode.

C0ICBCE Bit

This bit is cleared to 0 in global reset mode.

16.3.14.2 RSCANnGTSTCTR — Global Test Control Register

Access: RSCANnGTSTCTR can be read/written in 32-bit units.
RSCANnGTSTCTRL and RSCANnGTSTCTRH can be read/written in 16-bit units.
RSCANnGTSTCTRL, RSCANnGTSTCTRLH, RSCANnGTSTCTRHL, and RSCANnGTSTCTRHH can be read/written in 8-bit units.

Address: RSCANnGTSTCTR: <RSCFDn_base> + 046C_H

RSCANnGTSTCTRL: <RSCFDn_base> + 046C_H, RSCANnGTSTCTRH: <RSCFDn_base> + 046E_H

RSCANnGTSTCTRL: <RSCFDn_base> + 046C_H, RSCANnGTSTCTRLH: <RSCFDn_base> + 046D_H,
RSCANnGTSTCTRHL: <RSCFDn_base> + 046E_H, RSCANnGTSTCTRHH: <RSCFDn_base> + 046F_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	RTME	—	ICBC TME
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W

Table 16.83 RSCANnGTSTCTR Register Contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
2	RTME	RAM Test Enable 0: RAM test is disabled. 1: RAM test is enabled.
1	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
0	ICBCTME	Inter-Channel Communication Test Enable 0: Inter-channel communication test is disabled. 1: Inter-channel communication test is enabled.

RTME Bit

Setting this bit to 1 enables RAM test. Modify this bit in global test mode. This bit is cleared to 0 in global reset mode. (See **Figure 16.37**)

1. Set the GMDC[1:0] bits in the RSCANnGCTR register to 10_B (global test mode).
2. Set the RTME bit to 1.
3. Check that the RTME bit is set to 1.

ICBCTME Bit

When this bit is set to 1, a communication test is enabled between the channels for which the CmICBCE bit (m = 0 to 3) in the RSCANnGTSTCFG register has been set to 1. Modify the ICBCTME bit only in global test mode. This bit is cleared to 0 in global reset mode.

16.3.14.3 RSCANnGLOCKK — Global Lock Key Register

Access: RSCANnGLOCKK can be read/written in 32-bit units.
RSCANnGLOCKKL and RSCANnGLOCKKH can be read/written in 16-bit units.

Address: RSCANnGLOCKK: <RSCFDn_base> + 047C_H

RSCANnGLOCKKL: <RSCFDn_base> + 047C_H, RSCANnGLOCKKH: <RSCFDn_base> + 047E_H

Value after reset: 0000 0000_H.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LOCK[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1

Note 1. Writing to these bits is effective only when the RS-CANFD module is in global test mode.

Table 16.84 RSCANnGLOCKK Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
15 to 0	LOCK[15:0]	Lock Key These bits are key bits to release protection of test mode.

The RSCANnGLOCKK register is a write-only register to release protection of special test bits. For protection released data, **Section 16.11.4.2, Procedure for Releasing the Protection**.

LOCK[15:0] Bits

Writing the protection release data to the LOCK[15:0] bits in succession enables writing 1 to the RTME bit in the GTSTCTR register.

After the protection has been released, writing to the I/O register area of CAN (<RSCFDn_base> + 0000_H to <RSCFDn_base> + 04FF_H), excluding the RAM, enables the protection again.

Reading from the register of the CAN I/O register area or reading from/writing to other areas does not enable the protection.

16.3.14.4 RSCANnRPGACCr — RAM Test Page Access Register (r = 0 to 63)

Access: RSCANnRPGACCr can be read/written in 32-bit units.
RSCANnRPGACCrL and RSCANnRPGACCrH can be read/written in 16-bit units.
RSCANnRPGACCrLL, RSCANnRPGACCrLH, RSCANnRPGACCrHL, and RSCANnRPGACCrHH can be read/written in 8-bit units.

Address: RSCANnRPGACCr: $\langle \text{RSCFDn_base} \rangle + 1900_{\text{H}} + (04_{\text{H}} \times r)$

RSCANnRPGACCrL: $\langle \text{RSCFDn_base} \rangle + 1900_{\text{H}} + (04_{\text{H}} \times r)$,
RSCANnRPGACCrH: $\langle \text{RSCFDn_base} \rangle + 1902_{\text{H}} + (04_{\text{H}} \times r)$

RSCANnRPGACCrLL: $\langle \text{RSCFDn_base} \rangle + 1900_{\text{H}} + (04_{\text{H}} \times r)$,
RSCANnRPGACCrLH: $\langle \text{RSCFDn_base} \rangle + 1901_{\text{H}} + (04_{\text{H}} \times r)$,
RSCANnRPGACCrHL: $\langle \text{RSCFDn_base} \rangle + 1902_{\text{H}} + (04_{\text{H}} \times r)$,
RSCANnRPGACCrHH: $\langle \text{RSCFDn_base} \rangle + 1903_{\text{H}} + (04_{\text{H}} \times r)$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.85 RSCANnRPGACCr Register Contents

Bit Position	Bit Name	Function
31 to 0	RDTA [31:0]	RAM Data Test Access Data can be read and written in CAN RAM.

Modify the RSCANnRPGACCr register in global test mode with the RTME bit in the RSCANnGTSTCTR register set to 1 (RAM test is enabled).

The RSCANnRPGACCr register is readable and writable when the RTME bit is set to 1.

16.4 Registers (CAN FD Mode)

This section describes all registers to be used when the RS-CANFD is used in CAN FD mode.

16.4.1 List of Registers

The following tables list RS-CANFD registers to be used in CAN FD mode.

For details about <RSCFDn_base>, see **Section 16.1.2, Register Base Address**.

For details about registers initialized in Global reset mode or Channel reset mode, see following.

- **Table 16.174, Registers Initialized in Global Reset Mode or Channel Reset Mode**
- **Table 16.175, Registers Initialized Only in Global Reset Mode**

Table 16.86 Registers (1/3)

Module	Register	Symbol	Address
Interface mode-related registers			
RSCFDn	Global interface mode select register	RSCFDnCFDGRMCFG	<RSCFDn_base> + 04FC _H
Channel-related registers			
RSCFDn	Channel m nominal bit rate configuration register	RSCFDnCFDCmNCFG	<RSCFDn_base> + 0000 _H + (10 _H × m)
RSCFDn	Channel m control register	RSCFDnCFDCmCTR	<RSCFDn_base> + 0004 _H + (10 _H × m)
RSCFDn	Channel m status register	RSCFDnCFDCmSTS	<RSCFDn_base> + 0008 _H + (10 _H × m)
RSCFDn	Channel m error flag register	RSCFDnCFDCmERFL	<RSCFDn_base> + 000C _H + (10 _H × m)
RSCFDn	Channel m data bit rate configuration register	RSCFDnCFDCmDCFG	<RSCFDn_base> + 0500 _H + (20 _H × m)
RSCFDn	Channel m CAN FD configuration register	RSCFDnCFDCmFDCFG	<RSCFDn_base> + 0504 _H + (20 _H × m)
RSCFDn	Channel m CAN FD control register	RSCFDnCFDCmFDCTR	<RSCFDn_base> + 0508 _H + (20 _H × m)
RSCFDn	Channel m CAN FD status register	RSCFDnCFDCmFDSTS	<RSCFDn_base> + 050C _H + (20 _H × m)
RSCFDn	Channel m CAN FD CRC register	RSCFDnCFDCmFDCRC	<RSCFDn_base> + 0510 _H + (20 _H × m)
Global-related registers			
RSCFDn	Global configuration register	RSCFDnCFDGCFCFG	<RSCFDn_base> + 0084 _H
RSCFDn	Global control register	RSCFDnCFDGCCTR	<RSCFDn_base> + 0088 _H
RSCFDn	Global status register	RSCFDnCFDGSTS	<RSCFDn_base> + 008C _H
RSCFDn	Global error flag register	RSCFDnCFDGERFL	<RSCFDn_base> + 0090 _H
RSCFDn	Global timestamp counter register	RSCFDnCFDGTSC	<RSCFDn_base> + 0094 _H

1111 _B	Transmit buffer $16 \times m + 15$ to $16 \times m + 0$

16.4.2 Details of Interface Mode-Related Registers

16.4.2.1 RSCFDnCFDGRMCFG — Global Interface Mode Select Register

Access: RSCFDnCFDGRMCFG register can be read/written in 32-bit units
 RSCFDnCFDGRMCFG, RSCFDnCFDGRMCFGH registers can be read/written in 16-bit units
 RSCFDnCFDGRMCFGLL, RSCFDnCFDGRMCFGHL, RSCFDnCFDGRMCFGHLL,
 RSCFDnCFDGRMCFGHHL registers can be read/written in 8-bit units

Address: RSCFDnCFDGRMCFG: <RSCFDn_base> + 04FC_H
 RSCFDnCFDGRMCFG: <RSCFDn_base> + 04FC_H,
 RSCFDnCFDGRMCFGH: <RSCFDn_base> + 04FE_H
 RSCFDnCFDGRMCFGLL: <RSCFDn_base> + 04FC_H,
 RSCFDnCFDGRMCFGHL: <RSCFDn_base> + 04FD_H,
 RSCFDnCFDGRMCFGHLL: <RSCFDn_base> + 04FE_H,
 RSCFDnCFDGRMCFGHHL: <RSCFDn_base> + 04FF_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 16.91 RSCFDnCFDGRMCFG Register Contents

Bit Position	Bit Name	Function
31 to 1	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
0	RCMC	Interface Mode Select 0: Classical CAN mode 1: CAN FD mode

Note 1. The RSCANnGRMCFG and RSCFDnCFDGRMCFG registers are identical. Set either of these registers.

Modify the RSCFDnCFDGRMCFG register only in global reset mode. Before setting other RS-CANFD registers, set this register.

RCMC Bit

Setting this bit to 1 makes CAN-FD mode available. To switch classical CAN mode to CAN FD mode, set the value after reset to all registers and bits allocated to the register map of classical CAN mode and then modify the RSCFDnCFDGRMCFG register.

16.4.3 Details of Channel-Related Registers

16.4.3.1 RSCFDnCFDCmNCFG — Channel Nominal Bit Rate Configuration Register (m = 0 to 3)

Access: RSCFDnCFDCmNCFG register can be read/written in 32-bit units
RSCFDnCFDCmNCFGL, RSCFDnCFDCmNCFGH registers can be read/written in 16-bit units
RSCFDnCFDCmNCFGLL, RSCFDnCFDCmNCFGLH, RSCFDnCFDCmNCFGHL,
RSCFDnCFDCmNCFGHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCmNCFG: <RSCFDn_base> + 0000_H + (10_H × m)
RSCFDnCFDCmNCFGL: <RSCFDn_base> + 0000_H + (10_H × m),
RSCFDnCFDCmNCFGH: <RSCFDn_base> + 0002_H + (10_H × m)
RSCFDnCFDCmNCFGLL: <RSCFDn_base> + 0000_H + (10_H × m),
RSCFDnCFDCmNCFGLH: <RSCFDn_base> + 0001_H + (10_H × m),
RSCFDnCFDCmNCFGHL: <RSCFDn_base> + 0002_H + (10_H × m),
RSCFDnCFDCmNCFGHH: <RSCFDn_base> + 0003_H + (10_H × m)

23	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
22 to 16	NTSEG1[6:0]	Nominal Bit Rate Time Segment 1 Control b22 b21 b20 b19 b18 b17 b16 0 0 0 0 0 0 0: Setting is prohibited for channels for CAN communications. 0 0 0 0 0 0 1: Setting is prohibited for channels for CAN communications. 0 0 0 0 0 1 0: Setting is prohibited for channels for CAN communications. 0 0 0 0 0 1 1: 4 T _q : : 1 1 1 1 1 1 0: 127 T _q 1 1 1 1 1 1 1: 128 T _q

Table 16.92 RSCFDnCFDCmNCFG Register Contents (2/2)

Bit Position	Bit Name	Function
15 to 11	NSJW[4:0]	Nominal Bit Rate Resynchronization Jump Width Control b15 b14 b13 b12 b11 0 0 0 0 0: 1 Tq 0 0 0 0 1: 2 Tq 0 0 0 1 0: 3 Tq : : 1 1 1 1 0: 31 Tq 1 1 1 1 1: 32 Tq
10	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
9 to 0	NBRP[9:0]	Nominal Bit Rate Prescaler Division Ratio Setting When the set value = P (0 to 1023), the nominal bit rate prescaler divides fCAN by (P + 1).

Modify the RSCFDnCFDCmNCFG register in channel reset mode or channel halt mode. Set this register in channel reset mode, and then transition to channel communication mode or channel halt mode. For the description and settings of bit timing parameters, see **Section 16.11.1, Initial Settings**.

NTSEG2[4:0] Bits

These bits are used to specify a Tq value for the length of phase segment 2 (PHASE_SEG2) of nominal bit rate.

Allowed values are 2 Tq to 32 Tq, inclusive.

Set a value smaller than the value of the NTSEG1[6:0] bits.

NTSEG1[6:0] Bits

These bits specify the total length of propagation segment (PROP_SEG) and phase segment 1 (PHASE_SEG1) of nominal bit rate as a Tq value.

A value of 4 to 128 Tq is settable.

NSJW[4:0] Bits

These bits specify the resynchronization jump width of nominal bit rate as a Tq value. A value of 1 to 32 Tq is settable. Specify a value equal to or smaller than the NTSEG2[4:0] value.

NBRP[9:0] Bits

The clock obtained by dividing the CAN clock (fCAN) by the nominal bit rate prescaler ((NBRP[9:0]) + 1) becomes CANmTq(N) clock (fCANTQ(N)m). One clock of the CANmTq(N) clock becomes one Time Quantum (Tq).

The NBRP[9:0] value and the DBRP[7:0] value should be equal and the two corresponding bit rate values are different according to the respective segment values.

16.4.3.2 RSCFDnCFDCmCTR — Channel Control Register (m = 0 to 3)

Access: RSCFDnCFDCmCTR register can be read/written in 32-bit units
 RSCFDnCFDCmCTRL, RSCFDnCFDCmCTRHL registers can be read/written in 16-bit units
 RSCFDnCFDCmCTRLL, RSCFDnCFDCmCTRLLH, RSCFDnCFDCmCTRHL, RSCFDnCFDCmCTRHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCmCTR: <RSCFDn_base> + 0004_H + (10_H × m)
 RSCFDnCFDCmCTRL: <RSCFDn_base> + 0004_H + (10_H × m),

1, 0	CHMDC[1:0]	Mode Select b1 b0 0 0: Channel communication mode 0 1: Channel reset mode 1 0: Channel halt mode 1 1: Setting prohibited

ROM Bit

When the ROM bit and the CTME bit in the RSCFDnCFDCmCTR register are set to 1, restricted operation mode is enabled. Use the restricted operation mode only when the CTMS[1:0] value in the RSCFDnCFDCmCTR register is 00_B (standard test mode). Modify this bit only in channel halt mode. This bit is always 0 in channel reset mode.

CRCT Bit

This bit is used to test the CRC generation circuit in the RS-CANFD module. Setting this bit to 1 inverts the first bit of the ID field when a message is received. With this inversion of bit, the CRC calculation result does not match the normal CRC value of the received frame, which can detect a CRC error (the CERR bit in the RSCFDnCFDCmERFL register is 1). When using this function, note the following.

- This function is available while the CTME bit in the RSCFDnCFDCmCTR register is 1 (communication test mode enabled).
- This function cannot communicate with other CAN nodes. Use this function for inter-channel communication test (the CmICBCE bit in the RSCFDnCFDGTSTCFG register is 1).
- Bit inversion in the ID field may cause bit stuffing rule violation. In that case, no CRC error is detected but a stuff error is detected.

Modify this bit only in channel halt mode. This bit is always 0 in channel reset mode.

CTMS[1:0] Bits

These bits are used to select a communication test mode. Modify these bits in channel halt mode only. These bits are set to 0 in channel reset mode.

CTME Bit

Setting this bit to 1 enables communication test mode. Modify these bits in channel halt mode. This bit is set to 0 in channel reset mode.

ERRD Bit

This bit is used to control the display mode of bits 14 to 8 in the RSCFDnCFDCmERFL register.

When this bit is cleared (0), if an error is detected with all bits 14 to 8 of RSCFDnCFDCmERFL set to 0, only the flag corresponding to the first error is set to 1.

When this bit is set to 1, if two or more errors occur, the flags for both or all detected errors are set to 1.

Modify this bit only in channel reset mode or channel halt mode.

BOM[1:0] Bits

These bits are used to select the bus off recovery mode of the RS-CANFD module.

When the BOM[1:0] bits are set to 00_B, return from the bus off state to the error active state is compliant with the CAN specifications. That is, the RS-CANFD module reenters the CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. A bus off recovery interrupt request is generated at the time of return from the bus off state. Even if the CHMDC[1:0] bits are set to 10_B (channel halt mode) before recessive bits are detected 128 times, the RS-CANFD module does not transition to channel halt mode until recessive bits are detected 128 times.

When the RS-CANFD module reaches the bus off state when the BOM[1:0] bits are set to 01_B, the CHMDC[1:0] bits in the RSCFDnCFDCmCTR register (m = 0 to 3) are set to 10_B and the RS-CANFD module transitions to channel halt mode. No bus off recovery interrupt request is generated and the TEC[7:0] and REC[7:0] bits in the RSCFDnCFDCmSTS register are cleared to 00_H.

When the RS-CANFD module reaches the bus off state when the BOM[1:0] bits are set to 10_B, the CHMDC[1:0] bits are set to 10_B and the RS-CANFD module transitions to channel halt mode after

return from the bus off state (11 consecutive recessive bits are detected 128 times). A bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to 00_H.

When the BOM[1:0] bits are set to 11_B and the CHMDC[1:0] bits are set to 10_B while the RS-CANFD module is in the bus off state, the RS-CANFD module transitions to channel halt mode. No bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to 00_H. However, if 11 consecutive recessive bits are detected 128 times and the RS-CANFD module has recovered to the error active state from the bus off state before the CHMDC[1:0] bits are set to 10_B, a bus off recovery interrupt request is generated.

If a program writes to the CHMDC[1:0] bit at the same time as the RS-CANFD module transition to channel halt mode (at bus off entry when the BOM[1:0] bits are 01_B or at bus off end when the BOM[1:0] bits are 10_B), the program's writing takes precedence. Modify the BOM[1:0] bits only in channel reset mode.

TDCVFIE Bit

When the TDCVF flag in the RSCFDnCFDCmFDSTS register is set to 1 after the TDCVFIE bit is set to 1, an interrupt request occurs. Modify this bit only in channel reset mode.

SOCOIE Bit

When the SOCO flag in the RSCFDnCFDCmFDSTS register is set to 1 after the SOCOIE bit is set to 1, an interrupt request occurs. Modify this bit only in channel reset mode.

EOCOIE Bit

When the EOCO flag in the RSCFDnCFDCmFDSTS register is set to 1 after the EOCOIE bit is set to 1, an interrupt request occurs. Modify this bit only in channel reset mode.

TAIE Bit

When transmit abort of the transmit buffer is completed with the TAIE bit set to 1, an interrupt request is generated. Modify this bit only in channel reset mode.

ALIE Bit

When the ALF flag in the RSCFDnCFDCmERFL register is set to 1 with the ALIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BLIE Bit

When the BLF flag in the RSCFDnCFDCmERFL register is set to 1 with the BLIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

OLIE Bit

When the OVLF flag in the RSCFDnCFDCmERFL register is set to 1 with the OLIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BORIE Bit

When the BORF flag in the RSCFDnCFDCmERFL register is set to 1 with the BORIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BOEIE Bit

When the BOEF flag in the RSCFDnCFDCmERFL register is set to 1 with the BOEIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

EPIE Bit

When the EPF flag in the RSCFDnCFDCmERFL register is set to 1 with the EPIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

EWIE Bit

When the EWF flag in the RSCFDnCFDCmERFL register is set to 1 with the EWIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

BEIE Bit

When the BEF flag in the RSCFDnCFDCmERFL register is set to 1 with the BEIE bit set to 1, an error interrupt request is generated. Modify this bit only in channel reset mode.

RTBO Bit

Setting this bit to 1 in the bus off state forcibly returns the state from the bus off state to the error active state. This bit is automatically cleared to 0. Setting this bit to 1 clears the TEC[7:0] and REC[7:0] bits in the RSCFDnCFDCmSTS register to 00_H and also clears the BOSTS flag in the RSCFDnCFDCmSTS register to 0 (not in bus off state). The other registers remain unchanged. No bus off recovery interrupt request is generated upon return from the bus off state in this case. Use this bit only when the BOM[1:0] bits in the RSCFDnCFDCmCTR register are 00_B (ISO11898-1 compliant).

A delay of up to 1 CAN bit time occurs after the RTBO bit is set to 1 until the RSCFD module transitions to the error active state. Set this bit to 1 in channel communication mode.

CSLPR Bit

Setting this bit to 1 places the channel into channel stop mode.

Clearing this bit to 0 makes the channel exit channel stop mode.

This bit should not be modified in channel communication mode or channel halt mode.

CHMDC[1:0] Bits

These bits are used to select a channel mode (channel communication mode, channel reset mode, or channel halt mode). For details, see **Section 16.6.2, Channel Modes**. Setting the CSLPR bit to 1 in channel reset mode allows transition to channel stop mode. Do not set the CHMDC[1:0] bits to 11_B.

When the CAN module has automatically transitioned to channel halt mode based on the setting of the BOM[1:0] bits, the CHMDC[1:0] bits automatically become 10_B.

16.4.3.3 RSCFDnCFDCmSTS — Channel Status Register (m = 0 to 3)

Access: RSCFDnCFDCmSTS register can be read/written in 32-bit units
 RSCFDnCFDCmSTSL, RSCFDnCFDCmSTSH registers can be read/written in 16-bit units
 RSCFDnCFDCmSTSLL, RSCFDnCFDCmSTSLH, RSCFDnCFDCmSTSHL, RSCFDnCFDCmSTSHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCmSTS: $\langle \text{RSCFDn_base} \rangle + 0008_{\text{H}} + (10_{\text{H}} \times m)$
 RSCFDnCFDCmSTSL: $\langle \text{RSCFDn_base} \rangle + 0008_{\text{H}} + (10_{\text{H}} \times m)$,
 RSCFDnCFDCmSTSH: $\langle \text{RSCFDn_base} \rangle + 000A_{\text{H}} + (10_{\text{H}} \times m)$
 RSCFDnCFDCmSTSLL: $\langle \text{RSCFDn_base} \rangle + 0008_{\text{H}} + (10_{\text{H}} \times m)$,
 RSCFDnCFDCmSTSLH: $\langle \text{RSCFDn_base} \rangle + 0009_{\text{H}} + (10_{\text{H}} \times m)$,
 RSCFDnCFDCmSTSHL: $\langle \text{RSCFDn_base} \rangle + 000A_{\text{H}} + (10_{\text{H}} \times m)$,
 RSCFDnCFDCmSTSHH: $\langle \text{RSCFDn_base} \rangle + 000B_{\text{H}} + (10_{\text{H}} \times m)$

Value after reset: 0000 0005_H

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 16.94 RSCFDnCFDCmSTS Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 24	TEC[7:0]	The transmit error counter (TEC) can be read.
23 to 16	REC[7:0]	The receive error counter (REC) can be read.
15 to 9	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
8	ESIF	Error State Indication Flag 0: No CAN FD message whose ESI bit is recessive has been received. 1: At least one CAN FD message whose ESI bit is recessive has been received.
7	COMSTS	Communication Status Flag 0: Communication is not ready. 1: Communication is ready.
6	RECSTS	Receive Status Flag 0: Bus idle, in transmission or bus off state 1: In reception
5	TRMSTS	Transmit Status Flag 0: Bus idle or in reception 1: In transmission or bus off state
4	BOSTS	Bus Off Status Flag 0: Not in bus off state 1: In bus off state
3	EPSTS	Error Passive Status Flag 0: Not in error passive state 1: In error passive state
2	CSLPSTS	Channel Stop Status Flag 0: Not in channel stop mode 1: In channel stop mode

Table 16.94 RSCFDnCFDCmSTS Register Contents (2/2)

Bit Position	Bit Name	Function
1	CHLTSTS	Channel Halt Status Flag 0: Not in channel halt mode 1: In channel halt mode
0	CRSTSTS	Channel Reset Status Flag 0: Not in channel reset mode 1: In channel reset mode

TEC[7:0] Bits

These bits contain the transmit error counter value. For transmit error counter increment/decrement conditions, see the CAN specification (ISO11898-1).

These bits are cleared to 0 in channel reset mode.

REC[7:0] Bits

These bits contain the receive error counter value. For receive error counter increment/decrement conditions, see the CAN specifications (ISO11898-1).

These bits are cleared to 0 in channel reset mode.

ESIF Flag

When the recessive ESI bit is detected in a successfully received message, this flag is set to 1. In loopback mode or mirror mode, the own transmission message is regarded as a received message. To clear this flag to 0, write 0 to this bit by the program. This bit cannot be set to 1 by the program. If the flag setting (to 1) timing matches the writing 0 (by the program) timing, this flag is set to 1.

This flag is 0 in channel reset mode.

COMSTS Flag

This bit indicates that communication is ready.

This flag becomes 1 when the CAN module has detected 11 consecutive recessive bits after it has transitioned from channel reset mode or channel halt mode to channel communication mode. This flag is cleared to 0 in channel reset mode or channel halt mode.

RECSTS Flag

This flag is set to 1 when reception has started, and is cleared to 0 when the bus has become idle or transmission has started.

TRMSTS Flag

This flag is set to 1 when transmission has started, and is cleared to 0 when the bus has become idle or reception has started. This flag remains 1 in the bus off state.

BOSTS Flag

This flag is set to 1 when the bus off state ($TEC[7:0] > 255$) is entered. It is cleared to 0 when the CAN module has exited the bus off state.

EPSTS Flag

This flag is set to 1 when the RS-CANFD module has entered the error passive state ($(128 \leq \text{TEC}[7:0] \leq 255)$ or $(128 \leq \text{REC}[7:0])$), It is cleared to 0 when the RS-CANFD module has exited the error passive state or has entered channel reset mode.

CSLPSTS Flag

This flag is set to 1 when the CAN module has transitioned to channel stop mode, and is cleared to 0 when the CAN module has returned from channel stop mode.

CHLTSTS Flag

This flag is set to 1 when the CAN module has transitioned to channel halt mode, and is cleared to 0 when the CAN module has returned from channel halt mode.

CRSTSTS Flag

This flag is set to 1 when the CAN module has transitioned to channel reset mode, and is cleared to 0 when the CAN module has transitioned to channel communication mode or channel halt mode. This flag remains 1 when the CAN module transitions from channel reset mode to channel stop mode.

16.4.3.4 RSCFDnCFDCmERFL — Channel Error Flag Register (m = 0 to 3)

Access: RSCFDnCFDCmERFL register can be read/written in 32-bit units
 RSCFDnCFDCmERFLL, RSCFDnCFDCmERFLH registers can be read/written in 16-bit units
 RSCFDnCFDCmERFLLL, RSCFDnCFDCmERFLLH, RSCFDnCFDCmERFLHL, RSCFDnCFDCmERFLHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCmERFL: <RSCFDn_base> + 000C_H + (10_H × m)
 RSCFDnCFDCmERFLL: <RSCFDn_base> + 000C_H + (10_H × m),
 RSCFDnCFDCmERFLH: <RSCFDn_base> + 000E_H + (10_H × m)
 RSCFDnCFDCmERFLLL: <RSCFDn_base> + 000C_H + (10_H × m),
 RSCFDnCFDCmERFLLH: <RSCFDn_base> + 000D_H + (10_H × m),
 RSCFDnCFDCmERFLHL: <RSCFDn_base> + 000E_H + (10_H × m),
 RSCFDnCFDCmERFLHH: <RSCFDn_base> + 000F_H + (10_H × m)

Value after reset: 0000 0000_H

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 16.95 RSCFDnCFDCmERFL Register Contents (1/2)

Bit Position	Bit Name	Function
31	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
30 to 16	CRCREG[14:0]	CRC Calculation Data (CRC length:15 bits) A CRC value calculated based on the transmit message or receive message is indicated.
15	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
14	ADERR	ACK Delimiter Error Flag 0: No ACK delimiter error is detected. 1: ACK delimiter error is detected.
13	B0ERR	Dominant Bit Error Flag 0: No dominant bit error is detected. 1: Dominant bit error is detected.
12	B1ERR	Recessive Bit Error Flag 0: No recessive bit error is detected. 1: Recessive bit error is detected.
11	CERR	CRC Error Flag 0: No CRC error is detected. 1: CRC error is detected.
10	AERR	ACK Error Flag 0: No ACK error is detected. 1: ACK error is detected.
9	FERR	Form Error Flag 0: No form error is detected. 1: Form error is detected.

Table 16.95 RSCFDnCFDCmERFL Register Contents (2/2)

Bit Position	Bit Name	Function
8	SERR	Stuff Error Flag 0: No stuff error is detected. 1: Stuff error is detected.
7	ALF	Arbitration-lost Flag 0: No arbitration-lost is detected. 1: Arbitration-lost is detected.
6	BLF	Bus Lock Flag 0: No channel bus is detected. 1: Channel bus is detected.
5	OVLf	Overload Flag 0: No overload is detected. 1: Overload is detected.
4	BORF	Bus Off Recovery Flag 0: No bus off recovery is detected. 1: Bus off recovery is detected.
3	BOEF	Bus Off Entry Flag 0: No bus off entry is detected. 1: Bus off entry is detected.
2	EPF	Error Passive Flag 0: No error passive is detected. 1: Error passive is detected.
1	EWf	Error Warning Flag 0: No error warning is detected. 1: Error warning is detected.
0	BEF	Bus Error Flag 0: No channel bus error is detected. 1: Channel bus error is detected.

See the CAN specification (ISO11898-1) for a description of error occurrence conditions. To clear each flag of this register, the program must write a 0 to the corresponding bit. These flags cannot be set to 1 by the program. If any of these flags is set to 0 at the same time that the program writes 0 to the flag, the flag is still set to 1. The channel reset mode transition clears all of these flags to 0.

If the ERRD bit in the RSCFDnCFDCmCTR register is set to 0 (ie, only the flags for the first error event are displayed) and an error related to bits 14 to 8 of RSCFDnCFDCmERFL is detected, the flag bits are only set by the error event if bits 14 to 8 were all 0 at the when time the error occurred.

CRCREG[14:0] Flag

When the CTME bit in the RSCFDnCFDCmCTR register is set to 1 (communication test mode is enabled), if transmit or receive message is a classical CAN frame (CRC length = 15 bits), this flag is updated and the CRC value calculated based on the message can be read. When a CAN FD frame is sent or received, the value of CRCREG[20:0] bits in the RSCFDnCFDCmFDCRC register is updated. When the CTME bit is set to 0 (communication test mode is disabled), these bits are always read as 0.

ADERR Flag

This flag is set to 1 when a form error has been detected in the ACK delimiter during transmission.

B0ERR Flag

This flag is set to 1 when a recessive bit has been detected though a dominant bit was transmitted.

B1ERR Flag

This flag is set to 1 when a dominant bit has been detected though a recessive bit was transmitted.

CERR Flag

This flag is set to 1 when a CRC error has been detected.

AERR Flag

This flag is set to 1 when an ACK error has been detected.

FERR Flag

This flag is set to 1 when a form error has been detected.

SERR Flag

This flag is set to 1 when a stuff error has been detected.

ALF Flag

This flag is set to 1 when an arbitration-lost has been detected.

BLF Flag

This flag is set to 1 when 32 consecutive dominant bits have been detected on the CAN bus in channel communication mode. After that, detection of a dominant lock is restarted when either of the following conditions is met.

- A recessive bit is detected after the BLF bit has been cleared from 1 to 0.
- The CAN module transitions to channel reset mode and returns to channel communication mode after the BLF bit has been cleared from 1 to 0.

OVLf Flag

This flag is set to 1 when the overload frame transmit condition has been detected when performing reception or transmission.

BORF Flag

This flag is set to 1 when 11 consecutive recessive bits have been detected 128 times and the CAN module returns from the bus off state. However, this flag is not set to 1 if the CAN module returns from the bus off state in any of the following ways before 11 consecutive recessive bits are detected 128 times.

- The CHMDC[1:0] bits in the RSCFDnCFDCmCTR register are set to 01_B (channel reset mode).
- The RTBO bit in the RSCFDnCFDCmCTR register is set to 1 (forcible return from the bus off state is made).
- The BOM[1:0] bits in the RSCFDnCFDCmCTR register are set to 01_B (transition to channel halt mode at bus off entry).
- The CHMDC[1:0] bits in the RSCFDnCFDCmCTR register are set to 10_B (channel halt mode) before 11 consecutive recessive bits are detected 128 times with the BOM[1:0] bits set to 11_B (transition to channel halt mode upon a request from the program during bus off).

BOEF Flag

This flag is set to 1 when the bus off state is reached (TEC[7:0] value > 255). This flag is also set to 1 if the bus off state is reached when the BOM[1:0] bits in the RSCFDnCFDCmCTR register (m = 0 to 3) set to 01_B (transition to channel halt mode at bus off entry).

EPF Flag

This flag becomes 1 when the error passive state is reached (REC[7:0] or TEC[7:0] value > 127). This flag becomes 1 only when the REC[7:0] or TEC[7:0] value first exceeds 127. Therefore, if the program writes 0 to this flag while the value of REC[7:0] or TEC[7:0] remains over 127, this bit is not set to 1 until both REC [7:0] and TEC[7:0] values become 127 or less and then the REC[7:0] or TEC[7:0] value exceeds 127 again.

EWF Flag

This flag is set to 1 only when the REC[7:0] or TEC[7:0] value first exceeds 95. Therefore, if the program writes 0 to this flag while the value of REC[7:0] or TEC[7:0] remains over 95, this bit is not set to 1 until both REC [7:0] and TEC[7:0] values become 95 or less and then the REC[7:0] or TEC[7:0] value exceeds 95 again.

BEF Flag

This flag is set to 1 when any one of the ADERR, B0ERR, B1ERR, CERR, AERR, FERR, and SERR flags in the RSCFDnCFDCmERFL register is set to 1.

NOTE

To clear the flag of this register to 0, use a store instruction to write "0" to the given flag and "1" to the other flags.

16.4.3.5 RSCFDnCFDCmDCFG — Channel Data Bit Rate Configuration register (m = 0 to 3)

Access: RSCFDnCFDCmDCFG register can be read/written in 32-bit units
 RSCFDnCFDCmDCFGL, RSCFDnCFDCmDCFGLH registers can be read/written in 16-bit units
 RSCFDnCFDCmDCFGLL, RSCFDnCFDCmDCFGLH, RSCFDnCFDCmDCFGLH, RSCFDnCFDCmDCFGLH,
 RSCFDnCFDCmDCFGLH registers can be read/written in 8-bit units

Address: RSCFDnCFDCmDCFG: <RSCFDn_base> + 0500_H + (20_H × m)
 RSCFDnCFDCmDCFGL: <RSCFDn_base> + 0500_H + (20_H × m),

Table 16.96 RSCFDnCFDCmDCFG Register Contents (2/2)

Bit Position	Bit Name	Function
19 to 16	DTSEG1[3:0]	Data Bit Rate Time Segment 1 Control b19 b18 b17 b16 0 0 0 0: Setting is prohibited for channels for CAN communications. 0 0 0 1: 2 Tq 0 0 1 0: 3 Tq 0 0 1 1: 4 Tq 0 1 0 0: 5 Tq 0 1 0 1: 6 Tq 0 1 1 0: 7 Tq 0 1 1 1: 8 Tq 1 0 0 0: 9 Tq 1 0 0 1: 10 Tq 1 0 1 0: 11 Tq 1 0 1 1: 12 Tq 1 1 0 0: 13 Tq 1 1 0 1: 14 Tq 1 1 1 0: 15 Tq 1 1 1 1: 16 Tq
15 to 8	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
7 to 0	DBRP[7:0]	Data Bit Rate Prescaler Division Ratio Setting When the set value = P (0 to 255), the data bit rate prescaler divides fCAN by (P + 1).

Modify the RSCFDnCFDCmDCFG register in channel reset mode or channel halt mode. Set this register in channel reset mode, and then transition to channel communication mode or channel halt mode. When only classical CAN frames are used in CAN FD mode, set the RSCFDnCFDCmDCFG register to the value equal to the set RSCFDnCFDCmNCFG register value. For the description and settings of bit timing parameters, see **Section 16.11.1, Initial Settings**.

DSJW[2:0] Bits

These bits specify the resynchronization jump width of data bit rate as a Tq value. A value of 1 to 8 Tq is settable. Specify a value equal to or smaller than the DTSEG2[2:0] bits value.

DTSEG2[2:0] Bits

These bits are used to specify a Tq value for the length of phase segment 2 (PHASE_SEG2) of nominal bit rate.

Allowed values are 2 Tq to 8 Tq, inclusive.

Set a value smaller than the value of the DTSEG1[3:0] bits.

DTSEG1[3:0] Bits

These bits specify the total length of propagation segment (PROP_SEG) and phase segment 1 (PHASE_SEG1) of data bit rate as a Tq value.

A value of 2 to 16 Tq is settable.

DBRP[7:0] Bits

The clock obtained by dividing the CAN clock (f_{CAN}) by the data bit rate prescaler ($(DBRP[7:0] + 1)$) becomes $CANmTq(D)$ clock ($f_{CANTQ(D)m}$). One clock of the $CANmTq(D)$ clock becomes one Time Quantum (Tq).

Be sure to specify the same value for both $NBRP[9:0]$ and $DBRP[7:0]$.

To specify different values for the nominal bit rate and the data bit rate, change the values of the $RSCFDnCFDCmNCFG.NTSEG1$ and $NTSEG2$ bits and $RSCFDnCFDCmDCFG.DTSEG1$ and $DTSEG2$ bits, respectively.

When the $TDCE$ bit is set to 1 (Transmitter delay compensation is enabled) in the $RSCFDnCFDCmFDCFG$ register, set the equal value of 1 or less to the bits $NBRP[9:0]$ and $DBRP[7:0]$.

16.4.3.6 RSCFDnCFDCmFDCFG — Channel CAN FD Configuration Register (m = 0 to 3)

Access: RSCFDnCFDCmFDCFG register can be read/written in 32-bit units
 RSCFDnCFDCmFDCFGL, RSCFDnCFDCmFDCFGH registers can be read/written in 16-bit units
 RSCFDnCFDCmFDCFGLL, RSCFDnCFDCmFDCFGLH, RSCFDnCFDCmFDCFGHL,
 RSCFDnCFDCmFDCFGHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCmFDCFG: <RSCFDn_base> + 0504_H + (20_H × m)
 RSCFDnCFDCmFDCFGL: <RSCFDn_base> + 0504_H + (20_H × m),
 RSCFDnCFDCmFDCFGH: <RSCFDn_base> + 0506_H + (20_H × m)
 RSCFDnCFDCmFDCFGLL: <RSCFDn_base> + 0504_H + (20_H × m),
 RSCFDnCFDCmFDCFGLH: <RSCFDn_base> + 0505_H + (20_H × m),
 RSCFDnCFDCmFDCFGHL: <RSCFDn_base> + 0506_H + (20_H × m),
 RSCFDnCFDCmFDCFGHH: <RSCFDn_base> + 0507_H + (20_H × m)

27	TMME	Transmit Buffer Merge Mode Enable 0: Transmit buffer merge mode is disabled. 1: Transmit buffer merge mode is enabled.
26	GWBR S	Gateway BRS 0: A frame is transmitted with the BRS bit in the received frame set to 0. 1: A frame is transmitted with the BRS bit in the received frame set to 1.
25	GWDFD	Gateway FDF 0: A frame is transmitted regarding the received frame as a classical CAN frame. 1: A frame is transmitted regarding the received frame as a CAN FD frame.
24	GWEN	CAN-CAN FD Gateway Enable 0: The CAN-CAN FD gateway is disabled. 1: The CAN-CAN FD gateway is enabled.
23	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
22 to 16	TDCO[6:0]	Transmitter Delay Compensation Offset These bits are set to the transmitter delay compensation offset value.
15 to 11	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.

Table 16.97 RSCFDnCFDCmFDCFG Register Contents (2/2)

Bit Position	Bit Name	Function
10	ESIC	Error State Display Mode Select 0: Always displays the node error state. 1: When the node is not in the error passive state: Displays the message buffer error state. When the node is in the error passive state: Displays the node error state.
9	TDCE	Transmitter Delay Compensation Enable 0: Transmitter delay compensation is disabled. 1: Transmitter delay compensation is enabled.
8	TDCOC	Transmitter Delay Compensation Measurement Select 0: Measurement and offset 1: Only offset
7 to 3	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
2 to 0	EOCCFG[2:0]	Error Occurrence Counting Method Select b2 b1 b0 0 0 0: All transmit messages and receive messages 0 0 1: All transmit messages 0 1 0: All receive messages 0 1 1: Setting prohibited 1 0 0: Only data phase of transmitted or received CAN FD message 1 0 1: Only data phase of transmitted CAN FD message 1 1 0: Only data phase of received CAN FD message 1 1 1: Setting prohibited

REFE Bit

Setting this bit to 1 enables reception data edge filtering when the idle condition is detected, and a dominant level with less than 2 time quanta is ignored. A dominant level with more than or equal to 2 time quanta is detected as an edge.

Modify this bit only in channel reset mode.

FDOE Bit

Setting this bit to 1 enables FD-only mode. When data is transmitted, a CAN FD frame will be sent regardless of the setting of the CFFDF bit in the RSCFDnCFDCFFDCSTSk register or the TMFDF bit in the RSCFDnCFDTMFDCSTRp register. When a Classical CAN frame is received, a form error is detected. Modify this bit only in channel reset mode.

TMME Bit

Setting this bit to 1 enables transmit buffer merge mode. Modify this bit only in channel reset mode or channel halt mode.

GWBRs Bit

When the GWEN bit is 1, the BRS bit in a CAN FD frame to be transmitted by the gateway function is set. When the GWFDF bit is set to 0, write 0 to this bit. Modify this bit only in channel reset mode.

GWFDF Bit

When the GWEN bit is 1, the FDF bit in a CAN FD frame to be transmitted by the gateway function is set. Modify this bit only in channel reset mode.

GWEN Bit

This bit is used to control the operation of the transmit/receive FIFO buffer with the CFM[1:0] bits in the RSCFDnCFDCFCCK register set to 10_B (gateway mode).

Setting this bit to 1 enables the CAN-CAN FD gateway, enabling transmission in a format different from that of frames received by the gateway function. Received frames are replaced in accordance with the settings of the GWDFD bit and the GWBRS bit. When the DLC value in the received classical CAN frame is 1001_B or more and the GWDFD bit is 1 (CAN FD frame), the DLC value is replaced with 1000_B.

While this bit is 1, do not perform routing the following frames by using the gateway function.

- CAN FD frames with a payload length of more than 8 bytes
- Remote frames

While this bit is 1, the following frame should be transmitted in the channel by setting of GWDFD.

- When GWDFD bit is set to 0, only classical CAN frame should be transmitted.
- When GWDFD bit is set to 1, only CAN FD frame should be transmitted.

Modify this bit only in channel reset mode.

Table 16.98 shows the settings and formats of transmit frame and receive frame while the CAN-CAN FD gateway is enabled.

Table 16.98 Operation when the CAN-CAN FD Gateway is Enabled

Receive Frame			GWDFD Bit	Transmit Frame		
Format	BRS Bit	Received DLC Value		Format	BRS Bit	DLC Value to be Transmitted
Classical CAN	None	DLC ≤ 1000 _B	0	Classical CAN	None	Not replaced
		DLC > 1000 _B				
CAN FD	Arbitrary	DLC ≤ 1000 _B				
Classical CAN	None	DLC ≤ 1000 _B	1	CAN FD	According to GWBRS bit setting	Not replaced
		DLC > 1000 _B				Replaced with 1000 _B
CAN FD	Arbitrary	DLC ≤ 1000 _B				Not replaced

TDCO[6:0] Bits

These bits are set to the SSP offset value. How to use this value depends on the TDCOC bit in the RSCFDnCFDCmFDCFG register.

When the TDCOC bit is 0, the transmitter delay compensation result equals to the total value of the measured delay value and the TDCO[6:0] value (rounded to the nearest integer T_q).

When the TDCOC bit is 1, the transmitter delay compensation result equals to the TDCO[6:0] value.

The SSP offset value = (set value of TDCO[6:0] bits + 1).

Modify these bits only in channel reset mode or channel halt mode.

ESIC Bit

When the ESIC bit is set to 1, if the channel is in the error active state, the ESI bit value (CFESI bit in the RSCFDnCFDCFFDCSTSk register or TMESI bit in the RSCFDnCFDTMFDCTRp register) set in the transmit/receive FIFO buffer or transmit buffer is transmitted as an ESI bit value of the transmit

message. When the channel is in the error passive state or the ESIC bit is 0, the channel status is transmitted as an ESI bit value. Modify this bit only in channel reset mode or channel halt mode.

Table 16.99 ESI Value to Be Transmitted

ESIC Bit	Channel Status	ESI Value to be Transmitted
0	Error active	0 (error active node)
	Error passive	1 (error passive node)
1	Error active	ESI value set in the transmit/receive FIFO buffer or transmit buffer CFESI bit in the RSCFDnCFDCFFDCSTSk register or TMESI bit in the RSCFDnCFDTMFDCTRp register)
	Error passive	1 (error passive node)

TDCE Bit

Setting this bit to 1 enables transmitter delay compensation. Modify this bit only in channel reset mode or channel halt mode.

TDCOC Bit

When this bit is 0, the SSP position is defined by the total of the measured delay value and the SSP offset value (fixed value).

When this bit is 1, the SSP position is defined only by the SSP offset value.

Modify this bit only in channel reset mode or channel halt mode.

EOCCFG[2:0] Bits

These bits are used to select a frame format and a transmission/reception direction when the error occurrence counter counts CAN bus errors.

Modify these bits only in channel reset mode or channel halt mode.

16.4.3.7 RSCFDnCFDCmFDCTR — Channel CAN FD Control Register (m = 0 to 3)

Access: RSCFDnCFDCmFDCTR register can be read/written in 32-bit units
 RSCFDnCFDCmFDCTRL, RSCFDnCFDCmFDCTRH registers can be read/written in 16-bit units
 RSCFDnCFDCmFDCTRL, RSCFDnCFDCmFDCTRLH, RSCFDnCFDCmFDCTRHL,
 RSCFDnCFDCmFDCTRHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCmFDCTR: <RSCFDn_base> + 0508_H + (20_H × m)
 RSCFDnCFDCmFDCTRL: <RSCFDn_base> + 0508_H + (20_H × m),
 RSCFDnCFDCmFDCTRH: <RSCFDn_base> + 050A_H + (20_H × m)
 RSCFDnCFDCmFDCTRL: <RSCFDn_base> + 0508_H + (20_H × m),
 RSCFDnCFDCmFDCTRLH: <RSCFDn_base> + 0509_H + (20_H × m),
 RSCFDnCFDCmFDCTRHL: <RSCFDn_base> + 050A_H + (20_H × m),
 RSCFDnCFDCmFDCTRHH: <RSCFDn_base> + 050B_H + (20_H × m)

Value after reset: 0000 0000_H

Table 16.100 RSCFDnCFDCmFDCTR Register Contents

Bit Position	Bit Name	Function
31 to 2	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
1	SOCCLR	Successful Occurrence Counter Clear Setting the SOCCLR bit to 1 clears the successful occurrence counter. This bit is always read as 0.
0	EOCCLR	Error Occurrence Counter Clear Setting the EOCCLR bit to 1 clears the error occurrence counter. This bit is always read as 0.

SOCCLR Bit

Setting this bit to 1 clears the successful occurrence counter (SOC[7:0] bits in the RSCFDnCFDCmFDSTS register). This bit is automatically cleared to 0.

EOCCLR Bit

Setting this bit to 1 clears the error occurrence counter (EOC[7:0] bits in the RSCFDnCFDCmFDSTS register). This bit is automatically cleared to 0.

16.4.3.8 RSCFDnCFDCmFDSTS — Channel CAN FD Status Register (m = 0 to 3)

Access: RSCFDnCFDCmFDSTS register can be read/written in 32-bit units
 RSCFDnCFDCmFDSTSL, RSCFDnCFDCmFDSTSH registers can be read/written in 16-bit units
 RSCFDnCFDCmFDSTSL, RSCFDnCFDCmFDSTSLH, RSCFDnCFDCmFDSTSHL,
 RSCFDnCFDCmFDSTSHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCmFDSTS: <RSCFDn_base> + 050C_H + (20_H × m)
 RSCFDnCFDCmFDSTSL: <RSCFDn_base> + 050C_H + (20_H × m),

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 16.101 RSCFDnCFDCmFDSTS Register Contents

Bit Position	Bit Name	Function
31 to 24	SOC[7:0]	Successful Occurrence Counter The successful occurrence counter value can be read.
23 to 16	EOC[7:0]	Error Occurrence Counter The error occurrence counter value can be read.
15 to 10	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
9	SOCO	Successful Occurrence Counter Overflow Flag 0: The successful occurrence counter does not overflow. 1: The successful occurrence counter has overflowed.
8	EOCO	Error Occurrence Counter Overflow Flag 0: The error occurrence counter does not overflow. 1: The error occurrence counter has overflowed.
7	TDCVF	Transmitter Delay Compensation Violation Flag 0: No transmitter delay compensation violation is present. 1: A transmitter delay compensation violation is present.
6 to 0	TDCR[6:0]	Transmitter Delay Compensation Result Status The transmitter delay compensation result can be read.

SOC[7:0] Bits

These bits show the successful occurrence counter value. The successful occurrence counter is incremented upon completion of message reception or transmission without an error. This counter stops counting when it reaches FF_H. In loopback mode, this counter is incremented twice.

These bits are cleared to 0 by writing 1 to the SOCCLR bit in the RSCFDnCFDCmCTR register. These bits are 0 in channel reset mode.

EOC[7:0] Bits

These bits show the error occurrence counter value. The error occurrence counter is incremented each time an error occurs according to the condition specified by the EOCCFG[2:0] bits in the RSCFDnCFDCmFDCFG register. This counter stops counting when it reaches FF_H.

These bits are cleared to 0 by writing 1 to the EOCCLR bit in the RSCFDnCFDCmCTR register. These bits are 0 in channel reset mode.

SOCO Flag

This bit indicates that successful occurrence counter overflow has occurred.

This flag is set to 1 when message reception or transmission is completed while the SOC[7:0] value has reached FF_H. This flag is 0 in channel reset mode.

EOCO Flag

This bit indicates that error occurrence counter overflow has occurred.

This flag is set to 1 when a CAN bus error is detected under the condition specified by the EOCCFG[2:0] bits in the RSCFDnCFDCmFDCFG register when the EOC[7:0] value has reached FF_H. This flag is 0 in channel reset mode.

TDCVF Flag

This bit indicates violation of transmitter delay compensation.

The transmit data is compared with the reception CAN bus level delayed due to the transceiver's loop delay. This delay changes due to physical factors such as temperature. Because the TDCR[6:0] flags are updated for each message, temporary maximum delay cannot be confirmed.

This bit is set to 1 when the transmitter delay compensation exceeds the maximum compensation $3 \text{ CANm bit times} - 2 \text{ fCAN}$ (CANm bit time is the value of data bit rate).

This flag is 0 in channel reset mode.

TDCR[6:0] Flags

These bits indicate the transmitter delay compensation result as a multiple of CAN clock frequency (fCAN).

This result depends on the settings of the TDCOC bit and TDCO[6:0] bits in the RSCFDnCFDCmFDCFG register.

This flag is updated at a falling edge between the FDF bit and res bit when the TDCE bit in the RSCFDnCFDCmFDCFG register is set to 1 (transmitter delay compensation enabled) and also the TDCOC bit in this register is set to 0 (measurement and offset).

This flag is 0 in channel reset mode.

NOTE

To clear the flag of this register to 0, use a store instruction to write 0 to the given flag and 1 to the other flags.

16.4.3.9 RSCFDnCFDCmFDCRC — Channel CAN FD CRC Register (m = 0 to 3)

Access: RSCFDnCFDCmFDCRC register can be read only in 32-bit units
 RSCFDnCFDCmFDCRCL, RSCFDnCFDCmFDCRCH registers can be read only in 16-bit units
 RSCFDnCFDCmFDCRCLL, RSCFDnCFDCmFDCRCLH, RSCFDnCFDCmFDCRCHL,
 RSCFDnCFDCmFDCRCHH registers can be read only in 8-bit units

Address: RSCFDnCFDCmFDCRC: <RSCFDn_base> + 0510_H + (20_H × m)
 RSCFDnCFDCmFDCRCL: <RSCFDn_base> + 0510_H + (20_H × m),
 RSCFDnCFDCmFDCRCH: <RSCFDn_base> + 0512_H + (20_H × m)
 RSCFDnCFDCmFDCRCLL: <RSCFDn_base> + 0510_H + (20_H × m),
 RSCFDnCFDCmFDCRCLH: <RSCFDn_base> + 0511_H + (20_H × m),
 RSCFDnCFDCmFDCRCHL: <RSCFDn_base> + 0512_H + (20_H × m),
 RSCFDnCFDCmFDCRCHH: <RSCFDn_base> + 0513_H + (20_H × m)

Value after reset: 0000 0000_H

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 16.102 RSCFDnCFDCmFDCRC Register Contents

Bit Position	Bit Name	Function
31 to 28	Reserved	When read, the value after reset is returned.
27 to 24	SCNT[3:0]	Stuff Count These bits indicate a value of the stuff count in a CAN FD frame. Bits 27 to 25 indicate the Gray-coded value of the stuff bit count module 8 in the transmitted/received frames. Bit 24 indicates an even parity value of bits 27 to 25.
23 to 21	Reserved	When read, the value after reset is returned.
20 to 0	CRCREG[20:0]	CRC Calculation Data (CRC Length: 17 Bit or 21 Bit) These bits show the CRC value calculated based on the transmit message or receive message. When the CRC length is 17 bits, bits b20 to b17 are read as 0.

SCNT[3:0] Flags

When the CTME bit in the RSCFDnCFDCmCTR register is set to 1 (communication test mode enabled), a stuff count bit value of the CAN FD frame can be read if a message transmitted/received is a CAN FD frame. When the CTME bit is 0 (communication test mode disabled), these flags are always read as 0. The value of these flags is updated at the first bit in the CRC field of the CAN FD frame. These flags are cleared to 0 in channel reset mode.

CRCREG[20:0] Flag

When the CTME bit in the RSCFDnCFDCmCTR register is 1 (communication test mode enabled), if transmit or receive message is a CAN FD frame (CRC length = 17 or 21 bits), these flags are updated and the CRC value calculated based on the message can be read. When the CRC length of the message is 17 bits, bits b20 to b17 are always read as 0. When a classical CAN frame is transmitted or received,

the CRCREG[14:0] value in the RSCFDnCFDCmERFL register is updated. When the CTME bit is 0 (communication test mode disabled), these bits are always read as 0.

16.4.4 Details of Global-Related Registers

16.4.4.1 RSCFDnCFDGCFCG — Global Configuration Register

Access: RSCFDnCFDGCFCG register can be read/written in 32-bit units
 RSCFDnCFDGCFCGL, RSCFDnCFDGCFCGH registers can be read/written in 16-bit units
 RSCFDnCFDGCFCGLL, RSCFDnCFDGCFCGLH, RSCFDnCFDGCFCGHL, RSCFDnCFDGCFCGHH registers
 can be read/written in 8-bit units

Address: RSCFDnCFDGCFCG: <RSCFDn_base> + 0084_H
 RSCFDnCFDGCFCGL: <RSCFDn_base> + 0084_H, RSCFDnCFDGCFCGH: <RSCFDn_base> + 0086_H
 RSCFDnCFDGCFCGLL: <RSCFDn_base> + 0084_H, RSCFDnCFDGCFCGLH: <RSCFDn_base> + 0085_H,
 RSCFDnCFDGCFCGHL: <RSCFDn_base> + 0086_H, RSCFDnCFDGCFCGHH: <RSCFDn_base> + 0087_H

Value after reset: 0000 0000_H

11 to 8	TSP[3:0]	Timestamp Clock Source Division b11 b10 b9 b8 0 0 0 0: Not divided 0 0 0 1: Divided by 2 0 0 1 0: Divided by 4 0 0 1 1: Divided by 8 0 1 0 0: Divided by 16 0 1 0 1: Divided by 32 0 1 1 0: Divided by 64 0 1 1 1: Divided by 128 1 0 0 0: Divided by 256 1 0 0 1: Divided by 512 1 0 1 0: Divided by 1024 1 0 1 1: Divided by 2048 1 1 0 0: Divided by 4096 1 1 0 1: Divided by 8192 1 1 1 0: Divided by 16384 1 1 1 1: Divided by 32768
7, 6	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
5	CMPOC	Payload Overflow Mode Select 0: No message is stored. 1: Messages are stored and payloads exceeding the buffer size are discarded.
4	DCS	CAN Clock Source Select 0: clkc 1: clk_xincan
3	MME	Mirror Function Enable 0: Mirror function is disabled. 1: Mirror function is enabled.
2	DRE	DLC Replacement Enable 0: DLC replacement is disabled. 1: DLC replacement is enabled.
1	DCE	DLC Check Enable 0: DLC check is disabled. 1: DLC check is enabled.
0	TPRI	Transmit Priority Select 0: ID priority 1: Transmit buffer number priority

Note 1. When specifying pclk/2 as the timestamp counter count source, set bits TSBTCS[2:0] to 000_B.

Modify the RSCFDnCFDGCFG register only in global reset mode.

ITRCP[15:0] Bits

These bits are used to set a clock source division value of the interval timer for FIFO buffers. See **Section 16.8.3.1, Interval Transmission Function**.

TSBTCS[2:0] Bits

When the TSSS bit is 1, these bits are used to select the channel of the nominal bit time clock that will be the clock source of the timestamp counter. However, do not select the channel that handles the CAN FD frames.

TSSS Bit

This bit is used to select a clock source of the timestamp counter. Select pclk if there is no channel that handles only classical CAN frames.

TSP[3:0] Bits

A clock obtained by dividing the clock source selected with the TSBTCS[2:0] bits and TSSS bit according to the TSP[3:0] bits is used as the timestamp counter count source.

CMPOC Bit

This bit is used to select operation in case the payload length of received message exceeds the payload storage size of the storage buffer.

When this bit is 0, the received message in which the payload overflows is not stored in the buffer.

When this bit is 1, the received message in which the payload overflows is stored in the buffer, and depending on the DRE bit the received DLC value or the DLC value of the receive rule is stored in the buffer. At this time, payloads exceeding the buffer's payload storage size are discarded.

The buffer's payload storage size is set by the following bits.

- Receive buffer: RMPLS[1:0] bits in the RSCFDnCFDRMNB register
- Receive FIFO buffer: RFPLS[2:0] bits in the RSCFDnCFDRFCCx register
- Transmit/receive FIFO buffer: CFPLS[2:0] bits in the RSCFDnCFDCFCCK register

DCS Bit

When this bit is set to 0, clk is used as the clock source of the CAN clock (fCAN).

When this bit is set to 1, clk_xincan is used as the clock source of the CAN clock (fCAN).

MME Bit

Setting this bit to 1 makes the mirror function available.

DRE Bit

When the DRE bit is set to 1, the DLC value of the receive rule is stored in the buffer instead of the DLC value of the received message after the DLC value has passed through the DLC filter. In this case, a value of 00_H is stored in each data byte beyond the DLC value of the receive rule.

The DLC replacement function is only available when the DCE bit is set to 1 (DLC check is enabled).

DCE Bit

Setting this bit to 1 makes the DLC check function available. When disabling the DLC check function, set the GAFLDLC[3:0] bits in the RSCFDnCFDGAFLP0_j register to 0000_B before clearing the DCE bit in the RSCFDnCFDGCFCFG register to 0.

TPRI Bit

This bit is used to set the transmit priority.

When this bit is set to 0, ID priority is selected and the transmit priority complies with the CAN bus arbitration rule (ISO11898-1 specifications). When this bit is set to 1, transmit buffer number priority is selected and the lowest transmit buffer number of those has the highest priority.

While the transmit queue is in use, this bit should be set to 0.

16.4.4.2 RSCFDnCFDGCTR — Global Control Register

Access: RSCFDnCFDGCTR register can be read/written in 32-bit units
 RSCFDnCFDGCTRL, RSCFDnCFDGCTRH registers can be read/written in 16-bit units
 RSCFDnCFDGCTRLL, RSCFDnCFDGCTRLLH, RSCFDnCFDGCTRHL, RSCFDnCFDGCTRHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGCTR: <RSCFDn_base> + 0088_H
 RSCFDnCFDGCTRL: <RSCFDn_base> + 0088_H, RSCFDnCFDGCTRH: <RSCFDn_base> + 008A_H
 RSCFDnCFDGCTRLL: <RSCFDn_base> + 0088_H, RSCFDnCFDGCTRLLH: <RSCFDn_base> + 0089_H,
 RSCFDnCFDGCTRHL: <RSCFDn_base> + 008A_H, RSCFDnCFDGCTRHH: <RSCFDn_base> + 008B_H

Value after reset: 0000 0005_H

Table 16.104 RSCFDnCFDGCTR Register Contents

Bit Position	Bit Name	Function
31 to 17	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
16	TSRST	Timestamp Counter Reset Setting the TSRST bit to 1 resets the timestamp counter. This bit is always read as 0.
15 to 12	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
11	CMPOFIE	Payload Overflow Interrupt Enable 0: A payload overflow interrupt is disabled. 1: A payload overflow interrupt is enabled.
10	THLEIE	Transmit History Buffer Overflow Interrupt Enable 0: Transmit history buffer overflow interrupt is disabled. 1: Transmit history buffer overflow interrupt is enabled.
9	MEIE	FIFO Message Lost Interrupt Enable 0: FIFO message lost interrupt is disabled. 1: FIFO message lost interrupt is enabled.
8	DEIE	DLC Error Interrupt Enable 0: DLC error interrupt is disabled. 1: DLC error interrupt is enabled.
7 to 3	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
2	GSLPR	Global Stop Mode 0: Other than global stop mode 1: Global stop mode
1, 0	GMDC[1:0]	Global Mode Select b1 b0 0 0: Global operating mode 0 1: Global reset mode 1 0: Global test mode 1 1: Setting prohibited

TSRST Bit

This bit is used to reset the timestamp counter. When this bit is set to 1, the RSCFDnCFDGTSC register is cleared to 0000_H.

CMPOFIE Bit

When the CMPOF flag in the RSCFDnCFDGERFL register is set to 1 after the CMPOFIE bit is set to 1, an interrupt request occurs. Modify this bit only in global reset mode.

THLEIE Bit

When the THLEIE bit is set to 1 and the THLES flag in the RSCFDnCFDGERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode.

MEIE Bit

When the MEIE bit is set to 1 and the MES flag in the RSCFDnCFDGERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode.

DEIE Bit

When the DEIE bit is set to 1 and the DEF flag in the RSCFDnCFDGERFL register is set to 1, an interrupt request is generated. Modify this bit only in global reset mode.

GSLPR Bit

Setting this bit to 1 places the RSCFD module into global stop mode.
Clearing this bit to 0 makes the RSCFD module leave from global stop mode.
This bit should not be modified in global operating mode or global test mode.

GMDC[1:0] Bits

These bits are used to select the mode of entire RS-CANFD module (global operating mode, global reset mode, or global test mode). For details, see **Section 16.6.1, Global Modes**. Setting the GSLPR bit to 1 when in global reset mode places the RS-CANFD module into global stop mode.

16.4.4.3 RSCFDnCFDGSTS — Global Status Register

Access: RSCFDnCFDGSTS register can be read only in 32-bit units
 RSCFDnCFDGSTSL, RSCFDnCFDGSTSH registers can be read only in 16-bit units
 RSCFDnCFDGSTSL, RSCFDnCFDGSTSLH, RSCFDnCFDGSTSHL, RSCFDnCFDGSTSHH registers can be read only in 8-bit units

Address: RSCFDnCFDGSTS: <RSCFDn_base> + 008C_H
 RSCFDnCFDGSTSL: <RSCFDn_base> + 008C_H, RSCFDnCFDGSTSH: <RSCFDn_base> + 008E_H
 RSCFDnCFDGSTSL: <RSCFDn_base> + 008C_H, RSCFDnCFDGSTSLH: <RSCFDn_base> + 008D_H,
 RSCFDnCFDGSTSHL: <RSCFDn_base> + 008E_H, RSCFDnCFDGSTSHH: <RSCFDn_base> + 008F_H

Value after reset: 0000 000D_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	GRAMINIT	GSLPSTS	GHLTSTS	GRSTSTS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 16.105 RSCFDnCFDGSTS Register Contents

Bit Position	Bit Name	Function
31 to 4	Reserved	When read, the value after reset is returned.
3	GRAMINIT	CAN RAM Initialization Status Flag 0: CAN RAM initialization is completed. 1: CAN RAM initialization is ongoing.
2	GSLPSTS	Global Stop Status Flag 0: Not in global stop mode 1: In global stop mode
1	GHLTSTS	Global Test Status Flag 0: Not in global test mode 1: In global test mode
0	GRSTSTS	Global Reset Status Flag 0: Not in global reset mode 1: In global reset mode

GRAMINIT Flag

This flag indicates the initialization status of the CAN RAM.

This flag is set to 1 after the MCU has been reset, and is cleared to 0 when CAN RAM initialization is completed.

GSLPSTS Flag

This flag is set to 1 when the CAN module has transitioned to global stop mode, and is cleared to 0 when the CAN module has returned from global stop mode.

GHLTSTS Flag

This flag is set to 1 when the CAN module has transitioned to global test mode, and is cleared to 0 when the CAN module has exited global test mode.

GRSTSTS Flag

This flag is set to 1 when the CAN module has transitioned to global reset mode, and is cleared to 0 when the CAN module has exited global reset mode. This flag remains 1 even when the CAN module has transitioned from global reset mode to global stop mode.

16.4.4.4 RSCFDnCFDGERFL — Global Error Flag Register

Access: RSCFDnCFDGERFL register can be read/written in 32-bit units
 RSCFDnCFDGERFLL, RSCFDnCFDGERFLH registers can be read/written in 16-bit units
 RSCFDnCFDGERFLLL, RSCFDnCFDGERFLLH, RSCFDnCFDGERFLHL, RSCFDnCFDGERFLHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGERFL: <RSCFDn_base> + 0090_H
 RSCFDnCFDGERFLL: <RSCFDn_base> + 0090_H, RSCFDnCFDGERFLH: <RSCFDn_base> + 0092_H
 RSCFDnCFDGERFLLL: <RSCFDn_base> + 0090_H, RSCFDnCFDGERFLLH: <RSCFDn_base> + 0091_H,
 RSCFDnCFDGERFLHL: <RSCFDn_base> + 0092_H, RSCFDnCFDGERFLHH: <RSCFDn_base> + 0093_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	EEF3	EEF2	EEF1	EEF0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R/W*1	R/W*1	R/W*1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	CMPOF	THLES	MES	DEF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R	R	R/W*1

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 16.106 RSCFDnCFDGERFL Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned. When writing these bits, write the value after reset.
19	EEF3	ECC Error Flag for Channel 3 0: No 2-bit ECC error when deciding transmission priority 1: A 2-bit ECC error when deciding transmission priority
18	EEF2	ECC Error Flag for Channel 2 0: No 2-bit ECC error when deciding transmission priority 1: A 2-bit ECC error when deciding transmission priority
17	EEF1	ECC Error Flag for Channel 1 0: No 2-bit ECC error when deciding transmission priority 1: A 2-bit ECC error when deciding transmission priority
16	EEF0	ECC Error Flag for Channel 0 0: No 2-bit ECC error when deciding transmission priority 1: A 2-bit ECC error when deciding transmission priority
15, 14	Reserved	When read, the undefined value is returned. When writing to these bits, write the value after reset.
13 to 8	Reserved	When read, the undefined value is returned. When writing to these bits, write the value after reset.
7, 6	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
5	Reserved	When read, the undefined value is returned. When writing to this bit, write the value after reset.
4	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
3	CMPOF	Payload Overflow Flag 0: No payload overflow has occurred. 1: A payload overflow has occurred.

Table 16.106 RSCFDnCFDGERFL Register Contents (2/2)

Bit Position	Bit Name	Function
2	THLES	Transmit History Buffer Overflow Status Flag 0: No transmit history buffer overflow has occurred. 1: A transmit history buffer overflow has occurred.
1	MES	FIFO Message Lost Status Flag 0: No FIFO message lost error has occurred. 1: A FIFO message lost error has occurred.
0	DEF	DLC Error Flag 0: No DLC error has occurred. 1: A DLC error has occurred.

All flags in the RSCFDnCFDGERFL register are cleared to 0 in global reset mode.

EEFm Flag

When a 2-bit ECC error is detected during the transmission priority determination of channel m ($m = 0$ to 3), the EEFm flag is set to 1, disabling message transmission. This flag can be cleared to 0 by writing 0 by the program.

THLES Flag

The THLES flag is set to 1 when any one of the THLELT flags in the RSCFDnCFDTHLSTSm register ($m = 0$ to 3) is set to 1.

This flag is cleared to 0 when the THLELT flags of all channels are set to 0.

MES Flag

The MES flag is set to 1 when any one of the RFMLT flags in the RSCFDnCFDRFSTStx register ($x = 0$ to 7) or the CFMLT flags in the RSCFDnCFDCFSTSk register ($k = 0$ to 11) is set to 1.

This flag is cleared to 0 when all RFMLT flags and CFMLT flags are set to 0.

DEF Flag

The DEF flag is set to 1 when an error has been detected during the DLC check. The program can clear this flag by writing 0 to this bit.

NOTE

To clear the flag of this register to 0, use a store instruction to write 0 to the given flag and 1 to the other flags.

16.4.4.5 RSCFDnCFDGTSC — Global Timestamp Counter Register

Access: RSCFDnCFDGTSC register can be read only in 32-bit units.
RSCFDnCFDGTSC_L, RSCFDnCFDGTSC_H registers can be read only in 16-bit units.

Address: RSCFDnCFDGTSC: <RSCFDn_base> + 0094_H
RSCFDnCFDGTSC_L: <RSCFDn_base> + 0094_H, RSCFDnCFDGTSC_H: <RSCFDn_base> + 0096_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TS[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 16.107 RSCFDnCFDGTSC Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned.
15 to 0	TS[15:0]	Timestamp Value The timestamp counter value can be read. Counter Value: 0000 _H to FFFF _H

TS[15:0] Bits

When the TS[15:0] bits are read, the read value shows the timestamp counter (16-bit free-running counter) value at that time. When the SOF is detected, the TS[15:0] value is captured and later stored in the receive buffer or the FIFO buffer. Furthermore, the TS[15:0] value is stored in the transmit history buffer. The timestamp counter is initialized in global reset mode.

The timestamp counter starts and stops counting differently, depending on the count source.

- When the TSSS bit in the RSCFDnCFDGCFCFG register is 0 (pclk):
The timestamp counter starts counting when the RSCFD module has transitioned to global operating mode.
This counter stops counting when the RSCFD module has transitioned to global stop mode or global test mode.
- When the TSSS bit is 1 (CANm nominal bit time clock):
The timestamp counter starts counting when the corresponding channel has transitioned to channel communication mode.
This counter stops counting when the corresponding channel has transitioned to channel reset mode or channel halt mode.

16.4.4.6 RSCFDnCFDGTINTSTS0 — Global TX Interrupt Status Register 0

Access: RSCFDnCFDGTINTSTS0 register can be read only in 32-bit units
 RSCFDnCFDGTINTSTS0L, RSCFDnCFDGTINTSTS0H registers can be read only in 16-bit units
 RSCFDnCFDGTINTSTS0LL, RSCFDnCFDGTINTSTS0LH, RSCFDnCFDGTINTSTS0HL,
 RSCFDnCFDGTINTSTS0HH registers can be read only in 8-bit units

Address: RSCFDnCFDGTINTSTS0: <RSCFDn_base> + 0460_H
 RSCFDnCFDGTINTSTS0L: <RSCFDn_base> + 0460_H, RSCFDnCFDGTINTSTS0H: <RSCFDn_base> +
 0462_H

26	TQIF3	Channel 3 Transmit Queue Interrupt Status Flag 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested.
25	TAIF3	Channel 3 Transmit Buffer Abort Interrupt Status Flag 0: Transmit buffer abort interrupt is not requested. 1: Transmit buffer abort interrupt is requested.
24	TSIF3	Channel 3 Transmit Buffer Transmit Complete Interrupt Status Flag 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested.
23 to 21	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
20	THIF2	Channel 2 Transmit History Interrupt Status Flag 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested.
19	CFTIF2	Channel 2 Transmit/receive FIFO Transmit Interrupt Status Flag 0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested.
18	TQIF2	Channel 2 Transmit Queue Interrupt Status Flag 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested.

Table 16.108 RSCFDnCFDGTINTSTS0 Register Contents (2/2)

Bit Position	Bit Name	Function
17	TAIF2	Channel 2 Transmit Buffer Abort Interrupt Status Flag 0: Transmit buffer abort interrupt is not requested. 1: Transmit buffer abort interrupt is requested.
16	TSIF2	Channel 2 Transmit Buffer Interrupt Status Flag 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested.
15 to 13	Reserved	When read, the value after reset is returned.
12	THIF1	Channel 1 Transmit History Interrupt Status Flag 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested.
11	CFTIF1	Channel 1 Transmit/receive FIFO Transmit Interrupt Status Flag 0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested.
10	TQIF1	Channel 1 Transmit Queue Interrupt Status Flag 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested.
9	TAIF1	Channel 1 Transmit Buffer Abort Interrupt Status Flag 0: Transmit buffer abort interrupt is not requested. 1: Transmit buffer abort interrupt is requested.
8	TSIF1	Channel 1 Transmit Buffer Interrupt Status Flag 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested.
7 to 5	Reserved	When read, the value after reset is returned.
4	THIF0	Channel 0 Transmit History Interrupt Status Flag 0: Transmit history interrupt is not requested. 1: Transmit history interrupt is requested.
3	CFTIF0	Channel 0 Transmit/receive FIFO Transmit Interrupt Status Flag 0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested.
2	TQIF0	Channel 0 Transmit Queue Interrupt Status Flag 0: Transmit queue interrupt is not requested. 1: Transmit queue interrupt is requested.
1	TAIF0	Channel 0 Transmit Buffer Abort Interrupt Status Flag 0: Transmit buffer abort interrupt is not requested. 1: Transmit buffer abort interrupt is requested.
0	TSIF0	Channel 0 Transmit Buffer Interrupt Status Flag 0: Transmit buffer transmit complete interrupt is not requested. 1: Transmit buffer transmit complete interrupt is requested.

TSIFm Bits

The TSIFm bit is set to 1 when the TMIEp bit in the RSCFDnCFDTMIECy register is set to 1 (transmit buffer interrupt enabled) and the TMTRF[1:0] flags in the RSCFDnCFDTMSTSp register are set to 10_B (transmit completed without abort request) or 11_B (transmit completed with abort request).

When the TMTRF[1:0] flags are cleared to 00_B under the condition that the TSIFm bit can be set to 1, this flag is cleared to 0. In addition, clearing the TMIEp bit to 0 also clears this flag to 0.

TAIFm Bits

The TAIFm bit is set to 1 when the TAIE bit in the RSCFDnCFDCmCTR register is 1 (transmit abort interrupt enabled) and the TMTRF[1:0] flags in the RSCFDnCFDTMSTSp register are set to 01_B (transmit abort completed).

This flag is cleared to 0 when the TMTRF[1:0] flags are cleared to 00_B after the transmit abort is completed.

TQIFm Bits

When the TXQIE bit in the RSCFDnCFDnTXQCCm register is set to 1 (transmit queue interrupt enabled) and the TXQIF bit in the RSCFDnCFDnTXQSTSm register is set to 1 (transmit queue interrupt request), the TQIFm bit is set to 1.

When the TXQIF bit (transmit queue interrupt request) in the RSCFDnCFDnTXQSTSm register is cleared to 0, this bit is cleared to 0. This flag is also cleared to 0 when the TXQIE bit is cleared to 0.

CFTIFm Bits

When the CFTXIE bit in the RSCFDnCFDnCFCCk register is set to 1 (transmit/receive FIFO transmit interrupt enabled) and the CFTXIF bit in the RSCFDnCFDnCFSTSk register is set to 1 (transmit/receive FIFO transmit interrupt request), the CFTIFm bit is set to 1.

