H'1	H'000	Same size (no scale-up/-down)
	H'001 to H'FFF	Scale-down
H'2 to H'F	H'000 to H'FFF	

Described here is the method for calculating the size of the upscaled/downscaled image that was obtained based on this register setting. First, define the variables necessary for calculating the horizontal size of the upscaled/downscaled image, as shown below.

$$hscale = \frac{4096}{4096 \times m_h + f_h}$$

m_h is the value of VI6_UDSn_SCALE.HMANT, and f_h is the value of VI6_UDSn_SCALE.HFRAC. This formula expresses the estimate of the scale-up/-down factor processed by the UDS. If the horizontal size of the image before scale-up/-down is set as $hsize_{org}$, the horizontal size of the image after scale-up/-down can be roughly obtained through $hsize_{org} \times hscale$.

Similarly, define the variables necessary for calculating the vertical size of the upscaled/downscaled image.

$$vscale = \frac{4096}{4096 \times m_v + f_v}$$

When setting m_v as the value of VI6_UDSn_SCALE.VMANT , f_v as the value of VI6_UDSn_SCALE.VFRAC, and $vsize_{org}$ as the vertical size of the image before scale-up/-down, the vertical size of the image after scale-up/-down can be roughly obtained through $vsize_{org} \times vscale$.

When the UDSn performs scale-down with the settings of Table 25.30, using the variables defined so far, the horizontal size of the downscaled image $hsize_{down\_scaled}$ and the vertical size of the downscaled image $vsize_{down\_scaled}$ become as follows:

$$hsize_{down\_scaled} = \left\langle 1 + \left(\left\langle 1 + \frac{\langle hsize_{org} - 1 \rangle}{m_h'} \right\rangle - 1 \right) \times m_h' \times hscale \right\rangle$$

$$vsize_{down\_scaled} = \left\langle 1 + \left(\left\langle 1 + \frac{\langle vsize_{org} - 1 \rangle}{m_v'} \right\rangle - 1 \right) \times m_v' \times vscale \right\rangle$$

Since the division of hscale and vscale has to be executed at the end of the above formulas, respectively, formulas considering the order of operation become as follows:

$$hsize_{down\_scaled} = \left\langle 1 + \left\{ \left(\left\langle 1 + \frac{\langle hsize_{org} - 1 \rangle}{m_h'} \right\rangle - 1 \right) \times m_h' \times 4096 \right\} \middle/ \left(4096 \times m_h + f_h \right) \right\rangle$$

$$vsize_{down\_scaled} = \left\langle 1 + \left\{ \left(\left\langle 1 + \frac{\langle vsize_{org} - 1 \rangle}{m_v'} \right\rangle - 1 \right) \times m_v' \times 4096 \right\} \middle/ \left(4096 \times m_v + f_v \right) \right\rangle$$

The value of m_h' or m_v', which is shown in Table 25.31, changes according to the setting of VI6_UDSn_SCALE.HMANT or VI6_UDSn_SCALE.VMANT.

Table 25.31 m_h' or m_v' Setting

VI6_UDSn_SCALE.HMANT Setting (VI6_UDSn_SCALE.VMANT Setting)	m_h' (m_v')
1 to 3	1
4 to 7	2
8 to 15	4

When the UDSn performs scale-up with the settings of Table 25.30 and VI6_UDSn_CTRL.AMD is 0, the horizontal size of the upscaled image $hsize_{up\_scaled}$ and the vertical size of the upscaled image $vsize_{up\_scaled}$ become as follows:

$$hsize_{up\_scaled} = \langle 1 + (hsize_{org} - 1) \times hscale \rangle$$

$$vsize_{up\_scaled} = \langle 1 + (vsize_{org} - 1) \times vscale \rangle$$

Similar to the scale-down case, formulas considering the division of hscale and vscale become as follows:

$$hsize_{up\_scaled} = \langle 1 + ((hsize_{org} - 1) \times 4096) / (4096 \times m_h + f_h) \rangle$$

$$vsize_{up\_scaled} = \langle 1 + ((vsize_{org} - 1) \times 4096) / (4096 \times m_v + f_v) \rangle$$

When VI6_UDSn_CTRL.AMD is 1, the horizontal size of the upscaled image $hsize_{up\_scaled}$ and the vertical size of the upscaled image $vsize_{up\_scaled}$ become as follows:

$$hsize_{up\_scaled} = \langle hsize_{org} \times hscale \rangle$$

$$vsize_{up\_scaled} = \langle vsize_{org} \times vscale \rangle$$

After considering the division of hscale and vscale, the formulas become as follows:

$$hsize_{up\_scaled} = \langle (hsize_{org} \times 4096) / (4096 \times m_h + f_h) \rangle$$

$$vsize_{up\_scaled} = \langle (vsize_{org} \times 4096) / (4096 \times m_v + f_v) \rangle$$

25.2.11.3 α Data Threshold Setting Registers (VI6_UDSn_ALPTH)

Note: n = 0 for this product.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

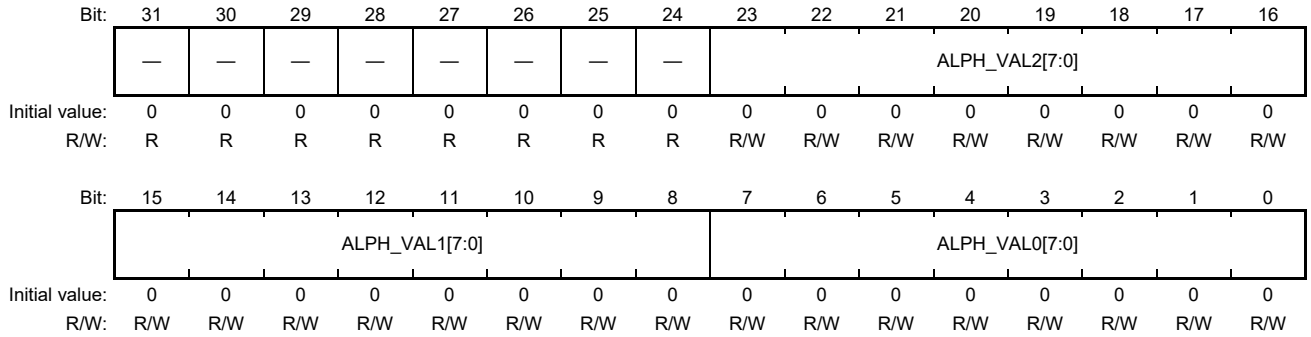
Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 8	ALPH_TH1 [7:0]	H'00	R/W	α Data Threshold Setting 1 When the α value is equal to or greater than the value of the ALPH_TH1 bits, the α value is replaced with that of VI6_UDSn_ALPVAL.ALPH_VAL2. When VI6_UDSn_CTRL.AON is 0 (scale-up/-down of the α plane is disabled), the setting of these bits has no effect. A value from H'00 to H'FF can be specified.
7 to 0	ALPH_TH0 [7:0]	H'00	R/W	α Data Threshold Setting 0 When the α value is equal to or smaller than the value of the ALPH_TH0 bits, the α value is replaced with that of VI6_UDSn_ALPVAL.ALPH_VAL0. When VI6_UDSn_CTRL.AON is 0 (scale-up/-down of the α plane is disabled), the setting of these bits has no effect. A value from H'00 to H'FF can be specified.

25.2.11.4 α Data Replacing Value Setting Registers (VI6_UDSn_ALPVAL)

Note: n = 0 for this product.



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	ALPH_VAL2 [7:0]	H'00	R/W	Replacing α Value Setting 2 These bits set a value that replaces the α value when it is equal to or greater than the value of VI6_UDSn_ALPTH.ALPH_TH1. When VI6_UDSn_CTRL.AON is 0 (scale-up/-down of the α plane is disabled), the setting of these bits has no effect. A value from H'00 to H'FF can be specified.
15 to 8	ALPH_VAL1 [7:0]	H'00	R/W	Replacing α Value Setting 1 These bits set a value that replaces the α value when it is greater than the value of VI6_UDSn_ALPTH.ALPH_TH0 and also smaller than that of VI6_UDSn_ALPTH.ALPH_TH1. When VI6_UDSn_CTRL.AON is 0 (scale-up/-down of the α plane is disabled), the setting of these bits has no effect. A value from H'00 to H'FF can be specified.
7 to 0	ALPH_VAL0 [7:0]	H'00	R/W	Replacing α Value Setting 0 These bits set a value that replaces the α value when it is equal to or smaller than the value of VI6_UDSn_ALPTH.ALPH_TH0. When VI6_UDSn_CTRL.AON is 0 (scale-up/-down of the α plane is disabled), α output value for the UDS is the fixed value specified in these bits. A value from H'00 to H'FF can be specified.

25.2.11.5 Passband Registers (VI6_UDSn_PASS_BWIDTH)

Note: n = 0 for this product.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	BWIDTH_H[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	BWIDTH_V[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 16	BWIDTH_H [6:0]	H'00	R/W	Horizontal Signal Passband at Image Scale-Up/Down Set these bits following the method described later.
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	BWIDTH_V [6:0]	H'00	R/W	Vertical Signal Passband at Image Scale-Up/Down Set these bits following the method described later.

The method for setting the passband in the horizontal direction of an image is described. When the VI6_UDSn_SCALE.HMANT bits for horizontal scale-up/-down factor setting are not 0, set the BWIDTH_H bits according to the following formula. When the VI6_UDSn_SCALE.HMANT bits are 0, set 64 in the BWIDTH_H bits.

$$BWIDTH\_H = \left\langle 64 \times \frac{4096 \times m_h'}{4096 \times m_h + f_h} \right\rangle \quad (\text{VI6\_UDSn\_SCALE.HMANT} \neq 0)$$

$$BWIDTH\_H = 64 \quad (\text{VI6\_UDSn\_SCALE.HMANT} = 0)$$

m_h is the value of VI6_UDSn_SCALE.HMANT, and f_h is the value of VI6_UDSn_SCALE.HFRAC. For the m_h' value, see Table 25.31. The method for setting the passband in the vertical direction of an image is similar to that for the horizontal direction described earlier. Since only the correspondence relationship of the registers is changed as shown below, replace the variables in the previous explanation as shown below when reading.

BWIDTH_H → BWIDTH_V
m_h' → m_v'
m_h → m_v
f_h → f_v
VI6_UDSn_SCALE.HMANT → VI6_UDSn_SCALE.VMANT
VI6_UDSn_SCALE.HFRAC → VI6_UDSn_SCALE.VFRAC

25.2.11.6 2D IPC Setting Register (VI6_UDSn_IPC)

Note: n = 0 for this product.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	FIELD	—	—	—	—	—	—	—	—	—	—	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27	FIELD	0	R/W	Top/Bottom Field Select Select Top/Bottom Field of image data when 2D IPC function is enabled (VI6_UDSn_CTRL.TDIPC = 1). 0: Top Field 1: Bottom Field
26 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

1. Set 1 to VI6_UDSn_CTRL.TDIPC.
2. Set appropriate setting of processing image
   Top Field: H'0000 0000
   Bottom Field: H'0800 0000

Notes: 1. Recommend usage case: Frame rate after 2D UPC is more than 50 fps.
2. Be sure to set H'0000 0000 this register and set VI6_UDSn_CTRL.TDIPC

This register can be used for the image division mode or 2D interlace to progressive conversion (2D-IPC). When this register is not used, set VI6_UDSn_CTRL.TDIPC to 00. If the 2D-IPC mode is used, contact to Renesas for detail.

25.2.11.7 UDS Output Size Clipping Registers (VI6_UDSn_CLIP_SIZE)

Note: n = 0 for this product.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	CL_HSIZE[11:0]

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 16	CL_HSIZE [11:0]	H'000	R/W	Clipping Size of Horizontal Pixel Count after Scale-Up/-Down The horizontal width of an image output from the scaling filter is adjusted (clipped or padded) to match the pixel count set in the CL_HSIZE bits. The setting range is 4 to 2,048 in a scale-down operation (see Table 25.30) and 4 to 2,048 in a scale-up operation. These bits always have to be set when using the UDSn, regardless of the scale-up, scale-down, or no-scaling setting by the VI6_UDSn_SCALE register.
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 0	CL_VSIZE [11:0]	H'000	R/W	Clipping Size of Vertical Pixel Count after Scale-Up/-Down The vertical width of an image output from the scaling filter is adjusted (clipped or padded) to match the pixel count set in the CL_VSIZE bits. The setting range is 4 to 2,048 in a scale-down operation (see Table 25.30) and 4 to 2,048 in a scale-up operation. These bits always have to be set when using the UDSn, regardless of the scale-up, scale-down, or no-scaling setting by the VI6_UDSn_SCALE register.

Figure 25.35 shows the configuration of the UDSn. The UDSn consists of a scaling filter and clipping circuit, such as the configuration shown in Figure 25.35. The scaling filter and clipping circuit are independent of each other.

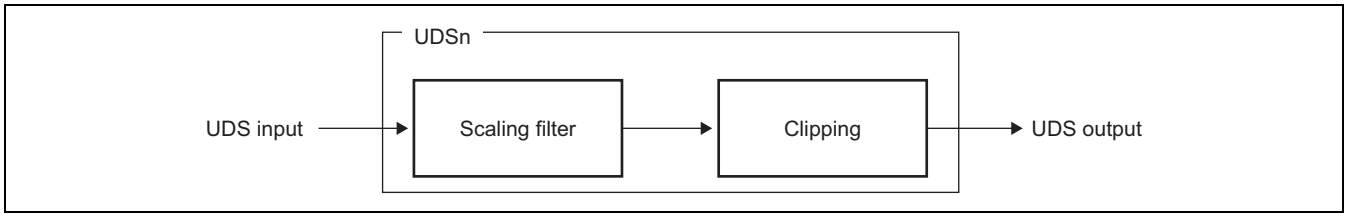

Figure 25.35 UDSn Configuration

The size of the image actually output by the scaling filter (refer to section 25.2.11.2 for calculation) is determined from the size of the image input to the scaling filter and the VI6_UDSn_SCALE setting; that is, three types of image are

output by the UDSn according to the relationship between the size of the image actually output from the scaling filter ($hsize_{scaled}$ and $vsize_{scaled}$) and this register setting as shown in Figure 25.36.

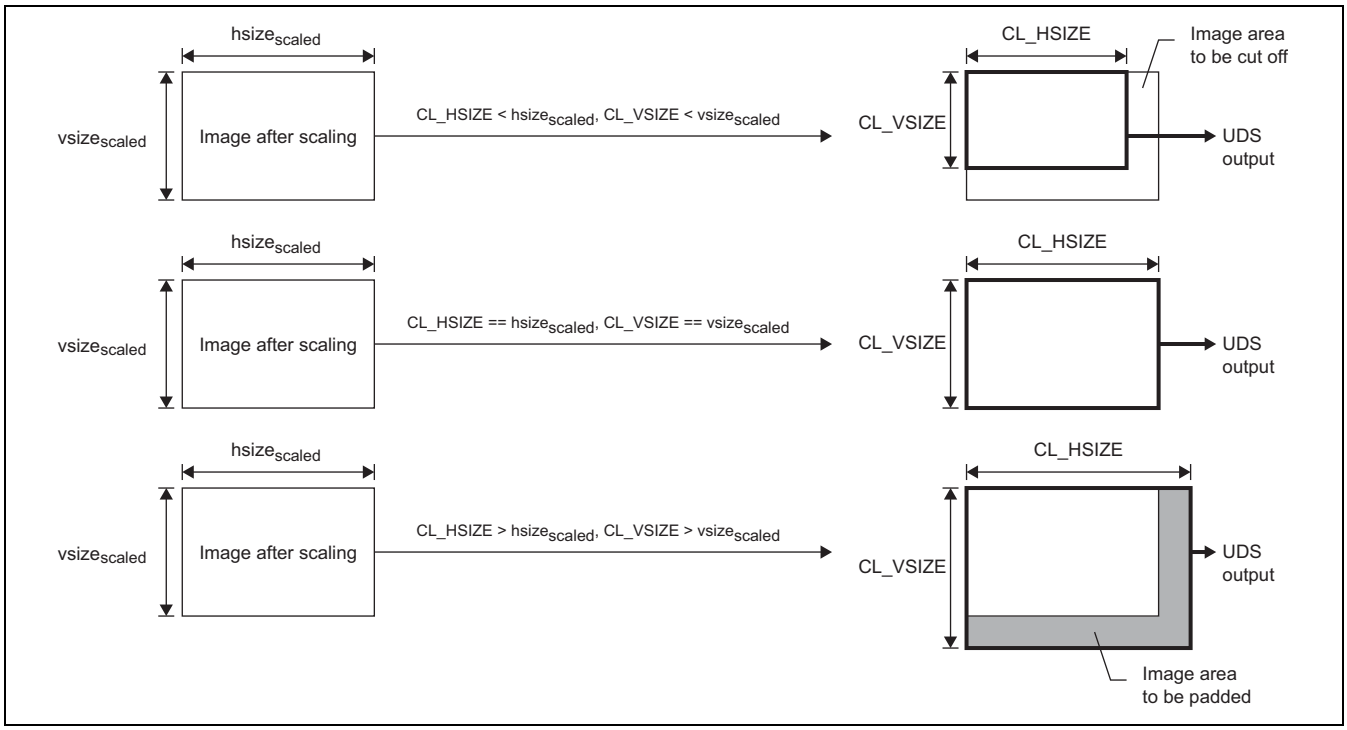

Figure 25.36 UDS Output Image for Each CL_HSIZE/VSIZE Setting

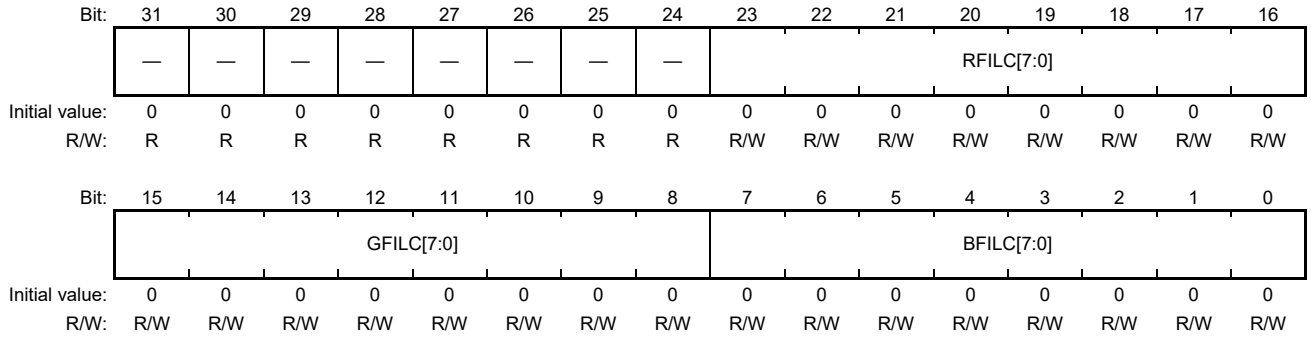
When the settings of the CL_HSIZE and CL_VSIZE bits are smaller than the horizontal and vertical pixel counts ($hsize_{scaled}$ and $vsize_{scaled}$) actually output by the scaling filter, the upscaled/downscaled image is clipped to become the UDSn output image.

When the settings of the CL_HSIZE and CL_VSIZE bits are equal to the horizontal and vertical pixel counts ($hsize_{scaled}$ and $vsize_{scaled}$) actually output by the scaling filter, the image actually output by the scaling filter becomes the UDSn output image without change.

When the settings of the CL_HSIZE and CL_VSIZE bits are greater than the horizontal and vertical pixel counts ($hsize_{scaled}$ and $vsize_{scaled}$) actually output by the scaling filter, in order to obtain the UDSn output image, the image is padded in the mode set by VI6_UDSn_CTRL.FMD for the area in which the settings of the CL_HSIZE and CL_VSIZE bits have exceeded the number of pixels actually output by the scaling filter.

25.2.11.8 Color Fill Register (VI6_UDSn_FILL_COLOR)

Note: n = 0 for this product.



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	RFILC[7:0]	H'00	R/W	R/Cr Component of Fill Color A value from H'00 to H'FF can be specified.
15 to 8	GFILC[7:0]	H'00	R/W	G/Y Component of Fill Color A value from H'00 to H'FF can be specified.
7 to 0	BFILC[7:0]	H'00	R/W	B/Cb Component of Fill Color A value from H'00 to H'FF can be specified.

The scaling filter creates an upscaled/downscaled image based on the scaling factor settings of the VI6_UDSn_SCALE register. If the size of the upscaled/downscaled image created by the scaling filter smaller than the clipping size set in the VI6_UDSn_CLIP_SIZE register (lowest case in Figure 25.36) while VI6_UDSn_CTRL.FMD is set to 1, the color specified by this register is used to fill the space until the clipping size is reached.

The α value of the area to be padded by this register is dependent on VI6_UDSn_CTRL.FMD setting. When VI6_UDSn_CTRL.FMD is 0 (repetition), the pixel value at the right edge (bottom edge) of the image is repeated as the α value. When VI6_UDSn_CTRL.FMD is 1 (color information of this register is used), the α value is 0.

25.2.12 LUT Control Register

25.2.12.1 LUT Control Register (VI6_LUT_CTRL)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LUT_EN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	LUT_EN	0	R/W	1D-LUT Enable/Disable Enables or disables the 1D-LUT function by the LUT. When the 1D-LUT is used, the color component curve information needs to be set separately in the LUT table. For the LUT table settings, refer to section 25.2.1. 0: 1D-LUT function is disabled 1: 1D-LUT function is enabled

In the LUT, various image processing, such as curves with high operation load (e.g., γ correction), negative-positive conversion, and gain adjustment of images, can be achieved by the data replacement processing by the 1D-LUT. As shown in Figure 25.37, the LUT replaces each component of the input pixel data using the set replacement table of 256 entries. For example, if the LUT is set as in Figure 25.38, when there is an input of 150, the data stored in address 150 of the 1D-LUT is read and output as the LUT output. Figure 25.38 shows a case in which the input and output become equal for convenience in explaining.

In the LUT settings shown in Figure 25.39, the input bits are reversed. This has the effect of negative-positive flipping. In Figure 25.40, γ correction (γ = 1.8 is shown as an example) is possible. As described above, information to be set in the LUT indicates LUT processing characteristics. If the same value is set for each component in the LUT, an equal effect can be obtained for each component of the input image when it is processed. If the LUT is set with different characteristics for each component, the processing characteristics can be changed for each component.

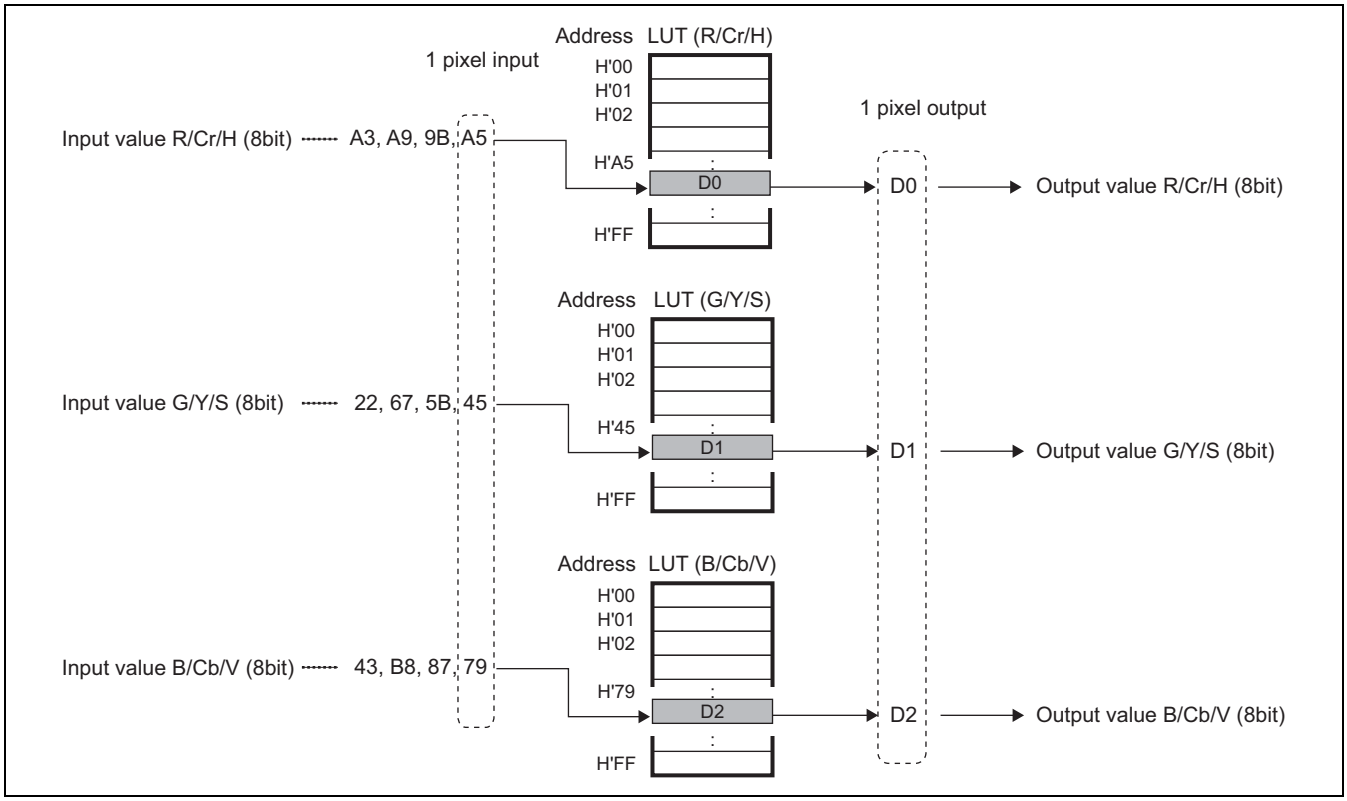


Figure 25.37 Relationship between Input and Output for 1D-LUT Table

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28	AAI	0	R/W	Automatic Table Address Increment Selects whether to specify the CLU table address in VI6_CLU_ADDR (refer to section 25.2.2) every time or update the address automatically. For details, refer to section 25.2.2. 0: CLU table address should be specified every time 1: CLU table address is automatically incremented
27 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	MVS	0	R/W	Max Value Stretch Select calculation method in max value region. 0: Method 0 (Lower compatible) 1: Method 1 (Improved characteristics)
23 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15, 14	AX1I[1:0]	00	R/W	Input Control 0 in 2D Mode When setting the M2D bit to 0, be sure to set these bits to 0. When setting the M2D bit to 1, be sure to set these bits to 3.
13, 12	AX2I[1:0]	00	R/W	Input Control 1 in 2D Mode When setting the M2D bit to 0, be sure to set these bits to 0. When setting the M2D bit to 1, be sure to set these bits to 1.
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	OS0[1:0]	00	R/W	Output Control 0 in 2D Mode When setting the M2D bit to 0, be sure to set these bits to 0. When setting the M2D bit to 1, be sure to set these bits to 3.
7, 6	OS1[1:0]	00	R/W	Output Control 1 in 2D Mode When setting the M2D bit to 0, be sure to set these bits to 0. When setting the M2D bit to 1, be sure to set these bits to 1.

Bit	Bit Name	Initial Value	R/W	Description
5, 4	OS2[1:0]	00	R/W	Output Control 2 in 2D Mode When setting the M2D bit to 0, be sure to set these bits to 0. When setting the M2D bit to 1, be sure to set these bits to 3.
3, 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	M2D	0	R/W	LUT Dimension Number Specifies the number of LUT dimensions. The details of each mode will be described later. 2D mode can be used only when the CLU input color space is YCbCr. 0: Operates in 3D mode 1: Operates in 2D mode
0	CLU_EN	0	R/W	CLU Processing Enable/Disable Enables or disables the 3D/2D color correction function by the CLU. When the CLU is used, the color component information needs to be set in the CLU table. For how to set data in the CLU table, see section 25.2.2. 0: CLU color correction is disabled 1: CLU color correction is enabled

The CLU handles three-dimensional or two-dimensional LUTs. A three-dimensional LUT is called a 3D-LUT and a two-dimensional LUT is called a 2D-LUT. The 3D or 2D operating mode of the CLU is selected by the M2D bit.

In 3D mode, a three-dimensional space such as that shown in Figure 25.41 (a) is considered. The total number of coordinate points that can exist in this three-dimensional space is the total number of combinations of input data. For the CLU, this becomes the cube of each 8-bit component (= 16,777,216 points). Since it is impractical to have table values (= table memory) for the same number of these coordinate points, the CLU divides the three-dimensional space of Figure 25.41 (a) into grids as shown in Figure 25.41 (b) in 3D mode. The apex in each divided grid is defined as the coordinate point in the three-dimensional space, and a table value with three component values is set for all of these coordinate points. The total number of coordinate points in Figure 25.41 (b) is 173 = 4,913. For the method of setting the table value for these 4,913 points, refer to section 25.2.2.

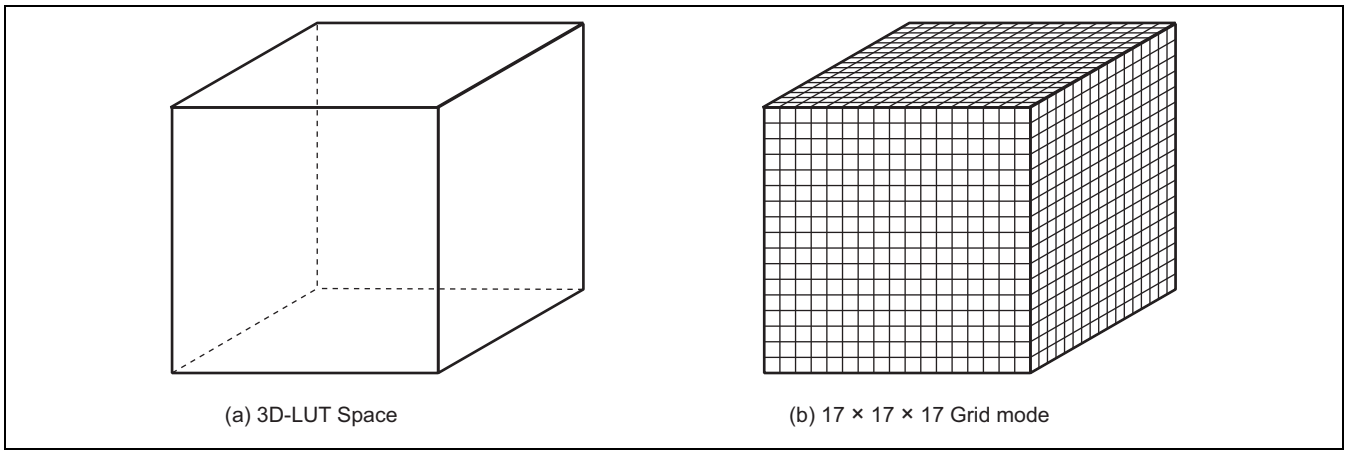

Figure 25.41 Concept and Division Count of a 3-Dimensional LUT

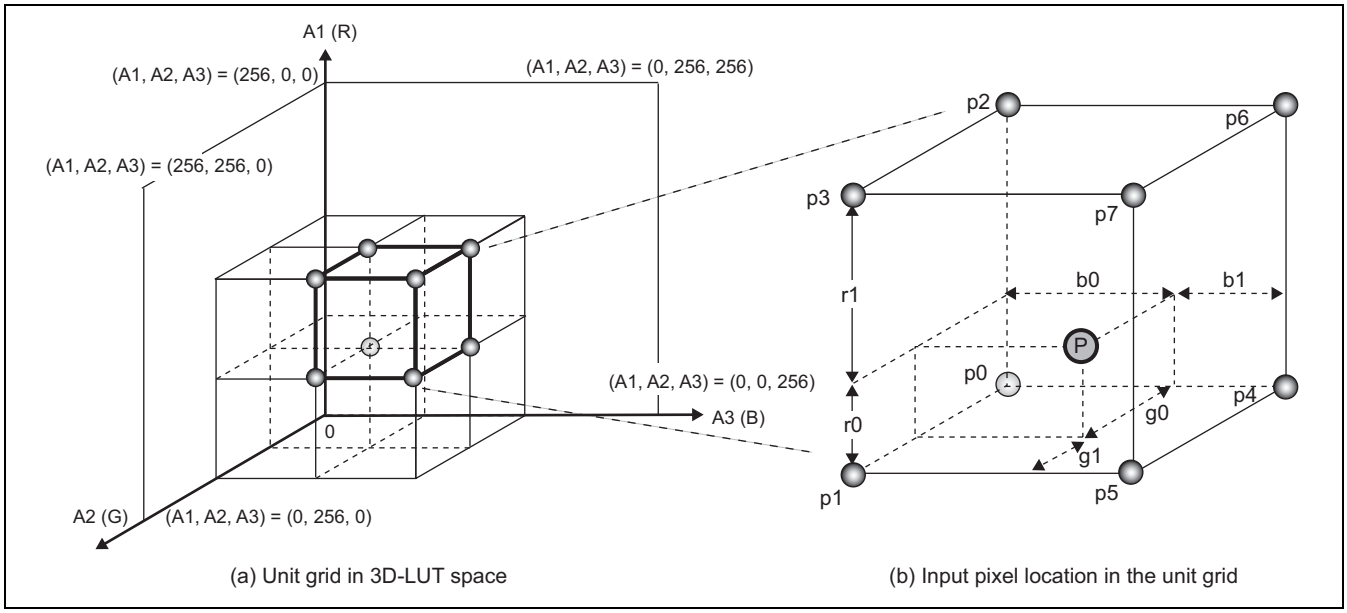

Figure 25.42 Conceptual Diagram of LUT Space When CLU Is in 3D Mode

To express a three-dimensional space such as that shown in Figure 25.41, consider the three-dimensional coordinates and axes shown in Figure 25.42 and define the minimum value and maximum value of each axis as 0 and 256, respectively. In 3D-LUT operation, the CLU forcibly assigns the four components of input data (α, R/Cr/H, G/Y/S, and B/Cb/V) to axes: R, Cr, and H components to the first axis (A1), G, Y, and S components to the second axis (A2), and B, Cb, and V components to the third axis (A3). (The case of 2D mode is described later.) Among multiple components assigned to each axis (e.g., R, Cr, and H components for the first axis), one component is selected according to the format of the data input to the CLU. For example, when the color space of the data input to the CLU is RGB, the first axis (A1) shows the R component, the second axis (A2) shows the G component, and the third axis (A3) shows the B component. In a YCbCr color space, the first axis (A1) shows the Cr component, the second axis (A2) shows the Y component, and the third axis (A3) shows the Cb component.

Each component value of the CLU input data becomes a value on each axis. Since the input data ranges from 0 to 255, the maximum value of 256 is handled as a virtual point in a grid space like that shown in Figure 25.41. In a case where the coordinates obtained by plotting the values of the input three components on axes are exactly on a grid point (e.g., p0 in Figure 25.42 (b)), the 3-component value of the table value (p0) set to that location becomes the CLU output. If the input value of the three components result in an intermediate location between grid points and not on a grid point, such as position P in Figure 25.42 (b), value P of the three components is interpolated from the table values (p0 to p7 in Figure 25.42 (b)) for the eight surrounding grid points and this is used as the CLU output.

By setting arbitrary table value for a three-dimensional LUT space (three-dimensional color space) such as that shown in Figure 25.41 using the processing described above, not only color conversion or color correction for the entire color space, but color conversion or color correction (memory color correction, skin smoothing, etc.) for a particular color area can be achieved.

Next, a 2D-LUT that is used when the CLU is operating in 2D mode is described (M2D bit should be set to 1 for operation in 2D mode). 2D-LUT mode is similar to 3D-LUT mode. However, since the axes for selecting the LUT become two-dimensional, the concept of a 3D-LUT space illustrated in Figure 25.42 changes to a 2D-LUT space like that shown in Figure 25.43.

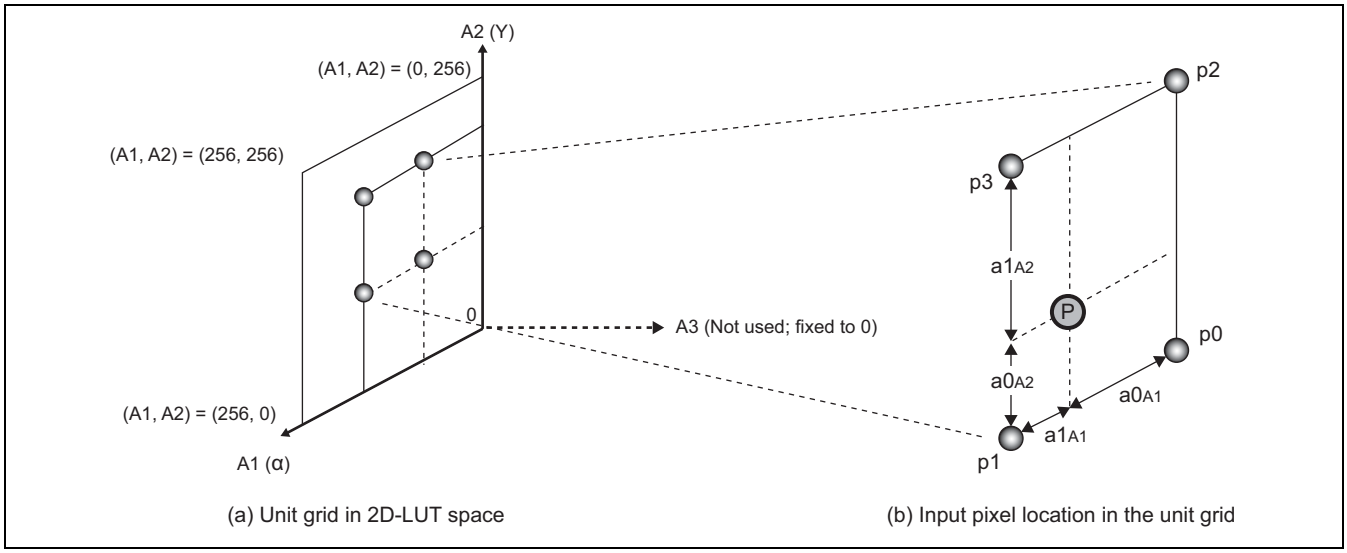

Figure 25.43 Conceptual Diagram of LUT Space when CLU is in 2D Mode

As shown in Figure 25.43 (a), the first axis (A1) and second axis (A2) are used, and the A1-A2 plane becomes the LUT space in 2D mode. Because the third axis (A3) is not used, the CLU always handles the value on the A3 axis as 0.

2D mode can be used only when the CLU input is in the YCbCr color space. The input value of axis A1 is the input α value of the CLU, and the input value of axis A2 is the input luminance Y of the CLU. If the coordinates in the 2D-LUT space which were determined by the input values are exactly on a grid point (e.g., p2 in Figure 25.43 (b)), the table value (p2) set to that location becomes the output value of the 2D-LUT. If the input 2-component value exists at an intermediate location between grid points and not on a grid point, such as position P in Figure 25.43 (b), value P is interpolated from the table values (p0 to p3 in Figure 25.43 (b)) for the four surrounding grid points and this is used as the 2D-LUT output. The interpolated component of the second axis of the 2D-LUT output acquired in this manner becomes the Y component output of the CLU. In 2D mode, the Cb/Cr component is a pass-through output.

For the CLU table values in Figure 25.43 in 2D mode, set a value for only the component value of the second axis, and set 0 for the component values of the first and third axes. For details on the setting method, see section 25.2.2.

25.2.14 HST Control Register

25.2.14.1 HST Control Register (VI6_HST_CTRL)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	HST_EN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	HST_EN	0	R/W	HSV Conversion (RGB → HSV) Enable/Disable Enables or disables RGB → HSV conversion. H indicates hue, S indicates saturation, and V indicates a value (brightness). 0: RGB → HSV conversion is disabled 1: RGB → HSV conversion is enabled

Various color correction processing can be applied to HSV-format images by combining the 1D-LUT and 3D-LUT. For details on the 1D-LUT and 3D-LUT, see sections 25.2.12.1 and 25.2.13.1.

To return HSV-converted data to RGB data, HSV → RGB conversion is used (see section 25.2.15.1). RGB ↔ HSV conversion causes an operation error. Therefore, even when only just performing conversion of RGB → HSV → RGB, the original RGB value and converted RGB value will not completely match.

25.2.15 HSI Control Register

25.2.15.1 HSI Control Register (VI6_HSI_CTRL)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	HSI_EN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	HSI_EN	0	R/W	Reversed HSV Conversion (HSV → RGB) Enable/Disable Enables or disables HSV → RGB conversion to return HSV data that was converted by HSV conversion (see section 25.2.14.1) back to RGB data. 0: HSV → RGB conversion is disabled 1: HSV → RGB conversion is enabled

RGB ↔ HSV conversion causes an operation error. Therefore, even when only just performing conversion of RGB → HSV → RGB, the original RGB value and converted RGB value will not completely match.

25.2.16 BRU Control Registers

25.2.16.1 BRU Input Control Register (VI6_BRU_INCTRL)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	NRM	—	—	—	—	—	—	—	—	D3ON	D2ON	D1ON	D0ON
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	DITH3[2:0]			—	DITH2[2:0]			—	DITH1[2:0]			—	DITH0[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28	NRM	0	R/W	Color Data Normalization Enables or disables division by the α value of the color data in BRU blending operation. This is used when converting the RGB color data format to which the α value is multiplied (premultiplied color) into the RGB color data format to which the α value is not multiplied (non-premultiplied color). Do not use this for the YCbCr format. 0: Divider (DIV unit in Figure 25.44) does not divide the color value by α 1: Divider (DIV unit in Figure 25.44) divides the color value by α
27 to 20	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
19	D3ON	0	R/W	Dithering Enable of BRU Input 3 Enables or disables dithering (color reduction) of BRU input 3 (BRUin3 in Figure 25.44). 0: Dithering of BRUin3 is disabled 1: Dithering of BRUin3 is enabled
18	D2ON	0	R/W	Dithering Enable of BRU Input 2 Enables or disables dithering (color reduction) of BRU input 2 (BRUin2 in Figure 25.44). 0: Dithering of BRUin2 is disabled 1: Dithering of BRUin2 is enabled
17	D1ON	0	R/W	Dithering Enable of BRU Input 1 Enables or disables dithering (color reduction) of BRU input 1 (BRUin1 in Figure 25.44). 0: Dithering of BRUin1 is disabled 1: Dithering of BRUin1 is enabled
16	D0ON	0	R/W	Dithering Enable of BRU Input 0 Enables or disables dithering (color reduction) of BRU input 0 (BRUin0 in Figure 25.44). 0: Dithering of BRUin0 is disabled 1: Dithering of BRUin0 is enabled

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
14 to 12	DITH3[2:0]	000	R/W	Dithering of CH3 Input to BRU These bits specify the number of colors for pixels after dithering (color reduction) when dithering (color reduction) for pixel information is enabled through the D3ON bit. When dithering (color reduction) for pixel information is disabled, specify 0 in these bits. 000: Dithering of BRUin3 input image is disabled 001: Dithering of BRUin3 input image at 18 bpp (RGB666: 262,144 colors) 010: Dithering of BRUin3 input image at 16 bpp (RGB565: 65,536 colors) 011: Dithering of BRUin3 input image at 15 bpp (RGB555: 32,768 colors) 100: Dithering of BRUin3 input image at 12 bpp (RGB444: 4,096 colors) 101: Dithering of BRUin3 input image at 8 bpp (RGB332: 256 colors) 110, 111: Setting prohibited
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
10 to 8	DITH2[2:0]	000	R/W	Dithering of CH2 Input to BRU These bits specify how to perform dithering of the CH2 input to the BRU. The setting method is the same as that for the DITH3 bits. Read the description of the DITH3 bits with BRUin2 and D2ON replacing BRUin3 and D3ON, respectively.
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6 to 4	DITH1[2:0]	000	R/W	Dithering of CH1 Input to BRU These bits specify how to perform dithering of the CH1 input to the BRU. The setting method is the same as that for the DITH3 bits. Read the description of the DITH3 bits with BRUin1 and D1ON replacing BRUin3 and D3ON, respectively.
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
2 to 0	DITH0[2:0]	000	R/W	Dithering of CH0 Input to BRU These bits specify how to perform dithering of the CH0 input to the BRU. The setting method is the same as that for the DITH3 bits. Read the description of the DITH3 bits with BRUin0 and D0ON replacing BRUin3 and D3ON, respectively.

Figure 25.44 shows the configuration of the BRU. For the BRU inputs, there are four inputs from the DPR and one internal input as a virtual RPF. BRUin0 to BRUin3 are input ports that have the target node values shown in Figure 25.33, and they can be connected to any module on the DPR. The same color space (YCbCr or RGB) has to be used for the four inputs from the DPR to the BRU.

The virtual RPF inside the BRU is an input unit not connected to the DPR. It is called the "virtual RPF" because it outputs images internally created by the BRU. Starting of the virtual RPF is controlled by VI6_WPFn_SRCRPF.VIR_ACT, and the single-color data created at the virtual RPF can be used for blending or raster operation (ROP) with data from the other input units BRUin0 to BRUin3. The color space for the single color to be set

for the virtual RPF needs to match the color space of the four inputs from the DPR to the BRU. For this setting method, see section 25.2.16.4.

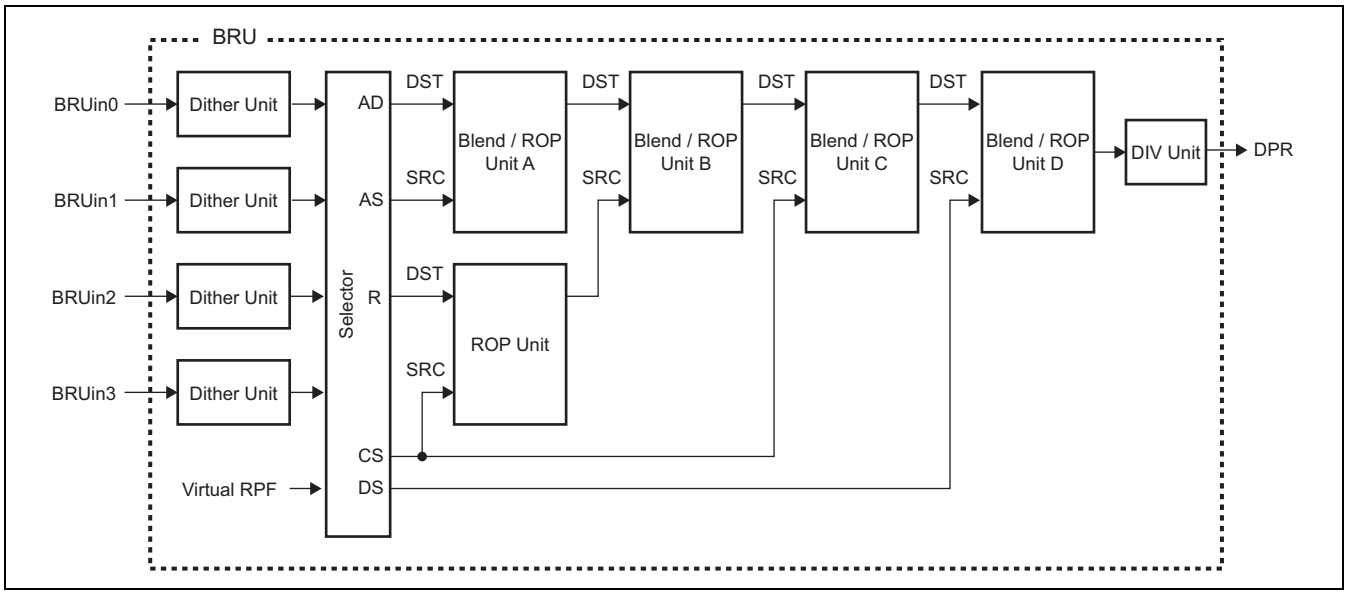

Figure 25.44 BRU Configuration

The selector in Figure 25.44 is used to select the SRC and DST inputs to blending/ROP units A to D and the ROP unit from BRUin0 to BRUin3 which are inputs from the DPR and the virtual RPF. The SRC and DST input sources for blending/ROP units A to D and the ROP unit are either uniquely determined based on the configuration shown in Figure 25.44 (Table 25.32) or selected as desired by registers. The input sources that can be arbitrarily selected by registers are AD, AS, R, CS, and DS, which correspond to the registers shown in Table 25.33.

Table 25.32 SRC and DST with Unique Input Sources

Input	Input Source	Register Bits
Blending/ROP unit B - DST	Output from blending/ROP unit A	—
Blending/ROP unit B - SRC	Output from ROP unit	—
Blending/ROP unit C - DST	Output from blending/ROP unit B	—
Blending/ROP unit D - DST	Output from blending/ROP unit C	—
ROP unit - SRC	CS which is a selector output	VI6_BRUC_CTRL.SRCSEL

Table 25.33 Correspondence between Selector Output Destinations and Register Bits

Selector Output	Output Destination	Register Bits
AD	Blending/ROP unit A - DST	VI6_BRUA_CTRL.DSTSEL
AS	Blending/ROP unit A - SRC	VI6_BRUA_CTRL.SRCSEL
R	ROP unit - DST	VI6_BRU_ROP.DSTSEL
CS	Blending/ROP unit C - SRC	VI6_BRUC_CTRL.SRCSEL
DS	Blending/ROP unit D - SRC	VI6_BRUD_CTRL.SRCSEL

25.2.16.2 Size Register of BRU Input Virtual RPF (VI6_BRU_VIRRPF_SIZE)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	VIR_HSIZE[12:0]												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

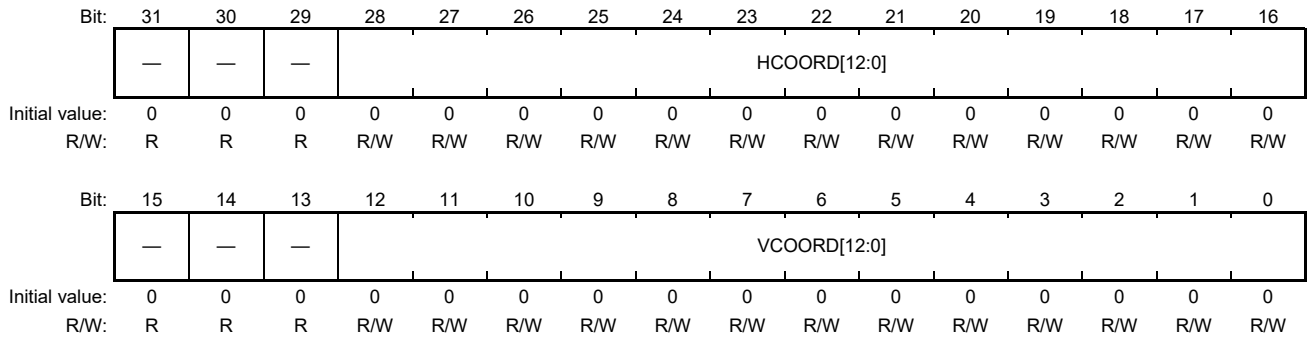
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	VIR_VSIZE[12:0]												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 16	VIR_HSIZE [12:0]	H'0000	R/W	Virtual RPF Horizontal Size These bits set the horizontal size of an image from the virtual RPF shown in Figure 25.44. A value from 1 to 8,190 can be specified.
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 0	VIR_VSIZE [12:0]	H'0000	R/W	Virtual RPF Vertical Size These bits set the vertical size of an image from the virtual RPF shown in Figure 25.44. A value from 1 to 8,190 can be specified.

The virtual RPF has only a function to output a fixed α value and a fixed pixel value. The virtual RPF can internally create a single-color image without accessing external memory via the MAU. Same as images from the other BRU input ports, a sub layer can be blended on an image created in this manner with the image used as the background (master layer). In turn, when using the image as a sub layer, it can be drawn on the master layer as a window.

Note that the virtual RPF is fixed to input port 5 of the BRU, and the data path route cannot be changed by the DPR.

25.2.16.3 Display Location Register of BRU Input Virtual RPF (VI6_BRU_VIRRPF_LOC)



Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 16	HCOORD [12:0]	H'0000	R/W	Horizontal Coordinate of Virtual RPF Location on Master Layer These bits specify the horizontal coordinate of where to locate the left-edge pixel of the virtual RPF's layer, with the left-edge pixel of the master layer set at coordinate 0. This setting should be made in pixel units. A value from 0 to 8,189 can be specified. When the virtual RPF is specified as the master layer by VI6_WPFn_SRCRPF.VIR_ACT, set these bits to 0.
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 0	VCOORD [12:0]	H'0000	R/W	Vertical Coordinate of Virtual RPF Location on Master Layer These bits specify the vertical coordinate of where to locate the top-edge pixel of the virtual RPF's layer, with the top-edge pixel of the master layer set at coordinate 0. This setting should be made in pixel units. A value from 0 to 8,189 can be specified. When the virtual RPF is specified as the master layer by VI6_WPFn_SRCRPF.VIR_ACT, set these bits to 0.

25.2.16.4 Color Information Register of BRU Input Virtual RPF (VI6_BRU_VIRRPF_COL)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	COL_A[7:0]								COL_RCR[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	COL_GY[7:0]								COL_BCB[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	COL_A[7:0]	H'00	R/W	Fixed α of Virtual RPF These bits set the fixed α value when the virtual RPF creates a virtual plane. A value from 0 to 255 can be specified.
23 to 16	COL_RCR [7:0]	H'00	R/W	Fixed R/Cr of Virtual RPF These bits set the fixed R/Cr value when the virtual RPF creates a virtual plane. A value from 0 to 255 can be specified.
15 to 8	COL_GY [7:0]	H'00	R/W	Fixed G/Y of Virtual RPF These bits set the fixed G/Y value when the virtual RPF creates a virtual plane. A value from 0 to 255 can be specified.
7 to 0	COL_BCB [7:0]	H'00	R/W	Fixed B/Cb of Virtual RPF These bits set the fixed B/Cb value when the virtual RPF creates a virtual plane. A value from 0 to 255 can be specified.

The transparency information and color information of the single color that is created by the virtual RPF are set in the bits of this register. As described earlier, the color information is set for the YCbCr or RGB color space. The color space to be set in this register depends on the register settings of the environment and other modules to which the BRU is connected by the DPR. Two cases can be considered. Since the α value (COL_A) is transparency information and irrelevant to the concept of color space, the same setting is made for either the YCbCr or RGB color space.

(Case 1: When an input other than the virtual RPF is used)

When the source RPF is connected to any one of the BRU input ports (BRUin0 to BRUin3) other than the virtual RPF and valid data is being supplied, the same color space data as the color space for the BRU inputs should be set in this register as the color space for the virtual RPF's color information. This is based on the restriction of "all BRU inputs must have the same color space", as described in section 25.2.9.1 or 25.2.16.1.

(Case 2: When only the virtual RPF is used)

When only the virtual RPF is used as the source RPF of WPFn, RPFn is not connected to the BRU, as shown in Figure 25.45. Thus, there is no color space for another input that the color space for the virtual RPF has to follow, as in case 1. This means that the color space of the data output by the BRU is determined by the WPF setting.

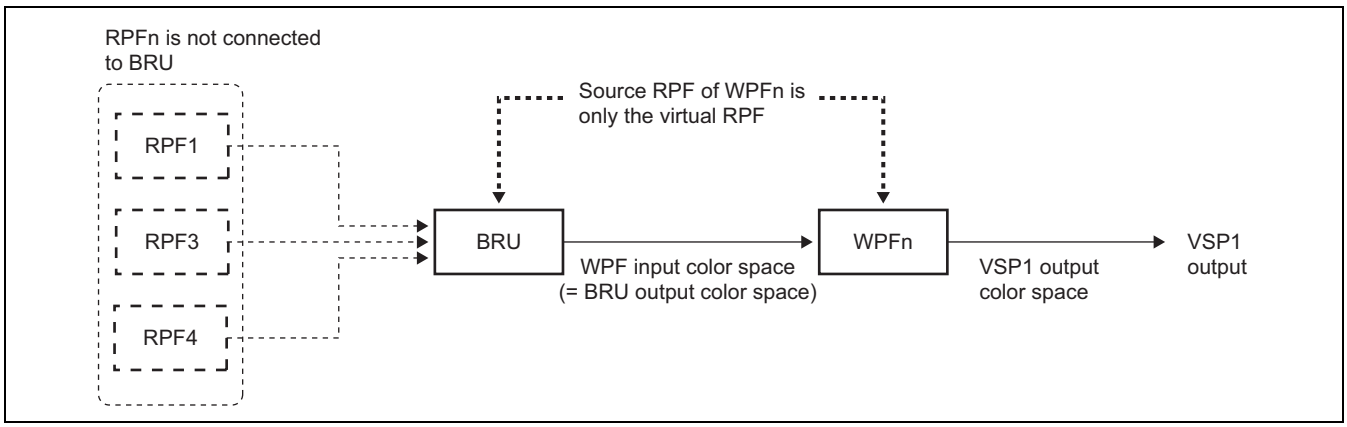


Figure 25.45 Relationship between DPR Connection and Color Space when Only Virtual RPF is Used

As shown in Figure 25.45, the output color space of the VSP1 (= output color space of WPFn) is determined by VI6_WPFn_OUTFMT.WRFMT. When bit 6 in VI6_WPFn_OUTFMT.WRFMT (WRFMT[6]) is 0, the color space is RGB, while when it is 1, the color space is YCbCr. Next, the WPF input color space (= BRU output color space) is determined by the relationship between the WPF output color space and VI6_WPFn_OUTFMT.CSC. When VI6_WPFn_OUTFMT.CSC is 0, the WPF output color space and WPF input color space (= BRU output color space) are the same. When VI6_WPFn_OUTFMT.CSC is 1, the WPF output color space and WPF input color space (= BRU output color space) are the opposite. This relationship is summarized in Table 25.34.

The color space for the virtual RPF's color information should be set in this register according to the "BRU output color space" shown in Table 25.34.

Table 25.34 Relationship between WPF Output Color Space and BRU Output Color Space

VI6_WPFn_OUTFMT Register Bit Settings				BRU Output Color Space (= WPF Input Color Space)
Bit 6 in WRFMT		CSC		
0	(WPF output is RGB)	0	(YCbCr → RGB conversion is disabled)	RGB
0	(WPF output is RGB)	1	(YCbCr → RGB conversion is enabled)	YCbCr
1	(WPF output is YCbCr)	0	(RGB → YCbCr conversion is disabled)	YCbCr
1	(WPF output is YCbCr)	1	(RGB → YCbCr conversion is enabled)	RGB

25.2.16.5 BRU Control Registers (VI6_BRUm_CTRL: m = A, B, C, D)

R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	RBC	0	R/W	Operation Type of Blending/ROP Unit m (m = A, B, C, D) Specifies the operation type for blending/ROP unit m (m = A, B, C, D) shown in Figure 25.44. 0: ROP (raster operation) 1: Blending operation
30 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 20	DSTSEL[2:0]	000	R/W	Input Selection for DST Side of Blending/ROP Unit A These bits select the input for the DST side of blending/ROP unit A shown in Figure 25.44. These bits specify the connection between the BRU input port and the DST separately from the setting of connections between other modules and the BRU input port through the DPR. 000: BRU input 0 (BRUin0) is input to DST 001: BRU input 1 (BRUin1) is input to DST 010: BRU input 2 (BRUin2) is input to DST 011: BRU input 3 (BRUin3) is input to DST 100: Virtual RPF is input to DST 101 to 111: Setting prohibited Note: The DSTSEL bits for blending/ROP unit m (m = B, C, D) are reserved according to Table 25.32. The write value should always be 0.
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
18 to 16	SRCSEL[2:0]	000	R/W	Input Selection for SRC Side of Blending/ROP Unit m (m = A, C, D) These bits select the input for the SRC side of blending/ROP unit m (m = A, C, D) shown in Figure 25.44. These bits specify the connection between the BRU input port and the SRC separately from the setting of connections between other modules and the BRU input port through the DPR. 000: BRU input 0 (BRUin0) is input to SRC 001: BRU input 1 (BRUin1) is input to SRC 010: BRU input 2 (BRUin2) is input to SRC 011: BRU input 3 (BRUin3) is input to SRC 100: Virtual RPF is input to SRC 101 to 111: Setting prohibited Note: The SRCSEL bits for blending/ROP unit B are reserved according to Table 25.32. The write value should always be 0.
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 4	CROP[3:0]	0000	R/W	Color Data ROP Operator These bits select the ROP operator of the color data in blending/ROP unit m (m = A, B, C, D). Select the opcode for ROP operation from Table 25.35.
3 to 0	AROP[3:0]	0000	R/W	α Data ROP Operator These bits select the ROP operator of the α data in blending/ROP unit m (m = A, B, C, D). Select the opcode for ROP operation from Table 25.35.

Table 25.35 ROP Operator of Blending/ROP Unit m (m = A, B, C, D)

Opcode	Operator
B'0000	NOP(D)
B'0001	AND(S & D)
B'0010	AND_REVERSE(S & ~D)
B'0011	COPY(S)
B'0100	AND_INVERTED(~S & D)
B'0101	CLEAR(0)
B'0110	XOR(S ^ D)
B'0111	OR(S | D)
B'1000	NOR(~(S | D))
B'1001	EQUIV(~(S ^ D))
B'1010	INVERT(~D)
B'1011	OR_REVERSE(S | ~D)
B'1100	COPY_INVERTED(~S)
B'1101	OR_INVERTED(~S | D)
B'1110	NAND(~(S & D))
B'1111	SET(all1)

25.2.16.6 BRU Blend Control Registers (VI6_BRUm_BLD: m = A , B, C, D)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	CBES	0	R/W	Blending Expression Selection Selects the blending expression of the color data in the BRU (VI6_BRUm_CTRL.RBC = 1). Blending coefficients are specified by the CCMDX and CCMDY bits. 0: CCMDX × (DST color data) + CCMDY × (SRC color data) 1: CCMDX × (DST color data) – CCMDY × (SRC color data)
30 to 28	CCMDX[2:0]	000	R/W	Blending Coefficient X Selection These bits specify coefficient X used in the blending expression determined by the CBES bit. 000: DST α data is used as blending coefficient X 001: 255 – (DST α data) is used as blending coefficient X 010: SRC α data is used as blending coefficient X 011: 255 – (SRC α data) is used as blending coefficient X 100: Fixed α value 0 (COEFX setting)
27	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
26 to 24	CCMDY[2:0]	000	R/W	Blending Coefficient Y Selection These bits specify coefficient Y used in the blending expression determined by the CBES bit. 000: DST α data is used as blending coefficient Y 001: 255 – (DST α data) is used as blending coefficient Y 010: SRC α data is used as blending coefficient Y 011: 255 – (SRC α data) is used as blending coefficient Y 100: Fixed α value 1 (COEFY setting)
23	ABES	0	R/W	Blending α Creation Expression Specifies the expression for creating α data after blending by blending/ROP unit m (m = A, B, C, D). α creation coefficients are specified by the ACMDX and ACMDY bits. 0: ACMDX × (DST α data) + ACMDXY × (SRC α data) 1: ACMDX × (DST α data) – ACMDXY × (SRC α data)

Bit	Bit Name	Initial Value	R/W	Description
22 to 20	ACMDX[2:0]	000	R/W	α Creation Coefficient X These bits specify α creation coefficient X used in the α creation expression determined by the ABES bit. 000: (α creation coefficient X) = (DST α data) 001: (α creation coefficient X) = 255 – (DST α data) 010: (α creation coefficient X) = (SRC α data) 011: (α creation coefficient X) = 255 – (SRC α data) 100: (α creation coefficient X) = Fixed α value 0 (COEFX setting) 101 to 111: Setting prohibited
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
18 to 16	ACMDY[2:0]	000	R/W	α Creation Coefficient Y These bits specify α creation coefficient Y used in the α creation expression determined by the ABES bit. 000: (α creation coefficient Y) = (DST α data) 001: (α creation coefficient Y) = 255 – (DST α data) 010: (α creation coefficient Y) = (SRC α data) 011: (α creation coefficient Y) = 255 – (SRC α data) 100: (α creation coefficient Y) = Fixed α value 1 (COEFY setting) 101 to 111: Setting prohibited
15 to 8	COEFX[7:0]	H'00	R/W	Fixed α Value 0 These bits specify fixed α value 0 used when the CCMDX or ACMDX bits are set to B'100. A value from H'00 to H'FF can be specified.
7 to 0	COEFY[7:0]	H'00	R/W	Fixed α Value 1 These bits specify fixed α value 1 used when the CCMDY or ACMDY bits are set to B'100. A value from H'00 to H'FF can be specified.

25.2.16.7 BRU Raster Operation Control Register (VI6_BRU_ROP)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	DSTSEL[2:0]			—	—	—	—

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	CROP[3:0]				AROP[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22 to 20	DSTSEL[2:0]	000	R/W	Input Selection for DST Side of ROP Unit These bits select the input for the DST side of the ROP unit. For the SRC side, the same data as the input for the SRC side of blending/ROP unit C is input. 000: BRU input 0 (BRUin0) is input to DST 001: BRU input 1 (BRUin1) is input to DST 010: BRU input 2 (BRUin2) is input to DST 011: BRU input 3 (BRUin3) is input to DST 100: Virtual RPF is input to DST 101 to 111: Setting prohibited
19 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 4	CROP[3:0]	0000	R/W	Color Data ROP Operator These bits select the ROP operator of the color data in the ROP unit. Select the opcode for ROP operation from Table 25.35.
3 to 0	AROP[3:0]	0000	R/W	α Data ROP Operator These bits select the ROP operator of the α data in the ROP unit. Select the opcode for ROP operation from Table 25.35.

25.2.17 HGO Control Registers

25.2.17.1 HGO Detection Window Offset Register (VI6_HGO_OFFSET)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	HOFFSET[13:0]													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	VOFFSET[13:0]													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29 to 16	HOFFSET[13:0]	H'0000	R/W	Horizontal Offset of Histogram Detection Window The HGO creates a histogram for the detection window in the input image (Figure 25.46). In these bits, specify the value of horizontal offset (hoffset shown in Figure 25.46) in pixel units. A value from 0 to 8,191 can be specified. The value of HOFFSET shall be smaller than that of the input image size of HGO.
15, 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 0	VOFFSET[13:0]	H'0000	R/W	Vertical Offset of Histogram Detection Window The HGO creates a histogram for the detection window in the input image (Figure 25.46). In these bits, specify the value of vertical offset (voffset shown in Figure 25.46) in pixel units. A value from 0 to 8,191 can be specified. The value of VOFFSET shall be smaller than that of the input image size of HGO.

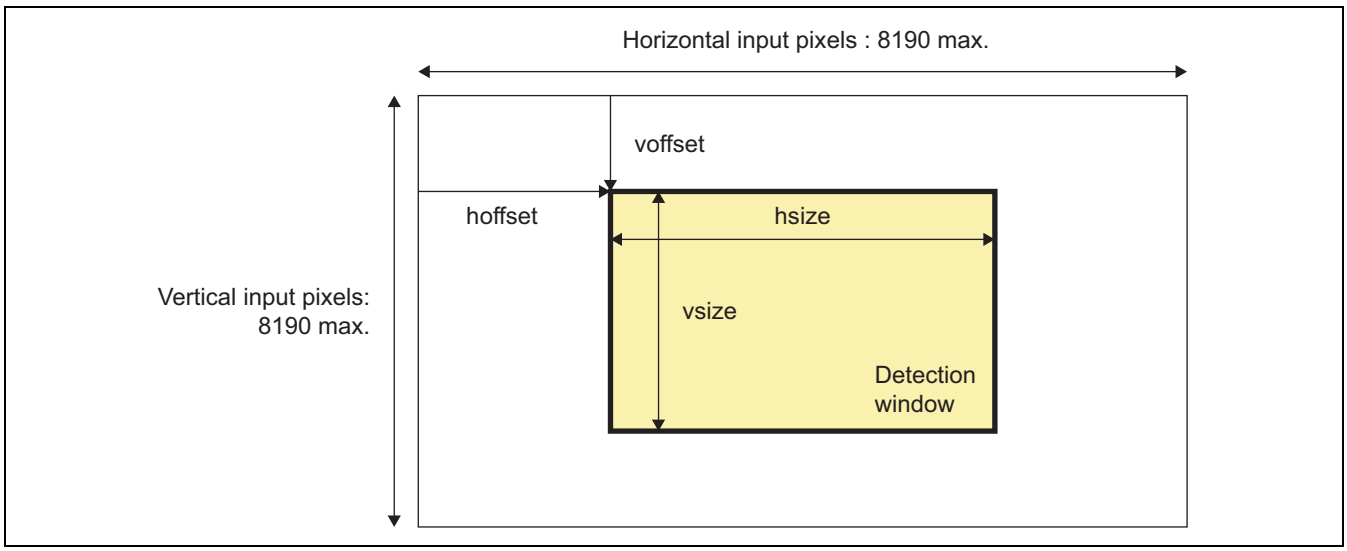

Figure 25.46 Histogram Detection Window of HGO

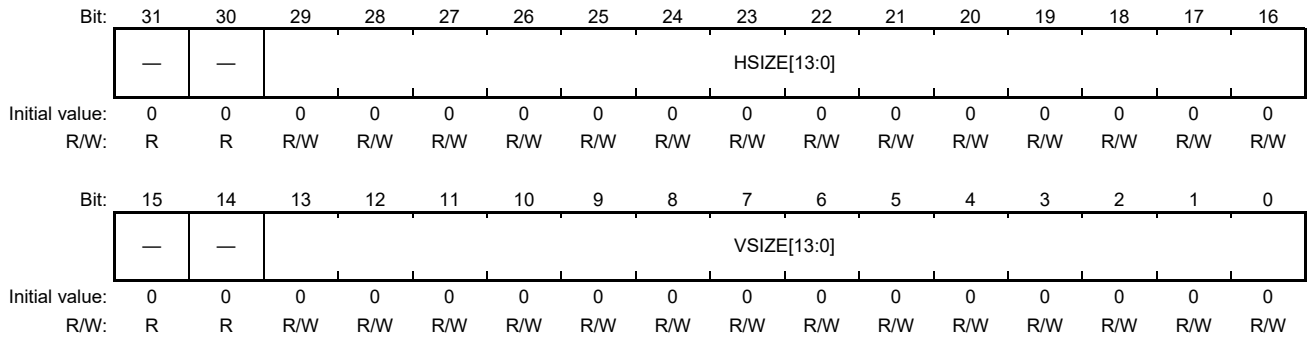
25.2.17.2 HGO Detection Window Size Register (VI6_HGO_SIZE)



Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29 to 16	HSIZE[13:0]	H'0000	R/W	Horizontal Size of Histogram Detection Window The HGO creates a histogram for the detection window in the input image (Figure 25.46). In these bits, specify the value of horizontal size (hsize shown in Figure 25.46) in pixel units. A value from 1 to 8,192 can be specified.
15, 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 0	VSIZE[13:0]	H'0000	R/W	Vertical Size of Histogram Detection Window The HGO creates a histogram for the detection window in the input image (Figure 25.46). In these bits, specify the value of vertical size (vsize shown in Figure 25.46) in pixel units. A value from 1 to 8,192 can be specified.

25.2.17.3 HGO Mode Register (VI6_HGO_MODE)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	MAX RGB	OFSB_ R	OFSB_ G	OFSB_ B	HRATIO[1:0]		VRATIO[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	MAXRGB	0	R/W	Histogram Source Component Setting 0: The histogram is generated from 3 color components independently. 1: The histogram is generated from the maximum value of input R, G and B data.
6	OFSB_R	0	R/W	Offset Binary Mode for R/Cr/H Component 0: Straight binary 1: Offset binary In offset binary mode, values are converted to absolute values before they are used to detect the maximum value, minimum value, sum, and black band. Note that values without conversion are always used for histogram creation regardless of this mode setting.
5	OFSB_G	0	R/W	Offset Binary Mode for G/Y/S/max (R, G, B) Component 0: Straight binary 1: Offset binary In offset binary mode, values are converted to absolute values before they are used to detect the maximum value, minimum value, sum, and black band. Note that values without conversion are always used for histogram creation regardless of this mode setting.
4	OFSB_B	0	R/W	Offset Binary Mode for B/Cb/V Component 0: Straight binary 1: Offset binary In offset binary mode, values are converted to absolute values before they are used to detect the maximum value, minimum value, sum, and black band. Note that values without conversion are always used for histogram creation regardless of this mode setting.

Bit	Bit Name	Initial Value	R/W	Description
3, 2	HRATIO[1:0]	00	R/W	Horizontal Pixel Skipping Mode for Histogram Detection 00: No skipping for horizontal pixels. 01: Horizontal 1/2 skipping. One pixel is discarded from every two pixels before a histogram is created. 10: Horizontal 1/4 skipping. Three pixels are discarded from every four pixels before a histogram is created. The first pixel in the horizontal direction is not discarded but subsequent pixels are discarded (regardless of the histogram detection window). Among the pixels that have not been discarded, only the pixels within the detection window are used to create a histogram.
1, 0	VRATIO[1:0]	00	R/W	Vertical Pixel Skipping Mode for Histogram Detection 00: No skipping for vertical pixels. 01: Vertical 1/2 skipping. One pixel is discarded from every two pixels before a histogram is created. 10: Vertical 1/4 skipping. Three pixels are discarded from every four pixels before a histogram is created. The first pixel in the vertical direction is not discarded but subsequent pixels are discarded (regardless of the histogram detection window). Among the pixels that have not been discarded, only the pixels within the detection window are used to create a histogram.

25.2.17.4 HGO LB Detection Threshold Register (VI6_HGO_LB_TH)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	BLACK_TH[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	BLACK_TH[7:0]	H'00	R/W	Threshold for Black Level Determination in Letter Box Detection In letter box detection, when all input pixels have the value equal to or smaller than the value specified in these bits, the image data is determined as black. Note that the letter box detection is not affected by the histogram detection window illustrated in Figure 25.46. A value from 0 to 255 can be specified.

25.2.17.5 HGO Horizontal Position Register for LB Detection Zone-n (VI6_HGO_LBn_H: n = 0, 1, 2, 3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	HPOS0[13:0]													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	HPOS1[13:0]													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29 to 16	HPOS0[13:0]	H'0000	R/W	Horizontal Start Position for Letter Box Detection Zone-n When all pixels on a line (shown in Figure 25.47) in the input image have the value equal to or smaller than the threshold value, the HGO determines that there is a letter box. In these bits, specify the value of hpos0 of the detection zone-n (Figure 25.47) in pixel units. A value from 0 to 8,191 can be specified. HPOS0 ≤ HPOS1 should be satisfied. These bits are valid for Zone-0 and 1. For Zone-2 and 3, these bits are reserved.
15, 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 0	HPOS1[13:0]	H'0000	R/W	Horizontal End Position for Letter Box Detection Zone-n When all pixels on a line (shown in Figure 25.47) in the input image have the value equal to or smaller than the threshold value, the HGO determines that there is a letter box. In these bits, specify the value of hpos1 of the detection zone-n (Figure 25.47) in pixel units. A value from 0 to 8,191 can be specified. HPOS0 ≤ HPOS1 should be satisfied.

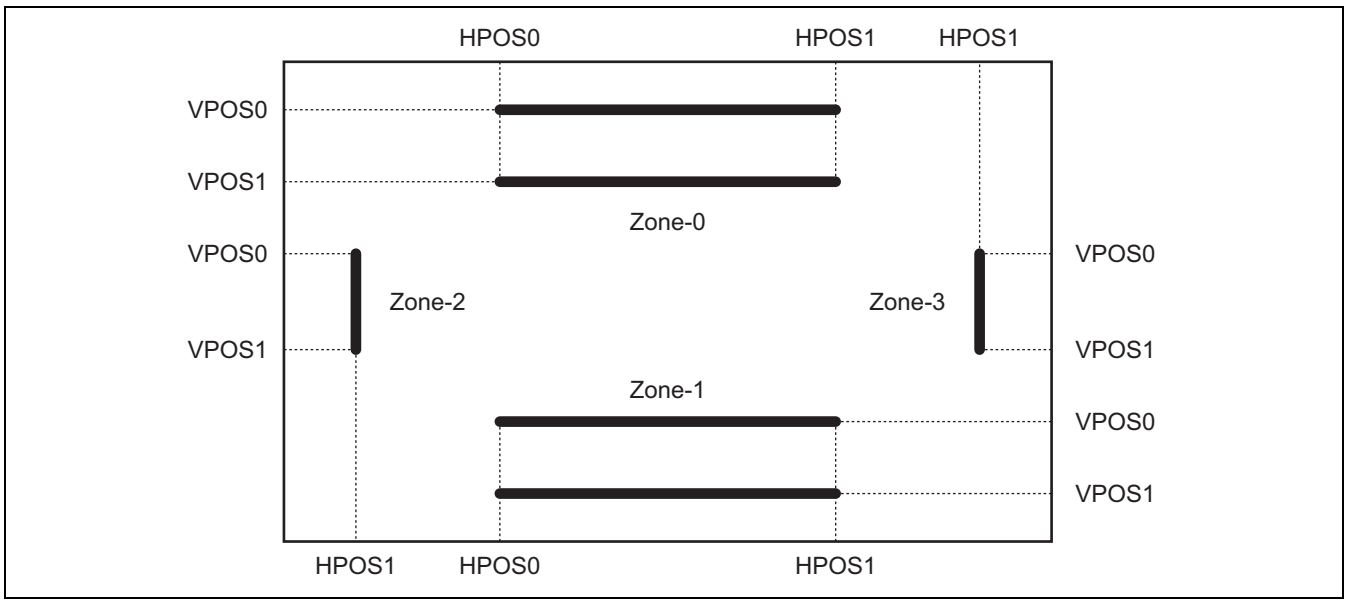


Figure 25.47 Letter Box Detection Position Settings for HGO

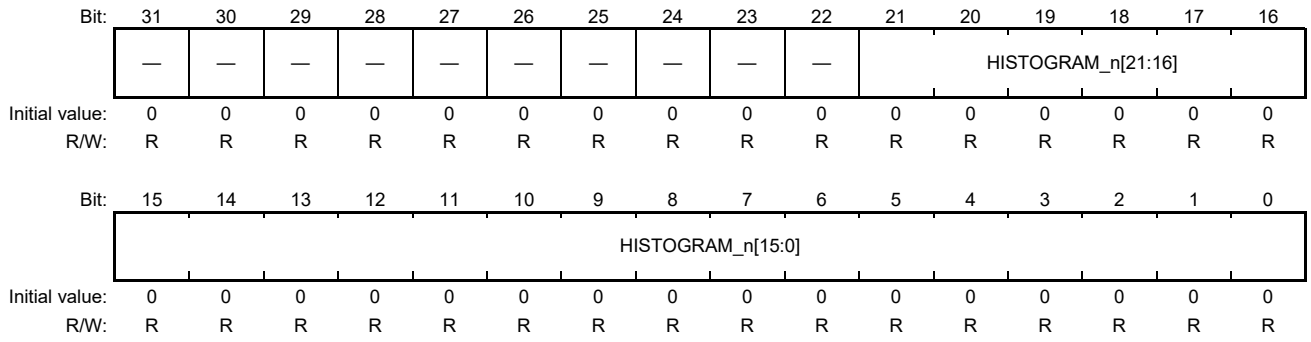
25.2.17.6 HGO Vertical Position Register for LB Detection Zone-n (VI6_HGO_LBn_V: n = 0, 1, 2, 3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	VPOS0[13:0]													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	VPOS1[13:0]													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29 to 16	VPOS0[13:0]	H'0000	R/W	Vertical Start Position for Letter Box Detection Zone-n When all pixels on a line (shown in Figure 25.47) in the input image have the value equal to or smaller than the threshold value, the HGO determines that there is a letter box In these bits, specify the value of vpos0 of the detection zone-n (Figure 25.47) in pixel units. A value from 0 to 8,191 can be specified. VPOS0 ≤ VPOS1 should be satisfied.
15, 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 0	VPOS1[13:0]	H'0000	R/W	Vertical End Position for Letter Box Detection Zone-n When all pixels on a line (shown in Figure 25.47) in the input image have the value equal to or smaller than the threshold value, the HGO determines that there is a letter box. In these bits, specify the value of vpos1 of the detection zone-n (Figure 25.47) in pixel units. A value from 0 to 8,191 can be specified. VPOS0 ≤ VPOS1 should be satisfied.

25.2.17.7 HGO Component-m Histogram Register (VI6_HGO_m_HISTO_n: m = R, G, B, n = 0 to 63)



Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21 to 0	HISTOGRAM_n [21:0]	H'00 0000	R	Frequency of Component-m in the value range-n From these bits, the count of the pixels whose component-m value (val) satisfies the following condition within the histogram detection window (Figure 25.46) is read (after pixel skipping is applied when skipping mode is selected). $4 \times n \leq val < 4 \times (n + 1)$ Counting starts after the HGO is activated. To read the histogram, read these bits after the HGO has completed processing of one screen of data and before the HGO is activated again.

The component-m in a color space is determined by the following table.

	Color Space			
	RGB		YCbCr	HSV
Index-m	VI6_HGO_MODE. MAXRGB = 0	VI6_HGO_MODE. MAXRGB = 1	VI6_HGO_MODE. MAXRGB = 0*1	VI6_HGO_MODE. MAXRGB = 0*1
R	R	n/a*2	Cr	H
G	G	max (R, G, B)*3	Y	S
B	B	n/a*2	Cb	V

Notes: 1. When color space of input data is in YCbCr or HSV, set VI6_HGO_MODE.MAXRGB = 0.
2. When VI6_HGO_MODE.MAXRGB = 1, the histogram of index-R / index-B are not ensured.
3. max (R, G, B) indicates maximum value of input R, G and B data.

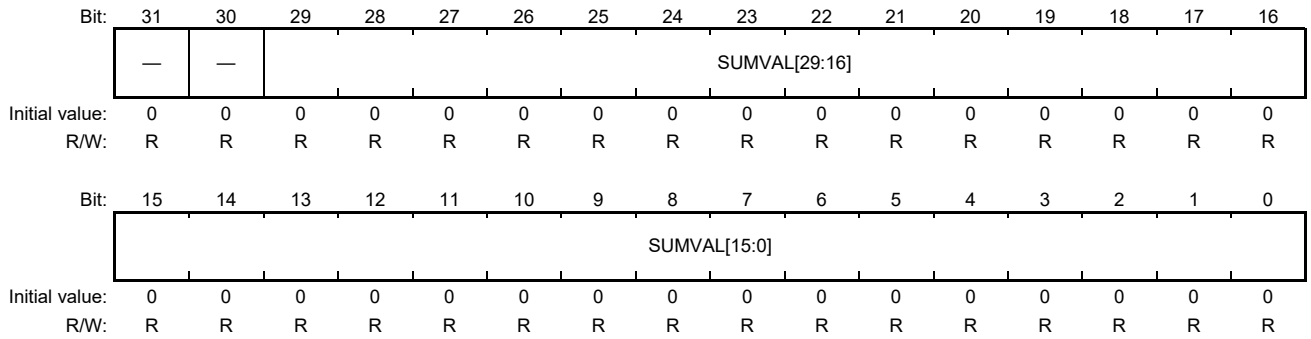
25.2.17.8 HGO Component-m Min/Max Value Register (VI6_HGO_m_MAXMIN: m = R, G, B)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	MAXVAL[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	MINVAL[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	MAXVAL[7:0]	H'00	R	Maximum Value of Component-m From these bits, the maximum value of the component-m of the pixels within the histogram detection window (Figure 25.46) is read (after pixel skipping is applied when skipping mode is selected). Maximum value detection starts after the HGO is activated. To read the maximum value, read these bits after the HGO has completed processing of one screen of data and before the HGO is activated again.
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	MINVAL[7:0]	H'00	R	Minimum Value of Component-m From these bits, the minimum value of the component-m of the pixels within the histogram detection window (Figure 25.46) is read (after pixel skipping is applied when skipping mode is selected). Minimum value detection starts after the HGO is activated. To read the minimum value, read these bits after the HGO has completed processing of one screen of data and before the HGO is activated again.

25.2.17.9 HGO Component-m Sum Register (VI6_HGO_m_SUM: m = R, G, B)



Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29 to 0	SUMVAL[29:0]	H'0000 0000	R	Sum of Component-m From these bits, the sum of the component-m of the pixels within the histogram detection window (Figure 25.46) is read (after pixel skipping is applied when skipping mode is selected). Accumulation starts after the HGO is activated. To read the sum, read these bits after the HGO has completed processing of one screen of data and before the HGO is activated again.

25.2.17.10 HGO Component-m LB Detection Result Register (VI6_HGO_m_LB_DET: m = R, G, B)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	LTRBOX1	LTRBOX2	SIDE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	LTRBOX1	0	R	Letter Box Detection Result #1 of Zone-0/1 for Component-m This bit is set to 1 when none of the component-m of the pixels on the lines of zone-0/vpos0 and zone-1/vpos1 (two lines in total) in Figure 25.47 exceeds the threshold (BLACK_TH). If any pixel is greater than the threshold, this bit is set to 0. Read this bit after the HGO has completed processing of one screen of data and before the HGO is activated again. The value read during processing is not guaranteed to be correct.
1	LTRBOX2	0	R	Letter Box Detection Result #2 of Zone-0/1 for Component-m This bit is set to 1 when none of the component-m of the pixels on the four lines of zone-0 and 1 in Figure 25.47 exceeds the threshold (BLACK_TH). If any pixel is greater than the threshold, this bit is set to 0. Read this bit after the HGO has completed processing of one screen of data and before the HGO is activated again. The value read during processing is not guaranteed to be correct.
0	SIDE	0	R	Letter Box Detection Result of Zone-2/3 for Component-m This bit is set to 1 when none of the component-m of the pixels on the two lines of zone-2 and 3 in Figure 25.47 exceeds the threshold (BLACK_TH). If any pixel is greater than the threshold, this bit is set to 0. Read this bit after the HGO has completed processing of one screen of data and before the HGO is activated again. The value read during processing is not guaranteed to be correct.

25.2.17.11 HGO Parameter Register Reset (VI6_HGO_REGRST)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RCLEA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	RCLEA	0	W	Register Reset Writing 1 to this bit resets all read-only registers (sections 25.2.17.7 to 25.2.17.10) to their initial values. This register is write-only and is always read as 0. Note that R/W registers (sections 25.2.17.1 to 25.2.17.6) are not affected by write access to this register.

25.2.18 HGT Control Registers

25.2.18.1 HGT Detection Window Offset Register (VI6_HGT_OFFSET)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	HOFFSET[13:0]													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	VOFFSET[13:0]													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29 to 16	HOFFSET[13:0]	H'0000	R/W	Horizontal Offset of Histogram Detection Window The HGT creates a histogram for the detection window in the input image (Figure 25.48). In these bits, specify the value of horizontal offset (hoffset shown Figure 25.48) in pixel units. A value from 0 to 8,191 can be specified. The value of HOFFSET shall be smaller than that of the input image size of HGT.
15, 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 0	VOFFSET[13:0]	H'0000	R/W	Vertical Offset of Histogram Detection Window The HGT creates a histogram for the detection window in the input image (Figure 25.48). In these bits, specify the value of vertical offset (voffset shown in Figure 25.48) in pixel units. A value from 0 to 8,191 can be specified. The value of VOFFSET shall be smaller than that of the input image size of HGT.

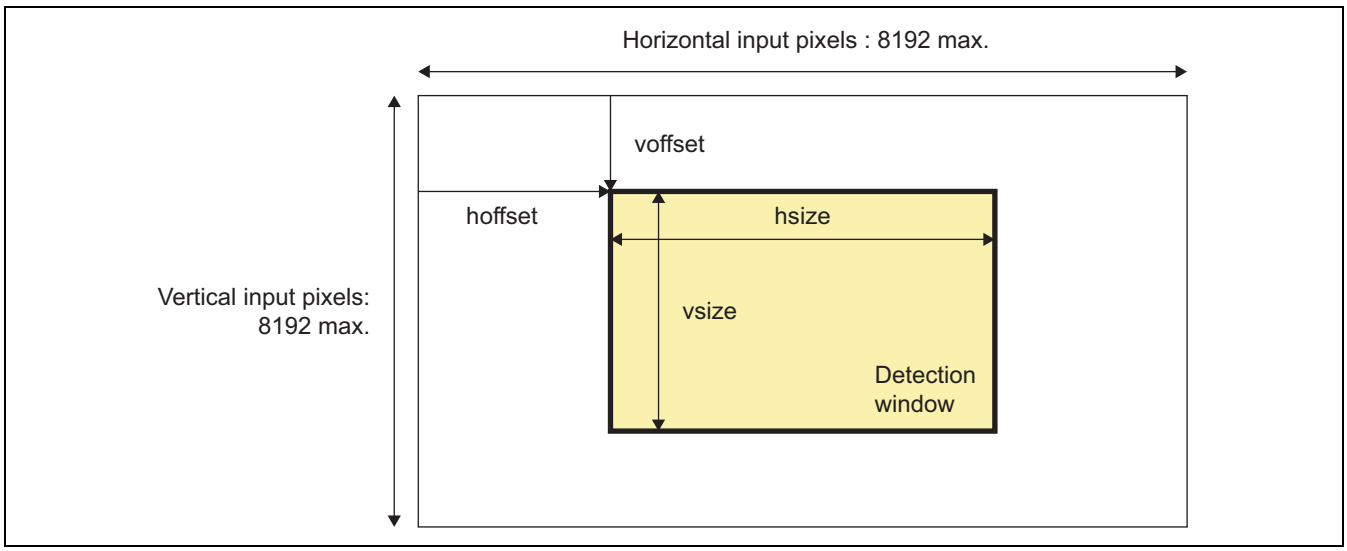


Figure 25.48 Histogram Detection Window of HGT

25.2.18.2 HGT Detection Window Size Register (VI6_HGT_SIZE)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	HSIZE[13:0]													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	VSIZE[13:0]													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29 to 16	HSIZE[13:0]	H'0000	R/W	Horizontal Size of Histogram Detection Window The HGT creates a histogram for the detection window in the input image (Figure 25.48). In these bits, specify the value of horizontal offset (hsize shown in Figure 25.48) in pixel units. A value from 1 to 8,192 can be specified.
15, 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 0	VSIZE[13:0]	H'0000	R/W	Vertical Size of Histogram Detection Window The HGT creates a histogram for the detection window in the input image (Figure 25.48). In these bits, specify the value of vertical offset (vsize shown in Figure 25.48) in pixel units. A value from 1 to 8,192 can be specified.

25.2.18.3 HGT Mode Register (VI6_HGT_MODE)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	HRATIO[1:0]		VRATIO[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

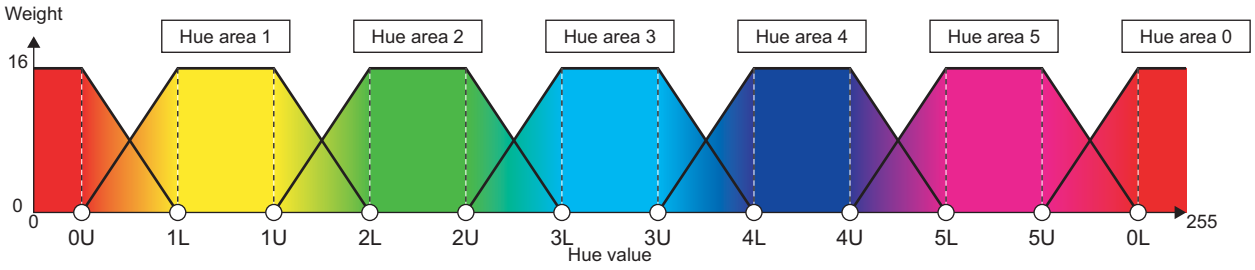
Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3, 2	HRATIO[1:0]	00	R/W	Horizontal Pixel Skipping Mode for Histogram Detection 00: No skipping for horizontal pixels. 01: Horizontal 1/2 skipping. One pixel is discarded from every two pixels before a histogram is created. 10: Horizontal 1/4 skipping. Three pixels are discarded from every four pixels before a histogram is created. The first pixel in the horizontal direction is not discarded but subsequent pixels are discarded (regardless of the histogram detection window). Among the pixels that have not been discarded, only the pixels within the detection window are used to create a histogram.
1, 0	VRATIO[1:0]	00	R/W	Vertical Pixel Skipping Mode for Histogram Detection 00: No skipping for vertical pixels. 01: Vertical 1/2 skipping. One pixel is discarded from every two pixels before a histogram is created. 10: Vertical 1/4 skipping. Three pixels are discarded from every four pixels before a histogram is created. The first pixel in the vertical direction is not discarded but subsequent pixels are discarded (regardless of the histogram detection window). Among the pixels that have not been discarded, only the pixels within the detection window are used to create a histogram.

25.2.18.4 HGT Hue Area Register (VI6_HGT_HUE_AREA_n: n = 0 to 5)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	HUE_LOWER_n[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	HUE_UPPER_n[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	HUE_LOWER_n [7:0]	H'00	R/W	Lower Boundary Value for Hue Area – n The HGT creates a two-dimensional histogram of H (hue) and S (saturation) components. Division of hue areas and overlapping of adjacent hue areas can be specified through these bits. In these bits, specify the value of n L (hue_lower n) shown in Figure 25.49. A value from 0 to 255 can be specified. The specified value should satisfy the restrictions shown in Figure 25.49.
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	HUE_UPPER_n [7:0]	H'00	R/W	Upper Boundary Value for Hue Area – n The HGT creates a two-dimensional histogram of H (hue) and S (saturation) components. Division of hue areas and overlapping of adjacent hue areas can be specified through these bits. In these bits, specify the value of n U (hue_upper n) shown in Figure 25.49. A value from 0 to 255 can be specified. The specified value should satisfy the restrictions shown in Figure 25.49.



Restrictions: 0U ≤ 1L ≤ 1U ≤ 2L ≤ 2U ≤ 3L ≤ 3U ≤ 4L ≤ 4U ≤ 5L ≤ 5U, 0L ≤ 0U, or 5U ≤ 0L

- Values are rounded down in the diagonal-line sections.
- When overlapped areas are not specified, the boundary value is included in the lower-value

0L = HUE_LOWER_0 register setting	0U = HUE_UPPER_0 register setting
1L = HUE_LOWER_1 register setting	1U = HUE_UPPER_1 register setting
2L = HUE_LOWER_2 register setting	2U = HUE_UPPER_2 register setting
3L = HUE_LOWER_3 register setting	3U = HUE_UPPER_3 register setting
4L = HUE_LOWER_4 register setting	4U = HUE_UPPER_4 register setting
5L = HUE_LOWER_5 register setting	5U = HUE_UPPER_5 register setting

Figure 25.49 Weighting Histogram Using Hue

25.2.18.5 HGT LB Detection Threshold Register (VI6_HGT_LB_TH)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	BLACK_TH[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	BLACK_TH[7:0]	H'00	R/W	Threshold for Black Level Determination in Letter Box Detection In letter box detection, when all pixels of the input image data have the value equal to or smaller than the value specified in these bits, the data is determined as black. Note that the letter box detection is not affected by the histogram detection window illustrated in Figure 25.48 A value from 0 to 255 can be specified.

25.2.18.6 HGT Horizontal Position Register for LB Detection Zone-n (VI6_HGT_LBn_H: n = 0, 1, 2, 3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	HPOS0[13:0]													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	HPOS1[13:0]													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29 to 16	HPOS0[13:0]	H'0000	R/W	Horizontal Start Position for Letter Box Detection Zone-n When all pixels on a line (shown in Figure 25.50) in the input image have the value equal to or smaller than the threshold value, the HGT determines that there is a letter box. In these bits, specify the value of hpos0 of the detection zone-n (Figure 25.50) in pixel units. A value from 0 to 8,191 can be specified. HPOS0 ≤ HPOS1 should be satisfied. These bits are valid for Zone-0 and 1. For Zone-2 and 3, these bits are reserved.
15, 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 0	HPOS1[13:0]	H'0000	R/W	Horizontal End Position for Letter Box Detection Zone-n When all pixels on a line (shown in Figure 25.50) in the input image have the value equal to or smaller than the threshold value, the HGT determines that there is a letter box. In these bits, specify the value of hpos1 of the detection zone-n (Figure 25.50) in pixel units. A value from 0 to 8,191 can be specified. HPOS0 ≤ HPOS1 should be satisfied.

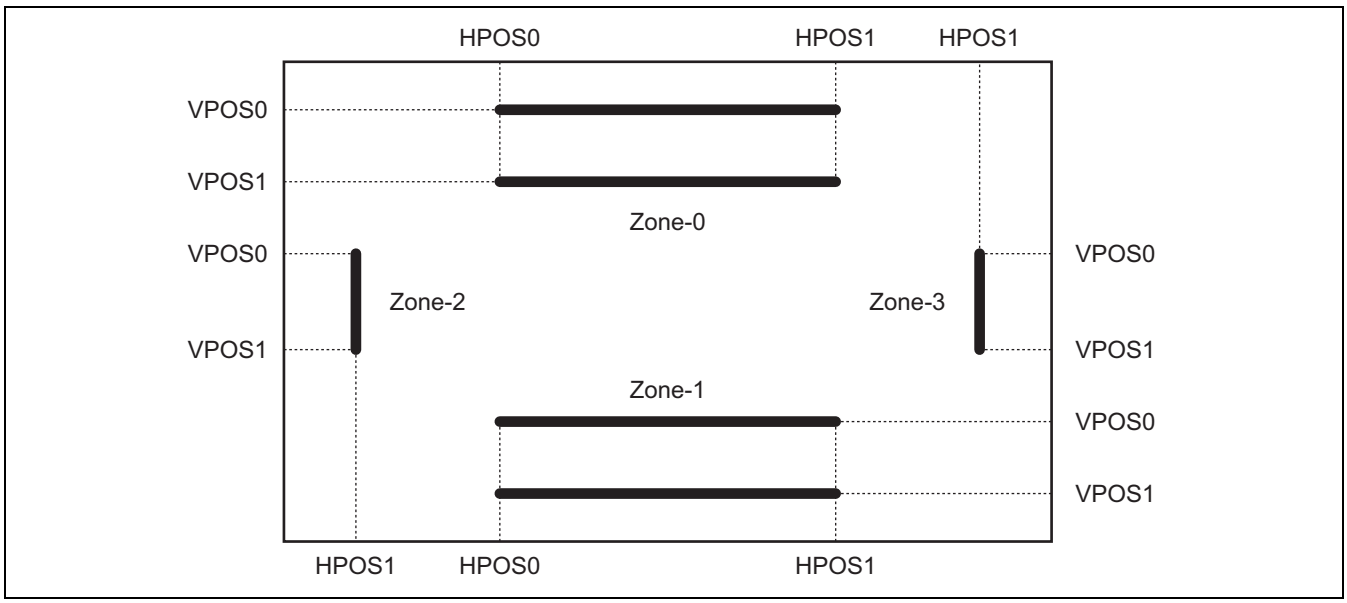


Figure 25.50 Letter Box Detection Position Settings for HGT

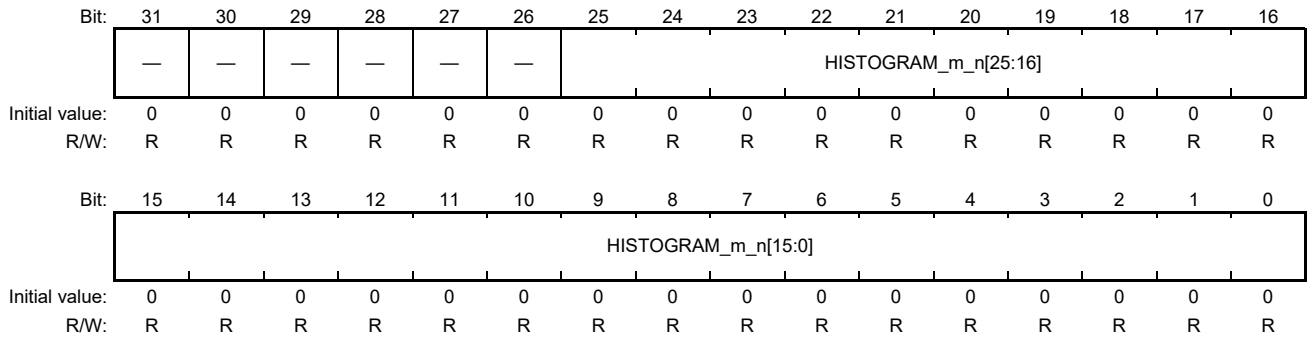
25.2.18.7 HGT Vertical Position Register for LB Detection Zone-n (VI6_HGT_LBn_V: n = 0, 1, 2, 3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	VPOS0[13:0]													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	VPOS1[13:0]													
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

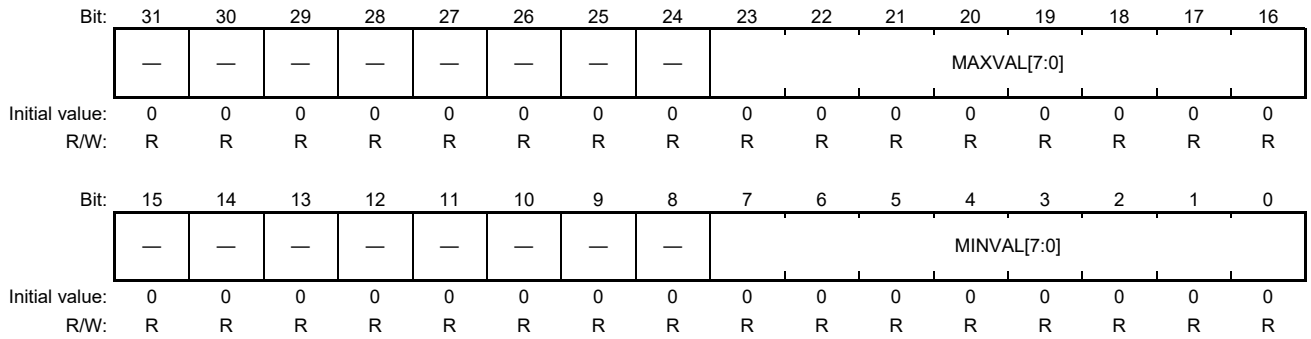
Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29 to 16	VPOS0[13:0]	H'0000	R/W	Vertical Start Position for Letter Box Detection Zone-n When all pixels on a line (shown in Figure 25.50) in the input image have the value equal to or smaller than the threshold value, the HGT determines that there is a letter box. In these bits, specify the value of vpos0 of the detection zone-n (Figure 25.50) in pixel units. A value from 0 to 8,191 can be specified. VPOS0 ≤ VPOS1 should be satisfied.
15, 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13 to 0	VPOS1[13:0]	H'0000	R/W	Vertical Position for Letter Box Detection Zone-n When all pixels on a line (shown in Figure 25.50) in the input image have the value equal to or smaller than the threshold value, the HGT determines that there is a letter box. In these bits, specify the value of vpos1 of the detection zone-n (Figure 25.50) in pixel units. A value from 0 to 8,191 can be specified. VPOS0 ≤ VPOS1 should be satisfied.

25.2.18.8 HGT Histogram Register (VI6_HGT_HISTO_m_n: m = 0 to 5, n = 0 to 31)



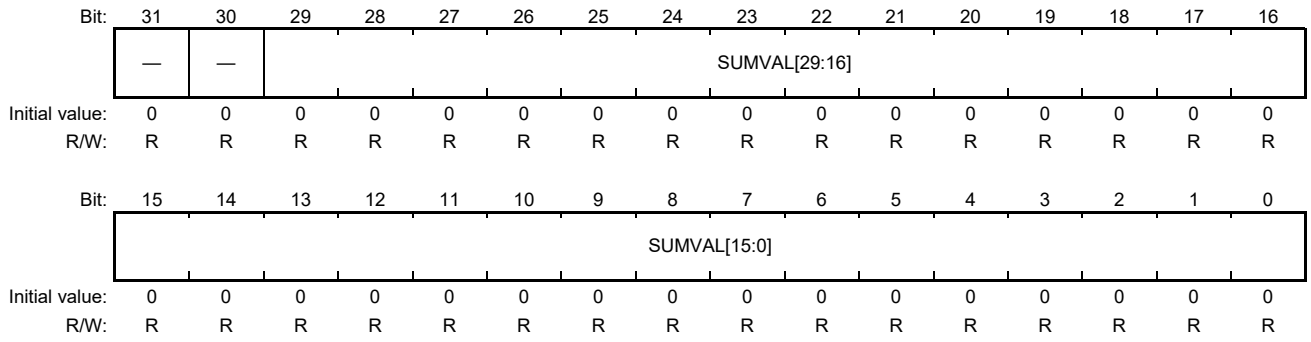
Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25 to 0	HISTOGRAM_m_n [25:0]	H'000 0000	R	Weighted Frequency of Hue Area-m and Saturation Area-n From these bits, the count of weighting for the pixels whose H component value is in hue area m (Figure 25.49) and whose S component value (val) satisfies the following condition within the histogram detection window (Figure 25.48) is read (after pixel skipping is applied when skipping mode is selected). $8 \times n \leq val < 8 \times (n + 1)$ The weight is determined by the H component value as shown in Figure 25.49 and the maximum weight is 16. Counting starts after the HGT is activated. To read the histogram, read these bits after the HGT has completed processing of one screen of data and before the HGT is activated again.

25.2.18.9 HGT Max/Min Value Register (VI6_HGT_MAXMIN)



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 16	MAXVAL[7:0]	H'00	R	Maximum Value of S Components From these bits, the maximum value of the S components of the pixels within the histogram detection window (Figure 25.48) is read (after pixel skipping is applied when skipping mode is selected). Maximum value detection starts after the HGT is activated. To read the maximum value, read these bits after the HGT has completed processing of one screen of data and before the HGT is activated again.
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 0	MINVAL[7:0]	H'00	R	Minimum Value of S Components From these bits, the minimum value of the S components of the pixels within the histogram detection window (Figure 25.48) is read (after pixel skipping is applied when skipping mode is selected). Minimum value detection starts after the HGT is activated. To read the minimum value, read these bits after the HGT has completed processing of one screen of data and before the HGT is activated again.

25.2.18.10 HGT Sum Register (VI6_HGT_SUM)



Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29 to 0	SUMVAL[29:0]	H'0000 0000	R	Sum of V Components From these bits, the sum of the V components of the pixels within the histogram detection window (Figure 25.48) is read (after pixel skipping is applied when skipping mode is selected). Accumulation starts after the HGT is activated. To read the sum, read these bits after the HGT has completed processing of one screen of data and before the HGT is activated again.

25.2.18.11 HGT LB Detection Result Register (VI6_HGT_LB_DET)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	LTRBOX1	LTRBOX2	SIDE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	LTRBOX1	0	R	Letter Box Detection Result #1 of Zone-0/1 for V Component This bit is set to 1 when none of the V components of the pixels on the lines of zone-0/VPOS0 and zone-1/VPOS1 (two lines in total) in Figure 25.50 exceeds the threshold (BLACK_TH). If any pixel is greater than the threshold, this bit is set to 0. Read this bit after the HGT has completed processing of one screen of data and before the HGT is activated again. The value read during processing is not guaranteed to be correct.
1	LTRBOX2	0	R	Letter Box Detection Result #2 of Zone-0/1 for V Component This bit is set to 1 when none of the V components of the pixels on the four lines of zone-0 and 1 in Figure 25.50 exceeds the threshold (BLACK_TH). If any pixel is greater than the threshold, this bit is set to 0. Read this bit after the HGT has completed processing of one screen of data and before the HGT is activated again. The value read during processing is not guaranteed to be correct.
0	SIDE	0	R	Letter Box Detection Result of Zone-2/3 for V Component This bit is set to 1 when none of the V components of the pixels on the two lines of zone-2 and 3 in Figure 25.50 exceeds the threshold (BLACK_TH). If any pixel is greater than the threshold, this bit is set to 0. Read this bit after the HGT has completed processing of one screen of data and before the HGT is activated again. The value read during processing is not guaranteed to be correct.

25.2.18.12 HGT Parameter Register Reset (VI6_HGT_REGRST)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RCLEA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	RCLEA	0	W	Register Reset Writing 1 to this bit resets all read-only registers (sections 25.2.18.8 to 25.2.18.11) to their initial values. This register is write-only and is always read as 0. Note that R/W registers (sections 25.2.18.1 to 25.2.18.7) are not affected by write access to this register.

25.2.19 LIF Control Registers

25.2.19.1 LIF Control Register (VI6_LIF_CTRL)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	OBTH[10:0]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	CFMT	—	—	REQSEL	LIF_EN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 16	OBTH[10:0]	H'000	R/W	Buffer Threshold for Start Ready Notification to Display Module When outputting data to the external module, the VSP stores data in the buffer in the LIF. When the amount of data stored in the buffer reaches the value specified in these bits, the VSP notifies the external display module of the start of a frame through an interrupt source (VI6_DISP_IRQ_STA.DST: see section 25.2.5.8). A value from 1 to 1,536 can be specified. Note: The OBTH value should satisfy the following conditions. • The value should not be larger than the VI6_LIF_CSBTH.HBTH bit setting. • When the horizontal and vertical sizes of the image input to the LIF are hlif_in, and vlif_in, OBTH should be specified so that the following is satisfied. $(<h_{lif\_in}+1>/2)\times v_{lif\_in}-4\geq OBTH$ The LIF input image size (hlif_in, and vlif_in) is the same as the WPF0 output image size. Recommendation value of OBTH is 128.
15 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	CFMT	0	R/W	Chroma Format This bit selects the output format from the LIF module to the display module. When RGB format is used, this bit shall be set to 0. 0: YCbCr444 or RGB Format 1: Reserved Note: ARBG8888 or RGB888 can be used for DU input format.
3, 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
1	REQSEL	0	R/W	External Display Module Selection This bit should always be set to 1. 0: Prohibited. 1: DU is selected as the destination external display module.
0	LIF_EN	0	R/W	Enable/Disable of Data Output to External Display Module Enables or disables data output from the LIF to DU. 0: Data output to the DU is disabled. 1: Data output to the DU is enabled.

25.2.19.2 LIF Clock Stop Buffer Control Register (VI6_LIF_CSBTH)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	HBTH[10:0]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	LBTH[10:0]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 16	HBTH[10:0]	H'000	R/W	Buffer Threshold for Clock Stop in Dynamic Clock Control When the remaining data amount in the buffer in the LIF reaches the value specified in these bits while data is output from the LIF to the external display module, the VSP clock is stopped. A value from 2 to 1,536 can be specified. The specified value should satisfy HBTH > LBTH. Recommendation value of HBTH is 1536.
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 0	LBTH[10:0]	H'000	R/W	Buffer Threshold for Clock Start in Dynamic Clock Control When the remaining data amount in the buffer in the LIF decreases to the value specified in these bits while data is output from the LIF to the external display module and the clock is stopped through the setting in the HBTH bits, the VSP clock supply is restarted. A value from 1 to 1,535 can be specified. The specified value should satisfy LBTH < HBTH. Recommendation value of LBTH is 1520.

25.2.20 Security Control Registers

25.2.20.1 Secure Access Control Register 0 (VI6_SECURE_CTRL0)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	SCCH3	SCCH2	SCCH1	SCCH0	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	SCWPF3	SCWPF2	SCWPF1	SCWPF0	—	—	—	SCRPF4	SCRPF3	SCRPF2	SCRPF1	SCRPF0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Each bit is used for specifying the secure attribute of the corresponding registers. If a bit is set to 1 (secure), the corresponding registers can be written only by the secure CPU access.

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27	SCCH3	0	R/W	Secure Attribute for Display List 3 Registers 0: Non-secure 1: Secure
26	SCCH2	0	R/W	Secure Attribute for Display List 2 Registers 0: Non-secure 1: Secure
25	SCCH1	0	R/W	Secure Attribute for Display List 1 Registers 0: Non-secure 1: Secure
24	SCCH0	0	R/W	Secure Attribute for Display List 0 Registers 0: Non-secure 1: Secure
23 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	SCWPF3	0	R/W	Secure Attribute for WPF3 Registers 0: Non-secure 1: Secure
10	SCWPF2	0	R/W	Secure Attribute for WPF2 Registers 0: Non-secure 1: Secure
9	SCWPF1	0	R/W	Secure Attribute for WPF1 Registers 0: Non-secure 1: Secure
8	SCWPF0	0	R/W	Secure Attribute for WPF0 Registers 0: Non-secure 1: Secure

Bit	Bit Name	Initial Value	R/W	Description
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	SCRPF4	0	R/W	Secure Attribute for RPF4 Registers 0: Non-secure 1: Secure
3	SCRPF3	0	R/W	Secure Attribute for RPF3 Registers 0: Non-secure 1: Secure
2	SCRPF2	0	R/W	Secure Attribute for RPF2 Registers 0: Non-secure 1: Secure
1	SCRPF1	0	R/W	Secure Attribute for RPF1 Registers 0: Non-secure 1: Secure
0	SCRPF0	0	R/W	Secure Attribute for RPF0 Registers 0: Non-secure 1: Secure

25.2.20.2 Secure Access Control Register 1 (VI6_SECURE_CTRL1)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	SCLIF	SCHGT	SCHGO	—	SCBRU	SCHSI	SCHST	SCCLU	SCLUT	—	—	SCUDS2	SCUDS1	SCUDS0	SCSRU
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W

Each bit is used for specifying the secure attribute of the corresponding registers. If a bit is set to 1 (secure), the corresponding registers can be read or written only by the secure CPU access.

Bit	Bit Name	Initial Value	R/W	Description
31 to 15	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
14	SCLIF	0	R/W	Secure Attribute for LIF Registers 0: Non-secure 1: Secure
13	SCHGT	0	R/W	Secure Attribute for HGT Registers 0: Non-secure 1: Secure
12	SCHGO	0	R/W	Secure Attribute for HGO Registers 0: Non-secure 1: Secure
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
10	SCBRU	0	R/W	Secure Attribute for BRU Registers 0: Non-secure 1: Secure
9	SCHSI	0	R/W	Secure Attribute for HSI Registers 0: Non-secure 1: Secure
8	SCHST	0	R/W	Secure Attribute for HST Registers 0: Non-secure 1: Secure
7	SCCLU	0	R/W	Secure Attribute for CLU Registers 0: Non-secure 1: Secure
6	SCLUT	0	R/W	Secure Attribute for LUT Registers 0: Non-secure 1: Secure
5, 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3	SCUDS2	0	R/W	Secure Attribute for UDS2 Registers 0: Non-secure 1: Secure
2	SCUDS1	0	R/W	Secure Attribute for UDS1 Registers 0: Non-secure 1: Secure
1	SCUDS0	0	R/W	Secure Attribute for UDS0 Registers 0: Non-secure 1: Secure
0	SCSRU	0	R/W	Secure Attribute for SRU Registers 0: Non-secure 1: Secure

25.3 Lookup Table Settings

25.3.1 CLUT or LUT

For a single entry to the CLUT space (see Table 25.36) or LUT space (see Table 25.36) of the VSP1, the CLUT or LUT data is set by a write access in the format shown in Figure 25.51.

The entry address of each space is (start address of the space) + (entry number counting from the base point 0 × 4). For example, the address of entry 7 to the LUT space is $VSP_BASE + H'7000 + 7 × 4 (H'FE92_701C (VSPR case)).

Table 25.36 shows the spaces for which entries can be made. Note that if the module that references that space is operating, write accesses to the relevant space are prohibited. For example, while RPF2 is operating, accesses to the entire space of VI6_CLUT2_TBL are prohibited. When a read access is made to the relevant space during operation of the referencing module, undefined values will be read out.

The operating/stopped state of each module in Table 25.36 is the operating state of the WPF to which each module is connected. Determine whether the module is operating or stopped using each WPF operating status bit in the VI6_STATUS register.

Table 25.36 CLUT Space and LUT Space Addresses

Space Name	Space Addresses	Entry Count	Module that References the Space in the Left Column
VI6_CLUT0_TBL	$VSP_BASE + H'4000 to $VSP_BASE + H'43FF	256	RPF0
VI6_CLUT1_TBL	$VSP_BASE + H'4400 to $VSP_BASE + H'47FF	256	RPF1
VI6_CLUT2_TBL	$VSP_BASE + H'4800 to $VSP_BASE + H'4BFF	256	RPF2
VI6_CLUT3_TBL	$VSP_BASE + H'4C00 to $VSP_BASE + H'4FFF	256	RPF3
VI6_CLUT4_TBL	$VSP_BASE + H'5000 to $VSP_BASE + H'53FF	256	RPF4
VI6_LUT_TBL	$VSP_BASE + H'7000 to $VSP_BASE + H'73FF	256	LUT

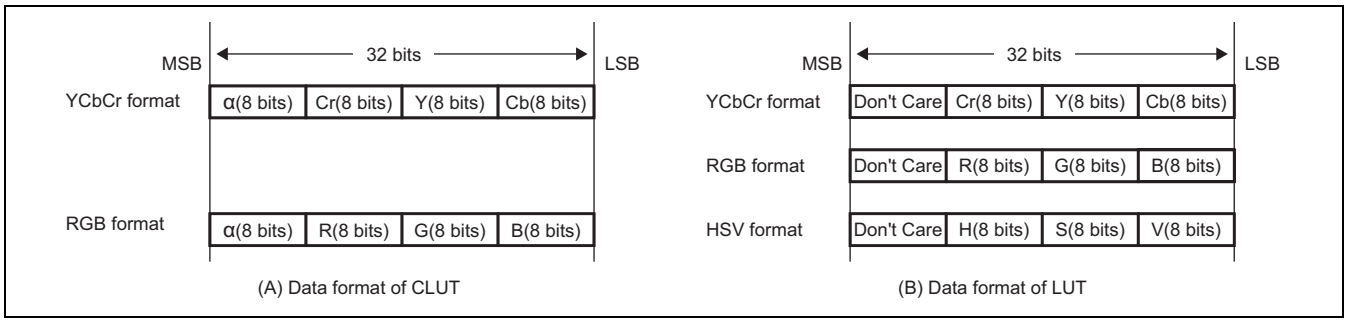


Figure 25.51 VI6_CLUT_TBL and VI6_LUT_TBL Formats

25.3.2 CLU Table

Data is set in the CLU table in the space shown in Table 25.37 through indirect addressing.

Table 25.37 CLU Space Addresses

Space Name	Space Addresses	Module that References the Space in the Left Column
VI6_CLU_TBL	$VSP_BASE + H'7400 to $VSP_BASE + H'7407	CLU

The addresses used in indirect addressing (VI6_CLU_ADDR, VI6_CLU_DATA) are shown in Table 25.38. The CLU table can be accessed by setting the VI6_CLU_ADDR register and then reading from or writing to the VI6_CLU_DATA register. To write-access the CLU table continuously, such as when setting data to the CLU table, perform the following.

(1) Set the first CLU table coordinates in VI6_CLU_ADDR.
(2) Write the first data to be set in VI6_CLU_DATA.
(3) Set the next CLU table coordinates in VI6_CLU_ADDR.
(4) Write the next data to be set in VI6_CLU_DATA.
... Execute these processes in a similar manner.

Accesses to VI6_CLU_ADDR and VI6_CLU_DATA registers are repeated in this way. The location where to access the CLU table to write the VI6_CLU_DATA contents immediately takes effect after a value is set in the VI6_CLU_ADDR register.

To read-access the CLU table continuously, change the write-access operation to the read-access operation in the sequence of processes of (1) to (4) above.

The following describes how to specify VI6_CLU_ADDR.

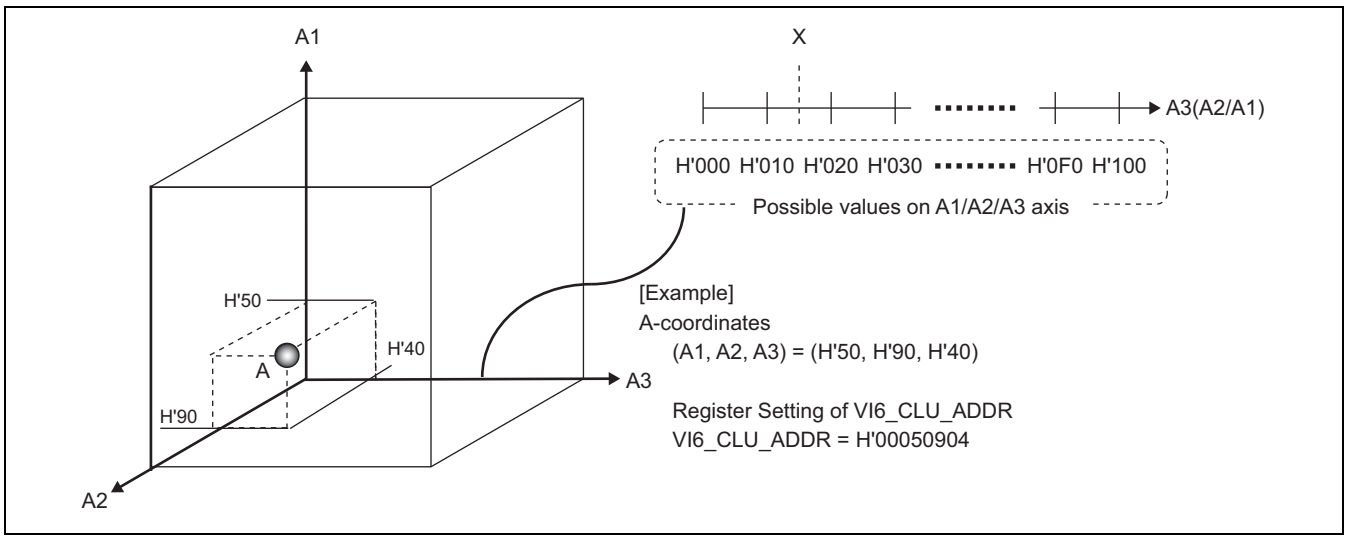

Figure 25.52 VI6_CLU_ADDR Setting

In the CLU table, a table value should be specified for every increase by H'10 along each of the axes and for every intersection between two axes. For a certain axis, as shown in the top right of Figure 25.52, a value to be set in the table corresponds to a scale mark at an interval of H'10. The location of a point between two scale marks (for example, point X in Figure 25.52) is calculated through interpolation by the CLU (refer to section 25.2.13.1). Accordingly, the lower four bits of table settings for each axis has no meaning; only the upper-order five bits of the desired coordinate for each component should be specified in VI6_CLU_ADDR (which should be shifted to the right by four bits) as shown in Figure 25.52.

Table 25.38 Address Spaces Used in Indirect Addressing to CLU Table

Address (Name)	Bit	Initial Value	R/W	Description
$VSP_BASE + H'7400 (VI6_CLU_ADDR)	31 to 24	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
	23 to 16	H'00	R/W	Coordinate Value of First Axis These bits set the coordinate value of the first axis on the three-dimensional space coordinates of the CLU table. A value from 0 to 16 can be specified.
	15 to 8	H'00	R/W	Coordinate Value of Second Axis These bits set the coordinate value of the second axis on the three-dimensional space coordinates of the CLU table. A value from 0 to 16 can be specified.
	7 to 0	H'00	R/W	Coordinate Value of Third Axis These bits set the coordinate value of the third axis on the three-dimensional space coordinates of the CLU table. A value from 0 to 16 can be specified when the CLU is in 3D mode. In 2D mode, these bits must be set to 0.
$VSP_BASE + H'7404 (VI6_CLU_DATA)	31 to 24	Undefined	R	Reserved These bits are always read as 0. The write value should always be 0.
	23 to 16	Undefined	R/W	Component Value of First Axis These bits set the component value of the first axis on the three-dimensional space coordinates of the CLU table, which is defined by the VI6_CLU_ADDR register. A value from 0 to 255 can be specified when the CLU is in 3D mode. In 2D mode, these bits must be set to 0.
$VSP_BASE + H'7404 (VI6_CLU_DATA)	15 to 8	Undefined	R/W	Component Value of Second Axis These bits set the component value of the second axis on the three-dimensional space coordinates of the CLU table, which is defined by the VI6_CLU_ADDR register. A value from 0 to 255 can be specified.
	7 to 0	Undefined	R/W	Component Value of Third Axis These bits set the component value of the third axis on the three-dimensional space coordinates of the CLU table, which is defined by the VI6_CLU_ADDR register. A value from 0 to 255 can be specified when the CLU is in 3D mode. In 2D mode, these bits must be set to 0.

25.4 Operation Linked with Display Unit (DU)

25.4.1 Starting LCD Display

Use the following procedure to display images on the LCD by operating the VSP1 and DU together.

To display images on the LCD by inputting VSYNC to the DU:

(1) Activate the VSP1.
(2) After the VSP1 starts operation, wait until a VI6_DISP_IRQ_STA.DST interrupt source is generated.
(3) After a VI6_DISP_IRQ_STA.DST interrupt source is generated, activate the DU.

To display images on the LCD with VSYNC being output from the DU:

(1) Activate the VSP.
(2) After that, activate the DU.

25.4.2 Stopping LCD Display

To stop the image display on the LCD while the VSP1 and DU work together to display images, stop the DU first by a software reset or the like (refer to section 24, Display Unit (DU) for the software reset of the DU). After checking that the DU has stopped, apply software reset to the VSP1. After both the DU and VSP1 software reset processes are complete, the LCD display stop process ends.

25.4.3 Entire Operation Flow

The VSP1 operation is linked with the DU operation. As the DU operates in real-time, the VSP1 also operates in real-time. However, the VSP1 only provides one plane of registers. Accordingly, modifying registers between frames should be done within the short blanking period between the end of one-frame display (VI6_WPFn_IRQ_STA.FRE interrupt) and the start of the next frame display (VSYNC). To do this, use the display list function of the VSP1 (see section 25.1.8 (3)) to implement two virtual register planes and ensure the one-frame time for modifying registers by software (see section 25.4.4). When using the display list function, make the current-frame settings in a register plane and store the next-frame settings as a display list in external memory such as SDRAM. In this way, the next-frame settings can be modified in the display list in external memory until the end of the current frame processing.

The timing chart of this procedure is shown in Figure 25.53

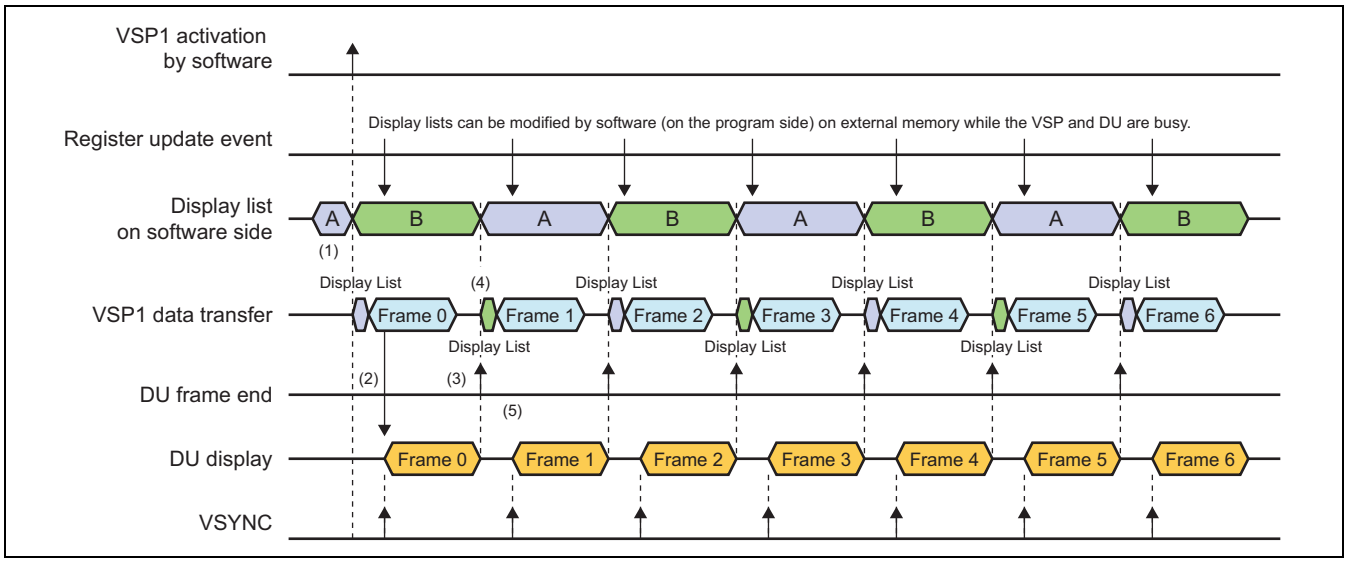

Figure 25.53 Timing when VSP1 Operation is linked with DU

(1) The VSP1 is activated by software, and then the VSP1 downloads a display list.
(2) The VSP1 informs the ready state to the DU, and then the DU starts the display process.
(3) The DU generates a frame end interrupt.
(4) The VSP updates its register settings by downloading the next display list. After that, the VSP reads the next frame data.
(5) The DU generates VSYNC for the next frame and starts transfer of display data.

Figure 25.53 shows the detailed timing of frame switching. The number of VSP1 operating clock cycles necessary for each timing is shown as a reference value in Figure 25.54 where it is assumed that the bus transfer is at the logically fastest speed and the size of the display list to be downloaded is the worst case (downloading of data for all registers and tables in the VSP1).

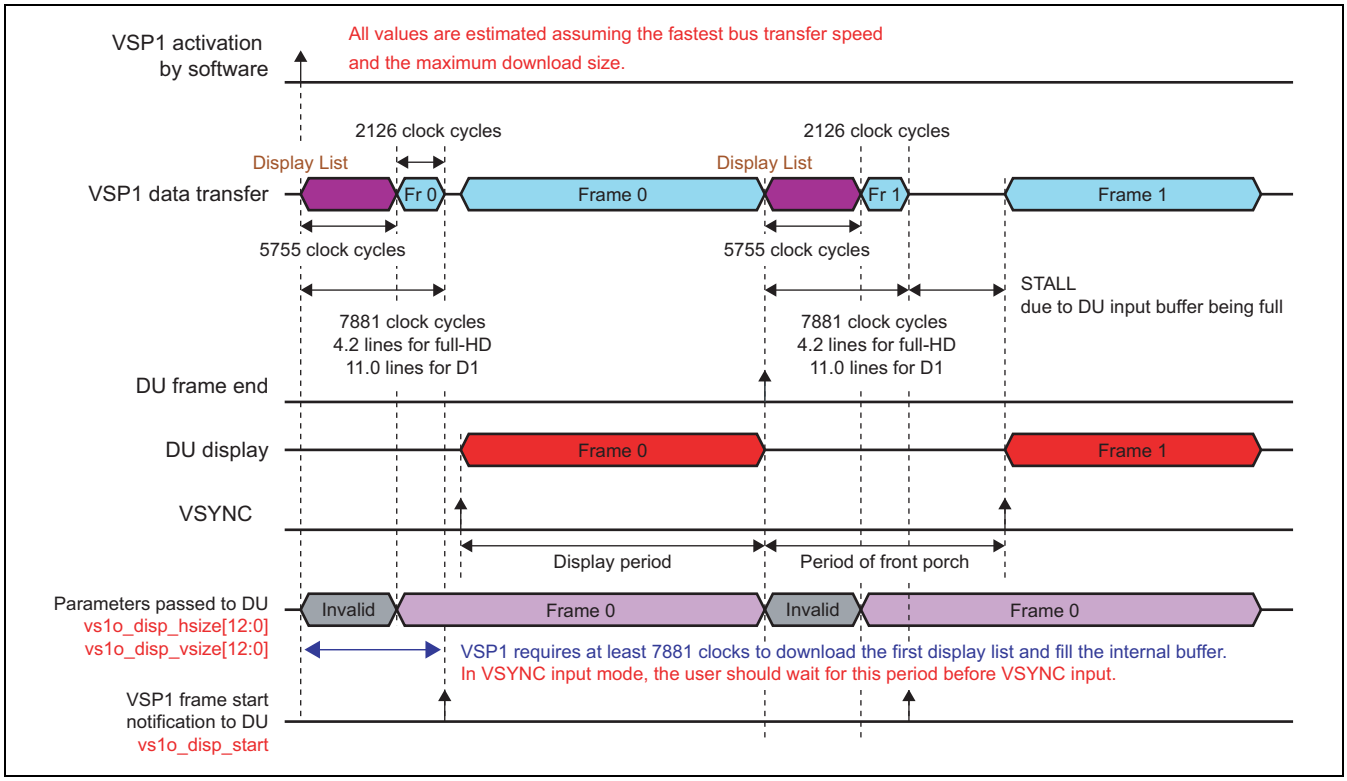

Figure 25.54 Detailed Timing of Frame Switching

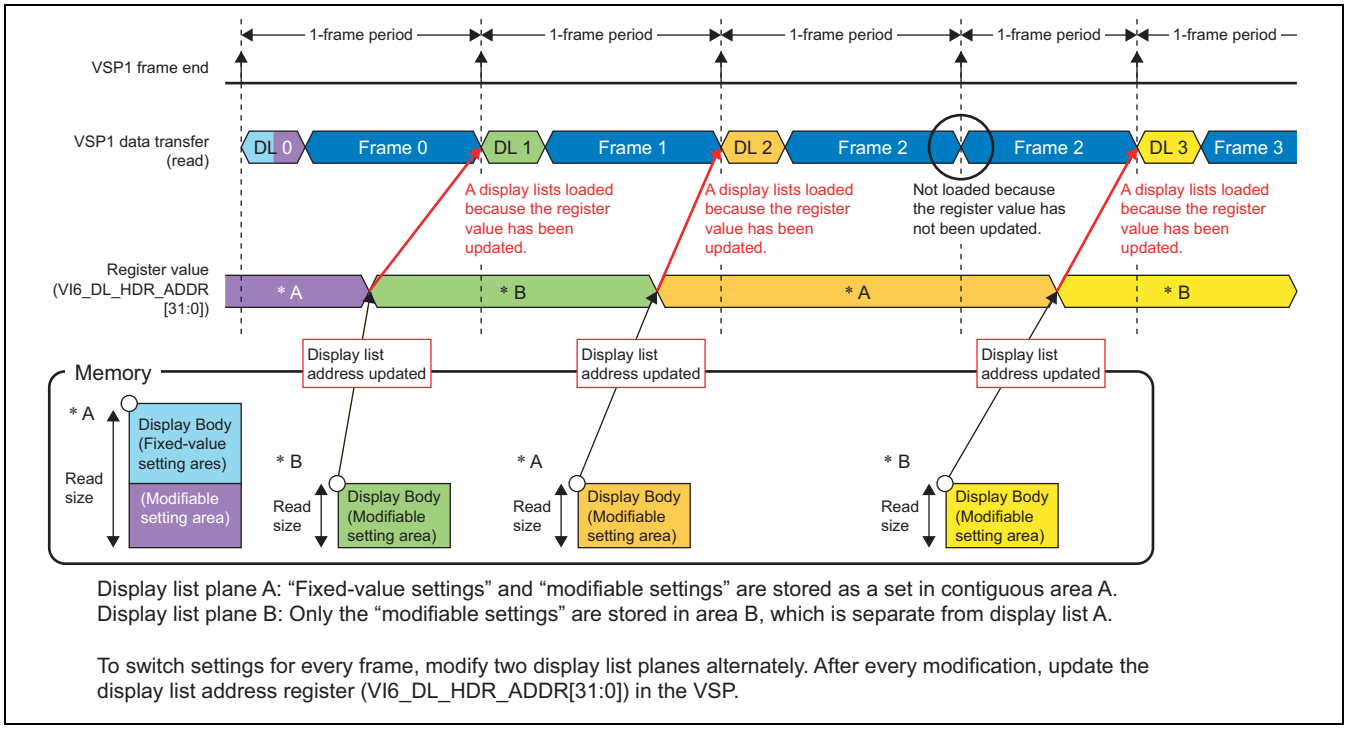
25.4.4 Controlling Two Register Planes Using Display Lists

Figure 25.55 shows the control of two register planes using header-less display lists (see section 25.1.8 (3)) and its timing. In the description hereafter, the use of header-less display lists is always assumed and they are simply called display lists.



Display list plane A: “Fixed-value settings” and “modifiable settings” are stored as a set in contiguous area A.
Display list plane B: Only the “modifiable settings” are stored in area B, which is separate from display list A.

To switch settings for every frame, modify two display list planes alternately. After every modification, update the display list address register (VI6_DL_HDR_ADDR[31:0]) in the VSP.

Figure 25.55 Controlling Two Register Planes Using a Display List

The VSP1 downloads a display list immediately after activation. In the start frame, download the display list that contains all necessary settings. From the next frame on, only the necessary register or table values should be specified in a display list.

Only when the destination address (VI6_DL_HDR_ADDR0; see section 25.2.6.2) or the display body size (VI6_DL_BODY_SIZE0; see section 25.2.6.5) has been written to, the VSP1 downloads a new display list at the start of the next frame. When the update flag of VI6_DL_BODY_SIZE0.UPD0 is set to 0, the register settings acquired from the display list previously downloaded are retained and used for the next operation without downloading a new display list.

25.5 Assignment in Memory Space

Make sure that VSP1 memory space shall be mapped to Non-Cache region.

26. Image Extraction Direct Memory Access Controller (2D-DMAC)

This LSI has an image extraction direct memory access controller (2D-DMAC). This module reads the image data in the frame buffer memory, performs image extraction/shift/simple magnification and format conversion, and then rewrites the processed image data to the frame buffer memory.

26.1 Features

- Image extraction

  2D-DMAC extracts an image in the rectangular area from a point (Sx, Sy) shifting from the source image data origin to a point in the frame memory, and then writes the extracted image data to another frame memory. Extraction of data is possible in two-pixel units for YCbCr formats and in one-pixel units for RGB formats. This function is available for image clipping and image motion compensation.
- Image rotation/inversion

  Vertical/horizontal inversion and the 90°/270° rotation can be performed.
- Simple enlargement

  When writing a destination image, it can simply be enlarged twice in the X and Y directions.
- Format conversion

  RGB formats can be converted to each other.

  YCbCr formats (YCbCr4:2:0 and YCbCr4:2:2) can be converted to each other.

  No format conversion is possible between RGB and YCbCr.

  The format conversion method is equivalent to that of VSP.
- Channels

  Settings for eight channels are enabled. For the YCbCr formats, settings for one channel for each Y plane and C plane are enabled. Therefore, concurrent processing is possible for up to four planes (YCbCr formats) or up to eight planes (RGB formats).

  Provided with an outstanding buffer for each channel, even if data transfer of a channel is blocked, 2D-DMAC can continue operation of other channels. Transition of processing between channels is performed upon completion of each line processing.
- Interrupt

  Each channel has interrupt request signals that can be output at the time of data transfer half end and data transfer end respectively.

Figure 26.1 shows a block diagram of 2D-DMAC and Figure 26.2 shows a flow for the pixel processing block.

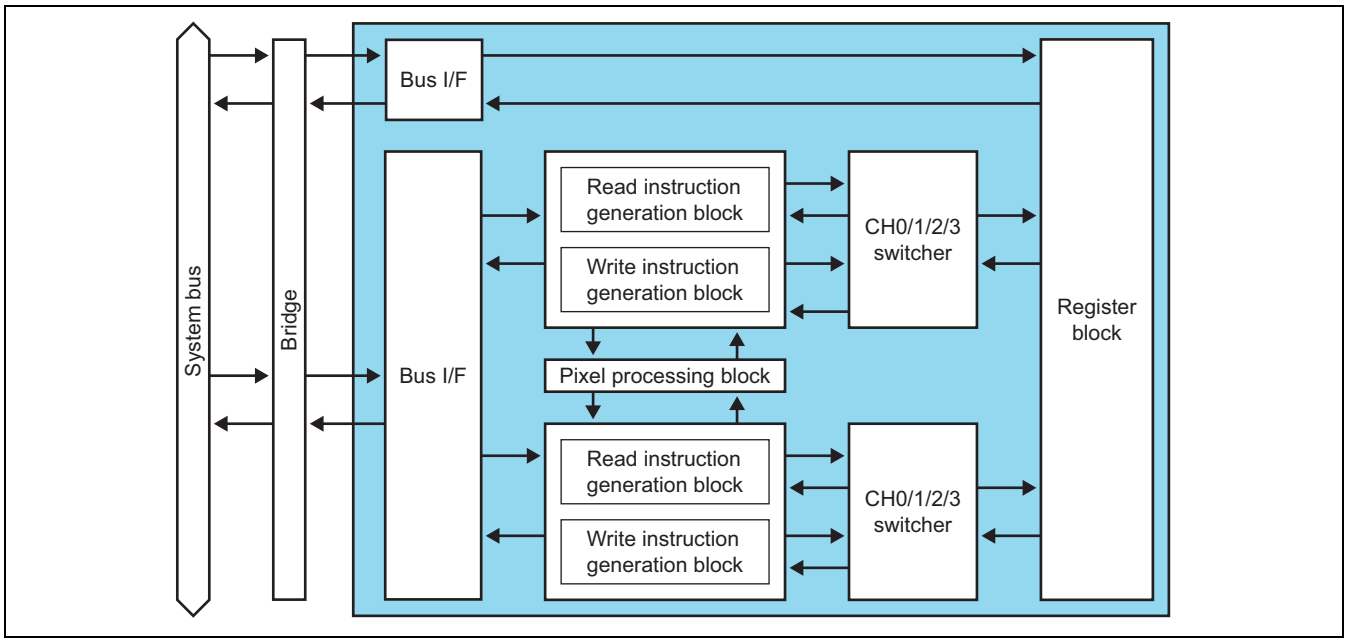


Figure 26.1 Block Diagram of 2D-DMAC

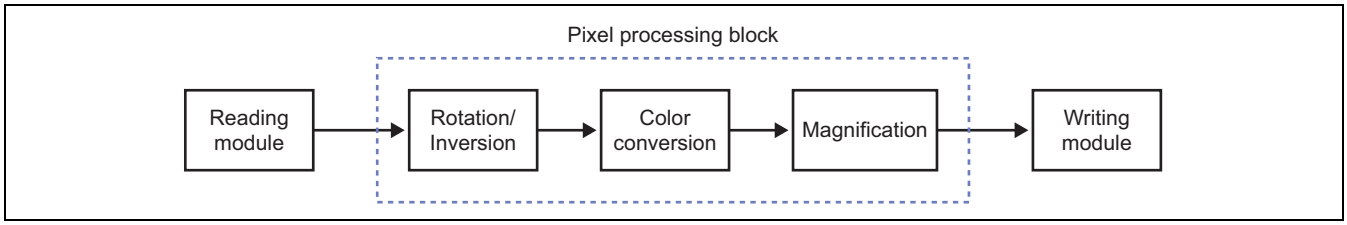

Figure 26.2 Block Flow of Pixel Block

26.2 Register Descriptions

Table 26.1 lists the registers used in 2D-DMAC. Table 26.2 shows the register status in each processing mode.

Table 26.1 Register Configuration

Register Name	Abbreviation	R/W	Address	Access Size
Transaction control register	CHTCTRL	R/W	H'FEA0 0008	32
Interrupt status clear register	CHSTCLR	R/W	H'FEA0 0010	32
CH0 control register	CH0CTRL	R/W	H'FEA0 0020	32

26.2.1 Transaction Control Register (CHTCTRL)

CHTCTRL register is a 32-bit readable/writable register that controls bus transaction among all channels.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	OUT	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
5	OUT	0	R/W	Transaction control When operating 2D-DMAC, this bit should always be 1.
4 to 0	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.

26.2.2 Control Registers (CHnCTRL)

CHnCTRL (n = 0 to 7) is a 32-bit readable/writable register that controls transfer mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	HMRR	VMRR	ROTL	ROTR	—	MX	—	MY	HIE	HE	TIE	TE	LINK[1] / —	LINK[0] / —	STP	DMAEN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	HMRR	0	R/W	Horizontal Inversion (symmetric to the vertical axis) The source image inverted horizontally is output. See Table 26.5 for details on the relations between this bit and inversion/rotation. 0: Horizontal inversion is not performed. 1: Inverted horizontally source image is output.
14	VMRR	0	R/W	Vertical Inversion (symmetric to the horizontal axis) The source image inverted vertically is output. See Table 26.5 for details on the relations between this bit and inversion/rotation. 0: Vertical inversion is not performed. 1: Inverted vertically source image is output.
13	ROTL	0	R/W	270° Rotation (clockwise) The source image rotated 270° is output. When this bit is 1, set the ROTR bit to 0. See Table 26.5 for details on the relations between this bit and inversion/rotation. 0: 270° rotation is not performed. 1: Rotated 270° source image is output.
12	ROTR	0	R/W	90° Rotation (clockwise) The source image rotated 90° is output. When this bit is 1, set the ROTR bit to 0. See Table 26.5 for details on the relations between this bit and inversion/rotation. 0: 90° rotation is not performed. 1: Rotated 90° source image is output.
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
10	MX	0	R/W	Magnify X Direction 0: No magnification 1: Outputs with double magnification in the X direction. When ROTR or ROTL is 1, set this bit to 0.
9	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
8	MY	0	R/W	Magnify Y Direction 0: No magnification 1: Outputs with double magnification in the Y direction. When ROTR or ROTL is 1, set this bit to 0.
7	HIE	0	R/W	Half End Interrupt Enable Specifies whether to output the half end flag as an interrupt request. 0: A half end interrupt is disabled. 1: A half end interrupt is enabled.
6	HE	0	R/W	Half End Indicates that data transfer for half the setting lines has been completed. This bit is set to 1 when the DVPXLE bit in CHnDPXLE becomes half (a value of 1-bit right shift) of the DVPXL bit value in CHnDPXL that was set before starting transfer. If CHnCTRL.ROTR = 1 or CHnCTRL.ROTL = 1, this bit is set to 1 when the DHPXLE bit in CHnDPXLE becomes half of the DHPXL bit value in CHnDPXL that was set before starting transfer. Only clearing to 0 after reading 1 is enabled. Clearing by the CHSTCLR register is also enabled.
5	TIE	0	R/W	Transfer End Interrupt Enable Specifies whether to output the transfer end flag as an interrupt request. 0: A transfer end interrupt is disabled. 1: A transfer end interrupt is enabled.
4	TE	0	R/W	Transfer End This bit is set to 1 when the DVPXL bit in CHxDPXL that was set by the DVPXLE bit in CHxDPXLE before starting transfer and the entire DMA transfer are completed. When this bit is set to 1, the DMAEN bit is automatically cleared. Only clearing to 0 after reading 1 is enabled. Clearing by the CHSTCLR register is also enabled.
3, 2	LINK[1:0] (n = 0, 2, 4, 6) — (n = 1, 3, 5, 7)	00	R/W (n = 0, 2, 4, 6) R (n = 1, 3, 5, 7)	(n = 0, 2, 4, 6) Link Transfer Mode This mode enables alternate block line transfers between a master channel (CHn) and a slave channel (CHn+1). When these bits are set to 10, specify the DVPXL bit in CH(n+1)DPXL equal to half of the DVPXL in CHnDPXL. When these bits are set to 11, specify the DVPXL bit in CH(n+1)DPXL equal to the DVPXL in CHnDPXL. In this mode, start the transfer of the master channel before that of the slave channel. 00: Link transfer mode is disabled. 01: Setting prohibited. 10: A block line transfer of a slave channel is performed every two block line transfers of a master channel. 11: Alternate transfers are performed. (n = 1, 3, 5, 6) Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
1	STP	0	R/W	Transfer Stop Stops DMA transfer temporarily. When this bit is set to 1, DMA transfer is suspended upon completion of the line that is being transferred, and the DMAEN bit is cleared to 0. At this time, this bit is also cleared. To restart DMA transfer after that, set the DMAEN bit to 1. To reset the operation of a channel, rewrite data to the SAR, DAR, and DPXL registers of the channel. [Writing] 0: NOP 1: Stops DMA transfer temporarily. [Reading] 0: Transfer is in progress or suspended. 1: Pending until the line being transferred is completed
0	DMAEN	0	R/W	DMA Transfer Enable Enables DMA transfer. Only writing 1 is enabled. This bit shows 1 during transfer, and is automatically cleared when a DMA transfer is completed. Writing 0 to this bit is disabled. A DMA transfer can be suspended by setting the STP bit to 1. [Writing] 0: NOP 1: Performs DMA transfer. [Reading] 0: No DMA transfer is in progress. 1: A DMA transfer is in progress.

26.2.3 Input/Output Swap Register (CHnSWAP)

CHnSWAP (n = 0 to 7) controls 64-bit data swapping in the data input/output section of 2D-DMAC.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	OLS	OWS	OBS	—	ILS	IWS	IBS
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	OLS	0	R/W	Output Longword Swap Setting In the output section of 2D-DMAC, 64 bits of data are swapped with 32 bits of the MSB and 32 bits of the LSB in longword units. 0: Output longword swap is not performed. 1: Output longword swap is performed.
5	OWS	0	R/W	Output Word Swap Setting In the output section of 2D-DMAC, 64 bits of data are swapped with 32 bits of the MSB and 32 bits of the LSB in word units. 0: Output word swap is not performed. 1: Output word swap is performed.
4	OBS	0	R/W	Output Byte Swap Setting In the output section of 2D-DMAC, 64 bits of data are swapped with 16-bit groups in byte units. 0: Output byte swap is not performed. 1: Output byte swap is performed.
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
2	ILS	0	R/W	Input Longword Swap Setting In the input section of 2D-DMAC, 64 bits of data are swapped with 32 bits of the MSB and 32 bits of the LSB in longword units. 0: Input longword swap is not performed. 1: Input longword swap is performed.
1	IWS	0	R/W	Input Word Swap Setting In the input section of 2D-DMAC, 64 bits of data are swapped with 32 bits of the MSB and 32 bits of the LSB in word units. 0: Input word swap is not performed. 1: Input word swap is performed.
0	IBS	0	R/W	Input Byte Swap Setting In the input section of 2D-DMAC, 64 bits of data are swapped with 16-bit groups in byte units. 0: Input byte swap is not performed. 1: Input byte swap is performed.

When the system is operated in little-endian mode, this register should be used to select the swapping method conforming to the input/output format. The data relationships available when swapping methods are set are shown in Figure 26.3, Figure 26.4, and Figure 26.5.

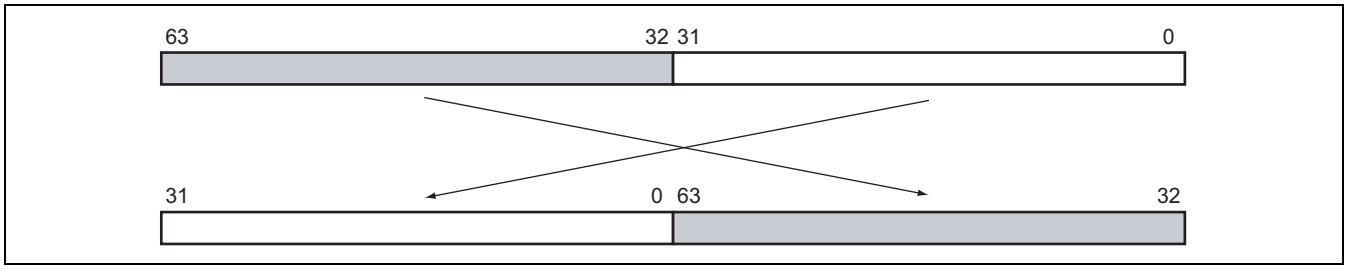

Figure 26.3 Data Relationship Before and After Longword Swapping

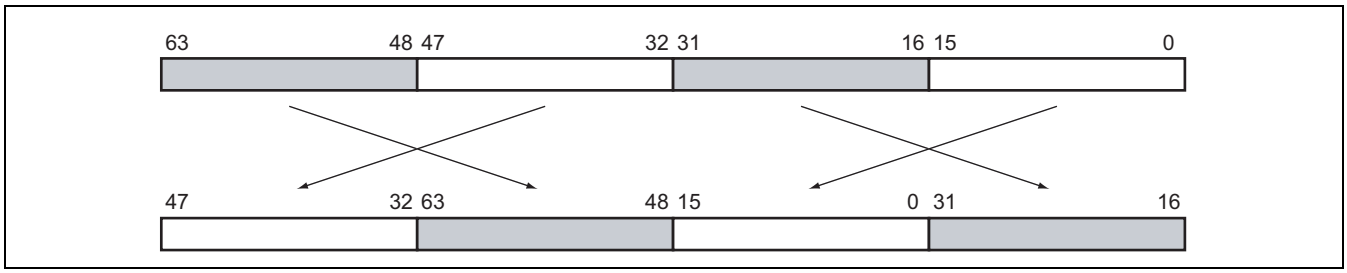

Figure 26.4 Data Relationship Before and After Word Swapping

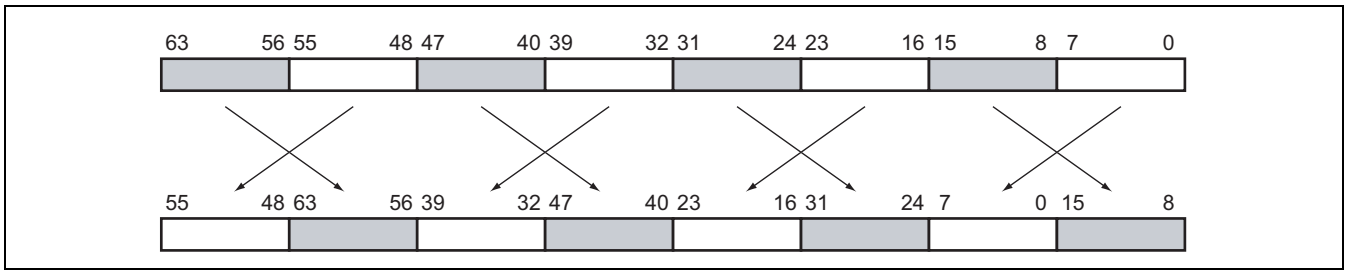

Figure 26.5 Data Relationship Before and After Byte Swapping

26.2.4 Source Format Registers (CHnSFMT)

CHnSFMT (n = 0 to 7) is a 32-bit readable/writable register for setting the source image.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	HWTH[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

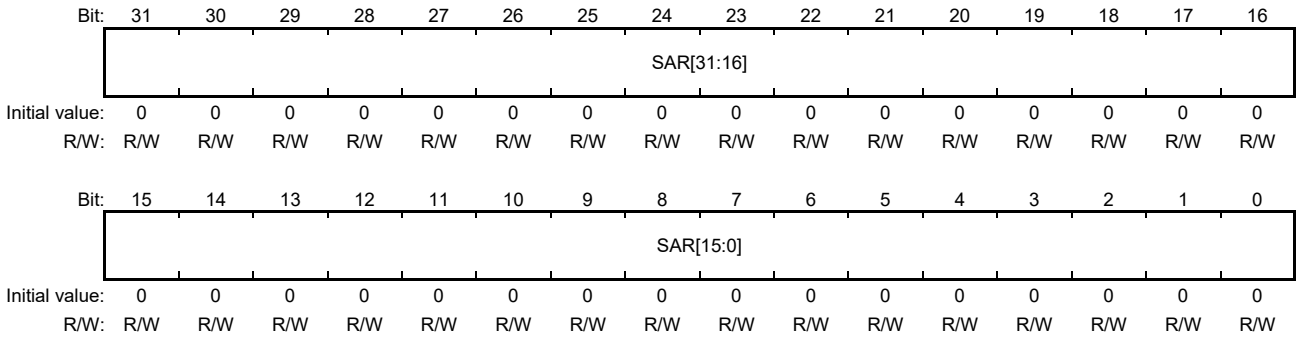
26.2.5 Source Address Registers (CHnSAR)

CHnSAR (n = 0 to 7) is a 32-bit readable/writable register for setting the transfer start address of the source image.



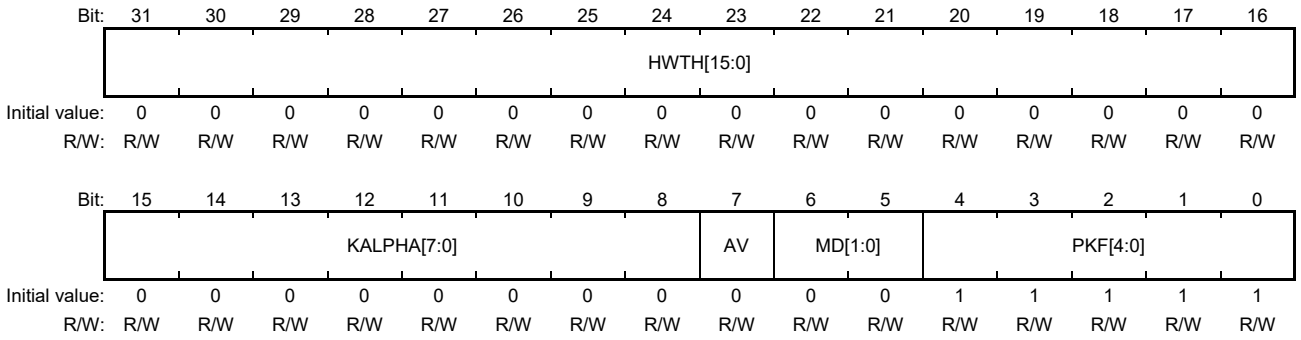
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SAR[31:0]	H'00000000	R/W	Source Image Extraction Start Address Specify the address of the extraction start pixel in the source image data.

When the source image fills CHnSAR ≠ 16n and cutting out effective pixel bytes number ≤ 16-byte, line finality access = address where line terminal address is rounded up to 16n + 16-byte.

Address where source image final pixel address of cutting out object is rounded up to 16n + 16, secure it as an input image area.

26.2.6 Destination Format Registers (CHnDFMT)

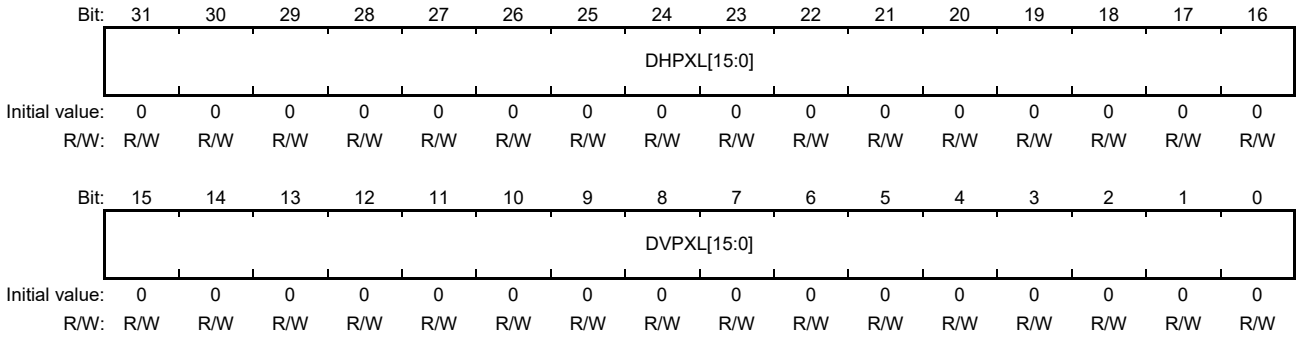
CHnDFMT (n = 0 to 7) is a 32-bit readable/writable register for setting a destination image format and so on.



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	HWTH[15:0]	H'0000	R/W	Destination Image Horizontal Byte Size Specify the one-line width of the destination image in units of bytes. Set a multiple of 16. When CTRL.MX is 1, set a value after magnification.
15 to 8	KALPHA[7:0]	H'00	R/W	Alpha Value Specify an alpha value used for output if the source image is in a format without alpha or the AV bit is set to 0.
7	AV	0	R/W	Alpha Enable 0: Disables the alpha value when the source image is in a format with alpha. When the output is in a format with alpha, the KALPHA value is output. 1: Enables the alpha value when the source image is in a format with alpha, and outputs the alpha value when the output is in a format with alpha.
6, 5	MD[1:0]	00	R/W	Destination Image Format 00: RGB data 01: Y data 10: CbCr data (YCbCr4:2:0) 11: CbCr data (YCbCr4:2:2)
4 to 0	PKF[4:0]	11111	R/W	Destination Image RGB Data Packed Format Specify the packed format for destination image data in the RGB format. These bits are available only when MD = 00. Table 26.3 shows the packed RGB formats.

26.2.7 Destination Pixel Registers (CHnDPXL)

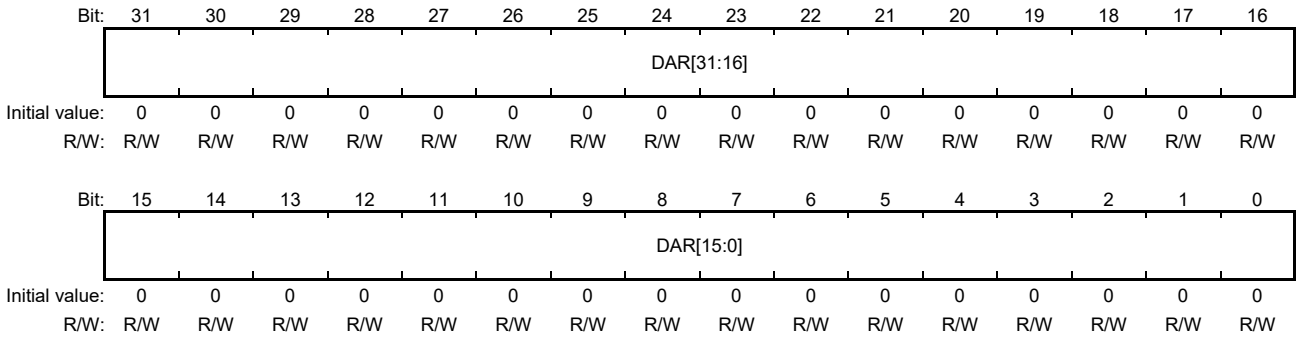
CHnDPXL (n = 0 to 7) is a 32-bit readable/writable register for setting the horizontal pixel size and vertical pixel size of the destination image.



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	DHPXL[15:0]	H'0000	R/W	Destination Image Horizontal Pixel Size Specify the horizontal pixel size of the destination image. When the MX bit in CTRL is 1, set a value before magnification. For the CbCr plane in YCbCr4:2:2 or YCbCr4:2:0, set a value of half of the number of pixels. The minimum pixel size will be 1; set 1 or a larger value.
15 to 0	DVPXL[15:0]	H'0000	R/W	Destination Image Vertical Pixel Size Specify the vertical pixel size of the destination image. When the MY bit in CTRL is 1, set a value before magnification. For the CbCr plane in YCbCr4:2:0, set a value of half of the number of lines. The minimum pixel size will be 1; set 1 or a larger value.

26.2.8 Destination Address Registers (CHnDAR)

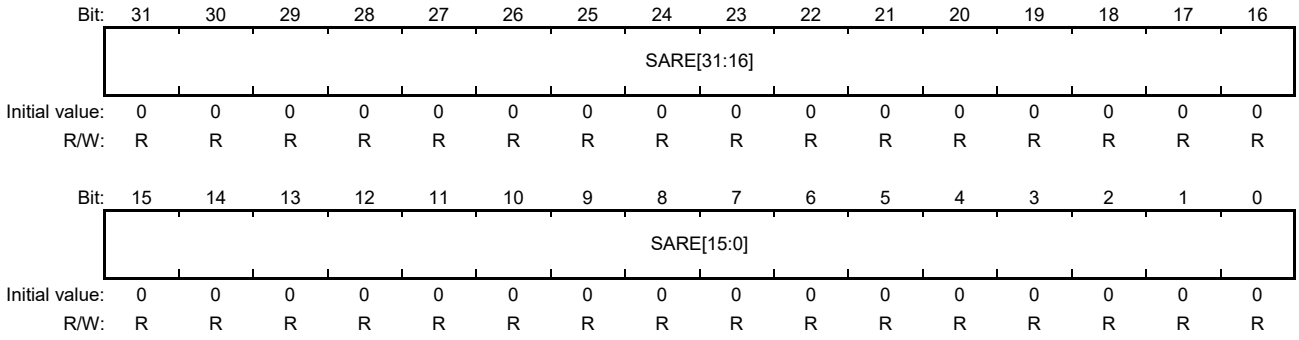
CHnDAR (n = 0 to 7) is a 32-bit readable/writable register for setting the transfer start address of the destination image.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DAR[31:0]	H'00000000	R/W	Specify the start address of the destination image. Only a multiple of 16 can be set. The specified address point is to be changed according to the settings to the VMRR, HMRR, ROTR, ROTL, and MY bits. For details, see section 26.3.2, Image Rotation/Inversion.

26.2.9 Source Line Address Registers (CHnSARE)

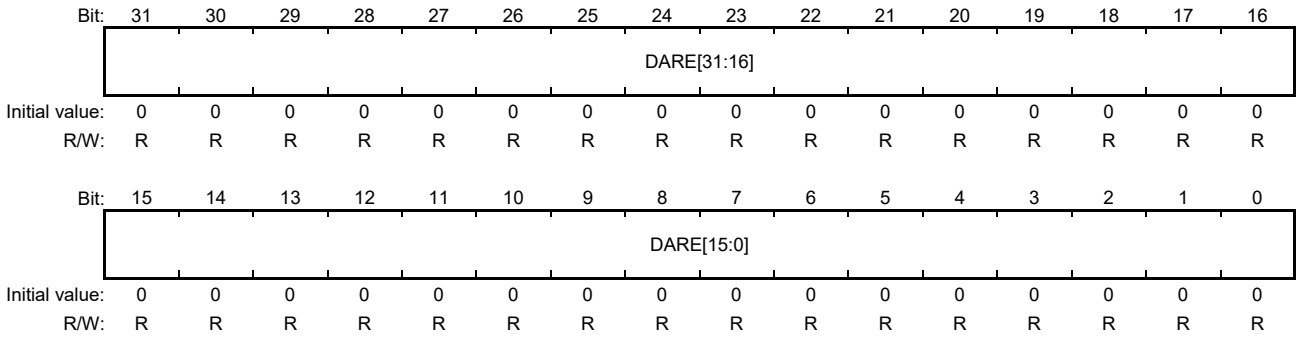
CHnSARE (n = 0 to 7) is a 32-bit read-only register that shows the start address of the line in processing of the source image.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SARE [31:0]	H'00000000	R	This read-only register used for internal processing shows the start address of the line in processing of the source image.

26.2.10 Destination Line Address Registers (CHnDARE)

CHnDARE (n = 0 to 7) is a 32-bit read-only register that shows the start address of the line in processing of the destination image.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DARE [31:0]	H'00000000	R	This read-only register used for internal processing shows the start address of the line in processing of the destination image.

26.2.11 Destination Pixel Processing Registers (CHnDPXLE)

CHnDPXLE (n = 0 to 7) is a 32-bit read-only register that shows the number of unprocessed lines of the destination image.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DHPXLE[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DVPXLE[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	DHPXLE[15:0]	H'0000	R	This read-only register used for internal processing shows the number of unprocessed horizontal lines of the destination image.
15 to 0	DVPXLE[15:0]	H'0000	R	This read-only register used for internal processing shows the number of unprocessed vertical lines of the destination image.

26.2.12 Interrupt Status Clear Register (CHSTCLR)

CHSTCLR is a register that indicates the status of HE and TE bits in each channel. By writing 1 in a bit in CHSTCLR, HE or TE bit in the corresponding channel is to be cleared.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CHnHE[7:0]								CHnTE[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15 to 8	CHnHE[7:0]	H'00	R/W	Indicates the status of the HE bit in CHnCTRL (n = 0 to 7). Writing 1 in this bit, the HE bit in corresponding channel is to be cleared. [Writing] 0: NOP 1: HE bit is cleared. [Reading] 0: 0 is set in the HE bit. 1: 1 is set in the HE bit.
7 to 0	CHnTE[7:0]	H'00	R/W	Indicates the status of the TE bit in CHnCTRL (n = 0 to 7). Writing 1 in this bit, the TE bit in corresponding channel is to be cleared. [Writing] 0: NOP 1: TE bit is cleared. [Reading] 0: 0 is set in the TE bit. 1: 1 is set in the TE bit.

26.3 Operation

This module can extract image data of required size from the source image and store it as a destination image, and also can convert the format, rotation/inversion, and magnify the image at that time.

26.3.1 Image Extraction

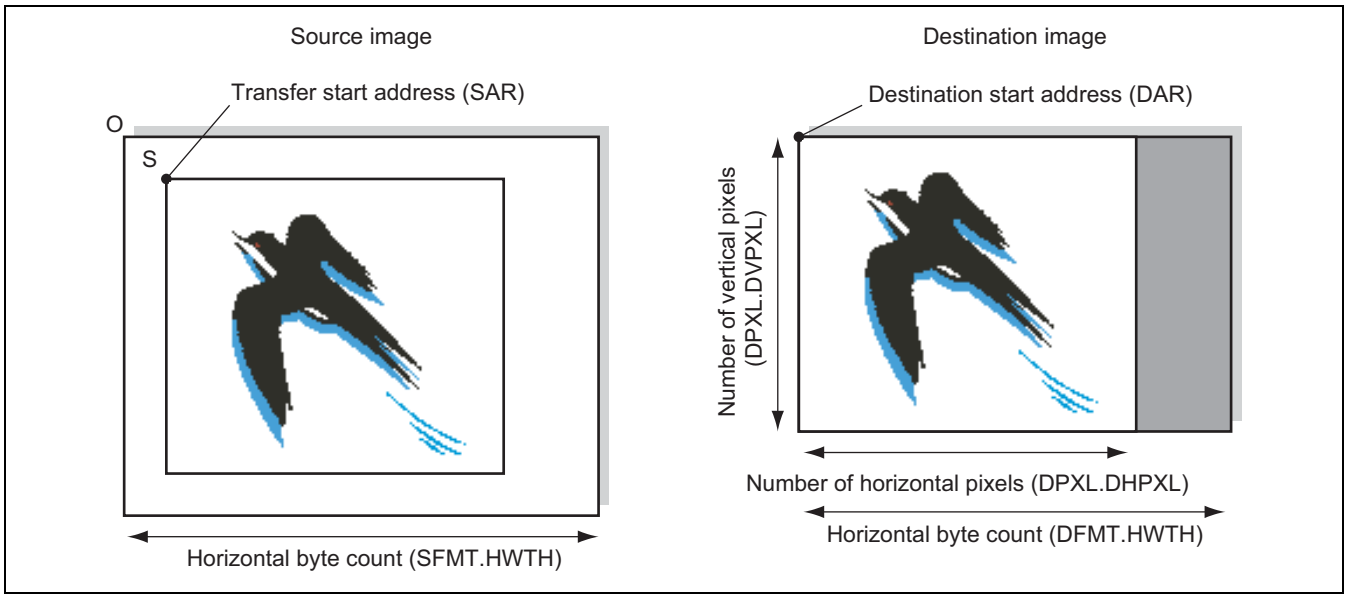


Figure 26.6 Schematic Diagram of Image Extraction

Figure 26.6 shows a schematic diagram of image extraction.

The image format conforms to the YCbCr4:2:0, YCbCr4:2:2, and RGB formats. Extraction of data is possible in two-pixel units for YCbCr formats and in one-pixel units for RGB formats. However, since the Y data and C data are independently stored in the memory in the YCbCr format, set them in different channels respectively.

For source images, the address of extraction start coordinates S and the horizontal byte size must be set in respective registers. Set the start address of the extraction start pixel in SAR. If the X coordinate of extraction start coordinates S (SAR) is an odd number with origin O in the YCbCr format, a deviation is generated between Y data and C data in the horizontal direction. Furthermore, in the YCbCr4:2:0 format, if the Y coordinate of extraction start coordinates S is an odd number with origin O, a deviation is generated between Y data and C data in the vertical direction. For each case, extract image data from the even pixel coordinates where truncation is made.

For destination images, destination start address, numbers of horizontal and vertical pixels, and the horizontal byte size must be set. Set an integer multiple of 16 (≥ DHPXL in DPXL x bytes per pixel) for the horizontal byte size (HWTH in DFMT). Discard the gray area in Figure 26.6 as invalid data. For YCbCr formats, set an even number for the number of Y data horizontal pixels. In addition, for the YCbCr4:2:0 format, the number of vertical pixels must also be set to an even number.

Table 26.4 lists these restrictions.

Table 26.4 Restrictions for Each Format

Format	Item	Restrictions
Common	Destination image horizontal byte size (CHnDFMT.HWTH)	Set an integer multiple of 16.
Y data (YCbCr4:2:2)	Source image horizontal extraction start position (CHnSAR.SAR)	In a case that the X-coordinate of starting coordinate-S (SAR) relative to the coordinate origin 0 of source image is odd number, a deviation is generated between Y data and C data in the horizontal direction.
	Destination image horizontal pixel size (CHnDPXL.DHPXL)	In a case that the horizontal pixel size is odd number of the destination image, the invalid data might be generated right side in the image.
Y data (YCbCr4:2:0)	Source image horizontal extraction start position (CHnSAR.SAR)	In a case that the X-coordinate of starting coordinate-S (SAR) relative to the coordinate origin 0 of source image is odd number, a deviation is generated between Y data and C data in the horizontal direction.
	Source image vertical extraction start position (CHnSAR.SAR)	In a case that the Y-coordinate of starting coordinate-S (SAR) relative to the coordinate origin 0 of source image is odd number, the vertical throw between Y and CbCr is to be generated.
	Destination image horizontal pixel size (CHnDPXL.DHPXL)	In a case that the horizontal pixel size is odd number of the destination image, the invalid data might be generated right side in the image.
	Destination image vertical pixel size (CHnDPXL.DVPXL)	In a case that the vertical pixel size is odd number of the destination image, the invalid data might be generated bottom in the image.

26.3.2 Image Rotation/Inversion

Table 26.5 The Combination of the Bits, VMRR, HMRR, ROTL, and ROTR and the Rotation/Inversion

VMRR bit	HMRR bit	ROTL bit	ROTR bit	DAR specified point	Rotation/Inversion Performance
0	0	0	0	A	Rotation/Inversion is not performed
0	0	0	1	C	Clockwise 90 degrees rotation
0	0	1	0	B	Clockwise 270 degrees rotation
0	1	0	1	A	After rotating clockwise 90 degrees, inverse horizontally (After rotating clockwise 270 degrees, inverse vertically)
1	0	1	0		
1	0	0	1	D	After rotating clockwise 90 degrees, inverse vertically (After rotating clockwise 270 degrees, inverse horizontally)
0	1	1	0		
0	1	0	0	C	Inversing horizontally
1	0	0	0	B	Inversing vertically
1	1	0	0	D	180 degrees rotation
Others				—	Setting prohibited

The rotation/inversion performance in 90 degrees units can be executed arbitrarily effects of combination of the bits, VMRR, HMRR, ROTR, and ROTL as shown in Table 26.5. Figure 26.7 shows the relations between the source image and the destination image in operating with rotation/inversion performance and Figure 26.8 shows only with inversion performance.

During the rotation/ inversion operating, the address specified point setting in CHnDAR is to be changed according to the setting of the bits, VMRR, HMRR, ROTR, and ROTL. See Figure 26.9 for details on the specified address point corresponding to the processing respectively.

Lists the formulas for the address settings as follows.

offset_add Address at the left above end of the destination image.
dest_hwidth Horizontal byte size of the destination image (CHnDFMT.DHWTH)
dest_vpxl Vertical pixel size of the destination image (CHnDPXL.DVPXL)

A DAR = offset_add
B DAR = offset_add + (dest_hwidth × (dest_vpxl − 1))
C DAR = offset_add + dest_hwidth
D DAR = offset_add + (dest_hwidth × dest_vpxl)

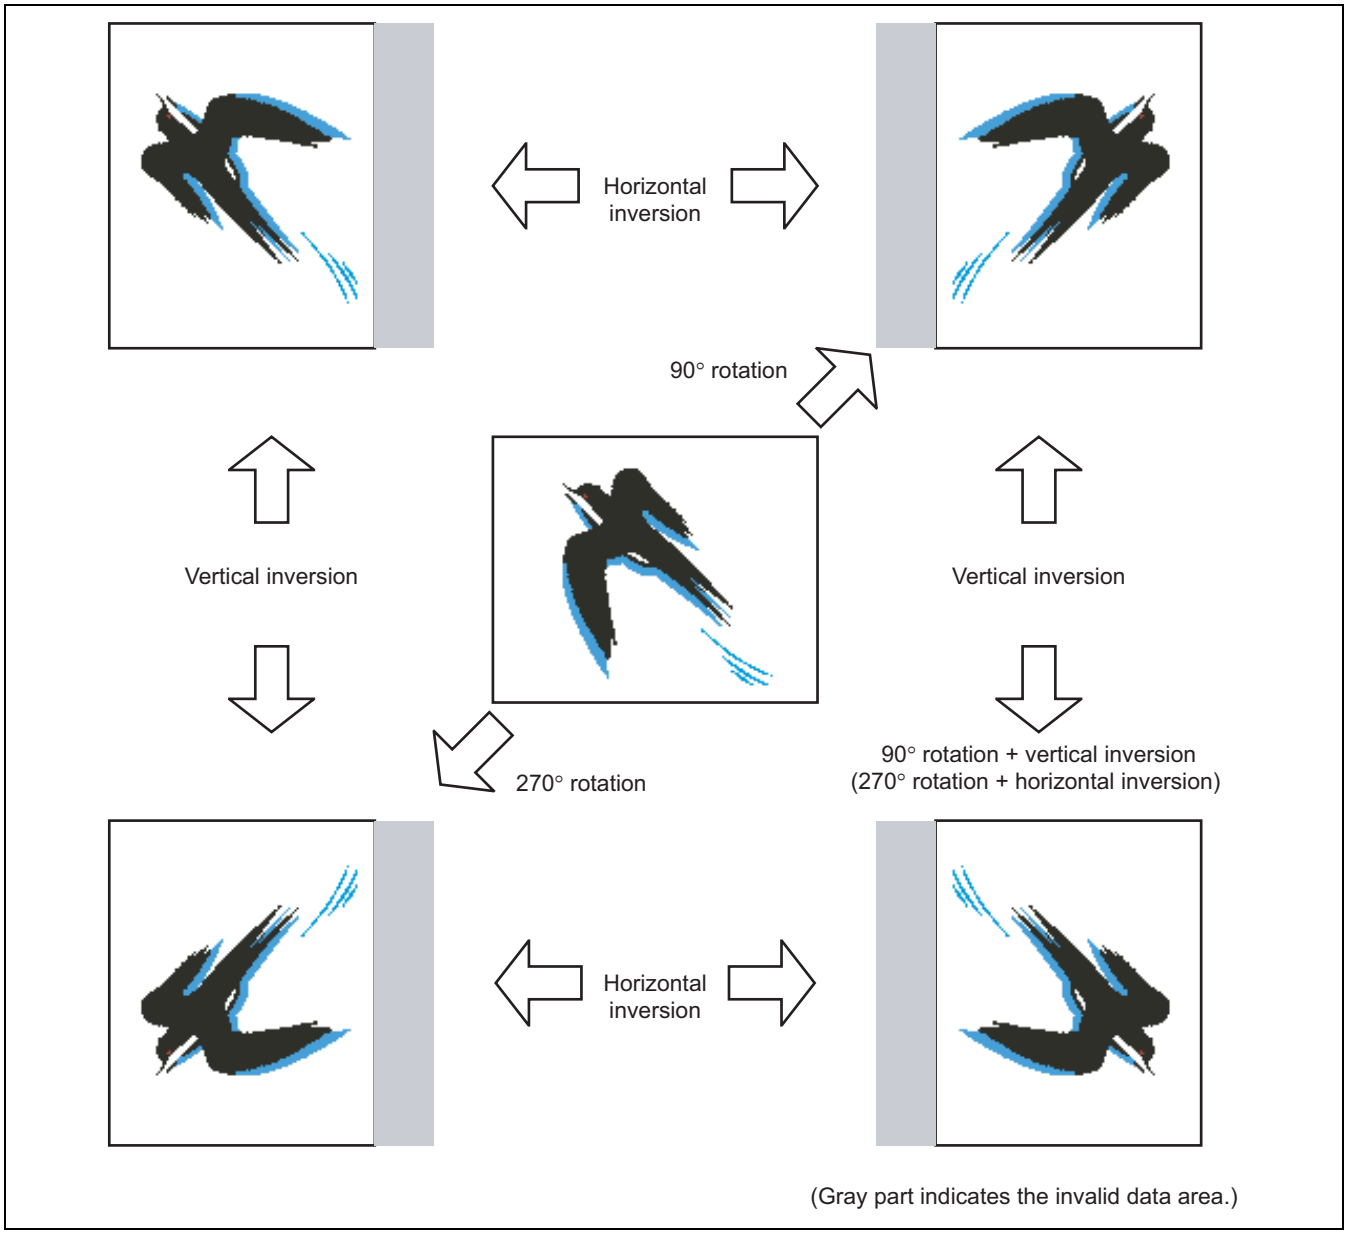

Figure 26.7 Relations between the Source Image and the Destination Image in Operating with Rotation/Inversion Performance

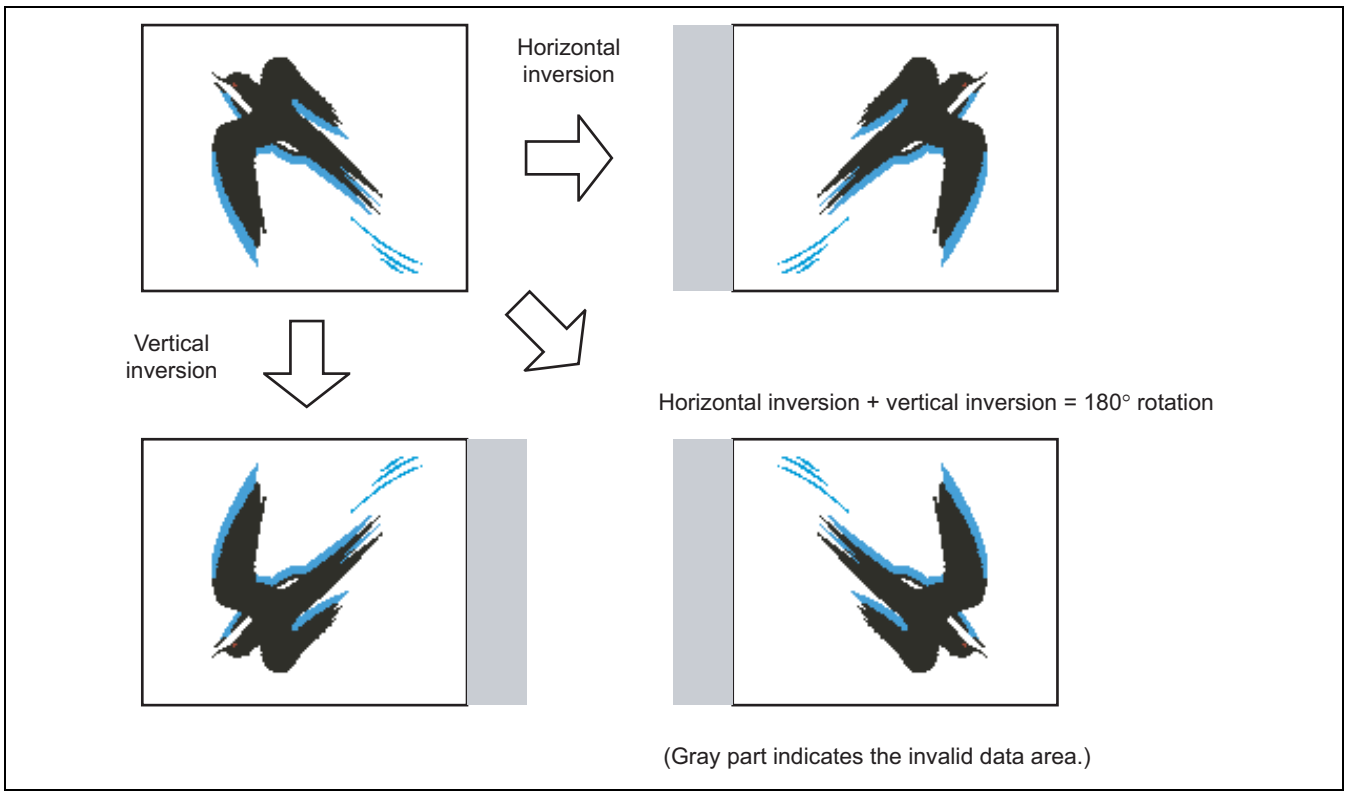

Figure 26.8 Relations between the Source Image and the Destination Image in Operating with Inversion Performance

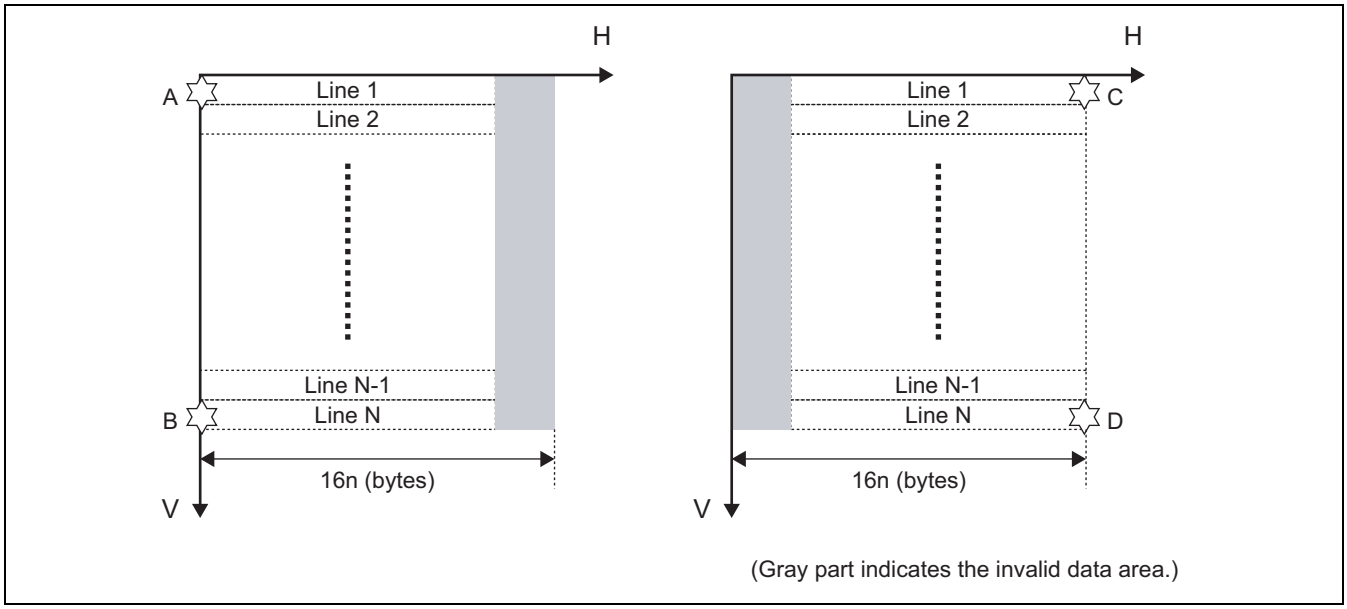

Figure 26.9 The specified Address point of CHnDAR

26.3.3 Format Conversion

Conversions are possible between RGB formats and between YCbCr formats (YCbCr4:2:0 and YCbCr4:2:2). For available RGB formats, see Table 26.3. However, no format conversion is possible between RGB and YCbCr.

26.3.4 Simple Magnification

Setting the MX and MY bits in CTRL allows enlarged output in the X and Y directions respectively.

Simple magnification method is used for the magnification processing where the pixels in the source image are copied in the X and Y directions and are then output.

Figure 26.10 is a schematic diagram of simple magnification of pixels.

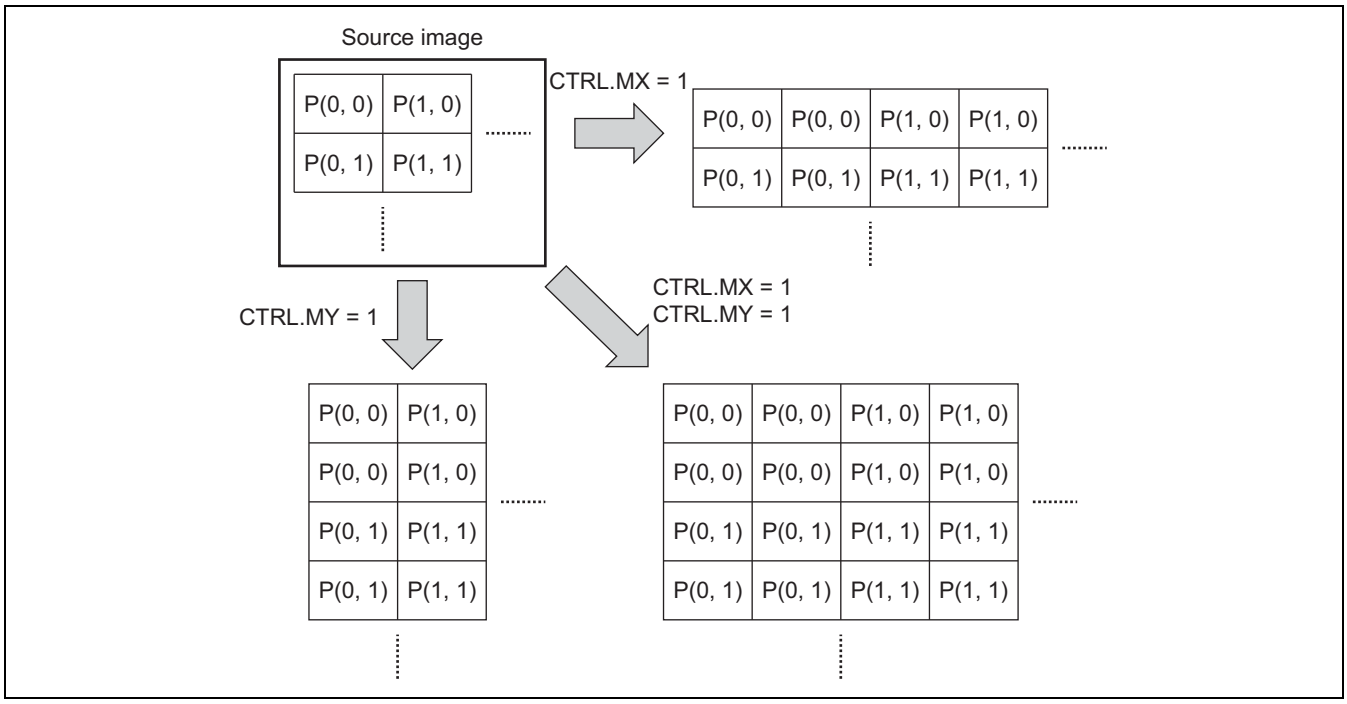

Figure 26.10 Enlarged Output of Pixels

26.4 Transfer Flow

Figure 26.11 shows a flowchart of DMAC transfer using 2D-DMAC.

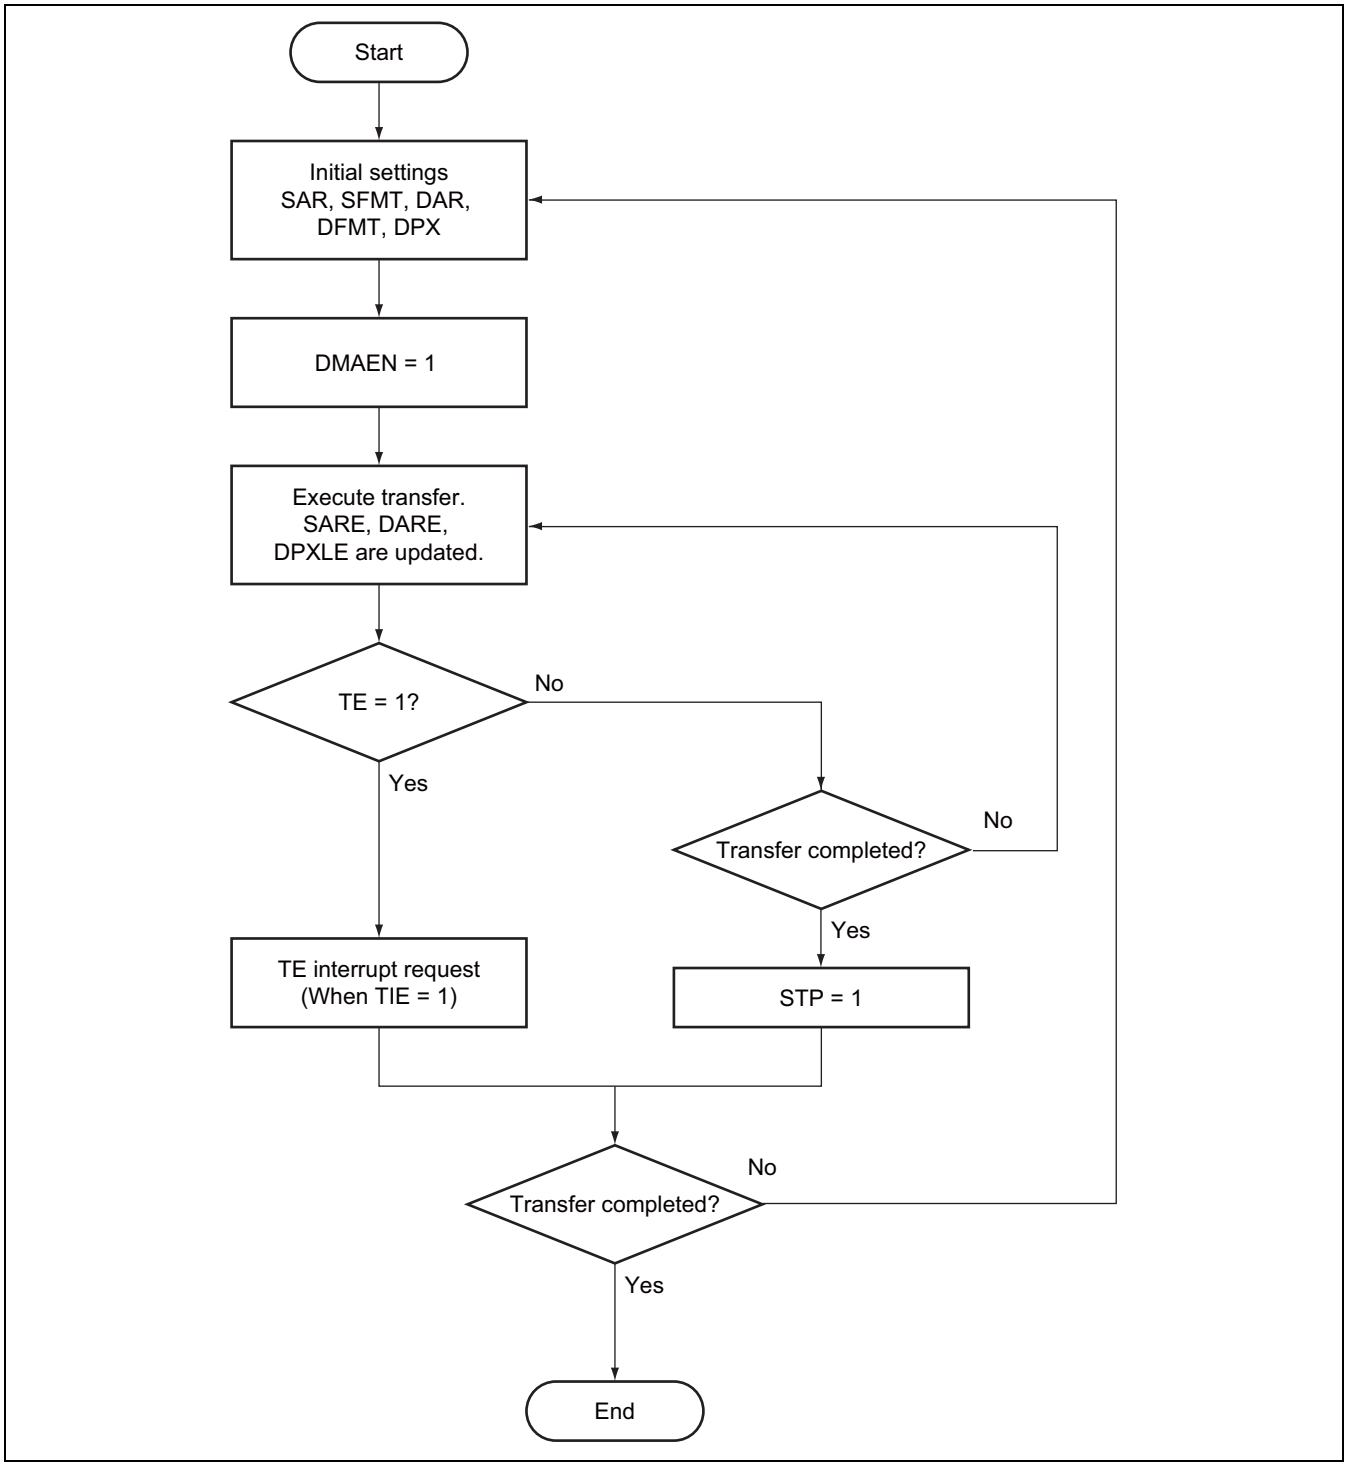

Figure 26.11 Flowchart of DMAC Transfer Using 2D-DMAC

26.5 Handling Interrupts from the 2D-DMAC

The 2D-DMAC module issues an interrupt (TEI = 1) when it completes data output without receiving a confirmation of completion of the data transaction with external memory. This raises the possibility of unexpected (out-of-date) data being read from external memory when a request for access from any module reaches external memory ahead of the 2D-DMAC's interrupt request. This behavior will only appear if the module is accessing 2D-DMAC output data for the part of the bottom line in the right corner (e.g. the CPU is reading image data for 180-degree image rotation.). Avoiding this behavior requires either of the procedures described below.

1. Dummy transaction

   After detecting the TE interruption, set up a dummy transfer with the below conditions:

   Stride size of source image: 2048 bytes

   Output image size: W: 128, H: 32

   Image format: ARGB8888 (PKF = B'00000)

   No image rotation and scaling

   The TE interrupt in response to the dummy transfer guarantees the completion of data output for the target transaction to external memory.

2. Insertion of a wait period

   After detecting the TE interrupt, insert 20 μs of waiting to guarantee completion of the data transaction with external memory.

27. Audio

27.1 Overview

This section describes the data path between audio modules, list of routings, and transfer flow.

27.1.1 Data Paths between Audio Modules

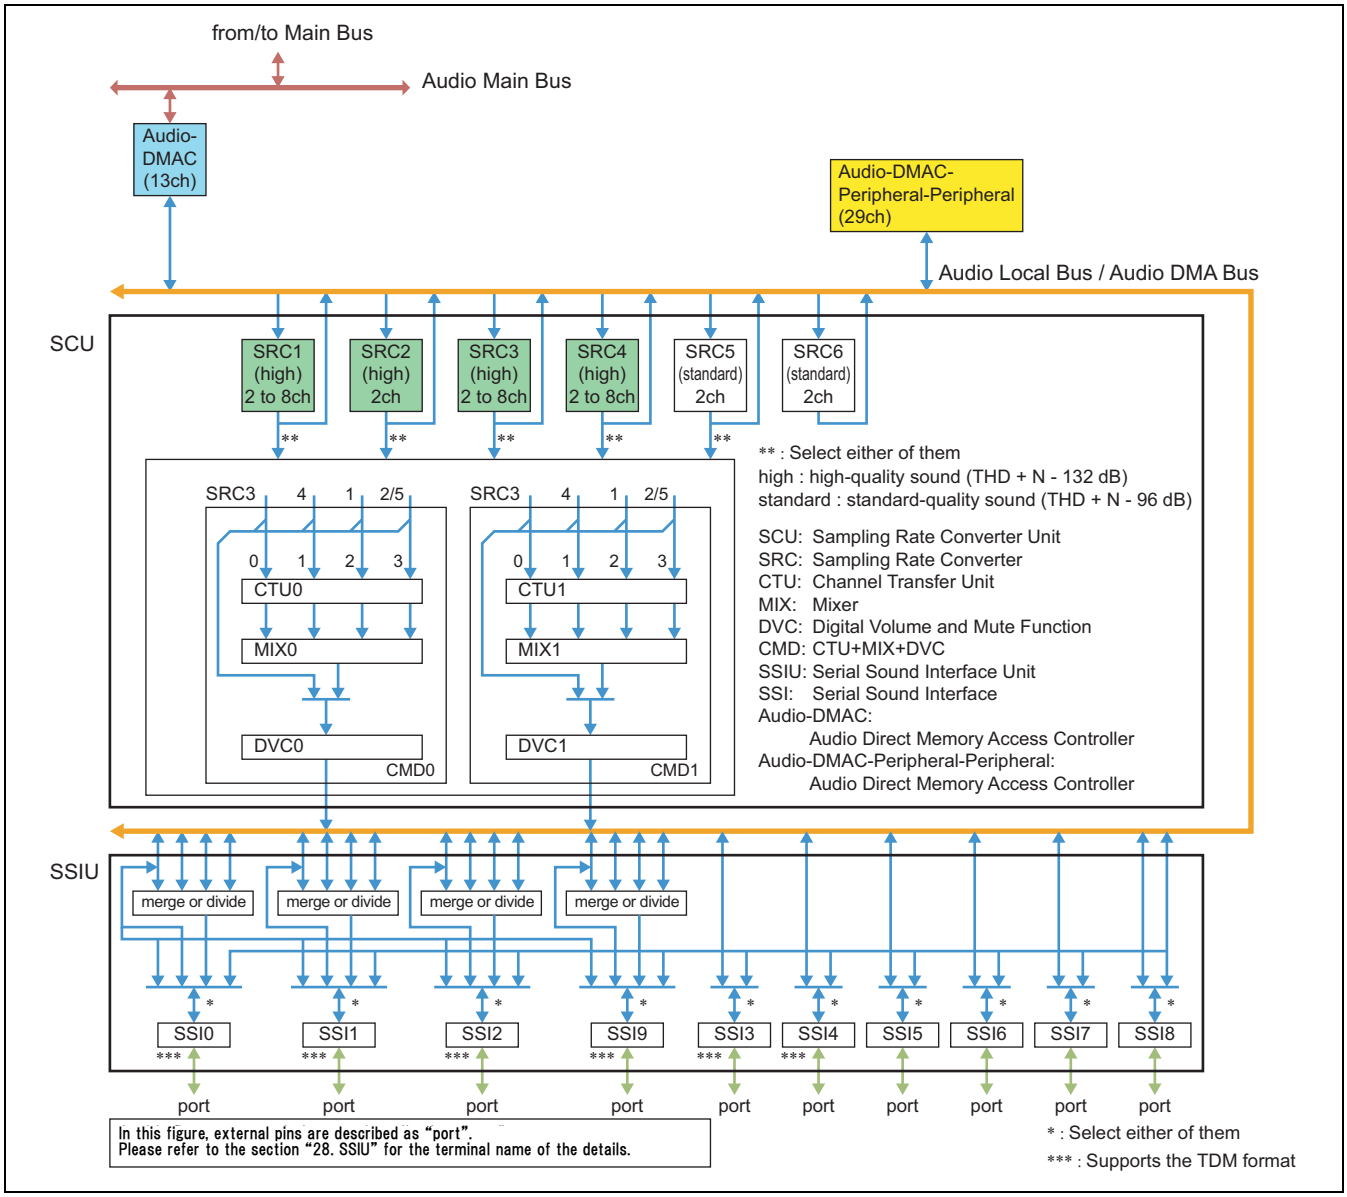

Figure 27.1 Data Paths between Audio Modules List of Routings

Data transmission paths in the Audio module are shown in Figure 27.2.

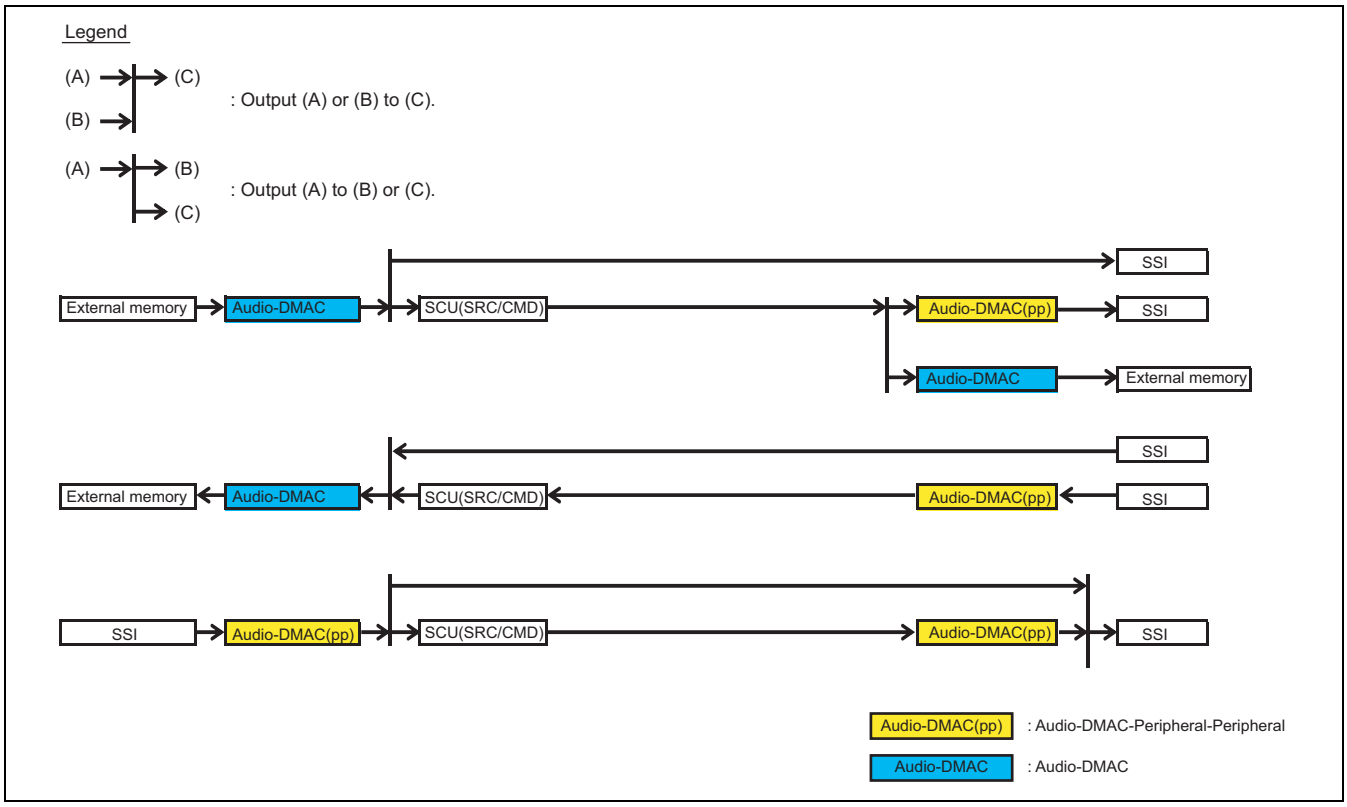

Figure 27.2 List of Routings

27.1.2 Audio-DMAC

The Audio-DMAC is used by data transfer between the external memory and audio modules. The setting values of DMASAR and DMADAR of the Audio-DMAC are shown in Table 27.1.

Table 27.1 Setting Values of DMASAR and DMADAR of Audio-DMAC

Name of Register	DMASAR/DMADAR	
SSI0-0_BUSIF	H'EC10	0000
SSI0-1_BUSIF		0400
SSI0-2_BUSIF		0800
SSI0-3_BUSIF		0C00
SSI1-0_BUSIF		1000
SSI1-1_BUSIF		1400
SSI1-2_BUSIF		1800
SSI1-3_BUSIF		1C00
SSI2-0_BUSIF		2000
SSI2-1_BUSIF		2400
SSI2-2_BUSIF		2800
SSI2-3_BUSIF		2C00
SSI3_BUSIF		3000
SSI4_BUSIF		4000
SSI5_BUSIF		5000
SSI6_BUSIF		6000
SSI7_BUSIF		7000
SSI8_BUSIF		8000
SSI9-0_BUSIF		9000
SSI9-1_BUSIF		9400
SSI9-2_BUSIF		9800
SSI9-3_BUSIF		9C00
SSITDR0*2	H'EC24	1008
SSIRDR0*1		100C
SSITDR1*2		1048
SSIRDR1*1		104C
SSITDR2*2		1088
SSIRDR2*1		108C
SSITDR3*2		10C8
SSIRDR3*1		10CC
SSITDR4*2		1108
SSIRDR4*1		110C
SSITDR5*2		1148
SSIRDR5*1		114C

Name of Register	DMASAR/DMADAR	
SSITDR6*2	H'EC24	1188
SSIRDR6*1		118C
SSITDR7*2		11C8
SSIRDR7*1		11CC
SSITDR8*2		1208
SSIRDR8*1		120C
SSITDR9*2		1248
SSIRDR9*1		124C
SRC1in_BUSIF*2	H'EC00	0400
SRC2in_BUSIF*2		0800
SRC3in_BUSIF*2		0C00
SRC4in_BUSIF*2		1000
SRC5in_BUSIF*2		1400
SRC6in_BUSIF*2		1800
SRC1out_BUSIF*1		4400
SRC2out_BUSIF*1		4800
SRC3out_BUSIF*1		4C00
SRC4out_BUSIF*1		5000
SRC5out_BUSIF*1		5400
SRC6out_BUSIF*1		5800
CMD0out_BUSIF*1		8000
CMD1out_BUSIF*1		8400

Notes: 1. Used only by DMASAR.
2. Used only by DMADAR.

27.1.3 Data Format on Audio Local Bus

Figure 27.3 shows the data formats handled in the audio local bus. When writing or reading data through the Audio-DMAC, align data to match the appropriate data format from those in Figure 27.3.

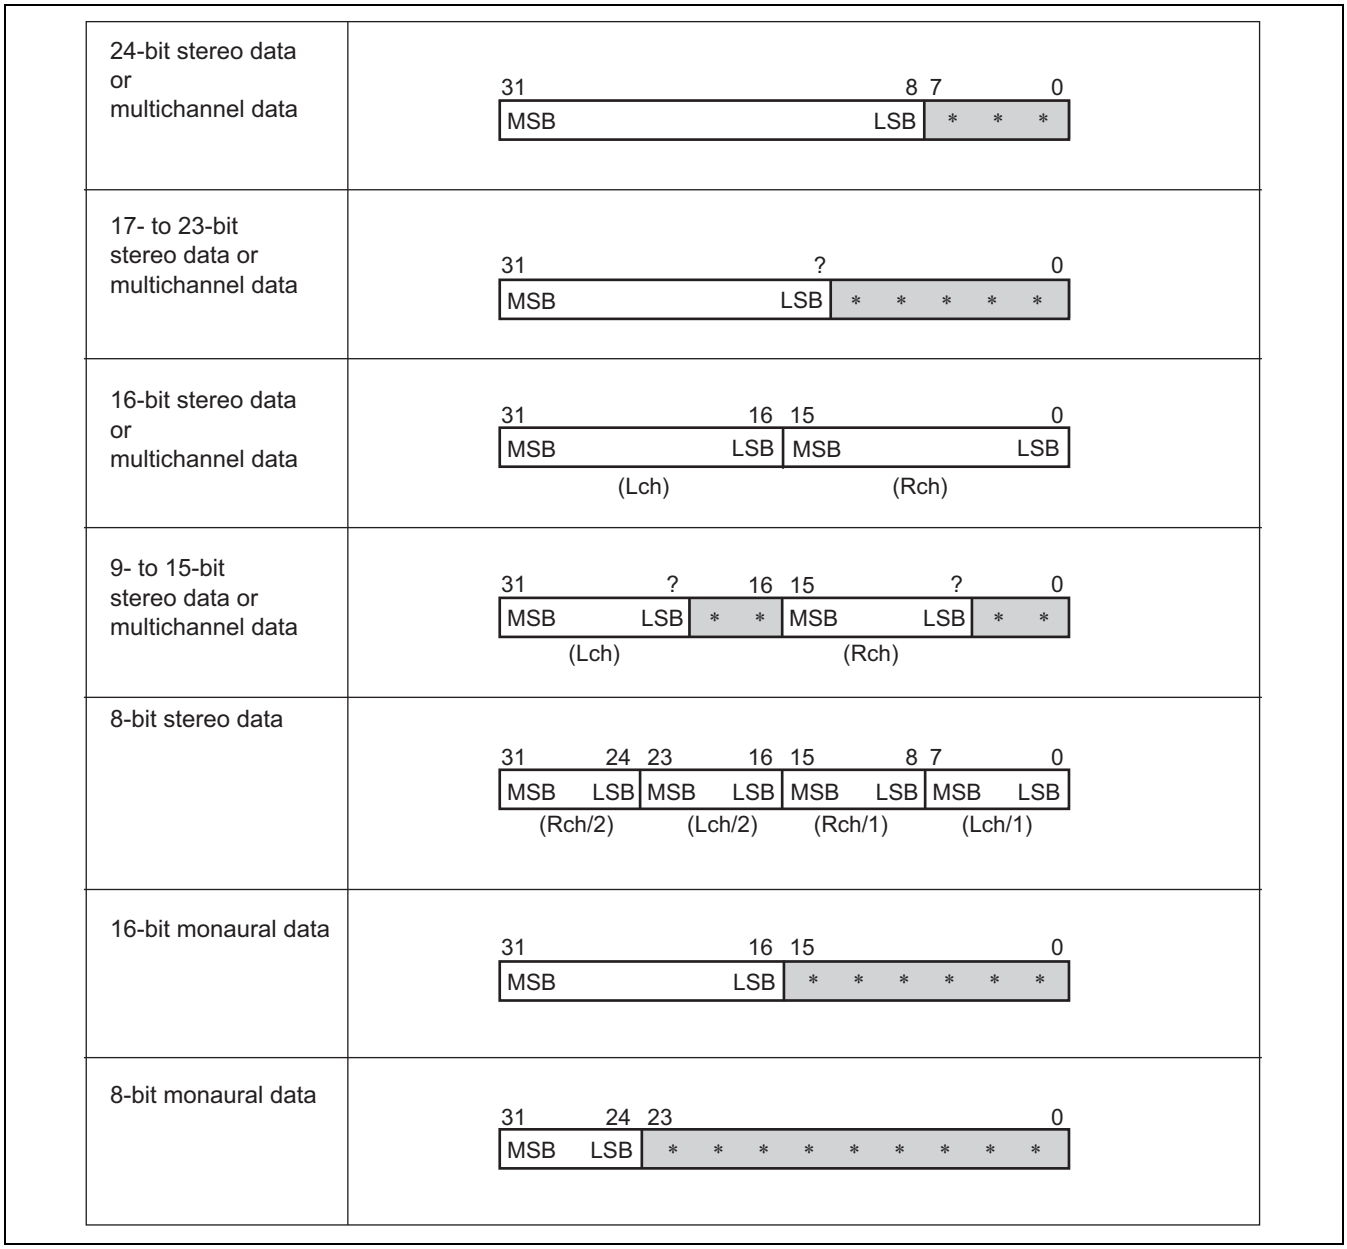

Figure 27.3 Data Format

Notes: 1. Write 0 to the * bits in the figure when writing data. When reading data, ignore the values read from these bits.
2. In the 8-bit stereo data format, (Lch/1) and (Rch/1) indicate the data pair to be processed first and (Lch/2) and (Rch/2) indicate the next data pair to be processed.
3. Only the MSB-first data formats can be used.
4. In Data Format of "16-bit stereo data or multichannel data" and "9- to 15-bitstereo data or multichannel data", set SSIU.SSI_MODE0.ind_word_swap*(* = 0-9) in the setup of independent SSI transmission (SSIU.SSI_MODE0.ind*(* = 0-9) = 1).

27.1.4 Rearranging the Order of Data

For the audio modules (SSI and SCU), rearranging the order of data is possible in the channel unit. Places of data in each data format are defined as in Tables 27.2 to 27.4.

Table 27.2 Definition of Data Places in Each Data Format (1)

SSI · Stereo (2 channels)	SSI · Stereo x 3 (6 channels)	
SSI · TDM (6 channels)	SSI · Stereo x 4 (8 channels)	SSI · TDM (8 channels)	
Table 27.3 Definition of Data Places in Each Data Format (2)

BUSIF · Stereo (2 channels) · 24 bits	External memory image BUSIF · Stereo (2 channels) · 16 bits	External memory image BUSIF · Stereo (2 channels) · 8 bits	External memory image BUSIF · Monaural (1 channel) · 8/16 bits	External memory image BUSIF · Multichannel (4 channels) · 24 bits	External memory image BUSIF · Multichannel (4 channels) · 16 bits	External memory image 
Table 27.4 Definition of Data Places in Each Data Format (3)

BUSIF · Multichannel (6 channels) · 24 bits	External memory image 31 0 H'00 Place 0 * H'04 Place 1 * H'08 Place 2 * H'0C Place 3 * H'10 Place 4 * H'14 Place 5 * H'18 Place 0 * H'1C Place 1 * ... ... *
BUSIF · Multichannel (6 channels) · 16 bits	External memory image 31 0 H'00 Place 0 Place 1 H'04 Place 2 Place 3 H'08 Place 4 Place 5 H'0C Place 0 Place 1 ... ...
BUSIF · Multichannel (8 channels) · 24 bits	External memory image 31 0 H'00 Place 0 * H'04 Place 1 * H'08 Place 2 * H'0C Place 3 * H'10 Place 4 * H'14 Place 5 * H'18 Place 6 * H'1C Place 7 * H'20 Place 0 * ... ... *
BUSIF · Multichannel (8 channels) · 16 bits	External memory image 31 0 H'00 Place 0 Place 1 H'04 Place 2 Place 3 H'08 Place 4 Place 5 H'0C Place 6 Place 7 H'10 Place 0 Place 1 ... ...

27.1.5 Transfer Flow

When data transfer is performed between the audio modules, which are used in a set of audio routing, use the Audio-DMAC and Audio-DMAC-Peripheral-Peripheral to perform settings in accord with the transfer flow shown in Figure 27.4.

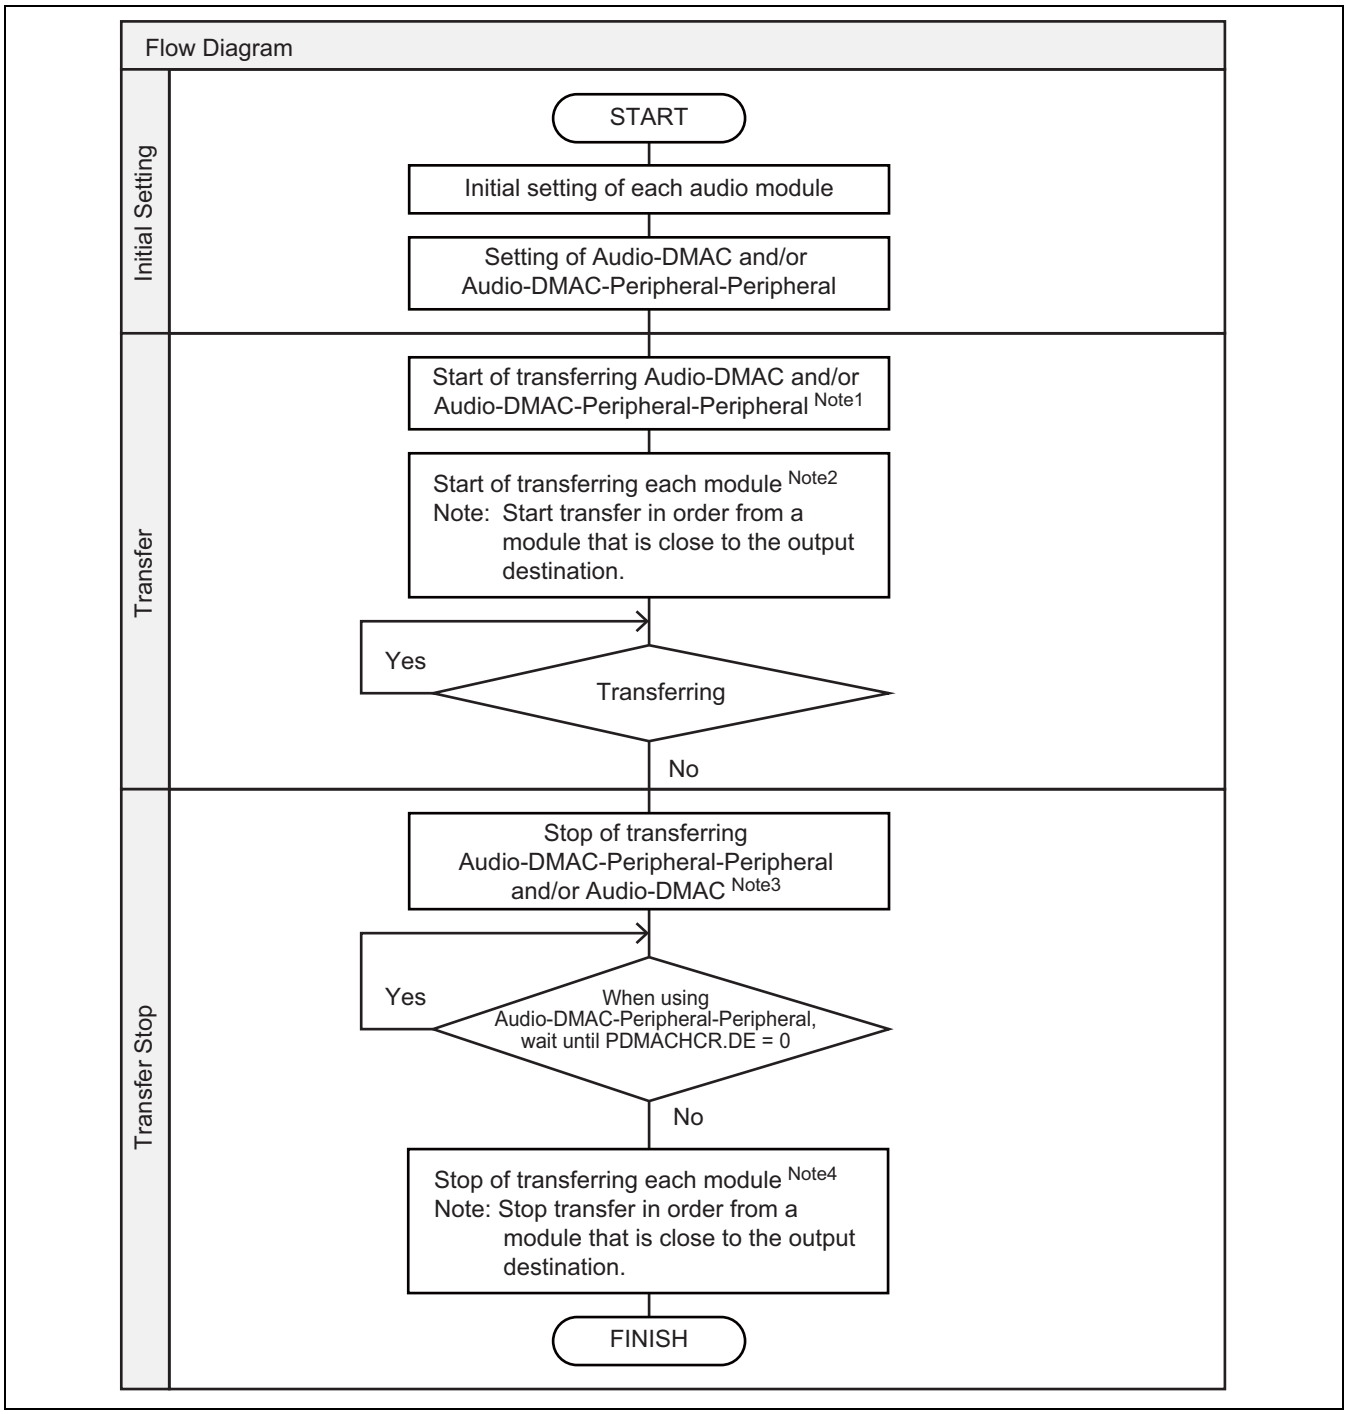

Figure 27.4 Transfer Flow

Notes: 1. For Audio-DMAC, set DMACHCR.DE.
For Audio-DMAC-Peripheral-Peripheral, set PDMACHCR.DE.
Set up registers except the above in "setting of Audio-DMAC and/or Audio-DMAC-Peripheral-Peripheral."

2. For SSI (except for the case when TDM split mode, SSI independent transfer, SSI0, SSI1, SSI2, or SSI9, and SSI3 or SSI4 are used at the same time), when transmitting (from SSI to the external device), set

SSIq/r_CONTROL.start after setting SSICR.en/dmen). When receiving (from the external device to SSI), set SSICR.en/dmen after setting SSIq/r_CONTROL.start.

For SSI (In the case of TDM split mode) regardless of transmission and reception, set SSIq/r_CONTROL.start after setting SSICR.en/dmen.

For SSI (In the case of SSI independent transfer), set SSICR.en/dmen.

For SSI (When using SSI0, SSI1, SSI2, or SSI9 and SSI3 or SSI4 at the same time), when transmitting (from SSI to the external device) set SSIq/r_CONTROL.start after setting SSI_CONTROL. When receiving (from the external device to SSI), set SSI_CONTROL after setting SSIq/r_CONTROL.start. (Set SSICR.dmen at the time of the initial setting.)

For SCU, Set SRCm_CONTROL and CMDn_CONTROL.

Set up registers except the above in “initial setting of each audio module”.

3. For Audio-DMAC-Peripheral-Peripheral, clear PDMACHCR.DE. (mandatory)
   For Audio-DMAC, clear DMACHCR.DE. Clear processing of Audio-DMAC can be cleared anywhere in a TransferStop sequence.
4. For SSI (except for the case when TDM split mode, SSI independent transfer, SSI0, SSI1, SSI2, or SSI9, and SSI3 or SSI4 are used at the same time), when transmitting (from SSI to the external device), clear SSIq/r_CONTROL.start after clearing SSICR.en/dmen. When receiving (from the external device to SSI), clear SSICR.en/dmen after clearing SSIq/r_CONTROL.start.

   For SSI (In the case of TDM split mode), regardless of transmission and reception, clear all SSIq/r_CONTROL.start of the relevant channels to clear SSICR.en/dmen.

   For SSI (In the case of SSI independent transfer), clear SSICR.en/dmen.

   For SSI (When using SSI0, SSI1, SSI2, or SSI9 and SSI3 or SSI4 at the same time), when transmitting (from SSI to the external device) clear SSIq/r_CONTROL.start after clearing SSICR.dmen of each module and SSI_CONTROL. When receiving (from the external device to SSI), clear SSICR.dmen of each module and SSI_CONTROL after clearing SSIq/r_CONTROL.start.

   For SCU, clear SRCm_CONTROL and CMDn_CONTROL.

27.1.6 Module Standby Function

For the register settings to make a transition to or from module standby mode, refer to section 7A, Module Standby and Software Reset.

(1) Transition to Module Standby Mode

To make a transition to module standby mode by the module standby function, refer to the following transition procedure for each module.

(a) SSIU/SSI

1. Check the following registers' settings.
   [SSIU]
   — All bits in the SSIq control register (SSIq_CONTROL) (q = 0-0, 1-0, 2-0, or 9-0) are cleared to 0 (data transfer stopped).
   — All bits in the SSIr control register (SSIr_CONTROL) (r = 3 to 8) are cleared to 0 (data transfer stopped).
   — All bits in the SSIq interrupt enable register (SSIq_INT_ENABLE_MAIN) (q = 0-0, 1-0, 2-0, or 9-0) are cleared to 0 (interrupt disabled).
   — All bits in the SSIr interrupt enable register (SSIr_INT_ENABLE_MAIN) (r = 3 to 8) are cleared to 0 (interrupt disabled).
   — All bits in the SSI control register (SSI_CONTROL) are cleared to 0 (data transfer stopped)

   [SSI]
   — The DMEN and EN bits in the control register (SSICRn) (n = 0 to 9) are cleared to 0 (disabled).
   — The IDST bit in the status register (SSISRn) (n = 0 to 9) is set to 1.
   — The CONT bit in the WS mode register (SSIWSRn) (n = 0 to 9) is cleared to 0 (disabled).

2. Set the MSTP1005 to MSTP1015 bits in the module stop control register (SMSTPCR10)

Note: The above bits should be set while the module operation has been completed and is placed in the idle state in which the module cannot be activated by external pins or other modules.

(b) SCU

1. Check the following registers' settings.
   — All bits in the SRCm control register (SRCm_CONTROL) (m = 1 to 6) are cleared to 0 (data transfer stopped).
   — All bits in the CMDn control register (CMDn_CONTROL) (n = 0, 1) are cleared to 0 (data transfer stopped).
   — All bits in the SRCm interrupt enable register 0 (SRCm_INT_ENABLE0) (m = 1 to 5) are cleared to 0 (interrupt disabled).
   — All bits in the SRCn interrupt enable register 0 (SRCn_INT_ENABLE0) (n = 6) are cleared to 0 (interrupt disabled).
2. Set the MSTP1017 to MSTP1021 and MSTP1025 to MSTP1030 bits in the module stop control register (SMSTPCR10)

Note: The above bits should be set while the module operation has been completed and is placed in the idle state in which the module cannot be activated by external pins or other modules.

(2) Releasing and Restarting from Module Standby Mode

After the transition to module standby mode, modules can be released from module standby mode by a power-on reset or the appropriate procedure from the list below.

(a) SSIU/SSI

1. Supply the clock signal to the ADG and SSIU/SSI modules.
2. Clear the MSTP1005 to MSTP1015 bits in the module stop control register (SMSTPCR10).

(b) SCU

1. Clear the MSTP1017 to MSTP1021 and MSTP1025 to MSTP1030 bits in the module stop control register (SMSTPCR10).

27.2 Usage Notes

27.2.1 Notes on Route Switching and Setting Changes

When switching the transfer route, stop the current transfer, specify the new transfer route, and then start transfer. Also, when changing the quantization bit count or the formats, once stop transfer, and then start transfer again after resetting. If this procedure is not followed, correct operation is not guaranteed.

27.2.2 Use of SSI3 and SSI4

Table 27.5 shows the combinations of SSI3 and SSI4 usage and register settings.

Table 27.5 Combinations of SSI3 and SSI4 Usage and Register Settings

	SSI_MODE1 Register Settings		Bit Used to Control Start or Stop Operation
	ssi34_sync	ssi4_pin	
Operating SSI3 and SSI4 independently	0	00	SSICRn.EN (n = 3 and 4)
Operating SSI4 with the SCK and WS signals of SSI3 being shared by both SSI3 and SSI4	0	01 or 10	SSICRn.EN (n = 3 and 4)
Synchronizing serial data of SSI3 and SSI4	1	01 or 10	SSI_CONTROL.ssi34

27.2.3 Notes on CMD Block Usage

When a single sound source is split into two routes, CMD0 and CMD1, and output to SSI3 and SSI4, use the settings for "Synchronizing serial data of SSI3 and SSI4" in Table 27.5, Combinations of SSI3 and SSI4 Usage and Register Settings. The quantization bit count and sampling frequency settings should be the same between SSI3 and SSI4. Note that only the stereo format can be specified for SSI3 and SSI4. For example, it is not possible to output TDM-format data from SSI3 and stereo-format data from SSI4. The reverse combination is not possible either (stereo-format data from SSI3 or TDM-format data from SSI4).

When a single sound source is split into two routes, CMD0 and CMD1, transfer to different types of destination is impossible. For example, outputting CMD0 to SSI and CMD1 to External memory is not allowed.

27.2.4 Note when SSI0, SSI1, and SSI2, or SSI0, SSI1, SSI2, and SSI9 are Used for Single-Source Audio Data

When SSI0, SSI1, and SSI2, or SSI0, SSI1, SSI2, and SSI9 are used for single-source audio data, specifying eight-bit quantization and six- or eight-channel operation at the same time is not possible.

27.2.5 Note on Transfer

When an underflow or an overflow occurs in any audio module, stop the transfer.

27.2.6 Note on Usage of the SCU Module

Before starting data transfer, the SCU module needs certain “input data timing” and “output data timing”. When “input data timing” and “output data timing” are not inputted before the transmission start, it does not operate correctly.

In addition, if the SSI module operates in master mode, and if the WS signal is used as “input/output timing signal for the SRC”, set SSIWSRn.CONT to 1.

(The WS signal inputted into the ADG module is the same signal as the SSI_WS terminal.)

28. Serial Sound Interface Unit (SSIU)

28.1 Overview

The SSIU, incorporating ten SSI modules, allows independent operation of SSI modules, operation of multiple SSI modules sharing the same serial clock, and connection or split of multichannel data.

Refer to section 28A to understand single SSI module in detail.

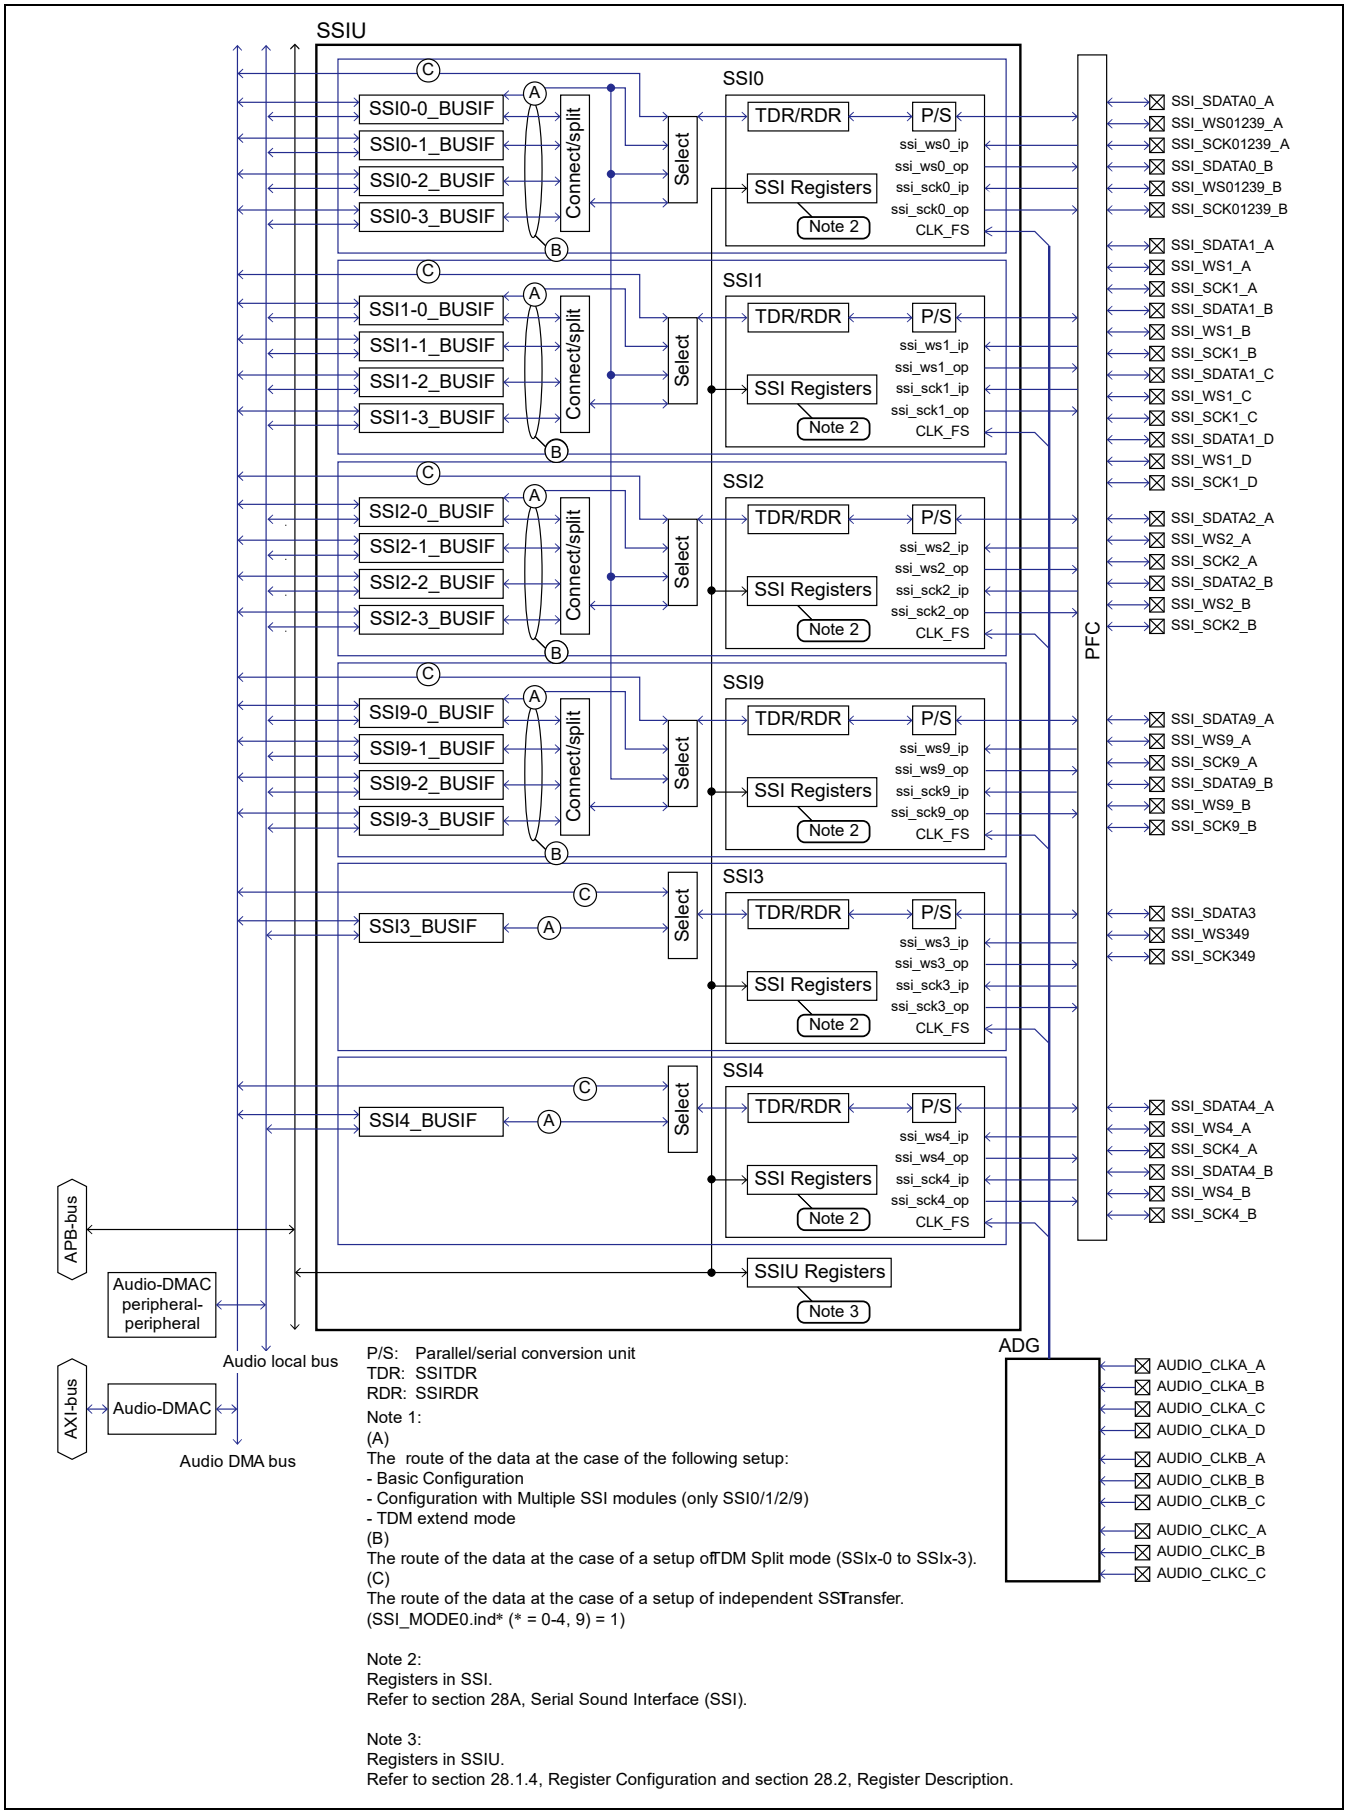
Note: Configure the system so that connected external devices can operate on the same clock source.

28.1.1 Features

- Incorporates ten SSI modules.
- Supports 6 channels/1 sound source with three SSI modules (SSI0, SSI1, and SSI2).
- Supports 8 channels/1 sound source with four SSI modules (SSI0, SSI1, SSI2, and SSI9).
- Operation of multiple modules on the same serial clock (SSI0/SSI1/SSI2/SSI3/SSI9, SSI3/SSI4/SSI9, or SSI7/SSI8).
- TDM format (Basic Configuration) corresponds to 4-, 6-, or 8-channel data.
- Handles 8-channel data on the serial bus and 6-channel data in the RZ/G1C (TDM extend mode).
- Handles 6-channel data on the serial bus and 8-channel data in the RZ/G1C (TDM extend mode).
- Connects monaural or stereo data to output TDM format data (TDM split mode).
- Splits TDM format input data into monaural or stereo data (TDM split mode).
- The frequency range of SCK signal is from 297.3 kHz to 12.5 MHz at master mode, and from 297.3 kHz to 15.1 MHz at slave mode.

28.1.2 Block Diagram

Figures 28.1 and 28.2 show the SSIU block diagrams.



P/S: Parallel/serial conversion unit
TDR: SSITDR
RDR: SSIRDR

Note 1:
(A)
The route of the data at the case of the following setup:
- Basic Configuration
- Configuration with Multiple SSI modules (only SSI0/1/2/9)
- TDM extend mode
(B)
The route of the data at the case of a setup of TDM Split mode (SSIx-0 to SSIx-3).
(C)
The route of the data at the case of a setup of independent SSI transfer.
(SSI_MODE0.ind* (* = 0-4, 9) = 1)

Note 2:
Registers in SSI.
Refer to section 28A, Serial Sound Interface (SSI).

Note 3:
Registers in SSIU.
Refer to section 28.1.4, Register Configuration and section 28.2, Register Description.

Figure 28.1 Block Diagram of SSIU (SSI0, SSI1, SSI2, SSI3, SSI4, and SSI9)

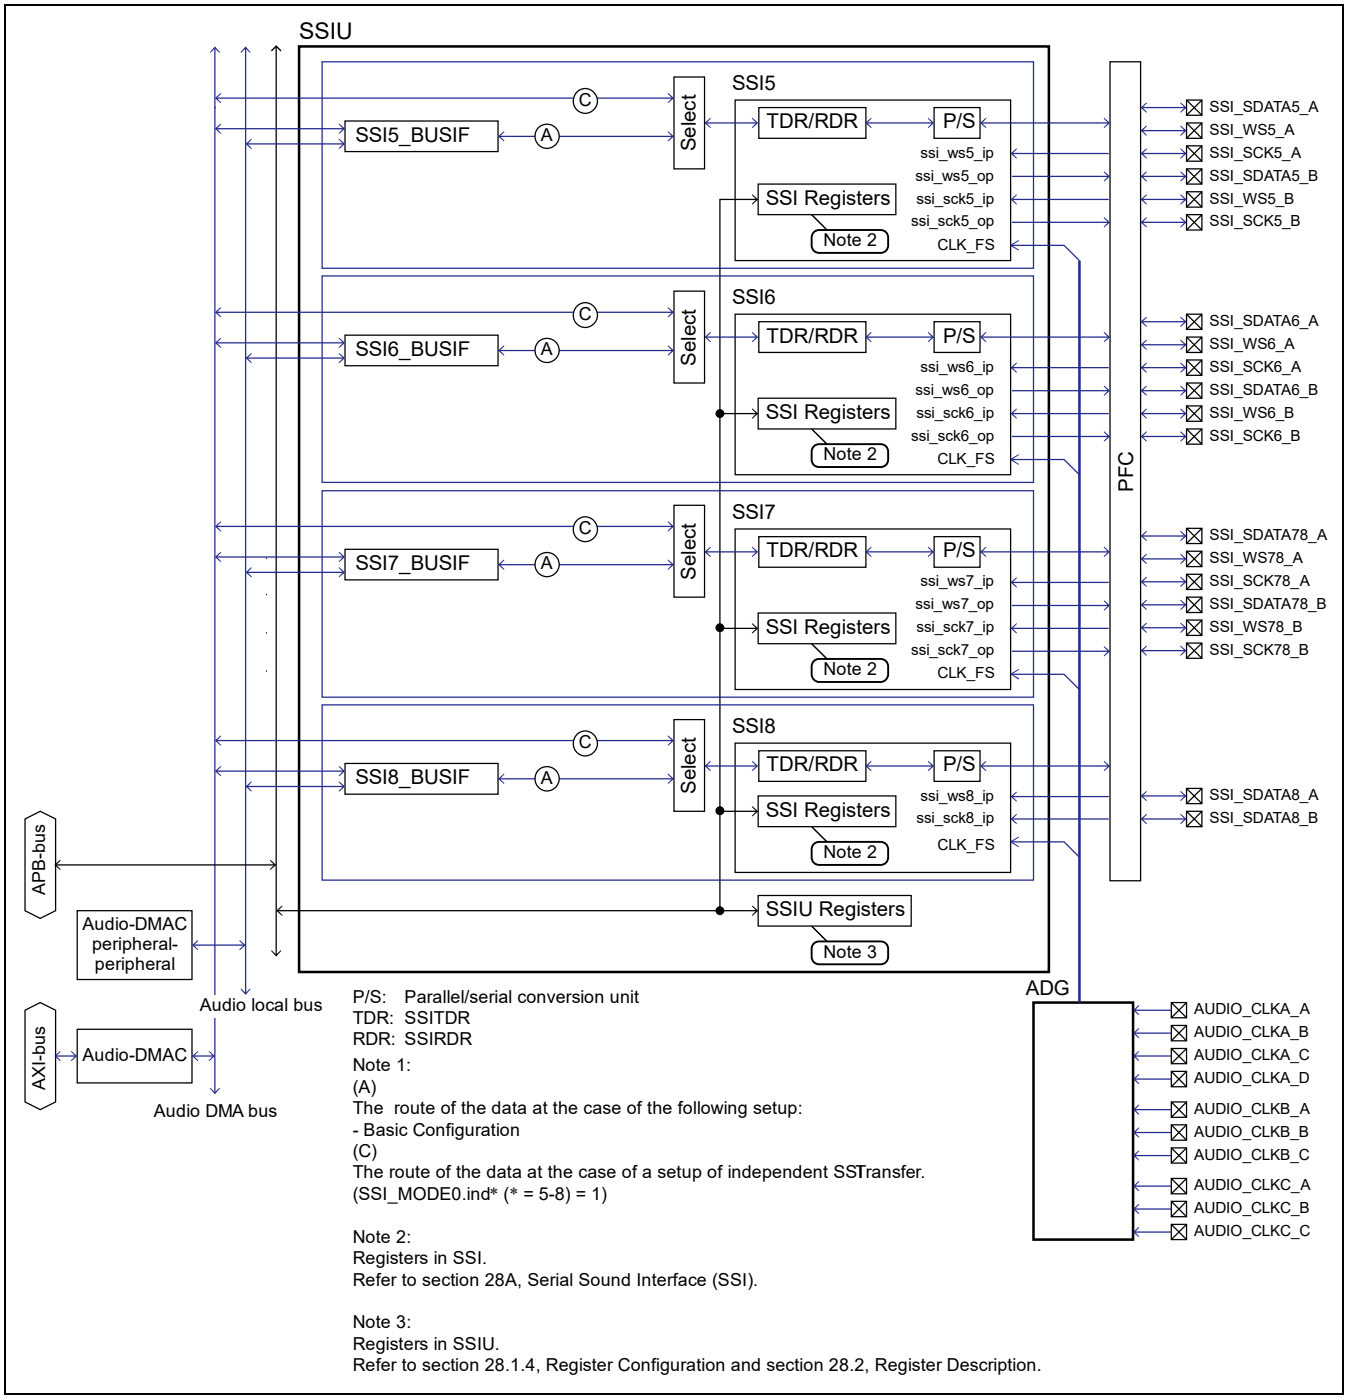


Figure 28.2 Block Diagram of SSIU (SSI5, SSI6, SSI7, and SSI8)

28.1.3 Input/Output Pins

Table 28.1 shows the pin configuration.

Table 28.1 Pin Configuration

Name	Pin Name	I/O	Function
Serial clock pin for SSI0, SSI1, SSI2, SSI3 and SSI9 (Group A)	SSI_SCK0129_A (SSI_SCK01239_A)	I/O	Serial clock (SSI0 only or combination of SSI0, SSI1, SSI2, SSI3, and SSI9) (Group A)
Serial clock pin for SSI0, SSI1, SSI2, SSI3 and SSI9 (Group B)	SSI_SCK0129_B (SSI_SCK01239_B)	I/O	Serial clock (SSI0 only or combination of SSI0, SSI1, SSI2, SSI3, and SSI9) (Group B)
Word select pin for SSI0, SSI1, SSI2, SSI3 and SSI9 (Group A)	SSI_WS0129_A (SSI_WS01239_A)	I/O	Word select (SSI0 only or combination of SSI0, SSI1, SSI2, SSI3, and SSI9) (Group A)
Word select pin for SSI0, SSI1, SSI2, SSI3 and SSI9 (Group B)	SSI_WS0129_B (SSI_WS01239_B)	I/O	Word select (SSI0 only or combination of SSI0, SSI1, SSI2, SSI3, and SSI9) (Group B)
Serial data pin for SSI0 (Group A)	SSI_SDATA0_A	I/O	Serial data (Group A)
Serial data pin for SSI0 (Group B)	SSI_SDATA0_B	I/O	Serial data (Group B)
Serial clock pin for SSI1 (Group A)	SSI_SCK1_A	I/O	Serial clock (Group A)
Serial clock pin for SSI1 (Group B)	SSI_SCK1_B	I/O	Serial clock (Group B)
Serial clock pin for SSI1 (Group C)	SSI_SCK1_C	I/O	Serial clock (Group C)
Serial clock pin for SSI1 (Group D)	SSI_SCK1_D	I/O	Serial clock (Group D)
Word select pin for SSI1 (Group A)	SSI_WS1_A	I/O	Word select (Group A)
Word select pin for SSI1 (Group B)	SSI_WS1_B	I/O	Word select (Group B)
Word select pin for SSI1 (Group C)	SSI_WS1_C	I/O	Word select (Group C)
Word select pin for SSI1 (Group D)	SSI_WS1_D	I/O	Word select (Group D)
Serial data pin for SSI1 (Group A)	SSI_SDATA1_A	I/O	Serial data (Group A)
Serial data pin for SSI1 (Group B)	SSI_SDATA1_B	I/O	Serial data (Group B)
Serial data pin for SSI1 (Group C)	SSI_SDATA1_C	I/O	Serial data (Group C)
Serial data pin for SSI1 (Group D)	SSI_SDATA1_D	I/O	Serial data (Group D)
Serial clock pin for SSI2 (Group A)	SSI_SCK2_A	I/O	Serial clock (Group A)
Serial clock pin for SSI2 (Group B)	SSI_SCK2_B	I/O	Serial clock (Group B)
Word select pin for SSI2 (Group A)	SSI_WS2_A	I/O	Word select (Group A)
Word select pin for SSI2 (Group B)	SSI_WS2_B	I/O	Word select (Group B)
Serial data pin for SSI2 (Group A)	SSI_SDATA2_A	I/O	Serial data (Group A)
Serial data pin for SSI2 (Group B)	SSI_SDATA2_B	I/O	Serial data (Group B)
Serial clock pin for SSI3, SSI4 and SSI9	SSI_SCK34 (SSI_SCK349)	I/O	Serial clock (SSI3 only, common to SSI3 and SSI4, or combination of SSI3, SSI4, and SSI9)
Word select pin for SSI3, SSI4 and SSI9	SSI_WS34 (SSI_WS349)	I/O	Word select (SSI3 only, common to SSI3 and SSI4, or combination of SSI3, SSI4, and SSI9)
Serial data pin for SSI3	SSI_SDATA3	I/O	Serial data
Serial clock pin for SSI4 (Group A)	SSI_SCK4_A	I/O	Serial clock (Group A)
Serial clock pin for SSI4 (Group B)	SSI_SCK4_B	I/O	Serial clock (Group B)
Word select pin for SSI4 (Group A)	SSI_WS4_A	I/O	Word select (Group A)
Word select pin for SSI4 (Group B)	SSI_WS4_B	I/O	Word select (Group B)
Serial data pin for SSI4 (Group A)	SSI_SDATA4_A	I/O	Serial data (Group A)
Serial data pin for SSI4 (Group B)	SSI_SDATA4_B	I/O	Serial data (Group B)
Serial clock pin for SSI5 (Group A)	SSI_SCK5_A	I/O	Serial clock (Group A)
Serial clock pin for SSI5 (Group B)	SSI_SCK5_B	I/O	Serial clock (Group B)

Name	Pin Name	I/O	Function
Word select pin for SSI5 (Group A)	SSI_WS5_A	I/O	Word select (Group A)
Word select pin for SSI5 (Group B)	SSI_WS5_B	I/O	Word select (Group B)
Serial data pin for SSI5 (Group A)	SSI_SDATA5_A	I/O	Serial data (Group A)
Serial data pin for SSI5 (Group B)	SSI_SDATA5_B	I/O	Serial data (Group B)
Serial clock pin for SSI6 (Group A)	SSI_SCK6_A	I/O	Serial clock (Group A)
Serial clock pin for SSI6 (Group B)	SSI_SCK6_B	I/O	Serial clock (Group B)
Word select pin for SSI6 (Group A)	SSI_WS6_A	I/O	Word select (Group A)
Word select pin for SSI6 (Group B)	SSI_WS6_B	I/O	Word select (Group B)
Serial data pin for SSI6 (Group A)	SSI_SDATA6_A	I/O	Serial data (Group A)
Serial data pin for SSI6 (Group B)	SSI_SDATA6_B	I/O	Serial data (Group B)
Serial clock pin for SSI7 and SSI8 (Group A)	SSI_SCK78_A	I/O	Serial clock (common to SSI7 and SSI8) (Group A)
Serial clock pin for SSI7 and SSI8 (Group B)	SSI_SCK78_B	I/O	Serial clock (common to SSI7 and SSI8 (Group B))
Word select pin for SSI7 and SSI8 (Group A)	SSI_WS78_A	I/O	Word select (common to SSI7 and SSI8) (Group A)
Word select pin for SSI7 and SSI8 (Group B)	SSI_WS78_B	I/O	Word select (common to SSI7 and SSI8 (Group B))
Serial data pin for SSI7 (Group A)	SSI_SDATA7_A	I/O	Serial data (Group A)
Serial data pin for SSI7 (Group B)	SSI_SDATA7_B	I/O	Serial data (Group B)
Serial data pin for SSI8 (Group A)	SSI_SDATA8_A	I/O	Serial data (Group A)
Serial data pin for SSI8 (Group B)	SSI_SDATA8_B	I/O	Serial data (Group B)
Serial clock pin for SSI9 (Group A)	SSI_SCK9_A	I/O	Serial clock (Group A)
Serial clock pin for SSI9 (Group B)	SSI_SCK9_B	I/O	Serial clock (Group B)
Word select pin for SSI9 (Group A)	SSI_WS9_A	I/O	Word select (Group A)
Word select pin for SSI9 (Group B)	SSI_WS9_B	I/O	Word select (Group B)
Serial data pin for SSI9 (Group A)	SSI_SDATA9_A	I/O	Serial data (Group A)
Serial data pin for SSI9 (Group B)	SSI_SDATA9_B	I/O	Serial data (Group B)

Note: Although each SSI is multiplexed on multiple LSI pins, the combinations of pins in use must be from the same group. For Example, the use of combinations such as SSI_SCK1_A, SSI_WS1_B, and SSI_SDATA1_C is prohibited. Refer to section 5, Pin Function Controller (PFC) for details.

28.1.4 Register Configuration

Table 28.2 shows the register configuration. Do not write to any addresses other than listed below. Operations cannot be guaranteed if writing is attempted. Values read from addresses other than those listed below are undefined. Access the register as a longword (32 bits). Operation cannot be guaranteed if the register is not accessed as a longword.

Table 28.2 Register Configuration

Name	Abbreviation	R/W	Address	Initial Value	Access Size

Note: * Address H'EC10 XXXX is used for data transfer with the Audio-DMAC. Address H'EC40 XXXX is used for data transfer with the Audio-DMAC-Peripheral-Peripheral.

28.2 Register Description

Legend for Register Description

Initial value: Register value after a reset. H'xxxx represents a hexadecimal number. Others are represented in binary numbers.

—: Undefined value

R/W: Readable/writable. The written value can be read.

R: Read-only. The write value should always be 0.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R/WC1: Readable/writable. Writing 1 initializes the bit. Writing 0 is ignored.

W: Write-only. Reading this bit is prohibited. When the bit is reserved, the write value should always be 0.

—/W: Write-only. The read value is undefined.

All access to registers is made in longword units.

28.2.1 SSIn BUSIF Mode Register (SSIn_BUSIF_MODE)

Note: n = 0-0 to 0-3, 1-0 to 1-3, 2-0 to 2-3, 3 to 8, or 9-0 to 9-3

Function: SSIn_BUSIF_MODE determines the initial settings of the bus interface.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	sft_dir	sft_num			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	word_swap	—	—	—	—	—	—	—	dma
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	sft_dir	0	R/W	ssi***n***_busif_shift_dir Selects the bit-shift direction for valid bit position adjustment in the SSI***n***_BUSIF input and output data. 0: Shift to left. 1: Shift to right.
19 to 16	sft_num	0000	R/W	ssi***n***_busif_shift_num Selects the bit-shift count for valid bit position adjustment in the SSI***n***_BUSIF input and output data. 0000: 0 bit 0001: 1 bit 0010: 2 bits 0011: 3 bits 0100: 4 bits 0101: 5 bits 0110: 6 bits 0111: 7 bits 1000: 8 bits 1001: 9 bits 1010: 10 bits 1011: 11 bits 1100: 12 bits 1101: 13 bits 1110: 14 bits 1111: 15 bits
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	word_swap	0	R/W	word_swap_en Swaps the word order in SSI***n***_BUSIF. 0: Word order is not swapped. 1: Word order is swapped. Note: Select this function only when the data length is 16 bits.

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	dma	1	R/W	ssi***n***_dma Selects the access type for SSI***n***_BUSIF. 0: PIO access (setting prohibited) 1: DMA access Be sure to specify the DMA access.

28.2.2 SSIm BUSIF Audio Information Register (SSIm_BUSIF_ADINR)

Note: m = 0-0, 1-0, 2-0, 3 to 8, or 9-0

Function: SSIm_BUSIF_ADINR is a 32-bit readable/writable register that selects channel number and bit length of output audio data.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	OTBL[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	CHNUM[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20 to 16	OTBL[4:0]	00000	R/W	Bit Length of Output Audio Data. These bits set the bit length of output audio data. 00000: 24 bits 00001: Reserved 00010: 22 bits 00011: Reserved 00100: 20 bits 00101: Reserved 00110: 18 bits 00111: Reserved 01000: 16 bits 01001 to 01111: Reserved 10000: 8 bits 10001 to 11111: Reversed
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	CHNUM[3:0]	0000	R/W	Channel Number These bits set the channel number. 0000: 0 (None) 0001: 1 channel 0010: 2 channels 0011: Reserved 0100: 4 channels 0101: Reserved 0110: 6 channels 0111: Reserved 1000: 8 channels 1001 to 1111: Reserved

28.2.3 SSIp BUSIF Audio Information Register (SSIp_BUSIF_ADINR)

Note: p = 0-1 to 0-3, 1-1 to 1-3, 2-1 to 2-3, or 9-1 to 9-3

Function: SSIp_BUSIF_ADINR is a 32-bit readable/writable register that selects channel number and bit length of output audio data.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	OTBL[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	CHNUM[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20 to 16	OTBL[4:0]	00000	R/W	Bit Length of Output Audio Data. These bits set the bit length of output audio data. 00000: 24 bits 00001: Reserved 00010: 22 bits 00011: Reserved 00100: 20 bits 00101: Reserved 00110: 18 bits 00111: Reserved 01000: 16 bits 01001 to 01111: Reserved 10000: 8 bits 10001 to 11111: Reversed
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	CHNUM[3:0]	0000	R/W	Channel Number These bits set the channel number. 0000: 0 (none) 0001: 1 channel 0010: 2 channels 0011 to 1111: Reserved

28.2.4 SSIm BUSIF Data Align Register (SSIm_BUSIF_DALIGN)

Note: m = 0-0, 1-0, 2-0, 3 to 8, or 9-0

Function: SSIm_BUSIF_DALIGN determines the initial settings of the SSIm route.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	place7			—	place6			—	place5			—	place4		
Initial value:	0	1	1	1	0	1	1	0	0	1	0	1	0	1	0	0
R/W:	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	place3			—	place2			—	place1			—	place0		
Initial value:	0	0	1	1	0	0	1	0	0	0	0	1	0	0	0	0
R/W:	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30 to 28	place7	111	R/W	Changes the stream data order. These bits are used for the 8-channel setting. For the 6- or less channel setting or TDM split mode setting (tdm_split = 1), the initial value should not be changed. The data order is changed between the SSI and bus interface. Selects the input-side data to be output to place 7 on the output side. 000: Data at input-side place 0 is sent to output-side place 7. 001: Data at input-side place 1 is sent to output-side place 7. 010: Data at input-side place 2 is sent to output-side place 7. 011: Data at input-side place 3 is sent to output-side place 7. 100: Data at input-side place 4 is sent to output-side place 7. 101: Data at input-side place 5 is sent to output-side place 7. 110: Data at input-side place 6 is sent to output-side place 7. 111: Data at input-side place 7 is sent to output-side place 7.
27	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
26 to 24	place6	110	R/W	Changes the stream data order. These bits are used for the 8-channel setting. For the 6- or less channel setting or TDM split mode setting (tdm_split = 1), the initial value should not be changed. The data order is changed between the SSI and bus interface. Selects the input-side data to be output to place 6 on the output side. 000: Data at input-side place 0 is sent to output-side place 6. 001: Data at input-side place 1 is sent to output-side place 6. 010: Data at input-side place 2 is sent to output-side place 6. 011: Data at input-side place 3 is sent to output-side place 6. 100: Data at input-side place 4 is sent to output-side place 6. 101: Data at input-side place 5 is sent to output-side place 6. 110: Data at input-side place 6 is sent to output-side place 6. 111: Data at input-side place 7 is sent to output-side place 6.
23	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
22 to 20	place5	101	R/W	Changes the stream data order. These bits are used for the 6- or more channel setting. For the 4- or less channel setting or TDM split mode setting (tdm_split = 1), the initial value should not be changed. The data order is changed between the SSI and bus interface. Selects the input-side data to be output to place 5 on the output side. 000: Data at input-side place 0 is sent to output-side place 5. 001: Data at input-side place 1 is sent to output-side place 5. 010: Data at input-side place 2 is sent to output-side place 5. 011: Data at input-side place 3 is sent to output-side place 5. 100: Data at input-side place 4 is sent to output-side place 5. 101: Data at input-side place 5 is sent to output-side place 5. 110: Data at input-side place 6 is sent to output-side place 5. 111: Data at input-side place 7 is sent to output-side place 5.
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
18 to 16	place4	100	R/W	Changes the stream data order. These bits are used for the 6- or more channel setting. For the 4- or less channel setting or TDM split mode setting (tdm_split = 1), the initial value should not be changed. The data order is changed between the SSI and bus interface. Selects the input-side data to be output to place 4 on the output side. 000: Data at input-side place 0 is sent to output-side place 4. 001: Data at input-side place 1 is sent to output-side place 4. 010: Data at input-side place 2 is sent to output-side place 4. 011: Data at input-side place 3 is sent to output-side place 4. 100: Data at input-side place 4 is sent to output-side place 4. 101: Data at input-side place 5 is sent to output-side place 4. 110: Data at input-side place 6 is sent to output-side place 4. 111: Data at input-side place 7 is sent to output-side place 4.
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
14 to 12	place3	011	R/W	Changes the stream data order. These bits are used for the 4- or more channel setting. For the 2- or less channel setting or TDM split mode setting (tdm_split = 1), the initial value should not be changed. The data order is changed between the SSI and bus interface. Selects the input-side data to be output to place 3 on the output side. 000: Data at input-side place 0 is sent to output-side place 3. 001: Data at input-side place 1 is sent to output-side place 3. 010: Data at input-side place 2 is sent to output-side place 3. 011: Data at input-side place 3 is sent to output-side place 3. 100: Data at input-side place 4 is sent to output-side place 3. 101: Data at input-side place 5 is sent to output-side place 3. 110: Data at input-side place 6 is sent to output-side place 3. 111: Data at input-side place 7 is sent to output-side place 3.
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10 to 8	place2	010	R/W	Changes the stream data order. These bits are used for the 4- or more channel setting. For the 2- or less channel setting or TDM split mode setting (tdm_split = 1), the initial value should not be changed. The data order is changed between the SSI and bus interface. Selects the input-side data to be output to place 2 on the output side. 000: Data at input-side place 0 is sent to output-side place 2. 001: Data at input-side place 1 is sent to output-side place 2. 010: Data at input-side place 2 is sent to output-side place 2. 011: Data at input-side place 3 is sent to output-side place 2. 100: Data at input-side place 4 is sent to output-side place 2. 101: Data at input-side place 5 is sent to output-side place 2. 110: Data at input-side place 6 is sent to output-side place 2. 111: Data at input-side place 7 is sent to output-side place 2.
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6 to 4	place1	001	R/W	Changes the stream data order. The data order is changed between the SSI and bus interface. Selects the input-side data to be output to place 1 on the output side. • When TDM split mode is used (tdm_split = 1) 000: Data at input-side place 0 is sent to output-side place 1. 001: Data at input-side place 1 is sent to output-side place 1. Other settings are prohibited. • When TDM split mode is not used (tdm_split = 0) 000: Data at input-side place 0 is sent to output-side place 1. 001: Data at input-side place 1 is sent to output-side place 1. 010: Data at input-side place 2 is sent to output-side place 1. 011: Data at input-side place 3 is sent to output-side place 1. 100: Data at input-side place 4 is sent to output-side place 1. 101: Data at input-side place 5 is sent to output-side place 1. 110: Data at input-side place 6 is sent to output-side place 1. 111: Data at input-side place 7 is sent to output-side place 1.
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
2 to 0	place0	000	R/W	Changes the stream data order. The data order is changed between the SSI and bus interface. Selects the input-side data to be output to place 0 on the output side. • When TDM split mode is used (tdm_split = 1) 000: Data at input-side place 0 is sent to output-side place 0. 001: Data at input-side place 1 is sent to output-side place 0. Other settings are prohibited. • When TDM split mode is not used (tdm_split = 0) 000: Data at input-side place 0 is sent to output-side place 0. 001: Data at input-side place 1 is sent to output-side place 0. 010: Data at input-side place 2 is sent to output-side place 0. 011: Data at input-side place 3 is sent to output-side place 0. 100: Data at input-side place 4 is sent to output-side place 0. 101: Data at input-side place 5 is sent to output-side place 0. 110: Data at input-side place 6 is sent to output-side place 0. 111: Data at input-side place 7 is sent to output-side place 0.

28.2.5 SSIp BUSIF Data Align Register (SSIp_BUSIF_DALIGN)

Note: p = 0-1 to 0-3, 1-1 to 1-3, 2-1 to 2-3, or 9-1 to 9-3

Function: SSIp_BUSIF_DALIGN determines the initial settings of the SSIp route.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	place1	—	—	—	place0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	place1	1	R/W	Changes the stream data order. The data order is changed between the SSI and bus interface. Selects the input-side data to be output to place 1 on the output side. 0: Data at input-side place 0 is sent to output-side place 1. 1: Data at input-side place 1 is sent to output-side place 1.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	place0	0	R/W	Changes the stream data order. The data order is changed between the SSI and bus interface. Selects the input-side data to be output to place 0 on the output side. 0: Data at input-side place 0 is sent to output-side place 0. 1: Data at input-side place 1 is sent to output-side place 0.

28.2.6 SSIq Mode Register (SSIq_MODE)

Note: q = 0-0, 1-0, 2-0, or 9-0

Function: SSIq_MODE determines the initial settings of the SSIq route.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	fs_mode	—	—	—	—	tdm_split	—	—	—	—	—	—	—	tdm_ext
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13	fs_mode	0	R/W	ssi***i***_fs_mode (***i*** = 0, 1, 2, or 9) Selects fs to be used with TDM split mode for ssi***i***. 0: ssi***i*** TDM split mode is used with 256 fs (stereo x 4). 1: ssi***i*** TDM split mode is used with 128 fs (monaural x 4).
12 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	tdm_split	0	R/W	ssi***i***_tdm_split (***i*** = 0, 1, 2, or 9) Selects whether or not TDM split mode is used for ssi***i***. 0: TDM split mode is not used for ssi***i*** (only ssi***i*** -0_BUSIF is used). 1: TDM split mode is used for ssi***i*** (ssi***i*** -1_BUSIF to ssi***i***-3_BUSIF are also used).
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	tdm_ext	0	R/W	ssi***i***_tdm_ext (***i*** = 0, 1, 2, or 9) Selects whether or not TDM extend mode is used for ssi***i***. 0: ssi***i*** TDM extend mode is not used. 1: ssi***i*** TDM extend mode is used.

Note: Bit 0 (tdm_ext) and bit 8 (tdm_split) cannot be set to 1 at the same time.

28.2.7 SSIr Mode Register (SSIr_MODE)

Note: r = 3 or 4

Function: SSIr_MODE determines the initial settings of the SSIr route.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	tdm_ext
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	tdm_ext	0	R/W	ssi*r*_tdm_ext Selects whether or not TDM extend mode is used for ssi*r*. 0: ssi*r* TDM extend mode is not used. 1: ssi*r* TDM extend mode is used.

28.2.8 SSIq Control Register (SSIq_CONTROL)

Note: q = 0-0, 1-0, 2-0, or 9-0

Function: SSIq_CONTROL controls the start and stop of data transfer.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	start_3	—	—	—	start_2	—	—	—	start_1	—	—	—	start_0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	start_3	0	R/W	SSI***i-3***_start_flag (i = 0 to 2, 9) Starts or stops data transfer through SSI***i-3***. 0: Transfer is stopped. 1: Transfer is started.
11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	start_2	0	R/W	SSI***i-2***_start_flag (i = 0 to 2, 9) Starts or stops data transfer through SSI***i-2***. 0: Transfer is stopped. 1: Transfer is started.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	start_1	0	R/W	SSI***i-1***_start_flag (i = 0 to 2, 9) Starts or stops data transfer through SSI***i-1***. 0: Transfer is stopped. 1: Transfer is started.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	start_0	0	R/W	SSI***i-0***_start_flag (i = 0 to 2, 9) Starts or stops data transfer through SSI***i-0***. 0: Transfer is stopped. 1: Transfer is started.

Note: If only SSI***i-0*** is used and TDM split mode is not used, SSI***i-1***_start flag to SSI***i-3***_start flag should be set to 0 (transfer stopped).

28.2.9 SSIr Control Register (SSIr_CONTROL)

Note: r = 3 to 8

Function: SSIr_CONTROL controls the start and stop of data transfer.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	start
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	start	0	R/W	SSI*r*_start_flag Starts or stops data transfer through SSI*r*. 0: Transfer is stopped. 1: Transfer is started.

28.2.10 SSIq Status Register (SSIq_STATUS)

Note: q = 0-0, 1-0, 2-0, 9-0

Function: SSIq_STATUS indicates the internal buffer state. When a bit in this register is set, its status is indicated by the corresponding interrupt signal. However, when the interrupt output is masked by the SSIq interrupt enable register, the interrupt signal is not output.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	FCST	DTST	UIRQ	OIRQ	IIRQ	DIRQ	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	uf_3	uf_2	uf_1	uf_0	of_3	of_2	of_1	of_0	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29	FCST	0	R	SSI***i***_FCST (i = 0 to 2, 9) Indicates the state of SSIFSR***i***_FCST. 0: — 1: The WS signal has stopped.
28	DTST	0	R	SSI***i***_DTST (i = 0 to 2, 9) Indicates the state of SSIFSR***i***_DTST. 0: — 1: The frequency switching has been detected.
27	UIRQ	0	R	SSI***i***_UIRQ (i = 0 to 2, 9) Indicates the state of SSISR***i***_UIRQ. 0: — 1: An underflow has occurred. Note: Not indicated by the interrupt signal when SSICR***i***.UIEN = 0.
26	OIRQ	0	R	SSI***i***_OIRQ (i = 0 to 2, 9) Indicates the state of SSISR***i***_OIRQ. 0: — 1: An overflow has occurred. Note: Not indicated by the interrupt signal when SSICR***i***.OIEN = 0.
25	IIRQ	0	R	SSI***i***_IIRQ (i = 0 to 2, 9) Indicates the state of SSISR***i***_IIRQ. 0: — 1: Idle state Note: Not indicated by the interrupt signal when SSICR***i***.IIEN = 0.

Bit	Bit Name	Initial Value	R/W	Description
24	DIRQ	0	R	SSI*i*_DIRQ (i = 0 to 2, 9) Indicates the state of SSISR*i*_DIRQ. 0: — 1: When SSICR*i*.TRMD is 0, DIRQ = 1 indicates that there are unread data in SSIRDR. When SSICR*i*.TRMD is 1, DIRQ = 1 indicates that data can be written to SSITDR. Note: Not indicated by the interrupt signal when SSICR*i*.DIEN = 0.
23 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	uf_3	0	R	buf_under_flow*i*-3 (i = 0 to 2, 9) Indicates the state of SSI_SYSTEM_STATUS2/3.uf*i*-3. 0: — 1: An underflow has occurred. Note: Not indicated by the interrupt signal when SSI_SYSTEM_INT_ENABLE2/3.uf*i*-3_ie = 0.
14	uf_2	0	R	buf_under_flow*i*-2 (i = 0 to 2, 9) Indicates the state of SSI_SYSTEM_STATUS2/3.uf*i*-2. 0: — 1: An underflow has occurred. Note: Not indicated by the interrupt signal when SSI_SYSTEM_INT_ENABLE2/3.uf*i*-2_ie = 0.
13	uf_1	0	R	buf_under_flow*i*-1 (i = 0 to 2, 9) Indicates the state of SSI_SYSTEM_STATUS2/3.uf*i*-1. 0: — 1: An underflow has occurred. Note: Not indicated by the interrupt signal when SSI_SYSTEM_INT_ENABLE2/3.uf*i*-1_ie = 0.
12	uf_0	0	R	buf_under_flow*i*-0 (i = 0 to 2, 9) Indicates the state of SSI_SYSTEM_STATUS2/3.uf*i*-0. 0: — 1: An underflow has occurred. Note: Not indicated by the interrupt signal when SSI_SYSTEM_INT_ENABLE2/3.uf*i*-0_ie = 0.
11	of_3	0	R	buf_over_flow*i*-3 (i = 0 to 2, 9) Indicates the state of SSI_SYSTEM_STATUS2/3.of*i*-3. 0: — 1: An overflow has occurred. Note: Not indicated by the interrupt signal when SSI_SYSTEM_INT_ENABLE2/3.of*i*-3_ie = 0.
10	of_2	0	R	buf_over_flow*i*-2 (i = 0 to 2, 9) Indicates the state of SSI_SYSTEM_STATUS2/3.of*i*-2. 0: — 1: An overflow has occurred. Note: Not indicated by the interrupt signal when SSI_SYSTEM_INT_ENABLE2/3.of*i*-2_ie = 0.

Bit	Bit Name	Initial Value	R/W	Description
9	of_1	0	R	buf_over_flow*i*-1 (i = 0 to 2, 9) Indicates the state of SSI_SYSTEM_STATUS2/3.of*i*-1. 0: — 1: An overflow has occurred. Note: Not indicated by the interrupt signal when SSI_SYSTEM_INT_ENABLE2/3.of*i*-1_ie = 0.
8	of_0	0	R	buf_over_flow*i*-0 (i = 0 to 2, 9) Indicates the state of SSI_SYSTEM_STATUS2/3.of*i*-0. 0: — 1: An overflow has occurred. Note: Not indicated by the interrupt signal when SSI_SYSTEM_INT_ENABLE2/3.of*i*-0_ie = 0.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

28.2.11 SSIr Status Register (SSIr_STATUS)

Note: r = 3 to 8

Function: SSIr_STATUS indicates the internal buffer state. When a bit in this register is set, its status is indicated by the corresponding interrupt signal. However, when the interrupt output is masked by the SSIr interrupt enable register, the interrupt signal is not output.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	FCST	DTST	UIRQ	OIRQ	IIRQ	DIRQ	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29	FCST	0	R	SSI***i***_FCST (i = 3 to 8) Indicates the state of SSIFSR***i***_FCST. 0: — 1: The WS signal has stopped.
28	DTST	0	R	SSI***i***_DTST (i = 3 to 8) Indicates the state of SSIFSR***i***_DTST. 0: — 1: The frequency switching has been detected.
27	UIRQ	0	R	SSI***i***_UIRQ (i = 3 to 8) Indicates the state of SSISR***i***_UIRQ. 0: — 1: An underflow has occurred. Note: Not indicated by the interrupt signal when SSICR***i***.UIEN = 0.
26	OIRQ	0	R	SSI***i***_OIRQ (i = 3 to 8) Indicates the state of SSISR***i***_OIRQ. 0: — 1: An overflow has occurred. Note: Not indicated by the interrupt signal when SSICR***i***.OIEN = 0.
25	IIRQ	0	R	SSI***i***_IIRQ (i = 3 to 8) Indicates the state of SSISR***i***_IIRQ. 0: — 1: Idle state Note: Not indicated by the interrupt signal when SSICR***i***.IIEN = 0.

Bit	Bit Name	Initial Value	R/W	Description
24	DIRQ	0	R	SSI*i*_DIRQ (i = 3 to 8) Indicates the state of SSISR*i*_DIRQ. 0: — 1: When SSICR*i*.TRMD is 0, DIRQ = 1 indicates that there are unread data in SSIRDR. When SSICR*i*.TRMD is 1, DIRQ = 1 indicates that data can be written to SSITDR. Note: Not indicated by the interrupt signal when SSICR*i*.DIEN = 0.
23 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

28.2.12 SSIq Interrupt Enable Register (SSIq_INT_ENABLE_MAIN)

Note: q = 0-0, 1-0, 2-0, or 9-0

Function: SSIq_INT_ENABLE_MAIN enables or disables output of interrupts corresponding to the states indicated in the SSIq status register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	FCST_ie	DTST_ie	UIRQ_ie	OIRQ_ie	IIRQ_ie	DIRQ_ie	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29	FCST_ie	0	R/W	SSI*i*_FCST_int_enable (i = 0 to 2,9) 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
28	DTST_ie	0	R/W	SSI*i*_DTST_int_enable (i = 0 to 2,9) 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
27	UIRQ_ie	0	R/W	SSI*i*_UIRQ_int_enable (i = 0 to 2,9) 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
26	OIRQ_ie	0	R/W	SSI*i*_OIRQ_int_enable (i = 0 to 2,9) 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
25	IIRQ_ie	0	R/W	SSI*i*_IIRQ_int_enable (i = 0 to 2,9) 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
24	DIRQ_ie	0	R/W	SSI*i*_DIRQ_int_enable (i = 0 to 2,9) 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
23 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	uf_3_ie	0	R/W	buf_under_flow*i*-3_int_enable (i = 0 to 2, 9) 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
14	uf_2_ie	0	R/W	buf_under_flow*i*-2_int_enable (i = 0 to 2, 9) 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

Bit	Bit Name	Initial Value	R/W	Description
13	uf_1_ie	0	R/W	buf_under_flow*i*-1_int_enable (i = 0 to 2, 9) 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
12	uf_0_ie	0	R/W	buf_under_flow*i*-0_int_enable (i = 0 to 2, 9) 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
11	of_3_ie	0	R/W	buf_over_flow*i*-3_int_enable (i = 0 to 2, 9) 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
10	of_2_ie	0	R/W	buf_over_flow*i*-2_int_enable (i = 0 to 2, 9) 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
9	of_1_ie	0	R/W	buf_ over_flow*i*-1_int_enable (i = 0 to 2, 9) 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
8	of_0_ie	0	R/W	buf_over_flow*i*-0_int_enable (i = 0 to 2, 9) 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

28.2.13 SSIr Interrupt Enable Register (SSIr_INT_ENABLE_MAIN)

Note: r = 3 to 8

Function: SSIr_INT_ENABLE_MAIN enables or disables output of interrupts corresponding to the states indicated in the SSIr status register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

23 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	—	—	R	Reserved The read value is undefined. The write value should always be 0.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

28.2.14 SSI Mode Register 0 (SSI_MODE0)

Function: SSI_MODE0 specifies the independent SSI transfer.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	ind_word_swap9	ind_word_swap8	ind_word_swap7	ind_word_swap6	ind_word_swap5	ind_word_swap4	ind_word_swap3	ind_word_swap2	ind_word_swap1	ind_word_swap0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	ind9	ind8	ind7	ind6	ind5	ind4	ind3	ind2	ind1	ind0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25	ind_word_swap9	0	R/W	ind_word_swap_en9 Swaps the word order (only for access to SSITDR or SSIRDR). 0: Word order is not swapped. 1: Word order is swapped. Note: Select this function only when the data length is 16 bits.
24	ind_word_swap8	0	R/W	ind_word_swap_en8 Swaps the word order (only for access to SSITDR or SSIRDR). 0: Word order is not swapped. 1: Word order is swapped. Note: Select this function only when the data length is 16 bits.
23	ind_word_swap7	0	R/W	ind_word_swap_en7 Swaps the word order (only for access to SSITDR or SSIRDR). 0: Word order is not swapped. 1: Word order is swapped. Note: Select this function only when the data length is 16 bits.
22	ind_word_swap6	0	R/W	ind_word_swap_en6 Swaps the word order (only for access to SSITDR or SSIRDR). 0: Word order is not swapped. 1: Word order is swapped. Note: Select this function only when the data length is 16 bits.
21	ind_word_swap5	0	R/W	ind_word_swap_en5 Swaps the word order (only for access to SSITDR or SSIRDR). 0: Word order is not swapped. 1: Word order is swapped. Note: Select this function only when the data length is 16 bits.
20	ind_word_swap4	0	R/W	ind_word_swap_en4 Swaps the word order (only for access to SSITDR or SSIRDR). 0: Word order is not swapped. 1: Word order is swapped. Note: Select this function only when the data length is 16 bits.

Bit	Bit Name	Initial Value	R/W	Description
19	ind_word_swap3	0	R/W	ind_word_swap_en3 Swaps the word order (only for access to SSITDR or SSIRDR). 0: Word order is not swapped. 1: Word order is swapped. Note: Select this function only when the data length is 16 bits.
18	ind_word_swap2	0	R/W	ind_word_swap_en2 Swaps the word order (only for access to SSITDR or SSIRDR). 0: Word order is not swapped. 1: Word order is swapped. Note: Select this function only when the data length is 16 bits.
17	ind_word_swap1	0	R/W	ind_word_swap_en1 Swaps the word order (only for access to SSITDR or SSIRDR). 0: Word order is not swapped. 1: Word order is swapped. Note: Select this function only when the data length is 16 bits.
16	ind_word_swap0	0	R/W	ind_word_swap_en0 Swaps the word order (only for access to SSITDR or SSIRDR). 0: Word order is not swapped. 1: Word order is swapped. Note: Select this function only when the data length is 16 bits.
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	ind9	0	R/W	Independent SSI9 transfer setting 0: Independent SSI9 transfer is not performed. 1: Independent SSI9 transfer is performed.
8	ind8	0	R/W	Independent SSI8 transfer setting 0: Independent SSI8 transfer is not performed. 1: Independent SSI8 transfer is performed.
7	ind7	0	R/W	Independent SSI7 transfer setting 0: Independent SSI7 transfer is not performed. 1: Independent SSI7 transfer is performed.
6	ind6	0	R/W	Independent SSI6 transfer setting 0: Independent SSI6 transfer is not performed. 1: Independent SSI6 transfer is performed.
5	ind5	0	R/W	Independent SSI5 transfer setting 0: Independent SSI5 transfer is not performed. 1: Independent SSI5 transfer is performed.
4	ind4	0	R/W	Independent SSI transfer setting 0: Independent SSI transfer is not performed. 1: Independent SSI transfer is performed. These bits correspond to the SSI modules as follows. SSI3 = ssi_ind3 SSI4 = ssi_ind4
3	ind3	0	R/W	
2	ind2	0	R/W	Independent SSI2 transfer setting 0: Independent SSI2 transfer is not performed. 1: Independent SSI2 transfer is performed.

Bit	Bit Name	Initial Value	R/W	Description
1	ind1	0	R/W	Independent SSI1 transfer setting 0: Independent SSI1 transfer is not performed. 1: Independent SSI1 transfer is performed.
0	ind0	0	R/W	Independent SSI0 transfer setting 0: Independent SSI0 transfer is not performed. 1: Independent SSI0 transfer is performed.

28.2.15 SSI Mode Register 1 (SSI_MODE1)

Function: SSI_MODE1 specifies the SSI pin modes.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	ssi34_sync	—	—	ssi4_pin	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	ssi012_3mod	ssi2_pin		ssi1_pin	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	ssi34_sync	0	R/W	ssi34_sync_mode Selects whether to synchronize SSI3 and SSI4. 0: SSI3 and SSI4 are not synchronized. 1: SSI3 and SSI4 are synchronized. This bit can be set to 1 only when the ssi4_pin_mode bits are set to 01 or 10.
19, 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17, 16	ssi4_pin	00	R/W	ssi4_pin_mode Select the connections of the SSI_SCK4 and SSI_WS4 pins. 00: SSI3 and SSI4 use their own pins independently. 01: The SSI3 pins are used in common by SSI3 and SSI4. Both modules work as slaves. The SSI_WS and SSI_SCK pins of SSI3 are used. 10: The SSI3 pins are used in common by SSI3 and SSI4. SSI3 works as the master and SSI4 works as a slave. The SSI_WS and SSI_SCK pins of SSI3 are used. 11: Setting prohibited
15 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	ssi012_3mod	0	R/W	ssi012_3module_mode Selects whether to use three modules (SSI0, SSI1, and SSI2) together as six channels. 0: SSI0, SSI1, and SSI2 are not used as six channels. 1: SSI0, SSI1, and SSI2 are used as six channels. This bit should be cleared to 0 when the ssi1_pin_mode or ssi2_pin_mode bits are set to 00. It can be set to 1 only when the ssi1_pin_mode and ssi2_pin_mode bits are set to 01 or when the ssi1_pin_mode and ssi2_pin_mode bits are set to 10. Either ssi012_3module_mode or ssi0129_4module_mode must be set to 1.

Bit	Bit Name	Initial Value	R/W	Description
3, 2	ssi2_pin	00	R/W	ssi2_pin_mode Select the connections of the SSI_SCK2 and SSI_WS2 pins. 00: SSI0 and SSI2 use their own pins independently. 01: The SSI0 pins are used in common by SSI0 and SSI2. Both modules work as slaves. The SSI_WS and SSI_SCK pins of SSI0 are used. 10: The SSI0 pins are used in common by SSI0 and SSI2. SSI0 works as the master and SSI2 works as a slave. The SSI_WS and SSI_SCK pins of SSI0 are used. 11: Setting prohibited
1, 0	ssi1_pin	00	R/W	ssi1_pin_mode Select the connections of the SSI_SCK1 and SSI_WS1 pins. 00: SSI0 and SSI1 use their own pins independently. 01: The SSI0 pins are used in common by SSI0 and SSI1. Both modules work as slaves. The SSI_WS and SSI_SCK pins of SSI0 are used. 10: The SSI0 pins are used in common by SSI0 and SSI1. SSI0 works as the master and SSI1 works as a slave. The SSI_WS and SSI_SCK pins of SSI0 are used. 11: Setting prohibited

28.2.16 SSI Mode Register 2 (SSI_MODE2)

Function: SSI_MODE2 specifies the SSI pin modes.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	ssi0129_4mod	—	ssi9_pin		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	ssi0129_4mod	0	R/W	ssi0129_4module_mode Selects whether to use four modules (SSI0, SSI1, SSI2, and SSI9) together as eight channels. 0: SSI0, SSI1, SSI2, and SSI9 are not used as eight channels. 1: SSI0, SSI1, SSI2, and SSI9 are used as eight channels. This bit should be cleared to 0 when the ssi1_pin_mode or ssi2_pin_mode bits are set to 00, or when ssi9_pin_mode bits are set to 000. It can be set to 1 only when the ssi1_pin_mode and ssi2_pin_mode bits are set to 01 and the ssi9_pin_mode bits are set to 001, or when the ssi1_pin_mode and ssi2_pin_mode bits are set to 10 and the ssi9_pin_mode bits are set to 010. Either ssi0129_4module_mode or ssi012_3module_mode must be set to 1.
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
2 to 0	ssi9_pin	000	R/W	ssi9_pin_mode Selects the connections of the SSI_SCK9 and SSI_WS9 pins. 000: SSI0 and SSI9 use their own pins independently. 001: The SSI0 pins are used in common by SSI0 and SSI9. Both modules work as slaves. The SSI_WS and SSI_SCK pins of SSI0 are used. 010: The SSI0 pins are used in common by SSI0 and SSI9. SSI0 works as the master and SSI9 works as a slave. The SSI_WS and SSI_SCK pins of SSI0 are used. 011: Setting prohibited 100: Setting prohibited 101: The SSI3 pins are used in common by SSI3 and SSI9. Both modules work as slaves. The SSI_WS and SSI_SCK pins of SSI3 are used. 110: The SSI3 pins are used in common by SSI3 and SSI9. SSI3 works as the master and SSI9 works as a slave. The SSI_WS and SSI_SCK pins of SSI3 are used. 111: Setting prohibited

28.2.17 SSI Mode Register 3 (SSI_MODE3)

Function: SSI_MODE3 specifies the SSI pin modes.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ssi3_pin	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	ssi3_pin	00	R/W	ssi3_pin_mode Select the connections of the SSI_SCK3 and SSI_WS3 pins. 00: SSI0 and SSI3 use their own pins independently. 01: The SSI0 pins are used in common by SSI0 and SSI3. Both modules work as slaves. The SSI_WS and SSI_SCK pins of SSI0 are used. 10: The SSI0 pins are used in common by SSI0 and SSI3. SSI0 works as the master and SSI3 works as a slave. The SSI_WS and SSI_SCK pins of SSI0 are used. 11: Setting prohibited When setting these bits to use the pins in common by SSI0 and SSI3, ssi4_pin_mode should be 00 and ssi9_pin_mode should be 000, 001, or 010 (selection of the SSI3 pins is prohibited).

28.2.18 SSI Control Register (SSI_CONTROL)

Function: SSI_CONTROL controls the startup of the SSI modules when multiple SSI modules are used at the same time.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	ssi34	—	—	—	ssi0129
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	ssi34	0	R/W	ssi34_enable Starts or stops data transfer through two SSI modules (SSI3 and SSI4) at the same time. 0: Transfer through SSI3 and SSI4 is stopped. 1: Transfer through SSI3 and SSI4 is started.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	ssi0129	0	R/W	ssi0129_enable • When ssi012_3module_mode is 1 Starts or stops data transfer through three SSI modules (SSI0, SSI1, and SSI2) at the same time. 0: Transfer through SSI0, SSI1, and SSI2 is stopped. 1: Transfer through SSI0, SSI1, and SSI2 is started. • When ssi0129_4module_mode is 1 Starts or stops data transfer through four SSI modules (SSI0, SSI1, SSI2, and SSI9) at the same time. 0: Transfer through SSI0, SSI1, SSI2, and SSI9 is stopped. 1: Transfer through SSI0, SSI1, SSI2, and SSI9 is started.

Note: This function should be used only when data is transferred through multiple SSI modules in synchronization. When using each SSI module independently, use the EN bit of SSICRn (n = 0 to 4 and 9) for the SSI module to control the transfer.

28.2.19 SSI SYSTEM Status Register 0 (SSI_SYSTEM_STATUS0)

Function: SSI_SYSTEM_STATUS0 indicates the internal buffer state. When a bit in this register is set, its status is indicated by the corresponding interrupt signal. However, when the interrupt output is masked by the SSI_SYSTEM interrupt enable register 0, the interrupt signal is not output.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	of2-3	of2-2	of2-1	of2-0	of1-3	of1-2	of1-1	of1-0	of0-3	of0-2	of0-1	of0-0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	of2-3	0	R/WC1	buf_over_flow2-3 Indicates the state of the SSI2-3_BUSIF buffer. 0: Normal operation 1: An overflow has occurred.
10	of2-2	0	R/WC1	buf_over_flow2-2 Indicates the state of the SSI2-2_BUSIF buffer. 0: Normal operation 1: An overflow has occurred.
9	of2-1	0	R/WC1	buf_over_flow2-1 Indicates the state of the SSI2-1_BUSIF buffer. 0: Normal operation 1: An overflow has occurred.
8	of2-0	0	R/WC1	buf_over_flow2-0 Indicates the state of the SSI2-0_BUSIF buffer. 0: Normal operation 1: An overflow has occurred.
7	of1-3	0	R/WC1	buf_over_flow1-3 Indicates the state of the SSI1-3_BUSIF buffer. 0: Normal operation 1: An overflow has occurred.
6	of1-2	0	R/WC1	buf_over_flow1-2 Indicates the state of the SSI1-2_BUSIF buffer. 0: Normal operation 1: An overflow has occurred.
5	of1-1	0	R/WC1	buf_over_flow1-1 Indicates the state of the SSI1-1_BUSIF buffer. 0: Normal operation 1: An overflow has occurred.

Bit	Bit Name	Initial Value	R/W	Description
4	of1-0	0	R/WC1	buf_over_flow1-0 Indicates the state of the SSI1-0_BUSIF buffer. 0: Normal operation 1: An overflow has occurred.
3	of0-3	0	R/WC1	buf_over_flow0-3 Indicates the state of the SSI0-3_BUSIF buffer. 0: Normal operation 1: An overflow has occurred.
2	of0-2	0	R/WC1	buf_over_flow0-2 Indicates the state of the SSI0-2_BUSIF buffer. 0: Normal operation 1: An overflow has occurred.
1	of0-1	0	R/WC1	buf_over_flow0-1 Indicates the state of the SSI0-1_BUSIF buffer. 0: Normal operation 1: An overflow has occurred.
0	of0-0	0	R/WC1	buf_over_flow0-0 Indicates the state of the SSI0-0_BUSIF buffer. 0: Normal operation 1: An overflow has occurred.

28.2.20 SSI SYSTEM Status Register 1 (SSI_SYSTEM_STATUS1)

Function: SSI_SYSTEM_STATUS1 indicates the internal buffer state. When a bit in this register is set, its status is indicated by the corresponding interrupt signal. However, when the interrupt output is masked by the SSI_SYSTEM interrupt enable register 1, the interrupt signal is not output.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	of9-3	of9-2	of9-1	of9-0	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/WC1	R/WC1	R/WC1	R/WC1	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	of9-3	0	R/WC1	buf_over_flow9-3 Indicates the state of the SSI9-3_BUSIF buffer. 0: Normal operation 1: An overflow has occurred.
6	of9-2	0	R/WC1	buf_over_flow9-2 Indicates the state of the SSI9-2_BUSIF buffer. 0: Normal operation 1: An overflow has occurred.
5	of9-1	0	R/WC1	buf_over_flow9-1 Indicates the state of the SSI9-1_BUSIF buffer. 0: Normal operation 1: An overflow has occurred.
4	of9-0	0	R/WC1	buf_over_flow9-0 Indicates the state of the SSI9-0_BUSIF buffer. 0: Normal operation 1: An overflow has occurred.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

28.2.21 SSI SYSTEM Status Register 2 (SSI_SYSTEM_STATUS2)

Function: SSI_SYSTEM_STATUS2 indicates the internal buffer state. When a bit in this register is set, its status is indicated by the corresponding interrupt signal. However, when the interrupt output is masked by the SSI_SYSTEM interrupt enable register 2, the interrupt signal is not output.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	uf2-3	uf2-2	uf2-1	uf2-0	uf1-3	uf1-2	uf1-1	uf1-0	uf0-3	uf0-2	uf0-1	uf0-0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	uf2-3	0	R/WC1	buf_under_flow2-3 Indicates the state of the SSI2-3_BUSIF buffer. 0: Normal operation 1: An underflow has occurred.
10	uf2-2	0	R/WC1	buf_under_flow2-2 Indicates the state of the SSI2-2_BUSIF buffer. 0: Normal operation 1: An underflow has occurred.
9	uf2-1	0	R/WC1	buf_under_flow2-1 Indicates the state of the SSI2-1_BUSIF buffer. 0: Normal operation 1: An underflow has occurred.
8	uf2-0	0	R/WC1	buf_under_flow2-0 Indicates the state of the SSI2-0_BUSIF buffer. 0: Normal operation 1: An underflow has occurred.
7	uf1-3	0	R/WC1	buf_under_flow1-3 Indicates the state of the SSI1-3_BUSIF buffer. 0: Normal operation 1: An underflow has occurred.
6	uf1-2	0	R/WC1	buf_under_flow1-2 Indicates the state of the SSI1-2_BUSIF buffer. 0: Normal operation 1: An underflow has occurred.
5	uf1-1	0	R/WC1	buf_under_flow1-1 Indicates the state of the SSI1-1_BUSIF buffer. 0: Normal operation 1: An underflow has occurred.

Bit	Bit Name	Initial Value	R/W	Description
4	uf1-0	0	R/WC1	buf_under_flow1-0 Indicates the state of the SSI1-0_BUSIF buffer. 0: Normal operation 1: An underflow has occurred.
3	uf0-3	0	R/WC1	buf_under_flow0-3 Indicates the state of the SSI0-3_BUSIF buffer. 0: Normal operation 1: An underflow has occurred.
2	uf0-2	0	R/WC1	buf_under_flow0-2 Indicates the state of the SSI0-2_BUSIF buffer. 0: Normal operation 1: An underflow has occurred.
1	uf0-1	0	R/WC1	buf_under_flow0-1 Indicates the state of the SSI0-1_BUSIF buffer. 0: Normal operation 1: An underflow has occurred.
0	uf0-0	0	R/WC1	buf_under_flow0-0 Indicates the state of the SSI0-0_BUSIF buffer. 0: Normal operation 1: An underflow has occurred.

28.2.22 SSI SYSTEM Status Register 3 (SSI_SYSTEM_STATUS3)

Function: SSI_SYSTEM_STATUS3 indicates the internal buffer state. When a bit in this register is set, its status is indicated by the corresponding interrupt signal. However, when the interrupt output is masked by the SSI_SYSTEM interrupt enable register 3, the interrupt signal is not output.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/WC1	R/WC1	R/WC1	R/WC1	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	uf9-3	0	R/WC1	buf_under_flow9-3 Indicates the state of the SSI9-3_BUSIF buffer. 0: Normal operation 1: An underflow has occurred.
6	uf9-2	0	R/WC1	buf_under_flow9-2 Indicates the state of the SSI9-2_BUSIF buffer. 0: Normal operation 1: An underflow has occurred.
5	uf9-1	0	R/WC1	buf_under_flow9-1 Indicates the state of the SSI9-1_BUSIF buffer. 0: Normal operation 1: An underflow has occurred.
4	uf9-0	0	R/WC1	buf_under_flow9-0 Indicates the state of the SSI9-0_BUSIF buffer. 0: Normal operation 1: An underflow has occurred.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

28.2.23 SSI SYSTEM Interrupt Enable Register 0 (SSI_SYSTEM_INT_ENABLE0)

Function: SSI_SYSTEM_INT_ENABLE0 enables or disables output of interrupts corresponding to the states indicated in the SSI SYSTEM status register 0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	uf2-3_ie	0	R/W	buf_under_flow2-3_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
10	uf2-2_ie	0	R/W	buf_under_flow2-2_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
9	uf2-1_ie	0	R/W	buf_under_flow2-1_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
8	uf2-0_ie	0	R/W	buf_under_flow2-0_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
7	uf1-3_ie	0	R/W	buf_under_flow1-3_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
6	uf1-2_ie	0	R/W	buf_under_flow1-2_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
5	uf1-1_ie	0	R/W	buf_under_flow1-1_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
4	uf1-0_ie	0	R/W	buf_under_flow1-0_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
3	uf0-3_ie	0	R/W	buf_under_flow0-3_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
2	uf0-2_ie	0	R/W	buf_under_flow0-2_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

Bit	Bit Name	Initial Value	R/W	Description
1	uf0-1_ie	0	R/W	buf_under_flow0-1_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
0	uf0-0_ie	0	R/W	buf_under_flow0-0_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

28.2.26 SSI SYSTEM Interrupt Enable Register 3 (SSI_SYSTEM_INT_ENABLE3)

Function: SSI_SYSTEM_INT_ENABLE3 enables or disables output of interrupts corresponding to the states indicated in the SSI SYSTEM status register 3.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

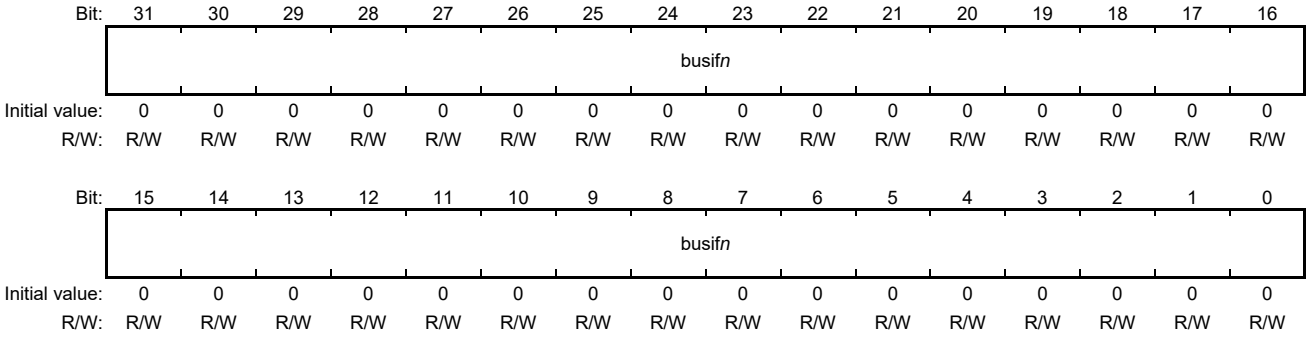
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	uf9-3_ie	uf9-2_ie	uf9-1_ie	uf9-0_ie	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	uf9-3_ie	0	R/W	buf_under_flow9-3_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
6	uf9-2_ie	0	R/W	buf_under_flow9-2_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
5	uf9-1_ie	0	R/W	buf_under_flow9-1_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
4	uf9-0_ie	0	R/W	buf_under_flow9-0_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

28.2.27 SSIn_BUSIF Data Registers (SSIn_BUSIF)

Note: n = 0-0 to 0-3, 1-0 to 1-3, 2-0 to 2-3, 3 to 8, or 9-0 to 9-3

Function: SSIn_BUSIF is a window register in which data is stored during data transfer via SSIn_BUSIF. These registers are used for both transmission and reception.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	busif***n***	H'00000000	R/W	These bits are used to hold the data during data transfer via SSIn_BUSIFn. This register is used for both transmission and reception. This register can only be written to during transmission and only be read from during reception.

28.3 Operation

28.3.1 Module Specifications

Table 28.3 shows the correspondences between the modules and functions.

Table 28.3 Function Correspondences

			Format		
		External Interface	**Basic Configuration**	**TDM Extend Mode**	**TDM Split Mode**
1	SSI0 SSI1 SSI2 SSI9	I2S	Supported	Not supported	Not supported
2	SSI0 SSI1 SSI2 SSI9	TDM	Supported	Supported	Supported
3	SSI0 SSI1 SSI2	I2S × 3 (multichannel)	Supported	Not supported	Not supported
4	SSI0 SSI1 SSI2 SSI9	I2S × 4 (multichannel)	Supported	Not supported	Not supported
5	SSI3 SSI4	I2S	Supported	Not supported	Not supported
6	SSI3 SSI4	TDM	Supported	Supported	Not supported
7	SSI5 SSI6 SSI7 SSI8	I2S	Supported	Not supported	Not supported
8	SSI5 SSI6 SSI7 SSI8	TDM	Not supported	Not supported	Not supported

28.3.2 Basic Configuration

Data transfer is performed between the SSIU and other audio modules or external memories via BUSIF connected to the audio local bus and the audio DMA bus. Figure 28.3 shows the data transfer of SSI0. As shown in Figure 28.3, SSI0_1_BUSIF, SSI0_2_BUSIF, and SSI0_3_BUSIF are not used. This basic configuration is also applied to SSI1, SSI2, and SSI9. Figure 28.4 shows the data transfer of SSI3, which is also applied to SSI4 to SSI8.

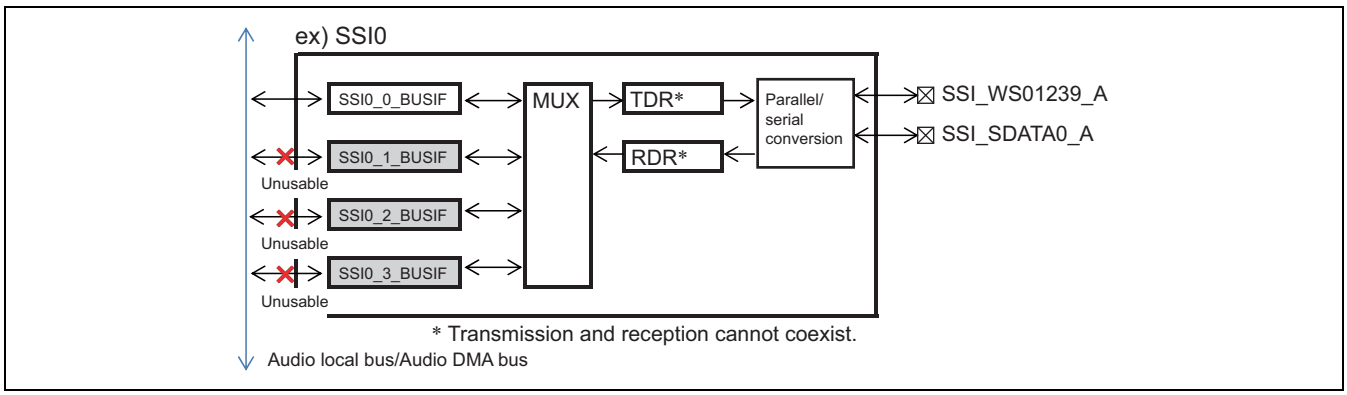


Figure 28.3 Basic Configuration (SSI0)

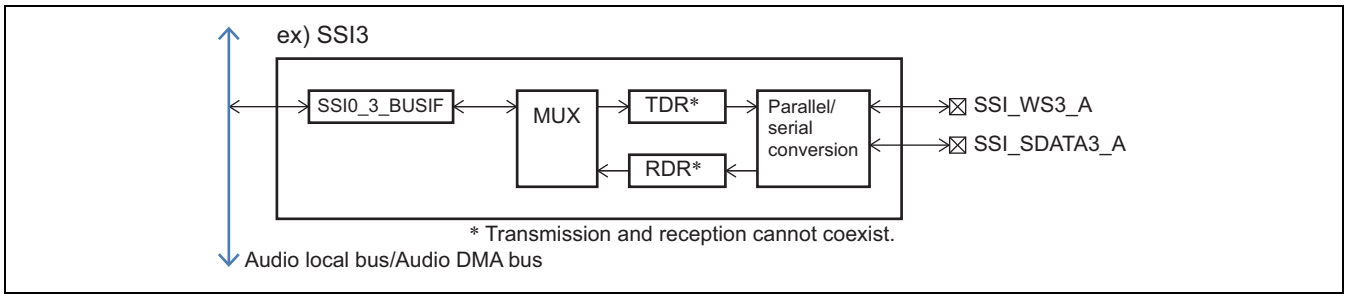

Figure 28.4 Basic Configuration (SSI3)

28.3.3 Configuration with Multiple SSI Modules

Multichannel data transfer can be performed by using multiple SSI modules. The available combination of modules is SSI0, SSI1, and SSI2 or SSI0, SSI1, SSI2, and SSI9.

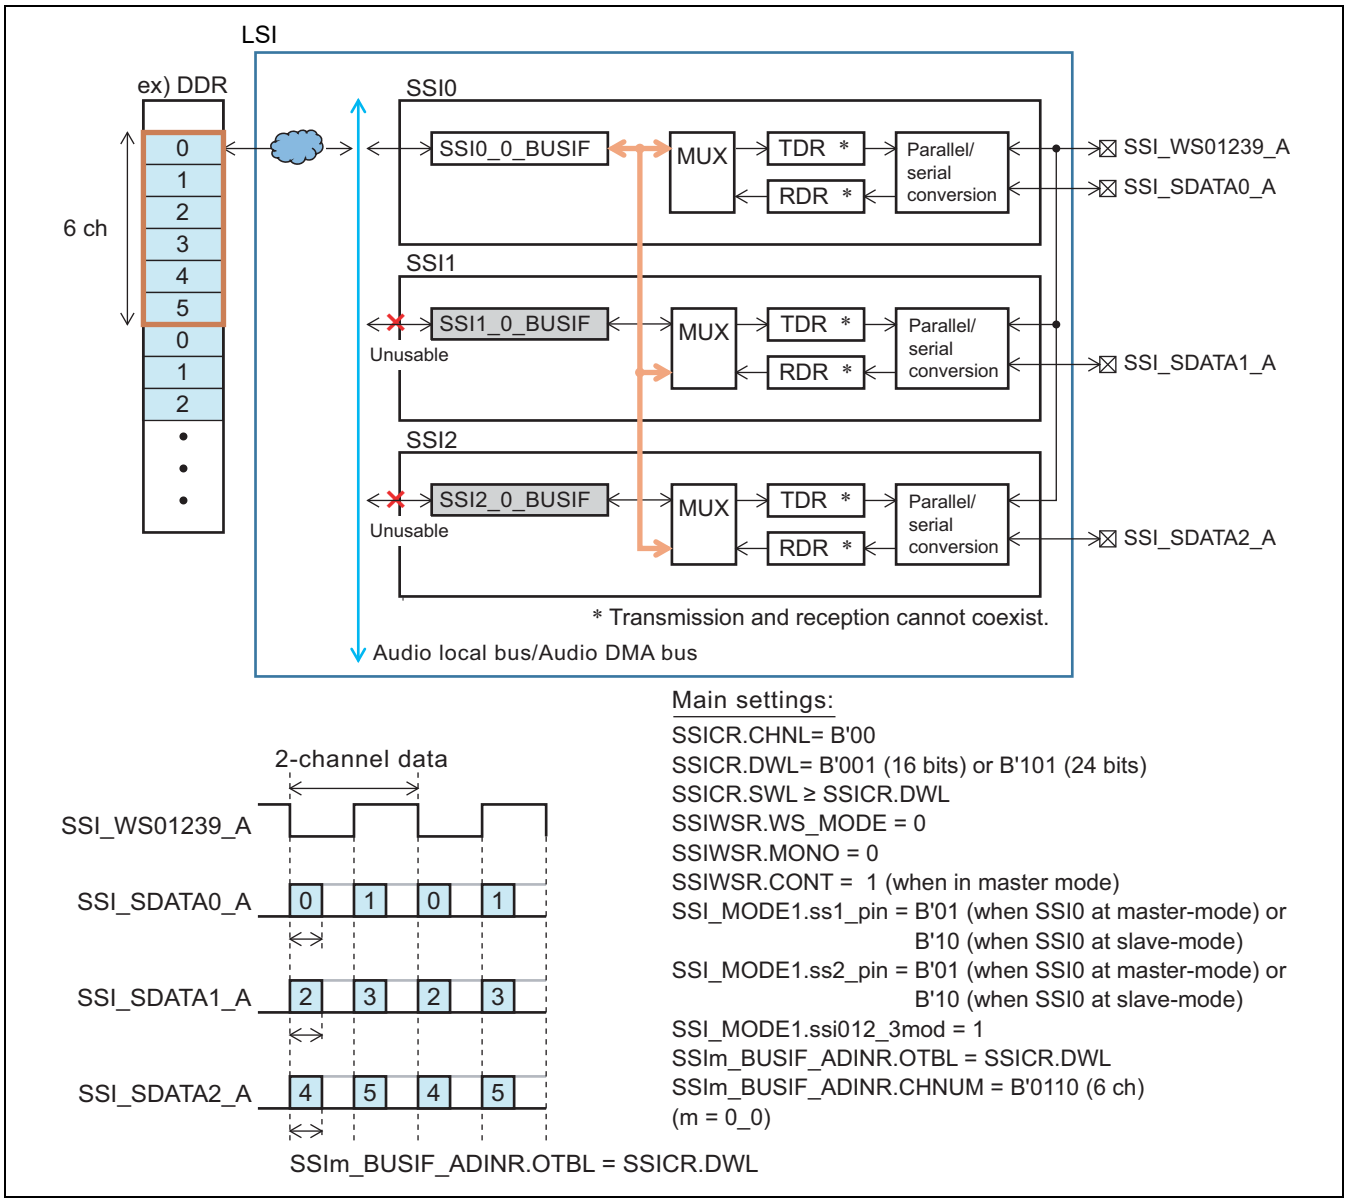

Figure 28.5 Multichannel Data Transfer (Using SSI0, SSI1 and SSI2)

Note: When the above configuration is used, SSI0_1_BUSIF, SSI0_2_BUSIF, SSI0_3_BUSIF, all the BUSIFs of SSI1and SSI2 cannot be used.

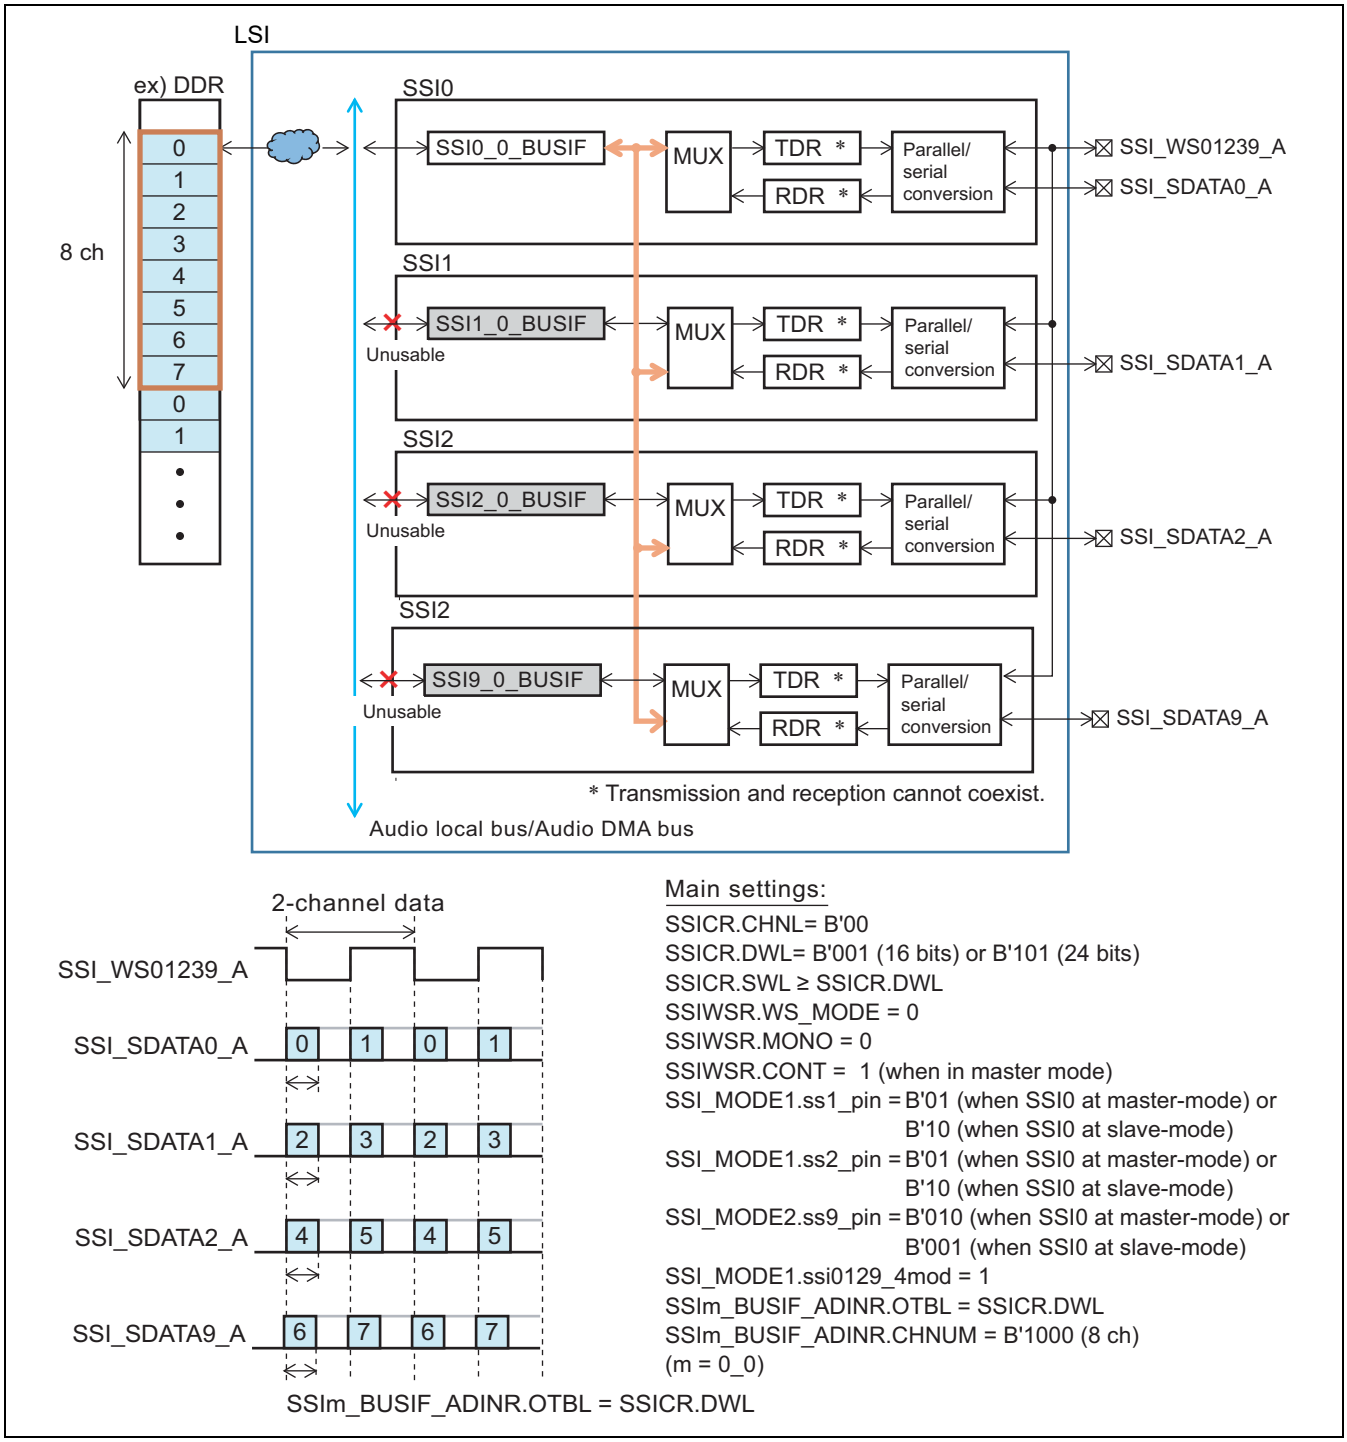

Figure 28.6 Multichannel Data Transfer (Using SSI0, SSI1, SSI2 and SSI9)

Note: When the above configuration is used, SSI0_1_BUSIF, SSI0_2_BUSIF, SSI0_3_BUSIF, all the BUSIFs of SSI1, SSI2, and SSI9 cannot be used.

28.3.4 TDM Format Extension Function (TDM Extend Mode)

The TDM format extension function allows operation with 8-channel data in the serial bus and 6-channel data inside the RZ/G1C, or operation with 6-channel data in the serial bus and 8-channel data inside the RZ/G1C. This function is supported by SSI0, SSI1, SSI2, SSI3, SSI4, and SSI9.

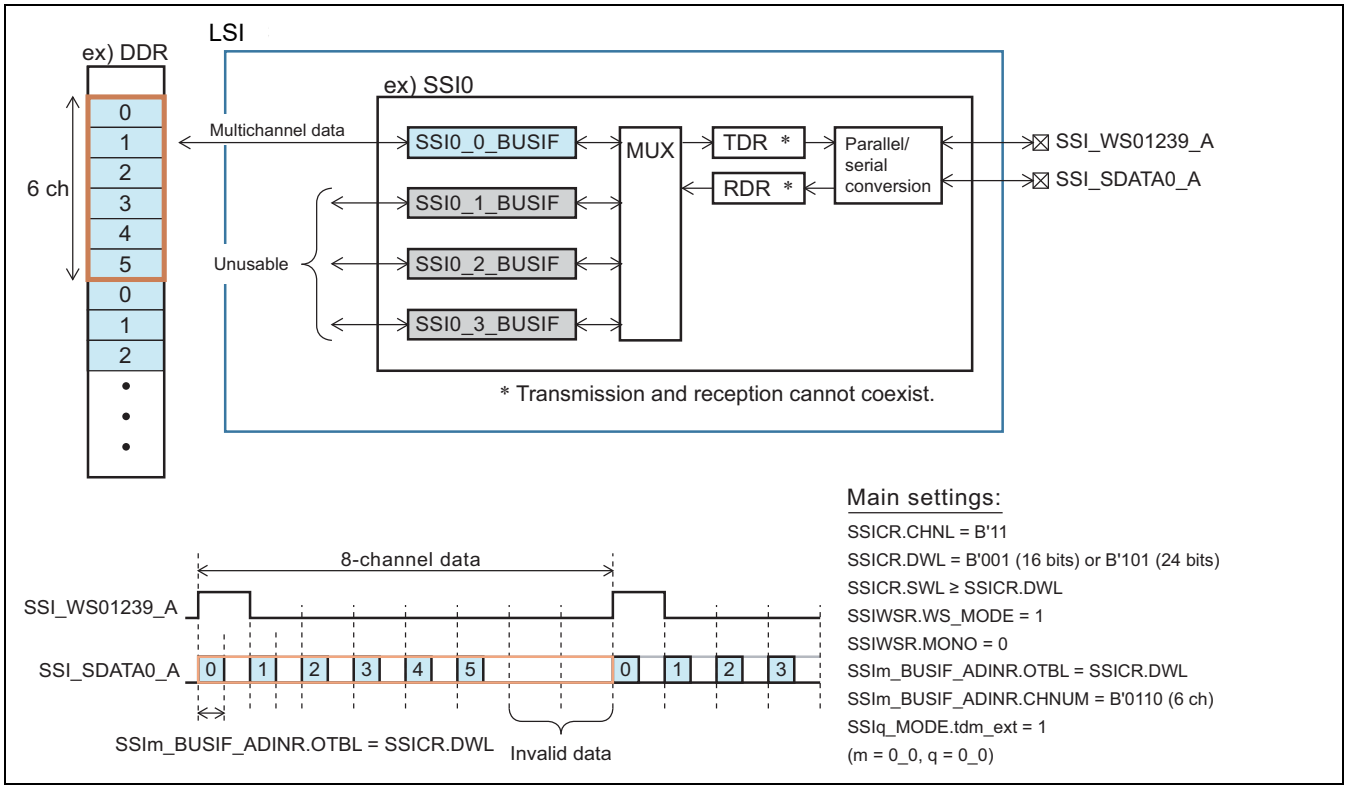

Figure 28.7 TDM Extend Mode Operation with 8-channel Data in Serial Bus and 6-channel Data Inside the RZ/G1C (SSI0)

Note: When the above configuration is used, SSI0_1_BUSIF, SSI0_2_BUSIF, and SSI0_3_BUSIF cannot be used.

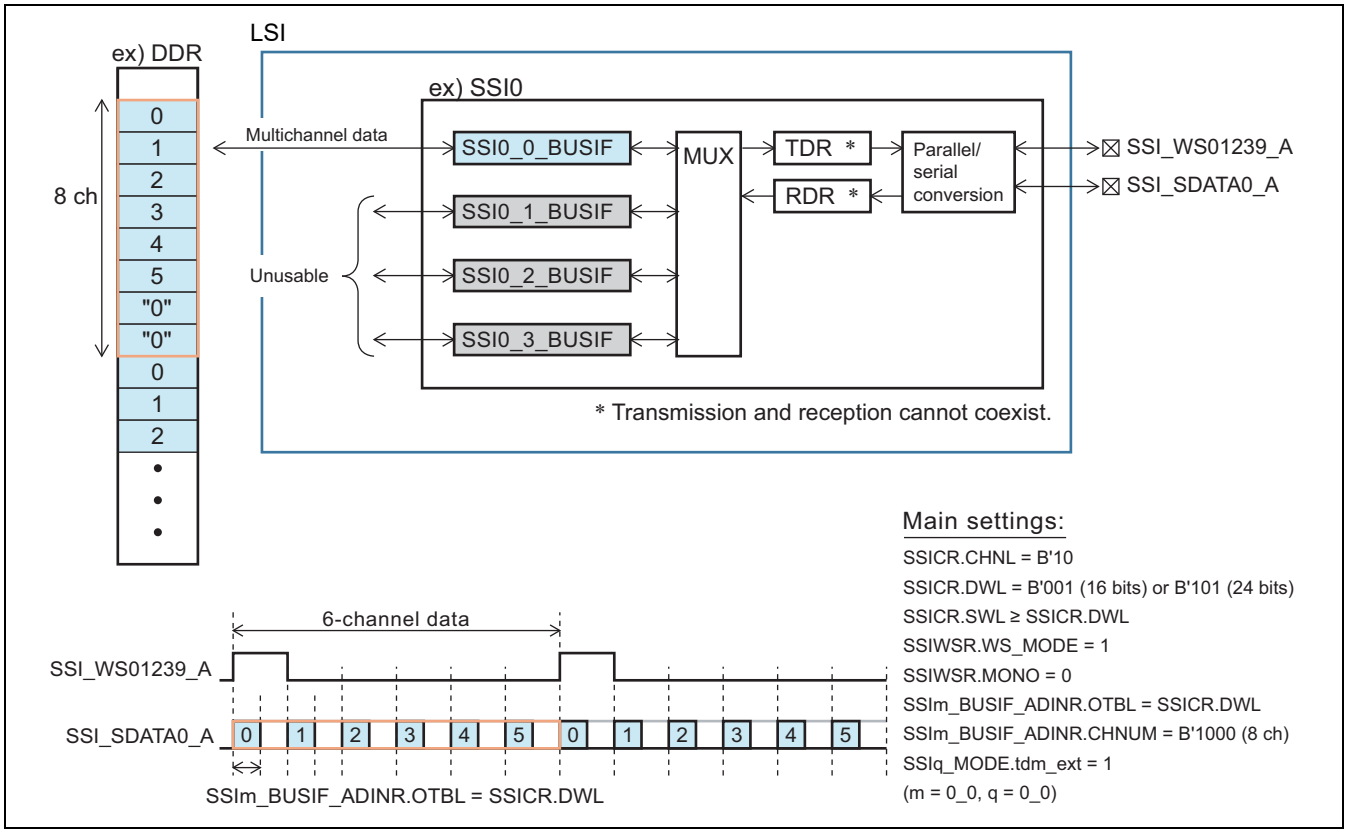

Figure 28.8 TDM Extend Mode Operation with 6-channel Data in Serial Bus and 8-channel Data Inside the RZ/G1C (SSI0)

Note: When the above configuration is used, SSI0_1_BUSIF, SSI0_2_BUSIF, and SSI0_3_BUSIF cannot be used.

28.3.5 TDM Format Split Function (TDM Split Mode)

The TDM format split function (TDM split mode) allows connecting four independent monaural or stereo data inside the RZ/G1C and outputting the data in the TDM format, and splitting TDM format input data into four independent monaural or stereo data and distributing the data inside the RZ/G1C. This function is supported by SSI0, SSI1, SSI2, and SSI9.

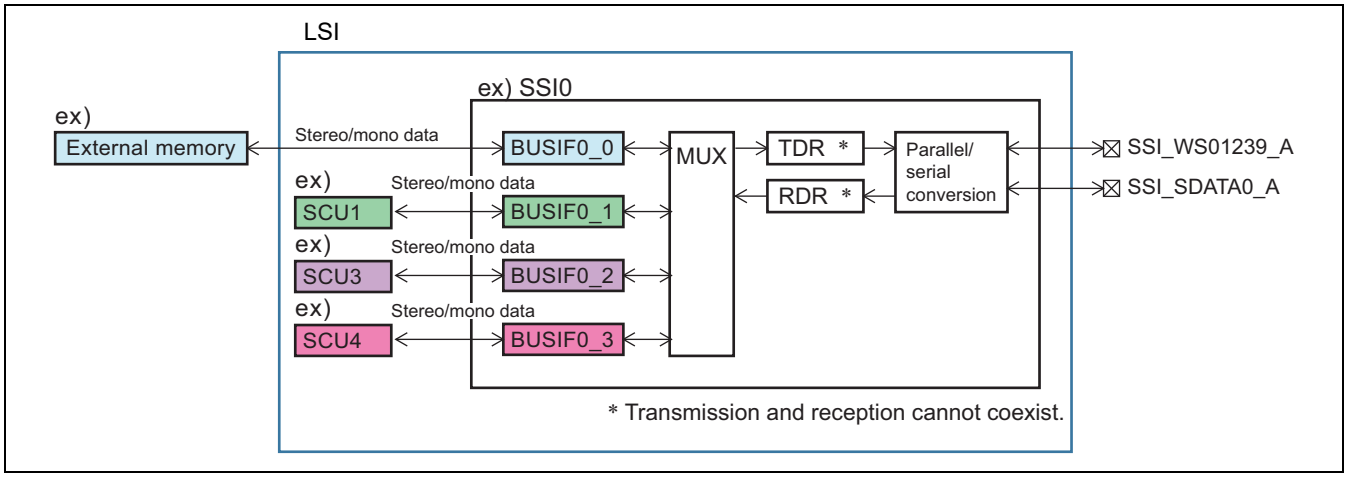

Figure 28.9 TDM Split Mode

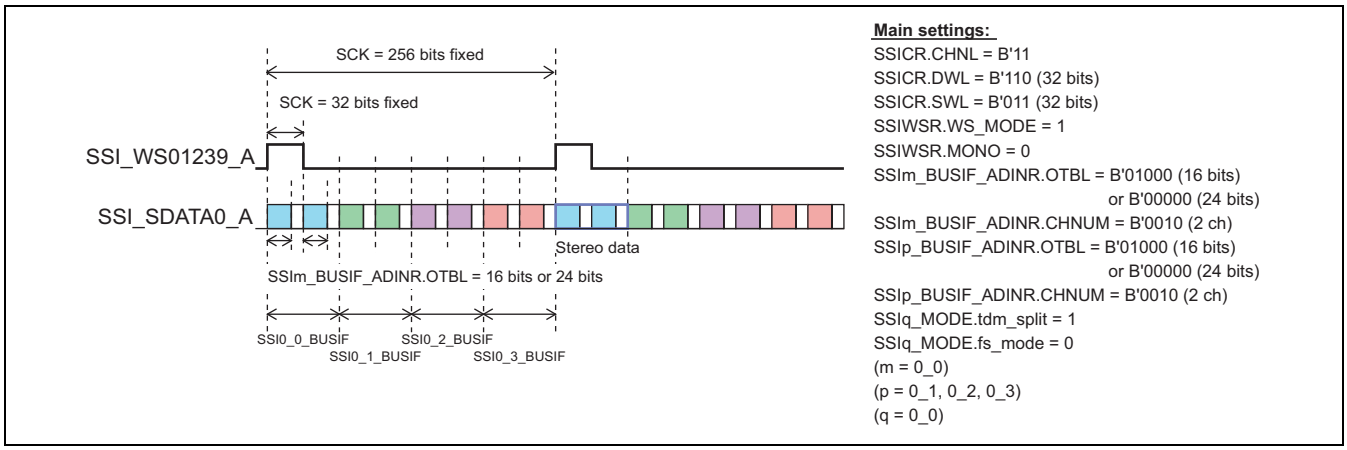

Figure 28.10 TDM Split Mode (Stereo × 4)

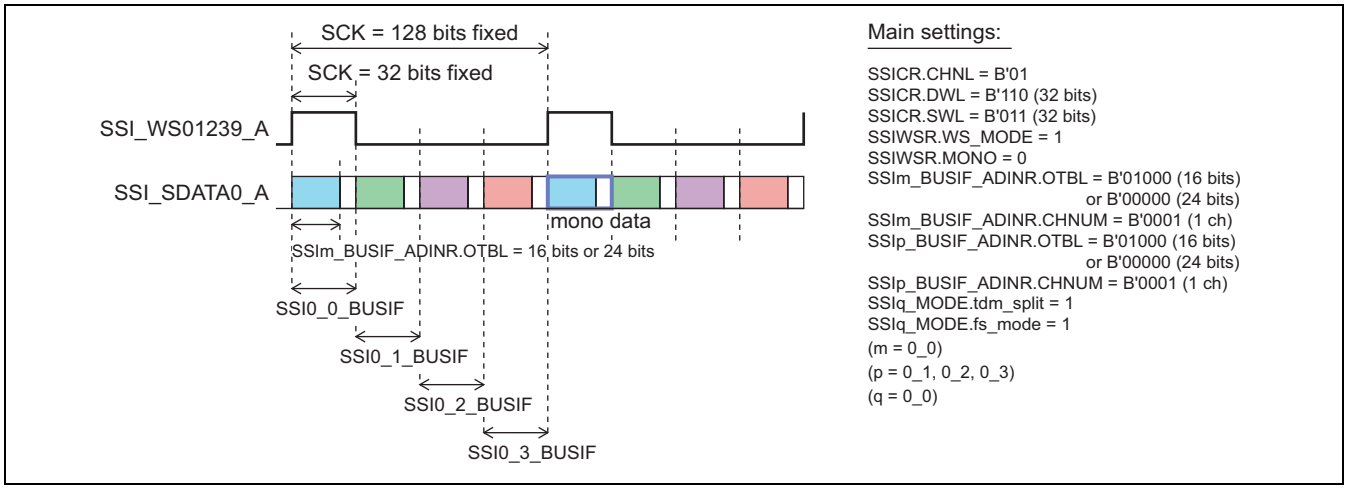

Figure 28.11 TDM Split Mode (Monaural × 4)

Notes: 1. The SWL and DWL bits in SSICR should be fixed at 32-bit setting.
2. Transmission and reception cannot coexist.
3. Data input to BUSIFn 0 to 3 (n = 0, 1, 2, 9) should be operated synchronously with the SSI sampling frequency (WS signal cycle).

28.3.6 SSI Pin Connections

Multiple SSI modules (in combinations of SSI0, SSI1, SSI2, SSI3, and SSI9, SSI3, SSI4, and SSI9, and SSI7 and SSI8) can operate in synchronization with sharing of the same SSI_SCK and SSI_WS signals. Figures 28.12 to 28.17 show how to connect the pins for each combination of SSIs.

In the case of the combination of SSI0, SSI1, SSI2, SSI3, and SSI9, SSI0 as the master should start transfer first thus allowing output on SSI_WS01239_A and SSI_SCK01239_A, after which SSI1, SSI2, SSI3, and SSI9 as the slaves should be used. If the master-side transfer is stopped by setting the CONT bit in SSIWSR to 0, the slave-side SSI1, SSI2, SSI3, and SSI9 should be stopped because output through SSI_WS01239_A is not possible. This also applies to the master and slaves in the combination of SSI3, SSI4, and SSI9, and to the master and slave in the combination of SSI7 and SSI8. All of the multiple SSI modules have to belong to same group (Group A or Group B).

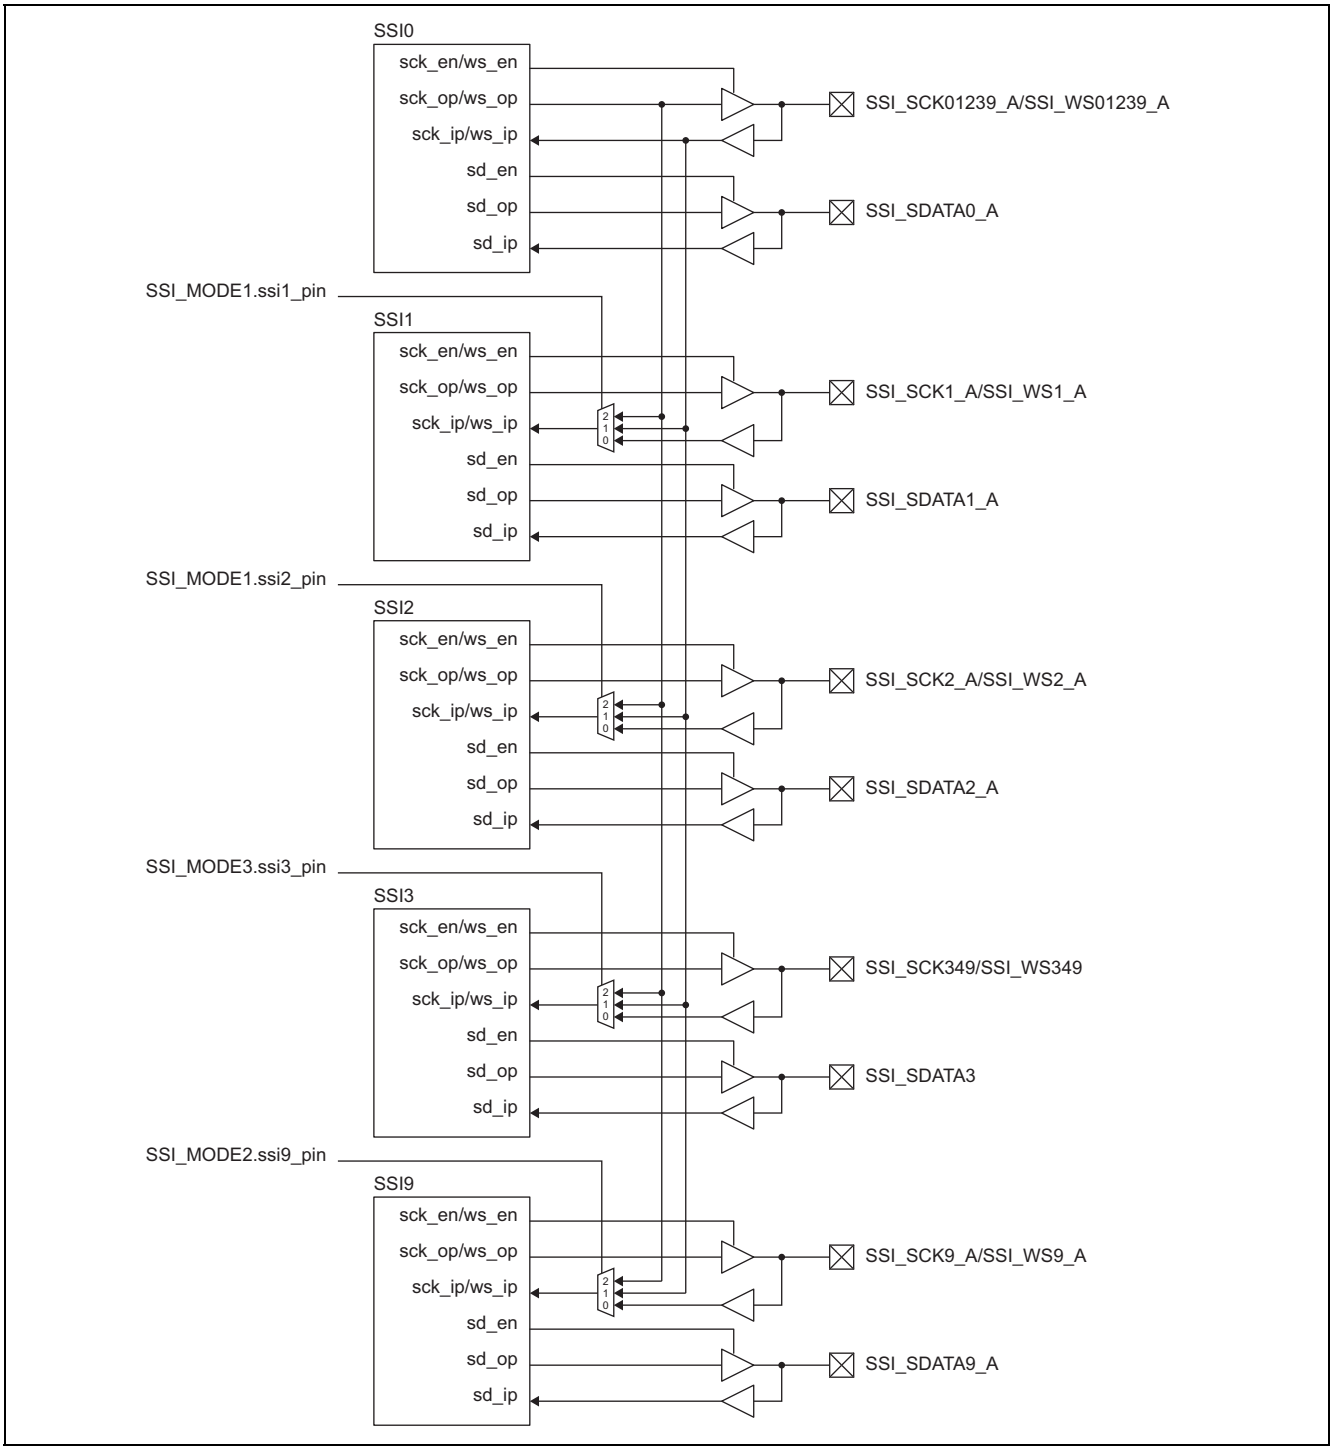

Figure 28.12 Pin Connections for Combination of SSI0, SSI1, SSI2, SSI3, and SSI9 (Group A)

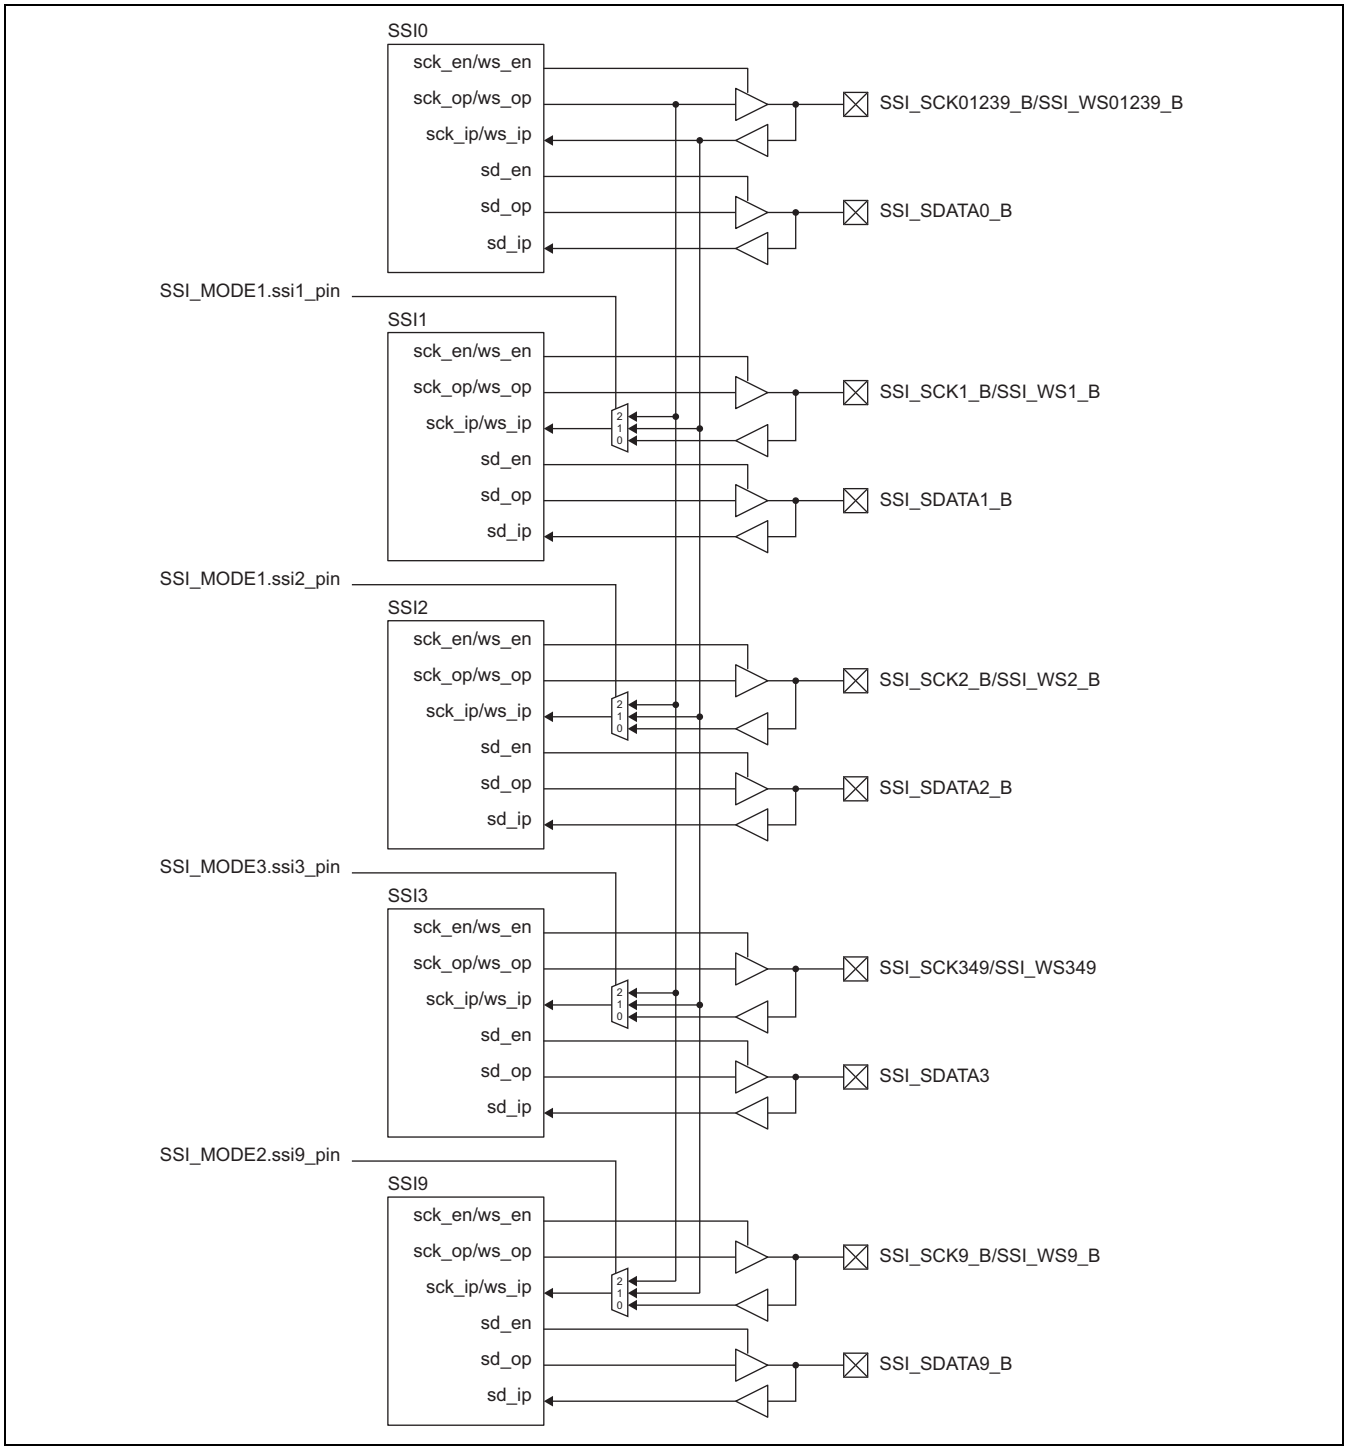

Figure 28.13 Pin Connections for Combination of SSI0, SSI1, SSI2, SSI3, and SSI9 (Group B)

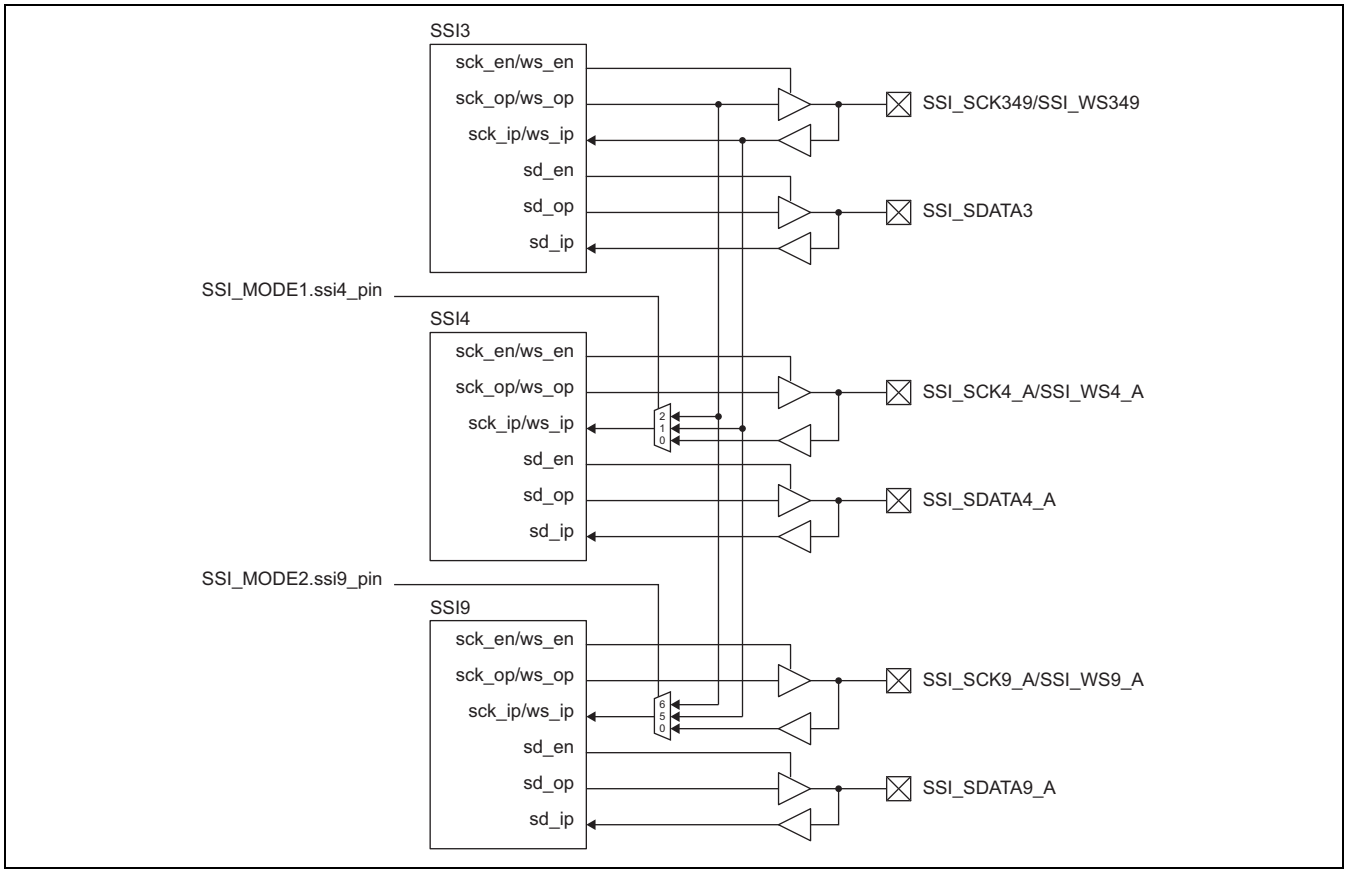

Figure 28.14 Pin Connections for Combination of SSI3, SSI4, and SSI9 (Group A)

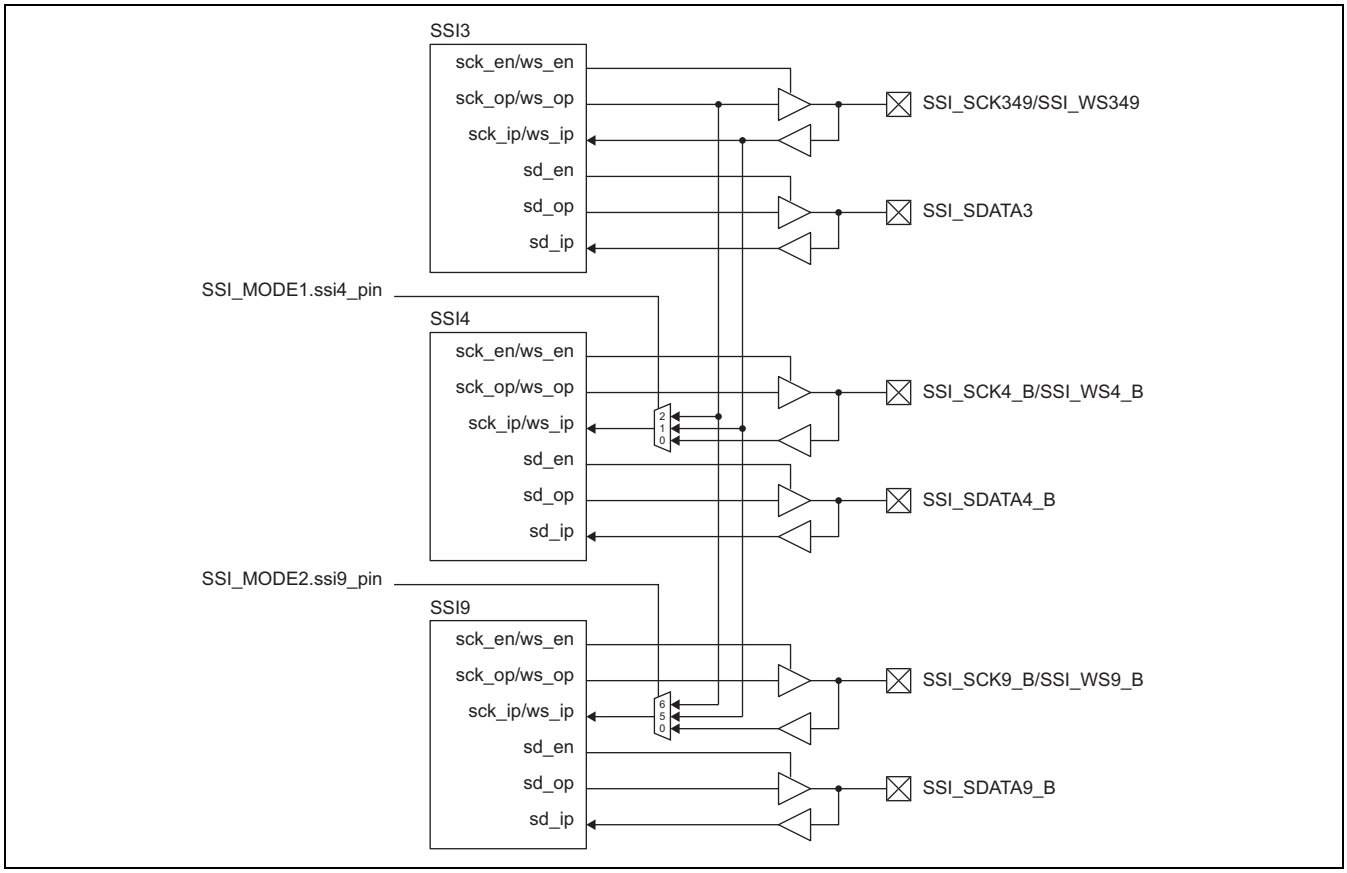

Figure 28.15 Pin Connections for Combination of SSI3, SSI4, and SSI9 (Group B)

Note: The above configuration in Figures 28.14 and 28.15 is prohibited if SSI0 SCK/WS is selected for SSI3 as shown in Figures 28.12 and 28.13.

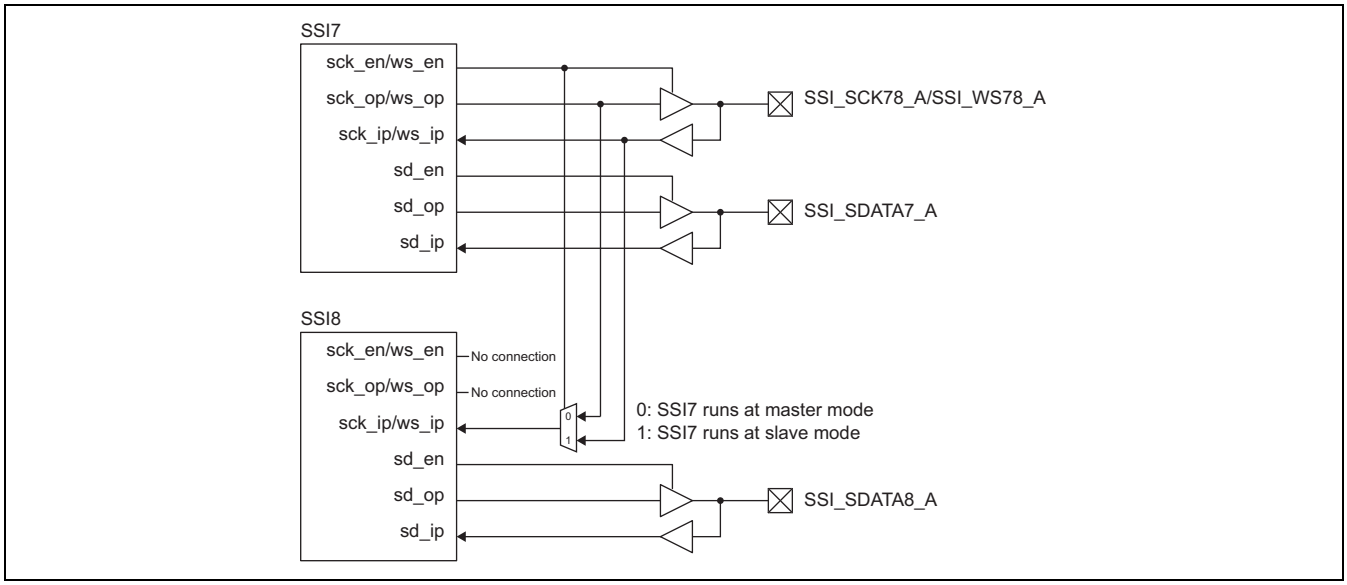

Figure 28.16 Pin Connections for Combination of SSI7 and SSI8 (Group A)

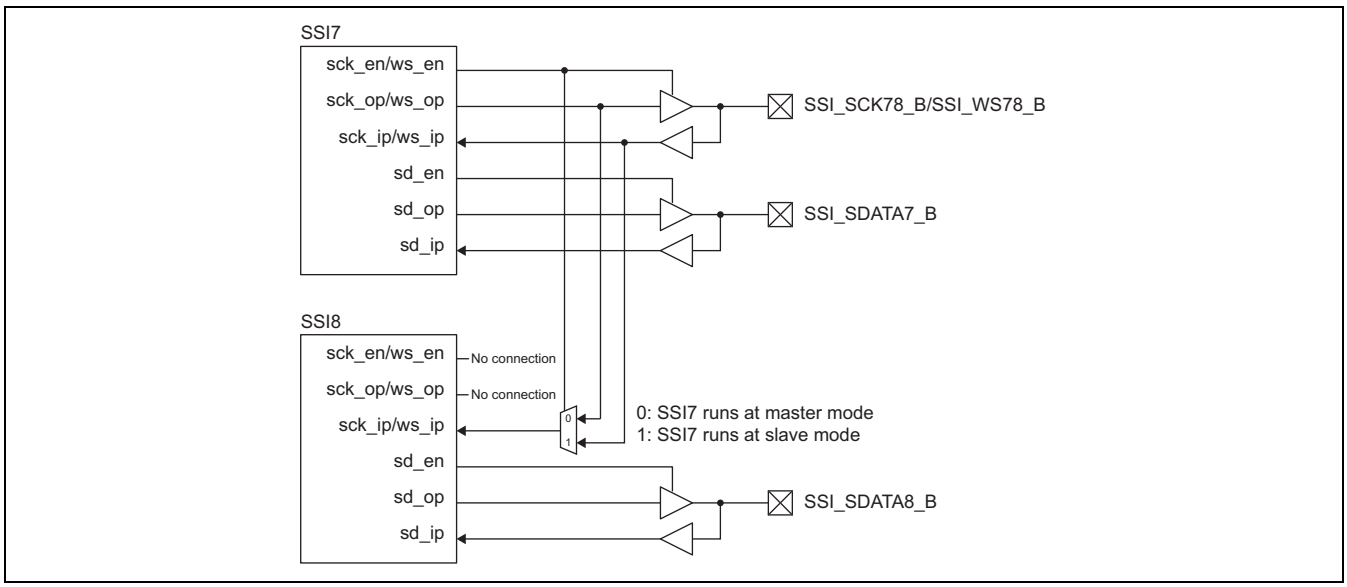

Figure 28.17 Pin Connections for Combination of SSI7 and SSI8 (Group B)

28.3.7 Procedure of SSIU Transfer

Figures 28.18 to 28.21 show the operation flow.

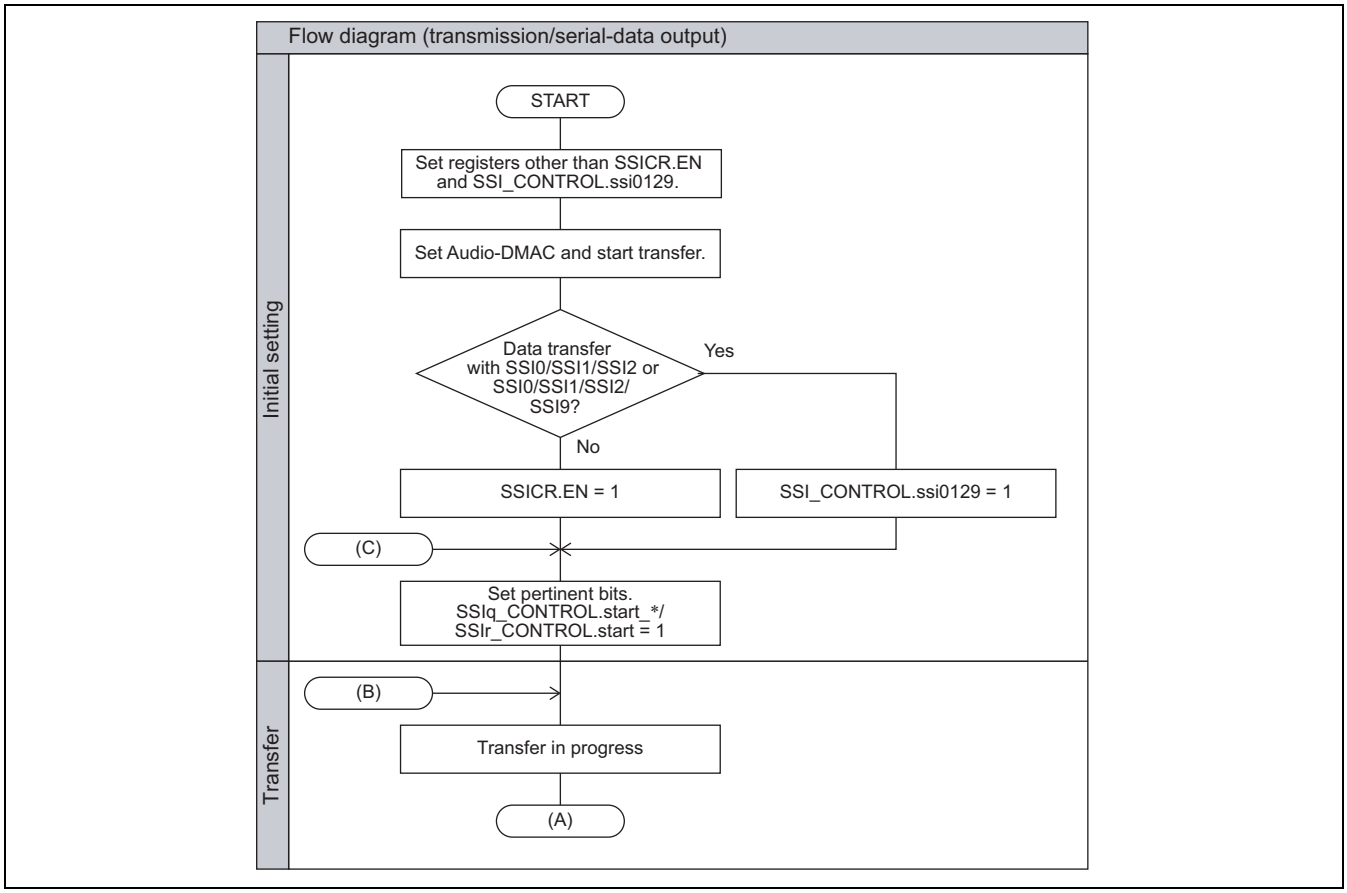

Figure 28.18 Transmission (1)

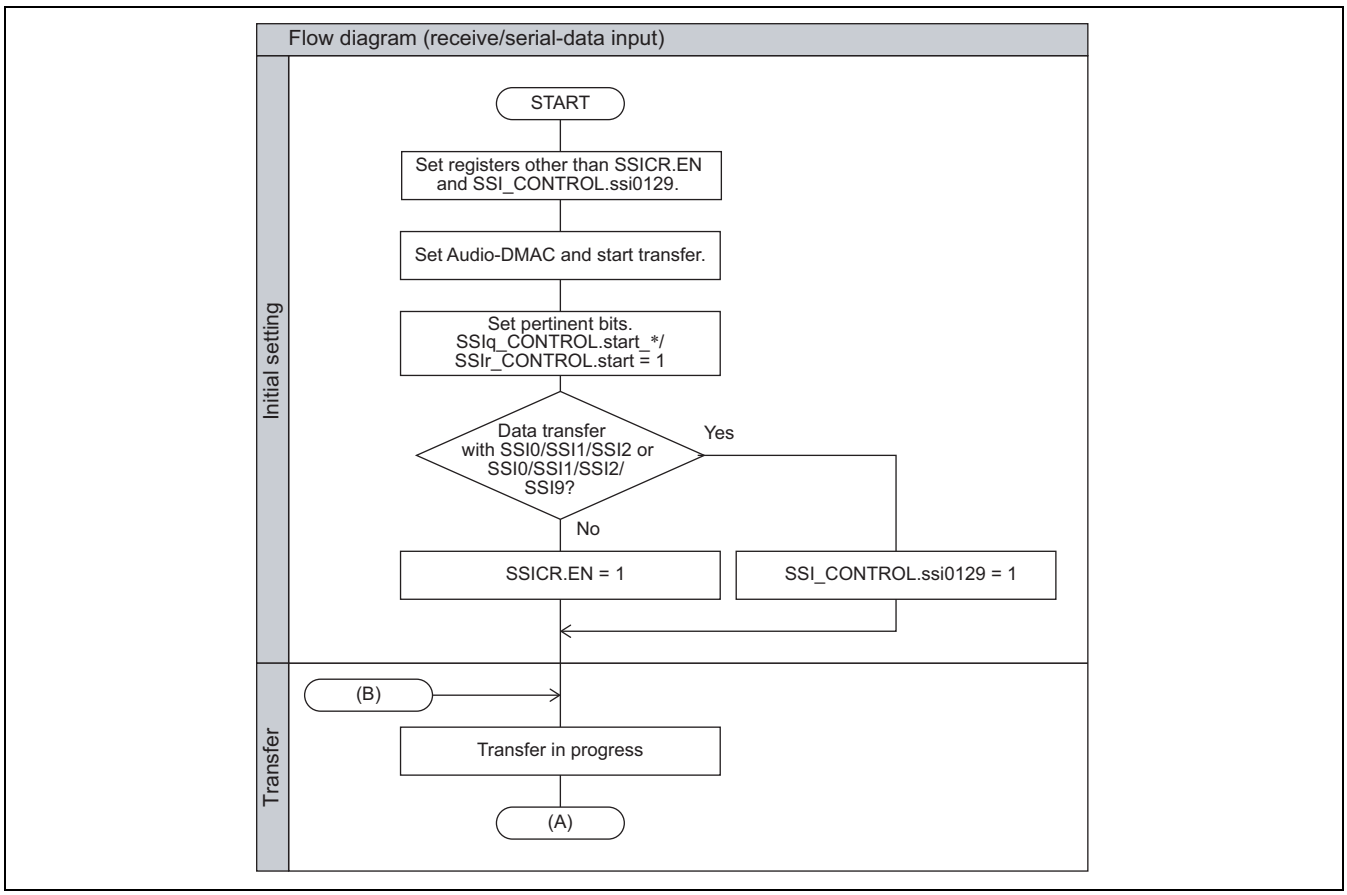

Figure 28.20 Reception (1)

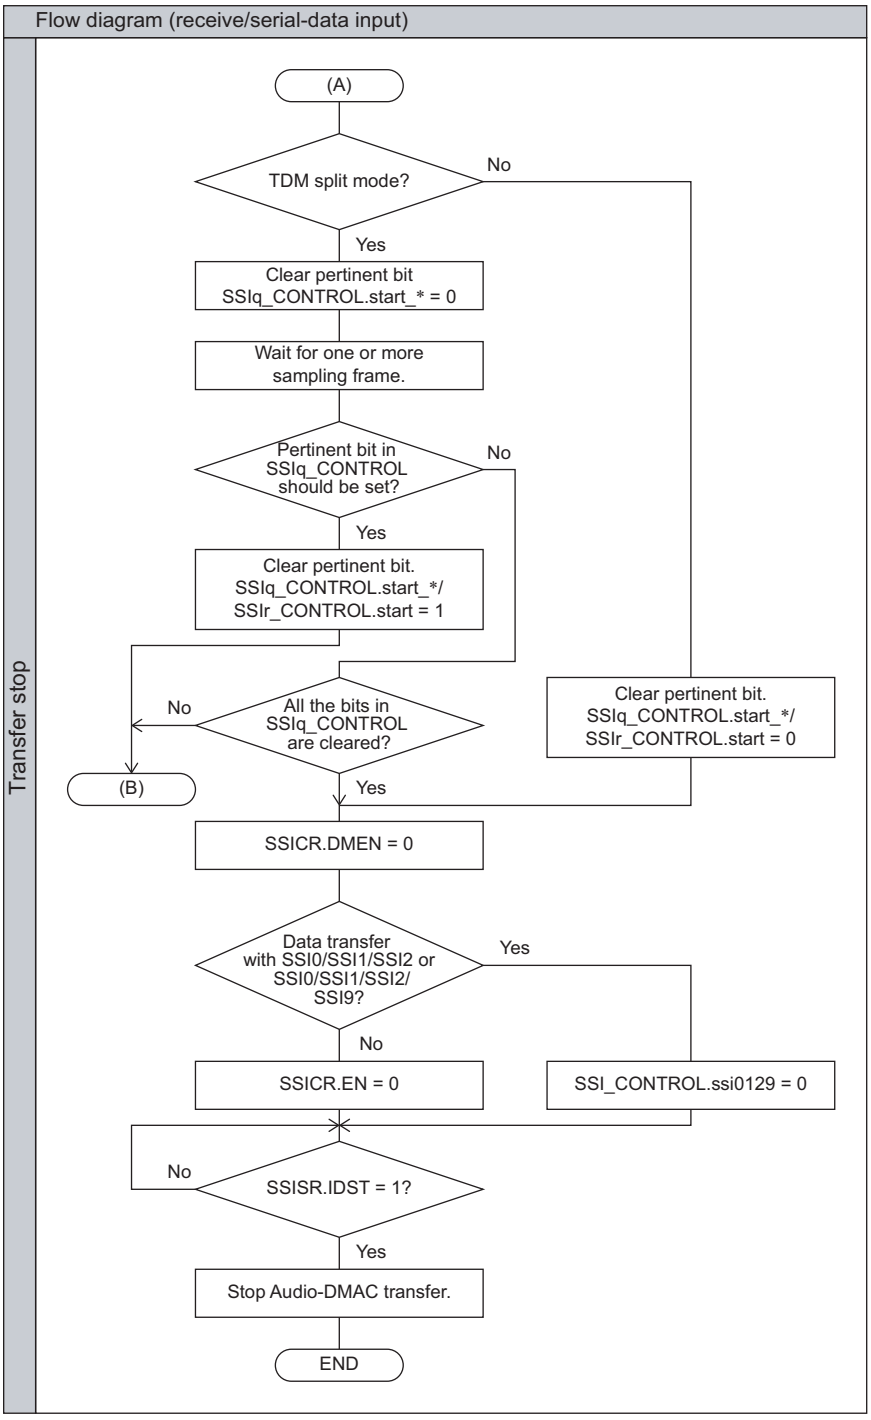

Figure 28.21 Reception (2)

28.3.8 Interrupts of SSI Setting

SSI can output interrupt signals when one of several events happen. Figure 28.22 illustrates how SSI generates interrupt signals and Table 28.4 and Table 28.5 indicate combinations of relevant registers for each SSI to generate interrupt signals (refer to explanations of relevant registers (Section 28.2) and SSI (Section 28A))

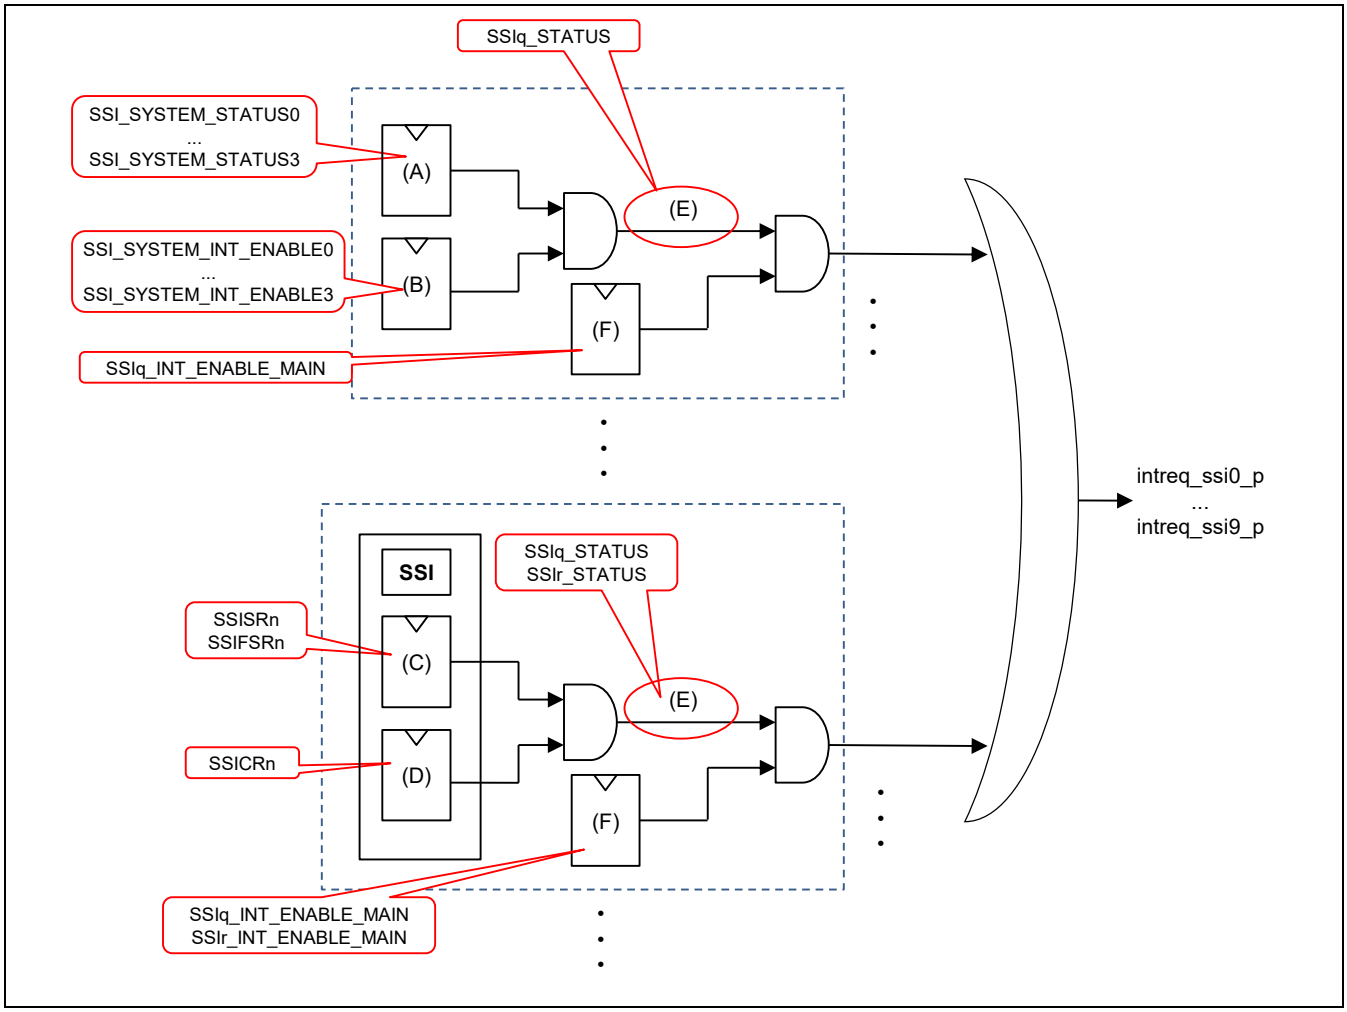

Figure 28.22 Mechanism of generating interrupt signals

Table 28.4 Combinations of relevant registers for each SSI (1)

		(A)	(B)	(E)	(F)
SSI	**BUSIF**	**Register Name (Interrupt Factor)**	**Register Name (Interrupt Enable)**	**Register Name (Interrupt Factor)**	**Register Name (Interrupt Enable)**

28.4 Usage Note

28.4.1 Note on Transfer

If an underflow or overflow occurs, stop the transfer and restart it.

Do not stop serial clock (SCK) and word select (WS) signals during data transfer. Confirm that SSISR.IDST = 1 before stopping SCK and WS signals.

28A. Serial Sound Interface (SSI)

28A.1 Overview

The serial sound interface (hereinafter referred to as the "SSI") is a transceiver module designed to send or receive audio data interfacing with a variety of devices offering I2S format. It also supports multi-channel mode in addition to other common formats.

28A.1.1 Features

The SSI has the following features:

- Number of channels: Maximum of four (when a multichannel format is specified)
- The SSI module can serve as both a transmitter and a receiver.
- Asynchronous transfer takes place between the data buffer and the shift register.
- Only the MSB first data alignment is supported.
- A value as the dividing ratio for the clock used by the serial bus interface is selectable.
- Controlling of data transmission or reception with DMAC or interrupt requests is possible.
- TDM format is supported.
- The frequency range of SCK signal is from 297.3 kHz to 12.5MHz at master mode, and from 297.3 kHz to 15.1 MHz at slave mode.
- The WS continue function by which operation can be performed without stopping WS signal is supported.
- Monaural mode (8 bits or 16 bits) is supported.
- In monaural mode, WS signal pulse width can be changed (short or long frame).
- If the sampling clock frequency is switched during transfer, it will be notified of the CPU with interrupts (a function to detect switching frequency).

28A.1.2 Block Diagram

Figure 28A.1 shows a block diagram of a single SSI module.

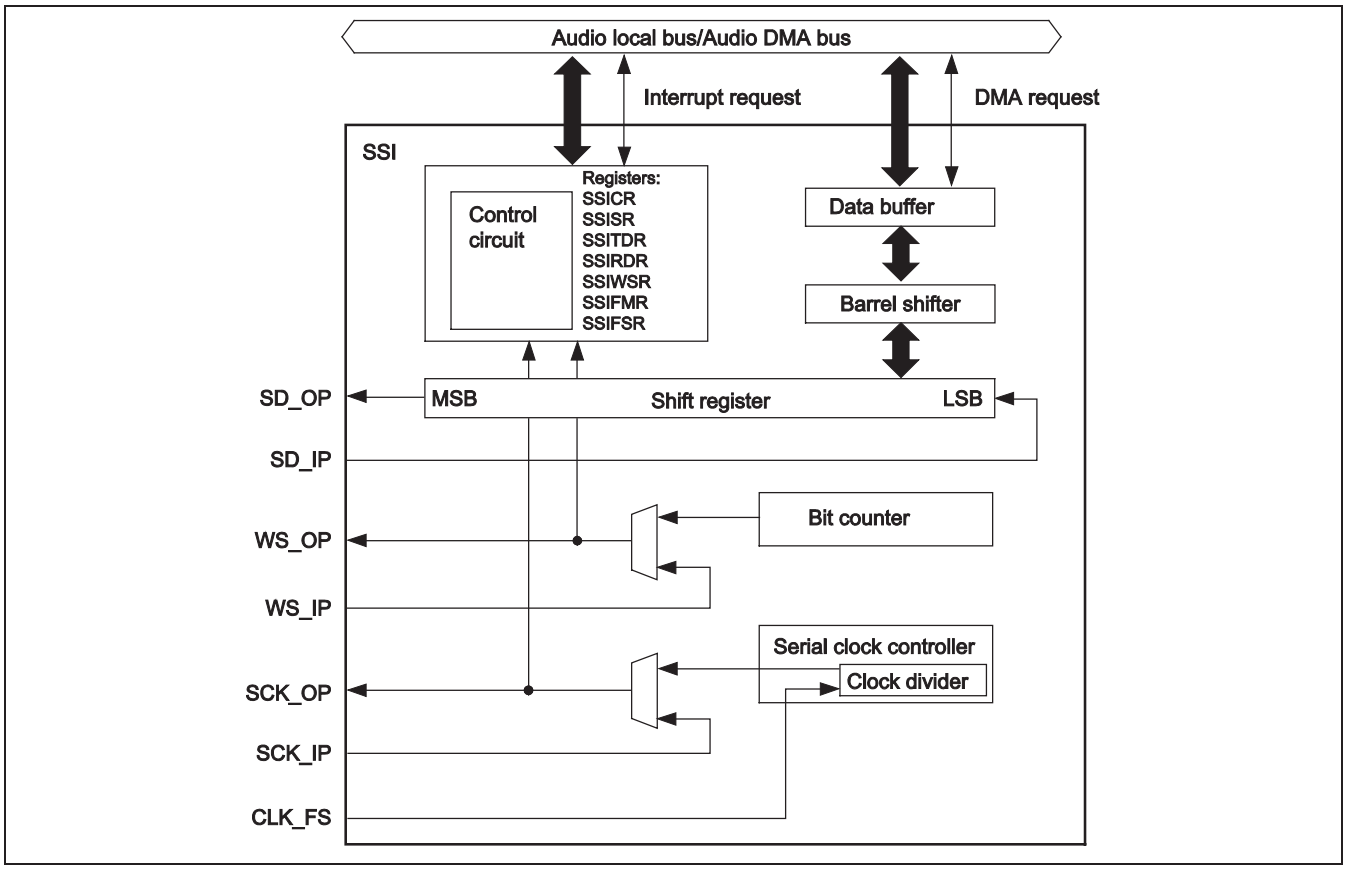

Figure 28A.1 Block Diagram of SSI

28A.1.3 Input/Output Pins

No external pins

28A.1.4 Register Configuration

The SSI has the following registers. Note that the module numbers are basically omitted from the register names in the text.

Table 28A.1 Register Configurations

Module	Register Name	Abbreviation	R/W	Address	Access Size
0	Control Register 0	SSICR0	R/W	H'EC54 1000	32
	Status Register 0	SSISR0	R/W*1	H'EC54 1004	32
	Transmit Data Register 0	SSITDR0	R/W	H'EC54 1008/ H'EC24 1008*3	32
	Receive Data Register 0	SSIRDR0	R	H'EC54 100C/ H'EC24 100C*3	32
	WS Mode Register 0	SSIWSR0	R/W	H'EC54 1020	32
	FS Mode Register 0	SSIFMR0	R/W	H'EC54 1024	32

	FS Status Register 9	SSIFSR9	R/W*2	H'EC54 1268	32

Notes: Do not write to any addresses other than listed above. Operations cannot be guaranteed if writing is attempted.
Values read from addresses other than those listed above are undefined.

1. For this register, bits 26 and 27 are readable/writable bits, although the others are read-only bits. For details, refer to section 28A.2.2 Status Register (SSISRn) (n = 0 to 9).
2. For this register, bits 14 and 15 are readable/writable bits, although the others are read-only bits. For details, refer to section 28A.2.7 FS Status Register (SSIFSRn) (n = 0 to 9).
3. H'EC54 1XXX and H'EC24 1XXX are used with PIO access and Audio-DMAC, respectively.

28A.2 Register Description

[Legend for Register Descriptions]

Initial value: Register value after a reset

—: Undefined value

R/W: Readable/writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R: Read-only. The write value should always be 0.

28A.2.1 Control Register (SSICRn) (n = 0 to 9)

SSICR is a readable/writable 32-bit register that controls the IRQ, selects the polarity status, and sets operating mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31	FORCE	0	R/W	Fixed The bit should always be set to 1.
30	—	0	R	Reserved The read value is 0. The write value should always be 0.
29	FIEN	0	R/W	Frequency Switching Detection Interrupt Enable 0: Frequency switching detection interrupt is disabled. 1: Frequency switching detection interrupt is enabled.
28	DMEN	0	R/W	DMA Enable Enables or disables the DMA request. 0: DMA request is disabled. 1: DMA request is enabled.
27	UIEN	0	R/W	Underflow Interrupt Enable 0: Underflow interrupt is disabled. 1: Underflow Interrupt is enabled.
26	OIEN	0	R/W	Overflow Interrupt Enable 0: Overflow interrupt is disabled. 1: Overflow interrupt is enabled.
25	IIEN	0	R/W	Idle Mode Interrupt Enable 0: Idle mode interrupt is disabled. 1: Idle mode interrupt is enabled.

Bit	Bit Name	Initial Value	R/W	Description
24	DIEN	0	R/W	Data Interrupt Enable 0: Data interrupt is disabled. 1: Data interrupt is enabled.
23, 22	CHNL[1:0]	00	R/W	Channels These bits set the number of channels in each system word. When the stereo format or multi-channel format is used (WS_MODE = 0, MONO = 0, and WIDTH = B'00000 in the WS Mode Register): 00: A system word has one channel. 01: A system word has two channels. 10: A system word has three channels. 11: A system word has four channels. When the TDM format is used (WS_MODE = 1, MONO = 0, and WIDTH = B'00000 in the WS Mode Register): 00: Setting prohibited* 01: A TDM frame consists of four system words. 10: A TDM frame consists of six system words. 11: A TDM frame consists of eight system words. When the monaural format is used (WS_MODE = 1, MONO = 1, and WIDTH = B'00001 to B'11111 in the WS Mode Register): 00: A monaural frame consists of one system word. 01: Setting prohibited 10: Setting prohibited 11: Setting prohibited
21 to 19	DWL[2:0]	000	R/W	Data Word Length These bits set the number of bits in a data word. When the stereo format or multi-channel format (WS_MODE = 0, MONO = 0, and WIDTH = B'00000 in the WS Mode Register) or TDM format (WS_MODE = 1, MONO = 0, and WIDTH = B'00000 in the WS Mode Register) is used: 000: 8 bits 001: 16 bits 010: 18 bits 011: 20 bits 100: 22 bits 101: 24 bits 110: 32 bits 111: Setting prohibited When the monaural format is used (WS_MODE = 1, MONO = 1, and WIDTH = B'00001 to B'11111 in the WS Mode Register): 000: 8 bits 001: 16 bits Other than above: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Description
18 to 16	SWL[2:0]	000	R/W	System Word Length These bits set the number of bits in a system word. When the stereo format or multi-channel format (WS_MODE = 0, MONO = 0, and WIDTH = B'00000 in the WS Mode Register) or TDM format (WS_MODE = 1, MONO = 0, and WIDTH = B'00000 in the WS Mode Register) is used: 000: 8 bits 001: 16 bits 010: 24 bits 011: 32 bits 100: 48 bits 101: 64 bits 110: 128 bits 111: 256 bits When the monaural format is used (WS_MODE = 1, MONO = 1, and WIDTH = B'00001 to B'11111 in the WS Mode Register): 000: 16 bits 001: 32 bits 010: 48 bits 011: 64 bits 100: 96 bits 101: 128 bits 110: 256 bits 111: 512 bits
15	SCKD	0	R/W	Serial Bit Clock Direction 0: Serial bit clock is input, slave mode. 1: Serial bit clock is output, master mode. Note: (SCKD, SWSD) = (0, 0) or (1, 1) can be set to SSI0 to SSI7 and SSI9. To SSI8, only (SCKD, SWSD) = (0, 0) can be set. Other settings are prohibited.
14	SWSD	0	R/W	Serial WS Direction 0: Serial word select is input, slave mode. 1: Serial word select is output, master mode. Note: (SCKD, SWSD) = (0, 0) or (1, 1) can be set to SSI0 to SSI7 and SSI9. To SSI8, only (SCKD, SWSD) = (0, 0) can be set. Other settings are prohibited.

Bit	Bit Name	Initial Value	R/W	Description
13	SCKP	0	R/W	Serial Bit Clock Polarity 0: SSI_WS and SSI_SDATA change at the SSI_SCK falling edge (sampled at the SCK rising edge). 1: SSI_WS and SSI_SDATA change at the SSI_SCK rising edge (sampled at the SCK falling edge).

	SCKP = 0	SCKP = 1
SSI_SDATA input sampling timing at the time of reception (TRMD = 0)	SSI_SCK rising edge	SSI_SCK falling edge
SSI_SDATA output change timing at the time of transmission (TRMD = 1)	SSI_SCK falling edge	SSI_SCK rising edge
SSI_WS input sampling timing at the time of slave mode (SWSD = 0)	SSI_SCK rising edge	SSI_SCK falling edge
SSI_WS output change timing at the time of master mode (SWSD = 1)	SSI_SCK falling edge	SSI_SCK rising edge

Bit	Bit Name	Initial Value	R/W	Description
12	SWSP	0	R/W	Serial WS Polarity The value of this bit must not be changed when the SSI module enable (EN) bit in this register is set to 1. • When the stereo format or multi-channel format is used (WS_MODE = 0, MONO = 0, and WIDTH = B'00000 in the WS Mode Register): 0: SSI_WS is low for 1st channel, high for 2nd channel. 1: SSI_WS is high for 1st channel, low for 2nd channel. • When the TDM format is used (WS_MODE = 1, MONO = 0, and WIDTH = B'00000 in the WS Mode Register): 0: The SYNC pulse is high over the period of system word 1, and low otherwise. 1: The SYNC pulse is low for over the period of system word 1, and high otherwise. • When the monaural format is used (WS_MODE = 1, MONO = 1, and WIDTH = B'00001 to B'11111 in the WS Mode Register): 0: WS pulse is high over the period specified with the WIDTH bits in the WS Mode Register, and low otherwise. 1: WS pulse is low over the period specified with the WIDTH bits in the WS Mode Register, and high otherwise.
11	SPDP	0	R/W	Serial Padding Polarity 0: Padding bits are low. 1: Padding bits are high. Padding bits are low when MUEN = 1. (The mute function takes priority.)
10	SDTA	0	R/W	Serial Data Alignment This bit should be set to 0 when the monaural format is used (WS_MODE = 1, MONO = 1, and WIDTH = B'00001 to B'11111 in the WS Mode Register). 0: Transmitting and receiving in the order of serial data and padding bits. 1: Transmitting and receiving in the order of padding bits and serial data.

Bit	Bit Name	Initial Value	R/W	Description
9	PDTA	0	R/W	Parallel Data Alignment When the length of data word is 32, 16 or 8 bits, this configuration field has no meaning. This bit should be set to 0 when the monaural format is used (WS_MODE = 1, MONO = 1, and WIDTH = B'00001 to B'11111 in the WS Mode Register). This bit applies to SSIRDR in receive mode and SSITDR in transmit mode. 0: Parallel data (SSITDR, SSIRDR) is left-aligned. 1: Parallel data (SSITDR, SSIRDR) is right-aligned. DWL = 000 (with a data word length of 8 bits), the PDTA setting is ignored. All data bits in SSIRDR or SSITDR are used on the audio serial bus. Four data words are transmitted or received at each 32-bit access. The first data word is derived from bits 7 to 0, the second from bits 15 to 8, the third from bits 23 to 16 and the last data word is derived from bits 31 to 24. DWL = 001 (with a data word length of 16 bits), the PDTA setting is ignored. All data bits in SSIRDR or SSITDR are used on the audio serial bus. Two data words are transmitted or received at each 32-bit access. The first data word is derived from bits 15 to 0 and the second data word is derived from bits 31 to 16. DWL = 010, 011, 100, 101 (with a data word length of 18, 20, 22 or 24 bits), PDTA = 0 (left-aligned) The data bits used in SSIRDR or SSITDR are the following: Bits 31 down to (32 minus the number of bits in the data word length specified by DWL). That is, if DWL = 011, the data word length is 20 bits; therefore, bits 31 to 12 in either SSIRDR or SSITDR are used. All other bits are ignored or reserved. DWL = 010, 011, 100, 101 (with a data word length of 18, 20, 22 or 24 bits), PDTA = 1 (right-aligned) The data bits used in SSIRDR or SSITDR are the following: Bits (the number of bits in the data word length specified by DWL minus 1) to 0 i.e. if DWL = 011, then DWL = 20 and bits 19 to 0 are used in either SSIRDR or SSITDR. All other bits are ignored or reserved. DWL = 110 (with a data word length of 32 bits), the PDTA setting is ignored. All data bits in SSIRDR or SSITDR are used on the audio serial bus.
8	DEL	0	R/W	Serial Data Delay 0: One clock cycle delay between SSI_WS and SSI_SDATA 1: No delay between SSI_WS and SSI_SDATA
7	—	0	R	Reserved The read value is 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
6 to 4	CKDV[2:0]	000	R/W	Serial Oversampling Clock Division Ratio Set the ratio between oversampling clock, CLK_FS, and the serial bit clock. These bits are ignored if SCKD = 0. The serial bit clock is used in the shift register and is provided on the SSI_SCK module pin. 000: Serial bit clock frequency = oversampling clock frequency/1 001: Serial bit clock frequency = oversampling clock frequency/2 010: Serial bit clock frequency = oversampling clock frequency/4 011: Serial bit clock frequency = oversampling clock frequency/8 100: Serial bit clock frequency = oversampling clock frequency/16 101: Serial bit clock frequency = oversampling clock frequency/6 110: Serial bit clock frequency = oversampling clock frequency/12 111: Setting prohibited CKDV = 000 is invalid when WS_MODE = 1 or CONT = 1 in the WS Mode Register.
3	MUEN	0	R/W	Serial Data Output Disable 0: Module is not muted. 1: Module is muted. Note: This bit can be used to stop output (low output) or to enable output. However, the operation is not synchronized with the change of SSI_WS.
2	—	0	R	Reserved The read value is 0. The write value should always be 0.
1	TRMD	0	R/W	Transmit/Receive Mode Select 0: Module is in receive mode. 1: Module is in transmit mode.
0	EN	0	R/W	SSI Module Enable 0: Module is disabled. 1: Module is enabled.

28A.2.2 Status Register (SSISRn) (n = 0 to 9)

SSISR consists of status flags indicating the operational status of the SSI module and bits indicating the current channel numbers and word numbers.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	DMRQ	UIRQ	OIRQ	IIRQ	DIRQ	—	—	—	—	—	—	—	—
Initial value:	—	—	—	0	0	0	—	0	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R/WC0	R/WC0	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	CHNO[1:0]		SWNO	IDST
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	0	0	1	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	Undefined	R	Reserved The read value is not guaranteed. The write value should always be 0.
28	DMRQ	0	R	DMA Request Status Flag This status flag allows the CPU to recognize the value of the DMA request pin on the SSI module. • TRMD = 0 (receive mode) If DMRQ = 1, the SSIRDR has unread data. If SSIRDR is read, DMRQ = 0 until there is new unread data. • TRMD = 1 (transmit mode) If DMRQ = 1, SSITDR requires data to be written to continue the transmission to the audio serial bus. Once data is written to SSITDR, DMRQ = 0 until it requires further transmit data.
27	UIRQ	0	R/WC0	Underflow Error Interrupt Status Flag This status flag indicates that data was supplied at a lower rate than was required. In either case, this bit is set to 1 regardless of the value of the UIEN bit and can be cleared by writing 0 to this bit. If UIRQ = 1 and UIEN = 1, an interrupt occurs. • TRMD = 0 (receive mode) If UIRQ = 1, SSIRDR was read before there was new unread data indicated by the DMRQ or DIRQ bit. This can lead to the same received data being stored twice by the host leading to potential corruption of multi-channel data. • TRMD = 1 (transmit mode) If UIRQ = 1, SSITDR did not have data written to it before it was required for transmission. This will lead to the same data being transmitted once more and a potential corruption of multi-channel data. This is more serious error than a receive mode underflow as the output SSI data results in error. Note: When underflow error occurs, the current data in the data buffer of this module is transmitted until the next data is filled.

Bit	Bit Name	Initial Value	R/W	Description
26	OIRQ	0	R/WC0	Overflow Error Interrupt Status Flag This status flag indicates that data was supplied at a higher rate than was required. In either case this bit is set to 1 regardless of the value of the OIEN bit and can be cleared by writing 0 to this bit. If OIRQ = 1 and OIEN = 1, an interrupt occurs. • TRMD = 0 (receive mode) If OIRQ = 1, SSIRDR was not read before there was new unread data written to it. This will lead to the loss of a data and a potential corruption of multi-channel data. Note: When overflow error occurs, the current data in the data buffer of this module is overwritten by the next incoming data from the SSI interface. • TRMD = 1 (transmit mode) If OIRQ = 1, SSITDR had data written to it before it was transferred to the shift register. This will lead to the loss of a data and a potential corruption of multi-channel data.
25	IIRQ	Undefined	R	Idle Mode Interrupt Status Flag This interrupt status flag indicates whether the SSI module is in idle state. This bit is set regardless of the value of the IIEN bit to allow polling. “Idle state” refers to the state where the serial bus has been stopped after activation of the SSI. The interrupt can be masked by clearing IIEN, but cannot be cleared by writing to this bit. If IIRQ = 1 and IIEN = 1, an interrupt occurs. 0: The SSI module is not in idle state. 1: The SSI module is in idle state.
24	DIRQ	0	R	Data Interrupt Status Flag This status flag indicates that the module has data to be read or requires data to be written. In either case this bit is set to 1 regardless of the value of the DIEN bit to allow polling. The interrupt can be masked by clearing DIEN, but cannot be cleared by writing to this bit. If DIRQ = 1 and DIEN = 1, an interrupt occurs. • TRMD = 0 (receive mode) 0: No unread data in SSIRDR 1: Unread data in SSIRDR • TRMD = 1 (transmit mode) 0: Transmit buffer is full. 1: Transmit buffer is empty and requires data to be written to SSITDR.
23 to 4	—	—	R	Reserved The read value is not guaranteed. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3, 2	CHNO[1:0]	00	R	Channel Number These bits indicate the current channel number. However, if the length of data words is 8 or 16 bits, the value of these bits is meaningless. 00: 1st channel 01: 2nd channel 10: 3rd channel 11: 4th channel • TRMD = 0 (receive mode) CHNO indicates which channel the data in SSIRDR currently represents. This value will change as the data in SSIRDR is updated from the shift register. • TRMD = 1 (transmit mode) CHNO indicates which channel is required to be written to SSITDR. This value will change as the data is copied to the shift register, regardless of whether the data is written to SSITDR. These bits cannot be used when WS_MODE = 1 or CONT = 1 in the WS Mode Register.
1	SWNO	1	R	System Word Number This status bit indicates the current word number. However, if the length of data words is 8 or 16 bits, the value of this bit is meaningless. • TRMD = 0 (receive mode) SWNO indicates which system word the data in SSIRDR currently represents. This value will change as the data in SSIRDR is updated from the shift register, regardless of whether SSIRDR has been read. • TRMD = 1 (transmit mode) SWNO indicates which system word is required to be written to SSITDR. This value will change as the data is copied to the shift register, regardless of whether the data is written to SSITDR. This bit cannot be used when WS_MODE = 1 or CONT = 1 in the WS Mode Register.
0	IDST	Undefined	R	Idle Mode Status Flag This status flag indicates that the serial bus activity has stopped. This bit is cleared if EN = 1 and the serial bus are currently active. This bit is automatically set to 1 under the following conditions. • SSI = Master transmitter (SWSD = 1 and TRMD = 1) This bit is set to 1 when the EN bit is cleared and data written in SSITDR has been output from the serial data input/output pin (SSI_SDATA). • SSI = Master receiver (SWSD = 1 and TRMD = 0) This bit is set to 1 when the EN bit is cleared and transfer of the current system word is completed. • SSI = Slave transmitter/receiver (SWSD = 0) This bit is set to 1 when the EN bit is cleared and transfer of the current system word is completed. Note: If an external device stops the serial bus clock before transfer of the current system word is completed, this bit is not set.

28A.2.3 Transmit Data Register (SSITDRn) (n = 0 to 9)

SSITDR is a 32-bit register that holds data to be transmitted.

Data written to this register is transferred to the shift register upon transmission request. If the data word length is less than 32 bits, the alignment is determined by the setting of the PDTA control bit in SSICR. The data in the buffer can be accessed by reading this register.

28A.2.4 Receive Data Register (SSIRDRn) (n = 0 to 9)

SSIRDR is a 32-bit register that stores receive messages.

Data in this register is transferred from the shift register each time data word is received. If the data word length is less than 32 bits, the alignment is determined by the setting of the PDTA control bit in SSICR.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15 to 6	—	All 0	R	Reserved The read value is 0. The write value should always be 0.
5, 4	CTDV[1:0]	00	R/W	Bus Clock Division Ratio Sets the bus clock division ratio used for the frequency switching detection function. 11: Set the switching detection clock frequency = bus clock frequency/8.
3 to 1	—	All 0	R	Reserved The read value is 0. The write value should always be 0.
0	FSEN	0	R/W	Frequency Switching Detection Function Enable 0: The frequency switching detection function is disabled. 1: The frequency switching detection function is enabled. Note: This bit must be enabled after the desired settings have been made for SWSP in SSICR and WS_MODE in SSIWSR.

28A.2.7 FS Status Register (SSIFSRn) (n = 0 to 9)

SSIFSR is used to read the frequency switching detection status and information on the frequency counter.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/WC0	R/WC0	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved The read value is 0. The write value should always be 0.
15	FCST	0	R/WC0	WS Stopped Status Flag In the frequency switching detection function, this status flag reflects the state that the WS signal is stopped. When FCST = 1, this bit indicates that the WS signal has stopped (the state is detected only when FSEN in SSIFMR = 1). Write 0 if this bit is cleared to 0.
14	DTST	0	R/WC0	Frequency Switching Detection Status Flag In the frequency switching detection function, this status flag reflects the state that frequency switching has been detected. When DTST = 1, this bit indicates that the switching has been detected (the state is detected only when FSEN in SSIFMR = 1). Write 0 if this bit is cleared to 0.
13, 12	—	0	R	Reserved The read value is 0. The write value should always be 0.
11 to 0	FCNT[11:0]	H'000	R	Frequency Count Monitor When the frequency switching detection function is enabled, the count value between WS signal edges is reflected according to the setting of the operating mode and the serial WS polarity (SWSP in SSICR). This value is updated when the frequency is switched and the WS signal has been detected.

28A.3 Operation

28A.3.1 Bus Format

The SSI module can operate as a transmitter or a receiver and can be configured into many serial bus formats in either mode.

The bus format can be selected from one of the four major modes shown in Table 28A.2.

Table 28A.2 Bus Format for SSI Module

	SSICR																	SSIWSR		
	TRMD	SCKD	SWSD	EN	MUEN	DIEN	IIEN	OIEN	UIEN	DEL	PDTA	SDTA	SPDP	SWSP	SCKP	SWL[2:0]	DWL[2:0]	CHNL[1:0]	WS_MODE	MONO	CONT
Slave receiver	0	0	0	Control bits						Configuration bits									WS mode bits		
Slave transmitter	1	0	0																		
Master receiver	0	1	1																		
Master transmitter	1	1	1																		

(1) Slave receiver

This mode allows the module to receive serial data from another device. The clock and word select signal used for the serial data stream is also supplied from an external device. If these signals do not conform to the format specified in the configuration fields of the SSI module, operation is not guaranteed.

(2) Slave transmitter

This mode allows the module to transmit serial data to another device. The clock and word select signal used for the serial data stream is also supplied from an external device. If these signals do not conform to the format specified in the configuration fields of the SSI module, operation is not guaranteed.

(3) Master receiver

This mode allows the module to receive serial data from another device. The clock and word select signals are internally derived from the CLK_FS input clock. The format of these signals is defined in the configuration fields of the SSI module. If the incoming data does not follow the configured format, operation is not guaranteed.

(4) Master transmitter

This mode allows the module to transmit serial data to another device. The clock and word select signals are internally derived from the CLK_FS input clock. The format of these signals is defined in the configuration fields of the SSI module.

(5) Setting for each format

Table 28A.3 shows the setting for each format:

Table 28A.3 Setting for Each Format

	SSICR	SSIWSR		
Format	**CHNL[1:0]**	**WS_MODE**	**MONO**	**WIDTH[4:0]**
Stereo format	B'00	0	0	B'00000
Multi-channel format	B'01/B'10/B'11	0	0	B'00000
Monaural format	B'00	1	1	B'00001 to B'11111
TDM format	B'00/B'01/B'10/B'11 *	1	0	B'00000

(6) Configuration bits (related to word length)

There are many configurations the SSI module supports, but only some of the combinations are shown below for the I2S, left-aligned, and right-aligned formats.

Figure 28A.2 and Figure 28A.3 demonstrate the supported I2S format both with and without padding. Padding occurs when the data word length is smaller than the system word length.

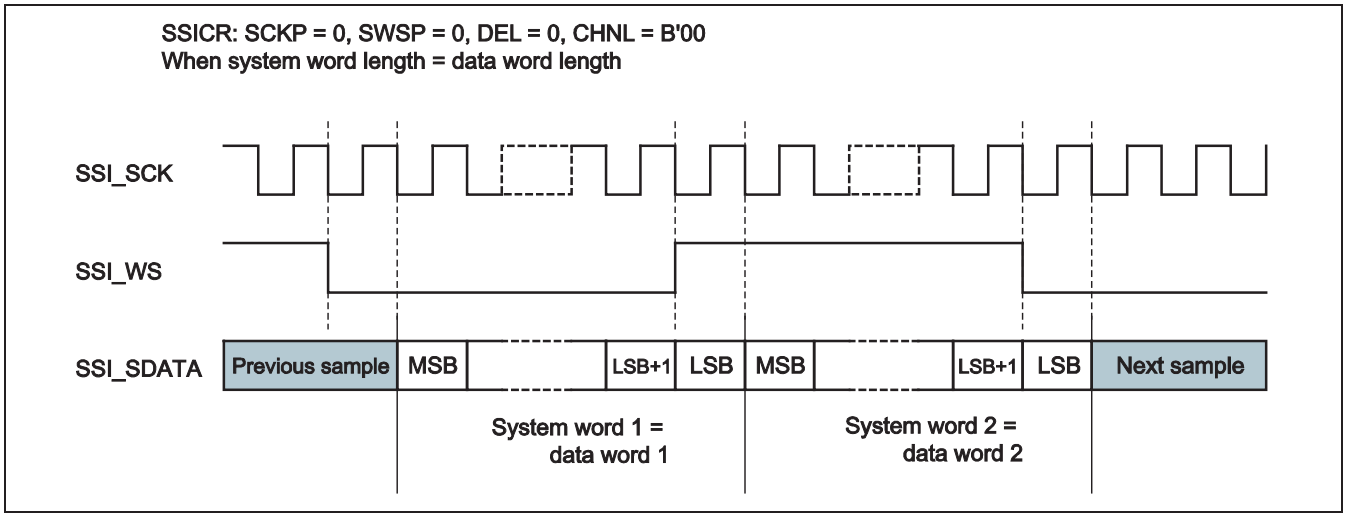

Figure 28A.2 I2S Format (without Padding)

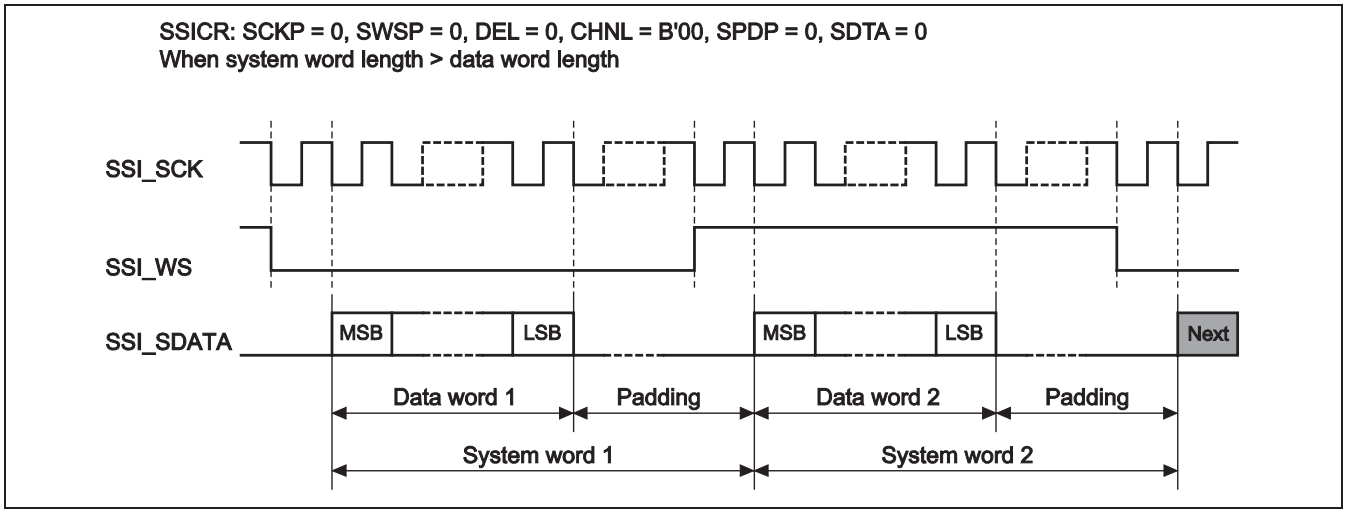

Figure 28A.3 I2S Format (with Padding)

Figure 28A.4 shows the left-aligned format and Figure 28A.5 shows the right-aligned format. Padding is assumed in both cases, but may not be present in a final implementation if the system word length equals the data word length.

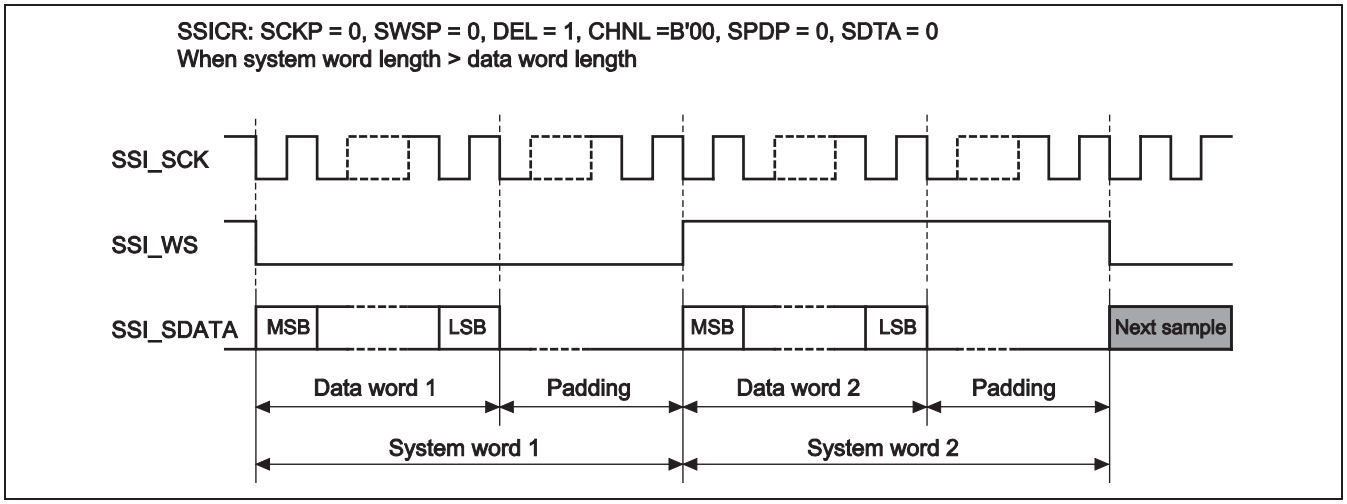

Figure 28A.4 Left-Aligned Format
(Transmitting and Receiving in the Order of Serial Data and Padding Bits)

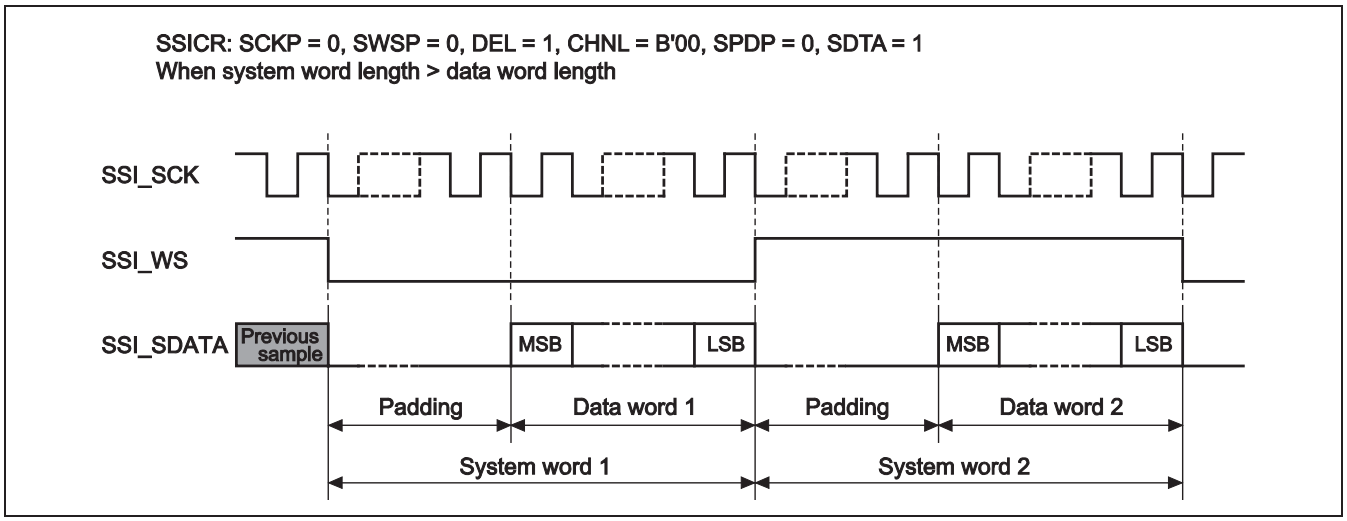

Figure 28A.5 Right-Aligned Format
(Transmitting and Receiving in the Order of Padding Bits and Serial Data)

(7) Multi-channel formats

Some devices extend the definition of the I2S format and allow more than two channels to be transferred within two system words.

The SSI module supports the transfer of two, three, and four channels by using the CHNL, SWL and DWL bits only when the system word length (SWL) is greater than or equal to the data word length (DWL) multiplied by channels (CHNL).

Table 28A.4 shows the number of padding bits for each of the valid setting. If setting is not valid, "—" is indicated instead of a number.

Table 28A.4 The Number of Padding Bits for Each Valid Setting

Padding Bits Per System Word			DWL[2:0]	B'000	B'001	B'010	B'011	B'100	B'101	B'110

When the SSI module acts as a transmitter, each word written to SSITDR is transmitted to the serial audio bus in the order they are written. When the SSI module acts as a receiver, each word received by the serial audio bus is read in the order received from SSIRDR.

Figure 28A.6 to Figure 28A.8 show how two, three and four channels are transferred to the serial audio bus. Note that there are no padding bits in the first example, the second example is left-aligned and the third is right-aligned. This selection is arbitrary and is just for demonstration purposes only.

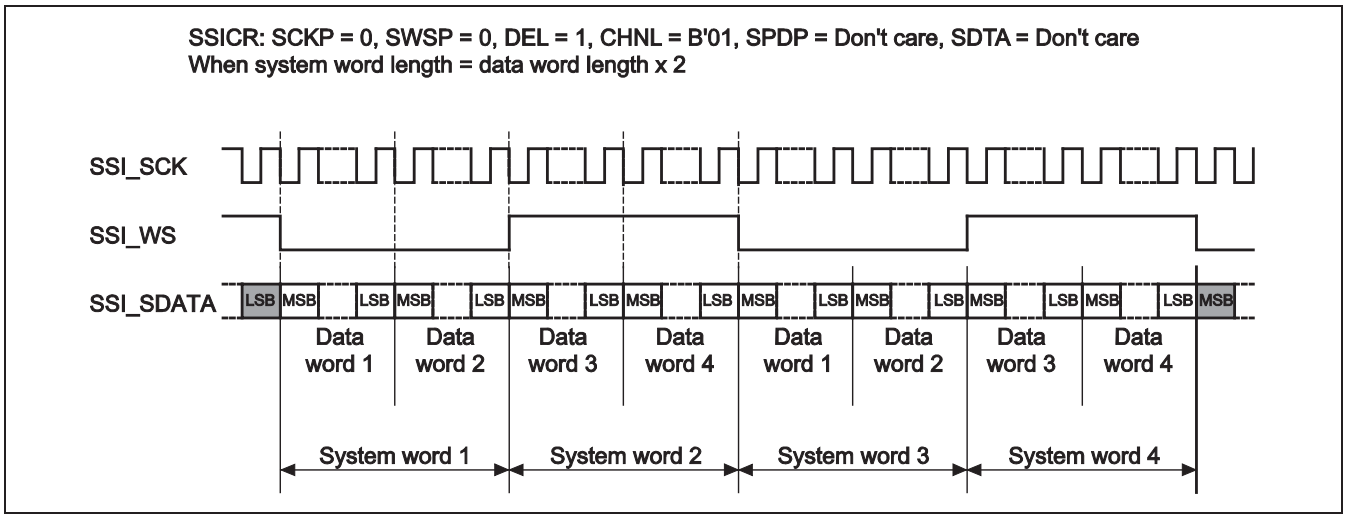

Figure 28A.6 Multi-Channel Format (Two Channels without Padding)

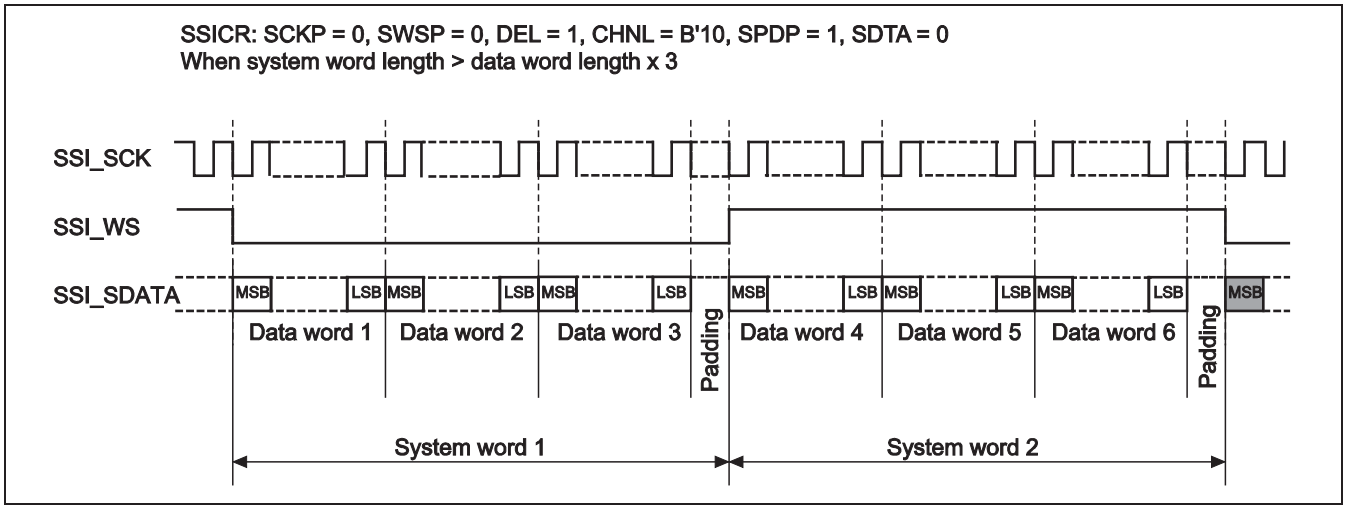

Figure 28A.7 Multi-Channel Format (Three Channels with High Padding)

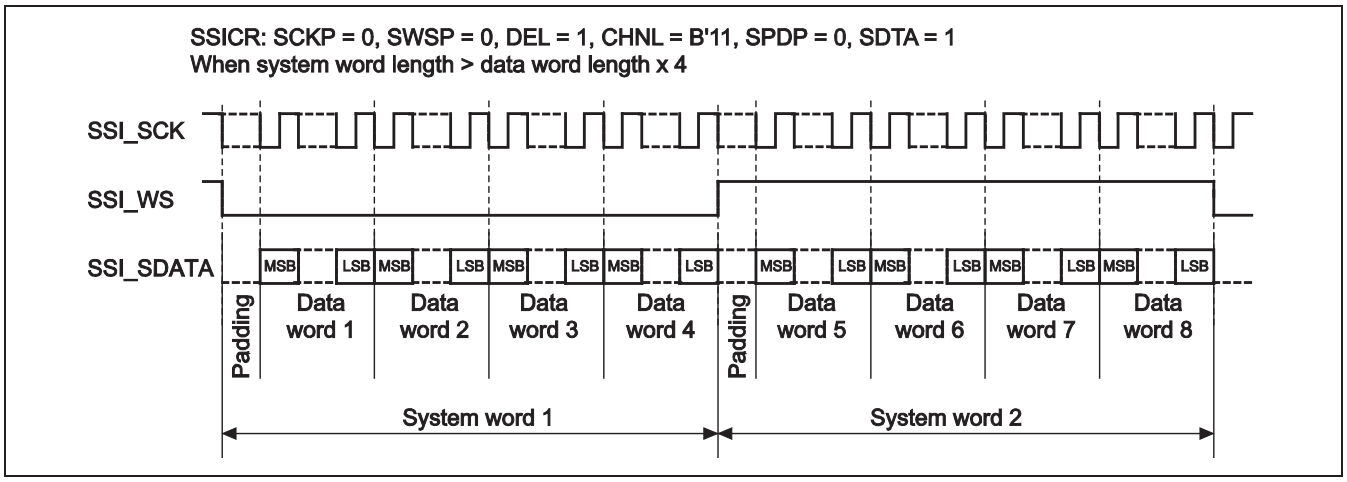

Figure 28A.8 Multi-Channel Format (Four Channels; Transmitting and Receiving in the Order of Padding Bits and Serial Data; with Padding)

(8) TDM formats

The TDM format is used for connecting the SSI with a multi-channel device which supports TDM. The TDM format is set by using the WS_MODE and MONO bits in SSIWSR. When the SWSP bit in SSICR is 0 with the TDM format, SSI_WS is driven high over the period of system word 1, and pulled low otherwise. When the SWSP bit is 1, SSI_WS is pulled low over the period of system word 1, and driven high otherwise. The pulses generated on the SSI_WS signal are referred to as SYNC pulses.

Figure 28A.9 and Figure 28A.10 show the TDM formats without padding and with padding.

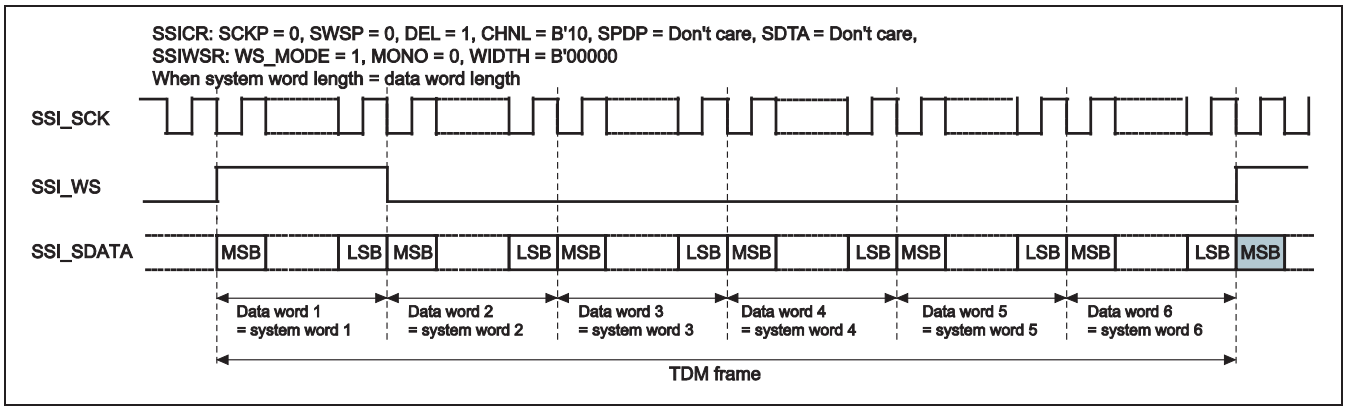

Figure 28A.9 TDM Format (Six System Words, without Padding)

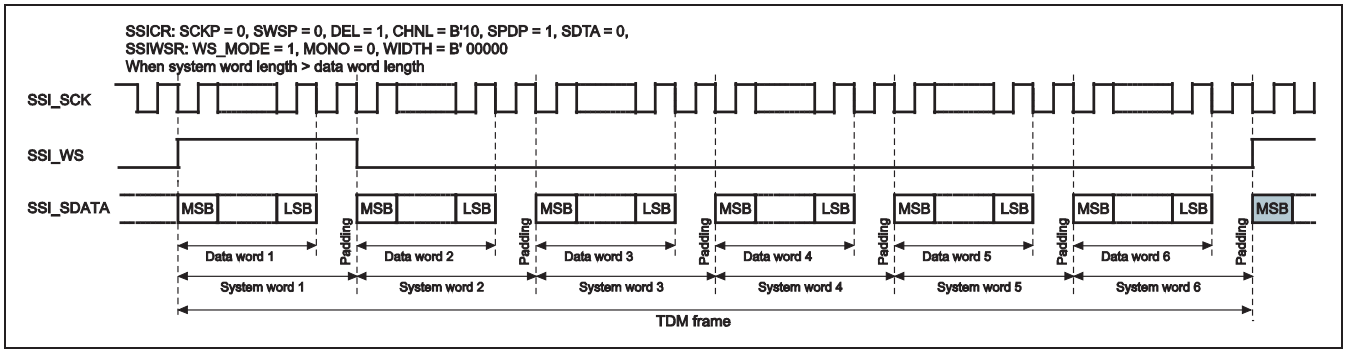

Figure 28A.10 TDM Format (Six System Words, with Padding)

The following describes operation in each mode:

(a) Master transmitter

By a transfer start trigger (setting the EN bit in the control register to 1), a transfer of system word 1 begins synchronously with the SYNC pulses.

By a transfer stop trigger (setting the EN bit in the control register to 0), a transfer is stopped at the end of the currently-transferred system word and the SDATA signal is output according to the SPDP setting in SSICR (when SPDP = 0, a low-level signal is output).

If transmit data is not ready in the SSI module during transmission, an underflow will occur. When an underflow occurs, data to be output for the SYNC pulses cannot be determined. Therefore, stop and reconfigure the transfer.

(b) Master receiver

By a transfer start trigger (setting the EN bit in the control register to 1), a reception of system word 1 data begins at the point where the SSI module recognizes a SYNC pulse.

By a transfer stop trigger (setting the EN bit in the control register to 0), a reception is stopped at the end of the currently-transferred system word.

The receive data register should not be read when it does not have data. If read, an underflow will occur. When an underflow occurs, stop and reconfigure the transfer.

The receive data should not be written to before read. If written to, an overflow will occur. When an overflow occurs, stop and reconfigure the transfer.

(c) Slave transmitter

By a transfer start trigger (setting the EN bit in the control register to 1), a transfer of system word 1 begins synchronously with the SYNC pulses.

By a transfer stop trigger (setting the EN bit in the control register to 0), a transfer is stopped at the end of the currently-transferred system word and the SDATA signal is output according to the SPDP setting in SSICR (when SPDP = 0, a low-level signal is output).

If transmit data is not ready in the SSI module during transmission, an underflow will occur. When an underflow occurs, data to be output for SYNC pulses cannot be determined. Therefore, stop and re-set the transfer.

Transfers cannot be performed if the SCK signal and SYNC pulses are not provided to the SSI module during transfer.

(d) Slave receiver

By a transfer start trigger (setting the EN bit in the control register to 1), a reception of system word 1 data begins at the point where the SSI module recognizes a SYNC pulse.

By a transfer stop trigger (setting the EN bit in the control register to 0), a reception is stopped at the end of the currently-transferred system word.

The receive data should not be read when it does not have data. If read, an underflow will occur. When an underflow occurs, stop and reconfigure the transfer.

The receive data register should not be written to before read. If written to, an overflow will occur. When an overflow occurs, stop and reconfigure the transfer.

Transfer cannot proceed if the SCK signal and SYNC pulses are not being provided to the SSI module during transfer.

(9) Monaural format

The monaural format is set by using the WS_MODE and MONO bits in SSIWSR. The available data lengths are 8 bits and 16 bits. When the SWSP bit in SSICR is 0 and the monaural format is selected, SSI_WS is driven high over the period from bit 1 to bit 31, and pulled low otherwise. When the SWSP bit is 1, SSI_WS is pulled low over the period from bit 1 to bit 31, and driven high otherwise. The pulses generated as the SSI_WS signal are referred to as SYNC pulses. The width of the SYNC pulses can be set to a value in bits between 1 and 31 by using the WIDTH bits in SSIWSR. The setting must be smaller than the system word length (SSICR.SWL). In the monaural format, the system word length is equal to one monaural frame period.

Figure 28A.11 shows the left-aligned monaural format and Figure 28A.12 shows the monaural format with a delay of one bit-period.

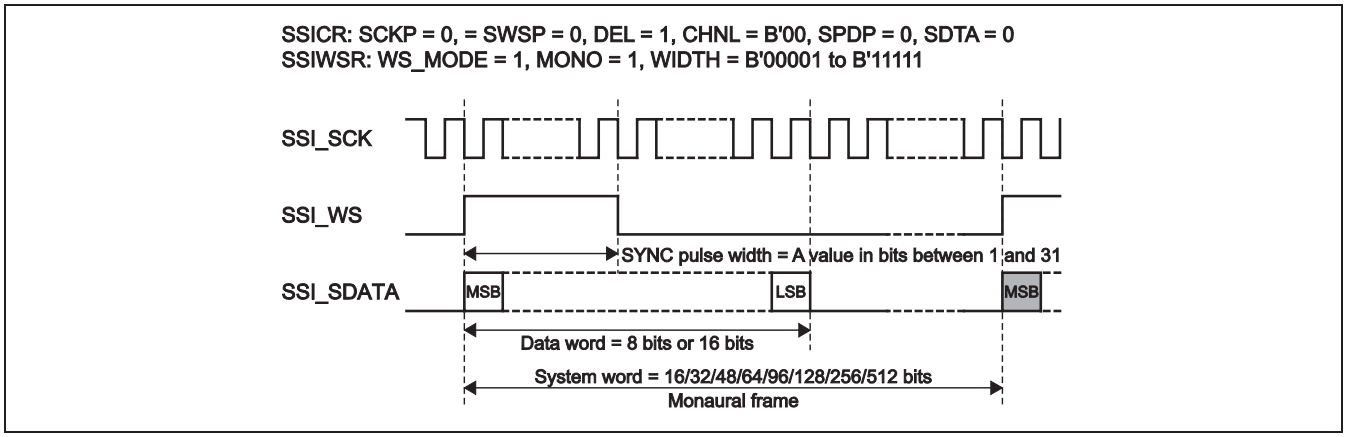

Figure 28A.11 Monaural Format (Left-Aligned)

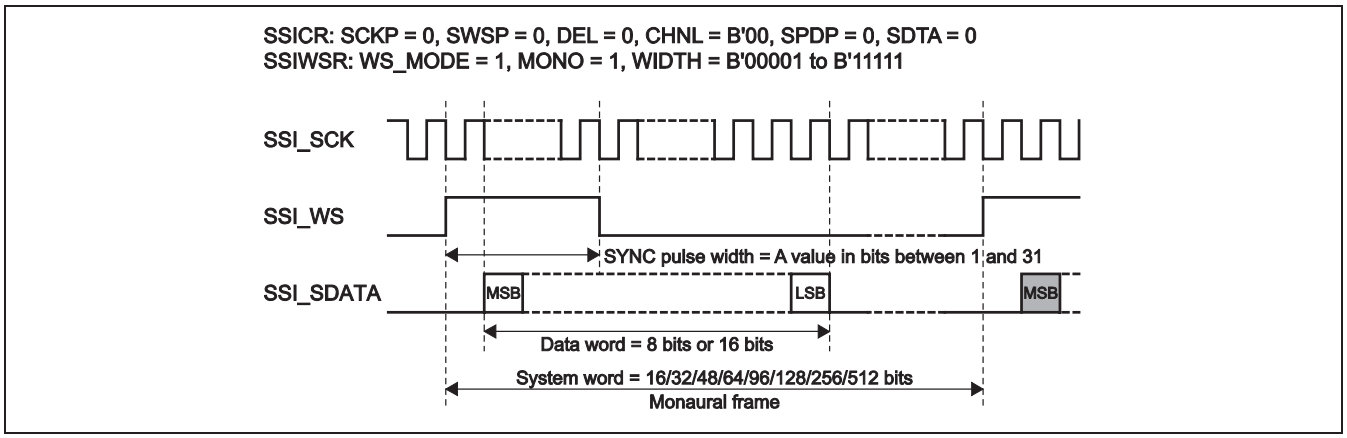

Figure 28A.12 Monaural Format (with 1-bit Delay)

(10) Configuration bits

Several more configuration bits are shown below. These bits are not mutually exclusive, but some combinations may not be useful for any other device.

These configuration bits are described below with reference to Figure 28A.13, Basic Sample Format.

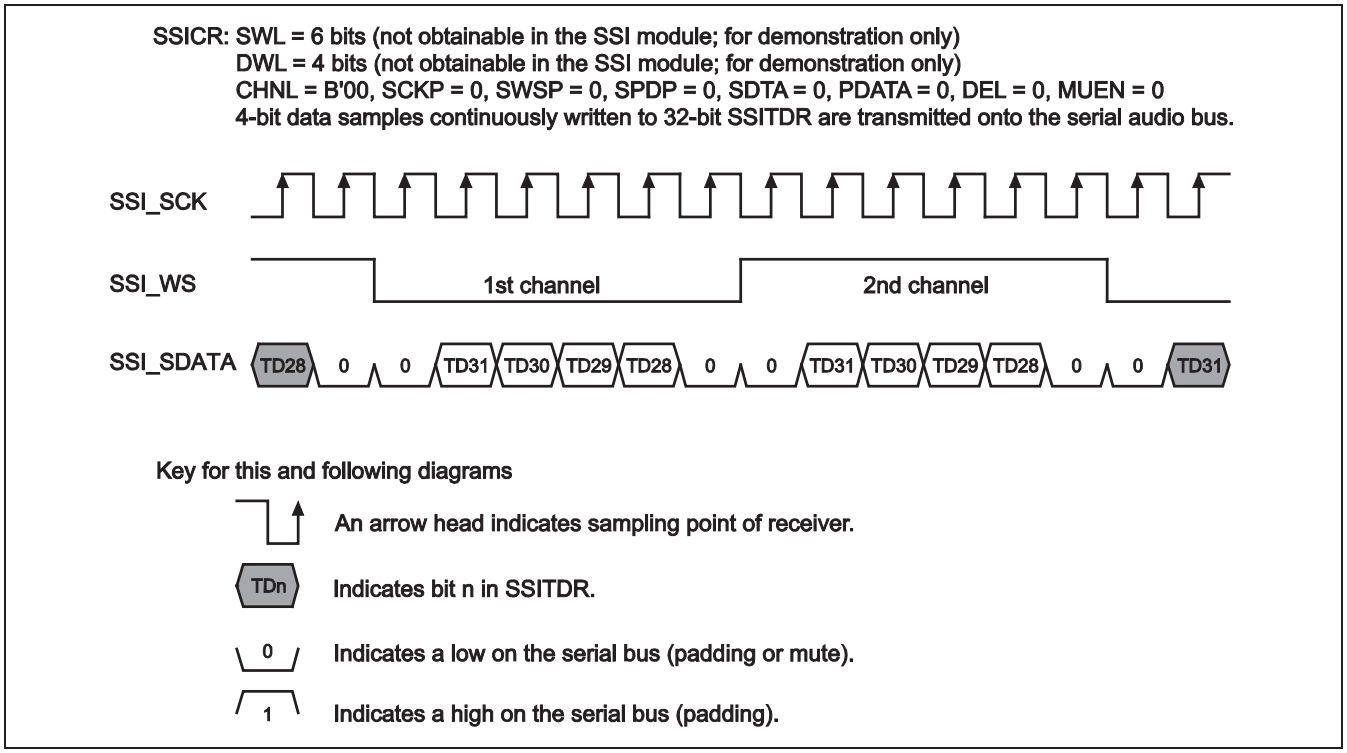

Figure 28A.13 Basic Sample Format (Transmit Mode with Example System/Data Word Length)

Figure 28A.13 uses a system word length of 6 bits and a data word length of 4 bits. These settings are not possible with the SSI module but are used only for clarification of the other configuration bits.

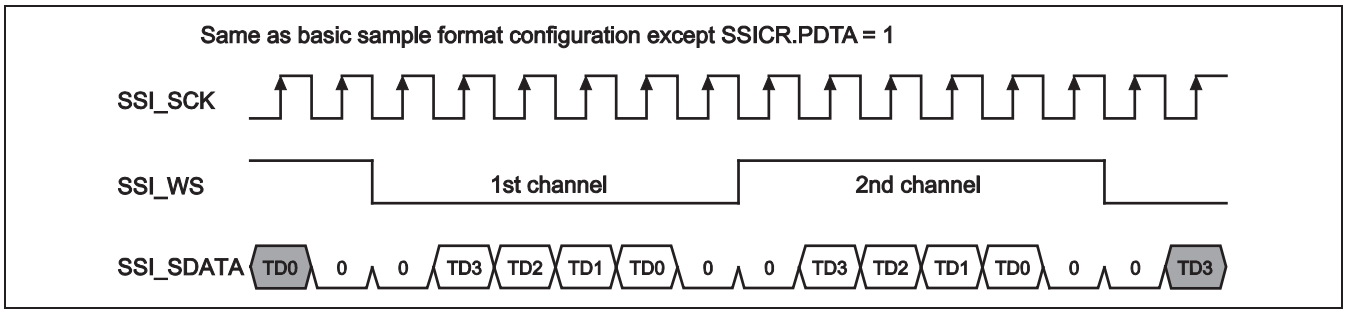

Figure 28A.20 Parallel Right-Aligned with Delay

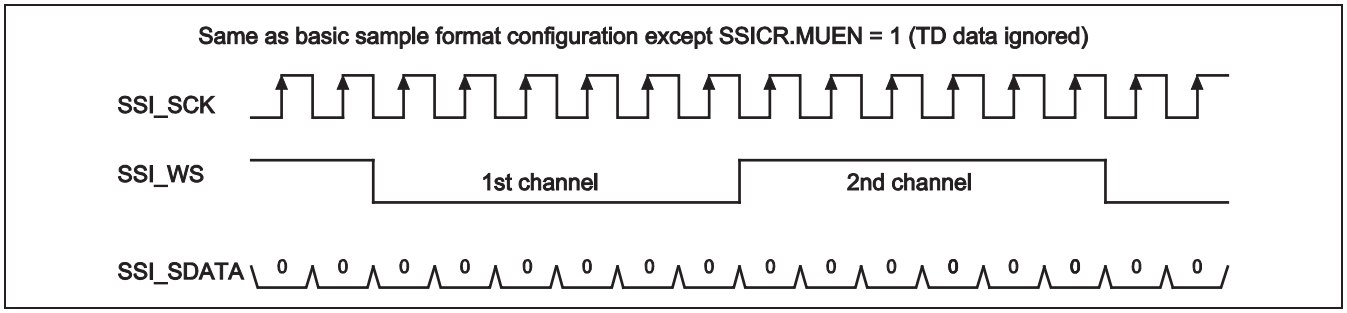

Figure 28A.21 Mute Enabled

(11) WS continue function

The WS continue function is used to output SSI_WS signal continuously regardless of whether data transfer is enabled or disabled. The WS continue function can be set by using the CONT bit in SSIWSR. This function can be combined with master mode only. When this function is enabled, the SSI_WS signal continues to operate even if the EN bit in SSICR is cleared to 0 (stopping a transfer). When this function is disabled, the SSI_WS signal operates synchronously with the EN bit.

Figure 28A.22 and Figure 28A.23 show operations when the WS continue function is enabled and disabled, respectively.

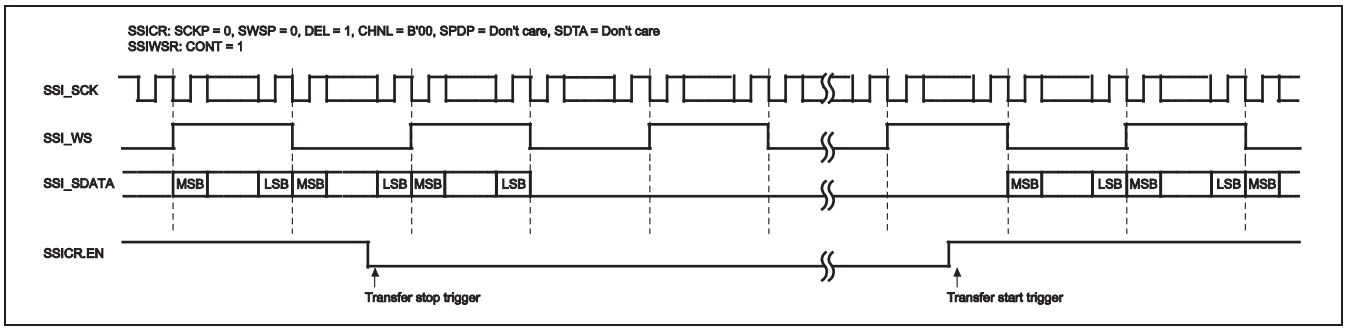

Figure 28A.22 WS Continue Function Operation (When the Function is Enabled)

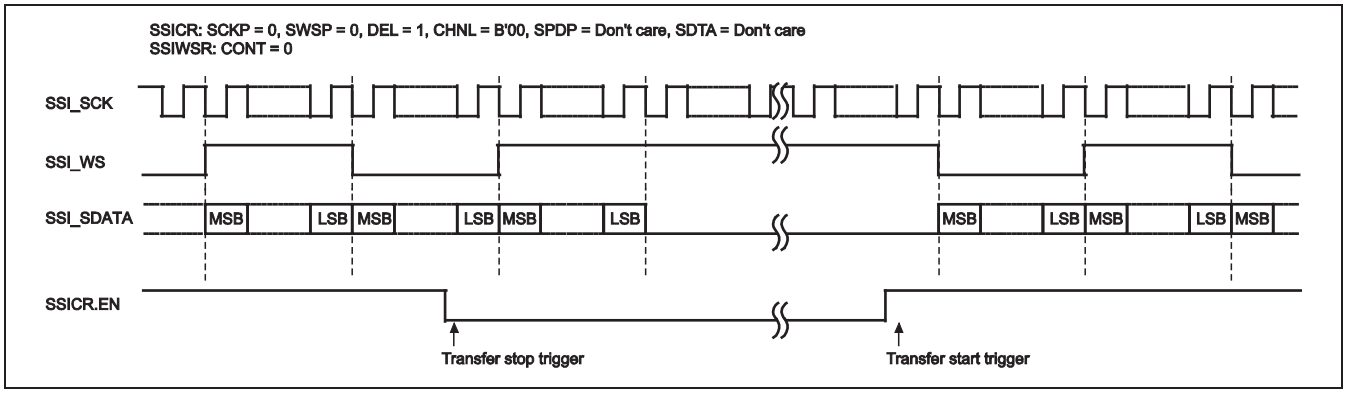

Figure 28A.23 WS Continue Function Operation (When the Function is Disabled)

(12) Bit alignment in transferred data

Figure 28A.24 to Figure 28A.36 show the bit alignment in transmit or receive data. Only the MSB first alignment is available. The waveforms in Figure 28A.24 to Figure 28A.36 are setting examples without delay (SSICR.DEL is set to 1, the number of bits specified with SSICR.DWL is the same as that specified with SSICR.SWL).

28A.3.2 Operating Modes

There are three modes of operation: configuration, module enabled and module disabled. Figure 28A.37 shows how the module enters each of these modes.

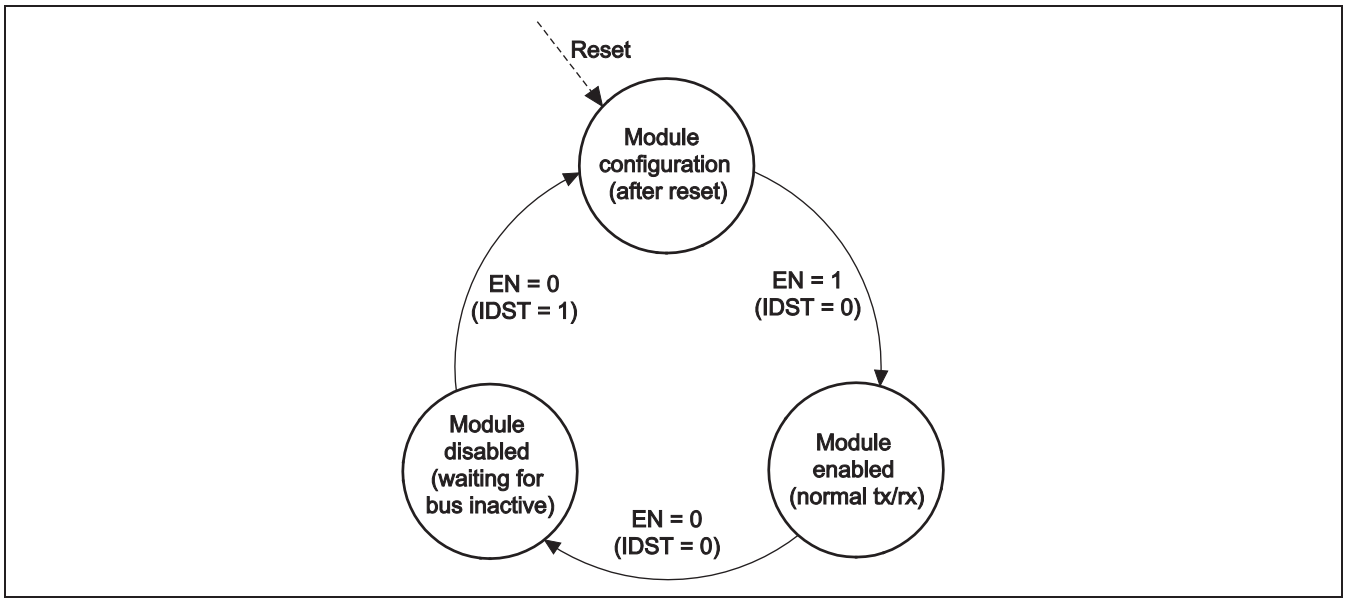

Figure 28A.37 Operating Modes

(1) Configuration mode

This mode is entered after the module is released from reset. All required configuration fields in the control register should be defined in this mode, before the SSI module is enabled by setting the EN bit.

Setting the EN bit causes the module to enter the module enabled mode.

(2) Module enabled mode

Operation of the module in this mode is dependent on the operating mode selected. For details, refer to Section 28A.3.3 Transmit Operation and Section 28A.3.4, Receive Operation, below.

28A.3.3 Transmit Operation

Transmission can be controlled either by DMA or interrupt.

DMA control is preferred to reduce the processor load. In DMA control mode, the processor will only receive interrupts if there is an underflow or overflow of data or the DMAC has finished its transfer.

The alternative method is using the interrupts that the SSI module generates to supply data as required. This mode has a higher interrupt load as the module is only double buffered and will require data to be written at least every system word period.

When disabling the module, the SSI clock* must remain present until the SSI module is in idle state, indicated by the SSISR.IIRQ bit.

Figure 28A.38 shows the transmit operation in DMA control mode, and Figure 28A.39 shows the transmit operation in interrupt control mode.

Note: * Input clock from the SSI_SCK pin when SCKD = 0.
Input clock from the CLK_FS pin when SCKD = 1.

Use the flowcharts in Figure 28A.38 and Figure 28A.39 when bits ind9 to ind0, which are covered in the description of SSI Mode Register 0 (SSI_MODE0) in Section 28, Serial Sound Interface Unit (SSIU), are set to 1 (independent SSI transfer).

(1) Transmission using DMA controller

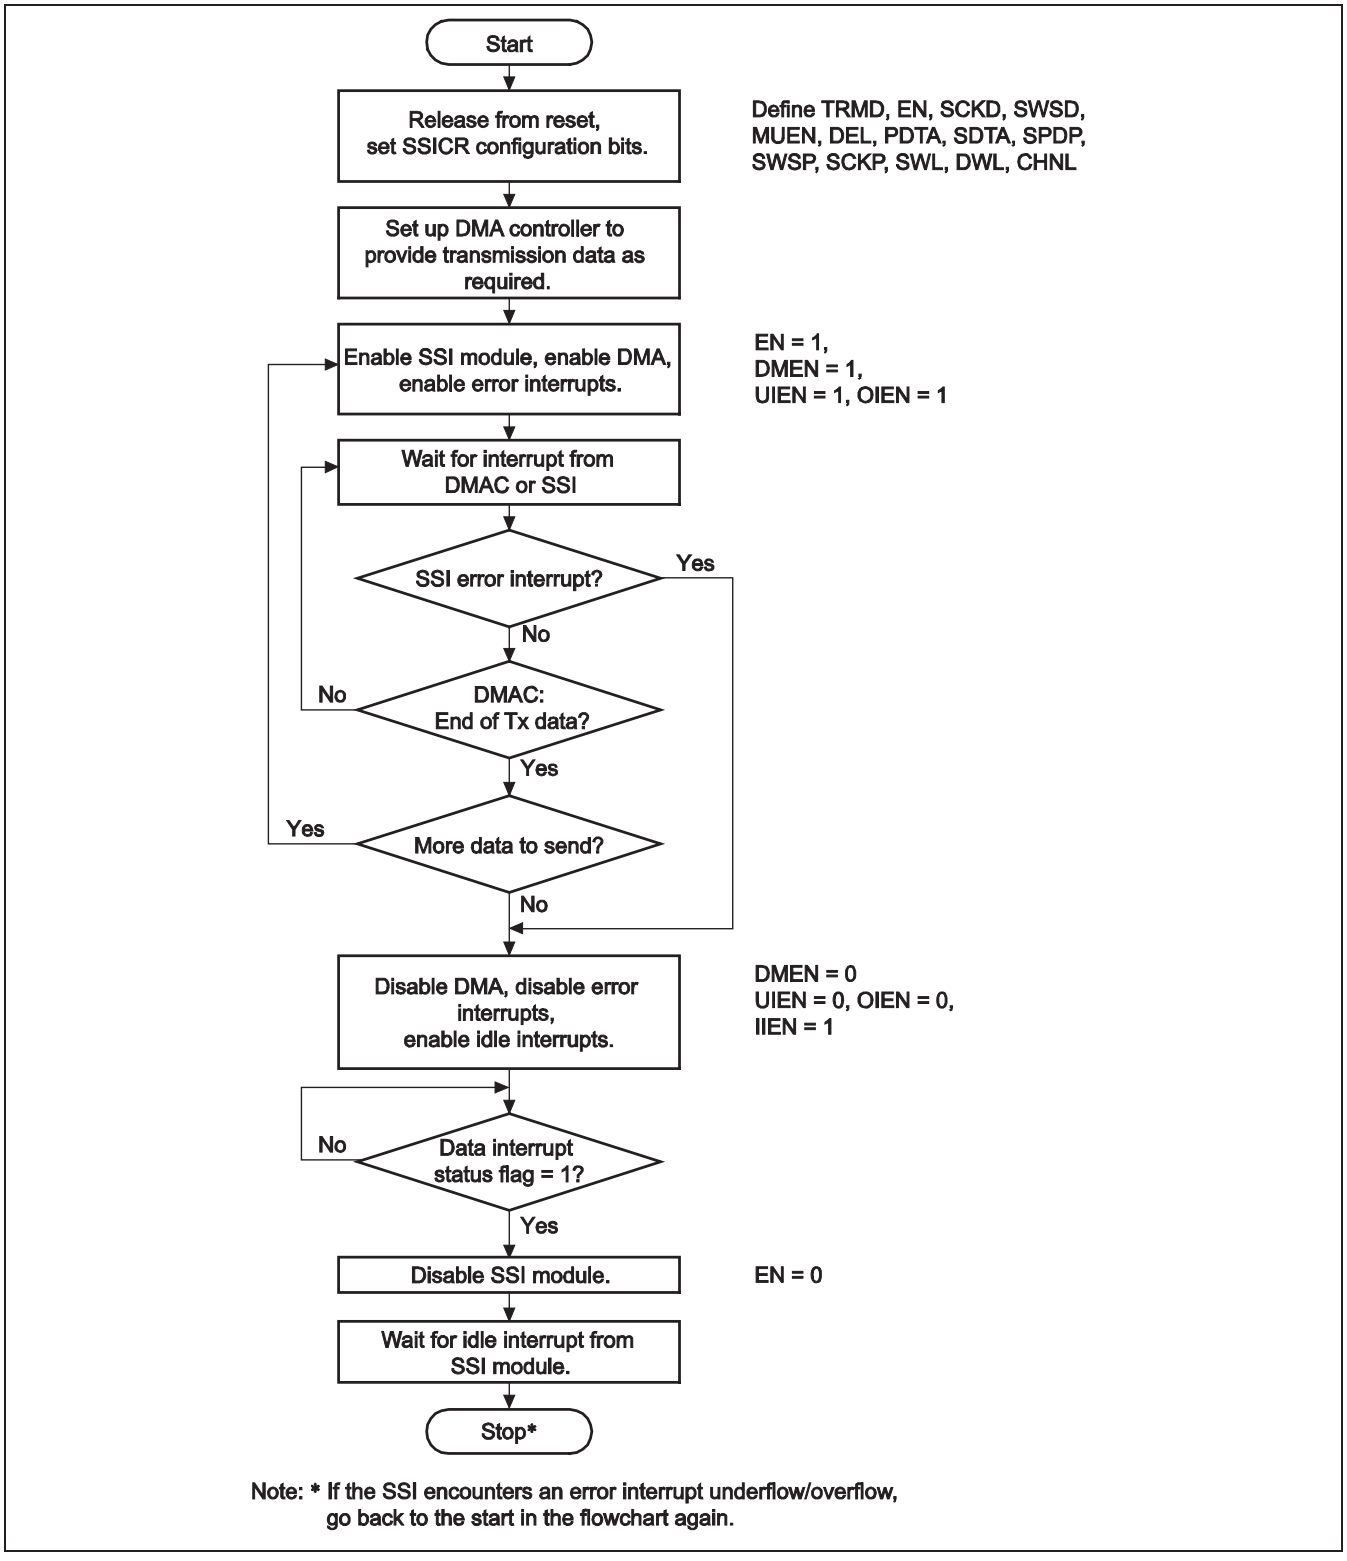

Figure 28A.38 Transmission Using DMA Controller

(2) Transmission using interrupt data flow control

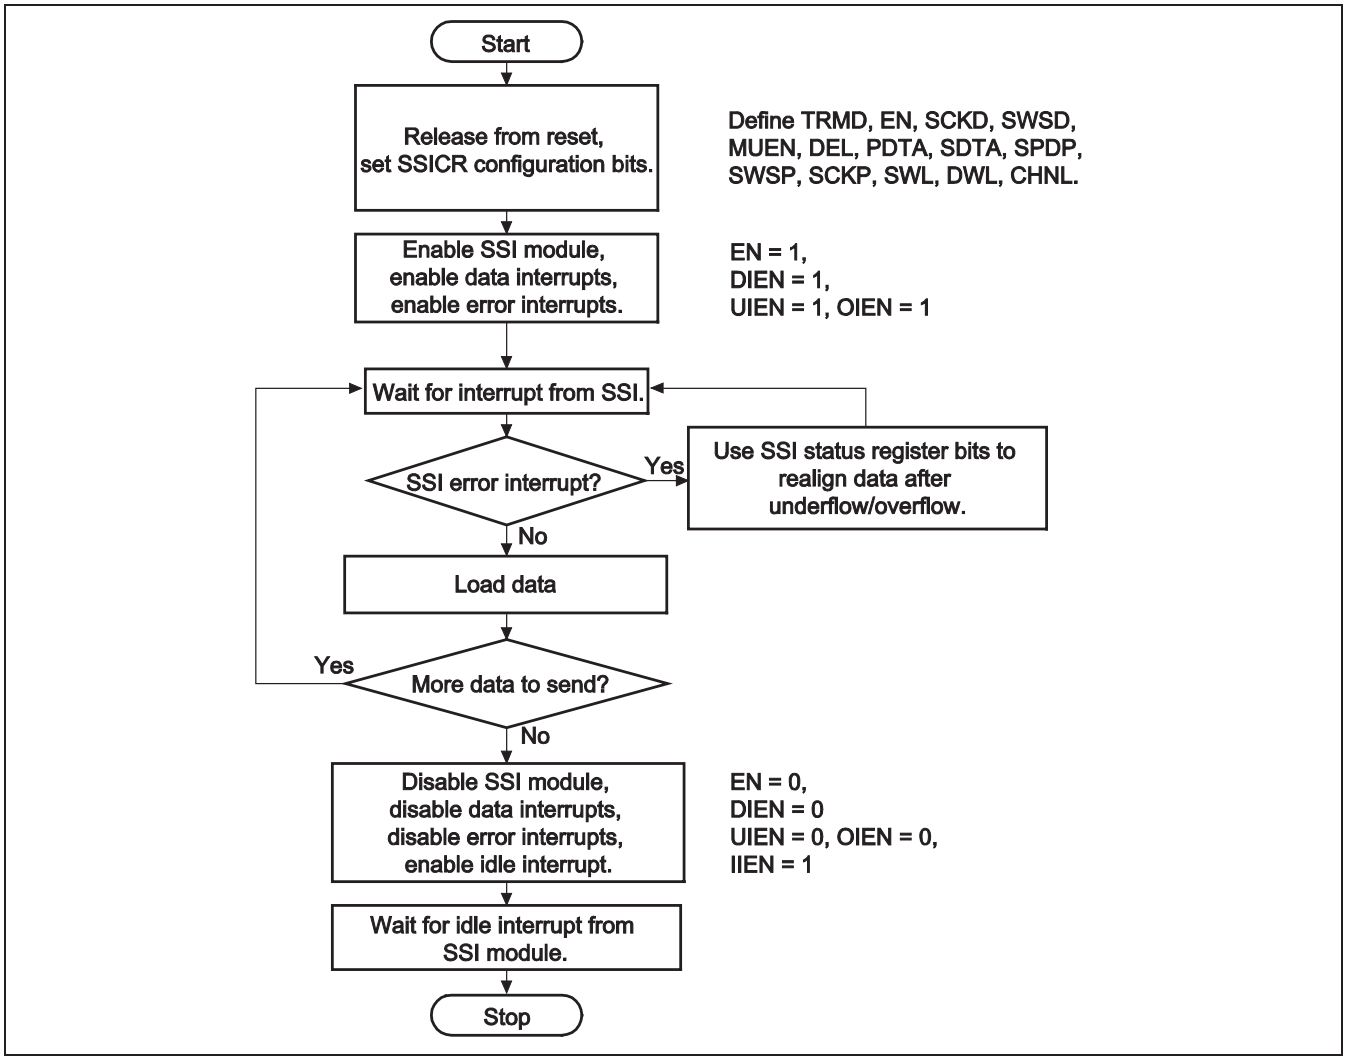

Figure 28A.39 Transmission Using Interrupt Data Flow Control

28A.3.4 Receive Operation

Like transmission, reception can be controlled either by DMA or interrupt.

Figure 28A.40 and Figure 28A.41 show the flow of operation.

When disabling the SSI module, the SSI clock* must be kept supplied until the SSISR.IIRQ bit is in idle state.

Note: * Input clock from the SSI_SCK pin when SCKD = 0.
Input clock from the CLK_FS pin when SCKD = 1.

Use the flowcharts in Figure 28A.40 and Figure 28A.41 when bits ind9 to ind0, which are covered in the description of SSI Mode Register 0 (SSI_MODE0) in Section 28, Serial Sound Interface Unit (SSIU), are set to 1 (independent SSI transfer).

(1) Reception using DMA controller

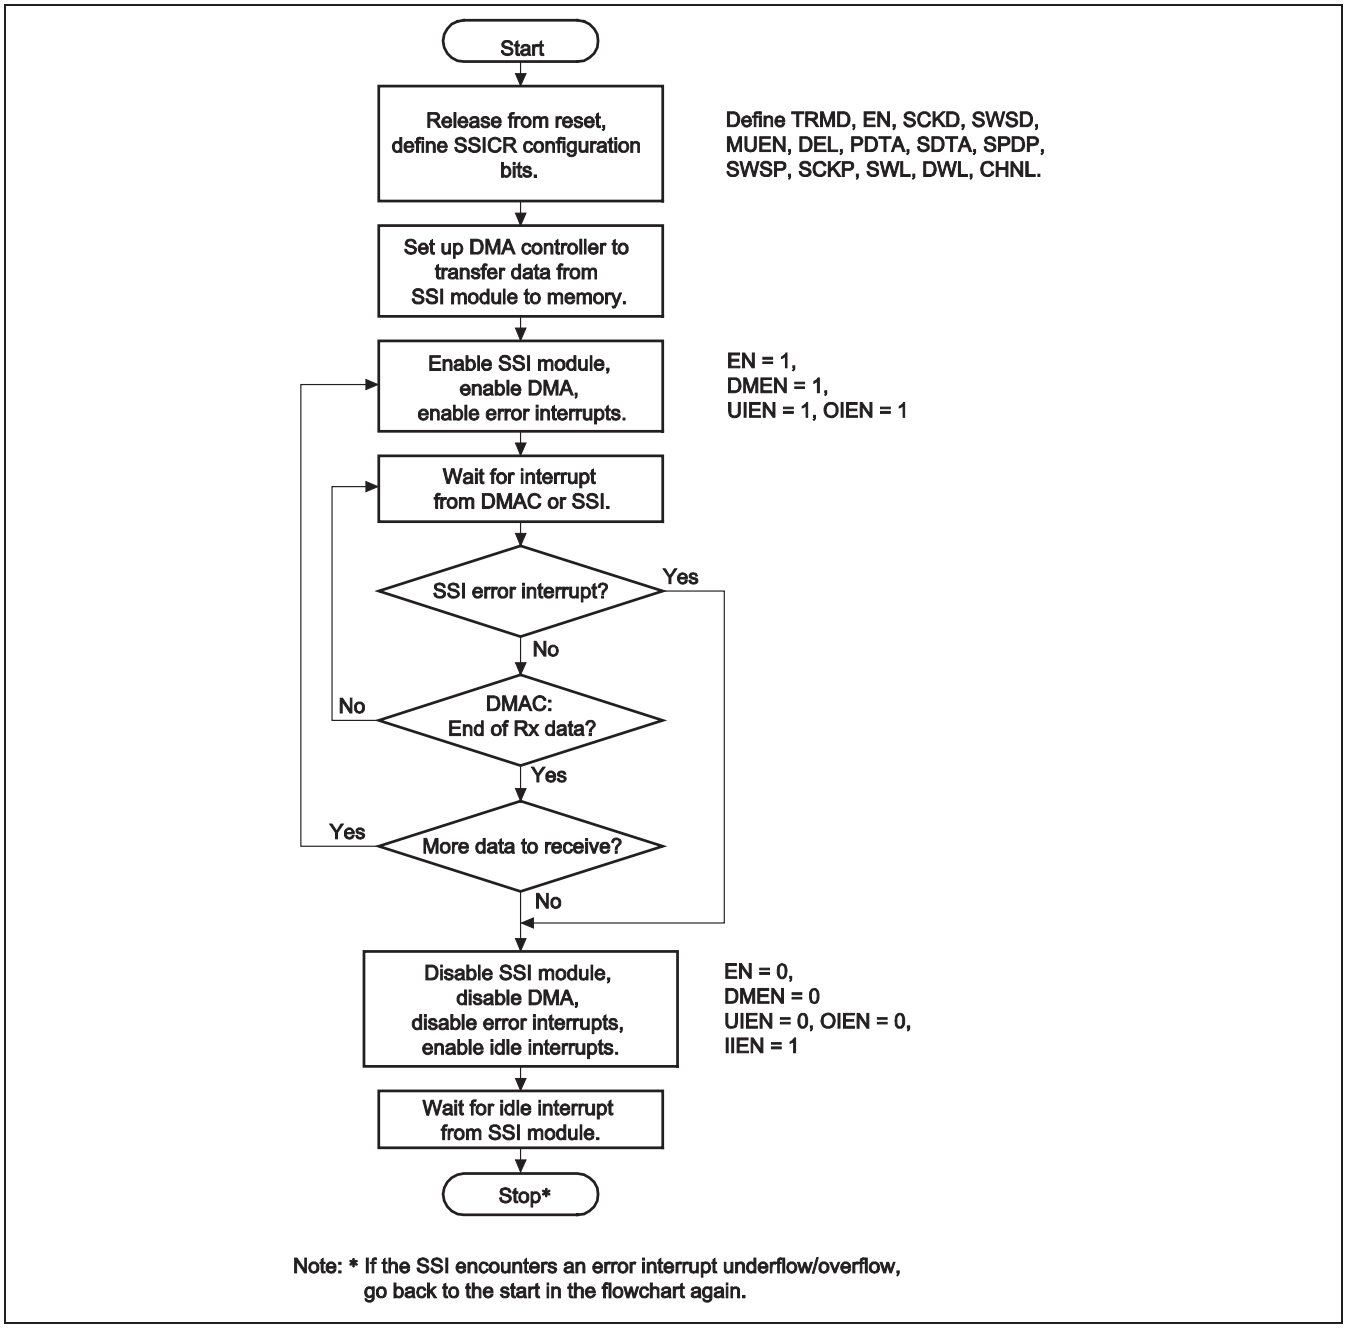

Figure 28A.40 Reception Using DMA Controller

(2) Reception using interrupt data flow control

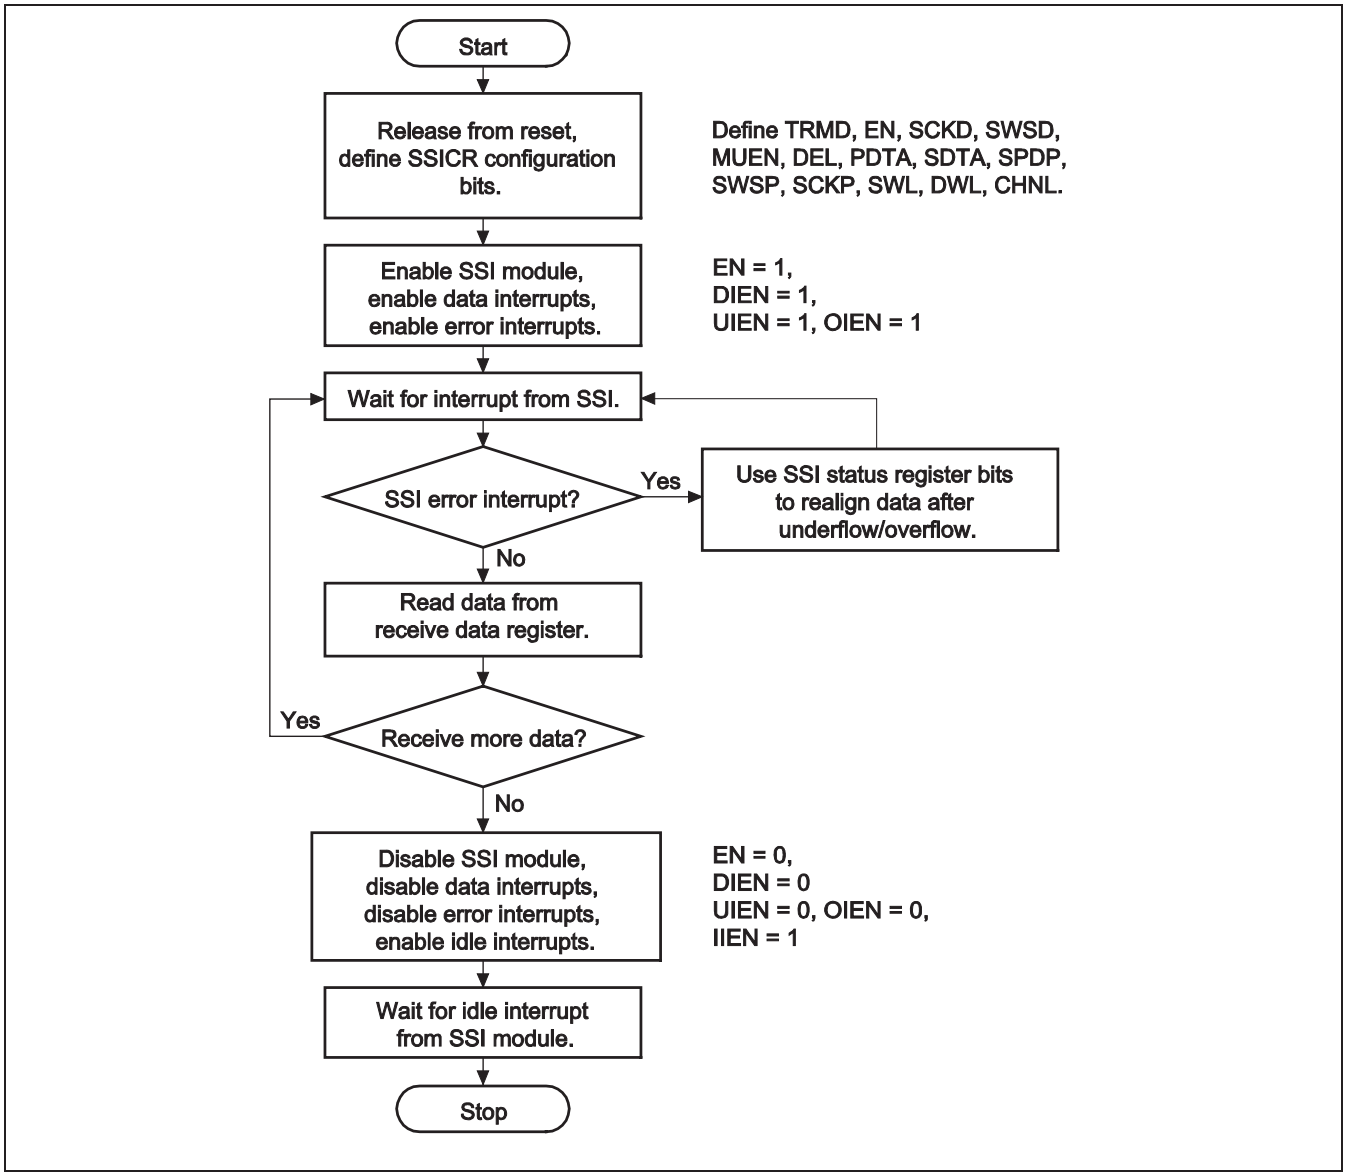

Figure 28A.41 Reception Using Interrupt Data Flow Control

28A.3.5 Serial Bit Clock Control

This function is used to control and select which clock is used for the serial bus interface.

If the serial clock direction is set to input (SSICR.SCKD = 0), the SSI module is in clock slave mode and the shift register uses the bit clock that was input to the SSI_SCK pin.

If the serial clock direction is set to output (SSICR.SCKD = 1), the SSI module is in clock master mode, and the shift register uses the bit clock that is input from the CLK_FS pin or the bit clock that is obtained by dividing the input from the CLK_FS pin. In the latter case, the clock input from the CLK_FS pin is divided by the ratio in the serial oversampling clock divide ratio (CKDV) in SSICR and used as the bit clock in the shift register.

In either case, the SSI_SCK pin output is the same as the bit clock.

28A.4 Usage Notes

28A.4.1 Limitations from Overflow during Receive DMA Operation

If an overflow occurs while the receive DMA is in operation, the module should be restarted. The receive buffer in the SSI consists of 32-bit registers that share the L and R channels. Therefore, data to be received at the L channel may sometimes be received at the R channel if an overflow occurs, for example, under the following condition: the control register (SSICR) has a 32-bit setting for both data word length (DWL2 to DWL0) and system word length (SWL2 to SWL).

If an overflow is confirmed with the overflow error interrupt or overflow error status flag (SSISR. OIRQ), write 0 to the EN and DMEN bits in SSICR to disable DMA in the SSI module, thus stopping the operation (In this case, the controller setting should also be stopped). After this, write 0 to the OIRQ bit in SSISR to clear the overflow status, set DMA again and restart the transfer.

28A.4.2 Limitations on Combinations of Modes Related to Common Pins to SSI7 and SSI8

Table 28A.5 shows the available combinations of operating modes for SSI7 and SSI8. Operating modes can be set with the control registers for the SSI7 and SSI8 (SSICR).

Table 28A.5 Usable Operating Mode Combinations for SSI7 and SSI8

	Operating Mode		Operating Mode of External Device		
No.	SSI7	SSI8	SSI7 Side	SSI8 Side	Function
1	Slave	Slave	Master	Slave	SSI7 and SSI8 operate synchronously with SSI_WS78_A/B and SSI_SCK78_A/B input.
			Slave	Master	
			Slave	Slave	
2	Master	Slave	Slave	Slave	SSI8 and an external device operate synchronously with WS and SCK of SSI7.
3	Slave	Master	—	—	Setting prohibited
4	Master	Master	—	—	Setting prohibited

There are the following limitations on the operating mode combinations shown in Table 28A.5.

For No. 1, SSI_WS78_A/B and SSI_SCK78_A/B should be input before either of SSI7 or SSI8 starts data transfer.

For No. 2, the SSI7 as the master should start transfer first thus allowing SSI_WS78_A/B and SSI_SCK78_A/B to be output, and then the SSI8 as the slave should be used. If the master-side transfer is stopped with the CONT bit in SSIWSR being 0, the slave-side SSI8 should be stopped because SSI_WS78_A/B is not output.

28A.4.3 Limitations on Slave Mode Operation

When this LSI is used in slave mode, in ending a data transfer process, data transfer on this LSI should be stopped (SSICR.EN = 0) before the input word selection signal (SSI_WS) is stopped.

In slave mode, data transfer is stopped by clearing the EN bit in SSICR (setting to stop transfer) and detecting the falling edge of the word selection signal (SSI_WS). If the input word selection signal is stopped first, the falling edge of the word selection signal cannot be detected and data transfer cannot be ended successfully.

28A.4.4 Limitations on Changes to Settings

The SSI_SCK and SSI_WS signals are not guaranteed immediately after changes of the WS mode bit in the WS Mode Register (SSIWSR) and configuration bits in the control register (SSICR). Settings must not be changed dynamically if this would affect any connected device.

28A.4.5 Stopping or Resuming Transmission

Follow the procedure below to stop or resume transmission.

Stopping transmission:

1. Set the DMEN bit in SSICR to 0 for stopping transmission.
2. Wait for SSISR.DIRQ = 1 by using polling or interrupts.
3. Set the EN bit in SSICR to 0 to stop transmission.
4. Check that SSISR.IDST is 1.

Resuming transmission:

Set DMEN and EN bits in SSICR to 1 for resuming transmission (The DMEN bit should be set to 1 at the same time of or before the EN bit).

29. Audio Clock Generator (ADG)

29.1 Overview

The audio clock generator (ADG) selects and supplies the necessary clock for the SSI or SCU module. It also divides the frequency of the selected clock and sends it outside the chip.

29.1.1 Features

- Selects the clock signal from the AUDIO_CLKA, AUDIO_CLKB or AUDIO_CLKC pin or the internal clock and supplies it to the SSI or SCU module.
- The frequency of the clock signals from the AUDIO_CLKA, AUDIO_CLKB or AUDIO_CLKC pins and the internal clock can be divided before use.
- The divided clock can be output through the AUDIO_CLKOUT pin.

29.1.2 Block Diagram

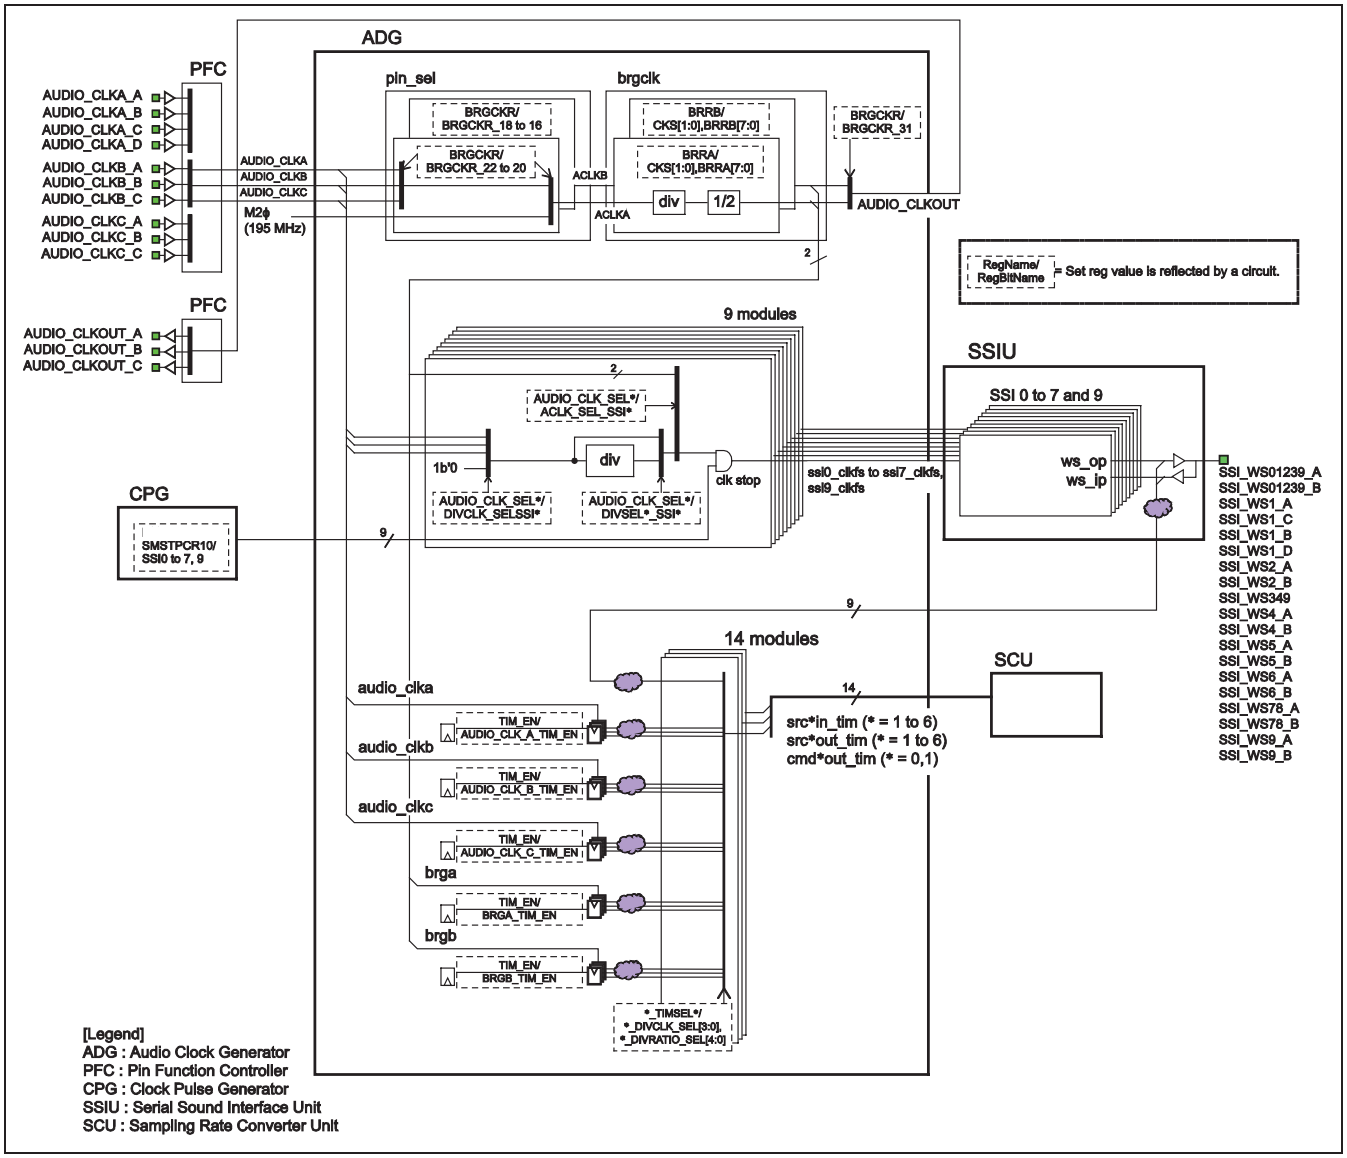

Figure 29.1 Block Diagram

29.1.3 Input/Output Pins

Table 29.1 Pin Configuration

Pin Name	I/O	Function
AUDIO_CLKA_A	Input	AUDIO CLOCK A
AUDIO_CLKA_B	Input	AUDIO CLOCK A
AUDIO_CLKA_C	Input	AUDIO CLOCK A
AUDIO_CLKA_D	Input	AUDIO CLOCK A

Note: * Some restrictions apply.

29.2 Register Descriptions

[Legend for Register Description]

Initial value: Register value after a reset.

—: Undefined value

R/W: Bit or field is readable and writable. The written value can be read.

All registers are accessed in longword units.

29.2.1 BRGA Baud Rate Setting Register (BRRA)

Function: BRRA is a 32-bit readable/writable register that specifies the baud rate for ACLK_A (see Table 29.3).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	CKS[1:0]		BRRA[7:0]							
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved The initial value is always read from these bits. The write value should always be the initial value.
9, 8	CKS[1:0]	B'00	R/W	These bits specify the clock source for the on-chip baud rate generator. 00: ACLK_A 01: ACLK_A/4 10: ACLK_A/16 11: ACLK_A/64
7 to 0	BRRA[7:0]	H'FF	R/W	These bits specify the division ratio. For details, see Table 29.3.

Table 29.3 Division Ratio for BRGA

BRGA Operating Clock (CKS[1], CKS[0])	Division Ratio BRRA (N = 0 to 255)	Calculating Formula
ACLK_A	1/2, 1/4, 1/6, ..., 1/512	1 / (2(N + 1))
ACLK_A/4	1/8, 1/16, 1/24, ..., 1/2048	1 / (8(N + 1))
ACLK_A/16	1/32, 1/64, 1/96, ..., 1/8192	1 / (32(N + 1))
ACLK_A/64	1/128, 1/256, 1/384, ..., 1/32768	1 / (128(N + 1))

Note: Use the output of BRGA in less than 25 MHz.

29.2.2 BRGB Baud Rate Setting Register (BRRB)

Function: BRRB is a 32-bit readable/writable register that specifies the baud rate for ACLK_B (see Table 29.4).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	CKS[1:0]		BRRB[7:0]							
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved The initial value is always read from these bits. The write value should always be the initial value.
9, 8	CKS[1:0]	B'00	R/W	These bits specify the clock source for the on-chip baud rate generator. 00: ACLK_B 01: ACLK_B/4 10: ACLK_B/16 11: ACLK_B/64
7 to 0	BRRB[7:0]	H'FF	R/W	These bits specify the division ratio. For details, see Table 29.4.

Table 29.4 Division Ratio for BRGB

BRGB Operating Clock (CKS[1], CKS[0])	Division Ratio BRRB (N = 0 to 255)	Calculating Formula
ACLK_B	1/2, 1/4, 1/6, ..., 1/512	1 / (2(N + 1))
ACLK_B/4	1/8, 1/16, 1/24, ..., 1/2048	1 / (8(N + 1))
ACLK_B/16	1/32, 1/64, 1/96, ..., 1/8192	1 / (32(N + 1))
ACLK_B/64	1/128, 1/256, 1/384, ..., 1/32768	1 / (128(N + 1))

Note: Use the output of BRGB in less than 25 MHz.

29.2.3 BRG Clock Select Register (BRGCKR)

Function: BRGCKR selects the clocks input to and output from the ADG.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BRGCKR_31	—	—	—	—	—	—	—	—	BRGCKR_22	BRGCKR_21	BRGCKR_20	—	BRGCKR_18	BRGCKR_17	BRGCKR_16
Initial value:	0	0	1	0	0	0	1	1	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	BRGCKR_31	B'0	R/W	This bit selects the clock signal output to the AUDIO_CLKOUT_A, AUDIO_CLKOUT_B or AUDIO_CLKOUT_C external pin. 0: BRGA output clock 1: BRGB output clock
30 to 23	—	H'46	R	Reserved The initial value is always read from these bits. The write value should always be the initial value.
22 21 20	BRGCKR_22 BRGCKR_21 BRGCKR_20	B'0 B'0 B'0	R/W	These bits select the clock signal input to the BRGA. 000: AUDIO_CLKA 001: AUDIO_CLKB 01x: M2ϕ (195 MHz) 100: AUDIO_CLKC 101: Fixed at 0 11x: Fixed at 0 x = Don't care
19	—	B'0	R	Reserved The initial value is always read from this bit. The write value should always be the initial value.
18 17 16	BRGCKR_18 BRGCKR_17 BRGCKR_16	B'0 B'0 B'0	R/W	These bits select the clock signal input to the BRGB. 000: AUDIO_CLKA 001: AUDIO_CLKB 01x: M2ϕ (195 MHz) 100: AUDIO_CLKC 101: Fixed at 0 11x: Fixed at 0 x = Don't care
15 to 0	—	All 0	R	Reserved The initial value is always read from these bits. The write value should always be the initial value.

29.2.4 Audio Clock Select Register 0 (AUDIO_CLK_SEL0)

Function: AUDIO_CLK_SEL0 selects the clocks for the SSIU (for SSI0 to SSI3).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DIVSEL_SSI3 [1:0]		ACLK_SEL _SSI3[1:0]		DIVSEL 2_SSI3	DIVCLK_SEL_SSI3 [2:0]			DIVSEL_SSI2 [1:0]		ACLK_SEL _SSI2[1:0]		DIVSEL 2_SSI2	DIVCLK_SEL_SSI2 [2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DIVSEL_SSI1 [1:0]		ACLK_SEL _SSI1[1:0]		DIVSEL 2_SSI1	DIVCLK_SEL_SSI1 [2:0]			DIVSEL_SSI0 [1:0]		ACLK_SEL _SSI0[1:0]		DIVSEL 2_SSI0	DIVCLK_SEL_SSI0 [2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31, 30	DIVSEL_SSI3[1:0]	B'00	R/W	SSI3 Frequency Divider Select

2 to 0	DIVCLK_SEL_SSI4 [2:0]	B'000	R/W	SSI4 Clock Select 000: Fixed at 0 001: AUDIO_CLKA 010: AUDIO_CLKB 011: AUDIO_CLKC Others: Setting Prohibited

29.2.6 Audio Clock Select Register 2 (AUDIO_CLK_SEL2)

Function: AUDIO_CLK_SEL2 selects the clocks for the SSIU (for SSI9).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DIVSEL_SSI9 [1:0]		ACLK_SEL _SSI9[1:0]		DIVSEL 2_SSI9	DIVCLK_SEL_SSI9 [2:0]			—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved The initial value is always read from these bits. The write value should always be the initial value.
15, 14 11	DIVSEL_SSI9[1:0] DIVSEL2_SSI9	B'00 B'0	R/W R/W	SSI9 Frequency Divider Select [11], [15:14] 000: Not divided 001: Divided by 2 010: Divided by 4 011: Divided by 8 100: Divided by 16 101: Divided by 32 110, 111: Fixed at 0
13, 12	ACLK_SEL_SSI9[1:0]	B'00	R/W	SSI9 Clock Select 00: DIVCLK 01: BRGA output clock 10: BRGB output clock 11: Setting prohibited
10 to 8	DIVCLK_SEL_SSI9[2:0]	B'000	R/W	SSI9 Clock Select 000: Fixed at 0 001: AUDIO_CLKA 010: AUDIO_CLKB 011: AUDIO_CLKC Others: Setting Prohibited
7 to 0	—	All 0	R	Reserved The initial value is always read from these bits. The write value should always be the initial value.

29.2.7 Timing Signal Enable Register (TIM_EN)

Function: TIM_EN is enabling of the Timing Signal supplied to SCU.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	BRGB_TIM_EN	BRGA_TIM_EN	AUDIO_CLKC_TIM_EN	AUDIO_CLKB_TIM_EN	AUDIO_CLKA_TIM_EN	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	—	All 0	R	Reserved The initial value is always read from this bit. The write value should always be the initial value.
5	BRGB_TIM_EN	B'0	R/W	This bit is enabling of the Timing Signal generated from the BRGB frequency divider. 0: Disables timing signal. 1: Enables timing signal.
4	BRGA_TIM_EN	B'0	R/W	This bit is enabling of the Timing Signal generated from the BRGA frequency divider. 0: Disables timing signal. 1: Enables timing signal.
3	AUDIO_CLKC_TIM_EN	B'0	R/W	This bit is enabling of the Timing Signal generated from the AUDIO_CLKC frequency divider. 0: Disables timing signal. 1: Enables timing signal.
2	AUDIO_CLKB_TIM_EN	B'0	R/W	This bit is enabling of the Timing Signal generated from the AUDIO_CLKB frequency divider. 0: Disables timing signal. 1: Enables timing signal.
1	AUDIO_CLKA_TIM_EN	B'0	R/W	This bit is enabling of the Timing Signal generated from the AUDIO_CLKA frequency divider. 0: Disables timing signal. 1: Enables timing signal.
0	—	B'0	R/W	Reserved The write value should always be the initial value.

29.2.8 SRC Input Timing Select Register 0 (SRCIN_TIMSEL0)

Function: SRCIN_TIMSEL0 selects the input timing signals for SRC1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	SRC1_IN_DIVCLK_SEL[3:0]				—	—	—	SRC1_IN_DIVRATIO_SEL[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R/W	Reserved The write value should always be the initial value.
27 to 24	SRC1_IN_DIVCLK_SEL [3:0]	B'0000	R/W	SRC1 Input Timing Signal Select 0000: Divided AUDIO_CLKA 0001: Divided AUDIO_CLKB 0010: Divided AUDIO_CLKC 0011: Divided BRGA 0100: Divided BRGB 0101: Setting prohibited 0110: ssi_ws0 0111: ssi_ws1 1000: ssi_ws2 1001: ssi_ws3 1010: ssi_ws4 1011: ssi_ws5 1100: ssi_ws6 1101: ssi_ws7 1110: ssi_ws9 1111: Setting prohibited
23 to 21	—	All 0	R/W	Reserved The write value should always be the initial value.

Bit	Bit Name	Initial Value	R/W	Description
20 to 16	SRC1_IN_DIVRATIO_SEL [4:0]	B'00000	R/W	SRC1 Input Timing Signal Frequency Division Ratio Select These bits select the frequency division ratio for the clock signal selected using SRC1_IN_DIVCLK_SEL[3:0]. Note that ssi_ws signals cannot be divided. 0_0000: Divided by 2 0_0001: Divided by 4 0_0010: Divided by 6 0_0011: Divided by 8 0_0100: Divided by 12 0_0101: Divided by 16 0_0110: Divided by 24 0_0111: Divided by 32 0_1000: Divided by 48 0_1001: Divided by 64 0_1010: Divided by 96 0_1011: Divided by 128 0_1100: Divided by 192 0_1101: Divided by 256 0_1110: Divided by 384 0_1111: Divided by 512 1_0000: Divided by 768 1_0001: Divided by 1024 1_0010: Divided by 1536 1_0011: Divided by 2048 1_0100: Divided by 3072 1_0101: Divided by 4096 1_0110: Divided by 6144 1_0111: Divided by 8192 1_1000: Divided by 12288 1_1001: Divided by 16384 1_1010: Divided by 24576 1_1011: Divided by 32768 1_1100: Divided by 49152 1_1101: Divided by 98304 Others: Setting prohibited
15 to 0	—	All 0	R/W	Reserved The write value should always be the initial value.

29.2.9 SRC Input Timing Select Register 1 (SRCIN_TIMSEL1)

Function: SRCIN_TIMSEL1 selects the input timing signals for SRC2 and SRC3.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	SRC3_IN_DIVCLK_SEL[3:0]				—	—	—	SRC3_IN_DIVRATIO_SEL[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	SRC2_IN_DIVCLK_SEL[3:0]				—	—	—	SRC2_IN_DIVRATIO_SEL[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R/W	Reserved The write value should always be the initial value.
27 to 24	SRC3_IN_DIVCLK_SEL [3:0]	B'0000	R/W	SRC3 Input Timing Signal Select 0000: Divided AUDIO_CLKA 0001: Divided AUDIO_CLKB 0010: Divided AUDIO_CLKC 0011: Divided BRGA 0100: Divided BRGB 0101: Setting prohibited 0110: ssi_ws0 0111: ssi_ws1 1000: ssi_ws2 1001: ssi_ws3 1010: ssi_ws4 1011: ssi_ws5 1100: ssi_ws6 1101: ssi_ws7 1110: ssi_ws9 1111: Setting prohibited
23 to 21	—	All 0	R/W	Reserved The write value should always be the initial value.

Bit	Bit Name	Initial Value	R/W	Description
20 to 16	SRC3_IN_DIVRATIO_SEL[4:0]	B'00000	R/W	SRC3 Input Timing Signal Frequency Division Ratio Select These bits select the frequency division ratio for the clock signal selected using SRC3_IN_DIVCLK_SEL[3:0]. Note that ssi_ws signals cannot be divided. 0_0000: Divided by 2 0_0001: Divided by 4 0_0010: Divided by 6 0_0011: Divided by 8 0_0100: Divided by 12 0_0101: Divided by 16 0_0110: Divided by 24 0_0111: Divided by 32 0_1000: Divided by 48 0_1001: Divided by 64 0_1010: Divided by 96 0_1011: Divided by 128 0_1100: Divided by 192 0_1101: Divided by 256 0_1110: Divided by 384 0_1111: Divided by 512 1_0000: Divided by 768 1_0001: Divided by 1024 1_0010: Divided by 1536 1_0011: Divided by 2048 1_0100: Divided by 3072 1_0101: Divided by 4096 1_0110: Divided by 6144 1_0111: Divided by 8192 1_1000: Divided by 12288 1_1001: Divided by 16384 1_1010: Divided by 24576 1_1011: Divided by 32768 1_1100: Divided by 49152 1_1101: Divided by 98304 Others: Setting prohibited

29.3 Operation

The following sections give examples of setting the ADG registers.

(1) Supplying SSI3 with Audio Clock

The following procedure can be used to divide the internal clock (195-MHz) by d'18 and supply the resulting BRGB clock (10.833-MHz) to SSI3. (If the procedure is applied before starting SSI3, steps 1 to 5 can be executed in any order.)

1. Set BRRB so that the frequency division ratio should be d'18.
2. Select internal clock (M2ϕ) as the clock to be input to BRGB using BRGCKR.
3. Select the BRGB output clock as SSI3 clock using AUDIO_CLK_SEL0.
4. Release the ADG from the module standby state using SMSTPCR1 of the CPG module.
5. Release SSI3 from the module standby state using SMSTPCR10 of the CPG module.

Table 29.5 Setting Example 1

Register Name	Address	Setting Value	Description
BRRB	H'EC5A 0004	H'0000 0008	Divided by d'18
BRGCKR	H'EC5A 0008	H'2302 0000	Selects M2ϕ as the clock to be input to BRGB.
AUDIO_CLK_SEL0	H'EC5A 000C	H'2000 0000	Selects the BRGB output clock as the clock to be output to SSI3.
SMSTPCR1	H'E615 0134	Set bit 6 to 0.	Releases the ADG from the module standby state.
SMSTPCR10	H'E615 0998	Set bits 12 to 0.	Releases the SSI3 from the module standby state.

29.4 Usage Notes

There is no attention of the usage.

30. Sampling Rate Converter Unit (SCU)

30.1 Overview

The SCU has six SRC modules (four for high-sound-quality type; two for general-sound-quality type) that are useful for synchronization of asynchronous data, which is necessary for data transfer with external memory or external devices. It also provides the functions to change the number of channels, perform mixing, and control the volume.

Note: When the SRCs are not in use, configure the system with the same clock sources for AUDIO CLOCK that is input to ADG, and INIC or devices for I2S that are connected to external modules, and all thus operate at the same sampling frequency.

30.1.1 Features

(1) Sampling Rate Converter (SRC)

- Asynchronous sampling rate conversion is available
- Supports resolutions up to 24 bits
- High-sound-quality type (THD + N* is -132 dB) and general-sound-quality type (THD + N* is -96 dB)
- Automatically generates antialiasing filter coefficients
- Three modules support one, two, four, six, or eight channels, and three modules support one or two channels.

Note: * Total harmonic distortion plus noise

(2) Channel Transfer Unit (CTU)

- Downmixing and splitter functions
  - Conversion of eight input channels into two output channels
  - Conversion of six input channels into two output channels
  - Conversion of two input channels into four sets of two output channels
  - Conversion of one input channel into eight sets of one output channel
  - No conversion

(3) Mixer (MIX)

- Mixing (adds) two to four sources into one
- Ratio for adding sources is selectable
- Ratio is dynamically changeable
- Mixing with volume ramp is available (ramp period is selectable)

(4) Digital Volume and Mute Function (DVC)

- Volume control function including digital volume, volume ramp, and zero-crossing mute
- The digital volume function is specified by a 24-bit fixed-point value within the range from 0 to 8 times (mute or -120 to 18 dB)
- The volume ramp function can be used for soft mute, fade-in, fade-out, or desired volume adjustment
- The volume ramp period can be changed within the sampling range from the 0th to 23rd power of 2
- The zero-crossing mute function silences the sound at the zero-crossing point of the audio data

The CTU, MIX, and DVC functional blocks are collectively called "CMD".

30.1.2 Block Diagram

Figure 30.1 shows the SCU block diagram.

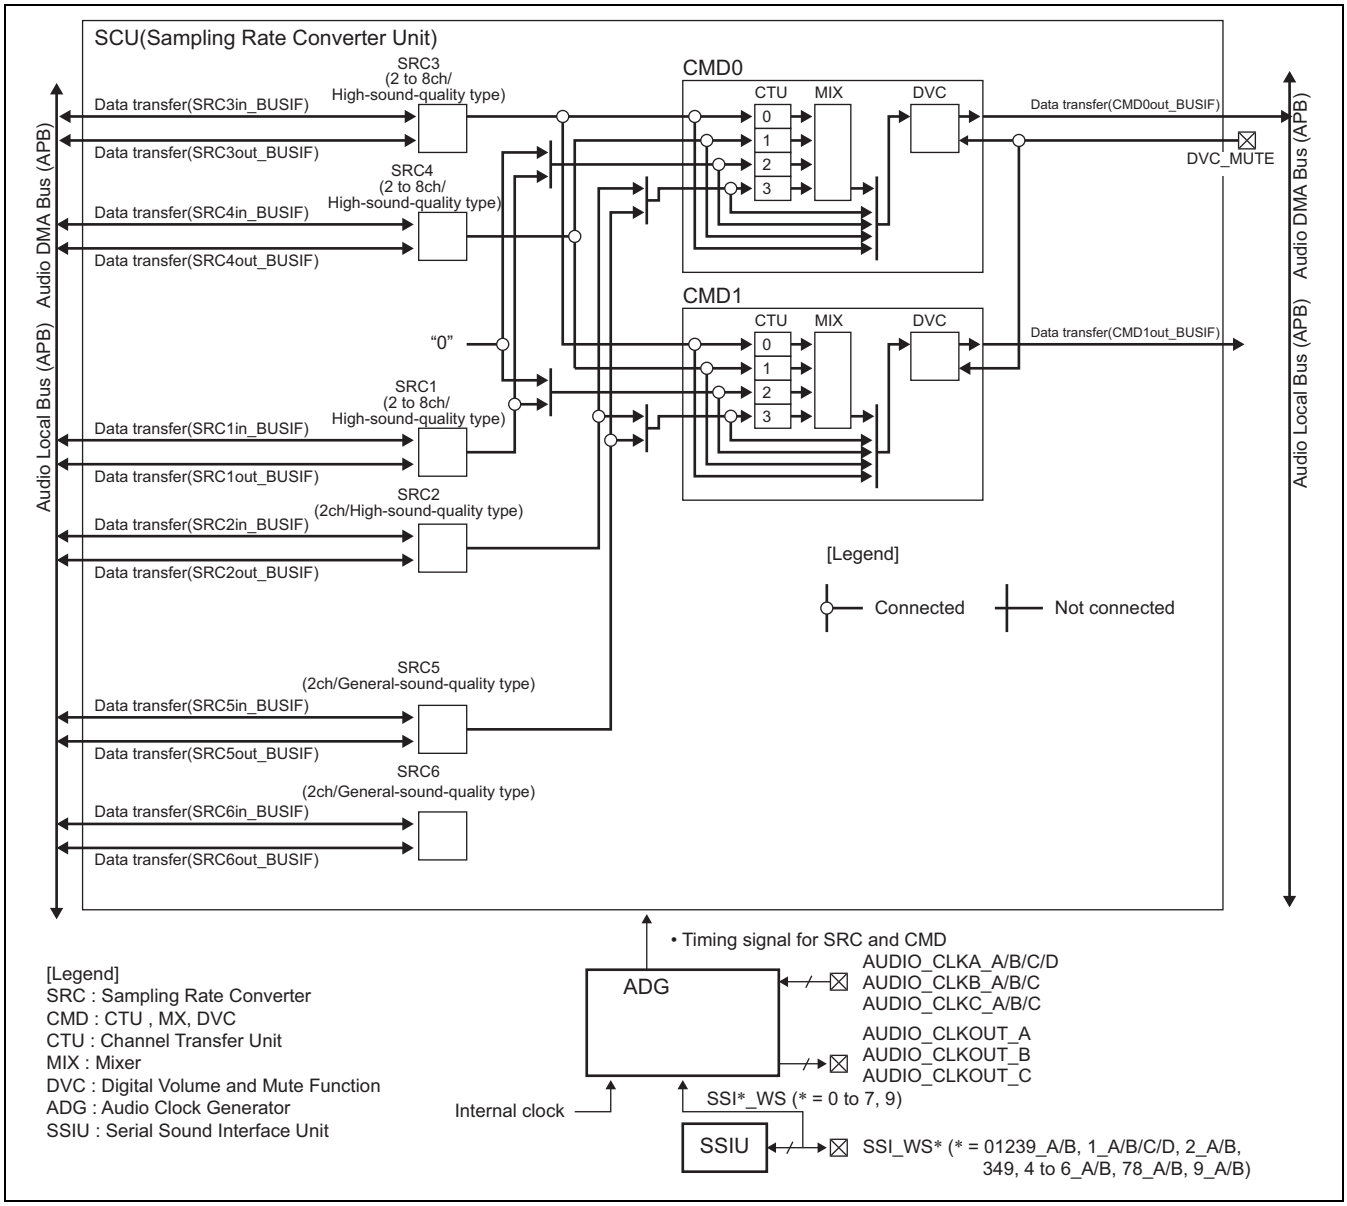

Figure 30.1 Block Diagram of SCU

30.1.3 Input/Output Pins

Table 30.1 shows the pin configuration.

Table 30.1 Pin Configuration

Name	Pin Name	I/O	Function
DVC_MUTE pin	DVC_MUTE	Input	DVCEN

30.1.4 Register Configuration

Table 30.2 shows the register configuration. Do not write to any addresses other than listed below. Operations cannot be guaranteed if writing is attempted. Values read from addresses other than those listed below are undefined. Access the register as a longword (32 bits). Operation cannot be guaranteed if the register is not accessed as a longword.

Table 30.2 Register Configuration

CMD1 out Read Data Register	CMD1out_BUSIF	R	H'EC00 8400/ H'EC30 8400*	H'0000 0000	32

Notes: m = 1 to 6; n = 00, 01, 02, 03, 10, 11, 12, or 13; p = 0 or 1

* H'EC00 XXXX is the address for transferring by Audio-DMAC. H'EC30 XXXX is the address for transferring by Audio-DMAC-Peripheral-Peripheral.

** This register is just what to show the initial value here, but, set a value according to section 30.2.23 by all means when you use it.

30.2 Register Description

Legend for Register Description

Initial value: Register value after a reset. H'xxxx represents a hexadecimal number. Others are represented in binary numbers.

—: Undefined value

R/W: Readable/writable. The written value can be read.

R: Read-only. The write value should always be 0.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R/WC1: Readable/writable. Writing 1 initializes the bit. Writing 0 is ignored.

W: Write-only. Reading this bit is prohibited. When the bit is reserved, the write value should always be 0.

—/W: Write-only. The read value is undefined.

All access to registers is made in longword units.

30.2.1 SRCm(in/out)_BUSIF_MODE Register (SRCm(in/out)_BUSIF_MODE)

Note: m = 1 to 6

Function: SRCm (in/out)_BUSIF_MODE sets the initial setting for the bus interface.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	sft_dir	sft_num			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	dma
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	sft_dir	0	R/W	src*m*(in/out)_busif_shift_dir Selects the bit-shift direction for position adjustment of the valid SRC*m*(in/out)_BUSIF input and output data. 0: Shift to left. 1: Shift to right.
19 to 16	sft_num	0000	R/W	src*m*(in/out)_busif _shift_num Selects the bit-shift count for position adjustment of the valid SRC*m*(in/out)_BUSIF input and output data. 0000: 0 bit 0001: 1 bit 0010: 2 bits 0011: 3 bits 0100: 4 bits 0101: 5 bits 0110: 6 bits 0111: 7 bits 1000: 8 bits 1001: 9 bits 1010: 10 bits 1011: 11 bits 1100: 12 bits 1101: 13 bits 1110: 14 bits 1111: 15 bits
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	dma	1	R/W	src*m*(in/out)_busif _dma Selects the access type for SRC*m*(in/out)_BUSIF. 0: PIO access (setting prohibited) 1: DMA access Be sure to specify the DMA access.

30.2.2 SRCm_BUSIF_DALIGN Register (SRCm_BUSIF_DALIGN)

Note: m = 1, 3, or 4

Function: SRCm_BUSIF_DALIGN determines the initial settings of the SRCm route.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	place7			—	place6			—	place5			—	place4		
Initial value:	0	1	1	1	0	1	1	0	0	1	0	1	0	1	0	0
R/W:	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	place3			—	place2			—	place1			—	place0		
Initial value:	0	0	1	1	0	0	1	0	0	0	0	1	0	0	0	0
R/W:	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30 to 28	place7	111	R/W	Changes the stream data order. These bits are used for the 8-channel setting. **For the 6- or less-channel setting, the initial value should not be changed.** The data order is changed before input to the SRC. Selects the input-side data to be output to place 7 on the output side. 000: Data at input-side place 0 is sent to output-side place 7. 001: Data at input-side place 1 is sent to output-side place 7. 010: Data at input-side place 2 is sent to output-side place 7. 011: Data at input-side place 3 is sent to output-side place 7. 100: Data at input-side place 4 is sent to output-side place 7. 101: Data at input-side place 5 is sent to output-side place 7. 110: Data at input-side place 6 is sent to output-side place 7. 111: Data at input-side place 7 is sent to output-side place 7.
27	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
26 to 24	place6	110	R/W	Changes the stream data order. These bits are used for the 8-channel setting. **For the 6- or less-channel setting, the initial value should not be changed.** The data order is changed before input to the SRC. Selects the input-side data to be output to place 6 on the output side. 000: Data at input-side place 0 is sent to output-side place 6. 001: Data at input-side place 1 is sent to output-side place 6. 010: Data at input-side place 2 is sent to output-side place 6. 011: Data at input-side place 3 is sent to output-side place 6. 100: Data at input-side place 4 is sent to output-side place 6. 101: Data at input-side place 5 is sent to output-side place 6. 110: Data at input-side place 6 is sent to output-side place 6. 111: Data at input-side place 7 is sent to output-side place 6.
23	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
22 to 20	place5	101	R/W	Changes the stream data order. These bits are used for the 6- or more-channel setting. **For the 4- or less-channel setting, the initial value should not be changed.** The data order is changed before input to the SRC. Selects the input-side data to be output to place 5 on the output side. 000: Data at input-side place 0 is sent to output-side place 5. 001: Data at input-side place 1 is sent to output-side place 5. 010: Data at input-side place 2 is sent to output-side place 5. 011: Data at input-side place 3 is sent to output-side place 5. 100: Data at input-side place 4 is sent to output-side place 5. 101: Data at input-side place 5 is sent to output-side place 5. 110: Data at input-side place 6 is sent to output-side place 5. 111: Data at input-side place 7 is sent to output-side place 5.
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
18 to 16	place4	100	R/W	Changes the stream data order. These bits are used for the 6- or more-channel setting. **For the 4- or less-channel setting, the initial value should not be changed.** The data order is changed before input to the SRC. Selects the input-side data to be output to place 4 on the output side. 000: Data at input-side place 0 is sent to output-side place 4. 001: Data at input-side place 1 is sent to output-side place 4. 010: Data at input-side place 2 is sent to output-side place 4. 011: Data at input-side place 3 is sent to output-side place 4. 100: Data at input-side place 4 is sent to output-side place 4. 101: Data at input-side place 5 is sent to output-side place 4. 110: Data at input-side place 6 is sent to output-side place 4. 111: Data at input-side place 7 is sent to output-side place 4.
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
14 to 12	place3	011	R/W	Changes the stream data order. These bits are used for the 4- or more-channel setting. **For the 2- or less-channel setting, the initial value should not be changed.** The data order is changed before input to the SRC. Selects the input-side data to be output to place 3 on the output side. 000: Data at input-side place 0 is sent to output-side place 3. 001: Data at input-side place 1 is sent to output-side place 3. 010: Data at input-side place 2 is sent to output-side place 3. 011: Data at input-side place 3 is sent to output-side place 3. 100: Data at input-side place 4 is sent to output-side place 3. 101: Data at input-side place 5 is sent to output-side place 3. 110: Data at input-side place 6 is sent to output-side place 3. 111: Data at input-side place 7 is sent to output-side place 3.
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10 to 8	place2	010	R/W	Changes the stream data order. These bits are used for the 4- or more-channel setting. **For the 2- or less-channel setting, the initial value should not be changed.** The data order is changed before input to the SRC. Selects the input-side data to be output to place 2 on the output side. 000: Data at input-side place 0 is sent to output-side place 2. 001: Data at input-side place 1 is sent to output-side place 2. 010: Data at input-side place 2 is sent to output-side place 2. 011: Data at input-side place 3 is sent to output-side place 2. 100: Data at input-side place 4 is sent to output-side place 2. 101: Data at input-side place 5 is sent to output-side place 2. 110: Data at input-side place 6 is sent to output-side place 2. 111: Data at input-side place 7 is sent to output-side place 2.
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6 to 4	place1	001	R/W	Changes the stream data order. The data order is changed before input to the SRC. Selects the input-side data to be output to place 1 on the output side. 000: Data at input-side place 0 is sent to output-side place 1. 001: Data at input-side place 1 is sent to output-side place 1. 010: Data at input-side place 2 is sent to output-side place 1. 011: Data at input-side place 3 is sent to output-side place 1. 100: Data at input-side place 4 is sent to output-side place 1. 101: Data at input-side place 5 is sent to output-side place 1. 110: Data at input-side place 6 is sent to output-side place 1. 111: Data at input-side place 7 is sent to output-side place 1.
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
2 to 0	place0	000	R/W	Changes the stream data order. The data order is changed before input to the SRC. Selects the input-side data to be output to place 0 on the output side. 000: Data at input-side place 0 is sent to output-side place 0. 001: Data at input-side place 1 is sent to output-side place 0. 010: Data at input-side place 2 is sent to output-side place 0. 011: Data at input-side place 3 is sent to output-side place 0. 100: Data at input-side place 4 is sent to output-side place 0. 101: Data at input-side place 5 is sent to output-side place 0. 110: Data at input-side place 6 is sent to output-side place 0. 111: Data at input-side place 7 is sent to output-side place 0.

30.2.3 SRCn_BUSIF_DALIGN Register (SRCn_BUSIF_DALIGN)

Note: n = 2, 5, or 6

Function: SRCn_BUSIF_DALIGN determines the initial settings of the SRCn route.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	place1	—	—	—	place0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	place1	1	R/W	Changes the stream data order. The data order is changed before input to the SRC. Selects the input-side data to be output to place 1 on the output side. 0: Data at input-side place 0 is sent to output-side place 1. 1: Data at input-side place 1 is sent to output-side place 1.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	place0	0	R/W	Changes the stream data order. The data order is changed before input to the SRC. Selects the input-side data to be output to place 0 on the output side. 0: Data at input-side place 0 is sent to output-side place 0. 1: Data at input-side place 1 is sent to output-side place 0.

30.2.4 SRCm_MODE Register (SRCm_MODE)

Note: m = 1 to 6

Function: SRCm_MODE determines the initial settings of the SRCm route.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	sync_out	sync_in	—	—	—	—	—	—	—	uf_data
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	src
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25	sync_out	0	R/W	src*m*out_sync Selects how to treat data in the SRC output buffer. 0: Asynchronous SRC 1: Synchronous SRC
24	sync_in	0	R/W	src*m*in_sync Selects how to treat data in the SRC input buffer. 0: Asynchronous SRC 1: Synchronous SRC
23 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	uf_data	0	R/W	src*m*_uf_data_sel Selects how to treat data when an underflow occurs in the SRC input buffer. 0: Data before the underflow occurs is output. 1: All 0s are output.
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	src	0	R/W	src*m*_src Selects whether to use SRC*m*. 0: SRC*m* is not used. 1: SRC*m* is used.

Notes: 1. Set one of sync_in and sync_out bits, when SRC*m* is used in synchronous mode by setting SRCMD bit in SRCm_SRCCR register.
2. If sync_out is set in synchronous mode, data should directly transmit to memory. (Data should not transmit throughout CMD.)

30.2.5 SRCm Control Register (SRCm_CONTROL)

Note: m = 1 to 6

Function: SRCm_CONTROL starts or stops transfer.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	start_ out	—	—	—	start_ in
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	start_out	0	R/W	SRC*m*out_start_flag Starts or stops transfer via SRC*m*. 0: Stops transfer. 1: Starts transfer.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	start_in	0	R/W	SRC*m*in_start_flag Starts or stops transfer via SRC*m*. 0: Stops transfer. 1: Starts transfer.

When CMD is used with route SRC1, SRC2, SRC3, SRC4, or SRC5, SRC*m*out_start_flag should be set to 0 to stop transfer. When CMD is not used with route SRC1, SRC2, SRC3, SRC4, or SRC5, SRC*m*in_start_flag and SRC*m*out_start_flag should be set simultaneously.

When CMD is used and the sync_in bit in the SRCm_MODE register is set for synchronous mode, SRC*m*out_start_flag should be set to 1 to start transfer. However, in this case, use of the output data SRCm out_BUSIF is prohibited and ignore the value of over_flow_srcout in the SRCm_STATUS register.

30.2.6 SRCm Status Register (SRCm_STATUS)

Note: m = 1 to 5

Function: SRCm_STATUS indicates the state of each SRC. When a register bit is set, the corresponding interrupt signal is output. However, if interrupt outputs are masked by the SRC*m* interrupt enable register, interrupt signals are not output.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	dvc1	—	—	—	dvc0	—	—	—	—	—	—	—	—

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28	dvc1	0	R	dvc1 Indicates the state of the DVC1_DVUSR register collectively. The state information is used only for the interrupt signal that is enabled by DVC1_DVIER.
27 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	dvc0	0	R	dvc0 Indicates the state of the DVC0_DVUSR register collectively. The state information is used only for the interrupt signal that is enabled by DVC0_DVIER.
23 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13	uf_srco	0	R	under_flow_srcout Indicates the state of the output buffer of SRCout in the SCU_SYSTEM_STATUS1 register. The state information is used when the interrupt signal is enabled by SCU_SYSTEM_INT_ENABLE1.
12	of_srco	0	R	over_flow_srcout Indicates the state of the output buffer of SRCout in the SCU_SYSTEM_STATUS0 register. The state information is used when the interrupt signal is enabled by SCU_SYSTEM_INT_ENABLE0.
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	of_srci	0	R	over_flow_srcin Indicates the state of the output buffer of SRCin in the SCU_SYSTEM_STATUS1 register. The state information is used when the interrupt signal is enabled by SCU_SYSTEM_INT_ENABLE1.

Bit	Bit Name	Initial Value	R/W	Description
8	uf_srci	0	R	under_flow_srcin Indicates the state of the output buffer of SRCin in the SCU_SYSTEM_STATUS0 register. The state information is used when the interrupt signal is enabled by SCU_SYSTEM_INT_ENABLE0.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

30.2.7 SRCn Status Register (SRCn_STATUS)

Note: n = 6

Function: SRCn_STATUS indicates the state of each SRC. When a register bit is set, the corresponding interrupt signal is output. However, if interrupt outputs are masked by the SRCn interrupt enable register, interrupt signals are not output.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13	uf_srco	0	R	under_flow_srcout Indicates the state of the output buffer of SRCout in the SCU_SYSTEM_STATUS1 register. The state information is used when the interrupt signal is enabled by SCU_SYSTEM_INT_ENABLE1.
12	of_srco	0	R	over_flow_srcout Indicates the state of the output buffer of SRCout in the SCU_SYSTEM_STATUS0 register. The state information is used when the interrupt signal is enabled by SCU_SYSTEM_INT_ENABLE0.
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	of_srci	0	R	over_flow_srcin Indicates the state of the output buffer of SRCin in the SCU_SYSTEM_STATUS1 register. The state information is used when the interrupt signal is enabled by SCU_SYSTEM_INT_ENABLE1.
8	uf_srci	0	R	under_flow_srcin Indicates the state of the output buffer of SRCin in the SCU_SYSTEM_STATUS0 register. The state information is used when the interrupt signal is enabled by SCU_SYSTEM_INT_ENABLE0.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

30.2.8 SRCm Interrupt Enable Register 0 (SRCm_INT_ENABLE0)

Note: m = 1 to 5

Function: SRCm_INT_ENABLE0 enables or disables output of interrupts corresponding to the states indicated in the SRCm status register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R/W	R/W	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28	dvc1_ie	0	R/W	dvc1_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
27 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	dvc0_ie	0	R/W	dvc0_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
23 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13	uf_srco_ie	0	R/W	under_flow_srcout_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
12	of_srco_ie	0	R/W	over_flow_srcout_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	of_srci_ie	0	R/W	over_flow_srcin_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
8	uf_srci_ie	0	R/W	under_flow_srcin_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

30.2.9 SRCn Interrupt Enable Register 0 (SRCn_INT_ENABLE0)

Note: n = 6

Function: SRCn_INT_ENABLE0 enables or disables output of interrupts corresponding to the states indicated in the SRCn status register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
13	uf_srco_ie	0	R/W	under_flow_srcout_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
12	of_srco_ie	0	R/W	over_flow_srcout_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	of_srci_ie	0	R/W	over_flow_srcin_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
8	uf_srci_ie	0	R/W	under_flow_srcin_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

30.2.10 CMDn out_BUSIF_MODE Register (CMDn out_BUSIF_MODE)

Note: n = 0, 1

Function: CMDn out_BUSIF_MODE sets the initial setting for the bus interface

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	sft_dir	sft_num			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	dma
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	sft_dir	0	R/W	cmd*n*out_busif_shift_dir Selects the bit-shift direction for position adjustment of the valid CMD*n*out_BUSIF input and output data. 0: Shift to left. 1: Shift to right.
19 to 16	sft_num	0000	R/W	cmd*n*out_busif_shift_num Selects the bit-shift count for position adjustment of the valid CMD*n*out_BUSIF input and output data. 0000: 0 bit 0001: 1 bit 0010: 2 bits 0011: 3 bits 0100: 4 bits 0101: 5 bits 0110: 6 bits 0111: 7 bits 1000: 8 bits 1001: 9 bits 1010: 10 bits 1011: 11 bits 1100: 12 bits 1101: 13 bits 1110: 14 bits 1111: 15 bits
15 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	dma	1	R/W	CMDnout_busif _dma Selects the access type for CMDnout_BUSIF. 0: PIO access (setting prohibited) 1: DMA access Be sure to specify the DMA access.

30.2.11 CMDn_BUSIF_DALIGN Register (CMDn_BUSIF_DALIGN)

Note: n = 0, 1

Function: CMDn_BUSIF_DALIGN determines the initial settings of the CMDn route.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	place7			—	place6			—	place5			—	place4		
Initial value:	0	1	1	1	0	1	1	0	0	1	0	1	0	1	0	0
R/W:	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	place3			—	place2			—	place1			—	place0		
Initial value:	0	0	1	1	0	0	1	0	0	0	0	1	0	0	0	0
R/W:	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30 to 28	place7	111	R/W	Changes the stream data order. These bits are used for the 8-channel setting. **For the 6- or less-channel setting, the initial value should not be changed.** The data order is changed after output from the CMD. Selects the input-side data to be output to place 7 on the output side. 000: Data at input-side place 0 is sent to output-side place 7. 001: Data at input-side place 1 is sent to output-side place 7. 010: Data at input-side place 2 is sent to output-side place 7. 011: Data at input-side place 3 is sent to output-side place 7. 100: Data at input-side place 4 is sent to output-side place 7. 101: Data at input-side place 5 is sent to output-side place 7. 110: Data at input-side place 6 is sent to output-side place 7. 111: Data at input-side place 7 is sent to output-side place 7.
27	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
26 to 24	place6	110	R/W	Changes the stream data order. These bits are used for the 8-channel setting. **For the 6- or less-channel setting, the initial value should not be changed.** The data order is changed after output from the CMD. Selects the input-side data to be output to place 6 on the output side. 000: Data at input-side place 0 is sent to output-side place 6. 001: Data at input-side place 1 is sent to output-side place 6. 010: Data at input-side place 2 is sent to output-side place 6. 011: Data at input-side place 3 is sent to output-side place 6. 100: Data at input-side place 4 is sent to output-side place 6. 101: Data at input-side place 5 is sent to output-side place 6. 110: Data at input-side place 6 is sent to output-side place 6. 111: Data at input-side place 7 is sent to output-side place 6.
23	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
22 to 20	place5	101	R/W	Changes the stream data order. These bits are used for the 6- or more-channel setting. **For the 4- or less-channel setting, the initial value should not be changed.** The data order is changed after output from the CMD. Selects the input-side data to be output to place 5 on the output side. 000: Data at input-side place 0 is sent to output-side place 5. 001: Data at input-side place 1 is sent to output-side place 5. 010: Data at input-side place 2 is sent to output-side place 5. 011: Data at input-side place 3 is sent to output-side place 5. 100: Data at input-side place 4 is sent to output-side place 5. 101: Data at input-side place 5 is sent to output-side place 5. 110: Data at input-side place 6 is sent to output-side place 5. 111: Data at input-side place 7 is sent to output-side place 5.
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
18 to 16	place4	100	R/W	Changes the stream data order. These bits are used for the 6- or more-channel setting. **For the 4- or less-channel setting, the initial value should not be changed.** The data order is changed after output from the CMD. Selects the input-side data to be output to place 4 on the output side. 000: Data at input-side place 0 is sent to output-side place 4. 001: Data at input-side place 1 is sent to output-side place 4. 010: Data at input-side place 2 is sent to output-side place 4. 011: Data at input-side place 3 is sent to output-side place 4. 100: Data at input-side place 4 is sent to output-side place 4. 101: Data at input-side place 5 is sent to output-side place 4. 110: Data at input-side place 6 is sent to output-side place 4. 111: Data at input-side place 7 is sent to output-side place 4.
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
14 to 12	place3	011	R/W	Changes the stream data order. These bits are used for the 4- or more-channel setting. **For the 2- or less-channel setting, the initial value should not be changed.** The data order is changed after output from the CMD. Selects the input-side data to be output to place 3 on the output side. 000: Data at input-side place 0 is sent to output-side place 3. 001: Data at input-side place 1 is sent to output-side place 3. 010: Data at input-side place 2 is sent to output-side place 3. 011: Data at input-side place 3 is sent to output-side place 3. 100: Data at input-side place 4 is sent to output-side place 3. 101: Data at input-side place 5 is sent to output-side place 3. 110: Data at input-side place 6 is sent to output-side place 3. 111: Data at input-side place 7 is sent to output-side place 3.
11	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10 to 8	place2	010	R/W	Changes the stream data order. These bits are used for the 4- or more-channel setting. **For the 2- or less-channel setting, the initial value should not be changed.** The data order is changed after output from the CMD. Selects the input-side data to be output to place 2 on the output side. 000: Data at input-side place 0 is sent to output-side place 2. 001: Data at input-side place 1 is sent to output-side place 2. 010: Data at input-side place 2 is sent to output-side place 2. 011: Data at input-side place 3 is sent to output-side place 2. 100: Data at input-side place 4 is sent to output-side place 2. 101: Data at input-side place 5 is sent to output-side place 2. 110: Data at input-side place 6 is sent to output-side place 2. 111: Data at input-side place 7 is sent to output-side place 2.
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6 to 4	place1	001	R/W	Changes the stream data order. The data order is changed after output from the CMD. Selects the input-side data to be output to place 1 on the output side. 000: Data at input-side place 0 is sent to output-side place 1. 001: Data at input-side place 1 is sent to output-side place 1. 010: Data at input-side place 2 is sent to output-side place 1. 011: Data at input-side place 3 is sent to output-side place 1. 100: Data at input-side place 4 is sent to output-side place 1. 101: Data at input-side place 5 is sent to output-side place 1. 110: Data at input-side place 6 is sent to output-side place 1. 111: Data at input-side place 7 is sent to output-side place 1.
3	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
2 to 0	place0	000	R/W	Changes the stream data order. The data order is changed after output from the CMD. Selects the input-side data to be output to place 0 on the output side. 000: Data at input-side place 0 is sent to output-side place 0. 001: Data at input-side place 1 is sent to output-side place 0. 010: Data at input-side place 2 is sent to output-side place 0. 011: Data at input-side place 3 is sent to output-side place 0. 100: Data at input-side place 4 is sent to output-side place 0. 101: Data at input-side place 5 is sent to output-side place 0. 110: Data at input-side place 6 is sent to output-side place 0. 111: Data at input-side place 7 is sent to output-side place 0.

30.2.12 CMDn_ROUTE_SELECT Register (CMDn_ROUTE_SELECT)

Note: n = 0, 1

Function: CMDn_ROUTE_SELECT selects the sound route for each CMD (CTU, MIX, and DVC). Refer to Figures 30.1 and 30.11 for the sound routes.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	cmd_case		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	cmdin_ctu3	—	—	—	—	—	—	—	cmdin_ctu2
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 19	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
18 to 16	cmd_case	000	R/W	cmd*n*_case_sel Selects the route in CMD*n*. 000: Input audio data0 to 3 → CTU → MIX → DVC route is used. 001: Input audio data0 (from SRC3) → DVC route is used. 010: Input audio data1 (from SRC4) → DVC route is used. 011: Input audio data2 (from SRC1) → DVC route is used. 100: Input audio data3 (from SRC2 or SRC5) → DVC route is used. Others: Setting prohibited.
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	cmdin_ctu3	0	R/W	cmd*n*in_ctu3_sel Selects SRC for Input audio data3 of CMD*n*. 0: SRC2 route is used. 1: SRC5 route is used.
7 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	cmdin_ctu2	0	R/W	cmd*n*in_ctu2_sel Selects SRC for Input audio data2 of CMD*n*. 0: No operation 1: SRC1 route is used.

30.2.13 CMDn Control Register (CMDn_CONTROL)

Note: n = 0, 1

Function: CMDn_CONTROL starts or stops transfer.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	start_ out	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	start_out	0	R/W	CMD*n*out_start_flag Starts or stops transfer via CMD*n*. 0: Stops transfer. 1: Starts transfer.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

30.2.14 SCU_SYSTEM Status Register 0 (SCU_SYSTEM_STATUS0)

Function: SCU_SYSTEM_STATUS0 indicates the internal buffer state. When a register bit is set, the corresponding interrupt signal is output. However, if interrupt outputs are masked by the SYSTEM interrupt enable register 0, interrupt signals are not output.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	of_cmd1o	of_cmd0o	—	—	—	—	—	of_src6o	of_src5o	of_src4o	of_src3o	of_src2o	of_src1o	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/WC1	R/WC1	R	R	R	R	R	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	uf_src6i	uf_src5i	uf_src4i	uf_src3i	uf_src2i	uf_src1i	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29	of_cmd1o	0	R/WC1	over_flow_cmd1out Indicates the state of the CMD1out output buffer. 0: Normal operation 1: An overflow has occurred.
28	of_cmd0o	0	R/WC1	over_flow_cmd0out Indicates the state of the CMD0out output buffer. 0: Normal operation 1: An overflow has occurred.
27 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22	of_src6o	0	R/WC1	over_flow_src6out Indicates the state of the SRC6out output buffer. 0: Normal operation 1: An overflow has occurred.
21	of_src5o	0	R/WC1	over_flow_src5out Indicates the state of the SRC5out output buffer. 0: Normal operation 1: An overflow has occurred.
20	of_src4o	0	R/WC1	over_flow_src4out Indicates the state of the SRC4out output buffer. 0: Normal operation 1: An overflow has occurred.
19	of_src3o	0	R/WC1	over_flow_src3out Indicates the state of the SRC3out output buffer. 0: Normal operation 1: An overflow has occurred.

Bit	Bit Name	Initial Value	R/W	Description
18	of_src2o	0	R/WC1	over_flow_src2out Indicates the state of the SRC2out output buffer. 0: Normal operation 1: An overflow has occurred.
17	of_src1o	0	R/WC1	over_flow_src1out Indicates the state of the SRC1out output buffer. 0: Normal operation 1: An overflow has occurred.
16 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	uf_src6i	0	R/WC1	under_flow_src6in Indicates the state of the SRC6in input buffer. 0: Normal operation 1: An underflow has occurred.
5	uf_src5i	0	R/WC1	under_flow_src5in Indicates the state of the SRC5in input buffer. 0: Normal operation 1: An underflow has occurred.
4	uf_src4i	0	R/WC1	under_flow_src4in Indicates the state of the SRC4in input buffer. 0: Normal operation 1: An underflow has occurred.
3	uf_src3i	0	R/WC1	under_flow_src3in Indicates the state of the SRC3in input buffer. 0: Normal operation 1: An underflow has occurred.
2	uf_src2i	0	R/WC1	under_flow_src2in Indicates the state of the SRC2in input buffer. 0: Normal operation 1: An underflow has occurred.
1	uf_src1i	0	R/WC1	under_flow_src1in Indicates the state of the SRC1in input buffer. 0: Normal operation 1: An underflow has occurred.
0	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

30.2.15 SCU_SYSTEM Interrupt Enable Register 0 (SCU_SYSTEM_INT_ENABLE0)

Function: SCU_SYSTEM_INT_ENABLE0 enables or disables output of interrupts corresponding to the states indicated in the SCU_SYSTEM status register 0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	of_cmd1o_ie	of_cmd0o_ie	—	—	—	—	—	of_src6o_ie	of_src5o_ie	of_src4o_ie	of_src3o_ie	of_src2o_ie	of_src1o_ie	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	uf_src6i_ie	uf_src5i_ie	uf_src4i_ie	uf_src3i_ie	uf_src2i_ie	uf_src1i_ie	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R

Bit	Bit Name	Initial Value	R/W	Description
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29	of_cmd1o_ie	0	R/W	over_flow_cmd1out_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
28	of_cmd0o_ie	0	R/W	over_flow_cmd0out_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
27 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22	of_src6o_ie	0	R/W	over_flow_src6out_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
21	of_src5o_ie	0	R/W	over_flow_src5out_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
20	of_src4o_ie	0	R/W	over_flow_src4out_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
19	of_src3o_ie	0	R/W	over_flow_src3out_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
18	of_src2o_ie	0	R/W	over_flow_src2out_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
17	of_src1o_ie	0	R/W	over_flow_src1out_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
16 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
6	uf_src6i_ie	0	R/W	under_flow_src6in_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
5	uf_src5i_ie	0	R/W	under_flow_src5in_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
4	uf_src4i_ie	0	R/W	under_flow_src4in_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
3	uf_src3i_ie	0	R/W	under_flow_src3in_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
2	uf_src2i_ie	0	R/W	under_flow_src2in_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
1	uf_src1i_ie	0	R/W	under_flow_src1in_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
0	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

30.2.16 SCU_SYSTEM Status Register 1 (SCU_SYSTEM_STATUS1)

Function: SCU_SYSTEM_STATUS1 indicates the internal buffer state in synchronous mode. When a register bit is set, the corresponding interrupt signal is output. However, if interrupt outputs are masked by the SYSTEM interrupt enable register 1, interrupt signals are not output.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	uf_src6o	uf_src5o	uf_src4o	uf_src3o	uf_src2o	uf_src1o	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	of_src6i	of_src5i	of_src4i	of_src3i	of_src2i	of_src1i	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R/WC1	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22	uf_src6o	0	R/WC1	under_flow_src6out Indicates the state of the SRC6out output buffer. 0: Normal operation 1: An underflow has occurred.
21	uf_src5o	0	R/WC1	under_flow_src5out Indicates the state of the SRC5out output buffer. 0: Normal operation 1: An underflow has occurred.
20	uf_src4o	0	R/WC1	under_flow_src4out Indicates the state of the SRC4out output buffer. 0: Normal operation 1: An underflow has occurred.
19	uf_src3o	0	R/WC1	under_flow_src3out Indicates the state of the SRC3out output buffer. 0: Normal operation 1: An underflow has occurred.
18	uf_src2o	0	R/WC1	under_flow_src2out Indicates the state of the SRC2out output buffer. 0: Normal operation 1: An underflow has occurred.
17	uf_src1o	0	R/WC1	under_flow_src1out Indicates the state of the SRC1out output buffer. 0: Normal operation 1: An underflow has occurred.
16 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
6	of_src6i	0	R/WC1	over_flow_src6in Indicates the state of the SRC6in input buffer. 0: Normal operation 1: An overflow has occurred.
5	of_src5i	0	R/WC1	over_flow_src5in Indicates the state of the SRC5in input buffer. 0: Normal operation 1: An overflow has occurred.
4	of_src4i	0	R/WC1	over_flow_src4in Indicates the state of the SRC4in input buffer. 0: Normal operation 1: An overflow has occurred.
3	of_src3i	0	R/WC1	over_flow_src3in Indicates the state of the SRC3in input buffer. 0: Normal operation 1: An overflow has occurred.
2	of_src2i	0	R/WC1	over_flow_src2in Indicates the state of the SRC2in input buffer. 0: Normal operation 1: An overflow has occurred.
1	of_src1i	0	R/WC1	over_flow_src1in Indicates the state of the SRC1in input buffer. 0: Normal operation 1: An overflow has occurred.
0	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

30.2.17 SCU_SYSTEM Interrupt Enable Register 1 (SCU_SYSTEM_INT_ENABLE1)

Function: SCU_SYSTEM_INT_ENABLE1 enables or disables output of interrupts corresponding to the states indicated in the SCU_SYSTEM status register 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	uf_src6o_ie	uf_src5o_ie	uf_src4o_ie	uf_src3o_ie	uf_src2o_ie	uf_src1o_ie	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	of_src6i_ie	of_src5i_ie	of_src4i_ie	of_src3i_ie	of_src2i_ie	of_src1i_ie	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22	uf_src6o_ie	0	R/W	under_flow_src6out_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
21	uf_src5o_ie	0	R/W	under_flow_src5out_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
20	uf_src4o_ie	0	R/W	under_flow_src4out_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
19	uf_src3o_ie	0	R/W	under_flow_src3out_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
18	uf_src2o_ie	0	R/W	under_flow_src2out_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
17	uf_src1o_ie	0	R/W	under_flow_src1out_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
16 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	of_src6i_ie	0	R/W	over_flow_src6in_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
5	of_src5i_ie	0	R/W	over_flow_src5in_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
4	of_src4i_ie	0	R/W	over_flow_src4in_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

Bit	Bit Name	Initial Value	R/W	Description
3	of_src3i_ie	0	R/W	over_flow_src3in_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
2	of_src2i_ie	0	R/W	over_flow_src2in_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
1	of_src1i_ie	0	R/W	over_flow_src1in_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
0	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

30.2.18 SRCm Software Reset Register (SRCm_SWRSR)

Note: m = 1 to 6

Function: SRCm_SWRSR is a 32-bit readable/writable register that controls operation/reset of the SRC internal circuits.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SWRST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SWRST	1	R/W	Software Reset While this bit is 0, the SRC internal circuits are put in the reset state. SRCm_* registers except this register are reset. Therefore, they should be set again after the reset is canceled. 0: Resets the SRC 1: SRC enters the operating state

30.2.19 SRCm SRC Initialization Register (SRCm_SRCIR)

Note: m = 1 to 6

Function: SRCm_SRCIR is a 32-bit readable/writable register that initializes the operation of the SRC internal circuits.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	INIT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	INIT	1	R/W	Initialization of Processing When this bit is set to 1, the SRC processing is initialized. This bit should be cleared to 0 after it was set to 1. 0: Processing State 1: Initialization (sets the initial setting of other registers)

30.2.20 SRCm Audio Information Register (SRCm_ADINR)

Note: m = 1 to 6

Function: SRCm_ADINR is a 32-bit readable/writable register that selects channel number and bit length of output audio data.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	OTBL[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	CHNUM[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20 to 16	OTBL[4:0]	00000	R/W	Bit Length of Output Audio Data. These bits set the bit length of output audio data. 00000: 24 bits 00001: Reserved 00010: 22 bits 00011: Reserved 00100: 20 bits 00101: Reserved 00110: 18 bits 00111: Reserved 01000: 16 bits 01001 to 01111: Reserved 10000: 8 bits 10001 to 11111: Reversed
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	CHNUM[3:0]	0000	R/W	Channel Number (For m = 1, 3, or 4) These bits set the channel number. 0000: 0 (None) 0001: 1 channel 0010: 2 channels 0011: Reserved 0100: 4 channels 0101: Reserved 0110: 6 channels 0111: Reserved 1000: 8 channels 1001 to 1111: Reserved Channel Number (For m = 2, 5, or 6) These bits set the channel number. 0000: 0 (None) 0001: 1 channel 0010: 2 channels 0011 to 1111: Reserved

30.2.21 SRCm IFS Control Register (SRCm_IFSCR)

Note: m = 1 to 6

Function: SRCm_IFSCR is a 32-bit readable/writable register that controls INTIFS value.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	INTIFS EN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	INTIFSEN	0	R/W	INTIFS Value Setting Enable This bit controls the INTIFS bit of SRCm_IFSVR register. This bit is effective only in asynchronous SRC Mode (bit SRCMD in SRCm_SRCCR register is 0) 0: Disables INTIFS bit of SRCm_IFSVR register 1: Enables INTIFS bit of SRCm_IFSVR register Basically, this bit should be set to 1.

30.2.22 SRCm IFS Value Setting Register (SRCm_IFSVR)

Note: m = 1 to 6

Function: SRCm_IFSVR is a 32-bit readable/writable register that sets the value of INTIFS. The INTIFS is the initial value of FSI of sampling rate conversion function. SRC detects input sampling rate and output sampling rate automatically. By doing this, it calculates the FSI value so that the below formula is satisfied.

Fin/Fout ≈ FSI/FSO

The INTIFS value is used for the initial value of FSI. If this setting is disabled (INTIFSEN bit of SRCm_IFSCR register is 0), SRC will use FSO for initial value of FSI.

INTIFS = Fin × FSO/Fout

Note: Fin: Input sampling frequency
Fout: Output sampling frequency
FSI: Input sampling rate
FSO: Output sampling rate (Fixed value: 2^{22} = H'040 0000)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	INTIFS[27:16]											
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	INTIFS[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
27 to 0	INTIFS[27:0]	H'000 0000	R/W	Initial Value of FSI These bits set initial value of FSI. These bits should be set the ratio of input and output sampling-rate within the range of the restriction decided from channel number. Example: Fin = 32 kHz Fout = 44.1 kHz FSI = 2^{22} × 32000 / 44100 = 3043485 = H'02E709D For the setting value examples, see Table 30.8.

Note: When SRCm is used in synchronous mode (SRCMD bit in SRCm_SRCCR register is 1), INTIFS can change without SRC initialization. On the operating state, INTIFS can change within 1%.
However, the change of the SRC conversion rate means that it will set jitter by manual operation. Evaluate sound quality, and use this function as far as you judged sound quality is no problem.
If on the occasion of the change more than 1%, it should do SRC initialization (cf. section 30.3.5 (1) (d)) after changing INTIFS.

30.2.23 SRCm SRC Control Register (SRCm_SRCCR)

Note: m = 1 to 6

Function: SRCm_SRCCR is a 32-bit readable/writable register that controls the operation of sampling rate converter.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	—	0	R/W	This bit should be set to 1.
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	—	0	R/W	This bit should be set to 1.
11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	—	0	R/W	This bit should be set to 1.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	—	0	R/W	This bit should be set to 1.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SRCMD	0	R/W	Select SRC Mode 0: Asynchronous SRC 1: Synchronous SRC

Note: Set sync_in or sync_out bit in SRCm_MODE register, when SRCm is used in synchronous mode by setting SRCMD = 1.

30.2.24 SRCm Buffer Size DATA RAM Setting Register (SRCm_BSDSR)

Note: m = 1 to 4

Function: SRCm_BSDSR is a 32-bit readable/writable register that controls the buffer size of DATA RAM. This register should set with SRCm_BSISR register. See Table 30.7 for the combination of settings.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	BUFDATA[10:0]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 16	BUFDATA [10:0]	H'000	R/W	These bits should be set appropriately according to the following table. Refer to Table 30.7 for the combination of FSO/FSI ratio, channel number, and latency.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

FSO/FSI Ratio	Value
6 – 1/6	H'180
6 – 1/4	H'100
6 – 1/3	H'0C0
6 – 1/2	H'080
6 – 2/3	H'060
6 – 1	H'040

30.2.25 SRCn Buffer Size DATA RAM Setting Register (SRCn_BSDSR)

Note: n = 5 or 6

Function: SRCn_BSDSR is a 32-bit readable/writable register that controls the buffer size of DATA RAM. This register should set with SRCm_BSISR register. See Table 30.7 for the combination of settings.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	BUFDATA[10:0]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 16	BUFDATA [10:0]	H'000	R/W	These bits should be set appropriately according to the following table. Refer to Table 30.7 for the combination of FSO/FSI ratio, channel number, and latency.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

FSO/FSI Ratio	Value
6 – 1/6	H'240
6 – 1/4	H'180
6 – 1/3	H'120
6 – 1/2	H'0C0
6 – 2/3	H'090
6 – 1	H'060

30.2.26 SRCm Buffer Size IJEC RAM Setting Register (SRCm_BSISR)

Note: m = 1 to 6

Function: SRCm_BSISR is a 32-bit readable/writable register that controls the precision value and buffer size of IJEC RAM. This register should set with SRCm_BSDSR/SRCn_BSDSR register. See Table 30.7 for the combination of settings.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	IJECPREC[5:0]					
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	IJECSIZE[8:0]								
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21 to 16	IJECPREC[5:0]	H'00	R/W	These bits should be set to H'10.
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8 to 0	IJECSIZE[8:0]	H'000	R/W	These bits should be set appropriately according to the following table. Refer to Table 30.7 for the combination of FSO/FSI ratio, channel number, and latency.

FSO/FSI Ratio	Value
6 – 1/6	H'60
6 – 1/4	H'40
6 – 1/3	H'30
6 – 1/2	H'20
6 – 2/3	H'20
6 – 1	H'20

30.2.27 CTUn Software Reset Register (CTUn_SWRSR)

Note: n = 00, 01, 02, 03, 10, 11, 12, or 13

Function: CTUn_SWRSR is a 32-bit readable/writable register that controls operation/reset of the CTU internal circuits.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SWRST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SWRST	1	R/W	Software Reset While this bit is 0, the CTU internal circuits are put in the reset state. CTUn_* registers except this register are reset. Therefore, they should be set again after the reset is canceled. 0: Resets the CTU 1: Operating state

30.2.28 CTUn CTU Initialization Register (CTUn_CTUIR)

Note: n = 00, 01, 02, 03, 10, 11, 12, or 13

Function: CTUn_CTUIR is a 32-bit readable/writable register that initializes the operation of the CTU internal circuits.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	INIT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	INIT	1	R/W	Initialization of Processing When this bit is set to 1, the CTU processing is initialized. This bit should be cleared to 0 after it was set to 1. 0: Processing State 1: Initialization (sets the initial setting of other registers)

30.2.29 CTUn Audio Information Register (CTUn_ADINR)

Note: n = 00, 01, 02, 03, 10, 11, 12, or 13

Function: CTUn_ADINR is a 32-bit readable/writable register that selects channel number.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	CHNUM[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	CHNUM[3:0]	0000	R/W	Channel Number These bits set the channel number 0000: 0 (None) 0001: 1 channel 0010: 2 channels 0011: Reserved 0100: 4 channels 0101: Reserved 0110: 6 channels 0111: Reserved 1000: 8 channels 1001 to 1111: Reserved

30.2.30 CTUn CTU Pass Mode Register (CTUn_CPMDR)

Note: n = 00, 01, 02, 03, 10, 11, 12, or 13

Function: CTUn_CPMDR is a 32-bit readable/writable register that controls the pass of channel data for each output.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SELOT0[3:0]				SELOT1[3:0]				SELOT2[3:0]				SELOT3[3:0]

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	SELOT0[3:0]	0000	R/W	Select output data for channel 0 These bits select the output data for channel 0. 0000: Connect input data of channel 0 0001: Connect input data of channel 0 0010: Connect input data of channel 1 0011: Connect input data of channel 2 0100: Connect input data of channel 3 0101: Connect input data of channel 4 0110: Connect input data of channel 5 0111: Connect input data of channel 6 1000: Connect input data of channel 7 1001: Connect calculated data by scale values of matrix row 0 1010: Connect calculated data by scale values of matrix row 1 1011: Connect calculated data by scale values of matrix row 2 1100: Connect calculated data by scale values of matrix row 3
27 to 24	SELOT1[3:0]	0000	R/W	Select output data for channel 1 These bits select the output data for channel 1. 0000: Connect input data of channel 1 0001: Connect input data of channel 0 0010: Connect input data of channel 1 0011: Connect input data of channel 2 0100: Connect input data of channel 3 0101: Connect input data of channel 4 0110: Connect input data of channel 5 0111: Connect input data of channel 6 1000: Connect input data of channel 7 1001: Connect calculated data by scale values of matrix row 0 1010: Connect calculated data by scale values of matrix row 1 1011: Connect calculated data by scale values of matrix row 2 1100: Connect calculated data by scale values of matrix row 3

Bit	Bit Name	Initial Value	R/W	Description
23 to 20	SELOT2[3:0]	0000	R/W	Select output data for channel 2 These bits select the output data for channel 2. 0000: Connect input data of channel 2 0001: Connect input data of channel 0 0010: Connect input data of channel 1 0011: Connect input data of channel 2 0100: Connect input data of channel 3 0101: Connect input data of channel 4 0110: Connect input data of channel 5 0111: Connect input data of channel 6 1000: Connect input data of channel 7 1001: Connect calculated data by scale values of matrix row 0 1010: Connect calculated data by scale values of matrix row 1 1011: Connect calculated data by scale values of matrix row 2 1100: Connect calculated data by scale values of matrix row 3
19 to 16	SELOT3[3:0]	0000	R/W	Select output data for channel 3 These bits select the output data for channel 3. 0000: Connect input data of channel 3 0001: Connect input data of channel 0 0010: Connect input data of channel 1 0011: Connect input data of channel 2 0100: Connect input data of channel 3 0101: Connect input data of channel 4 0110: Connect input data of channel 5 0111: Connect input data of channel 6 1000: Connect input data of channel 7 1001: Connect calculated data by scale values of matrix row 0 1010: Connect calculated data by scale values of matrix row 1 1011: Connect calculated data by scale values of matrix row 2 1100: Connect calculated data by scale values of matrix row 3
15 to 12	SELOT4[3:0]	0000	R/W	Select output data for channel 4 These bits select the output data for channel 4. 0000: Connect input data of channel 4 0001: Connect input data of channel 0 0010: Connect input data of channel 1 0011: Connect input data of channel 2 0100: Connect input data of channel 3 0101: Connect input data of channel 4 0110: Connect input data of channel 5 0111: Connect input data of channel 6 1000: Connect input data of channel 7 1001: Connect calculated data by scale values of matrix row 0 1010: Connect calculated data by scale values of matrix row 1 1011: Connect calculated data by scale values of matrix row 2 1100: Connect calculated data by scale values of matrix row 3

Bit	Bit Name	Initial Value	R/W	Description
11 to 8	SELOT5[3:0]	0000	R/W	Select output data for channel 5 These bits select the output data for channel 5. 0000: Connect input data of channel 5 0001: Connect input data of channel 0 0010: Connect input data of channel 1 0011: Connect input data of channel 2 0100: Connect input data of channel 3 0101: Connect input data of channel 4 0110: Connect input data of channel 5 0111: Connect input data of channel 6 1000: Connect input data of channel 7 1001: Connect calculated data by scale values of matrix row 0 1010: Connect calculated data by scale values of matrix row 1 1011: Connect calculated data by scale values of matrix row 2 1100: Connect calculated data by scale values of matrix row 3
7 to 4	SELOT6[3:0]	0000	R/W	Select output data for channel 6 These bits select the output data for channel 6. 0000: Connect input data of channel 6 0001: Connect input data of channel 0 0010: Connect input data of channel 1 0011: Connect input data of channel 2 0100: Connect input data of channel 3 0101: Connect input data of channel 4 0110: Connect input data of channel 5 0111: Connect input data of channel 6 1000: Connect input data of channel 7 1001: Connect calculated data by scale values of matrix row 0 1010: Connect calculated data by scale values of matrix row 1 1011: Connect calculated data by scale values of matrix row 2 1100: Connect calculated data by scale values of matrix row 3
3 to 0	SELOT7[3:0]	0000	R/W	Select output data for channel 7 These bits select the output data for channel 7. 0000: Connect input data of channel 7 0001: Connect input data of channel 0 0010: Connect input data of channel 1 0011: Connect input data of channel 2 0100: Connect input data of channel 3 0101: Connect input data of channel 4 0110: Connect input data of channel 5 0111: Connect input data of channel 6 1000: Connect input data of channel 7 1001: Connect calculated data by scale values of matrix row 0 1010: Connect calculated data by scale values of matrix row 1 1011: Connect calculated data by scale values of matrix row 2 1100: Connect calculated data by scale values of matrix row 3

30.2.31 CTUn Scale Mode Register (CTUn_SCMDR)

Note: n = 00, 01, 02, 03, 10, 11, 12, or 13

Function: CTUn_SCMDR is a 32-bit readable/writable register that selects the number of rows calculated by matrix.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

30.2.64 MIXp Software Reset Register (MIXp_SWRSR)

Note: p = 0 or 1

Function: MIXp_SWRSR is a 32-bit readable/writable register that controls operation/reset of the MIX internal circuits.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SWRST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SWRST	1	R/W	Software Reset While this bit is 0, the MIX internal circuits are put in the reset state. MIXp_* registers except this register are reset. Therefore, they should be set again after the reset is canceled. 0: Resets the MIX 1: Operating state

30.2.65 MIXp MIX Initialization Register (MIXp_MIXIR)

Note: p = 0 or 1

Function: MIXp_MIXIR is a 32-bit readable/writable register that initializes the operation of the MIX internal circuits.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	INIT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	INIT	1	R/W	Initialization of Processing When this bit is set to 1, the MIX processing is initialized. This bit should be cleared to 0 after it was set to 1. 0: Processing State 1: Initialization (sets the initial setting of other registers)

30.2.66 MIXp Audio Information Register (MIXp_ADINR)

Note: p = 0 or 1

Function: MIXp_ADINR is a 32-bit readable/writable register that selects channel number.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	CHNUM[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	CHNUM[3:0]	0000	R/W	Channel Number These bits set the channel number 0000: 0 (None) 0001: 1 channel 0010: 2 channels 0011: Reserved 0100: 4 channels 0101: Reserved 0110: 6 channels 0111: Reserved 1000: 8 channels 1001 to 1111: Reserved

30.2.67 MIXp MIX Mode Register (MIXp_MIXMR)

Note: p = 0 or 1

Function: MIXp_MIXMR is a 32-bit readable/writable register that controls the mix mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MIX MODE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	MIXMODE	0	R/W	MIX Mode This bit controls the mix mode. 0: Selects volume step mixer 1: Selects volume ramp mixer

30.2.68 MIXp MIX Volume Period Register (MIXp_MVPDR)

Note: p = 0 or 1

Function: MIXp_MVPDR is a 32-bit readable/writable register that sets the value of the change of the volume a sample.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	MXPDUP[3:0]				—	—	—	—	MXPDDW[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 8	MXPDUP[3:0]	0000	R/W	MIX Period for Volume Up These bits set the decibel value that changed by one sample for volume up. And when MIXMODE bit of MIXp_MIXMR register is 1, this setting can be used. 0000: 128 dB / 1 sample 0001: 64 dB / 1 sample 0010: 32 dB / 1 sample 0011: 16 dB / 1 sample 0100: 8 dB / 1 sample 0101: 4 dB / 1 sample 0110: 2 dB / 1 sample 0111: 1 dB / 1 sample 1000: 0.5 dB / 1 sample 1001: 0.25 dB / 1 sample 1010: 0.125 dB / 1 sample 1011 to 1111: Reserved
7 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	MXPDDW[3:0]	0000	R/W	MIX Period for Volume Down These bits set the decibel value that changed by one sample for volume down. And when MIXMODE bit of MIXp_MIXMR register is 1, this setting can be used. 0000: -128 dB / 1 sample 0001: -64 dB / 1 sample 0010: -32 dB / 1 sample 0011: -16 dB / 1 sample 0100: -8 dB / 1 sample 0101: -4 dB / 1 sample 0110: -2 dB / 1 sample 0111: -1 dB / 1 sample 1000: -0.5 dB / 1 sample 1001: -0.25 dB / 1 sample 1010: -0.125 dB / 1 sample 1011 to 1111: Reserved

30.2.69 MIXp MIX Decibel A Register (MIXp_MDBAR)

Note: p = 0 or 1

Function: MIXp_MDBAR is a 32-bit readable/writable register that sets the decibel (gain level) of system A.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	MIXDBA[9:0]									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9 to 0	MIXDBA[9:0]	H'000	R/W	dB of System A These bits control the decibel (gain level) of system A. The value can select 1024 points from 0 dB to -∞ dB at intervals of 0.125 dB.

Value	[time]	[dB]	Value	[time]	[dB]
H'000	1	0	……	……	……
.....	.....	.....	H'091	0.125	-18.125
H'031	0.5	-6.125	.....	……	……
.....	.....	.....	H'3FE	4.1×10^{-7}	-127.75
H'061	0.25	-12.125	H'3FF	0 (Mute)	-∞

The relation between the setting value and the decibel is shown in Tables 30.9, 30.10, 30.11 and 30.12.

30.2.70 MIXp MIX Decibel B Register (MIXp_MDBBR)

Note: p = 0 or 1

Function: MIXp_MDBBR is a 32-bit readable/writable register that sets the decibel (gain level) of system B.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	MIXDBB[9:0]									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9 to 0	MIXDBB[9:0]	H'000	R/W	dB of System B These bits control the decibel (gain level) of system B. The value can select 1024 points from 0 dB to -∞ dB at intervals of 0.125 dB.

Value	[time]	[dB]	Value	[time]	[dB]
H'000	1	0	……	……	……
.....	.....	.....	H'091	0.125	-18.125
H'031	0.5	-6.125	.....	……	……
.....	.....	.....	H'3FE	4.1×10^{-7}	-127.75
H'061	0.25	-12.125	H'3FF	0 (Mute)	-∞

The relation between the setting value and the decibel is shown in Tables 30.9, 30.10, 30.11 and 30.12.

30.2.71 MIXp MIX Decibel C Register (MIXp_MDBCR)

Note: p = 0 or 1

Function: MIXp_MDBCR is a 32-bit readable/writable register that sets the decibel (gain level) of system C.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	MIXDBC[9:0]									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9 to 0	MIXDBC[9:0]	H'000	R/W	dB of System C These bits control the decibel (gain level) of system C. The value can select 1024 points from 0 dB to -∞ dB at intervals of 0.125 dB.

Value	[time]	[dB]	Value	[time]	[dB]
H'000	1	0	……	……	……
.....	.....	.....	H'091	0.125	-18.125
H'031	0.5	-6.125	.....	……	……
.....	.....	.....	H'3FE	4.1×10^{-7}	-127.75
H'061	0.25	-12.125	H'3FF	0 (Mute)	-∞

The relation between the setting value and the decibel is shown in Tables 30.9, 30.10, 30.11 and 30.12.

30.2.72 MIXp MIX Decibel D Register (MIXp_MDBDR)

Note: p = 0 or 1

Function: MIXp_MDBDR is a 32-bit readable/writable register that sets the decibel (gain level) of system D.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	MIXDBD[9:0]									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9 to 0	MIXDBD[9:0]	H'000	R/W	dB of System D These bits control the decibel (gain level) of system D. The value can select 1024 points from 0 dB to -∞ dB at intervals of 0.125 dB.

Value	[time]	[dB]	Value	[time]	[dB]
H'000	1	0	……	……	……
.....	.....	.....	H'091	0.125	-18.125
H'031	0.5	-6.125	.....	……	……
.....	.....	.....	H'3FE	4.1×10^{-7}	-127.75
H'061	0.25	-12.125	H'3FF	0 (Mute)	-∞

The relation between the setting value and the decibel is shown in Tables 30.9, 30.10, 30.11 and 30.12.

30.2.73 MIXp MIX Decibel Enable Register (MIXp_MDBER)

Note: p = 0 or 1

Function: MIXp_MDBER is a 32-bit readable/writable register that controls the dB value.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MIX DBEN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	MIXDBEN	0	R/W	MIX dB Enable This bit controls the dB value that sets in MIXp_MDBAR, MIXp_MDBBR, MIXp_MDBCR and MIXp_MDBDR registers. 0: Disables the setting of dB 1: Enables the setting of dB

30.2.74 MIXp MIX Status Register (MIXp_MIXSR)

Note: p = 0 or 1

Function: MIXp_MIXSR is a 32-bit readable register that indicates the status of the volume ramp.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MRPSTS	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	MRPSTS	00	R	MIX Volume Ramp Status These bits indicate the volume ramp status of mix operation. 00: Level of volume ramp is stable 01: Volume ramp down 10: Volume ramp up

30.2.75 DVCp Software Reset Register (DVCp_SWRSR)

Note: p = 0 or 1

Function: DVCp_SWRSR is a 32-bit readable/writable register that controls operation/reset of the DVC internal circuits.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SWRST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SWRST	1	R/W	Software Reset While this bit is 0, the DVC internal circuits are put in the reset state. DVCp_* registers except this register are reset. Therefore, they should be set again after the reset is canceled. 0: Resets the DVC 1: Operating state

30.2.76 DVCp DVU Initialization Register (DVCp_DVUIR)

Note: p = 0 or 1

Function: DVCp_DVUIR is a 32-bit readable/writable register that initializes the operation of the DVC internal circuits.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	INIT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	INIT	1	R/W	Initialization of Processing When this bit is set to 1, the DVC processing is initialized. This bit should be cleared to 0 after it was set to 1. 0: Processing State 1: Initialization (sets the initial setting of other registers)

30.2.77 DVCp Audio Information Register (DVCp_ADINR)

Note: p = 0 or 1

Function: DVCp_ADINR is a 32-bit readable/writable register that selects channel number and bit length of output audio data.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	OTBL[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20 to 16	OTBL[4:0]	00000	R/W	Bit Length of Output Audio Data. These bits set the bit length of output audio data. 00000: 24 bits 00001: Reserved 00010: 22 bits 00011: Reserved 00100: 20 bits 00101: Reserved 00110: 18 bits 00111: Reserved 01000: 16 bits 01001 to 01111: Reserved 10000: 8 bits 10001 to 11111: Reversed
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	CHNUM[3:0]	0000	R/W	Channel Number These bits set the channel number 0000: 0 (None) 0001: 1 channel 0010: 2 channels 0011: Reserved 0100: 4 channels 0101: Reserved 0110: 6 channels 0111: Reserved 1000: 8 channels 1001 to 1111: Reserved

30.2.78 DVCp DVU Control Register (DVCp_DVUCR)

Note: p = 0 or 1

Function: DVCp_DVUCR is a 32-bit readable/writable register that selects the mode of function to operate.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	HWMD
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	VVMD	—	—	—	VRMD	—	—	—	ZCMD
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	HWMD	0	R/W	Enable the DVC_MUTE pin This bit enables DVC_MUTE pin for the setting of DVCEN bit of DVCp_DVUER register. (Set enable only. To set disable, write 0 DVCEN bit) 0: Disables the DVC_MUTE pin 1: Enables the DVC_MUTE pin
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	VVMD	0	R/W	Select Digital Volume Value Mode This bit selects the digital volume value function. 0: Sleep the digital volume value function 1: Use the digital volume value function
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	VRMD	0	R/W	Select Volume Ramp Mode This bit selects the volume ramp function. 0: Sleep the volume ramp function 1: Use the volume ramp function
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	ZCMD	0	R/W	Select Zero Cross Mute Mode This bit selects the zero cross mute function. 0: Sleep the zero cross mute function 1: Use the zero cross mute function

30.2.79 DVCp Zero Cross Mute Control Register (DVCp_ZCMCR)

Note: p = 0 or 1

Function: DVCp_ZCMCR is a 32-bit readable/writable register that controls the operation of the zero cross mute function for each channel.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	ZCEN7	ZCEN6	ZCEN5	ZCEN4	ZCEN3	ZCEN2	ZCEN1	ZCEN0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	ZCEN7	0	R/W	Zero Cross Mute Enable for Channel 7 This bit controls the operation of the zero cross mute function for channel 7. 0: Disables the operation of the zero cross mute function 1: Enables the operation of the zero cross mute function
6	ZCEN6	0	R/W	Zero Cross Mute Enable for Channel 6 This bit controls the operation of the zero cross mute function for channel 6. 0: Disables the operation of the zero cross mute function 1: Enables the operation of the zero cross mute function
5	ZCEN5	0	R/W	Zero Cross Mute Enable for Channel 5 This bit controls the operation of the zero cross mute function for channel 5. 0: Disables the operation of the zero cross mute function 1: Enables the operation of the zero cross mute function
4	ZCEN4	0	R/W	Zero Cross Mute Enable for Channel 4 This bit controls the operation of the zero cross mute function for channel 4. 0: Disables the operation of the zero cross mute function 1: Enables the operation of the zero cross mute function
3	ZCEN3	0	R/W	Zero Cross Mute Enable for Channel 3 This bit controls the operation of the zero cross mute function for channel 3. 0: Disables the operation of the zero cross mute function 1: Enables the operation of the zero cross mute function

Bit	Bit Name	Initial Value	R/W	Description
2	ZCEN2	0	R/W	Zero Cross Mute Enable for Channel 2 This bit controls the operation of the zero cross mute function for channel 2. 0: Disables the operation of the zero cross mute function 1: Enables the operation of the zero cross mute function
1	ZCEN1	0	R/W	Zero Cross Mute Enable for Channel 1 This bit controls the operation of the zero cross mute function for channel 1. 0: Disables the operation of the zero cross mute function 1: Enables the operation of the zero cross mute function
0	ZCEN0	0	R/W	Zero Cross Mute Enable for Channel 0 This bit controls the operation of the zero cross mute function for channel 0. 0: Disables the operation of the zero cross mute function 1: Enables the operation of the zero cross mute function

30.2.80 DVCp Volume Ramp Control Register (DVCp_VRCTR)

Note: p = 0 or 1

Function: DVCp_VRCTR is a 32-bit readable/writable register that controls the operation of the volume ramp function for each channel.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	VREN7	VREN6	VREN5	VREN4	VREN3	VREN2	VREN1	VREN0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	VREN7	0	R/W	Volume Ramp Enable for Channel 7 This bit controls the operation of the volume ramp function for channel 7. 0: Disables the operation of the volume ramp function 1: Enables the operation of the volume ramp function
6	VREN6	0	R/W	Volume Ramp Enable for Channel 6 This bit controls the operation of the volume ramp function for channel 6. 0: Disables the operation of the volume ramp function 1: Enables the operation of the volume ramp function
5	VREN5	0	R/W	Volume Ramp Enable for Channel 5 This bit controls the operation of the volume ramp function for channel 5. 0: Disables the operation of the volume ramp function 1: Enables the operation of the volume ramp function
4	VREN4	0	R/W	Volume Ramp Enable for Channel 4 This bit controls the operation of the volume ramp function for channel 4. 0: Disables the operation of the volume ramp function 1: Enables the operation of the volume ramp function
3	VREN3	0	R/W	Volume Ramp Enable for Channel 3 This bit controls the operation of the volume ramp function for channel 3. 0: Disables the operation of the volume ramp function 1: Enables the operation of the volume ramp function
2	VREN2	0	R/W	Volume Ramp Enable for Channel 2 This bit controls the operation of the volume ramp function for channel 2. 0: Disables the operation of the volume ramp function 1: Enables the operation of the volume ramp function
1	VREN1	0	R/W	Volume Ramp Enable for Channel 1 This bit controls the operation of the volume ramp function for channel 1. 0: Disables the operation of the volume ramp function 1: Enables the operation of the volume ramp function

Bit	Bit Name	Initial Value	R/W	Description
0	VREN0	0	R/W	Volume Ramp Enable for Channel 0 This bit controls the operation of the volume ramp function for channel 0. 0: Disables the operation of the volume ramp function 1: Enables the operation of the volume ramp function

Note: All of these bits should be set to 1 when VRMD bit of DVCp_DVUCR register is 1.

30.2.81 DVCp Volume Ramp Period Register (DVCp_VRPDR)

Note: p = 0 or 1

Function: DVCp_VRPDR is a 32-bit readable/writable register that controls.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	VRPDUP[4:0]					—	—	—	VRPDDW[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 8	VRPDUP[4:0]	00000	R/W	Volume Ramp Period for Volume Up 00000: 1 [sample] (128 dB/1 step) 00001: 2 [sample] (64 dB/1 step) 00010: 4 [sample] (32 dB/1 step) 00011: 8 [sample] (16 dB/1 step) 00100: 16 [sample] (8 dB/1 step) 00101: 32 [sample] (4 dB/1 step) 00110: 64 [sample] (2 dB/1 step) 00111: 128 [sample] (1 dB/1 step) 01000: 256 [sample] (0.5 dB/1 step) 01001: 512 [sample] (0.25 dB/1 step) 01010: 1024 [sample] (0.125 dB/1 step) 01011: 2048 [sample] (0.125 dB/2 steps) 01100: 4096 [sample] (0.125 dB/4 steps) 01101: 8192 [sample] (0.125 dB/8 steps) 01110: 16384 [sample] (0.125 dB/16 steps) 01111: 32768 [sample] (0.125 dB/32 steps) 10000: 65536 [sample] (0.125 dB/64 steps) 10001: 131072 [sample] (0.125 dB/128 steps) 10010: 262144 [sample] (0.125 dB/256 steps) 10011: 524288 [sample] (0.125 dB/512 steps) 10100: 1048576 [sample] (0.125 dB/1024 steps) 10101: 2097152 [sample] (0.125 dB/2048 steps) 10110: 4194304 [sample] (0.125 dB/4096 steps) 10111: 8388608 [sample] (0.125 dB/8192 steps) 11000 to 11111: Reserved
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
4 to 0	VRPDDW[4:0]	00000	R/W	Volume Ramp Period for Volume Down 00000: 1 [sample] (-128 dB/1 step) 00001: 2 [sample] (-64 dB/1 step) 00010: 4 [sample] (-32 dB/1 step) 00011: 8 [sample] (-16 dB/1 step) 00100: 16 [sample] (-8 dB/1 step) 00101: 32 [sample] (-4 dB/1 step) 00110: 64 [sample] (-2 dB/1 step) 00111: 128 [sample] (-1 dB/1 step) 01000: 256 [sample] (-0.5 dB/1 step) 01001: 512 [sample] (-0.25 dB/1 step) 01010: 1024 [sample] (-0.125 dB/1 step) 01011: 2048 [sample] (-0.125 dB/2 steps) 01100: 4096 [sample] (-0.125 dB/4 steps) 01101: 8192 [sample] (-0.125 dB/8 steps) 01110: 16384 [sample] (-0.125 dB/16 steps) 01111: 32768 [sample] (-0.125 dB/32 steps) 10000: 65536 [sample] (-0.125 dB/64 steps) 10001: 131072 [sample] (-0.125 dB/128 steps) 10010: 262144 [sample] (-0.125 dB/256 steps) 10011: 524288 [sample] (-0.125 dB/512 steps) 10100: 1048576 [sample] (-0.125 dB/1024 steps) 10101: 2097152 [sample] (-0.125 dB/2048 steps) 10110: 4194304 [sample] (-0.125 dB/4096 steps) 10111: 8388608 [sample] (-0.125 dB/8192 steps) 11000 to 11111: Reserved

30.2.82 DVCp Volume Ramp Decibel Register (DVCp_VRDBR)

Note: p = 0 or 1

Function: DVCp_VRDBR is a 32-bit readable/writable register that sets the decibel (gain level) of volume ramp.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	VRDB[9:0]									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9 to 0	VRDB[9:0]	H'000	R/W	dB of Volume Ramp These bits control the decibel (gain level) of volume ramp. The value can select 1024 points from 0 dB to -∞ dB at intervals of 0.125 dB.

Value	[time]	[dB]	Value	[time]	[dB]
H'000	1	0	……	……	……
.....	.....	.....	H'091	0.125	-18.125
H'031	0.5	-6.125	.....	……	……
.....	.....	.....	H'3FE	4.1×10^{-7}	-127.75
H'061	0.25	-12.125	H'3FF	0 (Mute)	-∞

The relation between the setting value and the decibel is shown in Tables 30.9, 30.10, 30.11 and 30.12.

30.2.83 DVCp Volume Ramp Wait Time Register (DVCp_VRWTR)

Note: p = 0 or 1

Function: DVCp_VRWTR is a 32-bit readable/writable register that sets the standby time to start the operation of the volume ramp function.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	VRWT[23:16]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VRWT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 0	VRWT[23:0]	H'00 0000	R/W	Volume Ramp Wait Time These bits set the standby time to adjust the start timing of operation of the volume ramp function when the setting of DVCp_VRDBR register is changed. If the internal counter of the DVC logic reached to the value of these bits, the volume ramp function starts to operate to change the volume to target volume of DVCp_VRDBR register.

30.2.84 DVCp Volume Value Setting 0 Register (DVCp_VOL0R)

Note: p = 0 or 1

Function: DVCp_VOL0R is a 32-bit readable/writable register that sets digital volume value for channel 0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	VOLVAL0[23:16]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VOLVAL0[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 0	VOLVAL0 [23:0]	H'00 0000	R/W	Digital Volume Value for Channel 0 These bits set the digital volume of channel 0. The maximum value is 8-time (18 dB) and the minimum value is 0 (-∞ dB). VOLVAL0[23]: Sign bit (The write value should be 0.) VOLVAL0[22:20]: Integer bits VOLVAL0[19:0]: Decimal bits

Value	[time]	[dB]	Value	[time]	[dB]
H'7F FFFF	8	18	H'08 0000	0.5	-6
…	…	…	…	…	…
H'10 0000	1	0	H'00 0001	9.5×10^{-7}	-120
…	…	…	H'00 0000	0	-∞

30.2.85 DVCp Volume Value Setting 1 Register (DVCp_VOL1R)

Note: p = 0 or 1

Function: DVCp_VOL1R is a 32-bit readable/writable register that sets digital volume value for channel 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	VOLVAL1[23:16]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VOLVAL1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

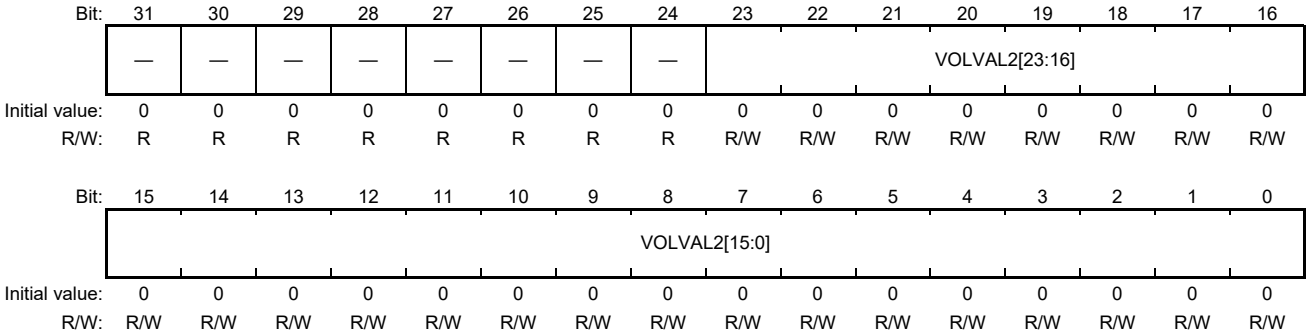
Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 0	VOLVAL1 [23:0]	H'00 0000	R/W	Digital Volume Value for Channel 1 These bits set the digital volume of channel 1. The maximum value is 8-time (18 dB) and the minimum value is 0 (-∞ dB). VOLVAL1[23]: Sign bit (The write value should be 0.) VOLVAL1[22:20]: Integer bits VOLVAL1[19:0]: Decimal bits

Value	[time]	[dB]	Value	[time]	[dB]
H'7F FFFF	8	18	H'08 0000	0.5	-6
…	…	…	…	…	…
H'10 0000	1	0	H'00 0001	9.5×10^{-7}	-120
…	…	…	H'00 0000	0	-∞

30.2.86 DVCp Volume Value Setting 2 Register (DVCp_VOL2R)

Note: p = 0 or 1

Function: DVCp_VOL2R is a 32-bit readable/writable register that sets digital volume value for channel 2.



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 0	VOLVAL2 [23:0]	H'00 0000	R/W	Digital Volume Value for Channel 2 These bits set the digital volume of channel 2. The maximum value is 8-time (18 dB) and the minimum value is 0 (-∞ dB). VOLVAL2[23]: Sign bit (The write value should be 0.) VOLVAL2[22:20]: Integer bits VOLVAL2[19:0]: Decimal bits

Value	[time]	[dB]	Value	[time]	[dB]
H'7F FFFF	8	18	H'08 0000	0.5	-6
…	…	…	…	…	…

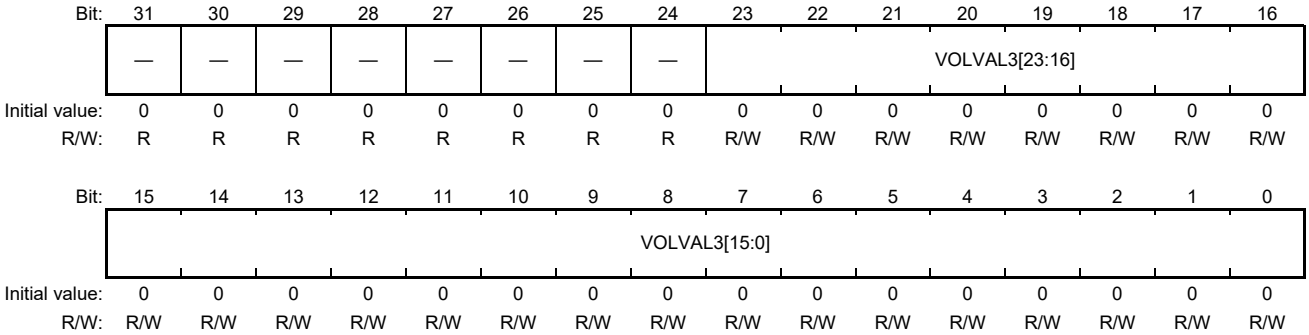
30.2.87 DVCp Volume Value Setting 3 Register (DVCp_VOL3R)

Note: p = 0 or 1

Function: DVCp_VOL3R is a 32-bit readable/writable register that sets digital volume value for channel 3.



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 0	VOLVAL3 [23:0]	H'00 0000	R/W	Digital Volume Value for Channel 3 These bits set the digital volume of channel 3. The maximum value is 8-time (18 dB) and the minimum value is 0 (-∞ dB). VOLVAL3[23]: Sign bit (The write value should be 0.) VOLVAL3[22:20]: Integer bits VOLVAL3[19:0]: Decimal bits

Value	[time]	[dB]	Value	[time]	[dB]
H'7F FFFF	8	18	H'08 0000	0.5	-6
…	…	…	…	…	…
H'10 0000	1	0	H'00 0001	9.5×10^{-7}	-120
…	…	…	H'00 0000	0	-∞

30.2.88 DVCp Volume Value Setting 4 Register (DVCp_VOL4R)

Note: p = 0 or 1

Function: DVCp_VOL4R is a 32-bit readable/writable register that sets digital volume value for channel 4.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	VOLVAL4[23:16]

H'7F FFFF	8	18	H'08 0000	0.5	-6
…	…	…	…	…	…
H'10 0000	1	0	H'00 0001	9.5×10^{-7}	-120
…	…	…	H'00 0000	0	-∞

30.2.90 DVCp Volume Value Setting 6 Register (DVCp_VOL6R)

Note: p = 0 or 1

Function: DVCp_VOL6R is a 32-bit readable/writable register that sets digital volume value for channel 6.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	VOLVAL6[23:16]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VOLVAL6[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 0	VOLVAL6 [23:0]	H'00 0000	R/W	Digital Volume Value for Channel 6 These bits set the digital volume of channel 6. The maximum value is 8-time (18 dB) and the minimum value is 0 (-∞ dB). VOLVAL6[23]: Sign bit (The write value should be 0.) VOLVAL6[22:20]: Integer bits VOLVAL6[19:0]: Decimal bits

Value	[time]	[dB]	Value	[time]	[dB]
H'7F FFFF	8	18	H'08 0000	0.5	-6
…	…	…	…	…	…
H'10 0000	1	0	H'00 0001	9.5×10^{-7}	-120
…	…	…	H'00 0000	0	-∞

30.2.91 DVCp Volume Value Setting 7 Register (DVCp_VOL7R)

Note: p = 0 or 1

Function: DVCp_VOL7R is a 32-bit readable/writable register that sets digital volume value for channel 7.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	VOLVAL7[23:16]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VOLVAL7[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 0	VOLVAL7 [23:0]	H'00 0000	R/W	Digital Volume Value for Channel 7 These bits set the digital volume of channel 7. The maximum value is 8-time (18 dB) and the minimum value is 0 (-∞ dB). VOLVAL7[23]: Sign bit (The write value should be 0.) VOLVAL7[22:20]: Integer bits VOLVAL7[19:0]: Decimal bits

Value	[time]	[dB]	Value	[time]	[dB]
H'7F FFFF	8	18	H'08 0000	0.5	-6
…	…	…	…	…	…
H'10 0000	1	0	H'00 0001	9.5×10^{-7}	-120
…	…	…	H'00 0000	0	-∞

30.2.92 DVCp DVU Enable Register (DVCp_DVUER)

Note: p = 0 or 1

Function: DVCp_DVUER is a 32-bit readable/writable register that controls the setting of DVC registers.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DVCEN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	DVCEN	0	R/W	DVC Register Setting Enable This bit controls the setting of DVC registers (DVCp_ZCMCR, DVCp_VRCTR, DVCp_VRPDR, DVCp_VRDBR, DVCp_VOL0R, DVCp_VOL1R, DVCp_VOL2R, DVCp_VOL3R, DVCp_VOL4R, DVCp_VOL5R, DVCp_VOL6R, DVCp_VOL7R). 0: Disables the setting of dvc registers to DVC logic 1: Enables the setting of dvc registers to DVC logic

30.2.93 DVCp DVU Status Register (DVCp_DVUSR)

Note: p = 0, 1

Function: DVCp_DVUSR is a 32-bit readable register that indicates the status of the zero cross mute and the volume ramp. This register is used for debug.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	ALLZSTS	ZSTS7	ZSTS6	ZSTS5	ZSTS4	ZSTS3	ZSTS2	ZSTS1	ZSTS0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	VRSTS_LEVEL	VRSTS_MUTE	VRSTS[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	ALLZSTS	0	R	All-Channel Zero Cross Mute Status 0: Not all-channel zero cross mute state 1: All-channel zero cross mute state Note: The state is determined only based on the channels for which the zero cross mute function is set.
23	ZSTS7	0	R	Zero Cross Mute Status of Channel 7 This bit indicates the zero cross mute status of channel 7. 0: Not mute status 1: Mute status
22	ZSTS6	0	R	Zero Cross Mute Status of Channel 6 This bit indicates the zero cross mute status of channel 6. 0: Not mute status 1: Mute status
21	ZSTS5	0	R	Zero Cross Mute Status of Channel 5 This bit indicates the zero cross mute status of channel 5. 0: Not mute status 1: Mute status
20	ZSTS4	0	R	Zero Cross Mute Status of Channel 4 This bit indicates the zero cross mute status of channel 4. 0: Not mute status 1: Mute status
19	ZSTS3	0	R	Zero Cross Mute Status of Channel 3 This bit indicates the zero cross mute status of channel 3. 0: Not mute status 1: Mute status
18	ZSTS2	0	R	Zero Cross Mute Status of Channel 2 This bit indicates the zero cross mute status of channel 2. 0: Not mute status 1: Mute status

Bit	Bit Name	Initial Value	R/W	Description
17	ZSTS1	0	R	Zero Cross Mute Status of Channel 1 This bit indicates the zero cross mute status of channel 1. 0: Not mute status 1: Mute status
16	ZSTS0	0	R	Zero Cross Mute Status of Channel 0 This bit indicates the zero cross mute status of channel 0. 0: Not mute status 1: Mute status
15 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	VRSTS_LEVEL	0	R	Volume Ramp Level Status 0: The volume ramp level is not the level specified by the DVCp_VRDBR register. (VRSTS is not 011.) 1: The volume ramp level is the level specified by the DVCp_VRDBR register. (VRSTS is 011.)
3	VRSTS_MUTE	1	R	Volume Ramp Mute Status 0: Not mute status 1: Mute status
2 to 0	VRSTS[2:0]	000	R	Volume Ramp Status These bits indicate the volume ramp status. 000: Mute status 001: Volume ramp down 010: Volume ramp up 011: The volume ramp level is not the level specified by the DVCp_VRDBR register. 100: Volume of input data is maintained (Volume is 1-time) 101~111: Reserved bits

30.2.94 DVCp Interrupt Enable Register (DVCp_DVIER)

Note: p = 0, 1

Function: DVCp_DVIER enables or disables output of interrupts corresponding to the states indicated in the DVCp_DVUSR register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	ALLZSTS_ie	ZSTS7_ie	ZSTS6_ie	ZSTS5_ie	ZSTS4_ie	ZSTS3_ie	ZSTS2_ie	ZSTS1_ie	ZSTS0_ie
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	VRSTS_LEVEL_ie	VRSTS_MUTE_ie	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	ALLZSTS_ie	0	R/W	allzsts_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
23	ZSTS7_ie	0	R/W	zsts7_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
22	ZSTS6_ie	0	R/W	zsts6_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
21	ZSTS5_ie	0	R/W	zsts5_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
20	ZSTS4_ie	0	R/W	zsts4_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
19	ZSTS3_ie	0	R/W	zsts3_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
18	ZSTS2_ie	0	R/W	zsts2_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
17	ZSTS1_ie	0	R/W	zsts1_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
16	ZSTS0_ie	0	R/W	zsts0_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

Bit	Bit Name	Initial Value	R/W	Description
15 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	VRSTS_LEVEL_ie	0	R/W	vrsts_level_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
3	VRSTS_MUTE_ie	0	R/W	vrsts_mute_int_enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
2 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

30.2.95 SRCm in Write Data Register (SRCm in_BUSIF)

Note: m = 1 to 6

Function: SRCm in_BUSIF are window registers in which data is stored during data transfer via SRCm in_BUSIF. These registers are used for transmission.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SRC*m* in_BUSIF															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	-/W	-/W	-/W	-/W	-/W	-/W	-/W	-/W	-/W	-/W	-/W	-/W	-/W	-/W	-/W	-/W

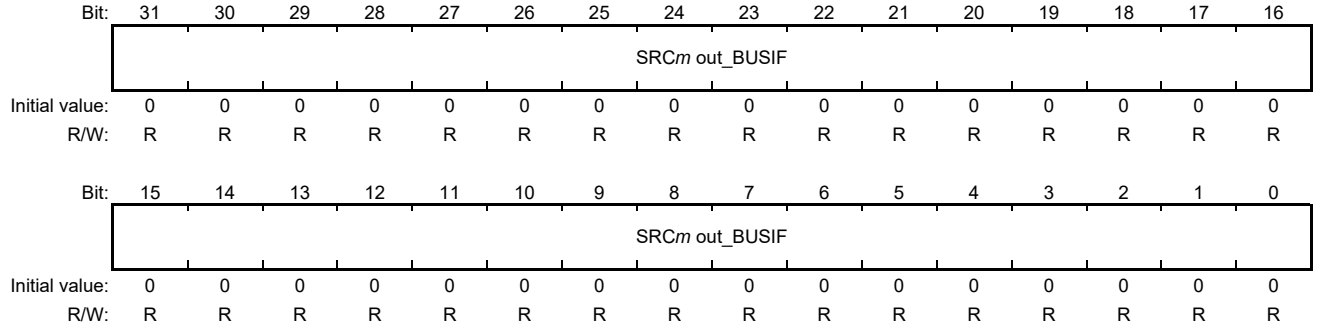
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SRC*m* in_BUSIF															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	-/W	-/W	-/W	-/W	-/W	-/W	-/W	-/W	-/W	-/W	-/W	-/W	-/W	-/W	-/W	-/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SRC*m* in_BUSIF	All 0	-/W	These bits are a window register in which data is stored during data transfer via SRC*m*in_BUSIF. This register is used for transmission.

30.2.96 SRCm out Read Data Register (SRCm out_BUSIF)

Note: m = 1 to 6

Function: SRCm out_BUSIF are window registers in which data is stored during data transfer via SRCm out_BUSIF. These registers are used for reception.

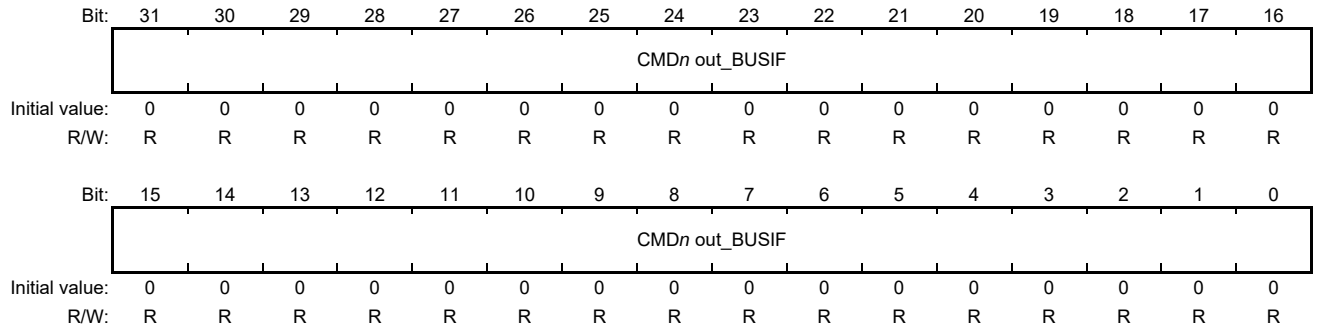


Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SRC*m* out_BUSIF	All 0	R	These bits are a window register in which data is stored during data transfer via SRC*m*out_BUSIF. This register is used for reception.

30.2.97 CMDn out Read Data Register (CMDn out_BUSIF)

Note: n = 0 or 1

Function: CMDn out_BUSIF are window registers in which data is stored during data transfer via CMDn out_BUSIF. These registers are used for reception.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CMD*n* out_BUSIF	All 0	R	These bits are a window register in which data is stored during data transfer via CMD*n*out_BUSIF. This register is used for reception.

30.3 Operation

30.3.1 Procedure for Initializing the SCU

Figures 30.2 and 30.3 show the procedure for initializing the SCU. For details on the register settings, refer to section 30.2, Register Description.

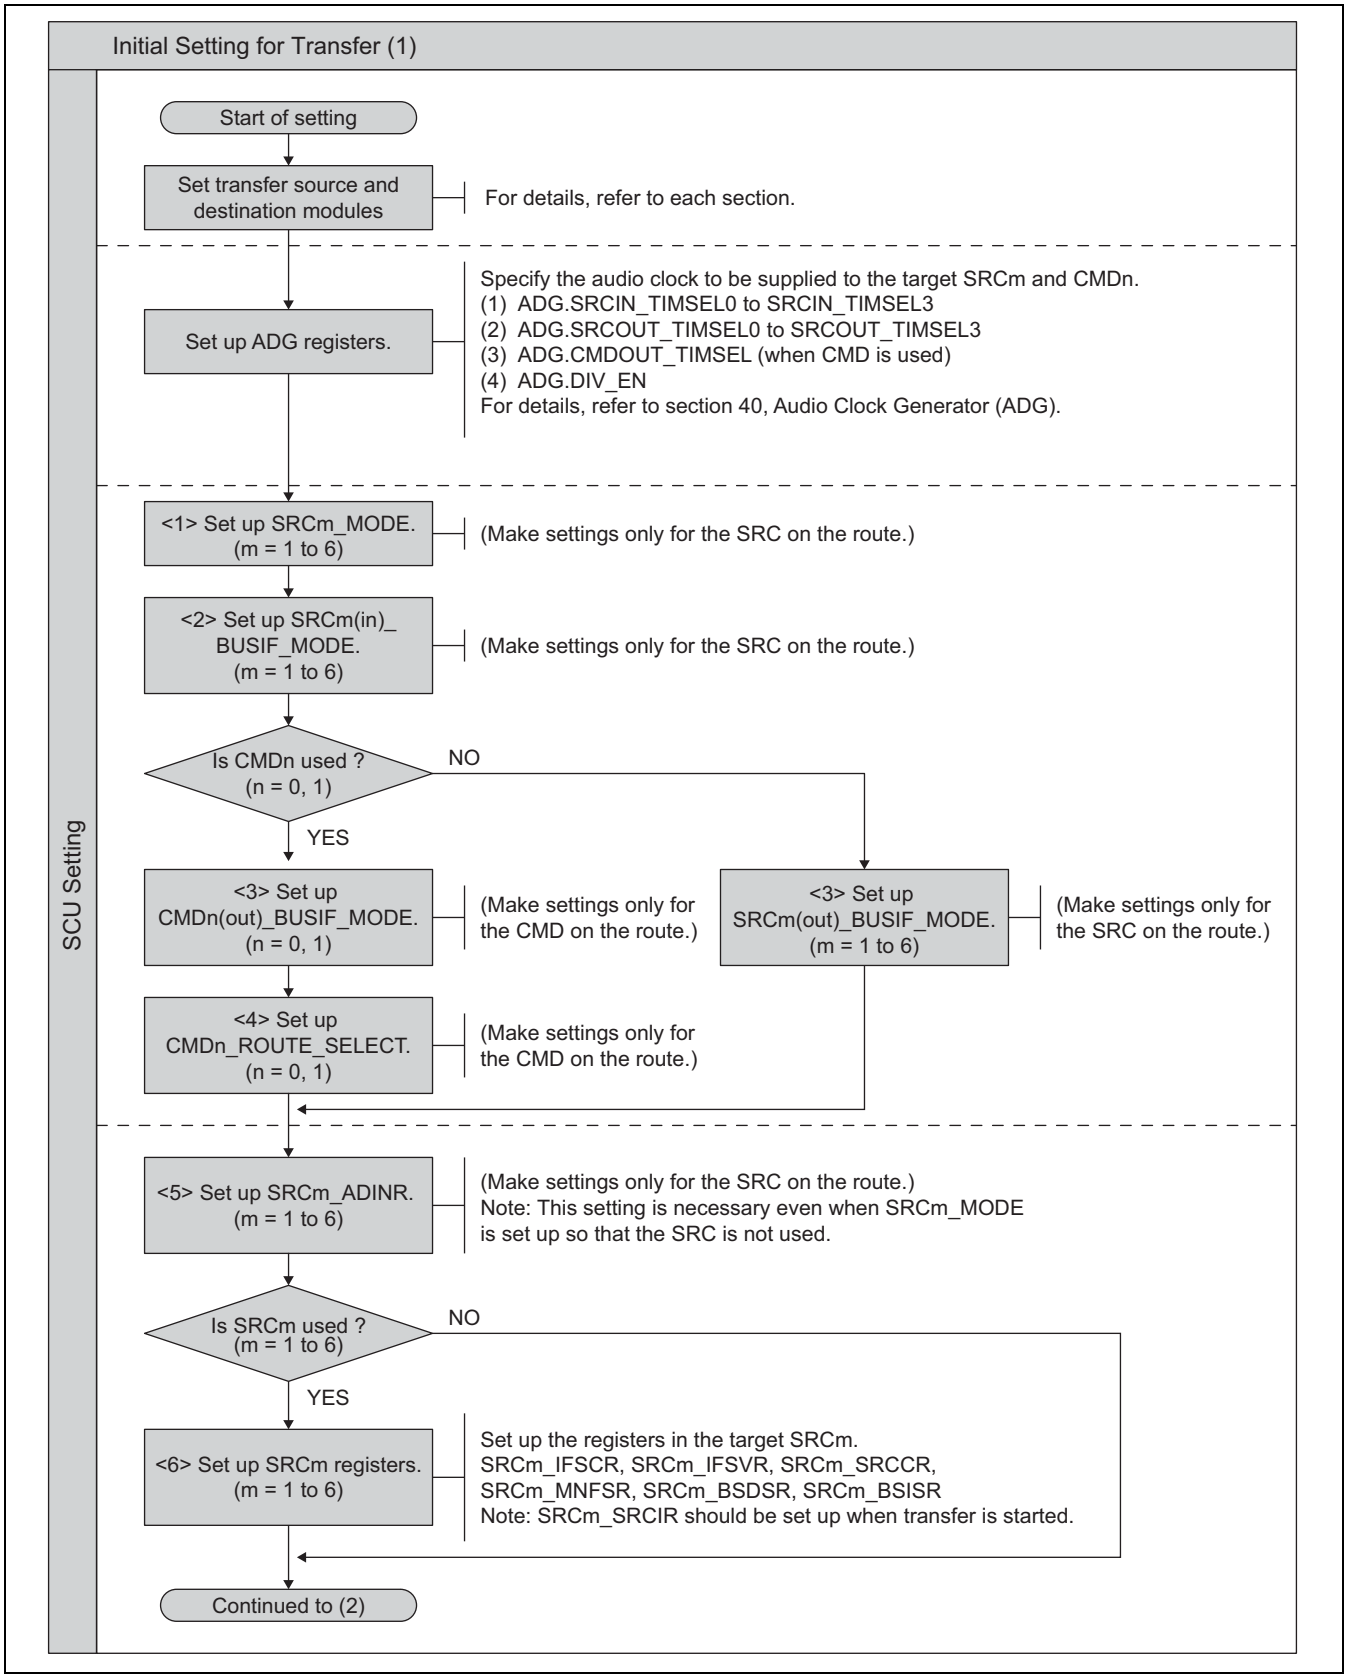


Figure 30.2 Procedure for Initializing the SCU (1)

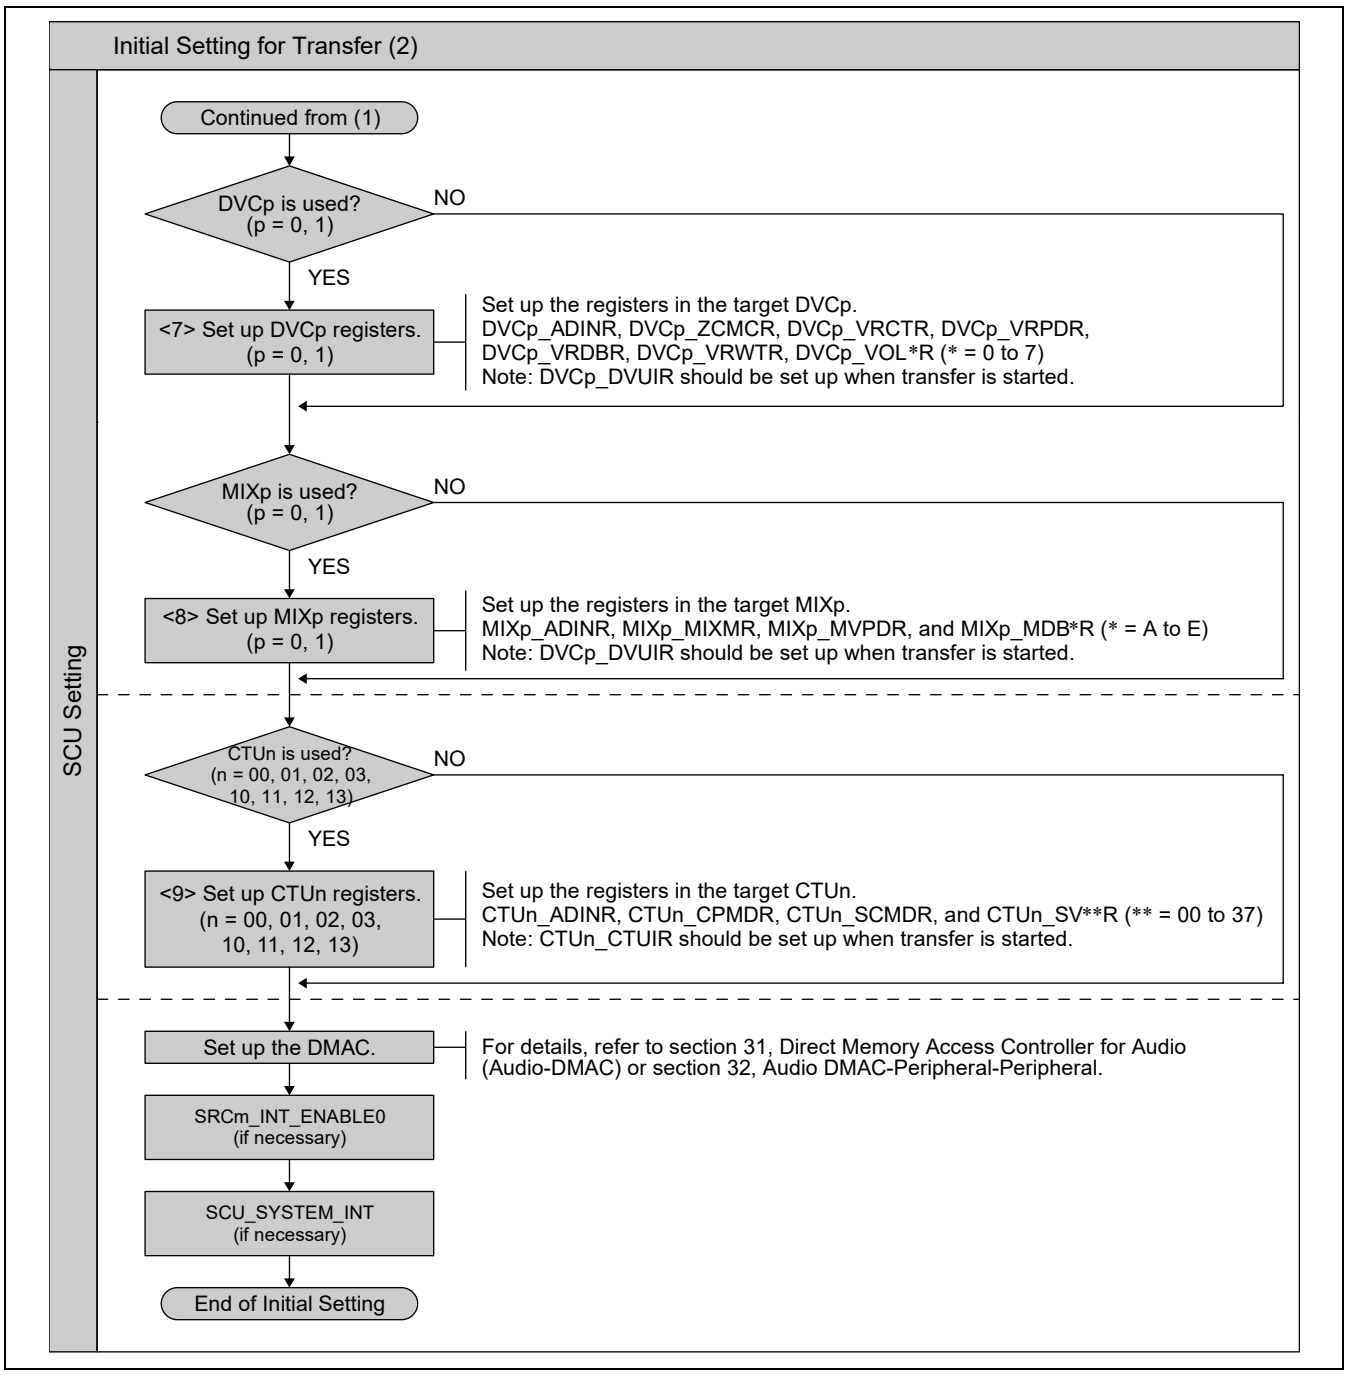

Figure 30.3 Procedure for Initializing the SCU (2)

30.3.2 Procedure for Starting and Stopping Transfer by the SCU

Figure 30.4 shows the procedure for starting and stopping the transfer by the SCU. For details on the register settings, refer to section 30.2, Register Description.

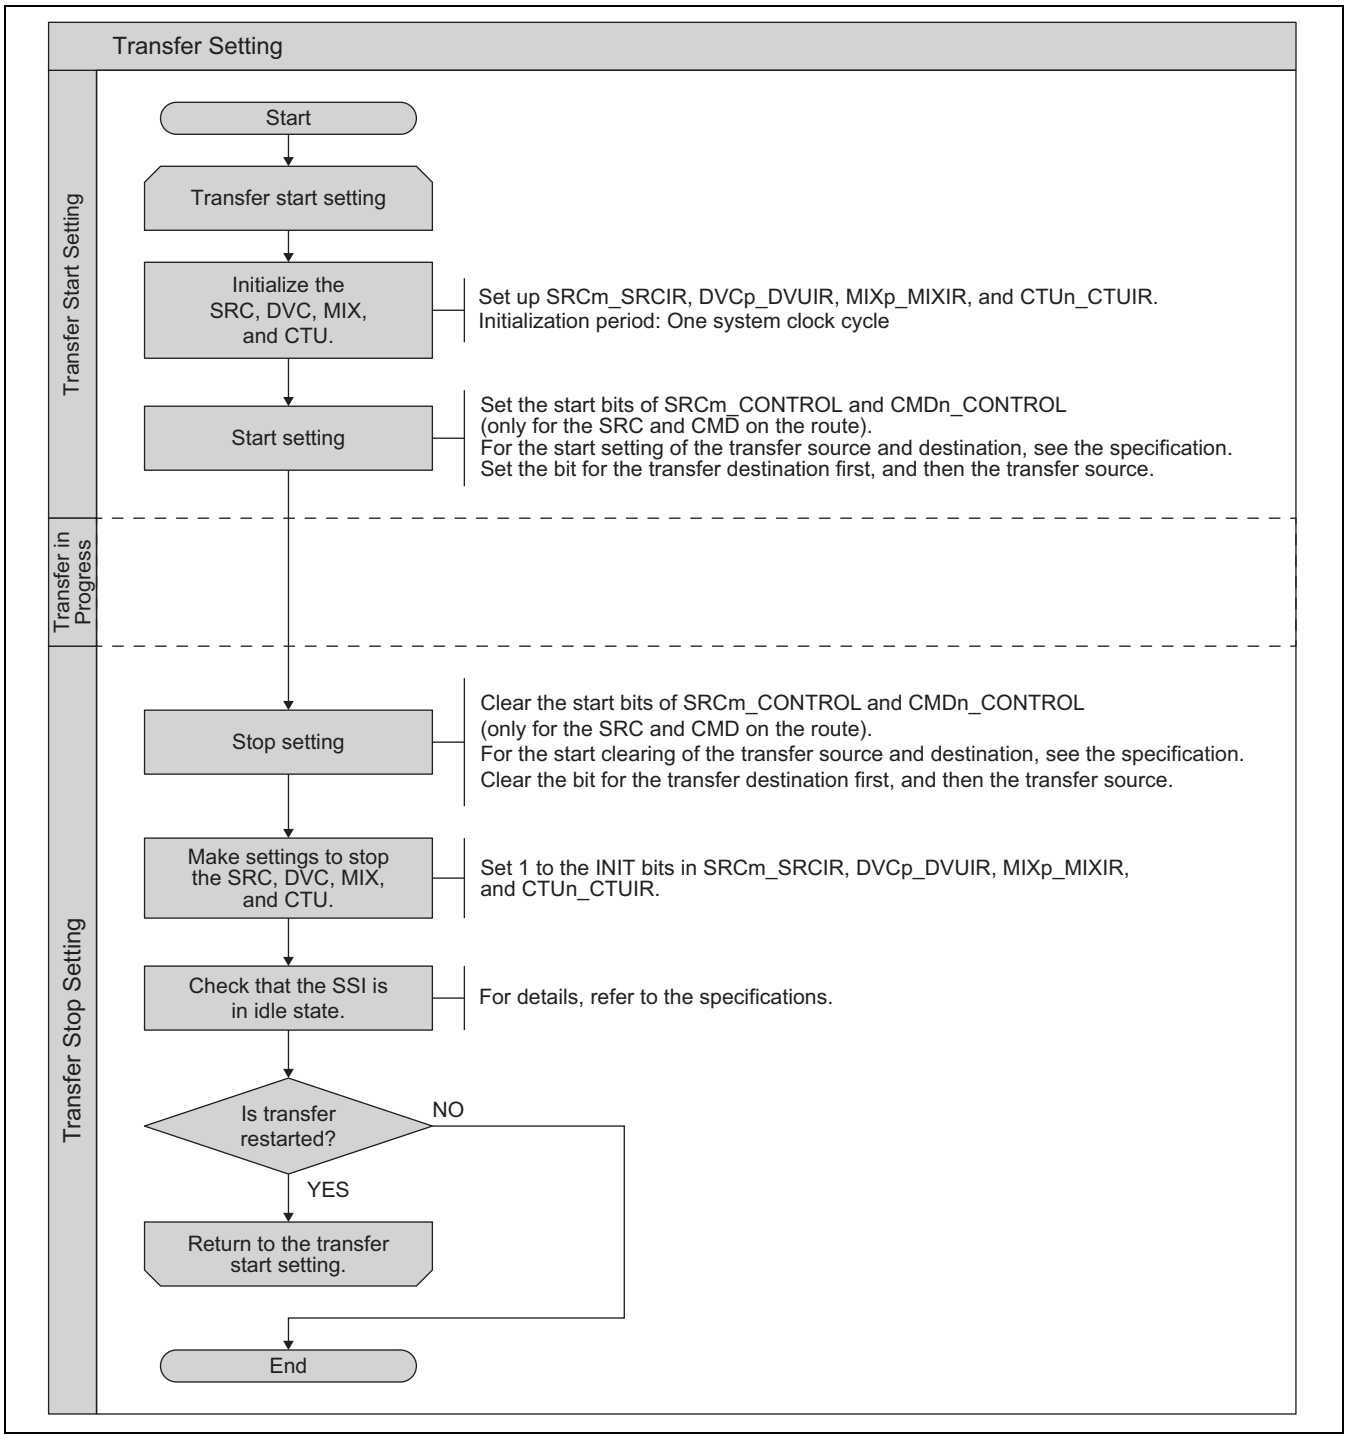

Figure 30.4 Procedure for Starting and Stopping Transfer by the SCU

30.3.3 Data Format for Data Transfer BUSIF

Table 30.3 shows the data formats handled in the SCU. When writing or reading data through the data transfer BUSIF (SRCm in_BUSIF, SRCm out_BUSIF, or CMDn out_BUSIF), align data to match the appropriate data format from those in Table 30.3. Data alignment can be changed through the SRCm(in/out)_BUSIF_MODE, SRCm_MODE register or CMDnout_BUSIF_MODE register (see section 30.2.4, SRCm_MODE Register (SRCm_MODE) or section 30.2.10, CMDn out_BUSIF_MODE Register (CMDn out_BUSIF_MODE)).

Table 30.3 Data Formats Handled in the SCU

24-bit stereo data, multichannel data	17- to 23-bit stereo data, multichannel data	16-bit stereo data, multichannel data	9- to 15-bit stereo data, multichannel data	8-bit stereo data	16-bit monaural data	8-bit monaural data	
Notes: 1. Write 0 to the "x" bits in the table when writing data through the data transfer SRCm in_BUSIF. When reading data through the SRCm out_BUSIF or CMDn out_BUSIF, ignore the values read from these bits.
2. In the 8-bit stereo data format, (Lch/1) and (Rch/1) indicate the data pair to be processed first and (Lch/2) and (Rch/2) indicate the next data pair to be processed.
3. Only the MSB-first data formats can be used in the SRU.

30.3.4 Changing Data Order in Channel Units

The data order can be changed in channel units in the SCU immediately before input to the SRC and immediately after output from the CMD. Tables 30.4 and 30.5 show the data places in each data format. Use SRCm_BUSIF_DALIGN or SRCn_BUSIF_DALIGN to change the order before input to the SRC (see section 30.2.2, SRCm_BUSIF_DALIGN Register (SRCm_BUSIF_DALIGN) or section 30.2.3, SRCn_BUSIF_DALIGN Register (SRCn_BUSIF_DALIGN). Use CMDn_BUSIF_DALIGN to change the order immediately after output from the CMD (see section 30.2.11, CMDn_BUSIF_DALIGN Register (CMDn_BUSIF_DALIGN)). Tables 30.4 and 30.5 show the data places when these registers are set to the initial values.

Table 30.4 Data Places in Each Data Format (1)

BUSIF · Stereo (2 channels) · 24 bits	External memory image BUSIF · Stereo (2 channels) · 16 bits	External memory image BUSIF · Stereo (2 channels) · 8 bits	External memory image BUSIF · Monaural (1 channel) · 8/16 bits	External memory image BUSIF · Multichannel (4 channels) · 24 bits	External memory image BUSIF · Multichannel (4 channels) · 16 bits	External memory image 
Table 30.5 Data Places in Each Data Format (2)

30.3.5 SRC Block

The SRC is a block for implementing the sampling rate conversion function, which can convert asynchronous sampling rates.

- Asynchronous sampling rate conversion is available
- Supports resolutions up to 24 bits
- High-sound-quality type (THD+N is -132 dB) and general-sound-quality type (THD+N is -96 dB)
- Automatically generates antialiasing filter coefficients
- Three modules support one, two, four, six, or eight channels, and six three modules support one or two channels.

Figure 30.5 shows the SRC block diagram.

The "Input audio data" in the figure indicates the data before SRC processing is applied. The "Output audio data" indicates the data after SRC processing is applied.

The "Input data timing" is a signal to show the sampling period for the input audio data. The "Output data timing" is a signal to show the sampling period for the output audio data. When CMD is used in the route, the output data timing signal is the same signal as the output data timing signal used in the CMD.

In synchronous mode specified by setting the SRCMD bit in the SRCm_SRCCR register, when the sync_in bit in the SRCm_MODE register is set to 1, the SRCm doesn't need the input data timing signal, and when the sync_out bit in the SRCm_MODE register is set to 1, the SRCm doesn't need the output data timing signal.

Before using the SRC function, be sure to specify the sampling rate through the SRCm IFS value setting register (see section 30.2.22, SRCm IFS Value Setting Register (SRCm_IFSVR).

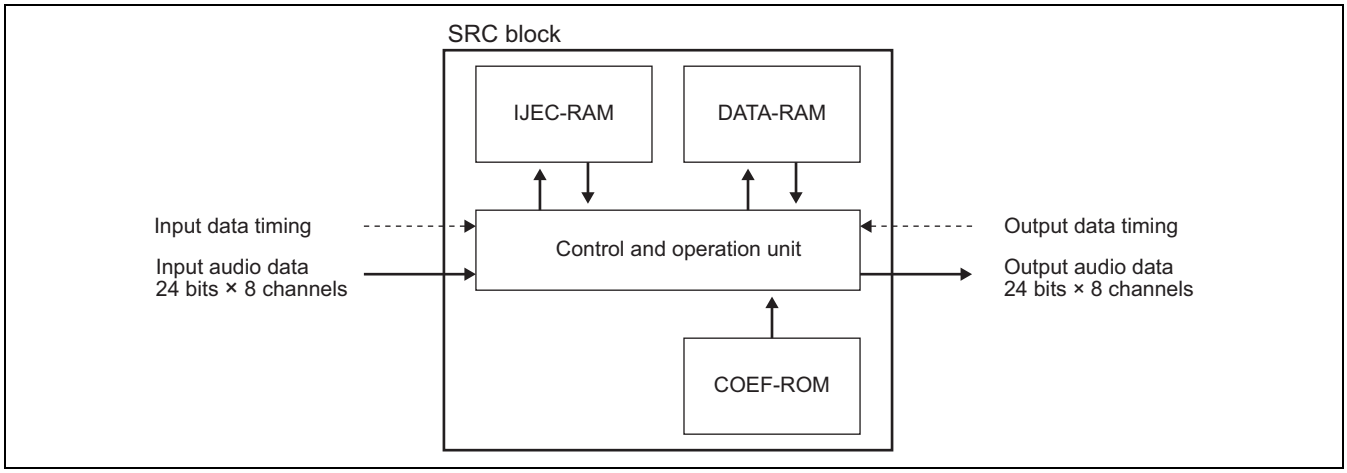

Figure 30.5 SRC Block Diagram

Table 30.6 shows the SRC functions.

Table 30.6 SRC Functions

Item		Performance			
Type of SRC		Asynchronous/ Synchronous SRC			
Channel number		1 or 2	4	6	8
Sampling rate of input source	SRC1, SRC3, SRC4	8k to 192k [Hz]	8k to 192k [Hz]	8k to 128k [Hz]	8k to 96k [Hz]
	SRC2	8k to 192k [Hz]	—	—	—
	SRC5, SRC6	8k to 192k [Hz]	—	—	—
Sampling rate of output source	SRC1, SRC3, SRC4	8k to 192k [Hz]	8k to 192k [Hz]	8k to 128k [Hz]	8k to 96k [Hz]
	SRC2	8k to 192k [Hz]	—	—	—
	SRC5, SRC6	8k to 192k [Hz]	—	—	—
Ratio of input and output sampling rates (FSO/FSI ratio)	SRC1, SRC3, SRC4	6 to 1/6 [times]	6 to 1/4 [times]	6 to 1/2 [times]	6 to 1/2 [times]
	SRC2	6 to 1/6 [times]	—	—	—
	SRC5, SRC6	6 to 1/6 [times]	—	—	—
Sound quality (THD+N)	SRC1 to SRC4	-132 dB (for high-quality type)			
	SRC5, SRC6	-96 dB (for general-quality type)			

Table 30.7 shows the IJEC RAM and DATA RAM buffer size settings and the latencies.

Latency is different by setting of channel number.

Select the combination of settings BUFDATA[10:0] bits in SRCm_BSDSR/ SRCn_BSDSR register and IJECSIZE[8:0] bits in SRCm_BSISR register from Table 30.7. Operation cannot be guaranteed if the register is not set as specified combination.

Output delay depends on FSO/FSI ratio and it is calculated from following formula.

Output delay [sample] = (Processing delay) × (FSO/FSI ratio) + (Logic delay)

Table 30.7 Combination of Register Setting Related to FSO/FSI Ratio and Channel, Latency

Item	Setting Range FSO/FSI Ratio	Channel Number	Register Setting IJEC SIZE [8:0]	Register Setting BUF DATA [10:0]	Processing Delay [sample]	Latency (Example case calculated by formula, Logic delay = 3) 6	4	3	2	1	2/3	1/2	1/3	1/4	1/6	Note
SRC1 SRC3 SRC4	6 to 1/6	1 to 2	H'60	H'180	241	1449	967	726	485	244	164	124	83	63	43	*
	6 to 1/4	1 to 4	H'40	H'100	161	969	647	486	325	164	110	84	57	43		
	6 to 1/3	1 to 4	H'30	H'0C0	121	729	487	366	245	124	84	64	43			
	6 to 1/2	1 to 8	H'20	H'080	81	489	327	246	165	84	57	44				
	6 to 2/3	1 to 8	H'20	H'060	65	393	263	198	133	68	46

(1) Register Setting Procedure

The following describes the SRC register setting procedures. The register should be used according to the following procedures.

(a) SRC Processing Procedure

Figure 30.6 shows the processing procedure of SRC.

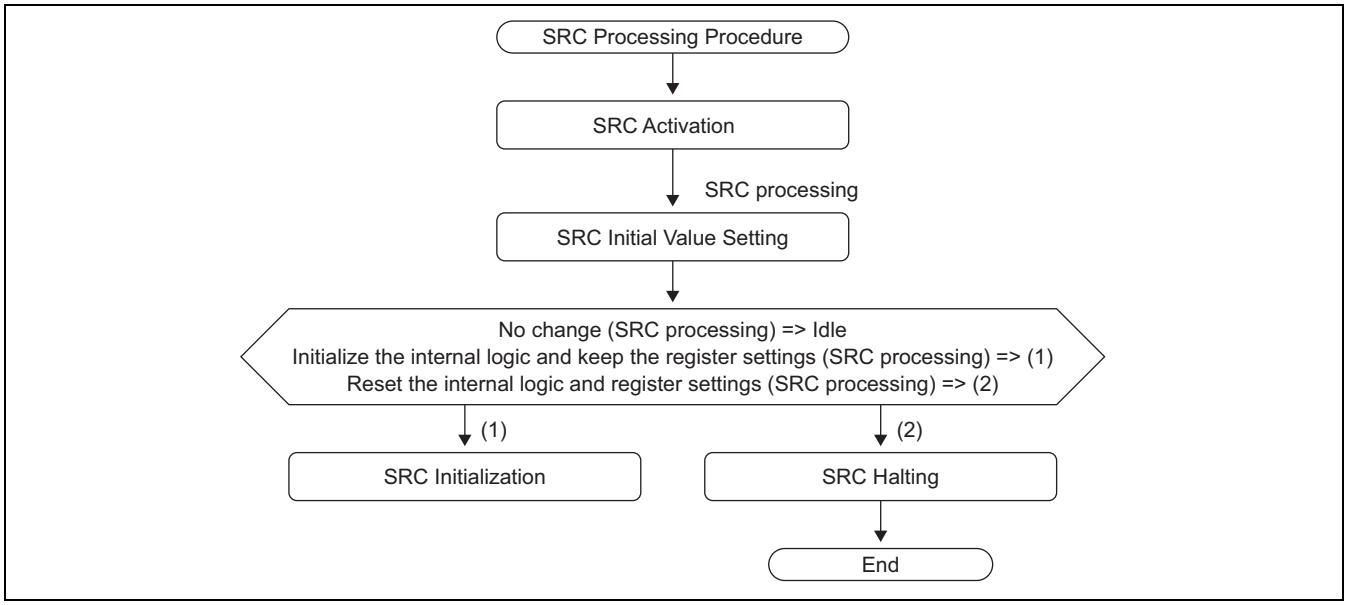

Figure 30.6 SRC Processing Procedure

(b) SRC Activation

Figure 30.7 shows the SRC activation flowchart. When the SRC is activated, a software reset should be set to initialize logic and register setting. Then, the software reset should be cleared and ready to operate SRC. When reset the SRC function, all registers are initialized. If the SRC function was initialized by a hardware reset, it doesn't need to initialize the SRC function by software reset.

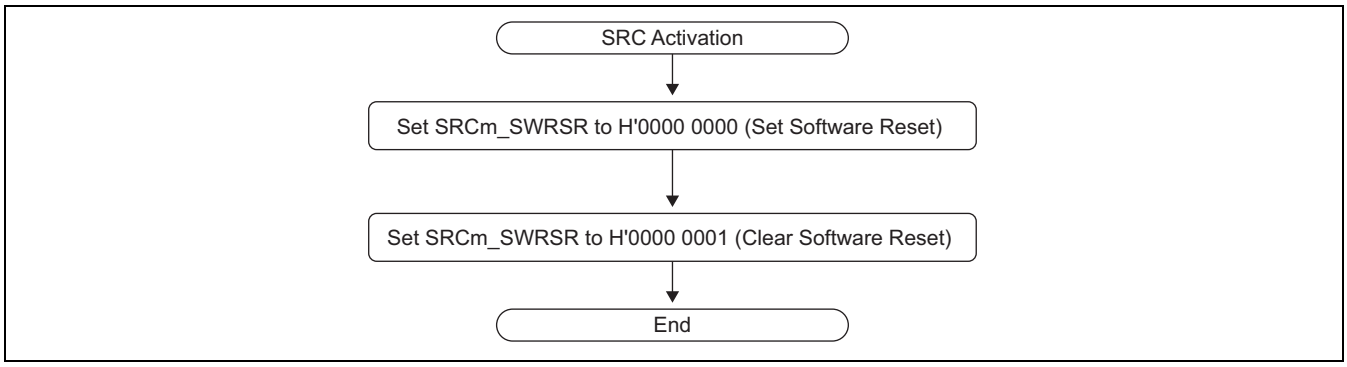

Figure 30.7 SRC Activation Flowchart

(c) SRC Initial Value Setting

Figure 30.8 shows the flowchart of the SRC initial value setting. Before operating SRC function, the initial values should be set.

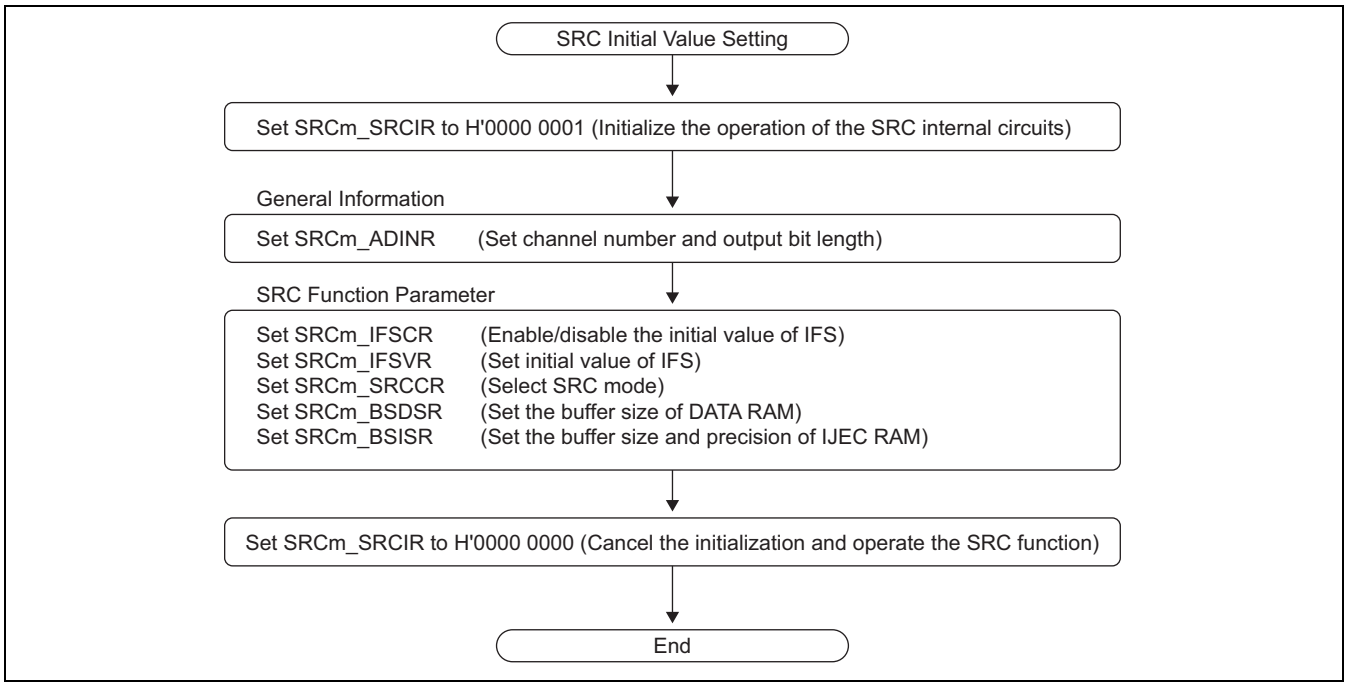

Figure 30.8 SRC Initial Value Setting Flowchart

(d) SRC Initialization

Figure 30.9 shows the SRC initialization flowchart. SRCm_SRCIR register doesn't initialize the register settings and these values are maintained. Before cancel the initialization, it is necessary to set or check the register settings of peripheral IP. And also it is necessary to provide the input and output timing signal.

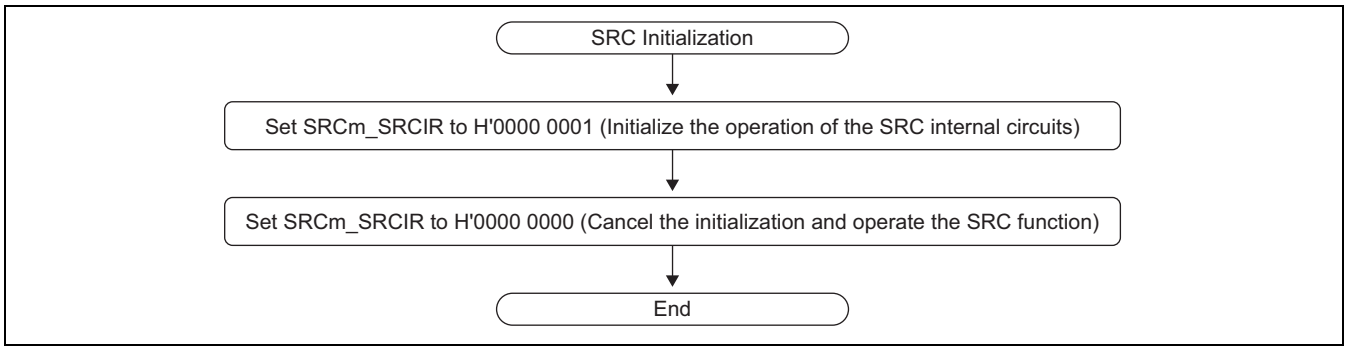

Figure 30.9 SRC Initialization Flowchart

(e) SRC Halting

Figure 30.10 shows the flowchart of SRC halting. When SRC is halting, it should be initialized or reset by software reset or hardware reset. Before initializing or reset the SRC function, it is necessary to confirm the register settings and operation of peripheral IP.

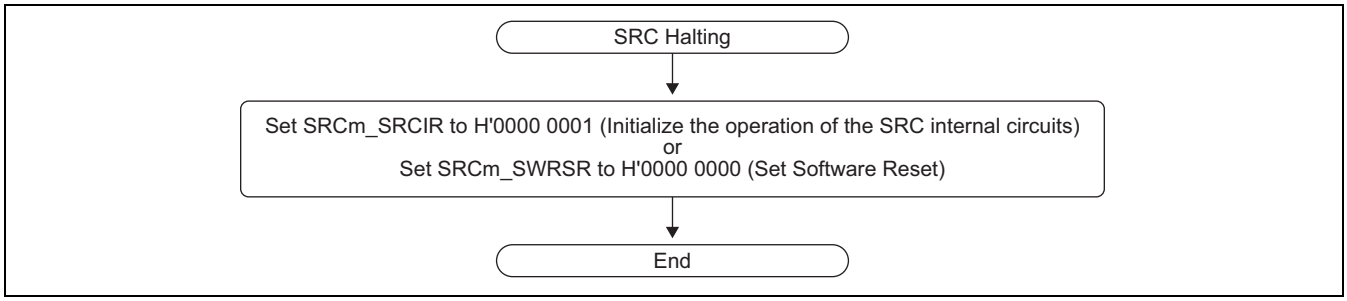

Figure 30.10 SRC Halting Flowchart

30.3.6 CMD Block

The CMD is a block for implementing the channel transfer unit (CTU block), mixing (MIX block), and digital volume and mute (DVC block) functions. Figure 30.11 shows the CMD block diagram.

The "Input audio data 0" to "Input audio data 3" in the figure indicate the data before the CMD function is applied. The "Output audio data" indicates the data after the CMD function is applied.

The "Output data timing" is a signal to show the sampling period for the output audio data. In addition, give the same signals to CMD output timing signal and output data timing signal used in the SRC.

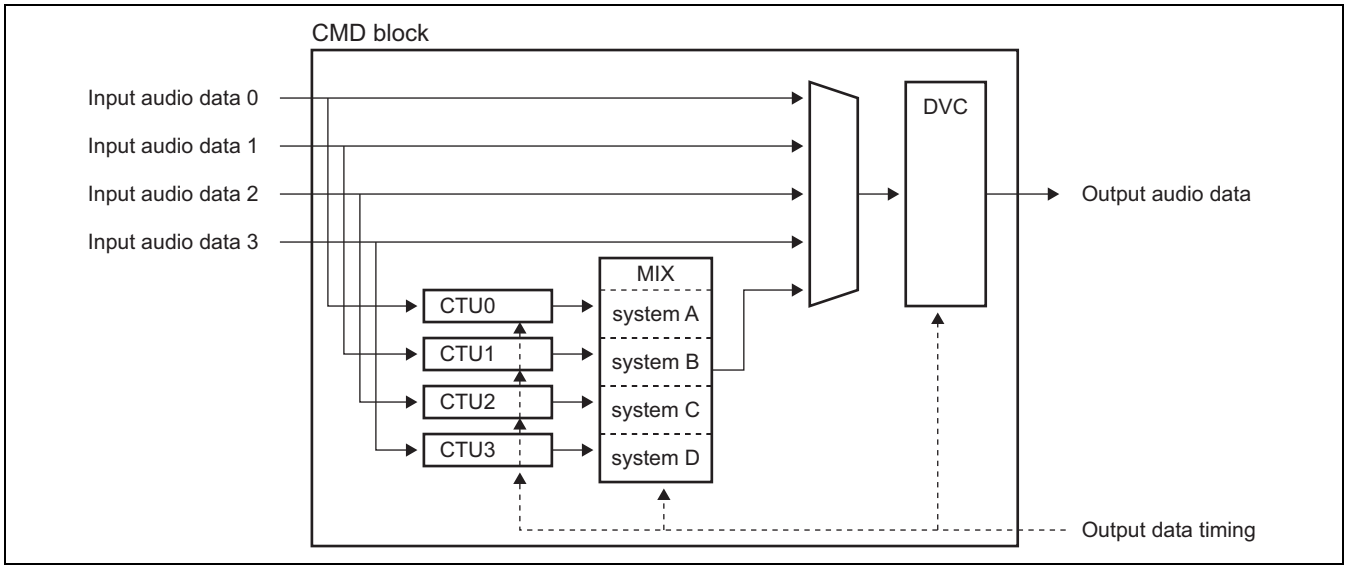

Figure 30.11 CMD Block Diagram

30.3.7 Functional Blocks in CMD

(1) CTU Block

The CTU is a block for implementing channel transfer unit functions such as downmixing and splitter functions.

- Conversion of eight input channels into two output channels
- Conversion of six input channels into two output channels
- Conversion of two input channels into four sets of two output channels
- Conversion of one input channel into eight sets of one output channel
- No conversion

The settings of the Scale Value e00 to Scale Value e37 registers are calculated by using the following formula (signed bits are excluded):

Setting (decimal) = $10^{X} \times 4194304$
X = (value in dB) / 20

(a) Register Setting Procedure

The following describes the CTU register setting procedures. The register should be used according to the following procedures.

- CTU Processing Procedure
  Figure 30.12 shows the processing procedure of CTU.

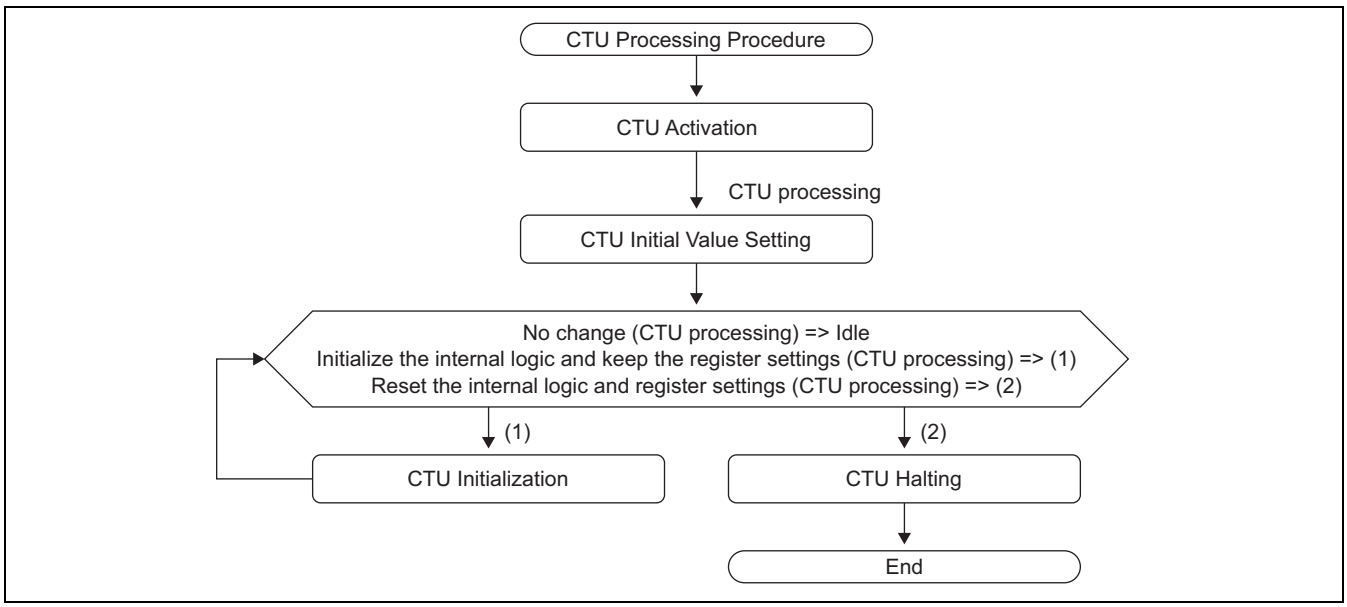

Figure 30.12 CTU Processing Procedure

- CTU Activation
  Figure 30.13 shows the CTU activation flowchart. When the CTU is activated, a software reset should be set to initialize logic and register setting. Then, the software reset should be cleared and ready to operate CTU. When reset the CTU function, all registers are initialized. If the CTU function was initialized by a hardware reset, it doesn't need to initialize the CTU function by software reset.

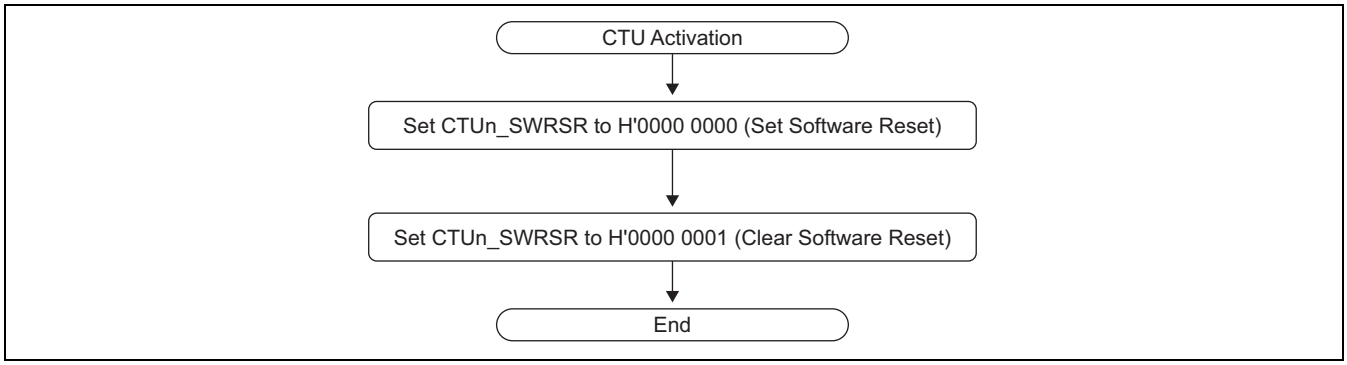

Figure 30.13 CTU Activation Flowchart

- CTU Initial Value Setting

  Figure 30.14 shows the flowchart of the CTU initial value setting. Before operating CTU function, the initial values should be set. After set the register setting and cancel the initialization, CTU module starts the operation.

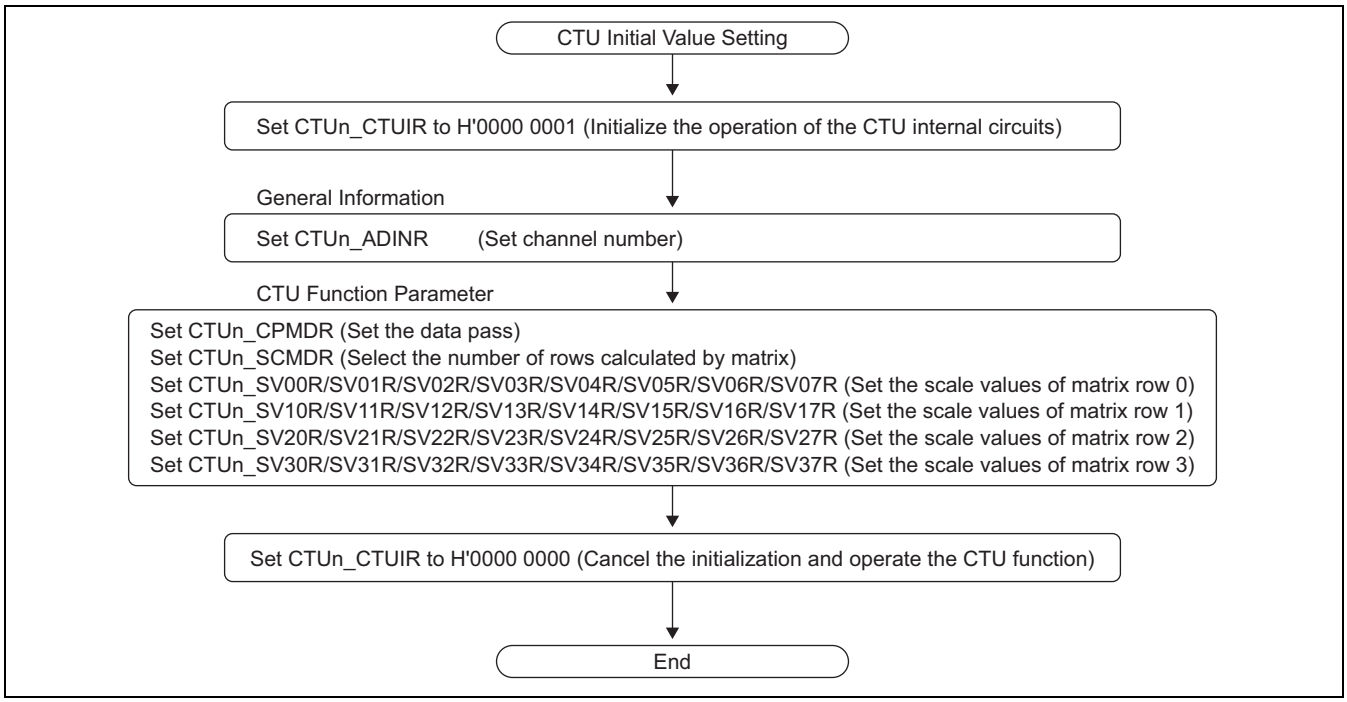

Figure 30.14 CTU Initial Value Setting Flowchart

- CTU Initialization

  Figure 30.15 shows the CTU initialization flowchart. CTUn_CTUIR register doesn't initialize the register settings and these values are maintained. Before cancel the initialization, it is necessary to set or check the register settings of peripheral IP.

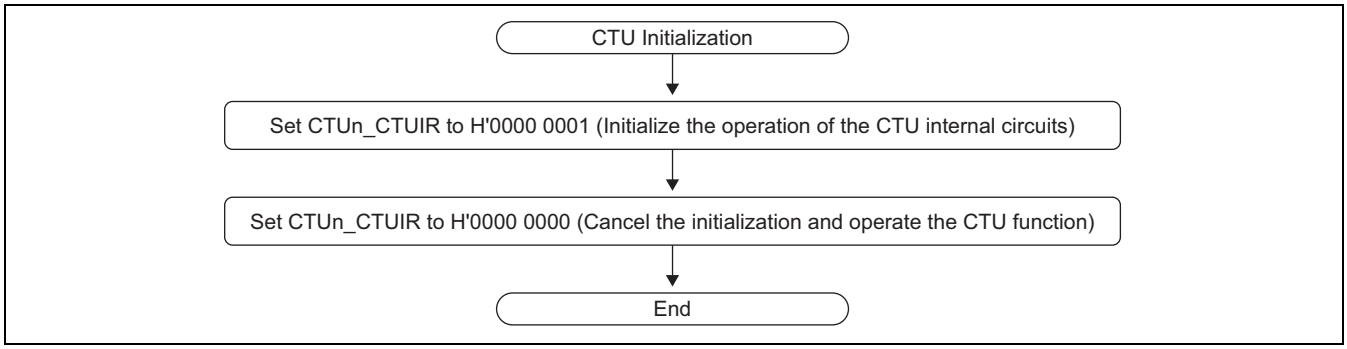

Figure 30.15 CTU Initialization Flowchart

- CTU Halting

  Figure 30.16 shows the flowchart of CTU halting. When CTU is halting, it should be initialized or reset by software reset or hardware reset. Before initializing or reset the CTU function, it is necessary to confirm the register settings and operation of peripheral IP.

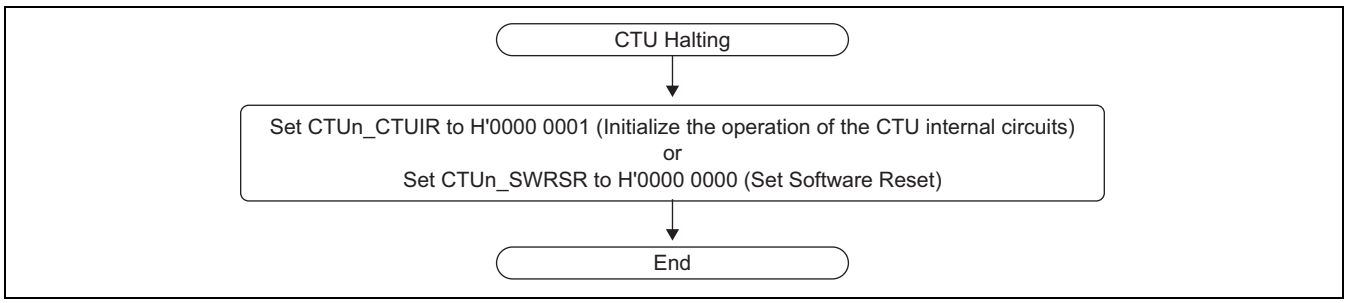

Figure 30.16 CTU Halting Flowchart

- CTU – Example

  The channel conversion executes the linear transformation (matrix operation) as follows.

$$\begin{pmatrix} y_0 \\ y_1 \\ y_2 \\ y_3 \\ y_4 \\ y_5 \\ y_6 \\ y_7 \end{pmatrix} = \begin{pmatrix} e_{00} & e_{01} & e_{02} & e_{03} & e_{04} & e_{05} & e_{06} & e_{07} \\ e_{10} & e_{11} & e_{12} & e_{13} & e_{14} & e_{15} & e_{16} & e_{17} \\ e_{20} & e_{21} & e_{22} & e_{23} & e_{24} & e_{25} & e_{26} & e_{27} \\ e_{30} & e_{31} & e_{32} & e_{33} & e_{34} & e_{35} & e_{36} & e_{37} \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix} \times \begin{pmatrix} x_0 \\ x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \\ x_6 \\ x_7 \end{pmatrix}$$

x_i : Input data of channel i (i = 0 to 7)
y_i: Output data of channel i (i = 0 to 7)
e_j: CTUn_SVjR.SVEj (j = 00, 01, 02, 03, 04, 05, 06, 07,

(a) Register Setting Procedure

The following describes the MIX register setting procedures. The register should be used according to the following procedures.

- MIX Processing Procedure
  Figure 30.20 shows the processing procedure of MIX.

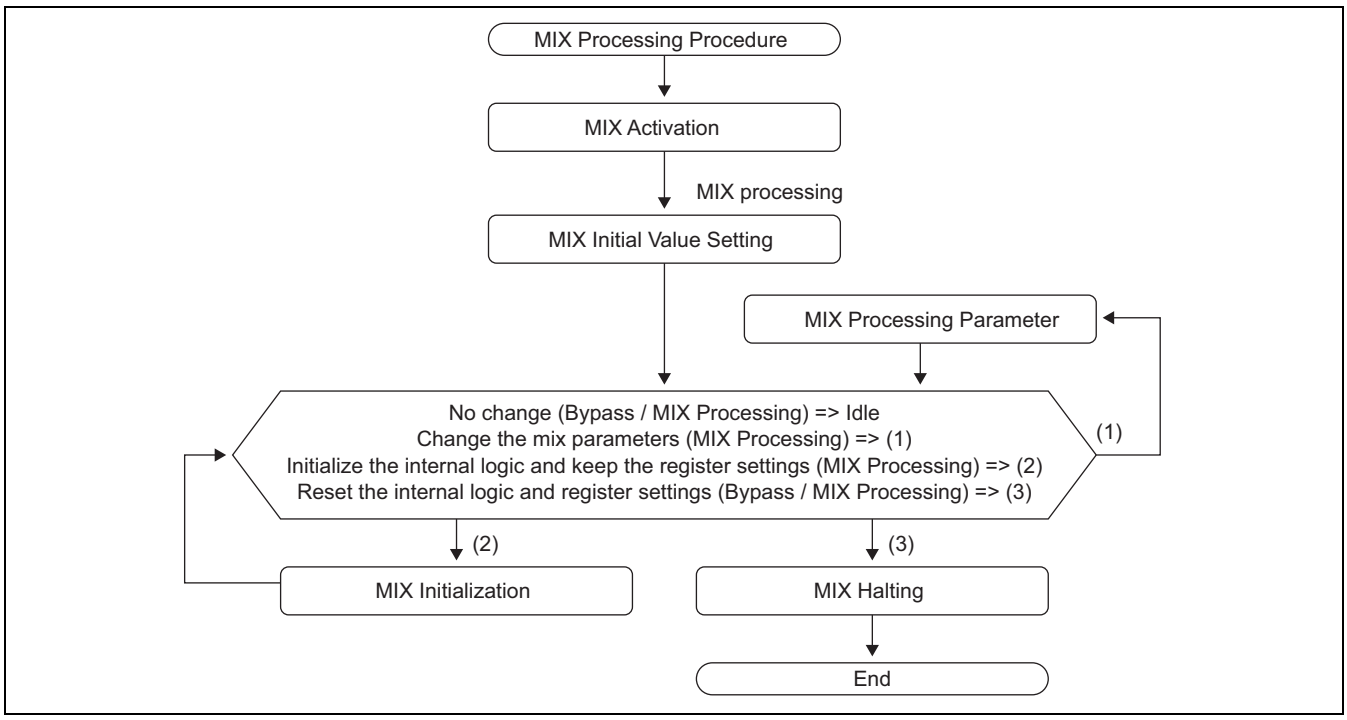

Figure 30.20 MIX Processing Procedure

- MIX Activation
  Figure 30.21 shows the MIX activation flowchart. When the MIX is activated, a software reset should be set to initialize logic and register setting. Then, the software reset should be cleared and ready to operate MIX. When reset the MIX function, all registers are initialized. If the MIX function was initialized by a hardware reset, it doesn't need to initialize the MIX function by software reset.

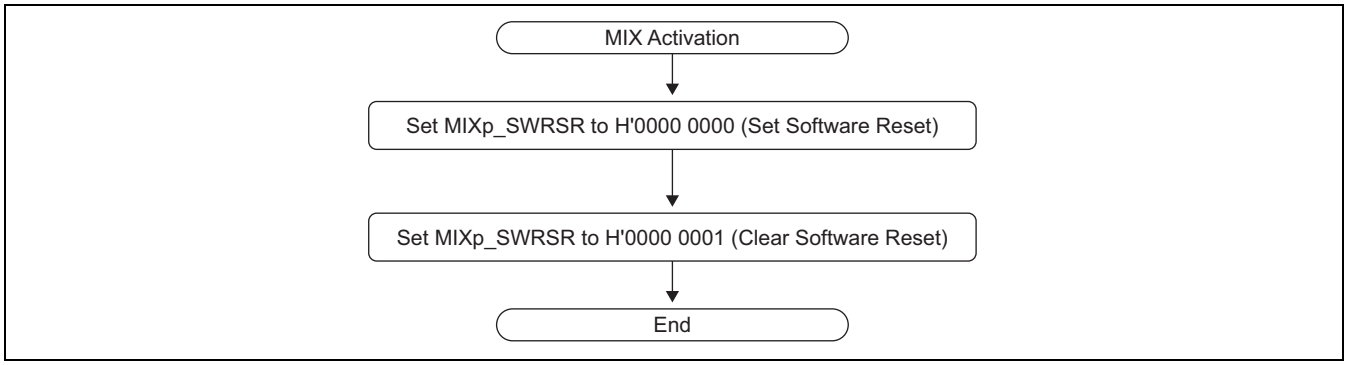

Figure 30.21 MIX Activation Flowchart

- MIX Initial Value Setting

  Figure 30.22 shows the flowchart of the MIX initial value setting. Before operating MIX function, the initial values should be set. After set the register setting and cancel the initialization, MIX module changes the volume of each system by volume step to the dB value of MIXp_MDBAR and MIXp_MDBBR and MIXp_MDBCR and MIXp_MDBDR regardless of MIXp_MIXMR setting.

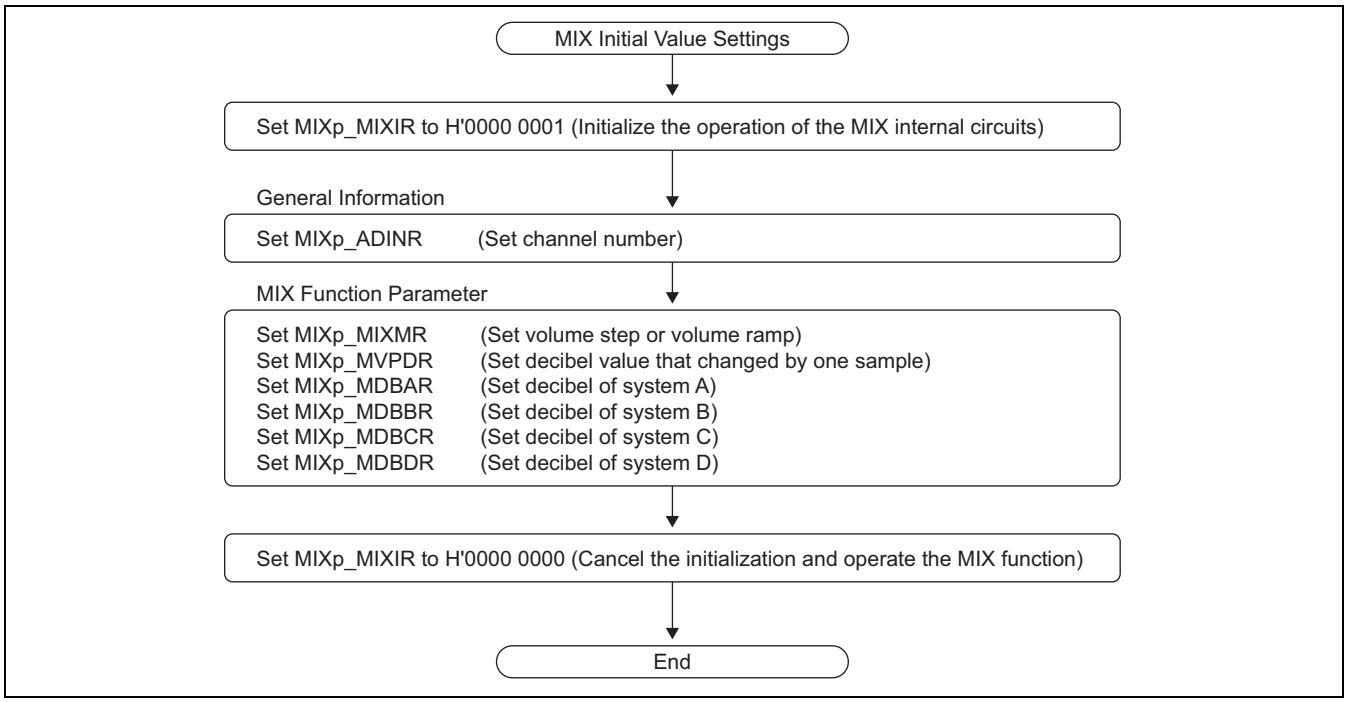

Figure 30.22 MIX Initial Value Setting Flowchart

- MIX Processing Parameter

  Figure 30.23 shows the MIX processing parameter flowchart. Before change the parameter of decibel for each system, the setting of the MIXp_MDBER should be disables. After that set the decibels of MIXp_MDBAR and MIXp_MDBBR and MIXp_MDBCR and MIXp_MDBDR and enables the MIXp_MDBER for reflect the decibel setting to the MIX processing.

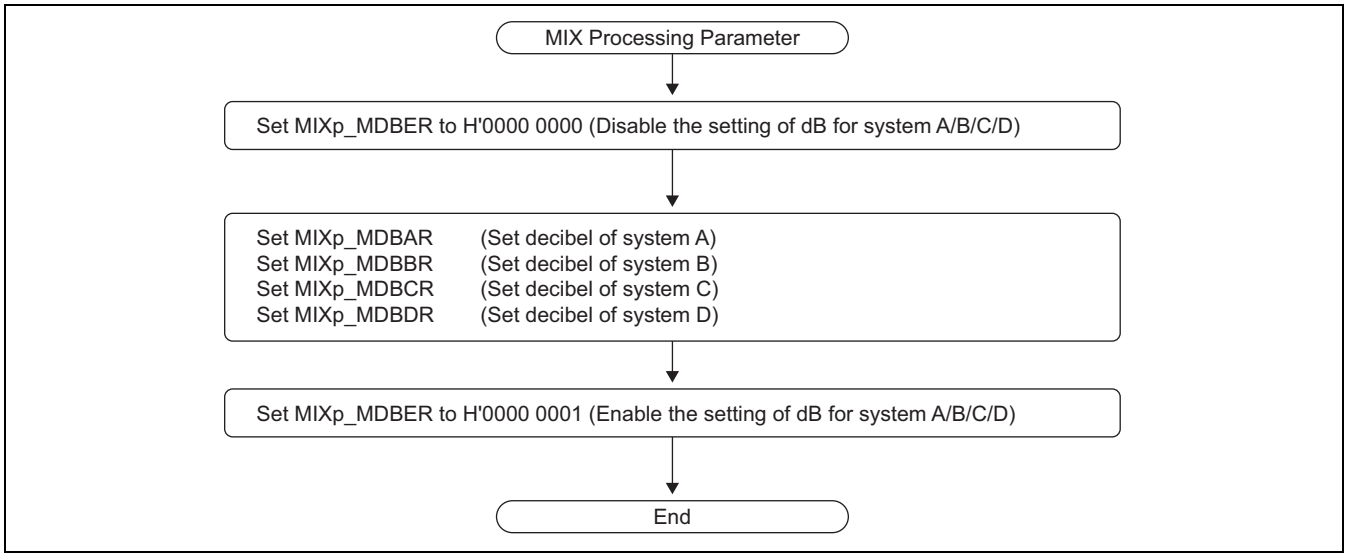

Figure 30.23 MIX Processing Parameter Flowchart

- MIX Initialization

  Figure 30.24 shows the MIX initialization flowchart. MIXp_MIXIR register doesn't initialize the register settings and these values are maintained. Before cancel the initialization, it is necessary to set or check the register settings of peripheral IP.

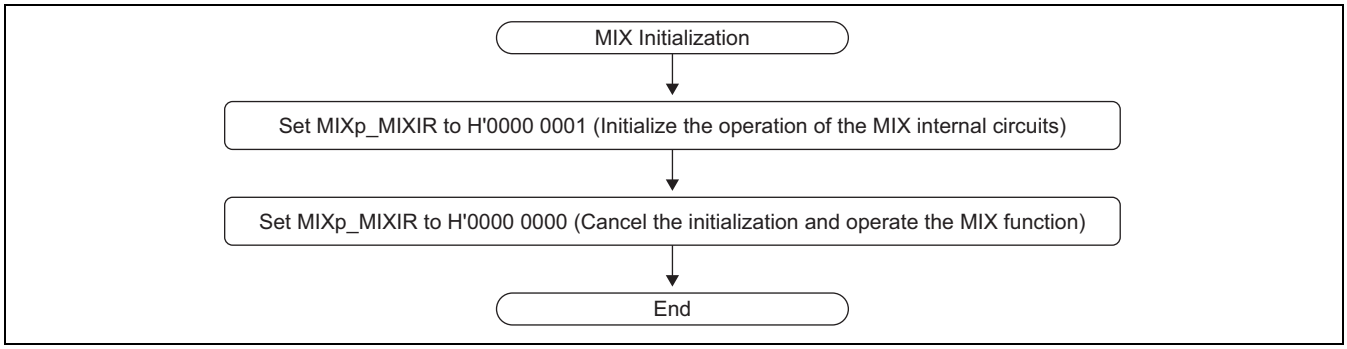

Figure 30.24 MIX Initialization Flowchart

- MIX Halting

  Figure 30.25 shows the flowchart of MIX halting. When MIX is halting, it should be initialized or reset by software reset or hardware reset. Before initializing or reset the MIX function, it is necessary to confirm the register settings and operation of peripheral IP.

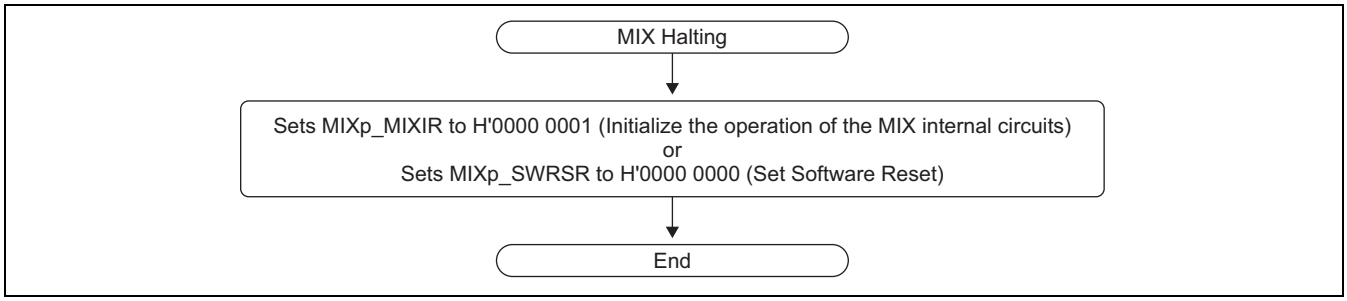

Figure 30.25 MIX Halting Flowchart

(3) DVC Block

The DVC is a block for implementing the volume and mute functions.

- Volume control function including digital volume, volume ramp, and zero-crossing mute
- The digital volume function is specified by a 24-bit fixed-point value within the range from 0 to 8 times (mute or -120 to 18 dB)
- The volume ramp function can be used for soft mute, fade-in, fade-out, or desired volume adjustment
- The volume ramp period can be changed within the sampling range from the 0th to 23rd power of 2
- The zero-crossing mute function silences the sound at the zero-crossing point of the audio data

Table 30.13 shows the DVC functions.

Table 30.13 DVC Functions

Item	Performance
Digital volume	Range: -120 dB to 18 dB (9.5×10^{-7} times to 8 times)
Volume ramp	Volume ramp is used for many kinds of operation (soft mute, fade-in, fade-out, and volume adjustment by ramp) Ramp period: 2^0/fso to 2^{23}/fso Examples: (1/fso: -128 dB/1 step) (2/fso: -64 dB/1 step) (4/fso: -32 dB/1 step) : (128/fso: -1 dB/1 step) (256/fso: -0.5 dB/1 step) (512/fso: -0.25 dB/1 step) (1024/fso: -0.125 dB/1 step) (2048/fso: -0.125 dB/2 steps) (4096/fso: -0.125 dB/4 steps) : (8388608/fso: -0.125 dB/8192 steps)
Zero-crossing mute	Mute the signal at zero-crossing point

The settings and corresponding values for the volume ramp are the same as those listed in Tables 30.9 to 30.12.

The settings and corresponding values for the digital volume are calculated by using the following formula:

Setting (decimal) = $10^X \times 1048576$
X = (value in dB) / 20

(a) Register Setting Procedure

The following describes the DVC register setting procedures. The register should be used according to the following procedures.

- DVC Processing Procedure
  Figure 30.26 shows the processing procedure of DVC.

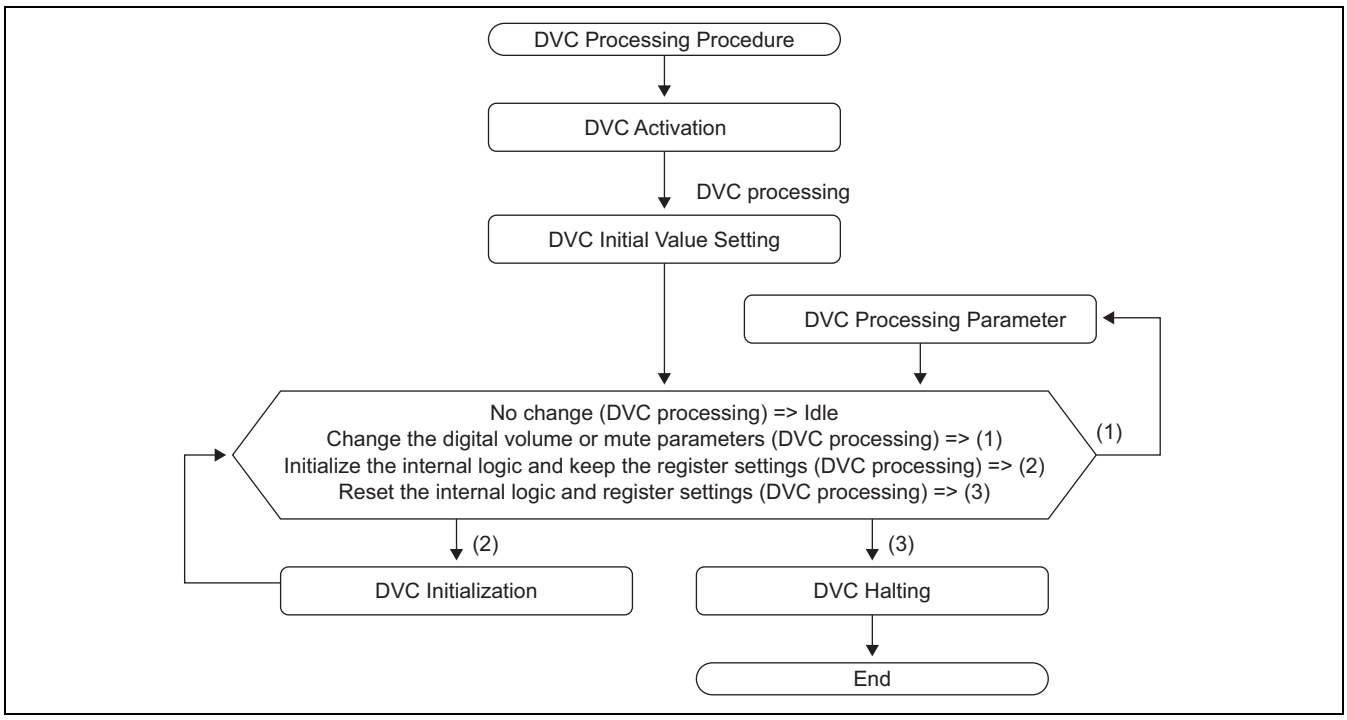

Figure 30.26 DVC Processing Procedure

- DVC Activation
  Figure 30.27 shows the DVC activation flowchart. When the DVC is activated, a software reset should be set to initialize logic and register setting. Then, the software reset should be cleared and ready to operate DVC. When reset the DVC function, all registers are initialized. If the DVC function was initialized by a hardware reset, it doesn't need to initialize the DVC function by software reset.

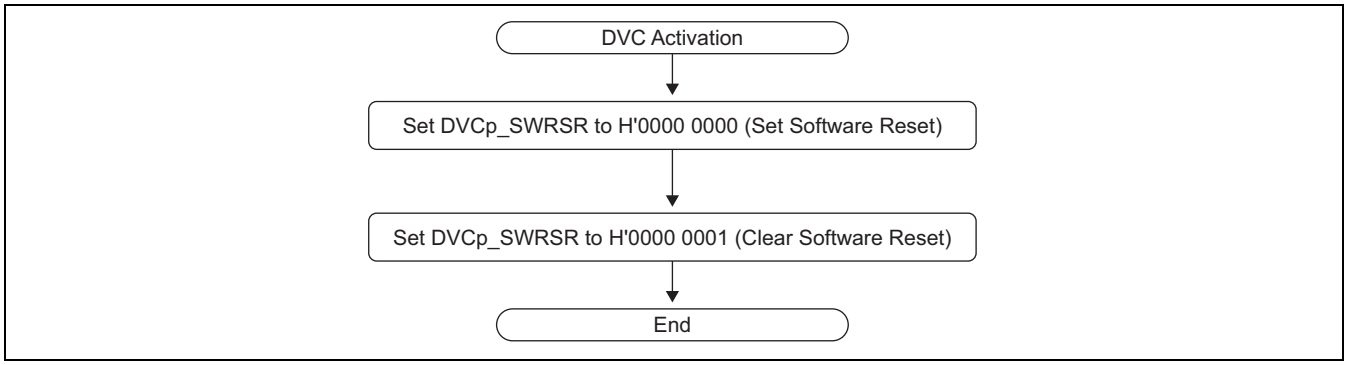

Figure 30.27 DVC Activation Flowchart

- DVC Initial Value Setting

  Figure 30.28 shows the flowchart of the DVC initial value setting. Before operating DVC function, the initial values should be set.

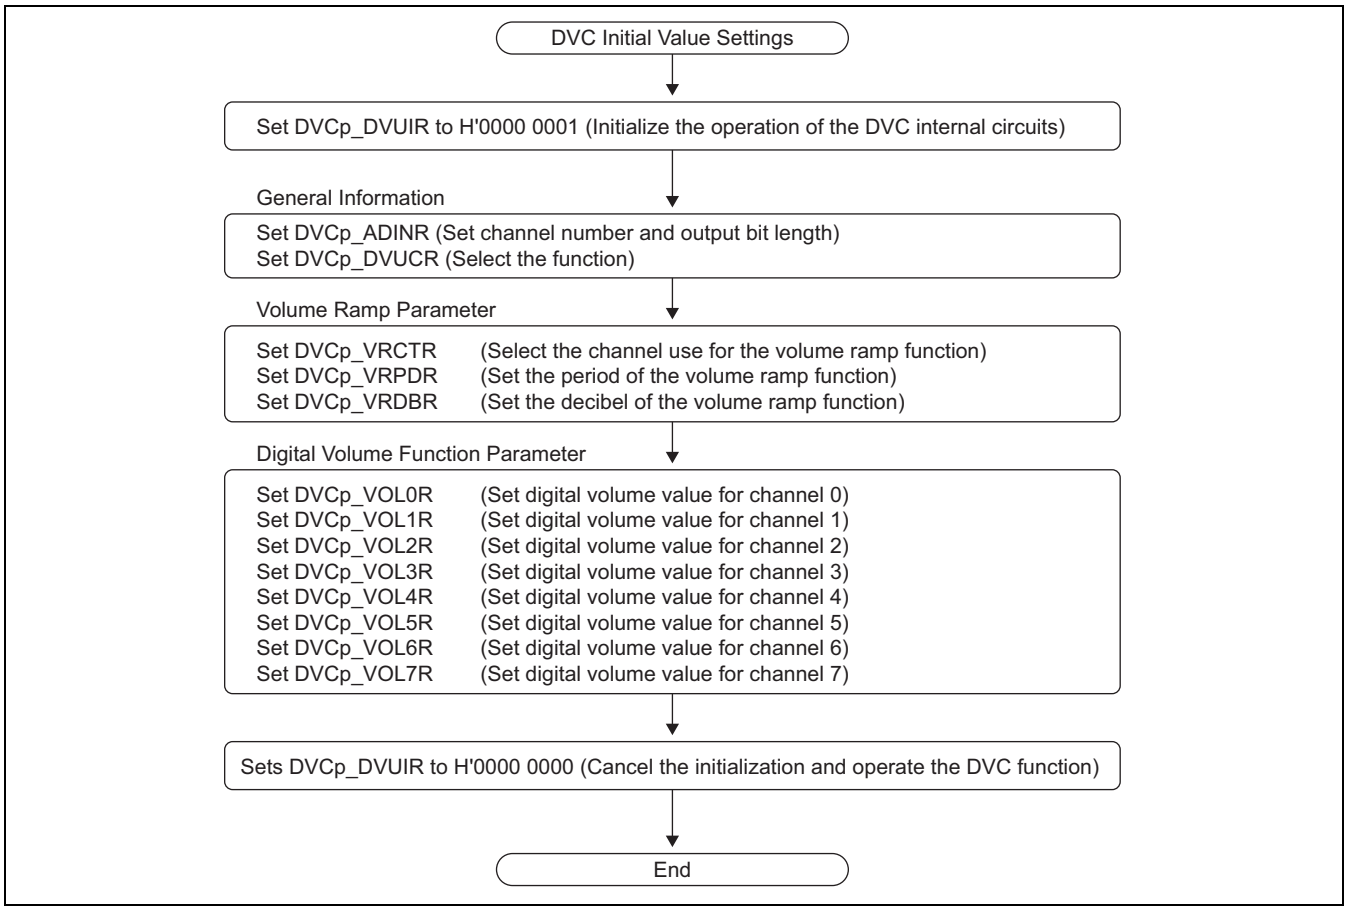

Figure 30.28 DVC Initial Value Setting Flowchart

- DVC Processing Parameter

  Figure 30.29 shows the DVC processing parameter flowchart. When DVC is processing, user can control the zero cross mute and the volume ramp and the digital volume value or by changing the setting value of registers. Before change the parameter of each function, the setting of DVCp_DVUER should be disables. After that set the setting of each function and enables the DVCp_DVUER for reflect the register setting to the DVC processing.

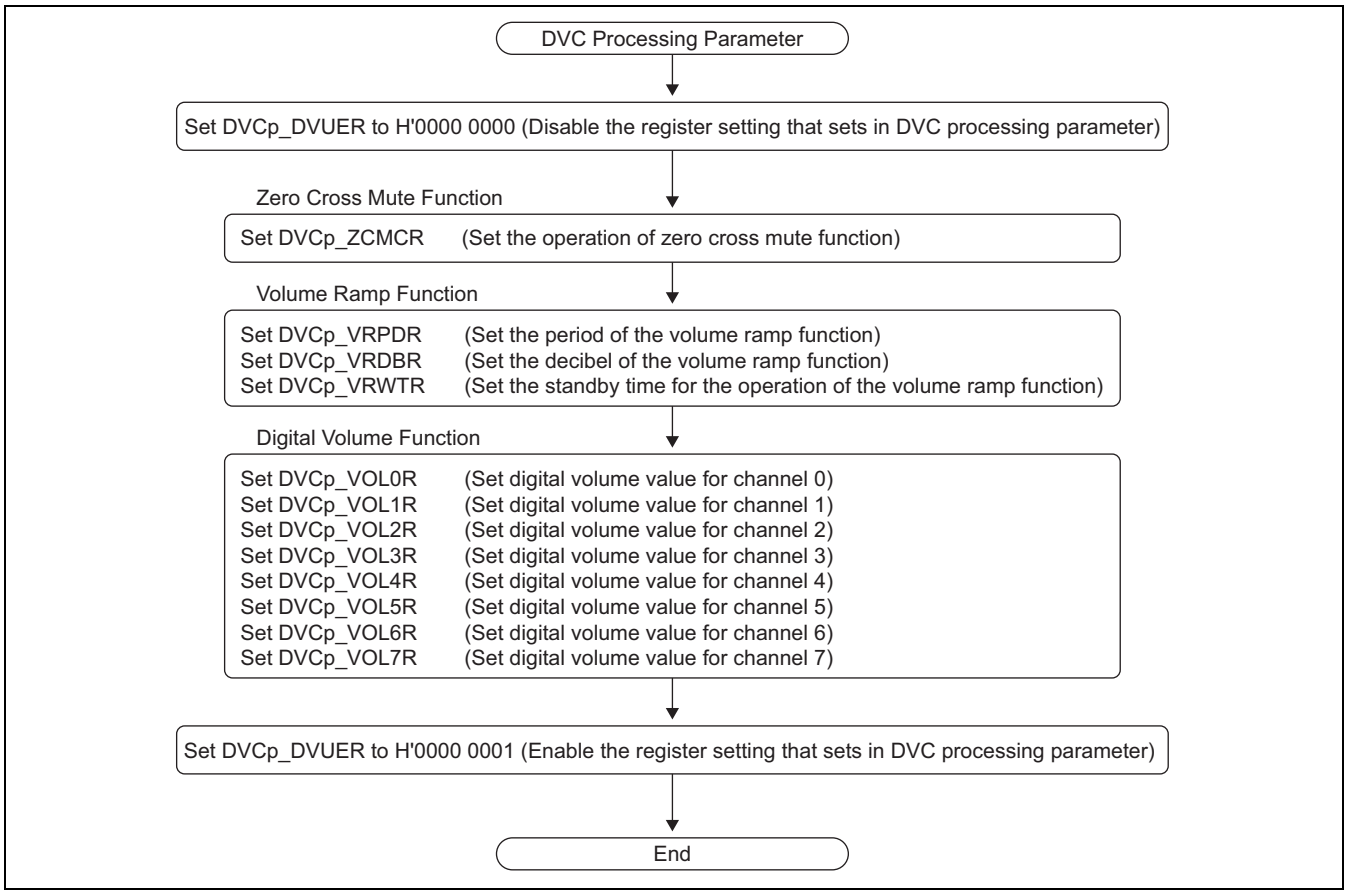

Figure 30.29 DVC Processing Parameter Flowchart

- DVC Initialization

  Figure 30.30 shows the flowchart of DVC Initialization. DVCp_DVUIR register doesn't initialize the register settings and these values are maintained. Before cancel the initialization, it is necessary to set or check the register settings of peripheral IP.

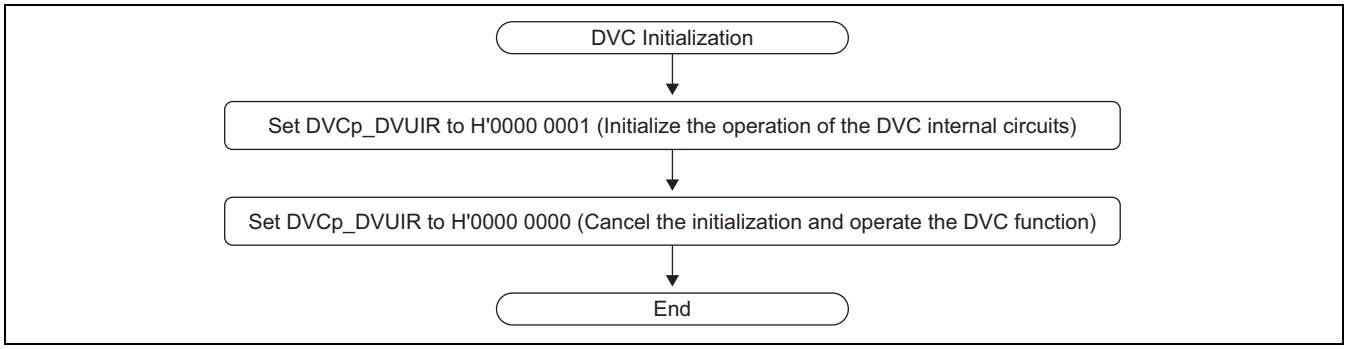

Figure 30.30 DVC Initialization Flowchart

- DVC Halting

  Figure 30.31 shows the flowchart of DVC halting. When DVC is halting, it should be initialized or reset by software reset or hardware reset. Before initializing or reset the DVC function, it is necessary to confirm the register settings and operation of peripheral IP.

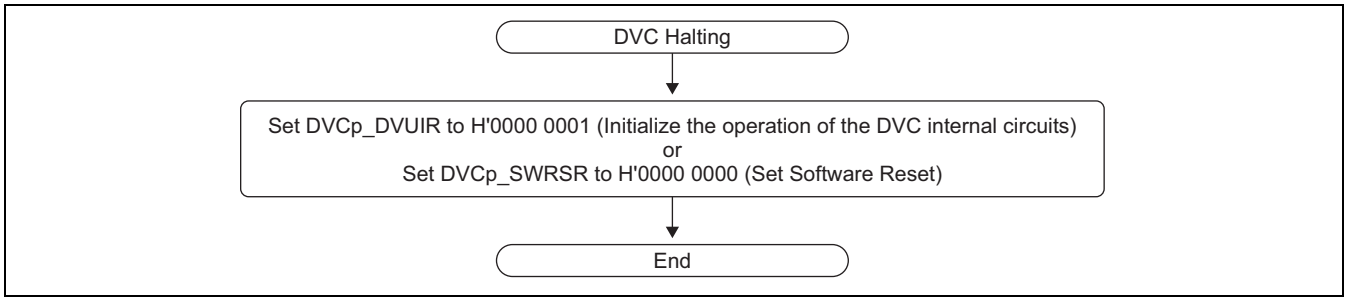

Figure 30.31 DVC Halting Flowchart

30.3.8 Input Data Timing and Output Data Timing

When using the SRC or CMD, the input data timing and output data timing should be specified. For details of the settings, refer to section 29, Audio Clock Generator (ADG).

30.4 Usage Notes

There is no attention of the usage.

31. Direct Memory Access Controller for Audio (Audio-DMAC)

This LSI includes a direct memory access controller for audio (audio-DMAC). The audio-DMAC can be used in place of the CPU to handle high-speed data transfer to and from an external memory, the on-chip memory, memory-mapped external devices, or on-chip peripheral modules.

31.1 Features

- 13 channels are available.
  Support: 13 channels (channels 0 to 12)
- 4-Gbyte physical address space
- Transfer data length: Byte, word (2 bytes), longword (4 bytes), 8 bytes, 16 bytes, 32 bytes, and 64 bytes
- Maximum number of transfer times: 16,777,215
- Address mode: Dual address mode
- Transfer requests:
  Requests from on-chip peripheral modules or auto requests can be selected. The following modules can issue on-chip peripheral module requests.
  SSI0 to SSI9, SCU1 to SCU6
- Selectable bus modes:
  Normal speed mode or slow mode can be selected for each channel.
- Either fixed priority or round-robin arbitration can be selected for use in arbitration among the transfer channels.
- Interrupt request:
  The audio-DMAC can be set up to generate an interrupt request for the CPU upon completion of transfer under the control of one stage of the descriptor memory, at the end of the data transfer, in response to an MMU error, and in response to an address error.
- Descriptor memory function:
  Up to 128 sets of the settings for the source address register, destination address register, and transfer count register are available (if use of the descriptor memory is only enabled for one channel) for use in setting up consecutive DMA transfers (the memory can hold register values for up to 256 stages of transfer when the external memory is selected). An infinite repeat mode is also available.

Figure 31.1 shows the block diagram of the audio-DMAC.

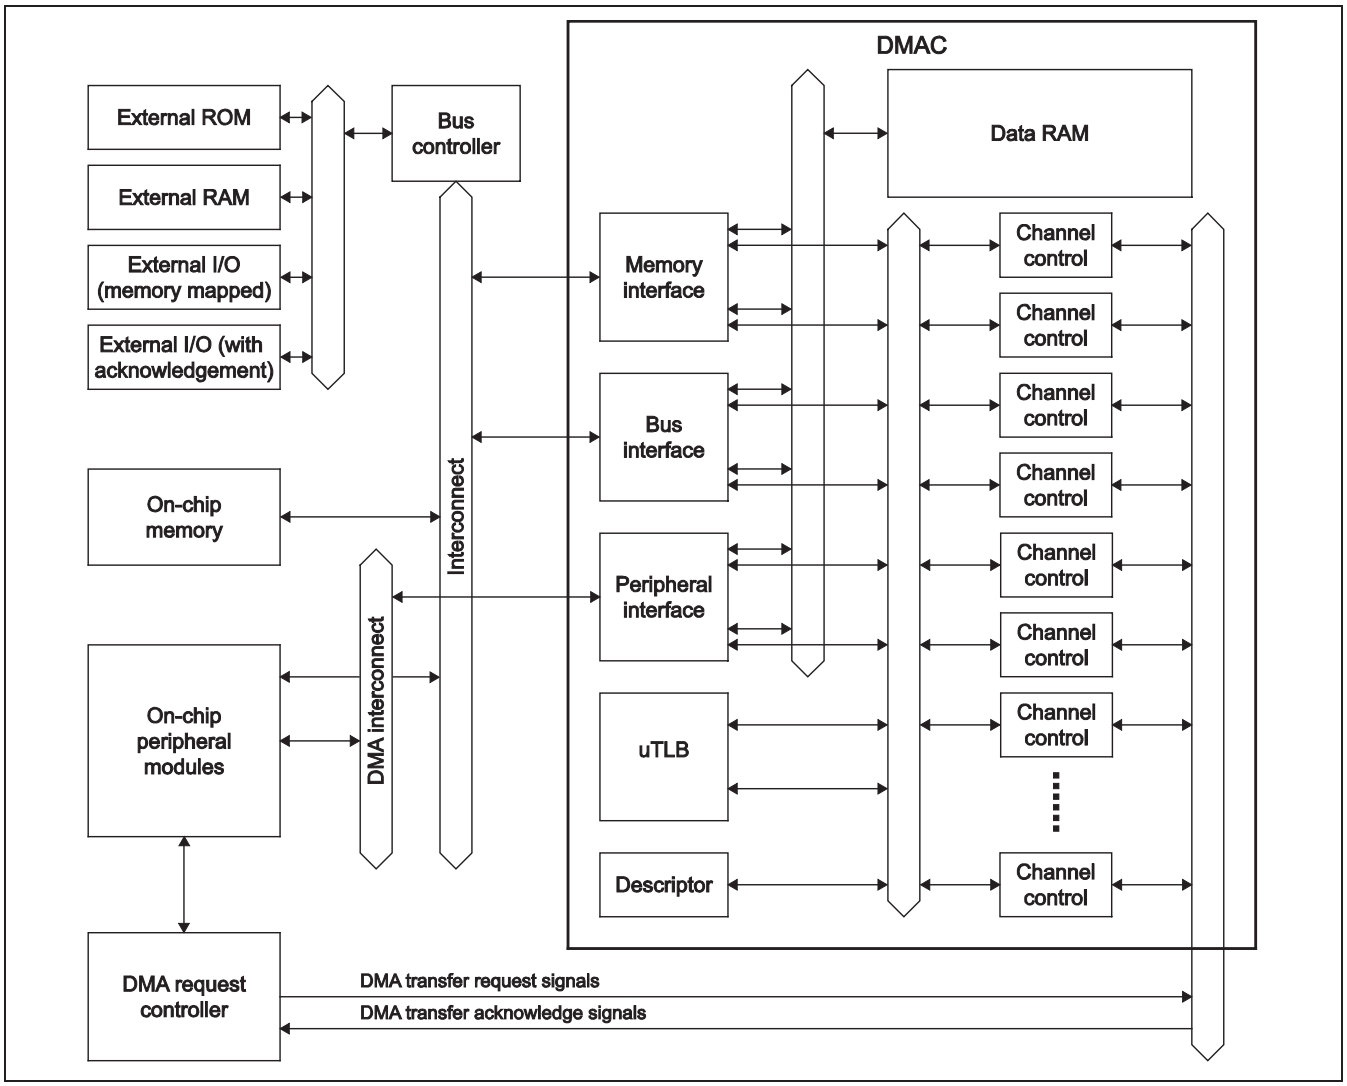

Figure 31.1 Block Diagram of the Audio-DMAC

31.2 Input/Output Pins

There are no external pins relevant to the audio-DMAC.

31.3 Register Descriptions

Table 31.1 lists the registers of the audio-DMAC. Table 31.2 shows the register states of the audio-DMAC in each operating mode.

Table 31.1 Register Configuration of the Audio-DMAC

Name	Abbreviation	R/W	Address	Access Size
DMA interrupt status register	DMAISTA	R	H'EC70 0020	32

DescriptorMEM	Undefined	Retained

31.3.1 DMA Interrupt Status Register (DMAISTA)

DMAISTA is a 32-bit readable register that indicates the states of the interrupt signals for each of the lower-numbered channels.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	I12	I11	I10	I9	I8	I7	I6	I5	I4	I3	I2	I1	I0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	I12	0	R	Interrupt State in Channel 12 0: An interrupt is not present. 1: An interrupt is present.
11	I11	0	R	Interrupt State in Channel 11 0: An interrupt is not present. 1: An interrupt is present.
10	I10	0	R	Interrupt State in Channel 10 0: An interrupt is not present. 1: An interrupt is present.
9	I9	0	R	Interrupt State in Channel 9 0: An interrupt is not present. 1: An interrupt is present.
8	I8	0	R	Interrupt State in Channel 8 0: An interrupt is not present. 1: An interrupt is present.

Bit	Bit Name	Initial Value	R/W	Descriptions
7	I7	0	R	Interrupt State in Channel 7 0: An interrupt is not present. 1: An interrupt is present.
6	I6	0	R	Interrupt State in Channel 6 0: An interrupt is not present. 1: An interrupt is present.
5	I5	0	R	Interrupt State in Channel 5 0: An interrupt is not present. 1: An interrupt is present.
4	I4	0	R	Interrupt State in Channel 4 0: An interrupt is not present. 1: An interrupt is present.
3	I3	0	R	Interrupt State in Channel 3 0: An interrupt is not present. 1: An interrupt is present.
2	I2	0	R	Interrupt State in Channel 2 0: An interrupt is not present. 1: An interrupt is present.
1	I1	0	R	Interrupt State in Channel 1 0: An interrupt is not present. 1: An interrupt is present.
0	I0	0	R	Interrupt State in Channel 0 0: An interrupt is not present. 1: An interrupt is present.

31.3.2 DMA Secure Control Register (DMASEC)

DMASEC is a 32-bit readable/writeable register that controls the security attribute of each channels. Only the initiator in the secure mode can change the setting of this register.

Only secure access is allowed to registers of channels with the secure mode setting. The following registers are protected by the secure mode.

DMASAR, DMADAR, DMATCR, DMATSR, DMACHCR, DMATCRB, DMATSRB, DMACHCRB, DMARS, DMABUFCR, DMADPBASE, DMADPCR, DMAFIXSAR, DMAFIXDAR, and DMAFIXDPBASE

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	S12	S11	S10	S9	S8	S7	S6	S5	S4	S3	S2	S1	S0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	S12	0	R/W	Secure Mode Setting for Channel 12 0: Non-secure mode 1: Secure mode
11	S11	0	R/W	Secure Mode Setting for Channel 11 0: Non-secure mode 1: Secure mode
10	S10	0	R/W	Secure Mode Setting for Channel 10 0: Non-secure mode 1: Secure mode
9	S9	0	R/W	Secure Mode Setting for Channel 9 0: Non-secure mode 1: Secure mode
8	S8	0	R/W	Secure Mode Setting for Channel 8 0: Non-secure mode 1: Secure mode
7	S7	0	R/W	Secure Mode Setting for Channel 7 0: Non-secure mode 1: Secure mode
6	S6	0	R/W	Secure Mode Setting for Channel 6 0: Non-secure mode 1: Secure mode

Bit	Bit Name	Initial Value	R/W	Descriptions
5	S5	0	R/W	Secure Mode Setting for Channel 5 0: Non-secure mode 1: Secure mode
4	S4	0	R/W	Secure Mode Setting for Channel 4 0: Non-secure mode 1: Secure mode
3	S3	0	R/W	Secure Mode Setting for Channel 3 0: Non-secure mode 1: Secure mode
2	S2	0	R/W	Secure Mode Setting for Channel 2 0: Non-secure mode 1: Secure mode
1	S1	0	R/W	Secure Mode Setting for Channel 1 0: Non-secure mode 1: Secure mode
0	S0	0	R/W	Secure Mode Setting for Channel 0 0: Non-secure mode 1: Secure mode

31.3.3 DMA Operation Register (DMAOR)

DMAOR is a 16-bit readable/writable register that enables DMA transfer on all channels and specifies the method used to determine the priority levels for all DMA channels. This register also indicates address errors.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	PR[1:0]		—	—	—	—	—	AE	—	DME
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R/(W)*	R	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	PR[1:0]	00	R/W	Priority Mode Select the method for setting the order of priority of channels when transfer requests for multiple channels arrive simultaneously. 00: Fixed CH0 > CH1 > ... > CH11 > CH12 11: Round-robin priority Other than above: Setting prohibited
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	AE	0	R/(W)*	Address Error Flag Indicates that an address error interrupt occurred during DMA transfer. This bit is set under the following conditions: The value set in DMASAR or DMADAR does not fall on a boundary corresponding to the transfer size. The source or destination for transfer is in an invalid space. The source or destination for transfer is in module stop mode. If this bit is set, DMA transfer through the channel is not possible even if the DE bit is set to 1. To clear the AE bit, write 0 to the AE bit after reading 1 from it or clear the CAE bit for each channel for which it is set. Clearing the AE bit clears the channel address error bits for all channels. 0: An audio-DMAC address error interrupt is not present. [Clearing condition] (*) Writing CAE = 0 after reading CAE = 1 1: An audio-DMAC address error interrupt being generated during DMA transfer.
1	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
0	DME	0	R/W	DMA Master Enable Enables or disables DMA transfer on all channels. If the DME bit and the DE bit in DMACHCR are both set to 1, DMA transfer is enabled. At this time all AE bits in DMAOR must have the value 0. For DMA transfer on a channel to then proceed, the TE bit in DMACHCR for the channel must also have the value 0. Clearing this bit during transfer aborts transfer on all channels. 0: Disables DMA transfers on all channels 1: Enables DMA transfers on all channels

31.3.4 DMA Channel Clear Register (DMACHCLR)

DMACHCLR is a 32-bit writable register that initializes each of channels.

When a bit of this register is set, the state of the corresponding channel is completely initialized.
This includes initialization of the following registers.

DMASAR, DMADAR, DMATCR, DMATSR, DMACHCR, DMATCRB, DMATSRB, DMACHCRB, DMARS, DMABUFCR, DMADPBASE, DMADPCR, DMAFIXSAR, DMAFIXDAR, and DMAFIXDPBASE

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	CLR[12:0]												
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 0	CLR[12:0]	All 0	W	Writing to a bit leads to clearing of all registers for the corresponding channel. CLR[0] 0: Ignored 1: All registers for channel 0 are cleared. CLR[1] 0: Ignored 1: All registers for channel 1 are cleared. CLR[2] 0: Ignored 1: All registers for channel 2 are cleared. ... CLR[12] 0: Ignored 1: All registers for channel 12 are cleared. When writing to this register, confirm that the DE bit is set to 0.

31.3.5 DPRAM Secure Control Register (DMADPSEC)

DMADPSEC is a 32-bit readable/writeable register that controls the security attribute of the descriptor memory. Only the initiator in the secure mode can change the setting of this register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SEC	—	—	—	—	—	—	SA[8:0]								
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	SM[8:0]								
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	SEC	0	R/W	Security Attribute Setting for Descriptor Memory Specifies the security attribute of the address space used for the descriptor memory. 0: Non-secure 1: Secure
30 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24 to 16	SA[8:0]	H'000	R/W	Security Attribute Setting for Base Address of Descriptor Memory Specify the base address of the descriptor memory to be assigned the security attribute. H'000: H'A000 H'001: H'A004 ... H'1FF: H'A7FC
15 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8 to 0	SM[8:0]	H'000	R/W	Security Attribute Setting for Base Address Mask of Descriptor Memory Specify the security attribute base address mask of the descriptor memory. The range of memory to be assigned the security attribute is specified by this register. See Figure 31.4.

31.3.6 DMA Source Address Registers 0 to 12 (DMASAR_0 to DMASAR_12)

DMASAR is a 32-bit readable/writable register that specifies the source address of a DMA transfer. While a DMA transfer is in progress, this register indicates the next source address.

When the address mode is incrementation, sources in memory only have byte boundaries. For details, refer to Table 31.3.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SAR[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SAR[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

31.3.7 DMA Destination Address Registers 0 to 12 (DMADAR_0 to DMADAR_12)

DMADAR is 32-bit readable/writable register that specify the destination address of a DMA transfer. While a DMA transfer is in progress, this register indicates the next destination address.

When the address mode is incrementation, destinations in memory only have byte boundaries. For details, refer to Table 31.3.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DAR[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DAR[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Table 31.3 SAR/DAR Address Restriction

Resource Selection	Address Mode	Restriction
Auto request	Incrementation	No restriction (byte boundaries)
	Others	Boundary corresponding to the DMA transfer size
On-chip peripheral module request Transmission/DAR, Reception/SAR	All	Boundary corresponding to the DMA transfer size
On-chip peripheral module request Transmission/SAR, Reception/DAR	Incrementation	No restriction (byte boundaries)
	Others	Boundary corresponding to the DMA transfer size

31.3.8 DMA Transfer Count Registers 0 to 12 (DMATCR_0 to DMATCR_12)

DMATCR is a 32-bit readable/writable register that specifies the number of rounds of DMA transfer. The number of rounds of DMA transfer is 1 when the setting is H'00000001 and 16,777,215 (the maximum) when the setting is H'00FFFFFF. During a DMA transfer, this register indicates the remaining number of rounds of transfer.

The audio-DMAC includes independent data buffers for reading and writing. Therefore, the read transfer counter and write transfer counter have different values. This register indicates the counter value used in reading.

The eight higher-order bits of DMATCR are always read as 0, and the write value should always be 0.

The value of this register should be set before DMA transfer starting.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	TCR[23:16]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TCR[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

31.3.9 DMA Transfer Count Registers B_0 to 12 (DMATCRB_0 to DMATCRB_12)

DMATCRB is a 32-bit readable/writable register that specifies the number of rounds of DMA transfer. The number of rounds of DMA transfer is 1 when the setting is H'00000001 and 16,777,215 (the maximum) when the setting is H'00FFFFFF. During a DMA transfer, this register indicates the remaining number of rounds of transfer.

The audio-DMAC includes independent data buffers for reading and writing. Therefore, the read transfer counter and write transfer counter have different values. This register indicates the counter value used in writing.

The eight higher-order bits of DMATCRB are always read as 0, and the write value should always be 0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	TCR[23:16]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TCR[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

31.3.10 DMA Transfer Size Registers 0 to 12 (DMATSR_0 to DMATSR_12)

DMATSR is a 32-bit readable/writable register that specifies a total amount of memory to be transferred. The total size of DMA transfer is 1 byte when the setting is H'00000001, 4,294,967295 bytes when the setting is H'FFFFFFFF, and 4,294,967,296 bytes (the maximum) when the setting is H'00000000. During a DMA transfer, this register indicates the remaining amount of memory to be transferred. This register is used in total size transmission.

The audio-DMAC includes independent data buffers for reading and writing. Therefore, reading and writing will have different transfer sizes. This register indicates the value of the read transfer size.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSR[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

31.3.11 DMA Transfer Size Registers B_0 to 12 (DMATSRB_0 to DMATSRB_12)

DMATSRB is a 32-bit readable/writable register that specifies a total amount of memory to be transferred. The total size of DMA transfer is 1 byte when the setting is H'00000001, 4,294,967295 bytes when the setting is H'FFFFFFFF, and 4,294,967,296 bytes (the maximum) when the setting is H'00000000. During a DMA transfer, this register indicates the remaining amount of memory to be transferred. This register is used in total size transmission.

The audio-DMAC includes independent data buffers for reading and writing. Therefore, reading and writing will have different transfer sizes. This register indicates the value of the write transfer size.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSR[31:16]

	DM[1:0]		SM[1:0]		RS[3:0]				—	—	—	TS[1:0]		IE	TE	DE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/(W)*	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31	CAE	0	R/(W)*	Channel Address Error Flag Indicates that an address error interrupt occurred during DMA transfer. This bit is set under the following conditions: The value set in DMASAR or DMADAR does not fall on a boundary corresponding to the transfer size. The source or destination for transfer is in an invalid space. The source or destination for transfer is in module stop mode. If this bit is set, DMA transfer through the channel is not possible even if the DE bit is set to 1. To clear the CAE bit, write 0 to the CAE bit after reading 1 from it or clear the AE bit in DMAOR. Clearing the CAE bit clears the channel address error bits for all channels. 0: An audio-DMAC address error interrupt is not present. (*) [Clearing condition] Writing CAE = 0 after reading CAE = 1 1: An audio-DMAC address error interrupt being generated during DMA transfer.
30	CAIE	0	R/W	Channel Address Error Interrupt Enable Enables or disables the generation of interrupt requests for the CPU when address errors occur. When the CAIE bit is set to 1, if the CAE bit is also set, an interrupt (DEI 0 to 25) from the corresponding channel will be generated for the CPU in response to address errors. Note: An address error interrupt (DADERR) is also asserted simultaneously. See section 11, Interrupt Controller for AP-System Core (INTC-SYS) for more details. 0: Interrupt requests are disabled. 1: Interrupt requests are enabled.
29, 28	DPM[1:0]	00	R/W	Operating Mode of Descriptor Memory Enable or disable the descriptor memory and specify its operating mode. 00: Disabled (normal use) 01: Enabled (normal mode) 10: Enabled (repeat mode) 11: Enabled (read-out interrupt mode, infinite repeat mode)

Bit	Bit Name	Initial Value	R/W	Descriptions
27 to 25	RPT[2:0]	000	R/W	Descriptor Setting Update Specify the parameters to be updated from the descriptor memory. RPT[2]: Enables or disables updating of the source address register RPT[1]: Enables or disables updating of the destination address register RPT[0]: Enables or disables updating of the transfer count register 0: Disabled 1: Enabled
24, 23	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
22	DPB	0	R/W	Descriptor Start Specifies configuration to be loaded when transfer under control of the descriptor memory begins. This bit is cleared after the descriptor memory is read. 0: Processing starts with the values in DMASAR, DMADAR, and DMATCR. 1: Processing starts after the first set of descriptors is read out.
21, 20	TS[3:2]	00	R/W	DMA Transfer Size In combination with TS[1:0], these bits specify the DMA transfer size. When the transfer source or transfer destination is a register of an on-chip peripheral module for which a transfer size is specified, be sure to select the specified transfer size. For the transfer source or destination address specified by DMASAR or DMADAR, an appropriate boundary address should be set according to the transfer data size. Transfer size must be specified to satisfy both source and destination access sizes. For example, the MSIOF must be accessed by 4-byte (TS [3:0] = B'0010) unit only except for SITSCR. TS[3:2] + TS[1:0] (“+” here indicates concatenation, not addition) 0000: Transfer is in byte units. 0001: Transfer is in word (2-byte) units. 0010: Transfer is in longword (4-byte) units. 0011: Transfer is in 16-byte units. 0100: Transfer is in 32-byte units. 0101: Transfer is in 64-byte units. 0111: Transfer is in 8-byte units. Other than above: Setting prohibited
19	DSE	0	R/(W)*	Descriptor Stage End When the DSIE bit is set to 1 and the descriptor memory is enabled, the DSE bit is set to 1 on completion of the DMA transfer. This bit is not set when the DPM bit is set to 0 (descriptors are disabled). (*) To clear the DSE bit, start by reading it as 1, and then write 0 to the bit. 0: DMA transfer is still running or has been aborted. 1: Transfer under the control of one stage of the descriptor memory has been completed.

Bit	Bit Name	Initial Value	R/W	Descriptions
18	DSIE	0	R/W	Descriptor Stage End Interrupt Enable Specifies whether an interrupt request is generated for the CPU on completion of transfer under the control of one stage of the descriptor memory. When this bit is set to 1, an interrupt (DEI) is generated for the CPU whenever the DSE is set to 1. 0: Interrupt requests are disabled. 1: Interrupt requests are enabled.
17, 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15, 14	DM[1:0]	00	R/W	Destination Address Mode Specify whether the DMA destination address is incremented, fixed, or decremented. The unit of transfer (transfer size) determines the size of the increment. 00: Destination address is fixed. 01: Destination addresses are incremented. + 1 when transfer is in byte units. + 2 when transfer is in word units. + 4 when transfer is in longword units. + 8 when transfer is in 8-byte units. + 16 when transfer is in 16-byte units. + 32 when transfer is in 32-byte units. + 64 when transfer is in 64-byte units. 10: Destination addresses are decremented. – 1 when transfer is in byte units. – 2 when transfer is in word units. – 4 when transfer is in longword units. Setting prohibited when transfer is in 8-, 16-, 32-, or 64-byte units. 11: Setting Prohibited
13, 12	SM[1:0]	00	R/W	Source Address Mode Specify whether the DMA source address is incremented, fixed, or decremented. The unit of transfer (transfer size) determines the size of the increment. 00: Source address is fixed. 01: Source addresses are incremented. + 1 when transfer is in byte units. + 2 when transfer is in word units. + 4 when transfer is in longword units. + 8 when transfer is in 8-byte units. + 16 when transfer is in 16-byte units. + 32 when transfer is in 32-byte units. + 64 when transfer is in 64-byte units. 10: Source addresses are decremented. – 1 when transfer is in byte units. – 2 when transfer is in word units. – 4 when transfer is in longword units. Setting prohibited when transfer is in 8-, 16-, 32-, or 64-byte units. 11: Setting Prohibited

Bit	Bit Name	Initial Value	R/W	Descriptions
11 to 8	RS[3:0]	0000	R/W	Resource Selection Specify the source of transfer requests. Only change the transfer request source while the DMA enable bit (DE) is set to 0. 0100: Auto request 1000: Source is selected by the DMA extended resource selector. Other than above: Settings prohibited
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4, 3	TS[1:0]	00	R/W	DMA Transfer Size See the description of TS[3:2] (bits 21 and 20).
2	IE	0	R/W	Interrupt Enable Specifies whether or not an interrupt request is generated for the CPU on completion of DMA transfer. When this bit is set to 1, an interrupt request (DEI) for the CPU is generated whenever the TE bit is set to 1. 0: Interrupt request is disabled. 1: Interrupt request is enabled.
1	TE	0	R/(W)*	Transfer End Flag When the descriptor memory is not in use, the TE bit is set to 1 when DMATCR and DMATSR become 0 on completion of the DMA transfer. When the descriptor memory is in use, the TE bit is set to 1 on completion of all transfers set up in the descriptor memory. The TE bit is not set to 1 in the following cases. • DMA transfer ends due to a DMA address error before DMATCR and DMATSR become 0. • DMA transfer is aborted by clearing the DE and DME bits in DMAOR. To clear the TE bit, start by reading it as 1, and then write 0 to it. When the TE bit is set to 1, transfer is not possible even if the DE bit is set to 1. 0: DMA transfer is in progress or was aborted (*) [Clearing condition] Writing of 0 after reading of 1 1: DMA transfer ended on the specified count (TCR = 0 and TSR = 0)
0	DE	0	R/W	DMA Enable Enables or disables DMA transfer. In the auto request mode, a DMA transfer is started by setting the DE and DME bits in DMAOR to 1. At this time, the setting of both the AE and TE bits in DMAOR must be 0. In a peripheral module request, a DMA transfer starts if the transfer request is generated by the selected device or on-chip peripheral module after setting the DE and DME bits to 1. In this case too, the settings of both the TE and AE bits must be 0. Clearing the DE bit to 0 aborts all DMA transfer. Note: Ensure that the setting of the DE bit is actually 0 after clearing it. 0: DMA transfer is disabled. 1: DMA transfer is enabled.

Note: * Writing 0 is possible to clear the flag.