When the CFTXIF bit is cleared to 0 under the conditions that the CFTIFm bit can be set to 1, this bit is cleared to 0. This flag is also cleared to 0 when the CFTXIE bit is cleared to 0.

THIFm Bits

When the THLIE bit in the RSCFDnCFDnTHLCCm register is set to 1 (transmit history interrupt enabled) and the THLIF bit in the RSCFDnCFDnTHLSTSm register is set to 1 (transmit history interrupt request), the THIFm bit is set to 1.

When the THLIF bit in the RSCFDnCFDnTHLSTSm register is cleared to 0, this bit is cleared to 0. This flag is also cleared to 0 when the THLIE bit is cleared to 0.

16.4.4.7 RSCFDnCFDGFDCFG — Global FD Configuration Register

Access: RSCFDnCFDGFDCFG can be read/written in 32-bit units.
RSCFDnCFDGFDCFG L and RSCFDnCFDGFDCFG H can be read/written in 16-bit units.
RSCFDnCFDGFDCFG LL, RSCFDnCFDGFDCFG LH, RSCFDnCFDGFDCFG HL, and
RSCFDnCFDGFDCFG HH can be read/written in 8-bit units.

Address: RSCFDnCFDGFDCFG: <RSCFDn_base> + 0474_H
RSCFDnCFDGFDCFG L: <RSCFDn_base> + 0474_H, RSCFDnCFDGFDCFG H: <RSCFDn_base> + 0476_H
RSCFDnCFDGFDCFG LL: <RSCFDn_base> + 0474_H, RSCFDnCFDGFDCFG LH: <RSCFDn_base> +
0475_H, RSCFDnCFDGFDCFG HL: <RSCFDn_base> + 0476_H, RSCFDnCFDGFDCFG HH: <RSCFDn_base>
+ 0477_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.109 RSCFDnCFDGFDCFG Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
9, 8	TSCCFG[1:0]	Timestamp Capture Setting b9 b8 0 0: Captured at a sample point in the SOF bit. 0 1: Captured when a valid frame has been transmitted/received. 1 0: Captured at a sample point of the res bit.*1 1 1: Setting prohibited
7 to 1	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
0	RPED	Protocol Exception Event Detection Disable Bit 0: Protocol exception event detection enabled 1: Protocol exception event detection disabled

Note 1. When a Classical CAN frame is transmitted/received, a timestamp value will be captured at the sample point in the SOF bit.

TSCCFG Bits

These bits select a point where a time-stamp value is captured. Modify this bit only in global reset mode.

RPED Bit

Setting this bit to 1 disables the protocol exception event detection. When a protocol exception event is detected while this bit is set to 1, the event is regarded as a form error and an error frame will be output. Modify this bit only in global reset mode.

16.4.5 Details of Receive Rule-related Registers

16.4.5.1 RSCFDnCFDGAFLECTR — Receive Rule Entry Control Register

Access: RSCFDnCFDGAFLECTR register can be read/written in 32-bit units
RSCFDnCFDGAFLECTRL, RSCFDnCFDGAFLECTRH registers can be read/written in 16-bit units
RSCFDnCFDGAFLECTRLL, RSCFDnCFDGAFLECTRLH, RSCFDnCFDGAFLECTRHL,
RSCFDnCFDGAFLECTRHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGAFLECTR: <RSCFDn_base> + 0098_H
RSCFDnCFDGAFLECTRL: <RSCFDn_base> + 0098_H, RSCFDnCFDGAFLECTRH: <RSCFDn_base> + 009A_H
RSCFDnCFDGAFLECTRLL: <RSCFDn_base> + 0098_H, RSCFDnCFDGAFLECTRLH: <RSCFDn_base> + 0099_H,
RSCFDnCFDGAFLECTRHL: <RSCFDn_base> + 009A_H, RSCFDnCFDGAFLECTRHH: <RSCFDn_base> + 009B_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.110 RSCFDnCFDGAFLECTR Register Contents

Bit Position	Bit Name	Function
31 to 9	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
8	AFLDAE	Receive Rule Table Write Enable 0: Receive rule table write is disabled. 1: Receive rule table write is enabled.
7 to 5	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
4 to 0	AFLPN[4:0]	Receive Rule Table Page Number Configuration A page number can be selected from a range of page 0 (0000 _B) to page 15 (0111 _B).

AFLDAE Bit

Setting this bit to 0 disables the write to the receive rule table. After writes to the receive rule table are completed, set this bit to 0 to disable the write to the table. The receive rule table can be read regardless of the value of this bit.

Set the AFLDAE bit to 1 only in global reset mode.

AFLPN[4:0] Bits

These bits are used to set the page number of the receive rule table. Sixteen receive rules can be set per page.

Set these bits to a value within the range of 0000_B to 0111_B.

16.4.5.2 RSCFDnCFDGAFLCFG0 — Receive Rule Configuration Register 0

Access: RSCFDnCFDGAFLCFG0 register can be read/written in 32-bit units
 RSCFDnCFDGAFLCFG0L, RSCFDnCFDGAFLCFG0H registers can be read/written in 16-bit units
 RSCFDnCFDGAFLCFG0LL, RSCFDnCFDGAFLCFG0LH, RSCFDnCFDGAFLCFG0HL,
 RSCFDnCFDGAFLCFG0HH registers can be read/written in 8-bit units

Address: RSCFDnCFDGAFLCFG0: <RSCFDn_base> + 009C_H

Table 16.111 RSCFDnCFDGAFLCFG0 Register Contents

Bit Position	Bit Name	Function
31 to 24	RNC0[7:0]	Number of Rules for Channel 0 Set the number of receive rules exclusively used for channel 0.
23 to 16	RNC1[7:0]	Number of Rules for Channel 1 Set the number of receive rules exclusively used for channel 1.
15 to 8	RNC2[7:0]	Number of Rules for Channel 2 Set the number of receive rules exclusively used for channel 2.
7 to 0	RNC3[7:0]	Number of Rules for Channel 3 Set the number of receive rules exclusively used for channel 3.

Modify the RSCFDnCFDGAFLCFG0 register only in global reset mode.

Up to 64 × (number of channels) rules can be registered in the receive rule table as the entire unit. The number of receive rules per channel should meet the following conditions.

- The maximum number of rules per channel is 128.
- The total of the number of rules allocated to each channel is not larger than the number of rules that can be registered in the entire unit.

RNC0[7:0] Bits

These bits are used to set the number of rules to be registered in the channel 0 receive rule table.

Set these bits to a value within the range of 00_H to 80_H.

RNC1[7:0] Bits

These bits are used to set the number of rules to be registered in the channel 1 receive rule table.

Set these bits to a value within the range of 00_H to 80_H.

RNC2[7:0] Bits

These bits are used to set the number of rules to be registered in the channel 2 receive rule table.

Set these bits to a value within the range of 00_H to 80_H.

RNC3[7:0] Bits

These bits are used to set the number of rules to be registered in the channel 3 receive rule table.

Set these bits to a value within the range of 00_H to 80_H.

16.4.5.3 RSCFDnCFDGAFLIDj — Receive Rule ID Register (j = 0 to 15)

Access: RSCFDnCFDGAFLIDj register can be read/written in 32-bit units
 RSCFDnCFDGAFLIDjL, RSCFDnCFDGAFLIDjH registers can be read/written in 16-bit units
 RSCFDnCFDGAFLIDjLL, RSCFDnCFDGAFLIDjLH, RSCFDnCFDGAFLIDjHL, RSCFDnCFDGAFLIDjHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGAFLIDj: <RSCFDn_base> + 1000_H + (10_H × j)
 RSCFDnCFDGAFLIDjL: <RSCFDn_base> + 1000_H + (10_H × j),
 RSCFDnCFDGAFLIDjH: <RSCFDn_base> + 1002_H + (10_H × j)
 RSCFDnCFDGAFLIDjLL: <RSCFDn_base> + 1000_H + (10_H × j),
 RSCFDnCFDGAFLIDjLH: <RSCFDn_base> + 1001_H + (10_H × j),
 RSCFDnCFDGAFLIDjHL: <RSCFDn_base> + 1002_H + (10_H × j),
 RSCFDnCFDGAFLIDjHH: <RSCFDn_base> + 1003_H + (10_H × j)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.112 RSCFDnCFDGAFLIDj Register Contents

Bit Position	Bit Name	Function
31	GAFLIDE	IDE Select 0: Standard ID 1: Extended ID
30	GAFLRTR	RTR Select 0: Data frame 1: Remote frame
29	GAFLLB	Receive Rule Target Message Select 0: When a message transmitted from another CAN node is received 1: When the own transmitted message is received
28 to 0	GAFLID[28:0]	ID Set the ID of the receive rule. For the standard ID, set the ID in bits b10 to b0 and set bits b28 to b11 to 0.

Modify the RSCFDnCFDGAFLIDj register when the AFLDAE bit in the RSCFDnCFDGAFLLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLIDE Bit

This bit is used to select the ID format (standard ID or extended ID) of the receive rule. This bit is compared with the IDE bit in the received message during the acceptance filter processing.

GAFLRTR Bit

This bit is used to select the frame format (data frame or remote frame) of the receive rule. This bit is compared with the RTR bit in the received message during the acceptance filter processing.

GAFLLB Bit

When this bit is set to 0, data processing using the receive rule is performed when receiving messages transmitted from another CAN node.

When this bit is set to 1 when the mirror function is used, data processing using the receive rule is performed when the CAN node is receiving its own transmitted messages.

GAFLLD[28:0] Bits

These bits are used to set the ID field of the receive rule. The ID value set by these bits is compared with the ID of the received message during the acceptance filter processing.

16.4.5.4 RSCFDnCFDGAFLMj — Receive Rule Mask Register (j = 0 to 15)

Access: RSCFDnCFDGAFLMj register can be read/written in 32-bit units
 RSCFDnCFDGAFLMjL, RSCFDnCFDGAFLMjH registers can be read/written in 16-bit units
 RSCFDnCFDGAFLMjLL, RSCFDnCFDGAFLMjLH, RSCFDnCFDGAFLMjHL, RSCFDnCFDGAFLMjHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGAFLMj: <RSCFDn_base> + 1004_H + (10_H × j)
 RSCFDnCFDGAFLMjL: <RSCFDn_base> + 1004_H + (10_H × j),
 RSCFDnCFDGAFLMjH: <RSCFDn_base> + 1006_H + (10_H × j)
 RSCFDnCFDGAFLMjLL: <RSCFDn_base> + 1004_H + (10_H × j),
 RSCFDnCFDGAFLMjLH: <RSCFDn_base> + 1005_H + (10_H × j),
 RSCFDnCFDGAFLMjHL: <RSCFDn_base> + 1006_H + (10_H × j),
 RSCFDnCFDGAFLMjHH: <RSCFDn_base> + 1007_H + (10_H × j)

Value after reset: 0000 0000_H

Table 16.113 RSCFDnCFDGAFLMj Register Contents

Bit Position	Bit Name	Function
31	GAFLIDEM	IDE Mask 0: The IDE bit is not compared. 1: The IDE bit is compared.
30	GAFLRTRM	RTR Mask 0: The RTR bit is not compared. 1: The RTR bit is compared
29	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
28 to 0	GAFLIDM[28:0]	ID Mask 0: The corresponding ID bit is not compared. 1: The corresponding ID bit is compared.

Modify the RSCFDnCFDGAFLMj register when the AFLDAE bit in the RSCFDnCFDGAFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLIDEM Bit

When this bit is set to 1, filter processing is performed only for messages of the ID format specified by the GAFLIDE bit in the RSCFDnCFDGAFLIDj register.

When this bit is cleared to 0, the IDs of all the receive messages and the specified IDs are regarded as matched. To set the GAFLIDEM bit to 0, set the GAFLIDM[28:0] bits to all 0 at the same time.

GAFLRTRM Bit

This bit is used to mask the RTR bit of the receive rule.

GAFLIDM[28:0] Bits

These bits are used to mask the corresponding ID bit of the receive rule.

16.4.5.5 RSCFDnCFDGAFLP0_j — Receive Rule Pointer 0 Register (j = 0 to 15)

Access: RSCFDnCFDGAFLP0j register can be read/written in 32-bit units
 RSCFDnCFDGAFLP0jL, RSCFDnCFDGAFLP0jH registers can be read/written in 16-bit units
 RSCFDnCFDGAFLP0jLL, RSCFDnCFDGAFLP0jLH, RSCFDnCFDGAFLP0jHL, RSCFDnCFDGAFLP0jHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGAFLP0j: <RSCFDn_base> + 1008_H + (10_H × j)
 RSCFDnCFDGAFLP0jL: <RSCFDn_base> + 1008_H + (10_H × j),

14 to 8	GAFLRMDP[6:0]	Receive Buffer Number Select Set the receive buffer number to store receive messages.																																																																																																

Table 16.114 RSCFDnCFDGAFLP0_j Register Contents (2/2)

Bit Position	Bit Name	Function
7 to 0	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.

Modify the RSCFDnCFDGAFLP0_j register when the AFLDAE bit in the RSCFDnCFDGAFLP0_j register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLDLC[3:0] Bits

These bits are used to set the minimum data length necessary for receiving messages. If the data length of a message that is being filtered is equal to or larger than the value set by the GAFLDLC[3:0] bits, the message passes the DLC check. Setting these bits to 0000_B disables the DLC check function allowing messages with any data length to pass the DLC check.

GAFLPTR[11:0] Bits

These bits are used to set a 12-bit label to be attached to messages that have passed through the filter. A label is attached when a message is stored in the receive buffer or the FIFO buffer.

GAFLRMV Bit

When this bit is set to 1, receive messages that have passed through the filter are stored in the receive buffer selected by the GAFLRMDP[6:0] bits.

GAFLRMDP[6:0] Bits

These bits are used to select the number of the receive buffer that stores receive messages that have passed through the filter when the GAFLRMV bit is set to 1. Set these bits to a value smaller than the value set by the NRXMB[7:0] bits in the RSCFDnCFDRMNB register.

16.4.5.6 RSCFDnCFDGAFLP1_j — Receive Rule Pointer 1 Register (j = 0 to 15)

Access: RSCFDnCFDGAFLP1_j register can be read/written in 32-bit units
 RSCFDnCFDGAFLP1_jL, RSCFDnCFDGAFLP1_jH registers can be read/written in 16-bit units
 RSCFDnCFDGAFLP1_jLL, RSCFDnCFDGAFLP1_jLH, RSCFDnCFDGAFLP1_jHL,
 RSCFDnCFDGAFLP1_jHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGAFLP1_j: <RSCFDn_base> + 100C_H + (10_H × j)
 RSCFDnCFDGAFLP1_jL: <RSCFDn_base> + 100C_H + (10_H × j),
 RSCFDnCFDGAFLP1_jH: <RSCFDn_base> + 100E_H + (10_H × j)
 RSCFDnCFDGAFLP1_jLL: <RSCFDn_base> + 100C_H + (10_H × j),
 RSCFDnCFDGAFLP1_jLH: <RSCFDn_base> + 100D_H + (10_H × j),
 RSCFDnCFDGAFLP1_jHL: <RSCFDn_base> + 100E_H + (10_H × j),
 RSCFDnCFDGAFLP1_jHH: <RSCFDn_base> + 100F_H + (10_H × j)

Value after reset: 0000 0000_H

Table 16.115 RSCFDnCFDGAFLP1_j Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
19 to 8	GAFLFDP[19:8]	Transmit/Receive FIFO Buffer k Select (Bit position –8 = target transmit/receive FIFO buffer number k) 0: Transmit/receive FIFO buffer is not selected. 1: Transmit/receive FIFO buffer is selected.
7 to 0	GAFLFDP[7:0]	Receive FIFO Buffer x Select (Bit position = target receive FIFO buffer number x) 0: Receive FIFO buffer is not selected. 1: Receive FIFO buffer is selected.

Modify the RSCFDnCFDGAFLP1_j register when the AFLDAE bit in the RSCFDnCFDGAFLFLECTR register is set to 1 (receive rule table write is enabled) in global reset mode.

GAFLFDP[19:0] Bits

These bits are used to specify FIFO buffers that store receive messages that have passed through the filter. Up to eight FIFO buffers are selectable. However, when the GAFLRMV bit in the RSCFDnCFDGAFLP0_j register is set to 1 (a message is stored in the receive buffer), up to seven FIFO buffers can be selected. Only receive FIFO buffers and the transmit/receive FIFO buffer for which the CFM[1:0] bits in the RSCFDnCFDGFCCk register are set to 00_B (receive mode) or 10_B (gateway mode) are selectable.

16.4.6 Details of Receive Buffer-related Registers

16.4.6.1 RSCFDnCFDRMNB — Receive Buffer Number Register

Access: RSCFDnCFDRMNB register can be read/written in 32-bit units
RSCFDnCFDRMNBL, RSCFDnCFDRMNBH registers can be read/written in 16-bit units
RSCFDnCFDRMNBLL, RSCFDnCFDRMNBHL, RSCFDnCFDRMNBHL, RSCFDnCFDRMNBHH registers can be read/written in 8-bit units

Address: RSCFDnCFDRMNB: <RSCFDn_base> + 00A4_H
RSCFDnCFDRMNBL: <RSCFDn_base> + 00A4_H, RSCFDnCFDRMNBH: <RSCFDn_base> + 00A6_H
RSCFDnCFDRMNBLL: <RSCFDn_base> + 00A4_H, RSCFDnCFDRMNBHL: <RSCFDn_base> + 00A5_H,
RSCFDnCFDRMNBHL: <RSCFDn_base> + 00A6_H, RSCFDnCFDRMNBHH: <RSCFDn_base> + 00A7_H

Value after reset: 0000 0000_H

Table 16.116 RSCFDnCFDRMNB Register Contents

Bit Position	Bit Name	Function
31 to 10	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
9, 8	RMPLS[1:0]	Receive Buffer Payload Storage Size Select b9 b8 0 0: 8 bytes 0 1: 12 bytes 1 0: 16 bytes 1 1: 20 bytes
7 to 0	NRXMB[7:0]	Receive Buffer Number Configuration Set the number of receive buffers. Set a value of 0 to 64

Modify the RSCFDnCFDRMNB register only in global reset mode.

RMPLS[1:0] Bits

These bits are used to select the maximum payload size that can be stored in the receive buffer.

NRXMB[7:0] Bits

These bits are used to set the total number of receive buffers of the RS-CANFD module. The maximum value is $16 \times$ (number of channels).

Setting these bits all to 0 makes receive buffers unavailable.

16.4.6.2 RSCFDnCFDRMNDy — Receive Buffer New Data Register (y = 0, 1)

Access: RSCFDnCFDRMNDy register can be read/written in 32-bit units
RSCFDnCFDRMNDyL, RSCFDnCFDRMNDyH registers can be read/written in 16-bit units
RSCFDnCFDRMNDyLL, RSCFDnCFDRMNDyLH, RSCFDnCFDRMNDyHL, RSCFDnCFDRMNDyHH registers can be read/written in 8-bit units

Address: RSCFDnCFDRMNDy: <RSCFDn_base> + 00A8_H + (04_H × y)
RSCFDnCFDRMNDyL: <RSCFDn_base> + 00A8_H + (04_H × y),
RSCFDnCFDRMNDyH: <RSCFDn_base> + 00AA_H + (04_H × y)

Table 16.117 RSCFDnCFDRMNDy Register Contents

Bit Position	Bit Name	Function
31 to 16	RMNSq	Receive Buffer Receive Complete Flag q (q = y × 32 + 31 to y × 32 + 16) 0: There is no new message in receive buffer q. 1: There is a new message in receive buffer q.
15 to 0	RMNSq	Receive Buffer Receive Complete Flag q (q = y × 32 + 15 to y × 32 + 0) 0: There is no new message in receive buffer q. 1: There is a new message in receive buffer q.

Write 0 to the RSCFDnCFDRMNDy register in global operating mode or global test mode.

RMNSq Flags (q = 0 to 63)

Each RMNSq flag is set to 1 when the processing for storing a message in the corresponding receive buffer starts.

To clear a flag to 0, the program must write 0 to the flag. Use a store instruction to write “0” to the flag and “1” to other flags. These bits cannot be set to 0 while a message is being stored. The message storing time depends on the storage payload size of the receive buffer. When the RMPLS[1:0] value in the RSCFDnCFDRMNB register is 00_B (8 bytes), the message storing time is 12 pclk clock cycles. When the RMPLS[1:0] value is 11_B (20 bytes), the message storing time is 18 pclk clock cycles. (2 pclk clock cycles per 4 bytes of storage payload size).

These flags are cleared to 0 in global reset mode.

16.4.6.3 RSCFDnCFDRMIDq — Receive Buffer ID Register (q = 0 to 63)

Access: RSCFDnCFDRMIDq register can be read only in 32-bit units
 RSCFDnCFDRMIDqL, RSCFDnCFDRMIDqH registers can be read only in 16-bit units
 RSCFDnCFDRMIDqLL, RSCFDnCFDRMIDqLH, RSCFDnCFDRMIDqHL, RSCFDnCFDRMIDqHH registers
 can be read only in 8-bit units

Address: RSCFDnCFDRMIDq: $\langle \text{RSCFDn_base} \rangle + 2000_{\text{H}} + (20_{\text{H}} \times q)$
 RSCFDnCFDRMIDqL: $\langle \text{RSCFDn_base} \rangle + 2000_{\text{H}} + (20_{\text{H}} \times q)$,
 RSCFDnCFDRMIDqH: $\langle \text{RSCFDn_base} \rangle + 2002_{\text{H}} + (20_{\text{H}} \times q)$
 RSCFDnCFDRMIDqLL: $\langle \text{RSCFDn_base} \rangle + 2000_{\text{H}} + (20_{\text{H}} \times q)$,
 RSCFDnCFDRMIDqLH: $\langle \text{RSCFDn_base} \rangle + 2001_{\text{H}} + (20_{\text{H}} \times q)$,
 RSCFDnCFDRMIDqHL: $\langle \text{RSCFDn_base} \rangle + 2002_{\text{H}} + (20_{\text{H}} \times q)$,
 RSCFDnCFDRMIDqHH: $\langle \text{RSCFDn_base} \rangle + 2003_{\text{H}} + (20_{\text{H}} \times q)$

Value after reset: 0000 0000_H

Bit Position	Bit Name	Function
31	RMIDE	Receive Buffer IDE 0: Standard ID 1: Extended ID
30	RMRTR	Receive Buffer RTR/RRS <ul style="list-style-type: none"> When the received message is a classical CAN frame <ul style="list-style-type: none"> 0: Data frame 1: Remote frame When the received message is a CAN FD frame The RRS bit value of the received message can be read.
29	Reserved	When read, the value after reset is returned.
28 to 0	RMID[28:0]	Receive Buffer ID Data These bits contain the standard ID or extended ID of the received message. Read bits b10 to b0 for standard ID. Bits b28 to b11 are read as 0.

RMIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the message stored in the receive buffer.

RMRTR Bit

When the received message is a classical CAN frame, this bit indicates the frame format (data frame or remote frame) of the message stored in the receive buffer. When the received message is a CAN FD frame, this bit indicates the RRS bit value in the message.

RMID[28:0] Bits

These bits contain the ID of the message stored in the receive buffer.

16.4.6.4 RSCFDnCFDRMPTRq — Receive Buffer Pointer Register (q = 0 to 63)

Access: RSCFDnCFDRMPTRq register can be read only in 32-bit units
 RSCFDnCFDRMPTRqL, RSCFDnCFDRMPTRqH registers can be read only in 16-bit units
 RSCFDnCFDRMPTRqLL, RSCFDnCFDRMPTRqLH, RSCFDnCFDRMPTRqHL, RSCFDnCFDRMPTRqHH registers can be read only in 8-bit units

Address: RSCFDnCFDRMPTRq: <RSCFDn_base> + 2004_H + (20_H × q)
 RSCFDnCFDRMPTRqL: <RSCFDn_base> + 2004_H + (20_H × q),

			1 0 1 0		16 data bytes
			1 0 1 1		20 data bytes
			1 1 0 0		24 data bytes
			1 1 0 1		32 data bytes
1 1 1 0	48 data bytes				
1 1 1 1	64 data bytes				
27 to 16	RMPTR[11:0]	Receive Buffer Label Data Label information of the received message.			
15 to 0	RMTS[15:0]	Receive Buffer Timestamp Data Timestamp value of the received message.			

RMDLC[3:0] Bits

These bits indicate the data length of the message stored in the receive buffer. The number of bytes of the payload to be stored in the receive buffer is determined by the RMPLS[1:0] bits in the RSCFDnCFDRMNB register.

RMPTR[11:0] Bits

These bits indicate the label information of the message stored in the receive buffer.

RMTS[15:0] Bits

These bits indicate the timestamp value of the message stored in the receive buffer.

16.4.6.5 RSCFDnCFDRMFDSTSq — Receive Buffer CAN FD Status Register (q = 0 to 63)

Access: RSCFDnCFDRMFDSTSq register can be read only in 32-bit units
 RSCFDnCFDRMFDSTSqL, RSCFDnCFDRMFDSTSqH registers can be read only in 16-bit units
 RSCFDnCFDRMFDSTSqLL, RSCFDnCFDRMFDSTSqLH, RSCFDnCFDRMFDSTSqHL,
 RSCFDnCFDRMFDSTSqHH registers can be read only in 8-bit units

Address: RSCFDnCFDRMFDSTSq: <RSCFDn_base> + 2008_H + (20_H × q)
 RSCFDnCFDRMFDSTSqL: <RSCFDn_base> + 2008_H + (20_H × q),

Table 16.120 RSCFDnCFDRMFDSTSq Register Contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is returned.
2	RMFDF	FDF 0: Classical CAN frame 1: CAN FD frame
1	RMBRS	BRS 0: The bit rate in the data area does not change. 1: The bit rate in the data area changes.
0	RMESI	ESI 0: Error active node 1: Error passive node

RMFDF Bit

This bit indicates the FD format (classical CAN frame or CAN FD frame) of the message stored in the receive buffer.

RMBRS Bit

When the RMFDF bit is 1, this bit indicates the BRS bit value of the message stored in the receive buffer. When the RMFDF bit is 0, this bit is always read as 0.

RMESI Bit

When the RMFDF bit is 1, this bit indicates the ESI bit value of the message stored in the receive buffer. When the RMFDF bit is 0, this bit is always read as 0.

16.4.6.6 RSCFDnCFDRMDFb_q — Receive Buffer Data Field b Register (b = 0 to 4, q = 0 to 63)

Access: RSCFDnCFDRMDFb_q register can be read only in 32-bit units
RSCFDnCFDRMDFb_qL, RSCFDnCFDRMDFb_qH registers can be read only in 16-bit units
RSCFDnCFDRMDFb_qLL, RSCFDnCFDRMDFb_qLH, RSCFDnCFDRMDFb_qHL,
RSCFDnCFDRMDFb_qHH registers can be read only in 8-bit units

Address: RSCFDnCFDRMDFb_q: $\langle \text{RSCFDn_base} \rangle + 200\text{C}_\text{H} + (04_\text{H} \times b) + (20_\text{H} \times q)$
RSCFDnCFDRMDFb_qL: $\langle \text{RSCFDn_base} \rangle + 200\text{C}_\text{H} + (04_\text{H} \times b) + (20_\text{H} \times q)$,
RSCFDnCFDRMDFb_qH: $\langle \text{RSCFDn_base} \rangle + 200\text{E}_\text{H} + (04_\text{H} \times b) + (20_\text{H} \times q)$

Table 16.121 RSCFDnCFDRMDFb_q Register Contents

Bit Position	Bit Name	Function
31 to 24	RMDB4 × b + 3 [7:0]	Receive Buffer Data Byte 4 × b + 3
		Receive Buffer Data Byte 4 × b + 2
23 to 16	RMDB4 × b + 2 [7:0]	Receive Buffer Data Byte 4 × b + 1
		Receive Buffer Data Byte 4 × b + 0
15 to 8	RMDB4 × b + 1 [7:0]	Data for a message stored in the receive buffer can be read.
7 to 0	RMDB4 × b + 0 [7:0]	

When the RMDLC[3:0] value in the RSCFDnCFDRMPTRq register is smaller than the payload storage size of the receive buffer, data bytes for which no data is set are read as 00_H.

Specify the payload storage size of the receive buffer by the RMPLS[1:0] bits in the RSCFDnCFDRMNB register. Do not read or write the RSCFDnCFDRMDFb_q register corresponding to an area larger than the specified size.

16.4.7 Details of Receive FIFO Buffer-related Registers

16.4.7.1 RSCFDnCFDRFCCx — Receive FIFO Buffer Configuration and Control Register (x = 0 to 7)

Access: RSCFDnCFDRFCCx register can be read/written in 32-bit units
 RSCFDnCFDRFCCxL, RSCFDnCFDRFCCxH registers can be read/written in 16-bit units
 RSCFDnCFDRFCCxLL, RSCFDnCFDRFCCxLH, RSCFDnCFDRFCCxHL, RSCFDnCFDRFCCxHH registers can be read/written in 8-bit units

Address: RSCFDnCFDRFCCx: <RSCFDn_base> + 00B8_H + (04_H × x)
 RSCFDnCFDRFCCxL: <RSCFDn_base> + 00B8_H + (04_H × x),
 RSCFDnCFDRFCCxH: <RSCFDn_base> + 00BA_H + (04_H × x)
 RSCFDnCFDRFCCxLL: <RSCFDn_base> + 00B8_H + (04_H × x),
 RSCFDnCFDRFCCxLH: <RSCFDn_base> + 00B9_H + (04_H × x),
 RSCFDnCFDRFCCxHL: <RSCFDn_base> + 00BA_H + (04_H × x),
 RSCFDnCFDRFCCxHH: <RSCFDn_base> + 00BB_H + (04_H × x)

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
15 to 13	RFIGCV[2:0]	Receive FIFO Interrupt Request Timing Select $b_{15} \ b_{14} \ b_{13}$ 0 0 0: When FIFO is 1/8 full. 0 0 1: When FIFO is 2/8 full. 0 1 0: When FIFO is 3/8 full. 0 1 1: When FIFO is 4/8 full. 1 0 0: When FIFO is 5/8 full. 1 0 1: When FIFO is 6/8 full. 1 1 0: When FIFO is 7/8 full. 1 1 1: When FIFO is full.
12	RFIM	Receive FIFO Interrupt Source Select 0: An interrupt occurs when the condition set by the RFIGCV[2:0] bits is met. 1: An interrupt occurs each time a message has been received.
11	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
10 to 8	RFDC[2:0]	Receive FIFO Buffer Depth Configuration $b_{10} \ b_9 \ b_8$ 0 0 0: 0 messages 0 0 1: 4 messages 0 1 0: 8 messages 0 1 1: 16 messages 1 0 0: 32 messages 1 0 1: 48 messages 1 1 0: 64 messages 1 1 1: 128 messages

Table 16.122 RSCFDnCFDRFCCx Register Contents (2/2)

Bit Position	Bit Name	Function
7	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
6 to 4	RFPLS[2:0]	Receive FIFO Buffer Payload Storage Size Select b6 b5 b4 0 0 0: 8 bytes 0 0 1: 12 bytes 0 1 0: 16 bytes 0 1 1: 20 bytes 1 0 0: 24 bytes 1 0 1: 32 bytes 1 1 0: 48 bytes 1 1 1: 64 bytes
3, 2	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
1	RFIE	Receive FIFO Interrupt Enable 0: Receive FIFO interrupt is disabled. 1: Receive FIFO interrupt is enabled.
0	RFE	Receive FIFO Buffer Enable 0: No receive FIFO buffer is used. 1: Receive FIFO buffers are used.

RFIGCV[2:0] Bits

These bits are used to specify the number of received messages for generating a receive FIFO interrupt request when the RFIM bit is set to 0 with a fraction for the total number of buffers (the setting of RFDC[2:0]).

When the RFDC[2:0] bits are set to 001_B (4 messages), set the RFIGCV[2:0] bits to 001_B, 011_B, 101_B, or 111_B. Modify these bits only in global reset mode.

RFIM Bit

This bit is used to select a FIFO interrupt source. Modify this bit only in global reset mode.

RFDC[2:0] Bits

These bits are used to select the number of messages that can be stored in a single receive FIFO buffer. When these bits are set to 000_B, no receive FIFO buffer should be used. Modify these bits only in global reset mode.

RFPLS[2:0] Bits

These bits are used to select the maximum payload size that can be stored in the receive FIFO buffer. Modify these bits only in global reset mode.

RFIE Bit

Setting the RFIE bit to 1 enables receive FIFO interrupts. Modify this bit when the RFE bit set to 0 (no receive FIFO buffer is used).

RFE Bit

Setting the RFE bit to 1 makes receive FIFO buffers available. Clearing this bit to 0 sets the RFEMP flag in the RSCFDnCFDRFSTSx register to 1 (buffer empty). Modify this bit in global operating mode or global test mode.

After all other bits in the RSCFDnCFDRFCCx register have been set, set this bit to 1 by using another instruction.

This bit is set to 0 in global reset mode.

16.4.7.2 RSCFDnCFDRFSTSx — Receive FIFO Buffer Status Register (x = 0 to 7)

Access: RSCFDnCFDRFSTSx register can be read/written in 32-bit units
 RSCFDnCFDRFSTSxL, RSCFDnCFDRFSTSxH registers can be read/written in 16-bit units
 RSCFDnCFDRFSTSxLL, RSCFDnCFDRFSTSxLH, RSCFDnCFDRFSTSxHL, RSCFDnCFDRFSTSxHH registers can be read/written in 8-bit units

Address: RSCFDnCFDRFSTSx: <RSCFDn_base> + 00D8_H + (04_H × x)
 RSCFDnCFDRFSTSxL: <RSCFDn_base> + 00D8_H + (04_H × x),
 RSCFDnCFDRFSTSxH: <RSCFDn_base> + 00DA_H + (04_H × x)
 RSCFDnCFDRFSTSxLL: <RSCFDn_base> + 00D8_H + (04_H × x),
 RSCFDnCFDRFSTSxLH: <RSCFDn_base> + 00D9_H + (04_H × x),
 RSCFDnCFDRFSTSxHL: <RSCFDn_base> + 00DA_H + (04_H × x),
 RSCFDnCFDRFSTSxHH: <RSCFDn_base> + 00DB_H + (04_H × x)

Value after reset: 0000 0001_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFMC[7:0]							—	—	—	—	RFIF	RFMLT	RFFLL	RFEMP	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R/W*1	R	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 16.123 RSCFDnCFDRFSTSx Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
15 to 8	RFMC[7:0]	Receive FIFO Unread Message Counter The number of unread messages stored in the receive FIFO buffer is displayed.
7 to 4	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
3	RFIF	Receive FIFO Interrupt Request Flag 0: No receive FIFO interrupt request is present. 1: A receive FIFO interrupt request is present.
2	RFMLT	Receive FIFO Message Lost Flag 0: No receive FIFO message is lost. 1: A receive FIFO message is lost.
1	RFFLL	Receive FIFO Buffer Full Status Flag 0: The receive FIFO buffer is not full. 1: The receive FIFO buffer is full.
0	RFEMP	Receive FIFO Buffer Empty Status Flag 0: The receive FIFO buffer contains unread message. 1: The receive FIFO buffer contains no unread message (buffer empty).

RFMC[7:0] Flag

This flag indicates the number of unread messages in the receive FIFO buffer. This flag becomes 00_H when the RFE bit in the RSCFDnCFDRFCCx register is set to 0.

This flag becomes 00_H in global reset mode.

RFIF Flag

This flag is set to 1 when the receive FIFO interrupt request generation conditions set by the RFIGCV[2:0] bits and the RFIM bit in the RSCFDnCFDRFCCx register are met. This flag is cleared to 0 in global reset mode or by writing 0 to this flag. Modify this bit in global operating mode or global test mode.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

RFMLT Flag

This flag is set to 1 when an attempt is made to store a new message while the receive FIFO buffer is full. In this case, the new message is discarded.

This flag is cleared to 0 in global reset mode or by writing 0 to this flag.

Modify this bit in global operating mode or global test mode.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

RFFLL Flag

This flag is set to 1 when the number of messages stored in the receive FIFO buffer matches the FIFO buffer depth set by the RFDC[2:0] bits in the RSCFDnCFDRFCCx register.

If the number of messages stored in the receive FIFO buffer becomes smaller than the FIFO buffer depth set by the RFDC[2:0] bits, this flag is cleared to 0. This flag is also cleared to 0 when the RFE bit in the RSCFDnCFDRFCCx register is set to 0 (no receive FIFO buffer is used) or in global reset mode.

RFEMP Flag

This flag is set to 1 when all messages in the receive FIFO buffer have been read. This flag is also set to 1 when the RFE bit in the RSCFDnCFDRFCCx register is 0 or in global reset mode.

This flag is cleared to 0 when even a single received message has been stored in the receive FIFO buffer.

NOTE

To clear the RFMLT or RFIF flag to 0, use a store instruction to write “0” to the given flag and “1” to the other flags.

16.4.7.3 RSCFDnCFDRFPCTR_x — Receive FIFO Buffer Pointer Control Register ($x = 0$ to 7)

Access: RSCFDnCFDRFPCTR_x register can only be written in 32-bit units
RSCFDnCFDRFPCTR_{xL}, RSCFDnCFDRFPCTR_{xH} registers can only be written in 16-bit units
RSCFDnCFDRFPCTR_{xLL}, RSCFDnCFDRFPCTR_{xLH}, RSCFDnCFDRFPCTR_{xHL},
RSCFDnCFDRFPCTR_{xHH} registers can only be written in 8-bit units

Address: RSCFDnCFDRFPCTR_x: <RSCFDn_base> + 00F8_H + (04_H × x)
RSCFDnCFDRFPCTR_{xL}: <RSCFDn_base> + 00F8_H + (04_H × x),
RSCFDnCFDRFPCTR_{xH}: <RSCFDn_base> + 00FA_H + (04_H × x)
RSCFDnCFDRFPCTR_{xLL}: <RSCFDn_base> + 00F8_H + (04_H × x),
RSCFDnCFDRFPCTR_{xLH}: <RSCFDn_base> + 00F9_H + (04_H × x),
RSCFDnCFDRFPCTR_{xHL}: <RSCFDn_base> + 00FA_H + (04_H × x),
RSCFDnCFDRFPCTR_{xHH}: <RSCFDn_base> + 00FB_H + (04_H × x)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R/W	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Table 16.124 RSCFDnCFDRFPCTR_x Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	The write value should be the value after reset.
7 to 0	RFPC[7:0]	Receive FIFO Pointer Control When these bits are set to FF _H , the read pointer moves to the next unread message in the receive FIFO buffer.

RFPC[7:0] Bits

When the RFPC[7:0] bits are set to FF_H, the read pointer moves to the next unread message in the receive FIFO buffer. At this time, the RFMC[7:0] (receive FIFO unread message counter) value in the RSCFDnCFDRFSTS_x register is decremented. Read the RSCFDnCFDRFID_x, RSCFDnCFDRFPTR_x, RSCFDnCFDRFDSTS_x, and RSCFDnCFDRFDf_x registers to read messages in the receive FIFO buffer, and then write FF_H to the RFPC[7:0] bits.

When writing FF_H to these bits, make sure that the RFE bit in the RSCFDnCFDRFCC_x register is set to 1 (receive FIFO buffers are used) and the RFEMP flag in the RSCFDnCFDRFSTS_x register is 0 (the receive FIFO buffer contains unread messages).

16.4.7.4 RSCFDnCFDRFIDx — Receive FIFO Buffer Access ID Register (x = 0 to 7)

Access: RSCFDnCFDRFIDx register can be read only in 32-bit units
 RSCFDnCFDRFIDxL, RSCFDnCFDRFIDxH registers can be read only in 16-bit units
 RSCFDnCFDRFIDxLL, RSCFDnCFDRFIDxLH, RSCFDnCFDRFIDxHL, RSCFDnCFDRFIDxHH registers can be read only in 8-bit units

Address: RSCFDnCFDRFIDx: <RSCFDn_base> + 3000_H + (80_H × x)
 RSCFDnCFDRFIDxL: <RSCFDn_base> + 3000_H + (80_H × x),
 RSCFDnCFDRFIDxH: <RSCFDn_base> + 3002_H + (80_H × x)
 RSCFDnCFDRFIDxLL: <RSCFDn_base> + 3000_H + (80_H × x),

29	Reserved	When read, the value after reset is returned.
28 to 0	RFID[28:0]	Receive FIFO Buffer ID Data The standard ID or extended ID of received message can be read. Read bits b10 to b0 for standard ID. Bits b28 to b11 are read as 0.

RFIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the message stored in the receive FIFO buffer.

RFRTR Bit

When the received message is a classical CAN frame, this bit indicates the frame format (data frame or remote frame) of the message stored in the receive FIFO buffer. When the received message is a CAN FD frame, this bit indicates the RRS bit value in the message.

RFID[28:0] Bits

These bits indicate the ID of the message stored in the receive FIFO buffer.

16.4.7.5 RSCFDnCFDRFPTRx — Receive FIFO Buffer Access Pointer Register (x = 0 to 7)

Access: RSCFDnCFDRFPTRx register can be read only in 32-bit units
 RSCFDnCFDRFPTRxL, RSCFDnCFDRFPTRxH registers can be read only in 16-bit units
 RSCFDnCFDRFPTRxLL, RSCFDnCFDRFPTRxLH, RSCFDnCFDRFPTRxHL, RSCFDnCFDRFPTRxHH registers can be read only in 8-bit units

Address: RSCFDnCFDRFPTRx: <RSCFDn_base> + 3004_H + (80_H × x)
 RSCFDnCFDRFPTRxL: <RSCFDn_base> + 3004_H + (80_H × x),

RFDLC[3:0] Bits

These bits contain the data length of the message stored in the receive FIFO buffer.

RFPTR[11:0] Bits

These bits contain the label information of the message stored in the receive FIFO buffer.

RFTS[15:0] Bits

These bits contain the timestamp value of the message stored in the receive FIFO buffer.

16.4.7.6 RSCFDnCFDRFFDSTSx — Receive FIFO CAN FD Status Register (x = 0 to 7)

Access: RSCFDnCFDRFFDSTSx register can be read only in 32-bit units
 RSCFDnCFDRFFDSTSxL, RSCFDnCFDRFFDSTSxH registers can be read only in 16-bit units
 RSCFDnCFDRFFDSTSxLL, RSCFDnCFDRFFDSTSxLH, RSCFDnCFDRFFDSTSxHL,
 RSCFDnCFDRFFDSTSxHH registers can be read only in 8-bit units

Address: RSCFDnCFDRFFDSTSx: <RSCFDn_base> + 3008_H + (80_H × x)
 RSCFDnCFDRFFDSTSxL: <RSCFDn_base> + 3008_H + (80_H × x),

2	RFFDF	FD Format 0: Classical CAN frame 1: CAN FD frame
1	RFBRS	BRS 0: The bit rate in the data area does not change. 1: The bit rate in the data area changes.
0	RFESI	ESI 0: Error active node 1: Error passive node

RFFDF Bit

This bit indicates the FD format (classical CAN frame or CAN FD frame) of the message stored in the receive FIFO buffer.

RFBRS Bit

When the RFFDF bit is 1, this bit indicates the BRS bit value of the message stored in the receive FIFO buffer. When the RFFDF bit is 0, this bit is always read as 0.

RFESI Bit

When the RFFDF bit is 1, this bit indicates the ESI bit value of the message stored in the receive FIFO buffer. When the RFFDF bit is 0, this bit is always read as 0.

16.4.7.7 RSCFDnCFDRFDFd_x — Receive FIFO Buffer Access Data Field d Register (d = 0 to 15, x = 0 to 7)

Access: RSCFDnCFDRFDFd_x registers can be read only in 32-bit units
RSCFDnCFDRFDFdx_L, RSCFDnCFDRFDFdx_H registers can be read only in 16-bit units
RSCFDnCFDRFDFdx_LL, RSCFDnCFDRFDFdx_LH, RSCFDnCFDRFDFdx_HL, RSCFDnCFDRFDFdx_HH registers can be read only in 8-bit units

3	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
2	CFTXIE	Transmit/Receive FIFO Transmit Interrupt Enable 0: Transmit/receive FIFO transmit interrupt is disabled. 1: Transmit/receive FIFO transmit interrupt is enabled.
1	CFRXIE	Transmit/Receive FIFO Receive Interrupt Enable 0: Transmit/receive FIFO receive interrupt is disabled. 1: Transmit/receive FIFO receive interrupt is enabled.
0	CFE	Transmit/Receive FIFO Buffer Enable 0: No transmit/receive FIFO buffer is used. 1: Transmit/receive FIFO buffers are used.

CFITT[7:0] Bits

These bits are used to set a message transmission interval when transmitting messages continuously from a transmit/receive FIFO buffer whose CFM[1:0] bits are set to 01_B (transmit mode) or 10_B (gateway mode).

Clear the CFE bit to 0 (no transmit/receive FIFO buffer is used) before modifying the CFITT[7:0] bits.

CFTML[3:0] Bits

These bits are used to set the number of transmit buffer on the channel which will be linked to transmit/receive FIFO buffer k when the CFM[1:0] bits are set to 01_B (transmit mode) or 10_B (gateway mode). There are three transmit/receive FIFO buffers per channel, so channel number m of FIFO buffer k is calculated as $m = k/3$ (integer division). The actual assigned transmit buffer number p linked to FIFO buffer k will be $((16 \times m) + \text{CFTML}[3:0])$ (See **Table 16.89**).

See **Table 16.95** and **Table 16.95**, as for the relationship between transmit/receive FIFO buffer k and transmit buffer p .

Setting the CFDC[2:0] bits to 001_B or more enables the setting of the CFTML[3:0] bits.

Do not link to any transmit buffer which is already allocated to a transmit queue on the identical channel or to another transmit/receive FIFO buffer. Modify these bits only in global reset mode.

CFITR Bit

This bit is enabled when the CFITSS bit is 0.

When this bit is 0, the interval timer clock source is the $\text{pclk}/2$ clock divided by the value of the ITRCP[15:0] bits in the RSCFDnCFDGCFG register.

When this bit is 1, the interval timer clock source is the $\text{pclk}/2$ clock divided by (the value of the ITRCP[15:0] bits in the RSCFDnCFDGCFG register $\times 10$).

Modify this bit while the CFE bit is set to 0 (no transmit/receive FIFO buffer is used).

CFITSS Bit

When this bit is 0, the clock selected by the CFITR bit is the count source of the interval timer.

When this bit is 1, the nominal bit time clock of the channel to which the FIFO is linked is the count source of the interval timer. Use this count source only for the channel does not handle the CAN FD frames.

Modify this bit while the CFE bit is set to 0 (no transmit/receive FIFO buffer is used).

CFM[1:0] Bits

These bits are used to select transmit/receive FIFO mode. Modify these bits only in global reset mode.

CFIGCV[2:0] Bits

These bits are used to specify the number of received messages for generating a transmit/receive FIFO receive interrupt request when the CFM[1:0] bits are set to 00_B (receive mode) or 10_B (gateway mode) and the CFIM bit is set to 0 with a fraction for the total number of buffers (the setting of CFDC[2:0]).

When the CFDC[2:0] bits are set to 001_B (4 messages), set the CFIGCV[2:0] bits to 001_B , 011_B , 101_B , or 111_B .

Modify these bits only in global reset mode.

CFIM Bit

This bit is used to select a transmit/receive FIFO interrupt source. Modify this bit only in global reset mode.

CFDC[2:0] Bits

These bits are used to set the number of messages that can be stored in a single transmit/receive FIFO buffer. When these bits are set to 000_B, do not use a transmit/receive FIFO buffer. Modify these bits only in global reset mode.

CFPLS[2:0] Bits

These bits are used to select the maximum payload size that can be stored in the transmit/receive FIFO buffer. Modify these bits only in global reset mode.

CFTXIE Bit

When this bit is set to 1 and the CFTXIF flag in the RSCFDnCFDCFSTSk register is set to 1, a transmit/receive FIFO transmit interrupt request is generated.

Modify this bit with the CFE bit set to 0 (no transmit/receive FIFO buffer is used).

CFRXIE Bit

When this bit is set to 1 and the CFRXIF flag in the RSCFDnCFDCFSTSk register is set to 1, a transmit/receive FIFO receive interrupt request is generated.

Modify this bit with the CFE bit set to 0.

CFE Bit

Setting this bit to 1 makes transmit/receive FIFO buffers available.

When this bit is set to 0 in transmit mode or gateway mode, if a message in the transmit/receive FIFO buffer is being transmitted or will be transmitted next, the transmit/receive FIFO buffer becomes empty after completion of transmission of that message, or upon detection of a CAN bus error, or arbitration-lost. In other cases or in receive mode, the transmit/receive FIFO buffer becomes empty immediately.

This bit is cleared to 0 when the following conditions are met.

- Receive mode: Global reset mode
- Transmit mode or gateway mode: Channel reset mode

Modify this bit in the following mode.

- Receive mode: Global operating mode or global test mode
- Transmit mode or gateway mode: Channel communication mode or channel halt mode

After all other bits in the RSCFDnCFDCFCCK register have been set, set this bit to 1 by using another instruction.

16.4.8.2 RSCFDnCFDCFSTSk — Transmit/receive FIFO Buffer Status Register (k = 0 to 11)

Access: RSCFDnCFDCFSTSk register can be read/written in 32-bit units
 RSCFDnCFDCFSTSkL, RSCFDnCFDCFSTSkH registers can be read/written in 16-bit units
 RSCFDnCFDCFSTSkLL, RSCFDnCFDCFSTSkLH, RSCFDnCFDCFSTSkHL, RSCFDnCFDCFSTSkHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCFSTSk: $\langle \text{RSCFDn_base} \rangle + 0178_{\text{H}} + (04_{\text{H}} \times k)$
 RSCFDnCFDCFSTSkL: $\langle \text{RSCFDn_base} \rangle + 0178_{\text{H}} + (04_{\text{H}} \times k)$,
 RSCFDnCFDCFSTSkH: $\langle \text{RSCFDn_base} \rangle + 017A_{\text{H}} + (04_{\text{H}} \times k)$
 RSCFDnCFDCFSTSkLL: $\langle \text{RSCFDn_base} \rangle + 0178_{\text{H}} + (04_{\text{H}} \times k)$,
 RSCFDnCFDCFSTSkLH: $\langle \text{RSCFDn_base} \rangle + 0179_{\text{H}} + (04_{\text{H}} \times k)$,
 RSCFDnCFDCFSTSkHL: $\langle \text{RSCFDn_base} \rangle + 017A_{\text{H}} + (04_{\text{H}} \times k)$,
 RSCFDnCFDCFSTSkHH: $\langle \text{RSCFDn_base} \rangle + 017B_{\text{H}} + (04_{\text{H}} \times k)$

Value after reset: 0000 0001_H

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 16.130 RSCFDnCFDCFSTSk Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
15 to 8	CFMC[7:0]	Transmit/Receive FIFO Message Counter The number of messages stored in the transmit/receive FIFO buffer.
7 to 5	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
4	CFTXIF	Transmit/Receive FIFO Transmit Interrupt Request Flag 0: No transmit/receive FIFO transmit interrupt request is present. 1: A transmit/receive FIFO transmit interrupt request is present.
3	CFRXIF	Transmit/Receive FIFO Receive Interrupt Request Flag 0: No transmit/receive FIFO receive interrupt request is present. 1: A transmit/receive FIFO receive interrupt request is present.
2	CFMLT	Transmit/Receive FIFO Message Lost Flag 0: No transmit/receive FIFO message is lost. 1: A transmit/receive FIFO message is lost.
1	CFLL	Transmit/Receive FIFO Buffer Full Status Flag 0: The transmit/receive FIFO buffer is not full. 1: The transmit/receive FIFO buffer is full.
0	CFEMP	Transmit/Receive FIFO Buffer Empty Status Flag 0: The transmit/receive FIFO buffer contains messages. 1: The transmit/receive FIFO buffer contains no message (buffer empty).

CFMC[7:0] Bits

The CFMC[7:0] bits indicate the following values that depend on the setting of the CFM[1:0] bits in the RSCFDnCFDCFCCK register.

- When CFM[1:0] value is 01_B (transmit mode): Number of untransmitted messages in the buffer
- When CFM[1:0] value is 00_B (receive mode): Number of unread received messages in the buffer
- When CFM[1:0] value is 10_B (gateway mode): Number of untransmitted received messages in the buffer

These bits are cleared to 0 when any of the following conditions is met.

- When CFM[1:0] value is 00_B: In global reset mode
- When CFM[1:0] value is 01_B or 10_B: In channel reset mode
- When the CFE bit value in RSCFDnCFDCFCCK is 0

CFTXIF Flag

The CFTXIF flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 01_B or 10_B, and the factor selected by the CFIM bit in the RSCFDnCFDCFCCK register occurs

The CFTXIF flag is cleared to 0 when any of the following conditions is met.

- When 0 is written to the CFTXIF flag
- When the CFM[1:0] bits are set to 00_B: In global reset mode
- When the CFM[1:0] bits are set to 01_B or 10_B: In channel reset mode

Write 0 to this flag in global operating mode or global test mode.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

CFRXIF Flag

The CFRXIF flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 00_B or 10_B, and the factor selected by the CFIM bit in the RSCFDnCFDCFCCK register occurs

The CFRXIF flag is cleared to 0 when any of the following conditions is met.

- When 0 is written to the CFRXIF flag
- When the CFM[1:0] bits are set to 00_B: In global reset mode
- When the CFM[1:0] bits are set to 01_B or 10_B: In channel reset mode

Write 0 to this flag in global operating mode or global test mode.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared.

When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

CFMLT Flag

The CFMLT flag is set to 1 when any of the following conditions is met.

- When an attempt is made to store a new message while the transmit/receive FIFO buffer is full. In this case, the new message is discarded.

The CFMLT flag is cleared to 0 when any of the following conditions is met.

- When 0 is written to the CFMLT flag
- When the CFM[1:0] bits are set to 00_B: In global reset mode
- When the CFM[1:0] bits are set to 01_B or 10_B: In channel reset mode

Write 0 to this flag in global operating mode or global test mode

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

CFLL Flag

The CFLL flag is set to 1 when any of the following conditions is met.

- When the number of messages stored in the transmit/receive FIFO buffer matches the FIFO buffer depth set by the CFDC[2:0] bits in the RSCFDnCFDCFCCK register.

The CFLL flag is cleared to 0 when any of the following conditions is met.

- When the number of messages stored in the transmit/receive FIFO buffer becomes smaller than the FIFO buffer depth set by the CFDC[2:0] bits.
- When the CFE bit in the RSCFDnCFDCFCCK register is 0 (no transmit/receive FIFO buffer is used): When not in the transmit abort
- When the CFM[1:0] bits are set to 00_B: In global reset mode
- When the CFM[1:0] bits are set to 01_B or 10_B: In channel reset mode

CFEMP Flag

The CFEMP flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 00_B: All messages have been read, or in global reset mode
- When the CFM[1:0] bits are set to 01_B or 10_B: All messages have been transmitted, or in channel reset mode
- When the CFE bit is 0 (no transmit/receive FIFO buffer is used): Not in the transmit abort

The CFEMP flag is cleared to 0 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 00_B or 10_B: At least one received message has been stored in the transmit/receive FIFO buffer.
- When the CFM[1:0] bits are set to 01_B: A value of FF_H has been written to the RSCFDnCFDCFPCTRk register after data was written to the RSCFDnCFDCFIDk, RSCFDnCFDCFPTRk, RSCFDnCFDCFFDCSTSk, and RSCFDnCFDCFDf_k registers.

NOTE

To clear CFTXIF, CFRXIF, or CFMLT flag to 0, the program must write 0. When writing, use a store instruction to write “0” to the given flag and “1” to other flags.

16.4.8.3 RSCFDnCFDCFPCTRk — Transmit/receive FIFO Buffer Pointer Control Register (k = 0 to 11)

Access: RSCFDnCFDCFPCTRk register can only be written in 32-bit units
RSCFDnCFDCFPCTRkL, RSCFDnCFDCFPCTRkH registers can only be written in 16-bit units
RSCFDnCFDCFPCTRkLL, RSCFDnCFDCFPCTRkLH, RSCFDnCFDCFPCTRkHL,
RSCFDnCFDCFPCTRkHH registers can only be written in 8-bit units

Address: RSCFDnCFDCFPCTRk: $\langle \text{RSCFDn_base} \rangle + 01D8_H + (04_H \times k)$
RSCFDnCFDCFPCTRkL: $\langle \text{RSCFDn_base} \rangle + 01D8_H + (04_H \times k)$,
RSCFDnCFDCFPCTRkH: $\langle \text{RSCFDn_base} \rangle + 01DA_H + (04_H \times k)$
RSCFDnCFDCFPCTRkLL: $\langle \text{RSCFDn_base} \rangle + 01D8_H + (04_H \times k)$,
RSCFDnCFDCFPCTRkLH: $\langle \text{RSCFDn_base} \rangle + 01D9_H + (04_H \times k)$,
RSCFDnCFDCFPCTRkHL: $\langle \text{RSCFDn_base} \rangle + 01DA_H + (04_H \times k)$,
RSCFDnCFDCFPCTRkHH: $\langle \text{RSCFDn_base} \rangle + 01DB_H + (04_H \times k)$

Table 16.131 RSCFDnCFDCFPCTRk Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	The write value should be the value after reset.
7 to 0	CFPC[7:0]	Transmit/Receive FIFO Pointer Control <ul style="list-style-type: none"> Receive mode: Writing FF_H to these bits moves the read pointer to the next unread message in the transmit/receive FIFO buffer. Transmit mode: Writing FF_H to these bits moves the write pointer to the next stage of the transmit/receive FIFO buffer. Gateway mode: Setting prohibited

CFPC[7:0] Bits

- Receive mode (CFM[1:0] value in the RSCFDnCFDCFCCK register is 00_B):
Writing FF_H to the CFPC[7:0] bits moves the read pointer to the next unread message in the transmit/receive FIFO buffer. At this time, the CFMC[7:0] value (transmit/receive FIFO message counter) in the RSCFDnCFDCFSTSk register is decremented. Read the RSCFDnCFDCFIDk, RSCFDnCFDCFPTRk, RSCFDnCFDCFFDCSTSk, and RSCFDnCFDCFDf_k registers to read messages from the transmit/receive FIFO buffer, and then write FF_H to the CFPC[7:0] bits.

When writing FF_H to these bits, make sure that the CFE bit in the RSCFDnCFDCFCCK register is set to 1 (transmit/receive FIFO buffers are used) and the CFEMP flag in the RSCFDnCFDCFSTSk register is 0 (the transmit/receive FIFO buffer contains messages).

- Transmit mode (CFM[1:0] value in the RSCFDnCFDCFCCK register is 01_B):
Writing FF_H to the CFPC[7:0] bits stores the data written to the RSCFDnCFDCFIDk, RSCFDnCFDCFPTRk, RSCFDnCFDCFFDCSTSk, and RSCFDnCFDCFDFd_k registers in the transmit/receive FIFO buffer and moves the write pointer to the next stage of the transmit/receive FIFO buffer. At this time, the CFMC[7:0] value is incremented. Write transmit messages to the RSCFDnCFDCFIDk, RSCFDnCFDCFPTRk, RSCFDnCFDCFFDCSTSk, and RSCFDnCFDCFDFd_k registers before writing FF_H to the CFPC[7:0] bits.
When writing FF_H to these bits, make sure that the CFE bit in the RSCFDnCFDCFCCK register is set to 1 and the CFFLL flag in the RSCFDnCFDCFSTSk register is 0 (the transmit/receive FIFO buffer is not full).
- Gateway mode (CFM[1:0] value in the RSCFDnCFDCFCCK register is 10_B):
Setting prohibited

16.4.8.4 RSCFDnCFDCFDk — Transmit/receive FIFO Buffer Access ID Register (k = 0 to 11)

Access: RSCFDnCFDCFDk register can be read/written in 32-bit units
 RSCFDnCFDCFDkL, RSCFDnCFDCFDkH registers can be read/written in 16-bit units
 RSCFDnCFDCFDkLL, RSCFDnCFDCFDkLH, RSCFDnCFDCFDkHL, RSCFDnCFDCFDkHH registers can be read/written in 8-bit units

Bit Position	Bit Name	Function
31	CFIDE	Transmit/Receive FIFO Buffer IDE 0: Standard ID 1: Extended ID
30	CFRTR	Transmit/Receive FIFO Buffer RTR/RRS <ul style="list-style-type: none"> When the CFM[1:0] value is 01_B (transmit mode) <ul style="list-style-type: none"> When the transmit message is a classical CAN frame 0: Data frame 1: Remote frame When the transmit message is a CAN FD frame Write 0 to this bit. When the CFM[1:0] value is 00_B (receive mode) <ul style="list-style-type: none"> When the received message is a classical CAN frame 0: Data frame 1: Remote frame When the received message is a CAN FD frame The RRS bit value of the received message can be read.
29	THLEN	Transmit History Data Store Enable This bit is valid only when the CFM[1:0] value is 01 _B (transmit mode). 0: Transmit history data is not stored in the buffer. 1: Transmit history data is stored in the buffer.
28 to 0	CFID[28:0]	Transmit/Receive FIFO Buffer ID Data <ul style="list-style-type: none"> When CFM[1:0] value is 01_B (transmit mode): Set standard ID or extended ID. For standard ID, write an ID to bits 10 to 0 and write 0 to bits 28 to 11. When CFM[1:0] value is 00_B (receive mode): Standard ID or extended ID in the received message can be read. For standard ID, read bits 10 to 0. Bits 28 to 11 are read as 0.

This register is writable only when the CFM[1:0] value in the RSCFDnCFDCFCCK register is 01_B (transmit mode). This register is readable only when the CFM[1:0] value is 00_B (receive mode). This RSCFDnCFDCFIDk register should not be read or written when the CFM[1:0] value is 10_B (gateway mode).

CFIDE Bit

This bit indicates the ID format (standard ID or extended ID) of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, these bits are used to set the ID format of the message to be transmitted from the transmit/receive FIFO buffer.

CFRTR Bit

If the the received message is a classical CAN frame, this bit indicates the data format (data frame or remote frame) of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. If the received message is a CAN FD frame, this bit indicates the RRS bit value of the received message.

When the CFM[1:0] value is 01_B, this bit is used to set the data format of the message to be transmitted from the transmit/receive FIFO buffer.

When the CFFDF bit in the RSCFDnCFDCFFDCSTSk register is 1 (CAN FD frame), set this bit to 0.

THLEN Bit

When this bit is set to 1, the transmit history data (label information, buffer number, buffer type, and timestamp) of transmit messages is stored in the transmit history buffer after transmission is completed.

This bit is enabled when the CFM[1:0] value is 01_B (transmit mode).

CFID[28:0] Bits

These bits contain the ID of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B.

When the CFM[1:0] value is 01_B, this bit is used to set the ID of the message to be transmitted from the transmit/receive FIFO buffer.

16.4.8.5 RSCFDnCFDCFPTRk — Transmit/receive FIFO Buffer Access Pointer Register (k = 0 to 11)

Access: RSCFDnCFDCFPTRk register can be read/written in 32-bit units
 RSCFDnCFDCFPTRkL, RSCFDnCFDCFPTRkH registers can be read/written in 16-bit units
 RSCFDnCFDCFPTRkLL, RSCFDnCFDCFPTRkLH, RSCFDnCFDCFPTRkHL, RSCFDnCFDCFPTRkHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCFPTRk: <RSCFDn_base> + 3404_H + (80_H × k)
 RSCFDnCFDCFPTRkL: <RSCFDn_base> + 3404_H + (80_H × k),

		<ul style="list-style-type: none"> When CFM[1:0] value is 01_B (transmit mode): Set the label information to be stored in the transmit history buffer. Only bits CFPTR[7:0] are valid. When CFM[1:0] value is 00_B (receive mode): The label information of the received message can be read. 																																																																																																

Table 16.133 RSCFDnCFDCFPTRk Register Contents (2/2)

Bit Position	Bit Name	Function
15 to 0	CFTS[15:0]	Transmit/Receive FIFO Buffer Timestamp Data These bits are valid only when the CFM[1:0] value is 00 _B (receive mode). The timestamp value of the received message can be read.

This register is writable only when the CFM[1:0] value in the RSCFDnCFDCFCCK register is 01_B (transmit mode). This register is readable only when the CFM[1:0] value is 00_B (receive mode). This register should not be read or written when the CFM[1:0] value is 10_B (gateway mode).

CFDLC[3:0] Bits

These bits indicate the data length of the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B.

When the CFM[1:0] value is 01_B, these bits are used to set the data length of the message to be transmitted from the transmit/receive FIFO buffer.

When the CFDLC[3:0] bits are set to 1001_B or more while the CFFDF bit in the RSCFDnCFDCFFDCSTSk register is 0 (CAN frame), 8-byte data is transmitted actually. When the CFFDF bit is 1 (CAN FD frame), the settable value range varies depending on the settings of the TMME bit in the RSCFDnCFDCmFDCFG register and the CFPLS[2:0] bits in the RSCFDnCFDCFCCK register.

- When TMME bit = 0 (transmit buffer merge mode disabled):
A value of 0000_B to 1111_B is settable. If the specified data length exceeds the payload storage size specified by the CFPLS[2:0] bits, excessive payloads are padded by CC_H.
- When TMME bit = 1 (transmit buffer merge mode enabled):
Set the data length within the payload storage size specified by the CFPLS[2:0] bits.

CFPTR[11:0] Bits

These bits indicate the label information attached to the received message stored in the transmit/receive FIFO buffer when the CFM[1:0] value is 00_B. When the CFM[1:0] value is 01_B, the CFPTR[7:0] value is stored in the transmit history buffer when message transmission has been completed.

CFTS[15:0] Bits

These bits indicate the timestamp value of the message stored in the transmit/receive FIFO buffer.

These bits are valid when the CFM[1:0] value is 00_B.

16.4.8.6 RSCFDnCFDCFFDCSTSk — Transmit/Receive FIFO CAN FD Configuration/Status Register (k = 0 to 11)

Access: RSCFDnCFDCFFDCSTSk register can be read/written in 32-bit units
 RSCFDnCFDCFFDCSTSkL, RSCFDnCFDCFFDCSTSkH registers can be read/written in 16-bit units
 RSCFDnCFDCFFDCSTSkLL, RSCFDnCFDCFFDCSTSkLH, RSCFDnCFDCFFDCSTSkHL,
 RSCFDnCFDCFFDCSTSkHH registers can be read/written in 8-bit units

1	CFBRS	BRS 0: The bit rate in the data area does not change. 1: The bit rate in the data area changes.
0	CFESI	ESI 0: Error active node 1: Error passive node

This register is writable only when the CFM[1:0] value in the RSCFDnCFDCFCCK register is 01_B (transmit mode). This register is readable only when the CFM[1:0] value is 00_B (receive mode). Do not read or write this register when the CFM[1:0] value is 10_B (gateway mode).

CFFDF Bit

When the CFM[1:0] value is 00_B, this bit indicates the FD format (classical CAN frame or CAN FD frame) of the message stored in the transmit/receive FIFO buffer. When the CFM[1:0] value is 01_B, this bit is used to set the FD format of the message to be transmitted from the transmit/receive FIFO buffer.

CFBRS Bit

When the CFM[1:0] value is 00_B, if the CFFDF bit is 1, this bit indicates the BRS bit value of the message stored in the transmit/receive FIFO buffer. If the CFFDF bit is 0, this bit is always read as 0.

When the CFM[1:0] value is 01_B, if the CFFDF bit is 1, this bit is used to set the BRS bit value of the message to be transmitted from the transmit/receive FIFO buffer. If the CFFDF bit is 0, write 0 to this bit.

CFESI Bit

When the CFM[1:0] value is 00_B, if the CFFDF bit is 1, this bit indicates the ESI bit value of the message stored in the transmit/receive FIFO buffer. If the CFFDF bit is 0, this bit is always read as 0.

When the CFM[1:0] value is 01_B, if the CFFDF bit is 1, this bit is used to set the ESI bit value of the message to be transmitted from the transmit/receive FIFO buffer. The set value is transmitted when the ESIC bit in the RSCFDnCFDCmFDCFG register is 1 and the channel is in the error active state. When the channel is in the error passive state, the ESI bit value that shows an error passive node is transmitted regardless of this bit value. When the CFFDF bit is 0, write 0 to this bit.

16.4.8.7 RSCFDnCFDCFDf_d_k — Transmit/receive FIFO Buffer Access Data Field d Register (d = 0 to 15, k = 0 to 11)

Access: RSCFDnCFDCFDf_d_k register can be read/written in 32-bit units
 RSCFDnCFDCFDf_d_kL, RSCFDnCFDCFDf_d_kH registers can be read/written in 16-bit units
 RSCFDnCFDCFDf_d_kLL, RSCFDnCFDCFDf_d_kLH, RSCFDnCFDCFDf_d_kHL, RSCFDnCFDCFDf_d_kHH registers can be read/written in 8-bit units

Address: RSCFDnCFDCFDf_d_k: $\langle \text{RSCFDn_base} \rangle + 340C_H + (04_H \times d) + (80_H \times k)$
 RSCFDnCFDCFDf_d_kL: $\langle \text{RSCFDn_base} \rangle + 340C_H + (04_H \times d) + (80_H \times k)$,
 RSCFDnCFDCFDf_d_kH: $\langle \text{RSCFDn_base} \rangle + 340E_H + (04_H \times d) + (80_H \times k)$
 RSCFDnCFDCFDf_d_kLL: $\langle \text{RSCFDn_base} \rangle + 340C_H + (04_H \times d) + (80_H \times k)$,
 RSCFDnCFDCFDf_d_kLH: $\langle \text{RSCFDn_base} \rangle + 340D_H + (04_H \times d) + (80_H \times k)$,
 RSCFDnCFDCFDf_d_kHL: $\langle \text{RSCFDn_base} \rangle + 340E_H + (04_H \times d) + (80_H \times k)$,
 RSCFDnCFDCFDf_d_kHH: $\langle \text{RSCFDn_base} \rangle + 340F_H + (04_H \times d) + (80_H \times k)$

Initial value: 0000 0000_H

Table 16.135 RSCFDnCFDCFDf_d_k Register Contents

Bit Position	Bit Name	Function
31 to 24	CFDB4 × d + 3 [7:0]	Transmit/Receive FIFO Buffer Data Byte 4 × d + 3 Transmit/Receive FIFO Buffer Data Byte 4 × d + 2
23 to 16	CFDB4 × d + 2 [7:0]	Transmit/Receive FIFO Buffer Data Byte 4 × d + 1 Transmit/Receive FIFO Buffer Data Byte 4 × d + 0
15 to 8	CFDB4 × d + 1 [7:0]	<ul style="list-style-type: none"> When CFM[1:0] value is 01_B (transmit mode): Set the transmit/receive FIFO buffer data.
7 to 0	CFDB4 × d + 0 [7:0]	<ul style="list-style-type: none"> When CFM[1:0] value is 00_B (receive mode): The message data stored in the transmit/receive FIFO buffer can be read.

This register is writable only when the CFM[1:0] value in the RSCFDnCFDCFCCK register is 01_B (transmit mode).

This register is readable only when the CFM[1:0] value is 00_B (receive mode). When the CFDLC[3:0] value in the RSCFDnCFDCFPTRk register is smaller than the payload storage size of the transmit/receive FIFO buffer, data bytes for which no data is set are read as 00_H.

Specify the payload storage size of the transmit/receive FIFO buffer by the CFPLS[2:0] bits in the RSCFDnCFDCFCCK register. Do not read or write the RSCFDnCFDCFDf_d_k register corresponding to an area larger than the specified size.

This register should not be read or written when the CFM[1:0] value is 10_B (gateway mode).

16.4.9 Details of FIFO Status-related Registers

16.4.9.1 RSCFDnCFDFESTS — FIFO Empty Status Register

Access: RSCFDnCFDFESTS registers can be read only in 32-bit units
 RSCFDnCFDFESTSL, RSCFDnCFDFESTSH registers can be read only in 16-bit units
 RSCFDnCFDFESTSLL, RSCFDnCFDFESTSLH, RSCFDnCFDFESTSHL, RSCFDnCFDFESTSHH registers can be read only in 8-bit units

Address: RSCFDnCFDFESTS: <RSCFDn_base> + 0238_H
 RSCFDnCFDFESTSL: <RSCFDn_base> + 0238_H, RSCFDnCFDFESTSH: <RSCFDn_base> + 023A_H
 RSCFDnCFDFESTSLL: <RSCFDn_base> + 0238_H, RSCFDnCFDFESTSLH: <RSCFDn_base> + 0239_H,
 RSCFDnCFDFESTSHL: <RSCFDn_base> + 023A_H, RSCFDnCFDFESTSHH: <RSCFDn_base> + 023B_H

Value after reset: 03FF FFFF_H

Table 16.136 RSCFDnCFDFESTS Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned.
19	CF11EMP	Transmit/Receive FIFO Buffer Empty Status Flag
18	CF10EMP	0: Transmit/receive FIFO buffer k contains a message. 1: Transmit/receive FIFO buffer k contains no message.
17	CF9EMP	(k = 0 to 11)
16	CF8EMP	
15	CF7EMP	
14	CF6EMP	
13	CF5EMP	
12	CF4EMP	
11	CF3EMP	
10	CF2EMP	
9	CF1EMP	
8	CF0EMP	
7	RF7EMP	Receive FIFO Buffer Empty Status Flag
6	RF6EMP	0: Receive FIFO buffer x contains an unread message. 1: Receive FIFO buffer x contains no unread message (buffer empty).
5	RF5EMP	(x = 0 to 7)
4	RF4EMP	
3	RF3EMP	
2	RF2EMP	
1	RF1EMP	
0	RF0EMP	

The RSCFDnCFDFESTS register is set to 03FF FFFF_H in global reset mode.

CFkEMP Flag (k = 0 to 11)

The CFkEMP flag is set to 1 when the CFEMP flag in the RSCFDnCFDCFSTSk register is set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)). When the CFEMP flag is cleared to 0 (the transmit/receive FIFO buffer contains messages), the CFkEMP flag is cleared to 0.

RFxEMP Flag (x = 0 to 7)

The RFxEMP flag is set to 1 when the RFEMP flag in the RSCFDnCFDRFSTx register is set to 1 (the receive FIFO buffer contains no unread message). When the RFEMP flag is cleared to 0 (the receive FIFO buffer contains unread messages), the RFxEMP flag is cleared to 0.

16.4.9.2 RSCFDnCFDFFSTS — FIFO Full Status Register

Access: RSCFDnCFDFFSTS register can be read only in 32-bit units
 RSCFDnCFDFFSTSL, RSCFDnCFDFFSTSH registers can be read only in 16-bit units
 RSCFDnCFDFFSTSL, RSCFDnCFDFFSTSLH, RSCFDnCFDFFSTSHL, RSCFDnCFDFFSTSHH registers can be read only in 8-bit units

Address: RSCFDnCFDFFSTS: <RSCFDn_base> + 023C_H
 RSCFDnCFDFFSTSL: <RSCFDn_base> + 023C_H, RSCFDnCFDFFSTSH: <RSCFDn_base> + 023E_H
 RSCFDnCFDFFSTSL: <RSCFDn_base> + 023C_H, RSCFDnCFDFFSTSLH: <RSCFDn_base> + 023D_H,
 RSCFDnCFDFFSTSHL: <RSCFDn_base> + 023E_H, RSCFDnCFDFFSTSHH: <RSCFDn_base> + 023F_H

Value after reset: 0000 0000_H

Table 16.137 RSCFDnCFDFFSTS Register Contents

Bit Position	Bit Name	Function
31 to 20	Reserved	When read, the value after reset is returned.
19	CF11FLL	Transmit/Receive FIFO Buffer Full Status Flag
18	CF10FLL	0: Transmit/receive buffer k is not full.
17	CF9FLL	1: Transmit/receive buffer k is full.
16	CF8FLL	(k = 0 to 11)
15	CF7FLL	
14	CF6FLL	
13	CF5FLL	
12	CF4FLL	
11	CF3FLL	
10	CF2FLL	
9	CF1FLL	
8	CF0FLL	
7	RF7FLL	Receive FIFO Buffer Full Status Flag
6	RF6FLL	0: Receive FIFO buffer x is not full.
5	RF5FLL	1: Receive FIFO buffer x is full.
4	RF4FLL	(x = 0 to 7)
3	RF3FLL	
2	RF2FLL	
1	RF1FLL	
0	RF0FLL	

The RSCFDnCFDFFSTS register is cleared to 0000 0000_H in global reset mode.

CFkFLL Flag (k = 0 to 11)

The CFkFLL flag is set to 1 when the CFFLL flag in the RSCFDnCFDCFSTSk register is set to 1 (the transmit/receive FIFO buffer is full).

When the CFFLL flag is cleared to 0 (the transmit/receive FIFO buffer is not full), the CFkFLL flag is cleared to 0.

RFxFLl Flag (x = 0 to 7)

The RFxFLl flag is set to 1 when the RFFLL flag in the RSCFDnCFDRFSTsx register is set to 1 (the receive FIFO buffer is full). When the RFFLL flag is cleared to 0 (the receive FIFO buffer is not full), the RFxFLl flag is cleared to 0.

16.4.9.3 RSCFDnCFDFMSTS — FIFO Message Lost Status Register

Access: RSCFDnCFDFMSTS register can be read only in 32-bit units
RSCFDnCFDFMSTSL, RSCFDnCFDFMSTSH registers can be read only in 16-bit units
RSCFDnCFDFMSTSLL, RSCFDnCFDFMSTSLH, RSCFDnCFDFMSTSHL, RSCFDnCFDFMSTSHH registers can be read only in 8-bit units

Address: RSCFDnCFDFMSTS: <RSCFDn_base> + 0240_H
RSCFDnCFDFMSTSL: <RSCFDn_base> + 0240_H, RSCFDnCFDFMSTSH: <RSCFDn_base> + 0242_H
RSCFDnCFDFMSTSLL: <RSCFDn_base> + 0240_H, RSCFDnCFDFMSTSLH: <RSCFDn_base> + 0241_H,
RSCFDnCFDFMSTSHL: <RSCFDn_base> + 0242_H, RSCFDnCFDFMSTSHH: <RSCFDn_base> + 0243_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

5	RF5MLT	
4	RF4MLT	
3	RF3MLT	
2	RF2MLT	
1	RF1MLT	
0	RF0MLT	

The RSCFDnCFDFMSTS register is cleared to 0000 0000_H in global reset mode.

CFkMLT Flag (k = 0 to 11)

The CFkMLT flag is set to 1 when the CFMLT flag in the RSCFDnCFDCFSTSk register is set to 1 (a transmit/receive FIFO message is lost). When the CFMLT flag is cleared to 0, the CFkMLT flag is cleared to 0.

RFxMLT Flag (x = 0 to 7)

The RFxMLT flag is set to 1 when the RFMLT flag in the RSCFDnCFDRFSTx register is set to 1 (a receive FIFO message is lost). When the RFMLT flag is cleared to 0, the RFxMLT flag is cleared to 0.

16.4.9.4 RSCFDnCFDRFISTS — Receive FIFO Buffer Interrupt Flag Status Register

Access: RSCFDnCFDRFISTS register can be read only in 32-bit units
 RSCFDnCFDRFISTS_{SL}, RSCFDnCFDRFISTS_{SH} registers can be read only in 16-bit units
 RSCFDnCFDRFISTS_{SLL}, RSCFDnCFDRFISTS_{SLH}, RSCFDnCFDRFISTS_{SHL}, RSCFDnCFDRFISTS_{SHH}
 registers can be read only in 8-bit units

Address: RSCFDnCFDRFISTS: <RSCFDn_base> + 0244_H
 RSCFDnCFDRFISTS_{SL}: <RSCFDn_base> + 0244_H, RSCFDnCFDRFISTS_{SH}: <RSCFDn_base> + 0246_H
 RSCFDnCFDRFISTS_{SLL}: <RSCFDn_base> + 0244_H, RSCFDnCFDRFISTS_{SLH}: <RSCFDn_base> + 0245_H,
 RSCFDnCFDRFISTS_{SHL}: <RSCFDn_base> + 0246_H, RSCFDnCFDRFISTS_{SHH}: <RSCFDn_base> + 0247_H

Value after reset: 0000 0000_H

Table 16.141 RSCFDnCFDCFTISTS Register Contents

Bit Position	Bit Name	Function
31 to 12	Reserved	When read, the value after reset is returned.
11	CF11TXIF	Transmit/Receive FIFO Buffer Transmit Interrupt Request Status Flag 0: No transmit/receive FIFO buffer k transmit interrupt request is present. 1: A transmit/receive FIFO buffer k transmit interrupt request is present. (k = 0 to 11)
10	CF10TXIF	
9	CF9TXIF	
8	CF8TXIF	
7	CF7TXIF	
6	CF6TXIF	
5	CF5TXIF	
4	CF4TXIF	
3	CF3TXIF	
2	CF2TXIF	
1	CF1TXIF	
0	CF0TXIF	

The RSCFDnCFDCFTISTS register is cleared to 0000 0000_H in global reset mode.

CFkTXIF Flag (k = 0 to 11)

The CFkTXIF flag is set to 1 when the CFTXIF flag in the RSCFDnCFDCFSTSk register is set to 1 (a transmit/receive FIFO transmit interrupt request is present). When the CFTXIF flag is cleared to 0, the CFkTXIF flag is cleared to 0.

16.4.10 Details of Transmit Buffer-related Registers

16.4.10.1 RSCFDnCFDTMCp — Transmit Buffer Control Register (p = 0 to 63)

Access: RSCFDnCFDTMCp register can be read/written in 8-bit units

Address: RSCFDnCFDTMCp: <RSCFDn_base> + 0250_H + (01_H × p)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	—	—	TMOM	TMTAR	TMTR
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W* ¹	R/W* ¹

Note 1. The only effective value for writing to this bit is 1, which sets the bit. Otherwise writing to the bit results in retention of its state.

Table 16.142 RSCFDnCFDTMCp Register Contents

Bit Position	Bit Name	Function
7 to 3	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
2	TMOM	One-Shot Transmission Enable 0: One-shot transmission is disabled. 1: One-shot transmission is enabled.
1	TMTAR	Transmit Abort Request 0: Transmit abort is not requested. 1: Transmit abort is requested.
0	TMTR	Transmit Request 0: Transmission is not requested. 1: Transmission is requested.

When the RSCFDnCFDTMCp register meets any of the following conditions, set it to 00_H.

- The RSCFDnCFDTMCp register corresponds to the transmit buffer number selected by the CFTML[3:0] bits in the RSCFDnCFDCFCCK register (p = m × 16 + the value of CFTML[3:0] bits).
- The RSCFDnCFDTMCp register corresponds to the transmit buffer allocated to the transmit queue by the TXQDC[3:0] bits in the RSCFDnCFDCTXQCCm (m = 0 to 3) register (p = (m × 16 + 15) to (m × 16 + 15 + the value of TXQDC[3:0] bits)).
- RSCFDnCFDTMCp register (p = (m × 16) + 1, (m × 16) + 2, (m × 16) + 4, or (m × 16) + 5) corresponding to the transmit buffer allocated as a payload storage area when the TMME bit in the RSCFDnCFDCmFDCFG register is 1 (transmit buffer merge mode)

Bits in the RSCFDnCFDTMCp register are all cleared to 0 in channel reset mode. Modify the RSCFDnCFDTMCp register in channel communication mode or channel halt mode.

TMOM Bit

Setting this bit to 1 enables one-shot transmission. When transmission fails, retransmission defined in the CAN protocol is not performed.

Modify the TMOM bit when the TMTRM flag in the RSCFDnCFDTMSTSp register is set to 0. Set the TMOM bit to 1 together with the TMTR bit.

TMTAR Bit

Setting this bit to 1 generates a transmit abort request for the message stored in the transmit buffer. However, a message that is being transmitted or one that will be transmitted next cannot be aborted.

The TMTAR bit can be set to 1 when TMTR bit is 1.

The TMTAR bit is cleared to 0 when any of the following conditions is met, but cannot be cleared by the program writing 0 to the bit.

- Transmission has been completed.
- Transmit abort has been completed.
- An error or arbitration loss has been detected.

If this bit becomes 0 at the same time as the program writes 1 to this bit, this bit becomes 0.

TMTR Bit

Setting this bit to 1 transmits the message stored in the transmit buffer.

The TMTR bit is cleared to 0 when any of the following conditions is met, but cannot be cleared by the program writing 0 to the bit.

- Transmission has been completed.
- Transmit abort has been completed after the TMTAR bit was set to 1.
- An error or arbitration-lost has been detected with the TMOM bit set to 1.

Set the TMTR bit to 1 when the value of TMTRF[1:0] in the RSCFDnCFDTMSTSp register is 00_B.

16.4.10.2 RSCFDnCFDTMSTSp — Transmit Buffer Status Register (p = 0 to 63)

Access: RSCFDnCFDTMSTSp register can be read/written in 8-bit units

Address: RSCFDnCFDTMSTSp: <RSCFDn_base> + 02D0_H + (01_H × p)

Value after reset: 00_H

Bit	7	6	5	4	3	2	1	0
	—	—	—	TMTARM	TMTRM	TMTRF[1:0]		TMTSTS
Value after reset	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R

Table 16.143 RSCFDnCFDTMSTSp Register Contents

Bit Position	Bit Name	Function
7 to 5	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
4	TMTARM	Transmit Buffer Transmit Abort Request Status Flag 0: No transmit abort request is present. 1: A transmit abort request is present.
3	TMTRM	Transmit Buffer Transmit Request Status Flag 0: No transmit request is present. 1: A transmit request is present.
2, 1	TMTRF[1:0]	Transmit Buffer Transmit Result Status Flag b2 b1 0 0: Transmission is in progress or no transmit request is present. 0 1: Transmit abort has been completed. 1 0: Transmission has been completed (without transmit abort request). 1 1: Transmission has been completed (with transmit abort request).
0	TMTSTS	Transmit Buffer Transmit Status Flag 0: Transmission is not in progress. 1: Transmission is in progress.

The RSCFDnCFDTMSTSp register is cleared to all 0 in channel reset mode.

TMTARM Flag

The TMTARM flag is set to 1 when the TMTAR bit in the RSCFDnCFDTMCp register is set to 1.

The TMTARM flag is set to 0 when the TMTAR bit in the RSCFDnCFDTMCp register is set to 0.

TMTRM Flag

The TMTRM flag is set to 1 when the TMTR bit in the RSCFDnCFDTMCp register is set to 1.

The TMTRM flag is set to 0 when the TMTR bit in the RSCFDnCFDTMCp register is set to 0.

TMTRF[1:0] Flag

This flag indicates the result of transmission from the transmit buffer.

00_B: Transmission is in progress or no transmit request is present.

01_B: Transmission from the transmit buffer was aborted.

10_B: Transmission has been completed with the TMTAR bit in the RSCFDnCFDTMCp register set to 0 (transmit abort is not requested).

11_B: Transmission has been completed with the TMTAR bit in the RSCFDnCFDTMCp register set to 1 (transmit abort is requested).

Write 00_B to the TMTRF[1:0] flag in channel communication mode or channel halt mode. Do not write any value other than 00_B to this flag.

TMTSTS Flag

This flag is set to 1 when transmission from the transmit buffer starts, and is cleared to 0 when transmission from the transmit buffer has been completed or terminated due to a bus error or arbitration lost.

16.4.10.3 RSCFDnCFDTMIDp — Transmit Buffer ID Register (p = 0 to 63)

Access: RSCFDnCFDTMIDp register can be read/written in 32-bit units
 RSCFDnCFDTMIDpL, RSCFDnCFDTMIDpH registers can be read/written in 16-bit units
 RSCFDnCFDTMIDpLL, RSCFDnCFDTMIDpLH, RSCFDnCFDTMIDpHL, RSCFDnCFDTMIDpHH registers
 can be read/written in 8-bit units

Address: RSCFDnCFDTMIDp: $\langle \text{RSCFDn_base} \rangle + 4000_{\text{H}} + (20_{\text{H}} \times p)$
 RSCFDnCFDTMIDpL: $\langle \text{RSCFDn_base} \rangle + 4000_{\text{H}} + (20_{\text{H}} \times p)$,
 RSCFDnCFDTMIDpH: $\langle \text{RSCFDn_base} \rangle + 4002_{\text{H}} + (20_{\text{H}} \times p)$
 RSCFDnCFDTMIDpLL: $\langle \text{RSCFDn_base} \rangle + 4000_{\text{H}} + (20_{\text{H}} \times p)$,
 RSCFDnCFDTMIDpLH: $\langle \text{RSCFDn_base} \rangle + 4001_{\text{H}} + (20_{\text{H}} \times p)$,
 RSCFDnCFDTMIDpHL: $\langle \text{RSCFDn_base} \rangle + 4002_{\text{H}} + (20_{\text{H}} \times p)$,
 RSCFDnCFDTMIDpHH: $\langle \text{RSCFDn_base} \rangle + 4003_{\text{H}} + (20_{\text{H}} \times p)$

Value after reset: 0000 0000_H

Table 16.144 RSCFDnCFDTMIDp Register Contents

Bit Position	Bit Name	Function
31	TMIDE	Transmit Buffer IDE 0: Standard ID 1: Extended ID
30	TMRTR	Transmit Buffer RTR/RRS <ul style="list-style-type: none"> When the transmit message is a classical CAN frame 0: Data frame 1: Remote frame When the transmit message is a CAN FD frame Write 0 to this bit.
29	THLEN	Transmit History Data Store Enable 0: Transmit history data is not stored in the buffer. 1: Transmit history data is stored in the buffer.
28 to 0	TMID[28:0]	Transmit Buffer ID Data Set standard ID or extended ID. For standard ID, write an ID to bits 10 to 0 and write 0 to bits 28 to 11.

Modify this register when the TMTRM bit in the corresponding RSCFDnCFDTMSTSp register is set to 0 (no transmit request is present). If this register is linked to a transmit/receive FIFO buffer, do not write data to this register. If this register is allocated to the transmit queue, only write data to a transmit buffer p ($p = m \times 16 + 15$) for the corresponding channel.

TMIDE Bit

This bit is used to set the ID format of the message to be transmitted from the transmit buffer.

TMRTR Bit

This bit is used to set the data format of the message to be transmitted from the transmit buffer.

Set this bit to 0 when the TMFDF bit in the RSCFDnCFDTMFDCTR_p register is 1 (CAN FD frame).

THLEN Bit

When this bit is set to 1, the transmit history data (label information, buffer number, buffer type, and timestamp) of transmit messages is stored in the transmit history buffer after transmission is completed.

TMID[28:0] Bits

These bits are used to set the ID of the message to be transmitted from the transmit buffer.

16.4.10.4 RSCFDnCFDTMPTRp — Transmit Buffer Pointer Register (p = 0 to 63)

Access: RSCFDnCFDTMPTRp register can be read/written in 32-bit units
 RSCFDnCFDTMPTRpL, RSCFDnCFDTMPTRpH registers can be read/written in 16-bit units
 RSCFDnCFDTMPTRpLL, RSCFDnCFDTMPTRpLH, RSCFDnCFDTMPTRpHL, RSCFDnCFDTMPTRpHH registers can be read/written in 8-bit units

Address: RSCFDnCFDTMPTRp: <RSCFDn_base> + 4004_H + (20_H × p)
 RSCFDnCFDTMPTRpL: <RSCFDn_base> + 4004_H + (20_H × p),
 RSCFDnCFDTMPTRpH: <RSCFDn_base> + 4006_H + (20_H × p)
 RSCFDnCFDTMPTRpLL: <RSCFDn_base> + 4004_H + (20_H × p),
 RSCFDnCFDTMPTRpLH: <RSCFDn_base> + 4005_H + (20_H × p),
 RSCFDnCFDTMPTRpHL: <RSCFDn_base> + 4006_H + (20_H × p),
 RSCFDnCFDTMPTRpHH: <RSCFDn_base> + 4007_H + (20_H × p)

27 to 24	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.																																																																																																
23 to 16	TMPTR[7:0]	Transmit Buffer Label Data Set the label information to be stored in the transmit history buffer.																																																																																																
15 to 0	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.																																																																																																

Modify this register when the TMTRM bit in the corresponding RSCFDnCFDTMSTSp register is set to 0 (no transmit request is present). If this register is linked to a transmit/receive FIFO buffer, do not write to this register. If this register is allocated to the transmit queue, only write to a transmit buffer p ($p = m \times 16 + 15$) for the corresponding channel.

TMDLC[3:0] Bits

These bits are used to set the data length of the message to be transmitted from the transmit buffer when the TMRTR bit in the RSCFDnCFDTMIDp register is set to 0 (data frame).

When the TMDLC[3:0] bits are set to 1001_B or more while the TMFDF bit in the RSCFDnCFDTMFDCTRp register is 0 (classical CAN frame), 8-byte data is transmitted actually. When the MFDF bit is 1 (CAN FD frame), the settable value range varies depending on the setting of the TMME bit in the RSCFDnCFDCmFDCFG register.

- When the TMME bit = 0 (transmit buffer merge mode disabled):
A value of 0000_B to 1111_B is settable. If a value larger than 1100_B is set, payloads exceeding 20 bytes are padded by CC_H .
- When the TMME bit = 1 (transmit buffer merge mode enabled):
When the corresponding transmit buffer number $p = (m \times 16) + 0$ or $(m \times 16) + 3$, a value of 0000_B to 1111_B is settable. In other cases, set a value of 0000_B to 1011_B (20 data bytes).

When the TMRTR bit is 1 (remote frame), set the data length of a message to be requested.

TMPTR[7:0] Bits

When message transmission has been completed, the TMPTR[7:0] value is stored in the transmit history buffer.

16.4.10.5 RSCFDnCFDTMFDCTR_p — Transmit Buffer CAN FD Configuration Register (p = 0 to 63)

Access: RSCFDnCFDTMFDCTR_p register can be read/written in 32-bit units
RSCFDnCFDTMFDCTR_{pL}, RSCFDnCFDTMFDCTR_{pH} registers can be read/written in 16-bit units
RSCFDnCFDTMFDCTR_{pLL}, RSCFDnCFDTMFDCTR_{pLH}, RSCFDnCFDTMFDCTR_{pHL},
RSCFDnCFDTMFDCTR_{pHH} registers can be read/written in 8-bit units

Address: RSCFDnCFDTMFDCTR_p: <RSCFDn_base> + 4008_H + (20_H × p)
RSCFDnCFDTMFDCTR_{pL}: <RSCFDn_base> + 4008_H + (20_H × p),
RSCFDnCFDTMFDCTR_{pH}: <RSCFDn_base> + 400A_H + (20_H × p)
RSCFDnCFDTMFDCTR_{pLL}: <RSCFDn_base> + 4008_H + (20_H × p),
RSCFDnCFDTMFDCTR_{pLH}: <RSCFDn_base> + 4009_H + (20_H × p),
RSCFDnCFDTMFDCTR_{pHL}: <RSCFDn_base> + 400A_H + (20_H × p),
RSCFDnCFDTMFDCTR_{pHH}: <RSCFDn_base> + 400B_H + (20_H × p)

Initial value: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.146 RSCFDnCFDTMFDCTR_p Register Contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
2	TMFDF	FDFormat 0: Classical CAN frame 1: CAN FD frame
1	TMBRS	BitRateSwitch 0: The bit rate in the data area does not change. 1: The bit rate in the data area changes.
0	TMESI	ErrorStatusIndicator 0: Error active node 1: Error passive node

Modify this register when the TMTRM bit in the corresponding RSCFDnCFDTMSTSp register is 0 (transmission not requested). When this register is linked to the transmit/receive FIFO buffer, do not write data to this register. When this register is allocated to the transmit queue, write data only to transmit buffer p (p = m × 16 + 15) of the corresponding channel.

TMFDF Bit

This bit is used to set the FD format of the message to be transmitted from the transmit buffer.

TMBRS Bit

When this bit is set to 1 while the TMFDF bit is 1, the data area of a transmit message is transmitted at the data bit rate. When the TMFDF bit is 0, write 0 to this bit.

TMESI Bit

This bit is used to set the ESI bit value of the message to be transmitted from the transmit buffer when the TMFDF bit is 1. The set value is transmitted when the ESIC bit in the RSCFDnCFDCmFDCFG register is 1 and the channel is in the error active state. When the channel is in the error passive state, the ESI bit value that shows an error passive node is transmitted regardless of this bit value. When the TMFDF bit is 0, write 0 to this bit.

16.4.10.6 RSCFDnCFDTMDFb_p — Transmit Buffer Data Field b Register (b = 0 to 4, p = 0 to 63)

Access: RSCFDnCFDTMDFb_p register can be read/written in 32-bit units
RSCFDnCFDTMDFb_pL, RSCFDnCFDTMDFb_pH registers can be read/written in 16-bit units
RSCFDnCFDTMDFb_pLL, RSCFDnCFDTMDFb_pLH, RSCFDnCFDTMDFb_pHL,
RSCFDnCFDTMDFb_pHH registers can be read/written in 8-bit units

Address: RSCFDnCFDTMDFb_p: $\langle \text{RSCFDn_base} \rangle + 400\text{C}_\text{H} + (04_\text{H} \times b) + (20_\text{H} \times p)$
RSCFDnCFDTMDFb_pL: $\langle \text{RSCFDn_base} \rangle + 400\text{C}_\text{H} + (04_\text{H} \times b) + (20_\text{H} \times p)$,
RSCFDnCFDTMDFb_pH: $\langle \text{RSCFDn_base} \rangle + 400\text{E}_\text{H} + (04_\text{H} \times b) + (20_\text{H} \times p)$
RSCFDnCFDTMDFb_pLL: $\langle \text{RSCFDn_base} \rangle + 400\text{C}_\text{H} + (04_\text{H} \times b) + (20_\text{H} \times p)$,
RSCFDnCFDTMDFb_pLH: $\langle \text{RSCFDn_base} \rangle + 400\text{D}_\text{H} + (04_\text{H} \times b) + (20_\text{H} \times p)$,

Table 16.147 RSCFDnCFDTMDFb_p Register Contents

Bit Position	Bit Name	Function
31 to 24	TMDB4 × b + 3 [7:0]	Transmit Buffer Data Byte 4 × b + 3 Transmit Buffer Data Byte 4 × b + 2
23 to 16	TMDB4 × b + 2 [7:0]	Transmit Buffer Data Byte 4 × b + 1 Transmit Buffer Data Byte 4 × b + 0
15 to 8	TMDB4 × b + 1 [7:0]	Set the transmit buffer data.
7 to 0	TMDB4 × b + 0 [7:0]	

Modify this register when the TMTRM bit in the corresponding RSCFDnCFDTMSTSp register is set to 0 (no transmit request is present). If this register is linked to a transmit/receive FIFO buffer, do not write to this register. If this register is allocated to the transmit queue, only write to a transmit buffer p ($p = m \times 16 + 15$) for the corresponding channel.

16.4.10.7 RSCFDnCFDTMIECy — Transmit Buffer Interrupt Enable Configuration Register (y = 0, 1)

Access: RSCFDnCFDTMIECy register can be read/written in 32-bit units
 RSCFDnCFDTMIECyL, RSCFDnCFDTMIECyH registers can be read/written in 16-bit units
 RSCFDnCFDTMIECyLL, RSCFDnCFDTMIECyLH, RSCFDnCFDTMIECyHL, RSCFDnCFDTMIECyHH registers can be read/written in 8-bit units

Table 16.148 RSCFDnCFDTMIECy Register Contents

Bit Position	Bit Name	Function
31 to 16	TMIEp	Transmit Buffer Interrupt Enable p (p = y × 32 + 31 to y × 32 + 16) 0: Transmit buffer interrupt is disabled 1: Transmit buffer interrupt is enabled
15 to 0	TMIEp	Transmit Buffer Interrupt Enable p (p = y × 32 + 15 to y × 32 + 0) 0: Transmit buffer interrupt is disabled. 1: Transmit buffer interrupt is enabled.

TMIEp Bits (p = 0 to 63)

When any of these bits is set to 1 and the corresponding transmission has been completed, a transmit buffer interrupt request is generated.

Modify these bits when the TMTRM flag in the corresponding RSCFDnCFDTMSTSp register is 0 (no transmit request is present).

Write 0 to bits corresponding to transmit buffers linked to transmit/receive FIFO buffers or transmit buffers allocated to the transmit queue.

When the TMME bit in the RSCFDnCFDCmFDCFG register is 1 (transmit buffer merge mode enable), set the bit corresponding to the transmit buffer allocated as a payload storage area to 0.

Table 16.149 shows the bit assignment.

Table 16.150 RSCFDnCFDTMTRSTSy Register Contents

Bit Position	Bit Name	Function
31 to 16	TMTRSTSp	Transmit Buffer Transmit Request Status Flag p (p = y × 32 + 31 to y × 32 + 16) 0: No transmit request is present. 1: A transmit request is present.
15 to 0	TMTRSTSp	Transmit Buffer Transmit Request Status Flag p (p = y × 32 + 15 to y × 32 + 0) 0: No transmit request is present. 1: A transmit request is present.

TMTRSTSp Flags (p = 0 to 63)

These flags indicate the status of the TMTR bit in the RSCFDnCFDTMCP register.

When the TMTR bit is set to 1 (transmission is requested), the corresponding TMTRSTSp flag is set to 1.

The corresponding TMTRSTSp flag is cleared to 0 when the TMTR bit is set to 0 (transmission is not requested) or in channel reset mode.

Table 16.151 shows the bit assignment.

31 to 16	TMTARSTSp	Transmit Buffer Transmit Abort Request Status Flag p (p = y × 32 + 31 to y × 32 + 16) 0: No transmit abort request is present. 1: A transmit abort request is present.
15 to 0	TMTARSTSp	Transmit Buffer Transmit Abort Request Status Flag p (p = y × 32 + 15 to y × 32 + 0) 0: No transmit abort request is present. 1: A transmit abort request is present.

TMTARSTSp Flags (p = 0 to 63)

These flags indicate the status of the TMTAR bit in the RSCFDnCFDTMCp register.

When the TMTAR bit is set to 1 (transmit abort is requested), the corresponding TMTARSTSp flag is set to 1.

The corresponding TMTARSTSp flag is cleared to 0 when the TMTAR bit is set to 0 (transmit abort is not requested) or in channel reset mode.

Table 16.156 RSCFDnCFDTMTASTSy Register Contents

Bit Position	Bit Name	Function
31 to 16	TMTASTSp	Transmit Buffer Transmit Abort Status Flag p (p = y × 32 + 31 to y × 32 + 16) 0: Transmission is not aborted 1: Transmission is aborted
15 to 0	TMTASTSp	Transmit Buffer Transmit Abort Status Flag p (p = y × 32 + 15 to y × 32 + 0) 0: Transmission is not aborted. 1: Transmission is aborted.

TMTASTSp Flags (p = 0 to 63)

When the TMTRF[1:0] flag in the RSCFDnCFDTMSTSp register is set to 01_B (transmit abort has been completed), the corresponding TMTASTSp flag is set to 1.

A TMTASTSp flag is cleared to 0 when the corresponding TMTRF[1:0] flag is set to 00_B or in channel reset mode.

Table 16.157 shows the bit assignment.

16.4.12 Details of Transmit Queue-related Registers

16.4.12.1 RSCFDnCFDnTXQCCm — Transmit Queue Configuration and Control Register (m = 0 to 3)

Access: RSCFDnCFDnTXQCCm register can be read/written in 32-bit units
 RSCFDnCFDnTXQCCmL, RSCFDnCFDnTXQCCmH registers can be read/written in 16-bit units
 RSCFDnCFDnTXQCCmLL, RSCFDnCFDnTXQCCmLH, RSCFDnCFDnTXQCCmHL, RSCFDnCFDnTXQCCmHH registers can be read/written in 8-bit units

Address: RSCFDnCFDnTXQCCm: <RSCFDn_base> + 03A0_H + (04_H × m)
 RSCFDnCFDnTXQCCmL: <RSCFDn_base> + 03A0_H + (04_H × m),
 RSCFDnCFDnTXQCCmH: <RSCFDn_base> + 03A2_H + (04_H × m)
 RSCFDnCFDnTXQCCmLL: <RSCFDn_base> + 03A0_H + (04_H × m),
 RSCFDnCFDnTXQCCmLH: <RSCFDn_base> + 03A1_H + (04_H × m),
 RSCFDnCFDnTXQCCmHL: <RSCFDn_base> + 03A2_H + (04_H × m),
 RSCFDnCFDnTXQCCmHH: <RSCFDn_base> + 03A3_H + (04_H × m)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 16.158 RSCFDnCFDnTXQCCm Register Contents

Bit Position	Bit Name	Function
31 to 14	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
13	TXQIM	Transmit Queue Interrupt Source Select 0: When the transmit queue becomes empty upon completion of message transmission, a transmit queue interrupt request is generated. 1: A transmit queue interrupt request is generated each time a message has been transmitted.
12	TXQIE	Transmit Queue Interrupt Enable 0: Transmit queue interrupt is disabled. 1: Transmit queue interrupt is enabled.
11 to 8	TXQDC[3:0]	Transmit Queue Depth Configuration Setting these bits to g (g = 2 to 15) makes the (g + 1)-buffer transmit queue available. Setting these bits to 0 disables the transmit queue. Setting these bits to 1 is prohibited. For transmit buffer merge mode, set g to 2 to 9.
7 to 1	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
0	TXQE	Transmit Queue Enable 0: The transmit queue is not used. 1: The transmit queue is used.

TXQIM Bit

This bit is used to select a transmit queue interrupt source. Modify this bit in channel reset mode.

TXQIE Bit

When the TXQIE bit is set to 1 and the source selected by the TXQIM bit occurs, an interrupt request is generated.

Set the TXQE bit to 0 before modifying the TXQIE bit.

TXQDC[3:0] Bits

These bits are used to specify the number of transmit buffers to be allocated to the transmit queues. Transmit buffers are allocated to transmit queues in descending order of buffer number, that is, from $(m \times 16 + 15)$ to $(m \times 16 + 0)$ (See **Table 16.90**). For examples of how buffer allocation is done, see **Figure 16.9**.

When the TMME bit in the RSCFDnCFDCmFDCFG register is 1 (transmit buffer merge mode), transmit buffers $(m \times 16 + 5)$ to $(m \times 16 + 0)$ are merged and cannot be allocated to the transmit queue. Therefore, do not set TXQDC[3:0] bits to 10 to 15.

Modify these bits only in channel reset mode.

TXQE Bit

Setting this bit to 1 makes the transmit queue available. Modify this bit in channel communication mode or channel halt mode. This bit is cleared to 0 in channel reset mode.

Before setting the TXQE bit to 1, set the TXQDC[3:0] bits to 0010_B or more.

16.4.12.2 RSCFDnCFDTXQSTSm — Transmit Queue Status Register (m = 0 to 3)

Access: RSCFDnCFDTXQSTSm register can be read/written in 32-bit units
 RSCFDnCFDTXQSTSmL, RSCFDnCFDTXQSTSmH registers can be read/written in 16-bit units
 RSCFDnCFDTXQSTSmLL, RSCFDnCFDTXQSTSmLH, RSCFDnCFDTXQSTSmHL,
 RSCFDnCFDTXQSTSmHH registers can be read/written in 8-bit units

Address: RSCFDnCFDTXQSTSm: <RSCFDn_base> + 03C0_H + (04_H × m)
 RSCFDnCFDTXQSTSmL: <RSCFDn_base> + 03C0_H + (04_H × m),
 RSCFDnCFDTXQSTSmH: <RSCFDn_base> + 03C2_H + (04_H × m)
 RSCFDnCFDTXQSTSmLL: <RSCFDn_base> + 03C0_H + (04_H × m),
 RSCFDnCFDTXQSTSmLH: <RSCFDn_base> + 03C1_H + (04_H × m),
 RSCFDnCFDTXQSTSmHL: <RSCFDn_base> + 03C2_H + (04_H × m),
 RSCFDnCFDTXQSTSmHH: <RSCFDn_base> + 03C3_H + (04_H × m)

Value after reset: 0000 0001_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 16.159 RSCFDnCFDTXQSTSm Register Contents

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
12 to 8	Reserved	When read, the undefined value is returned. When writing to these bits, write the value after reset.
7 to 3	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
2	TXQIF	Transmit Queue Interrupt Request Flag 0: No transmit queue interrupt request is present. 1: A transmit queue interrupt request is present.
1	TXQFL	Transmit Queue Full Status Flag 0: The transmit queue is not full. 1: The transmit queue is full.
0	TXQEMP	Transmit Queue Empty Status Flag 0: The transmit queue contains messages. 1: The transmit queue contains no message (transmit queue empty).

TXQIF Flag

The TXQIF flag is set to 1 when the event specified by the TXQIM bit in the RSCFDnCFDTXQCCm register has occurred.

The TXQIF flag is cleared to 0 in channel reset mode or by writing 0 to this flag. This flag is not cleared to 0 by setting the TXQE bit in the RSCFDnCFDTXQCCm register to 0 (the transmit queue is not used).

TXQFLL Flag

The TXQFLL flag is set to 1 when the number of messages set for the transmit queue matches the transmit queue depth set by the TXQDC[3:0] bits in the RSCFDnCFDTXQCCm register.

This flag is cleared to 0 in any of the following cases.

- The number of messages set for the transmit queue is smaller than the transmit queue depth set by the TXQDC[3:0] bits.
- In channel reset mode

TXQEMP Flag

The TXQEMP flag is cleared to 0 when even a single message is set for the transmit queue.

This flag is set to 1 in any of the following cases.

- The TXQE bit is set to 0 (the transmit queue is not used).
- The transmit queue becomes empty.
- In channel reset mode

16.4.12.3 RSCFDnCFDTXQPCTRm — Transmit Queue Pointer Control Register (m = 0 to 3)

Access: RSCFDnCFDTXQPCTRm registers can only be written in 32-bit units
 RSCFDnCFDTXQPCTRmL, RSCFDnCFDTXQPCTRmH registers can only be written in 16-bit units
 RSCFDnCFDTXQPCTRmLL, RSCFDnCFDTXQPCTRmLH, RSCFDnCFDTXQPCTRmHL,
 RSCFDnCFDTXQPCTRmHH registers can only be written in 8-bit units

Address: RSCFDnCFDTXQPCTRm: <RSCFDn_base> + 03E0_H + (04_H × m)
 RSCFDnCFDTXQPCTRmL: <RSCFDn_base> + 03E0_H + (04_H × m),
 RSCFDnCFDTXQPCTRmH: <RSCFDn_base> + 03E2_H + (04_H × m)
 RSCFDnCFDTXQPCTRmLL: <RSCFDn_base> + 03E0_H + (04_H × m),
 RSCFDnCFDTXQPCTRmLH: <RSCFDn_base> + 03E1_H + (04_H × m),
 RSCFDnCFDTXQPCTRmHL: <RSCFDn_base> + 03E2_H + (04_H × m),
 RSCFDnCFDTXQPCTRmHH: <RSCFDn_base> + 03E3_H + (04_H × m)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	TXQPC[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Table 16.160 RSCFDnCFDTXQPCTRm Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	The write value should be the value after reset.
7 to 0	TXQPC[7:0]	Transmit Queue Pointer Control Writing FF _H to these bits moves the write pointer of the transmit queue to the next queue buffer.

TXQPC[7:0] Bits

Writing FF_H to the TXQPC[7:0] bits moves the write pointer to the next transmit queue buffer and generates a transmit request of the message. Write transmit messages to the RSCFDnCFDTMIDp, RSCFDnCFDTMPTRp, RSCFDnCFDTMFDCTRp, and RSCFDnCFDTMDFb_p registers (p = 15, 31, 47, and 63) before writing FF_H to the TXQPC[7:0] bits.

When writing FF_H to these bits, make sure that the TXQE bit in the RSCFDnCFDTXQCCm register is set to 1 (the transmit queue is used) and the TXQFLL flag in the RSCFDnCFDTXQSTSm register is 0 (the transmit queue is not full).

16.4.13 Details of Transmit History-related Registers

16.4.13.1 RSCFDnCFDTHLCCm — Transmit History Configuration and Control Register (m = 0 to 3)

Access: RSCFDnCFDTHLCCm register can be read/written in 32-bit units
RSCFDnCFDTHLCCmL, RSCFDnCFDTHLCCmH registers can be read/written in 16-bit units
RSCFDnCFDTHLCCmLL, RSCFDnCFDTHLCCmLH, RSCFDnCFDTHLCCmHL, RSCFDnCFDTHLCCmHH registers can be read/written in 8-bit units

Address: RSCFDnCFDTHLCCm: $\langle \text{RSCFDn_base} \rangle + 0400_{\text{H}} + (04_{\text{H}} \times m)$
RSCFDnCFDTHLCCmL: $\langle \text{RSCFDn_base} \rangle + 0400_{\text{H}} + (04_{\text{H}} \times m)$,
RSCFDnCFDTHLCCmH: $\langle \text{RSCFDn_base} \rangle + 0402_{\text{H}} + (04_{\text{H}} \times m)$
RSCFDnCFDTHLCCmLL: $\langle \text{RSCFDn_base} \rangle + 0400_{\text{H}} + (04_{\text{H}} \times m)$,
RSCFDnCFDTHLCCmLH: $\langle \text{RSCFDn_base} \rangle + 0401_{\text{H}} + (04_{\text{H}} \times m)$,
RSCFDnCFDTHLCCmHL: $\langle \text{RSCFDn_base} \rangle + 0402_{\text{H}} + (04_{\text{H}} \times m)$,
RSCFDnCFDTHLCCmHH: $\langle \text{RSCFDn_base} \rangle + 0403_{\text{H}} + (04_{\text{H}} \times m)$

Table 16.161 RSCFDnCFDTHLCCm Register Contents

Bit Position	Bit Name	Function
31 to 11	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
10	THLDTE	Transmit History Target Buffer Select 0: Entry from transmit/receive FIFO buffers and transmit queue 1: Entry from transmit buffers, transmit/receive FIFO buffers, and transmit queue
9	THLIM	Transmit History Interrupt Source Select 0: When 12 sets of data have been stored in the transmit history buffer 1: When a single set of transmit history data has been stored
8	THLIE	Transmit History Interrupt Enable 0: Transmit history interrupt is disabled. 1: Transmit history interrupt is enabled.
7 to 1	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
0	THLE	Transmit History Buffer Enable 0: Transmit history buffer is not used. 1: Transmit history buffer is used.

THLDTE Bit

When this bit is set to 0, the transmit history data of messages transmitted from transmit/receive FIFO buffers and the transmit queue is stored in the transmit history buffer. When this bit is set to 1, the transmit history data of messages transmitted from transmit buffers, transmit/receive FIFO buffers, and the transmit queue is stored in the transmit history buffer.

Modify this bit only in channel reset mode.

THLIM Bit

This bit is used to select a transmit history interrupt source.

Modify this bit only in channel reset mode.

THLIE Bit

When the THLIE bit is set to 1 and the source selected by the THLIM bit has occurred, a transmit history interrupt request is generated. Modify the THLIE bit only when the THLE bit set to 0.

THLE Bit

Setting this bit to 1 makes the transmit history buffer available. When data transmission from the buffer selected by the THLDTE bit has been completed, the transmit history data of transmit messages is stored in the transmit history buffer.

Modify this bit in channel communication mode or channel halt mode.

This bit is cleared to 0 in channel reset mode.

16.4.13.2 RSCFDnCFDTHLSTSm — Transmit History Status Register (m = 0 to 3)

Access: RSCFDnCFDTHLSTSm register can be read/written in 32-bit units
 RSCFDnCFDTHLSTSmL, RSCFDnCFDTHLSTSmH register can be read/written in 16-bit units
 RSCFDnCFDTHLSTSmLL, RSCFDnCFDTHLSTSmLH, RSCFDnCFDTHLSTSmHL,
 RSCFDnCFDTHLSTSmHH registers can be read/written in 8-bit units

Address: RSCFDnCFDTHLSTSm: <RSCFDn_base> + 0420_H + (04_H × m)
 RSCFDnCFDTHLSTSmL: <RSCFDn_base> + 0420_H + (04_H × m),
 RSCFDnCFDTHLSTSmH: <RSCFDn_base> + 0422_H + (04_H × m)
 RSCFDnCFDTHLSTSmLL: <RSCFDn_base> + 0420_H + (04_H × m),
 RSCFDnCFDTHLSTSmLH: <RSCFDn_base> + 0421_H + (04_H × m),
 RSCFDnCFDTHLSTSmHL: <RSCFDn_base> + 0422_H + (04_H × m),
 RSCFDnCFDTHLSTSmHH: <RSCFDn_base> + 0423_H + (04_H × m)

Value after reset: 0000 0001_H

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W*1	R/W*1	R	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

Table 16.162 RSCFDnCFDTHLSTSm Register Contents

Bit Position	Bit Name	Function
31 to 13	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
12 to 8	THLMC[4:0]	Transmit History Buffer Unread Data Counter These bits indicate the number of unread data sets stored in the transmit history buffer.
7 to 4	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
3	THLIF	Transmit History Interrupt Request Flag 0: No transmit history interrupt request is present. 1: A transmit history interrupt request is present.
2	THLELT	Transmit History Buffer Overflow Flag 0: Transmit history buffer overflow has not occurred. 1: Transmit history buffer overflow has occurred.
1	THLFLL	Transmit history Buffer Full Status Flag 0: Transmit history buffer is not full. 1: Transmit history buffer is full.
0	THLEMP	Transmit History Buffer Empty Status Flag 0: Transmit history buffer contains unread data. 1: Transmit history buffer contains no unread data (buffer empty).

THLMC[4:0] Bits

These bits indicate the number of unread data sets stored in the transmit history buffer. These bits are cleared to 0 in channel reset mode.

THLIF Flag

The THLIF flag is set to 1 when the interrupt source specified with the THLIM bit in the RSCFDnCFDTHLCCm register occurs.

This flag is cleared to 0 in channel reset mode or by the program writing 0 to this flag.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared.

When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

THLELT Flag

The THLELT flag is set to 1 when an attempt is made to store new transmit history data while the transmit history buffer is full. In this case, the new data is discarded. This flag becomes 0 in channel reset mode or by the program writing 0 to this flag.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared.

When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

THLFLL Flag

The THLFLL flag is set to 1 when 16 data sets have been stored in the transmit history buffer, and is cleared to 0 when the number of data sets stored in the transmit history buffer has decreased to less than 16. This bit is also cleared to 0 in channel reset mode or when the THLE bit in the RSCFDnCFDTHLCCm register is set to 0 (transmit history buffer is not used).

THLEMP Flag

The THLEMP flag is cleared to 0 when even a single set of transmit history data has been stored in the transmit history buffer.

This flag is set to 1 when all the data in the transmit history buffer has been read. This flag is also set to 1 in channel reset mode or when the THLE bit in the RSCFDnCFDTHLCCm register is set to 0 (transmit history buffer is not used).

NOTE

To clear THLIF or THLELT flag to 0, the program must write 0. When writing, use a store instruction to write “0” to the given flag and “1” to other flags.

16.4.13.3 RSCFDnCFDTHLPCTRm — Transmit History Pointer Control Register (m = 0 to 3)

Access: RSCFDnCFDTHLPCTRm register can only be written in 32-bit units
 RSCFDnCFDTHLPCTRmL, RSCFDnCFDTHLPCTRmH registers can only be written in 16-bit units
 RSCFDnCFDTHLPCTRmLL, RSCFDnCFDTHLPCTRmLH, RSCFDnCFDTHLPCTRmHL,
 RSCFDnCFDTHLPCTRmHH registers can only be written in 8-bit units

Address: RSCFDnCFDTHLPCTRm: $\langle \text{RSCFDn_base} \rangle + 0440_{\text{H}} + (04_{\text{H}} \times m)$
 RSCFDnCFDTHLPCTRmL: $\langle \text{RSCFDn_base} \rangle + 0440_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCFDnCFDTHLPCTRmH: $\langle \text{RSCFDn_base} \rangle + 0442_{\text{H}} + (04_{\text{H}} \times m)$
 RSCFDnCFDTHLPCTRmLL: $\langle \text{RSCFDn_base} \rangle + 0440_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCFDnCFDTHLPCTRmLH: $\langle \text{RSCFDn_base} \rangle + 0441_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCFDnCFDTHLPCTRmHL: $\langle \text{RSCFDn_base} \rangle + 0442_{\text{H}} + (04_{\text{H}} \times m)$,
 RSCFDnCFDTHLPCTRmHH: $\langle \text{RSCFDn_base} \rangle + 0443_{\text{H}} + (04_{\text{H}} \times m)$

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 16.163 RSCFDnCFDTHLPCTRm Register Contents

Bit Position	Bit Name	Function
31 to 8	Reserved	When writing to these bits, write the value after reset.
7 to 0	THLPC[7:0]	Transmit History List Pointer Control Writing FF _H to these bits moves the read pointer to the next unread data in the transmit history buffer.

THLPC[7:0] Bits

When the THLPC[7:0] bits are set to FF_H, the read pointer moves to the next data in the transmit history buffer. At this time, the THLMC[4:0] (transmit history buffer unread data counter) value in the RSCFDnCFDTHLSTSm register is decremented. Write FF_H to the THLPC[7:0] bits after reading from the RSCFDnCFDTHLACCm register.

When writing FF_H to these bits, make sure that the THLE bit in the RSCFDnCFDTHLCCm register is set to 1 (transmit history buffer is used) and the THLEMP flag in the RSCFDnCFDTHLSTSm register is 0.

16.4.13.4 RSCFDnCFDTHLACCm — Transmit History Access Register (m = 0 to 3)

Access: RSCFDnCFDTHLACCm register can be read only in 32-bit units
 RSCFDnCFDTHLACCmL, RSCFDnCFDTHLACCmH registers can be read only in 16-bit units
 RSCFDnCFDTHLACCmLL, RSCFDnCFDTHLACCmLH, RSCFDnCFDTHLACCmHL,
 RSCFDnCFDTHLACCmHH registers can be read only in 8-bit units

Address: RSCFDnCFDTHLACCm: <RSCFDn_base> + 6000_H + (04_H × m)
 RSCFDnCFDTHLACCmL: <RSCFDn_base> + 6000_H + (04_H × m),

TMTS[15:0] Bits

Timestamp values in transmit history data stored in the transmit history buffer are displayed.

TID[7:0] Bits

These bits indicate the label information of transmit history data stored in the transmit history buffer.

BN[3:0] Bits

These bits indicate the transmit source buffer number in the transmit history data stored in the transmit history buffer.

BT[2:0] Bits

These bits indicate the type of the transmit source buffer in the transmit history data stored in the transmit history buffer.

16.4.14 Details of Test-related Registers

16.4.14.1 RSCFDnCFDGTSTCFG — Global Test Configuration Register

Access: RSCFDnCFDGTSTCFG register can be read/written in 32-bit units
 RSCFDnCFDGTSTCFG_L, RSCFDnCFDGTSTCFG_H registers can be read/written in 16-bit units
 RSCFDnCFDGTSTCFG_LL, RSCFDnCFDGTSTCFG_LH, RSCFDnCFDGTSTCFG_HL,
 RSCFDnCFDGTSTCFG_HH registers can be read/written in 8-bit units

Address: RSCFDnCFDGTSTCFG: <RSCFDn_base> + 0468_H
 RSCFDnCFDGTSTCFG_L: <RSCFDn_base> + 0468_H, RSCFDnCFDGTSTCFG_H: <RSCFDn_base> + 046A_H
 RSCFDnCFDGTSTCFG_LL: <RSCFDn_base> + 0468_H, RSCFDnCFDGTSTCFG_LH: <RSCFDn_base> +
 0469_H,
 RSCFDnCFDGTSTCFG_HL: <RSCFDn_base> + 046A_H, RSCFDnCFDGTSTCFG_HH: <RSCFDn_base> +
 046B_H

Value after reset: 0000 0000_H

Table 16.165 RSCFDnCFDGTSTCFG Register Contents

Bit Position	Bit Name	Function
31 to 23	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
22 to 16	RTMPS[6:0]	RAM Test Page Configuration Set a value within a range of page 0 (00 _H) to page 69 (45 _H).
15 to 4	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
3	C3ICBCE	CAN3 Inter-channel Communication Test Enable 0: CAN3 inter-channel communication test is disabled 1: CAN3 inter-channel communication test is enabled.
2	C2ICBCE	CAN2 Inter-channel Communication Test Enable 0: CAN2 inter-channel communication test is disabled 1: CAN2 inter-channel communication test is enabled.
1	C1ICBCE	CAN1 Inter-Channel Communication Test Enable 0: CAN1 inter-channel communication test is disabled. 1: CAN1 inter-channel communication test is enabled.
0	C0ICBCE	CAN0 Inter-Channel Communication Test Enable 0: CAN0 inter-channel communication test is disabled. 1: CAN0 inter-channel communication test is enabled.

Modify the RSCFDnCFDGTSTCFG register only in global test mode.

RTMPS[6:0] Bits

These bits are used to set the RAM test target page number for RAM test. Set a value in the range of 00_H to 45_H, inclusive.

C3ICBCE Bit

This bit is cleared to 0 in global reset mode.

C2ICBCE Bit

This bit is cleared to 0 in global reset mode.

C1ICBCE Bit

This bit is cleared to 0 in global reset mode.

C0ICBCE Bit

This bit is cleared to 0 in global reset mode.

16.4.14.2 RSCFDnCFDGTSTCTR — Global Test Control Register

Access: RSCFDnCFDGTSTCTR register can be read/written in 32-bit units
 RSCFDnCFDGTSTCTRL, RSCFDnCFDGTSTCTRH registers can be read/written in 16-bit units
 RSCFDnCFDGTSTCTRL, RSCFDnCFDGTSTCTRLH, RSCFDnCFDGTSTCTRHL,
 RSCFDnCFDGTSTCTRHH registers can be read/written in 8-bit units

Address: RSCFDnCFDGTSTCTR: <RSCFDn_base> + 046C_H
 RSCFDnCFDGTSTCTRL: <RSCFDn_base> + 046C_H, RSCFDnCFDGTSTCTRH: <RSCFDn_base> + 046E_H
 RSCFDnCFDGTSTCTRL: <RSCFDn_base> + 046C_H, RSCFDnCFDGTSTCTRLH: <RSCFDn_base> +
 046D_H,
 RSCFDnCFDGTSTCTRHL: <RSCFDn_base> + 046E_H, RSCFDnCFDGTSTCTRHH: <RSCFDn_base> +
 046F_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W

Table 16.166 RSCFDnCFDGTSTCTR Register Contents

Bit Position	Bit Name	Function
31 to 3	Reserved	When read, the value after reset is returned. When writing to these bits, write the value after reset.
2	RTME	RAM Test Enable 0: RAM test is disabled. 1: RAM test is enabled.
1	Reserved	When read, the value after reset is returned. When writing to this bit, write the value after reset.
0	ICBCTME	Communication Test between Channels Enable 0: Communication test between channels disabled 1: Communication test between channels enabled

RTME Bit

Setting this bit to 1 enables the RAM test. Modify this bit only in global test mode. This bit is cleared to 0 in global reset mode. (See **Figure 16.37**)

1. Set the GMDC[1:0] bits in the RSCFDnCFDGCTR register to 10_B (Global test mode).
2. Set the RTME bit to 1.
3. Check that the RTME bit is set to 1.

ICBCTME Bit

When this bit is set to 1, a communication test is enabled between the channels for which the CmICBCE bit (m = 0 to 5) in the RSCFDnCFDGTSTCFG register has been set to 1. Modify the ICBCTME bit only in global test mode. This bit is cleared to 0 in global reset mode.

16.4.14.3 RSCFDnCFDGLOCKK — Global Lock Key Register

Access: RSCFDnCFDGLOCKK register can be write only in 32-bit units.
RSCFDnCFDGLOCKKL, RSCFDnCFDGLOCKKH registers can be write only in 16-bit units.

Address: RSCFDnCFDGLOCKK: <RSCFDn_base> + 047C_H
RSCFDnCFDGLOCKKL: <RSCFDn_base> + 047C_H, RSCFDnCFDGLOCKKH: <RSCFDn_base> + 047E_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LOCK[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1	W*1

Note 1. Writing to these bits is effective only when the RS-CANFD module is in global test mode.

Table 16.167 RSCFDnCFDGLOCKK Register Contents

Bit Position	Bit Name	Function
31 to 16	Reserved	When writing these bits, write the value after reset.
15 to 0	LOCK[15:0]	Lock Key These bits are key bits to release protection of test mode.

The RSCFDnCFDGLOCKK register releases protection of special test bits and is write only.

For the protection release data, see **Section 16.11.4.2, Procedure for Releasing the Protection.**

LOCK[15:0] Bits

Writing the protection release data to the LOCK[15:0] bits in succession enables writing 1 to the RTME bit in the RSCFDnCFDGTSTCTR register.

After the protection has been released, writing to the I/O register area (<RSCFDn_base> + 0000_H to <RSCFDn_base> + 0FFF_H) of the CAN (except the RAM) enables the protection again.

Reading from the I/O register area of the CAN or reading from/writing to other areas does not enable the protection.

16.4.14.4 RSCFDnCFDRPGACC_r — RAM Test Page Access Register (r = 0 to 63)

Access: RSCFDnCFDRPGACC_r register can be read/written in 32-bit units
 RSCFDnCFDRPGACC_{rL}, RSCFDnCFDRPGACC_{rH} registers can be read/written in 16-bit units
 RSCFDnCFDRPGACC_{rLL}, RSCFDnCFDRPGACC_{rLH}, RSCFDnCFDRPGACC_{rHL},
 RSCFDnCFDRPGACC_{rHH} registers can be read/written in 8-bit units

Address: RSCFDnCFDRPGACC_r: <RSCFDn_base> + 6400_H + (04_H × r)
 RSCFDnCFDRPGACC_{rL}: <RSCFDn_base> + 6400_H + (04_H × r),
 RSCFDnCFDRPGACC_{rH}: <RSCFDn_base> + 6402_H + (04_H × r)
 RSCFDnCFDRPGACC_{rLL}: <RSCFDn_base> + 6400_H + (04_H × r),
 RSCFDnCFDRPGACC_{rLH}: <RSCFDn_base> + 6401_H + (04_H × r),
 RSCFDnCFDRPGACC_{rHL}: <RSCFDn_base> + 6402_H + (04_H × r),
 RSCFDnCFDRPGACC_{rHH}: <RSCFDn_base> + 6403_H + (04_H × r)

Value after reset: 0000 0000_H

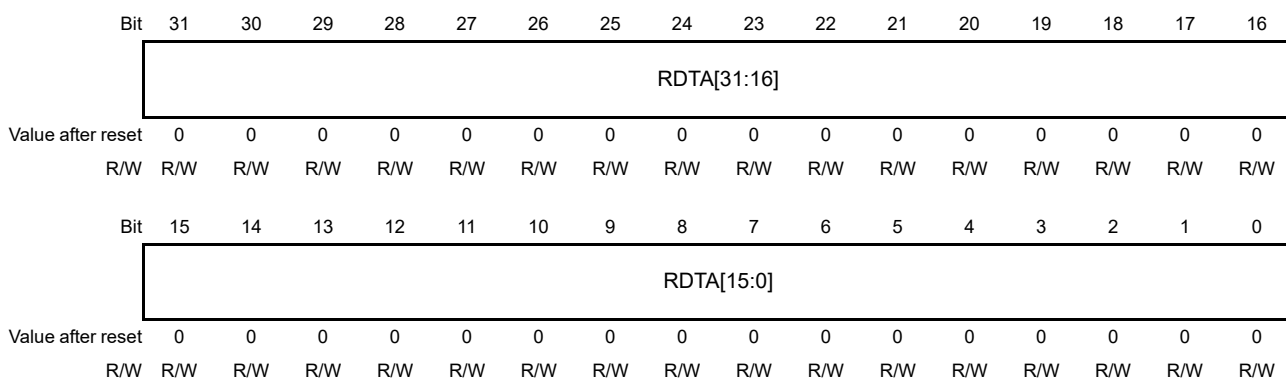

Table 16.168 RSCFDnCFDRPGACC_r Register Contents

Bit Position	Bit Name	Function
31 to 0	RDTA[31:0]	RAM Data Test Access Data can be read and written in RSCFD RAM.

Modify the RSCFDnCFDRPGACC_r register in global test mode with the RTME bit in the RSCFDnCFDGTSTCTR register set to 1 (RAM test is enabled).

The RSCFDnCFDRPGACC_r register is readable and writable when the RTME bit is set to 1.

16.5 Interrupt Sources

16.5.1 Interrupt Sources

The RS-CANFD module has 14 interrupts that are grouped into global interrupts and channel interrupts.

- Global interrupts (2 interrupts):
 - Receive FIFO interrupt
 - Global error interrupt
- Channel interrupts (3 interrupts per channel):
 - CANm transmit interrupt (m = 0 to 3)
 - CANm transmit complete interrupt
 - CANm transmit abort interrupt
 - CANm transmit/receive FIFO transmit complete interrupt (in transmit mode or gateway mode)
 - CANm transmit history interrupt
 - CANm transmit queue interrupt
 - CANm transmit/receive FIFO receive complete interrupt (in receive mode or gateway mode)
 - CANm error interrupt

When an interrupt request is generated, the corresponding interrupt request flag is set to 1 (interrupt request present). In that case, when the interrupt enable bit is 1 (enabling interrupts), an interrupt request is output from the RS-CANFD module. (Generation of interrupts also depends on the interrupt control register settings of the interrupt controller.)

Setting the interrupt request flag to 0 (no interrupt request present) or setting the interrupt enable bit to 0 (disabling interrupts) clears the interrupt request. The interrupt request is kept being output until the interrupt request flag is cleared.

Table 16.169 lists the CAN interrupt sources. **Figure 16.2** shows the CAN global interrupt block diagram, and **Figure 16.3** shows the CAN channel interrupt block diagram.

Table 16.169 List of CAN Interrupt Sources

		Interrupt Source	Corresponding Interrupt Request Flag	Corresponding Interrupt Enable Bit
Global interrupts	Receive FIFO	Receive FIFO 0	RFIF flag in the RSCFDn(CFD)RFSTS0 register	RFIE bit in the RSCFDn(CFD)RFCC0 register
		Receive FIFO 1	RFIF flag in the RSCFDn(CFD)RFSTS1 register	RFIE bit in the RSCFDn(CFD)RFCC1 register
		Receive FIFO 2	RFIF flag in the RSCFDn(CFD)RFSTS2 register	RFIE bit in the RSCFDn(CFD)RFCC2 register
		Receive FIFO 3	RFIF flag in the RSCFDn(CFD)RFSTS3 register	RFIE bit in the RSCFDn(CFD)RFCC3 register
		Receive FIFO 4	RFIF flag in the RSCFDn(CFD)RFSTS4 register	RFIE bit in the RSCFDn(CFD)RFCC4 register
		Receive FIFO 5	RFIF flag in the RSCFDn(CFD)RFSTS5 register	RFIE bit in the RSCFDn(CFD)RFCC5 register
		Receive FIFO 6	RFIF flag in the RSCFDn(CFD)RFSTS6 register	RFIE bit in the RSCFDn(CFD)RFCC6 register
		Receive FIFO 7	RFIF flag in the RSCFDn(CFD)RFSTS7 register	RFIE bit in the RSCFDn(CFD)RFCC7 register
	Global error	DEF flag in the RSCFDn(CFD)GERFL register MES flag in the RSCFDn(CFD)GERFL register THLES flag in the RSCFDn(CFD)GERFL register CMPOF flag in the RSCFDnCFDGERFL register	DEIE bit in the RSCFDn(CFD)GCTR register MEIE bit in the RSCFDn(CFD)GCTR register THLEIE bit in the RSCFDn(CFD)GCTR register CMPOFIE bit in the RSCFDnCFDGCTR register	

Table 16.169 List of CAN Interrupt Sources

		Interrupt Source	Corresponding Interrupt Request Flag	Corresponding Interrupt Enable Bit
Channel interrupts (m = 0 to 3)	CANm transmit	CANm transmit complete	TMTRF[1:0] flag in the RSCFDn(CFD)TMSTSp register	TMIE bit in the RSCFDn(CFD)TMIECy register
		CANm transmit abort	TMTRF[1:0] flag in the RSCFDn(CFD)TMSTSp register	TAIE bit in the RSCFDn(CFD)CmCTR register
		CANm transmit/receive FIFO transmit complete	CFTXIF flag in the RSCFDn(CFD)CFSTSk register	CFTXIE bit in the RSCFDn(CFD)CFCCk register
		CANm transmit queue	TXQIF flag in the RSCFDn(CFD)TXQSTSm register	TXQIE bit in the RSCFDn(CFD)TXQCCm register
		CANm transmit history	THLIF flag in the RSCFDn(CFD)THLSTSm register	THLIE bit in the RSCFDn(CFD)THLCCm register
CANm transmit/receive FIFO receive complete		CFRXIF flag in the RSCFDn(CFD)CFSTSk register	CFRXIE bit in the RSCFDn(CFD)CFCCk register	
CANm error		BEF flag in the RSCFDn(CFD)CmERFL register	BEIE bit in the RSCFDn(CFD)CmCTR register	
		ALF flag in the RSCFDn(CFD)CmERFL register	ALIE bit in the RSCFDn(CFD)CmCTR register	
		BLF flag in the RSCFDn(CFD)CmERFL register	BLIE bit in the RSCFDn(CFD)CmCTR register	
		OVLF flag in the RSCFDn(CFD)CmERFL register	OLIE bit in the RSCFDn(CFD)CmCTR register	
		BORF flag in the RSCFDn(CFD)CmERFL register	BORIE bit in the RSCFDn(CFD)CmCTR register	
		BOEF flag in the RSCFDn(CFD)CmERFL register	BOEIE bit in the RSCFDn(CFD)CmCTR register	
		EPF flag in the RSCFDn(CFD)CmERFL register	EPIE bit in the RSCFDn(CFD)CmCTR register	
		EWVF flag in the RSCFDn(CFD)CmERFL register	EWVIE bit in the RSCFDn(CFD)CmCTR register	
		SOCO flag in the RSCFDnCFDCmFDSTS register	SOCOIE bit in the RSCFDnCFDCmCTR register	
		EOCO flag in the RSCFDnCFDCmFDSTS register	EOCOIE bit in the RSCFDnCFDCmCTR register	
		TDCVF flag in the RSCFDnCFDCmFDSTS register	TDCVIE bit in the RSCFDnCFDCmCTR register	

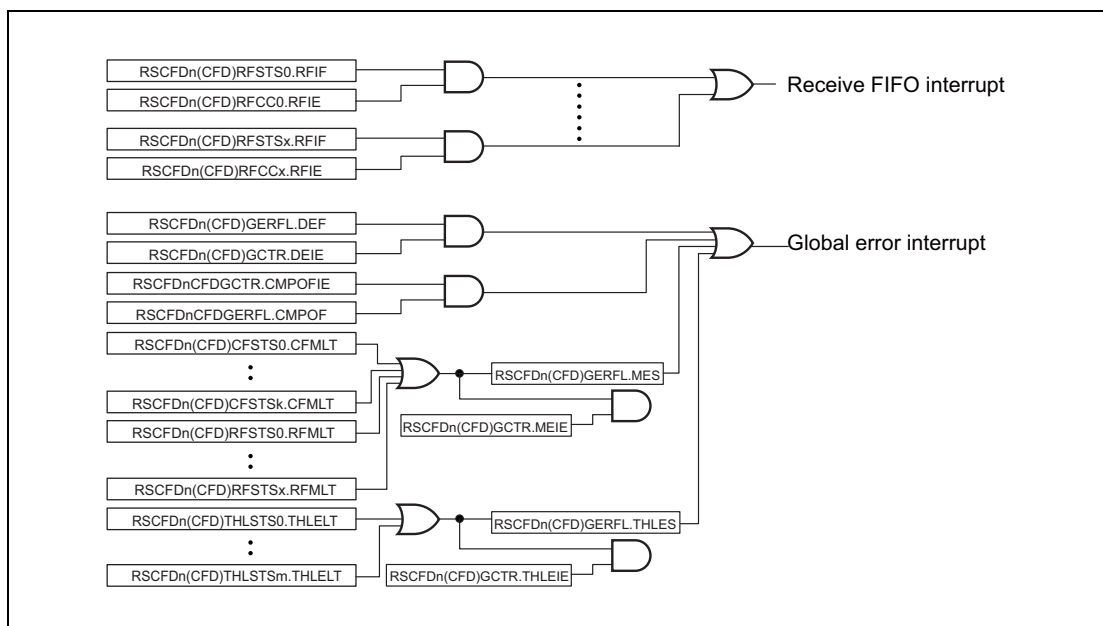

Figure 16.2 CAN Global Interrupt Block Diagram

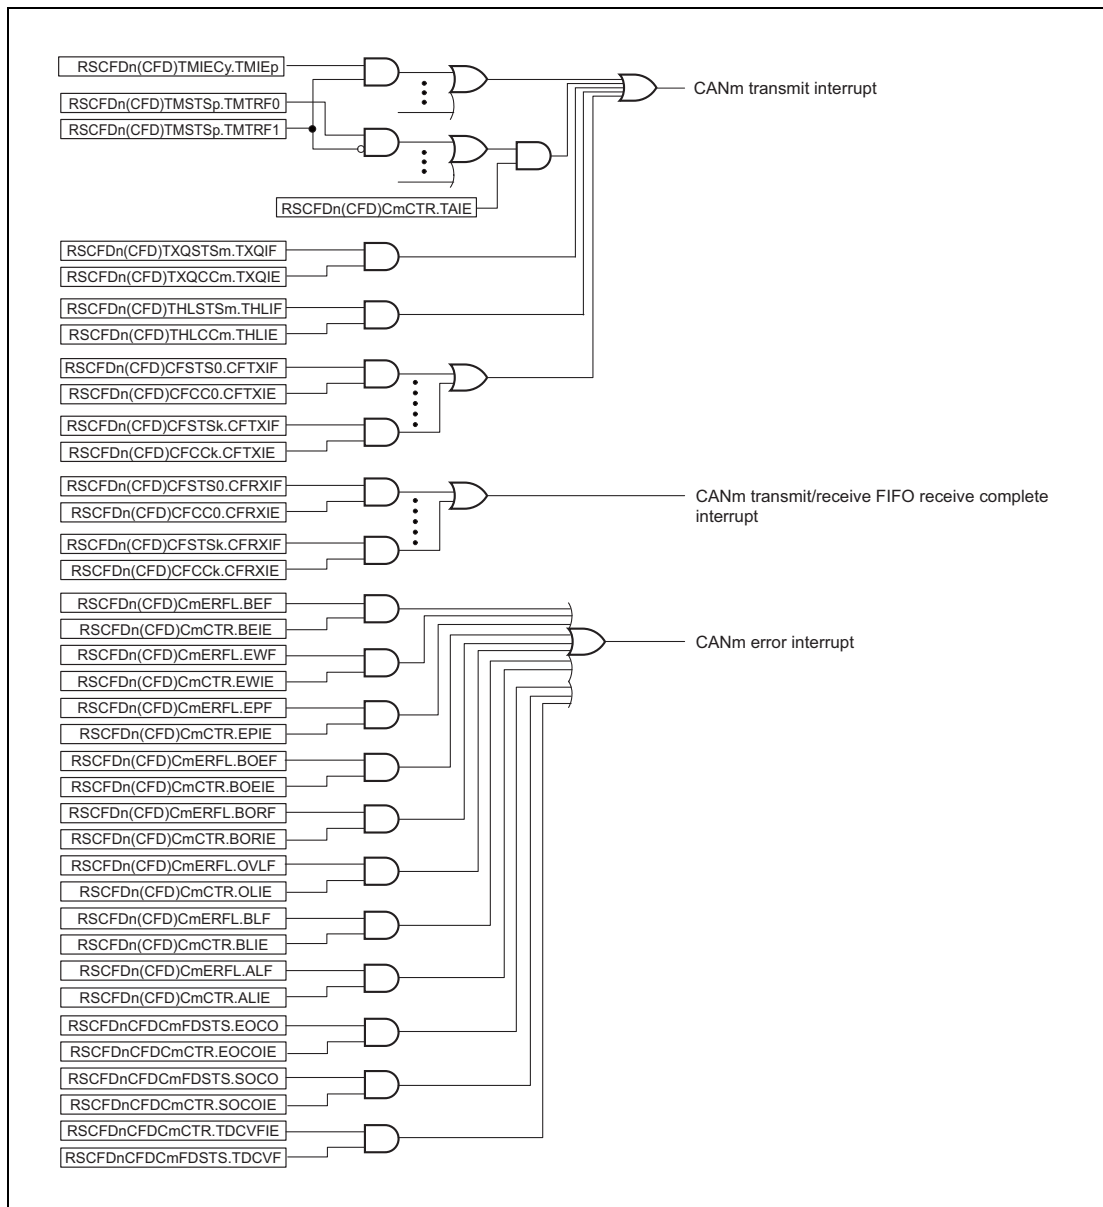

Figure 16.3 CAN Channel Interrupt Block Diagram

16.6 CAN Modes

The RS-CANFD module has four global modes to control entire RS-CANFD module status and four channel modes to control individual channel status. Details of global modes are described in **Section 16.6.1, Global Modes**, and details of channel modes are described in **Section 16.6.2, Channel Modes**.

- Global stop mode: Stops clocks of the entire module to achieve low power consumption.
- Global reset mode: Performs initial settings for the entire module.
- Global test mode: Performs test settings and performs RAM test.
- Global operating mode: Makes the entire module operable.
- Channel stop mode: Stops the channel clock.
- Channel reset mode: Performs initial settings for the channel.
- Channel halt mode: Stops CAN communication and performs channel test.
- Channel communication mode: Performs CAN communication.

16.6.1 Global Modes

Figure 16.4 shows the transitions of global modes.

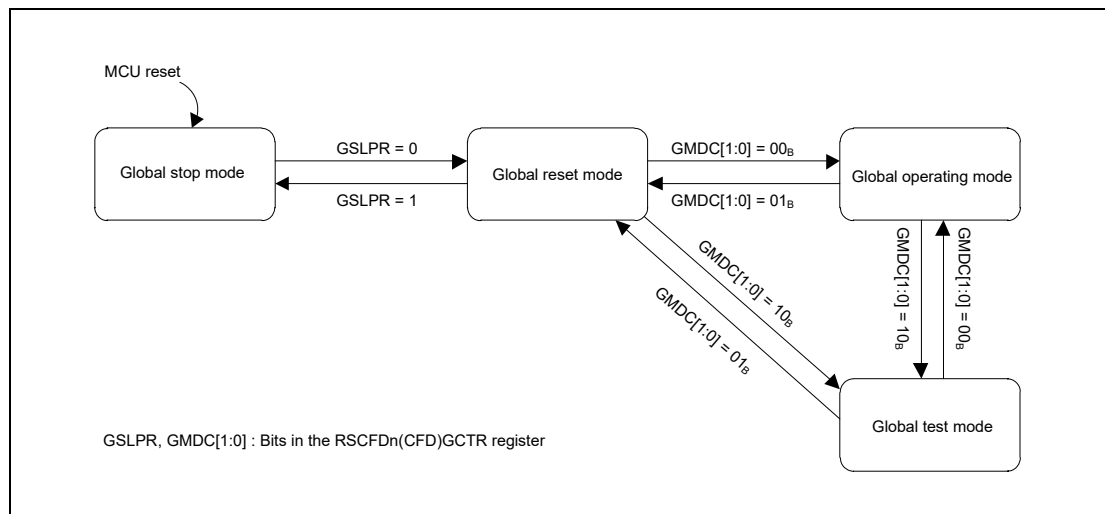

Figure 16.4 Transitions of Global Modes

Channel modes may transition in accordance with transitions of global modes. **Table 16.170** shows the transitions of channel modes depending on the global mode setting (GMDC[1:0] bits and GSLPR bit).

Table 16.170 Transitions of Channel Modes Depending on Global Mode Setting (GMDC[1:0] and GSLPR Bits)

Channel Mode before Setting	Channel Mode after Setting			
	GMDC[1:0] = 00 _B GSLPR = 0 (Global Operating)	GMDC[1:0] = 10 _B GSLPR = 0 (Global Test)	GMDC[1:0] = 01 _B GSLPR = 0 (Global Reset)	GMDC[1:0] = 01 _B GSLPR = 1 (Global Stop)
Channel communication	Channel communication	Channel halt	Channel reset	Transition prohibited
Channel halt	Channel halt	Channel halt	Channel reset	Transition prohibited
Channel reset	Channel reset	Channel reset	Channel reset	Channel stop
Channel stop	Channel stop	Channel stop	Channel stop	Channel stop

Note: GMDC[1:0], GSLPR: Bits in the RSCFDn(CFD)GCTR register

Table 16.171 shows the transition time between each global mode.

Table 16.171 Transition Time of Global Mode

Mode before Transition	Mode after Transition	Maximum Transition Time
Global stop	Global reset	3 clocks of pclk
Global reset	Global stop	3 clocks of pclk
Global reset	Global test	10 clocks of pclk
Global reset	Global operation	10 clocks of pclk
Global test	Global reset	Two CAN bit times ^{*1, *2}
Global test	Global operation	3 clocks of pclk
Global operation	Global reset	Two CAN bit times ^{*1, *2}
Global operation	Global test	2 times of CAN frame ^{*1}

Note 1. CAN frame time of the channel whose communication speed is lowest among the channels in use.

Note 2. In CAN FD mode, this time value is the CAN bit time of the nominal bit rate.

16.6.1.1 Global Stop Mode

In global stop mode, the CAN clocks do not run and therefore power consumption is reduced. CAN registers can be read, but writing data to them is prohibited. Register values are retained. In global stop mode, only the clock for CPU writing to the GSLPR bit is running.

After the MCU is reset, the RS-CANFD module transitions to global stop mode. Setting the GSLPR bit in the RSCFDn(CFD)GCTR register to 1 (in global stop mode) in global reset mode sets the CSLPR bit in each of the RSCFDn(CFD)CmCTR register to 1 (channel stop mode). If all channels are forcibly caused to transition to channel stop mode, the RS-CANFD module transitions to global stop mode. The GSLPR bit should not be modified in global operating mode and global test mode.

16.6.1.2 Global Reset Mode

In global reset mode, RS-CANFD module settings are performed. When the RS-CANFD module transitions to global reset mode, some registers are initialized. **Table 16.174** and **Table 16.175** list the registers to be initialized.

Setting the GMDC[1:0] bits in the RSCFDn(CFD)GCTR register to 01_B sets the CHMDC[1:0] bits in each of the RSCFDn(CFD)CmCTR register (m = 0 to 3) to 01_B (channel reset mode). If all channels are forcibly caused to transition to channel reset mode, the RS-CANFD module transitions to global

reset mode. Channels that are already in channel reset mode or channel stop mode do not transition (because the CHMDC[1:0] bits have already been set to 01_B).

16.6.1.3 Global Test Mode

In global test mode, settings for test-related registers are performed. When the RS-CANFD module transitions to global test mode, all CAN communications are disabled.

Setting the GMDC[1:0] bits in the RSCFDn(CFD)GCTR register to 10_B sets the CHMDC[1:0] bits in each of the RSCFDn(CFD)CmCTR register to 10_B (channel halt mode). If all channels are forcibly caused to transition to channel halt mode, the RS-CANFD module transitions to global test mode. Channels that are in channel stop mode, channel reset mode, or channel halt mode do not transition.

16.6.1.4 Global Operating Mode

In global operating mode, entire RS-CANFD module operates.

When the GMDC[1:0] bits in the RSCFDn(CFD)GCTR register are set to 00_B, the RS-CANFD module transitions to global operating mode.

16.6.2 Channel Modes

Figure 16.5 shows a channel mode state transition chart. Table 16.172 shows transition time between channel modes.