31.3.13 DMA Channel Control Register B_0 to 12 (DMACHCRB_0 to DMACHCRB_12)

DMACHCRB is a 32-bit readable/writable register that controls the DMA transfer mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DCNT[7:0]								DPTR[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DRST	—	—	—	—	—	—	DTS	SLM[3:0]				PRI[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 24	DCNT[7:0]	H'00	R/W	Number of Stages of Descriptor Memory Specify the number of stages of the descriptor memory as DCNT + 1. When the descriptor memory is enabled, a transfer end (TE) interrupt is only generated for the CPU on completion of transfer under control of the specified number of stages.
23 to 16	DPTR[7:0]	H'00	R	Descriptor Pointer This bit indicates the pointer to the next descriptor to be read. It is cleared to 0 when the last descriptor of the number of stages specified by DCNT[7:0] is read. It is also cleared to 0 when 1 is written to DRST.
15	DRST	0	W	Descriptor Reset Resets the descriptor pointer. Before the descriptor memory is used, the pointer must be reset by writing 1 to this bit. This bit is always read as 0.
14 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	DTS	0	R/W	Total Size Transmission under Descriptor Control This bit is only effective when total size transmission is selected. 0: The TCR fields of the descriptors are used as transfer count settings. 1: The TCR fields of the descriptors are used as total size settings.
7 to 4	SLM[3:0]	0000	R/W	DMA Transfer Low-Speed Mode Specify the number of cycles of the clock (ZSϕ) for the DMA transfer. One round of DMA transfer is executed in the number of cycles of the clock specified by this bit. 0000: Normal mode 1000: On round in 256 cycles of the clock. 1001: On round in 512 cycles of the clock. 1010: On round in 1024 cycles of the clock. : 1111: On round in 32768 cycles of the clock. Other than above: Setting prohibited

Bit	Bit Name	Initial Value	R/W	Descriptions
3 to 0	PRI[3:0]	0000	R/W	Channel Request Priority Setting These bits set the priority of requests for transfer on the given channel. 1111: Highest priority : 0111 to 0000: Lowest priority

31.3.14 DMA Buffer Control Registers 0 to 12 (DMABUFCR_0 to DMABUFCR_12)

DMABUFCR is a 32-bit readable/writable register that controls the upper limit on buffer size in and burst unit for the SDRAM.

Use this register when the upper limit on buffering requires control.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	MBU[8:0]								
Initial value:	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	ULB[9:0]									
Initial value:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24 to 16	MBU[8:0]	H'080	R/W	Maximum Burst Unit for SDRAM This register is only effective for SDRAM access, and everything other than that is under control of the transfer size (unit). Settings bigger than UBL are prohibited. Power-of-two settings are recommended. Maximum value is 256 (bytes).
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9 to 0	ULB[9:0]	H'100	R/W	Upper Limit on Buffer Size This register controls the upper limit value for buffering. Power-of-two settings are recommended. Maximum value is 512 (bytes).

31.3.15 DMA Extended Resource Selectors 0 to 12 (DMARS_0 to DMARS_12)

DMARS is a 16-bit readable/writable register that specifies the on-chip peripheral module to be the source of the DMA transfer request for the given channel. DMARS_0 specifies the source for channel 0, DMARS_1 specifies the source for channel 1 and so on.

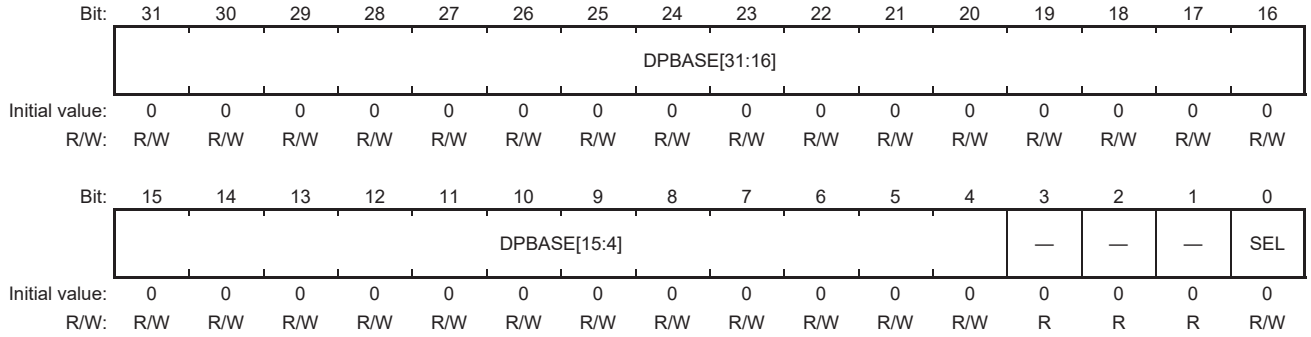
When bits MID and RID are set to a value other than the values listed in Table 31.4, the operation of this LSI is not guaranteed. Transfer requests from the source selected in DMARS are only valid when the resource selection bits (RS[3:0]) in DMACHCR have been set to B'1000. Otherwise, even if DMARS has been set, requests from the corresponding transfer request source are not accepted.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	MID[5:0]						RID[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
15 to 8	—	—	R	Reserved These bits are always read as 0. The write value should always be 0.
7 to 2	MID[5:0]	000000	R/W	DMA Request Source Adoption ID5 to ID0 (MID) See Table 31.4.
1, 0	RID[1:0]	00	R/W	DMA Request Source Adoption ID1 and ID0 (RID) See Table 31.4.

31.3.16 DMA Descriptor Base Address Registers 0 to 12 (DMADPBASE_0 to DMADPBASE_12)

DMADPBASE specifies the base address of the descriptor memory. The address range of the descriptor memory is specified by setting this register.



Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 4	DPBASE[31:4]	All 0	R/W	Base Address of Descriptor Memory Place each stage of the descriptor memory on a 16-byte boundary. Setting example: When Built-in memory is used, [Audio-DMAC]: H'EC70 A00 to H'EC70 A7F When External memory is used, Other memory area on a 16-byte boundary
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SEL	0	R/W	Descriptor Memory Selection Selects the memory to be used as descriptor memory. 0: Setting Prohibited 1: Built-in memory or External memory is used.

31.3.17 DMA Descriptor Control Registers 0 to 12 (DMADPCR_0 to DMADPCR_12)

DMADPCR is a 32-bit readable/writable register that controls the timing with which interrupts are output in read-out interrupt mode (descriptor mode 3).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DIPT[7:0]								—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 24	DIPT[7:0]	H'00	R/W	Descriptor Read-out Interrupt Pointer The number of stages for which descriptor read-out interrupts are generated in descriptor mode 3. DIPT + 1 specifies the number of descriptor stages.
23 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

31.3.18 DMA Fixed Source Address Registers 0 to 12 (DMAFIXSAR_0 to DMAFIXSAR_12)

DMAFIXSAR is a 32-bit readable/writable register that specifies the most significant 8 bits of the 40-bit source address for a DMA transfer.

This register is not incremented by carrying when DMASAR overflows.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

31.3.19 DMA Fixed Destination Address Registers 0 to 12 (DMAFIXDAR_0 to DMAFIXDAR_12)

DMAFIXDAR is a 32-bit readable/writable register that specifies the most significant 8 bits of the 40-bit destination address for a DMA transfer.

This register is not incremented by carrying when DMADAR overflows.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

31.3.21 Descriptor Memory (DescriptorMEM)

See section 31.4.4, Descriptor Memory for the descriptor memory.

31.4 Operation

When there is a DMA transfer request, the DMAC starts the transfer according to the predetermined channel priority; when the transfer end conditions are satisfied, it ends the transfer. Transfers can be requested in two modes: auto request and on-chip peripheral module request. The bus mode can be selected from normal speed mode and slow speed mode).

31.4.1 DMA Transfer Requests

Most commonly, DMA transfer requests are generated by either the source or destination for transfer, but they can also be generated by on-chip peripheral modules that are neither the source nor the destination. Transfers can be requested in two modes: auto request, and on-chip peripheral module request. The request mode is selected for each channel by DMARS.

(1) Auto-Request Mode

When there is no transfer request signal from an external source, as in a memory-to-memory transfer or a transfer between memory and an on-chip peripheral module unable to request a transfer, auto-request mode allows the audio-DMAC to automatically generate a transfer request signal internally. When the DE bit in DMACHCR and the DME bit in DMAOR are set to 1 for the target channel, the transfer begins so long as the CAE bit in DMACHCR is 0.

(2) On-Chip Peripheral Module Request Mode

In this mode, a transfer is performed at the transfer request signal of an on-chip peripheral module. The source (on-chip peripheral module) of the DMA transfer request is specified by DMARS.

When this mode is selected, if the DMA transfer is enabled (DE = 1, DME = 1, TE = 0, CAE = 0), a transfer is performed upon the input of a transfer request signal.

When a transmit data empty transfer request of the SCIF is set as the transfer request, the transfer destination must be the SCIF's transmit data register. Likewise, when receive data full transfer request of the SCIF is set as the transfer request, the transfer source must be the SCIF's receive data register. These conditions also apply to the other on-chip peripheral modules.

The number of the receive FIFO triggers can be set as a transfer request depending on an on-chip peripheral module. Data needs to be read after the DMA transfer is ended, because data may be left in the receive FIFO when the receive FIFO trigger condition is not satisfied.

Table 31.4 Selecting On-Chip Peripheral Module Request Modes

DMARS MID + RID	DMA Transfer Request Source	DMA Transfer Request Signal	Source	Destination
H'87	SCU1	Transmit	Arbitrary	
H'89	SCU2	Transmit	Arbitrary	
H'8B	SCU3	Transmit	Arbitrary

31.4.2 Channel Priority

When the audio-DMAC receives simultaneous transfer requests on two or more channels, it transfers data according to a predetermined priority. Two modes (fixed mode and round-robin mode) are selected by the PR[1:0] bits in DMAOR.

(a) Fixed Mode

In this mode, the priority levels among the channels remain fixed.

CH0 > CH1 > ... > CH11 > CH12

(b) Round-Robin Mode

In round-robin mode, each time data of one transfer unit (byte, word, longword, 8-byte or 16-byte units) is transferred on one channel, the priority is rotated. The channel on which the transfer was just finished rotates to the bottom of the priority. The priority of round-robin mode is CH0 > CH1 > ... >CH11 > CH12 immediately after reset.

31.4.3 Slow Speed Mode

In the low-speed mode, a single round of DMA transfer is performed every time the number of clock cycles specified by the SLM bits in DMACHCRB elapse. This mode can be selected per DMA channel. Transfer on other channels can proceed after each round of transfer for a channel in the low-speed mode is completed.

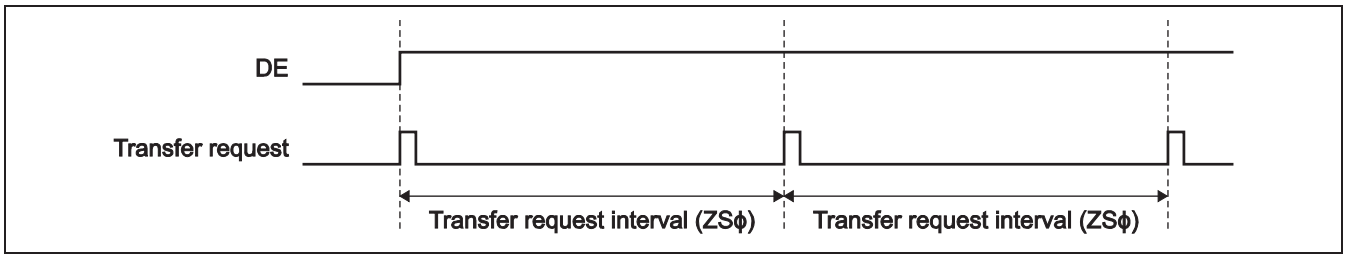

Figure 31.2 Slow Speed Mode

31.4.4 Descriptor Memory

The descriptor memory function is selected by setting the DPM[1:0] bits in DMACHCR to B'01, B'10, or B'11. When DMATCR is set to 0 and the DMA transfer is completed, the next set of settings is read, and if only a single channel is enabled, the contents defined by up to 128 stages of descriptor memory can be consecutively transferred when the built-in descriptor memory is used. External memory can also be used as the descriptor memory. In that case, the contents defined by up to 256 stages of descriptor memory can be transferred.

The following initial settings are required to use the descriptor memory.

- Set the base address of the descriptor memory for the DMA transfer in DMADPBASE.
- Set the DRST bit in DMACHCRB to reset the descriptor memory.
- Set the number of stages of the descriptor memory in the DCNT bits of DMACHCRB.

The descriptor memory is shared between all channels. Ensure that the areas of descriptor memory for use by each of the channels do not overlap. It is necessary to arrange each stage of the descriptor memory on a 16-byte boundary.

There are two methods to activate the descriptor memory as follows.

- Specify the first DMA transfer settings in DMASAR, DMADAR, and DMATCR, and specify the subsequent settings in the descriptor memory. Then, set the DPB bit in DMACHCR to 0 to activate the descriptor memory. In this case, after completion of the transfer specified in DMASAR, DMADAR, and DMATCR, transfer continues after new settings are read from the descriptor memory. Note, however, that, when the operating mode of the descriptor memory is set to the repeat mode, the values specified in DMASAR, DMADAR, and DMATCR are not read, and the transfer starts and is repeated from the head of the descriptor memory.
- Write the DMA transfer settings to the descriptor memory, and write 1 to the DPB bit in DMACHCR to activate the descriptor memory. In this case, the DMA transfer starts from the first settings in the descriptor memory.

There are three operating modes of the descriptor memory, which can be selected by setting the DPM bits in DMACHCR.

For details on these operating modes, see the descriptions of each operating mode in this section.

(1) Configuration of Descriptor Memory

Figure 31.3 shows the configuration of the built-in descriptor memory.

The capacity of the built-in descriptor memory is 16 bytes per stage × 128 stages.

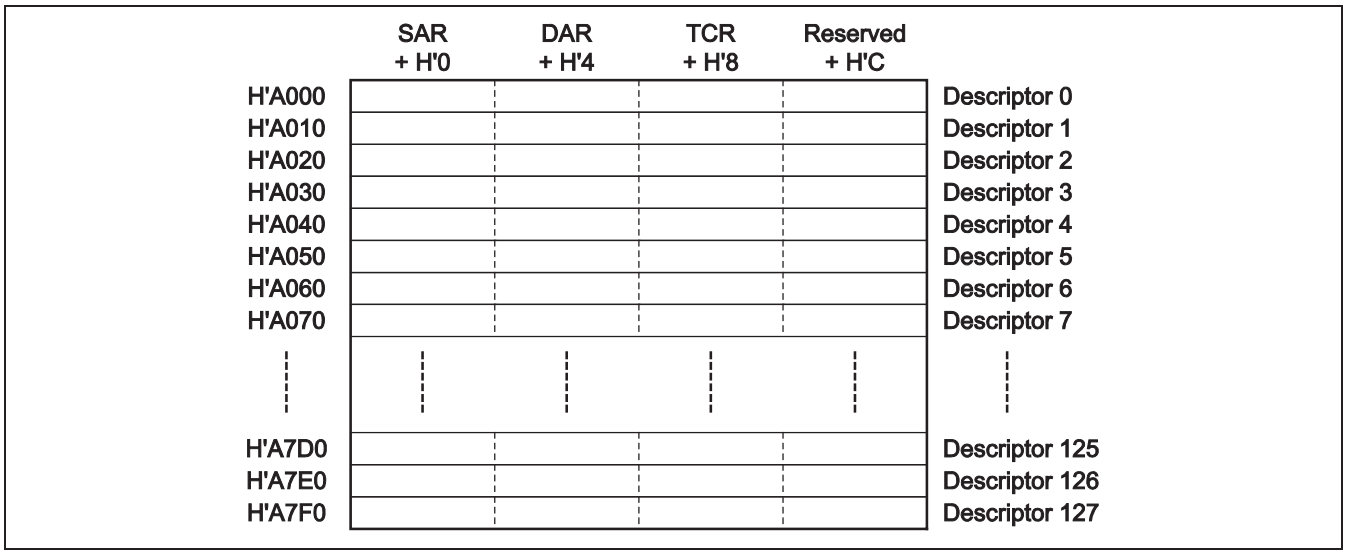

Figure 31.3 Configuration of Built-in Descriptor Memory

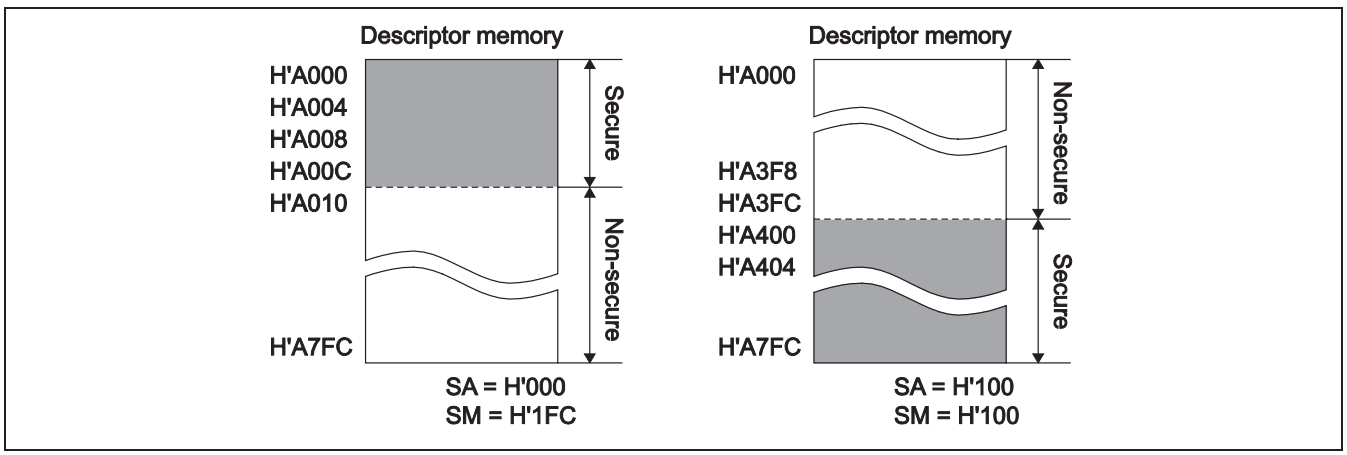

Figure 31.4 Example of DMADPSEC Setting

(2) Flow of Updating from Descriptor Memory

The RPT bits in DMACHCR can be used to specify which registers are to be updated from the descriptor memory.

The DPTR bits in DMACHCRB are incremented when updating from the descriptor memory is completed. If the DPTR value matches the DCNT value, the DPTR value is reset to 0.

This flow is automatically processed by hardware.

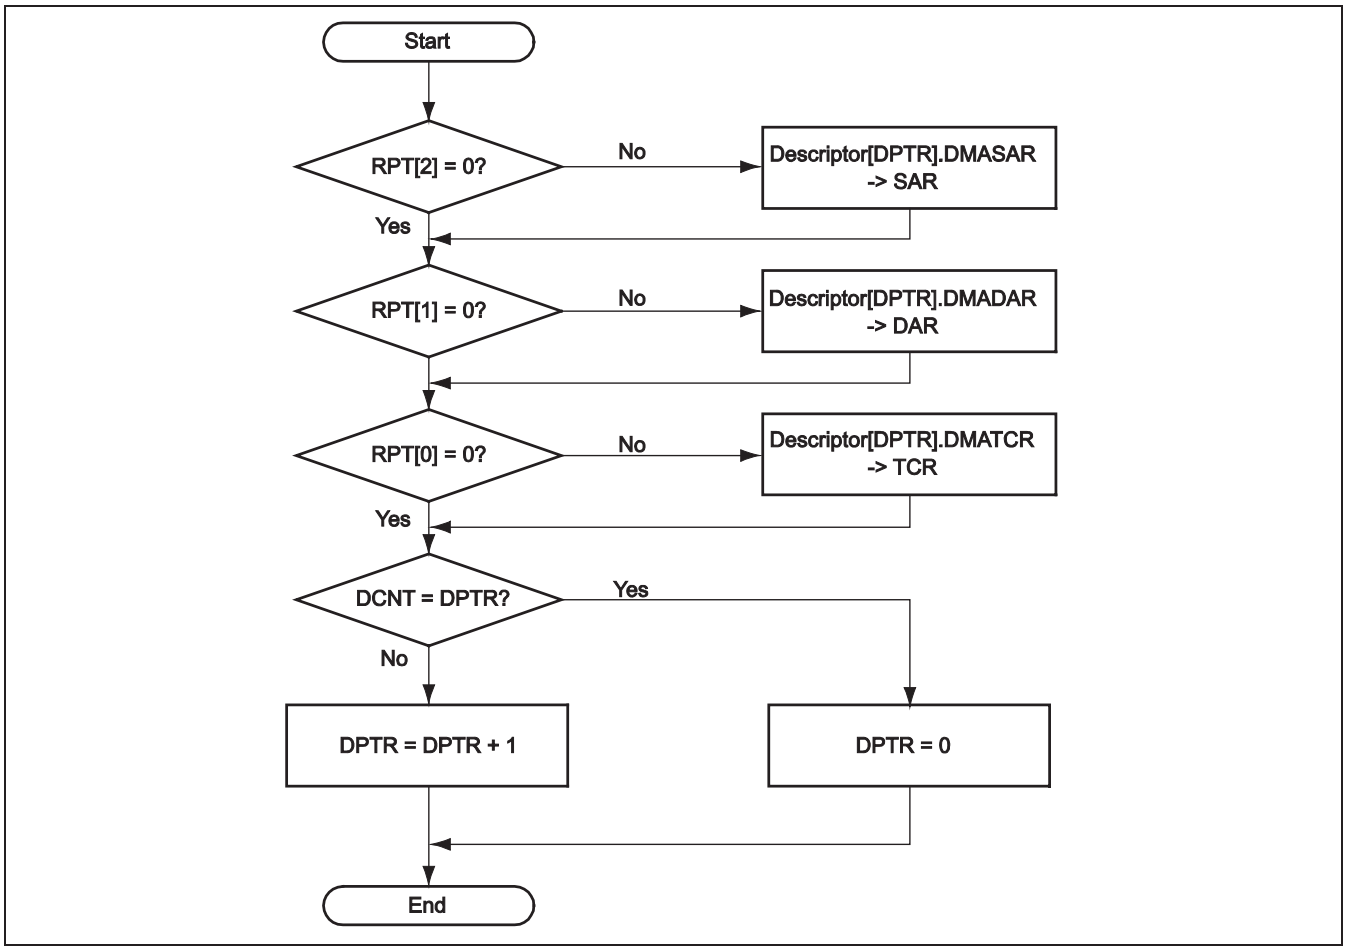

Figure 31.5 Flow of Updating from Descriptor Memory

(3) Operating Mode 1 of Descriptor Memory

Set the DPM bits in DMACHCR to B'01 to select operating mode 1 (normal mode). This mode allows consecutive transfer under control of the descriptor memory.

In this mode, the DMA transfer is complete when the TE bit in DMACHCR is set to 1 after transfer under control of the number of stages of the descriptor memory specified in the DCNT bits in DMACHCRB.

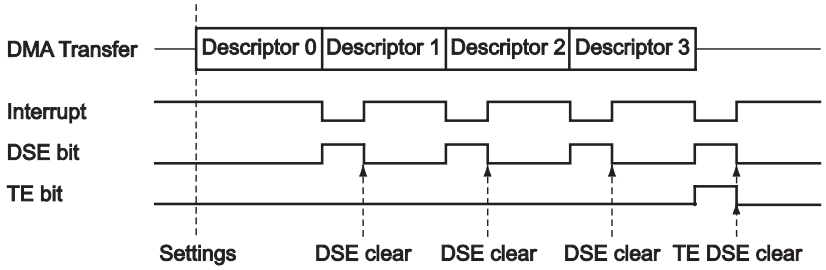
When the DSIE bit in DMACHCR is set to 1, a DSE interrupt is generated every time transfer under the control of one stage of descriptor memory is complete. If a first DSE interrupt has not been processed when a further DSE interrupt is generated, the contents of the next stage of the descriptor memory are not read and the DMA transfer is aborted. Clearing the DSE bit only causes clearing of the first interrupt and reading of the next stage of the descriptor memory.

Figure 31.6 is an example of transfer when operating mode 1 is selected and the TE and DSE bits are set to 1.

Figure 31.7 is an example of transfer when there is a delay in processing of the DSE interrupt when operating mode 1 is selected and the TE and DSE bits are set to 1.

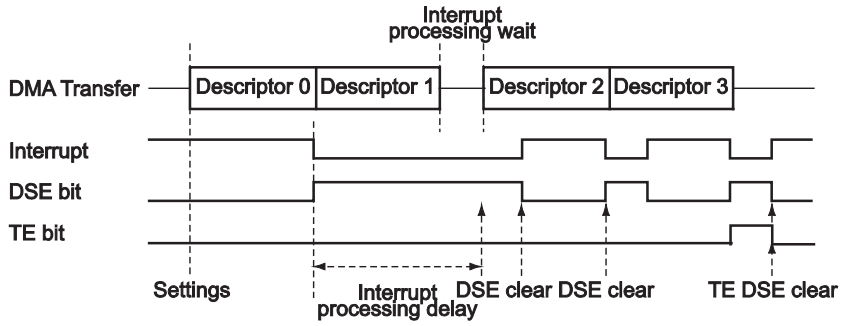
Figure 31.8 is an example of transfer when operating mode 1 is selected and the TE bit is set to 1.

In each example, there are four descriptor stages.



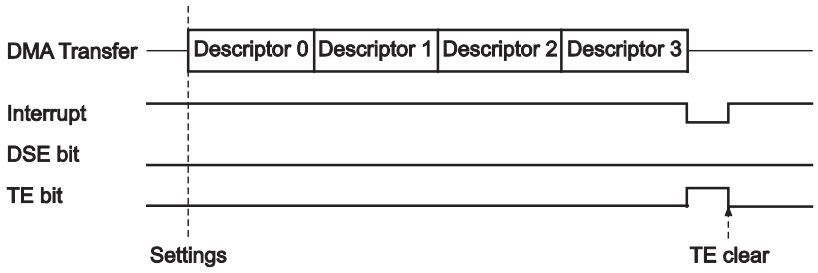
Settings: 1. The descriptor has four setting (DMASAR, DMADAR, DMATCR) stages.
2. Set the DMACHCRB register (DCNT = 3).
3. Set the DMACHCR register (DPM = B'01, DRST = B'1, DB = B'1, DSIE = B'1, IE = B'1).

Figure 31.6 Operating Mode 1 (Example 1)



Settings: 1. The descriptor has four setting (DMASAR, DMADAR, DMATCR) stages.
2. Set the DMACHCRB register (DCNT = 3).
3. Set the DMACHCR register (DPM = B'01, DRST = B'1, DB = B'1, DSIE = B'1, IE = B'1).

Figure 31.7 Operating Mode 1 (Example 2)



Settings: 1. The descriptor has four setting (DMASAR, DMADAR, DMATCR) stages.
2. Set the DMACHCRB register (DCNT = 3).
3. Set the DMACHCR register (DPM = B'01, DRST = B'1, DB = B'1, DSIE = B'0, IE = B'1).

Figure 31.8 Operating Mode 1 (Example 3)

(4) Operating Mode 2 of Descriptor Memory

Set the DPM bits in DMACHCR to B'10 to select operating mode 2 (repeat mode). This mode allows consecutive transfer under control of the descriptor memory.

In this mode, after transfer under control of the number of stages of descriptor memory specified in the DCNT bits in DMACHCRB, the TE bit in DMACHCR is set to 1. This operation is then repeated from the head of the descriptor memory.

When the DSIE bit in DMACHCR is set to 1, a DSE interrupt is generated every time transfer under the control of one stage of descriptor memory is complete. If a first DSE interrupt has not been processed when a further DSE interrupt is generated, the contents of the next stage of the descriptor memory are not read and the DMA transfer is aborted. Clearing the DSE bit only causes clearing of the first interrupt and reading of the next stage of the descriptor memory.

When the DSIE bit in DMACHCR is set to 0, after transfer under control of all stages of the descriptor memory is complete, the TE bit in DMACHCR is set to 1 and a TE interrupt is generated. If a TE interrupt has not been processed when a further interrupt is generated, the contents of the next stage of the descriptor memory are not read and the DMA transfer is aborted. Clearing the TE bit only causes clearing of the first interrupt and reading of the next stage of the descriptor memory.

To end operation in mode 2, change the mode to mode 1 by using the TE interrupt processing. When the mode is changed to mode 1, the DMA transfer is completed when the next TE interrupt is generated.

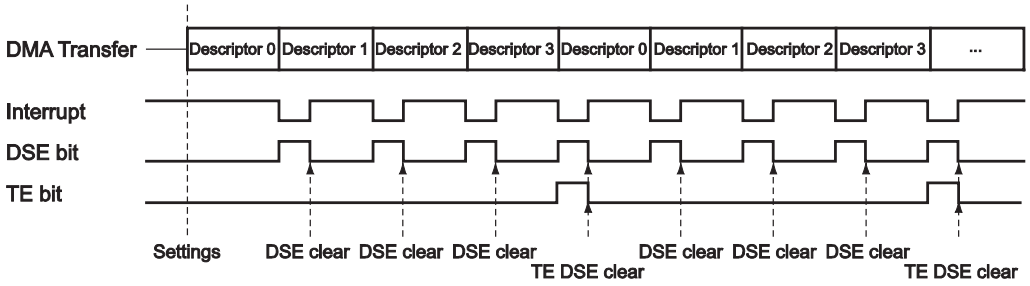
Figure 31.9 is an example of transfer when operating mode 2 is selected and the TE and DSE bits are set to 1.

Figure 31.10 is an example of transfer when there is a delay in processing of the DSE interrupt when operating mode 2 is selected and the TE and DSE bits are set to 1.

Figure 31.11 is an example of transfer when operating mode 2 is selected and the TE bit is set to 1.

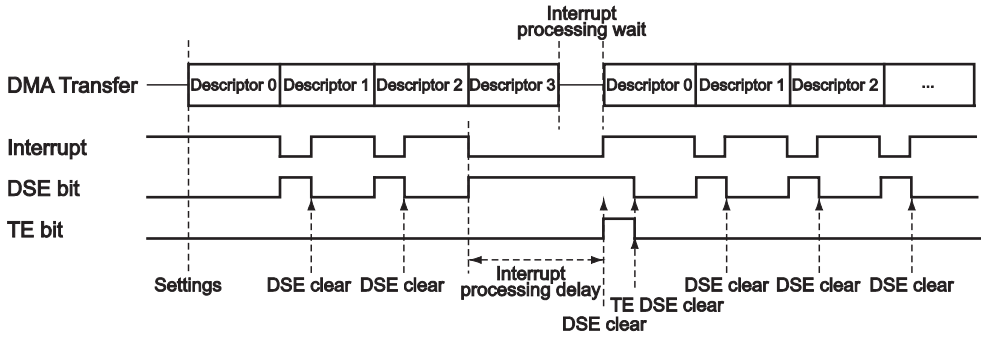
Figure 31.12 is an example of transfer when there is a delay in processing of the DSE interrupt when operating mode 2 is selected and the TE is set to 1.

In each example, there are four descriptor stages.



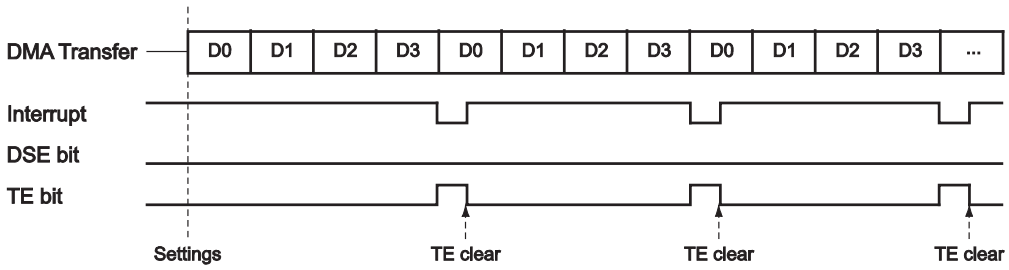
Settings: 1. The descriptor has four setting (DMASAR, DMADAR, DMATCR) stages.
2. Set the DMACHCRB register (DCNT = 3).
3. Set the DMACHCR register (DPM = B'01, DRST = B'1, DB = B'1, DSIE = B'1, IE = B'1).

Figure 31.9 Operating Mode 2 (Example 1)



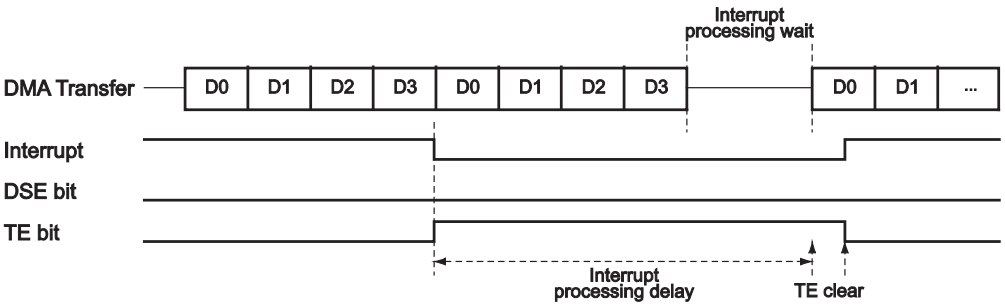
Settings: 1. The descriptor has four setting (DMASAR, DMADAR, DMATCR) stages.
2. Set the DMACHCRB register (DCNT = 3).
3. Set the DMACHCR register (DPM = B'10, DRST = B'1, DB = B'1, DSIE = B'1, IE = B'1).

Figure 31.10 Operating Mode 2 (Example 2)



Settings: 1. The descriptor has four setting (DMASAR, DMADAR, DMATCR) stages.
2. Set the DMACHCRB register (DCNT = 3).
3. Set the DMACHCR register (DPM = B'10, DRST = B'1, DB = B'1, DSIE = B'0, IE = B'1).

Figure 31.11 Operating Mode 2 (Example 3)



Settings: 1. The descriptor has four setting (DMASAR, DMADAR, DMATCR) stages.
2. Set the DMACHCRB register (DCNT = 3).
3. Set the DMACHCR register (DPM = B'10, DRST = B'1, DB = B'1, DSIE = B'0, IE = B'1).

Figure 31.12 Operating Mode 2 (Example 4)

(5) Operating Mode 3 of Descriptor Memory

Set the DPM bits in DMACHCR to B'11 to select operating mode 3 (infinite repeat mode). This mode allows consecutive transfer under control of the descriptor memory.

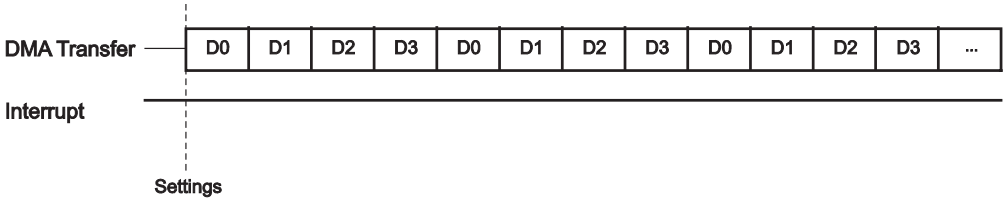
In this mode, after transfer under control of the number of stages of descriptor memory specified in the DCNT bits in DMACHCRB, the TE bit in DMACHCR is set to 1. This operation is then repeated from the head of the descriptor memory.

When the DSIE bit in DMACHCR is set to 1, a DSE interrupt is generated every time transfer under the control of one stage of descriptor memory is complete. Even if a first DSE interrupt has not been processed when a further DSE interrupt is generated, the DMA transfer is not aborted. Regardless of the number of DSE interrupts that have been generated, the DSE bit can be cleared by writing to it once. Similarly, even if a first TE interrupt has not been processed when a further TE interrupt is generated, the DMA transfer is not aborted. Regardless of the number of TE interrupts that have been generated, the TE bit can be cleared by writing to it once.

Figure 31.13 is an example of transfer when infinite repeat mode is selected.

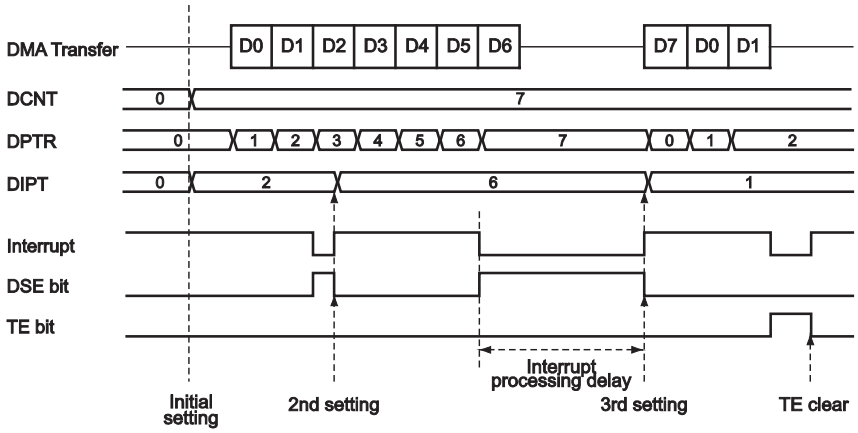
Figure 31.14 is an example of transfer when read-out interrupt mode is selected.

In each example, there are four descriptor stages.



Settings: 1. The descriptor has four setting (DMASAR, DMADAR, DMATCR) stages.
2. Set the DMACHCRB register (DCNT = 3).
3. Set the DMACHCR register (DPM = B'11, DRST = B'1, DB = B'1, DSIE = B'0, IE = B'0).

Figure 31.13 Operating Mode 3 (Infinite Repeat Mode)



Initial setting:
1. Set the DMACHCRB register (DCNT = 7).
2. The descriptor has three setting (DMASAR, DMADAR, DMATCR) stages.
3. Set the DMADPCR register (DIPT = 2).
4. Set the DMACHCR register (DPM = B'11, DRST = B'1, DB = B'1, DSIE = B'1, IE = B'0).

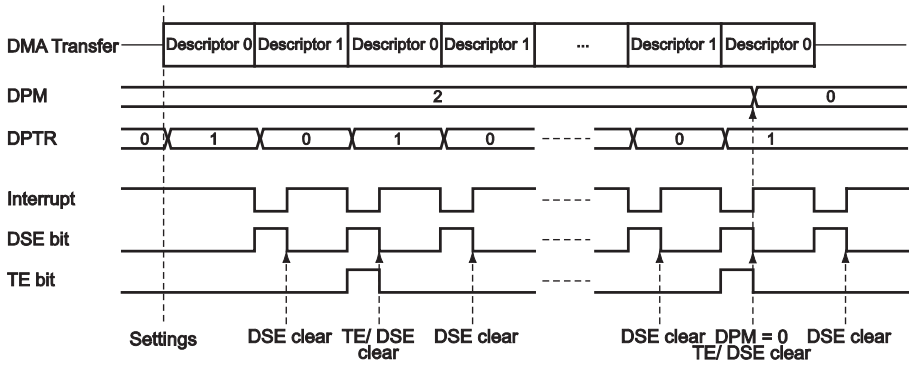
2nd setting:
1. The descriptor has four setting (DMASAR, DMADAR, DMATCR) stages.
2. Set the DMADPCR register (DIPT = 6).
   (3 stages + 4 stages -1) mod 8 = 6
3. Clear DSE.

3rd setting: (Transfer end)
1. The descriptor has three setting (DMASAR, DMADAR, DMATCR) stages.
2. Set the DMADPCR register (DIPT =1).
   (3 stages + 4 stages + 3 stages -1) mod 8 = 1
3. Clear the DSE bit and set the DMACHCR register (DPM = B'11, DB = B'0, DSIE = B'0, IE = B'1).

Figure 31.14 Operating Mode 3 (Read-Out Interrupt Mode)

(6) Using the Descriptor Memory for Double Buffering

To use the descriptor memory for double buffering, set the number of stages of descriptor memory to 2, set the buffer configuration to the descriptor memory, and activate the memory in operating mode 2. The DSE interrupt is used in double buffering. To end the use of double buffering, disable the descriptor operating mode, which stops the transfer on completion of the transfer currently in progress.



Settings: 1. The descriptor has two setting (buffer A, buffer B) stages.
2. Set the DMACHCRB register (DCNT = 1).
3. Set the DMACHCR register (DPM = B'10, DRST = B'1, DB = B'1, DSIE = B'1, IE = B'0).

Figure 31.15 Using the Descriptor Memory for Double Buffering

31.4.5 Transmission Flow

Set the transfer conditions as required in the following registers:

DMA source address register (DMASAR), DMA destination address register (DMADAR), DMA transfer count register (DMATCR), DMA Channel control register (DMACHCR), DMA operation register (DMAOR) and DMA extended resource selector (DMARS)

The DMAC then transmits data in the following order.

- A transfer request is generated and the controller checks whether the transfer is allowed (DE = 1, DME = 1, TE = 0, DSE = 0, CAE = 0). When a channel is in the auto request mode, the transfer starts automatically.
- The controller checks whether updating from the descriptor memory is required.
  Updating from the descriptor memory proceeds when the DPB bit in DMACHCR is set to 1 or the descriptor memory is enabled, if DMATCR is set to 0.
  For updating by using the descriptor memory, see section 31.4.4, Descriptor Memory.
- Check whether address translation by the IPMMU is required.
  Address translation by the IPMMU proceeds if the address exceeds the effective size for address translation when the DE bit in DMACHCR is enabled and updating of transfer settings from the descriptor memory is executed.
- Each time a transfer request is generated, the amount of data for a single round of transfer (specified by the TS[3:0] bits) is transmitted. The value in DMATCR is decremented by 1 every time the DMA transfer is completed.
- When the specified number of rounds of transfer are completed (the value in DMATCR is set to 0), the transfer ends normally. A TE interrupt is generated for the CPU upon the end of the transfer if the IE bit in DMACHCR is set to 1. If the descriptor memory is enabled, the processing differs with the mode of the descriptor memory. For more details, see section 31.4.4, Descriptor Memory.
- Transfer is aborted when the DMAC encounters an address error. Transfer is also aborted when the DE bit in DMACHCR or the DME bit in DMAOR is set to 0.

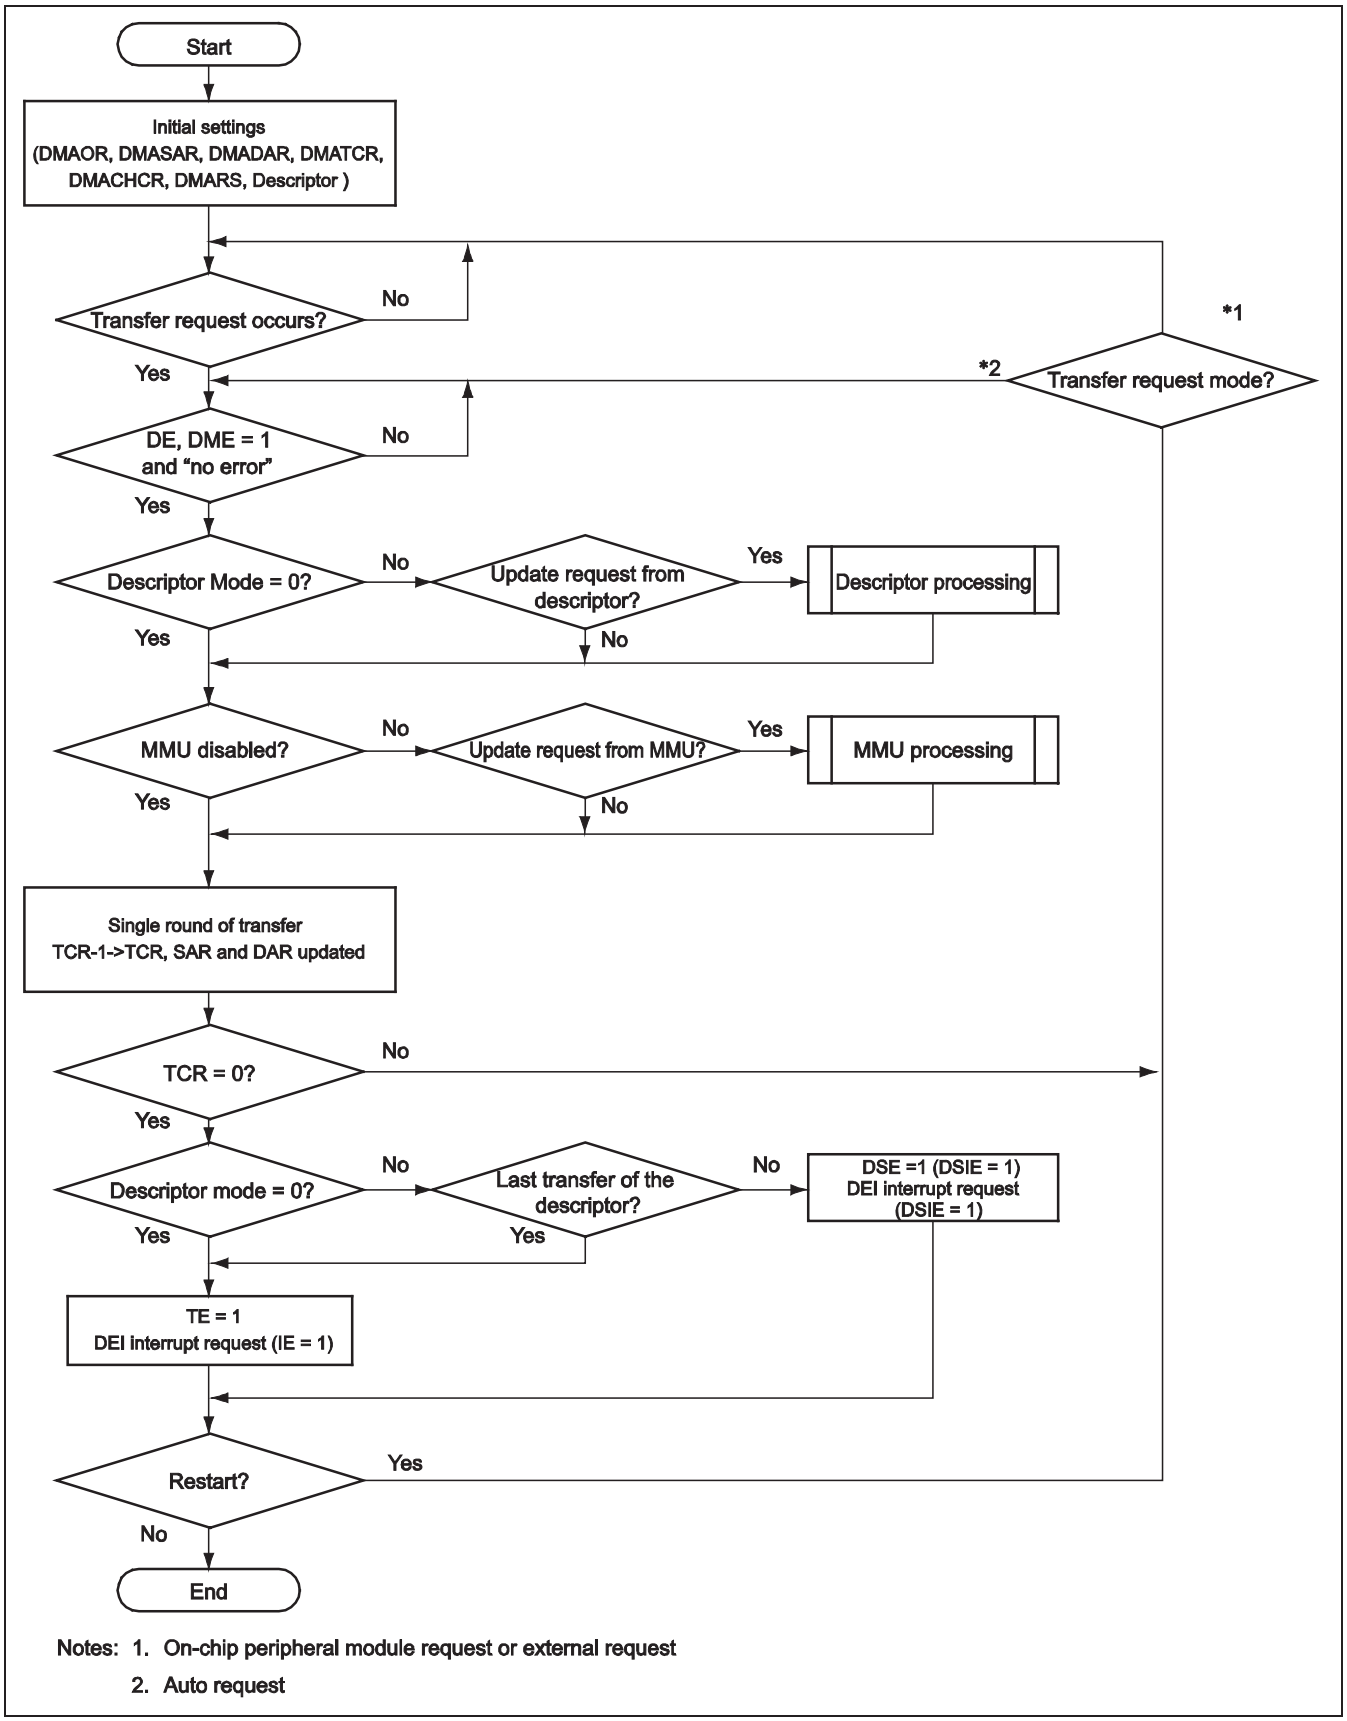


Figure 31.16 Transmission Flow

31.4.6 Total Size Transmission

The amount of data for total size transmission can be set in DMATSR (in bytes), and this setting is effective regardless of the size specified in the TS bits in DMACHCR. Thereby, the desired size can be transmitted in a single round of DMA transfer.

To use this function, make the settings for total size transmission in DMASAR, DMADAR, DMATSR, DMATSRB and DMACHCR.

Total size is set in the TCR (TSR) field of descriptors and 1 is set in DMACHCRB.DTS when total size transmission and descriptors are in use.

31.5 Usage Notes

Pay attention to the following notes when using the audio-DMAC.

(1) DMA Transfer for Peripheral Modules

When executing DMA transfer for an on-chip peripheral module, set addresses on the appropriate boundary (in terms of the amount of data for each round of transfer) for the transfer source and destination addresses. Otherwise, an address error may occur.

(2) Module Stop

While the audio-DMAC is operating, the module stop register (MSTPCR5) should not be set to stop the audio-DMAC. If the audio-DMAC is stopped in this way, results of the transfer that was in progress cannot be guaranteed.

(3) Address Error

When a DMA address error is generated, reset the registers of the channel on which the error has occurred and then start transfer anew.

(4) Aborting DMA Transfer

To abort a DMA transfer, disable the interrupt signal and set the DE bit in the DMA channel control register (DMACHCR) to 0 to disable the DMA transfer. If the TE and DSE bits are set when DMA transfer is aborted, these bits should be initialized. There is a possibility that TE and DSE will not be set with synchronized timing after transmission, so it's necessary to recognize the following three possibilities and take measures accordingly.

1. The DSE and TE bits are set to 1 before initialization of DMACHCR, but after the interrupt was disabled.
   The TE and DSE bits are initialized within the DMA transfer initialization sequence.
2. The DSE and TE bits are set to1 and the controller fails to abort the transfer, after the interrupt was disabled.
   When the DE bit has become 0 after DMA transfer initialization, check the TE and DSE bits. If the TE or DSE bit is 1, go through the DMA transfer initialization process.
3. The TE and DSE bits are not cleared to 0 but the transfer is aborted, after the interrupt is disabled.
   The TE or DSE bits are not set because data for transfer still remain after transfer is aborted.

Note: Initialization of DMA transfer during execution of the last transfer leads to a delay in setting of the TE and DSE bits, so include a dummy read.

Figure 31.17 shows an example of processing to abort DMA transfer.

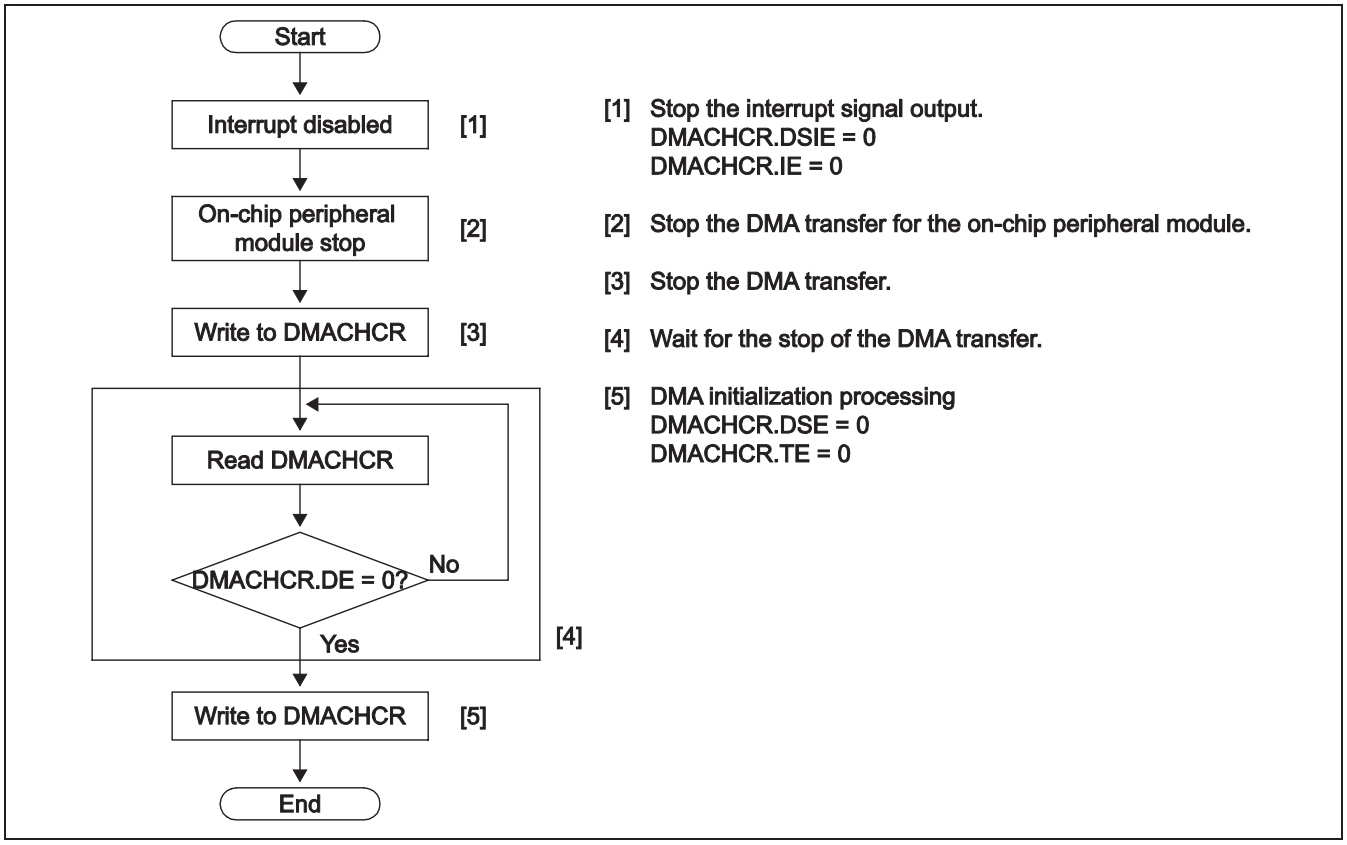

Figure 31.17 Example of Processing to Abort DMA Transfer

32. Audio-DMAC-Peripheral-Peripheral (Audio-DMACpp)

32.1 Overview

The Audio DMAC-Peripheral-Peripheral module controls data transfer between the audio modules connected to the audio local bus.

32.1.1 Features

- Number of channels: 29 channels
- Data transfer size: Longword (4 bytes)
- Addressing mode: Dual addressing; fixed access size
- Transfer count: Not programmable
- Interrupt processing: None

32.1.2 Block Diagram

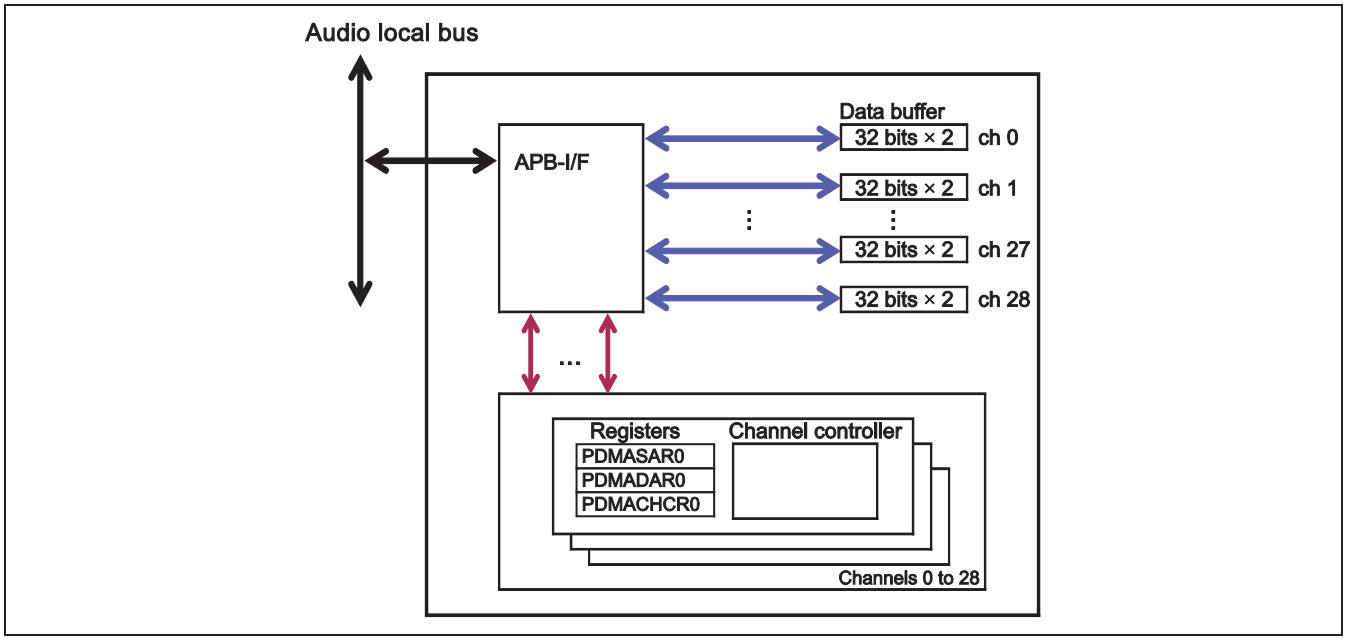

Figure 32.1 Block Diagram

32.1.3 Input/Output Pins

No external pins are provided.

32.1.4 Register Configuration

Table 32.1 List of Registers

Register Name	Abbreviation	R/W	Address	Initial Value	Access Size
PDMA Source Address n Register	PDMASARn	R/W	H'EC74 0020 + H'10 × [n]	H'0000 0000	32
PDMA Destination Address n Register	PDMADARn	R/W	H'EC74 0024 + H'10 × [n]	H'0000 0000	32
PDMA Channel Control n Register	PDMACHCRn	R/W	H'EC74 002C + H'10 × [n]	H'0000 0000	32

Notes: 1. n indicates the DMAC channel number (n = 0 to 28).
2. Access the listed registers from the CPU in longword (32-bit) units; byte or word access is prohibited.
3. Do not write to any addresses other than listed above. Operations cannot be guaranteed if writing is attempted. Values read from addresses other than those listed above are undefined.

32.2 Register Description

[Legend]

Initial value: Register value after a reset

—: Undefined value

R/W: Readable/writable. The written value can be read.

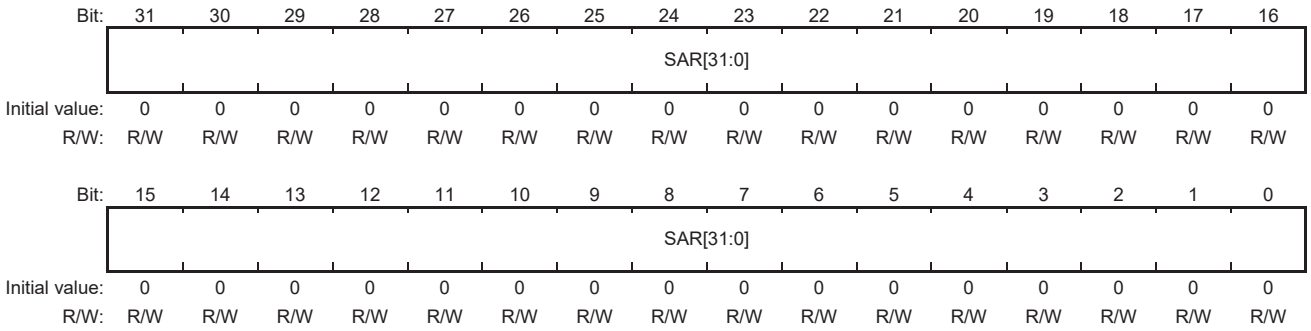
R/WC1: Readable/writable. Writing 1 initializes the bit, and writing 0 is ignored.

R: Read-only. The write value should always be 0.

—/W: Write-only. The read value is undefined.

32.2.1 PDMA Source Address n Register (PDMASARn)

Function: Sets the DMA transfer source address.

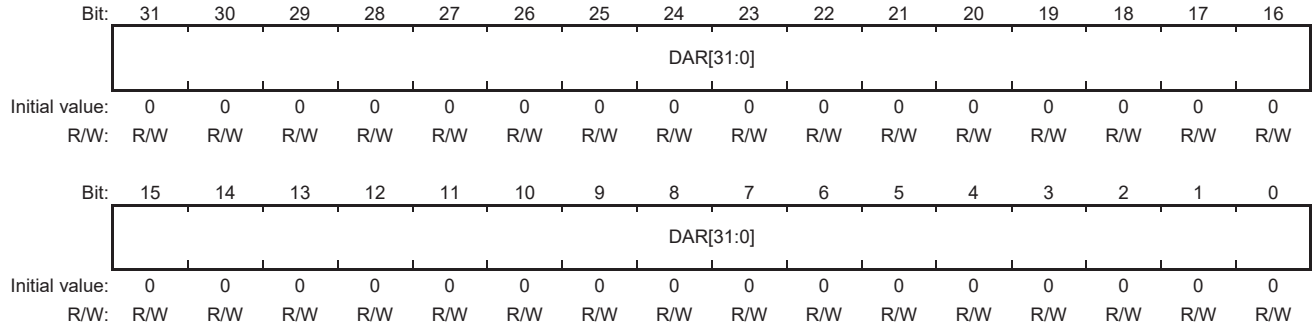


Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SAR	All 0	R/W	Sets the DMA transfer source address.

Note: It's prohibited to set same source address in other channels including.

32.2.2 PDMA Destination Address n Register (PDMADARn)

Function: Sets the DMA transfer destination address.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DAR	All 0	R/W	Sets the DMA transfer destination address.

Note: It's prohibited to set same source address in other channels including.

32.2.3 PDMA Channel Control n Register (PDMACHCRn)

Function: Selects the request sources of DMA transfer source and destination, and also starts or stops DMA.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	SRS[6:0]							—	DRS[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

32.3.2 Setting Flow

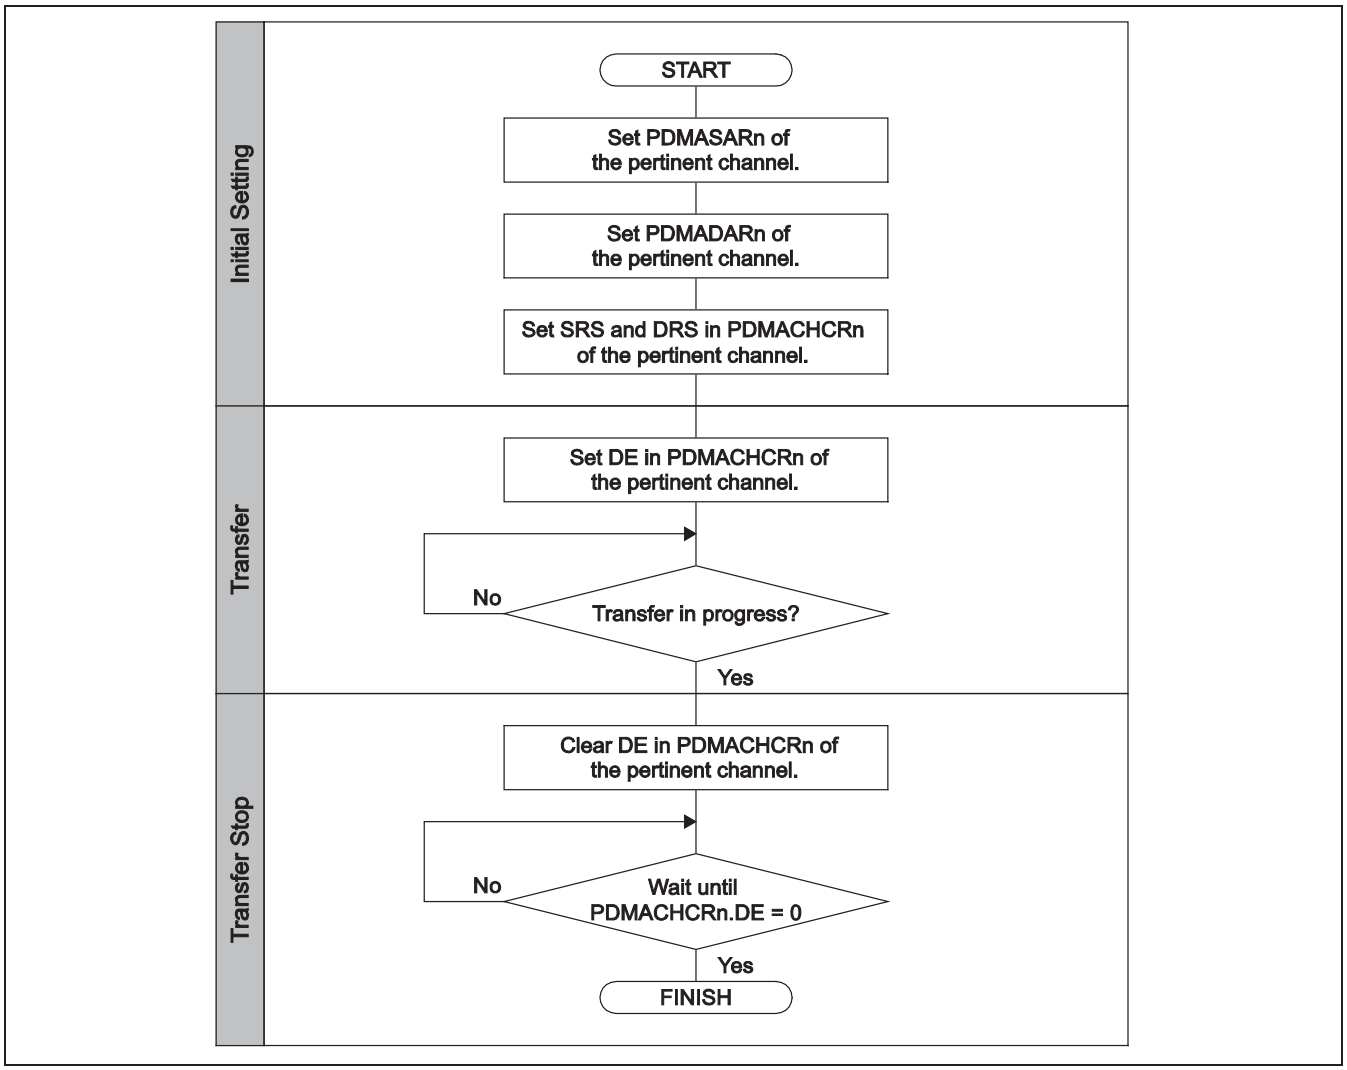

Figure 32.2 Setting Flow

32.4 Usage Notes

There is no attention of the usage.

33. Ethernet MAC Controller (Ether)

33.1 Overview

The Ether is a control unit which incorporates a function core conforming to the IEEE802.3u MAC (media access control) layer standard.

33.1.1 Features

- IEEE802.3u MAC (Ether) function
- Transmits and receives data frames
- Supports transfer at 10 and 100 Mbps
- Conforms to IEEE802.3u
- Reduced media independent interface (RMII)
- Magic packet detection
- Flow control conforming to IEEE802.3x or back pressure system
- On-chip DMA controller

Figure 33.1 shows a block diagram of the Ether. Table 33.1 lists the functions of each block.

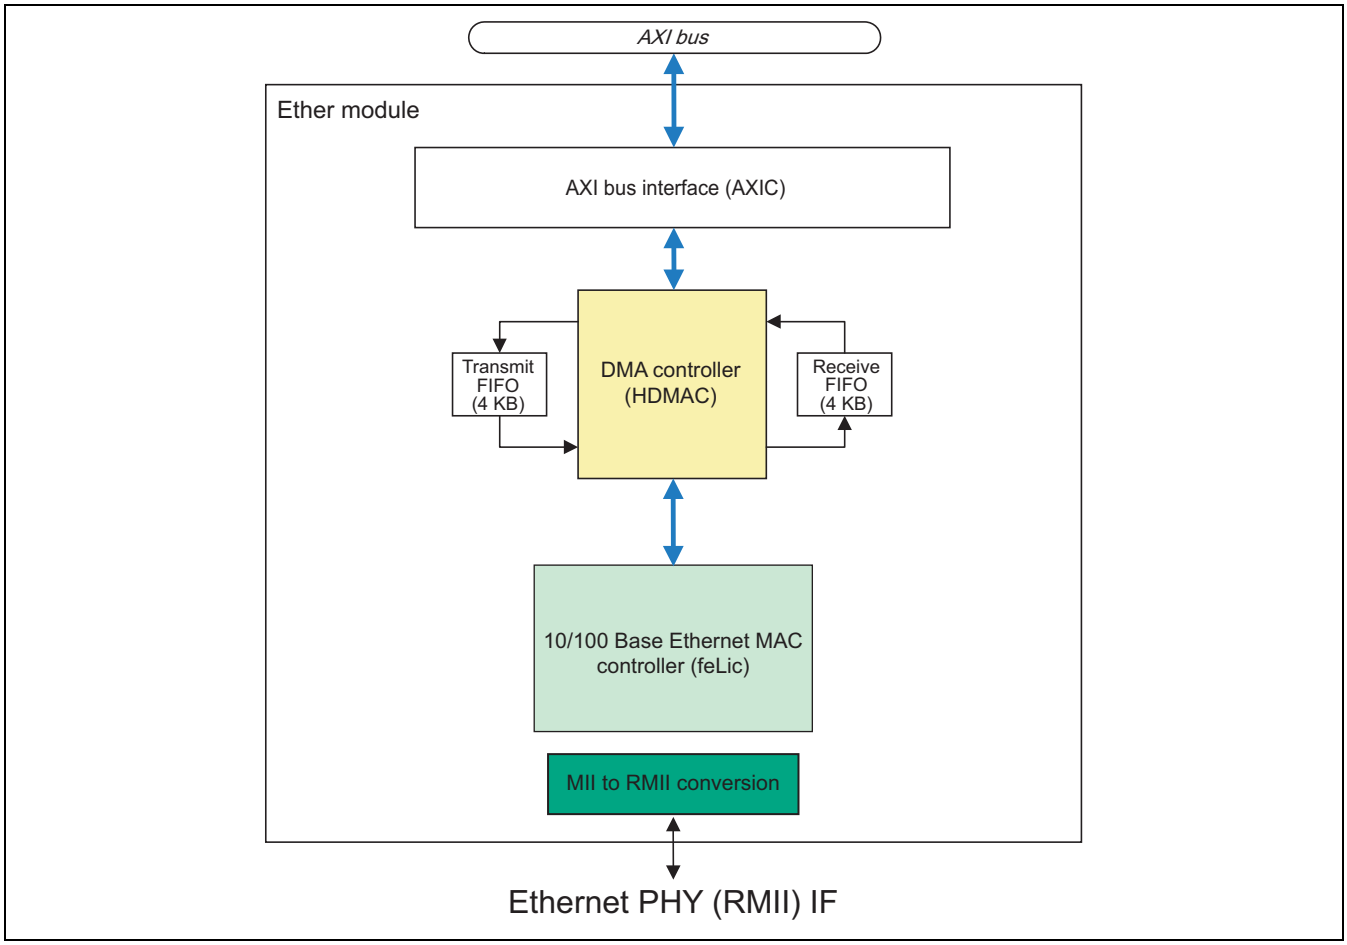

Figure 33.1 Block Diagram of Ether

Table 33.1 Functions of Each Block

Block	Function
AXI bus interface (AXIC)	• Controls AXI bus interface.
DMA controller (HDMAC)	• DMA transfer of data transmitted from and received in the 10/100 Base Ethernet MAC controller between the transmit/receive buffer on memory and internal FIFOs • For details, see section 33.8, HDMAC Function Specifications.
10/100 Base Ethernet MAC controller (feLic)	• Conforms to the IEEE802.3u MAC layer standard. • Transmits and receives data frames. • Supports transfer at 10/100 Mbps. • Magic packet detection • Flow control conforming to IEEE802.3x or back pressure system • For details, see section 33.9, feLic Function Specifications.
MII to RMII conversion	• MII to RMII interface conversion
Transmit/receive FIFO (TFIFO/RFIFO)	• Transmit/receive FIFO for DMA controller • Transmit FIFO depth: 4 Kbytes • Receive FIFO depth: 4 Kbytes

33.2 Input/Output Pins

Table 33.2 lists the external pin functions.

Table 33.2 External Pin Function

Pin Name	I/O	Function
ETH_REF_CLK	Input	Reference input clock
ETH_TXD0 ETH_TXD1	Output	Transmit data
ETH_TX_EN	Output	Transmit data enable
ETH_CRS_DV	Input	Carrier sense
ETH_RX_ER	Input	Receive error
ETH_RXD0 ETH_RXD1	Input	Receive data
ETH_MDC	Output	Management data clock
ETH_MDIO	I/O	Management data
ETH_LINK	Input	PHY output LINK signal
ETH_MAGIC	Output	Magic packet detection

33.3 Endian

The Ether has a 32-bit interface. Figure 33.2 shows data arrangement. The Ether allows endian conversion for DMA data through the setting of the CXR0 register of the HDMAC.

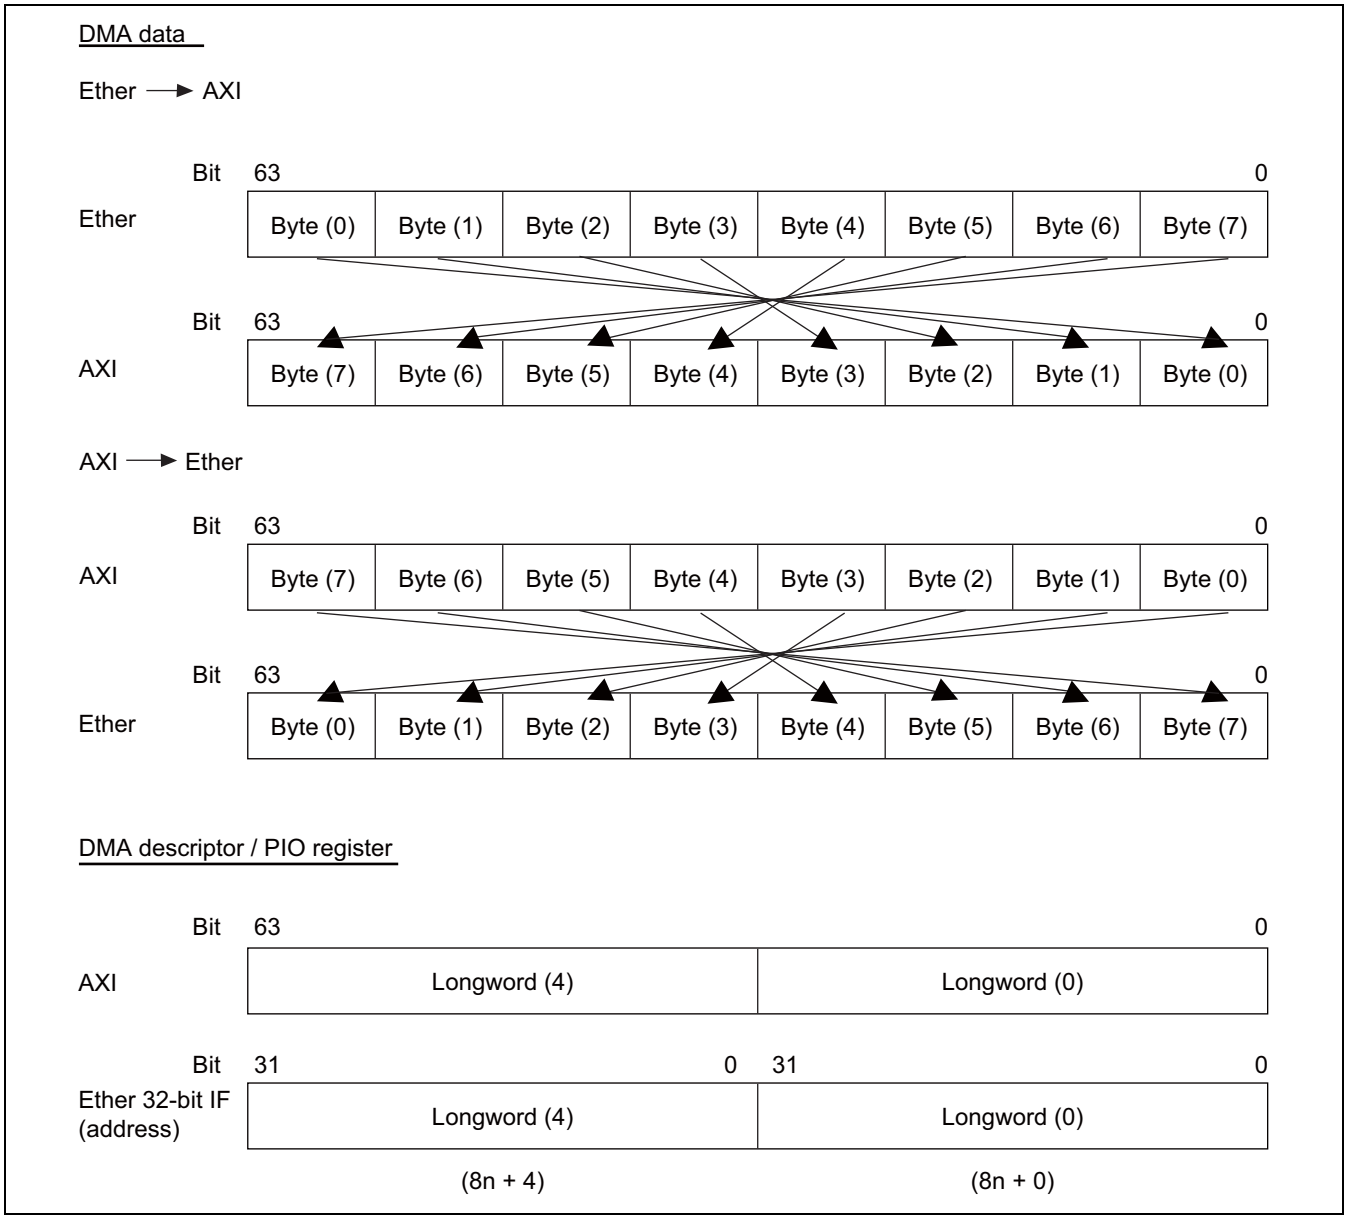

Figure 33.2 Data Arrangement

33.4 Register Descriptions

(1) Notes on Register Access

To access the registers, the following restrictions and notes should be obeyed.

1. For the register bits not defined implicitly in this specifications document, the write value should always be 0, and the read value should always be handled as undefined.
2. Even when there are no restrictions on writing to each register, the undefined bits should be written to as described in the above restriction.
3. Each register is a 32-bit long and should be accessed in 32-bit units. Accordingly, any register cannot be partially read from or written to.

(2) Register Configuration

Table 33.3 shows the configuration of HDMAC registers. Table 33.4 shows the configuration of feLic registers.

Table 33.3 HDMAC Register Configuration

Name	Abbreviation	R/W	Address	Initial Value	Access Size
HDMAC operating mode setting register	CXR0	R/W*	H'EE70 0200	H'0000 0000	32
Transmit activation register	CXR1	R/W*	H'EE70 0208	H'0000 0000	32
Receive activation register	CXR2	R/W	H'EE70 0210	H'0000 0000	32
Transmit descriptor start address setting register	CXR3	R/W*	H'EE70 0218	H'0000 0000	32

Manual PAUSE parameter setting register	CXR72	W	H'EE70 0358	H'0000 0000	32
Receive PAUSE frame counter register	CXR80	R	H'EE70 0360	H'0000 0000	32
PAUSE frame retransmit count setting register	CXR81	R/W*	H'EE70 0364	H'0000 0000	32
PAUSE frame retransmit counter register	CXR82	R	H'EE70 0368	H'0000 0000	32
MAC address high register	CXR24	R/W*	H'EE70 03C0	H'0000 0000	32
MAC address low register	CXR25	R/W*	H'EE70 03C8	H'0000 0000	32
TINT1 count register	CXR40	R/W	H'EE70 03D0	H'0000 0000	32
TINT2 count register	CXR41	R/W	H'EE70 03D4	H'0000 0000	32
TINT3 count register	CXR42	R/W	H'EE70 03D8	H'0000 0000	32
TINT4 count register	CXR43	R/W	H'EE70 03DC	H'0000 0000	32
RINT1 count register	CXR50	R/W	H'EE70 03E4	H'0000 0000	32
RINT2 count register	CXR51	R/W	H'EE70 03E8	H'0000 0000	32
RINT3 count register	CXR52	R/W	H'EE70 03EC	H'0000 0000	32
RINT4 count register	CXR53	R/W	H'EE70 03F0	H'0000 0000	32
RINT5 count register	CXR54	R/W	H'EE70 03F4	H'0000 0000	32
RINT8 count register	CXR55	R/W	H'EE70 03F8	H'0000 0000	32

Note: * There are restrictions on write access.

33.4.1 HDMAC Operating Mode Setting Register (CXR0)

CXR0 is used for specifying the operating mode of the HDMAC.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	DE	DL1	DL0	—	—	—	SWR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 7	—	All 0	R	Reserved
6	DE	0	R/W	DMA Data Endian Conversion 0: Does not perform endian conversion for DMA data. 1: Performs endian conversion for DMA data. Endian conversion for descriptors and registers is not performed. Note: Be sure to set this bit to 1 before operating the Ethernet MAC controller (Ether).
5, 4	DL1 and DL0	00	R/W	Transmit/Receive Descriptor Length Setting Descriptor length 00: 16 bytes 01: 32 bytes 10: 64 bytes 11: Reserved
3 to 1	—	All 0	R	Reserved
0	SWR	0	R/W	HDMAC/feLic Software Reset Writing 1 resets the HDMAC/feLic module except for CXR3, CXR4, CXR8, CXR13 and CXR14. Note: Registers should not be accessed until 64 clock cycles have elapsed after the SWR bit is set to 1. When writing to registers (except for the SWR bit), the transmitting and receiving function should be disabled.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.2 Transmit Activation Register (CXR1)

CXR1 initiates transmission by the HDMAC.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TRNS
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 1	—	All 0	R	Reserved
0	TRNS	0	R/W	Transmit Activation If 1 is written to this bit, the HDMAC accesses the transmit descriptor ring and transmits frames for all the valid descriptors. This bit is automatically cleared when transmission of all the valid frames has been completed, or the transmit descriptor depletion occurs. Note: Writing 0 is disabled.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.3 Receive Activation Register (CXR2)

CXR2 initiates reception by the HDMAC.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	R
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

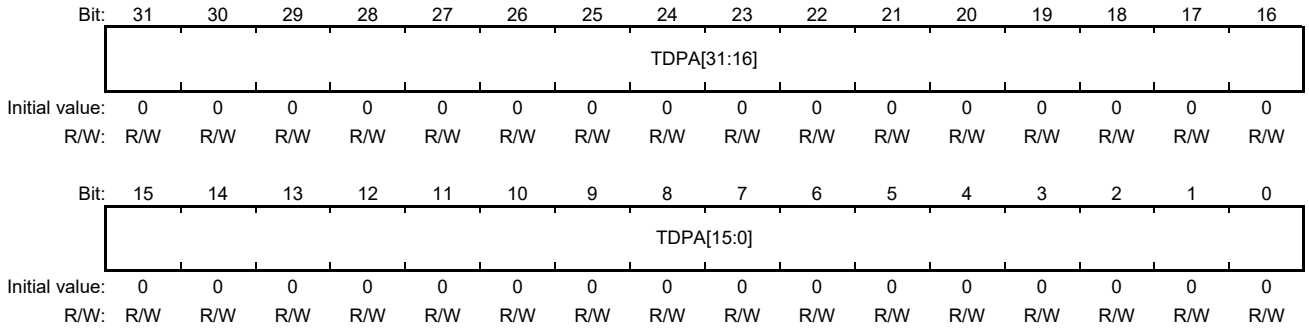
Bit	Bit Name	Initial Value*	R/W	Description
31 to 1	—	All 0	R	Reserved
0	R	0	R/W	Receive Ready If 1 is written to this bit, the HDMAC accesses the receive descriptor ring and enters the receive wait state. For operation of this bit after completion of reception, which depends on the CXR11 settings, see section 33.4.12, Receive Activation Reset Method Setting Register (CXR11). If 0 is written to this bit, the HDMAC completes reception of the frame being processed, and then disables the receiving function. This bit is reset to 0 when the RACT bit of the fetched descriptor is 0 (when the receive descriptor depletion occurs).

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.4 Transmit Descriptor Start Address Setting Register (CXR3)

CXR3 specifies the start address of the transmit descriptor ring. The start address of the descriptor ring should be aligned to the boundary consistent with the descriptor length specified by the DL bits in CXR0.

Writing to CXR3 should be performed before transmission is started. Writing to CXR3 after transmission has been started is prohibited and operation according to the written value cannot be guaranteed.

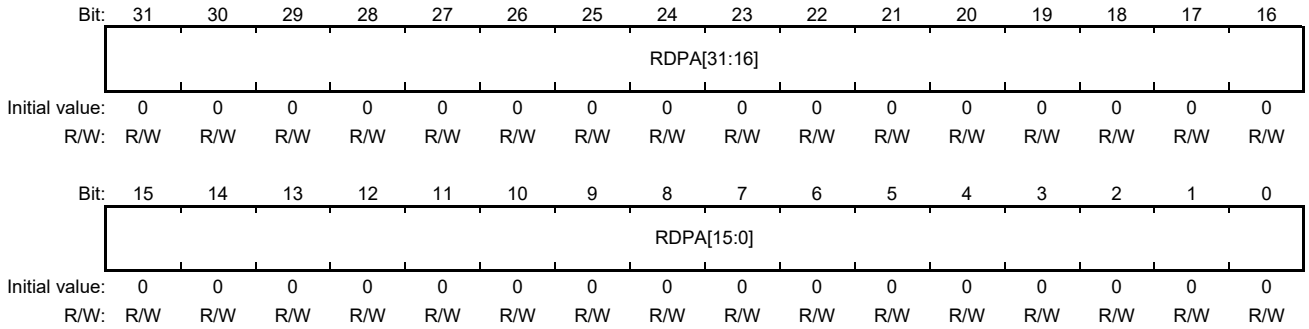


Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TDPA [31:0]	All 0	R/W	Transmit Descriptor Start Address Bits 3 to 0 should be set to 0 for alignment of the descriptor. Note: A value other than 0 must not be set to bits 3 to 0. Writing is prohibited after transmission has been started.

33.4.5 Receive Descriptor Start Address Setting Register (CXR4)

CXR4 specifies the start address of the receive descriptor ring. The start address of the descriptor ring should be aligned to the boundary consistent with the descriptor length specified by the DL bits in CXR0.

Writing to CXR4 should be performed before reception is started. Writing to CXR4 after reception has been started is prohibited and operation according to the written value cannot be guaranteed.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	RDPA [31:0]	All 0	R/W	Receive Descriptor Start Address Bits 3 to 0 should be set to 0 for alignment of the descriptor. Note: A value other than 0 must not be set to bits 3 to 0. Writing is prohibited after transmission has been started.

33.4.6 Status Register (CXR5)

CXR5 is a register that indicates HDMAC interrupt sources.

The status sources are output to the INTC module by a signal of each source.

Each bit is cleared by writing 1 to the corresponding bit. The MINT bit is set to 0 by clearing CXR21. Generation of interrupts can be masked by the corresponding bits in CXR6.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TINT8	TINT7	TINT6	TINT5	TINT4	TINT3	TINT2	TINT1	RINT8	RINT7	RINT6	RINT5	RINT4	RINT3	RINT2	RINT1
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1	R/W*1

Bit	Bit Name	Initial Value*2	R/W	Description
31	—	0	R	Reserved
30	TWB	0	R/W*1	Indicates that write-back to the transmit descriptor whose TWBI bit is set has been performed. The interrupt can be generated every frame by so setting CXR18. <Interrupt source>
29	BINT	0	R/W*1	Reserved This bit should always be set to 0.
28	AINT	0	R/W*1	Reserved This bit should always be set to 0.
27	LKON	0	R/W*1	Reserved This bit should always be set to 0.
26	TABT	0	R/W*1	Transmit Abort Detect <Interrupt source>
25	RABT	0	R/W*1	Receive Abort Detect <Interrupt source>
24	RFRMER	0	R/W*1	Receive Frame Count Overflow Occurrence <Interrupt source>
23	BER	0	R/W*1	Indicates that a DMA error is input.
22	MINT	0	R	M Port Interrupt Occurrence <Interrupt source> Indicates that an interrupt signal from the feLic is asserted.
21	FTC	0	R/W*1	Frame Transmit Completion <Interrupt source> Indicates that transmission of all the frames specified by the transmit descriptor has been completed. This bit is not set for each frame.
20	TDE	0	R/W*1	Reserved This bit should always be set to 0.
19	TFE	0	R/W*1	Transmit FIFO Underflow Error Occurrence <Interrupt source> Indicates that the transmit FIFO becomes empty during frame transmission.

Bit	Bit Name	Initial Value*2	R/W	Description
18	FRC	0	R/W*1	Frame Receive Completion <Interrupt source> Indicates that the receive descriptor is updated by frame reception. This bit is set when reception of one frame has been completed regardless of the setting of the RR bit in CXR11.
17	RDE	0	R/W*1	Receive Descriptor Depletion <Interrupt source> Indicates that the fetched receive descriptor is invalid. Occurrence of this source resets the R bit in CXR2 to 0.
16	RFE	0	R/W*1	Receive FIFO Overflow Error Occurrence <Interrupt source>
15 to 8	TINT8 to TINT1	All 0	R/W*1	Transmit Port Interrupt
7 to 0	RINT8 to RINT1	All 0	R/W*1	Receive Port Interrupt

Notes: 1. These bits are cleared by writing 1 to the corresponding bits. Writing 0 has no meaning.
2. This register is initialized by an HDMAC/feLic software reset.

33.4.7 Interrupt Mask Setting Register (CXR6)

CXR6 is a register that masks the interrupts indicated by CXR5.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	TWB	BINT	AINT	LKON	TABT	RABT	RFRMER	BER	MINT	FTC	TDE	TFE	FRC	RDE	RFE

15 to 8	TINT8 to TINT1	All 0	R/W	
7 to 0	RINT8 to RINT0	All 0	R/W	

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.8 Error Mask Setting Register (CXR7)

CXR7 is a register that specifies whether or not to allow the status of the descriptor information (indicated by the RFS7 bit in RD0) to be reflected in the RFE bit in the receive descriptor 0 (RD0) as a summary.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

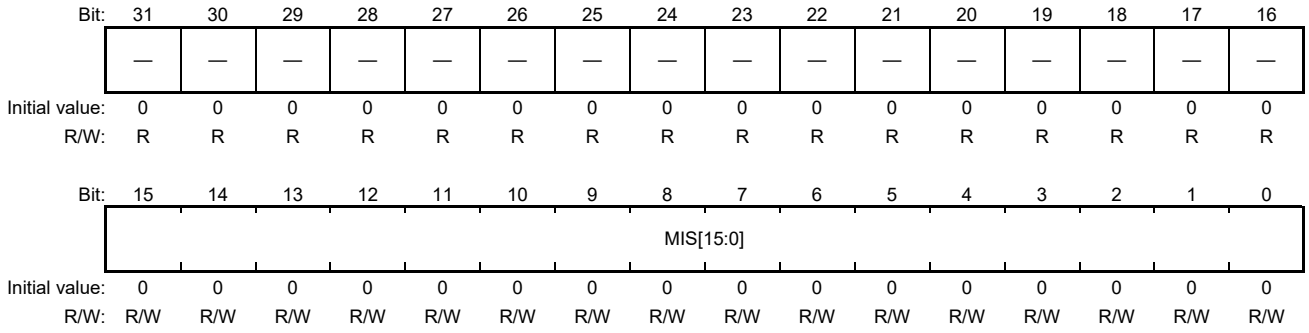
R/W:	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value*	R/W	Description
31 to 8	—	All 0	R	Reserved
7	RINT8	All 0	R/W	Receive Descriptor Error Flag (RFE) Mask 0: Allows RINT8 (RFS7 bit in RD0) to be reflected in RFE. 1: Does not allow RINT8 (RFS7 bit in RD0) to be reflected in RFE.
6 to 0	—	All 0	R	Reserved

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.9 Discarded Frame Counter Register (CXR8)

CXR8 is a register that indicates the number of discarded frames.



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved
15 to 0	MIS[15:0]	H'0000	R/W	Discarded Frame Counter These bits indicate the number of frames which are discarded because the receive descriptor is disabled, for example. The counter stops counting when all bits are set to 1 (H'FFFF). Note: Writing any data clears these bits.

33.4.10 Transmit FIFO Threshold Setting Register (CXR9)

CXR9 is a register that specifies the threshold for the transmit FIFO.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	FO[10:0]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R	R	R	R	R	R/W	R	R	R	R

Bit	Bit Name	Initial Value*	R/W	Description
31 to 11	—	All 0	R	Reserved
10 to 0	FO[10:0]	H'000	R/W	Transmit FIFO Threshold Setting Threshold H'000: Store and forward H'001: 4 bytes H'002: 8 bytes : : H'0FE: 1016 bytes H'0FF: 1020 bytes H'100: 1024 bytes : : H'1FE: 1040 bytes H'1FF: 2044 bytes H'200: 2048 bytes : : H'3FE: 4088 bytes H'3FF: 4092 bytes H'400 to H'7FF: Setting prohibited Reading (transmission) is started when one frame data has been written to the FIFO or when data in the FIFO exceeds the above setting. Using on the initial value (store and forward) is recommended to prevent from occurring underflow error on sending. Note: Writing is disabled when the TRNS bit in CXR1 = 1.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.11 External FIFO Depth Setting Register (CXR10)

CXR10 is a register that specifies the depth of the transmit and receive FIFOs.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	TA[4:0]					—	—	—	RA[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 13	—	All 0	R	Reserved
12 to 8	TA[4:0]	H'00	R/W	Transmit FIFO Depth Setting Depth H'00: 256 bytes H'01: 512 bytes H'02: 768 bytes H'03: 1024 bytes : : H'07: 2048 bytes : : H'0F: 4096 bytes H'10 to H'1F: Setting prohibited Note: Writing to bits 12 to 8 is disabled when the TRNS bit in CXR1 = 1.
7 to 5	—	All 0	R	Reserved
4 to 0	RA[4:0]	H'00	R/W	Receive FIFO Depth Setting Depth H'00: 256 bytes H'01: 512 bytes H'02: 768 bytes H'03: 1024 bytes : : H'07: 2048 bytes : : H'0F: 4096 bytes H'10 to H'1F: Setting prohibited Note: Writing to bits 4 to 0 is disabled when the R bit in CXR2 = 1.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.12 Receive Activation Reset Method Setting Register (CXR11)

CXR11 is a register that specifies a method for resetting the receive ready bit (R bit in CXR2).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RNR	RR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 2	—	All 0	R	Reserved
1	RNR	0	R/W	Reserved This bit should always be set to 0.
0	RR	0	R/W	Receive Ready Reset 0: (initial value) Automatically clears the receive ready bit (R bit in CXR2) by hardware. The receive ready bit (R bit in CXR2) is automatically cleared by receiving one frame, thus disabling reception of the following frames. In this mode, interrupt control for each frame is possible. 1: Normal operating mode Resets the receive ready bit (R bit in CXR2 by software. After 1 is written to the receive ready bit (R bit in CXR2), the HDMAC automatically fetches the receive descriptor and receives frames until 0 is written to the receive ready bit (R bit in CXR2). Continuous reception of multiple frames is possible. Note that the receive ready bit (R bit in CXR2) is reset to 0 when the RACT bit in the fetched descriptor is 0. Note: Writing to this bit is disabled when the R bit in CXR2 = 1.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.13 Transmit FIFO Underflow Counter Register (CXR13)

CXR13 is a register that indicates the number of times the transmit FIFO underflow occurs.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TFUF[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved
15 to 0	TFUF[15:0]	H'0000	R/W	Transmit FIFO Underflow Counter The counter stops counting when all bits are set to 1 (H'FFFF). Note: Writing any data clears these bits.

33.4.14 Receive FIFO Overflow Counter Register (CXR14)

CXR14 is a register that indicates the number of times the receive FIFO overflow occurs.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFOF[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved
15 to 0	RFOF[15:0]	H'0000	R/W	Receive FIFO Overflow Counter The counter stops counting when all bits are set to 1 (H'FFFF). Note: Writing any data clears these bits.

33.4.15 RMII Mode Register (CXR15)

CXR15 sets the RMII mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RMII
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 1	—	All 0	R	Reserved
0	RMII	0	R/W	RMII Mode Specification 0: (initial value) 1: RMII mode Be sure to set this bit to 1 before operating the Ethernet MAC controller (Ether).

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.16 Receive FIFO Busy Transmit Threshold Setting Register (CXR16)

CXR16 is a register that specifies the threshold value for sending the receive FIFO busy to the feLic based on the number of frames and number of data bytes stored in the receive FIFO.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	RFF[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	RFD[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R

Bit	Bit Name	Initial Value*	R/W	Description
31 to 19	—	All 0	R	Reserved
18 to 16	RFF[2:0]	100	R/W	Busy Transmit Threshold based on the Number of Receive Frames Setting Threshold 000: Transmits the busy when two frames have been stored. 001: Transmits the busy when four frames have been stored. 010: Transmits the busy when six frames have been stored. : 110: Transmits the busy when 14 frames have been stored. 111: Transmits the busy when 16 frames have been stored.
15 to 3	—	All 0	R	Reserved
2 to 0	RFD[2:0]	100	R/W	Busy Transmit Threshold based on the Amount of Data in the Receive FIFO Setting Threshold 000: Transmits the busy when 224 (256 – 32) bytes have been stored. 001: Transmits the busy when 480 (512 – 32) bytes have been stored. 010: Transmits the busy when 736 (768 – 32) bytes have been stored. 011: Transmits the busy when 992 (1024 – 32) bytes have been stored. : 110: Transmits the busy when 1760 (1792 – 32) bytes have been stored. 111: See the following note. Note: The set value to these bits should be smaller than the set value to the RA bits in CXR10. If the former and latter values are equal, the busy will be sent out when (receive FIFO depth – 64 bytes) have been stored in the receive FIFO, not when (receive FIFO depth – 32 bytes) have been stored. For example, when the RA bits in CXR10 and RFD bits in CXR16 are both 7, the busy will be sent out when 1984 (= 2048 – 64) bytes have been stored in the receive FIFO.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.17 Transmit Interrupt Mode Setting Register (CXR18)

CXR18 is used for setting transmit interrupt operating mode for the HDMAC.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	TIM	—	—	—	TIS
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 5	—	All 0	R	Reserved
4	TIM	0	R/W	Transmit Interrupt Mode 0: Mode in which the interrupt is issued each time a frame has been transmitted. 1: Mode in which the interrupt is issued when write-back to the descriptor whose TWBI bit is set has been completed.
3 to 1	—	All 0	R	Reserved
0	TIS	0	R/W	Interrupt Mode Enable 0: TIM setting is disabled. 1: TIM setting is enabled.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.18 feLic Operating Mode Setting Register (CXR20)

CXR20 is a register that specifies the operating mode of the feLic. Some mode bits in this register should not be modified while the transmitting and receiving functions are enabled.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	TPC	ZPF	PFR	RXF	TXF
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	CER	—	—	MPM	—	—	RPE	TPE	—	ILB	OLB	DPM	PRM
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R/W	R	R	R/W	R/W	R	R/W*1	R/W*1	R/W*1	R/W*1

Bit	Bit Name	Initial Value*2	R/W	Description
31 to 21	—	All 0	R	Reserved
20	TPC	0	R/W	PAUSE Frame Transmission 0: Transmission of a PAUSE frame is enabled even during a PAUSE period. 1: Transmission of a PAUSE frame is disabled during PAUSE period.
19	ZPF	0	R/W	PAUSE Frame Enable with TIME = 0 0: Control of a PAUSE frame whose TIME parameter value is 0 is disabled. 1: Control of a PAUSE frame whose TIME parameter value is 0 is enabled.
18	PFR	0	R/W	PAUSE Frame Receive Mode 0: PAUSE frame is not transferred to the upper module. 1: PAUSE frame is transferred to the upper module.
17	RXF	0	R/W	Operating Mode for Reception Flow Control 0: Reception flow control is disabled. 1: Reception flow control is enabled.
16	TXF	0	R/W	Operating Mode for Transmission Flow Control 0: Transmission flow control is disabled. 1: Transmission flow control is enabled.
15 to 13	—	All 0	R	Reserved
12	CER	0	R/W	CRC Error Frame Receive Mode 0: Normal mode (an error frame is regarded as an error). 1: Mode in which the received frame with a CRC error is not regarded as an error.
11, 10	—	All 0	R	Reserved
9	MPM	0	R/W	Magic Packet Detection Enable 0: Magic packet detection is disabled. 1: Magic packet detection is enabled.
8, 7	—	All 0	R	Reserved

Bit	Bit Name	Initial Value*2	R/W	Description
6	RPE	0	R/W	Reception Enable 0: Receiving function is disabled after completion of current frame reception. 1: Frame receiving function is enabled and receive data is transferred to the HDMAC.
5	TPE	0	R/W	Transmission Enable 0: Transmitting function is disabled after completion of current frame transmission. 1: A frame transmit request from the HDMAC is enabled.
4	—	0	R	Reserved
3	ILB	0	R/W*1	feLic Loopback Mode 0: The feLic enters normal mode. 1: The feLic enters loopback mode.
2	OLB	0	R/W*1	10-Base T or 100-Base TX Transfer Setting (Transfer at 10 or 100 Mbps) 0: Transfer is 10-base T (i.e. at 10 Mbps). 1: Transfer is 100-base TX (i.e. at 100 Mbps).
1	DPM	0	R/W*1	Duplex Mode 0: The feLic enters half-duplex mode. Note that feLic loopback mode should not be specified during this mode. 1: The feLic enters full-duplex mode.
0	PRM	0	R/W*1	Promiscuous Mode 0: The feLic enters normal mode. (When the MPM bit is set, the feLic operates in normal mode regardless of the status of this bit.) 1: The feLic enters promiscuous mode.

Notes: 1. Bits 3 to 0 should not be modified while the transmitting and receiving functions are enabled.
2. This register is initialized by an HDMAC/feLic software reset.

33.4.19 Long Frame Length Check Value Setting Register (CXR2A)

CXR2A is a register that specifies the upper limit of the receive frame length used for checking the length.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	FLUL[11:0]											
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 12	—	All 0	R	Reserved
11 to 0	FLUL[11:0]	H'000	R/W	Frame Length Upper Limit The specified value is used as the frame length check value. When the received frame length value exceeds this value, it is regarded as RINT4 (frame length error). (See below.) Setting Check Value H'000 to H'5EE: 1518 bytes H'5EF: 1519 bytes : : H'7FF: 2047 bytes H'800 to H'FFF: 2048 bytes Note: The CXR20 register should not be modified while the receiving function is enabled.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.20 Status Register (CXR21)

CXR21 is a register that indicates the feLic status.

The status sources are output to the INTC module by a signal of each source.

Each bit is cleared by writing 1 to the corresponding bit. Generation of interrupts can be masked by the corresponding bits in CXR22.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	BCR	PRO	—	LNK	MPR	FCD
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W*1	R/W*1	R	R/W*1	R/W*1	R/W*1

Bit	Bit Name	Initial Value*2	R/W	Description
31 to 6	—	All 0	R	Reserved
5	BCR	0	R/W*1	Reserved This bit should always be set to 0.
4	PRO	0	R/W*1	PAUSE Frame Retransmit Retry Over <Interrupt Source> Indicates that the PAUSE frame retransmission count has reached the upper limit of retransmission set in the CXR81 register.
3	—	0	R	Reserved
2	LNK	0	R/W*1	LINK Signal Change Interrupt <Interrupt Source> Indicates that the LINK signal output from the PHY has changed from high to low or low to high.
1	MPR	0	R/W*1	Magic Packet Receive Interrupt <Interrupt Source> Indicates that a magic packet has been received. (This bit is cleared by writing 1 to the bit; however, the MAGIC signal is not cleared because it is an external output signal.)
0	FCD	0	R/W*1	Illegal Carrier Detection Interrupt <Interrupt Source> Indicates that an illegal carrier is detected on the line.

Notes: 1. These bits are cleared by writing 1 to the corresponding bits. Writing 0 has no meaning.
2. This register is initialized by an HDMAC/feLic software reset.

33.4.21 Interrupt Mask Setting Register (CXR22)

CXR22 is a register that masks the interrupts indicated by CXR21.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	BCRE	PROE	—	LNKE	MPRE	FCDE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 6	—	All 0	R	Reserved
5	BCRE	0	R/W	Reserved This bit should always be set to 0.
4	PROE	0	R/W	PAUSE Frame Retransmit Retry Over Interrupt Enable 0: Disables an interrupt indicated by the corresponding bit in CXR21. 1: Enables an interrupt indicated by the corresponding bit in CXR21.
3	—	0	R	Reserved
2	LKNE	0	R/W	LINK Signal Change Interrupt Enable 0: Disables an interrupt indicated by the corresponding bit in CXR21. 1: Enables an interrupt indicated by the corresponding bit in CXR21.
1	MPRE	0	R/W	Magic Packet Receive Interrupt Enable 0: Disables an interrupt indicated by the corresponding bit in CXR21. 1: Enables an interrupt indicated by the corresponding bit in CXR21.
0	FCDE	0	R/W	Illegal Carrier Detection Interrupt Enable 0: Disables an interrupt indicated by the corresponding bit in CXR21. 1: Enables an interrupt indicated by the corresponding bit in CXR21.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.22 MII Control Register (CXR23)

CXR23 is a register that controls the MII interface to access the PHY register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	MDI	MDO	MMD	MDC
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	—	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 4	—	All 0	R	Reserved
3	MDI	—	R	MII Management Data In Read data from MII
2	MDO	0	R/W	MII Management Data Out Write data to MII
1	MMD	0	R/W	MII Management Mode 1: Data is written to MII. 0: Data is read from MII.
0	MDC	0	R/W	MII Management Clock Clock for MII

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.23 PHY Status Register (CXR2B)

CXR2B is a register that can monitor the PHY status signal.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

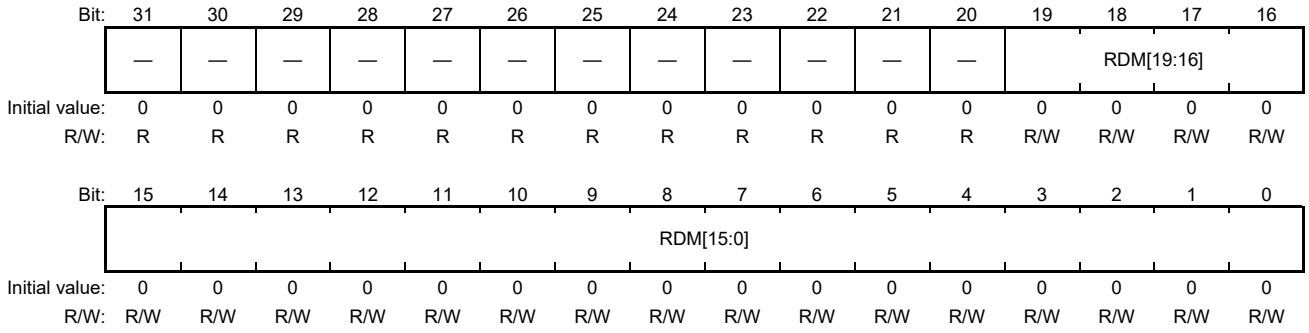
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LINK
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value*	R/W	Description
31 to 1	—	All 0	R	Reserved
0	LINK	—	R	The status of the PHY output LINK signal can be monitored. See the specifications of the PHY to be connected.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.24 Random Number Generating Counter Upper Limit Setting Register (CXR30)

CXR30 is a register that can set the upper limit of the counter used for the random number generator.



Bit	Bit Name	Initial Value*	R/W	Description
31 to 20	—	All 0	R	Reserved
19 to 0	RDM[19:0]	H'00000	R/W	Upper limit of the Counter used for the Random Number Generator H'00000: Setting for normal operation H'00001 to H'FFFFE: Counter upper limit Note: Since the operation of the feLic random number generator depends on the value set to this register, take care when setting a value other than 0.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.25 IPG Counter Setting Register (CXR70)

CXR70 is a register that specifies the IPG (inter packet gap) value.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	IPG[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	1	0	1	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 5	—	All 0	R	Reserved
4 to 0	IPG[4:0]	H'14	R/W	These bits set the IPG value in 40 ns units. Setting IPG value H'00 to H'06: 400 ns H'07: 440 ns : H'13: 920 ns H'14: 960 ns (default) : H'1F: 1440 ns Note: The CXR20 register should not be modified while the transmitting and receiving functions are enabled.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.26 Automatic PAUSE Parameter Setting Register (CXR71)

CXR71 is used to set the TIME parameter value of an automatic PAUSE frame. When an automatic PAUSE frame is transmitted, the value set in this register is used as the TIME parameter of the PAUSE frame.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	APAUSE[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 16	—	All 0	R	Reserved
15 to 0	APAUSE[15:0]	H'0000	R/W	TIME Parameter Value of an Automatic PAUSE Frame One bit is equivalent to 512 bit-time.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.27 Manual PAUSE Parameter Setting Register (CXR72)

CXR72 is used to set the TIME parameter value of a manual PAUSE frame. When a manual PAUSE frame is transmitted, the value set in this register is used as the TIME parameter of the PAUSE frame.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MPAUSE[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 16	—	All 0	W	Reserved These bits should always be set to 0.
15 to 0	MPAUSE[15:0]	H'0000	W	TIME Parameter Value of an Manual PAUSE Frame One bit is equivalent to 512 bit-time.

Note: This register can't be read.
* This register is initialized by an HDMAC/feLic software reset.

33.4.28 Receive PAUSE Frame Counter Register (CXR80)

CXR80 is used to the counter of received the PAUSE frame.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	RPAUSE[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value*	R/W	Description
31 to 8	—	All 0	R	Reserved
7 to 0	RPAUSE[7:0]	H'00	R	Received PAUSE frame Counter

Note: Writing to this register has no meaning.

* This register is initialized by an HDMAC/feLic software reset.

33.4.29 PAUSE Frame Retransmit Count Setting Register (CXR81)

CXR81 is used to set the upper limit of the automatic PAUSE frame retransmission count. For details of this register, see section 33.9.2 (6), Flow Control Conforming to IEEE802.3.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TXPAUSE[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value*1	R/W	Description
31 to 16	—	All 0	R	Reserved
15 to 0	TXPAUSE[15:0]	H'0000	R/W	Upper Limit of PAUSE Frame Retransmission Setting Retransmit count H'0000: Unlimited*2 H'0001: 1 : : H'FFFF: 65535 Note: The CXR20 register should not be modified while the transmitting function is enabled.

Notes: 1. This register is initialized by an HDMAC/feLic software reset.
2. When using in unlimited setting, the time parameter MPAUSE of CXR71 should be set other than zero.

33.4.30 PAUSE Frame Retransmit Counter Register (CXR82)

CXR82 is used to the counter of retransmitting of the PAUSE frame. For details of this register, see section 33.9.2 (6), Flow Control Conforming to IEEE802.3.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TXP[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value*	R/W	Description
31 to 16	—	All 0	R	Reserved
15 to 0	TXP[15:0]	H'0000	R	PAUSE Frame Retransmit Counter

Note: Writing to this register has no meaning.
* This register is initialized by an HDMAC/feLic software reset.

33.4.31 MAC Address High Register (CXR24)

CXR24 is used to set the upper 32 bits of the universal MAC address.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MACH[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MACH[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 0	MACH[31:0]	H'00000000	R/W	MAC Address Upper 32 Bits Note: These bits should not be written to while the transmission enable and reception enable bits in CXR20 are set.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.32 MAC Address Low Register (CXR25)

CXR25 is used to set the lower 16 bits of the universal MAC address.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MACL[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 16	—	All 0	R	Reserved
15 to 0	MACL[15:0]	H'0000	R/W	MAC Address Lower 16 Bits Note: These bits should not be written to while the transmission enable and reception enable bits in CXR20 are set.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.33 TINT1 Count Register (CXR40)

CXR40 is a register with which the TINT1 source signal count value can be read and refer to.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TINT1C[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TINT1C[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 0	TINT1C[31:0]	H'00000000	R/W	TINT1 (Transmit Timeout) Counter This counter is not automatically updated after incremented to H'FFFFFFFF. To update the counter continuously and restart increment from H'00000000, write-access to the counter and clear it. Note: Cleared by write access.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.34 TINT2 Count Register (CXR41)

CXR41 is a register with which the TINT2 source signal count value can be read and refer to.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TINT2C[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TINT2C[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 0	TINT2C[31:0]	H'00000000	R/W	TINT2 (Collision Detection during Frame Transmission) Counter This counter is not automatically updated after incremented to H'FFFFFFFF. To update the counter continuously and restart increment from H'00000000, write-access to the counter and clear it. Note: Cleared by write access.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.35 TINT3 Count Register (CXR42)

CXR42 is a register with which the TINT3 source signal count value can be read and refer to.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TINT3C[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TINT3C[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 0	TINT3C[31:0]	H'00000000	R/W	TINT3 (Carrier Loss during Frame Transmission) Counter This counter is not automatically updated after incremented to H'FFFFFFFF. To update the counter continuously and restart increment from H'00000000, write-access to the counter and clear it. Note: Cleared by write access.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.36 TINT4 Count Register (CXR43)

CXR43 is a register with which the TINT4 source signal count value can be read and refer to.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TINT4C[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TINT4C[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 0	TINT4C[31:0]	H'00000000	R/W	TINT4 (Carrier not Detected) Counter This counter is not automatically updated after incremented to H'FFFFFFFF. To update the counter continuously and restart increment from H'00000000, write-access to the counter and clear it. Note: Cleared by write access.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.37 RINT1 Count Register (CXR50)

CXR50 is a register with which the RINT1 source signal count value can be read and refer to.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RINT1C[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RINT1C[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value*	R/W	Description
31 to 0	RINT1C[31:0]	H'00000000	R/W	RINT1 (CRC Error) Counter This counter is not automatically updated after incremented to H'FFFFFFFF. To update the counter continuously and restart increment from H'00000000, write-access to the counter and clear it. Note: Cleared by write access.

Note: * This register is initialized by an HDMAC/feLic software reset.

33.4.38 RINT2 Count Register (CXR51)

CXR51 is a register with which the RINT2 source signal count value can be read and refer to.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RINT2C[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

33.6 Software Control Flow

33.6.1 Ether Software Control Flow

(1) Example of Ethernet Transmission and Reception Procedure

Figure 33.5 shows an example of initialization procedure for Ethernet transmission and reception. Figure 33.6 shows an example of Ethernet transmission and reception procedure.

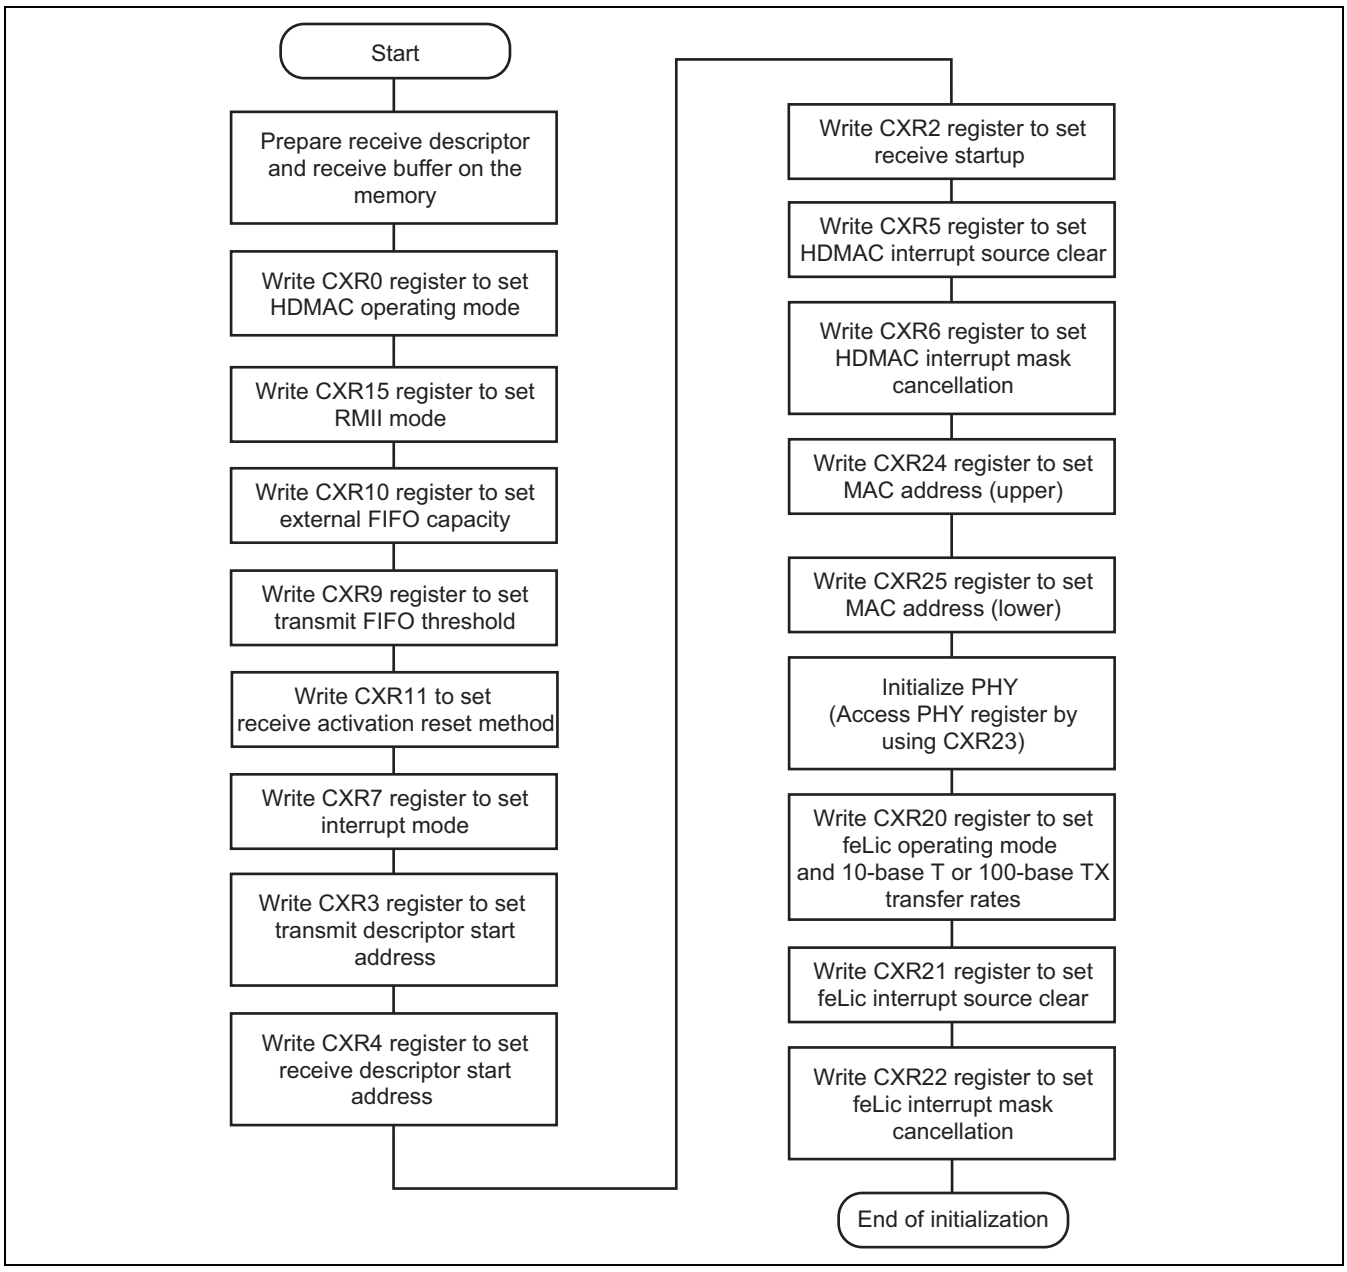

Figure 33.5 Initialization Procedure for Ethernet Transmission and Reception

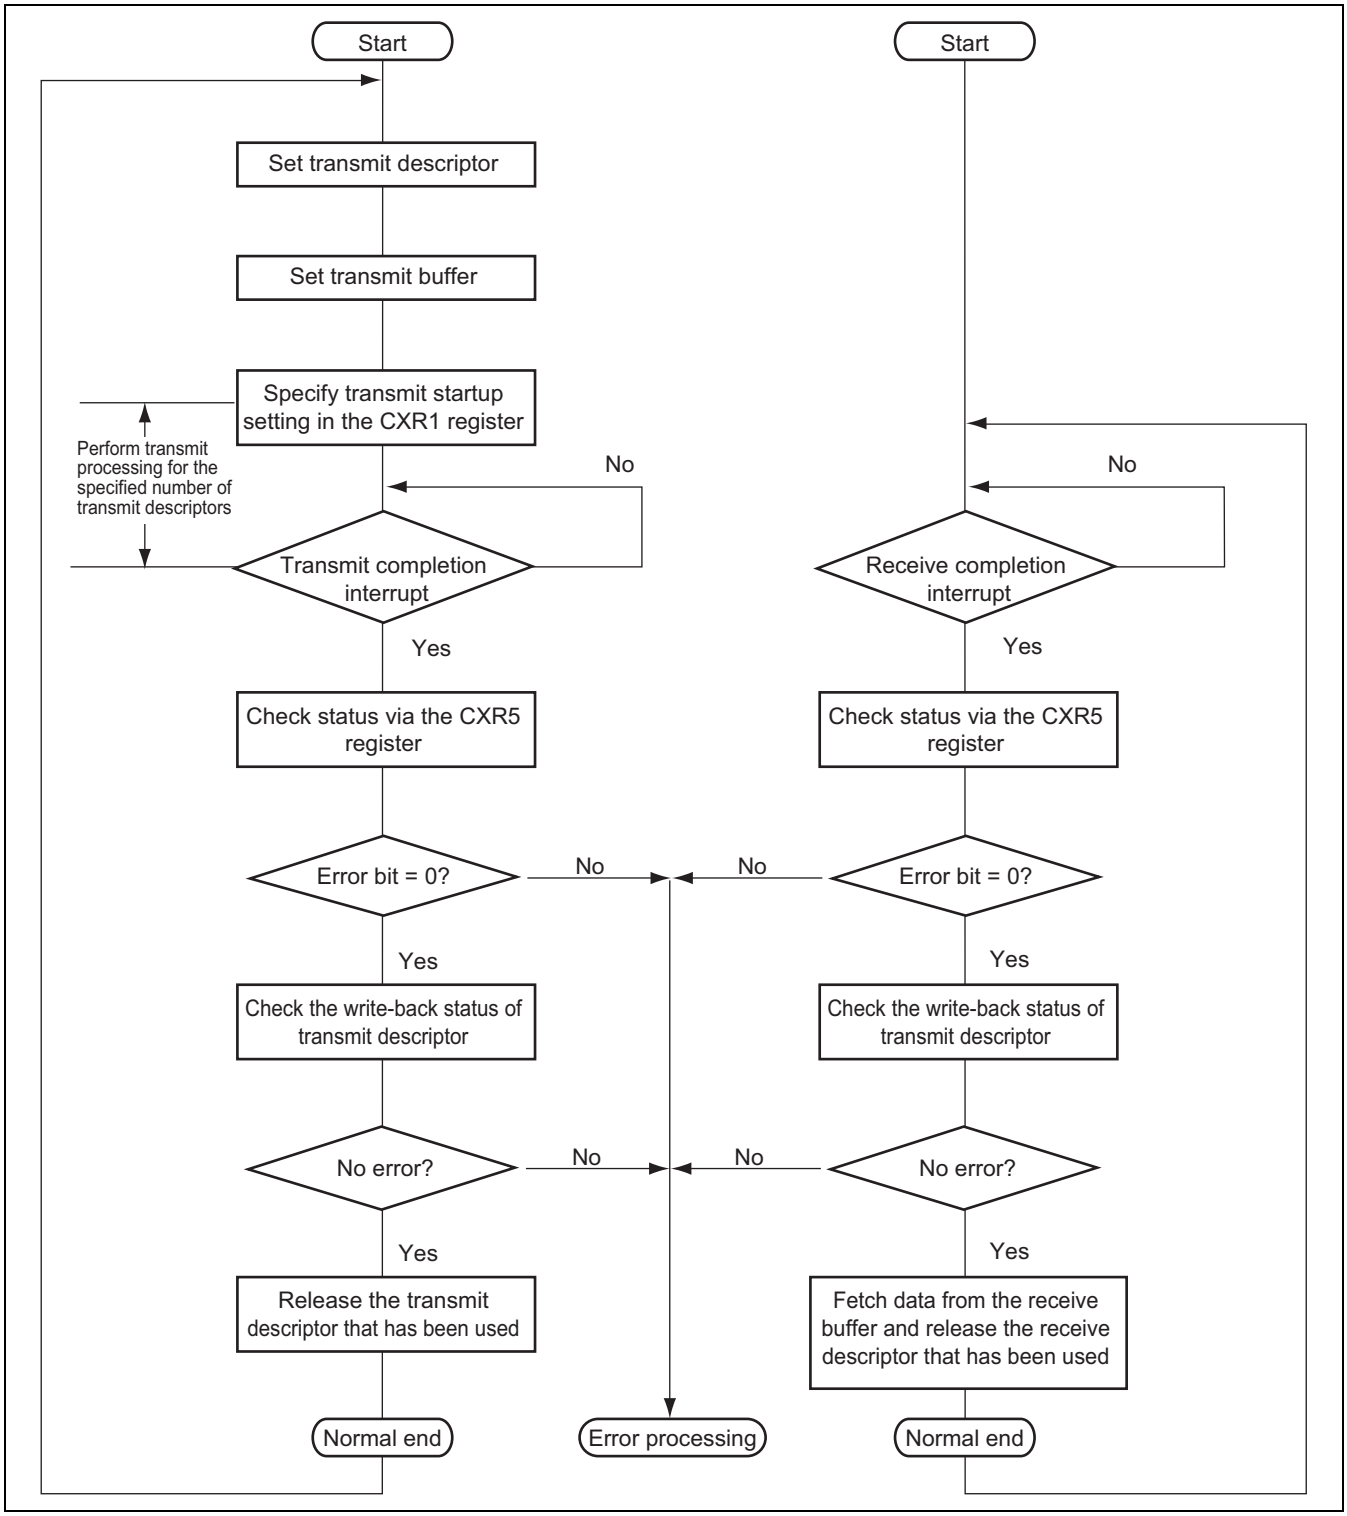

Figure 33.6 Ethernet Transmission and Reception Procedure

(2) Example of PHY Register Accessing Procedure

The PHY register is accessed by using the CXR23 register. This access should be performed using the MII management frame format as shown in Figure 33.7. Figure 33.8 shows an example of 1-bit data writing procedure to achieve the MII management frame. Figure 33.9 shows an example of bus releasing procedure. Figure 33.10 shows an example of 1-bit data reading procedure. Figure 33.11 shows an example of single bus releasing procedure.

Access Type	MII Management Frame							
Item	PRE	ST	OP	PHYAD	REGAD	TA	DATA	IDLE
Number of Bits	32	2	2	5	5	2	16	
Read	1..1	01	10	AAAAA	RRRRR	Z0	D....D	
Write	1..1	01	01	AAAAA	RRRRR	10	D....D	X

Legend:

PRE: 32 consecutive 1s

ST: Write B'01 to indicate the start of a frame

OP: Write a code to indicate an access type

PHYAD: Write B'00001 if a PHY-LSI address is 1 (write sequentially from MSB). The values of these bits change according to the PHY-LSI address.

REGAD: Write B'00001 when a register address is 1 (write sequentially from MSB). The value of these bits change according to the PHY-LSI address.

TA: Data transmit source switch time on the MII interface.
(a) Write B'10 during write
(b) Release bus (indicated as Z0) during read

DATA: 16-bit data. Written to or read sequentially from MSB.
(a) Write 16-bit data during write
(b) Read 16-bit data during read

IDLE: Wait time until next MII management format is input
(a) Release a single bus (indicated as X) during write
(b) Control not required because a bus has been released using the TA bits during read

(3) Example of the Procedure for Setting 10-Base T or 100-Base TX Transfer Rates

An example of the procedure for setting 10-base T and 100-base TX transfer rates is given below. Follow this procedure when setting the transfer rate.

This section describes the procedure during operation. For the initial settings, follow the flow in subsection (1), Example of Ethernet Transmission and Reception Procedure, above.

1. Detecting the PHY chip link being down
   Use the CXR2B or CXR21 register to detect the PHY chip link being down.
2. On finding the linking from the PHY chip down
   On detecting the link from the PHY chip being down, proceed with processing for that situation in accord with the PHY chip specification.
3. Transfer Rate Settings
   Make settings on the feLic side as required by the state of the PHY chip. Use the OLB bit in the CXR20 register to set the transfer rate.

33.7 Notes

33.7.1 Software Reset

The ether can be software-reset by setting the SWR bit in the CXR0 register of the HDMAC to 1. If software reset is applied during DMA transfer, the current DMA transfer can be completed but the data transferred by DMA transfer cannot be guaranteed.

33.7.2 Standby

If the ether is requested to enter the standby state, the ether first completes the current AXI bus operation, and then enters the standby state. After returning from the standby state, the ether should be reset and initialized.

33.7.3 Input Signal on the ETH_RX_ER Pin

If an error signal received from PHY is not at the active level for more than one cycle of the RMII reference clock at 50 MHz, the signal is not detected as an error signal.

33.8 HDMAC Function Specifications

33.8.1 Operation

(1) Basic Operation

Figure 33.12 shows an image of control between this logic core (HDMAC) and device driver (software).

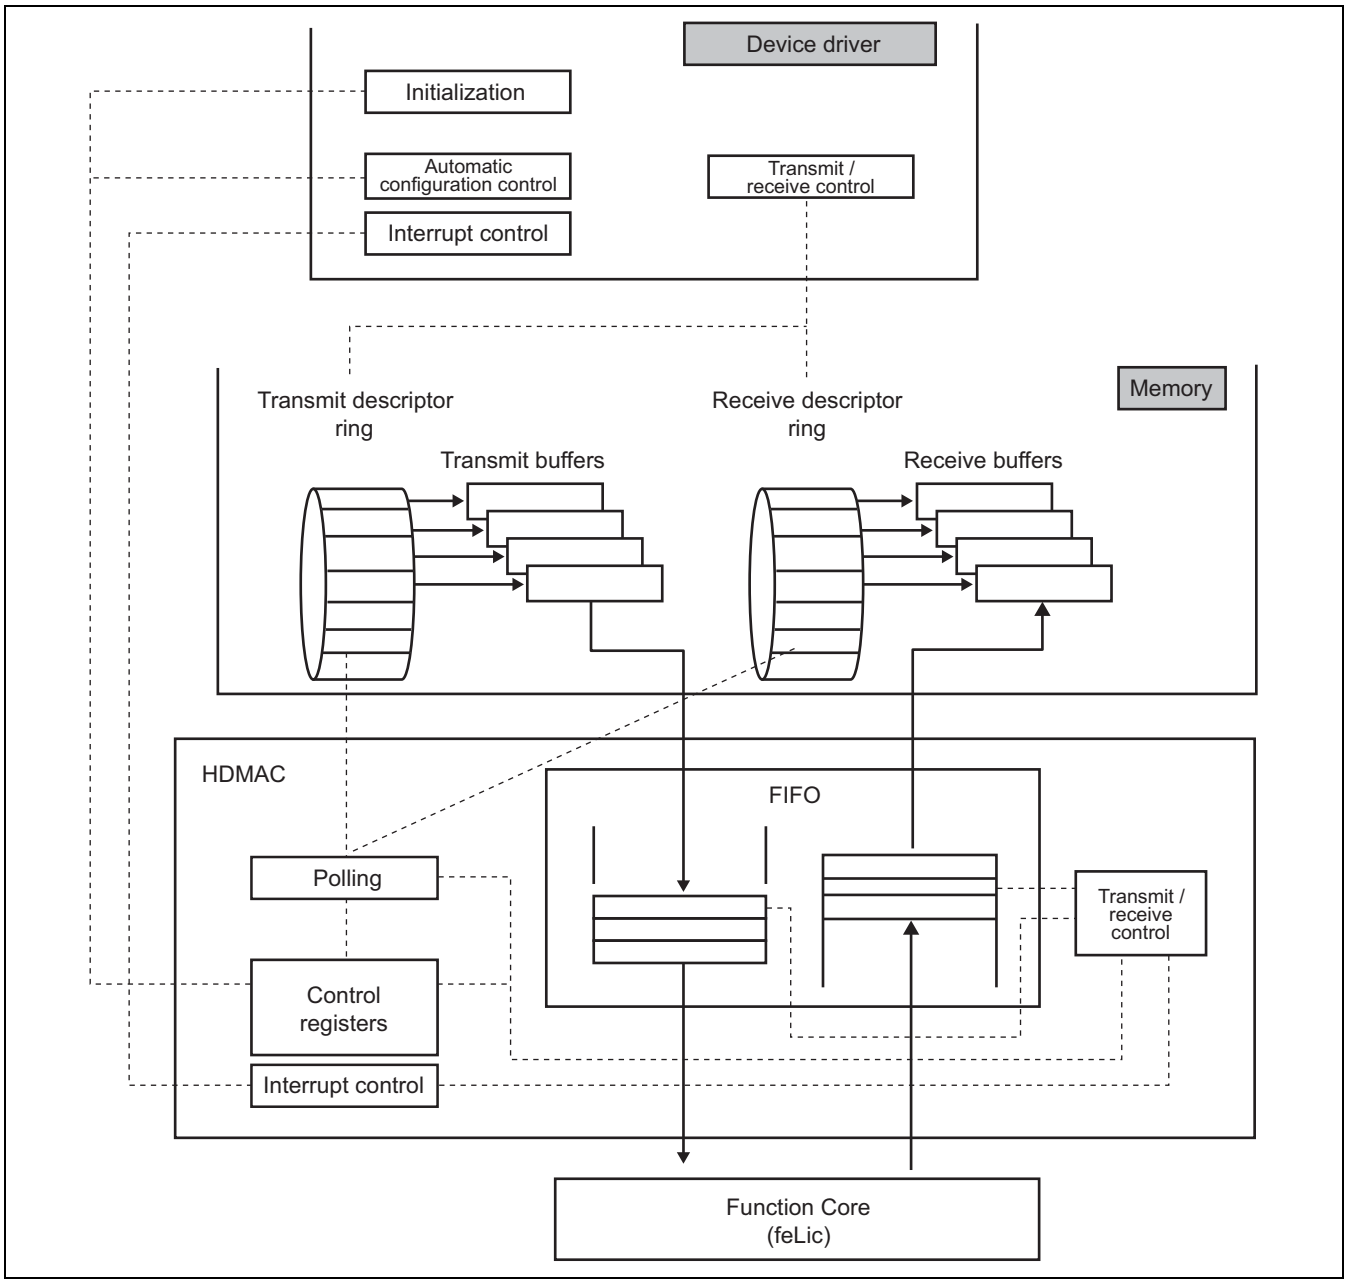

Figure 33.12 Image of Control between Device Driver and HDMAC

The device driver should create the transmit and receive descriptor rings and their corresponding transmit and receive buffers on the memory.

During transmission, this logic core fetches the transmit descriptor to obtain the transmit buffer address and the number of transmit bytes, and transmits data from the transmit buffer to the function core via the transmit FIFO. During reception, this logic core fetches the receive descriptor to obtain the receive buffer address and buffer size, and stores data received from the function core in the receive buffer via the receive FIFO.

(2) Descriptor Rings

There is no restriction on the number of descriptors. It is recommended, however, that multiple descriptors are provided.

This logic core uses the descriptor from the start descriptor to the last descriptor sequentially. If it reaches the last descriptor, it returns to use the start descriptor.

The start descriptor address is specified by the start address setting registers (CXR3 and CXR4). The last descriptor is specified by the descriptor ring end bits (TDL, RDL) = 1 in the descriptor. The descriptor boundary is specified by the descriptor length bits (DL) in the operating mode setting register (CXR0).

There is no restriction on the number of receive descriptors in terms of a ring configuration. Note that if only one receive descriptor is used, a receive descriptor depletion occurs when one frame has been received. (For details, refer to section 33.8.1 (8) (g), Receive Descriptor Depletion.)

For details on the descriptor description format, refer to section 33.8.2, Transmit Descriptors, and section 33.8.3, Receive Descriptors.

(3) Multiple Frames and Multiple Buffers

Multiple frames and multiple buffers enable consecutive frame transmission and reception.

In the receiver, a frame can be divided and stored in multiple buffers separately by specifying the frame in multiple descriptors.

In the transmitter, a frame is specified by a descriptor.

During transmission, after having transmitted data (frame) specified by a transmit descriptor, this logic core fetches the next descriptor. This logic core then determines that there is data (frame) to be transmitted next if the TACT bit in the fetched transmit descriptor is 1 and transmits the data (frame). If the TACT bit in the fetched transmit descriptor is 0, this logic core completes the transmit operation.

Note that bits 29 and 28 in the transmit descriptor TD0 should be set to 11. Otherwise, correct operation cannot be guaranteed.

During reception, after having received a frame, this logic core fetches the next receive descriptor. This logic core determines that the reception is ready if the RACT bit in the fetched receive descriptor is 1 and stores the received frame. If the RACT bit in the fetched receive descriptor is 0, this logic core determines that the receive descriptors have been depleted and completes the receive operation.

If this logic core receives a frame longer than the buffer length specified in the receive descriptor, it stores the frame up to the specified buffer length and then fetches the next receive descriptor. If this logic core further receives a frame longer than the buffer length specified in the fetched receive descriptor, it stores the frame up to the specified buffer length and then fetches the following descriptor. If this logic core receives a frame whose frame length is within the buffer size specified by the fetched receive descriptor, it stores the last byte of the frame and writes back the number of bytes so far stored in the receive buffer to the receive frame length (RFL) in the receive descriptor. The logic core then fetches the next descriptor to prepare for the next frame reception.

Note that correct operation cannot be guaranteed if the receive buffer length is specified as 0 in the receive descriptor.

(4) DMA Operation

(a) Burst Operation

This logic core accesses the descriptors and buffers in longword units via DMA transfer.

During descriptor (16 bytes as standard) fetch, 16-byte DMA transfer is performed per bus acquisition.

During transmit descriptor write back, 4-byte DMA transfer is performed per bus acquisition.

During receive descriptor write back, 8-byte DMA transfer is performed per bus acquisition.

During buffer data transfer, a maximum of 32-byte DMA transfer is performed per bus acquisition.

If the remaining data in a frame to be transferred is 17 to 32 bytes, 32-byte DMA transfer is performed per bus acquisition.

If the remaining data in a frame to be transferred is 9 to 16 bytes, 16-byte DMA transfer is performed per bus acquisition.

If the remaining data in a frame to be transferred is 5 to 8 bytes, 8-byte DMA transfer is performed per bus acquisition.

If the remaining data in a frame to be transferred is 1 to 4 bytes, 4-byte DMA transfer is performed per bus acquisition.

(b) DMA Operation Error Report

If a DMA error is detected during DMA operation, the BER bit in the status register (CXR5) is set to 1 to generate an interrupt. After interrupt, DMA operation should be restarted by a reset (system reset or software reset).

(5) Transmit and Receive Buffers

A transmit buffer address and transmit buffer length to be specified by a transmit descriptor can be set in byte units. However, if 1 to 16 bytes is specified as the transmit buffer length, the transmit buffer address should be aligned on a 32-byte boundary. Note that correct operation cannot be guaranteed if 0 byte is specified as the transfer buffer length.

A receive buffer address to be specified by a receive descriptor should be aligned on a 32-byte boundary to prevent the DMA burst operation from being performed beyond SDRAM boundary.

In addition, if the number of data bytes remaining in a frame to be transferred cannot be divided by DMA burst bytes (32 bytes), the receive buffer length to be specified by the receive descriptor should be specified on a 32-byte boundary since extra data is transmitted.

For example, if the number of last data bytes remaining in a receive frame is 17 bytes, invalid data is written in the 18th to 32nd bytes in the corresponding address of the receive buffer since 32-byte DMA burst transfer is performed.

(6) Endian

Endian conversion can be used for the data arrangement in the transmit and receive buffers according to the DE bit setting in the operating mode setting register (CXR0).

Note that only the endian of the data in the transmit and receive buffers can be changed. Endian of descriptors and registers cannot be changed.

Note: Be sure to set DE bit to 1 before operating the Ethernet MAC controller (Ether).

(7) Transmit Operation

(a) Normal Transmit Operation

This logic core starts the transmit processing when 1 is written to the TRNS bit in the transmit activation register (CXR1).

This logic core fetches a descriptor next to the previous descriptor from the transmit descriptor ring.

If the TACT bit in the fetched transmit descriptor is 1, data in the transmit buffer is read out and written in the transmit FIFO sequentially according to the specified transmit buffer address and the number of bytes.

If the TACT bit in the fetched transmit descriptor is 0, the TRNS bit in the transmit activation register (CXR1) is cleared to 0 and transmit processing is completed without any operation.

When data of the buffer length indicated by the descriptor has been transmitted to the function core via the transmit FIFO (normally completed or aborted), the transmit descriptor is written back to, and the next descriptor is fetched.

While the TACT bit in the fetched transmit descriptor is 1, the transmit descriptor fetch and DMA transfer are performed continuously.

If the TACT bit in the fetched transmit descriptor is 0, the FTC bit in the status register (CXR5) is set to 1 to indicate the completion of transmission thus requesting an interrupt to the CPU, and simultaneously the TRNS bit in the transmit activation register (CXR1) is cleared to 0 to stop transmit processing.

If data in the transmit FIFO exceeds the threshold (changes according to the register setting), if data of a frame has been stored, or if the transmit FIFO becomes full, the function core is activated and data in the transmit FIFO is transmitted to the function core synchronously with the RDY signal in the function core.

When a transmit completion signal or abort signal is input from the function core, the above transmit operation is ended.

(b) Continuous Frame Transmit Operation

Multiple frames can be specified in a transmit descriptor.

This logic core clears the TACT bit in the transmit descriptor to 0 when data transmission indicated in the transmit descriptor has been completed, and fetches the next transmit descriptor. While the TACT bit in the fetched descriptor is 1, the frame transmission is performed continuously. When the TACT bit in the transmit descriptor is 0, the FTC bit in the status register (CXR5) is set to 1 to indicate the transmission completion thus requesting an interrupt to the CPU, and the TRNS bit in the transmit activation register (CXR1) is cleared to 0 to stop transmit processing.

Generation of a transmit completion interrupt (the FTC bit in CXR1 is set to 1) informs the CPU that all the specified frames have been transmitted.

(c) Transmit Abort

If this logic core receives an abort signal (ATABT) from the function core during frame transmission, it aborts data transmission of the corresponding frame from transmit FIFO to the function core.

When the transmission is aborted, this logic core clears the TACT bit in the transmit descriptor to 0, sets bit 8 in the transmit frame status (TFS) to 1.

The following operations are the same as (1) Normal Transmit Operation or (2) Continuous Frame Transmit Operation described above.

When detected the TACT bit in the fetched transmit descriptor is 0, the FTC bit in the status register (CXR5) is set to 1 to indicate the transmission completion, and TABT bit is also set to 1 to indicate the transmission abort to requesting an interrupt to the CPU.

(d) Transmit FIFO Underflow

This logic core does not transmit data to the function core until data in the transmit FIFO exceeds the specified threshold (changes according to the register setting), data of a frame is stored in the transmit FIFO, or the transmit FIFO becomes full to prevent the transmit FIFO from underflow.

An underflow will occur if the transmit FIFO becomes empty (there is no data to be transmitted) because the bus mastership cannot be obtained.

In this case, the TFE bit in the status register (CXR5) is set to 1 to indicate transmit FIFO underflow and an interrupt is requested to the CPU.

The frame where an underflow occurred is transmitted to the function core in the same way as the normal frame. After the frame transmission, the TACT bit in the transmit descriptor is cleared to 0 and transmit frame status (TFS) is set to 1. The following operations are the same as (1) Normal Transmit Operation or (2) Continuous Frame Transmit Operation described above.

(e) Transmit Frame Retry

If this logic core receives an ATRTRY signal from the function core after having transmitted the last byte of a frame to the function core, this logic core fetches the start descriptor of the current frame again, and re-transmits the data of the current frame from the start to last bytes to the transmit FIFO.

(8) Receive Operation

(a) Normal Receive Operation

This logic core starts receive processing when 1 is written to the R bit in the receive activation register (CXR2).

This logic core fetches the receive descriptor (Nth receive descriptor) next to the previous receive descriptor ((N – 1)th receive descriptor) from the receive descriptor ring, and enters the receive wait state.

In the receive wait state, if the receive FIFO contains data of 32 bytes or more or the last byte, data is transferred from the receive FIFO to the receive buffer.

When the receive buffer specified by the receive descriptor becomes full, this logic core writes 0 to the RACT bit in the receive descriptor and fetches the (N + 1)th receive descriptor. If the RACT bit in the (N + 1)th receive descriptor is 1, this logic core enters the receive wait state again.

If the last byte of a frame has been transferred, this logic core writes 0 and 1 in the RACT bit and the RFP[0] bit in the receive descriptor, respectively, sets the FRC bit in the status register (CXR5) to 1 to indicate the completion of frame reception, requests an interrupt to the CPU, and finally fetches the (N + 2)th receive descriptor.

If the RACT bit in the (N + 2)th receive descriptor is 1, this logic core enters the receive wait state. Contrarily, if the RACT bit in the (N + 2)th receive descriptor is 0, a receive descriptor depletion occurs. (For details, refer to section 33.8.1 (8) (g), Receive Descriptor Depletion.)

(b) Continuous Frame Receive Operation

As described in (1) Normal Receive Operation, when a frame has been received and the last byte of the frame has been transferred, this logic core writes 0 and 1 in the RACT bit and RFP[0] bit in the Nth receive descriptor, respectively, sets the FRC bit in the status register (CXR5) to 1 to indicate the completion of frame reception, generates an interrupt to the CPU, fetches the (N + 1)th receive descriptor, and enters the receive wait state.

When the last byte in the (N + 1)th receive descriptor has been transferred, this logic core writes 0 and 1 in the RACT bit and RFP[0] bit in the (N + 1)th receive descriptor, respectively, sets the FRC bit in the status register (CXR5) to 1 to indicate the completion of frame reception, generates an interrupt to the CPU, fetches the (N + 2)th receive descriptor, and enters the receive wait state.

This logic core then receives frames continuously until the RACT bit in the fetched descriptor is cleared to 0 (a receive descriptor depletion occurs).

(c) Receive Operation of Multiple Frames and Multiple Buffers

If the byte count of the received Mth frame is greater than the buffer length specified by the Nth receive descriptor, this logic core transfers data of the specified receive buffer length and then writes 0s in the RACT bit and RFP[0] bit in the Nth receive descriptor and fetches the (N + 1)th receive descriptor.

With the (N + 1)th receive descriptor, this logic core performs the data transfer of the same frame (Mth frame). If the byte count of the received Mth frame is greater than the buffer length specified by the (N + 1)th receive descriptor, this logic core transfers data of the specified receive buffer length and writes 0s in the RACT bit and RFP[0] bit in the (N + 1)th receive descriptor and fetches the (N + 2)th receive descriptor as described above. Contrarily, if the byte count of the received Mth frame is smaller than the buffer length specified by the (N + 1)th receive descriptor, this logic core, after having transferred the last byte, writes 0 and 1 in the RACT bit and RFP[0] bit in the (N + 1)th receive descriptor, sets the FRC bit in the status register (CRX5) to 1 to indicate the completion of frame reception, generates an interrupt to the CPU, fetches the (N + 2)th receive descriptor, and enters the receive wait state, as described in (1) Normal Receive Operation.

(d) Receive Abort

If this logic core receives a receive abort (ARABT) signal from the function core during frame reception, it aborts reception of the corresponding frame data from the function core.

This logic core transfers data stored in the receive FIFO before receive abortion to the receive buffer. When the last byte has been transferred, this logic core clears the RACT bit in the receive descriptor to 0, sets bit 8 of receive frame status in the receive descriptor to 1, sets the FRC and RABT bits in the status register (CRX5) to 1s to indicate the frame transmission completion and receive abort detection, respectively, and finally generates an interrupt to the CPU.

If this logic core receives an ARABT signal from the function core while the number of data bytes of the stored frame in the receive FIFO is less than 16 bytes, this logic core deletes the corresponding frame.

(e) Receive FIFO Overflow

If the receive FIFO becomes full because the bus mastership cannot be obtained, an overflow error occurs because the next data cannot be stored in the receive FIFO.

If an overflow error occurs, the receive FIFO terminates the data reception and sets the RFE bit in the status register (CXR5) to 1 to indicate the receive FIFO overflow, and generates an interrupt to the CPU. When the transfer of the byte immediately before the overflow has been completed, this logic core writes 0 and 1 to the RACT bit and bit 9 of receive frame status (RFS) in the receive descriptor, respectively, sets the FRC and RFE bits in the status register (CXR5) to 1s to indicate the frame reception completion and receive FIFO overflow, respectively, and finally generates an interrupt to the CPU.

While the receive FIFO is full, the next frame is received but discarded. Simultaneously, the discarded frame counter register (CXR8) is incremented.

If the receive FIFO becomes not full after data has been transferred from the receive FIFO to the receive buffer, this logic core restarts the reception from the start byte of the next receive frame.

The number of frames that can be simultaneously stored in the receive FIFO is limited to 16 frames due to the frame management restriction. Accordingly, this logic core cannot receive a frame if 16 frames have been stored in the receive FIFO. If this logic core receives the start data of the 17th frame, it sets the RFRMER bit in the status register (CXR5) to 1 to indicate the receive frame count overflow, and generates an interrupt to the CPU.

This logic core receives the next frame but discards it, and simultaneously increments the discarded frame counter register (CXR8).

If a space of 1 frame or more is produced in the receive FIFO after data has been transferred from the receive FIFO to the receive buffer, this logic core restarts the reception from the start byte of the next receive frame.

(f) Flow Control Support

This function core provides an ARBSY signal to inform the function core of the receive FIFO status. It can output the ARBSY signal based on the data amount stored in the receive FIFO according to the setting of the receive FIFO busy transmit threshold setting register (CXR16).

Accordingly, the flow can be controlled by sending "BUSY" to the function core before the receive FIFO overflows.

The BUSY status can be cancelled when the data byte count or the frame count in the receive FIFO become (the byte count value causing a transition to the BUSY state − 32 bytes) or smaller and (the frame count value causing a transition to the BUSY state − 1 frame) or smaller, respectively.

(g) Receive Descriptor Depletion

When this logic core has transferred data of the Mth frame to the receive buffer specified by the Nth receive descriptor, it fetches the (N + 1)th receive descriptor to prepare for the reception of the (M + 1)th frame.

If the RACT bit of the fetched descriptor ((N + 1)th descriptor) is 0, this logic core regards it as receive descriptor depletion, sets the RDE bit in the status register (CXR5) to 1 to indicate the receive descriptor depletion, and generates an interrupt to the CPU.

Simultaneously, this logic core clears the R bit in the receive activation register (CXR2) to 0 and terminates the receive processing. In this case, data transfer from the function core to the receive FIFO continues.

In this situation, the CPU should clear the interrupt source and reset the receive descriptor correctly.

If the valid receive descriptor is set before a receive FIFO overflow occurs, a frame reception can be continued without data loss.

33.8.2 Transmit Descriptors

Figure 33.13 shows a transmit descriptor format.

If 1 to 16 bytes is specified as the transmit buffer length, the transmit buffer address should be aligned on a 32-byte boundary. Note that correct operation cannot be guaranteed if 0 byte is specified as the transfer buffer length.

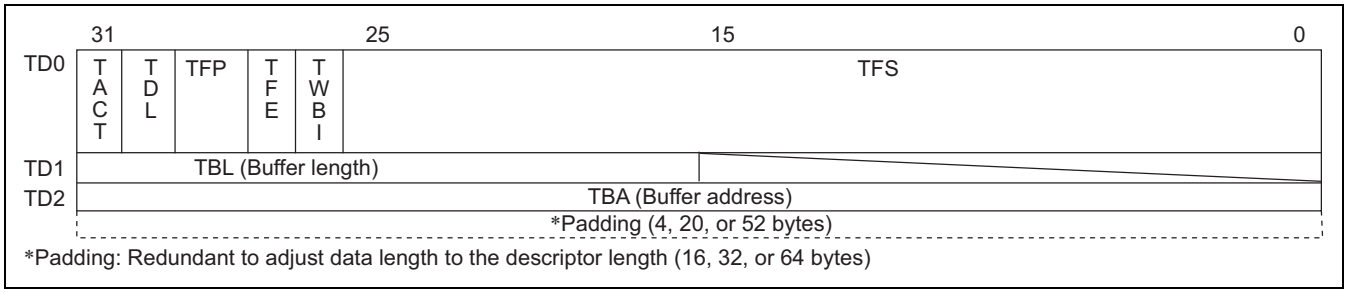

Figure 33.13 Transmit Descriptor Format

(1) Transmit Descriptor 0 (TD0)

Table 33.7 shows a definition of transmit descriptor 0. (A bit to be written back to is underlined.)

Table 33.7 Definition of Transmit Descriptor 0

Bit	Bit Name	Initial Value	R/W	Definition
31	TACT	Undefined	R/W	Descriptor Valid Indicates that the corresponding descriptor is valid. This bit is set to 1 by a driver, and reset (cleared to 0) by this logic core when a frame transmission has been completed or a frame transmission has been aborted for some reason.
30	TDL	Undefined	R/W	Descriptor Ring End Set to 1 to indicate that the corresponding descriptor is an end of the transmit descriptor ring.
29, 28	TFP	Undefined	R/W	Position in a Frame 11: Indicate that the information in this descriptor includes one whole frame. This field should be set to 11.
27	TFE	Undefined	R/W	Transmit Frame Error Set to 1 to indicate that an error occurs in TFS.
26	TWBI	Undefined	R/W	Write-Back Completion Interrupt Request (Enabled according to CXR18 settings) 0: nop 1: Requests an interrupt after a write-back to this descriptor has been completed.
25 to 0	TFS	Undefined	R/W	Transmit Frame Status Bit 8: Set to 1 to indicate that the underflow occurs shown as an abort signal is set to 1 during transmission of the frame, (TFE set source). Bits 7 to 0: Set to 1 to indicate that a corresponding bit among TINT8 to TINT1 is set to 1.

(2) Transmit Descriptor 1 (TD1)

Table 33.8 shows a definition of transmit descriptor 1.

Table 33.8 Definition of Transmit Descriptor 1

Bit	Bit Name	Initial Value	R/W	Definition
31 to 16	TBL	Undefined	R/W	Buffer length: Indicates the valid byte count in the target transmit buffer.
15 to 0	—	Undefined	R/W	Reserved

(3) Transmit Descriptor 2 (TD2)

Table 33.9 shows a definition of transmit descriptor 2.

Table 33.9 Definition of Transmit Descriptor 2

Bit	Bit Name	Initial Value	R/W	Definition
31 to 0	TBA	Undefined	R/W	Buffer address: Indicates the start address of the transmit buffer.

33.8.3 Receive Descriptors

Figure 33.14 shows a receive descriptor format.

A receive buffer address specified by a receive descriptor should be aligned on a 32-byte boundary. Note that correct operation cannot be guaranteed if 0 byte is specified as the receive buffer length (RBL).

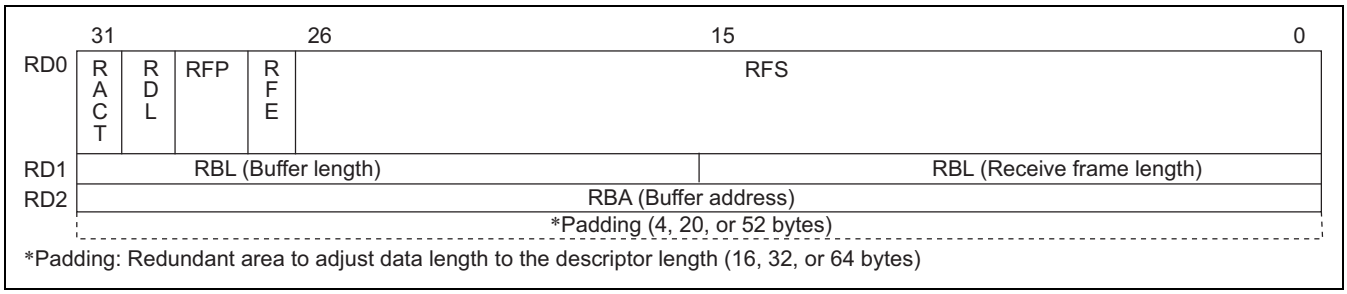

Figure 33.14 Receive Descriptor Format

(1) Receive Descriptor 0 (RD0)

Table 33.10 shows a definition of receive descriptor 0. (A bit to be written back to is underlined.)

Table 33.10 Definition of Receive Descriptor 0

Bit	Bit Name	Initial Value	R/W	Definition
31	RACT	Undefined	R/W	Descriptor Valid Indicates that the corresponding descriptor is valid. This bit is set to 1 by a driver, and reset (cleared to 0) by this logic core when a frame transmission has been completed or the receive buffers have become full.
30	RDL	Undefined	R/W	Descriptor Ring End Set to 1 to indicate that the corresponding descriptor is an end of the receive descriptor ring.
29, 28	RFP	Undefined	R/W	Position in a Frame 10: Indicate that the information in this descriptor includes the start of a frame. 11: Indicate that the information in this descriptor includes one whole frame. 01: indicate that the information in this descriptor includes the end of a frame. 00: Indicate that the information in this descriptor is other than above.
27	RFE	Undefined	R/W	Receive Frame Error Set to 1 to indicate that an error occurs in RFS.
26 to 0	RFS	Undefined	R/W	Receive Frame Status Bit 9: Set to 1 to indicate that an aborted frame is written back due to a receive FIFO overflow (FRE setting source). Bit 8: Set to 1 to indicate that an abort signal is set to 1 during frame reception (RFE set source). Bits 7 to 0: Set to 1 to indicate that a corresponding bit among RINT8 to TINT1 is set to 1 (RFE setting sources specified by CXR7).

(2) Receive Descriptor 1 (RD1)

Table 33.11 shows a definition of receive descriptor 1. (A bit to be written back to is underlined.)

Table 33.11 Definition of Receive Descriptor 1

Bit	Bit Name	Initial Value	R/W	Definition
31 to 16	RBL	Undefined	R/W	Buffer length Indicate the byte count in the target receive buffer. The buffer length should be specified by 32 bytes x n.
15 to 0	RFL	Undefined	R/W	Receive Frame Length Indicate the receive frame length (bytes) stores in the receive buffer. This receive frame length does not include the number of bytes for padding specified in the CXRS5. This receive frame length is written back in the receive descriptor that includes the last of a frame.

(3) Receive Descriptor 1 (RD2)

Table 33.12 shows a definition of receive descriptor 2.

Table 33.12 Definition of Receive Descriptor 2

Bit	Bit Name	Initial Value	R/W	Definition
31 to 0	RBA	Undefined	R/W	Buffer Address These bits indicate the start address of a receive buffer. The buffer address should be aligned on a 32-byte boundary.

33.8.4 Error Detection and Report

The error sources are classified into two types: those detected by the HDMAC and those detected and reported by the feLic.

Each error is described below. If an error is detected, the detected error is indicated in the status register (CXR5) and an interrupt signal is output.

(1) Error Sources Detected by the HDMAC

(a) Descriptor Depletion

If no descriptor whose descriptor valid bit is set can be detected during frame reception, a receive descriptor depletion error occurs and the R bit in the receive activation register (CXR2) is reset to complete the receive processing.

(b) External FIFO Underflow/Overflow

If a transmit FIFO becomes empty during frame transmission, an underflow error occurs because there is no data to be transmitted.

If a receive FIFO becomes full during frame reception, an overflow error occurs because the next receive data cannot be stored in the receive FIFO.

If an underflow error in a transmit FIFO or an overflow error in a receive FIFO is detected, it is indicated in the status register (CXR5).

(2) Error Sources Detected and Reported by the Function Core (feLic)

(a) Transmit Interrupt

Interrupt sources detected by the function core (feLic) during frame transmission are reported to the transmit descriptor of the corresponding frame and status register (CXR5) as TINT1 to TINT8, or transmit abort detect (TABT).

(b) Receive Interrupt

Interrupt sources detected by the function core (feLic) during frame reception are reported to the receive descriptor of the corresponding frame and status register (CXR5) as RINT1 to RINT8, and receive abort detect (RABT).

(c) MPORT Interrupt (MINT)

If an error is detected other than during transmission or reception, it is reported as an MPORT interrupt.

For details on TINT, RINT, and MINT bits, see the Function Core Function Specifications.

(3) Error Log Information

This logic core provides the following log collection registers.

1. Discarded frame counter register (CXR8)
2. Transmit FIFO underflow counter register (CXR13)
3. Receive FIFO overflow counter register (CXR14)

33.8.5 Firmware/Software Interface

(1) Interrupts

Interrupts sources in this logic module are as follows.

1. RINT1 to RINT8
2. TINT1 to TINT8
3. Receive FIFO overflow
4. Receive descriptor depletion
5. Frame receive completion
6. Transmit FIFO underflow
7. Transmit descriptor depletion (not used)
8. Frame transmit completion
9. M port interrupt
10. DMA error
11. Receive frame count overflow
12. Receive abort detection
13. Transmit abort detection
14. External EXIN signal assertion detection (not used)
15. Transmit descriptor write-back

The above interrupt sources are indicated in the status register (CXR5). An interrupt source (other than M port interrupt signal (MINT) bit) can be reset by writing 1 to the corresponding bit in the CXR5 register. An M port interrupt signal (MINT) can be reset by resetting the corresponding source in the function core. The above interrupt sources can be separately masked by setting the interrupt mask register (CXR6).

33.9 feLic Function Specifications

33.9.1 Configuration

Figure 33.15 shows a block diagram of feLic.

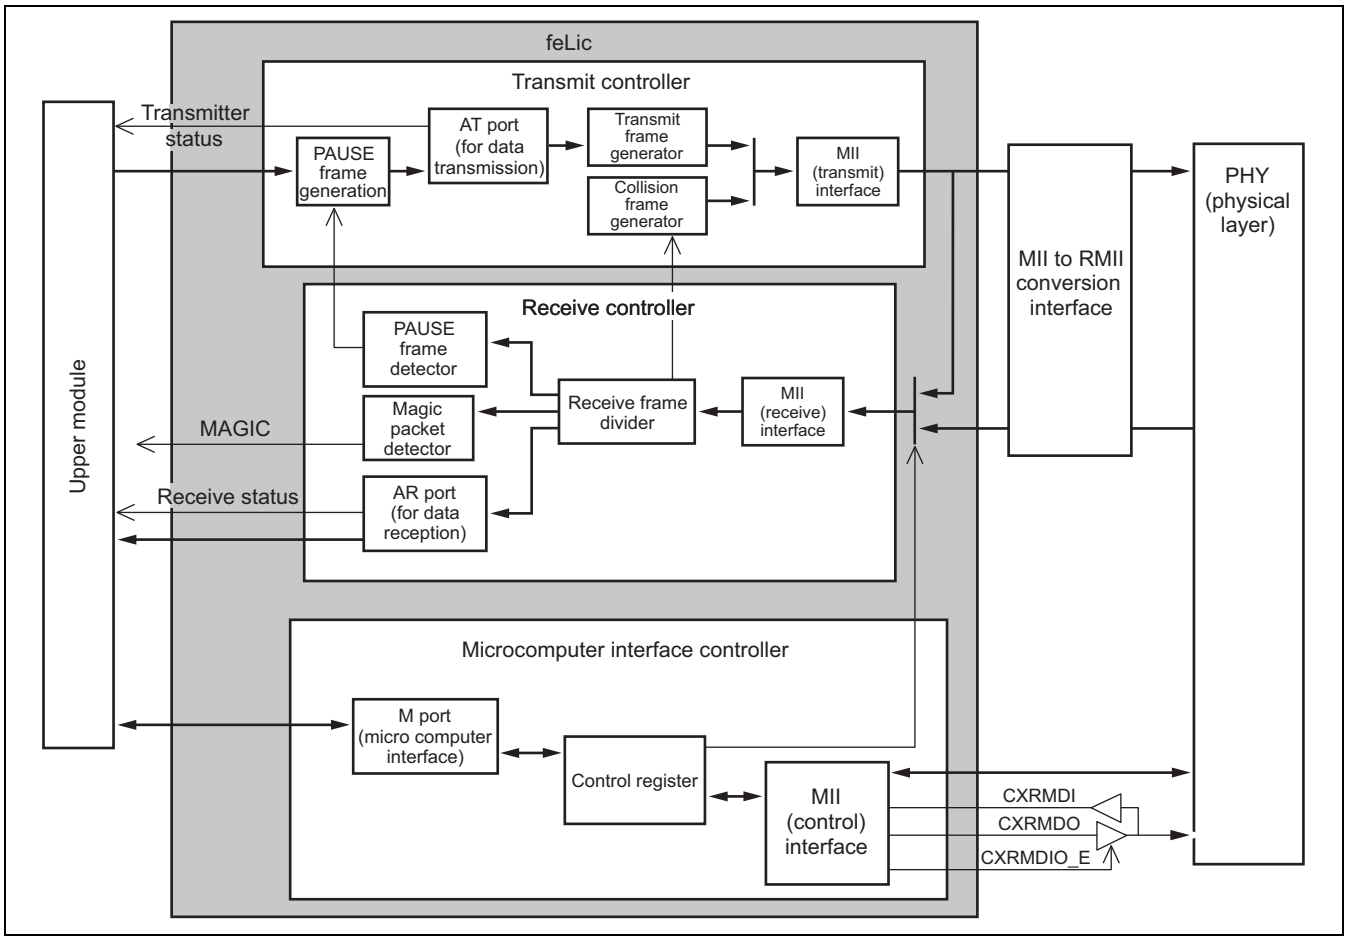

Figure 33.15 feLic Block Diagram

33.9.2 feLic Function

(1) Transmit Controller

The transmit controller assembles data received from AT port into the IEEE802.3 format frames, and transmits them via the MII interface.

The main functions of the transmit controller are listed below.

1. Assembles data received from the AT port into the IEEE802.3 format frames and transmits them.
2. Performs CRC calculation and adds it to the frame.
3. Retransmits frames (up to 15 times) when a collision occurs.
4. Provides the MII interface function conforming to the IEEE802.3u.
5. Performs serial and parallel conversion according to the PHY chip speed.
6. Provides transmit frame data padding function.
7. Generates a PAUSE frame.

(2) Receive Controller

Upon receiving a frame via the MII interface, the receive controller checks the frame address to see if the address matches the self-node; it also checks CRC and the frame length of the data and transfers the data to the AR port.

The main functions of the receive controller are listed below.

1. Checks the format of the received frame header.
2. Checks the CRC and frame length of the received frame data.
3. Transfers frames addressed to itself, multicast frames, and broadcast frames to the AR port.
4. Provides the MII interface function conforming to the IEEE802.3u.
5. Performs serial and parallel conversion according to the PHY chip speed.
6. Monitors a magic packet.
7. Analyzes a PAUSE frame.

(3) Microcomputer Interface Controller

The microcomputer interface controller incorporates a function to interface to the upper microprocessor. The data width of the M port is 32 bits. The M port operates synchronously with the external clock. The upper microprocessor controls the registers in this microcomputer interface controller block and the registers in PHY via the MII interface.

The main functions of the microcomputer interface controller are listed below.

1. Controls the operation of transmitter and receiver.
2. Accesses the PHY registers via the serial bus.

(4) Magic Packet Monitor Function

The receive controller monitors the magic packet and report the magic packet detection to an external device in magic packet monitor mode. This function becomes effective by the MPM bit in the CXR20 register. When the magic packet is detected, "ETH_MAGIC" signal that is an output is asserted and the CXR21 register is updated. Their detecting functions are explained as follows.

(a) Assertion by the ETH_MAGIC signal

ETH_MAGIC signal that is an output signal of the feLic is asserted synchronizing with the rising edge of the received clock from PHY. Detection of the magic packet can be informed to external circuits by using this signal. The ETH_MAGIC signal is negated by the hardware reset and the software reset of the HDMAC/feLic using CXR0 register.

(b) Assertion by the CXR21 register

Updating CXR21 can assert as software interruption. The detecting information is cleared by writing a 1 to the corresponding bit. Note that if a magic packet is received again, CXR21 register is not updated while the ETH_MAGIC signal is asserting. Set the feLic again after clearing by the procedure described (1).

(5) Transmit and Receive Status Statistical Function

The interrupt source signals (TINT/RINT) to be output to the upper modules can be counted and referenced as statistical information by accessing a register via the M port.

The interrupt source signal counting starts after reset (includes a soft reset by CXR0 register) and the count value can be cleared only by a write access.

(6) Flow Control Conforming to IEEE802.3

As the flow control during full-duplex operation, the flow control conforming to IEEE802.3x is supported. Transmission of a PAUSE frame used in flow control is performed in the following methods. These methods can be used by mutually combining.

(a) Automatic PAUSE Frame Transmission

A PAUSE frame is transmitted automatically by asserting the ARBSY signal. Note that as the Timer value included in the PAUSE frame, the value set in the automatic PAUSE parameter setting register (see CXR71) is used. If the ARBSY signal is not negated when the time indicated by the Timer value has passed after transmitting a PAUSE frame, a PAUSE frame is transmitted again. The number of PAUSE frame re-transmissions (upper limit) can be specified from 1 to 65535 times by setting the PAUSE frame retransmit count setting register (CXR81). If the number of PAUSE frame re-transmissions reaches the upper limit, the following PAUSE frame re-transmissions will not be performed.

Transmission can be restarted when ARBSY signal is negated once and then asserted again thus resetting the PAUSE frame re-transmission counter (CXR82). In addition, it is possible not to set the upper limit of the re-transmissions (unlimited).

(b) Manual PAUSE Frame Transmission

This method can send the PAUSE frame by calling of software. Set the Timer value to the CXR72 register to sending the PAUSE frame. It is sent just one time (one frame) in this method.

(c) PAUSE Timer Value

For the PAUSE frame whose Timer value is 0, it is possible to enable or disable the PAUSE frame control.

- During transmission
  When control of a PAUSE frame whose Timer value is 0 is enabled, a PAUSE frame with Timer value 0 is transmitted if the ARBSY signal is negated before the time indicated by the Timer value has passed.
  When control of a PAUSE frame whose Timer value is 0 is disabled, the next frame will not be transmitted until the time indicated by the Timer value has passed.
- During reception
  When control of a PAUSE frame whose Timer value is 0 is enabled, a PAUSE frame is set in the receive wait counter even if the time indicated by Timer value is 0. (The receive wait state is cancelled.)
  When control of a PAUSE frame whose Timer value is 0 is disabled, the PAUSE frame is discarded if the time indicated by Timer value is 0.

(d) PAUSE Frame Reception

When a PAUSE frame is received, this logic function suspends transmission of the next frame until the time indicated by the Timer value has passed. However, transmission of the frame being transmitted continues. A number of the PAUSE frame receiving is counted to CXR80.

(7) Back-Pressure Flow Control

As the flow control during half-duplex operation, the back-pressure flow control is supported. This method generates a pseudo collision (transmits a collision frame) to stop the frame reception if the remaining space in the FIFO is not sufficient when the frame is received. This method does not refer to the DA.

33.9.3 Detailed Description of Transmit and Receive Controllers

(1) Transmit Controller

The transmit controller assembles the transmit data from the AT port into the frames based on the appropriate format and transmits them via the MII interface. Here, an error may occur according to the status of the communication lines. If an error of TINT1 to RINT8 occurs, the transmission is aborted and the error source is reported to the upper block using the abort signal (ARABT). If the transmission is completed normally, it is reported via the transmit completion signal (ATCOMP).

The conditions of generating each error source and operation are described below.

- TINT1: Transmit timeout
  When a collision occurs (the COL signal assertion) during frame transmission, the transmission is retried after the back-off time has passed. A transmit timeout is generated if a collision occurs again during the 15th transmission retry.
- TINT2: Collision detection during frame transmission
  Generated if a delay collision described in the IEEE802.3 standard occurs.
  Description in the standard: It is regarded as a delay collision if a collision occurs after the collision window at 512-bit time from the transmission start.
- TINT3: Carrier loss during frame transmission
  Generated when a carrier is lost (the CRS signal is negated) during frame transmission.
- TINT4: Carrier not detected
  Generated when a carrier is not detected (the CRS signal is not asserted) during preamble field transmission.
- TINT5: Not assigned
- TINT6: Not assigned
- TINT7: Not assigned
- TINT8: Not assigned

If any transmit error described above occurs, the feLic enters the wait state for the next frame transmission request and starts the next frame transmission when the next frame transmission is requested.

(2) Receive Controller

The receive controller transfers a frame received via the MII interface to the AR port. Here, an error may occur according to the status of the communication lines. If an error of RINT1 to RINT4 occurs, the reception is aborted and the error source is reported to the upper block using the abort signal (ARABT). RINT5 indicates that a fractional number bit error has occurred. Note, however, that a frame with an RINT5 error but with no CRC error can be received normally. A frame with RINT8 can also be received normally. RINT8 is an error source allowing normal frame reception and is reported by using the receive completion signal (ARCOMP) when the frame destination address is a multicast address.

The conditions of generating each error source and operation are described below.

- RINT1: CRC error
  Generated when an error is detected in the FCS field in the receive frame.
- RINT2: Frame receive error
  Reported when the RX_ER signal in the MII interface is asserted during frame reception. For details on the RX_ER signal assertion, see the Data Book of the PHY to be connected.
- RINT3: Frame length error
  Reported when the receive frame length is less than 64 bytes.
- RINT4: Frame length error
  Reported when the receive frame length exceeds the value specified in the CXR2A register. An excess of data field over the specified frame length is discarded in the feLic and will not be transferred to the upper block.

- RINT5: Fractional number bit error

  Reported when the received frame length is not the multiple of an octet. In this case, the last 1 to 4 octets in the data field will not be transferred to the upper block.
- RINT6: Not assigned
- RINT7: Not assigned
- RINT8: Multicast frame reception

  Reported when the frame destination address is a multicast address. This error source is reported with a receive completion signal only when other error source is not generated.

If any receive error described above occurs, the feLic enters the wait state for the next frame reception and starts the next frame reception when the next frame is received.

33.10 MII-RMII Interface Conversion

This LSI supports an RMII interface. The RMII signals are generated by converting the MII signals in the MII-RMII conversion circuit.

(1) Clock

ETH_REFCLK (50 MHz) from the RMII interface is divided and ET_TX-CLK/ET_RX-CLK (25 MHz or 2.5 MHz) is output.

(2) Reception

Waveforms received from the RMII interface are converted to MII waveforms and output (10 Mbps or 100 Mbps). Illegal carrier detection signal received from the RMII interface is converted to MII signal and output. ETH_RX_ER signal received from the RMII interface is converted to MII interface signal and output.

Note: Illegal carrier detection is not generated from preamble detection to reception completion.

(3) Transmission

Transmit waveforms from the MII interface is converted to the RMII interface waveforms and output (10 Mbps or 100 Mbps). The collision signal, ET_COL, is generated by AND operation of the ET_CRS and ET_TX-EN signals.

(4) Full-Duplex/Half-Duplex Selection

In full-duplex transfer mode, the assertion of the COL is suppressed. Figure 33.16 shows a schematic of the conversion circuit.

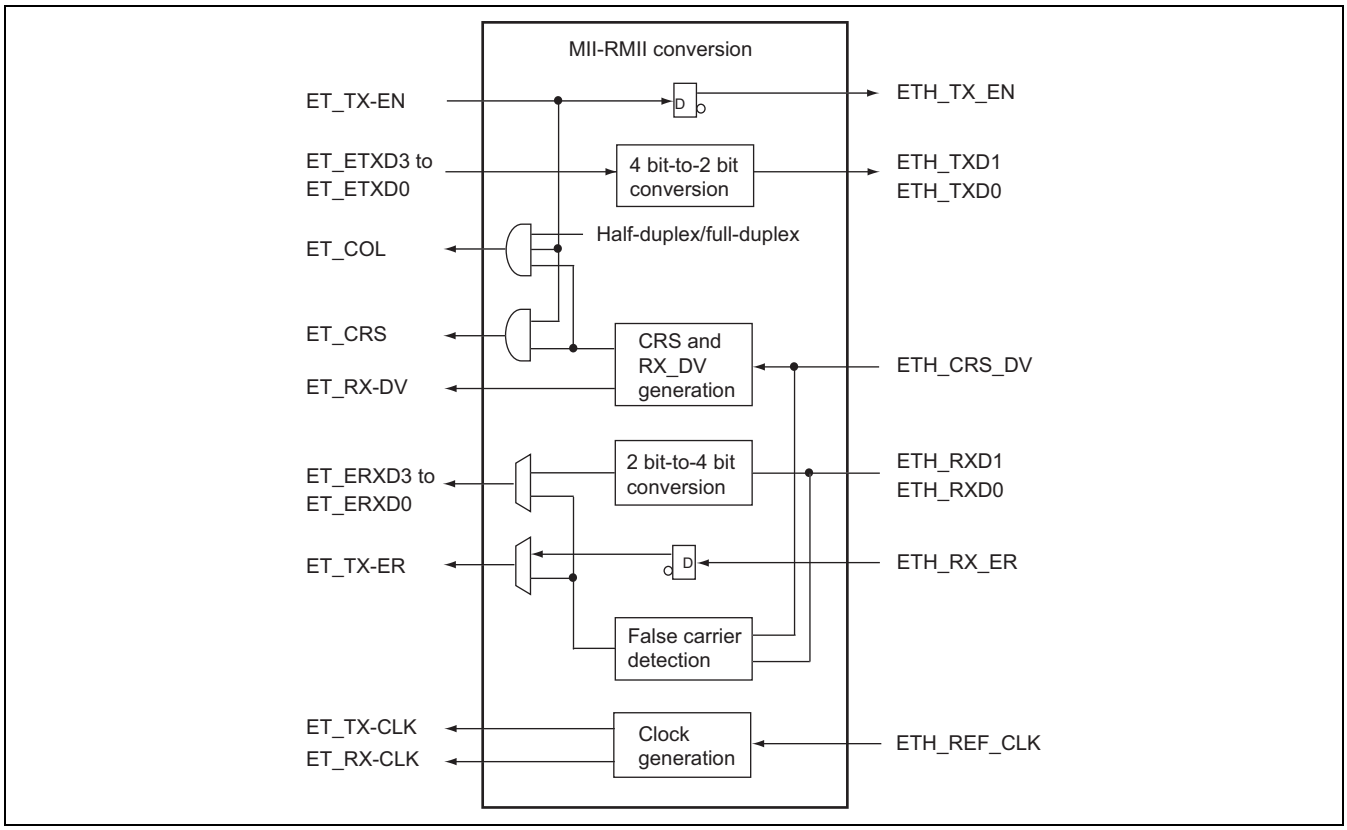

Figure 33.16 MII-RMII Conversion Circuit

33A. EthernetAVB

33A.1 Overview

The EthernetAVB includes an Ethernet controller (E-MAC) that conforms to the definition of the MAC (Media Access Control) layer for Ethernet in the IEEE 802.3 standard.

When connected with a physical-layer LSI chip (PHY-LSI) that complies with the standard, the E-MAC is able to transmit and receive Ethernet (IEEE 802.3) frames. The E-MAC has a single MAC layer interface.

The EthernetAVB has a dedicated direct memory access controller (AVB-DMAC) for transferring transmitted Ethernet frames to and received Ethernet frames from respective storage areas in the User RAM(URAM) at high speed.

The AVB-DMAC is compliant with the following three standards formulated for IEEE 802.1BA: the IEEE 802.1AS timing and synchronization protocol, the IEEE 802.1Qav real-time transfer, and the IEEE 802.1Qat stream reservation protocol.

In this section, URAM refers to the local RAM and external memory.

Descriptors are recommended to be located at addresses H'00 EE0E 8000 to H'00 EE0E BFFF.

33A.1.1 Features

Table 33A.1 lists the specifications of the EthernetAVB module.

Table 33A.1 Specifications (Functions)

Item	Description
Protocol	Flow control conforming with the IEEE 802.3x standard
Data transmission and reception	Transmission and reception of Ethernet (IEEE 802.3) frames
Transfer speed	Supports transfer at 100 and 1000 Mbps
Mode	Full-duplex mode
Interface	Supports the IEEE 802.3 standard MII (Media Independent Interface) and GMII (Gigabit Media Independent Interface)
Summary of the EthernetAVB function	An intelligent frame separation DMAC (AVB-DMAC) conforming with the following standards stipulated for IEEE 802.1BA: IEEE 802.1AS (time synchronization protocol) IEEE 802.1Qav (real-time transfer) IEEE 1722 (AVTP presentation timestamp) IEEE 802.1Qat is supported by software. Descriptor management system Identification and sorting of frame data, and extraction and gathering of valid data Controllable interrupt frequency (reducing the load on the CPU)
Magic Packet™	Detection of Magic Packets™* and output of a detected signal

Note: * Magic Packet™ is a trademark of Advanced Micro Devices, Inc.

33A.2 Register Description

33A.2.1 AVB-DMAC Mode Register (CCC)

The CCC register specifies the operating mode of the AVB-DMAC.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	FCE	LBME	—	—	—	—	—	—	CSEL[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	DTSR	GAC	—	—	—	—	—	OPC[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
25	FCE	0	R/W	Flow Control Enable This bit enables the flow control support of E-MAC. When flow control is enabled, the E-MAC gets informed about the Rx-FIFO level (Rx-FIFO fill level reached RCR.RFCL). 0: Flow control disabled 1: Flow control enabled
24	LBME	0	R/W	Loopback Mode Enable This bit enables loopback mode. In loopback mode, the transmission lines are internally connected to the reception lines. When loopback mode is to be used, the Ethernet transmission clock must be supplied to the RGMII interface. A received clock signal is not required. Writing to this bit is only possible when the current operating mode is configuration mode. 0: Normal operation 1: Loopback mode is enabled. Note: Data for transmission are still output normally. To eliminate effects on external modules, pin control should be applied to block the output of data.
23 to 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
17, 16	CSEL[1:0]	00	R/W	gPTP Clock Select These bits select the clock source for the gPTP timer. Writing to these bits is only possible when the current operating mode is configuration mode and CCC.GAC is 0. Writing to these bits is only possible when the current operating mode is Reset mode when writing CCC.GAC to 1 and CCC.OPC to B'01 by same write access. 00: gPTP is disabled 01: High-speed peripheral bus clockOther: Setting prohibited
15 to 9	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.

Bit	Bit Name	Initial Value	R/W	Description
8	DTSR	0	R/W	Data Transmission Suspend Request This bit can suspend access to the URAM. The access is suspended on completion of the transfer of the AXI transaction currently being transferred. This function disables access to the URAM without affecting normal operation of the AVB-DMAC. Use this bit when exclusive control over the contents of the URAM is necessary, for example, in checking its integrity. Note that the transmission and reception queues are not processed while access is suspended. Change neither the AVB-DMAC settings nor the mode while access is suspended. 0: Normal operation 1: Requests suspension
7	GAC	0	R/W	Gptp Active in Config This bit enables the gPTP support of EthernetAVB in CONFIG mode. Function of gPTP support in OPERATION and STANDBY is not influenced by this bit. When gPTP support is active in CONFIG, CCC.CSEL defines the timer clock source. The CPU can only write 1 to this bit if CSR.OPS is RESET when writing CCC.OPC to B'01 by same write access. 0: Normal operation 1: gPTP support active in CONFIG mode
6 to 2	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
1, 0	OPC[1:0]	00	R/W	Operating Mode Configuration These bits specify the operating mode. For the operating modes, see section 33A.3.1.1 Operating Modes. Writing to these bits is possible in any of the operating modes, but should not be done after the application system has issued a Power Off request. When CCC.GAC is 1 CPU should not write B'11 to these bits. [Changing condition] These bits are set to B'00 when RESET mode is entered due to 'enter power off' request. 00: Reset mode 01: Configuration mode 10: Operation mode 11: standby mode

33A.2.2 Descriptor Base Address Table Register (DBAT)

The DBAT register specifies the base address of the descriptor table in the URAM. For the structure of this table, see section 33A.3.3 Descriptors. Writing to this bit is only possible when the current operating mode is configuration mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TA[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TA[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TA[31:0]	H'0000 0000	R/W	Descriptor Base Table Address Base address of the descriptor table in the URAM Note: The setting of this bit must be a multiple of four (i.e. bit 0 and bit 1 must be set to 0).

33A.2.3 Descriptor Base Address Load Request Register (DLR)

The DLR register is used to issue a request to load the values from the current descriptor address register q (CDARq) for each queue to the descriptor base address table register (DBAT).

Setting a bit to 1 issues a request for loading the descriptor base address for the queue q. If transfer is currently in progress, loading is executed on completion of transfer for the current frame. Completion of loading leads to automatic setting of the corresponding bit to 0.

For the transmission queues, base address load requests are executed even while fetching is in progress (the transmit start request bit in the transmit configuration control register (TCCR.TSRQt) is 1). Therefore, be sure to check that fetching is not in progress before issuing a request.

Writing to a bit of this register is only possible when the current operating mode is operation mode. Only 1 can be written to this bit.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	LBA21	LBA20	LBA19	LBA18	LBA17	LBA16

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
21	LBA21	1	R/W	Base Address Load Request (Rx17: Stream 15) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
20	LBA20	1	R/W	Base Address Load Request (Rx16: Stream 14) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
19	LBA19	1	R/W	Base Address Load Request (Rx15: Stream 13) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
18	LBA18	1	R/W	Base Address Load Request (Rx14: Stream 12) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.

Bit	Bit Name	Initial Value	R/W	Description
17	LBA17	1	R/W	Base Address Load Request (Rx13: Stream 11) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
16	LBA16	1	R/W	Base Address Load Request (Rx12: Stream 10) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
15	LBA15	1	R/W	Base Address Load Request (Rx11: Stream 9) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
14	LBA14	1	R/W	Base Address Load Request (Rx10: Stream 8) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
13	LBA13	1	R/W	Base Address Load Request (Rx9: Stream 7) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
12	LBA12	1	R/W	Base Address Load Request (Rx8: Stream 6) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
11	LBA11	1	R/W	Base Address Load Request (Rx7: Stream 5) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
10	LBA10	1	R/W	Base Address Load Request (Rx6: Stream 4) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
9	LBA9	1	R/W	Base Address Load Request (Rx5: Stream 3) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
8	LBA8	1	R/W	Base Address Load Request (Rx4: Stream 2) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.

Bit	Bit Name	Initial Value	R/W	Description
7	LBA7	1	R/W	Base Address Load Request (Rx3: Stream 1) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
6	LBA6	1	R/W	Base Address Load Request (Rx2: Stream 0) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
5	LBA5	1	R/W	Base Address Load Request (Rx1: Network Control) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
4	LBA4	1	R/W	Base Address Load Request (Rx0: Best Effort) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
3	LBA3	1	R/W	Base Address Load Request (Tx3: Stream Class A) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
2	LBA2	1	R/W	Base Address Load Request (Tx2: Stream Class B) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
1	LBA1	1	R/W	Base Address Load Request (Tx1: Network Control) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.
0	LBA0	1	R/W	Base Address Load Request (Tx0: Best Effort) 0: No load request is issued. 1: When written: A request for loading the corresponding base address is issued. When read: The given base address is being loaded.

33A.2.4 AVB-DMAC Status Register (CSR)

The CSR register is used to indicate the operating mode in which the AVB-DMAC is running and the individual communications states.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	TDUO	RPO	TPO3	TPO2	TPO1	TPO0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	DTS	—	—	—	—	OPS[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved These bits are read as 0.
21	TDUO	0	R	Transmission Descriptor Update On-going This bit indicates that there is pending descriptor update for one or more transmit queues. When this bit is 1, there are descriptors of already or currently processed transmit storage elements not updated in URAM. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when all transmit queue related storage elements processed. This bit is set to 1 when descriptor related status update procedure starts (descriptor update and register flagging). 0: No pending descriptor update 1: Pending descriptor update in URAM
20	RPO	0	R	Receive Process Status This bit indicates whether a reception queue contains an unread received frame. This bit being set to 1 indicates that a received frame is yet to be stored in the URAM. 0: Normal operation [Clearing conditions] — The current operating mode is not operation mode. — Received frames in the reception FIFO all being stored in the URAM. 1: Reception is in progress. [Setting condition] — A received frame being stored in the reception FIFO (but not yet in the URAM).

Bit	Bit Name	Initial Value	R/W	Description
19	TPO3	0	R	Transmit Process Status 3 (Stream Class A) This bit indicates whether a class A stream is being transmitted. This bit being set to 1 indicates that the AVB-DMAC is fetching data for transmission from the URAM, or the E-MAC is transmitting data. 0: Normal operation [Clearing conditions] — The current operating mode is not operation mode. — Completion of transfer of all frames for transmission from the transmission FIFO and TCCR.TSRQ3 is 0. 1: Transmission is in progress. [Setting condition] — Transmission being started (by writing 1 to the transmit start request bit in the transmit configuration control register (TCCR.TSRQ3)).
18	TPO2	0	R	Transmit Process Status 2 (Stream Class B) This bit indicates whether a class B stream is being transmitted. This bit being set to 1 indicates that the AVB-DMAC is fetching data for transmission from the URAM, or the E-MAC is transmitting data. 0: Normal operation [Clearing conditions] — The current operating mode is not operation mode. — Completion of transfer of all frames for transmission from the transmission FIFO and TCCR.TSRQ2 is 0. 1: Transmission is in progress. [Setting condition] — Transmission being started (by writing 1 to the transmit start request bit in the transmit configuration control register (TCCR.TSRQ2)).
17	TPO1	0	R	Transmit Process Status 1 (Network Control) This bit indicates whether a network control is being transmitted. This bit being set to 1 indicates that the AVB-DMAC is fetching data for transmission from the URAM, or the E-MAC is transmitting data. 0: Normal operation [Clearing conditions] — The current operating mode is not operation mode. — Completion of transfer of all frames for transmission from the transmission FIFO and TCCR.TSRQ1 is 0. 1: Transmission is in progress. [Setting condition] — Transmission being started (by writing 1 to the transmit start request bit in the transmit configuration control register (TCCR.TSRQ1)).

Bit	Bit Name	Initial Value	R/W	Description
16	TPO0	0	R	Transmit Process Status 0 (Best Effort) This bit indicates whether a best effort is being transmitted. This bit being set to 1 indicates that the AVB-DMAC is fetching data for transmission from the URAM, or the E-MAC is transmitting data. 0: Normal operation [Clearing conditions] — The current operating mode is not operation mode. — Completion of transfer of all frames for transmission from the transmission FIFO and TCCR.TSRQ0 is 0. 1: Transmission is in progress. [Setting condition] — Transmission being started (by writing 1 to the transmit start request bit in the transmit configuration control register (TCCR.TSRQ0)).
15 to 9	—	All 0	R	Reserved These bits are read as 0.
8	DTS	0	R	Data Transmission Suspended Status This bit indicates whether access to the URAM is enabled. 0: Normal operation [Clearing conditions] — The data transmission suspend request bit in the AVB-DMAC mode register (CCC.DTSR) being 0. 1: Transmission is in progress. [Setting condition] — Access to the URAM not proceeding while the data transmission suspend request bit (CCC.DTSR) in the AVB-DMAC mode register (CCC) is 1 (if the URAM is being accessed, this bit is set to 1 on completion of access).
7 to 4	—	All 0	R	Reserved These bits are read as 0.
3 to 0	OPS[3:0]	0001	R	Operating Mode Status These bits indicate the current operating mode. For the operating modes, see section 33A.3.1.1 Operating Modes. 0001: Reset mode 0010: Configuration mode 0100: Operation mode 1000: standby mode Other settings are reserved.

33A.2.5 Current Descriptor Address Register q (CDARq) (q = 0 to 21)

The CDARq register indicates the current descriptor address.

CDAR0 to CDAR3 indicate the addresses of the current descriptors for the corresponding transmission queues while CDAR4 to CDAR21 indicate the addresses of the current descriptors for the corresponding reception queues.

If the operating mode is changed to operation mode, the contents of the register for the queue to be used are set in the descriptor base address table register (DBAT).

Also, when the descriptor base address load request register (DLR) issues a load request, the contents of the descriptor base address table register (DBAT) are set in to the corresponding CDAR registers.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CDA[31:16]

	CDA[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CDA[31:0]	H'0000 0000	R	Current Descriptor Address The address of the current descriptors for the transmission queues. Conditions for updating: • These bits are set to 0 when the operating mode is not operation mode. This register is updated in response to processing of the descriptor for a queue.

33A.2.6 Error Status Register (ESR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	EIL	ET[3:0]				—	—	—	EQN[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	All 0	R	Reserved These bits are read as 0.
12	EIL	0	R	Error Information Lost This bit indicates that error information detect by EthernetAVB is lost, because the previous reported error has not been processed by CPU. [Changing conditions] — This bit is set to 0 when leaving operation mode. — This bit is set to 0 when CPU writes 0 to EIS.QEF. — This bit is set to 1 when the set condition of EIS.QEF is fulfilled while EIS.QEF is 1. 0: No loss of error information 1: Lost of error information detected

Bit	Bit Name	Initial Value	R/W	Description
11 to 8	ET[3:0]	0000	R	Error Type These bits indicate details about the transfer stage which was handled when EthernetAVB has detected an error. When the fault is related to the read descriptor (ESR.ET = B'0000 or B'0010), CPU needs to correct the faulty descriptor before the related queue can continue processing. Because the queue halts at the faulty descriptor CDARq.CDA (q = ESR.EQN) is identifying the faulty descriptor directly. When the fault is related to descriptor writing (ESR.ET = B'0001), CPU needs to recognize the not-updated or incorrectly updated descriptor in queue ESR.EQN. The write problem is not influencing how EthernetAVB processes the descriptor chain. When the fault is related to the Tx-buffer (ESR.ET = B'0011), CPU needs to clean-up the Tx-buffer to correct the buffer control structures. All other errors are transient in nature and may be corrected by continuation of hardware or software operation; so there is no strong demand on CPU interaction. Refer to section 33A.3.2.2 Checking Integrity for details of error handling. The CPU should only evaluate these bits when the EIS.QEF bit is 1. [Changing condition] — These bits are updated when the set condition of the EIS.QEF bit is fulfilled and the EIS.QEF bit is 0. 0000: Read descriptor from URAM 0001: Write descriptor to URAM 0010: Interpret data descriptor 0011: Tx-buffer is corrupted 0100: Read data from URAM 0101: Write data or timestamp to URAM 0110: Reading from Rx-FIFO 0111: Rx-FIFO is corrupted 1000: Frame size error during reception detected 1001: Frame size error during transmission detected 1010: Tx-buffer overflow 1011: AVTP FIFO error
7 to 5	—	All 0	R	Reserved These bits are read as 0.
4 to 0	EQN[4:0]	00000	R	Error Queue Number These bits indicate the queue number which was handled when EthernetAVB has detected an error. A fault reported for ESR.EQN = 0 to 3 is related to transmit queue t (t = 0 to 3). From ESR.EQN = 4, the fault is related to receive queue r (r = ESR.EQN – 4). The CPU should only evaluate these bits when the EIS.QEF bit is 1. The CPU should not evaluate these bits when the ESR.ET bit is B'0011, B'0111 or B'1011. [Changing condition] — These bits are updated when the set condition of the EIS.QEF bit is fulfilled and the EIS.QEF bit is 0.

33A.2.7 Receive Configuration Register (RCR)

The RCR register is used to make settings related to reception for the AVB-DMAC.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	RFCL[12:0]												
Initial value:	0	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	ETS2	ETS0	ESF[1:0]		ENCF	EFFS
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 29	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
28 to 16	RFCL[12:0]	H'1800	R/W	Receive FIFO Caution Level These bits set the caution level for the reception FIFO and are used to maintain the priority order of the storage of received data and the fetching of data for transmission. If the reception FIFO contains less data than this level, processing of both transmission and reception queues becomes pending. If the reception FIFO contains more data than this level, only data in the reception queue are transferred, and processing of the transmission queue becomes pending. Writing to this bit is only possible when the current operating mode is configuration mode. Recommended value: H'1800 Notes: • The setting of this bit must be a multiple of four (i.e. set RFCL[1:0] = B'00). • In the case of this LSI chip, set these bits to H'1800.
15 to 6	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
5	ETS2	0	R/W	Time Stamp Enable (Stream) Enables the inclusion of time-stamp information in reception queues 2 to 17. Writing to this bit is only possible when the current operating mode is configuration mode. 0: Time stamping is disabled. 1: Time stamping is enabled. Recommended value: 0
4	ETS0	0	R/W	Time Stamp Enable (Best Effort) Enables the inclusion of time-stamp information in reception queue 0. Writing to this bit is only possible when the current operating mode is configuration mode. 0: Time stamping is disabled. 1: Time stamping is enabled. Recommended value: 0

Bit	Bit Name	Initial Value	R/W	Description
3, 2	ESF[1:0]	00	R/W	Stream Filtering Select Settings for reception queues 2 to 17. These bits select separation filtering for reception queues 2 to 17. The queue-dependent separation filter can be used in combination with the identification of AVB stream frames. When the value is B'00, filtering is disabled and frames from streams are processed in reception queue 0 (best effort). When the value is B'01, the separation filter is enabled for both AVB stream frames and non-AVB stream frames; frames from non-matching streams are processed in reception queue 0 (best effort). When the value is B'10, the separation filter is enabled for AVB stream frames; frames from non-matching streams are discarded. When the value is B'11, the separation filter is enabled for AVB stream frames; frames from non-matching streams are processed in reception queue 0 (best effort). For separation filtering, see section 33A.3.4.1(1) Separation Filtering. Writing to this bit is only possible when the current operating mode is configuration mode. 00: Filtering is disabled. Frames are processed in queue 0 (best effort). 01: The filter for both AVB stream frames and non-AVB stream frames is enabled; non-matching frames from the stream are processed in queue 0 (best effort). 10: The filter for separating AVB stream frames from non-AVB stream frames is enabled; non-matching frames are discarded. 11: The filter for separating AVB stream frames from non-AVB stream frames is enabled; non-matching frames from a stream are processed in queue 0 (best effort). Recommended value: B'10 or B'11
1	ENCF	0	R/W	Network Control Filtering Enable Setting for reception queue 1 (network control) Enables the AVB network control frame for reception queue 1. When reception queue 1 is disabled, a received frame is stored in reception queue 0 (best effort). Writing to this bit is only possible when the current operating mode is configuration mode. 0: Network control is disabled. 1: Network control is enabled.
0	EFFS	0	R/W	Error Frame Enable Enables or disables the reception of frames that have been classified as error frames by the E-MAC. Received error frames are stored in reception queue 0 (best effort). An indicator of error detection by the E-MAC during reception is stored in the descriptor (DESCR.MS). Writing to this bit is only possible when the current operating mode is configuration mode. 0: Error frames are disabled. 1: Error frames are enabled. Recommended value: 0

33A.2.8 Receive Queue Configuration Register i (RQCi) (i = 0 to 4)

The RQC0 register is used to set up reception queues 0 to 3.

The RQC1 register is used to set up reception queues 4 to 7.

The RQC2 register is used to set up reception queues 8 to 11.

The RQC3 register is used to set up reception queues 12 to 15.

The RQC4 register is used to set up reception queues 16 to 17.

Bit	Bit Name	Initial Value	R/W	Description
31	—	0	R/W	Reserved These bits are read as 0. The write value should be 0.
30	PIA3	0	R/W	Packed Incremental data Area (Receive Queue 3+i×4) This bit defines how addresses inside the incremental data area of queue 3+i×4 are handled. When this bit is 0, frame data in incremental data area starts always at a 32 bit address. Depending on received frame length there are up to 3 undefined bytes between two frames in URAM. When this bit is 1, there will no gaps generated between two frames in incremental data area. The CPU can only write to this bit if CSR.OPS is CONFIG. 0: Frame data starts always 32 bit aligned 1: No gaps between frame data in incremental data area
29, 28	UFCC3[1:0]	00	R/W	Unread Frame Counter Configuration (Receive Queue 3+i×4) These bits set the unread frame counter used in reception queue 3+i×4. With the AVB-DMAC, four patterns of settings are available for the unread frame counter. Use the unread frame counter warning level configuration register (UFCW) and the unread frame counter stop level configuration register (UFCS) to set the warning level and stop level of the unread frame counter. Set the pattern number 3 set in the unread frame counter warning level configuration register (UFCW) and unread frame counter stop level configuration register (UFCS) in this bit. When the value is B'00, the stop function is disabled. Writing to the bits is only possible when the current operating mode is configuration mode.

Bit	Bit Name	Initial Value	R/W	Description
27, 26	TSEL3	00	R/W	Truncation SELection (Receive Queue 3+i×4) This bit defines a maximum number of bytes for storing frames in receive queue 3+i×4. Frames longer than the selected maximum are truncated. EthernetAVB provides 2 common configurations for the maximum frame length. This bit selects one of the configurations j defined by RTCi.MFLj. 00: Maximum frame length defined by RTC0.MFL0 01: Maximum frame length defined by RTC0.MFL1 Other configurations are Invalid The CPU can only write to these bits if CSR.OPS is CONFIG.
25, 24	RSM3[1:0]	00	R/W	Receive Synchronous Mode (Receive Queue 3+i×4) These bits set receive synchronous mode. Set B'00 in this bit. For receive synchronous mode, see section 33A.3.4.3(3) Mode with Write-Back. Writing to the bits is only possible when the current operating mode is configuration mode. 00: Mode with write-back 01: Keep DT mode (no update of DT field at descriptor write back) 10: No write-back (no descriptor write back) 11: Invalid
23	—	0	R/W	Reserved These bits are read as 0. The write value should be 0.
22	PIA2	0	R/W	Packed Incremental data Area (Receive Queue 2+i×4) This bit defines how addresses inside the incremental data area of queue 2+i×4 are handled. When this bit is 0, frame data in incremental data area starts always at a 32 bit address. Depending on received frame length there are up to 3 undefined bytes between two frames in URAM. When this bit is 1, there will no gaps generated between two frames in incremental data area. The CPU can only write to this bit if CSR.OPS is CONFIG. 0: Frame data starts always 32 bit aligned 1: No gaps between frame data in incremental data area
21, 20	UFCC2[1:0]	00	R/W	Unread Frame Counter Configuration (Receive Queue 2+i×4) These bits set the unread frame counter used in reception queue 2+i×4. With the AVB-DMAC, four patterns of settings are available for the unread frame counter. Use the unread frame counter warning level configuration register (UFCW) and the unread frame counter stop level configuration register (UFCS) to set the warning level and stop level of the unread frame counter. Set the pattern number 2 set in the unread frame counter warning level configuration register (UFCW) and unread frame counter stop level configuration register (UFCS) in this bit. When the value is B'00, the stop function is disabled. Writing to the bits is only possible when the current operating mode is configuration mode.

Bit	Bit Name	Initial Value	R/W	Description
19, 18	TSEL2	00	R/W	Truncation SELection (Receive Queue 2+i×4) This bit defines a maximum number of bytes for storing frames in receive queue 2+i×4. Frames longer than the selected maximum are truncated. EthernetAVB provides 2 common configurations for the maximum frame length. This bit selects one of the configurations j defined by RTCi.MFLj. 00: Maximum frame length defined by RTC0.MFL0 01: Maximum frame length defined by RTC0.MFL1 Other configurations are Invalid The CPU can only write to these bits if CSR.OPS is CONFIG.
17, 16	RSM2[1:0]	00	R/W	Receive Synchronous Mode (Receive Queue 2+i×4) These bits set receive synchronous mode. Set B'00 in this bit. For receive synchronous mode, see section 33A.3.4.3(3) Mode with Write-Back. Writing to the bits is only possible when the current operating mode is configuration mode. 00: Mode with write-back 01: Keep DT mode (no update of DT field at descriptor write back) 10: No write-back (no descriptor write back) 11: Invalid
15	—	0	R/W	Reserved These bits are read as 0. The write value should be 0.
14	PIA1	0	R/W	Packed Incremental data Area (Receive Queue 1+i×4) This bit defines how addresses inside the incremental data area of queue 1+i×4 are handled. When this bit is 0, frame data in incremental data area starts always at a 32 bit address. Depending on received frame length there are up to 3 undefined bytes between two frames in URAM. When this bit is 1, there will no gaps generated between two frames in incremental data area. The CPU can only write to this bit if CSR.OPS is CONFIG. 0: Frame data starts always 32 bit aligned 1: No gaps between frame data in incremental data area
13, 12	UFCC1[1:0]	00	R/W	Unread Frame Counter Configuration (Receive Queue 1+i×4) These bits set the unread frame counter used in reception queue 1+i×4. With the AVB-DMAC, four patterns of settings are available for the unread frame counter. Use the unread frame counter warning level configuration register (UFCW) and the unread frame counter stop level configuration register (UFCS) to set the warning level and stop level of the unread frame counter. Set the pattern number 1 set in the unread frame counter warning level configuration register (UFCW) and unread frame counter stop level configuration register (UFCS) in this bit. When the value is B'00, the stop function is disabled. Writing to the bits is only possible when the current operating mode is configuration mode.

Bit	Bit Name	Initial Value	R/W	Description
11, 10	TSEL1	00	R/W	Truncation SELection (Receive Queue 1+i×4) This bit defines a maximum number of bytes for storing frames in receive queue 1+i×4. Frames longer than the selected maximum are truncated. EthernetAVB provides 2 common configurations for the maximum frame length. This bit selects one of the configurations j defined by RTCi.MFLj. 00: Maximum frame length defined by RTC0.MFL0 01: Maximum frame length defined by RTC0.MFL1 Other configurations are Invalid The CPU can only write to these bits if CSR.OPS is CONFIG.
9, 8	RSM1[1:0]	00	R/W	Receive Synchronous Mode (Receive Queue 1+i×4) These bits set receive synchronous mode. Set B'00 in this bit. For receive synchronous mode, see section 33A.3.4.3(3) Mode with Write-Back. Writing to the bits is only possible when the current operating mode is configuration mode. 00: Mode with write-back 01: Keep DT mode (no update of DT field at descriptor write back) 10: No write-back (no descriptor write back) 11: Invalid
7	—	0	R/W	Reserved These bits are read as 0. The write value should be 0.
6	PIA0	0	R/W	Packed Incremental data Area (Receive Queue 0+i×4) This bit defines how addresses inside the incremental data area of queue 0+i×4 are handled. When this bit is 0, frame data in incremental data area starts always at a 32 bit address. Depending on received frame length there are up to 3 undefined bytes between two frames in URAM. When this bit is 1, there will no gaps generated between two frames in incremental data area. The CPU can only write to this bit if CSR.OPS is CONFIG. 0: Frame data starts always 32 bit aligned 1: No gaps between frame data in incremental data area
5, 4	UFCC0[1:0]	00	R/W	Unread Frame Counter Configuration (Receive Queue 0+i×4) These bits set the unread frame counter used in reception queue 0+i×4. With the AVB-DMAC, four patterns of settings are available for the unread frame counter. Use the unread frame counter warning level configuration register (UFCW) and the unread frame counter stop level configuration register (UFCS) to set the warning level and stop level of the unread frame counter. Set the pattern number 0 set in the unread frame counter warning level configuration register (UFCW) and unread frame counter stop level configuration register (UFCS) in this bit. When the value is B'00, the stop function is disabled. Writing to the bits is only possible when the current operating mode is configuration mode.

Bit	Bit Name	Initial Value	R/W	Description
3, 2	TSEL0	00	R/W	Truncation SELection (Receive Queue 0+i×4) This bit defines a maximum number of bytes for storing frames in receive queue 0+i×4. Frames longer than the selected maximum are truncated. EthernetAVB provides 2 common configurations for the maximum frame length. This bit selects one of the configurations j defined by RTCi.MFLj. 00: Maximum frame length defined by RTC0.MFL0 01: Maximum frame length defined by RTC0.MFL1 Other configurations are Invalid The CPU can only write to these bits if CSR.OPS is CONFIG.
1, 0	RSM0[1:0]	00	R/W	Receive Synchronous Mode (Receive Queue 0+i×4) These bits set receive synchronous mode. Set B'00 in this bit. For receive synchronous mode, see section 33A.3.4.3(3) Mode with Write-Back. Writing to the bits is only possible when the current operating mode is configuration mode. 00: Mode with write-back 01: Keep DT mode (no update of DT field at descriptor write back) 10: No write-back (no descriptor write back) 11: Invalid

33A.2.9 Receive Padding Configuration Register (RPC)

The RPC register is used to set padding for received frames.

Note: Padding can be used to extend frame lengths, but frame lengths should not exceed 4 Kbytes.

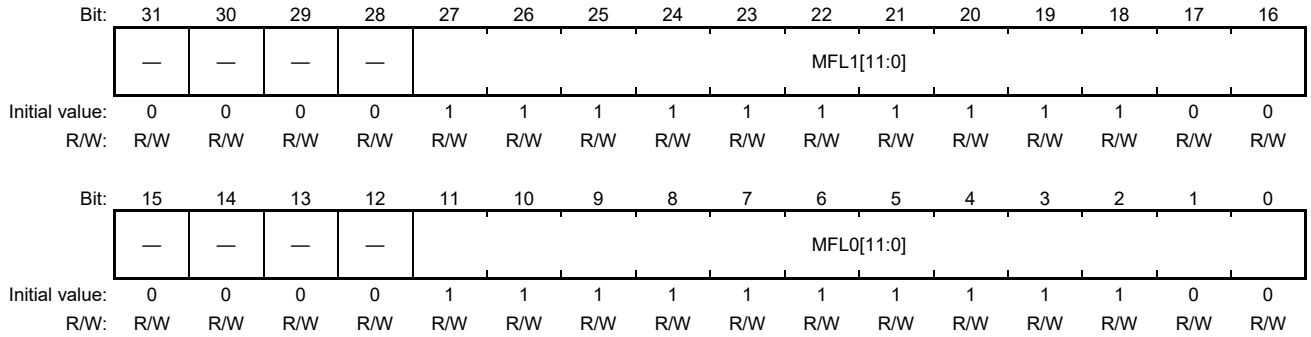
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	DCNT[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	PCNT[2:0]			—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
23 to 16	DCNT[7:0]	H'00	R/W	Stored Data Counter These bits specify the amount of the frame data (1 to 255) to be stored following the padding. Counting by one indicates one word (4 bytes). For example, when these bits are set to 47, the amount of data is 47 words (= 188 bytes). When these bits are 0, all received data have been stored following the initial padding. Writing to the bits is only possible when the current operating mode is configuration mode. For details on padding, see section 33A.3.4.3(2) Incremental Data Areas.
15 to 11	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
10 to 8	PCNT[2:0]	001	R/W	Stored Padding Counter These bits specify the amount of padding to be appended to the URAM. Counting by one indicates one word (4 bytes). For example, when these bits are set to 1, the amount of padding is one word (= 4 bytes). Writing to the bits is only possible when the current operating mode is configuration mode. For details on padding, see section 33A.3.4.3(2) Incremental Data Areas. The CPU should not write 0 to these bits.
7 to 0	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.

33A.2.10 Reception Truncation Configuration register (RTC)

The RTC register is used to set Maximum Number of bytes stored per received frame.



Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
27 to 16	MFL1[11:0]	H'FFC	R/W	Maximum Frame Length 1 These bits define the maximum frame length (64 to 4092 bytes) stored to URAM. For each receive queue one parameter 1 used for truncation is selected. When a frame received by E-MAC is truncated, CPU gets informed by EIS.QEF and frame size error (ESR.ET is B'1000). Additionally the DESCR.TI in the updated descriptor is set to 1. The CPU can only write to these bits if CSR.OPS is CONFIG. The CPU should only write values which are a multiple of 4 to these bits. The CPU should not write values less than 64 to these bits. The CPU should not write values less then SFO.FBP + 8 to these bits when RCR.ESF is not equal to B'00.
15 to 12	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
11 to 0	MFL0[11:0]	H'FFC	R/W	Maximum Frame Length 0 These bits define the maximum frame length (64 to 4092 bytes) stored to URAM. For each receive queue one parameter 0 used for truncation is selected. When a frame received by E-MAC is truncated, CPU gets informed by EIS.QEF and frame size error (ESR.ET is B'1000). Additionally the DESCR.TI in the updated descriptor is set to 1. The CPU can only write to these bits if CSR.OPS is CONFIG. The CPU should only write values which are a multiple of 4 to these bits. The CPU should not write values less than 64 to these bits. The CPU should not write values less then SFO.FBP + 8 to these bits when RCR.ESF is not equal to B'00.

33A.2.11 Unread frame counter warning level register (UFCW)

The UFCW register sets the warning levels for the number of unread frames.

One of the four warning levels from 0 to 3 can be set for each reception queue. When these bits are set to 0, the stop function is disabled. The level to be used is specified by the receive queue configuration register i (RQCi) (i = 0 to 4).

Writing to the bits is only possible when the current operating mode is configuration mode.

The CPU should not write 63 to these bits.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

33A.2.12 Unread frame counter stop level register (UFCS)

The UFCS register sets the stop levels for unread frames.

One of the four stop levels from 0 to 3 can be set for each reception queue. When these bits are set to 0, the stop function is disabled. The level to be used is specified by the receive queue configuration register i (RQCi) (i = 0 to 4).

Writing to the bits is only possible when the current operating mode is configuration mode.

33A.2.13 Unread Frame Counter Register i (UFCVi) (i = 0 to 4)

The UFCV0 register indicates the number of unread frames in reception queues 0 to 3.

The UFCV1 register indicates the number of unread frames in reception queues 4 to 7.

The UFCV2 register indicates the number of unread frames in reception queues 8 to 11.

The UFCV3 register indicates the number of unread frames in reception queues 12 to 15.

The UFCV4 register indicates the number of unread frames in reception queues 16 and 17.

For a description of how to use unread frames, refer to section 33A.3.4.4, Unread Frame Counters.

Conditions for updating:

The bits are set to 0 when the operating mode is not operation mode and when the descriptor base address load request register (DLR) issues a base address load request.

The number is incremented when data received in reception queue r are stored normally. The maximum increment is H'3F. If the value exceeds H'3F, incrementation will not proceed.)

The number is decremented by the value written to the unread frame counter decrement register i (UFCDi).

5 to 0	CV0[5:0]	000000	R	Unread Frame Count 0+4×i Number of unread frames in reception queue 0+4×i

33A.2.14 Unread Frame Counter Decrement Register i (UFCDi) (i = 0 to 4)

The UFCD0 register is used to decrement unread counters in reception queues 0 to 3.

The UFCD1 register is used to decrement unread counters in reception queues 4 to 7.

The UFCD2 register is used to decrement unread counters in reception queues 8 to 11.

The UFCD3 register is used to decrement unread counters in reception queues 12 to 15.

The UFCD4 register is used to decrement unread counters in reception queues 16 and 17.

Write H'3F to these bits to reset the unread counters in reception queue r (r = 0 to 17). These bits are always read as 0.

33A.2.15 Separation Filter Offset Register (SFO)

The SFO register sets an offset into frames for use by the separation filter.

Note: Received frames having fewer bytes than the setting of these bits + 8 bytes are judged to be non-matching by the separation filter. In this case, the data will either be sorted into a reception queue or discarded in accord with the setting of the separation filtering select bits in the receive configuration register (RCR.ESF).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
5 to 0	FBP[5:0]	000000	R/W	First Byte Position These bits set the position in Ethernet frames of the first byte of the bytes to be used by the separation filter. When these bits are 0, the separation filter starts from the start of each Ethernet frame (first byte of the destination address). For bytes in Ethernet frames, see Figure 33A.2 Operating Mode of AVB-DMAC, in section 33A.3.1.1 Operating Modes. Writing to the bits is only possible when the current operating mode is configuration mode. [Changing condition] These bits are updated to the value of SFVi.LV[5:0] when SFL.LC changes from 30 (Load SFO.FBP) to 31 while CSR.OPS is OPERATION. For separation filtering, see section 33A.3.4.1(1) Separation Filtering.

33A.2.16 Separation Filter Pattern Register i (SFPi) (i = 0 to 31)

A pair of SFPi registers set the pattern for the separation filters to be used by the corresponding reception queues 2 to 17 (for streams 0 to 15).

Each queue shares a 64-bit setting; reception queue 2 (for stream 0) uses SFP0 and SFP1, reception queue 17 (for stream 15) uses SFP30 and SFP31, and so on.

The separation filter passes a frame when, after masking by the mask value set in the separation filter mask register (SFMi), data from received frames match the value defined in these bits.

SFPi.FP[7:0] (where i is an even number) are used for the byte of Ethernet frame data specified by the separation filter offset register, while SFPi.FP[63:56] (where i is the corresponding odd number) are used for the byte at the address specified by the separation filter offset register (SFO) + 7.

Writing to the bits is only possible when the current operating mode is configuration mode.

[Changing condition]

These bits are updated to the value of SFVi.LV[63:0] when SFL.LC changes from s (Load SFPi.FPs) to 31 while CSR.OPS is OPERATION.

For separation filtering, see section 33A.3.4.1(1) Separation Filtering.

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	FP[31:0]	H'0000 0000	R/W	Separation Filter Pattern These bits set the pattern of the separation filter. The 64-bit filter pattern is set for each queue.

33A.2.17 Separation Filter Value register i (SFVi) (i = 0 to 1)

These bits define the 64 bit value to be loaded for separation filtering.

When loading the first by position (SFO.FBP), SFVi.LV[63:6] are ignored.

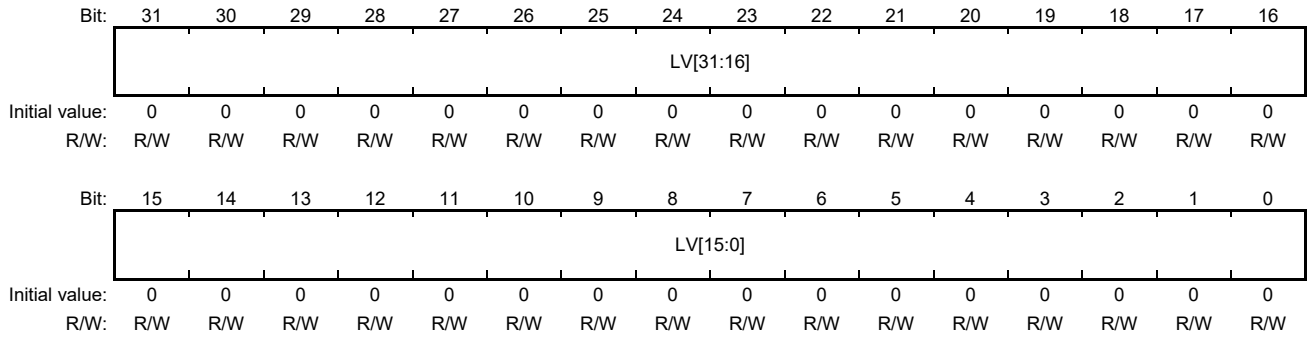
The CPU can only write to these bits if CSR.OPS is OPERATION.

The CPU can only write to these bits if SFL.LC is 31.

[Changing condition]

These bits are set to 0 when leaving OPERATION mode.

For separation filtering, see section 33A.3.4.1(1) Separation Filtering.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	LV[31:0]	H'0000 0000	R/W	Separation Filter Value These bits set the Load value of the separation filter.

33A.2.18 Separation Filter Mask Register i (SFMi) (i = 0 or 1)

A pair of SFMi registers sets the mask value for the separation filter used by the corresponding reception queue 2 to 17 (stream 0 to 15).

SFM0.CFM[7:0] are used for bytes of Ethernet frame data specified by the separation filter offset register, while SFM1.CFM[63:56] are used for the separation filter offset register (SFO) + 7.

Frame data at the positions of mask bits that are set to 0 are masked; that is, they do not affect pattern-matching by the separation filter.

Writing to the bits is only possible when the current operating mode is configuration mode.

[Changing condition]

These bits are updated to the value of SFVi.LV[63:0] when SFL.LC changes from 29 (Load SFMi.CFM) to 31 while CSR.OPS is OPERATION.

For separation filtering, see section 33A.3.4.1(1) Separation Filtering.

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CFM[31:0]	H'0000 0000	R/W	Separation Filter Mask These bits set the mask value for the separation filter.

33A.2.19 Separation Filter Load register (SFL)

The SFL register is used to separation filter load.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	LC[4:0]

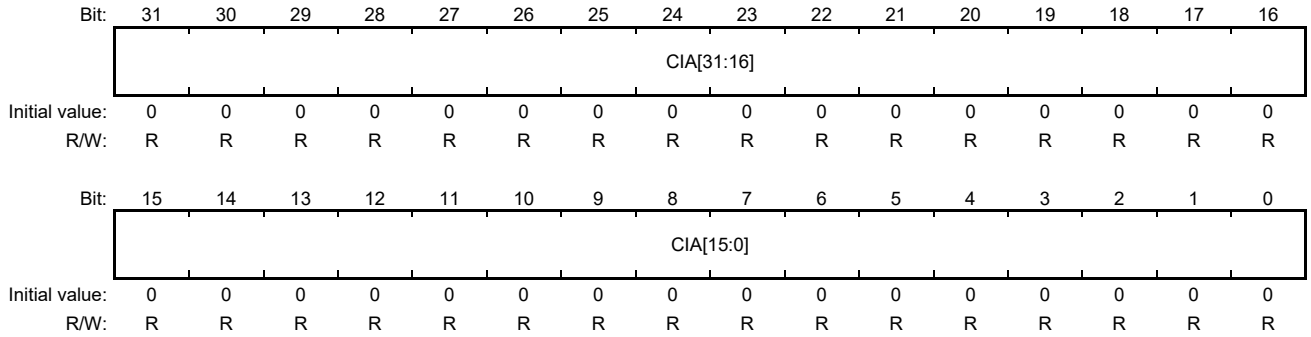
Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
4 to 0	LC[4:0]	H'1F	R/W	Load Command These bits control update of separation filter configuration in OPERATION mode. By writing 30 to these bits CPU triggers an update of First Byte Position (SFO.FBP) value. By writing 29 to these bits CPU triggers an update of Common Filter Mask (SFMi.CFM) value. By writing number between 0 and 15 to these bits CPU triggers an update of Filter Pattern s (SFPi.FPs) value. The number written to SFL.LC defines the index s of the updated Filter Pattern. The CPU can only write to these bits if CSR.OPS is OPERATION. The CPU can only write to these bits if SFL.LC is 31. [Changing condition] These bits are set to 31 when leaving OPERATION mode. These bits are set to 31 when the requested update has been processed. 0-15: Load of SFPi.FPs with s = SFL.LC 16-28: Invalid 29: Load of SFMi.CFM 30: Load of SFO.FBP 31: No pending load request

33A.2.20 Current Incremental Address Register r (CIARr) (r = 0 to 17)

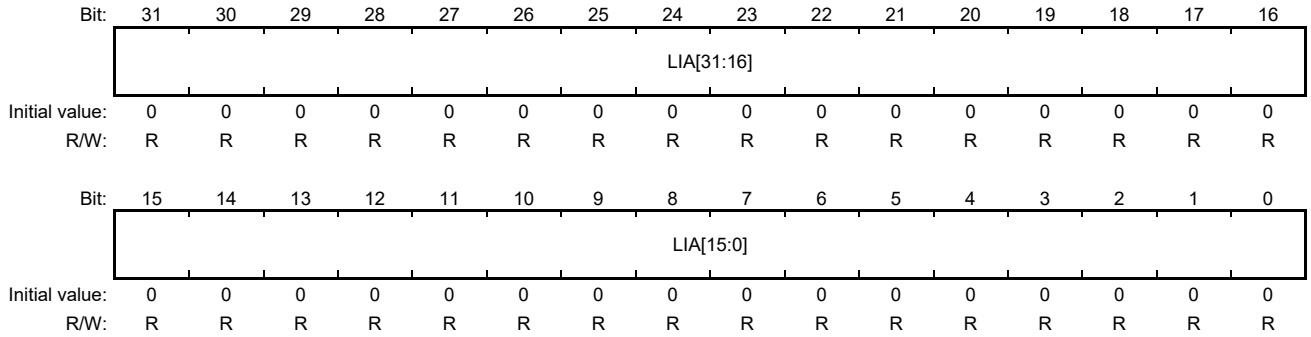
The CIARr register is used to check queue address.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CIA[31:0]	H'0000 0000	R	Current incremental address used by receive queue These bits indicate the incremental address of receive queue r, where currently frame data is stored or where frame data will be stored when queue r gets active. Refer to section 33A.3.4.3(2) Incremental Data Areas. [Changing condition] These bits are set to 0 when leaving OPERATION mode. These bits are updated to next address in incremental data area when processing a FEMPTY_IS or FEMPTY_IC descriptor.

33A.2.21 Last Incremental Address Register r (LIARr) (r = 0 to 17)

The LIARr register is used to check queue address.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	LIA[31:0]	H'0000 0000	R	Last incremental address used by receive queue These bits indicate the current incremental address of receive queue r (CIARr.CIA) before its address was updated due to processing a FEMPTY_IS descriptor. So it describes the first not used address inside the incremental data area of receive queue r. Refer to section 33A.3.4.3(2) Incremental Data Areas. [Changing condition] These bits are set to 0 when leaving OPERATION mode. These bits are set to CIARr.CIA when processing a FEMPTY_IS descriptor.

33A.2.22 Transmit Configuration Register (TGC)

The TGC register is used to make settings related to transmission for the AVB-DMAC.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
21, 20	TBD3[1:0]	10	R/W	Transmit FIFO Size (Stream Class A) These bits set the sizes of the transmission FIFO buffers for use with each of the transmission queue 3 (for stream class A). Writing to these bits is only possible when the current operating mode is configuration mode. Set these bits to B'10.
19, 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
17, 16	TBD2[1:0]	10	R/W	Transmit FIFO Size (Stream Class B) These bits set the sizes of the transmission FIFO buffers for use with each of the transmission queue 2 (for stream class B). Writing to these bits is only possible when the current operating mode is configuration mode. Set these bits to B'10.
15, 14	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
13, 12	TBD1[1:0]	10	R/W	Transmit FIFO Size (Network Control) These bits set the sizes of the transmission FIFO buffers for use with each of the transmission queue 1 (for network control). Writing to these bits is only possible when the current operating mode is configuration mode.
11, 10	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
9, 8	TBD0[1:0]	10	R/W	Transmit FIFO Size (Best Effort) These bits set the sizes of the transmission FIFO buffers for use with each of the transmission queue 0 (for best effort). Writing to these bits is only possible when the current operating mode is configuration mode.
7, 6	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.

Bit	Bit Name	Initial Value	R/W	Description
5	TQP	0	R/W	Transmission Queues Priority This bit defines how EtherAVB-IF prioritises between transmit queues when scheduling transmission. For fetching always the queue with highest priority is selected, for transmission the queue with highest priority where data is available in Tx-Buffer. Transmission priority of queue 2 and 3 can be influenced by the credit based shaping algorithm. The priority of the transmit queues is given from high to low. 0: Default priority: Q3(CBS), Q2(CBS), Q1, Q0 1: Alternate priority: Q1, Q3(CBS), Q2(CBS), Q0 For the credit-based shaping (CBS) algorithm, see section 33A.3.6 CBS (Credit-Based Shaping). Writing to the bits is only possible when the current operating mode is configuration mode.
4	ECBS	0	R/W	Enable Credit Based Shaping This bit defines if CBS algorithm is used for transmit queue 2 and 3 to prioritise between transmit queues when scheduling transmission. When CBS is enabled, the shaping bases on queue specific configuration in CIVRc, CDVRc, CULc and CLLc. 0: CBS globally disabled 1: CBS enabled based on queue specific configuration For the credit-based shaping (CBS) algorithm, see section 33A.3.6 CBS (Credit-Based Shaping). Writing to the bits is only possible when the current operating mode is configuration mode.
3	TSM3	0	R/W	Transmit Synchronous Mode (Stream Class A) Set these bits to 0. 0: With write-back 1: Setting prohibited
2	TSM2	0	R/W	Transmit Synchronous Mode (Stream Class B) Set these bits to 0. 0: With write-back 1: Setting prohibited
1	TSM1	0	R/W	Transmit Synchronous Mode (Network Control) Set these bits to 0. 0: With write-back 1: Setting prohibited
0	TSM0	0	R/W	Transmit Synchronous Mode (Best Effort) Set these bits to 0. 0: With write-back 1: Setting prohibited

33A.2.23 Transmit Configuration Control Register (TCCR)

The TCCR register controls transmission by the AVB-DMAC and is used to make related settings.

Conditions for updating:

The bit is set to 0 when the operating mode is not operation mode, when a descriptor of type EEMPTY, FEMPTY or LEMPTY (no usable data) is processed, when an EOS descriptor is processed, and when a descriptor with defective data is processed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	MFR	MFEN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TFR	TFEN	—	—	—	—	TSRQ3	TSRQ2	TSRQ1	TSRQ0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
17	MFR	0	R/W	E-MAC status FIFO Release This bit releases the oldest entry of the E-MAC status FIFO. When 1 is written to this bit, EthernetAVB gets informed that CPU has processed the oldest E-MAC status FIFO entry as visible in MFA register. The oldest entry is removed from E-MAC status FIFO. This bit is always read as 0. 0: No request to E-MAC status FIFO 1: Release oldest entry of E-MAC status FIFO
16	MFEN	0	R/W	E-MAC status FIFO ENable This bit enables the storage of transmission status information (the MAC flags for frame transmission) in the E-MAC status FIFO. Additionally CPU can control the status storage for each frame provided for transmission using DESCR.MSR. When this bit is set to 0 all pending FIFO entries are removed. 0: Disabled 1: Enabled
15 to 10	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
9	TFR	0	R/W	Time Stamp FIFO Release This bit releases the oldest entry in the time-stamp FIFO. For a description of how to use the time-stamp FIFO, see section 33A.3.5.4 Time Stamping in Transmission. 0: (Not operating) 1: Releases the oldest entry in the time-stamp FIFO.

Bit	Bit Name	Initial Value	R/W	Description
8	TFEN	0	R/W	Time Stamp FIFO Enable This bit enables storage in the time-stamp FIFO. When it is set, time-stamp information is stored for descriptors with DESCR.TSR set to 1 (for DESCR.TSR, see section 33A.3.5.2(2) Configuration of Transmission Frame Data Descriptors. When 0 is set in this bit, no entries are made in the time-stamp FIFO. For a description of how to use the time-stamp FIFO, see section 33A.3.5.4 Time Stamping in Transmission. 0: Recording of transmission time stamps in the time-stamp FIFO is disabled. 1: Recording of transmission time stamps in the time-stamp FIFO is enabled.
7 to 4	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
3	TSRQ3	0	R/W	Transmit Start Request (Queue 3 (Stream Class A)) This bit issues a request to start transmission for transmission queue 3. When read, this bit being set to 1 indicates that transmission queue t has a frame that has not yet been fetched to the transmission FIFO. Frame transmission by the E-MAC is processed independently from fetching to the transmission FIFO. The timing of transmission from a queue depends on the priority order of transmission. For the scheduling of transmission queues, see section 33A.3.5.1 Transmission Modes. Writing to this bit is only possible when the current operating mode is operation mode. Only 1 can be written to the bit. Writing 0 to the bit has no effect. 0: Transmission queue is empty or stopped. 1: When written: A transmission start request is issued. When read: Fetching of data for transmission is pending.
2	TSRQ2	0	R/W	Transmit Start Request (Queue 2 (Stream Class B)) This bit issues a request to start transmission for transmission queue 2. When read, this bit being set to 1 indicates that transmission queue t has a frame that has not yet been fetched to the transmission FIFO. Frame transmission by the E-MAC is processed independently from fetching to the transmission FIFO. The timing of transmission from a queue depends on the priority order of transmission. For the scheduling of transmission queues, see section 33A.3.5.1 Transmission Modes. Writing to this bit is only possible when the current operating mode is operation mode. Only 1 can be written to the bit. Writing 0 to the bit has no effect. 0: Transmission queue is empty or stopped. 1: When written: A transmission start request is issued. When read: Fetching of data for transmission is pending.

Bit	Bit Name	Initial Value	R/W	Description
1	TSRQ1	0	R/W	Transmit Start Request (Queue 1 (Network Control)) This bit issues a request to start transmission for transmission queue 1. When read, this bit being set to 1 indicates that transmission queue t has a frame that has not yet been fetched to the transmission FIFO. Frame transmission by the E-MAC is processed independently from fetching to the transmission FIFO. The timing of transmission from a queue depends on the priority order of transmission. For the scheduling of transmission queues, see section 33A.3.5.1 Transmission Modes. Writing to this bit is only possible when the current operating mode is operation mode. Only 1 can be written to the bit. Writing 0 to the bit has no effect. 0: Transmission queue is empty or stopped. 1: When written: A transmission start request is issued. When read: Fetching of data for transmission is pending.
0	TSRQ0	0	R/W	Transmit Start Request (Queue 0 (Best Effort)) This bit issues a request to start transmission for transmission queue 0. When read, this bit being set to 1 indicates that transmission queue t has a frame that has not yet been fetched to the transmission FIFO. Frame transmission by the E-MAC is processed independently from fetching to the transmission FIFO. The timing of transmission from a queue depends on the priority order of transmission. For the scheduling of transmission queues, see section 33A.3.5.1 Transmission Modes. Writing to this bit is only possible when the current operating mode is operation mode. Only 1 can be written to the bit. Writing 0 to the bit has no effect. 0: Transmission queue is empty or stopped. 1: When written: A transmission start request is issued. When read: Fetching of data for transmission is pending.

33A.2.24 Transmit Status Register (TSR)

The TSR register indicates the state of transmission by the AVB-DMAC.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	MFFL[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

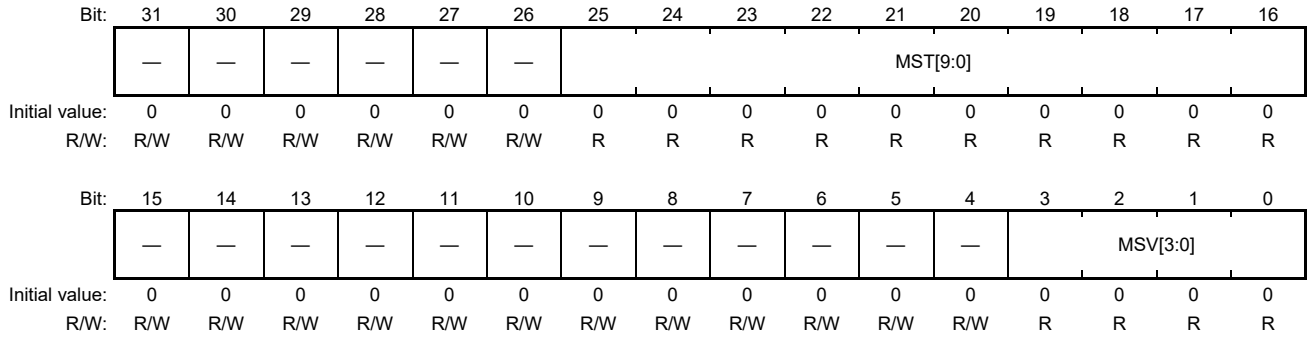
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	TFFL[2:0]			—	—	—	—	CCS1[1:0]		CCS0[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 21	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
20 to 16	MFFL[4:0]	H'00	R	Number of entries stored in the E-MAC status FIFO E-MAC status FIFO Fill Level These bits indicate the number of entries available in the MAC status FIFO. If this value is 0, the FIFO is empty. If this value is 16, the FIFO is full. The values 17 to 31 are reserved. [Changing condition] These bits are set to 0 when leaving OPERATION mode. These bits are set to 0 when TCCR.MFEN is 0. This value is incremented when frame with DESCR.MSR has been transmitted by E-MAC, TCCR.MFEN is 1 and TSR.MFFL is not 16. This value is incremented when E-MAC detects an error during transmission, TCCR.MFEN is 1 and TSR.MFFL is not 16. This value is decremented when 1 is written to TCCR.MFR and TSR.MFFL is not 0.
15 to 11	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
10 to 8	TFFL[2:0]	00	R	Time Stamp FIFO Count These bits indicate the number of time stamps in the time-stamp FIFO. The values 0 and 3 indicate that the time-stamp FIFO is empty and full, respectively (values 4 to 7 are reserved). Conditions for updating: • The bits are set to 0 when the operating mode is not operation mode and when the time stamp FIFO enable bit in the transmit configuration control register (TCCR.TFEN) = 0. • When the time stamp FIFO enable bit (TCCR.TFEN) is 1 and these bits are not 3, the value of these bits is incremented after a frame with DESCR.TSR set has been transmitted by the E-MAC (for DESCR.TSR, see section 33A.3.5.2(2) Configuration of Transmission Frame Data Descriptors. • The value of these bits is decremented if it is not 0 when 1 is written to the time stamp FIFO release bit in the transmit configuration control register (TCCR.TFR).

Bit	Bit Name	Initial Value	R/W	Description
7 to 4	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
3, 2	CCS1[1:0]	00	R	CBS Counter Status 1 (Class A) These bits indicate the CBS (credit-based shaping) state of stream data transmission queue 1. If the calculated credit value is outside the range specified by CBS upper limit register c (CULc) and CBS lower limit register c (CLLc), it falls outside the range for CBS. Conditions for updating: • The bits are set to B'00 when the operating mode is not operation mode. The bits are set to B'00 when the CBS is inside the condition limits. • The bits are set to B'01 if the credit value calculated by the CBS is lower than the value in CBS lower limit register c (CLLc). • The bits are set to B'10 if the credit value calculated by the CBS is higher than the value in CBS upper limit register c (CULc). 00: The current credit value is within the limit. 01: The current credit value is less than or equal to the lower limit. 10: The current credit value is greater than or equal to the upper limit. 11: (Reserved)
1, 0	CCS0[1:0]	00	R	CBS Counter Status 0 (Class B) These bits indicate the CBS (credit-based shaping) state of stream data transmission queue 0. If the calculated credit value is outside the range specified by CBS upper limit register c (CULc) and CBS lower limit register c (CLLc), it falls outside the range for CBS. Conditions for updating: • The bits are set to B'00 when the operating mode is not operation mode. The bits are set to B'00 when the CBS is inside the condition limits. • The bits are set to B'01 if the credit value calculated by the CBS is lower than the value in CBS lower limit register c (CLLc). • The bits are set to B'10 if the credit value calculated by the CBS is higher than the value in CBS upper limit register c (CULc). 00: The current credit value is within the limit. 01: The current credit value is less than or equal to the lower limit. 10: The current credit value is greater than or equal to the upper limit. 11: (Reserved)

33A.2.25 E-MAC status FIFO Access register (MFA)

The MFA register indicates the state of MAC.



Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	MST[9:0]									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R

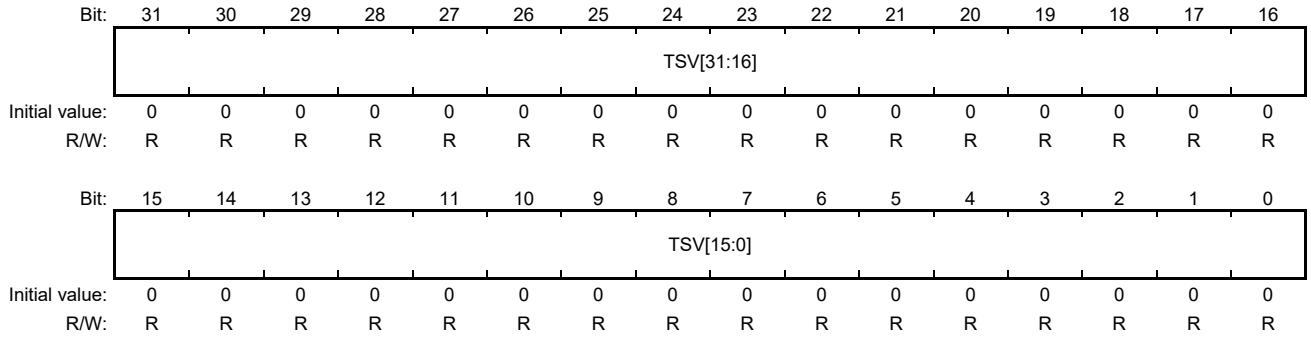
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	MSV[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
25 to 16	MST[9:0]	H'000	R	Tag number from descriptor identifying the frame E-MAC status relation E-MAC Status Tag These bits represent the DESCR.TAG bits from the descriptor defining the data for frame transmission. The tag is used to get the relation between the frame inside a transmit queue and the E-MAC status available in the FIFO (MFA.MSV). The CPU should not read these bits when TSR.MFFL is 0. [Changing condition] These bits are updated when the first entry is stored in FIFO (TSR.MFFL changes from 0 to 1). These bits are updated when the oldest entry is released (writing 1 to TCCR.MFR). These bits are updated when the FIFO is overwritten (a frame with DESCR.MSR in descriptor has been transmitted by MAC, TCCR.MFEN is 1 and TSR.MFFL is 16). These bits are updated when the FIFO is overwritten (E-MAC detects an error during transmission and TSR.MFFL is 16). Note for verification: These bits are set to 0 when leaving OPERATION mode.
15 to 4	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	MSV[3:0]	H'0	R	E-MAC Status Value These bits represent the E-MAC status bits as stored in the oldest E-MAC status FIFO entry. MSV[3] Reserved MSV[2] Carrier lost during frame transmission MSV[1] Delay collision MSV[0] Transmission time out The CPU should not read these bits when TSR.MFFL is 0. [Changing condition] These bits are updated when the first entry is stored in FIFO (TSR.MFFL changes from 0 to 1). These bits are updated when the oldest entry is released (writing 1 to TCCR.MFR). These bits are updated when the FIFO overwritten (a frame with DESCR.MSR in descriptor has been transmitted by E-MAC, TCCR.MFEN is 1 and TSR.MFFL is 16). These bits are updated when the FIFO is overwritten (E-MAC detects an error during transmission and TSR.MFFL is 16). Note for verification: These bits are set to 0 when leaving OPERATION mode.

33A.2.26 Time Stamp FIFO Access Register 0 (TFA0)

TFA0 indicates the nano seconds portion of the timestamp value.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TSV[31:0]	H'0000 0000	R	Time Stamp Value These 80 bits consist of TFA0.TSV[31:0], TFA1.TSV[63:32], and TFA2.TSV[79:64], which together indicate the oldest time stamp value stored in the time-stamp FIFO. Once the time-stamp FIFO is full, no further time-stamp values are stored. Conditions for updating: • The bits are set to H'0000 0000 when the operating mode is not operation mode. • The register is updated whenever a value is stored in the time-stamp FIFO (when the time-stamp FIFO count bit in the transmit status register (TSR.TFFL) changes from 0 to 1). • The register is updated when the oldest entry is released (when the time stamp FIFO release bit in the transmit configuration control register (TCCR.TFR) is set to 1).

33A.2.27 Time Stamp FIFO Access Register 1 (TFA1)

The TFA1 register indicates the lower seconds portion of the timestamp value.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSV[63:48]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSV[47:32]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TSV[63:32]	H'0000 0000	R	Time Stamp Value For details, see section 33A.2.26 Time Stamp FIFO Access Register 0 (TFA0).

33A.2.28 Time Stamp FIFO Access Register 2 (TFA2)

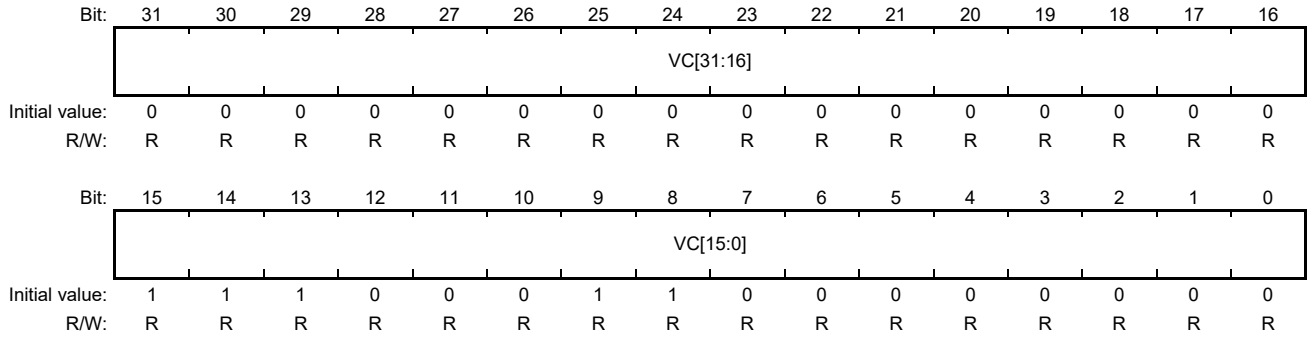
The TFA2 register indicates the timestamp tag and the higher seconds portion of the timestamp value.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	TST[9:0]									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSV[79:64]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved These bits are read as 0.
25 to 16	TST[9:0]	H'000	R	Time Stamp Tag These bits indicate the contents of the DESCR.TAG bit within the descriptor for frame transmission. These values are used to check the correlation between frames within the transmission queue and the time-stamp values (accessible through time stamp FIFO access register i (TFAi)) which can be placed in the FIFO. For the tagging of frames in transmission, see section 33A.3.5.4 Time Stamping in Transmission. Conditions for updating: • The bits are set to H'000 when the operating mode is not operation mode. • Updated when a value is stored in the time-stamp FIFO (when the value of the time stamp FIFO count bit in the transmit status register (TSR.TFFL) changes from 0 to 1). • Updated when the oldest entry has been released (1 is set in the time stamp FIFO release bit in the transmit configuration control register (TCCR.TFR)).
15 to 0	TSV[79:64]	H'0000	R	Time Stamp Value For details, see section 33A.2.26 Time Stamp FIFO Access Register 0 (TFA0).

33A.2.29 Version and Release Register (VRR)

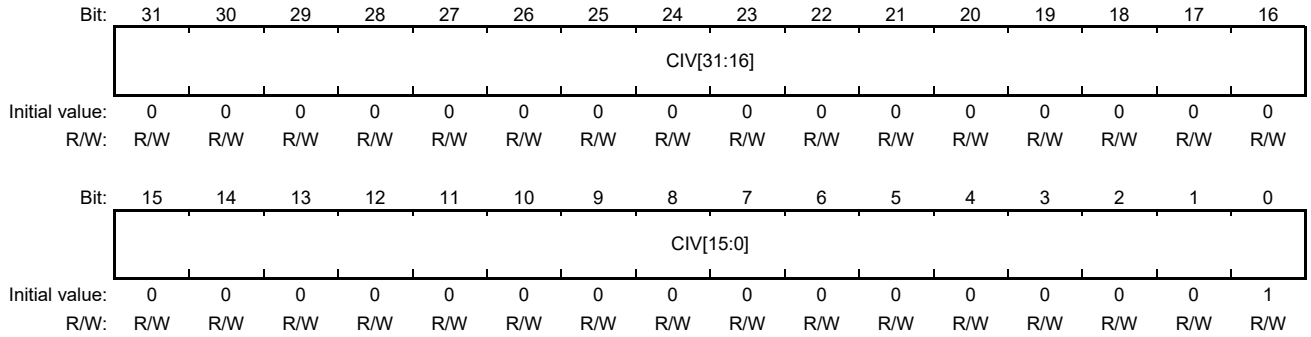


Bit	Bit Name	Initial Value	R/W	Description
31 to 0	VC[31:0]	H'0000 E300	R	Version Code These bits identify the version of used EthernetAVB. H'0000 E300: RAVBES3

33A.2.30 CBS Increment Value Register c (CIVRc) (c = 0 or 1)

The CIVR0 register sets the increment in the CBS algorithm for transmission queue 2 (for stream class B).

The CIVR1 register sets the increment in the CBS algorithm for transmission queue 3 (for stream class A).

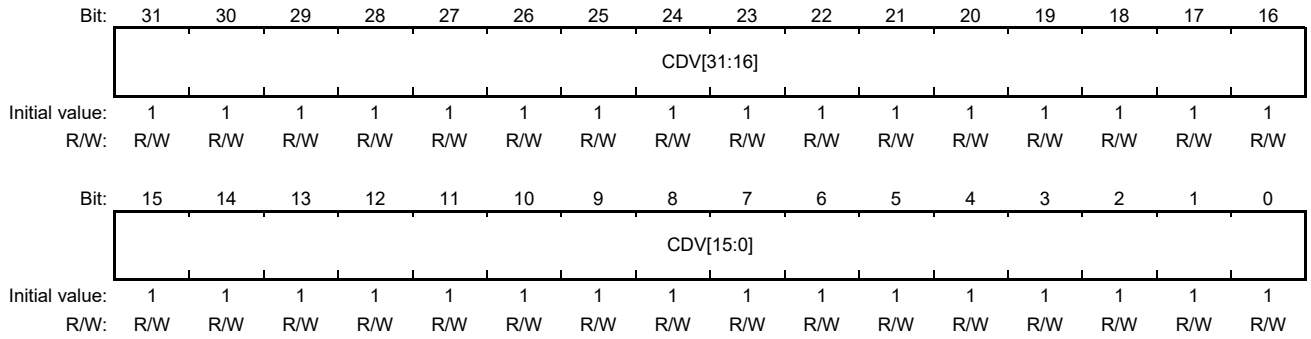


Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CIV[31:0]	H'0000 0001	R/W	CBS Increment Value CBS increment value (1 to H'FFFF) These bits define the increment value related to idleSlope for the CBS algorithm. Set a value in the range from H'0000 0001 to H'0000 FFFF. The value to be written to these bits depends on the Ethernet bit rate and HPϕ (high-speed peripheral clock). For details, see section 33A.3.6 CBS (Credit-Based Shaping).

33A.2.31 CBS Decrement Value Register c (CDVRc) (c = 0 or 1)

The CDVR0 register sets the decrement in the CBS algorithm for transmission queue 2 (for stream class B).

The CDVR1 register sets the decrement in the CBS algorithm for transmission queue 3 (for stream class A).

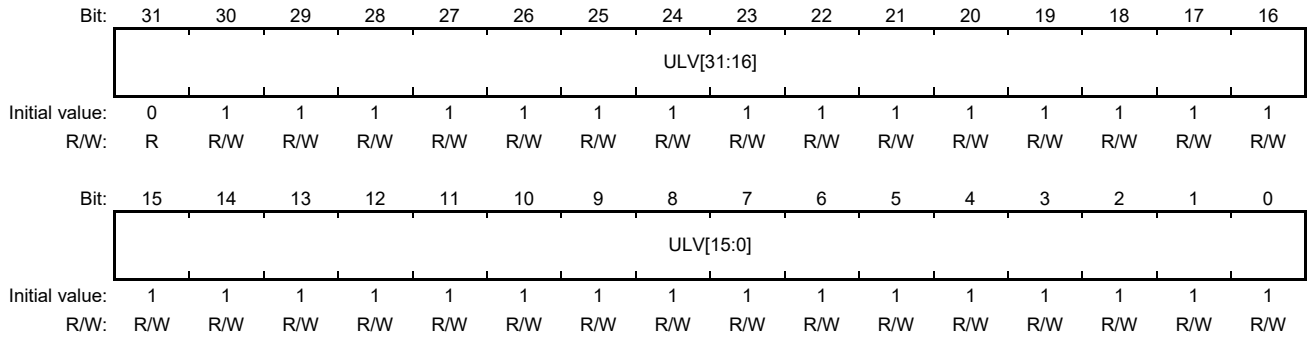


Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CDV[31:0]	H'FFFF FFFF	R/W	CBS Decrement Value Setting value: -1 to -65536 (H'FFFF FFFF to H'FFFF 0000) These bits set the decrement for the CBS algorithm. These bits define the decrement value related to sendSlope for CBS algorithm. The value to be written to these bits depends on the Ethernet bit rate and HPϕ (high-speed peripheral clock). For details, see section 33A.3.6 CBS (Credit-Based Shaping).

33A.2.32 CBS Upper Limit Register c (CULc) (c = 0 or 1)

The CUL0 register sets the upper limit for credit values calculated by using the CBS algorithm for transmission queue 2 (for stream class B).

The CUL1 register sets the upper limit for credit values calculated by using the CBS algorithm for transmission queue 3 (for stream class A).



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	ULV[31:0]	H'7FFF FFFF	R/W	CBS Upper Limit These bits set the upper limit for credit values calculated by using the CBS algorithm. The setting is a limiting value for error detection and does not normally affect operation of the algorithm. Write a positive value to these bits. For details, see section 33A.3.6 CBS (Credit-Based Shaping). Note: The write value to the bit 31 should always be 0.

33A.2.33 CBS Lower Limit Register c (CLLc) (c = 0 or 1)

The CUL0 register sets the lower limit for credit values calculated by using the CBS algorithm for transmission queue 2 (for stream class B).

The CUL1 register sets the lower limit for credit values calculated by using the CBS algorithm for transmission queue 3 (for stream class A).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	LLV[31:16]															
Initial value:	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LLV[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	LLV[31:0]	H'8000 0001	R/W	CBS Lower Limit These bits set the lower limit for credit values calculated by using the CBS algorithm. The setting is a limiting value for error detection and does not normally affect operation of the algorithm. Write a negative value to these bits. For details, see section 33A.3.6 CBS (Credit-Based Shaping). Note: The write value to the bit 31 should always be 1.

33A.2.34 Descriptor Interrupt Control Register (DIC)

The DIC register is used to control descriptor interrupts 1 to 15.

When an interrupt source flag is set (a bit from DPF1 to DPF15 bits in the descriptor interrupt status register (DIS) = 1) while the interrupt is enabled, the interrupt is issued.

[Changing condition]

This bit is set to 0 when writing 1 to DID.DPDi.

This bit is set to 1 when writing 1 to DIE.DPSi.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
15	DPF15	0	R/W	Descriptor Interrupt Status15 0: The interrupt is not pending. 1: The interrupt is pending.
14	DPF14	0	R/W	Descriptor Interrupt Status14 0: The interrupt is not pending. 1: The interrupt is pending.
13	DPF13	0	R/W	Descriptor Interrupt Status13 0: The interrupt is not pending. 1: The interrupt is pending.
12	DPF12	0	R/W	Descriptor Interrupt Status12 0: The interrupt is not pending. 1: The interrupt is pending.
11	DPF11	0	R/W	Descriptor Interrupt Status11 0: The interrupt is not pending. 1: The interrupt is pending.
10	DPF10	0	R/W	Descriptor Interrupt Status10 0: The interrupt is not pending. 1: The interrupt is pending.
9	DPF9	0	R/W	Descriptor Interrupt Status9 0: The interrupt is not pending. 1: The interrupt is pending.
8	DPF8	0	R/W	Descriptor Interrupt Status8 0: The interrupt is not pending. 1: The interrupt is pending.
7	DPF7	0	R/W	Descriptor Interrupt Status7 0: The interrupt is not pending. 1: The interrupt is pending.
6	DPF6	0	R/W	Descriptor Interrupt Status6 0: The interrupt is not pending. 1: The interrupt is pending.

Bit	Bit Name	Initial Value	R/W	Description
5	DPF5	0	R/W	Descriptor Interrupt Status5 0: The interrupt is not pending. 1: The interrupt is pending.
4	DPF4	0	R/W	Descriptor Interrupt Status4 0: The interrupt is not pending. 1: The interrupt is pending.
3	DPF3	0	R/W	Descriptor Interrupt Status3 0: The interrupt is not pending. 1: The interrupt is pending.
2	DPF2	0	R/W	Descriptor Interrupt Status2 0: The interrupt is not pending. 1: The interrupt is pending.
1	DPF1	0	R/W	Descriptor Interrupt Status1 0: The interrupt is not pending. 1: The interrupt is pending.
0	—	0	R/W	Reserved These bits are read as 0. The write value should be 0.

DPF1 to DPF15 Descriptor Interrupt Status Bits:

When DESCR.DIE is 1 to 15, the corresponding bit indicates completion of the processing of a descriptor within the reception or transmission queue.

When DESCR.DIE is 0, the descriptor interrupt is not generated.

When DESCR.DIE is B'0001, in addition a queue specific descriptor interrupt is generated.

Only 0 can be written to these bits.

[Conditions for Changing]

— A bit is set to 0 when the operating mode is not operation mode.
— A bit is set to 1 when a descriptor with DESCR.DIE set to the corresponding number from 1 to 15 is processed.

33A.2.36 Error Interrupt Control Register (EIC)

The EIC register controls the AVB-DMAC-related error interrupts.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	TBFE	MFFE	TFFE	CULE1	CULE0	CLLE1	CLLE0	SEE	QEE	MTEE	MREE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
10	TBFE	0	R/W	Tx-Buffer Full interrupt Enable While this bit is 1 an interrupt will be generated when EIS.TBFF is 1. [Changing condition] This bit is set to 0 when writing 1 to EID.TBFD. This bit is set to 1 when writing 1 to EIE.TBFS. 0: Disabled 1: Enabled
9	MFFE	0	R/W	MAC status FIFO Full interrupt Enable While this bit is 1 an interrupt will be generated when EIS.MFFF is 1. [Changing condition] This bit is set to 0 when writing 1 to EID.MFFD. This bit is set to 1 when writing 1 to EIE.MFFS. 0: Disabled 1: Enabled
8	TFFE	0	R/W	Time Stamp FIFO Full-Error Interrupt Enable When the time stamp FIFO is full (TFFF in the error interrupt status register (EIS) = 1) and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to EID.TFFD. This bit is set to 1 when writing 1 to EIE.TFFS. 0: Disabled 1: Enabled

Bit	Bit Name	Initial Value	R/W	Description
7	CULE1	0	R/W	CBS Upper Limit Error Interrupt Enable (Class A) When the Class A CBS reaches its upper limit (CULF1 in the error interrupt status register (EIS) = 1), the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to EID.CULD1. This bit is set to 1 when writing 1 to EIE.CULS1. 0: Disabled 1: Enabled
6	CULE0	0	R/W	CBS Upper Limit Error Interrupt Enable (Class B) When the Class B CBS reaches its upper limit (CULF0 in the error interrupt status register (EIS) = 1), the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to EID.CULD0. This bit is set to 1 when writing 1 to EIE.CULS0. 0: Disabled 1: Enabled
5	CLLE1	0	R/W	CBS Lower Limit Error Interrupt Enable (Class A) When the Class A CBS reaches its lower limit (CLLF1 in the error interrupt status register (EIS) = 1), the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to EID.CLLD1. This bit is set to 1 when writing 1 to EIE.CLLS1. 0: Disabled 1: Enabled
4	CLLE0	0	R/W	CBS Lower Limit Error Interrupt Enable (Class B) When the Class B CBS reaches its lower limit (CLLF0 in the error interrupt status register (EIS) = 1), the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to EID.CLLD0. This bit is set to 1 when writing 1 to EIE.CLLS0. 0: Disabled 1: Enabled
3	SEE	0	R/W	Separation Error Interrupt Enable While this bit is 1, an interrupt will be generated when the EIS.SEF bit is 1. [Changing condition] This bit is set to 0 when writing 1 to EID.SED. This bit is set to 1 when writing 1 to EIE.SES. 0: Disabled 1: Enabled
2	QEE	0	R/W	Queue Error Interrupt Enable While this bit is 1, an interrupt will be generated when the EIS.QEF bit is 1. [Changing condition] This bit is set to 0 when writing 1 to EID.QED. This bit is set to 1 when writing 1 to EIE.QES. 0: Disabled 1: Enabled

Bit	Bit Name	Initial Value	R/W	Description
1	MTEE	0	R/W	E-MAC Transmission Error Interrupt Enable While this bit is 1, an interrupt will be generated when the EIS.MTEF bit is 1. [Changing condition] This bit is set to 0 when writing 1 to EID.MTED. This bit is set to 1 when writing 1 to EIE.MTES. 0: Disabled 1: Enabled
0	MREE	0	R/W	E-MAC Reception Error Interrupt Enable While this bit is 1, an interrupt will be generated when the EIS.MREF bit is 1. [Changing condition] This bit is set to 0 when writing 1 to EID.MRED. This bit is set to 1 when writing 1 to EIE.MRES. 0: Disabled 1: Enabled

33A.2.37 Error Interrupt Status Register (EIS)

The EIS register indicates the states of AVB-DMAC-related error interrupts.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	QFS
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	TBFF	MFFF	TFFF	CULF1	CULF0	CLLF1	CLLF0	SEF	QEF	MTEF	MREF
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 17	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
16	QFS	0	R/W	Queue Full Error Interrupt Status With the interrupts enabled, this bit indicates that a queue is full (the receive queue r full interrupt status bit (QFFr) or the receive FIFO full interrupt status bit (RFFF) in receive interrupt status register 2 (RIS2) = 1). [Conditions for Changing] — If the receive queue r full interrupt status bit (RIS2.QFFr) and/or the receive queue r full interrupt enable bit in the - receive interrupt control register 2 (RIC2.QFEr) are updated, this bit is also updated. — If the receive FIFO full interrupt status bit (RIS2.RFFF) and/or the receive FIFO full interrupt enable bit (RIC2.RFFE) are updated, this bit is also updated. 0: The interrupt is not pending. 1: The interrupt is pending.
15 to 11	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
10	TBFF	0	R/W	Tx-Buffer Full Flag This bit indicates that fetching transmit data was delayed because the Tx-Buffer has no sufficient storage available to store fetched frame. It depends on configuration of TGC.TBDt (refer to section 33A.3.5.1) if a full Tx-Buffer is expected during normal operation. No frame gets lost but transmission priority may be influenced. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when frame data has been fetched from URAM but there is no storage available in Tx-Buffer. 0: No interrupt pending 1: Tx-Buffer full condition detected

Bit	Bit Name	Initial Value	R/W	Description
9	MFFF	0	R/W	E-MAC status FIFO Full Flag This bit indicates that a transmission E-MAC status is overwritten because the E-MAC status FIFO is full (overwrite condition). The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a frame with DESCR.MSR has been transmitted by E-MAC, TCCR.MFEN is 1 and TSR.MFFL is 16. This bit is set to 1 when E-MAC detects an error during transmission and TSR.MFFL is 16. 0: No interrupt pending 1: E-MAC status FIFO full, oldest E-MAC status lost
8	TFFF	0	R/W	Time Stamp FIFO Full Error Interrupt Status This bit indicates that a new transmission time stamp has been discarded due to the time-stamp FIFO being full (i.e. has reached the overflow state). Only 0 can be written to the bit. [Conditions for Changing] — The bit is set to 0 when the operating mode is not operation mode. — The bit is set to 1 when a frame with DESCR.TSR set is transmitted while the time stamp FIFO enable bit in the transmit configuration control register (TCCR.TFEN) is set to 1 and the time stamp FIFO count bit in the transmit status register (TSR.TFFL) is set to 3. 0: The interrupt is not pending. 1: The interrupt is pending.
7	CULF1	0	R/W	CBS Upper Limit Error Interrupt Status (Class A) This bit indicates that CBS counter 1 has exceeded the set upper limit (CUL1.ULV in the CBS upper limit register c (CULc)). Only 0 can be written to the bit. [Conditions for Changing] — This bit is set to 0 when the operating mode is not operation mode. — This bit is set to 1 when the value of the CBS counter status 1 (Class A) bits in the transmit status register (TSR.CCS1) change from B'00 (indicating a value within the range between the limits) to B'10 (indicating a value over the upper limit). 0: The interrupt is not pending. 1: The interrupt is pending.

Bit	Bit Name	Initial Value	R/W	Description
6	CULF0	0	R/W	CBS Upper Limit Error Interrupt Status (Class B) This bit indicates that CBS counter 0 has exceeded the set upper limit (CUL0.ULV in the CBS upper limit register c (CULc)). Only 0 can be written to the bit. [Conditions for Changing] — The bit is set to 0 when the operating mode is not operation mode. — The bit is set to 1 when the value of the CBS counter status 0 (Class B) bit in the transmit status register changes from B'00 (indicating a value within the range between the limits) to B'10 (indicating a value over the upper limit). 0: The interrupt is not pending. 1: The interrupt is pending.
5	CLLF1	0	R/W	CBS Lower Limit Error Interrupt Status (Class A) This bit indicates that CBS counter 1 has fallen below the set lower limit (CLL1.LLV in CBS lower limit register c (CLLc)). Only 0 can be written to the bit. [Conditions for Changing] — The bit is set to 0 when the operating mode is not operation mode. — The bit is set to 1 when the value of the CBS counter status 1 (Class A) bit in the transmit status register (TSR.CCS1) changes from B'00 (indicating a value within the range between the limits) to B'01 (indicating a value less than the lower limit). 0: The interrupt is not pending. 1: The interrupt is pending.
4	CLLF0	0	R/W	CBS Lower Limit Error Interrupt Status (Class B) This bit indicates that CBS counter 0 has fallen below the set lower limit (CLL0.LLV in the CBS lower limit register c (CLLc)). Only 0 can be written to the bit. [Conditions for Changing] — The bit is set to 0 when the operating mode is not operation mode. — The bit is set to 1 when the value of the CBS counter status 0 (Class B) bit in the transmit status register (TSR.CCS0) changes from B'00 (indicating a value within the range between the limits) to B'01 (indicating a value less than the lower limit). 0: The interrupt is not pending. 1: The interrupt is pending.

Bit	Bit Name	Initial Value	R/W	Description
3	SEF	0	R/W	Separation Error Flag This bit indicates that a received frame was discarded because it has not matched any configurated separation filter for AVB stream data frames. The CPU can only write 0 to this bit. [Conditions for Changing] — This bit is set to 0 when leaving operation mode. — This bit is set to 1 when a valid AVB stream data frame was received by E-MAC but discarded because the RCR.ESF bits are B'10 and no separation filter has matched. 0: No interrupt pending. 1: AVB stream data frame has discarded.
2	QEF	0	R/W	Queue Error Flag This bit indicates that an error has been detected while processing reception or transmit queue or while processing AVTP FIFO entries. Details about the detected error is indicated by ESR. Section 33A.3.2.2 gives an overview of detail error conditions and the required interaction. The CPU can only write 0 to this bit. [Conditions for Changing] — This bit is set to 0 when leaving operating mode. — This bit is set to 1 when an error condition is detected. 0: No interrupt pending. 1: Interrupt pending.
1	MTEF	0	R/W	E-MAC Transmission Error Flag This bit indicates that the E-MAC has detected a fault during transmission. For detail, the E-MAC registers have to be checked. The CPU can only write 0 to this bit. [Conditions for Changing] — This bit is set to 0 when leaving operating mode. — This bit is set to 1 when E-MAC detects an error during frame transmission. 0: No interrupt pending. 1: E-MAC has reported an error during transmission.

Bit	Bit Name	Initial Value	R/W	Description
0	MREF	0	R/W	E-MAC Reception Error Flag This bit indicates that the E-MAC has detected a fault during reception. For detail, the E-MAC registers have to be checked. Note: When the storage of faulty received frames (RCR.EFFS) is enabled, the E-MAC error code (DESCR.MSC) is stored in the descriptor. By evaluating this information, CPU can identify corrupted frames in URAM. The CPU can only write 0 to this bit. [Conditions for Changing] — This bit is set to 0 when leaving operating mode. — This bit is set to 1 when E-MAC detects an error during frame reception. 0: No interrupt pending. 1: E-MAC has reported an error during reception.

33A.2.38 Receive Interrupt Control Register 0 (RIC0)

The RIC0 register controls the AVB-DMAC receive interrupts.

When an interrupt source flag is set (a bit from among the receive interrupt status bits in the receive interrupt status register (RIS0.FRF0 to 17) = 1) while the interrupt is enabled, the interrupt is issued.

[Changing condition]

This bit is set to 0 when writing 1 to RID0.FRDr.

This bit is set to 1 when writing 1 to RIE0.FRSr.

4	FRF4	0	R/W	Receive Frame Interrupt Status 4 (Stream) 0: The interrupt is not pending. 1: The interrupt is pending.
3	FRF3	0	R/W	Receive Frame Interrupt Status 3 (Stream) 0: The interrupt is not pending. 1: The interrupt is pending.
2	FRF2	0	R/W	Receive Frame Interrupt Status 2 (Stream) 0: The interrupt is not pending. 1: The interrupt is pending.
1	FRF1	0	R/W	Receive Frame Interrupt Status 1 (Network Control) 0: The interrupt is not pending. 1: The interrupt is pending.
0	FRF0	0	R/W	Receive Frame Interrupt Status 0 (Best Effort) 0: The interrupt is not pending. 1: The interrupt is pending.

FRF0 to FRF17 Receive Frame Interrupt Status Bits 0 to 17:

Each bit indicates that a corresponding frame has been stored normally in reception queues 0 to 17 and that data are ready for CPU processing.

Only 0 can be written to the bit.

[Conditions for Changing]

- A bit is set to 0 when the operating mode is not operation mode.
- A bit is set to 0 when a value is written to the unread frame counter decrement register i (UFCDi) (i = 0 to 4), and this decrements the value of unread frame counter register i (UFCVi) (i = 0 to 4) to 0.
- When a frame is stored normally in a reception queue, the corresponding bit is set to 1.

33A.2.40 Receive Interrupt Control Register 1 (RIC1)

The RIC1 register controls the AVB-DMAC receive interrupts.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RFWE	—	—	—	—	—	—	—	—	—	—	—	—	—	RWE17	RWE16

Bit	Bit Name	Initial Value	R/W	Description
31	RFWE	0	R/W	Receive FIFO Warning Interrupt Enable If the reception FIFO reaches the caution level (the value set in the receive FIFO caution level bits in the receive configuration register (RCR.RFCL)) with the corresponding interrupt enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID1.RFWD. This bit is set to 1 when writing 1 to RIE1.RFWS. 0: Disabled 1: Enabled
30 to 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
17	RWE17	0	R/W	Reception Warning interrupt Enable 17 While this bit is 1 an interrupt will be generated when RIS1.RWF17 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID1.RWD17. This bit is set to 1 when writing 1 to RIE1.RWS17. 0: Disabled 1: Enabled
16	RWE16	0	R/W	Reception Warning interrupt Enable 16 While this bit is 1 an interrupt will be generated when RIS1.RWF16 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID1.RWD16. This bit is set to 1 when writing 1 to RIE1.RWS16. 0: Disabled 1: Enabled

Bit	Bit Name	Initial Value	R/W	Description
15	RWE15	0	R/W	Reception Warning interrupt Enable 15 While this bit is 1 an interrupt will be generated when RIS1.RWF15 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID1.RWD15. This bit is set to 1 when writing 1 to RIE1.RWS15. 0: Disabled 1: Enabled
14	RWE14	0	R/W	Reception Warning interrupt Enable 14 While this bit is 1 an interrupt will be generated when RIS1.RWF14 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID1.RWD14. This bit is set to 1 when writing 1 to RIE1.RWS14. 0: Disabled 1: Enabled
13	RWE13	0	R/W	Reception Warning interrupt Enable 13 While this bit is 1 an interrupt will be generated when RIS1.RWF13 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID1.RWD13. This bit is set to 1 when writing 1 to RIE1.RWS13. 0: Disabled 1: Enabled
12	RWE12	0	R/W	Reception Warning interrupt Enable 17 While this bit is 1 an interrupt will be generated when RIS1.RWF12 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID1.RWD12. This bit is set to 1 when writing 1 to RIE1.RWS12. 0: Disabled 1: Enabled
11	RWE11	0	R/W	Reception Warning interrupt Enable 11 While this bit is 1 an interrupt will be generated when RIS1.RWF11 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID1.RWD11. This bit is set to 1 when writing 1 to RIE1.RWS11. 0: Disabled 1: Enabled
10	RWE10	0	R/W	Reception Warning interrupt Enable 10 While this bit is 1 an interrupt will be generated when RIS1.RWF10 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID1.RWD10. This bit is set to 1 when writing 1 to RIE1.RWS10. 0: Disabled 1: Enabled

Bit	Bit Name	Initial Value	R/W	Description
9	RWE9	0	R/W	Reception Warning interrupt Enable 9 While this bit is 1 an interrupt will be generated when RIS1.RWF9 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID1.RWD9. This bit is set to 1 when writing 1 to RIE1.RWS9. 0: Disabled 1: Enabled
8	RWE8	0	R/W	Reception Warning interrupt Enable 8 While this bit is 1 an interrupt will be generated when RIS1.RWF8 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID1.RWD18. This bit is set to 1 when writing 1 to RIE1.RWS18. 0: Disabled 1: Enabled
7	RWE7	0	R/W	Reception Warning interrupt Enable 7 While this bit is 1 an interrupt will be generated when RIS1.RWF7 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID1.RWD7. This bit is set to 1 when writing 1 to RIE1.RWS7. 0: Disabled 1: Enabled
6	RWE6	0	R/W	Reception Warning interrupt Enable 6 While this bit is 1 an interrupt will be generated when RIS1.RWF6 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID1.RWD6. This bit is set to 1 when writing 1 to RIE1.RWS6. 0: Disabled 1: Enabled
5	RWE5	0	R/W	Reception Warning interrupt Enable 5 While this bit is 1 an interrupt will be generated when RIS1.RWF5 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID1.RWD5. This bit is set to 1 when writing 1 to RIE1.RWS5. 0: Disabled 1: Enabled
4	RWE4	0	R/W	Reception Warning interrupt Enable 4 While this bit is 1 an interrupt will be generated when RIS1.RWF4 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID1.RWD4. This bit is set to 1 when writing 1 to RIE1.RWS4. 0: Disabled 1: Enabled

Bit	Bit Name	Initial Value	R/W	Description
3	RWE3	0	R/W	Reception Warning interrupt Enable 3 While this bit is 1 an interrupt will be generated when RIS1.RWF3 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID1.RWD3. This bit is set to 1 when writing 1 to RIE1.RWS3. 0: Disabled 1: Enabled
2	RWE2	0	R/W	Reception Warning interrupt Enable 2 While this bit is 1 an interrupt will be generated when RIS1.RWF2 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID1.RWD2. This bit is set to 1 when writing 1 to RIE1.RWS2. 0: Disabled 1: Enabled
1	RWE1	0	R/W	Reception Warning interrupt Enable 1 While this bit is 1 an interrupt will be generated when RIS1.RWF1 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID1.RWD1. This bit is set to 1 when writing 1 to RIE1.RWS1. 0: Disabled 1: Enabled
0	RWE0	0	R/W	Reception Warning interrupt Enable 0 While this bit is 1 an interrupt will be generated when RIS1.RWF0 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID1.RWD0. This bit is set to 1 when writing 1 to RIE1.RWS0. 0: Disabled 1: Enabled

33A.2.41 Receive Interrupt Status Register 1 (RIS1)

The RIS1 register indicates the states of the AVB-DMAC receive interrupts.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RFWF	—	—	—	—	—	—	—	—	—	—	—	—	—	RWF17	RWF16

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	RFWF	0	R/W	Receive FIFO Warning Interrupt Status This bit indicates that the reception FIFO has exceeded the set caution level (the value set in the receive FIFO caution level bits in the receive configuration register (RCR.RFCL)). Only 0 can be written to the bit. [Conditions for Changing] — The bit is set to 0 when the operating mode is not operation mode. — The bit is set to 1 when the reception FIFO exceeded the set caution level (the value set in the receive FIFO caution level bits in the receive configuration register (RCR.RFCL)). 0: The interrupt is not pending. 1: The interrupt is pending.
30 to 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
17	RWF17	0	R/W	Reception Warning Flag 17 This bit indicates that the unread frame counter of receive queue 17 has reached the configured warning level. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when CPU request a reload of the base address (DLR.LBA21 is 1). This bit is set to 0 when CPU writes to UFCD4.DV1 and UFCV4.CV1 is decremented to a value less than the selected warning level UFCW.WLj. This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (UFCV4.CV1 + 1 == UFCW.WLj). 0: No interrupt pending 1: Unread frame counter warning level reached

Bit	Bit Name	Initial Value	R/W	Description
16	RWF16	0	R/W	Reception Warning Flag 16 This bit indicates that the unread frame counter of receive queue 16 has reached the configured warning level. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when CPU request a reload of the base address (DLR.LBA20 is 1). This bit is set to 0 when CPU writes to UFCD4.DV0 and UFCV4.CV0 is decremented to a value less than the selected warning level UFCW.WLj. This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (UFCV4.CV0 + 1 == UFCW.WLj). 0: No interrupt pending 1: Unread frame counter warning level reached
15	RWF15	0	R/W	Reception Warning Flag 15 This bit indicates that the unread frame counter of receive queue 15 has reached the configured warning level. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when CPU request a reload of the base address (DLR.LBA19 is 1). This bit is set to 0 when CPU writes to UFCD3.DV3 and UFCV3.CV3 is decremented to a value less than the selected warning level UFCW.WLj. This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (UFCV3.CV3 + 1 == UFCW.WLj). 0: No interrupt pending 1: Unread frame counter warning level reached
14	RWF14	0	R/W	Reception Warning Flag 14 This bit indicates that the unread frame counter of receive queue 14 has reached the configured warning level. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when CPU request a reload of the base address (DLR.LBA18 is 1). This bit is set to 0 when CPU writes to UFCD3.DV2 and UFCV3.CV2 is decremented to a value less than the selected warning level UFCW.WLj. This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (UFCV3.CV2 + 1 == UFCW.WLj). 0: No interrupt pending 1: Unread frame counter warning level reached

Bit	Bit Name	Initial Value	R/W	Description
13	RWF13	0	R/W	Reception Warning Flag 13 This bit indicates that the unread frame counter of receive queue 13 has reached the configured warning level. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when CPU request a reload of the base address (DLR.LBA17 is 1). This bit is set to 0 when CPU writes to UFCD3.DV1 and UFCV3.CV1 is decremented to a value less than the selected warning level UFCW.WLj. This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (UFCV3.CV1 + 1 == UFCW.WLj). 0: No interrupt pending 1: Unread frame counter warning level reached
12	RWF12	0	R/W	Reception Warning Flag 12 This bit indicates that the unread frame counter of receive queue 12 has reached the configured warning level. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when CPU request a reload of the base address (DLR.LBA16 is 1). This bit is set to 0 when CPU writes to UFCD3.DV0 and UFCV3.CV0 is decremented to a value less than the selected warning level UFCW.WLj. This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (UFCV3.CV0 + 1 == UFCW.WLj). 0: No interrupt pending 1: Unread frame counter warning level reached
11	RWF11	0	R/W	Reception Warning Flag 11 This bit indicates that the unread frame counter of receive queue 11 has reached the configured warning level. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when CPU request a reload of the base address (DLR.LBA15 is 1). This bit is set to 0 when CPU writes to UFCD2.DV3 and UFCV2.CV3 is decremented to a value less than the selected warning level UFCW.WLj. This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (UFCV2.CV3 + 1 == UFCW.WLj). 0: No interrupt pending 1: Unread frame counter warning level reached

Bit	Bit Name	Initial Value	R/W	Description
10	RWF10	0	R/W	Reception Warning Flag 10 This bit indicates that the unread frame counter of receive queue 10 has reached the configured warning level. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when CPU request a reload of the base address (DLR.LBA14 is 1). This bit is set to 0 when CPU writes to UFCD2.DV2 and UFCV2.CV2 is decremented to a value less than the selected warning level UFCW.WLj. This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (UFCV2.CV2 + 1 == UFCW.WLj). 0: No interrupt pending 1: Unread frame counter warning level reached
9	RWF9	0	R/W	Reception Warning Flag 9 This bit indicates that the unread frame counter of receive queue 9 has reached the configured warning level. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when CPU request a reload of the base address (DLR.LBA13 is 1). This bit is set to 0 when CPU writes to UFCD2.DV1 and UFCV2.CV1 is decremented to a value less than the selected warning level UFCW.WLj. This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (UFCV2.CV1 + 1 == UFCW.WLj). 0: No interrupt pending 1: Unread frame counter warning level reached
8	RWF8	0	R/W	Reception Warning Flag 8 This bit indicates that the unread frame counter of receive queue 8 has reached the configured warning level. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when CPU request a reload of the base address (DLR.LBA12 is 1). This bit is set to 0 when CPU writes to UFCD2.DV0 and UFCV2.CV0 is decremented to a value less than the selected warning level UFCW.WLj. This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (UFCV2.CV0 + 1 == UFCW.WLj). 0: No interrupt pending 1: Unread frame counter warning level reached

Bit	Bit Name	Initial Value	R/W	Description
7	RWF7	0	R/W	Reception Warning Flag 7 This bit indicates that the unread frame counter of receive queue 7 has reached the configured warning level. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when CPU request a reload of the base address (DLR.LBA11 is 1). This bit is set to 0 when CPU writes to UFCD1.DV3 and UFCV1.CV3 is decremented to a value less than the selected warning level UFCW.WLj. This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (UFCV1.CV3 + 1 == UFCW.WLj). 0: No interrupt pending 1: Unread frame counter warning level reached
6	RWF6	0	R/W	Reception Warning Flag 6 This bit indicates that the unread frame counter of receive queue 6 has reached the configured warning level. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when CPU request a reload of the base address (DLR.LBA10 is 1). This bit is set to 0 when CPU writes to UFCD1.DV2 and UFCV1.CV2 is decremented to a value less than the selected warning level UFCW.WLj. This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (UFCV1.CV2 + 1 == UFCW.WLj). 0: No interrupt pending 1: Unread frame counter warning level reached
5	RWF5	0	R/W	Reception Warning Flag 5 This bit indicates that the unread frame counter of receive queue 5 has reached the configured warning level. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when CPU request a reload of the base address (DLR.LBA9 is 1). This bit is set to 0 when CPU writes to UFCD1.DV1 and UFCV1.CV1 is decremented to a value less than the selected warning level UFCW.WLj. This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (UFCV1.CV1 + 1 == UFCW.WLj). 0: No interrupt pending 1: Unread frame counter warning level reached

Bit	Bit Name	Initial Value	R/W	Description
4	RWF4	0	R/W	Reception Warning Flag 4 This bit indicates that the unread frame counter of receive queue 4 has reached the configured warning level. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when CPU request a reload of the base address (DLR.LBA8 is 1). This bit is set to 0 when CPU writes to UFCD1.DV0 and UFCV1.CV0 is decremented to a value less than the selected warning level UFCW.WLj. This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (UFCV1.CV0 + 1 == UFCW.WLj). 0: No interrupt pending 1: Unread frame counter warning level reached
3	RWF3	0	R/W	Reception Warning Flag 3 This bit indicates that the unread frame counter of receive queue 3 has reached the configured warning level. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when CPU request a reload of the base address (DLR.LBA7 is 1). This bit is set to 0 when CPU writes to UFCD0.DV3 and UFCV0.CV3 is decremented to a value less than the selected warning level UFCW.WLj. This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (UFCV0.CV3 + 1 == UFCW.WLj). 0: No interrupt pending 1: Unread frame counter warning level reached
2	RWF2	0	R/W	Reception Warning Flag 2 This bit indicates that the unread frame counter of receive queue 2 has reached the configured warning level. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when CPU request a reload of the base address (DLR.LBA6 is 1). This bit is set to 0 when CPU writes to UFCD0.DV2 and UFCV0.CV2 is decremented to a value less than the selected warning level UFCW.WLj. This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (UFCV0.CV2 + 1 == UFCW.WLj). 0: No interrupt pending 1: Unread frame counter warning level reached

Bit	Bit Name	Initial Value	R/W	Description
1	RWF1	0	R/W	Reception Warning Flag 1 This bit indicates that the unread frame counter of receive queue 1 has reached the configured warning level. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when CPU request a reload of the base address (DLR.LBA5 is 1). This bit is set to 0 when CPU writes to UFCD0.DV1 and UFCV0.CV1 is decremented to a value less than the selected warning level UFCW.WLj. This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (UFCV0.CV1 + 1 == UFCW.WLj). 0: No interrupt pending 1: Unread frame counter warning level reached
0	RWF0	0	R/W	Reception Warning Flag 0 This bit indicates that the unread frame counter of receive queue 0 has reached the configured warning level. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when CPU request a reload of the base address (DLR.LBA4 is 1). This bit is set to 0 when CPU writes to UFCD0.DV0 and UFCV0.CV0 is decremented to a value less than the selected warning level UFCW.WLj. This bit is set to 1 when a frame is stored in queue r and the unread frame counter value r is incremented to the selected warning level j (UFCV0.CV0 + 1 == UFCW.WLj). 0: No interrupt pending 1: Unread frame counter warning level reached

33A.2.42 Receive Interrupt Control Register 2 (RIC2)

The RIC2 register controls the AVB-DMAC receive interrupts.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RFFE	—	—	—	—	—	—	—	—	—	—	—	—	—	QFE17	QFE16

Bit	Bit Name	Initial Value	R/W	Description
31	RFFE	0	R/W	Receive FIFO Full Interrupt Enable When the reception FIFO is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.RFFD. This bit is set to 1 when writing 1 to RIE2.RFFS. 0: Disabled 1: Enabled
30 to 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
17	QFE17	0	R/W	Receive Queue 17 (Stream) Full Interrupt Enable When a reception queue is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.QFD17. This bit is set to 1 when writing 1 to RIE2.QFS17. 0: Disabled 1: Enabled
16	QFE16	0	R/W	Receive Queue 16 (Stream) Full Interrupt Enable When a reception queue is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.QFD16. This bit is set to 1 when writing 1 to RIE2.QFS16. 0: Disabled 1: Enabled
15	QFE15	0	R/W	Receive Queue 15 (Stream) Full Interrupt Enable When a reception queue is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.QFD15. This bit is set to 1 when writing 1 to RIE2.QFS15. 0: Disabled 1: Enabled

Bit	Bit Name	Initial Value	R/W	Description
14	QFE14	0	R/W	Receive Queue 14 (Stream) Full Interrupt Enable When a reception queue is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.QFD14. This bit is set to 1 when writing 1 to RIE2.QFS14. 0: Disabled 1: Enabled
13	QFE13	0	R/W	Receive Queue 13 (Stream) Full Interrupt Enable When a reception queue is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.QFD13. This bit is set to 1 when writing 1 to RIE2.QFS13. 0: Disabled 1: Enabled
12	QFE12	0	R/W	Receive Queue 12 (Stream) Full Interrupt Enable When a reception queue is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.QFD12. This bit is set to 1 when writing 1 to RIE2.QFS12. 0: Disabled 1: Enabled
11	QFE11	0	R/W	Receive Queue 11 (Stream) Full Interrupt Enable When a reception queue is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.QFD11. This bit is set to 1 when writing 1 to RIE2.QFS11. 0: Disabled 1: Enabled
10	QFE10	0	R/W	Receive Queue 10 (Stream) Full Interrupt Enable When a reception queue is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.QFD10. This bit is set to 1 when writing 1 to RIE2.QFS10. 0: Disabled 1: Enabled
9	QFE9	0	R/W	Receive Queue 9 (Stream) Full Interrupt Enable When a reception queue is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.QFD9. This bit is set to 1 when writing 1 to RIE2.QFS9. 0: Disabled 1: Enabled

Bit	Bit Name	Initial Value	R/W	Description
8	QFE8	0	R/W	Receive Queue 8 (Stream) Full Interrupt Enable When a reception queue is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.QFD8. This bit is set to 1 when writing 1 to RIE2.QFS8. 0: Disabled 1: Enabled
7	QFE7	0	R/W	Receive Queue 7 (Stream) Full Interrupt Enable When a reception queue is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.QFD7. This bit is set to 1 when writing 1 to RIE2.QFS7. 0: Disabled 1: Enabled
6	QFE6	0	R/W	Receive Queue 6 (Stream) Full Interrupt Enable When a reception queue is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.QFD6. This bit is set to 1 when writing 1 to RIE2.QFS6. 0: Disabled 1: Enabled
5	QFE5	0	R/W	Receive Queue 5 (Stream) Full Interrupt Enable When a reception queue is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.QFD5. This bit is set to 1 when writing 1 to RIE2.QFS5. 0: Disabled 1: Enabled
4	QFE4	0	R/W	Receive Queue 4 (Stream) Full Interrupt Enable When a reception queue is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.QFD4. This bit is set to 1 when writing 1 to RIE2.QFS4. 0: Disabled 1: Enabled
3	QFE3	0	R/W	Receive Queue 3 (Stream) Full Interrupt Enable When a reception queue is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.QFD3. This bit is set to 1 when writing 1 to RIE2.QFS3. 0: Disabled 1: Enabled

Bit	Bit Name	Initial Value	R/W	Description
2	QFE2	0	R/W	Receive Queue 2 (Stream) Full Interrupt Enable When a reception queue is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.QFD2. This bit is set to 1 when writing 1 to RIE2.QFS2. 0: Disabled 1: Enabled
1	QFE1	0	R/W	Receive Queue 1 (Network Control) Full Interrupt Enable When a reception queue is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.QFD1. This bit is set to 1 when writing 1 to RIE2.QFS1. 0: Disabled 1: Enabled
0	QFE0	0	R/W	Receive Queue 0 (Best Effort) Full Interrupt Enable When a reception queue is full and the interrupt is enabled, the interrupt is issued. [Changing condition] This bit is set to 0 when writing 1 to RID2.QFD0. This bit is set to 1 when writing 1 to RIE2.QFS0. 0: Disabled 1: Enabled

33A.2.43 Receive Interrupt Status Register 2 (RIS2)

The RIS2 register indicates the states of the AVB-DMAC receive interrupts.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RFFF	—	—	—	—	—	—	—	—	—	—	—	—	—	QFF17	QFF16
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	QFF15	QFF14	QFF13	QFF12	QFF11	QFF10	QFF9	QFF8	QFF7	QFF6	QFF5	QFF4	QFF3	QFF2	QFF1	QFF0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	RFFF	0	R/W	Receive FIFO Full Interrupt Status This bit indicates that a frame was received but storing it was not possible due to the reception FIFO being full. When receiving a frame is not possible, the frame will be discarded. Other information regarding discarded frames is not retained. Even if the frame is discarded, this bit may also be set to 1 if the E-MAC determines that the frame is an error frame Only 0 can be written to the bit. [Conditions for Changing] — The bit is set to 0 when the operating mode is not operation mode. — The bit is set to 1 when frame data provided by the E-MAC cannot be stored in the reception FIFO. 0: The interrupt is not pending. 1: The interrupt is pending
30 to 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
17	QFF17	0	R/W	Receive Queue 17 (Stream) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
16	QFF16	0	R/W	Receive Queue 16 (Stream) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
15	QFF15	0	R/W	Receive Queue 15 (Stream) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
14	QFF14	0	R/W	Receive Queue 14 (Stream) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
13	QFF13	0	R/W	Receive Queue 13 (Stream) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.

Bit	Bit Name	Initial Value	R/W	Description
12	QFF12	0	R/W	Receive Queue 12 (Stream) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
11	QFF11	0	R/W	Receive Queue 11 (Stream) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
10	QFF10	0	R/W	Receive Queue 10 (Stream) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
9	QFF9	0	R/W	Receive Queue 9 (Stream) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
8	QFF8	0	R/W	Receive Queue 8 (Stream) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
7	QFF7	0	R/W	Receive Queue 7 (Stream) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
6	QFF6	0	R/W	Receive Queue 6 (Stream) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
5	QFF5	0	R/W	Receive Queue 5 (Stream) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
4	QFF4	0	R/W	Receive Queue 4 (Stream) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
3	QFF3	0	R/W	Receive Queue 3 (Stream) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
2	QFF2	0	R/W	Receive Queue 2 (Stream) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
1	QFF1	0	R/W	Receive Queue 1 (Network Control) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.
0	QFF0	0	R/W	Receive Queue 0 (Best Effort) Full Interrupt Status 0: The interrupt is not pending. 1: The interrupt is pending.

QFF0 to 17 Receive 0 to 17 Full Interrupt Status Bits:

These bits indicate that reception queue r did not have space for storing a received frame.

A reception queue is treated as full when it has no descriptors (descriptor type (DESCR.DT) = FEMPTY, FEMPTY_IS, FEMPTY_IC, or FEMPTY_ND) available or reaches the set level for stopping.

Note: If no FEMPTY descriptors or no empty space for descriptors remains in the queue during storing of a divided frame (see section 33A.3.4.3(1) Storing Frame Data in the Descriptor Data Area, for storing a frame as a divided frame), an error frame is stored in the queue. Such error frames are treated as descriptor sequence errors.

[Conditions for Changing]

- A bit is set to 0 when the operating mode is not operation mode.
- A bit is set to 1 when reception queue r has no space available for storage.
- A bit is set to 1 when a SW defined stop point (EOS descriptor) reached within a split frame.
- A bit is set to 1 when the unread frame counter (unread frame counter register i (UFCVi) (i = 0 to 4)) reaches the set level for stopping.

33A.2.44 Transmit Interrupt Control Register (TIC)

The TIC register controls the AVB-DMAC transmit interrupts.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
19	TDPE3	0	R/W	Transmit Descriptor Processed interrupt Enable 3 While this bit is 1 an interrupt will be generated when TIS.TDPF3 is 1. [Changing condition] This bit is set to 0 when writing 1 to TID.TDPD3. This bit is set to 1 when writing 1 to TIE.TDPS3. 0: Disabled 1: Enabled
18	TDPE2	0	R/W	Transmit Descriptor Processed interrupt Enable 2 While this bit is 1 an interrupt will be generated when TIS.TDPF2 is 1. [Changing condition] This bit is set to 0 when writing 1 to TID.TDPD2. This bit is set to 1 when writing 1 to TIE.TDPS2. 0: Disabled 1: Enabled
17	TDPE1	0	R/W	Transmit Descriptor Processed interrupt Enable 1 While this bit is 1 an interrupt will be generated when TIS.TDPF1 is 1. [Changing condition] This bit is set to 0 when writing 1 to TID.TDPD1. This bit is set to 1 when writing 1 to TIE.TDPS1. 0: Disabled 1: Enabled
16	TDPE0	0	R/W	Transmit Descriptor Processed interrupt Enable 0 While this bit is 1 an interrupt will be generated when TIS.TDPF0 is 1. [Changing condition] This bit is set to 0 when writing 1 to TID.TDPD0. This bit is set to 1 when writing 1 to TIE.TDPS0. 0: Disabled 1: Enabled

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
11	MFWE	0	R/W	MAC status FIFO Warning interrupt Enable While this bit is 1 an interrupt will be generated when TIS.MFWF is 1. [Changing condition] This bit is set to 0 when writing 1 to TID.MFWD. This bit is set to 1 when writing 1 to TIE.MFWS. 0: Disabled 1: Enabled
10	MFUE	0	R/W	MAC status FIFO Updated interrupt Enable While this bit is 1 an interrupt will be generated when TIS.MFUF is 1. [Changing condition] This bit is set to 0 when writing 1 to TID.MFUD. This bit is set to 1 when writing 1 to TIE.MFUS. 0: Disabled 1: Enabled
9	TFWE	0	R/W	Time Stamp FIFO Warning Interrupt Enable When the time-stamp FIFO reaches the warning level while the interrupt is enabled, the interrupt is issued. 0: Disabled 1: Enabled
8	TFUE	0	R/W	Time Stamp FIFO Update Interrupt Enable When the time-stamp FIFO is updated while the interrupt is enabled, the interrupt is issued. 0: Disabled 1: Enabled
7 to 4	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
3	FTE3	0	R/W	Frame Transmitted interrupt Enable 3 While this bit is 1 an interrupt will be generated when TIS.FTF3 is 1. [Changing condition] This bit is set to 0 when writing 1 to TID.FTD3. This bit is set to 1 when writing 1 to TIE.FTS3. 0: Disabled 1: Enabled
2	FTE2	0	R/W	Frame Transmitted interrupt Enable 2 While this bit is 1 an interrupt will be generated when TIS.FTF2 is 1. [Changing condition] This bit is set to 0 when writing 1 to TID.FTD2. This bit is set to 1 when writing 1 to TIE.FTS2. 0: Disabled 1: Enabled

Bit	Bit Name	Initial Value	R/W	Description
1	FTE1	0	R/W	Frame Transmitted interrupt Enable 1 While this bit is 1 an interrupt will be generated when TIS.FTF1 is 1. [Changing condition] This bit is set to 0 when writing 1 to TID.FTD1. This bit is set to 1 when writing 1 to TIE.FTS1. 0: Disabled 1: Enabled
0	FTE0	0	R/W	Frame Transmitted interrupt Enable 0 While this bit is 1 an interrupt will be generated when TIS.FTF0 is 1. [Changing condition] This bit is set to 0 when writing 1 to TID.FTD0. This bit is set to 1 when writing 1 to TIE.FTS0. 0: Disabled 1: Enabled

33A.2.45 Transmit Interrupt Status Register (TIS)

The TIS register indicates the states of the AVB-DMAC transmit interrupts.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	TDPF3	TDPF2	TDPF1	TDPF0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	MFWF	MFUF	TFWF	TFUF	—	—	—	—	FTF3	FTF2	FTF1	FTF0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
19	TDPF3	0	R/W	Transmit Descriptor Processed Flag 3 This bit indicates that a descriptor in transmit queue 3 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in transmit queue 3 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending
18	TDPF2	0	R/W	Transmit Descriptor Processed Flag 2 This bit indicates that a descriptor in transmit queue 2 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in transmit queue 2 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending

Bit	Bit Name	Initial Value	R/W	Description
17	TDPF1	0	R/W	Transmit Descriptor Processed Flag 1 This bit indicates that a descriptor in transmit queue 1 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in transmit queue 1 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending
16	TDPF0	0	R/W	Transmit Descriptor Processed Flag 0 This bit indicates that a descriptor in transmit queue 0 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in transmit queue 0 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending
15 to 12	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
11	MFWF	0	R/W	E-MAC status FIFO Warning Flag This bit indicates that the warning level of the E-MAC status FIFO (12 out of 16 entries) has been reached. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when TCCR.MFEN is 0. This bit is set to 0 when writing 1 to TCCR.MFR. This bit is set to 1 when a frame with DESCR.MSR has been transmitted by E-MAC and the E-MAC Status FIFO contains already 11 entries (TSR.MFFL is 11). This bit is set to 1 when E-MAC detects an error during transmission and the E-MAC Status FIFO contains already 11 entries (TSR.MFFL is 11). 0: No interrupt pending 1: Tx Status FIFO warning level has been reached

Bit	Bit Name	Initial Value	R/W	Description
10	MFUF	0	R/W	E-MAC status FIFO Updated Flag This bit indicates that the E-MAC status FIFO has been updated after the E-MAC has transmitted a frame. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 0 when TCCR.MFEN is 0. This bit is set to 0 when writing 1 to TCCR.MFR. This bit is set to 1 when a frame with DESCR.MSR has been transmitted by E-MAC and TCCR.MFEN is 1. This bit is set to 1 when E-MAC detects an error during transmission and TCCR.MFEN is 1. 0: No interrupt pending 1: Tx Status FIFO has been updated
9	TFWF	0	R/W	Time Stamp FIFO Warning Interrupt Status This bit indicates that the transmission time-stamp FIFO has reached the warning level. Only 0 can be written to the bit. [Conditions for Changing] — The bit is set to 0 when the operating mode is not operation mode and when the time stamp FIFO enable bit in the transmit configuration control register (TCCR.TFEN) is 0. — The bit is set to 1 after a frame including DESCR.TSR set has been transmitted and one entry has already been stored in the time-stamp FIFO. 0: The interrupt is not pending. 1: The time-stamp FIFO has reached the warning level.
8	TFUF	0	R/W	Time Stamp FIFO Update Interrupt Status This bit indicates that the transmission time-stamp FIFO has been updated. Only 0 can be written to the bit. [Conditions for Changing] — The bit is set to 0 when the operating mode is not operation mode, when the time stamp FIFO enable bit in the transmit configuration control register (TCCR.TFEN) is 0, and when 1 is written to the time stamp FIFO release bit in the transmit configuration control register (TCCR.TFR). — The bit is set to 1 when the time stamp FIFO enable bit (TCCR.TFEN) is 1 after a frame including DESCR.TSR set has been transmitted. 0: The interrupt is not pending. 1: The time-stamp FIFO has been updated.
7 to 4	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.

Bit	Bit Name	Initial Value	R/W	Description
3	FTF3	0	R/W	Frame Transmitted Flag 3 This bit indicates that from transmit queue a frame is transmitted by E-MAC. Note: This interrupt flag refers to the end of frame transmission by E-MAC whereas the descriptor interrupt (DIS.DPFi) refers to the end of processing storage element. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a frame from transmit queue 3 has been transmitted by the E-MAC. 0: No interrupt pending 1: Frame transmitted by E-MAC
2	FTF2	0	R/W	Frame Transmitted Flag 2 This bit indicates that from transmit queue a frame is transmitted by E-MAC. Note: This interrupt flag refers to the end of frame transmission by E-MAC whereas the descriptor interrupt (DIS.DPFi) refers to the end of processing storage element. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a frame from transmit queue 2 has been transmitted by the E-MAC. 0: No interrupt pending 1: Frame transmitted by E-MAC
1	FTF1	0	R/W	Frame Transmitted Flag 1 This bit indicates that from transmit queue a frame is transmitted by E-MAC. Note: This interrupt flag refers to the end of frame transmission by E-MAC whereas the descriptor interrupt (DIS.DPFi) refers to the end of processing storage element. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a frame from transmit queue 1 has been transmitted by the E-MAC. 0: No interrupt pending 1: Frame transmitted by E-MAC

Bit	Bit Name	Initial Value	R/W	Description
0	FTF0	0	R/W	Frame Transmitted Flag 0 This bit indicates that from transmit queue a frame is transmitted by E-MAC. Note: This interrupt flag refers to the end of frame transmission by E-MAC whereas the descriptor interrupt (DIS.DPFi) refers to the end of processing storage element. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a frame from transmit queue 0 has been transmitted by the E-MAC. 0: No interrupt pending 1: Frame transmitted by E-MAC

33A.2.46 Interrupt Summary Status Register (ISS)

The ISS register gives a summary of the states of AVB-DMAC-related interrupts.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	DPM15	0	R	Descriptor Interrupt 15 Mirror This bit is set to 1 when the given descriptor interrupt enable bit (DIC.DPE15) and descriptor interrupt status flag (DIS.DPF15) are both 1. 0: The interrupt is not pending. 1: The interrupt is pending.
30	DPM14	0	R	Descriptor Interrupt 14 Mirror This bit is set to 1 when the given descriptor interrupt enable bit (DIC.DPE14) and descriptor interrupt status flag (DIS.DPF14) are both 1. 0: The interrupt is not pending. 1: The interrupt is pending.
29	DPM13	0	R	Descriptor Interrupt 13 Mirror This bit is set to 1 when the given descriptor interrupt enable bit (DIC.DPE13) and descriptor interrupt status flag (DIS.DPF13) are both 1. 0: The interrupt is not pending. 1: The interrupt is pending.
28	DPM12	0	R	Descriptor Interrupt 12 Mirror This bit is set to 1 when the given descriptor interrupt enable bit (DIC.DPE12) and descriptor interrupt status flag (DIS.DPF12) are both 1. 0: The interrupt is not pending. 1: The interrupt is pending.
27	DPM11	0	R	Descriptor Interrupt 11 Mirror This bit is set to 1 when the given descriptor interrupt enable bit (DIC.DPE11) and descriptor interrupt status flag (DIS.DPF11) are both 1. 0: The interrupt is not pending. 1: The interrupt is pending.
26	DPM10	0	R	Descriptor Interrupt 10 Mirror This bit is set to 1 when the given descriptor interrupt enable bit (DIC.DPE10) and descriptor interrupt status flag (DIS.DPF10) are both 1. 0: The interrupt is not pending. 1: The interrupt is pending.

Bit	Bit Name	Initial Value	R/W	Description
25	DPM9	0	R	Descriptor Interrupt 9 Mirror This bit is set to 1 when the given descriptor interrupt enable bit (DIC.DPE9) and descriptor interrupt status flag (DIS.DPF9) are both 1. 0: The interrupt is not pending. 1: The interrupt is pending.
24	DPM8	0	R	Descriptor Interrupt 8 Mirror This bit is set to 1 when the given descriptor interrupt enable bit (DIC.DPE8) and descriptor interrupt status flag (DIS.DPF8) are both 1. 0: The interrupt is not pending. 1: The interrupt is pending.
23	DPM7	0	R	Descriptor Interrupt 7 Mirror This bit is set to 1 when the given descriptor interrupt enable bit (DIC.DPE7) and descriptor interrupt status flag (DIS.DPF7) are both 1. 0: The interrupt is not pending. 1: The interrupt is pending.
22	DPM6	0	R	Descriptor Interrupt 6 Mirror This bit is set to 1 when the given descriptor interrupt enable bit (DIC.DPE6) and descriptor interrupt status flag (DIS.DPF6) are both 1. 0: The interrupt is not pending. 1: The interrupt is pending.
21	DPM5	0	R	Descriptor Interrupt 5 Mirror This bit is set to 1 when the given descriptor interrupt enable bit (DIC.DPE5) and descriptor interrupt status flag (DIS.DPF5) are both 1. 0: The interrupt is not pending. 1: The interrupt is pending.
20	DPM4	0	R	Descriptor Interrupt 4 Mirror This bit is set to 1 when the given descriptor interrupt enable bit (DIC.DPE4) and descriptor interrupt status flag (DIS.DPF4) are both 1. 0: The interrupt is not pending. 1: The interrupt is pending.
19	DPM3	0	R	Descriptor Interrupt 3 Mirror This bit is set to 1 when the given descriptor interrupt enable bit (DIC.DPE3) and descriptor interrupt status flag (DIS.DPF3) are both 1. 0: The interrupt is not pending. 1: The interrupt is pending.
18	DPM2	0	R	Descriptor Interrupt 2 Mirror This bit is set to 1 when the given descriptor interrupt enable bit (DIC.DPE2) and descriptor interrupt status flag (DIS.DPF2) are both 1. 0: The interrupt is not pending. 1: The interrupt is pending.

Bit	Bit Name	Initial Value	R/W	Description
17	DPM1	0	R	Descriptor Interrupt 1 Mirror This bit is set to 1 when the given descriptor interrupt enable bit (DIC.DPE1) and descriptor interrupt status flag (DIS.DPF1) are both 1. 0: The interrupt is not pending. 1: The interrupt is pending.
16 to 14	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
13	CGIM	0	R	gPTP Interrupt Mirror This bit is set to 1 when either interrupt-related bit in the two gPTP-related interrupt registers (GIC and GIS) is 1. 0: The interrupt is not pending. 1: The interrupt is pending.
12	RFWM	0	R	Receive FIFO Warning Interrupt Mirror This bit is set to 1 when the receive FIFO warning interrupt enable bit (RIC1.RFWE) and receive FIFO warning interrupt status flag (RIS1.RFWF) are both 1. 0: The interrupt is not pending. 1: The interrupt is pending.
11	MFWM	0	R	E-MAC status FIFO Warning Mirror This bit indicates that TIS.MFWF is 1 and TIC.MFWE is 1. [Changing condition] This bit is updated when TIS.MFWF or TIC.MFWE changes. 0: No interrupt pending 1: E-MAC status FIFO warning interrupt pending
10	MFUM	0	R	E-MAC status FIFO Updated Mirror This bit indicates that TIS.MFUF is 1 and TIC.MFUE is 1. [Changing condition] This bit is updated when TIS.MFUF or TIC.MFUE changes. 0: No interrupt pending 1: E-MAC status FIFO updated interrupt pending
9	TFWM	0	R	Time Stamp FIFO Warning Interrupt Mirror This bit is set to 1 when the time stamp FIFO warning interrupt enable bit (TIC.TFWE) and time stamp FIFO warning interrupt status flag (TIS.TFWF) are both 1. 0: The interrupt is not pending. 1: The interrupt is pending.
8	TFUM	0	R	Time Stamp FIFO Update Mirror This bit is set to 1 when the time stamp FIFO update interrupt enable bit (TIC.TFUE) and time stamp FIFO update interrupt status flag (TIS.TFUF) are both 1. 0: The interrupt is not pending. 1: The interrupt is pending.
7	MM	0	R	E-MAC Interrupt Mirror This bit is set to 1 when an E-MAC interrupt is issued. 0: The interrupt is not pending. 1: The interrupt is pending.

Bit	Bit Name	Initial Value	R/W	Description
6	EM	0	R	Error Interrupt Mirror This bit is set to 1 when an error interrupt is issued (both of a bit in EIS and corresponding to the bit in EIC are 1). 0: The interrupt is not pending. 1: The interrupt is pending.
5 to 3	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
2	FTM	0	R	Frame Transmitted Mirror [Changing condition] This bit is set when any matching pair of TIC.FTEt enable and TIS.FTFt flag are both 1. This bit is set when any matching pair of TIC.TDPEt enable and TIS.TDPFt flag are both 1. 0: No interrupt pending 1: Frame transmitted interrupt pending
1	RWM	0	R	Reception Warning Mirror [Changing condition] This bit is set when any matching pair of RIC1.RWEr enable and RIS1.RWFr flag are both 1. 0: No interrupt pending 1: Frame transmitted interrupt pending
0	FRM	0	R	Frame Received Mirror [Changing condition] This bit is set when any matching pair of RIC0.FREr enable and RIS0.FRFr flag are both 1. This bit is set when any matching pair of RIC3.RDPEr enable and RIS3.RDPFr flag are both 1. 0: No interrupt pending 1: Frame received interrupt pending

33A.2.47 Common Interrupt Enable register (CIE)

The CIE register is used to control the Common Interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	RFFL	RFWL	CL0M	RQFM
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	CTIE	—	—	—	—	—	—	—	CRIE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
19	RFFL	0	R/W	Rx-FIFO Full interrupt Line select This bit selects the interrupt line of notification flagged by RIS2.RFFF. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
18	RFWL	0	R/W	Rx-FIFO Warning interrupt Line select This bit selects the interrupt line of notification flagged by RIS1.RFWF. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
17	CL0M	0	R/W	Common Line 0 Mode This bit controls if all data related interrupts using a common interrupt line or if queue specific interrupt lines for data related interrupts are used. The selected mode has no influence to internal flagging in EthernetAVB register (e.g. ISS). To prevent interrupt notifications on different lines, it is recommended to set all CIE.CTIE, CIE.CRIE, and DIL.DPLi (i=2 to 15) to 0 when this bit is 1. 0: Use common interrupt line 0 1: Use queue specific interrupt line 0
16	RQFM	0	R/W	Reception Queue Full Mode This bit controls if queue full notification is mapped to error interrupt line or to queue data interrupt line. The selected mode has no influence to internal flagging in EthernetAVB register (e.g. ISS). 0: Use for error interrupt line 1: Use for queue specific interrupt line
15 to 9	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.

Bit	Bit Name	Initial Value	R/W	Description
8	CTIE	0	R/W	Common Transmit Interrupt Enable This bit controls transmit related interrupt line outputs of EthernetAVB. It has no influence to internal flagging in EthernetAVB register (e.g. ISS). These lines are controlled by this bit: line0_Tx[3:0] -- individual transmit queue interrupts Transmission interrupts mapped on other lines are not influenced. 0: Disabled 1: Enabled
7 to 1	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
0	CRIE	0	R/W	Common Receive Interrupt enable This bit controls receive related interrupt line outputs of EthernetAVB. It has no influence to internal flagging in EthernetAVB register (e.g. ISS). These lines are controlled by this bit: line0_Rx[17:0] -- individual receive queue interrupts Receive interrupts mapped on other lines are not influenced. 0: Disabled 1: Enabled

33A.2.48 Reception Interrupt Control register 3 (RIC3)

The RIC3 register controls the AVB-DMAC receive descriptor interrupts.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RDPE17	RDPE16

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
17	RDPE17	0	R/W	Receive Descriptor Processed interrupt Enable 17 While this bit is 1 an interrupt will be generated when RIS3.RDPF17 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID3.RDPD17. This bit is set to 1 when writing 1 to RIE3.RDPS17. 0: Disabled 1: Enabled
16	RDPE16	0	R/W	Receive Descriptor Processed interrupt Enable 16 While this bit is 1 an interrupt will be generated when RIS3.RDPF16 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID3.RDPD16. This bit is set to 1 when writing 1 to RIE3.RDPS16. 0: Disabled 1: Enabled
15	RDPE15	0	R/W	Receive Descriptor Processed interrupt Enable 15 While this bit is 1 an interrupt will be generated when RIS3.RDPF15 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID3.RDPD15. This bit is set to 1 when writing 1 to RIE3.RDPS15. 0: Disabled 1: Enabled
14	RDPE14	0	R/W	Receive Descriptor Processed interrupt Enable 14 While this bit is 1 an interrupt will be generated when RIS3.RDPF14 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID3.RDPD14. This bit is set to 1 when writing 1 to RIE3.RDPS14. 0: Disabled 1: Enabled

Bit	Bit Name	Initial Value	R/W	Description
13	RDPE13	0	R/W	Receive Descriptor Processed interrupt Enable 13 While this bit is 1 an interrupt will be generated when RIS3.RDPF13 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID3.RDPD13. This bit is set to 1 when writing 1 to RIE3.RDPS13. 0: Disabled 1: Enabled
12	RDPE12	0	R/W	Receive Descriptor Processed interrupt Enable 12 While this bit is 1 an interrupt will be generated when RIS3.RDPF12 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID3.RDPD12. This bit is set to 1 when writing 1 to RIE3.RDPS12. 0: Disabled 1: Enabled
11	RDPE11	0	R/W	Receive Descriptor Processed interrupt Enable 11 While this bit is 1 an interrupt will be generated when RIS3.RDPF11 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID3.RDPD11. This bit is set to 1 when writing 1 to RIE3.RDPS11. 0: Disabled 1: Enabled
10	RDPE10	0	R/W	Receive Descriptor Processed interrupt Enable 10 While this bit is 1 an interrupt will be generated when RIS3.RDPF10 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID3.RDPD10. This bit is set to 1 when writing 1 to RIE3.RDPS10. 0: Disabled 1: Enabled
9	RDPE9	0	R/W	Receive Descriptor Processed interrupt Enable 9 While this bit is 1 an interrupt will be generated when RIS3.RDPF9 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID3.RDPD9. This bit is set to 1 when writing 1 to RIE3.RDPS9. 0: Disabled 1: Enabled
8	RDPE8	0	R/W	Receive Descriptor Processed interrupt Enable 8 While this bit is 1 an interrupt will be generated when RIS3.RDPF8 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID3.RDPD8. This bit is set to 1 when writing 1 to RIE3.RDPS8. 0: Disabled 1: Enabled

Bit	Bit Name	Initial Value	R/W	Description
7	RDPE7	0	R/W	Receive Descriptor Processed interrupt Enable 7 While this bit is 1 an interrupt will be generated when RIS3.RDPF7 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID3.RDPD7. This bit is set to 1 when writing 1 to RIE3.RDPS7. 0: Disabled 1: Enabled
6	RDPE6	0	R/W	Receive Descriptor Processed interrupt Enable 6 While this bit is 1 an interrupt will be generated when RIS3.RDPF6 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID3.RDPD6. This bit is set to 1 when writing 1 to RIE3.RDPS6. 0 Disabled 1 Enabled
5	RDPE5	0	R/W	Receive Descriptor Processed interrupt Enable 5 While this bit is 1 an interrupt will be generated when RIS3.RDPF5 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID3.RDPD5. This bit is set to 1 when writing 1 to RIE3.RDPS5. 0: Disabled 1: Enabled
4	RDPE4	0	R/W	Receive Descriptor Processed interrupt Enable 4 While this bit is 1 an interrupt will be generated when RIS3.RDPF4 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID3.RDPD4. This bit is set to 1 when writing 1 to RIE3.RDPS4. 0: Disabled 1: Enabled
3	RDPE3	0	R/W	Receive Descriptor Processed interrupt Enable 3 While this bit is 1 an interrupt will be generated when RIS3.RDPF3 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID3.RDPD3. This bit is set to 1 when writing 1 to RIE3.RDPS3. 0: Disabled 1: Enabled
2	RDPE2	0	R/W	Receive Descriptor Processed interrupt Enable 2 While this bit is 1 an interrupt will be generated when RIS3.RDPF2 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID3.RDPD2. This bit is set to 1 when writing 1 to RIE3.RDPS2. 0: Disabled 1: Enabled

Bit	Bit Name	Initial Value	R/W	Description
1	RDPE1	0	R/W	Receive Descriptor Processed interrupt Enable 1 While this bit is 1 an interrupt will be generated when RIS3.RDPF1 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID3.RDPD1. This bit is set to 1 when writing 1 to RIE3.RDPS1. 0: Disabled 1: Enabled
0	RDPE0	0	R/W	Receive Descriptor Processed interrupt Enable 0 While this bit is 1 an interrupt will be generated when RIS3.RDPF0 is 1. [Changing condition] This bit is set to 0 when writing 1 to RID3.RDPD0. This bit is set to 1 when writing 1 to RIE3.RDPS0. 0: Disabled 1: Enabled

33A.2.49 Reception Interrupt Status register 3 (RIS3)

The RIS3 register indicates the states of the AVB-DMAC receive descriptor interrupts.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
17	RDPF17	0	R/W	Receive Descriptor Processed Flag 17 This bit indicates that a descriptor in reception queue 17 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in reception queue 17 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending
16	RDPF16	0	R/W	Receive Descriptor Processed Flag 16 This bit indicates that a descriptor in reception queue 16 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in reception queue 16 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending

Bit	Bit Name	Initial Value	R/W	Description
15	RDPF15	0	R/W	Receive Descriptor Processed Flag 15 This bit indicates that a descriptor in reception queue 15 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in reception queue 15 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending
14	RDPF14	0	R/W	Receive Descriptor Processed Flag 14 This bit indicates that a descriptor in reception queue 14 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in reception queue 14 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending
13	RDPF13	0	R/W	Receive Descriptor Processed Flag 13 This bit indicates that a descriptor in reception queue 13 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in reception queue 13 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending
12	RDPF12	0	R/W	Receive Descriptor Processed Flag 12 This bit indicates that a descriptor in reception queue 12 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in reception queue 12 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending

Bit	Bit Name	Initial Value	R/W	Description
11	RDPF11	0	R/W	Receive Descriptor Processed Flag 11 This bit indicates that a descriptor in reception queue 11 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in reception queue 11 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending
10	RDPF10	0	R/W	Receive Descriptor Processed Flag 10 This bit indicates that a descriptor in reception queue 10 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in reception queue 10 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending
9	RDPF9	0	R/W	Receive Descriptor Processed Flag 9 This bit indicates that a descriptor in reception queue 9 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in reception queue 9 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending
8	RDPF8	0	R/W	Receive Descriptor Processed Flag 8 This bit indicates that a descriptor in reception queue 8 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in reception queue 8 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending

Bit	Bit Name	Initial Value	R/W	Description
7	RDPF7	0	R/W	Receive Descriptor Processed Flag 7 This bit indicates that a descriptor in reception queue 7 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in reception queue 7 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending
6	RDPF6	0	R/W	Receive Descriptor Processed Flag 6 This bit indicates that a descriptor in reception queue 6 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in reception queue 6 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending
5	RDPF5	0	R/W	Receive Descriptor Processed Flag 5 This bit indicates that a descriptor in reception queue 5 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in reception queue 5 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending
4	RDPF4	0	R/W	Receive Descriptor Processed Flag 4 This bit indicates that a descriptor in reception queue 4 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in reception queue 4 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending

Bit	Bit Name	Initial Value	R/W	Description
3	RDPF3	0	R/W	Receive Descriptor Processed Flag 3 This bit indicates that a descriptor in reception queue 3 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in reception queue 3 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending
2	RDPF2	0	R/W	Receive Descriptor Processed Flag 2 This bit indicates that a descriptor in reception queue 2 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in reception queue 2 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending
1	RDPF1	0	R/W	Receive Descriptor Processed Flag 1 This bit indicates that a descriptor in reception queue 1 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in reception queue 1 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending
0	RDPF0	0	R/W	Receive Descriptor Processed Flag 0 This bit indicates that a descriptor in reception queue 0 has been processed where DESCR.DIE is B'0001. Note: The descriptor with DESCR.DIE is 1, which sets this bit, sets in addition the universal descriptor interrupt DIS.DPF1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode. This bit is set to 1 when a descriptor in reception queue 0 has been processed where DESCR.DIE is 1. 0: No interrupt pending 1: Descriptor interrupt pending

33A.2.50 gPTP Configuration Control Register (GCCR)

The GCCR register is used to set and control the gPTP (generalized precision time protocol).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	LI[2:0]			SPC	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TCSS[1:0]		—	—	LMTT	LPTC	LTI	LTO	TCR[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	1	0	1	1	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

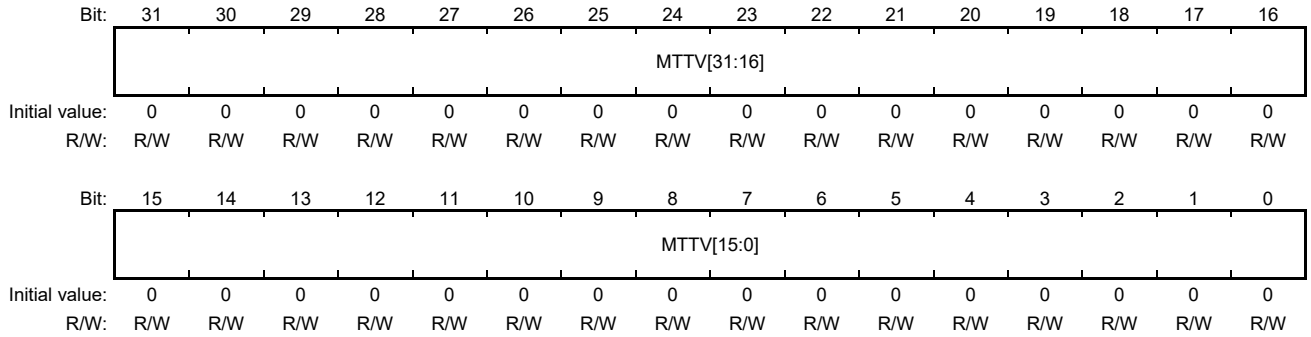
Bit	Bit Name	Initial Value	R/W	Description
31 to 23	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
22 to 20	LI[2:0]	000	R/W	Index number of compare unit to be loaded Load Index These bits define the target unit to be updated by GCCR.LPTC. The CPU can only write to these bits if GCCR.LPTC is 0.
19	SPC	0	R/W	Start Periodic Comparison This bit defines if the absolute comparison value or the periodicity value is updated to the value of GPTC.PTCV on GCCR.LPTC request. Periodic comparison starts when updating the periodic comparison value; periodic comparison stops when updating the absolute comparison value. The CPU can only write to these bits if GCCR.LPTC is 0. 0: Absolute comparison value updated by GCCR.LPTC request 1: Periodic comparison value updated by GCCR.LPTC request
18 to 10	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
9, 8	TCSS[1:0]	00	R/W	Timer Capture Source Select These bits select the source used for updating the captured timer register (gPTP timer capture register (GCTi.CTV)). These bits should still be controlled when timer control is not being requested (GCCR.TCR = 0). 00: gPTP timer value 01: Adjusted gPTP timer value 10: AVTP presentation time 11: Setting prohibited
7, 6	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.

Bit	Bit Name	Initial Value	R/W	Description
5	LMTT	1	R/W	Maximum Transit Time Configuration Request This bit issues requests for configuring the gPTP maximum transit time configuration register (GMTT). Only 1 can be written to the bit. [Conditions for Changing] — The bit is set to 1 when the operating mode is not operation mode. — The bit is set to 0 when the value of the gPTP maximum transit time configuration register (GMTT) is loaded. 0: Setting completed 1: When written: Issue a configuration request. When read: Completion of settings is pending.
4	LPTC	0	R/W	Presentation Time Compare Value Configuration Request This bit issues requests for configuring the gPTP presentation time comparison register (GPTC). Only 1 can be written to the bit. The CPU cannot write to this bit if CSR.OPS is CONFIG and CCC.GAC is 0. The CPU should not write 1 to this bit when AVTP FIFO of selected compare unit is in use. [Conditions for Changing] — The bit is set to 1 when the operating mode is not operation mode and CCC.GAC is 0. — The bit is set to 0 when the value of the gPTP presentation time comparison register (GPTC) is loaded. 0: Setting completed 1: When written: Issue a configuration request. When read: Completion of settings is pending.
3	LTI	1	R/W	Timer Increment Value Configuration Request This bit issues requests for configuring the gPTP timer increment configuration register (GTI). Only 1 can be written to the bit. [Conditions for Changing] — The bit is set to 1 when the operating mode is not operation mode and CCC.GAC is 0. — The bit is set to 0 when the value of the gPTP timer increment configuration register (GTI) is loaded. 0: Setting completed 1: When written: Issue a configuration request. When read: Completion of settings is pending.

Bit	Bit Name	Initial Value	R/W	Description
2	LTO	1	R/W	Timer Offset Value Configuration Request This bit issues requests for configuring gPTP timer offset configuration register i (GTOi). Only 1 can be written to the bit. [Conditions for Changing] — The bit is set to 1 when the operating mode is not operation mode and CCC.GAC is 0. — The bit is set to 0 when the value of gPTP timer offset configuration register i (GTOi) is loaded. 0: Setting completed 1: When written: Issue a configuration request. When read: Completion of settings is pending.
1, 0	TCR[1:0]	00	R/W	Timer Control Request These bits issue requests for controlling the gPTP timer. The source selection (GCCR.TCSS) can be done by same write access. Writing to the bits is only possible when the current operating mode is operation mode, or if CSR.OPS is CONFIG and CCC.GAC is 1. Do not write to the bit when the gPTP timer clock select bit in the AVB-DMAC mode register is B'00. Write to these bits while GCCR.TCR is B'00 or B'10. The CPU should not write other values than B'11 to these bits if GCCR.TCR is B'10. The CPU should only use continuous capture (B'10) for AVTP presentation time value (GCCR.TCSS is B'10). [Conditions for Changing] — The bits are set to B'00 when the operating mode is not operation mode and CCC.GAC is 0. — The bits are also set to B'00 on completion of the requested processing. 00: Timer control is not requested. 01: gPTP/AVTP presentation time reset 10: Continuous capture of AVTP to GCTt.CTV 11: Captures the value set in the TCSS bit.

33A.2.51 gPTP Maximum Transit Time Configuration Register (GMTT)

The GMTT register sets the maximum time for transitions of the gPTP timer.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	MTTV[31:0]	H'0000 0000	R/W	Maximum Transit Time These bits set the maximum transition time for use in calculating AVTP presentation time. Write the desired setting to the bits, then issue the configuration request by setting the maximum transit time configuration request bit in the gPTP configuration control register (GCCR.LMTT) to 1.

Note: Do not write a value to these bits when the operating mode is operation mode or CCC.GAC is 1 and the maximum transit time configuration request bit (GCCR.LMTT) is 1.

33A.2.52 gPTP Presentation Time Comparison Register (GPTC)

The GPTC register sets a value for comparison with presentation times in the gPTP timer.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PTCV[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

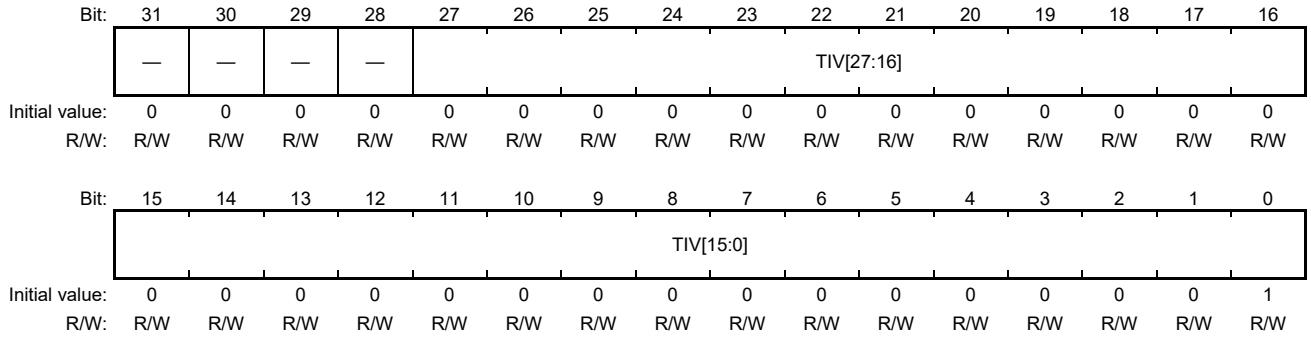
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PTCV[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	PTCV[31:0]	H'0000 0000	R/W	Presentation Time Comparison Value These bits set a value for comparison with AVTP timer values to which a maximum transit time is not appended. Write the desired setting to the bits, then issue the configuration request by setting the presentation time comparison value configuration request bit in the gPTP configuration control register (GCCR.LPTC) to 1.

Note: Do not write a value to these bits when the presentation time comparison value configuration request bit (GCCR.LPTC) is 1.
The CPU should only write values in range of 0 to 3FFF_FFFFh to these bits when they are defining the period value of AVTP comparison unit (controlled by GCCR.SPC).

33A.2.53 gPTP Timer Increment Configuration Register (GTI)

The GTI register sets the increment for the gPTP timer.



Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
27 to 0	TIV[27:0]	H'000 0001	R/W	gPTP Timer Increment Value When the gPTP clock select bits in the AVB-DMAC mode register (CCC.CSEL) are selecting a clock signal, these bits set the value by which the timer is incremented each time a cycle of that clock signal elapses. Write the desired setting to the bits, then issue the configuration request by setting the timer increment value configuration request bit in the gPTP configuration control register (GCCR.LTI) to 1.

Note: Do not write a value to these bits when the operating mode is operation mode or CCC.GAC is 1 and the timer increment value configuration request bit (GCCR.LTI) is 1.

Do not write 0 to the bits.

Keep comparison value in the following range

$x \leq comparison\_value \leq 2^{32} - x$

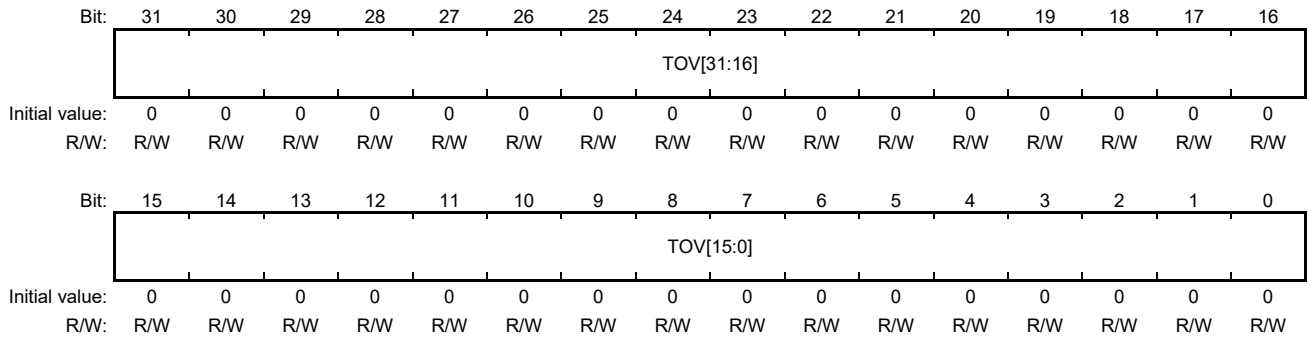
, where x is amount of nanoseconds of the configured increment value in GTI.TIV

The CPU should not program increment values less than H'0010 0000

33A.2.54 gPTP timer offset register i (GTOi) (i = 0 to 2)

The GTOi register sets an offset value for the gPTP timer.

The offset value is added to the combination of bits 0 to 31 in GTO0, 32 to 63 in GTO1, and 64 to 79 in GTO2, which together make up the gPTP timer.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	TOV[31:0]	H'0000 0000	R/W	Timer Offset Value This is an 80-bit value consisting of the settings in GTO0.TOV[31:0], GTO1.TOV[63:32], and GTO2.TOV[79:64], and is used to set an offset for adding to the value of the gPTP timer. Write the desired setting to the bits, then issue the configuration request by setting the timer offset value configuration request bit in the gPTP configuration control register (GCCR.LTO) to 1.

Note: Do not write a value to these bits when the operating mode is operation mode or CCC.GAC is 1 and the timer offset value configuration request bit (GCCR.LTO) is 1. Write H'0000 to GTO2.TOV[95:80].
Set a value in the range from 0 to 10^9-1 (H'0000 0000 to H'3B9A C9FF) in GTOi.TOV[31:0].

33A.2.55 gPTP Interrupt Control Register (GIC)

The GCI register is used to control gPTP-related interrupts.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
9	PTME7	0	R/W	Presentation Time Matched interrupt Enable 7 While this bit is 1 an interrupt will be generated when GIS.PTMF7 is 1. [Changing condition] This bit is set to 0 when writing 1 to GID.PTMD7. This bit is set to 1 when writing 1 to GIE.PTMS7. 0: Disabled 1: Enabled
8	PTME6	0	R/W	Presentation Time Matched interrupt Enable 6 While this bit is 1 an interrupt will be generated when GIS.PTMF6 is 1. [Changing condition] This bit is set to 0 when writing 1 to GID.PTMD6. This bit is set to 1 when writing 1 to GIE.PTMS6. 0: Disabled 1: Enabled
7	PTME5	0	R/W	Presentation Time Matched interrupt Enable 5 While this bit is 1 an interrupt will be generated when GIS.PTMF5 is 1. [Changing condition] This bit is set to 0 when writing 1 to GID.PTMD5. This bit is set to 1 when writing 1 to GIE.PTMS5. 0: Disabled 1: Enabled
6	PTME4	0	R/W	Presentation Time Matched interrupt Enable 4 While this bit is 1 an interrupt will be generated when GIS.PTMF4 is 1. [Changing condition] This bit is set to 0 when writing 1 to GID.PTMD4. This bit is set to 1 when writing 1 to GIE.PTMS4. 0: Disabled 1: Enabled

Bit	Bit Name	Initial Value	R/W	Description
5	PTME3	0	R/W	Presentation Time Matched interrupt Enable 3 While this bit is 1 an interrupt will be generated when GIS.PTMF3 is 1. [Changing condition] This bit is set to 0 when writing 1 to GID.PTMD3. This bit is set to 1 when writing 1 to GIE.PTMS3. 0: Disabled 1: Enabled
4	PTME2	0	R/W	Presentation Time Matched interrupt Enable 2 While this bit is 1 an interrupt will be generated when GIS.PTMF2 is 1. [Changing condition] This bit is set to 0 when writing 1 to GID.PTMD2. This bit is set to 1 when writing 1 to GIE.PTMS2. 0: Disabled 1: Enabled
3	PTME1	0	R/W	Presentation Time Matched interrupt Enable 1 While this bit is 1 an interrupt will be generated when GIS.PTMF1 is 1. [Changing condition] This bit is set to 0 when writing 1 to GID.PTMD1. This bit is set to 1 when writing 1 to GIE.PTMS1. 0: Disabled 1: Enabled
2	PTME0	0	R/W	Presentation Time Match Interrupt Enable 0 When this bit is 1, setting of the presentation time match interrupt flag in the gPTP interrupt status register (GIS.PTMF) to 1 leads to generation of that interrupt. [Changing condition] This bit is set to 0 when writing 1 to GID.PTMD0. This bit is set to 1 when writing 1 to GIE.PTMS0. 0: Disabled 1: Enabled
1	PTOE	0	R/W	Presentation Time Overrun interrupt Enable While this bit is 1 an interrupt will be generated when GIS.PTOF is 1. [Changing condition] This bit is set to 0 when writing 1 to GID.PTOD. This bit is set to 1 when writing 1 to GIE.PTOS. 0: Disabled 1: Enabled
0	PTCE	0	R/W	Presentation Time Captured interrupt Enable While this bit is 1 an interrupt will be generated when GIS.PTCF is 1. [Changing condition] This bit is set to 0 when writing 1 to GID.PTCD. This bit is set to 1 when writing 1 to GIE.PTCS. 0: Disabled 1: Enabled

33A.2.56 gPTP interrupt status register (GIS)

The GIC register indicates the state of the gPTP-related interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	PTMF7	PTMF6	PTMF5	PTMF4	PTMF3	PTMF2	PTMF1	PTMF0	PTOF	PTCF
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
9	PTMF7	0	R/W	Presentation Time Matched Flag 7 This bit indicates that the AVTP timer value has matched the configured comparison value of AVTP comparator 7. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 1 when the AVTP timer value reaches or exceeds the comparison value of AVTP comparator 7. 0: No interrupt pending 1: Presentation time exceeded
8	PTMF6	0	R/W	Presentation Time Matched Flag 6 This bit indicates that the AVTP timer value has matched the configured comparison value of AVTP comparator 6. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 1 when the AVTP timer value reaches or exceeds the comparison value of AVTP comparator 6. 0: No interrupt pending 1: Presentation time exceeded
7	PTMF5	0	R/W	Presentation Time Matched Flag 5 This bit indicates that the AVTP timer value has matched the configured comparison value of AVTP comparator 5. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 1 when the AVTP timer value reaches or exceeds the comparison value of AVTP comparator 5. 0: No interrupt pending 1: Presentation time exceeded

Bit	Bit Name	Initial Value	R/W	Description
6	PTMF4	0	R/W	Presentation Time Matched Flag 4 This bit indicates that the AVTP timer value has matched the configured comparison value of AVTP comparator 4. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 1 when the AVTP timer value reaches or exceeds the comparison value of AVTP comparator 4. 0: No interrupt pending 1: Presentation time exceeded
5	PTMF3	0	R/W	Presentation Time Matched Flag 3 This bit indicates that the AVTP timer value has matched the configured comparison value of AVTP comparator 3. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 1 when the AVTP timer value reaches or exceeds the comparison value of AVTP comparator 3. 0: No interrupt pending 1: Presentation time exceeded
4	PTMF2	0	R/W	Presentation Time Matched Flag 2 This bit indicates that the AVTP timer value has matched the configured comparison value of AVTP comparator 2. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 1 when the AVTP timer value reaches or exceeds the comparison value of AVTP comparator 2. 0: No interrupt pending 1: Presentation time exceeded
3	PTMF1	0	R/W	Presentation Time Matched Flag 1 This bit indicates that the AVTP timer value has matched the configured comparison value of AVTP comparator 1. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 1 when the AVTP timer value reaches or exceeds the comparison value of AVTP comparator 1. 0: No interrupt pending 1: Presentation time exceeded

Bit	Bit Name	Initial Value	R/W	Description
2	PTMF0	0	R/W	Presentation Time Match Interrupt Flag 0 This bit indicates that the value of the AVTP timer exceeds the value of the gPTP presentation time comparison register (GPTC). Only 0 can be written to the bit. [Conditions for Changing] — The bit is set to 0 when the operating mode is not operation mode. — The bit is set to 1 when the AVTP timer value is greater than or equal to the value of the gPTP presentation time comparison register (GPTC). 0: The interrupt is not pending. 1: The interrupt is pending.
1	PTOF	0	R/W	Presentation Time Overrun Flag This bit indicates that an external capture event (rising edge of avb_pt_capture[0] signal) has occurred before the last captured value was processed by CPU. The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 1 when EthernetAVB gets an external capture trigger while GIS.PTCF is 1. 0: No interrupt pending 1: Presentation time overrun
0	PTCF	0	R/W	Presentation Time Capture Flag This bit indicates that the AVTP presentation time has been captured based on external capture event (rising edge of avb_pt_capture[0] signal). The CPU can only write 0 to this bit. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 1 when EthernetAVB gets an external capture trigger. 0: No interrupt pending 1: Presentation time captured

33A.2.57 gPTP Captured Presentation Time register (GCPT)

The GCPT registers that captured presentation the gPTP timer value.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CPTV[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CPTV[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CPTV[31:0]	H'0000 0000	R	Captured Presentation Time Value These bits represent the captured AVTP presentation time (with Max Transit Time added) due to HW trigger. The CPU should not read these bits when GIS.PTCF is 0. [Changing condition] These bits are updated with the current AVTP presentation time when an external capture trigger (avb_pt_capture[0]) occurs and GIS.PTCF is 0. Note for verification: These bits are set to 0 when leaving OPERATION mode and CCC.GAC is 0.

33A.2.58 gPTP Timer Capture Register i (GCTi) (i = 0 to 2)

The GCTi registers form an 80-bit register that captures the gPTP timer value.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CTV[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CTV[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	CTV[31:0]	H'0000 0000	R/W	gPTP Timer Capture Value These 80 bits consist of GCT0.CTV[31:0], GCT1.CTV[63:32 and GCT2.CTV[79:64], which together indicate captured timer values. When B'00 (value of the gPTP timer) or B'01 (adjusted gPTP timer value) is selected by the timer capture source select bits in the gPTP configuration control register, the corresponding 80-bit values are stored in these bits. When B'10 (AVTP presentation time) is selected by the timer capture source select bit, the corresponding 32-bit values are stored in these bits. In case of continuous update (GCCR.TCR is B'10) CPU should only use 32 bit read access to get consistent value. Actual writing of the timer value specified by the timer capture source select bits (GCCR.TCSS) proceeds when B'11 (timer capture request) is written to the timer control request bits in the gPTP configuration control register (GCCR.TCR). Do not read the value while the value of the timer control request bits (GCCR.TCR) is B'11, because this indicates that storage is still in progress. Note for verification: These bits are set to 0 when leaving OPERATION mode and CCC.GAC is 0.

33A.2.59 gPTP Status Register (GSR)

The GSR register indicates the state of the gPTP.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
27	AFU3	0	R	Avtp Fifo Update 3 This bit indicates an ongoing update of the AVTP-FIFO of compare unit 3. When this bit is 0, the AVTP-FIFO is able to process adding new values. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 0 when AVTP compare value is added to the AVTP-FIFO. This bit is set to 1 when CPU writes a new value to GPTF3.PTFV and GSR.AFFL3 is not 15. 0: No update of AVTP FIFO pending 1: Update of AVTP FIFO with value from GPTF3.PTFV is ongoing
26	AFU2	0	R	Avtp Fifo Update 2 This bit indicates an ongoing update of the AVTP-FIFO of compare unit 2. When this bit is 0, the AVTP-FIFO is able to process adding new values. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 0 when AVTP compare value is added to the AVTP-FIFO. This bit is set to 1 when CPU writes a new value to GPTF2.PTFV and GSR.AFFL2 is not 15. 0: No update of AVTP FIFO pending 1: Update of AVTP FIFO with value from GPTF2.PTFV is ongoing

Bit	Bit Name	Initial Value	R/W	Description
25	AFU1	0	R	Avtp Fifo Update 1 This bit indicates an ongoing update of the AVTP-FIFO of compare unit 1. When this bit is 0, the AVTP-FIFO is able to process adding new values. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 0 when AVTP compare value is added to the AVTP-FIFO. This bit is set to 1 when CPU writes a new value to GPTF1.PTFV and GSR.AFFL1 is not 15. 0: No update of AVTP FIFO pending 1: Update of AVTP FIFO with value from GPTF1.PTFV is ongoing
24	AFU0	0	R	Avtp Fifo Update 0 This bit indicates an ongoing update of the AVTP-FIFO of compare unit 0. When this bit is 0, the AVTP-FIFO is able to process adding new values. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 0 when AVTP compare value is added to the AVTP-FIFO. This bit is set to 1 when CPU writes a new value to GPTF0.PTFV and GSR.AFFL0 is not 15. 0: No update of AVTP FIFO pending 1: Update of AVTP FIFO with value from GPTF0.PTFV is ongoing
23 to 20	AFFL3[3:0]	H'0	R	FIFO fill level of AVTP compare unit 3 These bits indicate the number of AVTP timestamps pending in AVTP-FIFO of compare unit 3. The timestamps are provided by CPU and taken by compare unit when no comparison on AVTP comparator 3 is active. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This value is incremented when a new value is added to AVTP-FIFO (GSR.AFU3 changes to 0). This value is decremented when a timestamp value from FIFO has been loaded to the AVTP comparator.
19 to 16	AFFL2[3:0]	H'0	R	FIFO fill level of AVTP compare unit 2 These bits indicate the number of AVTP timestamps pending in AVTP-FIFO of compare unit 2. The timestamps are provided by CPU and taken by compare unit when no comparison on AVTP comparator 2 is active. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This value is incremented when a new value is added to AVTP-FIFO (GSR.AFU2 changes to 0). This value is decremented when a timestamp value from FIFO has been loaded to the AVTP comparator.

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	AFFL1[3:0]	H'0	R	FIFO fill level of AVTP compare unit 1 These bits indicate the number of AVTP timestamps pending in AVTP-FIFO of compare unit 1. The timestamps are provided by CPU and taken by compare unit when no comparison on AVTP comparator 1 is active. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This value is incremented when a new value is added to AVTP-FIFO (GSR.AFU1 changes to 0). This value is decremented when a timestamp value from FIFO has been loaded to the AVTP comparator.
11 to 8	AFFL0[3:0]	H'0	R	FIFO fill level of AVTP compare unit 0 These bits indicate the number of AVTP timestamps pending in AVTP-FIFO of compare unit 0. The timestamps are provided by CPU and taken by compare unit when no comparison on AVTP comparator 0 is active. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This value is incremented when a new value is added to AVTP-FIFO (GSR.AFU0 changes to 0). This value is decremented when a timestamp value from FIFO has been loaded to the AVTP comparator.
7	PCM7	0	R	Periodic Comparison Mode 7 This bit indicates if single shot or periodic comparison mode is active on AVTP comparator unit 7. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 0 when the last match has happened after CPU has requested entering single shot mode. This bit is set to 1 when loading a period value for the AVTP comparator. 0: Single shot comparison 1: Periodic comparison
6	PCM6	0	R	Periodic Comparison Mode 6 This bit indicates if single shot or periodic comparison mode is active on AVTP comparator unit 6. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 0 when the last match has happened after CPU has requested entering single shot mode. This bit is set to 1 when loading a period value for the AVTP comparator. 0: Single shot comparison 1: Periodic comparison

Bit	Bit Name	Initial Value	R/W	Description
5	PCM5	0	R	Periodic Comparison Mode 5 This bit indicates if single shot or periodic comparison mode is active on AVTP comparator unit 5. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 0 when the last match has happened after CPU has requested entering single shot mode. This bit is set to 1 when loading a period value for the AVTP comparator. 0: Single shot comparison 1: Periodic comparison
4	PCM4	0	R	Periodic Comparison Mode 4 This bit indicates if single shot or periodic comparison mode is active on AVTP comparator unit 4. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 0 when the last match has happened after CPU has requested entering single shot mode. This bit is set to 1 when loading a period value for the AVTP comparator. 0: Single shot comparison 1: Periodic comparison
3	PCM3	0	R	Periodic Comparison Mode 3 This bit indicates if single shot or periodic comparison mode is active on AVTP comparator unit 3. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 0 when the last match has happened after CPU has requested entering single shot mode. This bit is set to 1 when loading a period value for the AVTP comparator. 0: Single shot comparison 1: Periodic comparison
2	PCM2	0	R	Periodic Comparison Mode 2 This bit indicates if single shot or periodic comparison mode is active on AVTP comparator unit 2. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 0 when the last match has happened after CPU has requested entering single shot mode. This bit is set to 1 when loading a period value for the AVTP comparator. 0: Single shot comparison 1: Periodic comparison

Bit	Bit Name	Initial Value	R/W	Description
1	PCM1	0	R	Periodic Comparison Mode 1 This bit indicates if single shot or periodic comparison mode is active on AVTP comparator unit 1. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 0 when the last match has happened after CPU has requested entering single shot mode. This bit is set to 1 when loading a period value for the AVTP comparator. 0: Single shot comparison 1: Periodic comparison
0	PCM0	0	R	Periodic Comparison Mode 0 This bit indicates if single shot or periodic comparison mode is active on AVTP comparator unit 0. [Changing condition] This bit is set to 0 when leaving OPERATION mode and CCC.GAC is 0. This bit is set to 0 when the last match has happened after CPU has requested entering single shot mode. This bit is set to 1 when loading a period value for the AVTP comparator. 0: Single shot comparison 1: Periodic comparison

33A.2.60 gPTP Interrupt Enable register (GIE)

The GIE register is used to control the gPTP Interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
9	PTMS7	0	R/W	Presentation Time Matched interrupt Set 7 This bit supports interrupt enable. It controls set of GIC.PTME7. This bit is always read as 0. 0: No change of GIC.PTME7 1: Set GIC.PTME7 to 1
8	PTMS6	0	R/W	Presentation Time Matched interrupt Set 6 This bit supports interrupt enable. It controls set of GIC.PTME6. This bit is always read as 0. 0: No change of GIC.PTME6 1: Set GIC.PTME6 to 1
7	PTMS5	0	R/W	Presentation Time Matched interrupt Set 5 This bit supports interrupt enable. It controls set of GIC.PTME5. This bit is always read as 0. 0: No change of GIC.PTME5 1: Set GIC.PTME5 to 1
6	PTMS4	0	R/W	Presentation Time Matched interrupt Set 4 This bit supports interrupt enable. It controls set of GIC.PTME4. This bit is always read as 0. 0: No change of GIC.PTME4 1: Set GIC.PTME4 to 1
5	PTMS3	0	R/W	Presentation Time Matched interrupt Set 3 This bit supports interrupt enable. It controls set of GIC.PTME3. This bit is always read as 0. 0: No change of GIC.PTME3 1: Set GIC.PTME3 to 1
4	PTMS2	0	R/W	Presentation Time Matched interrupt Set 2 This bit supports interrupt enable. It controls set of GIC.PTME2. This bit is always read as 0. 0: No change of GIC.PTME2 1: Set GIC.PTME2 to 1

Bit	Bit Name	Initial Value	R/W	Description
3	PTMS1	0	R/W	Presentation Time Matched interrupt Set 1 This bit supports interrupt enable. It controls set of GIC.PTME1. This bit is always read as 0. 0: No change of GIC.PTME1 1: Set GIC.PTME1 to 1
2	PTMS0	0	R/W	Presentation Time Matched interrupt Set 0 This bit supports interrupt enable. It controls set of GIC.PTME0. This bit is always read as 0. 0: No change of GIC.PTME0 1: Set GIC.PTME0 to 1
1	PTOS	0	R/W	Presentation Time Overrun interrupt Set This bit supports interrupt enable. It controls set of GIC.PTOE. This bit is always read as 0. 0: No change of GIC.PTOE 1: Set GIC.PTOE to 1
0	PTCS	0	R/W	Presentation Time Captured interrupt Set This bit supports interrupt enable. It controls set of GIC.PTCE. This bit is always read as 0. 0: No change of GIC.PTCE 1: Set GIC.PTCE to 1

33A.2.61 gPTP Interrupt Disable register (GID)

The GID register is used to control the gPTP Interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	PTMD7	PTMD6	PTMD5	PTMD4	PTMD3	PTMD2	PTMD1	PTMD0	PTOD	PTCD
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
9	PTMD7	0	R/W	Presentation Time Matched interrupt Disable 7 This bit supports interrupt enable. It controls set of GIC.PTME7. This bit is always read as 0. 0: No change of GIC.PTME7 1: Set GIC.PTME7 to 0
8	PTMD6	0	R/W	Presentation Time Matched interrupt Disable 6 This bit supports interrupt enable. It controls set of GIC.PTME6. This bit is always read as 0. 0: No change of GIC.PTME6 1: Set GIC.PTME6 to 0
7	PTMD5	0	R/W	Presentation Time Matched interrupt Disable 5 This bit supports interrupt enable. It controls set of GIC.PTME5. This bit is always read as 0. 0: No change of GIC.PTME5 1: Set GIC.PTME5 to 0
6	PTMD4	0	R/W	Presentation Time Matched interrupt Disable 4 This bit supports interrupt enable. It controls set of GIC.PTME4. This bit is always read as 0. 0: No change of GIC.PTME4 1: Set GIC.PTME4 to 0
5	PTMD3	0	R/W	Presentation Time Matched interrupt Disable 3 This bit supports interrupt enable. It controls set of GIC.PTME3. This bit is always read as 0. 0: No change of GIC.PTME3 1: Set GIC.PTME3 to 0
4	PTMD2	0	R/W	Presentation Time Matched interrupt Disable 2 This bit supports interrupt enable. It controls set of GIC.PTME2. This bit is always read as 0. 0: No change of GIC.PTME2 1: Set GIC.PTME2 to 0

Bit	Bit Name	Initial Value	R/W	Description
3	PTMD1	0	R/W	Presentation Time Matched interrupt Disable 1 This bit supports interrupt enable. It controls set of GIC.PTME1. This bit is always read as 0. 0: No change of GIC.PTME1 1: Set GIC.PTME1 to 0
2	PTMD0	0	R/W	Presentation Time Matched interrupt Disable 0 This bit supports interrupt enable. It controls set of GIC.PTME0. This bit is always read as 0. 0: No change of GIC.PTME0 1: Set GIC.PTME0 to 0
1	PTOD	0	R/W	Presentation Time Overrun interrupt Disable This bit supports interrupt enable. It controls set of GIC.PTOE. This bit is always read as 0. 0: No change of GIC.PTOE 1: Set GIC.PTOE to 0
0	PTCD	0	R/W	Presentation Time Captured interrupt Disable This bit supports interrupt enable. It controls set of GIC.PTCE. This bit is always read as 0. 0: No change of GIC.PTCE 1: Set GIC.PTCE to 0

33A.2.62 gPTP Interrupt Line select register (GIL)

The GIL register is used to control the gPTP Interrupt line.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

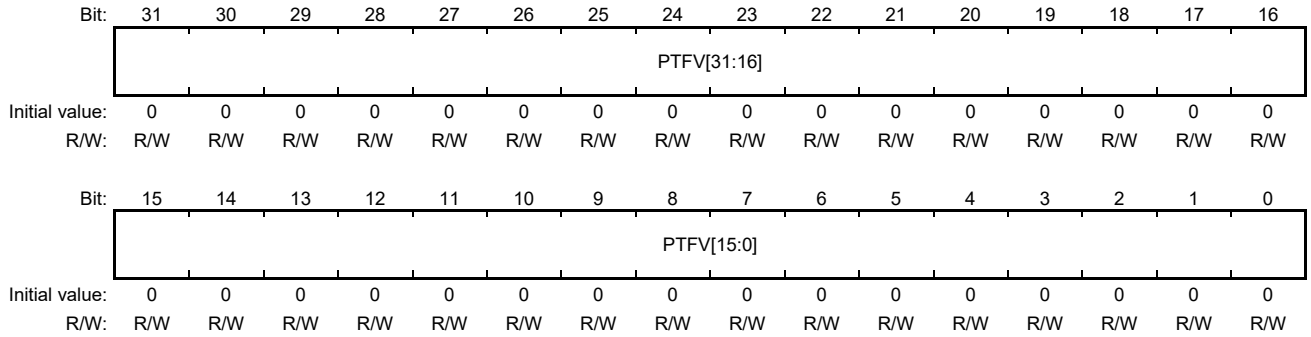
Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
9	PTML7	0	R/W	Presentation Time Matched interrupt Line select 7 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
8	PTML6	0	R/W	Presentation Time Matched interrupt Line select 6 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
7	PTML5	0	R/W	Presentation Time Matched interrupt Line select 5 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
6	PTML4	0	R/W	Presentation Time Matched interrupt Line select 4 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
5	PTML3	0	R/W	Presentation Time Matched interrupt Line select 3 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
4	PTML2	0	R/W	Presentation Time Matched interrupt Line select 2 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification

Bit	Bit Name	Initial Value	R/W	Description
3	PTML1	0	R/W	Presentation Time Matched interrupt Line select 1 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
2	PTML0	0	R/W	Presentation Time Matched interrupt Line select 0 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
1	PTOL	0	R/W	Presentation Time Overrun interrupt Line select This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
0	PTCL	0	R/W	Presentation Time Captured interrupt Line select This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification

33A.2.63 gPTP Presentation Time Fifo register i (GPTFi) (i = 0 to 3)

The GPTFi register is used to control the gPTP FIFO.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	PTFV[31:0]	H'0000 0000	R/W	Presentation Time Fifo Value These bits define a value to be compared with the AVTP timer value (without Max Transit Time added). When writing to this register the value is added to AVTP-FIFO of comparator unit i. These bits are always read as 0. The CPU cannot write to these bits if CSR.OPS is CONFIG and CCC.GAC is 0. The CPU should not write to these bits when GSR.PCMi is 1. The CPU should not write to these bits when GSR.AFUi is 1. The CPU should not write to these bits when GSR.AFFLi is 15.