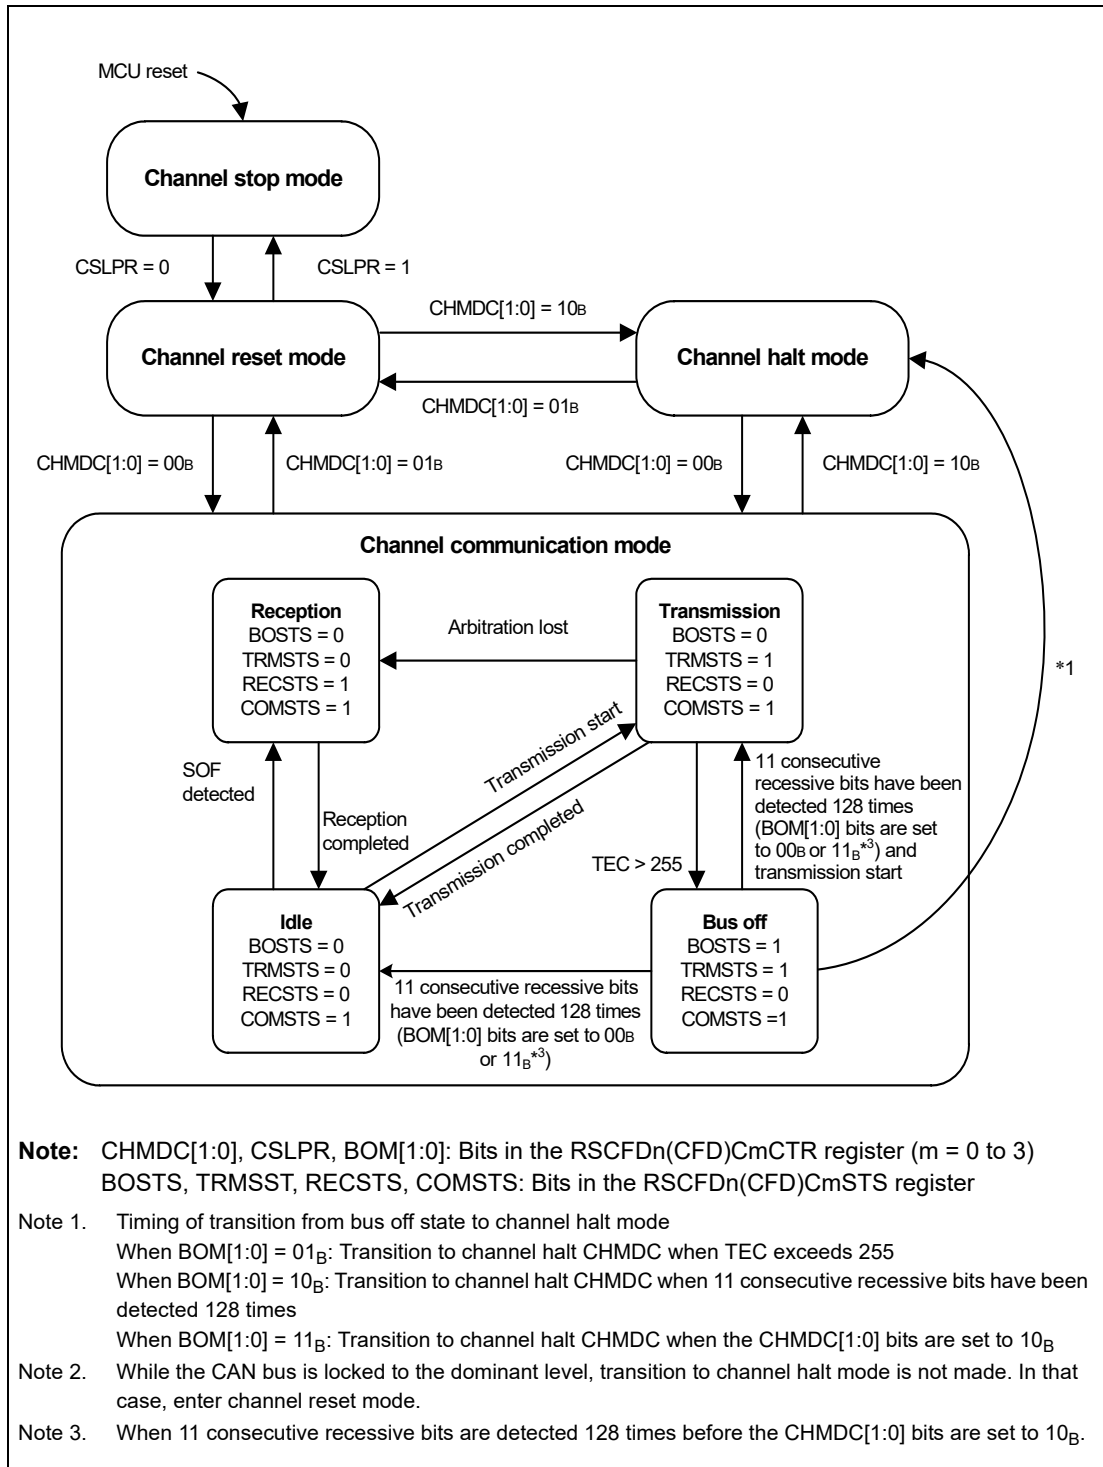

Figure 16.5 Channel Mode State Transition Chart

Table 16.172 Transition Time of Channel Mode (m = 0 to 3)

Mode before Transition	Mode after Transition	Maximum Transition Time
Channel stop	Channel reset	3 clocks of pclk
Channel reset	Channel stop	3 clocks of pclk
Channel reset	Channel Halt	3 CANm bit time* ¹
Channel reset	Channel communication	4 CANm bit time* ¹
Channel Halt	Channel reset	2 CANm bit times* ¹
Channel Halt	Channel communication	4 CANm bit times* ¹
Channel communication	Channel reset	2 CANm bit times* ¹
Channel communication	Channel Halt	2 times of CANm frame

Note 1. In CAN FD mode, this time value is the CANm bit time of the nominal bit rate.

16.6.2.1 Channel Stop Mode

In channel stop mode, clocks are not supplied to channels and therefore power consumption is reduced. CAN registers can be read, but writing data to them is prohibited. Register values are retained.

Each channel enters channel stop mode after the MCU is reset. The channel transitions to channel stop mode when the CSLPR bit in the RSCFDn(CFD)CmCTR register (m = 0 to 3) is set to 1 (channel stop mode) in channel reset mode. The CSLPR bit should not be modified in channel communication mode and channel halt mode.

16.6.2.2 Channel Reset Mode

In channel reset mode, channel settings are performed. When a channel transitions to channel reset mode, some channel-related registers are initialized. **Table 16.174** lists the registers to be initialized.

When the CHMDC[1:0] bits in the RSCFDn(CFD)CmCTR register are set to 01_B (channel reset mode) during CAN communication, communication is terminated before it is completed and the channel transitions to channel reset mode. **Table 16.173** shows the operation when the CHMDC[1:0] bits are set to 01_B (channel reset mode) during CAN communication.

16.6.2.3 Channel Halt Mode

In channel halt mode, settings for test-related registers of channels are performed. When a channel transitions to channel halt mode, CAN communication of the channel stops.

Table 16.173 shows operation when the CHMDC[1:0] bits are set to 10_B (channel halt mode) during CAN communication.

Table 16.173 Operation When a Channel Transitions to Channel Reset Mode/Channel Halt Mode

Mode	During Reception	During Transmission	Bus Off State
Channel reset (CHMDC[1:0] = "01 _B ")	Transitions to channel reset mode before reception is completed.* ¹	Transitions to channel reset mode before transmission is completed.* ¹	Transitions to channel reset mode before bus off recovery is completed.
Channel halt* ³ (CHMDC[1:0] = "10 _B ")	Transitions to channel halt mode after reception is completed.* ²	Transitions to channel halt mode after transmission is completed.	[When BOM[1:0] = 00 _B] Transitions to channel halt mode (CHMDC[1:0] = 10 _B) only after bus off recovery. [When BOM[1:0] = 01 _B] Transitions to channel halt mode automatically when the condition for transition to bus off state is met. [When BOM[1:0] = 10 _B] Transitions to channel halt mode automatically after bus off recovery is completed. [When BOM[1:0] = 11 _B] Transitions to channel halt mode immediately after the CHMDC[1:0] bits are set to 10 _B before bus off recovery is completed.

Note 1. To allow transition to channel reset mode after communication is completed, set the CHMDC[1:0] bits to 10_B and confirm that communication has been completed and transition to channel halt mode has been made, and then set the CHMDC[1:0] bits to 01_B.

Note 2. While the CAN bus is locked at the dominant level, transition to channel halt mode is not made. In that case, enter channel reset mode. The CAN bus status can be confirmed with the BLF flag of the RSCFDn(CFD)CmERFL register that becomes 1 when dominant lock is detected.

Note 3. In classical CAN mode, when the transition from channel reset mode to channel halt mode is to be made, set the RSCANnCmCFG register in channel reset mode and then shift to channel halt mode. In CAN FD mode, set the SCFDnCFDCmNCFG register and the RSCFDnCFDCmDCFG register, and then make a transition.

16.6.2.4 Channel Communication Mode

In channel communication mode, CAN communication is performed. Each channel is in the following communication states during CAN communication.

- Idle : Neither reception nor transmission is in progress.
- Reception : Receiving a message sent from another node.
- Transmission : Transmitting a message.
- Bus off : Isolated from CAN communication.

When the CHMDC[1:0] bits in the RSCFDn(CFD)CmCTR register are set to 00_B, the channel transitions to channel communication mode. After that, when 11 consecutive recessive bits have been detected, the COMSTS flag in the RSCFDn(CFD)CmSTS register (m = 0 to 3) is set to 1 (communication is ready) and transmission and reception are enabled on the CAN network as an active node. At this time, transmission and reception of messages can be started.

16.6.2.5 Bus Off State

A channel transitions to the bus off state according to the transmit/receive error counter increment/decrement rules of the CAN specifications. How to return from the bus off state is set by the BOM[1:0] bits in the RSCFDn(CFD)CmCTR register.

- When BOM[1:0] = 00_B:
Bus off recovery is compliant with the CAN specification. After 11 consecutive recessive bits have been detected 128 times, a channel returns from the bus off state to the CAN communication ready state (error active state). At that time, the TEC[7:0] and REC[7:0] bits in the RSCFDn(CFD)CmSTS register are initialized to 00_H, the BORF flag in the RSCFDn(CFD)CmERFL register is set to 1 (bus off recovery is detected), and a bus off recovery interrupt request is generated. When the CHMDC[1:0] bits in the RSCFDn(CFD)CmCTR register are set to 10_B (channel halt mode) in the bus off state, the channel transitions to channel halt mode after completion of bus off recovery (11 consecutive recessive bits have been detected 128 times).
- When BOM[1:0] = 01_B:
When a channel transitions to the bus off state, the CHMDC[1:0] bits are set to 10_B and the channel transitions to channel halt mode. At that time, the TEC[7:0] and REC[7:0] bits are initialized to 00_H but the BORF flag is not set to 1 and a bus off recovery interrupt request is not generated.
- When BOM[1:0] = 10_B:
When a channel has transitioned to the bus off state, the CHMDC[1:0] bits are set to 10_B. After completion of bus off recovery (11 consecutive recessive bits have been detected 128 times), the channel transitions to channel halt mode. At that time, the TEC[7:0] and REC[7:0] bits are initialized to 00_H and the BORF flag is set to 1, and bus off recovery interrupt request is generated.
- When BOM[1:0] = 11_B:
When the CHMDC[1:0] bits are set to 10_B in the bus off state, the channel transitions to channel halt mode before bus off recovery is completed. At that time, the TEC[7:0] and REC[7:0] bits are initialized to 00_H but the BORF flag is not set to 1. And bus off recovery interrupt request is not generated.
However, the BORF flag becomes 1, and bus off recovery interrupt request is generated if a RS-CANFD module transitions to error active state (by detecting 128 times of 11 consecutive recessive bits) before CHMDC[1:0] bits are set to 10_B.

If the channel transitions to channel halt mode by the RS-CANFD module simultaneously when the program writes a value to the CHMDC[1:0] bits, writing by the program takes precedence. An automatic transition to channel halt mode when the BOM[1:0] bits are set to 01_B or 10_B is made only when the CHMDC[1:0] bits are 00_B (channel communication mode).

Furthermore, setting the RTBO bit in the RSCFDn(CFD)CmCTR register to 1 allows forcible return from the bus off state. As soon as the RTBO bit is set to 1, the state changes to the error active state. After 11 consecutive recessive bits have been detected, the RS-CANFD module becomes ready for communication. In this case, the BORF flag is not set to 1 and the TEC[7:0] and REC[7:0] bits are initialized to 00_H. Write 1 to the RTBO bit when the BOM[1:0] value is 00_B. If you write 1 to the RTBO bit in any other cases than the bus off state, writing is ignored and the RTBO bit becomes 0 immediately.

16.6.3 Initializing Registers by Transition to CAN Mode

Table 16.174 lists bits and flags to be initialized by a transition to channel reset mode. These bits and flags are also initialized by a transition to global reset mode. Furthermore, **Table 16.175** lists bits and flags to be initialized only by a transition to global reset mode.

Table 16.174 Registers Initialized in Global Reset Mode or Channel Reset Mode

Register	Bit / Flag
RSCFDn(CFD)CmCTR register	(ROM), CRCT, CTMS[1:0], CTME, CHMDC[1:0]
RSCFDn(CFD)CmSTS register	CHLTSTS, EPSTS, BOSTS, TRMSTS, RECSTS, COMSTS, (ESIF), REC[7:0], TEC[7:0]
RSCFDn(CFD)CmERFL register	CRCREG[14:0], ADERR, B0ERR, B1ERR, CERR, AERR, FERR, SERR, ALF, BLF, OVLF, BORF, BOEF, EPF, EWF, BEF
RSCFDnCFDCmFDCTR register	EOCCLR, SOCCLR
RSCFDnCFDCmFDSTS register	SOC[7:0], EOC[7:0], SOCO, EOCO, TDCVF, TDCR[6:0]
RSCFDnCFDCmFDCRC register	CRCREG[20:0], SCNT[3:0]
RSCFDn(CFD)CFCCk register	When transmit/receive FIFO buffer is in transmit mode or gateway mode: CFE
RSCFDn(CFD)CFSTSk register	When transmit/receive FIFO buffer is in transmit mode or gateway mode: CFMC[7:0], CFFLL, CFEMP, CFMLT, CFRXIF, CFTXIF
RSCFDn(CFD)CFTISTS register	CFKTXIF
RSCFDn(CFD)TMCp register	TMOM, TMTAR, TMTR
RSCFDn(CFD)TMSTSp register	TMTARM, TMTRM, TMTRF[1:0], TMTSTS
RSCFDn(CFD)TMTRSTSy register	TMTRSTSp (Bits of corresponding channel are initialized in channel reset mode.)
RSCFDn(CFD)TMTARSTSy register	TMTARSTSp (Bits of corresponding channel are initialized in channel reset mode.)
RSCFDn(CFD)TMTCASTSy register	TMTCASTSp (Bits of corresponding channel are initialized in channel reset mode.)
RSCFDn(CFD)TMTASTSy register	TMTASTSp (Bits of corresponding channel are initialized in channel reset mode.)
RSCFDn(CFD)TXQCCm register	TXQE
RSCFDn(CFD)TXQSTSm register	TXQIF, TXQFLL, TXQEMP
RSCFDn(CFD)THLCCm register	THLE
RSCFDn(CFD)THLSTSm register	THLMC[4:0], THLIF, THLELT, THLFLL, THLEMP
RSCFDn(CFD)GTINTSTS0 register	TSIFm, TAIFm, TQIFm, CFTIFm, THIFm (m = 0 to 3)

Table 16.175 Registers Initialized Only in Global Reset Mode

Register	Bit / Flag
RSCFDn(CFD)GSTS register	GHLTSTS
RSCFDn(CFD)GERFL register	EEF0, EEF1, EEF2, EEF3 (CMPOF), THLES, MES, DEF
RSCFDn(CFD)GTSC register	TS[15:0]
RSCFDn(CFD)RMNDy register	RMNSq
RSCFDn(CFD)RFCCx register	RFE
RSCFDn(CFD)RFSTsx register	RFMC[7:0], RFIF, RFMLT, RFFLL, RFEMP
RSCFDn(CFD)CFCK register	When transmit/receive FIFO buffer is in receive mode: CFE
RSCFDn(CFD)CFSTSk register	When transmit/receive FIFO buffer is in receive mode: CFMC[7:0], CFFLL, CFEMP, CFTXIF, CFRXIF, CFMLT
RSCFDn(CFD)FESTS register	CFkEMP, RFxEMP
RSCFDn(CFD)FFSTS register	CFkFLL, RFxFLL
RSCFDn(CFD)FMSTS register	CFkMLT, RFxMLT
RSCFDn(CFD)RFISTS register	RFxIF
RSCFDn(CFD)CFRISTS register	CFkRXIF
RSCFDn(CFD)GTSTCFG register	RTMPS[6:0], C0ICBCE, C1ICBCE, C2ICBCE, C3ICBCE
RSCFDn(CFD)GTSTCTR register	RTME, ICBCTME

16.7 Reception Function

There are two reception types.

- Reception by receive buffers:
0 to 64 receive buffers can be shared by all channels. Since messages stored in receive buffers are overwritten at each reception, the latest received data can always be read.
- Reception by receive FIFO buffers and transmit/receive FIFO buffers (receive mode):
Eight receive FIFO buffers can be shared by all channels and three dedicated transmit/receive FIFO buffers are provided for each channel. Messages of the number specified by the buffer depth can be stored in FIFO buffers and can be read sequentially from the oldest.

16.7.1 Data Processing Using the Receive Rule Table

Data processing using the receive rule table allows selected messages to be stored in the specified buffer. Data processing includes acceptance filter processing, DLC filter processing, routing processing, label addition processing, and mirror function processing.

Up to 128 receive rules can be registered per channel and up to “64 × number of channels” receive rules can be registered in the entire module. (Up to 256 receive rules can be registered in this module that has four channels.) Set receive rules for each channel. No receive rule can be shared with other channels. If receive rules are not set, no message can be received. **Figure 16.6** illustrates how receive rules are registered, giving an example using 2 channels of RS-CANFD.

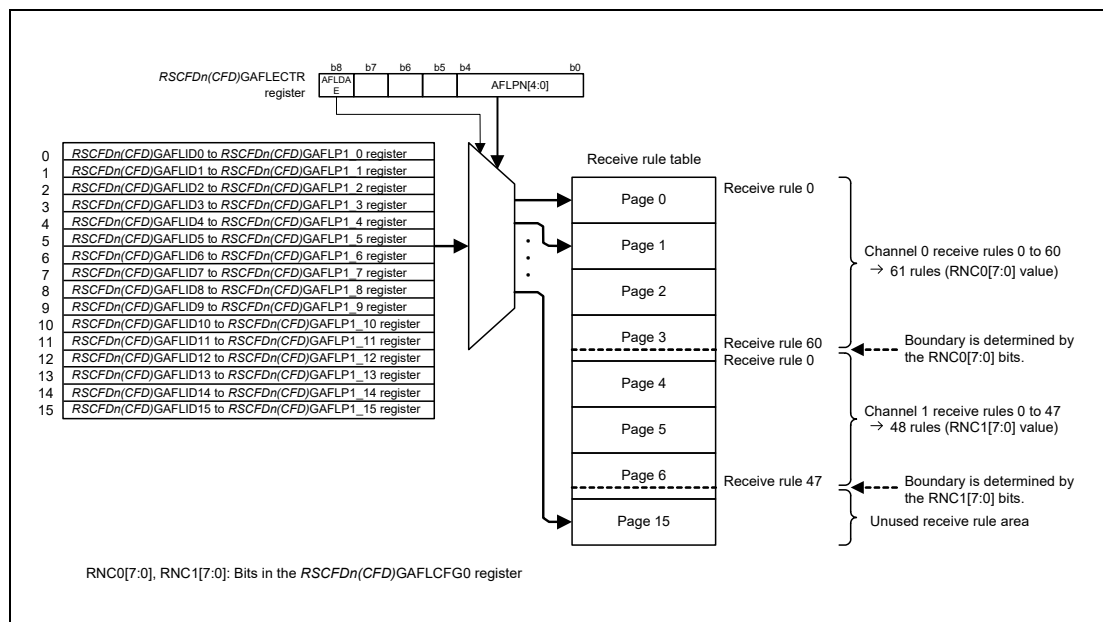

Figure 16.6 Entry of Receive Rules (in the case of setting channel 0,1)

CAUTION

Set receive rules of each channel in succession.
It is not possible to set channel 0 receive rules and channel 1 receive rules alternately.

Each receive rule consists of 16 bytes of the *RSCFDn(CFD)GAFLIDj*, *RSCFDn(CFD)GAFLMj*, *RSCFDn(CFD)GAFLP0j*, and *RSCFDn(CFD)GAFLP1j* registers ($j = 0$ to 15). The *RSCFDn(CFD)GAFLIDj* register is used to set GAFLID, GAFLIDE bit, GAFLRTR bit, and the mirror function. The *RSCFDn(CFD)GAFLMj* register is used to set mask. The *RSCFDn(CFD)GAFLP0j* register is used to set label information to be added, DLC value, and destination receive buffer. The *RSCFDn(CFD)GAFLP1j* register is used to set a destination FIFO buffer. Up to 16 receive rules can be set per page.

16.7.1.1 Acceptance Filter Processing

In the acceptance filter processing, the ID data, IDE bit, and RTR bit in a received message are compared with the ID data, IDE bit, and RTR bit set in the receive rule of the corresponding channel. When all these bits match, the message passes through the acceptance filter processing. Bits set to 0 (bits are not compared) in the $RSCFDn(CFD)GAFLMj$ register are not compared and are regarded as matched.

Check begins with the lowest-numbered receive rule. When all the bits to be compared in a received message match the bits set in the receive rule or when all the receive rules are compared without any match, filter processing stops. If there is no matching receive rule, the received message is not stored in the receive buffer or FIFO buffer.

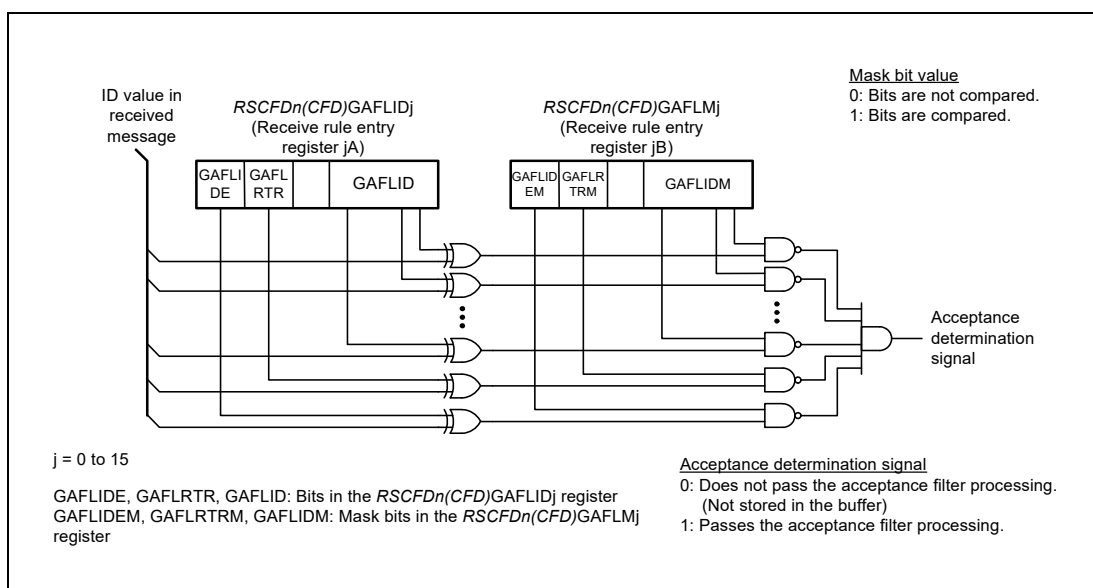

Figure 16.7 Acceptance Filter Function

16.7.1.2 DLC Filter Processing

When the DCE bit in the $RSCFDn(CFD)GCFG$ register is set to 1 (DLC check is enabled), DLC filter processing is added to messages that passed through the acceptance filter processing. When the DLC value in a message is equal to or larger than the DLC value set in the receive rule, the message passes through the DLC filter processing.

When a message has passed through the DLC filter processing with the DRE bit in the $RSCFDn(CFD)GCFG$ register set to 0 (DLC replacement is disabled), the DLC value of the received message is stored in the buffer. In this case, all the data bytes in the received message are stored in the buffer.

When a message has passed through the DLC filter processing with the DRE bit in the $RSCFDn(CFD)GCFG$ register set to 1 (DLC replacement is enabled), the DLC value of the receive rule is stored in the buffer instead of the DLC value of the received message. In this case, a value of 00_H is written to data bytes that are larger than the DLC value of the receive rule.

When the DLC value of the received message is smaller than that of the receive rule, the message does not pass through the DLC filter processing. In this case, the message is not stored in the receive buffer or the FIFO buffer and the DEF flag in the $RSCFDn(CFD)GERFL$ register is set to 1 (a DLC error is present).

16.7.1.3 Routing Processing

Messages that passed through the acceptance filter processing and the DLC filter processing are stored in receive buffers, receive FIFO buffers, or transmit/receive FIFO buffers set to receive mode or gateway mode. Message storage destination is set by the GAFLRMV and GAFLRMDP[6:0] bits in the RSCFDn(CFD)GAFLP0_j register (j = 0 to 15) and by the RSCFDn(CFD)GAFLP1_j register. Messages that passed through the acceptance filter processing and the DLC filter processing can be stored in up to 8 buffers.

In CAN FD mode, if the payload length of the received message exceeds the payload storage size of the storage buffer, the CMPOF flag in the RSCFDnCFDGERFL register is set to 1 (payload overflow) and the processing is handled according to the CMPOC bit in the RSCFDnCFDGCFCFG register. When the CMPOC bit is 0, the received message which exceeds the payload storage size is not stored in the buffer. When the CMPOC bit is 1, the received message is stored in the buffer with payloads exceeding the storage size being discarded, and depending on the DRE bit in the RSCFDnCFDGCFCFG register the received DLC value or the DLC value of the receive rule is stored in the buffer.

16.7.1.4 Label Addition Processing

It is possible to add 12-bit label information to messages that passed through the filter processing and store them in buffers. This label information is set in the GAFLPTR[11:0] bits of the RSCFDn(CFD)GAFLP0_j register.

16.7.1.5 Mirror Function Processing

The mirror function allows reception of messages transmitted from the own CAN node. The mirror function is made available by setting the MME bit in the RSCFDn(CFD)GCFCFG register to 1 (mirror function is enabled).

When the mirror function is in use, receive rules for which the GAFLLB bit in the RSCFDn(CFD)GAFLIDj register is set to 0 are applied to the data processing for messages received from other CAN nodes. When messages transmitted from the own CAN node are received, receive rules for which the GAFLLB bit is set to 1 are used for data processing.

16.7.1.6 Timestamp

The timestamp counter is a 16-bit free-running counter used for recording the message reception time and transmission time. The timestamp counter value is fetched with the timing set by the TSCCFG[1:0] bits and is then stored in a receive buffer or a FIFO buffer together with the message ID and data during data reception. The clock source of the timestamp counter is selected by the TSBTCS[2:0] and TSSS bits in the RSCFDn(CFD)GFDCFCFG register. In classical CAN mode, the clock source is selectable from pclk/2 or the CANm bit time clock (m = 0 to 3). In CAN FD mode, the clock source is selectable from pclk/2 or nominal CANm bit time clock. However, do not select the nominal CANm bit time clock of channels that handle CAN FD frames. The clock obtained by dividing the selected clock source by the TSP[3:0] value of the RSCFDn(CFD)GCFCFG register is used as the count source of the timestamp counter.

When the CANm bit time clock is used as a clock source, the timestamp counter stops when the corresponding channel transitions to channel reset mode or channel halt mode. When pclk/2 is used as a clock source, the timestamp function is not affected by channel mode.

The timestamp counter value is reset to 0000_H by setting the TSRST bit in the RSCFDn(CFD)GCTR register to 1.

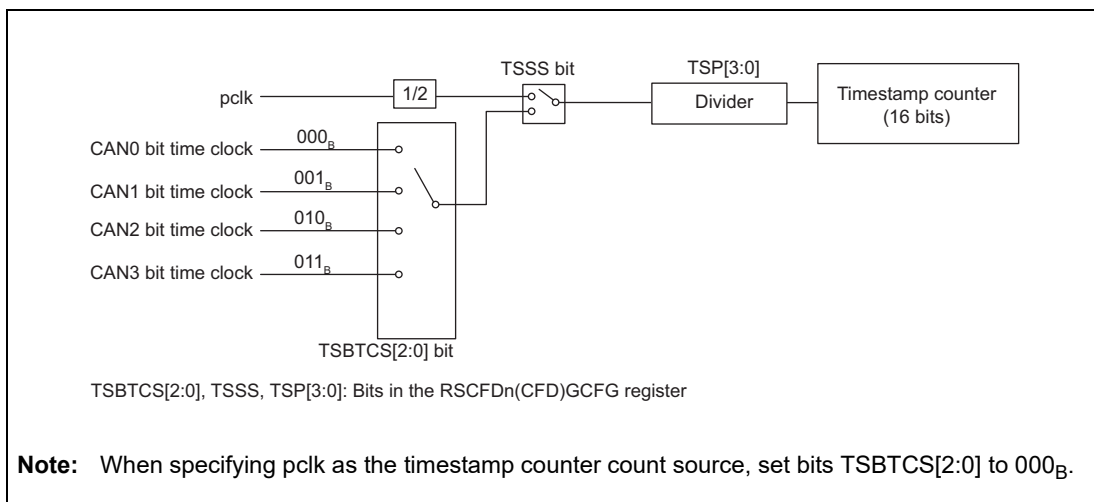

Figure 16.8 Timestamp Function Block Diagram

16.8 Transmission Functions

There are three types of transmission. In classical CAN mode, transmittable payload length is 8 bytes in every transmission type. In CAN FD mode, transmittable payload length varies with transmission types.

- Transmission using transmit buffers:
Each channel has 16 buffers. Transmittable payload length in CAN FD mode is 20 bytes. However, when transmit buffer merge mode is used, four buffers out of 16 buffers are allocated as a payload-only storage area and two buffers are able to transmit payloads with a length of more than 20 bytes.
- Transmission using transmit/receive FIFO buffers (transmit mode):
Each channel has three FIFO buffers. Up to 128 messages can be saved in a single FIFO buffer. Transmittable payload length in CAN FD mode is 64 bytes. Each FIFO buffer is used with a link to a transmit buffer. Only the message to be transmitted next in a FIFO buffer becomes a target of transmit priority determination. Messages are transmitted sequentially on a first-in, first-out basis.
- Transmission using transmit queues:
Up to 16 transmit buffers per channel can be allocated to transmit queues. Transmittable payload length in CAN FD mode is 20 bytes. Transmit buffer number (16 x m) + 15 is used as a common access window. Transmit buffers are allocated to transmit queues in descending order of buffer numbers. All messages in transmit queues, which are targets of priority determination, are transmitted in the order of ID numbers.

Figure 16.9 shows the allocation of transmit queues and transmit/receive FIFO buffer link.

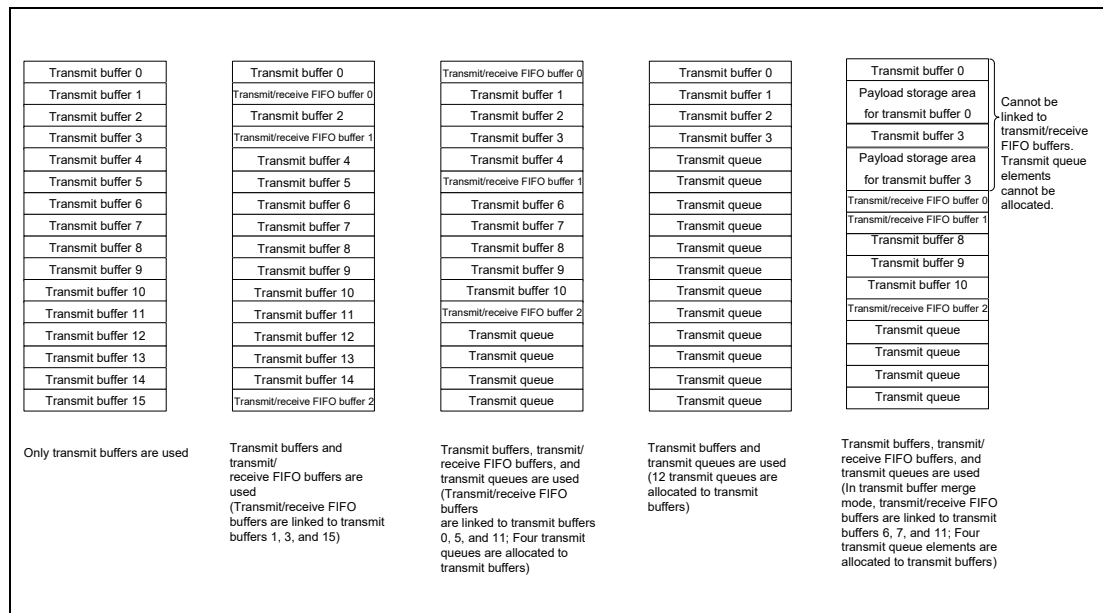

Figure 16.9 Allocation of Transmit Queues and Transmit/Receive FIFO Buffer Links

16.8.1 Transmit Priority Determination

If transmit requests are issued from multiple buffers or queues in the same channel, transmit priority is determined.

The priority is determined by using one of the following methods.

- ID priority (TPRI bit = 0)
- Transmit buffer number priority (TPRI bit = 1)

The setting of the TPRI bit in the RSCFDn(CFD)GCFG register is effective in all CAN channels.

When the TPRI bit is set to 0, messages are transmitted according to the priority of stored message IDs. Priority of IDs conforms to the CAN bus arbitration specification defined in the CAN specification. Targets of priority determination are IDs of messages placed in transmit buffers, transmit/receive FIFO buffers (set to transmit mode or gateway mode), and transmit queues. When one or more transmit queues are used, select the ID priority method. When transmit/receive FIFO buffers are used, the oldest message in a FIFO buffer becomes a target of priority determination. When a message is being transmitted from a transmit/receive FIFO buffer, the next message in the same FIFO buffer becomes a target of priority determination. When transmit queues are used, all messages in transmit queues are targets of priority determination. If the same ID is set for two or more buffers, the buffer with a lower number takes precedence.

When the TPRI bit is set to 1, the message in the transmit buffer whose number is the lowest among buffers having transmit requests is transmitted first. When transmit/receive FIFO buffers are linked to transmit buffers, transmit priority is determined according to the linked transmit buffer numbers.

When messages are retransmitted due to an arbitration lost or an error, transmit priority determination is made again regardless of the TPRI bit. When a 2-bit ECC error is detected in the priority determination processing, no message is transmitted (only when the EEFE bit in the RSCANnGCFG register is 1 in classical CAN mode).

16.8.2 Transmission Using Transmit Buffers

Setting the transmit request bit (TMTR bit in the RSCFDn(CFD)TMCp register) of a transmit buffer to 1 (transmission is requested) allows transmission of data frames or remote frames.

Transmit result is shown by the TMTRF[1:0] flag in the corresponding RSCFDn(CFD)TMSTSp register (p = 0 to 63). When transmit completes successfully, the TMTRF[1:0] flag is set to 10_B (transmission has been completed (without transmit abort request)) or 11_B (transmission has been completed (with transmit abort request)).

16.8.2.1 Transmit Abort Function

Setting the TMTAR bit in the RSCFDn(CFD)TMCp register to 1 (transmit abort is requested) cancels the transmit request from a transmit buffer for which the TMTRM bit in the RSCFDn(CFD)TMSTSp register is set to 1 (a transmit request is present). When transmit abort is completed, the TMTRF[1:0] flag of the RSCFDn(CFD)TMSTSp register is set to 01_B (transmit abort has been completed) and the transmit request is canceled (clearing the TMTRM bit to 0).

A message that is being transmitted or a message to be transmitted next according to the transmit priority determination cannot be aborted. However, if an arbitration lost or an error has occurred while a message for which the TMTAR bit is set to 1 is being transmitted, retransmission is not performed.

16.8.2.2 One-Shot Transmission Function (Retransmission Disabling Function)

When the TMOM bit of the RSCFDn(CFD)TMCp register is set to 1 (one-shot transmission is enabled), transmission is performed only once. Even if an arbitration lost or an error occurs, retransmission is not performed.

One-shot transmission result is shown by the TMTRF[1:0] flag in the corresponding RSCFDn(CFD)TMSTSp register. When one-shot transmission completes successfully, the TMTRF[1:0] flag is set to 10_B or 11_B. When an arbitration lost or an error has occurred, the TMTRF[1:0] flag is set to 01_B (transmit abort has been completed).

16.8.2.3 Transmit Buffer Merge Mode (Only in CAN FD Mode)

Transmit buffers can transmit messages with a payload length of 20 bytes, but can transmit messages with a payload length of up to 64 bytes by merging three transmit buffers in transmit buffer merge mode.

Setting the TMME bit to 1 in the RSCFDnCFDCmFDCFG register enables transmit buffer merge mode. In this mode, six buffers per channel become a merge area and two sets of transmit buffers (16 × m) + 0 to (16 × m) + 2 and transmit buffers (16 × m) + 3 to (16 × m) + 5 are merged. A transmission request is made by the first transmit buffer, and subsequent two buffers are used as a payload storage area. Do not set the transmission request bit (TMTR bit in the RSCFDnCFDTMCp register) and the transmission abort request bit (TMTAR bit in the RSCFDnCFDTMCp register) to 1 for transmit buffers except for the first buffer.

While transmit buffer merge mode is enabled, do not link the transmit/receive FIFO buffer to six merged buffers or allocate it to the transmit queue.

16.8.3 Transmission Using FIFO Buffers

A single transmit/receive FIFO buffer can save as many messages as specified by the CFDC[2:0] bits of the RSCFDn(CFD)CFCCk register (k = 0 to 11). Messages are transmitted sequentially on a first-in, first out basis.

Transmit/receive FIFO buffers are linked to transmit buffers selected by the CFTML[3:0] bits in the RSCFDn(CFD)CFCCk register. When the CFE bit of the RSCFDn(CFD)CFCCk register is set to 1 (transmit/receive FIFO buffers are used), transmit/receive FIFO buffers become targets of transmit priority determination. Priority determination is applied only to the message to be transmitted next in a FIFO buffer.

When the CFE bit is set to 0 (no transmit/receive FIFO buffer is used), the CFEMP flag is set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)) at the timing below.

- The transmit/receive FIFO buffer becomes empty immediately when the message in it is not being transmitted or is not to be transmitted next.
- The transmit/receive FIFO buffer becomes empty after transmission completion, CAN bus error detection, arbitration lost, or transition to channel halt mode when the message in it is being transmitted or to be transmitted next.

When the CFE bit is cleared to 0, all messages in transmit/receive FIFO buffers are lost and messages cannot be stored in FIFO buffers. Confirm that the CFEMP flag is set to 1 before setting the CFE bit to 1 again.

16.8.3.1 Interval Transmission Function

To transmit messages continuously from the same transmit/receive FIFO buffer that is set to transmit mode or gateway mode, message transmission interval time can be set.

Immediately after the first message has been transmitted successfully from the FIFO buffer with the CFE bit set to 1 in the RSCFDn(CFD)CFCCk register, the interval timer starts counting (after EOF7 of the CAN protocol). After that, when the interval time has passed, the next message is transmitted. The interval timer stops in channel reset mode or by clearing the CFE bit to 0.

The interval time is set by the CFITT[7:0] bits in the RSCFDn(CFD)CFCCk register. When the interval timer is not used, set the CFITT[7:0] bits to 00_H.

Select an interval timer count source using the CFITR and CFITSS bits in the RSCFDn(CFD)CFCCk register. When the CFITR and CFITSS bits are set to 00_B, the count source is obtained by dividing $plk/2$ by the value of the ITRCP[15:0] bits. When the CFITR and CFITSS bits are set to 10_B, the count source is obtained by dividing $plk/2$ by (the value of the ITRCP[15:0] bits \times 10). When the CFITR and CFITSS bits are set to x1_B, the CANm bit time clock becomes a count source in classical CAN mode and the nominal CANm bit time clock becomes a count source in CAN FD mode (Use this count source only for the channel does not handle the CAN FD frames in CAN FD mode).

The interval time is calculated by the following formulae where M is the ITRCP[15:0] value and N is the CFITT[7:0] value.

- When CFITR and CFITSS bits are 00_B

$$\frac{1}{plk\ frequency} \times 2 \times M \times N$$

- When CFITR and CFITSS bits are 10_B

$$\frac{1}{plk\ frequency} \times 2 \times M \times 10 \times N$$

- When CFITR and CFITSS bits are x1_B

$$\text{Classical CAN mode} \quad : \quad \frac{1}{\text{CANm bit time clock frequency}} \times N$$

$$\text{CAN FD mode:} \quad : \quad \frac{1}{\text{Nominal CANm bit time clock frequency}} \times N$$

Figure 16.10 shows the interval timer block diagram.

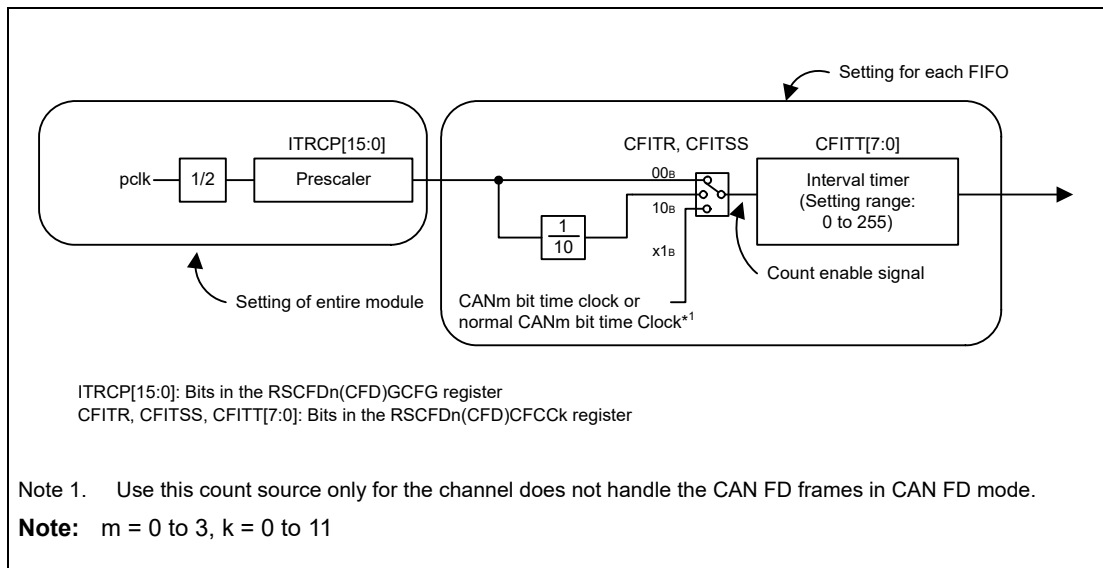

Figure 16.10 Interval Timer Block Diagram

Figure 16.11 shows the interval timer timing chart.

Figure 16.11 Interval Timer Timing Chart

1. The interval timer starts counting upon completion of transmission. Since the prescaler is not initialized at the time of transmission completion, the first interval time has a margin of error of up to one interval timer count.
2. The interval timer is decremented by 1 by the next count enable signal.
3. When the interval timer has decreased to 0, the transmit/receive FIFO buffer issues a transmit request.
4. When the transmit/receive FIFO buffer is determined for the next transmission by the priority determination, it starts transmitting data. Transmission starts usually with a delay of three CANm bit time clock cycles or less from the issue of transmit request.
 Transmission start may delay up to 1367 plck clock cycles if several internal processing including receive filter processing, message routing, and transmit priority determination are performed at all channels.

16.8.4 Transmission Using Transmit Queues

Three to sixteen buffers (up to 10 buffers in transmit buffer merge mode) are allocated to a transmit queue for each channel, and the transmit buffer $(16 \times m) + 15$ is used as a common access window.

All messages in a transmit queue are targets of transmit priority determination and are transmitted in the ID priority order regardless of the storing order. If two messages having the same ID are stored in a transmit queue, these messages are not always be transmitted in the storing order in the transmit queue.

Setting the TXQE bit in the RSCFDn(CFD)TXQCCm register to 0 disables transmit queues. When the TXQE bit is set to 0, the TXQEMP flag in the RSCFDn(CFD)TXQSTSm register is set to 1 (the transmit queue contains no message (transmit queue empty)) at the timing below.

- The transmit queue becomes empty immediately when the message in it is not being transmitted or is not to be transmitted next.
- The transmit queue becomes empty after transmission completion, CAN bus error detection, arbitration lost, or transition to channel halt mode when the message in it is being transmitted or to be transmitted next.

When the TXQE bit is cleared to 0, all messages in transmit queues are lost and messages cannot be stored in transmit queues. Confirm that the TXQEMP flag is set to 1 before setting the TXQE bit to 1 again.

16.8.5 Transmit Data Padding (Only in CAN FD Mode)

When the payload length indicated by the set DLC value in a transmit message exceeds the payload storage area size of a buffer to be used for transmission, excessive payloads are padded by CCH.

This processing is performed in the following cases when the transmit buffer merge mode is disabled (TMME bit in the RSCFDnCFDCmFDCFG register is 0).

· Transmit/receive FIFO set to transmission or gateway mode:

When the payload length of the transmit DLC exceeds the transmit/receive FIFO payload storage area size set by the CFPLS[2:0] bits in the RSCFDnCFDCFCCK register

· Transmit buffer (including transmit queue):

When the payload length of the transmit DLC exceeds 20 bytes

When the transmit buffer merge mode is enabled, no transmit data is padded in any transmission using a transmit buffer, transmit/receive FIFO buffer, or transmit queue. At this time, do not set a payload length more than the payload storage size of the buffer for transmitting as the DLC value in the transmit message.

16.8.6 Transmit History Function

Information of transmitted messages can be stored in the transmit history buffer. Each channel has a single transmit history buffer that can contain 16 sets of transmit history data.

A message transmit source buffer type can be selected by the THLDTE bit in the RSCFDn(CFD)THLCCm register. Whether to store transmit history data for each message can be set by the THLEN bit in the RSCFDn(CFD)CFIDk register (k = 0 to 11).

In classical CAN mode, the TMTSCE bit in the RSCANnCFG register can be used to set whether to include a timestamp value in the transmit history data. In CAN FD mode, a timestamp value is always included.

The following information on a transmitted message will be stored in the transmit history buffer after the successful completion of transmission.

Storage of the transmit history data after the successful completion of transmission may take up to 152 cycles of pclk in classical CAN mode or 420 cycles of pclk in CAN FD mode.

- Buffer type 001_B: Transmit buffer
 010_B: Transmit/receive FIFO buffer
 100_B: Transmit queue
- Buffer number Number assigned to source transmit buffer, transmit queue, or transmit/receive FIFO buffer. This number depends on buffer types. See **Table 16.176**.
- Label data Label information of transmitted message
- Timestamp value of the transmit message (When the TMTSCE bit is 1 in classical CANmode)

Table 16.176 Transmit History Data Buffer Numbers

Buffer type			
Buffer No.	001 _B	010 _B	100 _B
0000 _B	Transmit buffer 16 × m + 0	Numbers of transmit buffers linked to transmit/receive FIFO buffers by the CFTML[3:0] bits in the RSCFDn(CFD)FCCK register (k = 0 to 11)	Numbers of transmit buffers allocated to the transmit queue that performed transmission
0001 _B	Transmit buffer 16 × m + 1		
0010 _B	Transmit buffer 16 × m + 2		
0011 _B	Transmit buffer 16 × m + 3		
0100 _B	Transmit buffer 16 × m + 4		
0101 _B	Transmit buffer 16 × m + 5		
0110 _B	Transmit buffer 16 × m + 6		
0111 _B	Transmit buffer 16 × m + 7		
1000 _B	Transmit buffer 16 × m + 8		
1001 _B	Transmit buffer 16 × m + 9		
1010 _B	Transmit buffer 16 × m + 10		
1011 _B	Transmit buffer 16 × m + 11		
1100 _B	Transmit buffer 16 × m + 12		
1101 _B	Transmit buffer 16 × m + 13		
1110 _B	Transmit buffer 16 × m + 14		
1111 _B	Transmit buffer 16 × m + 15		

Label data is used to identify each message. A unique label data can be added to each message transmitted from a transmit buffer, transmit queue, or transmit/receive FIFO buffer.

The timestamp value is fetched from the timestamp counter at the SOF (start of frame) timing of the message. For details about the timestamp counter, see **Section 16.7.1.6, Timestamp**.

Transmit history data can be read from the RSCFDn(CFD)THLACCm register. If it is attempted to store new transmit history data while the buffer is full, the buffer overflows and the new data is discarded.

16.9 Gateway Function

When a transmit/receive FIFO buffer is set to gateway mode, received messages can be transmitted from an arbitrary channel without CPU intervention.

When a transmit/receive FIFO buffer for which the CFM[1:0] bits of the RSCFDn(CFD)CFCCk register are set to 10_B (gateway mode) is selected by the RSCFDn(CFD)GAFLP1_j register, messages that passed through the filter processing of the receive rule are stored in the specified transmit/receive FIFO buffer and are automatically transmitted from the buffer.

Messages stored in a transmit/receive FIFO buffer are transmitted sequentially on a first-in, first-out basis. Only the message to be transmitted next becomes a target of transmit priority determination.

Transmit/receive FIFO buffers in the gateway mode are disabled by setting the CFE bit in the RSCFDn(CFD)CFCCk register to 0. When the CFE bit is set to 0, the CFEMP flag becomes 1 at the timing below.

- The transmit/receive FIFO buffer becomes empty immediately when the message in it is not being transmitted or is not to be transmitted next.
- The transmit/receive FIFO buffer becomes empty after transmission completion, CAN bus error detection, or arbitration lost when the message in it is being transmitted or to be transmitted next.

When the CFE bit is cleared to 0, all messages in transmit/receive FIFO buffers are lost and messages can no longer be stored in transmit/receive FIFO buffers. Confirm that the CFEMP flag is set to 1 before setting the CFE bit to 1 again.

16.9.1 CAN-CAN FD Gateway (Only in CAN FD Mode)

When the gateway function is to be used in CAN FD mode, frames for transmission can be replaced with classical CAN frames or CAN FD frames.

The CAN-CAN FD gateway is enabled when the GWEN bit in the RSCFDnCFDCmFDCFG register is set to 1. The GWDF and GWBRS bits in the RSCFDnCFDCmFDCFG register can be used to select the FDF and BRS bits of the transmission frame. If the DLC value of the received CAN frame is 1001B or above and the setting of the GWDF bit is 1 (CAN FD frame), the DLC value is replaced with 1000B.

While the CAN-CAN FD gateway is enabled, do not route the following frames.

- CAN FD frames with a payload length of more than 8 bytes
- Remote frames

Also, while the CAN-CAN FD gateway is enabled, transmit only the following frames from the corresponding channel by setting GWDF.

- When GWDF = 0, transmit only classical CAN frames.
- When GWDF = 1, transmit only CAN FD frames.

16.10 Test Function

The test function is classified into communication tests and global tests.

- Communication tests: Performed for each channel.
 - Standard test mode
 - Listen-only mode
 - Self-test mode 0 (external loopback mode)
 - Self-test mode 1 (internal loopback mode)
 - Restricted operation mode (only in CAN FD mode)
- Global tests: Performed in entire module
 - RAM test (read/write test)
 - Inter-channel communication test (CRC error test enabled)

16.10.1 Standard Test Mode

Standard test mode allows CRC test. The CRC value calculated by the RS-CANFD module based on the transmit message or receive message is stored in the register. This CRC value is stored in the CRCREG[14:0] bits in the RSCFDn(CFD)CmERFL register when the message is a classical CAN frame (CRC length = 15 bits) or in the CRCREG[20:0] bits in the RSCFDnCFDCmFDCRC register when the message is a CAN FD frame (CRC length = 17 or 21 bits). Use the inter-channel communication test function for CRC error tests. For details, see **Section 16.10.6.1, CRC Error Test**.

16.10.2 Listen-Only Mode

Listen-only mode allows reception of data frames and remote frames. Only recessive bits are transmitted on the CAN bus, and the ACK bit, overload flag, and active error flag are not transmitted.

Listen-only mode is available for detecting the communication speed.

Do not make a transmit request from any buffer or queue in listen-only mode.

Figure 16.12 shows the connection when listen-only mode is selected.

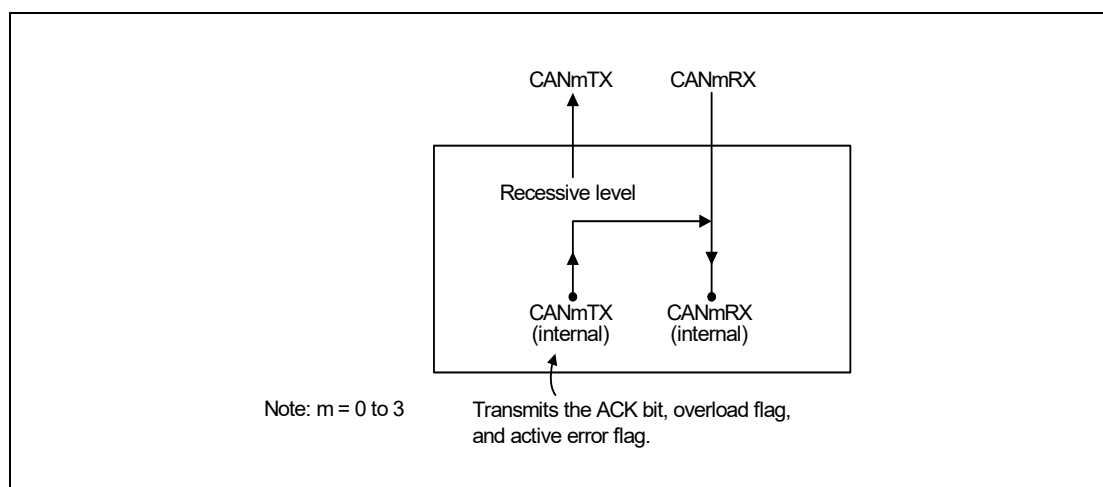

Figure 16.12 Connection When Listen-Only Mode is Selected

16.10.3 Self-Test Mode (Loopback Mode)

In self-test mode, messages transmitted from a channel are compared with the receive rule of the same channel. Messages are stored in a buffer if they have passed through the filter processing. Messages transmitted from other CAN nodes are compared only with the receive rule for which the GAFLLB bit in the RSCFDn(CFD)GAFLIDj register ($j = 0$ to 15) is set to 0 (when a message transmitted from another CAN node is received).

If the mirror function and self-test mode are both enabled, the self-test mode setting takes precedence.

16.10.3.1 Self-Test Mode 0 (External Loopback Mode)

Self-test mode 0 is used to perform a loopback test within a channel including the CAN transceiver.

In self-test mode 0, transmitted messages are handled as messages received through the CAN transceiver and are stored in a buffer. An ACK bit is generated to receive messages transmitted from the own CAN node.

Figure 16.13 shows the connection when self-test mode 0 is selected.

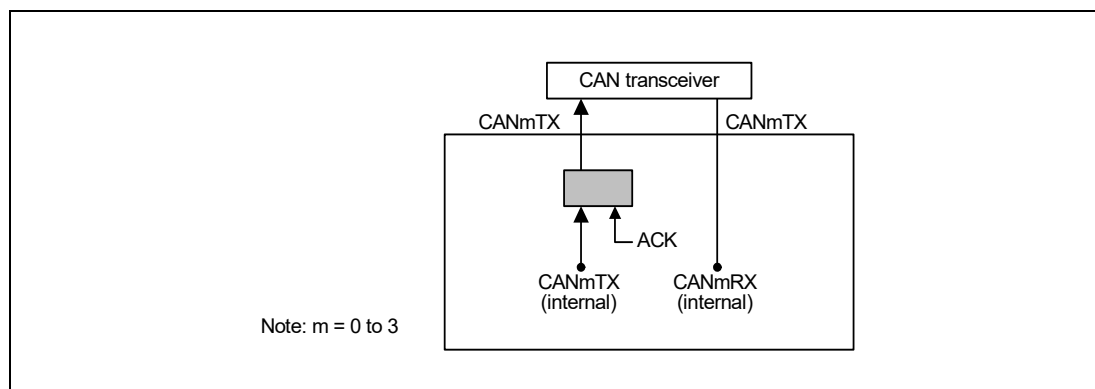

Figure 16.13 Connection When Self-Test Mode 0 is Selected

16.10.3.2 Self-Test Mode 1 (Internal Loopback Mode)

In self-test mode 1, transmitted messages are handled as received messages and are stored in a buffer. An ACK bit is generated to receive messages transmitted from the own CAN node.

In self-test mode 1, internal feedback from the internal TXm pin ($m = 0$ to 3) to the internal RXm pin is performed. The external CRXm pin input is isolated. The external CTXm pin outputs only recessive bits.

Figure 16.14 shows the connection when self-test mode 1 is selected.

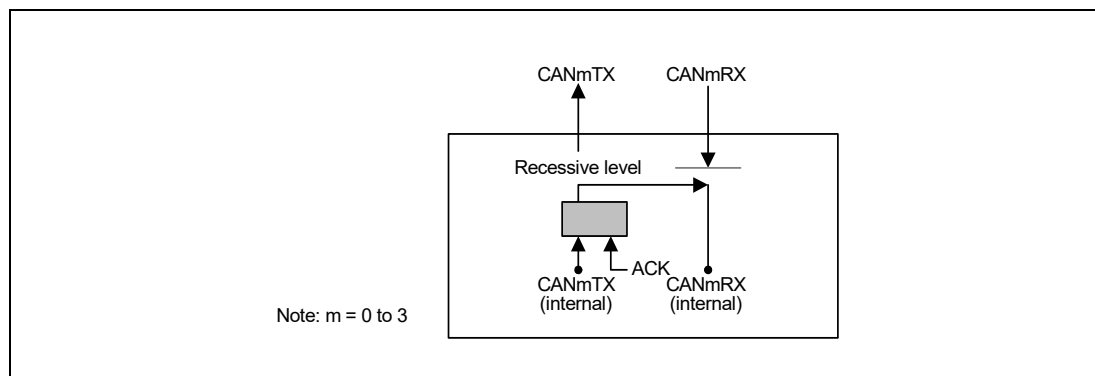

Figure 16.14 Connection When Self-Test Mode 1 is Selected

16.10.4 Restricted Operation Mode (Only in CAN FD Mode)

In restricted operation mode, an ACK bit is generated when a valid data frame and a remote frame have been received, but these frames are not transmitted even if an error frame or an overload frame transmit condition is detected. When a condition is detected, operation is suspended until the bus idle state comes for resynchronization with the CAN communication. The receive error counter (REC) and the transmit error counter (TEC) do not change due to an error.

A desired transmission request can be made for transmission without restrictions.

16.10.5 RAM Test

The RAM test function allows accesses to all CAN RAM addresses. RAM initialization which is performed after resetting the MCU does not initialize all CAN RAM areas.

When the RAM test function is used, the RAM is divided into pages of 256 bytes each. A RAM test page is selected by the RTMPS[6:0] bits in the RSCFDn(CFD)GTSTCFG register. Data in the set page can be read from and written to the RSCFDn(CFD)RPGACCr register (r = 0 to 63). The available total RAM size is 12640 bytes (3160_H) in classical CAN mode or 17760 bytes (4560_H) in CAN FD mode. Do not access more than 96 bytes in the last page (RTMPS[6:0] = 31_H in classical CAN mode, RTMPS[6:0] = 45_H in CAN FD mode) during RAM test.

16.10.6 Inter-Channel Communication Test

The inter-channel communication test function allows communication test by internally and mutually connecting CAN channels. During this test, channels are isolated from the external CAN bus.

Before starting data transmission/reception in channel communication mode, make transmission/reception settings for each channel. Channels not included in the test must be placed in channel halt mode.

Figure 16.15 shows the connection for inter-channel communication test.

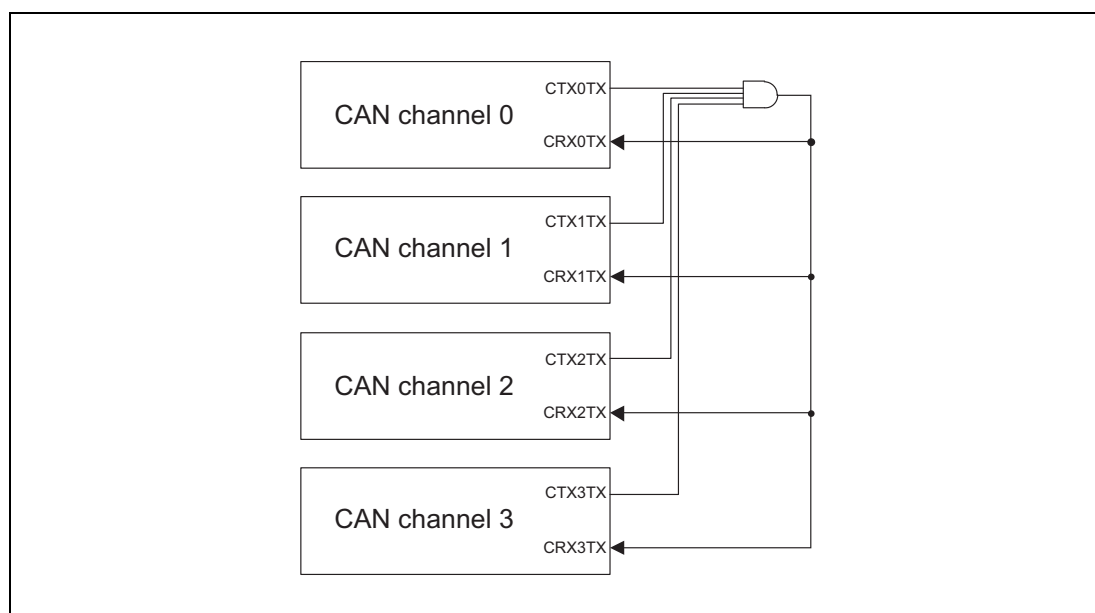

Figure 16.15 Connection for Inter-Channel Communication Test

16.10.6.1 CRC Error Test

A CRC error test is enabled during an inter-channel communication test. The following shows an example of channel 0 CRC error test procedure during a communication test between channel 0 and channel 1.

Preconditions

- Inter-channel communication test is enabled.
- Channel 0 and channel 1 are in standard test mode.

Procedure

1. Make a setting to send a message from the transmit buffer p of channel 1.
2. Set the CRCT bit in the RSCFDn(CFD)C0CTR register to 1 (to enable inversion of the first bit in the received ID field).
3. Set the TMTR bit in the RSCFDn(CFD)TMCp register to 1 (to issue a transmission request to the transmit buffer p of channel 1).
4. Wait for occurrence of a CAN0 error interrupt due to a channel bus error.
5. Read the CRCREG[14:0] bits in the RSCFDn(CFD)CmERFL register or the CRCREG[14:0] bits in the RSCFDnCFDCmFDCRC register of channel 0 and channel 1, and confirm that the CRC values are different on the transmission and the reception side.
6. Confirm that the CERR bit in RSCFDm(CFD)C0ERFL is 1 (CRC error detected).

The CRC error test function generates an incorrect CRC value by inverting the first bit in the received ID field. Therefore, note that not a CRC error but a stuff error (continuous 6-bit data of the same level) is detected when a message in which ID's upper 5-bit value is 10000_B or ID's upper 6-bit value is 011111_B is received.

The CRC generation circuit of the RS-CANFD module is contained in the protocol controller of each channel. Another CRC calculation test is not necessary during transmission because the same circuit is used for both transmission and reception.

16.11 RS-CANFD Setting Procedure

16.11.1 Initial Settings

The RS-CANFD module initializes the CAN RAM after the MCU is reset. The RAM initialization time is 6322 cycles/plk. The GRAMINIT flag in the RSCFDn(CFD)GSTS register is set to 1 (CAN RAM initialization is ongoing) during the RAM initialization and is cleared to 0 (CAN RAM initialization is finished) when the initialization is completed. Configure CAN settings after the GRAMINIT flag is cleared to 0. **Figure 16.16** shows the CAN setting procedure after the MCU is reset.

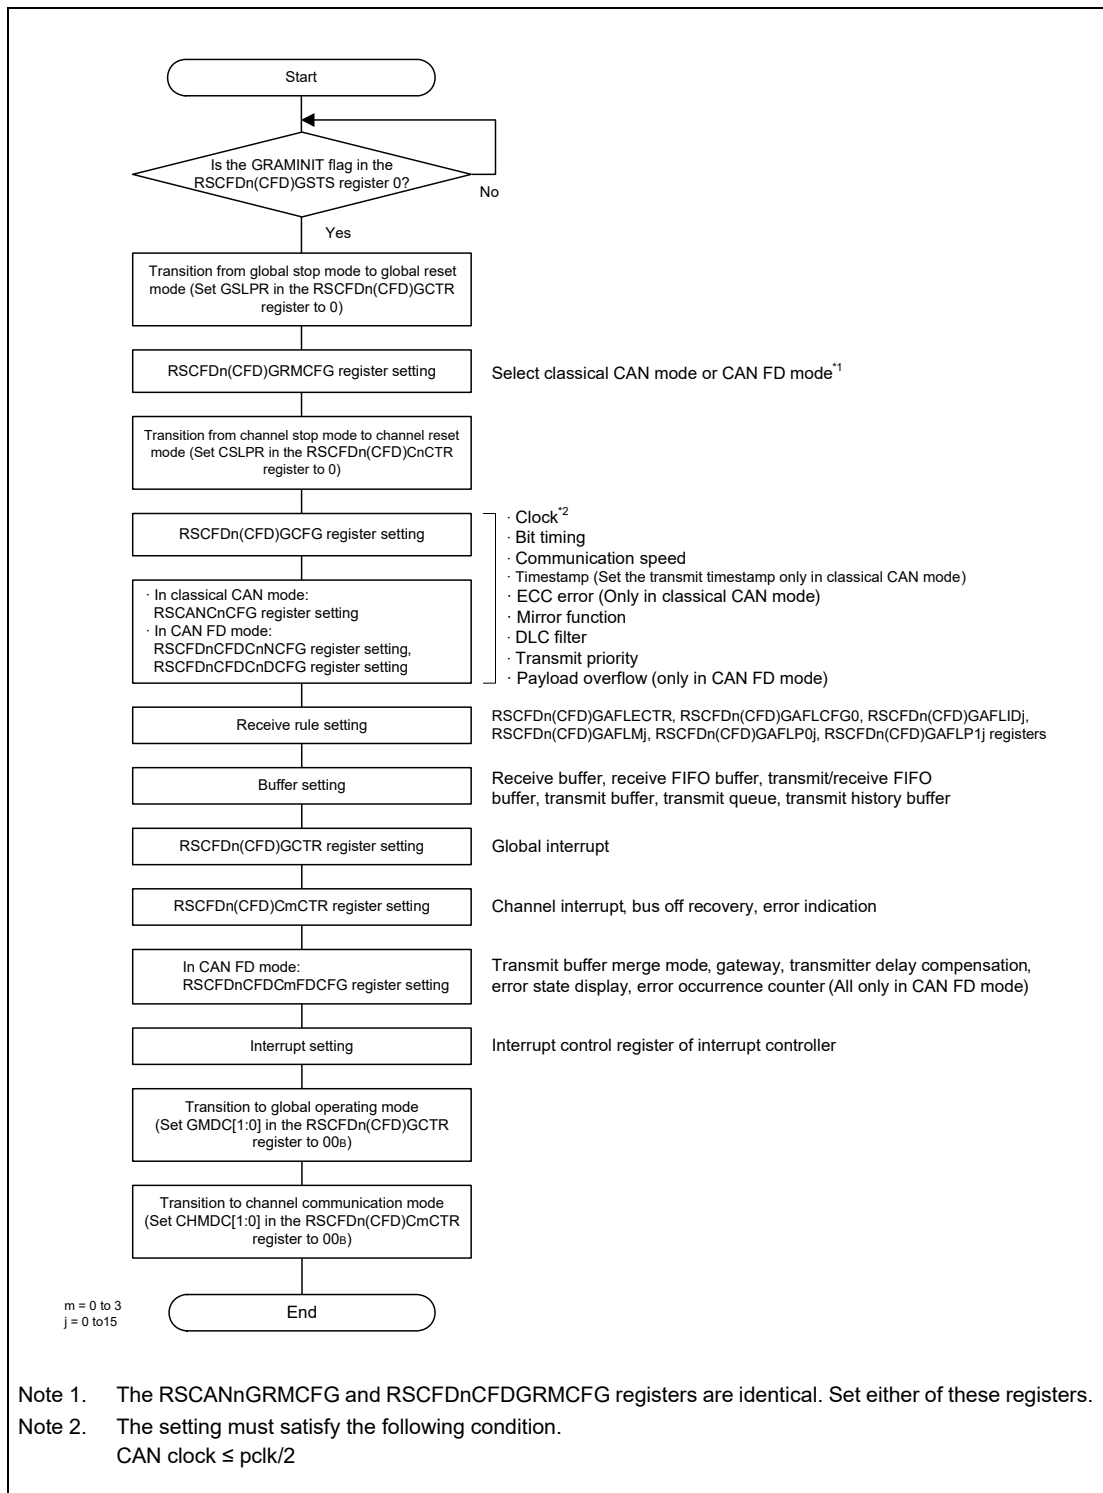

Figure 16.16 CAN Setting Procedure after the MCU is Reset

16.11.1.1 Clock Setting

Set the CAN clock (fCAN) which is the clock source of the RS-CANFD module. Select clk or clk_xincan by the DCS bit in the RSCFDn(CFD)GCFG register.

16.11.1.2 Bit Timing Setting

In the CAN protocol, one bit of a communication frame consists of three segments SS, TSEG1, and TSEG2, of which two segments TSEG1 and TSEG2 can be set by the corresponding registers for each channel. In classical CAN mode, set these two segments in the RSCANnCMCFG register. Two bit rates (nominal bit rate and data bit rate) are provided for CAN FD mode. Set the nominal bit rate in the RSCFDnCFDCmNCFG register and set the data bit rate in the RSCFDnCFDCmDCFG register.

Sample point timing can be determined by setting these two segments. This timing can be adjusted in units of 1 time quantum (hereafter referred to as Tq). A single Tq is the cycle of clock obtained by dividing the clock selected by the DCS bit in the RSCFDn(CFD)GCFG register. Set a division ratio by the BRP[9:0] bits in the RSCANnCMCFG register in classical CAN mode (CANmTq clock), and by the NBRP[9:0] bits in the RSCFDnCFDCmNCFG register and the DBRP[7:0] bits in the RSCFDnCFDCmDCFG register in CAN FD mode (CANmTq(N) clock and CANmTq(D) clock). ISO 11898-1 allows independent division ratio for nominal bit rate and data bit rate. However, if different division ratio values are set, a loss of synchronization may occur between CAN nodes at the timing of change from nominal bit rate to data bit rate. For this reason, it is recommended that the NBRP[9:0] value and the DBRP[7:0] value be equal and the two bit rate values be different according to the respective segment values.

To specify different values for the nominal bit rate and the data bit rate, change the values of the RSCFDnCFDCmNCFG.NTSEG1 and NTSEG2 bits and RSCFDnCFDCmDCFG.DTSEG1 and DTSEG2 bits, respectively.

When the TDCE bit is set to 1 (Transmitter delay compensation is enabled) in the RSCFDnCFDCmFDCFG register, set the equal value of 1 or less to the bits NBRP[9:0] and DBRP[7:0].

Figure 16.17 shows the bit timing chart. **Table 16.177** shows an example of bit timing setting.

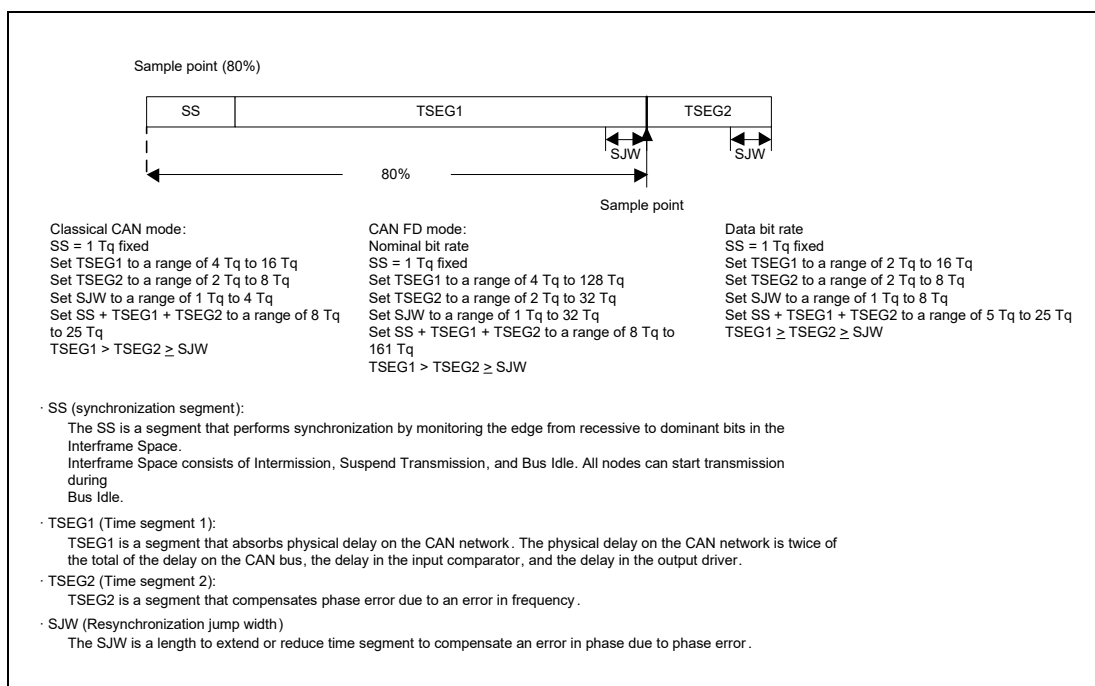

Figure 16.17 Bit Timing Chart

Table 16.177 Example of Bit Timing Setting

1 Bit	Set Value (Tq)				Sampling Point (%) Note: See Figure 16.17.
	SS	TSEG1	TSEG2	SJW	
5 Tq*1	1	2	2	1	60.00
8 Tq	1	4	3	1	62.50
	1	5	2	1	75.00
10 Tq	1	6	3	1	70.00
	1	7	2	1	80.00
16 Tq	1	10	5	1	68.75
	1	11	4	1	75.00
20 Tq	1	12	7	1	65.00
	1	13	6	1	70.00
50 Tq*1	1	39	10	4	80.00

Note 1. Only in CAN FD mode

16.11.1.3 Communication Speed Setting

Set the CAN communication speed for each channel using the fCAN, baud rate prescaler division value, and Tq count per bit time. For CAN FD mode, set two types of transmission rate (arbitration phase and data phase) for each channel.

Figure 16.18 shows the CAN clock control block diagram, and **Table 16.178** and **Table 16.179** show an example of the communication speed setting.

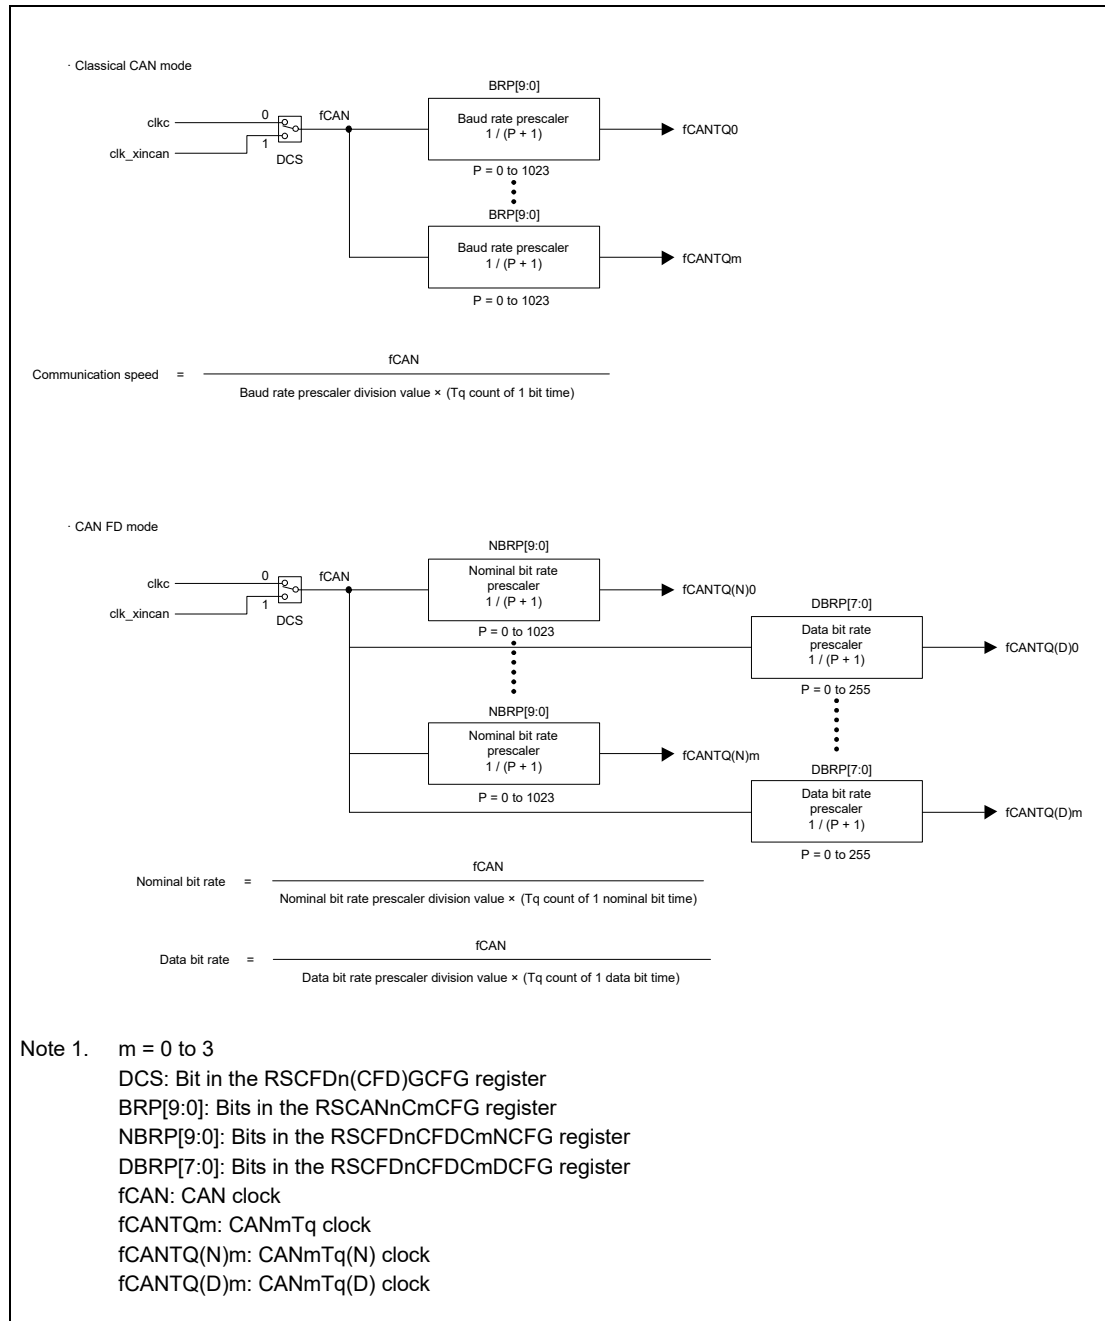

Figure 16.18 CAN Clock Control Block Diagram

Table 16.178 Example of Communication Speed Setting (in Classical CAN Mode)

fCAN						
Communication Speed	40 MHz	32 MHz	24 MHz	20 MHz	16 MHz	8 MHz
1 Mbps	8 Tq (5) 20 Tq (2)	8 Tq (4) 16 Tq (2)	8 Tq (3) 12 Tq (2) 24 Tq (1)	10 Tq (2) 20 Tq (1)	8 Tq (2) 16 Tq (1)	8 Tq (1)

Communication Speed	40 MHz	20 MHz
Nominal 1 Mbps Data 5 Mbps	Nominal 40 Tq (1) Data 8 Tq (1)	None
Nominal 500 kbps Data 2 Mbps	Nominal 80 Tq (1) Data 20 Tq (1)	Nominal 40 Tq (1) Data 10 Tq (1)

Note: Values in () are baud rate prescaler division values.

16.11.1.4 Receive Rule Setting

Receive rules can be set using receive rule-related registers.

Up to 16 receive rules can be registered per page. Specify pages 0 to 15 (for 4-channel unit) by the AFLPN[4:0] bits in the RSCFDn(CFD)GAFLECTR register. Use the AFLDAE bit to enable or disable writing to the receive rule table.

Figure 16.19 shows the receive rule setting procedure.

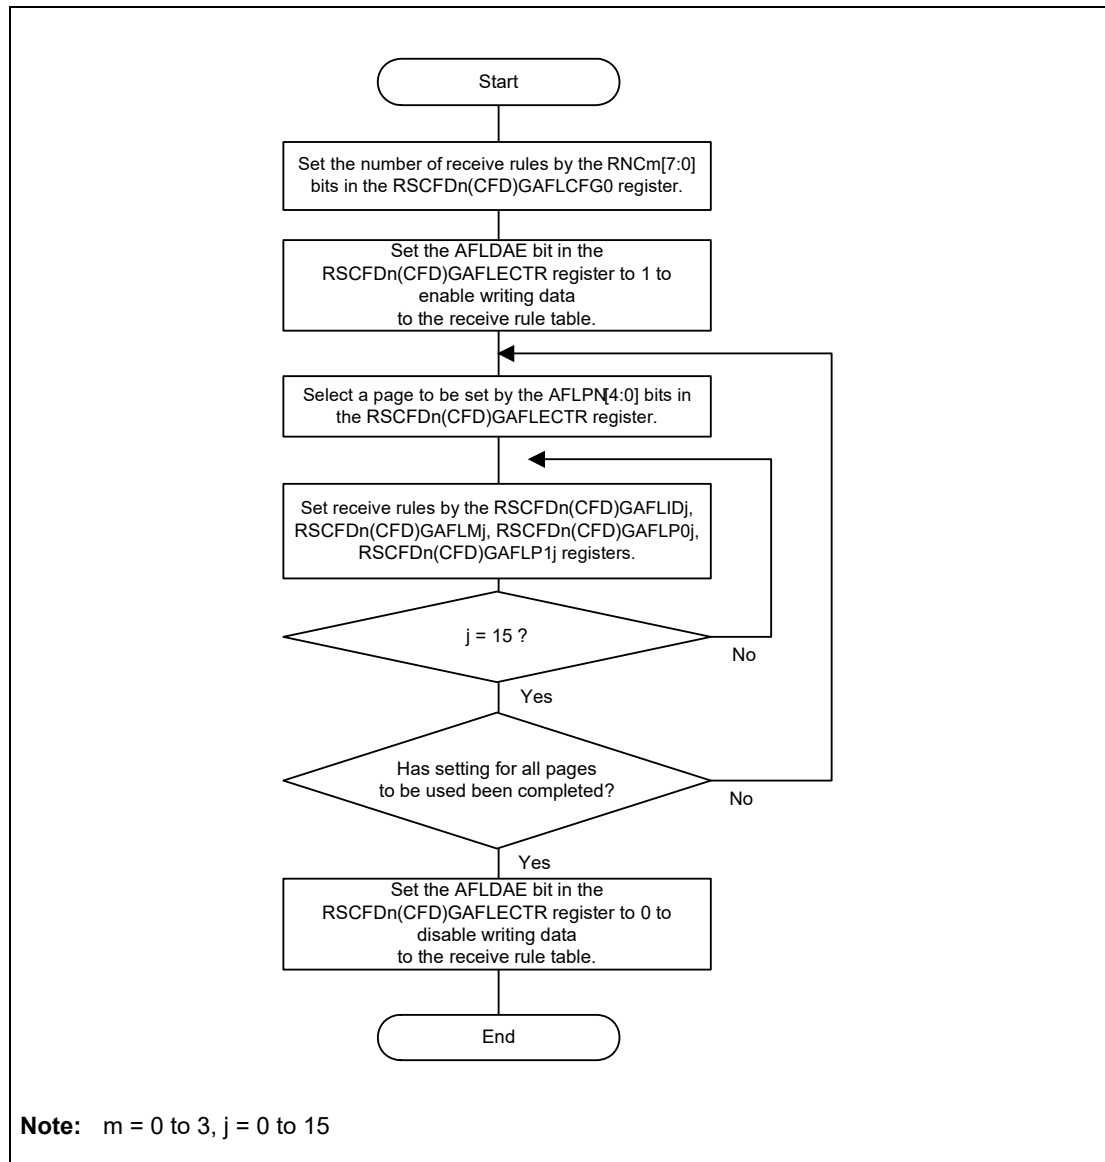

Figure 16.19 Receive Rule Setting Procedure

16.11.1.5 Buffer Setting

Set the number of buffers to be used (number of messages to be stored) and interrupt sources. Also set the payload storage size for CAN FD mode. For transmit/receive FIFO buffers that are set to transmit mode, set transmit buffers to be linked.

In classical CAN mode, up to 4096 bytes of the RAM can be used in receive buffers and FIFO buffers. Up to 256 buffers are available, and 16 bytes are used per buffer. Configure the buffers so that the following conditions are met.

Number of receive buffers

+ total number of depth of receive FIFO buffers x

+ total number of depth of transmit/receive FIFO buffers $k \leq 256$ buffers

In CAN FD mode, up to 7168 bytes of the RAM can be used in receive buffers and FIFO buffers. Configure the buffers so that the following conditions are met.

Number of receive buffers $\times (12 + \text{payload storage size})$

+ total of (number of depth $\times (12 + \text{payload storage size})$) of receive FIFO buffers x

+ total of (number of depth $\times (12 + \text{payload storage size})$) of transmit/receive FIFO buffers $k \leq 7168$ bytes.

Figure 16.20 shows the buffer configuration. **Figure 16.21** shows the buffer setting procedure.

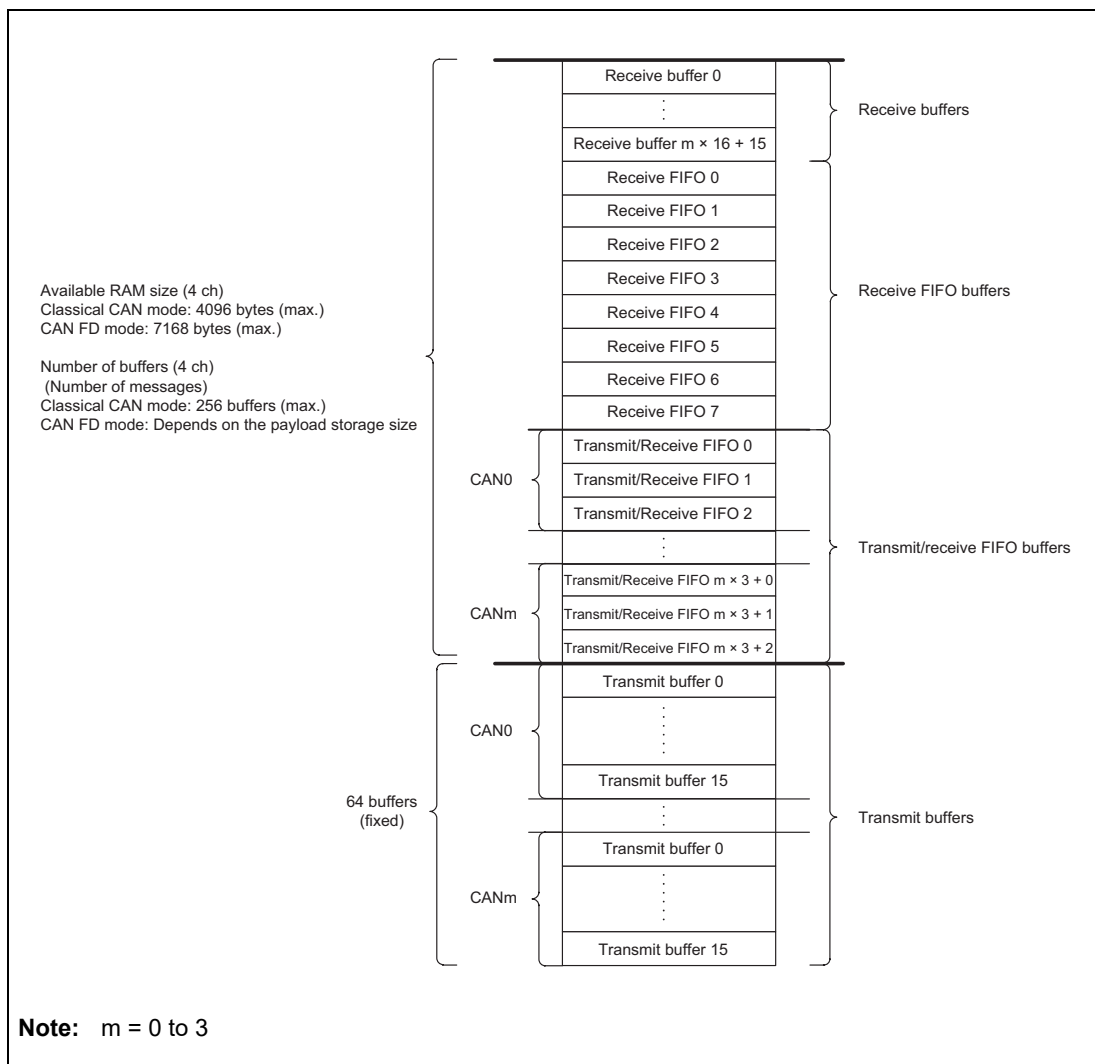

Figure 16.20 Buffer Configuration

CAUTION

Receive buffers, receive FIFO buffers, transmit/receive FIFO buffers, and transmit buffers are located in succession.

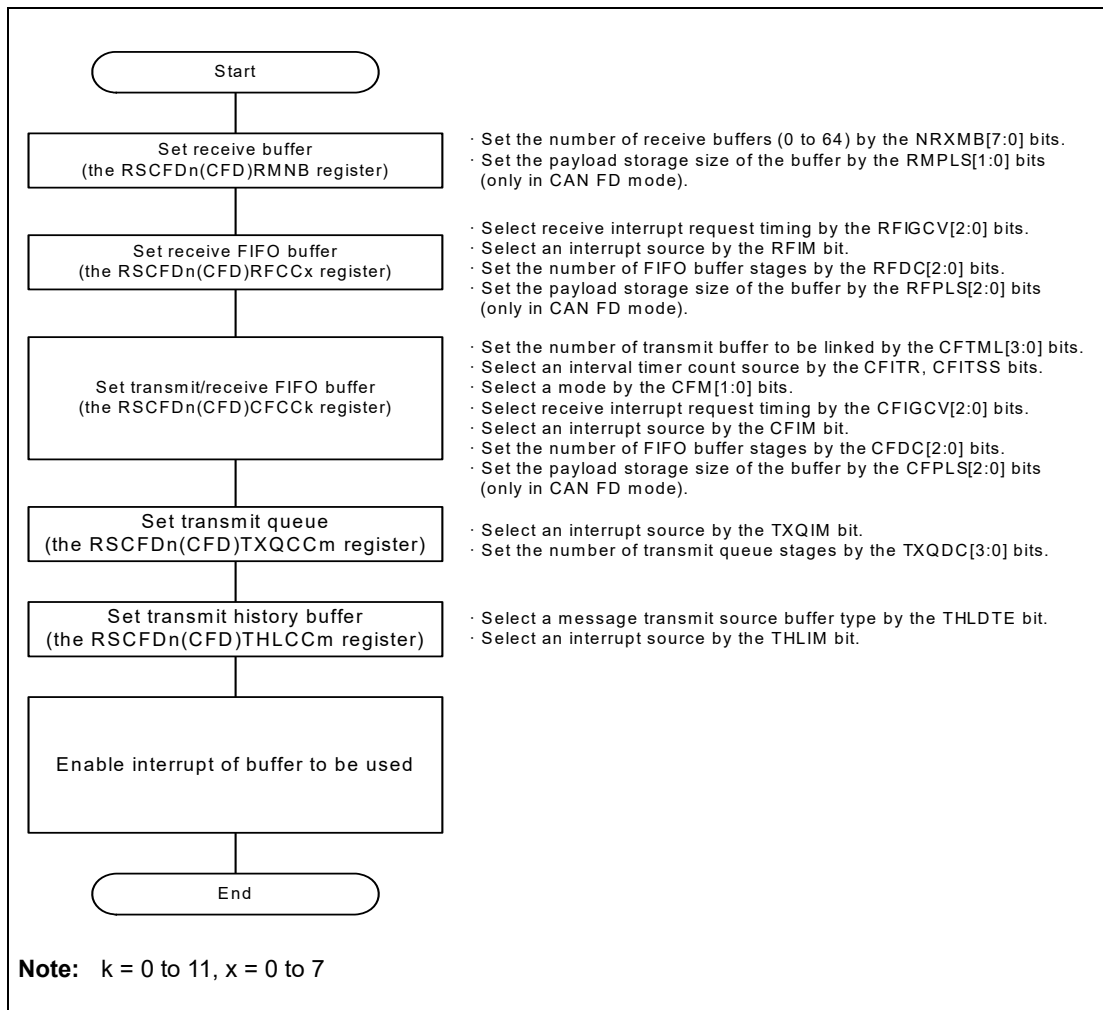

Figure 16.21 Buffer Setting Procedure

16.11.1.6 Transmitter Delay Compensation (Only in CAN FD Mode)

A high baud rate is used in CAN FD mode. Transmitter delay compensation is provided as a function to accept propagation delay in this case.

To use this function, set the TDCE bit in the RSCFDnCFDCmFDCFG register to 1. Also set the secondary sample point (SSP) timing used in the data phase by the TDCOC bit and TDCO[6:0] bits in the RSCFDnCFDCmFDCFG register.

When the TDCOC bit is 0, the SSP timing equals the total value of the delay measured by the RS-CANFD module and the TDCO[6:0] value. (This value is rounded off to the nearest integer of T_q .)

Usually, the TDCO[6:0] value must be equal to SS + TSEG1, the sample point timing.

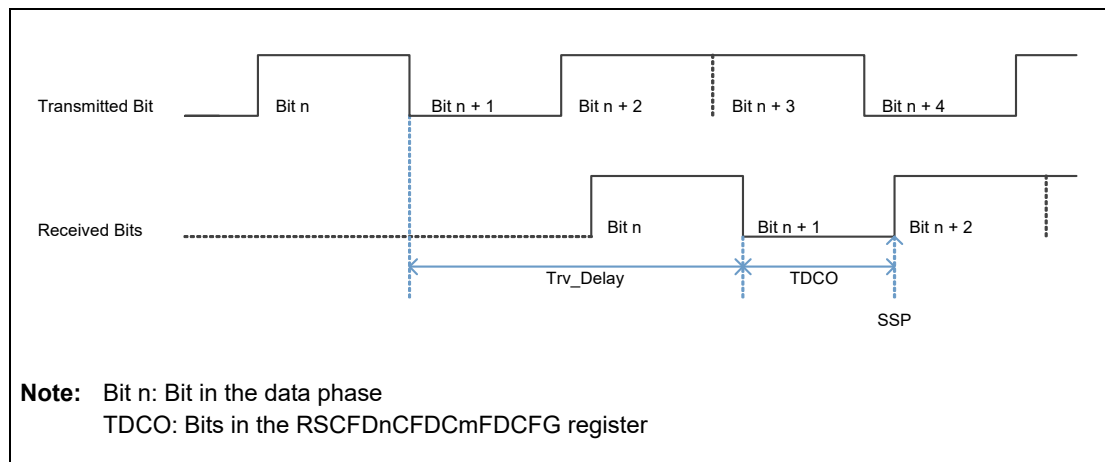

Figure 16.22 SSP timing

When the TDCOC bit is 1, the SSP timing is determined only by the TDCO[6:0] value. (When the DBRP[7:0] value in the RSCFDnCFDCmDCFG register is larger than 0, the TDCO[6:0] value is also rounded off to the nearest integer of T_q .)

The RS-CANFD module compensates a delay up to $(3 \text{ CANm bit time} - 2 f_{\text{CAN}})$. (CANm bit time is the value of data bit rate.)

When the TDCE bit is set to 1 (Transmitter delay compensation is enabled) in the RSCFDnCFDCmFDCFG register, set the equal value of 1 or less to the bits NBRP[9:0] and DBRP[7:0].

16.11.2 Reception Procedure

16.11.2.1 Receive Buffer Reading Procedure

When the processing to store received messages in a receive buffer starts, the RMNSq flag in the RSCFDn(CFD)RMNDy register (y = 0, 1, q = 0 to 63) is set to 1 (receive buffer q contains a new message). Messages can be read from registers RSCFDn(CFD)RMIDq, RSCFDn(CFD)RMPTRq, RSCFDn(CFD)RMDFb_q (b = 0 or 1 in classical CAN mode, b = 0 to 4 in CAN FD mode). If the next message has been received before the current message is read from the receive buffer, the message is overwritten.

Figure 16.23 shows the receive buffer reading procedure. This procedure ensures the consistency of messages read from registers RSCFDn(CFD)RMIDq, RSCFDn(CFD)RMPTRq, RSCFDn(CFD)RMDFb_q, and RSCFDn(CFD)RMNDy.

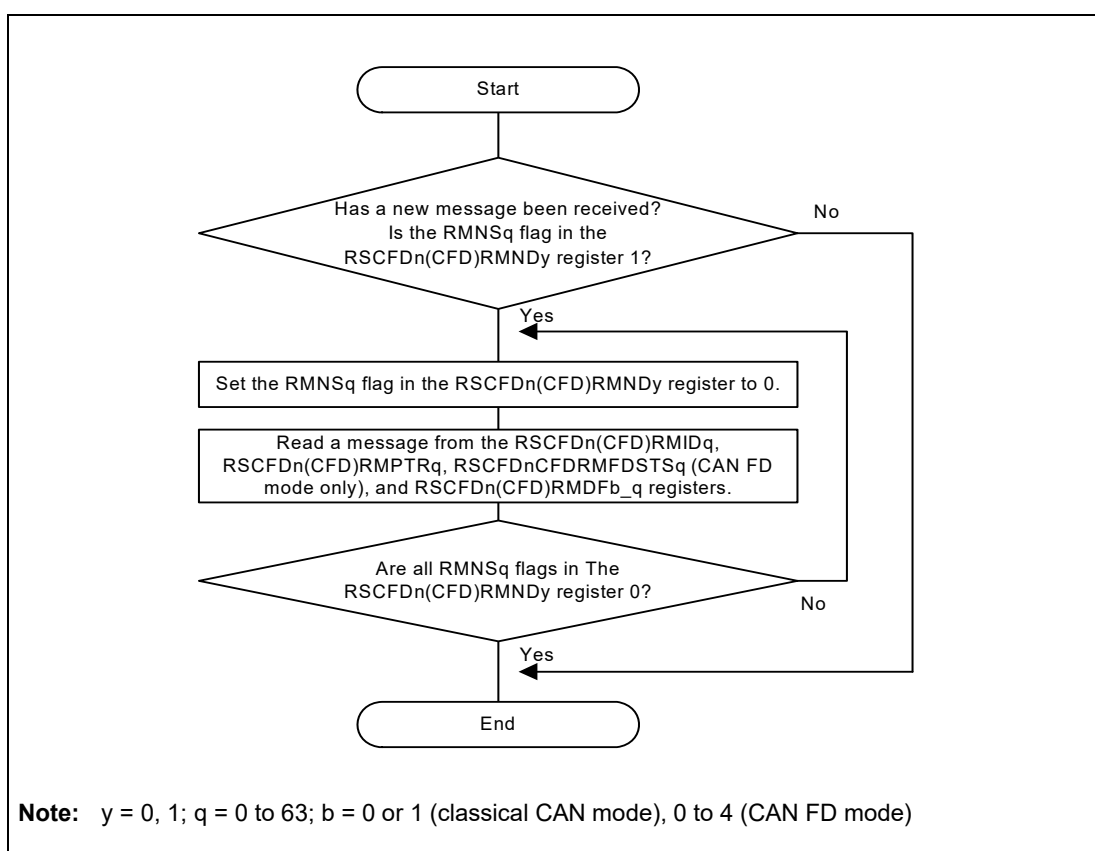

Figure 16.23 Receive Buffer Reading Procedure

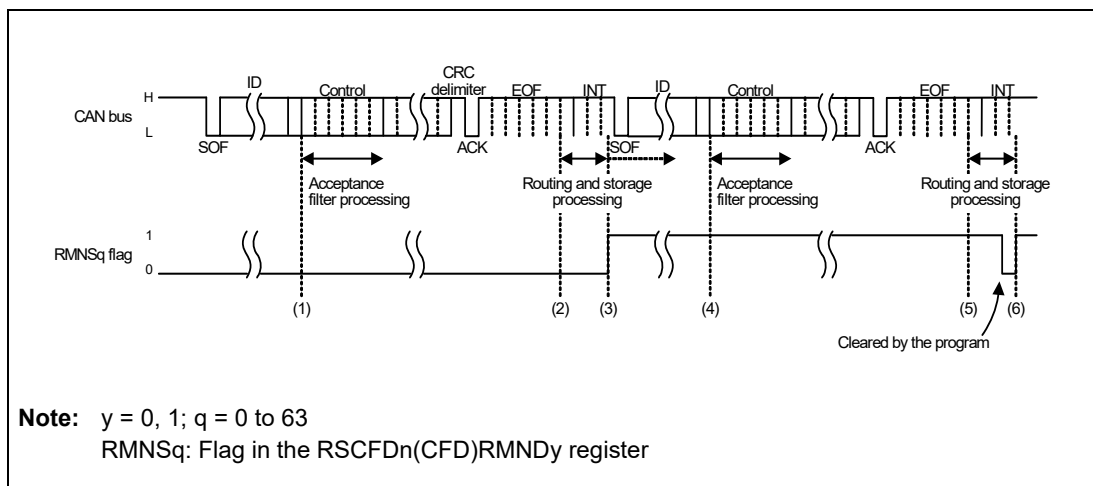

Figure 16.24 Receive Buffer Reception Timing Chart

- (1) When the ID field of a message has been received, the acceptance filter processing starts.
- (2) When the message matches the receive rule of the corresponding channel and has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCFDn(CFD)GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.
- (3) When the message has passed through the DLC filter processing, the processing to store the message in the specified receive buffer starts. When the message storage processing starts, the RMNSq flag in the corresponding RSCFDn(CFD)RMNDy register is set to 1 (receive buffer n contains a new message). If any other channels are performing filter processing or transmit priority determination processing, the routing processing and the storage processing may be delayed.
- (4) When the ID field of the next message has been received, the acceptance filter processing starts.
- (5) When the message matches the receive rule of the corresponding channel and has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCFDn(CFD)GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.
- (6) When the corresponding RMNSq flag is cleared to 0 (receive buffer n contains no new message), this flag is set to 1 again when the message storage processing starts. If the RMNSq flag remains 1, a new message is overwritten in the receive buffer. The RMNSq flag cannot be cleared to 0 during storage of messages.

16.11.2.2 FIFO Buffer Reading Procedure

When received messages have been stored in one or more receive FIFO buffers or transmit/receive FIFO buffers that are set to receive mode or gateway mode, the corresponding message count display counter (RFMC[7:0] bits in the RSCFDn(CFD)RFSTSx register (x = 0 to 7) or CFMC[7:0] bits in the RSCFDn(CFD)CFSTS_k register (k = 0 to 11)) is incremented by 1. At this time, if the RFIE bit (receive FIFO interrupt is enabled) in the RSCFDn(CFD)RFCCx register or the CFRXIE bit (transmit/receive FIFO receive interrupt is enabled) in the RSCFDn(CFD)CFCC_k register is set to 1, an interrupt request is generated. Received messages can be read from the RSCFDn(CFD)RFID_x, RSCFDn(CFD)RFPTR_x, RSCFDn(CFD)RFFDSTS_x (only in CAN FD mode), and RSCFDn(CFD)RFDFd_x (d = 0 or 1 in classical CAN mode, d = 0 to 15 in CAN FD mode) registers for receive FIFO buffers, or from the RSCFDn(CFD)CFID_k, RSCFDn(CFD)CFPTR_k, RSCFDn(CFD)CFDCSTSk (only in CAN FD mode), and RSCFDn(CFD)CFDFd_k registers for transmit/receive FIFO buffers. Messages in FIFO buffers can be read sequentially on a first-in, first-out basis.

When the message count display counter value matches the FIFO buffer depth (a value set by the RFDC[2:0] bits in the RSCFDn(CFD)RFCCx register or the CFDC[2:0] bits in the RSCFDn(CFD)CFCC_k register), the RFFLL or CFFLL flag is set to 1 (the receive FIFO buffer is full.).

When all messages have been read out of the FIFO buffer, the RFEMP flag in the RSCFDn(CFD)RFSTSx register or the CFEMP flag in the RSCFDn(CFD)CFSTS_k register is set to 1 (the receive FIFO buffer contains no unread message (buffer empty)).

If the RFE bit or the CFE bit is cleared to 0 (no receive FIFO buffer is used) with the interrupt request flag (RFIF flag in the RSCFDn(CFD)RFSTSx register or CFRXIF flag in the RSCFDn(CFD)CFSTS_k register) set to 1 (a receive FIFO interrupt request is present), the interrupt request flag is not automatically cleared to 0. Clear the interrupt request flag to 0 by the program.

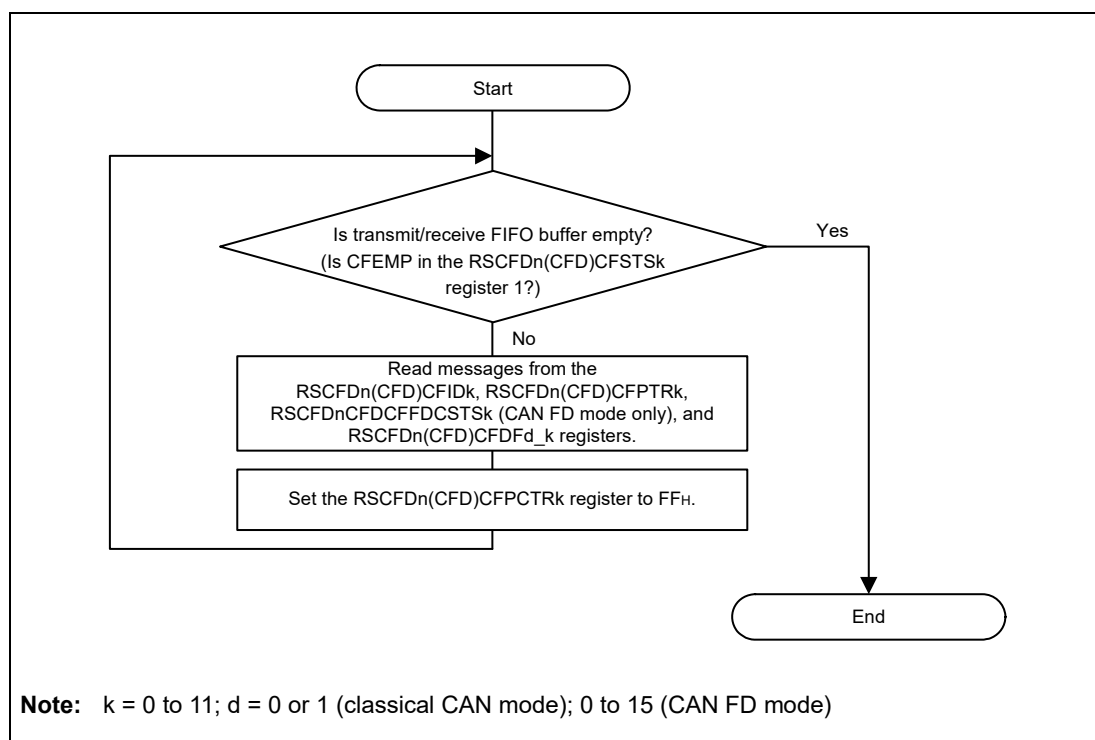

Figure 16.25 Transmit/Receive FIFO Buffer Reading Procedure

When reading a message in CAN FD mode, do not read the RSCFDnCFDRFDFd_x or RSCFDnCFDCFDf_k register corresponding to the area exceeding the payload storage size specified by the RFPLS[2:0] bits in the RSCFDnCFDRFCCx register or the CFPLS[2:0] bits in the RSCFDnCFDCFCCK register.

Table 16.180 Payload Storage Area of Receive FIFO Buffer

Setting of RFPLS[2:0] Bits	Payload Storage Size	Corresponding Data Field Registers
000 _B	8 bytes	RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF1_x
001 _B	12 bytes	RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF2_x
010 _B	16 bytes	RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF3_x
011 _B	20 bytes	RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF4_x
100 _B	24 bytes	RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF5_x
101 _B	32 bytes	RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF7_x
110 _B	48 bytes	RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF11_x
111 _B	64 bytes	RSCFDnCFDRFDF0_x to RSCFDnCFDRFDF15_x

Table 16.181 Payload Storage Area of Transmit/Receive FIFO Buffer

Setting of RFPLS[2:0] Bits	Payload Storage Size	Corresponding Data Field Registers
000 _B	8 bytes	RSCFDnCFDCFDf0_k to RSCFDnCFDCFDf1_k
001 _B	12 bytes	RSCFDnCFDCFDf0_k to RSCFDnCFDCFDf2_k
010 _B	16 bytes	RSCFDnCFDCFDf0_k to RSCFDnCFDCFDf3_k
011 _B	20 bytes	RSCFDnCFDCFDf0_k to RSCFDnCFDCFDf4_k
100 _B	24 bytes	RSCFDnCFDCFDf0_k to RSCFDnCFDCFDf5_k
101 _B	32 bytes	RSCFDnCFDCFDf0_k to RSCFDnCFDCFDf7_k
110 _B	48 bytes	RSCFDnCFDCFDf0_k to RSCFDnCFDCFDf11_k
111 _B	64 bytes	RSCFDnCFDCFDf0_k to RSCFDnCFDCFDf15_k

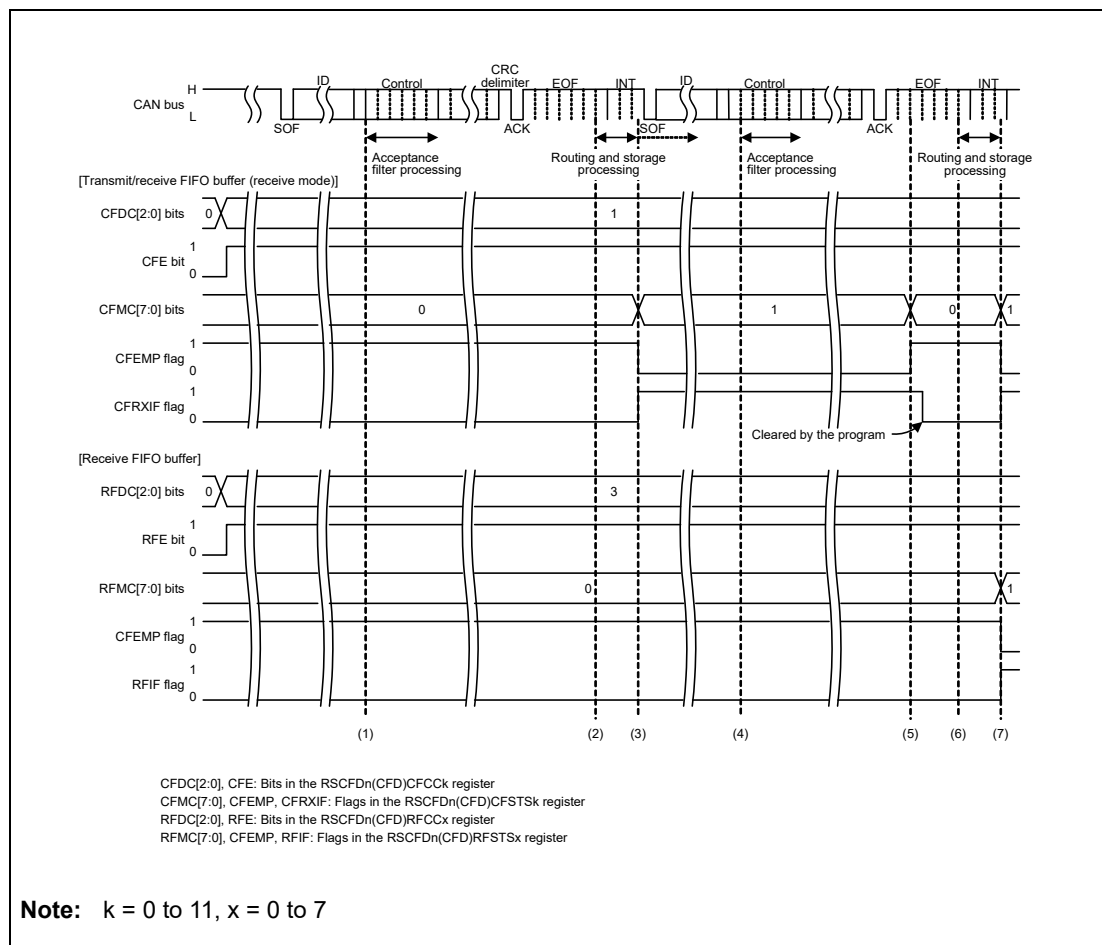

Figure 16.26 FIFO Buffer Reception Timing Chart

- (1) When the ID field of a message has been received, the acceptance filter processing starts.
- (2) When the message matches the receive rule of the corresponding channel and has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCFDn(CFD)GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.
- (3) When the message has passed through the DLC filter processing and the CFE value in the RSCFDn(CFD)CFCCk register is 1 (transmit/receive FIFO buffers are used) and the CFDC[2:0] value in the RSCFDn(CFD)CFCCk register is 001_B or more, the message is stored in the transmit/receive FIFO buffer that is set to receive mode. The CFMC[7:0] value in the RSCFDn(CFD)CFSTSk register is incremented by 1 and becomes 01_H . When the CFIM bit in the RSCFDn(CFD)CFCCk register is set to 1 (a FIFO receive interrupt request is generated each time a message has been received), the CFRXIF flag in the RSCFDn(CFD)CFSTSk register is set to 1 (a transmit/receive FIFO receive interrupt request is present). The CFRXIF flag can be cleared to 0 by the program.
- (4) When the ID field of the next message has been received, the acceptance filter processing starts.
- (5) Read received messages from the RSCFDn(CFD)CFIDk, RSCFDn(CFD)CFPTRk, RSCFDn(CFD)CFDF_k, and RSCFDn(CFD)CFDFk registers and write FF_H to the RSCFDn(CFD)CFPCTRk register. Thereby the CFMC[7:0] value in the RSCFDn(CFD)CFSTSk register is decremented by 1 and become 00_H , and the CFEMP flag in the

RSCFDn(CFD)CFSTSk register becomes 1 (the transmit/receive FIFO buffer contains no message (buffer empty)).

- (6) When the message matches the receive rule of the corresponding channel and has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCFDn(CFD)GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.
- (7) The message having passed through the DLC filter process is stored in the transmit/receive FIFO buffer which is set to receive mode, when the CFE bit is set to 1 (transmit/receive FIFO buffers are used) and the CFDC[2:0] bits are set to 001_B or more. The CFMC[7:0] value is incremented by 1 to 01H. When the CFIM bit is set to 1 (an interrupt occurs each time a message has been received), the CFRXIF flag is set to 1 (a transmit/receive FIFO receive interrupt request is present). The message is stored in the receive FIFO buffer when the RFE bit in the RSCFDn(CFD)RFCCx register is set to 1 (receive FIFO buffers are used.) and RFDC[2:0] bits in the RSCFDn(CFD)RFCCx register are set to 001_B or more. The RFMC[7:0] value in the RSCFDn(CFD)RFSTx register is incremented by 1 to 01H. When the RFIM bit in the RSCFDn(CFD)RFCCx register are set to 1 (an interrupt occurs each time a message has been received), the RFIF flag in the RSCFDn(CFD)RFSTx register is set to 1 (a receive FIFO interrupt request is present).

16.11.3 Transmission Procedure

16.11.3.1 Procedure for Transmission from Transmit Buffers

Figure 16.27 shows the procedure for transmission from transmit buffers.

Figure 16.28 shows a timing chart where messages are transmitted from two transmit buffers in the same channel and transmission has been successfully completed. **Figure 16.29** shows a timing chart where messages are transmitted from two transmit buffers in the same channel and transmit abort has been completed.

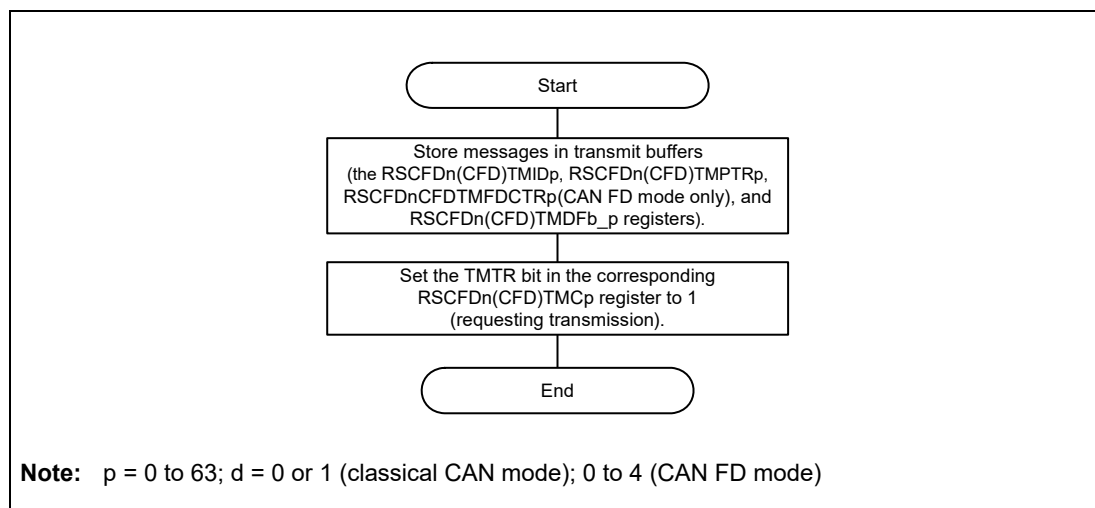

Figure 16.27 Procedure for Transmission from Transmit Buffers

In CAN FD mode and transmit buffer merge mode, messages with a payload size of more than 20 bytes can be transmitted from transmit buffers $(16 \times m) + 0$ and transmit buffers $(16 \times m) + 3$. At this time, transmit buffers $(16 \times m) + 1$ to $(16 \times m) + 2$ and transmit buffers $(16 \times m) + 4$ to $(16 \times m) + 5$ are allocated as a payload storage area. Registers RSCFDnCFDTMIDp, RSCFDnCFDTMPTRp, and RSCFDnCFDTMFDCTRp corresponding to these buffers can be used as data field registers that can store 4-byte data bytes (payload) like the RSCFDnCFDTMDFb_p register. **Table 16.182** shows message storage registers when transmitting a message with a payload size of more than 20 bytes from transmit buffer 0.

**Table 16.182 Message Storage Registers in Transmit Buffer Merge Mode
(Example of Transmit Buffer 0)**

Transmit Buffer	Offset from Base Address	Symbol	Register Function in Transmit Buffer Merge Mode
Transmit buffer 0	4000 _H	RSCFDnCFDTMID0	Transmit buffer 0 ID data, transmit history data store enable bit, RTR bit, and IDE bit
	4004 _H	RSCFDnCFDTMPTR0	Transmit buffer 0 label data and DLC data
	4008 _H	RSCFDnCFDTMFDCTR0	Transmit buffer 0 ESI bit, BRS bit, and FDF bit
	400C _H to 401C _H	RSCFDnCFDTMDF0_0 to RSCFDnCFDTMDF4_0	Transmit buffer 0 data bytes 0, 1, 2, and 3 to transmit buffer 0 data bytes 16, 17, 18, and 19
Transmit buffer 1	4020 _H	RSCFDnCFDTMID1	Transmit buffer 0 data bytes 20, 21, 22, and 23
	4024 _H	RSCFDnCFDTMPTR1	Transmit buffer 0 data bytes 24, 25, 26, and 27
	4028 _H	RSCFDnCFDTMFDCTR1	Transmit buffer 0 data bytes 28, 29, 30, and 31
	402C _H to 403C _H	RSCFDnCFDTMDF0_1 to RSCFDnCFDTMDF4_1	Transmit buffer 0 data bytes 32, 33, 34, and 35 to transmit buffer 0 data bytes 48, 49, 50, and 51
Transmit buffer 2	4040 _H	RSCFDnCFDTMID2	Transmit buffer 0 data bytes 52, 53, 54, and 55
	4044 _H	RSCFDnCFDTMPTR2	Transmit buffer 0 data bytes 56, 57, 58, and 59
	4048 _H	RSCFDnCFDTMFDCTR2	Transmit buffer 0 data bytes 60, 61, 62, and 63
	404C _H to 405C _H	RSCFDnCFDTMDF0_2 to RSCFDnCFDTMDF4_2	Not used

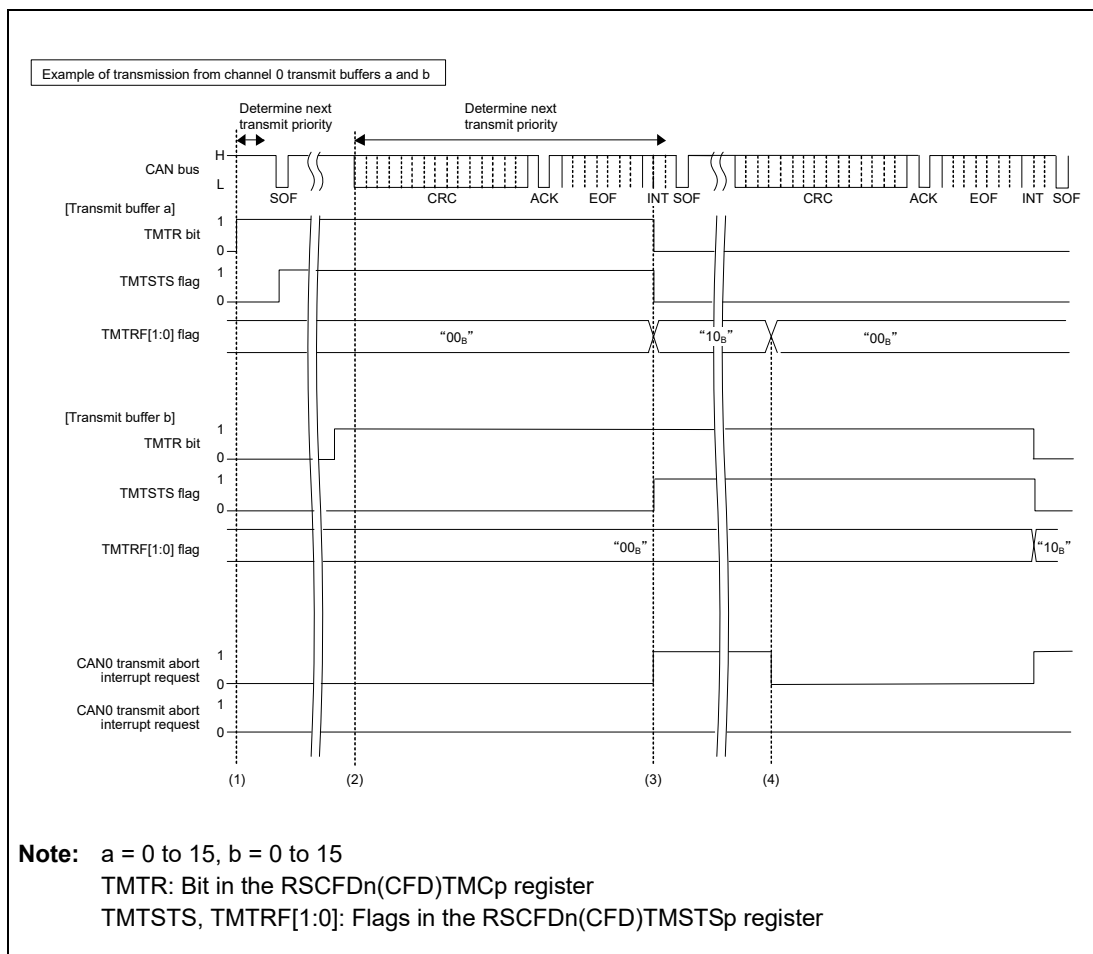

Figure 16.28 Transmit Buffer Transmission Timing Chart (Transmission Completed Successfully)

- (1) When the TMTR bit in the RSCFDn(CFD)TMCa register is set to 1 while the CAN bus is idle, the transmit priority determination processing starts to determine the highest-priority transmit buffer. If transmit buffer a is determined to be the highest-priority transmit buffer, the TMTSTS flag in the corresponding RSCFDn(CFD)TMSTSa register is set to 1 (transmission is in progress) and the CAN channel starts transmitting data.
- (2) When a transmit request from a buffer is present, the priority determination starts at the first bit of CRC field for the next transmission. Some delay may occur in the determination time if any other channels are performing the transmit priority determination processing. However, it does not affect the transmission interval because the determination will be completed before bit 3 of intermission.
- (3) When transmit completes successfully, the TMTRF[1:0] flag in the RSCFDn(CFD)TMSTSa register is set to 10_B (transmission has been completed (without transmit abort request)) and the TMTSTS flag and the TMTR bit in the RSCFDn(CFD)TMSTSa register are cleared to 0. When the TMIEa bit in the RSCFDn(CFD)TMIEC0 register is 1 (transmit buffer interrupt is enabled), a CAN0 transmit complete interrupt request is generated. To clear the interrupt request, set the TMTRF[1:0] flag to 00_B (transmission is in progress or no transmit request is present).
- (4) Before starting the next transmission, set the TMTRF[1:0] flag to 00_B. Write the next message to the transmit buffer, and then set the TMTR bit to 1 (transmission is requested). The TMTR bit can be set to 1 only when the TMTRF[1:0] flag value is 00_B.

If an arbitration lost has occurred after transmission started, the TMTSTS flag is cleared to 0. The transmit priority determination is reexecuted at the beginning of the CRC delimiter to search for the highest-priority transmit buffer. If an error has occurred during transmission or after arbitration lost, the priority determination processing is reexecuted during transmission of an error frame.

When a 2-bit ECC error is detected during the priority determination processing, no data is transmitted (in classical CAN mode, only when the EEFE bit in the RSCANnGCFG register is 1).

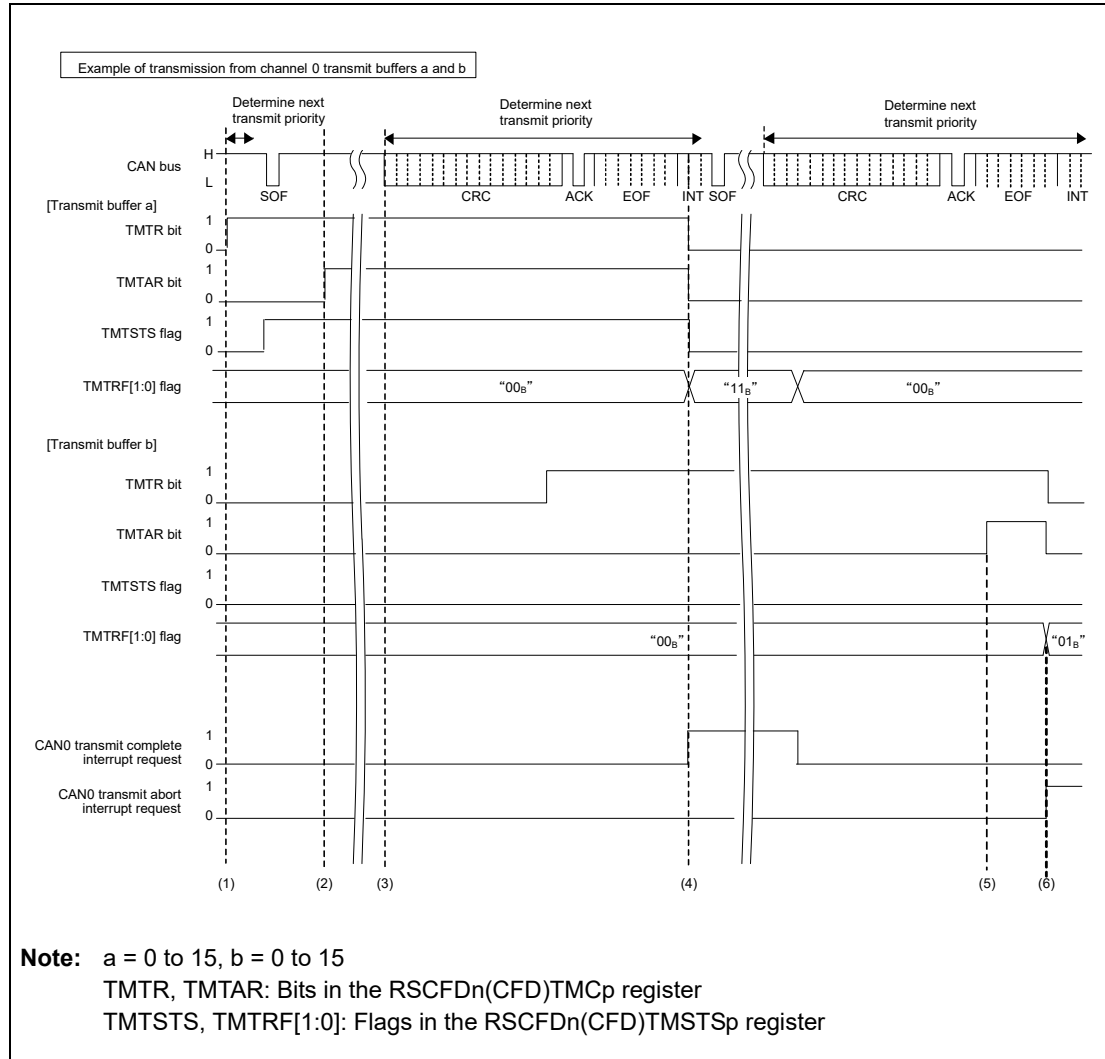

Figure 16.29 Transmit Buffer Transmission Timing Chart (Transmit Abort Completed)

- (1) When the TMTR bit in the RSCFDn(CFD)TMCa register is set to 1 while the CAN bus is idle, the transmit priority determination processing starts to determine the highest-priority transmit buffer. If transmit buffer a is determined to be the highest-priority transmit buffer, the TMTSTS flag in the corresponding RSCFDn(CFD)TMSTSa register is set to 1 (transmission is in progress) and the CAN channel starts transmitting data.
- (2) When the transmit buffer is determined for the next transmission or is in progress of transmission, message transmission is not aborted unless an error or arbitration lost occurs even if the TMTAR bit is set to 1 (transmit abort is requested).
- (3) The priority determination starts with the CRC delimiter for the next transmission. In this timing chart, buffer b is not selected as the next transmit buffer. Some delay may occur in the determination time if any other channels are performing the transmit priority determination processing. However, it does not affect the transmission interval because the determination will be completed before bit 3 of intermission.
- (4) When transmit completes successfully, the TMTRF[1:0] flag in the RSCFDn(CFD)TMSTSa register is set to 11_B (transmission has been completed (with transmit abort request)) and the TMTSTS flag and the TMTR bit in the RSCFDn(CFD)TMCa register are cleared to 0. When the TMIEa bit in the RSCFDn(CFD)TMIEC0 register is 1 (transmit buffer interrupt is enabled), a CAN0 transmit complete interrupt request is generated. To clear the interrupt request, set the TMTRF[1:0] flag to 00_B (transmission is in progress or no transmit request is present).
- (5) When another CAN node is transmitting data on the CAN bus (TMTSTS flag = 0), the TMTR bit cannot be cleared to 0 if the TMTAR bit is set to 1 while the corresponding channel is determining transmit priority.
- (6) After the internal processing time has passed, the transmission is terminated and the TMTRF[1:0] flag is set to 01_B. When the transmit buffer is neither transmitting data nor selected as the next transmit buffer and when priority determination is not being made, an abort request is immediately accepted and the TMTRF[1:0] flag is set to 01_B. At this time, the TMTR and TMTAR bits are cleared to 0. When transmit abort is completed with the TAIE bit in the RSCFDn(CFD)CmCTR register set to 1 (transmit abort interrupt is enabled), an interrupt request is generated. To clear the interrupt request, set the TMTRF[1:0] flag to 00_B.

If an arbitration lost has occurred after the CAN channel started transmission, the TMTSTS bit is cleared to 0. The transmit priority determination is reexecuted at the beginning of the CRC delimiter to search for the highest-priority transmit buffer. If an error has occurred during transmission or after arbitration lost, the priority determination processing is reexecuted during transmission of an error frame.

When a 2-bit ECC error is detected during the priority determination processing, no data is transmitted (in classical CAN mode, only when the EEFE bit in the RSCANnGCFG register is 1).

16.11.3.2 Procedure for Transmission from Transmit/Receive FIFO Buffers

Figure 16.30 shows the procedure for transmission from transmit/receive FIFO buffers.

Figure 16.31 shows a timing chart where messages are transmitted from two transmit/receive FIFO buffers in the same channel and transmission has been successfully completed. Figure 16.32 shows a timing chart where messages are transmitted from two transmit/receive FIFO buffers in the same channel and transmit abort has been completed.

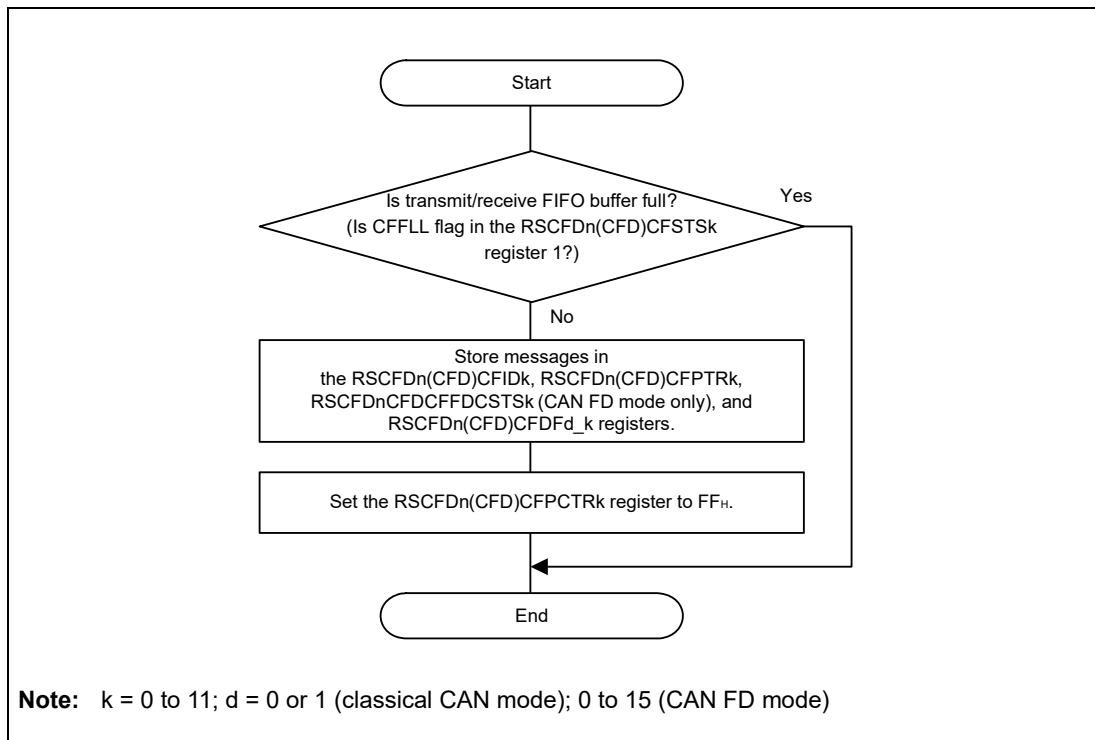

Figure 16.30 Procedure for Transmission from Transmit/Receive FIFO Buffers

When storing a message, do not write a value to the RSCFDnCFDCFDf_d_k register corresponding to the area exceeding the payload storage size specified by the CFPLS[2:0] bits in the RSCFDnCFDCFCCK register.

Table 16.183 Payload Storage Area of Transmit/Receive FIFO Buffer

Setting of CFPLS[2:0] Bits	Payload Storage Size	Corresponding Data Field Registers
000 _B	8 bytes	RSCFDnCFDCFDf0_k to RSCFDnCFDCFDf1_k
001 _B	12 bytes	RSCFDnCFDCFDf0_k to RSCFDnCFDCFDf2_k
010 _B	16 bytes	RSCFDnCFDCFDf0_k to RSCFDnCFDCFDf3_k
011 _B	20 bytes	RSCFDnCFDCFDf0_k to RSCFDnCFDCFDf4_k
100 _B	24 bytes	RSCFDnCFDCFDf0_k to RSCFDnCFDCFDf5_k
101 _B	32 bytes	RSCFDnCFDCFDf0_k to RSCFDnCFDCFDf7_k
110 _B	48 bytes	RSCFDnCFDCFDf0_k to RSCFDnCFDCFDf11_k
111 _B	64 bytes	RSCFDnCFDCFDf0_k to RSCFDnCFDCFDf15_k

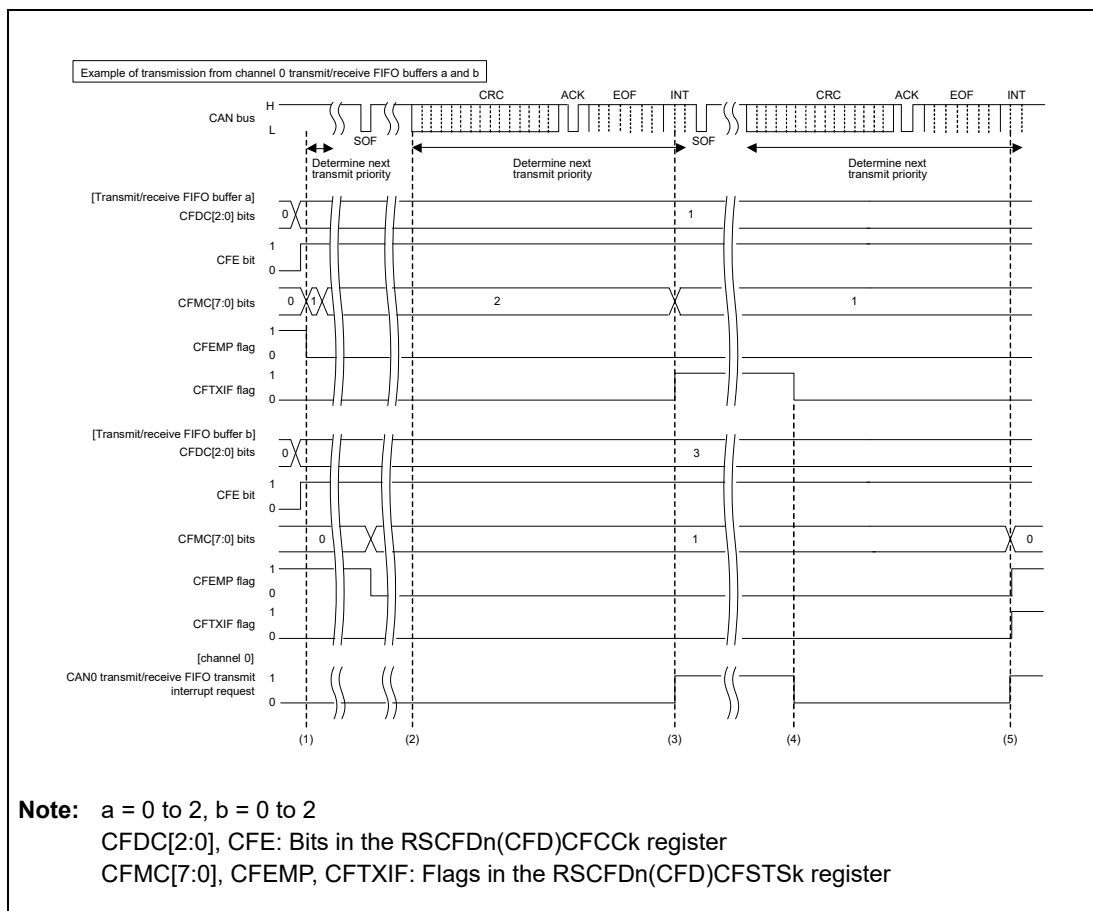

Figure 16.31 Transmit/Receive FIFO Buffer Transmission Timing Chart (Transmission Completed Successfully)

- (1) While the CAN bus is idle, the priority determination processing starts to determine the highest-priority transmit message when the CFE bit in the RSCFDn(CFD)CFCCa register is 1 (transmit/receive FIFO buffers are used), the CFDC[2:0] value in the RSCFDn(CFD)CFCCa register is 001_B (4 messages) or more, and the CFMC[7:0] value in the RSCFDn(CFD)CFSTSa register is 01_H or more. When the highest-priority transmit message has been determined, transmission of the message starts. In this figure, the message is transmitted from transmit/receive FIFO buffer a of channel 0.
- (2) When a transmit request from a buffer is present, the priority determination starts at the first bit of the CRC field for the next transmission. Some delay may occur in the determination time if any other channels are performing the transmit priority determination processing. However, it does not affect the transmission interval because the determination will be completed before bit 3 of intermission.
- (3) When transmit completes successfully, the CFMC[7:0] value in the RSCFDn(CFD)CFSTSa register is decremented by 1. Setting the CFIM bit in the RSCFDn(CFD)CFCCa register to 1 (a FIFO transmit interrupt request is generated each time a message has been transmitted) sets the CCTXIF flag in the RSCFDn(CFD)CFSTS_k register to 1 (a transmit/receive FIFO transmit interrupt request is present).
- (4) The CCTXIF flag can be cleared by the program.

- (5) Message transmission from transmit/receive FIFO buffer b of channel 0 has been completed and the CFMC[7:0] value in the RSCFDn(CFD)CFSTSB register is decremented by 1. The CFMC[7:0] bits are cleared to 00_H and therefore the CFEMP flag in the RSCFDn(CFD)CFSTSk register is set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)).

Transmission is continued until the CFEMP flag is set to 1. It is possible to continuously store transmit messages in FIFO buffers until the CFFLL flag in the RSCFDn(CFD)CFSTSa register and RSCFDn(CFD)CFSTSB register are set to 1 (the transmit/receive FIFO buffer is full).

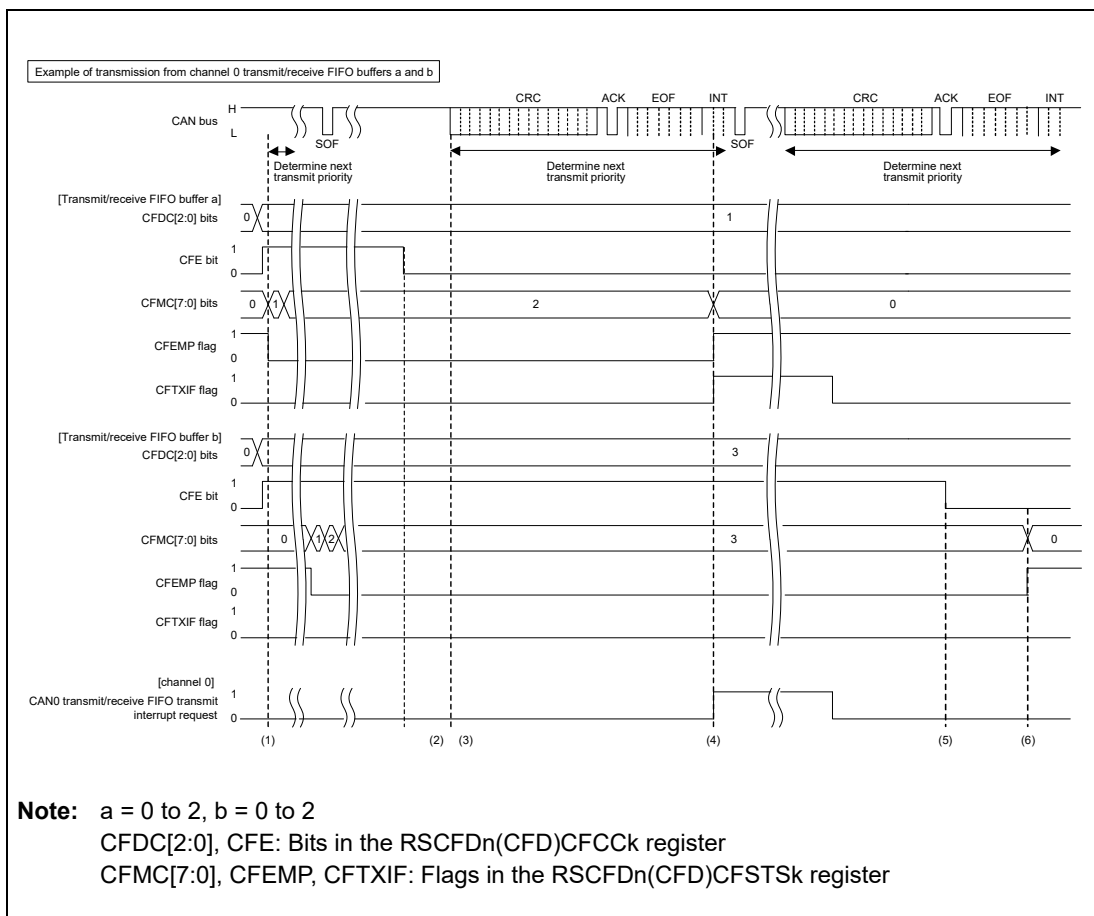

Figure 16.32 Transmit/Receive FIFO Buffer Transmission Timing Chart (Transmit Abort Completed)

- (1) While the CAN bus is idle, the priority determination processing starts to determine the highest-priority transmit message when the CFE bit in the RSCFDn(CFD)CFCCa register (a = 0 to 11) is 1 (transmit/receive FIFO buffers are used), the CFDC[2:0] value in the RSCFDn(CFD)CFCCa register is 001_B (4 messages) or more, and the CFMC[7:0] value in the RSCFDn(CFD)CFSTSa register is 01_H or more. When the highest-priority transmit message has been determined, transmission of the message starts. In this figure, the message is transmitted from transmit/receive FIFO buffer a of channel 0.
- (2) When transmission is in progress or the transmit/receive FIFO buffer is determined for the next transmission, message transmission is not aborted unless an error or arbitration lost occurs even if the CFE bit is set to 0 (no transmit/receive FIFO buffer is used).
- (3) When a transmit request from a buffer is present, the priority determination starts at the first bit of the CRC field for the next transmission. In this figure, transmit/receive FIFO buffer b is not selected as a buffer for the next transmission. Some delay may occur in the determination time if any other channels are performing the transmit priority determination processing. However, it does not affect the transmission interval because the determination will be completed before bit 3 of intermission.

- (4) When transmit completes successfully, the CFMC[7:0] value is cleared to 00_H. Setting the CFIM bit to 1 (a FIFO transmit interrupt request is generated each time a message has been transmitted) sets the CFTXIF flag in the RSCFDn(CFD)CFSTSa register to 1 (a transmit/receive FIFO transmit interrupt request is present). The CFTXIF flag can be cleared by the program.
- (5) If another CAN node on the CAN bus is transmitting data (not from transmit/receive FIFO buffer b), transmit/receive FIFO buffers cannot be disabled immediately even if the CFE bit in the RSCFDn(CFD)CFCCb register is cleared to 0 (no transmit/receive FIFO buffer is used) during transmit priority determination. (The CFEMP flag in the RSCFDn(CFD)CFSTsb register is not set to 1 (the transmit/receive FIFO buffer contains no message (buffer empty)) immediately.)
- (6) After the internal processing time has passed, transmit/receive FIFO buffers are disabled and the CFMC[7:0] bits in the RSCFDn(CFD)CFSTsb register are cleared to 00_H and the CFEMP flag is set to 1. When the transmit/receive FIFO buffer is neither transmitting data nor selected as the next transmit buffer and when priority determination is not in progress, the transmit/receive FIFO buffer is immediately disabled. (The CFMC[7:0] bits are cleared to 00_H and the CFEMP flag is set to 1.)

16.11.3.3 Procedure for Transmission from the Transmit Queue

Figure 16.33 shows the procedure for transmission from the transmit queue.

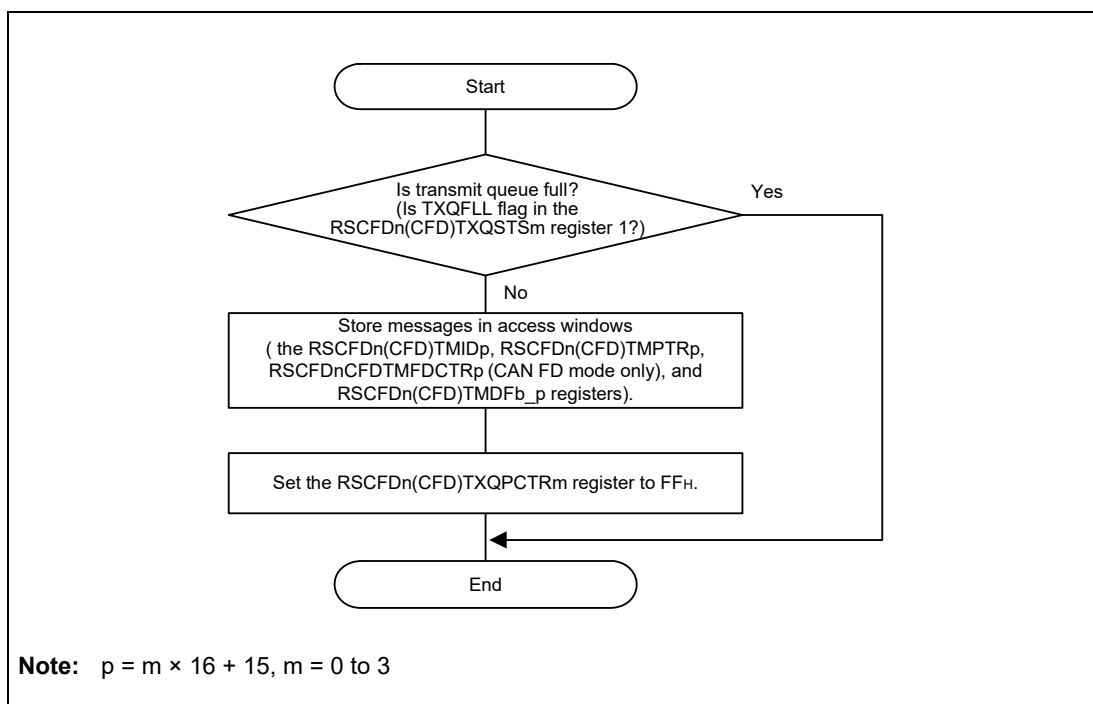

Figure 16.33 Procedure for Transmission from the Transmit Queue

16.11.3.4 Transmit History Buffer Reading Procedure

Transmit history data can be read from the RSCFDn(CFD)THLACCm register. The next data can be accessed by writing FF_H to the corresponding RSCFDn(CFD)THLPCTRm register (m = 0 to 3) after reading a set of data. **Figure 16.34** shows the transmit history buffer reading procedure.

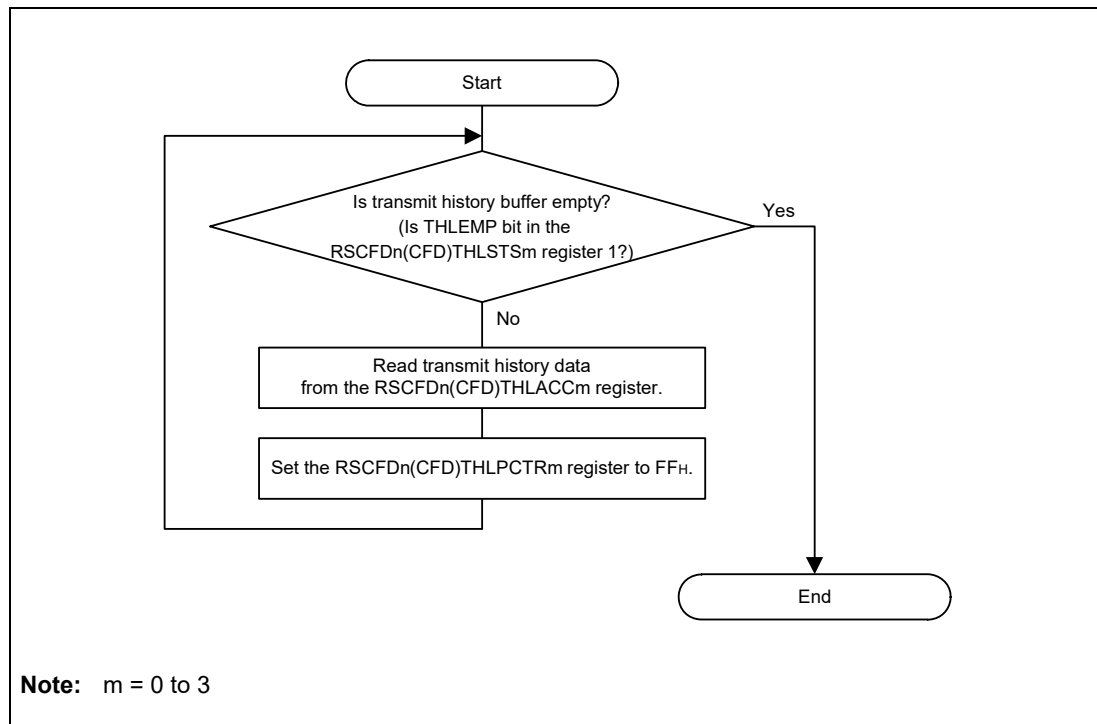

Figure 16.34 Transmit History Buffer Reading Procedure

16.11.4 Test Settings

16.11.4.1 Self-Test Mode Setting Procedure

Self-test mode allows communication test on a channel basis by receiving messages transmitted from the own node.