33A.2.64 Descriptor Interrupt Line selection register (DIL)

The DIL register is used to control the Descriptor Interrupt line.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

	DPL15	DPL14	DPL13	DPL12	DPL11	DPL10	DPL9	DPL8	DPL7	DPL6	DPL5	DPL4	DPL3	DPL2	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
15	DPL15	0	R/W	Descriptor Processed interrupt Line select 15 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
14	DPL14	0	R/W	Descriptor Processed interrupt Line select 14 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
13	DPL13	0	R/W	Descriptor Processed interrupt Line select 13 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
12	DPL12	0	R/W	Descriptor Processed interrupt Line select 12 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
11	DPL11	0	R/W	Descriptor Processed interrupt Line select 11 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
10	DPL10	0	R/W	Descriptor Processed interrupt Line select 10 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification

Bit	Bit Name	Initial Value	R/W	Description
9	DPL9	0	R/W	Descriptor Processed interrupt Line select 9 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
8	DPL8	0	R/W	Descriptor Processed interrupt Line select 8 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
7	DPL7	0	R/W	Descriptor Processed interrupt Line select 7 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
6	DPL6	0	R/W	Descriptor Processed interrupt Line select 6 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
5	DPL5	0	R/W	Descriptor Processed interrupt Line select 5 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
4	DPL4	0	R/W	Descriptor Processed interrupt Line select 4 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
3	DPL3	0	R/W	Descriptor Processed interrupt Line select 3 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
2	DPL2	0	R/W	Descriptor Processed interrupt Line select 2 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
1, 0	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.

33A.2.65 Error Interrupt Line selection register (EIL)

The EIL register is used to control the Error Interrupt line.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
10	TBFL	0	R/W	Tx-Buffer Full interrupt Line select This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
9	MFFL	0	R/W	E-MAC status FIFO Full interrupt Line select This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
8	TFFL	0	R/W	Timestamp FIFO Full interrupt Line select This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
7	CULL1	0	R/W	CBS Upper Limit reached interrupt Line select 1 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
6	CULL0	0	R/W	CBS Upper Limit reached interrupt Line select 0 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
5	CLLL1	0	R/W	CBS Lower Limit reached interrupt Line select 1 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification

Bit	Bit Name	Initial Value	R/W	Description
4	CLLL0	0	R/W	CBS Lower Limit reached interrupt Line select 0 This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
3	SEL	0	R/W	Separation Error interrupt Line select This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
2	QEL	0	R/W	Queue Error interrupt Line select This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
1	MTEL	0	R/W	E-MAC Transmission Error interrupt Line select This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
0	MREL	0	R/W	E-MAC Reception Error interrupt Line select This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification

33A.2.66 Transmission Interrupt Line select register (TIL)

The TIL register is used to control the Transmission Interrupt line.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	MFWL	MFUL	TFWL	TFUL	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 12	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
11	MFWL	0	R/W	E-MAC status FIFO Warning interrupt Line select This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
10	MFUL	0	R/W	E-MAC status FIFO Updated interrupt Line select This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
9	TFWL	0	R/W	Timestamp FIFO Warning interrupt Line select This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
8	TFUL	0	R/W	Timestamp FIFO Updated interrupt Line select This bit selects the interrupt line used for this notification. It is recommended to disable interrupt before change the line. 0: Interrupt line A used for this notification 1: Interrupt line B used for this notification
7 to 0	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.

33A.2.67 Descriptor Interrupt Enable register (DIE)

The DIE register is used to control the Descriptor Interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	DPS15	DPS14	DPS13	DPS12	DPS11	DPS10	DPS9	DPS8	DPS7	DPS6	DPS5	DPS4	DPS3	DPS2	DPS1	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
15	DPS15	0	R/W	Descriptor Processed interrupt Set 15 This bit supports interrupt enable. It controls set of DIC.DPE15. This bit is always read as 0. 0: No change of DIC.DPE15 1: Set DIC.DPE15 to 1
14	DPS14	0	R/W	Descriptor Processed interrupt Set 14 This bit supports interrupt enable. It controls set of DIC.DPE14. This bit is always read as 0. 0: No change of DIC.DPE14 1: Set DIC.DPE14 to 1
13	DPS13	0	R/W	Descriptor Processed interrupt Set 13 This bit supports interrupt enable. It controls set of DIC.DPE13. This bit is always read as 0. 0: No change of DIC.DPE13 1: Set DIC.DPE13 to 1
12	DPS12	0	R/W	Descriptor Processed interrupt Set 12 This bit supports interrupt enable. It controls set of DIC.DPE12. This bit is always read as 0. 0: No change of DIC.DPE12 1: Set DIC.DPE12 to 1
11	DPS11	0	R/W	Descriptor Processed interrupt Set 11 This bit supports interrupt enable. It controls set of DIC.DPE11. This bit is always read as 0. 0: No change of DIC.DPE11 1: Set DIC.DPE11 to 1
10	DPS10	0	R/W	Descriptor Processed interrupt Set 10 This bit supports interrupt enable. It controls set of DIC.DPE10. This bit is always read as 0. 0: No change of DIC.DPE10 1: Set DIC.DPE10 to 1

Bit	Bit Name	Initial Value	R/W	Description
9	DPS9	0	R/W	Descriptor Processed interrupt Set 9 This bit supports interrupt enable. It controls set of DIC.DPE9. This bit is always read as 0. 0: No change of DIC.DPE9 1: Set DIC.DPE9 to 1
8	DPS8	0	R/W	Descriptor Processed interrupt Set 8 This bit supports interrupt enable. It controls set of DIC.DPE8. This bit is always read as 0. 0: No change of DIC.DPE8 1: Set DIC.DPE8 to 1
7	DPS7	0	R/W	Descriptor Processed interrupt Set 7 This bit supports interrupt enable. It controls set of DIC.DPE7. This bit is always read as 0. 0: No change of DIC.DPE7 1: Set DIC.DPE7 to 1
6	DPS6	0	R/W	Descriptor Processed interrupt Set 6 This bit supports interrupt enable. It controls set of DIC.DPE6. This bit is always read as 0. 0: No change of DIC.DPE6 1: Set DIC.DPE6 to 1
5	DPS5	0	R/W	Descriptor Processed interrupt Set 5 This bit supports interrupt enable. It controls set of DIC.DPE5. This bit is always read as 0. 0: No change of DIC.DPE5 1: Set DIC.DPE5 to 1
4	DPS4	0	R/W	Descriptor Processed interrupt Set 4 This bit supports interrupt enable. It controls set of DIC.DPE4. This bit is always read as 0. 0: No change of DIC.DPE4 1: Set DIC.DPE4 to 1
3	DPS3	0	R/W	Descriptor Processed interrupt Set 3 This bit supports interrupt enable. It controls set of DIC.DPE3. This bit is always read as 0. 0: No change of DIC.DPE3 1: Set DIC.DPE3 to 1
2	DPS2	0	R/W	Descriptor Processed interrupt Set 2 This bit supports interrupt enable. It controls set of DIC.DPE2. This bit is always read as 0. 0: No change of DIC.DPE2 1: Set DIC.DPEi to 1
1	DPS1	0	R/W	Descriptor Processed interrupt Set 1 This bit supports interrupt enable. It controls set of DIC.DPE1. This bit is always read as 0. 0: No change of DIC.DPE1 1: Set DIC.DPE1 to 1
0	—	0	R/W	Reserved These bits are read as 0. The write value should be 0.

33A.2.68 Descriptor Interrupt Disable register (DID)

The DID register is used to control the Descriptor Interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DPD15	DPD14	DPD13	DPD12	DPD11	DPD10	DPD9	DPD8	DPD7	DPD6	DPD5	DPD4	DPD3	DPD2	DPD1	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
15	DPD15	0	R/W	Descriptor Processed interrupt Disable 15 This bit supports interrupt enable. It controls set of DIC.DPE15. This bit is always read as 0. 0: No change of DIC.DPE15 1: Set DIC.DPE15 to 0
14	DPD14	0	R/W	Descriptor Processed interrupt Disable 14 This bit supports interrupt enable. It controls set of DIC.DPE14. This bit is always read as 0. 0: No change of DIC.DPE14 1: Set DIC.DPE14 to 0
13	DPD13	0	R/W	Descriptor Processed interrupt Disable 13 This bit supports interrupt enable. It controls set of DIC.DPE13. This bit is always read as 0. 0: No change of DIC.DPE13 1: Set DIC.DPE13 to 0
12	DPD12	0	R/W	Descriptor Processed interrupt Disable 12 This bit supports interrupt enable. It controls set of DIC.DPE12. This bit is always read as 0. 0: No change of DIC.DPE12 1: Set DIC.DPE12 to 0
11	DPD11	0	R/W	Descriptor Processed interrupt Disable 11 This bit supports interrupt enable. It controls set of DIC.DPE11. This bit is always read as 0. 0: No change of DIC.DPE11 1: Set DIC.DPE11 to 0
10	DPD10	0	R/W	Descriptor Processed interrupt Disable 10 This bit supports interrupt enable. It controls set of DIC.DPE10. This bit is always read as 0. 0: No change of DIC.DPE10 1: Set DIC.DPE10 to 0

Bit	Bit Name	Initial Value	R/W	Description
9	DPD9	0	R/W	Descriptor Processed interrupt Disable 9 This bit supports interrupt enable. It controls set of DIC.DPE9. This bit is always read as 0. 0: No change of DIC.DPE9 1: Set DIC.DPE9 to 0
8	DPD8	0	R/W	Descriptor Processed interrupt Disable 8 This bit supports interrupt enable. It controls set of DIC.DPE8. This bit is always read as 0. 0: No change of DIC.DPE8 1: Set DIC.DPE8 to 0
7	DPD7	0	R/W	Descriptor Processed interrupt Disable 7 This bit supports interrupt enable. It controls set of DIC.DPE7. This bit is always read as 0. 0: No change of DIC.DPE7 1: Set DIC.DPE7 to 0
6	DPD6	0	R/W	Descriptor Processed interrupt Disable 6 This bit supports interrupt enable. It controls set of DIC.DPE6. This bit is always read as 0. 0: No change of DIC.DPE6 1: Set DIC.DPE6 to 0
5	DPD5	0	R/W	Descriptor Processed interrupt Disable 5 This bit supports interrupt enable. It controls set of DIC.DPE5. This bit is always read as 0. 0: No change of DIC.DPE5 1: Set DIC.DPE5 to 0
4	DPD4	0	R/W	Descriptor Processed interrupt Disable 4 This bit supports interrupt enable. It controls set of DIC.DPE4. This bit is always read as 0. 0: No change of DIC.DPE4 1: Set DIC.DPE4 to 0
3	DPD3	0	R/W	Descriptor Processed interrupt Disable 3 This bit supports interrupt enable. It controls set of DIC.DPE3. This bit is always read as 0. 0: No change of DIC.DPE3 1: Set DIC.DPE3 to 0
2	DPD2	0	R/W	Descriptor Processed interrupt Disable 2 This bit supports interrupt enable. It controls set of DIC.DPE2. This bit is always read as 0. 0: No change of DIC.DPE2 1: Set DIC.DPE2 to 0
1	DPD1	0	R/W	Descriptor Processed interrupt Disable 1 This bit supports interrupt enable. It controls set of DIC.DPE1. This bit is always read as 0. 0: No change of DIC.DPE1 1: Set DIC.DPE1 to 0
0	—	0	R/W	Reserved This bit is read as 0. The write value should be 0.

33A.2.69 Error Interrupt Enable register (EIE)

The EIE register is used to control the Error Interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	TBFS	MFFS	TFFS	CULS 1	CULS 0	CLLS1	CLLS0	SES	QES	MTES	MRES
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
10	TBFS	0	R/W	Tx-Buffer Full interrupt Set This bit supports interrupt enable. It controls set of EIC.TBFE. This bit is always read as 0. 0: No change of EIC.TBFE 1: Set EIC.TBFE to 1
9	MFFS	0	R/W	E-MAC status FIFO Full interrupt Set This bit supports interrupt enable. It controls set of EIC.MFFE. This bit is always read as 0. 0: No change of EIC.MFFE 1: Set EIC.MFFE to 1
8	TFFS	0	R/W	Timestamp FIFO Full interrupt Set This bit supports interrupt enable. It controls set of EIC.TFFE. This bit is always read as 0. 0: No change of EIC.TFFE 1: Set EIC.TFFE to 1
7	CULS1	0	R/W	CBS Upper Limit reached interrupt Set 1 This bit supports interrupt enable. It controls set of EIC.CULE1. This bit is always read as 0. 0: No change of EIC.CULE1 1: Set EIC.CULE1 to 1
6	CULS0	0	R/W	CBS Upper Limit reached interrupt Set 0 This bit supports interrupt enable. It controls set of EIC.CULE0. This bit is always read as 0. 0: No change of EIC.CULE0 1: Set EIC.CULE0 to 1
5	CLLS1	0	R/W	CBS Lower Limit reached interrupt Set 1 This bit supports interrupt enable. It controls set of EIC.CLLE1. This bit is always read as 0. 0: No change of EIC.CLLE1 1: Set EIC.CLLE1 to 1

Bit	Bit Name	Initial Value	R/W	Description
4	CLLS0	0	R/W	CBS Lower Limit reached interrupt Set 0 This bit supports interrupt enable. It controls set of EIC.CLLE0. This bit is always read as 0. 0: No change of EIC.CLLE0 1: Set EIC.CLLE0 to 1
3	SES	0	R/W	Separation Error interrupt Set This bit supports interrupt enable. It controls set of EIC.SEE. This bit is always read as 0. 0: No change of EIC.SEE 1: Set EIC.QEE to 1
2	QES	0	R/W	Queue Error interrupt Set This bit supports interrupt enable. It controls set of EIC.QEE. This bit is always read as 0. 0: No change of EIC.QEE 1: Set EIC.QEE to 1
1	MTES	0	R/W	E-MAC Transmission Error interrupt Set This bit supports interrupt enable. It controls set of EIC.MTEE. This bit is always read as 0. 0: No change of EIC.MTEE 1: Set EIC.MTEE to 1
0	MRES	0	R/W	E-MAC Reception Error interrupt Set This bit supports interrupt enable. It controls set of EIC.MREE. This bit is always read as 0. 0: No change of EIC.MREE 1: Set EIC.MREE to 1

33A.2.70 Error Interrupt Disable register (EID)

The EID register is used to control the Error Interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	TBFD	MFFD	TFFD	CULD 1	CULD 0	CLLD1	CLLD0	SED	QED	MTED	MRED
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 11	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
10	TBFD	0	R/W	Tx-Buffer Full interrupt Disable This bit supports interrupt enable. It controls set of EIC.TBFE. This bit is always read as 0. 0: No change of EIC.TBFE 1: Set EIC.TBFE to 0
9	MFFD	0	R/W	E-MAC status FIFO Full interrupt Disable This bit supports interrupt enable. It controls set of EIC.MFFE. This bit is always read as 0. 0: No change of EIC.MFFE 1: Set EIC.MFFE to 0
8	TFFD	0	R/W	Timestamp FIFO Full interrupt Disable This bit supports interrupt enable. It controls set of EIC.TFFE. This bit is always read as 0. 0: No change of EIC.TFFE 1: Set EIC.TFFE to 0
7	CULD1	0	R/W	CBS Upper Limit reached interrupt Disable 1 This bit supports interrupt enable. It controls set of EIC.CULE1. This bit is always read as 0. 0: No change of EIC.CULE1 1: Set EIC.CULE1 to 0
6	CULD0	0	R/W	CBS Upper Limit reached interrupt Disable 0 This bit supports interrupt enable. It controls set of EIC.CULE0. This bit is always read as 0. 0: No change of EIC.CULE0 1: Set EIC.CULE0 to 0
5	CLLD1	0	R/W	CBS Lower Limit reached interrupt Disable 1 This bit supports interrupt enable. It controls set of EIC.CLLE1. This bit is always read as 0. 0: No change of EIC.CLLE1 1: Set EIC.CLLE1 to 0

Bit	Bit Name	Initial Value	R/W	Description
4	CLLD0	0	R/W	CBS Lower Limit reached interrupt Disable 0 This bit supports interrupt enable. It controls set of EIC.CLLE0. This bit is always read as 0. 0: No change of EIC.CLLE0 1: Set EIC.CLLE0 to 0
3	SED	0	R/W	Separation Error interrupt Disable This bit supports interrupt enable. It controls set of EIC.SEE. This bit is always read as 0. 0: No change of EIC.SEE 1: Set EIC.SEE to 0
2	QED	0	R/W	Queue Error interrupt Disable This bit supports interrupt enable. It controls set of EIC.QEE. This bit is always read as 0. 0: No change of EIC.QEE 1: Set EIC.QEE to 0
1	MTED	0	R/W	E-MAC Transmission Error interrupt Disable This bit supports interrupt enable. It controls set of EIC.MTEE. This bit is always read as 0. 0: No change of EIC.MTEE 1: Set EIC.MTEE to 0
0	MRED	0	R/W	E-MAC Reception Error interrupt Disable This bit supports interrupt enable. It controls set of EIC.MREE. This bit is always read as 0. 0: No change of EIC.MREE 1: Set EIC.MREE to 0

33A.2.71 Reception Interrupt Enable register 0 (RIE0)

The RIE0 register is used to control the Reception Interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FRS17	FRS16
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FRS15	FRS14	FRS13	FRS12	FRS11	FRS10	FRS9	FRS8	FRS7	FRS6	FRS5	FRS4	FRS3	FRS2	FRS1	FRS0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
17	FRS17	0	R/W	Frame Received interrupt Set 17 This bit supports interrupt enable. It controls set of RIC0.FRE17. This bit is always read as 0. 0: No change of RIC0.FRE17 1: Set RIC0.FRE17 to 1
16	FRS16	0	R/W	Frame Received interrupt Set 16 This bit supports interrupt enable. It controls set of RIC0.FRE16. This bit is always read as 0. 0: No change of RIC0.FRE16 1: Set RIC0.FRE16 to 1
15	FRS15	0	R/W	Frame Received interrupt Set 15 This bit supports interrupt enable. It controls set of RIC0.FRE15. This bit is always read as 0. 0: No change of RIC0.FRE15 1: Set RIC0.FRE15 to 1
14	FRS14	0	R/W	Frame Received interrupt Set 14 This bit supports interrupt enable. It controls set of RIC0.FRE14. This bit is always read as 0. 0: No change of RIC0.FRE14 1: Set RIC0.FRE14 to 1
13	FRS13	0	R/W	Frame Received interrupt Set 13 This bit supports interrupt enable. It controls set of RIC0.FRE13. This bit is always read as 0. 0: No change of RIC0.FRE13 1: Set RIC0.FRE13 to 1
12	FRS12	0	R/W	Frame Received interrupt Set 12 This bit supports interrupt enable. It controls set of RIC0.FRE12. This bit is always read as 0. 0: No change of RIC0.FRE12 1: Set RIC0.FRE12 to 1

Bit	Bit Name	Initial Value	R/W	Description
11	FRS11	0	R/W	Frame Received interrupt Set 11 This bit supports interrupt enable. It controls set of RIC0.FRE11. This bit is always read as 0. 0: No change of RIC0.FRE11 1: Set RIC0.FRE11 to 1
10	FRS10	0	R/W	Frame Received interrupt Set 10 This bit supports interrupt enable. It controls set of RIC0.FRE10. This bit is always read as 0. 0: No change of RIC0.FRE10 1: Set RIC0.FRE10 to 1
9	FRS9	0	R/W	Frame Received interrupt Set 9 This bit supports interrupt enable. It controls set of RIC0.FRE9. This bit is always read as 0. 0: No change of RIC0.FRE9 1: Set RIC0.FRE9 to 1
8	FRS8	0	R/W	Frame Received interrupt Set 8 This bit supports interrupt enable. It controls set of RIC0.FRE8. This bit is always read as 0. 0: No change of RIC0.FRE8 1: Set RIC0.FRE8 to 1
7	FRS7	0	R/W	Frame Received interrupt Set 7 This bit supports interrupt enable. It controls set of RIC0.FRE7. This bit is always read as 0. 0: No change of RIC0.FRE7 1: Set RIC0.FRE7 to 1
6	FRS6	0	R/W	Frame Received interrupt Set 6 This bit supports interrupt enable. It controls set of RIC0.FRE6. This bit is always read as 0. 0: No change of RIC0.FRE6 1: Set RIC0.FRE6 to 1
5	FRS5	0	R/W	Frame Received interrupt Set 5 This bit supports interrupt enable. It controls set of RIC0.FRE5. This bit is always read as 0. 0: No change of RIC0.FRE5 1: Set RIC0.FRE5 to 1
4	FRS4	0	R/W	Frame Received interrupt Set 4 This bit supports interrupt enable. It controls set of RIC0.FRE4. This bit is always read as 0. 0: No change of RIC0.FRE4 1: Set RIC0.FRE4 to 1
3	FRS3	0	R/W	Frame Received interrupt Set 3 This bit supports interrupt enable. It controls set of RIC0.FRE3. This bit is always read as 0. 0: No change of RIC0.FRE3 1: Set RIC0.FRE3 to 1

Bit	Bit Name	Initial Value	R/W	Description
2	FRS2	0	R/W	Frame Received interrupt Set 2 This bit supports interrupt enable. It controls set of RIC0.FRE2. This bit is always read as 0. 0: No change of RIC0.FRE2 1: Set RIC0.FRE2 to 1
1	FRS1	0	R/W	Frame Received interrupt Set 1 This bit supports interrupt enable. It controls set of RIC0.FRE1. This bit is always read as 0. 0: No change of RIC0.FRE1 1: Set RIC0.FRE1 to 1
0	FRS0	0	R/W	Frame Received interrupt Set 0 This bit supports interrupt enable. It controls set of RIC0.FRE0. This bit is always read as 0. 0: No change of RIC0.FRE0 1: Set RIC0.FRE0 to 1

33A.2.72 Reception Interrupt Disable register 0 (RID0)

The RID0 register is used to control the Reception Interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	FRD17	FRD16

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
17	FRD17	0	R/W	Frame Received interrupt Disable 17 This bit supports interrupt enable. It controls set of RIC0.FRE17. This bit is always read as 0. 0: No change of RIC0.FRE17 1: Set RIC0.FRE17 to 0
16	FRD16	0	R/W	Frame Received interrupt Disable 16 This bit supports interrupt enable. It controls set of RIC0.FRE16. This bit is always read as 0. 0: No change of RIC0.FRE16 1: Set RIC0.FRE16 to 0
15	FRD15	0	R/W	Frame Received interrupt Disable 15 This bit supports interrupt enable. It controls set of RIC0.FRE15. This bit is always read as 0. 0: No change of RIC0.FRE15 1: Set RIC0.FRE15 to 0
14	FRD14	0	R/W	Frame Received interrupt Disable 14 This bit supports interrupt enable. It controls set of RIC0.FRE14. This bit is always read as 0. 0: No change of RIC0.FRE14 1: Set RIC0.FRE14 to 0
13	FRD13	0	R/W	Frame Received interrupt Disable 13 This bit supports interrupt enable. It controls set of RIC0.FRE13. This bit is always read as 0. 0: No change of RIC0.FRE13 1: Set RIC0.FRE13 to 0
12	FRD12	0	R/W	Frame Received interrupt Disable 12 This bit supports interrupt enable. It controls set of RIC0.FRE12. This bit is always read as 0. 0: No change of RIC0.FRE12 1: Set RIC0.FRE12 to 0

Bit	Bit Name	Initial Value	R/W	Description
11	FRD11	0	R/W	Frame Received interrupt Disable 11 This bit supports interrupt enable. It controls set of RIC0.FRE11. This bit is always read as 0. 0: No change of RIC0.FRE11 1: Set RIC0.FRE11 to 0
10	FRD10	0	R/W	Frame Received interrupt Disable 10 This bit supports interrupt enable. It controls set of RIC0.FRE10. This bit is always read as 0. 0: No change of RIC0.FRE10 1: Set RIC0.FRE10 to 0
9	FRD9	0	R/W	Frame Received interrupt Disable 9 This bit supports interrupt enable. It controls set of RIC0.FRE9. This bit is always read as 0. 0: No change of RIC0.FRE9 1: Set RIC0.FRE9 to 0
8	FRD8	0	R/W	Frame Received interrupt Disable 8 This bit supports interrupt enable. It controls set of RIC0.FRE8. This bit is always read as 0. 0: No change of RIC0.FRE8 1: Set RIC0.FRE8 to 0
7	FRD7	0	R/W	Frame Received interrupt Disable 7 This bit supports interrupt enable. It controls set of RIC0.FRE7. This bit is always read as 0. 0: No change of RIC0.FRE7 1: Set RIC0.FRE7 to 0
6	FRD6	0	R/W	Frame Received interrupt Disable 6 This bit supports interrupt enable. It controls set of RIC0.FRE6. This bit is always read as 0. 0: No change of RIC0.FRE6 1: Set RIC0.FRE6 to 0
5	FRD5	0	R/W	Frame Received interrupt Disable 5 This bit supports interrupt enable. It controls set of RIC0.FRE5. This bit is always read as 0. 0: No change of RIC0.FRE5 1: Set RIC0.FRE5 to 0
4	FRD4	0	R/W	Frame Received interrupt Disable 4 This bit supports interrupt enable. It controls set of RIC0.FRE4. This bit is always read as 0. 0: No change of RIC0.FRE4 1: Set RIC0.FRE4 to 0
3	FRD3	0	R/W	Frame Received interrupt Disable 3 This bit supports interrupt enable. It controls set of RIC0.FRE3. This bit is always read as 0. 0: No change of RIC0.FRE3 1: Set RIC0.FRE3 to 0

Bit	Bit Name	Initial Value	R/W	Description
2	FRD2	0	R/W	Frame Received interrupt Disable 2 This bit supports interrupt enable. It controls set of RIC0.FRE2. This bit is always read as 0. 0: No change of RIC0.FRE2 1: Set RIC0.FRE2 to 0
1	FRD1	0	R/W	Frame Received interrupt Disable 1 This bit supports interrupt enable. It controls set of RIC0.FRE1. This bit is always read as 0. 0: No change of RIC0.FRE1 1: Set RIC0.FRE1 to 0
0	FRD0	0	R/W	Frame Received interrupt Disable 0 This bit supports interrupt enable. It controls set of RIC0.FRE0. This bit is always read as 0. 0: No change of RIC0.FRE0 1: Set RIC0.FRE0 to 0

33A.2.73 Reception Interrupt Enable register 1 (RIE1)

The RIE1 register is used to control the Reception Interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RFWS	—	—	—	—	—	—	—	—	—	—	—	—	—	RWS17	RWS16
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	RFWS	0	R/W	Rx-FIFO Warning interrupt Set This bit supports interrupt enable. It controls set of RIC1.RFWE. This bit is always read as 0. 0: No change of RIC1.RFWE 1: Set RIC1.RFWE to 1
30 to 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
17	RWS17	0	R/W	Reception Warning interrupt Set 17 This bit supports interrupt enable. It controls set of RIC1.RWE17. This bit is always read as 0. 0: No change of RIC1.RWE17 1: Set RIC1.RWE17 to 1
16	RWS16	0	R/W	Reception Warning interrupt Set 16 This bit supports interrupt enable. It controls set of RIC1.RWE16. This bit is always read as 0. 0: No change of RIC1.RWE16 1: Set RIC1.RWE16 to 1
15	RWS15	0	R/W	Reception Warning interrupt Set 15 This bit supports interrupt enable. It controls set of RIC1.RWE15. This bit is always read as 0. 0: No change of RIC1.RWE15 1: Set RIC1.RWE15 to 1
14	RWS14	0	R/W	Reception Warning interrupt Set 14 This bit supports interrupt enable. It controls set of RIC1.RWE14. This bit is always read as 0. 0: No change of RIC1.RWE14 1: Set RIC1.RWE14 to 1
13	RWS13	0	R/W	Reception Warning interrupt Set 13 This bit supports interrupt enable. It controls set of RIC1.RWE13. This bit is always read as 0. 0: No change of RIC1.RWE13 1: Set RIC1.RWE13 to 1

Bit	Bit Name	Initial Value	R/W	Description
12	RWS12	0	R/W	Reception Warning interrupt Set 12 This bit supports interrupt enable. It controls set of RIC1.RWE12. This bit is always read as 0. 0: No change of RIC1.RWE12 1: Set RIC1.RWE12 to 1
11	RWS11	0	R/W	Reception Warning interrupt Set 11 This bit supports interrupt enable. It controls set of RIC1.RWE11. This bit is always read as 0. 0: No change of RIC1.RWE11 1: Set RIC1.RWE11 to 1
10	RWS10	0	R/W	Reception Warning interrupt Set 10 This bit supports interrupt enable. It controls set of RIC1.RWE10. This bit is always read as 0. 0: No change of RIC1.RWE10 1: Set RIC1.RWE10 to 1
9	RWS9	0	R/W	Reception Warning interrupt Set 9 This bit supports interrupt enable. It controls set of RIC1.RWE9. This bit is always read as 0. 0: No change of RIC1.RWE9 1: Set RIC1.RWE9 to 1
8	RWS8	0	R/W	Reception Warning interrupt Set 8 This bit supports interrupt enable. It controls set of RIC1.RWE8. This bit is always read as 0. 0: No change of RIC1.RWE8 1: Set RIC1.RWE8 to 1
7	RWS7	0	R/W	Reception Warning interrupt Set 7 This bit supports interrupt enable. It controls set of RIC1.RWE7. This bit is always read as 0. 0: No change of RIC1.RWE7 1: Set RIC1.RWE7 to 1
6	RWS6	0	R/W	Reception Warning interrupt Set 6 This bit supports interrupt enable. It controls set of RIC1.RWE6. This bit is always read as 0. 0: No change of RIC1.RWE6 1: Set RIC1.RWE6 to 1
5	RWS5	0	R/W	Reception Warning interrupt Set 5 This bit supports interrupt enable. It controls set of RIC1.RWE5. This bit is always read as 0. 0: No change of RIC1.RWE5 1: Set RIC1.RWE5 to 1
4	RWS4	0	R/W	Reception Warning interrupt Set 4 This bit supports interrupt enable. It controls set of RIC1.RWE4. This bit is always read as 0. 0: No change of RIC1.RWE4 1: Set RIC1.RWE4 to 1

Bit	Bit Name	Initial Value	R/W	Description
3	RWS3	0	R/W	Reception Warning interrupt Set 3 This bit supports interrupt enable. It controls set of RIC1.RWE3. This bit is always read as 0. 0: No change of RIC1.RWE3 1: Set RIC1.RWE3 to 1
2	RWS2	0	R/W	Reception Warning interrupt Set 2 This bit supports interrupt enable. It controls set of RIC1.RWE2. This bit is always read as 0. 0: No change of RIC1.RWE2 1: Set RIC1.RWE2 to 1
1	RWS1	0	R/W	Reception Warning interrupt Set 1 This bit supports interrupt enable. It controls set of RIC1.RWE1. This bit is always read as 0. 0: No change of RIC1.RWE1 1: Set RIC1.RWE1 to 1
0	RWS0	0	R/W	Reception Warning interrupt Set 0 This bit supports interrupt enable. It controls set of RIC1.RWE0. This bit is always read as 0. 0: No change of RIC1.RWE0 1: Set RIC1.RWE0 to 1

33A.2.74 Reception Interrupt Disable register 1 (RID1)

The RID1 register is used to control the Reception Interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RFWD	—	—	—	—	—	—	—	—	—	—	—	—	—	RWD17	RWD16
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RWD15	RWD14	RWD13	RWD12	RWD11	RWD10	RWD9	RWD8	RWD7	RWD6	RWD5	RWD4	RWD3	RWD2	RWD1	RWD0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	RFWD	0	R/W	Rx-FIFO Warning interrupt Disable This bit supports interrupt enable. It controls set of RIC1.RFWE. This bit is always read as 0. 0: No change of RIC1.RFWE 1: Set RIC1.RFWE to 0
30 to 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
17	RWD17	0	R/W	Reception Warning interrupt Disable 17 This bit supports interrupt enable. It controls set of RIC1.RWE17. This bit is always read as 0. 0: No change of RIC1.RWE17 1: Set RIC1.RWE17 to 0
16	RWD16	0	R/W	Reception Warning interrupt Disable 16 This bit supports interrupt enable. It controls set of RIC1.RWE16. This bit is always read as 0. 0: No change of RIC1.RWE16 1: Set RIC1.RWE16 to 0
15	RWD15	0	R/W	Reception Warning interrupt Disable 15 This bit supports interrupt enable. It controls set of RIC1.RWE15. This bit is always read as 0. 0: No change of RIC1.RWE15 1: Set RIC1.RWE15 to 0
14	RWD14	0	R/W	Reception Warning interrupt Disable 14 This bit supports interrupt enable. It controls set of RIC1.RWE14. This bit is always read as 0. 0: No change of RIC1.RWE14 1: Set RIC1.RWE14 to 0
13	RWD13	0	R/W	Reception Warning interrupt Disable 13 This bit supports interrupt enable. It controls set of RIC1.RWE13. This bit is always read as 0. 0: No change of RIC1.RWE13 1: Set RIC1.RWE13 to 0

Bit	Bit Name	Initial Value	R/W	Description
12	RWD12	0	R/W	Reception Warning interrupt Disable 12 This bit supports interrupt enable. It controls set of RIC1.RWE12. This bit is always read as 0. 0: No change of RIC1.RWE12 1: Set RIC1.RWE12 to 0
11	RWD11	0	R/W	Reception Warning interrupt Disable 11 This bit supports interrupt enable. It controls set of RIC1.RWE11. This bit is always read as 0. 0: No change of RIC1.RWE11 1: Set RIC1.RWE11 to 0
10	RWD10	0	R/W	Reception Warning interrupt Disable 10 This bit supports interrupt enable. It controls set of RIC1.RWE10. This bit is always read as 0. 0: No change of RIC1.RWE10 1: Set RIC1.RWE10 to 0
9	RWD9	0	R/W	Reception Warning interrupt Disable 9 This bit supports interrupt enable. It controls set of RIC1.RWE9. This bit is always read as 0. 0: No change of RIC1.RWE9 1: Set RIC1.RWE9 to 0
8	RWD8	0	R/W	Reception Warning interrupt Disable 8 This bit supports interrupt enable. It controls set of RIC1.RWE8. This bit is always read as 0. 0: No change of RIC1.RWE8 1: Set RIC1.RWE8 to 0
7	RWD7	0	R/W	Reception Warning interrupt Disable 7 This bit supports interrupt enable. It controls set of RIC1.RWE7. This bit is always read as 0. 0: No change of RIC1.RWE7 1: Set RIC1.RWE7 to 0
6	RWD6	0	R/W	Reception Warning interrupt Disable 6 This bit supports interrupt enable. It controls set of RIC1.RWE6. This bit is always read as 0. 0: No change of RIC1.RWE6 1: Set RIC1.RWE6 to 0
5	RWD5	0	R/W	Reception Warning interrupt Disable 5 This bit supports interrupt enable. It controls set of RIC1.RWE5. This bit is always read as 0. 0: No change of RIC1.RWE5 1: Set RIC1.RWE5 to 0
4	RWD4	0	R/W	Reception Warning interrupt Disable 4 This bit supports interrupt enable. It controls set of RIC1.RWE4. This bit is always read as 0. 0: No change of RIC1.RWE4 1: Set RIC1.RWE4 to 0

Bit	Bit Name	Initial Value	R/W	Description
3	RWD3	0	R/W	Reception Warning interrupt Disable 3 This bit supports interrupt enable. It controls set of RIC1.RWE3. This bit is always read as 0. 0: No change of RIC1.RWE3 1: Set RIC1.RWE3 to 0
2	RWD2	0	R/W	Reception Warning interrupt Disable 2 This bit supports interrupt enable. It controls set of RIC1.RWE2. This bit is always read as 0. 0: No change of RIC1.RWE2 1: Set RIC1.RWE2 to 0
1	RWD1	0	R/W	Reception Warning interrupt Disable 1 This bit supports interrupt enable. It controls set of RIC1.RWE1. This bit is always read as 0. 0: No change of RIC1.RWE1 1: Set RIC1.RWE1 to 0
0	RWD0	0	R/W	Reception Warning interrupt Disable 0 This bit supports interrupt enable. It controls set of RIC1.RWE0. This bit is always read as 0. 0: No change of RIC1.RWE0 1: Set RIC1.RWE0 to 0

33A.2.75 Reception Interrupt Enable register 2 (RIE2)

The RIE2 register is used to control the Reception Interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RFFS	—	—	—	—	—	—	—	—	—	—	—	—	—	QFS17	QFS16

Bit	Bit Name	Initial Value	R/W	Description
31	RFFS	0	R/W	Rx-FIFO Full interrupt Set This bit supports interrupt enable. It controls set of RIC2.RFFE. This bit is always read as 0. 0: No change of RIC2.RFFE 1: Set RIC2.RFFE to 1
30 to 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
17	QFS17	0	R/W	Queue Full interrupt Set 17 This bit supports interrupt enable. It controls set of RIC2.QFE17. This bit is always read as 0. 0: No change of RIC2.QFE17 1: Set RIC2.QFE17 to 1
16	QFS16	0	R/W	Queue Full interrupt Set 16 This bit supports interrupt enable. It controls set of RIC2.QFE16. This bit is always read as 0. 0: No change of RIC2.QFE16 1: Set RIC2.QFE16 to 1
15	QFS15	0	R/W	Queue Full interrupt Set 15 This bit supports interrupt enable. It controls set of RIC2.QFE15. This bit is always read as 0. 0: No change of RIC2.QFE15 1: Set RIC2.QFE15 to 1
14	QFS14	0	R/W	Queue Full interrupt Set 14 This bit supports interrupt enable. It controls set of RIC2.QFE14. This bit is always read as 0. 0: No change of RIC2.QFE14 1: Set RIC2.QFE14 to 1
13	QFS13	0	R/W	Queue Full interrupt Set 13 This bit supports interrupt enable. It controls set of RIC2.QFE13. This bit is always read as 0. 0: No change of RIC2.QFE13 1: Set RIC2.QFE13 to 1

Bit	Bit Name	Initial Value	R/W	Description
12	QFS12	0	R/W	Queue Full interrupt Set 12 This bit supports interrupt enable. It controls set of RIC2.QFE12. This bit is always read as 0. 0: No change of RIC2.QFE12 1: Set RIC2.QFE12 to 1
11	QFS11	0	R/W	Queue Full interrupt Set 11 This bit supports interrupt enable. It controls set of RIC2.QFE11. This bit is always read as 0. 0: No change of RIC2.QFE11 1: Set RIC2.QFE11 to 1
10	QFS10	0	R/W	Queue Full interrupt Set 10 This bit supports interrupt enable. It controls set of RIC2.QFE10. This bit is always read as 0. 0: No change of RIC2.QFE10 1: Set RIC2.QFE10 to 1
9	QFS9	0	R/W	Queue Full interrupt Set 9 This bit supports interrupt enable. It controls set of RIC2.QFE9. This bit is always read as 0. 0: No change of RIC2.QFE9 1: Set RIC2.QFE9 to 1
8	QFS8	0	R/W	Queue Full interrupt Set 8 This bit supports interrupt enable. It controls set of RIC2.QFE8. This bit is always read as 0. 0: No change of RIC2.QFE8 1: Set RIC2.QFE8 to 1
7	QFS7	0	R/W	Queue Full interrupt Set 7 This bit supports interrupt enable. It controls set of RIC2.QFE7. This bit is always read as 0. 0: No change of RIC2.QFE7 1: Set RIC2.QFE7 to 1
6	QFS6	0	R/W	Queue Full interrupt Set 6 This bit supports interrupt enable. It controls set of RIC2.QFE6. This bit is always read as 0. 0: No change of RIC2.QFE6 1: Set RIC2.QFE6 to 1
5	QFS5	0	R/W	Queue Full interrupt Set 5 This bit supports interrupt enable. It controls set of RIC2.QFE5. This bit is always read as 0. 0: No change of RIC2.QFE5 1: Set RIC2.QFE5 to 1
4	QFS4	0	R/W	Queue Full interrupt Set 4 This bit supports interrupt enable. It controls set of RIC2.QFE4. This bit is always read as 0. 0: No change of RIC2.QFE4 1: Set RIC2.QFE4 to 1

Bit	Bit Name	Initial Value	R/W	Description
3	QFS3	0	R/W	Queue Full interrupt Set 3 This bit supports interrupt enable. It controls set of RIC2.QFE3. This bit is always read as 0. 0: No change of RIC2.QFE3 1: Set RIC2.QFE3 to 1
2	QFS2	0	R/W	Queue Full interrupt Set 2 This bit supports interrupt enable. It controls set of RIC2.QFE2. This bit is always read as 0. 0: No change of RIC2.QFE2 1: Set RIC2.QFE2 to 1
1	QFS1	0	R/W	Queue Full interrupt Set 1 This bit supports interrupt enable. It controls set of RIC2.QFE1. This bit is always read as 0. 0: No change of RIC2.QFE1 1: Set RIC2.QFE1 to 1
0	QFS0	0	R/W	Queue Full interrupt Set 0 This bit supports interrupt enable. It controls set of RIC2.QFE0. This bit is always read as 0. 0: No change of RIC2.QFE0 1: Set RIC2.QFE0 to 1

33A.2.76 Reception Interrupt Disable register 2 (RID2)

The RID2 register is used to control the Reception Interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RFFD	—	—	—	—	—	—	—	—	—	—	—	—	—	QFD17	QFD16
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	QFD15	QFD14	QFD13	QFD12	QFD11	QFD10	QFD9	QFD8	QFD7	QFD6	QFD5	QFD4	QFD3	QFD2	QFD1	QFD0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	RFFD	0	R/W	Rx-FIFO Full interrupt Disable This bit supports interrupt enable. It controls set of RIC2.RFFE. This bit is always read as 0. 0: No change of RIC2.RFFE 1: Set RIC2.RFFE to 0
30 to 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
17	QFD17	0	R/W	Queue Full interrupt Disable 17 This bit supports interrupt enable. It controls set of RIC2.QFE17. This bit is always read as 0. 0: No change of RIC2.QFE17 1: Set RIC2.QFE17 to 0
16	QFD16	0	R/W	Queue Full interrupt Disable 16 This bit supports interrupt enable. It controls set of RIC2.QFE16. This bit is always read as 0. 0: No change of RIC2.QFE16 1: Set RIC2.QFE16 to 0
15	QFD15	0	R/W	Queue Full interrupt Disable 15 This bit supports interrupt enable. It controls set of RIC2.QFE15. This bit is always read as 0. 0: No change of RIC2.QFE15 1: Set RIC2.QFE15 to 0
14	QFD14	0	R/W	Queue Full interrupt Disable 14 This bit supports interrupt enable. It controls set of RIC2.QFE14. This bit is always read as 0. 0: No change of RIC2.QFE14 1: Set RIC2.QFE14 to 0
13	QFD13	0	R/W	Queue Full interrupt Disable 13 This bit supports interrupt enable. It controls set of RIC2.QFE13. This bit is always read as 0. 0: No change of RIC2.QFE13 1: Set RIC2.QFE13 to 0

Bit	Bit Name	Initial Value	R/W	Description
12	QFD12	0	R/W	Queue Full interrupt Disable 12 This bit supports interrupt enable. It controls set of RIC2.QFE12. This bit is always read as 0. 0: No change of RIC2.QFE12 1: Set RIC2.QFE12 to 0
11	QFD11	0	R/W	Queue Full interrupt Disable 11 This bit supports interrupt enable. It controls set of RIC2.QFE11. This bit is always read as 0. 0: No change of RIC2.QFE11 1: Set RIC2.QFE11 to 0
10	QFD10	0	R/W	Queue Full interrupt Disable 10 This bit supports interrupt enable. It controls set of RIC2.QFE10. This bit is always read as 0. 0: No change of RIC2.QFE10 1: Set RIC2.QFE10 to 0
9	QFD9	0	R/W	Queue Full interrupt Disable 9 This bit supports interrupt enable. It controls set of RIC2.QFE9. This bit is always read as 0. 0: No change of RIC2.QFE9 1: Set RIC2.QFE9 to 0
8	QFD8	0	R/W	Queue Full interrupt Disable 8 This bit supports interrupt enable. It controls set of RIC2.QFE8. This bit is always read as 0. 0: No change of RIC2.QFE8 1: Set RIC2.QFE8 to 0
7	QFD7	0	R/W	Queue Full interrupt Disable 7 This bit supports interrupt enable. It controls set of RIC2.QFE7. This bit is always read as 0. 0: No change of RIC2.QFE7 1: Set RIC2.QFE7 to 0
6	QFD6	0	R/W	Queue Full interrupt Disable 6 This bit supports interrupt enable. It controls set of RIC2.QFE6. This bit is always read as 0. 0: No change of RIC2.QFE6 1: Set RIC2.QFE6 to 0
5	QFD5	0	R/W	Queue Full interrupt Disable 5 This bit supports interrupt enable. It controls set of RIC2.QFE5. This bit is always read as 0. 0: No change of RIC2.QFE5 1: Set RIC2.QFE5 to 0
4	QFD4	0	R/W	Queue Full interrupt Disable 4 This bit supports interrupt enable. It controls set of RIC2.QFE4. This bit is always read as 0. 0: No change of RIC2.QFE4 1: Set RIC2.QFE4 to 0

Bit	Bit Name	Initial Value	R/W	Description
3	QFD3	0	R/W	Queue Full interrupt Disable 3 This bit supports interrupt enable. It controls set of RIC2.QFE3. This bit is always read as 0. 0: No change of RIC2.QFE3 1: Set RIC2.QFE3 to 0
2	QFD2	0	R/W	Queue Full interrupt Disable 2 This bit supports interrupt enable. It controls set of RIC2.QFE2. This bit is always read as 0. 0: No change of RIC2.QFE2 1: Set RIC2.QFE2 to 0
1	QFD1	0	R/W	Queue Full interrupt Disable 1 This bit supports interrupt enable. It controls set of RIC2.QFE1. This bit is always read as 0. 0: No change of RIC2.QFE1 1: Set RIC2.QFE1 to 0
0	QFD0	0	R/W	Queue Full interrupt Disable 0 This bit supports interrupt enable. It controls set of RIC2.QFE0. This bit is always read as 0. 0: No change of RIC2.QFE0 1: Set RIC2.QFE0 to 0

33A.2.77 Transmission Interrupt Enable register (TIE)

The TIE register is used to control the Transmission Interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	TDPS3	TDPS2	TDPS1	TDPS0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	MFWS	MFUS	TFWS	TFUS	—	—	—	—	FTS3	FTS2	FTS1	FTS0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
19	TDPS3	0	R/W	Transmit Descriptor Processed interrupt Set 3 This bit supports interrupt enable. It controls set of TIC.TDPE3. This bit is always read as 0. 0: No change of TIC.TDPE3 1: Set TIC.TDPE3 to 1
18	TDPS2	0	R/W	Transmit Descriptor Processed interrupt Set 2 This bit supports interrupt enable. It controls set of TIC.TDPE2. This bit is always read as 0. 0: No change of TIC.TDPE2 1: Set TIC.TDPE2 to 1
17	TDPS1	0	R/W	Transmit Descriptor Processed interrupt Set 1 This bit supports interrupt enable. It controls set of TIC.TDPE1. This bit is always read as 0. 0: No change of TIC.TDPE1 1: Set TIC.TDPE1 to 1
16	TDPS0	0	R/W	Transmit Descriptor Processed interrupt Set 0 This bit supports interrupt enable. It controls set of TIC.TDPE0. This bit is always read as 0. 0: No change of TIC.TDPE0 1: Set TIC.TDPE0 to 1
15 to 12	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
11	MFWS	0	R/W	E-MAC status FIFO Warning interrupt Set This bit supports interrupt enable. It controls set of TIC.MFWE. This bit is always read as 0. 0: No change of TIC.MFWE 1: Set TIC.MFWE to 1

Bit	Bit Name	Initial Value	R/W	Description
10	MFUS	0	R/W	E-MAC status FIFO Updated interrupt Set This bit supports interrupt enable. It controls set of TIC.MFUE. This bit is always read as 0. 0: No change of TIC.MFUE 1: Set TIC.MFUE to 1
9	TFWS	0	R/W	Timestamp FIFO Warning interrupt Set This bit supports interrupt enable. It controls set of TIC.TFWE. This bit is always read as 0. 0: No change of TIC.TFWE 1: Set TIC.TFWE to 1
8	TFUS	0	R/W	Timestamp FIFO Updated interrupt Set This bit supports interrupt enable. It controls set of TIC.TFUE. This bit is always read as 0. 0: No change of TIC.TFUE 1: Set TIC.TFUE to 1
7 to 4	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
3	FTS3	0	R/W	Frame Transmitted interrupt Set 3 This bit supports interrupt enable. It controls set of TIC.FTE3. This bit is always read as 0. 0: No change of TIC.FTE3 1: Set TIC.FTE3 to 1
2	FTS2	0	R/W	Frame Transmitted interrupt Set 2 This bit supports interrupt enable. It controls set of TIC.FTE2. This bit is always read as 0. 0: No change of TIC.FTE2 1: Set TIC.FTE2 to 1
1	FTS1	0	R/W	Frame Transmitted interrupt Set 1 This bit supports interrupt enable. It controls set of TIC.FTE1. This bit is always read as 0. 0: No change of TIC.FTE1 1: Set TIC.FTE1 to 1
0	FTS0	0	R/W	Frame Transmitted interrupt Set 0 This bit supports interrupt enable. It controls set of TIC.FTE0. This bit is always read as 0. 0: No change of TIC.FTE0 1: Set TIC.FTE0 to 1

33A.2.78 Transmission Interrupt Disable register (TID)

The TID register is used to control the Transmission Interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	TDPD3	TDPD2	TDPD1	TDPD0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	MFWD	MFUD	TFWD	TFUD	—	—	—	—	FTD3	FTD2	FTD1	FTD0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
19	TDPD3	All 0	R/W	Transmit Descriptor Processed interrupt Disable 3 This bit supports interrupt enable. It controls set of TIC.TDPE3. This bit is always read as 0. 0: No change of TIC.TDPE3 1: Set TIC.TDPE3 to 0
18	TDPD2	All 0	R/W	Transmit Descriptor Processed interrupt Disable 2 This bit supports interrupt enable. It controls set of TIC.TDPE2. This bit is always read as 0. 0: No change of TIC.TDPE2 1: Set TIC.TDPE2 to 0
17	TDPD1	All 0	R/W	Transmit Descriptor Processed interrupt Disable 1 This bit supports interrupt enable. It controls set of TIC.TDPE1. This bit is always read as 0. 0: No change of TIC.TDPE1 1: Set TIC.TDPE1 to 0
16	TDPD0	All 0	R/W	Transmit Descriptor Processed interrupt Disable 0 This bit supports interrupt enable. It controls set of TIC.TDPE0. This bit is always read as 0. 0: No change of TIC.TDPE0 1: Set TIC.TDPE0 to 0
15 to 12	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
11	MFWD	0	R/W	E-MAC status FIFO Warning interrupt Disable This bit supports interrupt enable. It controls set of TIC.MFWE. This bit is always read as 0. 0: No change of TIC.MFWE 1: Set TIC.MFWE to 0

Bit	Bit Name	Initial Value	R/W	Description
10	MFUD	0	R/W	E-MAC status FIFO Updated interrupt Disable This bit supports interrupt enable. It controls set of TIC.MFUE. This bit is always read as 0. 0: No change of TIC.MFUE 1: Set TIC.MFUE to 0
9	TFWD	0	R/W	Timestamp FIFO Warning interrupt Disable This bit supports interrupt enable. It controls set of TIC.TFWE. This bit is always read as 0. 0: No change of TIC.TFWE 1: Set TIC.TFWE to 0
8	TFUD	0	R/W	Timestamp FIFO Updated interrupt Disable This bit supports interrupt enable. It controls set of TIC.TFUE. This bit is always read as 0. 0: No change of TIC.TFUE 1: Set TIC.TFUE to 0
7 to 4	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
3	FTD3	0	R/W	Frame Transmitted interrupt Disable 3 This bit supports interrupt enable. It controls set of TIC.FTE3. This bit is always read as 0. 0: No change of TIC.FTE3 1: Set TIC.FTE3 to 0
2	FTD2	0	R/W	Frame Transmitted interrupt Disable 2 This bit supports interrupt enable. It controls set of TIC.FTE2. This bit is always read as 0. 0: No change of TIC.FTE2 1: Set TIC.FTE2 to 0
1	FTD1	0	R/W	Frame Transmitted interrupt Disable 1 This bit supports interrupt enable. It controls set of TIC.FTE1. This bit is always read as 0. 0: No change of TIC.FTE1 1: Set TIC.FTE1 to 0
0	FTD0	0	R/W	Frame Transmitted interrupt Disable 0 This bit supports interrupt enable. It controls set of TIC.FTE0. This bit is always read as 0. 0: No change of TIC.FTE0 1: Set TIC.FTE0 to 0

33A.2.79 Reception Interrupt Enable register 3 (RIE3)

The RIE3 register is used to control the Reception Interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RDPS17	RDPS16
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RDPS15	RDPS14	RDPS13	RDPS12	RDPS11	RDPS10	RDPS9	RDPS8	RDPS7	RDPS6	RDPS5	RDPS4	RDPS3	RDPS2	RDPS1	RDPS0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
17	RDPS17	0	R/W	Receive Descriptor Processed interrupt Set 17 This bit supports interrupt enable. It controls set of RIC3.RDPE17. This bit is always read as 0. 0: No change of RIC3.RDPE17 1: Set RIC3.RDPE17 to 1
16	RDPS16	0	R/W	Receive Descriptor Processed interrupt Set 16 This bit supports interrupt enable. It controls set of RIC3.RDPE16. This bit is always read as 0. 0: No change of RIC3.RDPE16 1: Set RIC3.RDPE16 to 1
15	RDPS15	0	R/W	Receive Descriptor Processed interrupt Set 15 This bit supports interrupt enable. It controls set of RIC3.RDPE15. This bit is always read as 0. 0: No change of RIC3.RDPE15 1: Set RIC3.RDPE15 to 1
14	RDPS14	0	R/W	Receive Descriptor Processed interrupt Set 14 This bit supports interrupt enable. It controls set of RIC3.RDPE14. This bit is always read as 0. 0: No change of RIC3.RDPE14 1: Set RIC3.RDPE14 to 1
13	RDPS13	0	R/W	Receive Descriptor Processed interrupt Set 13 This bit supports interrupt enable. It controls set of RIC3.RDPE13. This bit is always read as 0. 0: No change of RIC3.RDPE13 1: Set RIC3.RDPE13 to 1
12	RDPS12	0	R/W	Receive Descriptor Processed interrupt Set 12 This bit supports interrupt enable. It controls set of RIC3.RDPE12. This bit is always read as 0. 0: No change of RIC3.RDPE12 1: Set RIC3.RDPE12 to 1

Bit	Bit Name	Initial Value	R/W	Description
11	RDPS11	0	R/W	Receive Descriptor Processed interrupt Set 11 This bit supports interrupt enable. It controls set of RIC3.RDPE11. This bit is always read as 0. 0: No change of RIC3.RDPE11 1: Set RIC3.RDPE11 to 1
10	RDPS10	0	R/W	Receive Descriptor Processed interrupt Set 10 This bit supports interrupt enable. It controls set of RIC3.RDPE10. This bit is always read as 0. 0: No change of RIC3.RDPE10 1: Set RIC3.RDPE10 to 1
9	RDPS9	0	R/W	Receive Descriptor Processed interrupt Set 9 This bit supports interrupt enable. It controls set of RIC3.RDPE9. This bit is always read as 0. 0: No change of RIC3.RDPE9 1: Set RIC3.RDPE9 to 1
8	RDPS8	0	R/W	Receive Descriptor Processed interrupt Set 8 This bit supports interrupt enable. It controls set of RIC3.RDPE8. This bit is always read as 0. 0: No change of RIC3.RDPE8 1: Set RIC3.RDPE8 to 1
7	RDPS7	0	R/W	Receive Descriptor Processed interrupt Set 7 This bit supports interrupt enable. It controls set of RIC3.RDPE7. This bit is always read as 0. 0: No change of RIC3.RDPE7 1: Set RIC3.RDPE7 to 1
6	RDPS6	0	R/W	Receive Descriptor Processed interrupt Set 6 This bit supports interrupt enable. It controls set of RIC3.RDPE6. This bit is always read as 0. 0: No change of RIC3.RDPE6 1: Set RIC3.RDPE6 to 1
5	RDPS5	0	R/W	Receive Descriptor Processed interrupt Set 5 This bit supports interrupt enable. It controls set of RIC3.RDPE5. This bit is always read as 0. 0: No change of RIC3.RDPE5 1: Set RIC3.RDPE5 to 1
4	RDPS4	0	R/W	Receive Descriptor Processed interrupt Set 4 This bit supports interrupt enable. It controls set of RIC3.RDPE4. This bit is always read as 0. 0: No change of RIC3.RDPE4 1: Set RIC3.RDPE4 to 1
3	RDPS3	0	R/W	Receive Descriptor Processed interrupt Set 3 This bit supports interrupt enable. It controls set of RIC3.RDPE3. This bit is always read as 0. 0: No change of RIC3.RDPE3 1: Set RIC3.RDPE3 to 1

Bit	Bit Name	Initial Value	R/W	Description
2	RDPS2	0	R/W	Receive Descriptor Processed interrupt Set 2 This bit supports interrupt enable. It controls set of RIC3.RDPE2. This bit is always read as 0. 0: No change of RIC3.RDPE2 1: Set RIC3.RDPE2 to 1
1	RDPS1	0	R/W	Receive Descriptor Processed interrupt Set 1 This bit supports interrupt enable. It controls set of RIC3.RDPE1. This bit is always read as 0. 0: No change of RIC3.RDPE1 1: Set RIC3.RDPE1 to 1
0	RDPS0	0	R/W	Receive Descriptor Processed interrupt Set 0 This bit supports interrupt enable. It controls set of RIC3.RDPE0. This bit is always read as 0. 0: No change of RIC3.RDPE0 1: Set RIC3.RDPE0 to 1

33A.2.80 Reception Interrupt Disable register 3 (RID3)

The RID3 register is used to control the Reception Interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RDPD17	RDPD16
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RDPD15	RDPD14	RDPD13	RDPD12	RDPD11	RDPD10	RDPD9	RDPD8	RDPD7	RDPD6	RDPD5	RDPD4	RDPD3	RDPD2	RDPD1	RDPD0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
17	RDPD17	0	R/W	Receive Descriptor Processed interrupt Disable 17 This bit supports interrupt enable. It controls set of RIC3.RDPE17. This bit is always read as 0. 0: No change of RIC3.RDPE17 1: Set RIC3.RDPE17 to 0
16	RDPD16	0	R/W	Receive Descriptor Processed interrupt Disable 16 This bit supports interrupt enable. It controls set of RIC3.RDPE16. This bit is always read as 0. 0: No change of RIC3.RDPE16 1: Set RIC3.RDPE16 to 0
15	RDPD15	0	R/W	Receive Descriptor Processed interrupt Disable 15 This bit supports interrupt enable. It controls set of RIC3.RDPE15. This bit is always read as 0. 0: No change of RIC3.RDPE15 1: Set RIC3.RDPE15 to 0
14	RDPD14	0	R/W	Receive Descriptor Processed interrupt Disable 14 This bit supports interrupt enable. It controls set of RIC3.RDPE14. This bit is always read as 0. 0: No change of RIC3.RDPE14 1: Set RIC3.RDPE14 to 0
13	RDPD13	0	R/W	Receive Descriptor Processed interrupt Disable 13 This bit supports interrupt enable. It controls set of RIC3.RDPE13. This bit is always read as 0. 0: No change of RIC3.RDPE13 1: Set RIC3.RDPE13 to 0
12	RDPD12	0	R/W	Receive Descriptor Processed interrupt Disable 12 This bit supports interrupt enable. It controls set of RIC3.RDPE12. This bit is always read as 0. 0: No change of RIC3.RDPE12 1: Set RIC3.RDPE12 to 0

Bit	Bit Name	Initial Value	R/W	Description
11	RDPD11	0	R/W	Receive Descriptor Processed interrupt Disable 11 This bit supports interrupt enable. It controls set of RIC3.RDPE11. This bit is always read as 0. 0: No change of RIC3.RDPE11 1: Set RIC3.RDPE11 to 0
10	RDPD10	0	R/W	Receive Descriptor Processed interrupt Disable 10 This bit supports interrupt enable. It controls set of RIC3.RDPE10. This bit is always read as 0. 0: No change of RIC3.RDPE10 1: Set RIC3.RDPE10 to 0
9	RDPD9	0	R/W	Receive Descriptor Processed interrupt Disable 9 This bit supports interrupt enable. It controls set of RIC3.RDPE9. This bit is always read as 0. 0: No change of RIC3.RDPE9 1: Set RIC3.RDPE9 to 0
8	RDPD8	0	R/W	Receive Descriptor Processed interrupt Disable 8 This bit supports interrupt enable. It controls set of RIC3.RDPE8. This bit is always read as 0. 0: No change of RIC3.RDPE8 1: Set RIC3.RDPE8 to 0
7	RDPD7	0	R/W	Receive Descriptor Processed interrupt Disable 7 This bit supports interrupt enable. It controls set of RIC3.RDPE7. This bit is always read as 0. 0: No change of RIC3.RDPE7 1: Set RIC3.RDPE7 to 0
6	RDPD6	0	R/W	Receive Descriptor Processed interrupt Disable 6 This bit supports interrupt enable. It controls set of RIC3.RDPE6. This bit is always read as 0. 0: No change of RIC3.RDPE6 1: Set RIC3.RDPE6 to 0
5	RDPD5	0	R/W	Receive Descriptor Processed interrupt Disable 5 This bit supports interrupt enable. It controls set of RIC3.RDPE5. This bit is always read as 0. 0: No change of RIC3.RDPE5 1: Set RIC3.RDPE5 to 0
4	RDPD4	0	R/W	Receive Descriptor Processed interrupt Disable 4 This bit supports interrupt enable. It controls set of RIC3.RDPE4. This bit is always read as 0. 0: No change of RIC3.RDPE4 1: Set RIC3.RDPE4 to 0
3	RDPD3	0	R/W	Receive Descriptor Processed interrupt Disable 3 This bit supports interrupt enable. It controls set of RIC3.RDPE3. This bit is always read as 0. 0: No change of RIC3.RDPE3 1: Set RIC3.RDPE3 to 0

Bit	Bit Name	Initial Value	R/W	Description
2	RDPD2	0	R/W	Receive Descriptor Processed interrupt Disable 2 This bit supports interrupt enable. It controls set of RIC3.RDPE2. This bit is always read as 0. 0: No change of RIC3.RDPE2 1: Set RIC3.RDPE2 to 0
1	RDPD1	0	R/W	Receive Descriptor Processed interrupt Disable 1 This bit supports interrupt enable. It controls set of RIC3.RDPE1. This bit is always read as 0. 0: No change of RIC3.RDPE1 1: Set RIC3.RDPE1 to 0
0	RDPD0	0	R/W	Receive Descriptor Processed interrupt Disable 0 This bit supports interrupt enable. It controls set of RIC3.RDPE0. This bit is always read as 0. 0: No change of RIC3.RDPE0 1: Set RIC3.RDPE0 to 0

33A.2.81 E-MAC Mode Register (ECMR)

ECMR is used to specify the operating mode of the E-MAC. The settings in this register are normally made in the initialization process following a reset.

The operating mode settings must not be changed while transmission or reception is enabled (i.e. while the RE or TE bit in this register is 1).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	TRCCM	—	—	RCSC	—	DPAD	RZPF	TZPF	PFR	RXF	TXF
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	MPDE	—	—	RE	TE	—	—	—	DM	PRM
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
26	TRCCM	0	R/W	Counter Clear Mode This bit sets the method for clearing the counter register. Refer to the descriptions of the counter registers. 0: Writing to a counter register leads to the register being cleared to 0. 1: Reading from a counter register leads to the register being cleared to 0.
25, 24	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
23	RCSC	0	R/W	Checksum Calculation Setting this bit to 1 enables automatic calculation of checksums for data in received frames. Only the data field of an Ethernet frame without a VLAN field is in the scope of checksum calculation. Specifically, the checksum is calculated from the data field, which follows the length/type field and is followed by the CRC field. Calculation only involves 16-bit addition; it does not involve bit inversion. 0: Checksums are not automatically calculated. 1: Checksums are automatically calculated.
22	—	0	R/W	Reserved This bit is read as 0. The write value should be 0.
21	DPAD	0	R/W	Data Padding This bit specifies padding or non-padding of data when less than 60 bytes are to be transmitted. When this bit is set to 1, data are transmitted without padding; when it is set to 0, data are padded to make up 60-byte units for transmission. 0: Padding to make up 60 bytes is inserted in data for transmission when fewer than 60 bytes are to be transmitted. 1: Padding is not inserted in data for transmission when fewer than 60 bytes are to be transmitted and the data are transmitted without being changed.

Bit	Bit Name	Initial Value	R/W	Description
20	RZPF	0	R/W	PAUSE Frame Reception with Time = 0 When the RZPF bit is set to 0, received PAUSE frames with the Timer value 0 are discarded. When the RZPF bit is set to 1, release from the transmission wait state follows reception of a PAUSE frame with the Timer value 0. 0: Reception of PAUSE frames with the TIME parameter value 0 is disabled. 1: Reception of PAUSE frames with the TIME parameter value 0 is enabled.
19	TZPF	0	R/W	Transmit Zero PAUSE Frame When setting CCC.FCE=1, and Rx FIFO become Warning Level. 0: Not transmit the PAUSE frame of TIME parameter value 0. 1: Transmit the PAUSE frame of TIME parameter value 0.
18	PFR	0	R/W	PAUSE Frame Receive Mode This bit specifies whether PAUSE frames are transferred to the AVB-DMAC. 0: PAUSE frames are not transferred to the AVB-DMAC. 1: PAUSE frames are transferred to the AVB-DMAC.
17	RXF	0	R/W	Operating Mode for Flow Control in Reception When the RXF bit is set to 1 and a PAUSE frame is received, a next frame to be transmitted is not transmitted until the time indicated by the Timer value in the PAUSE frame has elapsed. However, the transmission of a current frame is continued. The number of received PAUSE frames is also counted. For details, see section 33A.2.91 PAUSE Frame Receive Counter (PFRCR). Setting this bit to 0 disables PAUSE frame detection. 0: Detection of PAUSE frames is disabled. 1: Flow control for the receiving port is enabled.
16	TXF	0	R/W	Transmit Flow control mode 0: Flow control for the transmitting port is disabled. 1: Flow control for the transmitting port is enabled.
15 to 10	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
9	MPDE	0	R/W	Magic Packet™ Detection Enable The MPDE bit enables or disables Magic Packet™ detection by hardware to allow activation via the Ethernet connection. 0: Magic Packet™ detection is not enabled. 1: Magic Packet™ detection is enabled.
8, 7	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
6	RE	0	R/W	Reception Enable If this bit is switched from reception being enabled (RE = 1) to reception being disabled (RE = 0) while a frame is being received, reception will continue until reception of the frame is completed. 0: Reception is disabled. 1: Reception is enabled.

Bit	Bit Name	Initial Value	R/W	Description
5	TE	0	R/W	Transmission Enable If this bit is switched from transmission being enabled (TE = 1) to transmission being disabled (TE = 0) while a frame is being transmitted, transmission will continue until transmission of that frame is completed. 0: Transmission is disabled. 1: Transmission is enabled.
4 to 2	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
1	DM	0	R/W	Duplex Mode This bit should always be set to 1. The value after reset is 0. 0: Value after reset 1: Full-duplex operation This bit should always be set to 1.
0	PRM	0	R/W	Promiscuous Mode Setting the PRM bit enables all Ethernet frames to be received. All Ethernet frames mean all receivable frames, irrespective of differences of destination address (exclude PAUSE frame). 0: Normal operation 1: Promiscuous mode operation

33A.2.82 Receive Frame Length Register (RFLR)

The RFLR register specifies the maximum length (in bytes) of frames that can be received by this LSI. Settings in this register must not be changed while reception is enabled (while the RE bit in the E-MAC mode register (EMCR) is 1).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RFL[17:16]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFL[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
17 to 0	RFL[17:0]	H'0 0000	R/W	Receive Frame Length Frame data described here refers to all fields from the destination address up to the CRC data. Frame contents from the destination address up to the data are actually transferred to memory. CRC data are not included in the transfer. When more data than the specified number of bytes are received, the portion of data that exceeds the specified value and more 8 byte length is discarded. CAUTION: The prepared descriptor data size is just the specified value (RFLR.RFL). Therefore descriptor data size must be more than RFLR.RFL + 8 if you will receive such the long frame. H'0 0000 to H'0 05EE: 1,518 bytes H'0 05EF: 1,519 bytes H'0 05F0: 1,520 bytes : : H'0 07FF: 2,047 bytes H'0 0800: 2,048 bytes : : H'0 1000: 4,096 bytes : : H'1 0000: 65,535 bytes : : H'2 0000 to H'3 FFFF: 131,072 bytes

33A.2.83 E-MAC Status Register (ECSR)

The ECSR register indicates the state of the E-MAC. The CPU can be notified of the state. For bits associated with interrupts, the interrupt can be enabled or disabled by the corresponding bit in the E-MAC Interrupt Permission Register (ECSIPR) described in section 33A.2.84.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	PFRI	PHYI	LCHNG	MPD	ICD
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
4	PFRI	0	R/W	PAUSE Frame Retry Interrupt This bit indicate that reached to the number of PAUSE frame retransmission for register PFTTLR setting. Procedure for 0-clear to this bit is follows. 0: Read the PFTTCR register to clear the PFTTCR register. 1: Write to this bit 1.
3	PHYI	0	R/W	PHY interrupt terminal state bit This bit indicates the state of input to the PHY interrupt pin (AVB_PHY_INT) from the PHY-LSI. 0: PHY interrupt terminal (AVB_PHY_INT) is not asserted. 1: PHY interrupt terminal (AVB_PHY_INT) is asserted.
2	LCHNG	0	R/W	Link signal change bit This bit indicates a transition of the link status signal (AVB_LINK) input from the PHY-LSI from high to low or low to high. However, signal changes may also be detected at times when the link status signal (AVB_LINK) function is selected. To check the current link state, refer to the link status pin state bit in the PHY status register (PSR.LMON). 0: The change of Link status signal (AVB_LINK) is not detected. 1: The change of Link status signal (AVB_LINK) is detected.
1	MPD	0	R/W	Magic Packet™ Detection This bit indicates that a Magic Packet™ has been detected on the line. Writing 1 to this bit clears it to 0. 0: A Magic Packet™ has not been detected. 1: A Magic Packet™ has been detected.

Bit	Bit Name	Initial Value	R/W	Description
0	ICD	0	R/W	Illegal Carrier Detection This bit indicates that the PHY-LSI has detected an illegal carrier on the line. If a change in the signal input from the PHY-LSI occurs in a period shorter than the software recognition period, the correct information may not be obtained. Refer to the timing specification for the PHY-LSI used. Writing 1 to this bit clears it to 0. 0: PHY-LSI has not detected an illegal carrier on the line. 1: PHY-LSI has detected an illegal carrier on the line.

33A.2.84 E-MAC Interrupt Permission Register (ECSIPR)

The ECSIPR register enables or disables the states indicated by the ECSR register as interrupt sources. Each effective bit disables or enables interrupts corresponding to the bits in ECSR.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
4	PFRIM	0	R/W	PAUSE Frame Retry Interrupt Mask Setting this bit to 1 selects interrupt generation on setting of the PAUSE Frame Retry Interrupt bit (ECSR. PFRI) in the E-MAC status register to 1. 0: Interrupts on setting of the PFRI bit is disabled. 1: Interrupts on setting of the PFRI bit is enabled.
3	PHYIM	0	R/W	PHY Interrupt Mask Setting this bit to 1 selects interrupt generation on setting of the PHY interrupt terminal state bit (ECSR. PHYI) in the E-MAC status register to 1. 0: Interrupts on setting of the PHYI bit is disabled. 1: Interrupts on setting of the PHYI bit is enabled.
2	LINKIM	0	R/W	LINK Interrupt Mask Setting this bit to 1 selects interrupt generation on setting of the Link signal change bit (ECSR. LCHNG) in the E-MAC status register to 1. 0: Interrupts on setting of the LCHNG bit is disabled. 1: Interrupts on setting of the LCHNG bit is enabled.
1	MPDIP	0	R/W	Magic Packet™ Detect Interrupt Enable Setting this bit to 1 selects interrupt generation on setting of the Magic Packet™ detection bit (ECSR.MPD) in the E-MAC status register to 1. 0: Interrupts on setting of the MPD bit is disabled. 1: Interrupts on setting of the MPD bit is enabled.
0	ICDIP	0	R/W	Illegal Carrier Detect Interrupt Enable Setting this bit to 1 selects interrupt generation on setting of the illegal carrier detection bit (ECSR.ICD) in the E-MAC status register to 1. 0: Interrupts on setting of the ICD bit is disabled. 1: Interrupt on setting of the ICD bit is enabled.

33A.2.85 PHY Interface Register (PIR)

The PIR register provides a means of access to the PHY-LSI internal registers via the MII.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	MDI	MDO	MMD	MDC
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	—	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
3	MDI	—	R/W	MII Management Data-In This bit indicates the level of the AVB_MDIO pin.
2	MDO	0	R/W	MII Management Data-Out This bit holds data for output from the AVB_MDIO pin. The AVB_MDIO pin outputs data when the MMD bit is set to 1 (to specify writing as the direction). Data are not output while the MMD bit is set to 0 (to specify reading as the direction).
1	MMD	0	R/W	MII Management Mode This bit specifies the direction for data through MDIO (reading or writing). 0: Read direction is specified. 1: Write direction is specified.
0	MDC	0	R/W	MII Management Data Clock Values set in this bit are output on the AVB_MDC pin to supply the MII with the management data clock. For the method of access to the MII registers, see section 33A.3.13 Connection to PHY-LSI.

33A.2.86 PHY Status Register (PSR)

The PSR register is a read-only register that can read interface signals from the PHY-LSI.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LMON
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are read as 0.
0	LMON	0	R	Link Status Pin State The Link state can be read by connecting the Link signal output from the PHY-LSI to the link status pin (AVB_LNK) pin. For the active sense, refer to the specifications of the PHY-LSI to be connected. 0: The link status signal (AVB_LNK) is at the low level. 1: The link status signal (AVB_LNK) is at the high level.

33A.2.87 PHY_INT Polarity Register (PIPR)

The PIPR register is used to set the active sense of the AVB_PHY-INT pin.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

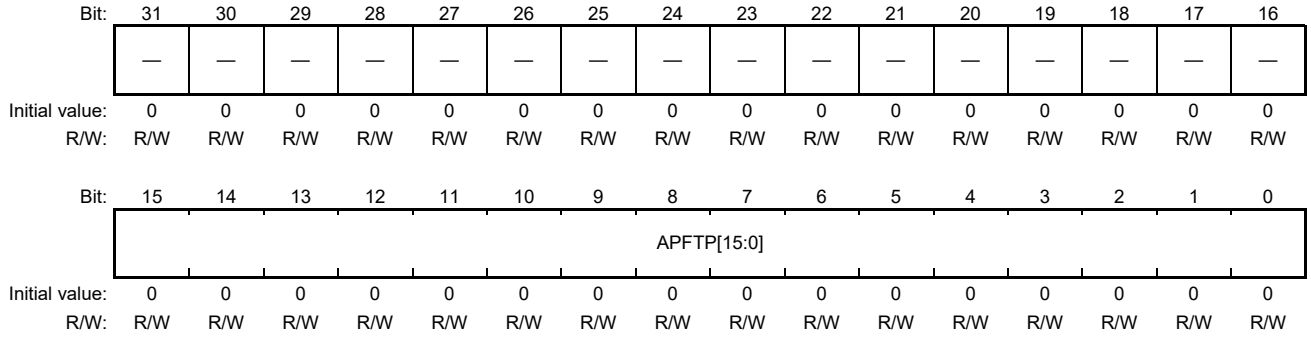
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PHYIP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
0	PHYIP	0	R/W	PHY Interrupt Input Pin Polarity This bit sets the active sense of the PHY interrupt pin (AVB_PHY-INT). For the active sense, refer to the specifications of the PHY-LSI to be connected. 0: PHY interrupt pin (AVB_PHY-INT) is active low (the low level triggers the interrupt state) 1: PHY interrupt pin (AVB_PHY-INT) is active high (the high level triggers the interrupt state)

33A.2.88 Automatic PAUSE frame register (APR)

The APR register is used to set the value for the TIME parameter of auto generated PAUSE frames.

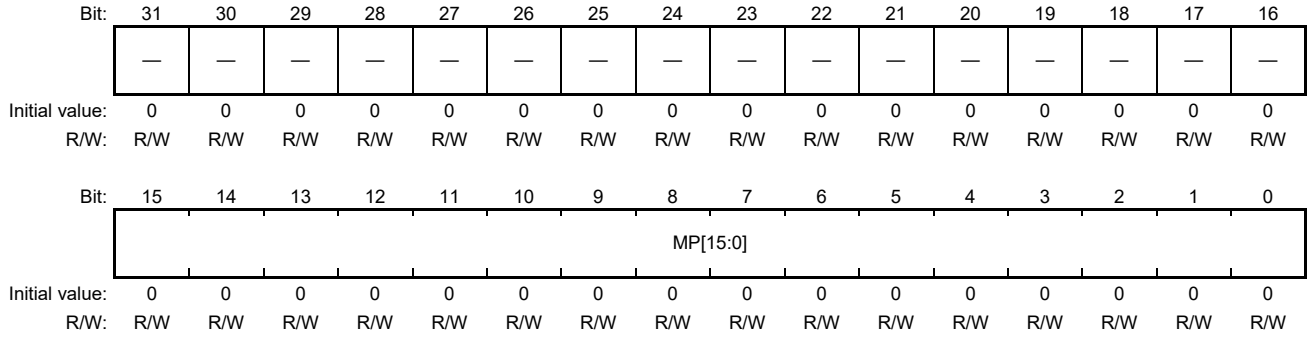
When ECMR.TXF = B'1, the value shouldn't set all 0 in this register.



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
15 to 0	APFTP[15:0]	H'0000	R/W	Auto Pause Frame Time Parameter When a PAUSE frame is auto transmitted, the value set in this register is used as its TIME parameter. H'0000: — H'0001: 1 × 512 bit time H'0002: 2 × 512 bit time : : H'FFFF: 65535 × 512 bit time A bit time changes relative to the transfer speed as follows. 1000 Mbps:1 bit time = 1 ns 100 Mbps: 1 bit time = 10 ns

33A.2.89 Manual PAUSE Frame Register (MPR)

The MPR register is used to set the value for the TIME parameter of manually generated PAUSE frames. When a PAUSE frame is manually transmitted, the value set in this register is used as its TIME parameter.



Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MP[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
15 to 0	MP[15:0]	H'0000	R/W	Manual PAUSE These bits set the value of the TIME parameter in manually generated PAUSE frames. The unit for the setting is 512 bit time. These bits set the TIME parameter value of a manual PAUSE frame. H'0000: — H'0001: 1 × 512 bit time H'0002: 2 × 512 bit time : : H'FFFF: 65535 × 512 bit time A bit time changes relative to the transfer speed as follows. 1000 Mbps: 1 bit time = 1 ns 100 Mbps: 1 bit time = 10 ns

33A.2.90 PAUSE Frame Transmit Counter (PFTCR)

The PFTCR register is a counter that indicates the number of times PAUSE frames have been transmitted.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFTXC[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
15 to 0	PFTXC[15:0]	H'0000	R	PAUSE Frame Transmit Counter Counter for counting the number of transmitted PAUSE frames The bits are cleared to 0 when they are read. If counting up and clearing of the counter coincide, clearing the counter takes priority.

33A.2.91 PAUSE Frame Receive Counter (PFRCR)

The RFRCR register is a counter that indicates the number of times PAUSE frames have been received.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFRXC[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are read as 0. The write value should be 0.
15 to 0	PFRXC[15:0]	H'0000	R	PAUSE Frame Receive Counter These bits indicate the number of PAUSE frames that have been received when flow control in reception is enabled (the RXF bit in ECMR = 1). The bits are cleared to 0 when they are read. If counting up and clearing the counter coincide, clearing the counter takes priority.

33A.2.92 Automatic PAUSE frame retransmit count register (TPAUSER)

The TPAUSER register is used to set the value for upper limit number of auto generated PAUSE frames.

The setting in this register must not be changed while transmission is enabled.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFRTULMT[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
15 to 0	PFRTULMT [15:0]	H'0000	R/W	Pause Frame Retry Upper LiMiT These bit's set the value for upper limit time of auto generated PAUSE frames while Receive FIFO caution. H'0000: unlimited H'0001: 1 time H'0002: 2 times : : H'FFFF: 65535 times

33A.2.93 PAUSE frame transmit times counter (PFTTCR)

The PFTTCR register is a counter that indicates the number of times auto PAUSE frames have been transmit.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PFRTC[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
15 to 0	PFRTC[15:0]	H'0000	R	Pause Frame Retry Counter These bits indicate the number of auto PAUSE frames that have been transmit while Receive FIFO caution. The bits are cleared to 0 when they are read and Receive FIFO caution start.

33A.2.94 E-MAC Mode Register 2 (GECMR)

The GECMR register specifies the operating mode for the E-MAC.

The setting in the GECMR register must not be changed while transmission or reception is enabled.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

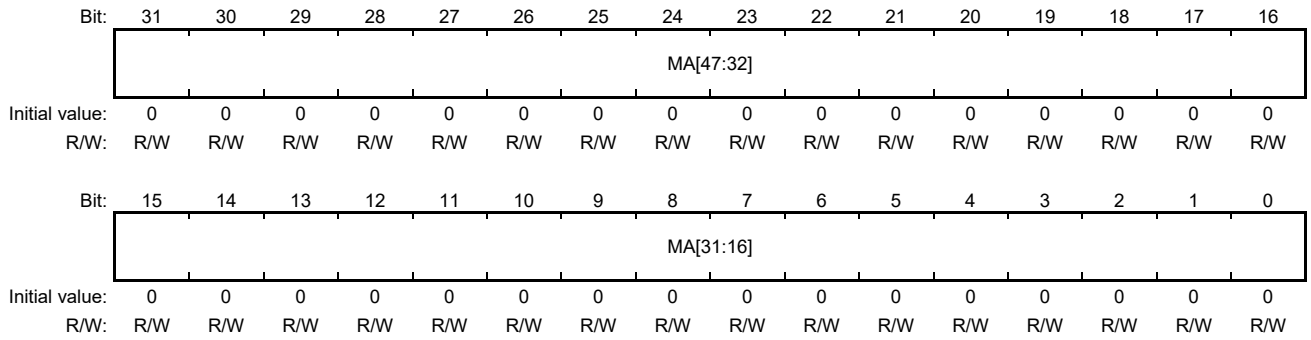
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SPEED
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
0	SPEED	0	R/W	Transfer Speed Setting This bit sets the transfer rate. 0: Transfer is at 100 Mbps. 1: Transfer is at 1000 Mbps.

33A.2.95 E-MAC Address High Register (MAHR)

The MAHR register specifies the 32 higher-order bits of the 48-bit E-MAC address. The settings in this register are normally made in the initialization process after a reset.

The settings in this register must not be changed while transmission or reception is enabled.

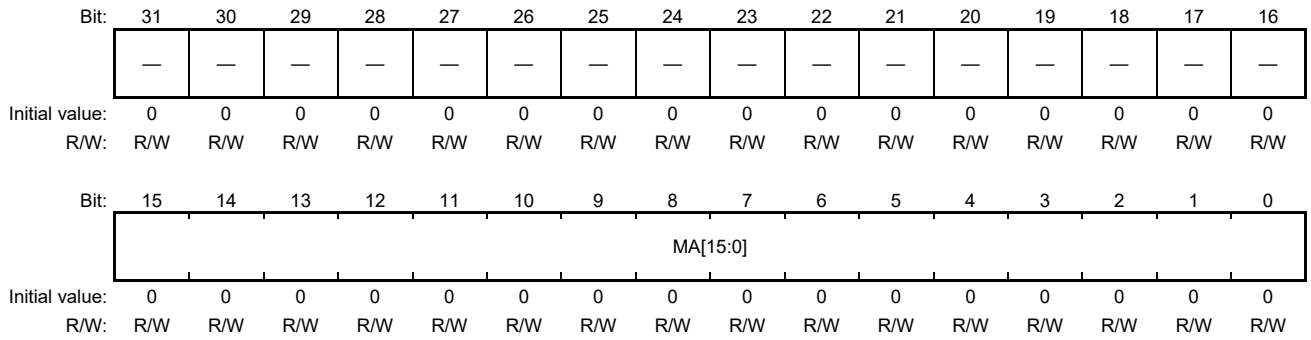


Bit	Bit Name	Initial Value	R/W	Description
31 to 0	MA[47:16]	H'0000 0000	R/W	E-MAC Address Bits 47 to 16 These bits are used to set the 32 higher-order bits of the E-MAC address. For example, if the E-MAC address is 01-23-45-67-89-AB (hexadecimal), set H'0123 4567 in the MAHR register.

33A.2.96 E-MAC Address Low Register (MALR)

The MALR register specifies the 16 lower-order bits of the 48-bit E-MAC address. The settings in this register are normally made in the initialization process after a reset.

The settings in this register must not be changed while transmission or reception is enabled.



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
15 to 0	MA[15:0]	H'0000	R/W	E-MAC Address Bits 15 to 0 These bits are used to set the 16 lower-order bits of the E-MAC address. For example, if the E-MAC address is 01-23-45-67-89-AB (hexadecimal), set H'89AB in the MALR register.

33A.2.97 Transmit retry over counter register (TROCR)

The TROCR register is a counter that indicates the number of times frames with time-out were transmit. Counting up stops when the value in this register reaches H'0000 FFFF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	FTTOC[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
15 to 0	FTTOC [15:0]	H'0000	R/W	Frame transmit time-out counter These bits indicate the number of transmit frames having time-out. The bits are cleared to 0 when they are read while the counter clear mode bit (TRCCM) in the E-MAC mode register is set to 1. When TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

33A.2.98 CRC Error Frame Receive Counter Register (CEFCR)

The CEFCR register is a counter that indicates the number of times frames with CRC errors were received. Counting up stops when the value in this register reaches H'0000 FFFF.

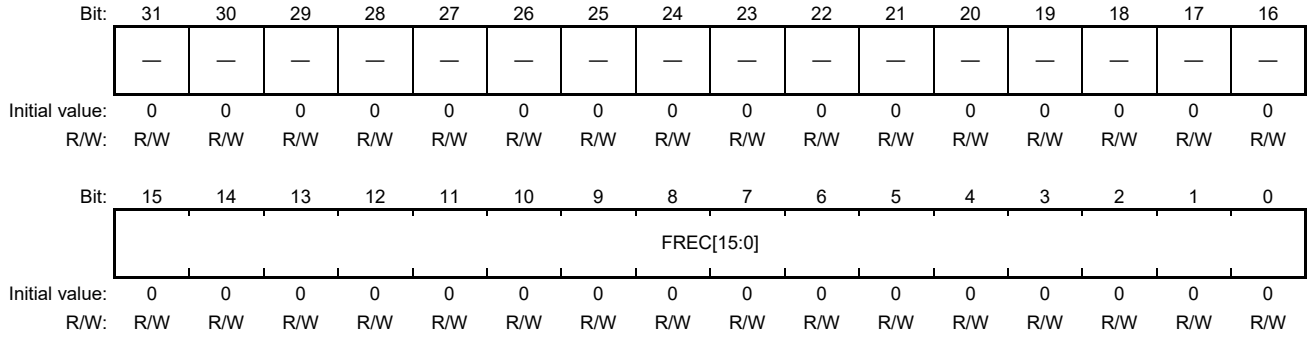
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CEFC[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
15 to 0	CEFC[15:0]	H'0000	R/W	CRC Error Frame Counter These bits indicate the number of received frames having CRC errors. The bits are cleared to 0 when they are read while the counter clear mode bit (TRCCM) in the E-MAC mode register is set to 1. When TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

33A.2.99 Frame Receive Error Counter Register (FRECR)

The FRECR register is a counter that indicates the number of frames for which receive errors were generated by input on the AVB_RX_ER pin from the PHY-LSI. Counting up stops when the value in this register reaches H'0000 FFFF.



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
15 to 0	FREC[15:0]	H'0000	R/W	Frame Receive Error Counter These bits indicate the number of errors during frame reception. The bits are cleared to 0 when they are read while the counter clear mode bit (TRCCM) in the E-MAC mode register is set to 1. When TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

33A.2.100 Too-Short Frame Receive Counter Register (TSFRCR)

The TSFRCR register is a counter that indicates the number of received frames that were fewer than 64 bytes in length. Counting stops when the value in this register reaches H'0000 FFFF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSFRC[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
15 to 0	TSFRC[15:0]	H'0000	R/W	Too-Short Frame Receive Counter These bits indicate the number of received frames that were fewer than 64 bytes in length. The bits are cleared to 0 when they are read while the counter clear mode bit (TRCCM) in the E-MAC mode register is set to 1. When TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

33A.2.101 Too-Long Frame Receive Counter Register (TLFRCR)

The TLFRCR register is a counter that indicates the number of received frames that were longer than the value specified in the receive frame length register (RFLR). Counting up stops when the value in the TLFRCR register reaches H'0000 FFFF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TLFC[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
15 to 0	TLFC[15:0]	H'0000	R/W	Too-Long Frame Receive Counter These bits indicate the number of received frames that were longer than the value in RFLR. The bits are cleared to 0 when they are read while the counter clear mode bit (TRCCM) in the E-MAC mode register is set to 1. When TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

33A.2.102 Residual-Bit Frame Receive Counter Register (RFCR)

The RFCR register is a counter that indicates the number of received frames containing “residual bits” (trailing bits not making up an 8-bit unit). Counting up stops when the value in this register reaches H'0000 FFFF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFC[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
15 to 0	RFC[15:0]	H'0000	R/W	Residual-Bit Frame Receive Counter These bits indicate the number of received frames containing residual bits. The bits are cleared to 0 when they are read while the counter clear mode bit (TRCCM) in the E-MAC mode register is set to 1. When TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

33A.2.103 Multicast Address Frame Receive Counter Register (MAFCR)

The MAFCR register is a counter that indicates the number of received frames for which a multicast address was specified. Counting up stops when the value in this register reaches H'0000 FFFF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MAFC[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R/W	Reserved These bits are read as 0. The write value should be 0.
15 to 0	MAFC[15:0]	H'0000	R/W	Multicast Address Frame Counter These bits indicate the number of multicast frames that have been received. The bits are cleared to 0 when they are read while the counter clear mode bit (TRCCM) in the E-MAC mode register is set to 1. When TRCCM = 0, they are cleared to 0 by the writing of any value to this register.

33A.3 Operation

The EthernetAVB consists of the following functional units:

- DMA transfer controller (AVB-DMAC): Handles DMA transfer between the data storage areas for reception and transmission in the URAM and the reception and transmission FIFO buffers
- MAC controller (E-MAC): Handles transfer between the reception and transmission FIFO buffers and the RGMII

Using its direct memory access (DMA) function, the AVB-DMAC handles DMA transfer of frame data between the destinations for storing Ethernet frame data for transmission and reception in the URAM and the FIFO buffers for reception and transmission. Data cannot be directly read from or written to the FIFO buffers.

To handle DMA transfer, the AVB-DMAC requires information that includes the addresses for storage of data for transmission and received data. These data are referred to as descriptors. The AVB-DMAC reads data for transmission from the storage area for data to be transmitted according to the information in descriptors and writes received data to the storage area for received data accompanied by information in descriptors. The descriptors are placed in the URAM. Arranging multiple descriptors in descriptor lists allows the continuous reception or transmission of multiple Ethernet frames.

The E-MAC supports a RGMII, which provides an interface format for the externally connected PHY-LSI. The E-MAC constructs Ethernet frames from data written to the transmission FIFO and transmits these frames to the RGMII. It also performs CRC checking of Ethernet frames received from the RGMII and writes the frames to the reception FIFO.

33A.3.1 AVB-DMAC Operating Modes

Figure 33A.2 illustrates the operating modes of the AVB-DMAC.

Transitions of AVB-DMAC operating mode are under the control of the items listed below.

- CPU operating mode (hardware reset and power-down mode)
- Configuration of the operating mode configuration bits (CCC.OPC) in the AVB-DMAC mode register

The current operating mode can be confirmed by reading the operating mode status bits in the AVB-DMAC status register (CSR.OPS).

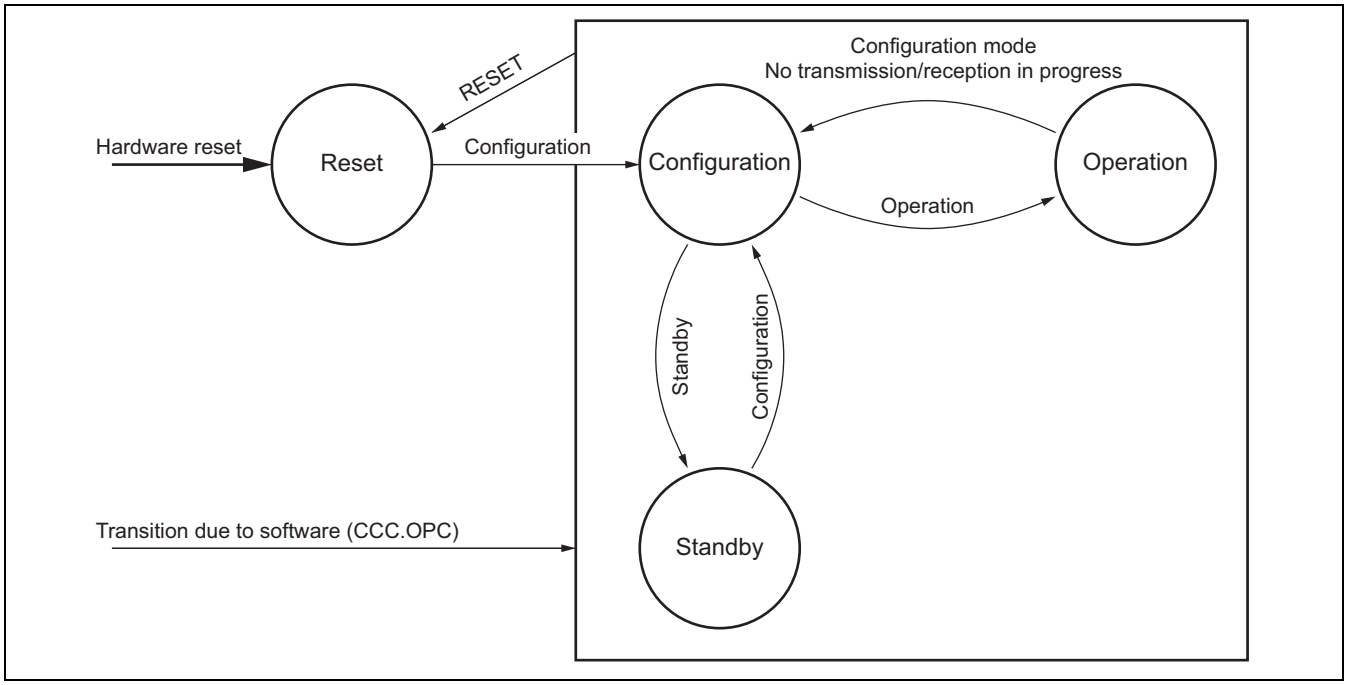


Figure 33A.2 Operating Mode of AVB-DMAC

33A.3.1.1 Operating Modes

(1) Reset mode

After a hardware reset, the AVB-DMAC enters reset mode.
In reset mode, only the AVB-DMAC operating mode control function is controllable and other functions are all stopped. This mode is designed for reduced power when the Ethernet function is not necessary.

(2) Configuration mode

In configuration mode, various settings for the AVB-DMAC can be made.
The operation of most functions is stopped and all status registers are initialized to their reset values. The E-MAC functions in this mode.
By CCC.GAC it is possible to enable gPTP support already in CONFIG mode.

(3) Operation mode

In operation mode, all functions of the AVB-DMAC can operate. Ethernet communications can only proceed in this mode.

(4) Standby mode

In standby mode, the E-MAC can only be used to control the operating mode. Other functions cannot be used.
When CCC.GAC is 1 CPU should not enter STANDBY mode.

33A.3.1.2 How to Set the Operating Mode

Set the operating mode configuration bits in the AVB-DMAC mode register (CCC.OPC) to select the operating mode. Furthermore, the current operating mode can be checked by reading the operating mode status bits in the AVB-DMAC status register (CSR.OPS).

Transitions other than from operation mode to configuration mode are made after the value is written to the operating mode configuration bits (CCC.OPC) (Figure 33A.3).

For transitions from operation mode to configuration mode, follow the procedure in Figure 33A.4 because any transmission and reception in progress will be executed before the transition to configuration mode.

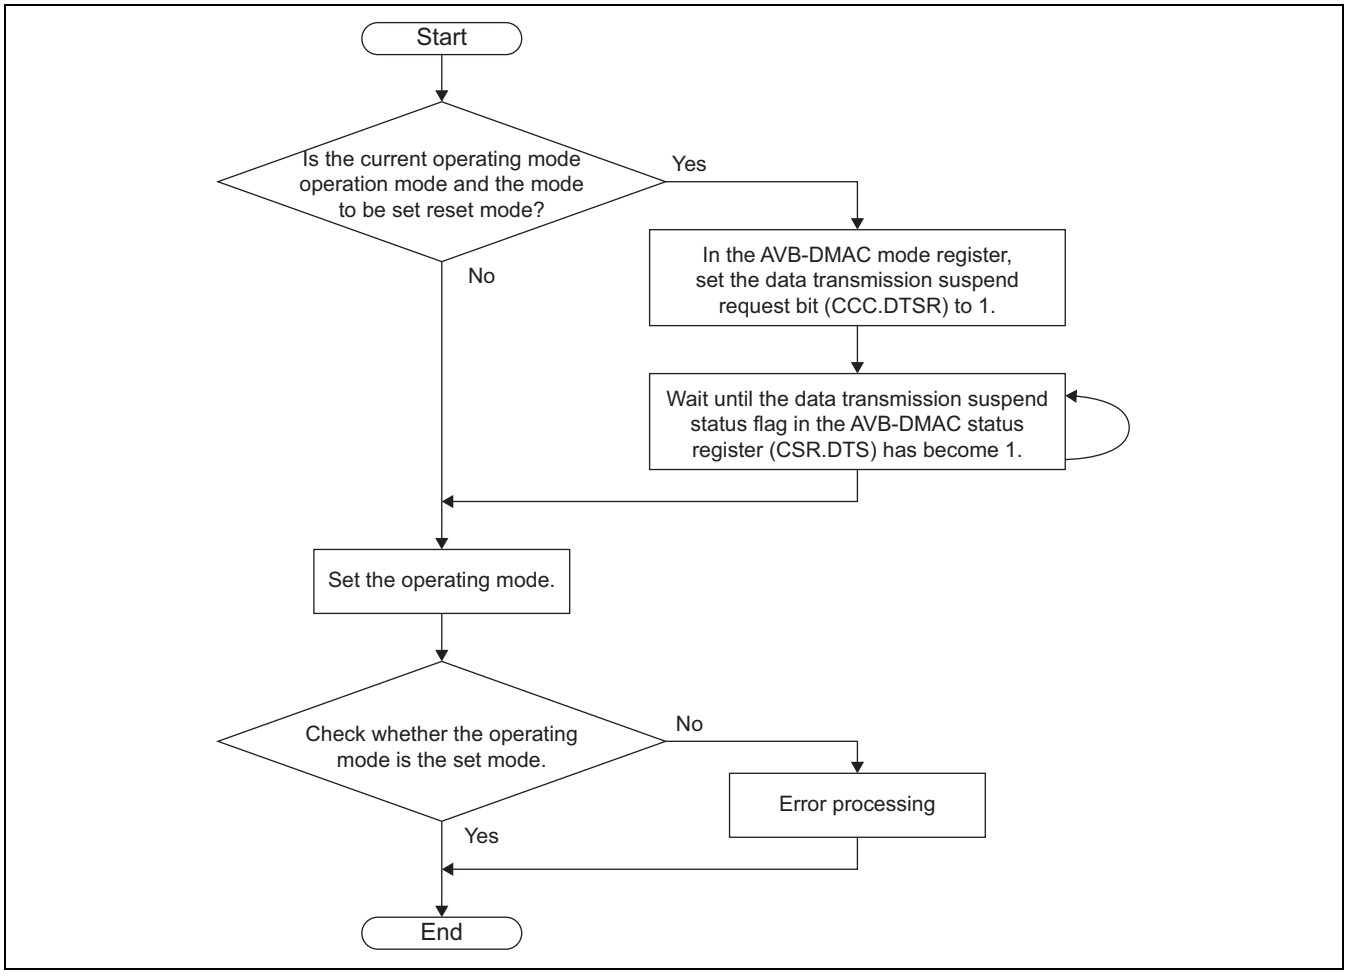

Figure 33A.3 Flow for Transitions of Operating Mode (Other than from Operation Mode to Configuration Mode)

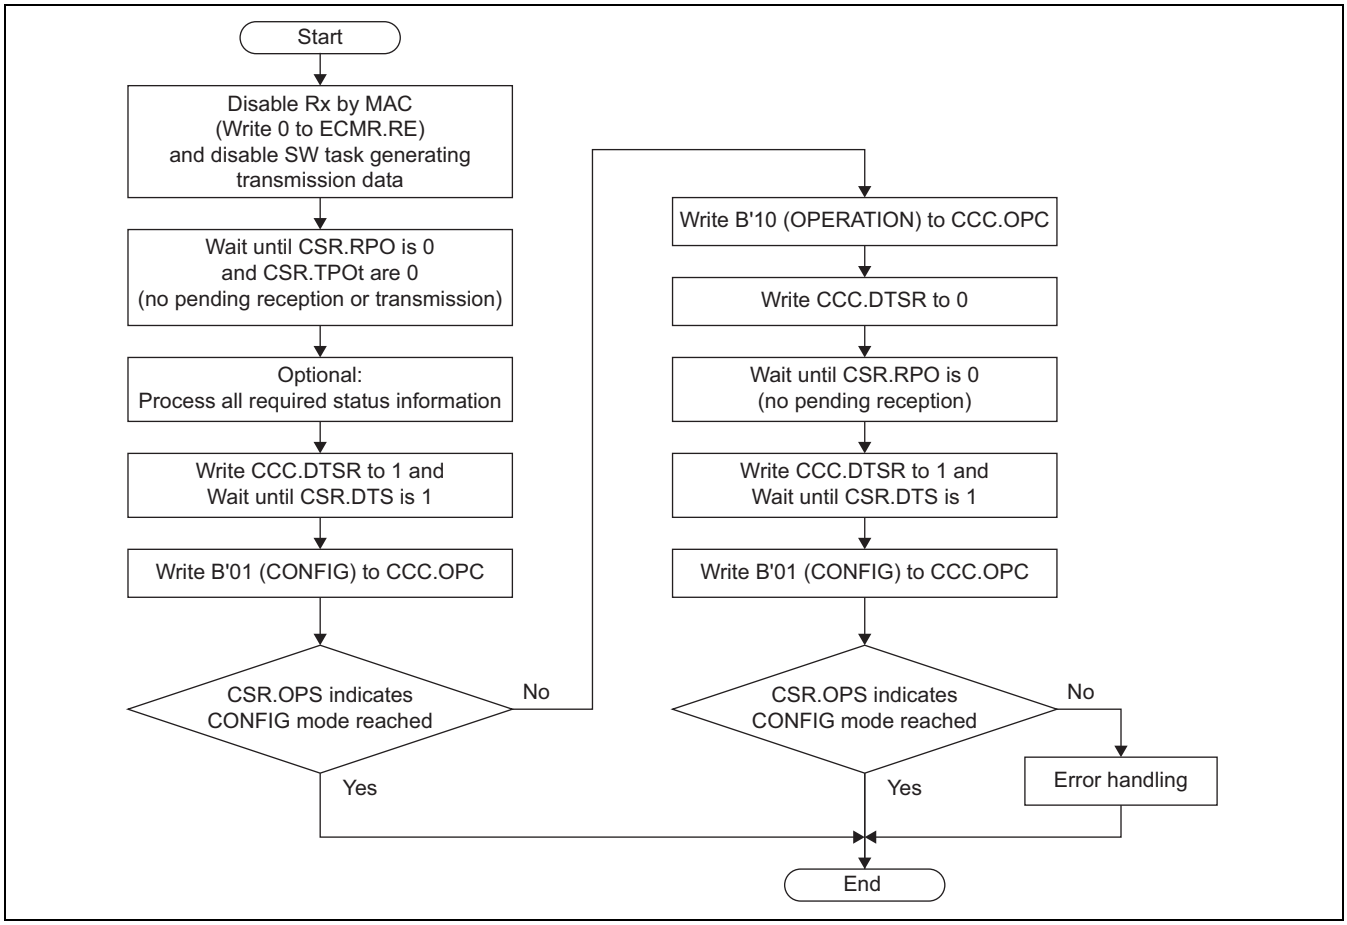

Figure 33A.4 Flow for Transitions of Operating Mode (from Operation Mode to Configuration Mode)

In the transition from operation mode to configuration mode, the AVB-DMAC executes the following operations before the transition is completed. Read the operating mode status bits in the AVB-DMAC status register (CSR.OPS) to check that the transition to configuration mode has been completed.

- If the transfer of a frame between the reception FIFO and URAM is in progress, this is completed (other received frames remaining in the FIFO and any frames that are subsequently received by the E-MAC are discarded).
- If the transfer of a frame is in progress between the transmission FIFO and URAM, this is completed (frames for transmission remaining in the URAM will not be transmitted).
- All frames for transmission in the transmission FIFO are transferred to the E-MAC.

The CPU should not disable URAM transfers by CCC.DTSR nor prevent transmission by MAC when requesting transition from OPERATION to CONFIG, else EthernetAVB cannot perform requested mode change.

Notes: When the operating mode shifts to configuration mode, all status registers are cleared.
We recommend following the procedure below in the case of this transition.

1. Disable reception.
2. Since reception actually stopping after being disabled requires time, wait for an interval equivalent to that for reception of a maximum length packet.
3. Stop the software task that is generating data for transmission.
4. Wait until the receive process status bit (CSR.RPO) and the transmit process status bits (CSR.TPO0 to 3) in the AVB-DMAC status register are set to 0.
5. Capture all of the required status information.

6. Set the operating mode configuration bits in the AVB-DMAC mode register (CCC.OPC) to initiate the transition to configuration mode.

33A.3.1.3 Leave RESET mode with additional configuration

When writing B'01 (CONFIG) to CCC.OPC while EthernetAVB is in RESET mode, it is possible to configure availability of gPTP support within CONFIG mode

To enable gPTP support in CONFIG mode use a 32 bit write access when setting CCC.OPC to B'01. This write should also set CCC.GAC to 1 and CCC.CSEL to intended configuration.

33A.3.1.4 Operating Mode Transitions Due to Hardware

The following hardware factors can also initiate transitions of the AVB-DMAC operating mode.

(1) Hardware reset

Resetting of the LSI chip leads to resetting of the entire EthernetAVB module. The operating mode shifts to reset mode.

(2) Transition during power-off by module standby

This transition is triggered by module standby of CPG during the power-off sequence.

The AVB-DMAC completes the bus master access in progress, and then shifts to reset mode. At this time, the operating mode configuration bits in the AVB-DMAC mode register (CCC.OPC) are set to B'00.

33A.3.2 Common Control for Transmission and Reception

33A.3.2.1 Initialization Procedure

Figure 33A.5 shows the overall initialization procedure in outline.

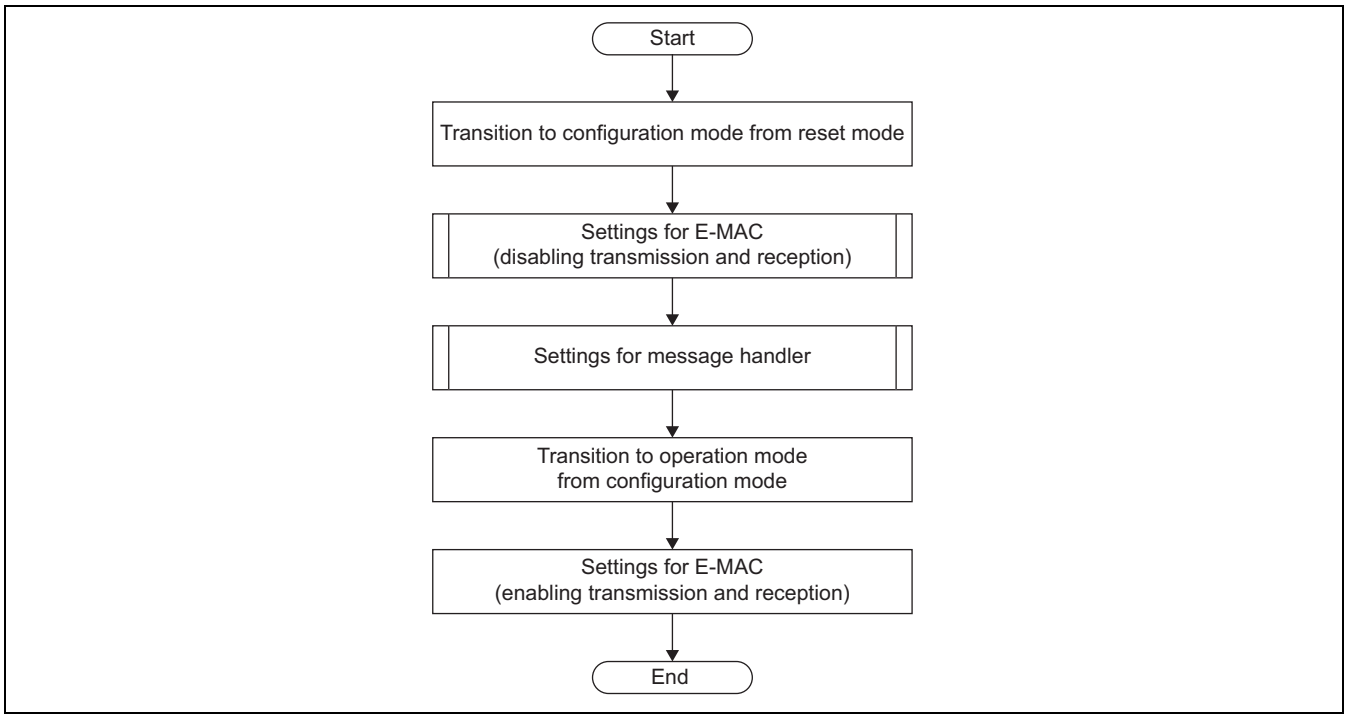

Figure 33A.5 Outline of the Initialization Procedure

(1) Initializing the Receiver Section

Before starting reception, follow the procedure below.

Keep the operating mode to configuration mode, and do not enable reception until the settings for the AVB-DMAC are completed.

- Set the operating mode to configuration mode.
- Set AVB filtering for network control frames and AVB stream frames to suit the specifications of the product the chip will be used in.
- Create a descriptor chain for each queue to be used.
- Set the base address for table address in the descriptor base address table register (DBAT).
- Specify the maximum frame length with the receive frame length upper limit register (RFLR).
- Specify whether padding is to be used with the receive padding configuration register (RPC).
- Set the unread frame counter for each queue with unread frame counter registers (UFCVs) 0 to 4.

(2) Initializing the Transmitter Section

Figure 33A.6 illustrates initialization of the transmitter section.

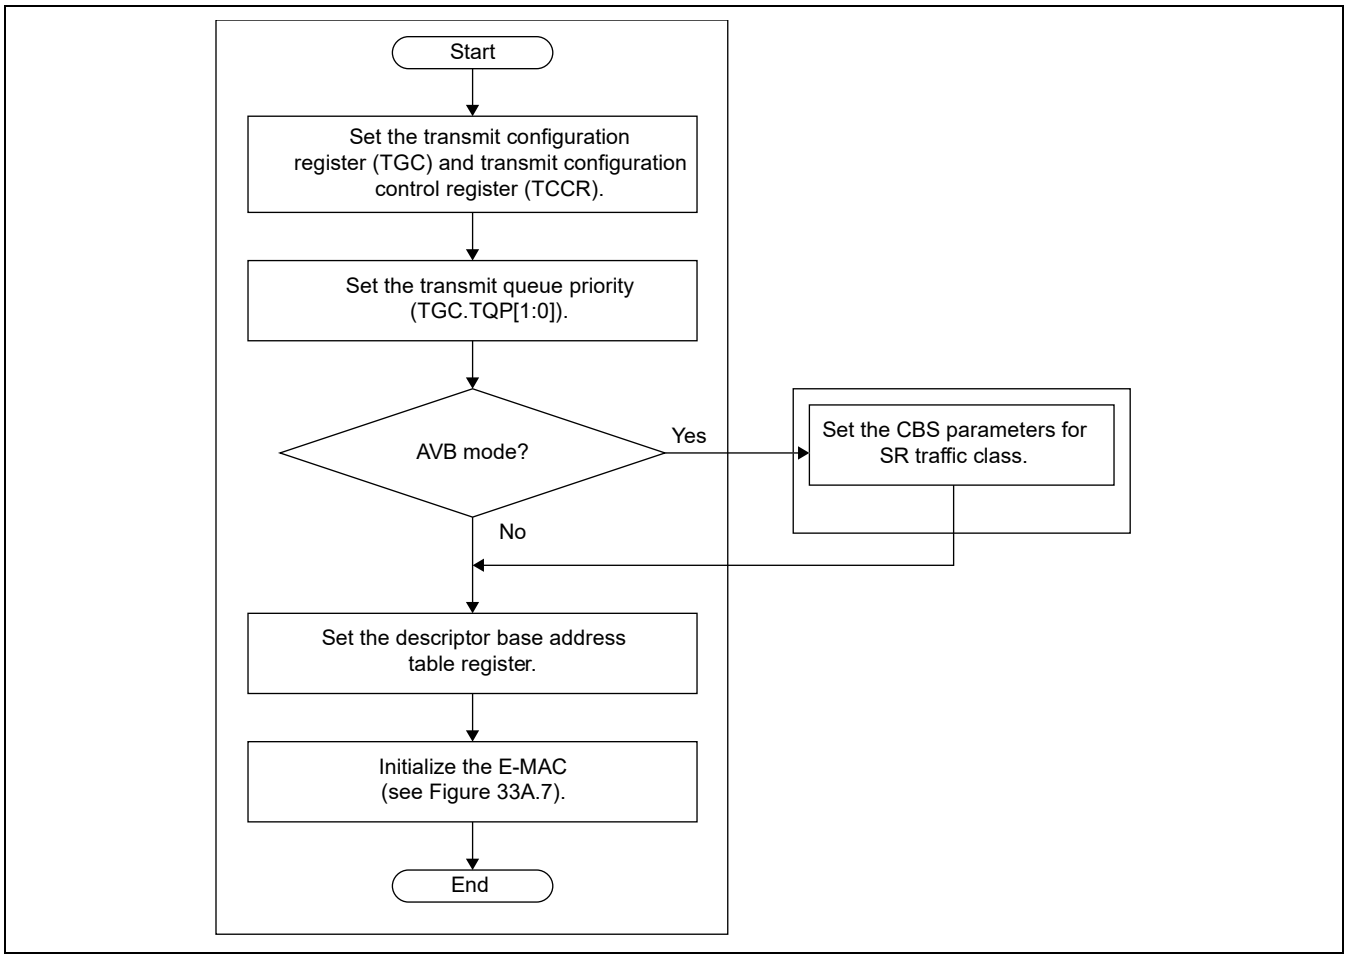

Figure 33A.6 Procedure for Initializing the Transmitter Section

(3) Initializing the E-MAC Section

Figure 33A.7 illustrates initialization of the E-MAC section.

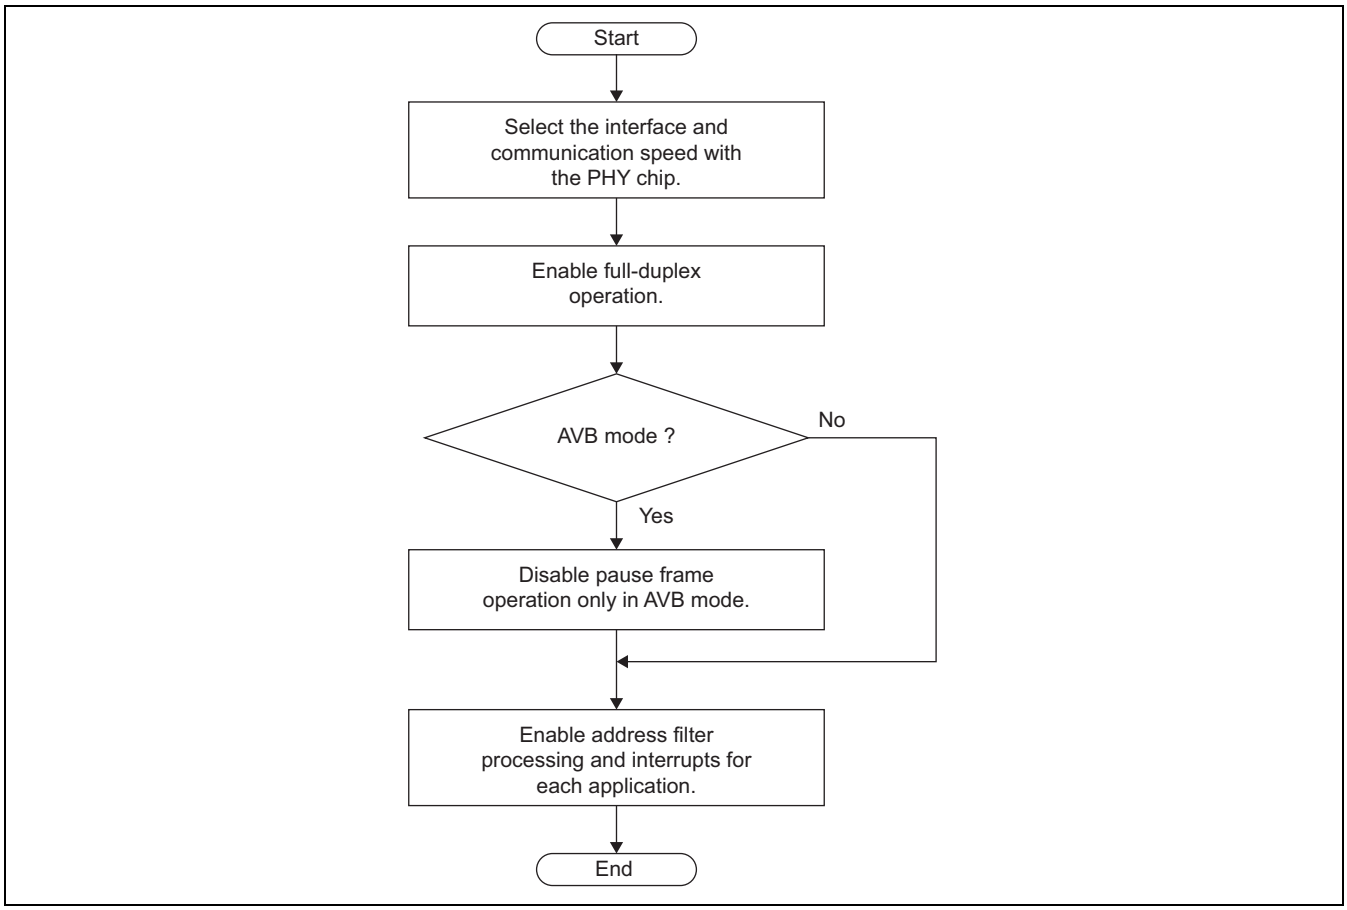

Figure 33A.7 Procedure for Initializing the E-MAC Section

(4) Initialization of the Application Unit

Figure 33A.8 illustrates initialization of the application unit.

For a description of how to set up the descriptors and the CBS traffic shaping parameters, see section 33A.3.3 Descriptors, and section 33A.3.6 CBS (Credit-Based Shaping).

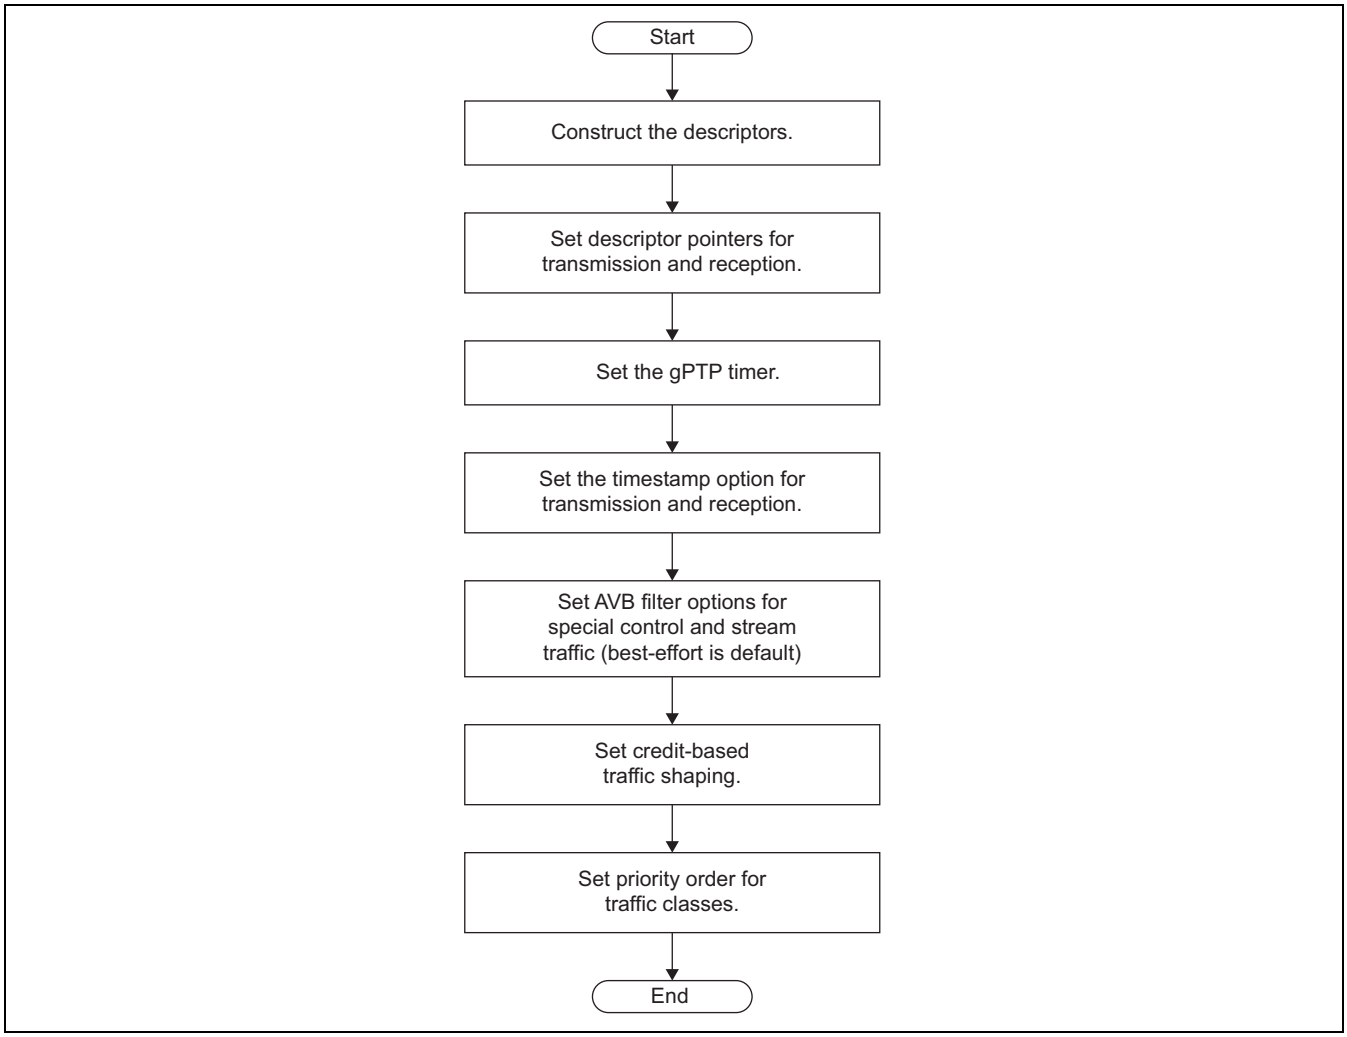

Figure 33A.8 Initializing the Sections for Use by the Application

(5) Relationship between Transmission Queue Numbers and Traffic Classes

In fetching, the relationships between the transmission queues and traffic classes are fixed, so the priority specified by the transmit queue priority bits in the transmit configuration register (TGC.TQP) has no effect.

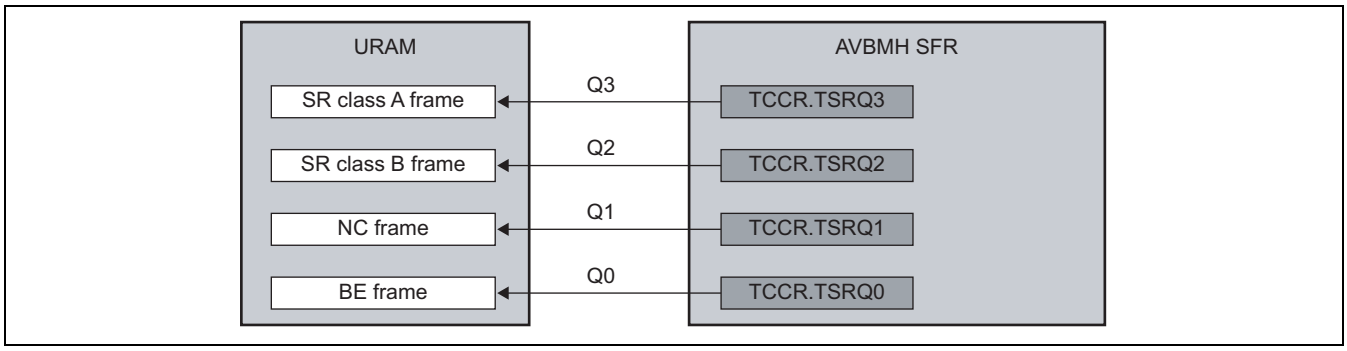

Figure 33A.9 Class Associations of Queues for the Scheduler

In fetching, the credit values for stream classes A and B are not taken into account. Behavior depends on the setting of the transfer FIFO size configuration bits in the transfer configuration registers (TGC.TBDt) and on the frame size that can be fetched to the transmission FIFO.

When the transmit queue priority bits in the transmit configuration register (TGC.TQP) are B'00 or B'01, the priority order is Q3 → Q 2 → Q1 → Q0.

When the transmit queue priority bits in the transmit configuration register (TGC.TQP) are B'11, the priority order is Q1 → Q3 → Q2 → Q0.

33A.3.2.2 Checking Integrity

The AVB-DMAC is capable of detecting and identifying errors produced in the processing of Ethernet frames and in the transfer of frame data for transmission and reception.

(1) Concept of Integrity Checking in Reception

The aim of integrity checking in reception is preventing the storage of error frames in the URAM. If an error frame is stored in the URAM, software can get information to identify the frame as an error frame.

Note: If a special descriptor chain is to be used for separation of received headers from the associated data, an error that breaks the sequence may lead to storage space for synchronization running out. In such cases, software interaction or re-synchronization via the EOS descriptor is required.

(2) Concept of Integrity Checking in Transmission

The purpose of integrity checking in transmission is to prevent the transmission of broken frames.

Since transmission of a frame by the E-MAC can neither be stopped nor disabled once it has started, this check involves intensive monitoring for problems that can arise during fetching.

(3) Items for Monitoring in Both Reception and Transmission

(a) Errors in access to the URAM for reading of descriptors

The same descriptor may be processed again because the current descriptor address (CDARq.CDA) was not changed. If this problem occurs in a divided frame, the sequence may be broken.

In reception

— The received frame will be lost.
— The same problem will occur for the next frame of data received for the same queue.

In transmission

— The transmit start request bit in the transmit configuration control register (TCCR.TSRQt) is set to 0.
— The frame will be lost from the transmission FIFO.

Errors in access to read descriptors from the URAM are detected from the response signal of the AXI-Bus. EthernetAVB flags only one access error per descriptor read.

(b) Illegal configuration of a descriptor by an application

The same descriptor may be processed again because the current descriptor address (CDARq.CDA) was not changed. If this problem occurs in a divided frame, the sequence may be broken.

In reception

— The received frame will be lost.
— The same problem will occur for the next frame of data received for the same queue.

In transmission

— The transmit start request bit in the transmit configuration control register (TCCR.TSRQt) is set to 0.
— The frame will be lost from the transmission FIFO.

(c) Errors in access to the URAM for writing of descriptors

As in the case where no error occurs, the current descriptor address (CDARq.CDA) and the transmit start request bit in the transmit configuration control register (TCCR.TSRQt) are updated.

As DESCR.DT was not updated, hardware and software synchronization may have been destroyed.

Errors in access to write descriptors to the URAM are detected from the response signal of the AXI-Bus.

(4) Items for Monitoring in Reception

(a) Errors in access to the URAM for writing of data or time stamps

— As in the case where no error occurs, the current descriptor address (CDARq.CDA) is updated.
— DESCR.EI is set to indicate incorrect contents.
— This problem occurring in a divided frame may break the descriptor sequence, making the queue unusable.

Errors in access to write data or descriptors to the URAM are detected from the response signal of the AXI-Bus.

EthernetAVB flags each access error individually, even they are related to same frame.

(b) Error of the Reception FIFO

— Received frames are all invalidated.
— All frames stored as received frames are discarded. At this time, the number of frames and queue information cannot be captured.

If the reception FIFO RAM faults, AVB-DMAC detects the fault as error of the reception FIFO.

(c) Queue Synchronisation Fault of the Reception

EthernetAVB will not continue splitting frame across EOS descriptor. A queue synchronisation fault is detected when read descriptor with DESCR.DT = EOS at position where FMID, or FEND should be written

— RIS2.QFFr is set 1
— CDARq.CDA is updated as in fault free operation.
— Neither CIARr.CIA nor LIARr.LIA is changed.
— Neither UFCVi.CVr nor RIS0.FRFr is changed.
— Received frame is lost. There is an incomplete frame (no FEND) in descriptor chain.

Note: Reading descriptor may be one or more storage elements ahead in descriptor chain.

(5) Items for Monitoring in Transmission

(a) Errors in Access for Reading Data from the URAM

— Data that have already been fetched are discarded from the transmission FIFO.
— When an error of this type occurs during processing of an FSINGLE or FEND descriptor:
As in the case where no error occurs, the current descriptor address (CDARq.CDA) and the transmit start bit in the transmit configuration control register (TCCR.TSRQt) are updated. Fetching resumes after the error frame.
— When an error of this type occurs during processing of an FSTART or FMID descriptor:
The current descriptor address (CDARq.CDA) is not updated.
The transmit start bit in the transmit configuration control register (TCCR.TSRQt) is set to 0.

Errors in access to read data from the URAM are detected from the response signal of the AXI-Bus.

(b) Overflow of the Transmission FIFO

— As in the case where no error occurs, the current descriptor address (CDARq.CDA) and the transmit start bit in the transmit configuration control register (TCCR.TSRQt) are updated. Fetching resumes after the error frame.
— The frame will be discarded from the FIFO.

(c) Frame size error during transmission

— As in the case where no error occurs, the current descriptor address (CDARq.CDA) and the transmit start bit in the transmit configuration control register (TCCR.TSRQt) are updated. Fetching resumes after the error frame.

A transmit frame size error is detected when the size setting in one or more (in the case of a divided frame) descriptors for frame transmission is 1966 or more bytes. Such frames are cut out and transmitted.

(d) Damaged Data in the Transmission FIFO

— Fetching is not affected by damaged data.
— Since damaged data from the FIFO is only detected during frame transmission, an error frame may be transmitted.

If damaged data in the transmission FIFO is an error due to the transmission FIFO, this is detected by the AVB-DMAC.

(6) Items for Monitoring in gPTP

(a) Access error while reading AVTP timestamps from Tx-Buffer RAM

— AVTP timestamps are invalidated.
— gPTP unit ignores the issue. It uses the value as read for AVTP comparison.

An access error when reading timestamps from Tx-Buffer RAM is flagged to EthernetAVB by external RAM protection logic.

33A.3.3 Descriptors

33A.3.3.1 Data Representation in URAM

The AVB-DMAC transfers data for transmission and received data to and from the application software via the URAM.

The memory in the URAM for use by the AVB-DMAC is configured with control structures referred to as descriptors and associated areas to which the frame data are allocated. Dividing the memory into a control area and data area allows the flexible allocation of frame data to the URAM. This enables sharing of the areas to which frame data are allocated and the use of non-contiguous areas. Frame data can be copied without using the CPU. Arbitration that ensures hardware and software access to the memory area is also available without access to registers of the AVB-DMAC.

Figure 33A.10 shows an example of the memory maps for descriptors and the descriptor data area in the URAM.

A descriptor consists of its type (DESCR.DT), which controls the descriptor functions, a descriptor pointer (DESCR.DPTR) indicating the start address for storage of the frame data in the descriptor area, and the data size field (DESCR.DS), indicating the amount of frame data. Post-processing interrupt generation can be set up for each descriptor. Enabling and disabling of the interrupt is controlled by the descriptor interrupt enable bits (DESCR.DIE).

The descriptor may also hold information related to content. This information does not affect general descriptor functions. It provides information other than the frame data proper, such as on the state of reception.

For details, see section 33A.3.4.2 Setting Up Reception Descriptors, and section 33A.3.5.2 Setting Up Transmission Descriptors.

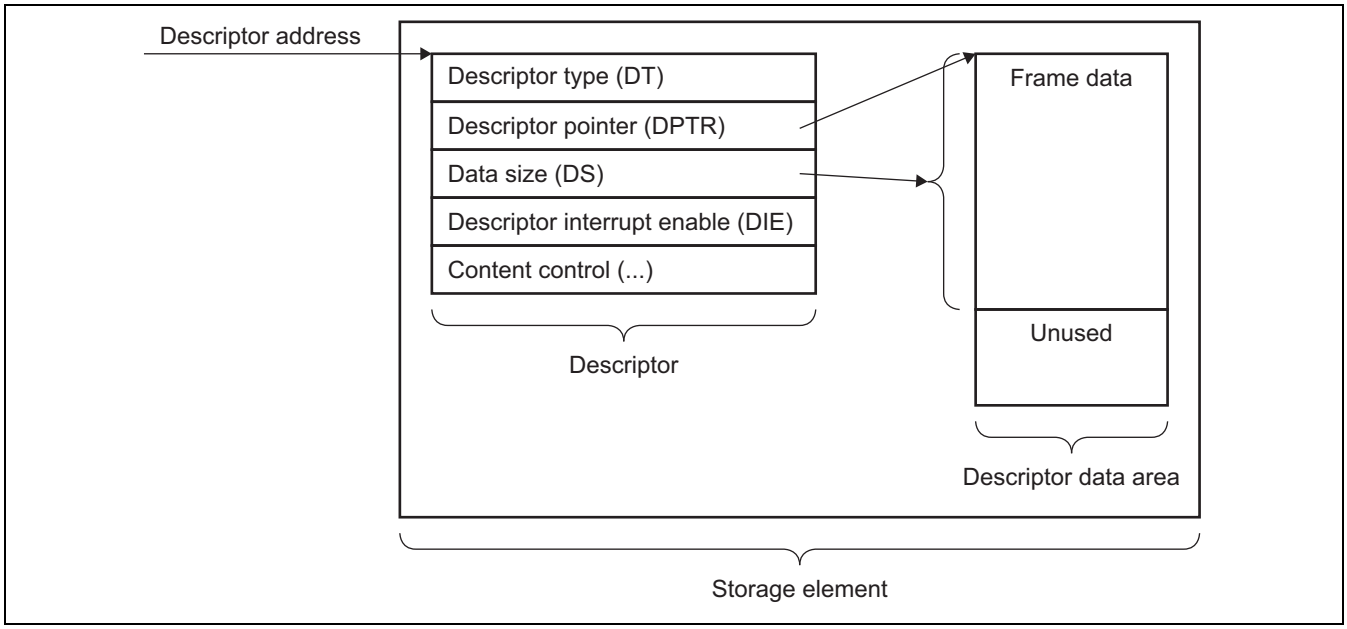

Figure 33A.10 Outline of Storage Element Used for Receive and Transmit Queues

The descriptor must be aligned with a 32-bit boundary in the URAM.

Descriptors are generally configured of 64 bits, but are configured of 160 bits when reception and storage of gPTP time stamps is enabled.

The amount of data in the frame is defined by the data size bits (DESCR.DS). In reception, these bits indicate the upper limit on the size of frames to be received. If the data size is not aligned with a 32-bit boundary, the bytes to the next 32-bit boundary in the data area will be an unused area.

33A.3.3.2 Using Descriptor Chains in Queues

Transmission and reception descriptors in the URAM are grouped into queues. Each queue handles frames so that they are transmitted in order of priority and received separately. A queue is capable of controlling one or more frames. Accordingly, multiple descriptors can be assigned to one queue. A combination of multiple descriptors is referred to as a descriptor chain.

For a descriptor chain, the three general descriptor types listed below are defined. For details on these descriptor types, see section 33A.3.3.6 Descriptor Type.

- Descriptors that define frame data
- Descriptors that control the descriptor chain itself (e.g. LINK, EOS).
- Descriptors that arbitrate access by hardware or software

Figure 33A.11 shows the two basic topologies for descriptor chains. In the simplified examples in the figure, all descriptors allocated to the chain are stored in the array.

- For a linear descriptor chain, the last descriptor in the array is a control descriptor indicating the end of the descriptors (e.g. EEMPTY).
- For a cyclic descriptor chain, the last descriptor in the array is a control descriptor that returns to the first descriptor in the array (e.g. LINK).

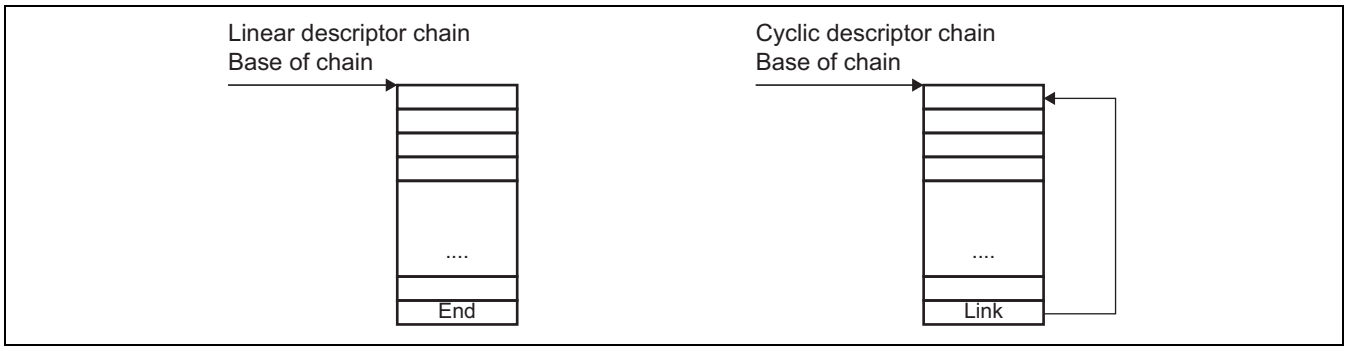

Figure 33A.11 Outline of the Basic Descriptor Chains

The relationship between queues and descriptor chains is defined by the base addresses of chains. A queue is connected to one descriptor chain over one round of processing. There is also a method of switching to a different chain while in operation mode.

There are no restrictions on the number of link descriptors and their locations within the chain. The last descriptor of a designed chain determines the topology.

Which chain structure is to be used or which topology is suitable depends on the application. A description of how to design descriptor chains to suit various applications is given in section 33A.3.4.2 Setting Up Reception Descriptors, and section 33A.3.5.2 Setting Up Transmission Descriptors.

33A.3.3.3 Descriptor Base Address Table

The base address table in the URAM contains the address of the first descriptor of all chains to be handled by the respective queues.

Entries 0 to 3 are used to access transmission queues 0 to 3. Subsequent entries are used to access reception queues. Entry 4 thus corresponds to reception queue 0.

The configuration of entries in the base address table is the same as the configuration of link descriptors. We recommend using the descriptor type (DESCR.DT) LINKFIX. Processing of this link descriptor does not change it, so it does not require updating. The first descriptor of a chain performs hardware and software synchronization. If the application requires hardware and software synchronization for the base addresses, use the descriptor type (DESCR.DT) LINK.

The CPU is only capable of using LINKFIX and LINK as descriptor types (DESCR.DT) of descriptors in the base address table.

Set the location of the base address table in the URAM in the descriptor base address table register (DBAT).

Figure 33A.12 shows an example of a base address table for controlling four transmission and three reception queues. The boxes to the right of the table represent descriptor chains with the desired topologies.

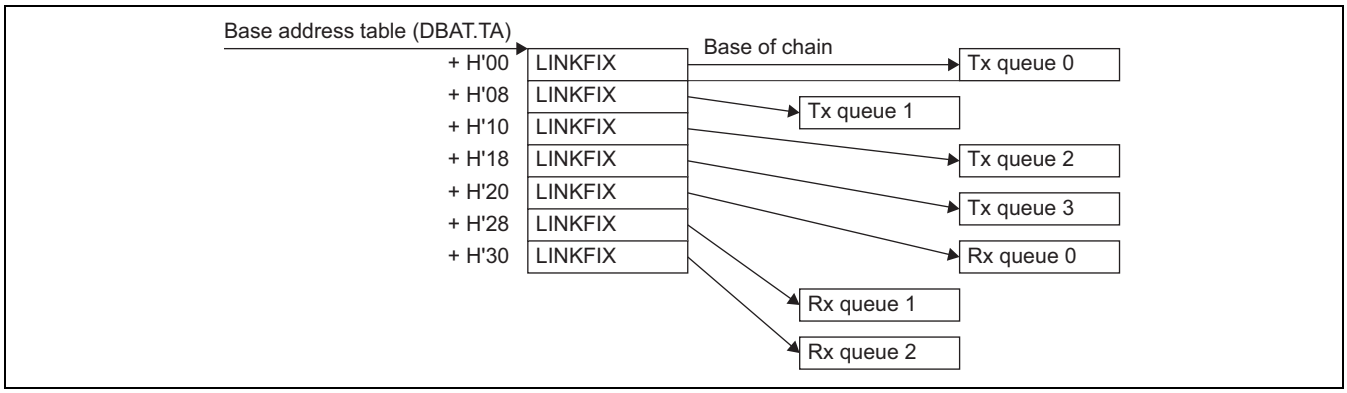

Figure 33A.12 Example of a Base Address Table for Reception and Transmission Queues

Note: The size of the descriptors in the base address table is always eight bytes even if the queue itself includes extended descriptors.

33A.3.3.4 Descriptor Chain Processing

The descriptor that is currently processed or will be processed when the related queue gets active is the current descriptor. The current descriptor address for use by a queue q can be checked in the current descriptor address register q (CDARq).

Current descriptors are stored in registers or in descriptors as described below in the given situations.

- In the descriptor base address table registers for all q queues (DBAT) (DBAT.TA+8*q) when the operating mode shifts to operation mode.
- In the descriptor base address table register (DBAT) (DBAT.TA+8*q) when a base address load request is issued for a queue q by setting the corresponding bit (DLR.LBAq) in the descriptor base address load request register (DLR).
- In DESCR.DPTR for a link descriptor (LINK, LINKFIX) to be processed.
- After a descriptor has been processed, the current descriptor for the same queue is incremented by the size of the descriptors being handled by the queue (8 bytes for normal descriptors and 20 bytes for extended descriptors). The AVB-DMAC updates the descriptor type and informs the CPU that the descriptor has been processed.

33A.3.3.5 Descriptor Interrupts

A descriptor is able to issue a descriptor interrupt on completion of its processing. The setting of the descriptor interrupt enable bits (DESCR.DIE) in each descriptor selects disabling or generation of the descriptor interrupt.

EthernetAVB provides two kinds of descriptor interrupts:

- Queue specific descriptor interrupt (1 per receive/transmit queue)
- Universal descriptor interrupt (15 shared between all receive/transmit queues)

The descriptor interrupt is a common resource that is shared between reception and transmission queues. Software control of the descriptor interrupt provides a flexible method of application-specific flag processing.

Figure 33A.13 illustrates the way in which the AVB-DMAC generates descriptor interrupts (or sets bits in the descriptor interrupt status register (DIS.DPFi)). Processing of a descriptor with the value i in the descriptor interrupt enable bits (DESCR.DIE) leads to the corresponding bit in the descriptor interrupt status register (DIS.DPFi) being set.

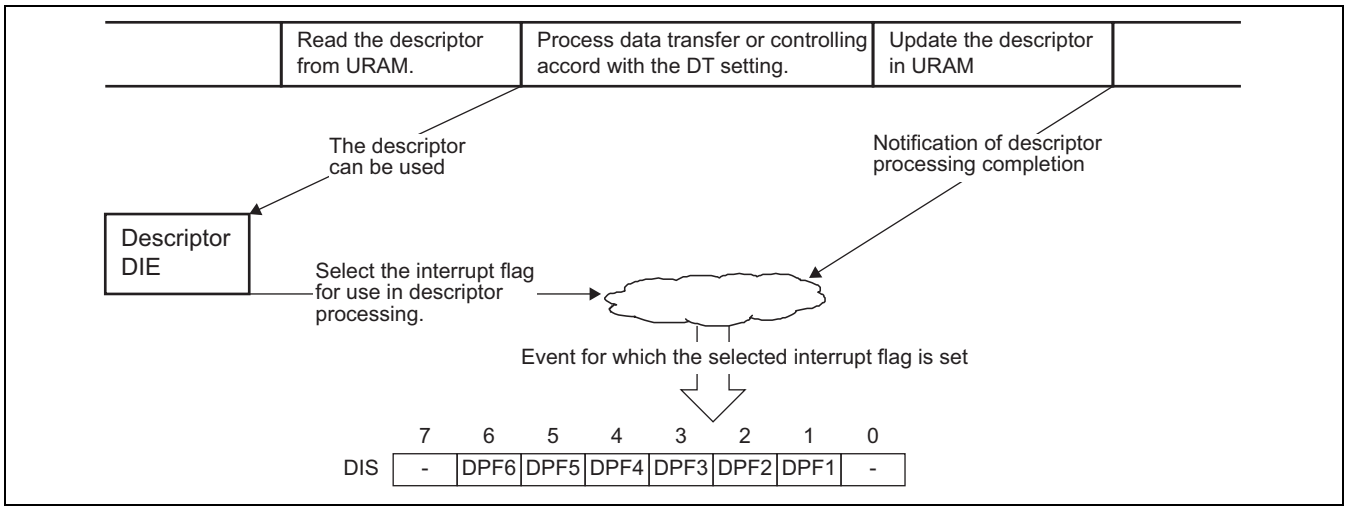

Figure 33A.13 Method of Descriptor Interrupt Generation

33A.3.3.6 Descriptor Type

The descriptor types (indicated by the DESCR.DT bits) supported by the AVB-DMAC fall into the following three categories.

- Definitions of frame data
- Control of descriptor chains
- Hardware and software arbitration

Table 33A.6 is a summary of the descriptor types available for the AVB-DMAC. Entries under “Name” are the names of the descriptor types and the values under “DT” are the corresponding values to be set in the descriptor type field (DESCR.DT). A given descriptor may be handled differently according to whether it is in a transmission or reception queue, so the transmission and reception columns list the scopes of control and processing of the descriptor types.

The abbreviations defined below are used in the transmission and reception columns.

Definition of SW:

— The descriptor is processed by software.
— Software has access to and may modify the descriptor and descriptor data area.
— This descriptor cannot be changed by hardware (AVB-DMAC).

Definition of HW:

— The descriptor is processed by hardware (AVB-DMAC).
— Software must modify neither the descriptor nor the descriptor data area.
— Hardware (AVB-DMAC) processes this descriptor and subsequently changes the descriptor type.

Invalid:

This descriptor type is not used in transfer in the given direction (transmission or reception).

Do not write this value to the descriptor type (DESCR.DT) field for transfer in the given direction.

Hardware does not process these descriptor types in the cases listed as invalid. The current descriptor address (CDARq.CDA) will not be changed when processing of a queue for the given direction arrives at a descriptor with this type setting.

Table 33A.6 Summary of Descriptor Types

Name	DT	Description	Reception	Transmission
Frame data				
FSTART	5	Frame Start The descriptor points to valid data for a frame. The frame starts with the given data and continues with that indicated by the next descriptor.	SW	HW
FMID	4	Frame Middle The descriptor points to valid data for a frame. The frame started with a previous descriptor and continues to the data indicated by the next descriptor.	SW	HW
FEND	6	Frame End The descriptor points to valid data for a frame. The frame continues from the previous descriptor and ends with the data indicated by in this descriptor.	SW	HW
FSINGLE	7	Frame Single The descriptor points to valid data for a complete frame.	SW	HW
Chain control				
LINK	8	Link Defines the next descriptor in the chain.	HW	HW
LINKFIX	9	Fixed Link Same as LINK, but not changed by AVB-DMAC after processing.	SW	SW
EOS	10	End Of Set Control element to split a descriptor chain. The chain stops and waits for user interaction.	HW	HW
HW/SW arbitration				
FEMPTY	12	Frame Empty A descriptor related to frame data but not containing valid data for a frame	HW	SW
FEMPTY_IS	13	Frame Empty Incremental Start A descriptor related to frame data but not containing valid data for a frame. DESCR.DPTR sets the base address of an “incremental data area” in the URAM.	HW	Invalid
FEMPTY_IC	14	Frame Empty Incremental Continue A descriptor related to frame data but not containing valid data for a frame. Data is stored to the incremental data area in the URAM.	HW	Invalid
FEMPTY_ND	15	Frame Empty No Data storage A descriptor related to frame data but not containing valid data for a frame. The descriptor is processed in the same way as FEMPTY but data are not stored in the URAM.	HW	Invalid
LEMPTY	2	Link Empty A link descriptor for processing by the AVB-DMAC	SW	SW
EEMPTY	3	EOS Empty An EOS descriptor for processing by the AVB-DMAC	SW	SW
DT0	0	Reserved	Invalid	Invalid
DT1	1	Reserved	Invalid	Invalid
DT11	11	Reserved	Invalid	Invalid

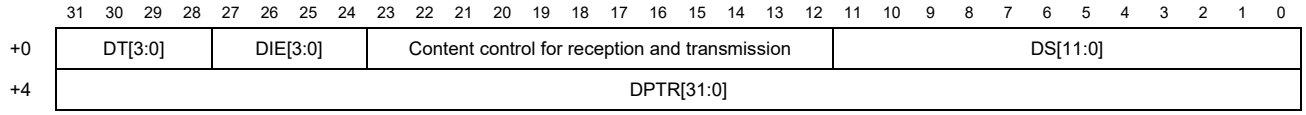
33A.3.3.7 Layout of General Descriptors in the URAM

The AVB-DMAC updates processed descriptors in the URAM. The field to be changed in the descriptor being updated depends upon whether the direction is transmission or reception and the queue mode. Other fields will not be changed. There are no restrictions on the values set in unused descriptor fields (indicated by "—" in the figure).

(1) Frame Data Descriptors

The allocation of bits in the frame data descriptors (FSTART, FMID, FEND, and FSINGLE) is shown below.

- Normal descriptor (usable in both reception and transmission)



- Extended descriptor (usable only in reception)

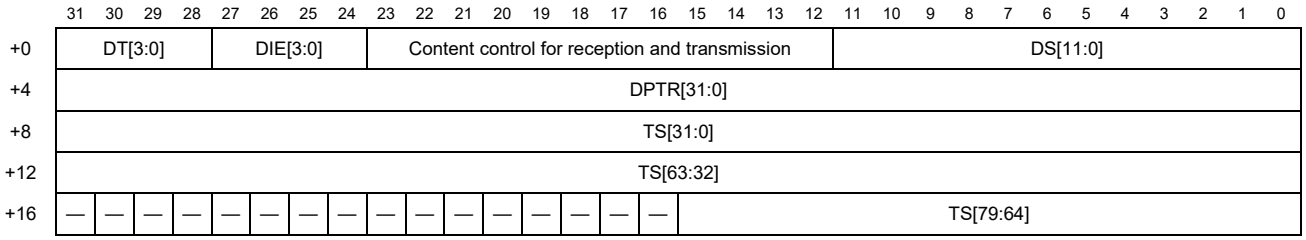


Table 33A.7 Contents of Frame Data Descriptors (DESCR)

Bit Name	Function
DT[3:0]	Descriptor Type 5: FSTART 4: FMID 6: FEND 7: FSINGLE For details, see section 33A.3.4.2, Setting Up Reception Descriptors, and section 33A.3.5.2, Setting Up Transmission Descriptors.
DIE[3:0]	Descriptor Interrupt Enable B'0000: Descriptor interrupt is disabled. B'0001 to B'1111: The corresponding descriptor interrupt is generated (DIS.DPFi).
—	Content Control For details, see section 33A.3.4.2, Setting Up Reception Descriptors, and section 33A.3.5.2, Setting Up Transmission Descriptors.
DS[11:0]	Data Size Size of the data area/frame data for the descriptor (in bytes)
DPTR[31:0]	Descriptor Pointer Pointer to the data area for the descriptor
TS[79:0]	Time Stamp Time stamp of the received frame (only available in extended descriptors)

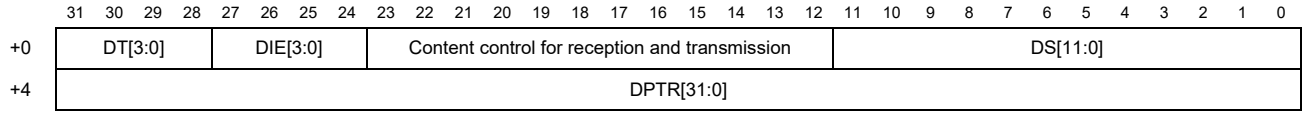
Note: Register an address aligned with a 32-bit boundary as the descriptor pointer (DESCR.DPTR).
Some bits in extended descriptors are reserved (The reserved bits (above DESCR.TS[79:64]) in an extended descriptor are set to H'0000 after the time stamp is stored).

(2) Hardware/Software Arbitration Descriptors (Only for Reception)

The allocation of bits in the descriptors for hardware/software arbitration (FEMPTY, FEMPTY_IS, FEMPTY_IC, and FEMPTY_ND) is shown below.

The allocation of bits in the arbitration descriptors for use in reception is the same as in frame data descriptors.

- Normal descriptor



- Extended descriptor (usable only in reception)

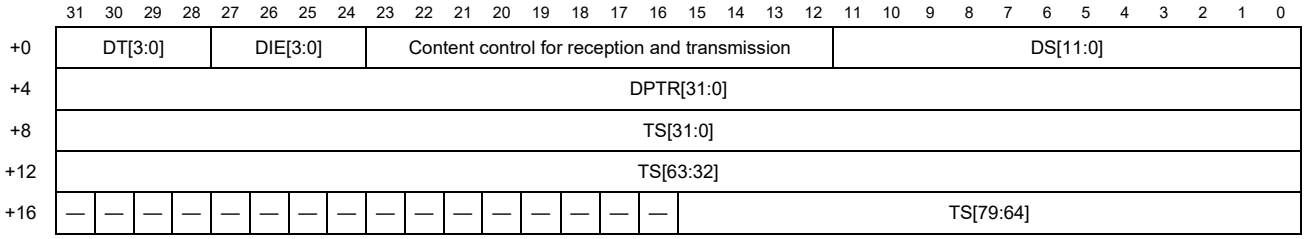


Table 33A.8 Contents of Hardware/Software Arbitration Descriptors (DESCR)

Bit Name	Function
DT[3:0]	Descriptor Type 12: FEMPTY 13: FEMPTY_IS 14: FEMPTY_IC 15: FEMPTY_ND For details, see Table 33A.6 Summary of Descriptor Types.
DIE[3:0]	Descriptor Interrupt Enable B'0000: Descriptor interrupt is disabled. B'0001 to B'1111: The corresponding descriptor interrupt is generated (DIS.DPFi).
—	Content Control For details, see section 33A.3.4.2, Setting Up Reception Descriptors, and section 33A.3.5.2, Setting Up Transmission Descriptors.
DS[11:0]	Data Size Size of the data area/frame data for the descriptor (in bytes)
DPTR[31:0]	Descriptor Pointer Pointer to the data area for the descriptor
TS[79:0]	Time Stamp Time stamp of the received frame (only available in extended descriptors)

Note: Register an address aligned with a 32-bit boundary as the descriptor pointer (DESCR.DPTR).
When the descriptor is an extended descriptor, it has a 12-byte unused area.

In an FEMPTY descriptor, the descriptor type (DT), descriptor interrupt enable (DIE), data size (DS), and descriptor pointer (DPTR) fields are used.

In an FEMPTY_IS descriptor, the descriptor type (DT), descriptor interrupt enable (DIE), and descriptor pointer (DPTR) fields are used.

In an FEMPTY_IC descriptor, the descriptor type (DT) and descriptor interrupt enable (DIE) are used.

In an FEMPTY_ND descriptor, the descriptor type (DT), descriptor interrupt enable (DIE), and data size (DS) are used.

(3) Link Descriptors

The allocation of bits in the link descriptors (LINK and LINKFIX) is shown below.

- Normal descriptor

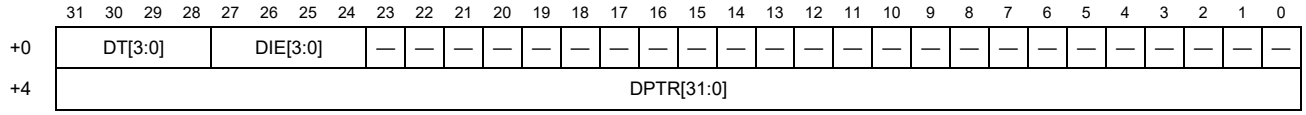

Table 33A.9 Contents of Link Descriptors (DESCR)

Bit Name	Function
DT[3:0]	Descriptor Type 8: LINK 9: LINKFIX For details, see Table 33A.6 Summary of Descriptor Types.
DIE[3:0]	Descriptor Interrupt Enable B'0000: Descriptor interrupt is disabled. B'0001 to B'1111: The corresponding descriptor interrupt is generated (DIS.DPFi).
DPTR[31:0]	Descriptor Pointer Pointer to the data area for the descriptor Register an address on a 32-bit boundary.

Note: Register an address aligned with a 32-bit boundary as the descriptor pointer (DESCR.DPTR).

(4) Other Descriptors

The allocation of bits in the other descriptors (EOS, FEMPTY (only for transmission), LEMPTY, and EEMPTY) is shown below.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
+0	DT[3:0]				DIE[3:0]				—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
+4	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Table 33A.10 Contents of Other Descriptors (DESCR)

Bit Name	Function
DT[3:0]	Descriptor Type 10: EOS 12: FEMPTY (only for transmission) 2: LEMPTY 3: EEMPTY For details, see Table 33A.6 Summary of Descriptor Types.
DIE[3:0]	Descriptor Interrupt Enable B'0000: Descriptor interrupt is disabled. B'0001 to B'1111: The corresponding descriptor interrupt is generated (DIS.DPFi).

33A.3.3.8 How to Use Frame Data Descriptors

The descriptor data area size field (DESCR.DS) can specify up to 2048 bytes of Ethernet frame data per data area. Settings higher than 2048 (bytes) cannot be made.

In general, Ethernet frames are not of uniform length. The AVB-DMAC is capable of dividing frame data into multiple descriptors in order to minimize the memory capacity for frame data. This function allows processing of frames that are longer than the limit for descriptor data areas. Division can also be applied to frames on the basis of their data structures.

To handle frames and descriptors, four descriptor types (DESCR.DT) as FSTART, FEND, FMID and FSINGLE are defined.

Figure 33A.14 shows the mapping of frame data by frame data descriptors. The descriptor data areas are allocated to the URAM. For frames that require division into four or more data areas, additional FMID descriptors can be added as required.

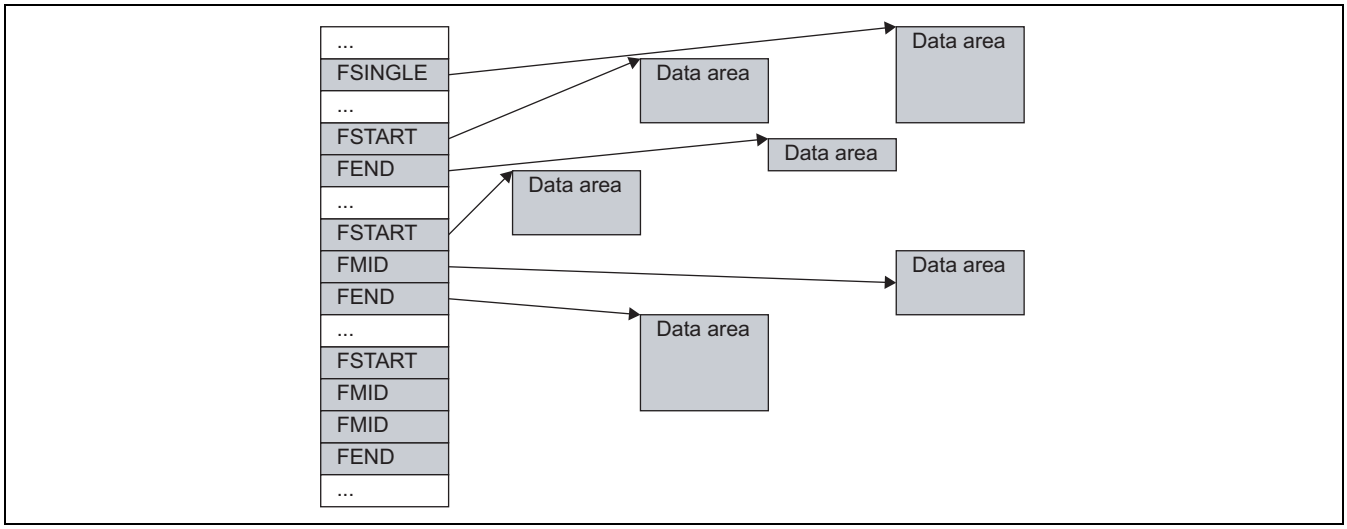

Figure 33A.14 Mapping of Frame Data

For reception, set the descriptor data areas to the maximum size (i.e. give DESCR.DS its maximum value). The AVB-DMAC will store received frame data in the given area. If a received frame has more data than the maximum size, the AVB-DMAC will divide the data up.

For transmission, set the descriptor data area size field to the actual data size. The AVB-DMAC modifies the descriptor type (DESCR.DT) to FEMPTY after processing the relevant descriptor. The data size (DESCR.DS) and descriptor pointer (DESCR.PTR) fields retain their settings.

A descriptor data area including unused space produces an empty space between data areas. In reception, an “incremental data area” can be used to prevent empty spaces. For incremental data areas, see section 33A.3.4.3(2) Incremental Data Areas.

As well as reducing the memory capacity taken up by the descriptor area in the URAM, division into frames can be used to identify different sections of data (e.g. for separating a header and data).

33A.3.3.9 How to Use Chain Control Descriptors

(a) Link Descriptors

The link descriptors can be used to set up cyclic descriptor chains (for details, see section 33A.3.3.2 Using Descriptor Chains in Queues)

After a LINK descriptor is processed, its descriptor type (DESCR.DT) is changed to LEMPTY. The descriptor pointer (DESCR.PTR) retains its setting.

After processing of a LINKFIX descriptor, the descriptor type (DESCR.DT) is not updated. Software can change the descriptor type (DESCR.DT), descriptor interrupt enable (DESCR.DIE), and descriptor pointer (DESCR.DPTR). However, DESCR.DT should not be modified by software. Take care to check the current descriptor address register (CDARq.CDA) before changing the descriptor pointer (DESCR.DPTR).

(b) EOS Descriptor

Use the EOS descriptor to divide a descriptor chain into various segments. The queue can continue even after an EOS descriptor.

In transmission, the response to an EOS descriptor is clearing of the transmit start request bit in the transmit configuration control register (TCCR.TSRQq) to 0.

In reception, the response is generation of a receive queue full interrupt (RIS2.QFFr), although if the frame currently being received is being divided for storage (received data such as those where some storage is in FMID- or FEND-type frames), the data are not completely stored.

33A.3.3.10 How to Use Hardware and Software Arbitration Descriptors

In hardware processing of descriptors, the empty descriptor types (FEMPTY, LEMPTY, and EEMPTY) are used to distinguish various descriptors. For software, they can be used to initiate checking for empty spaces, etc.

(a) FEMPTY, FEMPTY_IS, FEMPTY_IC, and FEMPTY_ND

These descriptor types (DESCR.DT) are used for descriptors that do not contain effective data. Of these, only FEMPTY is used in transmission. The descriptor pointer of a FEMPTYxxx descriptor refers to a descriptor data area.

(b) LEMPTY

This descriptor type (DESCR.DT) is assigned to LINK descriptors after they have been processed. The descriptor pointer (DESCR.DPTR) of an LEMPTY descriptor still points to the linked descriptor.

(c) EEMPTY

This descriptor type (DESCR.DT) is assigned to EOS descriptors after they have been processed. The descriptor pointer (DESCR.DPTR) of an EEMPTY descriptor is not used.

33A.3.3.11 Synchronization between Descriptor Access by Hardware and Software

The allocation of descriptor types (DESCR.DT) to the URAM can be used to set up the primary synchronization between hardware and software. By this, the number of CPU accesses to registers of EthernetAVB can be minimized and performance can be increased.

Basic concepts of synchronization:

- Each descriptor type in the set is exclusively for processing by hardware or software, depending on the direction of transfer (see Table 33A.6 Summary of Descriptor Types).
- Software must not change a descriptor assigned to hardware processing (the hardware does not change descriptors assigned to software processing).

In the case of software processing, the software must process the information in the descriptor and the corresponding frame data before changing the descriptor type. If a descriptor type for hardware is set in DESCR.DT, the software should not change any part of the descriptor or of the corresponding frame data.

33A.3.3.12 Tips for Optimizing Performance in Handling Descriptors

The following items are recommended as ways to ensure the optimal use of data structures in the URAM.

They are not requirements, but using a different approach may increase the load on the system bus within the LSI chip.

- Register descriptors with 64-bit alignment (this does not apply to extended descriptors).
- While in operation mode, use LINKFIX instead of LINK whenever a descriptor need not be changed. Hardware modifies the descriptor type (DESCR.DT) fields of LINK descriptors.
- Frame data is accessed in blocks up to 128 bytes.
- The number of 128 byte borders (addresses H'x xx00 and H'x xx80) and frame data inside should be minimized.
- Design the descriptor chains in ways that minimize parallelism of processing. This helps in dividing the chains into segments allocated to different cache pages, and in arranging the different segments exclusively for access by software or hardware.
- Minimize the number of divided frames. This can reduce the overhead of descriptor handling.

33A.3.4 Control in Reception

The point of the AVB-DMAC is to transfer data between the E-MAC and URAM without intervention by the CPU.

AVB-DMAC needs descriptors that define the amounts of frame data to be stored and the locations. After the E-MAC receives a frame, it stores the received frame data and the conditions of reception as the E-MAC state. If the descriptor is extended, the time stamp is also stored. For a description of how to set up descriptors for use in reception, see section 33A.3.4.2 Setting Up Reception Descriptors.

The AVB-DMAC filters received frames to separate them into various classifications (separation filtering). More specifically, this is done to separate received frames into the various reception queues and to set the priorities of different classes of received frames. For more on separation filtering, see section 33A.3.4.1(1) Separation Filtering.

Figure 33A.15 shows the reception data bus and the selection of queues for use in reception.

Each frame received from the E-MAC is stored in the reception FIFO; in parallel with this, the frame is analyzed to identify its type and the target queue number. After the E-MAC completes reception, the target queue number is generated and stored in the reception FIFO. Appending of a reception flag depends on the storage of one frame among the reception queues in the URAM, and the unread frame counter (UFC) is also associated with frame storage.

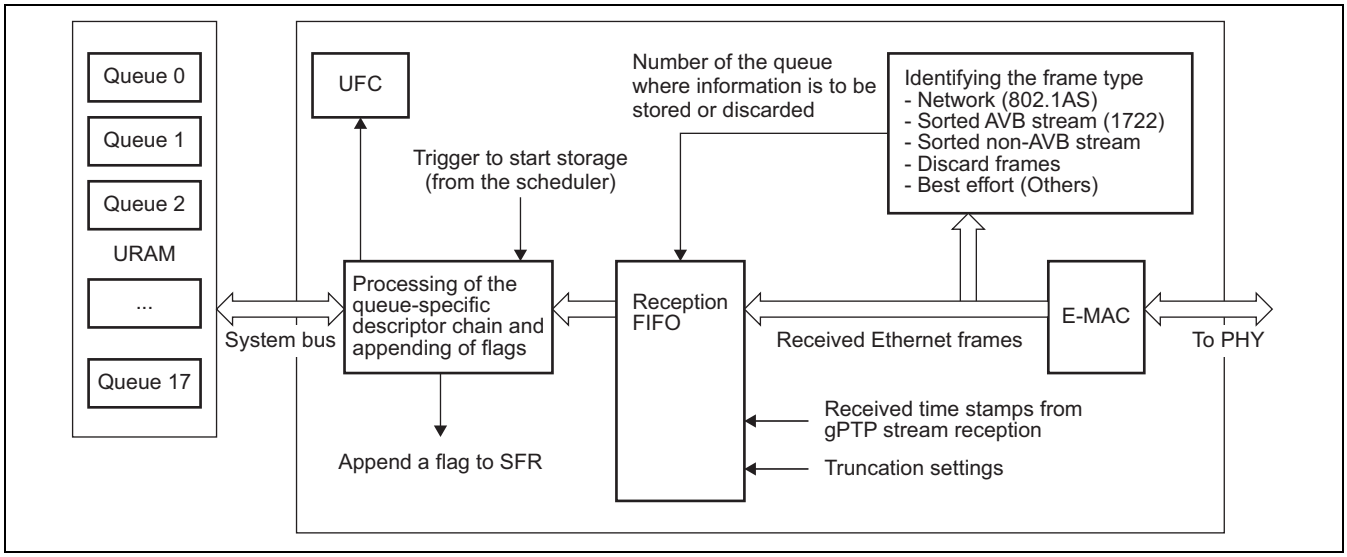

Figure 33A.15 Mechanism of General Reception Queue Selection

33A.3.4.1 Reception Queues

The AVB-DMAC applies its separation filtering mechanism to select the reception queue for storing a received frame. The AVB-DMAC stores all received frames in the URAM.

There are two conditions for the AVB-DMAC to discard a received frame.

- Detection of an error during reception by the E-MAC
  - Whether error frames are discarded or stored in reception queue 0 (best effort) depends on the setting of the error frame enable bit in the receive configuration register (RCR.EFFS). If error frames are to be stored (RCR.EFFS = 1), they are always stored in queue 0 (best effort). In this case, characteristics specific to the queue (e.g. truncation) will vary. If the storage of time stamps for reception queue 0 (best effort) is enabled (the time stamp enable bit in the receive configuration register RCR.ETS0 = 1), time stamps are stored even for error frames.
- Frame fails the separation filter
  - It depends on RCR.ESF if such frame is discarded or stored in receive queue 0 (best effort).

The flowchart in Figure 33A.16 shows how the AVB-DMAC selects the reception queue in accord with the frame type, including judgment by the separation filter. Selection of the queue starts when the E-MAC completes frame reception. The result is storage of the frame in the proper queue or the frame being discarded.

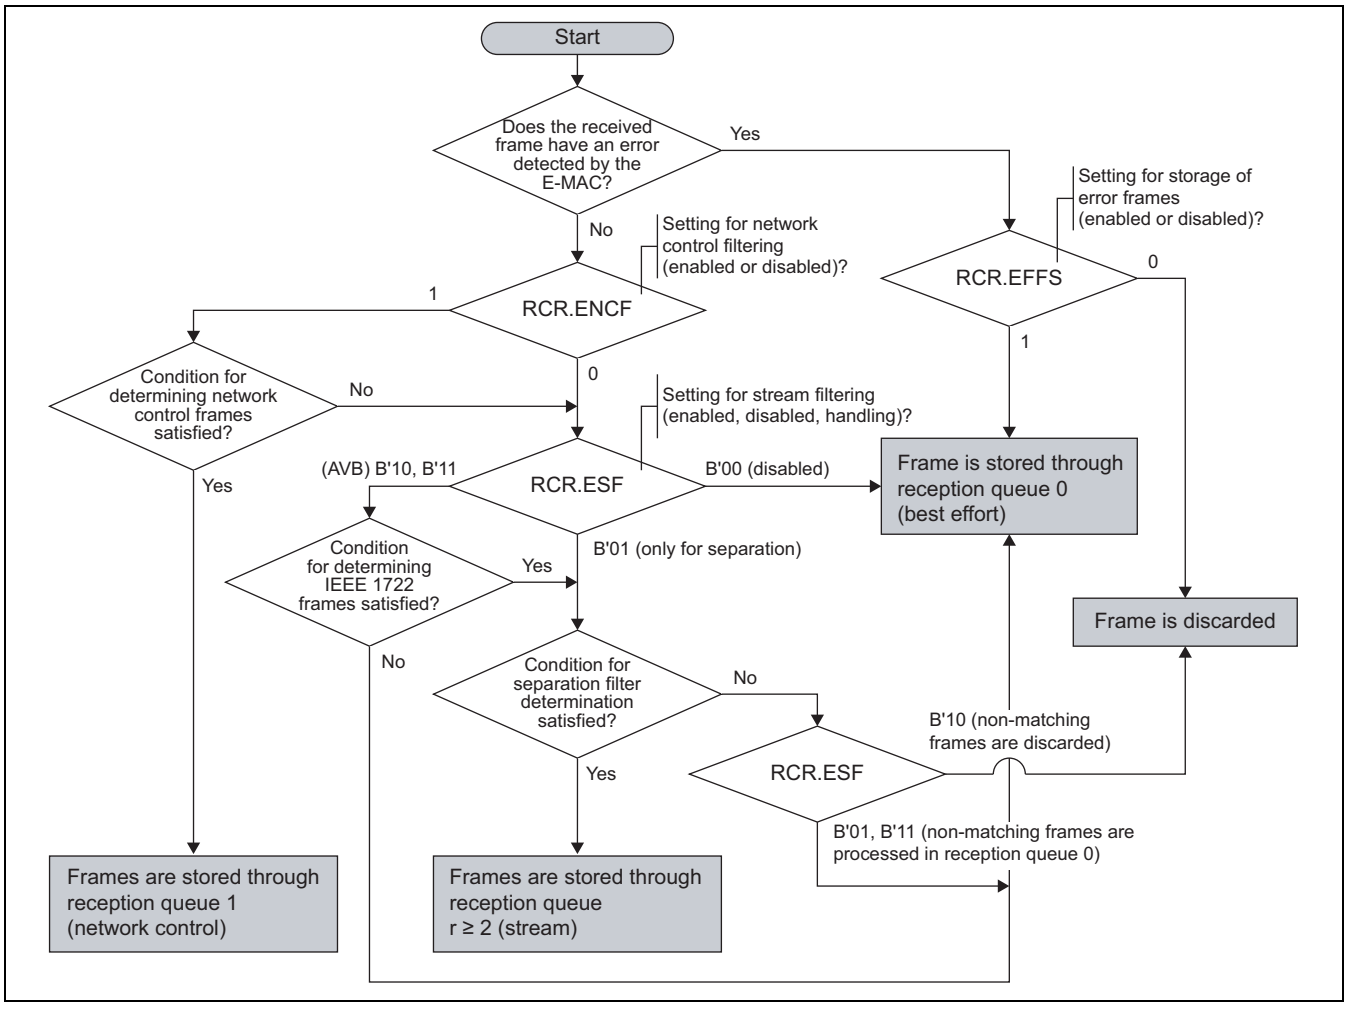

Figure 33A.16 Mechanism of Reception Queue Selection

Notes on the meanings of entries in the flowchart

- “Condition for determining network control frames”

The Ethernet destination address (DA) is 01:80:C2:00:00:0E.
The Ethernet type (ET) is 88:F7.

- “Condition for determining IEEE 1722 frames”

  The Ethernet destination address (DA) is within the range from 91:E0:F0:00:00:00 to 91:E0:F0:00:FE:FF.
  The VLAN tagged TPID (tag protocol identifier) field (VL) is 81:00.
  The Ethernet type (ET) is 22:F0.

- “Condition for separation filter determination”

  See section 33A.3.4.1(1) Separation Filtering.

Figure 33A.17 shows the allocation of bits related to the network and stream types in Ethernet frames. The preambles of Ethernet frames are not taken into account.

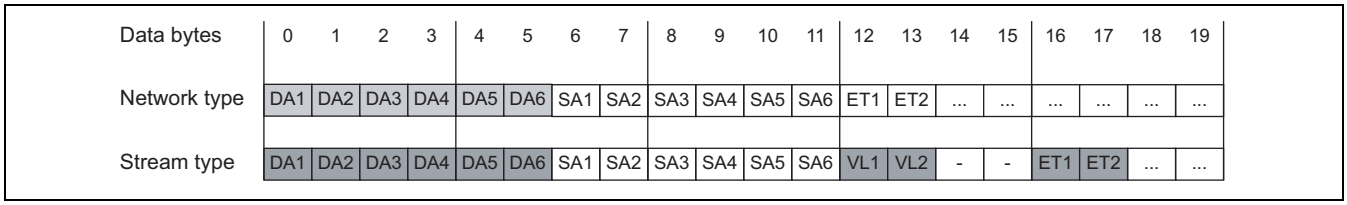

Figure 33A.17 Data Bytes of Ethernet Frames Used in Classification

(1) Separation Filtering

Separation filtering involves the checking of up to 64 bits (eight successive bytes) in received Ethernet frames. The setting for the first byte (i.e. the setting of the separation filter offset configuration register (SFO.FBP)), selects the part of frames to be used in separation filtering. There is also a common filter mask (set in the separation filter mask configuration register (SFMi.CFM)) that can be freely set to reduce the number of bytes used in separation filtering or to mask particular bits.

Examples

To use one byte in separation, set separation filter mask configuration register 0 (SFM0.CFM) to H'0000 00FF and separation filter mask configuration register 1 (SFM1.CFM) to H'0000 0000.

To use seven bytes in separation, set separation filter mask configuration register 0 (SFM0.CFM) to H'FFFF FFFF and separation filter mask configuration register 1 (SFM1.CFM) to H'00FF FFFF.

Note: If bits at some positions are set to 0 in the separation mask, in order to match with the pattern, the bits at the corresponding positions of the pattern must also be set to 0. Only those bits in which the separation filter pattern configuration register (SFPi.FPs) setting is equal to the separation filter mask configuration register (SFMi.CFM) are sorted by matching with received data.

Figure 33A.18 shows separation filtering. The selected data from a received frame (Rx_Frame[63:0]) are masked by the common filter mask. As a result, the selected frame data can be obtained. This value is compared with all filter patterns. The separation filter circuit in the AVB-DMAC selects the filter pattern that matches the queue having the lowest index s or selects a flag to indicate that there is no matching separation pattern.

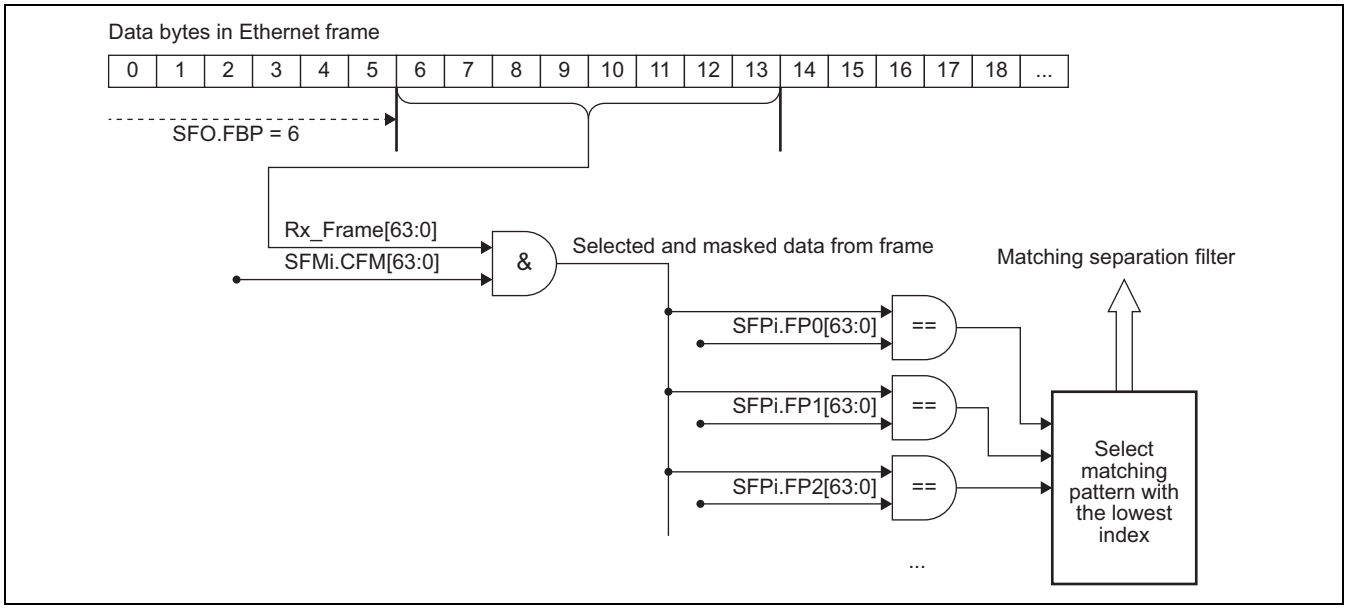

Figure 33A.18 Separation Filtering

(2) Separating Streams

The AVB-DMAC applies separation filtering to sort frames received in streams. An AVB network has a concept of “Talker” and “Listener”. A Talker is an end station that generates one or more streams. A Listener is an end station that has the role of being a sink for at least one stream. The various A/V streams are identified by 8-byte stream IDs.

The number of end stations within an AVB network and their roles differ with the application.

The stream ID is a general pattern of the AVB network for identifying one stream. Figure 33A.19 shows the bit allocation of bits in IEEE1722 Ethernet frames and stream ID fields.

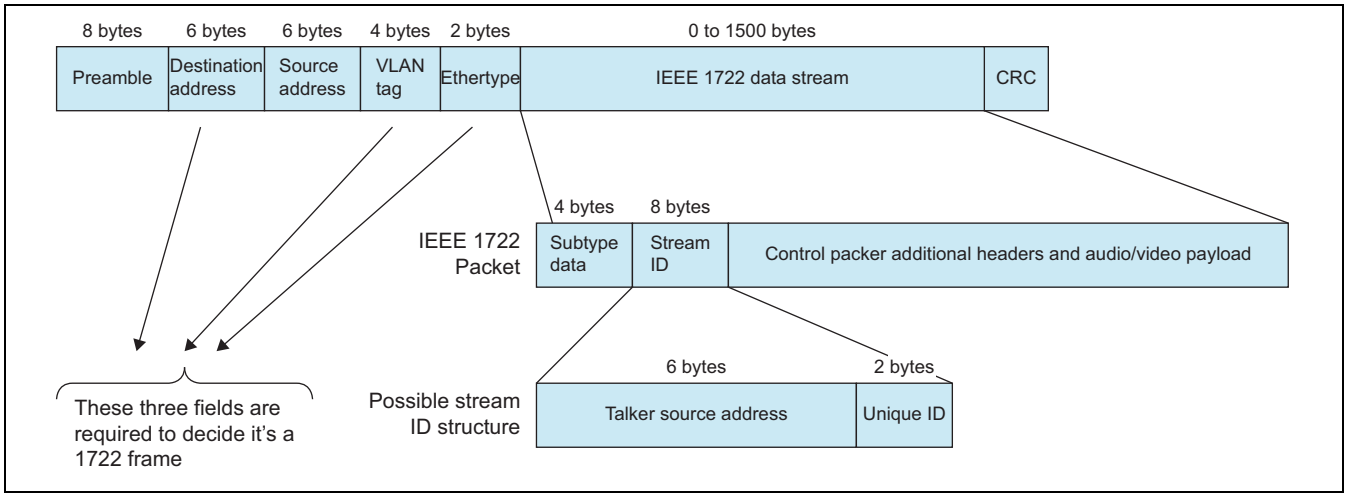

Figure 33A.19 IEEE 1722 Frame Layout and Stream ID

The IEEE 1722 standard stipulates that the stream ID field starts from the 23rd byte (not counting the preamble). Accordingly, set the separation filter offset (SFO.FBP) to 22 in operations on IEEE 1722 streams. Set the separation filter mask (SFMi) and separation filter pattern (SFPi) in accord with the specification of the product in which the chip is being used.

Example: In the example of a stream ID shown in Figure 33A.19, the current application divides the field into the talker source address and the unique stream ID. The unique ID is used to differentiate between multiple streams from the same talker. Based on this, there are two settings for separation filter masking:

- To divide various streams into individual queues, set SFM0.CFM to H'FFFF FFFF and SFM1.CFM to H'FFFF FFFF.
- To divide streams from various talkers into individual queues, set SFM0.CFM to H'FFFF FFFF and SFM1.CFM to H'0000 FFFF. This excludes the unique ID from the filter condition.

(3) Reconfiguration of separation filter during OPERATION

In CONFIG mode the initial separation filter configuration is defined. To prevent inconsistent filter results during OPERATION direct parameter change is not possible; instead update mechanism by SFVi.LV and SFL.LC should be used.

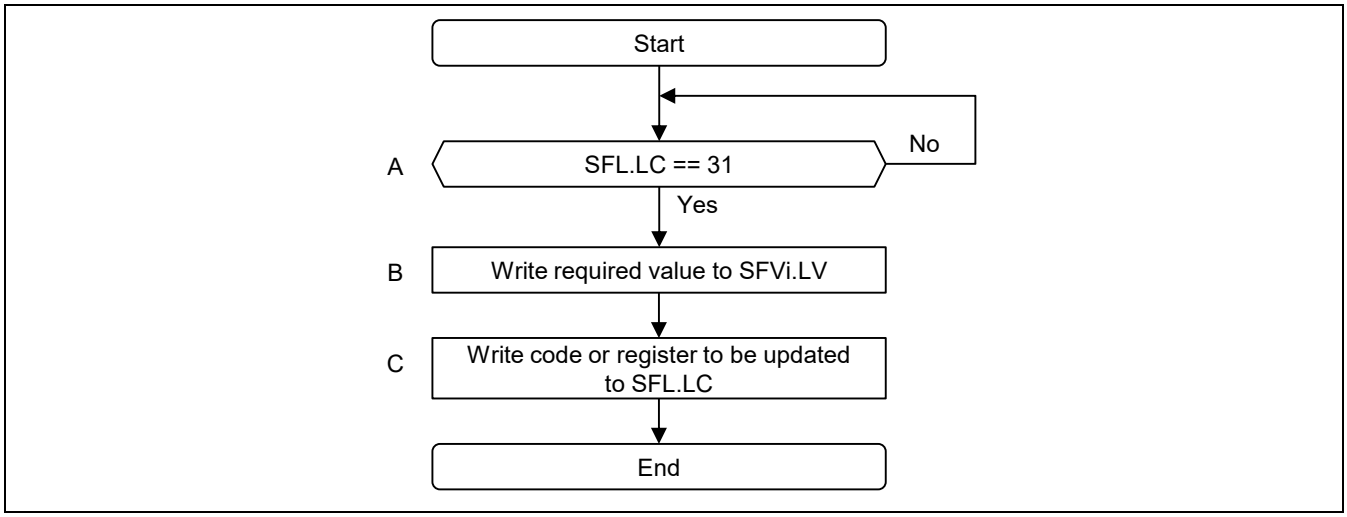

Figure 33A.20 SW flow to update separation filter during OPERATION

When reconfigure separation filter, EthernetAVB guarantees consistent classification for one received frame. If reconfiguration requires a sequence of parameter changes, CPU has to order reconfiguration based on application demand. EthernetAVB updates filter configurations when no frame reception is handled. In worse case the update is delayed by one frame reception. Exact duration depends on PHY speed and frame size. By reading SFL.LC CPU can observe when a previous update has been processed.

Note: Frame classification happens during frame reception and storage into internal Rx-FIFO. There may be frames with old classification pending in Rx-FIFO or under storage to URAM when filter reconfiguration is accepted.

33A.3.4.2 Setting Up Reception Descriptors

For reception, the descriptor mechanism is essentially as described in section 33A.3.3 Descriptors.

This section describes memory operations that are especially required in handling reception queues.

(1) Reception Descriptor Type

The type of a descriptor is defined by the descriptor type (DESCR.DT) field.

Table 33A.11 shows the descriptor types used in reception.

Table 33A.11 Descriptor Types in Reception

Descriptor Type (DESCR.DT)	Operation	Write-back
Frame Start (FSTART)	Condition for data not being stored in a reception queue: The RIS2.QFFr bit indicates that queue r is full and the received frame is not stored. Descriptor processing proceeds again in response to further reception.	Not changed
Frame Middle (FMID)	Same as FSTART	Not changed
Frame End (FEND)	Same as FSTART	Not changed
Frame Single (FSINGLE)	Same as FSTART	Not changed
Link (LINK)	Processing proceeds to the descriptor specified by DESCR.DPTR.	LEMPTY
Fixed Link (LINKFIX)	Same as LINK	Not changed
End Of Set (EOS)	A stop point defined by software has been reached. A descriptor of this type within a divided frame (writing of FMID or FEND) stops the frame being stored and the frame is lost. RIS2.QFFr indicates that the frame has been lost. If this happens at the start of a frame (writing of FSTART or FSINGLE), storing of frames starts from the next descriptor. In either case, processing shifts to the next descriptor in the chain.	EEMPTY
Frame Empty (FEMPTY)	The descriptor can be used to store received data. Up to DESCR.DS bytes are stored in the descriptor data area. For details, see section 33A.3.4.3(1) Storing Frame Data in the Descriptor Data Area.	FSTART, FMID, FEND, or FSINGLE
Frame Empty Incremental Start (FEMPTY_IS)	The descriptor can be used to store received data. All data for the frame are stored in the descriptor data area. DESCR.DPTR indicates the base address of the incremental data area. For details, see section 33A.3.4.3(2) Incremental Data Areas.	FEND or FSINGLE
Frame Empty Incremental Continue (FEMPTY_IC)	The descriptor can be used to store received data. The remaining bytes of frame data are stored in the descriptor data area. DESCR.DPTR is undefined, but is written back at the start position within the incremental data area after processing. For details, see section 33A.3.4.3(2) Incremental Data Areas.	FEND or FSINGLE
Frame Empty No Data storage (FEMPTY_ND)	The descriptor can be used to store received data. Up to DESCR.DS bytes are captured from the reception FIFO but not stored. After processing, DESCR.DS is written back as 0. For details, see section 33A.3.4.3(2) Incremental Data Areas.	FSTART, FMID, FEND or FSINGLE
Link Empty (LEMPTY)	Same as FSTART	Not changed
EOS Empty (EEMPTY)	Same as FSTART	Not changed

(2) Configuration of Reception Frame Data Descriptors

Figure 33A.21 shows the configuration of descriptors for use with reception queues. The reception-specific fields are the same whether the descriptor is normal or extended. The reception-specific fields (DESCR.MSC, DESCR.PS, DESCR.EI, and DESCR.TR) are described in Table 33A.12.

For the other fields and the descriptor types, see section 33A.3.3.6 Descriptor Type.

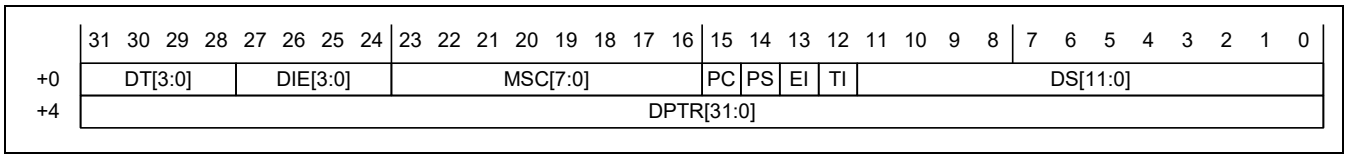

Figure 33A.21 Configuration of Descriptor for a Received Frame

Table 33A.12 Configuration of a Received Descriptor

Bit Name	Function
MSC	E-MAC Status Code These bits indicate errors in reception detected by the E-MAC. In the case of a divided frame, these bits are set to the same value within all descriptors for the frame data. Details of the bits are as follows. MSC[7]: Received frame has a multicast address. MSC[6]: Carrier extend error MSC[5]: Carrier sense error MSC[4]: Received frame has alignment error. MSC[3]: Received frame is too long. MSC[2]: Received frame is too short MSC[1]: Error in frame reception (PHY detects an error) MSC[0]: Received frame has a CRC error.
PC	Payload Crc status This bit informs about result of payload CRC check EthernetAVB does not make any confirmation if a frame contains a payload CRC. CPU need to analyse frame content before evaluating this bit. 0: Payload CRC is not matching 1: Payload CRC is correct
PS	Padding Selection These bits specify whether frame data are to be padded when stored in the incremental data area. Insertion of padding data is in accord with the settings in the RPC register. 0: Padding is not to be inserted. 1: Padding data may be inserted. This depends on the RPC settings.
EI	Error Indication This bit indicates the detection of an error in frame data while a frame was being stored. The bit is set to 1 for a descriptor in which an error has been detected. If the descriptor is for a divided frame, storage of the frame is aborted. 0: No error 1: Error is detected

Bit Name	Function
TI	Truncation Indication This bit indicates whether frame data received from the E-MAC have been truncated before being stored. These bits are set to the same value within all frame data descriptors for a divided frame. 0: Data have not been truncated. 1: Data have been truncated.

Note: The RCR.EFFS bit specifies whether or not frames with errors detected by the E-MAC are to be stored in the URAM. When the storing of error frames is disabled, error codes are not written to DESCR.MSC.

33A.3.4.3 Reception Processing

After initialization, the AVB-DMAC is able to select the proper reception queue and store received frames in the data area in the URAM as indicated by the descriptor. The AVB-DMAC continues to store received data in the URAM as long as space is available for descriptors and data areas.

Received frames are classified and stored in the reception FIFO in accord with the algorithm described in section 33A.3.4.1(1) Separation Filtering.

If the reception FIFO contains even one frame, storing is executed to the reception queue.

If there is even one empty data descriptor in a queue for which reception has started, the storage of frame data starts. Received frames for a queue that is already full (there is no empty frame descriptor or the UFC stop level has been reached) are discarded from the reception FIFO. This ensures that one queue being full does not prevent the storage of data in the other queues.

(1) Storing Frame Data in the Descriptor Data Area

Frame data for storage are assumed to be in either of the two patterns described below.

- The data for an entire frame will fit in the descriptor data area.
  - In this case, the descriptor type (DESCR.DT) is FSINGLE.
- Frame data to be stored in the descriptor data area arrive in divided form.
  - In this case, FSTART is written to the descriptor type (DESCR.DT) bits of the first descriptor of the frame data to arrive and FMID and FEND are written to the type bits of descriptors for subsequent data.

The descriptor type is updated by the AVB-DMAC in the last step of descriptor processing, so software can always access the descriptor assigned to DESCR.DT.

When normal synchronization mode is used, the CPU can write FEMPTYxxx directly to the descriptor type field after processing the stored element. Do not change the descriptor or any part of the descriptor data area after FEMPTYxxx is written to DESCR.DT.

(a) Storing Frame Data for a Whole Single Frame

For a frame with an FSINGLE descriptor, all data for the frame are held at the position defined by DESCR.DPTR. DESCR.DS indicates the length of the received frame.

If DESCR.DS is bigger than the actual size of a received frame, the FSINGLE descriptor is stored in place of the FEMPTY or FEMPTY_ND descriptor after processing.

Also, the FSINGLE descriptor is stored in place of the FEMPTY_IS or FEMPTY_IC descriptor, which always hold the descriptor data area greater than all frame data in Rx-FIFO after processing.

(b) Storing Frame Data as Divided Frames

Divided frames are handled in the same way as a single frame. A frame stored with divided descriptors must be recombined before use. DESCR.EI and DESCR.TS are only valid in the last descriptor of the sequence for a divided frame.

Note: If the data area size setting in DESCR.DS is not a multiple of four, the number of bytes set in DESCR.DS is fetched from the reception FIFO and the remaining bytes are used as the next storage area.
After a received frame is divided into different descriptors, each storage element is handled separately, and the descriptor type is assigned by software after processing. Accordingly, an error frame (FEMPTYxxx instead of FMID or FEND) may exist while a descriptor chain is being processed. In such a case, the CPU must postpone processing of the error frame to the next trigger point.

(c) No Data are Stored

The application specification may lead to some types of received frames being unimportant (for example, when the application only requires stream data from the Ethernet frames). Storing frames in divided form makes separating out the unnecessary parts of Ethernet frames possible.

If part of a divided frame is not required, use the FEMPTY_ND descriptor for that part so that it is not stored in the URAM. Not storing the data negates the need for bandwidth on the data bus, improving the overall performance.

When an FEMPTY_ND descriptor is processed, DESCR.DS is set to 0. This brings the frame data section of the descriptor into agreement with the FEMPTY type. DESCR.DS = 0 is for the unique identification of the descriptor after writing.

(2) Incremental Data Areas

Secure space in the URAM for storing received data. Even when data are placed in the URAM area such that all descriptor data areas of a chain are contiguous, a received frame being shorter than the descriptor data area will lead to an empty space. Figure 33A.22 shows an example of settings and the memory map.

Certain applications require that data areas be contiguous (e.g. when received data are to be processed other than by hardware as the A/V codec module). When the length of received frames differs (e.g. when payloads vary between having one or two A/V packages), the use of a static pointer in the descriptor produces empty spaces in the data area. This may necessitate direct additional processing to remove the empty spaces.

Accordingly, and to reduce the CPU load imposed by copying data, the AVB-DMAC supports an “incremental data area” function.

When incremental data areas are in use, all descriptors use a common data area for storage. One descriptor (FEMPTY_IS) defines the base address of the incremental data area and the next descriptor (FEMPTY_IC) within the descriptor chain holds received data. Figure 33A.23 shows an example of settings and the memory map.

Use of an incremental data area does not reduce the memory space in the individual descriptor data areas.

The hardware and software synchronization strategy and performance are also not changed.

It is also possible to divide a frame up among various descriptors in a way that reflects its structure (e.g. one descriptor for the Ethernet header and one for the data payload).

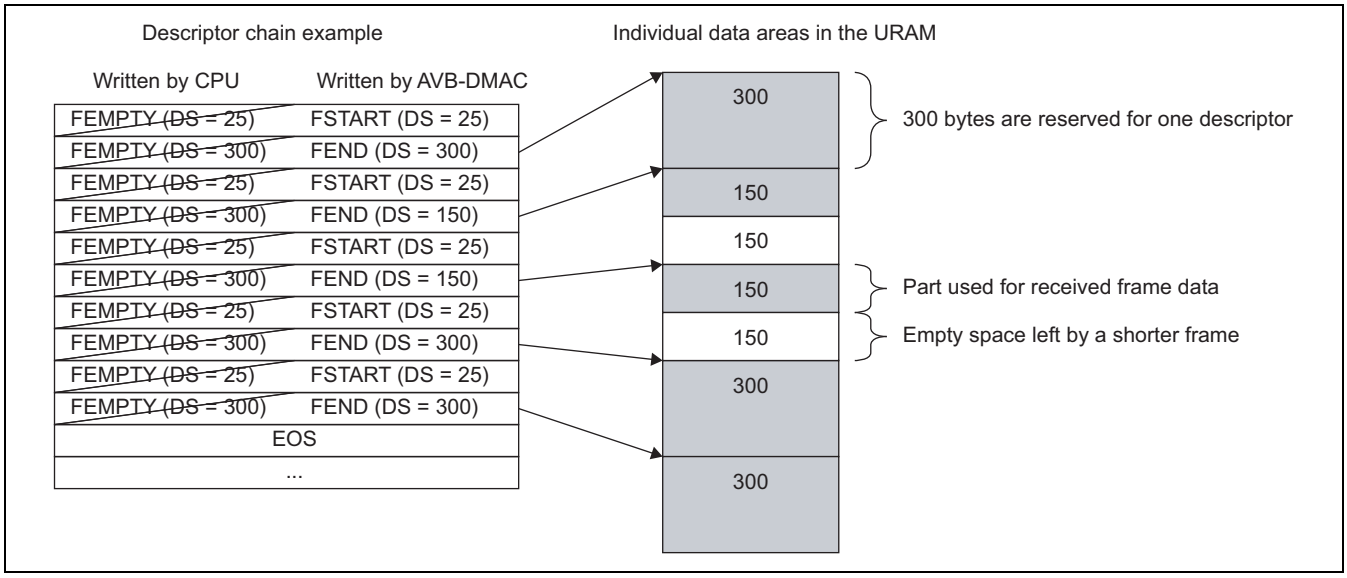

Figure 33A.22 A Reception Queue Using Individual Descriptor Data Areas

Figure 33A.22 and Figure 33A.23 show how control of the data storage areas by a descriptor chain varies according to whether individual or incremental data areas are in use. The chains are configured for storing received frames consisting of a 25-byte header (which is treated as one descriptor; and is outside the scope) and a 150- or 300-byte payload (whether one or two 150-byte payload packages are transmitted with one Ethernet frame depends on the data source).

In Figure 33A.22, the EOS descriptor is added as an example of a re-synchronization point. If the frame source transmits a frame containing more than 325 bytes, the frame will be divided among three descriptors, meaning that synchronization of the header and data sequences is lost. Despite this, however, the frame is not divided across the EOS descriptor, so recovery is automatic without software interaction. The EOS is not required with the incremental descriptors because all data being processed are always stored while an incremental data area is in use.

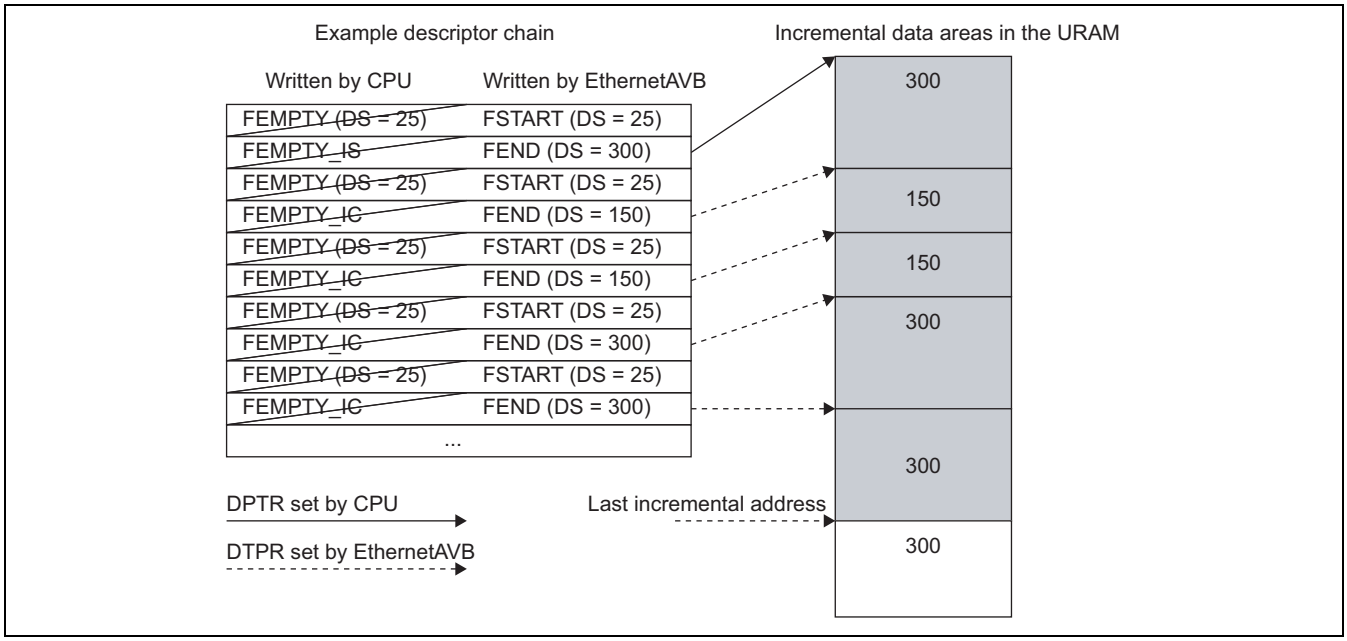

Figure 33A.23 Reception Queue Using a Common Incremental Data Area

As Figure 33A.23 shows, when data are stored in an incremental data area, the descriptor pointers in the FEMPTY_IC descriptors (DESCR.DPTR) are updated. Accordingly, the resulting FEND or FSINGLE descriptor is in the same format as after writing to an FEMPTY descriptor.

Software captures received data from an incremental data area, which has no empty storage areas between frame data. The only empty space is that at the end of the incremental data area. The sizes of incremental data areas and of blocks of data for storage in incremental data areas must be multiples of four bytes. When the amount of data for storage in an incremental data area is not a multiple of four bytes, from one to three bytes of empty space will be produced. DESCR.DS can be read to check for such empty spaces.

CPU cannot restrict directly the amount of received data stored by an incremental descriptor (FEMPTY_IS, FEMPTY_IC) as this is possible for other descriptors (FEMPTY, FEMPTY_ND) by DESCR.DS. Incremental descriptors store always all received data.

(a) Setting Up an Incremental Data Area

A descriptor chain in the incremental data area having N descriptors (one FEMPTY_IS and N-1 FEMPTY_IC) means that the incremental storage area of N times of maximum frame size is needed.

As Figure 33A.23 shows, DESCR.DPTR of an FEMPTY_IS descriptor indicates the base address of the incremental data area. The next FEMPTY_IS descriptor in the chain indicates the processing step where data must be stored in the incremental data area.

(b) Processing an Incremental Data Area Based on Descriptors

Since data processing by the CPU is the same regardless of how the AVB-DMAC stores the data, data stored in an incremental data area do not require any special handling.

(c) Padding

Use padding for received frame data that are not aligned correctly in the specified memory structure. Padding can be set individually for each descriptor. Accordingly, in the reception of divided frames, padding can be restricted to only those frames that require it (e.g. A/V payload data.)

Padding can also be used to optimize system performance in an incremental data area (e.g. to prevent inefficient access by aligning received data with 32-byte boundaries in the incremental data area), as well as to fulfill application-specific requirements for specified memory structures (e.g. formats required by other modules that will be processing the received data).

Padding can only be used in an incremental data area.

The value H'0000 0000 is always used in padding.

Padding is the addition of the number of words (from one to seven 32-bit words) set in the stored padding counter in the receive padding configuration register (RPC.PCNT). This padding is repeatedly inserted in accord with the value in the stored data counter (RPC.DCNT) (from one to 255 32-bit words). When the stored data counter (RPC.DCNT) reaches 0, however, padding is not repeated.

The first word of padding is always inserted at the position specified by DESCR.DPTR. When divided frames are in use, a padding word can be inserted at any byte position, and padding is handled on a 32-bit basis (e.g. an incremental data area where the first descriptor is for a 42-byte header data and the second descriptor holds padded payload data).

The next figure shows a general example of how padding is inserted and an example of setting up padding. A indicates frame data A received by the E-MAC, and B indicates the frame data stored in the descriptor data area (32-bit word units).

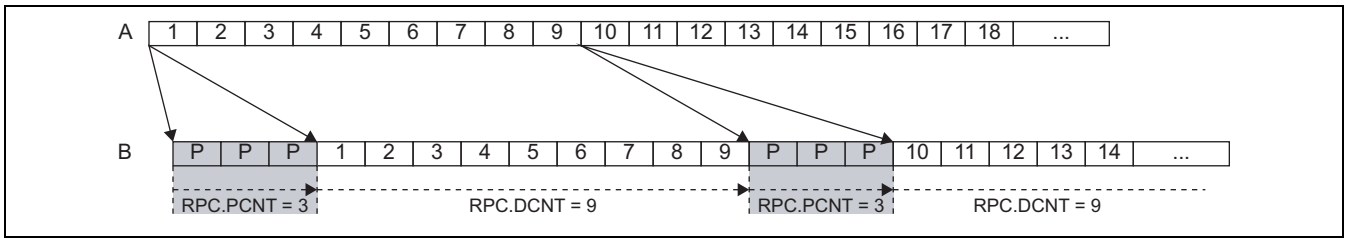

Figure 33A.24 Example of a Padding Setting

Both padding and received frame data are counted in the descriptor size (DESCR.DS).

(3) Mode with Write-Back

Constructing a descriptor chain requires software (see Figure 33A.25).

In the example in the figure, the variable SWdescr (software descriptor pointer) is a structure to identify a descriptor being processed. SWdescr must be initialized after operation mode is entered and a descriptor base address load request (DLR.LBAq) is executed (condition for starting the flow of software operations).

The frame_processing() function processes the stored data. The function can use SWdescr.DT to check whether processing of a frame is completed. How frame data are processed differs with the application, so create functions that handle processing in accord with the specification.

The processing section is common to all modes of reception. The number of frames processed in response to each trigger can be restricted. When multiple frames have to be processed in a batch, waiting for individual trigger boxes must be skipped for these frames.

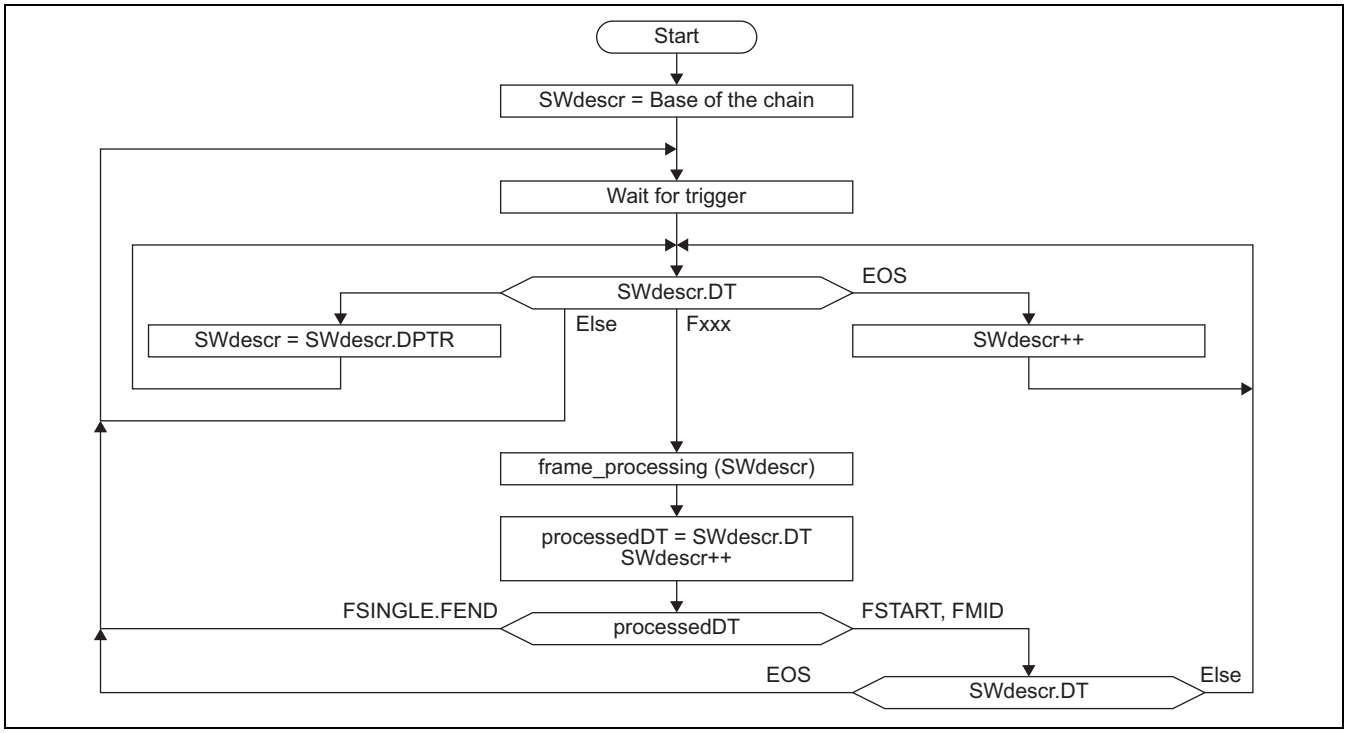

Figure 33A.25 Flow of Reception Descriptor Processing (with Write-Back)

(4) Support for Reception Time Stamps

Capturing reception time stamps is essential for IEEE 802.1AS time synchronization. Other types of received frames may also require that a reception time stamp be appended; this depends on the application. The AVB-DMAC supports reception time stamps based on the gPTP timer by storing time stamps, which have been captured when Start Frame Delimiter (SFD) of a received frame is arrived, in the last frame data descriptor (FEND or FSINGLE). For the gPTP timer, see section 33A.3.7.1 gPTP Timer.

When time stamps are to be stored, use extended descriptors for the entire reception queue. Furthermore, time stamps are always stored for reception queue 1 (network control). Time stamps for reception queue 0 (best effort) and reception queue r ($r \geq 2$; for stream data) can be selected by the time stamp enable bits in the receive configuration register (RCR.ETS0 or RCR.ETS2).

33A.3.4.4 Unread Frame Counters

Each reception queue has an unread frame counter (UFCVi). Use the unread frame counter configuration bits in the receive queue configuration register (RQCi.UFCCr) to select from among the four warning and stop levels for each unread frame counter. The 0 setting disables the stop and warning functions. For how to set this up, see Figure 33A.26.

Operations of the AVB-DMAC (hardware) and CPU (software) drive an unread frame counter (UFC) in the following ways.

- The hardware indicates that it has added a new frame to the descriptor chain for the queue (this increments the counter).
- Software indicates how many frames from the descriptor chain it has processed by writing to the corresponding bits of the unread frame counter decrement register for the queue (this decrements the register by the number written).

The unread frame counter is based on the number of frames stored in the URAM and is only incremented by one even when a received frame is divided into different descriptors. Failure in storing a descriptor chain requires care because this may unread frame counter may fail in synchronization as described in section 33A.3.4.4(1) Unread Frame (UFC) Synchronization Failure.

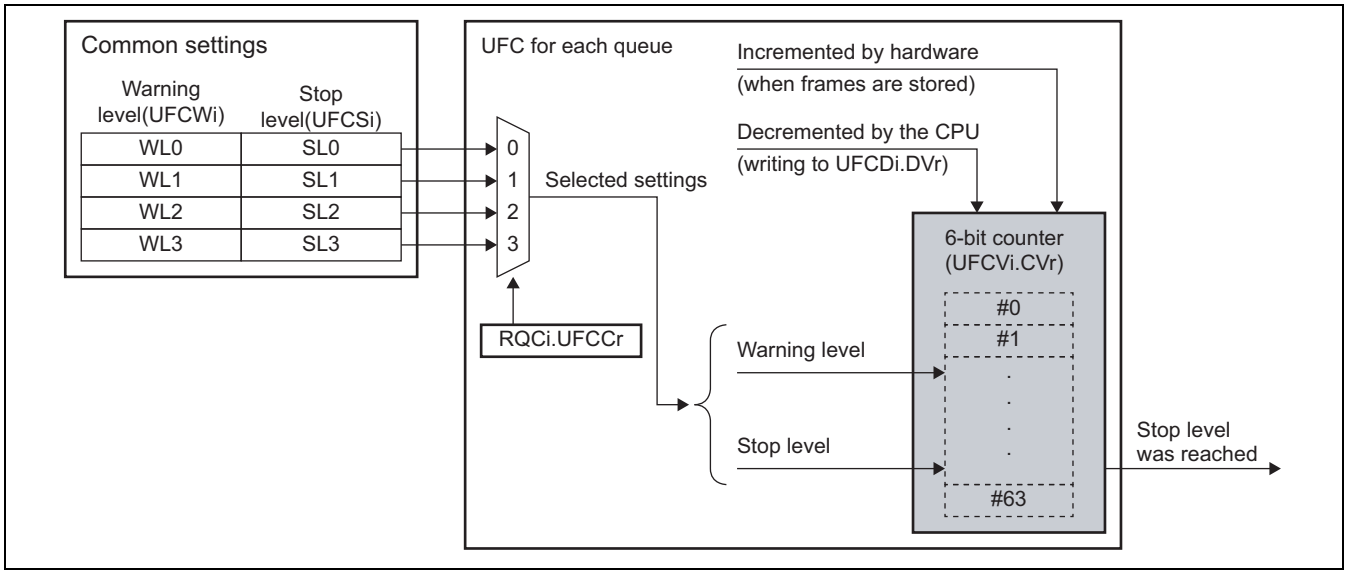

Figure 33A.26 Overview of an Unread Frame Counter

Unless synchronization of hardware and software is lost, the current unread frame counter value (UFCVi.CVr) indicates the number of unread frames in the queue.

The indicator that the stop level has been reached prevents the storage of further received frames in the descriptor chain. Selecting 0 as the stop level disables this function. Otherwise, further received frames for the queue are discarded once its unread frame counter reaches the stop level. Activation of the unread frame counter stop function is indicating by setting of the receive queue full interrupt flag in the receive interrupt status register 2 (RIS2.QFFr).

Set the unread frame counter warning level configuration register (UFCW) and the unread frame counter stop level configuration register (UFCS) for each reception queue that will use the unread frame counter function while the current operating mode is configuration mode.

(1) Unread Frame (UFC) Synchronization Failure

The unread frame counters do not recognize failure to store a frame in the URAM. In other words, the AVB-DMAC increments the counter for a queue each time it captures a frame for that queue from the reception FIFO whether or not it succeeds in storing the frame normally in the descriptor chain.

In general, synchronization of hardware and software fails under the following conditions.

- An unread frame counter reaching its maximum value
  When the value of a counter in an unread frame counter register i (UFCVi) (i = 0 to 4) reaches 63, synchronization for the corresponding queue can fail.
  The CPU can only judge that a failure in synchronization has not occurred when the stop level is set to 63.
- A queue not having enough space for a descriptor
  In this case, the corresponding receive queue full interrupt flag (RIS2.QFFr) in receive interrupt status register 2 (RIS2) is set.
  If an unread frame counter reaches its stop level while synchronization remains normal, the receive queue full interrupt flag (RIS2.QFFr) in the receive interrupt status register 2 (RIS2) is set. Software must respond to this.
- A problem occurring during access to memory

The result of a failure in synchronization is the unread frame counter indicating that the corresponding descriptor chain may contain more available frames than it actually can. To retrieve the correct starting point for operations, use the descriptor base address load request (DLR.LBAq) for the given queue.

33A.3.5 Transmission Control

Areas in the URAM for storing transmission descriptors must also be secured (for descriptors, see section 33A.3.3 Descriptors).

The AVB-DMAC fetches data from the URAM in accord with the procedure the descriptor describes. The descriptor also retains tag information once the frame has been fetched for transmission. The tag information is used to maintain the relationships between status and time stamps for the software and the AVB-DMAC. The status and time stamp information for transmitted frames remains accessible after their transmission is completed.

33A.3.5.1 Transmission Modes

The AVB-DMAC has two modes of transmission.

- AVB transmission mode
  This mode is selected by the priority level setting for the transmission queue in the transmit configuration register (setting of the TGC.TQP[1:0] bits) being B'01 or B'11.
- Non-AVB transmission mode
  This mode is selected by the priority level setting for the transmission queue in the transmit configuration register (setting of the TGC.TQP[1:0] bits) being B'00.

(1) AVB Transmission Mode

AVB transmission supports the control of traffic through the output port to implement various traffic classes.

(a) Support for Traffic Classes and Associated Priority

When transmission is in AVB transmission mode, streams of traffic are transmitted in accord with the part of the AVB specification called Forwarding and Queuing for Time Sensitive Streams (FQTSS; for details on this, see the IEEE 802.1Q standard).

In the AVB specification, at least one queue for a reserving stream under the Stream Reservation Protocol (SR stream) and at least one queue for a non-SR stream are present, and the queues for SR traffic is Highest priority queue.

The AVB-DMAC supports four traffic classes: SR class A, SR class B, network control (NC) traffic (gPTP frames), and best effort (BE) traffic. Allocating a specific queue to network control (NC) frames ensures the control of synchronization.

The AVB-DMAC realizes compliance with the AVB standards by handling queues with the following architecture (in terms of traffic classes).

- Four transmission queues (Q3, Q2, Q1, and Q0) are available.
- Q3 and Q2 are for SR streams (one each for class A and class B).
- Q1 is for low-bandwidth network control (NC) traffic (gPTP frames)
- Q0 is for other types of traffic (MSRPDU*1, MVRPDU*2, best effort (BE), etc.)

Notes: 1. MSRPDU: Multiple Stream Registration Protocol Data Unit
2. MVRPDU: Multiple VLAN Registration Protocol Data Unit

Fetching from queues proceeds in order of priority of the above traffic types. Three systems of priority are available through the setting of the transmit queue priority bits in the transmit configuration register (TGC.TQP[1:0]). In the default priority scheme, which is called AVB mode 1 (selected by TGC.TQP[1:0] = B'01), operation of the AVB-DMAC is fully in accord with the AVB specification. AVB mode 2 (transmit queue priority bits (TGC.TQP[1:0] = B'11) is an alternative priority scheme and varies from the AVB specification. Using this scheme thus requires more care. The other setting is for non-AVB-mode transmission.

Table 33A.13 Default and Alternative Priority Orders in AVB Transmission Mode

Priority Schemes (AVB Mode)	Priority Order of Queues
Default	Q3 (SR class A) > Q2 (SR class B) > Q1 (NC) > Q0 (BE)
Alternative	Q1 (NC) > Q3 (SR class A) > Q2 (SR class B) > Q0 (BE)

(b) Transmission Selecting Algorithm and CBS

The algorithm the AVB-DMAC applies to select frames for transmission is in accord with the specifications under section 8.6.8, Transmission selection, of the IEEE 802.1Q standard. For AVB mode, the CBS (credit-based shaping) algorithm is applied to the class A and class B SR queues (Q3 and Q2). Use of the CBS enables correct handling of the priorities of transmission from the SR queues. For the CBS algorithm, see section 33A.3.6 CBS (Credit-Based Shaping).

When the following conditions both hold, transmission from an SR queue (Q3 or Q2) proceeds at the specified time.

- The queue contains at least one frame ready for transmission.
- The queue has available credit.
- Unless an SR queue satisfies the above conditions, a higher priority queue is not present (not ready for transmission).

A non-SR queue (Q1 or Q0) is selected if the conditions below both hold.

- The queue contains at least one frame ready for transmission.
- As well as the above condition, a higher priority queue is not present (not ready for transmission).

Figure 33A.27 and Figure 33A.28 are flowcharts of selection for transmission in AVB mode 1 (default) and AVB mode 2 (alternative).

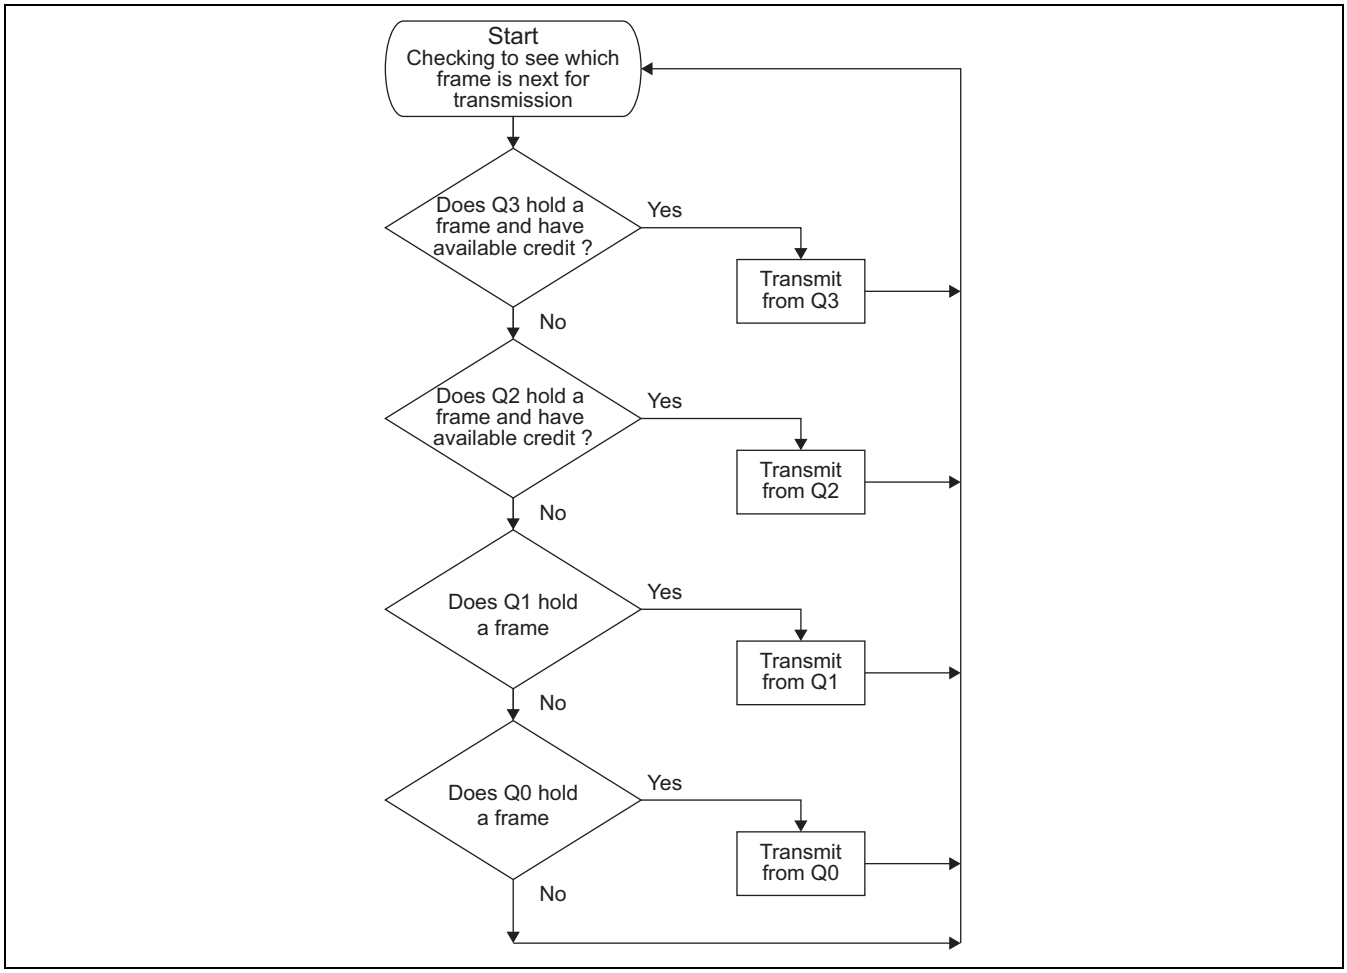

Figure 33A.27 Flow of Selection for Transmission in AVB Mode 1 (Default)

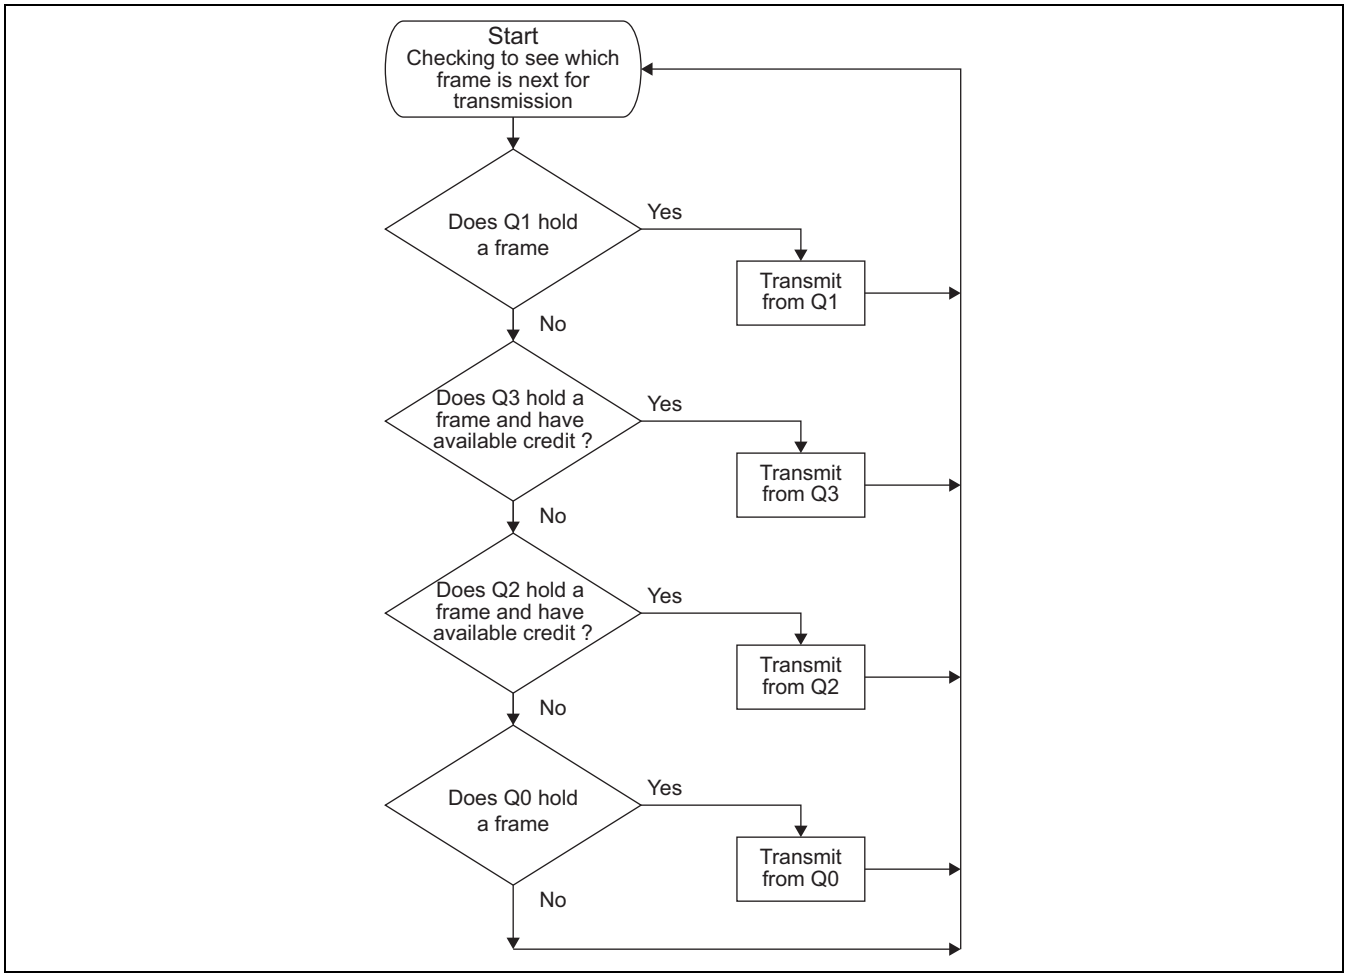

Figure 33A.28 Flow of Selection for Transmission in AVB Mode 2 (Alternative)

(2) Non-AVB Transmission Mode

In non-AVB transmission mode, an absolute priority scheme is used. The SR class is not supported and the CBS algorithm is not used.

In non-AVB transmission mode (when the transmit queue priority bits in the transmit configuration register (TGC.TQP[1:0]) are B'00), data is fetched for transmission in a strict order of priority (Q3 > Q2 > Q1 > Q0).

Figure 33A.29 shows the flow of selection in non-AVB transmission mode.

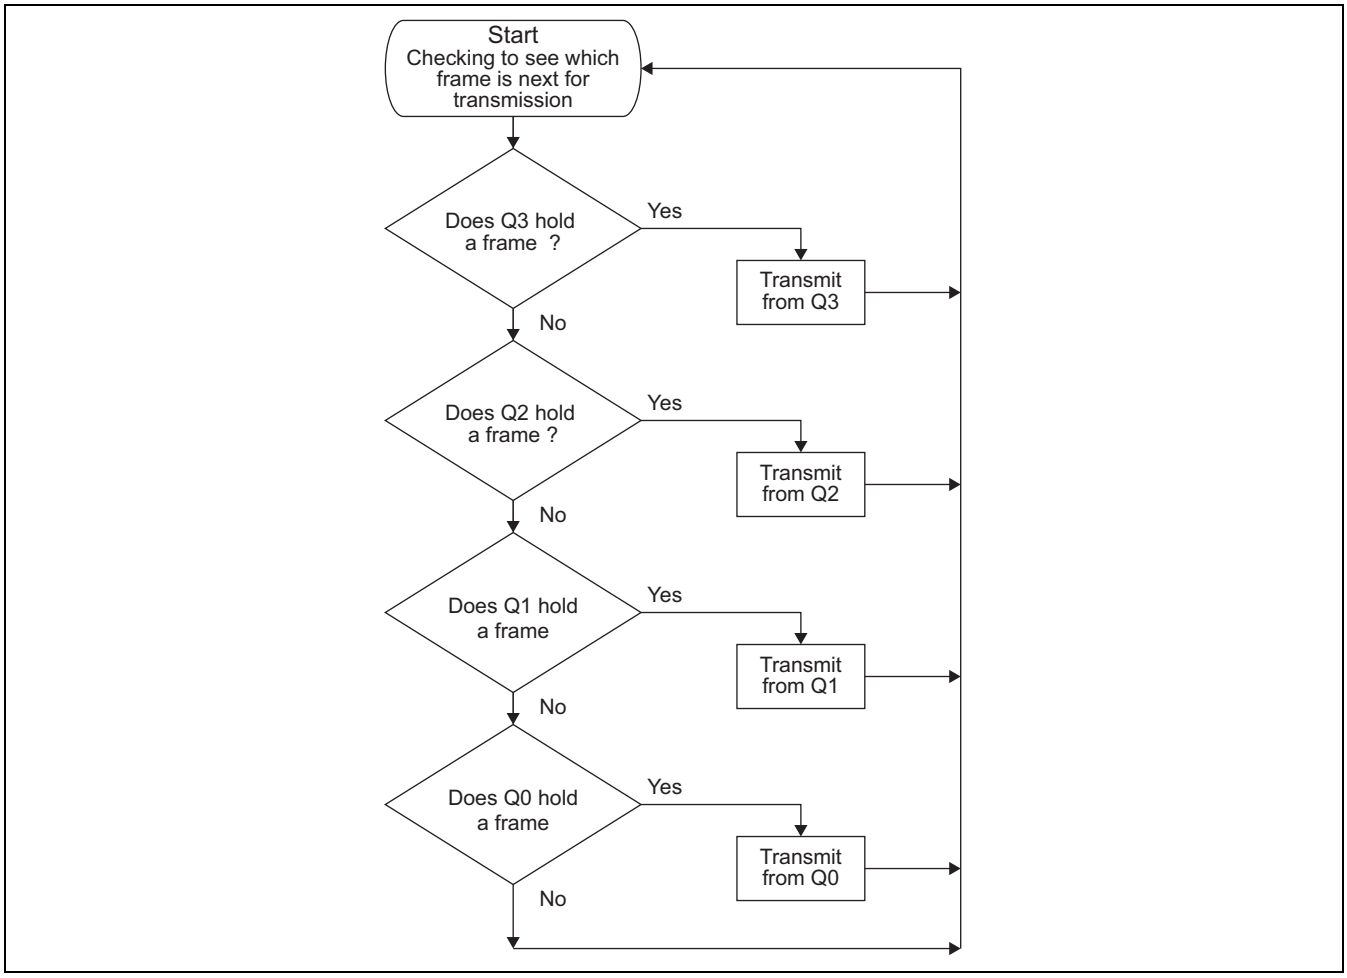

Figure 33A.29 Flow of Selection for Transmission in Non-AVB Mode

(3) Setting the Size of the Transmission FIFO

The transmission FIFO is made up of 122 clusters. Each cluster can hold up to 128 bytes.

The size of the part of the transmission FIFO for use by each of the four transmission queues can be set by the corresponding transmit queue configuration q bits in the transmit control register (TGC.TBDq). The setting of TGC.TBDq is fixed to 2.

General Usage Examples:

Q0: Frames containing up to 1500 bytes → 1500/128 = 11.7 → 12 clusters
Q1: Frames containing up to 1024 bytes → 1024/128 = 8.0 → 8 clusters
Q3: Frames containing up to 1996 bytes → 1996/128 = 15.6 → 16 clusters
Q4: Frames containing up to 1996 bytes → 1996/128 = 15.6 → 16 clusters
When the depth of all transmission queues is 2, only the following number of clusters is required.
$2 \times (12 + 8 + 16 + 16) + 16 = 2 \times 52 + 16 = 120$

In the worst case (each of the transmission queues holds 1996 bytes), $2 \times 64 + 16 = 144$ clusters are required, so the maximum length of transmission frames must be less than 1996 bytes for some queues.

33A.3.5.2 Setting Up Transmission Descriptors

(1) Transmission Descriptor Type

The type of a descriptor is defined by the descriptor type (DESCR.DT) field.

Table 33A.14 shows the descriptor types used in transmission.

Table 33A.14 Descriptor Types in Transmission

Descriptor Type (DESCR.DT)	Operation	Write-back
Frame Start (FSTART)	The AVB-DMAC fetches the first of the data for the divided frame and proceeds to processing of the next descriptor.	FEMPTY
Frame Middle (FMID)	The AVB-DMAC fetches the second or subsequent data for the divided frame and proceeds to processing of the next descriptor.	FEMPTY
Frame End (FEND)	The AVB-DMAC fetches the last of the data for the divided frame. The frame of data that has been fetched to the transmission FIFO is ready for transmission by the E-MAC, and then the AVB-DMAC proceeds to processing of the next descriptor.	FEMPTY
Frame Single (FSINGLE)	The AVB-DMAC fetches the frame of data. The frame of data that has been fetched to the transmission FIFO is ready for transmission by the E-MAC, and then the AVB-DMAC proceeds to processing of the next descriptor.	FEMPTY
Link (LINK)	Processing proceeds to the descriptor specified by DESCR.DPTR.	LEMPTY
Fixed Link (LINKFIX)	Same as LINK	Not changed
End Of Set (EOS)	This is a transmission stop point defined by software This leads to clearing of the transmit start request bit (TCCR.TSRQt), which stops transmission. When the TCCR.TSRQt is again set to 1 (a new transmission start request is issued), processing proceeds to the next descriptor.	EEMPTY
Frame Empty (FEMPTY)	No frame data are ready for transmission This leads to clearing of the transmit start request bit (TCCR.TSRQt), which stops transmission. When the TCCR.TSRQt is again set to 1 (a new transmission start request is issued), processing starts at this descriptor.	Not changed
Link Empty (LEMPTY)	Same as FEMPTY	Not changed
EOS Empty (EEMPTY)	Same as FEMPTY	Not changed

(2) Configuration of Transmission Frame Data Descriptors

Figure 33A.30 shows the configuration of descriptors for use with transmission queues. The transmission-specific fields (DESCR.MSR, DESCR.TSR, and DESCR.TAG) are described in Table 33A.15.

For the other fields and the descriptor types, see section 33A.3.3.6 Descriptor Type.

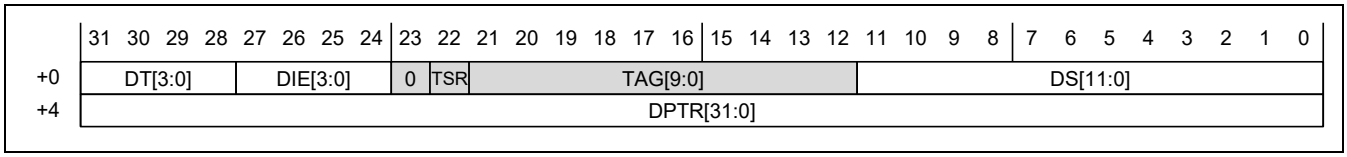

Figure 33A.30 Configuration of Descriptor for a Transmitted Frame

Table 33A.15 Configuration of a Transmission Descriptor

Bit Name	Function
TSR	Time Stamp Store Request This bit specifies whether the transmission time stamp is to be stored within the EthernetAVB module. 0: The time stamp status FIFO within the EthernetAVB module does not retain a transmission time stamp. 1: The time stamp status FIFO within the EthernetAVB module retains a transmission time stamp. This bit is available while the current DESCR.DT is FEND or FSINGLE.
TAG	Frame Tag This TAG field is used to associate each frame data with a time stamp. Frame TAG is not required but is recommended. This bit is available while the current DESCR.DT is FEND or FSINGLE.

For the time stamp FIFO function, see section 33A.3.5.4 Time Stamping in Transmission.

33A.3.5.3 Transmission

(1) Transmitting Frames

Setting the transmit start request bit in the transmit configuration control register (TCCR.TSRQt) starts the transfer of frames from the corresponding transmission queue.

The descriptor in the current descriptor address (CDARq.CDA) for the queue t (with q = t) is read first.

If this descriptor is a descriptor for frame transmission (FSINGLE, etc.), the AVB-DMAC fetches the frame data from the data area indicated by the descriptor, writes FEMPTY back to the descriptor type (DESCR.DT) bits to indicate completion of this processing, then proceeds to processing of the next descriptor.

If the descriptor is not for transmission, processing is as dictated by the given descriptor (for these descriptors, see the descriptions in section 33A.3.3 Descriptors).

If a base address load request is issued for a descriptor chain while it is being processed (by setting 1 in the LBAq bit for transmission queue q that is currently being processed in the descriptor base address load request register, DLR), processing proceeds to the new descriptor chain. Changing the chain does not interrupt frame fetching, but note that frames that have not been fetched from the old chain remain where they are.

Figure 33A.31 shows descriptor processing during transmission.

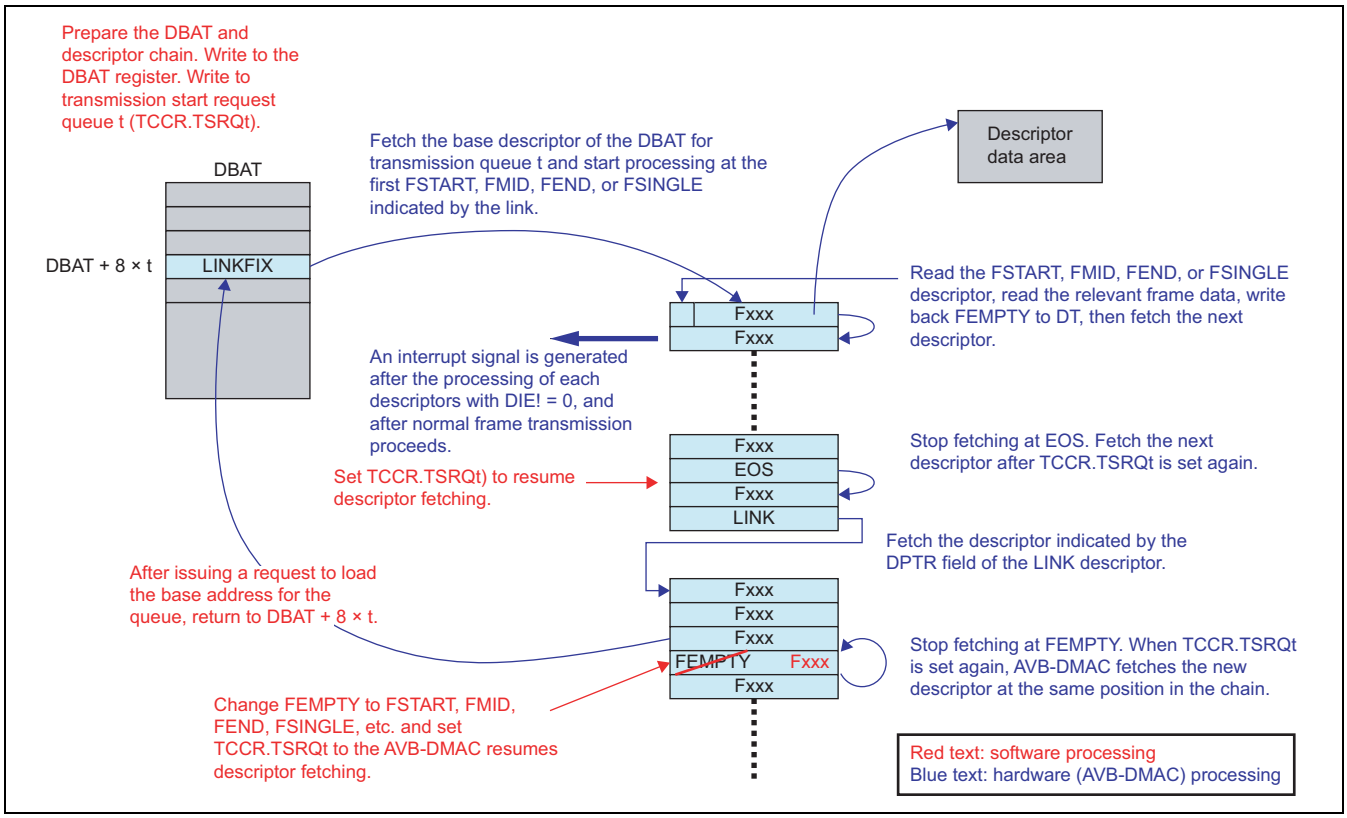

Figure 33A.31 Descriptor Processing During Transmission

(2) Examples of Descriptor Usage

(a) Immediate Frame Transmission

Immediate frame transmission is a pattern in which fetching by the AVB-DMAC starts whenever software adds data to a queue. FEMPTY descriptors are used as stop points to keep the hardware and software in synchronization.

Create descriptor chains that have FEMTPY descriptors at the stop points.

Figure 33A.32 shows the flow for software implementing this pattern. SW should read back written descriptor between changing FEMPTY descriptor before writing to TCCR.TSRQt.

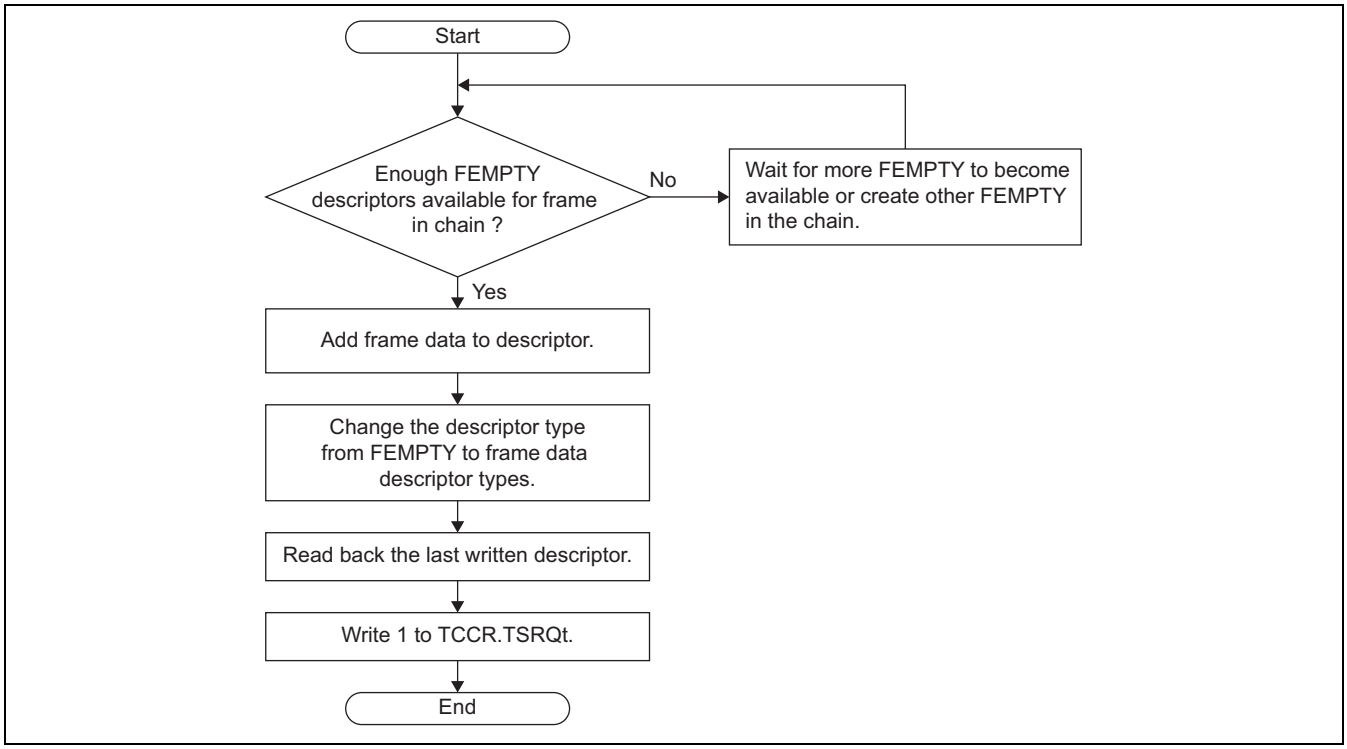

Figure 33A.32 Software Flow for Immediate Frame Transmission

Figure 33A.33 shows software and AVB-DMAC operations for immediate frame transmission.

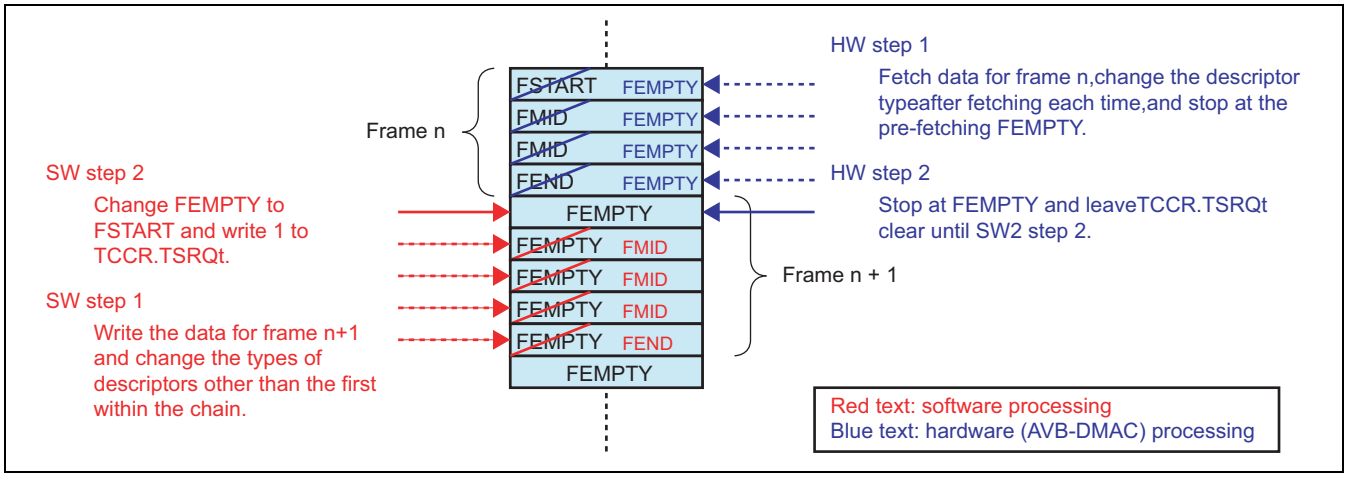

Figure 33A.33 Software and AVB-DMAC Operations for Immediate Frame Transmission

(b) Frame Set Transmission with Changing of the Active Descriptor Chain

This pattern is used when data are transmitted with a delay for software control to secure bandwidth or for other reasons, rather than immediately transmitted. EOS descriptors are used for the stop points. Start by creating a descriptor chain that has a FEMPTY descriptor as its stop point.

Figure 33A.34 shows the software flow in this pattern.

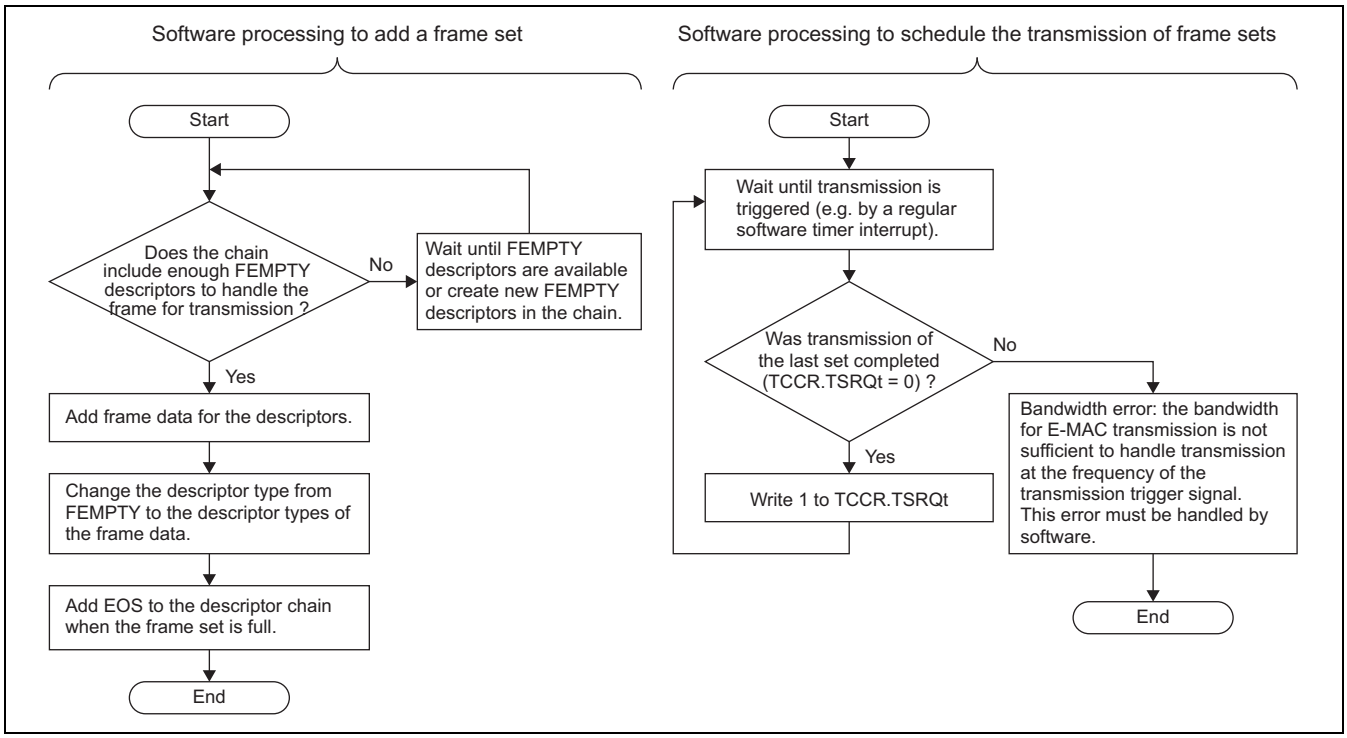

Figure 33A.34 Software Flow for Frame Set Transmission with Changing of the Active Descriptor Chain

Figure 33A.35 shows software and AVB-DMAC operations for frame set transmission.

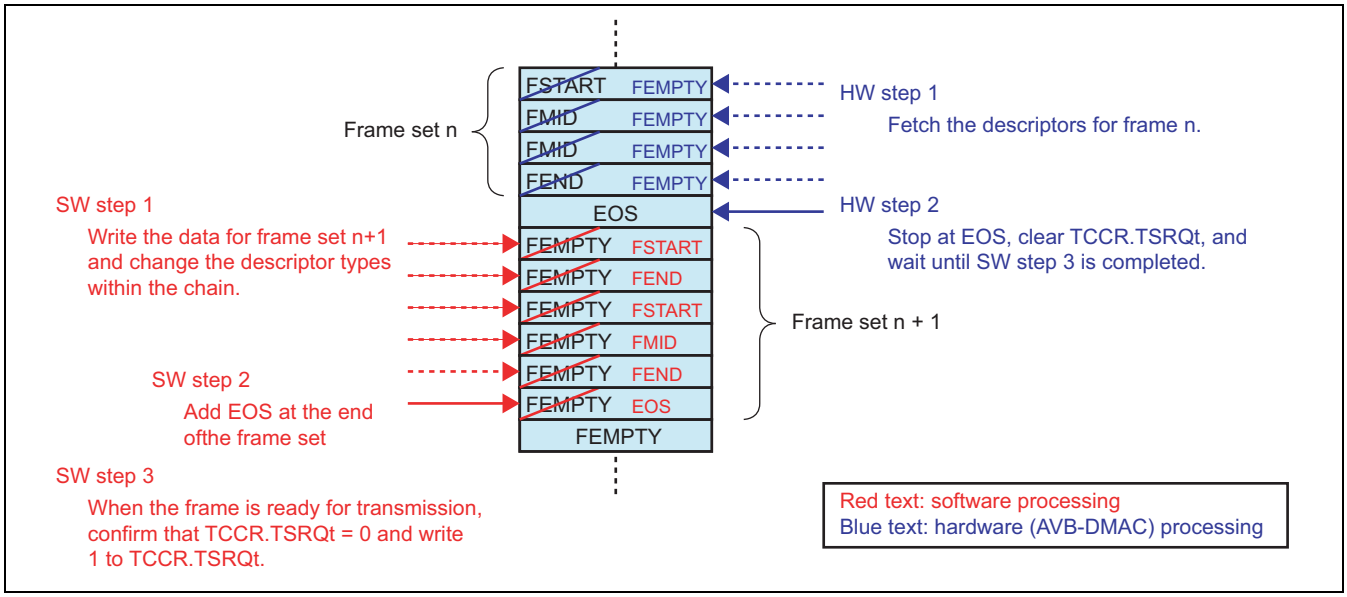

Figure 33A.35 SW and AVB-DMAC Operations for Frame Set Transmission with Changing of the Active Descriptor Chain

(c) Frame Set Transmission Using a Shadow Descriptor Chain

This pattern is used when data are transmitted with a delay for software control to secure bandwidth or for other reasons, rather than immediately transmitted. Two or more descriptor chains are used. The chains are classified as active or shadow chains. EOS descriptors are used for the stop points.

Create descriptor chains that have FEMPTY descriptors at the stop points.

Figure 33A.36 shows the flow for software implementing this pattern.

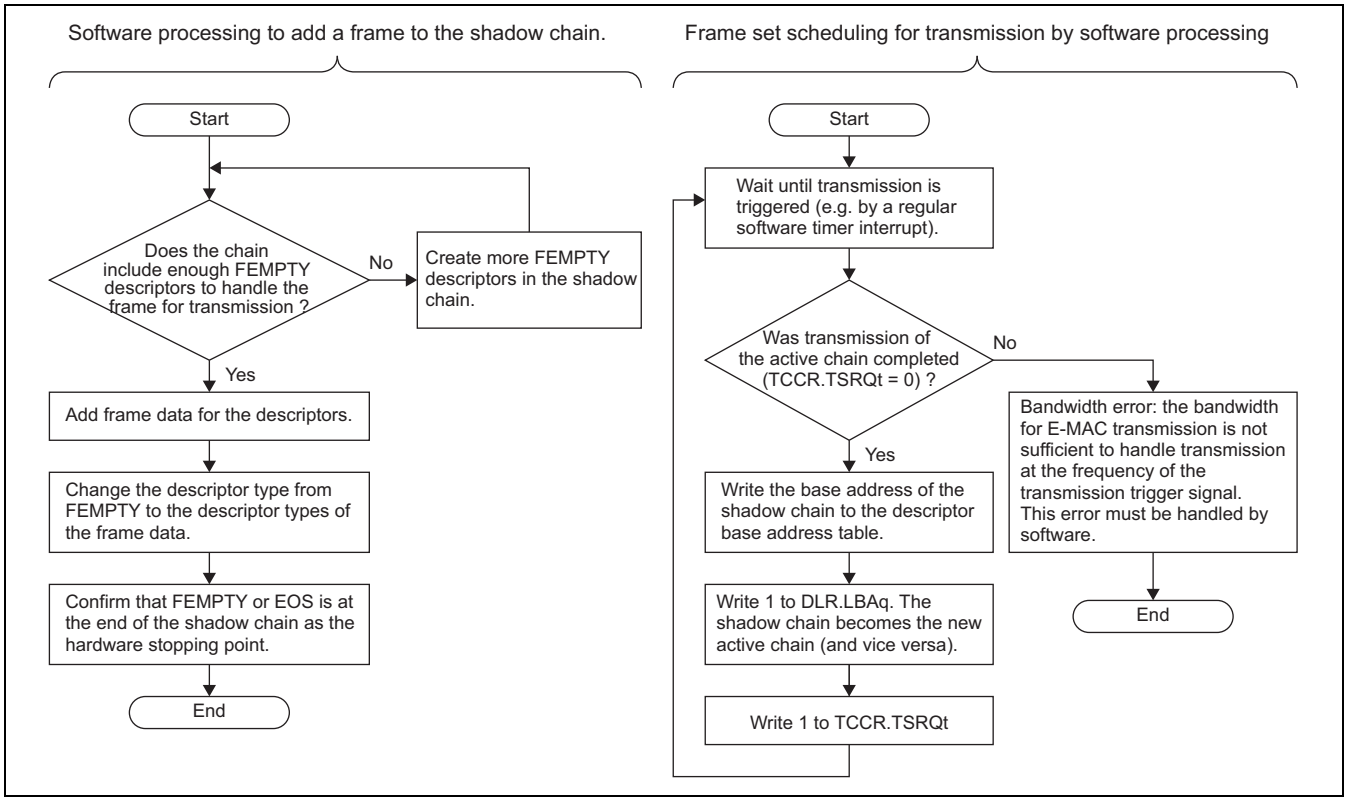

Figure 33A.36 Software Flow for Frame Set Transmission Using the Shadow Descriptor Chain

Figure 33A.37 shows software and AVB-DMAC operations for frame set transmission.

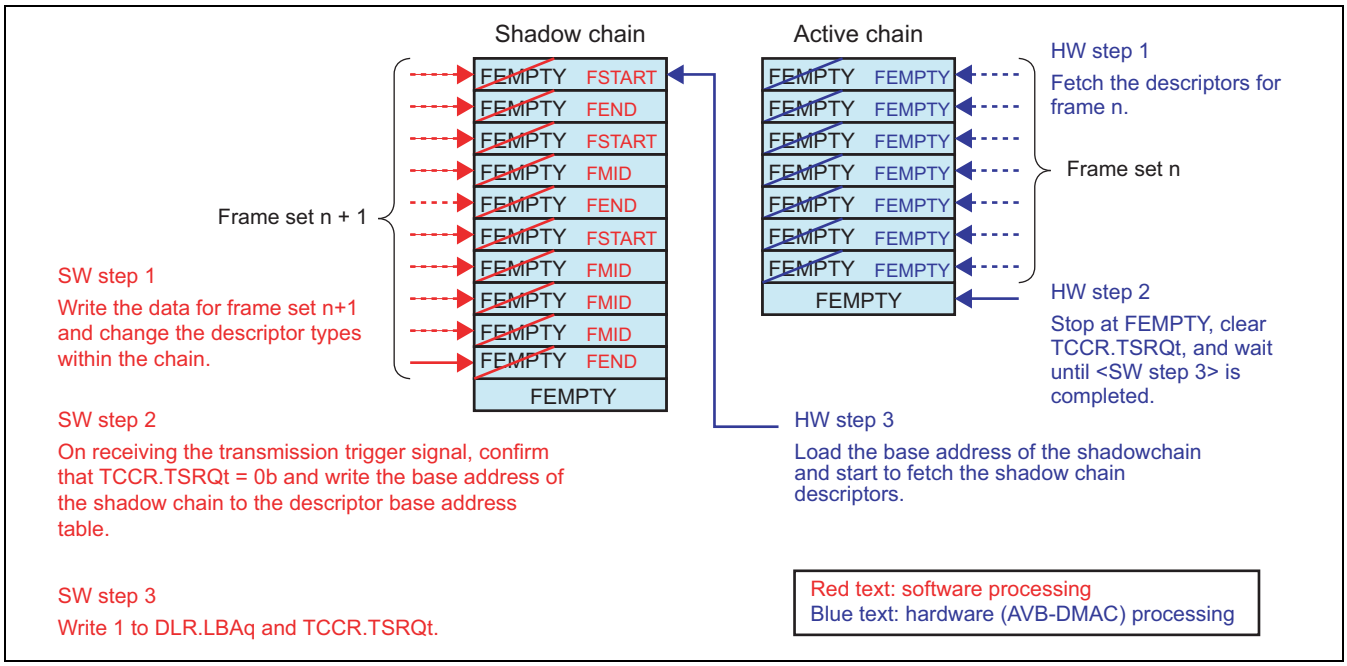

Figure 33A.37 SW and AVB-DMAC Operations for Frame Set Transmission Using the Shadow Descriptor Chain

33A.3.5.4 Time Stamping in Transmission

Transmission time stamps are important in satisfying the requirements for timing and synchronization of the IEEE 802.1AS standard. Reference to this information can also be useful to other applications and in testing. The AVB-DMAC supports the storage of time stamps for transmitted frames. The time-stamp values are based on the gPTP timer and are captured at the same time as sending of the Start of Frame Delimiter (SFD) for transmitted frames.

When the time stamp storage request field (DESCR.TSR) is set to 1, selecting storage of a time stamp, the tag number defined in the tag field (DESCR.TAG) of the last descriptor (FEND or FSINGLE) for the frame being transmitted is stored with the time stamp. This eases identification and association. The time-stamp FIFO is accessible at any time.

Figure 33A.38 shows the mechanism supporting transmission time stamping.

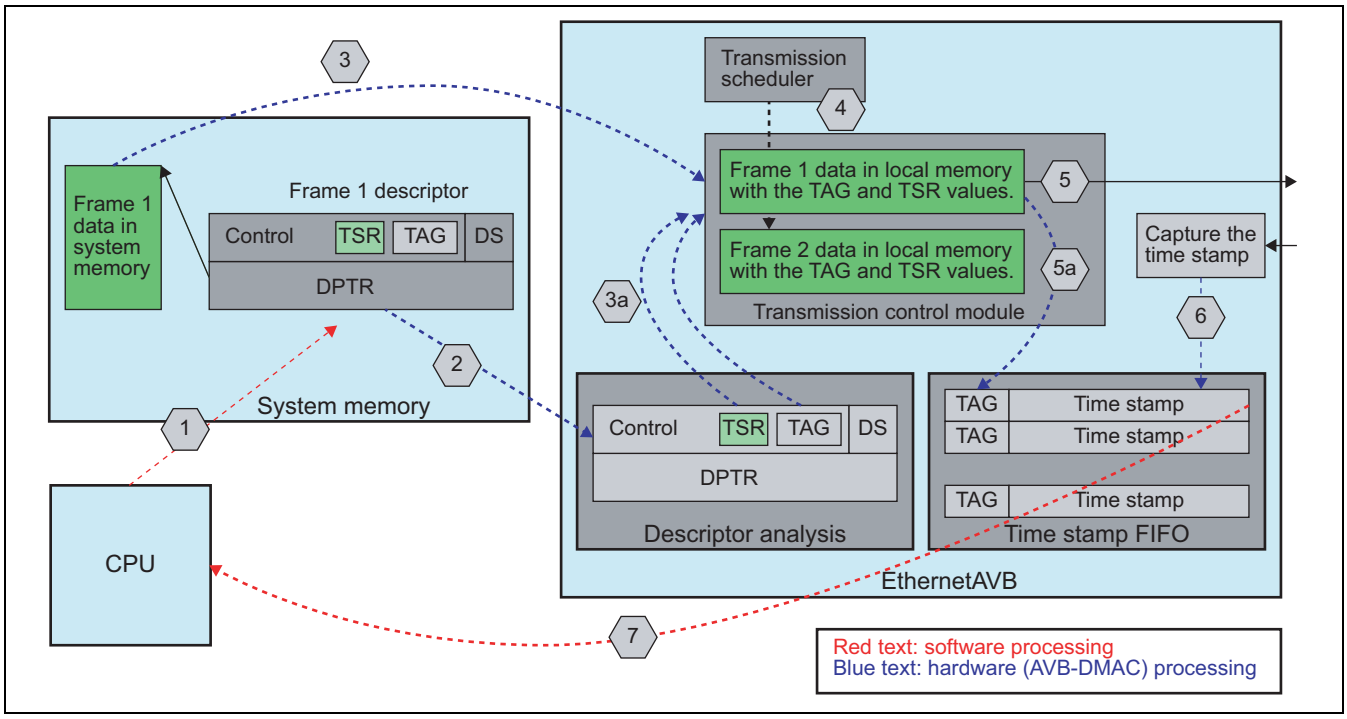

Figure 33A.38 Mechanism to Support Transmission Time Stamps

The method of using this function is described below:

1. Secure space in the URAM for the frame requiring time stamping.
   Write the tag number of the frame to the frame tag field (DESCR.TAG) and set the time stamp storage request field (DESCR.TSR) to 1.
2. The AVB-DMAC fetches and analyzes the descriptor. The time stamp storage request field (DESCR.TSR) is 1, so it recognizes that transmitting this frame also requires storage of the time stamp.
3. The AVB-DMAC fetches the data for frame 1 and temporarily stores the frame in internal memory for scheduling.
   3a: The frame tag field (DESCR.TAG) and time stamp storage request field (DESCR.TSR) are stored with the fetched data.)
4. Under the control of priority settings according to credit-based shaping (CBS) or another scheme, the transmission scheduler decides it is time to transmit frame 1.
5. Transmission of frame 1 starts.
   5a: Frame 1's tag is stored in the time-stamp FIFO.
6. The gPTP time stamp is captured at the start of frame delimiter (SFD) for transmission and stored with the tag in the time-stamp FIFO when the frame is completely transmitted. An interrupt is generated to indicate existence of new timestamp information. For this to happen, the descriptor interrupt control register (DIC) must be set beforehand.
7. The entry can now be read from the time-stamp FIFO.

Use the time-stamp FIFO for the timing and synchronization of frames with IEEE 802.1AS compliance.

Time stamping can also be used with other frames, but take care not to allow the time-stamp FIFO to overflow. When the FIFO is full, further time stamps supplied to it are lost.

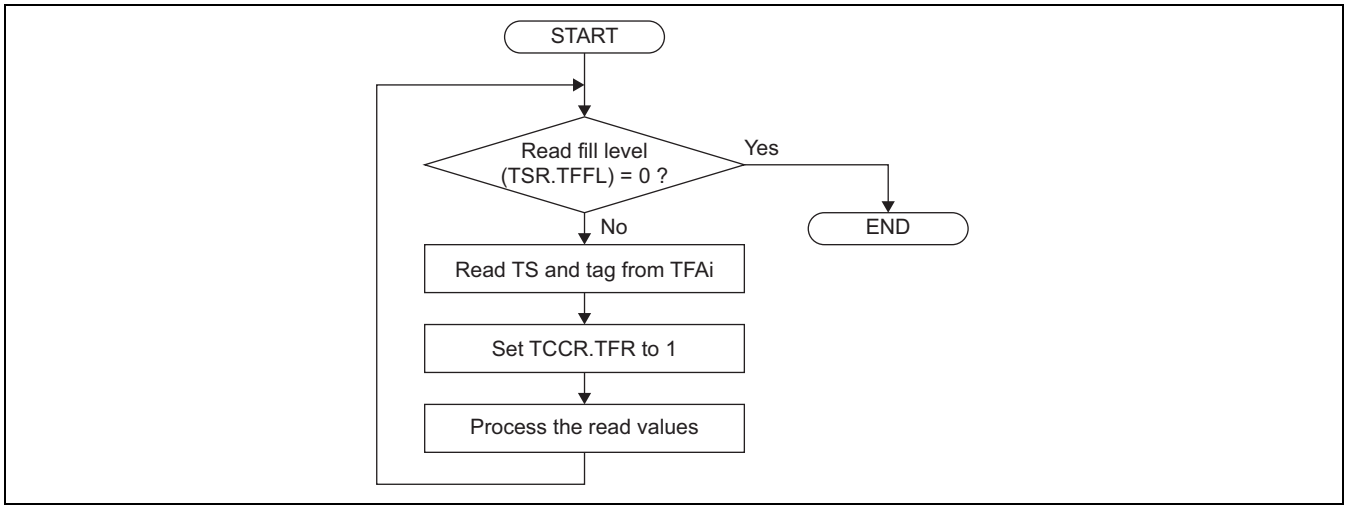

Figure 33A.39 Flow of Transmission Time Stamping

33A.3.5.5 Ending Transmission

Figure 33A.40 shows the procedure for ending transmission.

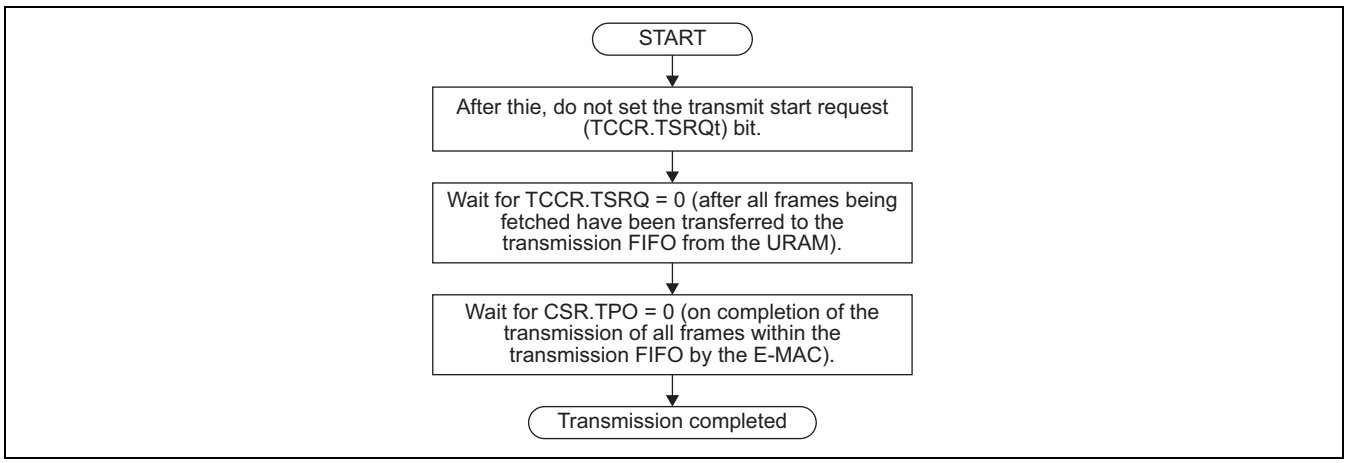

Figure 33A.40 Procedures for Ending Transmission

33A.3.6 CBS (Credit-Based Shaping)

In AVB transmission mode (i.e. when the transmit queue priority field in the transmit configuration register (TGC.TQP) is B'01 or B'11), transmission queues Q3 and Q2 are respectively assigned to class A and class B stream traffic and the CBS (Credit Based Shaping) algorithm is used to select the transmission queues in order to satisfy the Forwarding and Queuing for Time Sensitive Streams (FQTSS) specification (see section 8.6.8 or section 34 in IEEE 802.1Q).

The CBS algorithm is based on the concept of transmission credit for each queue. Credit can be thought of as the degree to which a queue has the “right” to transmit at a given time. Actually, in AVB transmission mode as specified in IEEE 802.1Q, queues that are subject to the CBS algorithm are able to transmit when the following conditions are met.

At least one frame is stored in the queue.

The credit for the queue is 0 or a positive value.

The credit for a transmission queue is incremented while one or more frames from the queue are present in the transmission FIFO but transmission of these frames is not proceeding. This state is indicated by the transmission process status bit for queue t in the AVB-DMAC status register (CSR.TPOt). The credit is decremented while transmission of a frame from the queue is in progress. This mechanism is used to control transmission so that the transmission of frames from the queues for each of the traffic classes does not exceed the specified maximum bandwidths.

IEEE 802.1Q defines the following parameters for queues under the control of the CBS algorithm.

portTransmitRate: Maximum transmission data rate of an external port. The E-MAC determines this parameter.

bandwidthFraction: Maximum fraction of portTransmitRate that can be used for a queue.

idleSlope: Rate of change of credit for a queue when transmission of frames from the queue is not proceeding so the credit value (in bits per second) is increasing. idleSlope is also equal to the maximum fraction of the total bandwidth (portTransmitRate) that is available to the given queue under a specified condition (frames from the queue can be placed in a continuous stream. See Annex L of IEEE 802.Q.
idleSlope = bandwidthFraction × portTransmitRate

sendSlope: Rate of change of credit for a queue while transmission of a frame from the queue is in progress so the credit value is decreasing.
The value of sendSlope is defined as follows:
sendSlope = idleSlope – portTransmitRate

Furthermore, the values below are used to define individual traffic classes (or queues for the classes) under control of the algorithm. See Annex L of IEEE 802.Q.

maxFrameSize: Maximum size of frames (in bits) of the corresponding traffic class that can be transmitted from a port

maxInterferenceSize: Maximum burst size (in bits) by which delays for the corresponding traffic class can be allowed

hiCredit: Maximum credit value (positive number). Can be calculated by using the following equation: hiCredit = maxInterferenceSize × (idleSlope / portTransmitRate)

loCredit: Minimum credit value (negative number). Can be calculated by using the following equation:
loCredit = maxFrameSize × (sendSlope / portTransmitRate)

Figure 33A.41 shows how the CBS algorithm works and the meaning of the above parameters.

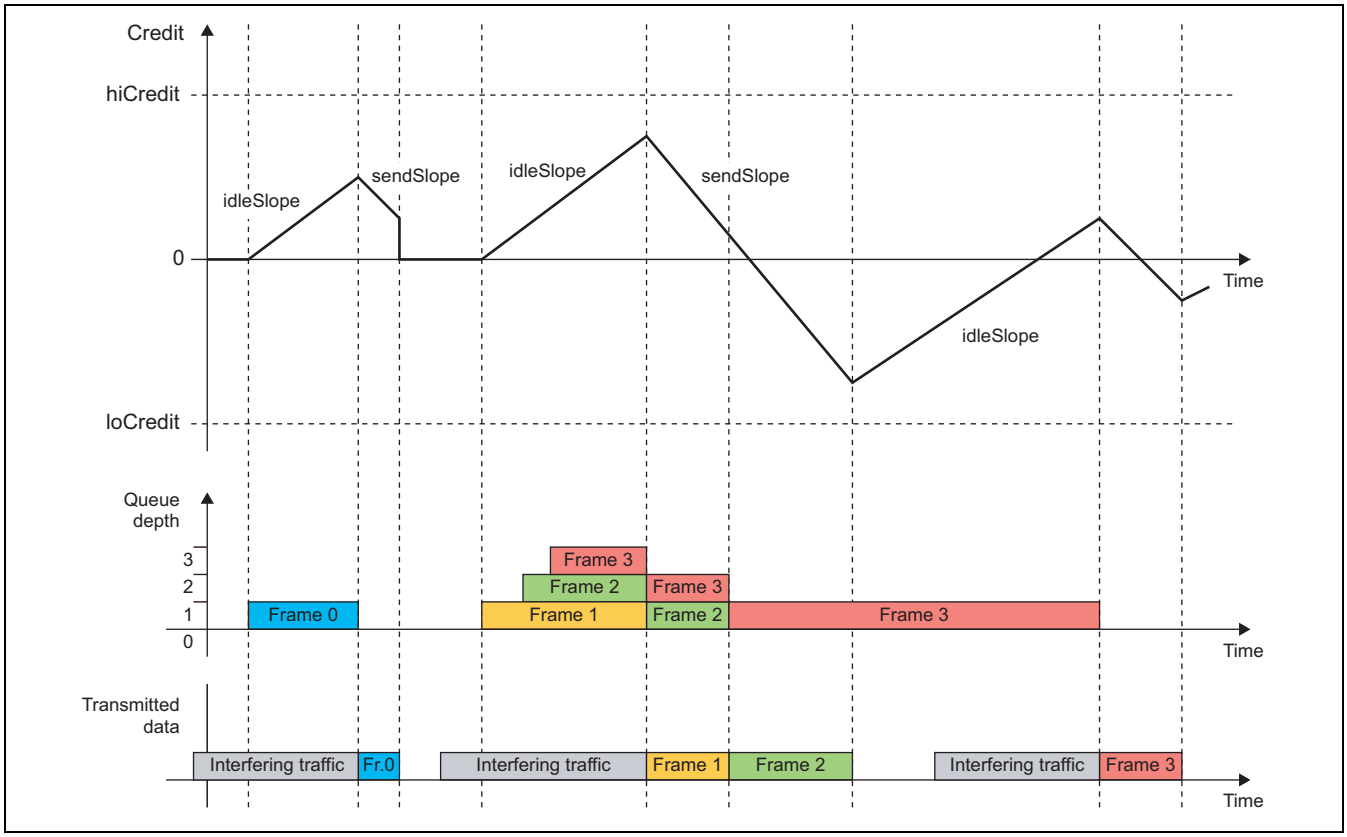

Figure 33A.41 CBS (Credit-Based Shaping) Operation

Figure 33A.42 shows the implementation of CBS in the AVB-DMAC.

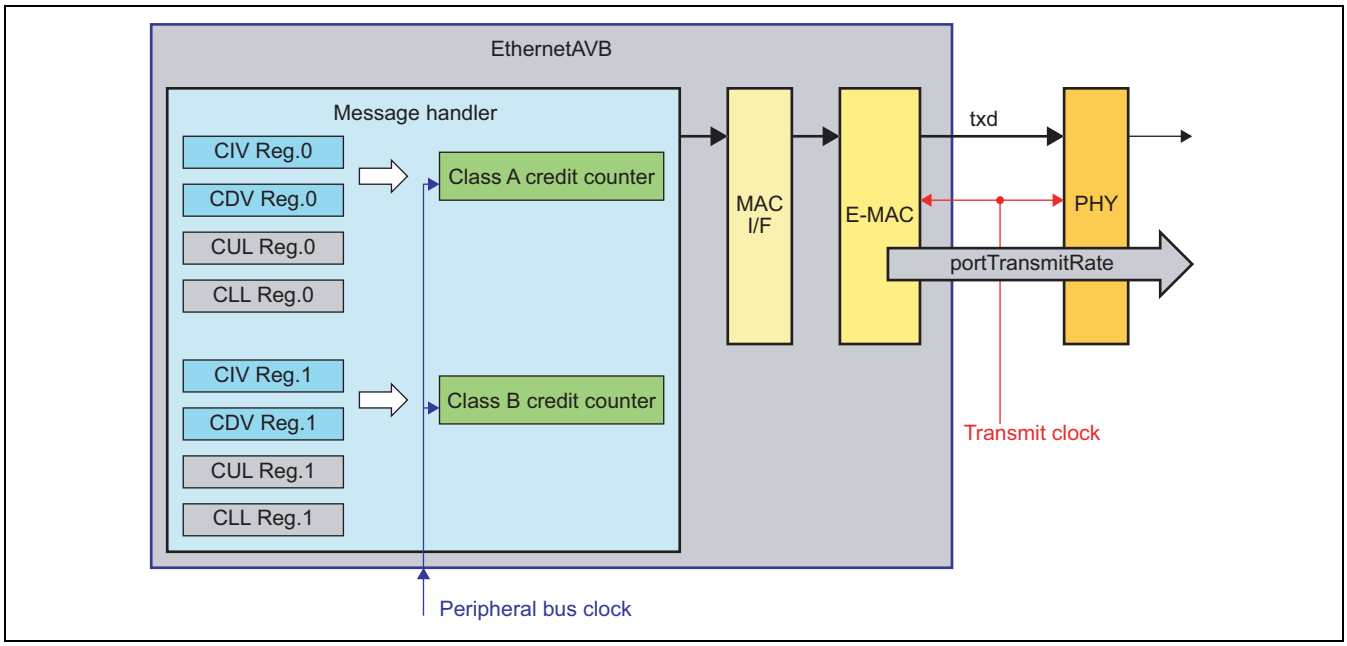

Figure 33A.42 CBS (Credit-Based Shaping) Operation in the AVB-DMAC

The above implementation is based on “credit counters” for the respective traffic classes (SR class A and class B). The following parameters apply for these classes.

CBS increment value (CIV): Signed positive number
The credit is incremented by this amount every high-speed peripheral bus clock cycle while a frame from the queue is pending but transmission has not started (idleSlope).

CBS decrement value (CDV): Signed negative number
The credit is decremented by this amount every high-speed peripheral bus clock cycle while transmission of a frame from the queue is proceeding (sendSlope).

The CBS increment value (CIV) and CBS decrement value (CDV) are defined as follows.

CIV = idleSlope × Mfactor
CDV = sendSlope × Mfactor

Mfactor is a multiplier factor to ensure accuracy for CIV and CDV. CIV and CDV are calculated by using the following equations.

CIV = (portTransmitRate/HPϕ) × bwFraction × Mfactor
CDV = (portTransmitRate/HPϕ) × (bwFraction – 1) × Mfactor

HPϕ is the frequency of the high-speed peripheral bus clock. The credit counters are driven by the high-speed peripheral bus clock, so calculating the slope parameters for CBS requires (1/HPϕ).

Use software to prepare Mfactor for the CBS parameters. All queues for the same class must have the same Mfactor for all CBS parameters. Mfactor for a specified class c can be changed during operation, unless transmission is pending for that class (i.e. the transmit process status bit in the AVB-DMAC status register (CSR.TPOt) = 0). At that time, the credit counter values for class A and class B are 0. Note that the credit value will not match a new incrementation or decrementation parameter if Mfactor is changed while the credit counter value is non-zero. Mfactor is not present in the AVB-DMAC registers.

Set the CIV and CDV parameters in the CBS increment value registers (CIVRc) and the CBS decrement value registers (CDVRc). These are treated as dynamic settings since they should be updated when streams are registered and erased in accord with IEEE 802.1Qat.

The AVB-DMAC also has CBS upper limit registers (CULc) (the upper limit registers for classes A and B) and CBS lower limit registers (CLLc) (the lower limit registers for classes A and B). Set Mfactor to match the credit value and set the upper limit (hiCredit) and the lower limit (loCredit) for each class as defined above.

CUL = hiCredit × Mfactor = maxInterferenceSize × bwFraction × Mfactor
CLL = loCredit × Mfactor = maxFrameSize × (bwFraction – 1) × Mfactor

Example:

Assume that portTransmitRate = 100 Mbps, HPϕ = 130 MHz and bwFraction = 3%. Then idleSlope and sendSlope represented as one bit vs. cycles of the high-speed peripheral bus clock are as follows.

idleSlope = (portTransmitRate/HPϕ) × bwFraction = 100/130 (Mbps/MHz) × 3% = 0.023 bit per high-speed peripheral bus clock cycle
sendSlope = idleSlope – (portTransmitRate / HPϕ) = –0.746 bits per high-speed peripheral bus clock cycle
Let Mfactor be 100, then CIV and CDV parameters are determined as follows.

CIV = idleSlope × Mfactor = 2.3
CDV = sendSlope × Mfactor = –74.6

33A.3.6.1 Restrictions on CIV, CDV and Mfactor

The maximum value (the minimum value for negative numbers) up to which the credit counter will not overflow determines the maximum values of CIV and CDV that can be set in the CBS registers. This maximum credit value is equivalent to the worst case of the hiCredit value, and the maximum values for class A and class B are calculated as follows.

<Conditions>

- Class A maximum value (hiCredit_max_classA)
  classA bwFraction ≅ 100%
  Maintaining the proper relations in the transmission priority order requires waiting for a period equivalent to the maximum frame size.
  hiCredit_max_classA ≅ maxInterferenceSize for class A = Interference due to one max. sized frame = header + max. size payload + CRC (2000 bytes) + preamble (8 bytes) + IFG (12 bytes) + processing_delay (≅ 80 bytes) ≅ 2100 bytes
- Class B maximum value (hiCredit_max_classB)
  classB bwFraction ≅ 100%
  Maintaining the proper relations in the transmission priority order requires waiting for a period equivalent to the maximum size of frames in the class A transmission queue and other transmission queues.
  hiCredit_max_classB ≅ maxInterferenceSize for class B = Interference due to two max-size frames = 2 × hiCredit_max_classA ≅ 4200 bytes

hiCredit_max_classA = 16800

hiCredit_max_classB = 33600

The maximum values that can be selected with Mfactor for the 32-bit signed counter without overflow are:

Mfactor_max_classA = 2^{31}–1 / hiCredit_max_classA ≅ 127826 and
Mfactor_max_classB = 2^{31}–1 / hiCredit_max_classB ≅ 63913.

A high degree of accuracy can be achieved even with a low bandwidth. In class B, bandwidthFraction = 0.05% and the bandwidth error < 0.1%.

The maximum value of CIV is calculated from the following equation.

CIV = idleSlope x Mfactor = (portTransmitRate / HPϕ) × bandwidthFraction × Mfactor

When Mfactor is the maximum value and bandwidthFraction is the maximum value (up to 100%):

CIV_max_classA = (portTransmitRate / HPϕ) × Mfactor_max_classA and
CIV_max_classB = (portTransmitRate / HPϕ) × Mfactor_max_classB.

The maximum values when portTransmitRate = 1000 Mbps and HPϕ = 130 MHz are as follows:

CIV_max_classA ≅ 983277

CIV_max_classB ≅ 491638

These values in the table are the limits of CIV up to which the 32-bit credit counter will not overflow. The CIV parameters are implemented as 16 bits + a sign bit, so a further limit of CIV ≤ 65535 applies to both class A and class B.

33A.3.6.2 Credit Incrementation during Inter-Frame Gaps (IFGs)

The inter-frame gap (IFG) after a frame is transmitted is not treated as part of frame transmission by the CBS credit counter. During an IFG, the credit is incremented for all SR queues that have pending frames or negative credit. Figure 33A.43 illustrates credit operations during IFGs.

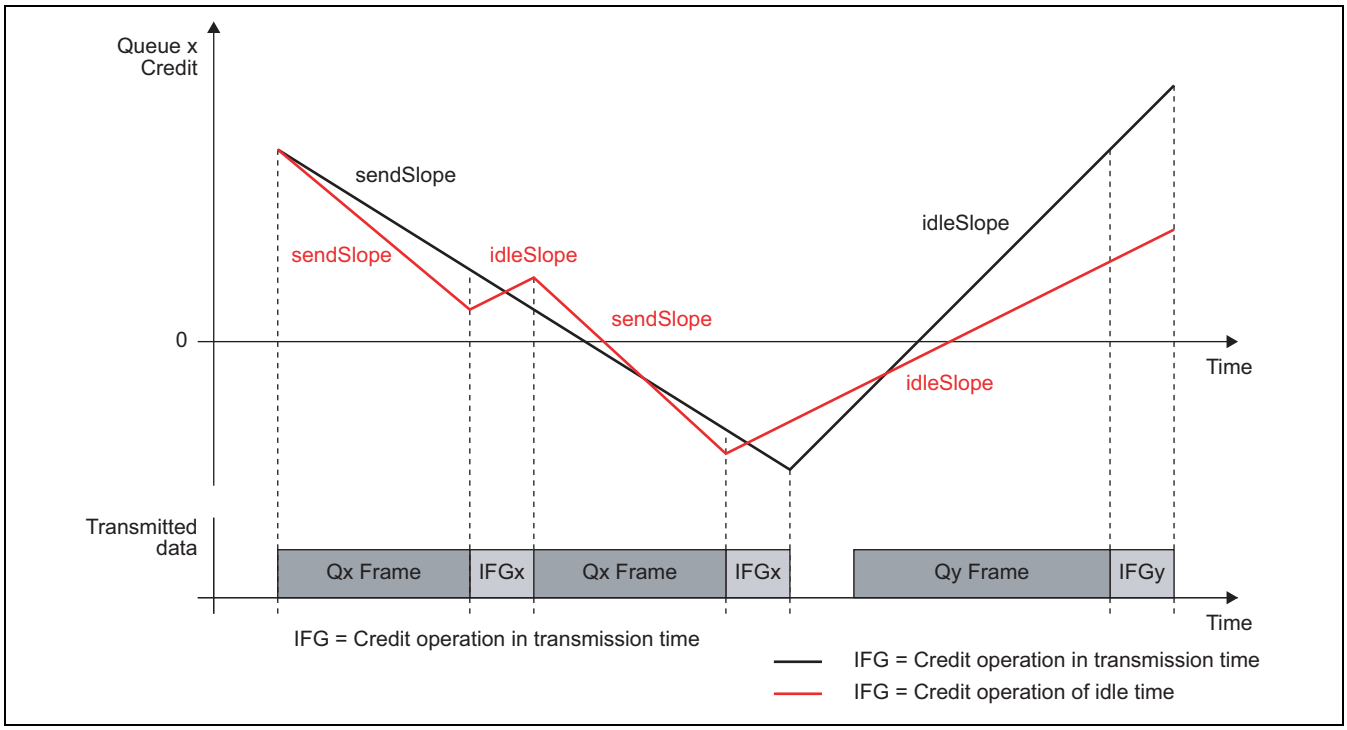

Figure 33A.43 Credit Operations during IFGs

Accordingly, the IFG need not be included in calculation of the bandwidth requirements for the specified SR class when deciding the idleSlope, sendSlope, and CIV and CDV parameters. However, IFG must also be included in the calculation in order to confirm that the total bandwidth allocated to all SR classes does not exceed 100% of portTransmitRate. This is described in *Section 35.2.2.8.4* of *IEEE 802.1Q*.

33A.3.6.3 Example

The case of a class A 48-kHz stereo audio stream among Ethernet frames is described as an example.

After every class A measurement interval (125 µs), 80 octets consisting of two sets of six 32-bit samples plus a 32-octet header are stored as audio data within a frame. The IEEE 802.3 also imposes a 42-octet media-specific framing overhead (an 8-octet preamble, 14-octet IEEE 802.3 header, 4-octet IEEE 802.1Q priority/VID Tag, 4-octet CRC, and 12-octet IFG) are also added. Accordingly, the total frame size is 80 + 42 = 122, and one such frame is transmitted after every class measurement interval.

This represents a total bandwidth of about 7.8 Mbits per second (122 octets × 8 bits per octet × 8000 frames per second) for this class. If the E-MAC is assumed to run at 1 Gbps (portTransmitRate), this is equivalent to the allocation of about 0.78% of the total bandwidth to each class A queue. If other traffic classes are to share the total transmission bandwidth, checking that this 0.78% allocation does not lead to the total allocation of bandwidth being greater than 100% of portTransmitRate is required.

To obtain the CIV and CDV parameters for a given class, the IFG must not be taken into account in calculation of the frame size must not include the IFG. For this case, therefore, we obtain an 80-bit payload + 30-bit overhead = 110-octet measurement interval for the class → the total bandwidth for the class = 7.04 Mbps = 0.704% of portTransmitRate.

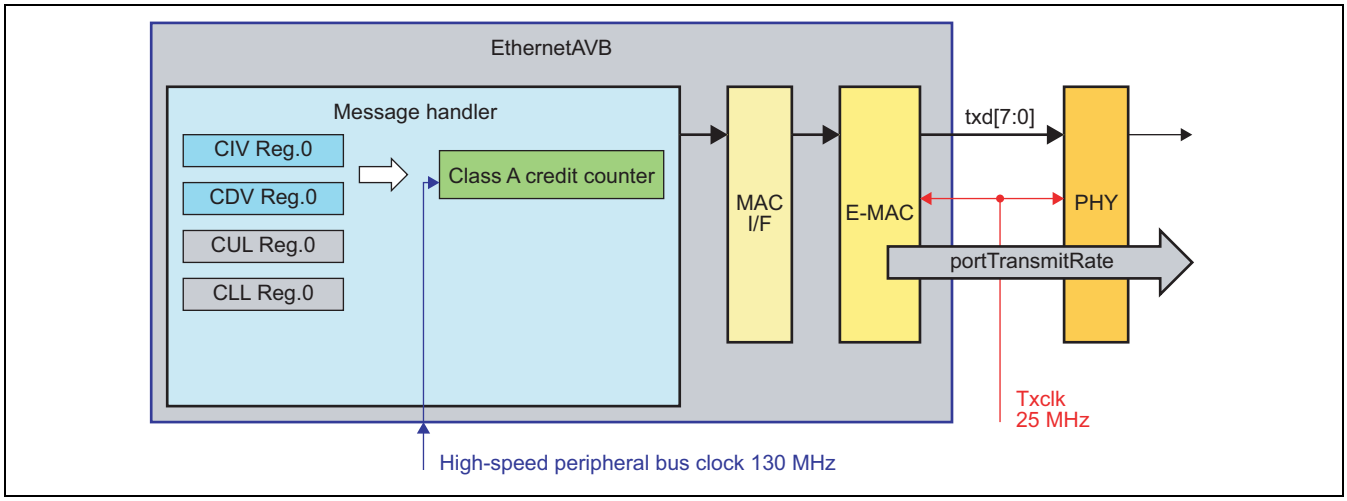

Figure 33A.44 Example of CBS Settings

Given that:

- the E-MAC runs at 100 Mbps, so portTransmitRate = 100 Mbps and
- high-speed peripheral bus clock (operating clock for the credit counter) frequency = 130 MHz, securing a bandwidth of 7.04 Mbits/sec for class A requires configuring the CBS parameters as follows.
  bandwidthFraction = 0.704%
  idleSlope = (portTransmitRate / HPϕ) × bandwidthFraction ≅ 0.0176 bits per high-speed peripheral bus clock cycle
  sendSlope = idleSlope – (portTransmitRate / HPϕ) ≅ –2.4824 bits per high-speed peripheral bus clock cycle

When Mfactor = 100000, the parameters are as follows.

- CIV = idleSlope × Mfactor = 1760 bits per high-speed peripheral bus clock cycle
- CDV = sendSlope × Mfactor = 248240 bits per high-speed peripheral bus clock cycle

These are the final values for setting in the CIVR1 and CDVR1 registers.

33A.3.7 Time Synchronization

33A.3.7.1 gPTP Timer

An 84-bit timer is provided to support the gPTP function. Figure 33A.45 shows the definitions of bits for the timer and in related registers.

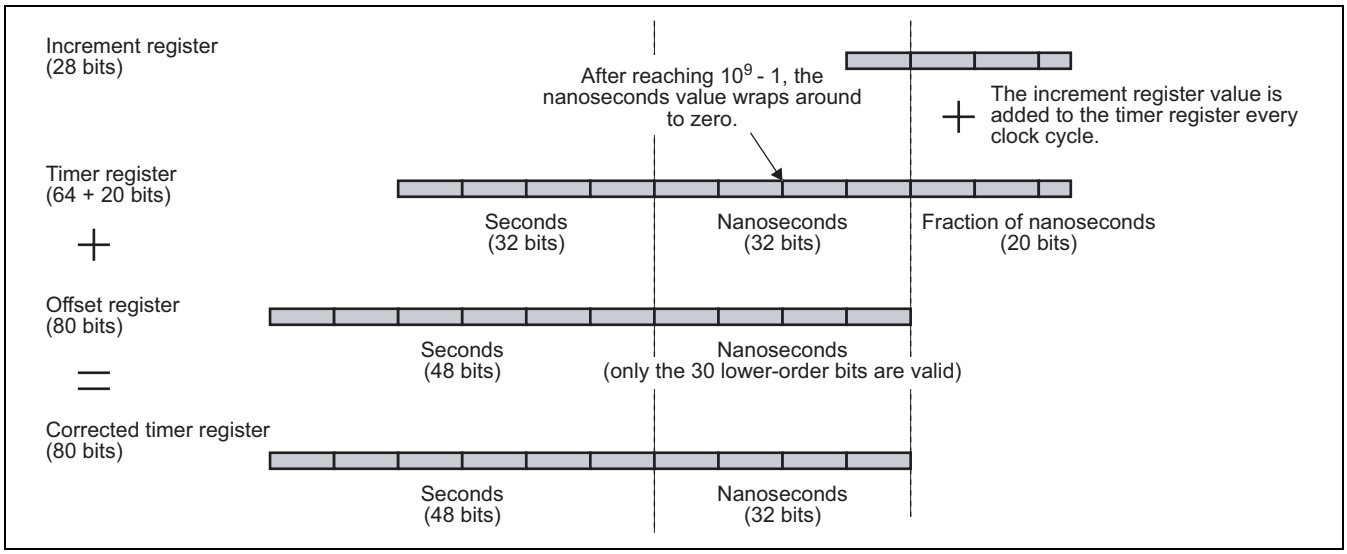

Figure 33A.45 Definitions of gPTP Timer Bits and Related Bits

The higher-order 32 bits indicate seconds. For the next 32 bits, counting by one corresponds to the passage of 1 ns. The lower-order 20 bits are a fractional value (less than 1 ns). Software can only read the 32 higher-order bits, indicating seconds, and the subsequent 32-bits, indicating nanoseconds. The 20 lower-order 20 bits, representing less than 1 ns, are not readable. They are only used within the AVB-DMAC to maintain accuracy in time measurement.

The timer can be reset by setting the timer control request bits in the gPTP configuration control register (GCCR.TCR[1:0]) to B'01. These bits are set to B'00 on completion of normal resetting of the timer.

After the timer starts, the value in the gPTP timer increment register (GTI.TIV) is added to the value of the gPTP timer every clock cycle.

Before setting a value in the gPTP timer increment register (GTI.TIV), set the timer increment value setting request bit in the gPTP configuration control register (GCCR.LTI). If this bit is not set to 1, new values that are written will not be reflected in the register. This bit returns to 0 after the setting is completed.

An offset to the gPTP timer is also available. If this is required, set the value in the gPTP timer offset register (GTO.TOV). Before setting a value in this register, set the timer offset value setting request bit in the gPTP configuration control register (GCCR.LTO). If this bit is not set to 1, new values that are written will not be reflected in the register. This bit returns to 0 after the setting is completed. When adding an offset, take care that it does not exceed 80 bits.

The value of the gPTP timer can be read from the gPTP timer capture register (GCTi.CTV). Set the timer capture source select bits in the gPTP configuration control register (TCCR.TCSS) to select the timer value for capture as the value of the gPTP timer, the corrected value of the gPTP timer (value with the offset added), or the AVTP presentation time. Setting the timer control request bits in the gPTP configuration control register (GCCR.TCR[1:0]) to B'11 initiates the capture. Once normal capture of the timer is complete, the value of the timer control request bits in the gPTP configuration control register (GCCR.TCR[1:0]) returns to B'00.

The timer for gPTP operates as a free-running timer but can be synchronized with the Grandmaster clock.

33A.3.7.2 Free-Running Operation

The IEEE 802.1 AS standard for timing and synchronization does not prescribe the physical adjustment of local clocks to the Grandmaster clock. To avoid negative effects from the correction procedure, we recommend the use of a free-running timer.

As a free-running timer, the timer counts the local time in seconds or nanoseconds. The gPTP timer increment register (GTI.TIV) is set to 1 ns (the setting value = H'0010 0000) and the gPTP timer offset register (GTOi.TOV) is set to 0. The ratio information captured at the time of the gPTP delay measurement and synchronization procedures is used to correct the frequency ratio to that of the Grandmaster clock. The Grandmaster clock can be calculated from the local clock by using the information collected during the gPTP measurement and synchronization procedures.

33A.3.7.3 Synchronization with the Grandmaster Clock

In situations requiring physical synchronization of the local clock with the Grandmaster clock, the fractional nanoseconds value (the 20 lower-order bits of the gPTP timer) is used to make the adjustment. Specifically, the increment value is finely adjusted to correct for deviations of the clock frequency from that of the Grandmaster clock.

Use the timer offset value (in the gPTP timer offset registers, GTOi.TOV) to correct for offsets from the theoretical value (at start-up, etc.). The sum of the timer value and the offset register is the “corrected timer” value.

Note that for the nanoseconds part of the Offset register GTOi.TOV[31:0] should be below 10^9.

The following equation gives a method of calculating the increment (GTI.TIV) from the frequency of the gPTP clock and its deviation from that of the Grandmaster clock. Variable d is the deviation (d = 10^{-6} for 1 ppm).

$$GTI.TIV = round\left(\frac{2^{20}\,GHz}{f_{GPTP}} \times (1 + d)\right)$$

After adjusting for the current deviation of clock frequency, reset the gPTP timer increment register (GTI.TIV).

After calculating the new offset value, reset the gPTP timer offset register (GTOi.TOV).

33A.3.7.4 Continuous AVTP capture

CPU can request a selected timer value by setting bit GCCR.TCR to B'11. GCCR.TCSS determines which of the three values:

- gPTP Timer value,
- Corrected Timer value or
- AVTP Timer value

is captured in GCTi.CTV. GCCR.TCR is set to B'00 after capturing the related timer value. Successful capturing operation can be confirmed by checking GCCR.TCR is B'00.

By setting GCCR.TCR to B'10 continuous AVTP timer value capture is activated. In this mode CPU has always access to current AVTP value by reading GCTi.CTV[31:0].

Flow to enter continuous AVTP capture mode:

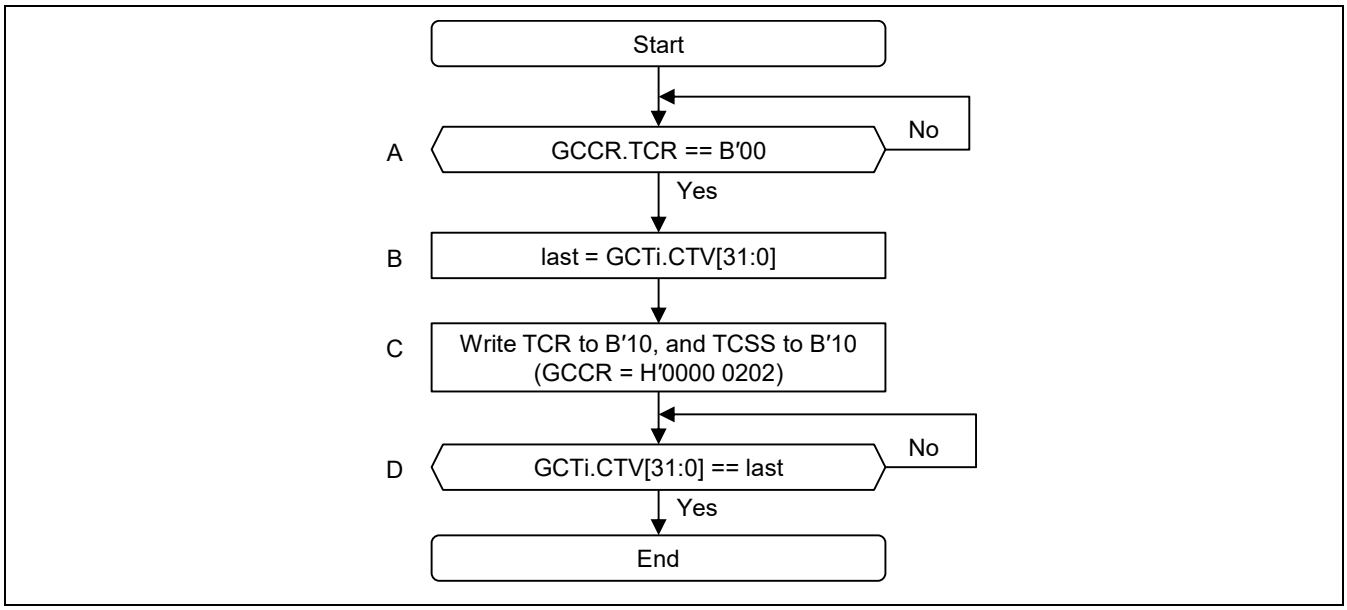

Figure 33A.46 SW flow entering continuous AVTP capture mode

Flow to leave continuous AVTP capture mode:

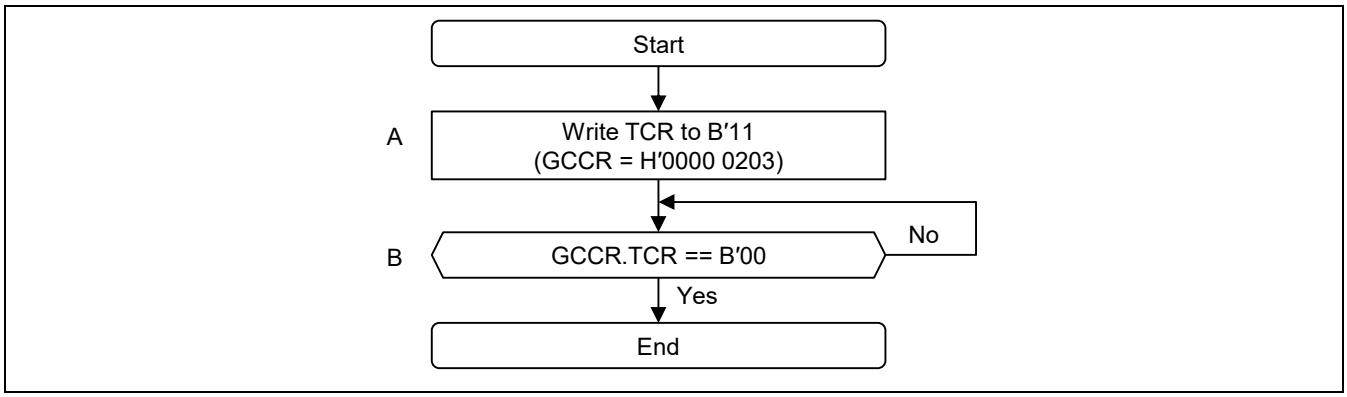

Figure 33A.47 SW flow leaving continuous AVTP capture mode

33A.3.7.5 Support Provided by the gPTP Timer in Transmission and Reception

The timer value described above is used in the time-stamp values captured when start frame delimiters are detected in reception and generated in transmission at PHY interface.

Captured time stamp values for received frames are stored in the corresponding descriptors. Those for transmitted frames are stored with tag information in the time-stamp FIFO. The time stamp values are thus correlated with both transmitted and received frames.

Note that the use of corrected timer values can introduce an error due to the offset correction in the gPTP synchronization procedure.

Due to asynchronous interface between the SFD notification and the timer modules, errors must also be taken into account.

33A.3.8 Support for IEEE 1722

For IEEE 1722, the following two functions are supported.

- Output and capture of values in the IEEE 1722 AVTP (Audio/Video Transport Protocol) presentation time format
- Comparison of IEEE 1722 AVTP presentation time stamps

The 32-bit AVTP time stamp field of IEEE 1722 frames holds the AVTP presentation time when the AVTP time-stamp enable bit in the frame is 1. The AVTP time stamp field is generated from the gPTP timer and is given as seconds (gPTP_seconds) and nanoseconds (gPTP_nanoseconds) according to the following equation.

AVTP time stamp = (gPTP_seconds $\times 10^9$ + gPTP_nanoseconds) modulo 2^{32}

The AVTP presentation time can be read from the gPTP timer capture register (GCTi.CTV). Set the timer capture source select bits in the gPTP configuration control register (GCCR.TCSS) to select the timer value for capture as the AVTP presentation time. Setting the timer control request bits in the gPTP configuration control register (GCCR.TCR[1:0]) to B'11 initiates the capture. The value is obtained by adding the maximum transit time defined in the gPTP maximum transit time register (GMTT.MTTV) to the corrected timer value. The AVTP presentation time wraps around approximately every four seconds.

Note: The AVTP presentation time captured in GCTi.CTV is only valid when the corrected timer value is in synchronization with the Grandmaster clock. That is, the timer increment and timer offset values for the corrected timer value must be adjusted during the synchronization procedure so that the corrected gPTP clock is physically adjusted to match the time kept by the Grandmaster clock.

33A.3.8.1 AVTP capture (HW)

EthernetAVB provides 1 units to capture AVTP based on external events.

Table 33A.16 lists the assignment of the EthernetAVB capture unit.

Table 33A.16 Capture unit assignment

Unit	signal	from	Function
avb_pt_capture[0]	AVB_AVTP_CAPTURE	External	External input

To allow proper detection of the edges of avb_pt_capture[0] signal, a pulse longer than 2 peripheral bus clock cycles should be provided on this input to trigger AVTP capture. Also SW should limit frequency of external capturing signal; period should be at least (6 peripheral bus clock periods + 3 gPTP periods).

There are two variants of capture units in EthernetAVB:

- First one captures AVTP presentation time (including max transit time) and have overflow flagging.
- Second one captures AVTP timer value (without max transit timing) and have prescaler.

The AVTP capture units provides always the first captured value until SW has acknowledged reading of this value.

(1) AVTP presentation time capture unit

EthernetAVB provides one capture unit of this functionality.

When a rising edge is applied to avb_pt_capture[0], AVTP presentation time is captured to GCPT.CPTV and the interrupt flag GIS.PTCF is set to 1.

The captured value includes the configured max transit time value.

Capture of a new AVTP presentation time is suppressed until CPU acknowledges processing of the captured value by setting GIS.PTCF to 0. GIS.PTOF informs about one or more lost capture events.

33A.3.8.2 AVTP compare

EthernetAVB provides 8 independent AVTP compare units. Each unit is able to handle single shot comparison as well as periodic comparison. GSR.PCMi informs about the current mode of unit i. To 4 units (0 to 3) the single shot compare value can provided via AVTP-FIFO to relax timing requirements to application SW.

When the AVTP Presentation Time value has reached or exceeded the configured comparison value the interrupt flag GIS.PTMFi is set to 1. And Comparison unit 0, a pulse of one or four High speed Peripheral clock cycle is applied to AVB_AVTP_MATCH.

The configured max transit time value is not taken in count when comparing.

SW should ensure that configured comparison value is well in future to take into account SW inaccuracy.

SW should ensure that comparison value is not too far in future (more than 2 seconds) with respect to current AVTP timer value to guarantee comparison functionality.

When writing to GCCR, SW can use a 32 bit access if GCCR.TCSS is written to B'11 and all other bits not required for comparison value programming are written to 0.

(1) Single shot compare

An AVTP compare unit used in single shot mode generates exactly one match after CPU programs the comparison value.

CPU should use this flow to program absolute comparison values in single shot mode:

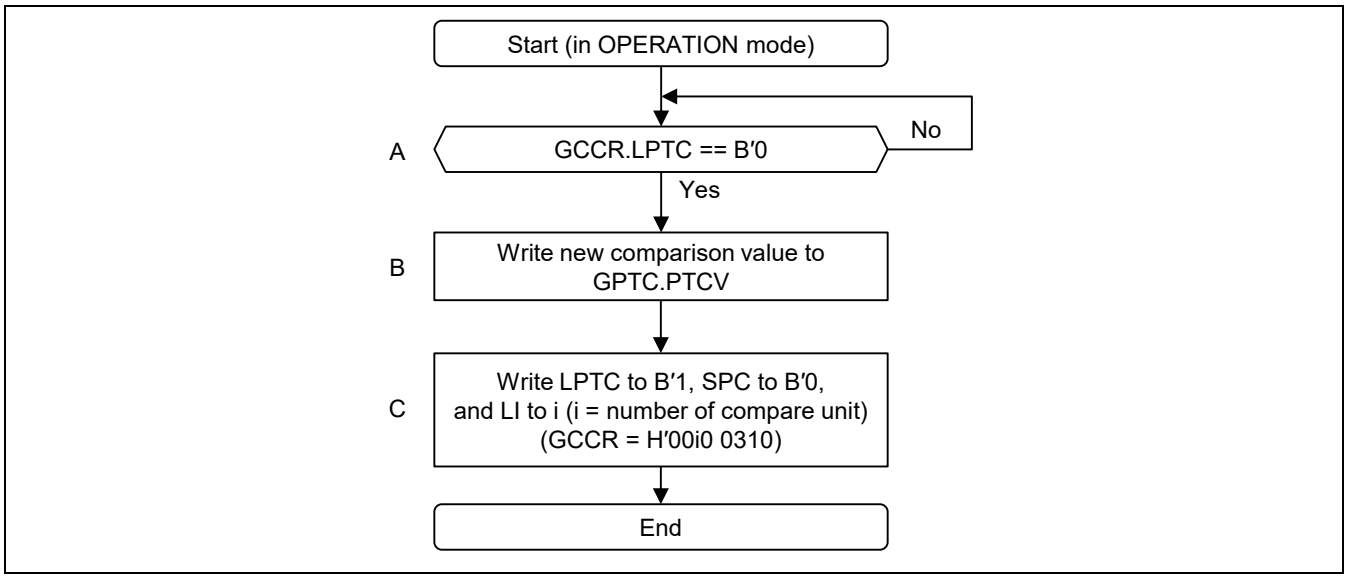

Figure 33A.48 SW flow to program a single shot compare value

(2) Periodic compare

An AVTP compare unit used in periodic compare mode generates matches of configured period until CPU disables periodic mode. Optional it is possible to define the initial phase before repetition starts.

CPU should use this flow to start periodic compare mode or to change period value:

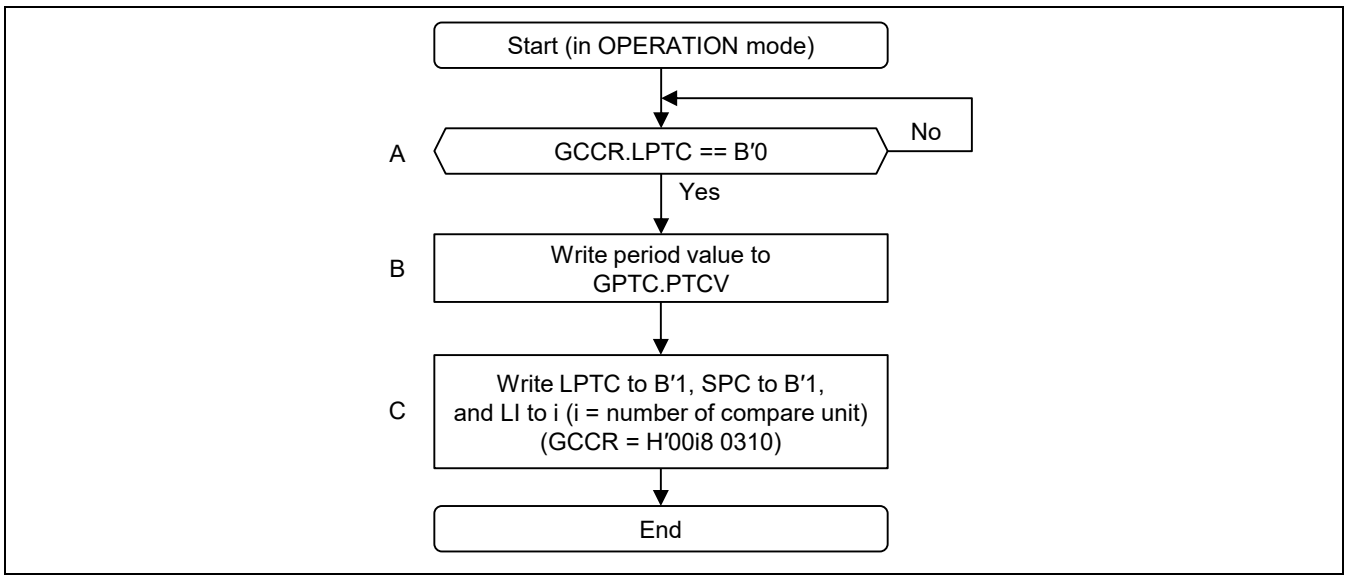

Figure 33A.49 SW flow to program period value (without phase relation)

Some application may require phase relation between periodical match events generated by different units. In this case the next flow can be used to enter periodic compare mode with phase relation. A compare unit will only start a period when there is no pending comparison. If the absolute starting point of all units (box B in flow) is well in future the period of all units start at the same time (e.g. 48 kHz on unit 1 and 96 kHz on unit 2).

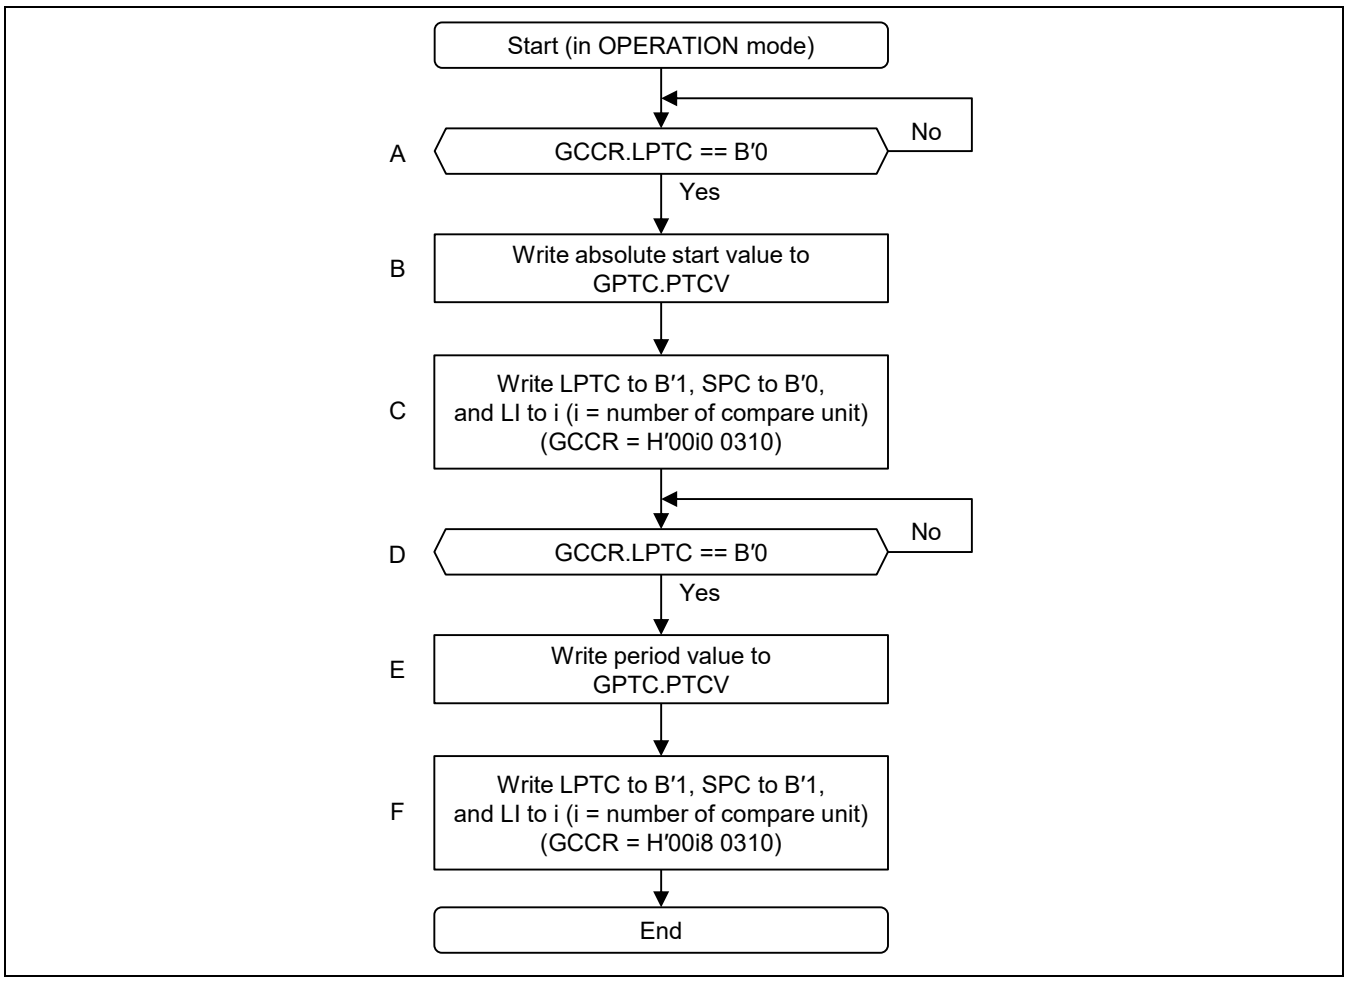

Figure 33A.50 SW flow to program period value (with phase relation)

The periodic mode is left by entering single-shot mode. Do not write new comparison value in GPTC.PTCV for changing mode as shown in flow below, this value will not be used as new comparison value.

CPU should use this flow to leave periodic compare mode:

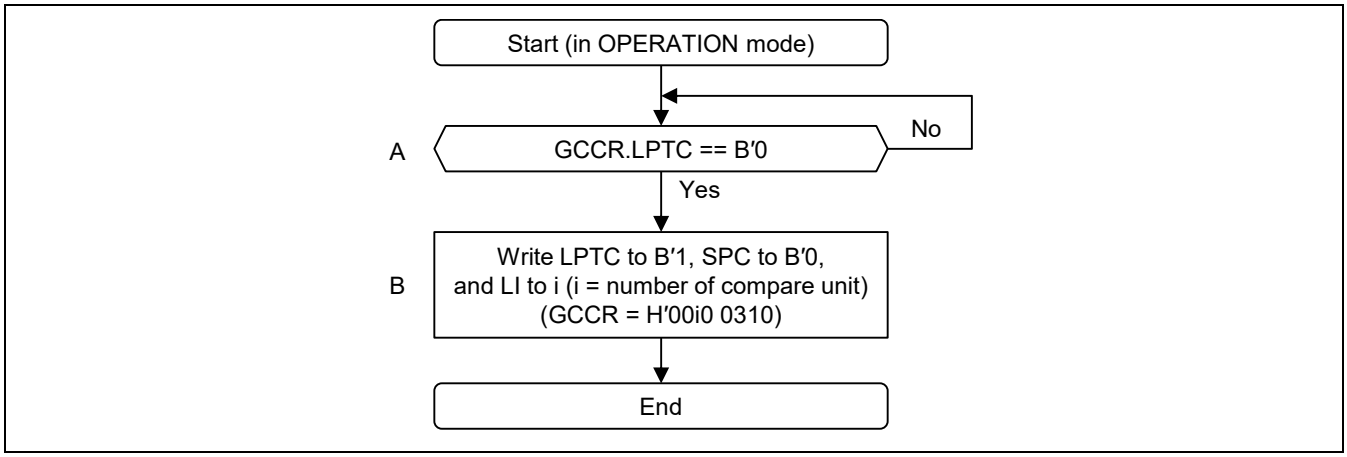

Figure 33A.51 SW flow to end period mode

The last periodical comparison happens after Point B in SW flow. EthernetAVB leaves periodic mode after last periodical comparison happens. This is flagged by GSR.PCMi. Comparison unit can only be reused after GCR.PCMi is 0.

(3) FIFO based single-shot comparison

Some comparison units provide the possibility to use timestamps from a FIFO. To use this possibility CPU writes AVTP timestamp to GPTFi instead of GPTC. By writing to GPTFi the value is added to FIFO, no load is required but CPU needs to check if AVTP-FIFO is able to accept new values.

FIFO usage may reduce CPU load because CPU can program a bunch of timestamps at same time.

When there is no comparison ongoing in AVTP compare unit, the next value from AVTP-FIFO is loaded and comparison starts. If the FIFO is empty no value is loaded and no further match event is generated.

When moving from single-shot comparison to FIFO based single-shot comparison, the 1st FIFO value is immediately loaded independent of an ongoing comparison.

By reading GSR.AFFLi CPU can observe number of pending timestamps.

CPU should use this flow to add timestamps to the AVTP-FIFO of compare unit. If FIFO depth is insufficient, FIFO size should be extended in SW (box E).

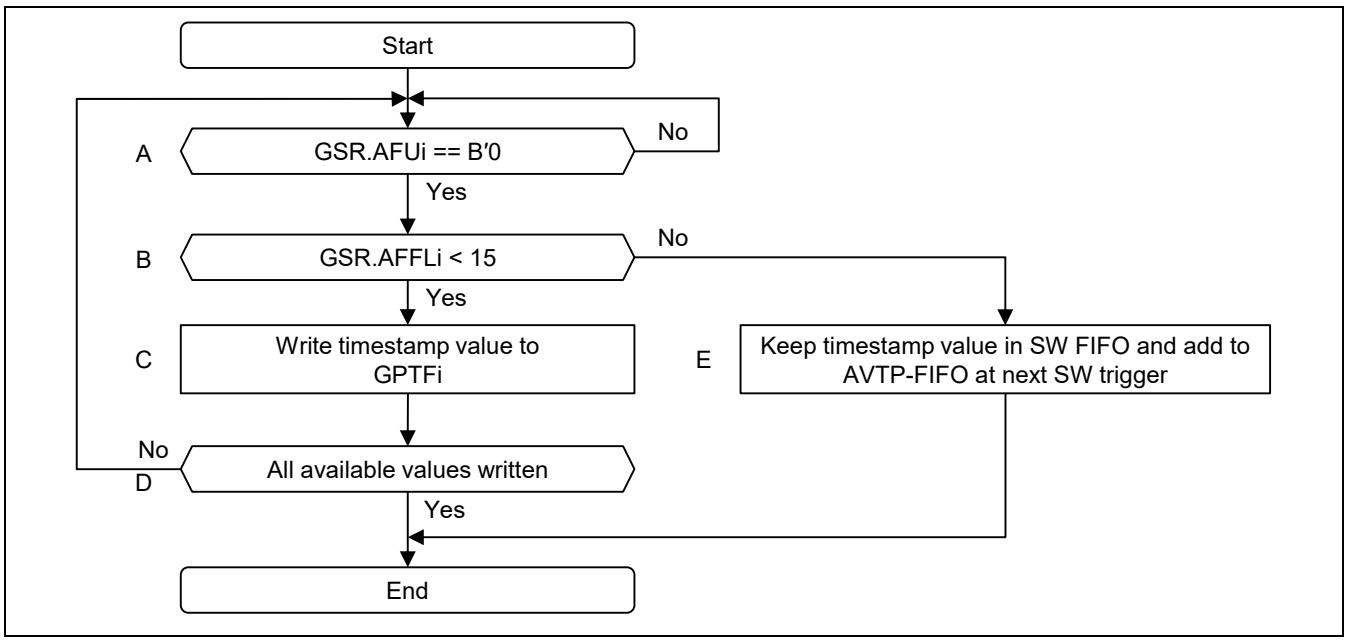

Figure 33A.52 SW flow to add timestamp to AVTP-FIFO

It is recommended to combine box A and B into one access to limit accesses to GSR register.

33A.3.8.3 gPTP timer functionality in CONFIG mode

When CCC.GAC is 1, it is possible to use some gPTP functions in CONFIG mode. Because the frame handling mechanisms are not available in CONFIG mode, usage of gPTP support is restricted. Only basic timer functions of gPTP support can be used:

- gPTP timer is running based on selected clock source (CCC.CSEL),
- Offset and increment value can be configured and adjusted
- SW capture function (timer, corrected timer, AVTP)
- HW capture function (AVTP)
- SW compare function

When AVTP FIFO functionality is used in CONFIG mode, there is no error flagging by ESR.ET = B'1011 available. CPU can use error flagging by external RAM protection directly, there are no other read accesses to RAM by EthernetAVB.

33A.3.9 Flow Control

The EthernetAVB does not support flow control in the specification. Flow control is only effective when transmitting and receiving only normal (non-AVB) packets.

The E-MAC supports flow control for full-duplex operation in compliance with the IEEE 802.3 standards. This flow control is applicable to both reception and transmission. In regard to the transmission of PAUSE frames, flow control operates in the following ways.

(1) PAUSE Frame Transmission

PAUSE frames can also be transmitted in response to software operations. Writing a timer value to the manual PAUSE frame register (MPR) starts the transmission of a PAUSE frame. This only causes the transmission of one PAUSE frame.

(2) PAUSE Frame Reception

After reception of a PAUSE frame, transmission of the next frame does not proceed until the time indicated by the Timer value elapses. However, transmission of a frame currently being transmitted continues. PAUSE frames are only received while the RXF bit in the E-MAC mode register (ECMR) is set to 1. The number of received PAUSE frames is counted.

(3) PAUSE Frames with the Timer Value 0

The setting of the 0-time PAUSE frame enable bit (ECMR.ZPF) enables or disables the reception of PAUSE frames with the TIME parameter value 0.

- When control of PAUSE frames with the TIME parameter value 0 is disabled

  PAUSE frames with the TIME parameter value 0 are not transmitted. Received PAUSE frames with the TIME parameter value 0 are discarded.

33A.3.10 Magic Packet Detection

The E-MAC has a Magic Packet detection function. This function provides a facility for host devices and other sources to start other peripheral devices connected to a LAN. A peripheral device that handles Magic Packets starts itself in response to receiving a Magic Packet.

When a Magic Packet is detected, data from broadcast packets that were previously being received are stored in the FIFO and the E-MAC is notified of the receiving status. To return to normal operation from the associated interrupt processing, the E-MAC and AVB-DMAC must be initialized by using the operating mode configuration bit in the AVB-DMAC mode register (CCC.OPC) to set the operating mode to reset mode.

Magic Packets are received regardless of the destination address. As a result, the AVB_MAGIC pin is only enabled in the case of a match with the destination address specified in the Magic Packet.

The procedure for using the Magic Packet detection function with this LSI chip is as follows.

1. Use the various interrupt enabling and masking registers to disable the output of interrupts from interrupt sources.
2. Set the Magic Packet detection enable bit in the E-MAC mode register (ECMR.MPDE).
3. Set the Magic Packet detection interrupt enable bit in the E-MAC interrupt enable register (ECSIPR.MPDIP) to enable the interrupt.
4. Place the CPU in sleep mode as required.
5. An interrupt is conveyed to the CPU on detection of a Magic Packet.
6. The AVB_MAGIC pin notifies connected devices of Magic Packet detection.

Note: The Magic Packet detection interrupt status can be read in the E-MAC status register (ECSR.MPD). The bit can be cleared by setting the E-MAC status register Magic Packet™ detection bit (ECSR.MPD) to 1.

But EthernetAVB can't detect 2nd or later Magic Packet™ and the AVB_MAGIC pin can be negated though the bit is cleared.

The AVB_MAGIC pin can be negated and EthernetAVB can detect Magic Packet™ again according to below way.

1) Hardware reset — set reset pin in the RZ/G1C to reset signal.
2) Software reset — set mstp/srst register for EthernetAVB to software reset mode.
3) Software reset register in AVB — set AVB DMAC mode register Operating Mode Configuration bits (CCC.OPC) to reset mode.

33A.3.11 Interrupts

The EthernetAVB is capable of generating one interrupt.

The interrupts of EthernetAVB are indicated by individual flags DIS, EIS, RISi, TIS, and GIS. Each interrupt is controllable by the corresponding interrupt enable bit. The status flags are independent from this enable bits.

Additionally grouped interrupt status available in ISS and EIS.QFS. The summary status allows CPU to locate the interrupt source with a minimum number of read accesses to EthernetAVB.

EthernetAVB interrupts are combined to 4 groups of interrupt lines for request an interrupt service by CPU. Interrupt requests in group 0 and 1 are only generated in OPERATION mode. Interrupt requests in group 2 are only generated in OPERATION mode and in CONFIG mode if gPTP support is enabled (CCC.GAC). Interrupt request on line 3 depends on E-MAC configuration and can be generated in CONFIG, OPERATION and STANDBY mode.

Interrupt lines are level output and each line is asserted when at least one of the interrupt status registers bits belonging to the group associated with that line is set to 1, and the corresponding enable bit in the related interrupt control register is also set to 1.

For ISS bits the combined flag/enable is used. The green dots in detailed interrupt figures in detailed interrupt line description illustrates the point where status information for ISS is taken.

33A.3.11.1 Concurrent interrupt enable support

The interrupt enable bits can be directly modified by writing the interrupt control registers (xxC.yyE). If concurrent processes enable/disable interrupts located in same interrupt control register inter-process communication is required. To reduce SW overhead there are dedicated registers available controlling conflict free enable/disable of interrupts.

To enable an interrupt CPU should write 1 to the corresponding bit (xxE.yyS) in the enable register. Because written 0 have no effect, there is no side effect to concurrent processes.

To disable an interrupt CPU should write 1 to the corresponding bit (xxD.yyD) in the disable register. Because written 0 have no effect, there is no side effect to concurrent processes.

The current interrupt enable status is readable in xxC.yyE.

Grouping of interrupts for each interrupt line is as described in following sub-chapters.

33A.3.11.2 Group 0 (Data related interrupts)

This group consists on:

Frame received interrupts RIS0.FRFr (for each received frame stored in URAM)
Receive warning interrupts RIS1.RWFr (when Unread Frame Counter reaches warning level)
Descriptor processed interrupts RIS3.RDPFr (for reception)
Frame transmitted interrupts TIS.FTFt (for completion of frame transmission by E-MAC)
Descriptor processed interrupts TIS.TDPFr (for transmission)
Descriptor processed interrupts DIS.DPFi (for reception and transmission)

By reading ISS, CPU get an overview of all data related interrupts (ISS.FRM, ISS.RWM, ISS.DPMi, ISS.FTM).

Interrupt group 0 consists on these 24 interrupt lines:

Line0_Rx[17:0]
Line0_Tx[3:0]
Line0_DiA
Line0_DiB

(1) Reception interrupts

There are 18 dedicated interrupt lines flagging frame reception. For the queue full flag it is configurable by CIE.RQFM if these notification are part of the queue specific reception interrupt lines or part of the error interrupt lines (group 1).

There is a common interrupt enable (CIE.CRIE) for all reception lines.

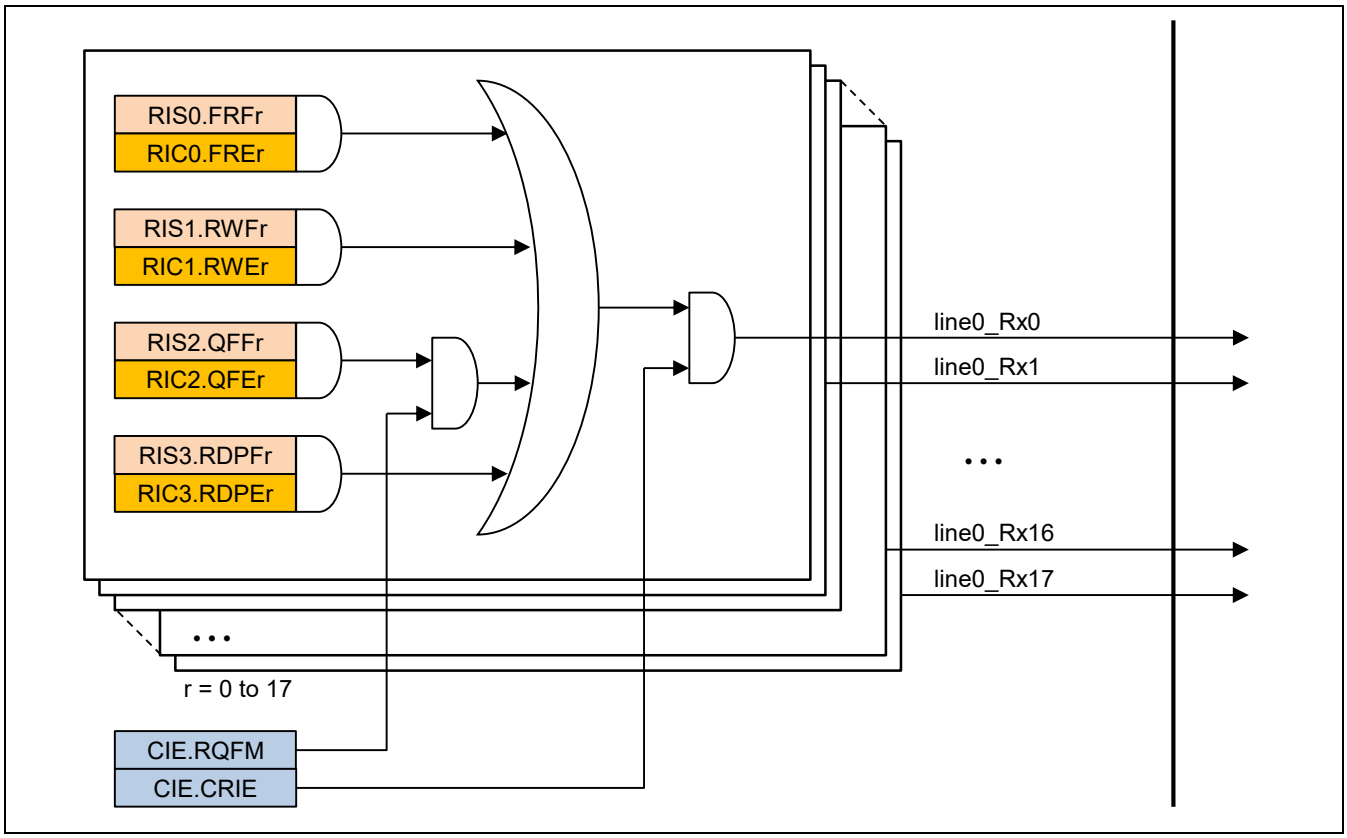

Figure 33A.53 Interrupt group 0, reception interrupt lines

(2) Transmission interrupts

There are 4 dedicated interrupt lines flagging frame transmission.

There is a common interrupt enable (CIE.CTIE) for all reception lines.

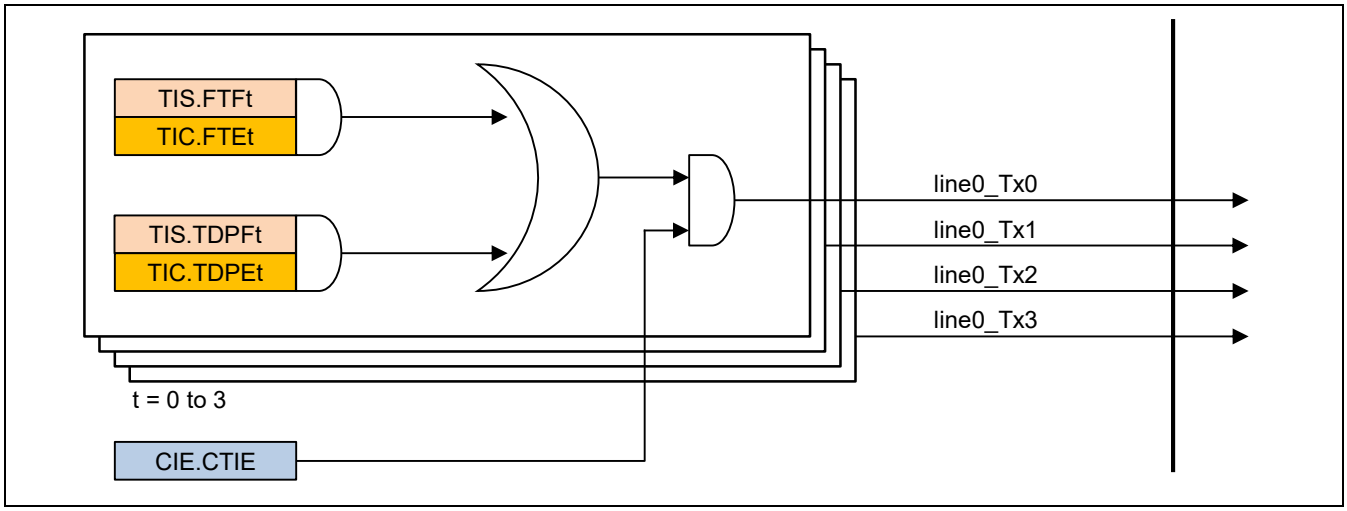

Figure 33A.54 Interrupt group 0, transmission interrupt lines

(3) Descriptor and merged interrupts

There are 2 interrupt lines flagging descriptor interrupts. Line line0_DiA has also the capability to generate a merged data interrupt (controlled by CIE.CL0M).

Descriptor interrupt 1 is not available as common descriptor interrupt; this descriptor interrupt is split into queue specific descriptor interrupts.

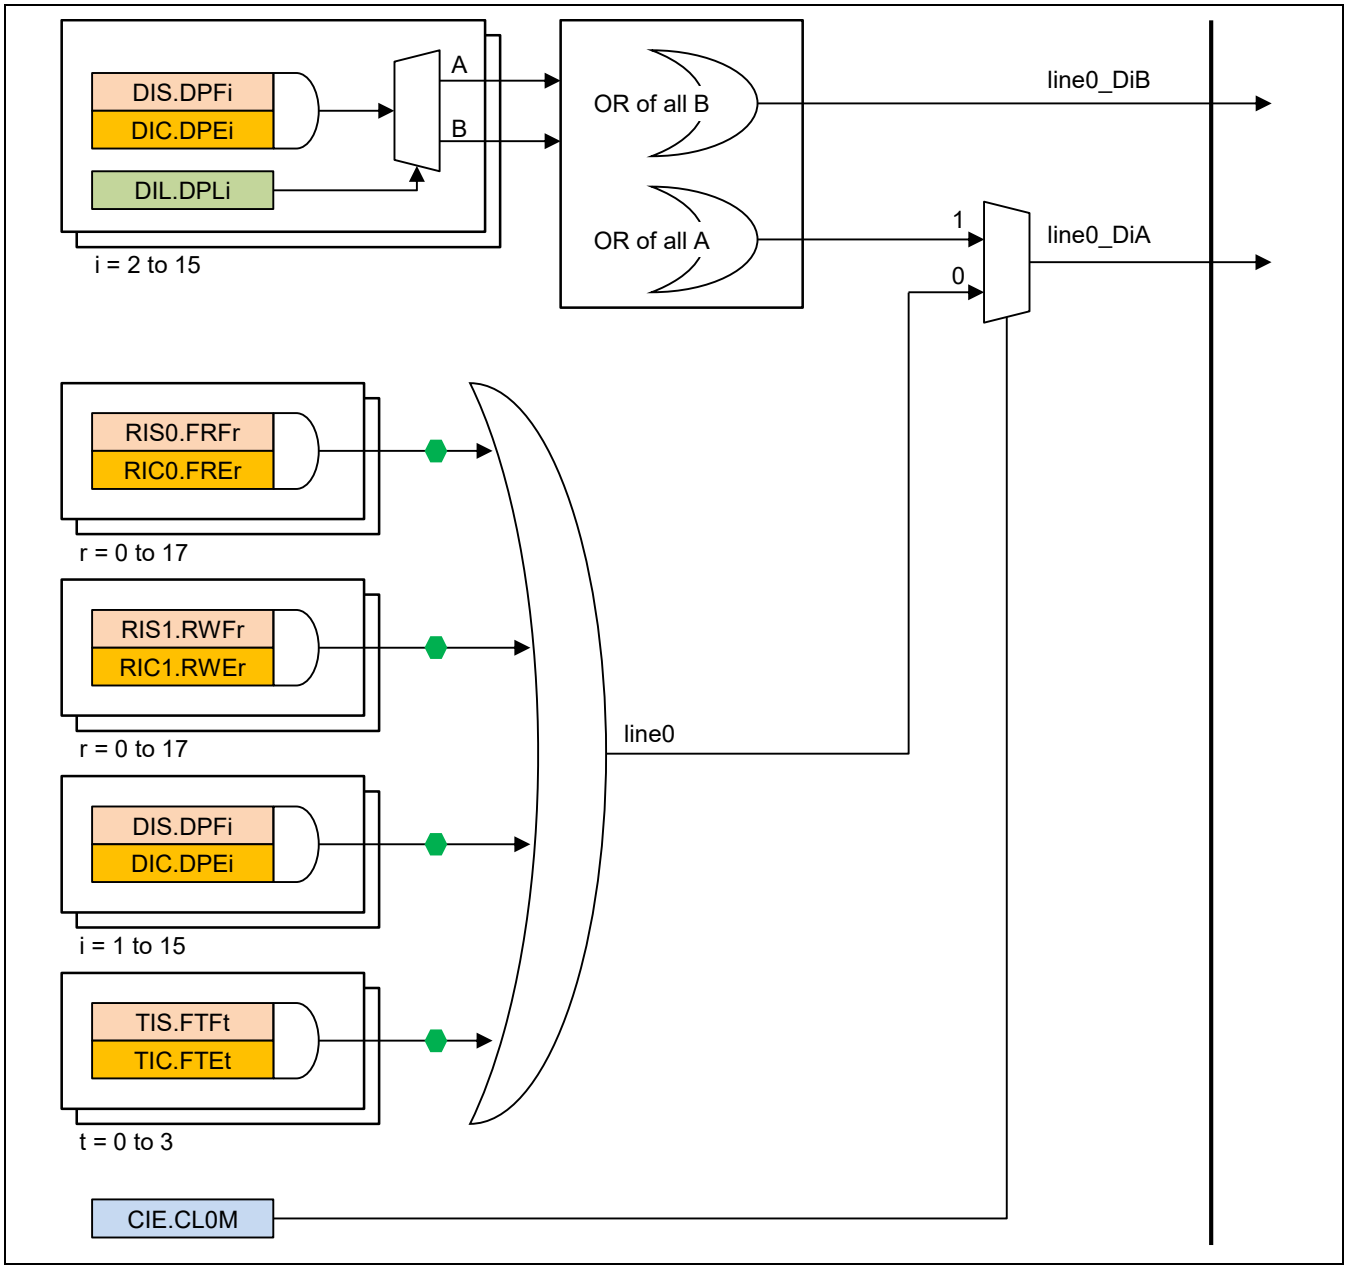

Figure 33A.55 Interrupt group 0, common descriptor and merged interrupt lines

33A.3.11.3 Group 1 (Error related interrupts)

This group consists on:

Tx-Buffer full interrupt EIS.TBFF (when delaying fetching of transmit frame)
Interrupt for E-MAC Status FIFO overwrite (EIS.MFFF)
Interrupt for Timestamp FIFO overrun (EIS.TFFF)
Interrupts for CBS limits (EIS.CULF1, EIS.CULF0, EIS.CLLF1, EIS.CLLF0)
Interrupt for separation filtering error (EIS.SEF)
Interrupt for queue error (error while processing receive or transmit queue) (EIS.QEF)
Interrupt for transmission error detected by E-MAC (EIS.MTEF, EIS.MREF)
Rx-FIFO full interrupt RIS2.RFFF (when Rx-FIFO overflows)
Receive queue full interrupts RIS2.QFFr (when no sufficient space is in receive queue)

By reading EIS, CPU get an overview of all error interrupts. Additionally ISS.EM informs about pending error related interrupt.