Figure 16.35 shows the self-test mode setting procedure.

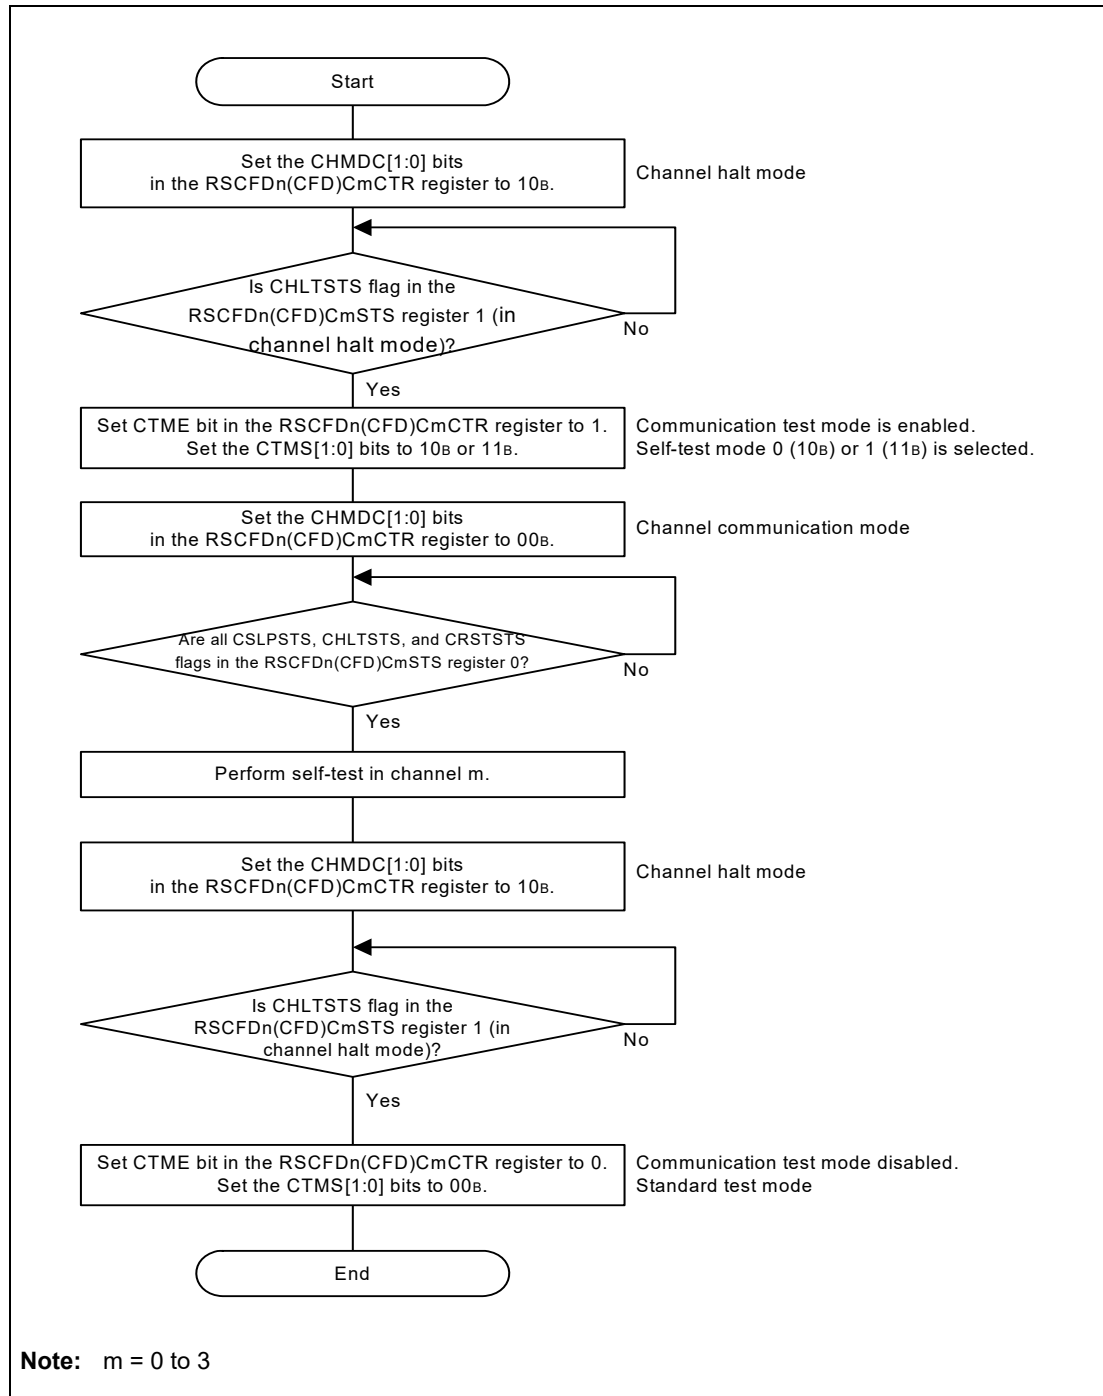

Figure 16.35 Self-Test Mode Setting Procedure

16.11.4.2 Procedure for Releasing the Protection

Since the global test function in **Table 16.184** is protected, write the protection release data 1 and release data 2 in succession to the LOCK[15:0] bits in the RSCFDn(CFD)GLOCKK register, then set the target test bit to 1.

Table 16.184 Protection Release Data for Test Function

Test Function	Protection Release Data 1	Protection Release Data 2	Target Bit
RAM test	7575 _H	8A8A _H	RTME bit in the RSCFDn(CFD)GTSTCTR register

If an incorrect value is written to the LOCK[15:0] bits, restart from writing the protection release data 1. **Figure 16.36** shows the procedure for releasing the protection.

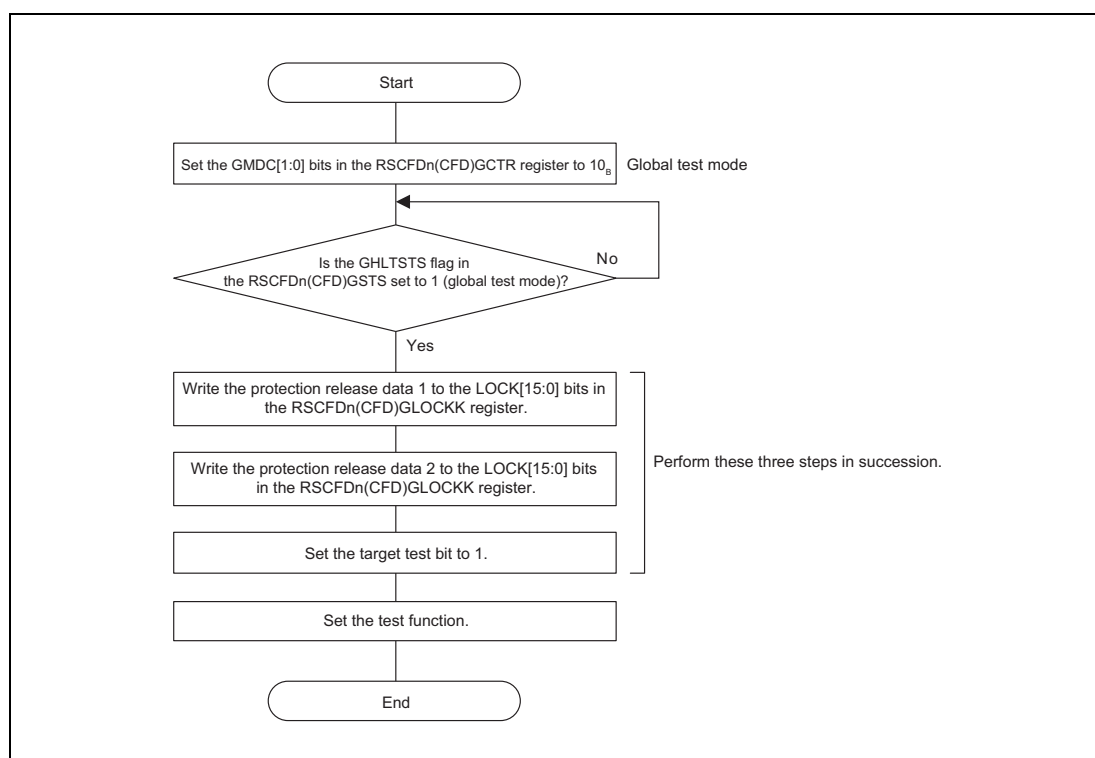

Figure 16.36 Protection Release Procedure

16.11.4.3 RAM Test Setting Procedure

RAM tests include CAN RAM read/write test. The read/write test verifies that data written to the RAM is read correctly. Before closing the RAM test, write 0000 0000_H to all pages of the CAN RAM.

Figure 16.37 shows the RAM test setting procedure.

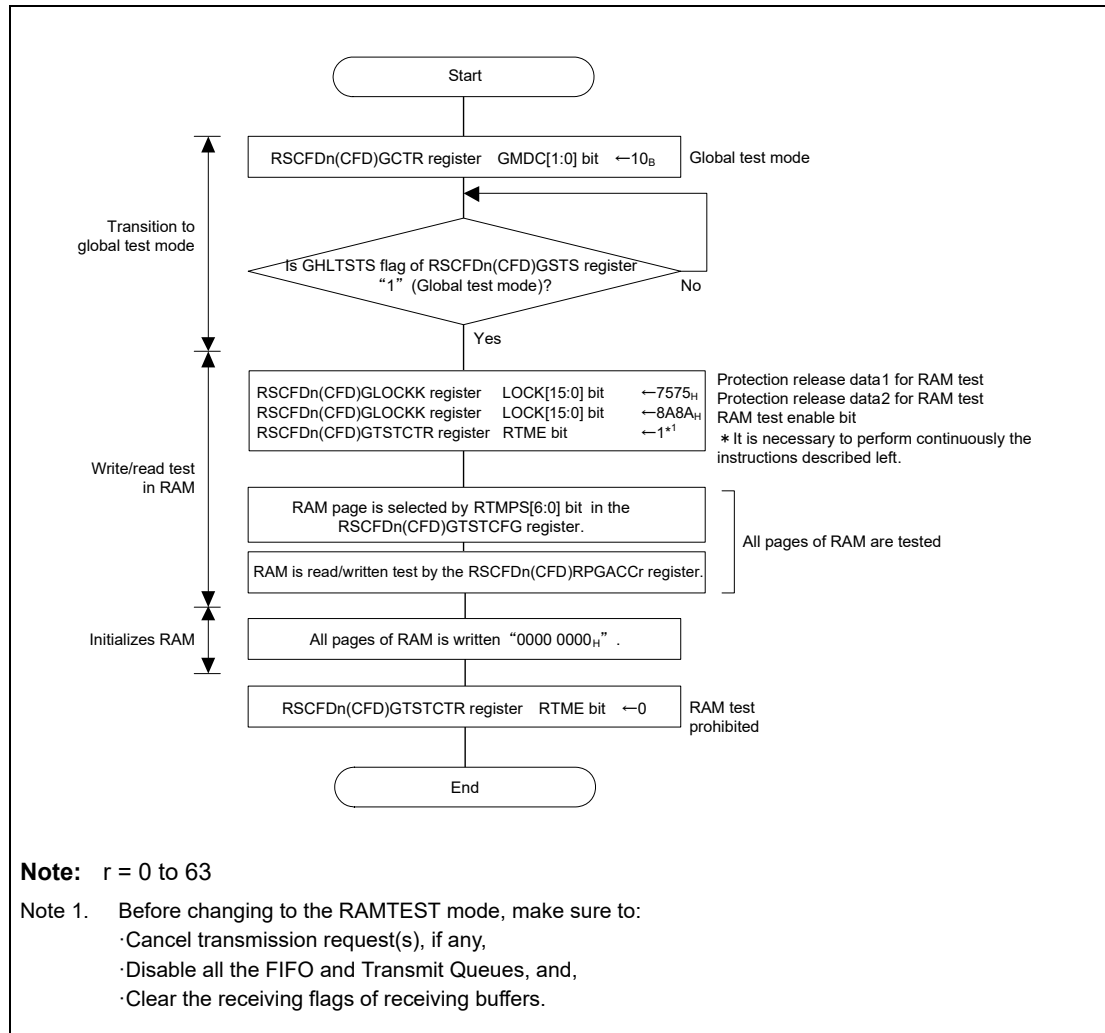

Figure 16.37 RAM Test Setting Procedure

16.11.4.4 Inter-Channel Communication Test Setting Procedure

Communication test can be performed by transmitting and receiving data between different channels.

Figure 16.38 shows the inter-channel communication test setting procedure.

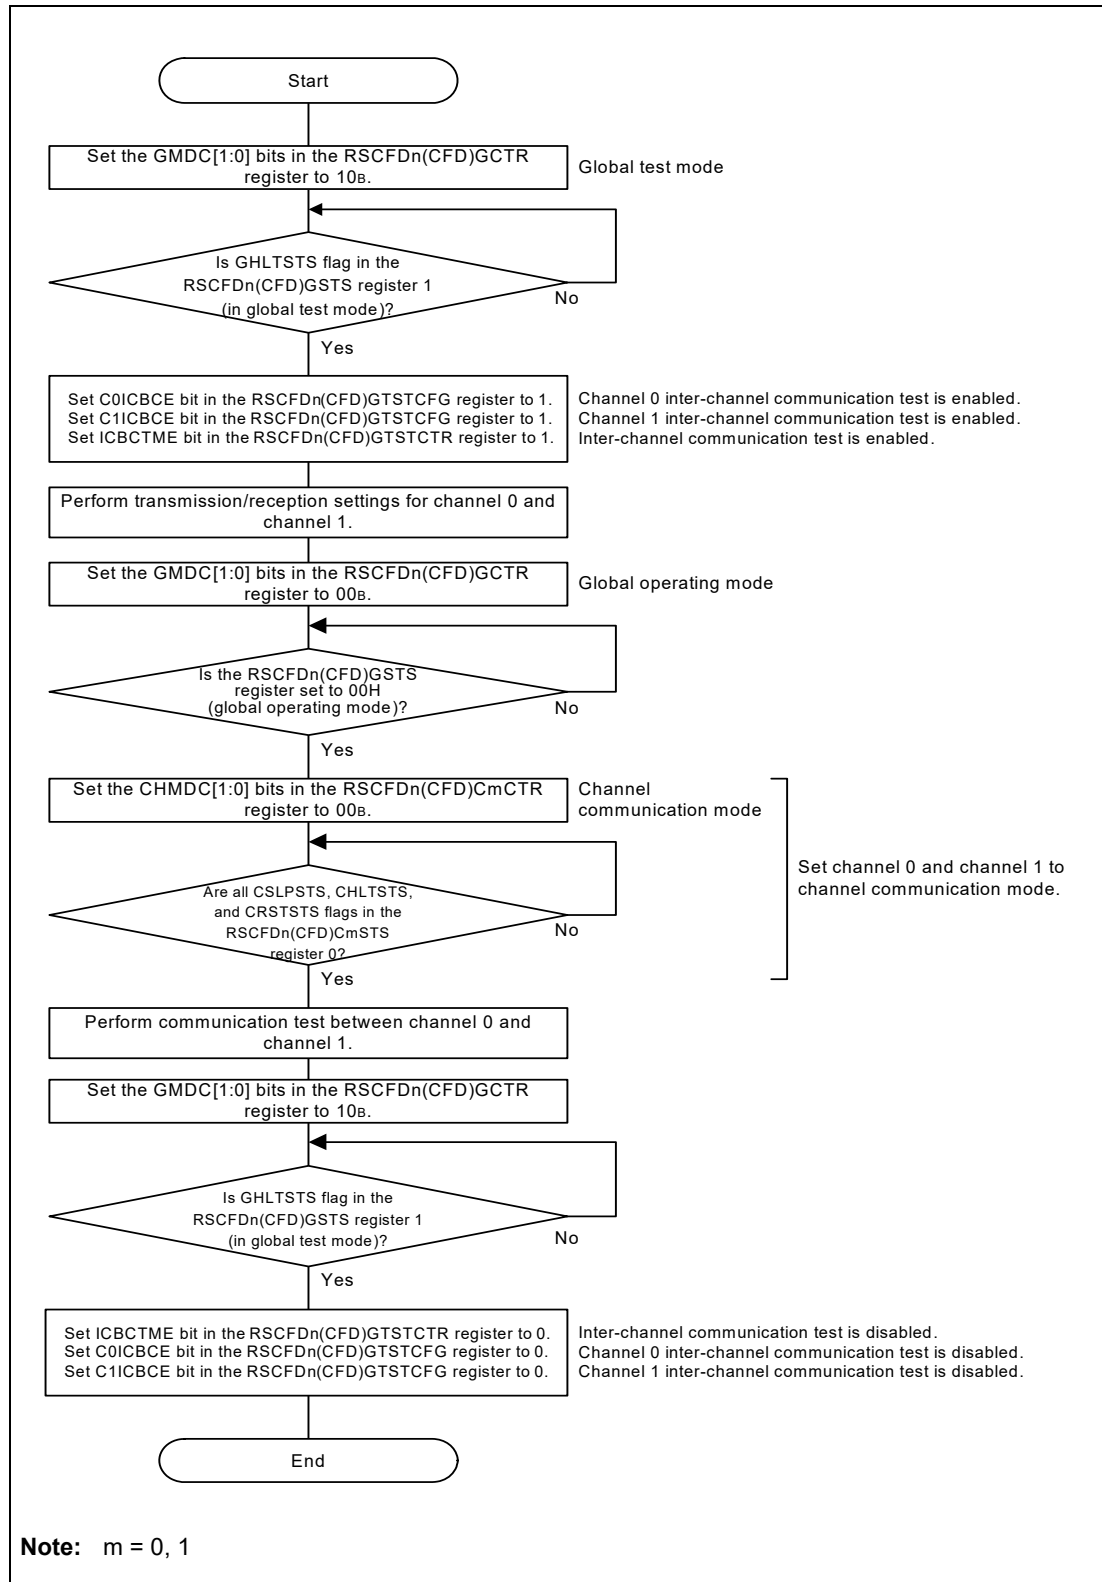

Figure 16.38 Inter-Channel Communication Test Setting Procedure

16.12 Notes on the RS-CANFD Module

- When changing interface mode without resetting the RS-CANFD, write the value after reset to all registers and bits that are not allocated to the register map after change and then modify the RSCFDn(CFD)GRMCFG register.
- When changing a global mode, check the GSLPSTS, GHLTSTS, and GRSTSTS flags in the RSCFDn(CFD)GSTS register for transitions. When changing a channel mode, check the CSLPSTS, CHLTSTS, and CRSTSTS flags in the RSCFDn(CFD)CmSTS register (m = 0 to 3) for transitions.
- When changing global mode, check the GSLPSTS, GHLTSTS, and GRSTSTS flags in the RSCFDn(CFD)GSTS register for transitions. When changing channel mode, check the CSLPSTS, CHLTSTS, and CRSTSTS flags in the RSCFDn(CFD)CmSTS register (m = 0 to 3) for transitions.
- The acceptance filter processing checks receive rules sequentially in ascending order from the lowest rule number. If the same ID, IDE bit, or RTR bit value is set in multiple receive rules, the lowest-numbered receive rule is used to pass the received message through the acceptance filter processing. If the message does not pass through the subsequent DLC filter processing, the data processing is terminated without returning to the acceptance filter processing and the message is not stored in the buffer.
- When linking transmit buffers to transmit/receive FIFO buffers or allocating transmit buffers to transmit queues, set the control register (RSCFDn(CFD)TMCp register) of the corresponding transmit buffer to 00_H. The status register (RSCFDn(CFD)TMSTSp register) of the corresponding transmit buffer should not be used. Flags in other status registers (RSCFDn(CFD)TMTRSTS0 to RSCFDn(CFD)TMTRSTS1, RSCFDn(CFD)TMTARSTS0 to RSCFDn(CFD)TMTARSTS1, RSCFDn(CFD)TMTCASTS0 to RSCFDn(CFD)TMTCASTS1, and RSCFDn(CFD)TMTASTS0 to RSCFDn(CFD)TMTASTS1 registers), which correspond to transmit buffers linked to transmit/receive FIFO buffers or allocated to transmit queues, remain unchanged. Set the enable bit in the corresponding interrupt enable register (RSCFDn(CFD)TMIEC0, RSCFDn(CFD)TMIEC1 register) to 0 (transmit buffer interrupt is disabled).
- When using transmit buffer merge mode (in CAN FD mode), write 00_H to the control register (RSCFDn(CFD)TMCp) of the transmit buffer corresponding to the transmit buffer allocated as a payload storage area. Set the enable bit of corresponding interrupt enable registers (RSCFDn(CFD)TMIEC0 to RSCFDn(CFD)TMIEC1) to 0 (to disable interrupts).
- Do not allocate transmit buffers that are linked to transmit/receive FIFO buffers to transmit queues. Transmit buffers that are linked to transmit/receive FIFO buffers must not be allocated to transmit queues. Do not allocate a transmit buffer allocated as a payload storage area in transmit buffer merge mode (in CAN FD mode) to the transmit queue either.
- Only a single transmit/receive FIFO buffer can be linked to a transmit buffer. Do not link two or more transmit/receive FIFO buffers to the same transmit buffer.
- When the CANm bit time clock is selected as a timestamp counter clock source in classical CAN mode, the timestamp counter stops when the corresponding channel has transitioned to channel reset mode or channel halt mode.
- If an attempt is made to store a new message when the receive FIFO buffer and the transmit/receive FIFO buffer are full, the new message is discarded. Before attempting to store a new message in the transmit/receive FIFO buffer or the transmit queue, check that the transmit/receive FIFO buffer or the transmit queue is not full.

- In the case of registers that access the RAM, the value after reset shown in **Section 16.3, Registers (Classical CAN Mode)** and **Section 16.4, Registers (CAN FD Mode)** indicate the values cleared by initialization of the CAN RAM. Values before clearing are undefined. The following registers apply.
 - Receive rule (RSCFDn(CFD)GAFLIDj, RSCFDn(CFD)GAFLMj, RSCFDn(CFD)GAFLP0_j, RSCFDn(CFD)GAFLP1_j registers)
 - Receive buffers (RSCFDn(CFD)RMIDq, RSCFDn(CFD)RMPTRq, RSCFDn(CFD)CFDRMFDSTSq, RSCFDn(CFD)RMDFb_q registers)
 - Receive FIFO buffer access registers (RSCFDn(CFD)RFIDx, RSCFDn(CFD)RFPTRx, RSCFDn(CFD)CFDRFFDSTSx, and RSCFDn(CFD)RFDFd_x registers)
 - Transmit/receive FIFO buffer access registers (RSCFDn(CFD)CFIDk, RSCFDn(CFD)CFPTRk, RSCFDn(CFD)CFDCFFDCSTSk, and RSCFDn(CFD)CFDFd_k registers)
 - Transmit buffers (RSCFDn(CFD)TMIDp, RSCFDn(CFD)TMPTRp, RSCFDn(CFD)CFDTMFDCTRp, and RSCFDn(CFD)TMDFb_p registers)
 - Transmit history access register (RSCFDn(CFD)THLACCm registers)
 - RAM test page access register (RSCFDn(CFD)RPGACCr registers)
- The values of unused receive buffers (the RSCFDn(CFD)RMIDq, RSCFDn(CFD)RMPTRq, RSCFDn(CFD)CFDRMFDSTSq, and RSCFDn(CFD)RMDFb_q registers), receive FIFO buffer access registers (the RSCFDn(CFD)RFIDx, RSCFDn(CFD)RFPTRx, RSCFDn(CFD)CFDRFFDSTSx, and RSCFDn(CFD)RFDFd_x registers) and transmit/receive FIFO buffer access registers (RSCFDn(CFD)CFIDk, RSCFDn(CFD)CFPTRk, RSCFDn(CFD)CFDCFFDCSTSk, and RSCFDn(CFD)CFDFd_k registers) become undefined once they exit global reset mode to enter global operation mode or global test mode.

Section 17 FlexRay

17.1 FlexRay Module

The FlexRay IP-module performs communication according to the FlexRay protocol specification v2.1. With maximum specified sample clock the bitrate is 10 MBit/s. Additional bus driver (BD) hardware is required for connection to the physical layer.

17.1.1 Overview

For communication on a FlexRay network, individual message buffers with up to 254 data bytes are configurable. The message storage consists of a single-ported Message RAM that holds up to 128 message buffers. All functions concerning the handling of messages are implemented in the message handler. Those functions are the acceptance filtering, the transfer of messages between the two FlexRay channel protocol controllers and the message RAM, maintaining the transmission schedule as well as providing message status information.

The register set of the FlexRay IP-module can be accessed directly by an external host via the module's host interface. These registers are used to control/configure/monitor the FlexRay channel protocol controllers, message handler, global time unit, system universal control, frame and symbol processing, network management, interrupt control, to access the message RAM via input/output buffer; and to control the data transfer between the message RAM and the local RAM/global RAM.

The FlexRay IP-module supports the following features:

Item	Specification
Communication	Conformance with FlexRay protocol specification v2.1
Data transfer rate	Up to 10 Mbit/s on each channel
Data link layer clock frequency	80 MHz
Input/output pins per channel	TxD, RxD, ExEN
FlexRay channels	2 (channel A and B)
Message buffer	Up to 128 message buffers configurable Configuration of message buffers with different payload lengths possible Each message buffer can be configured as receive buffer, as transmit buffer or as part of the receive FIFO Filtering for slot counter, cycle counter, and channel
Message RAM	8 Kbytes of message RAM for storage of e.g. 128 message buffers with the data section of up to 48 bytes Up to 30 message buffers with the data section of 254 bytes
FIFO	One configurable receive FIFO
Message buffer access	By host CPU via input and output buffer Input buffer: Holds message to be transferred to the message RAM Output buffer: Holds message read from the message RAM By data transfer function Input transfer: Message buffer content is transferred from local RAM/global RAM to message RAM on CPU request Output transfer: Message buffer content is transferred from message RAM to local RAM/global RAM automatically
Network management	Supported
Interrupts	Maskable module interrupts
Timer	Two absolute timers One relative timer One stop watch timer

17.1.2 Terms and Abbreviations

The terms and abbreviations used in this section are given below.

Abbreviation	Meaning
AP	Action Point
BD	Bus Driver
BSS	Byte Start Sequence
CAS	Collision Avoidance Symbol
CC	Communication Controller
CHI	Controller Host Interface
CIF	Host CPU Interface Block
CRC	Cyclic Redundancy Check
FES	Frame End Sequence
FSS	Frame Start Sequence
FIFO	FIFO (First In First Out) data buffer structure
FSM	Finite State Machine
FSP	Frame and Symbol Processing Block
FTM	Clock synchronization algorithm (Fault Tolerant Midpoint)
GIF	Generic CPU interface (Generic Interface Block)
GTU	Global Time Unit Block
IBF	Input Buffer
INT	Interrupt Control Block
MBF	Message (Buffer) RAM
MHD	Message Handler Block
MT	Microtick
MTS	Media Access Test Symbol
NCT	Network Communication Time
NEM	Network Management Block
NIT	Network Idle Time
NM	Network Management
OBF	Output Buffer
PE	Protocol Engine
POC	Protocol Operation Control
PRT	Protocol Controller Block
SDL	Specification and Description Language
SUC	System Universal Control Block
TBF	Transient Buffer
TDMA	Time Division Multiple Access (media access method)
TRH	Transfer Handler
TSS	Transmission Start Sequence
TT-D	Time Triggered Distributed synchronization (protocol mode)
URAM	RAM used to store FlexRay messages, message buffers, settings and states (User RAM)
μ T	Microtick
WUP	Wakeup Pattern
WUS	Wakeup Symbol

17.1.3 Block Diagram

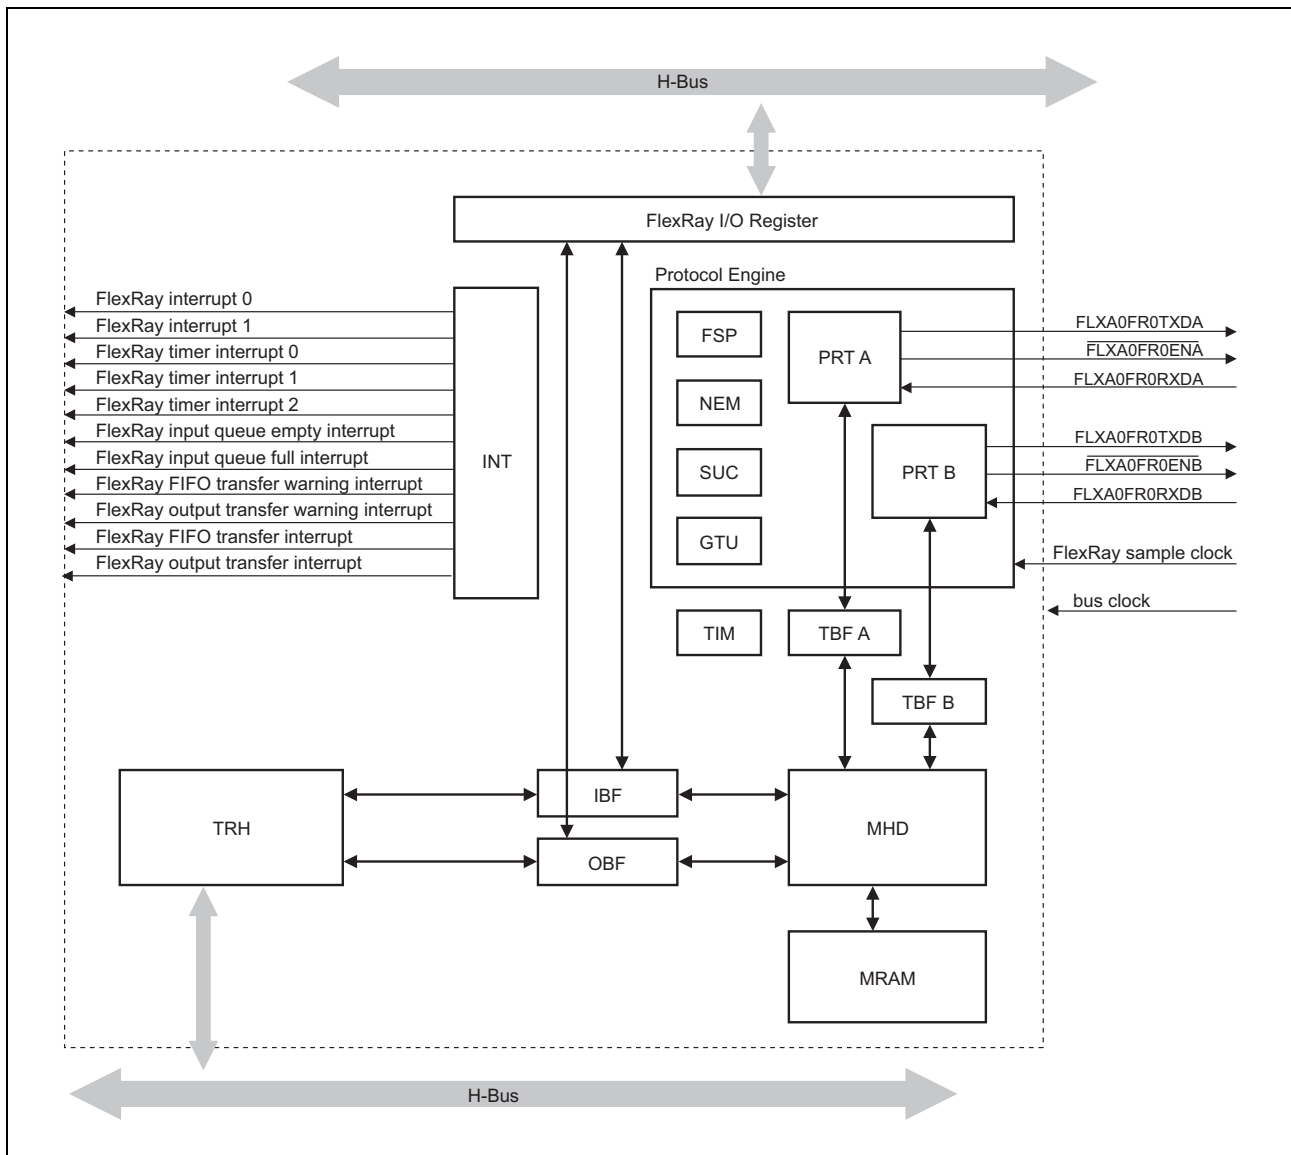

Figure 17.1 FlexRay IP Block Diagram

Input Buffer (IBF)

For write access to the message buffers configured in the message RAM, the host can write the header and data section for a specific message buffer to the input buffer. The message handler then transfers the data from the input buffer to the selected message buffer in the message RAM.

Output Buffer (OBF)

For read access to a message buffer configured in the message RAM the message handler transfers the selected message buffer to the output buffer. After the transfer has completed, the host can read the header and data section of the transferred message buffer from the output buffer.

Message Handler (MHD)

The FlexRay message handler controls data transfers between the following components:

- Input/output buffer and message RAM
- Temporary buffer RAMs of the two FlexRay protocol controllers and message RAM

Message RAM (MRAM)

The message RAM consists of a single-ported RAM that store up to 128 FlexRay message buffers together with the related configuration data (header and data partition).

Temporary Buffer RAM (TBF A/B)

Stores the data section of two complete messages.

FlexRay Channel Protocol Controller (PRT A/B)

The FlexRay channel protocol controllers consist of shift register and FlexRay protocol FSM. They are connected to the temporary buffer RAMs for intermediate message storage and to the physical layer via bus driver BD.

They perform the following functionality:

- Control and check of bit timing
- Reception/transmission of FlexRay frames and symbols
- Check of header CRC
- Generation/checking of frame CRC
- Interfacing to bus driver

Global Time Unit (GTU)

The global time unit performs the following functions:

- Generation of microtick
- Generation of macrotick
- Fault tolerant clock synchronization by FTM algorithm
 - Rate correction
 - Offset correction
- Cycle counter
- Timing control of static segment
- Timing control of dynamic segment (minislotting)
- Support of external clock correction

System Universal Controller (SUC)

The system universal controller controls the following functions:

- Configuration
- Wakeup
- Startup
- Normal Operation
- Passive Operation

Frame and Symbol Processing (FSP)

The frame and symbol processing controls the following functions:

- Checks the correct timing of frames and symbols
- Tests the syntactical and semantical correctness of received frames
- Sets the slot status flags

Network Management (NEM)

Handles the network management vector.

Interrupt Control (INT)

The interrupt controller performs the following functions:

- Provides error and status interrupt flags
- Enable/disable interrupt sources
- Assignment of interrupt sources to one of the two general module interrupt lines
- Enable/disable module interrupt lines

Timer (TIM)

The timer module includes the following macrotick timer:

- Two absolute timer
- One relative timer
- One stop watch timer

Transfer Handler (TRH)

Handles the data transfer between local RAM/global RAM and FlexRay module.

The Transfer Handler supports the following transfer types:

- Transfer of buffer configuration data from the local RAM/global RAM to the message RAM
- Transfer of payload data for transmit buffer from the local RAM/global RAM to the message RAM
- Transfer of buffer configuration data and payload data for transmit buffer from the local RAM/global RAM to the message RAM
- Automatic transfer of payload data from receive buffer to the local RAM/global RAM upon frame reception
- Automatic transfer of payload data, buffer configuration data and message buffer status data from receive buffer to the local RAM/global RAM upon frame reception
- Automatic transfer of buffer configuration data and message buffer status data from the dedicated transmit/receive buffer to the local RAM/global RAM in response to slot status update
- Manual transfer of payload data, buffer configuration data and message buffer status data from the dedicated transmit/receive buffer to the local RAM/global RAM

17.2 Programmer's Model

17.2.1 Register Map

The FlexRay module allocates an address space as shown in **Table 17.2**.

Within this specification the “values after reset” refers to the microcontroller’s HW reset. For registers in the address range 0010_H to 0FFF_H the “value after reset” is also applicable when the SW reset (using FLXA0FROC.OE) is applied.

The addresses in this specification are listed as offsets from a base address. The base address ERAY must thus be added to the addresses listed in **Table 17.1**. In addition, PE1 accesses the FlexRay registers in a range defined by a different base address (top address in **Table 17.1**) to that for access by the PCU (bottom address in **Table 17.1**). For access from the PCU, “FLXA0” in the register symbol should be replaced by “FLXA0PCU” and the base address becomes that given against “FlexRay (from PCU)” in **Table 17.1**. However, the registers have the same functions.

Table 17.1 Base Address <ERAY>

Base Address	ERAY (User)
FlexRay	1002 0000 _H
FlexRay (from PCU)	FC02 0000 _H

Table 17.2 FlexRay Register Map (1/3)

Register Name	Symbol	Value after Reset	Address	Access Size
FlexRay operation control register	FLXA0FROC	0000 0000 _H	<ERAY> + 0004 _H	8, 16, 32
FlexRay operation status register	FLXA0FROS	0000 0000 _H	<ERAY> + 000C _H	8, 16, 32
FlexRay lock register	FLXA0FRLCK	0000 0000 _H	<ERAY> + 001C _H	8, 16, 32

7	OEP	Operation Enable Bit Protection 0: OE bit is unprotected 1: OE bit is protected
6 to 2	—	Reserved These bits are always read as 0. When writing, always write 0.
1	BEC	Byte Endian Control 0: Little endian 1: Big endian
0	OE	Operation Enable 0: Operation stopped SW reset 1: Operation Enabled

(1) FLXA0FROC.T2IE

Timer 2 Interrupt enable

This bit controls the timer 2 interrupt.

0: Disabled

No interrupt will be requested and the timer 2 interrupt line will be released if pending.

1: Enabled

Timer 2 interrupt will be asserted when FLXA0FROTS.T2IS is '1'.

(2) FLXA0FROC.T1IE

Timer 1 Interrupt enable

The user should only set this bit to '1' when timer 1 interrupt is not enabled in the FlexRay Status interrupt enable register (FLXA0FRSIES.TI1E should be '0').

This bit controls the timer 1 interrupt.

0: Disabled

No interrupt will be requested and the timer 1 interrupt line will be released if pending.

1: Enabled

Timer 1 interrupt will be asserted when FLXA0FROTS.TI1S is '1'.

(3) FLXA0FROC.T0IE

Timer 0 Interrupt enable

The user should only set this bit to '1' when timer 0 interrupt is not enabled in the FlexRay Status interrupt enable register (FLXA0FRSIES.TI0E should be '0').

This bit controls the timer 0 interrupt.

0: Disabled

No interrupt will be requested and the timer 0 interrupt line will be released if pending.

1: Enabled

Timer 0 interrupt will be asserted when FLXA0FROTS.T0IS is '1'.

(4) FLXA0FROC.OEP

Operation Enable Bit Protection

This bit protects against unintended write access to the OE bit.

0: OE bit is unprotected

Write access to the OE bit is enabled

1: OE bit is protected

Write access to the OE bit is disabled

(5) FLXA0FROC.BEC

Byte Endian Control

The user should only change this bit when FLXA0FROS.OS is '1'.

This bit controls the byte order on reading and writing the FlexRay network management vector register (FLXA0FRNMVn), FlexRay write data section (FLXA0FRWRDSn) and FlexRay read data section (FLXA0FRRDDSn). This bit also controls the byte order when reading or writing FlexRay payload data using the data transfer function.

For details about the byte alignment please refer to **Section 17.3.17, Byte Alignment**.

0: Little endian

Byte alignment in FLXA0FRNMVn, FLXA0FRWRDSn and FLXA0FRRDDSn is in little endian style.

1: Big endian

Byte alignment in FLXA0FRNMVn, FLXA0FRWRDSn and FLXA0FRRDDSn is in big endian style.

(6) FLXA0FROC.OE

Operation Enable

The user can only write to this bit when FLXA0FROC.OEP is '0'.

The user should only write this bit with '0' when FLXA0FROS.OS is '1'.

The user should only write this bit with '1' when FLXA0FROS.OS is '0' and the FlexRay sample clock is enabled.

This bit controls the operation state and serves the software reset of the FlexRay module. The operation status bit (FLXA0FROS.OS) indicates whether the FlexRay module is in reset state or not.

0: Operation stopped SW reset

Forcibly moves the FlexRay module to its reset state, whatever the state of the FlexRay module is.

1: Operation Enabled

Reset state of the FlexRay module is released.

17.2.2.2 FLXA0FROS — FlexRay Operation Status Register

Do not rewrite this register using bit-manipulation instruction.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 000C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	T2IS	T1IS	T0IS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 17.4 FLXA0FROS Register Contents

Bit Position	Bit Name	Function
31 to 19	—	Reserved These bits are always read as 0. When writing, always write 0.
18	T2IS	Timer 2 Interrupt Status 0: Timer 2 has not matched the conditions configured in the FLXA0FRT2C register 1: Timer 2 matched the conditions configured in the FLXA0FRT2C register
17	T1IS	Timer 1 Interrupt Status 0: Timer 1 has not matched the conditions configured in the FLXA0FRT1C register 1: Timer 1 matched the conditions configured in the FLXA0FRT1C register
16	T0IS	Timer 0 Interrupt Status 0: Timer 0 has not matched the conditions configured in the FLXA0FRTOC register 1: Timer 0 matched the conditions configured in the FLXA0FRTOC register
15 to 1	—	Reserved These bits are always read as 0. When writing, always write 0.
0	OS	Operation Status 0: Operation disabled, reset state 1: Operation enabled

(1) FLXA0FROS.T2IS

Timer 2 Interrupt Status

Writing '0' has no effect on the bit value.

This bit represents that Timer 2 has matched the state configured in FLXA0FRT2C register.

If enabled in FLXA0FROC.T2IE the timer 2 interrupt is generated when FLXA0FROS.T2IS is '1'.

[Clearing condition]

This bit is cleared by writing '1' to FLXA0FROS.T2IS.

This bit is cleared when FLXA0FROS.OS changes from '1' to '0'.

[Setting condition]

This bit is set when Timer 2 matches the state configured in FLXA0FRT2C register.

(2) FLXA0FROS.T1IS

Timer 1 Interrupt Status

Writing '0' has no effect on the bit value.

This bit represents that Timer 1 has matched the state configured in FLXA0FRT1C register.

If enabled in FLXA0FROC.T1IE the timer 1 interrupt is generated when FLXA0FROS.T1IS is '1'.

[Clearing condition]

This bit is cleared by writing '1' to FLXA0FROS.T1IS.

This bit is cleared when FLXA0FROS.OS changes from '1' to '0'.

[Setting condition]

This bit is set when Timer 1 matches the state configured in FLXA0FRT1C register.

(3) FLXA0FROS.T0IS

Timer 0 Interrupt Status

Writing '0' has no effect on the bit value.

This bit represents that Timer 0 has matched the state configured in FLXA0FRT0C register.

If enabled in FLXA0FROC.T0IE the timer 1 interrupt is generated when FLXA0FROS.T0IS is '1'.

[Clearing condition]

This bit is cleared by writing '1' to FLXA0FROS.T0IS.

This bit is cleared when FLXA0FROS.OS changes from '1' to '0'.

[Setting condition]

This bit is set when Timer 0 matches the state configured in FLXA0FRT0C register.

(4) FLXA0FROS.OS

Operation Status

This bit represents if the FlexRay module is in the reset or the operation state.

When FLXA0FROS.OS is '0' the FlexRay module gets initialized and registers mapped to the address area $ERAY + 0010_H$ to $ERAY + 0FFF_H$ cannot be accessed; read access from these registers will return undefined data.

When FLXA0FROS.OS is '1' it is possible to access to the address area $ERAY + 0010_H$ to $ERAY + 0FFF_H$ and to perform FlexRay communication.

When FLXA0FROS.OS changes from '0' to '1' all registers in the address range $ERAY + 0010_H$ to $ERAY + 0FFF_H$ are set to the "Values after reset".

[Clearing condition]

When FLXA0FROC.OE is set to '0', It takes up to two peripheral bus clock cycles until FLXA0FROS.OS is set to '0'.

[Setting condition]

When FLXA0FROC.OE is set to '1' it takes up to four peripheral clock cycles of the clock with the lower frequency out of the FlexRay sample clock and peripheral bus clock until FLXA0FROS.OS is set to '1'.

17.2.3 Special Registers

17.2.3.1 FLXA0FRLCK — FlexRay Lock Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERA_Y + 001C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CLK[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 17.5 FLXA0FRLCK Register Contents

Bit	Symbol	Function
31 to 8	—	Reserved These bits are always read as 0. When writing, always write 0.
7 to 0	CLK[7:0]	Configuration Lock Key

(1) FLXA0FRLCK.CLK

Configuration Lock Key

The lock register is write-only. Reading the register will return 0000 0000_H.

To leave CONFIG state by writing FLXA0FRSUCC1.CMD (command READY), the write operation has to be directly preceded by two write accesses to the Configuration Lock Key (unlock sequence). If the write sequence below is interrupted by other write accesses between the second write to the configuration lock key and the write access to the FLXA0FRSUCC1 register, the CC remains in CONFIG state and the sequence has to be repeated.

First write: FLXA0FRLCK.CLK = “1100 1110” (CE_H)

Second write: FLXA0FRLCK.CLK = “0011 0001” (31_H)

Third write: FLXA0FRSUCC1.CMD

NOTE

In case that the host uses 8/16-bit accesses to write the listed bit fields, the programmer has to ensure that no “dummy accesses” e.g. to the remaining register bytes/words are inserted by the compiler.

17.2.4 Interrupt Registers

17.2.4.1 FLXA0FREIR — FlexRay Error Interrupt Register

Do not rewrite this register using bit-manipulation instruction.

The flags are set when the CC detects one of the listed error conditions. The flags remain set until the host clears them.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0020_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	TABB	LTVB	EDB	—	—	—	—	—	TABA	LTVA	EDA
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	MHF	IOBA	IIBA	EFA	RFO	AERR	CCL	CCF	SFO	SFBM	CNA	PEMC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 17.6 FLXA0FREIR Register Contents (1/2)

Bit Position	Bit Name	Function
31 to 27	—	Reserved These bits are always read as 0. When writing, always write 0.
26	TABB	Transmission Across Boundary Channel B Flag 0: No transmission across slot boundary detected on channel B 1: Transmission across slot boundary detected on channel B
25	LTVB	Latest Transmit Violation Channel B Flag 0: No latest transmit violation detected on channel B 1: Latest transmit violation detected on channel B
24	EDB	Error Detected on Channel B Flag 0: No error detected on channel B 1: Error detected on channel B
23 to 19	—	Reserved These bits are always read as 0. When writing, always write 0.
18	TABA	Transmission Across Boundary Channel A Flag 0: No transmission across slot boundary detected on channel A 1: Transmission across slot boundary detected on channel A
17	LTVA	Latest Transmit Violation Channel A Flag 0: No latest transmit violation detected on channel A 1: Latest transmit violation detected on channel A
16	EDA	Error Detected on Channel A Flag 0: No error detected on channel A 1: Error detected on channel A
15 to 12	—	Reserved These bits are always read as 0. When writing, always write 0.
11	MHF	Message Handler Constraints Flag 0: No message handler failure detected 1: Message handler failure detected

Table 17.6 FLXA0FREIR Register Contents (2/2)

Bit Position	Bit Name	Function
10	IOBA	Illegal Output Buffer Access Flag 0: No illegal host access to output buffer occurred 1: Illegal host access to output buffer occurred
9	IIBA	Illegal Input Buffer Access Flag 0: No illegal host access to input buffer occurred 1: Illegal host access to input buffer occurred
8	EFA	Empty FIFO Access Flag 0: No host access to empty FIFO occurred 1: Host access to empty FIFO occurred
7	RFO	Receive FIFO Overrun Flag 0: No receive FIFO overrun detected 1: A receive FIFO overrun has been detected
6	AERR	Access Error Flag 0: Access error is not detected. 1: Access error is detected.
5	CCL	CHI Command Locked Flag 0: CHI command accepted 1: CHI command not accepted
4	CCF	Clock Correction Failure Flag 0: No clock correction error 1: Clock correction failed
3	SFO	Sync Frame Overflow Flag 0: Number of received sync frames <= FLXA0FRGTUC2.SNM 1: More sync frames received than configured by FLXA0FRGTUC2.SNM
2	SFBM	Sync Frames Below Minimum Flag 0: Sync node: 1 or more sync frames received, non-sync node: 2 or more sync frames received 1: Less than the required minimum of sync frames received
1	CNA	Command Not Accepted Flag 0: CHI command accepted 1: CHI command not accepted
0	PEMC	POC Error Mode Changed Flag 0: Error mode has not changed 1: Error mode has changed

(1) FLXA0FREIR.TABB

Transmission Across Boundary Channel B Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing '1' to it.

The flag signals to the host that a transmission across a slot boundary occurred for channel B.

(2) FLXA0FREIR.LTVB

Latest Transmit Violation Channel B Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing '1' to it.

The flag signals a latest transmit violation on channel B to the host.

(3) FLXA0FREIR.EDB

Error Detected on Channel B Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing '1' to it.

This bit is set whenever one of the flags FLXA0FRACS.SEDB, FLXA0FRACS.CEDB, FLXA0FRACS.CIB, FLXA0FRACS.SBVB changes from '0' to '1'.

(4) FLXA0FREIR.TABA

Transmission Across Boundary Channel A Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

The flag signals to the host that a transmission across a slot boundary occurred for channel A.

(5) FLXA0FREIR.LTVA

Latest Transmit Violation Channel A Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

The flag signals a latest transmit violation on channel A to the host.

(6) FLXA0FREIR.EDA

Error Detected on Channel A Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This bit is set whenever one of the flags FLXA0FRACS.SEDA, FLXA0FRACS.CEDA, FLXA0FRACS.CIA, FLXA0FRACS.SBVA changes from '0' to '1'.

(7) FLXA0FREIR.MHF

Message Handler Constraints Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

The flag signals a message handler constraints violation condition. It is set whenever one of the flags FLXA0FRMHDF.SNUA, FLXA0FRMHDF.SNUB, FLXA0FRMHDF.FNFA, FLXA0FRMHDF.FNFB, FLXA0FRMHDF.TBFA, FLXA0FRMHDF.TBFB, FLXA0FRMHDF.WAHP changes from '0' to '1'.

(8) FLXA0FREIR.IOBA

Illegal Output Buffer Access Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when the host requests the transfer of a message buffer from the message RAM to the output buffer while FLXA0FROBCR.OBSYS is set to '1'.

(9) FLXA0FREIR.IIBA

Illegal Input Buffer Access Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when the host wants to modify a message buffer via input buffer and one of the following conditions applies:

1. The CC is not in CONFIG or DEFAULT_CONFIG state and the host writes to the input buffer command request register to modify the
 - Header section of message buffer 0, 1 if configured for transmission in key slot
 - Header section of static message buffers with buffer number < FLXA0FRMRC.FDB while FLXA0FRMRC.SEC = "01"
 - Header section of any static or dynamic message buffer while FLXA0FRMRC.SEC = "1x"
 - Header and/or data section of any message buffer belonging to the receive FIFO
2. The host writes to any register of the input buffer while FLXA0FRIBCR.IBSYH is set to '1'.

(10) FLXA0FREIR.EFA

Empty FIFO Access Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when the host requests the transfer of a message from the receive FIFO via output buffer while the receive FIFO is empty.

(11) FLXA0FREIR.RFO

Receive FIFO Overrun Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

The flag is set by the CC when a receive FIFO overrun is detected. When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. The actual state of the FIFO is monitored in register FLXA0FRFSR.

(12) FLXA0FREIR.AERR

Access Error flag

Writing 0 in this bit has no effect.

This bit is cleared when writing '1' to it.

Notifies of an access error.

When the AMR, ATBF1, or ATBF2 bit in the FLXA0FRMHDS register changes from 0 to 1, this bit is set to 1.

(13) FLXA0FREIR.CCL

CHI Command Locked Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

The flag signals that the write access to the CHI command vector FLXA0FRSUCC1.CMD was not successful because the execution of the previous CHI command has not yet completed. In this case bit FLXA0FREIR.CNA is also set to '1'.

(14) FLXA0FREIR.CCF

Clock Correction Failure Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set at the end of the communication cycle whenever one of the following errors occurred:

- Missing offset and/or rate correction
- Clock correction limit reached

The clock correction status is monitored in registers FLXA0FRCCEV and FLXA0FRSFS. A failure may occur during startup, therefore bit FLXA0FREIR.CCF should be set to "0" after the CC entered NORMAL_ACTIVE state.

(15) FLXA0FREIR.SFO

Sync Frame Overflow Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

It is set to "1" when either the number of sync frames received during the last communication cycle or the total number of different sync frame IDs received during the last double cycle exceeds the maximum number of sync frames as defined by FLXA0FRGTUC2.SNM.

(16) FLXA0FREIR.SFBM

Sync Frames Below Minimum Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set to "1" at the end of a cycle if the number of sync frames received during the last communication cycle was below the limit required for rate or offset correction term calculation (i.e. missing offset and/or missing rate correction). The clock correction status is monitored in FLXA0FRCCEV and FLXA0FRSFS.

This flag may be set to "1" during startup. Therefore this flag should be set to "0" by the host after the CC entered NORMAL_ACTIVE state.

(17) FLXA0FREIR.CNA

Command Not Accepted Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

The flag signals that the write access to the CHI command vector FLXA0FRSUCC1.CMD was not successful because the requested command was not valid in the actual POC state, or because the CHI command was locked (CCL = '1').

(18) FLXA0FREIR.PEMC

POC Error Mode Changed Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set to "1" whenever the error mode signaled by FLXA0FRCCEV.ERRM has changed.

17.2.4.2 FLXA0FRSIR — FlexRay Status Interrupt Register

Do not rewrite this register using bit-manipulation instruction.

The flags are set when the CC detects one of the listed events. The flags remain set until the host clears them.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0024_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

3	TXI	Transmit Interrupt Flag 0: No frame transmitted from a transmit buffer with MBI = '1' 1: At least one frame was transmitted from a transmit buffer with MBI = '1'
2	CYCS	Cycle Start Interrupt Flag 0: No communication cycle started 1: Communication cycle started
1	CAS	Collision Avoidance Symbol Flag 0: No bit pattern matching the CAS symbol received 1: Bit pattern matching the CAS symbol received
0	WST	Wakeup Status Flag 0: Wakeup status unchanged 1: Wakeup status changed

(1) FLXA0FRSIR.MTSB

MTS Received on Channel B Flag (vSS!ValidMTSB)

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

Media Access Test Symbol (MTS) received on channel B during the preceding symbol window.

Updated by the CC for each channel at the end of the symbol window.

(2) FLXA0FRSIR.WUPB

Wakeup Pattern Channel B Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set to "1" when a wakeup pattern was received on channel B in either of the following states:

- WAKEUP
- READY
- STARTUP

(3) FLXA0FRSIR.MTSA

MTS Received on Channel A Flag (vSS!ValidMTSA)

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

Media Access Test Symbol (MTS) received on channel A during the preceding symbol window.

Updated by the CC for each channel at the end of the symbol window.

(4) FLXA0FRSIR.WUPA

Wakeup Pattern Channel A Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set to "1" when a wakeup pattern was received on channel A in either of the following states:

- WAKEUP
- READY
- STARTUP

(5) FLXA0FRSIR.SDS

Start of Dynamic Segment Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when the dynamic segment starts.

(6) FLXA0FRSIR.MBSI

Message Buffer Status Interrupt Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set by the CC when the message buffer status FLXA0FRMBS has changed and if bit MBI of that message buffer is "1" (see **Table 17.100**).

(7) FLXA0FRSIR.SUCS

Startup Normal End Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set whenever a startup completed successfully and the CC entered NORMAL_ACTIVE state.

(8) FLXA0FRSIR.SWE

Stop Watch Event Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set after a stop watch activation when the actual cycle counter and macrotick value are stored in the Stop Watch register (see **Section 17.2.5.4, FLXA0FRSTPW1 — FlexRay Stop Watch Register 1**).

(9) FLXA0FRSIR.TOBC

Transfer Output Buffer Completed Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set whenever a transfer from the message RAM to the output buffer has completed and FLXA0FROBCR.OBSYS has been reset by the message handler.

(10) FLXA0FRSIR.TIBC

Transfer Input Buffer Completed Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set whenever a transfer from input buffer to the message RAM has completed and FLXA0FRIBCR.IBSYS has been reset by the message handler.

(11) FLXA0FRSIR.TI1

Timer Interrupt 1 Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set whenever timer 1 matches the conditions configured in register FLXA0FRT1C.

FlexRay timer interrupt 1 is generated when the T1IE bit in the FLXA0FROC register is effective.

(12) FLXA0FRSIR.TI0

Timer Interrupt 0 Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set whenever timer 0 matches the conditions configured in register FLXA0FRT0C.

FlexRay timer interrupt 0 is generated when the T0IE bit in the FLXA0FROC register is effective.

(13) FLXA0FRSIR.NMVC

Network Management Vector Changed Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This is set when a change in the Network Management Vector occurs.

(14) FLXA0FRSIR.RFCL

Receive FIFO Critical Level Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set when the receive FIFO fill level FLXA0FRFSR.RFFL is equal or greater than the critical level as configured by FLXA0RFCL.CL.

(15) FLXA0FRSIR.RFNE

Receive FIFO Not Empty Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set when a received valid frame was stored into the empty receive FIFO. The current state of the receive FIFO can be read in register FLXA0FRFSR.

(16) FLXA0FRSIR.RXI

Receive Interrupt Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set whenever the set condition of a message buffers ND flag is fulfilled (see **Section 17.2.9.6, FLXA0FRNDATi — FlexRay New Data Register i (i = 1 to 4)**), and if bit MBI of that message buffer is set to 1 (see **Table 17.100**).

(17) FLXA0FRSIR.TXI

Transmit Interrupt Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set at the end of frame transmission if bit MBI in the respective message buffer is set to 1 (see **Table 17.100**).

(18) FLXA0FRSIR.CYCS

Cycle Start Interrupt Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set to "1" every time a communication cycle starts.

(19) FLXA0FRSIR.CAS

Collision Avoidance Symbol Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set during STARTUP state when a CAS or an expected CAS was received.

(20) FLXA0FRSIR.WST

Wakeup Status Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set when FLXA0FRCCSV.WSV changes to a value other than UNDEFINED.

17.2.4.3 FLXA0FREILS — FlexRay Error Interrupt Line Select Register

The FlexRay error interrupt line select register assigns an interrupt generated by a specific error interrupt flag from register FLXA0FREIR to one of the two modules interrupt lines (FlexRay interrupt 0 or FlexRay interrupt 1).

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0028_H

Value after reset: 0000 0000_H

17.2.4.5 FLXA0FREIES — FlexRay Error Interrupt Enable Set Register

The settings in the FlexRay error interrupt enable set register (FLXA0FREIES) and FlexRay error interrupt enable reset register (FLXA0FREIER) determine which status changes in the FlexRay error interrupt register will result in an interrupt.

The enable bits are set by writing to FLXA0FREIES and reset by writing to FLXA0FREIER. Reading from both addresses will result in the same value.

Writing '0' has no effect on the bit value.

Writing a '1' sets the interrupt enable bit.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0030_H

Value after reset: 0000 0000_H

17.2.4.6 FLXA0FREIER — FlexRay Error Interrupt Enable Reset Register

The settings in the FlexRay error interrupt enable set register (FLXA0FREIES) and FlexRay error interrupt enable reset register (FLXA0FREIER) determine which status changes in the FlexRay error interrupt register will result in an interrupt.

The enable bits are set by writing to FLXA0FREIES and reset by writing to FLXA0FREIER. Reading from both addresses will result in the same value.

Writing '0' has no effect on the bit value.

Writing a '1' clears the interrupt enable bit.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0034_H

Value after reset: 0000 0000_H

17.2.4.7 FLXA0FRSIES — FlexRay Status Interrupt Enable Set Register

The settings in the FlexRay status interrupt enable set register (FLXA0FRSIES) and FlexRay status interrupt enable reset register (FLXA0FRSIER) determine which status changes in the FlexRay status interrupt register will result in an interrupt.

The enable bits are set by writing to FLXA0FRSIES and reset by writing to FLXA0FRSIER. Reading from both addresses will result in the same value.

Writing '0' has no effect on the bit value.

Writing a '1' sets the interrupt enable bit.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

17.2.4.8 FLXA0FRSIER — FlexRay Status Interrupt Enable Reset Register

The settings in the FlexRay status interrupt enable set register (FLXA0FRSIES) and FlexRay status interrupt enable reset register (FLXA0FRSIER) determine which status changes in the FlexRay status interrupt register will result in an interrupt.

The enable bits are set by writing to FLXA0FRSIES and reset by writing to FLXA0FRSIER. Reading from both addresses will result in the same value.

Writing '0' has no effect on the bit value.

Writing a '1' clears the interrupt enable bit.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 003C_H

17.2.4.9 FLXA0FRILE — FlexRay Interrupt Line Enable Register

Each of the two module interrupt lines (FlexRay interrupt 0, FlexRay interrupt 1) can be enabled or disabled separately by programming bit FLXA0FRILE.EINT0 and FLXA0FRILE.EINT1.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0040_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

17.2.5 FlexRay Timer Registers

17.2.5.1 FLXA0FRT0C — FlexRay Timer 0 Configuration Register

This register is an absolute timer. It specifies the point in time when a FlexRay timer 0 interrupt occurs as the values of cycle count and macrotick (MT). When the FlexRay timer 0 passes, FLXA0FRSIR.TI0 and FLXA0FROS.TOIS are set to '1'. A timer 0 interrupt then occurs while the FLXA0FROC.TOIE bit is effective.

NOTE

The configuration of timer 0 is compared against the macrotick counter value, there is no separate counter for timer 0.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0044_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.15 FLXA0FRT0C Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29 to 16	T0MO[13:0]	Timer 0 Macrotick Offset Timer 0 macrotick offset
15	—	Reserved This bit is always read as 0. When writing, always write 0.
14 to 8	T0CC[6:0]	Timer 0 Cycle Code timer 0 cycle code
7 to 2	—	Reserved These bits are always read as 0. When writing, always write 0.
1	T0MS	Timer 0 Mode Select 0: Single-shot mode 1: Continuous mode
0	T0RC	Timer 0 Run Control 0: Timer 0 halted 1: Timer 0 running

(1) FLXA0FRT0C.T0MO

Timer 0 Macrotick Offset

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXA0FRT0C.T0RC to '0'.

Configures the macrotick offset from the beginning of the communication cycle where the interrupt is to occur. The FlexRay timer 0 interrupt occurs at this offset for each cycle of the cycle set.

(2) FLXA0FRT0C.T0CC

Timer 0 Cycle Code

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXA0FRT0C.T0RC to '0'.

The 7-bit timer 0 cycle code determines the cycle set used for generation of the FlexRay timer 0 interrupt. For details about the configuration of the cycle code, see **Section 17.3.8.2, Cycle Counter Filtering**.

(3) FLXA0FRT0C.T0MS

Timer 0 Mode Select

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXA0FRT0C.T0RC to '0'.

Configures the timer run mode. In Single-shot mode the timer is deactivated when the timer configuration matches the configured cycle counter and macrotick value.

(4) FLXA0FRT0C.T0RC

Timer 0 Run Control

Timer 0 can be activated (set FLXA0FRT0C.T0RC to '1') when the POC is either in NORMAL_ACTIVE state or in NORMAL_PASSIVE state.

Timer 0 is deactivated when leaving NORMAL_ACTIVE state or NORMAL_PASSIVE state except for transitions between the two states.

17.2.5.2 FLXA0FRT1C — FlexRay Timer 1 Configuration Register

This register is a relative timer. After the specified number of macroticks (MT) has expired, a FlexRay timer 1 interrupt is asserted. When the FlexRay timer 1 passes, FLXA0FRSIR.TI1 and FLXA0FROS.TI1S are set to '1'. A timer 1 interrupt then occurs while the FLXA0FROC.T1IE bit is effective.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0048_H

Value after reset: 0002 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.16 FLXA0FRT1C Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29 to 16	T1MC[13:0]	Timer 1 Macrotick Count Timer 1 macrotick count
15 to 2	—	Reserved These bits are always read as 0. When writing, always write 0.
1	T1MS	Timer 1 Mode Select 0: Single-shot mode 1: Continuous mode
0	T1RC	Timer 1 Run Control 0: Timer 1 halted 1: Timer 1 running

(1) FLXA0FRT1C.T1MC

Timer 1 Macrotick Count

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXA0FRT1C.T1RC to '0'.

Valid values are 2 to 16383 MT in continuous mode

Valid values are 1 to 16383 MT in single-shot mode

When the configured macrotick count is reached the FlexRay timer 1 interrupt is generated.

(2) FLXA0FRT1C.T1MS

Timer 1 Mode Select

Before reconfiguration of the timer, the timer has to be halted first by writing bit FLXA0FRT1C.T1RC to '0'.

Configures the timer run mode. In Single-shot mode the timer is deactivated when the timer configuration matches the configured cycle counter and macrotick value.

(3) FLXA0FRT1C.T1RC

Timer 1 Run Control

Timer 1 can be activated (set FLXA0FRT1C.T1RC to '1') as long as the POC is either in NORMAL_ACTIVE state or in NORMAL_PASSIVE state.

Timer 1 is deactivated when leaving NORMAL_ACTIVE state or NORMAL_PASSIVE state except for transitions between the two states.

17.2.5.3 FLXA0FRT2C — FlexRay Timer 2 Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0844_H

Value after reset: 0000 0000_H

Table 17.17 FLXA0FRT2C Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29 to 16	T2MO[13:0]	Timer 2 Macrotick Offset Timer 2 macrotick offset
15	—	Reserved This bit is always read as 0. When writing, always write 0.
14 to 8	T2CC[6:0]	Timer 2 Cycle Code Timer 2 cycle code
7 to 2	—	Reserved These bits are always read as 0. When writing, always write 0.
1	T2MS	Timer 2 Mode Select 0: Single-shot mode 1: Continuous mode
0	T2RC	Timer 2 Run Control 0: Timer halted 1: Timer running

(1) FLXA0FRT2C.T2MO

Timer 2 Macrotick Offset

Write 0 to the FLXA0FRT2C.T2RC bit and halt the timer before changing the value of the timer.

Configures the macrotick offset from the beginning of the communication cycle where the timer 2 interrupt is generated. The timer 2 interrupt is generated at this offset for each cycle of the cycle set.

(2) FLXA0FRT2C.T2CC

Timer 2 Cycle Code

Before reconfiguration of the timer, the timer has to be halted first by writing 0 to bit FLXA0FRT2C.T2RC.

Configures the cycle set which generates timer 2 interrupt with the 7-bit timer 2 cycle code. For details, see **Section 17.3.8.2, Cycle Counter Filtering**.

(3) FLXA0FRT2C.T2MS

Timer 2 Mode Select

Before reconfiguration of the timer, the timer has to be halted first by writing 0 to bit FLXA0FRT2C.T2RC.

Configures the timer run mode. In single-shot mode, the timer is deactivated when the timer configuration matches the configured cycle counter and macrotick value.

(4) FLXA0FRT2C.T2RC

Timer 2 Run Control

Timer 2 can be operated when the POC is in NORMAL_ACTIVE or NORMAL_PASSIVE state. (set FLXA0FRT2C.T2RC to '1')

Timer 2 is deactivated when leaving NORMAL_ACTIVE state or NORMAL_PASSIVE state except for transitions between the two states.

17.2.5.4 FLXA0FRSTPW1 — FlexRay Stop Watch Register 1

The stop watch is activated by the following trigger events.

- FlexRay interrupt 0 or FlexRay interrupt 1
- Writing bit FLXA0FRSTPW1.SSWT to '1'

With the macrotick counter increment following next to the stop watch activation the actual cycle counter and macrotick values are captured in register FLXA0FRSTPW1 while the slot counter values for channel A and B are captured in register FLXA0FRSTPW2.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 004C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.18 FLXA0FRSTPW1 Register Contents (1/2)

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29 to 16	SMTV[13:0]	Stop Watch Captured Macrotick Value Stop watch captured macrotick value
15, 14	—	Reserved These bits are always read as 0. When writing, always write 0.
13 to 8	SCCV[5:0]	Stop Watch Captured Cycle Counter Value Stop watch captured cycle counter value
7	—	Reserved This bit is always read as 0. When writing, always write 0.
6	EINT1	Enable FlexRay Interrupt 1 Trigger 0: Stop watch trigger by FlexRay interrupt 1 disabled 1: FlexRay interrupt 1 event triggers stop watch
5	EINT0	Enable FlexRay Interrupt 0 Trigger 0: Stop watch trigger by FlexRay interrupt 0 disabled 1: FlexRay interrupt 0 event triggers stop watch
4	—	Reserved This bit is always read as 0. When writing, always write 0.
3	SSWT	Software Stop Watch Trigger 0: Software trigger reset 1: Stop watch activated by software trigger
2	EDGE	Stop Watch Trigger Edge Select 0: Falling edge 1: Rising edge

Table 17.18 FLXA0FRSTPW1 Register Contents (2/2)

Bit Position	Bit Name	Function
1	SWMS	Stop Watch Mode Select 0: Single-shot mode 1: Continuous mode
0	ESWT	Enable Hardware Stop Watch Trigger 0: Stop watch trigger disabled 1: Stop watch trigger enabled

(1) FLXA0FRSTPW1.SMTV

Stop Watch Captured Macrotick Value

State of the macrotick counter when the stop watch event occurred.

(2) FLXA0FRSTPW1.SCCV

Stop Watch Captured Cycle Counter Value

State of the cycle counter when the stop watch event occurred.

(3) FLXA0FRSTPW1.EINT1

Enable FlexRay Interrupt 1 Trigger

Enables stop watch trigger by FlexRay interrupt 1 when FLXA0FRSTPW1.ESWT = '1'.

(4) FLXA0FRSTPW1.EINT0

Enable FlexRay Interrupt 0 Trigger

Enables stop watch trigger by FlexRay interrupt 0 when FLXA0FRSTPW1.ESWT = '1'.

(5) FLXA0FRSTPW1.SSWT

Software Stop Watch Trigger

Bits FLXA0FRSTPW1.ESWT and FLXA0FRSTPW1.SSWT cannot be set to '1' simultaneously. In this case the write access to the register is ignored, and both bits keep their previous values. Either the external stop watch trigger or the software stop watch trigger may be used.

Writing 1 in this bit activates the stop watch. This bit is reset to '0' after the cycle count and slot count, and macrotick (MT) value are stored in the FlexRay stop watch register.

(6) FLXA0FRSTPW1.EDGE

Stop Watch Trigger Edge Select

(7) FLXA0FRSTPW1.SWMS

Stop Watch Mode Select

(8) FLXA0FRSTPW1.ESWT

Enable Stop Watch Trigger

Bits FLXA0FRSTPW1.ESWT and FLXA0FRSTPW1.SSWT cannot be set to '1' simultaneously. In this case the write access to the register is ignored, and both bits keep their previous values. Either the external stop watch trigger or the software stop watch trigger may be used.

If enabled, a FlexRay interrupt 0 event or a FlexRay interrupt 1 event activates the stop watch.

In single-shot mode, this bit is reset to '0' after the cycle count and slot count, and macrotick (MT) value are stored in the FlexRay stop watch register.

17.2.5.5 FLXA0FRSTPW2 — FlexRay Stop Watch Register 2

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0050_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	SSCVA[10:0]	Stop Watch Captured Slot Counter Value Channel A

(1) FLXA0FRSTPW2.SSCVB

Stop Watch Captured Slot Counter Value Channel B

State of the slot counter for channel B when the stop watch event occurred.

(2) FLXA0FRSTPW2.SSCVA

Stop Watch Captured Slot Counter Value Channel A

State of the slot counter for channel A when the stop watch event occurred.

17.2.6 CC Control Registers

This section describes the registers provided by the CC to allow the host to control the operation of the CC. The FlexRay protocol specification requires the host to write application configuration data in CONFIG state only. Please consider that the configuration registers are not locked for writing in DEFAULT_CONFIG state.

The configuration data is reset when DEFAULT_CONFIG state is entered from reset. To change POC state from DEFAULT_CONFIG to CONFIG state the host has to apply CHI command CONFIG. If the host wants the CC to leave CONFIG state, the host has to execute the lock release sequence as described in **Section 17.2.3.1, FLXA0FRLCK — FlexRay Lock Register**.

17.2.6.1 FLXA0FRSUCC1 — FlexRay SUC Configuration Register 1

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0080_H

Value after reset: 0C40 1080_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 28	—	Reserved These bits are always read as 0. When writing, always write 0.
27	CCHB	Connected to Channel B Configures pChannels 0: Node not connected to channel B 1: Node connected to channel B (default after reset)
26	CCHA	Connected to Channel A Configures pChannels 0: Node not connected to channel A 1: Node connected to channel A (default after reset)
25	MTSB	Select Channel B for MTS Transmission 0: Channel B disabled for MTS transmission 1: Channel B selected for MTS transmission
24	MTSA	Select Channel A for MTS Transmission 0: Channel A disabled for MTS transmission 1: Channel A selected for MTS transmission
23	HCSE	Halt due to Clock Sync Error Configures pAllowHaltDueToClock 0: CC will enter or remain in NORMAL_PASSIVE 1: CC will enter HALT state
22	TSM	Transmission Slot Mode Configures pSingleSlotEnabled 0: ALL Slot Mode 1: SINGLE Slot Mode (default after hard reset)

Table 17.20 FLXA0FRSUCC1 Register Contents (2/2)

Bit Position	Bit Name	Function
21	WUCS	Wakeup Channel Select Configures pWakeupChannel 0: Send wakeup pattern on channel A 1: Send wakeup pattern on channel B
20 to 16	PTA[4:0]	Passive to Active Configure pAllowPassiveToActive
15 to 11	CSA[4:0]	Cold Start Attempts Configure gColdStartAttempts
10	—	Reserved This bit is always read as 0. When writing, always write 0.
9	TXSY	Transmit Sync Frame in Key Slot Configure pKeySlotUsedForSync 0: No sync frame transmission in key slot, node is neither sync nor coldstart node 1: Key slot used to transmit sync frame, node is sync node
8	TXST	Transmit Startup Frame in Key Slot Configure pKeySlotUsedForStartup 0: No startup frame transmission in key slot, node is non-coldstarter 1: Key slot used to transmit startup frame, node is leading or following coldstarter
7	PBSY	POC Busy Flag 0: POC not busy, FLXA0FRSUCC1.CMD writeable 1: POC is busy, FLXA0FRSUCC1.CMD locked
6 to 4	—	Reserved These bits are always read as 0. When writing, always write 0.
3 to 0	CMD[3:0]	CHI Command Vector 0000: command_not_accepted 0001: CONFIG 0010: READY 0011: WAKEUP 0100: RUN 0101: ALL_SLOTS 0110: HALT 0111: FREEZE 1000: SEND_MTS 1001: ALLOW_COLDSTART 1010: RESET_STATUS_INDICATORS 1100: CLEAR_RAMs others: reserved

(1) FLXA0FRSUCC1.CCHB

Connected to Channel B

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.
Configures whether the node is connected to channel B (pChannels).

(2) FLXA0FRSUCC1.CCHA

Connected to Channel A

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.
Configures whether the node is connected to channel A (pChannels).

(3) FLXA0FRSUCC1.MTSB

Select Channel B for MTS Transmission

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

FLXA0FRSUCC1.MTSB may also be changed outside DEFAULT_CONFIG or CONFIG state when the write to FLXA0FRSUCC1 register is directly preceded by the unlock sequence for the Configuration Lock Key as described in **Section 17.2.3.1, FLXA0FRLCK — FlexRay Lock Register**. This may be combined with CHI command SEND_MTS. If both bits FLXA0FRSUCC1.MTSA and FLXA0FRSUCC1.MTSB are set to '1' an MTS symbol will be transmitted on both channels when requested by writing FLXA0FRSUCC1.CMD = "1000".