Interrupt group 1 consists on these 2 interrupt lines:

Line1_A
Line1_B

For the queue full flag it is configurable by CIE.RQFM if these notification are part of the queue specific reception interrupt lines or part of the error interrupt line line1_A.

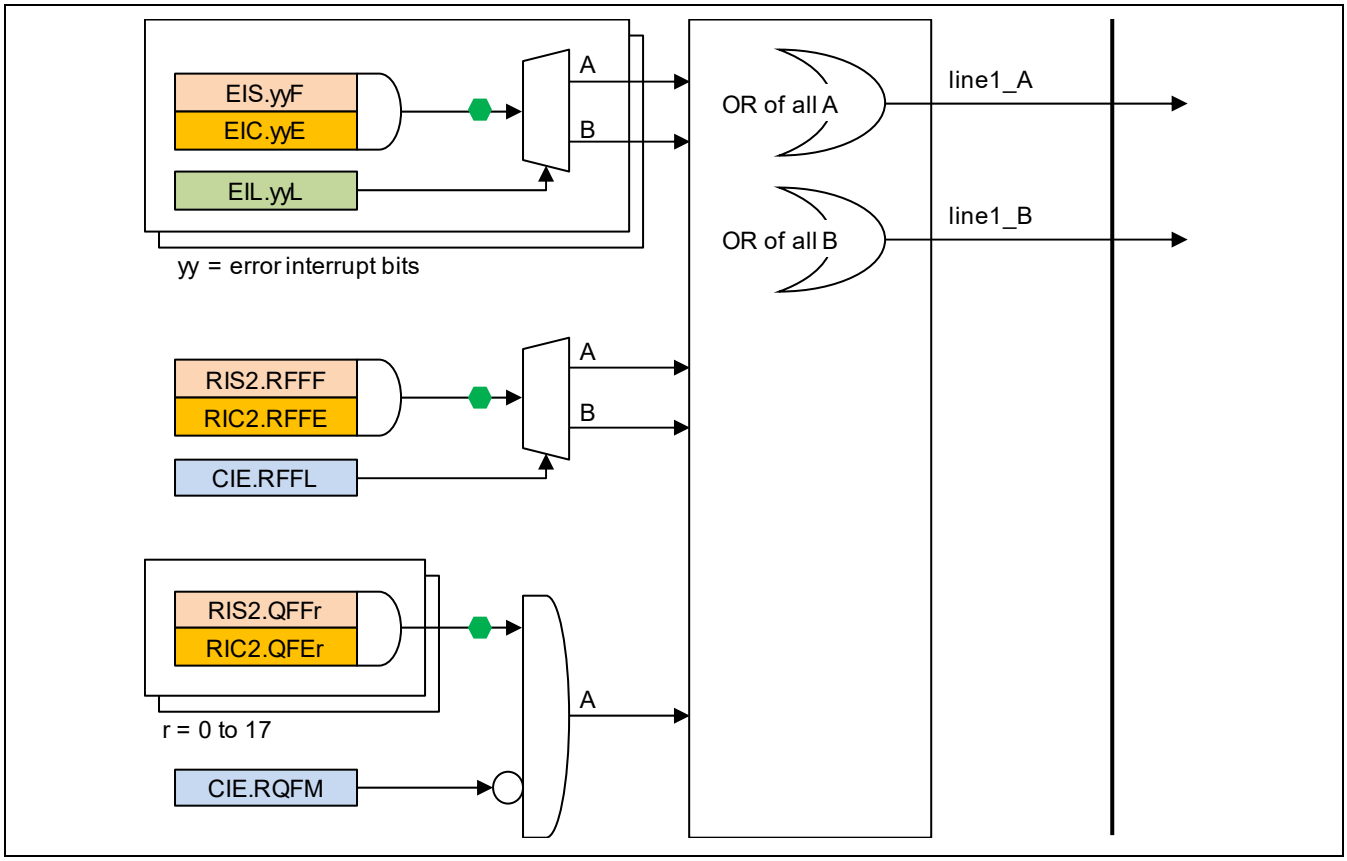

Figure 33A.56 Interrupt group 1, error interrupt lines

The abbreviation **yy** in figure indicates error interrupts: TBF, MFF, TFF, CULFc, CLLFc, SE, QE, MTE, and MRE.

33A.3.11.4 Group 2 (Management related interrupts)

Reception

Rx-FIFO Warning interrupt RIS1.RFWF (Rx-FIFO has reached configured warning level)

Transmission

E-MAC status FIFO warning interrupt TIS.MFWF
E-MAC Status FIFO updated interrupt TIS.MFUF
Timestamp FIFO warning interrupt TIS.TFWF
Timestamp FIFO updated interrupt TIS.TFUF

gPTP

AVTP time captured interrupt GIS.ATCFi
AVTP presentation target matched interrupt GIS.PTMFi
AVTP presentation time overrun interrupt GIS.PTOF (when external trigger before old value is processed)
AVTP presentation time captured interrupt GIS.PTCF

By reading ISS, CPU get an overview of all management related interrupts (ISS.RFWM, ISS.MFWM, ISS.MFUM, ISS.TFWM, ISS.TFUM, ISS.CGIM).

Interrupt group 2 consists on these 2 interrupt lines:

Line2_A
Line2_B

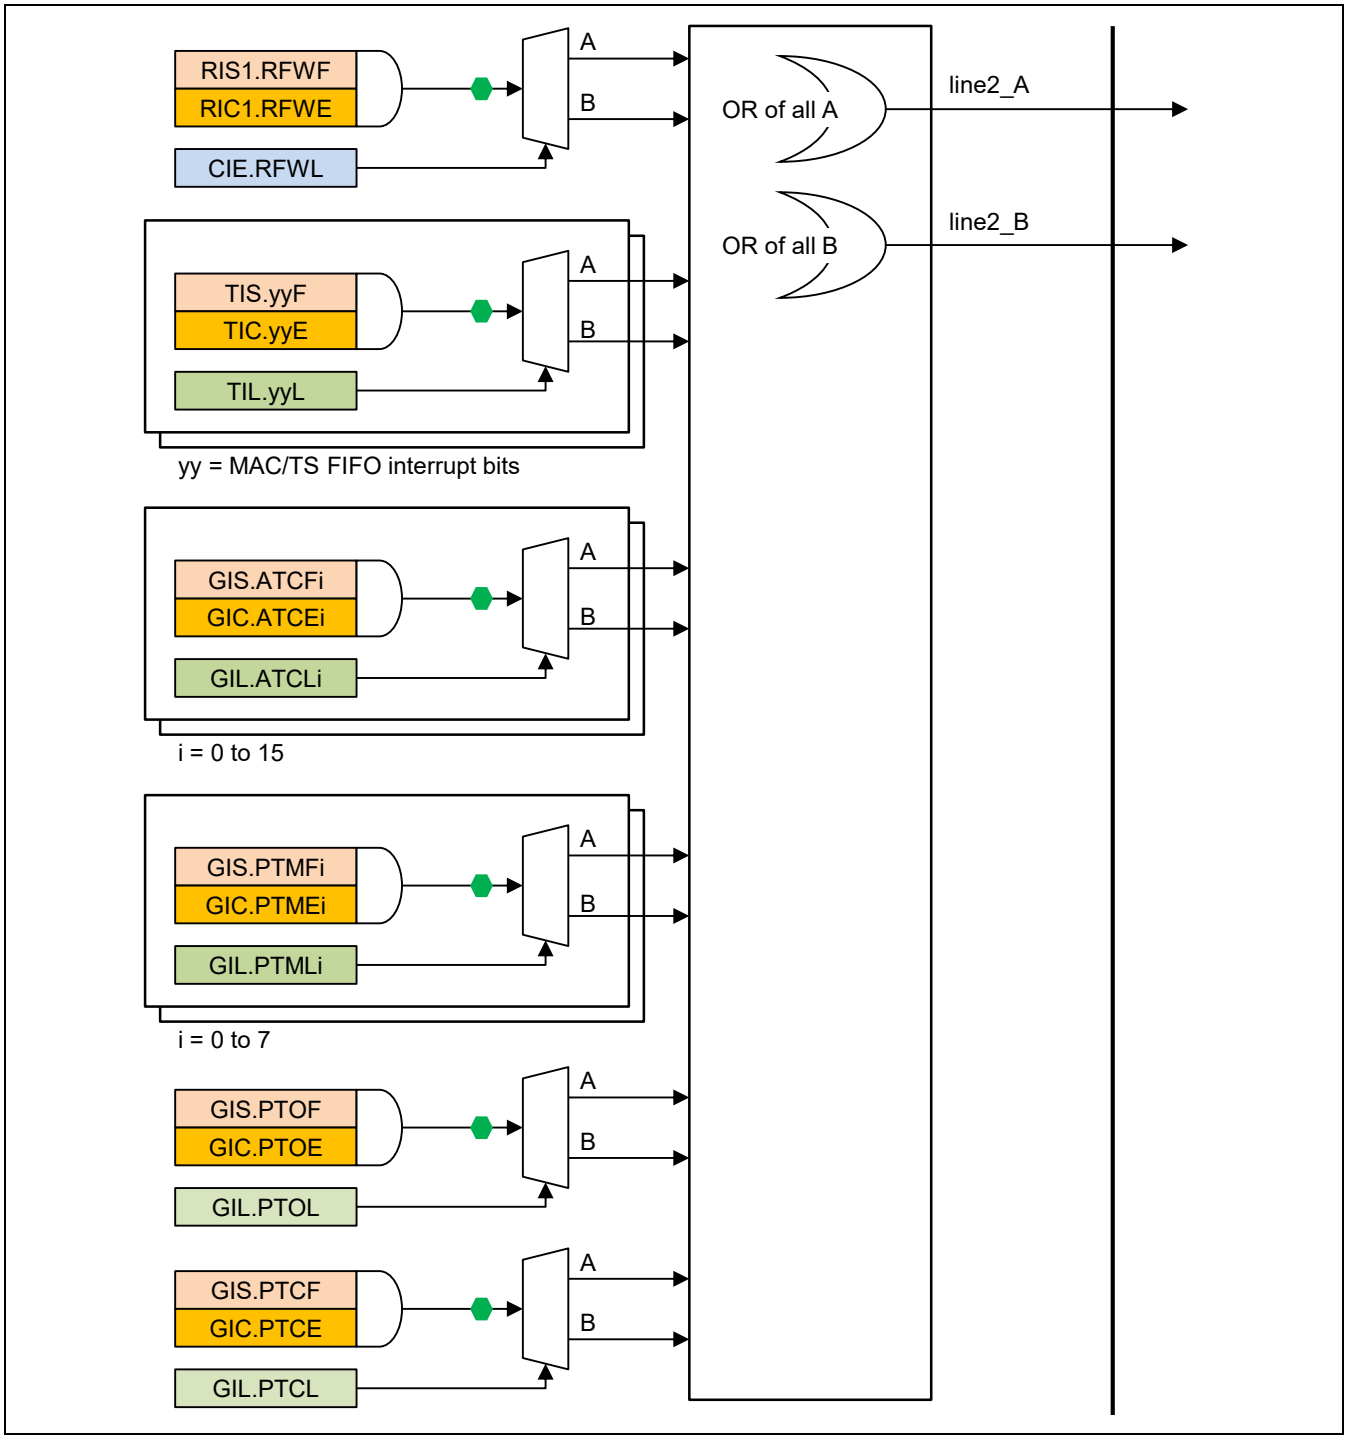

Figure 33A.57 Interrupt group 2, management interrupt lines

The abbreviation **yy** in figure indicates error interrupts: MFW, MFU, TFW, and TFU.

33A.3.11.5 Line 3 (E-MAC interrupt)

The E-MAC interrupt is conveyed when the E-MAC interrupt source is generated.

The general error interrupt state can be checked by reading the E-MAC interrupt summary bit in the interrupt summary status register (ISS.MS).

33A.3.12 Flows of Operations

33A.3.12.1 Flow of E-MAC Initialization

Figure 33A.58 shows the flow of E-MAC initialization (for AVB mode and full-duplex operation).

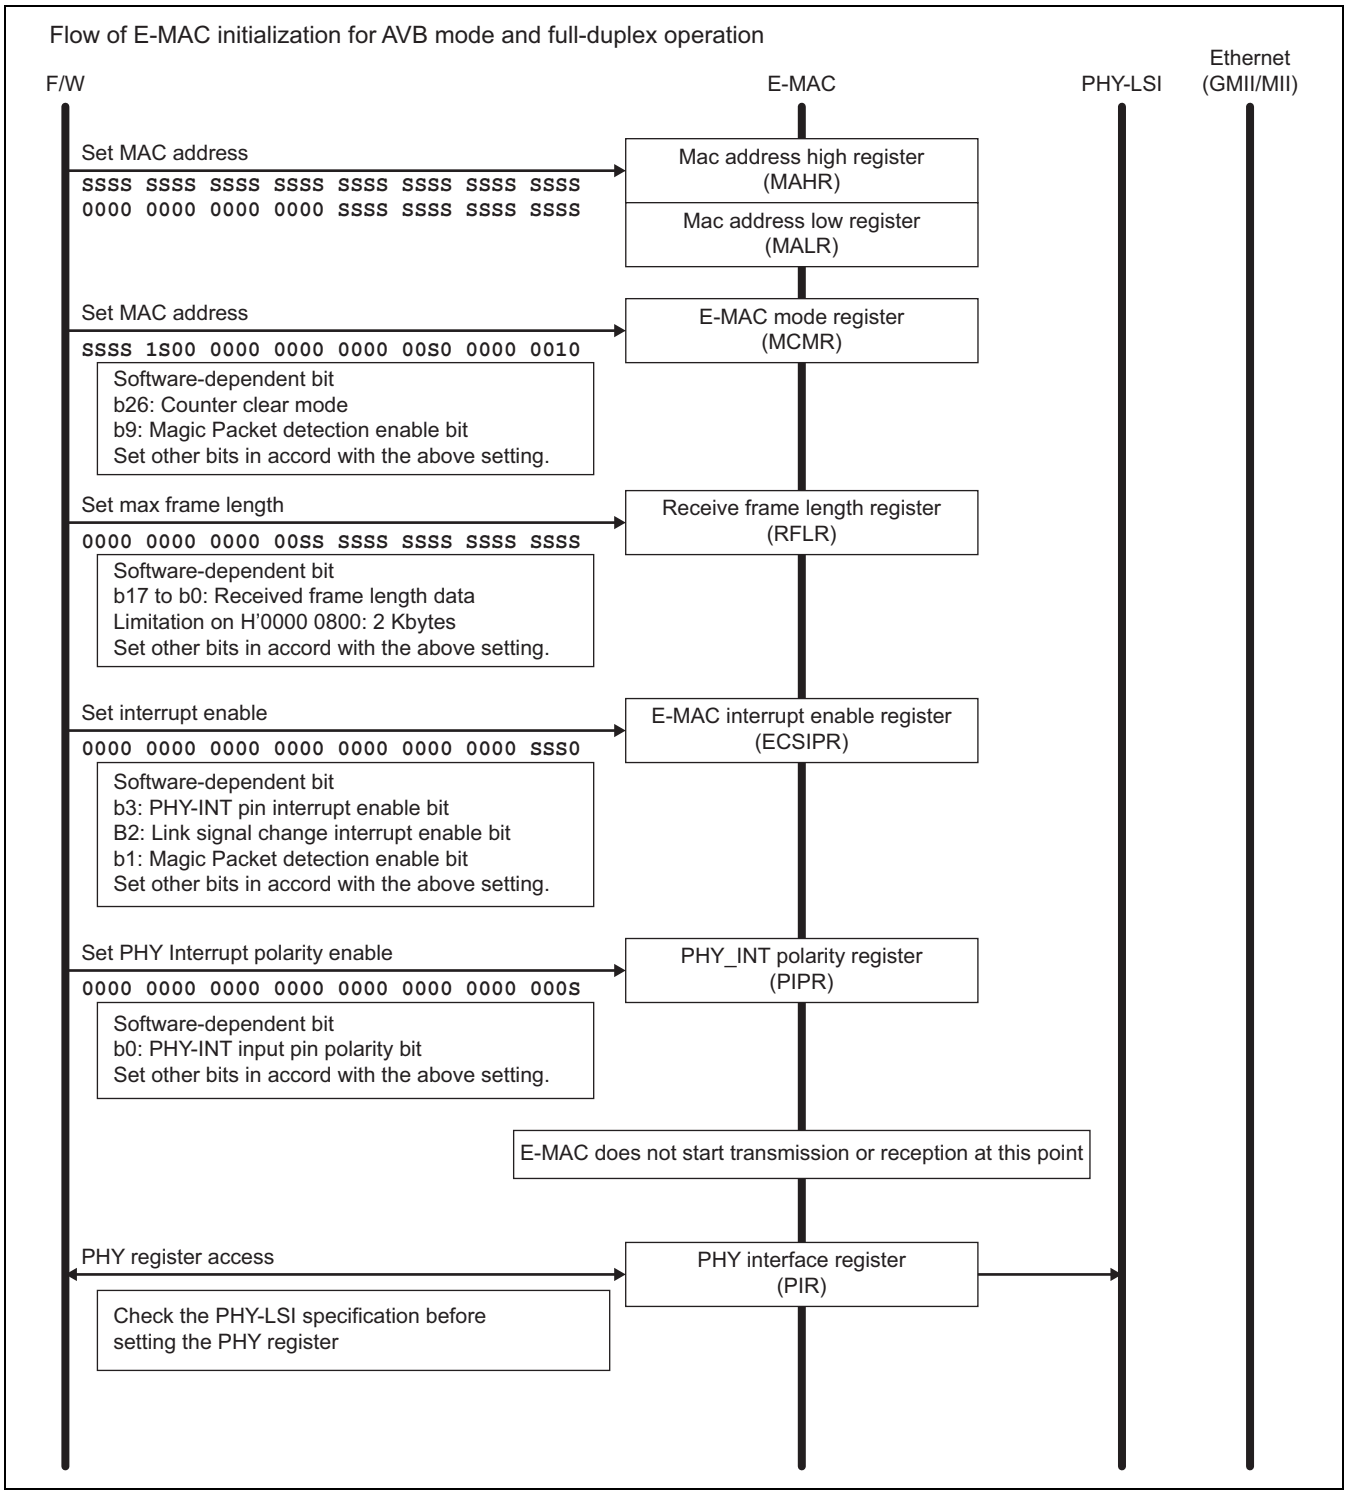

Figure 33A.58 Flow of E-MAC Initialization (for AVB Mode and Full-Duplex Operation)

33A.3.12.2 Flow of AVB-DMAC Initialization

33A.3.13.3 Accessing MII Management Registers

MII management registers in the PHY-LSI are accessed via PIR in this LSI. PIR is used as a serial interface conforming to the MII frame format specified in IEEE802.3u.

(1) MII Management Frame Format

Figure 33A.84 shows the format of an MII management frame. To access an MII management register, a management frame is implemented by the program in accordance with the procedures shown in MII Management Register Access Procedure.

Access Type	MII Management Frame							
Item	PRE	ST	OP	PHYAD	REGAD	TA	DATA	IDLE
Number of bits	32	2	2	5	5	2	16	
Read	1..1	01	10	00001	RRRRR	Z0	D...D	
Write	1..1	01	01	00001	RRRRR	10	D...D	X

[Legend]
PRE: 32 consecutive 1 s
ST: Write of B'01 indicating start of frame
OP: Write of code indicating access type
PHYAD: Write of B'00001 if the PHY-LSI address is 1 (sequential write starting with the MSB).
This bit changes depending on the PHY-LSI address.
REGAD: Write of 000q if the register address is 1 (sequential write starting with the MSB).
This bit changes depending on the PHY-LSI register address.
TA: Time for switching data transmission source on MII interface
(a) Write: 10 written
(b) Read: Bus release (notation: Z0) performed
DATA: 16-bit data. Sequential write or read from MSB
(a) Write: 16-bit data write
(b) Read: 16-bit data read
IDLE: Wait time until next MII management format input
(a) Write: Independent bus release (notation: X) performed
(b) Read: Bus already released in TA: control unnecessary

Figure 33A.84 MII Management Frame Format

(2) MII Management Register Access Procedure

The program accesses MII management registers via PIR. Access is implemented by a combination of 1-bit-unit data write, 1-bit-unit data read, bus release, and independent bus release. Figure 33A.85 to Figure 33A.88 show the MII management register timing. The timing will differ depending on the PHY-LSI type.

33A.4 Usage Notes

33A.4.1 Checksum Calculation of Ethernet Frames

This LSI is capable of calculating the checksum data of the received frames. Only the data fields of the Ethernet frames are subject to checksum calculation. Specifically, a data field follows the length/type field and is followed by the CRC field. Figure 33A.89 shows schematics indicating which parts of the Ethernet frames are calculated. Calculation involves 16-bit addition only; it does not involve bit inversion. Note that when the checksum data is valid, the CRC data (4 bytes) is not transferred as a receive frame, and the checksum data (sum data) is added automatically. Figure 33A.90 shows schematics of Ethernet frames to which the checksum data has been added.

Note: Also for the frames with VLANtag inserted, the 15th byte from the top and the following bytes before the CRC field are subject to calculation.

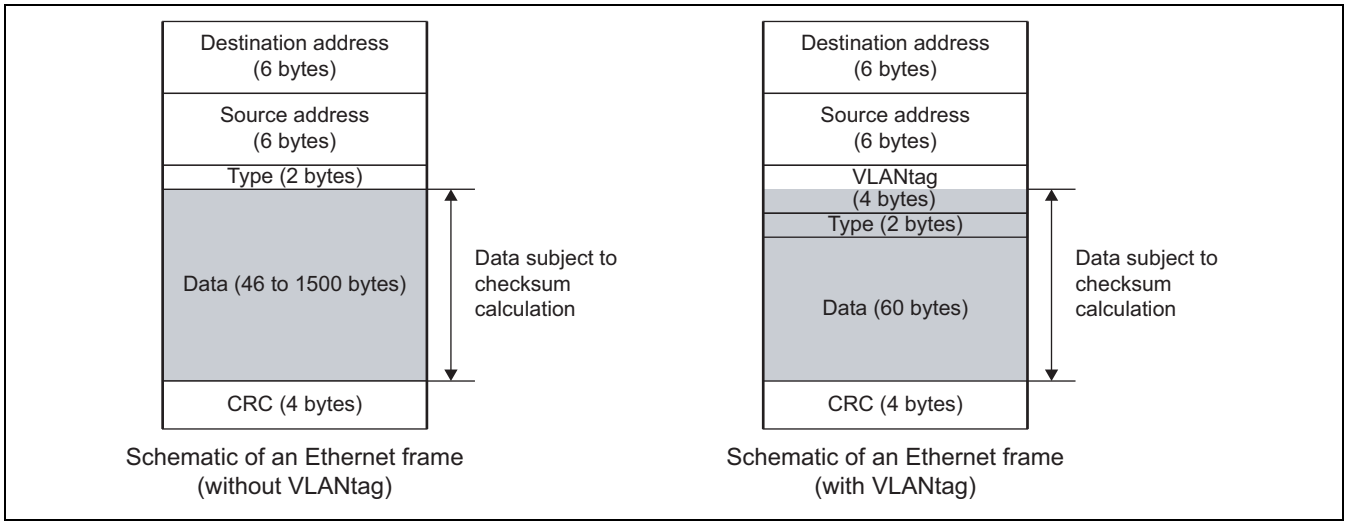

Figure 33A.89 Data Subject to Checksum Calculation

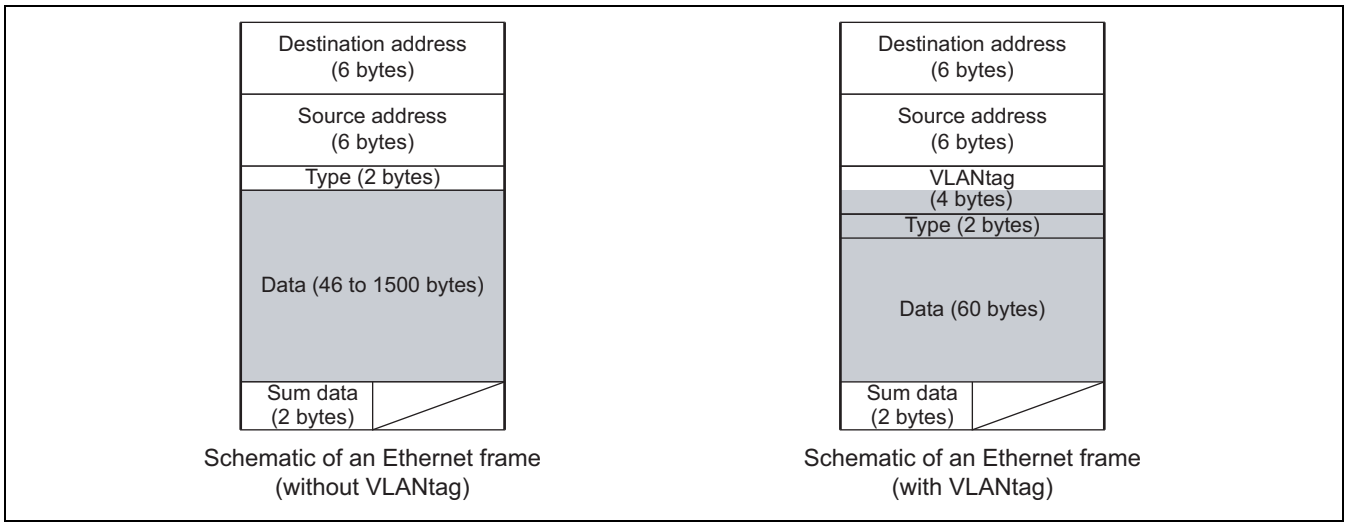

Figure 33A.90 Data after Checksum Data Addition

33A.4.2 Data Transfer Function Stops after Read Access Error

If EthernetAVB gets an access error when reading from work RAM, it may happen that no further work RAM accesses are issued. So transfer of receive/transmit frames is halted. By using the data transfer suspend function SW can observe if data transfer function is available or not.

Perform one of given SW flows which are triggered by this start condition: when AXI read access error has been flagged by EIS.QEF is 1, and ESR.ET is B'0000 or B'0100; additionally when ESR.EIL is 1 (this is an indication that an work RAM read error may be lost).

There are two possible SW flows given. Figure 33A.91 applies always the SW reset, independently if this is required or not. Figure 33A.92 checks in addition if SW reset is required; checking CSR.DTS after wait gives an indication that issue has been occurred.

Note that the wait after write of CCC.DTSR is mandatory to prevent cases where issue has not been occurred.

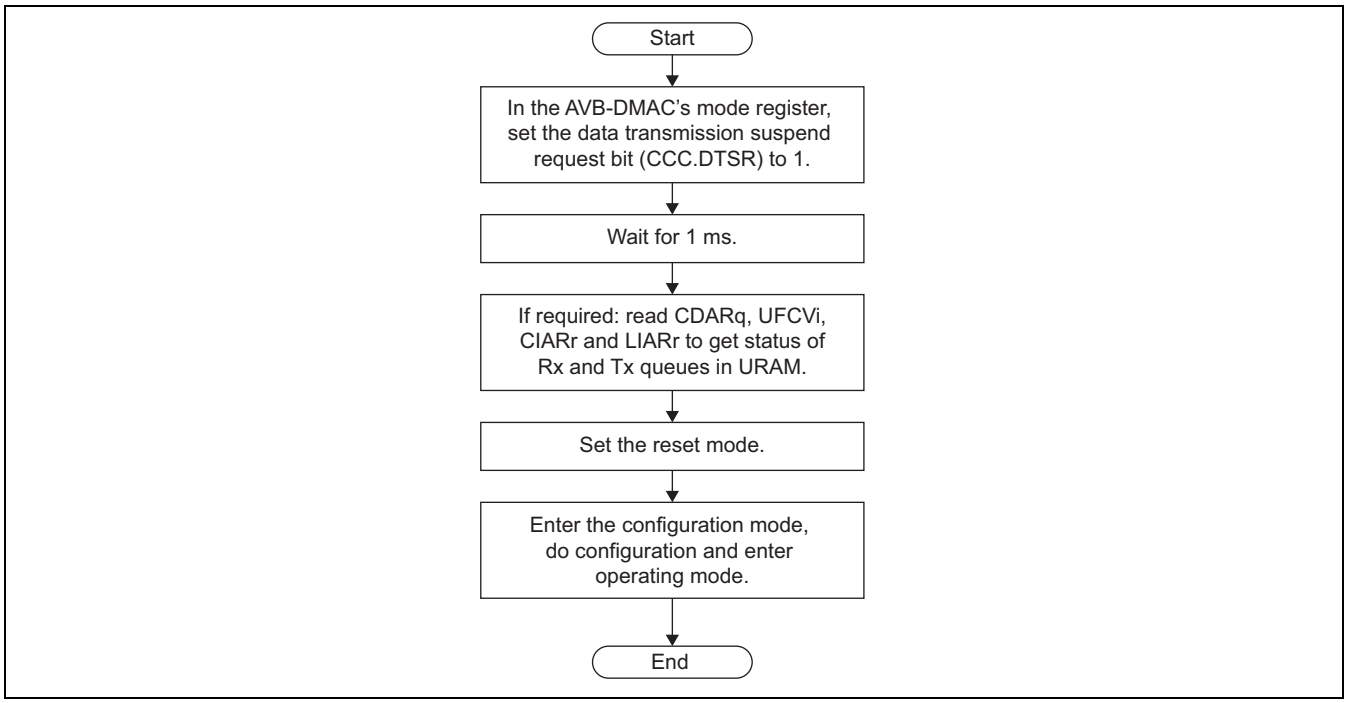

Figure 33A.91 Data Transfer Function Stop Flow1 after Read Access Error

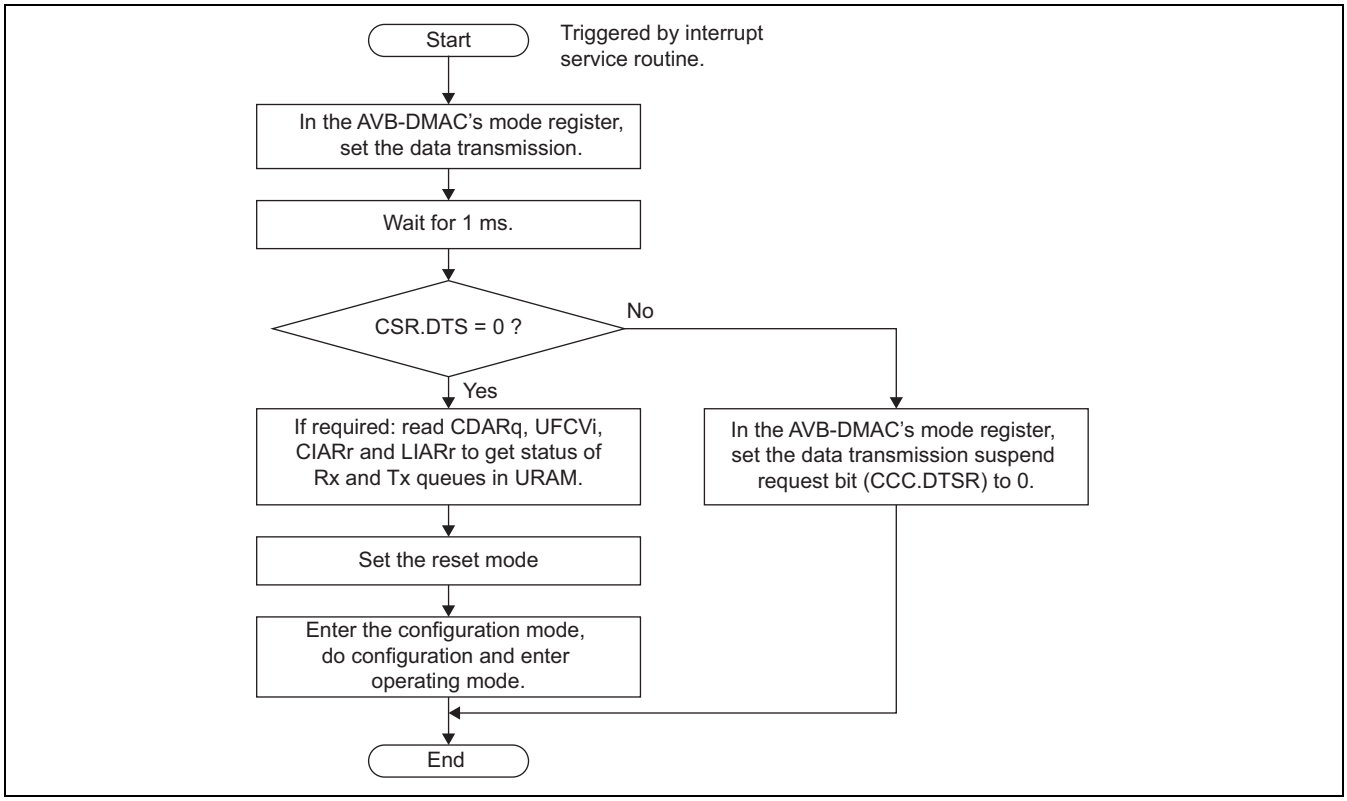

Figure 33A.92 Data Transfer Function Stop Flow2 after Read Access Error

33A.4.3 Power Down Request

If EthernetAVB gets a power down request while writing to work RAM, it may happen that the request is not accepted even if the transfer is completed. Due to this the external power down module cannot complete the power down sequence.

A power down request is acceptable only when EthernetAVB is in RESET state.

33A.4.4 Reception

(1) Reception is Ignored when AVB_RX_ER indicates an error from PHY is Flagged at 1st Data Byte

The issue is limited to reception of frames with physical faults. Flagging of occurrence in SFR is missing. When EthernetAVB is configured to store faulty frames in reception queue 0 (BE) by RCR.EFFS there is no storage.

(2) Unexpected Data are Exported when AVB_RX_ER indicates an error is Flagged at 8th Data Byte

The issue is limited to reception of frames with physical faults.

Flagging of occurrence in SFR is invalid. When EthernetAVB is configured to store faulty frames in reception queue 0 (BE) by RCR.EFFS corrupted data is stored and MAC status code is wrong.

(3) Receive Frame Interrupt and Descriptor Interrupt may be Issued before Completion of Writing Data

When receive frame interrupt and descriptor interrupt are issued, whether writing data is completed by DESCR.DT in a descriptor can be confirmed.

And CDARq register has the descriptor address which EthernetAVB is processing currently or is going to process at the next time.

The descriptors before one indicated by CDARq register are scope for receive frame interrupt and descriptor interrupt scope.

If there is a descriptor which wait for HW processing (ex. FEMPTY), it's delayed. Confirm the descriptor again after waiting for 1ms.

33B. Stream Buffer for EthernetAVB (STBE)

33B.1 Overview

The stream buffer for the EthernetAVB module (hereinafter referred to as STBE) incorporates a 16-Kbyte RAM for the EthernetAVB descriptors.

Using the STBE reduces the number of accesses to the DRAM and provides efficient access.

33B.1.1 Features

- 1-, 2-, 4-, 8-, or 16-byte access is available for transfer.
- Transfer to/from the EthernetAVB is performed via the AXI bus using the following addresses: H'EE0E_8000 to H'EE0E_BFFF (16 Kbytes)

Note: For use of the EthernetAVB descriptors, refer to section 33A, EthernetAVB.

33B.1.2 Block Diagram

Figure 33B.1 shows a block diagram of the STBE.

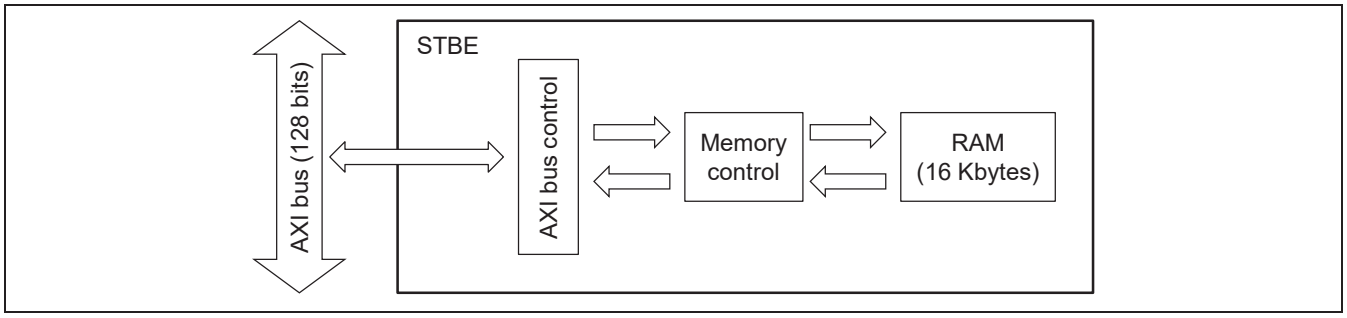

Figure 33B.1 Block Diagram

33B.2 Usage Notes

33B.2.1 Module Standby Mode

This module can be placed on module standby mode.

Ensure that this module is released from the module standby mode before using it.

33B.2.2 Transition to Module Standby Mode

1. Before stopping supply of the clock signal to this module, confirm that this module is not being accessed.
2. Set the relevant module stop control register in the clock pulse generator to stop supply of a clock signal to this module.

Note: Refer to section 7A, Module Standby and Software Reset, for the module stop control register.

33B.2.3 Release of Module Standby Mode and Restarting the STBE

Set the relevant module stop control register in the clock pulse generator to start supply of the clock signal to this module.

Note: Refer to section 7A, Module Standby and Software Reset, for the module stop control register.

34. Controller Area Network Interface (CAN interface)

34.1 Features

This MCU implements two channels (referred to as CAN0 and CAN1) of CAN (Controller Area Net-work) module that complies with the ISO11898-1 Specifications. The CAN module transmits and receives both formats of messages, namely the standard identifier (11 bits) (identifier hereafter referred to as ID) and extended ID (29 bits). Table 34.1 lists the CAN module overview and Figure 34.1 shows the CAN module block diagram. Connect the CAN bus transceiver externally.

Table 34.1 CAN Module Overview

Item	Overview
Protocol	• ISO11898-1 compliant
Bit-rate	• Up to 1 Mbps
Message box	• 64 mailboxes: Two selectable mailbox mode Normal mailbox mode: Of the 64 mailboxes, 32 can be configured for either transmission or reception (and the other 32 are reception-only). FIFO mailbox mode: 24 mailboxes configurable as transmission or reception (and the other 32 are reception-only). 4 stages FIFO for transmission and 4 stages FIFO for reception
Reception	• Data frame and remote frame can be received. • Selectable receiving ID format (only standard ID, only extended ID or both ID) • Programmable one-shot reception function • Selectable overwrite mode (message overwritten) or overrun mode (message discarded) • The reception complete interrupt can be enabled or disabled for each mailbox.
Acceptance filter	• 8 acceptance masks (one mask every 4 mailboxes) • 2 acceptance masks (one mask every 16 mailboxes) • The mask can be enabled or disabled for each mailbox.
Transmission	• Data frame and remote frame can be transmitted. • Selectable transmitting ID format (only standard ID, only extended ID or both ID) • Programmable one-shot transmission function (enable or disable) • Selectable ID priority mode or mailbox number priority mode • Transmission request can be aborted (The completion of abort can be confirmed with a flag.) • The transmission complete interrupt can be enabled or disabled for each mailbox.
Mode transition for bus-off recovery	• Mode transition for the recovery from the bus-off state can be selected: Automatic entry to CAN halt mode at bus-off entry Automatic entry to CAN halt mode at bus-off end Entry to CAN halt mode by a program Transition into error-active state by a program
Error status monitoring	• CAN bus errors (stuff error, form error, ACK error, CRC error, bit error, and ACK delimiter error) can be monitored. • Transition to error states can be detected (error-warning, error-passive, bus-off entry, and bus-off recovery). • The error counters can be read.
Time stamp function	• Time stamp function using a 16-bit counter • The reference clock can be selected from either 1-, 2-, 4- or 8-bit time periods.

Item	Overview
Interrupt sources	• 5 types: Reception complete Transmission complete Receive FIFO Transmit FIFO Error
CAN sleep mode	• Current consumption can be reduced by stopping the CAN clock.
Software support unit	• 3 software support units: Acceptance filter support Mailbox search support (receive mailbox search, transmit mailbox search and message lost search) Channel search support
CAN clock source (fCAN)	• Peripheral clocks (clkp1 or clkp2) or externally input clock is selectable. clkp1 = Pϕ, clkp2 = RCANϕ
Test mode	• 3 test modes available for user evaluation: Listen-only mode Self-test mode 0 (external loop back) Self-test mode 1 (internal loop back)

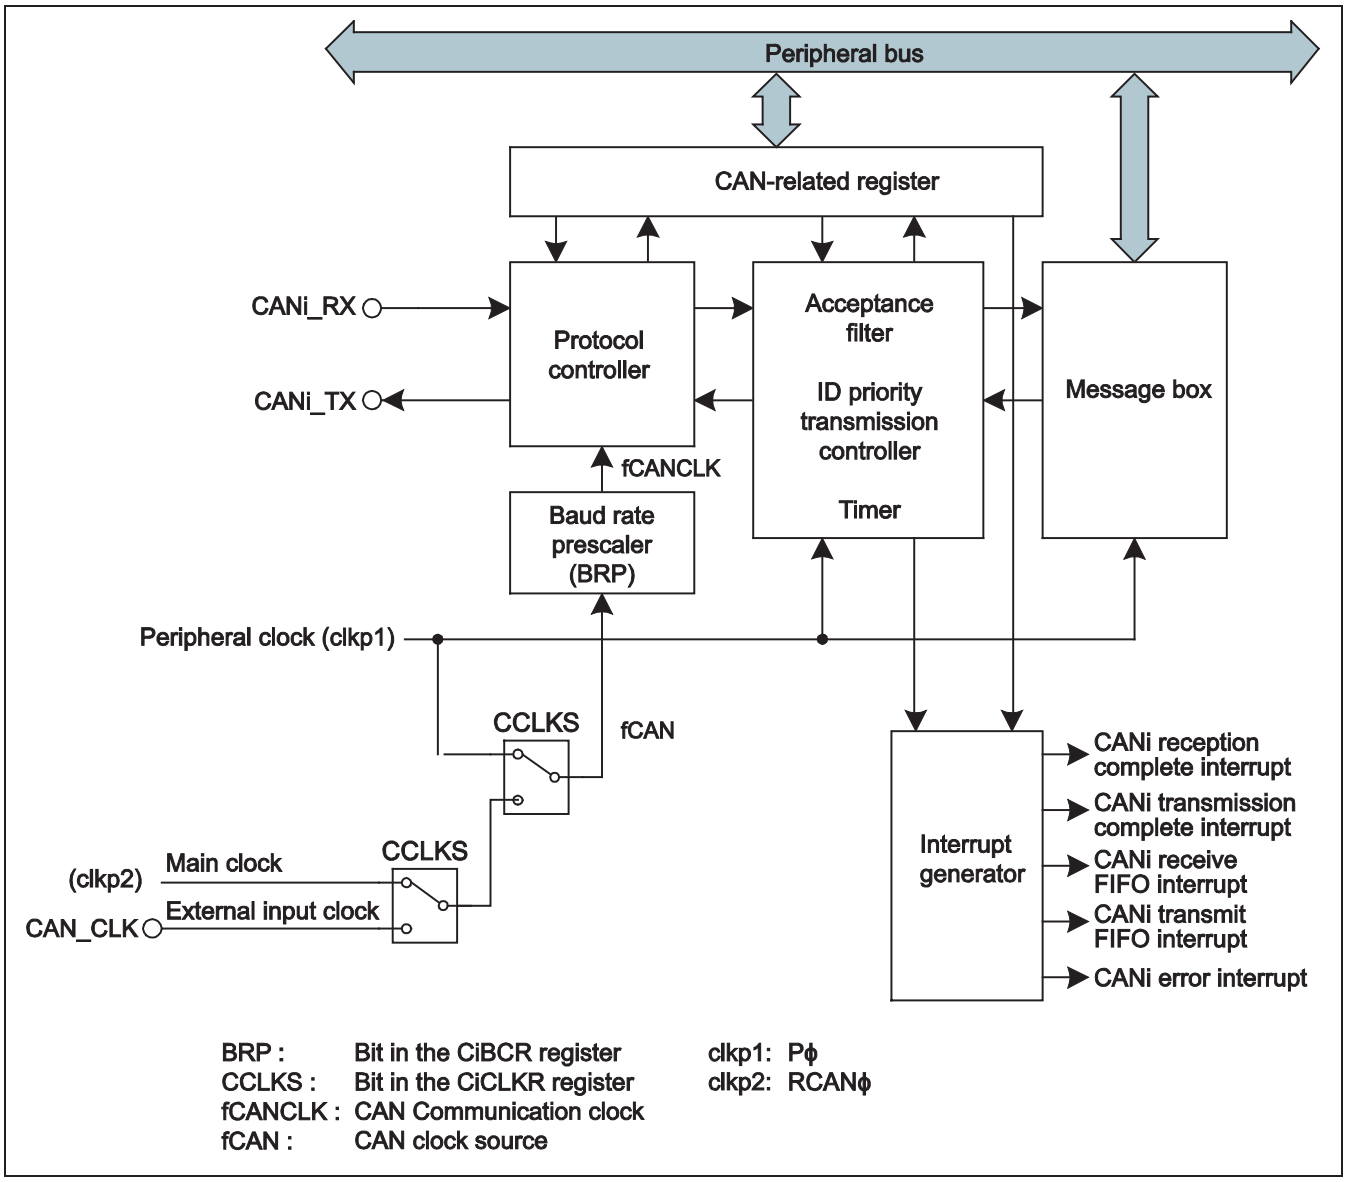

Figure 34.1 Block Diagram of CAN Module (i = 0, 1)

- CANi_RX/CANi_TX (i = 0 and 1):
  CAN input/output pins
- Protocol controller:
  Handles CAN protocol processing such as bus arbitration, bit timing at transmission and reception, stuffing, and error handling, etc.
- Message box:
  Consists of 64 mailboxes which can be configured as either transmit or receive mailboxes. Each mailbox has an individual ID, data length code, a data field (8 bytes), and a time stamp.
- Acceptance filter:
  Perform filtering of received messages. Registers CiMKR0 to CiMKR9 are used for the filtering process.
- Timer:
  Used for the time stamp function. The timer value when storing a message into the mailbox is written as the time stamp value.
- Interrupt generator:
  Generates the following five types of interrupts:
  CANi reception complete interrupt

CANi transmission complete interrupt
CANi receive FIFO interrupt
CANi transmit FIFO interrupt
CANi error interrupt

34.2 Input/Output Pins

Table 34.2 shows the CAN module pin.

Pin switching is required for pins which are multiplexed with other functions. For details, see section 5, Pin Function Controller (PFC).

Table 34.2 Pin Configuration

Pin Name	I/O	Function
CANi_RX	Input	Pins for receiving data
CANi_TX	Output	Pins for transmitting data
CAN_CLK	Input	Input pin used for external clock input.

Legend: i = 0 and 1

34.3 Register Descriptions

Table 34.3 Register Configuration

Register Name	Symbol	R/W	Value after Reset	Address	Access Size
CAN0 Control Register	C0CTLR	R/W	H'0500	H'E6E80840	8, 16

Legend:

Initial value: Register value after a reset

—: Undefined value

R/W: Readable/writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing1 is ignored.

R: Read-only. When writing to the register, read out the value of these bits and write it back without alteration.

W: Write-only. The read value is undefined.

34.3.1 CANi Control Register (CiCTLR) (i = 0, 1)

CAN0 Control Register (C0CTLR)
CAN1 Control Register (C1CTLR)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	RBOC	BOM		SLPM	CANM		TSPS		TSRC	TPM	MLM	IDFM		MBM
Initial value:	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

<After Reset: H'0500>

Bit	Symbol	Initial Value	R/W	Description
15, 14	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
13	RBOC	0	R/W	Forcible Return From Bus-OFF Bit*1 When the RBOC bit is set to "1" (forcible return from bus-off) in bus-off state, the CAN module forcibly returns from the bus-off state. This bit is automatically set to 0. The error state changes from bus-off to error-active. When the RBOC bit is set to "1", registers CiRECR and CiTECR are set to "H'00" and the BOST bit in the CiSTR register is set to "0" (the CAN module is not in bus-off state). The other registers remain unchanged. No bus-off recovery interrupt request is generated by this recovery from the bus-off state. Use the RBOC bit only when the BOM bit = "00" (normal mode). 0: Nothing occurred 1: Forcible return from bus-off*2

Bit	Symbol	Initial Value	R/W	Description
12, 11	BOM	00	R/W	Bus-Off Recovery Mode Bit*3 The BOM bit is used to select bus-off recovery mode. When the BOM bit is "00", the recovery from bus-off is compliant with ISO11898-1, i.e. the CAN module re-enters CAN communication (error-active state) after detecting 11 consecutive recessive bits 128 times. A bus-off recovery interrupt request is generated when recovering from bus-off. When the BOM bit is "01", as soon as the CAN reaches the bus-off state, the CANM bit in the CiCTLR register is set to "10" (CAN halt mode) and the CAN enters CAN halt mode. No bus-off recovery interrupt request is generated when recovering from bus-off and registers CiTECR and CiRECR are set to "H'00". When the BOM bit is "10", the CANM bit is set to 10b as soon as the CAN module reaches the bus-off state. The CAN module enters CAN halt mode after the recovery from the bus-off state, i.e. after detecting 11 consecutive recessive bits 128 times. A bus-off recovery interrupt request is generated when recovering from bus-off and registers CiTECR and CiRECR are set to "H'00". When the BOM bit is "11", the CAN module enters CAN halt mode by setting the CANM bit to "10" while the CAN module is still in bus-off state. No bus-off recovery interrupt request is generated when recovering from bus-off and registers CiTECR and CiRECR are set to "H'00". However, if the CAN module recovers from bus-off after detecting 11 consecutive recessive bits 128 times before the CANM bit is set to "10", a bus-off recovery interrupt request is generated. If the CPU requests an entry to CAN reset mode at the same time as the CAN module attempts to enter CAN halt mode (at bus-off entry when the BOM bit is "01", or at bus-off end when the BOM bit is "10"), then the CPU request to enter CAN reset mode has higher priority. 00: Normal mode (ISO11898-1 compliant) 01: Entry to CAN halt mode automatically at bus-off entry 10: Entry to CAN halt mode automatically at bus-off end 11: Entry to CAN halt mode (during bus-off recovery period) by a program request
10	SLPM	1	R/W	CAN Sleep Mode Bit*4*5 When the SLPM bit is set to "1", the CAN module enters CAN sleep mode. When the SLPM bit is set to "0", the CAN module exits CAN sleep mode. Refer to section 34.4, Operating Mode for detail. 0: Other than CAN sleep mode 1: CAN sleep mode
9, 8	CANM	01	R/W	CAN Operating Mode Select Bit*4 The CANM bit selects one of the following modes for the CAN module: CAN operation mode, CAN reset mode or CAN halt mode. Refer to section 34.4, Operating Mode for detail. CAN sleep mode is set by the SLPM bit. When the CAN module enters CAN halt mode according to the setting of the BOM bit, the CANM bit is automatically set to "10". 00: CAN operation mode 01: CAN reset mode 10: CAN halt mode 11: CAN reset mode (forcible transition)

Bit	Symbol	Initial Value	R/W	Description
7, 6	TSPS	00	R/W	Time Stamp Prescaler Select Bit*3 The TSPS bit selects the prescaler for the time stamp. The reference clock for the time stamp can be selected to be either 1-, 2-, 4- or 8-bit time periods. 00: Every bit time 01: Every 2-bit time 10: Every 4-bit time 11: Every 8-bit time
5	TSRC	0	R/W	Time Stamp Counter Reset Command Bit*6 The TSRC bit is used to reset the time stamp counter. When the TSRC bit is set to "1", the CiTSR register is set to H'0000. It is automatically set to 0. 0: Nothing occurred 1: Reset*2
4	TPM	0	R/W	Transmission Priority Mode Select Bit*3 The TPM bit specifies the priority of modes when transmitting messages. ID priority transmit mode or mailbox number transmit mode can be selected. All mailboxes are set for either ID priority transmission or mailbox number priority transmission. When the TPM bit is 0, ID priority transmit mode is selected and transmission priority complies with the CAN bus arbitration rule, as defined in the ISO 11898-1 Specifications. In ID priority transmit mode, mailboxes [0] to [63] (in normal mailbox mode), and mailboxes [0] to [55] (in FIFO mailbox mode), and the transmit FIFO are compared for the IDs of mailboxes configured for transmission. If two or more mailbox IDs are the same, the mailbox with the smaller number has higher priority. Only the next message to be transmitted from the transmit FIFO is included in the transmission arbitration. If a transmit FIFO message is being transmitted, the next pending message within the transmit FIFO is included in the transmission arbitration. When the TPM bit is 1, mailbox number transmit mode is selected and the transmit mailbox with the smallest mailbox number has the highest priority. In FIFO mailbox mode, the transmit FIFO has lower priority than normal mailboxes (mailboxes [0] to [55]). 0: ID priority transmit mode 1: Mailbox number priority transmit mode
3	MLM	0	R/W	Message Lost Mode Select Bit*3 The MLM bit specifies the operation when a new message is captured in the unread mailbox. Overwrite mode or overrun mode can be selected. All mailboxes (including the receive FIFO) are set to either overwrite mode or overrun mode. When the MLM bit is "0", all mailboxes are set to overwrite mode and the new message is overwriting the old message. When this bit is "1", all mailboxes are set to overrun mode and the new message is discarded. 0: Overwrite mode 1: Overrun mode

Bit	Symbol	Initial Value	R/W	Description
2, 1	IDFM	00	R/W	ID Format Mode Select Bit*3 The IDFM bit specifies the ID format. 00: Standard ID mode All mailboxes (including FIFO mailboxes) handle only standard IDs. 01: Extended ID mode All mailboxes (including FIFO mailboxes) handle only extended IDs. 10: Mixed ID mode All mailboxes (including FIFO mailboxes) handle both standard IDs and extended IDs. Standard IDs or extended IDs are specified by using the IDE bit in the corresponding mailbox in normal mail box mode. In FIFO mailbox mode, the IDE bit in the corresponding mailbox is used for mailboxes [0] to [55], the IDE bit in registers CiFIDCR0 and CiFIDCR1 is used for the receive FIFO, and the IDE bit in mailbox [56] is used for the transmit FIFO. 11: Do not use this combination
0	MBM	0	R/W	CAN Mailbox Mode Select Bit*3 When the MBM bit is "0" (normal mailbox mode), mailboxes [0] to [63] are configured as transmit or receive mailboxes. When the MBM bit is "1" (FIFO mailbox mode), mailboxes [0] to [55] are configured as transmit or receive mailboxes. Mailboxes [56] to [59] are configured as a transmit FIFO and mailboxes [60] to [63] as a receive FIFO. Transmit data is written into mailbox [56] (mailbox [56] is a window mailbox for the transmit FIFO). Receive data is read from mailbox [60] (mailbox [60] is a window mailbox for the receive FIFO). Table 34.4 lists the Mailbox Configuration. 0: Normal mailbox mode 1: FIFO mailbox mode

Notes:
1. Set the RBOC bit to "1" in bus-off state.
2. Bits RBOC and TSRC are automatically set back to "0" after being set to "1". It should be read as "0".
3. Write to bits BOM, MBM, IDFM, MLM, TPM, and TSPS in CAN reset mode.
4. When bits CANM and SLPM are changed, check the CiSTR register to ensure that the mode has been switched.
5. Write to the SLPM bit in CAN reset mode or CAN halt mode. When rewriting the SLPM bit, set only this bit to "0" or "1".
6. Set the TSRC bit to "1" in CAN operation mode.

Table 34.4 Mailbox Configuration

Mailbox	MBM Bit = "0" (Normal mailbox mode)	MBM Bit = "1" (FIFO mailbox mode)
Mailboxes [0] to [55]	Normal mailbox	Normal mailbox
Mailboxes [56] to [59]		Transmit FIFO
Mailboxes [60] to [63]		Receive FIFO

Notes: Points 1 to 5 below should be considered when the MBM bit is set to "1".

1. Transmit FIFO is controlled by the CiTFCR register.
   The CiMCTLj register of mailboxes [56] to [59] are disabled.
   Registers CiMCTL56 to CiMCTL59 cannot be used.
2. Receive FIFO is controlled by the CiRFCR register.
   The CiMCTLj register of mailboxes [60] to [63] are disabled.
   Registers CiMCTL60 to CiMCTL63 cannot be used.
3. Refer to the CiMIER1 register about the FIFO interrupts.
4. The corresponding bits in the CiMKIVLR register for mailboxes [56] to [63] are disabled. Set 0 to these bits.
5. Transmit/receive FIFOs can be used for both data frames and remote frames.

34.3.2 CANi Clock Select Register (CiCLKR) (i = 0, 1)

CAN0 Clock Select Register (C0CLKR)
CAN1 Clock Select Register (C1CLKR)

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	CCLKS	
Initial	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7 to 2	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
1, 0	CCLKS	0	R/W	CAN Clock Source Select Bits* The CCLKS bits select clock source from among the peripheral clock (clkp1 or clkp2) generated by the PLL frequency synthesizer, and an externally input clock. 00: Peripheral clock (clkp1) 01: Peripheral clock (clkp2) 10: Illegal value 11: Externally input clock

Note: * Write to the CCLKS bit in CAN reset mode.

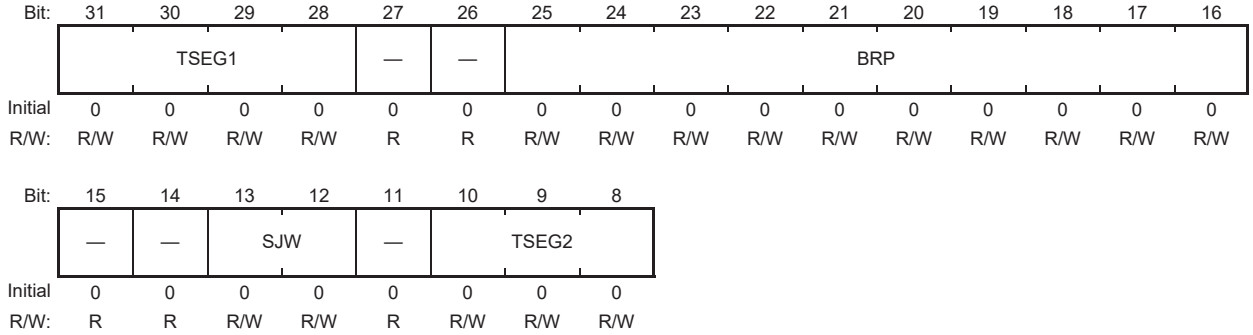
34.3.3 CANi Bit Configuration Register (CiBCR) (i = 0, 1)

For the bit timing configuration rule, refer to section 34.5, CAN Communication Speed Configuration.

Set the CiBCR register before entering CAN halt mode from CAN reset mode or CAN operation mode from CAN reset mode. After the setting is made once, this register can be written to in CAN reset mode or CAN halt mode.

The CiBCR register consists of 24 bits. A 32-bit read/write access should be performed carefully not to rewrite the CiCLKR register.

CAN0 Bit Configuration Register (C0BCR)
CAN1 Bit Configuration Register (C1BCR)



<After Reset: H'000000>

Bit	Symbol	Initial Value	R/W	Description
31 to 28	TSEG1	0000	R/W	Time Segment 1 Control Bits The TSEG1 bit is used to specify the total length of the propagation time segment (PROP_SEG) and phase buffer segment 1 (PHASE_SEG1) with the value of Tq. A value from 4 to 16 time quanta can be set. 0000: Do not use this combination 0001: Do not use this combination 0010: Do not use this combination 0011: 4 Tq 0100: 5 Tq 0101: 6 Tq 0110: 7 Tq 0111: 8 Tq 1000: 9 Tq 1001: 10 Tq 1010: 11 Tq 1011: 12 Tq 1100: 13 Tq 1101: 14 Tq 1110: 15 Tq 1111: 16 Tq
27, 26	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.

Bit	Symbol	Initial Value	R/W	Description
25 to 16	BRP	H'000	R/W	Prescaler Division Ratio Set Bits The BRP bit is used to set the peripheral bus clock periods contained in a Time Quantum. If the setting value is P (0 to 1023), the baud rate prescaler divides fCAN by P + 1.
15, 14	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
13, 12	SJW	00	R/W	Resynchronization Jump Width Control Bits The SJW bit is used to specify the resynchronization jump width with the value of Tq. A value from 1 to 4 time quanta can be set. Set the value smaller than or equal to that of the TSEG2 bit. 00: 1 Tq 01: 2 Tq 10: 3 Tq 11: 4 Tq
11	—	0	R	Reserved bit This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to this bit.
10 to 8	TSEG2	000	R/W	Time Segment 2 Control Bits The TSEG2 bit is used to specify the length of phase buffer segment 2 (PHASE_SEG2) with the value of Tq. A value from 2 to 8 time quanta can be set. Set the value smaller than that of the TSEG1 bit. 000: Do not use this combination 001: 2 Tq 010: 3 Tq 011: 4 Tq 100: 5 Tq 101: 6 Tq 110: 7 Tq 111: 8 Tq

34.3.4 CANi Mask Register k (CiMKRk) (i = 0, 1; k = 0 to 9)

For masking the function in FIFO mailbox mode, refer to section 34.7, Acceptance Filtering and Masking Function.

Write to registers CiMKR0 to CiMKR9 in CAN reset mode or CAN halt mode.

CAN0 Mask Register 0 (C0MKR0)
CAN0 Mask Register 1 (C0MKR1)
CAN0 Mask Register 2 (C0MKR2)
:
CAN0 Mask Register 9 (C0MKR9)
CAN1 Mask Register 0 (C1MKR0)
CAN1 Mask Register 1 (C1MKR1)
CAN1 Mask Register 2 (C1MKR2)
:
CAN1 Mask Register 9 (C1MKR9)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	SID											EID

R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EID															
Initial	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

<After Reset: Undefined>

Bit	Symbol	Initial Value	R/W	Description
31 to 29	—	Undefined	R	Reserved bits The reset value is undefined. The write value should be "0". These bits are read as "0" after "0" is written to.
28 to 18	SID	Undefined	R/W	Standard ID Bits The SID bit is the filter mask bit corresponding to the CAN standard ID bit. The SID bit is used to receive both standard ID and extended ID messages. When the SID bit is set to "0", the corresponding SID bit is not compared for the received ID and the mailbox ID. When the SID bit is set to "1", corresponding SID bit compares received ID with mailbox ID. 0: Corresponding SID bit is not compared 1: Corresponding SID bit is compared
17 to 0	EID	Undefined	R/W	Extended ID Bits The EID bit is the filter mask bit for CAN extended ID bit. This bit is used to receive extended ID messages. When the EID bit is set to "0", corresponding EID bit does not compare received ID with mailbox ID. When the EID bit is set to "1", corresponding EID bit compares received ID with mailbox ID. 0: Corresponding EID bit is not compared 1: Corresponding EID bit is compared

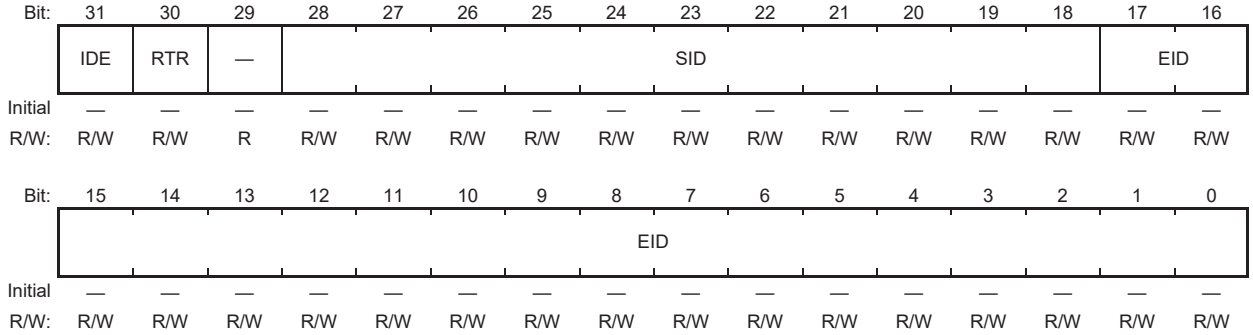
34.3.5 CANi FIFO Received ID Compare Registers (CiFIDCR0 and CiFIDCR1) (i = 0, 1)

Registers CiFIDCR0 and CiFIDCR1 are enabled when the MBM bit in the CiCTLR register is set to "1" (FIFO mailbox mode). Bits EID, SID, RTR, and IDE in registers CiMB60 to CiMB63 are disabled.

For the usage of these registers, refer to section 34.7, Acceptance Filtering and Masking Function.

Write to registers CiFIDCR0 and CiFIDCR1 in CAN reset mode or CAN halt mode.

CAN0 FIFO Received ID Compare Register 0 (C0FIDCR0)
CAN0 FIFO Received ID Compare Register 1 (C0FIDCR1)
CAN1 FIFO Received ID Compare Register 0 (C1FIDCR0)
CAN1 FIFO Received ID Compare Register 1 (C1FIDCR1)



<After Reset: Undefined>

Bit	Symbol	Initial Value	R/W	Description
31	IDE	Undefined	R/W	ID Extension Bit* The IDE bit sets the ID format to standard ID or extended ID. The IDE bit is enabled when the IDFM bit in the CiCTLR register is "10" (mixed ID mode). When the IDFM bit is "10", the IDE bit specifies the following operation. When both IDE bits in registers CiFIDCR0 and CiFIDCR1 are set to "0", only standard ID frames can be received. When both IDE bits in registers CiFIDCR0 and CiFIDCR1 are set to "1", only extended ID frames can be received. When the IDE bits in registers CiFIDCR0 and CiFIDCR1 are set to "0" or "1" individually, both standard ID and extended ID frames can be received. 0: Standard ID 1: Extended ID
30	RTR	Undefined	R/W	Remote Transmission Request Bit The RTR bit sets the specified frames format of data frame or remote frames. The RTR bit specifies the following operation. When both RTR bits in registers CiFIDCR0 and CiFIDCR1 are set to "0", only data frames can be received. When both RTR bits in registers CiFIDCR0 and CiFIDCR1 are set to "1", only remote frames can be received. When the RTR bits in registers CiFIDCR0 and CiFIDCR1 are set to "0" or "1" individually, both data frames and remote frames can be received. 0: Data frame 1: Remote frame

Bit	Symbol	Initial Value	R/W	Description
29	—	Undefined	R	Reserved bit The reset value is undefined. The write value should be "0". This bit is read as "0" after "0" is written to.
28 to 18	SID	Undefined	R/W	Standard ID Bits The SID bit sets the standard ID of data frames and remote frames. The SID bit is used to receive both standard ID and extended ID messages. 0: Corresponding SID bit is "0" 1: Corresponding SID bit is "1"
17 to 0	EID	Undefined	R/W	Extended ID Bits The EID bit sets the extended ID of data frames and remote frames. The EID bit is used to receive extended ID messages. 0: Corresponding EID bit is "0" 1: Corresponding EID bit is "1"

Note: * When the IDFM bit is not "10", the IDE bit should be written with "0".

34.3.6 CANi Mask Invalid Registers (CiMKIVLR0 and CiMKIVLR1) (i = 0, 1)

Each bit in registers CiMKIVLR0 and CiMKIVLR1 corresponds to a mailbox. The correspondence between the bits and mailboxes is as follows:

- Bit 0 in the CiMKIVLR0 register corresponds to mailbox 0 (MB0).
- Bit 31 in the CiMKIVLR0 register corresponds to mailbox 31 (MB31).
- Bit 0 in the CiMKIVLR1 register corresponds to mailbox 32 (MB32).
- Bit 31 in the CiMKIVLR1 register corresponds to mailbox 63 (MB63).

When each bit is "1", the acceptance mask for the mailbox corresponding to the bit number is disabled. In this case, a receiving message is stored into mailbox only its ID matches bits SID and EID in the CiMBj register.

Write to registers CiMKIVLR0 and CiMKIVLR1 either in CAN reset mode or CAN halt mode.

CAN0 Mask Invalid Register 0 (C0MKIVLR0)
CAN1 Mask Invalid Register 0 (C1MKIVLR0)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

34.3.7 CANi Mailbox Register j (CiMBj) (i = 0, 1; j = 0 to 63)

Table 34.5 lists the CANi mailbox memory mapping and Table 34.6 lists the CAN data frame construction.

The value after reset of CANi Mailbox is undefined.

Write to the CiMBj register only when the associated CiMCTLj register is "H00" and the corresponding mailbox is not processing an abort request.

Refer to Table 34.5 for detailed addresses.

Table 34.5 CANi Mailbox Memory Mapping (i = 0, 1)

Address		Message Content

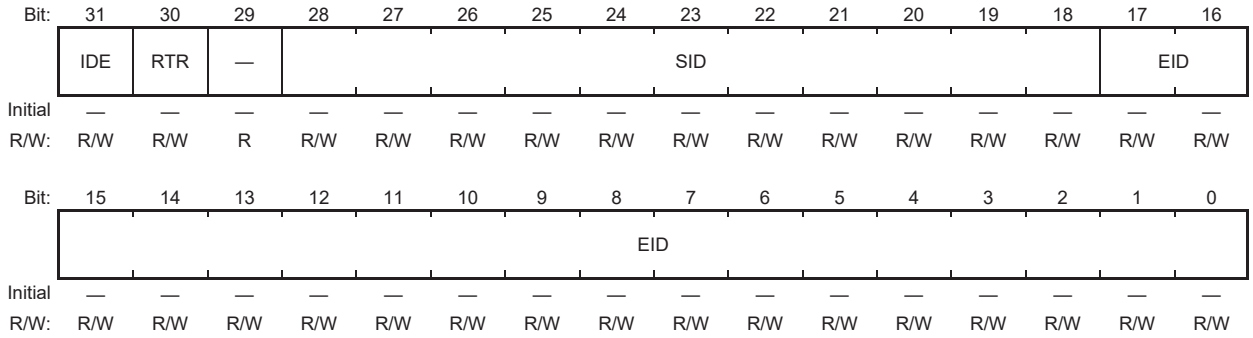
Table 34.6 CAN Data Frame Construction

SID10 to SID6	SID5 to SID0	EID17 to EID16	EID15 to EID8	EID7 to EID0	DLC3 to DLC0	DATA0	DATA1	…	DATA7

The previous value of each mailbox is retained unless a new message is received.

CAN0 Mailbox Register 0 to 63 (C0MB0 to 63)

CAN1 Mailbox Register 0 to 63 (C1MB0 to 63)



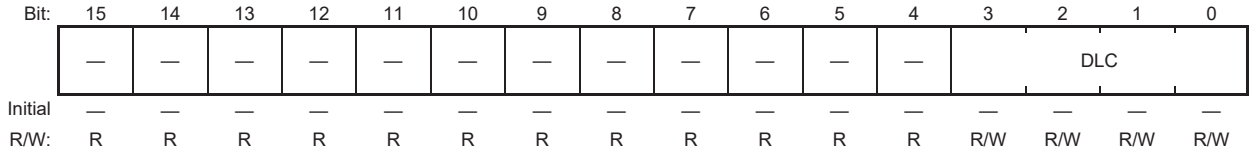
<After Reset: Undefined>

Bit	Symbol	Initial Value	R/W	Description
31	IDE	Undefined	R/W	ID Extension Bit*1 The IDE bit sets the ID format of standard IDs or extended IDs. The IDE bit is enabled when the IDFM bit in the CiCTLR register is "10" (mixed ID mode). When the IDFM bit is "10", the IDE bit specifies the following operation. Receive mailbox receives only ID format specified by the IDE bit. Transmit mailbox transmits with ID format specified by the IDE bit. Receive FIFO mailbox receives messages with the standard ID, extended ID, or both IDs specified by the IDE bit in registers CiFIDCR0 and CiFIDCR1. Transmit FIFO mailbox transmits messages with the standard ID or extended ID specified by the IDE bit in the relevant transmitting message. 0: Standard ID 1: Extended ID
30	RTR	Undefined	R/W	Remote Frame Request Bit The RTR bit sets the frame format of data frames or remote frames. This bit specifies the following operation: Receive mailbox receives only frames with the format specified by the RTR bit. Transmit mailbox transmits according to the frame format specified by the RTR bit. Receive FIFO mailbox receives the data frame, remote frame, or both frames specified by the RTR bit in registers CiFIDCR0 and CiFIDCR1. Transmit FIFO mailbox transmits the data frame or remote frame specified by the RTR bit in the relevant transmitting message. 0: Data frame 1: Remote frame
29	—	Undefined	R	Reserved bit The reset value is undefined. The write value should be "0". This bit is read as "0" after "0" is written to.
28 to 18	SID	Undefined	R/W	Standard ID Bits The SID bit sets the standard ID of data frames and remote frames. The SID bit is used to transmit or receive both standard ID and extended ID messages. 0: Corresponding SID bit is "0" 1: Corresponding SID bit is "1"

Bit	Symbol	Initial Value	R/W	Description
17 to 0	EID	Undefined	R/W	Extended ID Bits*2 The EID bit sets the extended ID of data frames and remote frames. The EID bit is used to transmit or receive extended ID messages. 0: Corresponding EID bit is "0" 1: Corresponding EID bit is "1"

Notes: 1. When the IDFM bit is not "10", it should be written with "0".
2. If the mailbox has received a standard ID message, the EID bit in the mailbox is undefined.

CAN0 Mailbox Register 0 to 63 (C0MB0 to 63)
CAN1 Mailbox Register 0 to 63 (C1MB0 to 63)

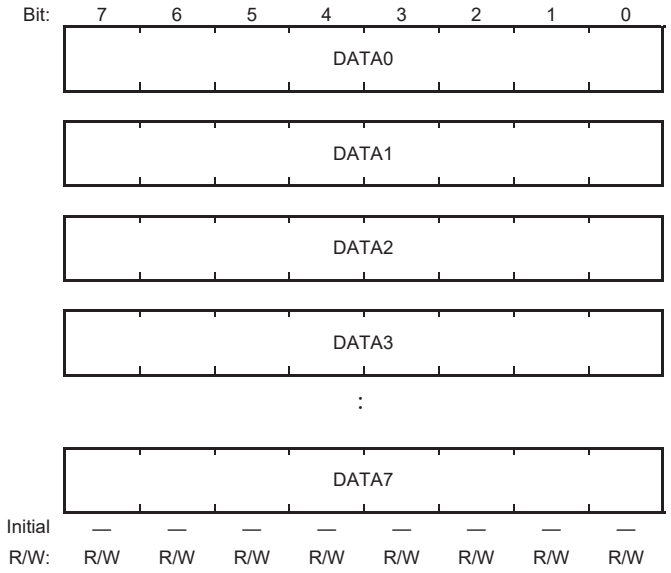


<After Reset: Undefined>

Bit	Symbol	Initial Value	R/W	Description
15 to 4	—	Undefined	R	Reserved bits The reset value is undefined. The write value should be "0". These bits are read as "0" after "0" is written to.
3 to 0	DLC	Undefined	R/W	Data Length Code Bits* The DLC is used to set the number of data bytes to be transmitted in a data frame. When data is requested using a remote frame, the number of data bytes to be requested is set. When a data frame is received, the number of received data bytes is stored. When a remote frame is received, the number of requested data bytes is stored. 0000: Data length = 0 byte 0001: Data length = 1 byte 0010: Data length = 2 bytes 0011: Data length = 3 bytes 0100: Data length = 4 bytes 0101: Data length = 5 bytes 0110: Data length = 6 bytes 0111: Data length = 7 bytes 1xxx: Data length = 8 bytes Legend: *x* represents any value.

Note: * If the mailbox has received a message with n bytes less than 8 bytes, the values of DATAn to DATA7 in the mailbox are undefined.

CAN0 Mailbox Register 0 to 63 (C0MB0 to 63)
CAN1 Mailbox Register 0 to 63 (C1MB0 to 63)

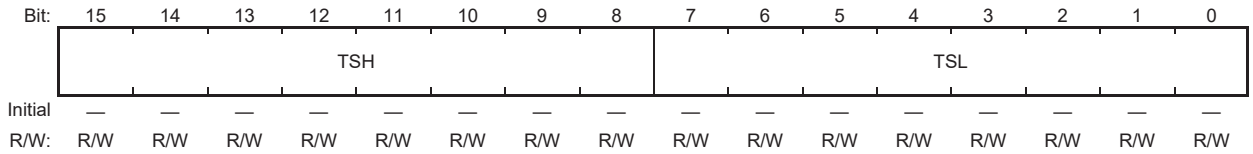


<After Reset: Undefined>

Bit	Symbol	Initial Value	R/W	Description
7 to 0	DATA0 to 7	Undefined	R/W	Data Bytes 0 to 7*1*2 DATA0 to DATA7 store the transmitted or received CAN message data. Transmission or reception starts from DATA0. The bit order on the CAN bus is MSB first, and transmission or reception starts from bit 7.

Notes: 1. If the mailbox has received a message with n bytes less than 8 bytes, the values of DATAn to DATA7 in the mailbox are undefined.
2. If the mailbox has received a remote frame, the previous values of DATA0 to DATA7 in the mailbox are retained.

CAN0 Mailbox Register 0 to 63 (C0MB0 to 63)
CAN1 Mailbox Register 0 to 63 (C1MB0 to 63)



<After Reset: Undefined>

Bit	Symbol	Initial Value	R/W	Description
15 to 8	TSH	Undefined	R/W	Time Stamp Higher Byte TSL and TSH store the counter value of the time stamp when received messages are stored in the mailbox.
7 to 0	TSL	Undefined	R/W	Time Stamp Lower Byte TSL and TSH store the counter value of the time stamp when received messages are stored in the mailbox.

34.3.8 CANi Mailbox Interrupt Enable Registers (CiMIER0 and CiMIER1) (i = 0, 1)

Interrupts can be enabled individually for each mailbox.

In normal mailbox mode (all bits) and in FIFO mailbox mode (bits 23 to 0 in the CiMIER1 register and all bits in the CiMIER0 register), each bit corresponds to the mailbox with the related number. These bits enable or disable transmission/reception complete interrupts for the corresponding mailboxes.

- Bit 0 in the CiMIER0 register corresponds to mailbox 0 (MB0).
- Bit 31 in the CiMIER0 register corresponds to mailbox 31 (MB31).
- Bit 0 in the CiMIER1 register corresponds to mailbox 32 (MB32).
- Bit 31 in the CiMIER1 register corresponds to mailbox 63 (MB63).

In FIFO mailbox mode, bits 29, 28, 25, and 24 of the CiMIER1 register specify whether transmit/receive FIFO interrupts are enabled/disabled and timing when interrupt requests are generated.

Write to registers CiMIER0 and CiMIER1 only when the associated CiMCTLj register (i = 0, 1) (j = 0 to 63) is "H'00" and the corresponding mailbox is not processing a transmission or reception abort request. In FIFO mailbox mode, change the bits in the CiMIER1 register for the associated FIFO only when:

— The TFE bit in the CiTFCR register is 0 and the TFEST bit is 1, and
— The RFE bit in the CiRFCR register is 0 and the RFEST bit is 1.

CAN0 Mailbox Interrupt Enable Register 1 (C0MIER1)
CAN1 Mailbox Interrupt Enable Register 1 (C1MIER1)

R/W:	R	R/W	R	R	R	R/W	R	R/W

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7	TRMREQ	0	R/W	Transmit Mailbox Request Bit*2*4 The TRMREQ bit selects transmit modes shown in Table 34.11. When TRMREQ bit is set to "1", the corresponding mailbox is configured for transmission of a data frame or a remote frame. When TRMREQ bit is set to "0", the corresponding mailbox is not configured for transmission of a data frame or a remote frame. If the TRMREQ bit is changed from "1" to "0" to cancel the corresponding transmission request, either the TRMABT or SENTDATA bit is set to "1". When setting the TRMREQ bit to "1", do not set the RECREQ bit to "1". To change the configuration of a mailbox from reception to transmission, first abort the reception and then set bits NEWDATA and MSGLOST to "0" before changing to transmission. 0: Not configured for transmission 1: Configured for transmission
	—	0	R	Reserved bit (Registers CiMCTL0 to CiMCTL31) This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to this bit.
6	RECREQ	0	R/W	Receive Mailbox Request Bit*2*4*5 The RECREQ bit selects receive modes shown in Table 34.11. When the RECREQ bit is set to "1", the corresponding mailbox is configured for reception of a data frame or a remote frame. When the RECREQ bit is set to "0", the corresponding mailbox is not configured for reception of a data frame or a remote frame. Due to hardware protection the RECREQ bit cannot be set to "0" by writing "0" by a program during the following period. Hardware protection is started From the acceptance filter procedure. (the beginning of CRC field) Hardware protection is released For the mailbox that is specified to receive the incoming message, after the received data is stored into the mailbox or a CAN bus error occurs. (i.e. a maximum period of hardware protection is from the beginning of CRC field to the end of the 7th bit of EOF.) For the other mailboxes, after the acceptance filter procedure. If no mailbox is specified to receive the message, after the acceptance filter procedure. When setting the RECREQ bit to "1", do not set "1" to the TRMREQ bit. To change the configuration of a mailbox from transmission to reception, first abort the transmission and then set bits SENTDATA and TRMABT to "0" before changing to reception. 0: Not configured for reception 1: Configured for reception
5	—	0	R	Reserved bit This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to this bit.

Bit	Symbol	Initial Value	R/W	Description
4	ONESHOT	0	R/W	One-shot Enable Bit*3 The ONESHOT bit can be used in the following two ways, receive mode and transmit mode: One-Shot Receive Mode When the ONESHOT bit is set to "1" in receive mode (RECREQ bit = "1" and TRMREQ bit = "0"), the mailbox receives a message only one time. The mailbox does not behave as a receive mailbox after having received a message one time. The behavior of bits NEWDATA and INVALDATA is the same as in normal reception mode. In one-shot receive mode, the MSGLOST bit is not set to "1". To set the ONESHOT bit to "0", first write "0" to the RECREQ bit and ensure that it has been set to "0". One-Shot Transmit Mode When the ONESHOT bit is set to "1" in transmit mode (RECREQ bit = "0" and TRMREQ bit = "1"), the CAN module transmits a message only one time. The CAN module does not transmit the message again if a CAN bus error or CAN bus arbitration lost occurs. When transmission is completed, the SENTDATA bit is set to "1". If transmission is not completed due to a CAN bus error or CAN bus arbitration lost, the TRMABT bit is set to "1". Set the ONESHOT bit to "0" after the SENTDATA or TRMABT bit is set to "1". 0: One-shot reception or one-shot transmission disabled 1: One-shot reception or one-shot transmission enabled
	—	0	R	Reserved bit (Registers CiMCTL0 to CiMCTL31) This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to this bit.
3	—	0	R	Reserved bit This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to this bit.
2	TRMABT	0	R/W	Transmission Abort Complete Flag (Transmit mailbox setting enabled)*1*2 The TRMABT bit is set to "1" in the following cases: Following a transmission abort request, when the transmission abort is completed before starting transmission. Following a transmission abort request, when the CAN module detects CAN bus arbitration lost or a CAN bus error. In one-shot transmission mode (RECREQ bit = "0", TRMREQ bit = "1", and ONESHOT bit = "1"), when the CAN module detects CAN bus arbitration lost or a CAN bus error. The TRMABT bit is not set to "1" when data transmission is completed. In this case, the SENTDATA bit is set to "1". The TRMABT bit is set to "0" by writing "0" by a program. 0: Transmission has started, transmission abort failed because transmission is completed, or transmission abort is not requested 1: Transmission abort is completed

Bit	Symbol	Initial Value	R/W	Description
	MSGLOST	0	R/W	Message Lost Flag (Receive mailbox setting enabled)*1*2 The MSGLOST bit is set to "1" when the mailbox is overwritten or overrun by a new received message while the NEWDATA bit is "1". The MSGLOST bit is set to "1" at the end of the 6th bit of EOF. The MSGLOST bit is set to "0" by writing "0" by a program. In both overwrite and overrun modes, the MSGLOST bit is not set to "0" by writing "0" by a program during the 5 peripheral clock (clkp1) cycles following the 6th bit of EOF. 0: Message is not overwritten or overrun 1: Message is overwritten or overrun
1	TRMACTIVE	0	R	Transmission-in-Progress Status Flag (Transmit mailbox setting enabled) The TRMACTIVE bit is set to "1" when the corresponding mailbox of the CAN module begins transmitting a message. The TRMACTIVE is set to "0" when the CAN module has lost CAN bus arbitration, a CAN bus error occurs, or data transmission is completed. 0: Transmission is pending or transmission is not requested 1: From acceptance of transmission request to completion of transmission, or error/arbitration lost
	INVALDATA	0	R	Reception-in-Progress Status Flag (Receive mailbox setting enabled) After the completion of a message reception, the INVALDATA bit is set to "1" while the received message is being updated into the corresponding mailbox. The INVALDATA bit is set to "0" immediately after the message has been stored. If the mailbox is read while the INVALDATA bit is "1", the data is undefined. 0: Message valid 1: Message being updated
0	SENTDATA	0	R/W	Transmission Complete Flag (Transmit mailbox setting enabled)*1*2 The SENTDATA bit is set to "1" when data transmission from the corresponding mailbox is completed. The SENTDATA bit is set to "0" by writing "0" by a program. To set the SENTDATA bit to "0", first set the TRMREQ bit to "0". Bits SENTDATA and TRMREQ cannot be set to "0" simultaneously. To transmit a new message from the corresponding mailbox, set the SENTDATA bit to "0". 0: Transmission is not completed (pending) 1: Transmission is completed (success)
	NEWDATA	0	R/W	Reception Complete Flag (Receive mailbox setting enabled)*1*2 The NEWDATA bit is set to "1 when a new message is being stored or has been stored to the mailbox. The timing for setting this bit to "1" is simultaneous with the INVALDATA bit. The NEWDATA bit is set to "0" by writing "0" by a program. The NEWDATA bit is not set to "0" by writing "0" by a program while the related INVALDATA bit is "1". 0: No data has been received or "0" is written to the NEWDATA bit 1: A new message is being stored or has been stored to the mailbox

Notes: 1. Writing "0" only. Writing "1" has no effect.
2. When writing "0" to bits NEWDATA, SENTDATA, MSGLOST, TRMABT, RECREQ, and TRMREQ by a program, only the specified bit is set to "0" and the other bits are set to "1".
3. To enter one-shot receive mode, write "1" to the ONESHOT bit at the same time as setting the RECREQ bit to "1".

To exit one-shot receive mode, write "0" to the ONESHOT bit after writing "0" to the RECREQ bit and confirming it has been set to "0".

To enter one-shot transmit mode, write "1" to the ONESHOT bit at the same time as setting the TRMREQ bit to "1".

To exit one-shot transmit mode, write "0" to the ONESHOT bit after the message has been transmitted or aborted.

4. Do not set both the RECREQ and TRMREQ bits to "1".
5. When setting the RECREQ bit to "0", set bits MSGLOST, NEWDATA, RECREQ to "0" simultaneously.

34.3.10 CANi Receive FIFO Control Register (CiRFCR) (i = 0, 1)

Write to the CiRFCR registers in CAN operation mode or CAN halt mode.

CAN0 Receive FIFO Control Register (C0RFCR)
CAN1 Receive FIFO Control Register (C1RFCR)

Bit:	7	6	5	4	3	2	1	0
	RFEST	RFWST	RFFST	RFMLF	RFUST			RFE
Initial	1	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W

<After Reset: H'80>

Bit	Symbol	Initial Value	R/W	Description
7	RFEST	1	R	Receive FIFO Empty Status Flag The RFEST bit is set to "1" (no unread message in receive FIFO) when the number of unread messages in the receive FIFO is "0". The RFEST bit is set to "1" when the RFE bit is set to "0". The RFEST bit is set to "0" (unread message in receive FIFO) when the number of unread messages in the receive FIFO is one or more. 0: Unread message in receive FIFO 1: No unread message in receive FIFO
6	RFWST	0	R	Receive FIFO Buffer Warning Status Flag The RFWST bit is set to "1" (receive FIFO is buffer warning) when the number of unread messages in the receive FIFO is 3. The RFWST bit is "0" (receive FIFO is not buffer warning) when the number of unread messages in the receive FIFO is less than 3 or equal to 4. The RFWST bit is set to "0" when the RFE bit is "0". 0: Receive FIFO is not buffer warning 1: Receive FIFO is buffer warning (3 unread messages)
5	RFFST	0	R	Receive FIFO Full Status Flag The RFFST bit is set to "1" (receive FIFO is full) when the number of unread messages in the receive FIFO is 4. The RFFST bit is "0" (receive FIFO is not full) when the number of unread messages in the receive FIFO is less than 4. The RFFST bit is set to "0" when the RFE bit is "0". 0: Receive FIFO is not full 1: Receive FIFO full (4 unread messages)
4	RFMLF	0	R	Receive FIFO Message Lost Flag The RFMLF bit is set to "1" (receive FIFO message lost has occurred) when the receive FIFO receives a new message and the receive FIFO is full. The timing for setting this bit to "1" is at the end of the 6th bit of EOF. The RFMLF bit is set to "0" by writing "0" by a program (writing "1" has no effect). In both overwrite and overrun modes, the RFMLF bit cannot be set to "0" (receive FIFO message lost has not occurred) by writing "0" by a program due to hardware protection during the five cycles of peripheral clock (clkp1) following the 6th bit of EOF, if the receive FIFO is full and determined to receive the message. 0: No receive FIFO message lost has occurred 1: Receive FIFO message lost has occurred

Bit	Symbol	Initial Value	R/W	Description
3 to 1	RFUST	000	R	Receive FIFO Unread Message Number Status Flag The RFUST bit indicates the number of unread messages in the receive FIFO. The value of the RFUST bit is initialized to "000" when the RFE bit is set to "0". 000: No unread message 001: 1 unread message 010: 2 unread messages 011: 3 unread messages 100: 4 unread messages 101: Reserved 110: Reserved 111: Reserved
0	RFE	0	R/W	Receive FIFO Enable Bit When the RFE bit is set to "1", the receive FIFO is enabled. When this bit is set to "0", the receive FIFO is disabled for reception and becomes empty (RFEST bit = "1"). Do not set this bit to "1" in normal mailbox mode (MBM bit in the CiCTLR register = "0"). Due to hardware protection, the RFE bit is not set to "0" by writing "0" by a program during the following period: The hardware protection is started From the acceptance filter procedure (the beginning of CRC field) The hardware protection is released If the receive FIFO is specified to receive the incoming message, after the received data is stored into the receive FIFO or a CAN bus error occurs. (i.e. maximum period of hardware protection is from the beginning of CRC field to the end of 7th bit of EOF.) If the receive FIFO is not specified to receive the message, after the acceptance filter procedure. 0: Receive FIFO disabled 1: Receive FIFO enabled

Figure 34.2 shows the receive FIFO mailbox operation.

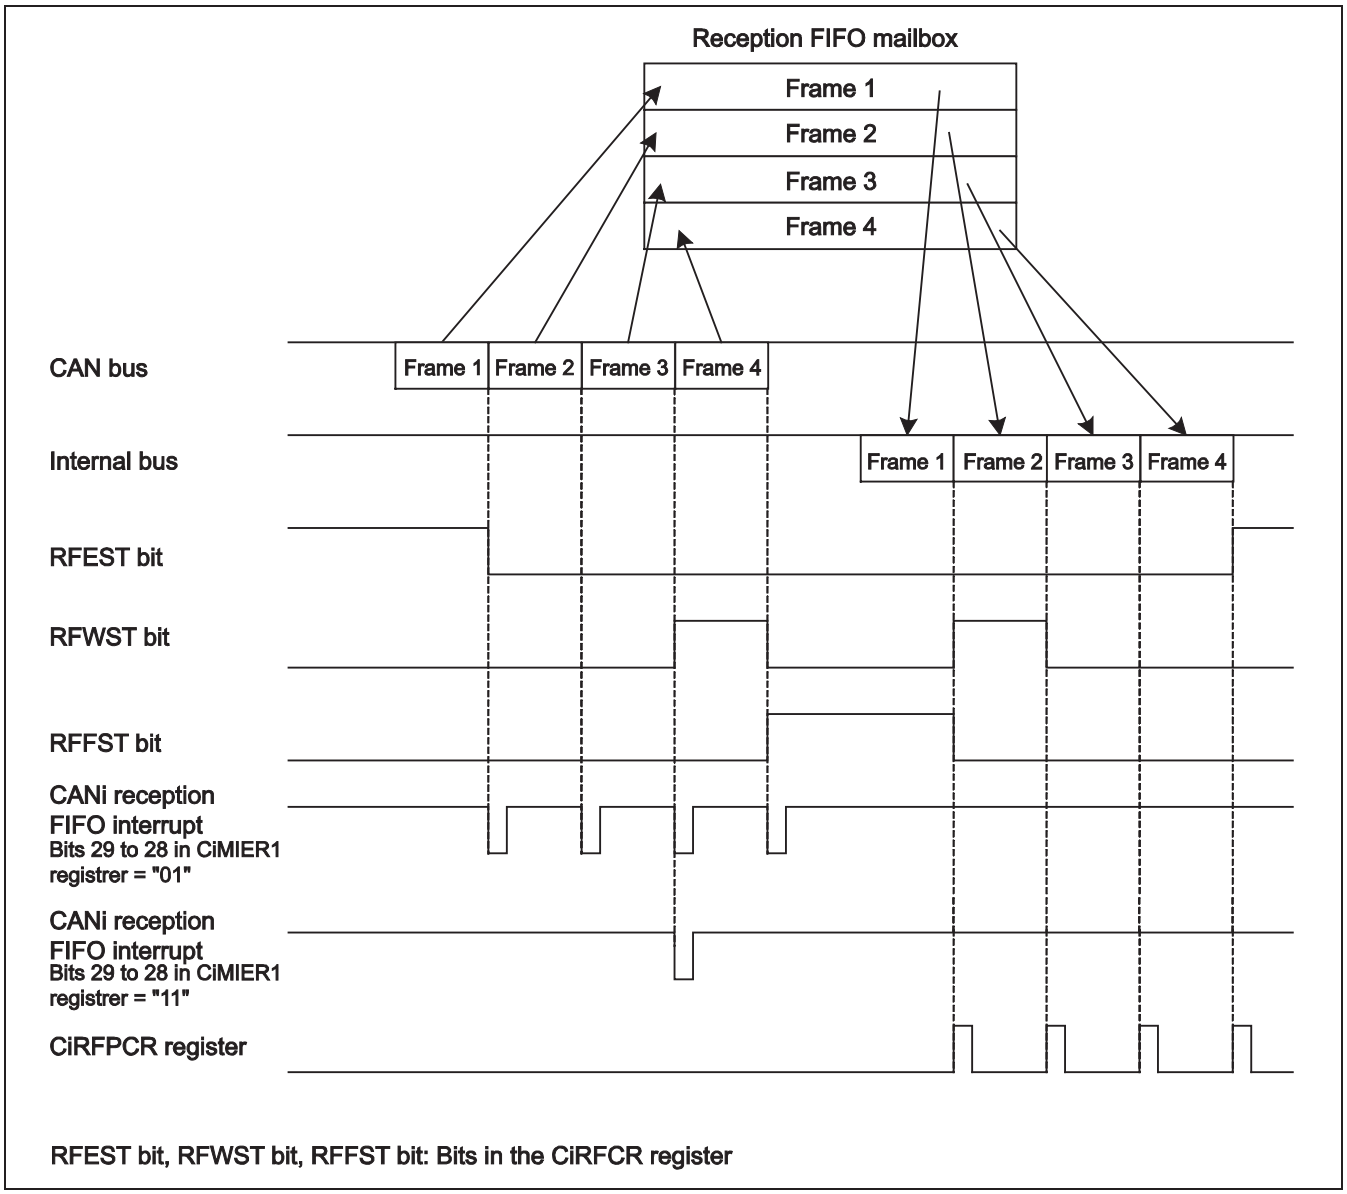

Figure 34.2 Receive FIFO Mailbox Operation
(Bits 29 and 28 in CiMIER1 Register = "01" and "11") (i = 0, 1)

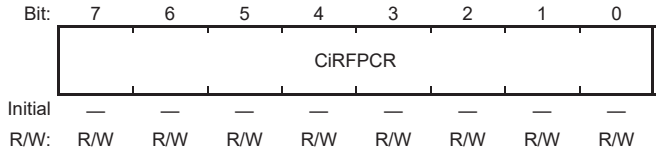
34.3.11 CANi Receive FIFO Pointer Control Register (CiRFPCR) (i = 0, 1)

When the receive FIFO is not empty, write "H'FF" to the CiRFPCR register by a program to increment the CPU-side pointer for the receive FIFO to the next mailbox location.

Do not write to the CiRFPCR register when the RFE bit in the CiRFCR register is "0" (receive FIFO disabled).

Both the CAN-side pointer and the CPU-side pointer are incremented when a new message is received and the RFFST bit is "1" (receive FIFO is full) in overwrite mode. When the RFMLF bit is "1" in this condition, the CPU-side pointer cannot be incremented by writing to the CiRFPCR register by a program.

CAN0 Receive FIFO Pointer Control Register (C0RFPCR)
CAN1 Receive FIFO Pointer Control Register (C1RFPCR)



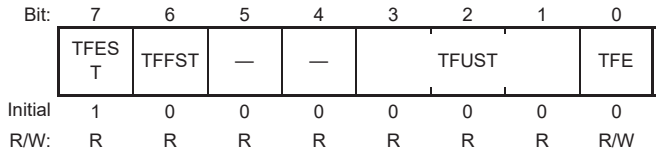
<After Reset: Undefined>

Bit	Symbol	Initial Value	R/W	Description
7 to 0	CiRFPCR	Undefined	R/W	The CPU-side pointer for the receive FIFO is incremented by writing "H'FF"

34.3.12 CANi Transmit FIFO Control Register (CiTFCR) (i = 0, 1)

Write to the CiTFCR register in CAN operation mode or CAN halt mode.

CAN0 Transmit FIFO Control Register (C0TFCR)
CAN1 Transmit FIFO Control Register (C1TFCR)



<After Reset: H'80>

Bit	Symbol	Initial Value	R/W	Description
7	TFEST	1	R	Transmit FIFO Empty Status Bit The TFEST bit is set to "1" (no message in transmit FIFO) when the number of unsent messages in the transmit FIFO is "0". The TFEST bit is set to "1" when transmission from the transmit FIFO has been aborted. The TFEST bit is set to "0" (message in transmit FIFO) when the number of unsent messages in the transmit FIFO is not "0". 0: Unsent message in transmit FIFO 1: No unsent message in transmit FIFO

Bit	Symbol	Initial Value	R/W	Description
6	TFFST	0	R	Transmit FIFO Full Status Bit The TFFST bit is set to "1" (transmit FIFO is full) when the number of unsent messages in the transmit FIFO is 4. The TFFST bit is set to "0" (transmit FIFO is not full) when the number of unsent messages in the transmit FIFO is less than 4. The TFFST bit is set to "0" when transmission from the transmit FIFO has been aborted. 0: Transmit FIFO is not full 1: Transmit FIFO is full (4 unsent messages)
5, 4	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
3 to 1	TFUST	000	R	Transmit FIFO Unsent Message Number Status Bits The TFUST bit indicates the number of unsent messages in the transmit FIFO. After the TFE bit is set to "0", the value of the TFUST bit is initialized to "000" when transmission abort or transmission is completed. 000: No unsent message 001: 1 unsent message 010: 2 unsent messages 011: 3 unsent messages 100: 4 unsent messages 101: Reserved 110: Reserved 111: Reserved
0	TFE	0	R/W	Transmit FIFO Enable Bit When the TFE bit is set to "1", the transmit FIFO is enabled. When the TFE bit is set to "0", the transmit FIFO becomes empty (TFEST bit = "1") and then unsent messages from the transmit FIFO are lost as described below: If a message from the transmit FIFO is not scheduled for the next transmission or during transmission. Following the completion of transmission, a CAN bus error, CAN bus arbitration lost, or entry to CAN halt mode if a message from the transmit FIFO is scheduled for the next transmission or already during transmission. Before setting the TFE bit to set to "1" again, ensure that the TFEST bit has been set to "1". After setting the TFE bit to "1", write transmit data into the CiMB56 register. Do not set the TFE bit to "1" in normal mailbox mode (MBM bit in the CiCTLR register = "0"). 0: Transmit FIFO disabled 1: Transmit FIFO enabled

Figure 34.3 shows the transmit FIFO mailbox operation.

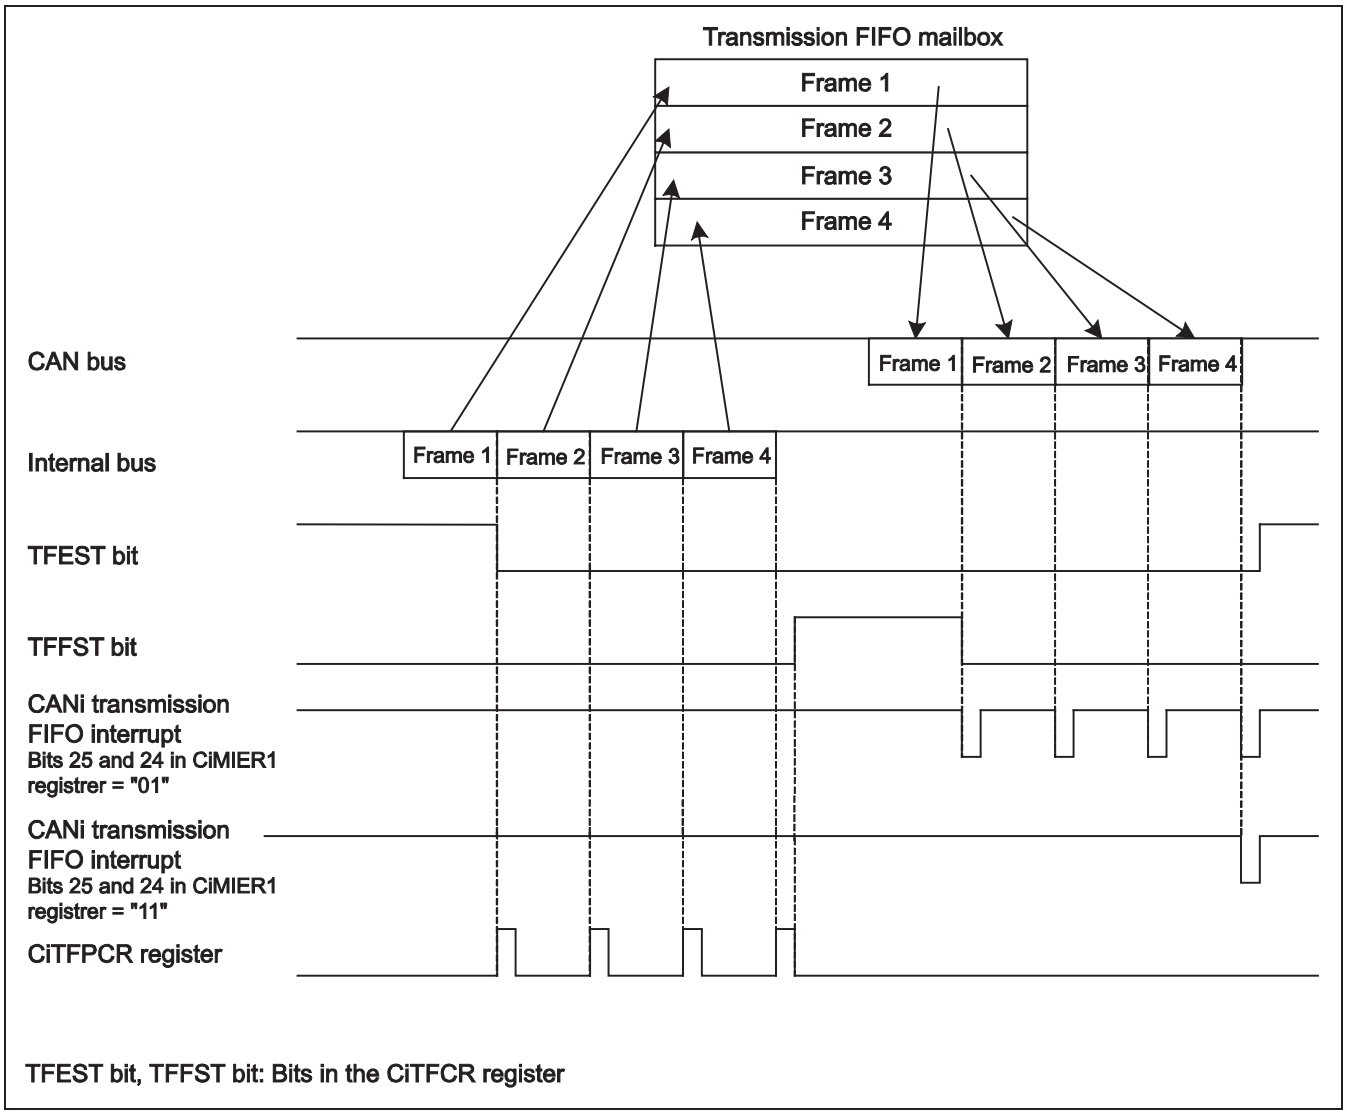


Figure 34.3 Transmit FIFO Mailbox Operation
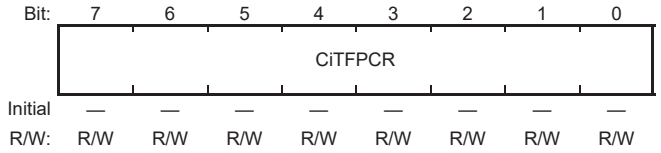
(Bits 25 and 24 in CiMIER1 Register = "01" and "11") (i = 0, 1)

34.3.13 CANi Transmit FIFO Pointer Control Register (CiTFPCR) (i = 0, 1)

When the transmit FIFO is not full, write "H'FF" to the CiTFPCR register by a program to increment the CPU-side pointer for the transmit FIFO to the next mailbox location.

Do not write to the CiTFPCR register when the TFE bit in the CiTFPCR register is "0" (transmit FIFO disabled).

CAN0 Transmit FIFO Pointer Control Register (C0TFPCR)
CAN1 Transmit FIFO Pointer Control Register (C1TFPCR)

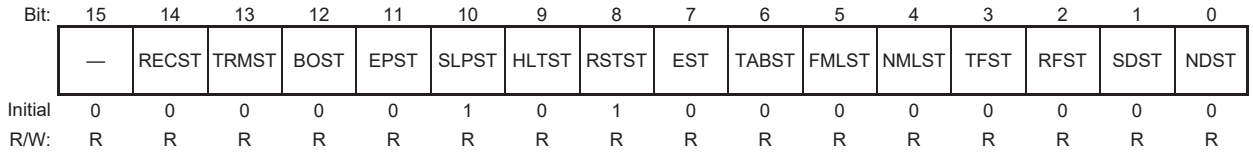


<After Reset: Undefined>

Bit	Symbol	Initial Value	R/W	Description
7 to 0	CiTFPCR	Undefined	R/W	The CPU-side pointer for the transmit FIFO is incremented by writing "H'FF"

34.3.14 CANi Status Register (CiSTR) (i = 0, 1)

CAN0 Status Register (C0STR)
CAN1 Status Register (C1STR)



<After Reset: H'0500>

Bit	Symbol	Initial Value	R/W	Description
15	—	0	R	Reserved bit This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to this bit.
14	RECST	0	R	Receive Status Flag (receiver) The RECST bit is set to "1" when the CAN module performs as a receiver node. The RECST bit is set to "0" when the CAN module performs as a transmitter node or is in bus-idle state. 0: Bus idle or transmission in progress 1: Reception in progress
13	TRMST	0	R	Transmit Status Flag (transmitter) The TRMST bit is set to "1" when the CAN module performs as a transmitter node or is in the bus-off state. The TRMST bit is set to "0" when the CAN module performs as a receiver node or is in bus-idle state. 0: Bus idle or reception in progress 1: Transmission in progress or in bus-off state

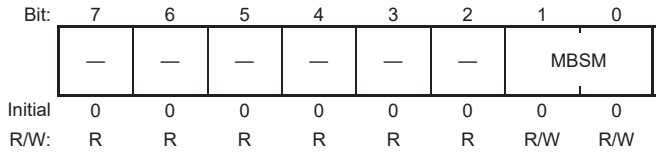
Bit	Symbol	Initial Value	R/W	Description
12	BOST	0	R	Bus-Off Status Flag The BOST bit is set to "1" when the value of the CiTECR register exceeds 255 and the CAN module is in the bus-off state (TEC ≥ 256). The BOST bit is set to "0" when the CAN module is not in the bus-off state. 0: Not in bus-off state 1: In bus-off state
11	EPST	0	R	Error-Passive Status Flag The EPST bit is set to "1" when the value of the CiTECR or CiRECR register exceeds 127 and the CAN module is in error-passive state (128 ≤ TEC < 256 or 128 ≤ REC < 256). The EPST bit is set to "0" when the CAN module is not in the error-passive state. TEC indicates the value of the transmit error counter (CiTECR register) and REC indicates the value of the receive error counter (CiRECR register). 0: Not in error-passive state 1: In error-passive state
10	SLPST	1	R	CAN Sleep Status Flag The SLPST bit is set to "1" when the CAN module is in CAN sleep mode. The SLPST bit is set to "0" when the CAN module is not in CAN sleep mode. 0: Not in CAN sleep mode 1: In CAN sleep mode
9	HLTST	0	R	CAN Halt Status Flag The HLTST bit is set to "1" when the CAN module is in CAN halt mode. The HLTST bit is set to "0" when the CAN module is not in CAN halt mode. Even when the state is changed from CAN halt mode to CAN sleep mode, the HLTST bit remains "1". 0: Not in CAN halt mode 1: In CAN halt mode
8	RSTST	1	R	CAN Reset Status Flag The RSTST bit is set to "1" when the CAN module is in CAN reset mode. The RSTST bit is "0" when the CAN module is not in CAN reset mode. Even when the state is changed from CAN reset mode to CAN sleep mode, the RSTST bit remains "1". 0: Not in CAN reset mode 1: In CAN reset mode
7	EST	0	R	Error Status Flag The EST bit is "1" when at least one error is detected by the CiEIFR register regardless of the value of the CiEIER register. The EST bit is set to "0" when no error is detected by the CiEIFR register. 0: No error occurred 1: Error occurred
6	TABST	0	R	Transmission Abort Status Flag The TABST bit is set to "1" when at least one TRMABT bit in the CiMCTLj register is "1" regardless of the value of the CiMIER register. The TABST bit is set to "0" when all TRMABT bits are "0". 0: No mailbox with TRMABT bit = "1" 1: Mailbox(es) with TRMABT bit = "1"

Bit	Symbol	Initial Value	R/W	Description
5	FMLST	0	R	FIFO Mailbox Message Lost Status Flag The FMLST bit is set to "1" when the RFMLF bit in the CiRFCR register is "1" regardless of the value of the CiMIER register. The FMLST bit is set to "0" when the RFMLF bit is "0". 0: RFMLF bit = "0" 1: RFMLF bit = "1"
4	NMLST	0	R	Normal Mailbox Message Lost Status Flag The NMLST bit is set to "1" when at least one MSGLOST bit in the CiMCTLj register is "1" regardless of the value of the CiMIER register. The NMLST bit is set to "0" when all MSGLOST bit is "0". 0: No mailbox with MSGLOST bit = "1" 1: Mailbox(es) with MSGLOST bit = "1"
3	TFST	0	R	Transmit FIFO Status Flag The TFST bit is set to "1" when the transmit FIFO is not full. The TFST bit is set to "0" when the transmit FIFO is full. The TFST bit is set to "0" when normal mailbox mode is selected. 0: Transmit FIFO is full 1: Transmit FIFO is not full
2	RFST	0	R	Receive FIFO Status Flag The RFST bit is set to "1" when the receive FIFO is not empty. The RFST bit is set to "0" when the receive FIFO is empty. The RFST bit is set to "0" when normal mailbox mode is selected. 0: No message in receive FIFO 1: Message in receive FIFO
1	SDST	0	R	SENTDATA Status Flag The SDST bit is set to "1" when at least one SENTDATA bit in the CiMCTLj register is "1" regardless of the value of the CiMIER register. The SDST bit is set to "0" when all SENTDATA bits are "0". 0: No mailbox with SENTDATA bit = "1" 1: Mailbox(es) with SENTDATA bit = "1"
0	NDST	0	R	NEWDATA Status Flag The NDST bit is set to "1" when at least one NEWDATA bit in the CiMCTLj register is "1" regardless of the value of the CiMIER register. The NDST bit is set to "0" when all NEWDATA bits are "0". 0: No mailbox with NEWDATA bit = "1" 1: Mailbox(es) with NEWDATA bit = "1"

34.3.15 CANi Mailbox Search Mode Register (CiMSMR) (i = 0, 1)

Write to the CiMSMR register in CAN operation mode or CAN halt mode.

CAN0 Mailbox Search Mode Register (C0MSMR)
CAN1 Mailbox Search Mode Register (C1MSMR)



<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7 to 2	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
1, 0	MBSM	00	R/W	Mailbox Search Mode Select Bits The MBSM bit selects the search mode for the mailbox search function. When the MBSM bit is "00", receive mailbox search mode is selected. In this mode, the search targets are the NEWDATA bit in the CiMCTLj register (j = 0 to 63) for the normal mailbox and the RFEST bit in the CiRFCR register. When the MBSM bit is "01", transmit mailbox search mode is selected. In this mode, targets the SENTDATA bit in the CiMCTLj register. When the MBSM bit is "10", message lost search mode is selected. In this mode, targets the MSGLOST bit in the CiMCTLj register for the normal mailbox and the RFMLF bit in the CiRFCR register. When the MBSM bit is "11", channel search mode is selected. In this mode, the search target is the CiCSSR register. Refer to section 34.3.17, CANi Channel Search Support Register (CiCSSR) (i = 0, 1). 00: Receive mailbox search mode 01: Transmit mailbox search mode 10: Message lost search mode 11: Channel search mode

34.3.16 CANi Mailbox Search Status Register (CiMSSR) (i = 0, 1)

CAN0 Mailbox Search Status Register (C0MSSR)
CAN1 Mailbox Search Status Register (C1MSSR)

Bit:	7	6	5	4	3	2	1	0
	SEST	—	MBNST					
Initial	1	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

<After Reset: H'80>

Bit	Symbol	Initial Value	R/W	Description
7	SEST	1	R	Search Result Status Bit The SEST bit is set to "1" when no corresponding mailbox is found after searching all mailboxes. For example, in transmit mailbox search mode, the SEST bit is set to "1" when no SENTDATA bit for mailboxes is "1". The SEST bit is set to "0" when at least one SENTDATA bit is "1". When the SEST bit is "1", the value of the MBNST bits is undefined. 0: Search result found 1: No search result
6	—	0	R	Reserved bit This bit is always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to this bit.
5 to 0	MBNST	000000	R	Search Result Mailbox Number Status Bits The MBNST bit outputs the smallest mailbox number that is searched in each mode of the CiMSMR register. In receive mailbox, transmit mailbox, and message lost search modes, the value of the mailbox i.e., the search result to be output, is updated as described below: When the NEWDATA, SENTDATA or MSGLOST bit for the output mailbox is set to "0". When the NEWDATA, SENTDATA or MSGLOST bit for a higher-priority mailbox is set to "1". In receive mailbox search and message lost search modes, the receive FIFO (mailbox [60]) is output when the receive FIFO is not empty and there are no unread received messages or no lost messages in any of the normal mailboxes (mailboxes [0] to [55]). In transmit mailbox search mode, the transmit FIFO (mailbox [56]) is not output. Table 34.7 lists the behavior of MBNST bit in FIFO mailbox mode. In channel search mode, the MBNST bit outputs the corresponding channel number. After the CiMSSR register is read by a program, the next target channel number is output.

Table 34.7 Operation of MBNST Bit in FIFO Mailbox Mode

MBSM Bit	Mailbox [56] (Transmit FIFO)	Mailbox [60] (Receive FIFO)
"00"	Mailbox [56] is not output.	Mailbox [60] is output when no NEWDATA bit for the normal mailbox is set to "1" and the receive FIFO is not empty.
"01"		Mailbox [60] is not output.
"10"		Mailbox [60] is output when no MSGLOST bit for the normal mailbox is set to "1" and the RFMLF bit is set to "1" (receive FIFO message lost has occurred) in the receive FIFO.
"11"		Mailbox [60] is not output.

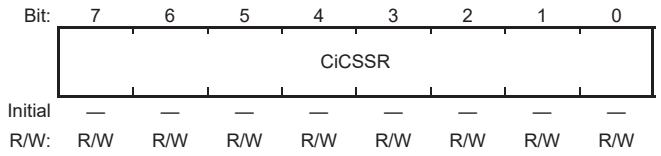
34.3.17 CANi Channel Search Support Register (CiCSSR) (i = 0, 1)

The bits in the CiCSSR register, which are set to "1", are encoded by an 8/3 encoder (the lower bit position, the higher priority) and output to the MBNST bits in the CiMSSR register.

The CiMSSR register outputs the updated value whenever the CiMSSR register is read by a program.

Write to the CiCSSR register only when the MBSM bit in the CiMSMR register is "11" (channel search mode). Write to this register in CAN operation mode or CAN halt mode.

CAN0 Channel Search Support Register (C0CSSR)
CAN1 Channel Search Support Register (C1CSSR)



<After Reset: Undefined>

Bit	Symbol	Initial Value	R/W	Description
7 to 0	CiCSSR	Undefined	R/W	When the value for the channel search is input, the channel number is output to the CiMSSR register.

Figure 34.4 shows the write and read of registers CiCSSR and CiMSSR.

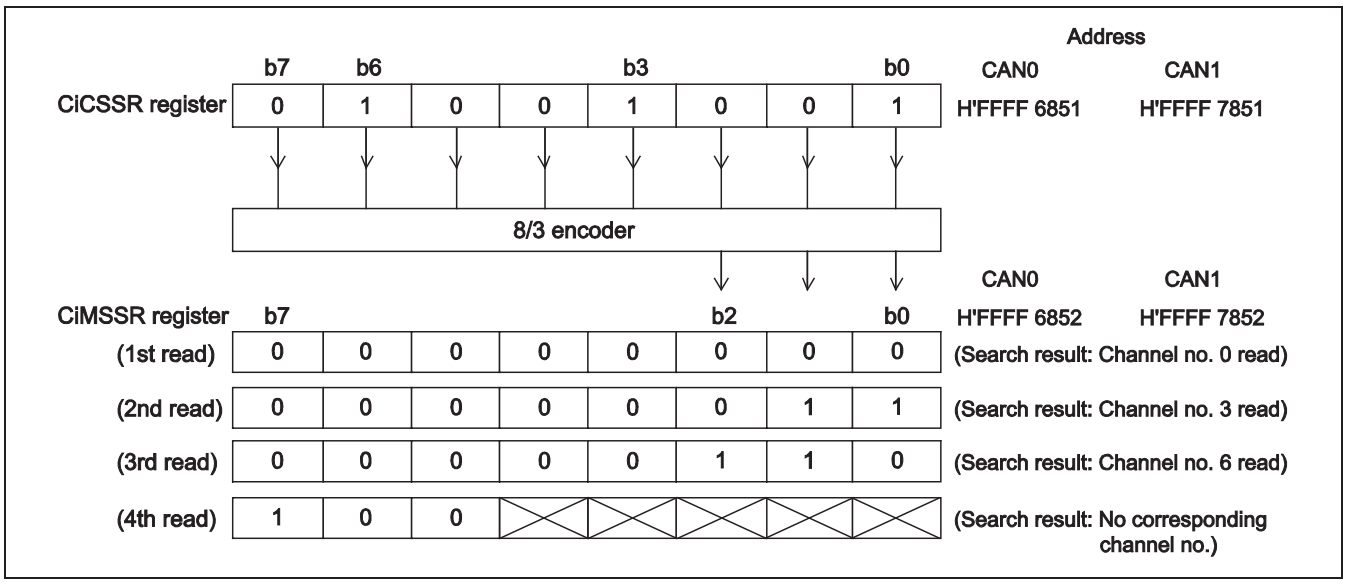


Figure 34.4 Write and Read of Registers CiCSSR and CiMSSR (i = 0, 1)

The value of the CiCSSR register is also updated whenever the CiMSSR register is read. When the CiCSSR register is read, the value before the 8/3 encoder conversion is read.

34.3.18 CANi Acceptance Filter Support Register (CiAFSR) (i = 0, 1)

The acceptance filter support unit (ASU) can be used for data table (8 bits × 256) search. In the data table, all standard IDs created by the user are set to be valid/invalid in bit units. When the CAFSR register is written with the 16-bit unit data including the SID bit in the CiMBj register (j = 0 to 63), in which a received ID is stored, a decoded row (byte offset) position and column (bit) position for data table search can be read. The ASU can be used for standard (11-bit) IDs only.

The ASU is enabled in the following cases:

- When the ID to receive cannot be masked by the acceptance filter.
  (Example) IDs to receive: H'078, H'087, H'111
- When there are too many IDs to receive and software filtering time is expected to be shortened.

Write to the CiAFSR register in CAN operation mode or CAN halt mode.

CAN0 Acceptance Filter Support Register (C0AFSR)
CAN1 Acceptance Filter Support Register (C1AFSR)

Bit	Symbol	Initial Value	R/W	Description
15 to 0	CiAFSR	Undefined	R/W	After the standard ID of a received message is written, the value converted for data table search can be read.

Figure 34.5 shows the write and read of CiAFSR register.

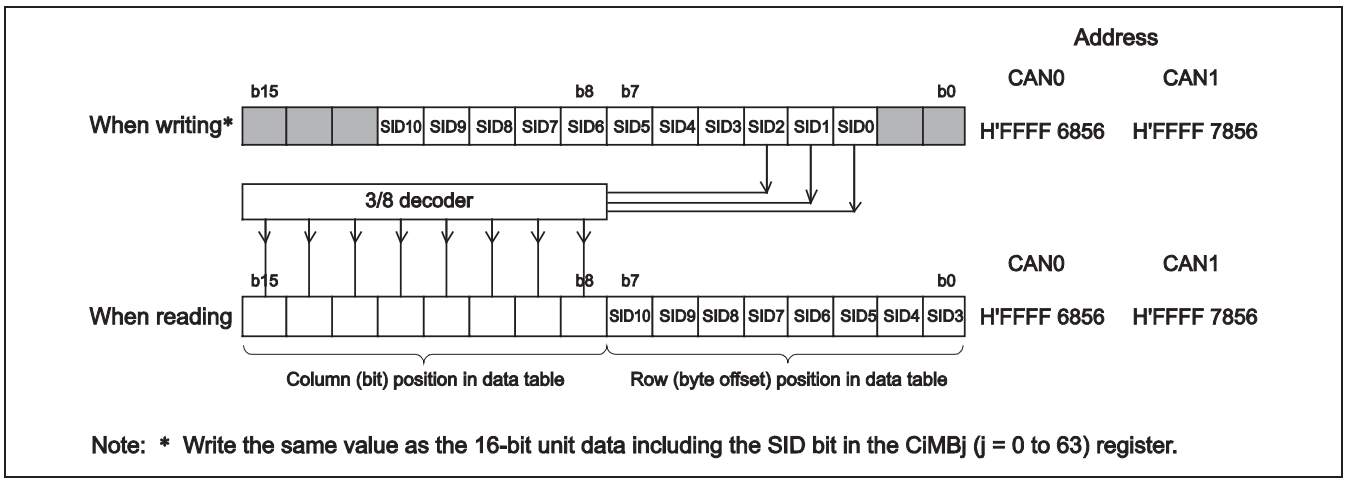

Figure 34.5 Write and Read of CiAFSR Register (i = 0, 1)

34.3.19 CANi Error Interrupt Enable Register (CiEIER) (i = 0, 1)

The CiEIER register is used to set the error interrupt enabled/disabled individually for each error interrupt source in the CiEIFR register.

Write to the CiEIER register in CAN reset mode.

CAN0 Error Interrupt Enable Register (C0EIER)
CAN1 Error Interrupt Enable Register (C1EIER)

Bit:	7	6	5	4	3	2	1	0
	BLIE	OLIE	ORIE	BORIE	BOEIE	EPIE	EWIE	BEIE

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7	BLIE	0	R/W	Bus Lock Interrupt Enable Bit When the BLIE bit is "0", no error interrupt request is generated even if the BLIF bit in the CiEIFR register is set to "1". When the BLIE bit is "1", an error interrupt request is generated if the BLIF bit is set to "1". 0: Bus lock interrupt disabled 1: Bus lock interrupt enabled
6	OLIE	0	R/W	Overload Frame Transmit Interrupt Enable Bit When the OLIE bit is "0", no error interrupt request is generated even if the OLIF bit in the CiEIFR register is set to "1". When the OLIE bit is "1", an error interrupt request is generated if the OLIF bit is set to "1". 0: Overload frame transmit interrupt disabled 1: Overload frame transmit interrupt enabled
5	ORIE	0	R/W	Receive Overrun Interrupt Enable Bit When the ORIE bit is "0", an error interrupt request is not generated even if the ORIF bit in the CiEIFR register is set to "1". When the ORIE bit is "1", an error interrupt request is generated if the ORIF bit is set to "1". 0: Receive overrun interrupt disabled 1: Receive overrun interrupt enabled
4	BORIE	0	R/W	Bus-Off Recovery Interrupt Enable Bit When the BORIE bit is "0", an error interrupt request is not generated even if the BORIF bit in the CiEIFR register is set to "1". When the BORIE bit is set to "1", an error interrupt request is generated if the BORIF bit is set to "1". 0: Bus-off recovery interrupt disabled 1: Bus-off recovery interrupt enabled
3	BOEIE	0	R/W	Bus-Off Entry Interrupt Enable Bit When the BOEIE bit is "0", no error interrupt request is generated even if the BOEIF bit in the CiEIFR register is set to "1". When the BOEIE bit is "1", an error interrupt request is generated if the BOEIF bit is set to "1". 0: Bus-off entry interrupt disabled 1: Bus-off entry interrupt enabled

Bit	Symbol	Initial Value	R/W	Description
2	EPIE	0	R/W	Error-Passive Interrupt Enable Bit When the EPIE bit is "0", no error interrupt request is generated even if the EPIF bit in the CiEIFR register is set to "1". When the EPIE bit is "1", an error interrupt request is generated if the EPIF bit is set to "1". 0: Error-passive interrupt disabled 1: Error-passive interrupt enabled
1	EWIE	0	R/W	Error-Warning Interrupt Enable Bit When the EWIE bit is "0", no error interrupt request is generated even if the EWIF bit in the CiEIFR register is set to "1". When the EWIE bit is "1", an error interrupt request is generated if the EWIF bit is set to "1". 0: Error-warning interrupt disabled 1: Error-warning interrupt enabled
0	BEIE	0	R/W	Bus Error Interrupt Enable Bit When the BEIE bit is "0", no error interrupt request is generated even if the BEIF bit in the CiEIFR register is set to "1". When the BEIE bit is "1", an error interrupt request is generated if the BEIF bit is set to "1". 0: Bus error interrupt disabled 1: Bus error interrupt enabled

34.3.20 CANi Error Interrupt Factor Judge Register (CiEIFR) (i = 0, 1)

If an event corresponding to each bit occurs, the corresponding bit in the CiEIFR register is set to "1" regardless of the setting of the CiEIER register.

To set each bit to "0", write "0" by a program. If the set timing occurs simultaneously with the clear timing by the program, the bit becomes "1".

When writing "0" to a single bit by a program, only the specified bit is set to "0" and the other bits are set to "1". Writing "1" has no effect to these bit values.

CAN0 Error Interrupt Factor Judge Register (C0EIFR)
CAN1 Error Interrupt Factor Judge Register (C1EIFR)

Bit:	7	6	5	4	3	2	1	0
	BLIF	OLIF	ORIF	BORIF	BOEIF	EPIF	EWIF	BEIF
Initial	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7	BLIF	0	R/W	Bus Lock Detect Flag* The BLIF bit becomes 1 if 32 consecutive dominant bits are detected on the CAN bus while the CAN module is in CAN operation mode. After the BLIF bit becomes 1, bus lock can be detected again after either of the following conditions is satisfied: • After this bit is set to 0 from 1, recessive bits are detected (bus lock is resolved). • After this bit is set to 0 from 1, the CAN module enters CAN reset mode and then enters CAN operation mode again (internal reset).0: No bus lock detected 1: Bus lock detected
6	OLIF	0	R/W	Overload Frame Transmission Detect Flag* The OLIF bit is set to "1" if the transmitting condition of an overload frame is detected when the CAN module performs transmission or reception. 0: No overload frame transmission detected 1: Overload frame transmission detected
5	ORIF	0	R/W	Receive Overrun Detect Flag* The ORIF bit is set to "1" when a receive overrun occurs. This bit is not to set to "1" in overwrite mode. In overwrite mode, a reception complete interrupt request is generated if an overwrite condition occurs and the ORIF bit is not set to "1". In normal mailbox mode, if an overrun occurs in any of mailboxes [0] to [63] in overrun mode, this bit is set to "1". In FIFO mailbox mode, if an overrun occurs in any of mailboxes [0] to [55] or the receive FIFO in overrun mode, this bit is set to "1". 0: No receive overrun detected 1: Receive overrun detected

Bit	Symbol	Initial Value	R/W	Description
4	BORIF	0	R/W	Bus-Off Recovery Detect Flag* The BORIF bit is set to "1" when the CAN module recovers from the bus-off state normally by detecting 11 consecutive bits 128 times in the following conditions: When the BOM bit in the CiCTLR register is "00". When the BOM bit is "10". When the BOM bit is "11". The BORIF bit is not set to "1" if the CAN module recovers from the bus-off state in the following conditions: When the CANM bit in the CiCTLR register is set to "01" or "11" (CAN reset mode). When the RBOC bit in the CiCTLR register is set to "1" (forcible return from bus-off). When the BOM bit is "01". When the BOM bit is "11" and the CANM bit is set to "10" (CAN halt mode) before normal recovery occurs. 0: No bus-off recovery detected 1: Bus-off recovery detected
3	BOEIF	0	R/W	Bus-Off Entry Detect Flag* The BOEIF bit is set to "1" when the CAN error state becomes bus-off (the TEC value exceeds 255). The BOEIF bit is also set to "1" when the BOM bit in the CiCTLR register is "01" (entry to CAN halt mode automatically at bus-off entry) and the CAN module becomes the bus-off state. 0: No bus-off entry detected 1: Bus-off entry detected
2	EPIF	0	R/W	Error Passive Detect Flag* The EPIF bit is set to "1" when the CAN error state becomes error-passive (the REC or TEC value exceeds 127). The EPIF bit is set to "1" only when the REC or TEC initially exceeds 127. Thus, if "0" is written to the EPIF bit by a program while the REC or TEC remains greater than 127, the EPIF bit is not set to "1" until the REC and TEC goes below 127 and then exceeds 127 again. 0: No error passive detected 1: Error passive detected
1	EWIF	0	R/W	Error Warning Detect Flag* The EWIF bit is set to "1" when the value of the receive error counter (REC) or transmit error counter (TEC) exceeds 95. The EWIF bit is set to "1" only when the REC or TEC initially exceeds 95. Thus, if "0" is written to the EWIF bit by a program while the REC or TEC remains greater than 95, the EWIF bit is not set to "1" until the REC and TEC goes below 95 and then exceeds 95 again. 0: No error warning detected 1: Error warning detected
0	BEIF	0	R/W	Bus Error Detect Flag* The BEIF bit is set to "1" when a bus error is detected. 0: No bus error detected 1: Bus error detected

Note: * Only "0" may be written to this bit. (Writing "1" has no effect.) When writing "0" to specific bits in software, write "0" to each bit to be cleared to "0" and "1" to all other bits.

Table 34.8 lists the behavior of bits BOEIF and BORIF according to BOM bit setting value.

Table 34.8 Behavior of Bits BOEIF and BORIF according to BOM Bit Setting Value

BOM Bit	BOEIF Bit	BORIF Bit
00	Set to "1" on entry to the bus-off state.	Set to "1" on exit from the bus-off state.
01		Do not set to "1".
10		Set to "1" on exit from the bus-off state.
11		Set to "1" if normal bus-off recovery occurs before the CANM bit is set to "10" (CAN halt mode).

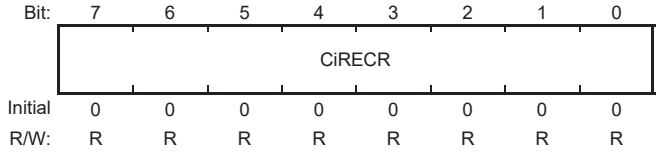
34.3.21 CANi Receive Error Count Register (CiRECR) (i = 0, 1)

The CiRECR register indicates the value of the receive error counter.

For the increment/decrement conditions of the receive error counter, refer to the CAN Specifications (ISO11898-1).

The value in bus-off state is undefined.

CAN0 Receive Error Count Register (C0RECR)
CAN1 Receive Error Count Register (C1RECR)



<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7 to 0	CiRECR	H'00	R	Receive Error Count Function The CiRECR register increments or decrements the counter value according to error status of the CAN module during reception.

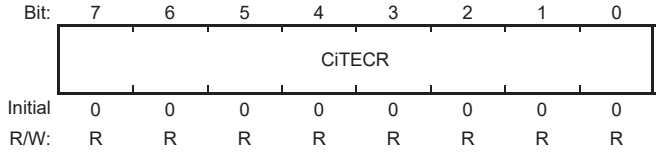
34.3.22 CANi Transmit Error Count Register (CiTECR) (i = 0, 1)

The CiTECR register indicates the value of the transmit error counter.

For the increment/decrement conditions of the transmit error counter, refer to the CAN Specifications (ISO11898-1).

The value in bus-off state is undefined.

CAN0 Transmit Error Count Register (C0TECR)
CAN1 Transmit Error Count Register (C1TECR)



<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7 to 0	CiTECR	H'00	R	Transmit Error Count Function The CiTECR register increments or decrements the counter value according to error status of the CAN module during transmission.

34.3.23 CANi Error Code Store Register (CiECSR) (i = 0, 1)

The CiECSR register can be used to monitor whether an error has occurred on the CAN bus. Refer to the CAN Specifications (ISO11898-1) to check the generation conditions of each error.

To set each bit except the EDPM bit to "0", write "0" by a program. If the timing at which each bit is set to "1" and the timing at which "0" is written by a program are the same, the relevant bit is set to "1".

CAN0 Error Code Store Register (C0ECSR)
CAN1 Error Code Store Register (C1ECSR)

Bit:	7	6	5	4	3	2	1	0
	EDPM	ADEF	BE0F	BE1F	CEF	AEF	FEF	SEF
Initial	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7	EDPM	0	R/W	Error Display Mode Select Bit*1*2 The EDPM bit selects the output mode of the CiECSR register. When the EDPM bit is set to "0", the CiECSR register outputs the first error code. When the EDPM bit is set to "1", the CiECSR register outputs the accumulated error code. 0: Output of first detected error code 1: Output of accumulated error code
6	ADEF	0	R/W	ACK Delimiter Error Flag*3*4 The ADEF bit is set to "1" when a form error is detected with the ACK delimiter during transmission. 0: No ACK delimiter error detected 1: ACK delimiter error detected
5	BE0F	0	R/W	Bit Error (dominant) Flag*3*4 The BE0F bit is set to "1" when a dominant bit error is detected. 0: No bit error (dominant) detected 1: Bit error (dominant) detected
4	BE1F	0	R/W	Bit Error (recessive) Flag*3*4 The BE1F bit is set to "1" when a recessive bit error is detected. 0: No bit error (recessive) detected 1: Bit error (recessive) detected
3	CEF	0	R/W	CRC Error Flag*3*4 The CEF bit is set to "1" when a CRC error is detected. 0: No CRC error detected 1: CRC error detected
2	AEF	0	R/W	ACK Error Flag*3*4 The AEF bit is set to "1" when an ACK error is detected. 0: No ACK error detected 1: ACK error detected

Bit	Symbol	Initial Value	R/W	Description
1	FEF	0	R/W	Form Error Flag*3*4 The FEF bit is set to "1" when a form error is detected. 0: No form error detected 1: Form error detected
0	SEF	0	R/W	Stuff Error Flag*3*4 The SEF bit is set to "1" when a stuff error is detected. 0: No stuff error detected 1: Stuff error detected

Notes: 1. Write to the EDPM bit in CAN reset mode or CAN halt mode.
2. If more than one error condition is detected simultaneously, all related bits are set to "1".
3. Writing "1" has no effect to these bit values.
4. When writing "0" to bits SEF, FEF, AEF, CEF, BE1F, BE0F, and ADEF by a program, only the specified bit is set to "0" and the other bits are set to "1".

34.3.24 CANi Time Stamp Register (CiTSR) (i = 0, 1)

When the CiTSR register is read, the value of the time stamp counter (16-bit free-running counter) at that moment is read.

The value of the time stamp counter reference clock is a multiple of 1 bit time, as configured by the TSPS bit in the CiCTLR register.

The time stamp counter stops in CAN sleep mode and CAN halt mode, and is initialized in CAN reset mode.

The time stamp counter value is stored to TSL and TSH in the CiMBj register when a received message is stored in a receive mailbox.

CAN0 Time Stamp Register (C0TSR)
CAN1 Time Stamp Register (C1TSR)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

<After Reset: H'0000>

Bit	Symbol	Initial Value	R/W	Description
15 to 0	CiTSR	All 0	R	Free-running counter value for the time stamp function

Note: Read the CiTSR register in 16-bit units.

34.3.25 CANi Test Control Register (CiTCR) (i = 0, 1)

Write to the CiTCR register in CAN halt mode only.

CAN0 Test Control Register (C0TCR)
CAN1 Test Control Register (C1TCR)

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	TSTM		TSTE
Initial	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7 to 3	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
2, 1	TSTM	00	R/W	CAN Test Mode Select Bits The TSTM bit selects the CAN test mode. For details on the CAN test modes, see section 34.3.25 (1), Listen-Only Mode, section 34.3.25 (2), Self-Test Mode 0 (External Loop Back), and section 34.3.25 (3), Self-Test Mode 1 (Internal Loop Back). 00: Other than CAN test mode 01: Listen-only mode 10: Self-test mode 0 (external loop back) 11: Self-test mode 1 (internal loop back)
0	TSTE	0	R/W	CAN Test Mode Enable Bit When the TSTE bit is set to "0", CAN test mode is disabled. When the TSTE bit is set to "1", CAN test mode is enabled. 0: CAN test mode disabled 1: CAN test mode enabled

(1) Listen-Only Mode

The ISO 11898-1 recommends an optional bus monitoring mode. In listen-only mode, the CAN node is able to receive valid data frames and valid remote frames. It sends only recessive bits on the CAN bus, and the protocol controller is not required to send the ACK bit, overload flag, or active error flag.

Listen-only mode can be used for baud rate detection.

Do not request transmission from any mailboxes in this mode.

Figure 34.6 shows the connection when listen-only mode is selected.

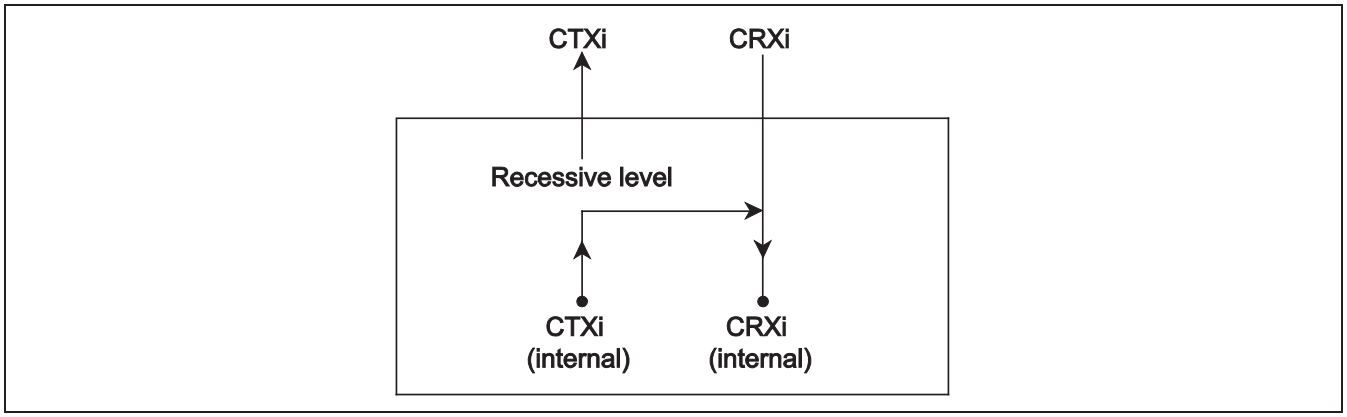

Figure 34.6 Connection when Listen-Only Mode is Selected

(2) Self-Test Mode 0 (External Loop Back)

Self-test mode 0 is provided for CAN transceiver tests.

In this mode, the protocol controller treats its own transmitted messages as messages received via the CAN transceiver and stores them into the receive mailbox. To be independent from external stimulation, the protocol controller generates the ACK bit.

Connect the CANi_TX/CANi_RX pins to the transceiver.

Figure 34.7 shows the connection when self-test mode 0 is selected.

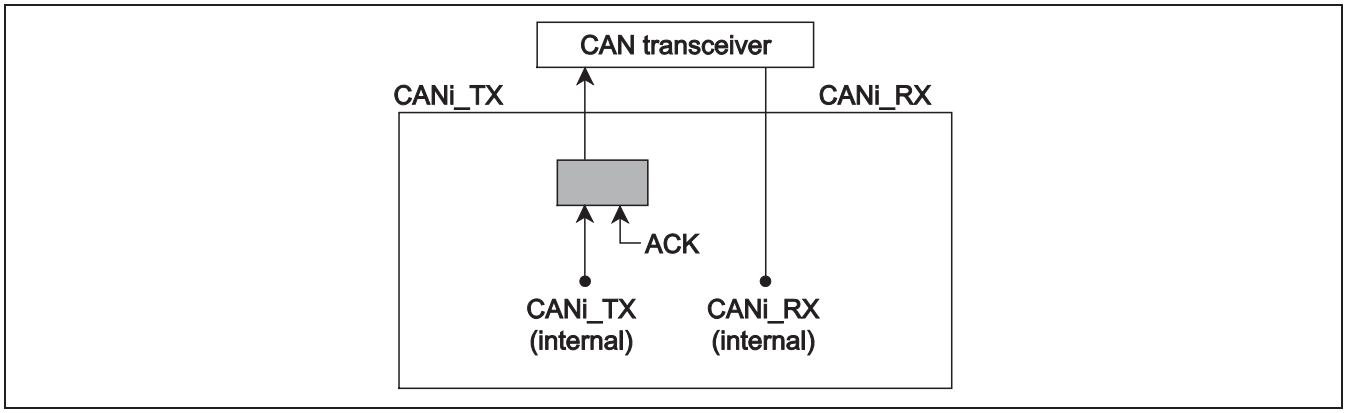

Figure 34.7 Connection when Self-Test Mode 0 is Selected

(3) Self-Test Mode 1 (Internal Loop Back)

Self-test mode 1 is provided for self-test functions.

In this mode, the protocol controller treats its transmitted messages as received messages and stores them into the receive mailbox. To be independent from external stimulation, the protocol controller generates the ACK bit.

In self-test mode 1, the protocol controller performs an internal feedback from the internal CANi_TX pin to the internal CANi_RX pin. The input value of the external CANi_RX pin is ignored. The external CANi_TX pin outputs only recessive bits. The CANi_TX/CANi_RX pins do not need to be connected to the CAN bus or any external device.

Figure 34.8 shows the connection when self-test mode 1 is selected.

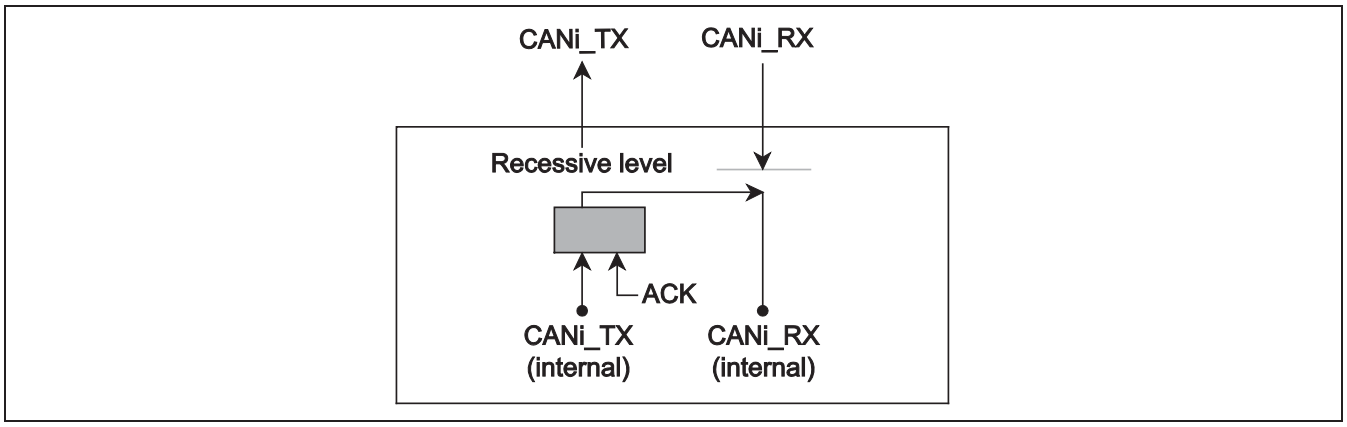

Figure 34.8 Connection when Self-Test Mode 1 is Selected

34.3.26 CANi Interrupt Status Register (CiISR) (i = 0, 1)

The CiISR register shows interrupt sources before masking by the CiIER register.

CAN0 Interrupt Status Register (C0ISR)
CAN1 Interrupt Status Register (C1ISR)

Bit:	7	6	5	4	3	2	1	0
	—	—	ERSF	RXFF	TXFF	RX M0F	RXM1 F	TXMF
Initial	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R	R

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7, 6	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
5	ERSF	0	R	Error (ERS) Interrupt Status Bit*1 The ERSF bit shows the error interrupt source status. 0: ERS interrupt source not detected 1: ERS interrupt source detected
4	RXFF	0	R/W	Reception FIFO (RXF) Interrupt Status Bit*2 The RXFF bit shows the FIFO receive interrupt source status. 0: RXF interrupt source not detected 1: RXF interrupt source detected The RXFF is cleared to "0" by writing "0" to it by software. (writing "1" has no effect)
3	TXFF	0	R/W	Transmission FIFO (TXF) Interrupt Status Bit*3 The TXFF bit shows the FIFO transmit interrupt source status. 0: TXF interrupt source not detected 1: TXF interrupt source detected The TXFF is cleared to "0" by writing "0" to it by software. (writing "1" has no effect)
2	RXM0F	0	R	Mailbox 0 Successful Reception (RXM0) Interrupt Status Bit*4 The RXM0F bit shows the successful reception interrupt source status for mailbox 0. 0: RXM0 interrupt source not detected 1: RXM0 interrupt source detected
1	RXM1F	0	R	Mailbox 1 to 63 Successful Reception (RXM1) Interrupt Status Bit*5 The RXM1F bit shows the successful reception interrupt source status for mailboxes 1 to 63. 0: RXM1 interrupt source not detected 1: RXM1 interrupt source detected
0	TXMF	0	R	Mailbox 32 to 63 Successful Transmission (TXM) Interrupt Status Bit*6 The TXMF bit shows the successful transmission interrupt source status for mailboxes 32 to 63. 0: TXM interrupt source not detected 1: TXM interrupt source detected

Notes: 1. The ERSF bit is set to "1" when a bit in one of the CiEIFR[j] registers is set to "1" due to a communication error while the corresponding bit in the CiEIER[j] register is set to "1" (j = 0 to 7).

2. The RXFF bit is set to "1" when bit 6 or 5 in the CiRFCR register is set to "1" because of a reception FIFO full or warning condition due to the setting of CiMIER[61].
3. The TXFF bit is set to "1" when the transmission FIFO message count reaches the specified value due to the setting of CiMIER[57].
4. After the NEWDATA bit in CiMCTL0 is set to "1" at the end of a receive operation, the RXM0F bit is set to "1" if storing of the receive data is complete (corresponding INVALDATA bit value changed from "1" to "0") and the CiMIER0[0] bit has been set to "1".
5. After the NEWDATA bit in CiMCTLj is set to "1" at the end of a receive operation, the RXM1F bit is set to "1" if storing of the receive data is complete (corresponding INVALDATA bit value changed from "1" to "0") and the bit in CiMIER0 or CiMIER1 corresponding to mailbox j has the been set to "1" (j = 1 to 63).
6. The TXMF bit is set to "1" when the bit in the CiMIER1 register corresponding to mailbox j is set to "1" while the value of the SENTDATA bit in the CiMCTLj register is "1" following a successful reception (j = 32 to 63).

34.3.27 CANi Interrupt Enable Register (CiIER) (i = 0, 1)

The CiIER register can be used by an application to cause some interrupts to be ignored while processing by an interrupt service routine is taking place. Each bit affects the individual interrupt source corresponding to it.

CAN0 Interrupt Enable Register (C0IER)
CAN1 Interrupt Enable Register (C1IER)

Bit:	7	6	5	4	3	2	1	0
	—	—	ERSIE	RXFIE	TXFIE	RXM 0IE	RXM 1IE	TXM IE
Initial	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7, 6	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
5	ERSIE	0	R/W	Error (ERS) Interrupt Enable Bit The ERSIE bit enables or disables the ERS interrupt controller. 0: ERS interrupt disabled 1: ERS interrupt enabled
4	RXFIE	0	R/W	Reception FIFO (RXF) Interrupt Enable Bit The RXFIE bit enables or disables the RXF interrupt controller. 0: RXF interrupt disabled 1: RXF interrupt enabled
3	TXFIE	0	R/W	Transmission FIFO (TXF) Interrupt Enable Bit The TXFIE bit enables or disables the TXF interrupt controller. 0: TXF interrupt disabled 1: TXF interrupt enabled
2	RXM0IE	0	R/W	Mailbox 0 Successful Reception (RXM0) Interrupt Enable Bit The RXM0IE bit enables or disables the RXM0 interrupt controller. 0: RXM0 interrupt disabled 1: RXM0 interrupt enabled
1	RXM1IE	0	R/W	Mailbox 1 to 63 Successful Reception (RXM1) Interrupt Enable Bit The RXM1IE bit enables or disables the RXM1 interrupt controller. 0: RXM1 interrupt disabled 1: RXM1 interrupt enabled
0	TXMIE	0	R/W	Mailbox 32 to 63 Successful Transmission (TXM) Interrupt Enable Bit The TXMIE bit enables or disables the TXM interrupt controller. 0: TXM interrupt disabled 1: TXM interrupt enabled

34.3.28 CANi Mailbox Search Mask Register (CiMBSMR) (i = 0, 1)

Write to the CiMBSMR register in CAN halt mode only.

CAN0 Mailbox Search Mask Register (C0MBSMR)
CAN1 Mailbox Search Mask Register (C1MBSMR)

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	MB0SM
Initial	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7 to 1	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
0	MB0SM	0	R/W	Mailbox 0 Search Mask Bit* When the MB0SM bit is set to "1", message box 0 is excluded from the search target for the CANi mailbox search status register.

Note: * The MB0SM bit is enabled in the search modes except channel search mode. In the RXM1 interrupt handling, this bit is usable to exclude message box 0 from the search target for the CiMSSR register in receive mailbox search mode.

34.3.29 CANi Parity Error Control Register (CiPECR) (i = 0, 1)

This register controls the function of the parity mode and displays a parity error flag.

Bit:	7	6	5	4	3	2	1	0
	PF	—	—	—	—	PIE	PME	PM
Initial	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W

<After Reset: H'00>

Bit	Symbol	Initial Value	R/W	Description
7	PF	0	R	Parity error flag *2 This bit is set to “1” when a parity error is detected. The bit has to be cleared by the program. As long as this bit is set no further parity error can be detected and the address value in the Parity Error Address Capture Register keeps the address for the first captured parity error. 0: Parity error is not detected 1: Parity error is detected
6 to 3	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
2	PIE	0	R/W	Parity error interrupt *1 This bit controls the parity error interrupt enable. When this bit is configured to “0”, the parity error interrupt is disabled. When this bit is set to “1”, the parity error interrupt is enabled. The parity error interrupt is one of the factors in the CAN error interrupt. When a parity error interrupt is generated, the parity error flag (CANi Parity Error Control Register, bit 7) should be checked to determine the interrupt source. 0: Parity error interrupt is disabled 1: Parity error interrupt is enabled
1	PME	0	R/W	Parity enable bit This bit controls the Dual Port RAM parity functionality. When this bit is set to “0”, parity checkers are disabled keeping the parity generators still active to store the correct parity bit for each byte when writing to the Dual Port RAM. When this bit is set to “1”, parity checkers and parity generators are both active. 0: Parity checker off 1: Parity checker on

Bit	Symbol	Initial Value	R/W	Description
0	PM	0	R/W	Parity mode This bit controls the action of the CAN Module following the detection of a parity error. When this bit is programmed to “1” and a parity error is detected while in Operation Mode the CAN module forces the cancellation of a possible pending communication (either reception or transmission) and then enters Halt mode. When the pending communication is cancelled, the Reception Error Counter and Transmission Error Counter are initialized. If a parity error is detected while the CAN module is in its Reset or Halt mode no state transition will take place. In case where CPU requests transition to Reset Mode at the same time as a parity error occurs then the CPU request to enter Reset Mode will have the highest priority. When this bit is set to “0”, CAN module continues in Operation Mode and the pending communication is not canceled. Regardless of the setting of ParMode (PM) when a parity error occurs and ParModeEn (PME) bit is set to ‘1’ (parity function enabled): • a parity error flag is set in bit 7 of the CAN Parity Error Control Register • a parity error interrupt is generated (providing the ParIntEn (PIE) bit is asserted) • the address where a parity error occurs is captured in the CANi Parity Error Capture Address Register. When parity error is detected 0: Continue operation mode 1: Go to Halt mode

Notes: 1. Do not write to this bit in Operation Mode
2. Write “0” only (writing “1” has no effect)
3. The software sequence required to set these bits is described in section 34.10, CPU is prevented from writing this bit in operation mode by H/W write protection.

34.3.30 CANi Parity Error Address Capture Register (CiPEACR) (i = 0, 1)

This register displays the address where the parity error occurred.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	PA										
Initial	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

<After Reset: H'0000>

Bit	Symbol	Initial Value	R/W	Description
15 to 11	—	All 0	R	Reserved bits These bits are always read as 0. The write value should always be 0. Operation is not guaranteed if a value other than 0 is written to these bits.
10 to 0	PA	H'000	R	Parity error captured address bits This register displays the address offset from a starting address of Mailbox 0 where parity error is detected. When a parity error is detected, the address in which the error occurred is captured in this register. Only the longword address is shown. The address is shown as below.

ParAddress value	Location
H'000 - H'00F	Mailbox 0*
H'010 – H'01F	Mailbox 1
H'020 – H'02F	Mailbox 2
...	…
H'3F0 – H'3FF	Mailbox 63
H'400 – H'41F	CiMKR 2 to 9
H'420 – H'427	FIFO ID 0 to 1
H'428 – H'42B	Mask Invalid 1
H'42C – H'42F	Interrupt enable 1
H'430 – H'433	CiMKR 0
H'434 – H'437	CiMKR 1
H'438 – H'43B	Mask Invalid 0
H'43C – H'43F	Interrupt enable 0

Note: * H'000 is the first byte of the mailbox 0.

Only the address related to the first parity error is reported. The program has to clear the ParFlag status to enable the capture of other locations leading to a parity error.

In case parity error is flagged at the same time from DPRAM CAN side parity checker and the DPRAM CPU side parity checker, the CPU side access address will be displayed in the parity error address capture register.

34.4 Operating Mode

The CAN module has the following four operating modes.

- CAN reset mode
- CAN halt mode
- CAN operation mode
- CAN sleep mode

Figure 34.9 shows the transition between CAN operating modes.

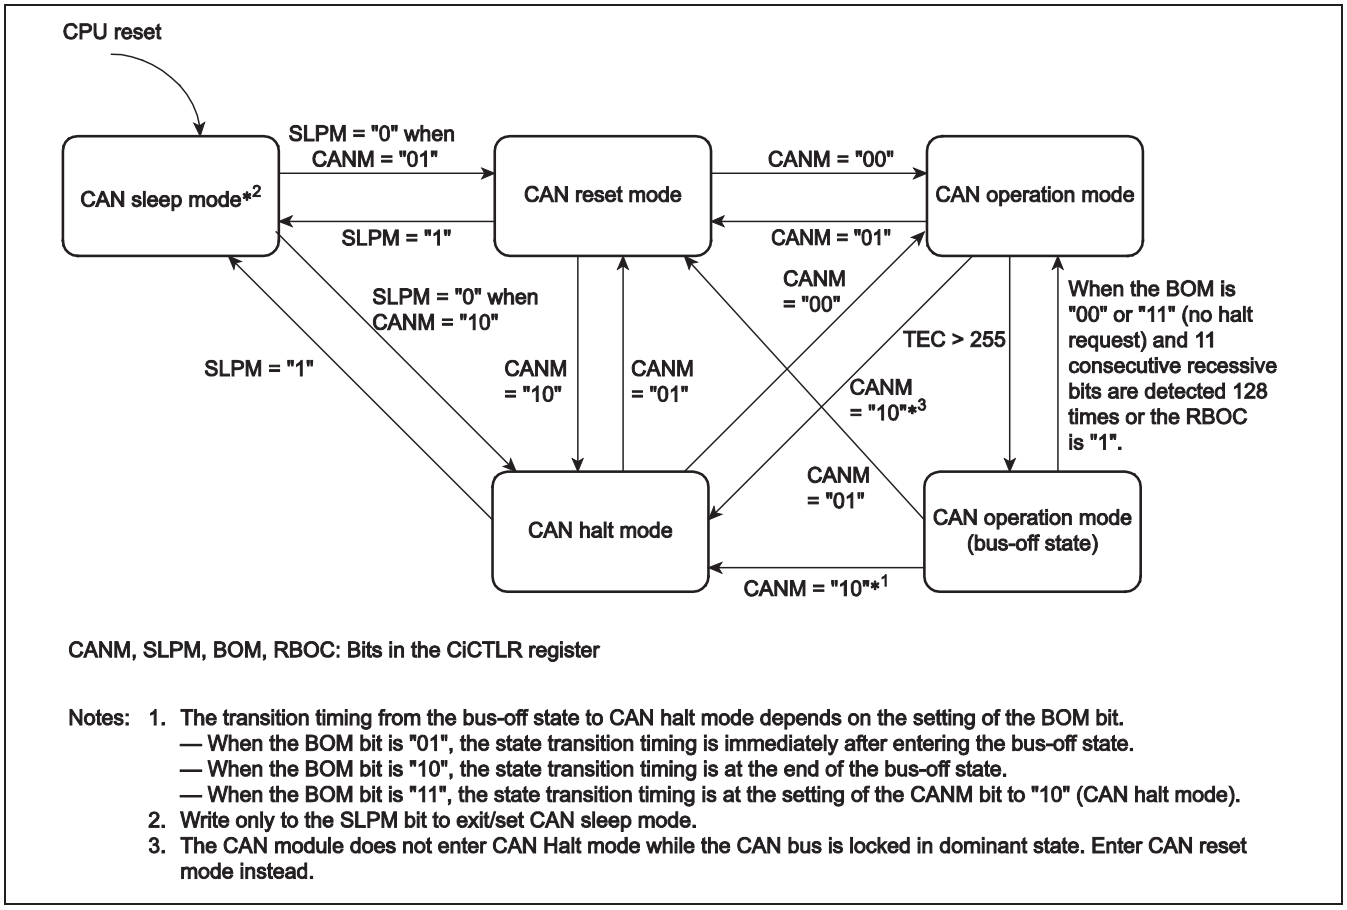

Figure 34.9 Transition between CAN Operating Modes (i = 0, 1)

34.4.1 CAN Reset Mode

CAN reset mode is provided for CAN communication configuration.

When the CANM bit in the CiCTLR register is set to "01" or "11", the CAN module enters CAN reset mode. Then the RSTST bit in the CiSTR register is set to "1". Do not change the CANM bit until the RSTST bit is set to "1". Configure the CiBCR register before exiting CAN reset mode to any other modes.

The following registers are initialized to their reset values after entering CAN reset mode and their initialized values are retained during CAN reset mode:

- CiMCTLj register
- CiSTR register (except bits SLPST and TFST)
- CiEIFR register
- CiRECR register
- CiTECR register
- CiTSR register
- CiMSSR register
- CiMSMR register
- CiRFCR register
- CiTFCR register
- CiTCR register
- CiECSR register (except EDPM bit)
- CiISR register
- CiMBSMR register

The following registers retain their values after entering CAN reset mode.

- CiCLKR register
- CiCTLR register
- CiSTR register (bits SLPST and TFST)
- Registers CiMIER0 and CiMIER1
- CiEIER register
- CiBCR register
- CiCSSR register
- CiECSR register (EDPM bit only)
- CiMBj register
- Registers CiMKR0 to CiMKR9
- Registers CiFIDCR0 and CiFIDCR1
- Registers CiMKIVLR0 and CiMKIVLR1
- CiAFSR register
- CiRFPCR register
- CiTFPCR register
- CiIER register

34.4.2 CAN Halt Mode

CAN halt mode is used for mailbox configuration and test mode setting.

When the CANM bit in the CiCTLR register is set to "10", CAN halt mode is selected. Then the HLTST bit in the CiSTR register is set to "1". Do not change the CANM bit until the HLTST bit is set to "1".

Refer to Table 34.9, Operation in CAN Reset Mode and CAN Halt Mode regarding the state transition conditions when transmitting or receiving.

All registers except bits RSTST, HLTST, and SLPST in the CiSTR register remain unchanged when the CAN module enters CAN halt mode.

Do not change registers CiCLKR, CiCTLR (except bits CANM and SLPM), and CiEIER in CAN halt mode. The CiBCR register can be changed in CAN halt mode only when listen-only mode is selected to use for automatic bit rate detection.

Table 34.9 Operation in CAN Reset Mode and CAN Halt Mode

Mode	Receiver	Transmitter	Bus-Off
CAN reset mode	CAN module enters CAN reset mode without waiting for the end of message reception	CAN module enters CAN reset mode after waiting for the end of message transmission (1, 4)	CAN module enters CAN reset mode without waiting for the end of bus-off recovery
CAN halt mode	CAN module enters CAN halt mode after waiting for the end of message reception (2, 3)	CAN module enters CAN halt mode after waiting for the end of message transmission (1, 2, 4)	• When the BOM bit is "B'00" A halt request from a program will be acknowledged only after bus-off recovery • When the BOM bit is "B'01" CAN module automatically enters CAN halt mode without waiting for the end of bus-off recovery (regardless of a halt request from a program) • When the BOM bit is "B'10" CAN module automatically enters CAN halt mode after waiting for the end of bus-off recovery (regardless of a halt request from a program) • When the BOM bit is "B'11" CAN module enters CAN halt mode (without waiting for the end of bus-off recovery) if a halt is requested by a program during bus-off

BOM bit: Bit in the CiCTLR register (i = 0, 1)

Notes: 1. If several messages are requested to be transmitted, mode transition occurs after the completion of the first message transmission. When CAN reset mode is being requested during suspend transmission, mode transition occurs when the bus is idle, the next transmission ends, or the CAN module becomes a receiver.
2. If the CAN bus is locked in dominant state, the program can detect this state by monitoring the BLIF bit in the CiEIFR register. The CAN module does not enter CAN Halt mode while the CAN bus is locked in dominant state. Enter CAN reset mode instead.
3. If a CAN bus error occurs during reception after CAN halt mode is requested, the CAN module enters CAN halt mode. However, the CAN module does not enter CAN Halt mode when the CAN bus is locked in dominant state.
4. If a CAN bus error or arbitration lost occurs during transmission after CAN reset mode or CAN halt mode is requested, the CAN module enters the requested operating mode. However, the CAN module does not enter CAN Halt mode when the CAN bus is locked in dominant state.

34.4.3 CAN Sleep Mode

CAN sleep mode is used for reducing current consumption by stopping the clock supply to the CAN module. After MCU hardware reset or software reset, the CAN module starts from CAN sleep mode.

When the SLPM bit in the CiCTLR register is set to "1", the CAN module enters CAN sleep mode. Then the SLPST bit in the CiSTR register is set to "1". Do not change the value of the SLPM bit until the SLPST bit is set to "1". The other registers remain unchanged when the MCU enters CAN sleep mode.

Write to the SLPM bit in CAN reset mode and CAN halt mode. Do not change any registers (except the SLPM bit) during CAN sleep mode. Read operation is still allowed. When the SLPM bit is set to "0", the CAN module is released from CAN sleep mode. When the CAN module exits CAN sleep mode, the other registers remain unchanged.

34.4.4 CAN Operation Mode (Excluding Bus-Off State)

CAN operation mode is used for CAN communication.

When the CANM bit in the CiCTLR register is set to "B'00", the CAN module enters CAN operation mode.

Then bits RSTST and HLTST in the CiSTR register are set to "0". Do not change the value of the CANM bit until these bits are set to "0".

If 11 consecutive recessive bits are detected after entering CAN operation mode, the CAN module is in the following states:

- The CAN module becomes an active node on the network that enables transmission and reception of CAN messages.
- Error monitoring of the CAN bus, such as receive and transmit error counters, is performed.

During CAN operation mode, the CAN module may be in one of the following three sub-modes, depending on the status of the CAN bus:

- Idle mode: Transmission or reception is not being performed.
- Receive mode: A CAN message sent by another node is being received.
- Transmit mode: A CAN message is being transmitted. The CAN module may receive its own message simultaneously when self-test mode 0 (TSTM bit in the CiTCR register = "B'10") or self-test mode 1 (TSTM bit = "B'11") is selected.

Figure 34.10 shows the sub mode in CAN operation mode.

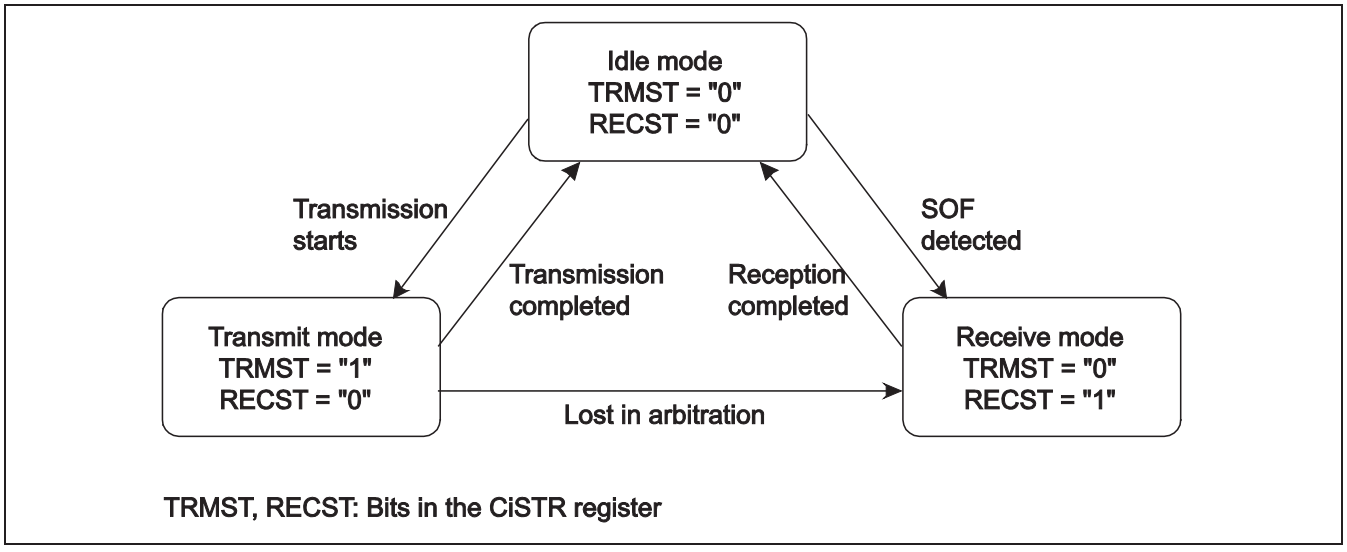

Figure 34.10 Sub Mode in CAN Operation Mode (i = 0, 1)

34.4.5 CAN Operation Mode (Bus-Off State)

The CAN module enters the bus-off state according to the increment/decrement rules for the transmit/error counters in the CAN Specifications.

The following cases apply when recovering from the bus-off state. When the CAN module is in bus-off state, the values of the associated registers, except registers CiSTR, CiEIFR, CiRECR, CiTECR and CiTSR, remain unchanged.

1. When the BOM bit in the CiCTLR register is "B'00" (normal mode)
   The CAN module enters the error-active state after it has completed the recovery from the bus-off state and CAN communication is enabled instantly. The BORIF bit in the CiEIFR register is set to "1" (bus-off recovery detected) at this time.
2. When the RBOC bit in the CiCTLR register is set to "1" (forcible return from bus-off)
   The CAN module enters the error-active state when it is in bus-off state and the RBOC bit is set to "1". CAN communication is enabled again after 11 consecutive recessive bits are detected. The BORIF bit is not set to "1" at this time.
3. When the BOM bit is "B'01" (entry to CAN halt mode automatically at bus-off entry)
   The CAN module enters CAN halt mode when it reaches the bus-off state. The BORIF bit is not set to "1" at this time.
4. When the BOM bit is "B'10" (entry to CAN halt mode automatically at bus-off end)
   The CAN module enters CAN halt mode when it has completed the recovery from bus-off. The BORIF bit is set to "1" at this time.
5. When the BOM bit is "B'11" (entry to CAN halt mode by a program) and the CANM bit in the CiCTLR register is set to "B'10" (CAN halt mode) during the bus-off state
   The CAN module enters CAN halt mode when it is in bus-off state and the CANM bit is set to "B'10" (CAN halt mode). The BORIF bit is not set to "1" at this time.
   If the CANM bit is not set to "B'10" during bus-off, the same behavior as (1) applies.

34.5 CAN Communication Speed Configuration

The following description explains about the CAN communication speed configuration.

34.5.1 CAN Clock Configuration

This MCU has a CAN clock selector. The CAN clock can be configured by setting the CCLKS bit in the CiCLKR register and the BRP bit in the CiBCR register.

Figure 34.11 shows the block diagram of CAN clock generator.

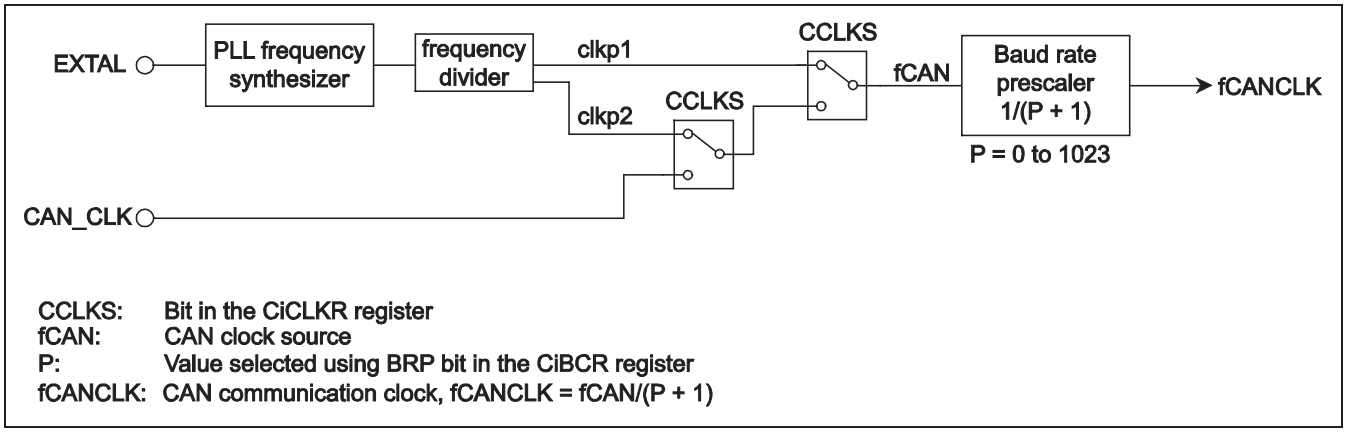

Figure 34.11 Block Diagram of CAN Clock Generator (i = 0, 1)

The CAN operating clock can be selected from the internal clock (clkp1, clkp2) from the CPG (PLL), and the external clock input to external pin (CAN_CLK).

In the initial state, clkp1 is selected. If an external clock input is to be selected, set the CiCLKR register (section 34.3.2) before accessing the CAN module. The range of frequencies that may be input as an external clock is 8 to 50 MHz.

34.5.2 Bit Timing Configuration

The bit time is a single bit time for transmitting/receiving a message and consists of the following three segments.

Figure 34.12 shows the bit timing.

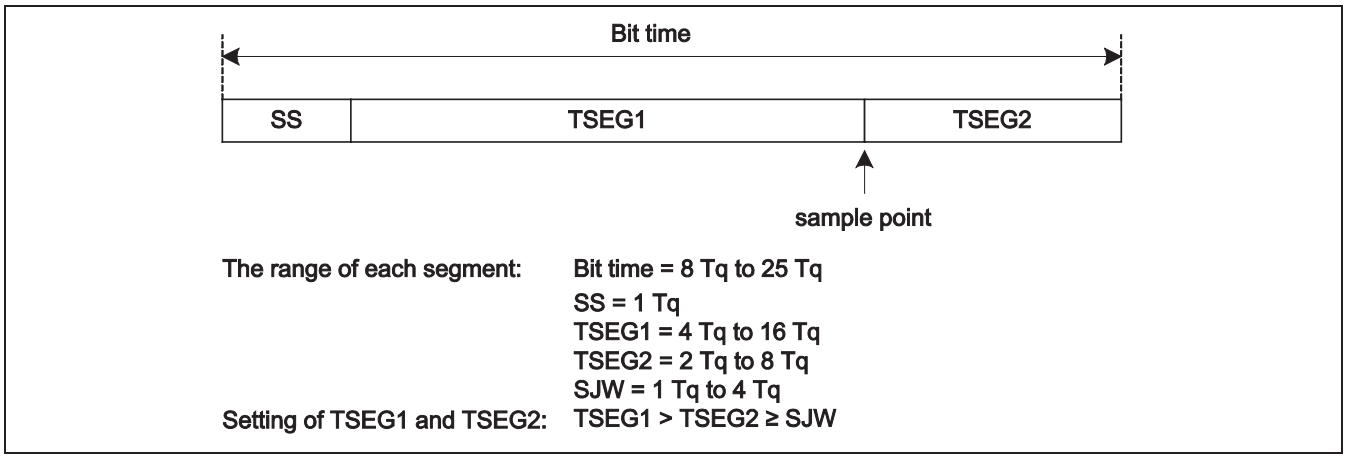

Figure 34.12 Bit Timing

34.5.3 Bit-rate

The bit rate depends on the division value of the fCAN (CAN clock source), the division value of the baud rate prescaler, and the number of Tq of one bit time.

$$\text{Bit rate [bps]} = \frac{fCAN}{\text{Baud rate prescaler division value}^* \times \text{number of Tq of one bit}} = \frac{fCANCLK}{\text{Number of Tq of one bit time}}$$

Note: * Division value of the baud rate prescaler = P + 1 (P: 0 to 1023)
P: Setting value of the BRP bit in the CiBCR register (i = 0, 1)

Table 34.10 lists bit rate examples.

Table 34.10 Example of Bit-rate

fCAN	40 MHz		32 MHz		20 MHz		16 MHz	
Bit-rate	**No. of Tq**	**P + 1**	**No. of Tq**	**P + 1**	**No. of Tq**	**P + 1**	**No. of Tq**	**P + 1**
1 Mbps	10Tq	4	8Tq	4	10Tq	2	8Tq	2
	20Tq	2	16Tq	2	20Tq	1	16Tq	1
500 kbps	10Tq	8	8Tq	8	10Tq	4	8Tq	4
	20Tq	4	16Tq	4	20Tq	2	16Tq	2
250 kbps	10Tq	16	8Tq	16	10Tq	8	8Tq	8

			20Tq	48			20Tq	24

34.6 Mailbox and Mask Register Structure

Figure 34.13 shows the structure of the CiMBj register.

There are 64 mailboxes with the same structure.

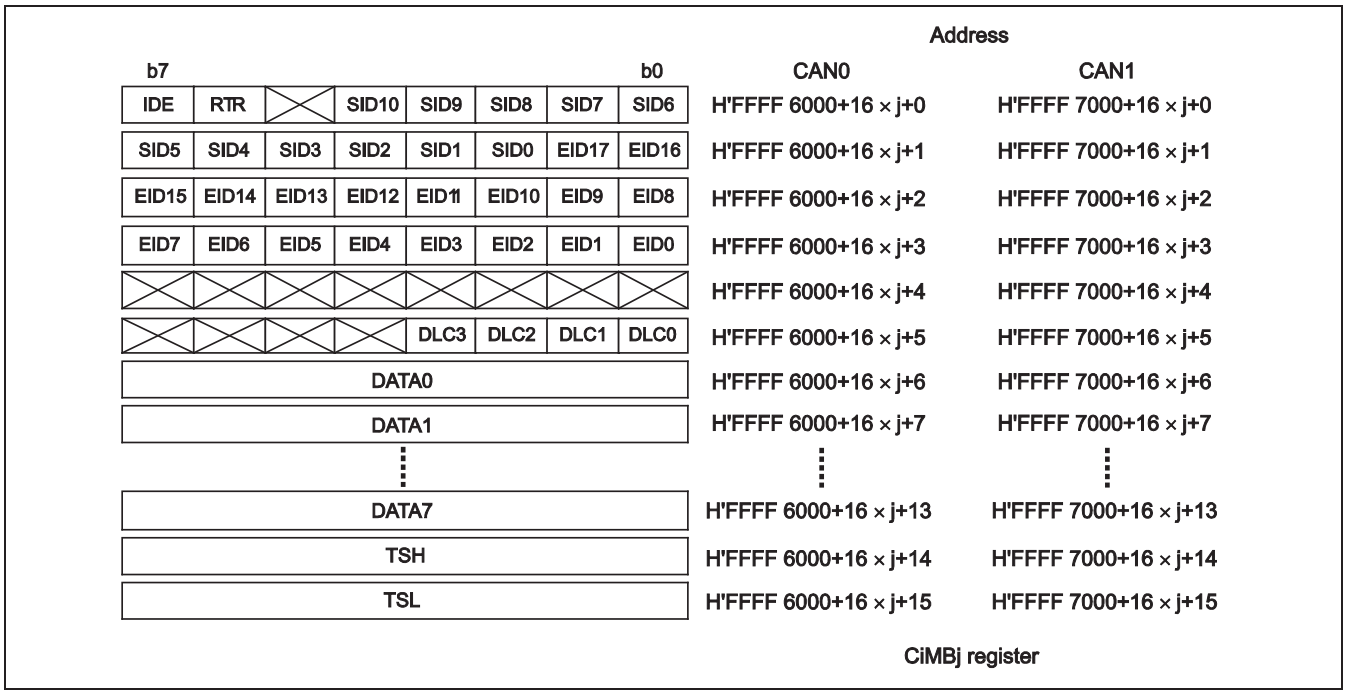

Figure 34.13 Structure of CiMBj Register (i = 0, 1; j = 0 to 63)

Figure 34.14 shows the structure of registers CiMKR0, CiMKR1, and CiMKR2 to CiMKR9.

There are 10 mask registers with the same structure.

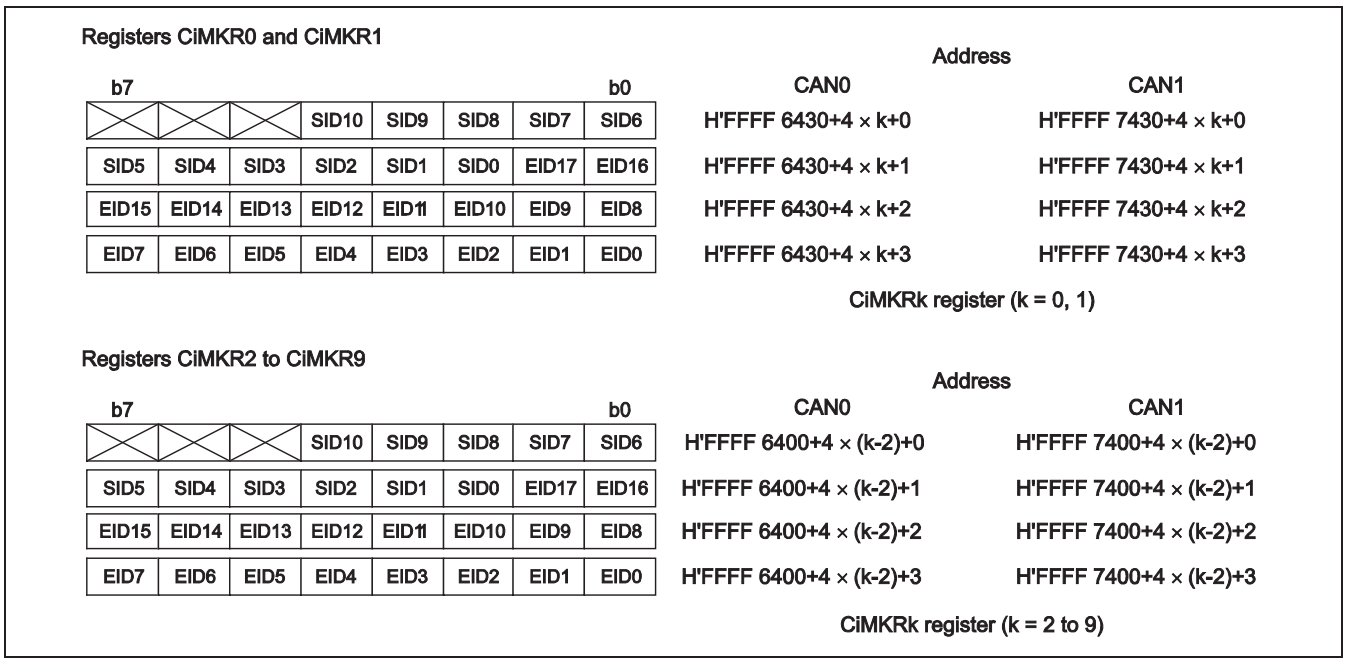

Figure 34.14 Structure of CiMKRk Register (i = 0, 1; k = 0 to 9)

Figure 34.15 shows the structure of the CiFIDCRn register.

There are 2 FIFO received ID compare registers with the same structure.

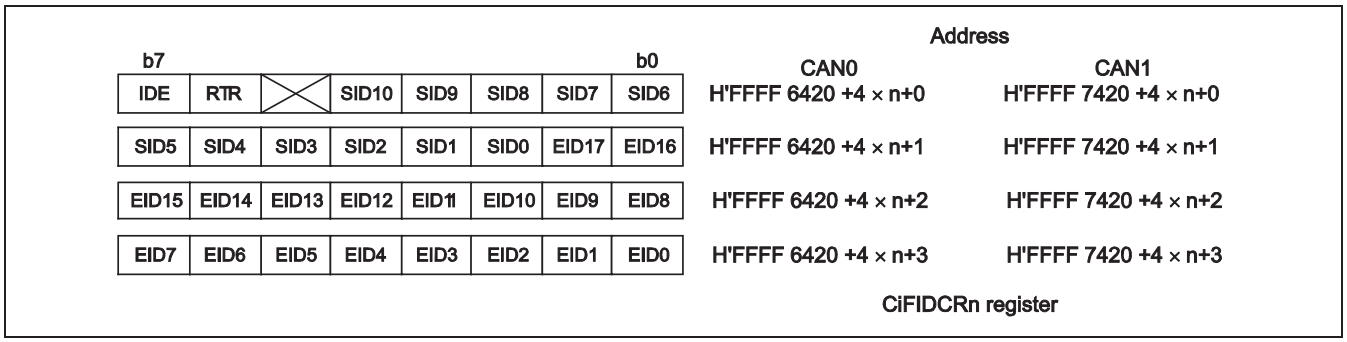

Figure 34.15 Structure of CiFIDCRn register (i = 0, 1; n = 0, 1)

34.7 Acceptance Filtering and Masking Function

Acceptance filtering allows the user to receive messages with a specified range of multiple IDs for mailboxes. Registers CiMKR0 to CiMKR9 can perform masking of the standard ID and the extended ID of 29 bits.

- The CiMKR0 register corresponds to mailboxes [0] to [15].
- The CiMKR1 register corresponds to mailboxes [16] to [31].
- The CiMKR2 register corresponds to mailboxes [32] to [35].
- The CiMKR3 register corresponds to mailboxes [36] to [39].
- The CiMKR4 register corresponds to mailboxes [40] to [43].
- The CiMKR5 register corresponds to mailboxes [44] to [47].
- The CiMKR6 register corresponds to mailboxes [48] to [51].
- The CiMKR7 register corresponds to mailboxes [52] to [55].
- The CiMKR8 register corresponds to mailboxes [56] to [59] in normal mailbox mode and the receive FIFO mailboxes [60] to [63] in FIFO mailbox mode.
- The CiMKR9 register corresponds to mailboxes [60] to [63] in normal mailbox mode and the receive FIFO mailboxes [60] to [63] in FIFO mailbox mode.

Registers CiMKIVLR0 and CiMKIVLR1 disable acceptance filtering individually for each mailbox.

The IDE bit in the CiMBj register is enabled when the IDFM bit in the CiCTLR register is "B'10" (mixed ID mode).

The RTR bit in the CiMBj register selects a data frame or a remote frame.

In FIFO mailbox mode, normal mailboxes (mailboxes [0] to [55]) use the single corresponding register among registers CiMKR0 to CiMKR7 for acceptance filtering. Receive FIFO mailboxes (mailboxes [60] to [63]) use two registers CiMKR8 and CiMKR9 for the acceptance filtering.
Also, the receive FIFO uses two registers CiFIDCR0 and CiFIDCR1 for ID comparison. Bits EID, SID, RTR, and IDE in registers CiMB60 to CiMB63 for the receive FIFO are disabled. As acceptance filtering depends on the result of two ID-mask sets, two ranges of IDs can be received into the receive FIFO.
Registers CiMKIVLR0 and CiMKIVLR1 are disabled for the receive FIFO.
If both setting of standard ID and extended ID are set in the IDE bits in registers CiFIDCR0 and CiFIDCR1 individually, both ID formats are received.
If both setting of data frame and remote frame are set in the RTR bits in registers CiFIDCR0 and CiFIDCR1 individually, both data and remote frames are received.
When combination with two ranges of IDs is not necessary, set the same mask value and the same ID into both of the FIFO ID/mask register sets.

Figure 34.16 shows the correspondence of mask registers to mailboxes. Figure 34.17 shows the acceptance filtering.

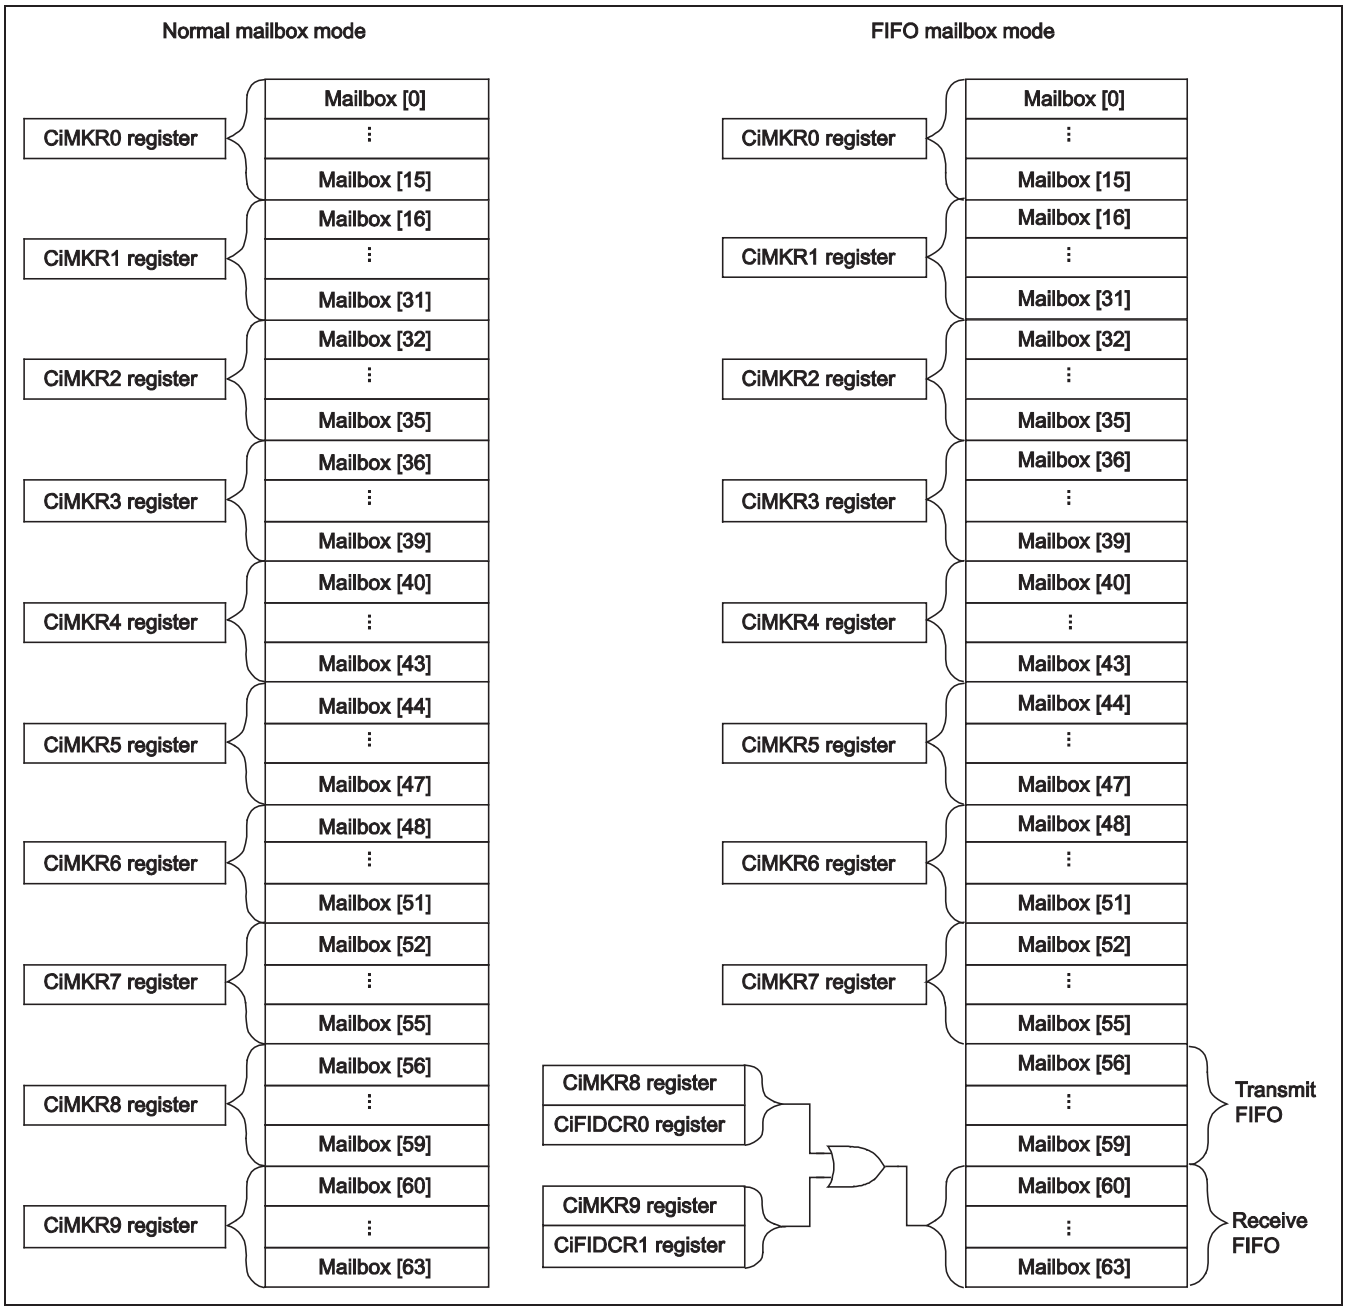

Figure 34.16 Correspondence of Mask Registers to Mailboxes (i = 0, 1)

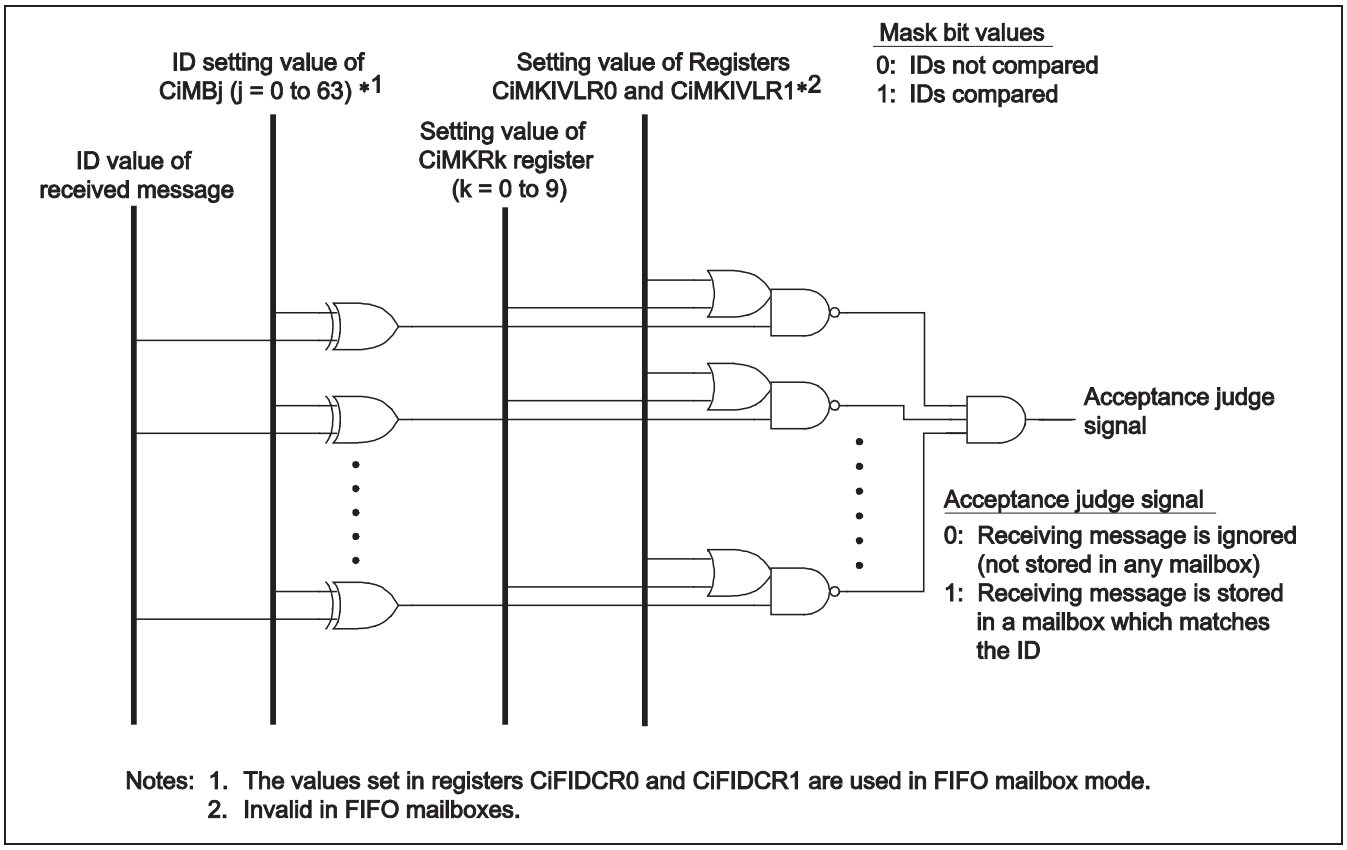

Figure 34.17 Acceptance Filtering (i = 0, 1)

34.8 Reception and Transmission

Table 34.11 lists the CAN communication mode configuration.

Table 34.11 Configuration for CAN Reception Mode and Transmission Mode

TRMREQ	RECREQ	ONESHOT	Communication Mode of Mailbox
0	0	0	Mailbox disabled or transmission being aborted
0	0	1	Configurable only when transmission or reception from a mailbox (programmed in one-shot mode) is aborted.
0	1	0	Configured as a receive mailbox for a data frame or a remote frame.
0	1	1	Configured as a one-shot receive mailbox for a data frame or a remote frame.
1	0	0	Configured as a transmit mailbox for a data frame or a remote frame.
1	0	1	Configured as a one-shot transmit mailbox for a data frame or a remote frame.
1	1	0	Do not set.
1	1	1	Do not set.

Note: TRMREQ, RECREQ, ONESHOT: Bits in CiMCTLj register (i = 0, 1; j = 32 to 63)

When a mailbox is configured as a receive mailbox or a one-shot receive mailbox, note the following:

1. Before a mailbox is configured as a receive mailbox or a one-shot receive mailbox, set the CiMCTLj register to "H'00".
2. A received message is stored into the first mailbox that matches the condition according to the result of receive mode configuration and acceptance filtering. Upon deciding a mailbox which stores the received message, the mailbox with the smaller number has higher priority.
3. In CAN operation mode, when a CAN module transmits a message whose ID matches with the ID/mask set of a mailbox configured to receive messages, the CAN module never receives the transmitted data. In self-test mode, however, the CAN module may receive its transmitted data. In this case, the CAN module sends an ACK.

When configuring a mailbox as a transmit mailbox or a one-shot transmit mailbox, note the following:

1. Before a mailbox is configured as a transmit mailbox or one-shot transmit mailbox, ensure that the CiMCTLj register is "H'00" and that there is no pending abort process.

34.8.1 Reception

Figure 34.18 shows an operation example of data frame reception in overwrite mode.

This example shows the operation of overwriting the first message when the CAN module receives two consecutive CAN messages that matches the receiving conditions of the CiMCTLj register.

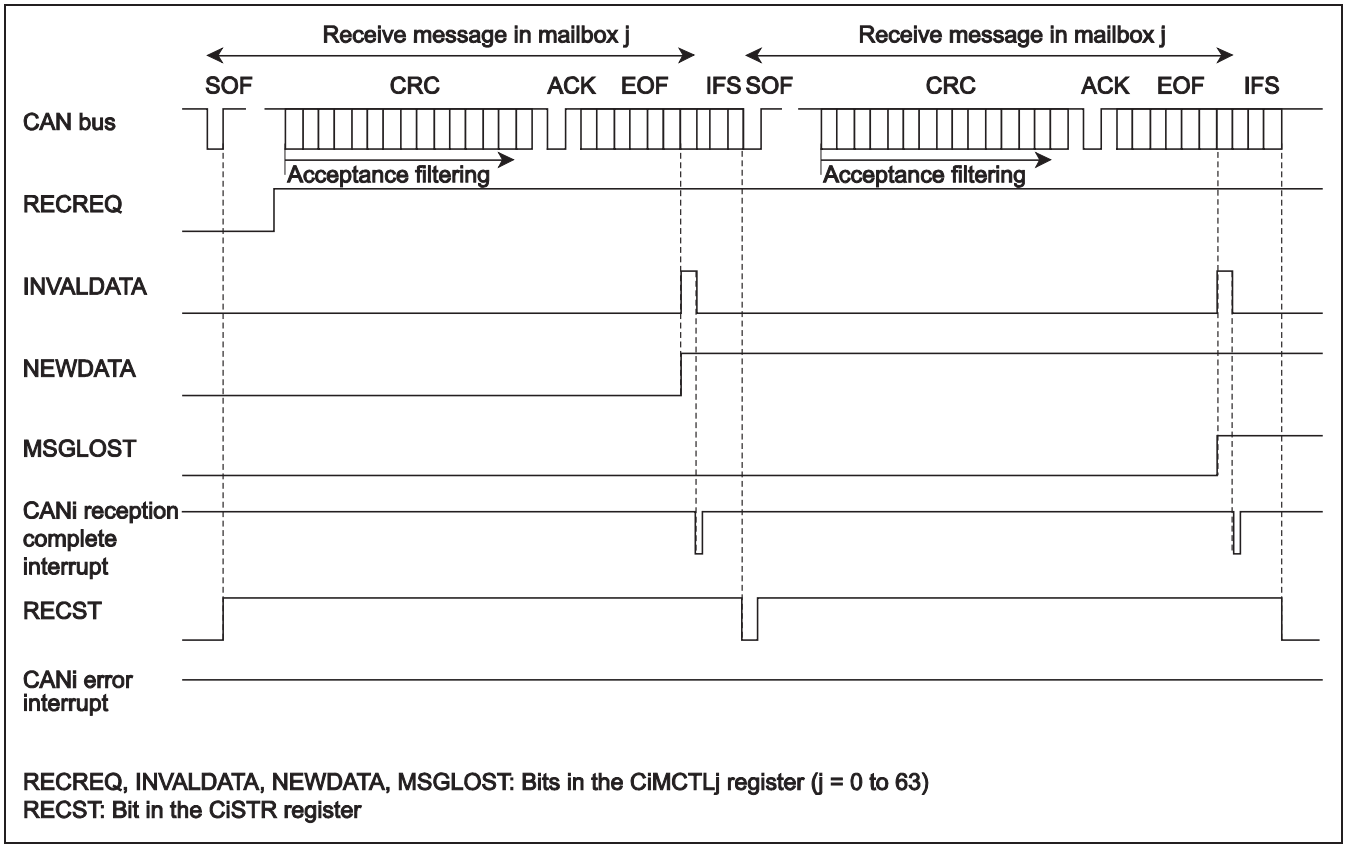

Figure 34.18 Operation Example of Data Frame Reception in Overwrite Mode (i = 0, 1)

1. When a SOF is detected on the CAN bus, the RECST bit in the CiSTR register is set to "1" (reception in progress) if the CAN module has no message ready to start transmission.
2. The acceptance filter procedure starts at the beginning of the CRC field to select the receive mailbox.
3. After a message has been received, the NEWDATA bit in the CiMCTLj register for the receive mailbox is set to "1" (new data being updated/stored in the mailbox). The INVALDATA bit in the CiMCTLj register is set to "1" (message is being updated) at the same time, and then the INVALDATA bit is set to "0" (message valid) again after the complete message is transferred to the mailbox.
4. When the interrupt enable bit in the CiMIER register for the receive mailbox is "1" (interrupt enabled), the CANi reception complete interrupt request is generated. This interrupt is generated when the INVALDATA bit is set to "0".
5. After reading the message from the mailbox, the NEWDATA bit needs to be set to "0" by a program.
6. In overwrite mode, if the next CAN message has been received into a mailbox whose NEWDATA bit is still set to "1", the MSGLOST bit in the CiMCTLj register is set to "1" (message has been overwritten). The new received message is transferred to the mailbox. The CANi reception complete interrupt request is generated the same as in 4.

Figure 34.19 shows the operation example of data frame reception in overrun mode. This example shows the operation of overrunning the second message when the CAN module receives two consecutive CAN messages that matches the receiving conditions of the CiMCTLj register.

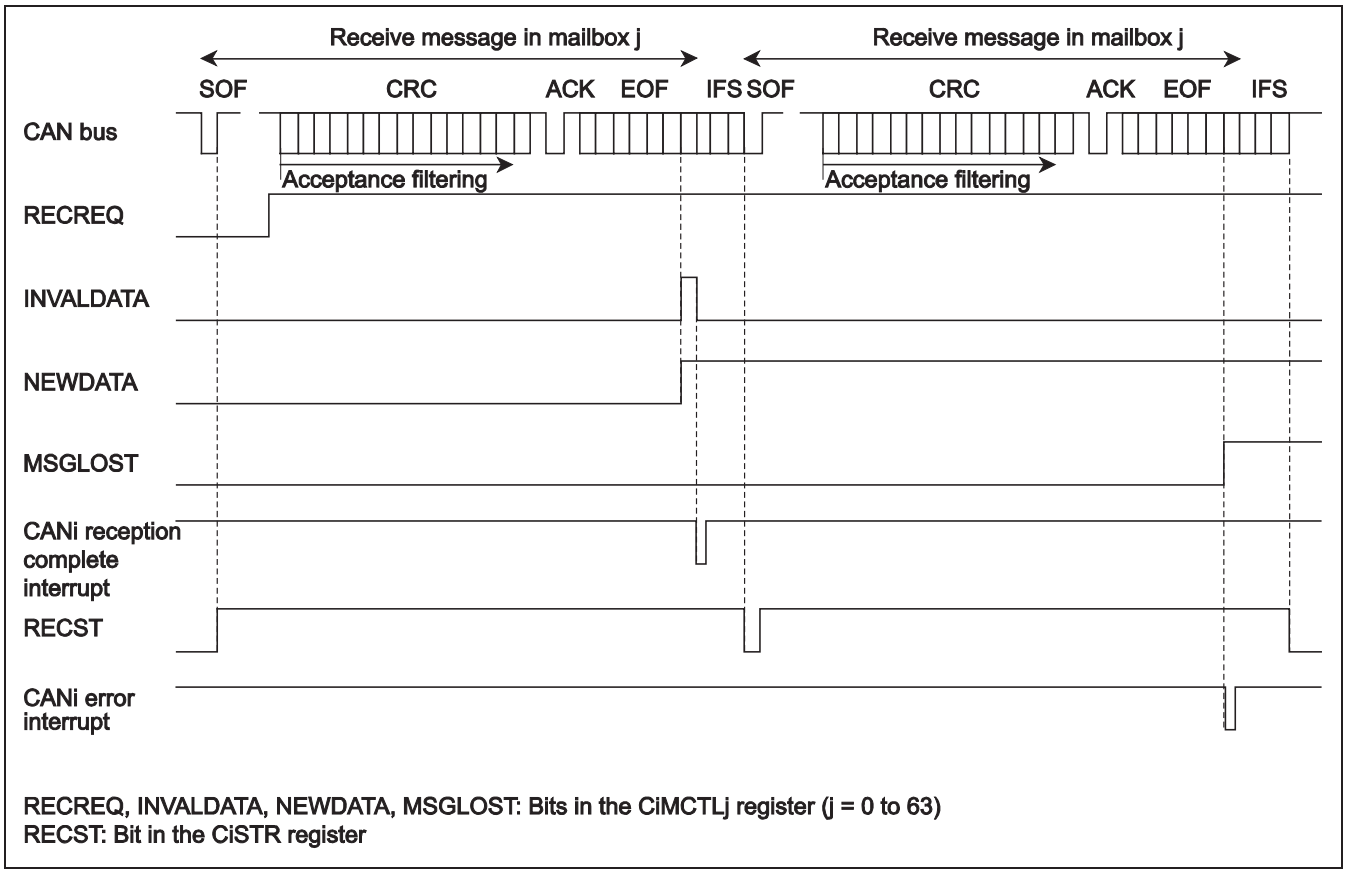

Figure 34.19 Operation Example of Data Frame Reception in Overrun Mode (i = 0, 1)

1. to 5. are the same as overwrite mode.

6. In overrun mode, if the next message has been received before the NEWDATA bit is set to "0", the MSGLOST bit in the CiMCTLj register is set to "1" (message has been overrun). The new received message is discarded and a CANi error interrupt request is generated if the corresponding interrupt enable bit in the CiEIER register is set to "1" (interrupt enabled).

34.8.2 Transmission

Figure 34.20 shows an operation example of data frame transmission.

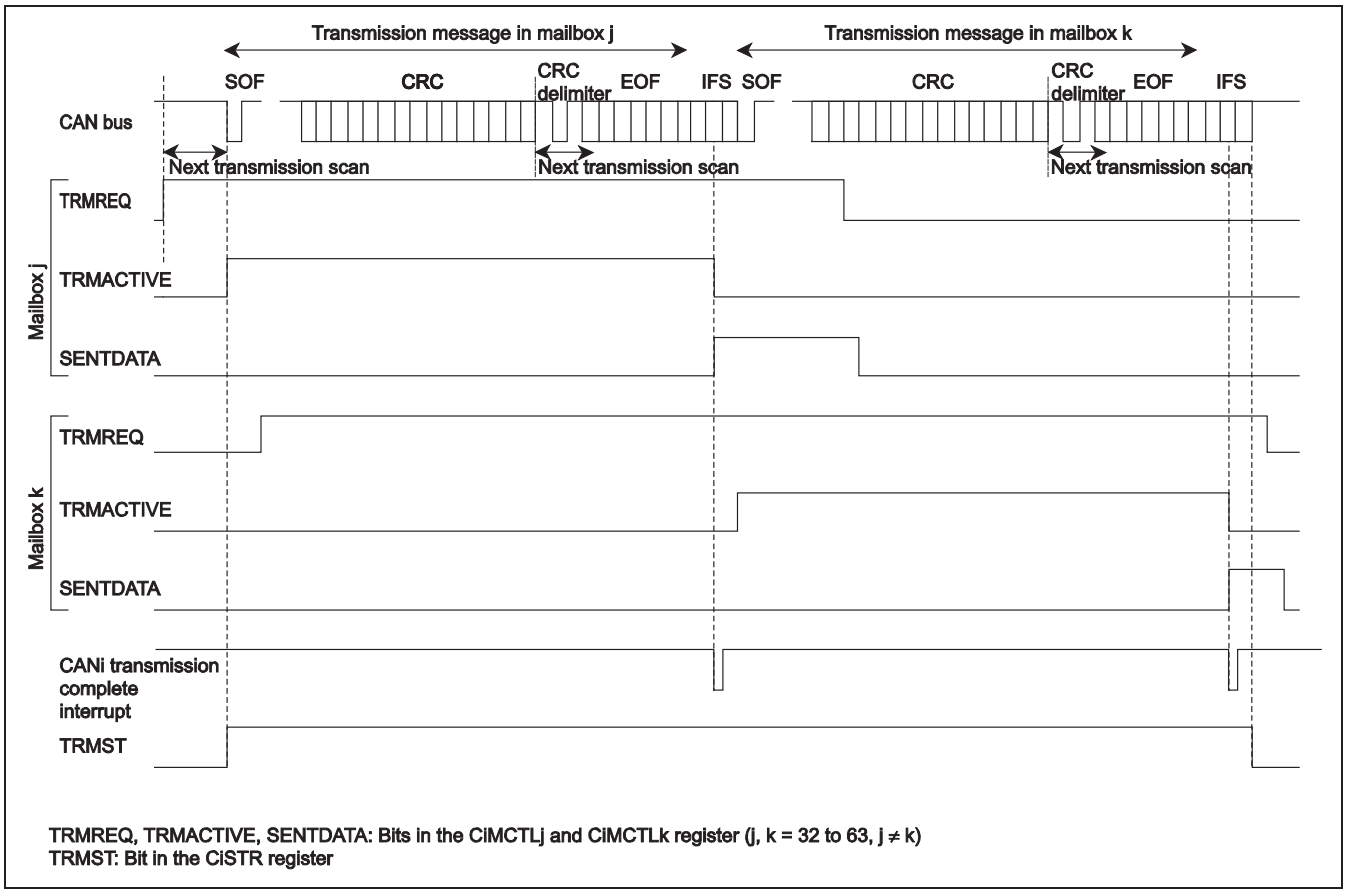

Figure 34.20 Operation Example of Data Frame Transmission (i = 0, 1)

1. When a TRMREQ bit in the CiMCTLj register is set to 1 (transmit mailbox) in bus-idle state, the mailbox scan procedure starts to decide the highest-priority mailbox for transmission. Once the transmit mailbox is decided, the TRMACTIVE bit in the CiMCTLj register is set to "1" (from when a transmission request is received until transmission is completed, or an error/arbitration lost has occurred), the TRMST bit in the CiSTR register is set to "1" (transmission in progress), and the CAN module starts transmission.*
2. If other TRMREQ bits are set, the transmission scan procedure starts with the CRC delimiter for the next transmission.
3. If transmission is completed without losing arbitration, the SENTDATA bit in the CiMCTLj register is set to "1" (transmission completed) and the TRMACTIVE bit is set to "0" (transmission is pending, or no transmission request). If the interrupt enable bit in the CiMIER register is "1" (interrupt enabled), the CANi transmission complete interrupt request is generated.
4. When requesting the next transmission from the same mailbox, set bits SENDTDATA and TRMREQ to "0", then set the TRMREQ bit to "1" after checking that bits SENDTDATA and TRMREQ have been set to "0".

Note: * If arbitration is lost after the CAN module starts transmission, the TRMACTIVE bit is set to "0". The transmission scan procedure is performed again to search for the highest-priority transmit mailbox from the beginning of the CRC delimiter. If an error occurs either during transmission or following the arbitration lost the transmission scan procedure is performed again from the start of the error delimiter to search for the highest-priority transmit mailbox.

34.9 CAN Interrupt

The CAN module provides the following CAN interrupts for each channel. Table 34.12 lists CAN interrupts.

- CANi reception complete interrupt (mailbox 0) [RXM0i]
- CANi reception complete interrupt (mailbox 1 to 63) [RXM1i]
- CANi transmission complete interrupt (mailbox 32 to 63) [TXMi]
- CANi reception FIFO interrupt [RXFi]
- CANi transmission FIFO interrupt [TXFi]
- CANi error interrupt [ERSi]

  There are eight types of interrupt sources for the CANi error interrupts. These sources can be determined by checking the CiEIFR register.
  - Bus error
  - Error-warning
  - Error-passive
  - Bus-off entry
  - Bus-off recovery
  - Receive overrun
  - Overload frame transmission
  - Bus lock

Table 34.12 CAN Interrupts

Module	Interrupt Symbol	Interrupt Source	Source Flag
CANi	ERSi	Bus lock detected	CiEIFR.BLIF
		Overload frame transmission detected	CiEIFR.OLIF
		Overrun detected	CiEIFR.ORIF
		Bus-off recovery detected	CiEIFR.BORIF
		Bus-off entry detected	CiEIFR.BOEIF
		Error-passive detected	CiEIFR.EPIF
		Error-warning detected	CiEIFR.EWIF
		Bus error detected	CiEIFR.BEIF
	RXFi	Receive FIFO message received (CiMIER1[29] = 0)	CiISR.RXFF
		Receive FIFO warning (CiMIER1[29] = 1)	
	TXFi	Transmit FIFO message transmission completed (CiMIER1[25] = 0)	CiISR.TXFF
		FIFO last message transmission completed (CiMIER1[25] = 1)	
	RXM0i	Mailbox 0 message received	CiMCTL0.NEWDATA
	RXM1i	Mailbox 1 to 63 message received	CiMCTL1.NEWDATA to CiMCTL63.NEWDATA
	TXMi	Mailbox 32 to 63 message transmission completed	CiMCTL32.SENTDATA to CiMCTL63.SENTDATA

Legend: i = 0, 1

(1) CANi reception complete interrupt (mailbox 0) [RXM0i]

After the CiMCTL0.NEWDATA bit is set by the completion of reception, if received data has been stored (the corresponding INVALDATA bit changes from "1" to "0"), the CiISR.RXM0F bit is set to "1" when CiMIER0[0] has been set to "1". When the mailbox 0 reception complete (RXM0) interrupt has been enabled, the RXM0 interrupt is requested to the interrupt controller.

To clear the RXM0 interrupt, clear the CiMCTL0.NEWDATA bit in the RXM0 interrupt handling routine. To change the CiIER.RXM0IE bit to disabled after having set the bit, make the change while no RXM0 interrupt is generated or during the RXM0 interrupt handling routine. This also applies to CiMIER0[0].

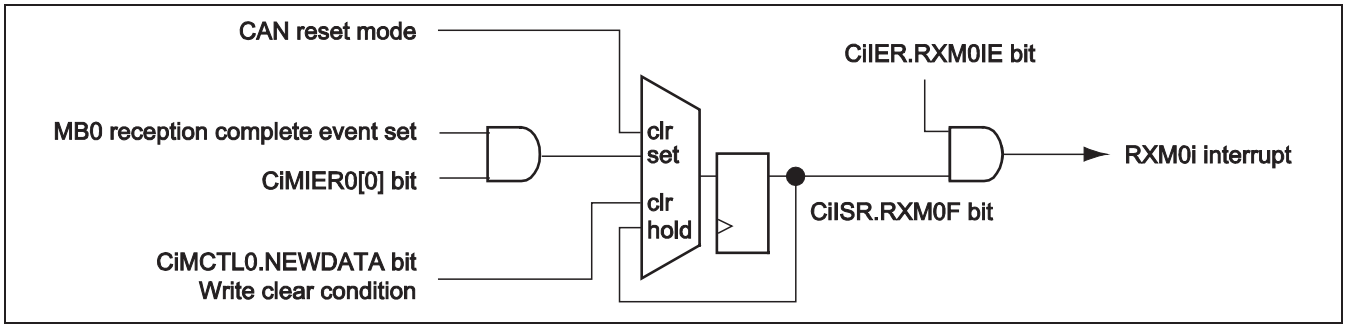

Figure 34.21 Block Diagram of CANi Reception Complete Interrupt (Mailbox 0) [RXM0i]

(2) CANi reception complete interrupt (mailbox 1 to 63) [RXM1i]

After the CiMCTLj.NEWDATA bit is set by the completion of reception, if received data has been stored (the corresponding INVALDATA bit changes from "1" to "0"), the CiISR.RXM1F bit is set to "1" when the CiMIER0 or CiMIER1 register bit corresponding to mailbox j has been set to "1". When the mailbox 1 to 63 reception complete (RXM1) interrupt has been enabled, the RXM1 interrupt is requested to the interrupt controller.

To clear the RXM1 interrupt, clear the CiMCTLj.NEWDATA bit in the RXM1 interrupt handling routine. To change the CiIER.RXM1IE bit to disabled after having set the bit, make the change while no RXM1 interrupt is generated or during the RXM1 interrupt handling routine. This also applies to CiMIER0[j] (j = 1 to 31) or CiMIER1[j-32] (j = 32 to 63).

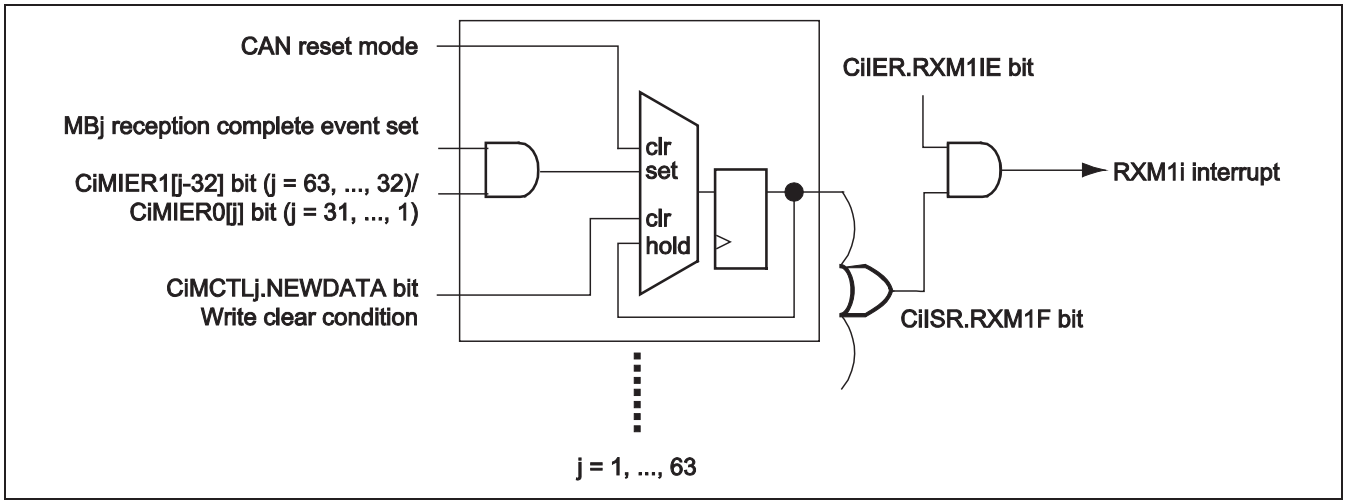

Figure 34.22 Block Diagram of CANi Reception Complete Interrupt (Mailbox 1 to 63) [RXM1i]

(3) CANi transmission complete interrupt (mailbox 32 to 63) [TXMi]

If the CiMCTLj.SENTDATA bit is set by the completion of transmission, the CiISR.TXMF bit is set to "1" when the CiMIER1 register bit corresponding to mailbox j has been set to "1". When the mailbox 32 to 63 transmission complete (TXM) interrupt has been enabled, the TXM interrupt is requested to the interrupt controller.

To clear the TXM interrupt, clear the CiMCTLj.SENTDATA bit in the TXM interrupt handling routine. To change the CiIER.TXMIE bit to disabled after having set the bit, make the change while no TXM interrupt is generated or during the TXM interrupt handling routine. This also applies to CiMIER1[j-32] (j = 32 to 63).

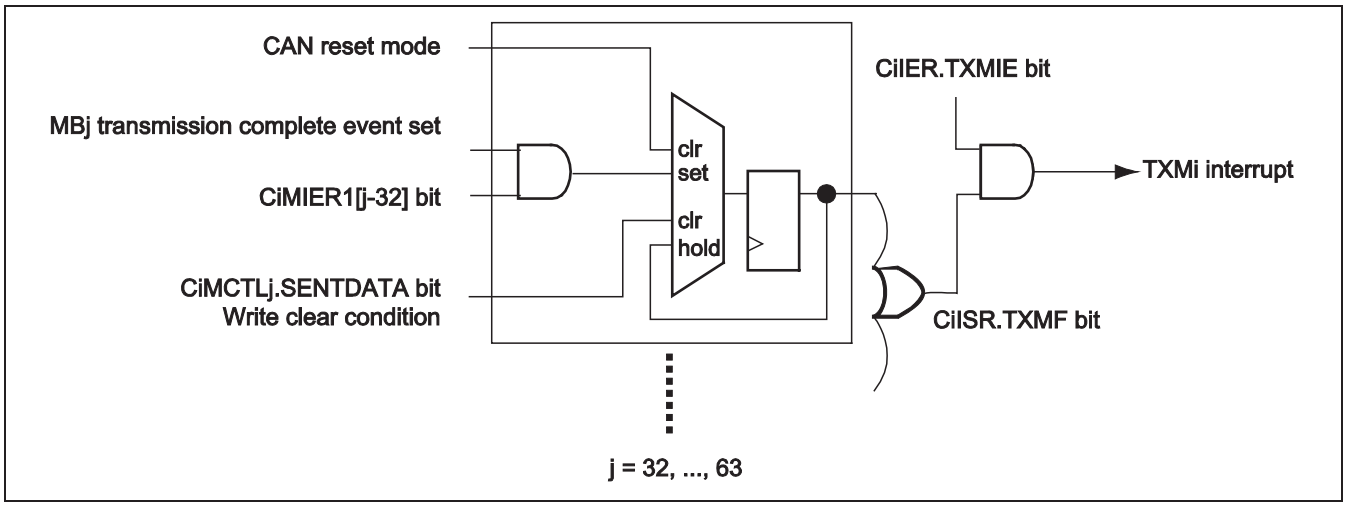

Figure 34.23 Block Diagram of CANi Transmission Complete Interrupt (Mailbox 32 to 63) [TXMi]

(4) CANi receive FIFO interrupt [RXFi]

If CiRFCR[6:5] are set by the reception of a receive FIFO message or by a warning with the settings of CiMIER1[29:28], the CiISR.RXFF bit is set to "1". When the receive FIFO (RXF) interrupt has been enabled with the CiIER.RXFIE bit, the RXF interrupt is requested to the interrupt controller.

To clear the RXF interrupt, clear the CiISR.RXFF bit in the RXF interrupt handling routine. To change the CiIER.RXFIE bit to disabled after having set the bit, make the change while no RXF interrupt is generated or during the RXF interrupt handling routine. This also applies to CiMIER1[28].

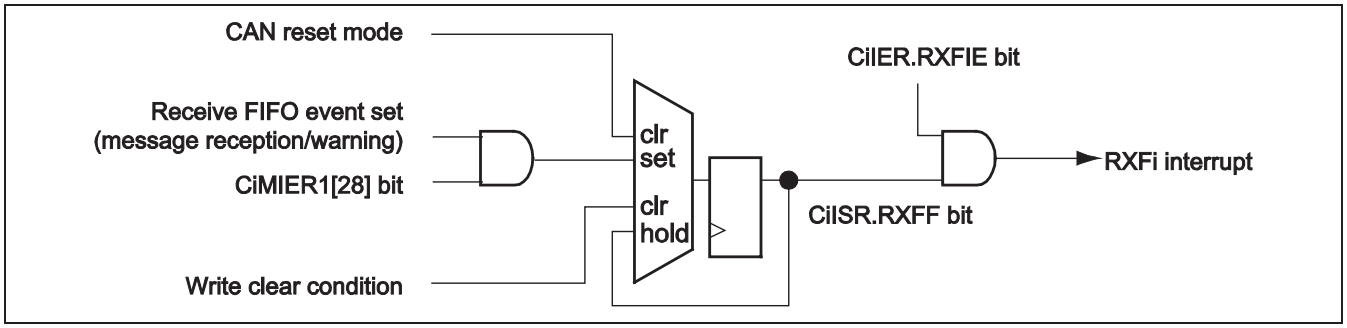

Figure 34.24 Block Diagram of CANi Receive FIFO Interrupt [RXFi]

(5) CANi transmit FIFO interrupt [TXFi]

When the transmission of a transmit FIFO message is counted for the specified number of times with the settings of CiMIER1 [25:24], the CiISR.TXFF bit is set to "1". When the transmit FIFO (TXF) interrupt has been enabled with the CiIER.TXFIE bit, the TXF interrupt is requested to the interrupt controller.

To clear the TXF interrupt, clear the CiISR.TXFF bit in the TXF interrupt handling routine. To change the CiIER.TXFIE bit to disabled after having set the bit, make the change while no TXF interrupt is generated or during the TXF interrupt handling routine. This also applies to CiMIER1[24].

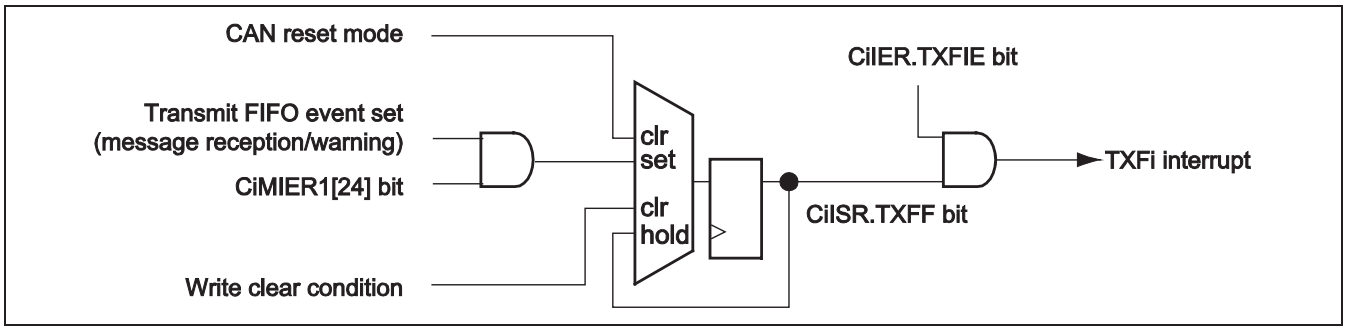

Figure 34.25 Block Diagram of CANi Transmit FIFO Interrupt [TXFi]

(6) CANi error interrupt [ERSi]

If CiEIFR[j] is set by a communication error, the CiISR.ERSF bit is set to "1" when the corresponding CiEIER[j] has been set to "1". When the error (ERS) interrupt has been enabled with the CiIER.ERSIE bit, the ERS interrupt is requested to the interrupt controller.

To clear the ERS interrupt, clear each CiEIFR[j] register bit in the ERS interrupt handling routine. To change the CiIER.ERSIE bit to disabled after having set the bit, make the change while no ERS interrupt is generated or during the ERS interrupt handling routine. This also applies to CiEIER[j] (j = 7 to 0).

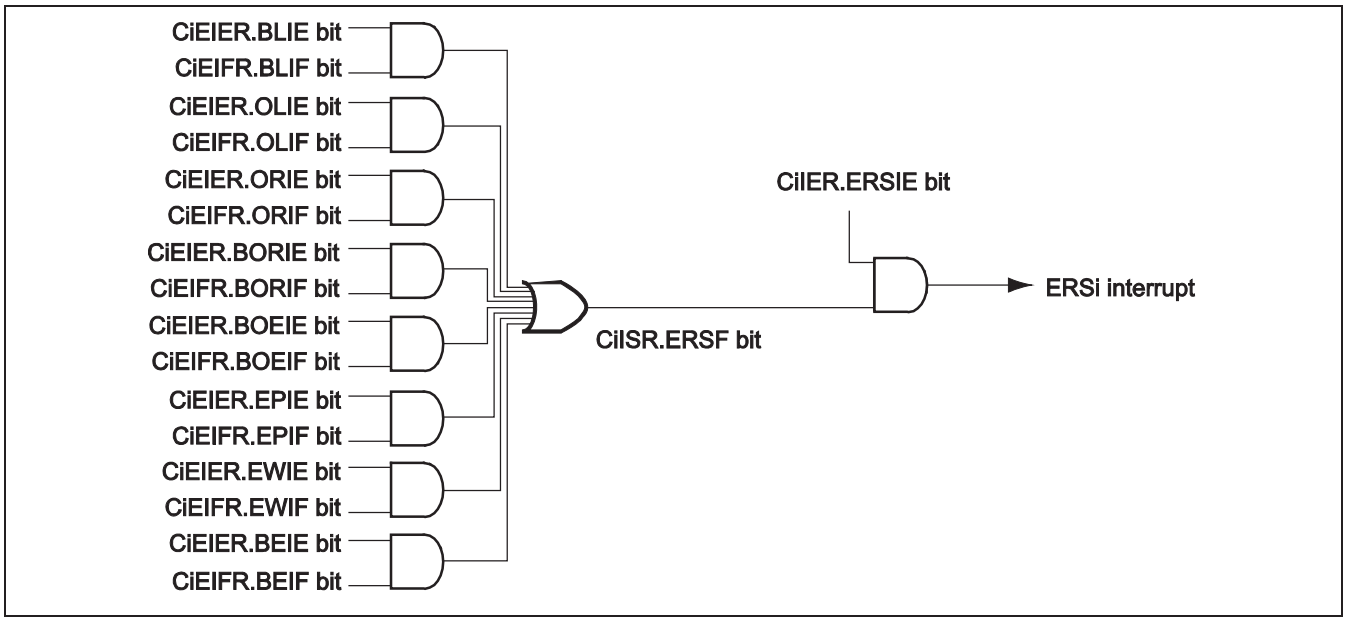

Figure 34.26 Block Diagram of CANi Error Interrupt [ERSi]

34.10 CAN Parity Check

The Parity bit generator for an Even Parity check is a simple XOR of each bit.

parity[0] = ^DataBus[7:0]

parity[1] = ^DataBus[15:8]

parity[2] = ^DataBus[23:16]

parity[3] = ^DataBus[31:24]

The Parity error detection for an Even Parity check is a simple XOR of each bit including the Parity bit. In case the result is equal to the Data Byte no error is generated. The detection logic is only working during read access for the selected byte.

parity_error[0] = { ^DataBus[7:0]} ^ parity[0]

parity_error[1] = { ^DataBus[15:8]} ^ parity[1]

parity_error[2] = { ^DataBus[23:16]} ^ parity[2]

parity_error[3] = { ^DataBus[31:24]} ^ parity[3]

Each memory location in the DPRAM consists of 36 bits. 32 bits are used for storage of user data. For each byte of a longword memory location a parity bit is allocated. The value of this parity bit is calculated by the parity generation logic for each byte and both data byte and parity bit are stored in memory during the same write access. The alignment of data bytes and corresponding parity bits in each memory location is shown in the following diagram:

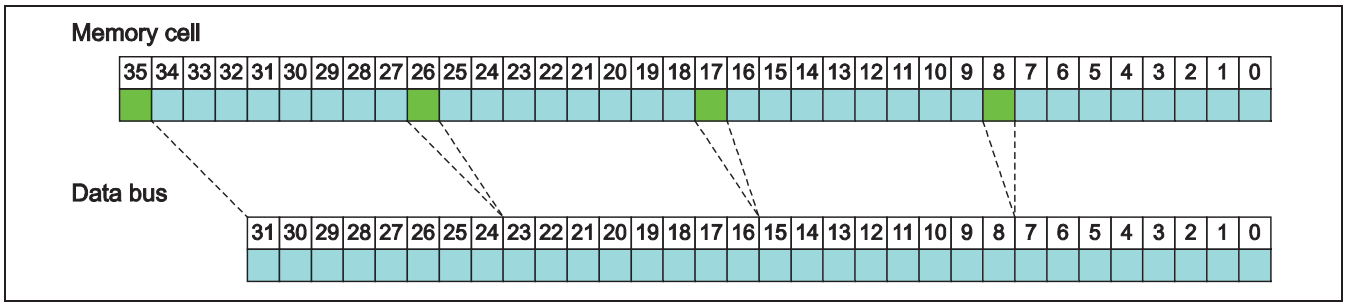

Figure 34.27 Parity bit alignment

35. Serial Communication Interface with FIFO (SCIF)

35.1 Overview

This LSI has serial communication interfaces with FIFO buffers (SCIF) that handles asynchronous communication and clock synchronous serial communication. The SCIF has two 16-stage FIFO buffers separately for transmission and reception, which enables fast, efficient, and uninterrupted communication. The following table lists the functions of each interface.

The presence of the SCK, RTS, and CTS pins depends on the product or channel. The synchronous mode and mode control functions are supported in the interface channel which has the pins related to these functions.

Modem control function is not supported by this product. The RTS# and CTS# pins, and related register bits are not supported also.

	Name	Function	Pin	Base Address	Remarks
0	SCIF-0	Asynchronous mode	RX0, TX0	H'E6E6 0000	—
1	SCIF-1	Asynchronous mode Clock synchronous mode	RX1, TX1 and SCK1*	H'E6E6 8000	Transmission/reception clock can be supplied externally from SCK1* pin.
2	SCIF-2	Asynchronous mode Clock synchronous mode	RX2, TX2 and SCK2*	H'E6E5 8000	Transmission/reception clock can be supplied externally from SCK2* pin.
3	SCIF-3	Asynchronous mode Clock synchronous mode	RX3, TX3 and SCK3*	H'E6EA 8000	Transmission/reception clock can be supplied externally from SCK3* pin.
4	SCIF-4	Asynchronous mode	RX4, TX4	H'E6EE 0000	—
5	SCIF-5	Asynchronous mode	RX5, TX5	H'E6EE 8000	—

Note: * SCKn respectively refer to SCIFn_SCK. (SCIF1: n = 1, SCIF2: n = 2, SCIF3: n = 3)

35.1.1 Features

The SCIF has the following features.

- Asynchronous serial communication mode

  The SCIF performs serial data communication based on a character-by-character asynchronous system. This feature enables serial data communication with standard asynchronous communication chips that support Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communication Interface Adapter (ACIA). There is a choice of eight serial data transfer formats.

  — Data length: 7 or 8 bits

  — Stop bit length: 1 or 2 bits

  — Parity: Even/odd/none

  — Receive error detection: Parity, framing, and overrun errors

  — Break detection:

  A break is detected when a framing error lasts for more than 1 frame length at Space 0 (low level).

  When a framing error occurs, a break can also be detected by reading the RX pin level directly from the serial port register (SCSPTR).
- Clock synchronous serial communication mode

  The SCIF performs serial data communication synchronized with a clock. This feature enables serial data communication with other LSIs that support synchronous communication. There is a single serial data communication format for clock synchronous serial communication.

  — Data length: 8 bits

  — Receive error detection: Overrun errors
- Full-duplex communication capability

  The SCIF has an independent transmitter and receiver that enable simultaneous transmission and reception. The transmitter and receiver both have a 16-stage FIFO buffer structure, enabling continuous serial data transmission and reception.
- On-chip baud rate generator, enabling any bit rate to be selected

  The SCIF enables choice of a clock source for transmission/reception: a clock from the on-chip baud rate generator based on the internal clock or an external clock.
- Eight interrupt sources

  The SCIF has eight types of interrupt sources – receive-data-ready, receive-FIFO-data-full, break, transmit-FIFO-data-empty, transmit-end, receive-error, overrun-error and time-out and enables any of them to be requested independently.
- DMA data transfer

  When the transmit FIFO register is empty or the receive FIFO register has received data, issuing a DMA transfer request activates the DMA controller (DMAC) to execute a data transfer.
- The amount of data in the transmit/receive FIFO registers and the number of receive errors in receive data in the receive FIFO register are available.
- In asynchronous mode, a receive data ready (DR) or a timeout error (TO) can be detected during reception.

35.1.2 Block Diagram

Figure 35.1 shows the SCIF block diagram.

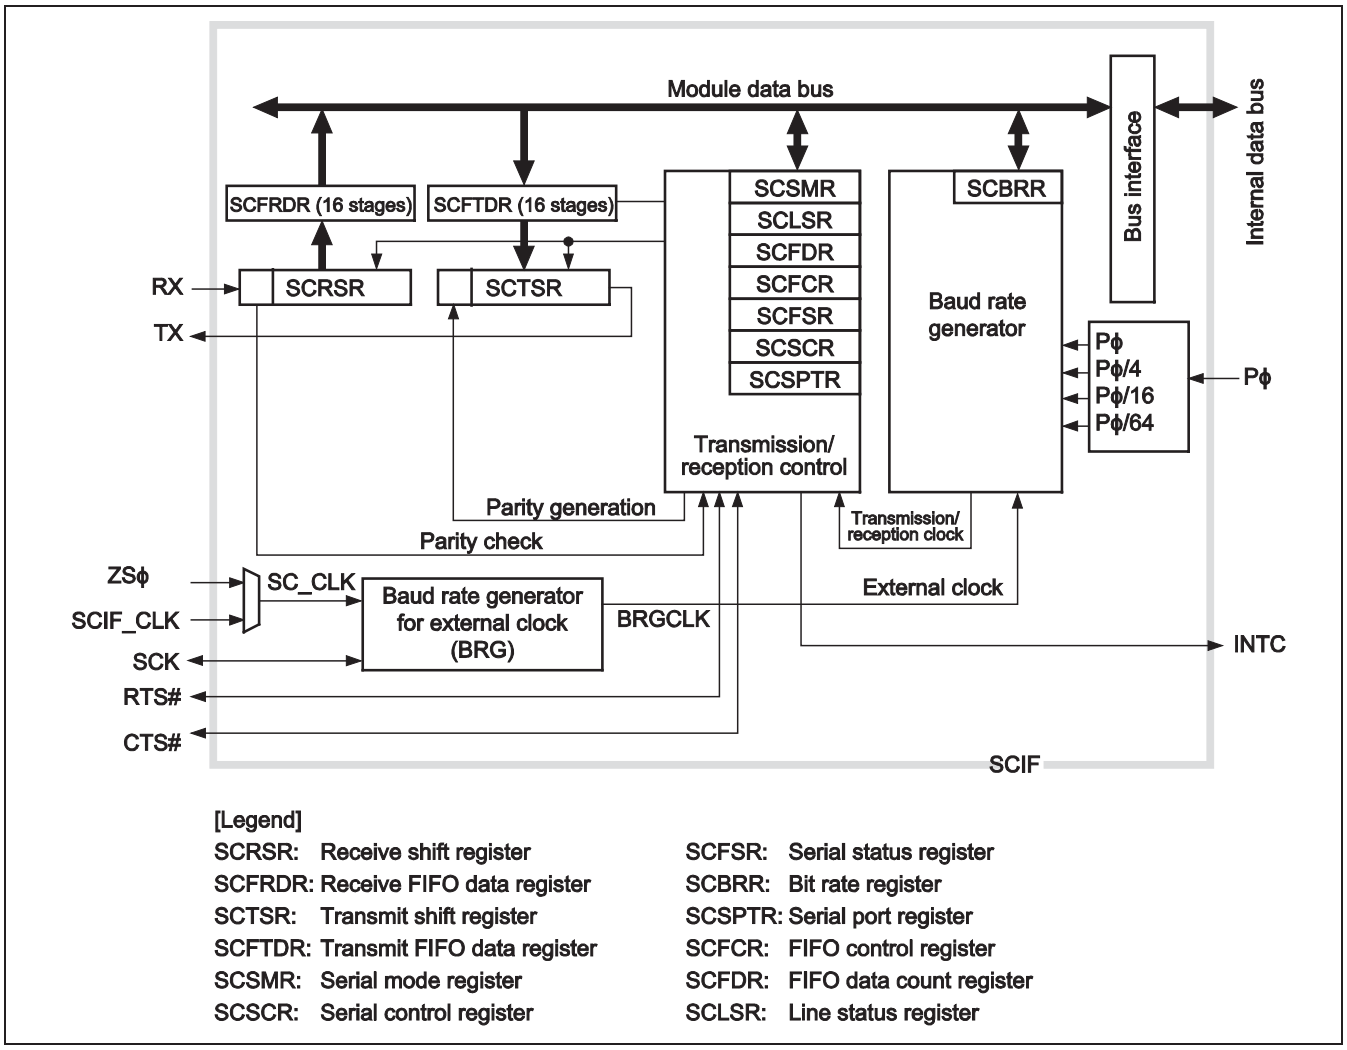

Figure 35.1 SCIF Block Diagram

35.1.3 Input/Output Pins

Table 35.1 shows the SCIF pin configuration. Pin functions can differ with the interface number. Other functions are also multiplexed on the same pins, so the multiplexed pin settings may restrict usage of the pins.

Table 35.1 Pin Configuration

Pin Name	Abbreviation	I/O	Function
Serial clock pin (SCIFn_SCK*)	SCK	I/O	Synchronous clock I/O
Receive data pin (RXn)	RX	Input	Receive data input
Transmit data pin (TXn)	TX	Output	Transmit data output
Baud rate generation clock pin	SCIF_CLK	Input	Clock for input to the baud rate generator for the external clock

Note: These pins are made to function as serial pins by setting up SCIF operation using bit C/A# in SCSMR, bits TE, RE, CKE[1:0] in SCSCR, and bit MCE in SCFCR. SCSPTR of the SCIF can be used to handle the transmission and detection of break states.

* n: Channel number

35.1.4 Register Configuration

Table 35.2 shows the registers in the SCIF.

Table 35.2 Register Configuration

Register Name	Abbreviation	R/W	Offset from Base Address	Initial Value	Access Size
Serial mode register	SCSMR	R/W	H'00	H'0000	16
Bit rate register	SCBRR	R/W	H'04	H'FF	8
Serial control register	SCSCR	R/W	H'08	H'0000	16
Transmit FIFO data register	SCFTDR	W	H’0C	Undefined	8
Serial status register	SCFSR	R/W*1	H'10	H'0060	16
Receive FIFO data register	SCFRDR	R	H’14	Undefined	8
FIFO control register	SCFCR	R/W	H'18	H'0000	16
FIFO data count register	SCFDR	R	H'1C	H'0000	16
Serial port register	SCSPTR	R/W	H'20	H'00XX*3	16
Line status register	SCLSR	R/W*2	H'24	H'0000	16
Frequency division register	DL	R/W	H'30	H'0000	16
Clock Select register	CKS	R/W	H'34	H'0000	16

Notes: 1. Only 0 can be written to bits 7 to 4, 1, and 0 to clear the flags. Bits 15 to 8, 3, and 2 are read-only bits and cannot be modified.
2. Only 0 can be written to bits 2 and 1 to clear the flags. Bits 15 to 3, and 1 are read-only bits and cannot be modified.
3. The initial values of SCSPTR bits 6, 4, 2, and 0 are undefined.

The table below lists the registers used in asynchronous mode, asynchronous mode with modem control, and clock synchronous mode. When setting up the registers, set the bits related to unsupported modes in each interface to their initial values. Otherwise, the SCIF may malfunction. Do not write to any registers other than listed below. Operations cannot be guaranteed if writing is attempted. Values read from registers other than listed below are undefined.

Table 35.3 Register Settings in Each Mode

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SCFRDR	—	—	—	—	—	—	—	—	*	*	*	*	*	*	*	*
SCFTDR	—	—	—	—	—	—	—	—	*	*	*	*	*	*	*	*
SCSMR	0	0	0	0	0	0	0	0	C	A	A	A	A	0	*	*

SCSPTR	0	0	0	0	0	0	0	0	M	M	M	M	C	C	*	*
SCLSR	0	0	0	0	0	0	0	0	0	0	0	0	0	A	0	*
DL	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*
CKS	*	*	0	0	0	0	0	0	0	0	0	0	0	0	0	0

[Legend]

* : Used in any mode.

A : Used in asynchronous mode.

M : Used in asynchronous mode (modem control is enabled) (in addition to A).

C : Used in clock synchronous mode.

0 : Reserved (the write value should always be 0.)

— : Undefined

35.2 Register Descriptions

35.2.1 Receive Shift Register (SCRSR)

SCRSR is a register that receives serial data.

The SCIF sets serial data input to the SCRSR from the RX pin in the order received, starting with the LSB (bit 0), and converts it to parallel data. When one byte of data has been received, it is transferred to the receive FIFO data register SCFRDR, automatically.

SCRSR cannot be read from and written to by the CPU.

Bit:	7	6	5	4	3	2	1	0
Initial value:	—	—	—	—	—	—	—	—
R/W:	—	—	—	—	—	—	—	—

35.2.2 Receive FIFO Data Register (SCFRDR)

SCFRDR is a 16-stage FIFO register that stores received serial data.

When the SCIF has received one byte of serial data, it transfers the received data from the receive shift register (SCRSR) to SCFRDR for storage, and reception is thus completed. SCRSR is then ready for reception, and is capable of receiving up to 16 consecutive bytes of data before SCFRDR is full.

SCFRDR is a read-only register and cannot be modified by the CPU. Note that the read value will be undefined while there is no receive data in SCFRDR. When SCFRDR is full of receive data, subsequent serial data is lost.

SCFRDR is read as an undefined value after a power-on reset.

Bit:	7	6	5	4	3	2	1	0
Initial value:	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R

35.2.3 Transmit Shift Register (SCTSR)

SCTSR is a register that transmits serial data.

To perform serial data transmission, the SCIF first transfers transmit data from the transmit FIFO data register (SCFTDR) to SCTSR, then sends the data to the TX pin starting with the LSB (bit 0). When transmission of one byte is completed, the SCIF transfers the next transmit data from SCFTDR to SCTSR automatically, then starts transmission.

SCTSR cannot be read from and written to directly by the CPU.

Bit:	7	6	5	4	3	2	1	0
Initial value:	—	—	—	—	—	—	—	—
R/W:	—	—	—	—	—	—	—	—

35.2.4 Transmit FIFO Data Register (SCFTDR)

SCFTDR is an 8-bit FIFO register of 16 stages that stores data for serial transmission.

If SCTSR is empty after transmit data has been written to SCFTDR, the SCIF transfers the data from SCFTDR to SCTSR and starts serial transmission.

SCFTDR is a write-only register and cannot be read from by the CPU. Writing further data to SCFTDR is no longer possible when it is full (contains 16 bytes of transmit data). Attempts at writing data to the register in this situation are ignored.

SCFTDR is read as an undefined value on a power-on reset.

Bit:	7	6	5	4	3	2	1	0
Initial value:	—	—	—	—	—	—	—	—
R/W:	W	W	W	W	W	W	W	W

35.2.5 Serial Mode Register (SCSMR)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	C/A#	CHR	PE	O/E#	STOP	—	CKS[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W

SCSMR is a 16-bit register that sets the SCIF's serial transfer format and selects the baud rate generator clock source.

SCSMR can always be read from and written to by the CPU.

SCSMR is initialized to H'0000 by a power-on reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	C/A#	0	R/W	Communication Mode Selects asynchronous mode or clock synchronous mode for the SCIF operation. 0: Asynchronous mode 1: Clock synchronous mode Note: Whether clock synchronous mode can be selected or not depends on the interface.
6	CHR	0	R/W	Character Length Selects 7 or 8 bits for asynchronous mode data length. In clock synchronous mode, the data length is fixed at 8 bits regardless of the CHR bit setting. 0: 8 bits 1: 7 bits* Note: * When the 7-bit data is selected, the MSB (bit 7) in the transmit FIFO data register (SCFTDR) is not transmitted.
5	PE	0	R/W	Parity Enable Determines whether parity bit is added in transmission or not, and parity bit is checked in reception in asynchronous mode or not. In clock synchronous mode, the parity bit is not added and checked regardless of the PE bit setting. When bit PE is set to 1, the parity (even or odd) specified by bit O/E# is added to transmit data. In reception, the parity bit is checked for the parity (even or odd) specified by bit O/E#. 0: Disables parity bit addition and check. 1: Enables parity bit addition and check.

Bit	Bit Name	Initial Value	R/W	Description
4	O/E#	0	R/W	Parity Mode Selects either even or odd parity to use in parity addition and check. In asynchronous mode, the O/E# bit setting is valid only when bit PE is set to 1, enabling parity bit addition and check. In clock synchronous mode or when parity addition or check is disabled in asynchronous mode, the O/E# bit setting is invalid. 0: Even parity*1 1: Odd parity*2 Notes: 1. When even parity is set, the parity bit is added in transmission so that the total number of 1-bits in the transmit character plus the parity bit is even. In reception, a check is performed to see if the total number of 1-bits in the receive character plus the parity bit is even. 2. When odd parity is set, the parity bit is added in transmission so that the total number of 1-bits in the transmit character plus the parity bit is odd. In reception, a check is performed to see if the total number of 1-bits in the receive character plus the parity bit is odd.
3	STOP	0	R/W	Stop Bit Length Selects 1 bit or 2 bits as the stop bit length in asynchronous mode. The stop bit setting is valid only in asynchronous mode. Since the stop bit is not added in clock synchronous mode, the STOP bit setting is invalid in this mode. In reception, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1, it is treated as a stop bit. If it is 0, it is treated as the start bit of the next transmit character. 0: 1 stop bit*1 1: 2 stop bits*2 Notes: 1. In transmission, a single 1-bit (stop bit) is added to the end of a transmit character before it is sent. 2. In transmission, two 1-bits (stop bits) are added to the end of a transmit character before it is sent.
2	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
1, 0	CKS[1:0]	00	R/W	Clock Select 1 and 0 These bits select the clock source for the on-chip baud rate generator. The clock source can be selected from Pϕ, Pϕ/4, Pϕ/16, and Pϕ/64, according to the setting of bits CKS1 and CKS0. 00: Pϕ 01: Pϕ/4 10: Pϕ/16 11: Pϕ/64 Note: Pϕ: Peripheral clock (frequency dividing CPU clock into 12)

35.2.6 Serial Control Register (SCSCR)

SCSCR is a register that enables or disables transmission/reception by the SCIF, enables or disables interrupt requests, and selects transmission/reception clock source for the SCIF.

SCSCR can always be read from and written to by the CPU.

SCSCR is initialized to H'0000 by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	TEIE	—	—	—	TIE	RIE	TE	RE	REIE	TOIE	CKE[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	TEIE	0	R/W	Transmit End Interrupt Enable When a transmit-end request is enabled by the TIE bit, the TEIE bit selects the source of the transmit end interrupt request from the following: • Setting the TDFE flag in SCFSR • Setting the TEND flag in SCFSR 0: The transmit FIFO data empty (TDFE) interrupt request is used. 1: The transmit end (TEND) interrupt request is used.
10 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
7	TIE	0	R/W	Transmit Interrupt Enable Enables or disables a transmit-FIFO-data-empty interrupt (TDFE) request when the TEIE bit in SCSCR is pulled 0, if the following conditions are satisfied: • Serial transmit data has been transferred from SCFTDR to SCTSR, • The number of data bytes in SCFTDR is equal to or less than the transmit trigger count, and • The TDFE flag in SCFSR is set to 1. Enables or disables a transmit-end interrupt (TEND) request when the TEIE bit of SCSCR is set to 1, if the following conditions are satisfied: • Transmission was ended because there is no valid data in SCFTDR when the last bit of the transmit character in SCTSR was transmitted, and • The TEND flag of SCFSR is set to 1. 0: When the TEIE bit is 0, disables transmit-FIFO-data-empty interrupt (TDFE) request.* When the TEIE bit is 1, disables transmit-end interrupt (TEND) request.* 1: When the TEIE bit is 0, enables transmit-FIFO-data-empty interrupt (TDFE) request. When the TEIE bit is 1, enables transmit-end interrupt (TEND) request.
6	RIE	0	R/W	Receive Interrupt Enable Enables or disables a receive-FIFO-data-full interrupt request when the RDF flag in SCFSR is set to 1, a receive-data-ready interrupt request when the DR flag in SCFSR is set to 1, a receive-error interrupt request when the ER flag in SCFSR is set to 1, a break interrupt request when the BRK flag in SCFSR is set to 1, and an overrun error interrupt request when the ORER flag in SCLSR is set to 1. 0: Disables receive-FIFO-data-full interrupt (RDF) requests, receive-data-ready interrupt (DR) requests, receive-error interrupt (ER) requests, break interrupt (BRK) requests, and overrun error interrupt (ORER) requests. 1: Enables receive-FIFO-data-full interrupt (RDF) requests, receive-data-ready interrupt (DR) requests, receive-error interrupt (ER) requests, break interrupt (BRK) requests, and overrun error interrupt (ORER) requests.
5	TE	0	R/W	Transmit Enable Enables or disables the start of SCIF serial transmission. The SCIF starts serial transmission when transmit data is written to the SCFTDR while TE is 1. Before setting TE to 1, set SCSMR and SCFCR to specify the transmission format and reset the transmit FIFO. 0: Disables transmission.* 1: Enables transmission.*

Bit	Bit Name	Initial Value	R/W	Description
4	RE	0	R/W	Receive Enable Enables or disables the start of SCIF serial reception. When RE is 1, the SCIF starts serial reception by detecting a start bit in asynchronous mode or by detecting a synchronization clock input in clock synchronous mode. Before setting RE to 1, set SCSMR and SCFCR to specify the reception format and reset the receive FIFO. 0: Disables reception.* 1: Enables reception. Note: Even if RE is cleared to 0, the DR, ER, BRK, RDF, FER, PER, TO and ORER flags are not affected, and retain their states.
3	REIE	0	R/W	Receive Error Interrupt Enable Enables or Disables generation of receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests. 0: Disables receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests.* 1: Enables receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests. Note: * When REIE is 1, ER, BRK or ORER interrupt requests will occur even if RIE is cleared to 0. This setting is used to notify the interrupt controller of ER, BRK, and ORER interrupt requests during DMAC transfer.
2	TOIE	0	R/W	Timeout Interrupt Enable Enables or disables generation of timeout interrupt (TO) requests when the TO flag in SCLSR is set to 1. 0: Disables timeout interrupts (TO). 1: Enables timeout interrupts (TO).
1, 0	CKE[1:0]	00	R/W	Clock Enable 1 and 0 These bits select the SCIF clock source and enables or disables the clock output from the SCK pin. Whether the SCK pin functions as a serial clock output pin or a serial clock input pin is determined by combination of the CKE[1:0] bits settings. To specify synchronization clock output in clock synchronous mode, set C/A# to 1 in SCSMR then set CKE[1:0]. See Table 35.4 for the bit settings.

Table 35.4 Clock Selection

CKE[1:0]	Mode	Clock Source	SCK Pin
00	Asynchronous mode	Internal clock (Pϕ, Pϕ/4, Pϕ/16, Pϕ/64)	The SCK pin is not used. The SCK pin functions as an input pin (Input signals are ignored). (Initial value)
	Clock synchronous mode		The SCK pin outputs the synchronization clock. (Initial value)
01	Asynchronous mode		The SCK pin outputs the clock (with a frequency 16 times the bit rate).
	Clock synchronous mode		The SCK pin outputs the synchronization clock.
10	Asynchronous mode	Baud rate generator output for external clock or SCK	When SC_CLK is selected: The SCK pin is an input pin (Input signals are ignored). Set the SC_CLK frequency so that the frequency of BRGCLK is 16 times the bit rate.
			When SCK is selected: The SCK pin inputs the clock (with a frequency 16 times the bit rate).
	Clock synchronous mode	SCK*	The SCK pin inputs the synchronization clock.
11	Prohibited		

Notes: Some interfaces cannot select the clock synchronous mode.
* It is not allowed to set synchronous communication using SC_CLK for input.

35.2.7 Serial Status Register (SCFSR)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PER[3:0]				FER[3:0]				ER	TEND	TDFE	BRK	FER	PER	RDF	DR
Initial value:	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W*	R/W*	R/W*	R/W*	R	R	R/W*	R/W*

Note: Only 0 can be written to clear the flag.

SCFSR is a 16-bit register. The lower 8 bits are a status flag that indicates the operating status of the SCIF, and the upper 8 bits indicate the number of reception errors of data in the receive FIFO register.

SCFSR can always be read from and written to by the CPU. However, the flags ER, TEND, TDFE, BRK, RDF, and DR cannot be written by 1. The FER and PER flags are read-only flags and cannot be modified.

SCFSR is initialized to H'0060 by a power-on reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	PER[3:0]	All 0	R	Parity Error Count These bits indicate the number of parity errors of receive data stored in the receive FIFO data register (SCFRDR). After the ER is set in SCFSR, the value represented by bits 15 to 12 indicates the number of parity errors. If a parity error occurs in all 16-byte receive data in SCFRDR, PER3 to PER0 are cleared to 0.
11 to 8	FER[3:0]	All 0	R	Framing Error Count These bits indicate the number of framing errors of receive data stored in the receive FIFO data register (SCFRDR). After the ER bit is set in SCFSR, the value represented by bits 11 to 8 indicates the number of framing errors. If a framing error occurs in all 16-byte receive data in SCFRDR, FER3 to FER0 are cleared to 0.
7	ER	0	R/W*	Receive Error Indicates that a framing error or a parity error has occurred in reception.*1 The ER flag is not affected by an error and retains its previous state when the RE bit is 0 in SCSCR. If a receive error occurs, receive data will be transferred to SCFRDR and reception operation will be continued. Whether there is a receive error in data read from SCFRDR can be determined by the FER and PER bits in SCFSR. 0: Indicates that no framing or parity error has occurred in reception. [Clearing conditions] • A power-on reset is executed. • 0 is written to ER. 1: Indicates that a framing error or a parity error has occurred in reception. [Setting conditions] • The SCIF checks whether the stop bit at the end of receive data is 1, but the stop bit is 0.*2 • The number of 1-bits in receive data plus the parity bit does not match the parity setting (even or odd) specified by the O/E# bit in SCSMR during reception. Note: In the 2-stop-bit mode, only the first stop bit is checked that the value is 1; the second stop bit is not checked.

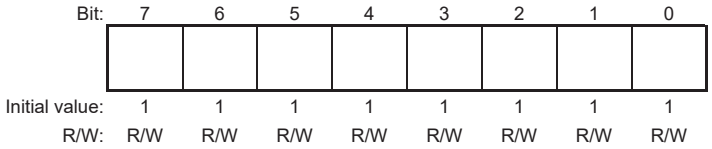
Bit	Bit Name	Initial Value	R/W	Description
6	TEND	1	R/W*	Indicates that transmission has been ended * because there was no valid data in SCFTDR when the last bit of the transmit character was transmitted. 0: Indicates that transmission is in progress. [Clearing conditions] • Transmit data is written to SCFTDR, and 0 is written to TEND. • Data is written to SCFTDR by the DMAC. 1: Indicates that transmission has been ended. [Setting conditions] • A power-on reset is executed. • The TE bit in SCSCR is 0. • There is no transmit data in SCFTDR when the last bit of a 1-byte serial transmission character is transmitted. Note: When transmit data is written to SCFTDR by the DMAC in clock synchronous mode, the TEND flag may not be cleared. Therefore, if the DMAC is used for transmission in clock synchronous mode, the TEND flag should be read using the following procedure. 1. Check that data transfer is completed in the DMAC. 2. Read the TEND flag. 3. If TEND = 1, clear the TEND flag to 0. 4. Read the TEND flag again. 5. Use the second read TEND flag.
5	TDFE	1	R/W*	Transmit FIFO Data Empty Indicates that the SCIF has transferred data from SCFTDR to SCTSR, the number of data bytes in SCFTDR becomes equal to or less than the transmit trigger count specified by the TTRG1 and TTRG0 bits in SCFCR, and SCFTDR is ready to be written by new transmit data. SCFTDR is a 16-byte FIFO register. The maximum number of bytes that can be written to when TDFE = 1 is “16 – [the transmit trigger count]”. If data exceeding this value is attempted to be written, the data will be ignored. The number of data bytes in SCFTDR is indicated by the upper bits of SCFDR. If the number of data written in SCFTDR is equal to or less than the transmit trigger count, this bit will be set to 1 even if it is cleared to 0 after it is read as 1. 0: Indicates that the number of transmit data written to SCFTDR exceeds the transmit trigger count. [Clearing conditions] • Transmit data exceeding the specified transmit trigger count have been written to SCFTDR, and 0 is written to TDFE. • Transmit data exceeding the specified transmit trigger count have been written to SCFTDR by the DMAC. 1: Indicates that the number of transmit data in SCFTDR is equal to or less than the transmit trigger count. [Setting conditions] • A power-on reset is executed. • The number of transmit data in SCFTDR is equal to or less than the transmit trigger count after transmission.

Bit	Bit Name	Initial Value	R/W	Description
4	BRK	0	R/W*	Break Detect Indicates that a receive data break signal has been detected. If a break signal is detected, receive data (H'00) transfer to SCFRDR is stopped. After the break is canceled and the receive signal returns to 1, the receive data transfer resumes. 0: Indicates that no break signal has been received. [Clearing conditions] • A power-on reset is executed. • 0 is written to BRK. 1: Indicates that a break signal has been received. [Setting condition] • Data with a framing error is received, followed by the space "0" (low level) for at least one frame length.
3	FER	0	R	Framing Error Indicates that a framing error has been found in the data that is to be read next from SCFRDR in asynchronous mode. 0: Indicates that there is no framing error in the receive data that is to be read from SCFRDR. [Clearing conditions] • A power-on reset is executed. • There is no framing error in the data that is to be read next from SCFRDR. 1: Indicates that there is a framing error in the receive data that is to be read from SCFRDR. [Setting condition] • There is a framing error in the data that is to be read next from SCFRDR.
2	PER	0	R	Parity Error This bit indicates that a parity error has been found in the data that is to be read next from SCFRDR in asynchronous mode. 0: Indicates that there is no parity error in the receive data that is to be read from SCFRDR. [Clearing conditions] • A power-on reset is executed. • There is no parity error in the data that is to be read next from SCFRDR. 1: Indicates that there is a parity error in the receive data that is to be read from SCFRDR. [Setting condition] • There is a parity error in the data that is to be read next from SCFRDR.

Bit	Bit Name	Initial Value	R/W	Description
1	RDF	0	R/W*	Receive FIFO Data Full Indicates that the received data has been transferred from SCRSR to SCFRDR, and the number of receive data bytes in SCFRDR becomes equal to or more than the receive trigger count specified by the RTRG1 and RTRG0 bits in SCFCR. SCFRDR is a 16-byte FIFO register. When RDF = 1, data equal to or more than the number of receive trigger data bytes can be read. When SCFRDR is empty, SCFRDR is read as an undefined value. The number of receive data bytes in SCFRDR is indicated by the lower bits of SCFDR. If the number of data in SCFRDR is equal to or more than the trigger count, this bit will be set to 1 even if it is cleared to 0. At this time, read receive data until the number of data in SCFRDR is less than the trigger count, read RDF as 1, and then clear RDF. 0: Indicates that the number of receive data bytes in SCFRDR is less than the specified receive trigger count. [Clearing conditions] • A power-on reset is executed. • SCFRDR is read until the number of receive data bytes in SCFRDR is less than the receive trigger count, and 0 is written to RDF. • SCFRDR is read by the DMAC until the number of receive data bytes in SCFRDR is less than the receive trigger count. 1: Indicates that the number of receive data bytes in SCFRDR is equal to or more than the specified receive trigger count. [Setting condition] • Receive data more than the receive trigger count have been stored in SDFRDR.
0	DR	0	R/W*	Receive Data Ready Indicates that the number of data bytes in SCFRDR is less than the receive trigger count and that no further data has been received for at least 15 etu after the stop bit of the data received last in asynchronous mode. This bit is not set in clock synchronous mode. 0: Indicates that data is being received or has been successfully received, and there is no receive data in SCFRDR. [Clearing conditions] • A power-on reset is executed. • All the receive data in SCFRDR has been read, and 0 is written to DR. • All the receive data in SCFRDR has been read by the DMAC. 1: Indicates that no further receive data has been received. [Setting condition] • The receive FIFO data register (SCFRDR) has the number of data byte that is below the receive trigger number of data bytes and no further data has arrived for at least 15 etu after the stop bit of the data received last. Note: etu: Elementary Time Unit (time for transfer of 1 bit) Equivalent to 1.5 frames with an 8-bit, 1-stop-bit format.

Note: Writing 0 is only available to clear the flag.

35.2.8 Bit Rate Register (SCBRR)



SCBRR is an 8-bit register that sets the serial transmission/reception bit rate in accordance with the baud rate generator operating clock selected by the CKS1 and CKS0 bits in SCSMR. This baud rate generator is intended for Pϕ, Pϕ/4, Pϕ/16, and Pϕ/64. For details on the baud rate generator for external clock, see section 35.6, Baud Rate Generator for External Clock (BRG).

SCBRR can always be read from and written to by the CPU except for during transfer.

SCBRR is initialized to H'FF by a power-on reset.

The SCBRR setting is determined by the following equation:

[Asynchronous mode]

$$N = \frac{P\phi}{64 \times 2^{2n-1} \times B} \times 10^6 - 1$$

[Clock synchronous mode]

$$N = \frac{P\phi}{8 \times 2^{2n-1} \times B} \times 10^6 - 1$$

B: Bit rate (bit/s)

N: SCBRR setting for the baud rate generator ($0 \leq N \leq 255$) (which satisfies the electrical characteristics)

Pϕ: Peripheral module operating frequency (MHz)

N: Baud rate generator input clock (n = 0, 1, 2, 3)
(See the Table 35.5 for the relation between n and the clock.)

Table 35.5 SCSMR Settings

n	Clock	SCSMR.CKS[1:0] Setting
0	Pϕ	00
1	Pϕ/4	01
2	Pϕ/16	10
3	Pϕ/64	11

The bit rate error in asynchronous mode is determined by the following equation:

$$\text{error (\%)} = \left\{ \frac{P\phi \times 10^6}{(N+1) \times B \times 64 \times 2^{2n-1}} - 1 \right\} \times 100$$

35.2.9 FIFO Control Register (SCFCR)

SCFCR is a register that resets data counts and sets the number of trigger data bytes for the transmit and receive FIFO registers. It also has a loopback test enable bit.

SCFCR can always be read from and written to by the CPU except for during transfer.

SCFCR is initialized to H'0000 by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	RSTRG[2:0]			RTRG[1:0]		TTRG[1:0]		MCE	TFRST	RF RST	LOO P
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 8	RSTRG[2:0]	000	R/W	RTS Output Active Trigger The RTS# signal is high when the number of receive data bytes stored in SCFRDR is equal to or more than the specified trigger number shown below: 000: 15 001: 1 010: 4 011: 6 100: 8 101: 10 110: 12 111: 14
7, 6	RTRG[1:0]	00	R/W	Receive FIFO Data Count Trigger These bits specify the number of receive data bytes that makes the RDF (receive data full) flag to be set in SCFSR. The RDF flag is set when the number of receive data bytes in SCFRDR is equal to or more than the specified trigger number shown below:

RTRG[1:0]	Asynchronous Mode	Clock Synchronous Mode
00	1	1
01	4	2
10	8	8
11	14	14

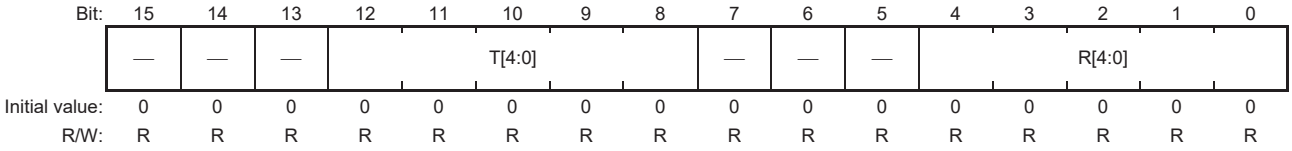
Bit	Bit Name	Initial Value	R/W	Description
5, 4	TTRG[1:0]	00	R/W	Transmit FIFO Data Count Trigger These bits specify the number of remaining transmit data bytes that makes the transmit FIFO data register empty (TDFE) flag to be set in SCFSR. The TDFE flag is set when the number of transmit data bytes in SCFTDR is equal to or less than the specified trigger count shown below, after transmission: 00: 8 (8) 01: 4 (12) 10: 2 (14) 11: 0 (16) Note: Values in parentheses indicate the empty space in SCFTDR in bytes.
3	MCE	0	R/W	Modem Control Enable Enables or disables modem control signals CTS# and RTS#. This bit should always be set to 0 in clock synchronous mode. Whether modem control can be selected or not depends on the interface. 0: Disables modem signals.* 1: Enables modem signals. Note: CTS# and RTS# control ports.
2	TFRST	0	R/W	Transmit FIFO Data Register Reset Enables or disables a transmit FIFO data register reset that empties the register. 0: Disables the reset.* 1: Enables the reset. Note: The register is reset by a power-on reset.
1	RFRST	0	R/W	Receive FIFO Data Register Reset Enables or disables a receive FIFO data register reset that empties the register. 0: Disables the reset.* 1: Enables the reset. Note: The register is reset by a power-on reset.
0	LOOP	0	R/W	Loopback Test Enables or disables the loopback test by internally connecting the transmit output pin (TX) and receive input pin (RX), and the RTS# pin and CTS# pin. If the loopback test is specified, the signal on the RTS# pin is internally conveyed to CTS# pin, and data transmission is automatically suspended when RTS# is asserted. 0: Disables the loopback test. 1: Enables the loopback test. Even if loopback test is specified by this bit, SCSPTR.RTSDT and SCSPTR.CTSDT bits does not reflect signal on loopback path, because those registers shows signals on RTS#/CTS# pins.

35.2.10 FIFO Data Count Register (SCFDR)

SCFDR is a 16-bit register that indicates the number of data bytes stored in SCFTDR and that in SCFRDR.

The upper 8 bits indicate the number of transmit data bytes in SCFTDR, and the lower 8 bits indicates the number of receive data bytes in SCFRDR.

SCFDR can always be read by the CPU.



Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12 to 8	T[4:0]	H'00	R	These bits show the number of data bytes untransmitted and still stored in SCFTDR. H'00 indicates that there is no transmit data in SCFTDR. H'10 indicates that SCFTDR is full of transmit data.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4 to 0	R[4:0]	H'00	R	These bits show the number of receive data stored in SCFRDR in bytes. H'00 indicates that there is no receive data in SCFRDR. H'10 indicates that SCFRDR is full of receive data.

35.2.11 Serial Port Register (SCSPTR)

SCSPTR controls multiplexed input/output and data on the serial communication interface (SCIF) ports. Bits 1 and 0 control breaks in serial transmission/reception by reading input data from the RX pin and writing output data to the TX pin. Bits 3 and 2 read input data from and write output data to the SCK pin. Bits 5 and 4 read input data from and write output data to the CTS# pin. Bits 7 and 6 read input data from and write output data to the RTS# pin.

SCSPTR is a 16-bit register that can always be read from and written to by the CPU.

All SCSPTR bits except bits 6, 4, 2, and 0 are initialized to 0 by a power-on reset. The values of bits 6, 4, 2, and 0 are undefined.

Note: Whether modem control can be selected or not depends on the interface.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	RTSIO	RTSDT	CTSIO	CTSDT	SCKIO	SCKDT	SPB2IO	SPB2DT
Initial value:	0	0	0	0	0	0	0	0	0	—	0	—	0	—	0	—
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	RTSIO	0	R/W	Serial Port RTS# Pin Input/Output Specifies input or output for the serial port RTS# pin. To actually set the RTS# pin as a port output pin to output the value set by the RTSDT bit, the MCE bit in SCFCR should be cleared to 0. 0: Indicates that this bit does not output the value of the RTSDT bit to the RTS# pin. 1: Indicates that this bit outputs the value of the RTSDT bit to the RTS# pin.
6	RTSDT	—	R/W	Serial Port RTS# Pin Data Specifies the input/output data level of the serial port RTS# pin. Whether the pin is set for input or output is determined by the RTSIO bit. When the pin is set for output, the value of the RTSDT bit is output to the RTS# pin. Regardless of the value of the RTSIO bit, the value of the RTS# pin is read from the RTSDT bit. The initial value of this bit is undefined after a power-on reset. 0: Indicates that the input/output data is low level. 1: Indicates that the input/output data is high level.
5	CTSIO	0	R/W	Serial Port CTS# Pin Input/Output Specifies input or output for the serial port CTS# pin. To actually set the CTS# pin as a port output pin to output the value set by the CTSDT bit, the MCE bit in SCFCR should be cleared to 0. 0: Indicates that the CTSDT bit value is not output to the CTS# pin. 1: Indicates that the CTSDT bit value is output to the CTS# pin.

Bit	Bit Name	Initial Value	R/W	Description
4	CTSDT	—	R/W	Serial Port CTS# Pin Data Specifies the input/output data level of the serial port CTS# pin. Whether the pin is set for input or output is determined by the CTSIO bit. When the pin is set for output, the value of the CTSDT bit is output to the CTS# pin. Regardless of the value of the CTSIO bit, the value of the CTS# pin is read from the CTSDT bit. The initial value of this bit is undefined after a power-on. 0: Indicates that the input/output data is low level. 1: Indicates that the input/output data is high level.
3	SCKIO	0	R/W	Serial Port Clock Pin Input/Output Specifies input or output for the serial port SCK pin. To actually set the SCK pin as a port output pin to output the value set by the SCKDT bit, the CKE[1:0] bits in SCSCR should be cleared to 0. 0: Indicates that the SCKDT bit value is not output to the SCK pin. 1: Indicates that the SCKDT bit value is output to the SCK pin.
2	SCKDT	—	R/W	Serial Port Clock Pin Data Specifies the input/output data level of the serial port SCK pin. Whether the pin is set for input or output is determined by the SCKIO bit. When the pin is set for output, the value of the SCKDT bit is output to the SCK pin. Regardless of the value of the SCKIO bit, the value of the SCK pin is read from the SCKDT bit. The initial value of this bit is undefined after a power-on reset. 0: Indicates that the input/output data is low level. 1: Indicates that the input/output data is high level.
1	SPB2IO	0	R/W	Serial Port Break Input/Output Specifies the output condition of the serial port TX pin. To actually set the TX pin as a port output pin to output the value set by the SPB2DT bit, the TE bit in SCSCR should be cleared to 0. 0: Indicates that the SPB2DT bit value is not output to the TX pin. 1: Indicates that the SPB2DT bit value is output to the TX pin.
0	SPB2DT	—	R/W	Serial Port Break Data Specifies the input level of the serial port RX pin and the output level of the TX pin. The TX pin output conditions are determined by the SPB2IO bit. When the TX pin is set for output, the value of the SPB2DT bit is output to the TX pin. Regardless of the value of the SPB2IO bit, the value of the RX pin is read from the SPB2DT bit. The initial value of this bit is undefined after a power-on reset. 0: Indicates that the input/output data is low level. 1: Indicates that the input/output data is high level.

35.2.12 Line Status Register (SCLSR)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	TO	—	ORER
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/(W)*	R	R/(W)*

Note: Only 0 can be written to clear the flag.

Bit	Bit Name	Initial Value	R/W	Description
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	TO	0	R/(W)*	Timeout Indicates that the number of data bytes in SCFRDR is less than the receive trigger count, and that no further data has been received for at least 15 etu after the stop bit of the last receive data in asynchronous mode. This bit is not set in clock synchronous mode. 0: Indicates that data is being received or has been successfully received and that there is no receive data in SCFRDR. [Clearing conditions] • A power-on reset is executed. • All the receive data in the SCFRDR has been read, and 0 is written to TO. 1: Indicates that no further receive data has been received (receive timeout). [Setting condition] • The number of data bytes in SCFRDR is less than the receive trigger count and no further data has been received for at least 15 etu after the stop bit of the last receive data.* Note: etu: Elementary Time Unit (time for transfer of 1 bit) Equivalent to 1.5 frames with an 8-bit, 1-stop-bit format.
1	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	ORER	0	R/(W)*	Overrun Error Indicates that an overrun error has occurred in reception and abnormal termination is caused. If an overrun error occurs, the receive data prior to the overrun error is retained in SCFRDR and the data received subsequently is discarded. Any subsequent serial reception is disabled while the ORER flag is 1. To resume data reception after clearing the ORER flag, be sure to first read (or clear) data in the receive FIFO and handle the error, then clear the ORER flag. 0: Indicates that data is being received or has been successfully received. [Clearing conditions] • A power-on reset is executed. • 0 is written to ORER. 1: Indicates that an overrun error has occurred in reception. [Setting condition] • The next serial reception has been completed while SCFRDR is full of 16-byte data. Note: When bit RE in SCSCR is cleared to 0, the ORER flag is not affected and its previous state is retained.

Note: Writing 0 is only available to clear the flag.

35.3 Operation

35.3.1 Operation in Asynchronous Mode

In asynchronous mode, the SCIF performs serial communication, in which data is transmitted/received in character units using the attached start bit indicating the start of communication and stop bit indicating the end of communication.

Figure 35.7 shows the general format for asynchronous serial communication.

In asynchronous serial communication, the transmission line is usually kept marked (high level). The SCIF monitors the transmission line, and when it finds a space (low level), it regards the space as a start bit and starts serial communication.

One character in serial communication consists of a start bit (low level), followed by transmit/receive data (LSB-first; from the lowest bit), a parity bit (high or low level), and a stop bit (high level).

During reception in asynchronous mode, the SCIF performs synchronization at the falling edge of the start bit. Communication data is acquired at the center of each bit because the SCIF samples data at the eighth pulse of the clock which has a frequency of 16 times the bit rate.

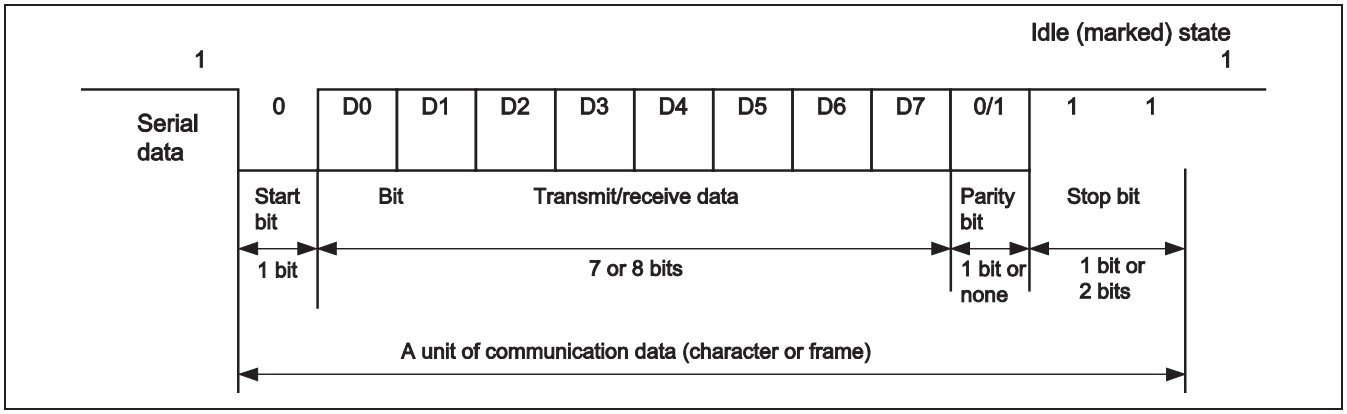

Figure 35.7 Data Format in Asynchronous Mode (Example of 8-Bit Data with Parity and Two Stop Bits)

(1) Transmission/Reception Format

Table 35.6 shows available data transfer formats. The SCIF supports 8 transfer formats, which can be specified by SCSMR.

Table 35.6 Serial Transmission/Reception Formats (Asynchronous Mode)

SCSMR Settings			Serial Transmission/Reception Format and Frame Length											
CHR	PE	STOP	1	2	3	4	5	6	7	8	9	10	11	12
0	0	0	S	8-bit data								STOP		
		1	S	8-bit data								STOP	STOP	
	1	0	S	8-bit data								P	STOP	
		1	S	8-bit data								P	STOP	STOP
1	0	0	S	7-bit data							STOP			
		1	S	7-bit data							STOP	STOP		
	1	0	S	7-bit data							P	STOP		
		1	S	7-bit data							P	STOP	STOP	

[Legend]
S: Start bit
STOP: Stop bit
P: Parity bit

(2) Clock

The transfer clock can be selected from the following two clocks using the CKE[1:0] bits in SCSCR:

- Internal clock generated by the on-chip baud rate generator
- External clock generated by an external clock baud rate generator

(3) Data Transmission/Reception

(a) Initialization of SCIF (Asynchronous Mode)

Before transmitting/receiving data or changing the operating mode or communication format, the SCIF should be initialized using the sample flowchart for SCIF initialization shown in Figure 35.8.

[Notes]

Clearing the TE bit to 0 initializes SCTSR. However, SCFSR, SCFTDR, and SCFRDR contents are retained even if the TE and RE bits are cleared to 0.

The TE bit should be cleared to 0 after all transmit data has been sent and the TEND flag has been set in SCFSR. The TE bit can be cleared to 0 during transmission, but the data being transmitted will enter the marked state after clearing. In addition, before setting the TE bit to 1 to restart the transmission, set the TFRST bit to 1 in SCFCR to reset SCFTDR.

When an external clock is used, do not stop the clock during operation or initialization. If stopped, the operation will be unreliable. Furthermore, when the baud rate generator for external clock is also to be used, be sure to make settings for it before starting initialization of the SCIF.

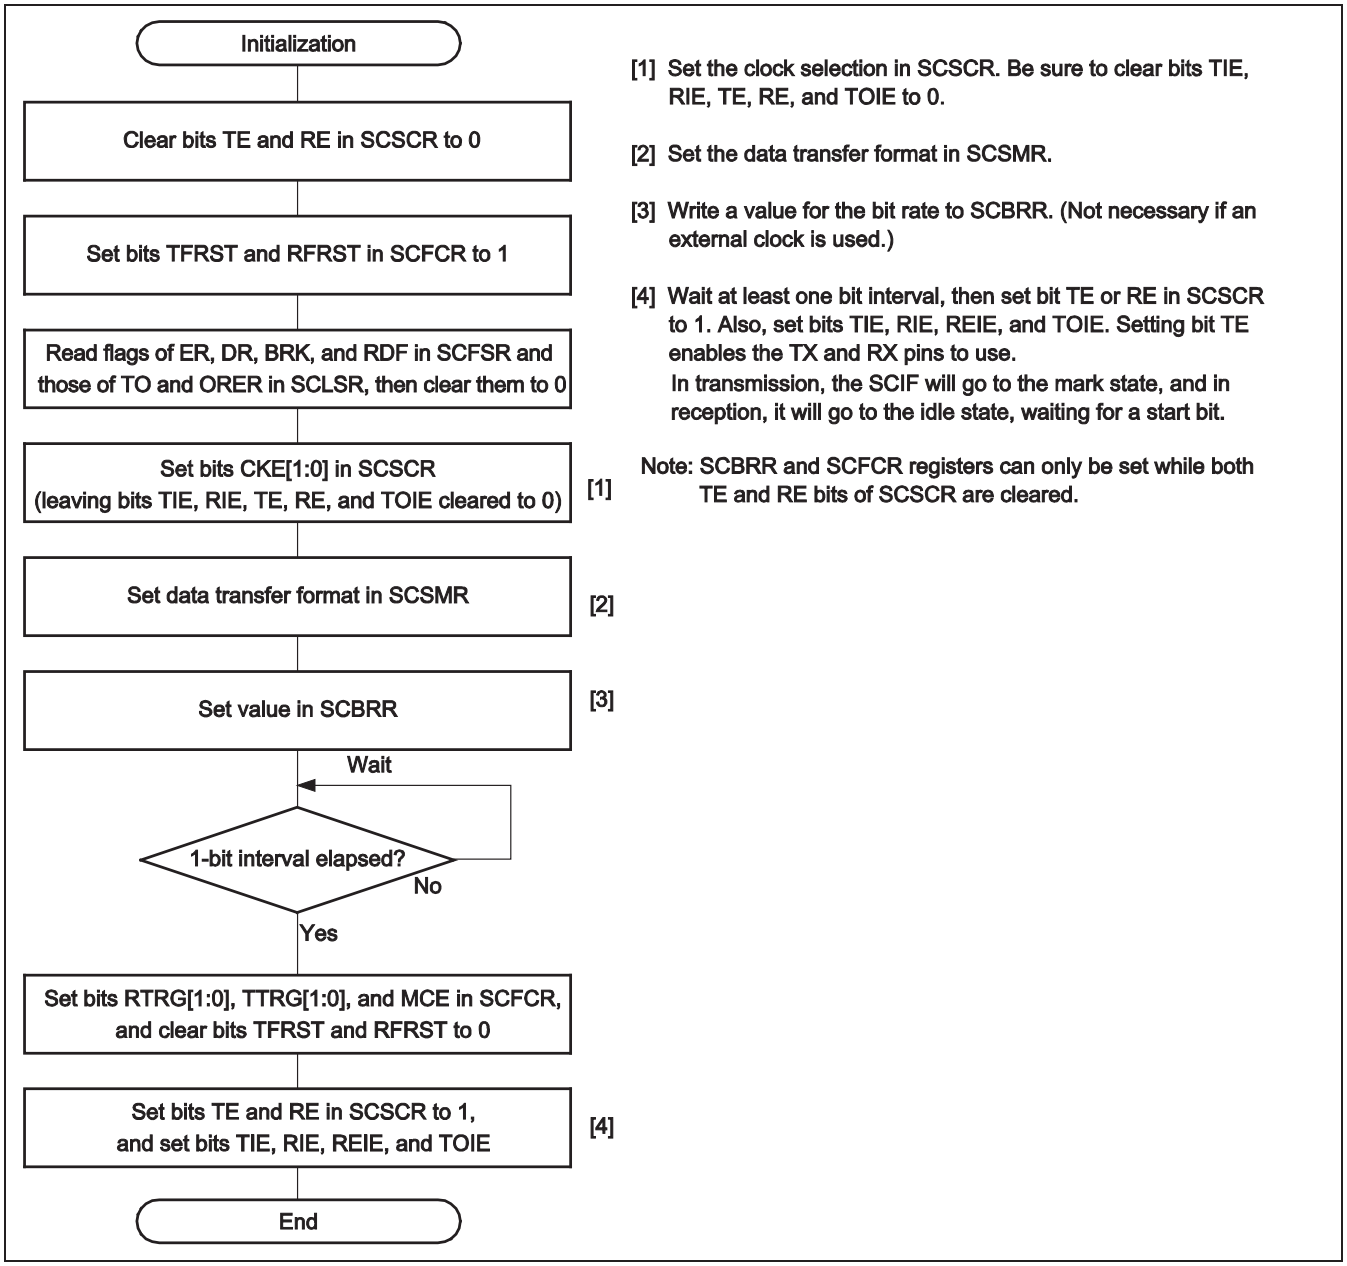

Figure 35.8 Sample Flowchart for Initializing the SCIF

(a) Serial Data Transmission (Asynchronous Mode)

Figure 35.9 shows a sample flowchart for serial transmission.

After the SCIF transmission operation is enabled, serial data transmission can be performed using the following procedure:

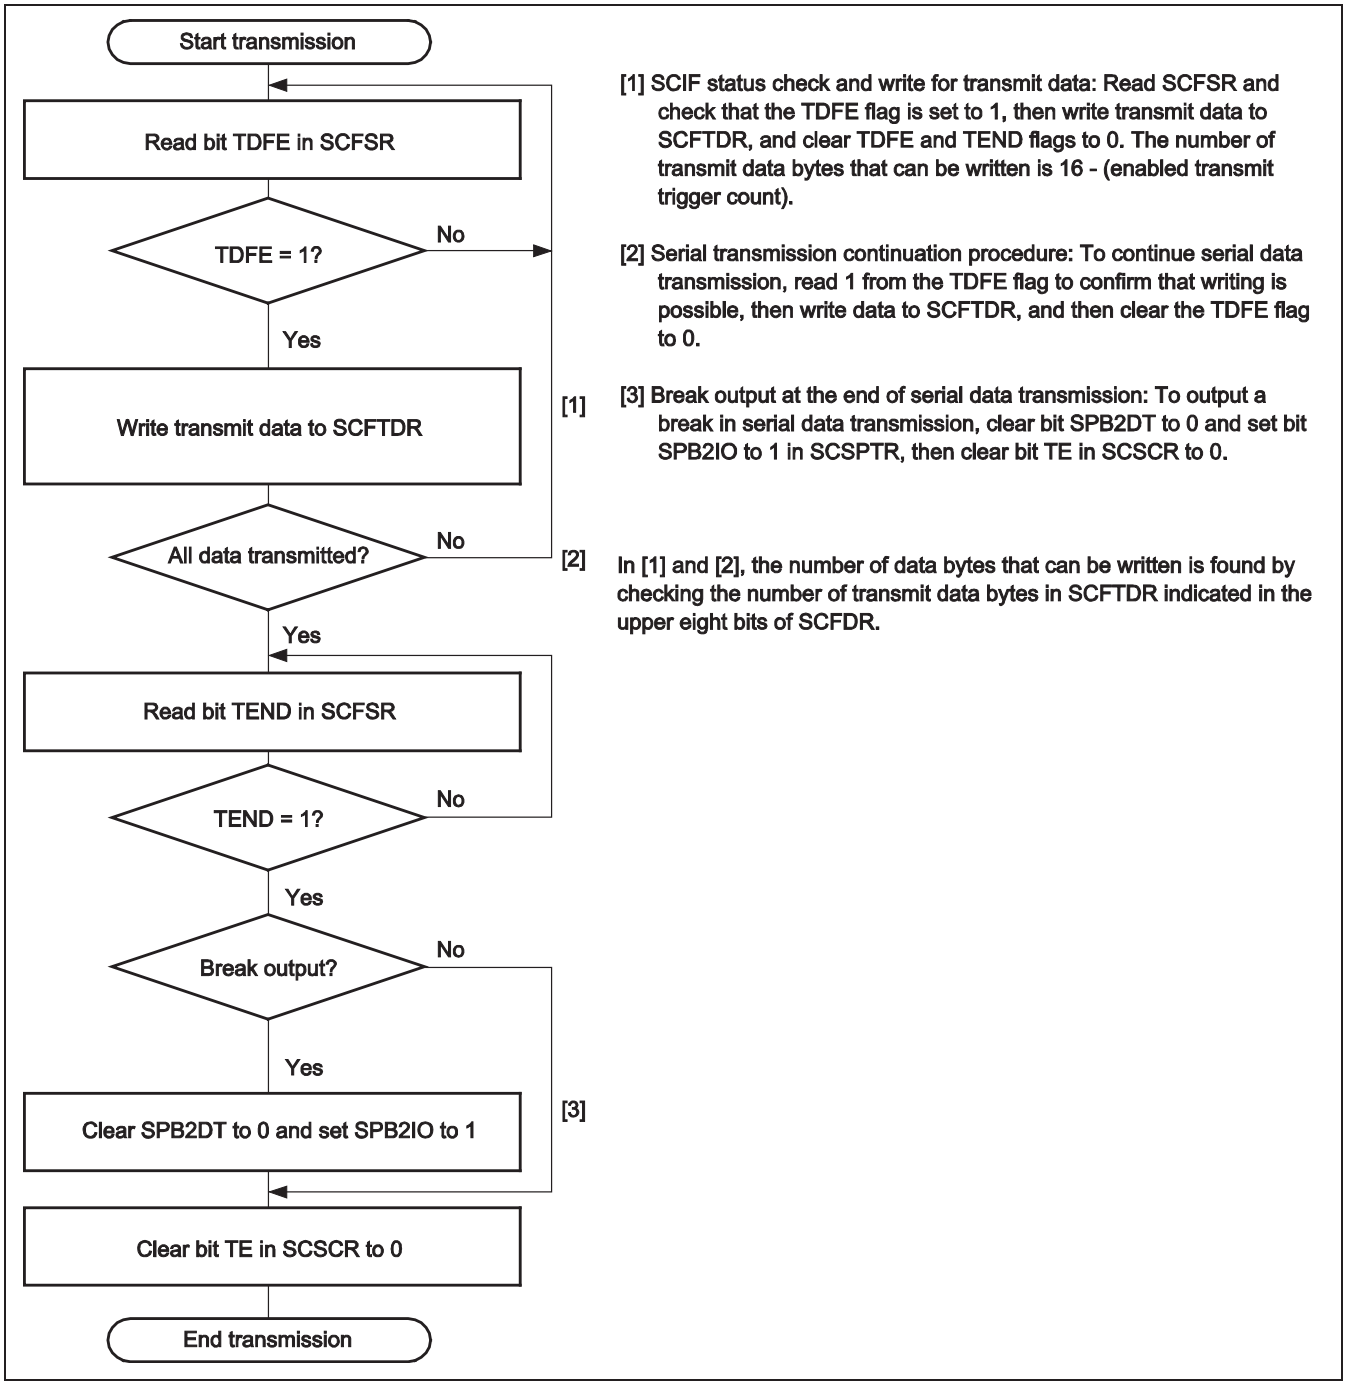

Figure 35.9 Sample Flowchart for Serial Transmission

In serial transmission, the SCIF operates as follows:

1. When data is written to SCFTDR, the SCIF transfers the data from SCFTDR to SCTSR and starts transmitting. Confirm that the TDFE flag in SCFSR is set to 1 before writing transmit data to SCFTDR. The number of data bytes that can be written is at least (16- (transmit trigger count)).
2. When data is transferred from SCFTDR to SCTSR and the SCIF starts transmission, consecutive transmission is performed until there is no transmit data left in SCFTDR. When the number of transmit data bytes in SCFTDR is equal to or less than the transmit trigger count specified in SCFCR, the TDFE flag is set. If the TIE and TEIE bits in SCSCR are set to 1 and 0, respectively at this time, a transmit-FIFO-data-empty interrupt (TDFE) request occurs. The serial transmit data is sent from the TX pin in the following order:
   A. Start bit: One 0-bit is output.
   B. Transmit data: 8- or 7-bit data is output in LSB-first order.
   C. Parity bit: One parity bit (even or odd parity) is output.
      A format that does not output a parity bit can also be selected.
   D. Stop bit(s): One or two 1-bits (stop bits) are output.
   E. Marked state: 1 is output continuously until the start bit that starts the next transmission is sent.
3. The SCIF checks transmit data in SCFTDR when sending the stop bit. If there is data in it, the SCIF transfers the data from SCFTDR to SCTSR, sends the stop bit, and then starts serial transmission of the next frame. If there is no transmit data, the SCIF sets the TEND flag to 1 in SCFSR and sends out the stop bit, and then the marked state is entered to output 1 continuously. At this time, if the TIE and TEIE bits in SCSCR are set to 1, a transmit-end interrupt (TEND) request occurs.

Figure 35.10 shows an example of transmission in asynchronous mode.

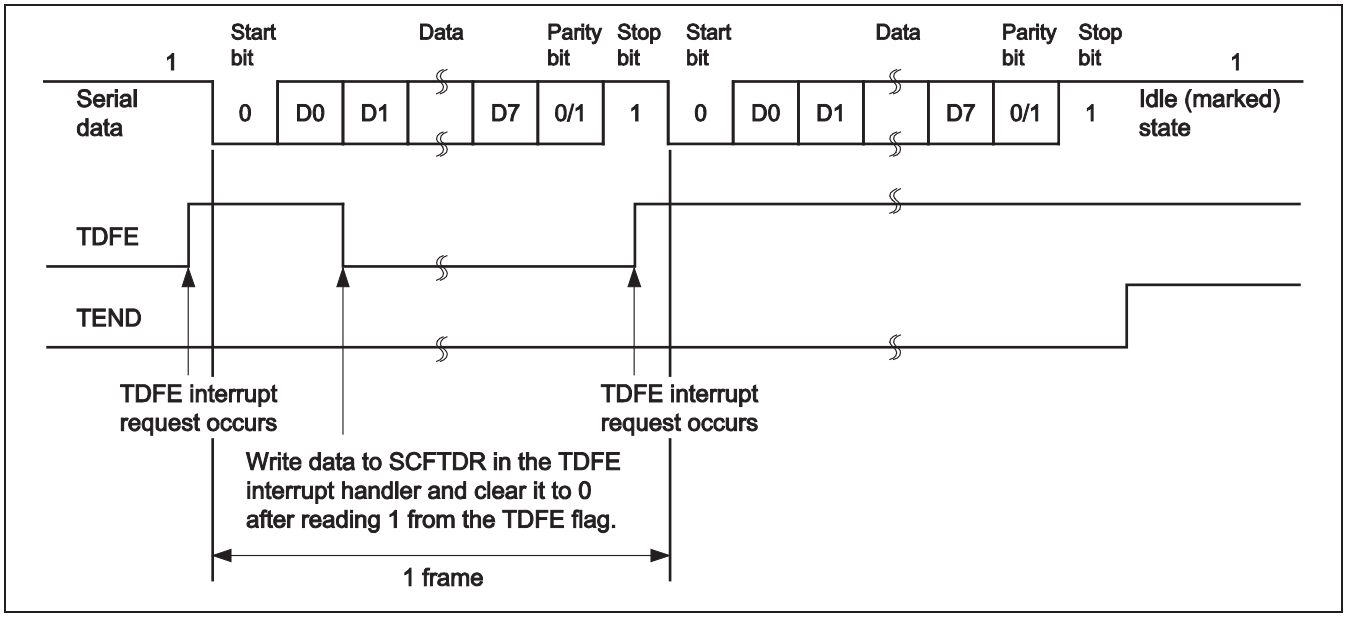

Figure 35.10 Sample SCIF Transmission Operation (Example of 8-Bit Data with Parity and One Stop Bit)

4. When modem control is enabled, transmission can be stopped or resumed in accordance with the CTS# input value. When CTS# is set to 1 during transmission, the marked state is entered after one frame of data transmission is ended. Setting CTS# to 0 restarts outputting the next transmit data from the start bit. Figure 35.11 shows an example of the operation with modem control enabled.

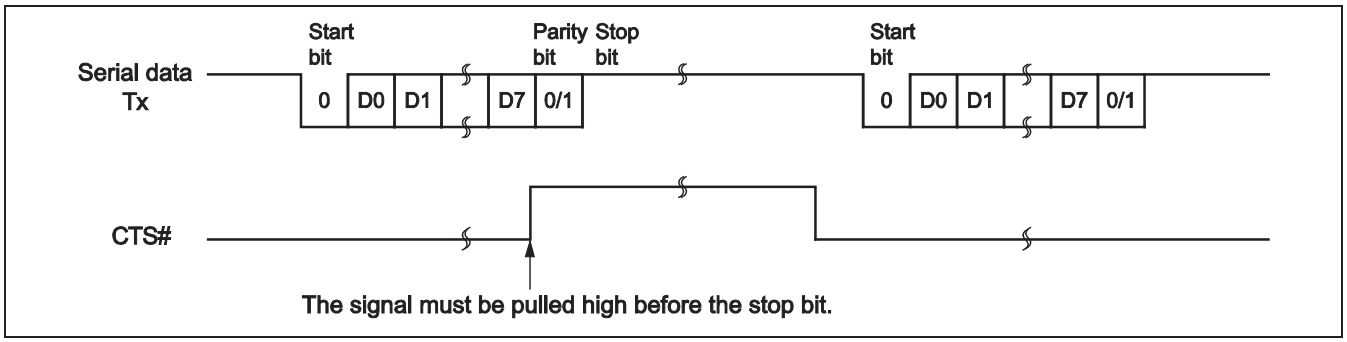

Figure 35.11 Sample Operation with Modem Control Enabled (CTS#)

(b) Serial Data Reception (Asynchronous Mode)

Figures 35.12 and 35.13 show sample flowcharts for serial reception.

After the SCIF reception operation is enabled, serial data reception can be performed using the following procedure:

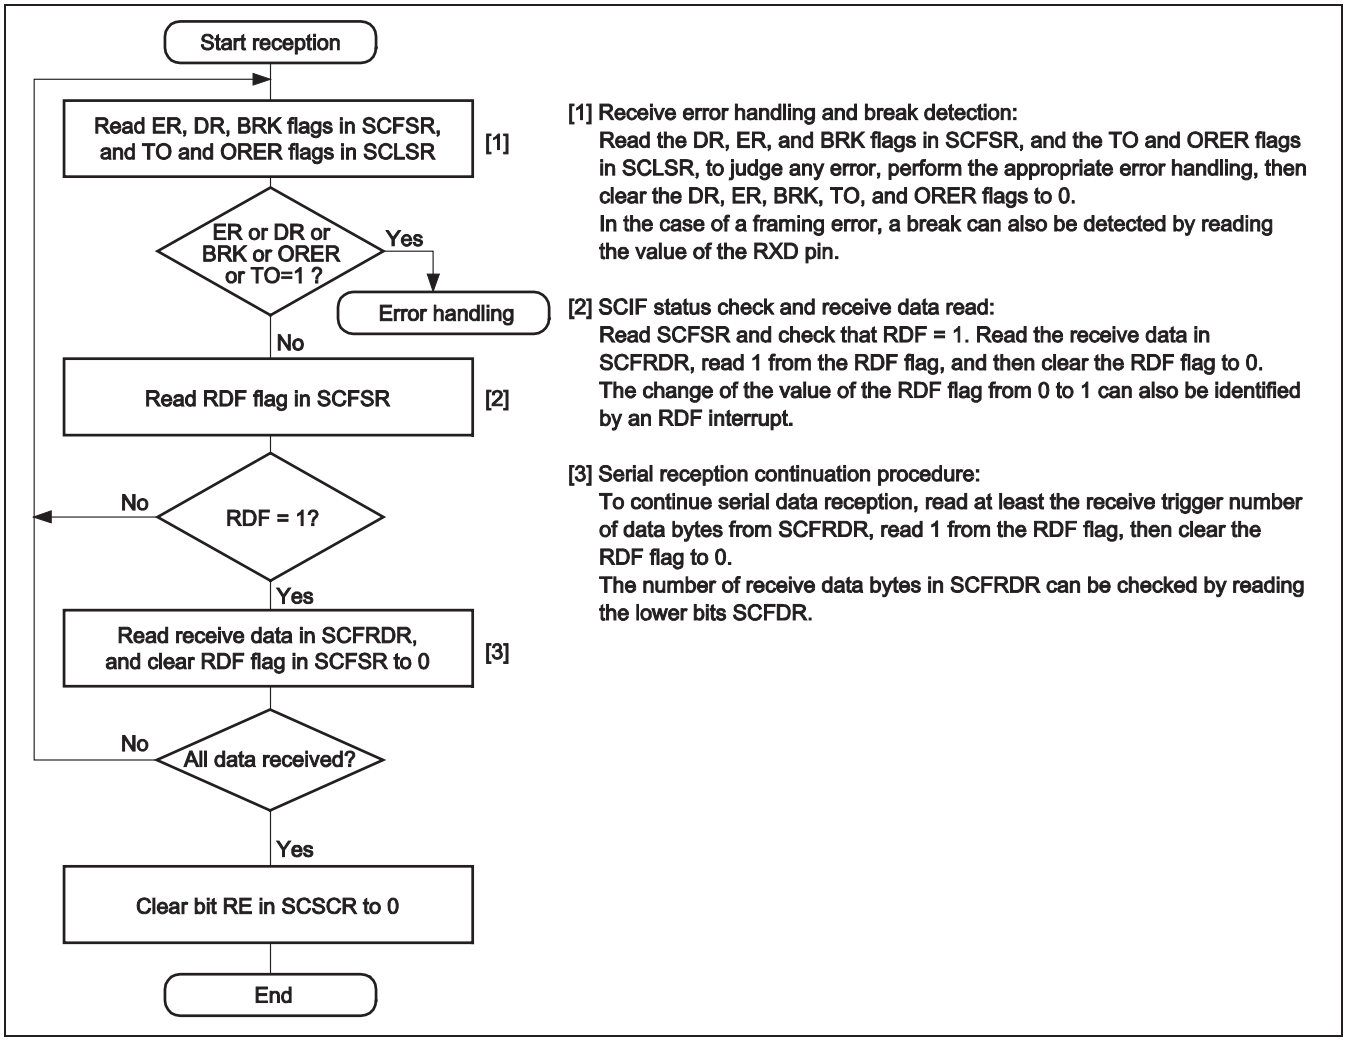

Figure 35.12 Sample Flowchart for Serial Reception (1)

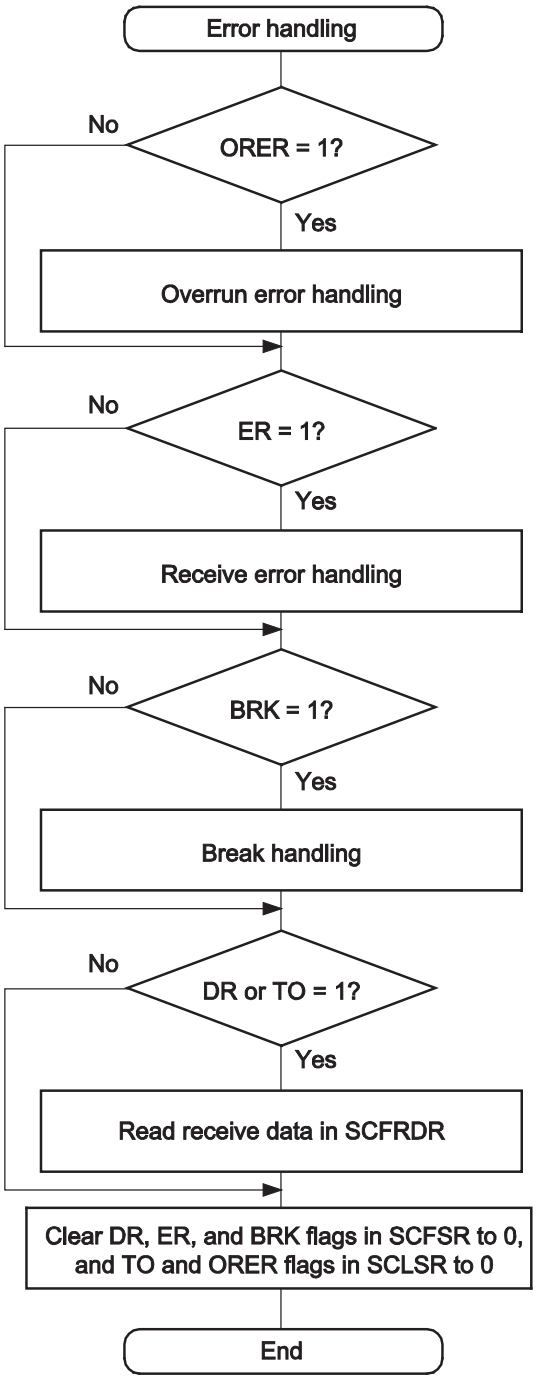

Whether a framing error or parity error has occurred in the receive data that is to be read from SCFRDR can be determined by checking bits FER and PER in SCFSR.

Figure 35.13 Sample Flowchart for Serial Reception (2)

In serial reception, the SCIF operates as follows:

1. The SCIF monitors the transmission line, and when detecting the start bit 0, it performs internal synchronization and starts reception.
2. The SCIF stores the received data in SCRSR in LSB-to-MSB order.
3. The SCIF receives the parity bit and stop bit.
   After receiving these bits, the SCIF performs the following checks:
   A. Stop bit: The SCIF checks whether the stop bit is 1.
      If there are two stop bits, it checks only the first stop bit.
   B. Receive data: The SCIF checks that receive data can be transferred from the receive shift register (SCRSR) to SCFRDR.
   C. Overrun error: The SCIF checks that the ORER flag is 0, indicating that no overrun error has occurred.
   D. Break state: The SCIF checks that the BRK flag is 0, indicating that the break state is not set.
   If the SCIF can confirm the conditions of (b), (c), and (d), it stores the receive data in SCFRDR.

   Note: The SCIF continues to receive data even when a parity error or a framing error occurs.

4. If the RDF flag changes to 1 while the RIE bit in SCSCR is 1, a receive-FIFO-data-full interrupt (RDF) request occurs.
   If the DR flag changes to 1 while the RIE bit in SCSCR is 1, a receive-data-ready interrupt (DR) request occurs.
   If the TO flag changes to 1 while the TOIE bit in SCSCR is 1, a timeout interrupt (TO) request occurs.
   If the ER flag changes to 1 while the RIE or REIE bit in SCSCR is 1, a receive-error interrupt (ER) request occurs.
   If the BRK flag changes to 1 while the RIE or REIE bit in SCSCR is 1, a break interrupt (BRK) request occurs.
   If the ORER flag changes to 1 while the RIE or REIE bit in SCSCR is 1, an overrun-error interrupt (ORER) request occurs.

Figure 35.14 shows an example of reception in asynchronous mode.

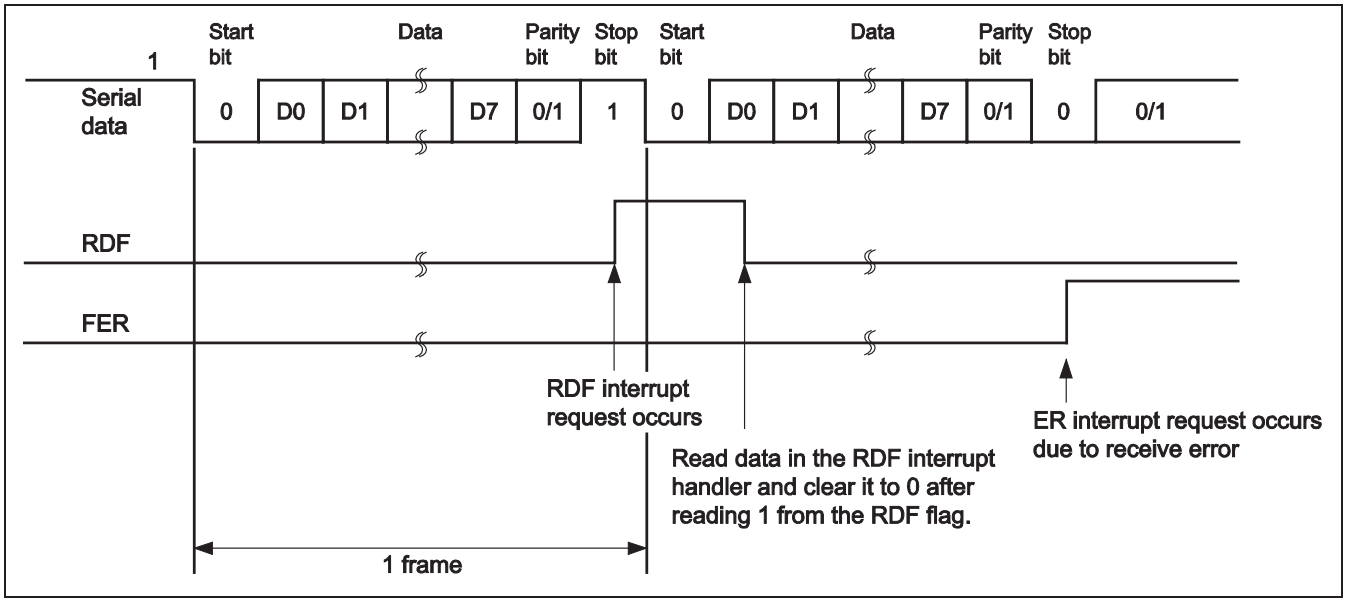

Figure 35.14 Sample SCIF Receive Operation (Example of 8-Bit Data with Parity and One Stop Bit)

5. When modem control is enabled, the RTS# signal is output when SCFRDR is empty. When RTS# is 0, data can be received. When RTS# is set to 1, the number of data bytes in SCFRDR is equal to or more than the RTS# output active trigger count.

Figure 35.15 shows an example of the operation with modem control enabled.

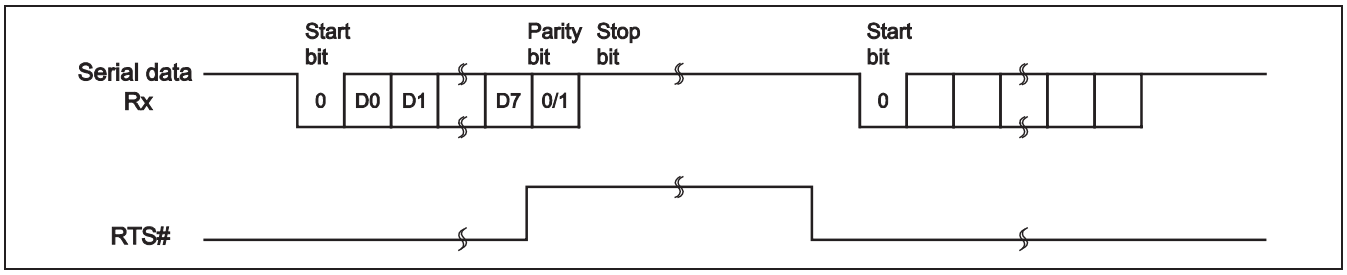

Figure 35.15 Example of the Operation with Modem Control Enabled (RTS#)

35.3.2 Operation in Clock Synchronous Mode

Clock synchronous mode, in which data is transmitted and received in synchronization with clock pulses, is suitable for fast serial communication.

Figure 35.16 shows the general format for clock synchronous serial communication. In the clock synchronous serial communication, data on the communication line is output between one falling edge of the synchronization clock and the next falling edge. The data decision is done at the rising edge of the clock.

In serial communication, each character is output starting with the LSB and ending with the MSB. After the MSB is output, the communication line retains the state of the last data.

In clock synchronous mode, the SCIF receives data in synchronization with a rising edge of the synchronization clock.

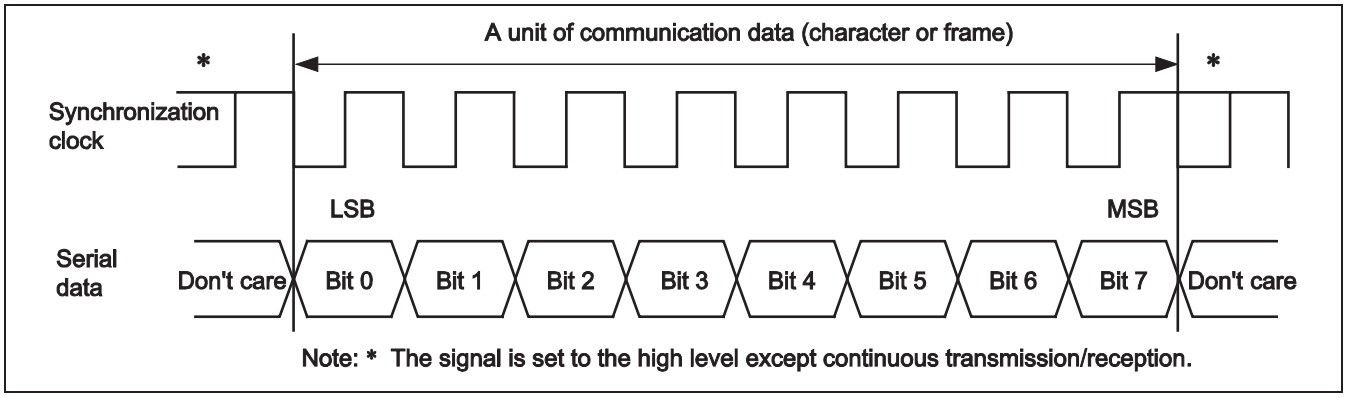

Figure 35.16 Data Format for Clock Synchronous Communication

(1) Data Transfer Format

The data transfer format is fixed to 8 bits. No parity bit can be added.

(2) Clock

The clock can be selected from the following two clocks using the C/A# bit in SCSMR and the CKE[1:0] bits in SCSCR:

- Internal clock generated by the on-chip baud rate generator
- External synchronization clock input at the SCK pin

When the SCIF is operated on an internal clock, the synchronization clock is output from the SCK pin. Eight synchronization clock pulses are output in one-character transfer, and when no transfer is performed the clock is fixed high. When only reception operation is performed, selecting an internal clock outputs clock pulses until the number of data bytes in the receive FIFO reaches the specified receive trigger count, while the RE bit in SCSCR is 1.

(3) Data Transmission/Reception

(a) Initialization of SCIF (Synchronous Mode)

Before transmitting/receiving data or changing the operating mode or communication format, the TE and RE bits in SCSCR to 0 and then the SCIF should be initialized using the sample flowchart for SCIF initialization shown in Figure 35.17.

[Note]

Clearing the TE bit to 0 initializes SCTSR. However, clearing the RE bit to 0 does not affect the RDF, PER, FER, and ORER flags and SCFRDR contents.

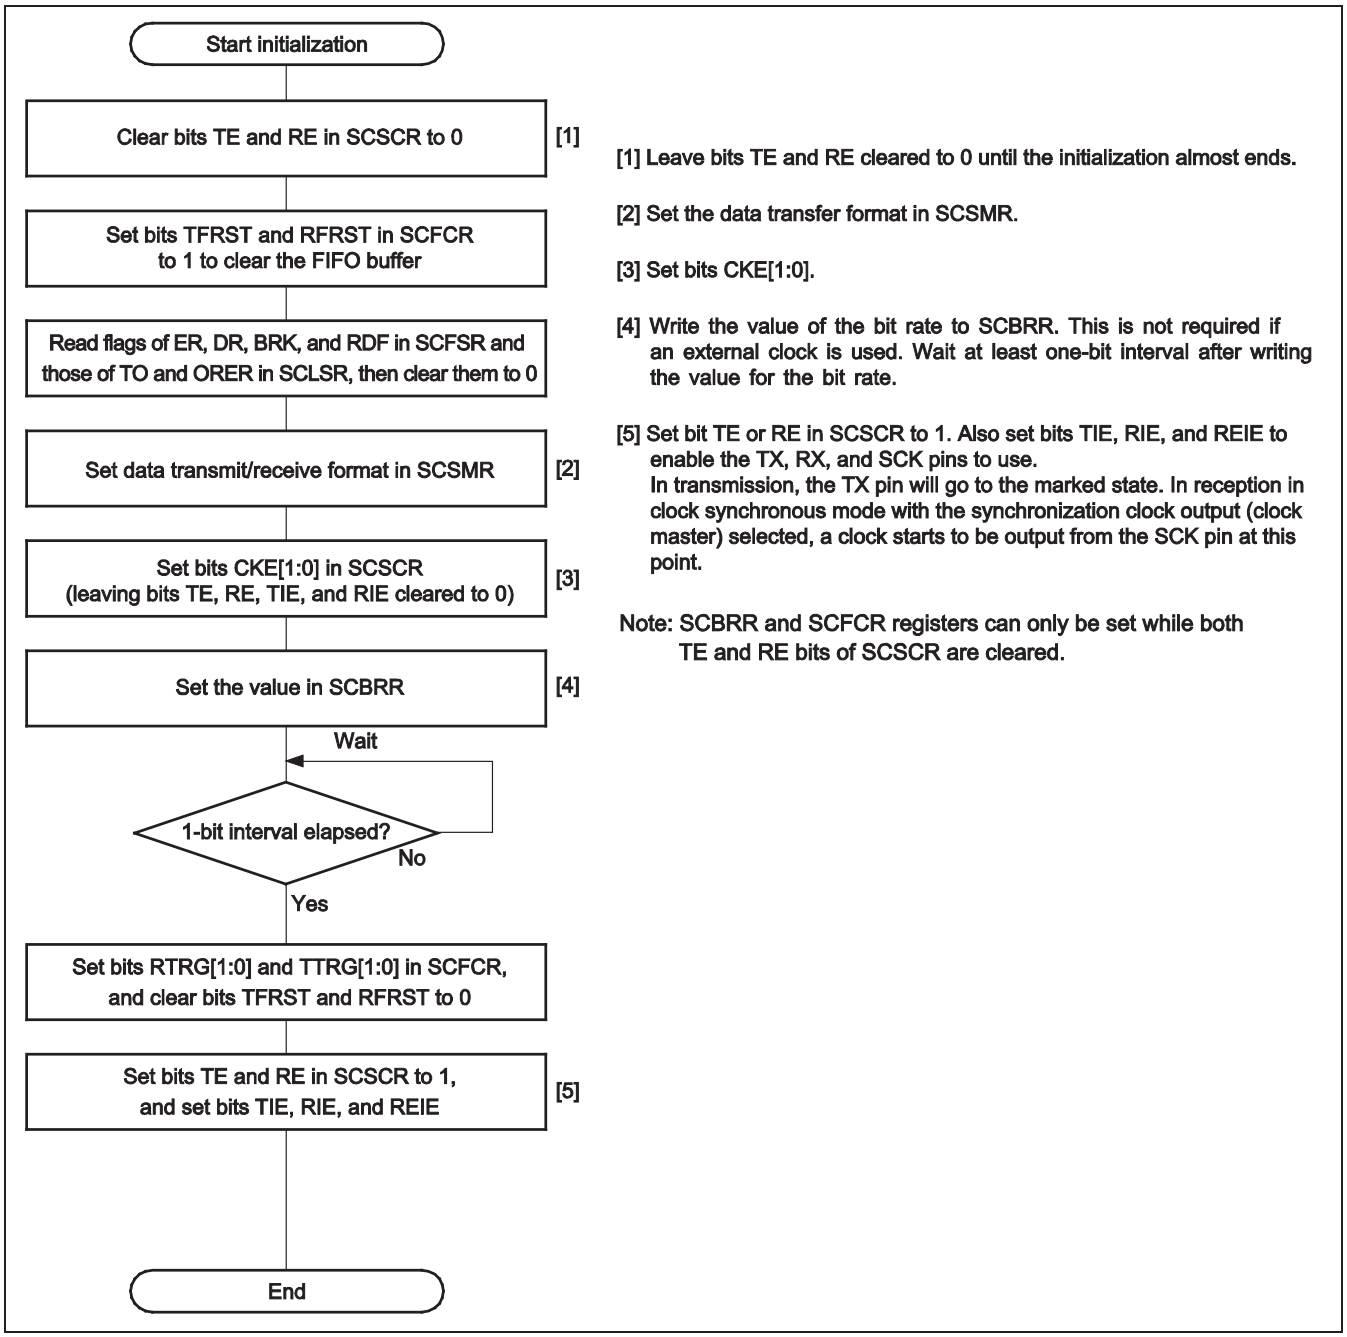

Figure 35.17 Sample Flowchart for SCIF Initialization

(b) Serial Data Transmission (Clock Synchronous mode)

Figure 35.18 shows a sample flowchart for serial transmission.

After the SCIF transmission operation is enabled, serial data transmission can be performed using the following procedure:

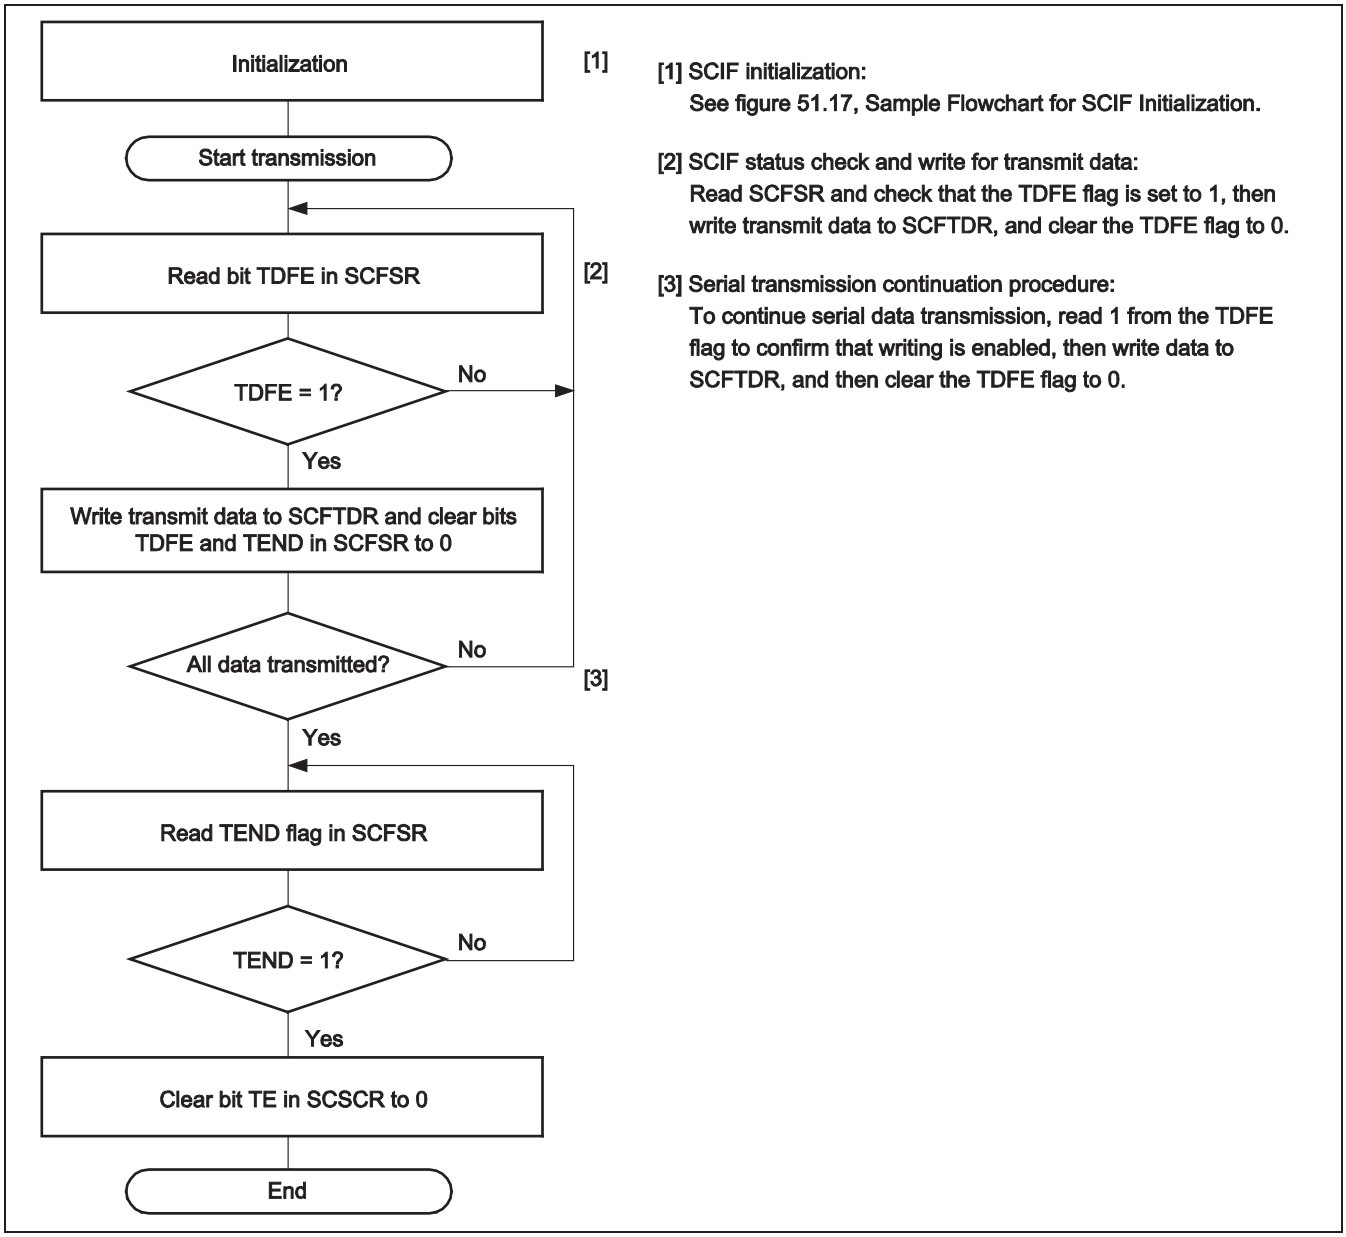

Figure 35.18 Sample Flowchart for Serial Transmission

In serial data transmission, the SCIF operates as described below:

1. When data is written to SCFTDR, the SCIF transfers the data from SCFTDR to SCTSR to start transmission. Confirm that the TDFE flag in SCFSR is set to 1 before writing transmit data to SCFTDR. The number of data bytes that can be written is at least (16- (the transmit trigger count)).
2. After the SCIF transfers data from SCFTDR to SCTSR and starts data serial transmission, the SCIF consecutively transmits it until there is no transmit data left in SCFTDR. When the number of transmit data bytes in SCFTDR is equal to or less than the transmit trigger count set in SCFCR, the TDFE flag is set. If the TIE and TEIE bits in SCSCR are set to 1 and 0, respectively at this time, a transmit-FIFO-data-empty interrupt (TDFE) request occurs. When the external clock is selected, data is output in synchronization with the input clock. The serial transmit data is output at the TX pin in the LSB-first order.
3. The SCIF checks transmit data in SCFTDR when sending the last bit. If there is transmit data, the SCIF transfers the data to SCTSR, and starts serial transmission of the next frame. If there is no transmit data left, the TEND flag in SCFSR is set to 1, and the transmit data pin (TX pin) retains its state after the last bit is sent. At this time, if the TIE and TEIE bits in SCSCR are set to 1, a transmit-end interrupt (TEND) request occurs.
4. After serial transmission ends, the SCK pin is fixed high.

Note: In clock synchronous mode, when transmit data is written to SCFTDR by the DMAC, the TEND flag may not be cleared. Therefore, if the DMAC is used for transmission in clock synchronous mode, read the TEND flag in the following method.

1. Confirm that data transfer is completed in the DMAC.
2. Read the TEND flag.
3. Clear the TEND flag to 0 if TEND = 1.
4. Read the TEND flag again.
5. Use the second-read TEND flag.

Figure 35.19 shows an example of SCIF serial transmission in clock synchronous mode.

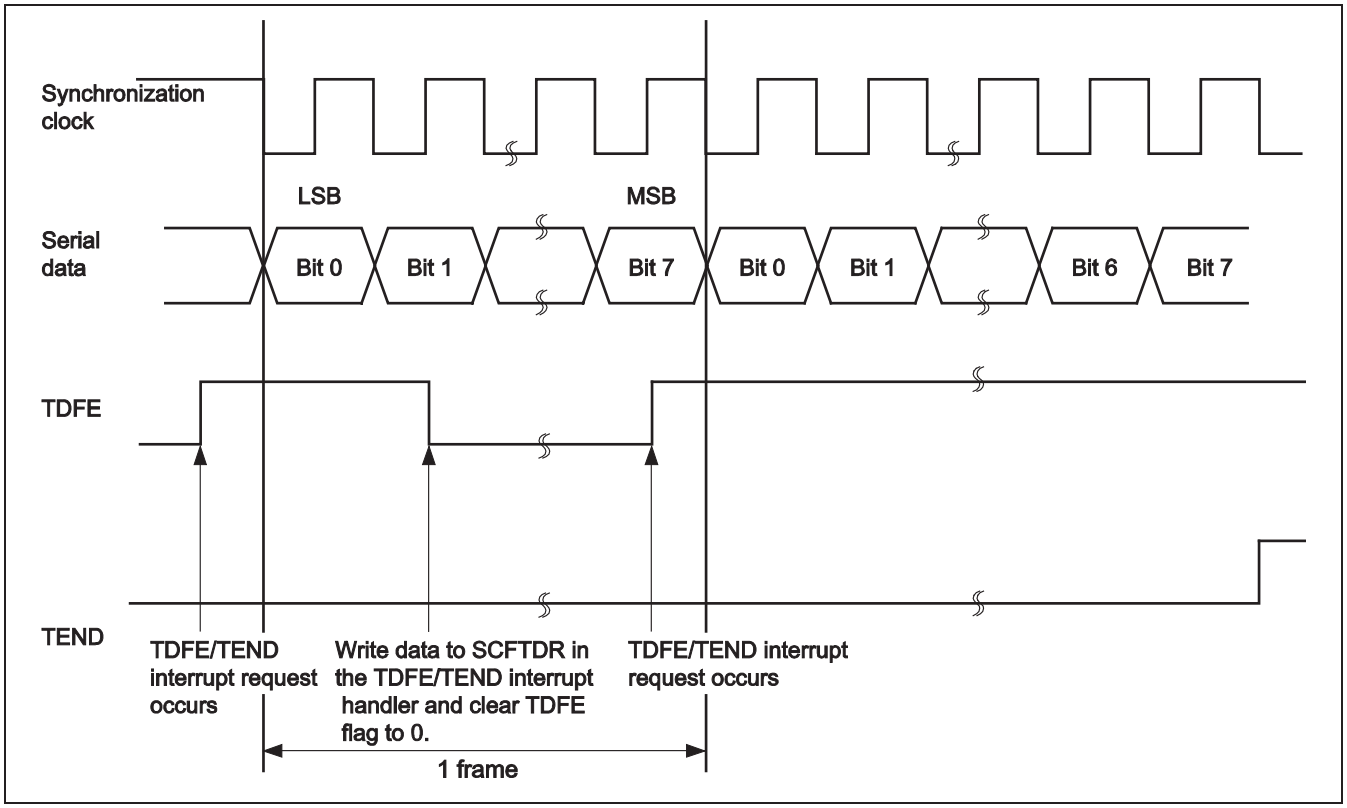

Figure 35.19 Example of SCIF Serial Transmission in Clock Synchronous Mode

(c) Serial Data Reception (Clock Synchronous Mode)

Figures 35.20 and 35.21 show sample flowcharts for serial reception.

The SCIF reception should be enabled before taking the following steps for serial data transmission.

When switching operating mode from asynchronous mode to clock synchronous mode without initializing the SCIF, check that the ORER, PER3 to PER0, and FER3 to FER0 flags are cleared to 0.

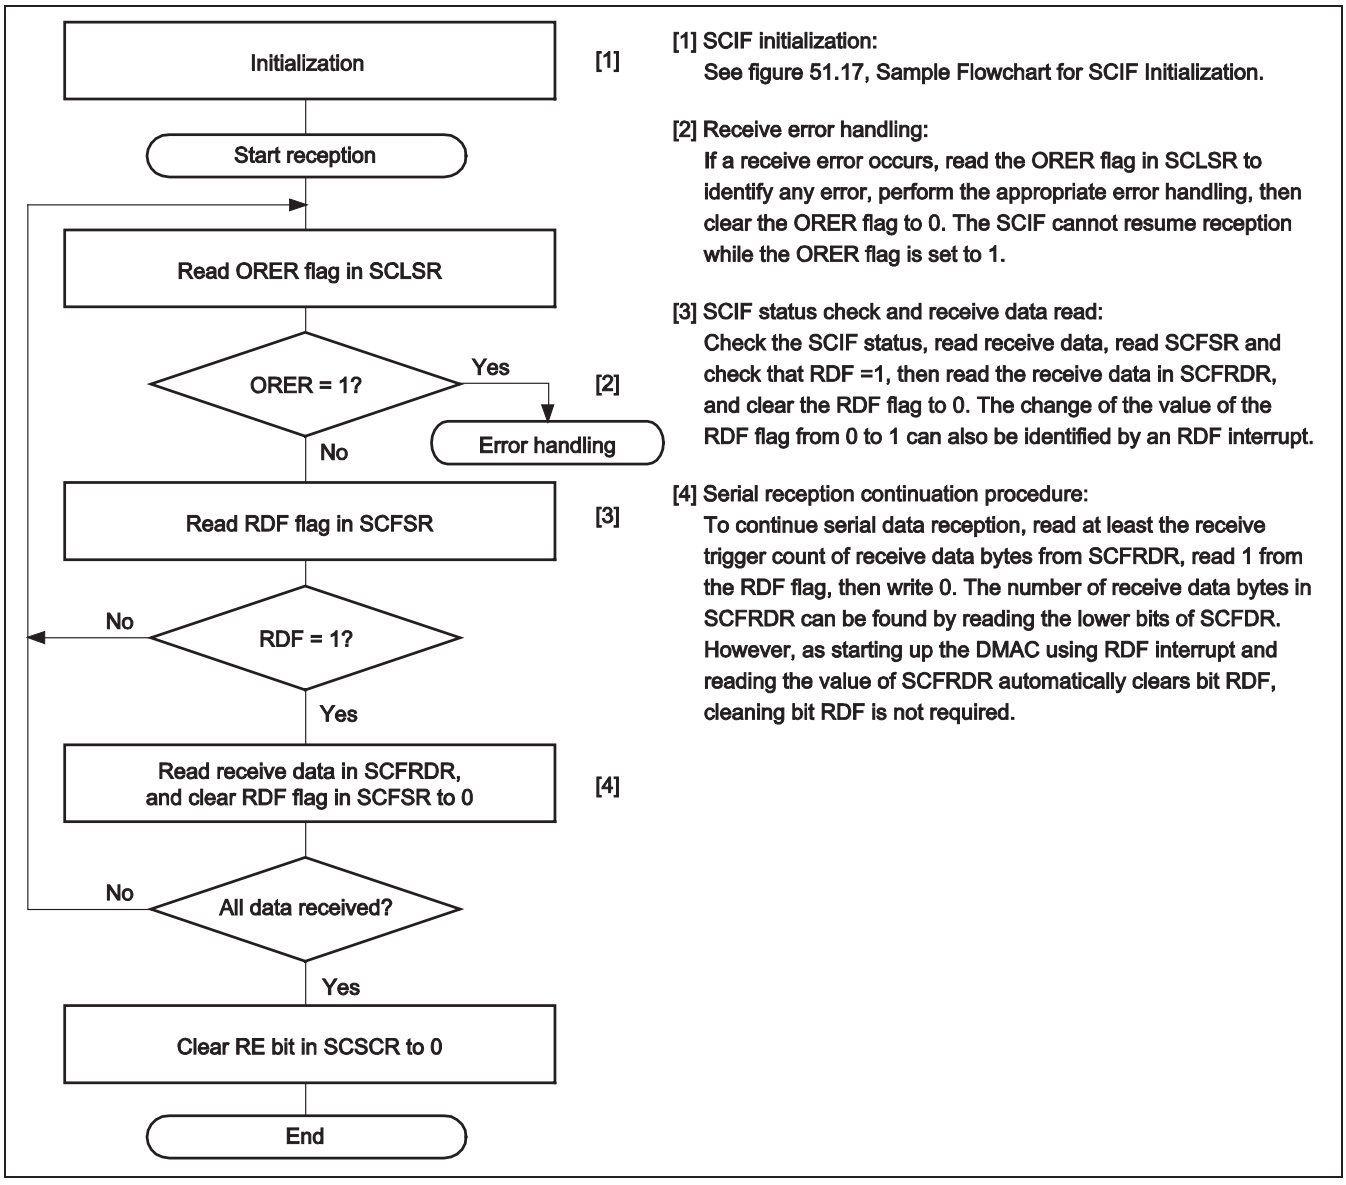

Figure 35.20 Sample Flowchart for Serial Data Reception

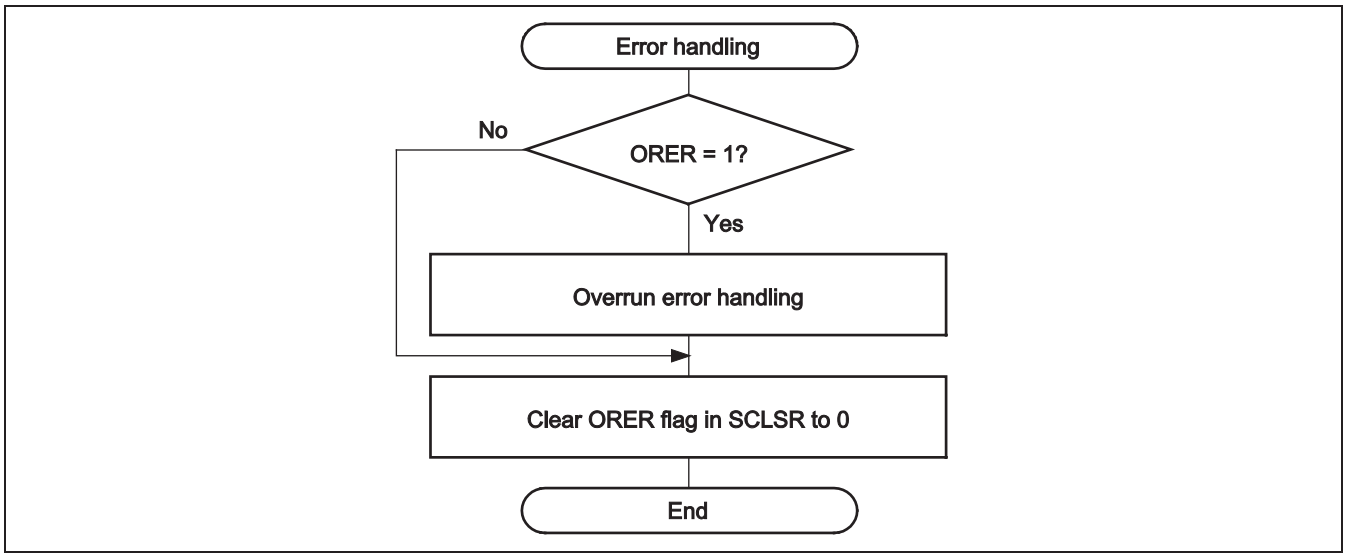

Figure 35.21 Sample Flowchart for Serial Data Reception

In serial data reception, the SCIF operates as described below:

1. The SCIF starts receiving data in synchronization with synchronization clock input or output.
2. The SCIF stores receive data in SCRSR in LSB-to-MSB order.
   After receiving the data, the SCIF first checks if the receive data can be transferred from SCRSR to SCFRDR, then starts storing the receive data in SCFRDR.
   If the SCIF detects an overrun error, the SCIF cannot receive subsequent data.
3. If the RDF flag changes to 1 while the RIE bit in SCSCR is 1, a receive-FIFO-data-full interrupt (RDF) request occurs. If the ORER flag changes to 1 while the RIE or REIE bit in SCSCR is 1, a break interrupt (BRI) request occurs.

Figure 35.22 shows an example of SCIF reception in clock synchronous mode.

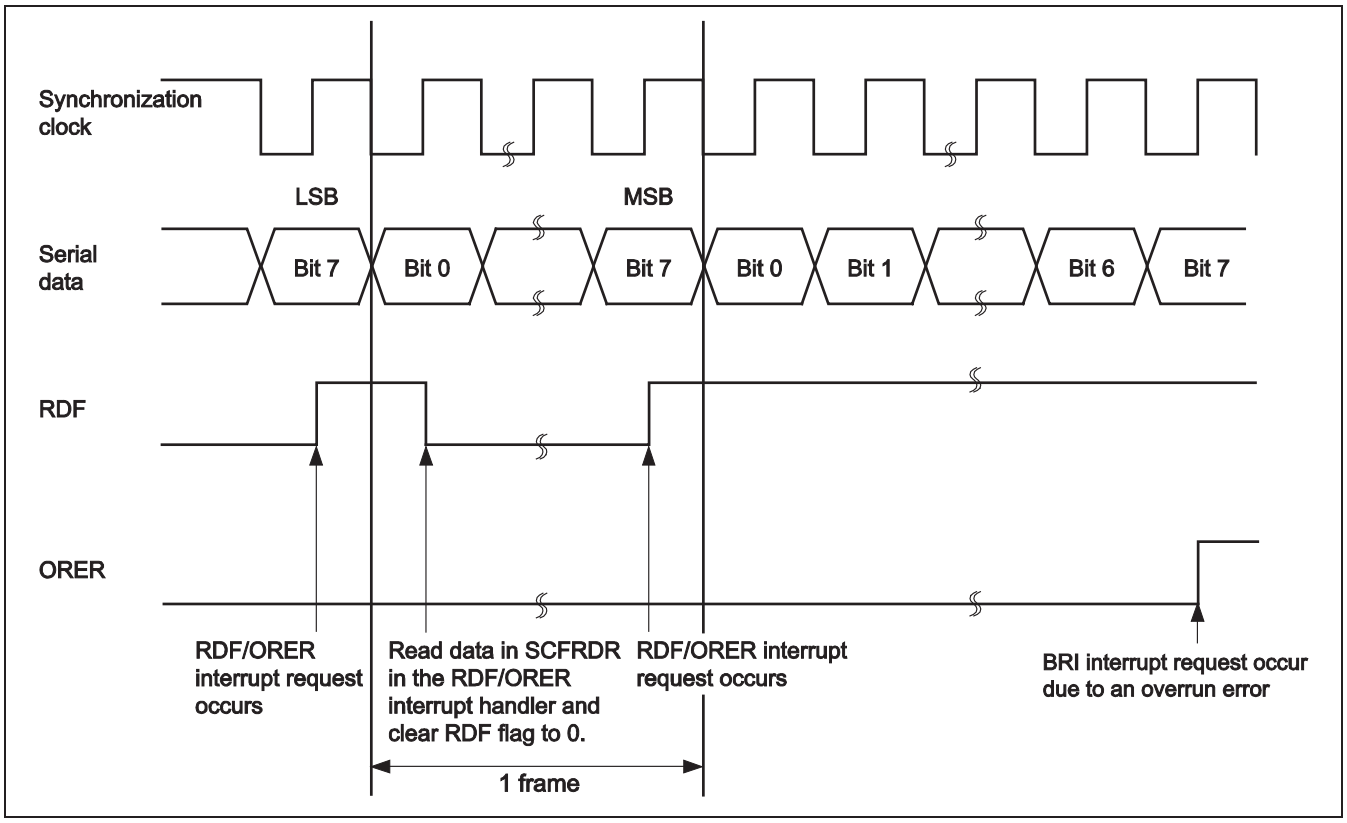

Figure 35.22 Example of SCIF Reception in Clock Synchronous Mode

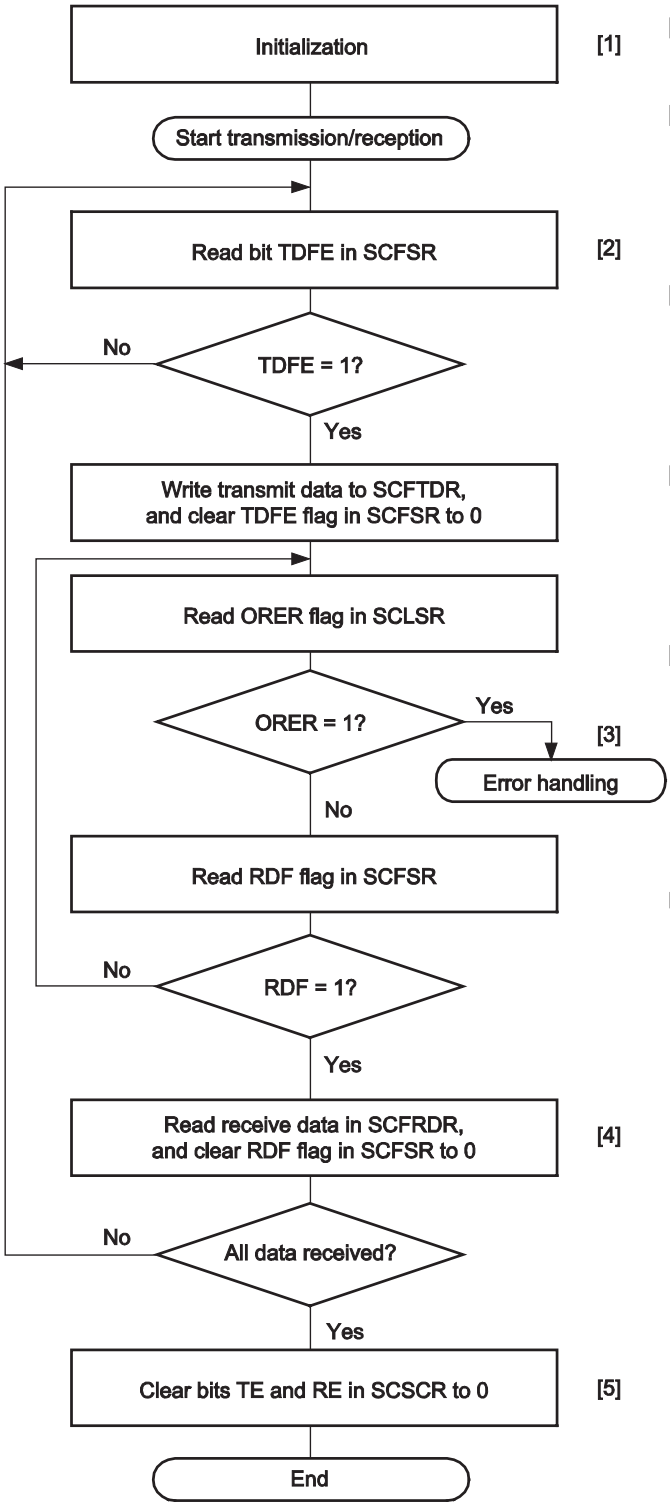
(d) Simultaneous Serial Data Transmission/Reception (Clock Synchronous Mode)

Figure 35.23 shows a sample flowchart for simultaneous serial data transmission/reception.

The SCIF transmission and reception should be enabled before taking the following steps for simultaneous serial data transmission/reception.



[1] SCIF initialization:
See figure 51.17, Sample Flowchart for SCIF Initialization.

[2] SCIF status check and write for transmit data:
Read SCFSR and check that the TDFE flag is set to 1, then write transmit data to SCFTDR, and clear the TDFE flag to 0. The change of the value of the TDFE flag from 0 to 1 can also be identified by a TDFE/TEND interrupt.

[3] Receive error handling:
If a receive error occurs, read the ORER flag in SCLSR, perform the appropriate error handling, then clear the ORER flag to 0. The SCIF cannot resume reception while the ORER flag is set to 1.

[4] SCIF status check and read for receive data:
Read SCFSR and check that RDF =1, then read the receive data in SCFRDR, and clear the RDF flag to 0. The change of the value of the RDF flag from 0 to 1 can also be identified by an RDF interrupt.

[5] Serial transmission and reception continuation procedure:
To continue serial data transmission and reception, read RDF flag and SCFRDR, and finish clearing the RDF flag to 0 before receiving the MSB in the current frame.
Similarly, read 1 from the TDFE flag to confirm that writing is enabled before transmitting the MSB in the current frame. Then write data to SCFTDR and clear the TDFE flag to 0.

Note : When switching from transmission or reception to simultaneous transmission and reception, clear bits TE and RE to 0, and then set them to 1 simultaneously.

Figure 35.23 Sample Flowchart for Simultaneous Serial Data Transmission/Reception

35.4 SCIF Interrupt Sources and the DMAC

If the DMAC is used for transmission/reception, set and enable the DMAC before setting the SCIF.

Transmission Interrupts and DMA Transfer:

If the TDFE/TEND flag in SCFSR is set to 1 when the TDFE/TEND interrupt is enabled by the TIE bit, a TDFE/TEND interrupt request and a transmit-FIFO-data-empty DMA transfer request will occur. If the TDFE/TEND flag is set to 1 when TDFE/TEND interrupt is disabled by the TIE bit, only the transmit-FIFO-data-empty DMA transfer request will occur. (A transmit-FIFO-data-empty DMA transfer request is generated when the TDFE flag is set while TEIE is 0, or when the TEND flag is set while TEIE is 1. DMA transfer requests are not affected by the TEIE bit.)