The bit selects channel B for MTS symbol transmission.

(4) FLXA0FRSUCC1.MTSA

Select Channel A for MTS Transmission

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

FLXA0FRSUCC1.MTSA may also be changed outside DEFAULT_CONFIG or CONFIG state when the write to FLXA0FRSUCC1 register is directly preceded by the unlock sequence for the Configuration Lock Key as described in **Section 17.2.3.1, FLXA0FRLCK — FlexRay Lock Register**. This may be combined with CHI command SEND_MTS. If both bits FLXA0FRSUCC1.MTSA and FLXA0FRSUCC1.MTSB are set to '1' an MTS symbol will be transmitted on both channels when requested by writing FLXA0FRSUCC1.CMD = "1000".

The bit selects channel A for MTS symbol transmission.

(5) FLXA0FRSUCC1.HCSE

Halt due to Clock Sync Error

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Controls the transition to HALT state due to a clock synchronization error (pAllowHaltDueToClock).

(6) FLXA0FRSUCC1.TSM

Transmission Slot Mode

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Selects the initial transmission slot mode (pSingleSlotEnabled).

In SINGLE slot mode the CC may only transmit in the preconfigured key slot. The key slot ID is configured in the header section of message buffer 0 respectively message buffers 0 and 1 depending on bit FLXA0FRMRC.SPLM.

In case FLXA0FRSUCC1.TSM = '1', message buffer 0 respectively message buffers 0,1 can be (re)configured in DEFAULT_CONFIG or CONFIG state only. In ALL slot mode the CC may transmit in all slots.

FLXA0FRSUCC1.TSM is a configuration bit which can only be set or reset by the host.

The CC changes to ALL slot mode when the host successfully applied the ALL_SLOTS command by writing FLXA0FRSUCC1.CMD = "0101" in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. The actual slot mode is monitored by FLXA0FRCCSV.SLM.

(7) FLXA0FRSUCC1.WUCS

Wakeup Channel Select

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

With this bit the host selects the channel on which the CC sends the Wakeup pattern (pWakeupChannel).

(8) FLXA0FRSUCC1.PTA

Passive to Active Condition Setting

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 31 even/odd cycle pairs.

Defines the number of consecutive even/odd cycle pairs that must have valid clock correction terms before the CC is allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state (pAllowPassiveToActive).

If set to "00000" the CC is not allowed to transit from NORMAL_PASSIVE to NORMAL_ACTIVE state.

(9) FLXA0FRSUCC1.CSA

Cold Start Attempt Count Setting

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Must be identical in all nodes of a cluster.

Valid values are 2 to 31.

Configures the maximum number of attempts that a cold starting node is permitted to try to start up the network without receiving any valid response from another node (gColdStartAttempts).

(10) FLXA0FRSUCC1.TXSY

Transmit Sync Frame in Key Slot

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Defines whether the key slot is used to transmit sync frames (pKeySlotUsedForSync).

NOTE

The protocol requires that both bits FLXA0FRSUCC1.TXST and FLXA0FRSUCC1.TXSY are set for coldstart nodes.

(11) FLXA0FRSUCC1.TXST

Transmit Startup Frame in Key Slot

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Defines whether the key slot is used to transmit startup frames (pKeySlotUsedForStartup).

NOTE

The protocol requires that both bits FLXA0FRSUCC1.TXST and FLXA0FRSUCC1.TXSY are set for coldstart nodes.

(12) FLXA0FRSUCC1.PBSY

POC Busy

Signals that the POC is busy and cannot accept a command from the host. FLXA0FRSUCC1.CMD is locked against write accesses.

Set to '1' after reset during initialization of internal RAM blocks.

(13) FLXA0FRSUCC1.CMD

CHI Command Vector

The host may write any CHI command at any time, but certain commands are enabled only in certain POC states. If a command is not enabled, it will not be executed, the CHI command vector FLXA0FRSUCC1.CMD will be reset to "0000" = command_not_accepted, and flag FLXA0FREIR.CNA will be set to '1'.

In general the host must check FLXA0FRSUCC1.PBSY before writing a new CHI command.

In case the previous CHI command has not yet completed, FLXA0FREIR.CCL is set to '1' together with FLXA0FREIR.CNA; the CHI command needs to be repeated.

Except for HALT state, a POC state change command applied while the CC is already in the requested POC state neither causes a state change nor will FLXA0FREIR.CNA be set.

Reading FLXA0FRSUCC1.CMD shows whether the last CHI command was accepted. The actual POC state is monitored by FLXA0FRCCSV.POCS.

- command_not_accepted

FLXA0FRSUCC1.CMD is reset to "0000" due to one of the following conditions:

- Illegal command applied by the host
- Host applied command to leave CONFIG state without preceding config lock key
- Host applied new command while execution of the previous host command has not completed
- Host writes command_not_accepted

When FLXA0FRSUCC1.CMD is reset to "0000", FLXA0FREIR.CNA is set to '1', and enabled, an interrupt is generated.

Commands which are not accepted are not executed.

CONFIG

Go to POC state CONFIG when called in POC states DEFAULT_CONFIG, or READY. When called in HALT state the CC transits to POC state DEFAULT_CONFIG. When called in any other state, FLXA0FRSUCC1.CMD will be reset to "0000" = command_not_accepted.

READY

Go to POC state READY when called in POC states CONFIG, NORMAL_ACTIVE, NORMAL_PASSIVE, STARTUP, or WAKEUP. When called in any other state, FLXA0FRSUCC1.CMD will be reset to “0000” = command_not_accepted.

WAKEUP

Go to POC state WAKEUP when called in POC state READY. When called in any other state, FLXA0FRSUCC1.CMD will be reset to “0000” = command_not_accepted.

RUN

Go to POC state STARTUP when called in POC state READY. When called in any other state, FLXA0FRSUCC1.CMD will be reset to “0000” = command_not_accepted.

ALL_SLOTS

Leave SINGLE slot mode and go to ALL-SLOTS mode after successful startup/integration at the next end of cycle when called in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. When called in any other state, FLXA0FRSUCC1.CMD will be reset to “0000” = command_not_accepted.

HALT

Set halt request FLXA0FRCCSV.HRQ to ‘1’ and go to POC state HALT at the next end of cycle when called in POC states NORMAL_ACTIVE or NORMAL_PASSIVE. When called in any other state, FLXA0FRSUCC1.CMD will be reset to “0000” = command_not_accepted.

FREEZE

Set the freeze status indicator FLXA0FRCCSV.FSI to ‘1’ and go to POC state HALT immediately. Can be called from any state.

SEND_MTS

Send single MTS symbol during the next following symbol window on the channel configured by FLXA0FRSUCC1.MTSA, FLXA0FRSUCC1.MTSB, when called in POC state NORMAL_ACTIVE after CC entered ALL slot mode (FLXA0FRCCSV.SLM = “11”). When called in any other state, or when called while a previously requested MTS has not yet been transmitted, FLXA0FRSUCC1.CMD will be reset to “0000” = command_not_accepted.

ALLOW_COLDSTART

The command resets FLXA0FRCCSV.CSI to enable the node to become leading coldstarter. When called in states DEFAULT_CONFIG, CONFIG, or HALT, FLXA0FRSUCC1.CMD will be reset to “0000” = command_not_accepted. To become leading coldstarter it is also required that both FLXA0FRSUCC1.TXST and FLXA0FRSUCC1.TXSY are set.

RESET_STATUS_INDICATORS

Resets status flags FLXA0FRCCSV.FSI, FLXA0FRCCSV.HRQ, FLXA0FRCCSV.CSNI, and FLXA0FRCCSV.CSAI to their default values. Can be called in POC states READY and STARTUP. When called in any other state, FLXA0FRSUCC1.CMD will be reset to “0000” = command_not_accepted.

CLEAR_RAMs

Sets FLXA0FRMHDS.CRAME to '1' when called in DEFAULT_CONFIG or CONFIG state. When called in any other state, FLXA0FRSUCC1.COMD will be reset to "0000" = command_not_accepted.

FLXA0FRMHDS.CRAME is also set to '1' when the CC leaves reset. By setting FLXA0FRMHDS.CRAME all internal RAM blocks are initialized to zero. During the initialization of the RAMs, FLXA0FRSUCC1.PBSY will show POC busy. Access to the configuration and status registers is possible during execution of CHI command CLEAR_RAMs.

The initialization of the internal RAM block requires 2048 bus clock cycles. There should be no host access to input buffer or output buffer during initialization of the internal RAM blocks after reset or after assertion of CHI command CLEAR_RAMs.

Before asserting CHI command CLEAR_RAMs, confirm that no transfer between message RAM and input buffer or output buffer or the temporary buffer RAMs is ongoing and that the data transfer handler is disabled (FLXA0FRITS.ITS = 0 and FLXA0FROTS.OTS = 0). This command also resets the message buffer status registers FLXA0FRMHDS, FLXA0FRLDTS, FLXA0FRFSR, FLXA0FRMHDF, FLXA0FRTRXQ1/2/3/4, FLXA0FRNDAT1/2/3/4, and FLXA0FRMBSC1/2/3/4.

NOTES

1. All accepted commands with exception of CLEAR_RAMs and SEND_MTS will cause a change of the POC state in the FlexRay domain after at most 8 cycles of the slower of the two clocks "bus clock" and "FlexRay", assumed that POC was not busy when the command was applied and that no POC state change was forced by bus activity in that time frame. Reading register FLXA0FRCCSV will show data that is additionally delayed by synchronization from the FlexRay domain to the bus clock domain. The maximum additional delay is 12 cycles of the slower of the two clocks "bus clock" and "FlexRay".
2. When a terminal restarts transfer as a leading coldstart node after transfer was stopped by using the FREEZE or READY command, the startup frame may not be transmitted in cycle 0. This depends on the internal state of the FlexRay module. This phenomenon occurs when the startup frame is set in a slot with a number from 1 to 7.
This phenomenon does not occur in a coldstart after a hardware reset.
Even if this phenomenon does occur, a second try of the coldstart will succeed.
While the coldstart time will be prolonged, this phenomenon does not otherwise affect a coldstart of the FlexRay system.
To avoid this phenomenon, allocate the Startup/Sync frame to static slot 8 or a slot with a higher number.

Table 17.21 below references the CHI commands from the FlexRay Protocol Specification (Section 2.2.1.1, Table 2.2) to the FlexRay CHI command vector FLXA0FRSUCC1.CMD.

Table 17.21 Reference to CHI Host Command Summary from FlexRay Protocol Specification

CHI Command	Where Processed (POC States)	CHI Command Vector CMD
ALL_SLOTS	POC: normal active, POC: normal passive	ALL_SLOTS
ALLOW_COLDSTART	All except POC: default config, POC: config, POC: halt	ALLOW_COLDSTART
CONFIG	POC: default config, POC: ready	CONFIG
CONFIG_COMPLETE	POC: config	Unlock sequence & READY
DEFAULT_CONFIG	POC: halt	CONFIG
FREEZE	All	FREEZE
HALT	POC: normal active, POC: normal passive	HALT
READY	All except POC: default config, POC: config, POC: ready, POC: halt	READY
RUN	POC: ready	RUN
WAKEUP	POC: ready	WAKEUP

17.2.6.2 FLXA0FRSUCC2 — FlexRay SUC Configuration Register 2

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0084_H

Value after reset: 0100 0504_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—			—			LTN[3:0]			—			LT[20:16]

Table 17.22 FLXA0FRSUCC2 Register Contents

Bit Position	Bit Name	Function
31 to 28	—	Reserved These bits are always read as 0. When writing, always write 0.
27 to 24	LTN[3:0]	Listen Timeout Noise Configure (gListenNoise - 1)
23 to 21	—	Reserved These bits are always read as 0. When writing, always write 0.
20 to 0	LT[20:0]	Listen Timeout Configure pdListenTimeout

(1) FLXA0FRSUCC2.LTN

Listen Timeout Noise

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 16.

FLXA0FRSUCC2.LTN must be configured identical in all nodes of a cluster.

Configures the upper limit for startup and wakeup listen timeout in the presence of noise expressed as a multiple of pdListenTimeout.

NOTE

The wakeup/startup noise timeout is calculated as follows:

$$\text{pdListenTimeout} \times \text{gListenNoise} = \text{FLXA0FRSUCC2.LT} \times (\text{FLXA0FRSUCC2.LTN} + 1)$$

(2) FLXA0FRSUCC2.LT

Listen Timeout

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 1284 to 1283846 μT .

Configures wakeup/startup listen timeout in μT .

17.2.6.3 FLXA0FRSUCC3 — FlexRay SUC Configuration Register 3

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0088_H

Value after reset: 0000 0011_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are always read as 0. When writing, always write 0.
7 to 4	WCF[3:0]	Maximum Without Clock Correction Fatal (condition for transition to HALT state) Configure gMaxWithoutClockCorrectionFatal
3 to 0	WCP[3:0]	Maximum Without Clock Correction Passive (condition for transition to NORMAL_PASSIVE state) Configure gMaxWithoutClockCorrectionPassive

(1) FLXA0FRSUCC3.WCF

Maximum Without Clock Correction Fatal (condition for transition to HALT state)

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 15 cycle pairs.

Setting must be identical in all nodes of a cluster.

Defines the number of consecutive even/odd cycle pairs with missing clock correction terms that will cause a transition from NORMAL_ACTIVE or NORMAL_PASSIVE to HALT state.

NOTE

The transition to HALT state is prevented if FLXA0FRSUCC1.HCSE is not set.

(2) FLXA0FRSUCC3.WCP

Maximum Without Clock Correction Passive (transition to NORMAL_PASSIVE state)

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 15 cycle pairs.

Setting must be identical in all nodes of a cluster.

Defines the number of consecutive even/odd cycle pairs with missing clock correction terms that will cause a transition from NORMAL_ACTIVE to NORMAL_PASSIVE state.

17.2.6.4 FLXA0FRNEMC — FlexRay NEM Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 008C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit Position	Bit Name	Function
31 to 4	—	Reserved These bits are always read as 0. When writing, always write 0.
3 to 0	NML[3:0]	Network Management Vector Length Configure gNetworkManagementVectorLength

(1) FLXA0FRNEMC.NML

Network Management Vector Length

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 12 bytes.

The configured length must be identical in all nodes of a cluster.

These bits configure the length of the NM vector.

17.2.6.5 FLXA0FRPRTC1 — FlexRay PRT Configuration Register 1

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0090_H

Value after reset: 084C 0633_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.25 FLXA0FRPRTC1 Register Contents

Bit Position	Bit Name	Function
31 to 26	RWP[5:0]	Repetitions of Tx Wakeup Pattern Configure pWakeupPattern
25	—	Reserved This bit is always read as 0. When writing, always write 0.
24 to 16	RXW[8:0]	Wakeup Symbol Receive Window Length Configure gdWakeupSymbolRxWindow
15, 14	BRP[1:0]	Baud Rate Prescaler Configure gdSampleClockPeriod and pSamplesPerMicrotick 00 = 10 Mbps 01 = 5 Mbps 10 = 2.5 Mbps 11 = 2.5 Mbps
13, 12	SPP[1:0]	Strobe Point Position Configure Strobe point position 00 = Sample 5 01 = Sample 4 10 = Sample 6 11 = Sample 5
11	—	Reserved This bit is always read as 0. When writing, always write 0.
10 to 4	CASM[6:0]	Collision Avoidance Symbol Max Configure gdCASRxLowMax
3 to 0	TSST[3:0]	Transmission Start Sequence Transmitter Configure gdTSSTransmitter

(1) FLXA0FRPRTC1.RWP

Repetitions of Tx Wakeup Pattern

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 63.

Configures the number of repetitions (sequences) of the Tx wakeup symbol.

(2) FLXA0FRPRTC1.RXW

Wakeup Symbol Receive Window Length

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 76 to 301 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to test the duration of the received wakeup pattern.

(3) FLXA0FRPRTC1.BRP

Baud Rate Prescaler

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

The Baud Rate Prescaler configures the baud rate on the FlexRay bus. The baud rates listed below are valid with a sample clock set to 80 MHz. One bit time always consists of 8 samples independent of the configured baud rate.

00 = 10 MBit/s

$$\text{gdSampleClockPeriod} = 12.5 \text{ ns} = 1 * \text{'sample clock'}$$

$$\text{pSamplesPerMicrotick} = 2 \text{ (1 } \mu\text{T} = 25 \text{ ns)}$$

01 = 5 MBit/s

$$\text{gdSampleClockPeriod} = 25 \text{ ns} = 2 * \text{'sample clock'}$$

$$\text{pSamplesPerMicrotick} = 1 \text{ (1 } \mu\text{T} = 25 \text{ ns)}$$

10, 11 = 2.5 MBit/s

$$\text{gdSampleClockPeriod} = 50 \text{ ns} = 4 * \text{'sample clock'}$$

$$\text{pSamplesPerMicrotick} = 1 \text{ (1 } \mu\text{T} = 50 \text{ ns)}$$

(4) FLXA0FRPRTC1.SPP

Strobe Point Position

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Defines the sample count value for strobing. The strobed bit value is set to the voted value when the sample count is incremented to the value configured by FLXA0FRPRTC1.SPP.

NOTE

The current revision 2.1 of the FlexRay protocol requires that FLXA0FRPRTC1.SPP = "00". The alternate strobe point positions could be used to compensate for asymmetries in the physical layer.

(5) FLXA0FRPRTC1.CASM

Collision Avoidance Symbol Max

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

CASM6 is fixed to '1'.

Valid values are 67 to 99 bit times.

Configures the upper limit of the acceptance window for a collision avoidance symbol (CAS).

(6) FLXA0FRPRTC1.TSST

Transmission Start Sequence Transmitter

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 3 to 15 bit times.

Must be identical in all nodes of a cluster.

Configures the duration of the Transmission Start Sequence (TSS) in terms of bit times (1 bit time = 4 μ T = 100ns at 10 Mbps).

17.2.6.6 FLXA0FRPRTC2 — FlexRay PRT Configuration Register 2

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0094_H

Value after reset: 0F2D 0A0E_H

7, 6	—	Reserved These bits are always read as 0. When writing, always write 0.
5 to 0	RXI[5:0]	Wakeup Symbol Rx Idle Configure gdWakeupSymbolRxIdle

(1) FLXA0FRPRTC2.TXL

Wakeup Symbol Transmit Low

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 15 to 60 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to transmit the low phase of the wakeup symbol.

(2) FLXA0FRPRTC2.TXI

Wakeup Symbol Transmit Idle

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 45 to 180 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to transmit the idle phase of the wakeup symbol.

(3) FLXA0FRPRTC2.RXL

Wakeup Symbol Receive Low

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 10 to 55 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to test the duration of the low phase of the received wakeup symbol.

(4) FLXA0FRPRTC2.RXI

Wakeup Symbol Rx Idle

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 14 to 59 bit times.

Must be identical in all nodes of a cluster.

Configures the number of bit times used by the node to test the duration of the idle phase of the received wakeup symbol.

17.2.6.7 FLXA0FRMHDC — FlexRay MHD Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0098_H

Value after reset: 0000 0000_H

Table 17.27 FLXA0FRMHDC Register Contents

Bit Position	Bit Name	Function
31 to 29	—	Reserved These bits are always read as 0. When writing, always write 0.
28 to 16	SLT[12:0]	Start of Latest Transmit Configure pLatestTx
15 to 7	—	Reserved These bits are always read as 0. When writing, always write 0.
6 to 0	SFDL[6:0]	Static Frame Data Length Configure gPayloadLengthStatic

(1) FLXA0FRMHDC.SLT

Start of Latest Transmit

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7981 minislots.

Configures the maximum minislot value allowed before inhibiting frame transmission in the dynamic segment of the cycle. There is no transmission in dynamic segment if FLXA0FRMHDC.SLT is set to zero.

(2) FLXA0FRMHDC.SFDL

Static Frame Data Length

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 127.

The payload length must be identical in all nodes of a cluster.

Configures the cluster-wide payload length for all frames sent in the static segment in double bytes.

17.2.6.8 FLXA0FRGTUC1 — FlexRay GTU Configuration Register 1

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 00A0_H

Value after reset: 0000 0280_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 20	—	Reserved These bits are always read as 0. When writing, always write 0.
19 to 0	UT[19:0]	Microtick per Cycle Configure pMicroPerCycle

(1) FLXA0FRGTUC1.UT

Microtick per Cycle

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 640 to 640000 μ T.

Configures the duration of the communication cycle in microticks.

17.2.6.9 FLXA0FRGTUC2 — FlexRay GTU Configuration Register 2

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 00A4_H

Value after reset: 0002 000A_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.29 FLXA0FRGTUC2 Register Contents

Bit Position	Bit Name	Function
31 to 20	—	Reserved These bits are always read as 0. When writing, always write 0.
19 to 16	SNM[3:0]	Sync Node Max
15, 14	—	Reserved These bits are always read as 0. When writing, always write 0.
13 to 0	MPC[13:0]	Macrotick Per Cycle Configure gMacroPerCycle

(1) FLXA0FRGTUC2.SNM

Sync Node Max

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 15.

Must be identical in all nodes of a cluster.

Maximum number of frames within a cluster with sync frame indicator bit SYN set to '1'.

(2) FLXA0FRGTUC2.MPC

Macrotick Per Cycle

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 10 to 16000 MT.

The cycle length must be identical in all nodes of a cluster.

Configures the duration of one communication cycle in macroticks.

17.2.6.10 FLXA0FRGTUC3 — FlexRay GTU Configuration Register 3

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 00A8_H

Value after reset: 0202 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.30 FLXA0FRGTUC3 Register Contents

Bit Position	Bit Name	Function
31	—	Reserved This bit is always read as 0. When writing, always write 0.
30 to 24	MIOB[6:0]	Macrotick Initial Offset Channel B Configure pMacroInitialOffset[B]
23	—	Reserved This bit is always read as 0. When writing, always write 0.
22 to 16	MIOA[6:0]	Macrotick Initial Offset Channel A Configure pMacroInitialOffset[A]
15 to 8	UIOB[7:0]	Microtick Initial Offset Channel B Configure pMicroInitialOffset[B]
7 to 0	UIOA[7:0]	Microtick Initial Offset Channel A Configure pMicroInitialOffset[A]

(1) FLXA0FRGTUC3.MIOB

Macrotick Initial Offset Channel B

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 72 MT.

Must be identical in all nodes of a cluster.

Configures the number of macroticks between the static slot boundary and the subsequent macrotick boundary of the secondary time reference point based on the nominal macrotick duration.

(2) FLXA0FRGTUC3.MIOA

Macrotick Initial Offset Channel A

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 72 MT.

Must be identical in all nodes of a cluster.

Configures the number of macroticks between the static slot boundary and the subsequent macrotick boundary of the secondary time reference point based on the nominal macrotick duration.

(3) FLXA0FRGTUC3.UIOB

Microtick Initial Offset Channel B

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 240 μ T.

Configures the number of microticks between the actual time reference point on channel B and the subsequent macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation [B] and therefore has to be set for each channel independently.

(4) FLXA0FRGTUC3.UIOA

Microtick Initial Offset Channel A

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 240 μ T.

Configures the number of microticks between the actual time reference point on channel A and the subsequent macrotick boundary of the secondary time reference point. The parameter depends on pDelayCompensation [A] in the FLXA0FRGTUC5 register and therefore has to be set for each channel independently.

17.2.6.11 FLXA0FRGTUC4 — FlexRay GTU Configuration Register 4

For details about configuration of FLXA0FRGTUC4.NIT and FLXA0FRGTUC4.OCS see **Section 17.3.2.5, Configuration of NIT Start and Offset Correction Start.**

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 00AC_H

Value after reset: 0008 0007_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.31 FLXA0FRGTUC4 Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29 to 16	OCS[13:0]	Offset Correction Start Configure (gOffsetCorrectionStart - 1)
15, 14	—	Reserved These bits are always read as 0. When writing, always write 0.
13 to 0	NIT[13:0]	Network Idle Time Start Configure (gMacroPerCycle -gdNIT - 1)

(1) FLXA0FRGTUC4.OCS

Offset Correction Start

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 8 to 15998 MT.

For cluster consisting of E-Ray implementations only, it is sufficient to program
 $FLXA0FRGTUC4.OCS = FLXA0FRGTUC4.NIT + 1$.

Must be identical in all nodes of a cluster.

Determines the start of the offset correction within the NIT phase, calculated from start of cycle.

(2) FLXA0FRGTUC4.NIT

Network Idle Time Start

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 7 to 15997 MT.

Must be identical in all nodes of a cluster.

Configures the starting point of the Network Idle Time NIT at the end of the communication cycle expressed in terms of macroticks from the beginning of the cycle. The start of NIT is recognized if $MacroTick = gMacroPerCycle - gdNIT - 1$ and the increment pulse of MacroTick is set.

17.2.6.12 FLXA0FRGTUC5 — FlexRay GTU Configuration Register 5

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 00B0_H

Value after reset: 0E00 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.32 FLXA0FRGTUC5 Register Contents

Bit Position	Bit Name	Function
31 to 24	DEC[7:0]	Decoding Correction Configure pDecodingCorrection
23 to 21	—	Reserved These bits are always read as 0. When writing, always write 0.
20 to 16	CDD[4:0]	Cluster Drift Damping Configure pClusterDriftDamping
15 to 8	DCB[7:0]	Delay Compensation Channel B Configure pDelayCompensation[B]
7 to 0	DCA[7:0]	Delay Compensation Channel A Configure pDelayCompensation[A]

(1) FLXA0FRGTUC5.DEC

Decoding Correction

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 14 to 143 μ T.

Configures the decoding correction value in microticks used to determine the primary time reference point.

(2) FLXA0FRGTUC5.CDD

Cluster Drift Damping

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 20 μ T.

Configures the cluster drift damping value in microticks used in clock synchronization to minimize accumulation of rounding errors.

(3) FLXA0FRGTUC5.DCB

Delay Compensation Channel B

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 200 μ T.

Used to compensate for reception delays on channel B. This covers assumed propagation delay up to cPropagationDelayMax for microticks in the range of 0.0125 to 0.05 μ s. In practice, the minimum of the propagation delays of all sync nodes should be applied.

(4) FLXA0FRGTUC5.DCA

Delay Compensation Channel A

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 200 μ T.

Used to compensate for reception delays on channel A. This covers assumed propagation delay up to cPropagationDelayMax for microticks in the range of 0.0125 to 0.05 μ s. In practice, the minimum of the propagation delays of all sync nodes should be applied.

17.2.6.13 FLXA0FRGTUC6 — FlexRay GTU Configuration Register 6

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 00B4_H

Value after reset: 0002 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.33 FLXA0FRGTUC6 Register Contents

Bit Position	Bit Name	Function
31 to 27	—	Reserved These bits are always read as 0. When writing, always write 0.
26 to 16	MOD[10:0]	Maximum Oscillator Drift Configure pdMaxDrift
15 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	ASR[10:0]	Accepted Startup Range Configure pdAcceptedStartupRange

(1) FLXA0FRGTUC6.MOD

Maximum Oscillator Drift

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 1923 μ T.

Maximum drift offset between two nodes that operate with unsynchronized clocks over one communication cycle in μ T.

(2) FLXA0FRGTUC6.ASR

Accepted Startup Range

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 1875 μ T.

Number of microticks constituting the expanded range of measured deviation for startup frames during integration.

17.2.6.14 FLXA0FRGTUC7 — FlexRay GTU Configuration Register 7

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 00B8_H

Value after reset: 0002 0004_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.34 FLXA0FRGTUC7 Register Contents

Bit Position	Bit Name	Function
31 to 26	—	Reserved These bits are always read as 0. When writing, always write 0.
25 to 16	NSS[9:0]	Number of Static Slots Configure gNumberOfStaticSlots
15 to 10	—	Reserved These bits are always read as 0. When writing, always write 0.
9 to 0	SSL[9:0]	Static Slot Length Configure gdStaticSlot

(1) FLXA0FRGTUC7.NSS

Number of Static Slots

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 1023.

The number of static slots must be identical in all nodes of a cluster.

Configures the number of static slots in a cycle.

(2) FLXA0FRGTUC7.SSL

Static Slot Length

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 4 to 659 MT.

The static slot length must be identical in all nodes of a cluster.

Configures the length of a static slot in macroticks.

17.2.6.15 FLXA0FRGTUC8 — FlexRay GTU Configuration Register 8

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 00BC_H

Value after reset: 0000 0002_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 29	—	Reserved These bits are always read as 0. When writing, always write 0.
28 to 16	NMS[12:0]	Number of Minislots Configure gNumberOfMinislots
15 to 6	—	Reserved These bits are always read as 0. When writing, always write 0.
5 to 0	MSL[5:0]	Minislot Length Configure gdMinislot

(1) FLXA0FRGTUC8.NMS

Number of Minislots

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7986.

The number of minislots must be identical in all nodes of a cluster.

Configures the number of minislots within the dynamic segment of a cycle.

(2) FLXA0FRGTUC8.MSL

Minislot Length

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 63 MT.

The minislot length must be identical in all nodes of a cluster.

Configures the length of a minislot in macroticks.

17.2.6.16 FLXA0FRGTUC9 — FlexRay GTU Configuration Register 9

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 00C0_H

Value after reset: 0000 0101_H

Table 17.36 FLXA0FRGTUC9 Register Contents

Bit Position	Bit Name	Function
31 to 18	—	Reserved These bits are always read as 0. When writing, always write 0.
17, 16	DSI[1:0]	Dynamic Slot Idle Phase Configure gdDynamicSlotIdlePhase
15 to 13	—	Reserved These bits are always read as 0. When writing, always write 0.
12 to 8	MAPO[4:0]	Minislot Action Point Offset Configure gdMinislotActionPointOffset
7, 6	—	Reserved These bits are always read as 0. When writing, always write 0.
5 to 0	APO[5:0]	Action Point Offset Configure gdActionPointOffset

(1) FLXA0FRGTUC9.DSI

Dynamic Slot Idle Phase

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 2 Minislots.

Must be identical in all nodes of a cluster.

Configures the duration of the dynamic slot idle phase in the number of minislots. The duration has to be greater or equal than the idle detection time.

(2) FLXA0FRGTUC9.MAPO

Minislot Action Point Offset

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 31 MT.

Must be identical in all nodes of a cluster.

Configures the action point offset in macroticks within the minislots of the dynamic segment.

(3) FLXA0FRGTUC9.APO

Action Point Offset

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 1 to 63 MT.

Must be identical in all nodes of a cluster.

Configures the action point offset in macroticks within static slots and symbol window.

17.2.6.17 FLXA0FRGTUC10 — FlexRay GTU Configuration Register 10

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 00C4_H

Table 17.37 FLXA0FRGTUC10 Register Contents

Bit Position	Bit Name	Function
31 to 27	—	Reserved These bits are always read as 0. When writing, always write 0.
26 to 16	MRC[10:0]	Maximum Rate Correction Configure pRateCorrectionOut
15, 14	—	Reserved These bits are always read as 0. When writing, always write 0.
13 to 0	MOC[13:0]	Maximum Offset Correction Configure pOffsetCorrectionOut

(1) FLXA0FRGTUC10.MRC

Maximum Rate Correction

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 2 to 1923 μ T.

Holds the maximum permitted rate correction value to be applied by the internal clock synchronization algorithm. The CC checks only the internal rate correction value against the maximum rate correction value (absolute value).

(2) FLXA0FRGTUC10.MOC

Maximum Offset Correction

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 5 to 15266 μ T.

Holds the maximum permitted offset correction value (absolute value) to be applied by the internal clock synchronization algorithm (absolute value). The CC checks only the internal offset correction value against the maximum offset correction value.

17.2.6.18 FLXA0FRGTUC11 — FlexRay GTU Configuration Register 11

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 00C8_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.38 FLXA0FRGTUC11 Register Contents

Bit Position	Bit Name	Function
31 to 27	—	Reserved These bits are always read as 0. When writing, always write 0.
26 to 24	ERC[2:0]	External Rate Correction Configure pExternRateCorrection
23 to 19	—	Reserved These bits are always read as 0. When writing, always write 0.
18 to 16	EOC[2:0]	External Offset Correction Configure pExternOffsetCorrection
15 to 10	—	Reserved These bits are always read as 0. When writing, always write 0.
9, 8	ERCC[1:0]	External Rate Correction Control Configure vExternRateControl 00: External rate correction is prohibited. 01: External rate correction is prohibited. 10: Subtract 11: Add
7 to 2	—	Reserved These bits are always read as 0. When writing, always write 0.
1, 0	EOCC[1:0]	External Offset Correction Control Configure vExternOffsetControl 00: External offset correction is prohibited. 01: External offset correction is prohibited. 10: Subtract 11: Add

(1) FLXA0FRGTUC11.ERC

External Rate Correction

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7 μ T.

Holds the external rate correction value in microticks to be applied by the internal clock synchronization algorithm. The value is subtracted or added from or to the calculated rate correction value. The value is applied during NIT.

(2) FLXA0FRGTUC11.EOC

External Offset Correction

A user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Valid values are 0 to 7 μ T.

Holds the external offset correction value in microticks to be applied by the internal clock synchronization algorithm. The value is subtracted or added from or to the calculated offset correction value. The value is applied during NIT.

(3) FLXA0FRGTUC11.ERCC

External Rate Correction Control

Should be modified only outside NIT (Network Idle Time).

By writing to FLXA0FRGTUC11.ERCC the external rate correction is enabled as specified below.

00 = External rate correction is prohibited.

01 = External rate correction is prohibited.

10 = Subtract

External rate correction value subtracted from calculated rate correction value

11 = Add

External rate correction value added to calculated rate correction value

(4) FLXA0FRGTUC11.EOCC

External Offset Correction Control

Should be modified only outside NIT (Network Idle Time).

By writing to FLXA0FRGTUC11.EOCC the external offset correction is enabled as specified below.

00 = External offset correction is prohibited.

01 = External offset correction is prohibited.

10 = Subtract

External offset correction value subtracted from calculated offset correction value

11 = Add

External offset correction value added to calculated offset correction value

17.2.7 CC Status Registers

During 8/16-bit accesses to status variables coded with more than 8/16-bit, the variable might be updated by the CC between two accesses (non-atomic read accesses).

17.2.7.1 FLXA0FRCCSV — FlexRay CC Status Vector Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0100_H

Value after reset: 0010 4000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	PSL[5:0]					RCA[4:0]				WSV[2:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Table 17.39 FLXA0FRCCSV Register Contents

Bit	Symbol	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29 to 24	PSL[5:0]	POC Status Log Flags Status of FLXA0FRCCSV.POCS immediately before entering HALT state.
23 to 19	RCA[4:0]	Remaining Coldstart Attempts Flags Indicate vRemainingColdstartAttempts
18 to 16	WSV[2:0]	Wakeup Status Flags Indicate vPOC!WakeupStatus
15	—	Reserved This bit is always read as 0. When writing, always write 0.
14	CSI	Cold Start Inhibit Flag Indicates vColdStartInhibit 0: Cold starting of node enabled 1: Cold starting of node disabled
13	CSAI	Coldstart Abort Indicator Flag
12	CSNI	Coldstart Noise Indicator Flag Indicates vPOC!ColdstartNoise
11, 10	—	Reserved These bits are always read as 0. When writing, always write 0.
9, 8	SLM[1:0]	Slot Mode Flags Indicate vPOC!SlotMode 00: SINGLE 01: reserved 10: ALL_PENDING 11: ALL
7	HRQ	Halt Request Flag Indicates vPOC!CHIHaltRequest
6	FSI	Freeze Status Indicator Flag Indicates vPOC!Freeze
5 to 0	POCS[5:0]	Protocol Operation Control Status Flags

(1) FLXA0FRCCSV.PSL

POC Status Log Flags

Set the value of FLXA0FRCCSV.POCS immediately before entering HALT state.

Set to HALT when FREEZE command is applied during HALT state and FLXA0FRCCSV.FSI is not already set i.e. the HALT state was not reached by FREEZE command.

Reset to “000000_p” when leaving HALT state.

(2) FLXA0FRCCSV.RCA

Remaining Coldstart Attempts Flags

Indicates the number of remaining coldstart attempts (vRemainingColdstartAttempts).

The initial value of FLXA0FRCCSV.RCA during CONFIG and DEFAULT_CONFIG state is also FLXA0FRSUCC1.CSA.

The RUN command resets this counter to the maximum number of coldstart attempts as configured by FLXA0FRSUCC1.CSA.

(3) FLXA0FRCCSV.WSV

Wakeup Status Flags

Indicates the status of the current wakeup attempt (vPOC!WakeupStatus).

Reset to “0” when entering Wakeup state, by CHI command RESET_STATUS_INDICATORS, or by transition from DEFAULT_CONFIG to CONFIG state

000 = UNDEFINED

Wakeup not yet executed by the CC.

001 = RECEIVED_HEADER

Set when the CC finishes wakeup due to the reception of a frame header without coding violation on either channel in WAKEUP_LISTEN state.

010 = RECEIVED_WUP

Set when the CC finishes wakeup due to the reception of a valid wakeup pattern on the configured wakeup channel in WAKEUP_LISTEN state.

011 = COLLISION_HEADER

Set when the CC stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid header on either channel.

100 = COLLISION_WUP

Set when the CC stops wakeup due to a detected collision during wakeup pattern transmission by receiving a valid wakeup pattern on the configured wakeup channel.

101 = COLLISION_UNKNOWN

Set when the CC stops wakeup by leaving WAKEUP_DETECT state after expiration of the wakeup timer without receiving a valid wakeup pattern or a valid frame header.

110 = TRANSMITTED

Set when the CC has successfully completed the transmission of the wakeup pattern.

111 = reserved

(4) FLXA0FRCCSV.CSI

Cold Start Inhibit Flag

Indicates that the node is disabled from cold starting (vColdStartInhibit).

The flag is set to “1” whenever the POC enters READY state due to CHI command READY.

The flag has to be reset under control of the host by CHI command ALLOW_COLDSTART (FLXA0FRSUCC1.CMD = “1001”).

(5) FLXA0FRCCSV.CSAI

Coldstart Abort Indicator Flag

Coldstart aborted.

Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state or from READY to STARTUP state.

(6) FLXA0FRCCSV.CSNI

Coldstart Noise Indicator Flag

Indicates that the cold start procedure occurred under noisy conditions (vPOC!ColdstartNoise).

Reset by CHI command RESET_STATUS_INDICATORS or by transition from HALT to DEFAULT_CONFIG state or from READY to STARTUP state.

(7) FLXA0FRCCSV.SLM

Slot Mode Flags

Indicates the actual slot mode of the POC (vPOC!SlotMode) in states READY, WAKEUP, STARTUP, NORMAL_ACTIVE, and NORMAL_PASSIVE.

Default value is SINGLE. Changes to ALL, depending on FLXA0FRSUCC1.TSM.

In NORMAL_ACTIVE or NORMAL_PASSIVE state the CHI command ALL_SLOTS will change the slot mode from SINGLE over ALL_PENDING to ALL.

Set FLXA0FRSUCC1.TSM to SINGLE except for NORMAL_ACTIVE or NORMAL_PASSIVE.

(8) FLXA0FRCCSV.HRQ

Halt Request Flag

Indicates that a request from the host has been received to halt the POC at the end of the communication cycle (vPOC!CHIHaltRequest).

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

(9) FLXA0FRCCSV.FSI

Freeze Status Indicator Flag

Indicates that the POC has entered the HALT state due to CHI command FREEZE or due to an error condition requiring an immediate POC halt (vPOC!Freeze).

Reset by transition from HALT to DEFAULT_CONFIG state.

(10) FLXA0FRCCSV.POCS

Protocol Operation Control Status Flag

Indicates the actual state of operation of the CC Protocol Operation Control

00 0000 = DEFAULT_CONFIG state

00 0001 = READY state

00 0010 = NORMAL_ACTIVE state

00 0011 = NORMAL_PASSIVE state

00 0100 = HALT state

00 0110...00 1110 = reserved

00 1111 = CONFIG state

Indicates the actual state of operation of the POC in the wakeup path

01 0000 = WAKEUP_STANDBY state

01 0001 = WAKEUP_LISTEN state

01 0010 = WAKEUP_SEND state

01 0011 = WAKEUP_DETECT state

Indicates the actual state of operation of the POC in the startup path

10 0000 = STARTUP_PREPARE state

10 0001 = COLDSTART_LISTEN state

10 0010 = COLDSTART_COLLISION_RESOLUTION state

10 0011 = COLDSTART_CONSISTENCY_CHECK state

10 0100 = COLDSTART_GAP state

10 0101 = COLDSTART_JOIN State

10 0110 = INTEGRATION_COLDSTART_CHECK state

10 0111 = INTEGRATION_LISTEN state

10 1000 = INTEGRATION_CONSISTENCY_CHECK state

10 1001 = INITIALIZE_SCHEDULE state

10 1010 = ABORT_STARTUP state

10 1011 = STARTUP_SUCCESS state

Others = reserved

17.2.7.2 FLXA0FRCCEV — FlexRay CC Error Vector Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0104_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	PTAC[4:0]				ERRM[1:0]		—	—	CCFC[3:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 17.40 FLXA0FRCCEV Register Contents

Bit Position	Bit Name	Function
31 to 13	—	Reserved These bits are always read as 0. When writing, always write 0.
12 to 8	PTAC[4:0]	Passive to Active Count Indicate vAllowPassiveToActive
7, 6	ERRM[1:0]	Error Mode Flags Indicates vPOC!ErrorMode 00: ACTIVE 01: PASSIVE 10: COMM_HALT 11: reserved
5, 4	—	Reserved These bits are always read as 0. When writing, always write 0.
3 to 0	CCFC[3:0]	Clock Correction Failed Counter Indicate vClockCorrectionFailed

(1) FLXA0FRCCEV.PTAC

Passive to Active Count

Indicates the number of consecutive even/odd cycle pairs that have passed with valid rate and offset correction terms, while the node is waiting to transit from NORMAL_PASSIVE state to NORMAL_ACTIVE state. The transition takes place when FLXA0FRCCEV.PTAC equals FLXA0FRSUCC1.PTA - 1.

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

(2) FLXA0FRCCEV.ERRM

Error Mode Flags

Indicates the actual error mode of the POC (vPOC!ErrorMode).

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

(3) FLXA0FRCCEV.CCFC

Clock Correction Failed Counter

Indicates the clock correction failed counter of the POC (vClockCorrectionFailed).

The Clock Correction Failed Counter is incremented by one at the end of any odd communication cycle where either the missing offset correction error or missing rate correction error are active.

The Clock Correction Failed Counter is reset to '0' at the end of an odd communication cycle if neither the offset correction failed nor the rate correction failed errors are active.

The Clock Correction Failed Counter stops at 15.

Reset by transition from HALT to DEFAULT_CONFIG state or when entering READY state.

17.2.7.3 FLXA0FRSCV — FlexRay Slot Counter Value Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0110_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.41 FLXA0FRSCV Register Contents

Bit Position	Bit Name	Function
31 to 27	—	Reserved These bits are always read as 0. When writing, always write 0.
26 to 16	SCCB[10:0]	Slot Counter Channel B Indicates vSlotCounter[B]
15 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	SCCA[10:0]	Slot Counter Channel A Indicates vSlotCounter[A]

(1) FLXA0FRSCV.SCCB

Slot Counter Channel B

Current slot counter value on channel B (vSlotCounter[B]). The value is incremented by the CC and reset at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXA0FRSCV.SCCA

Slot Counter Channel A

Current slot counter value on channel A (vSlotCounter[A]). The value is incremented by the CC and reset at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

17.2.7.4 FLXA0FRMTCCV — FlexRay Macrotick and Cycle Counter Value Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0114_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 22	—	Reserved These bits are always read as 0. When writing, always write 0.
21 to 16	CCV[5:0]	Cycle Counter Value Indicates vCycleCounter
15, 14	—	Reserved These bits are always read as 0. When writing, always write 0.
13 to 0	MTV[13:0]	Macrotick Value Indicates vMacrotick

(1) FLXA0FRMTCCV.CCV

Cycle Counter Value

Current cycle counter value (vCycleCounter). The value is incremented by the CC at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXA0FRMTCCV.MTV

Macrotick Value

Current macrotick value (vMacrotick). The value is incremented by the CC and reset at the start of a communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

17.2.7.5 FLXA0FRRCV — FlexRay Rate Correction Value Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0118_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 12	—	Reserved These bits are always read as 0. When writing, always write 0.
11 to 0	RCV[11:0]	Rate Correction Value Flags Indicates vRateCorrection

(1) FLXA0FRRCV.RCV

Rate Correction Value Flags

Indicates internal rate correction value (vRateCorrection/ two's complement) before limitation. If the FLXA0FRRCV.RCV value exceeds the limits defined by FLXA0FRGTUC10.MRC, flag FLXA0FRSFS.RCLR is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

NOTE

The external rate correction value is added to the limited rate correction value.

17.2.7.6 FLXA0FROCV — FlexRay Offset Correction Value Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 011C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 19	—	Reserved These bits are always read as 0. When writing, always write 0.
18 to 0	OCV[18:0]	Offset Correction Value Flags Indicate vOffsetCorrection

(1) FLXA0FROCV.OCV

Offset Correction Value Flags

Indicate offset correction value (vOffsetCorrection/ two's complement) before limitation. If the FLXA0FROCV.OCV value exceeds the limits defined by FLXA0FRGTUC10.MOC, flag FLXA0FRSFS.OCLR is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

NOTE

The external offset correction value is added to the limited offset correction value.

17.2.7.7 FLXA0FRSFS — FlexRay Sync Frame Status Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0120_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 17.45 FLXA0FRSFS Register Contents

Bit Position	Bit Name	Function
31 to 20	—	Reserved These bits are always read as 0. When writing, always write 0.
19	RCLR	Rate Correction Limit Reached Flag 0: Rate correction below limit 1: Rate correction limit reached
18	MRCS	Missing Rate Correction Signal Flag 0: Rate correction signal valid 1: Missing rate correction signal
17	OCLR	Offset Correction Limit Reached Flag 0: Offset correction below limit 1: Offset correction limit reached
16	MOCS	Missing Offset Correction Signal Flag 0: Offset correction signal valid 1: Missing offset correction signal
15 to 12	VSBO[3:0]	Valid Sync Frames Channel B, odd communication cycle
11 to 8	VSBE[3:0]	Valid Sync Frames Channel B, even communication cycle
7 to 4	VSAO[3:0]	Valid Sync Frames Channel A, odd communication cycle
3 to 0	VSAE[3:0]	Valid Sync Frames Channel A, even communication cycle

(1) FLXA0FRSFS.RCLR

Rate Correction Limit Reached Flag

The rate correction limit reached flag signals to the host, that the rate correction value has exceeded its limit as defined by FLXA0FRGTUC10.MRC10 - MRC0. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(2) FLXA0FRSFS.MRCS

Missing Rate Correction Signal Flag

The missing rate correction flag signals to the host, that no rate correction calculation can be performed because no pairs of even/odd sync frames were received. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(3) FLXA0FRSFS.OCLR

Offset Correction Limit Reached Flag

The offset correction limit reached flag signals to the host, that the offset correction value has exceeded its limit as defined by FLXA0FRGTUC10.MOC. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(4) FLXA0FRSFS.MOCS

Missing Offset Correction Signal Flag

The missing offset correction flag signals to the host, that no offset correction calculation can be performed because no sync frames were received. The flag is updated by the CC at start of offset correction phase.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(5) FLXA0FRSFS.VSBO

Valid Sync Frames Channel B, odd communication cycle

These bits are only valid when FLXA0FRSUCC1.CCHB is '1'.

Holds the number of valid sync frames received on channel B in the odd communication cycle. If transmission of sync frames is enabled by FLXA0FRSUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each odd communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(6) FLXA0FRSFS.VSBE

Valid Sync Frames Channel B, even communication cycle

These bits are only valid when FLXA0FRSUCC1.CCHB is '1'.

Holds the number of valid sync frames received on channel B in the even communication cycle. If transmission of sync frames is enabled by FLXA0FRSUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each even communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(7) FLXA0FRSFS.VSAO

Valid Sync Frames Channel A, odd communication cycle

These bits are only valid when FLXA0FRSUCC1.CCHA is '1'.

Holds the number of valid sync frames received on channel A in the odd communication cycle. If transmission of sync frames is enabled by FLXA0FRSUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each odd communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

(8) FLXA0FRSFS.VSAE

Valid Sync Frames Channel A, even communication cycle

These bits are only valid when FLXA0FRSUCC1.CCHA is '1'.

Holds the number of valid sync frames received on channel A in the even communication cycle. If transmission of sync frames is enabled by FLXA0FRSUCC1.TXSY the value is incremented by one. The value is updated during the NIT of each even communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state, INTEGRATION_COLDSTART_CHECK state or INTEGRATION_CONSISTENCY_CHECK state.

17.2.7.8 FLXA0FRSWNIT — FlexRay Symbol Window and NIT Status Register

Symbol window related status information is updated by the CC at the end of the symbol window for each channel. NIT related status information is updated by the CC at the end of the NIT for each channel.

During startup the status data is not updated.

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0124_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.46 FLXA0FRSWNIT Register Contents (1/2)

Bit Position	Symbol	Function
31 to 12	—	Reserved These bits are always read as 0. When writing, always write 0.
11	SBNB	Slot Boundary Violation during NIT Channel B Flag 0: No slot boundary violation detected 1: Slot boundary violation during NIT detected on channel B
10	SENB	Syntax Error during NIT Channel B Flag 0: No syntax error detected 1: Syntax error during NIT detected on channel B
9	SBNA	Slot Boundary Violation during NIT Channel A Flag 0: No slot boundary violation detected 1: Slot boundary violation during NIT detected on channel A
8	SENA	Syntax Error during NIT Channel A Flag 0: No syntax error detected 1: Syntax error during NIT detected on channel A
7	MTSB	MTS Received on Channel B Flag 0: No MTS symbol received on channel B 1: MTS symbol received on channel B
6	MTSA	MTS Received on Channel A Flag 0: No MTS symbol received on channel A 1: MTS symbol received on channel A
5	TCSB	Transmission Conflict in Symbol Window Channel B Flag 0: No transmission conflict detected 1: Transmission conflict in symbol window detected on channel B
4	SBSB	Slot Boundary Violation in Symbol Window Channel B Flag 0: No slot boundary violation detected 1: Slot boundary violation during symbol window detected on channel B
3	SESB	Syntax Error in Symbol Window Channel B Flag 0: No syntax error detected 1: Syntax error during symbol window detected on channel B

Table 17.46 FLXA0FRSWNIT Register Contents (2/2)

Bit Position	Symbol	Function
2	TCSA	Transmission Conflict in Symbol Window Channel A Flag 0: No transmission conflict detected 1: Transmission conflict in symbol window detected on channel A
1	SBSA	Slot Boundary Violation in Symbol Window Channel A Flag 0: No slot boundary violation detected 1: Slot boundary violation during symbol window detected on channel A
0	SESA	Syntax Error in Symbol Window Channel A Flag 0: No syntax error detected 1: Syntax error during symbol window detected on channel A

(1) FLXA0FRSWNIT.SBNB

Indicates a Slot Boundary Violation during NIT Channel B Flag (vSS!BViolationB).

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXA0FRSWNIT.SENB

Indicates a Syntax Error during NIT Channel B Flag (vSS!SyntaxErrorB).

Reset when leaving CONFIG state or when entering STARTUP state.

(3) FLXA0FRSWNIT.SBNA

Indicates a Slot Boundary Violation during NIT Channel A Flag (vSS!BViolationA).

Reset when leaving CONFIG state or when entering STARTUP state.

(4) FLXA0FRSWNIT.SENA

Indicates a Syntax Error during NIT Channel A Flag (vSS!SyntaxErrorA).

Reset when leaving CONFIG state or when entering STARTUP state.

(5) FLXA0FRSWNIT.MTSB

Indicates a MTS Received on Channel B Flag (vSS!ValidMTSB).

Media Access Test symbol received on channel B during the preceding symbol window. Updated by the CC for each channel at the end of the symbol window.

When this bit is set to '1', also interrupt flag FLXA0FRSIR.MTSB is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

(6) FLXA0FRSWNIT.MTSA

Indicates a MTS Received on Channel A Flag (vSS!ValidMTSA).

Media Access Test symbol received on channel A during the preceding symbol window. Updated by the CC for each channel at the end of the symbol window.

When this bit is set to '1', also interrupt flag FLXA0FRSIR.MTSA is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

(7) FLXA0FRSWNIT.TCSB

Indicates a Transmission Conflict in Symbol Window Channel B Flag (vSS!TxConflictB).

Reset when leaving CONFIG state or when entering STARTUP state.

(8) FLXA0FRSWNIT.SBSB

Indicates a Slot Boundary Violation in Symbol Window Channel B Flag (vSS!BViolationB).

Reset when leaving CONFIG state or when entering STARTUP state.

(9) FLXA0FRSWNIT.SESB

Indicates a Syntax Error in Symbol Window Channel B Flag (vSS!SyntaxErrorB).

Reset when leaving CONFIG state or when entering STARTUP state.

(10) FLXA0FRSWNIT.TCSA

Indicates a Transmission Conflict in Symbol Window Channel A Flag (vSS!TxConflictA).

Reset when leaving CONFIG state or when entering STARTUP state.

(11) FLXA0FRSWNIT.SBSA

Indicates a Slot Boundary Violation in Symbol Window Channel A Flag (vSS!BViolationA).

Reset when leaving CONFIG state or when entering STARTUP state.

(12) FLXA0FRSWNIT.SESA

Indicates a Syntax Error in Symbol Window Channel A Flag (vSS!SyntaxErrorA).

Reset when leaving CONFIG state or when entering STARTUP state.

17.2.7.9 FLXA0FRACS — FlexRay Aggregated Channel Status Register

Do not rewrite this register using bit-manipulation instruction.

The aggregated channel status provides the host with an accrued status of channel activity for all communication slots regardless of whether they are assigned for transmission or subscribed for reception.

The aggregated channel status also includes status data from the symbol window and the network idle time.

The status data is updated (set) after each slot and aggregated until it is reset by the host.

During startup the status data is not updated.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0128_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 13	—	Reserved These bits are always read as 0. When writing, always write 0.
12	SBVB	Slot Boundary Violation on Channel B Flag 0: No slot boundary violation observed 1: Slot boundary violation(s) observed on channel B
11	CIB	Communication Indicator Channel B Flag 0: No valid frame(s) received in slots containing any additional communication 1: Valid frame(s) received on channel B in slots containing any additional communication
10	CEDB	Content Error Detected on Channel B Flag 0: No frame with content error received 1: Frame(s) with content error received on channel B
9	SEDB	Syntax Error Detected on Channel B Flag 0: No syntax error observed 1: Syntax error(s) observed on channel B
8	VFRB	Valid Frame Received on Channel B Flag 0: No valid frame received 1: Valid frame(s) received on channel B
7 to 5	—	Reserved These bits are always read as 0. When writing, always write 0.
4	SBVA	Slot Boundary Violation on Channel A Flag 0: No slot boundary violation observed 1: Slot boundary violation(s) observed on channel A

Table 17.47 FLXA0FRACS Register Contents (2/2)

Bit Position	Bit Name	Function
3	CIA	Communication Indicator Channel A Flag 0: No valid frame(s) received in slots containing any additional communication 1: Valid frame(s) received on channel A in slots containing any additional communication
2	CEDA	Content Error Detected on Channel A Flag 0: No frame with content error received 1: Frame(s) with content error received on channel A
1	SEDA	Syntax Error Detected on Channel A Flag 0: No syntax error observed 1: Syntax error(s) observed on channel A
0	VFRA	Valid Frame Received on Channel A Flag 0: No valid frame received 1: Valid frame(s) received on channel A

(1) FLXA0FRACS.SBVB

Slot Boundary Violation on Channel B Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more slot boundary violations were observed on channel B at any time during the observation period (static or dynamic slots, symbol window, and NIT).

When this flag changes from '0' to '1', interrupt flag FLXA0FREIR.EDB is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXA0FRACS.CIB

Communication Indicator Channel B Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more valid frames were received on channel B in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid frame AND had any combination of either syntax error OR content error OR slot boundary violation.

When this flag changes from '0' to '1', interrupt flag FLXA0FREIR.EDB is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

NOTE

The set condition of the flag FLXA0FRACS.CIB is also fulfilled if there is only one single frame in the slot and the slot boundary at the end of the slot is reached during the frames channel idle recognition phase.

(3) FLXA0FRACS.CEDB

Content Error Detected on Channel B Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more frames with a content error were received on channel B in any static or dynamic slot during the observation period.

When this flag changes from '0' to '1', interrupt flag FLXA0FREIR.EDB is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

(4) FLXA0FRACS.SEDB

Syntax Error Detected on Channel B Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more syntax errors in static or dynamic slots, symbol window, and NIT were observed on channel B.

When this flag changes from '0' to '1', interrupt flag FLXA0FREIR.EDB is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

(5) FLXA0FRACS.VFRB

Valid Frame Received on Channel B Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more valid frames were received on channel B in any static or dynamic slot during the observation period.

Reset when leaving CONFIG state or when entering STARTUP state.

(6) FLXA0FRACS.SBVA

Slot Boundary Violation on Channel A Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

Slot boundary violations were observed on channel A at any time during the observation period (static or dynamic slots, symbol window, and NIT).

When this flag changes from '0' to '1', interrupt flag FLXA0FREIR.EDB is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

(7) FLXA0FRACS.CIA

Communication Indicator Channel A Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more valid frames were received on channel A in slots that also contained any additional communication during the observation period, i.e. one or more slots received a valid frame, and had one of syntax error, content error, or slot boundary violation.

When this flag changes from '0' to '1', interrupt flag FLXA0FREIR.EDB is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

NOTE

The set condition of the flag FLXA0FRACS.CIA is also fulfilled if there is only one single frame in the slot and the slot boundary at the end of the slot is reached during the frames channel idle recognition phase.

(8) FLXA0FRACS.CEDA

Content Error Detected on Channel A Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more frames with a content error were received on channel A in any static or dynamic slot during the observation period.

When this flag changes from '0' to '1', interrupt flag FLXA0FREIR.EDB is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

(9) FLXA0FRACS.SEDA

Syntax Error Detected on Channel A Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more syntax errors in static or dynamic slots, symbol window, and NIT were observed on channel A.

When this flag changes from '0' to '1', interrupt flag FLXA0FREIR.EDB is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

(10) FLXA0FRACS.VFRA

Valid Frame Received on Channel A Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

One or more valid frames were received on channel A in any static or dynamic slot during the observation period.

Reset when leaving CONFIG state or when entering STARTUP state.

17.2.7.10 FLXA0FRESIDn — FlexRay Even Sync ID Register n (n = 1 to 15)

Registers FLXA0FRESID1 to FLXA0FRESID15 hold the frame IDs of the sync frames received in even communication cycles used for clock synchronization up to the limit of gSyncNodeMax. The values are sorted in ascending order, with register FLXA0FRESID1 holding the lowest received sync frame ID. If the node itself transmits a sync frame in an even communication cycle, register FLXA0FRESID1 holds the respective sync frame ID as configured in message buffer 0 and flags FLXA0FRESID1.RXEA, FLXA0FRESID1.RXEB are set. The value is updated during the NIT of each even communication cycle.

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0130_H to ERAY + 0168_H (ERAY + 0130_H + (n - 1)*4)

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RXEB	RXEA	—	—	—	—	EID[9:0]									
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 17.48 FLXA0FRESIDn (n = 1 to 15) Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. When writing, always write 0.
15	RXEB	Received/Configured Even Sync ID on Channel B Flag 0: No sync frame received on channel B or node not configured to transmit sync frames 1: Sync frame received on channel B or node configured to transmit sync frames
14	RXEA	Received/Configured Even Sync ID on Channel A Flag 0: No sync frame received on channel A or node not configured to transmit sync frames 1: Sync frame received on channel A or node configured to transmit sync frames
13 to 10	—	Reserved These bits are always read as 0. When writing, always write 0.
9 to 0	EID[9:0]	Even Sync ID Flags (vsSyncIDListA,B even)

(1) FLXA0FRESIDn.RXEB

Received/Configured Even Sync ID on Channel B Flag

Signals that a sync frame corresponding to the stored even sync ID was received on channel B or that the node is configured to be a sync node with key slot indicated by the FLXA0FRESID1.EID.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXA0FRESIDn.RXEA

Received/Configured Even Sync ID on Channel A Flag

Signals that a sync frame corresponding to the stored even sync ID was received on channel A or that the node is configured to be a sync node with key slot indicated by the FLXA0FRESID1.EID.

Reset when leaving CONFIG state or when entering STARTUP state.

(3) FLXA0FRESIDn.EID

Even Sync ID Flags (vsSyncIDListA, B even)

Sync frame ID even communication cycle

Reset when leaving CONFIG state or when entering STARTUP state.

17.2.7.11 FLXA0FROSIDn — FlexRay Odd Sync ID Register n (n = 1 to 15)

Registers FLXA0FROSID1 to FLXA0FROSID15 hold the frame IDs of the sync frames received in odd communication cycles used for clock synchronization up to the limit of gSyncNodeMax. The values are sorted in ascending order, with register FLXA0FROSID1 holding the lowest received sync frame ID. If the node itself transmits a sync frame in an odd communication cycle, register FLXA0FROSID1 holds the respective sync frame ID as configured in message buffer 0 and flags FLXA0FROSID1.RXOA and FLXA0FROSID1.RXOB are set. The value is updated during the NIT of each odd communication cycle.

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0170_H to ERAY + 01A8_H (ERAY + 0170_H + (n - 1)*4)

Value after reset: 0000 0000_H

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	

Table 17.49 FLXA0FROSIDn Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. When writing, always write 0.
15	RXOB	Received/Configured Odd Sync ID on Channel B Flag 0: No sync frame received on channel B or node not configured to transmit sync frames 1: Sync frame received on channel B or node configured to transmit sync frames
14	RXOA	Received/Configured Odd Sync ID on Channel A Flag 0: No sync frame received on channel A or node not configured to transmit sync frames 1: Sync frame received on channel A or node configured to transmit sync frames
13 to 10	—	Reserved These bits are always read as 0. When writing, always write 0.
9 to 0	OID[9:0]	Odd Sync ID Flags (vsSyncIDListA,B odd)

(1) FLXA0FROSIDn.RXOB

Received/Configured Odd Sync ID on Channel B Flag

Signals that a sync frame corresponding to the stored odd sync ID was received on channel B or that the node is configured to be a sync node with key slot = FLXA0FROSID1.OID.

Reset when leaving CONFIG state or when entering STARTUP state.

(2) FLXA0FROSIDn.RXOA

Received/Configured Odd Sync ID on Channel A Flag

Signals that a sync frame corresponding to the stored odd sync ID was received on channel A or that the node is configured to be a sync node with key slot = FLXA0FRISID1.OID.

Reset when leaving CONFIG state or when entering STARTUP state.

(3) FLXA0FROSIDn.OID

Odd Sync ID Flags (vsSyncIDListA,B odd)

Sync frame ID odd communication cycle.

Reset when leaving CONFIG state or when entering STARTUP state.

17.2.7.12 FLXA0FRNMVn — FlexRay Network Management Vector Register n (n = 1 to 3)

The three network management registers hold the accrued NM vector (see **Section 17.3.7, Network Management**).

The CC updates the NM vector at the end of each communication cycle as long as the CC is either in NORMAL_ACTIVE or NORMAL_PASSIVE state.

NMVn-bytes exceeding the configured NM vector length are not valid.

For information about the byte alignment of the received NM vector in this register see **Section 17.3.17, Byte Alignment**.

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 01B0_H to ERAY + 01B8_H (ERAY + 01B0_H + (n - 1)*4)

Value after reset: 0000 0000_H

	NM[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 17.50 FLXA0FRNMVn Register Contents

Bit Position	Bit Name	Function
31 to 0	NM[31:0]	<p>NM Vector the three network management vector registers hold the accrued NM vector (configurable 0 to 12 bytes). The NM vector to be held is generated by bit-wise logic OR for each NM vector received on each channel (valid static frames with PPI = '1') (see Section 17.3.7, Network Management).</p> <p>For information about the byte alignment of the received NM vector in this register, see Section 17.3.17, Byte Alignment.</p> <p>NMVn-bytes exceeding the configured NM vector length are not valid.</p> <p>The register contents are updated at the end of each communication cycle as long as the CC is either in NORMAL_ACTIVE or NORMAL_PASSIVE state.</p> <p>These bits are cleared when leaving CONFIG state or when entering STARTUP state.</p>

17.2.8 Message Buffer Control Registers

17.2.8.1 FLXA0FRMRC — FlexRay Message RAM Configuration Register

The message RAM configuration register defines the number of message buffers assigned to the static segment, dynamic segment, and FIFO.

The message RAM can be divided into up three different areas; static buffer area, static and dynamic buffer area, FIFO area. If present, the static buffer area is starting at message buffer 0.

The start of the static and dynamic buffer area is configured by FLXA0FRMRC.FDB.

FLXA0FRMRC.FDB defines the end of the static buffer area. If no static buffer area is present, the static and dynamic buffer area starts at message buffer 0.

The start of the FIFO area is configured by FLXA0FRMRC.FFB. FLXA0FRMRC.FFB defines the end of the previous area, which can be either the static buffer area or the static and dynamic buffer area.

If no static buffer area and no static and dynamic buffer area is present, the FIFO area starts at message buffer 0.

With FLXA0FRMRC.LCB, the end of the last configured area is configured which can be the static buffer area, the static and dynamic buffer area, or the FIFO area.

Figure 17.2 shows an example configuration of the message RAM where all these areas are configured.

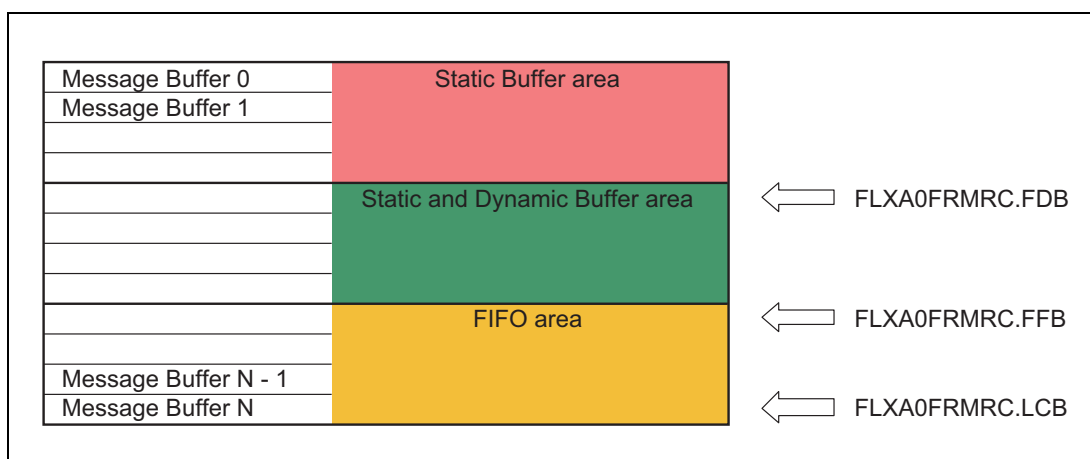

Figure 17.2 Message RAM Organization

NOTES

1. In case the node is configured as sync node (FLXA0FRSUCC1.TXSY = '1') or for single slot mode operation (FLXA0FRSUCC1.TSM = '1'), message buffer 0 and 1 are reserved for sync frames or single slot frames and have to be configured with the node-specific key slot ID. In case the node is neither configured as sync node nor for single slot operation message buffer 0 and 1 are treated like all other message buffers.
2. The maximum number of header sections is 128. This means a maximum of 128 message buffers can be configured. The maximum length of a data section is 254 bytes. The length of the data section can be configured separately for each message buffer. For details see **Section 17.3.13, Message RAM**.
3. In case two or more message buffers are assigned to slot 1 by use of cycle filtering, all of them must be located either in the "static buffers" or at the beginning of the "static + dynamic buffers" section.

4. The FlexRay protocol specification requires that each node has to send a frame in its key slot. Therefore at least message buffer 0 is reserved for transmission in the key slot. Due to this requirement a maximum number of 127 message buffers can be assigned to the FIFO. Nevertheless, a non-protocol-conforming configuration without a transmission slot in the static segment would still be operational.
5. The payload length and the length of the data section need to be configured identical for all message buffers belonging to the FIFO via FLXA0FRWRHS2.PLC and FLXA0FRWRHS3.DP. When the CC is not in DEFAULT_CONFIG or CONFIG state reconfiguration of message buffers belonging to the FIFO is locked.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0300_H

Table 17.51 FLXA0FRMRC Register Contents

Bit Position	Bit Name	Function
31 to 27	—	Reserved These bits are always read as 0. When writing, always write 0.
26	SPLM	Sync Frame Payload Multiplex 0: Writing to message buffer 0 is prohibited. 1: Writing to message buffer 0 or 1 is prohibited.
25, 24	SEC[1:0]	Secure Buffers 00: Writing is enabled for all buffers. 01: Writing is prohibited to static buffer and FIFO, limited transmission 10: Writing is prohibited for all buffers. 11: Writing is prohibited for all buffers, limited transmission
23 to 16	LCB[7:0]	Last Configured Buffer 0 to 127: Number of message buffers is FLXA0FRMRF.LCB + 1 128: No message buffer configured
15 to 8	FFB[7:0]	First Buffer of FIFO 0: All message buffers assigned to the FIFO 1 to 127: Message buffers from FLXA0FRMRC.FFB to FLXA0FRMRC.LCB assigned to the FIFO 128: No message buffer configured
7 to 0	FDB[7:0]	First Dynamic Buffer 0: No group of message buffers exclusively for the static segment configured 1 to 127: Message buffers 0 to FLXA0FRMRC.FDB - 1 reserved for static segment 128: No dynamic message buffers configured

(1) FLXA0FRMRC.SPLM

Sync Frame Payload Multiplex

The user can only write to this bit when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

This bit is only enabled if the node is configured as sync node (FLXA0FRSUCC1.TXSY = '1') or for single slot mode operation (FLXA0FRSUCC1.TSM = '1').

When this bit is set to '1', message buffers 0 and 1 are dedicated for sync frame transmission with separate payload data on channel A and B.

When this bit is set to '0', sync frames are transmitted from message buffer 0 with the same payload data on all channels configured. Note that the channel filter configuration for message buffer 0 and message buffer 1 are selected according to this SPLM bit setting.

(2) FLXA0FRMRC.SEC

Secure Buffer

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

These bits are disabled when the CC is in DEFAULT_CONFIG or CONFIG state.

For temporary unlocking, see **Section 17.3.13.4, Host Handling of Access Errors**.

00 = Writing is enabled for any buffers.

Reconfiguration of message buffers enabled with numbers < FLXA0FRMRC.FFB enabled

Exception: In nodes configured for sync frame transmission or for single slot mode operation, writing to message buffer 0 (and if FLXA0FRMRC.SPLM = '1', also message buffer 1) is prohibited.

01 = static buffers locked, FIFO locked, limited transmission

Reconfiguration of message buffers with numbers < FLXA0FRMRC.FDB and with numbers \geq FLXA0FRMRC.FFB locked and transmission of message buffers for static segment with numbers \geq FLXA0FRMRC.FDB disabled

10 = all buffers locked

Writing to any message buffers is prohibited.

11 = Writing to any buffers is prohibited.

Reconfiguration of all message buffers locked and transmission of message buffers for static segment with numbers \geq FLXA0FRMRC.FDB disabled

(3) FLXA0FRMRC.LCB

Last Buffer Setting

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

When a Static and Dynamic Buffer area is configured (FLXA0FRMRC.FDB < 128), the user should configure FLXA0FRMRC.LCB \geq FLXA0FRMRC.FDB.

When a FIFO area is configured (FLXA0FRMRC.FFB < 128), the user should configure FLXA0FRMRC.LCB \geq FLXA0FRMRC.FFB.

(4) FLXA0FRMRC.FFB

FIFO First Buffer Setting

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

When a Static and Dynamic Buffer area is configured (FLXA0FRMRC.FDB < 128), the user should configure FLXA0FRMRC.FFB > FLXA0FRMRC.FDB.

(5) FLXA0FRMRC.FDB

First Dynamic Buffer Setting

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

17.2.8.2 FLXA0FRFRF — FlexRay FIFO Rejection Filter Register

The FIFO Rejection Filter defines a user specified sequence of bits to which channel, frame ID, and cycle count of the incoming frames are compared. Together with the FIFO Rejection Filter Mask Register this register determines whether a message is rejected by the FIFO.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0304_H

Value after reset: 0180 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.52 FLXA0FRFRF Register Contents

Bit Position	Bit Name	Function
31 to 25	—	Reserved These bits are always read as 0. When writing, always write 0.
24	RNF	Reject Null Frames 0: Null frames are stored in the FIFO 1: Reject all null frames
23	RSS	Reject in Static Segment 0: FIFO also used for static segment 1: Reject messages in static segment
22 to 16	CYF[6:0]	Cycle Counter Filter
15 to 13	—	Reserved These bits are always read as 0. When writing, always write 0.
12 to 2	FID[10:0]	Frame ID Filter 0 to 2047: Frame ID filter values
1, 0	CH[1:0]	Channel Filter 00: receive on both channels 01: receive only on channel B 10: receive only on channel A 11: Reception prohibited

(1) FLXA0FRFRF.RNF

Reject Null Frame

The user can only write to this bit when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

If this bit is set to '1', received null frames are not stored in the FIFO.

(2) FLXA0FRFRF.RSS

Reject in Static Segment

The user can only write to this bit when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

If this bit is set to '1', the FIFO is used only for the dynamic segment.

(3) FLXA0FRFRF.CYF

Cycle Counter Filter

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

The 7-bit cycle counter filter determines the cycle set to which frame ID and channel rejection filter are applied. In cycles that are not specified by FLXA0FRFRF.CYF, all frames are rejected. For details about the configuration of the cycle counter filter see **Section 17.3.8.2, Cycle Counter Filtering**.

(4) FLXA0FRFRF.FID

Frame ID Filter

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

Determines the frame ID to be rejected by the FIFO. With the additional configuration of register FLXA0FRFRFM, the corresponding frame ID filter bits are ignored. When FLXA0FRFRFM.MFID is zero, a frame ID filter value of zero means that there is no frame ID to be rejected.

(5) FLXA0FRFRF.CH

Channel Filter

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

If reception on both channels is configured, also in static segment always both frames (from channel A and B) are stored in the FIFO, even if they are identical.

17.2.8.3 FLXA0FRFRFM — FlexRay FIFO Rejection Filter Mask Register

The FlexRay FIFO Rejection Filter Mask Register specifies frame ID filter bits relevant to rejection filtering. If a bit is set to '1', it indicates that the corresponding bit in the FLXA0FRFRF register will not be considered for rejection filtering.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0308_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit Position	Bit Name	Function
31 to 13	—	Reserved These bits are always read as 0. When writing, always write 0.
12 to 2	MFID[10:0]	Mask Frame ID Filter 0: Corresponding frame ID filter bit is used for rejection filtering 1: Ignore corresponding frame ID filter bit.
1, 0	—	Reserved These bits are always read as 0. When writing, always write 0.

(1) FLXA0FRFRFM.MFID

Mask Frame ID Filter

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

17.2.8.4 FLXA0FRFCL — FlexRay FIFO Critical Level Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 030C_H

Value after reset: 0000 0080_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.54 FLXA0FRFCL Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are always read as 0. When writing, always write 0.
7 to 0	CL[7:0]	Critical Level Setting Critical level setting

(1) FLXA0FRFCL.CL

Critical Level Setting

The user can only write to these bits when FLXA0FRCCSV.POCS is DEFAULT_CONFIG or CONFIG.

When the receive FIFO fill level FLXA0FRFSR.RFFL is equal or greater than the critical level configured by FLXA0FRFCL.CL, the receive FIFO critical level flag FLXA0FRFSR.RFCL is set to 1.

If FLXA0FRFCL.CL is programmed to values > 128, bit FLXA0FRFSR.RFCL is never set to 1.