When TDFE/TEND interrupt requests are enabled, the interrupt requests are cleared by the DMAC regardless of the interrupt handling program.

Reception Interrupts and DMA Transfer:

If the RDF/DR flag in SCFSR is set to 1 when RDF/DR interrupt is enabled by the RIE bit, an RDF/DR interrupt request occurs. If the RDF/DR flag is set to 1, a receive-FIFO-data-full DMA transfer request occurs. If the RDF/DR flag is set to 1 when RDF/DR interrupt is disabled by the RIE bit, and only a receive-FIFO-data-full DMA transfer request occurs and DMAC can be activated to perform data transfer.

Setting the RIE bit in SCSCR to 0 and the REIE it to 1 generates the ER/BRK/ORER interrupt requests without generating RDF/DR interrupt requests. When the BRK flag in SCFSR or the ORER flag in SCLSR is set to 1, BRK/ORER interrupt requests occur.

If the TO flag is set to 1 in SCLSR when TO interrupts are enabled by the TOIE bit, TO interrupt requests occur.

DR/TO interrupt requests generated by setting the DR or TO flag to 1 or receive-FIFO-data-full DMA transfer requests occur only in asynchronous mode.

When DR/TO interrupt requests are enabled to be issued, interrupt requests generated by the DR flag are cleared by the DMAC regardless of the interrupt handling program, however, those generated by the TO flag are not cleared by the DMAC. Therefore, the TO flag interrupt requests need to be cleared with the interrupt handling program. (The DR and TO flags are set at the same time, but cleared separately.)

Table 35.7 SCIF Interrupt Sources

Interrupt Source	DMAC Activation	Priority on Reset Release
Interrupts generated by receive error flag (ER)	Disabled	High
Interrupts generated by receive-FIFO-data-full (RDF), receive-data-ready (DR) or timeout (TO) *	Enabled	↕
Interrupts generated by break (BRK) or overrun error (ORER)	Disabled	↕
Interrupts generated by transmit FIFO data empty (TDFE)	Enabled	Low

Note: * RXI interrupts by means of the DR or TO flag are available only in asynchronous mode.

35.5 Usage Notes

Note the following on use of the SCIF.

(1) Break Detection and Operation

Break signals can also be detected by reading the RX pin value directly when a framing error (FER) is detected. In the break state, the input values from the RX pin are all 0s. So, the parity error flag (PER) may be set after the FER flag is set to 1.

Although the SCIF stops receive data transfer to SCFRDR after detecting a break, it continues data reception.

(2) Sending a Break Signal

The input/output condition and level of the TX pin are determined by the SPB2IO and SPB2DT bits in SCSPTR. This enables to send a break signal.

The pin does not function as the TX pin from the initialization of the serial transmitter to setting of the TE bit (enabling transmission). In this period, the marked state is substituted by the value of the SPB2DT bit. Therefore, the SPB2IO and SPB2DT bits should be set to 1 (designating output and high level) beforehand.

To send a break signal during serial transmission, clear the SPB2DT bit to 0 (low level), and then clear the TE bit to 0 (halting transmission). When the TE bit is cleared, the transmitter is initialized regardless of the current transmission state, and the TX pin outputs 0.

(3) Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCIF operates on the base clock with a frequency 16 times the bit rate.

In reception, the SCIF performs the internal synchronization by sampling the fall edge of the start bit using the base clock. In addition, the SCIF takes receive data at the rising edge of the eighth pulse on the base clock.

Figure 35.24 shows the timing of this operation.

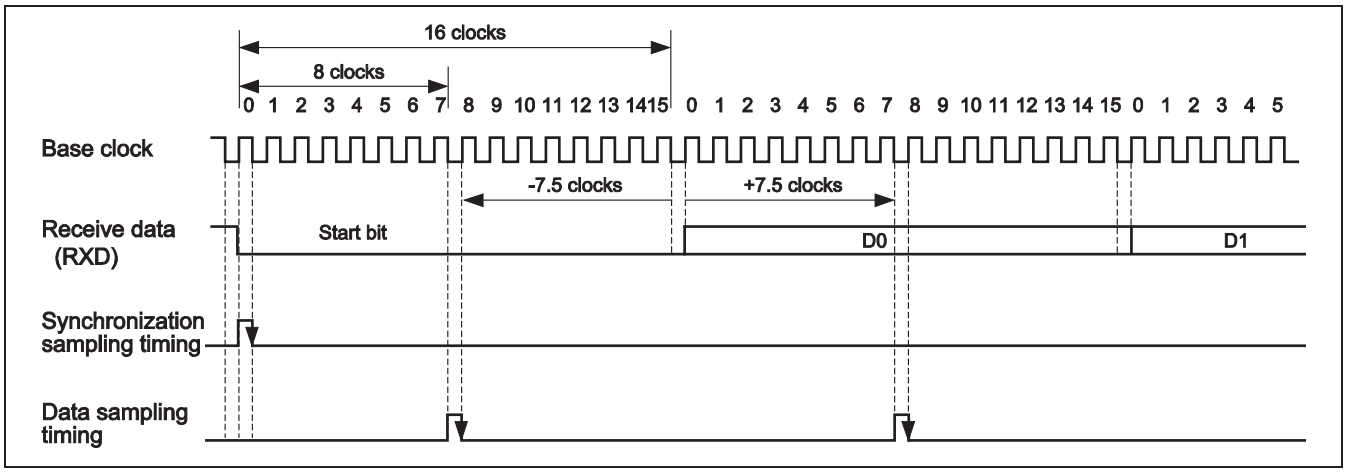


Figure 35.24 Timing Chart of Receive Data Sampling

The reception margin in asynchronous mode is given by expression (1).

$$M = \left| (0.5 - \frac{1}{2N}) - (L - 0.5)F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\% \quad \text{Expression (1)}$$

M: Receive margin (%)

N: Ratio of bit rate to clock (N = 16)

D: Clock duty (D = 0 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute value of clock frequency deviation

Assuming F = 0 and D = 0.5 for expression (1), the reception margin obtained with expression (2) is 46.875% as shown below:

Assuming D = 0.5 and F = 0

$M = (0.5 - 1/(2 \times 16)) \times 100\%$

$= 46.875\%$ ……expression (2)

This is a theoretical value. A reasonable margin allowed in system designs is 20% to 30%.

(4) Reception Margin and Baud Rate Error

The value of 46.875% obtained by the above expression (2) indicates the reception margin when the baud rate error is 0 (F = 0). If there is no error in the reception and transmission baud rates, reception is possible even with misalignment of approx. 1/2 bit. If there is an error in the reception and transmission baud rates, the errors are accumulated up to the stop bit reception, which reduces the reception margin. The allowable baud rate error can be obtained by modifying the F in expression (1). When D = 0.5:

$F = \{(15/32 - M)/(L - 0.5)\} \times 100\ (\%)$……expression (3)

By using expression (3), the relationship between the allowable error and reception margin with the frame length = 12 can be summarized as follows:

Allowed Error (%)	Reception Margin (%)
4.07	0
3.64	5
3.20	10
2.33	20
1.46	30

35.6 Baud Rate Generator for External Clock (BRG)

35.6.1 Overview

The SCIF incorporates a baud rate generator for external clock (abbreviated as BRG, hereafter). The BRG supplies a sampling clock (BRGCLK) to the SCIF core by dividing the external clock SC_CLK (selectable between SCIF_CLK and ZSϕ) by 1 to $2^{16} - 1$. In addition, the BRG switches the output between the external clock SCK and divided clock.

Figure 35.25 shows a block diagram of the BRG.

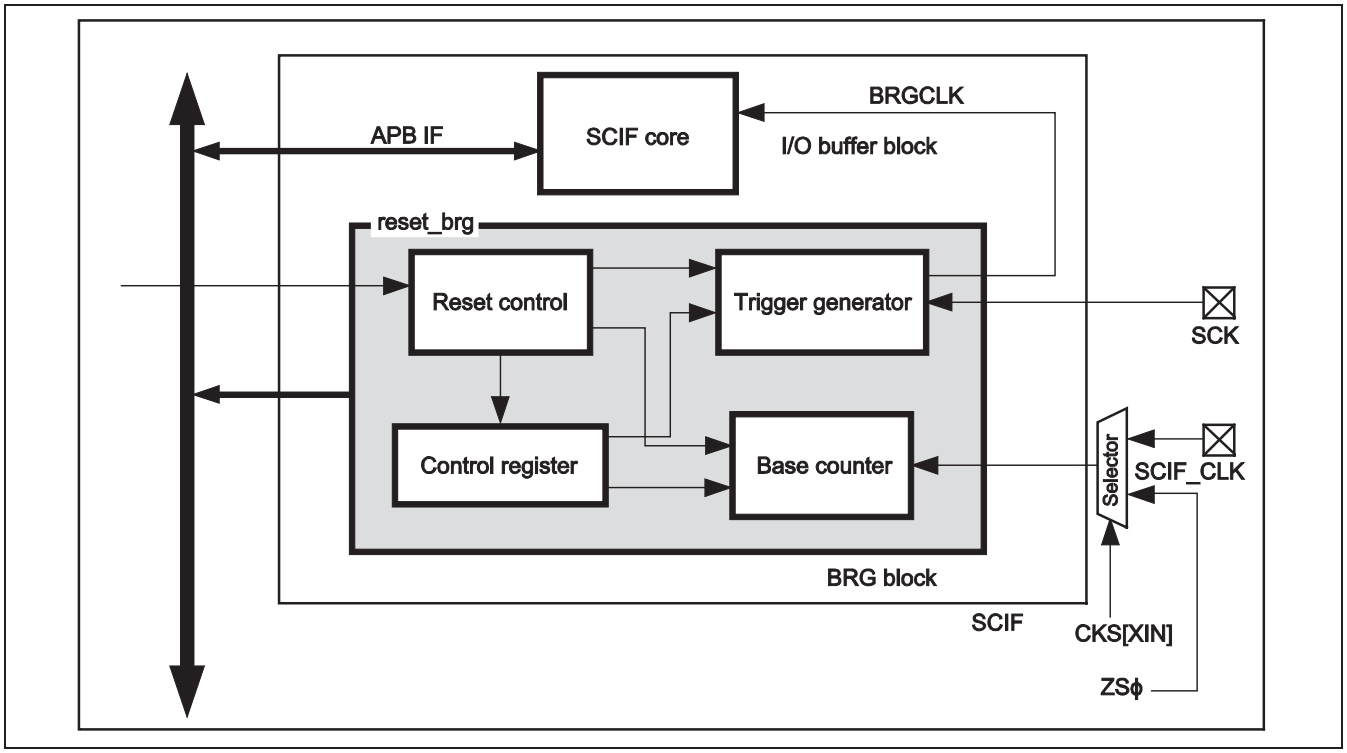

Figure 35.25 BRG Block Diagram

(1) Reset Controller:

The reset controller handles resetting the control register, base counter, and trigger generator.

(2) Control Register:

The control register has the frequency division register and clock select register.

(3) Base Counter:

The base counter is a 16-bit CLK synchronization counter that is used to determine the timing for generating a frequency divided clock.

(4) Trigger Generator:

The trigger generator generates rising-edge/falling-edge triggers for a frequency divided clock with the timing according to values of the frequency division register and base counter. The triggers are used to generate the frequency divided clock. In addition, the trigger generator switches the output between the SCK (external clock input) and frequency divided clock.

35.6.2 Register Configuration

Table 35.8 shows the registers in the BRG block.

Table 35.8 List of Registers

Name	Abbreviation	R/W	Initial Value	Relative Address	Access Size
Frequency division register	DL	R/W	H'0000	H'30	16
Clock select register	CKS	R/W	H'0000	H'34	16

35.6.2.1 Frequency Division Register (DL)

This register specifies the value of frequency division for the frequency divided clock generated by the BRG.

This register supports a 16-bit binary format that allows specifying a value in the rage of 1 to 65535.

Setting all 0s in this register makes the BRG output the frequency divided clock at the low level.

The value of frequency division is given by the following formula:

The value of frequency division = (clock input frequency)/(required baud rate × 16)

Table 35.9 shows how to use the baud rate generator with a 3.6864-MHz crystal resonator.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DL[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 0	DL[15:0]	All 0	R/W	Specifies a division value of frequency clock generated in BRG. The value settings enabled in the range of 1 to 65535.

Table 35.9 Baud Rate (3.6864-MHz clock)

Baud Rate	Value of Frequency Division	Error Rate
50	4608	—
75	3072	—
110	2095	–0.022
134.5	1713	0.001
150	1536	—
300	768	—
600	384	—
1200	192	—
1800	128	—
2000	115	0.174
2400	96	—
3600	64	—

7200	32	—
9600	24	—
14400	16	—
19200	12	—
38400	6	—
76800	3	—
115200	2	—

Note: — Indicates that the error rate is 0.

35.6.2.2 Clock Select Register (CKS)

This register switches the output between the frequency divided clock and specifies a source clock for the external baud rate.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CKS	XIN	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	CKS	0	R/W	This bit switches the output between the frequency divided clock (SC_CLK) and external clock (SCK). 0: Selects the frequency divided clock. 1: Selects the external clock.
14	XIN	0	R/W	Selects the baud rate generator clock source for the external clock between SCIF_CLK and ZSϕ. 0: Selects the external clock (SCIF_CLK). 1: Selects the internal clock (ZSϕ).
13 to 0	All 0	0	R	Reserved These bits are always read as 0. Only 0 should be written to these bits.

35.6.3 Restrictions in BRG

(1) Notes on Setting Frequency Division Register

1. For the initial setting of the register after a reset, at least one bit of waiting period is required to secure the clock stabilization time.
   (Example) One bit period when DL = 2

   $3.68\ (\text{MHz}) \times 1/2 \times 1/16 = 0.115\ (\text{MHz}) \rightarrow 8695\ (\text{ns})$

2. For modifying the register value after the setting stated in <1> above, at least one bit of waiting period at the maximum bit rate (DL = '65535') is required.
   The SCIF registers and BRG registers should be set as the following table:

- Asynchronous mode (SC_CLK external input)

SCIF		BRG	
Register Name	**Setting Value**	**Register Name**	**Setting Value**
SCSMR.C/A#	0	CKS	0000
SCSCR.CKE[1:0]	10	DL	1 to FFFF

- Asynchronous mode (SCK external input)

SCIF		BRG	
Register Name	**Setting Value**	**Register Name**	**Setting Value**
SCSMR.C/A#	0	CKS	8000
SCSCR[1:0]	10	DL	Don’t care

- Clock synchronous mode (external input)

SCIF		BRG	
Register Name	**Setting Value**	**Register Name**	**Setting Value**
SCSMR.C/A#	1	CKS	8000
SCSCR[1:0]	10	DL	Don’t care

3. The register settings for the baud rate generator for external clock should be made before starting initialization of the SCIF.

36. High Speed Serial Communication Interface with FIFO (HSCIF)

36.1 Overview

The RZ/G1C products have a high speed serial communication interface with built-in FIFO buffers (high-speed serial communication interface with FIFO: HSCIF) that handles asynchronous communication. The HSCIF has two 128-stage FIFO buffers separately for transmission and reception, which enables fast, efficient, and uninterrupted communication. The product has 3 channels. All functions of each channel are same.

36.1.1 Features

The HSCIF has the following features.

- Asynchronous serial communication mode
  The HSCIF performs serial data communication based on a character-by-character asynchronous system. This feature enables serial data communication with standard asynchronous communication chips that support universal asynchronous receiver/transmitter (UART) or asynchronous communication interface adapter (ACIA). There is a choice of eight serial data transfer formats.
  — Data length: 7 or 8 bits
  — Stop bit length: 1 or 2 bits
  — Parity: Even/odd/none
  — Receive error detection: Parity, framing, and overrun errors
  — Break detection:
    A break is detected when a framing error lasts for more than 1 frame length at space 0 (low level).
    When a framing error occurs, a break can also be detected by reading the HRX pin level directly from the serial port register (HSSPTR).
  — Sampling rate: Variable (integer number from 8 to 32)
- Capable of full-duplex communication
  The HSCIF has an independent transmitter and receiver that enable simultaneous transmission and reception. The transmitter and receiver both have a 128-stage FIFO buffer structure, enabling continuous serial data transmission and reception.
- On-chip baud rate generator, enabling any bit rate to be selected
  The HSCIF enables choice of a clock source for transmission/reception: a clock from the on-chip baud rate generator based on the internal clock or an external clock.
- Eight interrupt sources
  The HSCIF has eight types of interrupt sources: receive-data-ready, receive-FIFO-data-full, break detection, transmit-FIFO-data-empty, transmit-end, receive-error, overrun-error and time-out, and enables any of them to be requested independently.
- DMA data transfer
  When the transmit FIFO register is empty or the receive FIFO register has received data, issuing a DMA transfer request activates the DMA controller (DMAC) to execute a data transfer.
- Modem control functions (HRTS# and HCTS#) are stored.
- The amount of data in the transmit/receive FIFO registers and the number of receive errors in receive data in the receive FIFO register are available.
- A receive data ready (DR) or a timeout error (TO) can be detected during reception.

36.1.2 Block Diagram

Figure 36.1 shows the HSCIF block diagram.

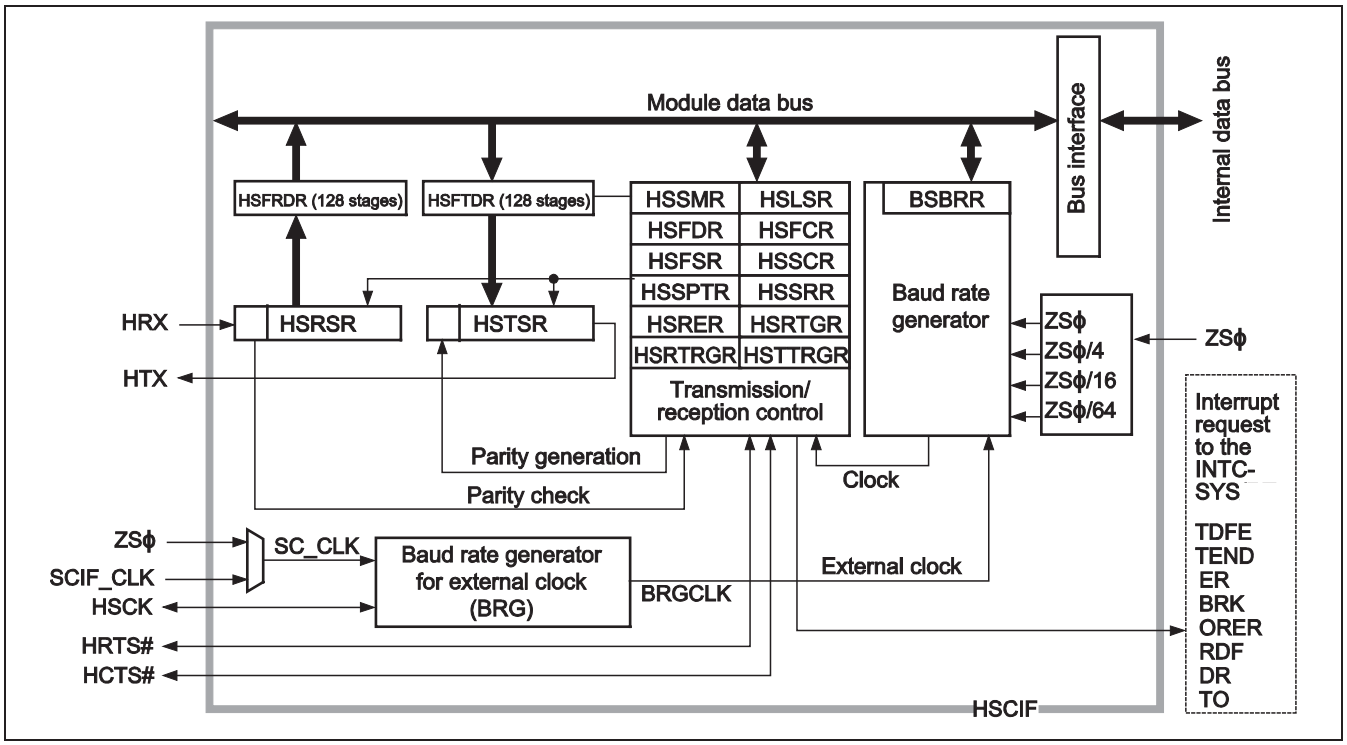

Figure 36.1 HSCIF Block Diagram

36.1.3 Pin Configuration

Table 36.1 shows the HSCIF pin configuration. These pins are multiplexed in other functions, so that the usage of the pins are may be restricted depending on the multiplexed pin settings.

Table 36.1 Pin Configuration

Name	Function	I/O	Descriptions
HSCK0	Serial clock pin	I/O	Clock I/O
HSCK1	Serial clock pin	I/O	Clock I/O
HSCK2	Serial clock pin	I/O	Clock I/O
HRX0	Receive data pin	Input	Receive data input
HRX1	Receive data pin	Input	Receive data input
HRX2	Receive data pin	Input	Receive data input
HTX0	Transmit data pin	Output	Transmit data output
HTX1	Transmit data pin	Output	Transmit data output
HTX2	Transmit data pin	Output	Transmit data output
HCTS0#	Modem control pin	I/O	Transmission enabled
HCTS1#	Modem control pin	I/O	Transmission enabled
HCTS2#	Modem control pin	I/O	Transmission enabled
HRTS0#	Modem control pin	I/O	Transmission request
HRTS1#	Modem control pin	I/O	Transmission request
HRTS2#	Modem control pin	I/O	Transmission request
SCIF_CLK	Baud rate generation clock pin	Input	Clock for input to the baud rate generator for the external clock

Note: These pins are made to function as serial pins by setting up HSCIF operation using bits TE, RE, CKE[1:0] in HSSCR, and bit MCE in HSFCR. HSSPTR of the HSCIF can be used to handle the transmission and detection of break states.

36.1.4 Register Configuration

Table 36.2 shows the registers in the HSCIF. Do not write to any addresses other than listed below. Operations cannot be guaranteed if writing is attempted. Values read from addresses other than those listed below are undefined.

Table 36.2 Register Configuration

Ch. No.	Register Name	Abbreviation	R/W	Value after Reset	Address	Access Size
0	Serial mode register	HSSMR	R/W	H'0000	H'E62C 0000	16
	Bit rate register	HSBRR	R/W	H'FF	H'E62C 0004	8
	Serial control register	HSSCR	R/W	H'0000	H'E62C 0008	16

	Transmit FIFO data count trigger register	HSTTRGR	R/W	H'0008	H'E62D 0058	16

Notes: 1. Only 0 can be written to clear the flags. Bits 15 to 8, 3, and 2 are read-only bits and cannot be modified.
2. Only 0 can be written to clear the flags. Bits 15 to 3, and 1 are read-only bits and cannot be modified.

36.2 Register Descriptions

36.2.1 Receive Shift Register (HSRSR)

HSRSR is a register that receives serial data.

The HSCIF sets serial data input to the HSRSR from the HRX pin in the order received, starting with the LSB (bit 0), and converts it to parallel data. When one byte of data has been received, it is transferred to the receive FIFO register HSFRDR, automatically.

HSRSR cannot be read from and written to by the CPU.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—
Initial value:	—	—	—	—	—	—	—	—
R/W:	—	—	—	—	—	—	—	—

36.2.2 Receive FIFO Data Register (HSFRDR)

HSFRDR is a 128-stage FIFO register that stores received serial data.

When HSCIF has received one byte of serial data, it transfers the received data from the receive shift register (HSRSR) to HSFRDR for storage, and reception is thus completed. HSRSR is then ready for reception, and is capable of receiving up to 128 consecutive bytes of data before HSFRDR is full.

HSFRDR is a read-only register and cannot be modified by the CPU. Note that the read value will be undefined while there is no receive data in HSFRDR. When HSFRDR is full of receive data, subsequent serial data is lost.

HSFRDR is read as an undefined value after a power-on reset.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—
Initial value:	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R

36.2.3 Transmit Shift Register (HSTSR)

HSTSR is a register that transmits serial data.

To perform serial data transmission, the HSCIF first transfers transmit data from the transmit fifo data register (HSFTDR) to HSTSR, then sends the data to the HTX pin starting with the LSB (bit 0). When transmission of one byte is completed, the HSCIF transfers the next transmit data from HSFTDR to HSTSR automatically, then starts transmission.

HSTSR cannot be read from and written to directly by the CPU.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—
Initial value:	—	—	—	—	—	—	—	—
R/W:	—	—	—	—	—	—	—	—

36.2.4 Transmit FIFO Data Register (HSFTDR)

HSFTDR is an 8-bit FIFO register of 128 stages that stores data for serial transmission.

If HSTSR is empty after transmit data has been written to HSFTDR, the HSCIF transfers the data from HSFTDR to HSTSR and starts serial transmission.

HSFTDR is a write-only register and cannot be read from by the CPU. Writing further data to HSFTDR is no longer possible when it is full. Attempts at writing data to the register in this situation are ignored.

HSFTDR is read as an undefined value on a power-on reset.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—
Initial value:	—	—	—	—	—	—	—	—
R/W:	W	W	W	W	W	W	W	W

36.2.5 Serial Mode Register (HSSMR)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	CHR	PE	O/E#	STOP	—	CKS[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R/W	R/W

HSSMR is a 16-bit register that sets the HSCIF's serial transfer format and selects the baud rate generator clock source.

HSSMR can always be read from and written to by the CPU.

HSSMR is initialized to H'0000 by a power-on reset.

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	CHR	0	R/W	Character Length Selects 7 or 8 bits for data length. When the 7-bit data is selected, the MSB (bit 7) in the transmit FIFO data register (HSFTDR) is not transmitted. 0: 8 bits 1: 7 bits
5	PE	0	R/W	Parity Enable Determines whether parity bit is added in transmission or not, and parity bit is checked in reception or not. When bit PE is set to 1, the parity (even or odd) specified by bit O/E# is added to transmit data. In reception, the parity bit is checked for the parity (even or odd) specified by bit O/E#. 0: Disables parity bit addition and check. 1: Enables parity bit addition and check.
4	O/E#	0	R/W	Parity Mode Selects either even or odd parity to use in parity addition and check. The O/E# bit setting is valid only when bit PE is set to 1, enabling parity bit addition and check. 0: Even parity 1: Odd parity When even parity is set, the parity bit is added in transmission so that the total number of 1-bit in the transmit character plus the parity bit is even. In reception, a check is performed to see if the total number of 1-bit in the receive character plus the parity bit is even. When odd parity is set, the parity bit is added in transmission so that the total number of 1-bit in the transmit character plus the parity bit is odd. In reception, a check is performed to see if the total number of 1-bit in the receive character plus the parity bit is odd.

Bit	Bit Name	Initial Value	R/W	Description
3	STOP	0	R/W	Stop Bit Length Selects 1 bit or 2 bits as the stop bit length. In reception, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1, it is treated as a stop bit. If it is 0, it is treated as the start bit of the next transmit character. 0: 1 stop bit*1 1: 2 stop bits*2 Notes: 1. In transmission, a single 1-bit (stop bit) is added to the end of a transmit character before it is sent. 2. In transmission, two 1-bit (stop bits) are added to the end of a transmit character before it is sent.
2	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
1, 0	CKS[1:0]	00	R/W	Clock Select 1 and 0 These bits select the clock source for the on-chip baud rate generator. The clock source can be selected from ZSϕ, ZSϕ/4, ZSϕ/16, and ZSϕ/64, according to the setting of bits CKS[1:0]. 00: ZSϕ 01: ZSϕ/4 10: ZSϕ/16 11: ZSϕ/64

36.2.6 Serial Control Register (HSSCR)

HSSCR is a register that enables or disables transmission/reception by the HSCIF, enables or disables interrupt requests, and selects transmission/reception clock source for the HSCIF.

HSSCR can always be read from and written to by the CPU.

HSSCR is initialized to H'0000 by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TOT[1:0]		—	—	TEIE	—	—	—	TIE	RIE	TE	RE	REIE	TOIE	CKE[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15, 14	TOT[1:0]	00	R/W	Set the time for a data ready (DR) or a timeout (TO) to be set in asynchronous mode. 00: 15 etu* 01: 31 etu 10: 47 etu 11: 63 etu Note: * ETU: Elementary Time Unit (time for transfer of one bit) Equivalent to 1.5 frames with an 8-bit, 1-stop-bit format.
13, 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11	TEIE	0	R/W	Transmit End Interrupt Enable When a transmit-end request is enabled by the TIE bit, the TEIE bit selects the source of the transmit end interrupt request from the following: • Setting the TDFE flag in HSFSR • Setting the TEND flag in HSFSR 0: The transmit FIFO data empty (TDFE) interrupt request is used. 1: The transmit end (TEND) interrupt request is used.
10 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
7	TIE	0	R/W	Transmit Interrupt Enable Enables or disables a transmit-FIFO-data-empty interrupt (TDFE) request when the TEIE bit in HSSCR is pulled 0, if the following conditions are satisfied: • Serial transmit data has been transferred from HSFTDR to HSTSR, • The number of data bytes in HSFTDR is equal to or less than the transmit trigger count, and • The TDFE flag in HSFSR is set to 1. Enables or disables a transmit-end interrupt (TEND) request when the TEIE bit of HSSCR is set to 1, if the following conditions are satisfied: • Transmission was ended because there is no valid data in HSFTDR when the last bit of the transmit character in HSTSR was transmitted, and • The TEND flag of HSFSR is set to 1. 0: When the TEIE bit is 0, disables transmit-FIFO-data-empty interrupt (TDFE) request. When the TEIE bit is 1, disables transmit-end interrupt (TEND) request. 1: When the TEIE bit is 0, enables transmit-FIFO-data-empty interrupt (TDFE) request. When the TEIE bit is 1, enables transmit-end interrupt (TEND) request.
6	RIE	0	R/W	Receive Interrupt Enable Enables or disables a receive-FIFO-data-full interrupt request when the RDF flag in HSFSR is set to 1, a receive-data-ready interrupt request when the DR flag in HSFSR is set to 1, a receive-error interrupt request when the ER flag in HSFSR is set to 1, a break interrupt request when the BRK flag in HSFSR is set to 1, and an overrun error interrupt request when the ORER flag in HSLSR is set to 1. 0: Disables receive-FIFO-data-full interrupt (RDF) requests, receive-data-ready interrupt (DR) requests, receive-error interrupt (ER) requests, break interrupt (BRK) requests, and overrun error interrupt (ORER) requests. 1: Enables receive-FIFO-data-full interrupt (RDF) requests, receive-data-ready interrupt (DR) requests, receive-error interrupt (ER) requests, break interrupt (BRK) requests, and overrun error interrupt (ORER) requests.
5	TE	0	R/W	Transmit Enable Enables or disables the start of HSCIF serial transmission. The HSCIF starts serial transmission when transmit data is written to the HSFTDR while TE is 1. Before setting TE to 1, set HSSMR and HSFCR to specify the transmission format and reset the transmit FIFO. 0: Disables transmission. 1: Enables transmission.

Bit	Bit Name	Initial Value	R/W	Description
4	RE	0	R/W	Receive Enable Enables or disables the start of HSCIF serial reception. When RE is 1, the HSCIF starts serial reception by detecting a start bit. Before setting RE to 1, set HSSMR and HSFCR to specify the reception format and reset the receive FIFO. 0: Disables reception.* 1: Enables reception. Note: * Even if RE is cleared to 0, the DR, ER, BRK, RDF, FER, PER, TO and ORER flags are not affected, and retain their states.
3	REIE	0	R/W	Receive Error Interrupt Enable Enables or Disables generation of receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests. 0: Disables receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests.* 1: Enables receive-error interrupt (ER) requests, break interrupt (BRK) requests and overrun-error interrupt (ORER) requests. Note: * When REIE is 1, ER, BRK or ORER interrupt requests will occur even if RIE is cleared to 0. This setting is used to notify the interrupt controller of ER, BRK, and ORER interrupt requests during DMAC transfer.
2	TOIE	0	R/W	Timeout Interrupt Enable Enables or disables generation of timeout interrupt (TO) requests when the TO flag in HSLSR is set to 1. 0: Disables timeout interrupts (TO). 1: Enables timeout interrupts (TO).
1, 0	CKE[1:0]	00	R/W	Clock Enable 1 and 0 These bits select the HSCIF clock source and enables or disables the clock output from the HSCK pin. Whether the HSCK pin functions as a serial clock output pin or a serial clock input pin is determined by CKE[1:0] bit settings. See Table 36.3 for the bit settings.

Table 36.3 Clock Selection

CKE[1]	CKE[0]	Clock Source	HSCK Pin
0	0	Internal clock (ZSϕ, ZSϕ/4, ZSϕ/16, and ZSϕ/64)	The HSCK pin is not used. The HSCK pin functions as an input pin (input signals are ignored). (Initial value)
0	1		The HSCK pin outputs the clock (with a bit rate multiplied by the sampling rate).
1	0	Baud rate generator output for external clock or HSCK	When SC_CLK is selected: The HSCK pin is an input pin (input signals are ignored). Set the SC_CLK frequency so that the frequency of BRGCLK is multiplied by the sampling rate.
			When HSCK is selected: The HSCK pin inputs the clock (with the bit rate multiplied by the sampling rate).
	1	Prohibited	

Note: It is not allowed to set synchronous communication using SC_CLK for input.

36.2.7 Serial Status Register (HSFSR)

HSFSR is a 16-bit register. The lower 8 bits are status flags that indicate the operating status of the HSCIF, and the upper 8 bits are all reserved.

HSFSR can always be read from and written to by the CPU. However, the flags ER, TEND, TDFE, BRK, RDF, and DR cannot be written by 1. The FER and PER flags are read-only flags and cannot be modified.

HSFSR is initialized to H'0060 by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	ER	TEND	TDFE	BRK	FER	PER	RDF	DR
Initial value:	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/(W)*	R/(W)*	R/(W)*	R/(W)*	R	R	R/(W)*	R/(W)*

Note: * Only 0 can be written to clear the flag.

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	ER	0	R/(W)*	Receive Error Indicates that a framing error or a parity error has occurred in reception. The ER flag is not affected by an error and retains its previous state when the RE bit is 0 in HSSCR. If a receive error occurs, receive data will be transferred to HSFRDR and reception operation will be continued. Whether there is a receive error in data read from HSFRDR can be determined by the FER and PER bits in HSFSR. 0: Indicates that no framing or parity error has occurred in reception. [Clearing conditions] • A power-on reset is executed. • 0 is written to ER. 1: Indicates that a framing error or a parity error has occurred in reception. [Setting conditions] • The HSCIF checks whether the stop bit at the end of receive data is 1, but the stop bit is 0.* • The number of 1-bit in receive data plus the parity bit does not match the parity setting (even or odd) specified by the O/E# bit in HSSMR during reception. Note: * In the 2-stop-bit mode, only the first stop bit is checked that the value is 1; the second stop bit is not checked.

Bit	Bit Name	Initial Value	R/W	Description
6	TEND	1	R/(W)*	Transmit End Indicates that transmission has been ended because there was no valid data in HSFTDR when the last bit of the transmit character was transmitted. 0: Indicates that transmission is in progress. [Clearing conditions] • Transmit data is written to HSFTDR, and 0 is written to TEND. • Data is written to HSFTDR by the DMAC. 1: Indicates that transmission has been ended. [Setting conditions] • A power-on reset is executed. • The TE bit in HSSCR is 0. • There is no transmit data in HSFTDR when the last bit of a 1-byte serial transmission character is transmitted.
5	TDFE	1	R/(W)*	Transmit FIFO Data Empty Indicates that the HSCIF has transferred data from HSFTDR to HSTSR, the number of data bytes in HSFTDR becomes equal to or less than the transmit trigger count specified by the HSTTRGR, and HSFTDR is ready to be written by new transmit data. HSFTDR is a 128-byte FIFO register. The maximum number of bytes that can be written to when TDFE = 1 is "128 – [the transmit trigger count]". If data exceeding this value is attempted to be written, the data will be ignored. The number of data bytes in HSFTDR is indicated by the upper bits of HSFDR. If the number of data written in HSFTDR is equal to or less than the transmit trigger count, this bit will be set to 1 even if it is cleared to 0 after it is read as 1. 0: Indicates that the number of transmit data written to HSFTDR exceeds the transmit trigger count. [Clearing conditions] • Transmit data exceeding the specified transmit trigger count have been written to HSFTDR, and 0 is written to TDFE. • Transmit data exceeding the specified transmit trigger count have been written to HSFTDR by the DMAC. 1: Indicates that the number of transmit data in HSFTDR is equal to or less than the transmit trigger count. [Setting conditions] • A power-on reset is executed. • The number of transmit data in HSFTDR is equal to or less than the transmit trigger count after transmission.

Bit	Bit Name	Initial Value	R/W	Description
4	BRK	0	R/(W)*	Break Detect Indicates that a receive data break signal has been detected. If a break signal is detected, receive data (H'00) transfer to HSFRDR is stopped. After the break is canceled and the receive signal returns to 1, the receive data transfer resumes. 0: Indicates that no break signal has been received. [Clearing conditions] • A power-on reset is executed. • 0 is written to BRK. 1: Indicates that a break signal has been received. [Setting condition] • Data with a framing error is received, followed by the space "0" (low level) for at least one frame length.
3	FER	0	R	Framing Error Indicates that a framing error has been found in the data that is to be read next from HSFRDR. 0: Indicates that there is no framing error in the receive data that is to be read from HSFRDR. [Clearing conditions] • A power-on reset is executed. • There is no framing error in the data that is to be read next from HSFRDR. 1: Indicates that there is a framing error in the receive data that is to be read from HSFRDR. [Setting condition] • There is a framing error in the data that is to be read next from HSFRDR.
2	PER	0	R	Parity Error This bit indicates that a parity error has been found in the data that is to be read next from HSFRDR. 0: Indicates that there is no parity error in the receive data that is to be read from HSFRDR. [Clearing conditions] • A power-on reset is executed. • There is no parity error in the data that is to be read next from HSFRDR. 1: Indicates that there is a parity error in the receive data that is to be read from HSFRDR. [Setting condition] • There is a parity error in the data that is to be read next from HSFRDR.

Bit	Bit Name	Initial Value	R/W	Description
1	RDF	0	R/(W)*	Receive FIFO Data Full Indicates that the received data has been transferred from HSRSR to HSFRDR, and the number of receive data bytes in HSFRDR becomes equal to or more than the receive trigger count specified by the HSRTRGR. HSFRDR is a 128-byte FIFO register. When RDF = 1, data equal to or more than the number of receive trigger data bytes can be read. When HSFRDR is empty, HSFRDR is read as an undefined value. The number of receive data bytes in HSFRDR is indicated by the lower bits of HSFDR. If the number of data in HSFRDR is equal to or more than the trigger count, this bit will be set to 1 even if it is cleared to 0. At this time, read receive data until the number of data in HSFRDR is less than the trigger count, read RDF as 1, and then clear RDF. 0: Indicates that the number of receive data bytes in HSFRDR is less than the specified receive trigger count. [Clearing conditions] • A power-on reset is executed. • HSFRDR is read until the number of receive data bytes in HSFRDR is less than the receive trigger count, and 0 is written to RDF. • HSFRDR is read by the DMAC until the number of receive data bytes in HSFRDR is less than the receive trigger count. 1: Indicates that the number of receive data bytes in HSFRDR is equal to or more than the specified receive trigger count. [Setting condition] • Receive data more than the receive trigger count have been stored in HSFRDR.

Bit	Bit Name	Initial Value	R/W	Description
0	DR	0	R/(W)*	Receive Data Ready Indicates that the receive FIFO data register (HSFRDR) contains fewer bytes than the trigger number for reception and no further data have arrived over at least the time corresponding to the setting of HSSCR[15:14]* since the stop bit for the byte to have been received. 0: Indicates that data is being received or has been successfully received, and there is no receive data in HSFRDR. [Clearing conditions] • A power-on reset is executed. • All the receive data in HSFRDR has been read, and 0 is written to DR. • All the receive data in HSFRDR has been read by the DMAC. 1: Indicates that no further receive data has been received. [Setting condition] The receive FIFO data register (HSFRDR) contains fewer bytes than the trigger number for reception and no further data have arrived over at least the time corresponding to the setting of HSSCR[15:14]* since the stop bit for the byte to have been received. Note: * When the setting is 00, the time is 15 etu. This is equivalent to 1.5 frames in an 8-bit, 1-stop-bit format. etu: Elementary Time Unit (time for transfer of one bit)

Note: * Only 0 can be written to clear the flag.

36.2.8 Bit Rate Register (HSBRR)

HSBRR is an 8-bit register that sets the serial transmission/reception bit rate in accordance with the baud rate generator operating clock selected by the CKS[1:0] bits in HSSMR. This baud rate generator is intended for ZSϕ, ZSϕ/4, ZSϕ/16, and ZSϕ/64. For details on the baud rate generator for external clock, see section 36.5, Baud Rate Generator for External Clock (BRG).

HSBRR can always be read from and written to by the CPU except for during transfer.

HSBRR is initialized to H'FF by a power-on reset.

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—
Initial value:	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

The HSBRR setting is determined by the following equation:

[Asynchronous mode]

$$N = \frac{ZS\phi}{Sr \times 2^{2n+1} \times B} \times 10^6 - 1$$

B: Bit rate (bit/s)

N: HSBRR setting for the baud rate generator ($0 \le N \le 255$) (which satisfies the electrical characteristics)

ZSϕ: AXI bus clock operating frequency (MHz)

n: Baud rate generator input clock (n = 0, 1, 2, 3)
(See the Table 36.4 for the relation between n and the clock.)

Sr: Sampling rate (8 to 32)

Table 36.4 HSSMR Settings

n	Baud Rate Generator Input Clock	HSSMR Setting	
		CKS[1]	CKS[0]
0	ZSϕ	0	0
1	ZSϕ/4	0	1
2	ZSϕ/16	1	0
3	ZSϕ/64	1	1

The bit rate error in asynchronous mode is determined by the following equation:

$$\text{error (\%)} = \left\{ \frac{ZS\phi \times 10^6}{(N + 1) \times B \times Sr \times 2^{2n+1}} - 1 \right\} \times 100$$

36.2.9 FIFO Control Register (HSFCR)

HSFCR is a register that resets data counts for the transmit and receive FIFO registers. It also has a modem control and a loopback test enable bit.

HSFCR can always be read from and written to by the CPU except for during transfer.

HSFCR is initialized to H'0000 by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	MCE	TFRST	RFRST	LOOP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

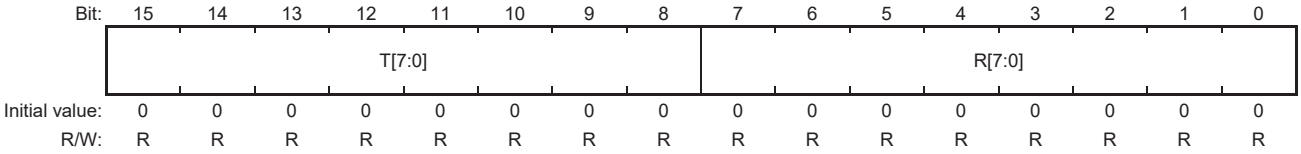
Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3	MCE	0	R/W	Modem Control Enable Enables or disables modem control signals HCTS# and HRTS#. 0: Disables modem signals.* 1: Enables modem signals. Note: * HCTS# and HRTS# control ports.
2	TFRST	0	R/W	Transmit FIFO Data Register Reset Enables or disables a transmit FIFO data register reset that empties the register. 0: Disables the reset.* 1: Enables the reset. Note: * The register is reset by a power-on reset.
1	RFRST	0	R/W	Receive FIFO Data Register Reset Enables or disables a receive FIFO data register (HSFRDR) reset that empties the register. 0: Disables the reset.* 1: Enables the reset. Note: * The register is reset by a power-on reset.
0	LOOP	0	R/W	Loopback Test Enables or disables the loopback test by internally connecting the transmit output pin (HTX) and receive input pin (HRX), and the HRTS# pin and HCTS# pin. 0: Disables the loopback test. 1: Enables the loopback test.

36.2.10 FIFO Data Count Register (HSFDR)

HSFDR is a 16-bit register that indicates the number of data bytes stored in HSFTDR and that in HSFRDR.

The upper 8 bits indicate the number of transmit data bytes in HSFTDR, and the lower 8 bits indicates the number of receive data bytes in HSFRDR.

HSFDR can always be read by the CPU.



Bit	Bit Name	Initial Value	R/W	Description
15 to 8	T[7:0]	H'00	R	These bits indicate the number of data bytes untransmitted and still stored in HSFTDR. H'00 indicates that there is no transmit data in HSFTDR, and H'80 indicates that HSFTDR is full of transmit data.
7 to 0	R[7:0]	H'00	R	These bits indicate the number of receive data stored in HSFRDR. H'00 indicates that there is no receive data in HSFRDR, and H'80 indicates that HSFRDR is full of receive data.

36.2.11 Serial Port Register (HSSPTR)

HSSPTR controls multiplexed input/output and data on the high speed serial communication interface (HSCIF) ports. Bits 1 and 0 control breaks in serial transmission/reception by reading input data from the HRX pin and writing output data to the HTX pin. Bits 3 and 2 read input data from and write output data to the HSCK pin. Bits 5 and 4 read input data from and write output data to the HCTS# pin. Bits 7 and 6 read input data from and write output data to the HRTS# pin.

HSSPTR is a 16-bit register that can always be read from and written to by the CPU.

All HSSPTR bits except bits 6, 4, 2, and 0 are initialized to 0 by a power-on reset. The values of bits 6, 4, 2, and 0 are undefined.

Note: Whether modem control can be selected or not depends on the channel.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	RTSIO	RTSDT	CTSIO	CTSDT	SCKIO	SCKDT	SPB 2IO	SPB 2DT
Initial value:	0	0	0	0	0	0	0	0	0	—	0	—	0	—	0	—
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	RTSIO	0	R/W	Serial Port – RTS Port Input/Output Specifies input or output for the serial port HRTS# pin. To actually set the HRTS# pin as a port output pin to output the value set by the RTSDT bit, the MCE bit in HSFCR should be cleared to 0. 0: Indicates that this bit does not output the value of the RTSDT bit to the HRTS# pin. 1: Indicates that this bit outputs the value of the RTSDT bit to the HRTS# pin.
6	RTSDT	—	R/W	Serial Port – RTS Port Data Specifies the input/output data level of the serial port HRTS# pin. Whether the pin is set for input or output is determined by the RTSIO bit. When the pin is set for output, the value of the RTSDT bit is output to the HRTS# pin. Regardless of the value of the RTSIO bit, the value of the HRTS# pin is read from the RTSDT bit. The initial value of this bit is undefined after a power-on reset. 0: Indicates that the input/output data is low level. 1: Indicates that the input/output data is high level.
5	CTSIO	0	R/W	Serial Port – CTS Port Input/Output Specifies input or output for the serial port HCTS# pin. To actually set the HCTS# pin as a port output pin to output the value set by the CTSDT bit, the MCE bit in HSFCR should be cleared to 0. 0: Indicates that the CTSDT bit value is not output to the HCTS# pin. 1: Indicates that the CTSDT bit value is output to the HCTS# pin.

Bit	Bit Name	Initial Value	R/W	Description
4	CTSDT	—	R/W	Serial Port – CTS Port Data Specifies the input/output data level of the serial port HCTS# pin. Whether the pin is set for input or output is determined by the CTSIO bit. When the pin is set for output, the value of the CTSDT bit is output to the HCTS# pin. Regardless of the value of the CTSIO bit, the value of the HCTS# pin is read from the CTSDT bit. The initial value of this bit is undefined after a power-on reset. 0: Indicates that the input/output data is low level. 1: Indicates that the input/output data is high level.
3	SCKIO	0	R/W	Serial Port – Clock Port Input/Output Specifies input or output for the serial port HSCK pin. To actually set the HSCK pin as a port output pin to output the value set by the SCKDT bit, the CKE1 and CKE0 bits in HSSCR should be cleared to 0. 0: Indicates that the SCKDT bit value is not output to the HSCK pin. 1: Indicates that the SCKDT bit value is output to the HSCK pin.
2	SCKDT	—	R/W	Serial Port – Clock Port Data Specifies the input/output data level of the serial port HSCK pin. Whether the pin is set for input or output is determined by the SCKIO bit. When the pin is set for output, the value of the SCKDT bit is output to the HSCK pin. Regardless of the value of the SCKIO bit, the value of the HSCK pin is read from the SCKDT bit. The initial value of this bit is undefined after a power-on reset. 0: Indicates that the input/output data is low level. 1: Indicates that the input/output data is high level.
1	SPB2IO	0	R/W	Serial Port – Break Input/Output Specifies the output condition of the serial port HTX pin. To actually set the HTX pin as a port output pin to output the value set by the SPB2DT bit, the TE bit in HSSCR should be cleared to 0. 0: Indicates that the SPB2DT bit value is not output to the HTX pin. 1: Indicates that the SPB2DT bit value is output to the HTX pin.
0	SPB2DT	—	R/W	Serial Port – Break Data Specifies the input level of the serial port HRX pin and the output level of the HTX pin. The HTX pin output conditions are determined by the SPB2IO bit. When the HTX pin is set for output, the value of the SPB2DT bit is output to the HTX pin. Regardless of the value of the SPB2IO bit, the value of the HRX pin is read from the SPB2DT bit. The initial value of this bit is undefined after a power-on reset. 0: Indicates that the input/output data is low level. 1: Indicates that the input/output data is high level.

36.2.12 Line Status Register (HSLSR)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	TO	—	ORER
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/(W)*	R	R/(W)*

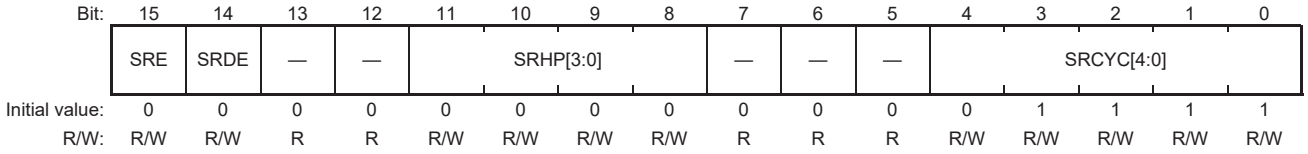
Note: * Only 0 can be written to clear the flag.

Bit	Bit Name	Initial Value	R/W	Description
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	TO	0	R/(W)*	Timeout Indicates that the receive FIFO data register (HSFRDR) contains fewer bytes than the trigger number for reception and no further data have arrived over at least the time corresponding to the setting of HSSCR[15:14]* since the stop bit for the byte to have been received. 0: Indicates that data is being received or has been successfully received and that there is no receive data in HSFRDR. [Clearing conditions] • A power-on reset is executed. • All the receive data in the HSFRDR has been read, and 0 is written to TO. 1: Indicates that no further receive data has been received (receive timeout). [Setting condition] • The receive FIFO data register (HSFRDR) contains fewer bytes than the trigger number for reception and no further data have arrived over at least the time corresponding to the setting of HSSCR[15:14]* since the stop bit for the byte to have been received.* Note: * When the setting is 00, the time is 15 etu. This is equivalent to 1.5 frames in an 8-bit, 1-stop-bit format. etu: Elementary Time Unit (time for transfer of one bit)
1	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
0	ORER	0	R/(W)*	Overrun Error Indicates that an overrun error has occurred in reception and abnormal termination is caused. If an overrun error occurs, the receive data prior to the overrun error is retained in HSFRDR and the data received subsequently is discarded. Any subsequent serial reception is disabled while the ORER flag is 1. To resume data reception after clearing the ORER flag, be sure to first read (or clear) data in the receive FIFO and handle the error, then clear the ORER flag. 0: Indicates that data is being received or has been successfully received. [Clearing conditions] • A power-on reset is executed. • 0 is written to ORER. 1: Indicates that an overrun error has occurred in reception. [Setting condition] • The next serial reception has been completed while HSFRDR is full of 128-byte data. Note: When bit RE in HSSCR is cleared to 0, the ORER flag is not affected and its previous state is retained.

Note: * Only 0 can be written to clear the flag.

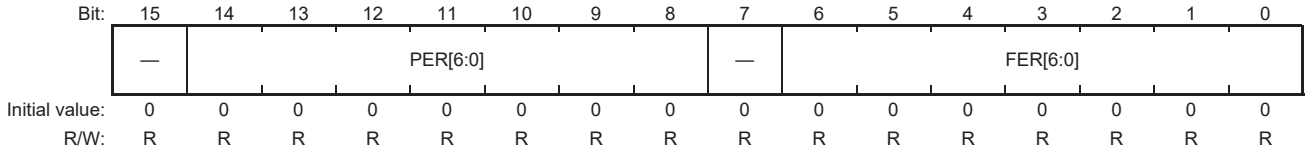
36.2.13 Sampling Rate Register (HSSRR)



Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SRE	SRDE	—	—	SRHP[3:0]				—	—	—	SRCYC[4:0]				
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1
R/W:	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	SRE	0	R/W	Sampling Rate Register Enable (SRE) 0: Set the SRCYC[4: 0] bits to 15 (initial value). 1: Validates the setting of the SRCYC[4:0] bits.
14	SRDE	0	R/W	Sampling Point Register Enable (SRDE) 0: Invalidates the setting of the SRHP[3:0] bits and the sampling point will be (S+1)/2 for an odd sampling rate (S) and S/2 for an even sampling rate. 1: Validates the setting of the SRHP[3:0] bits.
13, 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
11 to 8	SRHP[3:0]	0000	R/W	Sampling Point Register (SRHP) The sampling point can be moved by setting the SDRE bit to 1 and setting a value in these bits. Normally, the sampling point is the point of S/2 or (S+1)/2 for a sampling rate of S. By setting a signed 4-bit integer in these bits, the sampling point can be shifted by the amount of the specified sampling clock cycles. This will improve the receive margin. When setting a value in these bits, take notice that the sampling point does not become a negative value or it does not exceed the sampling rate. The shifted sampling point must satisfy the setup margin and hold margin.
7 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4 to 0	SRCYC[4:0]	01111	R/W	Bits 4 to 0: Sampling Rate Register (SRCYC) Data transfer at a desired sampling rate can be enabled by setting the SRE bit to 1 and setting a value in these bits. Set a value of "S – 1" in these bits for a sampling rate of S. Note that the sampling rate must be from 8 to 32 (a value from 7 to 31 can be set in these bits). Set these bits to 15 (initial value) when the SRE bit is set to 0.

36.2.14 Serial Error Register (HSRER)



Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
14 to 8	PER[6:0]	H'00	R	Parity Error Count These bits indicate the number of data items in which a parity error occurred in the receive data stored in the receive FIFO data register (HSFRDR). After the ER bit in HSFSR is set, the value in bits 14 to 8 will be the number of data items in which a parity error occurred. If all 128 bytes of receive data in HSFRDR have parity errors, bits PER[6:0] will have the value 0.
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6 to 0	FER[6:0]	H'00	R	Framing Error Count These bits indicate the number of data items in which a framing error occurred in the receive data stored in the receive FIFO data register (HSFRDR). After the ER bit in HSFSR is set, the value in bits 6 to 0 will be the number of data items in which a framing error occurred. If all 128 bytes of receive data in HSFRDR have framing errors, bits FER[6:0] will have the value 0.

36.2.15 RTS Output Active Trigger Register (HSRTGR)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	RSTRG[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

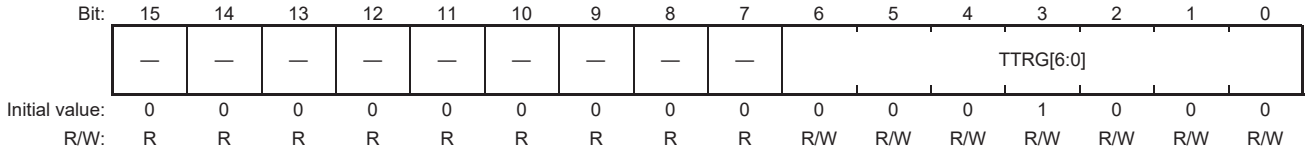
Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	RSTRG[6:0]	H'0F	R/W	RTS Output Active Trigger Count The HRTS# signal goes high when the number of receive data items stored in the receive FIFO data register (HSFRDR) exceeds the value set in these bits. The initial value is 15.

36.2.16 Receive FIFO Data Count Trigger Register (HSRTRGR)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	RTRG[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	RTRG[6:0]	H'01	R/W	Receive FIFO Data Count Trigger These bits set the receive data item count at which the receive data full (RDF) flag in the serial status register (HSFSR) is set. The RDF flag is set when the number of receive data items stored in the receive FIFO data register (HSFRDR) equals or exceeds the value set in these bits. The initial value is 1.

36.2.17 Transmit FIFO Data Count Trigger Register (HSTTRGR)



Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	TTRG[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	TTRG[6:0]	H'08	R/W	Transmit FIFO Data Count Trigger These bits set the untransmitted data item count at which the transmit FIFO data register empty (TDFE) flag in the serial status register (HSFSR) is set. The TDFE flag is set when the number of transmit data items in the transmit FIFO data register (HSFTDR) falls under the value set in these bits due to transmit operations. The initial value is 8.

36.3 Operation

36.3.1 Operation in Asynchronous Serial Communication Mode

In asynchronous serial communication mode, the HSCIF performs serial communication, in which data is transmitted/received in character units using the attached start bit indicating the start of communication and stop bit indicating the end of communication.

Figure 36.2 shows the general format for asynchronous serial communication.

In asynchronous serial communication, the transmission line is usually kept marked (high level). The HSCIF monitors the transmission line, and when it finds a space (low level), it regards the space as a start bit and starts serial communication.

One character in serial communication consists of a start bit (low level), followed by transmit/receive data (LSB-first; from the lowest bit), a parity bit (high or low level), and a stop bit (high level).

During reception in asynchronous mode, the HSCIF performs synchronization at the falling edge of the start bit. Transferred data is acquired at the center of each bit because the HSCIF samples on *S/2*th cycles of the clock which has a frequency of S times the bit rate, when the sampling rate as set in the sampling rate register (HSSRR) is S (if the sampling-rate setting is an odd number, the data is sampled on every *(S+1)/2*th pulse).

In addition, when the setting of the SRDE bit makes the setting of the sampling point bits effective, the point where the bits are latched can be intentionally moved from the centers of each bit.

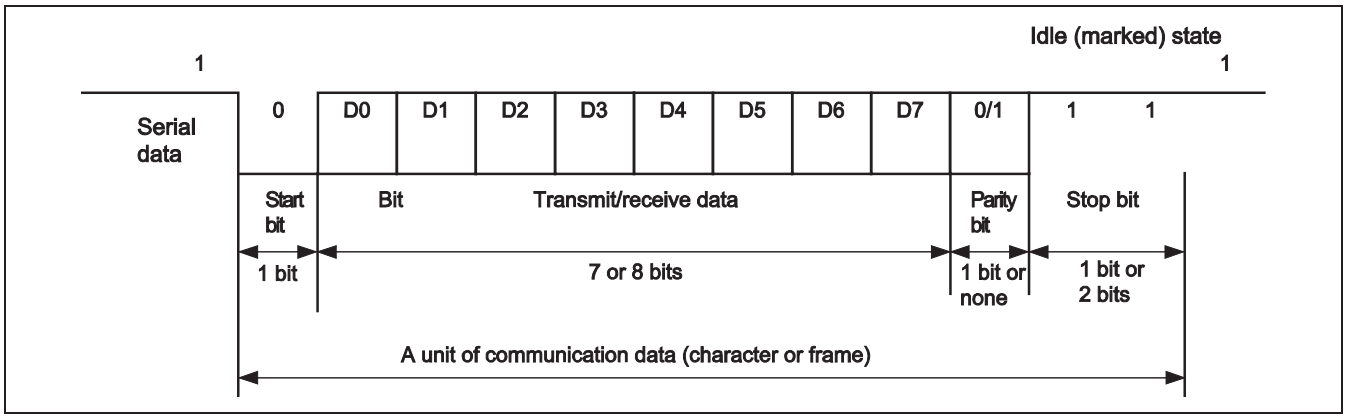


Figure 36.2 Data Format in Asynchronous Mode (Example of 8-Bit Data with Parity and Two Stop Bits)

(1) Transmission/reception format

Table 36.5 shows available data transfer formats. The HSCIF supports 8 transfer formats, which can be specified by HSSMR.

Table 36.5 Serial Transmission/Reception Formats (Asynchronous Mode)

SCSMR settings			Serial transmission/reception format and frame length											
CHR	PE	STOP	1	2	3	4	5	6	7	8	9	10	11	12
0	0	0	S	8-bit data								STOP		
0	0	1	S	8-bit data								STOP	STOP	
0	1	0	S	8-bit data								P	STOP	
0	1	1	S	8-bit data								P	STOP	STOP
1	0	0	S	7-bit data							STOP			
1	0	1	S	7-bit data							STOP	STOP		
1	1	0	S	7-bit data							P	STOP		
1	1	1	S	7-bit data							P	STOP	STOP	

[Legend]
S : Start bit
STOP : Stop bit
P : Parity bit

(2) Clock

The transfer clock can be selected from the following two clocks using the CKE[1:0] bits in HSSCR:

- Internal clock generated by the on-chip baud rate generator
- External clock generated by an external clock baud rate generator

(3) Data transmission/reception

(a) Initialization of HSCIF (asynchronous mode)

Before transmitting/receiving data or changing the operating mode or communication format, the HSCIF should be initialized using the sample flowchart for HSCIF initialization shown in Figure 36.3.

[Notes]

Clearing the TE bit to 0 initializes HSTSR. However, HSFSR, HSFTDR, and HSFRDR contents are retained even if the TE and RE bits are cleared to 0.

The TE bit should be cleared to 0 after all transmit data has been sent and the TEND flag has been set in HSFSR. The TE bit can be cleared to 0 during transmission, but the data being transmitted will enter the marked state after clearing.
In addition, before setting the TE bit to 1 to restart the transmission, set the TFRST bit to 1 in HSFCR to reset HSFTDR.

When an external clock is used, do not stop the clock during operation or initialization. If stopped, the operation will be unreliable. Furthermore, when the baud rate generator for external clock is also to be used, be sure to make settings for it before starting initialization of the HSCIF.

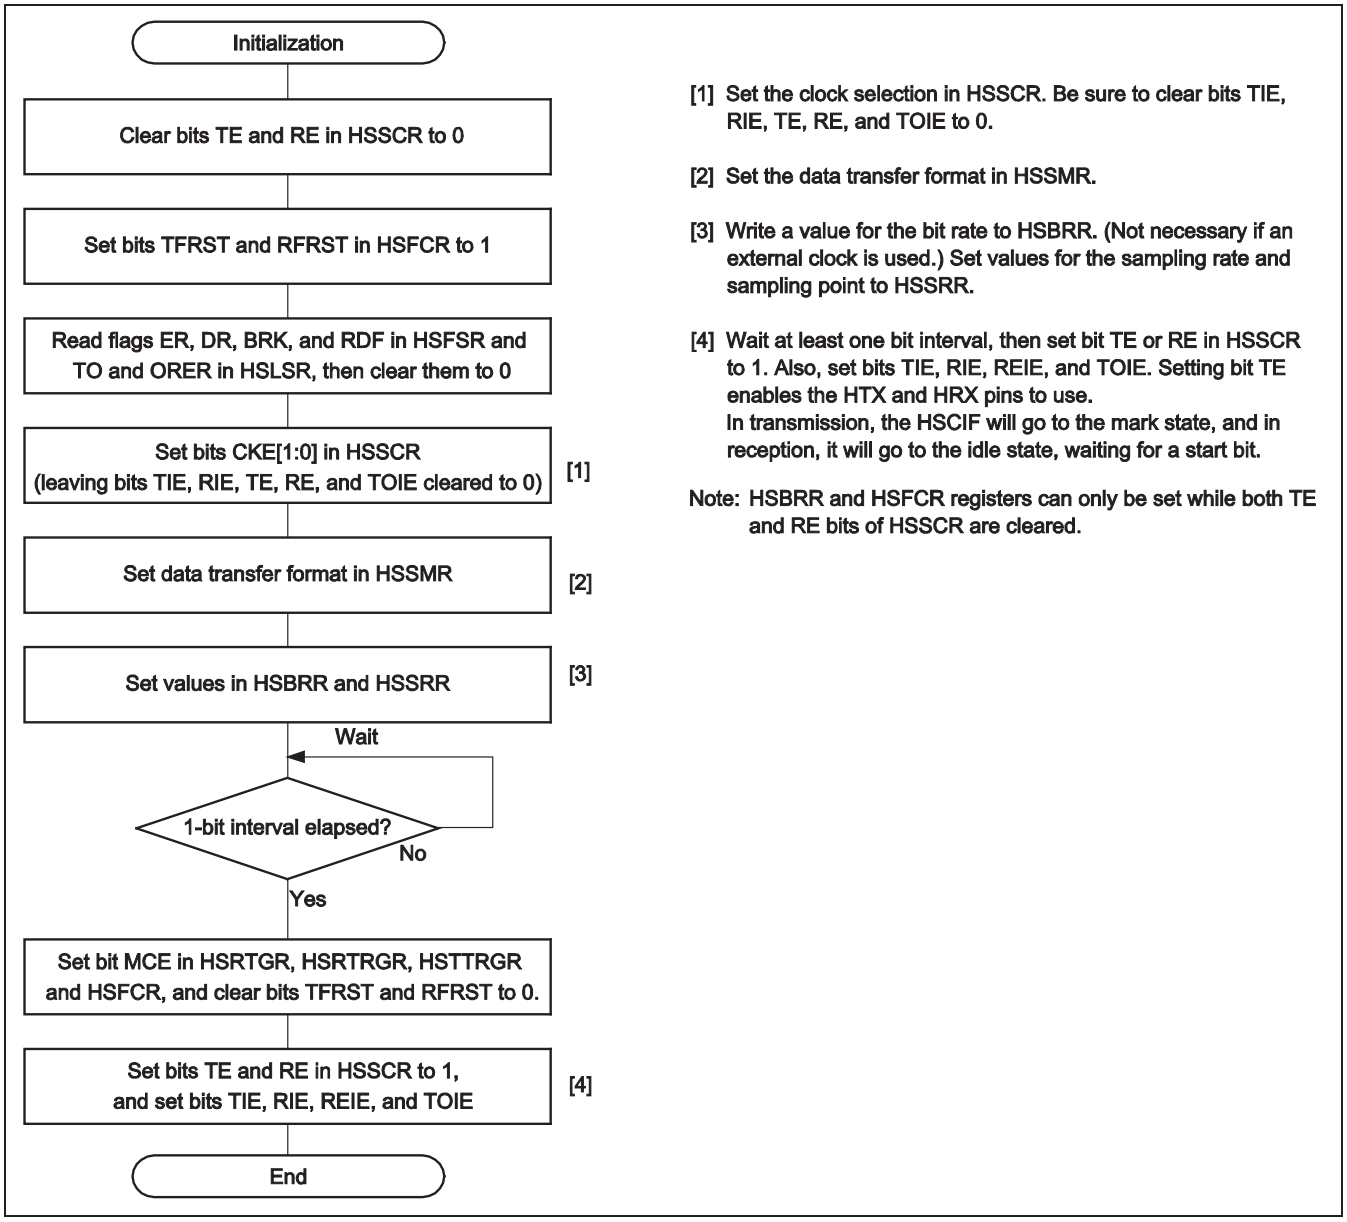

Figure 36.3 Sample Flowchart for Initializing the HSCIF

(b) Serial data transmission (asynchronous mode)

Figure 36.4 shows a sample flowchart for serial transmission.

After the HSCIF transmission operation is enabled, serial data transmission can be performed using the following procedure:

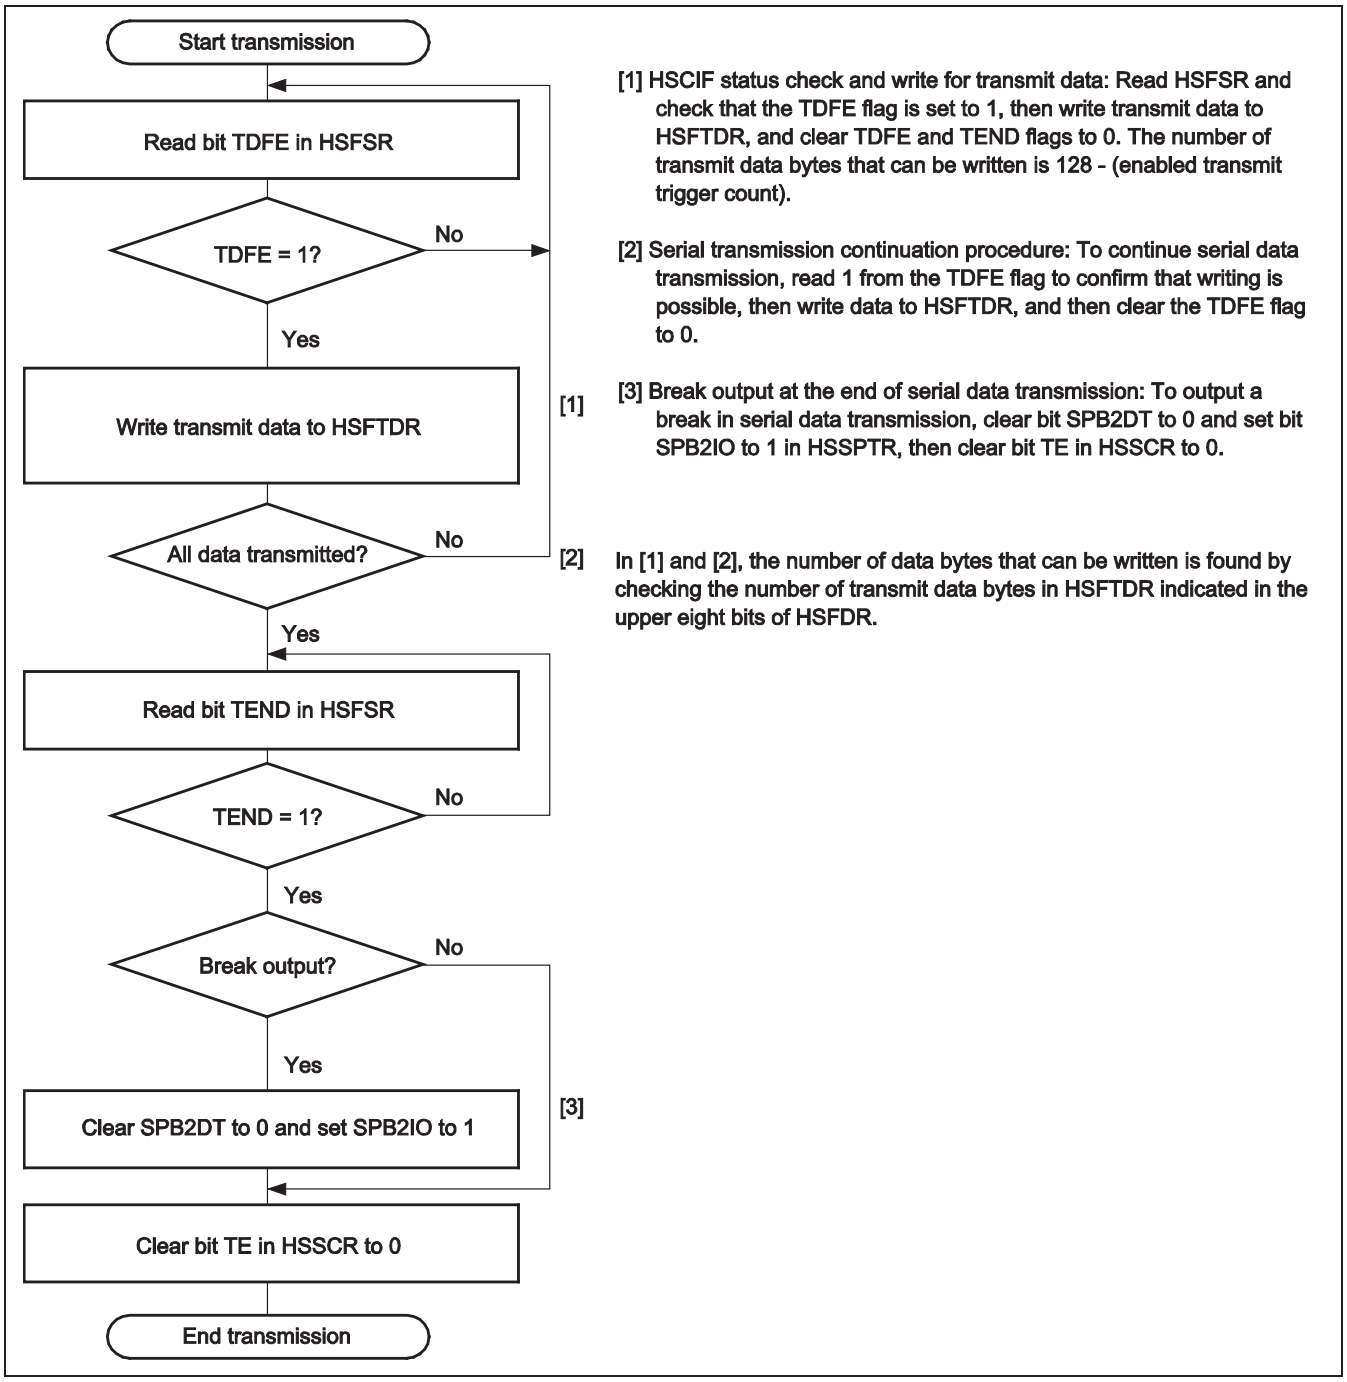

Figure 36.4 Sample Flowchart for Serial Transmission

In serial transmission, the HSCIF operates as follows:

1. When data is written to HSFTDR, the HSCIF transfers the data from HSFTDR to HSTSR and starts transmitting. Confirm that the TDFE flag in HSFSR is set to 1 before writing transmit data to HSFTDR. The number of data bytes that can be written is at least 128 – (transmit trigger count).
2. When data is transferred from HSFTDR to HSTSR and the HSCIF starts transmission, consecutive transmission is performed until there is no transmit data left in HSFTDR. When the number of transmit data bytes in HSFTDR is equal to or less than the transmit trigger count specified in HSTTRGR, the TDFE flag is set. If the TIE and TEIE bits in HSSCR are set to 1 and 0, respectively at this time, a transmit-FIFO-data-empty interrupt (TDFE) request occurs. The serial transmit data is sent from the HTX pin in the following order:
   A. Start bit: One 0-bit is output.
   B. Transmit data: 8- or 7-bit data is output in LSB-first order.
   C. Parity bit: One parity bit (even or odd parity) is output.
      A format that does not output a parity bit can also be selected.
   D. Stop bit(s): One or two 1-bit (stop bits) are output.
   E. Marked state: 1 is output continuously until the start bit that starts the next transmission is sent.
3. The HSCIF checks transmit data in HSFTDR when sending the stop bit. If there is data in it, the HSCIF transfers the data from HSFTDR to HSTSR, sends the stop bit, and then starts serial transmission of the next frame. If there is no transmit data, the HSCIF sets the TEND flag to 1 in HSFSR and sends out the stop bit, and then the marked state is entered to output 1 continuously. At this time, if the TIE and TEIE bits in HSSCR are set to 1, a transmit-end interrupt (TEND) request occurs.

Figure 36.5 shows an example of transmission in asynchronous mode.

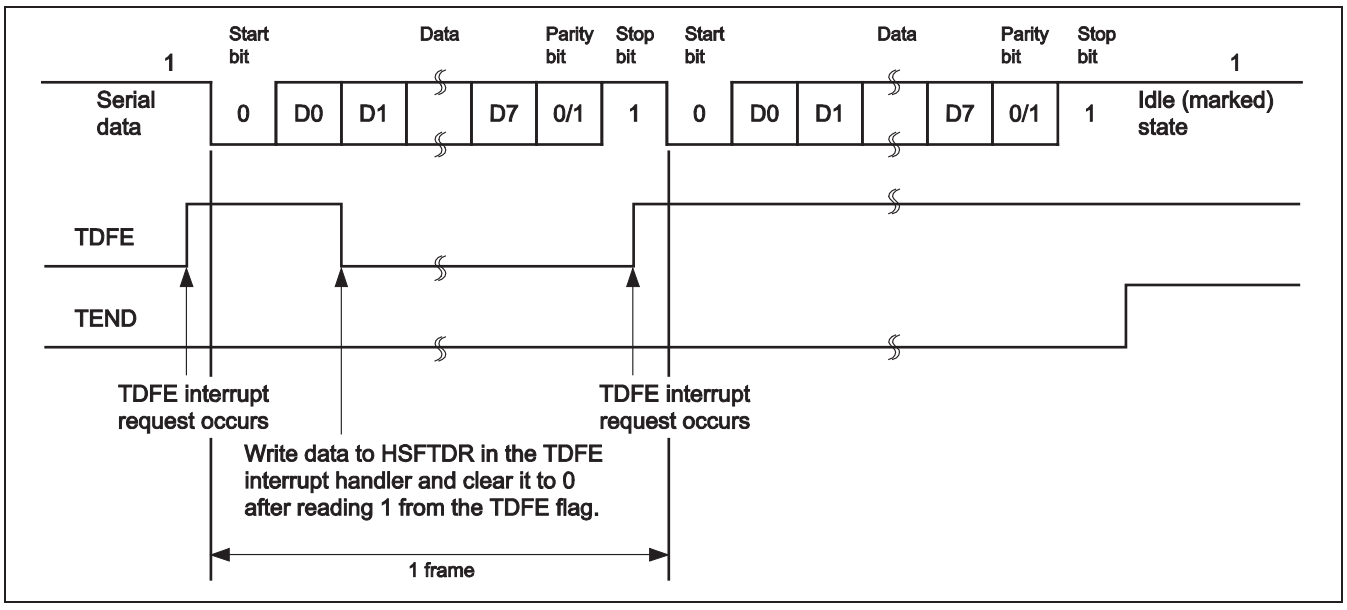

Figure 36.5 Sample HSCIF Transmission Operation (Example of 8-Bit Data with Parity and One Stop Bit)

4. When modem control is enabled, transmission can be stopped or resumed in accordance with the HCTS# input value. When HCTS# is set to 1 during transmission, the marked state is entered after one frame of data transmission is ended. Setting HCTS# to 0 restarts outputting the next transmit data from the start bit. Figure 36.6 shows an example of the operation with modem control enabled.

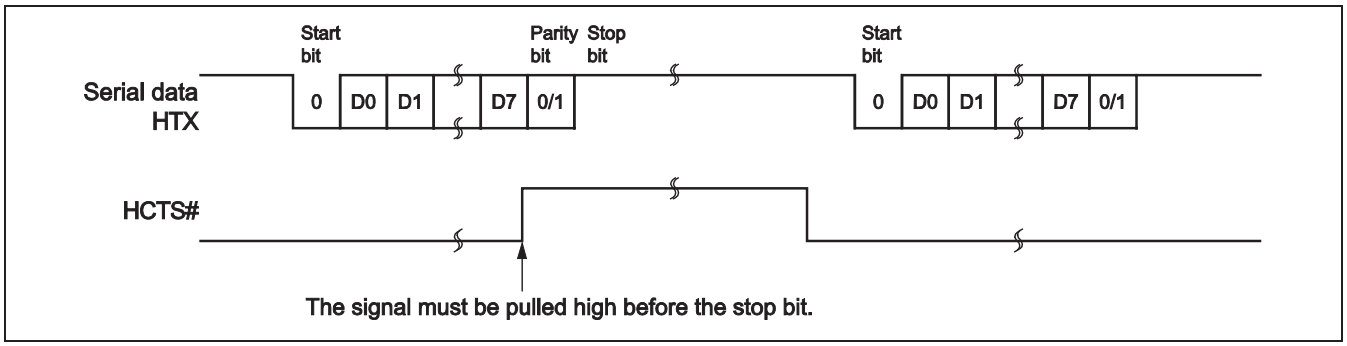

Figure 36.6 Sample Operation with Modem Control Enabled (HCTS#)

(c) Serial data reception (asynchronous mode)

Figures 36.7 and 36.8 show sample flowcharts for serial reception.

After the HSCIF reception operation is enabled, serial data reception can be performed using the following procedure:

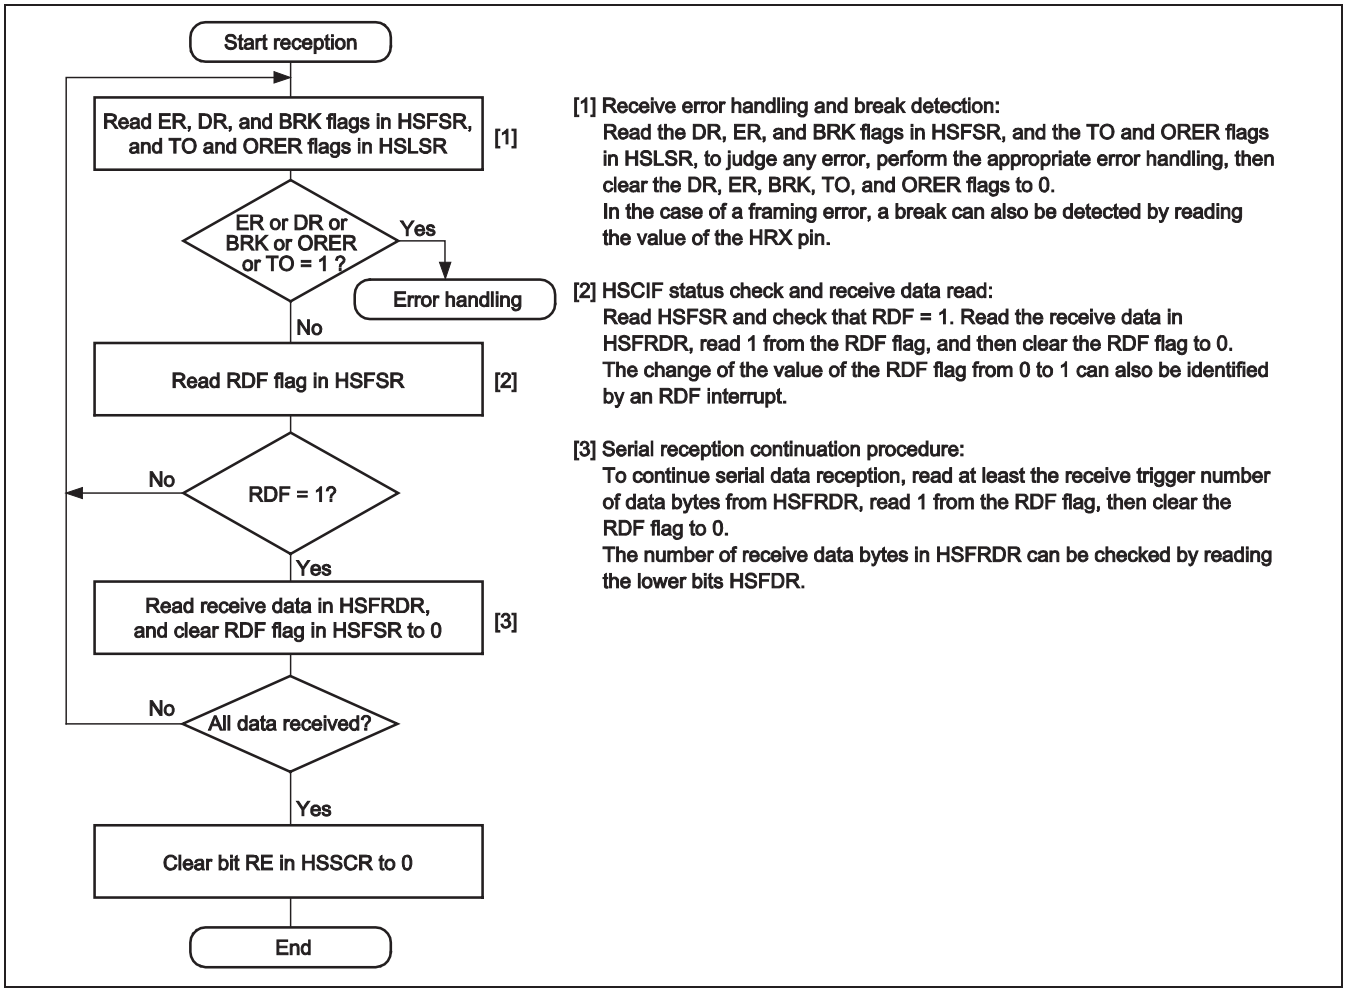

Figure 36.7 Sample Flowchart for Serial Reception (1)

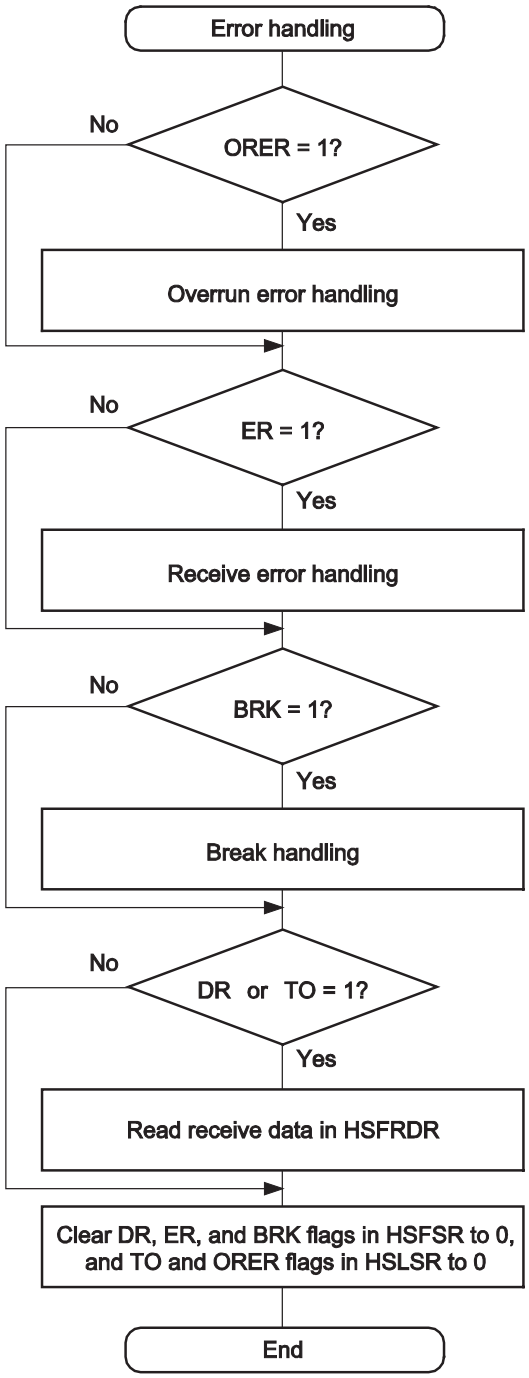

Whether a framing error or parity error has occurred in the receive data that is to be read from HSFRDR can be determined by checking bits FER and PER in HSRER.

Figure 36.8 Sample Flowchart for Serial Reception (2)

In serial reception, the HSCIF operates as follows:

1. The HSCIF monitors the transmission line, and when detecting the start bit 0, it performs internal synchronization and starts reception.
2. The HSCIF stores the received data in HSRSR in LSB-to-MSB order.
3. The HSCIF receives the parity bit and stop bit.
   After receiving these bits, the HSCIF performs the following checks:
   A. Stop bit: The HSCIF checks whether the stop bit is 1.
      If there are two stop bits, it checks only the first stop bit.
   B. Receive data: The HSCIF checks that receive data can be transferred from the receive shift register (HSRSR) to HSFRDR.
   C. Overrun error: The HSCIF checks that the ORER flag is 0, indicating that no overrun error has occurred.
   D. Break state: The HSCIF checks that the BRK flag is 0, indicating that the break state is not set.
   If the HSCIF can confirm the conditions of (b), (c), and (d), it stores the receive data in HSFRDR.

Note: The HSCIF continues to receive data even when a parity error or a framing error occurs.

4. If the RDF flag changes to 1 while the RIE bit in HSSCR is 1, a receive-FIFO-data-full interrupt (RDF) request occurs.
   If the DR flag changes to 1 while the RIE bit in HSSCR is 1, a receive-data-ready interrupt (DR) request occurs.
   If the TO flag changes to 1 while the TOIE bit in HSSCR is 1, a timeout interrupt (TO) request occurs.
   If the ER flag changes to 1 while the RIE or REIE bit in HSSCR is 1, a receive-error interrupt (ER) request occurs.
   If the BRK flag changes to 1 while the RIE or REIE bit in HSSCR is 1, a break interrupt (BRK) request occurs.
   If the ORER flag changes to 1 while the RIE or REIE bit in HSSCR is 1, an overrun-error interrupt (ORER) request occurs.

Figure 36.9 shows an example of reception in asynchronous mode.

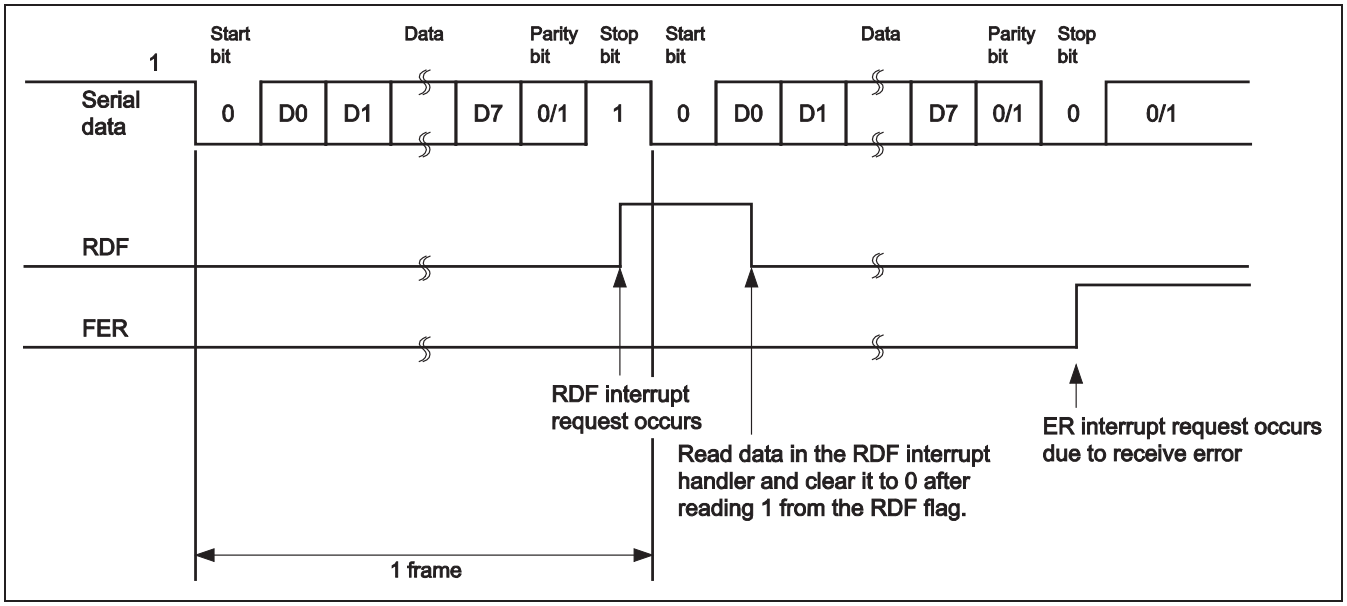

Figure 36.9 Sample HSCIF Receive Operation (Example of 8-Bit Data with Parity and One Stop Bit)

5. When modem control is enabled, the HRTS# signal is output when HSFRDR is empty. When HRTS# is 0, data can be received. When HRTS# is set to 1, the number of data bytes in HSFRDR is equal to or more than the RTS output active trigger count.

Figure 36.10 shows an example of the operation with modem control enabled.

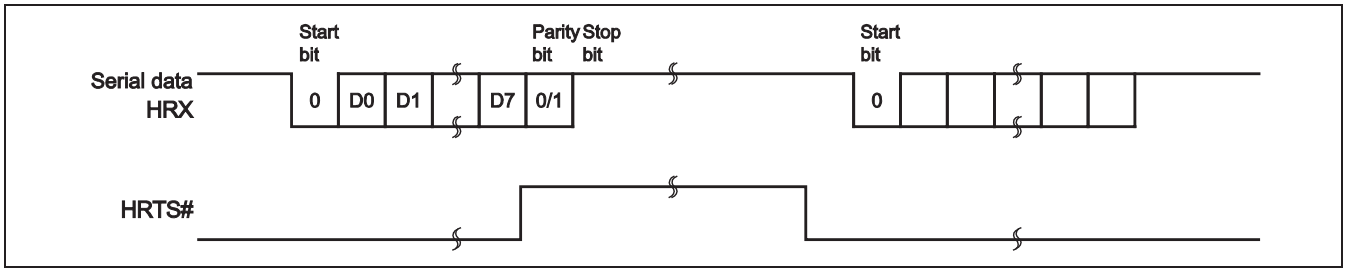

Figure 36.10 Example of the Operation with Modem Control Enabled (HRTS#)

36.3.2 HSCIF Interrupt Sources and the DMAC

If the DMAC is used for transmission/reception, set and enable the DMAC before setting the HSCIF.

Transmission interrupts and DMA transfer:
If the TDFE/TEND flag in HSFSR is set to 1 when the TDFE/TEND interrupt is enabled by the TIE bit, a TDFE/TEND interrupt request and a transmit-FIFO-data-empty DMA transfer request will occur. If the TDFE/TEND flag is set to 1 when TDFE/TEND interrupt is disabled by the TIE bit, only the transmit-FIFO-data-empty DMA transfer request will occur. (A transmit-FIFO-data-empty DMA transfer request is generated when the TDFE flag is set while TEIE is 0, or when the TEND flag is set while TEIE is 1. DMA transfer requests are not affected by the TEIE bit.)

When TDFE/TEND interrupt requests are enabled, the interrupt requests are cleared by the DMAC regardless of the interrupt handling program.

Reception interrupts and DMA transfer:
If the RDF/DR flag in HSFSR is set to 1 when RDF/DR interrupt is enabled by the RIE bit, an RDF/DR interrupt request occurs. If the RDF/DR flag is set to 1, a receive-FIFO-data-full DMA transfer request occurs. If the RDF/DR flag is set to 1 when RDF/DR interrupt is disabled by the RIE bit, and only a receive-FIFO-data-full DMA transfer request occurs and DMAC can be activated to perform data transfer.

Setting the RIE bit in HSSCR to 0 and the REIE it to 1 generates the ER/BRK/ORER interrupt requests without generating RDF/DR interrupt requests. When the BRK flag in HSFSR or the ORER flag in HSLSR is set to 1, BRK/ORER interrupt requests occur.

If the TO flag is set to 1 in HSLSR when TO interrupts are enabled by the TOIE bit, TO interrupt requests occur.

When DR/TO interrupt requests are enabled to be issued, interrupt requests generated by the DR flag are cleared by the DMAC regardless of the interrupt handling program, however, those generated by the TO flag are not cleared by the DMAC. Therefore, the TO flag interrupt requests need to be cleared with the interrupt handling program. (The DR and TO flags are set at the same time, but cleared separately.)

Table 36.6 HSCIF Interrupt Sources

Interrupt Source	DMAC Activation
Interrupts generated by receive error flag (ER)	Disabled
Interrupts generated by receive-FIFO-data-full (RDF), receive-data-ready (DR) or timeout (TO)	Enabled
Interrupts generated by break (BRK) or overrun error (ORER)	Disabled
Interrupts generated by transmit FIFO data empty (TDFE)	Enabled

36.4 Usage Notes

Note the following on use of the HSCIF.

(1) Break detection and operation

Break signals can also be detected by reading the HRX pin value directly when a framing error (FER) is detected. In the break state, the input values from the HRX pin are all 0s. So, the parity error flag (PER) may be set after the FER flag is set to 1.

Although the HSCIF stops receive data transfer to HSFRDR after detecting a break, it continues data reception.

(2) Sending a break signal

The input/output condition and level of the HTX pin are determined by the SPB2IO and SPB2DT bits in HSSPTR. This enables to send a break signal.

The pin does not function as the HTX pin from the initialization of the serial transmitter to setting of the TE bit (enabling transmission). In this period, the marked state is substituted by the value of the SPB2DT bit. Therefore, the SPB2IO and SPB2DT bits should be set to 1 (designating output and high level) beforehand.

To send a break signal during serial transmission, clear the SPB2DT bit to 0 (low level), and then clear the TE bit to 0 (halting transmission). When the TE bit is cleared, the transmitter is initialized regardless of the current transmission state, and the HTX pin outputs 0.

(3) Data sampling timing and reception margin in asynchronous mode

The HSCIF operates on the base clock with a frequency multiplied by the number which is set as a sampling rate for the bit rate.

In reception, the HSCIF performs the internal synchronization by sampling the falling edge of the start bit using the base clock. In addition, the HSCIF takes receive data at the rising edge of the S/2 pulse (when S is an even number) or (S+1)/2 pulse (when S is an odd number) on the base clock when sampling rate is S.

Figure 36.11 shows the timing of this operation when S = 16.

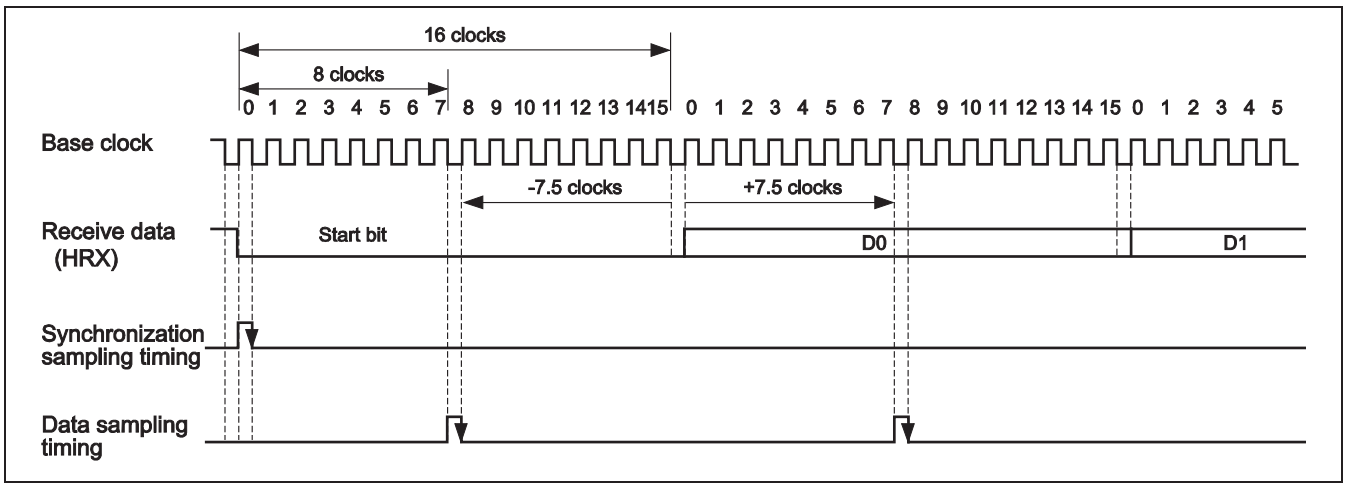

Figure 36.11 Timing Chart of Receive Data Sampling

The reception margin in asynchronous mode is given by expression (1).

$$M = \left| (0.5 - \frac{1}{2N}) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100\% \quad \text{Expression (1)}$$

M: Receive margin (%)

N: Ratio of bit rate to clock (N = sampling rate)

D: Clock duty (D = 0 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute value of clock frequency deviation

Assuming F = 0, D = 0.5 and sampling rate = 16 for expression (1), the reception margin obtained with expression (2) is 46.875% as shown below:

Assuming D = 0.5 and F = 0

M = (0.5 – 1/(2 × 16)) × 100%

= 46.875% ……expression (2)

This is a theoretical value. A reasonable margin allowed in system designs is 20% to 30%.

(4) Reception margin and baud rate error

The value of 46.875% obtained by the above expression (2) indicates the reception margin when the baud rate error is 0 (F = 0). If there is no error in the reception and transmission baud rates, reception is possible even with misalignment of approx. 1/2 bit. If there is an error in the reception and transmission baud rates, the errors are accumulated up to the stop bit reception, which reduces the reception margin. The allowable baud rate error can be obtained by modifying the F in expression (1). When D = 0.5:

F = {(15/32 – M)/(L – 0.5)} × 100 (%)……expression (3)

By using expression (3), the relationship between the allowable error and reception margin with the frame length = 12 can be summarized as follows:

Allowed Error (%)	Reception Margin (%)
4.07	0
3.64	5
3.20	10
2.33	20
1.46	30

(5) Usage method of SRHP bits

The method for using the SRHP bits in the sampling rate register is described below.

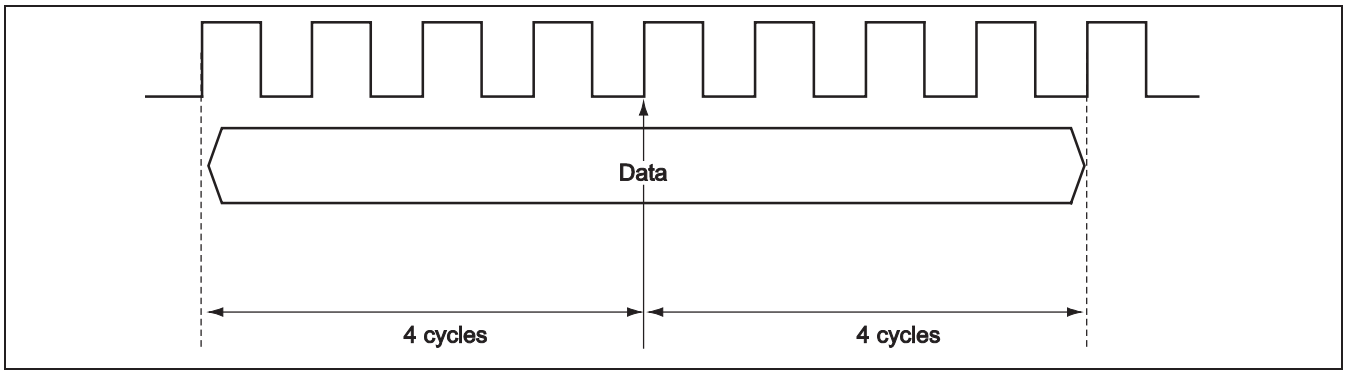

Figure 36.12 Sampling with Invalid SRHP Bits

Figure 36.12 shows a sampling example in which the SRHP bits are invalid (sampling rate = 8). In this case, the HSCIF samples data at half of the sampling rate, which is at the rising edge of the fourth pulse of the clock. This allows a setup margin and hold margin of 50% each to be provided.

However, if the ratio between the baud rate and sampling clock is not 1:1, either the setup margin or hold margin is omitted in data reception of a single frame. If the setup margin is omitted, the hold margin increases. On the other hand, if the hold margin is omitted, the setup margin increases. Figures 36.13 and 36.14 show examples.

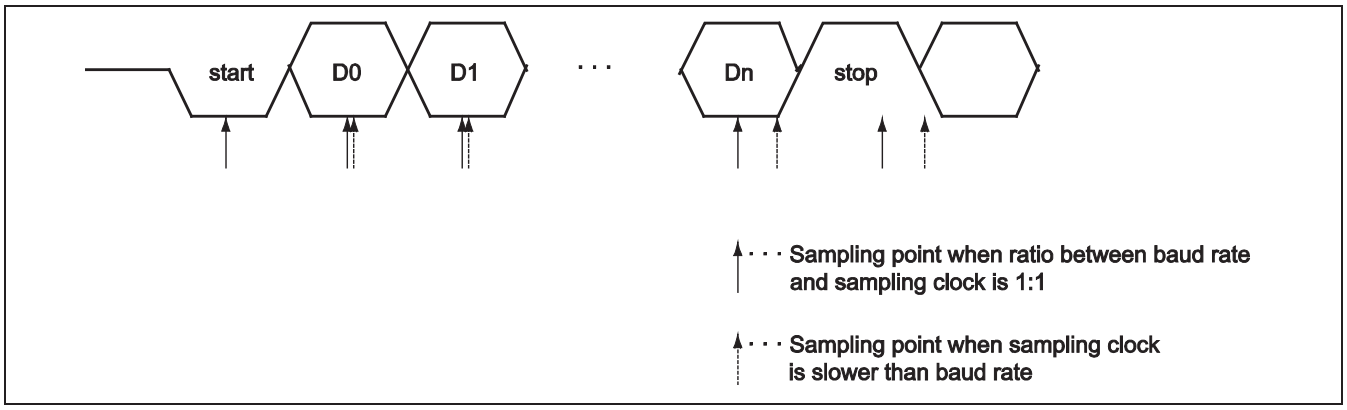

Figure 36.13 Sampling Point with Sampling Clock Slower Than Baud Rate

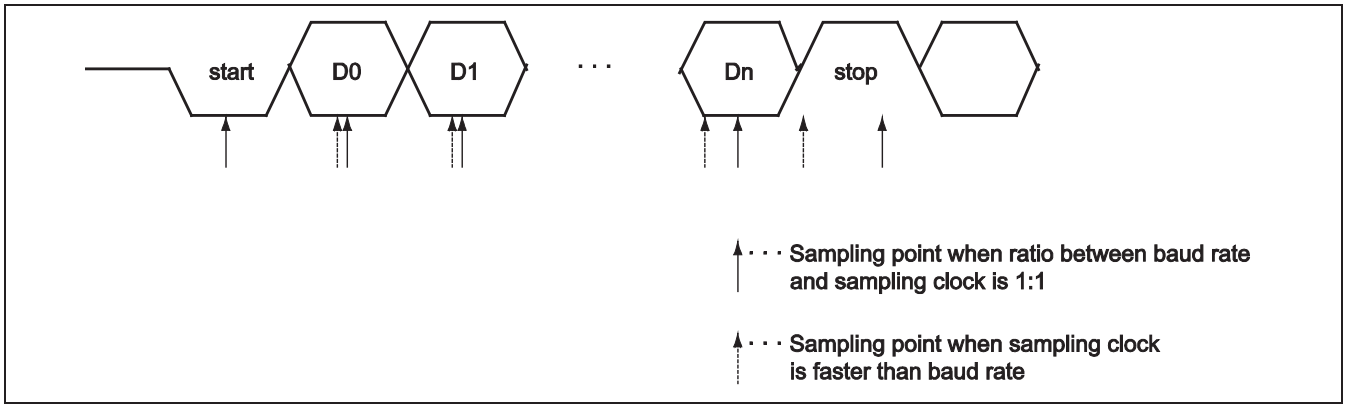

Figure 36.14 Sampling Point with Sampling Clock Faster Than Baud Rate

The ratio between the baud rate and sampling clock can be used to determine which margin among the setup margin and hold margin is to be omitted and which is to be increased. Based on this, the margin within a single frame can be increased by intentionally increasing the margin to be omitted in advance. The sampling point can be moved by setting a value in the SRHP bits. Figure 36.15 shows an example.

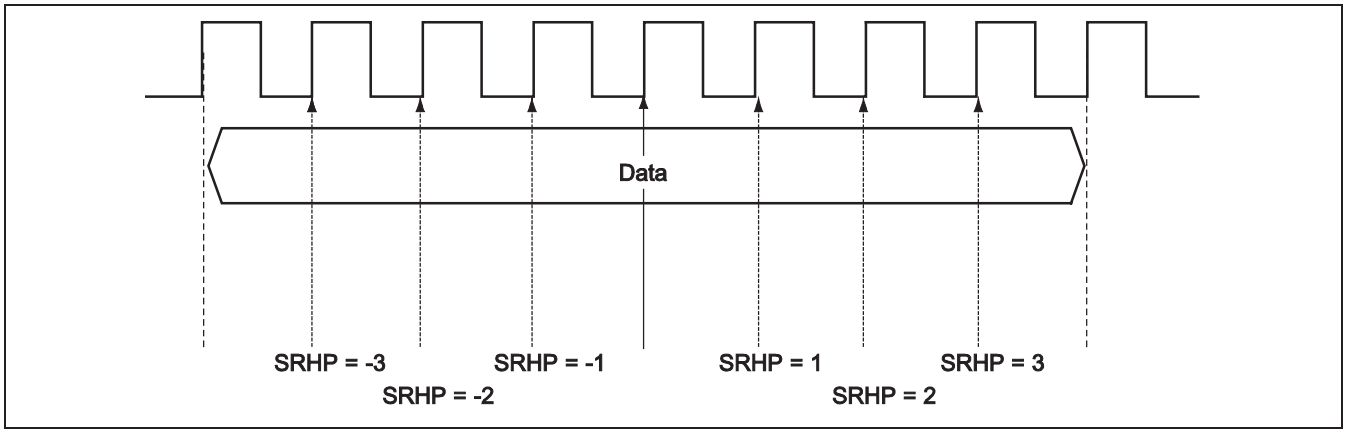

Figure 36.15 Sampling Point Moved by SRHP Bits

(6) Sampling rate and bit rate settings and respective margin

To set the baud rate in the HSCIF, in addition to setting the clock division ratio, the two registers, bit rate register (HSBRR) and sampling rate register (HSSRR), need to be set. These registers must be set so that the margin calculated by expression (1) in section 36.4 (3) will be a sufficient value.

The bit rate error is small when the value obtained by dividing the divided clock frequency used in the HSCIF with the sampling rate is near the desired baud rate. If there are many combinations of bit rate and sampling rate with the same bit rate error, choosing a combination with a large sampling rate provides a large margin. This is because when the bit rate error is constant in expression (1) in section 36.4 (3), that is, when the "absolute value of clock frequency deviation (F)" is constant, the margin (M) increases in accordance with the sampling rate (N).

If the sampling rate is made larger in a combination of bit rate and sampling rate with different bit rate errors, the bit rate error is increased. Accordingly, the "absolute value of clock frequency deviation (F)" on the right side in expression (1) in section 36.4 (3) gets larger and the margin (M) smaller.

Refer to the following procedure when selecting the sampling rate and bit rate settings.

1. Obtain the bit rate with the smallest bit rate error for sampling rates from 8 to 32.
2. Using expression (1) in section 36.4 (3), calculate the margin for each combination of sampling rate and bit rate which was obtained in step 1.
3. Select the combination with the largest margin among the combinations of sampling rate and bit rate.

36.5 Baud Rate Generator for External Clock (BRG)

36.5.1 Overview

The HSCIF incorporates a baud rate generator for external clock (abbreviated as BRG, hereafter). The BRG supplies a sampling clock (BRGCLK) to the HSCIF core by dividing the external clock SC_CLK (selectable between SCIF_CLK and ZSϕ) by 1 to $2^{16} - 1$. In addition, the BRG switches the output between the external clock HSCK and divided clock.

36.5.2 Block Descriptions

Figure 36.16 shows a block diagram of the BRG.

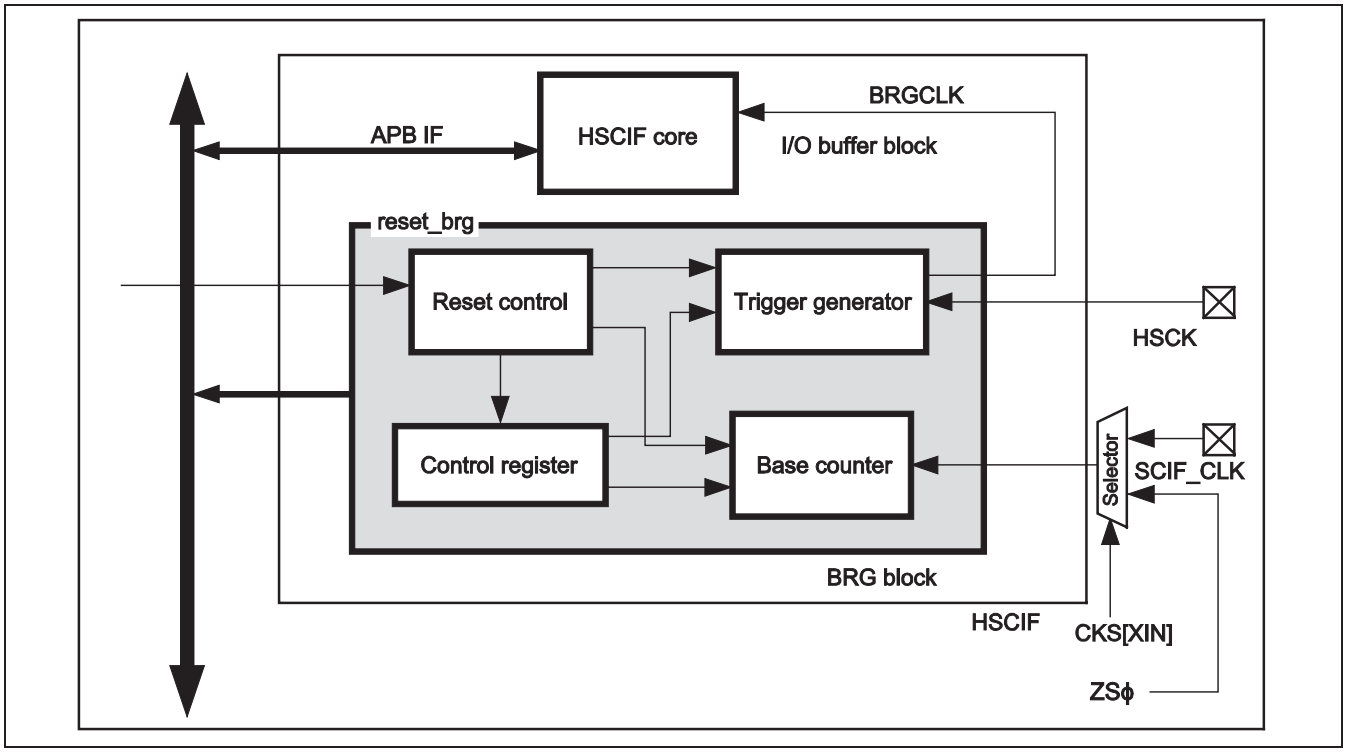

Figure 36.16 BRG Block Diagram

(1) Reset controller:

The reset controller handles resetting the control register, base counter, and trigger generator.

(2) Control register:

The control register has the frequency division register and clock select register.

(3) Base counter:

The base counter is a 16-bit CLK synchronization counter that is used to determine the timing for generating a frequency divided clock.

(4) Trigger generator:

The trigger generator generates rising-edge/falling-edge triggers for a frequency divided clock with the timing according to values of the frequency division register and base counter. The triggers are used to generate the frequency divided clock. In addition, the trigger generator switches the output between the HSCK (external clock input) and frequency divided clock.

36.5.3 BRG Register Configuration

Table 36.7 shows the registers in the BRG block.

Table 36.7 List of Registers

Ch. No.	Name	Code	R/W	Initial Value	Address	Access Size
0	Frequency division register 0	DL	R/W	H'00	H'E62C 0030	16
	Clock select register 0	CKS	R/W	H'00	H'E62C 0034	16
1	Frequency division register 1	DL	R/W	H'00	H'E62C 8030	16
	Clock select register 1	CKS	R/W	H'00	H'E62C 8034	16
2	Frequency division register 2	DL	R/W	H'00	H'E62D 0030	16
	Clock select register 2	CKS	R/W	H'00	H'E62D 0034	16

36.5.3.1 Frequency Division Register (DL)

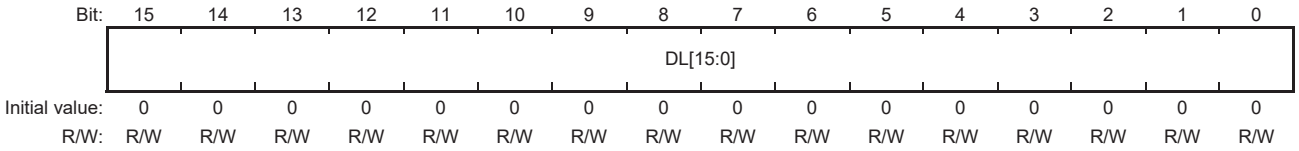
This register specifies the value of frequency division for the frequency divided clock generated by the BRG.

This register supports a 16-bit binary format that allows specifying a value in the range of 1 to 65535.

Setting all 0s in this register makes the BRG output the frequency divided clock at the low level.

The value of frequency division is given by the following formula:

The value of frequency division = (clock input frequency)/(required baud rate × sampling rate)



Bit	Bit Name	Initial Value	R/W	Description
15 to 0	DL[15:0]	All 0	R/W	Specifies a division value of frequency clock generated in BRG. The setting value is enabled in the range of 1 to 65535.

Table 36.8 and Table 36.9 show how to use the baud rate generator with a 3.6864-MHz crystal resonator, and a 26-MHz crystal resonator.

Table 36.8 Baud Rate (3.6864-MHz clock)

Baud Rate	Value of Frequency Division	Sampling Rate	Error Rate*
50	4608	16	—
75	3072	16	—
110	4189	8	-0.002
134.5	1713	16	0.001
150	1536	16	—
300	768	16	—
600	384	16	—
1200	192	16	—
1800	128	16	—
2000	123	15	0.098
2400	96	16	—
3600	64	16	—
4800	48	16	—
7200	32	16	—
9600	24	16	—
14400	16	16	—
19200	12	16	—
38400	6	16	—
76800	3	16	—
115200	2	16	—

Note: * "—" Indicates that the error rate is 0.

Table 36.9 Baud Rate (26-MHz clock)

Baud Rate	Value of Frequency Division	Sampling Rate	Error Rate*
9600	129	21	0.025
19200	52	26	-0.160
38400	26	26	-0.160
57600	15	30	-0.309
115200	9	25	-0.309
230400	4	28	-0.756
460800	2	28	-0.756
921600	1	28	-0.756
1843200	1	14	-0.756
3250000	1	8	—

Note: * "—" Indicates that the error rate is 0.

36.5.3.2 Clock Select Register (CKS)

This register switches the output between the frequency divided clock and specifies a source clock for the external baud rate.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CKS	XIN	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	CKS	0	R/W	This bit switches the output between the frequency divided clock (SC_CLK) and external clock (HSCK). 0: Selects the frequency divided clock. 1: Selects the external clock.
14	XIN	0	R/W	Selects the baud rate generator clock source for the external clock between SCIF_CLK and ZSϕ. 0: Selects the external clock (SCIF_CLK). 1: Selects the internal clock (ZSϕ).
13 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

36.5.4 Restrictions in BRG

(1) Notes on setting frequency division register

1. For the initial setting of the register after a reset, at least one bit of waiting period is required to secure the clock stabilization time.
   (Example) One bit period when DL = 2
   3.68 (MHz) × 1/2 × 1/16 = 0.115 (MHz) → 8695 (ns)

2. For modifying the register value after the setting stated in <1> above, at least one bit of waiting period at the maximum bit rate (DL = '65535') is required.
   The HSCIF registers and BRG registers should be set as the following table:

- Asynchronous mode (SC_CLK external input)

HSCIF		BRG	
Register Name	**Setting Value**	**Register Name**	**Setting Value**
HSSCR.CKE[1:0]	B'10	CKS	H'0000
		DL	H'1 to H'FFFF

- Asynchronous mode (HSCK external input)

HSCIF		BRG	
Register Name	**Setting Value**	**Register Name**	**Setting Value**
HSSCR.CKE[1:0]	B'10	CKS	H'8000
		DL	Don't care

3. The register settings for the baud rate generator for external clock should be made before starting initialization of the HSCIF.

37. I2C Bus Interface (I2C)

37.1 Overview

37.1.1 Features

Five I2C bus interfaces conformant with the Philips Semiconductors (now NXP Semiconductors) I2C bus (Inter-IC bus) specification. However, the configuration of registers that control the I2C bus differs partly from the NXP Semiconductors register configuration. The I2C bus interface has the following features. Note that "module clock (MOD_CLK)" refers to the peripheral module clock (HPϕ) in this section.

- The I2C interfaces support the I2C bus specification from NXP Semiconductors
- Multi-master compatible
- Seven- or ten-bit address compatible master
- Seven-bit slave address
- Fast mode compatible
- Variable clock frequencies

Figure 37.1 shows a block diagram of the I2C bus interface.

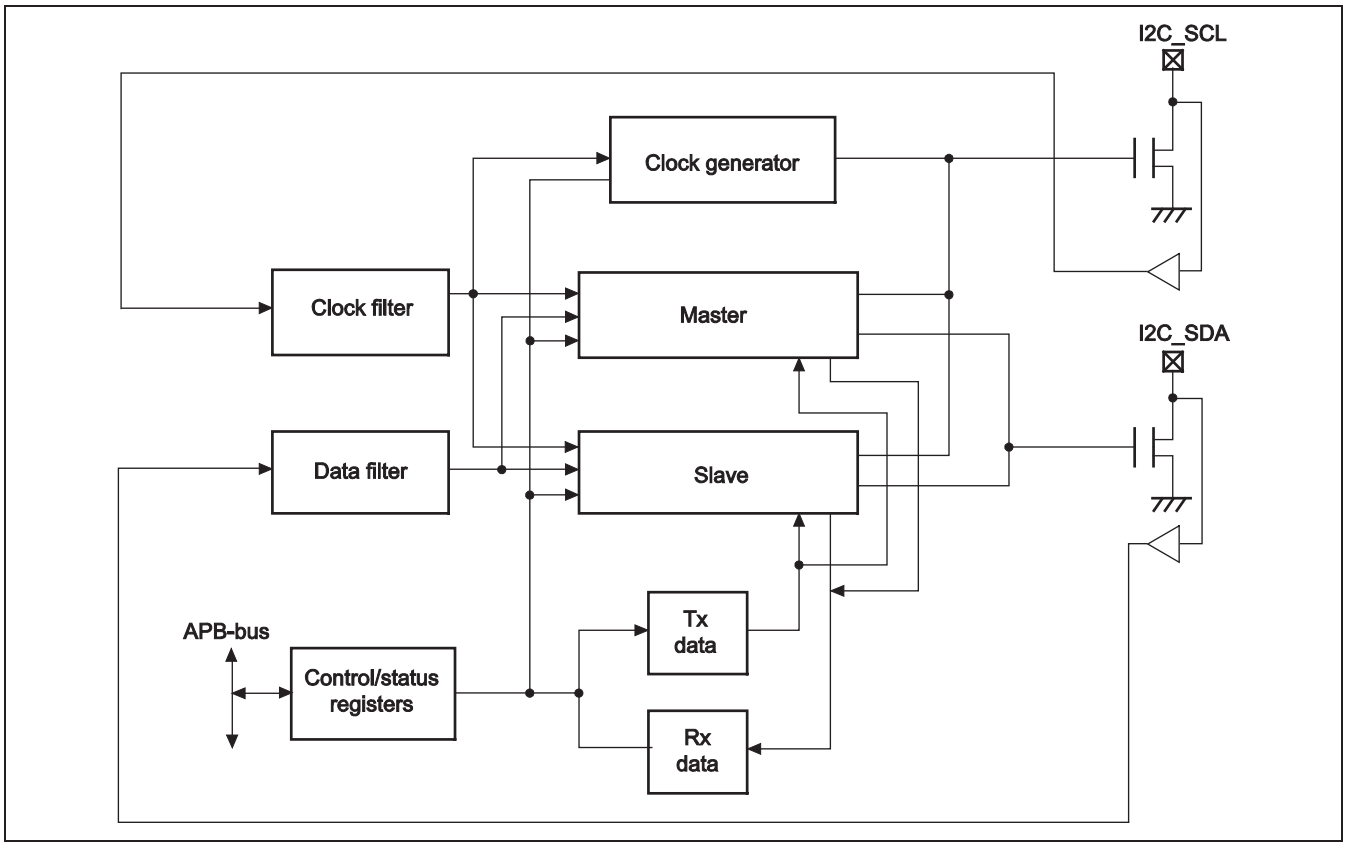


Figure 37.1 Block Diagram of I2C Bus Interface

37.1.2 Input/Output Pins

Table 37.1 lists the pins used in the I2C bus interface.

Table 37.1 I2C Bus Interface

Channel Number	Pin Name	I/O	Function	Output Buffer Type*
0	SCL	I/O	SCL: I2C serial clock input/output pin SDA: I2C serial data input/output pin	LVTTL
	SDA			
1	SCL			LVTTL
	SDA			
2	SCL			LVTTL
	SDA			
3	SCL			LVTTL
	SDA			
4	SCL			LVTTL
	SDA			

Note: * Output buffer type: "LVTTL" is low level drive only LVTTL buffer. LVTTL assigned channel pins are 3.3 V I/O.

The I2C buffer in this LSI is not compliant with the 5V-input. When turning off the I/O power source (3.3 V) of this LSI, turn off the power source of the pull-up resistors connected to the I2C pins.

37.2 Register Descriptions

The base address for each channel of registers of the I2C bus interface is as follows:

- I2C0: H'E650_8000
- I2C1: H'E651_8000
- I2C2: H'E653_0000
- I2C3: H'E654_0000
- I2C4: H'E652_0000

Each channel of the I2C bus interface has the registers below.

Table 37.2 Register Configuration (1)

Register Name	Abbreviation	R/W	Offset Address from Base Address	Size
Slave control register	ICSCR	R/W	H'00	32
Master control register	ICMCR	R/W	H'04	32
Slave status register	ICSSR	R/(W)*1	H'08	32
Master status register	ICMSR	R/(W)*2	H'0C	32
Slave interrupt enable register	ICSIER	R/W	H'10	32
Master interrupt enable register	ICMIER	R/W	H'14	32
Clock control register	ICCCR	R/W	H'18	32
Slave address register	ICSAR	R/W	H'1C	32
Master address register	ICMAR	R/W	H'20	32
Receive data register	ICRXD	R	H'24	32
Transmit data register	ICTXD	W	H'24	32
Clock control register 2	ICCCR2	R/W	H'28	32
SCL mask control register	ICMPR	R/W	H'2C	32
SCL high control register	ICHPR	R/W	H'30	32
SCL low control register	ICLPR	R/W	H'34	32

Notes: Do not write to any addresses other than listed above. Operations cannot be guaranteed if writing is attempted.
Values read from addresses other than those listed above are undefined.
Although the actual register name and its abbreviation have channel number as a suffix respectively, it is omitted in this section.

1. Only 0 can be written to bits 4 to 0 to clear the flags.
2. Only 0 can be written to bits 6 to 0 to clear the flags.

Table 37.3 Register Configuration (2)

Name	Abbreviation	Power-On Reset	Module Standby
Slave control register	ICSCR	H'0000 0000	Retained
Master control register	ICMCR	H'0000 0000*	Retained
Slave status register	ICSSR	H'0000 0000	Retained
Master status register	ICMSR	H'0000 0000	Retained
Slave interrupt enable register	ICSIER	H'0000 0000	Retained
Master interrupt enable register	ICMIER	H'0000 0000	Retained
Clock control register	ICCCR	H'0000 0000	Retained
Slave address register	ICSAR	H'0000 0000	Retained
Master address register	ICMAR	H'0000 0000	Retained
Receive data register	ICRXD	H'0000 0000	Retained
Transmit data register	ICTXD	—	—
Clock control register 2	ICCCR2	H'0000 0000	Retained
SCL mask control register	ICMPR	H'0000 0000	Retained
SCL high control register	ICHPR	H'0000 0000	Retained
SCL low control register	ICLPR	H'0000 0000	Retained

Note: * Bits 30, 29, 22, 21, 14, 13, 6, and 5 are undefined.

37.2.1 Slave Control Register (ICSCR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	SDBS	SIE	GCAE	FNA
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 4	—	All 0	R	Reserved When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
3	SDBS	0	R/W	Slave Data Buffer Select This bit is used to select the data buffer. Select the single-buffer mode supported in this module. When this bit is set to 1, the single-buffer mode is selected. SCL will be held low from the timing when the receive data register acquires the data packet until the SDR flag is cleared. 0: Setting prohibited 1: Single-buffer mode
2	SIE	0	R/W	Slave Interface Enable This bit must be set for the slave operation. If this bit is low, the slave interface is reset.
1	GCAE	0	R/W	General Call Acknowledgement Enable When slave devices are to issue an acknowledgement in response to a general call address sent from a master, this bit must be set to 1.
0	FNA	0	R/W	Forced Non Acknowledgement In the slave receive mode, the level of this bit is sent to the transmitting device as the acknowledge signal. This bit is set to 0 during the period that the data packet is being received, and set to 1 on completion of data reception. Forced non acknowledgement is returned to the master during slave reception. When the slave has received the last byte of data in a data packet, the slave communicates with the master by sending a NACK, meaning that the acknowledgement is not driven. The master issues a stop on the bus after receiving a NACK. The setting of this bit does not affect the acknowledgement of the slave address.

37.2.2 Slave Status Register (ICSSR)

Bits 0 to 4 among the status bits in the slave status register are cleared by writing 0 to the respective status bit positions. The individual bits are held 1 until 0 is written to (other than the GCAR and STM bits).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	GCAR	STM	SSR	SDE	SDT	SDR	SAR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W*	R/W*	R/W*	R/W*	R/W*

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	—	All 0	R	Reserved When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
6	GCAR	0	R	General Call Address Received Indicates that the address received from the bus is a general call address (H'00). This status bit does not cause an interrupt. This bit is automatically cleared by hardware when the SIE bit (bit 2 in the slave control register) is set to 0 or when the SSR bit (bit 4 in this register) is set to 1.
5	STM	0	R	Slave Transmit Mode Indicates whether the current slave transmit mode is read or write. When this bit is set to 0, the mode is write (slave reception). When this bit is set to 1, the mode is read (slave transmission). This status bit does not cause an interrupt. This bit is automatically cleared by hardware when the SIE bit (bit 2 in the slave control register) is set to 0 or when the SSR bit (bit 4 in the slave status register) is set to 1.
4	SSR	0	R/W*	Slave Stop Received A stop condition has been output on the bus. This status bit becomes active after the rising edge of SDA during reception of a stop bit.
3	SDE	0	R/W*	Slave Data Empty Indicates that data to be transmitted has been loaded into the shift register. At the start of byte data transmission, the contents of the ICTXD register are loaded into a shift register ready for outputting data on the bus. This status bit indicates that data has been loaded and the ICTXD register is again ready for further data. This status bit becomes active on the falling edge of SCL before reception of the first data bit. During the single-buffer mode, this bit must be reset every time new data has been written to ICTXD. This is because the slave holds SCL low to stop the bus while this bit is set to 1 even if a slave transmission cycle is started.
2	SDT	0	R/W*	Slave Data Transmitted A byte of data has been transmitted to the bus. This bit becomes active after the falling edge of SCL during reception of the last data bit.

Bit	Bit Name	Initial Value	R/W	Description
1	SDR	0	R/W*	Slave Data Received A byte of data has been received from the bus and is ready for reading from the receive data register. This bit becomes active after the falling edge of SCL during reception of the last data bit. During the single-buffer mode, this bit must be reset after data has been read from the ICRXD register. When SDBS is set to 1, SCL will be held low from the timing when the receive data register acquires the data packet until the SDR flag is cleared.
0	SAR	0	R/W*	Slave Address Received Indicates that the slave has recognized its own address on the bus (defined by the contents of the slave address register). If the general call acknowledgement enable bit is enabled in the slave control register, then this status bit is also set to 1 even if the address on the bus is a general call address. In this case, the GCAR bit in this register is used to determine whether or not the address is a general call address. The STM bit indicates whether the access is read (high) or write (low). This status becomes active after the falling edge of SCL during reception of the last address bit. The slave holds the SCL signal low from the start of the ACK phase until the software resets this status bit.

Note: * This bit can be read from or written to. Writing 0 clears this bit to 0 and writing 1 is ignored.

37.2.3 Slave Interrupt Enable Register (ICSIER)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	SSRE	SDEE	SDTE	SDRE	SARE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
4	SSRE	0	R/W	Slave Stop Received Interrupt Enable 0: Disables the SSR interrupt. 1: Enables the SSR interrupt.
3	SDEE	0	R/W	Slave Data Empty Interrupt Enable 0: Disables the SDE interrupt. 1: Enables the SDE interrupt.
2	SDTE	0	R/W	Slave Data Transmitted Interrupt Enable 0: Disables the SDT interrupt. 1: Enables the SDT interrupt.
1	SDRE	0	R/W	Slave Data Received Interrupt Enable 0: Disables the SDR interrupt. 1: Enables the SDR interrupt.
0	SARE	0	R/W	Slave Address Received Interrupt Enable 0: Disables the SAR interrupt. 1: Enables the SAR interrupt.

37.2.4 Slave Address Register (ICSAR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	SADD0_6	SADD0_5	SADD0_4	SADD0_3	SADD0_2	SADD0_1	SADD0_0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	—	All 0	R	Reserved When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
6 to 0	SADD0_6 to SADD0_0	All 0	R/W	Slave Address This is the unique 7-bit address allocated to the slave on the I2C bus. The slave interface compares this address with the first seven bits transmitted as the slave address, at the beginning of a data packet transmission.

37.2.5 Master Control Register (ICMCR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	—	—	0	0	0	0	0	0	—	—	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	MDBS	FSCL	FSDA	OBPC	MIE	TSBE	FSB	ESG
Initial value:	0	—	—	0	0	0	0	0	0	—	—	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0, except bits 30, 29, 22, 21, 14, and 13, in which case, initial value is undefined.	R	Reserved When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
7	MDBS	0	R/W	Master Data Buffer Select This bit is used to select the data buffer mode. Select the single-buffer mode supported in this module. When this bit is set to 1, the single-buffer mode is selected. SCL will be held low from the timing when the receive data register acquires the data packet until the MDR flag is cleared. 0: Setting prohibited 1: Single-buffer mode
6	FSCL	—	R/W	Forced SCL This bit controls the status of the I2C_SCL pin (reading reflects the current status of the I2C_SCL pin). When the OBPC bit is set, this bit directly controls the SCL line on the bus. During a read cycle, the level on this bit (which includes the reset level) will change depending on the level on I2C_SCL since it directly reflects the level on the I2C_SCL.
5	FSDA	—	R/W	Forced SDA This bit controls the status of the I2C_SDA pin (reading reflects the busy status level on the I2C bus). When the OBPC bit is set, then this bit directly controls the SDA line on the bus. During a read cycle, the level on this bit (which includes the reset level) will show the busy status of the I2C bus (1 for busy; 0 for not busy).
4	OBPC	0	R/W	Override Bus Pin Control When this bit is set to 1, the FSDA and FSCL bits in this register control SDA and SCL directly. This mode is used for testing purposes only.
3	MIE	0	R/W	Master Interface Enable When this bit is set to 1, the master interface is enabled. This bit is automatically cleared to 0 when this interface loses in arbitration of bus mastership. If 0 is not subsequently written to the bit, the value of the bit is restored to 1 on detection of a STOP condition on the I2C bus, and data transmission is retried. Regarding the state following a loss in arbitration of bus mastership, see the description of the MAL bit in ICMSR.

Bit	Bit Name	Initial Value	R/W	Description
2	TSBE	0	R/W	Start Byte Transmission Enable When this bit is set to 1, if the master issues a START or a repeated START condition, it continues by transmitting a start byte (01H) over the bus. The start byte is used for interfacing with slower microcontrollers that have I2C bus interfaces.
1	FSB	0	R/W	Forced Stop onto the Bus When this bit is set to 1, the master transmits a STOP condition on the bus at the end of the current transfer. If ESG is also set, the master immediately transmits a START condition and begins transmitting a new data packet. If ESG is not set, the master enters the idle state.
0	ESG	0	R/W	Enable Start Generation When this bit is set to 1, the master starts transmission of a data packet. If the bus is idle when ESG is set, the master transmits a START condition on the bus and then transmits the slave address. If the master is transferring data when ESG is set, at the end of that data byte transfer, the master transmits a repeated START condition before transmitting the slave address. When transmitting a data packet, the software must reset this bit when the slave address has been transmitted, otherwise a repeated START condition is transmitted after every transmission is completed.

37.2.6 Master Status Register (ICMSR)

The status bits (bits 0 to 6) in the master status register are cleared by writing 0 to the respective status bit positions. The individual status bits are held 1 until a reset by writing 0 to the appropriate bit position.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	MNR	MAL	MST	MDE	MDT	MDR	MAT
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*	R/W*

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	—	All 0	R	Reserved When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
6	MNR	0	R/W*	Master NACK Received When this bit is set to 1, this bit indicates that the master has received a NACK response (the SDA line is high during the acknowledge cycle on the bus) to either an address or data transmission.
5	MAL	0	R/W*	Master Arbitration Lost In a multi-master system, when this bit is set to 1, it indicates that the master has lost arbitration to other masters on the bus. At this point, MIE is reset and the master interface is disabled.
4	MST	0	R/W*	Master Stop Transmitted When this bit is set to 1, it indicates that the master has sent a STOP condition on the bus. A STOP condition can be sent either as a result of the setting of the forced stop bit in the control register, or from a NACK being received from a slave during a slave receive data packet.
3	MDE	0	R/W*	Master Data Empty At the start of a byte data transmission, the contents of the transmit data register are loaded into a shift register ready for transmitting on the bus. When this bit is set to 1, it indicates that the shift register has been loaded, so the transmit data register is ready to accept further data. During master transmission, the MDE bit is also set at the same time as the MAT bit is set after transmission of the slave address. In this case, you need to clear the MDE and MAT bits after the ICMCR's ESG bit is cleared. The clearing will restart the data transmission.
2	MDT	0	R/W*	Master Data Transmitted Byte data has been sent to the slave on the bus. This status bit becomes active after the falling edge of SCL during reception of the last data bit.

Bit	Bit Name	Initial Value	R/W	Description
1	MDR	0	R/W*	Master Data Received Byte data has been received from the bus and is in the receive data register. This status bit becomes active after the falling edge of SCL during reception of the last data bit. During single-buffer mode, this status bit must be reset after data has been read from the receive data register. When MDBS is set to 1, SCL will be held low from the timing when the receive data register acquires the data packet until the MDR flag is cleared. During master reception mode, the MDR bit is also set at the same time as the MAT bit is set after transmission of the salve address. In this case, you must clear the MDR and MAT bits after the ICMCR's ESG bit is cleared. Clearing will start the data reception
0	MAT	0	R/W*	Master Address Transmitted The master has been transmitted the slave address byte of a data packet. This bit becomes active after the falling edge of SCL during reception of the ACK bit following transmission of the address.

Note: * This bit can be read from or written to. Writing 0 clears this bit to 0 and writing 1 is ignored.

37.2.7 Master Interrupt Enable Register (ICMIER)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	MNRE	MALE	MSTE	MDEE	MDTE	MDRE	MATE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	—	All 0	R	Reserved When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
6	MNRE	0	R/W	Master NACK Received Interrupt Enable 0: Disables the MNR interrupt. 1: Enables the MNR interrupt.
5	MALE	0	R/W	Master Arbitration Lost Interrupt Enable 0: Disables the MAL interrupt. 1: Enables the MAL interrupt.
4	MSTE	0	R/W	Master Stop Transmitted Interrupt Enable 0: Disables the MST interrupt. 1: Enables the MST interrupt.
3	MDEE	0	R/W	Master Data Empty Interrupt Enable 0: Disables the MDE interrupt. 1: Enables the MDE interrupt.
2	MDTE	0	R/W	Master Data Transmitted Interrupt Enable 0: Disables the MDT interrupt. 1: Enables the MDT interrupt.
1	MDRE	0	R/W	Master Data Received Interrupt Enable 0: Disables the MDR interrupt. 1: Enables the MDR interrupt.
0	MATE	0	R/W	Master Address Transmitted Interrupt Enable 0: Disables the MAT interrupt. 1: Enables the MAT interrupt.

37.2.8 Master Address Register (ICMAR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	SADD1_6	SADD1_5	SADD1_4	SADD1_3	SADD1_2	SADD1_1	SADD1_0	STM1
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
7 to 1	SADD1_6 to SADD1_0	All 0	R/W	Slave Address These bits are the address of the slave which the master communicates with.
0	STM1	0	R/W	Slave Transfer Mode This bit specifies the mode in which the slave operates. Bit STM1 sets the operating mode (transmit or receive mode) of the slave, which is an external slave device whose address matches the slave address (SADD1) sent from the master. The slave device is automatically set to transmit/receive mode by hardware on reception of the STM1 signal. When this bit is set to 1, it indicates a read operation. When this bit is cleared to 0, it indicates a write operation.

37.2.9 Clock Control Register (ICCCR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	SCGD						CDF		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 9	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
8 to 3	SCGD	All 0	R/W	SCL Clock Generation Divider When operation is in master mode, the SCL clock is generated from the internal clock by using SCGD as the ratio. This is also the operating clock in slave-mode operation while SCL is being held low to stop the bus after an overflow has occurred. SCGD must be specified in both master and slave modes. The formula expressing the relationship is: Equation 2: SCL rate calculation SCLfreq = I2Cck/(20 + SCGD × 8 + F[(tICF + tr + IntDelay) × I2Cck]) I2Cck: I2C internal clock frequency tICF: I2C SCL falling time (depending on external load) tr: I2C SCL rising time (depending on external load) IntDelay: LSI internal delay LVTTL (low drive only) buffer: 5 ns (typ.), 6 ns (max.). F[n]: n rounded up to an integer Suggested settings for CDF and SCGD for CPU speeds and the two I2C bus speeds are given in Table 37.4.
2 to 0	CDF	All 0	R/W	Clock Division Factor The internal clock used in most blocks in the I2C module is a divided module clock. The internal I2C clock is generated from the module clock using the CDF as the division ratio: Equation 1: I2C internal clock frequency calculation I2Cck = MOD_CLK/(1 + CDF) MOD_CLK: module clock frequency Ensure that minimum values for setup and hold times of the SDA signal relative to the SCL signal on the bus are satisfied. The clock frequency is to ensure that the glitch filtering will operate with glitches of up to 50 ns as described in the fast mode I2C specification. Note: CDF must be set so that the clock frequency (I2Cck) is lower than 20 MHz.

Table 37.4 Recommended Settings for CDF and SCGD*1

- Recommended register values for LVTTL buffer (low drive only)

	100 kHz		400 kHz	
Module Clock Frequency	**CDF*2**	**SCGD*3**	**CDF*2**	**SCGD*3**
130 MHz	6	20	6	3
Error		+2.04%		+0.93%

Notes: 1. These recommended values are for the SCL rate with an external load that produces tICF = 20 ns and tr = 35 ns.
Recalculate to obtain the actual values after measuring tICF and tr under actual conditions of usage.
2. Recommended value for CDF bit of ICCCR.
3. Recommended value for SCGD bit of ICCCR.

37.2.10 Receive and Transmit Data Registers (ICRXD and ICTXD)

Reading from or writing to these registers access different physical internal registers. When data is to be transmitted, the contents of the shift register are loaded via TXD. After data has been received into the shift register from the I2C bus, it is then loaded into RXD.

(1) Receive data register (ICRXD)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	RXD							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved When these bits are read, bits 31 to 24, 23 to 16, and 15 to 8 reflect the values of bits 7 to 0. The write value should always be 0.
7 to 0	RXD	All 0	R	Read Receive Data Data received by master or slave.

(2) Transmit data register (ICTXD)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	TXD							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved The write value should always be 0.
7 to 0	TXD	All 0	W	Write Transmit Data Data to be transmitted by master or slave.

37.2.11 Clock Control Register 2 (ICCCR2)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	CDFD	HLSE	SME
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 3	—	All 0	R	Reserved When these bits are read, the value in bits 7 to 0 is set to bits 31 to 24, bits 23 to 16, and bits 15 to 8. The write value should always be 0.
2	CDFD	0	R/W	CDF Disable When this bit is set to 1, the module clock is used for internal clocks except the clock filter. For SCL rate computation, see equation 3 in Note 2. The clock filter always operates at a clock frequency divided by the CDF value.
1	HLSE	0	R/W	HIGH/LOW Separate Control Enable When this bit is set to 1, the SCGD setting is ignored and SCL is generated with the division ratio set by ICHPR during a high period and with the division ratio set by ICLPR during a low period. For SCL rate computation, see equation 3 in Note 2. The program should be prepared so that ICHPR and ICLPR should be written to before setting this bit.
0	SME	0	R/W	SCL Mask Enable When this bit is set to 1, a change of internal SCL is ignored after an SCL external input pin changes during the time equal to the number of internal clock cycles specified by ICMPR. For SCL rate computation, see equation 3 in Note 2. The program should be prepared so that ICMPR should be written to before setting this bit.

Notes: 1. The control bits should be set to "CDFD = 0, HLSE = 0, and SME = 0" or "CDFD = 1, HLSE = 1, and SME = 1". Otherwise, operation cannot be guaranteed. ICCCR2 should be written to prior to writing ICCCR.

2. Equation 3: SCL Rate Computation (CDFD = 1, HLSE = 1, and SME = 1)
   SCL freq = MOD_CLK/(8 + 2 × SMD + SCLD + SCHD), MOD_CLK: Module Clock Frequency
   SMD: SCL masked period (set by the SCL mask control register)
   SCLD: I2C SCL low clock period (set by the SCL HIGH control register)
   SCHD: I2C SCL high clock period (set by the SCL LOW control register)

Table 37.5 shows recommended register values for two types of I2C bus speeds.

Table 37.5 Recommended Register Values when CDFD = 1, HLSE = 1, and SME = 1

- Recommended Register Values for LVTTL buffer (low drive only)

Module Clock Frequency	100 kHz					400 kHz				
	CDF*1	SCGD*2	SMD*3	SCHD*4	SCLD*5	CDF*1	SCGD*2	SMD*3	SCHD*4	SCLD*5
130 MHz	6*6	0	10	632	640	6*6	0	15	135	152
Error	+0.00%					+0.00%				

Notes: 1. Recommended value for CDF bit of ICCCR.
2. Recommended value for SCGD bit of ICCCR.
3. Recommended value for SCGD bit of ICMPR.
4. Recommended value for SCGD bit of ICHPR.
5. Recommended value for SCGD bit of ICLPR.
6. In case of connecting to device, whose $t_{HD;DAT}$ is smaller than 100 ns, specifying 0 as CDF is recommended.

37.2.12 SCL Mask Control Register (ICMPR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	SMD							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved When these bits are read, the value in bits 7 to 0 is set to bits 31 to 24, bits 23 to 16, and bits 15 to 8. The write value should always be 0.
7 to 0	SMD	All 0	R/W	SCL Mask Division When SME = 1, a change of internal SCL is ignored after the external SCL changes during the time equal to the number of internal clock cycles specified by SMD. The value set in SMD should be smaller than SCHD or SCLD.

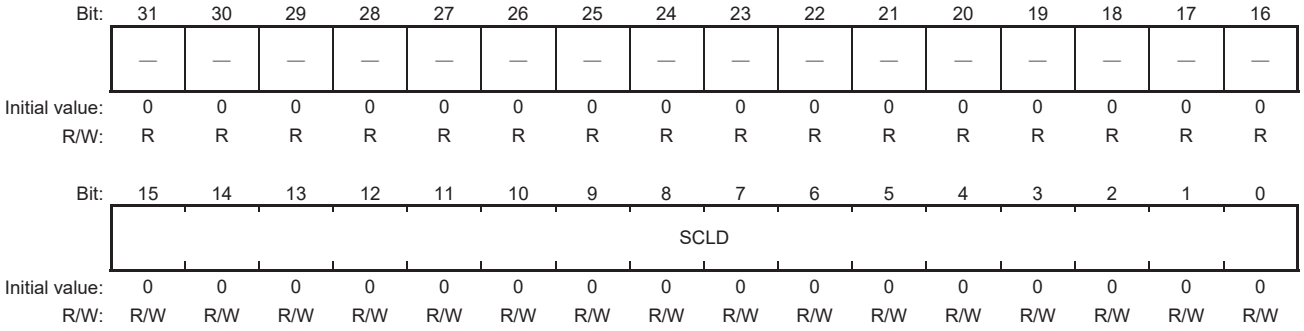
37.2.13 SCL HIGH Control Register (ICHPR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SCHD															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved The write value should always be 0.
15 to 0	SCHD	All 0	R/W	SCL HIGH Clock Division When HLSE is 1 and internal SCL is driven high, the clock generated using the SCHD internal clock division ratio is output. The period over the SCL signal is driven high can be calculated by the formula below. Period over SCL is driven high = 1/MOD_CLK * (4 + SMD + SCHD) + (tICF + tpd – tr) tICF: I2C SCL falling time (depending on external load) tr: I2C SCL rising time (depending on external load) tpd: I2C0 to I2C4 is 6 ns (max.).

37.2.14 SCL LOW Control Register (ICLPR)



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved The write value should always be 0.
15 to 0	SCLD	All 0	R/W	SCL LOW Clock Division When HLSE is 1 and internal SCL is driven low, the clock generated using the SCLD internal clock division ratio is output. The period over the SCL signal is driven low can be calculated by the formula below. Period over SCL is driven low = 1/MOD_CLK * (4 + SMD + SCLD) + (tICF + tpd – tr) tICF: I2C SCL falling time (depending on external load) tr: I2C SCL rising time (depending on external load) tpd: I2C0 to I2C4 is 6 ns (max.).

37.3 Operations

37.3.1 Data and Clock Filters

These blocks filter out glitches on signals coming from the I2C bus. Glitches up to one internal clock period in width are rejected (for details on the internal clock frequency, see section 37.2.9, Clock Control Register (ICCCR)). This is for the faster I2C bus rate (400 kHz) but does not violate the slower I2C bus rate specification.

These blocks also resynchronize bus signals with the internal clock.

37.3.2 Clock Generator

The clock generator has two functions. Firstly, it generates the SCL (I2C bus clock) according to commands of the master or slave interface. Secondly, it controls the internal clock rate, used by filtering blocks and the master and slave interfaces. This clock functions as a clock enable signal of the registers in these blocks.

37.3.3 Master/Slave Interfaces

These two interfaces run independently and in parallel. The master interface controls the transmission of address and data on the I2C bus. The slave interface monitors the I2C bus and takes part in transmissions if its programmed address is seen on the bus. The interfaces communicate with the control/status registers independently. There is only one interrupt line output from the I2C module. The interrupt source is either the master or the slave.

37.3.4 Software Status Interlocking

To make the software interface with the I2C module as robust and thus simple as possible, various interlocking status mechanisms have been included in the operation of the master and slave interfaces. The status bits involved are:

(1) MDR and SDR

MDR or SDR is set to 1 when data is received. Clear the status after reading the receive data register. If data is received while MDR or SDR is set, the hardware recognizes that unread data remains in the receive data register and automatically holds SCL at the low level to suspend data transmission. In this case, transmission can be resumed by clearing the status after reading the receive data.

Consequently, when receiving data continuously, be sure to clear the status bit (MDR or SDR) after reading the receive data register.

(2) MDE and SDE

If the MDE or SDE status bit is still set when data in the transmit data register is to be transmitted on the I2C bus by the slave or master, the SCL line must be held low until the MDE or SDE status bit is reset. The MDE or SDE status bit being set indicates that the data currently held in the transmit data register has already been transmitted on the I2C bus.

The software must clear this status bit when it writes to the transmit data register after transmission of the next data byte has become possible. This is not required for the first byte of data to be transmitted on the bus.

(3) MAL

When the master loses arbitration, the MAL bit (of the master status register) is set and the MIE bit (of the master control register) is reset. At this point, master mode is invalid and the I2C bus interface enters the slave mode. When master operation is restarted, data transfer from the master begins after the MAL bit has been cleared.

(4) SAR

The SAR status bit is set when the slave identifies its address on the I2C bus. At this point the slave interface forces the SCL line low until the SAR status bit is reset.

This is particularly important when a slave transmit is about to take place on the bus, and the slave will transmit the data from the transmit data register. The software responds to the SAR status by writing the required data into the transmit data register and then resetting the SAR status bit. This allows the slave interface to continue the access.

Unless the SAR bit is in use, when the slave is about to receive data, the software might still be reading out data that was loaded in previous access from the receive data register. In this case the valid data still held in the receive data register is overwritten. However, this is avoided using the SAR status bit. After the software has read data in the receive data register, reset the SAR bit (if it is set). Then overwriting the receive data register is avoided.

37.3.5 I2C Bus Data Format

Figure 37.2 shows a timing chart for the I2C bus interface. Table 37.6 describes the meaning of each symbol in Figure 37.2.

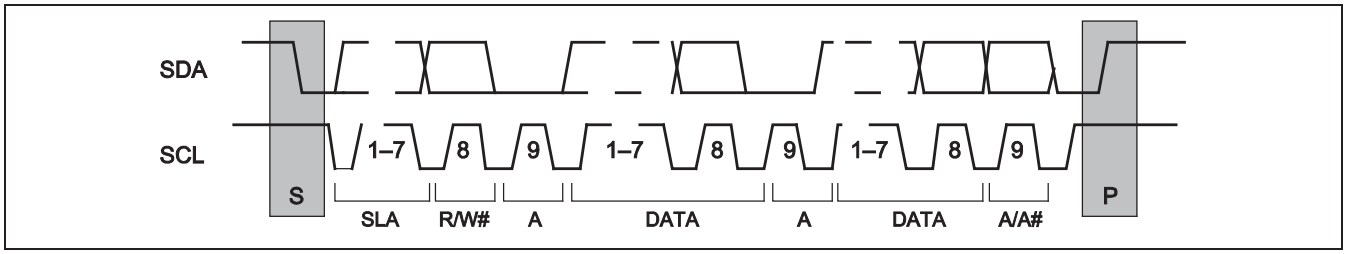


Figure 37.2 I2C Bus Timing

Table 37.6 Description on Symbols of I2C Bus Data Format

Symbol	Description
S	Indicates a start condition. A master device changes SDA from high to low while SCL is high level.
SLA	Indicates a slave address. A slave address is used when a master device selects a slave device.
R/$\overline{W}$	Indicates the direction of data transmission. If the R/$\overline{W}$ bit is 1, the data flows from the slave to the master device. If the bit is 0, the data flows from the master to the slave device.
A	Indicates data acknowledge. Data receiving device makes SDA low level (the slave device returns a data acknowledge signal in master transmission mode, and vice versa).
DATA	Indicates transmit or receive data. The data length is eight bits, which are transferred in the MSB first.
P	Indicates a stop condition. A master device changes SDA from low to high while SCL is high.

37.3.6 7-Bit Address Format

Figure 37.3 shows the format of data transfer from a master to a slave device (master data transmit format). Figure 37.4 shows the data transfer format (master data receive format) when a master device reads the second and the following byte data from a slave device.

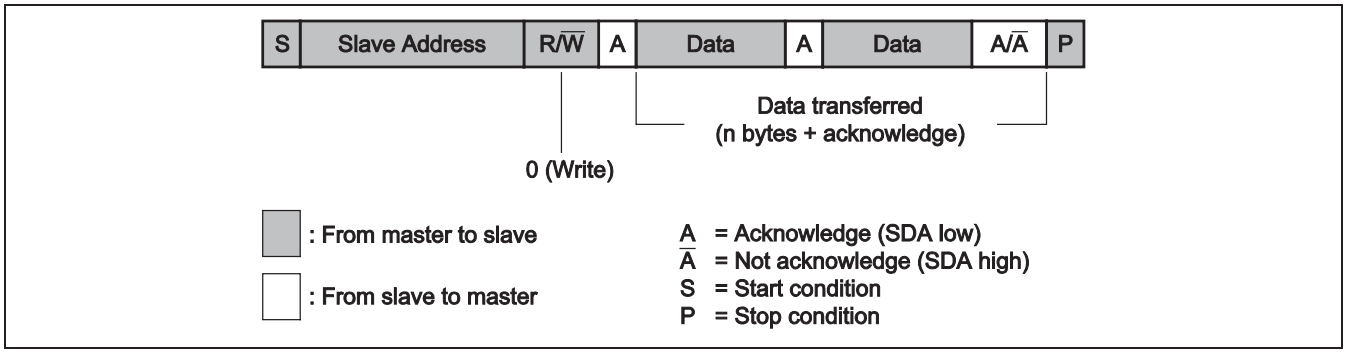

Figure 37.3 Master Data Transmit Format

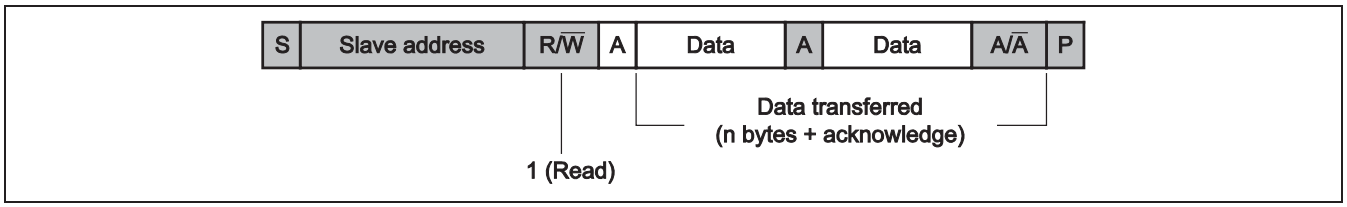

Figure 37.4 Master Data Receive Format

Figure 37.5 shows the combined format when the data transfer direction changes during one transfer. When changing the direction after the first transfer, the repeated START condition (Sr), slave address and R/$\overline{W}$ bits are transmitted. In this case, the R/$\overline{W}$ bit is set to the direction opposite to the first transfer direction. The repeated START condition is issued by the master at the end of a transmit or receive cycle if the enable start generation bit in the master control register has been set.

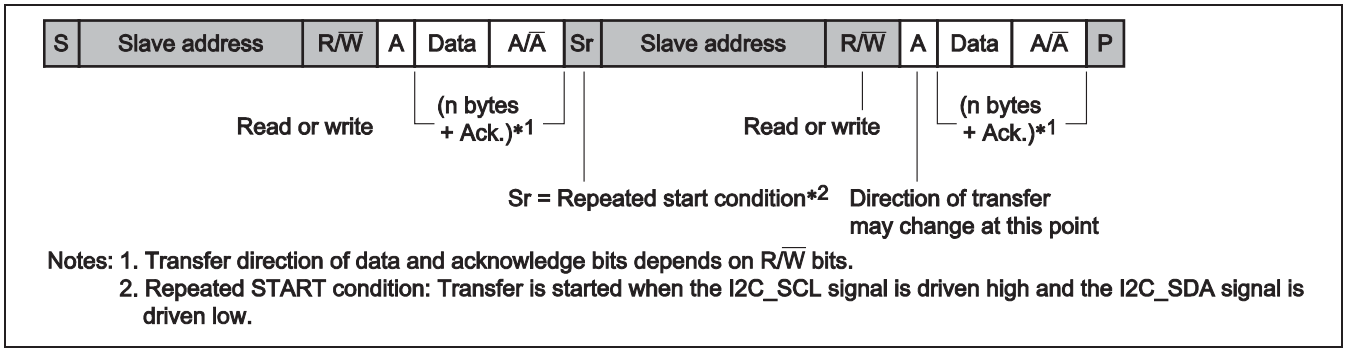

Figure 37.5 Combination Transfer Format of Master Transfer

37.3.7 10-Bit Address Format

Description is given below on the 10-bit address transfer format supported in master mode. This format has three transfer methods as the 7-bit address transfer format.

Figure 37.6 shows the data transmit format. The set value in the master address register is output in one byte following the first START condition (S). The value set in the transmit data register (TXD) is transmitted as a slave address in the second byte. Data on and after the third byte is transferred in the same way as the 7-bit address data.

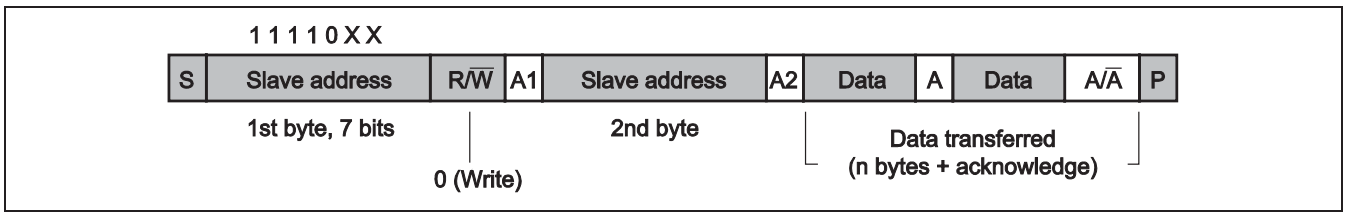

Figure 37.6 10-Bit Address Data Transmit Format

Figure 37.7 shows the data receive format. Two bytes of an address is transmitted in the same way as in the data transmit format. Then, repeated START condition (Sr) is transmitted and the value set in the address register is output. At this time, STM1 must be set to 1 (receive mode). Data is transferred in the same way as in the 7-bit address data receive format.

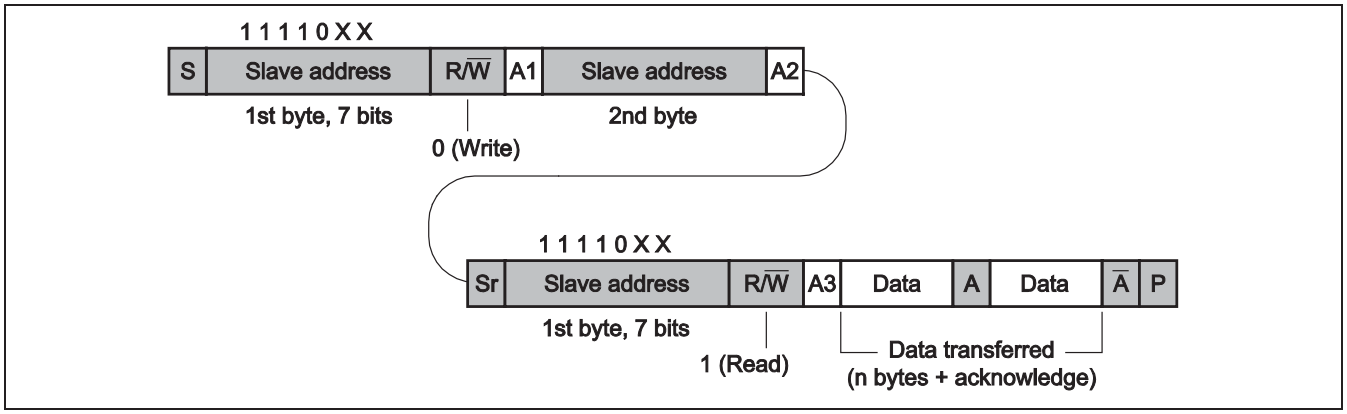

Figure 37.7 10-Bit Address Data Receive Format

Figure 37.8 shows the data transmit/receive combined format.

In the data transmit/receive combined format, data is transmitted after an address is transmitted with the first two bytes. Then, the repeated START condition (Sr) is transmitted instead of STOP condition (P). After Sr is transmitted, the procedure is the same as that in the data receive format.

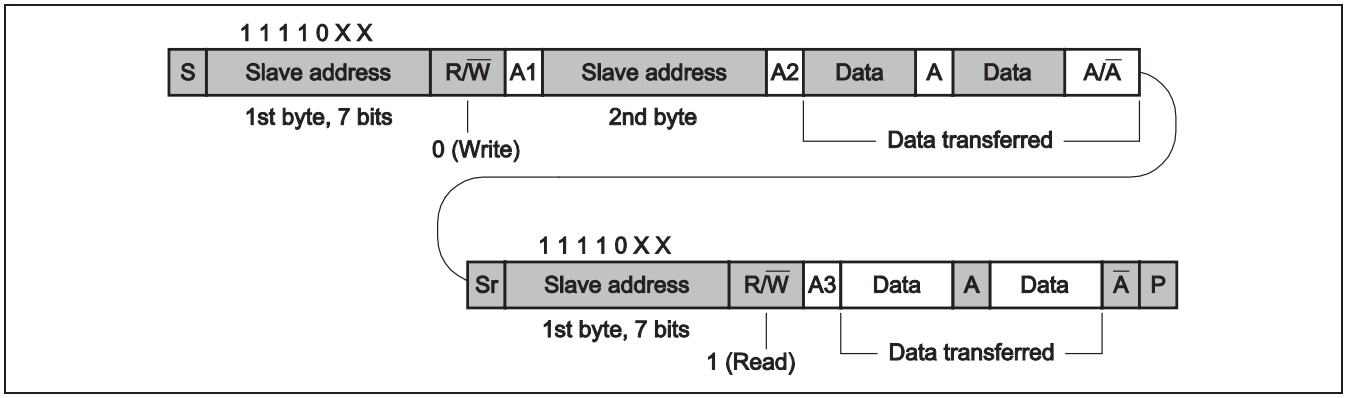

Figure 37.8 10-Bit Address Transmit/Receive Combined Format

37.3.8 Master Transmit Operation

The procedure and operations for transmission in master transmit mode are described below. Figure 37.9 shows the timing chart in master transmit mode. Setting the MDBS bit in the master control register allows the I2C to operate in single-buffer mode.

1. Set up the initial state by setting the slave address register, transmission data register, clock control register, and master interrupt enable register. Note that the setting of the clock control register must be in accord with the rate of transmission. Since slave mode is also required even when master mode is used, set the device address in the slave address register.
2. Monitor the FSDA bit in the master control register. Confirm that this bit is low, meaning that other I2C devices are not using the bus. After confirmation, set the MIE (bit 3) and ESG (bit 0) bits in the master control register to 1 to start master transmission.
3. After the transmit START condition, slave address, and data transfer direction bits are transmitted, an interrupt due to the MAT and MDE bits in the master status register is generated at the timing of (1) in Figure 37.9. At this time, clear the ESG bit to 0. To suspend the data transmission, the master device will hold SCL low until the MDE bit is cleared.
4. An interrupt due to the SAR bit is generated at the timing of (3) shown in Figure 37.9. If the IRQ handling in the slave device is delayed, the slave device extends the SCL period to suspend data transmission (at the timing of (7) in Figure 37.9). The slave device drives SDA low at the ninth clock and returns ACK.
5. Data is transmitted in units of nine bits: 8-bit data and 1-bit ACK. An interrupt of MDE (bit 3) is generated at the ninth clock before data transfer (at the timing of (2) in Figure 37.9). An interrupt of MDT (bit 2) is generated at the eighth clock after 1-byte data transfer (at the timing of (4) in Figure 37.9). Clear MDE to 0 after setting transmit data. An interrupt of SDR (slave data receive) of the slave device is generated at the eighth clock (at the timing of (6) in Figure 37.9). Clear SDR after the slave device reads the receive data. If this processing is delayed, the slave device extends the SCL period to suspend data transmit (at the timing of (8) in Figure 37.9).
6. To end data transfer, an interrupt of MNR (bit 6) in the master status register is generated at the ninth clock (at the timing of (5) in Figure 37.9) when ACK from the slave device is 1 (NACK). The master device receives this NACK and outputs the STOP condition. When data transmission ends on the master device side, set FSB (bit 1) in the master control register to 1 to output the STOP condition. After the I2C module fetches FSB on completion of transmission or reception of the last bit of byte data, it enters the stop state. Therefore in order to stop the communication after the predetermined number of byte data is transferred, the FSB bit needs to be set before the last byte data transfer is started.
7. The FSB bit needs to be set before the last byte data is transferred. In master transmit mode, after the last byte data is set, the MST (master stop transmitted) bit is checked by either interrupt or polling. At the same time MNR (master NACK received) bit must be checked. If NACK is returned, an error routine is executed to retransmit the last byte data.

Signal level changes of (1) to (6) in Figure 37.9 are generated after the falling edge of the clock.

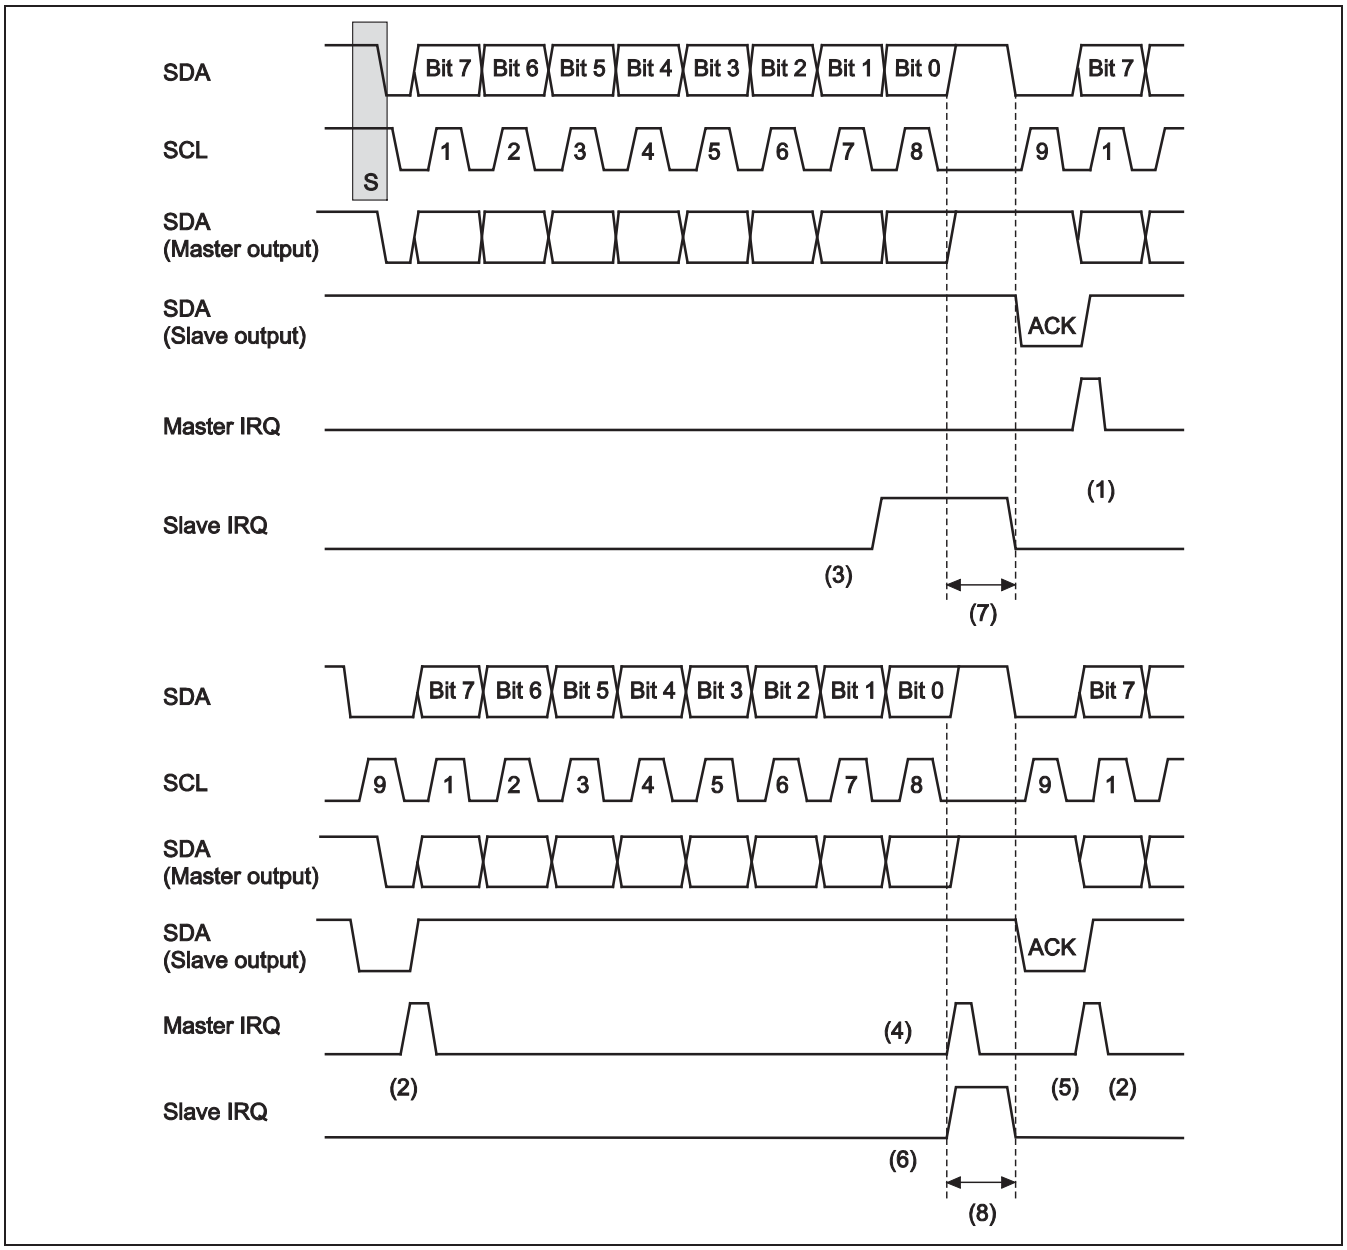

Figure 37.9 Data Transmit Mode Operation Timing

37.3.9 Master Receive Operation

The data receive procedure and operation in master receive mode are described below. Figure 37.10 shows the timing chart in master receive mode. Setting the MDBS bit in the master control register allows the I2C to operate in single-buffer mode.

1. In master receive mode, as to transmit of a slave address and a 1-bit signal indicating the data transfer direction, operation is the same as that in master transmit mode. At this time, set the data transfer direction to 1 (reception).
2. The slave device automatically enters the data transmit mode according to the signal that indicates the data transfer direction, and transmits 1-byte data in synchronization with the SCL clock output from the master device. The master device generates an interrupt of MDR (bit 1) at the eighth clock (at the timing of (2) in Figure 37.10). Clear the MDR bit after the master device reads receive data. If this processing is delayed, the master device extends the SCL period to suspend data transmission (at the timing of (3) in Figure 37.10).
3. The slave device generates an interrupt of the status SDT (bit 2) indicating 1-byte data transfer end at the eighth clock (at the timing of (2) in Figure 37.10) and an interrupt of the status SDE (bit 3) indicating data empty at the ninth clock (at the timing of (1) in Figure 37.10). Clear SDE after writing slave transmit data to TXD.
4. To end data transfer, set FSB (bit 1) in the master control register of the master device and output STOP condition. After the I2C module fetches FSB on completion of transmission or reception of the last of byte data, it enters the stop state. Therefore in order to stop the communication after predetermined number of byte data is transferred, FSB bit needs to be set before the last byte data transfer is started. After confirming reception of the last byte, even when the master receiver has completed the reception transaction, the protocol layer will inform the slave transmitter that retransmission is necessary if the last byte is incorrect.

Signal level changes of (1) to (3) in Figure 37.10 are generated after the falling edge of the clock.

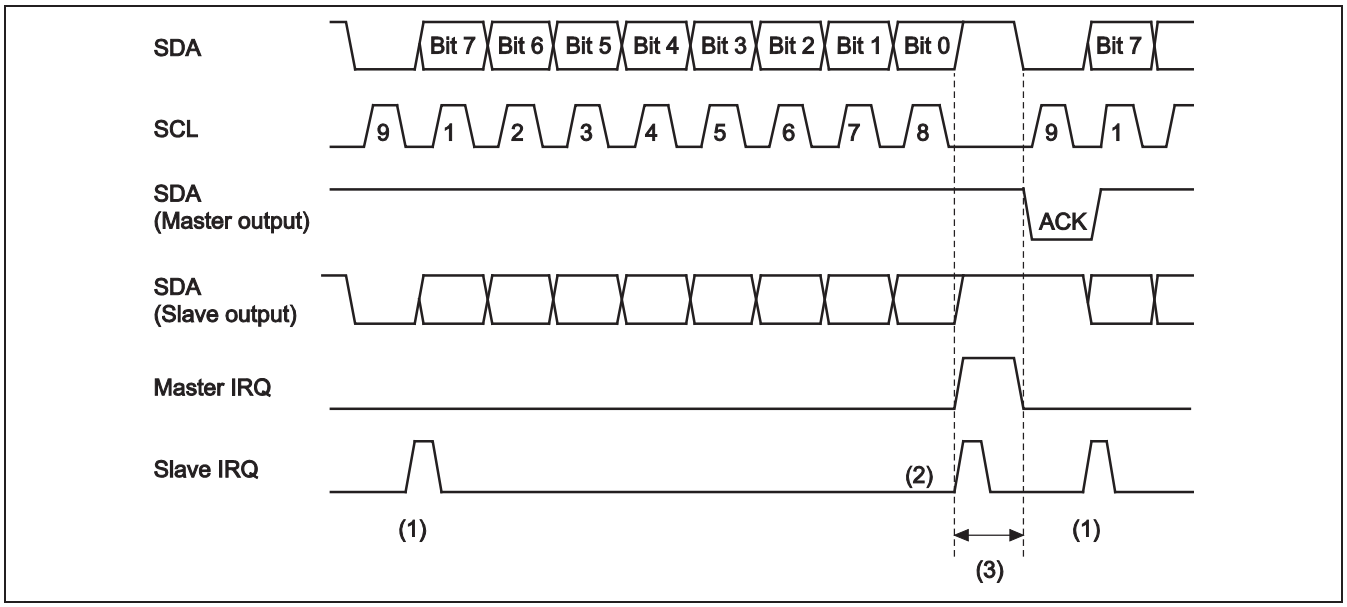

Figure 37.10 Data Receive Mode Operation Timing

37.4 Programming Examples

37.4.1 Master Transmitter

In order to set up the master interface to transmit a data packet on the I2C bus, follow the procedure below (an example for I2C0):

(1) Load value for the clock control register

(When the module clock frequency is 130 MHz and SCL clock frequency is set to 400 kHz)

1. Set the SCL clock generation divider bit (SCGD) to H'3.
2. Set the clock division ratio bit (CDF) to H'6 (I2C internal clock I2Cck: 18.57 MHz).

(2) Load value for the master control register, first data byte, and address

1. Master address register = address of slave being accessed and STM1 bit (write mode: 0)
2. Transmit data register = first data byte to be transmitted
3. Master control register = H'89 (MDBS = 1, MIE = 1, ESG = 1)

(3) Wait for outputting address

1. Wait for master event (an interrupt of the MAT and MDE bits in the master status register).
2. Set the master control register to H'88 (to suspend the data transmission, the master device will hold the SCL low until the MDE bit is cleared).

   If only one byte of data is transmitted, set the master control register to H'8A, meaning that the stop generation is enabled. This generates a stop on the bus as soon as one byte has been transmitted.
3. Reset the MAT and MDE bits.

(4) Monitor transmission of data

1. Wait for master event, MDE in the master status register.
2. Transmit data register = subsequent data.
3. Reset the MDE bit.

   Clear MDE after setting the last byte to be transmitted. After the last byte data is transmitted, MDE is generated. Before clearing MDE, you must set the master control register to H'8A (set the force stop control bit).

(5) Wait for end of transmission

1. Wait for the master event, MST in the master status register.
2. Reset the MST bit after confirming MNR (master NACK received).

37.4.2 Master Receiver

In order to set up the master interface to receive a data packet on the I2C bus, follow the procedure below:

(1) Load value for the clock control register

The same procedure as the master transmitter is applied. See the program example for the master transmitter.

(2) Load value for the master control register and address

1. Master address register = address of slave being accessed and STM1 bit (read mode: 1)
2. Master control register = H'89 (MDBS = 1, MIE = 1, ESG = 1)

(3) Wait for outputting address

1. Wait for master event (an interrupt of the MAT and MDR bits in the master status register).
2. Set the master control register to H'88 (to suspend the data transmission, the master device will hold the SCL low until the MDR bit is cleared).
   If only one byte of data is transmitted, set the master control register to H'8A, meaning that the stop generation is enabled. This generates a stop on the bus as soon as one byte has been transmitted.
3. Reset the MAT and MDR bits.

(4) Monitor reception of data

1. Wait for master event (the MDR bit in the master status register).
2. Read data from the received data register.
   If the next byte of data is the second to last byte to be transmitted by the slave device, the following applies to the receive interrupt (that is, MDR interrupt) in the second to last byte.
3. Set the master control register to H'8A (set the force stop control bit).
4. Reset the MDR bit.

(5) Wait for end of reception

1. Handle the receive interrupt (MDR) in the last byte: that is, read the data and clear the MDR.
2. Wait for master event, MST in the master status register.
3. Reset the MST bit.

37.4.3 Master Transmitter—Repeated START—Master Receiver

In order to set up the master interface to transmit a data packet on the I2C bus, issue a repeated START condition, then read byte data back from the slave, follows the procedure below:

(1) Load value for the clock control register

The same procedure as the master transmitter is applied. See the program example for the master transmitter.

(2) Load value for the master control register and address

1. Master address register = address of slave being accessed and STM1 bit (write mode: 0)
2. Transmit data register = first data byte to be transmitted
3. Master control register = H'89 (MDBS = 1, MIE = 1, ESG = 1)
4. Wait until slave-address transfer have started, and set master control register to H'88 (MDBS=1, MIE=1, ESG=0). (Start of slave address transfer can be checked by FSDA bit, or waiting enough time after setting ESG bit).

(3) Wait for outputting slave-address for master transmission

1. Wait for master event (an interrupt of the MAT and MDE bits in the master status register).
2. Set the master address register to address of slave being accessed and STM1 bit (read mode: 1).
   When the enable start generation bit in the master control register is still set, at the end of the byte transmission the master will issue a repeated START condition. Since the new address has been loaded above, the bus direction will be changed.
3. Reset the MAT and MDE bits.

(4) Monitor transmission of data

1. Wait for master event (an interrupt of the MDE bit in the master status register).
2. Master control register = H'89 (MDBS = 1, MIE = 1, ESG = 1)
3. Reset the MDE bit.

(5) Wait for outputting slave-address for master reception

1. Wait for master event (an interrupt of the MAT and MDR bits in the master status register).
2. Set the master control register to H'88. (To suspend stop the data transmission, the master device will hold the SCL low until the MDR bit is cleared.)
3. Reset the MAT and MDR bits.

(6) Monitor reception of data

1. Wait for master event (the MDR bit in the master status register).
2. Read data from the received data register.
   If the next byte of data is the second to last byte to be transmitted by the slave device, the following applies to the receive interrupt (that is, MDR interrupt) in the second to last byte.
3. Set the master control register to H'8A (set the force stop control bit).
4. Reset the MDR bit.

(7) Wait for end of reception

1. Handle the receive interrupt (MDR) in the last byte: that is, read the data and clear the MDR.
2. Wait for master event, MST in the master status register.
3. Reset the MST bit.

37.5 Usage Notes

In section 37.2.9, Clock Control Register (ICCCR), in the description of SCGD and CDF, following equation is described.

SCLfreq = I2Cck/(20 + SCGD × 8 + F[(tICF + tr + IntDelay) × I2Cck])

I2Cck: I2C internal clock frequency

tICF: I2C SCL falling time (depending on external load)

tr: I2C SCL rising time (depending on external load)

IntDelay: LSI internal delay

LVTTL (low drive only) buffer: 5 ns (typ.), 6 ns (max.).

F[n]: n rounded up to an integer

I2Cck = MOD_CLK/(1 + CDF)

MOD_CLK: module clock frequency

Based on parameter described above, this equation approximately estimates the SCL frequency, but includes some error in the resulting frequency. Before finalizing register setting to be used, measure actual SCL frequency on the board, and confirm that observed frequency satisfy the constraint. The reason why calculated result includes some error is parameters used in this equation varies depending on the characteristics of each sample. For example, tICF and tr depend on logical threshold of IO-cell, and intDelay depends on variation of fabrication process.

For adjustment of SCL frequency, modifying the setting of ICCCR[2:0].CDF and ICCCR[8:3].SCGD will be effective. Increasing the value of CDF or SCGD value will make SCL frequency lower. However, how they decrease SCL frequency is different. So, by increasing one register value and decreasing the other, SCL frequency can be adjusted.

38. Clock-Synchronized Serial Interface with FIFO (MSIOF)

This LSI includes clock-synchronized serial I/O module with FIFO (MSIOF). In this module, MPϕ is used as a module clock.

38.1 Features

- Number of channels: Three channels
- FIFO capacity: 32 bits × 64 stages for transmission and 32 bits × 128 stages for reception
  - For reception FIFO, receiving 1 FRAME with 2 groups with 64 words requires at most 128 FIFO stages.
- MSB first or LSB first selectable for data transmission and reception
- Synchronization by frame synchronization pulse, level, or left/right channel switch
- Supports master and slave modes
- Interrupts: One type
- Serial clock
- DMA transfer
- Serial format

  Supports serial formats: IIS, SPI (master and slave modes).
- CLK/SYNC (SPI) in common transmit/receive mode
  - Up to 26 MHz for all channels

Figure 38.1 shows a block diagram of the MSIOF.

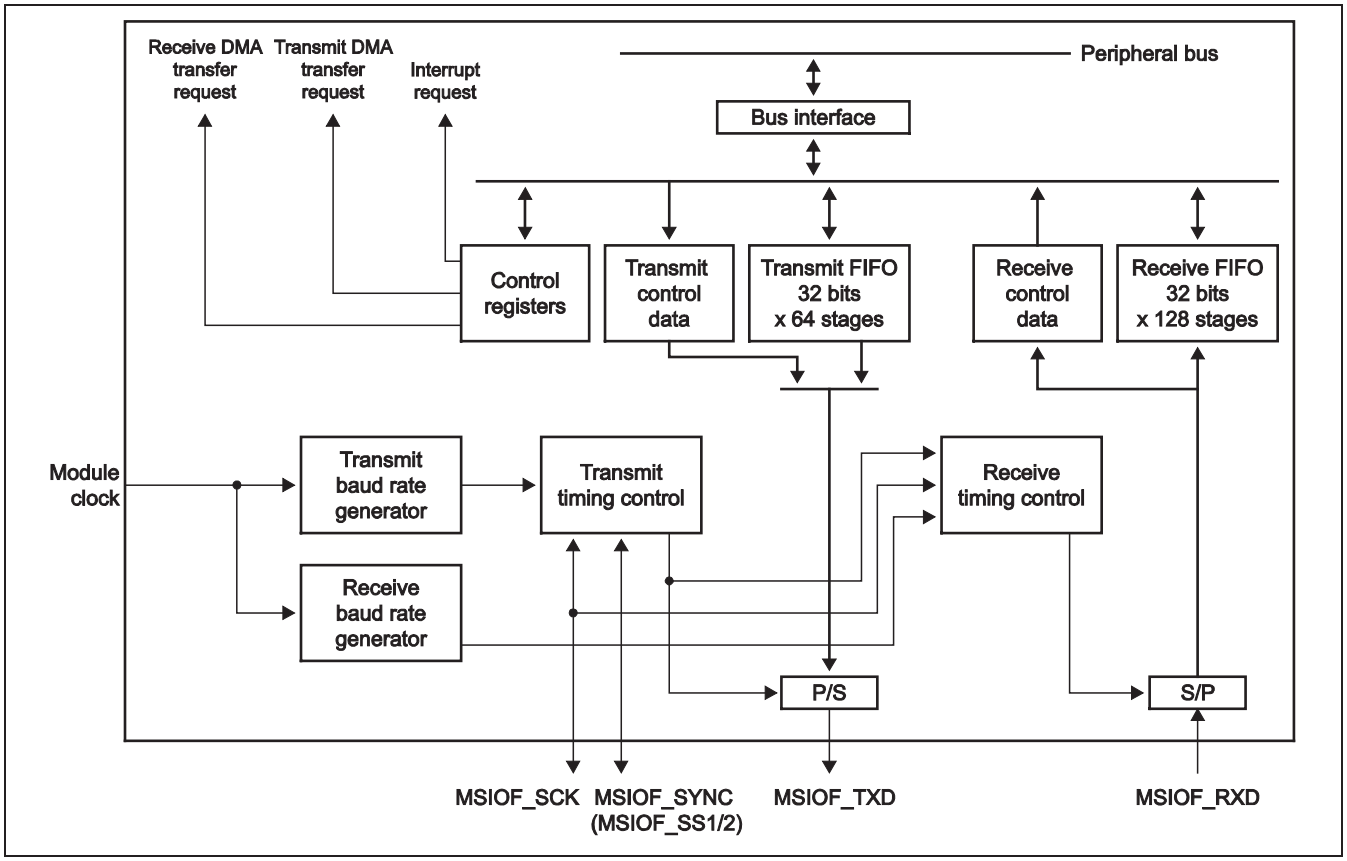

Figure 38.1 Block Diagram of MSIOF

38.2 Input/Output Pins

The pin configuration of this module is shown in Table 38.1.

Table 38.1 Pin Configuration

Name	Abbreviation	I/O	Function
MSIOF_SCK	SCK	I/O	MSIOF serial clock for transmission Works as SCK when a common clock is used for transmission and reception.
MSIOF_SYNC	SYNC	I/O	MSIOF frame synchronization signal for transmission Works as SYNC when a common synchronization signal is used for transmission and reception.
MSIOF_SS1	SS1	Output	MSIOF frame synchronization signal 1 for transmission This signal can work only master mode.
MSIOF_SS2	SS2	Output	MSIOF frame synchronization signal 2 for transmission This signal can work only master mode.
MSIOF_TXD (MOSI/MISO)	MOSI/MISO (TXD)	Output	MSIOF transmit data
MSIOF_RXD (MISO/MOSI)	MISO/MOSI (RXD)	Input	MSIOF receive data

38.3 Register Descriptions

Tables 38.2 and 38.3 show the MSIOF register configuration and Table 38.4 shows the register state in each processing mode.

Table 38.2 Module Base Address Summary

Module Name	Base Address
MSIOF0	H'E6E2 0000
MSIOF1	H'E6E1 0000
MSIOF2	H'E6E0 0000

Note: Address H'E6xx can be accessed only by CPU.

Table 38.3 Register Configuration

Name	Abbreviation	R/W	Address Offset	Access Size
MSIOF transmit mode register 1	SITMDR1	R/W	H'0000	32
MSIOF transmit mode register 2	SITMDR2	R/W	H'0004	32
MSIOF transmit mode register 3	SITMDR3	R/W	H'0008	32
MSIOF receive mode register 1	SIRMDR1	R/W	H'0010	32
MSIOF receive mode register 2	SIRMDR2	R/W	H'0014	32

38.3.1 MSIOF Transmit Mode Register 1 (SITMDR1)

SITMDR1 is a 32-bit readable/writable register that specifies the MSIOF transmit mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TRMD	PCON	SYNCMD[1:0]		SYNCCH[1:0]		SYNCAC	BITLSB	—	DTDL[2:0]			—	SYNCDL[2:0]		
Initial value:	1	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	FLD[1:0]		—	TXSTP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TRMD	1	R/W	Transfer Mode Selects the transfer mode. 0: Slave mode 1: Master mode
30	PCON	0	R/W	Transfer Signal Connection 0: Setting prohibited 1: MSIOF_SCK and MSIOF_SYNC are used as common signals for transmission and reception (MSIOF_SCK and MSIOF_SYNC).
29, 28	SYNCMD[1:0]	00	R/W	SYNC Mode These bits specify the mode for the MSIOF_SYNC signal. 00: Frame start synchronization pulse 01: Reserved 10: Level mode/SPI 11: L/R mode
27, 26	SYNCCH[1:0]	00	R/W	Synchronization Signal Channel Select These bits are valid only in master mode. 00: The frame synchronization signal output at MSIOF_SYNC. 01: The frame synchronization signal output at MSIOF_SS1. 10: The frame synchronization signal output at MSIOF_SS2. 11: Setting prohibited
25	SYNCAC	0	R/W	MSIOF_SYNC Polarity 0: Active-high signal in synchronization pulse or level mode, or driven high then low in L/R mode 1: Active-low signal in synchronization pulse or level mode, or driven low then high in L/R mode
24	BITLSB	0	R/W	MSB/LSB First 0: MSB first 1: LSB first
23	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
22 to 20	DTDL[2:0]	001	R/W	Data Pin Bit Delay for MSIOF_SYNC Pin The value specified with TXDIZ in SICTR is output during transmission. B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through DTDL and SYNCDL becomes an integer value. 000: No bit delay 001: 1-clock-cycle delay 010: 2-clock-cycle delay 101: 0.5-clock-cycle delay 110: 1.5-clock-cycle delay Other than above: Setting prohibited
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
18 to 16	SYNCDL[2:0]	000	R/W	Frame Synchronization Signal Timing Delay These bits extend the transmit frame synchronization signal. The value specified with TXDIZ in SICTR is output during transmission. These bits are invalid when SYNCMD[1:0] = B'01. B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through DTDL and SYNCDL becomes an integer value. When L/R mode, these bits should always be set to 000. 000: No bit delay 001: 1-clock-cycle delay 010: 2-clock-cycle delay 011: 3-clock-cycle delay 101: 0.5-clock-cycle delay 110: 1.5-clock-cycle delay Other than above: Setting prohibited
15 to 4	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
3, 2	FLD[1:0]	00	R/W	Frame Synchronization Signal Interval Specify the minimum idle time between frames in the number of serial clock cycles. This setting is valid only in master mode. When L/R mode, these bits should always be set to 00. When SPI mode, these bits shall not be set to 00. 00: 0-clock-cycle delay 01: 1-clock-cycle delay 10: 2-clock-cycle delay 11: 3-clock-cycle delay
1	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
0	TXSTP	0	R/W	Transmission Stop 0: Setting prohibited 1: Temporarily stops transmission when the number of transmit FIFO stages is not enough to valid.

38.3.2 MSIOF Transmit Mode Register 2 (SITMDR2)

SITMDR2 is a 32-bit readable/writable register that specifies the MSIOF transmit mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	GRP	—	BITLEN1					WDLEN1							
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30	GRP	0	R/W	Group Count The number of groups is set to the value specified in this bit + 1.
29	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
28 to 24	BITLEN1[4:0]	01111	R/W	Data Size (8 to 32 bits) The word size (bits) of groups 1 is set to the value specified in these bits + 1. Either 8, 16, 24, or 32 bits can be specified as word size.
23 to 16	WDLEN1[7:0]	H'00	R/W	Word Count (1 to 64 words) The word counts of groups 1 is set to WDLEN1 + 1 respectively. 8-bit value is set to WDLEN1.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

38.3.3 MSIOF Transmit Mode Register 3 (SITMDR3)

SITMDR3 is a 32-bit readable/writable register that specifies the MSIOF transmit mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	BITLEN2					WDLEN2							
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 24	BITLEN2	01111	R/W	Word Size (1 to 32 bits) The word size of groups 2 is set to the value specified in these bits + 1. Either 8, 16, 24, or 32 bits can be specified as word size.
23 to 16	WDLEN2	H'00	R/W	Word Count (1 to 64 words) The word counts of groups 2 are set to WDLEN2 + 1. 8-bit value is set to WDLEN2.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

38.3.4 MSIOF Receive Mode Register 1 (SIRMDR1)

SIRMDR1 is a 32-bit readable/writable register that specifies the MSIOF receive mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TRMD	—	SYNCMD[1:0]		—	—	SYNCAC	BITLSB	—	DTDL[2:0]			—	SYNCDL[2:0]		
Initial value:	1	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0
R/W:	R/W	R	R/W	R/W	R	R	R/W	R/W	R	R/W	R/W	R/W	R	R/W	R/W	R/W

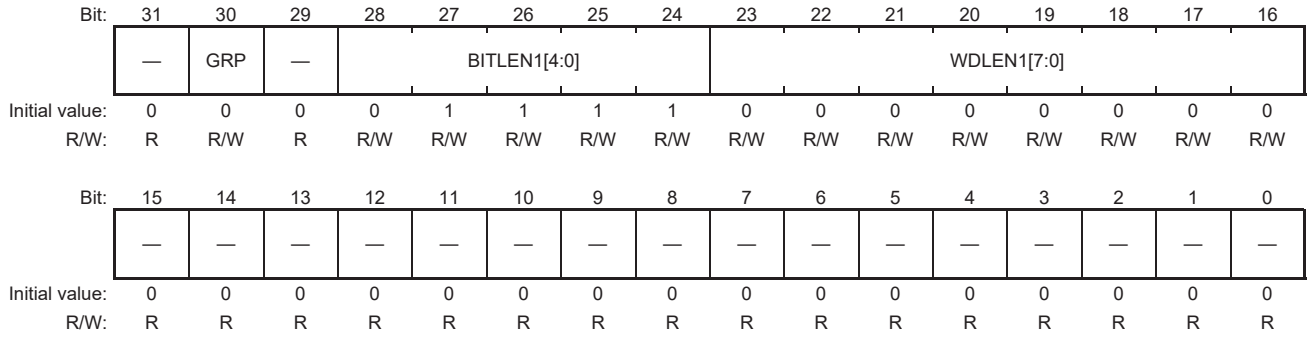
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TRMD	1	R/W	Transfer Mode Selects the transfer mode. This bit should be set to 0.
30	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
29, 28	SYNCMD [1:0]	00	R/W	SYNC Mode The mode setting in these bits should be the same as that in SITMDR1.SYNCMD. 00: Frame start synchronization pulse 01: Reserved 10: Level mode/SPI 11: L/R mode
27, 26	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
25	SYNCAC	0	R/W	SYNC Polarity 0: Active-high signal in synchronization pulse or level mode, or driven high then low in L/R mode 1: Active-low signal in synchronization pulse or level mode, or driven low then high in L/R mode This bit must have the same setting as the SYNCAC bit of SITMDR1.
24	BITLSB	0	R/W	MSB/LSB First 0: MSB first 1: LSB first
23	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
22 to 20	DTDL[2:0]	001	R/W	Data Pin Bit Delay for MSIOF_SYNC Pin B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through DTDL and SYNCDL becomes an integer value. 000: No bit delay 001: 1-clock-cycle delay 010: 2-clock-cycle delay 101: 0.5-clock-cycle delay 110: 1.5-clock-cycle delay Other than above: Setting prohibited In case of SPI mode, only 000 is allowed to set to this field.
19	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
18 to 16	SYNCDL [2:0]	000	R/W	MSIOF_SYNC Timing Delay The synchronization signal is extended for the clock cycles specified in these bits. These bits are invalid when SYNCMD[1:0] = B'01. B'1xx is valid only in SPI mode. In SPI mode, these bits should be specified so that the sum of the delays specified through DTDL and SYNCDL becomes an integer value. In L/R mode, these bits should always be set to 000. 000: No bit delay 001: 1-clock-cycle delay 010: 2-clock-cycle delay 011: 3-clock-cycle delay 101: 0.5-clock-cycle delay 110: 1.5-clock-cycle delay Other than above: Setting prohibited In case of SPI mode, only 000 is allowed to set to this field.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

38.3.5 MSIOF Receive Mode Register 2 (SIRMDR2)

SIRMDR2 is a 32-bit readable/writable register that specifies the MSIOF receive mode.



Bit	Bit Name	Initial Value	R/W	Descriptions
31	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
30	GRP	0	R/W	Group Count The number of groups is set to the value specified in this bit + 1. Set the same value as the value specified by the GRP bit in SITMDR2.
29	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
28 to 24	BITLEN1[4:0]	01111	R/W	Word Size (8 to 32 bits) The word size (bits) of groups 1 is set to the value specified in these bits + 1. Either 8, 16, 24, or 32 bits can be specified as word size. Set the same value as the value specified by the BITLEN1 bits in SITMDR2.
23 to 16	WDLEN1[7:0]	H'00	R/W	Word Count (1 to 64 words) The word counts of groups 1 is set to WDLEN1 + 1. When one or two groups are used, the 8-bit value is set to WDLEN1. Set the same value as the value specified by the WDLEN1 bits in SITMDR2.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

38.3.6 MSIOF Receive Mode Register 3 (SIRMDR3)

SIRMDR3 is a 32-bit readable/writable register that specifies the MSIOF receive mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	BITLEN2[4:0]					WDLEN2[7:0]							
Initial value:	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 29	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
28 to 24	BITLEN2[4:0]	01111	R/W	Word Size (1 to 32 bits) The word size is set to the value specified in these bits + 1. Either 8, 16, 24, or 32 bits can be specified as word size. Set the same value as the value specified by the BITLEN2 bits in SITMDR3.
23 to 16	WDLEN2[7:0]	H'00	R/W	Word Count (1 to 64 words) The word counts of groups 2 is set to WDLEN2 + 1. 8-bit value is set to WDLEN2. Set the same value as the value specified by the WDLEN2 bits in SITMDR3.
15 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

38.3.7 MSIOF Control Register (SICTR)

SICTR is a 32-bit readable/writable register that specifies the MSIOF operating state.

The values written to the TXE, RXE, TFSE, RFSE, TSCKE, and RSCKE bits become valid (can be read from the bits) several cycles after writing. These bits should not be modified at the same time. Modify one bit at a time, and check that the new value can be read from the bit, and then modify another bit.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TSCKIZ[1:0]		RSCKIZ[1:0]		TEDG	REDG	—	—	TXDIZ[1:0]		—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TSCKE	TFSE	RSCKE	RFSE	—	—	TXE	RXE	—	—	—	—	—	—	TXRST	RXRST
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
31, 30	TSCKIZ[1:0]	00	R/W	Transmit Clock Input/Output Polarity Select in SPI Mode When Transmission is Disabled When SPI mode is not used, these bits must always be set to 00. These bits must always be set 10 or 11 when SPI mode. [Master mode] 00: Outputs MSIOF_SCK when transmission is disabled. 01: Setting prohibited 10: Outputs 0. 11: Outputs 1. [Slave mode] 00: Inputs MSIOF_SCK when transmission is disabled. 01: Setting prohibited 10: Inputs 0 through MSIOF_SCK when transmission is disabled. 11: Inputs 1 through MSIOF_SCK when transmission is disabled.
29, 28	RSCKIZ[1:0]	00	R/W	Receive Clock Polarity Select in SPI Mode Set the same value as the value specified by the TSCKIZ bits. Other setting is prohibited.
27	TEDG	0	R/W	Transmit Timing 0: Outputs transmit data at the rising edge of the clock. 1: Outputs transmit data at the falling edge of the clock.
26	REDG	0	R/W	Receive Timing 0: Samples receive data at the falling edge of the clock. 1: Samples receive data at the rising edge of the clock.
25, 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
23, 22	TXDIZ[1:0]	00	R/W	Pin Output When Transmission is Disabled These bits specify the MSIOF_TXD pin output state when transmission is disabled. 00: Outputs 0. 01: Outputs 1. 10: Output is in high-impedance state. 11: Setting prohibited
21 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	TSCKE	0	R/W	Transmit Serial Clock Output Enable This bit is valid in master mode. When this bit is set to 1, the MSIOF initializes the baud rate generator and initiates the operation. At the same time, the MSIOF outputs the clock generated by the baud rate generator to the MSIOF_SCK pin. After the clock is output, 1 can be read. When transmitting data, set this bit to 1 before setting the TFSE and TXE bits. After data transmission, clear the TFSE and TXE bits and then clear this bit to 0. [Write data] 0: Disables the MSIOF_SCK output. (Outputs the value specified with TSCKIZ.) 1: Enables the MSIOF_SCK output. [Read data] 0: Does not output MSIOF_SCK. (Outputs the value specified with TSCKIZ.) 1: Outputs MSIOF_SCK.
14	TFSE	0	R/W	Transmit Frame Synchronization Signal Output Enable This bit is valid in master mode. When this bit is set to 1, the MSIOF initializes the frame counter and initiates the operation. After the transmit frame synchronization signal is output, 1 can be read. When 0 is written to this bit, 0 is set after transmission of the frame. [Write data] 0: Disables the MSIOF_SYNC output. (Outputs the value specified with SYNCAC.) 1: Enables the MSIOF_SYNC output. [Read data] 0: Does not output MSIOF_SYNC. (Outputs the value specified with SYNCAC.) 1: Outputs MSIOF_SYNC.
13	RSCKE	0	R/W	Receive Serial Clock Output Enable The write value should always be 0.
12	RFSE	0	R/W	Receive Frame Synchronization Signal Output Enable The write value should always be 0.
11, 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
9	TXE	0	R/W	Transmit Enable When this bit is set to 1, the MSIOF starts data transmission from the beginning of the next frame (at the rising edge of the frame synchronization signal). After the valid data is output, 1 can be read. When value 1 set to this bit becomes valid, the MSIOF issues a transmit data transfer request according to the setting of the TFWM bits in SIFCTR. When transmit data is stored in the transmit FIFO, transmission of data from the MSIOF_TXD pin begins. When 0 is written to this bit, 0 is set after transmission of the frame. This bit is initialized upon a transmit reset. [Write data] 0: Disables the MSIOF_TXD output. (Outputs the value specified with TXDIZ.) 1: Enables the MSIOF_TXD output. [Read data] 0: Does not output MSIOF_TXD. (Outputs the value specified with TXDIZ.) 1: Outputs MSIOF_TXD.
8	RXE	0	R/W	Receive Enable When this bit is set to 1, the MSIOF starts data reception from the beginning of the next frame (at the rising edge of the frame synchronization signal). When value 1 set to this bit becomes valid, the MSIOF starts receiving data through the MSIOF_RXD pin. When receive data is stored in the receive FIFO, the MSIOF issues a receive data transfer request according to the setting of the RFWM bits in SIFCTR. This bit is initialized upon a receive reset. [Write data] 0: Disables data reception through MSIOF_RXD. 1: Enables data reception through MSIOF_RXD. [Read data] 0: Data is not received through MSIOF_RXD. 1: Data can be received through MSIOF_RXD.
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
1	TXRST	0	R/W	Transmit Reset When value 1 set to this bit becomes valid, the MSIOF immediately sets transmit data through the MSIOF_TXD pin to 0, and initializes the transmit data registers and transmit-related status. When value 1 set to this bit becomes valid when PCON = 1, the RXRST bit is also becomes valid. The following registers and bits are initialized. SITFDR (Transmit FIFO write pointer) TDREQ bit in SISTR TXE bit This bit is read as 1 until the reset operation is completed for about 20 cycles of module clock. No data should be written to SICTR or the transmit FIFO during this time period. [Write data] 0: Does not reset transmit operation. 1: Resets transmit operation. [Read data] 0: Transmit operation reset is completed. 1: Transmit operation is being reset.
0	RXRST	0	R/W	Receive Reset When value 1 set to this bit becomes valid, the MSIOF immediately disables reception through the MSIOF_RXD pin, and initializes the receive data registers and receive-related status. The following registers and bits are initialized. SIRFDR (Receive FIFO read pointer) RDREQ bit in SISTR RXE bit This bit is read as 1 until the reset operation is completed for about 20 cycles of module clock. No data should be written to SICTR or read the receive FIFO during this time period. [Write data] 0: Does not reset receive operation. 1: Resets receive operation. [Read data] 0: Receive operation reset is completed. 1: Receive operation is being reset.

38.3.8 MSIOF Transmit Clock Select Register (SITSCR)

SITSCR is a 16-bit readable/writable register that specifies the conditions for generating transmit serial clock in master mode. SITSCR can be specified when the TRMD bit in SITMDR1 is set to B'1.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MSSEL[1:0]		MSIMM	BRPS[4:0]					—	—	—	—	—	BRDV[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Descriptions
15, 14	MSSEL[1:0]	00	R/W	Master Clock Source Select The master clock is the clock input to the baud rate generator. 00: Selects module clock as the source of master clock. Others: Setting prohibited
13	MSIMM	0	R/W	Master Clock Direct Select When setting MSIMM = 1, the master clock source should be set to 26 MHz or lower. Set 0 when MSSEL = B'00. 0: Selects the clock output from the baud rate generator as the serial clock. 1: Setting is not available.
12 to 8	BRPS[4:0]	00000	R/W	Prescalar Setting These bits specify the master clock (MPϕ) division ratio in the count value of the prescalar in the baud rate generator. The specifiable value is from B'00000 (× 1/1) to B'11111 (× 1/32).
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	BRDV[2:0]	000	R/W	Baud Rate Generator's Division Ratio These bits specify the frequency division ratio for the output stage of the baud rate generator. The final frequency division ratio of the baud rate generator is determined as BRPS × BRDV (1/1024 max.). 000: Prescalar output × 1/2 001: Prescalar output × 1/4 010: Prescalar output × 1/8 011: Prescalar output × 1/16 100: Prescalar output × 1/32 101: Setting prohibited 110: Setting prohibited 111: Prescalar output × 1/1 Note: B'111 is valid only when the BRPS[4:0] bits are set to B'00000 or B'00001.

38.3.9 MSIOF Transmit FIFO Data Register (SITFDR)

SITFDR is a 32-bit write-only register that specifies the transmit FIFO data of the MSIOF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SITFD1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SITFD2[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	SITFD1[15:0]	H'0000	W	These bits specify the upper 16 bits of the FIFO data to be output through MSIOF_TXD.
15 to 0	SITFD2[15:0]	H'0000	W	These bits specify the lower 16 bits of the FIFO data to be output through MSIOF_TXD.

38.3.10 MSIOF Receive FIFO Data Register (SIRFDR)

SIRFDR is a 32-bit read-only register that stores the receive FIFO data of the MSIOF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SIRFD1[15:0]															
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SIRFD2[15:0]															
Initial value:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 16	SIRFD1[15:0]	Undefined	R	Store the upper 16 bits of the FIFO data received through MSIOF_RXD.
15 to 0	SIRFD2[15:0]	Undefined	R	Store the lower 16 bits of the FIFO data received through MSIOF_RXD.

38.3.11 MSIOF Status Register (SISTR)

Each bit in SISTR becomes an MSIOF interrupt source when the corresponding bit in SIIER is set to 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	TFEMP	TDREQ	—	—	—	—	TEOF	—	TFS ERR	TFOVF	TFUDF	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	RFFUL	RDREQ	—	—	—	—	REOF	—	RFS ERR	RFUDF	RFOVF	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31, 30	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
29	TFEMP	0	R/W	Transmit FIFO Empty This bit is set to 1, when the TXE bit in SICTR is 1, and transmit FIFO is empty. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: Transmit FIFO is not empty. 1: Transmit FIFO is empty.
28	TDREQ	0	R	Transmit Data Transfer Request This bit is set, when the empty space in the transmit FIFO exceeds the size specified by the TFWM bits in SIFCTR. When transferring transmit data through the DMAC, this bit is always cleared after one DMAC access. After DMAC access, when the conditions for setting this bit are satisfied, the MSIOF again sets this bit to 1. This bit is valid when the TXE bit in SICTR is 1. This bit indicates a state; if the size of empty space in the transmit FIFO becomes less than the size specified by the TFWM bits in SIFCTR, the MSIOF clears this bit. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. However, when the TDMAE bit is 1, only a DMAC transfer request is issued. 0: The size of empty space in the transmit FIFO has not exceeded the size specified by the TFWM bits in SIFCTR. 1: The size of empty space in the transmit FIFO has exceeded the size specified by the TFWM bits in SIFCTR.
27 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
23	TEOF	0	R/W	Frame Transmission End This bit is set, when one-frame data transmission is completed. This bit is valid when the TXE bit in SICTR is 1. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: One-frame transmission end is not detected. 1: One-frame transmission end is detected.
22	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
21	TFSERR	0	R/W	Transmit Frame Synchronization Error This bit is set, when the next transmit frame synchronization timing arrives before the previous data or control data transmission has been completed. If a transmit frame synchronization error occurs, the MSIOF performs transmission only for the slots that can be transferred. This bit is valid when the TXE bit in SICTR is 1. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: No transmit frame synchronization error has occurred. 1: A transmit frame synchronization error has occurred.
20	TFOVF	0	R/W	Transmit FIFO Overflow A transmit FIFO overflow means that there has been an attempt to write to SITFDR when the transmit FIFO is full. If a transmit FIFO overflow occurs, the MSIOF ignores the write operation causing the overflow. This bit is valid when the TXE bit in SICTR is 1. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: No transmit FIFO overflow has occurred. 1: A transmit FIFO overflow has occurred.
19	TFUDF	0	R/W	Transmit FIFO Underflow A transmit FIFO underflow means that loading for transmission has occurred when the transmit FIFO is empty. Output data is unknown when under flow is occurred. This bit is valid when the TXE bit in SICTR is 1. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: No transmit FIFO underflow has occurred. 1: A transmit FIFO underflow has occurred.
18 to 14	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
13	RFFUL	0	R/W	Receive FIFO Full This bit is valid when the RXE bit in SICTR is 1. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: Receive FIFO is not full. 1: Receive FIFO is full.
12	RDREQ	0	R	Receive Data Transfer Request This bit is set, when the valid data space in the receive FIFO exceeds the size specified by the RFWM bits in SIFCTR. When transferring receive data through the DMAC, this bit is always cleared by one DMAC access. After DMAC access, when the conditions for setting this bit are satisfied, the MSIOF again sets this bit to 1. This bit is valid when the RXE bit in SICTR is 1. This bit indicates a state; if the size of valid data space in the receive FIFO becomes less than the size specified by the RFWM bits in SIFCTR, the MSIOF clears this bit. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. However, when the RDMAE bit is 1, only a DMAC transfer request is issued. 0: The size of valid data space in the receive FIFO has not exceeded the size specified by the RFWM bits in SIFCTR. 1: The size of valid data space in the receive FIFO has exceeded the size specified by the RFWM bits in SIFCTR.
11 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	REOF	0	R/W	Frame Reception End The MSIOF issues the frame reception end flag upon completion of one-frame data reception. This bit is valid when the RXE bit in SICTR is 1. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: One-frame reception end is not detected. 1: One-frame reception end is detected.
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
5	RFSERR	0	R/W	Receive Frame Synchronization Error A receive frame synchronization error occurs when the next receive frame synchronization timing arrives before the previous data or control data reception has been completed. If a receive frame synchronization error occurs, the MSIOF performs reception only for the slots that can be transferred. This bit is valid when the RXE bit in SICTR is 1. Writing 1 to this bit will clear this bit. Writing 0 to this bit will be ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: No receive frame synchronization error has occurred 1: A receive frame synchronization error has occurred
4	RFUDF	0	R/W	Receive FIFO Underflow A receive FIFO underflow means that reading of SIRFDR has occurred when the receive FIFO is empty. If a receive FIFO underflow occurs, the value read from SIRFDR is not guaranteed. This bit is valid when the RXE bit in SICTR is 1. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: No receive FIFO underflow has occurred. 1: A receive FIFO underflow has occurred.
3	RFOVF	0	R/W	Receive FIFO Overflow A receive FIFO overflow means that writing has been caused by receiving operation when the receive FIFO is full. If a receive FIFO overflow occurs, the receive data causing the overflow is lost. This bit is valid when the RXE bit in SICTR is 1. Writing 1 to this bit clears this bit. Writing 0 to this bit is ignored. If the interrupt request from this bit is enabled, an MSIOF interrupt is issued. 0: No receive FIFO overflow has occurred. 1: A receive FIFO overflow has occurred.
2 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

38.3.12 MSIOF Interrupt Enable Register (SIIER)

SIIER is a 32-bit readable/writable register that enables the issuance of MSIOF interrupts. When each bit in this register is set to 1 and the corresponding bit in SISTR is set to 1, the MSIOF issues an interrupt.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TDMAE	—	TFEMPE	TDREQE	—	—	—	—	TEOFE	—	TFSERRE	TFOVFE	TFUDFE	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R/W	R/W	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RDMAE	—	RFFULE	RDREQE	—	—	—	—	REOFE	—	RFSERRE	RFUDFE	RFOVFE	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R/W	R/W	R	R	R	R	R/W	R	R/W	R/W	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31	TDMAE	0	R/W	Transmit Data DMA Transfer Request Enable Specifies whether to send an interrupt as an interrupt request to the CPU or a transfer request to the DMAC. The TDREQE bit can be set as the request source. 0: Sends an interrupt request to the CPU. 1: Sends a DMA transfer request to the DMAC.
30	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
29	TFEMPE	0	R/W	Transmit FIFO Empty Enable 0: Disables interrupts due to transmit FIFO empty. 1: Enables interrupts due to transmit FIFO empty.
28	TDREQE	0	R/W	Transmit Data Transfer Request Enable 0: Disables interrupts due to transmit data transfer requests. 1: Enables interrupts due to transmit data transfer requests.
27 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23	TEOFE	0	R/W	Frame Transmission End Enable 0: Disables a frame transmission end interrupt. 1: Enables a frame transmission end interrupt.
22	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
21	TFSERRE	0	R/W	Transmit Frame Synchronization Error Enable 0: Disables interrupts due to transmit frame synchronization errors. 1: Enables interrupts due to transmit frame synchronization errors.
20	TFOVFE	0	R/W	Transmit FIFO Overflow Enable 0: Disables interrupts due to transmit FIFO overflow. 1: Enables interrupts due to transmit FIFO overflow.
19	TFUDFE	0	R/W	Transmit FIFO Underflow Enable 0: Disables interrupts due to transmit FIFO underflow. 1: Enables interrupts due to transmit FIFO underflow.

Bit	Bit Name	Initial Value	R/W	Descriptions
18 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	RDMAE	0	R/W	Receive Data DMA Transfer Request Enable Specifies whether to send an interrupt as an interrupt request to the CPU or a transfer request to the DMAC. The RDREQE bit can be set as the request source. 0: Sends an interrupt request to the CPU. 1: Sends a DMA transfer request to the DMAC.
14	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
13	RFFULE	0	R/W	Receive FIFO Full Enable 0: Disables interrupts due to receive FIFO full. 1: Enables interrupts due to receive FIFO full.
12	RDREQE	0	R/W	Receive Data Transfer Request Enable 0: Disables interrupts due to receive data transfer requests. 1: Enables interrupts due to receive data transfer requests.
11 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	REOFE	0	R/W	Frame Reception End Enable 0: Disables a frame reception end interrupt. 1: Enables a frame reception end interrupt.
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
5	RFSERRE	0	R/W	Receive Frame Synchronization Error Enable 0: Disables interrupts due to receive frame synchronization errors. 1: Enables interrupts due to receive frame synchronization errors.
4	RFUDFE	0	R/W	Receive FIFO Underflow Enable 0: Disables interrupts due to receive FIFO underflow. 1: Enables interrupts due to receive FIFO underflow.
3	RFOVFE	0	R/W	Receive FIFO Overflow Enable 0: Disables interrupts due to receive FIFO overflow. 1: Enables interrupts due to receive FIFO overflow.
2 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

38.3.13 MSIOF FIFO Control Register (SIFCTR)

SIFCTR is a 32-bit readable/writable register that indicates the area available for the transmit/receive FIFO transfer.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TFWM[2:0]			—	—	TFUA[6:0]							—	—	—	—
Initial value:	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RFWM[2:0]			RFUA[8:0]									—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 29	TFWM[2:0]	000	R/W	Transmit FIFO Watermark A transfer request of the transmit FIFO is issued by the TDREQE bit in SIIER. The transmit FIFO always operates as a 64-stage FIFO regardless of the setting of these bits. 000: Issues a transfer request when 64 stages of the transmit FIFO are empty. 001: Issues a transfer request when 32 or more stages of the transmit FIFO are empty. 010: Issues a transfer request when 24 or more stages of the transmit FIFO are empty. 011: Issues a transfer request when 16 or more stages of the transmit FIFO are empty. 100: Issues a transfer request when 12 or more stages of the transmit FIFO are empty. 101: Issues a transfer request when 8 or more stages of the transmit FIFO are empty. 110: Issues a transfer request when 4 or more stages of the transmit FIFO are empty. 111: Issues a transfer request when 1 or more stages of transmit FIFO are empty.
28, 27	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
26 to 20	TFUA[6:0]	H'40	R	Transmit FIFO Usable Area Indicate the number of words that can be transferred by the CPU or DMAC as B'0000000 (full) to B'1000000 (empty).
19 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Descriptions
15 to 13	RFWM[2:0]	000	R/W	Receive FIFO Watermark A transfer request of the receive FIFO is issued by the RDREQE bit in SIIER. The receive FIFO always operates as a 128-stage FIFO regardless of the setting of these bits. 000: Issues a transfer request when 1 stage or more of the receive FIFO are valid. 001: Issues a transfer request when 4 or more stages of the receive FIFO are valid. 010: Issues a transfer request when 8 or more stages of the receive FIFO are valid. 011: Issues a transfer request when 16 or more stages of the receive FIFO are valid. 100: Issues a transfer request when 32 or more stages of the receive FIFO are valid. 101: Issues a transfer request when 64 or more stages of the receive FIFO are valid. 110: Issues a transfer request when 128 stages of the receive FIFO are valid. The setting of 111 is prohibited.
12 to 4	RFUA[8:0]	H'000	R	Receive FIFO Usable Area Indicate the number of words that can be transferred by the CPU or DMAC as B'000000000 (empty) to B'010000000 (full).
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

38.4 Operation

38.4.1 Operating Mode

(1) Common transmit/receive mode

Common clock and frame synchronization signals are used for transmission and reception.

Master mode: MSIOF_SCK and MSIOF_SYNC are output.
Slave mode: MSIOF_SCK and MSIOF_SYNC are input.

38.4.2 Serial Clocks

(1) Clock output in master mode

In master mode, the baud rate generator is used to generate the serial clock. The division ratio is from 1/1 to 1/1024.

(2) Clock input in slave mode

In slave mode, the clock input for transmission and reception is used as the serial clock.

(3) Multiple channel function

This module provides the multiple channel function as shown in Figure 38.2.

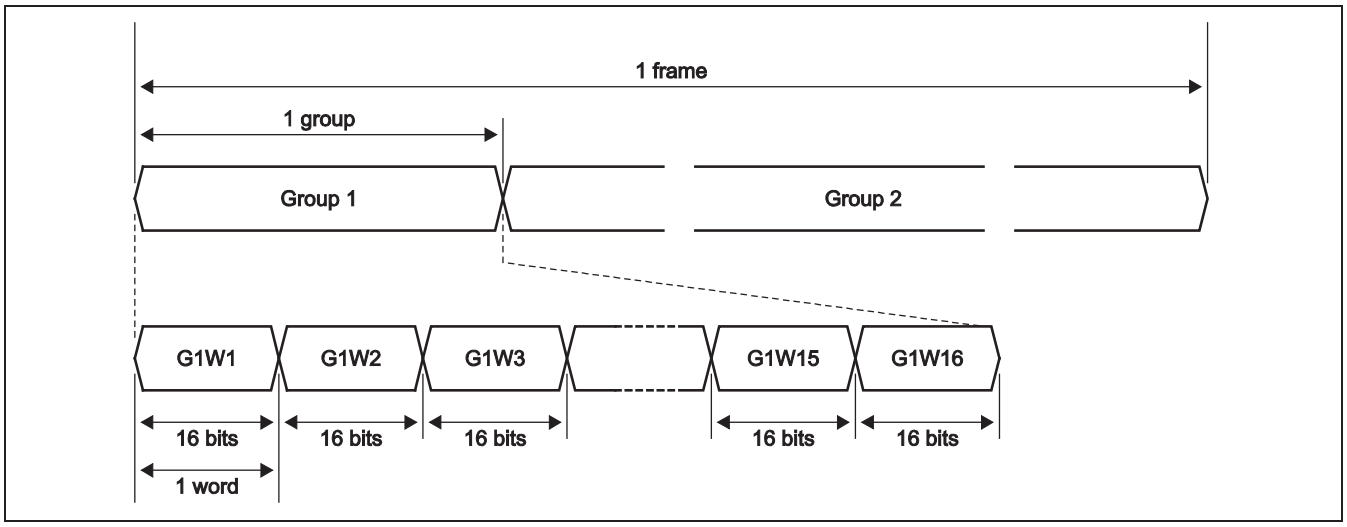


Figure 38.2 Multiple Channel Structure

The following conditions can be specified for the multiple channel function.

- Up to 2 groups in one frame
- Up to 64 words in one group
- 8, 16, 24, or 32 bits one word

38.4.3 Serial Timing

(1) MSIOF_SYNC

The MSIOF_SYNC is a frame synchronization signal. The following four modes are available.

- Frame start synchronization pulse: 1-bit-width pulse indicating the start of a frame
- Level/SPI: Level signal asserted during frame transmission
- L/R: 1/2-frame-width pulse indicating the first-half groups in a high level and the last-half groups in a low level

Figures 38.3 to 38.5 show the synchronization timing in these modes using the MSIOF_SYNC signal.

(a) Frame start synchronization pulse

The rising edge of the synchronization pulse indicates the start of a frame.

The delay between the rising edge of the synchronization signal and the start of data transmission or reception can be specified with the DTDL bits. The width of the synchronization pulse can be extended through the SYNCDL bit setting.

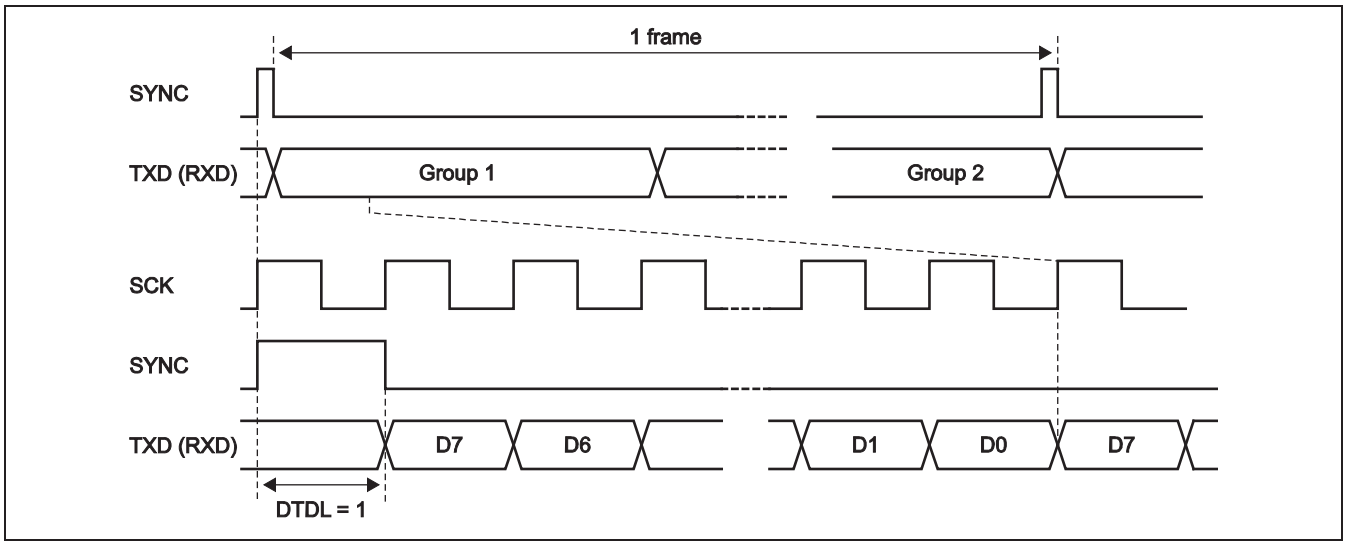

Figure 38.3 Synchronization Timing in Start Frame Synchronization Pulse Mode

(b) Level synchronization

The synchronization signal is driven high for the frame length.

The delay between the rising edge of the synchronization signal and the start of transmission or reception can be specified with the DTDL bits and the delay between the end of transmission or reception and the falling edge of the synchronization signal can be specified with the SYNCDL bits (DTDL = 0 to 2 and SYNCDL = 0 to 3). This mode is available for the SPI master or slave operation.

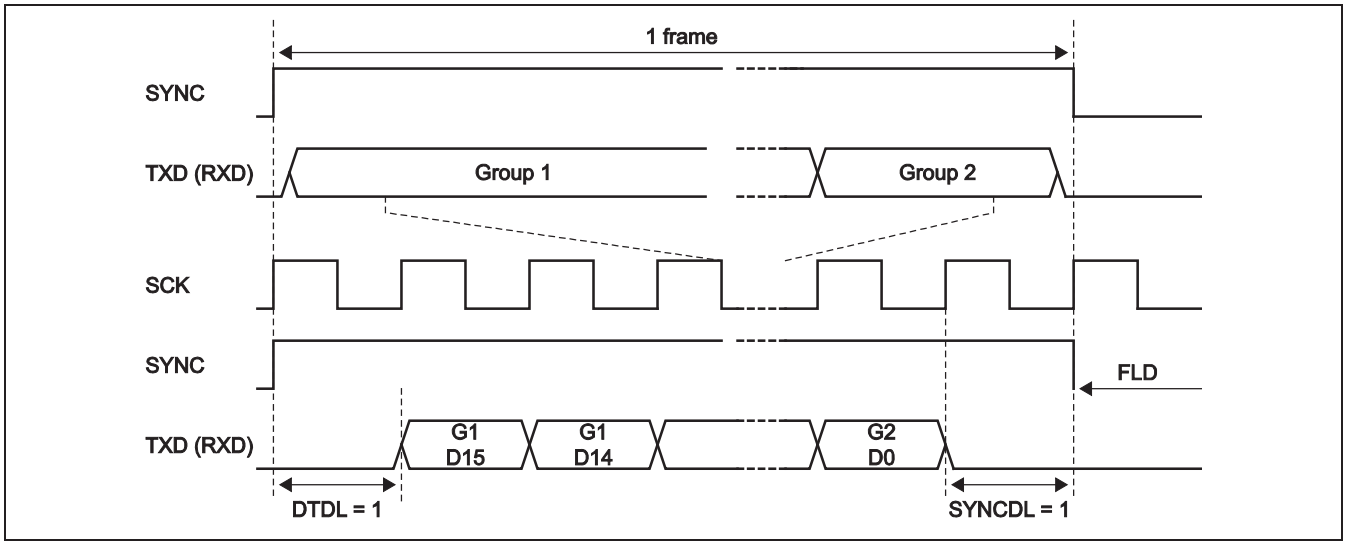

Figure 38.4 Synchronization Timing in Level Synchronization Mode

(c) L/R synchronization

A high level in the synchronization signal indicates the first-half groups and a low level indicates the last-half groups.

The delay between the rising or falling edge of the synchronization signal and the start of transmission or reception can be specified with the DTDL bits.

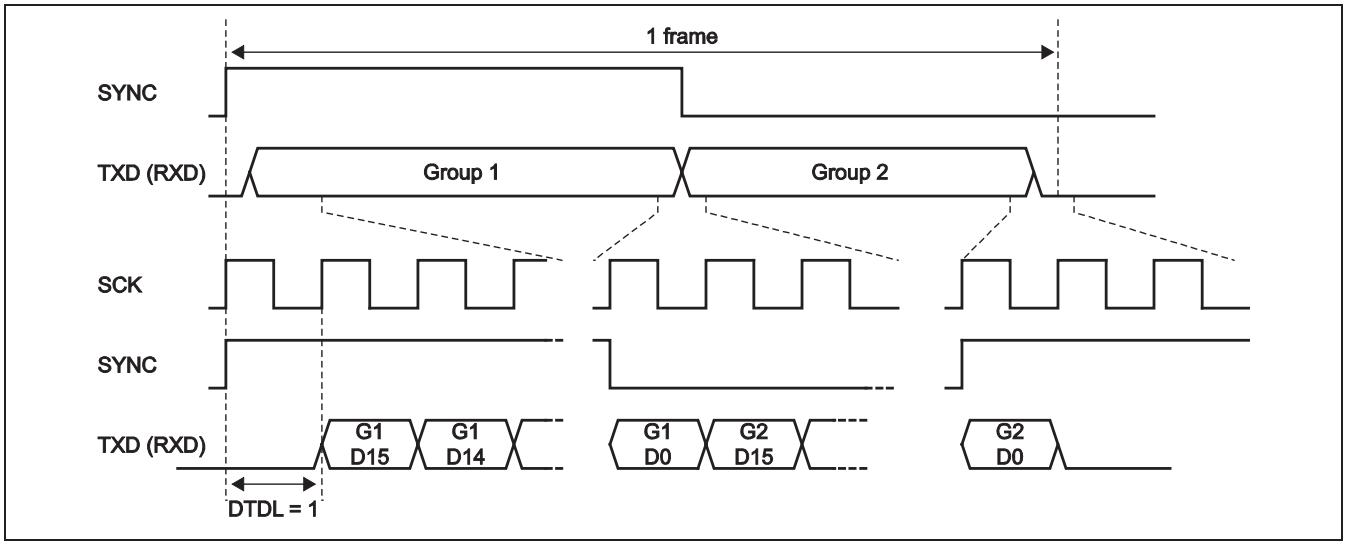

Figure 38.5 Synchronization Timing in L/R Synchronization Mode

(2) Transmit/receive timing

The timing of MSIOF_TXD transmission relative to MSIOF_SCK and of MSIOF_RXD can be specified as sampling on either edge, as listed below. The respective settings are made in TEDG and REDG bits of SICTR.

- Falling-edge sampling
- Rising-edge sampling

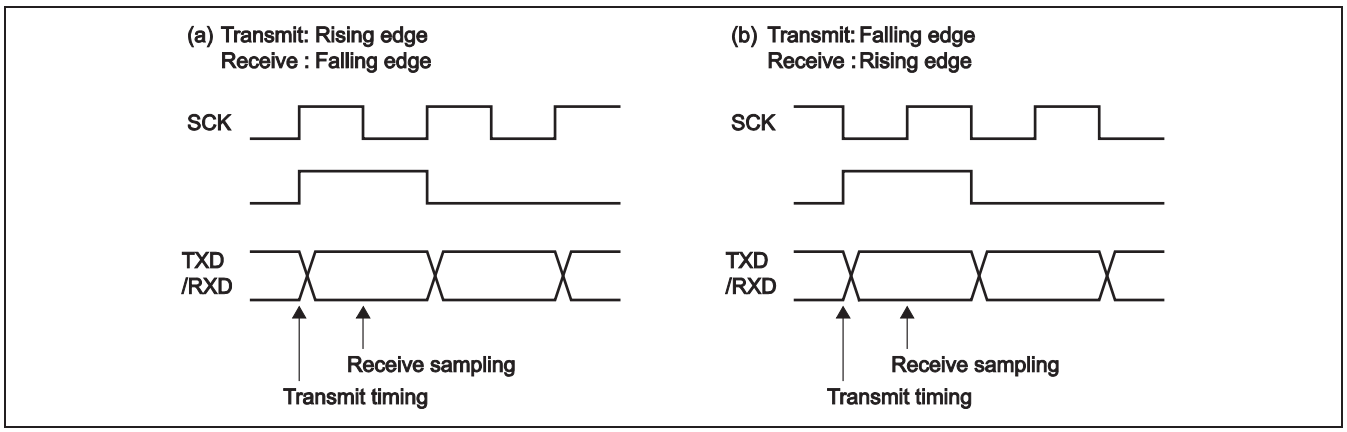

Figure 38.6 Transmit/Receive Timing

38.4.4 Transfer Data Allocation to Registers

(1) Transmit/receive data

Transmit/receive data (FIFO data and control data) should be written to or read from the following registers.

- Transmit FIFO data writing: SITFDR (32-bit access only by both CPU and DMAC)
- Receive FIFO data reading: SIRFDR (32-bit access only by both CPU and DMAC)

Figure 38.7 shows the bit alignment of these registers.

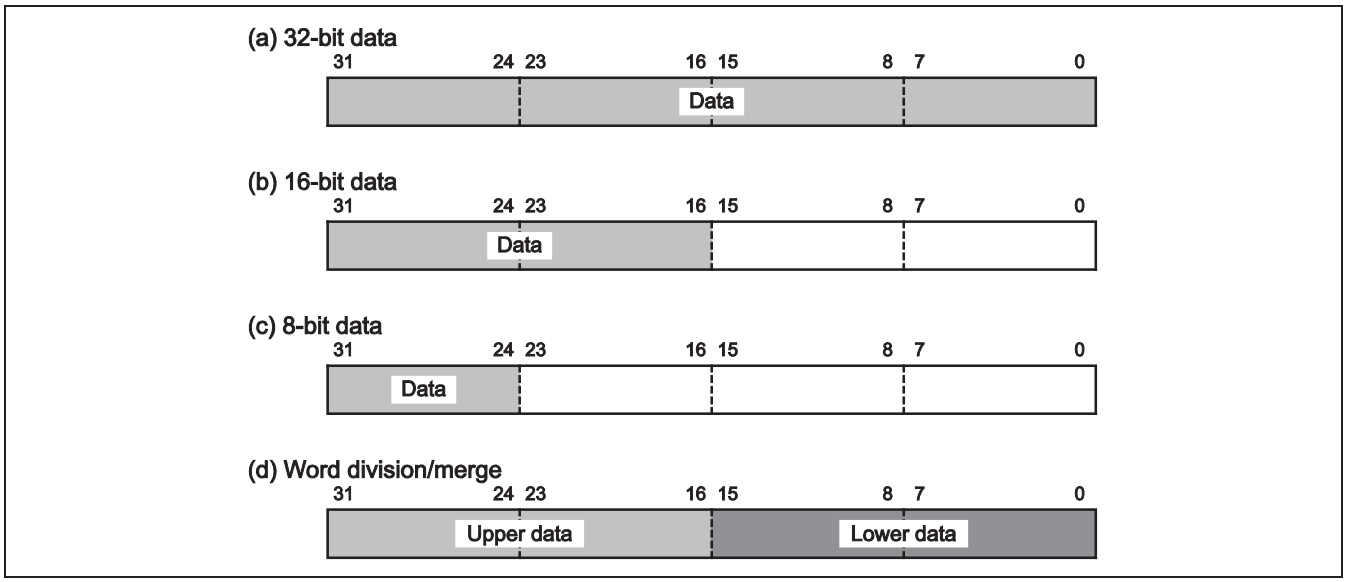

Figure 38.7 Transmit/Receive Data Bit Alignment

38.4.5 FIFO

(1) Overview

The transmit and receive FIFOs of the MSIOF have the following features.

- 32 bits × 64 stages for transmission and 32 bits × 128 stages for reception
- The FIFO pointer is updated in one read or write cycle regardless of the access size of the CPU or DMAC. (One access cannot be divided into multiple accesses.)

(2) Transfer request

A request for FIFO data transfer can be issued to the CPU or DMAC as the following interrupt sources.

- FIFO transmit request: TDREQ (interrupt source for transmission)
- FIFO receive request: RDREQ (interrupt source for reception)

The conditions for requesting FIFO data transfer can be specified separately for transmission and reception. The conditions for the transmit FIFO and receive FIFO are specified in the TFWM[2:0] bits and RFWM[2:0] bits in SIFCTR, respectively.

Table 38.5 Condition for Issuing Transmit Request

TFWM[2:0]	Number of Requested Stages	Condition for Transmit Request	Areas Used
000	1	64 stages of empty area	Smallest
001	32	32 or more stages of empty area	
010	40	24 or more stages of empty area	
011	48	16 or more stages of empty area	
100	52	12 or more stages of empty area	
101	56	8 or more stages of empty area	
110	60	4 or more stages of empty area	
111	64	1 or more stages of empty area	Largest

Table 38.6 Condition for Issuing Receive Request

RFWM[2:0]	Number of Requested Stages	Condition for Receive Request	Areas Used
000	1	1 or more stages of valid data	Smallest
001	4	4 or more stages of valid data	
010	8	8 or more stages of valid data	
011	16	16 or more stages of valid data	
100	32	32 or more stages of valid data	
101	64	64 or more stages of valid data	
110	128	128 stages of valid data	Largest

The maximum FIFO stages are always available even if the data area or empty area exceeds the size specified for the transfer condition. Accordingly, an overflow error or an underflow error occurs if the data area or empty area exceeds the maximum number of FIFO stages.

The FIFO transfer request is canceled when the specified condition is not satisfied even if the FIFO does not become empty or full.

(3) Number of FIFOs

The number of transmit and receive FIFO stages used are indicated by the following registers.

- Transmit FIFO: The number of empty FIFO stages is indicated by the TFUA[6:0] bits in SIFCTR.
- Receive FIFO: The number of valid data stages is indicated by the RFUA[8:0] bits in SIFCTR.

These registers show the number of data stages that can be transferred by the CPU. DMA transfer should be set the number of stage 1.

38.4.6 Transmit and Receive Procedures

(1) Transmission in master mode

Figure 38.8 shows an example of settings and operation for transmission in master mode.

No.	Operating flow	Description	Operation
1	SITMDR1/2/3 SITSCR SIFCTR SIIER setting	Operating mode Clock setting FIFO water mark Setting interrupt/DMA enable	
2	SICTR Set SICTR.TSCKE to 1	Transmission rate setting Baud rate generator starting	Output serial clock
3	TSCKE = 1 ? NO / YES	Read SICTR.TSCKE = 1	
4	SITFDR SITMDR1/2 setting	Write transmission data to FIFO	
5	Set SICTR.TXE to 1	Transmission enable	
6	TXE = 1 ? NO / YES	Read SICTR.TXE = 1	
7	Set SICTR.TFSE to 1	Starting MSIOF_SYNC output	
8	TFSE = 1 ? NO / YES	Read SICTR.TFSE = 1	
9	Starting transmission		Data transmission
10	TDREQ = 1 ? NO / YES		Generating interrupt/DMA request
11	Write transmission data to FIFO		
12	Transmission end ? NO / YES

16	TXE = 0 ? NO / YES Finish	Read SICTR.TXE = 0	

Figure 38.8 Example of Transmit Procedure in Master Mode

(2) Reception in master mode (with SITMDR1.PCON = 1)

Figure 38.9 shows an example of settings and operation for reception in master mode with SITMDR1.PCON = 1.

No.	Operating flow	Description	Operation
1	SIRMDR1/2/3 SITMDR1/2/3 SITSCR SIFCTR SIIER setting	Operating mode Operating mode (for SPI dummy transmission) Serial clock FIFO water mark Interrupt/DMA setting	
2	SICTR Set SICTR.TSCKE to 1	Baud rate setting Baud rate generator starting	Output serial clock
3	TSCKE = 1 ? NO YES	Read SICTR.TSCKE = 1	
4	SITFDR SITMDR1/2 setting	Write dummy transmission data to SITFDR The number of dummy data should equal the number of reception data.	
5	Set SICTR.TXE to 1 Set SICTR.RXE to 1	Transmission enable Reception enable	
6	TXE = 1 ? RXE = 1 ? NO YES	Read SICTR.TXE = 1 Read SICTR.RXE = 1	
7	Set SICTR.TFSE to 1	Frame sync enable	Output MSIOF_SYNC
8	TFSE = 1 ? NO YES	Read SICTR.TFSE = 1	
9	Synchronizing with MSIOF_SYNC (1) Transmission FIFO dummy data (2) Reception data		Transmission and reception
10	TDREQ=1? RDREQ=1? NO YES		Generating interrupt/DMA request
11	Write dummy data to FIFO Read fifo data from SIRFDR	Transmission dummy data Reception data reading	
12	Transmission/ reception end? NO YES		
13	Set SICTR.TFSE to 0	Disable frame sync enable	
14	TFSE = 0 ? NO YES	Read SICTR.TFSE = 0	
15	Set SICTR.TXE and SICTR.RXE to 0	Disable transmission enable and reception enable	
16	TXE = 0 ? RXE = 0 ? NO YES Finish	Read SICTR.TXE = 0 Read SICTR.RXE = 0	

Figure 38.9 Example of Receive Procedure in Master Mode (SITMDR1.PCON = 1)

(3) Transmission in slave mode

Figure 38.10 shows an example of settings and operation for transmission in slave mode.

No.	Operating flow	Description	Operation
1	Master device setting	Depend on master device	Signal polarity
2	SITMDR1/2/3 SIFCTR SIIER setting	Operating mode FIFO water mark Interrupt/DMA enable	
3	SITFDR SITMDR1/2 setting	Transmission data setting	
4	Set SICTR.TXE to 1	Setting transmission enable	
5		Read SICTR.TXE = 1	
6	Data transmission synchronize with MSIOF_SYNC		Data transmission
7			Generating interrupt/DMA request
8	Write FIFO data to SITFDR	Data transmission	
9			
10	Set SICTR.TXE to 0	Transmission disable	
11		Read SICTR.TXE = 0	

Figure 38.10 Example of Transmit Procedure in Slave Mode

(4) Reception in slave mode

Figure 38.11 shows an example of settings and operation for reception in slave mode.

No.	Operating flow	Description	Operation
1	Master device setting	Depend on master device	Signal polarity
2	SIRMDR1/2/3 SIFCTR SIIER setting	Operating mode FIFO water mark Interrupt/DMA enable	
3	Set SICTR.RXE to 1	Setting receive enable	
4		Read SICTR.RXE = 1	
5	Data reception		Receive data
6			Generating interrupt/DMA request
7	Read SIRFDR	Data read from FIFO	
8			
9	Set SICTR.RXE to 0	Reception disable	
10		Read SICTR.RXE = 0	

Figure 38.11 Example of Receive Procedure in Slave Mode

(5) Reset

After a power-on reset is applied, module stop state is canceled, or a reset signal is asserted through the TXRST or RXRST setting in SICTR, it takes about 20 cycles of module clock to complete the internal reset of the module. During a period from the beginning of reset until the TXRST or RXRST value is read as 0, do not modify the control register or access the FIFOs.

The MSIOF can separately reset the transmit and receive units by setting the following bits to 1.

- Transmit reset: TXRST bit in SICTR
- Receive reset: RXRST bit in SICTR

Table 38.7 Transmit and Receive Reset

Type	Objects Initialized
Transmit reset	SITFDR (Transmit FIFO write pointer) TDREQ bits in SISTR TXE bit in SICTR
Receive reset	SIRFDR (Receive FIFO read pointer) RDREQ bits in SISTR RXE bit in SICTR

(6) Initial operating mode

After a power-on reset, both transmit and receive units are initialized to master mode (0 is output through MSIOF_SCK and MSIOF_SYNC). When using slave mode, keep the connected device outputting 0 until the operating mode setting is completed.

38.4.7 Interrupts

The MSIOF has one type of interrupt.

(1) Interrupt sources

Interrupts can be generated by several sources. Each source is shown as an MSIOF status in SISTR. Table 38.8 lists the MSIOF interrupt sources.

Table 38.8 MSIOF Interrupt Sources

No.	Classification	Bit Name	Function Name	Description
1	Transmission	TDREQ	Transmit FIFO transfer request	The transmit FIFO has empty space of specified size or more.
2		TFEMP	Transmit FIFO empty	The transmit FIFO is empty.
3		TEOF	Frame transmission end	Transmission of data with a length of one frame is completed.
4	Reception	RDREQ	Receive FIFO transfer request	The receive FIFO stores data of specified size or more.
5		RFFUL	Receive FIFO full	The receive FIFO is full.
6		REOF	Frame reception end	Reception of data with a length of one frame is completed.
7	Error	TFUDF	Transmit FIFO underflow	Serial data transmit timing has arrived while the transmit FIFO is empty.
8		TFOVF	Transmit FIFO overflow	The transmit FIFO is written to while it is full.
9		RFOVF	Receive FIFO overflow	Serial data is received while the receive FIFO is full.
10		RFUDF	Receive FIFO underflow	The receive FIFO is read while the receive FIFO is empty.
11		TFSERR	Transmit FS error	A transmit frame synchronization signal is input before the specified number of bits has been reached (in slave mode).
12		RFSERR	Receive FS error	A receive frame synchronization signal is input before the specified number of bits has been reached (in slave mode).

Whether an interrupt is issued from an interrupt source is determined by the SIIER settings. If an interrupt source bit is set to 1 and the corresponding bit in SIIER is set to 1, an MSIOF interrupt is issued.

(2) TDREQ and RDREQ

The transmit FIFO transfer request (TDREQ) and receive FIFO transfer request (RDREQ) are signals indicating the state. If the state changes after TDREQ or RDREQ is set, it is automatically cleared by the MSIOF.

When the DMA transfer is used, a DMA transfer request signal is pulled low for one cycle at the end of DMA transfer.

(3) Processing when errors occur

- Transmit FIFO underflow (TFUDF)
  The value specified with TXDIZ in SICTR is output.
- Transmit FIFO overflow (TFOVF)
  The contents of the transmit FIFO are protected, and the write operation causing the overflow is ignored.
- Receive FIFO overflow (RFOVF)
  Data causing the overflow is discarded and lost.
- Receive FIFO underflow (RFUDF)
  An undefined value is output on the bus.
- Transmit FS error (TFSERR)
  The internal counter is reset according to the synchronization signal in which an error occurs.
- Receive FS error (RFSERR)
  The internal counter is reset according to the synchronization signal in which an error occurs.

38.4.8 Transmit and Receive Timing

Examples of the MSIOF serial transmission and reception are shown in Figures 38.12 and 38.13.

(1) 16-bit synchronization pulse

Synchronization pulse method, one group, one word, 16 bits in a word, no bit delay

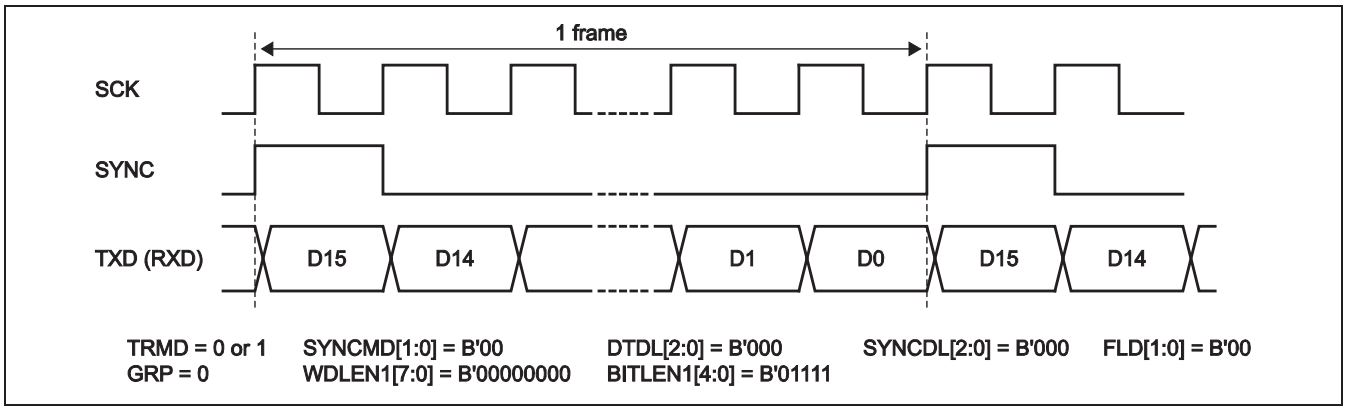

Figure 38.12 Transmit and Receive Timing (16 Bits)

(2) 32-bit synchronization pulse

Synchronization pulse method, one group, 32 words, 32 bits in a word, 1-bit delay

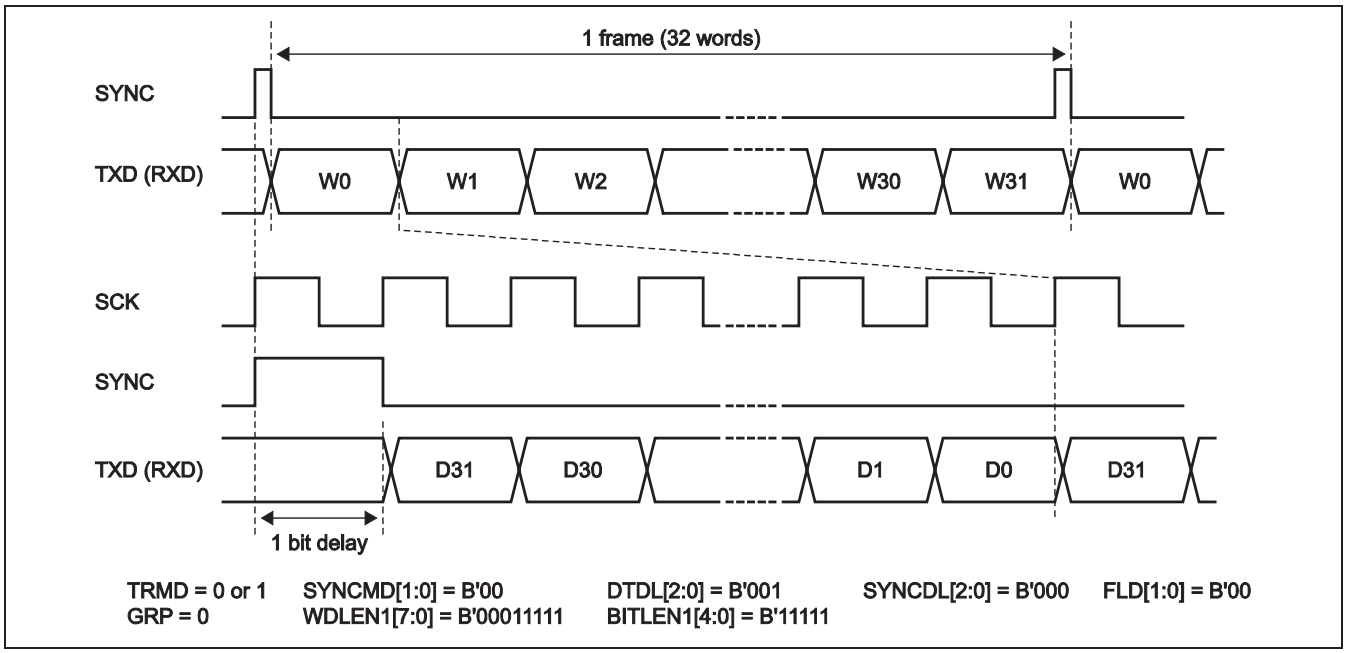

Figure 38.13 Transmit and Receive Timing (32 Bits)

(3) 32-bit iis transmission

L/R mode, 2 groups, 1 word for each group, 32-bit word for each group, 1-bit delay

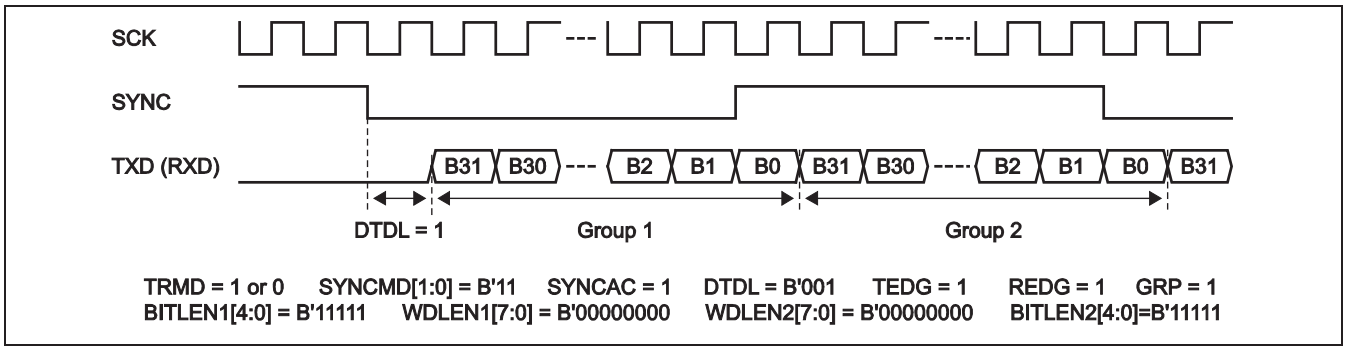

Figure 38.14 Transmit Timing (24-Bit IIS)

38.4.9 SPI

With the appropriate register settings, the MSIOF can be used as an SPI device.

(1) Example of SPI device connection

Figure 38.15 shows an example of connection with an SPI device.

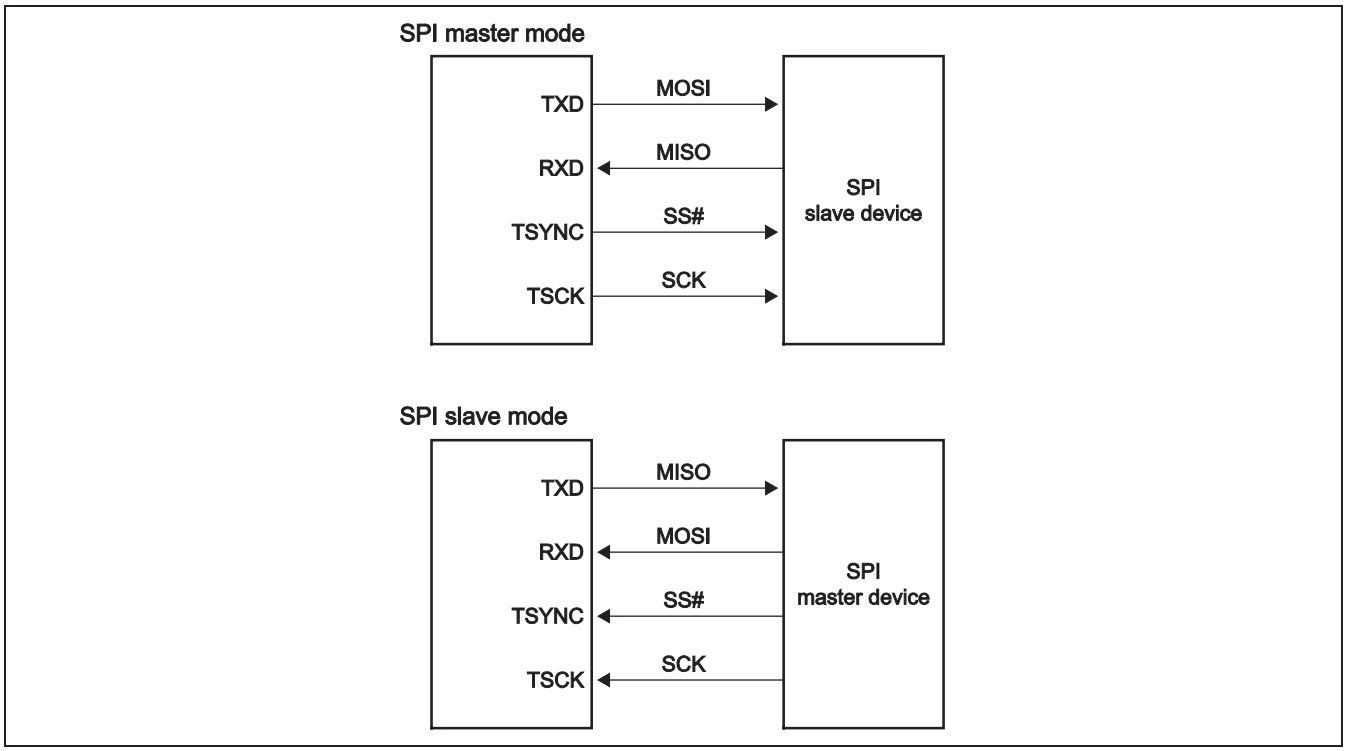

Figure 38.15 Example of SPI Device Connection

(2) SPI serial clock timing

Figures 38.16 and 38.17 show the data and clock timing in SPI mode. As shown in the figures, four types of serial transfer formats can be used.

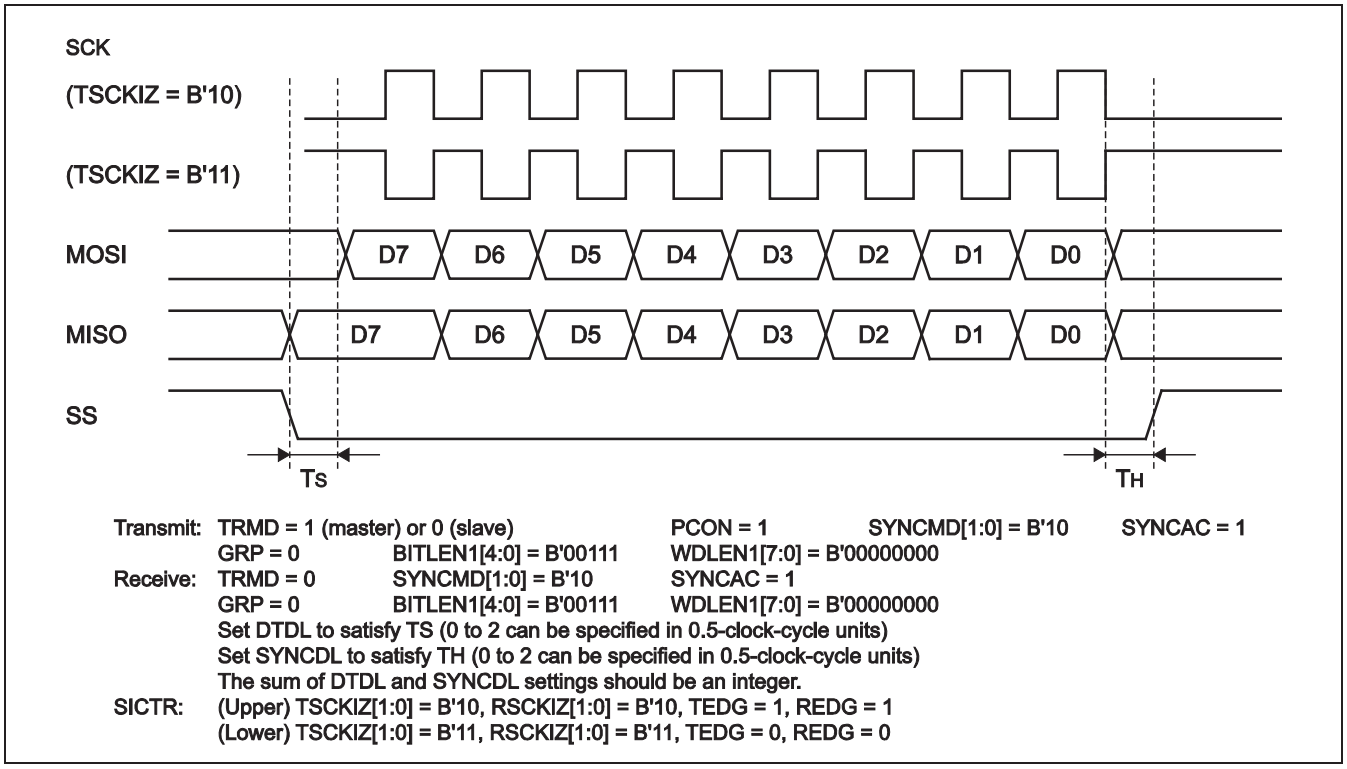

Figure 38.16 SPI Clock and Data Timing 1

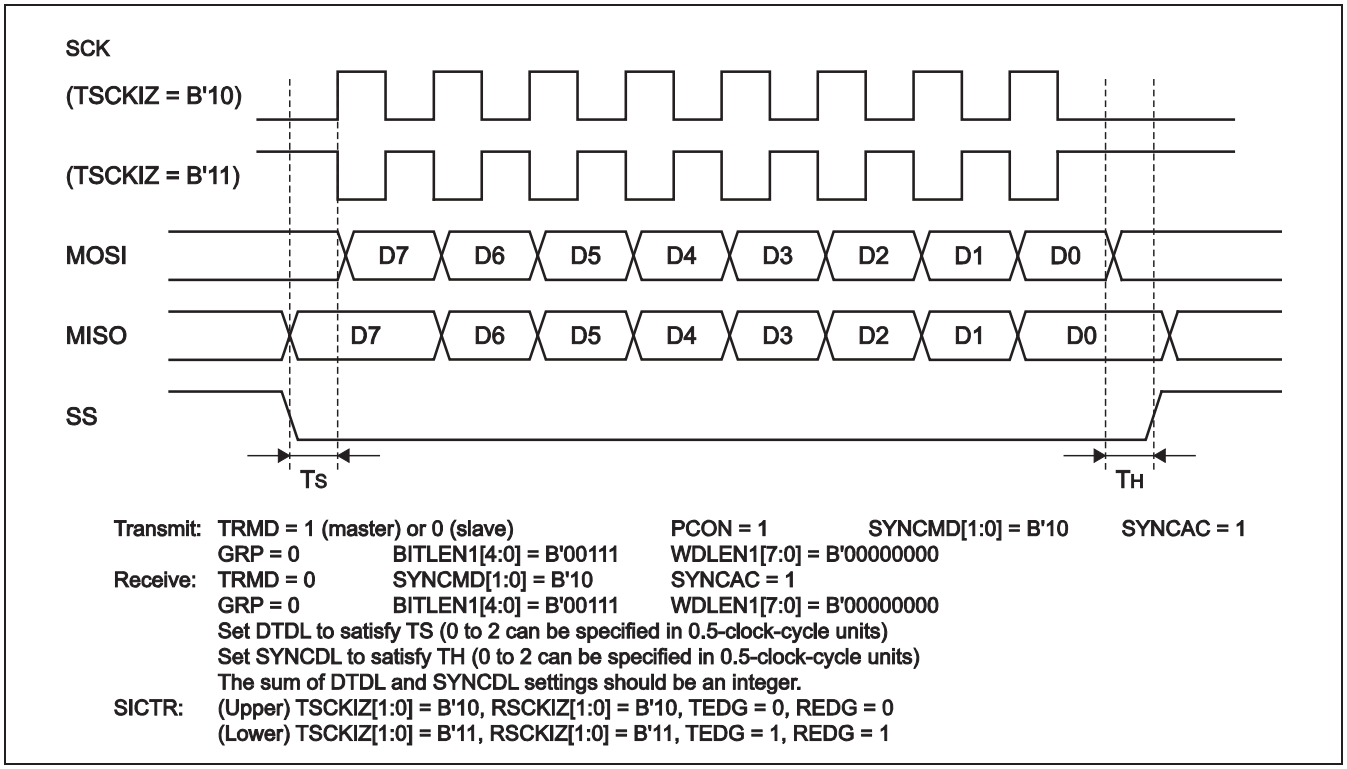

Figure 38.17 SPI Clock and Data Timing 2

38.4.10 Notes for Using SPI Mode

- For SPI master mode operation, set the FLD bits in SITMDR1 for at least 3 cycles of module clock.
- For SPI slave mode operation, set the frame synchronization signal interval to at least 4 cycles of module clock.
- For SPI slave mode operation, the setting for data delay should be always set to 0.
- For SPI slave mode operation, TXDIZ bits work on SS signal invalid state.
- Limitation:

  When the MSIOF operates with all of the following condition 1 to 3, the MSIOF in SPI slave mode cannot start the next transmission. The MSIOF cannot support SPI mode under following condition.

  1) MSIOF is in SPI slave mode (SITMDR1.TRMD = 0, SITMDR1.SYNCMD[1:0] = 10)

  2) SYNC (CS) signal is being asserted from master

  3) TXE or RXE in SICTR is set to 1 during SYNC (CS) is asserted

  — Description:

  This limitation means the MSIOF cannot respond to the SYNC (CS).

  It is necessary to control the MSIOF enabling timing by the master and system.

  — Work-around

  Use master mode for SPI.

  If use slave mode for SPI, consider following alternative.

  — Alternative

  If the master device can support handshaking, use the handshaking transmission.

  For the MSIOF in SPI slave mode, use with the GPIO output for SPI handshaking; the system operation must be tested and evaluated thoroughly by user.

38.4.11 IIS

This module can support IIS format with following setting which is shown in Figures 38.18 and 38.19. BITLEN1 and BITLEN2 bits will change by usage.

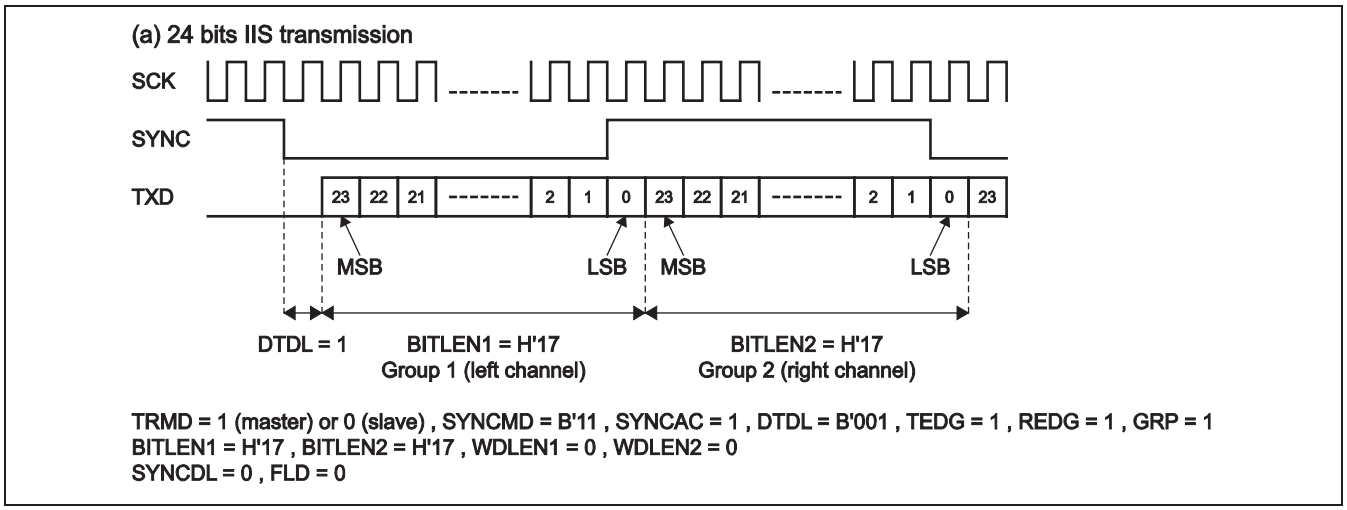

Figure 38.18 24 Bits IIS Transmission

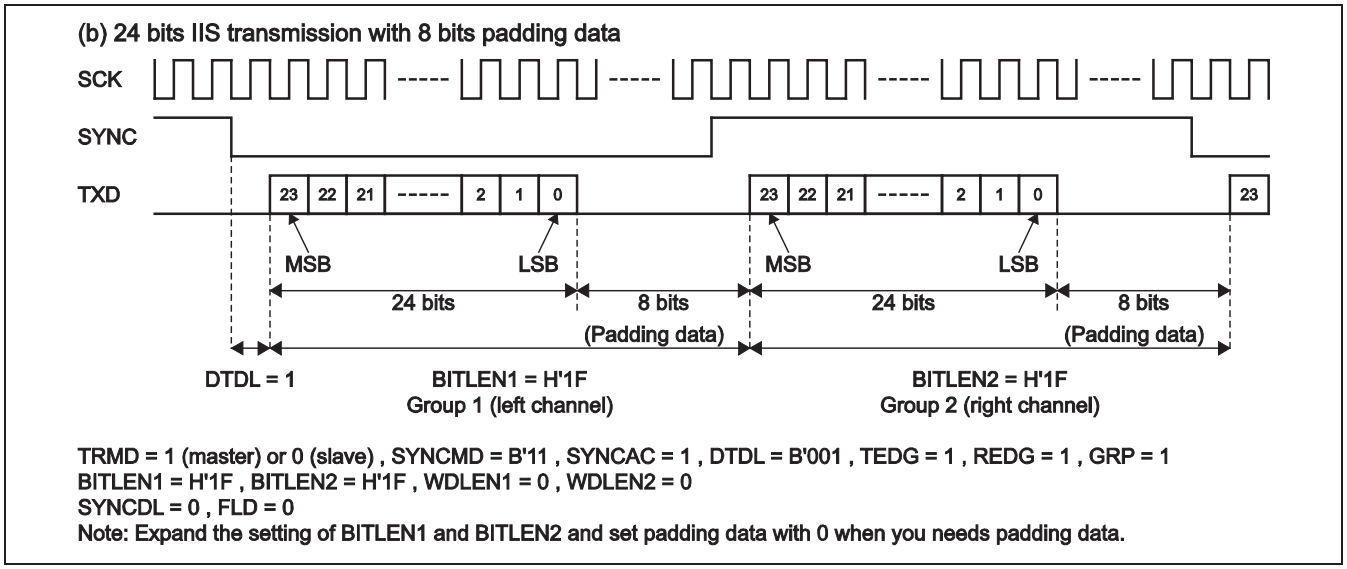

Figure 38.19 24 Bits IIS Transmission with 8 Bits Padding Data

39. Quad Serial Peripheral Interface

39.1 Overview

This LSI has two channels of QSPI. Features and functions of each product are basically the same, however, read value of WSWAP bit of SPCR register and BSWAP bit of SPCR register are always 0. See section 39.4.1.

39.2 Features

This module has the following features.

- Capable of serial communications through single-/dual-/quad-SPI operation
  - — Single-SPI operation
    Use of MOSI (master out–slave in), MISO (master in–slave out), SSL (slave select), and SPCLK (SPI clock) signals allows for serial access (four-wire method).
    Single-direction MOSI and MISO pins.
    Only master mode is available.
    SSL and SPCLK serve as output pins.
  - — Dual-SPI operation
    Use of IO1, IO0, SSL, and SPCLK signals allows for serial access (four-wire method).
    Bidirectional IO1 and IO0 pins.
    Only master mode is available.
  - — Quad-SPI operation
    Use of IO3 to IO0, SSL, and SPCLK signals allow for serial access (six-wire method).
    Bidirectional IO3 to IO0 pins.
    Only master mode is available.
- Transfer data length
  Transfer data length is selectable from 8 bits to 128 Gbits in single-SPI master mode or dual-/quad-SPI modes.
  Data is continuously transferred one through 4,294,967,296 times in 8-, 16-, or 32-bit units.
- Bit rate
  SPCLK is generated by the on-chip baud rate generator, by dividing QSPIϕ with division rate 1 to 4080 in master mode.
  (SPCLK can be generated by dividing QSPIϕ by the on-chip baud rate generator.)
- Buffer configuration
  8 bits × 32 buffers for transmission and 8 bits × 32 buffers for reception
- Shift registers
  32 bits each for transmission and reception
- SSL pin control function
  Master mode: Controllable delay from SSL output assertion to SPCLK operation (clock delay)
  Range: 0 to 8 SPCLK cycles (set in one SPCLK-cycle units)
  Controllable delay from SPCLK stoppage to SSL output negation (SSL negation delay)
  Range: 0 to 8 SPCLK cycles (set in one SPCLK-cycle units)
  Controllable wait for next-access SSL output assertion (next-access delay)
  Range: 0 to 8 SPCLK cycles (set in one SPCLK-cycle units)
  Capable of holding SSL output value from transfer end to next access
  Function for changing SSL polarity

- Master transfer control

  A transfer of up to four commands can be executed sequentially in looped execution.

  Single-SPI mode or dual-/quad-SPI write operation: A transfer can be started when data is written to the transmit buffer.

  Dual-/quad-SPI read operation: A transfer can be started when the SPI function is enabled while there is enough space for receiving the specified length of data in the receive buffer.

  IO3 to IO0 and MOSI output values can be specified during SSL negation.

  IO3 and IO2 output values can be specified in single-/dual-SPI modes.
- Interrupt sources

  Maskable interrupt sources:

  Receive buffer full interrupt

  Transmit buffer empty interrupt

  Error interrupt (underrun error, overrun error, and mode fault error)
- Others

  Provides loop back mode.

  Provides a function for initializing this module.

Hereafter, the single-/dual-/quad-SPI master modes are collectively called the maser mode.

39.3 Input/Output Pins

Table 39.1 shows the pin configuration.

Table 39.1 Pin Configuration

Name	Pin Name	I/O	Function
Clock pin	SPCLK	I/O	Clock input/output
Master transmit data pin/data 0 pin*1	MOSI/IO0	I/O	Master transmit data/data 0
Slave transmit data pin/data 1 pin*1	MISO/IO1	I/O	Slave transmit data/data 1
Data 2 pin*2	IO2	I/O	Data 2
Data 3 pin*2	IO3	I/O	Data 3
Slave select pin	SSL	I/O	Slave selection

Notes: 1. In single-SPI mode, MOSI and MISO are enabled; IO0 and IO1 in dual-/quad-SPI modes.
2. In single-/dual-SPI modes, a fixed value according to register setting is output; IO2 and IO3 are output in quad-SPI mode.

39.4 Register Descriptions

Table 39.2 shows the register configuration. The base address of QSPI0 is H'E6B1_0000, QSPI1 is H'EE20_0000.

Table 39.2 Register Configuration

Register Name	Abbreviation	R/W	Initial Value	Address	Access Size
Control register	SPCR	R/W	H'00000660	H'00	8, 16, 32
Slave select polarity register	SSLP	R/W	H'00000660	H'01	8, 16, 32
Pin control register	SPPCR	R/W	H'00000660	H'02	8, 16, 32
Status register	SPSR	R/(W)*	H'00000660	H'03	8, 16, 32
Data register	SPDR	R/W	Undefined	H'04	8, 16, 32
Sequence control register	SPSCR	R/W	H'0000FF00	H'08	8, 16, 32
Sequence status register	SPSSR	R	H'0000FF00	H'09	8, 16, 32
Bit Rate register	SPBR	R/W	H'0000FF00	H'0A	8, 16, 32
Data control register	SPDCR	R/W	H'0000FF00	H'0B	8, 16, 32
Clock delay register	SPCKD	R/W	H'00000000	H'0C	8, 16, 32
Slave select negation delay register	SSLND	R/W	H'00000000	H'0D	8, 16, 32
Next-access delay register	SPND	R/W	H'00000000	H'0E	8, 16, 32
Command register 0	SPCMD0	R/W	H'E001E001	H'10	16, 32
Command register 1	SPCMD1	R/W	H'E001E001	H'12	16, 32
Command register 2	SPCMD2	R/W	H'E001E001	H'14	16, 32
Command register 3	SPCMD3	R/W	H'E001E001	H'16	16, 32
Buffer control register	SPBFCR	R/W	H'00000000	H'18	8, 16, 32
Buffer data count register	SPBDCR	R/W	H'00000000	H'1A	16, 32
Transfer data length multiplier setting register 0	SPBMUL0	R/W	H'00000001	H'1C	32
Transfer data length multiplier setting register 1	SPBMUL1	R/W	H'00000001	H'20	32
Transfer data length multiplier setting register 2	SPBMUL2	R/W	H'00000001	H'24	32
Transfer data length multiplier setting register 3	SPBMUL3	R/W	H'00000001	H'28	32

Note: * Only 0 can be written to clear the flag.

39.4.1 Control Register (SPCR)

SPCR sets the operating mode. If the master/slave mode select bit (MSTR) is modified while the SPI function enable bit (SPE) is set to 1 (that is, this module is enabled), the subsequent operation cannot be guaranteed.

- Longword access:

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R/W	R/W	R	R/W	R/W	R/W	R	R	R	R	R	R	R	R

- Byte access:

Bit:	7	6	5	4	3	2	1	0
	SPRIE	SPE	SPTIE	SPEIE	MSTR	—	WSWAP	BSWAP
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	SPRIE	0	R/W	Receive Interrupt Enable Enables or disables generation of receive interrupt requests when the number of receive data units in the receive buffer is equal to or greater than the specified receive buffer data triggering number and the receive buffer full flag (SPRFF) in the status register (SPSR) is set to 1. 0: Disables the generation of receive interrupt requests. 1: Enables the generation of receive interrupt requests.
6	SPE	0	R/W	SPI Function Enable Setting this bit to 1 enables the SPI module function. Setting this bit to 0 initializes a part of the module function. 0: Disables the module function. 1: Enables the module function.
5	SPTIE	0	R/W	Transmit Interrupt Enable Enables or disables generation of transmit interrupt requests when the number of transmit data units in the transmit buffer is equal to or less than the specified transmit buffer data triggering number and the transmit buffer empty flag (SPTEF) in SPSR is set to 1. 0: Disables the generation of transmit interrupt requests. 1: Enables the generation of transmit interrupt requests.
4	SPEIE	0	R/W	Error Interrupt Enable Enables or disables generation of error interrupt requests when an underrun error, an overrun error, or a mode fault error is detected and the corresponding flag in SPSR is set to 1. 0: Disables the generation of error interrupt requests. 1: Enables the generation of error interrupt requests. Note: This setting is valid only in single-SPI slave mode.

Bit	Bit Name	Initial Value	R/W	Description
3	MSTR	0	R/W	Master/Slave Mode Select Selects the master or slave mode. This bit specifies the direction of the signals through the SPCLK and SSL pins. The slave mode can be selected only when the SPI operating mode is set to single-SPI. Master/slave switching should be done only while the SPE bit is 0; otherwise, the subsequent operation cannot be guaranteed. This module supports only the master mode; be sure to set this bit to 1 to use this module. 0: Slave mode 1: Master mode
2	—	0	R/W	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
1	WSWAP	0	R/W	Word Swap Selects word-swap of read-data for DMAC. By setting this bit to 1, read-data to DMAC is swapped in word units. That is, bit[31:16] and bit[15:0] are swapped. 0: No word swap for read-data for DMAC. 1: Perform word swap for read-data for DMAC. Note: The read value of this bit is always 0.
0	BSWAP	0	R/W	Byte Swap Selects byte-swap of read-data for DMAC. By setting this bit to 1, read-data to DMAC is swapped in byte units. That is, bit[31:24] and bit[23:16] are swapped, and at the same time, bit[15:8] and bit[7:0] are also swapped. 0: No byte swap for read-data for DMAC. 1: Perform byte swap for read-data for DMAC. Note: The read value of this bit is always 0.

39.4.2 Slave Select Polarity Register (SSLP)

SSLP sets the polarity of the SSL signal. If the contents of SSLP are modified while the SPE bit in the control register (SPCR) is set to 1, the subsequent operation cannot be guaranteed.

- Longword access:

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

- Byte access:

Bit:	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	SSLP
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 1	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
0	SSLP	0	R/W	SSL Signal Polarity Setting Sets the polarity of the SSL signal. 0: SSL signal low-active 1: SSL signal high-active

39.4.3 Pin Control Register (SPPCR)

SPPCR sets the modes of the pins. If the contents of SPPCR are modified while the SPE bit in SPCR is set to 1, the subsequent operation cannot be guaranteed.

- Longword access:

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SPRIE	SPE	SPTIE	SPEIE	MSTR	—	WSWAP	BSWAP	—	—	—	—	—	—	—	SSLP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	MOIFE	MOIFV	—	IO3FV	IO2FV	SPLP	SPRFF	TEND	SPTEF	—	—	—	—	—
Initial value:	0	0	0	0	0	1	1	0	0	1	1	0	0	0	0	0
R/W:	R	R	R/W	R/W	R	R/W	R/W	R/W	R	R	R	R	R	R	R	R

- Byte access:

Bit:	7	6	5	4	3	2	1	0
	—	—	MOIFE	MOIFV	—	IO3FV	IO2FV	SPLP
Initial value:	0	0	0	0	0	1	1	0
R/W:	R	R	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
5	MOIFE	0	R/W	Master-Mode Output Idle Value Fixing Enable Fixes the pin output value in an SSL negation period or the SSL keeping period during a burst transfer in master mode. In single-SPI mode, this bit setting applies to MOSI. In dual-SPI mode, the setting of this bit is applied to IO1 and IO0. In quad-SPI mode, the setting of this bit is applied to IO3 to IO0. 0: Output value equals final data from previous transfer. 1: Output value equals the value set in the MOIFV bit. Note: In dual-/quad-SPI modes, IO1 and IO0/IO3 to IO0 are driven to the Hi-Z state regardless of the setting of this bit (see section 39.5.2, Pin Control).
4	MOIFV	0	R/W	Master-Mode Output Idle Fixed Value If the MOIFE bit is 1 in master mode, this module, according to the setting of this bit, determines the output value during the SSL negation period. 0: Output pin idle fixed value equals 0. 1: Output pin idle fixed value equals 1.
3	—	0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.

Bit	Bit Name	Initial Value	R/W	Description
2	IO3FV	1	R/W	Single-/Dual-SPI Mode IO3 Output Fixed Value Fixes the output direction of the IO3 pin in single-/dual-SPI modes. This bit is valid only in single-/dual-SPI modes, and is not affected by the value of MOIFE or MOIFV bit. 0: IO3 output fixed value equals 0. 1: IO3 output fixed value equals 1.
1	IO2FV	1	R/W	Single-/Dual-SPI Mode IO2 Output Fixed Value Fixes the output direction of the IO2 pin in single-/dual-SPI modes. This bit is valid only in single-/dual-SPI modes, and is not affected by the value of MOIFE or MOIFV bit. 0: IO2 output fixed value equals 0. 1: IO2 output fixed value equals 1.
0	SPLP	0	R/W	Loopback Mode When the SPLP bit is set to 1, this module shuts off the path between the data I/O pin and the transmit/receive shift register, and connects the input path and the output path for the transmit/receive shift register. 0: Normal mode 1: Loopback mode Note: When the loopback mode is specified in dual-/quad-SPI modes, the SPI read/write access setting bit (SPRW) in command registers 0 to 3 (SPCMD0 to SPCMD3) should be set to 0 (write operation). Do not modify the setting of this bit during data transfer.

39.4.4 Status Register (SPSR)

SPSR indicates the operating status.

- Longword access:

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R/W	R/W	R	R/W	R/W	R/W	R	R	R	R	R	R	R	R

- Byte access:

Bit:	7	6	5	4	3	2	1	0
	SPRFF	TEND	SPTEF	—	—	—	—	—
Initial value:	0	1	1	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R

Note: Only 0 can be written to the flags after 1 is read.

Bit	Bit Name	Initial Value	R/W	Description
7	SPRFF	0	R	Receive Buffer Full Flag Indicates that the number of receive data units in the receive buffer is equal to or greater than the receive buffer data triggering number specified in the buffer control register. 0: The number of receive data units in the receive buffer is less than the receive buffer data triggering number. 1: The number of receive data units in the receive buffer is equal to or greater than the receive buffer data triggering number. [Clearing conditions] • The receive buffer data is read until the number of data units in the receive buffer becomes less than the specified receive buffer data triggering number. • Receive buffer data reset is enabled. • Power-on reset. [Setting condition] • The number of data units in the receive buffer is equal to or greater than the specified receive buffer data triggering number.

Bit	Bit Name	Initial Value	R/W	Description
6	TEND	1	R	Transmit End Flag This bit is set to 1 when transmission is completed, and this bit is 0 when transmission is not completed. [Clearing conditions] • When transmit data are moved from the transmit register to the transmit shift register. • When data reception is started in dual-/quad-SPI modes. [Setting conditions] • When the number of data units in the transmit buffer is zero when a serial transfer is completed (except when the dummy data transmission enable bit (TXDMY) is set to 1). • When there is not enough space for receiving the specified length of data in the receive buffer when a serial transfer is completed.
5	SPTEF	1	R	Transmit Buffer Empty Flag Indicates that the number of transmit data units in the transmit buffer is equal to or less than the transmit buffer data triggering number specified in the buffer control register. 0: The number of transmit data units in the transmit buffer exceeds the specified transmit buffer data triggering number. 1: The number of transmit data units in the transmit buffer is equal to or less than the specified transmit buffer data triggering number. [Clearing condition] • When data is written to the transmit buffer until the number of transmit data units in the transmit buffer exceeds the specified transmit buffer data triggering number. [Setting conditions] • When the number of transmit data units in the transmit buffer is equal to or less than the specified transmit buffer data triggering number. • When transmit buffer data reset is enabled. • Power-on reset.
4 to 0	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.

39.4.5 Data Register (SPDR)

SPDR accesses transmit/receive data buffer.

The transmit buffer (SPTXB) and receive buffer (SPRXB) are independent and are mapped to SPDR.

When data is written to SPDR, the data will be written to the transmit buffer.

When data is read from SPDR, the data will be read from the receive buffer.

SPDR should be read or written to in byte, word, or longword units.

When SPDR is read or written to with the longword-, word-, or byte-access width, the receive or transmit data should be read from or written to the following bits.

Longword: Bits 31 to 0
Word: Bits 15 to 0
Byte: Bits 7 to 0

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R/W:	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7 to 2	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
1, 0	SPSS[1:0]	00	R	Sequence Status During sequence control, these bits indicate one of SPCMD0 to SPCMD3 that is currently referenced. 00: SPCMD0 01: SPCMD1 10: SPCMD2 11: SPCMD3

39.4.8 Bit Rate Register (SPBR)

SPBR sets the bit rate when this module operates in master mode. If the contents of SPBR are modified while the SPE and MSTR bits in SPCR are 1, the subsequent operation cannot be guaranteed.

- Longword access:

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	SPSC[1:0]		—	—	—	—	—	—	SPSS[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SPBR[7:0]								TXDMY	—	—	—	—	—	—	—
Initial value:	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R

- Byte access:

Bit:	7	6	5	4	3	2	1	0
	SPBR[7:0]							
Initial value:	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

The bit rate is determined by combinations of SPBR settings and the values in the bit rate division setting bits (BRDV[1:0]) in SPCMD0 to SPCMD3.

In single-SPI slave mode, the bit rate depends on the input clock bit rate regardless of the setting of SPBR[1:0] and BRDV[1:0] bits.

When SPBR is set to 0, the base bit rate is selected.

The equation for calculating the bit rate when SPBR is not 0 is given below. In the equation, n denotes an SPBR setting (1, …, 255), and N denotes bit settings in the bits BRDV[1:0] (0, 1, 2, 3).

$$\text{Bit rate} = \frac{f(\text{QSPI}\phi)}{2 \times n \times 2^N}$$

Table 39.3 shows examples of the relationship between SPBR and BRDV[1:0] bits settings.

Table 39.3 Relationship between SPBR and BRDV[1:0] Settings

			Bit Rate	
SPBR[7:0] (n)	**BRDV[1:0] (N)**	**Division Ratio**	**QSPIϕ = 78 MHz**	**QSPIϕ = 97.5 MHz**
0	0	1	78.0 Mbps	97.50 Mbps
1	0	2	39.0 Mbps	48.75 Mbps
2	0	4	19.5 Mbps	24.38 Mbps
3	0	6	13.0 Mbps	16.25 Mbps
4	0	8	9.75 Mbps	12.19 Mbps
5	0	10	7.80 Mbps	9.75 Mbps
6	0	12	6.50 Mbps	8.13 Mbps
6	1	24	3.25 Mbps	4.06 Mbps
6	2	48	1.625 Mbps	2.03 Mbps
6	3	96	812.5 kbps	1.02 Mbps
255	3	4080	19.12 kbps	23.90 kbps

39.4.9 Data Control Register (SPDCR)

SPDCR enables or disables dummy data transmission when this module operates in master mode.

- Longword access:

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	SPSC[1:0]		—	—	—	—	—	—	SPSS[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SPBR[7:0]								TXDMY	—	—	—	—	—	—	—
Initial value:	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R

- Byte access:

Bit:	7	6	5	4	3	2	1	0
	TXDMY	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
7	TXDMY	0	R/W	Dummy Data Transmission Enable Enables or disables dummy data transmission from the MOSI pin when the transmit buffer is empty in single-SPI master mode. The last output value in the previous transmit data is used as dummy data. Specifically, if this bit is set to 1 when the transmit buffer is empty, 0 is output from the MOSI pin as dummy data. This bit setting can be changed while the transmit end flag (TEND) in SPSR is 1. Otherwise, operation cannot be guaranteed. 0: Disables dummy data transmission. 1: Enables dummy data transmission.
6 to 0	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.

39.4.10 Clock Delay Register (SPCKD)

SPCKD sets a period (clock delay) from the beginning of SSL signal assertion to SPCLK oscillation when the clock delay setting enable bit (SCKDEN) in SPCMD0 to SPCMD3 is 1 in master mode. If the contents of SPCKD are modified while the SPE and MSTR bits in SPCR are 1, the subsequent operation cannot be guaranteed.

Be sure to set this register to H'00 when using this module in single-SPI slave mode.

- Longword access:

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	SCKDL[2:0]			—	—	—	—	—	SLNDL[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W	R/W

Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
2 to 0	SCKDL[2:0]	000	R/W	Clock Delay Setting These bits set a period (clock delay) from the beginning of SSL signal assertion to SPCLK oscillation when the SCKDEN bit in SPCMD0 to SPCMD3 is 1. 000: 1 SPCLK cycle 001: 2 SPCLK cycles 010: 3 SPCLK cycles 011: 4 SPCLK cycles 100: 5 SPCLK cycles 101: 6 SPCLK cycles 110: 7 SPCLK cycles 111: 8 SPCLK cycles

39.4.11 Slave Select Negation Delay Register (SSLND)

SSLND sets a period (SSL negation delay) from the transmission of a final SPCLK edge to the negation of the SSL signal during a serial transfer when the SSL negation delay setting enable bit (SLNDEN) in SPCMD0 to SPCMD3 is 1 in master mode. If the contents of SSLND are modified while the SPE and MSTR bits in SPCR are 1, the subsequent operation cannot be guaranteed.

Be sure to set this register to H'00 when using this module in single-SPI slave mode.

- Longword access:

R/W:	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7 to 3	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
2 to 0	SLNDL[2:0]	000	R/W	SSL Negation Delay Setting These bits set a period (SSL negation delay) from the transmission of a final SPCLK edge to the negation of the SSL signal during a serial transfer when the SLNDEN bit in SPCMD0 to SPCMD3 is 1. 000: 0.5 SPCLK cycles 001: 1.5 SPCLK cycles 010: 2.5 SPCLK cycles 011: 3.5 SPCLK cycles 100: 4.5 SPCLK cycles 101: 5.5 SPCLK cycles 110: 6.5 SPCLK cycles 111: 7.5 SPCLK cycles

39.4.12 Next-Access Delay Register (SPND)

SPND sets a period (next-access delay) from termination of a serial transfer to the beginning of the next serial transfer when the next-access delay enable bit (SPNDEN) in SPCMD0 to SPCMD3 is 1 in master mode. If the contents of SPND are modified while the SPE and MSTR bits in SPCR are 1, the subsequent operation cannot be guaranteed.

Be sure to set this register to H'00 when using this module in single-SPI slave mode.

- Longword access:

7 to 3	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
2 to 0	SPNDL[2:0]	000	R/W	Next-Access Delay Setting These bits set a period (next-access delay) from termination of a serial transfer to the beginning of the next serial transfer when the SPNDEN bit in SPCMD0 to SPCMD3 is 1. 000: 1 SPCLK cycle 001: 2 SPCLK cycles 010: 3 SPCLK cycles 011: 4 SPCLK cycles 100: 5 SPCLK cycles 101: 6 SPCLK cycles 110: 7 SPCLK cycles 111: 8 SPCLK cycles

39.4.13 Command Register n (SPCMDn) (n = 0 to 3)

This module has four command registers (SPCMD0 to SPCMD3). SPCMD0 to SPCMD3 are used to set a transfer format in master mode. In master mode, this module sequentially references SPCMD0 to SPCMD3 according to the settings in the sequence control register (SPSCR), and executes the serial transfer that is set in the referenced SPCMD.

If the contents of currently referred-to SPCMD are modified while the TEND bit in SPSR indicates that communication has not been completed, the subsequent operation cannot be guaranteed. The currently referred-to SPCMD can be checked by reading the sequence status register (SPSSR). In addition, if the contents of SPCMD0 are modified during operation in single-SPI slave mode, the subsequent operation cannot be guaranteed.

- Longword access:

Bit	Bit Name	Initial Value	R/W	Description
15	SCKDEN	1	R/W	Clock Delay Setting Enable Sets a period (clock delay) from the beginning of SSL signal assertion to SPCLK oscillation in master mode. If this bit is 0, this module sets the clock delay to 0 SPCLK cycle. If this bit is 1, this module starts SPCLK oscillation in compliance with the clock delay register (SPCKD) settings. For the continuous access in which SSL is kept asserted over the multiple commands, this bit can be set to 0 only when the pertinent command is the second or subsequent one. Otherwise, this bit should be set to 1. 0: A clock delay of 0 SPCLK cycle 1: A clock delay equal to SPCKD settings.

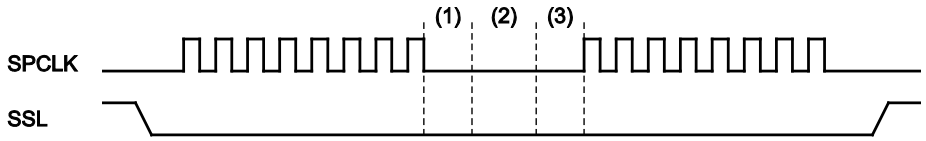
Bit	Bit Name	Initial Value	R/W	Description
14	SLNDEN	1	R/W	SSL Negation Delay Setting Enable Sets a period (SSL negation delay) from SPCLK oscillation stoppage to SSL signal negation in master mode. If this bit is 0, this module sets the SSL negation delay to 0 SPCLK cycle. If this bit is 1, this module negates the SSL signal in compliance with the slave select negation delay register (SSLND) settings. For the continuous access in which SSL is kept asserted over the multiplier commands, this bit can be set to 0 only when the pertinent command is not the last one. Otherwise, this bit should be set to 1. When using this module in single-SPI slave mode, set this bit to 1 and the slave select negation delay register (SSLND) to H'0. 0: An SSL negation delay of 0 SPCLK cycle 1: An SSL negation delay equal to SSLND settings.
13	SPNDEN	1	R/W	Next-Access Delay Enable Sets the period (next-access delay) from termination of a serial transfer to the beginning of the next serial transfer in master mode. If this bit is 0, this module sets the next-access delay to 0 SPCLK cycle. If this bit is 1, this module starts next serial transfer in compliance with the next-access delay register (SPND) settings. For the continuous access in which SSL is kept asserted over the multiple commands, this bit can be set to 0 only when the pertinent command is not the last one. Otherwise, this bit should be set to 1. When using this module in single-SPI slave mode, set this bit to 1 and the next-access delay register (SPND) to B'000. 0: A next-access delay of 0 SPCLK cycle. 1: A next-access delay equal to SPND settings.
12	LSBF	0	R/W	LSB First Sets the data format to MSB first or LSB first in master mode or single-SPI slave mode. 0: MSB first 1: LSB first
11 to 8	SPB[3:0]	0000	R/W	Transfer Data Length Setting These bits set the basic transfer data length for serial transfer. For LSB-first transfer, the transfer data is reversed within the data width specified with these bits. The actual amount of data to be transferred is determined by multiplying the value set with these bits by the value set with SPBMUL0 to SPBMUL3. 0000: 8 bits (1 byte) 0001: 16 bits (2 bytes) 0010: 32 bits (4 bytes) 0011 to 1111: Setting prohibited
7	SSLKP	0	R/W	SSL Signal Level Keeping Specifies whether or not the SSL signal level for the current command is to be kept from the end of the transfer for the current command to the beginning of the transfer for the next command in master mode. Setting this bit to 1 enables a transition to the next access while the SSL signal is kept asserted. 0: Negates all SSL signals upon completion of transfer. 1: Keeps the SSL signal level from the end of the transfer to the beginning of the next access.

Bit	Bit Name	Initial Value	R/W	Description
6, 5	SPIMOD[1:0]	00	R/W	SPI Operating Mode These bits select the operating mode of this module from single-, dual-, or quad-SPI. 00: Single-SPI 01: Dual-SPI 10: Quad-SPI 11: Setting prohibited
4	SPRW	0	R/W	SPI Read/Write Access Sets an access direction in dual-/quad-SPI modes. This bit is invalid in single-SPI mode 0: Write operation (IO1 and IO0/IO3 to IO0: Output) 1: Read operation (IO1 and IO0/IO3 to IO0: Input)
3, 2	BRDV[1:0]	00	R/W	Bit Rate Frequency Division Setting These bits are used to determine the bit rate in master mode. The settings of these bits and of the bit rate register (SPBR) together determine the bit rate. The base bit rate depends on the setting of the SPBR. The setting of this field selects division of the base bit rate by one, two, four, or eight. Individual BRDV[1:0] values can be set in each of command registers 0 to 3. Therefore, serial transfers can be at different bit rates for each of the commands. 00: Base bit rate 01: Two division of the base 10: Four division of the base 11: Eight division of the base
1	CPOL	0	R/W	SPCLK Polarity Setting Sets an SPCLK polarity. When data communication is performed between this quad serial peripheral interface module and another module, the same SPCLK polarity should be set for both modules. 0: Positive (SPCLK = 0 when idle) 1: Negative (SPCLK = 1 when idle)
0	CPHA	1	R/W	SPCLK Phase Setting Sets an SPCLK edge for latching and shifting data to be transferred. When data communication is performed between this quad serial peripheral interface module and another module, the same SPCLK edge should be set for both modules. 0: Data latch on odd edge, data shift on even edge 1: Data shift on odd edge, data latch on even edge Note: The first SPCLK edge is treated as the first edge.

Reference: Some serial flash memory datasheets refer to SPCLK specifications, which are determined by what this document refers to as CPOL and CPHA bits, as SPI modes 0 to 3. Assuming that SPI modes 0 to 3 are controlled by SPI mode bits [1:0], CPOL and CPHA in this document correspond to SPI mode bits 1 and 0, respectively.
In this module, the initial values of CPOL and CPHA are 0 and 1, respectively, selecting SPI mode 1 as the initial mode.

Notes: 1. When setting any or all of the clock delay period, SSL negation delay period, and next-access delay period to 0, be sure to set SSLKP to 1 to select the continuous access in which SSL is not negated. Otherwise, operation cannot be guaranteed. For the method of setting the various delay periods for the continuous access in which SSL is not negated, see below.

2. For the continuous access in which SSL is not negated, SPCLK clock stopping is followed by the SSL negation delay period, next-access delay period, and next command clock delay period, in this order. When setting any of the setting enable bit (SPCKDEN), SSL negation delay setting enable bit (SLNDEN), and next-access delay enable bit (SPNDEN) to 0, be sure to set the bit corresponding to the later period prior to the bit corresponding to the earlier period.



In the above figure, (1), (2), and (3) refer to the SSL negation delay period, next-access delay period, and next command clock delay period, respectively. When setting any of these bits to 0, be sure to set (3) first. In other words, setting 1 after 0 as in {(1), (2), (3)} = {0, 0, 1}, {0, 1, 1}, {0, 1, 0} … is prohibited. Allowed setting is {(1), (2), (3)} = {1, 1, 1}, {1, 1, 0}, {1, 0, 0}, {0, 0, 0}. If set otherwise, operation cannot be guaranteed.

3. When changing BRDV[1:0] or CPOL for each command for the continuous access in which the SSL level is held, be sure to insert the SSL negation delay period, next-access delay period, and clock delay period between commands. Otherwise, operation cannot be guaranteed.
4. When changing SPIMOD[1:0] or CPHA for each command for the continuous access in which the SSL level is held, be sure to insert one cycle or more between commands. Otherwise, operation cannot be guaranteed.

39.4.14 Buffer Control Register (SPBFCR)

SPBFCR resets the number of data units in the transmit buffer (SPTXB) or receive buffer (SPRXB) and sets the number of triggering data units.

- Longword access:

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TXRST	RXRST	TXTRG[1:0]		—	RXTRG[2:0]			—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	TXBC[5:0]						—	—	RXBC[5:0]					
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

- Byte access:

Bit:	7	6	5	4	3	2	1	0
	TXRST	RXRST	TXTRG[1:0]		—	RXTRG[2:0]		
Initial value:	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	TXRST	0	R/W	Transmit Buffer Data Reset Invalidates transmit data in the transmit buffer and resets the transmit buffer to an empty state. 0: Allows the transmit buffer normal operation. 1: Resets the transmit buffer.
6	RXRST	0	R/W	Receive Buffer Data Reset Invalidates receive data in the receive buffer and resets the receive buffer to an empty state. 0: Allows the receive buffer normal operation. 1: Resets the receive buffer.
5, 4	TXTRG[1:0]	00	R/W	Transmit Buffer Data Triggering Number Specifies the timing at which the transmit buffer empty state is determined, that is when the SPTEF flag in the status register is set. When the number of bytes of data in the transmit buffer (SPTXB) is equal to or less than the specified triggering number, the SPTEF flag is set to 1. 00: 31 bytes (1 byte available) 01: 30 bytes (2 bytes available) 10: 28 bytes (4 bytes available) 11: 0 byte (32 bytes available)
3	—	0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.

Bit	Bit Name	Initial Value	R/W	Description
2 to 0	RXTRG[2:0]	000	R/W	Receive Buffer Data Triggering Number Specify the timing at which the receive buffer full state is determined, that is when the SPRFF flag in the status register is set. When the number of bytes of data in the receive buffer (SPRXB) is equal to or greater than the specified triggering number, the SPRFF flag is set to 1. 000: 1 byte (31 bytes available) 001: 2 bytes (30 bytes available) 010: 4 bytes (28 bytes available) 011: 5 bytes (27 bytes available) 100: 8 bytes (24 bytes available) 101: 16 bytes (16 bytes available) 110: 24 bytes (8 bytes available) 111: 32 bytes (0 byte available)

39.4.15 Buffer Data Count Register (SPBDCR)

SPBDCR indicates the number of data units stored in the transmit buffer (SPTXB) and receive buffer (SPRXB). The upper eight bits indicate the number of transmit data units in the transmit buffer and the lower eight bits indicate the number of receive data units in the receive buffer.

- Longword access:

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15, 14	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
13 to 8	TXBC[5:0]	000000	R	Transmit Data Byte Counter Indicate the number of transmit data bytes in the transmit data buffer (SPTXB). B'000000 indicates that SPTXB is empty. B'100000 indicates that SPTXB is full.
7, 6	—	All 0	R	Reserved The write value should always be 0. Otherwise, operation cannot be guaranteed.
5 to 0	RXBC[5:0]	000000	R	Receive Data Byte Counter Indicates the number of receive data bytes in the receive data buffer (SPRXB). B'000000 indicates that SPRXB is empty. B'100000 indicates that SPRXB is full.

39.4.16 Transfer Data Length Multiplier Setting Register n (SPBMULn) (n = 0, 1, 2, 3)

SPBMUL0 to SPBMUL3 set the number of times to transfer the specific length of data defined by the transfer data length setting bits (SPB[3:0]) in SPCMD0 to SPCMD3. SPBMUL0 to SPBMUL3 correspond to SPCMD0 to SPCMD3, respectively. This register setting is valid only in master mode. In single-SPI slave mode, this register should be set to the initial value; other values are prohibited.

If a command register is referred to while the TEND bit in SPSR indicates that communication has not been completed and SPBMUL corresponding to the referred-to command register is modified, the subsequent operation is not guaranteed. The currently referred-to command register can be checked by reading the sequence status register (SPSSR).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SPBMUL[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SPBMUL[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SPBMUL [31:0]	H'0000 0001	R/W	Transfer Data Length Multiplier Setting These bits set the multiplier for transfer data; that is, the number of times to transfer the specific length of data defined by SPB[3:0] bits in SPCMD0 to SPCMD3. The actual amount of data to be transferred is determined by SPB[3:0] × SPBMUL[31:0]. Setting these bits to H'00000000 allows the defined size of data to be transferred 4,294,967,296 times.

39.5 Operation

In this section, the serial transfer period means a period from the beginning of driving valid data to the fetching of the final valid data, and the SSL negation period means the idle period.

39.5.1 Overview of Operations

This module is capable of serial transfers in single-/dual-/quad-SPI master modes and single-SPI slave mode. Table 39.4 gives the features of single-/dual-/quad-SPI modes.

Table 39.4 Features of Each SPI Mode

	Single-SPI	Dual-SPI	Quad-SPI
Number of data lines	One input line and one output line	Two IO lines	Four IO lines
Data line direction	Single-directional	Bidirectional	Bidirectional
Slave operation	Not supported	Not supported	Not supported
Simultaneous transmission/reception	Supported	Not supported	Not supported

Table 39.5 gives the overview of master-mode operation.

Table 39.5 Overview of Master Mode

Items	Master Mode
MSTR bit setting in the control register	1
SPCLK signal	Output
MOSI signal (single-SPI)	Output
MISO signal (single-SPI)	Input
IO1 and IO0 (dual-SPI)/ IO3 to IO0 (quad-SPI)	Input/output
SSL signal	Output
Switching SSL polarity	Supported
Transfer rate	Up to QSPIϕ
Clock source	On-chip baud rate generator
Clock polarity	Positive/negative
Clock phase	Latch at rising/output at falling Latch at falling/output at rising
Transfer bit order	MSB first/LSB first
Transfer data length	(8/16/32) × (1 to 4,294,967,296) bits
Burst transfer	Supported
SPCLK delay control	Supported
SSL negation delay control	Supported
Next-access delay control	Supported
Transfer start method	Writing data to the transmit buffer when SPE = 1 There is space in the receive buffer when SPE = 1*
Sequence control	Supported
Transmit buffer empty detection	Supported
Receive buffer full detection	Supported
Overrun error detection	Not supported
Underrun error detection	Not supported
Mode fault error detection	Not supported

Note: * During single-SPI operation and dual-/quad-SPI mode write operation, a transfer is started by setting SPE to 1 and writing data to the transmit buffer. During dual-/quad-SPI mode read operation, a transfer is started by setting SPE to 1 when there is space for the specified length of data in the receive buffer.

39.5.2 Pin Control

This module automatically switches the pin states according to the status after write/read transfer in single-SPI master or slave mode or dual-/quad-SPI mode. The status of the data pins (MOSI/MISO/IO[3:0]) in the idle state depends on the MOIFE and MOIFV bit settings, the single-/dual-SPI mode IO3 output fixed value bit (IO3FV) setting, and the single-/dual-SPI mode IO2 output fixed value bit (IO2FV) setting. Table 39.6 shows the pin states in single-SPI master mode. Table 39.7 shows the pin states in dual-/quad-SPI modes.

Table 39.6 Pin States in Single-SPI Master Mode

Items	Single-SPI Master Mode
SSL	Output
SPCLK	Output
MOSI	Output
MISO	Input
MOSI in the idle state	MOIFE = 0: Final output value MOIFE = 1: MOIFV setting value
MISO in the idle state	—
IO2	IO2FV setting value output or not used
IO3	IO3FV setting value output or not used

Table 39.7 Pin States in Dual-/Quad-SPI Modes

Items	Dual-SPI Mode	Quad-SPI Mode
SSL	Output	Output
SPCLK	Output	Output
IO0	I/O	I/O
IO1	I/O	I/O
IO2	IO2FV setting value output or not used	I/O
IO3	IO3FV setting value output or not used	I/O
IO0 in the idle state	After writing: MOIFE = 0: Final output value MOIFE = 1: MOIFV setting value After reading: Hi-Z	After writing: MOIFE = 0: Final output value MOIFE = 1: MOIFV setting value After reading: Hi-Z
IO1 in the idle state	After writing: MOIFE = 0: Final output value MOIFE = 1: MOIFV setting value After reading: Hi-Z	After writing: MOIFE = 0: Final output value MOIFE = 1: MOIFV setting value After reading: Hi-Z
IO2 in the idle state	IO2FV setting value output or not used	After writing: MOIFE = 0: Final output value MOIFE = 1: MOIFV setting value After reading: Hi-Z
IO3 in the idle state	IO3FV setting value output or not used	After writing: MOIFE = 0: Final output value MOIFE = 1: MOIFV setting value After reading: Hi-Z

39.5.3 Transfer Format

The SPI has four clock settings determined by the SPCLK polarity setting (CPOL) and SPCLK phase setting (CPHA) bits in SPCMD0 to SPCMD3. Figure 39.1 shows the data latch/shift timing based on each setting in an 8-bit MSB first transfer. In Figure 39.1, L indicates the latch timing and S indicates the shift timing. DATA corresponds to MISO/MOSI in single-SPI mode; IO1 and IO0 in dual-SPI mode; or IO3 to IO0 in quad-SPI mode. t_{ckd} indicates the clock delay period when the SCKDEN bit in SPCMD0 to SPCMD3 is set to 1. Similarly, t_{slnd} indicates the SSL negation delay period when the SLNDEN bit in SPCMD0 to SPCMD3 is set to 1, and t_{spnd} indicates the next-access delay period when the SPNDEN bit in SPCMD0 to SPCMD3 is set to 1.

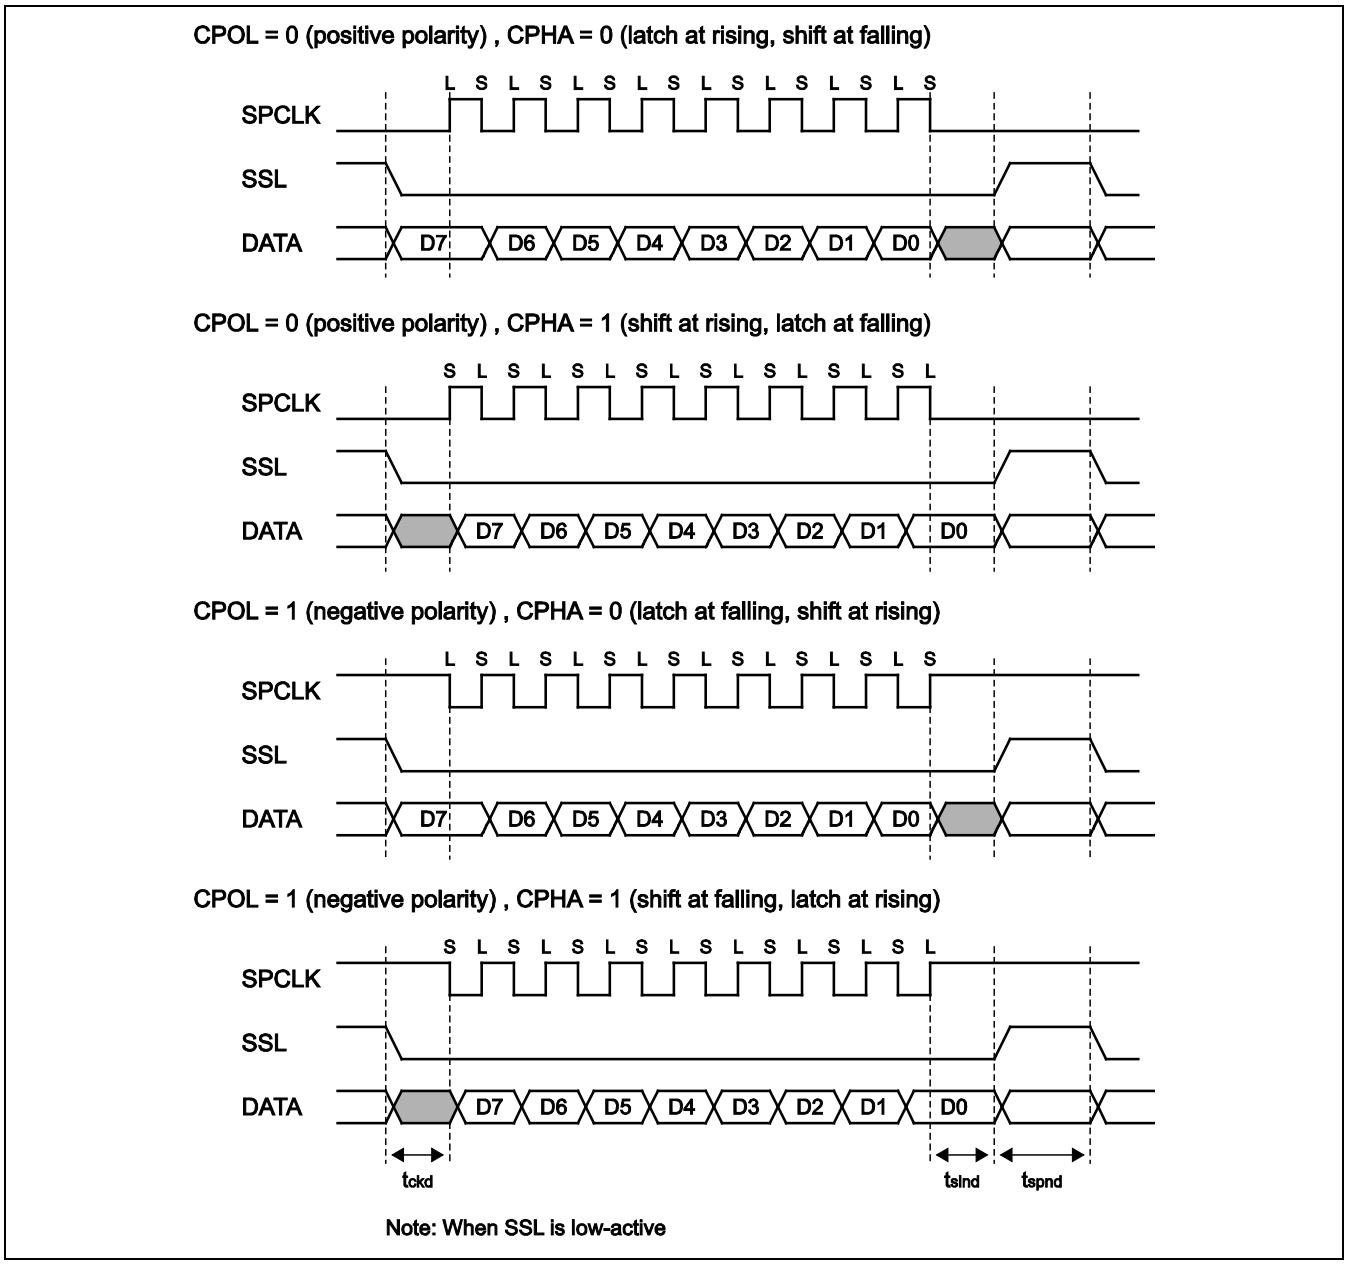

Figure 39.1 SPI Clock Setting and Transfer Timing

Note that when the base bit rate is used, transmission and reception when CPHA = 0 is not available.

The following describes 8-bit MSB first transfer in single-/dual-/quad-SPI modes when CPOL = 0 and CPHA = 0.

(1) Single-SPI mode

Figure 39.2 shows the transfer format in single-SPI mode. This mode provides transmission and reception simultaneously. Since one data line is used for serial communication both in transmission and reception, the communication speed is 1 bit per SPCLK clock cycle. Transfer data is specified using SPCMD0 to SPCMD3. For details of transfer data, see section 39.5.4, Transfer Data.

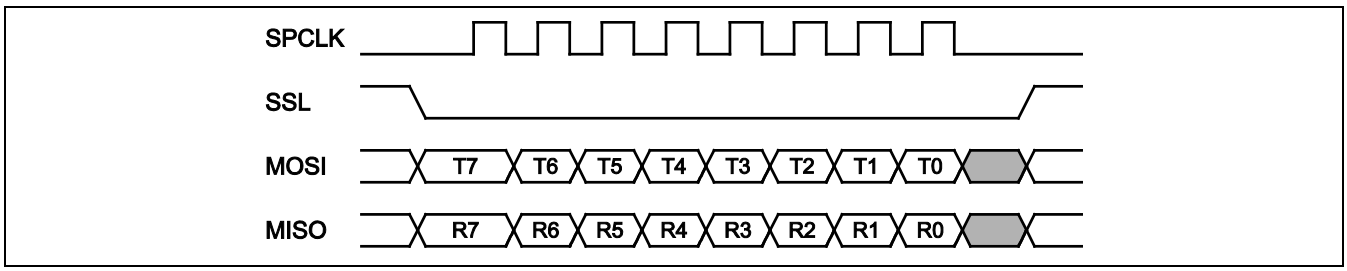

Figure 39.2 Transfer Format in Single-SPI Mode

(2) Dual-SPI mode

Figure 39.3 shows the transfer format in dual-SPI mode. This mode only provides operation of a single direction, that is, either transmission or reception. Transmission or reception can be set using the SPI read/write access setting bit (SPRW) in SPCMD0 to SPCMD3. Transmission is carried out by write operation and reception by read operation. The I/O directions of IO1 and IO0 are switched accordingly. Since two data lines are used for serial communication both in transmission and reception, the communication speed is 2 bits per SPCLK clock cycle. The start bit of the transfer data is output from IO1. Transfer data is specified using SPCMD0 to SPCMD3. For details of transfer data, see section 39.5.4, Transfer Data.

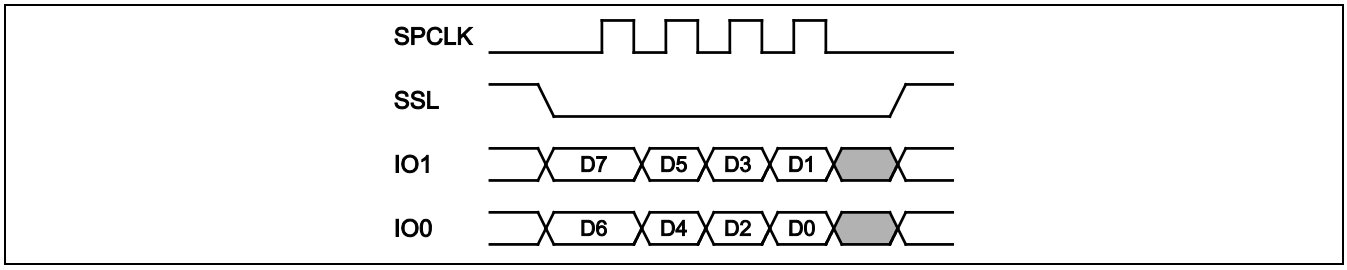

Figure 39.3 Transfer Format in Dual-SPI Mode

(3) Quad-SPI mode

Figure 39.4 shows the transfer format in quad-SPI mode. This mode provides operation of a single direction, that is, either transmission or reception. Transmission or reception can be set using the SPRW bit in SPCMD0 to SPCMD3. Transmission and reception are accomplished by writing and reading, respectively. The I/O directions of IO3 to IO0 are switched accordingly. Since four data lines are used for serial communication both in transmission and reception, the communication speed is 4 bits per SPCLK clock cycle. The start bit of the transfer data is output from IO3. Transfer data is specified using SPCMD0 to SPCMD3. For details of transfer data, see section 39.5.4, Transfer Data.

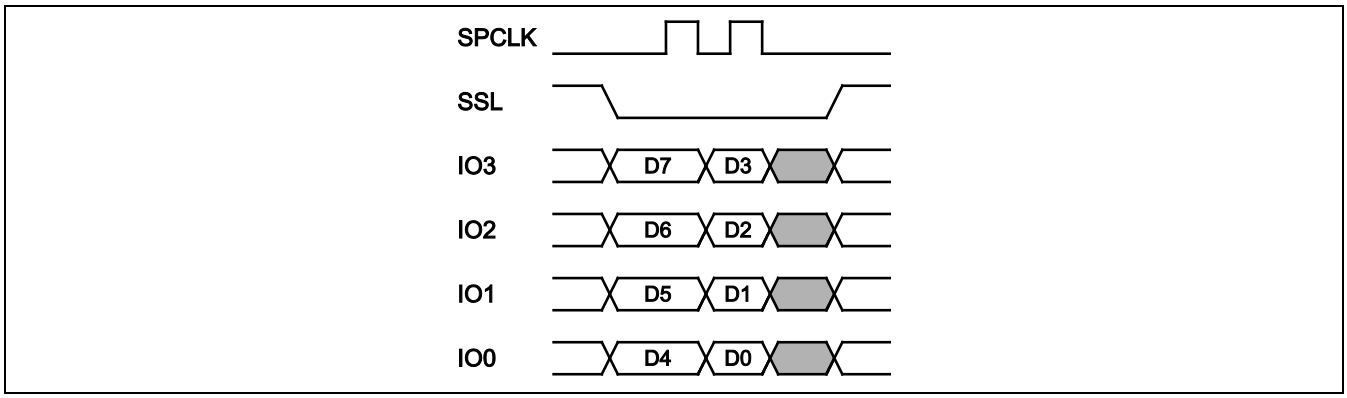

Figure 39.4 Transfer Format in Quad-SPI Mode

39.5.4 Transfer Data

The data format is determined by the SPB[3:0] and the LSB first (LSBF) bits in SPCMD0 to SPCMD3 and SPBMUL0 to SPBMUL3. In both MSB first and LSB first transfers, this module treats the specified size of data beginning at the MSB of the transmit shift register as transmit data, and the specified length of data beginning at the LSB of the receive shift register as receive data, regardless of whether the actual arrangement is MSB- or LSB-first. The following sections describe MSB-first and LSB-first transfers in 32-bit, 16-bit, and 8-bit data units.

(1) MSB-first transfer (32-bit data)

Figure 39.5 shows the operation of the transmit buffer and transmit shift register, and the receive shift register and receive buffer when this module performs a 32-bit MSB-first data transfer.

For data transmission, the CPU or direct memory access controller (DMAC) writes 32-bit transmit data to the transmit buffer (SPTXB). If the transmit shift register is empty, this module copies the data with MSB-aligned in the transmit buffer to the transmit shift register, and fills the transmit shift register. When data transmission is started, this module outputs data beginning at the MSB (bit 31) of the transmit shift register, and when the SPCLK clock cycle required for the serial transfer of 32 bits has passed, the transmit shift register becomes empty.

For data reception, data received from the data pin is stored in the receive shift register beginning at the LSB (bit 0). When the SPCLK clock cycle required for the serial transfer of 32 bits has passed, the receive shift register becomes full. If the receive buffer (SPRXB) has a space for 32 bits or more, this module copies the 32-bit data beginning at the LSB from the receive shift register to the receive buffer, and empties the receive shift register. If the receive buffer does not have a space for 32 bits or more in master mode, data reception is not carried out. In order to start reception, the specified length of data should be read from the receive buffer to secure the space for 32 bits or more in the receive buffer.

In actual transfer, this operation is repeated for the number of times defined by SPBMUL0 to SPBMUL3.

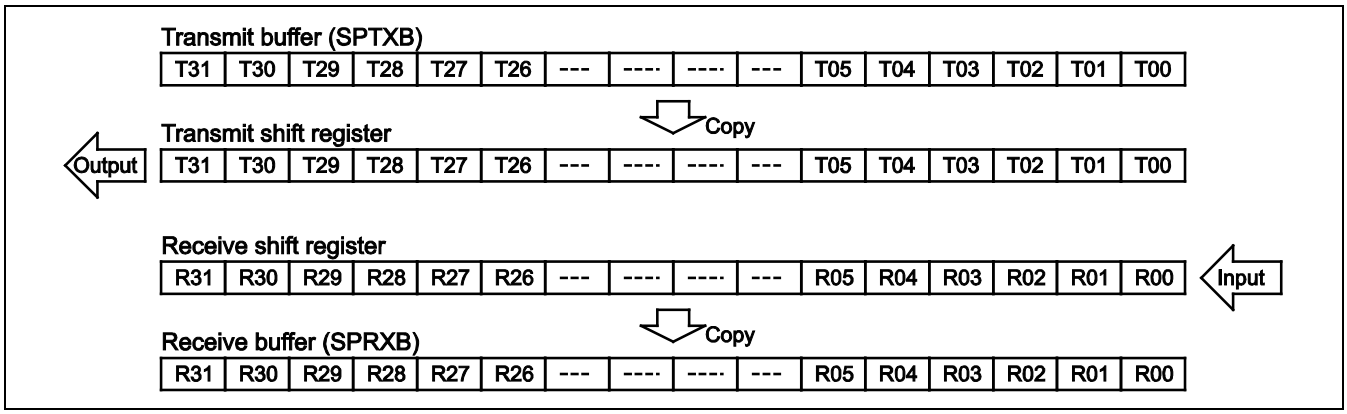

Figure 39.5 MSB-First Transfer (32-Bit Data)

(2) MSB-first transfer (16-bit data)

Figure 39.6 shows the operation of the transmit buffer and transmit shift register, and the receive shift register and receive buffer when this module performs a 16-bit MSB-first data transfer.

For data transmission, the CPU or direct memory access controller (DMAC) writes 16-bit transmit data to the transmit buffer (SPTXB). If the transmit shift register is empty, this module copies the data with MSB-aligned in the transmit buffer to the transmit shift register, and fills the transmit shift register. When data transmission is started, this module outputs data beginning at the MSB (bit 31) of the transmit shift register, and when the SPCLK clock cycle required for the serial transfer of 16 bits has passed, the transmit shift register becomes empty.

For data reception, data received from the data pin is stored in the receive shift register beginning at the LSB (bit 0). When the SPCLK clock cycle required for the serial transfer of 16 bits has passed, the receive shift register becomes full. If the receive buffer (SPRXB) has a space for 16 bits or more, this module copies the 16-bit data beginning at the LSB from the receive shift register to the receive buffer, and empties the receive shift register. If the receive buffer does not have a space for 16 bits or more in master mode, data reception is not carried out. In order to start reception, the specified length of data should be read from the receive buffer to secure the space for 16 bits or more in the receive buffer.

In actual transfer, this operation is repeated for the number of times defined by SPBMUL0 to SPBMUL3.

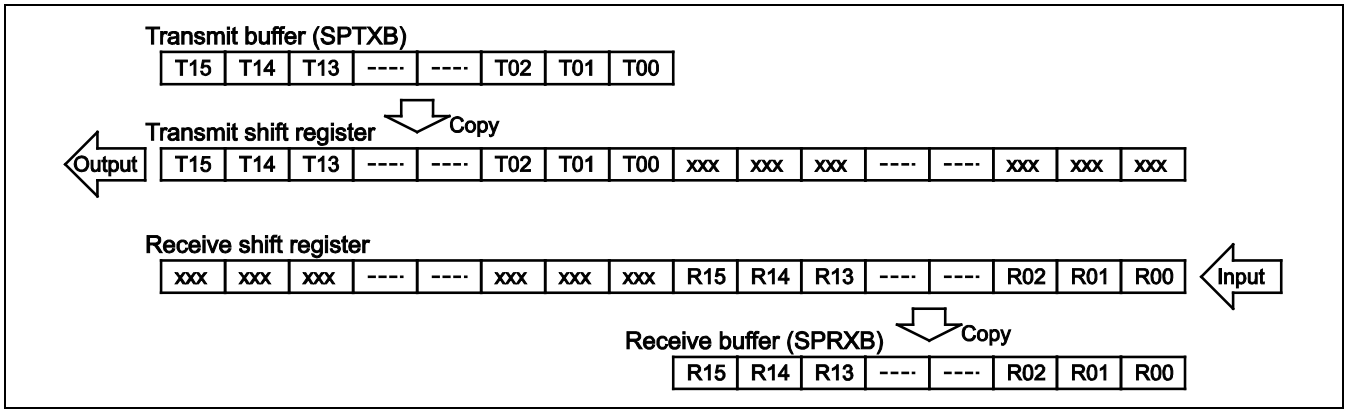

Figure 39.6 MSB-First Transfer (16-Bit Data)

(3) MSB-first transfer (8-bit data)

Figure 39.7 shows the operation of the transmit buffer and transmit shift register, and the receive shift register and receive buffer when this module performs an 8-bit MSB-first data transfer.

For data transmission, the CPU or direct memory access controller (DMAC) writes 8-bit transmit data to the transmit buffer (SPTXB). If the transmit shift register is empty, this module copies the data with MSB-aligned in the transmit buffer to the transmit shift register, and fills the transmit shift register. When data transmission is started, this module outputs data beginning at the MSB (bit 31) of the transmit shift register, and when the SPCLK clock cycle required for the serial transfer of 8 bits has passed, the transmit shift register becomes empty.

For data reception, data received from the data pin is stored in the receive shift register beginning at the LSB (bit 0). When the SPCLK clock cycle required for the serial transfer of 8 bits has passed, the receive shift register becomes full. If the receive buffer (SPRXB) has a space for 8 bits or more, this module copies the 8-bit data beginning at the LSB from the receive shift register to the receive buffer, and empties the receive shift register. If the receive buffer does not have a space for 8 bits or more in master mode, data reception is not carried out. In order to start reception, data for the specified length of data should be read from the receive buffer to secure the space for 8 bits or more in the receive buffer.

In actual transfer, this operation is repeated for the number of times defined by SPBMUL0 to SPBMUL3.

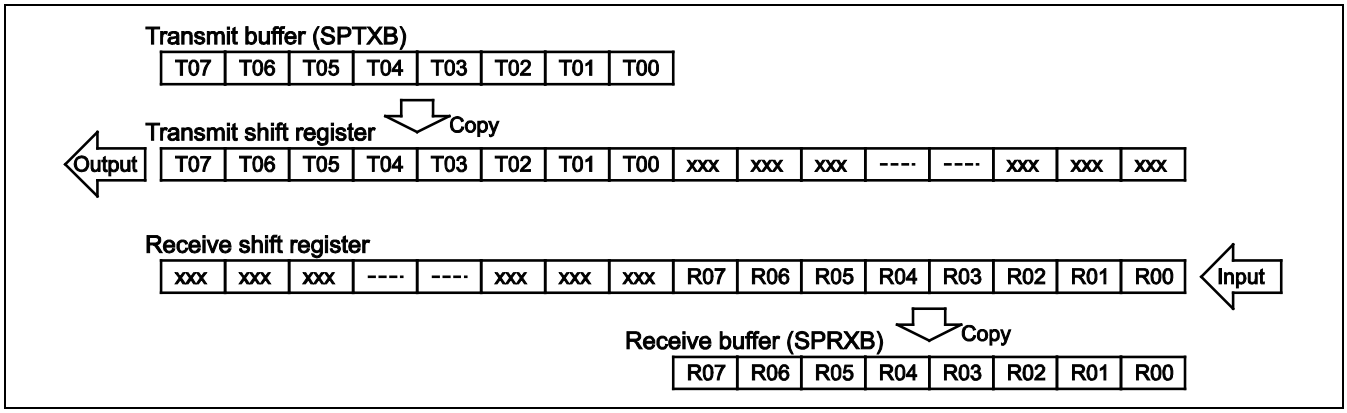

Figure 39.7 MSB-First Transfer (8-Bit Data)

(4) LSB-first transfer (32-bit data)

Figure 39.8 shows the operation of the transmit buffer and transmit shift register, and the receive shift register and receive buffer when this module performs a 32-bit LSB-first data transfer.

For data transmission, the CPU or direct memory access controller (DMAC) writes 32-bit transmit data to the transmit buffer (SPTXB). If the transmit shift register is empty, this module reverses the bit order in the 32-bit transmit data, copies it with MSB-aligned to the transmit shift register, and fills the transmit shift register. When data transmission is started, this module outputs data beginning at the MSB (bit 31) of the transmit shift register, and when the SPCLK clock cycle required for the serial transfer of 32 bits has passed, the transmit shift register becomes empty.

For data reception, data received from the data pin is stored in the receive shift register beginning at the LSB (bit 0). When the SPCLK clock cycle required for the serial transfer of 32 bits has passed, the receive shift register becomes full. If the receive buffer (SPRXB) has a space for 32 bits or more, this module reverses the order of the bits of the 32-bit data, copies it beginning at the LSB from the receive shift register to the receive buffer, and empties the receive shift register. If the receive buffer does not have a space for 32 bits or more in master mode, data reception is not carried out. In order to start reception, the specified length of data should be read from the receive buffer to secure the space for 32 bits or more in the receive buffer.

In actual transfer, this operation is repeated for the number of times defined by SPBMUL0 to SPBMUL3.

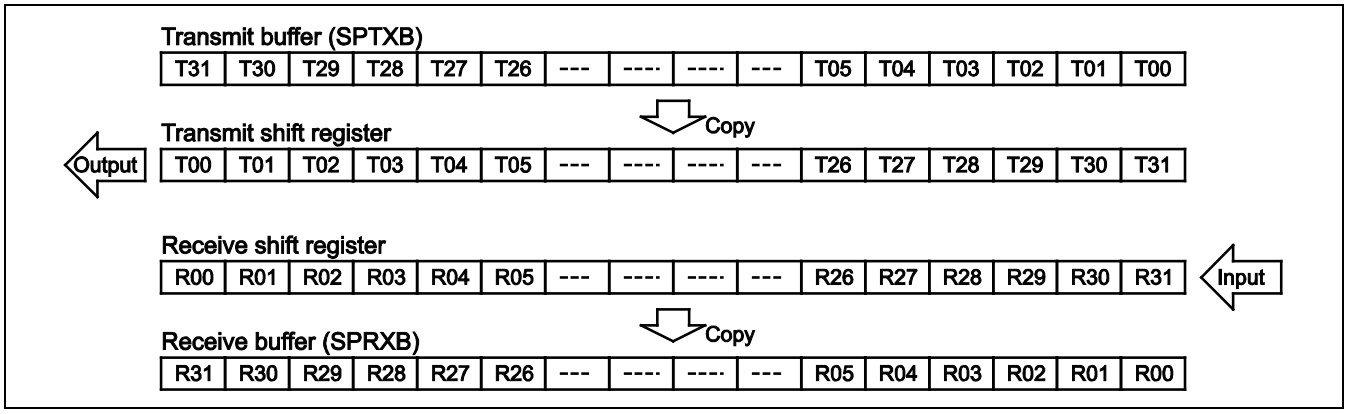

Figure 39.8 LSB-First Transfer (32-Bit Data)

(5) LSB-first transfer (16-bit data)

Figure 39.9 shows the operation of the transmit buffer and transmit shift register, and the receive shift register and receive buffer when this module performs a 16-bit LSB-first data transfer.

For data transmission, the CPU or direct memory access controller (DMAC) writes 16-bit transmit data to the transmit buffer (SPTXB). If the transmit shift register is empty, this module reverses the bit order in the 16-bit transmit data, copies it with MSB-aligned to the transmit shift register, and fills the transmit shift register. When data transmission is started, this module outputs data beginning at the MSB (bit 31) of the transmit shift register, and when the SPCLK clock cycle required for the serial transfer of 16 bits has passed, the transmit shift register becomes empty.

For data reception, data received from the data pin is stored in the receive shift register beginning at the LSB (bit 0). When the SPCLK clock cycle required for the serial transfer of 16 bits has passed, the receive shift register becomes full. If the receive buffer (SPRXB) has a space for 16 bits or more, this module reverses the bit order in the 16-bit data, copies it beginning at the LSB from the receive shift register to the receive buffer, and empties the receive shift register. If the receive buffer does not have a space for 16 bits or more in master mode, data reception is not carried out. In order to start reception, the specified length of data should be read from the receive buffer to secure the space for 16 bits or more in the receive buffer.

In actual transfer, this operation is repeated for the number of times defined by SPBMUL0 to SPBMUL3.

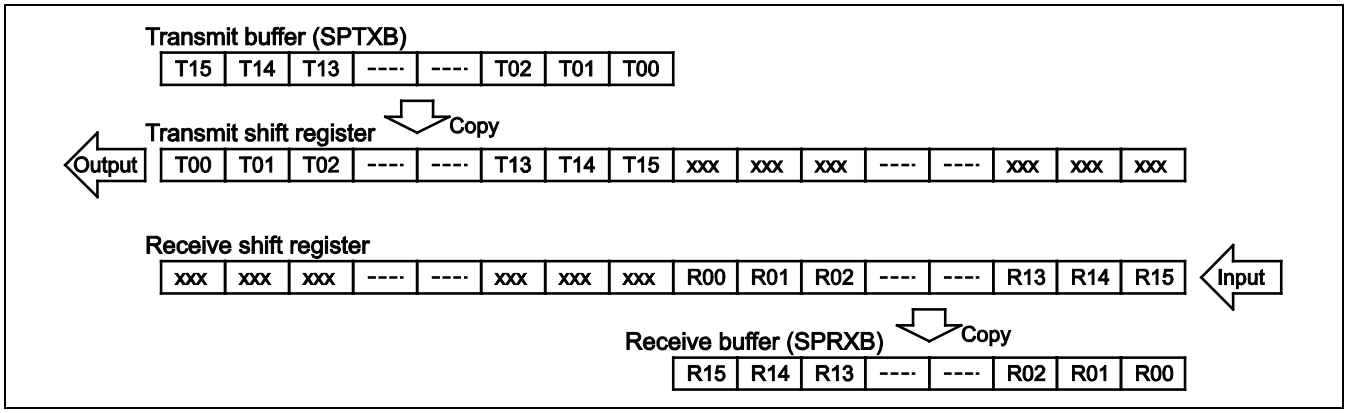

Figure 39.9 LSB-First Transfer (16-Bit Data)

(6) LSB-first transfer (8-bit data)

Figure 39.10 shows the operation of the transmit buffer and transmit shift register, and the receive shift register and receive buffer when this module performs an 8-bit LSB-first data transfer.

For data transmission, the CPU or direct memory access controller (DMAC) writes 8-bit transmit data to the transmit buffer (SPTXB). If the transmit shift register is empty, this module reverses the bit order in the 8-bit transmit data, copies it with MSB-aligned to the transmit shift register, and fills the transmit shift register. When data transmission is started, this module outputs data beginning at the MSB (bit 31) of the transmit shift register, and when the SPCLK clock cycle required for the serial transfer of 8 bits has passed, the transmit shift register becomes empty.

For data reception, data received from the data pin is stored in the received shift register beginning at the LSB (bit 0). When the SPCLK clock cycle required for the serial transfer of 8 bits has passed, the receive shift register becomes full. If the receive buffer (SPRXB) has a space for 8 bits or more, this module reverses the bit order in the 8-bit data, copies it beginning at the LSB from the receive shift register to the receive buffer, and empties the receive shift register. If the receive buffer does not have a space for 8 bits or more in master mode, data reception is not carried out. In order to start reception, the specified length of data should be read from the receive buffer to secure the space for 8 bits or more in the receive buffer.

In actual transfer, this operation is repeated for the number of times defined by SPBMUL0 to SPBMUL3.

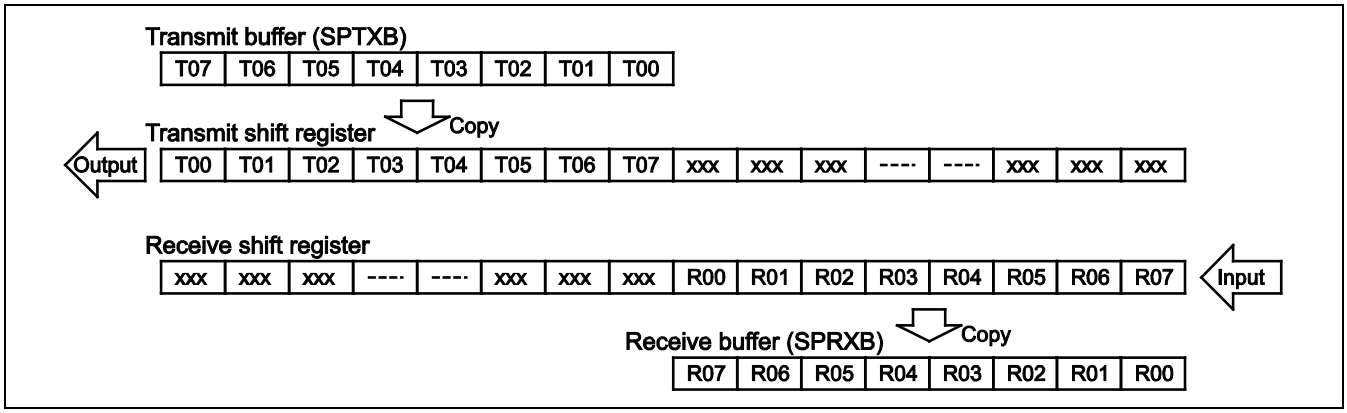

Figure 39.10 LSB-First Transfer (8-Bit Data)

39.5.5 Error Detection

In the normal serial transfer, the data written from SPDR to the transmit buffer is serially transmitted, and the serially received data can be read from the receive buffer of SPDR. If access is made to SPDR or serial transfer is started or completed, depending on the status of the transmit buffer/receive buffer, non-normal transfers may be executed in some cases.

This module detects certain types of non-normal transfers as underrun, overrun, or mode fault errors. Table 39.8 shows the relationship between non-normal transfer operations and the error detection function.

Table 39.8 Relationship between Non-Normal Transfer Operations and Error Detection Function

	Occurrence Condition	Operation	Error Detection
A	SPDR is written when the transmit buffer is full.	Missing write data.	Not detected
C	SPDR is read when the receive buffer is empty.	The output data is undefined.	Not detected

On operation A shown in Table 39.8, this module detects no error. Whether SPDR can be written to or not can be checked using the transmit data byte counter bits (TXBC[5:0]) in the buffer data count register (SPBDCR).

Similarly, on operation C shown in Table 39.8, this module detects no error. Whether the valid data is stored in the receive buffer or not can be checked by reading the receive data byte counter bits (RXBC[5:0]) in SPBDCR.

39.5.6 Initialization

If 0 is written to the SPE bit in SPCR, or a mode fault error is detected and the SPE bit is cleared to 0, this module disables the module function, and initializes a part of the module function. When a power-on reset is generated, this module initializes all of the module function.

When the SPE bit in SPCR is cleared to 0, this module performs the following initialization:

- Suspending any serial transfer that is being executed
- Initializing the transmit shift register and the receive shift register
- Initializing the internal state machine
- Initializing the sequence
- Initializing the TEND bit in SPSR

Initialization by clearing the SPE bit to 0 does not initialize the control bits of this module and the transmit/receive buffer. For this reason, this module can be started in the same transfer mode as prior to the initialization if the SPE bit is re-set to 1. However, clearing the SPE bit to 0 initializes the transmit shift register and the receive shift register and allows the data that is being transferred to be discarded.

39.5.7 SPI Operation

The operating modes of this module are listed below.

- Single-SPI master mode
- Dual-SPI mode/quad-SPI mode

The operation in each mode is described below.

(1) Single-SPI master mode

(a) Starting serial transfer

The serial transfer start conditions are: there is the specified length of data in the transmit buffer; and there is space for the specified length of data in the receive buffer.

(b) Terminating serial transfer

Irrespective of the clock setting, this module terminates the serial transfer after transmitting an SPCLK edge corresponding to the final sampling timing. After the serial transfer is completed, receive data is copied from the receive shift register to the receive buffer. If there is not enough space for the specified length of data in the receive buffer after receive data is copied from the receive shift register to the receive buffer, another serial transfer will not be performed.

(c) Sequence control

In single-SPI master mode, according to the sequence length that is assigned to the sequence control register (SPSCR), this module makes up a sequence comprised of a part or all of SPCMD0 to SPCMD3 and SPBMUL0 to SPBMUL3. This module contains a pointer to the SPCMD that makes up the sequence. The value of this pointer can be checked by reading SPSSR.

When the SPE bit in SPCR is set to 1 and the function of this module is enabled, this module loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 and SPBMUL0 settings into the transfer format at the beginning of serial transfer. This module increments the pointer each time the next-access delay period for a data transfer that corresponds to the referenced SPCMD0 to SPCMD3 ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, this module sets the pointer in SPCMD0, and in this manner the sequence is executed repeatedly.

The following items are set in command registers SPCMD0 to SPCMD3: basic transfer data length, MSB or LSB first, clock settings, some of the bit rate settings, SPI transfer mode and transfer direction (only in dual-/quad-SPI modes), whether SSL level is held, a clock delay period, an SSL negation delay period, and a next-access delay period. The total amount of data to be transferred is determined by multiplying the basic length of data to be transferred by the value set with SPBMUL0 to SPBMUL3.

Figure 39.11 shows an operation example when SPSCR is set to H'02, and the sequence is configured based on SPCMD0 to SPCMD2 settings. In Figure 39.11, shaded areas of MOSI/MISO indicate invalid data. Periods (1) to (3) in Figure 39.11 indicate the followings.

(1) Clock delay period (SPCKD) setting value = B'000 (one SPCLK cycle)

(2) SSL negation delay period (SSLND) setting value = B'000 (one SPCLK cycle)

(3) Next-access delay period (SPND) setting value = B'000 (one SPCLK cycle)

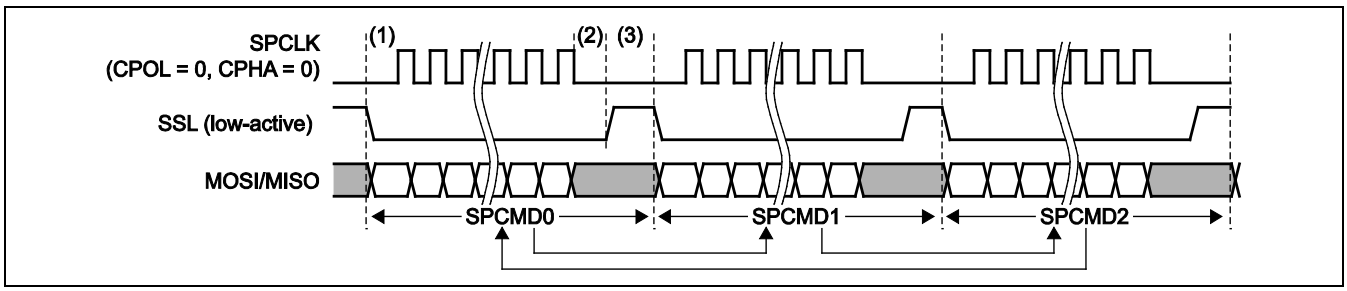

Figure 39.11 Sequence Control Operation

(d) Burst transfer

This module can execute burst transfer with the following two methods in single-SPI master mode.

One method uses the SPB[3:0] bits in SPCMD0 to SPCMD3 and SPBMUL0 to SPBMUL3. Setting SPB[3:0] to select 8, 16, or 32 bits and setting SPBMUL0 to SPBMUL3 to select one through 4,294,967,296 allows the specified length of data to be continuously transferred for the specified times, where the length is specified by SPB[3:0] and the number of times is specified by SPBMUL0 to SPBMUL3. However, if the transmit buffer (SPTXB) becomes empty during transfer, or the receive buffer (SPRXB) has no longer a space enough to receive the specified length of data defined by SPB[3:0], the clock is stopped until transfer is resumed. Figure 39.12 shows a burst transfer example in which SPB[3:0] are set to select 32 bits and SPBMUL to select four times thus specifying 128 bits as a total transfer data amount. The following describes operations (1) to (4) in the figure.

(1) First 32-bit data transfer

(2) Second 32-bit data transfer

(3) When the transmit buffer becomes empty or the receive buffer has no longer a space for 32 or more bits, the clock is stopped. Here, the MOSI continues outputting the previous value. When data is written to the transmit buffer or an enough space is created in the receive buffer, the clock output is resumed to restart transfer.

(4) Third and fourth 32-bit data transfer

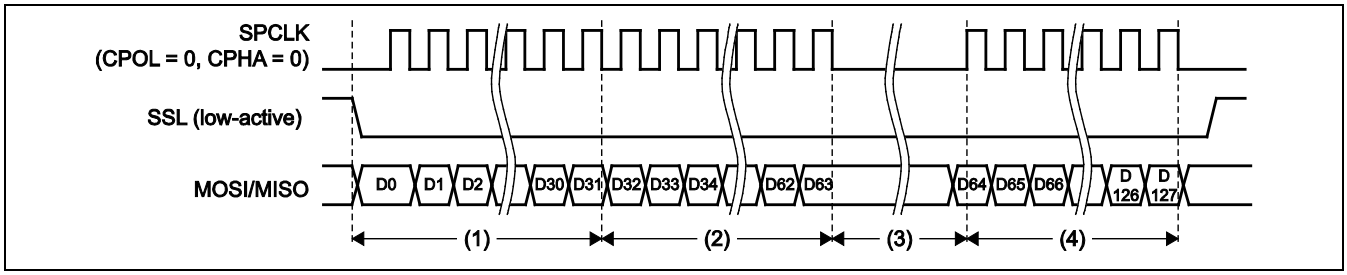

Figure 39.12 Burst Transfer Example in which Total Transfer Data Amount is 128 Bits (Single-SPI Master Mode Used)

In the other method, SSL is kept asserted after a serial transfer is completed until the next serial transfer. Setting the SSL signal level keeping bit (SSLKP) to 1 in SPCMD0 to SPCMD3 allows the SSL signal to be kept asserted after the transfer corresponding to the pertinent command register is completed until the next transfer. Figure 39.13 shows a burst transfer example in which the SSL signal level keeping function is used. The following describes operations (1) to (6) in the figure.

(1) Clock delay period according to the SPCMD0 setting. The setting must be made so that the delay period should be at least one SPCLK cycle for the first transfer in the burst transfer.

(2) SSL negation delay period according to the SPCMD0 setting. Since SSLKP is set to 1, SSL is not negated even after SSL negation delay period is over. The SSL negation delay period depends on the SLNDEN bit setting in SPCMD0. When SLNDEN is 1, the SSL negation delay period is determined by the SSLND setting, and the delay period is 0 SPCLK cycle when SLNDEN is 0.

(3) Next-access delay period according to the SPCMD0 setting. Since SSLKP is set to 1, SSL is not negated even during the next-access delay period. The next-access delay period depends on the SPNDEN bit setting in SPCMD0. When SPNDEN is 1, the next-access delay period is determined by the SPND setting, and the delay period is 0 SPCLK cycle when SPNDEN is 0.

(4) Clock delay period according to the SPCMD1 setting. The clock delay period depends on the SCKDEN bit setting in SPCMD1. When SCKDEN is 1, the clock delay period is determined by the SPCKD setting, and the delay period is 0 SPCLK cycle when SCKDEN is 0.

(5) SSL negation delay period according to the SPCMD1 setting. The setting must be made so that the delay period should be at least one SPCLK cycle for the last transfer in the burst transfer. Since SSLKP in SPCMD1 is set to 0, SSL is negated after SSL negation delay period is over.

(6) Next-access delay period according to the SPCMD1 setting. The setting must be made so that the delay period should be at least one SPCLK cycle for the last transfer in the burst transfer. Be sure to set SSLKP to 0 to negate SSL.

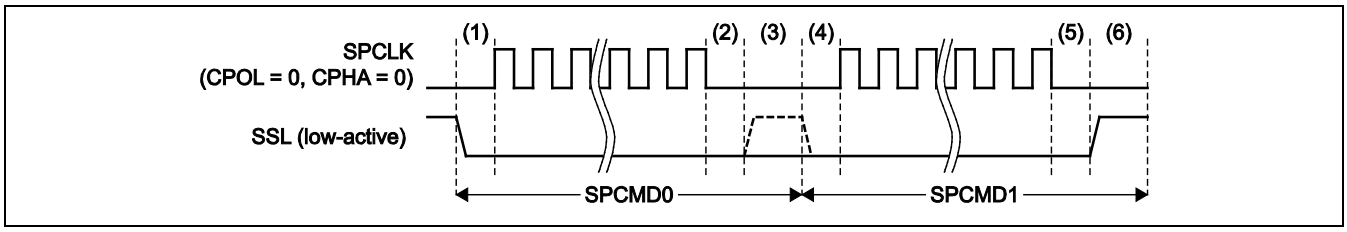

Figure 39.13 Burst Transfer Example in which SSL Signal Level Keeping Function is Used (Single-SPI Mode)

(e) Initialization flowchart

Figure 39.14 is a flowchart illustrating an example of initialization in SPI operation when this module is used in single-SPI master mode. For a description of how to set up the interrupt controller and direct memory access controller, see the descriptions given in the individual blocks.