17.2.9 Message Buffer Status Registers

17.2.9.1 FLXA0FRMHDS — FlexRay Message Handler Status Register

Do not rewrite this register using bit-manipulation instruction.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0310_H

Value after reset: 0000 0080_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.55 FLXA0FRMHDS Register Contents

Bit Position	Bit Name	Function
31	—	Reserved This bit is always read as 0. When writing, always write 0.
30 to 24	MBU[6:0]	Message Buffer Updated Flags
23	—	Reserved This bit is always read as 0. When writing, always write 0.
22 to 16	MBT[6:0]	Message Buffer Transmitted Flags
15	—	Reserved This bit is always read as 0. When writing, always write 0.
14 to 8	FMB[6:0]	Faulty Message Buffer Number Flags
7	CRAM	Internal RAM Clear Flag 0: No execution of the CHI command CLEAR_RAMs 1: Execution of the CHI command CLEAR_RAMs ongoing
6	MFMB	Multiple Faulty Message Buffer Detection Flag 0: No additional faulty message buffer 1: Additional faulty message buffer was detected while the FMBD flag is set to 1.
5	FMBD	Faulty Message Buffer Detection Flag 0: No faulty message buffer 1: Message buffer referenced by FLXA0FRMHDS.FMB holds faulty data with a parity error.
4	ATBF2	Temporary Buffer RAM B Access Error Flag 0: No access error 1: Access error occurred when reading the RAM B.
3	ATBF1	Temporary Buffer RAM A Access Error Flag 0: No access error 1: Access error occurred when reading the RAM A.
2	AMR	Message RAM Access Error Flag 0: No access error 1: Access error occurred when reading the message RAM.
1, 0	—	Reserved These bits are always read as 0. When writing, always write 0

(1) FLXA0FRMHDS.MBU

Message Buffer Updated Flags

These flags indicate the number of message buffer that was updated last by the CC. For this message buffer the respective ND and/or MBC flag in the FLXA0FRNDAT1/2/3/4 registers and the FLXA0FRMBSC1/2/3/4 registers are also set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(2) FLXA0FRMHDS.MBT

Message Buffer Transmitted Flags

These flags indicate the number of last successfully transmitted message buffer.

If the message buffer is configured for single-shot mode, the respective TXR flag in the FLXA0FRTXRQ1/2/3/4 registers are reset to '0'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(3) FLXA0FRMHDS.FMB

Faulty Message Buffer Number Flags

These flags indicate that an access error occurred when reading from the message buffer referenced by FLXA0FRMHDS.FMB.

The value of this flag is only valid whenever one of AMR flag, ATBF1 flag, ATBF2 flag, or FMBD flag in the FLXA0FRMHDS register is set to 1.

This flag is not updated while the FLXA0FRMHDS.FMBD flag is 1.

This flag is cleared by the CHI command CLEAR_RAMs.

(4) FLXA0FRMHDS.CRAM

Internal RAM Clear Flag

This flag indicates that the CHI command CLEAR_RAMs is ongoing (all bits of the message RAM, input buffer, output buffer and temporary buffer RAM are written to '0').

This flag is set by the CHI command CLEAR_RAMs.

(5) FLXA0FRMHDS.MFMB

Multiple Faulty Message Buffer Detection Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing '1' to it.

This bit indicates that an additional faulty message buffer was detected while the FMBD flag is set.

This bit is cleared by the CHI command CLEAR_RAMs.

(6) FLXA0FRMHDS.FMBD

Faulty Message Buffer Detection Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing '1' to it.

This bit indicates that the message buffer referenced by FLXA0FRMHDS.FMB holds faulty data due to an access error.

This bit is cleared by the CHI command CLEAR_RAMs.

(7) FLXA0FRMHDS.ATBF2

Temporary Buffer RAM B Access Error Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing '1' to it.

This flag indicates that an access error occurred when reading the temporary buffer RAM B.

NOTE

When this flag changes from '0' to '1', the AERR bit in the FLXA0FREIR register is set to '1'. This flag can be reset by the CHI command CLEAR_RAMs.

(8) FLXA0FRMHDS.ATBF1

Temporary Buffer RAM A Access Error Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing '1' to it.

This flag indicates that an access error occurred when reading the temporary buffer RAM A.

NOTE

When this flag changes from '0' to '1', the AERR bit in the FLXA0FREIR register is set to '1'. This flag can be reset by the CHI command CLEAR_RAMs.

(9) FLXA0FRMHDS.AMR

Message RAM Access Error Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing '1' to it.

This flag indicates that an access error occurred when reading the message RAM.

NOTE

When this flag changes from '0' to '1', the AERR bit in the FLXA0FREIR register is set to '1'. This flag can be reset by the CHI command CLEAR_RAMs.

17.2.9.2 FLXA0FRLDTS — FlexRay Last Dynamic Transmit Slot Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0314_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	LDTB[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 17.56 FLXA0FRLDTS Register Contents

Bit Position	Bit Name	Function
31 to 27	—	Reserved These bits are always read as 0. When writing, always write 0.
26 to 16	LDTB[10:0]	Last Dynamic Transmission Channel B Flags
15 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	LDTA[10:0]	Last Dynamic Transmission Channel A Flags

(1) FLXA0FRLDTS.LDTB

Last Dynamic Transmission Channel B Flags

Store the value of vSlotCounter at the time of the last frame transmission on channel B in the dynamic segment.

It is updated at the end of the dynamic segment and is reset to zero if no frame was transmitted during the dynamic segment.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(2) FLXA0FRLDTS.LDTA

Last Dynamic Transmission Channel A Flags

Store the value of vSlotCounter at the time of the last frame transmission on channel A in the dynamic segment.

It is updated at the end of the dynamic segment and is reset to zero if no frame was transmitted during the dynamic segment.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

17.2.9.3 FLXA0FRFSR — FlexRay FIFO Status Register

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0318_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFFL[7:0]							—	—	—	—	—	RFO	RFCL	RFNE	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 17.57 FLXA0FRFSR Register Contents

Bit Position	Bit Name	Function
31 to 16	—	Reserved These bits are always read as 0. When writing, always write 0.
15 to 8	RFFL[7:0]	Receive FIFO Fill Level Flags
7 to 3	—	Reserved These bits are always read as 0. When writing, always write 0.
2	RFO	Receive FIFO Overrun Flag 0: No receive FIFO overrun is detected 1: A receive FIFO overrun has been detected
1	RFCL	Receive FIFO Critical Level Flag 0: Receive FIFO is below critical level 1: Receive FIFO critical level is reached
0	RFNE	Receive FIFO Not Empty Flag 0: Receive FIFO is empty 1: Receive FIFO is not empty

(1) FLXA0FRFSR.RFFL

Receive FIFO Fill Level Flags

Indicate the number of FIFO buffers filled with new data not yet read by the host. Maximum value is 128.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(2) FLXA0FRFSR.RFO

Receive FIFO Overrun Flag

The flag is set to '1' by the CC when a receive FIFO overrun is detected.

When a receive FIFO overrun occurs, the oldest message is overwritten with the actual received message. In addition, interrupt flag FLXA0FREIR.RFO is set to '1'.

The flag is cleared when the FIFO is read.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(3) FLXA0FRFSR.RFCL

Receive FIFO Critical Level Flag

This flag is set to '1' when the receive FIFO fill level FLXA0FRFSR.RFFL is equal or greater than the critical level as configured by FLXA0FRFCL.CL.

When FLXA0FRFSR.RFCL changes from '0' to '1' bit FLXA0FRSIR.RFCL is set to '1', and if enabled, an interrupt is generated.

The flag is cleared by the CC as soon as FLXA0FRFSR.RFFL drops below FLXA0FRFCL.CL.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(4) FLXA0FRFSR.RFNE

Receive FIFO Not Empty Flag

This flag is set to '1' by the CC when a received valid frame (data or null frame depending on rejection mask) was stored in the FIFO. In addition, interrupt flag FLXA0FRSIR.RFNE is set to '1'.

The bit is reset to '0' after the host has read all messages from the FIFO.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

17.2.9.4 FLXA0FRMHDF — FlexRay Message Handler Constraints Flags Register

Do not rewrite this register using bit-manipulation instruction.

Some constraints exist for the message handler regarding bus clock frequency, message RAM configuration, and FlexRay bus traffic. To simplify software development, constraints violations are reported by setting flags in the FLXA0FRMHDF.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 031C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.58 FLXA0FRMHDF Register Contents

Bit Position	Bit Name	Function
31 to 9	—	Reserved These bits are always read as 0. When writing, always write 0.
8	WAHP	Write Attempt to Header Partition Flag 0: No write attempt to header partition 1: A write attempt to header partition
7	TNSB	Transmission Not Started Channel B Flag 0: No transmission not started on channel B 1: Transmission not started on channel B
6	TNSA	Transmission Not Started Channel A Flag 0: No transmission not started on channel A 1: Transmission not started on channel A
5	TBFB	Temporary Buffer Access Failure B Flag 0: No TBF B access failure 1: TBF B access failure
4	TBFA	Temporary Buffer Access Failure A Flag 0: No TBF A access failure 1: TBF A access failure
3	FNFB	Find Sequence Not Finished Channel B Flag 0: No find sequence not finished for channel B 1: Find sequence not finished for channel B
2	FNFA	Find Sequence Not Finished Channel A Flag 0: No find sequence not finished for channel A 1: Find sequence not finished for channel A
1	SNUB	Status Not Updated Channel B Flag 0: No overload condition occurred when updating MBS for channel B 1: Message buffer status (FLXA0FRMBS) for channel B not updated
0	SNUA	Status Not Updated Channel A Flag 0: No overload condition occurred when updating MBS for channel A 1: Message buffer status (FLXA0FRMBS) for channel A not updated

(1) FLXA0FRMHDF.WAHP

Write Attempt to Header Partition Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

Outside DEFAULT_CONFIG and CONFIG state this flag is set to '1' when the message handler tries to write message data into the header partition of the message RAM due to faulty configuration of a message buffer. The write attempt is not executed, to protect the header partition from unintended write accesses.

When this flag changes from '0' to '1' in addition interrupt flag FLXA0FREIR.MHF is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(2) FLXA0FRMHDF.TNSB Flag

Transmission Not Started Channel B

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set to '1' when the message handler was not ready to start a scheduled transmission on channel B at the action point of the configured slot.

When this flag changes from '0' to '1', interrupt flag FLXA0FREIR.MHF is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(3) FLXA0FRMHDF.TNSA

Transmission Not Started Channel A Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set when the message handler was not ready to start a scheduled transmission on channel A at the action point of the configured slot.

When this flag changes from '0' to '1', interrupt flag FLXA0FREIR.MHF is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(4) FLXA0FRMHDF.TBFB

Temporary Buffer Access Failure B Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set to '1' when a read or write access to TBF B requested by PRT (protocol controller) B could not complete within the specified time.

When this flag changes from '0' to '1', interrupt flag FLXA0FREIR.MHF is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(5) FLXA0FRMHDF.TBFA

Temporary Buffer Access Failure A Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set to '1' by the CC when a read or write access to TBF A requested by PRT A could not complete within the specified time.

When this flag changes from '0' to '1', interrupt flag FLXA0FREIR.MHF is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(6) FLXA0FRMHDF.FNFB

Find Sequence Not Finished Channel B Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set to '1' when the message handler, due to overload condition, was not able to finish a find sequence (scan of message RAM for matching message buffer).

When this flag changes from '0' to '1', interrupt flag FLXA0FREIR.MHF is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(7) FLXA0FRMHDF.FNFA

Find Sequence Not Finished Channel A Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set to '1' when the message handler, due to overload condition, was not able to finish a find sequence (scan of message RAM for matching message buffer).

When this flag changes from '0' to '1', interrupt flag FLXA0FREIR.MHF is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(8) FLXA0FRMHDF.SNUB

Status Not Updated Channel B Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set to '1' when the message handler, due to overload condition, was not able to update a message buffer's status MBS.

When this flag changes from '0' to '1', interrupt flag FLXA0FREIR.MHF is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

(9) FLXA0FRMHDF.SNUA

Status Not Updated Channel A Flag

Writing '0' has no effect on the bit value.

This bit is cleared when writing a '1' to it.

This flag is set to '1' when the message handler, due to overload condition, was not able to update a message buffer's status MBS.

When this flag changes from '0' to '1', interrupt flag FLXA0FREIR.MHF is set to '1'.

Reset when leaving CONFIG state or when entering STARTUP state.

Reset by the CHI command CLEAR_RAMs.

17.2.9.5 FLXA0FRTXRQi — FlexRay Transmission Request i (i = 1 to 4)

The four registers reflect the state of the TXR flags of all configured message buffers. The flags are evaluated for transmit buffers only. If the number of configured message buffers is less than 128, the remaining TXR flags have no meaning.

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0320_H to ERAY + 032C_H (ERAY + 0320_H + (i - 1)*4)

Bit Position	Bit Name	Function
31 to 0	TXRo	Transmission Request Flag o

(1) FLXA0FRTXRQi.TXRo (o = (i-1)*32 to (i*32-1))

Transmission Request Flag o

If the flag is set to '1', the respective message buffer is ready for transmission or transmission of this message buffer is in progress.

In single-shot mode the flags are reset to '0' after transmission has completed.

This bit is cleared by the CHI command CLEAR_RAMs.

17.2.9.6 FLXA0FRNDAT_i — FlexRay New Data Register *i* (*i* = 1 to 4)

The four registers reflect the state of the ND flags of all configured message buffers. ND flags belonging to transmit buffers have no meaning. If the number of configured message buffers is less than 128, the remaining ND flags have no meaning.

Access: This register can be read only in 8-, 16-, or 32-bit units.

Table 17.60 FLXA0FRNDAT_i Register Contents

Bit Position	Bit Name	Function
31 to 0	ND _n	New Data Flag <i>n</i>

(1) FLXA0FRNDAT_i.ND_n (n = (i-1)*32 to (i*32-1))

New Data Flag *n*

The flags are set to '1' when a valid received data frame matches the message buffer's filter configuration, independent of the payload length received or the payload length configured for that message buffer.

The flags are not set to '1' after reception of null frames except for message buffers belonging to the receive FIFO.

An ND flag is reset to '0' when the header section of the corresponding message buffer is reconfigured or when the data section has been transferred to the output buffer.

Reset when leaving CONFIG state or when entering STARTUP state.

This bit is cleared by the CHI command CLEAR_RAMs.

17.2.9.7 FLXA0FRMBSCi — FlexRay Message Buffer Status Changed Register i (i = 1 to 4)

The four registers reflect the state of the MBC flags of all configured message buffers. If the number of configured message buffers is less than 128, the remaining MBC flags have no meaning.

Access: This register can be read only in 8-, 16-, or 32-bit units.

Address: ERAY + 0340_H to ERAY + 034C_H (ERAY + 0340_H + (i - 1)*4)

Table 17.61 FLXA0FRMBSCi (i = 1 to 4) Register Contents

Bit Position	Bit Name	Function
31 to 0	MBCm	Message Buffer Status Changed Flag m

(1) FLXA0FRMBSCi.MBCm (m = (i-1)*32 to (i*32-1))

Message Buffer Status Changed Flag m

Indicates whether the message handler has changed one of the status flags VFRA, VFRB, SEOA, SEOB, CEOA, CEOB, SVOA, SVOB, TCIA, TCIB, ESA, ESB, MLST, FTA, FTB in the header section (see **Section 17.2.11.5, FLXA0FRMBS — FlexRay Message Buffer Status Register** and **Section 17.3.13.1, Header Partition** of the respective message buffer.

An MBC flag is reset to '0' when the header section of the corresponding message buffer is reconfigured or when it has been transferred to the output buffer.

Reset when leaving CONFIG state or when entering STARTUP state.

This bit is cleared by the CHI command CLEAR_RAMs.

17.2.10 Input Buffer

The input buffer (IBF) has a double structure of IBF host and IBF shadow. While the host can write to IBF host, the transfer to the message RAM is done from IBF shadow. The input buffer holds the header and data sections to be transferred to the selected message buffer in the message RAM. It is used to configure the message buffers in the message RAM and to update the data sections of transmit buffers.

When updating the header section of a message buffer in the message RAM from the input buffer, the message buffer status as described in **Section 17.2.11.5, FLXA0FRMBS — FlexRay Message Buffer Status Register** is automatically reset to 0.

The header sections of message buffers belonging to the receive FIFO can only be configured or reconfigured when the CC is in DEFAULT_CONFIG or CONFIG state. For those message buffers, only the payload length and the data pointer can be configured via FLXA0FRWRHS2.PLC and FLXA0FRWRHS3.DP. All information required for acceptance filtering is taken from the FIFO rejection filter and the FIFO rejection filter mask registers.

The data transfer between input buffer (IBF) and message RAM is described in detail in **Section 17.3.12.2, Host Access to Message RAM**.

These registers cannot be written when the input data transfer function shown in **Section 17.3.16.1, Input Data Transfer** is used and the FLXA0FRITS.ITS bit is 1.

17.2.10.1 FLXA0FRWRDSn — FlexRay Write Data Section Register n (n = 1 to 64)

This register holds the data words to be transferred to the data section of the specified message buffer. The number of data words (DW_n) written to the message RAM is defined by the payload length configured in the FLXA0FRWRHS2.PLC bit.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0400_H to ERAY + 04FC_H(ERAY + 0400_H + (n - 1)*4)

Value after reset: 0000 0000_H

Table 17.62 FLXA0FRWRDSn Register Contents

Bit Position	Bit Name	Function
31 to 0	MD[31:0]	Message Data

(1) FLXA0FRWRDSn.MD

Message Data Bits

For information about the byte alignment of the message data in this register see **Section 17.3.17, Byte Alignment**.

NOTE

1. In case FLXA0FRWRHS2.PLC specifies an odd payload length, the remaining message data bytes are unused.
2. When writing to FLXA0FRWRDSn, each 32-bit word has to be filled up by access in a single 32-bit unit, in two consecutive 16-bit units, or in four consecutive 8-bit units before transfer from the input buffer to the message RAM will start. If not all bytes of a 32-bit word have been written by the host (8- or 16-bit access only), FLXA0FRWRDSn holds partly undefined data.
Reset by the CHI command CLEAR_RAMs.

17.2.10.2 FLXA0FRWRHS1 — FlexRay Write Header Section Register 1

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0500_H

Value after reset: 0000 0000_H

Table 17.63 FLXA0FRWRHS1 Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29	MBI	Message Buffer Interrupt 0: The corresponding message buffer interrupt is disabled 1: The corresponding message buffer interrupt is enabled
28	TXM	Transmission Mode 0: Continuous mode 1: Single-shot mode
27	PPIT	Payload Preamble Indicator Transmit 0: Payload Preamble Indicator is set to '0' 1: Payload Preamble Indicator is set to '1'
26	CFG	Message Buffer Direction Configuration 0: The corresponding buffer is configured as receive buffer 1: The corresponding buffer is configured as transmit buffer
25, 24	CH[1:0]	Channel Filter Control
23	—	Reserved This bit is always read as 0. When writing, always write 0.
22 to 16	CYC[6:0]	Cycle Code
15 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	FID[10:0]	Frame ID

(1) FLXA0FRWRHS1.MBI

Message Buffer Interrupt Enable

This bit enables the receive/transmit interrupt for the corresponding message buffer.

After a dedicated receive buffer has been updated by the message handler, flag FLXA0FRSIR.RXI and/or FLXA0FRSIR.MBSI are set to '1'. After a transmission has completed, flag FLXA0FRSIR.TXI is set to '1'.

(2) FLXA0FRWRHS1.TXM

Transmission Mode Setting

This bit selects transmit mode of the corresponding message buffer. For transmit mode, see **Section 17.3.9.3, Transmit Buffers**.

(3) FLXA0FRWRHS1.PPIT

Payload Preamble Indicator Transmit

This bit is used to control the state of the Payload Preamble Indicator in transmit frames in transmit frames of the corresponding message buffer.

If the bit is set to '1' in a static message buffer, the respective message buffer holds network management information.

If the bit is set to '1' in a dynamic message buffer, the first two bytes of the payload segment may be used for message ID filtering by the receiver. Message ID filtering of received FlexRay frames is not supported by the FlexRay module, but can be done by the host.

(4) FLXA0FRWRHS1.CFG

Message Buffer Direction Configuration

This bit is used to configure the corresponding buffer as transmit buffer or as receive buffer. For message buffers belonging to the receive FIFO the bit is disabled.

If an unused area of at least 32 bits is not allocated at the start of the data partition, set this bit to 1 to select allocation of the data section of the message buffer as a transmission buffer immediately following (after the last buffer of) the header partition.

(5) FLXA0FRWRHS1.CH

Channel Filter Control

The 2-bit channel filtering field associated with each buffer serves as a filter for receive buffers, and as a control field for transmit buffers.

CH[1:0]	Transmit Buffer transmit frame on	Receive Buffer store frame received from
00	Transmission prohibited	ignore frame
01	channel A	channel A
10	channel B	channel B
11	both channels (static segment only)	channel A or B (store first semantically valid frame; static segment only)

NOTE

If a message buffer is configured for the dynamic segment and both bits of the channel filtering field are set to '1', no transmission nor reception of frames is performed. (same function as CH = "00")

(6) FLXA0FRWRHS1.CYC

Cycle Code

The 7-bit cycle code determines the cycle set used for cycle counter filtering.

For details about the configuration of the cycle code **Section 17.3.8.2, Cycle Counter Filtering**.

(7) FLXA0FRWRHS1.FID

Frame ID

Frame ID of the selected message buffer. The frame ID defines the slot number for transmission/reception of the respective message.

Message buffers with frame ID = '0' are considered as invalid.

17.2.10.3 FLXA0FRWRHS2 — FlexRay Write Header Section Register 2

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0504_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	PLC[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	CRC[10:0]										
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 17.64 FLXA0FRWRHS2 Register Contents

Bit Position	Bit Name	Function
31 to 23	—	Reserved These bits are always read as 0. When writing, always write 0.
22 to 16	PLC[6:0]	Payload Length Configured
15 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	CRC[10:0]	Header CRC (vRF!Header!HeaderCRC) Receive Buffer: Configuration is not required Transmit Buffer: Header CRC is configured

(1) FLXA0FRWRHS2.PLC

Payload Length Configured

Length of data section (number of 2-byte words) as configured by the host.

During static segment the static frame payload length as configured by FLXA0FRMHDC.SFDL defines the payload length for all static frames. If the payload length configured by FLXA0FRWRHS2.PLC is shorter than this value padding bytes are inserted to ensure that frames have proper physical length. The padding pattern is “0000_H” (see **Section 17.3.9.3, Transmit Buffers**).

(2) FLXA0FRWRHS2.CRC

Header CRC (vRF!Header!HeaderCRC)

Setting of the receive buffer is not required.

Transmitting of the message buffer needs the header CRC calculation and setting.

For calculation of the header CRC, the payload length of the frame to be sent has to be considered. In static segment the payload length of all frames is configured by FLXA0FRMHDC.SFDL.

17.2.10.4 FLXA0FRWRHS3 — FlexRay Write Header Section Register 3

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0508_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 17.65 FLXA0FRWRHS3 Register Contents

Bit Position	Bit Name	Function
31 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	DP[10:0]	Data Pointer

(1) FLXA0FRWRHS3.DP

Data Pointer

Configures the pointer to the first 32-bit word of the data section of the addressed message buffer in the message RAM.

17.2.10.5 FLXA0FRIBCM — FlexRay Input Buffer Command Mask Register

Configures how the message buffer in the message RAM selected by register FLXA0FRIBCR is updated. When IBF host and IBF shadow are swapped, also mask bits FLXA0FRIBCM.LHSH, FLXA0FRIBCM.LDSH, and FLXA0FRIBCM.STXRH are swapped with bits FLXA0FRIBCM.LHSS, FLXA0FRIBCM.LDSS, and FLXA0FRIBCM.STXRS.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0510_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	STXRS	LDSS	LHSS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	STXRH	LDSH	LHSH
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Table 17.66 FLXA0FRIBCM Register Contents

Bit Position	Bit Name	Function
31 to 19	—	Reserved These bits are always read as 0. When writing, always write 0.
18	STXRS	Transmission Request Shadow Set Flag 0: Reset TXR flag 1: Set TXR flag, transmit buffer released for transmission (operation ongoing or finished)
17	LDSS	Data Section Shadow Load Flag 0: Data section is not updated 1: Data section is transferred (transfer ongoing or finished)
16	LHSS	Header Section Shadow Load Flag 0: Header section is not updated 1: Header is transferred (transfer ongoing or finished)
15 to 3	—	Reserved These bits are always read as 0. When writing, always write 0.
2	STXRH	Transmission Request Host Set Flag 0: Reset TXR flag 1: Set TXR flag, transmit buffer released for transmission
1	LDSH	Data Section Host Load Flag 0: Data section is not updated 1: Data section is transferred
0	LHSH	Header Section Host Load Flag 0: Header section is not updated 1: Header is transferred

(1) FLXA0FRIBCM.STXRS

Transmission Request Shadow Set Flag

(2) FLXA0FRIBCM.LDSS

Data Section Shadow Load Flag

(3) FLXA0FRIBCM.LHSS

Header Section Shadow Load Flag

(4) FLXA0FRIBCM.STXRH

Transmission Request Host Set Flag

If this bit is set to '1', the TXR flag for the selected message buffer is set in the FLXA0FRTXRQ1/2/3/4 registers to release the message buffer for transmission. In single-shot mode the flag is cleared after transmission has completed.

TXR is enabled for transmit buffers only.

(5) FLXA0FRIBCM.LDSH

Data Section Host Load Flag

(6) FLXA0FRIBCM.LHSH

Header Section Host Load Flag

17.2.10.6 FLXA0FRIBCR — FlexRay Input Buffer Command Request Register

When the host writes the number of the target message buffer in the message RAM to FLXA0FRIBCR.IBRH,

IBF host and IBF shadow are switched. In addition the message buffer numbers stored under FLXA0FRIBCR.IBRH and FLXA0FRIBCR.IBRS are also switched (see **Section 17.3.12.2 (1), Data Transfer from Input Buffer to Message RAM**).

With this write operation, the FLXA0FRIBCR.IBSYS is set to '1'. The message handler then starts to transfer the contents of IBF shadow to the message buffer in the message RAM selected by FLXA0FRIBCR.IBRS.

After the transfer between IBF shadow and the message RAM has completed, FLXA0FRIBCR.IBSYS is set back to '0' and the next transfer to the message RAM may be started by the host by writing the respective target message buffer number to FLXA0FRIBCR.IBRH.

If a write access to FLXA0FRIBCR.IBRH occurs while FLXA0FRIBCR.IBSYS is '1', FLXA0FRIBCR.IBSYH is set to '1'. After completion of the ongoing data transfer from IBF Shadow to the message RAM, IBF host and IBF shadow are switched, FLXA0FRIBCR.IBSYH is reset to '0'. FLXA0FRIBCR.IBSYS remains set to '1', and the next transfer to the message RAM is started. In addition the message buffer numbers stored under FLXA0FRIBCR.IBRH and FLXA0FRIBCR.IBRS are also switched.

Any write access to an input buffer register while both FLXA0FRIBCR.IBSYS and FLXA0FRIBCR.IBSYH are set to '1' will cause the error flag FLXA0FREIR.IIBA to be set to '1'. In this case, this write access has no effect and the input buffer will not be changed.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0514_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.67 FLXA0FRIBCR Register Contents (1/2)

Bit Position	Bit Name	Function
31	IBSYS	Input Buffer Busy Shadow Flag 0: Transfer between IBF shadow and message RAM completed 1: Transfer between IBF shadow and message RAM in progress
30 to 23	—	Reserved These bits are always read as 0. When writing, always write 0.
22 to 16	IBRS[6:0]	Input Buffer Request Shadow Flags
15	IBSYH	Input Buffer Busy Host Flag 0: No request pending 1: Request while transfer between IBF shadow and message RAM in progress

Table 17.67 FLXA0FRIBCR Register Contents (2/2)

Bit Position	Bit Name	Function
14 to 7	—	Reserved These bits are always read as 0. When writing, always write 0.
6 to 0	IBRH[6:0]	Input Buffer Request Host

(1) FLXA0FRIBCR.IBSYS

Input Buffer Busy Shadow Flag

Set to '1' after writing FLXA0FRIBCR.IBRH.

This bit indicates transmitting between the IBF shadow and the message RAM is ongoing.

When the transfer between IBF shadow and the message RAM has completed, FLXA0FRIBCR.IBSYS is set back to '0'.

(2) FLXA0FRIBCR.IBRS

Input Buffer Request Shadow Flags

Number of the target message buffer actually updated or lately updated.

(3) FLXA0FRIBCR.IBSYH

Input Buffer Busy Host Flag

Set to '1' by writing FLXA0FRIBCR.IBRH while FLXA0FRIBCR.IBSYS is still '1'.

This bit indicates transmitting between the IBF shadow and the message RAM is ongoing.

After the ongoing transfer between IBF shadow and the message RAM has completed, the FLXA0FRIBCR.IBSYH is set back to '0'.

(4) FLXA0FRIBCR.IBRH

Input Buffer Request Host

Selects the target message buffer in the message RAM for data transfer from input buffer.

17.2.11 Output Buffer

The output buffer has a double structure of output buffer host and output buffer shadow and is used to read out message buffers from the message RAM. While the host can read from OBF host, the message handler transfers the selected message buffer from message RAM to output buffer shadow. The data transfer between message RAM and OBF is described in **Section 17.3.12.2 (2), Data Transfer from Message RAM to Output Buffer**.

These registers cannot be written when the output data transfer function shown in **Section 17.3.16.2, Output Data Transfer**, in output data transfer is used and the FLXA0FROTS.OTS bit is 1.

17.2.11.1 FLXA0FRRDDSn — FlexRay Read Data Section Register n (n = 1 to 64)

These registers hold the data words read from the data section of the specified message buffer. The number of data word read from the message RAM is defined by the payload length configured in the FLXA0FRRDHS2.PLC bit.

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: $ERAY + 0600_H$ to $ERAY + 06FC_H$ ($ERAY + 0600_H + (n - 1) * 4$)

Value after reset: 0000 0000_H

Table 17.68 FLXA0FRRDDSn Register Contents

Bit Position	Bit Name	Function
31 to 0	MD[31:0]	Message Data Flags

(1) FLXA0FRRDDSn.MD

Message Data Flags

For information about the byte alignment of the data words in this register, see **Section 17.3.17, Byte Alignment**.

NOTE

In case FLXA0FRWRHS2.PLC specifies an odd payload length, the remaining message data bytes are unused.

Reset by the CHI command CLEAR_RAMs.

17.2.11.2 FLXA0FRRDHS1 — FlexRay Read Header Section Register 1

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0700_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.69 FLXA0FRRDHS1 Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29	MBI	Message Buffer Interrupt Enable Flag
28	TXM	Transmission Mode Flag
27	PPIT	Payload Preamble Indicator Transmit Flag
26	CFG	Message Buffer Direction Configuration Bit Flag
25, 24	CH[1:0]	Channel Filter Control Flag
23	—	Reserved This bit is always read as 0. When writing, always write 0.
22 to 16	CYC[6:0]	Cycle Code
15 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	FID[10:0]	Frame ID

(1) FLXA0FRRDHS1.MBI

Message Buffer Interrupt Enable Flag

Values as configured by the host via FLXA0FRWRHS1.MBI.

In case that the message buffer read from the message RAM belongs to the receive FIFO, this bit is set to '0'.

(2) FLXA0FRRDHS1.TXM

Transmission Mode Flag

Values as configured by the host via FLXA0FRWRHS1.TXM.

In case that the message buffer read from the message RAM belongs to the receive FIFO, this bit is set to '0'.

(3) FLXA0FRRDHS1.PPIT

Payload Preamble Indicator Transmit Flag

Values as configured by the host via FLXA0FRWRHS1.PPIT.

In case that the message buffer read from the message RAM belongs to the receive FIFO, this bit is set to '0'.

(4) FLXA0FRRDHS1.CFG

Message Buffer Direction Configuration Flag

Values as configured by the host via FLXA0FRWRHS1.CFG.

In case that the message buffer read from the message RAM belongs to the receive FIFO, this bit is set to '0'.

(5) FLXA0FRRDHS1.CH

Channel Filter Control Flag

Values as configured by the host via FLXA0FRWRHS1.CH.

In case that the message buffer read from the message RAM belongs to the receive FIFO, these bits are set to '0'.

(6) FLXA0FRRDHS1.CYC

Cycle Code

Values as configured by the host via FLXA0FRWRHS1.CYC.

In case that the message buffer read from the message RAM belongs to the receive FIFO, these bits are set to '0'.

(7) FLXA0FRRDHS1.FID

Frame ID

Values as configured by the host via FLXA0FRWRHS1.FID

In case that the message buffer read from the message RAM belongs to the receive FIFO, these bits are holding the received frame ID.

17.2.11.3 FLXA0FRRDHS2 — FlexRay Read Header Section Register 2

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0704_H

Value after reset: 0000 0000_H

CAUTION

For message buffers belonging to the Static Buffer area or Static and Dynamic Buffer area FLXA0FRWRHS2 is updated from data frames only.

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Table 17.70 FLXA0FRRDHS2 Register Contents

Bit Position	Bit Name	Function
31	—	Reserved This bit is always read as 0. When writing, always write 0.
30 to 24	PLR[6:0]	Receive Frame Payload Length Flags (vRF!Header!Length)
23	—	Reserved This bit is always read as 0. When writing, always write 0.
22 to 16	PLC[6:0]	Configured Payload Length Flags
15 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	CRC[10:0]	Header CRC Flags (vRF!Header!HeaderCRC)

(1) FLXA0FRRDHS2.PLR

Receive Frame Payload Length Flags (vRF!Header!Length)

Payload length (vRF!Header!Length) value updated from received data frames (exception: To be updated even through null frames are received in the message buffer specified to the receive FIFO).

(2) FLXA0FRRDHS2.PLC

Configured Payload Length Flags

Length of data section (number of 2-byte words) as configured by the host.

(3) FLXA0FRRDHS2.CRC

Header CRC Flags (vRF!Header!HeaderCRC)

Receive Buffer: Header CRC (vRF!Header!HeaderCRC) updated from received data frames

Transmit Buffer: Header CRC configured by the host

(4) Data storage

When a message is stored into a message buffer the following processes with respect to payload length received and payload length configured are implemented:

FLXA0FRRDHS2.PLR > FLXA0FRRDHS2.PLC:

The payload data stored in the message buffer is truncated to the payload length configured if FLXA0FRRDHS2.PLC even or else truncated to FLXA0FRRDHS2.PLC + 1.

FLXA0FRRDHS2.PLR <= FLXA0FRRDHS2.PLC:

The received payload data is stored into the message buffers data section. The remaining data bytes of the data section as configured by FLXA0FRRDHS2.PLC are filled with undefined value.

FLXA0FRRDHS2.PLR = zero:

The message buffer's data section is filled with undefined value.

FLXA0FRRDHS2.PLC = zero:

No data section is configured in the message buffer. No data is stored into the message buffer's data section.

NOTE

- 1. The message RAM is organized in 4-byte words. When received data is stored into a message buffer's data section, the number of 2-byte data words written into the message buffer is FLXA0FRRDHS2.PLC rounded to the next even value.**
- 2. FLXA0FRRDHS2.PLC should be configured identical for all message buffers belonging to the receive FIFO.
For message buffers belonging to the Static Buffer area or Static and Dynamic Buffer area FLXA0FRWRHS2 is updated from data frames only.**

17.2.11.4 FLXA0FRRDHS3 — FlexRay Read Header Section Register 3

NOTE

For message buffers belonging to the Static Buffer area or Static and Dynamic Buffer area FLXA0FRWRHS3 is updated from data frames only.

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 0708_H

Value after reset: 0000 0000_H

Table 17.71 FLXA0FRRDHS3 Register Contents

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29	RES	Reserved Bit Indicator Flag (vRF!Header!Reserved)
28	PPI	Payload Preamble Indicator Flag (vRF!Header!PPIIndicator)
27	NFI	Null Frame Indicator Flag (vRF!Header!NFIndicator) 0 = Up to now no data frame has been stored into the respective message buffer 1 = At least one data frame has been stored into the respective message buffer
26	SYN	Sync Frame Indicator Flag (vRF!Header!SyFIndicator) 0: The received frame is not a sync frame 1: The received frame is a sync frame
25	SFI	Startup Frame Indicator Flag (vRF!Header!SuFIndicator) 0: The received frame is not a startup frame 1: The received frame is a startup frame
24	RCI	Received on Channel Indicator Flag (vSS!Channel) 0: Frame received on channel B 1: Frame received on channel A
23, 22	—	Reserved These bits are always read as 0. When writing, always write 0.
21 to 16	RCC[5:0]	Receive Cycle Count (vRF!Header!CycleCount)
15 to 11	—	Reserved These bits are always read as 0. When writing, always write 0.
10 to 0	DP[10:0]	Data Pointer Flags

(1) FLXA0FRRDHS3.RES

Reserved Bit Indicator Flag (vRF!Header!Reserved)

Reflects the value of the received reserved bit. The reserved bit is transmitted as '0'.

(2) FLXA0FRRDHS3.PPI

Payload Preamble Indicator Flag (vRF!Header!PPIndicator)

The payload preamble indicator defines whether a network management vector or message ID is contained in the payload segment of the received frame.

0 = The payload segment of the received frame does not contain a network management vector nor a message ID

1 = Static segment: contains network management vector is included in the first part of the payload

Dynamic segment: contains message ID is included in the first part of the payload

(3) FLXA0FRRDHS3.NFI

Null Frame Indicator Flag (vRF!Header!NFIndicator)

Is set to '1' after storage of the first received data frame.

(4) FLXA0FRRDHS3.SYN

Sync Frame Indicator Flag (vRF!Header!SyFIndicator)

A sync frame is indicated by the sync frame indicator.

(5) FLXA0FRRDHS3.SFI

Startup Frame Indicator Flag (vRF!Header!SuFIndicator)

A startup frame is indicated by the startup frame indicator.

(6) FLXA0FRRDHS3.RCI

Received on Channel Indicator Flag (vSS!Channel)

Indicates the channel from which the received data frame was taken to update the respective receive buffer.

(7) FLXA0FRRDHS3.RCC

Receive Cycle Count (vRF!Header!CycleCount)

Cycle counter value updated from received data frame is read.

(8) FLXA0FRRDHS3.DP

Data Pointer Flags

This flag indicates the position of the first 32-bit word of the data section of the addressed message buffer in the message RAM.

The bit value is the same as that set in the FLXA0FRWRHS3.DP bit.

17.2.11.5 FLXA0FRMBS — FlexRay Message Buffer Status Register

The message buffer status is updated by the CC with respect to the assigned channel(s) latest at the end of the slot following the slot assigned to the message buffer.

The flags are updated only when the CC is in NORMAL_ACTIVE or NORMAL_PASSIVE state.

If only one channel (A or B) is assigned to a message buffer, the channel-specific status flags of the other channel are written to zero. If both channels are assigned to a message buffer, the channel-specific status flags of both channels are updated.

The message buffer status is updated only when the slot counter reached the configured frame ID and when the cycle counter filter matched. When the host updates a message buffer via input buffer, all FLXA0FRMBS flags are reset to zero independent of which FLXA0FRIBCM bits are set or not.

For details about receive/transmit filtering see **Section 17.3.8, Filtering and Masking**, **Section 17.3.9, Transmit Process** and **Section 17.3.10, Receive Process**.

Whenever the message handler changes one of the flags FLXA0FRMBS.VFRA, FLXA0FRMBS.VFRB, FLXA0FRMBS.SEOA, FLXA0FRMBS.SEOB, FLXA0FRMBS.CEOA, FLXA0FRMBS.CEOB, FLXA0FRMBS.SVOA, FLXA0FRMBS.SVOB, FLXA0FRMBS.TCIA, FLXA0FRMBS.TCIB, FLXA0FRMBS.ESA, FLXA0FRMBS.ESB, FLXA0FRMBS.MLST, FLXA0FRMBS.FTA, FLXA0FRMBS.FTB the respective message buffer's MBC flag in registers FLXA0FRMBSC1/2/3/4 is set.

Access: This register can be read in 8-, 16-, or 32-bit units.

Address: ERAY + 070C_H

Value after reset: 0000 0000_H

Table 17.72 FLXA0FRMBS Register Contents (1/2)

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29	RESS	Reserved Bit Status Flag (vRF!Header!Reserved)
28	PPIS	Payload Preamble Indicator Status Flag (vRF!Header!PPIndicator) 0: PPI indicator set to '0' 1: PPI indicator set to '1'
27	NFIS	Null Frame Indicator Status Flag (vRF!Header!NFIndicator) 0: Received frame is a null frame 1: Received frame is not a null frame
26	SYNS	Sync Frame Indicator Status Flag (vRF!Header!SyFIndicator) 0: No sync frame received 1: The received frame is a sync frame

Table 17.72 FLXA0FRMBS Register Contents (2/2)

Bit Position	Bit Name	Function
25	SFIS	Startup Frame Indicator Status Flag (vRF!Header!SuIndicator) 0: No startup frame received 1: The received frame is a startup frame
24	RCIS	Received Channel Indicator Status Flag (vSS!Channel) 0: Frame received on channel B 1: Frame received on channel A
23, 22	—	Reserved These bits are always read as 0. When writing, always write 0.
21 to 16	CCS[5:0]	Cycle Count Status Flags
15	FTB	Frame Transmitted on Channel B Flag 0: No data frame transmitted on channel B 1: Data frame transmitted on channel B
14	FTA	Frame Transmitted on Channel A Flag 0: No data frame transmitted on channel A 1: Data frame transmitted on channel A
13	—	Reserved This bit is always read as 0. When writing, always write 0.
12	MLST	Message Lost Flag 0: No message lost 1: Unprocessed message was overwritten
11	ESB	Empty Slot Channel B Flag 0: Bus activity detected in the assigned slot on channel B 1: No bus activity detected in the assigned slot on channel B
10	ESA	Empty Slot Channel A Flag 0: Bus activity detected in the assigned slot on channel A 1: No bus activity detected in the assigned slot on channel A
9	TCIB	Transmission Conflict Indication Channel B Flag (vSS!TxConflictB) 0: No transmission conflict occurred on channel B 1: Transmission conflict occurred on channel B
8	TCIA	Transmission Conflict Indication Channel A Flag (vSS!TxConflictA) 0: No transmission conflict occurred on channel A 1: Transmission conflict occurred on channel A
7	SVOB	Slot Boundary Violation Observed on Channel B Flag (vSS!BViolationB) 0: No slot boundary violation observed on channel B 1: Slot boundary violation observed on channel B
6	SVOA	Slot Boundary Violation Observed on Channel A Flag (vSS!BViolationA) 0: No slot boundary violation observed on channel A 1: Slot boundary violation observed on channel A
5	CEOB	Content Error Observed on Channel B Flag (vSS!ContentErrorB) 0: No content error observed on channel B 1: Content error observed on channel B
4	CEOA	Content Error Observed on Channel A Flag (vSS!ContentErrorA) 0: No content error observed on channel A 1: Content error observed on channel A
3	SEOB	Syntax Error Observed on Channel B Flag (vSS!SyntaxErrorB) 0: No syntax error observed on channel B 1: Syntax error observed on channel B
2	SEOA	Syntax Error Observed on Channel A Flag (vSS!SyntaxErrorA) 0: No syntax error observed on channel A 1: Syntax error observed on channel A
1	VFRB	Valid Frame Received on Channel B Flag (vSS!ValidFrameB) 0: No valid frame received on channel B 1: Valid frame received on channel B
0	VFRA	Valid Frame Received on Channel A Flag (vSS!ValidFrameA) 0: No valid frame received on channel A 1: Valid frame received on channel A

(1) FLXA0FRMBS.RESS

Reserved Bit Status Flag (vRF!Header!Reserved)

Reflects the state of the received reserved bit. The reserved bit is transmitted as '0'.

For receive buffers (FLXA0FRWRHS1.CFG = '0') this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(2) FLXA0FRMBS.PPIS

Payload Preamble Indicator Status Flag (vRF!Header!PPIndicator)

The payload preamble indicator defines whether a network management vector or message ID is contained within the payload segment of the received frame.

For receive buffers (FLXA0FRWRHS1.CFG = '0') this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

0 = PPI indicator set to '0'

The payload segment of the received frame does not contain a network management vector or a message ID

1 = PPI indicator set to '1'

Static segment: contains network management vector at the beginning of the payload

Dynamic segment: contains message ID at the beginning of the payload

(3) FLXA0FRMBS.NFIS

Null Frame Indicator Status Flag (vRF!Header!NFIndicator)

If set to '0' the payload segment of the received frame contains no usable data.

For receive buffers (FLXA0FRWRHS1.CFG = '0') this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(4) FLXA0FRMBS.SYNS

Sync Frame Indicator Status Flag (vRF!Header!SyFIndicator)

A sync frame is indicated by the sync frame indicator.

For receive buffers (FLXA0FRWRHS1.CFG = '0') this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(5) FLXA0FRMBS.SFIS

Startup Frame Indicator Status Flag (vRF!Header!SuFIndicator)

The startup frame indicator specifies a startup frame.

For receive buffers (FLXA0FRWRHS1.CFG = '0') this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(6) FLXA0FRMBS.RCIS

Received Channel Indicator Status Flag (vSS!Channel)

Indicates the channel on which the frame was received.

For receive buffers (FLXA0FRWRHS1.CFG = '0') this bit is updated from both valid data and null frames. If no valid frame was received, the previous value is maintained. For transmit buffers the flag has no meaning and should be ignored.

(7) FLXA0FRMBS.CCS

Cycle Count Status Flag

Actual cycle count at a status update is read.

(8) FLXA0FRMBS.FTB

Frame Transmitted on Channel B Flag

Indicates that this node has transmitted a data frame in the configured slot on channel B.

NOTE

The FlexRay protocol specification requires that FLXA0FRMBS.FTB can only be reset by the host. Therefore the Cycle Count Status FLXA0FRMBS.CCS for this bit is only valid for the cycle where the bit is set to '1'.

(9) FLXA0FRMBS.FTA

Frame Transmitted on Channel A Flag

Indicates that this node has transmitted a data frame in the configured slot on channel A.

NOTE

The FlexRay protocol specification requires that FLXA0FRMBS.FTA can only be reset by the host. Therefore the Cycle Count Status FLXA0FRMBS.CCS for this bit is only valid for the cycle where this bit is set to '1'.

(10) FLXA0FRMBS.MLST

Message Lost Flag

The flag is set in case the host did not read the message before the message buffer was updated from a received data frame.

Not affected by reception of null frames except for message buffers belonging to the receive FIFO. The flag is reset to '0' by a host write to the message buffer via IBF or when a new message is stored into the message buffer after the message buffers ND flag was reset to '0' by reading out the message buffer via OBF.

(11) FLXA0FRMBS.ESB

Empty Slot Channel B Flag

In an empty slot, the bus is in idle state. This means that any frame transmission is not detected. This state can be checked in static and dynamic slots.

(12) FLXA0FRMBS.ESA

Empty Slot Channel A Flag

In an empty slot, the bus is in idle state. This means that any frame transmission is not detected. This state can be checked in static and dynamic slots.

(13) FLXA0FRMBS.TCIB

Transmission Conflict Indication Channel B Flag (vSS!TxConflictB)

A transmission conflict indication is set to '1' if a transmission conflict has occurred on channel B.

(14) FLXA0FRMBS.TCIA

Transmission Conflict Indication Channel A Flag (vSS!TxConflictA)

A transmission conflict indication is set if a transmission conflict has occurred on channel A.

(15) FLXA0FRMBS.SVOB

Slot Boundary Violation Observed on Channel B Flag (vSS!BViolationB)

A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel B.

(16) FLXA0FRMBS.SVOA

Slot Boundary Violation Observed on Channel A Flag (vSS!BViolationA)

A slot boundary violation (channel active at the start or at the end of the assigned slot) was observed on channel A.

(17) FLXA0FRMBS.CEOB

Content Error Observed on Channel B Flag (vSS!ContentErrorB)

A content error was observed in the assigned slot on channel B.

(18) FLXA0FRMBS.CEOA

Content Error Observed on Channel A Flag (vSS!ContentErrorA)

A content error was observed in the assigned slot on channel A.

(19) FLXA0FRMBS.SEOB

Syntax Error Observed on Channel B Flag (vSS!SyntaxErrorB)

A syntax error was observed in the assigned slot on channel B.

(20) FLXA0FRMBS.SEOA

Syntax Error Observed on Channel A Flag (vSS!SyntaxErrorA)

A syntax error was observed in the assigned slot on channel A.

(21) FLXA0FRMBS.VFRB

Valid Frame Received on Channel B Flag (vSS!ValidFrameB)

This flag is set to “1” when a valid frame was received on channel B.

(22) FLXA0FRMBS.VFRA

Valid Frame Received on Channel A Flag (vSS!ValidFrameA)

This flag is set to “1” when a valid frame was received on channel A.

17.2.11.6 FLXA0FROBCM — FlexRay Output Buffer Command Mask Register

This register configures how the output buffer is updated from the message buffer in the message RAM selected by FLXA0FROBCR.OBRS.

Mask bits FLXA0FROBCM.RDSS and FLXA0FROBCM.RHSS are copied to the register internal storage when a message RAM transfer is requested by FLXA0FROBCR.REQ.

When OBF host and OBF shadow are switched, mask bits FLXA0FROBCM.RDSH and FLXA0FROBCM.RHSH are switched with the register internal storage to keep them attached to the respective output buffer transfer.

The data transfer between output buffer and message RAM is described in detail in **Section 17.3.12.2 (2), Data Transfer from Message RAM to Output Buffer**.

CAUTION

After the transfer of the header section from the message RAM to OBF shadow has completed, the message buffer status changed flag MBC of the selected message buffer in the FLXA0FRMBSC1/2/3/4 registers is cleared. After the transfer of the data section from the message RAM to OBF shadow has completed, the new data flag ND of the selected message buffer in the FLXA0FRNDAT1/2/3/4 registers is cleared.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0710_H

Value after reset: 0000 0000_H

17.2.11.7 FLXA0FROBCR — FlexRay Output Buffer Command Request Register

After setting bit FLXA0FROBCR.REQ to '1' while FLXA0FROBCR.OBSYS is '0', FLXA0FROBCR.OBSYS is automatically set to '1', FLXA0FROBCR.OBRS is copied to the register internal storage, mask bits FLXA0FROBCM.RDSS and FLXA0FROBCM.RHSS are copied to register FLXA0FROBCM internal storage, and the transfer of the message buffer selected by FLXA0FROBCR.OBRS from the message RAM to OBF shadow is started. When the transfer between the message RAM and OBF shadow has completed, this is signaled by setting FLXA0FROBCM.OBSYS back to '0'.

By setting bit FLXA0FROBCR.VIEW to '1' while FLXA0FROBCR.OBSYS is '0', OBF host and OBF shadow are switched. Additionally mask bits FLXA0FROBCM.RDSH and FLXA0FROBCM.RHSH are switched with the register FLXA0FROBCM internal storage to keep them attached to the respective output buffer transfer. FLXA0FROBCR.OBRH signals the number of the message buffer currently accessible by the host.

If bits FLXA0FROBCR.REQ and FLXA0FROBCR.VIEW are set to '1' with the same write access while FLXA0FROBCR.OBSYS is '0', FLXA0FROBCR.OBSYS is automatically set to '1' and OBF shadow and OBF host are switched. Additionally mask bits FLXA0FROBCM.RDSH and FLXA0FROBCM.RHSH are switched with the registers internal storage to keep them attached to the respective output buffer transfer. Afterwards FLXA0FROBCR.OBRS is copied to the register internal storage, and the transfer of the selected message buffer from the message RAM to OBF shadow is started. While the transfer is ongoing the host can read the message buffer transferred by the previous transfer from OBF host. When the current transfer between message RAM and OBF shadow has completed, this is signaled by setting FLXA0FROBCR.OBSYS back to '0'.

Any write access to FLXA0FROBCR[15:8] while FLXA0FROBCR.OBSYS is set to '1' will cause the error flag FLXA0FREIR.IOBA to be set to '1'. In this case, this write access has no effect and the output buffer will not be changed.

The data transfer between output buffer and message RAM is described in detail in **Section 17.3.12.2 (2), Data Transfer from Message RAM to Output Buffer.**

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0714_H

Table 17.74 FLXA0FROBCR Register Contents

Bit Position	Bit Name	Function
31 to 23	—	Reserved Flags These bits are always read as 0. When writing, always write 0.
22 to 16	OBRH[6:0]	Output Buffer Request Host
15	OBSYS	Output Buffer Busy Shadow Flag 0: No transfer in progress 1: Transfer between message RAM and OBF shadow in progress
14 to 10	—	Reserved These bits are always read as 0. When writing, always write 0.
9	REQ	Request Message RAM Transfer 0: No request 1: Transfer to OBF shadow requested
8	VIEW	View Shadow Buffer 0: No action 1: Switch OBF shadow and OBF host
7	—	Reserved This bit is always read as 0. When writing, always write 0.
6 to 0	OBRS[6:0]	Output Buffer Request Shadow

(1) FLXA0FROBCR.OBRH

Output Buffer Request Host Flags

Indicate number of message buffer currently accessible by the host via FLXA0FRRDHS[1...3], FLXA0FRMBS, and FLXA0FRRDDS[1...64].

By writing FLXA0FROBCR.VIEW to '1', OBF host is switched and the transferred message buffer is accessible by the host.

(2) FLXA0FROBCR.OBSYS

Output Buffer Busy Shadow Flag

Sets to '1' after setting bit FLXA0FROBCR.REQ. When the transfer between the message RAM and OBF shadow has completed, FLXA0FROBCR.OBSYS is set back to '0'.

(3) FLXA0FROBCR.REQ

Request Message RAM Transfer

Only writeable while FLXA0FROBCR.OBSYS = '0'.

Requests transfer of message buffer addressed by FLXA0FROBCR.OBRS from message RAM to OBF shadow.

(4) FLXA0FROBCR.VIEW

View Shadow Buffer

Only writeable while FLXA0FROBCR.OBSYS = '0'.

Toggles between OBF shadow and OBF host.

(5) FLXA0FROBCR.OBRS

Output Buffer Request Shadow

Only writeable while FLXA0FROBCR.OBSYS = '0'.

Indicate number of source message buffer to be transferred from the message RAM to OBF shadow.

If the number of the first message buffer of the receive FIFO is written to this register, the message buffer addressed by the GET Index (GIDX, see **Section 17.3.11, FIFO Function**) is transferred to OBF shadow.

17.2.12 Data Transfer Control Register

17.2.12.1 FLXA0FRITC — FlexRay Input Transfer Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0800_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Table 17.75 FLXA0FRITC Register Contents

Bit Position	Bit Name	Function
31 to 23	—	Reserved These bits are always read as 0. When writing, always write 0.
22 to 16	ITM[6:0]	Input Queue Table Max These bits configure the number of entries in the input pointer table the input buffer handler is capable to maintain in the input queue.
15 to 10	—	Reserved These bits are always read as 0. When writing, always write 0.
9	IQEIE	Input Queue Empty Interrupt Enable 0: Disabled 1: Enabled
8	IQFIE	Input Queue Full Interrupt Enable 0: Disabled 1: Enabled
7 to 2	—	Reserved These bits are always read as 0. When writing, always write 0.
1	IQHR	Input Queue Halt Request 0: Input queue run request 1: Input queue halt request
0	ITE	Input Transfer Enable 0: Operation Disable request 1: Operation Enable request

(1) FLXA0FRITC.ITM

Input Queue Table Max

The user can only write to this bit when FLXA0FRITS.ITS is '0'.

These bits configure the number of entries in the input pointer table the input buffer handler is capable to maintain in the input queue.

Valid values are 00_H (1 queue entry) to 7F_H (128 queue entries).

Note that each entry requires two long words in the input pointer table.

(2) FLXA0FRITC.IQEIE

Input Queue Empty Interrupt Enable

This bit controls the input queue empty interrupt.

0: Disabled

No interrupt will be requested and the input queue empty interrupt will be not generated.

1: Enabled

Input queue empty interrupt will be generated when FLXA0FRITS.IQEIS is '1'.

(3) FLXA0FRITC.IQFIE

Input Queue Full Interrupt Enable

This bit controls the input queue full interrupt.

0: Disabled

No interrupt will be requested and the input queue full interrupt will be not generated.

1: Enabled

Input queue full interrupt will be generated when FLXA0FRITS.IQFIS is '1'.

(4) FLXA0FRITC.IQHR

Input Queue Halt Request

The IQHR bit should not be set to '1' when FLXA0FRITS.ITS is '0'.

This bit requests a halt of the input queue.

The status of the halt request is shown in the FLXA0FRITS.IQH register.

Refer to **Section 17.3.16.1 (5), Halting the input queue** about usage of this bit.

0: Input queue run request

The input queue resumes their operation.

1: Input queue halt request

The input queue gets halted. An active input transfer will be completed but no further transfer request will start.

(5) FLXA0FRITC.ITE

Input Transfer Enable

The user should only set this bit to '1' when FLXA0FRIBCR.IBSYS is '0'.

The user should only set this bit to '0' when FLXA0FRITC.IQHR '0'. Otherwise committed input transfers get lost.

This bit controls the operation mode of the input transfer queue.

The operation status of the input transfer queue function is shown in FLXA0FRITS.ITS.

Refer to **Section 17.3.16.1 (1), Activation and deactivation** about usage of this bit.

0: Operation Disable request

The input transfer queue gets disabled when it becomes empty.

1: Operation Enable request

The input transfer queue gets enabled. Input data structures are transferred to the FlexRay internal message RAM.

17.2.12.2 FLXA0FROTC — FlexRay Output Transfer Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0804_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.76 FLXA0FROTC Register Contents

Bit Position	Bit Name	Function
31 to 21	—	Reserved These bits are always read as 0. When writing, always write 0.
20 to 16	FTM[4:0]	FIFO Table Max Configure the number of FIFO entries the output transfer handler is capable to maintain in the local RAM/global RAM.
15 to 12	—	Reserved These bits are always read as 0. When writing, always write 0.
11	FWIE	FIFO Transfer Warning Interrupt Enable 0: Disabled 1: Enabled
10	OWIE	Output Transfer Warning Interrupt Enable 0: Disabled 1: Enabled
9	FIE	FIFO Transfer Interrupt Enable 0: Disabled 1: Enabled
8	OIE	Output Transfer Interrupt Enable 0: Disabled 1: Enabled
7 to 2	—	Reserved These bits are always read as 0. When writing, always write 0.
1	OTCS	Output Transfer Condition Select 0: New data only mode 1: New data and status changed mode
0	OTE	Output Transfer Enable 0: Operation Disable request 1: Operation Enable request

(1) FLXA0FROTC.FTM

FIFO Table Max

The user can only write to these bits when FLXA0FROTS.OTS is '0'.

These bits configure the number of FIFO entries the output transfer handler is capable to maintain in the local RAM/global RAM.

Valid values are 00_H (1 FIFO entry) to 1F_H (32 FIFO entries).

(2) FLXA0FROTC.FWIE

FIFO transfer Warning Interrupt Enable

This bit controls the FIFO transfer warning interrupt.

0: Disabled

No interrupt will be requested and the FIFO transfer warning interrupt will be not generated.

1: Enabled

FIFO transfer warning interrupt will be generated when FLXA0FROTS.FWIS is '1'.

(3) FLXA0FROTC.OWIE

Output Transfer Warning Interrupt Enable

This bit controls the output transfer warning interrupt.

0: Disabled

No interrupt will be requested and the output transfer warning interrupt will be not generated.

1: Enabled

Output transfer warning interrupt will be generated when FLXA0FROTS.OWIS is '1'.

(4) FLXA0FROTC.FIE

FIFO Transfer Interrupt Enable

This bit controls the FIFO transfer interrupt.

0: Disabled

No interrupt will be requested and the FIFO transfer interrupt will be not generated.

1: Enabled

FIFO transfer interrupt will be generated when FLXA0FROTS.FIS is '1'.

(5) FLXA0FROTC.OIE

Output Transfer Interrupt Enable

This bit controls the output transfer interrupt.

0: Disabled

No interrupt will be requested and the output transfer interrupt will be not generated.

1: Enabled

Output transfer interrupt will be generated when FLXA0FROTS.OTIS is '1'.

(6) FLXA0FROTC.OTCS

Output Transfer Condition Select

The user can only write to this bit when FLXA0FROTS.OTS is '0'.

This bit controls the output transfer condition.

0: New data only mode

The ND bits in the FLXA0FRNDAT_i registers are used to detect a transfer condition for dedicated receive buffer

1: New data and status changed mode

The ND bits in the FLXA0FRNDAT_i registers and the MBC bits in the FLXA0FRMBSC_i register are used to detect a transfer condition for dedicated transmit and receive buffer

(7) FLXA0FROTC.OTE

Output Transfer Enable

The user should only set this bit to '1' when FLXA0FROBCR.OBSYS is '0'.

This bit controls the operation mode of the output transfer function.

The operation status of the output buffer transfer function is shown in FLXA0FROTS.OTS.

Refer to **Section 17.3.16.2 (1), Activation and deactivation** about usage of this bit.

0: Operation Disable request

The output buffer transfer gets disabled.

An active message buffer transfer will be completed but no further transfer will start.

1: Operation Enable request

The output buffer transfer gets enabled. Message buffers are transferred from the FlexRay internal message RAM to output data structures.

The user should not change the E-Ray message RAM configuration by writing to the FLXA0FRMRC register.

17.2.12.3 FLXA0FRIBA — FlexRay Input Pointer Table Base Address Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0808_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ITA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ITA[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Table 17.77 FLXA0FRIBA Register Contents

Bit Position	Bit Name	Function
31 to 0	ITA[31:0]	Input Table Base Address These bits configure the base address of the input pointer table.

(1) FLXA0FRIBA.ITA

Input Table Base Address

The user can only write to these bits when FLXA0FRITS.ITS is '0'.

The address should be 32 bit aligned, thus the bits FLXA0FRIBA.ITA[1:0] are always '0'.

These bits configure the base address of the input pointer table.

The table is used for the input transfer queue transferring message buffers from the local RAM/global RAM into the FlexRay internal message RAM.

The size of the input queue is configured in FLXA0FRITC.ITM.

Note that each entry requires two long words in the input pointer table.

17.2.12.4 FLXA0FRFBA — FlexRay FIFO Pointer Table Base Address Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 080C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FTA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 17.78 FLXA0FRFBA Register Contents

Bit Position	Bit Name	Function
31 to 0	FTA[31:0]	FIFO Pointer Table Base Address These bits configure the base address of the FIFO pointer table.

(1) FLXA0FRFBA.FTA

FIFO Pointer Table Base Address

The user can only write to these bits when FLXA0FROTS.OTS is '0'.

The address should be 32 bit aligned, thus the bits FLXA0FRFBA.FTA[1:0] are always '0'.

These bits configure the base address of the FIFO pointer table.

The table is used for message buffers transferred from the FlexRay internal FIFO to the local RAM/global RAM.

The size of the FIFO is configured in FLXA0FROTC.FTM.

17.2.12.5 FLXA0FROBA — FlexRay Output Pointer Table Base Address Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0810_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OTA[31:16]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OTA[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R

Table 17.79 FLXA0FROBA Register Contents

Bit Position	Bit Name	Function
31 to 0	OTA[31:0]	Output Pointer Table Base Address These bits configure the base address of the output pointer table.

(1) FLXA0FROBA.OTA

Output Pointer Table Base Address

The user can only write to these bits when FLXA0FROTS.OTS is '0'.

The address should be 32 bit aligned, thus the bits FLXA0FROBA.OTA[1:0] are always '0'.

These bits configure the base address of the output pointer table.

The table is used for message buffers transferred from the FlexRay internal message RAM to the local RAM/global RAM.

The size of the table depends on the utilization of the FlexRay internal message RAM and can have up to 128 entries.

17.2.12.6 FLXA0FRIQC — FlexRay Input Queue Control Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0814_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	IMBNR[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W

Table 17.80 FLXA0FRIQC Register Contents

Bit Position	Bit Name	Function
31 to 7	—	Reserved These bits are always read as 0. When writing, always write 0.
6 to 0	IMBNR[6:0]	Input Message Buffer Number Message buffer number added to the input queue

(1) FLXA0FRIQC.IMBNR

Input Message Buffer Number

The user can only write to these bits when FLXA0FRITS.IQFP is '0'.

The user should not write to this register when FLXA0FRITS.ITS is '0' or when FLXA0FRITC.ITE is '0'.

These bits are read as "0".

This value specifies the message buffer added to the input queue.

The number has to be identical to FLXA0FRWRHS4.IMBNR (see **Section 17.3.16.1 (3), Input pointer table**) of the input pointer table.

The address to the input data structure has to be provided in the input pointer table at the put index (FLXA0FRITS.IPIDX) before writing to this register.

Writing to this register increments the input put index (FLXA0FRITS.IPIDX).

17.2.12.7 FLXA0FRUIR — FlexRay User Input Transfer Request Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0818_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	UIDX[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 17.81 FLXA0FRUIR Register Contents

Bit Position	Bit Name	Function
31 to 8	—	Reserved These bits are always read as 0. When writing, always write 0.
7 to 0	UIDX[7:0]	User Requested Input Index Input pointer table index requested for input transfer

(1) FLXA0FRUIR.UIDX

User Requested Input Index

The user can only write to these bits when FLXA0FRITS.UIRP is '0'.

The user should not write to this register when FLXA0FRITS.ITS is '0'.

The user should not write to this register when FLXA0FRITS.UIRP is '1'.

The user should not write to this register when FLXA0FRITS.IQH is '1'.

The user should only write FLXA0FRITC.ITM + 1 to this register.

This value configures the user input pointer table index requested for input transfer.

The address to the input data structure has to be provided in the input pointer table at the index UIDX before writing to this register.

When writing to this register, the requested input data structure will be transferred from input data structure position to the FlexRay internal message RAM.

In opposite to queued input transfers, the related DA flag in the FLXA0FRDA register is not affected by the user input transfer.

17.2.12.8 FLXA0FRUOR — FlexRay User Output Transfer Request Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 081C_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	URDS	—	—	UMBNR[6:0]						
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 17.82 FLXA0FRUOR Register Contents

Bit Position	Bit Name	Function
31 to 10	—	Reserved These bits are always read as 0. When writing, always write 0.
9	URDS	User Request Read Data Section 0: Data section is not transferred 1: Data section is transferred
8, 7	—	Reserved These bits are always read as 0. When writing, always write 0.
6 to 0	UMBNR[6:0]	User Requested Output Message Buffer Number Message buffer number requested for output transfer

(1) FLXA0FRUOR.URDS

User Request Read Data Section

The user can only write to this bit when FLXA0FROTS.UORP is '0'.

The user should not write to this register when FLXA0FROTS.OTS is '0'.

The user should not write to this register when FLXA0FROTS.UORP is '1'.

0: Data section is not transferred

The data section of the message buffer selected by the bits UMBNR is not requested

1: Data section is transferred

The data section of the message buffer selected by the bits UMBNR is requested

(2) FLXA0FRUOR.UMBNR

User Requested output Message Buffer Number

The user can only write to these bits when FLXA0FROTS.UORP is '0'.

The user should not write to this register when FLXA0FROTS.OTS is '0'.

The user should not write to this register when FLXA0FROTS.UORP is '1'.

The user should restrict this bit to dedicated receive and transmit buffers when the FlexRay module is not in the CONFIG state.

When writing to this register, the header sections and the optional data section (configurable by URDS) of the requested message buffer will be transferred from the FlexRay internal message RAM to the output data structure position defined by the output structure data pointer in the output pointer table.

17.2.12.9 FLXA0FRAHBC — FlexRay H-Bus Configuration Register

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0840_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	HPROT[3:0]				
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Table 17.83 FLXA0FRAHBC Register Contents

Bit Position	Bit Name	Function
31 to 4	—	Reserved These bits are always read as 0. When writing, always write 0.
3 to 0	HPROT[3:0]	Protection Control

(1) FLXA0FRAHBC.HPROT

Protection Control

The user should only write to this register when FLXA0FRITS.ITS is '0' and when FLXA0FROTS.OTS is '0'.

This register configures the value assigned to the H-Bus protection control signal.

17.2.13 Data Transfer Status Register

17.2.13.1 FLXA0FRITS — FlexRay Input Transfer Status Register

Do not rewrite this register using bit-manipulation instruction.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0820_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	IGIDX[6:0]						—	IPIDX[6:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	IQFP	—	—	IQEIS	IQFIS	—	—	—	—	—	UIRP	IQH	ITS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Table 17.84 FLXA0FRITS Register Contents

Bit Position	Bit Name	Function
31	—	Reserved This bit is always read as 0. When writing, always write 0.
30 to 24	IGIDX[6:0]	Input Queue Get Index Represents the get index of the input pointer table
23	—	Reserved This bit is always read as 0. When writing, always write 0.
22 to 16	IPIDX[6:0]	Input Queue Put Index Represents the put index of the input pointer table
15 to 13	—	Reserved These bits are always read as 0. When writing, always write 0.
12	IQFP	Input Queue Full Condition Pending 0: Entries in the input queue are available 1: All entries in the input queue are occupied
11, 10	—	Reserved These bits are always read as 0. When writing, always write 0.
9	IQEIS	Input Queue Empty Interrupt Status 0: No input queue empty condition detected 1: Input queue empty condition detected
8	IQFIS	Input Queue Full Interrupt Status 0: No input queue full condition detected 1: Input queue full condition detected
7 to 3	—	Reserved These bits are always read as 0. When writing, always write 0.
2	UIRP	User Input Transfer Request Pending 0: No user input transfer request pending 1: User input transfer request pending
1	IQH	Input Queue Halted 0: Input queue not halted 1: Input queue halted
0	ITS	Input Transfer Status 0: Disabled 1: Enabled

(1) FLXA0FRITS.IGIDX

Input Queue Get Index

These bits are only valid when FLXA0FRITS.IQH is '1'

These bits represent the input pointer index the input queue handler will transfer next.

Valid values are 00_H to FLXA0FRITC.ITM.

The get index is incremented when the input data structure has been transferred from the local RAM/global RAM and the related DA flag in the FLXA0FRDA register is cleared.

The index is set to 00_H when FLXA0FRITS.ITS changes from '0' to '1'.

(2) FLXA0FRITS.IPIDX

Input Queue Put Index

These bits represent the index where the next input data structure pointer in the input pointer table should be stored.

Valid values are 00_H to FLXA0FRITC.ITM.

After reaching the maximum value the put index continues from 00_H.

The index is incremented when writing to FLXA0FRIQC.IMBNR.

The index is set to 00_H when FLXA0FRITS.ITS changes from '0' to '1'.

(3) FLXA0FRITS.IQFP

Input Queue Full Condition Pending

This bit represents that the input queue is full.

There should be no further input transfer requests, by writing to FLXA0FRIQC.IMBNR, as long as FLXA0FRITS.IQFP is '1'.

[Clearing condition]

This bit is cleared when there is one free entry in the input queue.

[Setting condition]

This bit is set when all entries in the input queue are occupied.

(4) FLXA0FRITS.IQEIS

Input Queue Empty Interrupt Status

Writing '0' has no effect on the bit value.

If enabled in FLXA0FRITC.IQEIE the input queue empty interrupt is generated when FLXA0FRITS.IQEIS is '1'.

[Clearing condition]

This bit is cleared when writing a '1' to FLXA0FRITS.IQEIS.

This bit is cleared when FLXA0FRITS.ITS changes from '0' to '1'.

[Setting condition]

This bit is set when all pending input transfers have been processed and consequently the input queue becomes empty.

(5) FLXA0FRITS.IQFIS

Input Queue Full Interrupt Status

Writing '0' has no effect on the bit value.

If enabled in FLXA0FRITC.IQFIE the input queue full interrupt is generated when FLXA0FRITS.IQFIS is '1'.

This flag is intended as interrupt status flag. It does not represent the current input queue status; for this status refer to FLXA0FRITS.IQFP.

[Clearing condition]

This bit is cleared when writing a '1' to FLXA0FRITS.IQFIS.

This bit is cleared when FLXA0FRITS.ITS changes from '0' to '1'.

[Setting condition]

This bit is set when all entries in the input queue are occupied.

(6) FLXA0FRITS.UIRP

User Input Transfer Request Pending

This bit represents that a user input transfer is still pending.

There should be no further write access to FLXA0FRUIR.UIDX when this bit is '1'.

[Clearing condition]

This bit is cleared when the user input transfer request is processed by the input transfer handler.

[Setting condition]

This bit is set when writing to FLXA0FRUIR.UIDX.

(7) FLXA0FRITS.IQH

Input Queue Halted

This bit represents the status of the input queue.

There should be no further write access to FLXA0FRUIR.UIDX when this bit is '1'.

[Clearing condition]

This bit is cleared when FLXA0FRITC.IQHR is set to '0'.

[Setting condition]

This bit is set immediately when the FLXA0FRITC.IQHR is set to '1' and there is no ongoing input transfer.

This bit is set only after an ongoing input transfer has been completed and FLXA0FRITC.IQHR is set to '1'.

(8) FLXA0FRITS.ITS

Input Transfer Status

This bit represents the status of the input queue handler.

While this bit is '1', there should be no read or write access to the address area ERAY + 0400_H to ERAY + 05FF_H and there should be no CLEAR_RAM command applied to FLXA0FRSUCC1.CMD.

The input transfer queue indexes and related status flags are set to '0' when FLXA0FRITS.ITS changes from '0' to '1'.

[Clearing condition]

This bit is cleared immediately when FLXA0FRITC.ITE is set to '0' and there are no pending input transfers

This bit is cleared after all pending requests have been processed and FLXA0FRITC.ITE is '0'.

[Setting condition]

This bit is set when FLXA0FRITC.ITE is set to '1'.

17.2.13.2 FLXA0FROTS — FlexRay Output Transfer Status Register

Do not rewrite this register using bit-manipulation instruction.

Access: This register can be read/written in 8-, 16-, or 32-bit units.

Address: ERAY + 0824_H

Value after reset: 0000 0000_H

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 17.85 FLXA0FROTS Register Contents (1/2)

Bit Position	Bit Name	Function
31, 30	—	Reserved These bits are always read as 0. When writing, always write 0.
29 to 24	FFL[5:0]	FIFO Fill Level Represent the number of unprocessed output FIFO structures
23 to 21	—	Reserved These bits are always read as 0. When writing, always write 0.
20 to 16	FGIDX[4:0]	FIFO Get Index Represent the get index in the FIFO pointer table
15	FWP	FIFO Transfer Warning Condition Pending 0: No FIFO transfer warning condition pending 1: FIFO transfer warning condition pending
14	OWP	Output Transfer Warning Condition Pending 0: No output transfer warning condition pending 1: Output transfer warning condition pending
13	FDA	FIFO Data Available 0: No available FIFO structures 1: FIFO structures available at current FLXA0FROTS.FGIDX index
12	—	Reserved This bit is always read as 0. When writing, always write 0.
11	FWIS	FIFO Transfer Warning Interrupt Status 0: No FIFO transfer warning condition detected 1: FIFO transfer warning condition detected
10	OWIS	Output Transfer Warning Interrupt Status 0: No output transfer warning condition detected 1: Output transfer warning condition detected
9	FIS	FIFO Transfer Interrupt Status 0: No FIFO structure updated in local RAM/global RAM 1: FIFO structure updated in local RAM/global RAM
8	OTIS	Output Transfer Interrupt Status 0: No output structure updated in local RAM/global RAM 1: Output structure updated in local RAM/global RAM
7 to 3	—	Reserved These bits are always read as 0. When writing, always write 0.

Table 17.85 FLXA0FROTS Register Contents (2/2)

Bit Position	Bit Name	Function
2	UORP	User Output Transfer Request Pending 0: No user output transfer request pending 1: User output transfer request pending
1	—	Reserved This bit is always read as 0. When writing, always write 0.
0	OTS	Output Transfer Status 0: Disabled 1: Enabled

(1) FLXA0FROTS.FFL

FIFO Fill Level

These bits represent the number of available output FIFO structures in the local RAM/global RAM.

Valid values are 00_H to $FLXA0FROTC.FTM + 1$.

The value 00_H represents that the FIFO is empty.

The value $FLXA0FROTC.FTM + 1$ represents that the FIFO is full and no further FIFO transfers will be done.

These bits are incremented when a FIFO data structure has been transferred from the FlexRay internal FIFO into the local RAM/global RAM.

The FIFO fill level is decremented when the user releases a FIFO data structure in the local RAM/global RAM by writing '1' to $FLXA0FROTS.FDA$.

The FIFO fill level is set to 00_H when the bit $FLXA0FROTS.OTS$ changes from '0' to '1'.

(2) FLXA0FROTS.FGIDX

FIFO Get Index

These bits represent the index where the current output data structure pointer in the FIFO pointer table is available for reading.

Valid values are 00_H to $FLXA0FROTC.FTM$.