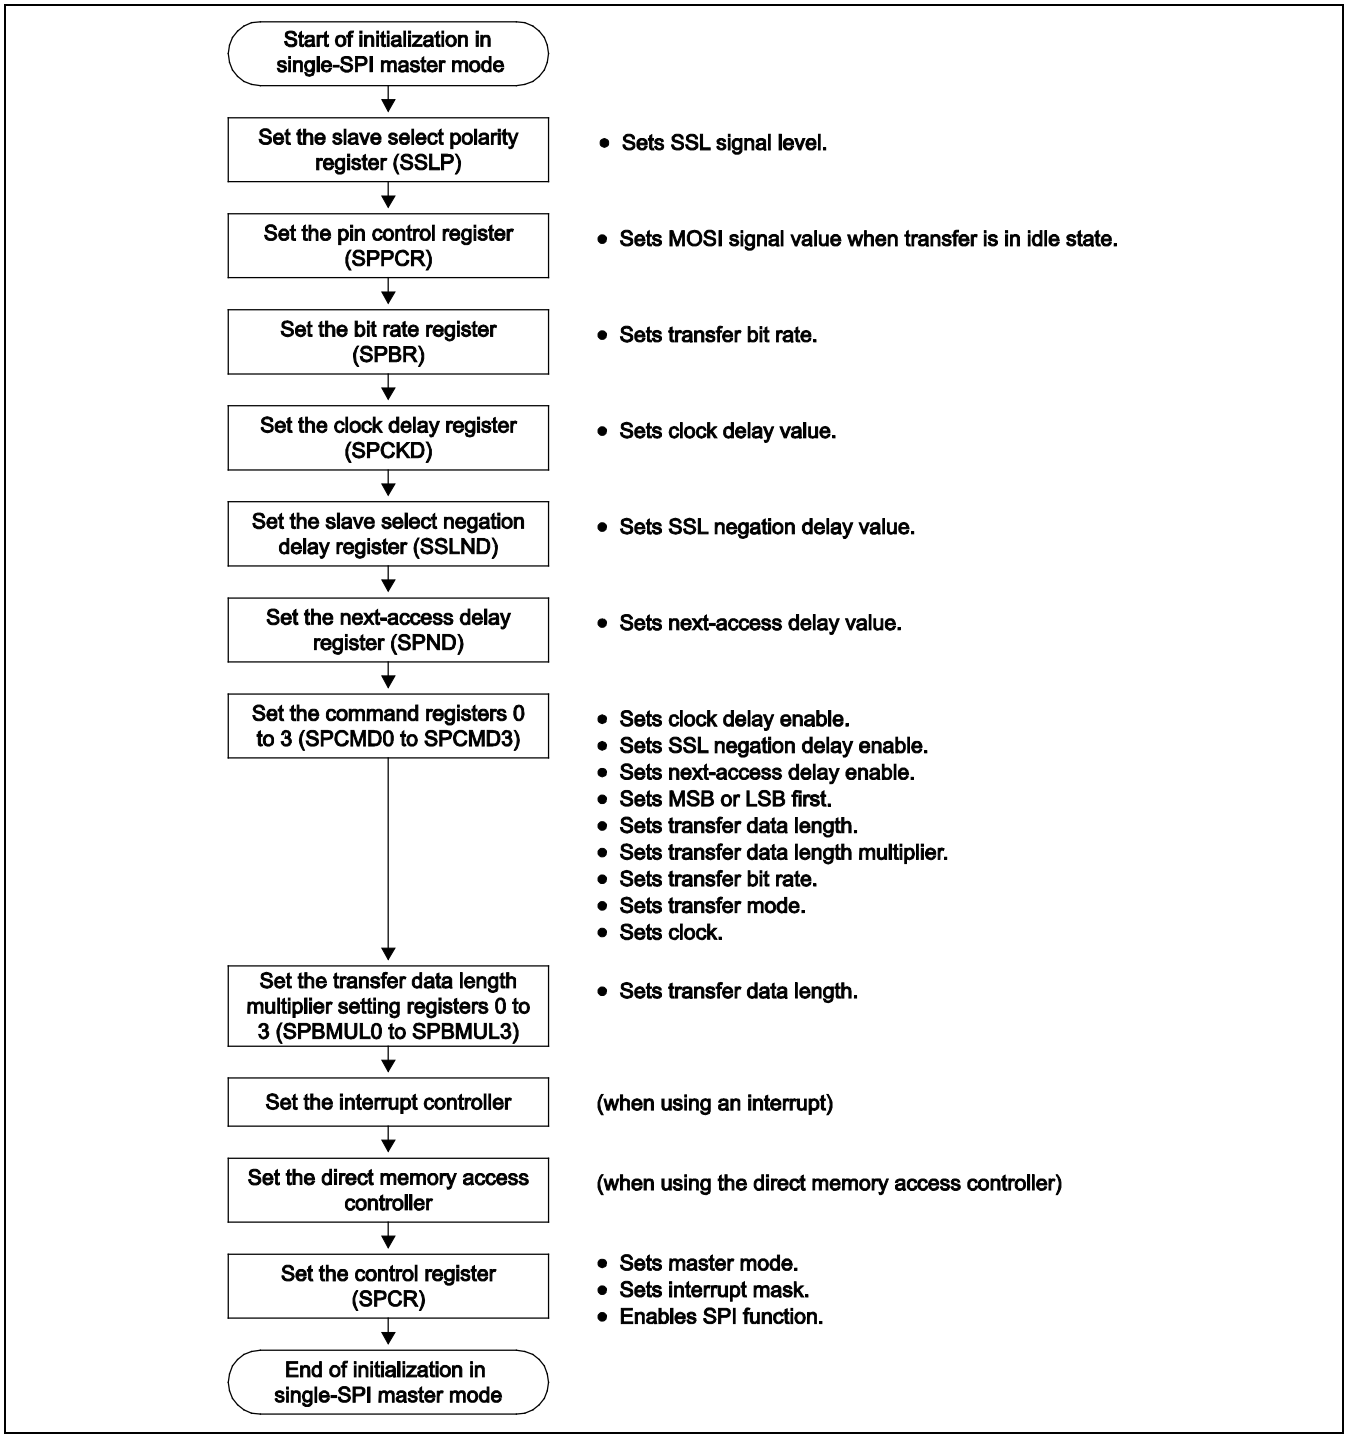

Figure 39.14 Example of Initialization Flowchart in Single-SPI Master Mode

(f) Transfer operation flowchart

Figure 39.15 is a flowchart illustrating a transfer in SPI operation when this module is used in single-SPI master mode. Burst transfer by setting the transfer data length is also executed based on this flowchart.

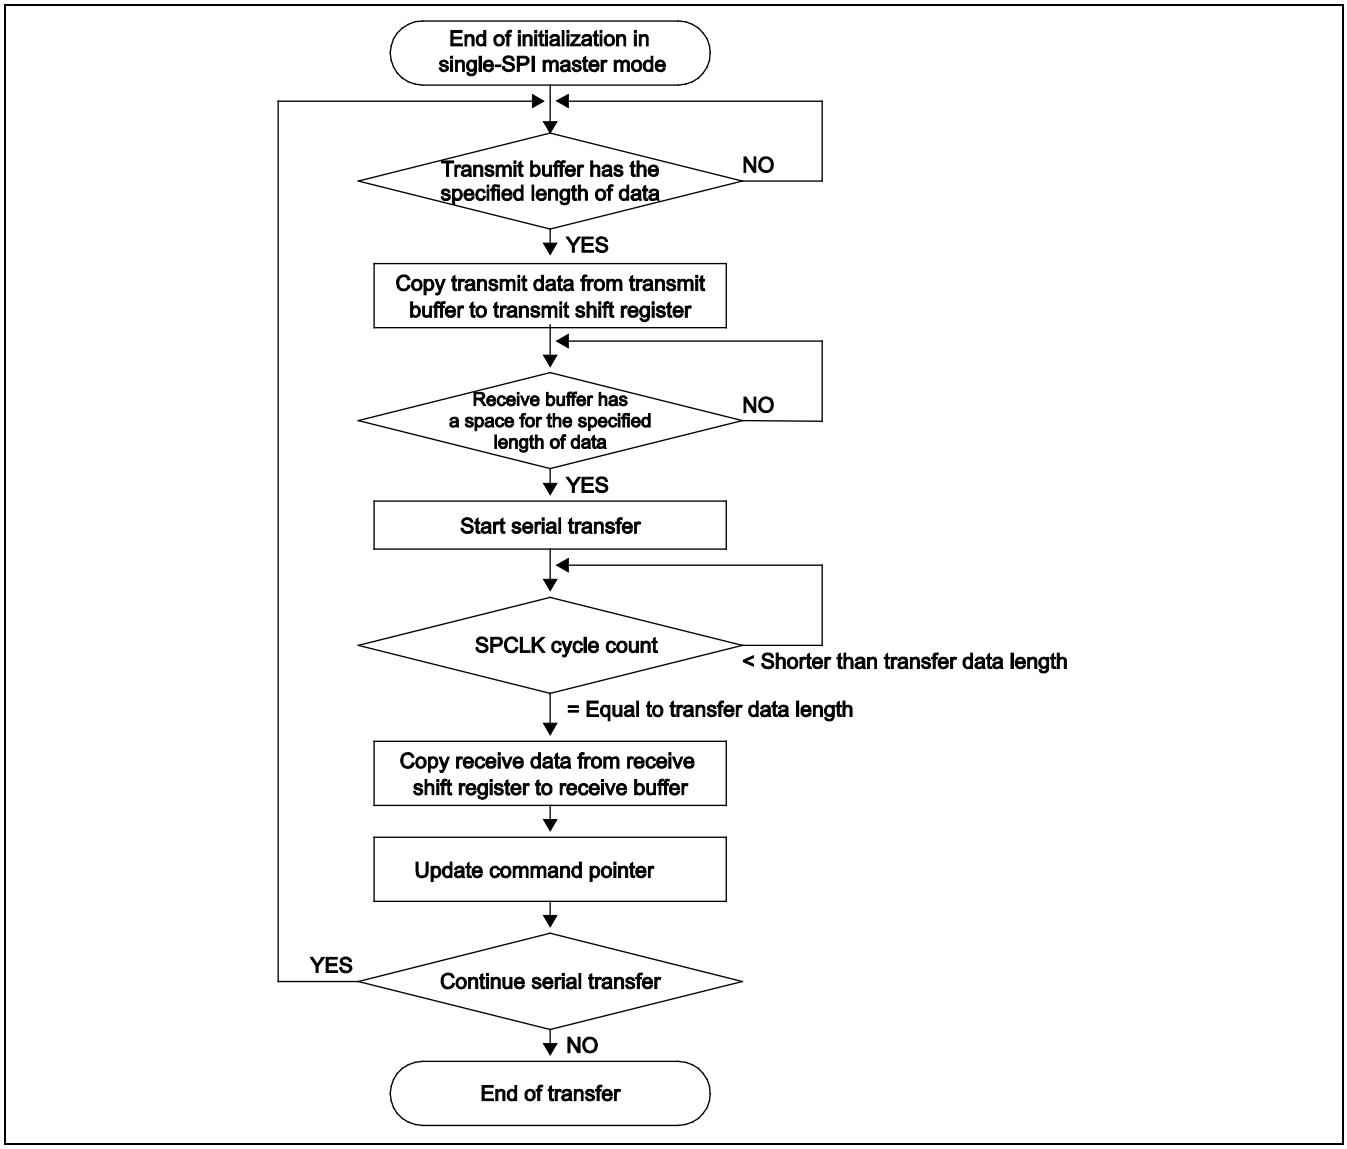

Figure 39.15 Transfer Operation Flowchart in Single-SPI Master Mode

(2) Dual-SPI/Quad-SPI mode

(a) Starting serial transfer

In dual-/quad-SPI modes, the serial transfer start condition differs depending on the data transfer direction (transmission or reception).

In data transmission, the serial transfer start condition is that there is the specified length of data in the transmit buffer.

In data reception, the serial transfer start condition is that there is a space for the specified length of data in the receive buffer.

(b) Terminating serial transfer

Irrespective of data transmission or reception, this module terminates the serial transfer after transmitting an SPCLK edge corresponding to the final sampling timing.

During idle cycles in dual-/quad-SPI modes, the IO pins are controlled differently depending on whether it is after write or read operation. Specifically, the IO pins output either the last output data or the fixed level depending on the register setting after write operation, whereas the IO pins are driven to the Hi-Z state after read operation. Figure 39.16 shows an example of the pin states after quad-SPI mode access is completed. The following describes operations (1) and (2) in the figure.

(1) During write operation, IO0 to IO3 serve as output pins. Thus, when SSL is negated upon completion of write operation, IO0 to IO3 output different values depending on the value of MOIFE in the SPPCR. Specifically, the IO pins output the level specified by MOIFV when MOIFE is 1, whereas the IO pins output the last output data when MOIFE is 0.

(2) During read operation, IO0 to IO3 serve as input pins. Thus, when SSL is negated upon completion of read operation, IO0 to IO3 are driven to Hi-Z state irrespective of the values of MOIFE and MOIFV.

For details on the pin control in dual-/quad-SPI modes, see section 39.5.2, Pin Control.

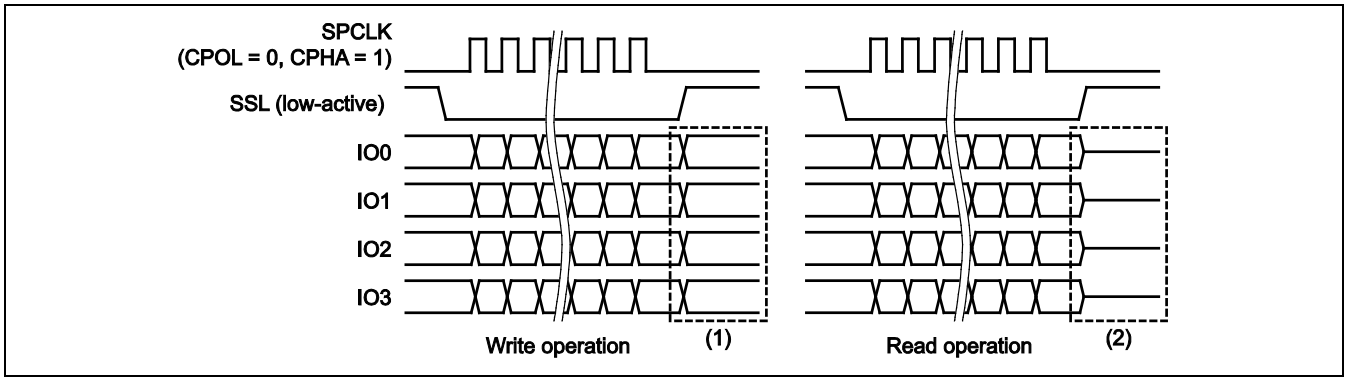

Figure 39.16 Example of Pin States after Quad-SPI Mode Access is Completed

(c) Sequence control

As with the single-SPI master mode, in dual-/quad-SPI modes, according to the sequence length that is assigned to SPSCR, this module makes up a sequence comprised of SPCMD0 to SPCMD3 and SPBMUL0 to SPBMUL3. For details on operation, see section 39.5.7 (1) (c), Sequence control.

Dual-/quad-SPI modes only provide operation of a single direction, that is, either transmission or reception for serial transfer. Transmission or reception is set using the SPI read/write access setting bit (SPRW) in SPCMD0 to SPCMD3. One of the three operating modes including dual-SPI mode, quad-SPI mode, and single-SPI master mode is set using the SPI operating mode setting bits (SPIMOD[1:0]) in SPCMD0 to SPCMD3. Combining these bits allows switching single-SPI master mode, dual-SPI mode transmission/reception, and quad-SPI mode transmission/reception to control sequence. Figure 39.17 shows an example of sequence configuration with transfer mode switching.

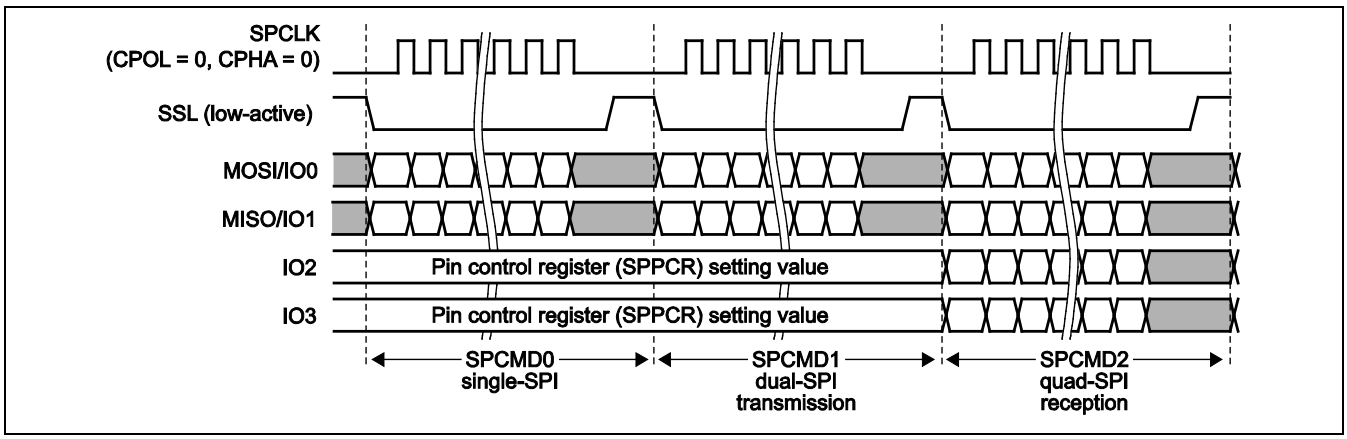

Figure 39.17 Example of Sequence Configuration with Transfer Mode Switching

Note the following when configuring a sequence in dual-/quad-SPI modes.

When all the commands configuring a sequence are dual-/quad-SPI read operations, the sequential operation is continued as long as the receive buffer has an enough space for the receive data.

To terminate read operation, clear the SPE bit to 0 in SPCR after receiving the required length of data, or execute write operation for the last sequence to empty the transmit buffer.

(d) Burst transfer

This module can execute burst transfer with the following two methods in dual/quad SPI modes.

One method uses the SPB[3:0] bits in SPCMD0 to SPCMD3 and SPBMUL0 to SPBMUL3. As with the single-SPI master mode, setting SPB[3:0] to select 8, 16, or 32 bits and setting SPBMUL0 to SPBMUL3 to select one through 4,294,967,296 allows the specified length of data to be continuously transferred for the specified times, where the length is specified by SPB[3:0] and the number of times is specified by SPBMUL0 to SPBMUL3. However, if the transmit buffer (SPTXB) becomes empty during transfer, or the receive buffer (SPRXB) has no longer a space enough to receive the specified length of data defined by SPB[3:0], the clock is stopped until transfer is resumed. This method is effective to transfer a large amount of data in dual-/quad SPI modes. Figure 39.18 shows a burst transfer example in which SPB[3:0] are set to select 32 bits and SPBMUL to select four times thus specifying 128 bits as a total transfer data amount. The following describes operations (1) to (4) in the figure.

(1) First 32-bit data transfer

(2) Second 32-bit data transfer

(3) When the transmit buffer becomes empty or the receive buffer has no longer a space for 32 or more bits, the clock is stopped. Here, when IO3 to IO0 serve as output pins, IO3 to IO0 continue outputting the previous value. When IO3 to IO0 serve as input pins, the inputs to IO3 to IO0 depend on the output value of the device to communicate with. When data is written to the transmit buffer or an enough space is created in the receive buffer, the clock output is resumed to restart transfer.

(4) Third and fourth 32-bit data transfers

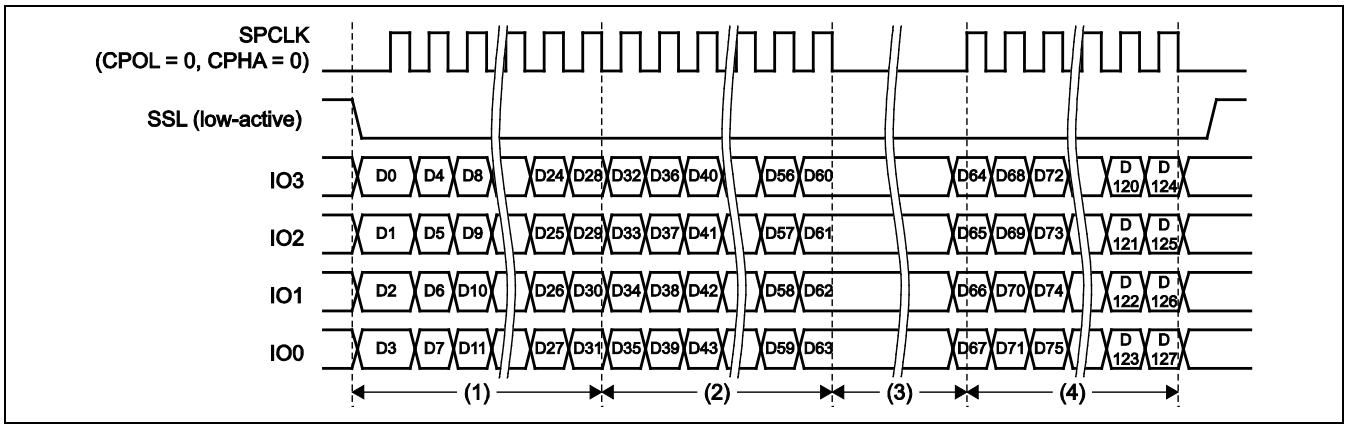

Figure 39.18 Burst Transfer Example in which Total Transfer Data Amount is 128 Bits (Quad-SPI Mode)

The other method uses the SSL signal level keeping function as in single-SPI master mode. Since this method allows switching the SPI transfer modes (single-/dual-/quad-SPI) during a transfer, it is particularly convenient when used with devices such as serial flash memory, where command data is written in single-SPI mode and data to be stored in memory is written in quad-SPI mode. Note, however, that at least one delay cycle should be inserted between transfers when switching the SPI transfer modes. Figure 39.19 shows a burst transfer example in which both single-SPI and quad-SPI modes are used. The following describes operations (1) to (6) in the figure.

(1) Clock delay period according to the SPCMD0 setting. The setting must be made so that the delay period should be at least one SPCLK cycle for the first transfer in the burst transfer.

(2) SSL negation delay period according to the SPCMD0 setting. Since SSLKP in SPCMD0 is set to 1, SSL is not negated even after SSL negation delay period is over. The SSL negation delay period depends on the SLNDEN bit setting in SPCMD0. When SLNDEN is 1, the SSL negation delay period is determined by the SSLND setting, and the delay period is 0 SPCLK cycle when SLNDEN is 0.

(3) Next-access delay period according to the SPCMD0 setting. Since SSLKP is set to 1, SSL is not negated even during the next-access delay period. The next-access delay period depends on the SPNDEN bit setting in SPCMD0. When SPNDEN is 1, the next-access delay period is determined by the SPND setting, and the delay period is 0 SPCLK cycle when SPNDEN is 0.

(4) Clock delay period according to the SPCMD1 setting. The clock delay period depends on the SCKDEN bit setting in SPCMD1. When SCKDEN is 1, the clock delay period is determined by the SPCKD setting, and the delay period is 0 SPCLK cycle when SCKDEN is 0.

(5) SSL negation delay period according to the SPCMD1 setting. The setting must be made so that the delay period should be at least one SPCLK cycle for the last transfer in the burst transfer. Since SSLKP in SPCMD1 is set to 0, SSL is negated after SSL negation delay period is over.

(6) Next-access delay period according to the SPCMD1 setting. The setting must be made so that the delay period should be at least one SPCLK cycle for the last transfer in the burst transfer. Be sure to set SSLKP to 0 to negate SSL.

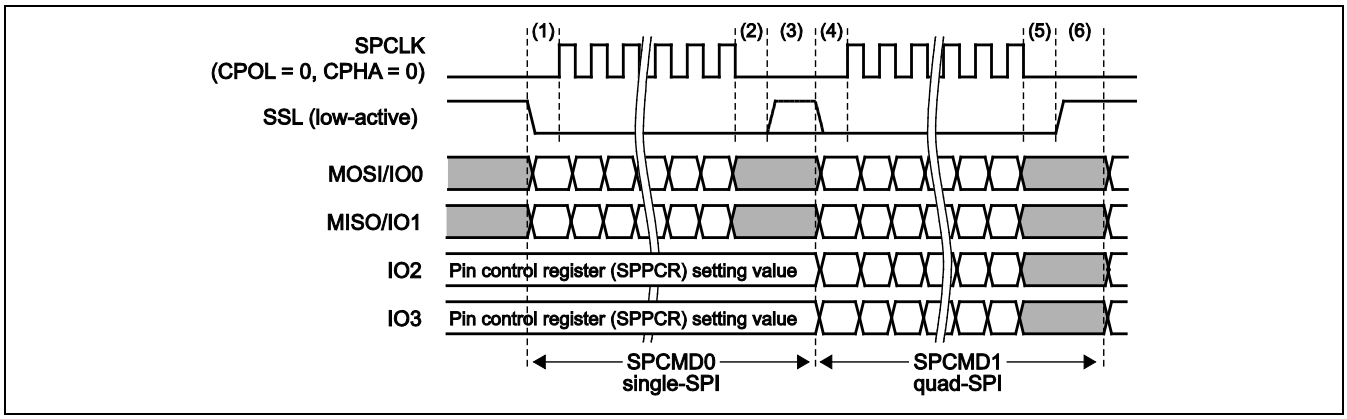

Figure 39.19 Burst Transfer Example in which SSL Signal Level Keeping Function is Used (Single- and Quad-SPI Modes Used)

(e) Initialization flowchart

Figure 39.20 is a flowchart illustrating an example of initialization in SPI operation when this module is used in dual-/quad-SPI mode. For a description of how to set up the interrupt controller and direct memory access controller, see the descriptions given in the individual blocks.

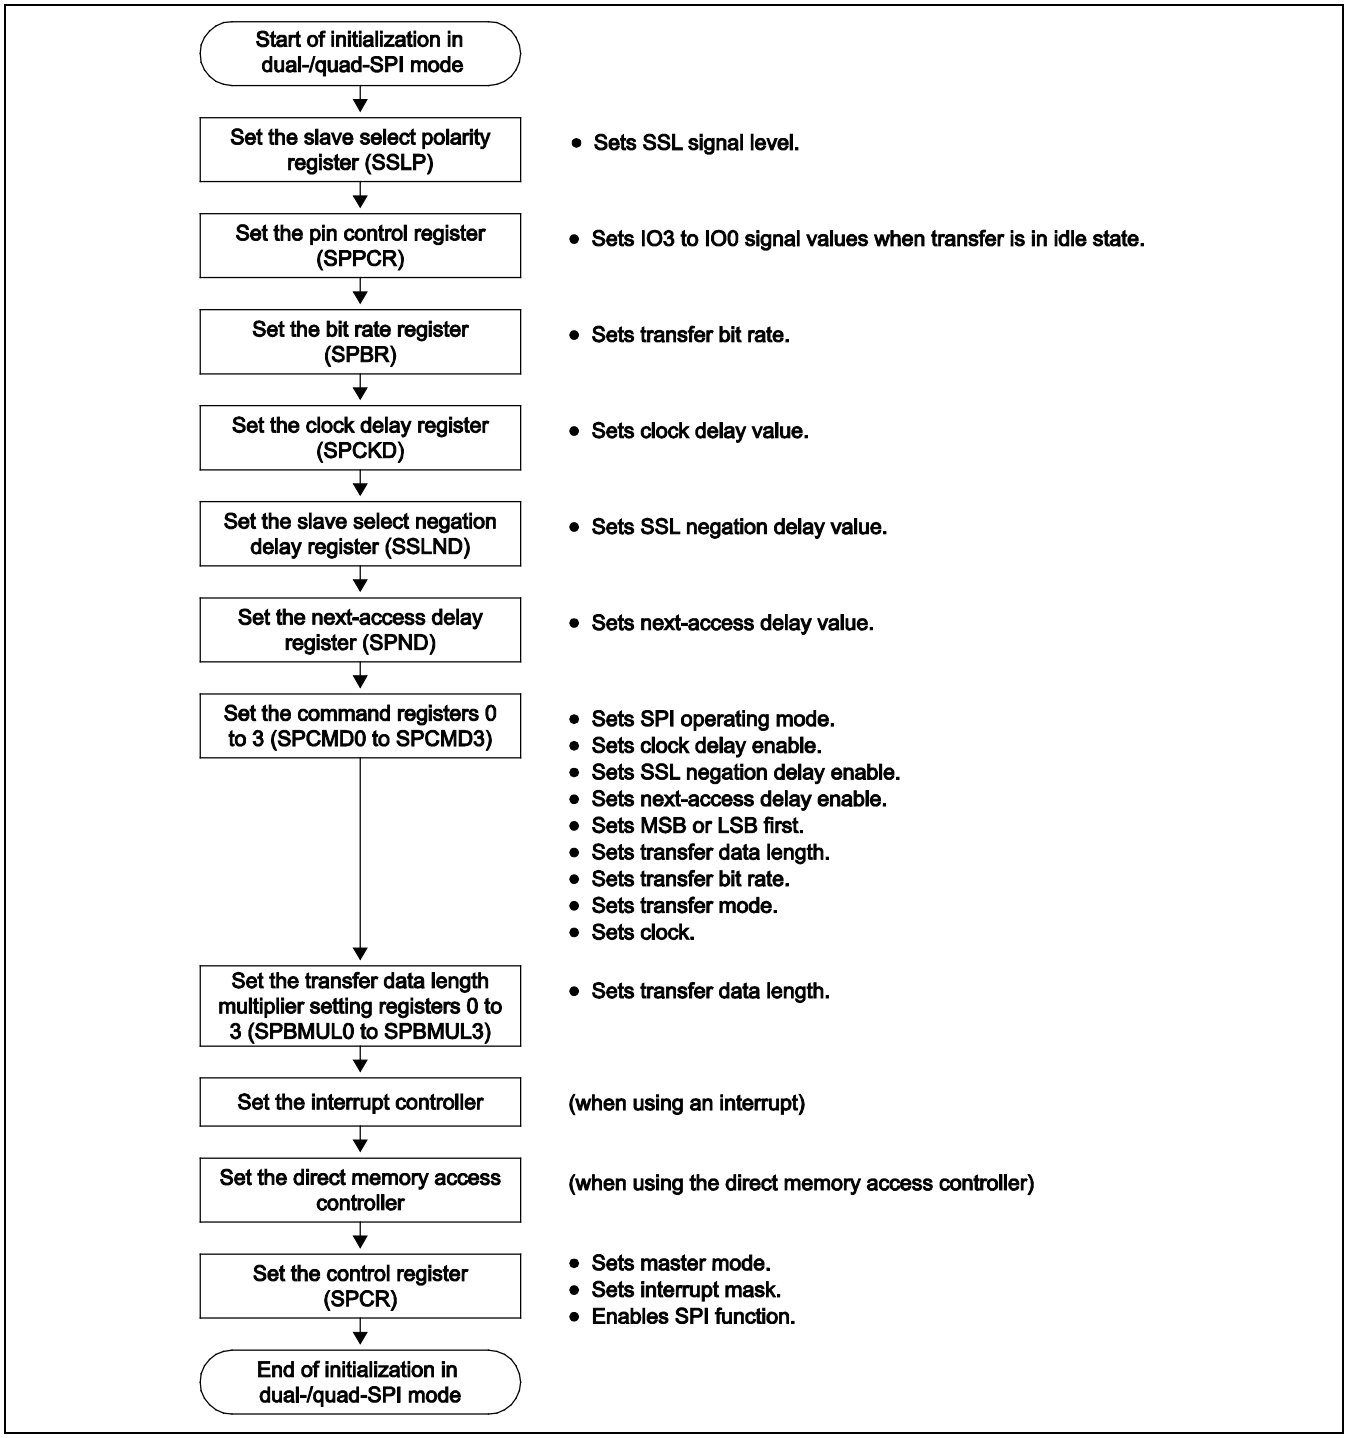

Figure 39.20 Example of Initialization Flowchart in Dual-/Quad-SPI Mode

(f) Transfer operation flowchart

Figure 39.21 is a flowchart illustrating a transfer in SPI operation when this module is used in dual-/quad-SPI mode.

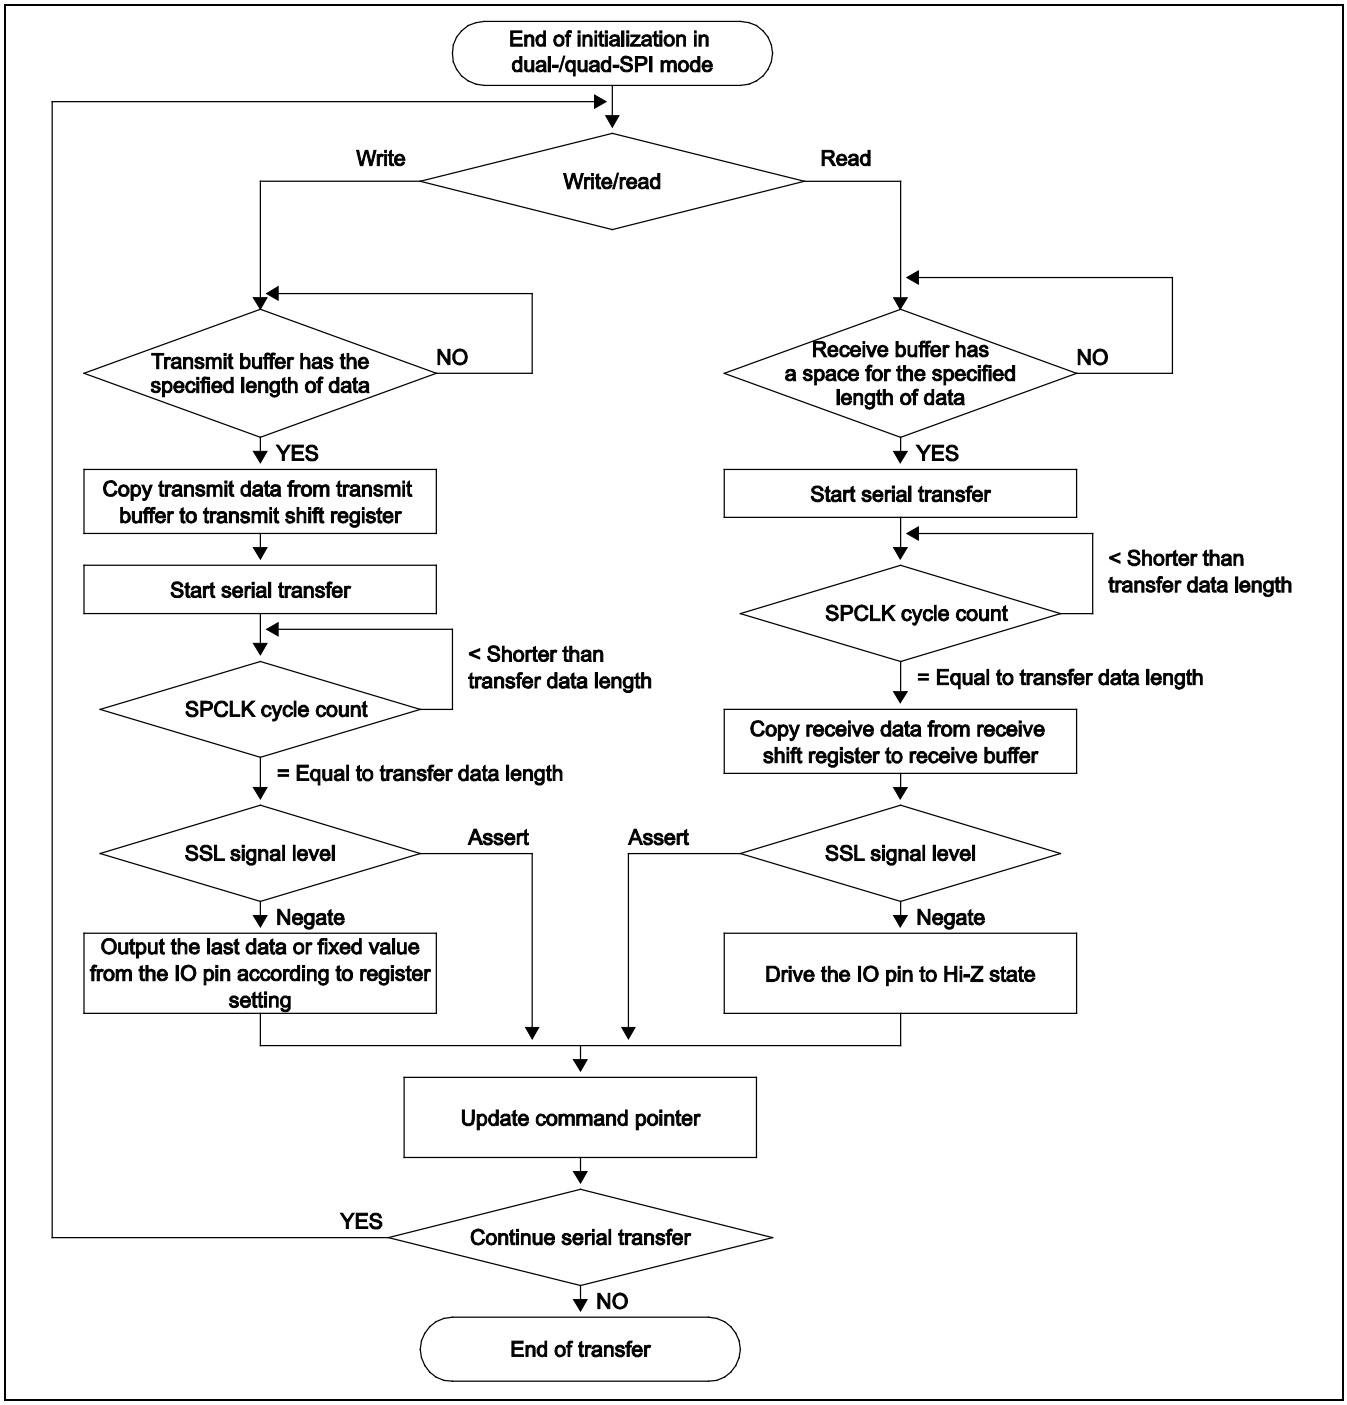

Figure 39.21 Transfer Operation Flowchart in Dual-/Quad-SPI Mode

39.5.8 Interrupt Sources

This module has interrupt sources of receive buffer full, transmit buffer empty, underrun error, overrun error, and mode fault error. In addition, the direct memory access controller can be activated by the receive buffer full or transmit buffer empty interrupt for data transfer.

Table 39.9 shows the interrupt sources.

When any of the interrupt conditions in Table 39.9 is met, an interrupt is generated. The interrupt sources should be cleared with data transfer by the CPU or direct memory access controller.

Table 39.9 Interrupt Sources

Name	Interrupt Source	Abbreviation	Interrupt Condition	Activation of Direct Memory Access Controller
SPRI	Receive buffer full	RXI	SPRIE = 1 and SPRFF = 1	Possible
SPTI	Transmit buffer empty	TXI	SPTIE = 1 and SPTEF = 1	Possible
SPEI	Underrun error	UDI	SPEIE = 1 and UDRF = 1	Not possible
	Overrun error	OVI	SPEIE = 1 and OVRF = 1	Not possible
	Mode fault error	MOI	SPEIE = 1 and MODF = 1	Not possible

39.5.9 Loopback Mode

This module provides loopback mode for testing. Writing 1 to the loopback mode bit (SPLP) in the pin control register (SPPCR) enables loopback mode. In loopback mode, this module disconnects the paths between the transmit/receive shift registers and the MISO/MOSI and IO3 to IO0 pins, and connects the outputs from the transmit shift register to the inputs to the receive shift register instead. Figure 39.22 shows a schematic internal connection in loopback mode.

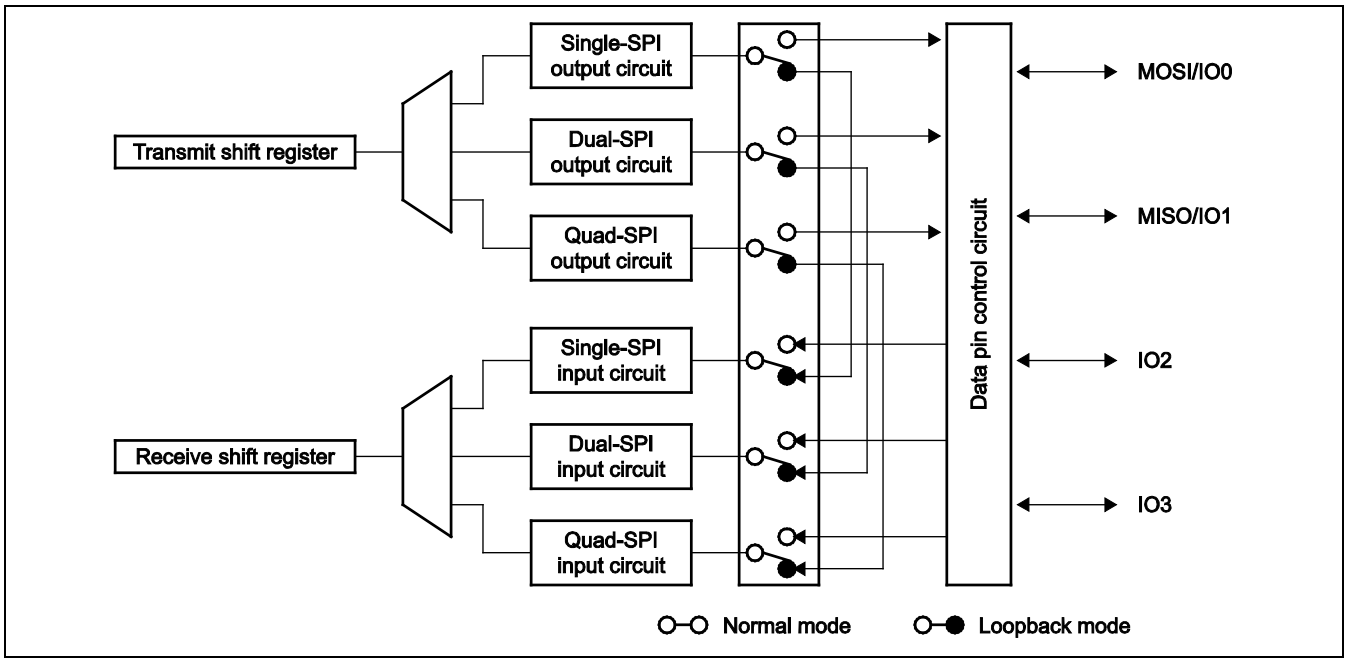

Figure 39.22 Schematic Internal Connection in Loopback Mode

40. SD Card/MMC Interfaces

40.1 Overview

40.1.1 Features

This LSI has three SD card interfaces (SDHI0 to SDHI2), one of which can also be used as MMC interfaces (SDHI1). The select setting of SDHI and MMC is unnecessary.

- SD memory/IO card interface (1-bit/4-bit SD bus)
- SD, SDHC, and SDXC SD memory card access supported
- Default, high-speed, UHS-I/SDR50, and SDR104 transfer modes supported
  SDR104 mode is only SDHI0 and SDHI1.
- SD clock (SDCLK) frequency = internal SDxϕ* frequency/2^n (n = 0 to 9)
- SDCLK = 156 MHz (SDR104)
- SDCLK = 78 MHz (SDR50)
- Error check function: CRC7 (for command/response), CRC16 (for data)
- Interrupt request: 2/CH
- Card detect function
- Write protect support
- MMC interface (1-bit/4-bit/8-bit MMC bus)
- eMMC device access supported
- Backward-compatible, high-speed, HS200 transfer modes supported
- MMCCLK = 156 MHz (HS200)
- High-priority interrupt (HPI) supported
- Alternative Boot operation supported

Note: * x = 0, 2

Development of the SD-related products needs the conclusion of the following agreement.

SD Host/Ancillary Product License Agreement (SD HALA)

40.1.2 Block Diagram

Figure 40.1 shows a block diagram of the SD host interface.

SDHI0 and SDHI2 is APB interface. SDHI1(MMC0) is AXI interface.

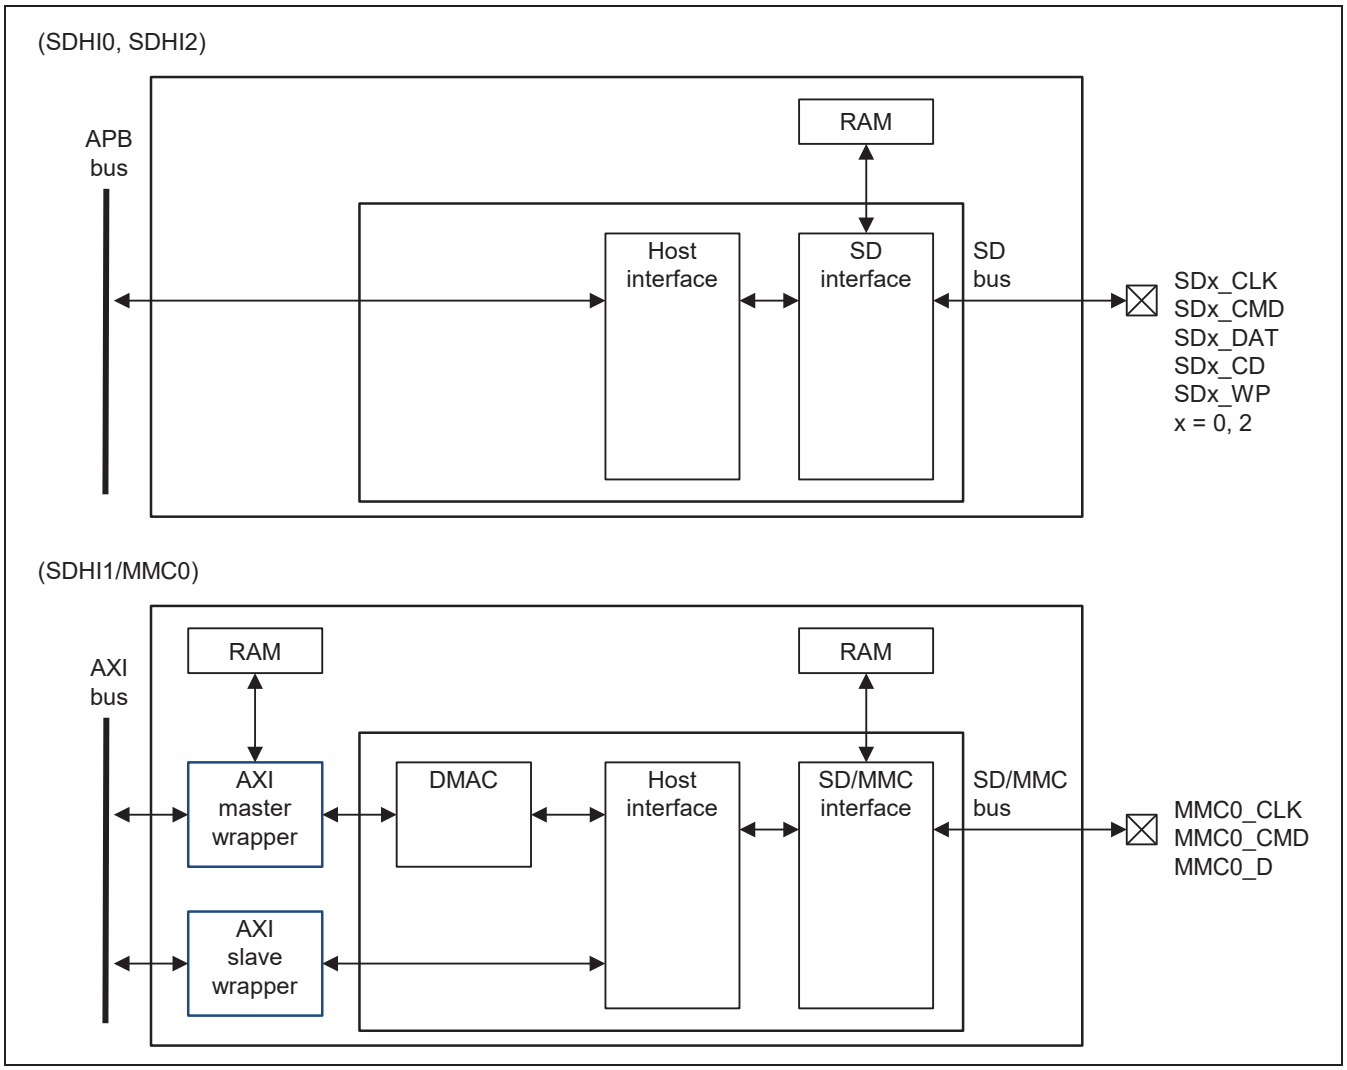

Figure 40.1 Block Diagram of SD Host Interface

40.1.3 Input / Output Pins

Table 40.1 lists the input and output pins used by the interface. The voltage of the SDHI terminal is variable. Therefore a power network is separate.

Table 40.1 Pin Configuration

PIN Name	I/O	Function	Voltage
SDx_CLK*	O	SD clock	Voltage switch of 1.8 V/3.3 V
SDx_CMD*	I/O	Command/response	Voltage switch of 1.8 V/3.3 V
SDx_DAT0*	I/O	Data [bit 0]	Voltage switch of 1.8 V/3.3 V
SDx_DAT1*	I/O	Data [bit 1]/SDIO interrupt	Voltage switch of 1.8 V/3.3 V
SDx_DAT2*	I/O	Data [bit 2]/Read wait	Voltage switch of 1.8 V/3.3 V
SDx_DAT3*	I/O	Data [bit 3]/Card detect	Voltage switch of 1.8 V/3.3 V
SDx_CD*	I	Card detect	3.3 V
SDx_WP*	I	Write protect	3.3 V
MMC0_CLK(SD1_CLK)	O	MMC clock	Voltage switch of 1.8 V/3.3 V
MMC0_CMD(SD1_CMD)	I/O	Command/response	Voltage switch of 1.8 V/3.3 V
MMC0_D0(SD1_DAT0)	I/O	Data [bit 0]	Voltage switch of 1.8 V/3.3 V
MMC0_D1(SD1_DAT1)	I/O	Data [bit 1]	Voltage switch of 1.8 V/3.3 V
MMC0_D2(SD1_DAT2)	I/O	Data [bit 2]	Voltage switch of 1.8 V/3.3 V
MMC0_D3(SD1_DAT3)	I/O	Data [bit 3]	Voltage switch of 1.8 V/3.3 V
MMC0_D4(SD1_CD)	I/O	Data [bit 4]	Voltage switch of 1.8 V/3.3 V
MMC0_D5(SD1_WP)	I/O	Data [bit 5]	Voltage switch of 1.8 V/3.3 V
MMC0_D6	I/O	Data [bit 6]	Voltage switch of 1.8 V/3.3 V
MMC0_D7	I/O	Data [bit 7]	Voltage switch of 1.8 V/3.3 V

Note: * x = 0, 2

It may lead to device destruction. Please the voltage setting and applied voltage to match.

41. USB2.0 Host (EHCI/OHCI)

41.1 Overview

This module is a USB2.0 host controller conforming to the Enhanced Host Controller Interface (EHCI) Specification for USB Rev. 1.1.

It can also be used as a dual-role device (DRD) in combination with a peripheral link module connected to the external UTMI+ interface.

41.1.1 Features

The following shows the features of this module.

Function	Description
Host function	• Supports High-speed (480 Mbps), Full-speed (12 Mbps), and Low-speed (1.5 Mbps) transfer. • Conforms to the Open Host Controller Interface (OHCI) Specification for USB Rev. 1.0a. • Conforms to the Enhanced Host Controller Interface (EHCI) Specification for USB Rev. 1.1.*1
Peripheral function	The peripheral function is available through a peripheral controller module connected to the external UTMI+ interface
Accessible memory space	32 bits
USB port count	Downstream port: 1 port for each channel Upstream port: 1 port*2
Other functions	• Dual-role device function (static switching between the USB host and peripheral functions)

Notes: 1. Some functions (specifications) are not supported.
2. Only when HS USB module is selected.
3. The peripheral function is assumed to be controlled by a HS USB module.

41.1.2 Input/Output Pins

Table 41.1 Pin Configuration of USB

Classification	Pin Name	Name	I/O	Description
USB bus interface	USB0_DP	USB channel 0 D+ data	I/O	D+ Input/output of the on-chip transceiver Connect this pin to the D+ pin of the USB bus channel 0
	USB0_DM	USB channel 0 D- data	I/O	D- Input/output of the on-chip transceiver Connect this pin to the D- pin of the USB bus channel 0
	USB1_DP	USB channel 1 D+ data	I/O	D+ Input/output of the on-chip transceiver Connect this pin to the D+ pin of the USB bus channel 1
	USB1_DM	USB channel 1 D- data	I/O	D- Input/output of the on-chip transceiver Connect this pin to the D- pin of the USB bus channel 1
Reference resistance	RREF	USB external reference resistor	I	Connect to external 5.6kΩ±1% resistor.
VBUS	USB0_VBUS	USB channel 0 VBUS	I	The external series resistor is not required Connect this pin to the USB VBUS channel 0. Supply 5V, even if the host function is used.
	USB1_VBUS	USB channel 1 VBUS	I	The external series resistor is not required Connect this pin to the USB VBUS channel 1. Supply 5V, even if the host function is used.
Over current	USB0_OVC	USB channel 0 Over current	I/O	Connect to over current detection pin of external power IC which supply VBUS power. This is low active signal
	USB1_OVC	USB channel 0 Over current	I/O	Connect to over current detection pin of external power IC which supply VBUS power. This is low active signal
Power Enable	USB0_PWEN	USB channel 0 Power enable	I/O	Connect to power enable pin of external power IC which supply VBUS power
	USB1_PWEN	USB channel 0 Power enable	I/O	Connect to power enable pin of external power IC which supply VBUS power

41.2 Register Configuration

41.2.1 Register Attributes

Table 41.2 Register Bit-field types

Register Attribute	Description
R/W	Register bits can be read and written.
RW1C	Register bits can be read. A clear bit may be set by writing “1”; writing 0 to RW1C bits has no effect.
RWT	Register bits can be read. An inversion bit may be set by writing “1”; writing 0 to RWT bits has no effect.
RW1S	Register bits can be read and written. A bit may be set to 1 by writing “1”; writing 0 to RW1S bits has no effect.
R	Register bits can only be read.
W	Register bits can only be written.
Reserved	Reserved bits are Read Only field.

Bit	**Bit Name**	**HCD**	**HC**	**Initial Value**	**Description**
31 to 8	—	R	R	All 0	Reserved
7 to 0	Revision	R	R	H'10	This field contains the BCD representation of the version of the OHCI specification that is implemented by this host controller core. This core supports OHCI 1.0a and this field shows H'10.

41.3.1.2 HcControl Register (offset: H'004)

Register symbol: HcControl

The HcControl register defines the operating modes as the classic host controller. Most of the fields in this register are modified only by software, except HostControllerFunctionalState and RemoteWakeupConnected.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 11	Reserved	R	R	All 0	This field shows a BCD encoding of the EHCI revision number supported by this host controller core. This host controller core supports EHCI v.1.1.
10	RWE	RW	R	0	RemoteWakeupEnable This bit is used by software to enable or disable the remote wakeup feature upon the detection of upstream resume signaling. When this bit is set and the ResumeDetected bit in HcInterruptStatus is set, a remote wakeup is signaled to the host system. Setting this bit has no impact on the generation of hardware interrupt. 0: An interrupt due to remote wakeup is not generated. 1: An interrupt due to remote wakeup is generated.
9	RWC	RW	RW	0	RemoteWakeupConnected This bit indicates whether the host controller supports remote wakeup signaling. Software should set this bit to 1 in the initialization sequence if it is required to support remote wakeup. The host controller clears this bit to 0 upon hardware reset but does not alter it upon software reset. 0: The remote wakeup is not supported. 1: The remote wakeup is supported.
8	IR	RW	R	0	InterruptRouting This bit determines the routing of interrupts generated by events registered in HcInterruptStatus. If this bit is 0, all interrupts are routed to the normal host bus interrupt mechanism. If this bit is set to 1, interrupts are routed to the System Management Interrupt. Software clears this bit upon a hardware reset, but it does not alter this bit upon a software reset.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
7, 6	HCFS	RW	RW	00	HostControllerFunctionalState 00: USB Reset 01: USB Resume 10: USB Operational 11: USB Suspend. This field defines the functional state of the host controller. The transition to USB Operational state from another state causes SOF generation to show 1-ms frame boundary. Software controls this bit basically; this field may be changed by the host controller only when in the USB Suspend state. The host controller may move from the USB Suspend state to the USB Resume state after detecting the resume signaling from a downstream port. The host controller enters USB Suspend state after software reset, whereas it enters USB Reset state after hardware reset.
5	BLE	RW	R	0	BulkListEnable This bit is set to 1 in order to enable the processing of the Bulk list in the next Frame. If this bit is 0, processing of the Bulk list does not occur after the next SOF. The host controller checks this bit whenever it determines to process the list. When software modifies the Bulk list, it should set this bit to 0 before modifying the list. 0: The processing of the Bulk list is disabled. 1: The processing of the Bulk list is enabled.
4	CLE	RW	R	0	ControlListEnable This bit is set to 1 in order to enable the processing of the Control list in the next Frame. If this bit is 0, processing of the Control list does not occur after the next SOF. The host controller checks this bit whenever it determines to process the list. When software modifies the Control list, it should set this bit to 0 before modifying the list. 0: The processing of the Control list is disabled. 1: The processing of the Control list is enabled.
3	IE	RW	R	0	IsochronousEnable This bit is set to 1 in order to enable the processing of isochronous EDs. While processing the periodic list in a Frame, the host controller checks the status of this bit when it finds an Isochronous ED (F = 1). If this bit is 1 (enabled), the host controller continues processing the EDs. If this bit is 0 (disabled), the host controller halts processing of the periodic list (which contains only isochronous EDs right now) and begins processing the Bulk/Control lists. Setting this bit is guaranteed to take effect in the next Frame (not the current Frame). 0: The processing of the isochronous ED is disabled. 1: The processing of the isochronous ED is enabled.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
2	PLE	RW	R	0	PeriodicListEnable This bit is set to enable the processing of the periodic list in the next Frame. If cleared to 0 by software, processing of the periodic list does not occur after the next SOF. The host controller checks this bit before it starts processing the periodic list. 0: The processing of the periodic list is disabled. 1: The processing of the periodic list is enabled.
1, 0	CBSR	RW	R	00	ControlBulkServiceRatio This field specifies the service ratio between Control and Bulk EDs. In case of reset, software should restore the value in this field. **CBSR No. of Control EDs Over Bulk EDs Served** 00: 1:1 01: 2:1 10: 3:1 11: 4:1

41.3.1.3 HcCommandStatus Register (offset: H'008)

Register symbol: HcCommandStatus

The HcCommandStatus register is used by the host controller to receive commands issued by software, as well as reflecting the current status of the host controller.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SOC	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	OCR	BLF	CLF	HCR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	W	R/W	R/W	W

		R/W			
Bit	**Bit Name**	**HCD**	**HC**	**Initial Value**	**Description**
31 to 18	—	R	R	All 0	Reserved
17, 16	SOC	R	RW	00	SchedulingOverrunCount This field is incremented on each scheduling overrun error. It is initialized to B'00 and wraps around at B'11. This field is incremented when a scheduling overrun is detected even if SchedulingOverrun in HcInterruptStatus register has already been set.
15 to 4	—	R	R	All 0	Reserved
3	OCR	W	RW	0	OwnershipChangeRequest This bit is set by software to request a change of control of the host controller. When this bit is set to 1, the host controller sets the OwnershipChange bit in HcInterruptStatus register. After the changeover, this bit is cleared to 0. 0: The change of control of the host controller is not requested. 1: The change of control of the host controller is requested.
2	BLF	RW	RW	0	BulkListFilled This bit is used to indicate whether there are any TDs on the Bulk list. It is set by software whenever it adds a TD to an ED in the Bulk list. When the host controller begins to process the head of the Bulk list, it checks BLF bit. As long as BLF bit is 0, the host controller does not start processing the Bulk list. If BLF bit is 1, the host controller starts processing the Bulk list and sets BLF bit to 0. If the host controller finds a TD on the list, then the host controller set BLF bit to 1 causing the Bulk list processing to continue. If no TD is found on the Bulk list, and if software does not set BLF bit, then BLF bit remains at 0 when the host controller completes processing the Bulk list and Bulk list processing will stop. 0: TD exists in the Bulk list. 1: TD does not exist in the Bulk list.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
1	CLF	RW	RW	0	ControlListFilled This bit is used to indicate whether there are any TDs on the Control list. It is set by software whenever it adds a TD to an ED in the Control list. When the host controller begins to process the head of the Control list, it checks CLF bit. As long as CLF bit is 0, the host controller does not start processing the Control list. If CLF bit is 1, the host controller starts processing the Control list and sets CLF bit to 0. If the host controller finds a TD on the list, then the host controller set CLF bit to 1 causing the Control list processing to continue. If no TD is found on the Control list, and if software does not set CLF bit, then CLF bit remains at 0 when the host controller completes processing the Control list and Control list processing will stop. 0: TD exists in the Control list. 1: TD does not exist in the Control list.
0	HCR	W	RW	0	HostControllerReset This bit is set by software to initiate software reset of the host controller. Regardless of the functional state of the host controller, it moves to the USB Suspend state. This bit is cleared to 0 by the host controller upon the completion of the reset operation. 0: The software reset of the host controller is not requested. 1: The software reset of the host controller is requested.

41.3.1.4 HcInterruptStatus Register (offset: H'00C)

Register symbol: HcInterruptStatus

This register provides status on various events that cause hardware interrupts. When an event occurs, the host controller sets the corresponding bit in this register. When a bit becomes set, an interrupt is generated if the interrupt is enabled in the HcInterruptEnable register and the MasterInterruptEnable bit is set.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	OC	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

	—	—	—	—	—	—	—	—	—	RHSC	FNO	UE	RD	SF	WDH	SO
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31	—	R	R	0	Reserved
30	OC	RW	RW	0	OwnershipChange This bit is set by the host controller when software sets the OwnershipChangeRequest field in HcCommandStatus register. 0: The ownership change has not been requested. 1: The ownership change has been requested.
29 to 7	—	R	R	All 0	Reserved
6	RHSC	RW	RW	0	RootHubStatusChange This bit is set when the content of HcRhStatus or the content of any of HcRhPortStatus [NumberofDownstreamPort] has changed. 0: The status of root hub has not changed. 1: The status of root hub has changed.
5	FNO	RW	RW	0	FrameNumberOverflow This bit is set when the MSB of HcFmNumber (bit 15) changes value, from 0 to 1 or from 1 to 0, and after HccaFrameNumber has been updated. 0: The overflow of frame number has not occurred. 1: The overflow of frame number has occurred.
4	UE	RW	RW	0	UnrecoverableError This bit is set when the host controller detects a system error not related to USB (system bus error, for example). The host controller should not proceed with any processing nor signaling before the system error has been corrected. Software clears this bit after the host controller has been reset in that case. 0: The unrecoverable error has not occurred. 1: The unrecoverable error has occurred.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
3	RD	RW	RW	0	ResumeDetected This bit is set when the host controller detects that USB device is asserting resume signaling. This bit is not set when Software sets the USB Resume state. 0: The host controller has not detected resume signaling. 1: The host controller has detected resume signaling.
2	SF	RW	RW	0	StartofFrame This bit is set by the host controller at each start of a frame and after the update of HccaFrameNumber. The host controller also generates a SOF token at the same time. 0: The host controller has not started new frame. 1: The host controller has started new frame.
1	WDH	RW	RW	0	WritebackDoneHead This bit is set immediately after the host controller has written HcDoneHead to HccaDoneHead. Further updates of the HccaDoneHead will not occur until this bit has been cleared. Software should only clear this bit after it has saved the content of HccaDoneHead. 0: The write back to HccaDoneHead has not occurred. 1: The write back to HccaDoneHead has occurred.
0	SO	RW	RW	0	SchedulingOverrun This bit is set when the USB schedule for the current Frame overruns and after the update of HccaFrameNumber. A scheduling overrun also increments the SchedulingOverrunCount of HcCommandSttus register. 0: The scheduling overrun has not occurred. 1: The scheduling overrun has occurred.

41.3.1.5 HcInterruptEnable Register (offset: H'010)

Register symbol: HcInterruptEnable

Each enable bit in the HcInterruptEnable register corresponds to an associated interrupt bit in the HcInterruptStatus register. The HcInterruptEnable register is used to control which events generate a hardware interrupt.

A hardware interrupt is generated when all conditions below are satisfied.

1. A bit is set in HcInterruptStatus register
2. The corresponding bit in HcInterruptEnable register is set
3. MIE (MasterInterruptEnable) bit in HcInterruptEnable register is set

Writing 1 to a bit in this register sets the corresponding bit, whereas writing 0 to a bit in this register leaves the corresponding bit unchanged. On read, the current value of this register is returned.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31	MIE	RW	R	0	MasterInterruptEnable Writing 1 to this bit enables an interrupt generation due to events specified in the other bits of this register. This bit is used by software as a Master interrupt Enable. Writing 0 to this bit is ignored by the host controller. 0: An interrupt generation due to events specified in the other bits of this register is disabled. 1: An interrupt generation due to events specified in the other bits of this register is enabled.
30	OCE	RW	R	0	Writing 1 to this bit enables an interrupt generation due to the request of ownership change. Writing 0 to this bit is ignored by the host controller. 0: An interrupt generation due to the request of ownership change is disabled. 1: An interrupt generation due to the request of ownership change is enabled. Write 1 to OC bit in HcInterruptDisable register in order to clear this bit.
29 to 7	—	R	R	All 0	Reserved

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
6	RHSCE	RW	R	0	Writing 1 to this bit enables an interrupt generation due to the change of the status of root hub. Writing 0 to this bit is ignored by the host controller. 0: An interrupt generation due to the change of the status of root hub is disabled. 1: An interrupt generation due to the change of the status of root hub is enabled. Write 1 to RHSC bit in HcInterruptDisable register in order to clear this bit.
5	FNOE	RW	R	0	Writing 1 to this bit enables an interrupt generation due to the overflow of frame number. Writing 0 to this bit is ignored by the host controller. 0: An interrupt generation due to the overflow of frame number is disabled. 1: An interrupt generation due to the overflow of frame number is enabled. Write 1 to FNO bit in HcInterruptDisable register in order to clear this bit.
4	UEE	RW	R	0	Writing 1 to this bit enables an interrupt generation due to the unrecoverable error. Writing 0 to this bit is ignored by the host controller. 0: An interrupt generation due to the unrecoverable error is disabled. 1: An interrupt generation due to the unrecoverable error is enabled. Write 1 to UE bit in HcInterruptDisable register in order to clear this bit.
3	RDE	RW	R	0	Writing 1 to this bit enables an interrupt generation due to the detection of resume signaling. Writing 0 to this bit is ignored by the host controller. 0: An interrupt generation due to the detection of resume signaling is disabled. 1: An interrupt generation due to the detection of resume signaling is enabled. Write 1 to RD bit in HcInterruptDisable register in order to clear this bit.
2	SFE	RW	R	0	Writing 1 to this bit enables an interrupt generation due to the start of frame. Writing 0 to this bit is ignored by the host controller. 0: An interrupt generation due to the start of frame is disabled. 1: An interrupt generation due to the start of frame is enabled. Write 1 to SF bit in HcInterruptDisable register in order to clear this bit.

Bit	Bit Name	R/W		Initial Value	Description
		HCD	HC		
1	WDHE	RW	R	0	Writing 1 to this bit enables an interrupt generation due to the write back to HccaDoneHead. Writing 0 to this bit is ignored by the host controller. 0: An interrupt generation due to the write back to HccaDoneHead is disabled. 1: An interrupt generation due to the write back to HccaDoneHead is enabled. Write 1 to WDH bit in HcInterruptDisable register in order to clear this bit.
0	SOE	RW	R	0	Writing 1 to this bit enables an interrupt generation due to the scheduling overrun. Writing 0 to this bit is ignored by the host controller. 0: An interrupt generation due to the scheduling overrun is disabled. 1: An interrupt generation due to the scheduling overrun is enabled. Write 1 to SO bit in HcInterruptDisable register in order to clear this bit.

41.3.1.6 HcInterruptDisable Register (offset: H'014)

Register symbol: HcInterruptDisable

Each disable bit in the HcInterruptDisable register corresponds to an associated interrupt bit in the HcInterruptStatus register. The HcInterruptDisable register is coupled with the HcInterruptEnable register. Thus, writing 1 to a bit in this register clears the corresponding bit in the HcInterruptEnable register, whereas writing 0 to a bit in this register leaves the corresponding bit in the HcInterruptEnable register unchanged.

When this register is read, the current value of the HcInterruptEnable register is returned.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

6	RHSCD	RW	R	0	Writing 1 disables an interrupt generation due to the change of the status of root hub. Writing 0 is ignored by the host controller. When read, the value of RHSC bit in HcInterruptEnable register is returned.
5	FNOD	RW	R	0	Writing 1 disables an interrupt generation due to the overflow of frame number. Writing 0 is ignored by the host controller. When read, the value of FNO bit in HcInterruptEnable register is returned.
4	UED	RW	R	0	Writing 1 disables an interrupt generation due to the unrecoverable error. Writing 0 is ignored by the host controller. When read, the value of UE bit in HcInterruptEnable register is returned.

Bit	Bit Name	R/W		Initial Value	Description
		HWD	HC		
3	RDD	RW	R	0	Writing 1 disables an interrupt generation due to the detection of resume signaling. Writing 0 is ignored by the host controller. When read, the value of RD bit in HcInterruptEnable register is returned.
2	SFD	RW	R	0	Writing 1 disables an interrupt generation due to the start of frame. Writing 0 is ignored by the host controller. When read, the value of SF bit in HcInterruptEnable register is returned.
1	WDHD	RW	R	0	Writing 1 disables an interrupt generation due to the write back to HccaDoneHead. Writing 0 is ignored by the host controller. When read, the value of WDH bit in HcInterruptEnable register is returned.
0	SOD	RW	R	0	Writing 1 disables an interrupt generation due to the scheduling overrun. Writing 0 is ignored by the host controller. When read, the value of SO bit in HcInterruptEnable register is returned.

41.3.1.7 HcHCCA Register (offset: H'018)

Register symbol: HcHCCA

The HcHCCA register contains the physical address of the Host Controller Communication Area.

As HCCA has 256-byte structure, this host controller core requires 256-byte alignment for HcHCCA register. Therefore, bit 0 through bit 7 always return 0 even after 1 is written to them.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		R/W			
Bit	**Bit Name**	**HCD**	**HC**	**Initial Value**	**Description**
31 to 4	DH	R	RW	H'000 0000	DoneHead When a TD is completed, the host controller writes the content of HcDoneHead to the NextTD field of the TD. The host controller then overwrites the content of HcDoneHead with the address of this TD. This is set to zero whenever the host controller writes the content of this register to HCCA. It also sets the WritebackDoneHead of HcInterruptStatus.
3 to 0	—	R	R	All 0	Reserved

41.3.1.14 HcFmInterval Register (offset: H'034)

Register symbol: HcFmInterval

The HcFmInterval register contains a 14-bit value which indicates the bit time interval in a Frame, (i.e., between two consecutive SOFs), and a 15-bit value indicating the Full Speed maximum packet size that the host controller may transmit or receive without causing scheduling overrun. Software can carry out minor adjustment on the FrameInterval by writing a new value over the present one at each SOF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 14	—	R	R	All 0	Reserved
13 to 0	PS	RW	R	H'0000	PeriodicStart This field specifies when host controller starts processing the periodic list. Software calculates the adequate value and set it to this filed during initialization. The value is calculated roughly as 10% off from FI field in HcFmInterval register. When FR field in HcFmRemaining register reaches the value specified, processing of the periodic lists has priority over Control/Bulk processing. Therefore the host controller starts processing the Interrupt list after completing the current Control or Bulk transaction that is in progress.

41.3.1.18 HcLSThreshold Register (offset: H'044)

Register symbol: HcLSThreshold

The HcLSThreshold register contains an 11-bit value used by the host controller to determine whether to commit to the transfer of a maximum of 8-byte LS packet before EOF. Neither the host controller nor software is allowed to change this value.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W:	R	R	R	R/W	R/W	R	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 24	POTPGT	RW	R	H'0F	PowerOnToPowerGoodTime This byte specifies the duration the host controller has to wait before accessing a powered-on port of the Root Hub. The unit of time is 2 ms. The duration is calculated as POTPGT * 2 ms.
23 to 13	—	R	R	All 0	Reserved
12	NOCP	RW	R	0	NoOverCurrentProtection This bit defines how the overcurrent status for the Root Hub ports is reported. When this bit is cleared, OCPM bit specifies global or per-port reporting. 0: Over-current status is reported collectively for all downstream ports 1: No overcurrent protection supported
11	OCPM	RW	R	1	OverCurrentProtectionMode This bit defines how the overcurrent status for the Root Hub ports is reported. This bit shows the same mode as PSM bit when it is reset. This bit is valid only if NOCP bit is cleared. 0: over-current status is reported collectively for all downstream ports. 1: over-current status is reported on a per-port basis.
10	DT	R	R	0	DeviceType This bit is always 0 in order to show that the root hub is not a compound device.
9	NPS	RW	R	0	NoPowerSwitching This bit is used to specify whether power switching is supported or port is always powered. When this bit is cleared, PSM bit specifies global or per-port switching. 0: Ports are power switched 1: Ports are always powered on when the HC is powered on

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
8	PSM	RW	R	1	PowerSwitchingMode This bit is used to specify how the power switching of the Root Hub ports is controlled. This bit is only valid if the NPS bit is cleared. 0: all ports are powered at the same time. 1: each port is powered individually. This mode allows port power to be controlled by either the global switch or per-port switching. If the PPCM bit in HcRhDescriptorB register is set, the port responds only to port power commands (Set/ClearPortPower). If the port mask is cleared, then the port is controlled only by the global power switch (Set/ClearGlobalPower).
7 to 0	NDP	R	R	H'01	NumberDownstreamPorts This field specifies the number of downstream ports supported by the Root Hub. The value in this field depends on the configuration of this host controller core.

41.3.1.20 HcRhDescriptorB Register (offset: H'04C)

Register symbol: HcRhDescriptorB

The HcRhDescriptorB register is the second register of two describing the characteristics of the Root Hub.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DR[15:8]								DR[7:0]							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 16	PPCM	RW	R	H'0002	PortPowerControlMask Each bit indicates if a port is affected by a global power control command when PSM bit in HcRhDescriptorA register is set. When set, the port's power state is only affected by per-port power control (Set/ClearPortPower). When cleared, the port is controlled by the global power switch (Set/ClearGlobalPower). If the device is configured to global switching mode (PSM bit = 0), this field is not valid. bit 0: Reserved bit 1: Ganged-power mask on Port #1 bit 2: Ganged-power mask on Port #2
15 to 0	DR	RW	R	H'0000	DeviceRemovable Each bit is dedicated to a port of the Root Hub. When cleared, the attached device is removable. When set, the attached device is not removable. bit 0: Reserved bit 1: Device attached to Port #1 bit 2: Device attached to Port #2

41.3.1.21 HcRhStatus Register (offset: H'050)

Register symbol: HcRhStatus

The HcRhStatus register is divided into two parts. The lower word of this dword represents the Hub Status field and the upper word represents the Hub Status Change field. Reserved bits should always be written 0.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CRWE	—	—	—	—	—	—	—	—	—	—	—	—	—	OCIC	LPSC

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31	CRWE	W	R	0	ClearRemoteWakeupEnable Writing 1 clears DRWE bit. Writing 0 has no effect.
30 to 18	—	R	R	All 0	Reserved
17	OCIC	RW	RW	0	OverCurrentIndicatorChange This bit is set by hardware when a change has occurred to the OCI bit. Writing 1 clears this bit when it is set. Writing 0 has no effect. 0: No change has occurred in over-current status. 1: A change has occurred in over-current status.
16	LPSC	RW	R	0	This bit has different meanings for read and write. (read) LocalPowerStatusChange This bit always returns 0 for read, since the Root Hub does not support the local power status feature. (write) SetGlobalPower In global power mode (PSM bit = 0 in HcRhDescriptorA register), this bit is written to 1 in order to turn on power to all ports (PPS bit in HcRhPortStatus[N] register is cleared). In per-port power mode, it sets PPS bit in HcRhPortStatus[N] register only on port whose PPCM bit in HcRhDescriptorB register is not set. Writing 0 has no effect.

written to this bit	PSM	PPCM[N]	description
0	—	—	no effect
1	0	—	PPS bit is set
	1	0	PPS bit is set
		1	no effect

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
15	DRWE	RW	R	0	(read) DeviceRemoteWakeupEnable This bit enables a CCS bit in HcRhPortStatus[N] register as a resume event, causing the transition from USB Suspend state to USB Resume state and setting the ResumeDetected interrupt. 0: CCS bit does not show a remote wakeup event. 1: CCS bit shows a remote wakeup event. (write) SetRemoteWakeupEnable Writing 1 sets this bit. Writing 0 has no effect.
14 to 2	—	R	R	All 0	Reserved
1	OCI	R	R	0	OverCurrentIndicator This bit reports overcurrent conditions when the global reporting is implemented. When set, an overcurrent condition exists. When cleared, all power operations are normal. If per-port overcurrent protection is implemented this bit is always ‘0’ 0: all power operations are normal 1: an overcurrent condition exists.
0	LPS	RW	RW	0	This bit has different meanings for read and write. (read) LocalPowerStatus This bit always returns 0 for read, since the Root Hub does not support the local power status feature. (write) ClearGlobalPower In global power mode (PSM bit = 0 in HcRhDescriptorA register), this bit is written to 1 in order to turn off power to all ports (PPS bit in HcRhPortStatus[N] register is cleared). In per-port power mode, it clears PPS bit in HcRhPortStatus[N] register only on port whose PPCM bit in HcRhDescriptorB register is not set. Writing 0 has no effect.

written to this bit	PSM	PPCM[N]	description
0	—	—	no effect
1	0	—	PPS bit is set
	1	0	PPS bit is set
		1	no effect

41.3.1.22 HcRhPortStatus[1] Register (offset: H'054)

Register symbol: HcRhPortStatus1

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	PRSC	OCIC	PSSC	PESC	CSC
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 21	—	R	R	All 0	Reserved
20	PRSC	RW	RW	0	PortResetStatusChange This bit shows the port reset has been completed. This bit is set at the end of the 10-ms port reset signal. Writing 1 clears this bit. Writing 0 has no effect. 0: port reset has not been completed. 1: port reset has been completed
19	OCIC	RW	RW	0	PortOverCurrentIndicatorChange This bit shows that overcurrent condition has been detected, and is set when the host controller changes POCI bit. This bit is valid only if overcurrent conditions are reported on a per-port basis. Writing 1 clears this bit. Writing 0 has no effect. 0: no change has occurred in POCI bit. 1: change has occurred in POCI bit.
18	PSSC	RW	RW	0	PortSuspendStatusChange This bit is set when the full resume sequence has been completed. This sequence includes the 20-s resume pulse, LS EOP, and 3-ms resynchronization delay. Writing 1 clears this bit. Writing 0 has no effect. This bit is also cleared when PRSC bit is set. 0: resume sequence has not been completed. 1: resume sequence has been completed.
17	PESC	RW	RW	0	PortEnableStatusChange This bit is set when hardware events cause PES bit to be cleared. Writing 1 clears this bit. Writing 0 has no effect. 0: no change has occurred in PES bit 1: change has occurred in PES bit

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
16	CSC	RW	RW	0	ConnectStatusChange This bit is set whenever connect or disconnect event occurs. Writing 1 means to clear this bit. Writing 0 has no effect. If CCS bit is cleared and writing to SetPortReset, SetPortEnable, or SetPortSuspend occurs, this bit is set to force the driver to re-evaluate the connection status since these write should not occur if the port is disconnected. 0: no change has occurred in CCS bit 1: change has occurred in CCS bit
15 to 10	—	R	R	All 0	Reserved
9	LSDA	RW	RW	0	This bit has different meanings for read and write. (read) LowSpeedDeviceAttached This bit indicates the speed of the device attached to this port. When set, a Low Speed device is attached to this port. When cleared, a Full Speed device is attached to this port. This field is valid only when the CCS bit is set (which means device is connected). 0: full speed device attached 1: low speed device attached (write) ClearPortPower Writing 1 clears PPS bit. Writing 0 has no effect.
8	PPS	RW	RW	0	This bit has different meanings for read and write. (read) PortPowerStatus This bit reflects the port's power status. This bit is cleared if an overcurrent condition is detected. 0: port power is off. 1: port power is on. (write) SetPortPower Writing 1 sets PPS bit. Writing 0 has no effect. The HCD writes a 1 to set the PortPowerStatus bit. Writing 0 has no effect.
7 to 5	—	R	R	All 0	Reserved

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
4	PRS	RW	RW	0	This bit has different meanings for read and write. (read) PortResetStatus When this bit is set by writing to SetPortReset, port reset signaling is asserted. When reset is completed, this bit is cleared when PRSC bit is set. This bit cannot be set if CCS bit is cleared (which means no device is connected) 0: port reset signal is not active 1: port reset signal is active (write) SetPortReset Writing 1 asserts the port reset signaling. Writing 0 has no effect. When CCS bit is cleared (which means no device is connected), PRS bit is not set even with writing 1. But it causes CSC bit to be set instead. This informs that a disconnected port is attempted to be reset.
3	POCI	RW	RW	0	This bit has different meanings for read and write. (read) PortOverCurrentIndicator This bit is only valid when the host controller is configured in such a way that overcurrent conditions are reported on a per-port basis. If per-port overcurrent reporting is disabled, this bit always returns 0 for read. If cleared, all power operations are normal for this port. If set, an overcurrent condition exists on this port. 0: no overcurrent condition exists 1: overcurrent condition exists. (write) ClearSuspendStatus Writing 1 initiates the resume sequence. Writing 0 has no effect. A resume is initiated only if PSS bit is set.
2	PSS	RW	RW	0	This bit has different meanings for read and write. (read) PortSuspendStatus This bit indicates the port is suspended or in the resume sequence. This bit cannot be set when CCS bit is cleared (which means no device is connected). This bit is cleared with following conditions. The resume sequence is completed and PSSC bit is set. The port reset is completed and PRSC bit asset. The host controller is placed in USB Resume state. 0: Port is not suspended. 1: Port is suspended. (write) SetPortSuspend Writing 1 sets PSS bit. Writing 0 has no effect. When CCS bit is cleared (which means no device is connected), PSS bit is not set even with writing 1. But it causes CSC bit to be set instead. This informs that a disconnected port is attempted to be suspended.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
1	PES	RW	RW	0	This bit has different meanings for read and write. (read) PortEnableStatus This bit indicates whether the port is enabled or disabled. This host controller core clears this bit in case of an overcurrent condition, disconnect event, switched-off power, or operational bus error such as babble is detected. This change also sets PESC bit. This bit cannot be set when CCS bit is cleared (which means no device is connected). This bit is also set when port reset is completed and PRSC bit is set or when port is suspended and PSSC bit is set. 0: Port is disabled 1: Port is enabled. (write) SetPortEnable Writing 1 sets PES bit. Writing 0 has no effect. If CCS bit is cleared, this write does not set PES bit, but instead sets CSC bit. This informs the driver that it attempted to enable a disconnected port.
0	CCS	RW	RW	0	This bit has different meanings for read and write. (read) CurrentConnectStatus This bit reflects the current state of the downstream port. 0: no device is connected 1: device is connected (write) ClearPortEnable Writing 1 to this bit clears PES bit. Writing 0 has no effect.

41.3.2 EHCI Controller Capability Registers

41.3.2.1 HCIVERSION/CAPLENGTH Register (offset: H'102/H'100)

Register symbol: CAPL_VERSION

This register is used as an offset to add to register base to find the beginning of the operational register space.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31 to 24	—	R	R	All 0	Reserved
23 to 20	Debug Port Number	R	R	H'0	This field always shows H'0 since this host controller core has no debug port.
19 to 17	—	R	R	All 0	Reserved
16	P_INDICATOR	R	R	0	Port Indicators (P_INDICATOR). This field always shows 0 since this host controller core does not have the function of port indicator.
15 to 12	N_CC	R	R	H'1	Number of Companion Controller This field indicates the number of companion controllers.
11 to 8	N_PCC	R	R	H'1	Number of Ports per Companion Controller (N_PCC). This field indicates the number of ports supported per companion host controller. It is used to indicate the port routing configuration to software.
7	Port Routing Rules	R	R	1	Port Routing Rules. This field indicates the method used by this implementation for how all ports are mapped to companion controllers. 0: The first N_PCC ports are routed to the lowest numbered function companion host controller, the next N_PCC port are routed to the next lowest function companion controller, and so on. 1: The port routing is explicitly enumerated by the first N_PORTS elements of the HCSP-PORTROUTE array.
6, 5	—	R	R	All 0	Reserved
4	PPC	R	R	1	Port Power Control (PPC). This field indicates whether the host controller implementation includes port power control.
3 to 0	N_PORTS	R	R	H'1	This field specifies the number of physical downstream ports implemented as host controller

41.3.2.3 HCCPARAMS Register (offset: H'108)

Register symbol: HCCPARAMS

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	32-Frame Periodic List Capability	Per-Port Change Event Capability	Link Power Management Capability	Hardware Prefetch Capability
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 20	—	R	R	All 0	Reserved
19	32-Frame Periodic List Capability	R	R	1	This bit shows 1 since this host controller has 32-Frame Periodic List Capability. When set (1) this optional field indicates the host controller supports a 32 frame periodic schedule as specified by using the value B'11 in the USBCMD *Frame List Size* field. Software must treat a *Flame List Size* values (B'01 = 512 frames, B'10 = 256 frames) continues to be indicated through the *Programmable Frame List Flag*, where this bit only indicates programmability for a 32-frame list.
18	Per-Port Change Event Capability	R	R	1	This bit shows 1 since this host controller has Per-Port Change Event Capability. When set (1) this optional field indicates host controller support for pre-port change events and associated USBCMD *Pre-Port Change Event Enable*, USBSTS *Port-n Change Detect*, and USBINT *Port-n Change Interrupt Enable* fields. Note that software should treat those fields as reserved when this bit is cleared (0).
17	Link Power Management Capability	R	R	0	This bit shows 0 since this host controller doesn't have Link Power Management Capability. When set (1) this optional field indicates host controller support for this the Link Power Management L1 state and associated PORTSC *Suspend using L1*, *Suspend Status*, and *Device Address* field. Note that software should treat those fields as reserved then this bit is cleared (0).
16	Hardware Prefetch Capability	R	R	0	This bit shows 0 since this host controller does not have Hardware Prefetch Capability. This host controller doesn’t support this function.
15 to 8	EECP	R	R	H'00	EHCI Extended Capabilities Pointer (EECP).
7 to 4	Isochronous Scheduling Threshold	R	R	H'0	This field shows 0 since this host controller core does not support the function to cache the isochronous data structure.
3	—	R	R	0	Reserved
2	Asynchronous Schedule Park Capability	R	R	1	This bit shows 1 since this host controller core has Asynchronous Schedule Park Capability.

Bit	Bit Name	R/W		Initial Value	Description
		HCD	HC		
1	Programmable Frame List Flag	R	R	1	This bit shows 1 since this host controller core supports Programmable Frame List.
0	64-bit addressing Capability	R	R	0	This field shows 0 since this host controller core does not support 64-bit addressing.

41.3.2.4 HCSP-PORTROUTE Register (offset: H'10C)

Register symbol: HCSP_PORTROUTE

This operational register is valid only if Port Routing Rules field in HCSPARAMs register.

In that case, this register shows how OHCI controller is routed to each port.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	Companion Port Route[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	R/W	Initial Value	Description
31 to 0	Companion Port Route[31:0]	R	H'0000 0000	These bits show the port controlled by the OHCI host controller. This module provides only one OHCI host controller and this bit is read as 0.

41.3.3 EHCI Operational Registers

41.3.3.1 USBCMD Register (offset: H'120)

Register symbol: USBCMD

The Command Register indicates the command to be executed by the serial bus host controller. Writing to the register causes a command to be executed.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	Host-Initiated Resume Duration				Interrupt Threshold Control							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	Per-Port Change Events Enable	Full Synchro-nized Prefetch	Asynchro-nous Schedule Prefetch Enable	Periodic Schedule Prefetch Enable	Asynchro-nous Schedule Park Mode Enable	—	Asynchronous Schedule Park Mode Count		Light Host Con-troller Reset	Interrupt on Async Advance Door-bell	Asynchron ous Schedule Enable	Periodic Schedule Enable	Frame List Size		HCRES ET	RS
Initial value:	0	0	0	0	1	0	1	1	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R/W	R	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 28	—	R	R	All 0	Reserved
27 to 24	Host-Initiated Resume Duration	RW	R	H'0	This field is used by software to specify the minimum amount of time the host controller will drive the K-state during a host-initiated resume from LPM (L1) state and is conveyed to each LPM-enabled device (via the *HIRD* bits within an LPM Token's *bmAttributes* field) upon entry into a low-power state. Encoding for this field is identical to the definition for the similarly named *HIRD* field within an LPM Token. Specifically, a value H'0 equals to 50 µs and each additional increment adds 75 µs. For example, the value H'1 equals 125 µs and H'F equals 1175 µs.
23 to 16	Interrupt Threshold Control	RW	R	H'08	This field is used by system software to select the maximum rate at which the host controller core issue interrupts. If software writes an invalid value to this field, the results are undefined. **Value — Maximum Interrupt Interval** H'00: Reserved H'01: 1 micro-frame H'02: 2 micro-frames H'04: 4 micro-frames H'08: 8 micro-frames (default, equals to 1 MS) H'10: 16 micro-frames (2 MS) H'20: 32 micro-frames (4 MS) H'40: 64 micro-frames (8 MS) Software should not set this bit to 0 while Halted bit is equal to 0.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
15	Per-Port Change Events Enable	RW	R	0	This field is used by software to enable the per-port change event capability as defined by the *Port-n Change Detect* field in the USBSTS register and *Port-n Change Detect Enable* field in the USBINTR register. When this bit is set to 1, the per-port change event is enabled. When this bit is set to 0, the per-port change event is disabled.
14	Full Synchronized Prefetch	R	R	0	Since this host controller core does not have Hardware Prefetch Capability, this bit is fixed to 0.
13	Asynchronous Schedule Prefetch Enable	R	R	0	Since this host controller core does not have Hardware Prefetch Capability, this bit is fixed to 0.
12	Periodic Schedule Prefetch Enable	R	R	0	Since this host controller core does not have Hardware Prefetch Capability, this bit is fixed to 0.
11	Asynchronous Schedule Park Mode Enable	RW	R	1	Software uses to enable or disable Asynchronous Schedule Park Mode. When this bit is set to 1, Park mode is enabled. When this bit is set to 0, Park mode is disabled.
10	—	R	R	0	Reserved
9:8	Asynchronous Schedule Park Mode Count	RW	R	11	This field defines a count of the number of successive transactions the host controller core is allowed to execute from a high-speed queue head on the Asynchronous schedule before continuing traversal of the Asynchronous schedule. This function is enabled when Asynchronous Schedule Park Mode Enable is set to 1. Software should not write 0 to this bit.
7	Light Host Controller Reset	R	R	0	Since this host controller core does not support the function of Light Host Controller Reset, this bit is fixed to 0.
6	Interrupt on Async Advance Doorbell	RW	RW	0	This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write 1 to this bit to ring the doorbell. When the host controller has evicted all appropriate cached schedule state, it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Async Advance Enable bit in the USBINTR register is 1 then the host controller will assert an interrupt at the next interrupt threshold. The host controller sets this bit to 0 after it has set the Interrupt on Async Advance status bit in the USBSTS register to 1. Software should not write 1 to this bit when the asynchronous schedule is disabled.
5	Asynchronous Schedule Enable	RW	R	0	This bit controls whether the host controller skips processing the Asynchronous Schedule. 0: Do not process the Asynchronous Schedule 1: Use the ASYNCLISTADDR register to access the Asynchronous Schedule.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
4	Periodic Schedule Enable	RW	R	0	This bit controls whether the host controller skips processing the Periodic Schedule. 0: Do not process the Periodic Schedule 1: Use the PERIODICLISTBASE register to access the Periodic Schedule.
3, 2	Frame List Size	RW	R	00	This field specifies the size of the frame list. The size the frame list and controls which bits in the Frame Index Register should be used for the Frame List Current index. This host controller core has 32-Frame Periodic List Capability. Value the number of frames in Frame List 00: 1024 frames (default) 01: 512 frames 10: 256 frames 11: 32 frames
1	HCRESET	RW	RW	0	Host Controller Reset (HCRESET). This control bit is used by software to reset the host controller. When software writes 1 to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines, etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Registers other than the EHCI Operational registers are not affected by this reset. All operational registers, including port registers and port state machines are set to their initial values. Port ownership reverts to the companion host controller(s). Software must reinitialize the host controller in order to return the host controller to an operational state. This bit is set to 0 by the Host Controller when the reset process is complete. Software cannot terminate the reset process early by writing 0 to this register. Software should not set this bit to 1 when the HCHalted bit in the USBSTS register is 0.
0	RS	RW	RW	0	Run/Stop (RS). When this bit is set to 1, the host controller proceeds with execution of the schedule. The host controller continues execution as long as this bit is set to 1. When this bit is set to 0, the host controller completes the current and any actively pipelined transactions on the USB and then halts. The HCHalted bit in the status register indicates when the host controller has finished its pending pipelined transactions and has entered the stopped state. Software should not write 1 to this field unless the host controller is in the Halted state (i.e. HCHalted in the USBSTS register is 1).

41.3.3.2 USBSTS Register (offset: H'124)

Register symbol: USBSTS

This register indicates pending interrupts and various states of the host controller. The status resulting from a transaction on the serial bus is not indicated in this register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	Asynchro-nous Schedule Status	Periodic Schedule Status	Reclama tion	HCHalte d	—	—	—	—	—	—	Interrupt on Async Advance	Host System Error	Frame List Rollover	Port Change Detect	USBERR INT	USBINT
Initial value:	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 16	Port-n Change Detect	RW	RW	H'0000	The definition of each bit is identical to the *Port Change Detect* field (bit 2 of this register) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set to 1 then a port change event was detected on Port 2, the N_PORTS field in HCSPARAMS specifies how many ports are exposed by the host controller and thus how many bits in this field are valid. The behavior of the *Port Change Detect* and related fields even when Per-Port Change Events are enabled. This field is only used by software when the *Per-Port Change Events Enable* bit within the USBCMD register is set to 1.
15	Asynchronous Schedule Status	R	RW	0	This bit reports the current real status of the Asynchronous Schedule. If this bit is 0 then the status of the Asynchronous Schedule is disabled. If this bit is 1 then the status of the Asynchronous Schedule is enabled. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (1) or disabled (0).
14	Periodic Schedule Status	R	RW	0	This bit reports the current real status of the Periodic Schedule. If this bit is 0 then the status of the Periodic Schedule is disabled. If this bit is 1 then the status of the Periodic Schedule is enabled. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (1) or disabled (0).
13	Reclamation	R	RW	0	This is a read-only status bit, which is used to detect an empty asynchronous schedule. When this bit is 1, asynchronous schedule is empty.
12	HCHalted	R	RW	1	This bit is 0 whenever the Run/Stop bit is 1. The host controller sets this bit to 1 after it has stopped executing as a result of the Run/Stop bit being set to 0, either by software or by the host controller hardware (e.g. internal error).

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
11 to 6	—	R	RW	All 0	Reserved
5	Interrupt on Async Advance	RW	RW	0	System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing 1 to the Interrupt on Async Advance Doorbell bit in the USBCMD register. This status bit indicates the assertion of that interrupt source. This bit is cleared to 0 by writing 1 to it. Writing 0 occurs no effect.
4	Host System Error	RW	RW	0	The host controller sets this bit to 1 when a serious error occurs. When this error occurs, the host controller clears the Run/Stop bit in the Command register to prevent further execution of the scheduled TDs. This bit is cleared to 0 by writing 1 to it. Writing 0 occurs no effect.
3	Frame List Rollover	RW	RW	0	The host controller sets this bit to 1 when a frame list rollover event occurs. The exact *Frame List Index* value at which the rollover occurs depends on the frame list size, nothing this generally occurs when FRINDEX rolls over from its maximum value to 0. For example, if the frame list size (as programmed in the *Frame List Size* field of the USBCMD register) is 1024 then a frame list rollover would occur every time FRINDEX[13] toggles. Similarly, a frame list rollover event would occur every time FRINDEX[12] toggles for a 512 frame list, and when FRINDEX[11] toggles for a 256 frame list. Note this behavior is different for a 32 frame list where a rollover event occurs every time FRINDEX[13] toggles (same as 1024). This bit is cleared to 0 by writing 1 to it. Writing 0 occurs no effect.
2	Port Change Detect	RW	RW	0	The host controller sets this bit to 1 when it detects any change of port status. The detailed conditions those set this bit to 1 are as follows. The connection or disconnection of device is detected and Connect Status Change bit (bit 1) of PORTSC[n] register is changed from 0 to 1. The enabled status of port is detected and Port Enable/Disable bit (bit 3) of PORTSC[n] register is changed from 0 to 1. The over current is detected and Over-current Change bit (bit 5) of PORTSC[n] register is changed from 0 to 1. J-K transition is detected on the suspended port and Force Port Resume bit (bit 6) of PORTSC[n] register is changed from 0 to 1. This bit is cleared to 0 by writing 1 to it. Writing 0 occurs no effect.
1	USBERRINT	RW	RW	0	USB Error Interrupt (USBERRINT). The host controller sets this bit to 1 when completion of a USB transaction results in an error condition. If the TD on which the error interrupt occurred also had its IOC bit set, both this bit and USBINT bit are set. This bit is cleared to 0 by writing 1 to it. Writing 0 occurs no effect.

Bit	Bit Name	R/W		Initial Value	Description
		HCD	HC		
0	USBINT	RW	RW	0	USB Interrupt (USBINT). The host controller sets this bit to 1 on the completion of a USB transaction, which results in the retirement of a Transfer Descriptor that had its IOC bit set. The host controller also sets this bit to 1 when a short packet is detected (actual number of bytes received was less than the expected number of bytes). This bit is cleared to 0 by writing 1 to it. Writing 0 occurs no effect.

41.3.3.3 USBINTR Register (offset: H'128)

Register symbol: USBINTR

This register enables and disables reporting of the corresponding interrupt to the software. When a bit is set and the corresponding interrupt is active, an interrupt is generated to the host. Interrupt sources that are disabled in this register still appear in the USBSTS to allow the software to poll for events.

Each interrupt enable bit description indicates whether it is dependent on the interrupt threshold mechanism.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 16	Port-n Change Event Enable	RW	R	H'0000	The definition for each bit in this field is identical to bit 2 of this register (Port Change Interrupt Enable bit) except these bits are specific to a given port, where bit 16 = Port 1, 17 = Port 2, etc. For example, if bit 17 is set to 1 then a port change event was detected on Port 2. When a bit in this field is 1 and the corresponding Port-n Change Detect bit in the USBSTS register is 1, the host controller will issue an interrupt. The interrupt is acknowledged by software clearing the *Port-n Change Detect* bit.
15 to 6	—	R	R	All 0	Reserved
5	Interrupt on Async Advance Enable	RW	R	0	When this bit is a one, and the Interrupt on Async Advance bit in the USBSTS register is 1, the host controller will issue an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the Interrupt on Async Advance bit.
4	Host System Error Enable	RW	R	0	When this bit is 1, and the Host System Error Status bit in the USBSTS register is 1, the host controller will issue an interrupt. The interrupt is acknowledged by software clearing the Host System Error bit.
3	Frame List Rollover Enable	RW	R	0	When this bit is 1, and the Frame List Rollover bit in the USBSTS register is 1, the host controller will issue an interrupt. The interrupt is acknowledged by software clearing the Frame List Rollover bit.
2	Port Change Detect Enable	RW	R	0	When this bit is 1, and the Port Change Detect bit in the USBSTS register is 1, the host controller will issue an interrupt. The interrupt is acknowledged by software clearing the Port Change Detect bit.
1	USB Error Interrupt Enable	RW	R	0	When this bit is 1, and the USBERRINT bit in the USBSTS register is 1, the host controller will issue an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the USBERRINT bit.

Bit	Bit Name	R/W		Initial Value	Description
		HCD	HC		
0	USB Interrupt Enable	RW	R	0	When this bit is 1, and the USBINT bit in the USBSTS register is 1, the host controller will issue an interrupt at the next interrupt threshold. The interrupt is acknowledged by software clearing the USBINT bit.

41.3.3.4 FRINDEX Register (offset: H'12C)

Register symbol: FRINDEX

This register is used by the host controller to index into the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Bits [N:3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the Frame List Size field in the USBCMD register

This register can't be written unless the host controller is in the Halted state as indicated by HCHalted bit of USBSTS register. It is not allowed to write to this register while the Run/Stop bit is 1 either.

The host controller behaves slightly different when using a 32-frame Frame List Size, specifically it continues to count FRINDEX up to a full 1024 frames, transmit SOF values from 0 to 2047, and generate Frame List Rollover events (when enabled) every 1024 frames - exactly as if a 1024 frame list size was employed. The host controller will only reference 32 elements on the periodic schedule, however. This is accomplished by formulating the Periodic Frame List Element Address using {FRINDEX[N:3] modulo 32} rather than FRINDEX[N:3]. The same mapping should be done by system software whenever it needs to correlate the current FRINDEX value to a specific periodic schedule element. Note this new behavior only applies to a 32-frame list.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 14	—	R	R	All 0	Reserved
13 to 0	Frame Index[13:0]	RW	RW	H'0000	The value in this register increments at the end of each time frame (e.g. micro-frame). Bits [N:3] are used for the Frame List current index. This means that each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index. The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register. **Frame List Size / Number of Frames / N** B'00 / 1024 / 12 B'01 / 512 / 11 B'10 / 256 / 10 B'11 / 32 / 12

41.3.3.5 CTRLDSSEGMENT Register (offset: H'130)

Register symbol: CTRLDSSEGMENT

Since this host controller does not have the 64-bit Addressing Capability and the 64-bit Addressing Capability bit in HCCPARAMS is 0, CTRLDSSEGMENT register is not used and fixed to H'00 0000.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

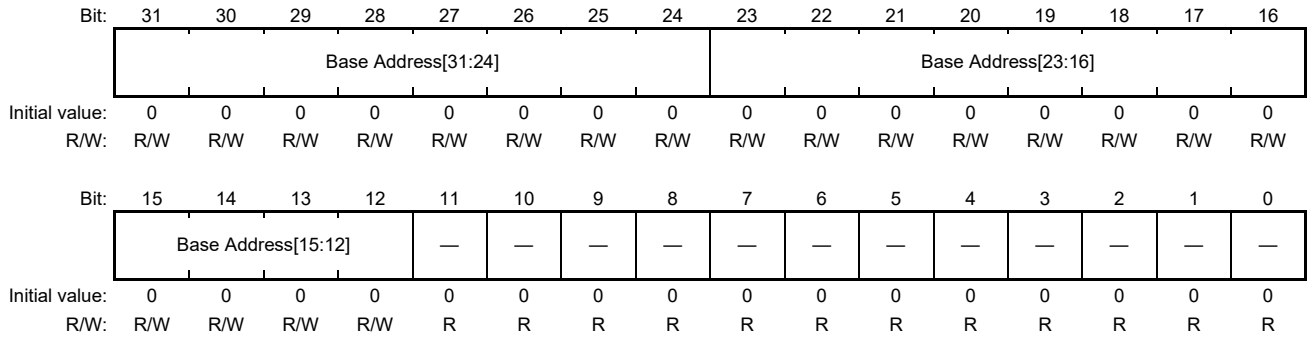
41.3.3.6 PERIODICLISTBASE Register (offset: H'134)

Register symbol: PERIODICLISTBASE

This register contains the beginning address of the Periodic Frame List in the system memory.

Software loads this register prior to starting the schedule execution by the host controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence.



Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 12	Base Address	RW	R	H'0 0000	This field defines the beginning address of the Periodic Frame List in the system memory. The pointer contained in this field should be 4-Kbyte aligned.
11 to 0	—	R	R	All 0	Reserved

41.3.3.7 ASYNCLISTADDR Register (offset: H'138)

Register symbol: ASYNCLISTADDR

This register contains the address of the next asynchronous queue head to be executed.

Bits [4:0] of this register cannot be modified by software and will always return H'00 when read. The memory structure referenced by this physical memory pointer is assumed to be 32-byte (cache line) aligned.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial value:	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
31 to 25	Device Address	RW	RW	H'00	The 7-bit USB device address for the device attached to and immediately downstream of the associated root port. A value of zero indicates no device is present or support for this feature is not present.
24, 23	Suspend Status	R	RW	00	These two bits are used by software to determine whether the most recent L1 suspend request was successful, specifically 00: Success: State transition was successful (ACK) 01: Not Yet: Device was unable to enter the L1 state at this time (NYET). 10: Not Supported: Device does not support the L1 state (STALL) 11: Timeout/Error: Device failed to respond or an error occurred This field is updated by hardware immediately following the completion of an L1 transition request (via an LPM token). To avoid any race conditions with hardware, software should only consume the contents of this field when Suspend = 0 (port no longer in L1).
22	WKOC_E	RW	RW	0	Wake on Over-current Enable. Writing 1 to this bit enables the port to detect the over-current conditions as wake-up events. Writing 0 to this bit has no effect. This bit is zero if PP bit is zero.
21	WKDSCNNT_E	RW	RW	0	Wake on Disconnect Enable. Writing 1 to this bit enables the port to detect the device disconnects as wake-up events. Writing 0 to this bit has no effect. This bit is zero if PP bit is zero.
20	WKCNNT_E	RW	RW	0	Wake on Connect Enable. Writing 1 to this bit enables the port to detect the device connects as wake-up events. Writing 0 to this bit has no effect. This field is zero if PP bit is zero.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
19 to 16	Port Test Control	RW	R	0000	Port Test Control. A non-zero value indicates that it is operating in test mode and the specific test mode is indicated by the specific value. When this field is zero, the port is NOT operating in a test mode. Value test mode 0000: Test mode not enabled 0001: Test J_STATE 0010: Test K_STATE 0011: Test SE0_NAK 0100: Test Packet 0101: Test FORCE_ENABLE Other: Reserved
15, 14	Port Indicator Control	R	R	00	This field always shows B'00 since this host controller does not support Port Indicator Control.
13	Port Owner	RW	RW	1	This bit unconditionally goes to 0 when the Configured bit in the CONFIGFLAG register makes a transition from 0 to 1. This bit unconditionally goes to 1 whenever the Configured bit is zero. Software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes 1 to this bit when the attached device is not a high-speed device. 0: EHCI controller owns the port. 1: OHCI controller owns the port.
12	PP	RW	RW	0	Port Power (PP). The function of this bit depends on the value of PPC bit in HCSPARAMS register. The behavior is as follows: PPC PP Operation 0 1 RO – The host controller does not have port power control switches. Each port is hard-wired to power. 1 1/0 R/W – The host controller has port power control switches. This bit represents the current setting of the switch (0 = off, 1 = on). When power is not available on a port (i.e. PP equals to 0), the port is non-functional and will not report attaches, detaches, etc. When an over-current condition is detected on a powered port and PPC bit is 1, the PP bit in each affected port may be transitioned by the host controller from 1 to 0 (which means removing power from the port).

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
11, 10	Line Status	R	RW	00	This field reflects the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. This field is used for detection of low-speed USB devices prior to the port reset and enable sequence. This field is valid only when Port Enable/Disable bit is 0 and Current Connect Status bit is set to 1. {bit11, bit10} USB state description 00 SE0 Not LS-device, perform EHCI reset. 10 J-state Not LS-device, perform EHCI reset. 01 K-state LS-device, change ownership from EHCI to OHCI. 11 Undefined Not LS-device, perform EHCI reset. The value in this field is undefined if PP bit is 0.
9	Suspend using L1	R	R	0	0: Suspend using L2
8	Port Reset	RW	RW	0	This bit shows the reset status of the port. When software writes 1 to this bit (from a zero), the bus reset is started. Software is required to write 0 to this bit to terminate the bus reset sequence. Software should keep this bit at 1 long enough to ensure the reset sequence completes as specified in the USB Specification. Do not write 1 to this bit when HCHalted bit in USBSTS register is 0. This bit is 0 if PP bit is 0. 0: The port is not in reset. 1: The port is in reset.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
7	Suspend	RW	RW	0	P*ort Enabled* Bit and *Suspend* bit of this register define the port states as follows: {Port Enabled, Suspend} — Port Status 0x — Disable 10 — Enable 11 — Suspend Software writes a one to this bit to transition a port to either the L1 or L2 suspend state. Which suspend state the host controller attempts depends on the value of the *Suspend Using L1* field. When in suspend state, downstream propagation of data is blocked on this port, except for port reset. If this bit is set to a one when a transaction is in progress then the blocking will not occur until the end of the current transaction. In the suspend state, the port is sensitive to resume detection. Note that the status of this bit does not change until the port is fully suspended and there may be a delay in suspending a port if a transaction is currently in progress on the USB. Addition status for L1-based transitions is provided to software via the *Suspend Status* field. Software writes 1 to this bit in order to set it. Writing 0 to this bit has no effect. Software can write to this bit only when PP bit is 1 and Port Owner bit is 0 and Current Connect Status bit is 1. The host controller unconditionally sets this bit to 0 when: Software sets Force Port Resume bit to 0 (from 1). Software sets Port Reset bit to 1 (from 0). Whenever Port Power is 0 This field is 0 if PP bit is 0.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
6	Force Port Resume	RW	RW	0	This bit indicates that the resume on the port is detected. 0: No resume signaling is detected or driven on the port. 1: The resume signaling is detected or driven on the port. The host controller set this bit to 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to 1 because a J-to-K transition is detected, the *Port Change Detect* and/or *Port-n Changes Detect* bits in the USBSTS register are also set to 1. If software sets this bit to 1, the host controller must not set the *Port Change Detect* and/or *Port-n Change Detect* bits. This functionality defined for manipulating this bit depends on the value of the *Suspend* and Suspend Using L1 bits. For example, if the port is not suspended (*Suspend* and *Enabled* bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. For legacy (L2) transitions, Software should set this bit to 0 when the appropriate amount of time has elapsed. Writing 0 (from 1) causes the port to return to high speed mode (forcing the bus below the port into a high-speed idle). This bit will remain 1 until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to 0. Software does not need to time resume signaling for L1 transactions as host controller hardware will automatically enforce the necessary timing and clear this bit when the port has fully resumed. Software can influence the amount of time hardware will drive resume signaling during L1 exit via the *Host-Initiated Resume Duration* field within the USBCMD register. This bit is 0 if PP bit is 0
5	Over-current Change	RW	RW	0	This bit indicates whether Over-current Active bit has been changed or not. Writing 1 to this bit clears it. Writing 0 to this bit has no effect. 0: Over-current Active bit has not changed. 1: Over-current Active bit has changed.
4	Over-current Active	R	RW	0	This bit shows the over-current status of the port. When the host controller detects the over-current condition, it disables the port and then sets this bit to 1. The host controller automatically clears this bit when the over-current condition has been removed. 0: No over-current condition exists on the port. 1: The over-current condition exists on the port.
3	Port Enable/Disable Change	RW	RW	0	This bit indicates whether Port Enabled/Disabled bit has been changed or not. This bit is set 1 only when a port is disabled due to the appropriate conditions existing at EOF2 point. Writing 1 to this bit clears it. Writing 0 to this bit has no effect. This bit is 0 if PP bit is 0.

Bit	Bit Name	R/W HCD	R/W HC	Initial Value	Description
2	Port Enabled/ Disabled	RW	RW	0	Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing 1 to this field. The host controller will only set this bit to 1 the reset sequence determines that the attached device is a high-speed device. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by software. When the port is disabled (0) downstream propagation of data is blocked on this port, except for reset. When Port Test Control is B'0101, the port is always enabled and this bit is set to 1 independent of the port status. This bit is 0 if PP bit is 0. 0: The port is disabled. 1: The port is enabled.
1	Connect Status Change	RW	RW	0	This bit indicates a change has occurred in the port's Current Connect Status. The host controller sets this bit for all changes to the port device connect status, even if software has not cleared an existing connect status change. Writing 1 to this bit clears it. Writing 0 to this bit has no effect. This field is 0 if PP bit is 0.
0	Current Connect Status	R	RW	0	This bit reflects the current state of the connection of the port. The host controller sets this bit to 1 when it detects the connection of device to the port. It also sets 1 to this bit with Port Test Control = B'0101, even when device is not connected. If it detects the device is disconnected, this bit is reset to 0. This bit is 0 if PP bit is 0 or if Port Owner bit is 0. 0: No device is present. 1: Device is present.

41.3.4 AHB Bridge Registers

41.3.4.1 INT_ENABLE Register (offset: H'200)

Register symbol: INT_ENABLE

This register enables or disables interrupt generation for each interrupt source bit in the INT_STATUS register. When a bit in this register is set to disabled, the interrupt signal is not asserted even when the interrupt condition for the corresponding source is satisfied and the corresponding source bit in the INT_STATUS register is set to 1.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31 to 5	—	All 0	R	Reserved The write value should be 0.
4	WAKEON_INTEN	0	R/W	Enables or disables interrupt generation due to WAKEON_INT (bit 4) in INT_STATUS. 0: Disabled 1: Enabled
3	UCOM_INTEN	0	R/W	Enables or disables interrupt generation due to UCOM_INT (bit 3) in INT_STATUS. 0: Disabled 1: Enabled
2	USBH_INTBEN	0	R/W	Enables or disables interrupt generation due to USBH_INTB (bit 2) in INT_STATUS. 0: Disabled 1: Enabled
1	USBH_INTAEN	0	R/W	Enables or disables interrupt generation due to USBH_INTA (bit 1) in INT_STATUS. 0: Disabled 1: Enabled
0	AHB_INTEN	0	R/W	Enables or disables interrupt generation due to AHB_INT (bit 0) in INT_STATUS. 0: Disabled 1: Enabled

41.3.4.2 INT_STATUS Register (offset: H'204)

Register symbol: INT_STATUS

This register indicates the state of the interrupt source in the AHB bridge and the state of each signal from the OHCI, EHCI, and UCOM modules.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W:	R	R	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved The write value should be 0.
4	WAKEON_INT	0	R/W	This bit indicates the state of the WAKEON interrupt from the host core. Writing 1 clears this bit. 0: No WAKEON interrupt has occurred. 1: A WAKEON interrupt has occurred.
3	UCOM_INT	0	R	This bit indicates the state of the interrupt from the UCOM registers. Use the UCOM2 registers to clear the interrupt. 0: No external register interrupt has occurred. 1: An external register interrupt has occurred.
2	USBH_INTB	0	R	This bit indicates the state of the EHCI interrupt. Use the HcInterruptStatus register (an OHCI operational register) to clear the interrupt. 0: No INTB interrupt has occurred. 1: An INTB interrupt has occurred.
1	USBH_INTA	0	R	This bit indicates the state of the OHCI interrupt. Use the USBSTS register (an EHCI operational register) to clear the interrupt. 0: No INTA interrupt has occurred. 1: An INTA interrupt has occurred.
0	AHB_INT	0	R/W	This bit indicates occurrence of an AHB bus error. Writing 1 clears this bit. 0: No AHB bus error has occurred. 1: An AHB bus error has occurred.

41.3.4.3 AHB_BUS_CTR Register (offset: H'208)

Register symbol: AHB_BUS_CTR

This register specifies the AHB master and slave functions.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PROT_TYPE				—	—	—	PROT_ MODE	—	—	ALIGN_ ADDRESS		—	—	MAX_BURST_ LEN	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R/W	R	R	R/W	R/W	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved The write value should be 0.
15 to 12	PROT_TYPE	0000	R/W	These bits specify the MHPROT[3:0] value for transfer from the AHB master interface. Bit [15] 0: Indicates a non-cacheable transfer. 1: Indicates a cacheable transfer. Bit [14] 0: Indicates a non-bufferable transfer. 1: Indicates a bufferable transfer. Bit [13] 0: Indicates user access. 1: Indicates privileged access. Bit [12] 0: Indicates an opcode. 1: Indicates data. For details of each bit meaning, refer to the AMBA AHB specifications
11 to 9	—	All 0	R	Reserved The write value should be 0.
8	PROT_MOD E	0	R/W	This bit selects the MHPROT[3:0] mode for transfer from the AHB master interface. 0: The PROT_TYPE value is output as MHPROT[3:0]. 1: During DMA transfer, H'0000 is output as MHPROT[3:0] in the last burst and the PROT_TYPE value is output in other burst transfers.
7, 6	—	All 0	R	Reserved The write value should be 0.

Bit	Bit Name	Initial Value	R/W	Description
5, 4	ALIGN_ADDRESS	00	R/W	These bits specify the address alignment for transfer from the AHB master interface. 00: Burst transfer is issued so as not to extend beyond a 1-Kbyte boundary. 01: Burst transfer is issued so as not to extend beyond a 64-byte boundary. 10: Burst transfer is issued so as not to extend beyond a 32 -byte boundary. (The maximum burst length is limited to INCR8 because transfer goes beyond a 32-byte boundary if INCR16 is specified.) 11: Burst transfer is issued so as not to extend beyond a 16-byte boundary. (The maximum burst length is limited to INCR4 because transfer goes beyond a 16-byte boundary if INCR8 or a longer length is specified.)
3, 2	—	All 0	R	Reserved The write value should be 0.
1, 0	MAX_BURST_LEN	00	R/W	These bits specify the maximum burst length for transfer from the AHB master interface. 00: INCR16 01: INCR8 10: INCR4 11: SINGLE

41.3.4.4 USBCTR Register (offset: H'20C)

Register symbol: USBCTR

This register makes settings for the host core.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

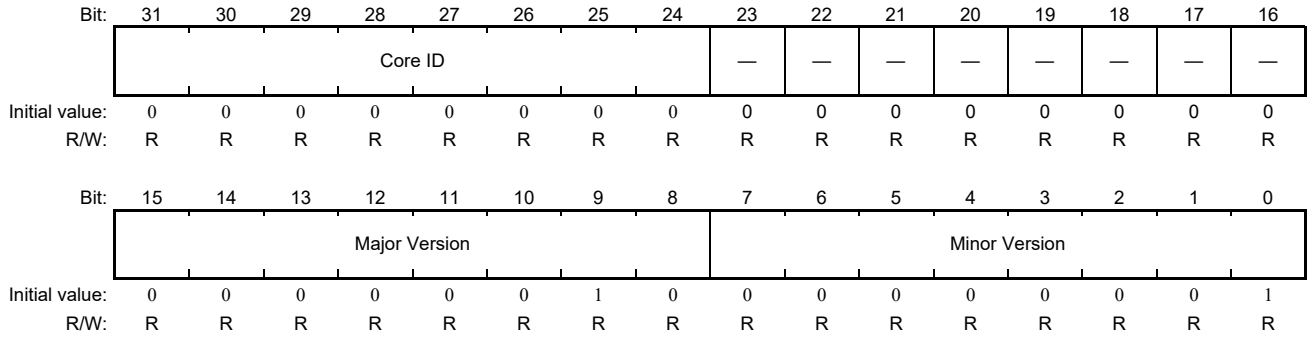
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	H'0001	R	Reserved The write value should be H'0001.
0	*Renesas Private*	0	W	The write value shall be 0.

41.3.5 Core Defined Registers

41.3.5.1 REVID Register (offset: H'300)

Register symbol: REVID



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	Core ID	All 0	R	These bits indicate the ID of the host core.
23 to 16	—	All 0	R	Reserved The write value should be 0.
15 to 8	Major Version	H’02	R	These bits indicate the major version number of the host core.
7 to 0	Minor Version	H’01	R	These bits indicate the minor version number of the host core.

41.3.5.2 Register Enable/Clock Gating Control Register (offset: H'304)

Register symbol: REGEN_CG_CTRL

Some registers are read-only in the initial state.

When such registers should be written to, set the corresponding bits in this register.

In addition, the clock can be gated for the unused sections in the host and peripheral function circuits.

Set the corresponding bits as necessary.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	NONUSE_CLK_MSK	—	HOST_CLK_MSK	PERI_CLK_MSK	—	—	—	*Renesas Private*	—	—	—	—	—	—	—	*Renesas Private*

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	NONUSE_CLK_MSK	0	R/W	This bit enables masking of the clock for the unused one of the host and peripheral function circuits. 0: Not masked. 1: Masked.
30	—	0	R	Reserved The write value should be 0.
29	HOST_CLK_MSK	0	R/W	This bit forcibly masks the clock to some circuits in the host core. 0: Not masked. 1: Masked.
28	PERI_CLK_MSK	0	R/W	This bit forcibly masks the clock to some circuits in the peripheral controller. 0: Not masked. 1: Masked.
27 to 25	—	All 0	R	Reserved The write value should be 0.
24	*Renesas Private*	0	R/W	The write value shall be 0.
23 to 17	—	All 0	R	Reserved The write value should be 0.
16	*Renesas Private*	0	R/W	The write value shall be 0.
15 to 1	—	All 0	R	Reserved The write value should be 0.
0	*Renesas Private*	0	R/W	The write value shall be 0.

41.3.5.3 Suspend Control Register (offset: H'308)

Register symbol: SPD_CTRL

This register controls the SUSPENDM pin in the UTMI+ interface.

Through this register setting, SUSPENDM can be asserted when the Suspend state is entered, and UTMI+ interface SUSPENDM can be forcibly asserted.

The equivalent control is also applied to the SLEEPM pin.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SUSPENDM_ENABLE	*Renesas Private*	—	—	—	—	—	—	WKCNNT_ENABLE	*Renesas Private*	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	*Renesas Private*	*Renesas Private*	—	—	—	—	—	—	GLOBAL_SUSPENDM_P2	GLOBAL_SUSPENDM_P1
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31	SUSPENDM_ENABLE	0	R/W	This bit provides a function to assert the UTMI+ interface SUSPENDM signal when the Suspend bit in the related OHCI or EHCI operational register is asserted. Setting this bit to 1 asserts the UTMI+ interface SUSPENDM signal in the target port after the Suspend-related bit in the OHCI or EHCI operational register shown below is set. This function is intended to reduce the power consumption in the UTMI+ PHY when this module enters the Suspend state. [Target OHCI and EHCI operational registers of this function] OHCI: Bit [2] (PSS bit) in the HcRhPortStatus register EHCI: Bit [7] (Suspend bit) in the PORTSC register
30	*Renesas Private*	0	R/W	The write value shall be 0.
29 to 24	—	All 0	R	Reserved The write value should be 0.
23	WKCNNT_ENABLE	0	R/W	Setting this bit to 1 deasserts SUSPENDM and SLEEPM when a change in the connection state is detected. This setting is valid when SUSPENDM_ENABLE or SLEEP_ENABLE is 1.
22	*Renesas Private*	0	R/W	The write value shall be 0.
21 to 10	—	All 0	R	Reserved The write value should be 0.
9	*Renesas Private*	0	R/W	The write value shall be 0.
8	*Renesas Private*	0	R/W	The write value shall be 0.
7 to 2	—	All 0	R	Reserved The write value should be 0.

Bit	Bit Name	Initial Value	R/W	Description
1	GLOBAL_SUSPENDM_P2	0	R/W	This bit provides a function to forcibly assert UTMI_P2SUSPENDM to 0. Setting this bit to 1 asserts the UTMI+ interface SUSPENDM pin (UTMI_P2SUSPENDM) in port 2. This function is intended to reduce the power consumption of the UTMI+ PHY by controlling this bit appropriately. [Note] Writing 1 to this bit is prohibited when the SUSPENDM_ENABLE bit is 1.
0	GLOBAL_SUSPENDM_P1	0	R/W	This bit provides a function to forcibly assert UTMI_P1SUSPENDM to 0. Setting this bit to 1 asserts the UTMI+ interface SUSPENDM pin (UTMI_P1SUSPENDM) for port 1. This function is intended to reduce the power consumption of the UTMI+ PHY by controlling this bit appropriately. [Note] Writing 1 to this bit is prohibited when the SUSPENDM_ENABLE bit is 1.

41.3.5.4 Suspend/Resume Timer Setting Register (offset: H'30C)

Register symbol: SPD_RSM_TIMSET

This register specifies the Connect/Disconnect detection time and Resume detection time when the clock from the UTMI+ PHY is stopped in the Suspend state.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TIMER_CONNECT[15:0]															
Initial value:	0	0	0	0	0	0	0	1	0	1	0	0	1	1	1	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TIMER_RESUME[15:0]															
Initial value:	0	0	0	0	0	0	1	0	1	0	0	1	1	0	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	TIMER_CONNECT[15:0]	H'014E	R/W	These bits specify the timer value used to detect Device Connect or Disconnect while the UTMI+ interface SUSPENDM is asserted. Assuming that the clock from the UTMI+ PHY stops while SUSPENDM is asserted, whether Connect or Disconnect has occurred is checked using the AHB clock (HCLK). Set this timer value so that the detection time is 2.5 µs or longer according to the AHB clock frequency used. A value of 1 specifies one cycle (µs). Reference setting values: AHB clock is 100 MHz: H'FA or a greater value AHB clock is 200 MHz: H'1F4 or a greater value
15 to 0	TIMER_RESUME[15:0]	H'029B	R/W	These bits specify the timer value used to detect the RemoteWakeup signal from the device while the UTMI+ interface SUSPENDM is asserted. Assuming that the clock from the UTMI+ PHY stops while SUSPENDM is asserted, whether the RemoteWakeup signal has been received is checked using the AHB clock (HCLK). Set this timer value so that the detection time is 5 µs or longer according to the AHB clock frequency used. A value of 1 specifies one cycle (µs). Reference setting values: AHB clock is 100 MHz: H'1F4 or a greater value AHB clock is 200 MHz: H'3E8 or a greater value

41.3.5.5 Overcurrent Detection Timer Setting Register (offset: H'310)

Register symbol: OC_TIMSET

This register specifies the overcurrent detection time.

When the overcurrent detection input signal (USBn_OVC) is asserted to 0 continuously for the time specified in this register, occurrence of an overcurrent is detected.

[Note]

This register setting is ignored when the OCISEL bit (bit [5]) in the host COMMON/OHCI extended register (offset: H'360) is 1.

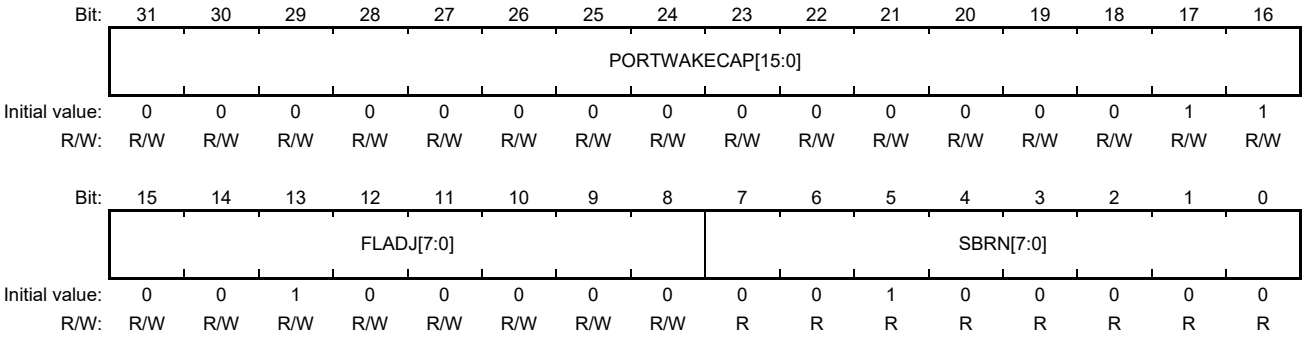
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	TIMER_OC[19:16]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TIMER_OC[15:0]															
Initial value:	0	0	0	0	1	0	0	1	1	0	1	0	1	0	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R	Reserved The write value should be 0.
19 to 0	TIMER_OC [19:0]	H’2 09AB	R/W	These bits specify the timer value used to detect an overcurrent. When the overcurrent detection input signal (USBn_OVC) is asserted to 0 continuously for the time specified in this field, this module determines that an overcurrent has occurred. Set this timer value so that the detection time is 1 to 2 ms or longer according to the AHB clock frequency used. A value of 1 specifies one cycle (μs). Note that occurrence of an overcurrent is detected when USBn_OVCis asserted to 0 continuously over a certain period. Specify the period in these bits according to the AHB clock frequency. Reference setting values: To specify 1 ms when the AHB clock is 100 MHz: H'1_86A0 or a greater value To specify 1 ms when the AHB clock is 200 MHz: H'3_0D40 or a greater value

41.3.5.6 SBRN, FLADJ, PORTWAKECAP Register (offset: H'314)

Register symbol: SBRN_FLADJ_PW



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	PORTWAKE CAP[15:0]	H'0003	R/W	The intended use of these bits are to establish a policy about which ports are to be used for wake events. This bit setting does not affect the operation of the host core.
15 to 8	FLADJ[7:0]	H'20	R/W	These bits adjust the length of one micro-frame in units of 16-HS-bit time. The initial value is H'20 (60000 HS-bit time).
7 to 0	SBRN[7:0]	H'20	R	These bits indicate the serial bus release number. This value is fixed to H'20.

41.4 Clock Specifications

41.4.1 Clock Gating Specifications

41.4.1.1 Overview

This module has a function for switching between the host and peripheral modes. In some case, no clock supply is needed for the unused circuits (stopping the clock causes no problem).

To reduce the power consumption through clock gating for the circuits that do not need clock supply, this module provides three clock control gating bits in the register enable/clock gating control register.

Control these bits appropriately to gate the clock supply to some circuits in the host core and peripheral controller.

Bit	Symbol
[31]	NONUSE_CLK_MSK
[29]	HOST_CLK_MSK
[28]	PERI_CLK_MSK

For the bus clock, the AHB clock for the AHB_IF module is excluded from the targets of clock gating assuming that there may be unexpected access from the system or switching between the host and peripheral modes through register settings. However, the AHB clock for the other circuits is gated.

41.5 Reset Specifications

41.5.1 Input Reset Specifications

This module has a software reset input from CPG module. Asserting this reset signal initializes all FFs in this module.

41.6 Interrupt Specifications

41.6.1 Interrupt Signal List

This module has the following six interrupt signal lines. Use all of them as level interrupts.

Interrupt Pin Name	Interrupt Type	Pulse/ Level	Minimum Pulse Width	Active Level	Synchro-nized with
U2H_INT	An interrupt signal output from the AHB_IF module. This is generated when a bus error occurs in the AHB master. It is controlled through the related AHB bridge register.	Level	—	H	HCLK
U2H_OHCI_INT	An interrupt signal output from OHCI. This is generated when data transfer is completed or a change in the USB bus state is detected in the FS or LS transfer. It is controlled through the related OHCI operational register.	Level	—	H	HCLK
U2H_EHCI_INT	An interrupt signal output from EHCI. This is generated when data transfer is completed or a change in the USB bus state is detected in the HS transfer. It is controlled through the related EHCI operational register.	Level	—	H	HCLK
U2H_WAKEON_INT	An interrupt signal output from EHCI. This is generated due to an EHCI wakeup event. It is controlled through the related EHCI operational register.	Level	—	H	HCLK
U2H_BIND_INT	Logical OR of the interrupt signals. (U2H_INT + U2H_OHCI_INT + U2H_EHCI_INT + U2H_WAKEON_INT)	Level	—	H	HCLK

41.6.2 Interrupt Sources and Control

41.6.2.1 U2H_INT Assertion Source and Control

Interrupt Enable Control in Register:

This interrupt signal is asserted when an interrupt source event occurs while the interrupt enable bit in the following register is set to enabled (1).

AHB bridge register: INT_ENABLE register (offset: H'200) Bit [0] (AHB_INTEN)

Interrupt Source:

A bus error occurs (MHRESP = 1) in the AHB master.

Clearing Interrupt:

To clear the interrupt, write 1 to the following register bit.

AHB bridge register: INT_STATUS register (offset: H'204) Bit [0] (AHB_INT)

41.6.2.2 U2H_OHCI_INT Assertion Sources and Control

Interrupt Enable Control in Registers:

This interrupt signal is asserted when an interrupt source event occurs while the interrupt enable bits in the following registers are set to enabled (1).

AHB bridge register: INT_ENABLE register (offset: H'200) Bit [1] (USBH_INTAEN)
OHCI operational register: HcInterruptEnable Register (offset: H'010) Bit [31] and bits [6:0]*

Note: * Set the necessary bits enabled as interrupt assertion source bits.

Interrupt Sources:

		Necessary Enable Settings in Register Bits							
			HcInterruptEnable						
			Bit[31]	Bit[6]	Bit[5]	Bit[3]	Bit[2]	Bit[1]	Bit[0]
	Interrupt Source	USBH_INTAEN	MIE	RHSCE	FNOE	ROE	SFE	WDHE	SOE
1	Device connection is detected.	√	√	√					
2	Device disconnection is detected.	√	√	√					
3	Port power is turned off (overcurrent detection is not included).	√	√	√					
4	Babble error is detected during USB transfer.	√	√	√					
5	Resume process is completed.	√	√	√					
6	Overcurrent is detected.	√	√	√					
7	Bus reset process is completed.	√	√	√					
8	OHCI enters the Operational state (HCFS[1:0] = B'10) or Suspend state (HCFS[1:0] = B'11]) while the DR bit in the HcRhDescritorB register is 1.	√	√	√					
9	1 is written to the OHCI HcRhPort status bit [0] (ClearPortEnable) while no device is connected (CCS bit = 0).	√	√	√					
10	1 is written to the OHCI HcRhPort status bit [1] (SetPortEnable) while no device is connected (CCS bit = 0).	√	√	√					
11	1 is written to the OHCI HcRhPort status bit [2] (SetPortSuspend) while no device is connected (CCS bit = 0).	√	√	√					
12	1 is written to the OHCI HcRhPort status bit [3] (ClearSuspendStatus) while no device is connected (CCS bit = 0).	√	√	√					
13	1 is written to the OHCI HcRhPort status bit [4] (SetPortReset) while no device is connected (CCS bit = 0).	√	√	√					
14	Port power is turned off while no device is connected (CCS bit = 0).	√	√	√					
15	MSB of bits [15:0] (FrameNumber) in the HcFmNumber register changes.	√	√		√				
16	RemoteWakeup signal (Resume signal) from a device is detected.	√	√			√			
17	HccaFrameNumber is updated (this means almost the same as an SOF transmission).	√	√				√		
18	Transfer (including an error) ends and the host core updates HccaDoneHead.	√	√					√	
19	USB schedule overrun occurs for a frame.	√	√						√

√: Necessary

Clearing Interrupt:

To clear the interrupt, write 1 to one of the following register bits that corresponds to the interrupt source.

OHCI operational register: HcInterruptStatus register (offset: H'00C) Bits [6:0]

41.6.2.3 U2H_EHCI_INT Assertion Sources and Control

Interrupt Enable Control in Registers:

This interrupt signal is asserted when an interrupt source event occurs while the interrupt enable bits in the following registers are set to enabled (1).

AHB bridge register: INT_ENABLE register (offset: H'200) Bit [2] (USBH_INTBEN)
EHCI operational register: USBINTR register (offset: H'128) Bits [17:16] and bits [5:0]*

Note: * Set the necessary bits enabled as interrupt assertion source bits.

In addition, control the following register bits as necessary.

EHCI operational register: USBCMD register (offset: H'120) Bit [15] and bit [6]

Interrupt Sources:

		Necessary Enable Settings in Register Bits								
			USBCMD		USBINTR					
			Bit[15]	Bit[6]	Bit[17]	Bit[16]	Bit[5]	Bit[3]	Bit[2]	Bit[1]	Bit[0]
	Interrupt Source	USBH_INTBEN	Per-Port Change Event	Door-bell	Port-n Change Event		Async Advance	Frame List Roll-over	Port Change	USB ERRINT	USB INT
1	Device connection is detected.	√							√		
2	Device disconnection is detected.	√							√		
3	Overcurrent is detected.	√							√		
4	RemoteWakeup signal (Resume signal) from a device is detected.	√							√		
5	Babble state is detected on the USB bus.	√							√		
6	USB transfer with qTD IOC = 1 is successfully completed.	√									√
7	Short packet is received.	√									√
8	USB transfer ends with an error. (Retry fails three times, a babble error is detected, or STALL is received.)	√								√	
9	QH processing with bit [6] (Interrupt on Async Advance Doorbell) in the USBCMD register set to 1 is successfully completed.	√		√			√				
10	FrameIndex bit in the FRINDEX register returns from the maximum value to H'000 (rollover is detected).	√						√			
11	Port Change Detect event (interrupt sources 1 to 5) is detected in USB port 1.	√	√			√					
12	Port Change Detect event (interrupt sources 1 to 5) is detected in USB port 2.	√	√		√						

√: Necessary

Clearing Interrupt:

To clear the interrupt, write 1 to one of the following register bits that corresponds to the interrupt source.

EHCI operational register: USBSTS register (offset: H'124) Bits [17:16] and bits [5:0]

41.6.2.4 U2H_WAKEON_INT Assertion Sources and Control

Interrupt Enable Control in Registers:

This interrupt signal is asserted when an interrupt source event occurs while the interrupt enable bits in the following registers are set to enabled (1).

AHB bridge register: INT_ENABLE register (offset: H'200) Bit [4] (WAKEON_INTEN)
EHCI operational register: PORTSC[1:2] registers (offset: H'164 and H'168) Bits [22:20]*

Note: * Set the necessary bits enabled as interrupt assertion source bits.

Interrupt Sources:

		Necessary Enable Settings in Register Bits			
			PORTSC		
			Bit[22]	Bit[21]	Bit[20]
	Interrupt Source	WAKEON_INTEN	WKOC_E	WKDSCNNT_E	WKCNNT_E
1	Device connection is detected.	√			√
2	Device disconnection is detected.	√		√	
3	Overcurrent is detected.	√	√		
4	RemoteWakeup signal (Resume signal) from a device is detected.	√			

√: Necessary

Clearing Interrupt:

To clear the interrupt, write 1 to the following register bit.

AHB bridge register: INT_STATUS register (offset: H'204) Bit [4] (WAKEON_INT)

41.6.3 Interrupt Signal Deassertion Timing

After a register is accessed to clear an interrupt source, it may take a certain period of time until the corresponding interrupt is actually cleared. Therefore, a measure should be taken to prevent misdetection of the previous interrupt between register access for clearing and correct detection of the next interrupt.

41.6.3.1 Connection of Interrupt Signal Lines

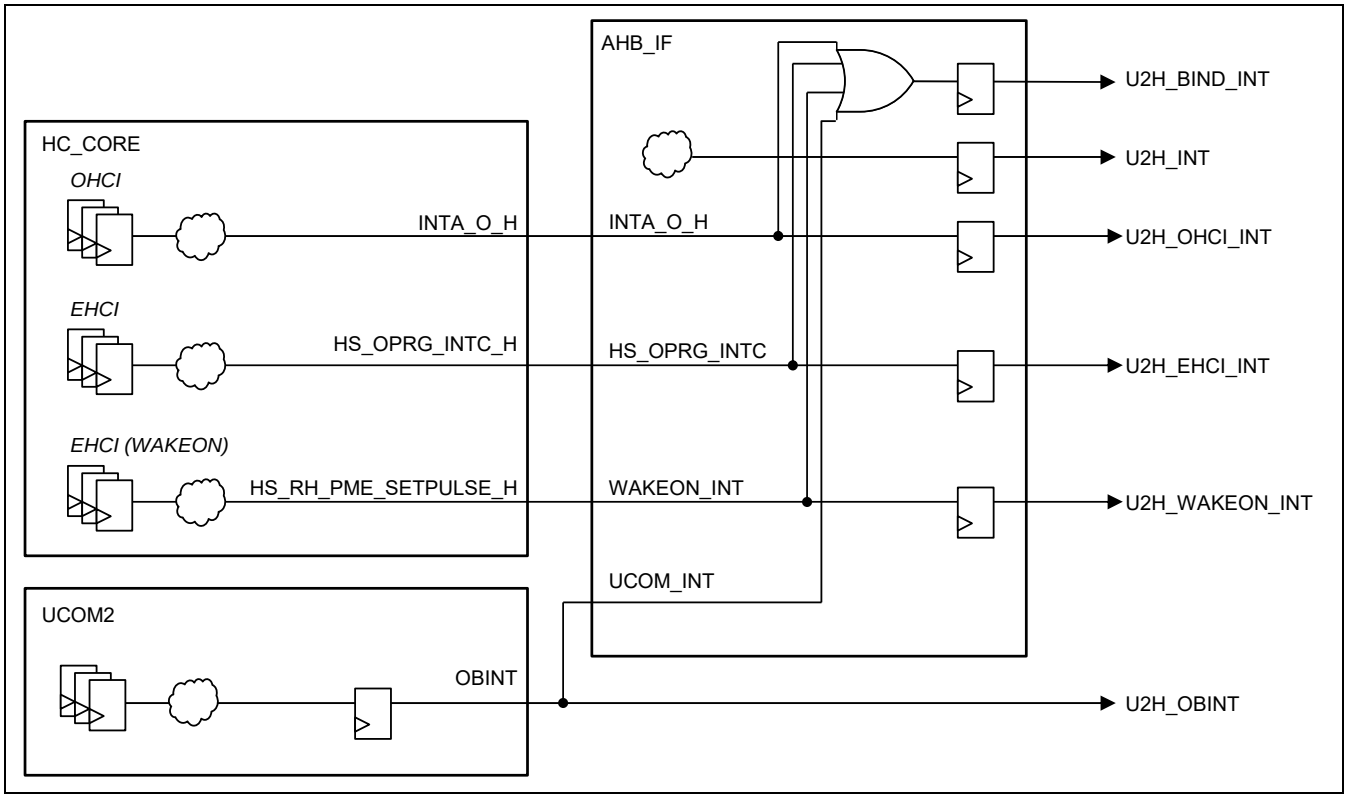


Figure 41.2 Connection diagram of Interrupt Signal Lines

41.7 Power Management

The system implementing this module provides the following two types of low-power control for the USB 2.0 core (including the UTMI+ PHY).

1. Controls the SUSPENDM and SLEEPM pins of the UTMI+ PHY.
2. Stops unnecessary clock supply to the host core internal circuits and the peripheral core through clock gating.

41.7.1 Controlling SUSPENDM and SLEEPM Pins of UTMI+ PHY

The following power-reducing effects are expected from assertion of the SUSPENDM and SLEEPM pins of the UTMI+ PHY.

- The power consumption in the UTMI+ PHY can be reduced (this depends on the PHY).
- The power consumption in the host core can be reduced because the clock from the PHY is stopped.

The SUSPENDM and SLEEPM pins of the UTMI+ PHY are not asserted in the default settings even when the EHCI or OHCI is placed in the Suspend state as described earlier.

See section 41.3.5.3, Suspend Control Register (offset: H'308), and set up the register appropriately.

41.7.2 Controlling Clock Gating Function

The clock supply to the unused one of the host and peripheral functions can be gated through register settings.

See section 41.3.5.2, Register Enable/Clock Gating Control Register (offset: H'304), and set up the register appropriately.

41.8 Operation

This section describes register operations required for the initial settings of this module and the registers required for the power consumption control.

41.8.1 Power control and Initialization

1. EHCI/OHCI module stop release and module reset assert.
2. PLLRESET release (Note: Refer to UGCTRL register in Section 42)
3. Wait min. 340 µs for USB PHY power stable.
4. USB0SEL[1:0] should be set to B'01 for EHCI/OHCI. (Note: Refer to UGCTRL2 register in Section 42)
5. Starting normal operation.

41.8.2 Transfer Overview

Transfer by the host controller must be performed in compliance with the following OHCI and EHCI specifications.

Open Host Controller Interface Specification for USB Rev 1.0a

Enhanced Host Controller Interface Specification for Universal Serial Bus Revision 1.0

42. USB High-Speed Module (HS-USB)

42.1 Overview

This module is a USB controller provided with the function controller function, and high-speed transfer and full-speed transfer are available. Provided with an on-chip USB transceiver, this module also supports all transfer types defined by the USB Specification.

This module can use up to 16 pipes. Furthermore, for pipes 1 to F, arbitrary endpoint numbers can be allocated according to peripheral devices to be communicated and user systems.

42.1.1 Features

(1) On-chip USB transceiver

(2) Achieves space-saving mount with less external elements

- On-chip D+ pull-up resistor (function operation mode)
- On-chip D+/D- terminating resistors (high-speed operation mode)
- On-chip D+/D- output resistors (full-speed operation mode)

(3) All Types of USB Transfers Supported

- Control transfer
- Bulk transfer
- Interrupt transfer (except for high bandwidth)
- Isochronous transfer (except for high bandwidth)

(4) Dedicated DMA interface

- On-chip 4-channel DMA interface

(5) Pipe configuration

- Up to sixteen pipes are selectable (including the default control pipe)
- Programmable pipe configuration
- Arbitrary endpoint numbers can be allocated to pipes 1 to F.
- Settable transfer conditions for each pipe are as follows:

Pipe 0:	A pipe only for control transfer with a 64-byte (fixed) single buffer
Pipes 1 and 2:	Bulk transfers/isochronous transfer, continuous transfer mode, programmable buffer size (up to 2-Kbytes: double buffer can be specified)
Pipes 3 to 5 and B to F:	Bulk transfer, continuous transfer mode, programmable buffer size (up to 2-Kbytes: double buffer can be specified)
Pipes 6 to 8:	Interrupt transfer, 64-byte fixed single buffer
Pipes 9 to A:	Interrupt transfer, Bulk transfer, continuous transfer mode, programmable (up to 2-Kbytes: double buffer can be specified)

(6) Other functions

- Transfer ending function using transaction count
- DMA transfer ending function using external triggers (TEND or WREND signal)
- SOF pulse output function
- BRDY interrupt event notification timing change function (BFRE)

- Function that automatically clears the buffer memory after the data for the pipe specified at the DnFIFO (n = 0 to 3) port has been read (DCLRM)
- NAK setting function (SHTNAK) for the response PID due to the transfer end
- The suspend and resume of whole LSI can be done by using USBHS.

(7) Embedded USB PHY

The embedded USB PHY consists of the following features.

- Contains the USB functions drivers and receivers for D+ and D- signaling

42.1.2 Input/Output Pins

Table 42.1 lists the input and output pins of the USB.

Table 42.1 Pin Configuration of USB

Classification	Pin Name	Name	I/O	Description
USB bus interface	USB0_DP	USB channel 0 D+ data	I/O	D+ Input/output of the on-chip transceiver Connect this pin to the D+ pin of the USB bus channel 0
	USB0_DM	USB channel 0 D- data	I/O	D- Input/output of the on-chip transceiver Connect this pin to the D- pin of the USB bus channel 0
	USB1_DP	USB channel 1 D+ data	I/O	D+ Input/output of the on-chip transceiver Connect this pin to the D+ pin of the USB bus channel 1
	USB1_DM	USB channel 1 D- data	I/O	D- Input/output of the on-chip transceiver Connect this pin to the D- pin of the USB bus channel 1
Reference resistance	RREF	USB external reference resistor	I	Connect to external 5.6kΩ±1% resistor.
VBUS	USB0_VBUS	USB channel 0 VBUS	I	The external series resistor is not required Connect this pin to the USB VBUS channel 0
	USB1_VBUS	USB channel 1 VBUS	I	The external series resistor is not required Connect this pin to the USB VBUS channel 1
Over current	USB0_OVC	USB channel 0 Over current	I/O	Connect to over current detection pin of external power IC which supply VBUS power. This is low active signal
	USB1_OVC	USB channel 0 Over current	I/O	Connect to over current detection pin of external power IC which supply VBUS power. This is low active signal
Power Enable	USB0_PWEN	USB channel 0 Power enable	I/O	Connect to power enable pin of external power IC which supply VBUS power
	USB1_PWEN	USB channel 0 Power enable	I/O	Connect to power enable pin of external power IC which supply VBUS power

42.2 Register Descriptions

HS-USB	Base Address
Channel 0	H'E659 0000
Channel 1	H'E659 8000

Table 42.2 lists the registers used in this module. Table 42.3 lists the register states in each processing mode.

Table 42.2 Register Configuration

Register Name	Abbreviation	R/W	Address Offset	Access Size

42.2.1 System Configuration Control Register (SYSCFG)

SYSCFG enables or disables high-speed operation controls USB0_DP/USB1_DP and USB0_DM/USB1_DM pins, and enables or disables the operation of this module.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	HSE	—	—	DPRPU	—	—	—	USBE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	HSE	0	R/W	High-Speed Operation Enable 0: High-speed operation is disabled. When the function controller function is selected: Full-speed operation only 1: High-speed operation is enabled. (This module detects the transmission rate.) When HSE is 0, this module performs full-speed operation. When HSE is 1, this module executes the reset handshake protocol, and according to the result, this module automatically performs high-speed or full-speed operation. Change this bit while the DPRPU bit is 0.
6, 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	DPRPU	0	R/W	D+ Line Resistance Control Enables or disables pull-up of the D+ line when the function controller function is selected. 0: Pull-up is disabled. 1: Pull-up is enabled. When this bit is set to 1 before using this module, this module pulls up the D+ line at 3.3V, and informs the USB host of ATTACH. Clearing this bit to 0 cancels the pull-up of the D+ line, and informs the USB host of DETACH. Set this bit to 1 when the function controller function is selected.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	USBE	0	R/W	USB Module Operation Enable Enables or disables the USB module operation. 0: The USB module operation is disabled. 1: The USB module operation is enabled. Table 42.4 lists the registers and bit names initialized when this bit is cleared to 0.

Table 42.4 Registers Initialized by Writing 0 in the USBE Bit

Register Name	Bit Name	Remarks
SYSSTS	LNST	
DVSTCTR	RHST	
INTSTS0	DVSQ	
USBADDR	USBADDR	
USEREQ	BRequest, bmRequestType	
USBVAL	wValue	
USBINDX	wIndex	
USBLENG	wLength	

42.2.2 CPU Bus Wait Register (BUSWAIT)

BUSWAIT specifies the number of access waits from the CPU to this module.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	BWAIT[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	BWAIT[3:0]	1111	R/W	CPU Bus Wait Specify the number of access waits to this module. 0000: 0 waits (2 access cycles) 0001: 1 wait (3 access cycles) 0010 to 1110: 2 to 14 waits (4 to 16 access cycles) 1111: 15 waits (17 access cycles) initial value The following restriction is provided for access cycles to the registers of addresses beginning with H'04 of this controller. Restriction for wait: The cycle of continuous accesses to the registers of this controller must be 80 ns or more. To satisfy this restriction, control waits using the frequency of system clock HPϕ. Choose the best value within the initial value of 17 clock cycles (maximum). This setting is the same as the waits in accesses to the FIFO port register. The maximum speed of accesses to the FIFO port is as follows: MBW = B'10 (32-bit width) : Max. 48 Mbytes/s MBW = B'01 (16-bit width) : Max. 24 Mbytes/s MBW = B'00 (8-bit width) : Max. 12 Mbytes/s

42.2.3 System Configuration Status Register (SYSSTS)

SYSSTS monitors the USB data bus line status (D+ and D- lines).

This register is initialized by a power-on reset or a USB reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LINE[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	—	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	LNST[1:0]	Undefined*	R	USB Data Line Status Monitor Indicate the USB data bus line (D+ and D- lines) status. Table 42.5 shows the USB data bus line status. Read these bits after the attach processing (DPRPU = 1)

Note: * These bits depend on the state of the USB0_DP/USB1_DP, USB0_DM/USB1_DM, and USB0_OVC/USB1_OVC pins.

Table 42.5 USB Data Bus Line Status

LNST[1]	LNST[0]	Full-Speed Operation	High-Speed Operation	Chirp Operation
0	0	SE0	Squelch	Squelch
0	1	J-State	UnSquelch	Chirp J
1	0	K-State	Invalid	Chirp K
1	1	SE1	Invalid	Invalid

Legend:

Chirp: The reset handshake protocol (RHSP) is being executed with high-speed operation is enabled (HSE = 1 in SYSCFG).
Squelch: SE0 or idle state
UnSquelch: High-speed J-State or high-speed K-State
Chirp J: Chirp J-State
Chirp K: Chirp K-State
Invalid: Invalid

42.2.4 Device State Control Register (DVSTCTR)

DVSTCTR controls and monitors the USB data bus state.

This register is initialized by a power-on reset. The WKUP bit is initialized and the RESUME bit becomes undefined by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	WKUP	—	—	—	—	—	RHST[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	WKUP	0	R/W*	Wakeup Output Enables or disables the remote wakeup (resume signal output) to the USB bus when the function controller function is selected. 0: The remote wakeup signal is not output. 1: The remote wakeup signal is output. This module controls the remote wakeup signal output time. When this bit is set to 1, this module outputs 10 ms K-State and then clears this bit. The USB Specification requires the USB bus idle state to be maintained for at least 5 ms before transmitting the remote wakeup signal. For this reason, this module outputs K-State after waiting for 2 ms even if 1 is written in this bit immediately after the suspended state is detected. Write 1 in this bit only when the device is in the suspended state (DVSQ = 1xx in INTSTS0) and remote wakeup is enabled by the USB host. When setting this bit to 1, do not stop the internal clock even in the suspended state (Write 1 in this bit with SUSPM set to 1).
7 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	RHST[2:0]	000	R	Reset Handshake Indicate the reset handshake state. 000: Transmission rate is undefined. 100: The reset handshake processing is in progress. 010: Full-speed connection 011: High-speed connection When this module detects a USB bus reset with the HSE bit set to 1 for the port, these bits become B'100. After that, when this module outputs ChirpK and detects ChirpJK from the USB host three times, these bits become B'011. Unless high-speed mode is fixed within 2.5 ms after the ChirpK output, these bits become B'010. When this module detects a USB bus reset with the HSE bit set to 0 for the port, these bits become B'010. When the RHST bits are fixed to B'010 or B'011 after this module detected a USB bus reset, the DVST interrupt occurs.

42.2.5 Test Mode Register (TESTMODE)

TESTMODE controls the USB test signal output in high-speed operation mode.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	UTST[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	UTST[3:0]	0000	R/W	Test Mode Table 42.6 shows the test mode operation of this module. Control the USB test signal output in high-speed operation mode. These bits are valid only in high-speed operation mode. Use this test mode when the RHST bits in DVSTCTR are B'011. After the test with these bits, cancel this test mode by a power-on reset. Set these bits according to the SetFeature request from the USB host during high-speed communication. While these bits are B'0001 to B'0100, this module does not enter the suspended state.

Table 42.6 Test Mode Operation

Test Mode	UTST Bits Setting
Normal operation	B'0000
Test_J	B'0001
Test_K	B'0010
Test_SE0_NAK	B'0011
Test_Packet	B'0100
Test_Force_Enable	—
Reserved	B'0101 to B'0111

42.2.6 CFIFO Port Register

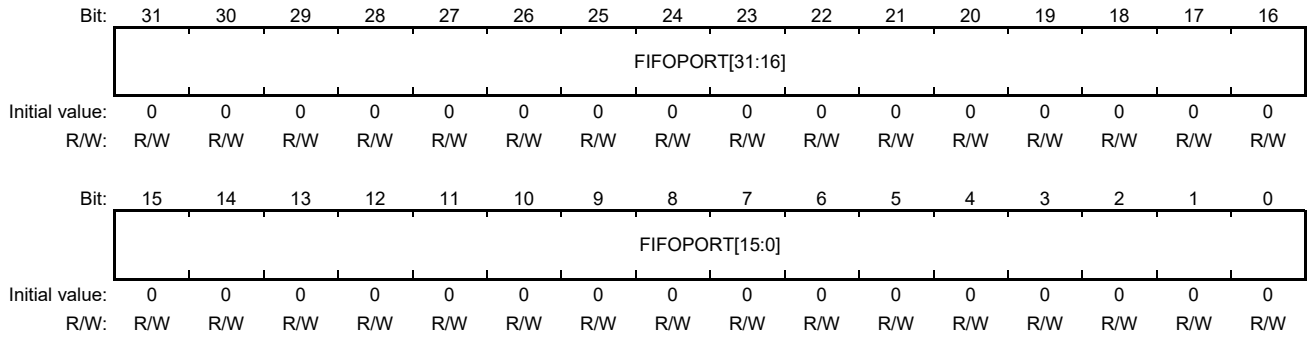
CFIFO is a port register to read data from or write data to the FIFO buffer memory.

Each FIFO port consists of this register (CFIFO) for data read/write from/to the FIFO buffer memory, the select registers (CFIFOSEL, D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL) to select pipes to be allocated to a FIFO port, and the control registers (CFIFOCTR, D0FIFOCTR, D1FIFOCTR, D2FIFOCTR and D3FIFOCTR).

Each FIFO port provides the following features.

- Make accesses to the FIFO buffer for DCP through the CFIFO port.
- Make accesses to the FIFO buffer with DMA transfers through the DMAC module for USB high-speed only.
- When using a function specific to FIFO ports (DMA transfer function, etc.), the pipe number (selected pipe) specified by the CURPIPE bits cannot be changed.
- Register groups of a FIFO port do not affect other FIFO ports.
- Do not allocate the same pipe number to different FIFO ports.
- There are two FIFO buffer states where the access mastership is on the CPU side and on the SIE side. When the FIFO buffer access mastership is on the SIE side, the CPU cannot make an access to the FIFO buffer.

This register is initialized by a power-on reset.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	FIFOPORT [31:0]	All 0	R/W	FIFO Port Read receive data from the FIFO buffer or write transmit data to the FIFO buffer using these bits. Access to this register is enabled only when the FRDY bit in each control register (CFIFOCTR, D0FIFOCTR, D1FIFOCTR, D2FIFOCTR and D3FIFOCTR) is set to 1. Valid bits in this register vary with the value of the MBW bits. Table 42.7 shows the valid bits in this register.

Table 42.7 Operation of This Register when Accessed

Access Size	Bits 31 to 24	Bits 23 to 16	Bits 15 to 8	Bits 7 to 0
32 bits	N + 3 address	N + 2 address	N + 1 address	N + 0 address
16 bits	Write: Invalid, Read: Prohibited*		N + 1 address	N + 0 address
8 bits	Write: Invalid, Read: Prohibited*			N + 0 address

Note: * Reading an invalid register with word access or byte access is prohibited.

42.2.7 FIFO Port Select Registers (CFIFOSEL, D0FIFOSEL, D1FIFOSEL, D2FIFOSEL, D3FIFOSEL)

CFIFOSEL, D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL select pipes to be allocated to FIFO ports and control accesses to each FIFO port.

Do not specify the same pipe number for the CURPIPE bits in CFIFOSEL, D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL When the CURPIPE bits in D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL are set to B'000, no pipe is specified.

Do not change any pipe number when DMA transfer is enabled.

This register is initialized by a power-on reset.

(1) CFIFOSEL

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RCNT	REW	—	—	MBW[1:0]		—	—	—	—	ISEL	—	CURPIPO[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R/W	R/W	R	R	R	R	R/W	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	RCNT	0	R/W	Read Count Mode Specifies read mode of the DTLN bits in CFIFOCTR. 0: Clears the DTLN bits after reading all receive data in the CFIFO (or after reading receive data of one side of the double buffer). 1: Counts down the DTLN bits at each reading of CFIFO receive data.
14	REW	0	R/W	Buffer Pointer Rewind Specifies whether to rewind the buffer pointer or not. 0: The buffer pointer is not rewound. 1: The buffer pointer is rewound. When the selected pipe is in the receive direction and this bit is set to 1 during FIFO buffer reading, the FIFO buffer can be read from the first data. (In the case of a double buffer, the first data of one side that is being read can be read again.) Do not set this bit to 1 concurrently with the CURPIPE setting change. Be sure to confirm that the FRDY bit is 1 when setting this bit to 1. To rewrite the FIFO buffer data from the first data for a pipe in the transmit direction, use the BCLR bit.
13, 12	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
11, 10	MBW[1:0]	00	R/W	CFIFO Port Access Bit Width Specify the bit width for accesses to the CFIFO port. 00: 8 bits 01: 16 bits 10: 32 bits 11: Setting prohibited When the selected pipe is in the receive direction and data read is started after these bits are set, do not change these bits until all data is completely read. When the selected pipe is in the receive direction, set the CURPIPE and MBW bits at the same time. When the selected pipe is in the transmit direction, no bit width can be changed (from 8 bits to 16/32 bits or from 16 bits to 32 bits) during data write to the buffer memory. When 8-bit width or 16-bit width is selected, data of odd bytes can also be written by controlling the byte access.
9 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5	ISEL	0	R/W	CFIFO Port Access Direction when DCP is Selected 0: Buffer memory read is selected. 1: Buffer memory write is selected. To change this bit when the selected pipe is DCP, write 1 or 0 in this bit, read the value of this bit, confirm that the write value equals the read value, and then proceed with the next processing. If this bit is changed in the middle of access to the FIFO buffer, accesses made before that time are retained, the value of this bit is rewritten, and then further access is enabled. Set this bit concurrently with the CURPIPE bits.
4	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
3 to 0	CURPIPE [3:0]	0000	R/W	CFIFO Port Access Pipe Select Set the number of pipe to be used for data read or write through the CFIFO port. 0000: DCP 0001: Pipe 1 0010: Pipe 2 0011: Pipe 3 0100: Pipe 4 0101: Pipe 5 0110: Pipe 6 0111: Pipe 7 1000: Pipe 8 1001: Pipe 9 1010: Pipe A 1011: Pipe B 1100: Pipe C 1101: Pipe D 1110: Pipe E 1111: Pipe F To change these bits, write a value in these bits, read the value of these bits, confirm that the write value equals the read value, and then proceed with the next processing. Do not write the same pipe number in the CURPIPE bits in CFIFOSEL, D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL If these bits are changed in the middle of access to the FIFO buffer, accesses made before that time are retained, the value of these bits is rewritten, and then further access is enabled.

Note: * Only reading 0 is enabled.

(2) D0FIFOSEL, D1FIFOSEL, D2FIFOSEL, D3FIFOSEL

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RCNT	REW	DCLRM	DREQE	MBW[1:0]		—	—	DEZPM	—	—	—	CURPIPO[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	RCNT	0	R/W	Read Count Mode Specifies read mode of the DTLN bits in DnFIFOCTR. 0: Clears the DTLN bits after reading all receive data in the DnFIFO (or after reading receive data of one side of the double buffer). 1: Counts down the DTLN bits at each reading of DnFIFO receive data. When making an access to the DnFIFO with the BFRE bit set to 1, set this bit to 0.
14	REW	0	R/W*	Buffer Pointer Rewind Specifies whether to rewind the buffer pointer or not. 0: The buffer pointer is not rewound. 1: The buffer pointer is rewound. When the selected pipe is in the receive direction and this bit is set to 1 during FIFO buffer reading, the FIFO buffer can be read from the first data. (In the case of a double buffer, the first data of one side that is being read can be read again.) Do not set this bit to 1 concurrently with the CURPIPE setting change. Be sure to confirm that the FRDY bit is 1 when setting this bit to 1. When making an access to the DnFIFO with the BFRE bit set to 1, do not set this bit to 1 when the short packet data is completely read. To rewrite the FIFO buffer data from the first data for a pipe in the transmit direction, use the BCLR bit.
13	DCLRM	0	R/W	Buffer Memory Auto-Clear Mode after Reading Data of Selected Pipe Enables or disables buffer memory auto-clear mode after reading data of the selected pipe. 0: Buffer memory auto-clear mode is disabled. 1: Buffer memory auto-clear mode is enabled. When this bit is 1 and a Zero-Length packet is received while the FIFO buffer allocated to the selected pipe is empty or when a short packet is received with the BFRE bit set to 1 and the packet data is completely read, this module performs buffer clear (BCLR = 1 processing) of the FIFO buffer. When using this module with the BRDYM bit set to 1, be sure to set this bit to 0.
12	DREQE	0	R/W	DMA Transfer Request Enable Enables or disables making a DMA transfer request. 0: DMA transfer request is disabled. 1: DMA transfer request is enabled. To enable a DMA transfer request, set the CURPIPE bits and then set this bit to 1. Set this bit to 0 before changing the CURPIPE setting.

Bit	Bit Name	Initial Value	R/W	Description
11, 10	MBW[1:0]	00	R/W	FIFO Port Access Bit Width Specify the bit width for accesses to the DnFIFO port. 00: 8 bits 01: 16 bits 10: 32 bits 11: Setting prohibited When the selected pipe is in the receive direction and data read is started after these bits are set, do not change these bits until all data is completely read. When the selected pipe is in the receive direction, set the CURPIPE and MBW bits at the same time. When the selected pipe is in the transmit direction, no bit width can be changed (from 8 bits to 16/32 bits or from 16 bits to 32 bits) during data write to the buffer memory. When 8-bit width or 16-bit width is selected, data of odd bytes can also be written by controlling the byte access.
9, 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
7	DEZPM	0	R/W	DEZPM: Zero-Length Packet Addition Mode If the DMA transfer size that is set for the USBHS-DMAC modules is an integral multiple of the maximum packet size, a null packet is added after all of the data has been sent. 0: Disables addition of packets. 1: Enables addition of packets. This bit is applied to pipes used to write to the FIFO buffer. DEZPM must be set before starting DMA transfers. If the DEZPM bit is set after DMA transfers complete, no null packets are added. Note: This mode depends on the buffer size (PIPEBUF.BUFSIZE[4:0]). A null packet is added after transferring data up to buffer size which is defined by PIPEBUF.BUFSIZE[4:0]. When transfer data size is over 2Kbytes, this mode must not be used because max size of buffer is 2Kbytes. In that case, please add the null packet by SW with BVAL bit of FIFO Port Control Registers.
6 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

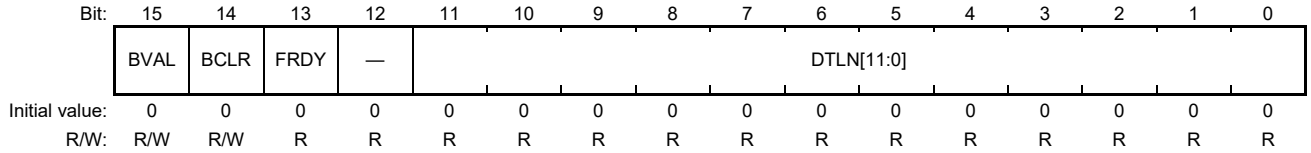
Bit	Bit Name	Initial Value	R/W	Description
3 to 0	CURPIPE [3:0]	0000	R/W	FIFO Port Access Pipe Select Set the number of pipe to be used for data read or write through the DnFIFO ports. 0000: No pipe 0001: Pipe 1 0010: Pipe 2 0011: Pipe 3 0100: Pipe 4 0101: Pipe 5 0110: Pipe 6 0111: Pipe 7 1000: Pipe 8 1001: Pipe 9 1010: Pipe A 1011: Pipe B 1100: Pipe C 1101: Pipe D 1110: Pipe E 1111: Pipe F To change these bits, write a value in these bits, read the value of these bits, confirm that the write value equals the read value, and then proceed with the next processing. Do not write the same pipe number in the CURPIPE bits in CFIFOSEL, DnFIFOSEL (n = 0 to 3). If these bits are changed in the middle of access to the FIFO buffer, accesses made before that time are retained, the value of these bits is rewritten, and then further access is enabled.

Note: * Only reading 0 is enabled.

42.2.8 FIFO Port Control Registers (CFIFOCTR, D0FIFOCTR, D1FIFOCTR, D2FIFOCTR, D3FIFOCTR)

CFIFOCTR and D0FIFOCTR, D1FIFOCTR, D2FIFOCTR and D3FIFIOCTR specify buffer memory write end and CPU buffer clear, as well as indicate whether the FIFO port is accessible or not. These registers correspond to each FIFO port.

These registers are initialized by a power-on reset.



Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BVAL	BCLR	FRDY	—	DTLN[11:0]											
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	BVAL	0	R/W*1	Buffer Memory Enable Flag This flag is set to 1 upon completion of data write in the FIFO buffer of the CPU of the pipe selected by the CURPIPE bits. 0: Invalid 1: Write end When the selected pipe is in the transmit direction, set this bit to 1 in the following cases. This module sets the FIFO buffer of the CPU to the SIE side to enable data transmission. To send a short packet, set this bit to 1 upon completion of data write. To send a Zero-Length packet, set this bit to 1 before writing data to the FIFO buffer. For pipes of continuous transfer mode, set this bit to 1 after writing data that is a positive integer multiple of MaxPacketSize and less than the BufferSize value. When data with the size specified by MaxPacketSize is written to a pipe of continuous transfer mode, this module writes 1 in this bit and sets the FIFO buffer of the CPU to the SIE side to enable data transmission. Set this bit to 1 when this module shows FRDY = 1. When the selected pipe is in the receive direction, do not set this bit to 1.
14	BCLR	0	R/W*2	CPU buffer clear Clears the CPU side FIFO buffer of the selected pipe. 0: Invalid 1: Clears the CPU side FIFO buffer. When the FIFO buffer assigned to the selected pipe is set to a double buffer, and even when both sides of the buffer are readable, this module clears only one side of the FIFO buffer. When the selected pipe is DCP, this module clears the FIFO buffer when this bit is set to 1 irrespective of whether the FIFO buffer is on the CPU side or SIE side. When clearing the SIE side FIFO buffer, be sure to set the PID bits in DCP to NAK and then set the BCLR bit to 1. When the selected pipe is in the transmit direction, and if 1 is written in the BVAL and BCLR bits at the same time, this module clears the previously written data, and makes a Zero-Length packet transmittable. When the selected pipe is not DCP, write 1 in this bit while the FRDY flag indicates 1.

Bit	Bit Name	Initial Value	R/W	Description
13	FRDY	0	R	FIFO Port Ready Indicates whether the CPU (DMAC) can access the FIFO port. 0: The FIFO port is not accessible. 1: The FIFO port is accessible. This module indicates FRDY = 1 in the following cases. However, since there is no data to read, no data can be read from the FIFO port. In these cases, set the BCLR bit to 1 to clear the FIFO buffer to make transmission/reception of the next data available. When a Zero-Length packet is received with the FIFO buffer assigned to the selected pipe empty When a short packet is received with BFRE set to 1 and the packet data is completely read
12	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
11 to 0	DTLN[11:0]	H'000	R	Receive Data Length Indicate the receive data length. The value of these bits during FIFO buffer reading varies as follows depending on the setting of the RCNT bit. When RCNT = 0: This module indicates the receive data length with these bits until the CPU (DMAC) finishes reading one side of the FIFO buffer. When BFRE is 1, this module retains the receive data length until the BCLR bit is set to 1 after the FIFO buffer read is completed. When RCNT = 1: This module decrements the value of the DTLN bits in each read cycle (-1 when MBW = 0, and -2 when MBW = 1) When reading out from a single FIFO buffer is complete, DTLN = 0 for this module. However, the behavior is different when double-buffering has been specified. If reading out of data from one side is not finished before the other side is full of received data, when all data have been read out from the first side, the DTLN bits reflect the amount of data received in the other side. When reading these bits during FIFO buffer reading while the RCNT bit is 1, note that this module updates the value in these bits within 150 ns after each FIFO port read cycle.

Notes: 1. Only writing 1 is enabled.
2. Only reading 0 and writing 1 are enabled.

42.2.9 Interrupt Enable Register 0 (INTENB0)

INTENB0 specifies masking of each interrupt when selection for function controller. When this module detects an interrupt for which 1 is written in the corresponding bit in this register by the software, this module generates a USB interrupt.

When interrupt source detection conditions are satisfied irrespective of the register setting (interrupt enable/disable), this module sets the corresponding status bit in INTSTS0.

When the software changes an interrupt enable bit (0 to 1) whose interrupt source status bit in INTSTS0 is set to 1, this module generates a USB interrupt.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VBSE	RSME	SOFE	DVSE	CTRE	BEMPE	NRDYE	BRDYE	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	VBSE	0	R/W	VBUS_0 and VBUSIN_0 Interrupt Enable Enables or disables USB interrupt outputs when the VBINT interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
14	RSME	0	R/W	Resume Interrupt Enable Enables or disables USB interrupt outputs when the RESM interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
13	SOFE	0	R/W	Frame Number Update Interrupt Enable Enables or disables USB interrupt outputs when the SOFR interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
12	DVSE	0	R/W	Device State Transition Interrupt Enable Enables or disables USB interrupt outputs when the DVST interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
11	CTRE	0	R/W	Control Transfer Stage Transition Interrupt Enable Enables or disables USB interrupt outputs when the CTRT interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
10	BEMPE	0	R/W	Buffer Empty Interrupt Enable Enables or disables USB interrupt outputs when the BEMP interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

Bit	Bit Name	Initial Value	R/W	Description
9	NRDYE	0	R/W	Buffer Not Ready Response Interrupt Enable Enables or disables USB interrupt outputs when the NRDY interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
8	BRDYE	0	R/W	Buffer Ready Interrupt Enable Enables or disables USB interrupt outputs when the BRDY interrupt is detected. 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

42.2.10 BRDY Interrupt Enable Register (BRDYENB)

BRDYENB enables or disables the BRDY bit to be set to 1 when the BRDY interrupt of a pipe is detected.

When this module detects the BRDY interrupt of a pipe for which the software sets the corresponding bit in this register to 1, this module sets the PIPEBRDY bit of the pipe in BRDYSTS and also sets the BRDY bit in INTSTS0 and generates the BRDY interrupt.

When one or more PIPEBRDY bits in BRDYSTS are 1 and the software changes the corresponding interrupt enable bit(s) in this register from 0 to 1, this module generates the BRDY interrupt.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

42.2.11 NRDY Interrupt Enable Register (NRDYENB)

NRDYENB enables or disables the NRDY bit to be set to 1 when the NRDY interrupt of a pipe is detected.

When this module detects the NRDY interrupt of a pipe for which the software sets the corresponding bit in this register to 1, this module sets the PIPENRDY bit of the pipe in NRDYSTS and also sets the NRDY bit in INTSTS0 and generates an NRDY interrupt.

When one or more PIPENRDY bits in NRDYSTS are 1 and the software changes the corresponding interrupt enable bit(s) in this register from 0 to 1, this module generates an NRDY interrupt.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIPEF NRDYE	PIPEE NRDYE	PIPED NRDYE	PIPEC NRDYE	PIPEB NRDYE	PIPEA NRDYE	PIPE9 NRDYE	PIPE8 NRDYE	PIPE7 NRDYE	PIPE6 NRDYE	PIPE5 NRDYE	PIPE4 NRDYE	PIPE3 NRDYE	PIPE2 NRDYE	PIPE1 NRDYE	PIPE0 NRDYE

0	PIPE0 NRDYE	0	R/W	Pipe 0 NRDY Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

42.2.12 BEMP Interrupt Enable Register (BEMPENB)

BEMPENB enables or disables the BEMP bit to be set to 1 when the BEMP interrupt of a pipe is detected.

When this module detects the BEMP interrupt of a pipe for which the software sets the corresponding bit in this register to 1, this module sets the PIPEBEMP bit of the pipe in BEMPSTS and the BEMP bit in INTSTS0 and generates the BEMP interrupt.

When one or more PIPEBEMP bits in BEMPSTS are 1 and the software changes the corresponding interrupt enable bit(s) in this register from 0 to 1, this module generates the BEMP interrupt.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIPEF BEMPE	PIPEE BEMPE	PIPED BEMPE	PIPEC BEMPE	PIPEB BEMPE	PIPEA BEMPE	PIPE9 BEMPE	PIPE8 BEMPE	PIPE7 BEMPE	PIPE6 BEMPE	PIPE5 BEMPE	PIPE4 BEMPE	PIPE3 BEMPE	PIPE2 BEMPE	PIPE1 BEMPE	PIPE0 BEMPE

0	PIPE0 BEMPE	0	R/W	Pipe 0 BEMP Interrupt Enable 0: Interrupt outputs are disabled. 1: Interrupt outputs are enabled.

42.2.13 SOF Output Configuration Register (SOFCFG)

SOFCFG specifies an effective period of transactions, the BRDY interrupt status clear timing, and others.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	BRDYM	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6	BRDYM	0	R/W	Status Clear Timing of Each Pipe BRDY Interrupt Specifies the timing to clear the BRDY interrupt status of each pipe. 0: The software clears the status. 1: This module clears the status by reading or writing the FIFO buffer.
5 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

42.2.14 Interrupt Status Register 0 (INTSTS0)

INTSTS0 can know the interrupt generation by referring to the register when the function controller is selected.

Please permit interrupt by the status change that each bit of this register shows only when you select the function.

This register is initialized by a power-on reset. The DVSQ2 to DVSQ0 bits are also initialized by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VBINT	RESM	SOFR	DVST	CTRT	BEMP	NRDY	BRDY	VBSTS	DVSQ[2:0]			VALID	CTSQ[2:0]		
Initial value:	0	0	0	0/1	0	0	0	0	0/1	0	0	0/1	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R	R	R	R	R	R	R	R/W	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	VBINT	0	R/W*6	VBUS_0 and VBUSIN_0 Interrupt Status*4*5 0: No VBUS_0 and VBUSIN_0 interrupt is generated. 1: A VBUS_0 and VBUSIN_0 interrupt is generated. This bit indicates 1 when this module detects a change in the VBUS_0 and VBUSIN_0 pin input level (high to low or low to high level). This module indicates the VBUS_0 and VBUSIN_0 pin input value using the VBSTS bit. When a VBINT interrupt occurs, read the VBSTS bit several times by the software and confirm that the read value is equal each time to eliminate chattering.
14	RESM	0	R/W*6	Resume Interrupt Status*4*5 0: No resume interrupt is generated. 1: A resume interrupt is generated. This bit indicates 1 when this module detects a falling of the DP_0 pin level in the suspended state (DVSQ = 1XX) with the function controller function selected.
13	SOFR	0	R/W*6	Frame Number Update Interrupt Status*4 0: No SOF interrupt is generated. 1: An SOF interrupt is generated. This module indicates SOFR = 1 at the frame number update timing. (This interrupt is detected every millisecond.) Even when an SOF packet from the USB host is corrupted, this module detects an SOFR interrupt using the internal interpolation.
12	DVST	0/1*1	R/W*6	Device State Transition Interrupt Status*4 0: No device state transition interrupt is generated. 1: A device state transition interrupt is generated. When this module detects a change in device state, this module updates the DVSQ value and set this bit to 1. When this interrupt occurred, clear the status before this module detects the next device state transition.
11	CTRT	0	R/W*6	Control Transfer Stage Transition Interrupt Status*4 0: No control transfer stage transition interrupt is generated. 1: A control transfer stage transition interrupt is generated. When this module detects a control transfer stage transition, this module updates the CTSQ value and set this bit to 1. When this interrupt occurred, clear the status before this module detects the next stage transition in control transfers.

Bit	Bit Name	Initial Value	R/W	Description
10	BEMP	0	R	Buffer Empty Interrupt Status 0: No BEMP interrupt is generated. 1: A BEMP interrupt is generated. This module indicates BEMP = 1 when at least one of the PIPEBEMP bits in BEMPSTS corresponding to the pipes for which 1 is set in the PIPEBEMPE bits in BEMPENB is set to 1 (when this module detects a BEMP interrupt of one or more pipes for which BEMP interrupts are enabled by the software). For PIPEBEMP status assertion conditions, see section 42.3.2 (3), BEMP Interrupt. When the software writes 0 to all PIPEBEMP bits corresponding to the pipes for which interrupts are enabled by the PIPEBEMPE bits, this module clears this bit to 0. This bit cannot be cleared to 0 by writing 0 by the software.
9	NRDY	0	R	Buffer Not Ready Interrupt Status 0: No NRDY interrupt is generated. 1: An NRDY interrupt is generated. This module indicates NRDY = 1 when at least one of the PIPENRDY bits in NRDYSTS corresponding to the pipes for which 1 is set in the PIPENRDYE bits in NRDYENB is set to 1 (when this module detects an NRDY interrupt of one or more pipes for which NRDY interrupts are enabled by the software). For PIPENRDY status assertion conditions, see section 42.3.2 (2), NRDY Interrupt. When the software writes 0 to all PIPENRDY bits corresponding to the pipes for which interrupts are enabled by the PIPENRDYE bits, this module clears this bit to 0. This bit cannot be cleared to 0 by writing 0 by the software.
8	BRDY	0	R	Buffer Ready Interrupt Status Indicates the BRDY interrupt status. 0: No BRDY interrupt is generated. 1: A BRDY interrupt is generated. This module indicates BRDY = 1 when at least one of the PIPEBRDY bits in BRDYSTS corresponding to the pipes for which 1 is set in the PIPEBRDYE bits in BRDYENB is set to 1 (when this module detects a BRDY interrupt of one or more pipes for which BRDY interrupts are enabled by the software). For PIPEBRDY status assertion conditions, see section 42.3.2 (1), BRDY Interrupt. When the software writes 0 to all PIPEBRDY bits corresponding to the pipes for which interrupts are enabled by the PIPEBRDYE bits, this module clears this bit to 0. This bit cannot be cleared to 0 by writing 0 by the software.
7	VBSTS	0/1*3	R	VBUS Input Status 0: The VBUS pin is low level. 1: The VBUS pin is high level.

Bit	Bit Name	Initial Value	R/W	Description
6 to 4	DVSQ[2:0]	000/001*2	R	Device State 000: Powered state 001: Default state 010: Address state 011: Configuration state 1xx: Suspended state
3	VALID	0	R/W*6	USB Request Receive 0: Not detected 1: A setup packet is received.
2 to 0	CTSQ[2:0]	000	R	Control Transfer Stage 000: Idle stage or setup stage 001: Control read data stage 010: Control read status stage 011: Control write data stage 100: Control write status stage 101: Control write (NoData) status stage 110: Control transfer sequence error 111: Setting prohibited

Notes: 1. The initial value is B'0 after a power-on reset, and B'1 after a USB bus reset.
2. The initial value is B'000 after a power-on reset, and B'001 after a USB bus reset.
3. The initial value is 1 when the VBUS pin is high level, and is 0 when the VBUS pin is low level.
4. To clear the VBINT, RESM, SOFR, DVST, or CTRT bit, write 0 only to bits to be cleared and write 1 to the other bits. Do not write 0 to status bits that indicate 0.
5. When a status change shown in the VBINT or RESM bit is detected while the clock is halted (SUSPM = 0) and the corresponding interrupt is enabled, the interrupt is output. Clear the interrupt status of these bits by the software after the clock is enabled.
6. Only writing 0 is enabled.

42.2.15 BRDY Interrupt Status Register (BRDYSTS)

BRDYSTS indicates the BRDY interrupt status of each pipe.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIPEF BRDY	PIPEE BRDY	PIPED BRDY	PIPEC BRDY	PIPEB BRDY	PIPEA BRDY	PIPE9 BRDY	PIPE8 BRDY	PIPE7 BRDY	PIPE6 BRDY	PIPE5 BRDY	PIPE4 BRDY	PIPE3 BRDY	PIPE2 BRDY	PIPE1 BRDY	PIPE0 BRDY
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	PIPEFBRDY	0	R/W*1	Pipe F BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
14	PIPEEBRDY	0	R/W*1	Pipe E BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
13	PIPEDBRDY	0	R/W*1	Pipe D BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
12	PIPECBRDY	0	R/W*1	Pipe C BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
11	PIPEBBRDY	0	R/W*1	Pipe B BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
10	PIPEABRDY	0	R/W*1	Pipe A BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
9	PIPE9BRDY	0	R/W*1	Pipe 9 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
8	PIPE8BRDY	0	R/W*1	Pipe 8 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
7	PIPE7BRDY	0	R/W*1	Pipe 7 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
6	PIPE6BRDY	0	R/W*1	Pipe 6 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
5	PIPE5BRDY	0	R/W*1	Pipe 5 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
4	PIPE4BRDY	0	R/W*1	Pipe 4 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
3	PIPE3BRDY	0	R/W*1	Pipe 3 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
2	PIPE2BRDY	0	R/W*1	Pipe 2 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
1	PIPE1BRDY	0	R/W*1	Pipe 1 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.
0	PIPE0BRDY	0	R/W*1	Pipe 0 BRDY Interrupt Status*2 0: No interrupt is generated. 1: An interrupt is generated.

Notes: 1. To clear the status of each bit in this register when BRDYM is 0, write 0 only to bits to be cleared and write 1 to the other bits.
2. When BRDYM is 0, be sure to clear this interrupt before making an access to the FIFO.

42.2.16 NRDY Interrupt Status Register (NRDYSTS)

NRDYSTS indicates the NRDY interrupt status of each pipe.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIPEF NRDY	PIPEE NRDY	PIPED NRDY	PIPEC NRDY	PIPEB NRDY	PIPEA NRDY	PIPE9 NRDY	PIPE8 NRDY	PIPE7 NRDY	PIPE6 NRDY	PIPE5 NRDY	PIPE4 NRDY	PIPE3 NRDY	PIPE2 NRDY	PIPE1 NRDY	PIPE0 NRDY
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	PIPEFNRDY	0	R/W*	Pipe F NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
14	PIPEENRDY	0	R/W*	Pipe E NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
13	PIPEDNRDY	0	R/W*	Pipe D NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
12	PIPECNRDY	0	R/W*	Pipe C NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
11	PIPEBNRDY	0	R/W*	Pipe B NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
10	PIPEANRDY	0	R/W*	Pipe A NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
9	PIPE9NRDY	0	R/W*	Pipe 9 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
8	PIPE8NRDY	0	R/W*	Pipe 8 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
7	PIPE7NRDY	0	R/W*	Pipe 7 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
6	PIPE6NRDY	0	R/W*	Pipe 6 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
5	PIPE5NRDY	0	R/W*	Pipe 5 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
4	PIPE4NRDY	0	R/W*	Pipe 4 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
3	PIPE3NRDY	0	R/W*	Pipe 3 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
2	PIPE2NRDY	0	R/W*	Pipe 2 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
1	PIPE1NRDY	0	R/W*	Pipe 1 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
0	PIPE0NRDY	0	R/W*	Pipe 0 NRDY Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Note: * To clear the status of each bit in this register, write 0 only to bits to be cleared and write 1 to the other bits.

42.2.17 BEMP Interrupt Status Register (BEMPSTS)

BEMPSTS indicates the BEMP interrupt status of each pipe.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	PIPEF BEMP	PIPEE BEMP	PIPED BEMP	PIPEC BEMP	PIPEB BEMP	PIPEA BEMP	PIPE9 BEMP	PIPE8 BEMP	PIPE7 BEMP	PIPE6 BEMP	PIPE5 BEMP	PIPE4 BEMP	PIPE3 BEMP	PIPE2 BEMP	PIPE1 BEMP	PIPE0 BEMP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	PIPEFBEMP	0	R/W*	Pipe F BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
14	PIPEEBEMP	0	R/W*	Pipe E BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
13	PIPEDBEMP	0	R/W*	Pipe D BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
12	PIPECBEMP	0	R/W*	Pipe C BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
11	PIPEBBEMP	0	R/W*	Pipe B BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
10	PIPEABEMP	0	R/W*	Pipe A BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
9	PIPE9BEMP	0	R/W*	Pipe 9 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
8	PIPE8BEMP	0	R/W*	Pipe 8 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
7	PIPE7BEMP	0	R/W*	Pipe 7 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
6	PIPE6BEMP	0	R/W*	Pipe 6 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
5	PIPE5BEMP	0	R/W*	Pipe 5 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Bit	Bit Name	Initial Value	R/W	Description
4	PIPE4BEMP	0	R/W*	Pipe 4 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
3	PIPE3BEMP	0	R/W*	Pipe 3 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
2	PIPE2BEMP	0	R/W*	Pipe 2 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
1	PIPE1BEMP	0	R/W*	Pipe 1 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.
0	PIPE0BEMP	0	R/W*	Pipe 0 BEMP Interrupt Status 0: No interrupt is generated. 1: An interrupt is generated.

Note: * To clear the status of each bit in this register, write 0 only to bits to be cleared and write 1 to the other bits.

42.2.18 Frame Number Register (FRMNUM)

FRMNUM indicates the sources of isochronous errors and a frame number.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OVRN	CRCE	—	—	—	FRNM[10:0]										
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

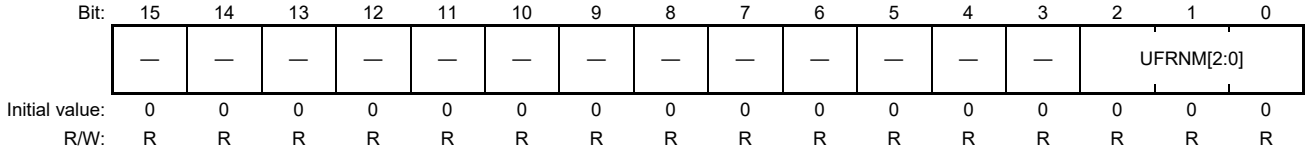
Bit	Bit Name	Initial Value	R/W	Description
15	OVRN	0	R/W*	Overrun/Underrun Detect Status Indicates whether an overrun or underrun error is detected or not in a pipe that is performing isochronous transfer. 0: No error is detected. 1: An error is detected. Writing 0 to this bit by the software clears this bit to 0. At this time, write 1 to the other bits in this register. This module indicates OVRN = 1 in any of the following cases. When the IN token is received when transmit data write to the FIFO buffer is not completed in a transmit direction pipe of isochronous transfer type When the OUT token is received with no side of the FIFO buffer empty in a receive direction pipe of isochronous transfer type
14	CRCE	0	R/W*	Receive Data Error Indicates whether a CRC error or bit stuffing error is detected or not in a pipe that is performing isochronous transfer. 0: No error is detected. 1: An error is detected. Writing 0 to this bit by the software clears this bit to 0. At this time, write 1 to the other bits in this register. When a CRC error is detected, this module does not generate an internal NRDY interrupt request.
13 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 0	FRNM [10:0]	H'000	R	Frame Number This module modifies this bit when an SOF is received and indicates the latest frame number. Read these bits twice and confirm that the read value is equal each time.

Note: * Only writing 0 is enabled.

42.2.19 μ Frame Number Register (UFRMNUM)

UFRMNUM indicates a μ frame number.

This register is initialized by a power-on reset.

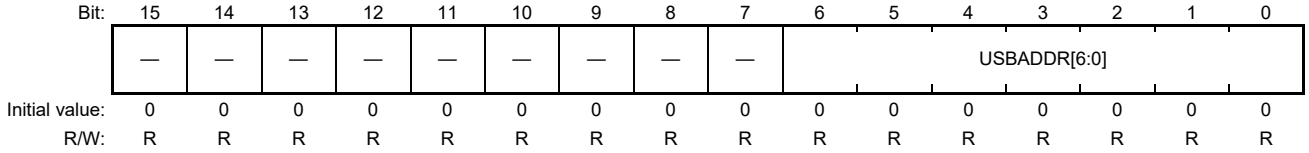


Bit	Bit Name	Initial Value	R/W	Description
15 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	UFRNM[2:0]	000	R	μ Frame Indicate a μ frame number. In high-speed operating mode, these bits indicate a μ frame number. In other operating modes, these bits indicate B'000. Read these bits twice and confirm that the read value is equal each time.

42.2.20 USB Address Register (USBADDR)

USBADDR indicates a USB address.

This register is initialized by a power-on reset or USB bus reset.



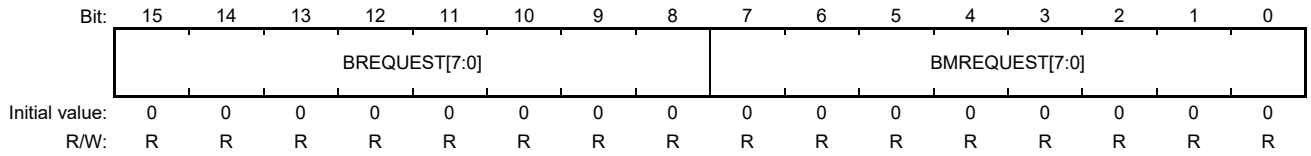
Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	USBADDR[6:0]	H'00	R	USB Address Indicate the USB address allocated by the host when the SET_ADRESS request is successfully processed. When this module detects a USB reset, these bits indicate H'00.

42.2.21 USB Request Type Register (USBREQ)

USBREQ stores the setup request for control transfers.

USBREQ stores the values of received bRequest and bmRequestType.

This register is initialized by a power-on reset or USB bus reset.

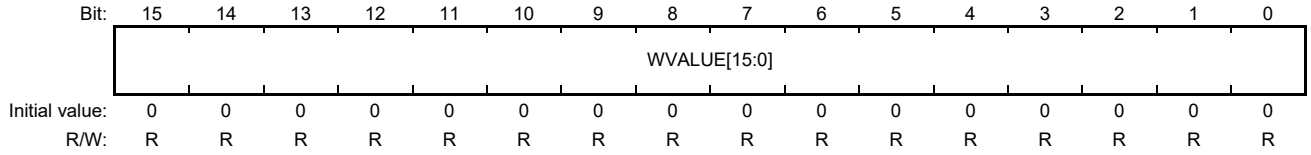


Bit	Bit Name	Initial Value	R/W	Description
15 to 8	BREQUEST [7:0]	H'00	R	Request Store the value of USB request bRequest. Indicate the USB request data received in the SETUP transaction. These bits cannot be modified.
7 to 0	BMREQUEST TYPE[7:0]	H'00	R	Request Type Store the value of USB request bmRequestType. Indicate the USB request data received in the SETUP transaction. These bits cannot be modified.

42.2.22 USB Request Value Register (USBVAL)

USBVAL stores the value of received wValue.

This register is initialized by a power-on reset or USB bus reset.



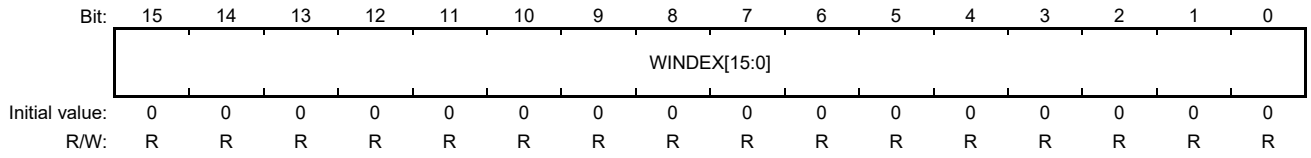
Bit	Bit Name	Initial Value	R/W	Description
15 to 0	WVALUE [15:0]	H'0000	R	Value Store the value of USB request wValue. Indicate the value of USB request wValue received in the SETUP transaction. These bits cannot be modified.

42.2.23 USB Request Index Register (USBINDX)

USBINDX stores the setup request for control transfers.

USBINDX stores the value of received wIndex.

This register is initialized by a power-on reset or USB bus reset.



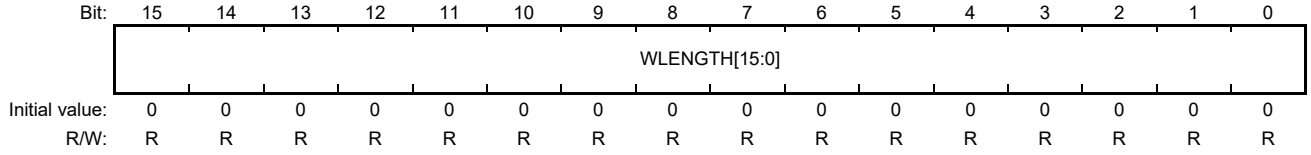
Bit	Bit Name	Initial Value	R/W	Description
15 to 0	WINDEX [15:0]	H'0000	R	Index Store the value of USB request wIndex. Indicate the value of USB request wIndex received in the SETUP transaction. These bits cannot be modified.

42.2.24 USB Request Length Register (USBLENG)

USBLENG stores the setup request of control transfers.

USBLENG stores the value of received wLength.

This register is initialized by a power-on reset or USB bus reset.



Bit	Bit Name	Initial Value	R/W	Description
15 to 0	WLENGTH [15:0]	H'0000	R	Length Store the value of USB request wLength. Indicate the value of USB request wLength received in the SETUP transaction. These bits cannot be modified.

42.2.25 DCP Maximum Packet Size Register (DCPMAXP)

DCPMAXP specifies the maximum packet size of the DCP.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	MXPS[6:0]						
Initial value:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6 to 0	MXPS [6:0]	H'40	R/W	Maximum Packet Size Set the payload of DCP data (maximum DCP packet size) in these bits. The initial value of these bits is H'40 (64 bytes). Set a value in the MXPS bits based on the USB Specification. Set the MXPS bits when PID = NAK, and the CURPIPE bits are not set. When setting these bits to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. Do not write the FIFO buffer when the MXPS bits are 0 or set the PID bits to BUF.

42.2.26 DCP Control Register (DCPCTR)

DCPCTR is used to monitor the buffer memory status, change/check the data PID sequence bit, and set the response PID for a DCP.

This register is initialized by a power-on reset. The PID2 to PID0 bits in CCPL are also initialized by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BSTS	—	—	—	—	—	—	SQCLR	SQSET	SQMON	PBUSY	—	—	CCPL	PID[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	BSTS	0	R	Buffer Status Indicates whether the DCP FIFO buffer is accessible or not. 0: The buffer is not accessible. 1: The buffer is accessible. This bit indicates as follows depending on the ISEL value. When ISEL = 0, this bit indicates whether the buffer is ready to read receive data. When ISEL = 1, this bit indicates whether the buffer is ready to write transmit data.
14 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8	SQCLR	0	R/W*	Toggle Bit Clear The expected value of the sequence toggle bit for the next transaction in DCP transfer can be set in DATA0. 0: Invalid 1: The expected value is set in DATA0. This bit always indicates 0. Do not set the SQCLR and SQSET bits to 1 at the same time. Set this bit to 1 when PID = NAK, and the CURPIPE bits are not set. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
7	SQSET	0	R/W*	Toggle Bit Set The expected value of the sequence toggle bit for the next transaction in DCP transfer can be set in DATA1. 0: Invalid 1: The expected value is set in DATA1. Do not set the SQCLR and SQSET bits to 1 at the same time. Set this bit to 1 when PID = NAK, and the CURPIPE bits are not set. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
6	SQMON	1	R	Sequence Toggle Bit Monitor Indicates the expected value of the sequence toggle bit for the next transaction in DCP transfer. 0: DATA0 1: DATA1 When the transaction is successfully completed, this module toggles this bit. However, when a DATA-PID mismatch occurs in the receive direction transfer, this bit is not toggled. When the function controller function is selected, this module sets this bit to 1 (sets the expected value in DATA1) when the setup packet is successfully received. When the function controller function is selected, this module does not read this bit in IN transactions or OUT transactions in the status stage.
5	PBUSY	0	R	Pipe Busy Indicates whether the DCP communication state is shifted to the NAK state or not when the DCP changed the PID bits from BUF to NAK. 0: Transition to the NAC state is not completed. 1: Transition to the NAC state is completed. When this module starts the USB transaction for the corresponding pipe, this module sets this bit to 1. This module clears this bit to 0 upon completion of each transaction. After the software sets PID = NAK, read this bit to check whether changing the pipe setting is enabled or not.
4, 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2	CCPL	0	R/W*	Control Transfer End Enable 0: Invalid 1: The control transfer end is enabled. When the software sets this bit to 1 while the corresponding PID bits are set to BUF, this module finishes the control transfer stage. That is, this module sends an ACK handshake in response to OUT transactions from the USB host in the control read transfer, and sends a Zero-Length packet in response to IN transactions from the USB host in control write and no-data control transfers. However, a SET_ADDRESS request is detected, this module automatically sends responses from the SETUP stage until the end of the status stage irrespective of the setting of this bit. When this module receives the next setup packet, this module clears this bit to 0. When VALID = 1, the software cannot write 1 to this bit.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	PID[1:0]	00	R/W	Response PID Control responses of this module in control transfers. 00: NAK response 01: BUF response (depending on buffer state) 10: STALL response 11: STALL response This module modifies these bits in the following cases. This module changes these bits to NAK upon receiving a SETUP packet. At this time, this module indicates VALID = 1. The software cannot modify these bits until the software sets VALID = 0. When this module receives data with a size exceeding the MaxPacketSize value while these bits are set to BUF by the software, this module indicates PID = STALL (11). When this module detects a control transfer sequence error, this module indicates PID = STALL (1x). When this module detects a USB bus reset, this module indicates PID = NAK. This module does not read the value of these bits during the SET_ADDRESS request processing (auto processing).

Note: * These bits are always read as 0. Only writing 1 is enabled.

42.2.27 Pipe Window Select Register (PIPESEL)

Make settings for pipes 1 to F using PIPESEL, PIPECFG, PIPEBUF, PIPEMAXP, PIPEPERI, PIPEnCTR, PIPEnTRE, and PIPEnTRN.

Specify a pipe to be used with PIPESEL, and then make function settings for each pipe in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI. The PIPEnCTR, PIPEnTRE, and PIPEnTRN registers can be set independently from pipe selection using PIPESEL.

Not only the selected pipe but also the corresponding bits in registers for all pipes are initialized by a power-on reset or USB bus reset.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	PIPESEL[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 4	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
3 to 0	PIPESEL [3:0]	0000	R/W	Pipe Window Select Specify a pipe number corresponding to PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI to be read or written. 0000: No pipe is selected. 0001: Pipe 1 0010: Pipe 2 0011: Pipe 3 0100: Pipe 4 0101: Pipe 5 0110: Pipe 6 0111: Pipe 7 1000: Pipe 8 1001: Pipe 9 1010: Pipe A 1011: Pipe B 1100: Pipe C 1101: Pipe D 1110: Pipe E 1111: Pipe F PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI corresponding to the pipe number specified by these bits can be read and written. When these bits are set to B'0000, all bits in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI are read as 0 and cannot be modified.

42.2.28 Pipe Configuration Register (PIPECFG)

PIPECFG specifies the transfer type, buffer memory access direction, and endpoint number for pipes 1 to F, selects continuous transfer mode or discontinuous transfer mode, and single buffer or double buffer, and also specifies whether to disable the operation of each pipe when data transfer finishes.

This register is initialized by a power-on reset. The TYPE1 and TYPE0 bits are also initialized by a USB bus reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TYPE[1:0]		—	—	—	BFRE	DBLB	CNTMD	SHTNAK	—	—	DIR	EPNUM[3:0]			
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R	R	R	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15, 14	TYPE[1:0]	00	R/W	Transfer Type Select the transfer type of the pipe specified by the PIPESEL bits (selected pipe). Pipes 1 and 2 00: No pipe is used. 01: Bulk transfer 10: Setting prohibited 11: Isochronous transfer Pipes 3 to 5, B to F 00: No pipe is used. 01: Bulk transfer 10: Setting prohibited 11: Setting prohibited Pipes 6 to 8 00: No pipe is used. 01: Setting prohibited 10: Interrupt transfer 11: Setting prohibited Pipes 9 and A 00: No pipe is used. 01: Setting prohibited 10: Interrupt transfer 11: Setting prohibited Before setting the selected pipe for PID = BUF (before starting USB communication using the selected pipe), be sure to set these bits to a value other than B'00. Modify these bits when the PID bits of the selected pipe are set to NAK. When changing the setting of these bits after changing the PID bits for the selected pipe from BUF to NAK, check that and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
13 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10	BFRE	0	R/W	BRDY Interrupt Operation Specifies the BRDY interrupt output timing from this module to the CPU for the selected pipe. 0: At a BRDY interrupt timing during data transmission or reception 1: At a BRDY interrupt timing after reading data When this bit is set to 1 by the software and the selected pipe is used in the receive direction, this module detects the transfer end and outputs a BRDY interrupt when the packet is completely read. When a BRDY interrupt occurs with this setting, the software must set BCLR = 1. Unless BCLR = 1 is set, the FIFO buffer allocated to the selected pipe does not enter the receive ready state. When this bit is set to 1 by the software and the selected pipe is used in the transmit direction, this module generates no BRDY interrupt. For details, see section 42.3.2 (1), BRDY Interrupt. Modify this bit when PID = NAK, and no pipe number is specified by the CURPIPE bits. Furthermore, when changing the setting of this bit after USB communication using the selected pipe, set the ACLRM bit to 1 and clear it to 0 continuously by the software to clear the FIFO buffer allocated to the selected pipe, in addition to the three register states above. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
9	DBLB	0	R/W	Double Buffer Mode Specifies a single buffer or double buffer for the FIFO buffer used in the selected pipe. 0: Single buffer 1: Double buffer This bit is valid when pipes 1 to 5, 9 to F are selected. When this bit is set to 1 by the software, this module allocates the FIFO buffer size specified by the BUFSIZE bits in PIPEBUF to the selected pipe for two sides. Thus the size of the FIFO buffer that this module allocates to the selected pipe is as follows: (BUFSIZE + 1) × 64 × (DBLB + 1) [bytes] When this bit is set to 1 by the software and the selected pipe is used in the transmit direction, this module generates no BRDY interrupt. For details, see section 42.3.2 (1), BRDY Interrupt. Modify this bit when PID = NAK, and no pipe number is specified by the CURPIPE bits. Furthermore, when changing the setting of this bit after USB communication using the selected pipe, set the ACLRM bit to 1 and clear it to 0 continuously by the software to clear the FIFO buffer allocated to the selected pipe, in addition to the three register states above. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

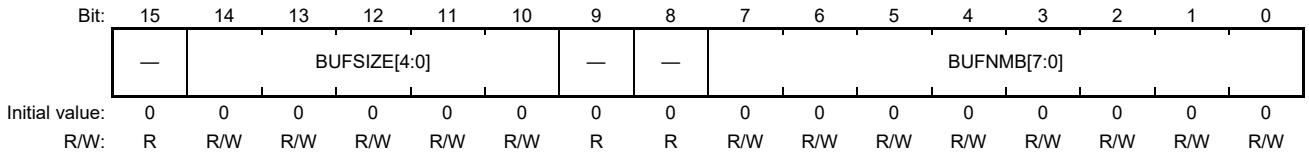
Bit	Bit Name	Initial Value	R/W	Description
8	CNTMD	0	R/W	Continuous Transfer Mode Selects continuous transfer mode or discontinuous transfer mode to be used in communication for the selected pipe. 0: Discontinuous transfer mode 1: Continuous transfer mode This bit is valid when pipes 1 to 5, 9 to F are selected by the PIPESEL bits and bulk transfer is selected (TYPE = 01). Modify this bit when PID = NAK, and no pipe number is specified by the CURPIPE bits. Furthermore, when changing the setting of this bit after USB communication using the selected pipe, set the ACLRM bit to 1 and clear it to 0 continuously by the software to clear the FIFO buffer allocated to the selected pipe, in addition to the three register states above. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
7	SHTNAK	0	R/W	Pipe Disable at the Time of Transfer End Specifies whether to change the setting of the PID bits to NAK at the end of transfer when the selected pipe is in the receive direction. 0: The pipe is continued at the end of transfer. 1: The pipe is disabled at the end of transfer. This bit is valid when the selected pipe is either of pipes 1 to 5, 9 to F and is in the receive direction. When the software sets this bit to 1 for a receive direction pipe, this module changes the setting of the PID bits corresponding to the selected pipe to NAK for the selected pipe when this module determines the transfer end. When the following conditions are satisfied, this module determines the transfer end. When short packet data (including a Zero-Length packet) is correctly received. When the transaction counter is used and packets with a size of the transaction counter are correctly received. Modify this bit when PID = NAK. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. For transmit direction pipes, set this bit to 0.
6, 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
4	DIR	0	R/W	Transfer Direction Selects the transfer direction of the selected pipe. 0: Receive direction 1: Transmit direction When this bit is set to 0 by the software, this module uses the selected pipe in the receive direction. When this bit is set to 1, this module uses the selected pipe in the transmit direction. Modify this bit when PID = NAK, and no pipe number is specified by the CURPIPE bits. Furthermore, when changing the setting of this bit after USB communication using the selected pipe, set the ACLRM bit to 1 and clear it to 0 continuously by the software to clear the FIFO buffer allocated to the selected pipe, in addition to the three register states above. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
3 to 0	EPNUM [3:0]	0000	R/W	Endpoint Number Specify the endpoint number of the selected pipe. The setting of B'0000 means an unused pipe. Modify these bits when PID = NAK. When changing the setting of these bits after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. Set these bits so that the combination of the DIR setting and the EPNUM setting does not overlap the setting of other pipes (EPNUM = B'0000 is allowed in this case.)

42.2.29 Pipe Buffer Register (PIPEBUF)

PIPEBUF specifies the buffer size and buffer number for pipes 1 to F.

This register is initialized by a power-on reset.



Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
14 to 10	BUFSIZE [4:0]	H'00	R/W	Buffer Size Specify the buffer size of the pipe specified by the PIPESEL bits (selected pipe) in units of blocks. One block is 64 bytes. 00000 (H'00): 64 bytes 00001 (H'01): 128 bytes : 11111 (H'1F): 2 Kbytes When DBLB = 1 is set by the software, this module allocates the FIFO buffer size specified by these bits to the selected pipe for two sides. Thus the size of the FIFO buffer that this module allocates to the selected pipe is as follows: (BUFSIZE + 1) × 64 × (DBLB + 1) [bytes] A value that can be set in these bits varies depending on pipes selected. For pipes 1 to 5, 9 to F: Set BUFSIZE to H'00 to H'1F. For pipes 6 to 8: Set BUFSIZE to H'00. When using the buffer with CNTMD = 1, set a value in multiples of MaxPacketSize in these bits. Modify these bits when PID = NAK, and no pipe number is specified by the CURPIPE bits. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
9, 8	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	BUFNMB [7:0]	H'00	R/W	Buffer Number Specify the FIFO buffer number of the selected pipe with a value from H'04 to H'FF. When the selected pipe is either of pipes 1 to 5, 9 to F, these bits can be set to a value according to user systems. Set BUFNMB to H'06 to H'4F. BUFNMB = 0 to 3 are for DCP only. BUFNMB = 4 is for pipe 6 only. However, when pipe 6 is not used, this is available for other pipes. When pipe 6 is selected, these bits cannot be modified and this module automatically allocates BUFNMB = 4. BUFNMB = 5 is for pipe 7 only. However, when pipe 7 is not used, this is available for other pipes. When pipe 7 is selected, these bits cannot be modified and this module automatically allocates BUFNMB = 5. BUFNMB = 6 is for pipe 8 only. However, when pipe 8 is not used, this is available for other pipes. When pipe 8 is selected, these bits cannot be modified and this module automatically allocates BUFNMB = 6. Modify these bits when PID = NAK, and no pipe number is set in the CURPIPE bits. When changing the setting of these bits after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

42.2.30 Pipe Maximum Packet Size Register (PIPEMAXP)

PIPEMAXP specifies the maximum packet size for pipes 1 to F.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	MXPS[10:0]										
Initial value:	0	0	0	0	0	*	*	*	*	*	*	*	*	*	*	*
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
10 to 0	MXPS[10:0]	*	R/W	Maximum Packet Size Specify the payload of data (maximum packet size) of the selected pipe. The settable value range for each pipe is as follows: Pipes 1 and 2: 1 byte (H'001) to 1024 bytes (H'400) Pipes 3 to 5, 9 to F: 8 (H'008), 16 (H'010), 32 (H'020), 64 (H'040), or 512 bytes (H'200) (MXPS2 to MXPS0 bits are not provided.) Pipes 6 to 8: 1 byte (H'001) to 64 bytes (H'040) Set a value in the MXPS bits based on the USB Specification for each transfer type. To transmit an isochronous pipe in split transactions, set a value of 188 bytes or less in the MXPS bits. When changing the setting of this bit after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. Do not write the FIFO buffer when the MXPS = 0 or set the PID bits to BUF.

Note: * The initial value is H'000 (when no pipe is selected by the PIPESEL bits in PIPESEL) or H'040 (when a pipe is selected).

42.2.31 Pipe Cycle Control Register (PIPEPERI)

PIPEPERI specifies whether to activate the buffer flush function or not at the time of an interval error during the isochronous IN transfer, and also specifies the interval error detection interval for pipes 1 to F.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	IFIS	—	—	—	—	—	—	—	—	—	IITV[2:0]		
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R/W	R	R	R	R	R	R	R	R	R	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	IFIS	0	R/W	Isochronous IN Buffer Flush Specifies whether to flush the FIFO buffer when the pipe specified by the PIPESEL bits (selected pipe) is isochronous IN transfer type. 0: The FIFO buffer is not flushed. 1: The FIFO buffer is flushed. Buffer flush is a function that this module automatically clears the FIFO buffer when this module does not receive IN-Token from the USB host in a (μ) frame for each interval specified in the IITV bits when the function controller function is selected and the selected pipe is isochronous IN transfer type. When double buffer is selected (DBLB = 1), this module clears data of only the older side. The FIFO buffer is cleared when an SOF packet is received immediately after the (μ) frame where IN-Token is to be received. Even if the SOF packet is corrupted, the FIFO buffer is cleared at the time when the SOF packet is to be received using the internal interpolation. When the selected pipe is not isochronous transfer type, set this bit to 0.
11 to 3	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
2 to 0	IITV[2:0]	000	R/W	Interval Error Detection Interval Specify the interval error detection interval of the selected pipe with a value of 2's n-th power of the frame timing. Set these bits when PID = NAK, and no pipe number is specified by the CURPIPE bits. When changing the setting of these bits after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. To change the setting of these bits after USB communication, set PID = NAK and then set ACLRM = 1 to initialize the interval timer. These bits are not provided for pipes 3 to F. Set B'000 in the position of these bits corresponding to pipes 3 to F.

42.2.32 Pipe n Control Register (PIPEnCTR) (n = 1 to F)

PIPEnCTR monitors the buffer memory status, changes/checks the data PID sequence bits, selects whether to use auto-response mode and buffer auto-clear mode, and specifies a response PID for pipes 1 to F. This register can be set independently of the pipe selection using PIPESEL.

This register is initialized by a power-on reset. The PID1 and PID0 bits are also initialized by a USB bus reset.

(1) PIPEnCTR (n = 1 to 5, 9 to F)

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	BSTS	INBUFM	—	—	—	ATREPM	ACLRM	SQCLR	SQSET	SQMON	PBUSY	—	—	—	PID[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R/W	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	BSTS	0	R	Buffer Status Indicates the FIFO buffer status of the pipe. 0: The buffer is not accessible from the CPU. 1: The buffer is accessible from the CPU. The meaning of this bit differs depending on the settings of the DIR, BFRE, and DCLRM bits as shown in Table 42.8.
14	INBUFM	0	R	Transmit Buffer Monitor Indicates the FIFO buffer status of the selected pipe in the transmit direction. 0: The buffer memory contains no transmittable data. 1: The buffer memory contains transmittable data. When transmit direction (DIR = 1) is set for the pipe, this module sets this bit to 1 when the software (or DMAC) finishes writing data to the FIFO buffer for at least one register set. When this module finishes sending all data on the register set (writing is completed) of the FIFO buffer, this bit indicates 0. In the case of a double buffer (DBLB = 1), when this module finishes sending all data on both register sets and the software (or DMAC) has not completed writing of data for one register set, this bit indicates 0. When receive direction (DIR = 0) is set for the selected pipe, this bit indicates the same value as the BSTS bit.
13 to 11	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
10	ATREPM	0	R/W	Auto-Response Mode Enables or disables auto-response for the selected pipe. 0: Auto-response is disabled. 1: Auto-response is enabled. When the transfer type of the selected pipe is set to bulk transfer, this bit can be set to 1. When this bit is 1, this module sends responses to tokens from the USB host as follows: (1) When the selected pipe is set for Bulk-IN transfer (TYPE = B'01 and DIR = 1) When ATREPM = 1 and PID = BUF, this module sends a Zero-Length packet in response to the IN-Token. Each time this module receives ACK from the USB host (flow of one transaction: receiving IN-Token -> sending Zero Length packet -> receiving ACK), this module updates the sequence toggle bit (DATA-PID) by toggling it. No BRDY interrupt or BEMP interrupt is generated. (2) When the selected pipe is set for Bulk-OUT transfer (TYPE = B'01 and DIR = 0) When ATREPM = 1 and PID = BUF, this module sends NAK in response to the OUT-Token (or PING-Token) and generates an NRDY interrupt. Modify this bit when PID = NAK. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. Be sure to set this bit to 1 for USB communication when the FIFO buffer is empty. Do not write data to the FIFO buffer during USB communication with this bit set to 1. When the selected pipe is set for isochronous transfer, be sure to set this bit to 0.
9	ACLRM	0	R/W	Buffer Auto-Clear Mode Enables or disables buffer auto-clear mode for the selected pipe. 0: Buffer auto-clear mode is disabled. 1: Buffer auto-clear mode is enabled. (All buffers are initialized.) To completely delete the data in the FIFO buffer allocated to the pipe, write 1 and then 0 continuously to the ACLRM bit. Table 42.9 shows data cleared by this module when this bit is set to 1 and then 0 and cases where such data is cleared. Modify this bit when PID = NAK. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
8	SQCLR	0	R/W*	Toggle Bit Clear Set this bit to 1 to clear the expected value (in DATA0) of the sequence toggle bit for the next transaction of the selected pipe. 0: Invalid 1: The expected value is cleared in DATA0. When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the pipe in DATA0. This module always indicates SQCLR = 0. Set the SQCLR bit to 1 when PID = NAK. When setting this bit to 1 after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
7	SQSET	0	R/W*	Toggle Bit Set Set this bit to 1 to set the expected value of the sequence toggle bit for the next transaction of the selected pipe. 0: Invalid 1: The expected value is set in DATA1. When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the pipe in DATA1. This module always indicates SQSET = 0. Set the SQSET bit to 1 when PID = NAK. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
6	SQMON	0	R	Toggle Bit Check Indicates the expected value of the sequence toggle bit for the next transaction of the selected pipe. 0: DATA0 1: DATA1 If the pipe is not the isochronous transfer type, when a transaction is successfully processed, this module toggles this bit. However, when a DATA-PID mismatch occurs in the receive direction transfer, this bit is not toggled.
5	PBUSY	0	R	Pipe Busy Indicates whether the pipe is currently used in the USB bus or not. 0: The selected pipe is not used in the USB bus. 1: The selected pipe is being used in the USB bus. When this module starts the USB transaction for the selected pipe, this module sets this bit to 1. This module clears this bit to 0 upon completion of each transaction. After the software sets PID = NAK, read this bit to see if changing the pipe setting is enabled or not.
4 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	PID[1:0]	00	R/W	Response PID Specify a response used in the next transaction for the selected pipe. 00: NAK response 01: BUF response (depending on buffer state) 10: STALL response 11: STALL response These bits are set to NAK by default. To perform USB transfer with the selected pipe, change the setting of these bits to BUF. Tables 42.8 and 42.10 show the basic operation (with no error in packets) of this module in each setting of the PID bits. When changing these bits from BUF to NAK by the software while the pipe is in USB communication, write 00 (NAK) to these bits and then check PBUSY = 1 to confirm that the USB transfer of the pipe entered the NAK state. However, when this module changed these bits to NAK, the software does not have to check the PBUSY bit. This module modifies these bits in the following cases. • When the pipe is in the receive direction and the software sets the SHTNAK bit of the selected pipe to 1, this module indicates PID = NAK when this module recognizes the transfer end. • When this module receives data with a payload exceeding the MaxPacketSize value for the pipe, this module indicates PID = STALL (11). • When this module detects a USB bus reset, this module indicates PID = NAK. Set these bits as follows: • To change the state from NAK (00) to STALL, write B'10. • To change the state from BUF (01) to STALL, write B'11. • To change the state from STALL (11) to NAK, write B'10 then B'00. • To change the state from STALL to BUF, set these bits to NAK and then to BUF.

Note: * Only reading 0 and writing 1 are enabled.

Table 42.8 Operations of BSTS Bit

DIR Bit	BFRE Bit	DCLRM Bit	Meaning of BSTS Bit
0	0	0	Indicates 1 when the FIFO buffer becomes ready to read receive data from the buffer, and indicates 0 upon completion of the data read.
		1	Setting prohibited
	1	0	Indicates 1 when the FIFO buffer becomes ready to read receive data from the buffer, and indicates 0 when the software sets BCLR = 1 after the buffer data read.
		1	Indicates 1 when the FIFO buffer becomes ready to read receive data from the buffer, and indicates 0 upon completion of the data read.
1	0	0	Indicates 1 when the FIFO buffer becomes ready to write transmit data to the buffer, and indicates 0 upon completion of the data write.
		1	Setting prohibited
	1	0	Setting prohibited
		1	Setting prohibited

Table 42.9 Data Cleared by This Module when ACLRM = 1

No.	Data Cleared by the ACLRM Bit	Clearing Timing
1	All data in the FIFO buffer (both sides for double FIFO buffer) allocated to the pipe	
2	Interval count value when the pipe is isochronous transfer type	When resetting the interval count value
3	Internal flags related to the BFRE bit	When changing the BFRE setting
4	FIFO buffer toggle control	When changing the DBLB setting
5	Internal flags related to the transaction count	When forcibly terminating the transaction count function

Table 42.10 Operations of This Module in Each Setting of PID Bits

PID Bits	Transfer Type	Transfer Direction (DIR Bit)	Operation of This Module
B'00 (NAK)	Bulk or interrupt	Independent of the setting	Sends a NAK response to a token from the USB host.
	Isochronous	Independent of the setting	Sends no response to a token from the USB host.
B'01 (BUF)	Bulk	Receive direction (DIR = 0)	Receives data and sends an ACK response to the OUT token from the USB host when the FIFO buffer for the pipe is ready to receive. Otherwise, sends a NAK response. Sends an ACK response to the PING token from the USB host when the FIFO buffer for the selected pipe is ready to receive. Otherwise, sends a NYET response.
	Interrupt	Receive direction (DIR = 0)	Receives data and sends an ACK response to the OUT token from the USB host when the FIFO buffer for the pipe is ready to receive. Otherwise, sends a NAK response.
	Bulk or interrupt	Transmit direction (DIR = 1)	Sends data in response to a token from the USB host when the FIFO buffer for the pipe is ready to transmit. Otherwise, sends a NAK response.
	Isochronous	Receive direction (DIR = 0)	Receives data in response to the OUT token from the USB host when the FIFO buffer for the pipe is ready to receive. Otherwise, ignores the data.
		Transmit direction (DIR = 1)	Sends data in response to a token from the USB host when the FIFO buffer for the pipe is ready to transmit. Otherwise, sends a Zero-Length packet.
B'10 (STALL) or B'11 (STALL)	Bulk or interrupt	Independent of the setting	Sends a STALL response to a token from the USB host.
	Isochronous	Independent of the setting	Sends no response to a token from the USB host.

(2) PIPEnCTR (n = 6 to 8)

R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15	BSTS	0	R	Buffer Status Indicates the state of the FIFO buffer of the selected pipe. 0: The buffer is not accessible. 1: The buffer is accessible. The meaning of this bit differs as shown in Table 42.8 depending on the settings of the DIR, BFRE, and DCLRM bits.
14 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	ACLRM	0	R/W	Buffer Auto-Clear Mode*2*3 Enables or disables buffer auto-clear mode for the selected pipe. 0: Buffer auto-clear mode is disabled. 1: Buffer auto-clear mode is enabled. (All buffers are initialized.) To completely delete the data in the FIFO buffer allocated to the pipe, write 1 and then 0 continuously to the ACLRM bit. Table 42.11 shows data cleared by this module when this bit is set to 1 and then 0 and cases where such data is cleared. Modify this bit when PID = NAK, and the pipe is not set in the CURPIPE bits. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
8	SQCLR	0	R/W*1	Toggle Bit Clear*2*3 Set this bit to 1 to clear the expected value (in DATA0) of the sequence toggle bit for the next transaction of the selected pipe. 0: Invalid 1: The expected value is cleared in DATA0. When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the pipe in DATA0. This module always indicates SQCLR = 0. Set the SQCLR bit to 1 when PID = NAK. When setting this bit to 1 after changing the PID bits for the pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Bit	Bit Name	Initial Value	R/W	Description
7	SQSET	0	R/W*1	Toggle Bit Set*2*3 Set this bit to 1 to set the expected value of the sequence toggle bit for the next transaction of the selected pipe. 0: Invalid 1: The expected value is set in DATA1. When the software sets this bit to 1, this module sets the expected value of the sequence toggle bit of the selected pipe in DATA1. This module always indicates SQSET = 0. Set the SQSET bit to 1 when PID = NAK. When setting this bit to 1 after changing the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.
6	SQMON	0	R	Toggle Bit Check Indicates the expected value of the sequence toggle bit for the next transaction of the pipe. 0: DATA0 1: DATA1 If the selected pipe that is not the isochronous transfer type, when a transaction is successfully processed, this module toggles this bit. However, when a DATA-PID mismatch occurs in the receive direction transfer, this bit is not toggled.
5	PBUSY	0	R	Pipe Busy Indicates whether the selected pipe is currently used in the USB bus or not. 0: The selected pipe is not used in the USB bus. 1: The selected pipe is being used in the USB bus. When this module starts the USB transaction for the selected pipe, this module sets this bit to 1. This module clears this bit to 0 upon completion of each transaction. After the software sets PID = NAK, read this bit to see if changing the pipe setting is enabled or not.
4 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
1, 0	PID[1:0]	00	R/W	Response PID Specify a response used in the next transaction for the selected pipe. 00: NAK response 01: BUF response (depending on buffer state) 10: STALL response 11: STALL response These bits are set to NAK by default. To perform USB transfer with the selected pipe, change the setting of these bits to BUF. Tables 42.8 and 42.10 show the basic operation (with no error in packets) of this module in each setting of the PID bits. When changing these bits from BUF to NAK by the software while the pipe is in USB communication, write 00 (NAK) to these bits and then check PBUSY = 1 to confirm that the USB transfer of the selected pipe entered the NAK state. However, when this module changed these bits to NAK, the software needs not check the PBUSY bit. This module modifies these bits in the following cases. • When the selected pipe is in the receive direction and the software sets the SHTNAK bit of the selected pipe to 1, this module indicates PID = NAK when this module recognizes the transfer end. • When this module receives data with a payload exceeding the MaxPacketSize value for the pipe, this module indicates PID = STALL (11). • When this module detects a USB bus reset, this module indicates PID = NAK. Set these bits as follows: • To change the state from NAK (00) to STALL, write B'10. • To change the state from BUF (01) to STALL, write B'11. • To change the state from STALL (11) to NAK, write B'10 then B'00. • To change the state from STALL to BUF, set these bits to NAK and then to BUF.

Notes: 1. Only reading 0 and writing 1 are enabled.
2. Set the ACLRM, SQCLR, or SQSET bit when PID = NAK, and the selected pipe is not set in the CURPIPE bits.
3. When setting the ACLRM, SQCLR, or SQSET bit after changing the PID bits from BUF to NAK, check that PBUSY = 0 for the pipe. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

Table 42.11 Data Cleared by This Module when ACLRM = 1

No.	Data Cleared by the ACLRM Bit	Clearing Timing
1	All data in the FIFO buffer allocated to the selected pipe	
2	Not Support	
3	Internal flags related to the BFRE bit	When changing the BFRE setting
4	Internal flags related to the transaction count	When forcibly terminating the transaction count function

42.2.33 Pipe n Transaction Counter Enable Register (PIPEnTRE) (n = 1 to 5, 9 to F)

PIPEnTRE enables or disables the transaction counter function and clears the counter for pipes 1 to 5, 9 to F.

This register is initialized by a power-on reset.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	TRENB	TRCLR	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R	R

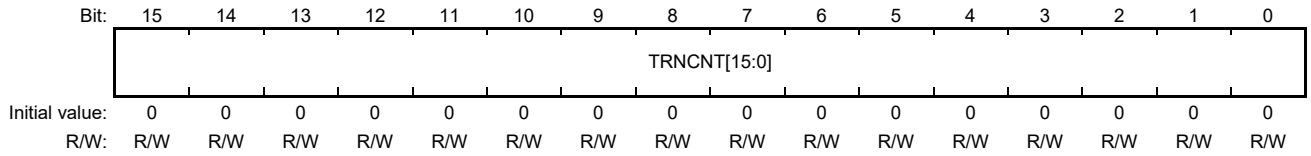
Bit	Bit Name	Initial Value	R/W	Description
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	TRENB	0	R/W	Transaction Counter Enable Enables or disables the transaction counter function. 0: The transaction counter function is disabled. 1: The transaction counter function is enabled. When the software sets the number of total packets in the TRNCNT bits in PIPEnTRN for the receive pipe and then sets this bit to 1, this module controls the following when it received the same number of packets as the setting of the TRNCNT bits. When continuous communication mode is used (CNTMD = 1), this module toggles the received data to the CPU even if the FIFO buffer is not full at the end of reception. When SHTNAK = 1, this module changes the PID bits for the corresponding pipe to NAK when this module received the same number of packets as the setting of the TRNCNT bits. When BFRE = 1, this module asserts the BRDY interrupt when this module received the same number of packets as the setting of the TRNCNT bits and read the receive data completely. For transmit pipes, set this bit to 0. When the transaction counter function is not used, set this bit to 0. When using the transaction counter function, set the TRNCNT bits and then set this bit to 1. Furthermore, set this bit to 1 before receiving the first packet that is included in the transaction count range.
8	TRCLR	0	R/W	Transaction Counter Clear Clears the current count value of the transaction counter for the pipe and indicates TRCLR = 0. 0: Invalid 1: The current count value is cleared.
7 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Note: Change the bits in this register when CSSTS = 0 and PID = NAK.
When changing the bits in this register after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK.

42.2.34 Pipe n Transaction Counter Register (PIPEnTRN) (n = 1 to 5, 9 to F)

PIPEnTRN is a transaction counter for pipes 1 to 5, 9 to F.

This register is initialized by a power-on reset, but the setting of this register is retained through a USB bus reset.



Bit	Bit Name	Initial Value	R/W	Description
15 to 0	TRNCNT [15:0]	All 0	R/W	Transaction Counter Writing: Specify the number of transactions of DMA transfer. Reading: When TRENB = 0, the set number of transactions is indicated. When TRENB = 1, the number of current transactions is indicated. This module increments (+1) the value of these bits when the following conditions are all satisfied. TRENB = 1 TRNCNT value ≠ current count value +1 when a packet is received. The payload of the received packet equals the value of the MXPS bits. This module clears these bits to 0 when any of the following is satisfied. When the following conditions are all satisfied — TRENB = 1 — TRNCNT value = current count value +1 when a packet is received. — The payload of the received packet equals the value of the MXPS bits. When the following conditions are all satisfied — TRENB = 1 — A short packet is received. When the following conditions are all satisfied — TRENB = 1 — The software sets the TRCLR bit to 1. For transmit pipes, set these bits to all 0. When the transaction counter function is not used, set these bits to all 0. Change these bits when CSSTS = 0, PID = NAK, and TRENB = 0. When setting these bits to 1 after changing the PID bits for the pipe from BUF to NAK, check that CSSTS = 0 and PBUSY = 0. However, the software does not have to check the PBUSY bit when this module changed the PID bits to NAK. When changing these bits, set TRNCNT = 1 and then set TRENB = 1.

42.2.35 Low Power Status register (LPSTS)

This register provides low power management control.

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	SUSPM	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
14	SUSPM	0	R/W	SuspendM control 0: UTMI suspend mode 1: UTMI normal mode This bit should set to 1 when normal operating. UTMI clock is halted if this bit set to 0. Note: This controller denies register access without as follow registers if this bit set to 0. SYSCFG0 BUSWAIT INTENB1 LPSTS UGCTRL2
13 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

42.2.36 USB General Control Register (UGCTRL)

This register provides embedded USB PHY control.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5, 4	USB0SEL	01	R/W	USB2.0 Selection 00: Reserved 01: Select EHCI/OHCI host module for USB2.0 10: Select HS USB module for USB2.0 11: Reserved
3 to 0	—	0001	R	Reserved These bits are always read as B'0001. The write value should always be B'0001.

42.3 Operation

42.3.1 System Control and Oscillation Control

This section describes register operations required for the initial settings of this module and the registers required for the power consumption control.

(1) Power control and Initialization

The following is the initialize power on procedure of USB subsystem.

1. Supply 1.8 V (VD181)
2. Supply 3.3 V (VD331) (Note: Do not supply 3.3 V when 1.8 V is not supplied.)
3. HS-USB module stop release and module reset assert.
4. PLLRESET release
5. Wait min. 340 µs for USB PHY power stable.
6. USB0SEL[1:0] should be set to B'10 for USB Function (HS-USB)
7. LPSTS.SUSPM set to normal mode.
8. Starting normal operation.

(2) Enabling High-Speed Operation

This module can set the USB transmission rate (communication bit rate) by the software.

When the function controller function is selected, high-speed operation or full-speed operation is selectable. To enable high-speed operation with this module, set the HSE bit in SYSCFG to 1. When high-speed operation is enabled, this module executes the reset handshake protocol and automatically sets the USB transmission rate. The reset handshake result can be checked by the RHST bits in DVSTCTR.

When high-speed operation is disabled, this module operates in full speed when the function controller function is selected.

(3) USB Data Bus Resistor Control

Figure 42.1 shows the connection between this module and the USB connector.

This module incorporates a pull-up resistor of the D+ signal. Specify pull-up using the DPRPU bits in SYSCFG.

Furthermore, this module controls the terminating resistors of the D+ and D- signals in high-speed operation, and the output resistors in full-speed operation. This module automatically switches the on-chip resistors after connection to the host controller detecting a reset handshake, suspended state, or resume.

When the DPRPU bit in SYSCFG is set to 0 during communication with the host controller, this module disables the pull-up resistors (or terminating resistors) of the USB data line. Therefore, the USB host can be notified of a disconnection from the device.

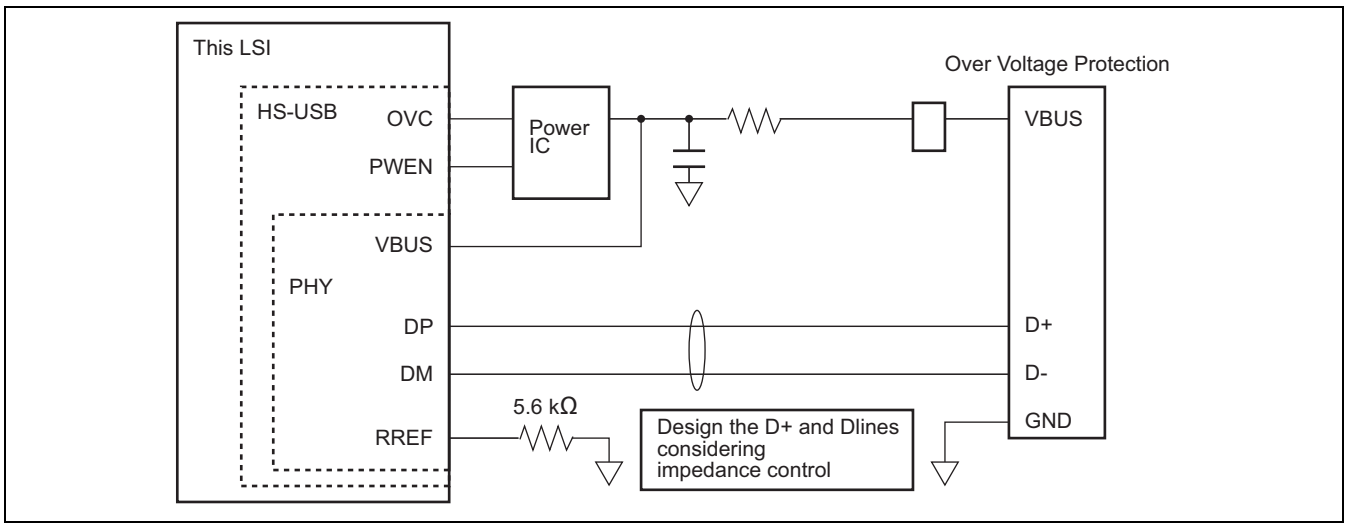

Figure 42.1 Connection to the USB Connector

(4) Software reset when the USB disconnection is detected

Issue a software reset of the USBHS module when the USB disconnection is detected. If the DMA interface is being used, issue a software reset of the USB-DMAC module as well. A software reset can be issued via a register in the CPG

Whether or not the USB disconnection is detected can be determined by the VBSTS in the INTSTS0 register when the function controller function is selected.

Note: USB-PHY might become inoperable to use by the instantaneous interruption of VBUS. As a result S/W on the LSI side (driver) becomes a state of the connection, and USB-PHY becomes a state of power cutoff. It's possible to cancel this state by putting the next way into effect by software.

1) When detecting a bus reset or cutoff of VBUS, please refer to the state bit of USB - PHY (USB_OFF bit of USBCR2 register in GPIO) and in case of USB_OFF = 1, set USB_START bit.
2) When 1) is performed and USB - PHY is started, USB_PHY_ON interrupt occurs, so please perform a soft reset to USBHS, USB-DMAC and do the setting by which USBHS,USB-DMAC is initialization and DP pull up --, etc. by this timing.

42.3.2 Interrupt Function

Table 42.12 lists the interrupt generating conditions of this module.

When any of the following interrupt generating conditions are satisfied and the interrupt output is enabled by the corresponding interrupt enable register, this module outputs a USB interrupt request to the interrupt controller (INTC).

Table 42.12 Interrupt Generating Conditions

Bit	Interrupt Name	Interrupt Generating Conditions	Function	Related Status
VBINT	VBUS interrupt	When VBUS input pin state change is detected (both L to H and H to L)		VBSTS
RESM	Resume interrupt	When a USB bus state change is detected in the suspended state (J-State to K-State or J-State to SE0)		—
SOFR	Frame number update interrupt	SOFRM = 0: When an SOF packet with a different frame number is received SOFRM = 1: When an SOF packet with a µ frame number of 0 cannot be received due to damage, etc.		—
DVST	Device state transition interrupt	When a device state transition is detected USB bus reset detected Suspended state detected SET_ADDRESS request received SET_CONFIGURATION request received		DVSQ
CTRT	Control transfer stage transition interrupt	When a control transfer stage transition is detected Setup stage completed Control write transfer status stage shifted Control read transfer status stage shifted Control transfer completed Control transfer sequence error occurred		CTSQ
BEMP	Buffer empty interrupt	When the buffer becomes empty after sending all buffer memory data When a packet with a size exceeding the maximum packet size is received		BEMPSTS.PIPEBEMP
NRDY	Buffer not ready interrupt	When NAK is sent in response to IN token, OUTtoken, or PING token When a CRC error or bit stuffing error occurred during data reception in isochronous transfer When an overrun or underrun error occurred during data reception in isochronous transfer		NRDYSTS.PIPENRDY
BRDY	Buffer ready interrupt	When the buffer becomes ready for reading or writing		BRDYSTS.PIPEBRDY
OVRCR	OVRCR interrupt	When an OVC input pin state change is detected		OVCMON

Note: These bits in this table are those of INTSTS0 if any register's name is not indicated.

Figure 42.2 shows a block diagram of the interrupt circuit of this module.

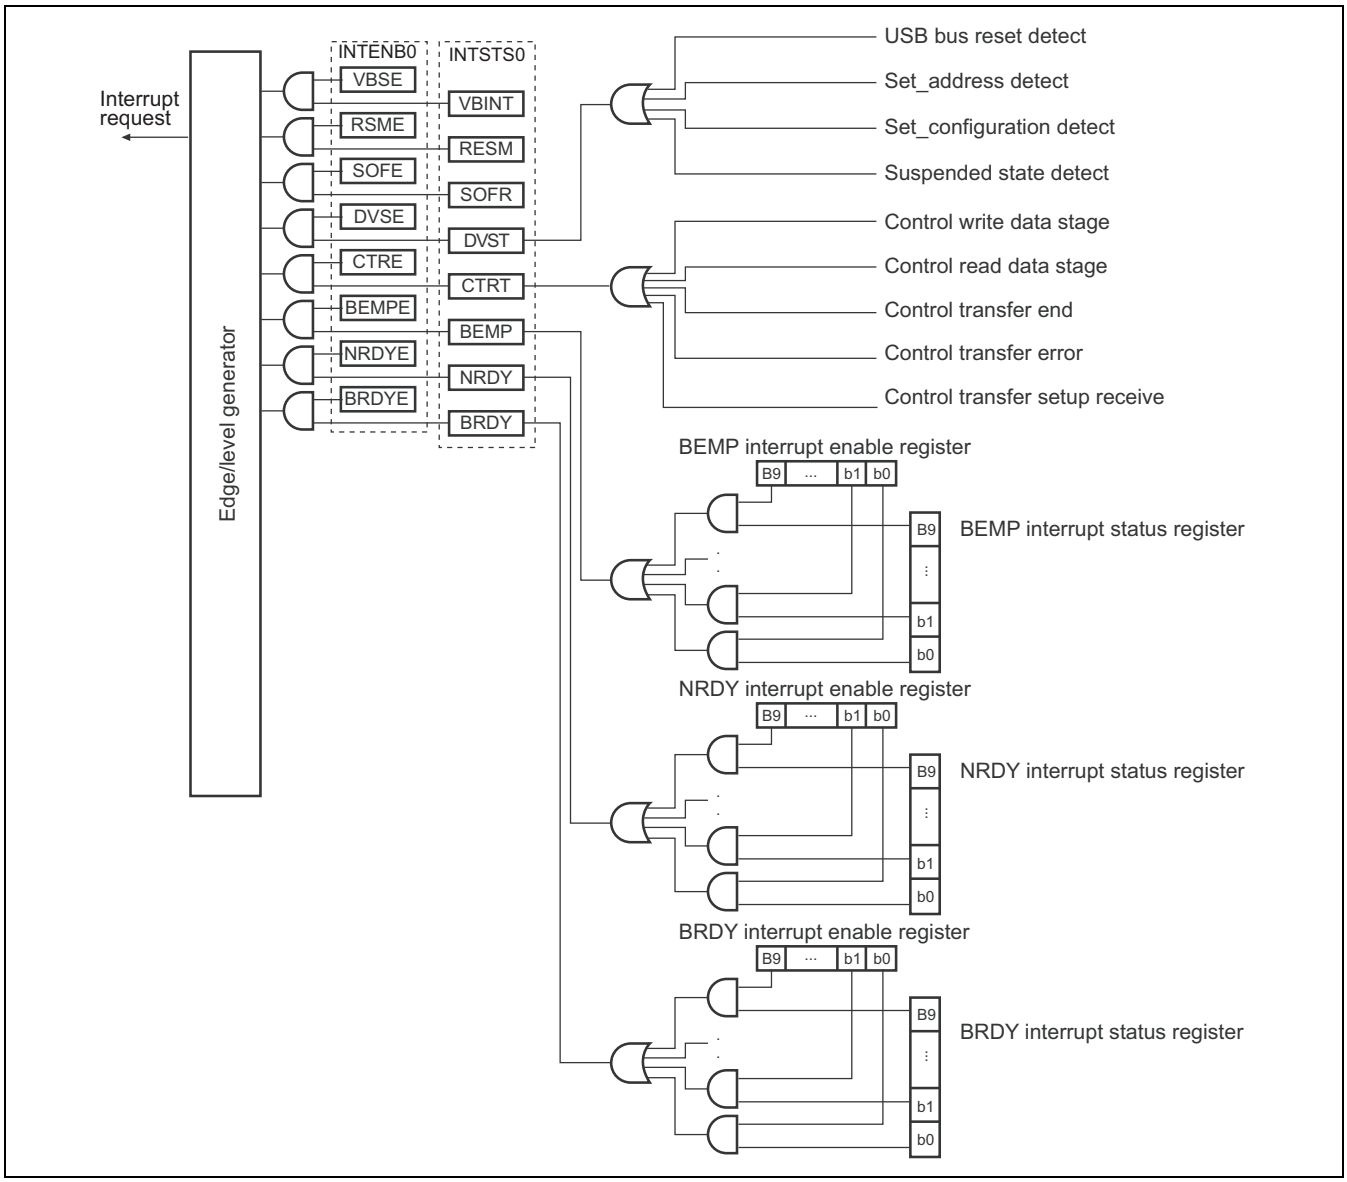

Figure 42.2 Block Diagram of Interrupt Circuit

(1) BRDY Interrupt

A BRDY interrupt can be generated. When the following conditions in each pipe are satisfied, this module sets the corresponding bit in BRDYSTS to 1. At this time, when the PIPEBRDYE bit for the pipe in BRDYENB is set to 1 and the BRDYE bit in INTENB0 is set to 1 by the software, this module generates a BRDY interrupt.

BRDY interrupt generating conditions and clearing method depend on the settings of the BRDYM bit and the BFRE bit for each pipe.

(a) When BRDY interrupt disable (BRDYM = 0) and BRDY interrupt output enable (BFRE = 0) at data reception/transmission are specified

With this setting, a BRDY interrupt indicates that the FIFO port is accessible.

This module generates an internal BRDY interrupt request trigger when the following conditions are satisfied, and sets the PIPEBRDY bit corresponding to the request trigger pipe to 1.

1. Pipes set for the transmit direction
   - When the software changes the DIR bit from 0 to 1
   - When this module finishes sending a packet of the pipe while data write from the CPU to the FIFO buffer allocated to the pipe is disabled (BSTS = 0)
   - When continuous communication mode is selected, this module generates a BRDY interrupt request trigger upon completion of sending data for one side of the FIFO buffer.
   - When a double FIFO buffer is specified and one side of the FIFO buffer is empty when data write to the other side of the FIFO buffer is completed.

     Even if one side of the FIFO buffer becomes empty while the other side is in data write processing, no BRDY interrupt is generated until the ongoing data write finishes.
   - When this module generates a buffer flush for a pipe of isochronous transfer type
   - When the FIFO buffer becomes write enable state by writing 1 to the ACLRM bit

No BRDY interrupt request trigger is generated for the DCP (in data transmission of control transfer).

2. Pipes set for the receive direction
   - When this module receives a packet successfully and the FIFO buffer becomes ready for reading while data read access from the CPU to the FIFO buffer allocated to the pipe is disabled (BSTS = 0)
   - No BRDY interrupt request trigger is generated in transactions with incorrect data PID.
   - When continuous communication mode is selected, no BRDY interrupt request trigger is generated for packets with a MaxPacketSize data size and when the FIFO buffer still has available space.
   - When this module receives a short packet, this module generates a BRDY interrupt request trigger even if the buffer has available space.
   - When a transaction counter is used, this module generates a BRDY interrupt request trigger when this module receives a packet with a size of the set value even if the FIFO buffer still has available space.
   - When a double FIFO buffer is specified and one side of the FIFO buffer is ready for reading when data read from the other side of the FIFO buffer is completed

     Even if data read for one side of the FIFO buffer is completed while the other side is undergoing data read, no BRDY interrupt request trigger is generated until the ongoing data read finishes.

This interrupt is not generated in communication in the control transfer status stage.

The software can clear the PIPEBRDY interrupt status of the pipe by writing 0 to the PIPEBRDY bit for the pipe in BRDYSTS. At this time, write 1 to the bits corresponding to other pipes.

Be sure to clear the BRDY interrupt status before accessing the FIFO buffer.

(b) When BRDY interrupt disable (BRDYM = 0) and BRDY interrupt output enable (BFRE = 1) at the end of data read are specified

With this setting, this module determines that a BRDY interrupt is generated upon completion of reading all data of one transfer in a receive pipe, and sets the bit for the pipe in this register to 1.

This module determines that the last data of a transfer was received in either of the following cases.

- A Zero-Length packet or another short packet is received.
- A transaction counter (TRNCNT bits) is used and a packet with a size of the value of the TRNCNT bits is received.

When either of these conditions is satisfied and the data read is completed, this module determines that reading all data for one transfer is completed.

When this module receives a Zero-Length packet with the FIFO buffer empty, this module determines that reading all data for one transfer is completed when the Zero-Length packet data is toggled to the CPU. In this case, write 1 to the BCLR bit in the corresponding FIFOCTR register by the software to start the next transfer.

With this setting, this module generates no BRDY interrupt for transmit pipes.

The software can clear the PIPEBRDY interrupt status of the pipe to 0 by writing 0 to the PIPEBRDY bit for the pipe. At this time, write 1 to the bits corresponding to other pipes.

When using this mode, do not change the BFRE setting until the processing for one transfer is completed.

To change the BFRE bit during processing, clear all FIFO buffers for the pipe by the ACLRM bit.

(c) When BRDY interrupt enable (BRDYM = 1) and BRDY interrupt output enable (BFRE = 0) at data reception/transmission are specified

With this setting, the value of the PIPEBRDY bit varies with the value of the BSTS bit for each pipe. That is, this module indicates 1 or 0 of the BRDY interrupt status according to the FIFO buffer status.

1. Pipes set for the transmit direction

   When the FIFO port is ready to write data, the PIPEBRDY bit indicates 1. When the FIFO port is not ready to write data, the PIPEBRDY bit indicates 0.

   However, even if the transmit pipe of the DCP is ready to write data, no BRDY interrupt is asserted.
2. Pipes set for the receive direction

   When the FIFO port is ready to read data, the PIPEBRDY bit indicates 1. When all data is read from the FIFO port (reading disabled), the PIPEBRDY bit indicates 0.

   When this module receives a Zero-Length packet with the FIFO buffer empty, this module indicates 1 with the corresponding bit until 1 is written to BCLR by the software, and continues to assert the BRDY interrupt.

   With this setting, the software cannot clear the PIPEBRDY bit to 0.

   When BRDYM = 1, set the BFRE bit to 0 for all pipes.

Figure 42.3 shows the BRDY interrupt generation timing.

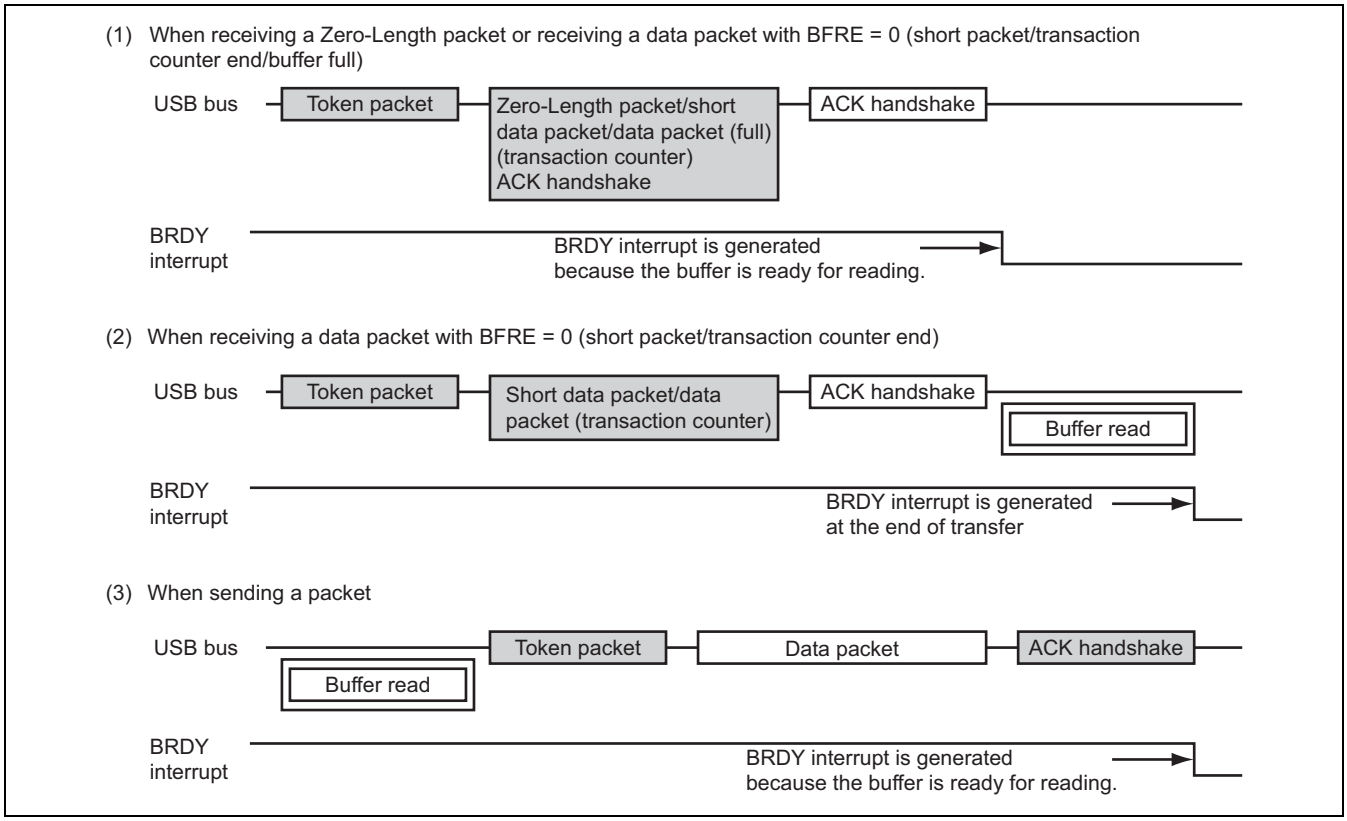

Figure 42.3 BRDY Interrupt Generation Timing

(2) NRDY Interrupt

When this module generates an internal NRDY interrupt request for the pipe in which PID = BUF is set by the software, this module indicates PIPENRDY = 1 for the pipe in NRDYSTS. At this time, when 1 is set in the corresponding bit in NRDYENB by the software, this module indicates NRDY = 1 in INTSTS0 and generates a USB interrupt.

The following shows the conditions for this module to generate an internal NRDY interrupt request for a pipe.

Furthermore, when executing the control transfer status stage, this module generates no interrupt request.

1. Pipes in the transmit direction
   - When this module receives an IN token with no transmit data in the FIFO buffer
     This module generates an NRDY interrupt request and indicates PIPENRDY = 1.
   - When the pipe in which the interrupt is generated is isochronous transfer type, this module sends a Zero-Length packet and indicates OVRN = 1.
2. Pipes in the receive direction pipe
   - When this module receives an OUT token with the FIFO buffer occupied
   - When the pipe in which the interrupt is generated is isochronous transfer type, this module generates an NRDY interrupt request when this module receives an OUT token, and indicates PIPENRDY = 1 and OVRN = 1.
   - When the pipe in which the interrupt is generated is not isochroous transfer type, this module generates an NRDY interrupt request when this module sends an NAK handshake response after receiving data following the OUT token, and indicates PIPENRDY = 1.
     However, this module generates no NRDY interrupt when resending data (in the case of DATA-PID mismatch) or when an error occurs in a data packet.
   - When this module receives a PING token with the FIFO buffer occupied
     This module generates an NRDY interrupt request when this module receives a PING token and indicates PIPENRDY = 1.
   - When a packet is not received correctly within the interval frame in an isochroous transfer-type pipe
     This module generates an NRDY interrupt request when this module receives SOF and indicates PIPENRDY = 1.

Figure 42.4 shows the NRDY interrupt generation timing when the function controller function is selected.

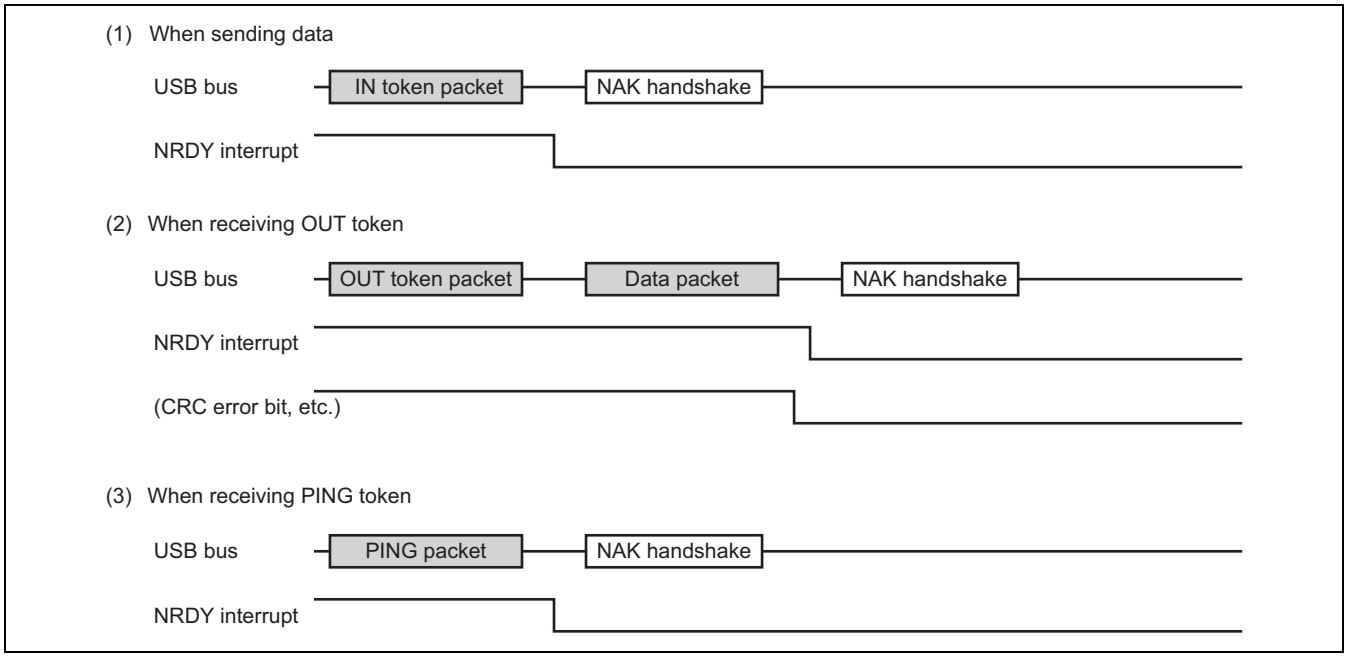

Figure 42.4 NRDY Interrupt Generation Timing when the Function Controller Function is selected

(3) BEMP Interrupt

When this module detects a BEMP interrupt for the pipe in which PID = BUF is set by the software, this module indicates PIPEBEMP = 1 for the pipe in BEMPSTS. At this time, when 1 is set in the corresponding bit in BEMPENB by the software, this module indicates BEMP = 1 in INTSTS0 and generates a USB interrupt.

This module generates an internal BEMP interrupt request in the following cases.

1. Transmit direction pipes
   — When the FIFO buffer for the pipe is empty at the end of transmission (including transmission of a Zero-Length packet)
   — When single buffer is set for the FIFO buffer, this module generates an internal BEMP interrupt request concurrently with a BRDY interrupt for pipes other than DCP.
   However, this module generates no internal BEMP interrupt request in the following cases.
   - In the case of double buffer, when the software (DMAC) already started writing data to the FIFO buffer of the CPU at the end of transmission for one-side data
   - When the buffer is cleared (empty) by writing 1 to the ACLRM or BCLR bit.
   - When sending a Zero-Length packet (IN transfer) of the control transfer status stage

2. Receive direction pipes
   — When this module receives a packet with a data size exceeding the MaxPacketSize value
   In this case, this module generates a BEMP interrupt request and indicates the PIPEBEMP = 1 for the pipe, ignores the received data, and changes the PID bits for the pipe to STALL (11).
   At this time, this module sends a STALL response.
   However, this module generates no BEMP interrupt request in the following cases.
   - When this module detects a CRC error or bit stuffing error in the receive data
   - When executing the SETUP transaction
     Writing 0 to the PIPEBEMP bits clears the status.
     Writing 0 to the PIPEBEMP bits has no effect on the operation of this module.

Figure 42.5 shows the BEMP interrupt generation timing when the function controller function is selected.

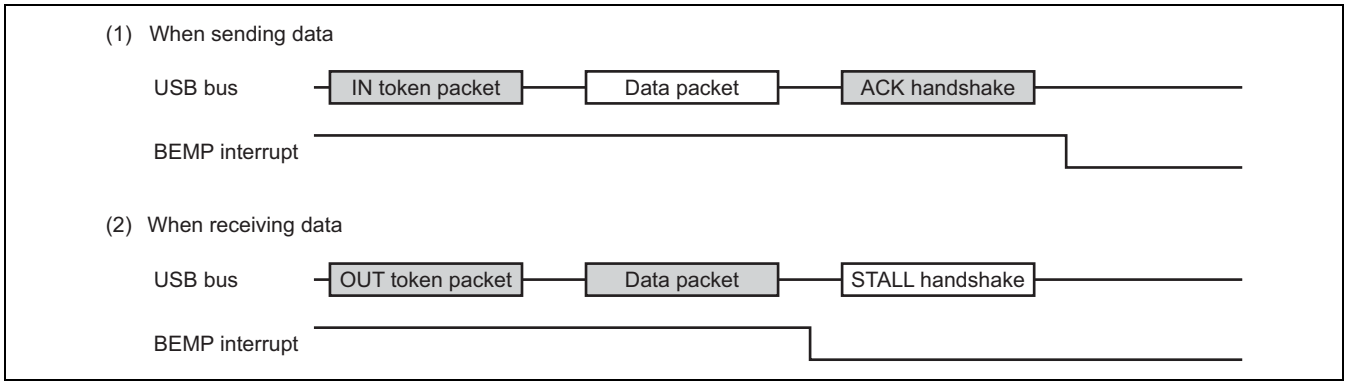

Figure 42.5 BEMP Interrupt Generation Timing when the Function Controller Function is selected

(4) Device State Transition Interrupt

Figure 42.6 shows the device state transitions of this module. This module controls device states and generates device state transition interrupts. However, when returning from the suspended state (detecting the resume signal), this module detects the transition with a resume interrupt. The device state transition interrupt is enabled or disabled by setting INTENB0. The current device state can be monitored using the DVSQ bits in INTSTS0.

When this module shifts to the default state, a device state transition interrupt occurs after executing the reset handshake protocol.

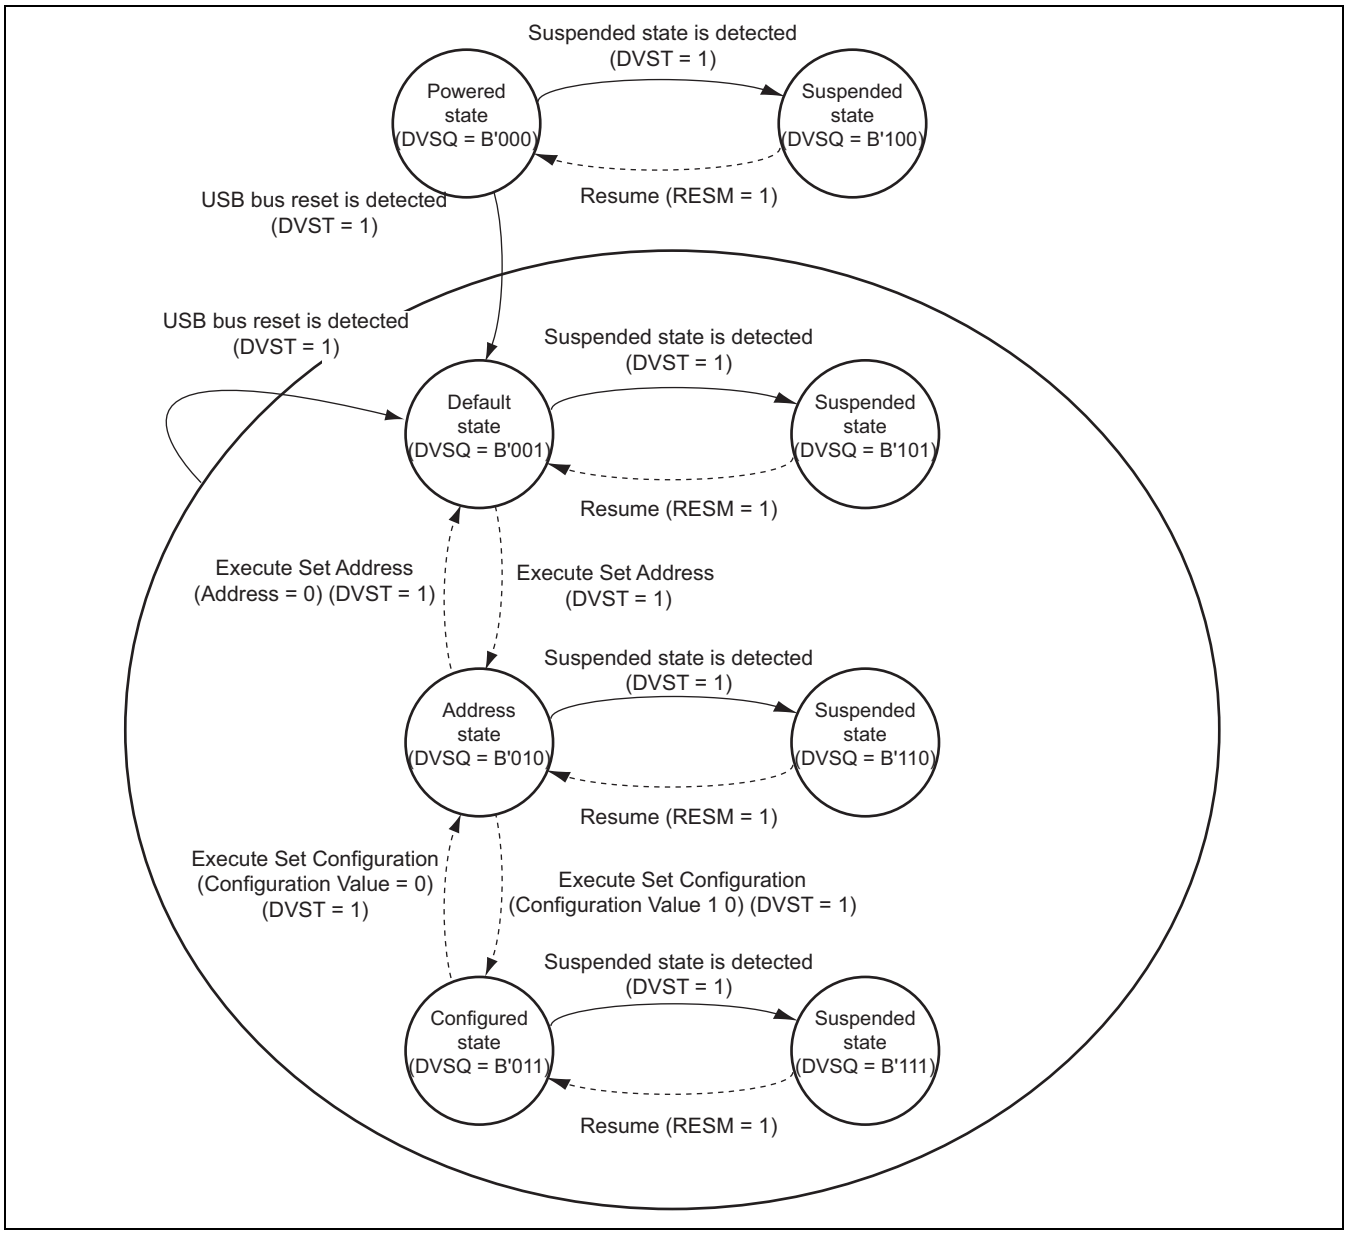

Figure 42.6 Device State Transitions

(5) Control Transfer Stage Transition Interrupt

Figure 42.7 shows control transfer stage transitions of this module. This module manages the sequence of control transfers and generates control transfer stage transition interrupts. Enabling or disabling each control transfer stage transition interrupt can be set by INTENB0. The current transfer stage after transition can be checked by the CTSQ bits in INTSTS0.

The following describes control transfer sequence errors. When an error occurs, the PID bits in DCPCTR indicate B'1x (STALL response).

1. Control read transfer
   - This module receives an OUT or PING token in response to the IN token in the data stage before starting data transfer.
   - This module receives an IN token in the status stage.
   - This module receives a packet with a data packet of DATAPID = DATA0 in the status stage.
2. Control write transfer
   - This module receives an IN token in response to the OUT token in the data stage before sending an ACK response.
   - This module receives a packet with the first data packet of DATAPID = DATA0.
   - This module receives an OUT or PING token in the status stage.
3. Control write no-data control transfer
   - This module receives an OUT or PING token in the status stage.

If the size of the receive data exceeds the wLength value of the USB request in the control write transfer data stage, this is not treated as a control transfer sequence error. This module sends ACK for normal end in response to a packet other than Zero-Length packet in the control read transfer status stage.

When a CTRT interrupt is generated (SERR = 1) due to a sequence error, CTSQ = B'110 is retained until the interrupt status is cleared (CTRT = 0) by the system. For this reason, while CTSQ = B'110, even if a new USB request is received, a CTRT interrupt at the end of the setup stage is not generated. (This module retains the setup stage end status and generates a setup stage end interrupt after the interrupt status is cleared by the software.)

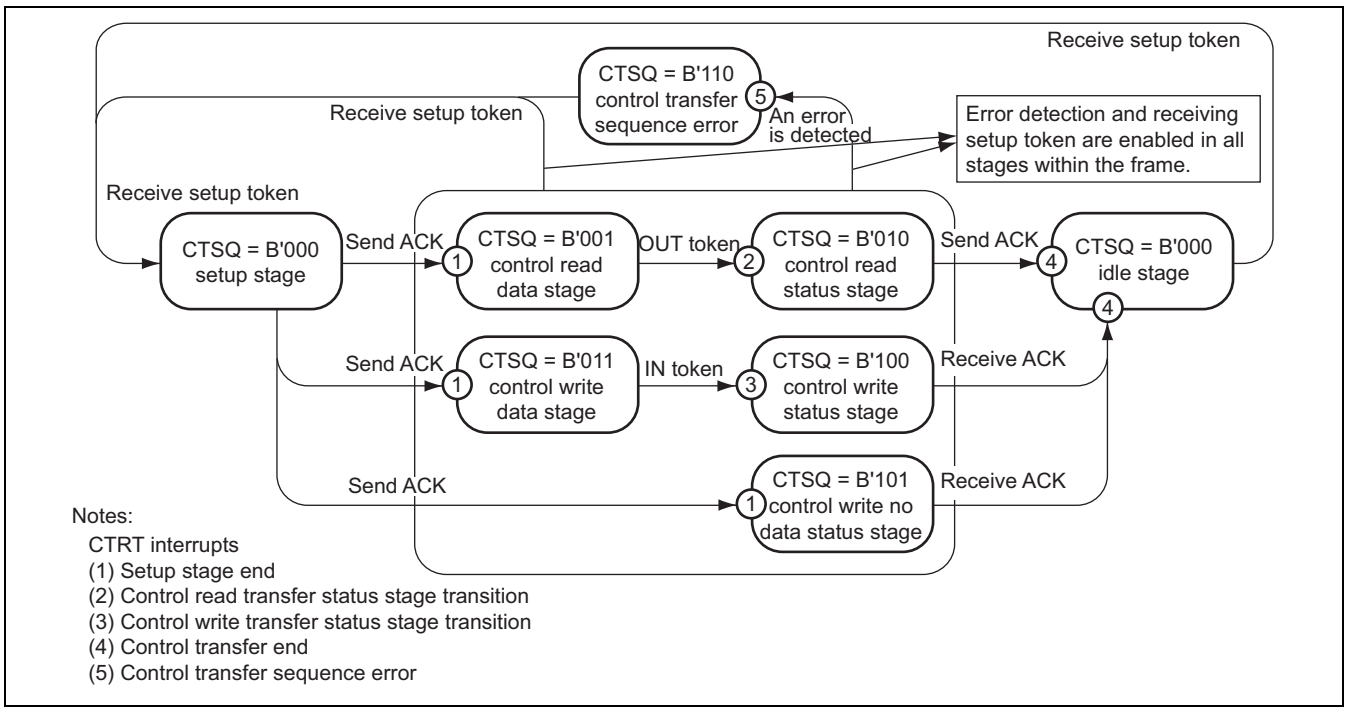

Figure 42.7 Control Transfer Stage Transitions

(6) Frame Update Interrupt

Figure 42.8 shows an example of the SOFR interrupt output timing of this module.

An SOFR interrupt is generated immediately after the frame number is updated.

When this module detects a new SOF packet during the full-speed operation, this module updates the frame number and generates an SOFR interrupt. In the high-speed operation, however, the frame number is not updated or no SOFR interrupt is generated unless the module enters the µ SOF lock state. Furthermore, the SOF interpolation function is not activated. The µ SOF lock state occurs when this module receives a µ SOF packet twice in a row with different frame numbers without an error.

The µ SOF lock monitoring start and stop conditions are as follows:

1. µ SOF lock monitoring start conditions
   USBE = 1
2. µ SOF lock monitoring stop conditions
   USBE = 0, receiving USB bus reset, or detection of suspended state

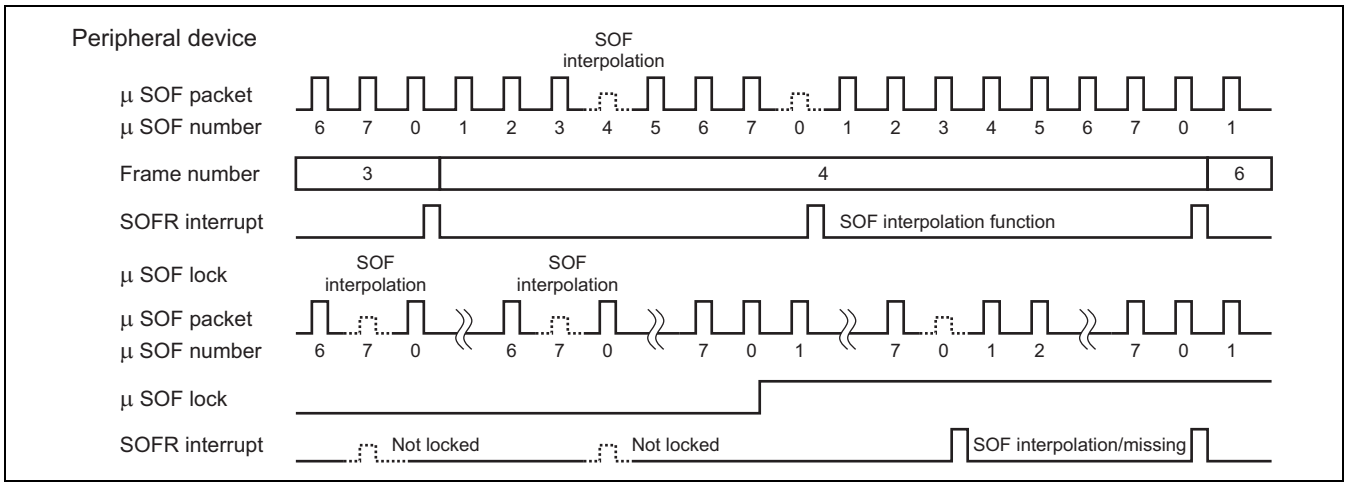

Figure 42.8 Example of SOFR Interrupt Output Timing

(7) VBUS Interrupt

When the VBUSIN_0 pin state changes, a VBUS interrupt is generated. The VBUSIN_0 pin level can be checked by the VBSTS bit in INTSTS0. The VBUS interrupt is used to check connection or disconnection to the host controller. However, when the system starts up with the host controller connected, the VBUSIN_0 pin state remains unchanged, and therefore the first VBUS interrupt is not generated.

(8) Resume Interrupt

When the function controller function is selected and the USB bus state changes (J-State to K-State or J-State to SE0) with the device state suspended, a resume interrupt is generated. The resume interrupt is used to detect the return from the suspended state.

42.3.3 Pipe Control

Table 42.13 lists the pipe settings of this module. In the USB data transfer, data must be transmitted or received using virtual pipes called “endpoint.” This module is provided with ten pipes for data transfer. Set each pipe according to system specifications.

Table 42.13 Pipe Settings

Register Name	Bit Name	Setting	Remarks
DCPCFG PIPECFG	TYPE	Transfer type	Pipes 1 to F: Setting allowed
	BFRE	BRDY interrupt mode	Pipes 1 to 5, B to F: Setting allowed
	DBLB	Double buffer	Pipes 1 to 5, B to F: Setting allowed Pipes 9, A: Setting allowed only when bulk transfer is selected
	CNTMD	Continuous transfer or discontinuous transfer	Pipes 1 to 2, 9, A: Setting allowed only when bulk transfer is selected Pipes 3 to 5, B to F: Setting allowed
	DIR	Transfer direction	IN or OUT selectable
	EPNUM	Endpoint number	Pipes 1 to F: Setting allowed Set a value other than 0000 when using pipes
	SHTNAK	Disabling pipes at the end of transfer	Pipes 1 to 2, 9, A: Setting allowed only when bulk transfer is selected Pipes 3 to 5, B to F: Setting allowed
PIPEBUF	BUFSIZE	Buffer memory size	DCP: Setting disallowed (256 bytes fixed) Pipes 1 to 5, A to F: Setting allowed (up to 2 Kbytes) Pipes 6 to 9: Setting disallowed (64 bytes fixed)
	BUFNMB	Buffer memory number	DCP: Setting disallowed (H'0 to H'3 fixed) Pipes 1 to 5, A to F: Setting allowed (H'8 to H'87) Pipes 6 to 9: Setting disallowed (H'4 to H'7 fixed)
DCPMAXP PIPEMAXP	MXPS	Maximum packet size	Setting conforming to the USB Specification
PIPEPERI	IFIS	Buffer flush	Pipes 1, 2: Setting allowed only when isochronous transfer is selected Pipes 3 to F: Setting disallowed
	IITV	Interval counter	Pipes 1, 2: Setting allowed only when isochronous transfer is selected Pipes 3 to F: Setting disallowed
DCPCTR PIPEnCTR	BSTS	Buffer status	For DCP, receive buffer status and transmit buffer status are switched by the ISEL bit.
	INBUFM	IN buffer monitor	Provided only for pipes 3 to 5, 9 to F.
	ATREPM	Auto-response mode	Pipes 1 to 5, 9 to F Setting allowed only when the function controller function is selected.
	ACLRM	Buffer auto-clear	Pipes 1 to F Setting allowed
	SQCLR	Sequence clear	Data toggle bit clear
	SQSET	Sequence setting	Data toggle bit setting
	SQMON	Sequence check	Data toggle bit check
	PBUSY	Pipe busy check	
	PID	Response PID	See section 42.3.3 (6), Response PID.

Register Name	Bit Name	Setting	Remarks
PIPEnTRE	TRENB	Transaction count enable	Pipes 1 to 5, 9 to F: Setting allowed
	TRCLR	Current transaction counter clear	Pipes 1 to 5, 9 to F: Setting allowed
PIPEnTRN	TRNCNT	Transaction counter	Pipes 1 to 5, 9 to F: Setting allowed

(1) Pipe Control Registers Switching Procedure

The following bits in the pipe control registers can be modified only when USB communication is set to disabled (PID = NAK).

Bits/registers that cannot be modified when USB communication is set to enabled (PID = BUF)

- Each bit in DCPCFG and DCPMAXP
- SQCLR and SQSET bits in DCPCTR
- Each bit in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI
- ATREPM, ACLRM, SQCLR, and SQSET bits in PIPEnCTR
- Each bit in PIPEnTRE and PIPEnTRN

When changing these bits from the state where USB communication is enabled (PID = BUF), follow the steps below.

1. Generate a pipe control register bit change request.
2. Change the PID bits for the pipe to NAK.
3. Wait until the PBUSY bit for the pipe is cleared to 0.
4. Change the bits in the pipe control registers.

The following bits in the pipe control registers can be modified only for pipe information that is not set in any of the CURPIPE bits in CFIFOSEL, D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL.

Bits/registers that cannot be modified while the CURPIPE bits in FIFO-PORT are being set

- Each bit in DCPCFG and DCPMAXP
- Each bit in PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI

Before changing the pipe information, set the CURPIPE bits to a pipe other than that to be changed. For the DCP, clear the buffer by the BCLR bit after modifying the pipe information.

(2) Transfer Type

Specify the transfer type of each pipe by the TYPE bits in PIPEPCFG as follows:

- DCP: Setting is not required (fixed to control transfer).
- Pipes 1, 2: Set bulk transfer or isochronous transfer.
- Pipes 3 to 5, B to F: Set bulk transfer.
- Pipes 6 to 8: Set interrupt transfer.
- Pipes 9, A: Set Bulk transfer or interrupt transfer.

(3) Endpoint Number

Specify the endpoint number of each pipe by the EPNUM bits in PIPEPCFG. The endpoint number of the DCP is always 0. For other pipes, endpoint 1 to endpoint 15 are selectable.

- DCP: Setting is not required (fixed to endpoint 0).
- Pipes 1 to F: Set an endpoint number by selecting a number 1 to 15.
  However, set an endpoint number so that combinations of the DIR bit and the EPNUM bits do not overlap.

(4) Maximum Packet Size

Specify the maximum packet size of each pipe by the MXPS bits in DCPMAXP and PIPEMAXP. For the DCP and pipes 1 to 5, 9 to F, any of the maximum packet sizes defined in the USB Specification can be set. For pipes 6 to 8 a maximum packet size up to 64 bytes can be set. Specify a maximum packet size as follows before starting transfer (PID = BUF):

- DCP: Set 64 for high-speed operation.
- DCP: Set 8, 16, 32, or 64 for full-speed operation.
- Pipes 1 to 5: Set 512 for high-speed bulk transfer.
- Pipes 1 to 5: Set 8, 16, 32, or 64 for full-speed bulk transfer.
- Pipes 1, 2: Set a value from 1 to 1024 for high-speed isochronous transfer.
- Pipes 1, 2: Set a value from 1 to 1023 for full-speed isochronous transfer.
- Pipes 6 to 9: Set a value from 1 to 64.
- Pipe 9: Set 512 for high-speed bulk transfer.
- Pipe 9: Set 8, 16, 32, or 64 for full-speed bulk transfer.
- Pipes 9 to A: Set a value from 1 to 64 for interrupt transfer.
- Pipes B to F: Set 512 for high-speed bulk transfer.
- Pipes B to F: Set 8, 16, 32, or 64 for full-speed bulk transfer.

High Bandwidth in interrupt and isochronous transfers is not supported.

(5) Transaction Counter (Pipes 1 to 5, 9 to F: Read Direction)

When the specified number of transactions with data packet in the receive direction are completed, this module recognizes this as a transfer end. The transaction counter works when the pipe selected for the D0FIFOSEL, D1FIFOSEL, D2FIFOSEL and D3FIFOSEL ports is set for the data read (from the buffer memory) direction. The transaction counter is provided with the TRNCNT register to specify the number of transactions and the current counter to count transactions internally. When the current counter reaches the specified value, the buffer memory becomes ready for reading. The current counter of the transaction counter function can be initialized by the TRCLR bit to count transactions again from the beginning. The TRNCNT read data varies depending on the TRENB setting.

- TRENB = 0: The set transaction counter value is read.
- TRENB = 1: The internally counted current counter value is read.
- Change the CURPIPE bits according to the following.
- Do not change the CURPIPE bits until the transaction for the specified pipe finishes.
- Change the CURPIPE bits when the current counter is cleared.
- Control the TRCLR bit according to the following.
- Do not clear the current counter during transaction count and PID = BUF.
- Do not clear the current counter while data is remaining in the buffer.

(6) Response PID

Specify the response PID for each pipe by the PID bits in DCPCTR and PIPEnCTR.

This module operates as follows according to the response PID setting.

The response PID specifies a response to transactions from the host.

- NAK setting: NAK is always sent in response to a transaction.
- BUF setting: A response is sent to a transaction according to the buffer memory status.
- STALL setting: STALL is always sent in response to a transaction.

Note: This module always sends ACK in response to a setup transaction irrespective of the PID setting, and stores a USB request in the register.

This module modifies the PID bits in the following cases depending on transaction results.

- When the response PID is set by the hardware
  - NAK setting: This module sets PID to NAK in the following cases and always sends NAK in response to a transaction.
- When a SETUP token is successfully received (DCP only)
- When the SHTNAK bit in PIPECFG is set to 1 in a bulk transfer and the transaction counter stops counting or this module receives a short packet
  - BUF setting: This module does not set the PID bits to BUF.
  - STALL setting: This module sets PID to STALL in the following cases and always sends STALL in response to a transaction.
- When a maximum packet size exceeded error is detected in a receive data packet
- When a control transfer sequence error is detected (DCP only)

(7) Data PID Sequence Bit

When data is successfully transferred in the control transfer data stage, bulk transfer, or interrupt transfer, this module automatically toggles the data PID sequence bit. The sequence bit of the data PID transmitted next can be monitored by the SQMON bit in DCPCTR and PIPEnCTR. In a data transmission period, the sequence bit switches at the ACK handshake receive timing. In a data reception period, the sequence bit switches at the ACK handshake transmit timing. The data PID sequence bit can also be changed by the SQCLR and SQSET bits in DCPCTR and PIPEnCTR.

In control transfers, this module automatically sets the sequence bit during a stage transition. DATA0 is indicated at the end of the setup stage, and DATA1 is used for responses in the status stage. This does not require the setting of the sequence bit by the software.

Note that the software must also set the data PID sequence bit when sending or receiving a ClearFeature request.

The sequence bit cannot be modified by the SQSET bit for isochronous transfer pipes.

(8) Response PID = NAK Function

This module has a function to disable the pipe operation (Response PID = NAK) at the last data packet receive timing in a transfer (this module automatically identifies the last data packet receive timing at the short packet receive timing or using the transaction counter) by setting the SHTNAK bit in PIPECFG to 1.

This function allows reception of data packets in transfer units when the buffer memory is used as a double buffer. Furthermore, when the pipe operation is disabled, the software must set the response PID to BUF to enable the pipe operation.

This function is available only for bulk transfers.

(9) Auto-Response Mode

When the ATREPM bit in PIPEnCTR is set to 1 in a bulk transfer pipe (pipes 1 to 5, 9 to F), this module enters auto-response mode: OUT-NAK mode in OUT transfers (DIR = 0) or null auto-response mode in IN transfers (DIR = 1).

1. OUT-NAK mode

   When the ATREPM bit is set to 1 in a bulk OUT transfer pipe, this module sends NAK in response to an OUT token or PING token and outputs an NRDY interrupt. To change response mode from normal mode to OUT-NAK mode, specify OUT-NAK mode with the pipe operation disabled (Response PID = NAK), and then enable the pipe operation (Response PID = BUF). After that, OUT-NAK mode is enabled. However, if an OUT token is received immediately before the pipe operation is disabled, this module receives the data of the token correctly and sends ACK to the host.

   To change response mode from OUT-NAK mode to normal mode, reset OUT-NAK mode with the pipe operation disabled (Response PID = NAK), and then enable the pipe operation (Response PID = BUF). In normal mode, this module can receive OUT data and sends ACK in response to a PING token when the buffer is ready for receiving.

2. Null auto-response mode

   When the ATREPM bit is set to 1 in a bulk IN transfer pipe, this module continues to send Zero-Length packets. To change response mode from normal mode to null auto-response mode, specify null auto-response mode with the pipe operation disabled (Response PID = NAK), and then enable the pipe operation (Response PID = BUF). After that, null auto-response mode is enabled. However, specify null auto-response mode while the buffer is empty. Verify this by checking INBUFM = 0. Since INBUFM = 1 indicates that the buffer contains data, clear the buffer by setting the ACLRM bit. Do not write data to the buffer from the FIFO port during setting to null auto-response mode.

To change response mode from null auto-response mode to normal mode, delay the pipe operation disabled state (Response PID = NAK) for a time period for sending a Zero-Length packet (full-speed: 10 µs, high-speed: 3 µs), and then reset null auto-response mode. Normal mode allows writing from the FIFO port, and also allows sending packets to the host by enabling the pipe operation (Response PID = BUF).

42.3.4 FIFO Buffer Memory

(1) Allocating FIFO Buffer Memory

Figure 42.9 shows an example of the FIFO buffer memory map of this module. The FIFO buffer memory is an area shared by the CPU and this module. There are two FIFO buffer memory states where the access right is given to the system (CPU) or to this module (SIE).

The FIFO buffer memory provides independent areas for each pipe. A memory area is set with the block start number and the number of blocks (BUFNMB and BUFSIZE bits in PIPEBUF) in 64-byte units as one block.

When continuous transfer mode is selected by the CNTMD bit in PIPEnCFG, be sure to set the BUFSIZE bits to a value in integral multiples of the maximum packet size. When double buffer is selected by the DBLB bit in PIPEnCFG, two sides of the memory area specified by the BUFSIZE bits in PIPEBUF are provided for the same pipe.

Furthermore, three FIFO ports are used for accesses (data read/write) to the buffer memory. The number of a pipe to be allocated to the FIFO ports is specified by the CURPIPE bits in CFIFOSEL and DnFIFOSEL.

The buffer status of each pipe can be monitored by the BSTS and INBUFM bits in DCPCTR and PIPEnCTR. The access right to the FIFO ports can be checked by the FRDY bit in CFIFOCTR and DnFIFOCTR.

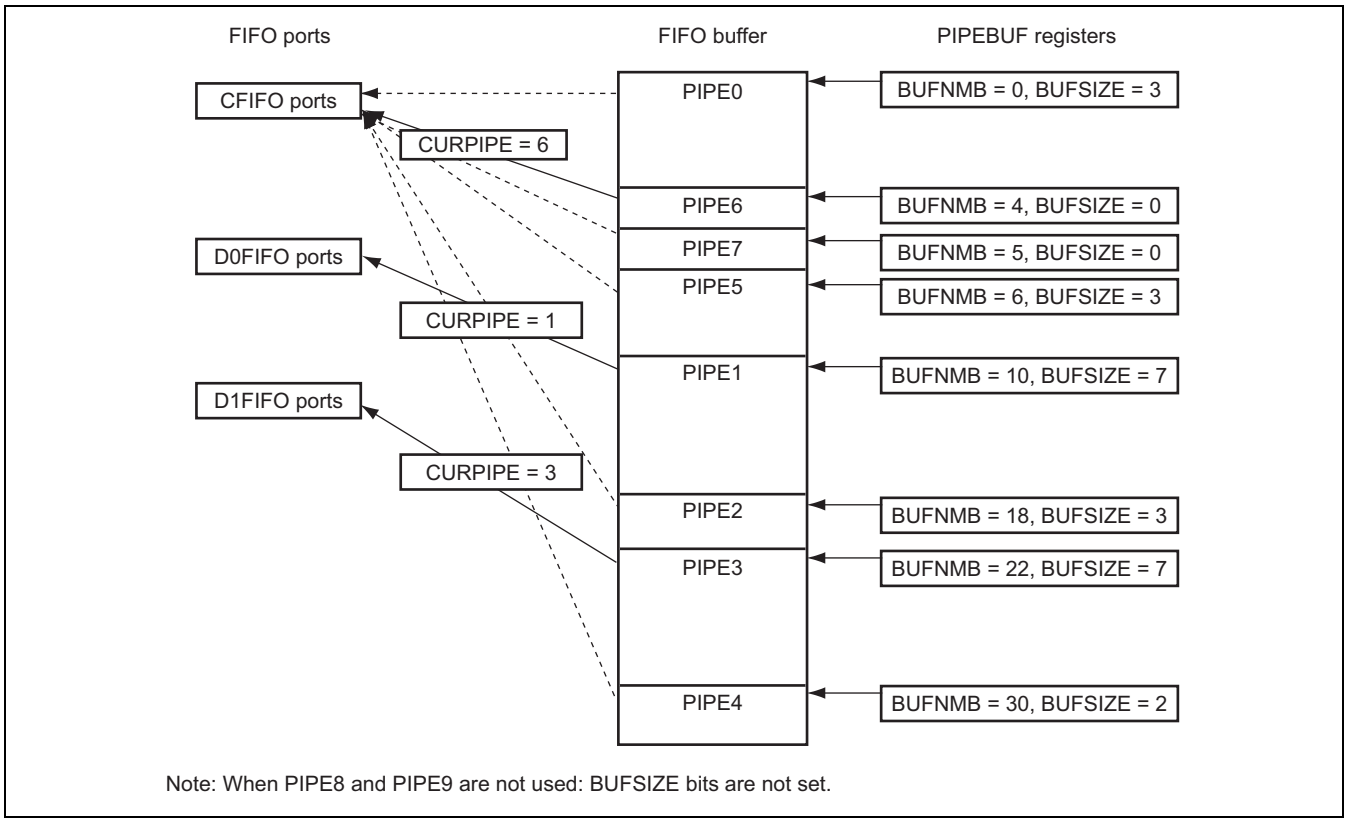

Figure 42.9 Example of Buffer Memory Map

- Buffer status

  Tables 42.14 and 42.15 show the buffer memory status of this module. The buffer memory status can be monitored by the BSTS bit in DCPCTR and the INBUFM bit in PIPEnCTR. The buffer memory access direction is specified by the DIR bit in PIPEnCFG or the ISEL bit in CFIFOSEL (when DCP is selected).

  The INBUFM bit is valid only for pipes 1 to 5, 9 to F in the transmit direction.

  When a transfer pipe in the transmit direction is set to double buffer, the BSTS bit is used to monitor the buffer status on the CPU side, and the INBUFM bit is used to monitor the buffer status on the SIE side. When data write to the FIFO port by the CPU (DMAC) takes time and buffer empty cannot be checked by the BEMP interrupt, the INBUFM bit is available to check completion of transmission.

Table 42.14 Buffer Memory Status That Varies Depending on the BSTS Bit

ISEL or DIR	BSTS	Buffer Memory Status
0 (receive direction)	0	No receive data in the buffer memory or data is being received. Data cannot be read from the FIFO port.
0 (receive direction)	1	Receive data in the buffer memory or a Zero-Length packet is received. Data can be read from the FIFO port. However, the buffer must be cleared because the FIFO port cannot be read when this module receives a Zero-Length packet.
1 (transmit direction)	0	Transmission of data is not completed. Data cannot be written to the FIFO port.
1 (transmit direction)	1	Transmission of data is completed. The CPU can write data to the buffer memory.

Table 42.15 Buffer Memory Status That Varies Depending on the INBUFM Bit

DIR	INBUFM	Buffer Memory Status
0 (receive direction)	Invalid	Invalid
1 (transmit direction)	0	Transmittable data is completely sent. No transmittable data is in the buffer memory.
1 (transmit direction)	1	Transmittable data is written from the FIFO port. The buffer memory contains transmittable data.

- FIFO buffer clear

  Table 42.16 shows clearing of the FIFO buffer memory of this module. The buffer memory can be cleared by the BCLR, DCLRM, and ACLRM bits.

Table 42.16 Buffer Clear

Bit Name	BCLR	DCLRM	ACLRM
Register	CFIFOCTR DnFIFOCTR	DnFIFOSEL	PIPEnCTR
Function	Clears the buffer memory of the CPU.	Automatically clears the buffer memory after reading data of the specified pipe.	Automatically clears the buffer memory by ignoring all received packets.
Clearing method	Writing 1 to this bit clears the buffer memory.	1: This mode is enabled. 0: This mode is disabled.	1: This mode is enabled. 0: This mode is disabled.

- Buffer area

  Table 42.17 shows a buffer memory map of this module. The buffer memory includes dedicated areas reserved beforehand for pipes and user areas provided for user settings.

  The buffer for DCP is a dedicated area commonly used in control read transfers and control write transfers.

  Areas for pipes 6 to 8 are allocated respectively in advance. However, when none of pipes 6 to 8 is used, the areas are available for pipes 1 to 5, 9 to F as user areas.

  Allocate different areas of the buffer memory to each pipe. Note that, when double buffer is specified, the size of an area is twice of the set value.

  Do not set the buffer size to a value smaller than the maximum packet size.

Table 42.17 Buffer Memory Map

Buffer Memory Number	Buffer Size	Pipe Setting	Remarks
H'0	64 bytes	Fixed only for DCP	Single buffer
H'1 to H'3	—	Unavailable	—
H'4	64 bytes	Fixed only for pipe 6	Single buffer
H'5	64 bytes	Fixed only for pipe 7	Single buffer
H'6	64 bytes	Fixed only for pipe 8	Single buffer
H'7 to H'7F	Max. 7616 bytes	User area for pipes 1 to 5, 9 to F	Double buffer and continuous transfer can be set

- Buffer auto-clear mode function

  When the ACLRM bit PIPEnCTR is set to 1, this module discards all data packets received. However, when this module receives a data packet successfully, it sends ACK to the host controller. This function is available only for the buffer memory read direction.

  Writing 1 and then 0 continuously to the ACLRM bit clears the buffer memory of the selected pipe irrespective of the access direction.

  Take at least 100 ns between writing 1 and writing 0 for the sequence execution time of the hardware.
- Buffer memory specifications (single buffer/double buffer setting)

  Single buffer or double buffer is selectable for pipes 1 to 5, 9 to F with the DBLB bit in PIPEnCFG. Double buffer is a function to provide two sides of the memory area specified by the BUFSIZE bits in PIPEBUF for the same pipe. Figure 42.10 shows an example of setting for the buffer memory of this module.

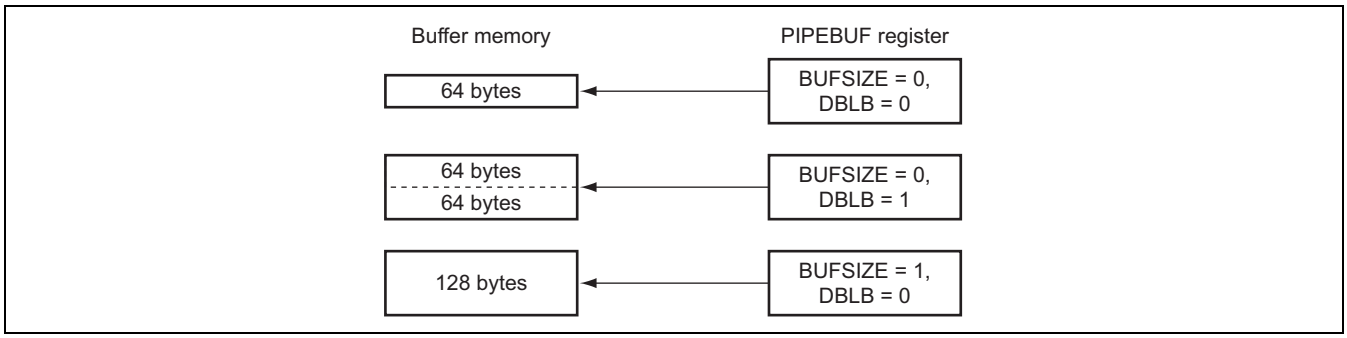

Figure 42.10 Example of Buffer Memory Setting

- Buffer memory operation (continuous transfer setting)

  Continuous transfer mode or discontinuous transfer mode is selectable with the CNTMD bit in PIPEnCFG. This selection is enabled for pipes 1 to 5, 9 to F.

  The continuous transfer mode function allows continuous transmission/reception of multiple transactions. When continuous transfer mode is selected, data up to the buffer size allocated to each pipe can be transferred without outputting an interrupt to the CPU.

  In continuous transmission mode, data in the buffer is divided by the maximum packet size and is then transmitted. To send data less than the buffer size (a short packet or a packet with a size of integral multiples of the maximum packet size and less than the buffer size), set BVAL = 1 after writing transmit data to the buffer.

  In continuous reception mode, no interrupt is generated until this module receives packets to the buffer size, the transaction count ends, or this module receives a short packet.

Table 42.18 shows the relationship between the CNTMD setting and determination of transmission/reception end of the FIFO buffer.

Table 42.18 Relationship between CNTMD Setting and Determination of Transmission/Reception End of FIFO Buffer

Transfer Mode	Determination of Buffer Readable State and Data Transmittable State
Discontinuous transfer (CNTMD = 0)	Conditions for FIFO buffer readable state when data receive direction is selected (DIR = 0): When this module receives one packet
	Conditions for FIFO buffer data transmittable state when data transmit direction is selected (DIR = 1): Any of the following cases: The software (or DMAC) writes data of the maximum packet size to the FIFO buffer. The software (or DMAC) writes data of a short packet (including 0 bytes) to the FIFO buffer, and then sets BVAL = 1.
Continuous transfer (CNTMD = 1)	Conditions for FIFO buffer readable state when data receive direction is selected (DIR = 0): When the bytes of data received in the FIFO buffer for the selected pipe equals the allocated bytes ((BUFSIZE + 1) × 64) When this module receives a short packet other than a Zero-Length packet When this module receives a Zero-Length packet when data is already stored in the FIFO buffer for the selected pipe When this module receives packets as large as the transaction counter value specified for the selected pipe by the software
	Conditions for FIFO buffer data transmittable state when data transmit direction is selected (DIR = 1): Any of the following cases: The volume of data written by the software (or DMAC) equals the size of one side of the FIFO buffer for the selected pipe. The software (or DMAC) writes data less than the size of one side of the FIFO buffer for the selected pipe to the FIFO buffer, and then sets BVAL = 1.

Figure 42.11 shows an example of buffer memory operation of this module.

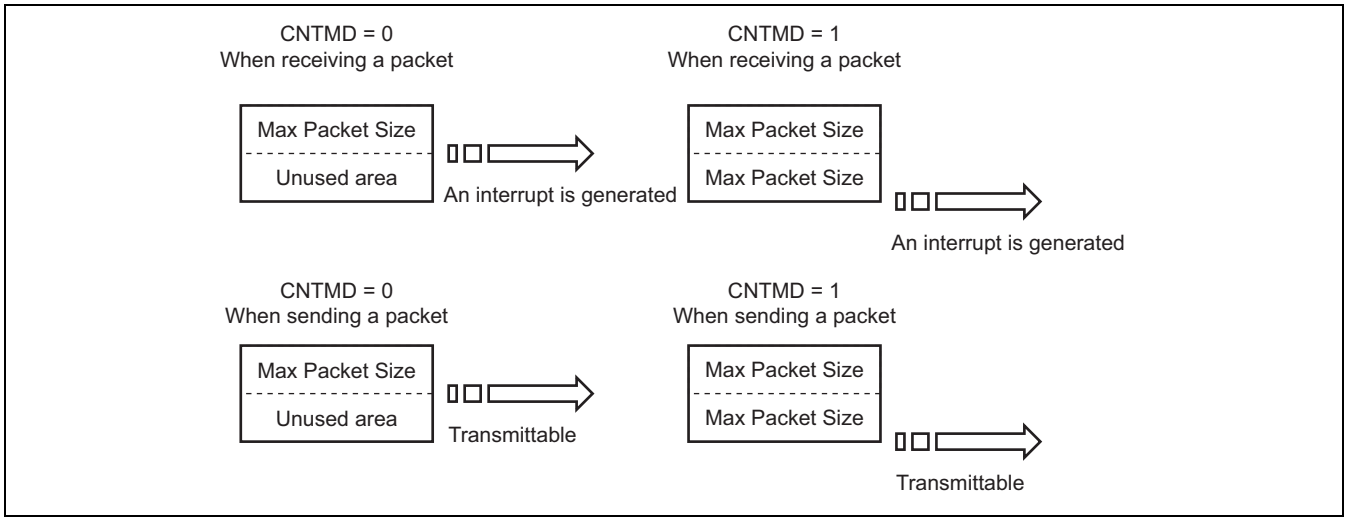

Figure 42.11 Example of Buffer Memory Operation

(2) FIFO Port Function

Table 42.19 lists the settings for the FIFO port functions of this module. During a data write access, when data up to buffer full (or up to the maximum packet size in discontinuous transfer) is written, the FIFO port automatically enters the data transmittable state. To make data less than buffer full (or the maximum packet size in discontinuous transfer) transmittable, set the BVAL bit in CFIFOCTR and DnFIFOCTR to 1 to set write end (DMA transfer: **TEND** signal). For transmission of a Zero-Length packet, clear the buffer using the BCLR bit in these registers and then set the BVAL bit to 1.

During a data read access, when all data is read, the FIFO port automatically enters the new packet receivable state. However, when receiving a Zero-Length packet (DTLN = 0), no data can be read. Therefore, clear the buffer using the BCLR bit in these registers. The receive data length can be checked by the DTLN bits in CFIFOCTR and DnFIFOCTR.

Table 42.19 FIFO Port Function Settings

Register Name	Bit Name	Function	Remarks
CFIFOSEL DnFIFOSEL	RCNT	Selects DTLN read mode.	
	REW	Rewinds the buffer memory (reread/rewrite).	
	DCLRM	Reads and clears receive data of the specified pipe.	DnFIFO only
	DREQE	Enables DMA transfer.	DnFIFO only
	MBW	Specify FIFO port access bit width.	
	BIGEND	Selects FIFO port endian.	
	ISEL	Selects FIFO port access direction.	DCP only
	CURPIPE	Select the current pipe.	
CFIFOCTR DnFIFOCTR	BVAL	Specifies buffer memory write end.	
	BCLR	Clears the buffer memory of the CPU.	
	DTLN	Check receive data length.	

(a) FIFO Port Selection

Table 42.20 shows pipes that can be selected in each FIFO port. Select a pipe to be accessed by the CURPIPE bits in CFIFOSEL and DnFIFOSEL. After selecting a pipe, confirm that the set CURPIPE value is read correctly, check FRDY = 1, and then make an access to the FIFO port. (If the previous pipe number is read, this controller is changing a pipe.)

Also select the bus width to be accessed by the MBW bits. The buffer memory access direction is specified by the DIR bit in PIPEnCFG. However, only the access direction of DCP is determined by the ISEL bit.

Table 42.20 FIFO Port Access

Pipe	Access	Available port
DCP	CPU access	CFIFO port register
Pipes 1 to F	CPU access	CFIFO port register
	DMA access	D0FIFO, D1FIFO, D2FIFO and D3FIFO port

(b) REW Bit

The current access to a pipe can be suspended temporarily, and it is also possible to make an access to another pipe to continue the ongoing pipe processing. This processing is allowed by using the REW bit in CFIFOSEL and DnFIFOSEL.

When the REW bit is set to 1 together with the CURPIPE bits in CFIFOSEL and DnFIFOSEL and a pipe is selected, the reading or writing pointer of the buffer memory is reset, which allows reading or writing data from the first byte. Furthermore, when a pipe is selected with the REW bit set to 0, data can be read or written following the data at the previous selection without resetting the reading or writing pointer of the buffer memory.

To make accesses to the FIFO port, select a pipe and check FRDY = 1.

(3) DMA Transfer (Dedicated DMA Interface)

(a) Overview of DMA Transfer

The FIFO port can be accessed by the DMAC for pipes 1 to F. When the buffer of a pipe specified for DMA transfer becomes accessible, this module outputs a DMA transfer request.

Specify the data transfer unit to the FIFO port by the MBW bits in DnFIFOSEL, and select a pipe used for DMA transfer by the CURPIPE bits in DnFIFOSEL. Do not change the selected pipe during a DMA transfer.

(b) DMA Transfer End Auto-Recognition

This module can terminate writing of data by DMA transfer to the FIFO buffer by controlling the DMA transfer end signal input. After sampling the transfer end signal, this module drives the buffer memory into the transmittable state (same state as BVAL = 1).

(c) DnFIFO Auto-Clear Mode (D0FIFO, D1FIFO, D2FIFO and D3FIFO Port Read Direction)

By setting the DCLRM bit in DnFIFOSEL to 1, this module automatically clears the buffer memory for the selected pipe upon completion of data read from the buffer memory.

Table 42.21 shows the relationship between packet reception and buffer memory clear by the software. As shown in the table, buffer clearing conditions vary with the BFRE setting. However, in any state that needs clearing, using the DCLRM bit makes buffer clearing by the software unnecessary. Thus DMA transfer is enabled without requiring any software control.

- This function is available only for the buffer memory read direction.

Table 42.21 Relationship between Packet Reception and Buffer Memory Clear by the Software

Buffer Status When Receiving a Packet	Register Setting			
	DCLRM = 0		DCLRM = 1	
	BFRE = 0	BFRE = 1	BFRE = 0	BFRE = 1
Buffer full	Clearing not required	Clearing not required	Clearing not required	Clearing not required
Zero-Length packet reception	Clearing required	Clearing required	Clearing not required	Clearing not required
Normal short packet reception	Clearing not required	Clearing required	Clearing not required	Clearing not required
Transaction count end	Clearing not required	Clearing required	Clearing not required	Clearing not required

42.3.5 Control Transfer (DCP)

The default control pipe (DCP) is used for data transfer in the control transfer data stage. The buffer memory for the DCP is a 64-byte single buffer of a fixed area used for both control read and control write. The buffer memory can be accessed only by the CFIFO ports.

(1) Setup Stage

1. This module always sends ACK in response to a normal setup packet to this module. The following describes the operation of this module in the setup stage.
   When this module receives a new setup packet, this module sets the following bits.
   — The VALID bit in INTSTS0 to 1
   — The PID bits in DCPCTR to NAK
   — The CCPL bit in DCPCTR to 0
2. When this module receives a data packet following a setup packet, this module stores the USB request parameters in USBREQ, USBVAL, USBINDX, and USBLENG.

Be sure to process responses to control transfers while VALID = 0. The PID bits cannot be set to BUF when VALID = 1, and therefore the data stage cannot be completed.

With the VALID bit function, this module can suspend the ongoing request processing if this module receives a new USB request during a control transfer, and send a response to the latest request.

This module also determines the direction bit (bit 8 of bmRequestType) of the received USB request and the request data length (wLength), identifies a control read transfer, control write transfer, and control write no-data transfer, and controls stage transitions. For an incorrect sequence, a sequence error of the control transfer stage transition interrupt occurs, and the error is reported to the software. For the stage control of this module, see Figure 42.7.

(2) Data Stage

Transfer data in response to the received USB request using the DCP. Before making an access to the DCP buffer memory, specify the access direction by the ISEL bit in CFIFOSEL.

When the transfer data size is larger than the DCP buffer memory size, use a BRDY interrupt for control write transfers and a BEMP interrupt for control read transfers.

In the high-speed control write transfer, this module sends responses using the NYET handshake according to the buffer memory status.

(3) Status Stage

Setting the CCPL bit to 1 with the PID bits in DCPCTR set to BUF finishes a control transfer.

After these settings, this module executes the status stage as follows according to the data transfer direction determined in the setup stage:

- Control read transfer
  This module sends a Zero-Length packet and receives an ACK response from the USB host.
- Control write transfer, no-data control transfer
  This module receives a Zero-Length packet from the USB host and sends an ACK response.

(4) Control Transfer Auto-Response Function

This module automatically responds to a correct SET_ADDRESS request. If any of the following errors occurs in the SET_ADDRESS request, the software must respond to the error.

- Other than control read transfer: bmRequestType ≠ H'00
- Request errors: wIndex ≠ H'00
- Other than no-data control transfer: wLength ≠ H'00
- Request errors: wValue > H'7F
- Control transfer of device state errors: DVSQ = B'011 (configured)

All requests other than SET_ADDRESS require a response made by the software.

42.3.6 Bulk Transfer (Pipes 1 to 5, 9 to F)

The buffer memory usage (single buffer/double buffer setting or continuous/discontinuous transfer mode setting) can be selected for bulk transfers. The buffer memory size can be set to up to 2 Kbytes. This module manages the buffer memory status and automatically responds to a PING packet and an NYET handshake.

(1) NYET Handshake Control

Table 42.22 lists NYET handshake responses of this module. This module sends a NYET response under the following conditions. However, when this module receives a short packet, this module sends ACK instead of NYET. The same is true of the control write transfer data stage.

Table 42.22 NYET Handshake Responses

Setting of PID Bits in DCPCTR	Buffer Memory Status	Token	Response	Remarks
NAK/STALL	—	SETUP	ACK	—
	—	IN/OUT/PING	NAK/STALL	—
BUF	—	SETUP	ACK	—
	RCV-BRDY1	OUT/PING	ACK	Receives a data packet when receiving an OUT token.
	RCV-BRDY2	OUT	NYET	Receives a data packet. Sends a “reception disable” response.
	RCV-BRDY2	OUT (Short)	ACK	Receives a data packet. Sends a “reception enable” response.
	RCV-BRDY2	PING	ACK	Sends a “reception enable” response.
	RCV-NRDY	OUT/PING	NAK	Sends a “reception disable” response.
	TRN-BRDY	IN	DATA0/1	Sends a data packet.
	TRN-NRDY	IN	NAK	TRN-NRDY

[Legend]
RCV-BRDY1: The buffer memory has available space for two packets or more when receiving an OUT or PING token.
RCV-BRDY2: The buffer memory has available space for only one packet when receiving an OUT token.
RCV-NRDY: The buffer memory is occupied when receiving an PING token.
TRN-BRDY: The buffer memory contains transmit data when receiving an IN token.
TRN-NRDY: The buffer memory contains no transmit data when receiving an IN token.

42.3.7 Interrupt Transfer (Pipes 6 to 8 and A)

This module performs interrupt transfer following the cycles controlled by the host controller. In interrupt transfers, this module ignores PING packets (no response), sends no NYET handshake, and sends ACK, NAK, and STALL responses.

This module does not support the High-Bandwidth interrupt transfer.

42.3.8 Isochronous Transfer (Pipes 1, 2)

This module is provided with the following functions for isochronous transfers.

- Reporting isochronous transfer error information
- Interval counter (IITV bits)
- Isochronous IN transfer data setup control (IDLY function)
- Isochronous IN transfer buffer flush function (IFIS bit)

This module does not support the isochronous High-Bandwidth transfer.

(1) Isochronous Transfer Error Detection

This module is provided with a function to detect the following error information so that the software can manage isochronous transfer errors. Tables 42.23 and 42.24 show the error detection priority of this module and interrupts generated as a result of error detection.

1. PID error
   — When the PID in a receive packet is invalid
2. CRC error, bit stuffing error
   — When a CRC error is found in a receive packet or bit stuffing is invalid
3. Maximum packet size exceeded error
   — When the data size of a receive packet is over the maximum packet size setting
4. Overrun/underrun error
   — When the buffer memory contains no data when this module receives an IN token in the IN direction (transmission) transfer
   — When the buffer memory is occupied when this module receives an OUT token in the OUT direction (reception) transfer
5. Interval error
   This module generates an interval error in the following cases.
   — When no IN token can be received in interval frames in the isochronous IN transfer
   — When this module receives an OUT token other than interval frames in the isochronous OUT transfer

Table 42.23 Error Detection when Receiving Tokens

Priority for Error Detection	Error	Interrupt and Status
1	PID error	This module generates no interrupt (ignores as a damaged packet).
2	CRC error, bit stuffing error	This module generates no interrupt (ignores as a damaged packet).
3	Overrun error, underrun error	This module generates an NRDY interrupt and sets the OVRN bit. This module sends a Zero-Length packet in response to the IN token. This module receives no data packet in response to the OUT token.
4	Interval error	This module generates an NRDY interrupt.

Table 42.24 Error Detection when Receiving Data Packets

Priority for Error Detection	Error	Interrupt and Status
1	PID error	This module generates no interrupt (ignores as a damaged packet).
2	CRC error, bit stuffing error	This module generates an NRDY interrupt and sets the CRCE bit.
3	Maximum packet size exceeded error	This module generates a BEMP interrupt and sets the PID bits to STALL.

(2) DATA-PID

This module does not support the High-Bandwidth transfer. The following lists responses to received PIDs when the function controller function is selected.

1. IN direction
   - DATA0: Sent correctly as the PID of data packet.
   - DATA1: Not sent
   - DATA2: Not sent
   - mDATA: Not sent
2. OUT direction (full-speed operation)
   - DATA0: Received correctly as the PID of a data packet.
   - DATA1: Received correctly as the PID of a data packet.
   - DATA2: The packet is ignored.
   - mDATA: The packet is ignored.
3. OUT direction (high-speed operation)
   - DATA0: Received correctly as the PID of a data packet.
   - DATA1: Received correctly as the PID of a data packet.
   - DATA2: Received correctly as the PID of a data packet.
   - mDATA: Received correctly as the PID of a data packet.

(3) Interval Counter

Intervals for isochronous transfers can be set by the IITV bits in PIPEPERI. The functions shown in Table 42.25 are made available with the interval counter.

Table 42.25 Interval Counter Functions

Transfer Direction	Function	Detection Conditions
IN	Transmit buffer flush	No IN token can be successfully received in the interval frame during the isochronous IN transfer.
OUT	Reporting reception of no token	No OUT token can be successfully received in the interval frame during the isochronous OUT transfer.

Since the interval counter is counted upon receiving an SOF or using the interpolated SOF, the isochronism can be maintained even if the SOF is damaged. The specifiable frame interval is 2^{IITV} frames or 2^{IITV} μ frames.

(a) Counter initialization

This module initializes the interval counter as follows:

- Power-on reset
  The IITV bits are initialized.
- Initializing buffer memory by ACLRM
  The IITV bits are not initialized but the interval counter is initialized. Clearing the ACLRM bit to 0 causes the counter to start counting from the set IITV value.
- USB bus reset.

After the interval counter is initialized, the interval counter starts counting in either of the following cases after a packet is correctly transferred.

1. When this module receives an SOF after sending data in response to the IN token with PID = BUF
2. When this module receives an SOF after receiving the OUT token data with PID = BUF

The interval counter is not initialized under the following conditions.

1. When PID = NAK or STALL
   The interval timer does not stop. Try to execute the transaction in the next interval.
2. USB bus reset and USB suspended
   The IITV bits are not initialized. When this module receives an SOF, the interval counter starts counting from the value before receiving the SOF.

(b) Interval count and transfer control

1. When the selected pipe is Isochronous-OUT transfer pipe
   When this module receives no data packet in (μ) frames at the intervals specified by the IITV bits, this controller generates an NRDY interrupt.
   When this module cannot receive data due to a CRC error in the data packet, FIFO buffer full, or other reasons, this module also generates an NRDY interrupt.
   An NRDY interrupt is generated at the SOF packet receive timing. Even if the SOF packet is damaged, this module generates an NRDY interrupt at the SOF packet receive timing using the internal interpolation function.
   When IITV ≠ 0, however, this module generates an NRDY interrupt at the SOF packet receive timing in each interval after the interval count starts.
   When PID = NAK is set by the software after the interval timer is activated, this module generates no NRDY interrupt even when this module receives an SOF packet.

The interval count start conditions vary with the set IITV value.

— When IITV = 0: The interval count starts from the next (μ) frame where the PID bits for the selected pipe is changed to BUF.

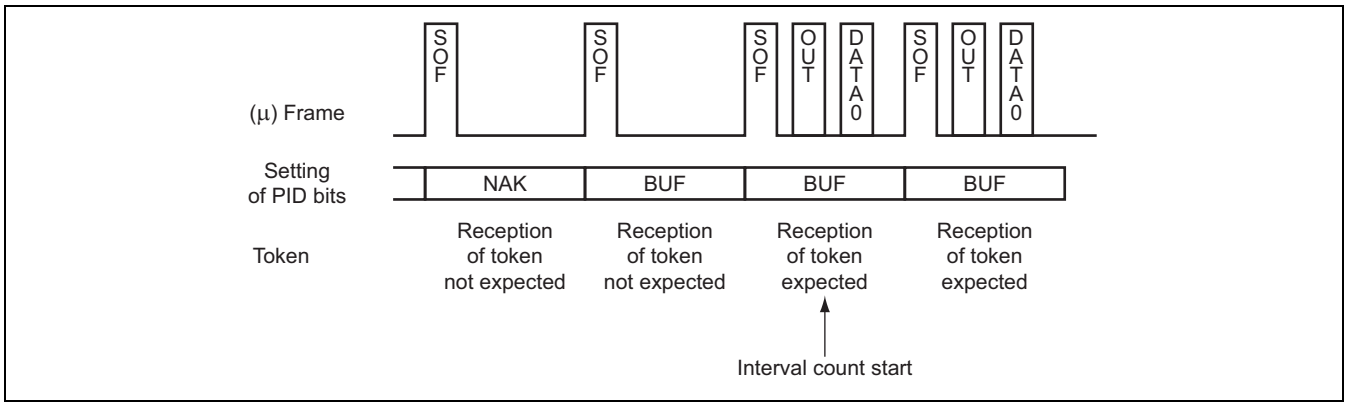

Figure 42.12 (μ) Frames and Expectation of Receiving a Token when IITV = 0

— When IITV ≠ 0: The interval count starts from the time when this module successfully receives the first data packet after the PID bits for the selected pipe is changed to BUF.

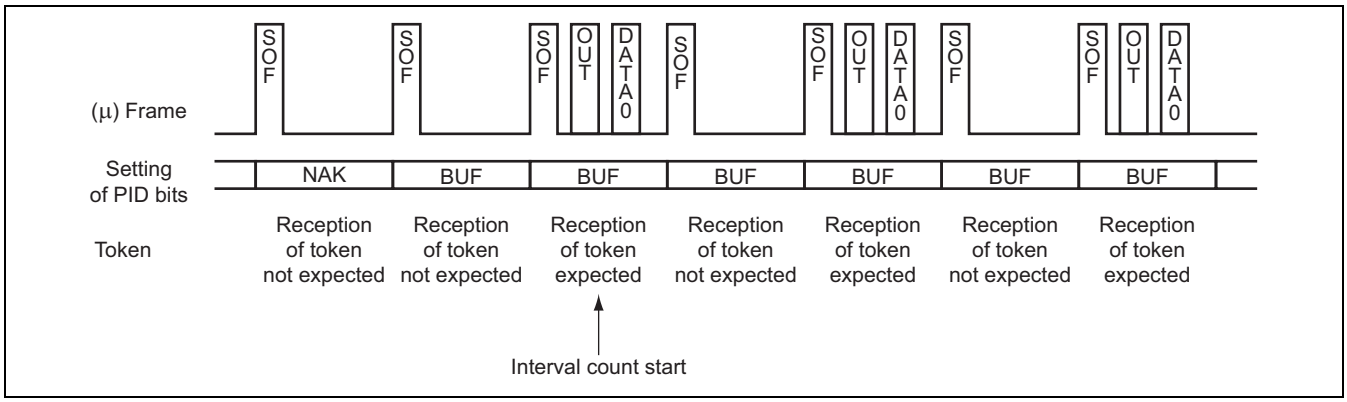

Figure 42.13 (μ) Frames and Expectation of Receiving a Token when IITV ≠ 0

2. When the selected pipe is Isochronous-IN transfer pipe

Use the selected pipe by combining with the setting of IFIS = 1. When IFIS = 0, this module sends data packets in response to received tokens irrespective of the IITV value.

When this module receives no IN-Token in (μ) frames at the intervals specified by the IITV bits with transmittable data stored in the FIFO buffer with IFIS = 1, this module clears the FIFO buffer.

When this module cannot receive data due to a CRC error or another bus error in the IN-Token, this module also clears the FIFO buffer.

The FIFO buffer is cleared at the SOF packet receive timing. Even if the SOF packet is damaged, this module clears the FIFO buffer at the SOF packet receive timing using the internal interpolation function.

The interval count start conditions vary with the set IITV value (same as Isochronous-OUT transfer).

When the function controller function is selected, the interval count start conditions are as follows:

— When this module is reset by the hardware (The set IITV value is also cleared to 0.)

— When ACLRM is set to 1 by the software

— When this module detects a USB reset

(4) Transmit Data Setup in Isochronous Transfer

In isochronous data transmission is selected, this module can send a data packet in the next frame after this module detects an SOF packet after writing data to the buffer. This function is referred to as the isochronous transfer transmit data setup function. With this function, the frame that started data transmission can be identified.

When the buffer memory is used as a double buffer, even if writing data to both buffers is completed, only one side that finished writing earlier becomes transferable. For this reason, even if multiple IN tokens are received in the same frame, only one packet of the buffer memory is sent.

When the buffer memory is ready for transmission in the IN token reception cycle, this module sends data and an ACK response. However, when the buffer memory is not ready for transmission, this module sends a Zero-Length packet and generates an underrun error.

Figure 42.14 shows an example of transmission using the isochronous transfer transmit data setup function of this module when IITV = 0 (each frame). Transmission of a Zero-Length packet is indicated as hatched “Null” in the figure.

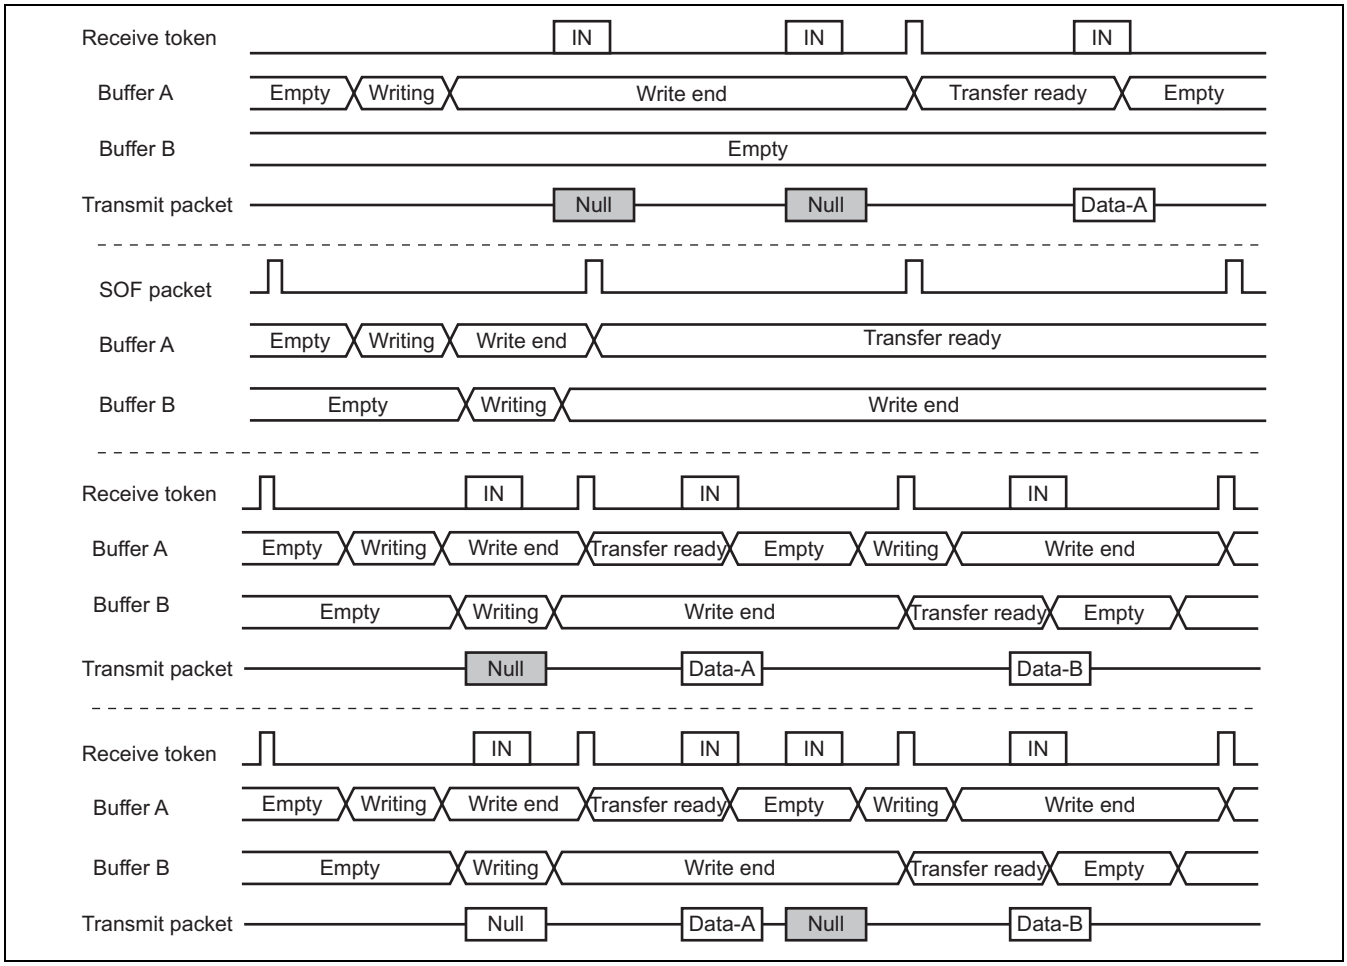

Figure 42.14 Example of Transmit Data Setup Function

(5) Transmit Buffer Flush in Isochronous Transfer

In isochronous data transmission is selected, this module receives no IN token in the interval frame. When this module receives the SOF or µ SOF packet of the next frame, this module regards the IN token as damaged and clears the buffer that is ready for transmission to make it writable.

At this time, when the buffer memory is used as a double buffer and writing data to both buffers is completed, this module regards the discarded buffer memory data as transmitted in the same interval frame, and drives the buffer memory that is not discarded due to the reception of an SOF or µ SOF packet into the transmission ready state.

The buffer flush function activation timing varies depending on the IITV value.

- When IITV = 0
  This module activates the buffer flush function from the next frame after the pipe is enabled.
- When IITV ≠ 0
  This module activates the buffer flush function from the first normal transaction.

Figure 42.15 shows an example of the buffer flush function of this module. For tokens before the interval frame (outside the specified interval), however, this module sends the data stored in the buffer according to the data setup state or sends a Zero-Length packet as an underrun error.

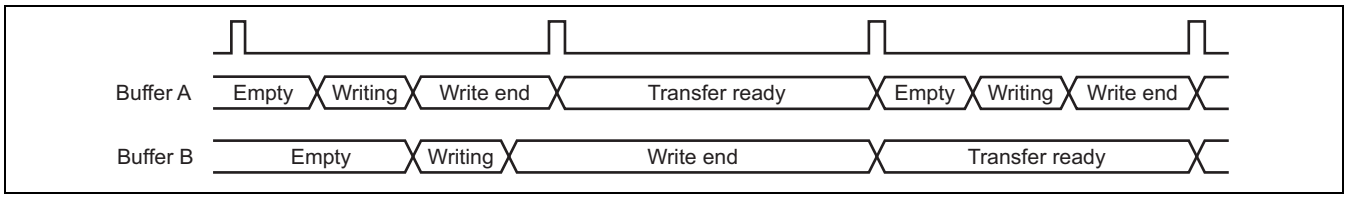

Figure 42.15 Example of Buffer Flush Function

Figure 42.16 shows an example of an interval error of this module. Interval errors are the following five. An interval error occurs at timing [1] in the figure, and the buffer flush function is activated.

When an interval error occurs, the buffer flush function is activated in the IN transfer and an NRDY interrupt occurs in the OUT transfer. Discriminate an NRDY interrupt (including a receive packet error) from an overrun error with the OVRN bit.

This module sends a response to the hatched tokens in the figure according to the buffer memory status.

1. IN direction
   — When the buffer is ready to transmit data, this module sends the data and an ACK response.
   — When the buffer is not ready to transmit data, this module sends a Zero-Length packet and generates an underrun error.
2. OUT direction
   — When the buffer is ready to receive data, this module receives data and sends an ACK response.
   — When the buffer is not ready to receive data, this module discards the data and generates an overrun error.

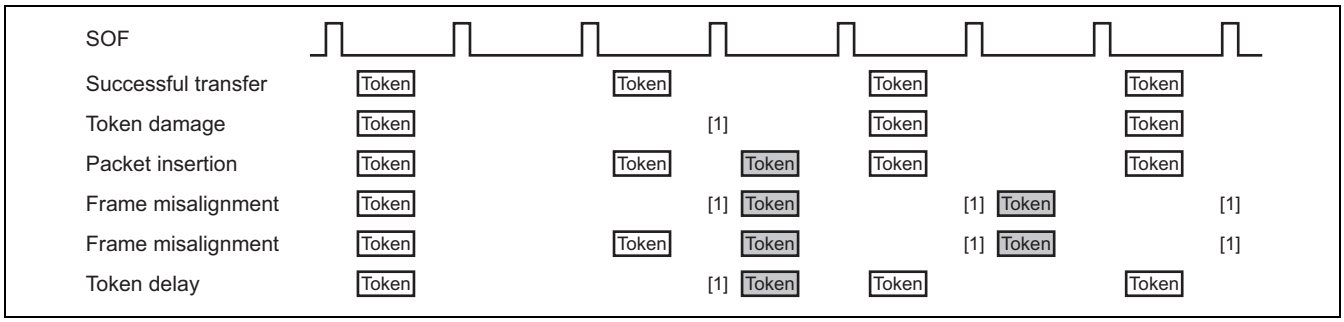

Figure 42.16 Example of Interval Error when IITV = 1

42.3.9 SOF Interpolation Function

In case this module cannot receive SOF packets at intervals of 1 ms (full-speed operation) or 125 µs (high-speed operation) due to damage or missing of SOF packets, this module interpolates the SOF. The SOF interpolation starts functioning when SYSCFG.USBE = 1 and at the SOF packet receive timing. Furthermore, the interpolation function is initialized in the following cases.

- Power-on reset
- USB bus reset
- When the suspended state is detected

The SOF interpolation functions with the following specifications.

- The frame intervals (125 µs or 1 ms) conform to the result of the reset handshake protocol.
- The SOF interpolation does not function until this module receives an SOF packet.
- After receiving the first SOF packet, 125 µs or 1 ms is counted by the internal 48-MHz clock to interpolate the SOF.
- After receiving the second SOF packet or a following packet, the SOF is interpolated using the previous receive intervals.
- The SOF interpolation does not function in the suspended state and during a USB bus reset.
  (When this module enters the suspended state in high-speed operation, the SOF interpolation continues for 3 ms from the final packet.)

This module activates the following functions based on the reception of SOF packets. When one or more SOF packets are lost, normal operation can be continued to perform the SOF interpolation.

- Updating frame numbers and µ frame numbers
- SOFR interrupt timing and µ SOF lock
- SOF pulse output
- Isochronous transfer interval count

When one or more SOF packets are lost in full-speed operation, the FRNM bits in FRMNUM are not updated. When one or more µ SOF packets are lost in high-speed operation, the UFRNM bits in the UFRMNUM are updated. However, when a µ SOF packet with UFRNM = B'000 is lost, the FRNM bits are not updated even if following µ SOF packets with UFRNM ≠ B'000 are successfully received.

42.4 Guidelines for Designing USB2.0 Hi-Speed Boards

42.4.1 USB Transmission Line.

The USB transmission line indicates the pattern that connects the USB connector and the USB transceiver with built-in this LSI.

The USB2.0 has three communication modes: Hi-Speed, Full-Speed and Low-Speed modes. The transmission speed in the Hi-Speed mode is 480 Mbps. Therefore, the USB transmission line must be designed as a high-frequency circuit. Impedance control is required for the USB transmission line.

- The characteristic impedance required for the USB Hi-Speed transmission line is differential impedance 90 Ω (±15%).
- The pattern width and pattern pitch for impedance control vary depending on the board thickness, material and layer configuration. For details, consult the board manufacturer.
- A maximum delay of 1 ns is allowed from the USB connector to this LSI. Therefore it is recommended that the pattern length from the USB device to the USB connector is less than 50 mm and the difference between the pattern lengths for D+ and D− is less than 2.5 mm for a generic PCB.
- The lower layer of the USB transmission line must be a solid ground plane. The ground must be wider than the USB transmission line by 2 mm or more. The power supply for a solid ground plane is VSS.
- Do not allocate other signal lines near to the USB transmission line. In particular, lines carrying widely fluctuating signals, such as clock and data bus lines, must be assigned far from the USB transmission line. Furthermore, layout of the USB transmission lines must be such that they do not cross with other signal lines.
- Locate the USB transmission line on the same layer without passing it through a through-hole. Do not create stubs.
- Place the USB transmission lines so that they are equally spaced from each other.
- Locate the USB transmission line as far as possible from the oscillator, power supply circuit, and other I/O connectors.
- Try to avoid bending the USB transmission line as far as possible. If it is absolutely necessary to bend it, do not bend it at acute or right angles. Bend it moderately, at not more than 45 degrees, or bend it into an arc.
- It is recommended to guard ring the clock, reset, read, write and chip select signals with grounds.

When a resistance is connected to the USB transmission line, locate it near to the USB transmission line. The connecting wire must be as short as possible.

42.4.2 Power Supply and Ground Pattern

Analog power supply:	VCCQA_USB(3.3 V), VDDA_USBPLL(1.2V)
Digital power supply:	VDD(1.2V), VCCQ(3.3V)
Analog ground:	VSSA_USB
Digital ground:	VSS

- It is recommended to separate power supplies and ground patterns into digital and analog.
- Connect the power supplies and grounds firmly on wide areas.
- Tantalum solid electrolytic capacitors or ceramic capacitors having excellent high-frequency characteristics are recommended as capacitors for power supplies.
- Aluminum electrolytic capacitors affect the jitter value during measurement of EYE diagram. Use the capacitors after adequately designing and testing them.
- It is recommended to place decoupling capacitors with values of 0.1 µF, 0.01 µF, and 0.001 µF as close as possible to the USB power supply.

42.4.3 Oscillation

- USB clock is supplied by the internal PLL.
- Provide an oscillation circuit near the clock input pin for USB (EXTAL). It is recommended to guard ring EXTAL with a ground.
- When using a crystal resonator, consult its manufacturer to determine the circuit constant.

42.4.4 VBUS

- The HS-USB subsystem can connect 5V VBUS signal to USB0_VBUS and USB1_VBUS pin. It enables to detect VBUS level but it can’t supply power to device.

42.4.5 RREF Pin

- Provide a resistor (hereafter called reference resistor) of 5.6kΩ ±1%, between the RREF pin and VSSA_USB.
- Locate the reference resistor as close as possible to this LSI.
- The RREF pin, the reference resistor, VSSA_USB should be wired on wide areas and the shortest length.
- Use a wiring pattern for and only for the reference resistor, VSSA_USB. The pattern should be connected to the analog ground. The pattern should be designed avoiding the possibility for common impedance between RREF and other signals.
- To prevent cross talk, very-frequently switched signals such as DP, DM, clocks, and control signals for addresses and data, should not be placed near to the reference resistor, and their patterns should neither get across nor go parallel to the wiring pattern between the reference resistor and the RREF pin.

It is recommended to guard ring the reference resistor and its wiring pattern with ground.

43. USB High-Speed DMAC (USB-DMAC)

43.1 Overview

43.1.1 Features

- Three types of clock: ZSϕ, HPϕ and HS-USB local bus clock (48 MHz), which are asynchronously absorbed in the local bus bridge and AXI bus bridge.
- The AXI bus interface functions are implemented.
- The AXI bus interface handles data transfer with the memory and register settings.
- Data communication is performed using the local DMA protocol.
- Supports two channels that can work concurrently.
- Interrupts
  - Setting count end interrupt
  - USB-DMAC is composed of USB-DMAC0 and USB-DMAC1. There are 2 channels in USB-DMAC0 and 2 channels in USB-DMAC1.
  - Transfer end interrupt upon receiving a short packet from the USB-IP

    This function allows generation of an interrupt even in the case where DMA transfer ends after receiving data less than the transfer size set in the DMAC.
  - Timeout interrupt

    A timeout interrupt can be generated after the specified cycles after the last HS-USB transfer request. (This interrupt is used for the timeout when the final packet received is Max packet.)
  - Interrupts can also be generated when a NULL packet is received or an address error is detected.

Table 43.1 Main Functions of This Module

Item	Description
Application	Transfer between USB-IP (FIFO) and AXI bus (4-Gbyte arbitrary space)
Purpose of DMA transfer	High-speed data transfer between USB-IP and AXI bus
DMA transfer end notification to the software	Interrupt signals (transfer count end, USB-IP short packet reception, timeout, etc.)
Transfer space/transfer address direction	4-Gbyte arbitrary space (forward direction) to 4-Gbyte arbitrary space (forward direction)
Maximum transfer count	16,777,216
Transfer unit	8, 16, or 32 bytes
Control signals generated	Address/data read/data write conforming to the USB-IP local bus interface and AXI bus protocols
Number of channels	2 (parallel operation enabled)
Bus specification	AXI bus, local bus (USB-IP local bus)
Clock	AXI bus clock (ZSϕ: 260 MHz), HPB bus clock (HPϕ: 130 MHz) USB local bus clock (48 MHz) Note: The restrictions of ratio of the clock ZSϕ ≥ HPϕ ≥ 48 MHz Please don't change the clock frequency during USB-DMAC0 or USB-DMAC1 transferring.

Item	Description
Maximum transfer rate	IN transfer: About 350 Mbps (USB-DMAC0) OUT transfer: About 340 Mbps (USB-DMAC0) IN transfer: About 175 Mbps (USB-DMAC1) OUT transfer: About 170 Mbps (USB-DMAC1)

Table 43.2 Bus Access Type

	Supported Access Type
AXI bus access (USB-DMAC master)	8-byte read/write 16-byte read/write 32-byte read/write
USB-DMAC register setting	4-byte read/write 8-byte read/write

The configuration of this module is shown below.

This module is provided with buffers and bus bridges and controls transfers between the AXI bus and USB High-Speed module (HS-USB).

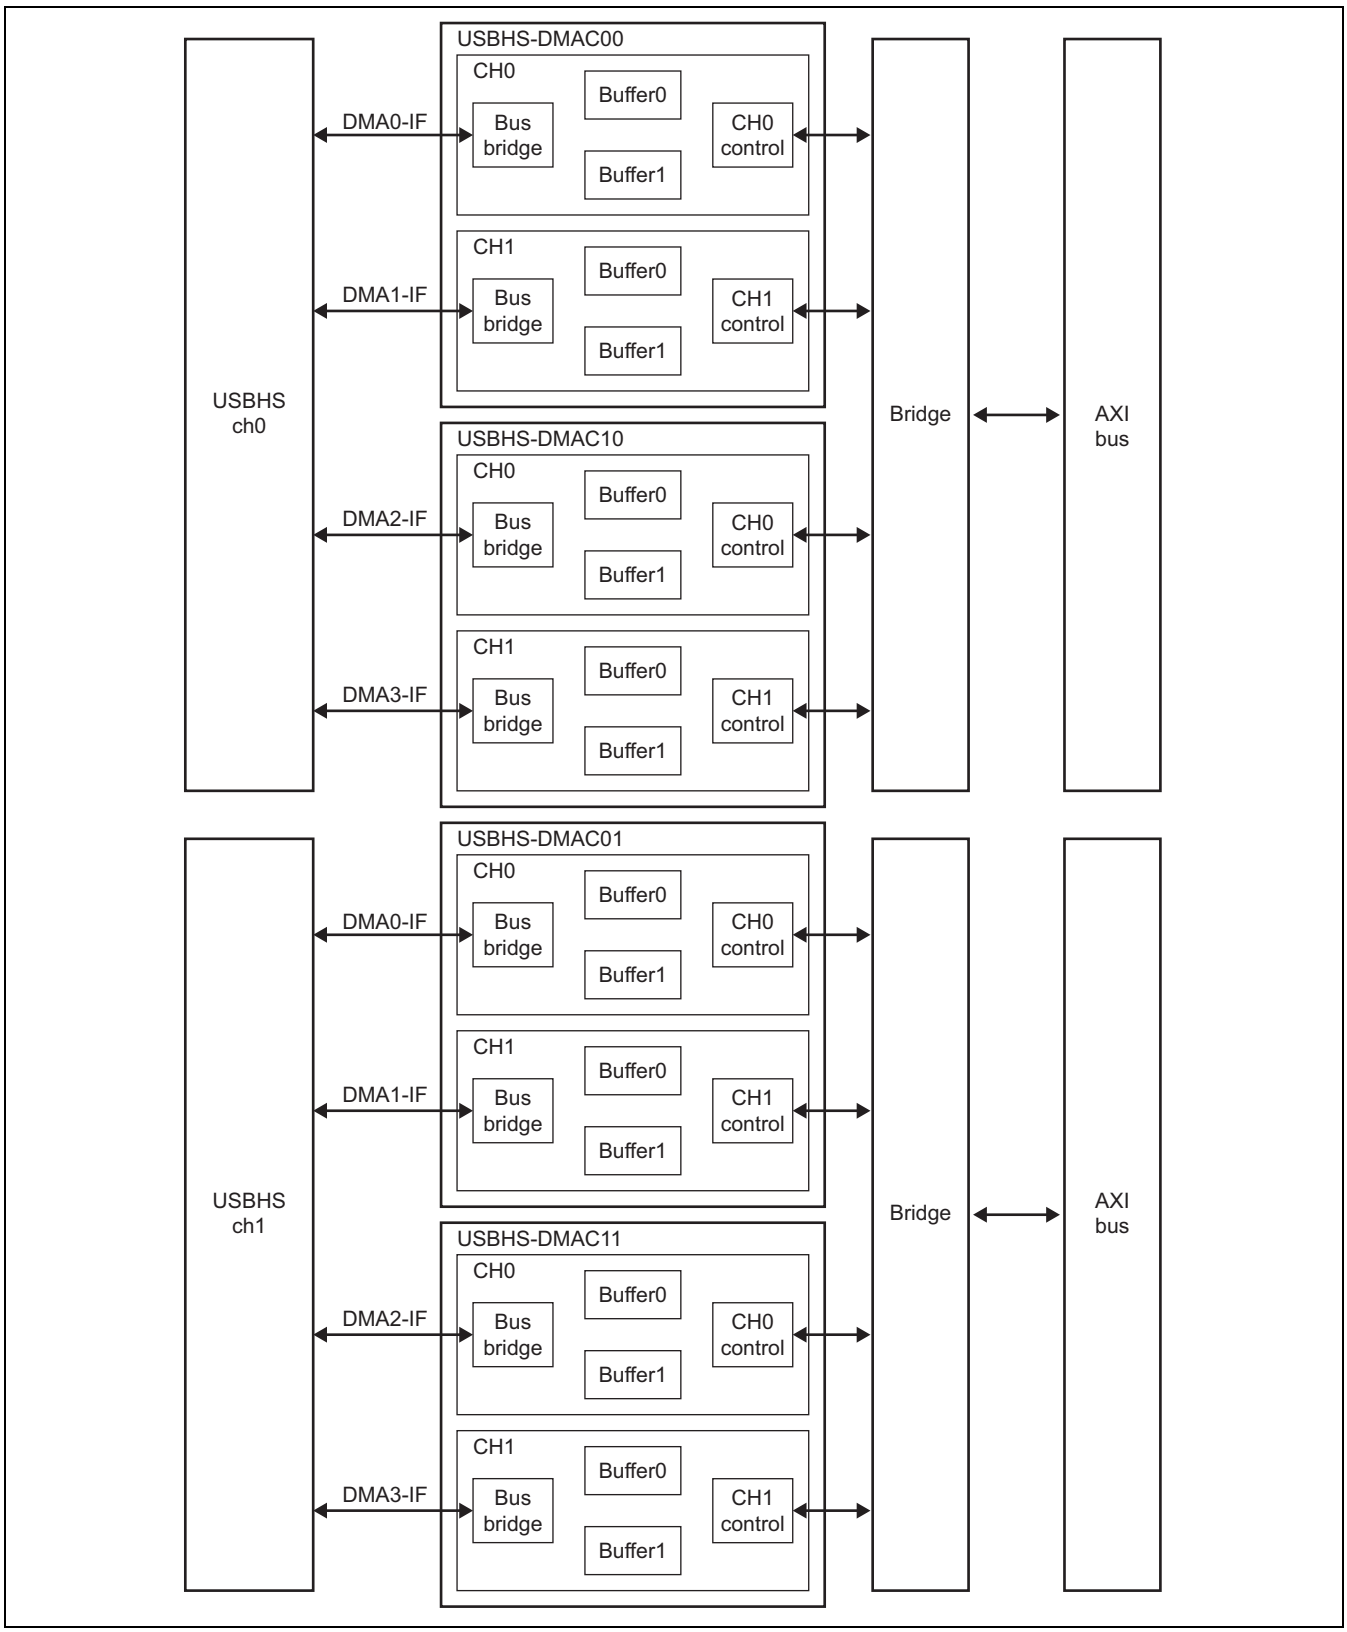

Figure 43.1 USB-DMAC Configuration

43.2 Register Descriptions

USB-DMAC Base Address

USB-DMAC	Base Address
USB-DMAC00	H'E65A 0000
USB-DMAC10	H'E65B 0000
USB-DMAC01	H'E65A 8000
USB-DMAC11	H'E65B 8000

Table 43.3 shows the register configuration. Table 43.4 shows the register states in each processing mode.

Table 43.3 Register Configuration

Register Name	Abbreviation	R/W	Address Offset	Access Size

43.2.1 DMA0/1 VCR Register (USBDMA0_VCR/USBDMA1_VCR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ERR_SNT	ERR_RCV
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	ERR_SNT	0	R/W	Send Error Response 0: No error is generated. [Clearing condition] Writing 0 after reading 1. 1: An error is generated.
0	ERR_RCV	0	R/W	Receive Error Response 0: No error is generated. [Clearing condition] Writing 0 after reading 1. 1: An error is generated.

43.2.2 DMA0/1 Software Reset Register (USBDMA0_SWR/USBDMA1_SWR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SWR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	SWR	0	R/W	Software Reset 0: Cancels reset. 1: Resets entire system. (No effect for register setting) Note: On software reset, this bit should be held high for long enough until the internal circuit stabilizes. When this bit is set to 1, it is recommended to allow several tens of clocks if operating at 260 MHz for a reset period before clearing the reset (setting this bit to 0) as a precaution.

43.2.3 DMA0/1 Interrupt Source Register (USBDMA0_DMICR/USBDMA1_DMICR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SHBSY1	—	—	—	—	—	—	—	SHBSY0	—	—	—	—	—	—	AE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

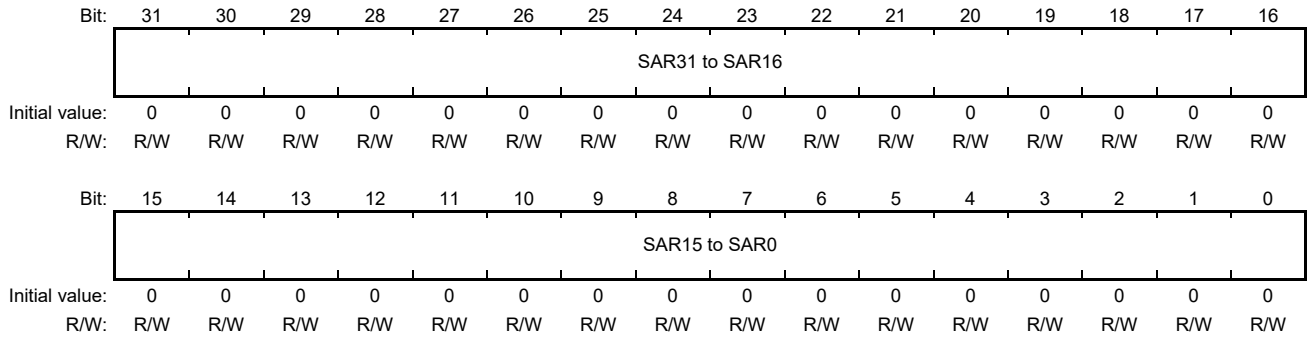
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31	SHBSY1	0	R	CH1 AXI Bus Busy Flag Monitor 0: The AXI bus is idle. 1: The AXI bus is busy.
30 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23	SHBSY0	0	R	CH0 AXI Bus Busy Flag Monitor 0: The AXI bus is idle. 1: The AXI bus is busy.
22 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	AE	0	R	Address Error Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (AE in the DMA operation register is reflected.)
15	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
14	TR1	0	R	CH1 Transaction End: Receive Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (TR in the channel 1 control register is reflected.)
13	BUF1	0	R	CH1 Buffer End Detect Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (BUF in the channel 1 control register is reflected.)
12	RW1	0	R	CH1 Final Buffer Access Detect Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (RW in the channel 1 control register is reflected.)
11	NULL1	0	R	CH1 NULL Packet Receive Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (NULL in the channel 1 control register is reflected.)

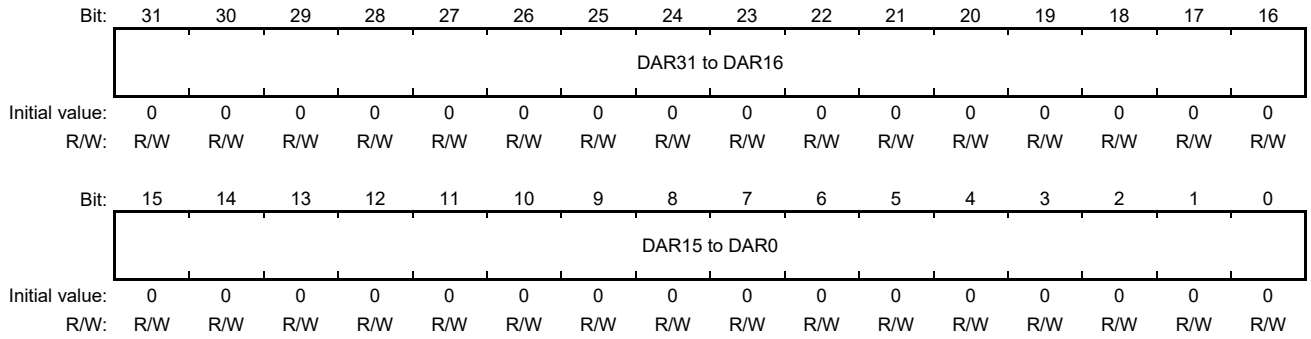
Bit	Bit Name	Initial Value	R/W	Description
10	TO1	0	R	CH1 Timeout Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (TO in the channel 1 control register is reflected.)
9	SP1	0	R	CH1 Short Packet Receive Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (SP in the channel 1 control register is reflected.)
8	TE1	0	R	CH1 Transfer End Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (TE in the channel 1 control register is reflected.)
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	TR0	0	R	CH0 Transaction End Detect Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (TR in the channel 0 control register is reflected.)
5	BUF0	0	R	CH0 Buffer End Detect Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (BUF in the channel 0 control register is reflected.)
4	RW0	0	R	CH0 RWEND Receive Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (RW in the channel 0 control register is reflected.)
3	NULL0	0	R	CH0 NULL Receive Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (NULL in the channel 0 control register is reflected.)
2	TO0	0	R	CH0 Timeout Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (TO in the channel 0 control register is reflected.)
1	SP0	0	R	CH0 Short Packet Receive Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (SP in the channel 0 control register is reflected.)
0	TE0	0	R	CH0 Transfer End Interrupt Source 0: No interrupt is generated. 1: An interrupt is generated. (TE in the channel 0 control register is reflected.)

43.2.4 DMA0/1 Source Address Registers 0 and 1 (USBDMA0_SAR_0/USBDMA1_SAR_1)



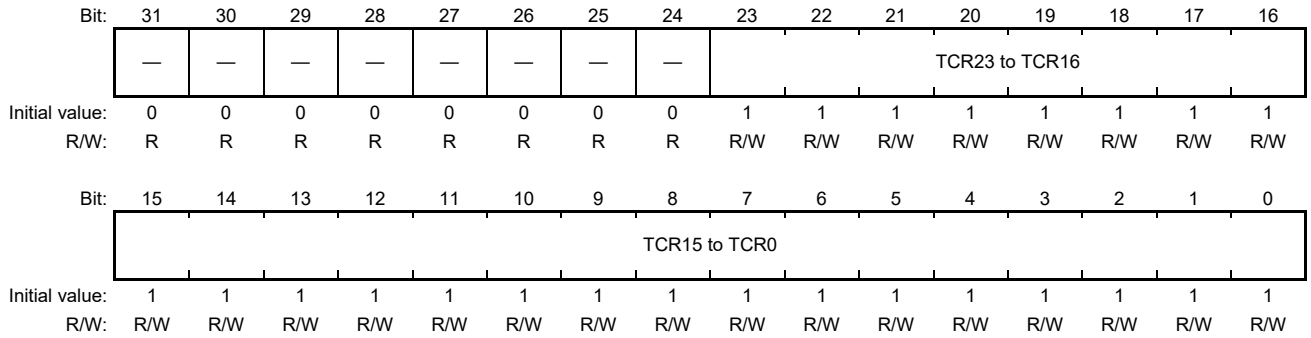
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	SAR31 to SAR0	H'0000 0000	R/W	Source Address (H'0000 0000 to H'FFFF FFFF (4 Gbytes)) Set a value of 8-byte, 16-byte, or 32-byte boundary. Indicate the next transfer source address during a DMA transfer.

43.2.5 DMA0/1 Destination Address Registers 0 and 1 (USBDMA0_DAR_0/USBDMA1_DAR_1)



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	DAR31 to DAR0	H'0000 0000	R/W	Destination Address (H'0000 0000 to H'FFFF FFFF (4 Gbytes)) Set a value of 8-byte, 16-byte, or 32-byte boundary. Indicate the next transfer destination address during a DMA transfer.

43.2.6 DMA0/1 Transfer Count Registers 0 and 1 (USBDMA0_TCR_0/USBDMA1_TCR_1)



Bit	Bit Name	Initial Value	R/W	Description
31 to 24	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
23 to 0	TCR23 to TCR0	H'FF FFFF*	R/W	Transfer Count • When H'00 0001 is set, total transfer volume is as follows: Transfer size = 32 bytes: 32 × 1 bytes Transfer size = 16 bytes: 16 × 1 bytes Transfer size = 8 bytes: 8 × 1 bytes • When H'FF FFFF is set, 16,777,215 times • When H'00 0000 is set, 16,777,216 times (maximum) • Indicate 0 when a DMA transfer completes successfully.

Note: * To read this register, read the internal transfer counter value (the TCR counter value) directly. This register is read as all 1 after a reset is cleared because the initial value of the TCR counter is all 1 (H'FF FFFF). When DMA is enabled (DE in USBDMA0/1_CHCR is asserted), the TCR counter is loaded with the value set in this register and decrements during DMA transfers. This means that the remaining transfer count is read back. Note that the read value may be different from the one set in this register due to this reason.

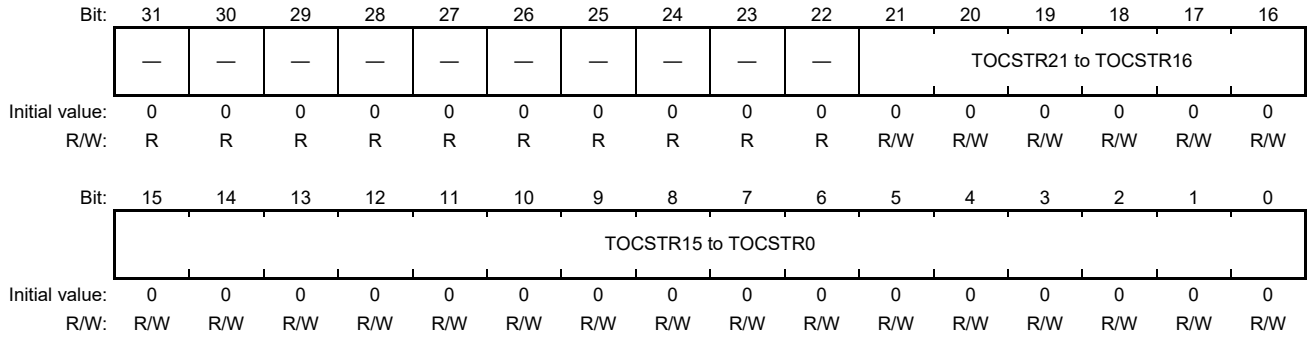
43.2.7 DMA0/1 Timeout Count Registers 0 and 1 (USBDMA0_TOCNTR_0/USBDMA1_TOCNTR_1)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	TOCNTR21 to TOCNTR16					
Initial value:	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TOCNTR15 to TOCNTR0															
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21 to 0	TOCNTR21 to TOCNTR0	H'3F FFFF	R	Timeout Counter Value (H'00 0000 to H'27 AC40) Indicate the remaining timeout count during timeout counting. (Countable up to H'3F FFFF (approximately 21 ms) by the hardware. See the descriptions of the USBDMA0/1_TOCSTR register.)

43.2.8 DMA0/1 Timeout Constant Registers 0 and 1 (USBDMA0_TOCSTR_0/USBDMA1_TOCSTR_1)



Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21 to 0	TOCSTR21 to TOCSTR0	H'00 0000	R/W	Timeout Constant Value (H'00 0000 to H'27 AC40) Set a timeout value (at 200 MHz cycle). The maximum timeout time is approximately 13ms. (Setting up to H'3F FFFF (approximately 21 ms) is allowed by the hardware.)

43.2.9 DMA0/1 Channel Control Registers 0 and 1 (USBDMA0_CHCR_0/USBDMA1_CHCR_1)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	FTE	—	—	—	SPIM	TRE	BUFE	RWE	NULLE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R/W	R	R	R	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TR	BUF	RW	NULL	—	—	—	—	TS1	TS0	IE	TOE	TO	SP	TE	DE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	FTE	0	(R)/W	Forced TE Set Register When a NULL packet is received, the TE bit is forced to 1 to terminate the transfer by setting 1 in this register. (The DREQE bit of the USB-IP should also be controlled accordingly. For details on the control procedure and restrictions, see section 43.3.2 (3), DMA transfer flow.) This bit is always read as 0. 0: No effect (nothing happens). 1: Forces the TE bit to 1.
23 to 21	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
20	SPIM	0	R/W	Short Packet Receive Interrupt Mask Enables or disables the reflection of the short packet (SP) receive flag in the interrupt signal. If this bit is set to 1, no interrupts are generated when an SP is received. However, the SP receive flag (the SP bit) is set regardless of this register setting. 0: The short packet receive interrupt is enabled (default). 1: The short packet receive interrupt is disabled.
19	TRE	0	R/W	Transaction End Detect Interrupt Flag Enable Enables or disables the reflection of TR in the interrupt signal and the DMA stop/restart control. (When this bit is set to 0, the TR bit is always 0.) 0: The TR flag is disabled. 1: The TR flag is enabled.
18	BUFE	0	R/W	Buffer End Detect Interrupt Flag Enable Enables or disables the reflection of BUF in the interrupt signal and the DMA stop/restart control. (When this bit is set to 0, the BUF bit is always 0.) 0: The BUF flag is disabled. 1: The BUF flag is enabled.

Bit	Bit Name	Initial Value	R/W	Description
17	RWE	0	R/W	Final Buffer Access Detect Interrupt Flag Enable Enables or disables the reflection of RW in the interrupt signal and the DMA stop/restart control. (When this bit is set to 0, the RW bit is always 0.) 0: The RW flag is disabled. 1: The RW flag is enabled.
16	NULLE	0	R/W	NULL Receive Interrupt Flag Enable Enables or disables the reflection of the NULL receive interrupt flag (NULL) in the interrupt signal. 0: The NULL receive interrupt flag is disabled. 1: The NULL receive interrupt flag is enabled.
15	TR	0	R/W*	Transaction End Detect Interrupt Flag When the transaction end is detected, an interrupt is generated. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A transaction end receive interrupt is generated.
14	BUF	0	R/W*	Buffer End Detect Interrupt Flag When the end of the buffer is detected, an interrupt is generated. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A buffer end detect interrupt is generated.
13	RW	0	R/W*	Final Buffer Access Detect Interrupt Flag When the final access to the buffer is detected, an interrupt is generated. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A final buffer access detect interrupt is generated.
12	NULL	0	R/W*	NULL Receive Interrupt Flag When NULL packet is received, an interrupt is generated. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A NULL packet receive interrupt is generated.
11 to 8	—	All 0	R	Reserved The bits should always be written as 0.
7, 6	TS1 to TS0	00	R/W	DMA Transfer Size 00: 8 bytes 01: 16 bytes 10: 32 bytes 11: Setting prohibited Specify the same transfer size and address boundary when setting addresses in USBDMA0/1_SAR and USBDMA0/1_DAR as a transfer source and transfer destination. If TS = 11 is set, an address error is generated and DMA transfer is disabled.

Bit	Bit Name	Initial Value	R/W	Description
5	IE	0	R/W	Interrupt Enable Enables or disables an interrupt request to the CPU when DMA transfer ends. When AE, TE, SP, TO, NULL, RW, BUF, or TR bit is set with this bit set to 1, an interrupt request is output to the CPU. However, when the TRE, BUFE, RWE, NULLE, or TOE bit is set to disabled, no interrupt due to TR, BUF, RW, NULL, or TO is generated. 0: An interrupt request is disabled. 1: An interrupt request is enabled.
4	TOE	0	R/W	Timeout Enable Enables or disables the reflection of the timeout flag (TO) in the interrupt. 0: Timeout flag is disabled. 1: Timeout flag is enabled.
3	TO	0	R/W*	Timeout Flag After a transfer request REQ is negated, a timeout interrupt is generated after the specified cycles. (Used for timeout when the final packet is Max packet.) 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: Timeout is generated.
2	SP	0	R/W*	Short Packet Receive Flag A transfer end interrupt is generated upon receiving a short packet from the USB-IP. For example, if DMA transfer size is set to 1 MB but actual data transfer is 900 KB, this interrupt is generated when transfer of 900 KB finishes. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: A short packet is received.
1	TE	0	R/W*	Transfer End Flag When a DMA transfer ends with USBDMA0/1_TCR = 0, the TE bit is set to 1. When a DMA address error occurs before USBDMA0/1_TCR is cleared to 0 and the transfer is suspended by clearing the DE bit and the DME bit in USBDMA0/1_DMAOR, the TE bit is not set to 1. To clear the TE bit, write 0 after reading 1. When TE = 1, DMA transfer is disabled even if the DE bit is set to 1. 0: DMA transfer is in progress or suspended. [Clearing condition] Writing 0 after reading 1. 1: DMA transfer end (TCR = 0)
0	DE	0	R/W	DMA Enable Enables or disables DMA transfer. Setting the DME bit in USBDMA0/1_DMAOR and the DE bit for the corresponding channel to 1 starts a DMA transfer, provided that all interrupt flags are 0. Clearing the DE bit to 0 suspends the ongoing transfer after the transfer of one transaction is completed. 0: DMA transfer is disabled. 1: DMA transfer is enabled.

Note: * Only writing 0 to clear the flag is enabled.

43.2.10 DMA0/1 Final Transaction Valid Data Transfer Enable Registers 0 and 1 (USBDMA0_TEND_0/USBDMA1_TEND_1)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	EDTEN31 to EDTEN16															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	EDTEN15 to EDTEN0															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	EDTEN31 to EDTEN0	H'0000 0000	R/W	Final Transaction Valid Data Transfer Enable (valid only for IN transfers) Specify valid data size in units of bytes in the final transaction of data transfer (see section 43.3.2, DMA Transfer Function). H’8000 0000: 32 bytes × (n-1) + 1 byte H’C000 0000: 32 bytes × (n-1) + 2 bytes : H’FFFF FFFF: 32 bytes × (n-1) + 32 bytes Notes: 1. n: Transfer count setting (TCR) 2. For the 8-byte transfer, set EDTEN23 to EDTEN0 to 0. For the 16-byte transfer, set EDTEN15 to EDTEN0 to 0.

43.2.11 DMA0/1 Operation Register (USBDMA0_DMAOR/USBDMA1_DMAOR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	TID1 and TID0		RM	PR1 and PR0		AE	DME
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W*	R/W*	R/W	R/W	R/W	R/W*	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6, 5	TID1 and TID0	00	R/W*	Response Error Channel Identity Information TID1 indicates the channel 1 error information, and TID0 indicates the channel 0 error information. TID1 0: No error 1: Channel 1 response packet error TID0 0: No error 1: Channel 0 response packet error [Setting condition] When a CH0 (1) response error occurs [Clearing condition] Clearing ERR_RCV in USBDMA0/1_VCR (Channel 0/channel 1 concurrent clear)
4	RM	0	R/W	Response Error Mask Mode 0: A response error is output. 1: A response error is masked.
3, 2	PR1 and PR0	00	R/W	Priority Mode Specify the priority of channels to execute transactions when transfer requests are made simultaneously in both channel 0 and channel 1 as follows: 00: Channel 0 > Channel 1 01: Channel 1 > Channel 0 10: Setting prohibited (If PR = 10 is set, channel 0 > channel 1) 11: Setting prohibit

Bit	Bit Name	Initial Value	R/W	Description
1	AE	0	R/W*	Address Error Flag Indicates that an address error interrupt occurred when setting USBDMA0/1_SAR or USBDMA0/1_DAR. This flag is set to 1 when the value of USBDMA0/1_SAR or USBDMA0/1_DAR differs from the transfer size (TS) boundary, and when the TS bits are set to 11 (setting prohibited). When the AE bit is set to 1, DMA transfer is not enabled even if the DE bit in DMACHCR and the DME bit in USBDMA0/1_DMAOR are set to 1. 0: No address error interrupt is generated by the DMAC. [Clearing condition] Setting USBDMA0/1_SAR and USBDMA0/1_DAR to values that match the transfer size boundary. 1: An address error interrupt is generated.
0	DME	0	R/W	DMA Master Enable Enables or disables DMA transfers for all channels. When the DME bit and the DE bit in USBDMA0/1_CHCR are set to 1, DMA transfer is enabled, provided that all interrupt flags in USBDMA0/1_CHCR of the transfer channel are 0. Clearing the DME bit suspends the DMA transfer for all channels. 0: DMA transfer for all channels is disabled. 1: DMA transfer for all channels is enabled.

Note: * Only writing 0 to clear the flag is enabled.

43.3 Operation

43.3.1 Interrupt/Error Detection Function

This section describes the interrupt/error detection function that is implemented in this module.

Table 43.5 lists the mask, source, and flag registers for each interrupt type.

Table 43.5 Registers by Interrupts/Errors

	Interrupt Generation	Interrupt Mask Register	Interrupt Mask Register (Individual Mask)	Source Register	Flag Register
Transfer count end	√	X*1_CHCR_x.IE	—	X*1_DMICR.TEx	X*1_CHCR_x.TE
Short packet receive	√	X*1_CHCR_x.IE	X*1_CHCR_x.SPIM	X*1_DMICR.SPx	X*1_CHCR_x.SP
NULL packet receive	√	X*1_CHCR_x.IE	X*1_CHCR_x.NULLE	X*1_DMICR.NULLx	X*1_CHCR_x.NULL
Timeout	√	X*1_CHCR_x.IE	X*1_CHCR_x.TOE	X*1_DMICR.TOx	X*1_CHCR_x.TO
Transaction end detect	√	X*1_CHCR_x.IE	X*1_CHCR_x.TRE*	X*1_DMICR.TRx	X*1_CHCR_x.TR
Buffer end detect	√	X*1_CHCR_x.IE	X*1_CHCR_x.BUFE*	X*1_DMICR.BUFx	X*1_CHCR_x.BUF
Final buffer access detect	√	X*1_CHCR_x.IE	X*1_CHCR_x.RWE*	X*1_DMICR.RWx	X*1_CHCR_x.RW
Address error	√	X*1_CHCR_x.IE	—	X*1_DMICR.AE	X*1_DMAOR.AE
Response packet error	—	—	—	—	X*1_VCR.ERR_SNT X*1_VCR.ERR_RCV

Legend: X*1: USBDMA0/USBDMA1

Note: These registers not only mask interrupt generation but also disable error processing (flag sources and flag clearing).

Table 43.6 shows the processing to be executed when different interrupts occur. DMA transfer control is not affected when the NULL packet is received, timeout, or response packet error interrupt occurs. When the transfer count end interrupt occurs, processing is restarted. Processing can be resumed or restarted after interrupts occur from other sources.

Table 43.6 Processing to be Executed When Interrupts Occur (Suspend/Resume/Restart)

	Suspend/Resume	Terminate/Restart	Suspend/Resume/Restart Control Mask Register
Transfer count end	—	√	—
Short packet receive	√	√	—
NULL packet receive	—	√*	—
Timeout	—	√	—
Transaction end detect	√	√	USBDMA0/1_CHCR_x.TRE
Buffer end detect	√	√	USBDMA0/1_CHCR_x.BUFE
Final buffer access detect	√	√	USBDMA0/1_CHCR_x.RWE
Address error	√	√	—
Response packet error	—	—	—

Note: * When a NULL packet is received, processing is forced to be terminated and restarted by the FTE bit (see section 43.3.2 (3), DMA transfer flow.).

The internal circuit is reloaded register values when restarted, but not when resumed.

Table 43.7 lists the interrupt generating conditions.

Table 43.7 Interrupt Generating Conditions

Interrupt Name	Interrupt Conditions
Transfer count end interrupt	When the final data transfer of the specified transfer count (in the USBDMA0/1_TCR register) completes IN transfer: When the final access to USB-IP completes OUT transfer: When the data transmission to the AXI completes
Short packet receive interrupt	When the data transfer at the time the end of a transaction is detected completes
NULL packet receive interrupt	When a NULL packet is detected or the forced TE register is set
Timeout interrupt	When the specified time elapses after the last transfer request
Transaction end detect interrupt	When the end of a transaction is detected
Buffer end detect interrupt	When the end of the buffer is detected
Final buffer access detect interrupt	When the final access to the buffer is detected
Address error interrupt	When invalid access to the DMAC register is attempted (With invalid USBDMA0/1_SAR/USBDMA0/1_DAR values or invalid transfer size (TS) specified)
Response packet error	Error Transmission (ERR_SNT) When accessed by a transaction that is not supported Error Reception (ERR_RCV) When received a response packet error from the system

Figure 43.2 shows a block diagram of the interrupt circuit.

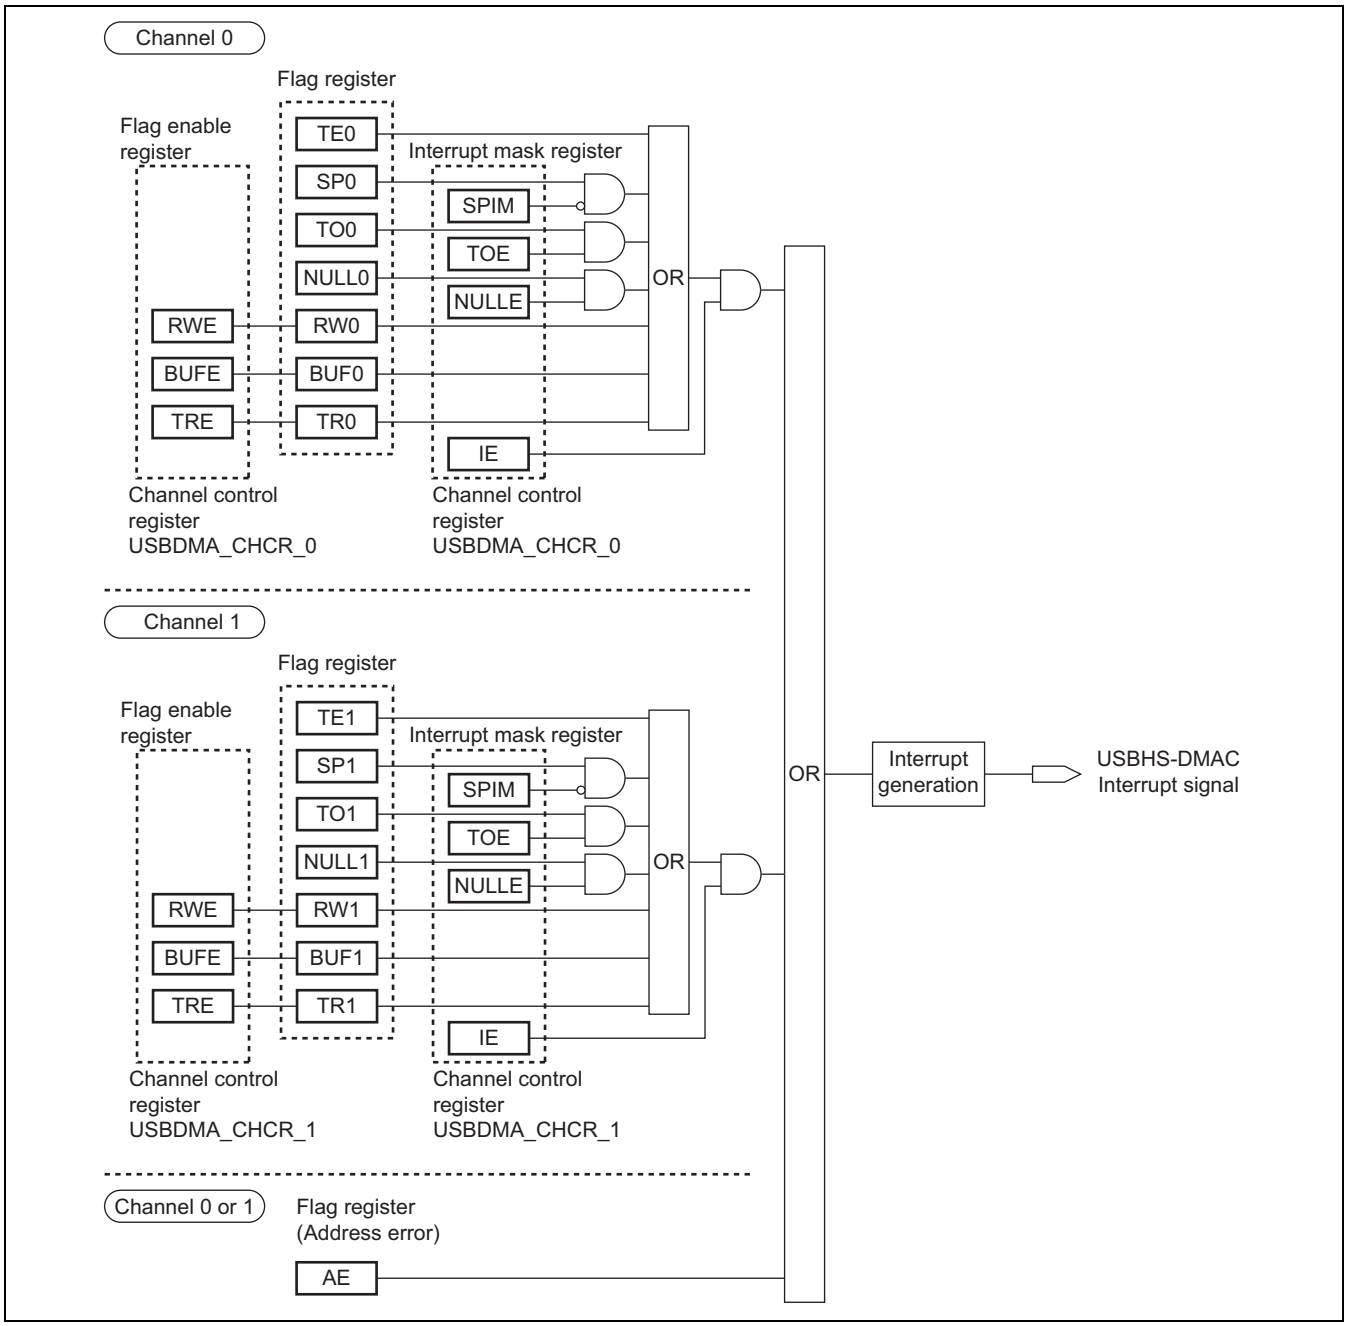


Figure 43.2 Block Diagram of Interrupt Circuit

(1) Transfer count end interrupt (TE flag)

Can be generated when the specified number of transfers complete or the FTE bit in the channel control register (USBDMA0/1_CHCR_0 to USBDMA0/1_CHCR_1) is set to 1. When the IE bit in the USBDMA0/1_CHCR_0 to USBDMA0/1_CHCR_1 is set to 0, no interrupts are generated. However, the TE bit in USBDMA0/1_CHCR_0 to USBDMA0/1_CHCR_1 and the TE0 or TE1 bit in the interrupt source register (USBDMA0/1_DMICR) are set to 1 regardless of the IE bit setting.

The internal transfer counter is loaded with the value set in the USBDMA0/1_TCR_x register and decrements based on the AXI clock every time one transaction (8-/16-/32-byte) completes. When the transfer count value reaches 0 (the end of a transfer count), the counter sets the TE (transfer end) flag from 0 to 1 (when the FTE bit is set, it is reflected on the TE flag immediately). The TE bit is cleared by writing 0 to it after reading it as 1 by software.

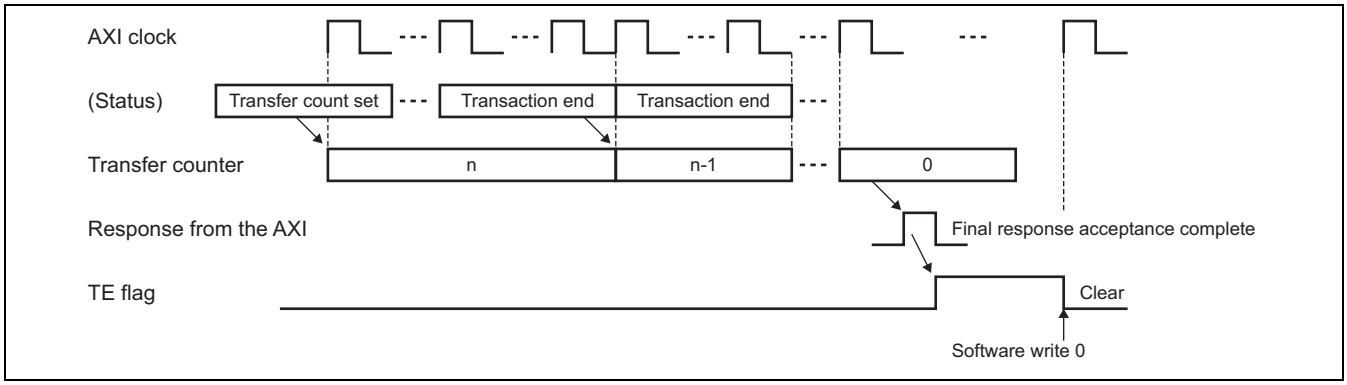

Figure 43.3 Transfer Count End Interrupt (TE) Generation Timing

(2) Short packet receive interrupt (SP flag)

Can be generated when a short packet is detected. When the SPIM bit in the USBDMA0/1_CHCR_x register is set to 1, no interrupts are generated. However, the SP bit (SP flag) in the USBDMA0/1_CHCR_x register and the SP0 or SP1 bit in the USBDMA0/1_DMICR register are set to 1, regardless of the SPIM bit setting. The SP bit is cleared by writing 0 to it after reading it as 1 by software.

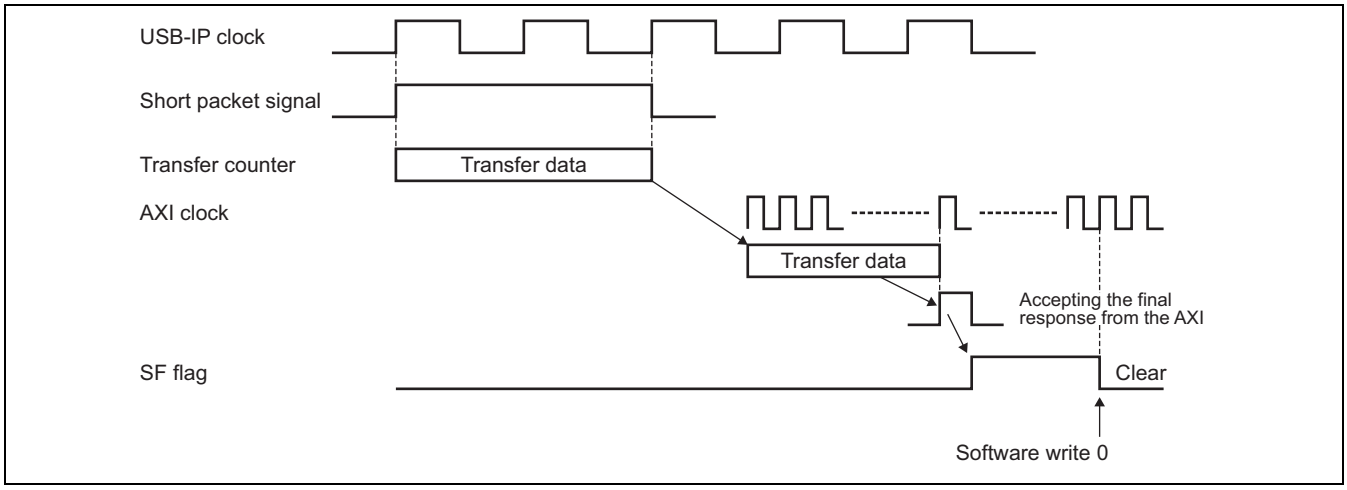

Figure 43.4 Short Packet Receive Interrupt (SP) Generation Timing

(3) NULL packet receive interrupt (NULL flag)

Can be generated when a NULL packet is detected. When the NULLE bit in the USBDMA0/1_CHCR_x register is set to 0, no interrupts are generated. However, the NULL bit (NULL flag) in the USBDMA0/1_CHCR_x register and the NULL0 or NULL1 bit in the USBDMA0/1_DMICR register are set to 1, regardless of the NULLE bit setting. Note also that the DMA transfer control in this module, such as stop, suspend, or resume, is not affected when a NULL packet is received. The software is responsible for implementing special processing if necessary since in this module this interrupt is designed only to signal the software that a NULL packet is received.

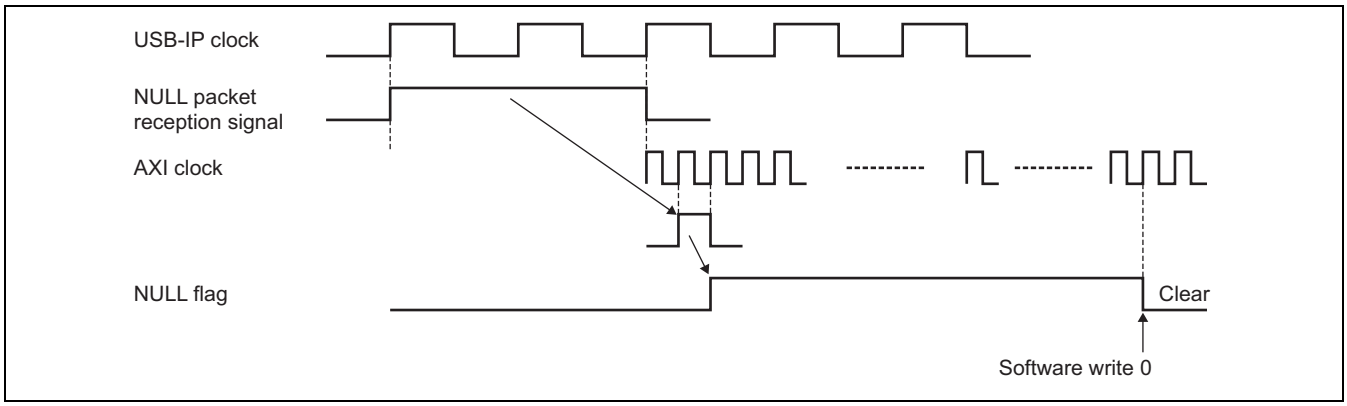

Figure 43.5 NULL Packet Receive Interrupt (NULL) Generation Timing

(4) Timeout interrupt (TO flag)

Can be generated when the time period that is specified in the timeout constant register (USBDMA0/1_TOCSTR_0 or USBDMA0/1_TOCSTR_1) elapses after the final transfer request is received from the USB-IP. On detecting the final transfer request, the internal counter is loaded with the value set in the USBDMA0/1_TOCSTR_x register and starts counting down. When the counter reaches 0, it generates a timeout interrupt. Note that the DMA transfer control in this module, such as stop, suspend, or resume, is not affected when a timeout interrupt occurs. The TO bit is cleared by writing 0 to it after reading it as 1 by software. Figure 43.6 and 43.7 show the timeout interrupt generation timing.

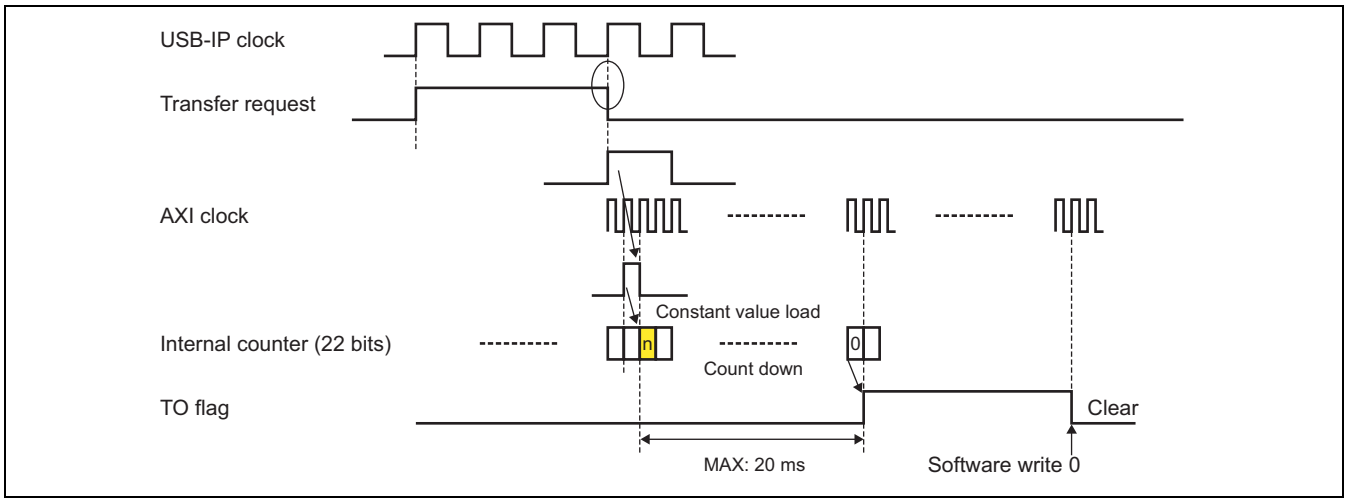

Figure 43.6 Timeout Interrupt (TO) Generation Timing

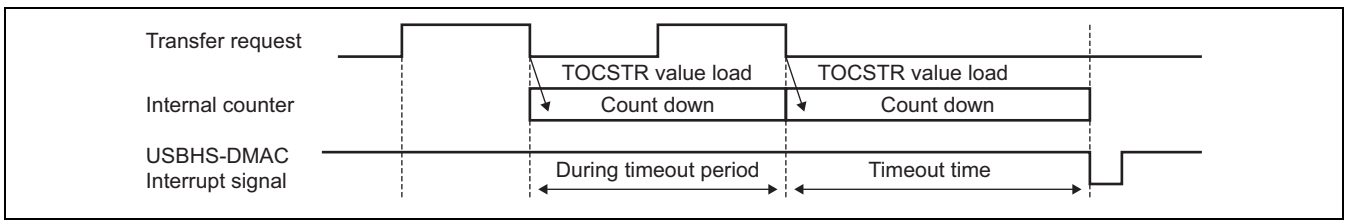

Figure 43.7 Timeout Interrupt Timing

The functions described in section 43.3.1 (5) to 43.3.1 (9) are added to detect and notify the transitions on an individual signal line to the software, but no use is defined. They can be used as required.

(5) Transaction end detect interrupt (TR flag)

Can be generated when the end of a transaction is detected within the USB-IP. Note that the TR bit in the USBDMA0/1_CHCR_x register and the TR0 or TR1 bit in the USBDMA0/1_DMICR register are not reflected in the interrupt signal when the TRE bit in the USBDMA0/1_CHCR_x register is set to 0.

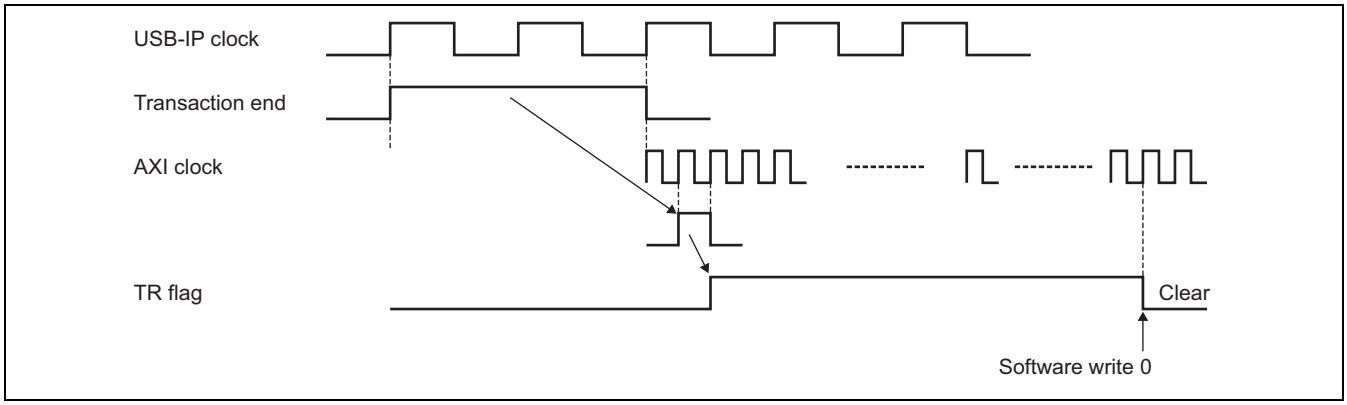

Figure 43.8 Transaction End Detect Interrupt Timing

(6) Buffer end detect interrupt (BUF flag)

Can be generated when the end of the buffer in the USB-IP is detected. Note that the BUF bit in the USBDMA0/1_CHCR_x register and the BUF0 or BUF1 bit in the USBDMA0/1_DMICR register are not reflected in the interrupt signal when the BUFE bit in the USBDMA0/1_CHCR_x register is set to 0.

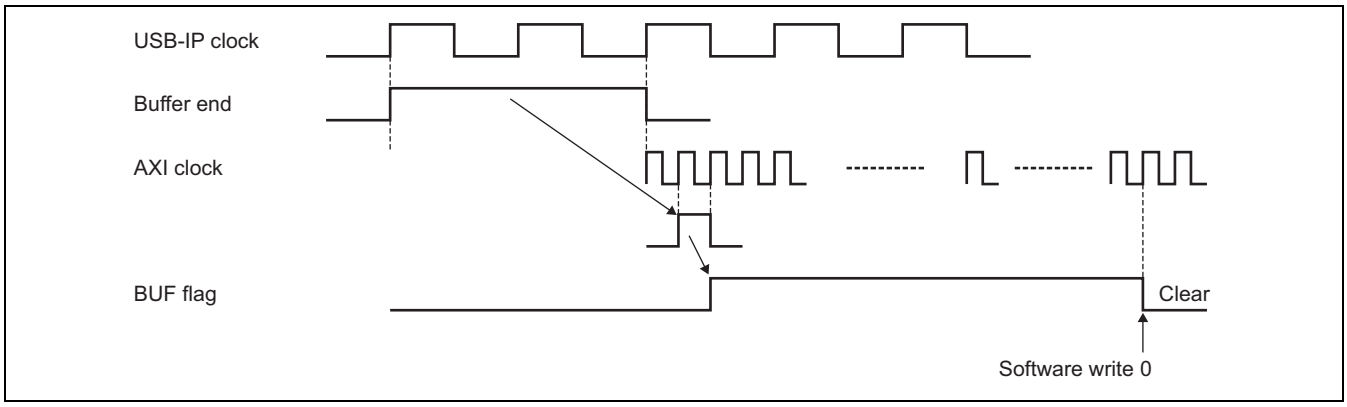

Figure 43.9 Buffer End Detect Interrupt Timing

(7) Final buffer access detect interrupt (RW flag)

Can be generated when the final access to the buffer in the USB-IP is detected. Note that the RW bit in the USBDMA0/1_CHCR_x register and the RW0 or RW1 bit in the USBDMA0/1_DMICR register are not reflected in the interrupt signal when the RWE bit in the USBDMA0/1_CHCR_x register is set to 0.

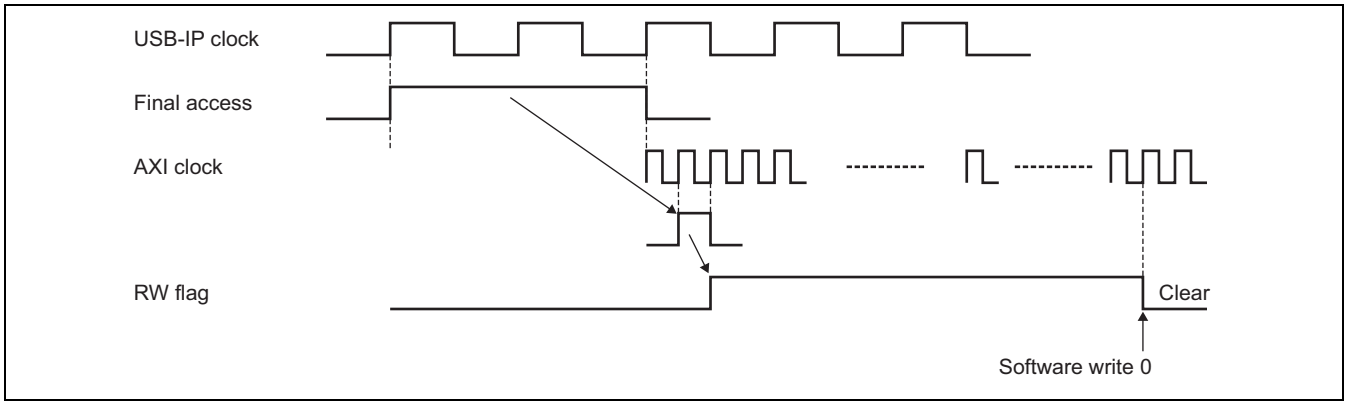

Figure 43.10 Final Buffer Access Detect Interrupt Timing

(8) Address error detection

This is a flag that indicates an address error interrupts has occurred when setting the source address register (USBDMA0/1_SAR0 to USBDMA0/1_SAR1) and the destination address register (USBDMA0/1_DAR0 to USBDMA0/1_DAR1). When the value written to the USBDMA0/1_SAR or USBDMA0/1_DAR register differs from the transfer size (TS) boundary, and when the TS bits are set to 11 (setting prohibited), the AE bit in the USBDMA0/1_DMAOR register is set to 1. There is no distinction between CH0 and CH1 for an address error (the AE bit is set to 1 when an address error occurs on CH0 or CH1).

While the AE is set, no DMA transfer is allowed even if the DE bit in the USBDMA0/1_CHCR_x register and the DME bit in the USBDMA0/1_DMAOR register are set to 1. The address error interrupt is cleared by setting correct addresses in USBDMA0/1_SAR_x and USBDMA0/1_DAR_x.

Table 43.8 Address Error Detection Conditions When Setting Transfer Sizes

Transfer Size	Address Error Detection Conditions
TS = B'00 (8-byte transfer)	When data that is not aligned to 8-byte boundaries is written to the USBDMA0/1_SAR/ USBDMA0/1_DAR registers (Writes to the USBDMA0/1_SAR/ USBDMA0/1_DAR registers are valid.)
TS = B'01 (16-byte transfer)	When data that is not aligned to 16-byte boundaries is written to the USBDMA0/1_SAR/ USBDMA0/1_DAR registers (Writes to the USBDMA0/1_SAR/ USBDMA0/1_DAR registers are valid.)
TS = B'10 (32-byte transfer)	When data that is not aligned to 32-byte boundaries is written to the USBDMA0/1_SAR/ USBDMA0/1_DAR registers (Writes to the USBDMA0/1_SAR/ USBDMA0/1_DAR registers are valid.)
—	When B'11 (setting prohibited) is written to the TS bit (Writes to the TS bit are valid.)

(9) Response packet error detection

This function reports response packet errors when the interface between the AXI and this module is accessed in ways that are not listed in Table 43.2.

(a) Transmitting response packet errors

When a response packet error occurs during accessing from the AXI to this module, the ERR_SNT bit in the USBDMA0/1_VCR register is set to 1.* The error signal is also sent to the AXI bus if the RM bit in the USBDMA0/1_DMAOR register is 0. If the RM bit is set to 1, the error signal is masked (0 is signaled).

Note: * When a response packet error occurs, the ERR_SNT bit is set to 1 regardless of the RM bit setting. The ERR_SNT bit is cleared by writing 0 after reading 1.

Table 43.9 Response Packet Error Generation

USBDMA0_DMAOR (RM bit) Setting	1 (Mask Mode)	0 (Normal Mode)
Response packet error signal notification to AXI	Signals the fixed value (0) to the AXI bus without determining if there is a response packet error.	Reports a response packet error to the AXI bus when it is accessed with a transfer size other than those supported in this module (4-byte read/write and 8-byte read).

(b) Receiving response packet errors

When a response packet error occurs during accessing from this module to the AXI, the ERR_RCV bit in the USBDMA0/1_VCR register is set to 1. The TID bit in the USBDMA0/1_DMAOR register indicates on which channel of this module the error has occurred (TID[1] = 1 means it has occurred on CH1 and TID[0] = 1 on CH0).

The ERR_RCV bit is cleared by writing 0 after reading 1.

43.3.2 DMA Transfer Function

(1) Operating mode

The following operating modes (a) to (b) are supported according to the setting of the PR bit in the DMA operation register (USBDMA0/1_DMAOR).

(a) CH0 first control

Forces CH1 to wait to start a DMA transfer until a DMA transfer completes on CH0.

When there is a timing conflict in starting a DMA transfer between CH0 and CH1, CH0 takes precedence over CH1. If a DMA transfer is in progress on CH1 when CH0 tries to start a DMA transfer, CH0 waits to start it until the ongoing DMA transfer completes on CH1.

(b) CH1 first control

Forces CH0 to wait to start a DMA transfer until a DMA transfer completes on CH1.

When there is a timing conflict in starting a DMA transfer between CH1 and CH0, CH1 takes precedence over CH0. If a DMA transfer is in progress on CH0 when CH1 tries to start a DMA transfer, CH1 waits to start it until the ongoing DMA transfer completes on CH0.

Figure 43.11 shows an overview of the processing of the AXI bridge in each operating mode.

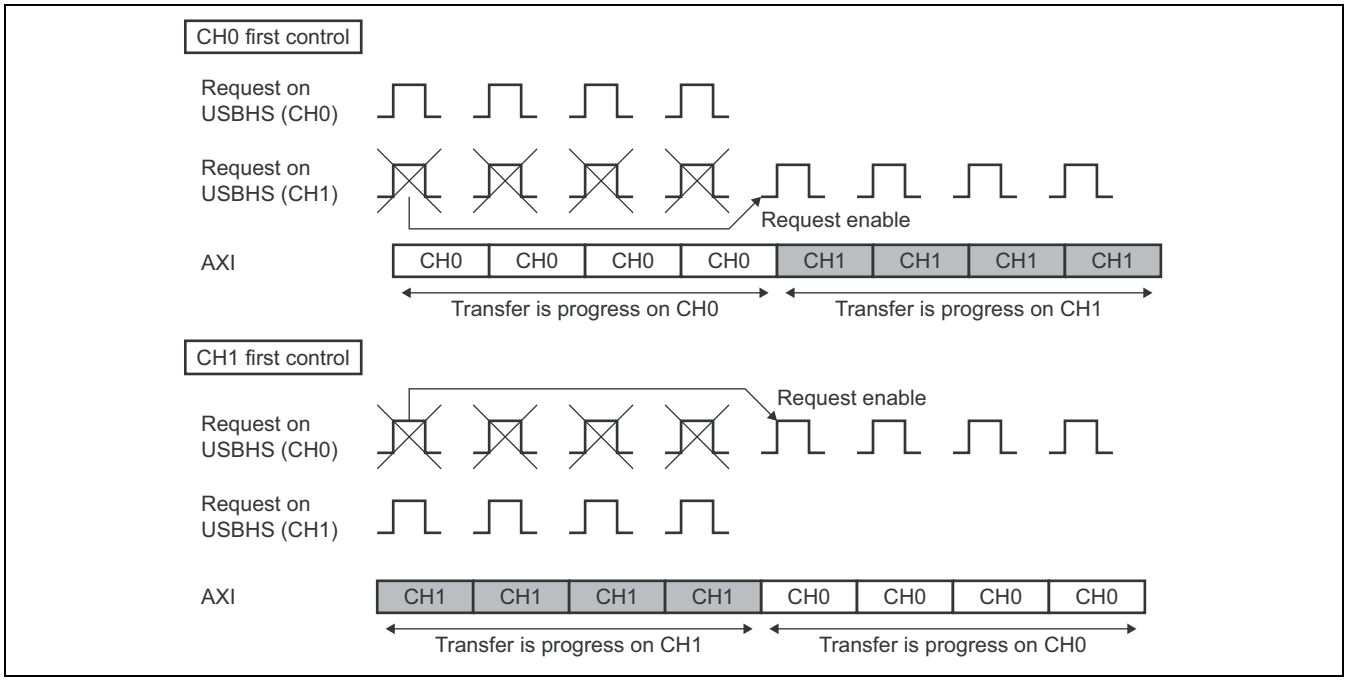

Figure 43.11 Overview of AXI Bridge Processing in Each Mode

(2) Transfer size

The transfer size on the AXI can be selected by setting the channel control register (the TS bit).

8-, 16-, and 32-byte can be set for each channel independently.

The following consideration should be observed during IN transfers.

The minimum transfer size that can be set to the TS bit is 8 bytes while the USB-IP can control transfers in 1-byte units. For example, if valid transfer data that is "8 × (n – 1) + α" (α is less than 7 bytes) in size is to be transferred to the USB-IP with the transfer size set to 8 bytes and the transfer count set to n, α is transferred as a valid transfer unit by controlling byte enables according to the DMA final transaction valid data transfer enable register (the EDTEN bits) setting. Likewise, data is transferred in "transfer size x transfer count" (the final transaction is controlled by EDTEN) for 16- and 32-byte transfer sizes. The EDTEN setting is valid only for IN transfer and is don't care for OUT transfer.

Figure 43.12 shows an example of EDTEN setting. When only EDTEN31 in EDTEN31 to EDTEN0 is 1, one byte is enabled. When only EDTEN31 and EDTEN30 in EDTEN31 to EDTEN0 are 1, two bytes are enabled. Therefore, the total transfer volumes in the example shown above are calculated as "(32 bytes × (n – 1)) bytes + 10 bytes" for 32-byte transfer, "(16 bytes × (n – 1)) bytes + 7 bytes" for 16-byte transfer, and "(8 bytes × (n – 1)) bytes + 2 bytes" for 8-byte transfer. EDTEN15 to EDTEN0 in 16-byte transfer, EDTEN23 to EDTEN0 in 8-byte transfer are invalid (their values are ignored).

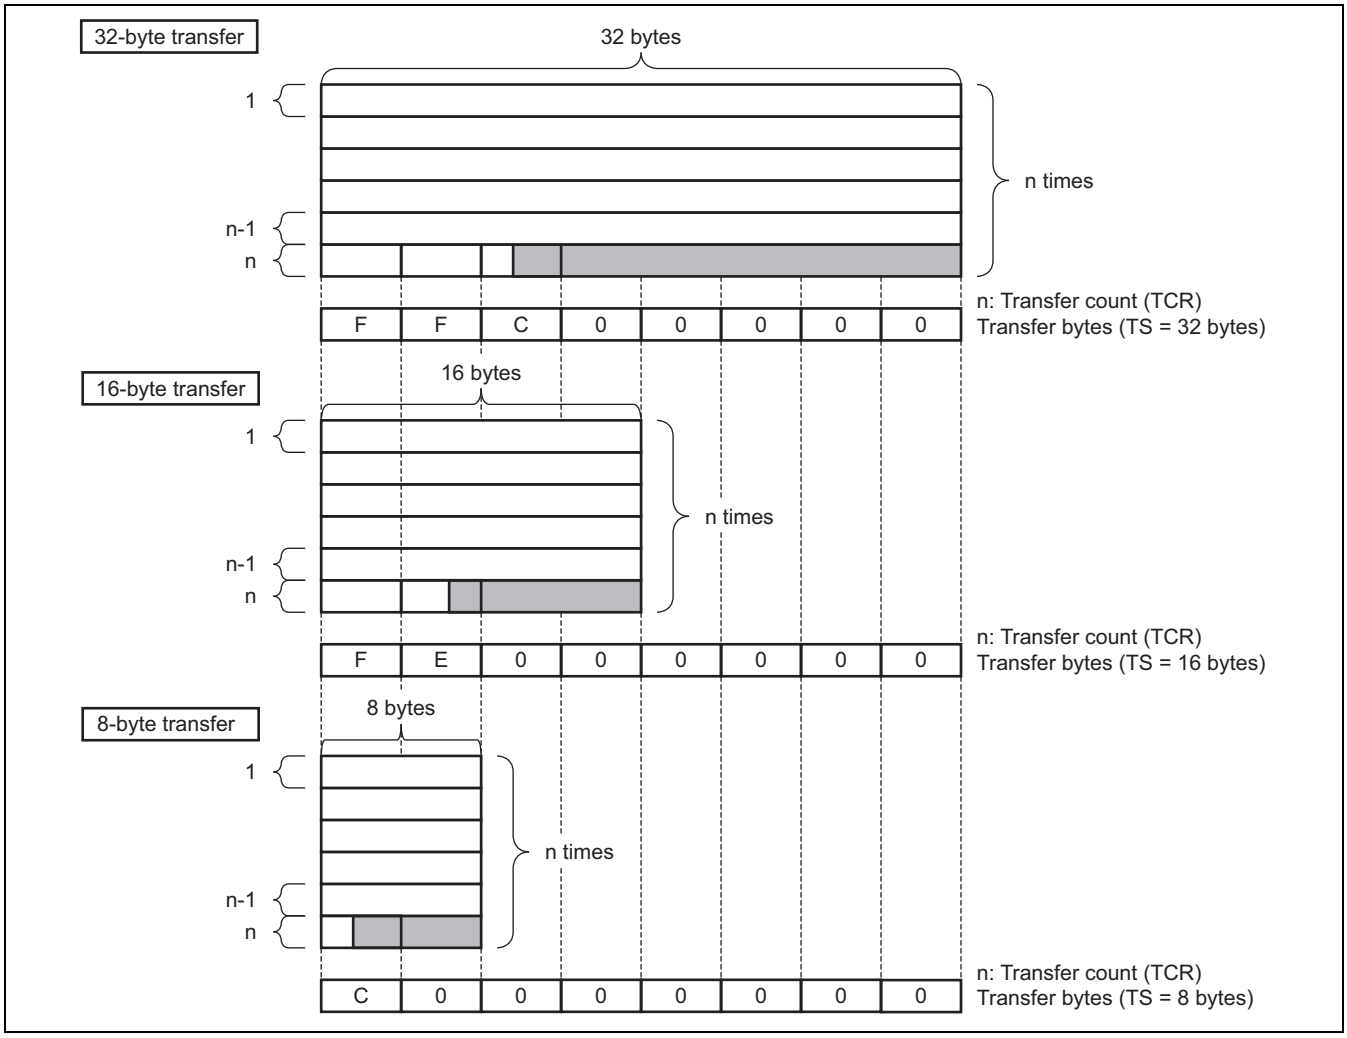

Figure 43.12 Example of Final Transaction Valid Data Transfer Enable (EDTEN) Setting

(3) DMA transfer flow

After the DMA source address register (USBDMA0/1_SAR), DMA destination address register (USBDMA0/1_DAR), DMA transfer count register (USBDMA0/1_TCR), DMA channel control register (USBDMA0/1_CHCR), final valid data transfer enable register (USBDMA0/1_TEND), and DMA operation register (USBDMA0/1_DMAOR) are set appropriately, the DMAC starts data transfer in the following sequence. The DMA timeout constant register (USBDMA0/1_TOCSTR) may also need to be set.

If the transfer enabling conditions are set as DE = 1, DME = 1, TE = 0, AE = 0, SP = 0, and (TR = 0, BUF = 0, RW = 0), transfers are performed according to the transfer request enables and transfer requests from the USB-IP. The transfer direction (IN/OUT transfer) is determined by the direction signal from the USB-IP. The transfer size is determined by the setting of TS1 to TS0.

Every time one AXI transaction (in the transfer size specified in the TS bit) completes, the internal counter of this module decrements the USBDMA0/1_TCR value by one. When the specified transfer count ends (the USBDMA0/1_TCR value reaches 0), it means all transfers complete. At this time, an USB-DMAC interrupt is generated if the IE bit in the USBDMA0/1_CHCR register is set to 1.

When a NULL packet is received, transfer can be stopped or restarted by setting FTE = 1 after negating the DREQE bit of the HS-USB module. Follow the steps described later in "Control when a NULL packet is received".

Table 43.10 shows the conditions for each DMA transfer.

Table 43.10 DMA Transfer Conditions

Transfer enabling condition	TE = 0, SP = 0, (*TR = 0, BUF = 0, RW = 0)
Transfer (starting) condition	When a transfer request is enabled by the USB-IP When a transfer request is issued by the USB-IP
Transfer completing (then restarting) condition	When the transfer count ends (the TE flag is set to 1), (can be restarted by setting DE and DME to 1.) When FTE = 1 (when DREQE = 1 in the HS-USB module is also set), and the steps described later should be followed. When reset (can enter into standby state by releasing the reset.)
Transfer suspending (then resuming) condition	When DE = 0 or DME = 0 (can be resumed by setting DE = 1 or DME = 1.) When SP = 1 (can be resumed by clearing the SP flag.) When RW = 1, BUF = 1, and TR = 1 (can be resumed by clearing the RW, BUF, and TR flag.)* When the module stops (can be resumed by resuming the module.)

Note: * Can be ignored when the RWE, BUFE, and TRE bits are disabled (set to 0).

Figure 43.13 illustrates the high-level DMA transfer flow.

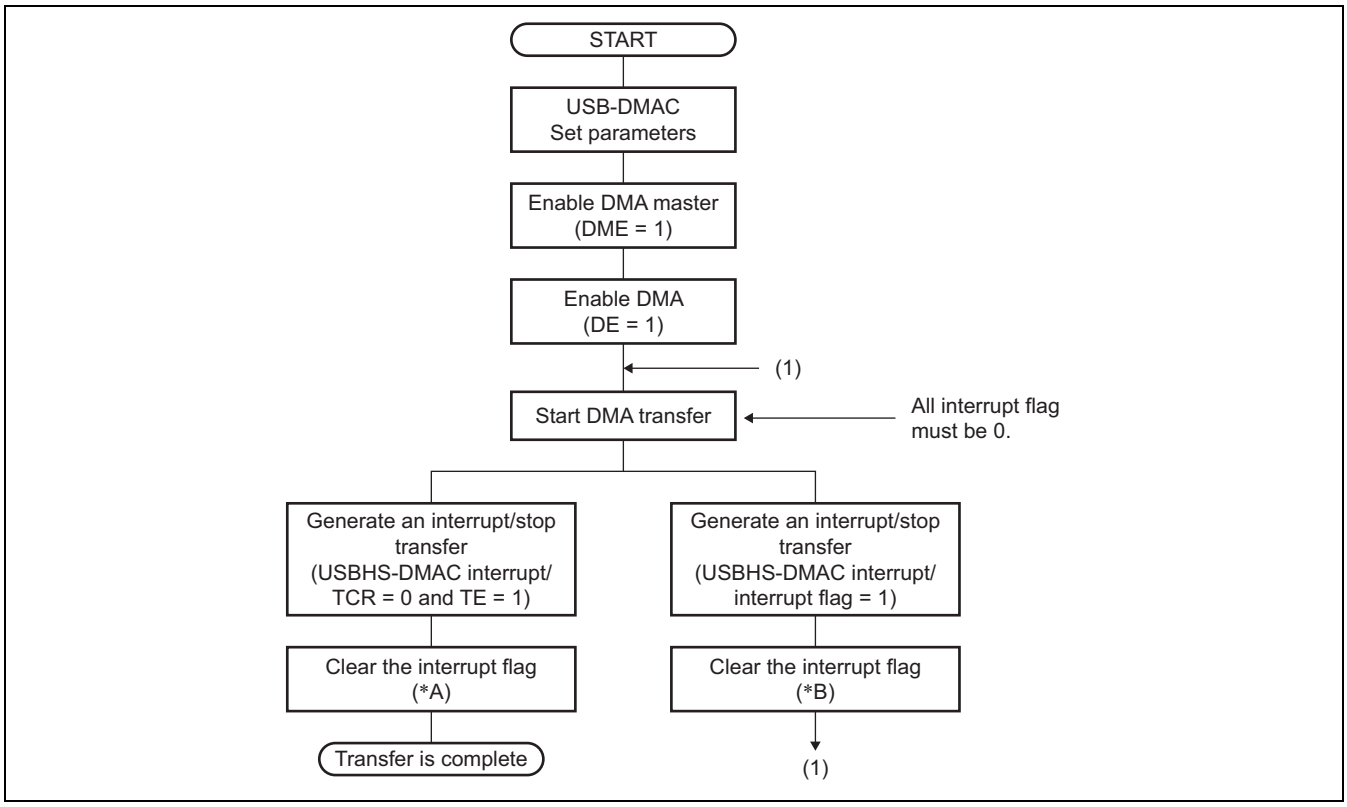

Figure 43.13 DMA Transfer Flow Overview

Where A and B apply to the following flags:

(Note that RW, BUF, and TR are not set when RWE, BUFE, and TRE are disabled, respectively.)

*A: TE flag

*B: SP, (RW, BUF, TR) flags

When to change USBDMAC parameters

USB-DMAC parameters (such as destination address or transfer count) should be changed while all interrupt flags are cleared and DE = 0 and DME = 0 are set (a transfer is started with the latest parameters when DME = 1 and DE = 1 are set). Furthermore, USB-DMAC parameters should not be changed while the DMA is enabled (DME = 1 and DE = 1).

What to do if freeze

If a transfer should freeze during operation, issue a software reset after setting DE = 0 and DME = 0 and clearing all interrupt flags. All hardware except configuration registers is initialized. Restart by setting DME and DE to 1 after updating USB-DMAC parameters if necessary.

Control when a timeout occurs

Since this module assumes bus access in the transfer units listed in Table 43.2, it cannot be restarted when a timeout occurs in an irregular case where it is being accessed with any size that are not in the table. This irregular case should be handled by software, such as by issuing a software reset (to both CH0 and CH1).

Control when a NULL packet is received

When a NULL packet is received during a DMA transfer, the DMA transfer can be suspended and resumed on each channel independently by controlling the FTE bit of this module and the DREQE bit of the HS-USB module in the following sequence.

[Control sequence]

During a DMA transfer (A)

(1) A NULL packet is received (an interrupt is generated and the NULL flag is detected).
(2) The DREQE bit of the HS-USB module is negated (= 0).
(3) Wait for the internal bus to be stabilized.
(4) Perform three actions at the same time; setting the FTE bit, clearing the NULL bit and negating the DE bit.

An interrupt is generated due to TE.

(5) Clear the interrupt caused by TE.
(6) Set the parameters (such as TCR or DAR) for the next transfer.
(7) Assert the DE bit (= 1). The DMA is restarted.
(8) Assert the DREQE bit (= 1).

Start a DMA transfer (B).

[Restrictions]

1) FTE bit set timing
   If this module is accessing the AXI (SHBSYx bit = 1) when setting the FTE bit, you need to wait to set the FTE bit until this module's internal buffer is empty and the AXI bus access is complete (SHBSYx bit = 0). Note that if you accidentally set the FTE bit while an AXI bus access is in progress, the transfer fails and transfer data may be lost or the transfer may be unable to be restarted.
2) DREQE bit assert (negate clear) timing
   It is necessary to allow at least 20clk@ZSϕ after the DE bit is asserted and before the DREQE is asserted. This is because DREQE needs to be asserted after transfers enabled by the DE bit are ready internally to be started. Asserting DREQE immediately after DE may cause malfunction such as initiating unnecessary bus access.
3) Fractional byte and NULL packet reception
   This module assumes bus access in the transfer units listed in Table 43.2 and goes out of control when it receives a NULL packet in an unsupported transfer unit. Therefore, data transfer in any transfer unit that is not in the table is prohibited.
4) IN/OUT switching after NULL packet reception
   After a NULL is received, transfers cannot be restarted with the transfer direction switched from OUT to IN. This is because this module still considers the terminated transfer as an OUT transfer until the transfer count reaches its end. Note that if you switch the transfer direction to IN transfer accidentally after a NULL packet is received, a conflict occurs between an IN and an OUT transfers, which may cause illegal bus access.
   Use CH0 and CH1 with their transfer direction fixed, or if the transfer direction needs to be switched on the same channel, make sure to do it every time a transfer completes successfully due to the end of transfer count or is terminated by software reset.

Figure 43.14 shows the state transitions for DMA transfers.

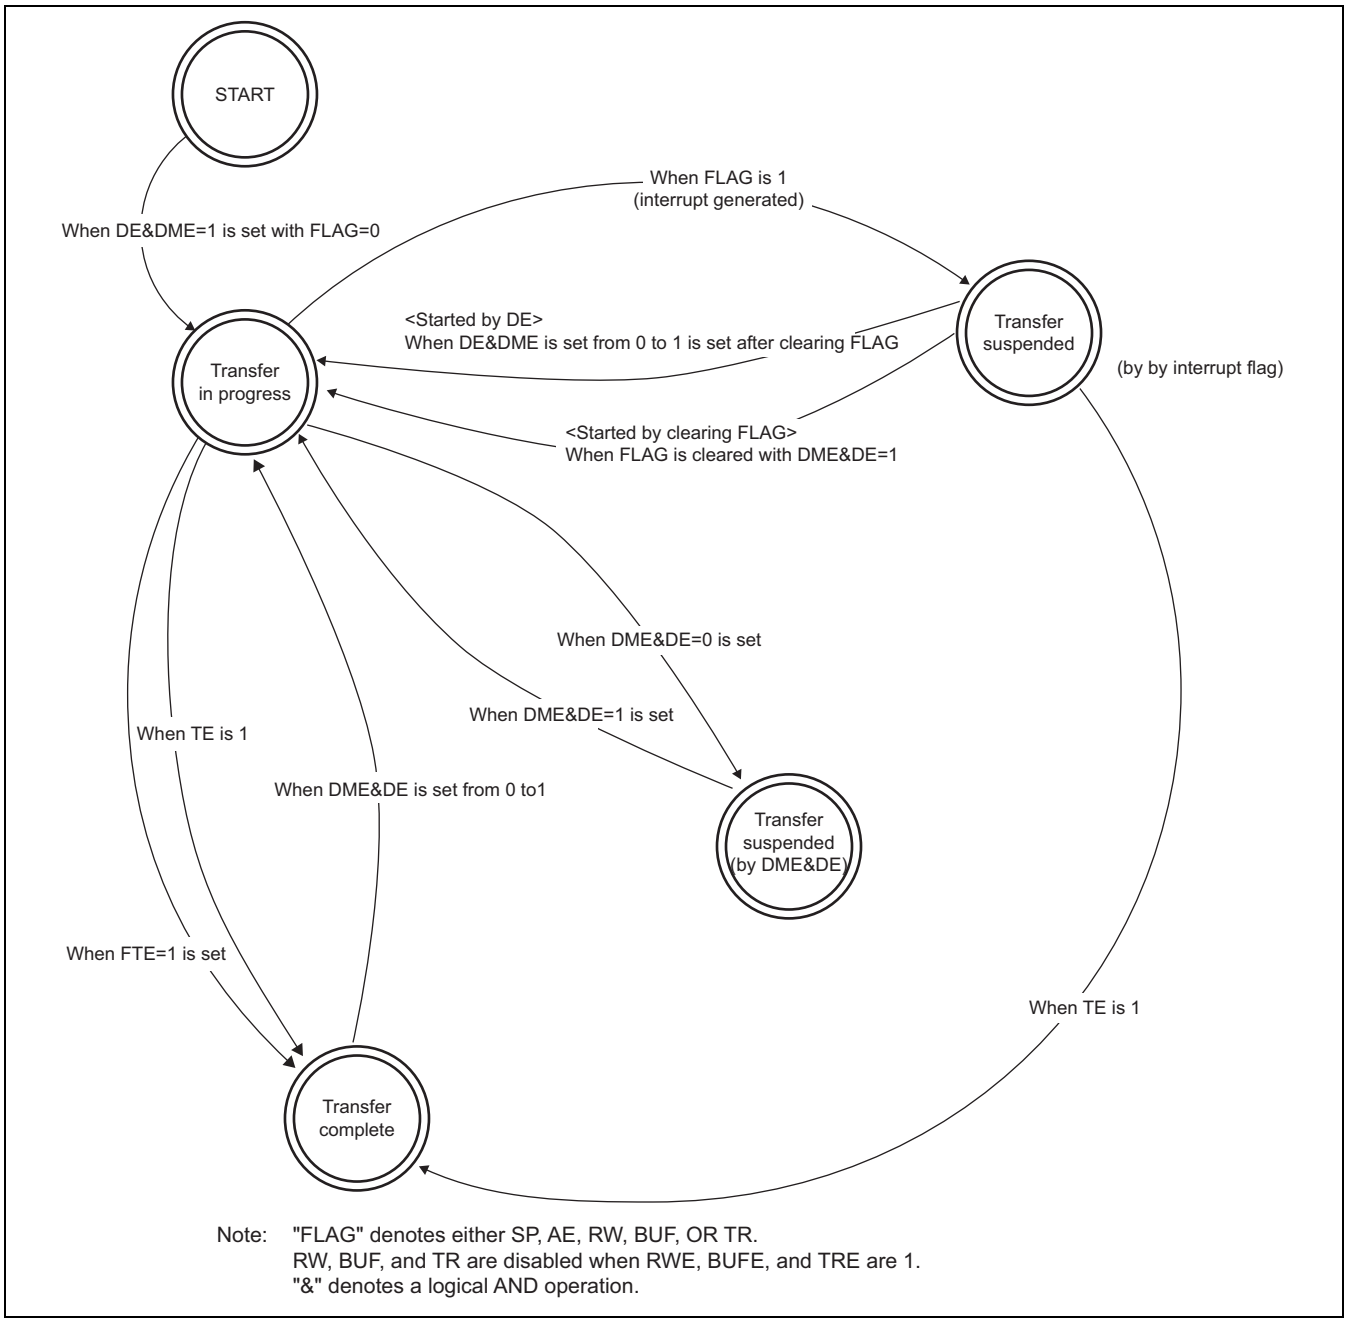

Figure 43.14 State Transitions for DMA Transfer

(4) Control sequence

Figure 43.15 shows an outline of the control sequence of this module.

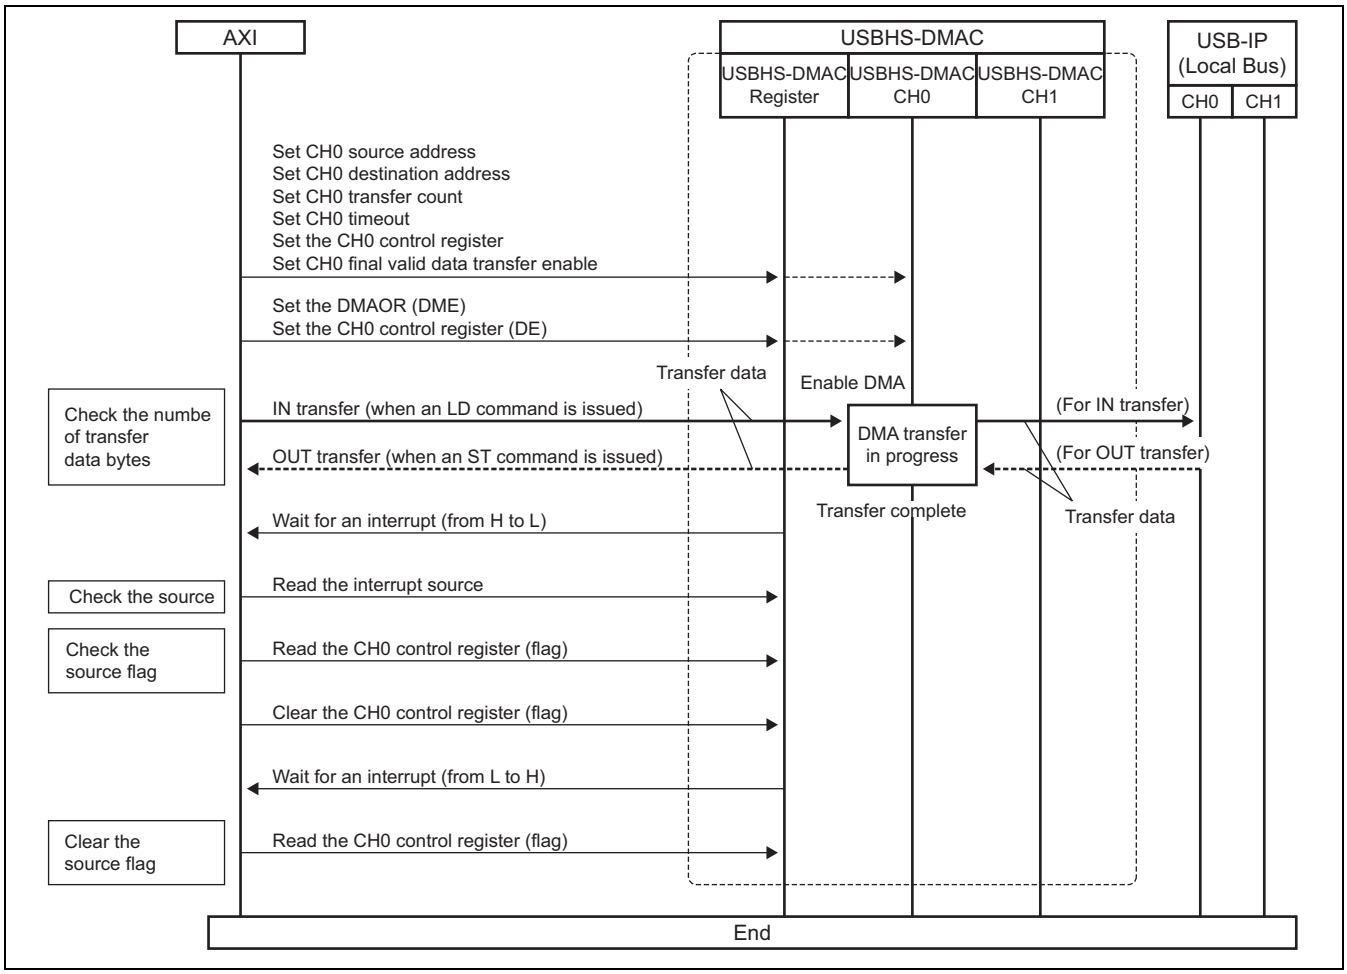

Figure 43.15 Control Sequence Overview

(5) Internal buffer configuration

This module has 64 bytes (64 bits × 8 words) of internal buffer for each of two channels. Thus, the total capacity of this module's internal buffers is 128 bytes (1,024 bits).

The internal buffers are composed of two planes each of which is organized as 64 bits × 4 words and are readable /writable on per-plane basis from the USB-IP local bus or AXI bus (plane 1 is writable when plane 0 is readable or vice versa). For 16-byte transfers, only 2 words in plane 0 and 2 words in plane 1 are used. For 8-byte transfers, only 1 word in plane 0 and 1 word in plane 1 are used.

Note that these internal buffers cannot be accessed directly by software.

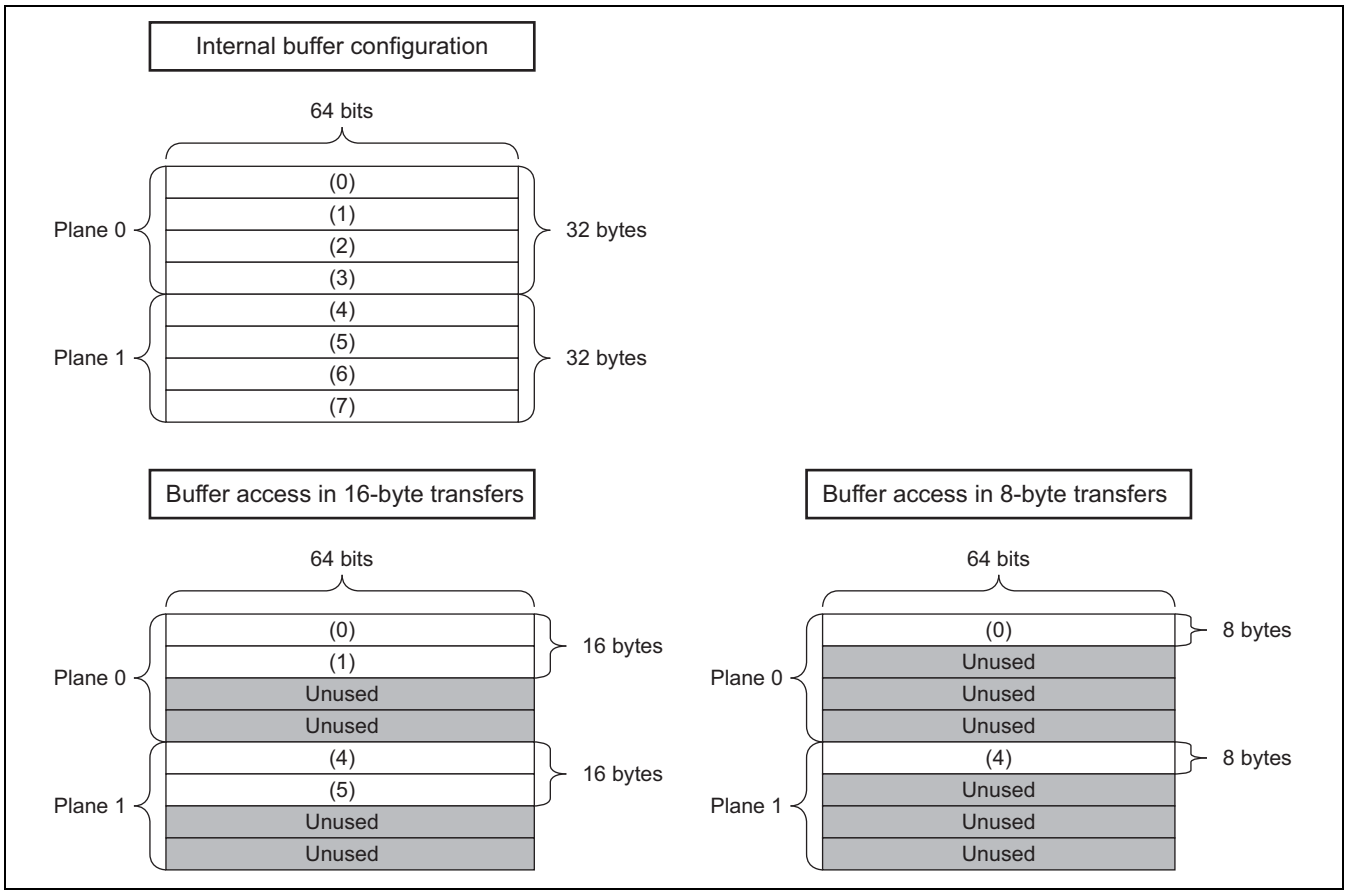

Figure 43.16 Internal Buffer Configuration and Used Area for Each Transfer Size

(6) Internal buffer control (hardware control, for reference)

(a) IN transfer (from AXI to USB)

Retrieves transfer data from a source on the AXI bus and writes it to this module's internal buffer. Reads the written data from the internal buffer and writes it to the USB-IP.

Figure 43.17 shows how the planes of this module's internal buffers are controlled during an IN transfer. In this figure, "read" and "write" indicate read/write operations to this module's internal buffers.

When a write to plane 0 or plane 1 is complete, the writable plane flag is toggled (every time 2 words* and 1 word* are written for 16-byte and 8-byte transfers, respectively). When a read from plane 0 or plane 1 and a transfer the read data to the USB-IP are complete, the readable plane flag is toggled (every time 2 words* and 1 word* are read for 16-byte and 8-byte transfers, respectively). Access to the AXI is prohibited during the period when both the writable plane flag and readable plane flag are set on the same plane as a read/write access conflict may occur.

Note: * 1 word = 64 bits

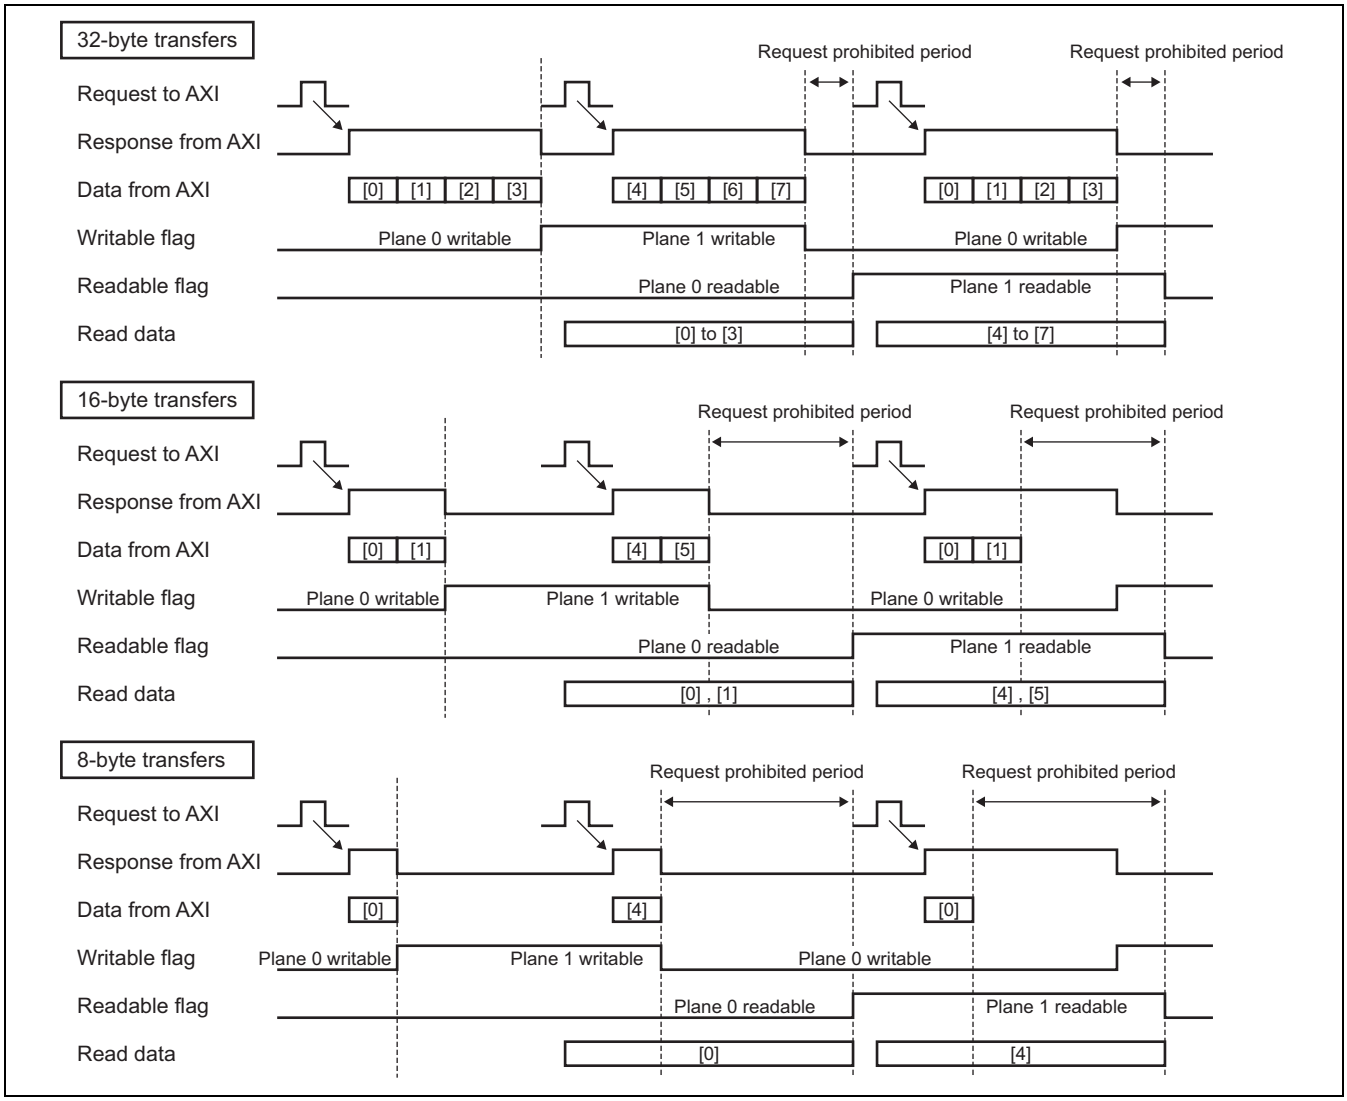

Figure 43.17 Read/Write Control for Internal Buffer: From AXI to USB (IN Transfer)

(b) OUT transfer (from USB to AXI)

Writes data read from the USB-IP to the internal buffers. Reads the written data from this module's internal buffers and writes it to the destination on the AXI bus (OUT transfer).

Figure 43.18 shows how the planes of this module's internal buffers are controlled during an OUT transfer. In this figure, "read" and "write" indicate read/write operations to this module's internal buffers.

When a write to plane 0 or plane 1 is complete, the writable plane flag is toggled (every time 2 words* and 1 word* are written for 16-byte and 8-byte transfers, respectively). When a read from plane 0 or plane 1 is complete, the readable plane flag is toggled (every time 2 words* and 1 word* are read for 16-byte and 8-byte transfers, respectively). Access to the AXI is prohibited during the period when both the writable plane flag and readable plane flag are set the same plane as a read/write access conflict may occur.

Note: * 1 word = 64 bits

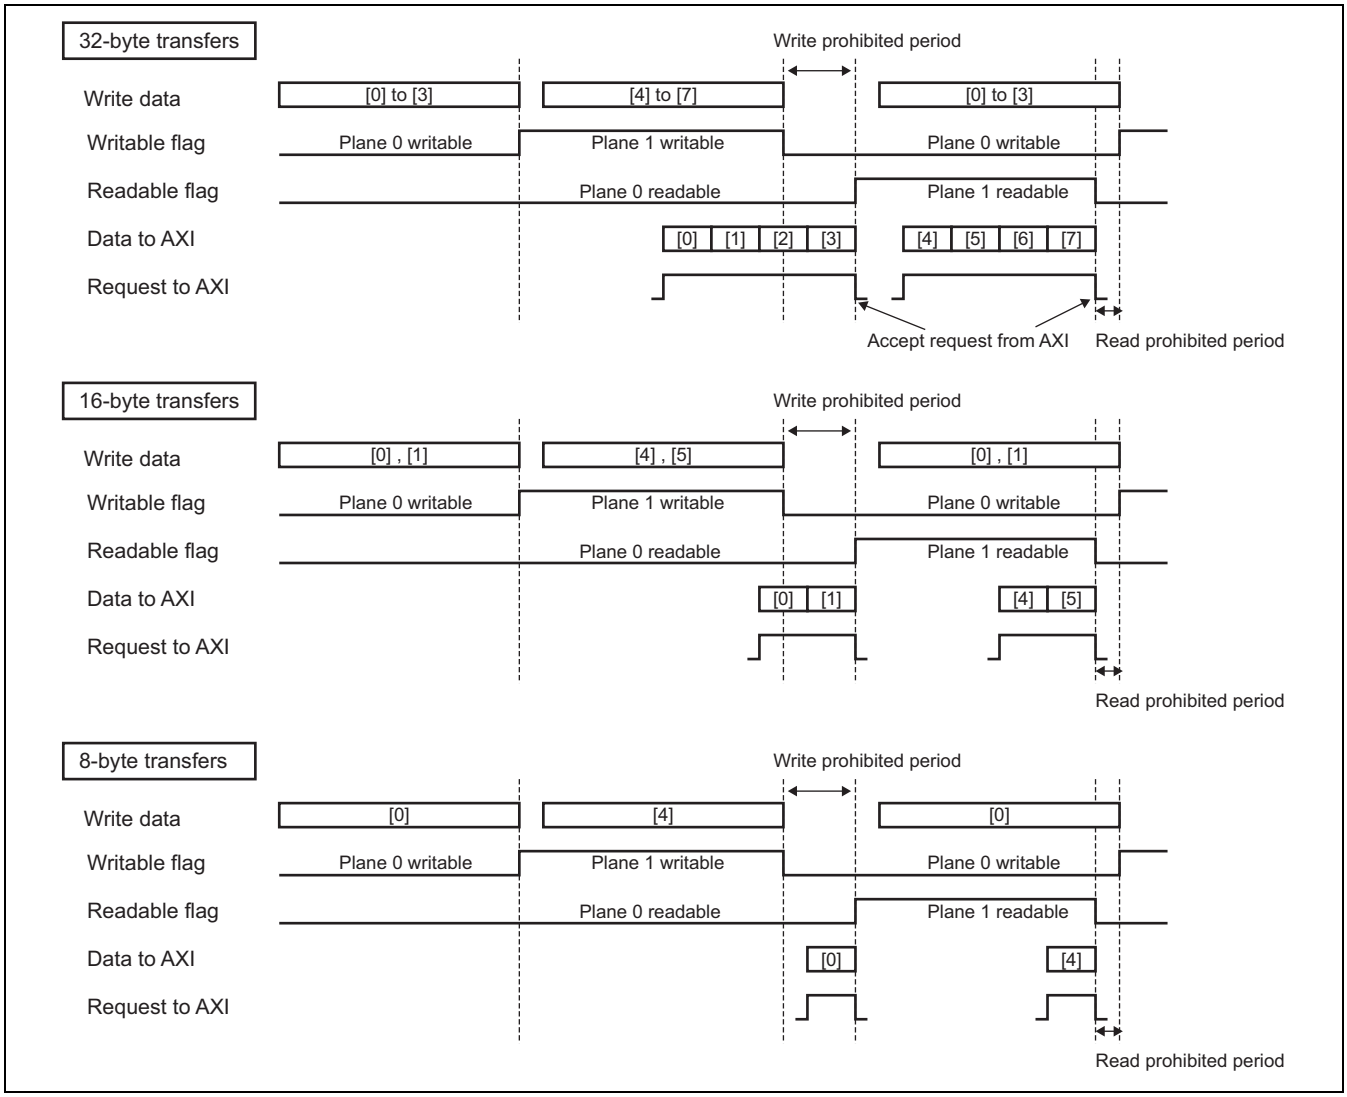

Figure 43.18 Read/Write Control for Internal Buffer: From USB to AXI (OUT Transfer)

43.4 DDM (Descriptor DMAC)

The DDM is a module that reconfigures USBDMAC. The OS on the main CPU is highly sophisticated and the overhead from interrupt notification to reconfiguration increases. To solve this problem, the DDM reconfigures the USBDMAC in a fast response time on behalf of the CPU.

Figure 43.19 shows the relationship diagram of DDM USBDMAC connection.

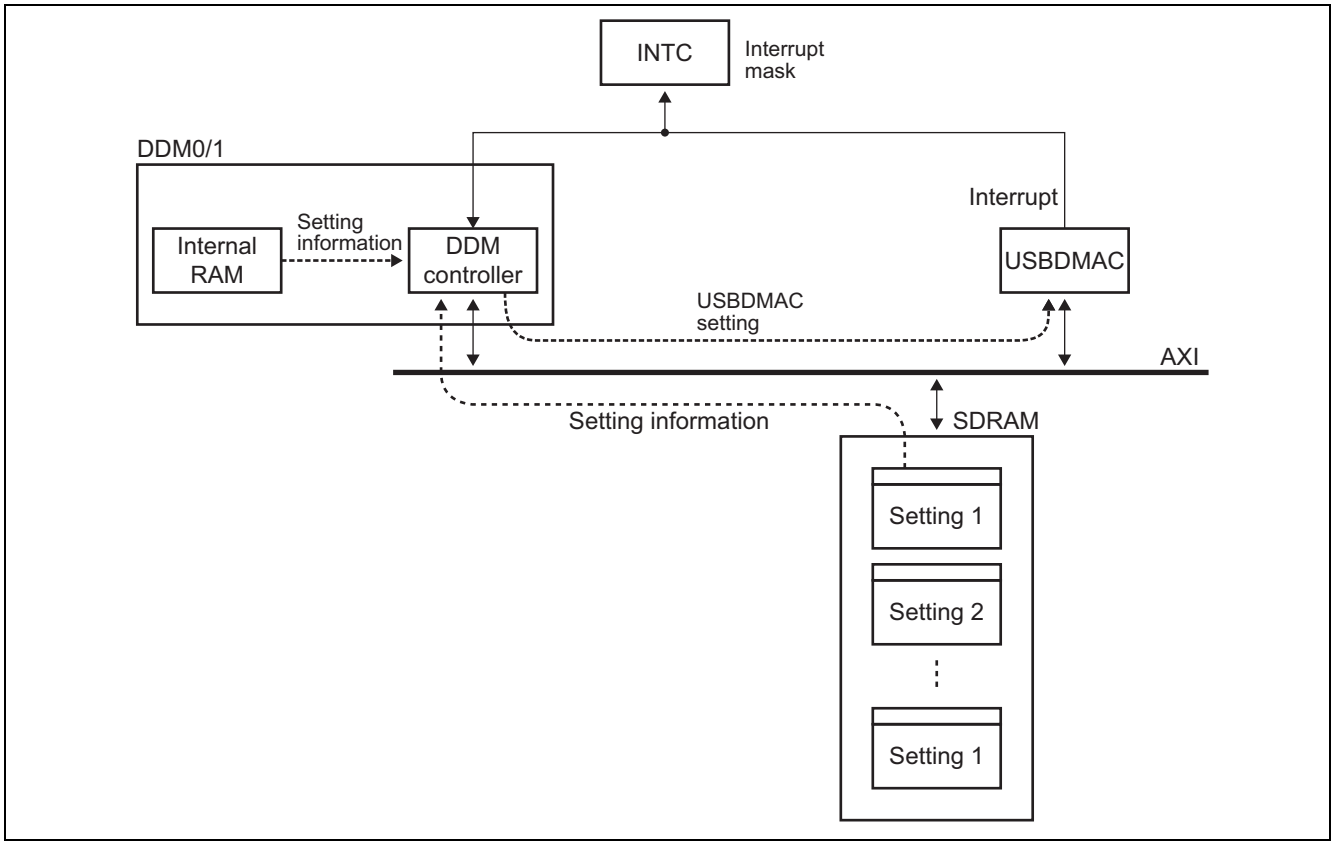

Figure 43.19 Relationship Diagram of DDM Connection

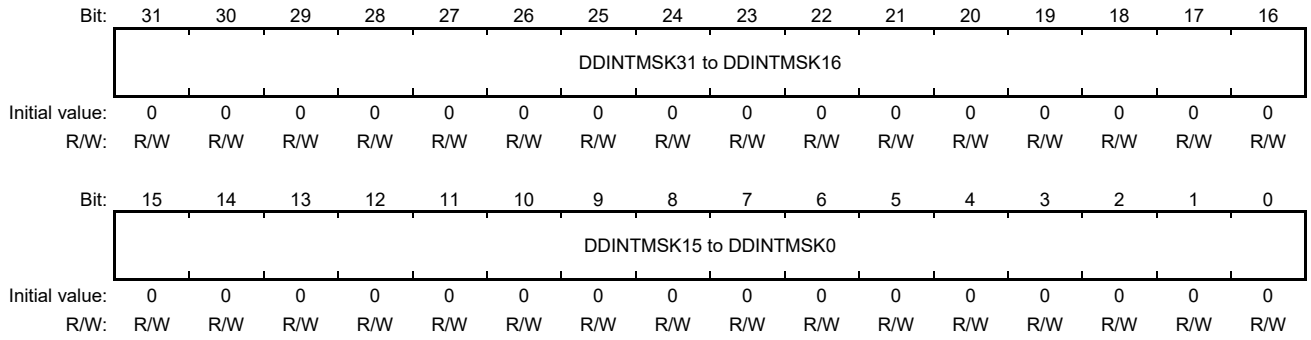
10	END6	0	R	Interrupt output by CH6 DDM_END 0: The interrupt is not output. 1: The interrupt is output.
9	ERR5	0	R	Interrupt output by CH5 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
8	END5	0	R	Interrupt output by CH5 DDM_END 0: The interrupt is not output. 1: The interrupt is output.
7	ERR4	0	R	Interrupt output by CH4 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
6	END4	0	R	Interrupt output by CH4 DDM_END 0: The interrupt is not output. 1: The interrupt is output.
5	ERR3	0	R	Interrupt output by CH3 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
4	END3	0	R	Interrupt output by CH3 DDM_END 0: The interrupt is not output. 1: The interrupt is output.
3	ERR2	0	R	Interrupt output by CH2 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
2	END2	0	R	Interrupt output by CH2 DDM_END 0: The interrupt is not output. 1: The interrupt is output.
1	ERR1	0	R	Interrupt output by CH1 DDM_ERR 0: The interrupt is not output. 1: The interrupt is output.
0	END1	0	R	Interrupt output by CH1 DDM_END 0: The interrupt is not output. 1: The interrupt is output.

43.4.4 DDM CHn Start Source Mask Registers 1 to 2 (DDINTMSKn1/DDINTMSKn2)

DDM CHn Start Source Mask Registers 1 to 2 mask DDM start sources.



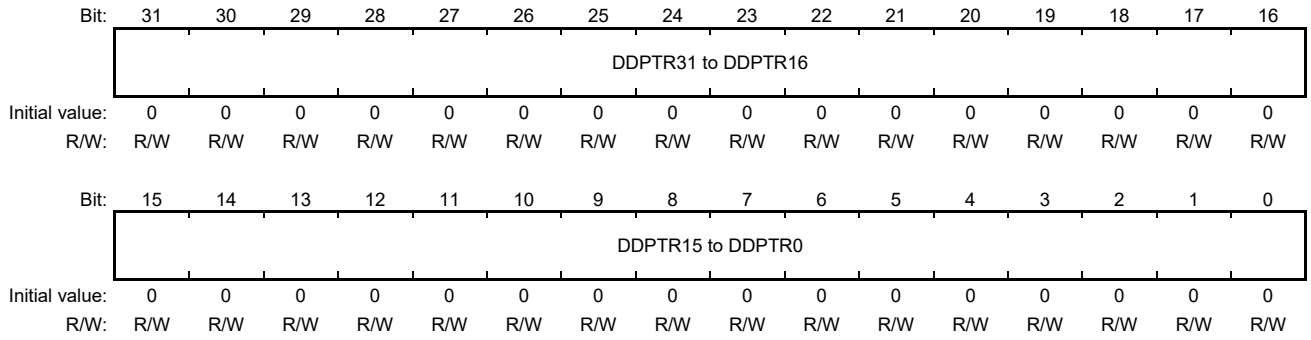
Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 0	DDINTMSK31 to DDINTMSK0	H'0000 0000	R/W	Start Source Mask 0: Does not mask the start source. 1: Masks the start source.

The current source assignment is as follows:

Bit Name	Bit	Assigned Start Source
DDINTMSKn (n = 1, 2)	31 to 20	Reserved
	19	DMACHCR19 TE bit
	18	DMACHCR18 TE bit
	17	DMACHCR17 TE bit
	16	DMACHCR16 TE bit
	15	DMACHCR15 TE bit
	14	DMACHCR14 TE bit
	13	DMACHCR13 TE bit
	12	DMACHCR12 TE bit
	11	DMACHCR11 TE bit
	10	DMACHCR10 TE bit
	9	DMACHCR9 TE bit
	8	DMACHCR8 TE bit
	7	DMACHCR7 TE bit
	6	DMACHCR6 TE bit
	5	DMACHCR5 TE bit
	4	DMACHCR4 TE bit
	3	DMACHCR3 TE bit
	2	DMACHCR2 TE bit
	1	DMACHCR1 TE bit
	0	DMACHCR0 TE bit
DDINTMSKn (n = 1, 2)	31 to 2	Reserved
	1	USBDMAC1 Interrupt
	0	USBDMAC0 Interrupt

43.4.5 DDM CHn Descriptor Pointer (DDPTRn)

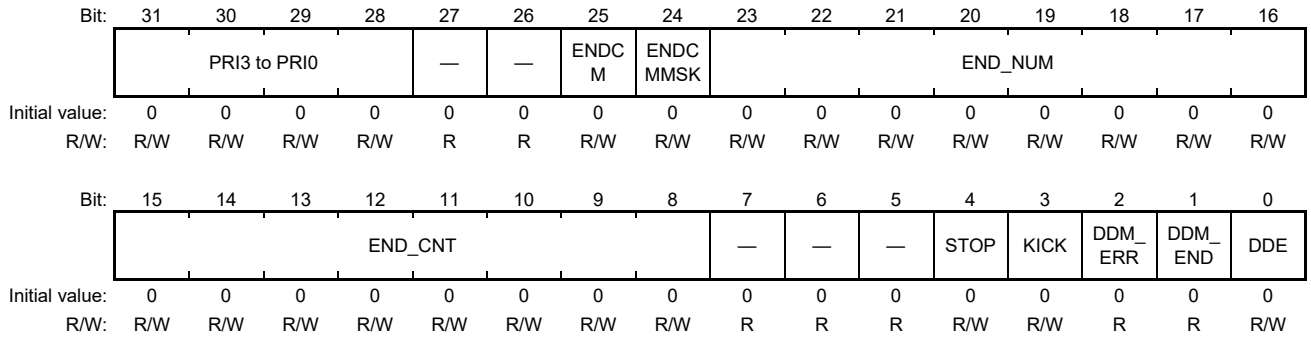
The DDM CHn Descriptor Pointer indicates the start address of setting code allocated onto memory.



Bit	Bit Name	Initial Value	R/W	Descriptions
31 to 0	DDPTR31 to DDPTR0	H'0000 0000	R/W	Descriptor pointer.

43.4.6 DDM CHn Control Register (DDCTRLn)

The DDM CHn Control Register controls start and stop of DDM.



Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PRI3 to PRI0				—	—	ENDCM	ENDCMMSK	END_NUM							
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	END_CNT								—	—	—	STOP	KICK	DDM_ERR	DDM_END	DDE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R	R	R/W	R/W	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	PRI3 to PRI0	H'0	R/W	PRI value on the AXI bus.
27, 26	—	00	R	Reserved
25	ENDCM	0	R/W	Descriptor end Counter Consistent Detection Writing 0 is possible to clear the flag. 0: Counter consistent is not detected. 1: Counter consistent is detected.
24	ENDCMMSK	0	R/W	Descriptor end Counter Consistent Detection Mask 0: Masks the ENDCM. (END_CNT is cleared to 0) 1: Does not mask the ENDCM.
23 to 16	END_NUM	All 0	R/W	Number of descriptor ends
15 to 8	END_CNT	All 0	R/W	Descriptor end Counter
7 to 5	—	000	R	Reserved
4	STOP	0	R/W	Forced Stop Function 0: Does not perform forced stop. 1: Performs forced stop.
3	KICK	0	R/W	Forced Start Function without Start Source 0: Does not perform forced start. 1: Performs forced start. This bit is automatically cleared to 0 after 1 is written.
2	DDM_ERR	0	R	Error Occurrence. The error is cleared by setting the DDE bit to 0. 0: No error occurred. 1: An error occurred.
1	DDM_END	0	R	DDM End. DDM end is cleared by setting the DDE bit to 0. 0: The DDM did not end. 1: The DDM ended.
0	DDE	0	R/W	Start Enable 0: Does not enable DDM start. 1: Enables DDM start according to the start source.

43.4.7 Internal RAM

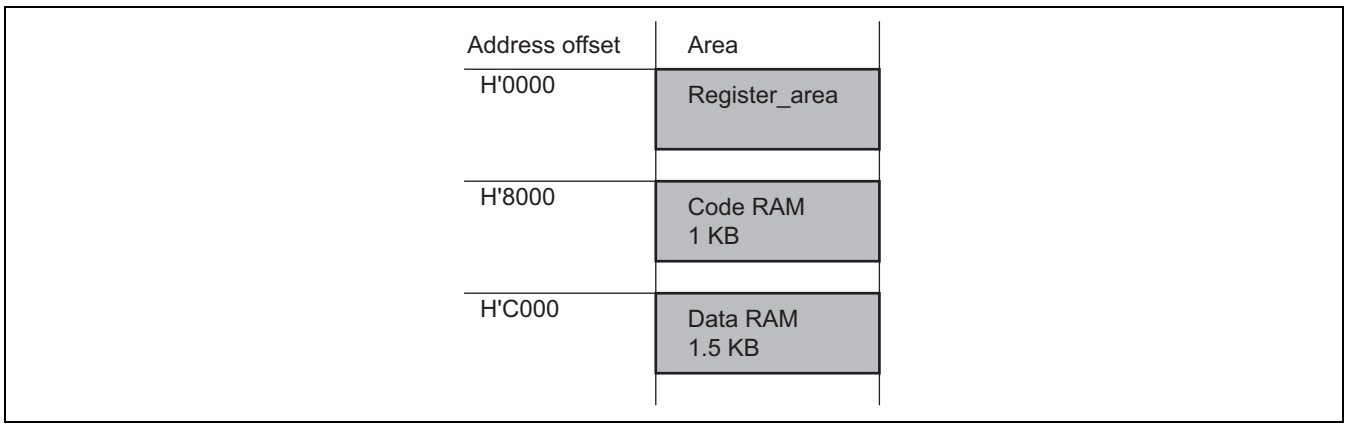


Figure 43.20 Internal RAM

DDM builds in RAM. It is the 2nd page composition of Code RAM and Data RAM. DDM can access without AXI. Access size is arbitrary. In addition, a functional difference is not in both depending on the way of calling depending on which Code RAM and Data RAM were conscious of the use.

43.4.8 Principles of Operation

To reconfigure the USBDMAC by using the DDM, use the following procedure:

1. Describing setting codes
2. Starting and ending the DDM

(1) Describing setting codes

(a) Data structure

A setting code is fixed-length data consisting of four longwords.

Setting code data consists of the following fields, starting from the beginning:

Field	bit
Operation field	32 bits
Address field	32 bits
Data field	32 bits
Bit mask field	32 bits

Note: Arrange a setting code in 16 bytes boundary.

The following describes the operation field.

(b) Operation field

The structure of the operation field is as follows:

Bit	Bit Name	Descriptions
31 to 16	HEADER	Indicates DDM setting data. H'DDDD: Normal DDM setting code Usually, set this value. H'EEEE: DDM end code Set this value when ending the channel without starting the DDM the next time. If the HEADER bits have other values, a DDM_ERR interrupt occurs. The channel of the DDM stops immediately.
15 to 8	OPERAND	Operand attribute B'00xxyyzz 00: immediately 01: register 10: pointer 11: pointer (Register value) xx: Bit mask field yy: Data field zz: Address field
7 to 4	SIZE	Specify the data access size to be set. 0000: Bytes 0001: Words 0010: Longwords
3	ENDFLG	End Flag of Setting Processing Based on This Start Source 0: Continuation 1: Setting end. The DDM waits for the next start source.
2 to 0	OPC	Operation Code 000: read (cmp/eq) (read) 001: write (write) 010: rmodw (read modify write) 011: add (addition) 100: jmp/eq (branch) 101: ror (rotate right) Others: DDM_ERR interrupt occurs

The address field, data field, and bit mask field each consist of 32 bits. The data field and bit mask field use the LSB side for word- and byte-size access.

Four of register R0-R3 of longword size can be used for every Ch.

(c) read (cmp/eq)

The read (cmp/eq) code reads the target address and compares the address with the expected values written in the data field and bit mask field.

When the comparison result becomes true, the TFLG internal variable is set to 1. TFLG is cleared to 0 when jmp/eq is executed or operation with ENDFLG is performed.

Description example 1:

The read (cmp/eq) code in this example reads the H'FE00 802C address in longwords and checks if bit 1 is set to 1.

H'DDDD 0020
H'FE00 802C
H'0000 0002
H'0000 0002

Description example 2:

The read (cmp/eq) code in this example reads the R1 in longwords and checks if bit 1 is set to 1.

H'DDDD 0120
H'0000 0001
H'0000 0002
H'0000 0002

(d) write

The write code writes data to the target address.

Description example 1:

The write code in this example accesses the H'FE00 802C address in longwords and writes H'0010 5400.

H'DDDD 0021
H'FE00 802C
H'0010 5400
H'FFFF FFFF (don't care)

Description example 2:

The write code in this example accesses the H'FE00 802C address in longwords and writes the value of H'0000 0001 address to H'FE00 802C address.

H'DDDD 0821
H'FE00 802C
H'0000 0001
H'FFFF FFFF (don't care)

(2) Description example 3:

The write code in this example accesses the H'FE00 802C address in longwords and writes the value of pointer of R1 to the H'FE00 802C address.

H'DDDD 0C21
H'FE00 802C
H'0000 0001
H'FFFF FFFF (don't care)

(a) rmodw

The rmodw code reads the target address and performs modify-write according to the values of the bit mask field.

Description example:

The rmodw code in this example reads the H'FE00 802C address in longwords and applies H'54 modify-write to bits 11 to 4.

H'DDDD 0022
H'FE00 802C
H'0000 0540
H'0000 0FF0

(b) add

The add code reads the target address and performs add-modify-write according to the values of the bit mask field.

Description example:

The add code in this example reads the H'FE00 802C address in longwords and applies H'200 add-modify-write to bits 11 to 0.

H'DDDD 0023
H'FE00 802C
H'0000 0200
H'0000 0FFF

Use 0 as the addition data corresponding to the area where the bit mask is 0.

(c) jmp/eq

If TFLG is set to 1 by the cmp/eq code, jmp/eq changes the descriptor pointer to the values of the data field. Descriptor pointer change by jmp/eq is not reflected in execution based on the next start source. Changing the descriptor pointer for the next start requires that the CHn descriptor pointer be reconfigured.

Description example:

The jmp/eq code in this example changes the descriptor pointer when TFLG is 1 to H'E558 000E.

H'DDDD 0024
H'0000 0000 (don't care)
H'E558 000E
H'0000 0000 (don't care)

(d) ror

The ror code reads the target address and performs rotate-right-write according to the values of the bit mask field. The shifted lower bits are rotated to higher bits. The ror command shifts according to the value of the data field.

Description example:

The ror code in this example reads the H'FE00 802C address in longwords and applies 8-bits right-shift.

H'DDDD 0025
H'FE00 802C
H'0000 0008
H'00FF FFFF

(e) Settings description order

Describe settings in the following order:

(1) Clearing the start source (source output side, not the DDM start source mask register)
(2) Changing the DDM source mask setting as required
(3) Reconfiguring registers such as DMAC
(4) Reconfiguring the next descriptor pointer

If several start sources are set, the last write may be unable to catch up with the next start. In such a case, end next descriptor pointer setting in (4) in read after write (do not end it in write).

(f) Example of setting DMAC restart

Use DDM CH1. The following shows an example of describing setting codes for reconfiguration when the TE bit of the DMAC1 CH0 channel control register is HI.

```
//TE bit read
    H'DDDD 0020
    H'FE00 802C
    H'0000 0002
    H'0000 0002
//TE bit clear
    H'DDDD 0021
    H'FE00 802C
    H'0010 5400
    H'FFFF FFFF
//SAR setting
    H'DDDD 0021
    H'FE00 8020
    H'5800 0000
    H'FFFF FFFF
//DAR setting
    H'DDDD 0021
    H'FE00 8024
    H'0000 0000
    H'FFFF FFFF
//TCR setting
    H'DDDD 0021
```

H'FE00 8028
H'0000 0010
H'FFFF FFFF
//DE bit write. DMA start
H'DDDD 0021
H'FE00 802C
H'0010 5401
H'FFFF FFFF
//Next descriptor pointer write.
H'DDDD 0021
H'E65C 0050
H'5800 02D0
H'FFFF FFFF
//Setting end by this start. (dummy read)
H'DDDD 0028
H'E65C 0050
H'0000 0000
H'0000 0000

(3) Start and end

(a) Starting the DDM

Make necessary settings in the DDM.

- Enabling interrupt output as required
  - Setting a DDM start source
    - Setting a descriptor pointer

After setting the above, set the DDM Enable bit of the DDM control register to 1 to enable DDM start.

Setting example:
Enable the interrupt by DDM CH1 end.
Address: H'E65C 0008 Write data: H'0000 0001
Enable DDM CH1 start when the DMAC1 TE bit is changed.
Address: H'E65C 0030 Write data: H'0000 1000
Set the DDM CH1 descriptor pointer to H'5800 0210.
Address: H'E65C 0050 Write data: H'5800 0210
Enable DDM CH1 start.
Address: H'E65C 0054 Write data: H'0000 0001

Set the KICK bit to forced start after setting the DDM Enable bit to 1. Do not set these bits at the same time.

(b) Ending the DDM

When the DDM ends, the DDM_END bit is set to 1. DDM end is cleared by setting the DDE bit to 0. To restart the DDM, you must clear the DDM_END bit by setting the DDE bit to 0.

Procedure for stopping the DDM by the STOP bit
Set the STOP bit to 1. Keep the DDE bit at 1.
Check that the DDM_END bit is 1.
Set the DDE bit to 0.

44. RCLK Watchdog Timer

44.1 Overview

This LSI includes the RCLK watchdog timer (RWDT).

This LSI can be reset by the overflow of the counter when the value of the counter has not been updated because of a system runaway.

The RWDT is a single-channel timer that uses the RCLK as an input and can be used as a watchdog timer.

RCLK is a clock, which is generated by the clock pulse generator (CPG).

44.1.1 Features

- One channel is provided.
- Can be used as a watchdog timer. Reset is generated when the counter overflows.
- A counter input clock can be chosen from:
  Clocks (RCLK/1 to RCLK/(128 × 60 × 30)) that are obtained by dividing the RCLK.

44.1.2 Block Diagram

Figure 44.1 shows block diagrams of the RWDT.

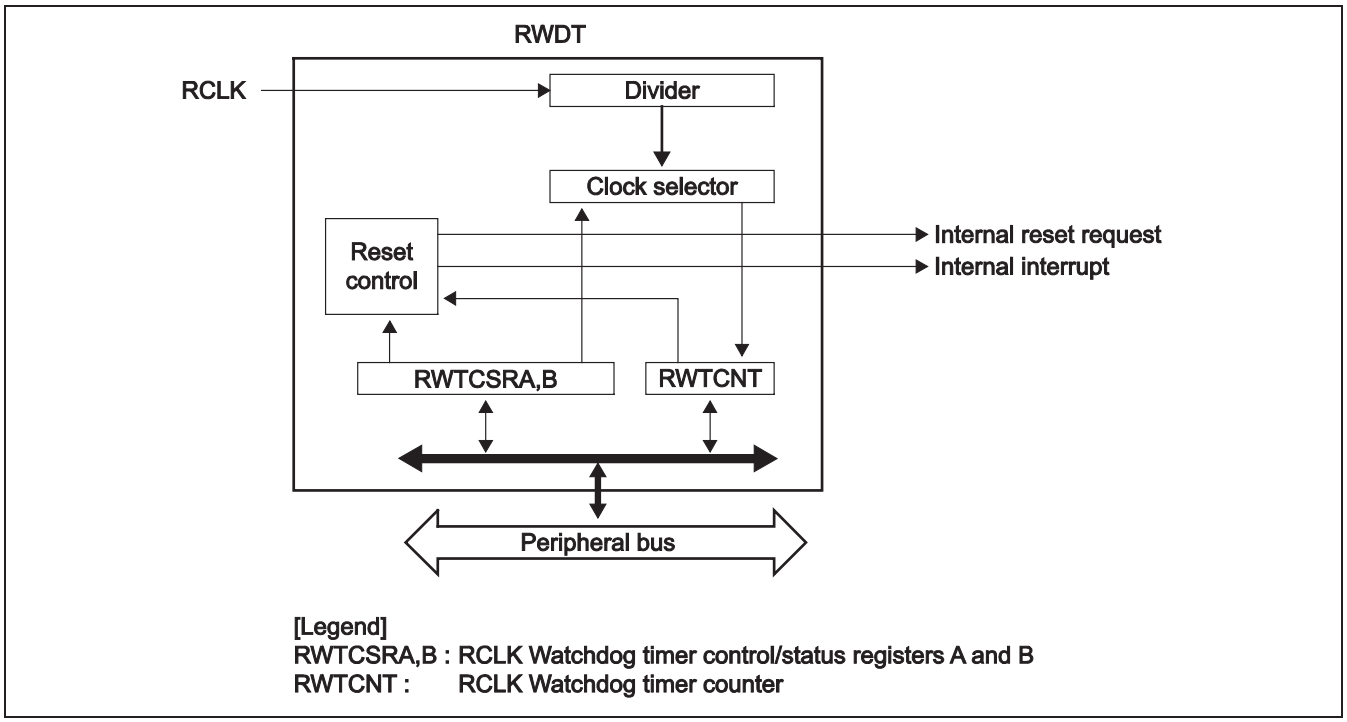

Figure 44.1 Block Diagram of RWDT

44.2 Register Descriptions for RWDT

Table 44.1 shows the RWDT register configuration. Table 44.2 shows the register state in each processing mode.

Table 44.1 Register Configuration of RWDT

Name	Abbreviation	R/W	Address	Access Size
RCLK watchdog timer counter	RWTCNT	R/W	H'E602 0000	16/32*
RCLK watchdog timer control/status register A	RWTCSRA	R/W	H'E602 0004	8/32*
RCLK watchdog timer control/status register B	RWTCSRB	R/W	H'E602 0008	8/32*

Note: * Write is performed in 32 bits and read in 16 or 8 bits.

Table 44.2 Register State of RWDT in Each Processing Mode

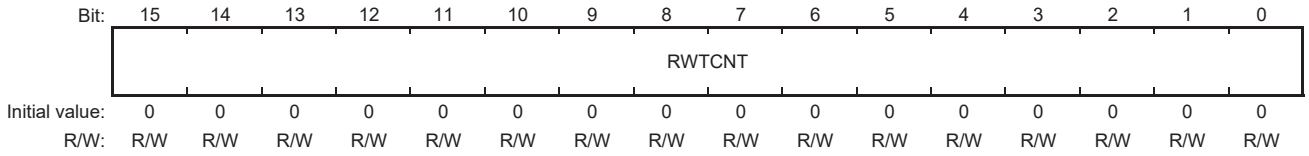
Register Abbreviation		Reset Caused by Other than Overflow	Reset Caused by Overflow*
Register	Bit		
RWTCNT	All	Initialized	Initialized
RWTCSRA	WOVF	Initialized	Retained
	Other than WOVF	Initialized	Initialized
RWTCSRB	All	Initialized	Initialized

Note: * RWDT overflow reset.

44.2.1 RCLK Watchdog Timer Counter (RWTCNT)

RWTCNT is a 16-bit readable/writable register that increments on the selected clock. When an overflow occurs, it generates a Reset. The RWTCNT counter is initialized to H'0000 by a power-on reset and RWDT software reset.

Use a long word access to write to the RWTCNT counter, with H'5A5A in the upper byte. Use a word access to read RWTCNT.



Bit	Bit Name	Initial Value	R/W	Description
15 to 0	RWTCNT	0	R/W	Timer Counter Up Bits

44.2.2 RCLK Watchdog Timer Control/Status Register A (RWTCSRA)

RWTCSRA is an 8-bit readable/writable register composed of bits to select the clock used for the count, overflow flag, and enable bit.

Use a long word access to write to RWTCSRA, with H'A5A5A5 in the upper byte. Use a byte access to read RWTCSRA.

Bit:	7	6	5	4	3	2	1	0
	TME	—	WRFLG	WOVF	WOVFE	CKS0[2:0]		
Initial value:	0	0	0	0	1	1	1	1
R/W:	R/W	R	R	R/(W)	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7	TME	0	R/W	Starts and stops timer operation. 0: Timer disabled: Count-up stops and RWTCNT value is retained 1: Timer enabled
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
5	WRFLG	0	R	Write Status Flag When this bit is 1, write access to RWTCNT is prohibited. If it isn't maintained, operation isn't secured. This bit indicates the period that the writing to RWTCNT is masked for synchronization after the writing to RWTCNT Confirm that this flag is 0 when RWTCNT is written to continuously.
4	WOVF	0	R/(W)	Indicates that the RWTCNT has overflowed. This bit isn't initialized by a generated reset by an overflow of RWDT. Write 0 to this bit before using the RWDT. 0: No overflow 1: RWTCNT has overflowed Note: Only 0 can be written to clear the flag.
3	WOVFE	1	R/W	Overflow Interrupt Disable/Enable 0: Disables interrupts due to overflow 1: Enables interrupts due to overflow

Bit	Bit Name	Initial Value	R/W	Description
2 to 0	CKS0[2:0]	111	R/W	RTC Clock Select These bits select the clock to be used for the RWTCNT count from the eight types obtainable by dividing the RCLK. The overflow period that is shown inside the parenthesis in the table is the value when the RCLK is 31.7 kHz*. Note. *: 1560 MHz / (1024 * 48) = 31.73828125 kHz. 000: Rϕ (2.1 s (RWTCNT: H'FF00 = 8.06 ms)) 001: Rϕ/4 (8.2 s (RWTCNT: H'FF00 = 32.2 ms)) 010: Rϕ/16 (33.0 s (RWTCNT: H'FF00 = 129.0 ms)) 011: Rϕ/32 (66.0 s (RWTCNT: H'FF00 = 258.0 ms)) 100: Rϕ/64 (132.0 s (RWTCNT: H'FF00 = 516.0 ms)) 101: Rϕ/128 (264.0 s (RWTCNT: H'FF00 = 1.03 s)) 110: Rϕ/1024 (2112.0 s (RWTCNT: H'FF00 = 8.25 s)) 111: RCLK select expanded mode The clock cycle varies depending on the CKS1 bit in RWTCSRB. Its initial value is Rϕ/4096 (8438.0 s (RWTCNT: H'FF00 = 33.0 s)). Note: These overflow periods are calculated from the rounded value of Rϕ = 31.7 kHz.

Note: If bits CKS0[2:0] are modified when the RWDT is operating, the up-count may not be performed correctly. Ensure that the bits CKS0[2:0] are modified only when the RWDT is not operating.

44.2.3 RCLK Watchdog Timer Control/Status Register B (RWTCSRB)

RWTCSRB is an 8-bit readable/writable register composed of bits to select the clock used for the count.

Use a word access to write to RWTCSRB, with H'A5A5A5 in the upper byte. Use a byte access to read RWTCSRB.

Bit:	7	6	5	4	3	2	1	0
	—	—	CKS1[5:0]					
Initial value:	0	0	0	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
7, 6	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
5 to 0	CKS1[5:0]	All 0	R/W	RCLK Select for RCLK Select Expanded Mode Selects the clock used for the RWTCNT count when the CKS0 bit in RWTCSRA is B'111. The following table shows the time values used to cause an overflow from the counter H'0000 (Overflow time from counter H'FF00). Assuming that Rϕ/128 = 264 s (1.01 s), the overflow cycle in the table is calculated for the case when the RCLK is 31.7 kHz.

CKS1[5:4] / CKS1[3:0]	B'00	B'01	B'10	B'11
H'0	8438 s (33 s)			
H'1	264 s (1.01 s)	1320 s (5.05 s)	264 min (1.01 min)	— (5.05 min)
H'2	528 s (2.02 s)	2640 s (10.1 s)	528 min (2.02 min)	— (10.1 min)
H'3	1055 s (3.03 s)	5280 s (15.2 s)	1056 min (3.03 min)	— (15.2 min)
H'4	4219 s (4.04 s)	— (20.2 s)	— (4.04 min)	— (20.2 min)
H'5	— (5.05 s)	— (25.3 s)	— (5.05 min)	— (25.3 min)
H'6	— (6.06 s)	— (30.3 s)	— (6.06 min)	— (30.3 min)
H'7	— (7.07 s)	— (35.4 s)	— (7.07 min)	— (—)
H'8	— (8.08 s)	— (40.4 s)	— (8.08 min)	— (—)
H'9	— (9.09 s)	— (45.5 s)	— (9.09 min)	— (—)
H'A	— (10.1 s)	— (50.5 s)	— (10.1 min)	— (—)
H'B	— (—)	— (55.6 s)	— (—)	— (—)
H'C	— (—)	— (60.6 s)	— (—)	— (—)
from H'D	— (—)	— (—)	— (—)	— (—)

Note: — (—): Reserved, — (xxx): Not recommendable
These overflow periods are calculated from the rounded value of Rϕ = 31.7 kHz.

Note: If the CKS1[5] to CKS1[0] bits are modified when the RWDT is running, the up-count may not be performed correctly. Ensure that these bits are modified only when the RWDT is not running.

44.2.4 Notes on Register Access

RWTCSRA: Bits TME, CKS0

RWTCSRB: Bits CKS1

After writing a value in this register, it is possible to read that value immediately, but it is not reflected in operation. 2 cycles of RCLK need to be inputted until the set-up value is reflected.

RWTCNT: Bits 15 to 0

After writing a value in this register, it is possible to read that value immediately, but it is not reflected in operation. 2 cycles of RCLK need to be inputted until the set-up value is reflected. Writing to this register, once started, is protected from further write operations until the writing operation has been completed. Read RWTCSRA. If WRFLG is 0, the next value can be written in RWTCNT.

The writing procedure to RWTCNT, RWTCSRA, and RWTCSRB differs from that of other registers with the purpose of preventing an unintended write. The procedure for writing to these registers is given below.

Writing to RWTCNT, RWTCSRA, and RWTCSRB:

- These registers must be written by a long word transfer instruction. They cannot be written by a byte or word transfer instruction.
- When writing to RWTCNT, set the upper byte to H'5A5A and transfer the lower byte as the write data. When writing to RWTCSRA and RWTCSRB, set the upper byte to H'A5A5A5 and transfer the lower byte as the write data.

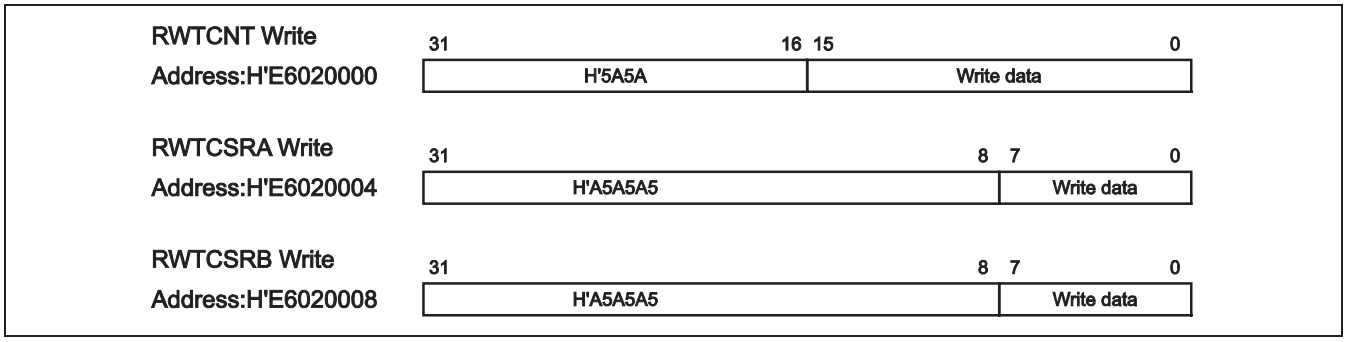


Figure 44.2 Writing to RWTCNT, RWTCSRA, and RWTCSRB

44.3 RWDT Usage

44.3.1 Control of System Runaway

After a reset, RWDT is disabled. When the counter overflow occurs after the counter starts, an internal reset is again generated. By this function, a reset can be automatically generated even when this LSI has caused a system runaway. While this LSI is operating correctly, write H'0000 (or the set value) to RWTCNT periodically so that RWTCNT does not overflow.

Take the following steps to use the RWDT.

1. Clear the TME bit in RWTCSRA to 0 to temporarily stop counting.
   (Confirm that RCLK was input more than 2 cycles.)
2. Write H'0000 or the set value in RWTCNT.
3. Clear the WOVF bit in RWTCSRA to 0.
4. Set the kind of count clock to the CKS0[2:0] bits in RWTCSRA, and CKS1[5:0] bits in RWTCSRB.
5. Confirm that RWTCSRA.WRFLG becomes 0.
   If WRFLG is 1, wait until it'll be 0.
6. Start the counting by setting the TME bit in RWTCSRA to 1.
   (TME and CKS0 can't be set at the same time. When setting that at the same time, behavior isn't guaranteed.)
7. While this LSI is operating correctly, write H'0000 (or the set value) to RWTCNT periodically so that RWTCNT does not overflow.
8. When RWTCNT overflows, Reset is generated because the RWDT sets the WOVF flag in RWTCSRA to 1. At this time, RWTCNT, RWTCSRA (excluding the WOVF bit), and RWTCSRB are initialized.

Execute a power-on reset or a software reset at that time and initialize RWDT.

When not initializing and using RWDT, behavior isn't guaranteed.

44.3.2 Module Stop

A setup of a stop of the Clock by a Module Stop signal is possible when RWDT is an Idle state. The Idle state of RWDT is when the condition of following all was satisfied.

- When RWTCSRA.TME bit is 0
- When RWTCSRA.WRFLG is 0
- When 3 or more cycles have passed in RCLK since the last Register access

44.3.3 Debugging Operation

When debugging the CPU core, stop counting up RWTCNT and retain the value of RWTCNT.

45A. Compare Match Timer 0 (CMT0)

45A.1 Features

- Two channels
- 16 bits/32 bits can be selected as counter size (bit-width).
- Provided with 32-bit constant registers and 32-bit up counters that can be written or read at any time.
- Following four clocks can be selected as counter clocks:
  — RCLK: 1/1, 1/8, 1/32, and 1/128
- One-shot operation or free-running operation is selectable.
- Compare match or overflow can be selected as interrupt source.
- Counter operation can be enabled or disabled at the time of debugging of CPU core using the debugging mode operation selector.

Figure 45A.1 shows a block diagram of the CMT0.

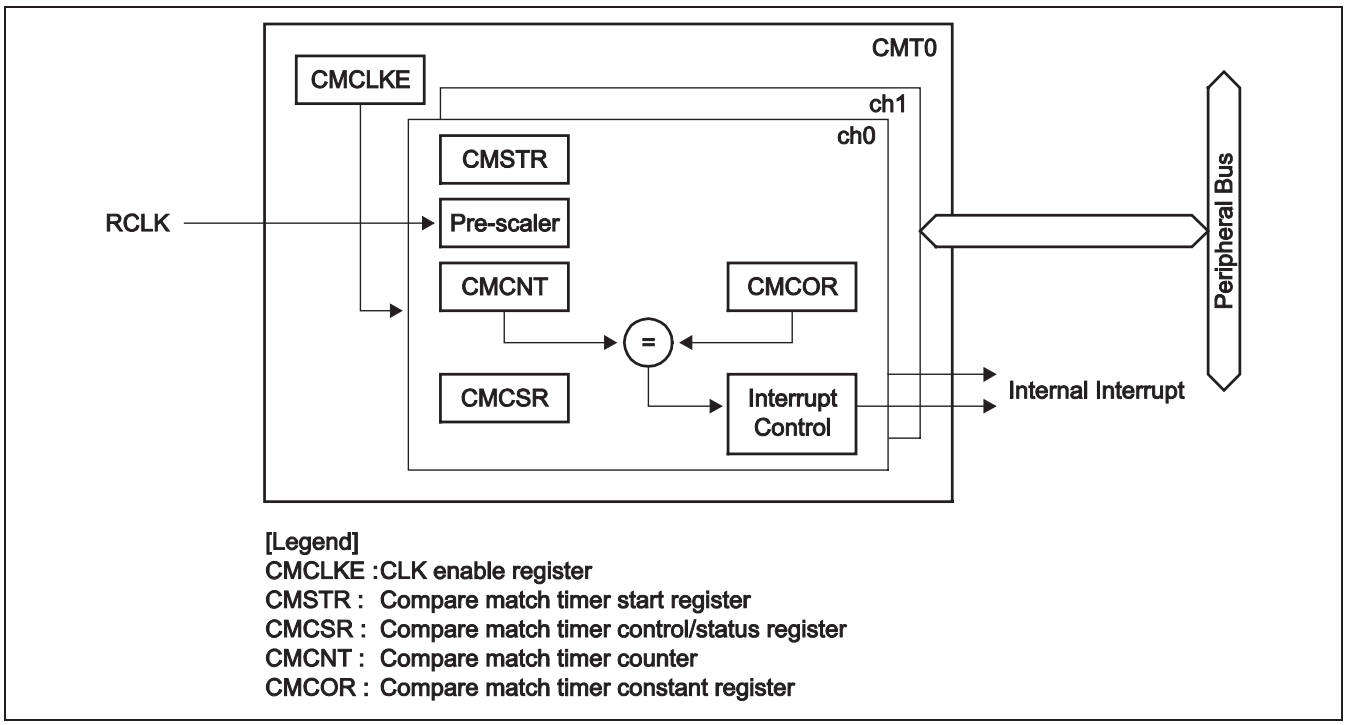

Figure 45A.1 Block Diagram of CMT0

45A.2 Register Descriptions

Table 45A.1 shows the CMT0 register configuration. Table 45A.2 shows the register states in each operating mode.

45A.2.1 CLK Enable Register (CMCLKE)

CMCLKE is a 32-bit register, which specifies clock supply to each channel. When there are unused channels, set 0 to this register, for stop supplying clock to the channel. It is prohibited to stop clock supply, while counter is working.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

15 to 7	—	All 1	R	Reserved These bits are always read as 1. The write value should always be 1.
6	Ch1clke	1	R/W	0: Clock isn't supplied to ch1. 1: Clock is supplied to ch1.
5	Ch0clke	1	R/W	0: Clock isn't supplied to ch0. 1: Clock is supplied to ch0.
4 to 0	—	All 1	R	Reserved These bits are always read as 1. The write value should always be 1.

45A.2.2 Compare Match Timer Start Registers 0 and 1 (CMSTR0, CMSTR1)

CMSTRn (n = 0/1) is a 32-bit register which specifies the operation of compare match timer counters (CMCNTn).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	STR0	1	R/W	Count Start These bits specify start/halt of compare match timer counter (CMCNTn). 0: CMCNTn halts 1: CMCNTn starts counting

45A.2.3 Compare Match Timer Control/Status Registers 0 and 1 (CMCSR0, CMCSR1)

CMCSRn (n = 0/1) is a 32-bit register that indicates the occurrence of compare matches, enables interrupts, and sets the counter input clocks.

Do not change bits other than the CMF and OVF bits, while compare match timer counter (CMCNTn) is under counting.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	CMF	OVF	WRFLG	—	—	—	CMS	CMM	—	—	CMR[1:0]		DBGIVD	CKS[2:0]		
Initial value:	0	0	0	0	0	0	0	1	0	0	0	0	1	1	1	1
R/W:	R/(W)	R/(W)	R	R	R	R	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	CMF	0	R/(W)	Compare Match Flag This flag indicates whether values of the compare match timer counter (CMCNTn) and compare match timer constant register (CMCORn) have matched or not. Software cannot write 1 to the bit. When one-shot is selected for the counter operation, counting resumes by clearing this bit. 0: CMCNTn and CMCORn values have not matched. [Clearing condition] Write 0 to CMF 1: CMCNTn and CMCORn values have matched. Note: Only 0 can be written to clear the flag.
14	OVF	0	R/(W)	Overflow Flag This flag indicates whether the compare match timer counter (CMCNTn) has overflowed or not. Software cannot write 1 to this bit. 0: CMCNTn has not overflowed. [Clearing condition] Write 0 to OVF 1: CMCNTn has overflowed. Note: Only 0 can be written to clear the flag.
13	WRFLG	0	R	Write State Flag Write access to CMCNTn is prohibited, while this this bit is 1. Further behavior is not guaranteed, if data is written while this bit is 1. This bit indicates CMCNTn is in synchronization period for setting previously written data. Confirm that this flag is 0, before writing to CMCNTn.
12 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
9	CMS	0	R/W	Compare Match Timer Counter Size Specify whether the compare match timer counter (CMCNTn) is used as a 16-bit counter or a 32-bit counter. This bit specifies the valid size of compare match timer constant register (CMCORn). 0: Operates as a 32-bit counter. 1: Operates as a 16-bit counter. Note: Refer to section 45A.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.
8	CMM	1	R/W	Compare Match Mode Specify counter operation mode. 0: One-shot operation 1: Free-running operation Note: Refer to section 45A.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.
7, 6	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
5, 4	CMR[1:0]	00	R/W	Compare Match Request These bits enable or disable an internal interrupt request in a compare match. 00: Disables an internal interrupt request. 01: Setting prohibited 10: Enables an internal interrupt request. 11: Setting prohibited Note: Refer to section 45A.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.
3	DBGIVD	1	R/W	Debug Mode Operation Select Sets the counter operation in debug mode. 0: Stops the counter operation in debug mode. 1: Enables the counter operation even in debug mode. Note: Refer to section 45A.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.
2 to 0	CKS[2:0]	111	R/W	Clock Select These bits select the input clock to CMCNTn. When the count start bit (STR0) in CMSTRn is set to 1, CMCNTn begins incrementing with the clock selected by these bits. 000: Setting prohibited 001: Setting prohibited 010: Setting prohibited 011: Setting prohibited 100: RCLK/8 101: RCLK/32 110: RCLK/128 111: RCLK/1 Note: Refer to section 45A.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.

45A.2.4 Compare Match Timer Counters 0 and 1 (CMCNT0, CMCNT1)

CMCNTn (n = 0 to 1) is a 32-bit register that is used as an up-counter.

To specify counter operation, set compare match timer control/status register n (CMCSRn), before starting operation of corresponding channel.

When the 16-bit counter operation is selected by the CMS bit, bits 31 to 16 of this register become invalid. When data is written to this register in 16-bit mode, write H'0000 to the upper 16 bits.

When CMCNTn is read during the counter operation, the read value may be wrong because different clock is used between counter and bus-interface. For exact value, read this register continuously, until same values are read from this register.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	—	All 0	R/W	Compare match timer counter bit31 to 0 Note: Refer to section 45A.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.

45A.2.5 Compare Match Timer Constant Registers 0 and 1 (CMCOR0, CMCOR1)

CMCORn (n = 0/1) is a 32-bit register that sets the compare match period with CMCNTn.

When the 16-bit counter operation is selected by the CMS bit in CMCSRn, bits 15 to 0 of this register become valid. Write H'0000 to upper 16bits in 16-bit counter operation.

An overflow is detected when CMCNTn is cleared to 0 and this register is H'FFFFFFFF.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	—	All 1	R/W	Compare match timer constant register bit31 to 0 Note: Refer to section 45A.3.5, CMT0 Register Access, for the note regarding writing to or reading from this bit.

45A.3 Operation

45A.3.1 Counter Operation

The CMT0 starts the operation of the counter by writing 1 to the STR0 bit in CMSTRn after each register has been set. Complete all of the settings before starting the operation. Do not change the register settings other than clearing flag bits, during the compare match timer n (CMCNTn) is under operation.

The counter operates in one of two ways.

- One-Shot Operation

  One-shot operation is selected by setting the CMM bit in CMCSRn to 0. When the value in CMCNTn matches the value in CMCORn, the value in CMCNTn is cleared to H'00000000 and the CMF bit in CMCSRn is set to 1. Counting by CMCNTn stops after it has been cleared.

  To detect an overflow interrupt, set the value in CMCORn to H'FFFFFFFF. When the value in CMCNTn matches the value in CMCORn, CMCNTn is cleared to H'00000000 and the CMF and OVF bits in CMCSRn are set to 1.

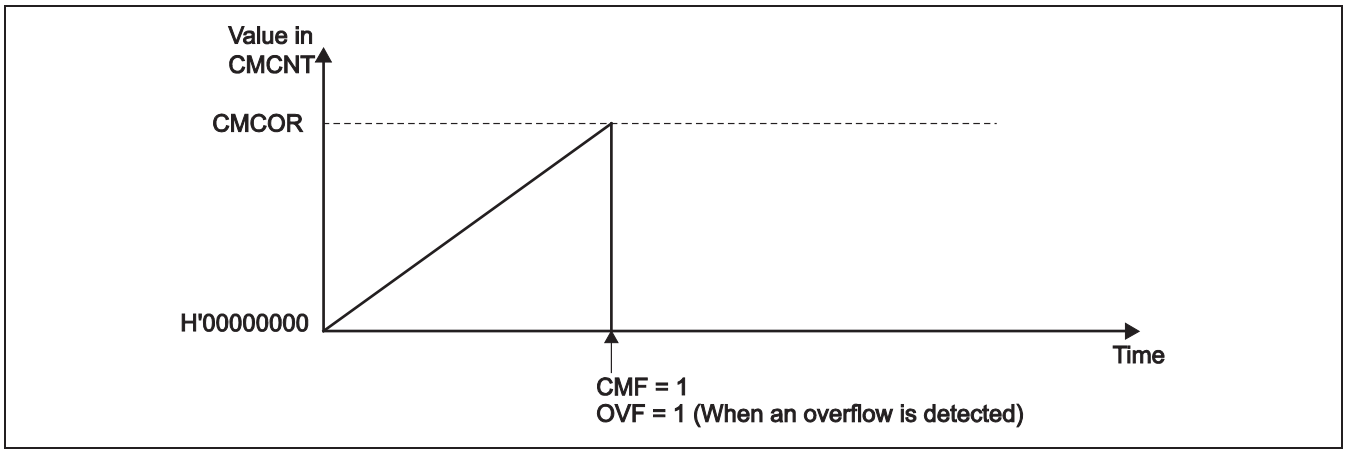

Figure 45A.2 Counter Operation (One-Shot Operation)

- Free-Running Operation

  Free-running operation is selected by setting the CMM bit in CMCSRn to 1. When the value in CMCNTn matches the value in CMCORn, CMCNTn is cleared to H'00000000 and the CMF bit in CMCSRn is set to 1. CMCNTn resumes counting-up after it has been cleared.

  To detect an overflow interrupt, set CMCORn to H'FFFFFFFF. When the values in CMCNTn and CMCORn match, CMCNTn is cleared to H'00000000 and the CMF and OVF bits in CMCSRn are set to 1.

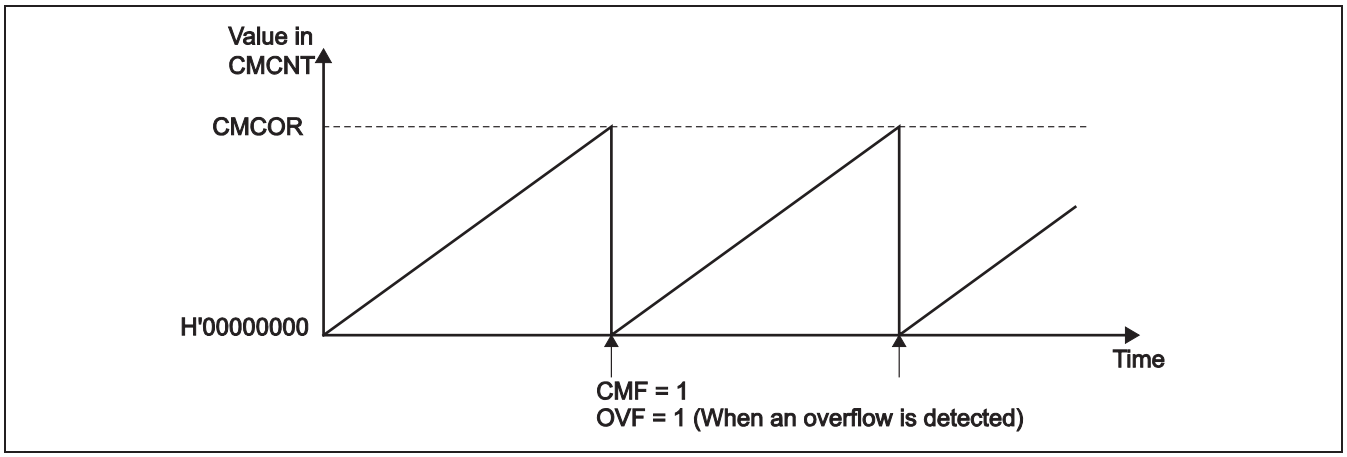

Figure 45A.3 Counter Operation (Free-Running Operation)

45A.3.2 Counter Size

In this module, the size of the counter can be selected from 16, or 32 bits. This is selected by the CMS bit in CMCSRn.

When the 16-bit size is selected, H'0000 should be used as upper 16 bits of write data to CMCORn. To detect an overflow interrupt, CMCORn must be set to H'0000FFFF.

45A.3.3 Timing for Counting by CMCNTn

In this module, the clock for the counter can be selected from among the following:

- RCLK: 1/1, 1/8, 1/32, and 1/128

The clock for the counter is selected by the CKS bits in CMCSRn. CMCNTn is incremented at the rising edge of the selected clock.

45A.3.4 Internal Interrupt Request to CPU

By CMR bits in CMCSRn, internal interrupt request to the CPU at a compare match can be asserted.

To clear the internal interrupt request to the CPU, the CMF bit should be set to 0. Set the CMF bit to 0 in the handling routine for the CMT0 interrupt.

45A.3.5 CMT0 Register Access

After writing to following registers, written data can be read after writing has finished. However, it takes 2 cycles in counter input clock (RCLK), for reflecting written data to counter behavior.

CMCSRn: Bits CKS, CMM, CMS, CMR, DBGIVD

CMCORn: Bits 31 to 0

CMSTRn: Bit STR0

After writing to following registers, written data can be read after writing has finished. However, it takes 2 cycles in counter input clock (RCLK), for reflecting written data to counter behavior.

And for following registers, write access is prohibited, while previously written data is under writing. Do not perform next write access, while CMCSRn.WRFLG is 1.

CMCNT*: Bits 31 to 0

45A.3.6 Compare Match Flag Set/Clear Timing

The CMF bit in CMCSRn is set to 1 by the compare match signal generated when CMCORn and CMCNTn match. The compare match signal is generated upon the final state of the match (timing at which the CMCNTn value is updated to 0). Consequently, after CMCORn and CMCNTn match, a compare match signal will not be generated until a CMCNTn counter clock is input. Figure 45A.4 shows the set timing of the CMF bit.

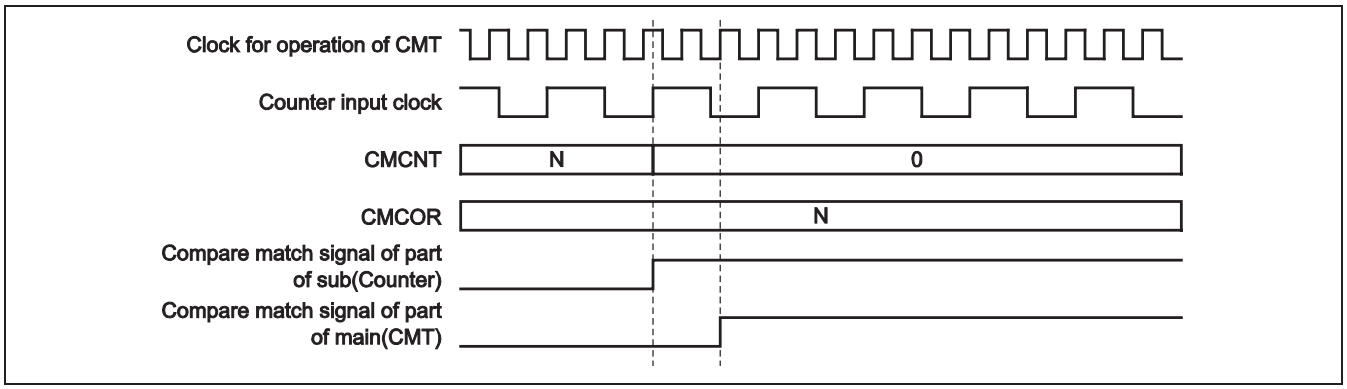

Figure 45A.4 CMF Set Timing

Set the CMF bit as 0. The CMF flag is cleared immediately.

45A.3.7 CMT0 Usage

Take the following steps to use the CMT0.

1. Clear the STR0 bit in CMSTRn to 0 to temporarily stop counting.
   (Confirm that RCLK was input more than 2 cycles.)
2. Write H'00000000 on CMCNTn.
3. Set counter size, compare match mode, type of counter clock and interrupt request and clear the bit of OVF and CMF in CMCSRn.
4. Set the value on CMCORn.
5. Confirm that CMCSRn.WRFLG is 0.
   If WRFLG is 1, wait until it'll be 0.
6. Start the counting by setting the STR0 bit in CMSTRn to 1.
   (Refer to section 45A.3.5, CMT0 Register Access)

45A.3.8 Module Stop/CMCLKE Setting

When counter is not used, clock of this module can be stopped by CMCLKE register. Please confirm that, following conditions are satisfied, before stopping counter’s clock.

- CMSTRn.STR0 bit is 0
- CMCSRn.WRFLG is 0
- 3 or more cycles have passed in RCLK, since the last Register access

45B. Compare Match Timer 1 (CMT1)

45B.1 Features

- Eight channels
- 16 bits/32 bits/48 bits can be selected as counter size (bit-width).
- 48-bit constant registers and 48-bit up counters that can be written or read at any time.
- For channel 0 to 4, following twelve clocks can be selected as counter clock.
  - CPEXϕ: 1/8, 1/32, 1/128, and 1/1
  - RCLK: 1/1, 1/8, 1/32, and 1/128
  - Pseudo 32 kHz: 1/1, 1/8, 1/32, and 1/128
- For channel 5 to 7, following four clocks can be selected as counter clock.
  - RCLK: 1/1,1/8, 1/32, and 1/128
- One-shot operation or free-running operations are selectable.
- Compare match can be used as interrupt source.
- Support Module standby mode.
- RCLK-synchronous counter start/stop mode for channel 0
- Counter operation can be enabled or disabled at the time of debugging of CPU core using the debugging mode operation selector.

Figure 45B.1 shows a block diagram of the CMT1.

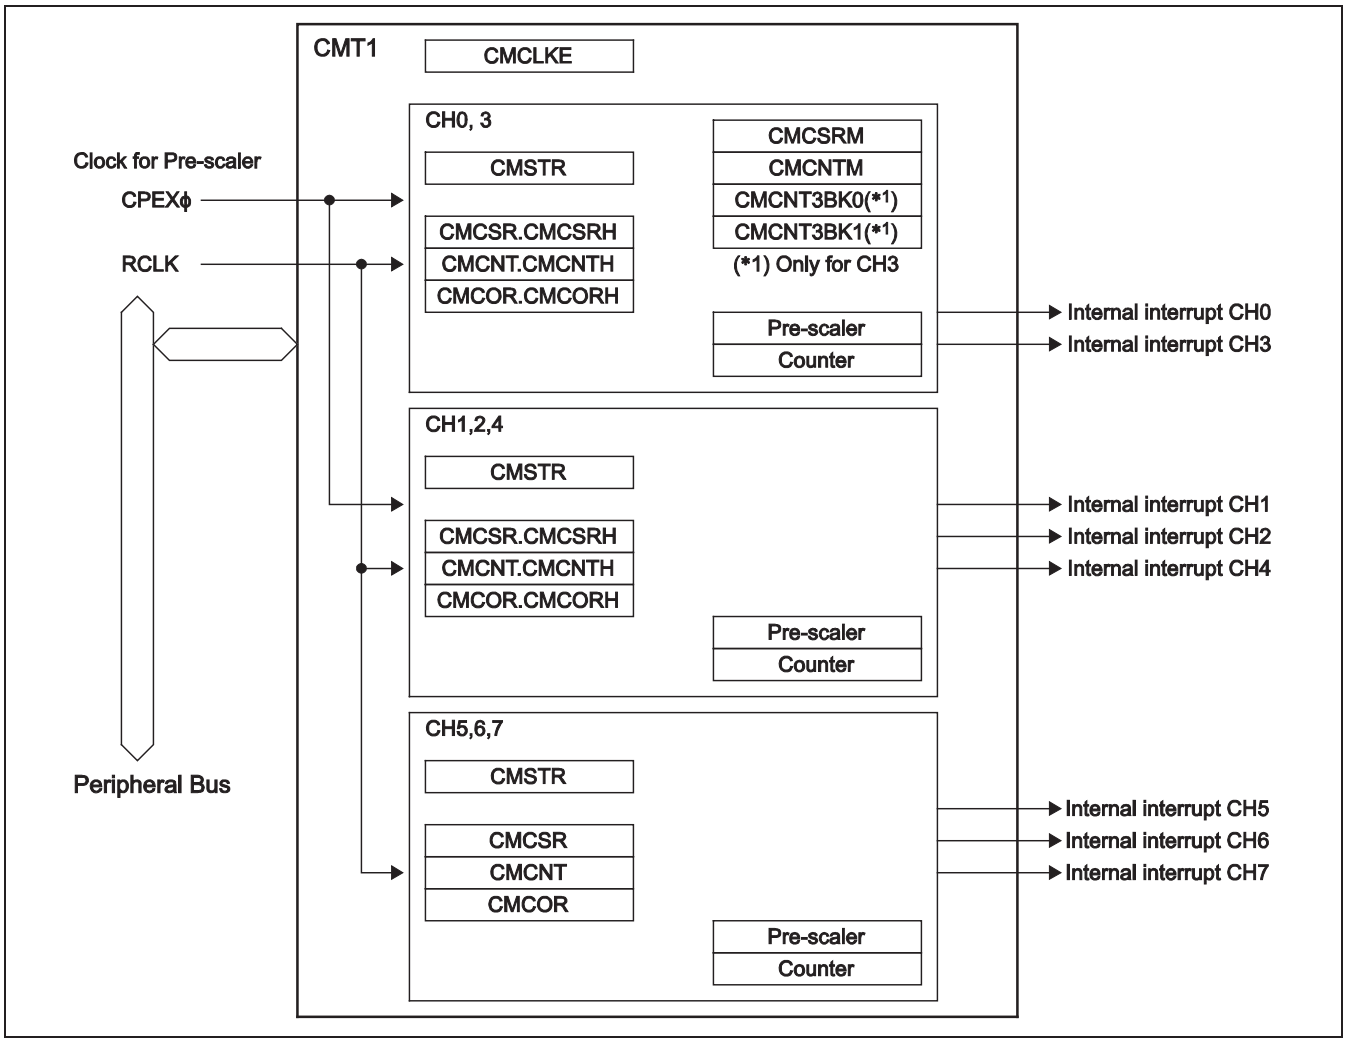

Figure 45B.1 Block Diagram of CMT1

45B.2 Register Descriptions

Table 45B.1 shows the CMT1 register configuration. Table 45B.2 shows the register states in each operating mode.

45B.2.1 CLK Enable Register (CMCLKE)

CMCLKE is a 32bits register, which specify clock supply to each channel. When there are unused channels, set ‘0’ as this register, to stop supplying clock to the channel. It is prohibited to stop clock supply, while counter is working.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

45B.2.2 Compare Match Timer Start Registers 0 to 7 (CMSTRn)

CMSTRn (n = 0 to 7) is a 32-bit register which specify the operation of compare match timer counter (CMCNTn). Refer to section 45B.3.5, Register Access, for register value update timing.

(1) CMSTR0

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	STR0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	STR0	1	R/W	Count Start 0 These bits specify start/halt of compare match timer counter (CMCNTn). 0: CMCNTn halts 1: CMCNTn starts counting

45B.2.3 Compare Match Timer Control/Status Registers 0 to 7 (CMCSRn)

CMCSRn (n = 0 to 7) is a 32-bit register that indicates the occurrence of compare match, enable interrupt and set the counter input clock.

Do not change bits other than the CMF and OVF bits, while compare match timer counter (CMCNTn) is under counting.

(1) CMCSR0

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1
R/W:	R/(W)	R/(W)	R	R/(W)	R/(W)	R/W	R/W	R/W	R	R	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	CMF	0	R/(W)	Compare Match Flag This flag indicates whether values of the compare match timer counter (CMCNT0) and compare match timer constant register (CMCOR0) have matched or not. Software cannot write 1 to the bit. When one-shot is selected for the counter operation, counting resumes by clearing this bit. 0: CMCNT0 and CMCOR0 values have not matched [Clearing conditions] • Write 0 to this bit 1: CMCNT0 and CMCOR0 values have matched Note: Only 0 can be written to clear the flag.
14	OVF	0	R/(W)	Overflow Flag This flag indicates whether the compare match timer counter (CMCNT0) has overflowed or not. Software cannot write 1 to this bit. 0: CMCNT0 has not overflowed [Clearing conditions] • Write 0 to this bit 1: CMCNT0 has overflowed Note: Only 0 can be written to clear the flag.
13	WRFLG	0	R	Write State Flag Write access to CMCNT0 is prohibited, while this bit is 1. Further behavior is not guaranteed, if data is written while this bit is 1. This bit indicates CMCNT0 is in synchronization period for setting previously written data. Confirm that this flag is 0, before writing to CMCNT0.

Bit	Bit Name	Initial Value	R/W	Description
12	CH0STTF	0	R/(W)	Channel 0 Start Flag When RCLK-synchronous channel 0 counter start/stop mode is selected, this flag indicates whether the counter in channel 0 started on detecting an RCLK rising edge after 1 was written to the STR0 bit in CMSR. 0: Channel 0 counter has not started. [Clearing condition] • Write 0 to CH0STTF. 1: Channel 0 counter has started. Note: Only 0 can be written to clear the flag.
11	CH0STPF	0	R/(W)	Channel 0 Stop Flag When RCLK-synchronous channel 0 counter start/stop mode is selected, this flag indicates whether the counter in channel 0 stopped on detecting an RCLK rising edge after 1 was written to the STR0 bit in CMSR. 0: Channel 0 counter has not stopped. [Clearing condition] • Write 0 to CH0STPF. 1: Channel 0 counter has stopped. Note: Only 0 can be written to clear the flag.
10	CH0SSIE	0	R/W	Channel 0 Start/Stop Interrupt Enable When RCLK-synchronous channel 0 counter start/stop mode is selected, this bit enables or disables an interrupt due to the start or stop of the counter in channel 0. 0: Disables an interrupt due to start or stop of channel 0 counter. 1: Enables an interrupt due to start or stop of channel 0 counter.
9	CMS	0	R/W	Compare Match Timer Counter Size This bit and CMCSRH0.CMSH select whether the compare match timer counter 0 (CMCNTH0[15:0], and CMCNT0[31:0]) is used as a 16-bit counter, a 32-bit counter, or a 48-bit counter. This bit also specifies valid size of the compare match timer constant register 0 (CMCORH0[15:0], and CMCOR0[31:0]). CMCSRH0[9].CMSH, and CMCSR0[9].CMS: 1x: Operates as a 48-bit counter 00: Operates as a 32-bit counter 01: Operates as a 16-bit counter
8	CMM	0	R/W	Compare Match Mode Specify operation mode of the counter. 0: One-shot operation 1: Free-running operation
7	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
6	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
5, 4	CMR[1:0]	00	R/W	Compare Match Request These bits enable or disable internal interrupt request in a compare match. 00: Disables internal interrupt request 01: Setting prohibited 10: Enables an internal interrupt request 11: Setting prohibited
3	DBGIVD	1	R/W	Debug Mode Operation Select Sets the counter operation in debugging mode. 0: Stops the counter operation in debugging mode. 1: Continues the counter operation even in debugging mode.
2 to 0	CKS[2:0]	111	R/W	Clock Select These bits and CMCSRH0.CKSH select the clock input to CMCNT0. When the count start bit (STR0) for the corresponding channel is set to 1, CMCNT0 begins incrementing with the clock selected by these bits. CMCSRH0.CKSH[0]+CMCSR0.CKS[2:0]: x000: CPEXϕ/8 x001: CPEXϕ/32 x010: CPEXϕ/128 x011: CPEXϕ/1 0100: RCLK/8 0101: RCLK/32 0110: RCLK/128 0111: RCLK/1 1100: Pseudo 32 kHz/8 1101: Pseudo 32 kHz/32 1110: Pseudo 32 kHz/128 1111: Pseudo 32 kHz/1

(2) CMCSRn (n = 1 to 4)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
15	CMF	0	R/(W)	Compare Match Flag This flag indicates whether values of the compare match timer counter (CMCNTn) and compare match timer constant register (CMCORn) have matched or not. Software cannot write 1 to the bit. When one-shot is selected for the counter operation, counting resumes by clearing this bit. 0: CMCNTn and CMCORn values have not matched [Clearing conditions] • Write 0 to this bit 1: CMCNTn and CMCORn values have matched Note: Only 0 can be written to clear the flag.
14	OVF	0	R/(W)	Overflow Flag This flag indicates whether the compare match timer counter (CMCNTn) has overflowed or not. Software cannot write 1 to this bit. 0: CMCNTn has not overflowed [Clearing conditions] • Write 0 to this bit 1: CMCNTn has overflowed Note: Only 0 can be written to clear the flag.
13	WRFLG	0	R	Write State Flag Write access to CMCNTn is prohibited, while this this bit is 1. Further behavior is not guaranteed, if data is written while this bit is 1. This bit indicates CMCNTn is in synchronization period for setting previously written data. Confirm that this flag is 0, before writing to CMCNTn.
12 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

Bit	Bit Name	Initial Value	R/W	Description
9	CMS	0	R/W	Compare Match Timer Counter Size This bit and CMCSRHn.CMSH specify whether the compare match timer counter (CMCNTHn[15:0] and CMCNTn[31:0]) is used as a 16-bit counter, a 32-bit counter, or a 48-bit counter. This setting becomes the valid size for the compare match timer constant register (CMCORHn[15:0], CMCORn[31:0]). CMCSRHn[9].CMSH+CMCSRn[9].CMS: 1x: Operates as a 48-bit counter 00: Operates as a 32-bit counter 01: Operates as a 16-bit counter
8	CMM	0	R/W	Compare Match Mode Specify counter operation mode. 0: One-shot operation 1: Free-running operation
7, 6	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
5, 4	CMR[1:0]	00	R/W	Compare Match Request These bits enable or disable internal interrupt request in a compare match. 00: Disables internal interrupt request 01: Setting prohibited 10: Enables an internal interrupt request 11: Setting prohibited
3	DBGIVD	1	R/W	Debug Mode Operation Select Sets the counter operation in debugging mode. 0: Stops the counter operation in debugging mode. 1: Continues the counter operation even in debugging mode.
2 to 0	CKS[2:0]	111	R/W	Clock Select These bits and CMCSRHn.CKSH specify the input clock to CMCNTn. When the count start bit (STR0) for the corresponding channel is set to 1, CMCNTn begins incrementing with the clock selected by these bits. CMCSRHn.CKSH[0], CMCSRn.CKS[2:0]: x000: CPEXϕ/8 x001: CPEXϕ/32 x010: CPEXϕ/128 x011: CPEXϕ/1 0100: RCLK/8 0101: RCLK/32 0110: RCLK/128 0111: RCLK/1 1100: Pseudo 32 kHz/8 1101: Pseudo 32 kHz/32 1110: Pseudo 32 kHz/128 1111: Pseudo 32 kHz/1

31 to 10	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
9	CMSH	0	R/W	Compare Match Timer Counter Size This bit and CMCSRn.CMS specify whether the compare match timer counter (CMCNTHn[15:0] and CMCNTn[31:0]) is used as a 16-bit counter, a 32-bit counter, or a 48-bit counter. This bit also specify valid size for the compare match timer constant register (CMCORHn[15:0], CMCORn[31:0]). CMCSRHn.CMSH[9], CMCSRn.CMS[9]: 1x: Operates as a 48-bit counter 00: Operates as a 32-bit counter 01: Operates as a 16-bit counter
8 to 1	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
0	CKSH	0	R/W	Clock Select This bit and CMCSRn.CKS[2:0] select the clock input to CMCNT. When the count start bit (STR0) for the corresponding channel is set to 1, CMCNTn begins incrementing with the clock selected by these bits. CMCSRHn.CKSH[0], CMCSRn.CKS[2:0]: x000: CPEXϕ/8 x001: CPEXϕ/32 x010: CPEXϕ/128 x011: CPEXϕ/1 0100: RCLK/8 0101: RCLK/32 0110: RCLK/128 0111: RCLK/1 1100: Pseudo 32kHz/8 1110: Pseudo 32kHz/32 1101: Pseudo 32kHz/128 1111: Pseudo 32kHz/1

Note: CMSH, CKSH For write or read, refer to section 45B.3.5, Register Access.

45B.2.5 Compare Match Timer Counters 0 to 7 (CMCNTn)

CMCNTn (n = 0 to 7) is a 32-bit register which is used as an up-counter of each channel.

To specify counter operation, set compare match timer control/status register n (CMCSRn), before starting operation of corresponding channel. When the 16-bit counter operation is selected by the CMCSRH.CMSH and CMCSR.CMS bits, bits 31 to 16 of this register is invalid. When data is written to this register in 16-bit mode, write H'0000 to the upper 16 bit.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	—	All 0	R/W	Compare match timer counter bit31 to 0 Note: For access to this register, refer to section 45B.3.5, Register Access.

45B.2.6 Compare Match Timer Counters H 0 to 4 (CMCNTHn)

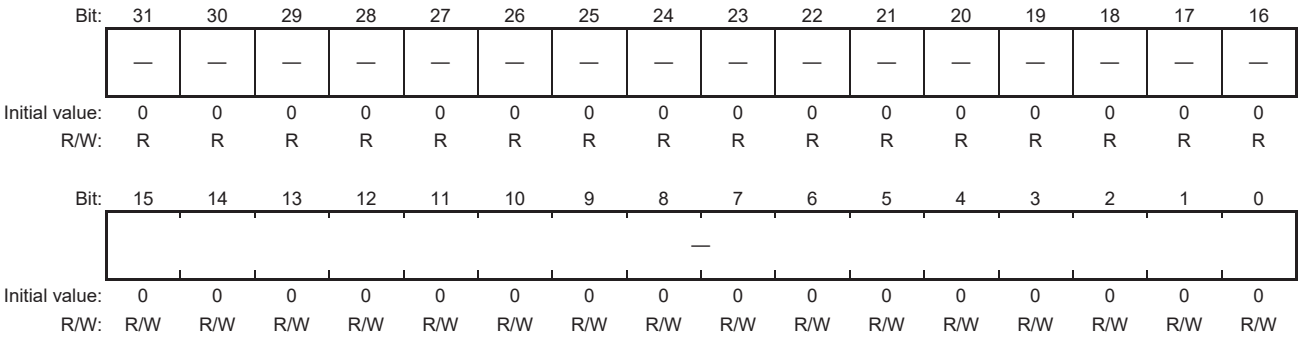
CMCNTHn (n = 0 to 4) is a 32-bit register which is used as an up-counter for channel0 to 4.

To specify counter operation, set compare match timer control/status register n (CMCSRn/CMCSRHn), before starting operation of corresponding channel. When the 48-bit counter operation is selected by the CMCSRHn.CMSH and CMCSRn.CMS bits, bits 15 to 0 of this register become valid as the upper 16-bit of 48-bit counter. The value written to this register is reflected to counter behavior, when lower data is written to CMCNTn. Write the upper data to this register first. The value is not reflected to counter's behavior, if data is not written to CMCNTn later.

When reading the value of 48-bit counter, upper 16-bit can be read out by reading bits 15 to 0 of this register.

At the same time of the reading, the value of 48-bit counter is stored to the read-buffer. After reading CMCNTHn, lower 32-bit can be read out by reading CMCNTn.

Note: If CMCNTn is read out before reading CMCNTHn, the read out value of 48-bit counter may not be correct.



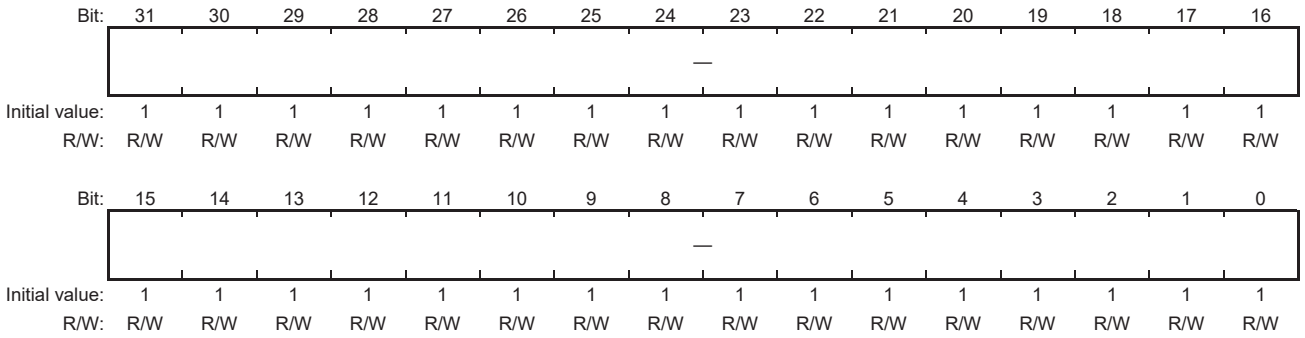
Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
15 to 0	—	All 0	R/W	Compare match timer counter H bit15 to 0 Note: For access to this register, refer to section 45B.3.5, Register Access.

45B.2.7 Compare Match Timer Constant Registers 0 to 7 (CMCORn)

CMCORn is a 32-bit register which specify the compare match period of CMCNTn for each channel.

When the 16-bit counter operation is selected by the CMCSRHn.CMSH and CMCSRn.CMS bits, bits 31 to 16 of this register is invalid. When data is written to this register in 16-bit operation mode, write H'0000 as upper 16bit.

An overflow is detected when CMCNTn is cleared to 0 and this register is H'FFFF FFFF (when the 16-bit counter operation it is H'0000 FFFF).



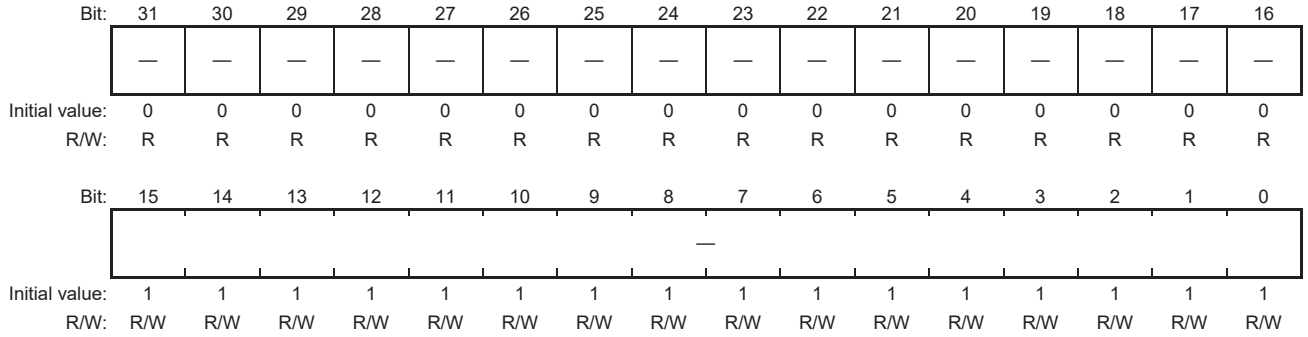
Bit	Bit Name	Initial Value	R/W	Description
31 to 0	—	All 1	R/W	Compare match timer constant register bit31 to 0 Note: For access to this register, refer to section 45B.3.5, Register Access.

45B.2.8 Compare Match Timer Constant Registers H0 to 4 (CMCORHn)

CMCORHn is a 32-bit register which specify the compare match period with CMCNTHn for channel0 to 4.

When the 48-bit counter operation is selected by the CMCSRHn.CMSH and CMCSRn.CMS bits, bits 15 to 0 of this register become valid as the upper 16-bit of 48-bit counter.

An overflow is detected when CMCNTHn is cleared to 0 and this register is H'FFFF.



Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
15 to 0	—	All 1	R/W	Compare match timer constant register H bit15 to 0 Note: For access to this register, refer to section 45B.3.5, Register Access.

45B.2.9 Compare Match Timer Counter 3 Backup 0 (CMCNT3BK0)

CMCNT3BK0 is a 32-bit register which stores a copy of the CMCNT3 value immediately after the counter in channel 0 stops in RCLK-synchronous channel 0 counter start/stop mode.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	—	All 0	R	Compare match timer counter 3 backup 1 bit31 to 0

45B.2.11 Compare Match Timer Match Control/Status Registers 0 and 3 (CMCSRMn)

CMCSRMn is a 32-bit register which resets to compare match timer match counter, and sets the counter start/halt. This register is only present in channels 0 and 3.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

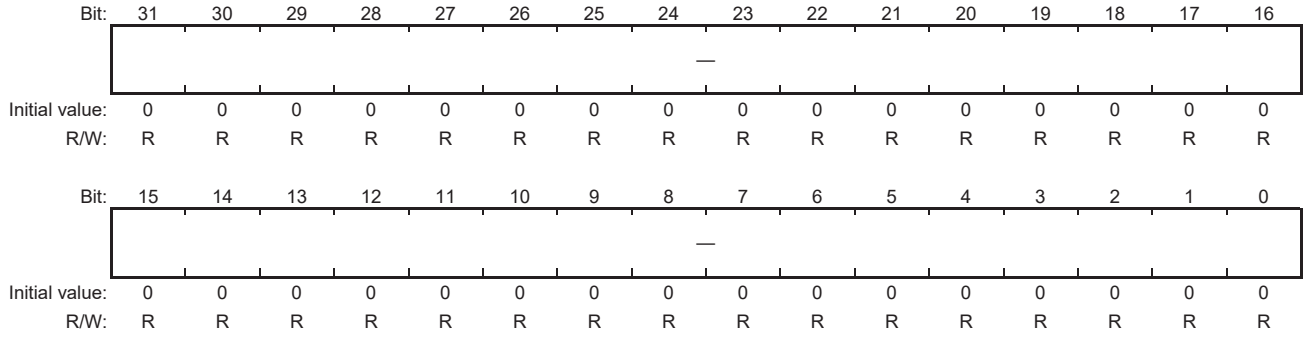
Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WRFLG	—	—	—	—	—	—	—	—	—	—	—	—	—	CMPCLR	CMPSTART
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
15	WRFLG	0	R	Write state flag. When this Bit is 1, CMCNTMn cannot be cleared. After CMCNTMn is cleared, this bit become 1 for a while (*), for indicating synchronization period. Needs to confirm this flag is 0 or wait the period enough when continuously clearing. Note: * In the maximum, "Counter input clock 6 cycle" • Counter input clock CMCSRn.CKS2 = 0: CPEXϕ CMCSRn.CKS2 = 1: RCLK
14 to 2	—	All 0	R	Reserved This bit is always read as 0. The write value should always be 0.
1	CMPCLR	0	R/W	Counter Clear [When writing] 0: No operation 1: Clears counter When CMPCLR and CMPSTART are written 1 at the same time, the counter starts after clearing the counter. [When reading] This bit is always read as 0.
0	CMPSTART	0	R/W	Count Start This bit specifies start/halt of the compare match timer match counter (CMCNTMn) of each channel. 0: CMCNTMn Halts 1: CMCNTMn Starts counting

45B.2.12 Compare Match Timer Match Counters 0 and 3 (CMCNTMn)

CMCNTMn is a 32-bit register which is used as an up-counter. This register is only present in channels 0 and 3.

A counter operation is set by the compare match timer match control/status register (CMCSRMn). After the counter CMCNTn starts, this counter increases whenever at a compare match.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	—	All 0	R	Compare match timer match counter bit31 to 0

45B.3 Operation

45B.3.1 Counter Operation

The CMT1 starts the operation of the counter by writing H'1 to the STR0 bit in CMSTRn after each register has been set. Complete all of the settings before starting the operation. Do not change the register settings other than clearing flag bits, while the compare match timer (CMCNTn) is under operation.

The counter operates in one of two ways.

- One-Shot Operation

  One-shot operation is selected by setting the CMM bit in CMCSRn to H'0. When the value in CMCNTn matches the value in CMCORn, the value in CMCNTn is cleared to H'0000 0000 and the CMF bit in CMCSRn is set to H'1. Counting by CMCNTn stops after it has been cleared.

  To detect an overflow interrupt, set the value in CMCORn to H'FFFF FFFF. When the value in CMCNTn matches the value in CMCORn, CMCNTn is cleared to H'0000 0000 and the CMF and OVF bits in CMCSRn are set to H'1.

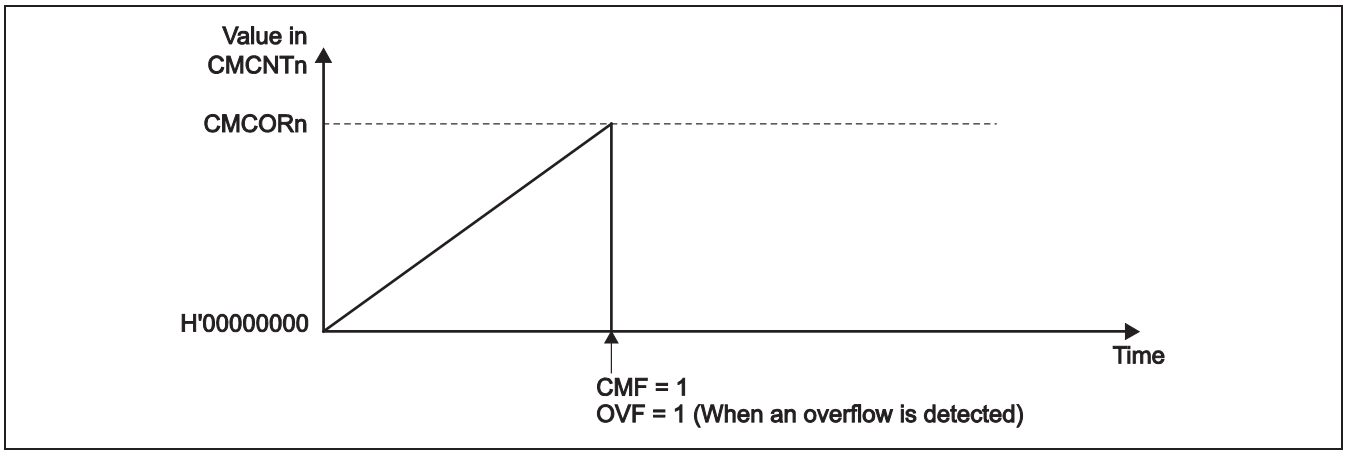


Figure 45B.2 Counter Operation (One-Shot Operation)

- Free-Running Operation

  Free-running operation is selected by setting the CMM bit in CMCSRn to H'1. When the value in CMCNTn matches the value in CMCORn, CMCNTn is cleared to H'0000 0000 and the CMF bit in CMCSRn is set to H'1. CMCNTn resumes counting-up after it has been cleared.

  To detect an overflow interrupt, set CMCORn to H'FFFF FFFF. When the values in CMCNTn and CMCORn match, CMCNTn is cleared to H'0000 0000 and the CMF and OVF bits in CMCSRn are set to H'1.

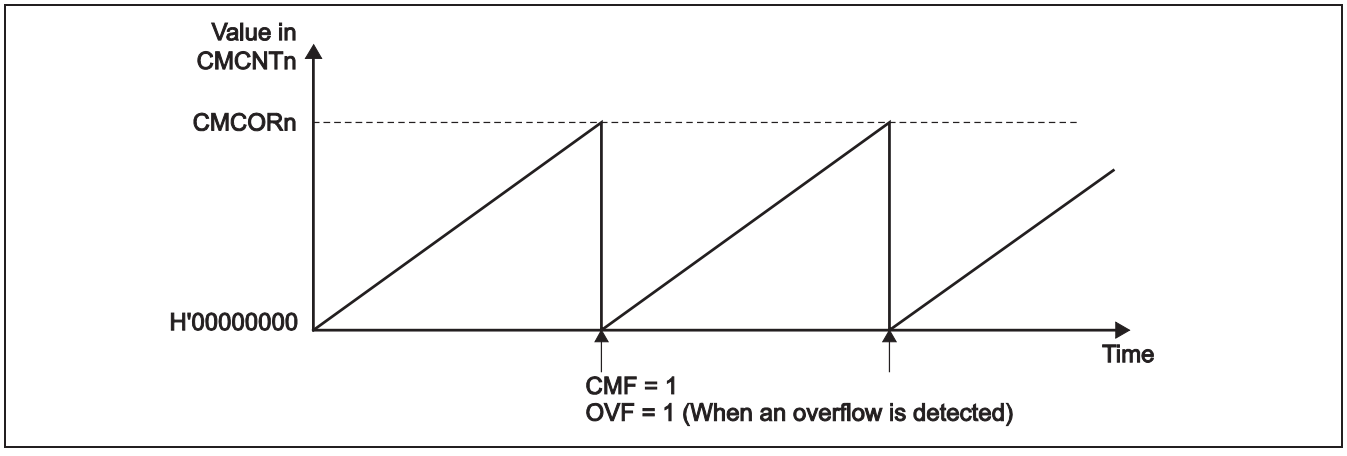

Figure 45B.3 Counter Operation (Free-Running Operation)

45B.3.2 Counter Size

In this module, the size of the counter can be selected from 16, 32, or 48 bits. This is selected by the CMS bit in CMCSRn and CMSH bit in CMCSRHn.

When the 16-bit/32-bit size is selected, upper 32 bits/16 bits of CMCORn is ignored. To detect an overflow interrupt, the value 1 must be set to valid bits of CMCORn.

(for example, H'00000000FFFF, H'0000FFFFFFFF)

45B.3.3 Timing for Counting by CMCNTn

In this module, the clock for the counter can be selected from among the following:

Channels 0 to 4:	CPEXϕ clock:	1/1, 1/8, 1/32, and 1/128
	RCLK:	1/1, 1/8, 1/32, and 1/128
	Pseudo 32-kHz:	1/1, 1/8, 1/32 and 1/128
Channel 5 to 7:	RCLK:	1/1, 1/8, 1/32, and 1/128

CPEXϕ is a clock from PLL1 via common divider. For details of these clocks, refer to section 7, Clock Pulse Generator (CPG).

Pseudo 32-kHz is a clock, which is generated inside this module. Refer to section 45B.3.8, Pseudo 32-kHz Counter.

The clock for the counter is selected by the CKS bits in CMCSRn and CKSH bit in CMCSRHn. CMCNTn is incremented at the rising edge of the selected clock.

45B.3.4 Internal Interrupt Request to CPU

By CMR bits in CMCSRn, internal interrupt request to the CPU at a compare match can be asserted.

To clear the internal interrupt request to the CPU, the CMF bit should be set to H'0. Set the CMF bit to 0 in the handling routine for the CMT1 interrupt.

45B.3.5 Register Access

After writing to following registers, written data can be read after writing has finished. However, it takes 2 cycles in counter input clock (RCLK), for reflecting written data to counter behavior.

- CMCSRn: Bits CH0SSIE(ch0), CMS, CMM, CMR[1:0], DBGIVD, CKS[2:0]
- CMCORn, CMCORHn
- CMSTRn: Bit STR0RS, STR0
- CMCSRMn: Bit CMPCLR, CMPSTART

After writing to following registers, written data can be read after writing has finished. However, it takes 2 cycles in counter input clock (RCLK or CPEXϕ), for reflecting written data to counter behavior. After writing data to this register, next write access is prohibited, until CMCSRn.WRFLG become 0.

- CMCNTn, CMCNTHn

45B.3.6 Compare Match Flag Set/Clear Timing

The CMF bit in CMCSRn is set to 1 by the compare match signal generated when CMCORn and CMCNTn match. The compare match signal is generated upon the final state of the match (timing at which the CMCNTn value is updated to H'0000). Consequently, after CMCORn and CMCNTn match, a compare match signal will not be generated until a CMCNTn counter clock is input. Figure 45B.4 shows the set timing of the CMF bit.

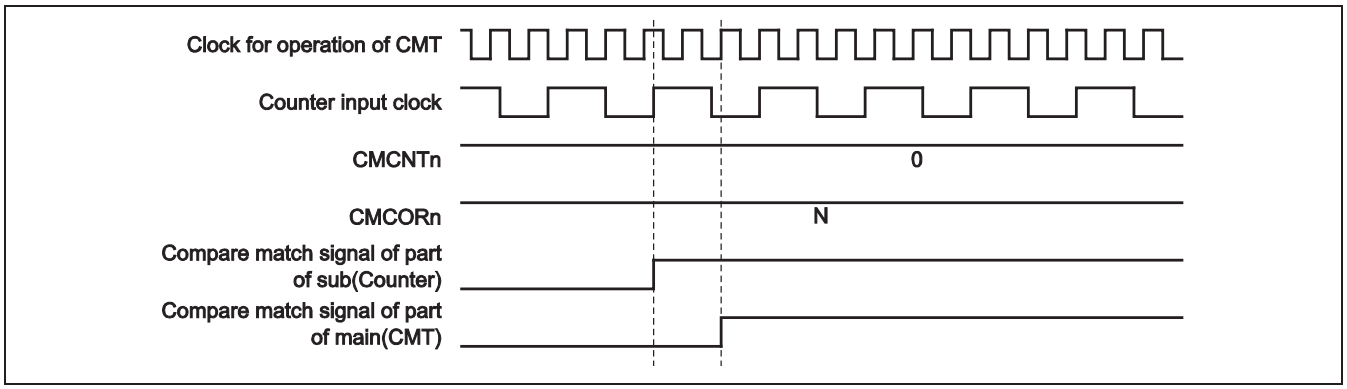

Figure 45B.4 CMF Set Timing

Set the CMF bit to 0. The CMF flag is cleared immediately.

45B.3.7 RCLK-Synchronous Counter Start/Stop Mode in Channel 0

The CMT1 provides the RCLK-synchronous counter start/stop mode in channel 0, in which channels 0 and 3 can be used together for time measurement.

Figure 45B.5 shows a flow chart for preparation.

Figure 45B.6 shows a flow chart for starting measurement.

Figure 45B.7 shows a flow chart for stopping measurement.

Figure 45B.8 shows a timing chart when measurement starts.

Figure 45B.9 shows a timing chart when measurement stops.

Figure 45B.10 shows how to calculate the time measured by the counters.

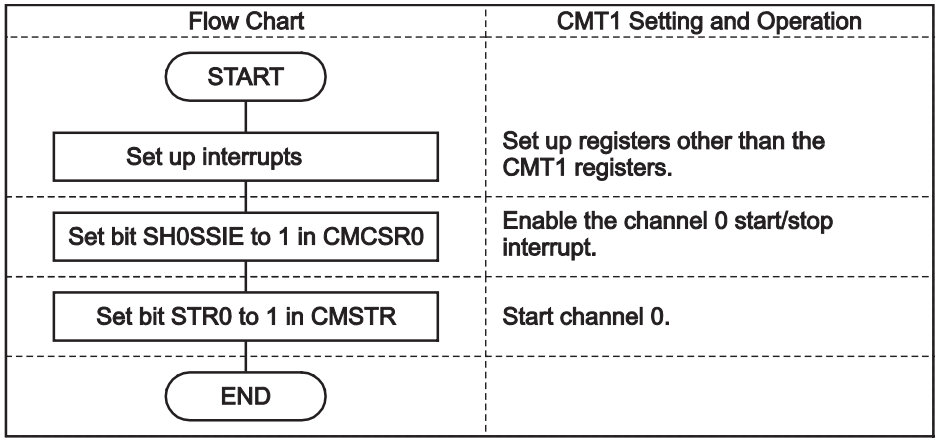

Figure 45B.5 Flow Chart for Preparation

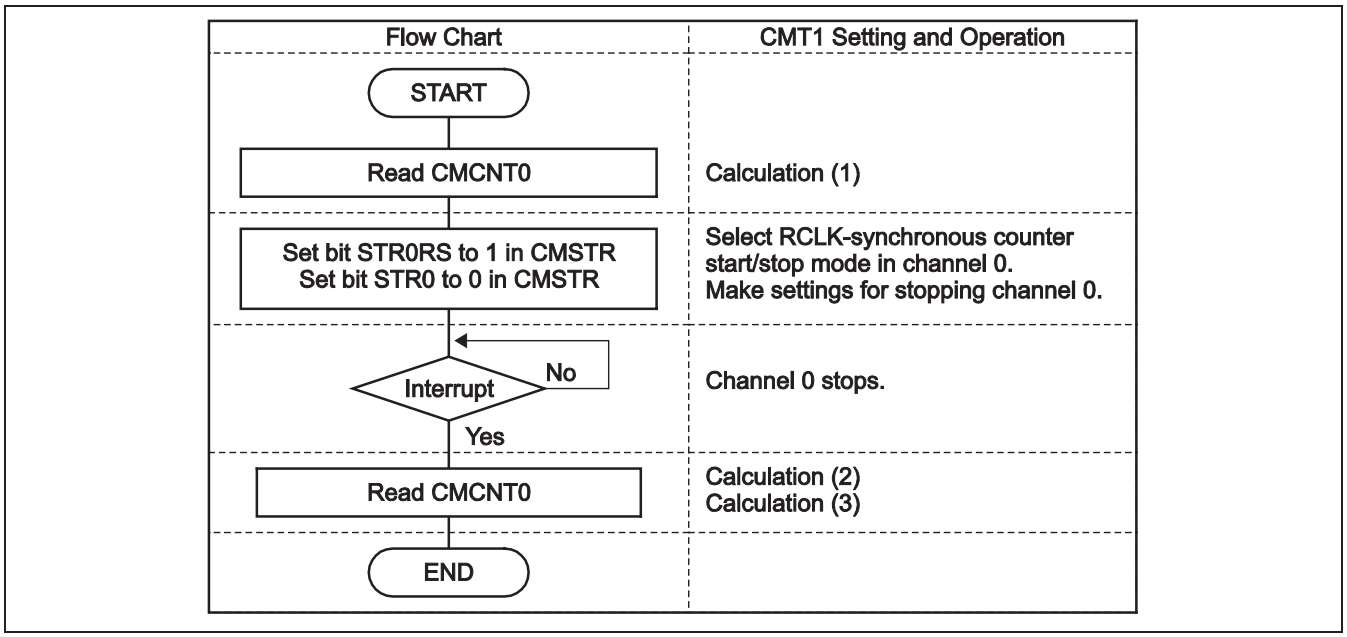

Figure 45B.6 Flow Chart for Starting Measurement

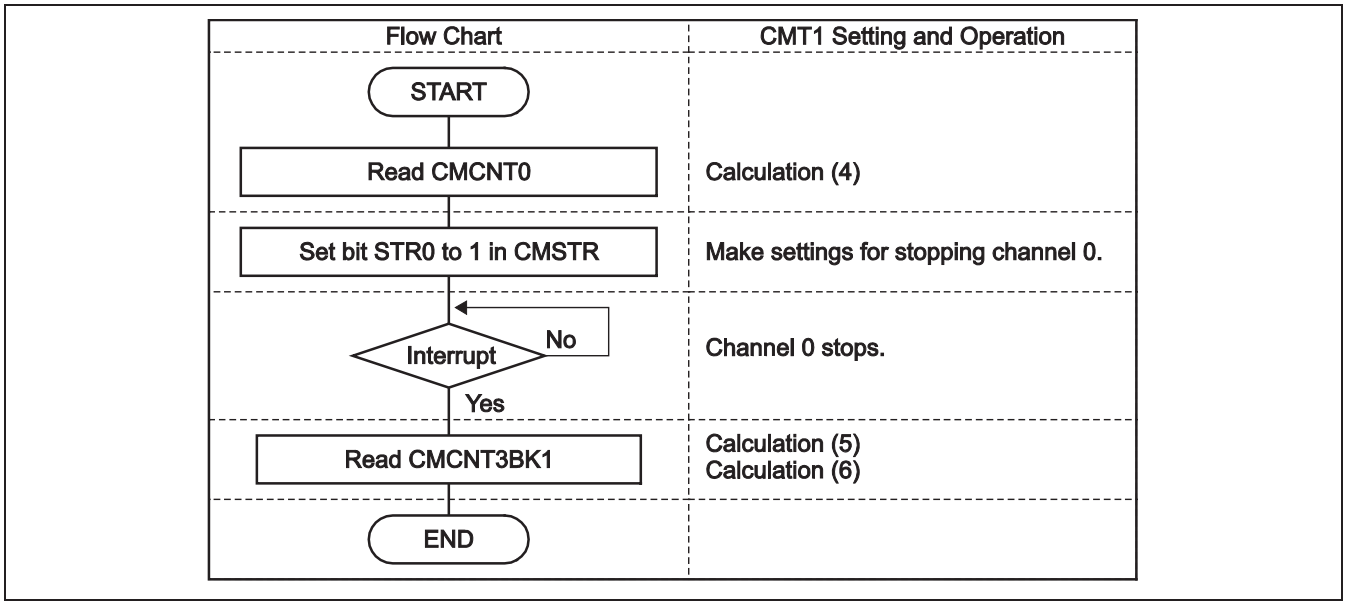

Figure 45B.7 Flow Chart for Stopping Measurement

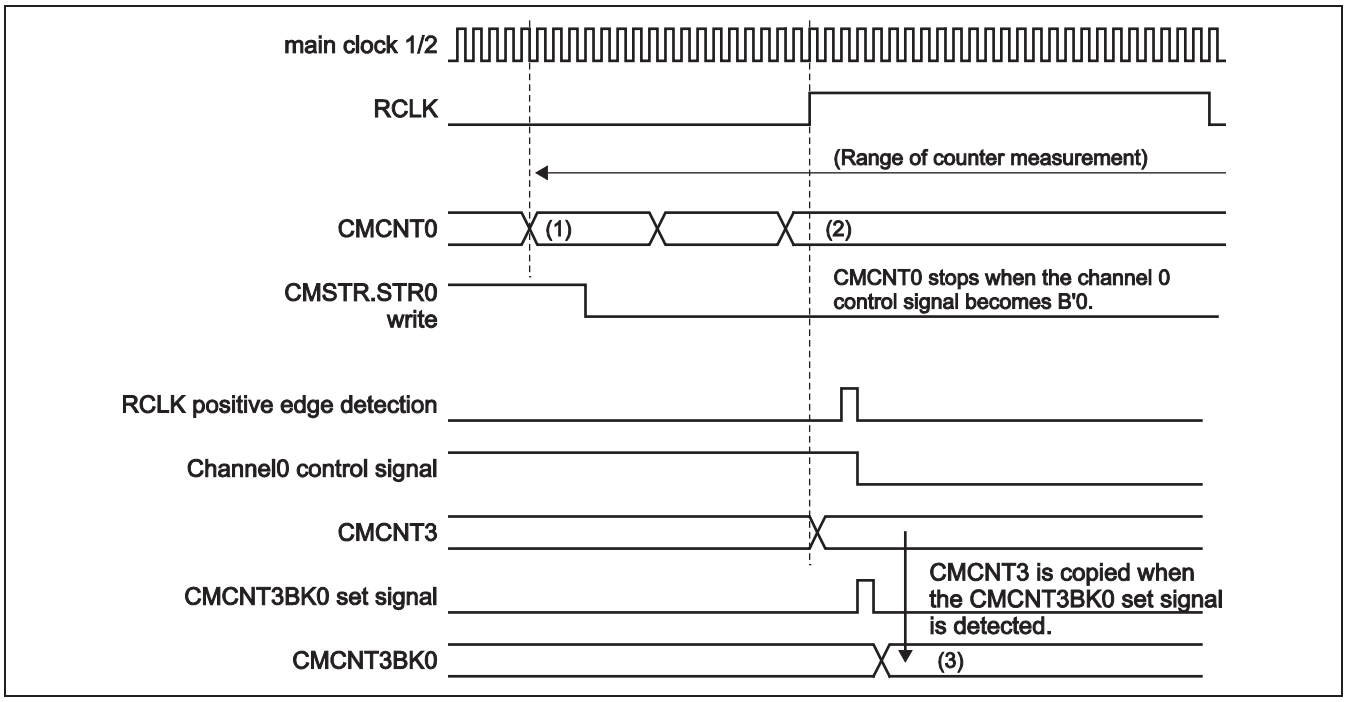

Figure 45B.8 Timing Chart When Measurement Starts

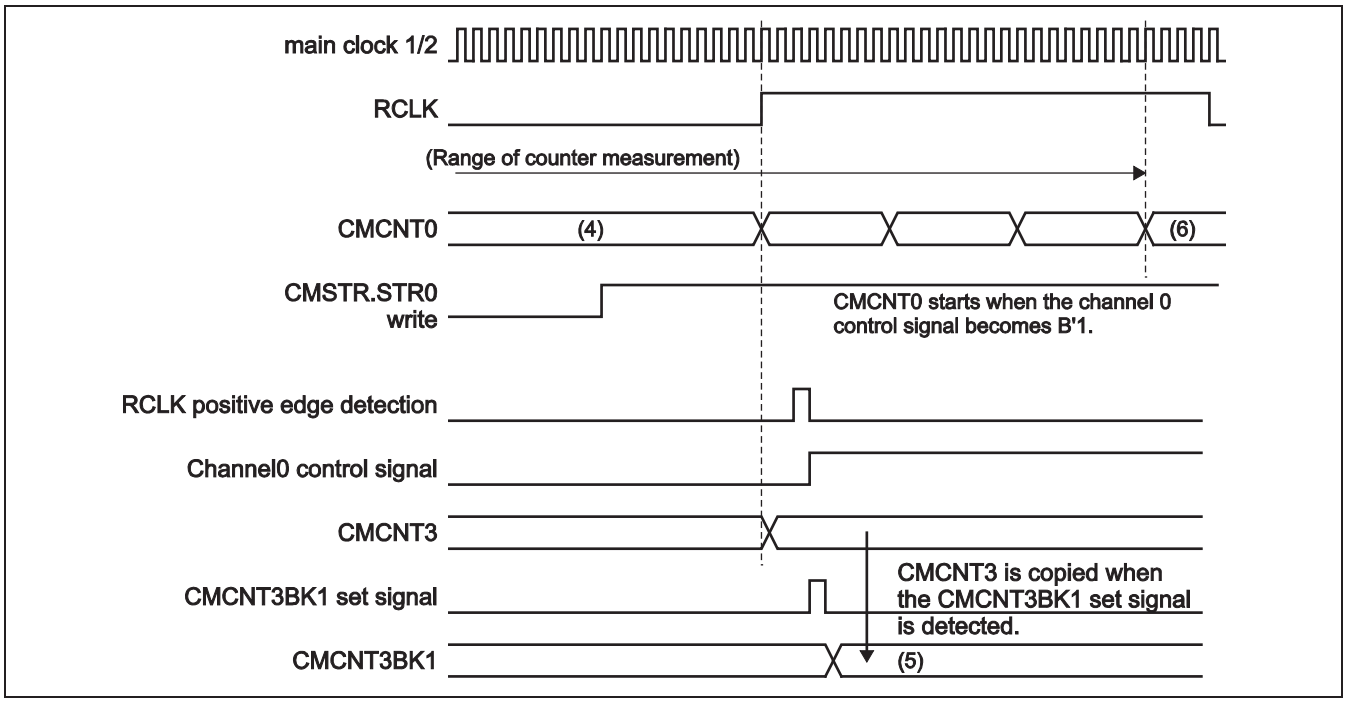

Figure 45B.9 Timing Chart When Measurement Stops

$$(((2) - (1)) + ((6) - (4) - 1)) \times Tapc + ((5) - (3)) \times Tr$$

Tapc : Cycle of main clock 1/2

Tr : Cycle of RCLK

Figure 45B.10 Calculation of Time Measured by Counters

45B.3.8 Pseudo 32-kHz Counter

Pseudo 32-kHz clock is created inside this module, based on RCLK by Pseudo 32-kHz Counter. By removing 3 edge of RCLK every 128 cycle, Pseudo 32-kHz clock is generated. By this edge removing, frequency of this clock becomes 128/131 of RCLK.

45B.3.9 CMT1 Usage

Take the following steps to use the CMT1.

1. Clear the STR0 bit in CMSTRn to 0 to temporarily stop counting.
   (Confirm that Counter input clock was input more than 2 cycles.)
2. Write H'00000000 on CMCNTn.
3. Set counter size, compare match mode, kind of count clock and interrupt request and clear the bit of OVF and CMF in CMCSRn.
4. Set the value on CMCORn.
5. Confirm that CMCSRn.WRFLG is 0.
   If WRFLG is 1, wait until it'll be 0.
6. Start the counting by setting the STR0 bit in CMSTRn to 1 (refer to section 45B.3.5, Register Access).

45B.3.10 Module Stop/ CMCLKE Setting

When counter is not used, clock of this module can be stopped by CMCLKE register. Please confirm that, following conditions are satisfied, before stopping counter’s clock.

- CMSTRn.STR0 bit is 0
- CMCSRn.WRFLG is 0
- 3 or more cycles have passed in Counter input clock since the last Register access

46. Timer Unit (TMU)

This LSI includes a 32-bit timer unit (TMU) with 12 channels (channels 0 to 11).

Channels 0 to 2, 3 to 5, 6 to 8, and 9 to 11 are grouped into timers 0, 1, 2 and 3, respectively.

For channels 0 to 2, CPϕ is provided as a base clock. For channels 3 to 11, Pϕ is provided.

46.1 Features

TMU has the following features:

- Auto-reload type 32-bit down counter is provided for each channel
- Input capture function provided: Channels 5 and 8
- Selection of rising edge or falling edge as external clock input edge when external clock is selected or input capture function is used: Channels 3 to 8
- 32-bit timer constant register for auto-reload use, readable/writable at any time, and 32-bit down-counter are provided for each channel
- Selection of five counter input clocks: Channels 0 to 2
  Five peripheral clocks (CPϕ/4, CPϕ/16, CPϕ/64, CPϕ/256, and CPϕ/1024)
- Selection of six counter input clocks: Channels 3 to 8
  External clock (TCLK1/2), and five peripheral clocks (Pϕ/4, Pϕ/16, Pϕ/64, Pϕ/256, and Pϕ/1024)
- Selection of five counter input clocks: Channels 9 to 11
  Five peripheral clocks (Pϕ/4, Pϕ/16, Pϕ/64, Pϕ/256, and Pϕ/1024)
- Two interrupt sources
  One underflow source (each channel) and one input capture source (channels 5 and 8)

Figure 46.1 show block diagrams of TMU.

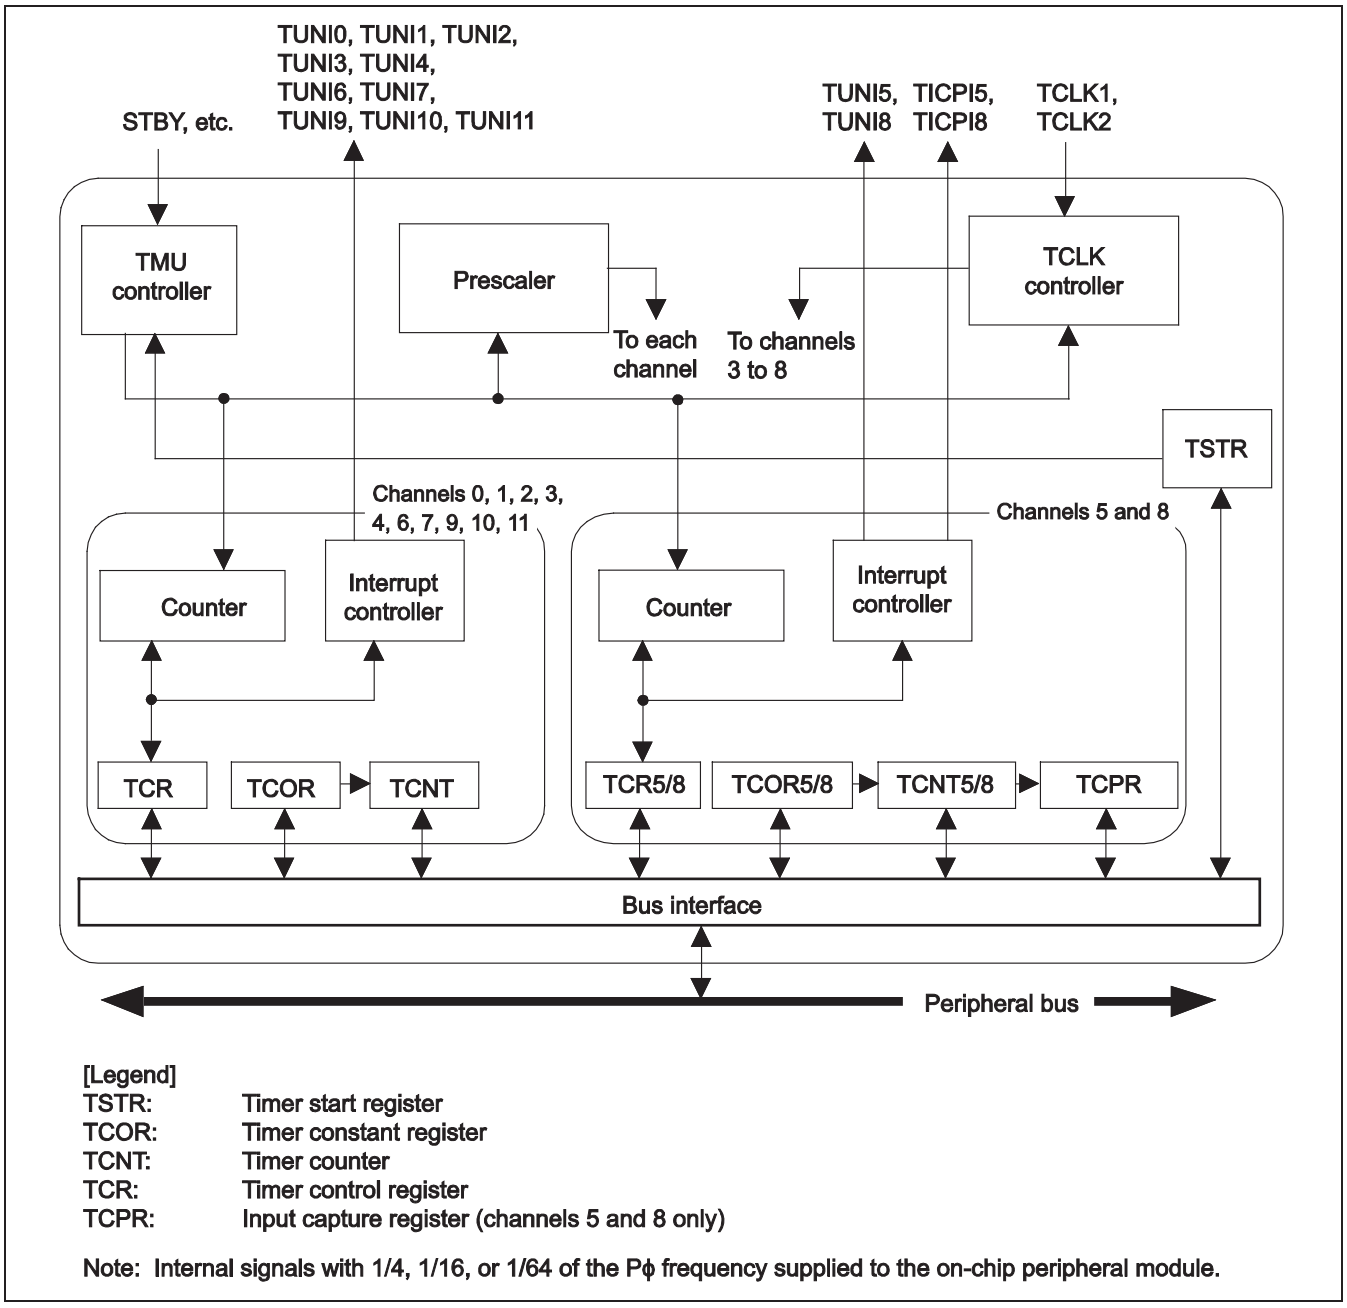

Figure 46.1 Block Diagram of TMU

46.2 Input/Output Pins

Table 46.1 shows the pin configuration of the TMU.

Table 46.1 Pin Configuration

Name	Abbreviation	I/O	Function
Clock input 1	TCLK1	Input	External clock input pin for channels 3 to 5/ input capture control input pin for channel 5
Clock input 2	TCLK2	Input	External clock input pin for channels 6 to 8/ input capture control input pin for channel 8

46.3 Register Descriptions

The TMU has the following registers. Do not write to any addresses other than listed below. Operations cannot be guaranteed if writing is attempted. Values read from addresses other than those listed below are undefined.

Table 46.2 Register Configuration (1)

Channel	Name	Abbreviation	R/W	Address	Size
Common to 0 to 2	Timer start register 0	TSTR0	R/W	H'E61E 0004	8

46.3.2 Timer Constant Registers (TCORn) (n = 0 to 11)

TCOR are 32-bit readable/writable registers. After underflow has been generated according to the result of the TCNT countdown, the value of TCOR is set to TCNT and TCNT continues countdown from the value.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	—	1	R/W	Value constant supply for counter.

46.3.3 Timer Counters (TCNTn) (n = 0 to 11)

TCNT are 32-bit readable/writable registers that count down upon the input clock selected using the bits TPSC2 to TPSC0 in TCR.

When a TCNT countdown results in an underflow, the UNF in TCR of corresponding channel is set. At the same time, the value of TCOR is set to TCNT and TCNT continues countdown from that value.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	—	1	R/W	Timer Counter Down Bits

46.3.4 Timer Control Registers (TCRn) (n = 0 to 11)

TCR are 16-bit readable/writable registers that select a count clock and edge when an external clock is selected, and control an interrupt generation when the flag that indicates the generation of a TCNT is set to 1. TCR of channels 5 and 8 control the input capture function and generation of an interrupt during the input capture.

- TCR0, TCR1, TCR2, TCR3, TCR4, TCR6, TCR7, TCR9, TCR10, TCR11

R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9	ICPF*1	0	R/W	Input Capture Interrupt Flag Status flag, provided in channels 5 and 8 only, which indicates the occurrence of input capture. 0: No input capture has occurred [Clearing condition] When 0 is written to ICPF 1: Input capture has occurred [Setting condition] When an input capture occurs*2
8	UNF	0	R/W	Underflow Flag Status flag which indicates the occurrence of a TCNT underflow. 0: TCNT has not underflow [Clearing condition] When 0 is written to UNF 1: TCNT has underflow [Setting condition] When TCNT underflows*2

Bit	Bit Name	Initial Value	R/W	Description
7, 6	ICPE*[1]	00	R/W	Input Capture Control A function of channels 5 and 8 only: determines whether the input capture function can be used, and when used, whether or not to enable interrupts. Use the CKEG bits to designate use of either the rising or falling edge of the TCLK pin to set the values of TCNT5 and TCNT8 to TCPR5 and TCPR8, respectively. Only when the ICPF bits in TCR5 and TCR8 are 0, the values of TCNT5 and TCNT8 are set to TCPR5 and TCPR8. When the ICPF bit is set to 1, neither TCPR5 nor TCPR8 is set even when input capture is generated. 00: Input capture function is not used. 01: Reserved (setting prohibited) 10: Input capture function is used. Interrupt due to input capture (TICPI5 and TICPI8) is not enabled. 11: Input capture function is used. Interrupt due to input capture (TICPI5 and TICPI8) is enabled.
5	UNIE	0	R/W	Underflow Interrupt Control Controls enabling of interrupt generation when the status flag (UNF) indicating TCNT underflow has been set to 1. 0: Interrupt due to underflow (TUNI) is not enabled 1: Interrupt due to underflow (TUNI) is enabled
4, 3	CKEG	00	R/W	Clock Edge Select an input edge of the external clock when the external clock is selected, or when the input capture function is used. 00: Count/capture register set on rising edge 01: Count/capture register set on falling edge 1X: Count/capture register set on both rising and falling edge
2 to 0	TPSC	000	R/W	Timer Prescaler 2 to 0 Select the TCNT count clock. 000: Count on (input-clock)/4 001: Count on (input-clock)/16 010: Count on (input-clock)/64 011: Count on (input-clock)/256 100: Count on (input-clock)/1024 101: Setting prohibited 110: Setting prohibited 111: Count on external clock (TCLK) (Not usable in channels 0, 1, 2, 9, 10 and 11) Note: Input-clock is CPϕ for channel 0/1/2, and Pϕ for channel 3/4/5/6/7/8/9/10/11.

[Legend]

X: Don't care

Notes: 1. Reserved in channels 0, 1, 2, 3, 4, 6, 7, 9, 10, and 11 (initial value is 0 and read-only).

2. Writing 1 does not change the value.

46.3.5 Input Capture Registers n (TCPRn)

TCPR5 and TCPR8 are read-only 32-bit registers used for the input capture function provided only in channels 5 and 8. The ICPE and CKEG bits in TCR5 and TCR8 control the input capture function. When an input capture occurs, the value of TCNT5 is copied to TCPR5, and the value of TCNT8 is copied to TCPR8. The values of TCNT5 and TCNT8 are set in TCPR5 and TCPR8, respectively, only when the ICPF bits in TCR5 and TCR8 are 0.

31 to 0	—	—	R/W	Input capture function (channel 5 and 8)

46.4 Operation

Each channel has a 32-bit timer counter (TCNT) and 32-bit timer constant register (TCOR). TCNT counts down. The auto-reload function enables synchronized counting and external-event counting. Channels 5 and 8 have an input capture function.

46.4.1 Counter Operation

When the bits STR8 to STR0 in TSTR0 to TSTR3 are set to 1, TCNT of corresponding channel starts counting. When TCNT underflows, the UNF flag of corresponding TCR is set. In this case, if the UNIE bit in TCR is set to 1, an interrupt request is sent to the CPU. Also, the value is copied from TCOR to TCNT and the down-count operation is continued (Auto reload function).

(1) Procedure for setting count operation

Figure 46.2 shows an example of the procedure for setting the count operation.

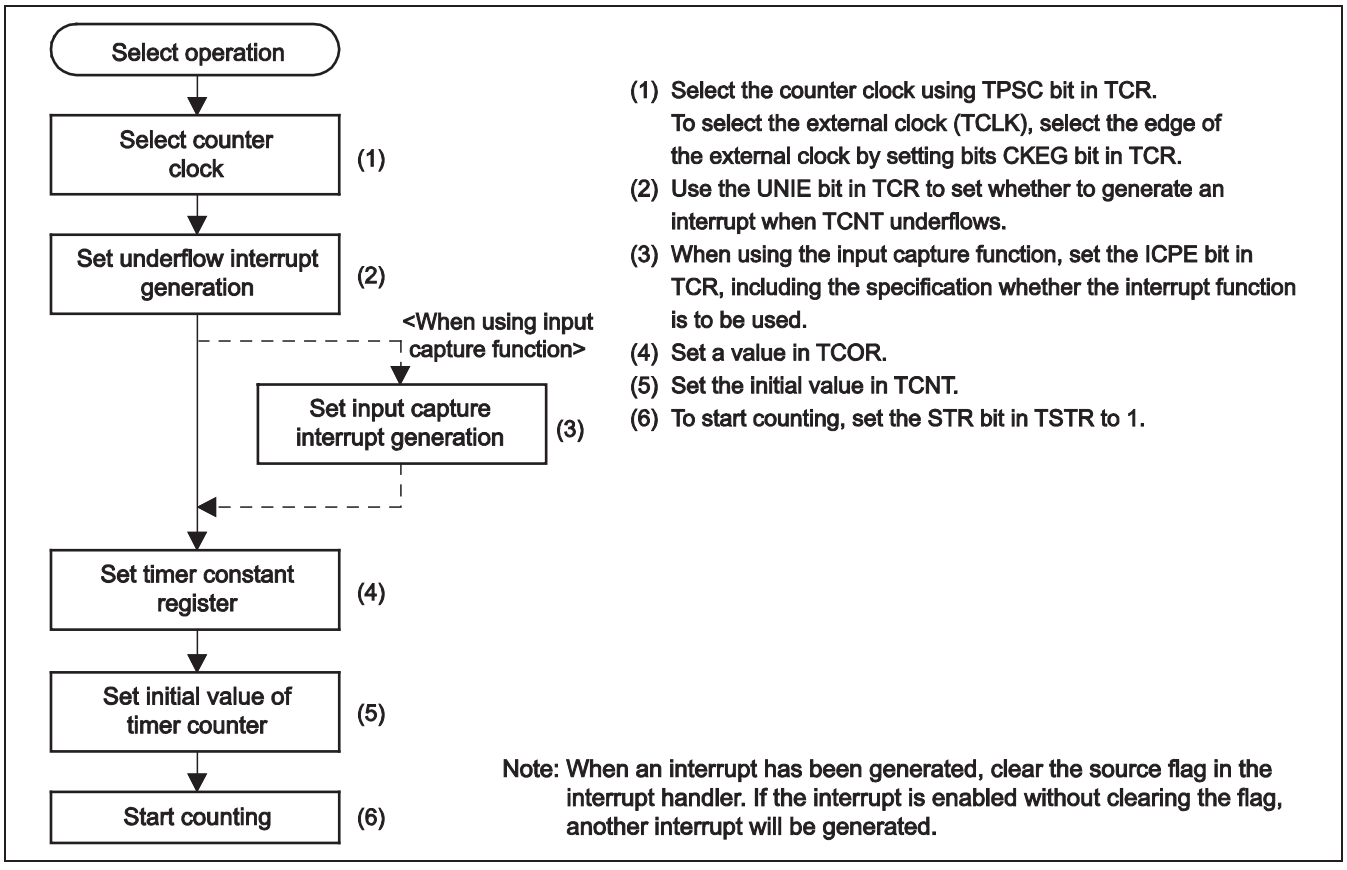

Figure 46.2 Procedure for Setting Count Operation

(2) Auto-reload count operation

Figure 46.3 shows the TCNT auto-reload operation.

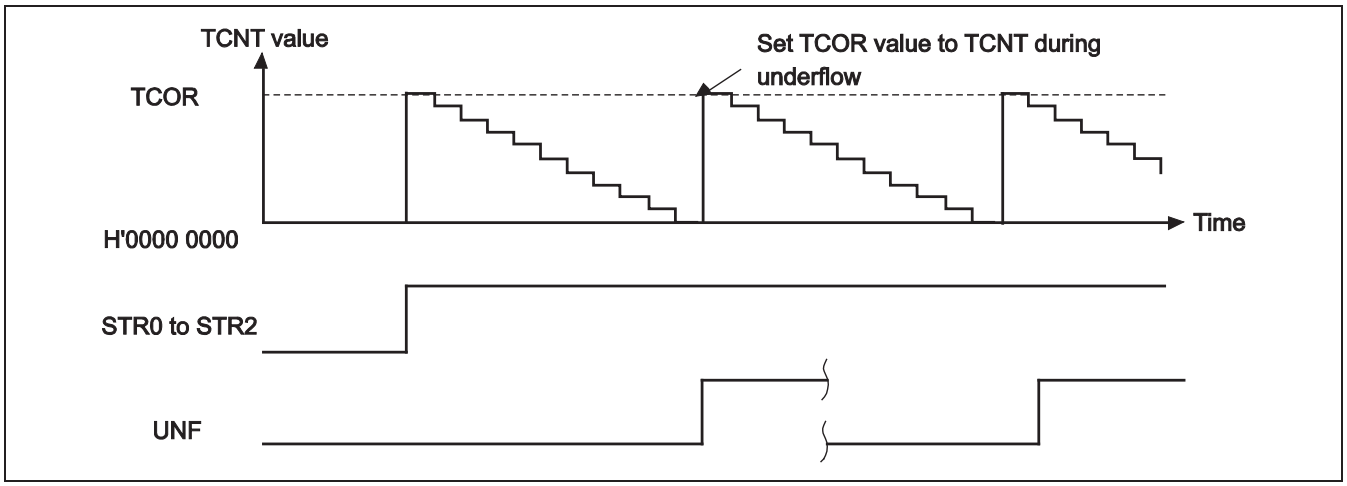

Figure 46.3 TCNT Auto-Reload Operation

(3) TCNT count timing

- Internal clock operation

  Five clocks (Pϕ/4, Pϕ/16, Pϕ/64, Pϕ/256, Pϕ/1024) that are created by dividing peripheral clocks are selected as count clocks by setting bits TPSC2 to TPSC0 in TCR. Figure 46.4 shows the timing.

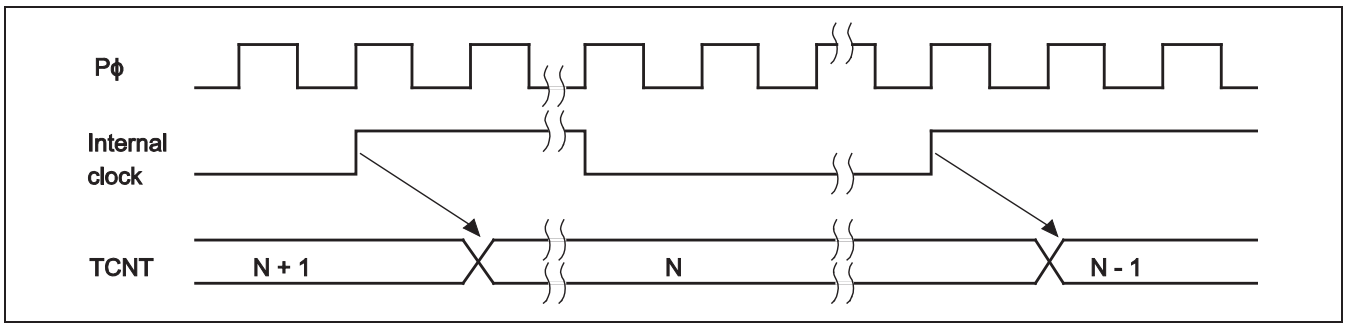

Figure 46.4 Count Timing when Internal Clock is Operating

- External clock operation

  Set the bits TPSC3 to TPSC0 in TCR to select the external clock pin (TCLK) as the timer clock. Use the bits CKEG1 and CKEG0 in TCR to select the detection edge. Rise, fall, or both can be selected.

  Figure 46.5 shows the timing for both-edge detection.

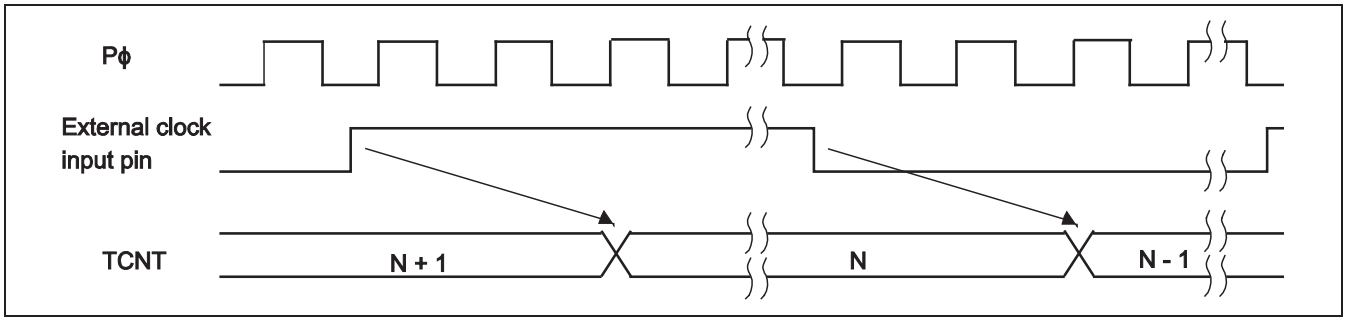

Figure 46.5 Count Timing when External Clock is Operating

46.4.2 Input Capture Function

Channels 5 and 8 have the input capture function. When using the input capture function, follow the procedure shown below.

1. Set the timer operating clock as an internal clock with bits TPSC3 to TPSC0 in TCR.
2. Set use of the input capture function and whether to generate an interrupt on using it with bits ICPE1 and ICPE0 in TCR.
3. Specify either rising edge or falling edge of the TCLK pin to be used to set the value of TCNT to TCPR5 and TCPR8 with bits CKEG1 and CKEG0 in TCR.

Only when an input capture is occurred and the ICPF bits in TCR5 and TCR8 are 0, the values of TCNT5 and TCNT8 are set in TCPR5 and TCPR8, respectively.

Figure 46.6 shows the operating timing when the input capture function is used (the rising edge of TCLK is used).

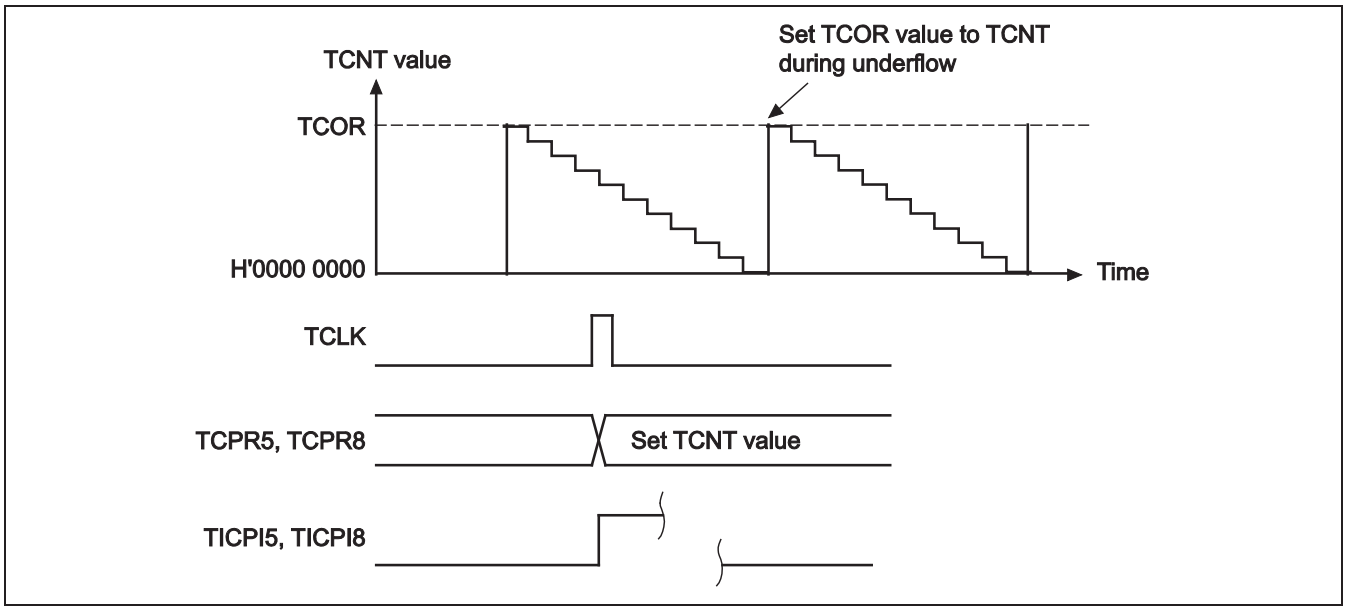

Figure 46.6 Operating Timing when Using Input Capture Function

46.5 Interrupt

The TMU interrupt sources are underflow interrupt or input capture interrupt when the input capture function is used. The underflow interrupt is generated at each channel. The input capture interrupt is generated at channels 5 and 8 only.

An underflow interrupt request is generated (for each channel) when both the UNF bit and the interrupt enable bit for that channel are set to 1.

When the input capture function is used and the input capture request is generated, an interrupt request is generated if the ICPF bit in TCR5 or TCR8 is 1 and the input capture control bits ICPE1 and ICPE0 in TCR5 and TCR8 are 11.

Table 46.4 shows the TMU interrupt sources.

Table 46.4 TMU Interrupt Sources

Channel	Interrupt Sources	Description
0	TUNI0	Underflow interrupt 0
1	TUNI1	Underflow interrupt 1
2	TUNI2	Underflow interrupt 2
3	TUNI3	Underflow interrupt 3
4	TUNI4	Underflow interrupt 4
5	TUNI5	Underflow interrupt 5
	TICPI5	Input capture interrupt 5
6	TUNI6	Underflow interrupt 6
7	TUNI7	Underflow interrupt 7
8	TUNI8	Underflow interrupt 8
	TICPI8	Input capture interrupt 8
9	TUNI9	Underflow interrupt 9
10	TUNI10	Underflow interrupt 10
11	TUNI11	Underflow interrupt 11

46.6 Usage Notes

46.6.1 Writing to Registers

When writing to the TMU registers, clear the start bits (STR11 to STR0) of the corresponding TSTR channel to stop the timer counting.

Writing to TSTR and clearing bits UNF and ICPF in TCR can be executed during counting. To clear flags UNF and ICPF during counting, do not change the values of bits other than those to be cleared.

46.6.2 Reading TCNT Register

Reading from TCNT is performed synchronously with the timer count operation. When timer counting and register read processing are performed simultaneously, the value before TCNT counting down is read.

46.6.3 External Clock Frequency

The frequency of external clock (TCLK) for each channel should be Pϕ/4 or less.

47. PWM Timer

47.1 Overview

This LSI incorporates a seven-channel pulse width modulation (PWM) timer.

47.1.1 Features

- PWM output cycle settable (10 bits)
- PWM output cycle settable within the range from 2 cycles to $2^{24} \times 1024$ cycles of internal bus clock Pϕ (i.e. from 30.77 ns to 264 seconds when Pϕ = 65 MHz)
- High-level width of the PWM output signal settable (10 bits)
- Continuous pulse output or single pulse output selectable

47.1.2 Block Diagram

Figure 47.1 shows a block diagram of the PWM timer.

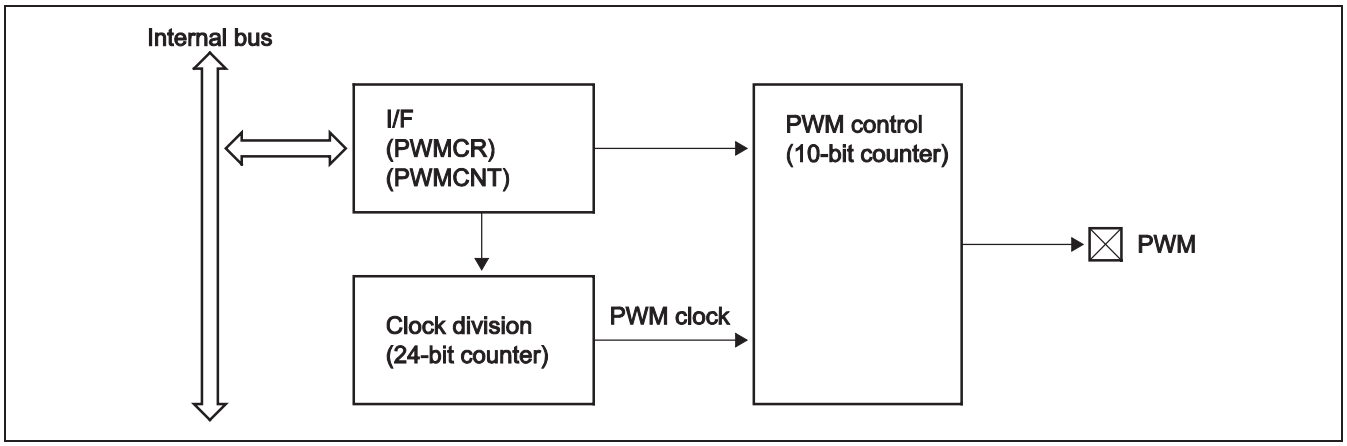

Figure 47.1 Block Diagram of PWM Timer

47.1.3 Input/Output pins

Table 47.1 shows the pin configuration of the PWM timer.

Table 47.1 Pin Configuration

Pin Name	I/O	Function
PWM0	Output	PWM0 timer pulse output
PWM1	Output	PWM1 timer pulse output
PWM2	Output	PWM2 timer pulse output
PWM3	Output	PWM3 timer pulse output
PWM4	Output	PWM4 timer pulse output
PWM5	Output	PWM5 timer pulse output
PWM6	Output	PWM6 timer pulse output

47.1.4 Register Descriptions

Table 47.2 lists the registers of the PWM timer.

Table 47.2 List of Registers

Channel	Name	Abbreviation	R/W	Address	Access Size
0	PWM control register	PWMCR	R/W	H'E6E3 0000	32
	PWM count register	PWMCNT	R/W	H'E6E3 0004	32
1	PWM control register	PWMCR	R/W	H'E6E3 1000	32
	PWM count register	PWMCNT	R/W	H'E6E3 1004	32
2	PWM control register	PWMCR	R/W	H'E6E3 2000	32
	PWM count register	PWMCNT	R/W	H'E6E3 2004	32
3	PWM control register	PWMCR	R/W	H'E6E3 3000	32
	PWM count register	PWMCNT	R/W	H'E6E3 3004	32
4	PWM control register	PWMCR	R/W	H'E6E3 4000	32
	PWM count register	PWMCNT	R/W	H'E6E3 4004	32
5	PWM control register	PWMCR	R/W	H'E6E3 5000	32
	PWM count register	PWMCNT	R/W	H'E6E3 5004	32
6	PWM control register	PWMCR	R/W	H'E6E3 6000	32
	PWM count register	PWMCNT	R/W	H'E6E3 6004	32

Note: Do not access addresses other than those listed above. If access is attempted, a malfunction may occur.

Table 47.3 Register States in Each Operating Mode

Name	Abbreviation	Power-on Reset	Module Standby
PWM control register	PWMCR	H'0000 0000	Retained
PWM count register	PWMCNT	H'0000 0000	Retained

The registers of the PWM timer are mapped into the internal bus address space.

47.2 Register Description

Registers in the PWM timer are allocated to and arranged in the address space of the internal bus.

Legend for Register Description

Initial value: Register value after a reset

—: Undefined value

R/W: Readable/writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R/WC1: Readable/writable. Writing 1 initializes the bit. Writing 0 is ignored.

R: Read-only. When the bit is reserved, the write value should always be 0.

—/W: Write-only. The read value is undefined.

47.2.1 PWM Control Register (PWMCR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	CC0

	CCMD	—	—	—	SYNC	—	—	—	—	—	—	SS0	—	—	—	EN0
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R	R	R	R/W	R	R	R	R	R	R	R/W	R	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 20	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
19 to 16	CC0	0000	R/W	Clock Control The clock frequency of the PWM counter is obtained by dividing the frequency of the clock signal Pϕ. When the Pϕ frequency is f MHz, the following PWM clock frequencies are obtained. 0000: f MHz 0001: f MHz/2^2 0010: f MHz/2^4 0011: f MHz/2^6 0100: f MHz/2^8 0101: f MHz/2^{10} 0110: f MHz/2^{12} 0111: f MHz/2^{14} 1000: f MHz/2^{16} 1001: f MHz/2^{18} 1010: f MHz/2^{20} 1011: f MHz/2^{22} 1100: f MHz/2^{24} When 1101, 1110, or 1111 is set, the PWM clock frequency is f MHz/2^{24}.

Bit	Bit Name	Initial Value	R/W	Description
15	CCMD	0	R/W	CC0 Frequency Division Mode Changes the PWM clock frequency set by the clock control (CC0) bits. 0: The PWM clock frequency set by CC0 is used. 1: The PWM clock frequency set by CC0 is changed as follows: 1 - 0000: f MHz/2 1 - 0001: f MHz/2^3 1 - 0010: f MHz/2^5 1 - 0011: f MHz/2^7 1 - 0100: f MHz/2^9 1 - 0101: f MHz/2^{11} 1 - 0110: f MHz/2^{13} 1 - 0111: f MHz/2^{15} 1 - 1000: f MHz/2^{17} 1 - 1001: f MHz/2^{19} 1 - 1010: f MHz/2^{21} 1 - 1011: f MHz/2^{23} If 1100, 1101, 1110, or 1111 is set for CC0, the PWM clock frequency is f MHz/2^{24} irrespective of the CCMD value.
14 to 12	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
11	SYNC	0	R/W	Specifies whether to allow the set values in the PWM count register (PWMCNT) to be reflected in the timer operation synchronously with setting the PWM control register (PWMCR). 0: Allows the PWMCNT set values to be reflected in the timer operation irrespective of PWMCR setting. 1: Allows the PWMCNT set values to be reflected in the timer operation synchronously with PWMCR setting. For details, refer to section 47.3, Description of Operation.
10 to 5	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
4	SS0	0	R/W	Single Pulse Output 0: The timer operates in continuous pulse output mode. 1: The timer operates only for a single cycle and then stops.
3 to 1	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
0	EN0	0	R/W	Channel Enable 0: The channel is held in the idle state, and outputs a high level. 1: The channel outputs high and low levels in a predetermined cycle. This bit is automatically cleared in single pulse output mode.

47.2.2 PWM Count Register (PWMCNT)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	CYC0									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	PH0									
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 26	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
25 to 16	CYC0	H’000	R/W	PWM Cycle Sets the PWM output cycle. The cycle set by these bits is the sum of the high-level and low-level periods. Setting H'000 is prohibited.
15 to 10	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
9 to 0	PH0	H’000	R/W	PWM High-Level Period Sets the period for which the PWM timer outputs a high-level signal. Setting H'000 is prohibited.

Note: For the CYC0 and PH0 bits, set the number of cycles to be counted of the PWM clock signal whose frequency has been set by the CC0 and CCMD bits in the PWM control register.

47.3 Description of Operation

The duty ratio of a PWM output pulse can be obtained by setting a high-level period and a cycle. The timer channel counts the PWM clock signal pulses using a 10-bit counter to generate the PWM output pulse having the specified period and cycle. When the channel function is enabled (EN0 = 1), the timer outputs a high level until the counter value reaches the value set in the PH0 bits of the PWM count register (PWMCNT). The output goes low when the PH0 value is reached, and is held low until the counter value reaches the value set in the CYC0 bits of PWMCNT. When the CYC0 value is reached, the output goes high and the counter is reset.

Unless the channel function is enabled, the output is held high, and the counter is held in the reset state.

Figure 47.2 shows the PWM state transition during the operation described above.

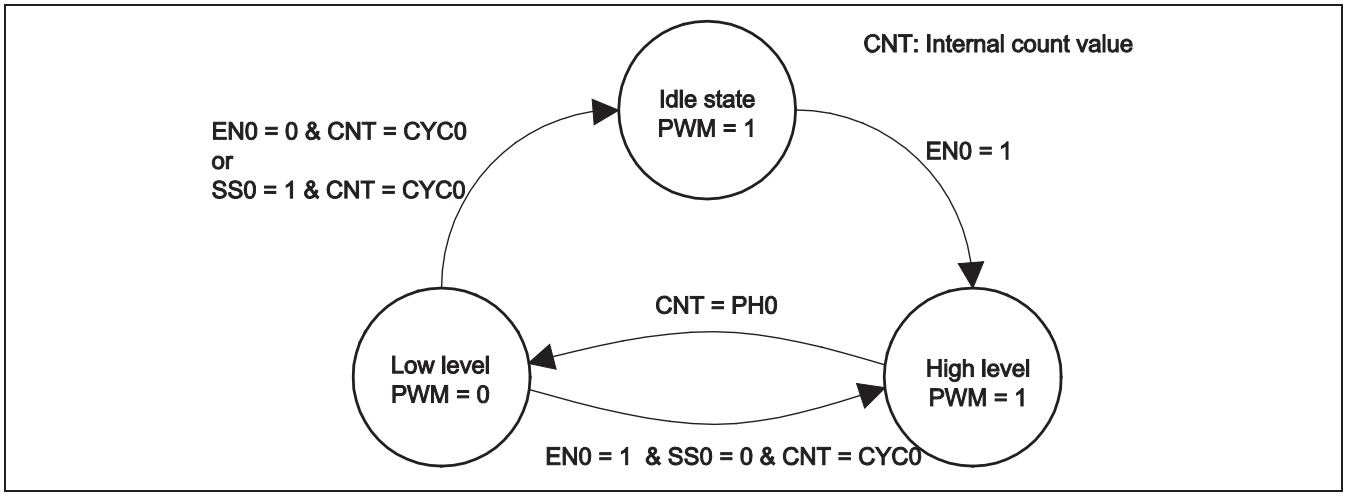

Figure 47.2 PWM Timer State Transition

Note that after a channel has been enabled by writing 1 to EN0, the number of clock pulses before output of the first falling edge from a channel is greater than the value set in the PWM control register and PWM count register by up to four cycles of the Pϕ clock. After that, the PWM output rises and falls according to a set timing.
Figure 47.3 schematically shows this output timing. This figure shows an internal operation.

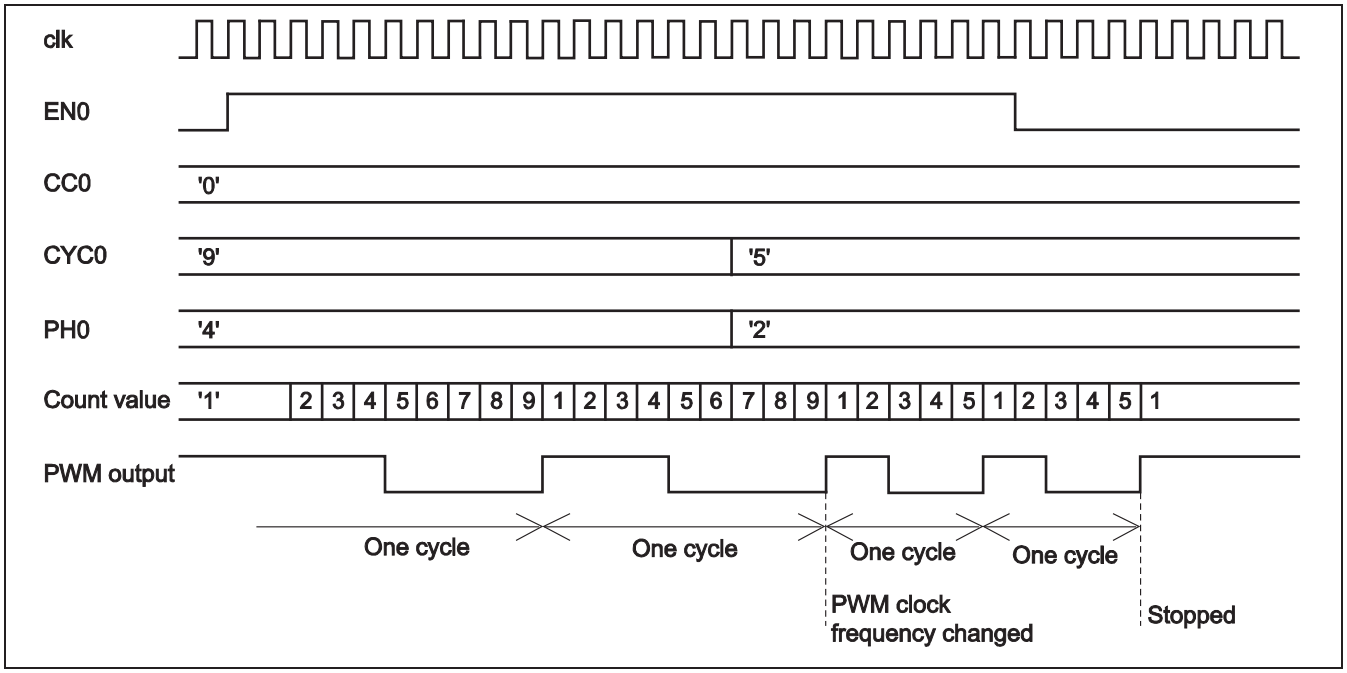

Figure 47.3 PWM Output Timing

1. The period from enabling the channel to the first falling edge output from the channel is the sum of a set value and up to four cycles of the Pϕ clock.
2. After that, the PWM high and low widths are the same as the set values.
3. When the PWM count register is changed during operation (EN0 = 1), timing of the output will be in accord with the new settings after output of the current cycle has been completed.
4. When the CC0 and CCMD bit values in the PWM control register are changed during operation (EN0 = 1), timing of the output will be in accord with the new settings after output of the current cycle has been completed.
5. To stop the timer operation, write 0 to the EN0 bit. The timer stops operation after completing the output of the current cycle. Note that, however, if 1 is written to EN0 again before completing the output of the current cycle, the timer does not stop but continues to operate.
6. For the PWM timer output, continuous pulse output mode and single pulse output mode are supported. In continuous pulse output mode, the timer outputs pulses continuously while EN0 is 1. In single pulse output mode, the timer outputs a single pulse. In this mode, EN0 is automatically cleared.
7. To change the values of the clock control bits (CC0) and the CC0 frequency division mode bit (CCMD) in the PWMCR register and of the PWM cycle bits (CYC0) and the PWM high-level period bits (PH0) in the PWMCNT register at the same time during the PWM operation, the following procedure should be followed:
   1. Write 1 to the SYNC bit. (Write the original set values to the other bits in PWMCR.)
   2. Change the PWMCNT value.
   3. Change the CC0 and CCMD values in PWMCR. (Write the original set values to the other bits in PWMCR. The SYNC bit should be held at 1.)

   By following the above procedure, the new PWMCNT value is reflected in the timer operation synchronously with PWMCR setting.
   When changing only the PWMCNT value while SYNC = 1, writing to PWMCR is required after changing the PWMCNT value. In this case, write the same values as the original set values to the PWMCR bits. On the other hand, when changing only the PWMCR value, writing to PWMCNT is not required.
   If PWMCNT and PWMCR values are changed while SYNC = 0, the change to the values might not be completed within a single PWM output cycle but actually take two or more cycles. This may disturb the period or duty cycle of the PWM output.
   Note that, when the PWCNT value is changed while SYNC = 1, the new values are read from PWMCNT even before PWMCR is set.

47.4 Usage Note

When using the PWM timer, note the following points.

When the CYC0 value is equal to or smaller than PH0 value in the PWM count register, the PWM output is held high. In this case, to start pulse output, clear EN0 to 0, set CYC0 to the value greater than the PH0 value, and then set EN0 to 1.

Note that, a maximum period equivalent to CYC0 = H'3FF at the set PWM clock frequency may be required before pulse output is started.

48. IR Receiver (IR)

48.1 Overview

This LSI incorporates an IR receiver (IR). The internal bus clock used in this module is 65 MHz.

48.1.1 Features

The IR receiver has the following features:

- Receiver block
  - Automatic leader code detection
  - Synchronization protection (prevention of malfunction caused by noise) circuit incorporated during leader code detection
  - Up to 64 bits of code per frame receivable
  - Up to 2 frame of code receivable

48.1.2 Block Diagram

A block diagram of the IR receiver is shown in Figure 48.1.

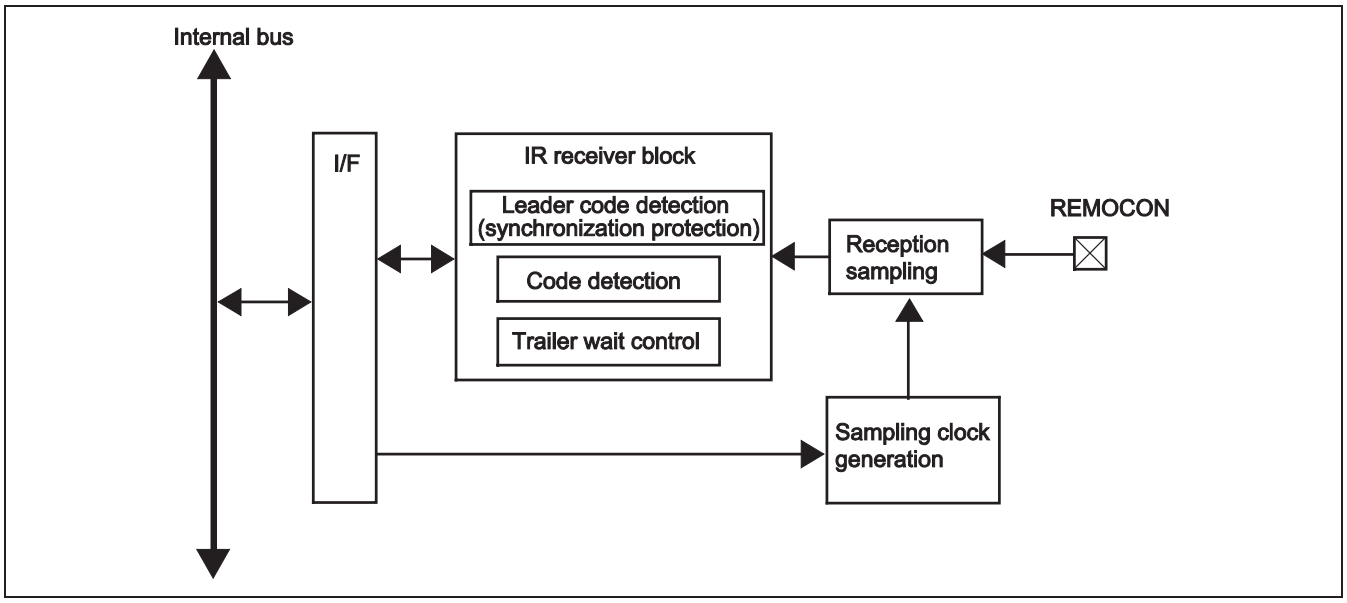

Figure 48.1 Block Diagram of IR Receiver

48.1.3 Input/Output Pins

Table 48.1 shows the pin configuration of the IR receiver.

Table 48.1 Pin Configuration

Pin Name	Function	I/O	Description
REMOCON	IR input data pin	Input	IR receive data input pin

48.1.4 Register Configuration

Table 48.2 shows the register configuration of the IR receiver. The registers of the IR receiver are mapped into the internal bus address space.

Do not write to any addresses other than listed below. Operations cannot be guaranteed if writing is attempted. Values read from addresses other than those listed below are undefined.

Table 48.2 Register Configuration

Register Name	Abbreviation	R/W	Value after Reset*1	Address	Access Size
IR mode register	IRMODE	R/W	H'0000 0000	H'E6E5 0000	32
IR command register	IRCOMM	R/W	H'0000 0000	H'E6E5 0004	32
IR status register	IRST	R/(W)*2	H'0000 0000	H'E6E5 0008	32

Receive code register 2-1	RCODE21	R	H'0000 0000	H'E6E5 0034	32
Receive code register 2-2	RCODE22	R	H'0000 0000	H'E6E5 0038	32

Notes: 1. The value is initialized by a reset.
2. Only 0 can be written to bits 7 and 6, to clear flags.

48.2 Register Descriptions

The registers of the IR receiver are mapped into the internal bus address space.

Legend for Register Description

Initial value: Register value after a reset.

—: Undefined value

R/W: Readable/writable. The written value can be read.

R/WC0: Readable/writable. Writing 0 initializes the bit. Writing 1 is ignored.

R/WC1: Readable/writable. Writing 1 initializes the bit. Writing 0 is ignored.

R: Read-only. The write value should always be 0.

—/W: Write-only. The read value is undefined.

48.2.1 IR Mode Register (IRMODE)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	RCDENDE	RFRENDE	RBUFM	INVERT	RMODE			RECON
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
7	RCDENDE	0	R/W	Receive Code End Interrupt Enable 0: Disables the RCDEND interrupt request. 1: Enables the RCDEND interrupt request.
6	RFRENDE	0	R/W	Receive Frame End Interrupt Enable 0: Disables the RFREND interrupt request. 1: Enables the RFREND interrupt request.
5	RBUFM	0	R/W	Receive Register Mode 0: Double buffer mode. Receive data is written to the RCODE11-RCODE12 registers and the RCODE21-RCODE22 registers. 1: Single buffer mode. Receive data is written to only the RCODE11-RCODE12 registers.
4	INVERT	0	R/W	Receive Signal Polarity Inversion 0: An inverted signal is being input to the REMOCON input pin. 1: A non-inverted signal is being input to the REMOCON input pin.
3 to 1	RMODE	000	R/W	Receive Operating Mode Specifies the operating mode of the IR receiver. 000: Leader code is included. 001: Leader code is not included. 010 to 111: Reserved
0	RECON	0	R/W	IR Receiver Start Setting this bit to 1 starts a receive operation. This bit should be set after all the registers have been set. When this bit is set to 0, the internal IR state and registers RCODE 11/12/21/22 are initialized; other registers are not initialized.

48.2.2 IR Command Register (IRCOMM)

The IR receiver supports error detection for the remote control format in which one frame is composed of four bytes of data (32 bits): the compo code byte following the leader, the inverse of the compo code, an instruction code byte, and its inverse, in that order.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	XCM								ARC			—	ICC	—	—	RCDM
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R	R	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
15 to 8	XCM	H'00	R/W	Specified Compo Code Specifies the reference compo code to be compared with the compo code of receive data. If the comparison result does not satisfy the condition specified by the ARC (Acknowledge Receive Code) bits, data is not written to the RCODE11-RCODE12 and RCODE21-RCODE22 registers.
7 to 5	ARC	000	R/W	Acknowledge Receive Code Data is identified as receive data and is written to the RCODE11-RCODE12 and RCODE21-RCODE22 registers only if the condition specified by the ARC and ICC (Instruction/Compo Code Check) bits is satisfied. In this case, an interrupt is generated. 000: Any compo code 001: The lower four bits of the compo code and of the XCM field match. 010: The upper four bits of the compo code and of the XCM field match. 011: The compo code matches the XCM field. 101: The lower four bits of the compo code and of the XCM field do not match. 110: The upper four bits of the compo code and of the XCM field do not match. 111: The compo code does not match the XCM field.
4	—	0	R	Reserved The read value is always 0. The write value should always be 0.
3	ICC	0	R/W	Instruction/Compo Code Check Data is identified as receive data and is written to the RCODE11-RCODE12 and RCODE21-RCODE22 registers only if the condition specified by the ARC and ICC bit is satisfied. In this case, an interrupt is generated. 0: Any compo code and instruction code 1: The compo code matches its inverted code, and the instruction code matches its inverted code.

Bit	Bit Name	Initial Value	R/W	Description
2, 1	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
0	RCDM	0	R/W	Receive Code Buffer Mode 0: Receive data is stored in the RCODE11 or RCODE21 register in the order of Rn[8]→Rn[15], Rn[24]→Rn[31], Rn[0]→Rn[7], and Rn[16]→Rn[23], and in the RCODE12 or RCODE22 register in the order of Rn[40]→Rn[47], Rn[56]→Rn[63], Rn[32]→Rn[39], and Rn[48]→Rn[55]. 1: Receive data is stored in the RCODE11-RCODE12 or RCODE21-RCODE22 registers in the order from Rn[0] to Rn[63].

48.2.3 IR Status Register (IRST)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	RCDEND	RFREND	—	—	—	—	—	RSEL12
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R/WC0	R/WC0	R	R	R	R	R	R

Note: Only 0 can be written to bits 7 and 6, to clear flags.

Bit	Bit Name	Initial Value	R/W	Description
31 to 8	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
7	RCDEND	0	R/WC0	Frame Receive Code End Status This bit is set to 1 when a frame of bitstream data (not including a trailer) that includes the compo and instruction codes satisfying the ARC and ICC conditions has been completely received. This bit is cleared by writing 0 to it. This bit is set by hardware, and cannot be set by writing 1 to it.
6	RFREND	0	R/WC0	Frame Receive End Status This bit is set to 1 when a frame of bitstream data (including trailer) that includes the compo and instruction codes satisfying the ARC and ICC conditions has been completely received. This bit is cleared by writing "0" to it. This bit is set by hardware, and cannot be set by writing "1" to it.
5 to 1	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
0	RSEL12	0	R	Receive Code Buffer Specification Status 0: The next receive data will be stored in the RCODE11 and RCODE12 registers. 1: The next receive data will be stored in the RCODE21 and RCODE22 registers. Note that this bit is set to 0 by hardware at a reset or when the RECON bit is cleared to 0 (when the IR receiver is stopped). The bit value changes when all the codes in a frame have been received. When the RBUFM bit is 1, this bit is fixed to 0. The write value should be 0.

48.2.4 clkp Division Ratio Register (CPD)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	CPD												
Initial value:	0	0	0	0	0	0	0	0	1	1	1	1	1	0	1	0
R/W:	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 13	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
12 to 0	CPD	H'00FA	R/W	clkp Division Ratio Sets the division ratio for generating a sampling clock for IR input signal. If the clock clkp is 65 MHz and the CPD bits are set to 325 (decimal number), the sampling clock period is 5 μs (325/65M); the IR receiver samples the input signal to determine the input level (0 or 1) at this sampling rate. These bits are initialized to H'00FA (250 in decimal number) at power-on reset.

48.2.5 Leader High Period (Upper and Lower Limits) Register (LDHL)

LDHL specifies the high period of a leader. Consecutive high-level detection period specified by the TN and DN bits in the receive frame total bit number register (RNOFBS) is not included in the leader high period specified in this register.

The values to be set in LDHL are the ratios of the leader high period to the sampling clock period generated according to the value specified by the clkp division ratio register (CPD).

LDHU and LDHL define the allowable upper and lower limits of the leader high period, respectively. For example, if the frequency of the clock clkp is 65 MHz, leader high period is 8.6 ms, the value of the CPD bits is decimal 325, and the allowable limits of the leader high period is from 6.9 ms to 10.3 ms, the values in registers LDHU and LDHL are 2060 (10.3 ms/5 µs) and 1380 (6.9 ms/5 µs), respectively.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	LDHU											
Initial value:	0	0	0	0	1	0	0	0	0	0	0	0	1	1	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	1	0	1	0	1	1	0	0	1	0	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
27 to 16	LDHU	H'80C	R/W	Leader High Period Upper Limit Sets the allowable upper limit of the leader high period.
15 to 12	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
11 to 0	LDHL	H'564	R/W	Leader High Period Lower Limit Sets the allowable lower limit of the leader high period.

48.2.6 Leader Low Period (Upper and Lower Limits) Register (LDLL)

LDLL specifies the low period of a leader. Continuous low-level detection period specified by the TN and DN bits in the receive frame total bit number register (RNOFBS) is not included in the leader low period specified in this register.

The values to be set in LDLL are the ratios of the leader low period to the sampling clock period specified by the clkp division ratio register (CPD).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
27 to 16	LDLU	H'370	R/W	Leader Low Period Upper Limit Sets the allowable upper limit of leader low period.
15 to 12	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
11 to 0	LDLL	H'320	R/W	Leader Low Period Lower Limit Sets the allowable lower limit of leader low period.

48.2.7 "0" Bit Period (Upper and Lower Limits) Register (BS0L)

BS0L specifies the "0" bit period.

The values to be set in BS0L are the ratios of the "0" bit period to the sampling clock period specified by the clkp division ratio register (CPD).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
27 to 16	BS0U	H'0F6	R/W	"0" Bit Period Upper Limit Sets the allowable upper limit of the "0" bit period.
15 to 12	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
11 to 0	BS0L	H'0B6	R/W	"0" Bit Period Lower Limit Sets the allowable lower limit of the "0" bit period.

48.2.8 "1" Bit Period (Upper and Lower Limits) Register (BS1L)

BS1L specifies the "1" bit period.

The values to be set in BS1L are the ratios of the "1" bit period to the sampling clock period specified by the clkp division ratio register (CPD).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	BS1U											
Initial value:	0	0	0	0	0	0	0	1	1	1	1	0	1	0	1	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	BS1L											
Initial value:	0	0	0	0	0	0	0	1	0	1	1	0	1	0	1	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
27 to 16	BS1U	H'1EA	R/W	"1" Bit Period Upper Limit Sets the allowable upper limit of the "1" bit period.
15 to 12	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
11 to 0	BS1L	H'16A	R/W	"1" Bit Period Lower Limit Sets the allowable lower limit of the "1" bit period.

48.2.9 "0" or "1" Bit High Period (Upper and Lower Limits) Register (BSHL)

BSHL specifies the high period of the "0" or "1" bit.

The values to be set in BSHL are the ratios of the high period to the sampling clock period specified by the clkp division ratio register (CPD).

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	BSHU											
Initial value:	0	0	0	0	0	0	0	0	1	0	1	0	1	0	1	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	BSHL											
Initial value:	0	0	0	0	0	0	0	0	0	0	1	1	0	1	1	0
R/W:	R	R	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 28	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
27 to 16	BSHU	H'0AA	R/W	"0" or "1" Bit High Period Upper Limit Sets the allowable upper limit of the high period of the "0" or "1" bit.
15 to 12	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
11 to 0	BSHL	H'036	R/W	"0" or "1" Bit High Period Lower Limit Sets the allowable lower limit of the high period of the "0" or "1" bit.

48.2.10 Trailer Wait Time Register (TWP)

TWP sets the wait time in a trailer.

The bit value is the ratio of the wait period to the sampling clock period specified by the clkp division ratio register (CPD).

After the time specified by this register has been elapsed, the IR receiver returns to the initial state and goes to the mode of detecting the next edge of the signal.

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TWP															
Initial value:	0	0	0	1	0	1	0	0	0	1	0	1	0	0	0	0
R/W:	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 16	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
15 to 0	TWP	H'1450	R/W	Trailer Wait Time Sets the wait time in a trailer.

48.2.11 Receive Frame Total Bit Number Register (RNOFBS)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	TN			DN			—	RNOFBS						
Initial value:	0	0	1	1	1	0	0	0	0	0	1	0	0	0	0	0
R/W:	R	R	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W	R/W	R/W	R/W	R/W	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 14	—	All 0	R	Reserved The read value is always 0. The write value should always be 0.
13 to 11	TN	111	R/W	Specifies the maximum number of times the receiver should attempt to receive a low- or high-level signal at the reception sampling frequency during leader code reception. (For details, refer to section 48.3, Description of Operation.) 000: Three times 001: Four times ….. 111: Ten times Set the value equal to or greater than that set in the DN bits.
10 to 8	DN	000	R/W	Specifies the number of times the receiver should detect a low- or high-level signal consecutively to determine the pulse level (low or high) during leader code reception. (For details, refer to section 48.3, Description of Operation.) 000: Three times 001: Four times ….. 111: Ten times Set the value equal to or smaller than that set in the TN bits.
7	—	0	R	Reserved The read value is always 0. The write value should always be 0.
6 to 0	RNOFBS	H'20	R/W	Sets the total number of bits in a frame. Set a value according to the format of the signal input to the IR receiver. The maximum settable value is H'40.

48.2.12 Receive Code Register 1-1 (RCODE11)

RCODE11 is a register in which receive codes are stored.

Error detection is supported for the 32-bit format with a compo code. For details, refer to section 48.2.2, IR Command Register (IRCOMM).

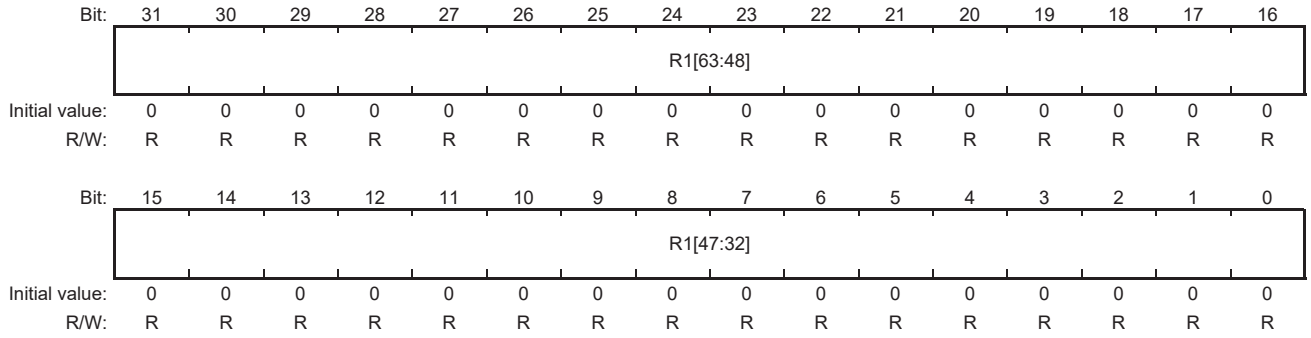
Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	R1[31:16]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	R1[15:0]															
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 0	R1[31:0]	H'0000 0000	R	Receive Code This register is not overwritten until it is read. RCDM = 1: Data is written in the received order to bits R1[0]→R1[31]. RCDM = 0: Data is written in the received order to bits R1[8]→R1[15], R1[24]→R1[31], R1[0]→R1[7], and then R1[16]→R1[23]. Data is written to RCODE11 and RCODE12, in that order. (Before receiving data, storing order and the total number of bits in a frame should be set in the RCDM and RNOFBS bits, respectively.)

48.2.13 Receive Code Register 1-2 (RCODE12)

RCODE12 is a register in which receive codes are stored.

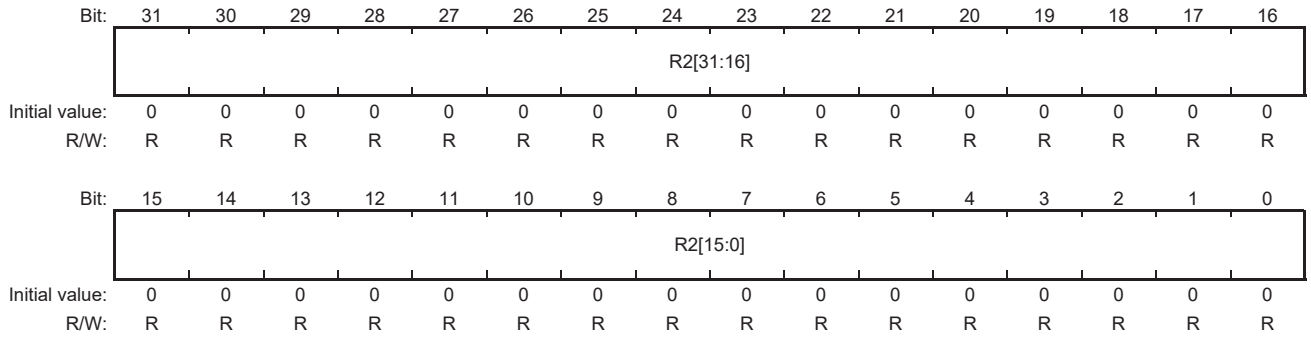


Bit	Bit Name	Initial Value	R/W	Description
31 to 0	R1[63:32]	H'0000 0000	R	Receive Code This register is not overwritten until the receive code register 1-1 (RCODE11) is read. RCDM = 1: Data is written in the received order to bits R1[32]→R1[63]. RCDM = 0: Data is written in the received order to bits R1[40]→R1[47], R1[56]→R1[63], R1[32]→R1[39], and then R1[48]→R1[55]. Data is written to RCODE11 and RCODE12, in that order. (Before receiving data, storing order and the total number of bits in a frame should be set in the RCDM and RNOFBS bits, respectively.)

48.2.14 Receive Code Register 2-1 (RCODE21)

RCODE21 is a register in which receive codes are stored.

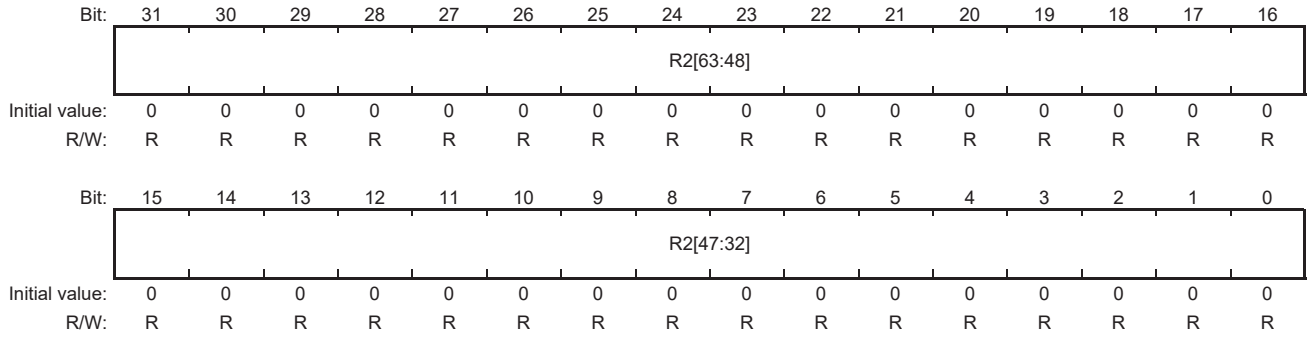
Error detection is supported for the 32-bit format with a compo code. For details, refer to section 48.2.2, IR Command Register (IRCOMM).



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	R2[31:0]	H'0000 0000	R	Receive Code This register is not overwritten until it is read. RCDM = 1: Data is written in the received order to bits R2[0]→R2[31]. RCDM = 0: Data is written in the received order to bits R2[8]→R2[15], R2[24]→R2[31], R2[0]→R2[7], and then R2[16]→R2[23]. Data is written to RCODE21 and RCODE22, in that order. (Before receiving data, storing order and the total number of bits in a frame should be set in the RCDM and RNOFBS bits, respectively.)

48.2.15 Receive Code Register 2-2 (RCODE22)

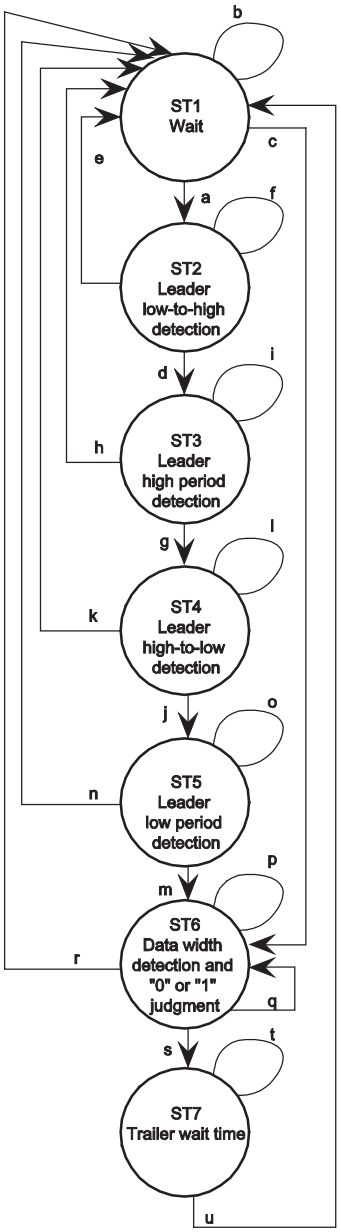
RCODE22 is a register in which receive codes are stored.



Bit	Bit Name	Initial Value	R/W	Description
31 to 0	R2[63:32]	H'00000000	R	Receive Code This register is not overwritten until the receive code register 2-1 (RCODE21) is read. RCDM = 1: Data is written in the received order to bits R2[32]→R2[63]. RCDM = 0: Data is written in the received order to bits R2[40]→R2[47], R2[56]→R2[63], R2[32]→R2[39], and then R2[48]→R2[55]. Data is written to RCODE21 and RCODE22, in that order. (Before receiving data, storing order and the total number of bits in a frame should be set in the RCDM and RNOFBS bits, respectively.)

48.3 Description of Operation

48.3.1 Overview of IR Receiver Operation



ST1: Wait
The global counter, sampling period counter (1), sampling period counter (2), and rising edge counter (3) are all reset.
a. In the case of RECON = 1, high level detection, and the data format including a leader code.
b. High level detection wait state
c. In the case of RECON = 1, high level detection, and the data format not including a leader code.

ST2: Leader low-to-high detection
The sampling period counter (1) is started. A maximum of TN times of attempts are made to detect a high level DN times consecutively. The global counter is started.
d. A high level is detected DN times consecutively.
e. TN times of attempts are made but failed, or a timeout*1 occurs.
f. Attempting is in progress.

ST3: Leader high period detection
The sampling period counter (2) is started. The counter is incremented each time a high level is detected. When a falling edge is detected, the counter value is compared with the LDHL register value. The sampling period counter (1) is reset.
g. The high period of a leader code is within the range between LDHU and LDHL.
h. The high period of a leader code is out of the range between LDHU and LDHL, or a timeout*1 occurs.
i. High level counting is in progress.

ST4: Leader high-to-low detection
The sampling period counter (1) is started. DN consecutive times of low-level detection are tried a maximum of TN times. The sampling period counter (2) is reset.
j. A low level is detected DN times consecutively.
k. TN times of attempts are made but failed, or a timeout*1 occurs.
l. Attempting is in progress.

ST5: Leader low period detection
The sampling period counter (2) is started. The counter is incremented each time a low level is detected. When a rising edge is detected, the counter value is compared with the LDLL register value. The sampling period counter (1) is reset.
m. The low period of a leader code is within the range between LDLU and LDLL.
n. The low period of a leader code is out of the range between LDLU and LDLL, or a timeout*1 occurs.
o. Low level counting is in progress.

ST6: Data width detection and "0" or "1" judgment
The sampling period counter (2) is reset and then started, and is incremented until a rising edge is detected. The counter value at the detection of the falling edge is compared with the BSHL register value, and the counter value at the detection of the following rising edge is compared with the BS0L and BS1L register values. The bit is judged as "0", "1", or "other than 0 and 1" according to the result of these comparisons.
The rising edge counter (3) is incremented each time a rising edge is detected.
p. A rising edge has not been detected.
q. A bit is judged as "0" or "1", and the value of the rising edge counter (3) is smaller than the number of bits specified by RNOFBS.
r. A bit is judged as "other than 0 and 1", or a timeout*1 occurs.
s. A bit is judged as "0" or "1", and the value of the rising edge counter (3) has reached the number of bits specified by RNOFBS.
When the compo code bits and instruction code bits satisfy the conditions specified by the ARC and ICC bits, the data is set in the receive code registers, and the receive code end interrupt is generated.

ST7: Trailer wait time
The sampling period counter (1) is started. The sampling period counter (2) and the rising edge counter (3) are reset.
t. The counter value has not reached the value specified by TWP.
u. The counter value has reached the value specified by TWP. The receive frame end interrupt is generated.

Notes: 1. A timeout occurs when the following time has elapsed after the start of the global counter.
36096 × sampling period
2. The receiver is returned to ST1 by a reset or clearing RECON to 0.

Figure 48.2 Operation Flow of IR Receiver

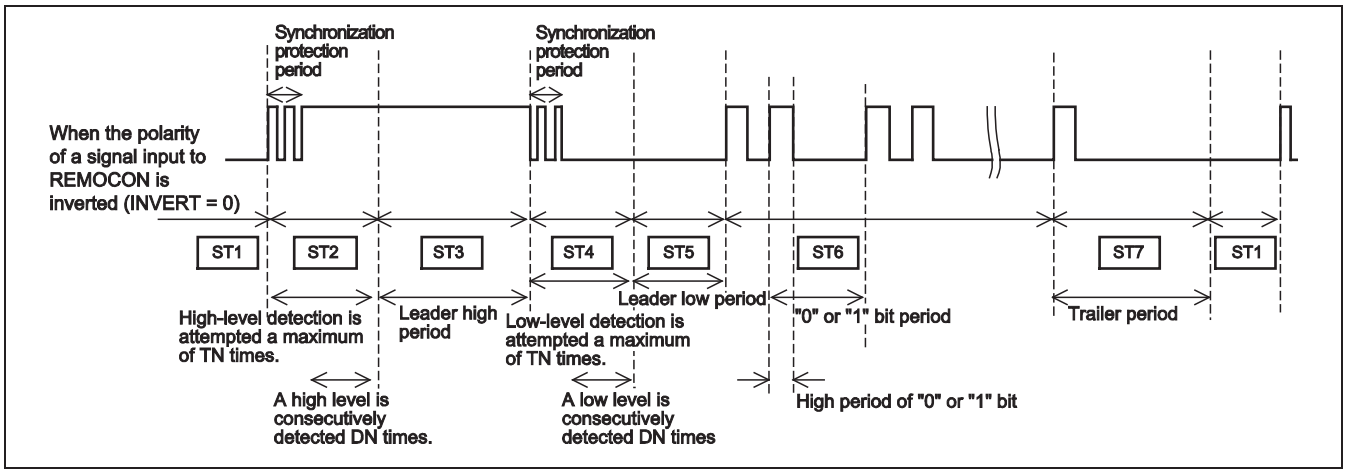


Figure 48.3 Operation Flow of IR Receiver (Continued from Figure 48.2)

48.3.2 Basic Use of IR Receiver

1. Initialize registers.

   The following registers should be set before using the IR receiver.

   Example: When the RMODE bit is B'000 (the mode in which leader code is included.)

   — CPD : Set the clkp division ratio.
   — LDHL : Set the leader high period (upper and lower limits).
   — LDLL : Set the leader low period (upper and lower limits).
   — BS0L : Set the "0" bit period (upper and lower limits).
   — BS1L : Set the "1" bit period (upper and lower limits).
   — BSHL : Set the "0" or "1" bit high period (upper and lower limits).
   — IRCOMM (XCM bits) : Set the specified compo code.
   — IRCOMM (ARC bits) : Set the acknowledge receive code.
   — IRCOMM (ICC bit) : Set the instruction/compo code check.
   — IRCOMM (RCDM bit) : Set receive code buffer mode.
   — IRMODE (RBUFM bit) : Set double buffer mode.
   — TWP : Set the trailer wait time.
   — RNOFBS : Set the total number of bits in a receive frame.
2. Set the interrupt, if required.
3. Lastly, set the RECON bit to 1 to start receive operation.

   Receive data is stored in the RCODE11 and RCODE12 registers.

   When RCDM = 1, data is written in the received order to bits R1[0]→R1[31].

   When RCDM = 0, data is written in the received order to bits R1[8]→R1[15], R1[24]→R1[31], R1[0]→R1[7], and then R1[16]→R1[23].

   When data has been stored in the RCODE11 and RCODE12 registers, the next receive data is automatically stored in the RCODE21 and RCODE22 registers.
4. Detect the interrupt signal and read the receive data from the buffers.
5. When all the data has been received, set the RECON bit to 0 to stop the IR receiver.

48.3.3 Interrupt Source

Table 48.3 shows the interrupt sources of the IR receiver.

To clear these interrupts, write 0 to the RFREND and RCDEND bits in the IR status register.

Table 48.3 Interrupt Sources

Interrupt System	Interrupt Source (Flag Register)	Description
IR receiver interrupt	Receive frame end interrupt (RFREND)	This interrupt is requested when a frame (including a trailer) has been completely received in the IR receiver block, where the received compo and instruction codes satisfy the conditions specified by the ARC and ICC bits.
	Receive code end interrupt (RCDEND)	This interrupt is requested when all the codes in a frame (excluding a trailer) have been received in the IR receiver block, where the received compo and instruction codes satisfy the conditions specified by the ARC and ICC bits.

49. System Controller (SYSC)

49.1 Overview

The SYSC module controls the supply of power (*) to CPUs (Cortex-A7), SGX with the aim of low leakage power.

Note: (*) Actual control of power shut off for those domains (CPUs (Cortex-A7), SGX) are not supported. Only control for deactivating or activation those domains by controlling clocks distribution and reset assert are supported. Description of power-resume or power-shutoff in this manual means power control in the meaning above.

49.1.1 Features

- Support shutoff and resumption of power in the following four power domains.
  Cortex-A7 CPU0/CPU1 (including the L1 cache)
  Cortex-A7 SCU (including the L2 cache)
  SGX
- Only power to the domains listed below is on (i.e. the domains are in the power-resume state) after a power-on reset.
  Cortex-A7 CPU0 and Cortex-A7 SCU, if MD6 = 1 and MD7 = 0 (Cortex-A7 boot)
  Other domains are in the shutoff state after a power-on reset.
- Control of supplying and shutting off power is independent for each target domain, with the following exceptions.
  SCU of the Cortex-A7s can't be switched off while power to either or both of Cortex-A7 CPU0/1 is on.
- Resumption of the supply of power to Cortex-A7s (CPU0 to CPU1 and SCU) is controlled by interrupts in each domain.
- Power for Cortex-A7s (CPU0 to CPU1) can be shut off by WFI instructions

49.1.2 Block Diagram

Figure 49.1 is block diagrams of the SYSC.

Connected to the internal peripheral bus (the APB bus), the SYSC operates in coordination with the CPG, the RESET module, the CPU, and the debugger; it contains a module that controls the objects of power shutoff.

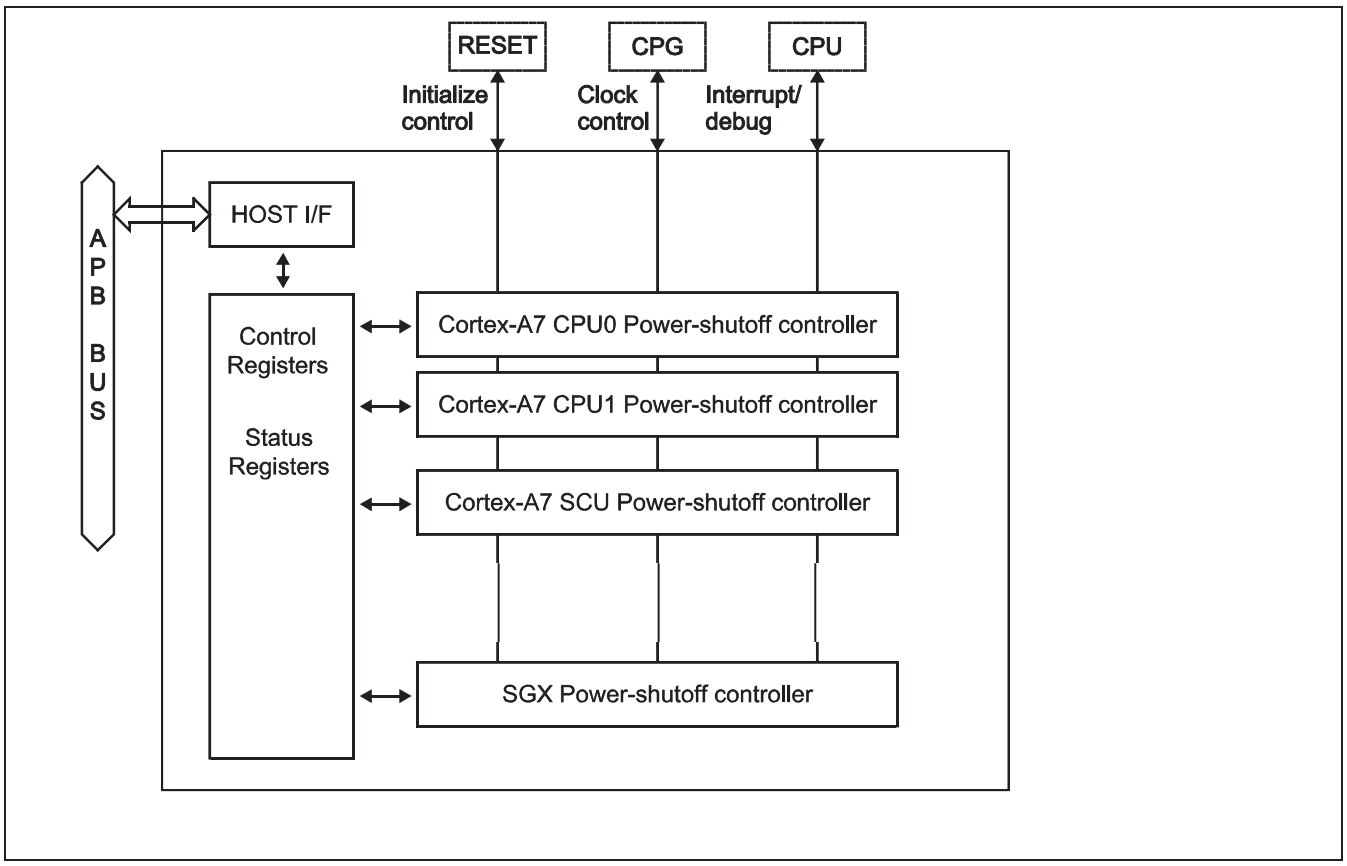

Figure 49.1 Block Diagram of the SYSC

49.1.3 Input/output Pins

The SYSC has no input/output pins.

49.2 Register Configuration

Tables 49.1 to 49.2 list the SYSC registers.

Base-address of SYSC is H'E618 0000.

Do not write to addresses other than those listed below, otherwise normal operation cannot be guaranteed. Values read from other addresses are undefined.

[Legend]

Initial value: Register value after a reset

—: Undefined value

R/W: Readable/writable. The written value can be read.

R: Read-only. The write value should always be the initial value.

—/W: Write-only. The read value is undefined.

Table 49.1 List of Registers (Common Registers)

Name	Abbreviation	R/W	Initial Value	Address	Access size

49.2.1 Common Registers

These registers are used to control the shutting off of power to the various modules with respect to the common settings, the interrupts, as well as external events.

49.2.1.1 SYSC Status Register (SYSCSR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PONENB	POFFENB
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1	PONENB	1	R	This bit indicates whether the SYSC is ready to accept power resume requests. Any power resume request issued when the SYSC is disabled from accepting power resume requests will be ignored. 1: Power resume request is acceptable. 0: Power resume request is not accepted.
0	POFFENB	1	R	This bit indicates whether the SYSC is ready to accept power shutoff requests. Any power shutoff request issued when the SYSC is disabled from accepting power shutoff requests will be ignored. 1: Power shutoff request is acceptable. 0: Power shutoff request is not acceptable.

49.2.1.2 Interrupt Status Register (SYSCISR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	CA7-SCU	SGX	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	CA7-CPU[1:0]		—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21	CA7-SCU	0	R	Indicates Cortex-A7 SCU power-processing status. This bit is set to 1 when the CA7-SCU bit in the interrupt enable register is 1 upon completion of the Cortex-A7 SCU power shutoff or power resume processing. If the CA7-SCU bit in the interrupt enable register is 0, this bit is not set to 1 even when the Cortex-A7 SCU power shutoff or power resume processing is completed. An interrupt request is issued when the CA7-SCU bit in the interrupt mask register is 0 and this bit is 1. 0: Power shutoff or power resume processing of Cortex-A7 SCU is not completed. 1: Power shutoff or power resume processing of Cortex-A7 SCU is completed.
20	SGX	0	R	Indicates SGX power-processing status. This bit is set to 1 when the SGX bit in the interrupt enable register is 1 upon completion of the SGX power shutoff or power resume processing. If the SGX bit in the interrupt enable register is 0, this bit is not set to 1 even when the SGX power shutoff or power resume processing is completed. An interrupt request is issued when the SGX bit in the interrupt mask register is 0 and this bit is 1. 0: Power shutoff or power resume processing of SGX is not completed. 1: Power shutoff or power resume processing of SGX is completed.
19 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6, 5	CA7-CPU[1:0]	00	R	Indicates Cortex-A7 CPU1-0 power-processing status. This bit is set to 1 when the CA7-CPU[1:0] bit in the interrupt enable register is 1 upon completion of the Cortex-A7 core CPU1-0 power shutoff or power resume processing. If the CA7-CPU[1:0] bit in the interrupt enable register is 0, this bit is not set to 1 even when power shutoff or power resume processing for the Cortex-A7 core CPU1-0 is completed. An interrupt request is issued when the CA7-CPU[1:0] bit in the interrupt mask register is 0 and this bit is 1. 0: Power shutoff or power resume processing of Cortex-A7 CPU1-0 is not completed. 1: Power shutoff or power resume processing of CPU1-0 is completed.
4 to 0	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

49.2.1.3 Interrupt Status Clear Register (SYSCISCR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	CA7-SCU	SGX	—	—	—	—
Initial value:	0	0	0	0	0	0	0	—	0	0	—	—	0	0	0	0

Initial value:	0	0	0	0	0	0	0	0	0	—	—	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	—/W	—/W	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21	CA7-SCU	—	—/W	Specify clear of Cortex-A7 SCU interrupt status. Writing 1 to this bit clears the CA7-SCU bit in the interrupt status register (SYSCISR) to 0. Writing 0 to this bit is ignored.
20	SGX	—	—/W	Specify clear of SGX interrupt status. Writing 1 to this bit clears the SGX bit in the interrupt status register (SYSCISR) to 0. Writing 0 to this bit is ignored.
19 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6, 5	CA7-CPU[1:0]	—	—/W	Specify clear of Cortex-A7 CPU1-0 interrupt status. Writing 1 to this bit clears the CA7-CPU[1:0] bit in the interrupt status register (SYSCISR) to 0. Writing 0 to this bit is ignored.
4 to 0	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

49.2.1.4 Interrupt Enable Register (SYSCIER)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	CA7-SCU	SGX	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	CA7-CPU[1:0]		—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21	CA7-SCU	0	R/W	Specifies that the status is indicated in the CA7-SCU bit in the interrupt status register (SYSCISR) when the Cortex-A7 SCU power shutoff or power resume processing is completed. 0: Does not indicate the status when power shutoff or power resume processing is completed. 1: Indicates the status when power shutoff or power resume processing is completed.
20	SGX	0	R/W	Specifies that the status is indicated in the SGX bit in the interrupt status register (SYSCISR) when the SGX power shutoff or power resume processing is completed. 0: Does not indicate the status when power shutoff or power resume processing is completed. 1: Indicates the status when power shutoff or power resume processing is completed.
19 to 7	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
6, 5	CA7-CPU[1:0]	00	R/W	Specifies that the status is indicated in the CA7-CPU[1:0] bit in the interrupt status register (SYSCISR) when power shutoff or power resume processing for the Cortex-A7 core CPU1-0 is completed. 0: Does not indicate the status when power shutoff or power resume processing is completed. 1: Indicates the status when power shutoff or power resume processing is completed.
4 to 0	—	0	R	Reserved These bits are always read as 0. The write value should always be 0.

49.2.1.5 Interrupt Mask Register (SYSCIMR)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	CA7-SCU	SGX	—	—	—	—
Initial value:	0	0	0	0	0	0	0	1	0	0	1	1	0	0	0	1
R/W:	R	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	CA7-CPU[1:0]		—	—	—	—	—
Initial value:	0	0	0	1	0	0	0	1	1	1	1	0	1	1	1	1
R/W:	R	R	R	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 25	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
24	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
23, 22	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
21	CA7-SCU	1	R/W	Controls the interrupt output when the Cortex-A7 SCU power shutoff or power resume processing is completed. If this bit is 1, no interrupt is issued even if the pertinent bit in the interrupt status register (SYSCISR) is set to 1. 0: Does not mask the interrupt when the Cortex-A7 SCU power shutoff or power resume processing is completed. 1: Masks the interrupt when the Cortex-A7 SCU power shutoff or power resume processing is completed.
20	SGX	1	R/W	Controls the interrupt output when the SGX power shutoff or power resume processing is completed. If this bit is 1, no interrupt is issued even if the pertinent bit in the interrupt status register (SYSCISR) is set to 1. 0: Does not mask the interrupt when the SGX power shutoff or power resume processing is completed. 1: Masks the interrupt when the SGX power shutoff or power resume processing is completed.
19 to 17	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
16	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
15 to 13	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
12	—	1	R	Reserved This bit is always read as 1. The write value should always be 1.
11 to 9	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
8, 7	—	All 1	R	Reserved These bits are always read as 1. The write value should always be 1.

Bit	Bit Name	Initial Value	R/W	Description
6, 5	CA7-CPU[1:0]	11	R/W	Controls the interrupt output when power shutoff or power resume processing for the Cortex-A7 core CPU [1:0] is completed. If this bit is 1, no interrupt is issued even if the pertinent bit in the interrupt status register (SYSCISR) is set to 1. 0: Does not mask the interrupt when power shutoff or power resume processing for the Cortex-A7 core CPU [1:0] is completed. 1: Masks the interrupt when power shutoff or power resume processing for the Cortex-A7 core CPU [1:0] is completed.
4	—	0	R	Reserved This bit is always read as 0. The write value should always be 0.
3 to 0	—	All 1	R	Reserved These bits are always read as 1. The write value should always be 1.

49.2.1.6 Cortex-A7 Wake Up Mask Register (WUPMSKCA7)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CSD[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R/W

	—	—	—	—	—	—	FIQ[1:0]		—	—	—	—	—	—	IRQ[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R	R	R	R	R/W	R/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 18	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
17, 16	CSD[1:0]	00	R/W	Enable/Disable wake up Cortex-A7 CPU0-1 + SCU area when receiving CSD[1:0] factor 0: Enable 1: Disable This setting is available only when Cortex-A7 SCU area is in OFF state
15 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	FIQ[1:0]	00	R/W	Enable/Disable wake up Cortex-A7 CPU0-1 + SCU area when receiving FIQ[1:0] factor 0: Enable 1: Disable This setting is available only when Cortex-A7 SCU area is in OFF state.
7 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	IRQ[1:0]	00	R/W	Enable/Disable wake up Cortex-A7 CPU0-1 + SCU area when receiving IRQ[1:0] factor 0: Enable 1: Disable This setting is available only when Cortex-A7 SCU area is in OFF state.

49.2.1.7 External Event Request Status Register2 (SYSCEERSR2)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	FIQ_CA7[1:0]		—	—	IRQ_CA7[1:0]		—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	FIQ_CA7[1:0]	00	R	If the FIQ_CA7[1:0] bit in the external event request status enable register is 1, this bit is set to 1 when a power resume request due to an FIQ interrupt is accepted by the Cortex-A7 core CPU1-0. If the FIQ_CA7[1:0] bit in the external event request status enable register is 0, this bit is not set to 1 even when a power resume request due to an FIQ interrupt is accepted. This bit is also set to 1 when the request is accepted when power for the Cortex-A7 core CPU1-0 is not shut off. 0: The power resume request due to an FIQ interrupt has not been accepted by the Cortex-A7 core CPU1-0. 1: The power resume request due to an FIQ interrupt has been accepted by the Cortex-A7 core CPU1-0. This bit is set, only when condition above is satisfied in Cortex-A7/SCU is power-shutoff state.
7, 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5, 4	IRQ_CA7[1:0]	00	R	If IRQ_CA7[1:0] bit in the external event request status enable register is 1, this bit is set to 1 when a power resume request due to an IRQ interrupt is accepted by the ARM core CPU1-0. If the IRQ_CA7[1:0] bit in the external event request status enable register is 0, this bit is not set to 1 even when a power resume request due to an IRQ interrupt is accepted. This bit is also set to 1 when the request is accepted when power for the Cortex-A7 core CPU1-0 is not shut off. 0: The power resume request due to an IRQ interrupt has not been accepted by the Cortex-A7 CPU1-0. 1: The power resume request due to an IRQ interrupt has been accepted by the Cortex-A7 core CPU1-0. This bit is set, only when condition above is satisfied in Cortex-A7/SCU is power-shutoff state.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

49.2.1.8 External Event Request Status Clear Register2 (SYSCEERSCR2)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	FIQ_CA7[1:0]		—	—	IRQ_CA7[1:0]		—	—	—	—
Initial value:	0	0	0	0	0	0	—	—	0	0	—	—	0	0	0	0
R/W:	R	R	R	R	R	R	—/W	—/W	R	R	—/W	—/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	FIQ_CA7[1:0]	—	—/W	Writing 1 to this bit clears FIQ_CA7[1:0] bit in the external event request status register 2 (SYSCEERSR2) to 0. If 0 is written to this bit or the pertinent bit in the external event request status register is 0, nothing happens. If the pertinent bit in the external event request status register is set to 1 and 1 is written to this bit simultaneously to clear it to 0, setting the bit to 1 takes precedence.
7, 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5, 4	IRQ_CA7[1:0]	—	—/W	Writing 1 to this bit clears the IRQ_CA7[1:0] bit in the external event request status register2 (SYSCEERSR2) to 0. If 0 is written to this bit or the pertinent bit in the external event request status register is 0, nothing happens. If the pertinent bit in the external event request status register is set to 1 and 1 is written to this bit simultaneously to clear it to 0, setting the bit to 1 takes precedence.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

49.2.1.9 External Event Request Status Enable Register2 (SYSCEERSER2)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R/W	R/W	R	R	R/W	R/W	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 10	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
9, 8	FIQ_CA7[1:0]	00	R/W	Specifies that the status be indicated in the FIQ_CA7[1:0] bit in the external event request status register (SYSCOFSR) when a power resume request due to an FIQ interrupt is accepted by the Cortex-A7 core CPU1-0. 0: Does not indicate the status when a power resume request is accepted. 1: Indicates the status when a power resume request is accepted.
7, 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5, 4	IRQ_CA7[1:0]	00	R/W	Specifies that the status be indicated in IRQ_CA7[1:0] bit in the external event request status register (SYSCOFSR) when a power resume request due to an IRQ interrupt is accepted by the Cortex-A7 core CPU1-0. 0: Does not indicate the status when a power resume request is accepted. 1: Indicates the status when a power resume request is accepted.
3 to 0	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.

49.2.2 Power Control Registers for ARM CPUs

These registers control power status of Cortex-A7 CPUs.

In the detailed description those registers, the register names corresponding to the modules Cortex-A7 is denoted as n = 6.

49.2.2.1 Power Status Register n (PWRSRn)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	PWRUP_CPU [1:0]		—	—	PWRDWN_CPU [1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 6	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
5, 4	PWRUP_CPU[1:0]	B'01	R	Indicates the non-power-shutoff state of CPU1-0 0: Not in non-power-shutoff state 1: In non-power-shutoff state
3, 2	—	All 1	R	Reserved These bits are always read as 1. The write value should always be 1.
1, 0	PWRDWN_CPU[1:0]	B'10	R	Indicates the power-shutoff state of CPU1-0 0: Not in power-shutoff state 1: In power-shutoff state

49.2.2.2 Power Shutoff Status Register n (PWROFFSRn)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CPU[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	CPU[1:0]	00	R	Indicates the power shutoff sequence execution status of CPU1-0. 0: The power shutoff sequence not being executed 1: The power shutoff sequence being executed

49.2.2.3 Power Resume Status Register n (PWRONSRn)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CPU[1:0]	
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	CPU[1:0]	00	R	Indicates the power resume sequence execution status of CPU1-0. 0: The power resume sequence not being executed 1: The power resume sequence being executed

49.2.2.4 Power Shutoff/Resume Error Register n (PWRERn)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Bit Name	Initial Value	R/W	Description
31 to 2	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
1, 0	CPU[1:0]	00	R	Indicates whether a power shutoff or power resume request by a preceding register write to CPU1-0 was accepted or not. 0: Either a preceding power shutoff or power resume request to CPU1-0 was accepted. 1: Either a preceding power shutoff or power resume request to CPU1-0 was not accepted.

49.2.3 Power Control Registers for SGX and SCU of Cortex-A7

These registers control power shutoff/resume of following modules. In the detailed description of these registers that follows, the register names corresponding to the modules are denoted as "n (n: 2/3)". The "n" and the module names correspond as follows:

SGX: n = 2
Cortex-A7 SCU: n = 3

49.2.3.1 Power Status Register n (PWRSRn) (n = 2/3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	PWR UP	—	—	—	PWR DWN

R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 5	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
4	PWRUP	0 for n = 2 1 for n = 3	R	Indicates the power non-shutoff status of a given module. 0: The module is not in the power non-shutoff state. 1: The module is in the power non-shutoff state.
3 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	PWRDWN	0 for n = 3 1 for n = 2	R	Indicates the power shutoff status of a given module. 0: The module is not in the power shutoff state. 1: The module is in the power shutoff state.

49.2.3.2 Power Shutoff Control Register n (PWROFFCRn) (n = 2/3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PWR DWN
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	—/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	PWRDWN	—	—/W	Specify the start of power-shutoff sequence. Writing 1 to this bit when the POFFENB bit in the SYSC status register is 1 starts the power shutoff sequence for the module. In this case, the ERR bit in the power shutoff/resume error register n is set to 0. Writing 1 to this bit when the POFFENB bit in the SYSC status register is 0 does not start the power shutoff sequence. In this case, the ERR bit in the power shutoff/resume error register n is set to 1. 0: Does not shut off power for the module. 1: Starts the power shutoff sequence for the module. When the power shutoff sequence is started, during the execution of the power shutoff sequence the shutoff processing status is indicated in the DWNSTATE bit in the power shutoff status register n. The PWRUP bit in the power status register n is set to 0. Upon completion of the power shutoff sequence, the PWRDWN bit in the power status register n is set to 1. The pertinent bit in the interrupt status register is set to 1 if it is enabled by the setting of the interrupt status enable register. If 1 is written to this bit when the module is in the power shutoff state, such a request is ignored. In this case, too, if 1 is written when the POFFENB bit is 1, the pertinent bit in the power shutoff/resume error register is set to 0, and if 1 is written when the POFFENB bit is 0, the pertinent bit in the power shutoff/resume error register is set to 1.

Note: Write the value H'0000 0002 to register that have address H'E6150840 before write 1 to “Power Shutoff Control” register.

49.2.3.3 Power Shutoff Status Register n (PWROFFSRn) (n = 2/3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DWN STATE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	DWNSTATE	0	R	Indicates the power shutoff sequence execution status for the module. 0: The power shutoff sequence not being executed 1: The power shutoff sequence being executed

49.2.3.4 Power Resume Control Register n (PWRONCRn) (n = 2/3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PWR UP
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	—
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	—/W

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	PWRUP	—	—/W	Specify the start of power-resume sequence. Writing 1 to this bit when the PONENB bit in the SYSC status register is 1 starts the power resume sequence for the module. In this case, the ERR bit in the power shutoff/resume error register n is set to 0. Writing 1 to this bit when the PONENB bit in the SYSC status register is 0 does not start the power resume sequence. In this case, the ERR bit in the power shutoff/resume error register n is set to 1. 0: Does not resume power for the module. 1: Starts the power resume sequence for the module. When the power resume sequence is started, during the execution of the power resume sequence the resume processing status is indicated in the UPSTATE bit in the power resume status register n. The PWRDWN bit in the power status register n is set to 0. Upon completion of the power resume sequence, the PWRUP bit in the power status register n is set to 1. The pertinent bit in the interrupt status register is set to 1 if it is enabled by the setting of the interrupt status enable register. If 1 is written to this bit when the module is in the power non-shutoff state, such a request is ignored. In this case, too, if 1 is written when the PONENB bit is 1, the pertinent bit in the power shutoff/resume error register is set to 0, and if 1 is written when the PONENB bit is 0, the pertinent bit in the power shutoff/resume error register is set to 1.

49.2.3.5 Power Resume Status Register n (PWRONSRn) (n = 2/3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	UP STATE
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	UPSTATE	0	R	Indicates the power resume sequence execution status for the module. 0: The power resume sequence not being executed 1: The power resume sequence being executed

49.2.3.6 Power Shutoff/Resume Error Register n (PWRERn) (n = 2/3)

Bit:	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit:	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ERR
Initial value:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Bit	Bit Name	Initial Value	R/W	Description
31 to 1	—	All 0	R	Reserved These bits are always read as 0. The write value should always be 0.
0	ERR	0	R	Indicates that either a power shutoff or power resume request by a preceding register write to the module was issued when such requests were not acceptable. 0: Either a preceding power shutoff or power resume request to the module was accepted. 1: Either a preceding power shutoff or power resume request to the module was not accepted.

49.3 Operations

49.3.1 Power Control of ARM CPUs

The ARM CPUs can be powered off by executing the WFI instruction. Similarly, power of ARM CPU core can be resumed either by controlling the CPG (APMU) registers or by an IRQ or FIQ interrupt.

For detail of power control by CPG (APMU) registers, see section 7B, Advanced Power Management Unit for AP-System Core (APMU).

(1) Power Control by WFI Instruction and Interrupts

The power shutdown by the WFI instruction is performed only when Cortex-A7 CPU n* power status control register (CA7CPUnCR*) is in the core standby mode. In case of other setting, power shutdown sequence is not activated by the WFI instruction. See section 7B, Advanced Power Management Unit for AP-System Core (APMU).

Power can be resumed by an IRQ or FIQ interrupt on the ARM core. After resuming power of Cortex-A7 CPUs by IRQ/FIQ, read the value of SYSCOFSR2 registers. Without reading those registers after power-resuming, the shutdown sequence of related CPUs will not start.

Note: * n = 0, 1.

49.3.2 Power Control of non-ARM-CPU modules

Power control on modules other than the ARM CPUs can be performed exclusively by means of SYSC registers. Such power control should be performed with reference to the flowchart given below:

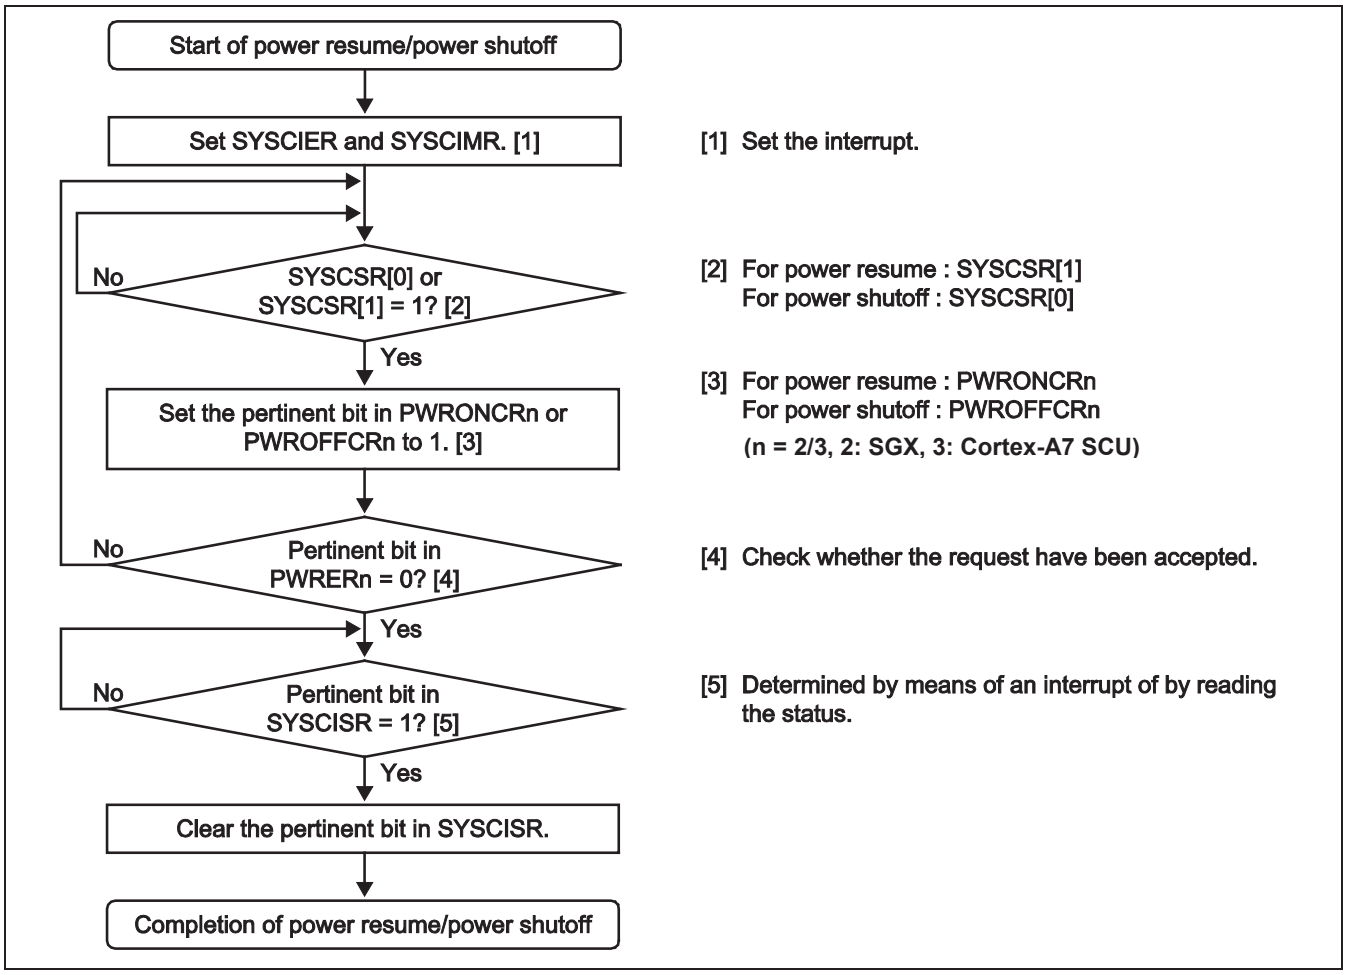

Figure 49.2 Power Resume/Shutoff Flowchart on non-ARM-CPU by Means of SYSC Registers

49.4 Usage Notes

1. For modules other than the ARM CPUs, resume or shutoff sequences on more than one module cannot be executed simultaneously. Whether or not a resume or shutoff sequence can be accepted is indicated in the SYSC status register.
2. The ARM CPUs can simultaneously execute resume or shutoff sequences for the CPU0 to CPU1 of the ARM core only if those sequences are simultaneously activated. Resume and shutoff sequences cannot be executed simultaneously even for the CPU0 to CPU1 of the ARM core.
3. If power for the ARM core is controlled by the WFI instruction or interrupts, such actions can potentially be in contention with power control by means of the SYSC register at an unexpected timing. Such control should be performed with references to the flowchart shown in Figure 49.2.
4. For a module for which power is shut down, register settings and memory contents are not retained; any necessary information should be saved before power is shut off.
5. Shut off and resuming power requires several hundreds of microseconds.

50. CoreSight

50.1 Overview

50.1.1 Features

- JTAG interface
  - — Supports dedicated 5-pin JTAG and SWD

  Supports the cross trigger between following IPs.
  - — Cortex-A7 CPUn.
  - — CoreSight
- Tracing function
  - — ETM is installed for each Cortex-A7 CPU
  - — A maximum of 16 bits × 390 Mbps (145-MHz DDR) trace* data pin output
  - — 16-Kbyte embedded trace FIFO (ETF)

Note: * Design frequency of internal logic. This is limited by IO buffer performance.

50.1.2 Block Diagram

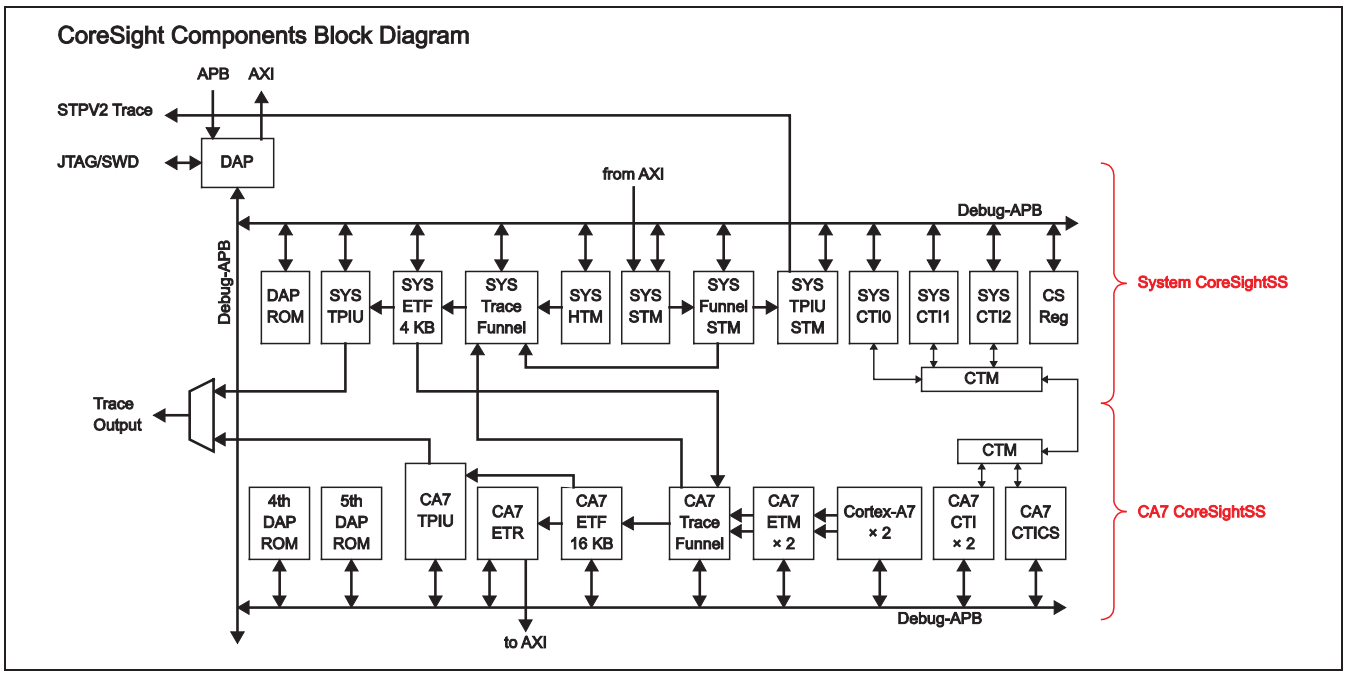

Figure 50.1 Block Diagram of CoreSight

50.1.3 Input/Output Pins

50.1.3.1 JTAG Pins

5-pin JTAG and SWD are supported as dedicated pins.

Table 50.1 JTAG Pins

Function Name	JTAG1 1.8V	JTAG2 1.8V	JTAG3 1.8V	I/O
TRST	TRST#	MMC0_CMD	SD2_CMD	Input
TCK/SWCLK	TCK	MMC0_D0	SD2_DAT0	Input
TMS/SWDIO	TMS	MMC0_D1	SD2_DAT1	Input/output
TDI	TDI	MMC0_D2	SD2_DAT2	Input
TDO/SWO	TDO	MMC0_CLK	SD2_CLK	Output
EDBGREQ	—	MMC0_D3	SD2_DAT3	IN

Notes: 1. Please refer section 5, Pin Function Controller (PFC) to know the other initial states of pull-up/down control each pins. Basically, the pull-up control initial states of JTAG2/3 multiplexed with SD/MMC pins are disabled.
2. If the JTAG Ports are not selected by debug related MD pins (MD[11:10], MD[21:20], MDT[1:0] pins are all low level), TRST# pin of JTAG1 should be set Low level or drove with the same level of PRESET# pin.
3. JTAG1, JTAG2 and JTAG3 and Trace ports support 1.8 V only.

50.1.3.2 Trace Pins

A maximum of 16-bit trace ports are supported as multiplexed pins.

Table 50.2 Trace Pins

Function Name	Pin Name	I/O
ARM_TRACEDATA_0	MMC0_D0	Output
ARM_TRACEDATA_1	SD0_DAT1	Output
ARM_TRACEDATA_2	SD0_DAT2	Output
ARM_TRACEDATA_3	SD0_DAT3	Output
ARM_TRACEDATA_4	MMC0_D6	Output
ARM_TRACEDATA_5	MMC0_D7	Output
ARM_TRACEDATA_6	MMC0_CLK	Output
ARM_TRACEDATA_7	MMC0_CMD	Output
ARM_TRACEDATA_8	MMC0_D2	Output
ARM_TRACEDATA_9	MMC0_D3	Output
ARM_TRACEDATA_10	MMC0_D4	Output
ARM_TRACEDATA_11	MMC0_D5	Output
ARM_TRACEDATA_12	SD2_CLK	Output
ARM_TRACEDATA_13	SD2_CMD	Output
ARM_TRACEDATA_14	SD2_DAT0	Output
ARM_TRACEDATA_15	SD2_DAT1	Output
TRACECLK	SD0_CLK	Output
TRACECTL	MMC0_D1	Output
CTIREQ	SD0_DAT0	Input
CTIACK	SD0_CMD	Output

51. Electrical Characteristics

51.1 Absolute Maximum Ratings

Table 51.1.1 Absolute Maximum Ratings

Item	Value	Unit	Remarks
Power supply voltage (3.3 V) (VCCQ, VCCQ_SD/VCCQ_MMC(SDHI), VCCQA_USB, VCCQA_LVDS, VCCQA_ADC, VCCQA_DAC)	-0.3 to +4.2	V	
Power supply voltage (1.8 V) (VCCQ18, VCCQ_SD/VCCQ_MMC(SDR50/SDR104))	-0.3 to +2.6	V	
Power supply voltage (1.5V) (VDDQ_M0)	-0.3 to +2.6	V	
Power supply voltage (1.2 V) (VDD, VDD_CPGPLL, VDD_DDRPLL, VDDA_USBPLL, VDDA_LVDSPLL)	-0.3 to +1.6	V	
Input voltage (3.3-V I/O)	-0.3 to VCCQ + 0.3	V	*1
Input voltage (3.3-V I/O [SDHI])	-0.3 to VCCQ_SD/VCCQ_MMC + 0.3	V	*1
Input voltage (1.8-V I/O)	-0.3 to VCCQ18 + 0.3	V	*2
Input voltage (1.8-V I/O [SDHI (SDR50/SDR104)])	-0.3 to VCCQ_SD/VCCQ_MMC + 0.3	V	*2
Input voltage (1.5-V I/O [DDR3])	-0.3 to VDDQ_M0 + 0.3	V	*3
Input voltage (USB0_OVC pin, USB1_OVC pin [USB2.0])	-0.3 to VCCQ + 0.3	V	*1
Input voltage (USB0_VBUS pin, USB1_VBUS pin [USB2.0])	-0.3 to + 5.5	V	
Output voltage (3.3-V I/O)	-0.3 to VCCQ + 0.3	V	*1
Output voltage (3.3-V I/O [SDHI])	-0.3 to VCCQ_SD/VCCQ_MMC + 0.3	V	*1
Output voltage (1.8-V)	-0.3 to VCCQ18 + 0.3	V	*2
Output voltage (1.8-V I/O [SDHI (SDR50/SDR104)])	-0.3 to VCCQ_SD/VCCQ_MMC + 0.3	V	*2
Output voltage (1.5-V I/O [DDR3])	-0.3 to VDDQ_M0 + 0.3	V	*3
Operating temperature	-40 to +115	°C	Tc (case)
	-40 to +85	°C	Ta (ambient)
Storage temperature	-55 to +125	°C	Ta (ambient)

Notes: Permanent damage to the LSI may result if absolute maximum ratings are exceeded. In normal operation, this LSI should be used within the specifications described in the following descriptions. If this LSI is not used within the specifications, the reliability of this LSI may lower.

Voltages are referenced at GND = VSS = 0 V.

1. Do not exceed 4.2 V.
2. Do not exceed 2.6 V.
3. Do not exceed 1.875 V.

51.2 Power Supply

Table 51.2.1 Power Supply

Item	Symbol	Voltage			Unit	Remarks
		Min.	Typ.	Max.		
Power supply (Internal)	VDD	1.16	1.21	1.26	V	VDD for power supply and VSS for ground
Power supply (3.3-V I/O)	VCCQ	3.0	3.3	3.6	V	VCCQ for power supply and VSS for ground

Power supply (1.5-V I/O [DDR3])	VDDQ_M0	1.425	1.5	1.575	V	VDDQ_M0 for power supply and VSS for ground
Power supply (PLL [CPG])	VDD_CPGPLL0, VDD_CPGPLL1, VDD_CPGPLL3	1.16	1.21	1.26	V	VDD_CPGPLL0, VDD_CPGPLL1, VDD_CPGPLL3 for power supply and VSS_CPGPLL0, VSS_CPGPLL1, VSS_CPGPLL3 for ground respectively V
Power supply (PLL [DDR3])	VDD_DDRPLL1, VDD_DDRPLL2	1.16	1.21	1.26	V	VDD_DDRPLL1, VDD_DDRPLL2 for power supply and VSS_DDRPLL1, VSS_DDRPLL2 for ground respectively
Power supply (PLL [USB2.0])	VDDA_USBPLL	1.16	1.21	1.26	V	VDDA_USBPLL for power supply and VSSA_USB for ground
Power supply (USB2.0)	VCCQA_USB	3.0	3.3	3.6	V	VCCQA_USB for power supply and VSSA_USB for ground
Power supply (LVDS)	VCCQA_LVDS	3.0	3.3	3.6	V	VCCQA_LVDS for power supply and VSSQA_LVDS for ground
	VDDA_LVDSPLL	1.16	1.21	1.26	V	VDDA_LVDSPLL for power supply and VSS for ground
Power supply (ADC [DVDEC])	VCCQA_ADC	3.0	3.3	3.6	V	VCCQA_ADC for power supply and VSSQA_ADC for ground
Power supply (DAC [DVENC])	VCCQA_DAC	3.0	3.3	3.6	V	VCCQA_DAC for power supply and VSSQA_DAC for ground

51.3 Sequence of Turning On/Off Power Supplies

51.3.1 Sequence of Turning On/Off Power Supplies with Different Voltage Levels

This subsection specifies the sequence of turning on/off power supplies with different voltage levels: 1.2-V power supplies (hereinafter referred to as VDD12 and the LSI pins are VDD, VDD_CPGPLL0, VDD_CPGPLL1, VDD_CPGPLL3, VDD_DDRPLL1, VDD_DDRPLL2, VDDA_USBPLL, VDDA_LVDSPLL), 1.5-V power supplies (referred to as VDD15, and the LSI pin is VDDQ_M0), 1.8-V power supplies (referred to as VDD18, and the LSI pins are VCCQ18, and VCCQ_SD0/VCCQ_MMC(SDR104), VCCQ_SD2(SDR50)), 3.3-V power supplies (referred to as VDD33, and the LSI pins are VCCQ, VCCQ_SD0/VCCQ_SD2/VCCQ_MMC(SDHI), and VCCQA_USB, VCCQA_LVDS, VCCQA_ADC, VCCQA_DAC), and grounds (referred to VSS**, and the LSI pins are VSS, VSS_CPGPLL0, VSS_CPGPLL1, VSS_CPGPLL3, VSS_DDRPLL1, VSS_DDRPLL2, and VSSA_USB, VSSQA_LVDS, VSSQA_ADC, VSSQA_DAC).

(1) Turning On Power Supply

There are no restrictions on the power-on sequence. Ensure that all other power supplies rise from the ground (VSS**) level within 300 ms of any single power supply rising from the ground (VSS**) level.

(2) Turning Off Power Supply

There are no restrictions on the power-off sequence. Ensure that all other power supplies fall to the ground (VSS**) level within 300 ms of any single power supply being turned off.

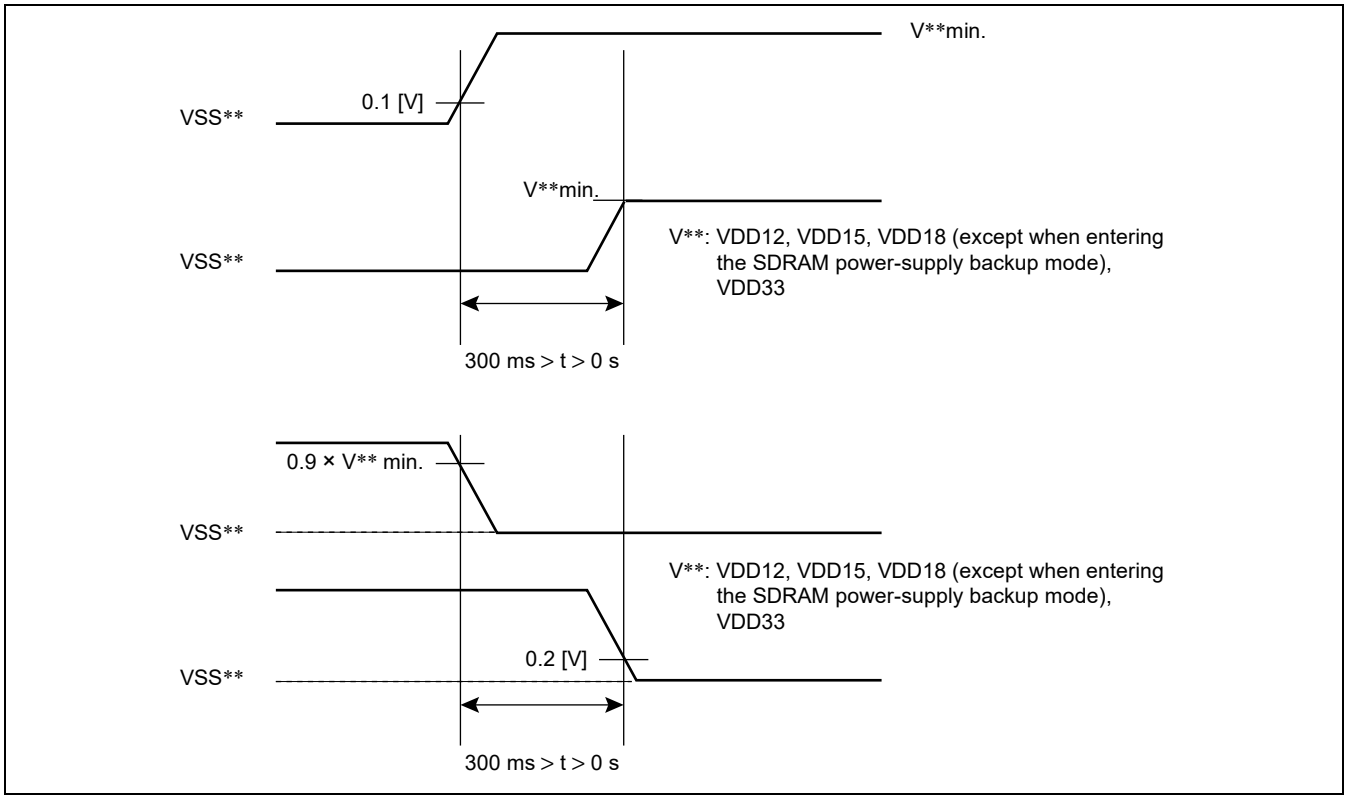

Figure 51.3.1 Sequence of Turning On Power Supplies with Different Voltage Levels

51.3.2 Sequence of Turning On/Off Power Supplies with Same Voltage Levels

This subsection specifies the sequence of turning on/off several power supplies with the same voltage levels (VDD12 power supplies, VDD18 power supplies, and VDD33 power supplies). The sequence of turning on/off VDD12 power supplies is shown in Figure 51.3.2. The voltage difference specified for the VDD12 supplies also applies to the VDD18 and VDD33 power supplies.

(1) Turning On Power Supply

There are no restrictions on the power-on sequence. Note that the voltage difference between the power supplies with the same voltage levels must be 0.3 V or lower.

(2) Turning Off Power Supply

There are no restrictions on the power-off sequence. Note that the voltage difference between the power supplies with the same voltage levels must be 0.3 V or lower.

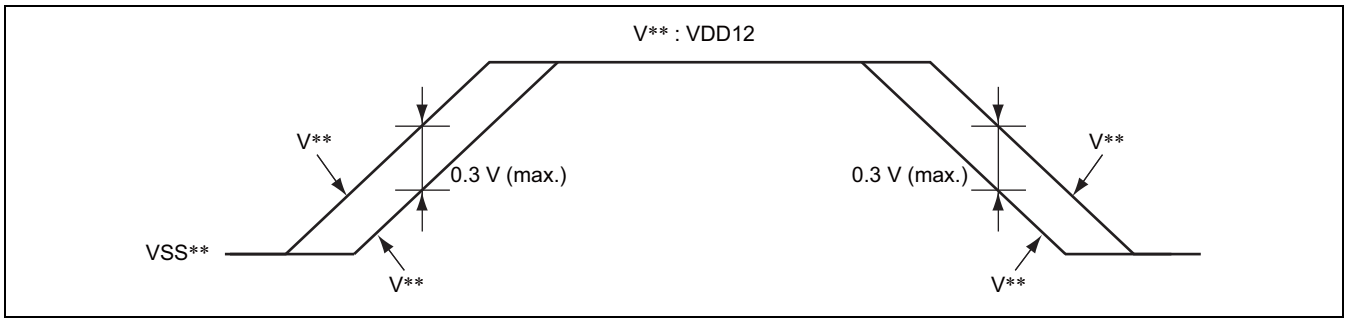

Figure 51.3.2 Sequence of Turning On/Off Power Supplies with Same Voltage Levels

51.4 DC Characteristics

Table 51.4.1 Supply Current

Conditions: Each power supply and ground are separated, ground is 0 V respectively,
Tc = -40 to +115 ºC (-20 to +115 °C for SDR104 only).

Item		Symbol	Min.	Typ.	Max.	Unit	Remarks
Supply current (internal)	Normal	IDD	—	—	4000	mA	VDD = 1.26 V
Supply current (3.3-V I/O)	Normal	ICCQ	—	—	200	mA	VCCQ = 3.6 V Local bus Access only case Current from/to external load is not included.
Supply current (3.3-V I/O [SDHI])	Normal	ICCQ_SD0	—	—	18.0	mA	VCCQ_SDn = VCCQ_MMC = 3.6 V (n = 0, 2)

Supply current (PLL [DDR3])		IDD_DDRPLLn	—	—	10.0	mA	VDD_DDRPLLn = 1.26 V (n = 1, 2)
Supply current (PLL [USB2.0])		IDDA_USBPLL	—	—	100.0	mA	VDDA_USBPLL = 1.26 V
Supply current (USB2.0)	Normal	ICCQA_USB	—	—	70.0	mA	VCCQA_USB = 3.6 V
Supply current (LVDS)	Normal	ICCQA_LVDS	—	—	64.0	mA	VCCQA_LVDS = 3.6 V
	Normal	IDDQA_LVDSPLL	—	—	2.5	mA	VDDA_LVDSPLL = 1.26 V
Supply current (ADC [DVDEC])	Normal	ICCQA_ADC	—	—	60.0	mA	VCCQA_ADC = 3.6 V
Supply current (DAC [DVENC])	Normal	ICCAQ_DAC	—	—	20.0	mA	VCCQA_DAC = 3.6 V

Table 51.4.2 DC Characteristics (3.3-V I/O)

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement conditions	Remarks
Input high voltage	VIH	2.0	—	VCCQ + 0.3	V	VCCQ = 3.0 to 3.6 V	—
Input low voltage	VIL	-0.3	—	0.8	V		
Schmitt Input high voltage	VT+	—	—	2.2	V	VCCQ = 3.0 to 3.6 V	PRESET#
Schmitt Input low voltage	VT-	0.8	—	—	V		
Output high voltage	VOH	2.4	—	VCCQ + 0.3	V	VCCQ = 3.0 to 3.6 V	IOH = -4 mA
Output low voltage	VOL	-0.3	—	0.4	V		IOL = 4 mA
Pin capacitance	CL	—	—	10	pF	—	All pins*2
Pin capacitance	CL	—	—	15	pF		DP/DM only
Input leakage current	ILI	—	—	1	µA	VCCQ = 3.0 to 3.6 V	All input pins*1
Input leakage current	ILI	—	—	10	µA		DP/DM only
Output leakage current	ILO	—	—	1	µA		Hi-Z output*1
Output leakage current	ILO	—	—	10	µA		DP/DM only
Pull-up current	IPU	8	—	250	µA		Vin = VSS

Notes: 1. This excludes pins with pull-up resistors, which are off and USBn_DP/USBn_DM. (n = 0, 1)
2. Except power supply and USB pins.

Table 51.4.3 DC Characteristics (3.3-V I/O [SDHI])

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement conditions	Remarks
Input high voltage	VIH	0.625 × VCCQ_SD	—	VCCQ_SD + 0.3	V	VCCQ_SD = 3.0 to 3.6 V	—
Input low voltage	VIL	VSS - 0.3	—	0.25 × VCCQ_SD	V	VSS = 0 V	—
Output high voltage	VOH	0.75 × VCCQ_SD	—	—	V		IOH = -2 mA VCCQ_SDmin
Output low voltage	VOL	—	—	0.125 × VCCQ_SD	V		IOL = 2 mA VCCQ_SDmin
Pin capacitance	CL	—	—	10	pF		—
Input leakage current	ILI	—	—	1	µA		—
Output leakage current	ILO	—	—	1	µA		Hi-Z output

Table 51.4.4 DC Characteristics (1.8-V I/O [SDHI (SDR50, SDR104)])

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement condition	Remarks
Input high voltage	VIH	1.27	—	2.00	V	VSS = 0 V	—
Input low voltage	VIL	VSS – 0.3	—	0.58	V		—
Output high voltage	VOH	1.4	—	—	V		IOH = -2 mA
Output low voltage	VOL	—	—	0.45	V		IOL = 2 mA
Pin capacitance	CL	—	—	10	pF		—
Input leakage current	ILI	—	—	1	µA		—
Output leakage current	ILO	—	—	1	µA		Hi-Z output

Table 51.4.5 DC Characteristics (1.8-V I/O)

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement condition	Remarks
Input high voltage	VIH	VCCQ18 × 0.8	—	VCCQ18 + 0.3	V	—	—
Input low voltage	VIL	-0.3	—	VCCQ18 × 0.2	V		
Output high voltage	VOH	0.7 × VCCQ18	—	VCCQ18 + 0.3	V	VCCQ18 = 1.7 to 1.9 V	IOH = -4 mA
Output low voltage	VOL	-0.3	—	0.4	V		IOL = 4 mA
Pin capacitance	CL	—	—	10	pF	—	—
Input leakage current	ILI	—	—	1	µA	VCCQ18 = 1.7 to 1.9 V	All input pins
Output leakage current	ILO	—	—	1	µA		Hi-Z output
Pull-up current	IPU	6	—	240	µA	—	Vin = VSS

Table 51.4.6 DC Characteristics (1.5-V I/O [DDR3])

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement conditions	Remarks
Input high voltage (MDQ pin)	VIH	VREF + 0.1	—	—	V	VDDQ_M0 = 1.425 to 1.575 V	M0DQ, M0DQS pins
Input low voltage (MDQ pin)	VIL	—	—	VREF – 0.1	V		
Input high voltage	VIH	0.7 × VDDQ_M0	—	—	V	VDDQ_M0 = 1.425 to 1.575 V	M0BKPRST#, M0SDBUP pins
Input low voltage	VIL	—	—	0.3 × VDDQ_M0,	V		
Differential input reference voltage	VREF	0.49 × VDDQ_M0	0.50 × VDDQ_M0	0.51 × VDDQ_M0	V	VDDQ_M0 = 1.425 to 1.575 V	*1
DC differential input voltage	VIHD	0.2	—	—	V	M0DQS = H, VIN = 0.5 × VDDQ_M0, VDD = 1.0 Vtyp, VDDQ_M0 = 1.425 to 1.575 V	M0DQS pins
DC differential input voltage	VILD	—	—	-0.2	V	M0DQS = L, VIN = 0.5 × VDDQ_M0, VDD = 1.16 to 1.26V, VDDQ_M0 = 1.425 to 1.575 V	
DC differential input voltage	VIN	0.5 × VDDQ_M0 – 0.250	—	0.5 × VDDQ_M0 + 0.250	V	VIHD = 200 mV or VILD = -200 mV, VDD = 1.16 to 1.26V, VDDQ_M0 = 1.425 to 1.575 V	
Input high voltage	VIH (AC)	VREF + 0.175	—	—	V	—	—
Input low voltage	VIL (AC)	—	—	VREF - 0.175	V	—	—
AC differential input cross point voltage	VIX (AC)	VDDQ_M0 – 0.15	—	VDDQ_M0 + 0.15	V	—	M0DQS pin *2
AC differential output cross point voltage	VOX (AC)	VREF – 0.125	—	VREF + 0.125	V	—	M0CK, M0DQS pins
High Hi-Z leak current	IOZH	—	—	4	µA	—	Other than M0ZQ pin
Low Hi-Z leak current	IOZL	-4	—	—	µA	—	
High Hi-Z leak current	IOZH	—	—	5	µA	—	M0ZQ pin
Low Hi-Z leak current	IOZL	-5	—	—	µA	—	
Pin capacitance	CL	—	—	10	pF	—	All pins*3

Notes: 1. Peak to peak ac noise on VREF may not exceed ±2 % of VREF.
2. The VIX (AC) indicates the voltage at which differential input signals cross each other. The typical value of VIX (AC) is expected to be 0.5 × VDDQ_M0.
3. Except power supply pins.

Table 51.4.7 DDR3 Interface ODT Characteristics

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement conditions	Remarks
ODT resistance (60 Ω)	RTT60	54.0	—	96.0	Ω	VDD = 1.26 V, VDDQ_M0 = 1.5 V	—
VM deviation	ΔVM	-6	—	+6	%		*

Note: VM is a voltage value measured with the ODT turned on without any load applied to this LSI chip. ΔVM is obtained by the following formula:
ΔVM = (2 × VM / VDDQ_M0 -1) × 100

Table 51.4.8 USB High-Speed Transceiver Characteristics

Item		Symbol	Min.	Typ.	Max.	Unit	Remarks
Input	Common mode voltage range	V_{HSCM}	-50	—	500	mV	—
	Squelch threshold	V_{HSSQ}	100	—	150	mV	
Output	Idle state	V_{HSOI}	-10	—	10	mV	—
	High level voltage	V_{HSOH}	360	—	440	mV	
	Low level voltage	V_{HSOL}	-10	—	10	mV	
	Chirp J state	V_{CHIRPJ}	700	—	1100	mV	
	Chirp K state	V_{CHIRPK}	-900	—	-500	mV	

Table 51.4.9 USB Low-/Full-speed Transceiver Characteristics

Item		Symbol	Min.	Typ.	Max.	Unit	Remarks
Input	High voltage (driven)	V_{IH}	2.0	—	—	V	—
	Low voltage	V_{IL}	—	—	0.8	V	—
	Differential input sensitivity	V_{DI}	0.2	—	—	V	|DP-DM|
	Differential common mode range	V_{CM}	0.8	—	2.5	V	—
Output	High voltage (driven)	V_{OH}	2.8	—	3.6	V	I_{OH} = -200 µA
	Low voltage	V_{OL}	0.0	—	0.3	V	I_{OL} = 2 mA
	Output signal crossover voltage	V_{CRS}	1.3	—	2.0	V	C_L = 50 pF (Full-speed), C_L = 200 to 600 pF (Low-speed)

Table 51.4.10 USB High-Speed Output Driver Impedance

Item		Symbol	Min.	Typ.	Max.	Unit	Remarks
DP pull-up resistor (on-chip)	Idle state	R_{PU}	0.9	—	1.575	kΩ	—
	Receiving state		1.425	—	3.090	kΩ	—
Pull-down resistor (on-chip)		R_{PD}	14.25	—	24.80	kΩ	—

Table 51.4.11 DC Characteristics of VBUS, USB_EXTAL pin

Item	Symbol	Min.	Typ.	Max.	Unit	Remarks
VBUS input voltage	VIH	4.02	—	5.25	V	—
	VIL	-0.3	—	0.5	V	—
USB_EXTAL input voltage	VIH	VCCQA_USB – 0.5	—	VCCQA_USB + 0.3	V	—
	VIL	-0.3	—	0.5	V	—

Table 51.4.12 DC Characteristics of LVDS pin*

Item	Symbol	Min.	Typ.	Max.	Unit	Measurement condition	Remarks
Differential output voltage	|Vod|	0.250	—	0.450	V	R_L = 100 Ω	—
Difference Vod between ‘H’ and ‘L’	ΔVod	—	—	50	mV	R_L = 100 Ω	—
Output offset voltage	Vos	1.125	—	1.375	V	R_L = 100 Ω	—
Difference Vos between ‘H’ and ‘L’	ΔVos	—	—	50	mV	R_L = 100 Ω	—

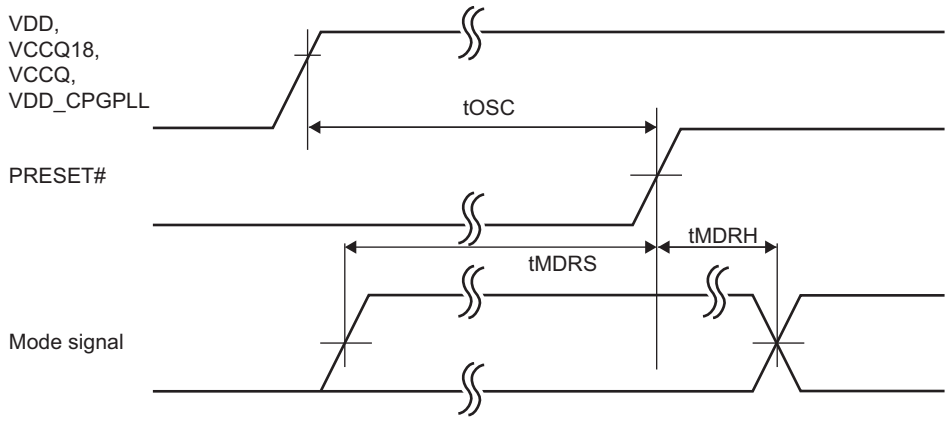
51.5 Clock and Reset Timings

Table 51.5.1 Clock and Reset Timings

Conditions: VCCQ = 3.3 V ± 0.3 V, VCCQ18 = 1.8 V ± 0.1 V, GND = VSS = 0 V, Tc = -40 to +115 °C

Pin	Item	Symbol	Min.	Max.	Unit	Figures
PRESET#, EXTAL	Power-on oscillation settling time	tOSC	20	—	ms	Figure 51.5.1
Mode signal*	MD reset setup time	tMDRS	20	—	ms	
Mode signal*	MD reset hold time	tMDRH	3	—	ns	

Note: * MDn (n = 0, 1, 2, ...) and MDT[1:0]. For details of mode signals, refer to section 3.2, Mode Pin Settings.



Note for PRESET# input
1. Note electromagnetic noise because that may cause malfunctions of the LSI.
2. Note an intermediate voltage level input because that may influence the long-term reliability of the LSI.

Item	Symbol	Min.	Max.	Unit	Figure	Remarks
MDQ input hold time from MDQS, MDQS# (read)	tRQH	0.35	—	tCK(avg)	Figure 51.7.9*2	*1

Notes: The signal timing is based on the following electric potential:
For MCK output, MDQS input/output: Differential input/output cross point voltage
For MDQ input: MVREF
For outputs other than MCK or MDQS: 0.5 × VDDQ_M0

1. Each timing specification are defined by assuming to connect DDR3-1333Mbps memory products
2. tWDQSH, tWDQSL specification are defined to guarantee operating with DDR-1333Mbps or DDR3-1600Mbps memory products which follows JEDEC JESD79-3E standards. (refer to Table 51.7.2 below)

   Minimum value of tWDQSH, tWDQSL can be calculated by using tCK(avg) according to either 1500ps (with min clock period of DDR3-1333Mbps product) or 1250ps (with min clock period of DDR3-1600Mbps product)

   Maximum value of tWDQSH, tWDQSL can be calculated by using tCK(avg) as 2500ps (with max clock period of both DDR3-1333Mbps and DDR3-1600Mpbs product)

Table 51.7.2 tDQSH/tDQSL Standard Specification of DDR3-1333Mbps/1600Mbps Products

			1333 Mbps		1600 Mbps	
Item	Symbol	Unit	Min.	Max.	Min.	Max.
MCK average clock period	tCK(avg)	ns	1.5	2.5	1.25	2.5
MDQS High/Low pulse width (Write)	tWDQSH/ tWDQSL	tCK(avg)	0.45	0.55	0.45	0.55
		ns	0.675	1.375	0.563	1.375

EXHSYNC# input high level width	tEXHHW	4tDCYC	—	—	ns	
EXVSYNC# input low level width	tEXVLW	3HC	—	—	tDCYC	
ODDF# setup time 1*4	tOD1	(ys+yw) × HC	—	—	tDCYC	
ODDF# setup time 2*4	tOD2	1HC	—	—	tDCYC	

Notes: 1. For correspondence between these signals and pin names, refer to Table 51.8.3.
2. Clock signal is input from DOTCLKIN and then output from DOTCLKOUT without being frequency-divided.
3. This electrical characteristic is applicable when the DR0D bit (bit 21) in the display output control register (DORCR) is set to 1. When the DR1D bit is cleared to 0, this characteristic is the same as the display digital data output delay time (tDD). Min value of tDCYC will be twice. This electrical characteristic applies to only DU0 output.
4. ys, yw and HC in Min value of ODDF# setup time 1 and ODDF# setup time 2 (tOD1 and tOD2);
ys: From rise of VSYNC to display start position in the vertical direction of the display screen (unit: raster line)
yw: Vertical display period of display screen (unit: raster line)
HC: Horizontal scan period (unit: dot clock).

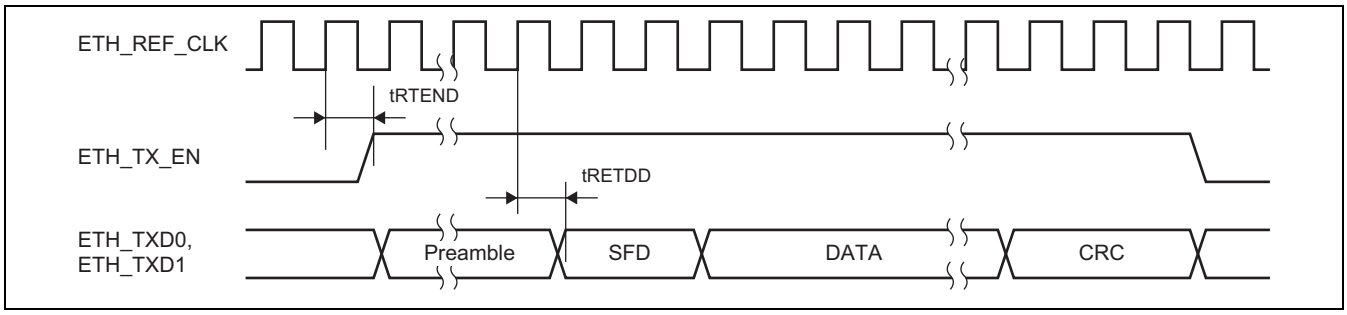

Figure 51.12.1 RMII Transmission Timing

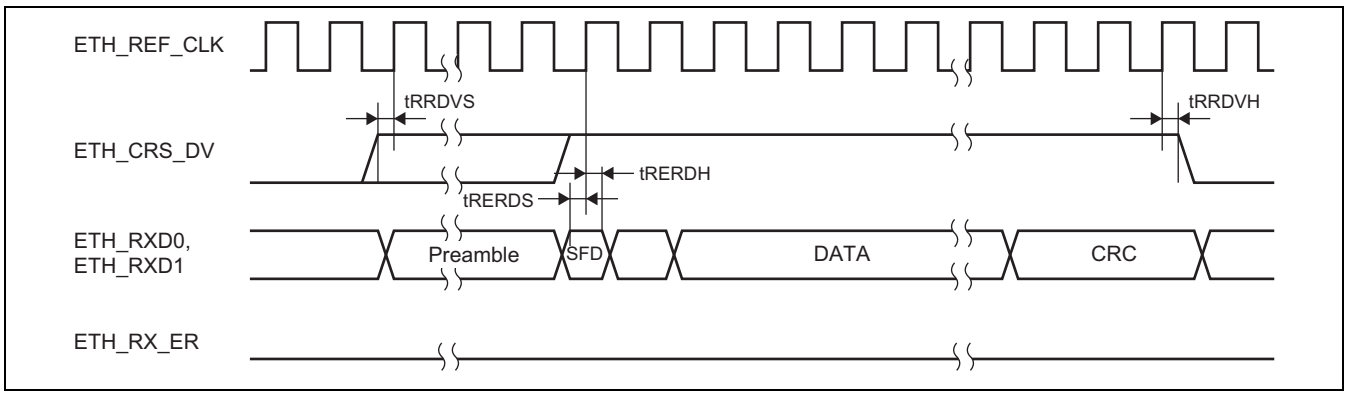

Figure 51.12.2 RMII Reception Timing (Normal Operation)

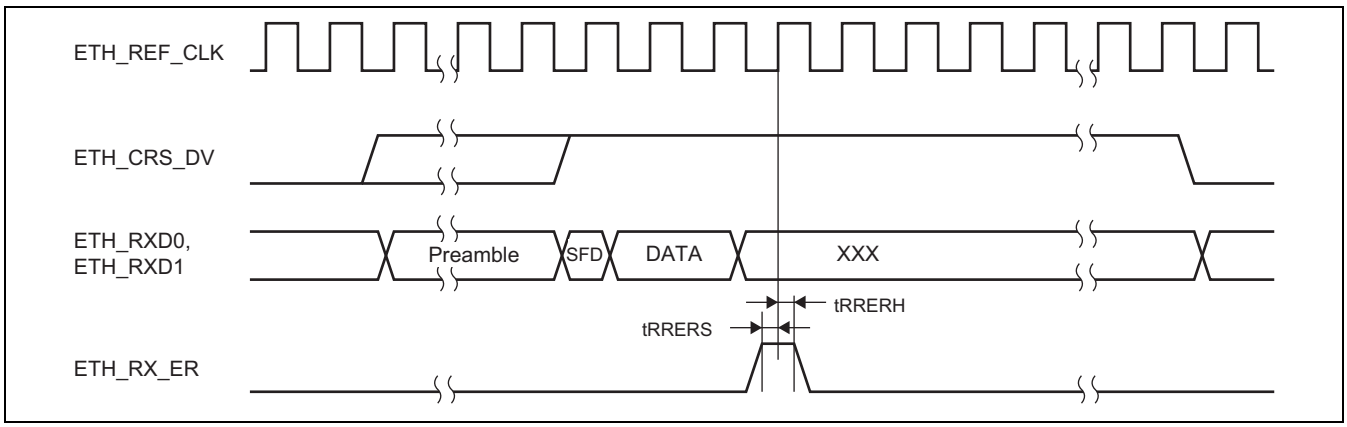

Figure 51.12.3 RMII Reception Timing (Case When Error Occurs)

(1) ETH_MDC timing specification (setup time and hold time)

Although ETH_MDC is a reference clock for the serial management interface (SMI), ETH_MDC input setup time and ETH_MDC input hold time are not specified.

(2) ETH_MDIO timing provision (setup time and hold time)

The AC specifications for the SMI (PHY side) from the IEEE are as follows:

ETH_MDC input cycle ≥ 400 ns.

ETH_MDC input pulse width at each level ≥ 160 ns

ETH_MDIO input setup and hold times ≥ 10 ns (PHY latches the MAC output on rising edges of ETH_MDC).

ETH_MDIO output delay time = 0 to 300 ns (delay time from a rising edge of ETH_MDC)

The ETH_MDC output, ETH_MDIO output, and ETH_MDIO input latching depend on software adjusting settings in the PHY interface register (PIR). Adjust the ETH_MDC output (period) and ETH_MDIO output (timing of changes) to satisfy the AC input specs on the PHY side. To adjust the timing of ETH_MDIO input latching, consider the AC output specifications on the PHY side.

51.13 Ethernet AVB Module Signal Timing

Table 51.13.1 Ethernet Control Timing (MII)

Initial value:	0	*	*	*	*	*	*	*	*	*	*	*	*	*	*	*
R/W:	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

Note: * The settings of these bits are explained overleaf. Bits 31 to 27 are fixed, they depend on the product and the configuration you have ordered. Bits for processors that are never present in a given product are read as 1.

Bit	Bit Name	Initial Value	R/W	Description
31 to 27	—	B'11111	R	Bit 31 Reserved. The read value is always 1. Bit 30 Reserved. The read value is always 1. Bit 29 Reserved. The read value is always 1. Bit 28 Reserved. The read value is always 1. Bit 27 Reserved. The read value is always 1.
26 to 22	CA7EN	It depends on the product. See the description.	R	Bit 26 Cortex-A7 State 0: The product has two Cortex-A7 CPUs. 1: The product does not have two Cortex-A7 CPUs. Bit 25 Reserved. The read value is always 1. Bit 24 Reserved. The read value is always 1. Bit 23 Cortex-A7 CPU1 State 0: The product has Cortex-A7 CPU1. 1: The product does not have Cortex-A7 CPU1. Bit 22 Cortex-A7 CPU0 State 0: The product has Cortex-A7 CPU0. 1: The product does not have Cortex-A7 CPU0.
21 to 15	—	All 0	R	Reserved

Bit	Bit Name	Initial Value	R/W	Description
14 to 8	PRODUCT	See the description.	R	Product ID Number 101 0011
7 to 0	CUT	See the description.	R	Cut Number ES1.0: 0000 0000 ES2.0: 0001 0000 ES3.0: 0010 0000

Possible Configuration of the ARM Cortex Cores are Cortex-A7 CPU0 and Cortex-A7 CPU1 of product.

Main Revisions and Additions in this Edition

Minor revisions such as corrections of errors in spelling and modifications of wording are not included in the revision history.
